[bit6] LVDH2S: Extended External Low-Voltage Detection Operation Selection Bit
This bit selects an operation when the extended external low-voltage detection occurs.

Bit	Description
0	Reset.
1	Interrupt.

Note:
- *These bits are reset by RSTX_SCUP. Refer Section 3.2.3 Reset of circuit in surrounding in CHAPTER RESET.*

[bit5:4] Reserved: Reserved Bits

[bit3:1] LVDH2V: Extended External Low-Voltage Detection Voltage Setting Bits
These bits set the detection voltage for extended external low-voltage detection.

Bits	Description
000	(product specification)
001	(product specification)
010	(product specification)
011	(product specification)
100	(product specification)
101	(product specification)
110	(product specification)
111	(product specification)

Notes:
- *After the detection voltage is changed, low-voltage detection is unavailable until the low-voltage detection stability time elapses.*
- *These bits are reset by RSTX_SCUP. Refer Section 3.2.3 Reset of circuit in surrounding in CHAPTER RESET.*

[bit0] LVDH2E: Extended External Low-Voltage Detection Operation Enable Bit
This bit sets the extended external low-voltage detection operation.

Bit	Description
0	Stop operation.
1	Enable operation.

Notes:
- *After this setting is changed from "0" (stop operation) to "1" (enable operation), low-voltage detection is unavailable until the low-voltage detection stability time elapses.*
- *These bits are reset by RSTX_SCUP. Refer Section 3.2.3 Reset of circuit in surrounding in CHAPTER RESET.*

<tr><td>0</td><td>External power supply control is reset by LVDH1</td></tr>
<tr><td>1</td><td>External power supply control is not reset by LVDH1</td></tr>
</table>
Note:
– This bit is reset by RSTX_POWER. Refer Section 3.2.3 Reset of circuit in surrounding in CHAPTER RESET.

Correct)
[bit24] HOLDIO_PD2: Setting bit for power domain 2 HOLD data latch
This bit sets whether to retain I/O control in power domain 2 when shutting off the power supply. See Table 5-60 Bit explanation (1).
Note:
– Make the decision on the model side about whether to use this setting.

[bit23] PSSPADCTRL: PSS-time port configuring bit
This bit sets whether to perform Hi-z control of I/O at the PSS time. See Table 5-61 Bit explanation (2).

[bit22] IO3RSTC: I/O3V reset configuring bit
This bit sets 3V I/O reset control. See Table 5-62 Bit explanation (3).

[bit21] IO35RSTC: I/O5/3V reset configuring bit
This bit sets 5/3V I/O reset control. See Table 5-62 Bit explanation (3).

[bit20:10] Reserved bits

[bit9] EXVRSTCNT: Reset level configuring bit for external power supply control
This bit sets requested reset level to the external power supply control.
<table>
<tr><th>Bit</th><th>Description</th></tr>
<tr><td>0</td><td>External power supply control is reset by LVDH1</td></tr>

571	CHAPTER 6 Low-power Consumption 6.1. Restrictions on Transitioning to the PSS	Revised the bellow: Error) This section describes restrictions on transitioning to the PSS. When transitioning to the PSS, create a 1:1:1:1 relationship among the CPU clock, the Memory Configuration clock, the SCU clock, and the MCUCH clock. The loss of this relationship among these clocks may cause abnormal operation. Correct) This section describes restrictions on transitioning to the PSS. 1. When transitioning to the PSS, create a 1:1:1:1 relationship among the CPU clock, the Memory Configuration clock, the SCU clock, and the MCUCH clock. The loss of this relationship among these clocks may cause abnormal operation. 2. When using in the following condition, Fast CR clock must be enabled. - Use PSS mode without PD2 shutdown - Use peripherals in PD6 at PSS mode shutdown Fast CR clock is enabled when it sets SYSC0_PSSCKSRER. CROSCEN=1.

This could be the Main clock (CLK_MAIN) divided by 2 (4/2 MHz), Sub clock (CLK_SUB) divided by 2 (32.768/2 kHz) or Slow RC clock (CLK_SRC) divided by 2 (100/2 kHz). Correct) 10. The Sub-second counter begins counting on the CLKRTC. This could be the Main clock (CLK_MAIN) divided by 2 (4/2 MHz), Sub clock (CLK_SUB) divided by 2 (32.768/2 kHz) or Slow CR clock (CLK_SRC) divided by 2 (100/2 kHz).

Page	Section	Change Results
683	CHAPTER 10 Real Time Clock 3.Operation of the Real Time Clock	Error) **Figure 3-2 WOT Pin Operation**  Correct) **Figure 3-2 WOT Pin Operation** 
Page	Section	Change Results
684	CHAPTER 10 Real Time Clock 3.Operation of the Real Time Clock	Error) **Automatic Calibration:** 4. Write the Calibration trigger counter value to RTC_CALTRG to configure the time interval between two calibration cycles. For low-power mode, this also defines the intervals to wake up the Main oscillator. 5. Set RTC_WTCR:ENUP to '1' to enable the automatic transfer of the measured calibration value to the Sub-Second Register (RTC_WTBR) at the end of every calibration cycle. 6. Set RTC_WTCR:ACAL to '1', to enable Automatic Calibration. When the RTC is operating (RTC_WTSR:RUN) = '1', the Calibration trigger counter will run and generate cyclic calibration trigger events. 7. Set RTC_WINE:CFDE to '1' to enable interrupt generation (and MCU wake-up) in case of a calibration failure. An interrupt request will be generated when a calibration failure is detected if RTC_WTBR is not updated within one second after the hardware trigger. This happens when the Main clock is missing. Correct) **Automatic Calibration:** 1. Write the Calibration trigger counter value to RTC_CALTRG to configure the time interval between two calibration cycles. For low-power mode, this also defines the intervals to wake up the Main oscillator. 2. Set RTC_WTCR:ENUP to '1' to enable the automatic transfer of the measured calibration value to the Sub-Second Register (RTC_WTBR) at the end of every calibration cycle. 3. Set RTC_WTCR:ACAL to '1', to enable Automatic Calibration. When the RTC is operating (RTC_WTSR:RUN) = '1', the Calibration trigger counter will run and generate cyclic calibration trigger events. 4. Set RTC_WINE:CFDE to '1' to enable interrupt generation (and MCU wake-up) in case of a calibration failure. An interrupt request will be generated when a calibration failure is detected if RTC_WTBR is not updated within one second after the hardware trigger. This happens when the Main clock is missing.
684 to 685	CHAPTER 10 Real Time Clock 3.Operation of the Real Time Clock	Error) ***Notes:*** - *For Automatic Calibration in low-power mode, ensure a valid stabilization time for CLK_MAIN* - *oscillation is configured. Information about stabilization time can be found in CHAPTER 2.* Correct) ***Note:*** - *For Automatic Calibration in low-power mode, ensure a valid stabilization time for CLK_MAIN oscillation is configured. Information about stabilization time can be found in CHAPTER 9.*

824	CHAPTER 14 Hardware Watchdog Timer 3. Explanation of Operation	Error) **Output of the Watchdog Counter Monitor Bit for MCU Output Pin** **For This Product, Output of the Watchdog Counter Monitor Bit of MCU Output Pin is Supported by the Hardware Watchdog Timer.** The Hardware watchdog timer outputs the watchdog counter monitor bit to the outside so that watchdog counter operation can be monitored from the outside. You can select any 1 bit in the watchdog counter (32 bits) by setting the OBSSEL[4:0] bits in the Hardware watchdog configuration register (HWDG_CFG). Correct) **Output of the Watchdog Counter Monitor Bit for MCU Output Pin** The Hardware watchdog timer outputs the watchdog counter monitor bit to the outside so that watchdog counter operation can be monitored from the outside. You can select any 1 bit in the watchdog counter (32 bits) by setting the OBSSEL[4:0] bits in the Hardware watchdog configuration register (HWDG_CFG). Support of this function is different depends on product specification.
826	CHAPTER 14 Hardware Watchdog Timer 3. Explanation of Operation	Error) ***Notes:*** *− The following register setting values are determined by a marker in the flash memory (BootROM marker).* − HWDT_INT − HWDT_TRG0CFG − HWDT_TRG1CFG − HWDT_RUNLLS − HWDT_RUNULS − HWDT_PSSLLS − HWDT_PSSULS − HWDT_RSTDLY − HWDT_CFG Correct) ***Notes:*** *− The following register setting values are determined by a marker in the flash memory (BootROM marker).* − HWDG_INT − HWDG_TRG0CFG − HWDG_TRG1CFG − HWDG_RUNLLS − HWDG_RUNULS − HWDG_PSSLLS − HWDG_PSSULS − HWDG_RSTDLY − HWDG_CFG

Page	Section	Change Results
831	CHAPTER 14 Hardware Watchdog Timer 3. Explanation of Operation	Error) The watchdog counter in RUN always operates. When the device state transitions from RUN to PSS, the processing transitions to the operation of the watchdog in PSS. For details, see The following figure shows the Hardware watchdog operation in PSS. During the operation of the watchdog counter, execute the watchdog counter clear protection trigger sequence within the range between the window upper limit value and lower limit value that have been specified beforehand. Do this to clear the watchdog counter periodically. 6. If a runaway state caused by a user program occurs and prevents periodic clearing, the watchdog counter reaches the window upper limit value. Then, processing transitions to the flow that generates the watchdog reset request or watchdog interrupt request (NMI). 7. According to the value of the IRQEN bit in the Hardware watchdog interrupt configuration register (HWDG_INT), the prior warning interrupt request is generated. At the same time, as many cycles as are set for the delay time in the Hardware watchdog reset delay counter register (HWDG_RSTDLY) are inserted. 8. After the elapse of the time corresponding to the number of cycles for the delay time, the watchdog reset request or watchdog interrupt request (NMI) is generated according to the value of the RSTEN bit in the Hardware watchdog interrupt configuration register (HWDG_INT). When the watchdog interrupt request (NMI) is generated, the processing transitions to the operation of the test function of the watchdog. For details, see Figure 3-6. Correct) 1. The watchdog counter in RUN always operates. 2. When the device state transitions from RUN to PSS, the processing transitions to the operation of the watchdog in PSS. For details, see Figure 3-5. 3. During the operation of the watchdog counter, execute the watchdog counter clear protection trigger sequence within the range between the window upper limit value and lower limit value that have been specified beforehand. Do this to clear the watchdog counter periodically. 4. If a runaway state caused by a user program occurs and prevents periodic clearing, the watchdog counter reaches the window upper limit value. Then, processing transitions to the flow that generates the watchdog reset request or watchdog interrupt request (NMI). 5. According to the value of the IRQEN bit in the Hardware watchdog interrupt configuration register (HWDG_INT), the prior warning interrupt request is generated. At the same time, as many cycles as are set for the delay time in the Hardware watchdog reset delay counter register (HWDG_RSTDLY) are inserted. 6. After the elapse of the time corresponding to the number of cycles for the delay time, the watchdog reset request or watchdog interrupt request (NMI) is generated according to the value of the RSTEN bit in the Hardware watchdog interrupt configuration register (HWDG_INT). When the watchdog interrupt request (NMI) is generated, the processing transitions to the operation of the test function of the watchdog. For details, see Figure 3-6.
834	CHAPTER 14 Hardware Watchdog Timer 3. Explanation of Operation	Error) ***Note:*** The notation * in The following figure shows the operation of the test function of the Hardware watchdog. Correct) ***Note:*** - The notation * in Figure 3-6 means "RUN" or "PSS".

