CHAPTER7: Low-voltage Detection 1.Overview 1.1.Features	The function should be deleted as indicated by the shading below. (Error) 3.3/5.0 V power supply low-voltage detection This section explains the features of 3.3/5.0 V power supply low-voltage detection. The 3.3/5.0 V power supply low-voltage detection circuit has two channels. ■Function: A 3.3/5.0 V power supply low-voltage detection reset or interrupt is generated upon the detection of a voltage within plus or minus the detection error value in volts from the preset detection voltage. ■Preset detection voltage: Detection voltage:2.35V±0.15V Release voltage:2.45V±0.15V Detection voltage:2.75V±0.15V Release voltage:2.85V±0.15V Detection voltage:2.85V±0.15V Release voltage:2.95V±0.15V Detection voltage:3.6V±0.2V Release voltage:3.7V±0.2V Detection voltage:3.8V±0.2V Release voltage:3.9V±0.2V Detection voltage:4.0V±0.2V Release voltage:4.1V±0.2V Detection voltage:4.2V±0.2V Release voltage:4.3V±0.2V Detection voltage:4.4V±0.2V Release voltage:4.5V±0.2V Detection voltage:4.65V±0.25V Release voltage:4.75V±0.25V ■Operation: Operation can be switched between the active and inactive states by user settings. The selection to generate an interrupt or reset is also available. Furthermore, the settings for RUN/PSS can be switched using a profile. In the case where a reset is generated, the reset is issued after all clocks are stopped in order to guarantee the RAM contents after an external low-voltage detection reset. For details, see the chapter "RESET." (Correct) 3.3/5.0 V power supply low-voltage detection This section explains the features of 3.3/5.0 V power supply low-voltage detection. The 3.3/5.0 V power supply low-voltage detection circuit has two channels. ■Function: A 3.3/5.0 V power supply low-voltage detection reset or interrupt is generated upon the detection of a voltage within plus or minus the detection error value in volts from the preset detection voltage. ■Operation: Operation can be switched between the active and inactive states by user settings. The selection to generate an interrupt or reset is also available. Furthermore, the settings for RUN/PSS can be switched using a profile. CHAPTER12: Backup RAM Interface 3.Explanation of Operation 3.3. RAM Initialization	Features of "For details" should be corrected as indicated by the shading below. (Error) This is specified by the ITYP bit in the TEST initialization function register (BURIF_TICR). The value corresponding to the write value is written in the ECC area. The scope of RAM initialization is specified by the TEST start address register (BURIF_TASAR) and the TEST end address register (BURIF_TAEAR). RAM diagnosis must be performed by applying the following procedure. 1.Before starting diagnosis, read TRUN in the TEST diagnosis function register (BURIF_TTCR) and IRUN in the TEST initialization function register (BURIF_TICR) to confirm that their values are "0". If BURIF_TTCR.TRUN or BURIF_TICR.IRUN is not "0": −Wait until BURIF_TTCR.TRUN = 0, and then clear BURIF_TTCR.TCI. −Wait until BURIF_TICR.IRUN = 0, and then clear BURIF_TICR.ICI. 2.Write to the TEST key code control register (BURIF_TKCCR) 4 times consecutively in the order of "01h", "41h", "81h", and then "C1h" to start the diagnosis. When RAM initialization ends, the IRUN bit in the TEST initialization function register (BURIF_TICR) goes to "0" and RAM initialization ends. RAM initialization is forcibly terminated by writing 4 times consecutively in the order of "00h", "40h", "80h", and then "C0h" in the TEST key code control register (BURIF_TKCCR). The RAM initialization is terminated even if it has not yet been completed. In this case, the initialization result is not guaranteed. (Correct) This is specified by the ITYP bit in the TEST initialization function register (BURIF_TICR). The value corresponding to the write value is written in the ECC area. The scope of RAM initialization is specified by the TEST start address register (BURIF_TASAR) and the TEST end address register (BURIF_TAEAR). RAM initialization must be performed by applying the following procedure. 1.Before starting initialization, read TRUN in the TEST diagnosis function register (BURIF_TTCR) and IRUN in the TEST initialization function register (BURIF_TICR) to confirm that their values are "0". If BURIF_TTCR.TRUN or BURIF_TICR.IRUN is not "0": −Wait until BURIF_TTCR.TRUN = 0, and then clear BURIF_TTCR.TCI. −Wait until BURIF_TICR.IRUN = 0, and then clear BURIF_TICR.ICI. 2.Write to the TEST key code control register (BURIF_TKCCR) 4 times consecutively in the order of "01h", "41h", "81h", and then "C1h" to start the initialization. When RAM initialization ends, the IRUN bit in the TEST initialization function register (BURIF_TICR) goes to "0" and RAM initialization ends. RAM initialization is forcibly terminated by writing 4 times consecutively in the order of "00h", "40h", "80h", and then "C0h" in the TEST key code control register (BURIF_TKCCR). The RAM initialization is terminated even if it has not yet been completed. In this case, the initialization result is not guaranteed.