Page	Section	Change Results
884	CHAPTER 15 Software Watchdog Timer 3. Explanation of Operation	Error) The watchdog counter in RUN always operates. When the device state transitions from RUN to PSS, the processing transitions to the operation of the watchdog in PSS. For details, see The following figure shows the Software watchdog operation in PSS. During the operation of the watchdog counter, execute the watchdog counter clear protection trigger sequence within the range between the window upper limit value and lower limit value that have been specified beforehand. Do this to clear the watchdog counter periodically. 5. If a runaway state of the software occurs and prevents periodic clearing, the watchdog counter reaches the window upper limit value. Then, processing transitions to the flow that generates the watchdog reset request or watchdog interrupt request (NMI). 6. According to the value of the IRQEN bit in the Software watchdog interrupt configuration register (SWDG_INT), the prior warning interrupt request is generated. At the same time, as many cycles as are set for the delay time in the Software watchdog reset delay counter register (SWDG_RSTDLY) are inserted. 7. After the elapse of the time corresponding to the number of cycles for the delay time, the watchdog reset request or watchdog interrupt request (NMI) is generated according to the value of the RSTEN bit in the Software watchdog interrupt configuration register (SWDG_INT). When the watchdog interrupt request (NMI) is generated, the processing transitions to the operation of the test function of the watchdog. For details, see Figure 3-6. 8. Correct) 1. The watchdog counter in RUN always operates. 2. When the device state transitions from RUN to PSS, the processing transitions to the operation of the watchdog in PSS. For details, see Figure 3-5. 3. During the operation of the watchdog counter, execute the watchdog counter clear protection trigger sequence within the range between the window upper limit value and lower limit value that have been specified beforehand. Do this to clear the watchdog counter periodically. 4. If a runaway state of the software occurs and prevents periodic clearing, the watchdog counter reaches the window upper limit value. Then, processing transitions to the flow that generates the watchdog reset request or watchdog interrupt request (NMI). 5. Overview** **2. Security Scope and Access Restriction by the Security** **3. Using and Configuring the Security** **4. Registers** In this chapter, there is a place with two specifications, "SWP_NOMAL_type" and "SWP_LITE_type". Basically please refer to "SWP_NORMAL_type" specification, but when SWP_LITE_type is used, please **refer to "SWP_LITE_type" specification and see the Product's HWM.**

Page	Section	Change Results
1268	CHAPTER 24:Security 1. Overview	Error) This section shows brief overview of security features in this product. This product has security features which forbid unauthorized access to Flash contents and unauthorized use of debugger. For authentication and unlocking there are two methods supported: 1. A 128 bit Debug Security Key defined by the user and stored in the Flash. For details about its usage refer to the chapter about Security Checker (SECURITYCHK) and to the BootROM Software Interface, about DDR Registers. 2. A freely programmable authentication method by the user application and a security state defined by registers described in this chapter. Several protection levels are achieved by the flexibility in configuration. Initial values for the security state registers are defined by markers stored in Flash. It can be decided later by the application, if those values can be altered or not. This chapter describes security features supported in this product and procedure to configure it. Correct) This section shows brief overview of security features in this product. This product has security features which forbid unauthorized access to Flash contents and unauthorized use of debugger. This chapter describes security features supported in this product and procedure to configure it.

Page	Section	Change Results
1269	CHAPTER 24:Security 2. Security Scope and Access Restriction by the Security 2.1. Security Scope	Added Error) The ability to execute “chip erase” always exists. The marker MK_CEER does not have any functionality. Correct) Refer to datasheet of product. If being written with "MK_CEER is Selectable", below is spec. The ability to execute “chip erase” function depends on the permission set by the marker MK_CEER. The possibility of doing chip erase can be removed, when the user intents to forbid the usage of other parties software on his system. However this removes any possibility for a recovery of a device when not implementing an unlock mechanism or forgetting the key for a device unlock. To protect the software IP only from being disassembled, debugged or copied – the normal security is enough and chip erase functionality should stay enabled. Other spec is below. The ability to execute “chip erase” always exists. The marker MK_CEER does not have any functionality.

Gaining program / erase permission to Flash Sectors	Added Error) The macro erase command is not supported by the WORKFLASH. Correct) The macro erase command is not supported by the WORKFLASH. ■ **SWP_LITE_type** Following procedure is required to ensure the operation of Sector Write Permissions. When programing to TCFLASH, all of following Sector Write Permissions register bits must be set to “1” to permit the TCFLASH programing. - Code Flash 0 Sector Write Permissions of the Small Sectors (TCFCFG0_CSWP0) - Code Flash 0 Sector Write Permissions of the Large Sectors (TCFCFG0_CSWP1) - Code Flash 1 Sector Write Permissions of the Large Sectors (TCFCFG0_CSWP2) - Code Flash 2 Sector Write Permissions of the Large Sectors (TCFCFG0_CSWP3) - Code Flash 3 Sector Write Permissions of the Large Sectors (TCFCFG0_CSWP4) - Code Flash 4 Sector Write Permissions of the Large Sectors (TCFCFG0_CSWP5) - Code Flash 5 Sector Write Permissions of the Large Sectors (TCFCFG0_CSWP6) - Code Flash 6 Sector Write Permissions of the Large Sectors (TCFCFG0_CSWP7) - Code Flash 7 Sector Write Permissions of the Large Sectors (TCFCFG0_CSWP8) After programing, set the original values of Sector Write Permissions again to protect the TCFLASH data. ■ **SWP_NORMAL_type** No additional prodecure is required. ■ **end_of_type_listing**

<table>
<tr><th>Page</th><th>Section</th><th>Change Results</th></tr>
<tr><td>1290</td><td>CHAPTER 24:Security
4. Registers</td><td>Error)

The registers listed in this section are a part of the TCFLASH interface instance #0 assigned to core #0. Security information is only available for this instance of TCFLASH#0 because it is required to maintain it centrally in sector S0 of TCFLASH#0. Additional core and TCFLASH instances #1 to #3 do not have any security information.

The base address of TCFLASH#0 registers is 0xB041_1000.

After each RSTX_PD2H, the security information fetched from Code Flash #0 is stored in registers. The security state registers can be read and written by the application, to change the security state. That is needed to implement several unlocking mechanisms by the application software, i.e. to temporary allow a debugger access after sending a user defined unlock key.

Correct)

After each RSTX_PD2H, the security information fetched from Code Flash #0 is stored in registers. 3.1.DMA
Channels</td><td>Error)

Block of Data
A block of data is determined by the setting of Block Count (DMAi_An:BC[3:0]) and Transfer Width (DMAi_Bn:TW[1:0]). The DMA Controller will make DMAi_An:BC + 1 data transfers from source address range starting at Source Address (DMAi_SAn:SA) to destination address range starting at Destination Address (DMAi_DAn:DA). If DMAi_An:BC is set to "0" a single data transfer from Source Address (DMAi_SAn:SA) to Destination Address (DMAi_DAn:DA) will be done. The settings of Block Count (DMAi_AN:BC[3:0]), Beat Limit (DMAi_An:BL[1:0]), Alternate (DMAi_An:AL), and Transfer Width (DMAi_Bn:TW[1:0]) define how the AHB master interface issues the DMAi_An:BC + 1 data transfers.

Correct)

Page	Section	Change Results
2097	CHAPTER 37:I2C Interface (I2C Communication Control Interface) 3 I2C Interface Operation 3.1 Master Mode	Error) **When DMA Mode is Enabled (SSR:DMA = 1)** ■ If the IBSR: RSA bit is "1", the interrupt flag (IBCR: INT) is set to "1" after the reserved address is received (before an acknowledgment), the SCL remains "L", and a wait is performed. After the RDR register is read, the IBCR:ACKE bit and transmission data are set, and "0" is written to the interrupt flag. This sets the interrupt flag to "0", which releases the wait. Correct) **When DMA Mode is Enabled (SSR:DMA = 1)** If the IBSR:RSA bit is "1", the interrupt flag (IBCR:INT) is set to "1" after the reserved address is received (before an acknowledgment), the SCL remains "L", and a wait is performed. After the RDR register is read, the IBCR:ACKE bit and transmission data are set, the writing "1" to the IBCRC:INTC sets the interrupt flag to "0", which releases the wait.
2131	CHAPTER 37:I2C Interface (I2C Communication Control Interface) 3 I2C Interface Operation 3.2. Slave Mode	Error) Operation is in slave mode after the (repeated) start condition is detected and an ACK response is returned when the combination of the ISBA register and the ISMK register matches the received address. **Notes:** ■ When EIBCR:BEC = 0 during address data transfer after the start condition has been detected or during transfer of bit2 to bit9 (acknowledgment bits), the start condition may be detected again. If so, a bus error is detected (IBCR:BER = 1) and reception is stopped, so the next data cannot be received. Correct) Operation is in slave mode after the start condition or the repeated start condition is detected and an ACK response is returned when the combination of the ISBA register and the ISMK register matches the received address. ***Notes:*** − *When EIBCR:BEC=0, if 2nd start condition is detected after 1st start condition is detected (during transfer of bit2 to bit9), a bus error is detected (IBCR:BER=1) and reception is stopped.*

Page	Section	Change Results
2131	CHAPTER 37:I2C Interface (I2C Communication Control Interface) 3 I2C Interface Operation 3.2. Slave Mode	Error) **Slave Address Match Detection** After the (repeated) start condition is detected, the next data is received as a 7-bit address. With regard to the bits that are set to "1" in the ISMK register, the bits in the ISBA register are compared with the bits of the received address. If they match, ACK is output. Correct) **Slave Address Match Detection** The 1st receiving data after the start condition or the repeated start condition is detected contains 7-bit slave address and the bit that shows the direction of the data transmission. The ISMK register is set the value that masks the slave address of the ISBA register. The bit value "0" means "don't care", and "1" means that it needs that the bit value of address corresponds with the data of received slave address. That is, the bit whose the value is set to "0" in the ISMK register is not compared to the bit of the address. When SAEN is set to "1", it enables the slave address detection. The data as the address sent by a master is compared with some slave address bits(SA[6:0]) that mask bits(SM[6:0]) corresponded to is set to "1". If they match, ACK is output. If not, ACK is not output. Example of the address detection For example, a master send the slave address 0x23. **Figure 3-2 The example of the slave address detection**  Just SA5, SA1, SA0 are compared the data as the address sent by the master. Because SM[6], SM[4:2] are set to "0", those bits are "don't care". As a result, the Multi-function serial interface outputs the ACK response.

Page	Section	Change Results
2133	CHAPTER 37:I2C Interface (I2C Communication Control Interface) 3 I2C Interface Operation 3.2. Slave Mode	Error) **When DMA Mode is Disabled (SSR:DMA = 0)** ■ When the reception FIFO is enabled 2. If the interrupt flag (IBCR:INT) was set to "1", read the received data from the RDR register. After reading all the data, write "0" to the interrupt flag to release the wait for the I2C bus. If the stop condition or the repeated start condition was detected, read all the received data from the RDR register, and clear the IBSR:SPC bit or the IBSR:RSC bit to "0". Correct) **When DMA Mode is Disabled (SSR:DMA = 0)** ■ When the reception FIFO is enabled 2. If the interrupt flag (IBCR:INT) was set to "1", read the received data from the RDR register. After reading all the data, write "1" to the interrupt flag clear bit (IBCRC:INTC) to release the wait for the I2C bus. If the stop condition or the repeated start condition was detected, read all the received data from the RDR register, and clear the IBSR:SPC bit or the IBSR:RSC bit to "0".
2140	CHAPTER 37:I2C Interface (I2C Communication Control Interface) 3 I2C Interface Operation 3.3. Bus Error	Error) Check the IBCR:BER bit when the interrupt flag (IBCR:INT) is set to "1" according to the status. If the IBCR:BER bit is "1", take action against the error. The IBCR:BER bit is cleared by the writing of "0" to the IBCR:INT bit. Correct) **When EIBCR:BEC=0** Check the IBCR:BER bit when the interrupt flag (IBCR:INT) is set to "1" according to the status. If the IBCR:BER bit is "1", take action against the error. The IBCR:BER bit is cleared by writing "1" to the interrupt flag clear bit (IBCRC:INTC).
2146	CHAPTER 37:I2C Interface (I2C Communication Control Interface) 6. Block Transfer	Error) The block size is set in the transmission/reception block size register. Correct) The block size is set in the transmission block size register or FBYTE register(reception side).
2151	CHAPTER 37:I2C Interface (I2C Communication Control Interface) 6. Block Transfer 6.2. RW Access Mode	Error) After the reception block transfer is requested, the reception block transfer request (RIRQ) is cleared when read access to the reception FIFO occurs. The read access to the reception FIFO decrements the Read counter. Correct) After the reception block transfer is requested, the reception block transfer request (RIRQ) is cleared when a read access to the reception data occurs. The read access to the reception data decrements the Read counter.

Page	Section	Change Results
2153	CHAPTER 37:I2C Interface (I2C Communication Control Interface) 6. Block Transfer 6.2. RW Access Mode	Error) **Transmission Block Transfer Error** The occurrence of write access before the assertion of the next transmission block transfer request (TIRQ) while the Write counter is "0" causes a transmission block transfer error. Then, the FSR:TBERR bit is asserted. Correct) **Transmission Block Transfer Error** The occurrence of write access before the assertion of the next transmission block transfer request (TIRQ) while the Write counter is "0" causes a transmission block transfer error. Then, the ESR:TBERR bit is asserted.
2172	CHAPTER 37:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.2. Serial Mode Register (SMR)	Error) **[bit7:5] MD[2:0] : Operation Mode Setting Bits** These bits set the operation mode. "0b000": Set operation mode 0 (asynchronous normal mode). "0b001": Set operation mode 1 (asynchronous multi-processor mode). "0b010": Set operation mode 2 (clock synchronous mode). "0b011": Set operation mode 3 (LIN communication mode). "0b100": Set operation mode 4 (I_2C mode). This section explains the register and its operations in operation mode 4 (I_2C mode). Correct) **[bit7:5] MD[2:0] : Operation Mode Setting Bits** These bits set the operation mode.
2174	CHAPTER 37:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.3. I2C Bus Status Register (IBSR)	Error) 1. The 2nd byte is transmitted and received. Correct) 1. The 2nd byte starts to be transmitted and received.

Page	Section	Change Results
2181	CHAPTER 37:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.4. Serial Status Register (SSR)	Error) **[bit10] RDRF : Reception Data Full Flag Bit** ■ When reading of the reception FIFO empties it during use, this bit is cleared to "0". **Notes:** ■ After RDRF becomes "1" when the reception FIFO is used, resetting the reception FIFO (FCR0:FCL2, FCL1= 1) does not cause RDRF to become "0". Therefore, to set RDRF to "0" after resetting the reception FIFO, perform a dummy read on the reception data register while reception is disabled (SCR:RXE= 0). Correct) **[bit10] RDRF : Reception Data Full Flag Bit** ■ When ECR:RXBLKEN=0 and reading of the reception FIFO empties it during use, this bit is cleared to "0". ■ When ECR: RXBLKEN=1 and using reception FIFO, this bit is clear to "0" when the number of the data in the reception FIFO is less than or equal to the value of the FBYTE register. **Notes:** − *After RDRF becomes "1" when the reception FIFO is used, resetting the reception FIFO (FCR0:FCL2,FCL1= 1) does not cause RDRF to become "0". Therefore, to set RDRF to "0" after resetting the reception FIFO, perform a dummy read on the reception data register while I2C mode is disabled (ISMK.I2CEN=0).*
2184	CHAPTER 37:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.5. Reception Data Register/Transmission Data Register (RDR/TDR)	Error) The reception and transmission data registers are allocated to the same address. This register functions as the reception data register when data is read, and as the transmission data register when data is written. Correct) The reception and transmission data registers are allocated to the same address. This register functions as the reception data register when data is read, and as the transmission data register when data is written. When the FIFO mode is enabled, RDR/TDR register address is the address of reading/writing of the FIFO.

Table 2-1 Interrupt Control Bits and Interrupt Factors of LIN Interface (v2.1) (Manual Mode)

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Clearing of Interrupt Request Flag
Reception	RDRF	SSR	1-byte reception	SCR:RIE	- Reading of reception data (RDR) - Software reset (SCR:UPCL = 1)
			Reception of as much data as the amount set in FBYTE		- Reading of reception data until the reception FIFO becomes empty - Software reset (SCR:UPCL = 1)
			Detection of reception idle for 8-bit time or longer while the FRIIE bit is "1" and the reception FIFO contains valid data		
	ORE	SSR	Overrun error	SCR:RIE ECR:REIE	- Writing "1" to the reception error flag clear bit (SSR:REC) - Software reset (SCR:UPCL = 1)
	FRE	SSR	Framing error		
	RXUDR	ESR	Reception FIFO underrun	ECR:REIE	- Writing "1" to the reception FIFO underrun clear flag bit (ESRC:RXUDRC) - Software reset (SCR:UPCL = 1) - Disable reception FIFO - When FCR1:FSEL=0, set FCR0:FE2=0 - When FCR1:FSEL=1, set FCR0:FE1=0
	RBERR	ESR	Reception block transfer error	ECR:REIE	- Writing "1" to the reception block transfer error clear bit (ESRC:RBERRC) - Software reset(SCR:UPCL=1) - Disable Block transfer mode (ECR:RXBLKEN=0)
Transmission	TDRE	SSR	The transmission register is empty.	SCR:TIE	Writing to the transmission data (TDR), or writing "1" to the transmission FIFO operation enable bit (FCR0:FE1 or FCR0:FE2) (retransmission) while the bit value is "0" and the transmission FIFO contains valid data *1
	TBI	SSR	No transmission operation	SCR:TBIE	Writing to the transmission data (TDR), writing "1" to the LIN Break Field setting bit (LBR), or writing "1" to the transmission FIFO operation enable bit (FCR0:FE1 or FCR0:FE2) (retransmission) while the bit value is "0" and the transmission FIFO contains valid data*1
	FDRQ	FCR1	The amount of data in the transmission FIFO is equal to or smaller than the FTICR setting value or it is empty.	FCR1:FTIE	Writing "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC) , or transmission FIFO full

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Clearing of Interrupt Request Flag
	TXOVR	ESR	Transmission FIFO overrun	ECR:TEIE	- Writing "1" to the transmission FIFO overrun flag clear bit (ESRC:TXOVRC) - Software reset (SCR:UPCL = 1) - Disable transmission FIFO - When FCR1:FSEL=0, set FCR0:FE1=0 - When FCR1:FSEL=1, set FCR0:FE2=0
	TBERR	ESR	Transmission block transfer error	ECR:TEIE	- Writing "1" to the transmission block transfer error clear bit (FSRC:TBERRC) - Software reset (SCR:UPCL=1) - Disable Block transfer mode (ECR:TXBLKEN=0)
Status (Manual Mode)	LBD	SSR	LIN Break Field detection	ESCR:LBIE	- Writing "1" to the SSRC:LBDC bit - Software reset (SCR:UPCL = 1)
	SFD	SACSR	Sync Field detection	SACSR:SFDE	- Writing "1" to the Sync Field detection flag clear bit (SACSRC:SFDC) - Software reset (SCR:UPCL=1)
	TINT	SACSR	Coincidence of the serial timer register (STMR) and the serial timer comparison register (STMCR) values	SACSR:TINTE	- Writing "1" to the timer interrupt flag clear bit (SACSRC:TINTC) - Software reset (SCR:UPCL=1)
Input Capture	ICP0	ICS0	1st falling edge of the LIN Sync Field	ICS0:ICE0	Disabling the ICP0
	ICP0	ICS0	5th falling edge of the LIN Sync Field

2252	CHAPTER 38: LIN Interface (V2.1) 2. LIN Interface (v2.1) Interrupts	Error)

Table 39.2-4 LIN Interface (v2.1) Interrupt Control Bits and Interrupt Factors (Assist Mode)

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Clearing of Interrupt Request Flag
Reception	RDRF	SSR	1-byte reception	SCR:RIE	Reading of reception data (RDR)
			Reception of as much data as the amount set in FBYTE		Reading of reception data (RDR) until the reception FIFO becomes empty
			Detection of reception idle for the 8-bit time or longer while the FRIIE bit is "1" and the reception FIFO contains valid data		
	ORE	SSR	Overrun error	SCR:RIE	Writing "1" to the reception error flag clear bit (SSR:REC)
	FRE	SSR	Framing error	ECR:REIE	
	LBSER	LAMESR	LIN bus error detection	LAMIER: LBSERIE	Writing "1" to LAMESRC:LBSERC
	LSFER	LAMESR	LIN Sync Data error detection	LAMIER: LSFERIE	Writing "1" to LAMESRC:LSFERC
	LPTER	LAMESR	LIN ID parity error detection	LAMIER: LPTERIE	Writing "1" to LAMESRC:LPTERC

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Clearing of Interrupt Request Flag
	LCSER	LAMESR	LIN checksum error detection	LAMIER: LCSERIE	Writing "1" to LAMESRC:LCSERC
	RXUDR	ESR	Reception FIFO underrun	ECR:REIE	Writing "1" to the reception FIFO underrun flag clear bit (ESRC:RXUDRC)
	RBERR	ESR	Reception block transfer error	ECR:REIE	Writing "1" to the reception block transfer error clear bit
Transmission	TDRE	SSR	The transmission register is empty.	SCR:TIE	Writing to the transmission data (TDR) , or writing "1" to the transmission FIFO operation enable bit (FCR0:FE1 or FCR0:FE2) (retransmission) when the bit value is "0" and the transmission FIFO contains valid data*1
	TBI	SSR	No transmission operation	SCR:TBIE	Writing to the transmission data (TDR), writing "1" to the LIN Break Field setting bit (LBR), or writing "1" to the transmission FIFO operation enable bit (retransmission) when the bit value is "0" and the transmission FIFO contains valid data *1
	FDRQ	FCR1	The amount of data in the transmission FIFO is equal to or less than the FTICR setting value or it is empty.	FCR1:FTIE	Writing "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC) , or the transmission FIFO is full
	TXOVR	ESR	Transmission FIFO overrun	ECR:TEIE	Writing "1" to the transmission FIFO overrun flag clear bit (ESRC:TVOVRC)
	TBERR	ESR	Transmission block transfer error	ESR:TEIE	Writing "1" to the transmission block transfer error clear bit (ESRC:TBERRC)
Status (Assist Mode)	LBD	SSR	LIN Break Field detection	ESCR:LBIE	Writing "1" to the SSRC:LBDC bit
	SFD	SACSR	Sync Field detection	SACSR: SFDE	Writing "1" to the Sync Field detection flag clear bit (SACSRC:SFDC)
	TINT	SACSR	Coincidence of the value in the serial timer register (STMR) and that in the serial timer comparison register (STMCR)	SACSR: TINTE	Writing "1" to the timer interrupt flag clear bit (SACSRC:TINTC)

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Clearing of Interrupt Request Flag
	LAHC	LAMSR	Completion of auto header	LAMIER: LAHCIE	Writing "1" to LAMSRC:LAHCC or reading from the ID register (LAMRID)
	LCSC	LAMSR	Completion of checksum calculation	LAMIER: LCSCIE	Writing "1" to LAMSRC:LCSCC

2262	CHAPTER 38: LIN Interface (V2.1) 2. LIN Interface (v2.1) Interrupts	Error) When the standard checksum calculation is set (LAMCR:LCSTYP = 0), the side that transmits a response (data and checksum) performs the checksum calculation based on the transmission data for the specified LIN data length (LAMCR:LDL). Then, after transmitting the last data, the transmission side automatically transmits the checksum. The side that receives a response (data and checksum) executes the checksum calculation based on the reception data for the specified LIN data length (LAMCR:LDL). If the received checksum differs from the calculation result value, then a LIN checksum error is detected and a flag is set (LAMESR:LCSER = 1). Correct) When the standard checksum calculation is set (LAMCR:LCSTYP = 0), the side that transmits a response (data and checksum) performs the checksum calculation based on the transmission data for the specified LIN data length (LAMCR:LDL3-0). Then, after transmitting the last data, the transmission side automatically transmits the checksum. The side that receives a response (data and checksum) executes the checksum calculation based on the reception data for the specified LIN data length (LAMCR:LDL3-0). If the received checksum differs from the calculation result value, then a LIN checksum error is detected and a flag is set (LAMESR:LCSER = 1).
2263	CHAPTER 38: LIN Interface (V2.1) 2. LIN Interface (v2.1) Interrupts	Error) When extended checksum calculation is set (LAMCR:LCSTYP = 1), the side that transmits a response (data and checksum) performs the checksum calculation based on the ID Field value and the transmission data for the specified LIN data length (LAMCR:LDL). Then, after transmitting the last data, the transmission side automatically transmits the checksum. The side that receives a response (data and checksum) executes the checksum calculation based on the ID Field value and the reception data for the specified LIN data length (LAMCR:LDL). If the received checksum differs from the calculation result value, then a LIN checksum error is detected and a flag is set (LAMESR:LCSER = 1). Correct) When extended checksum calculation is set (LAMCR:LCSTYP = 1), the side that transmits a response (data and checksum) performs the checksum calculation based on the ID Field value and the transmission data for the specified LIN data length (LAMCR:LDL3-0). Then, after transmitting the last data, the transmission side automatically transmits the checksum. The side that receives a response (data and checksum) executes the checksum calculation based on the ID Field value and the reception data for the specified LIN data length (LAMCR:LDL3-0). If the received checksum differs from the calculation result value, then a LIN checksum error is detected and a flag is set (LAMESR:LCSER = 1).
2288	CHAPTER 38: LIN Interface (V2.1) 6. Block Transfer	Error) The block size can be set with the transmission block size register and the reception block size register. Correct) The block size can be set with the transmission block size register and FBYTE register (for the reception side).