Section	Change Results
CHAPTER12: Backup RAM Interface 3.Explanation of Operation 3.3. RAM Initialization	Features of "For details" should be corrected as indicated by the shading below. (Error) Interrupt-related registers To generate an interrupt, write "1" to the interrupt generation enable bit (ICI) in the TEST initialization function register (BURIF_TICR) in accordance with the purpose, and then set the interrupt vector. The interrupt request flag is not cleared automatically. For this reason, clear it by software using the event clear register (BURIF_EVENTCLR.ICICLR) before returning from the interrupt processing. (Correct) Interrupt-related Registers To generate an interrupt, write "1" to the interrupt generation enable bit (ICIE) in the TEST initialization function register (BURIF_TICR) in accordance with the purpose, and then set the interrupt vector. The interrupt request flag is not cleared automatically. For this reason, clear it by software using the event clear register (BURIF_EVENTCLR.ICICLR) before returning from the interrupt processing.
CHAPTER12: Backup RAM Interface 3.Explanation of Operation 3.4.Required Number of Cycles	Features of "For details" should be corrected as indicated by the shading below. (Error) The above processing is required for each word address (for 16 K). In addition, 5 writes and 4 reads are required for each word address for the partial write function. (Correct) The above processing is required for each word address (for 16 K). In addition, 5 writes and 4 reads are required for a word address for the partial write function.
CHAPTER12: Backup RAM Interface 3.Explanation of Operation 3.5.Bus Error Response	Features of "For details" should be corrected as indicated by the shading below. (Error) 2.Write access to the Backup RAM interface register in the lock state (BURIF_STATUS. LOCKTATUS=1) (Correct) 2.Write access to the Backup RAM interface register in the lock state (BURIF_STATUS.LOCKSTATUS=1)