Page	Section	Change Results
2291	CHAPTER 38: LIN Interface (V2.1) 6. Block Transfer	Error) **Transmission Block Transfer Error** If, while the Write counter is "0", an acknowledgment is input before the next transmission block transfer request (TIRQ) is asserted, a transmission block transfer error occurs, and the FSR:TBERR bit is asserted. Correct) **Transmission Block Transfer Error** If, while the Write counter is "0", an acknowledgment is input before the next transmission block transfer request (TIRQ) is asserted, a transmission block transfer error occurs, and the ESR:TBERR bit is asserted.
2294	CHAPTER 38: LIN Interface (V2.1) 6. Block Transfer	Error) After the reception block transfer request, if a read access to the reception FIFO occurs, the reception block transfer request (RIRQ) is cleared. With a read access to the reception FIFO, the Read counter is decremented. Correct) After the reception block transfer request, if reading a reception data occurs, the reception block transfer request (RIRQ) is cleared. With reading a reception data, the Read counter is decremented.
2295	CHAPTER 38: LIN Interface (V2.1) 6. Block Transfer	Error) After the transmission block transfer request, if a write access to the transmission FIFO occurs, the transmission block transfer request (TIRQ) is cleared. With a write access to the transmission FIFO, the Write counter is decremented. Correct) After the transmission block transfer request, if writing a transmission data occurs, the transmission block transfer request (TIRQ) is cleared. By writing a transmission data, the Write counter is decremented.
2296	CHAPTER 38: LIN Interface (V2.1) 6. Block Transfer	Error) **Transmission Block Transfer Error** If, while the Write counter is "0", a write access occurs before the next transmission block transfer request (TIRQ) is asserted, a transmission block transfer error occurs, and the FSR:TBERR bit is asserted. Correct) **Transmission Block Transfer Error** If, while the Write counter is "0", a write access occurs before the next transmission block transfer request (TIRQ) is asserted, a transmission block transfer error occurs, and the ESR:TBERR bit is asserted.
2300	CHAPTER 38: LIN Interface (V2.1) 7. LIN Interface (V2.1) Operation	Error) ■ When the DATA Field is received, SSR:RDRF is set to 1. At this time, a reception interrupt occurs if the reception interrupt is enabled (SSR:RIE = 1). Correct) ■ When the DATA Field is received, SSR:RDRF is set to 1. At this time, a reception interrupt occurs if the reception interrupt is enabled (SCR:RIE = 1).

Page	Section	Change Results
2307	CHAPTER 38: LIN Interface (V2.1) 7. LIN Interface (V2.1) Operation	Error) ■ When the value of serial timer register (STMR) is between that of the Sync Field lower limit register (SFLR) and Sync Field upper limit register (SFUR), the value of the serial timer register (STMR) is set in the baud rate generator register (BGR), and the baud rate setting flag (SACSR:BST) is set to "1". ■ When the value of serial timer register (STMR) is below that of the Sync Field lower limit register (SFLR) or exceeds that of the Sync Field upper limit register (SFUR), the baud rate generator register (BGR) will not be changed and the baud rate setting flag (SACSR:BST) is reset to "0". Correct) − When the value of serial timer register (STMR) is between that of the Sync Field lower limit register (SFLR) and Sync Field upper limit register (SFUR), the value of the serial timer register (STMR) is set in the baud rate generator register (BGR1, BGR0), and the baud rate setting flag (SACSR:BST) is set to "1". − When the value of serial timer register (STMR) is below that of the Sync Field lower limit register (SFLR) or exceeds that of the Sync Field upper limit register (SFUR), the baud rate generator register (BGR1, BGR0) will not be changed and the baud rate setting flag (SACSR:BST) is reset to "0".
2316	CHAPTER 38: LIN Interface (V2.1) 7. LIN Interface (V2.1) Operation	Error) ■ When the LIN data length is set to 0 bytes (LAMCR:LDL3 to LD0 = 0000) for response transmission, write dummy data into the TDR register to automatically perform the checksum calculation and then transmit the data. (Any value can be written.) The TDR setting value does not affect the checksum calculation. ■ During the transmission of response data, do not change the transmission data length (LAMCR:LDL[3:0]). Correct) − *When the LIN data length is set to 0 bytes (LAMCR:LDL3 to LDL0 = 0000) for response transmission, write dummy data into the TDR register to automatically perform the checksum calculation and then transmit the data. (Any value can be written.) The TDR setting value does not affect the checksum calculation.* − *During the transmission of response data, do not change the transmission data length (LAMCR:LDL3 to LDL0).*
2317	CHAPTER 38: LIN Interface (V2.1) 7. LIN Interface (V2.1) Operation	Error) ■ When the DATA Field is received, SSR:RDRF is set to 1. At this time, a reception interrupt occurs if a reception interrupt is enabled (SSR:RIE = 1). Correct) ■ When the DATA Field is received, SSR:RDRF is set to 1. At this time, a reception interrupt occurs if a reception interrupt is enabled (SCR:RIE = 1).

Page	Section	Change Results
2318	CHAPTER 38: LIN Interface (V2.1) 7. LIN Interface (V2.1) Operation	Error) ■ During the reception of response data, do not change the reception data length (LAMCR:LDL[3:0]). Correct) − *During the reception of response data, do not change the reception data length (LAMCR:LDL3 to LDL0).*
2324	CHAPTER 38: LIN Interface (V2.1) 7. LIN Interface (V2.1) Operation	Error) ■ When the value of the serial timer register (STMR) is between that of the Sync Field lower limit register (SFLR) and Sync Field upper limit register (SFUR), the value of the serial timer register (STMR) is set in the baud rate generator register (BGR), and the baud rate setting flag (SACSR:BST) is set to "1". ■ When the value of the serial timer register (STMR) is below that of the Sync Field lower limit register (SFLR) or exceeds that of the Sync Field upper limit register (SFUR), the baud rate generator register (BGR) will not be changed and the baud rate setting flag (SACSR:BST) is reset to "0". Correct) ■ When the value of the serial timer register (STMR) is between that of the Sync Field lower limit register (SFLR) and Sync Field upper limit register (SFUR), the value of the serial timer register (STMR) is set in the baud rate generator register (BGR1, BGR0), and the baud rate setting flag (SACSR:BST) is set to "1". ■ When the value of the serial timer register (STMR) is below that of the Sync Field lower limit register (SFLR) or exceeds that of the Sync Field upper limit register (SFUR), the baud rate generator register (BGR1, BGR0) will not be changed and the baud rate setting flag (SACSR:BST) is reset to "0".
2329	CHAPTER 38: LIN Interface (V2.1) 7. LIN Interface (V2.1) Operation	Error) Notes: ■ For slave operation, when the LIN communication speed is 19.2 kbps, within about 25 µs after the auto header completion flag is set (LAMSR:LAHC = 1), set the checksum type (LAMCR:LCSTYP) and the LIN data length (LAMCR:LDL[3:0]), and disable the transmission (SCR:TXE), the transmission interrupt (SCR:TIE), the reception (SCR:RXE) and the reception interrupt (SCR:RIE) . (Set to a value less than half of one cycle time for LIN communication.) Correct) Notes: − *For slave operation, when the LIN communication speed is 19.2 kbps, within about 25 µs after the auto header completion flag is set (LAMSR:LAHC = 1), set the checksum type (LAMCR:LCSTYP) and the LIN data length (LAMCR:LDL3 to LDL0), and disable the transmission (SCR:TXE), the transmission interrupt (SCR:TIE), the reception (SCR:RXE) and the reception interrupt (SCR:RIE) . (Set to a value less than half of one cycle time for LIN communication.)*

2356	CHAPTER 38: LIN Interface (V2.1) 9. Interface (V2.1) Registers 9.3 Serial Status Register (SSR)	Error) **[bit10] RDRF: Reception Data Full Flag Bit** Correct) **[bit10] RDRF: Reception Data Full Flag Bit** ■ When reception FIFO available, SSR:RDRF is set "1" when conditions under below and the condition that the reception idle state continues for at least 8 clock pulses of the baud rate clock are satisfied. − The reception FIFO idle detection enable bit (FCR1:FRIIE) is set to "1". − The reception FIFO has not received the prescribed number of data items, and data remains in the reception FIFO. During an 8-clock count, the counter is reset to 0 when RDR is read, and starts to count the 8clocks again. Notes: − *This bit is set "0" when Software reset (SCR:UPCL = 1) is done.*
2357	CHAPTER 38: LIN Interface (V2.1) 9. Interface (V2.1) Registers 9.3 Serial Status Register (SSR)	Error) **[bit9] TDRE: Transmission Data Empty Flag Bit** ■ The TDRE bit is set to "1" when "1" is written to the UPCL bit in the serial control register (SCR). Correct) **[bit9] TDRE: Transmission Data Empty Flag Bit** ■ The TDRE bit is set to "1" when programmable clear (SCR:UPCL=1) is done.
2359	CHAPTER 38: LIN Interface (V2.1) 9. Interface (V2.1) Registers 9.4 Extended Communication Control Register (ESCR)	Error) **[bit5, bit3:2] LBL[2:0]: LIN Break Field Length Selection Bits (Effective Only for Master Operation)** ■ Set these bits before setting the LBR bit in the serial control register (SCR) to "1" (LIN Break Field transmission). Correct) **[bit5, bit3:2] LBL[2:0]: LIN Break Field Length Selection Bits (Effective Only for Master Operation)** ■ Set these bits before setting the LIN Break Field setting bit (SCR:LBR) to "1".

Page	Section	Change Results
2359	CHAPTER 38: LIN Interface (V2.1) 9. Interface (V2.1) Registers 9.4 Extended Communication Control Register (ESCR)	Error) **[bit1:0] DEL[1:0]: LIN Break Delimiter Length Selection Bits (Effective Only for Master Operation)** ■ Set these bits before setting the LBR bit in the serial control register (SCR) to "1" (LIN Break Field transmission). Correct) **[bit1:0] DEL[1:0]: LIN Break Delimiter Length Selection Bits (Effective Only for Master Operation)** ■ Set these bits before setting the LIN Break Field setting bit(SCR:LBR) to "1".
2369	CHAPTER 38: LIN Interface (V2.1) 9. Interface (V2.1) Registers 9.8 Serial Timer Comparison Register (STMCR)	Error) **[bit15:0] TC15-0: Compare Bits** **Note:** ■ The timer interrupt flag (SACSR:TINT) is fixed to "1" when this register is set to 0x0000, the timer is operating, and the division value (SACSR:TDIV) of the timer operation clock is set to 0b0000. Correct) **[bit15:0] TC15-0: Compare Bits** The period below is (STMCR:TC+1) X The timer clock (set by SACSR:TDIV3-0) ・SACSR:TINT is set "1" ***Notes:*** − *The timer interrupt flag (SACSR:TINT) is fixed to "1" when all of the following conditions are satisfied.* − Synchronous transmission is disabled (SACSR:TSYNE = 0). − 0x0000 is set in this register. − The timer is operating. − 0b0000 is set as the timer operating clock division value (SACSR:TDIV3-0).
2370	CHAPTER 38: LIN Interface (V2.1) 9. Interface (V2.1) Registers 9.9 Sync Field Upper Limit Register (SFUR)	Error) **[bit14:0] TU14-0: Upper Limit Bits** These bits set the upper limit on the values that can be set in the baud rate generator register (BGR) for auto baud rate adjustment. Then, the baud rate generator register (BGR) is set to the value of the serial timer register (STMR). Correct) **[bit14:0] TU14-0: Upper Limit Bits** These bits set the upper limit on the values that can be set in the baud rate generator register (BGR1,BGR0) for auto baud rate adjustment. Then, the baud rate generator register (BGR1, BGR0) is set to the value of the serial timer register (STMR).