CHAPTER27: DMA Controller 3.Operational Description	Features of "For details" should be corrected as indicated by the shading below. (Error) ■DMAi_R:DBE = '1', DMAi_R:DB[1:0] = '10' (stop on debug event), and a 'debug event' is pending ■DMAi_R:DBE = '1', DMAi_R:DB[1:0] = '01' (halt on debug event), and a 'debug event' is pending If any of the above conditions is true, DMA Stop/Halt Request Flag is '1' indicating that DMA transfers of all channels are requested to halt or stop. The condition that all channels are halted or have come to a stop after a global halt or stop request is indicated by DMA Stop/Halt Status Flag (DMAi_R:DSHS). DMA Stop/Halt Status Flag is '0' if one or more channels are not yet stopped or halted and '1' if all channels are stopped or halted DMAC debug behavior The DMA Controller can be configured to react in a predefined way on a 'debug event' (e.g. debugger break point). The feature to react on a 'debug event' can be enabled with bit Debug Enable (DMAi_R:DBE). If enabled the DMACs behavior depend on the setting of Debug Behavior (DMAi_R:DB[1:0]). This feature is disabled after reset. The behavior can be configured to stop all transfers (DMAi_R:DB[1:0] = '10'), or to halt all transfers (DMAi_R:DB[1:0] = '01'), or just to continue operation independent of debug events (DMAi_R:DB[1:0] = '00'). Initial value is to continue operation independent of debug events. (Correct) ■DMAi_R:DBE = 1, DMAi_R:DB[1:0] = 0b10 (stop on debug event), and a 'debug event' is pending ■DMAi_R:DBE = 1, DMAi_R:DB[1:0] = 0b01 (halt on debug event), and a 'debug event' is pending If any of the above conditions is true, DMA Stop/Halt Request Flag is "1" indicating that DMA transfers of all channels are requested to halt or stop. The condition that all channels are halted or have come to a stop after a global halt or stop request is indicated by DMA Stop/Halt Status Flag (DMAi_R:DSHS). DMA Stop/Halt Status Flag is "0" if one or more channels are not yet stopped or halted and "1" if all channels are stopped or halted DMAC Debug Behavior The DMA Controller can be configured to react in a predefined way on a 'debug event' (e.g. debugger break point). The feature to react on a 'debug event' can be enabled with bit Debug Enable (DMAi_R:DBE). If enabled the DMACs behavior depend on the setting of Debug Behavior (DMAi_R:DB[1:0]). This feature is disabled after reset. The behavior can be configured to stop all transfers (DMAi_R:DB[1:0] = 0b10), or to halt all transfers (DMAi_R:DB[1:0] = 0b01), or just to continue operation independent of debug events (DMAi_R:DB[1:0] = 0b00). Initial value is to continue operation independent of debug events.

Section	Change Results
CHAPTER27: DMA Controller 3.Operational Description 3.1.DMA Channels	Features of "For details" should be corrected as indicated by the shading below. (Error) If a DMA transfer is completed successfully and the completion interrupt raised, Stop Status will show 'normal end' (DMAi_Bn:SS = '101'). If it is ended in error and the error interrupt raised, Stop Status will show one of the following possibilities: ■Stop request (DMAi_Bn:SS = '010') ■Source access error (DMAi_Bn:SS = '011') ■Destination access error (DMAi_Bn:SS = '100') (Correct) If a DMA transfer is completed successfully and the completion interrupt raised, Stop Status will show 'normal end' (DMAi_Bn:SS = 0b101). If it is ended in error and the error interrupt raised, Stop Status will show one of the following possibilities: ■Stop request (DMAi_Bn:SS = 0b010) ■Source access error (DMAi_Bn:SS = 0b011) ■Destination access error (DMAi_Bn:SS = 0b100)
CHAPTER27: DMA Controller 3.Operational Description 3.1.DMA Channels	Features of "For details" should be corrected as indicated by the shading below. (Error) Both interrupts, completion as well as error interrupt can be masked with bits Completion Interrupt (DMAi_Bn:CI) and Error Interrupt (DMAi_Bn:EI) respective. If these bits are set to '1' the interrupts are not masked. All unmasked completion interrupts are ORed and signaled to the Interrupt Controller. The same is done for the error interrupts. All completion Interrupt Flags are in addition to the channel registers, available in two 32-bit registers (DMAi_DIRQ1 and DMAi_DIRQ2) for easier software handling. All Error Interrupts are handled in the same way and are available in register DMAi_EDIRQ1 and DMAi_EDIRQ2. Completion interrupt DMAi_Bn:DQ must be cleared by setting Clear DIRQ (DMAi_Cn:CD). Error interrupt EQ must be cleared by setting Clear EDIRQ (DMAi_Cn:CE). Stop Status will be cleared to 'initial value' (DMAi_Bn:SS = '000') if DMAi_Bn:DQ or DMAi_Bn:EQ is set to '1'. (Correct) Both interrupts, completion as well as error interrupt can be masked with bits Completion Interrupt (DMAi_Bn:CI) and Error Interrupt (DMAi_Bn:EI) respective. If these bits are set to "1" the interrupts are not masked. All unmasked completion interrupts are ORed and signaled to the Interrupt Controller. The same is done for the error interrupts. All completion Interrupt Flags are in addition to the channel registers, available in two 32-bit registers (DMAi_DIRQ1 and DMAi_DIRQ2) for easier software handling. All Error Interrupts are handled in the same way and are available in register DMAi_EDIRQ1 and DMAi_EDIRQ2. Completion interrupt DMAi_Bn:DQ must be cleared by setting Clear DIRQ (DMAi_Cn:CD). Error interrupt EQ must be cleared by setting Clear EDIRQ (DMAi_Cn:CE). Stop Status will be cleared to 'initial value' (DMAi_Bn:SS = 0b000) if DMAi_Bn:DQ or DMAi_Bn:EQ is set to "1".