2394	CHAPTER 38: LIN Interface (V2.1) 9. Interface (V2.1) Registers 9.19. FIFO Control Register 0 (FCR0)	Error) **[bit1] FE2: FIFO2 Operation Enable Bit** ■ When FIFO2 is specified as the transmission FIFO and "1" is written to this bit, transmission starts immediately if FIFO2 contains data and LIN interface (v2.1) transmission is enabled (SCR:TXE = 1). At this time, to set the TIE and TBIE bits to "1", first set them to "0" and write "1" to this bit, and then set the TIE and TBIE bits to "1". Correct) **[bit1] FE2: FIFO2 Operation Enable Bit** ■ When FIFO2 is specified as the transmission FIFO (FCR1:FSEL=1) and "1" is written to this bit, transmission starts immediately if FIFO2 contains data and LIN interface (v2.1) transmission is enabled (SCR:TXE = 1). At this time, to set the TIE and TBIE bits to "1", first set them to "0" and write "1" to this bit, and then set the TIE and TBIE bits to "1".
2396	CHAPTER 38: LIN Interface (V2.1) 9. Interface (V2.1) Registers 9.20. FIFO Byte Register (FBYTE)	Error) ■ The initial transfer count value for the FBYTE register is 0x08. Therefore, set 0x00 as the transfer count of the FBYTE to the transmission FIFO selected by the FSEL. ■ When both of the following conditions are satisfied, the continuation of the reception idle status for 8 baud rate clocks or longer sets the interrupt flag (RDRF) to "1". ☐ Reception FIFO idle detection enable bit (FRIIE) is "1". ☐ The number of data items in the reception FIFO does not reach the transfer count. During an 8-clock count, the counter is reset to 0 when RDR is read, and the system starts counting the 8 clocks again. The counter is reset to 0 when the reception FIFO is disabled. If the reception FIFO is enabled when data remains in the reception FIFO, counting restarts. Correct) ■ The initial transfer count value for the FBYTE register is 0x08. ■ When both of the following conditions are satisfied, the continuation of the reception idle status for 8 baud rate clocks or longer sets the interrupt flag (RDRF) to "1". − - Reception FIFO idle detection enable bit (FRIIE) is "1". − - The number of data items in the reception FIFO does not reach the transfer count. During an 8-clock count, the counter is reset to 0 when RDR is read, and the system starts counting the 8 clocks again. The counter is reset to 0 when the reception FIFO is disabled. If the reception FIFO is enabled when data remains in the reception FIFO, counting restarts. − The value of FBYTE of transmission FIFO is incremented by 1 when a transmission data is written to TDR 1 time. − The value of FBYTE of reception FIFO is decremented by 1 when a reception data is read from RDR 1 time.

2835 2836	CHAPTER 51: DDR High Speed SPI Controller 3. Serial Interface 3.4. SPI Data Learning Pattern	Added the below: The logic related to SDATA Sampling Points and DLP is illustrated as below. The internal flag is directly invisible from the CPU, however, its status is reflected to the Bus Error and the system can detect it. **Figure 3-5SDATA Sampling Points and Related Logics**  Notes: − Once having detected a DLP error, the following Memory Read access is affected as below. (1)When a DLP error occurs, it is held on the internal flag along DDRHSSPIn_FAULTF.DLPFS bit. (2)The software clears DLP-related flags (DDRHSSPIn_FAULTF.DLPFS and DDRHSSPIn_RXF.DLPERR) and adjusts the SDATA Sampling Points to proper values. (3)This internal flag affects the next Memory Read access depending on the address. *(a)Same word-line addresses: "Error"If ("new address" >> 2) = ("previous address" >> 2), the result is as below.-Bus Error on the System Bus-Internal flag = "1"-DDRHSSPIn_FAULTF.DLPFS = "1"-DDRHSSPIn_RXF.DLPERR = "0"-DDRHSSPIn_DLPSAMPLESTATUS = 0x00000000(b)Different word-line addresses: "Success"If ("new address" >> 2) ≠("previous address" >> 2), the result is as below.-No Bus Error on the System Bus-Internal flag = "0"-DDRHSSPIn_FAULTF.DLPFS = "0"-DDRHSSPIn_RXF.DLPERR = "0"-DDRHSSPIn_DLPSAMPLESTATUS 0x00000000Figure 3-6and Figure 3-7illustrate these cases (a) and (b). Each diagram depicts two consecutive Memory Read accesses -the first one failing to sample SDATA, and the second one with successful sampling. The address of the second access determines the result.* *− The proposed Calibration sequence is described in the section 4.4.4 "Using the DDRHSSPI in Command Sequencer Mode of Operation".* **Figure 3-6Memory Read accesses from "FAIL" to "PASS" ((a) Same Word-line)** 
Page	Section	Change Results
2837	CHAPTER 51: DDR High Speed SPI Controller 3. Serial Interface 3.4. SPI Data Learning Pattern	Added the below: **Figure 3-7Memory Read accesses from "FAIL" to "PASS" ((b) Different Word-line)** 2838	CHAPTER 51: DDR High Speed SPI Controller 3. Serial Interface 3.6. Shift Direction	Error) Figure 4-7 depicts the direction in which the data in the Shift Register is shifted to/from the serial data lines, under Quad Mode. The waveforms assume DDRHSSPIn_DMFIFOCFG.FWIDTH = 0b00. The Figures depict that the transmit data is loaded into the Shift Register from the TX-FIFO. However, the source of transmit data can be other registers, such as DDRHSSPIn_RDCSDC0-11.RDCSDATA. When DDRHSSPIn_MID.MID is 0x00000100 or 0x00000300, DDRHSSPI is available for Dual Legacy Mode and Dual Quad Mode. Figure 3-6 and Figure 3-7 depict the direction in which the data in the Shift Register is shifted to/from the serial data lines, under Dual Legacy Mode and Dual Quad Mode. Correct) The following figures Figure 4-7 depict the direction in which the data in the Shift Register is shifted to/from the serial data lines. The waveforms assume DDRHSSPIn_DMFIFOCFG.FWIDTH = 0b00 in Direct Mode. The Figures depict that the transmit data is loaded into the Shift Register from the TX-FIFO. However, the source of transmit data can be other registers, such as DDRHSSPIn_RDCSDC0-11.RDCSDATA. When DDRHSSPIn_MID.MID is 0x00000100 or 0x00000300, DDRHSSPI is available for Dual Legacy Mode and Dual Quad Mode. Figure 3-14 and Figure 3-15 depict the direction in which the data in the Shift Register is shifted to/from the serial data lines, under Dual Legacy Mode and Dual Quad Mode.

2850	CHAPTER 51: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.3. TX-FIFO Control	Error) **Table 4-1 Serial Data Output Control** The length of dummy cycles is limited as below. [Max Dummy Cycles] = [Bit number of 1 FIFO entry] / [1 Byte Time (cycle number)] For example, under the following conditions: − Quad Mode (by DDRHSSPIn_DMTRP.TRP[1:0]) − SDR data rate − number of dummy cycles is 4 − DDRHSSPIn_DMFIFOCFG.FWIDTH is 0b01 (16 bit-wide). In this example, the number of dummy cycle is within the limit. If the number of dummy cycles is larger than 4 in this example, the output serial data will be tri-stated for only 4 SCLK cycles and the rest will be ignored. In TX-and-RX Mode, data on the input port iDDRHSSPIn_SDATA is sampled along the output of oDDRHSSPIn_SDATA. The number of received byte data is calculated as below. [Rx Byte Count] = [Dummy Cycles] / [1 Byte Time (cycle number)] The number of dummy cycles shall be a multiple of 1 Byte Time. RX-FIFO is being filled also during the dummy cycles in TX-and-RX Mode, so the software needs to read RX-FIFO to remove these received data. Correct) **Table 4-1 Serial Data Output Control** The length of dummy cycles is limited as below. [Max Dummy Cycles] = [Bits per 1 FIFO entry] / [Bits per 1 SCLK cycle] For example, under the following conditions: − Quad Mode (by DDRHSSPIn_DMTRP.TRP[1:0]) − SDR data rate − number of dummy cycles is 4 − DDRHSSPIn_DMFIFOCFG.FWIDTH is 0b01 (16 bit-wide). In this example, the number of dummy cycle is within the limit. If the number of dummy cycles is larger than 4 in this example, the output serial data will be tri-stated for only 4 SCLK cycles and the rest will be ignored.
2852	CHAPTER 51: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.3. TX-FIFO Control	Added the below: (in the order of TXDATA[31:24]->[23:16] along the SCLK edge)

Page	Section	Change Results
2853	CHAPTER 51: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.4. Available Command Formats of Serial Flash Memory	Error) Note: − When in writing TXDATA[12:8] for SPI control on-the-fly, it is allowing regardless the setting of DDRHSSPIn_DMFIFOCFG.FWIDTH. The available command formats of Serial Flash are different according to the value of DDRHSSPIn_MID. MID. Correct) Note: − When in writing TXDATA[12:8] for SPI control on-the-fly, it is allowed regardless the setting of DDRHSSPIn_DMFIFOCFG.FWIDTH. The available command formats of Serial Flash are different according to the value of DDRHSSPIn_MID. MID bits.
2856	CHAPTER 51: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.5. FIFO Accesses in Direct Mode	Error) When in DDRHSSPIn_DMFIFOCFG.TXCTRL= 1, the setting of DDRHSSPIn_DMFIFOCFG.FWIDTH is ignored at writing into TX-FIFO, and up to 32 bits could be relevant. (please refer to the Table 4-1). Note: − In case that DDRHSSPI is configured in: − DDR Mode, AND − Dual Quad Mode setting DDRHSSPIn_DMFIFOCFG.FWIDTH to 0b00 (8-bit wide mode) is not allowed. Correct) When in DDRHSSPIn_DMFIFOCFG.TXCTRL= 1, the setting of DDRHSSPIn_DMFIFOCFG.FWIDTH is ignored at writing into TX-FIFO, and up to 32 bits could be relevant. (For details, please refer to the Table 4 1).
2856,2857	CHAPTER 51: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.6. Service Requests	Added the below: − The DDRHSSPIn_TXF.TFES is set if the DDRHSSPIn_DMFIFOSTATUS.TXFLEVEL is 0, i.e. TX-FIFO is empty. − The DDRHSSPIn_RXF.RFFS is set if the DDRHSSPIn_DMFIFOSTATUS.RXFLEVEL is 24, i.e. RX-FIFO is full.

Page	Section	Change Results
2857	CHAPTER 51: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.6. Service Requests	Error) Each of these counters is a 5 bits down counter, which is reloaded with the DMA Block size (for the respective channel) whenever the DMA Service Request for that channel is asserted. The counters are decremented with every successful read or write accesses to the RX-FIFO or TX-FIFO. In case of the RX-FIFO accesses, the RX Block Counter is decremented only if the access was from a System Bus master other than the DAP Controller. Correct) Each of these counters is a 5 bits down counter, which is reloaded with the DMA Block size (for the respective channel) each time the DMA Service Request for that channel is asserted. The counters are decremented with every successful read or write accesses to the RX-FIFO or TX-FIFO. In case of the RX-FIFO accesses, the RX Block Counter is decremented unless the access was from the DAP Controller.
2859	CHAPTER 51: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.7. SPI Transfers	Error) When the DDRHSSPI is working in Direct Mode, it can be interfaced with up to 4 Serial Flash Memories. Correct) When the DDRHSSPI is working in Direct Mode, it can be interfaced with up to 4 Serial Flash Memories at Legacy/Quad mode (8 at Dual Legacy/Dual Quad mode).
2860	CHAPTER 51: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.7. SPI Transfers	Deleted the below: Note: − When in TX-and-RX Mode, please avoid halting the serial transfer.

Page	Section	Change Results
2861	CHAPTER 51: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.2. Command Sequencer Mode	Error) Since the first SPI transaction is controlled under TX-Only Mode, the read data from the Serial Flash are ignored. Valid reading of Serial Flash is run at the Command Sequencer Mode. In memory reading, the bit width on the SPI from the address field should be constantly Quad. Correct) Since the first SPI transaction is controlled under TX-Only Mode, the read data from the Serial Flash are ignored in that transaction. Valid reading of Serial Flash is run at the Command Sequencer Mode. In memory reading, the bit width on the SPI from the address field should be constantly Quad (or Dual Quad).
2862	CHAPTER 51: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.2. Command Sequencer Mode	Error) Generation of 32-Bit Memory Address The Address Extension Mechanism allows the mapping of 256MB of the MCU address space to 4GB of address space on a Slave Select line. Every Serial Flash Memory can be visualized as entity, consisting of several memory banks. The size of each bank can be programmed in the DDRHSSPIn_CSCFG.MSEL. Each bank can be selected by changing the value in the DDRHSSPIn_CSAEXT Register. By reprogramming the DDRHSSPIn_CSAEXT Register, each time a new bank in the selected Serial Flash Memory is accessed. Through different banks, it is possible to address a Serial Flash Memory of up to 4GB size. Correct) Generation of 32-Bit Memory Address The Address Extension Mechanism allows the MCU to access each Serial Flash Memory of a size of 4GB. Each Serial Flash Memory is accessible by dividing into several memory banks. The size of each bank can be programmed in the DDRHSSPIn_CSCFG.MSEL. Each bank can be selected by changing the value in the DDRHSSPIn_CSAEXT Register. To select a new bank, the software shall program a new value to the DDRHSSPIn_CSAEXT Register. By switching banks, it is possible to address a Serial Flash Memory of 4GB size.

2863	CHAPTER 51: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI 4.2. Command Sequencer Mode	Error) **Figure 4-6 Addressing 4GB Serial Flash Memories on Each Slave Select, Through Different Banks (DDRHSSPIn_CSCFG.MSEL= 0b0000)**  Correct) **Figure 4-6 Addressing 4GB Serial Flash Memories on Each Slave Select, Through Different Banks (DDRHSSPIn_CSCFG.MSEL= 0b0000)** 
Page	Section	Change Results
2863	CHAPTER 51: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI 4.2. Command Sequencer Mode	Error) The Least Significant Bits of the System Bus Address received by the DDRHSSPI on the System Bus are used as the offset within the bank selected by the Address Extension bits. The concatenation of the appropriate number of bits from the Address Extension Register with the appropriate number of bits from the address bus, determine the 32-bit address of the memory to be accessed on the Serial Interface. Please refer to Table 4-5. Correct) The Least Significant Bits of the System Bus Address received by the DDRHSSPI on the System Bus are used as the offset within the bank selected by the Address Extension bits. The final 32-bit address on the SPI is generated by the following concatenation: − Upper bits: Register bits DDRHSSPIn_CSAEXT.AEXT[31:m] − Lower bits: Address on the System Bus[m-1:0] (m = DDRHSSPIn_CSCFG.MSEL[3:0] + 13.) For details, please refer to Table 4-5.

Page	Section	Change Results
2864	CHAPTER 51: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI 4.2. Command Sequencer Mode	Error) Last two columns in Table 4-5 indicate which bits from the DDRHSSPIn_CSAEXT.AEXT and the address bus (i.e. HADDR) are concatenated, to get the final 32-bit address of the Serial Flash Memory. Although, the final memory address generated in this way is a 32-bit address, it must be noted, that the software can choose the number of bytes (from this 32-bit address) to be sent to the Serial Flash Memory during the address phase of a memory read Command Sequence. Internal Prefetch Buffer In Command Sequencer Mode the DDRHSSPI internally has one Prefetch Buffer for temporary storage, of the data to be received (Prefetch Buffer). This Prefetch Buffer consists of 48 locations each 32-bit wide. Prefetch Buffer shall support 32 bits, 16 bits and 8 bits reads using the following mechanism: In generation of the Command Sequence the two least significant address bits shall be ignored. When a byte or halfword is read at a random (non-sequential) address, the Command Sequence shall be generated at the aligned word address which contains this byte or halfword. In any access scenario where the required data can be read from the top most position of the Prefetch Buffer, there will be no additional Command Sequence. When the Prefetch Buffer is read (as FIFO), only if the read includes the last byte within the actual Prefetch Buffer word, it will be popped. Following are typical read scenarios with explanation when the Prefetch Buffer pops: In order to obtain maximum throughput, 32-bit access is highly recommended. Correct) Last two columns in Table 4-5 indicate which bits from the DDRHSSPIn_CSAEXT.AEXT and the address bus (i.e. HADDR) are concatenated, to get the final 32-bit address of the Serial Flash Memory. The output memory address on the SPI can be 32 or 24 bits according to the Serial Flash Memory products, and this is controlled by the register settings of DDRHSSPIn_RDCSDC0-11 (for details, refer toTable 4-6). Internal Prefetch Buffer In Command Sequencer Mode the DDRHSSPI internally has one Prefetch Buffer for a temporary storage of received data. This Prefetch Buffer consists of 48 locations, 32-bit wide. Prefetch Buffer shall support 32 bits, 16 bits and 8 bits reads using the following mechanism: − When a byte or halfword is read at a random (non-sequential) address on the System Bus, the Command Sequence is generated with the address aligned to the word boundary, which covers the required data. − In the actual Command Sequence in transmission, the two least significant address bits are fixed to "00" (i.e. these two bits from the System Bus are ignored). As long as the software reads a series of continuous data from the top most position of the Prefetch Buffer, there will be no additional Command Sequence on the SPI. When the Prefetch Buffer is read, it internally works as a FIFO, and a word data in the next location pops out only when the current read data includes the last byte in the word line. The typical cases to pop the Prefetch Buffer are as below: In order to obtain the maximum throughput, word access (i.e. 32-bit access) is highly recommended.

Page	Section	Change Results
1642	CHAPTER 30: CAN FD Controller(MCAN3.2) 5. Registers	Add the below: **5.3. Data Bit Timing & Prescaler Register (MCG_CANFDx_DBTP,CPG_CANFDx_DBTP)** **[bit 20:16] DBPR[4:0] Data Bit Rate Prescaler.** Valid values for the Data Bit Rate Prescaler are 0 to 31. When DBTP.TDC = "1", the range is limited to 0, 1. This limitation is required by the ISO. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
1649	CHAPTER 30: CAN FD Controller(MCAN3.2) 5. Registers	Add the below: **5.6. CC Control Register (MCG_CANFDx_CCCR, CPG_CANFDx_CCCR)** **[bit6] DAR: Disable Automatic Retransmission** *Note:* − When CCCR.DAR is set "1", always set "00" to first two identifier (Arbitration field) bits on transmission frame configuration.
1687	CHAPTER 30: CAN FD Controller(MCAN3.2) 5. Registers	Add the below: **5.23. High Priority Message Status (MCG_CANFDx_HPMS, CPG_CANFDx_HPMS)** *Note:* − If all the following conditions are fulfilled, set at least 1 to both List Size Standard (SIDFC.LSS[7:0]) and List Size Extended (XIDFC.LSE[6:0]). − To use high priority events − To use both standard and extended frame format
1704	CHAPTER 30: CAN FD Controller(MCAN3.2) 5. Registers	Add the below: **5.34. Tx Buffer Configuration (MCG_CANFDx_TXBC, CPG_CANFDx_TXBC)** *Notes:* − Don't use combination Tx FIFO and Dedicated Tx Buffers. In case of setting "1" to Tx FIFO/Queue Mode (TXBC.TFQM), set 0 to TXBC.NDTB[5:0]

2885	CHAPTER 51: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI	Deleted the Below: **4.4. General Use Case Guidelines for DDRHSSPI** 4.4.5. Notice On Document Designations Cypress issues documents and data sheets with Advance Information or Preliminary designations to advise readers of product information or intended specifications throughout the product life cycle,including development, qualification, initial production, and full production. In all cases, however, readers are encouraged to verify that they have the latest information before finalizing their design. The following descriptions of Cypress data sheet designations are presented here to highlight their presence and definitions 4.4.6. Advance Information The Advance Information designation indicates that Cypress Semiconductor Corp. is developing one or more specific products, but has not committed any design to production. Information presented in a document with this designation is likely to change, and in some cases, development on the product may discontinue. Cypress Semiconductor Corp. therefore places the following conditions upon Advance Information content: This document contains information on one or more products under development at Cypress Semiconductor Corp. The information is intended to help you evaluate this product. Do not design in this product without contacting the Cypress Semiconductor Corp. Cypress Semiconductor Corp. reserves the right to change or discontinue work on this proposed product without notice.
002-07884 Rev. *E		
32	CHAPTER 1: Platform Overview	Revised the shading parts as below: Error) B/B is a latest effort of the MCU platform which targets instrument cluster, graphics controller, gateway and body controller application area. Correct) B/B is the MCU platform which targets instrument cluster, graphics controller, gateway and body controller application area.
		Removed the shading parts as below: Error) To minimize design efforts of the target MCU, B/B offers rich and competitive feature sets like power saving features and IP portfolio, easy-to-use parameter option to select them, and verification suite which proves its quality.

Page	Section	Change Results
		Revised the shading parts as below: ■ Computation features Error) Cortex-R5F single core, 16K I-Cache. Program Flash I/F which have advanced speculative prefetching algorithm. Correct) Cortex-R5F single core, 16K I-Cache. Main Flash I/F which have advanced speculative prefetching algorithm.

188, 189	CHAPTER 5: Clock System 3. Operations 3.4. Clock Gear	Added the shading parts as below: Error) Clock Gear Control Gear clock is output from clock gear circuit. The frequency of gear clock is gradually changed by the step-by-step outputting of the input clock. Gear clock is controlled the following configuration. ■ Start step configuration ■ Step loop configuration ■ Step width configuration Correct) Clock Gear Control Gear clock is output from clock gear circuit. The frequency of gear clock is gradually changed by the step-by-step outputting of the input clock. Gear clock is controlled the following configuration. ■ Start step configuration − Setting to select the range ("START STEP" to STEP 63) during Gear operation that defined by Start Step configuration (xxxCGSSN). − It is selectable from STEP 0 to 63. − At Gear Up, the Gear operation starts from the selected STEP 'n' and stops at STEP 63. (Refer to Step Width Configuration for the increment width of 'n' after 1 step operation.) − At Gear Down, the Gear operation starts from STEP 63 and stops at STEP 'n' the selected. (Refer to Step Width Configuration for the decrement width of 'n' after 1 step operation.) ■ Step loop configuration − STEP: − Loop that is repeated a defined number of times when the Loop configuration(xxxCGLP). − It is configurable from 1 to 256 loops. − 1 step is xxxCGLP <loop> = xxxCGLP x 64 <cycle>. − LOOP: − The minimum operation unit that configurates gear operation. − 1 Loop fixed at 64 <cycle>. ■ Step width configuration − The width defined by Step Width configration (xxxCGSTP) which "n" of STEP "n" is increment / decrement (when Gear Up / Gear Down) after 1 STEP execution. − Step width can be set to 1 to 4. − At Gear Up, the width to increment 'n' after 1 step of STEP 'n'. (In the case of Width = 2, STEP 0, STEP 2, STEP 4 ...). − At Gear Down, the width to decrement 'n' after 1 step of STEP 'n'. (In the case of Width 4, STEP 63, STEP 59, STEP 55 ...)

Page	Section	Change Results
		Added the shading parts as below: ■ Step width configuration Correct) **Note:** STEP 0 to 63: STEP 0 to 63: Clock output patterns of Gear operation. As the number of step increases, the clock output increases. STEP 0 to 1: clock/loop STEP 1 to 2: clock/loop : : : STEP 63 to 64 clock/loop (Clock output for all cycles in loop) # Refer to Figure 3-1 for details pattern. The length of STEP 0 to 63 (the number of Loop repetitions) is determined by the setting of STEP (xxxCGLP x 64 <cycle>).

Notes:
− Protection is applied to the SYSC register. To write to the register, the protection key must first be released. Invalid written data is discarded. The following shows an example of the procedure for accessing the SYSC register.
1. The accessing master releases the protection key.
2. The master that released the protection key writes to the SYSC register.
3. The hardware enables the protection key.
Repeat steps 1 to 3 until completing the required settings.
− The following shows protection effective conditions.
1. The protection target register was write-accessed from the master that released the protection key.
2. The protection target register was write-accessed from anything other than the master that released the protection key.

Correct)
Notes:
− Protection is applied to the SYSC register. To write to the register, the protection key must first be unlocked. Invalid written data is discarded. The following shows an example of the procedure for accessing the SYSC register.
1. The accessing master unlocks the protection key.
2. The master that unlocked the protection key writes to the SYSC register.
3. The hardware locks the protection key.
Repeat steps 1 to 3 until completing the required settings.
− The following shows protection effective conditions.
1. The protection target register was write-accessed from the master that unlocked the protection key.
2. The protection target register was write-accessed from anything other than the master that unlocked the protection key.</td></tr>

Address/Sector Map of TCFLASH	Removed the shading parts as below: **Figure 2-3 Position of TCFLASH on the Memory Map** Error) The size of the TCM region for each TCFLASH is 8 MB. The size of the AXI region is 16 MB. The sector placement for the respective region is shown in Table 2-1. Note that at FPP mode, the flash macros are reached via the AXI region for TCFLASH #0 and TCFLASH #1. Correct) The size of the TCM region for each TCFLASH is 8 MB. The size of the AXI region is 16 MB. The sector placement for the respective region is shown in Table 2-1.
980	CHAPTER 17: TCFLASH 3. Explanation of Operation 3.2. Programming and Erasing	Added the shading parts as below: Correct) ■ After erase operation completed, all the values of the flash memory cells in the target sectors are "1".
994	CHAPTER 17:TCFLASH 3. Explanation of Operation 3.9. Interrupt	Removed the shading parts as below: Correct) ■ When a hang-up state is detected When a timeout is detected during the execution of an automatic algorithm, etc., the hang-up state is detected, causing the HANGINT bit in the TCFCFGn_FSTAT register to show "1". In this case, if the HANGIE bit of the TCFCFGn_FICTRL register is "1", TCFLASH generates an interrupt request.

4. Registers
4.1. Security Status Register (TCFCFG0_SECSTAT)</td><td>
Revised the shading parts as below:

Error)

[bit31:20] Reserved: Reserved bits
These bits are not used. Writing has no effect.

Correct)

[bit31:18] Reserved: Reserved bits
These bits are not used. Writing has no effect.

Removed the shading parts as below:

[bit19] TBOSEC: ECC single error correction in TBO data (UID and configuration options)

<table>
<tr><th>Bit</th><th>Description</th></tr>
<tr><td>0</td><td>No correctable error was detected in the TBO data.</td></tr>
<tr><td>1</td><td>A correctable error was detected in the TBO data.</td></tr>
</table>

The register bit TBOSEC indicates that there was a correctable error detected in the traceability data (FUIDR). The bit could be used to check for reliable UID is stored in Flash.
The integrity of the TBO data from Flash is ensured, when this bit can be read back as 0.

[bit18] TBODED: ECC double error detection in TBO data (UID and configuration options)

<table>
<tr><th>Bit</th><th>Description</th></tr>
<tr><td>0</td><td>No fatal error was detected in the TBO data.</td></tr>
<tr><td>1</td><td>A fatal error was detected in the TBO data.</td></tr>
</table>

The register bit TBODED indicates that there was a fatal error in the traceability data (FUIDR). The bit could be used to check for reliable UID is stored.
The integrity of the TCFCFG_FUIDR0 to 7 is ensured, when this bit can be read back as 0.
Notes:
– In case both bits TBOSEC and TBODED are showing both 0, then there is no ECC error occurred in the TBO data of Flash.
– In case of an error detected either TBOSEC or TBODED is set to 1, depending on the type of error

<tr><td>1498</td><td>CHAPTER 27:DMA Controller 4. Register 4.8. DMA Controller Channel Configuration B Register Channel 'n' (DMAi_Bn)</td><td>Added the shading parts as below;

Correct)

[bit15:12] SP[3:0] : Source protection

Note:
– Configuration of SP[3] and SP[2] has no effect.

[bit11:8] DP[3:0] : Destination protection

Note:
– Configuration of DP[3] has an effect.
– DP[3]=1: Posted write buffer in HPM is used. Due to the posted write behavior, DMA cannot trap the error returned from the destination even if there is an error in the write access (e.g.: The destination register/memory requires Privilege level for writing, but DP[1] is "0").
– DP[3]=0: Posted write buffer in HPM is unused. DMA always traps the error when there is an error in the write access. (DMAi_Bn:EQ)
– Configuration of DP[2] has no effect.</td></tr>

1680	CHAPTER 30: CAN FD Controller(MCAN3.2) 5.15. Interrupt Register (MCG_CANFDx_IR, CPG_CANFDx_IR)	Revised the shading parts as below: [bit17] MRAF: Message RAM Access Failure Error) In both cases the Rx FIFO put index is not updated resp. the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location. Correct) The data of a received frame may be incompletely stored to the Message RAM after the flag is set by the Rx Handler operation. In addition, Rx FIFO 0 Status (RXF0S), Rx FIFO 1 Status (RXF1S), or New Data 1/2 (NDAT1/2) is also updated according as the storage location (Rx FIFO0, Rx FIFO1, or an Rx Buffer). Therefore, in this case discard the received frame data.
1680	CHAPTER 30: CAN FD Controller(MCAN3.2) 5.15. Interrupt Register (MCG_CANFDx_IR, CPG_CANFDx_IR)	Removed the shading parts as below: Note: - The data of a received frame may be incompletely stored to the Message RAM after the flag is set by the Rx Handler operation. In addition, Rx FIFO 0 Status (RXF0S), Rx FIFO 1 Status (RXF1S), or New Data 1/2 (NDAT1/2) is also updated according as the storage location (Rx FIFO0, Rx FIFO1, or an Rx Buffer). Therefore, in this case discard the received frame data.
1823	CHAPTER 35:UART (Asynchronous Serial Interface)	Removed the shading parts as below: Correct) ***Note:*** *- ACK Mode of Block Transfer is not supported for this device.*

Page	Section	Change Results
1825	CHAPTER 35:UART (Asynchronous Serial Interface) 1. Overview of the UART (Asynchronous Serial Interface)	Added the shading parts as below: Correct) **Interrupt request and DMA request** ■ Interrupt request of this module can be used for purposes below: 1. Interrupt request to CPU (via Interrupt Controller) 2. DMA request to DMA Controller ■ To use the interrupt as interrupt request to CPU, following configuration is necessary: – Enable the interrupt request in this module – Enable the interrupt channel of the interrupt in Interrupt Controller ■ To use the interrupt as DMA request to DMA Controller, following configuration is necessary: – Enable the interrupt request in this module – Select the DMA channel from this module as DMA client in DMA Controller ***Note:*** – *Interrupt request that supports for DMA request is product specification. Please refer to the product's HWM for detail.*
1860	CHAPTER 35:UART (Asynchronous Serial Interface) 7. Block Transfer	Revised the shading parts as below: Error) Block transfer can be performed in that mode in which it is operated with the acknowledgment standard (ACK mode) and in that mode in which it is operated with the READ/WRITE access standard (RW access mode). Correct) Block transfer can be performed in that mode in which it is operated with the READ/WRITE access standard (RW access mode).
		Removed the shading parts as below: Error) ***Note:*** *- ACK Mode of Block Transfer is not supported for this device.*
1861, 1862, 1863, 1864	CHAPTER 35: UART (Asynchronous Serial Interface) 7.1. ACK Mode	Removed the shading section as below: Error) **7.1. ACK Mode**

Page	Section	Change Results
1861	CHAPTER 35: UART (Asynchronous Serial Interface) 7.1. RW Access Mode	Revised the shading parts as below: Error) 7.2. RW Access mode Correct) 7.1. RW Access mode
1861	CHAPTER 35: UART (Asynchronous Serial Interface) 7.1. RW Access Mode	Added the shading parts as below: Correct) During application operation, if the next block transfer request occurs before the completion of the previous block transfer, this state might be reported to the system by a block transfer error. This state does not occur if you configure FBYTE=1. Completion of block transfer by DMA depends on occupation of bus transaction by application. You need to fully evaluate the application integrally, design the system, and choose the optimal number of block transfers.

Page	Section	Change Results
1861	CHAPTER 35: UART (Asynchronous Serial Interface) 7.1. RW Access Mode	Revised the shading parts as below: Figure 7.1 Reception Block Transfer in RW Access Mode Error)  Correct) 1878	CHAPTER 35:UART (Asynchronous Serial Interface) 10.2. Serial Mode Register (SMR)	Added the shading parts as below: Correct) **[bit4] WUCR: WAKE UP Control Bit** WUCR is not supported. This bit selects the pin to be used for external interrupts.

Page	Section	Change Results
1906	CHAPTER 35:UART (Asynchronous Serial Interface) 10.13. FIFO Byte Register (FBYTE)	Removed the shading parts as below: Table 10-4 Data Count Stored in FIFO Error) Note: - Set reception FIFO FBYTE to “2” or a larger value when block transfer. At other conditions, set "1" or a larger value in the FBYTE for the reception FIFO.
1924	CHAPTER 36: CSIO (Clock Synchronous Serial Interface)	Removed the shading parts as below: Error) ***Note:*** *- ACK Mode of Block Transfer is not supported for this device.*
2008	CHAPTER 36: CSIO (Clock Synchronous Serial Interface) 8. Block Transfer	Revised the shading parts as below: Error) Block transfer can be performed in that mode in which it is operated with the acknowledgment standard (ACK mode) and in that mode in which it is operated with the READ/WRITE access standard (RW access mode). Correct) Block transfer can be performed in that mode in which it is operated with the READ/WRITE access standard (RW access mode).
		Removed the shading parts as below: Error) ***Note:*** *- ACK Mode of Block Transfer is not supported for this device.*
2009, 2010, 2011, 2012	CHAPTER 36: CSIO (Clock Synchronous Serial Interface) 8.1. ACK Mode	Removed the shading section as below: Error) **8.1. ACK Mode**

Page	Section	Change Results
2009	CHAPTER 36: CSIO (Clock Synchronous Serial Interface) 8.1. RW Access Mode	Revised the shading parts as below: Error) 8.2. RW Access mode Correct) 8.1. RW Access mode
2009	CHAPTER 36: CSIO (Clock Synchronous Serial Interface) 8.1. RW Access Mode	Added the shading parts as below: Correct) During application operation, if the next block transfer request occurs before the completion of the previous block transfer, this state might be reported to the system by a block transfer error. This state does not occur if you configure FBYTE=1. Completion of block transfer by DMA depends on occupation of bus transaction by application. You need to fully evaluate the application integrally, design the system, and choose the optimal number of block transfers.

Page	Section	Change Results
2009	CHAPTER 36: CSIO (Clock Synchronous Serial Interface) 8.1. RW Access Mode	Revised the shading parts as below: Figure 8-1 Reception Block Transfer in RW Access Mode Error)  Correct) 2019	CHAPTER 36:CSIO (Clock Synchronous Serial Interface 9.2. Serial Mode Register (SMR)	Added the shading parts as below: **[bit4] WUCR: WAKE UP Control Bit** Correct) WUCR is not supported. This bit selects the pin to be used for external interrupts

Page	Section	Change Results
2022	CHAPTER 36:CSIO (Clock Synchronous Serial Interface 9.3. Serial Status Register (SSR)	Added the shading parts as below: **[bit12] Access width Control Bit** Correct) ***Notes:*** – *Change this bit only when transmission and reception are disabled (SCR:TXE = RXE = 0) and TDR and RDR are empty (SSR:TDRE = 1, SSR:RDRF = 0).* – *If the data length is 20, 24, or 32 bits, set "1" in this bit.* – *If the data length is 8 bits or less, the TDR and RDR registers can be byte-accessed.*

<tr><td>2060</td><td>CHAPTER 36:CSIO (Clock Synchronous Serial Interface)

9. Registers of the CSIO (Clock Synchronous Serial Interface)
9.14. FIFO Control Register 1 (FCR1)</td><td>
Revised the shading parts as below:

[bit10] FDRQ: Transmission FIFO Data Request Bit

Error)
FDRQ set conditions
■When transmission FIFO interrupt control is not used
– FBYTE (for transmission) = 0 (Transmission FIFO is empty.)
– Reset of the transmission FIFO
■When transmission FIFO interrupt control is used
– For ECR:TXBLKEN=0
– FTICR setting value ≥ FTICR read value (The amount of data in the transmission FIFO is at the interrupt trigger level or lower.)
– For ECR:TXBLKEN=1
– FTICR setting value ≦ number of vacant data items in the transmission FIFO
– Reset of the transmission FIFO

FDRQ reset conditions
■"1" is written to FCR1C:FDRQC.
■For ECR:TXBLKEN = 0
– The transmission FIFO is full.
■ For ECR:TXBLKEN = 1
– FTICR setting value ≥ number of vacant data items in the transmission FIFO

Correct)
ECR.TXBLKEN=0
<table>
<tr><th></th><th>FTICR=0</th><th>FTICR>0</th></tr>
<tr><td>Setting FDRQ</td><td>If transmission FIFO is empty</td><td>FTICR ≧ the number of valid data of transmitting FIFO</td></tr>
<tr><td>Clearing FDRQ</td><td>If transmission FIFO is full</td><td>If transmitting FIFO is full.</td></tr>
</table>

ECR.TXBLKEN=1
<table>
<tr><th></th><th>FTICR=0</th><th>FTICR>0</th></tr>
<tr><td>Setting FDRQ</td><td>If transmission FIFO is empty</td><td>FTICR ≦ empty data of transmitting FIFO</td></tr>
<tr><td>Clearing FDRQ</td><td>If transmission FIFO is full</td><td>FTICR > empty data of transmitting FIFO</td></tr>
</table>

Regardless of the setting value of ECR.TXBLKEN, the FDRQ bit is cleared by writing "1" to the FCR1C.FDRQC bit.
Regardless of the setting value of ECR.TXBLKEN, the FDRQ bit is set by resetting the transmission FIFO.
</td></tr>
</table>

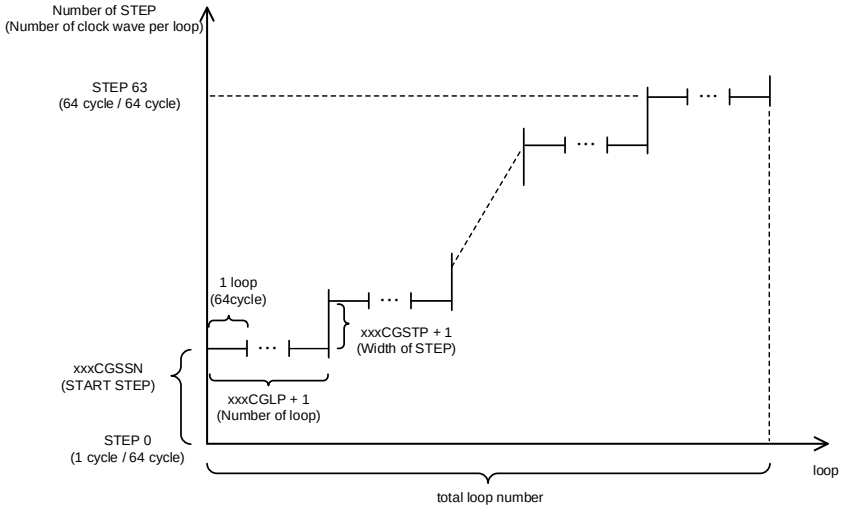
172	CHAPTER 5: Clock System 2.3. Clock Distributor Configuration and Block Diagram	Replaced the figure as below: **Figure 2-5 Clock domain0 Block Diagram** Error) ■ **Default_Type**  Correct) ■ **Default_Type** 
Page	Section	Change Results
173	CHAPTER 5: Clock System 2.3. Clock Distributor Configuration and Block Diagram	Replaced the figure as below: **Figure 2-5 Clock domain0 Block Diagram** Error) ■ **LP_Type**  Correct) ■ **LP_Type** 
Page	Section	Change Results
188	CHAPTER 5: Clock System 3.4. Clock Gear	Revised the shading parts as below: ***Note:*** Error) *STEP 0 to 63:* *STEP 0 to 63: Clock output patterns of Gear operation.* *As the number of step increases, the clock output increases.* *STEP 0 to 1: clock/loop* *STEP 1 to 2: clock/loop* *:* *:* *:* *STEP 63 to 64 clock/loop (Clock output for all cycles in loop)* Correct) *STEP 0 to 63: Clock output patterns of Gear operation.* *As the number of step increases, the clock output increases.* *STEP 0 : 1 clock/loop* *STEP 1 : 2 clock/loop* *:* *:* *:* *STEP 63 : 64 clock/loop (Clock output for all cycles in loop)*

Page	Section	Change Results
190	CHAPTER 5: Clock System 3.4. Clock Gear	Added Figure 3-2 and Figure 3-3. Correct) Figure.3-2(Gear Up) and Figure.3-3(Gear Down) show the relationship between the register configuration and the Clock Gear STEP.

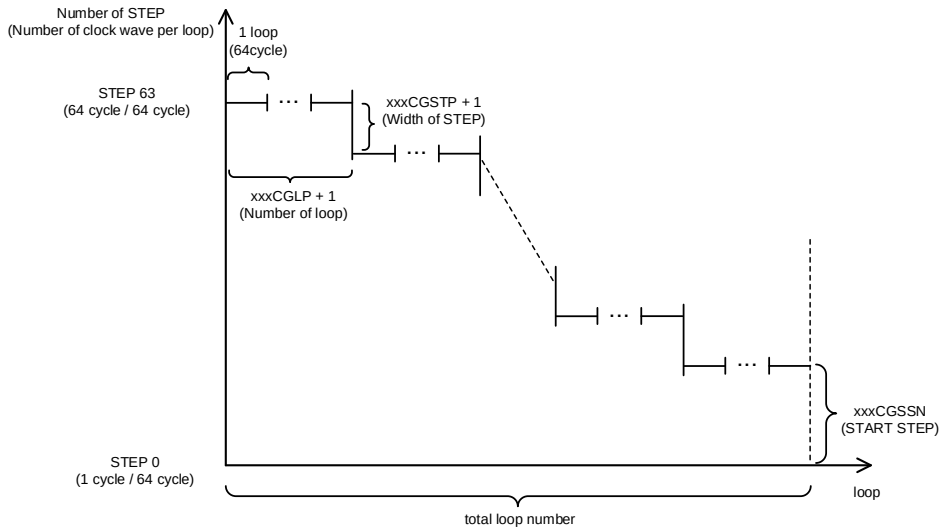
Figure 3-2 Clock Gear STEP by register configuration (Gear Up)



Transition time of clock gear = total loop number * 64cycle * (PLL or SSCG period)
= (xxxCGLP + 1) * (64 − xxxCGSSN) / (xxxCGSTP + 1) * 64cycle * (PLL or SSCG period)

Note: The number is rounded up after the decimal point in "(64 − xxxCGSSN) / (xxxCGSTP + 1)".

Figure 3-3 Clock Gear STEP by register configuration (Gear Down)



Transition time of clock gear = Same as gear up (Figure.3-2)

277	CHAPTER 6: Low-power Consumption 4.2. Transition from RUN to PSS	Revised the shading parts as below: Error) The following example explains an operation procedure for the transition of each CPU to PSS. Correct) The following example explains an operation procedure for the transition to PSS.
277	CHAPTER 6: Low-power Consumption 4.2. Transition from RUN to PSS	Revised the shading parts as below: Error) 5. The circuit sets the PSS profile setting state of each CPU (SYSC0_SYSSTSR:PSSSTS0) to "0" and the PSS profile completion flag of each CPU (SYSC0_SYSSTSR:PSSDF0) "1". Correct) 5. The circuit sets the PSS profile setting state (SYSC0_SYSSTSR:PSSSTS0) to "0" and the PSS profile completion flag (SYSC0_SYSSTSR:PSSDF0) "1".
277	CHAPTER 6: Low-power Consumption 4.2. Transition from RUN to PSS	Revised the shading parts as below: ***Notes:*** Error) − *To disconnect the power of PD2, enable the HOLD data latch setting bit. If you do not set it, I/O state can not be retained.* Correct) − *To turn OFF PD2, enable the HOLD data latch setting bit. If you do not set it, I/O state can not be retained.*
282	CHAPTER 6: Low-power Consumption 4.3. Transition from PSS to RUN	Revised the shading parts as below: Error) The following example shows a procedure that returns all CPUs from PSS to RUN. Correct) The following example shows a procedure that returns the CPU from PSS to RUN.

Page	Section	Change Results
282	CHAPTER 6: Low-power Consumption 4.3. Transition from PSS to RUN	Revised the shading parts as below: Error) 1. Generate a return factor. After the control circuit recognizes the return factor, the CPUs start to return. Correct) 1. Generate a return factor. After the control circuit recognizes the return factor, the CPU starts to return.
282	CHAPTER 6: Low-power Consumption 4.3. Transition from PSS to RUN	Revised the shading parts as below: Error) 2. If the high-speed CR clock has stopped, the CPUs wait for oscillation of the high-speed CR clock to stabilize. Correct) 2. If the high-speed CR clock has stopped, the CPU waits for oscillation of the high-speed CR clock to stabilize.
282	CHAPTER 6: Low-power Consumption 4.3. Transition from PSS to RUN	Revised the shading parts as below: Error) 4. When the RUN profile contents have no problem, the control circuit reflects the profile contents as follows. : 3. … …The circuit sets the RUN profile setting state (SYSC0_SYSSTSR:RUNSTS(product specification)) of each CPU to "0". Correct) 4. When the RUN profile contents have no problem, the control circuit reflects the profile contents as follows. : 3. … …The circuit sets the RUN profile setting state (SYSC0_SYSSTSR:RUNSTS(product specification)) to "0"

Page	Section	Change Results
282	CHAPTER 6: Low-power Consumption 4.3. Transition from PSS to RUN	Revised the shading parts as below: Error) 5. CPUs wait for Flash macro to stabilize from DeepStandby release. Stabilize wait time will occur for regulator if mode change occurs. Correct) 5. The CPU waits for the Flash macro to stabilize from DeepStandby release. Stabilize wait time will occur for the regulator if mode change occurs.
282	CHAPTER 6: Low-power Consumption 4.3. Transition from PSS to RUN	Revised the shading parts as below: Error) 6. There is a transition to RUN, and the CPUs start program operations. Correct) 6. There is a transition to RUN, and the CPU starts program operations.
282	CHAPTER 6: Low-power Consumption 4.3. Transition from PSS to RUN	Revised the shading parts as below: ***Notes:*** Error) − If the power domain 6 is turned OFF in PSS mode, it is prohibited that PLL/SSCG oscillation allowed. After the power domain 6 is turn ON in RUN mode, it please allowed PLL/SSCG oscillation in RUN profile updating. Correct) − If the power domain 6 is turned OFF in PSS mode, it is prohibited that PLL/SSCG oscillation enabled. After the power domain 6 is turn ON in RUN mode, it is allowed PLL/SSCG oscillation in RUN profile updating.
561	CHAPTER 6: Low-power Consumption 6.1. Restrictions on Transitioning to the PSS	Revised the shading parts as below: Error) When transitioning to the PSS, create a 1:1:1:1 relationship among the CPU clock, the Memory Configuration clock, the SCU clock, and the MCUCH clock. The loss of this relationship among these clocks may cause abnormal operation. Correct) When transitioning to the PSS, create a 1:1:1:1 relationship among the CPU clock (CLK_CPU), the Memory Configuration clock (CLK_MEMC), the SCU clock (Fast CR clock), and the MCUCH clock (CLK_SYSC0H) in PSS profile. The loss of this relationship among these clocks may cause abnormal operation.

Page	Section	Change Results
1604	CHAPTER 30: CAN FD Controller(MCAN3.2) 3.5: Tx Handling 3.5.2. Dedicated Tx Buffers	Added the shading parts as below: Correct) Dedicated Tx Buffers are intended for message transmission under complete control of the CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first. These Tx buffers shall be requested in ascending order with the lowest buffer number first. Alternatively all Tx buffers configured with the same Message ID can be requested simultaneously by a single write access to TXBAR.
1605	CHAPTER 30: CAN FD Controller(MCAN3.2) 3.5: Tx Handling 3.5.4. Tx Queue	Revised the shading parts as below: Error) Tx Queue operation is configured by programming the Tx FIFO/Queue Mode bit TXBC.TFQM to "1". Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first. Correct) Tx Queue operation is configured by programming the Tx FIFO/Queue Mode bit TXBC.TFQM to "1". Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). If multiple Tx Queue buffers are configured with the same Message ID, the transmission order depends on the numbers of the buffers where the messages were stored for transmission. As these buffer numbers depend on the then current states of the PUT index, a prediction of the transmission order is not possible.
1605	CHAPTER 30: CAN FD Controller(MCAN3.2) 3.5: Tx Handling 3.5.4. Tx Queue	Revised the shading parts as below: Error) **Adding Messages and Requesting Transmissions** New messages have to be written to the Tx Buffer referenced by the Tx FIFO/Queue Put Index TXFQS.TFQPI[4:0]. An Add Request cyclically increments the Put Index to the next free Tx Buffer. Correct) **Adding Messages and Requesting Transmissions** New messages have to be written to the Tx Buffer referenced by the Tx FIFO/Queue Put Index TXFQS.TFQPI[4:0]. The Put Index always points to that free buffer of the Tx Queue with the lowest buffer number.

Page	Section	Change Results
1791	CHAPTER 33: CAN Prescaler 5. Registers 5.1. CAN Prescaler Control Register (CANP_CTR)	Added the shading parts as below: Correct) ■ **Default_type:** − Note that the PLL clock is derived after the PLL(product specification)DIVM divider. Choose the CANP division accordingly and update it in case PLL(product specification)DIVM changes.

Revision History

Document Revision History

Document Title: 32-Bit Microcontroller TRAVEO™ T1G Family S6J33xx, S6J34xx, S6J35xx Series Hardware Manual Platform Part Document Number: 002-07884		
Revision	ECN No.	Description of Change
**	-	New Specification
*A	5035764	Added the specification of the Low Power Version, “LP Type”. Fixed some clerical errors. For details, please see the chapter 55 of Appendix: Major Changes.
*B	5390567	Fixed critical errors.
*C	5754652	Updated. Please refer to “Major Changes” about change points.
*D	5952391	Updated. Please refer to “Major Changes” about change points.
*E	6741175	Updated. Please refer to “Major Changes” about change points.
*F	6825029	Updated. Please refer to “Major Changes” about change points.
*G	7589161	Updated. Please refer to “Major Changes” about change points.