Features of "For details" should be corrected as indicated by the shading below.

(Error)
If the RSA bit is set to "1" in the 1st byte, the interrupt flag (IBCR:INT) is set to "1" and the SCL to "L" at the SCL falling of the 8th bit in the 1st byte. This occurs regardless of whether FIFO is enabled or disabled. To read reception data and have the device operate as a slave at this time, set IBCR:ACKE to "1", and clear the interrupt flag (IBCR:INT) to "0". After that, if the TRX bit is "0", the device receives data as a slave. To prevent the device from receiving data in midstream, set the IBCR:ACKE bit to "0". Then, the device does not receive subsequent data.

(Correct)
If the RSA bit is set to "1" in the 1st byte, the interrupt flag (IBCR:INT) is set to "1" and the SCL to "L" at the SCL falling of the 8th bit in the 1st byte. This occurs regardless of whether FIFO is enabled or disabled. To read reception data and have the device operate as a slave at this time, set IBCR:ACKE to "1", and clear the interrupt flag (IBCR:INT) to "0". After that, if the TRX bit is "0", the device receives data as a slave. To prevent the device from receiving data in midstream, set the IBCR:ACKE bit to "0". Then, the device does not receive subsequent data.

<tr><td>CHAPTER40:
Base Timer
4.32-bit Mode
Operation</td><td>Features of "For details" should be corrected as indicated by the shading below.

(Error)
32-bit mode settings
First, reset the state by setting the FMD2 to FMD0 bits in the TMCR register of the even-numbered channel to "000" for reset mode. Then, in the same way as in 16-bit mode, make reload timer or PWC timer selection and operation settings. To set 32-bit operation mode at this time, write "1" to the T32 bit in the TMCR register. Keep the T32 bit of the odd-numbered channel at "0". There is no need to set reset mode.
For the reload timer, set the upper 16-bit reload value of the 32 bits in the cycle setting register of the odd-numbered channel. Then, set the lower 16-bit reload value in the cycle setting register of the even-numbered channel.
After the writing of the T32 bit, the change to 32-bit operation mode is reflected immediately, so change the settings for both channels in the count stopped state.
To change from 32-bit mode to 16-bit mode, set the FMD2 to FMD0 bits in the TMCR register of the even-numbered channel to "000" for reset mode. This resets the states of both the even-numbered and odd-numbered channels. As a result, the settings for 16-bit mode can be made for each of the channels.

(Correct)
32-bit Mode Settings
First, reset the state by setting the FMD2 to FMD0 bits in the TMCR register of the even-numbered channel to 0b000 for reset mode. Then, in the same way as in 16-bit mode, make reload timer or PWC timer selection and operation settings. To set 32-bit operation mode at this time, write "1" to the T32 bit in the TMCR register. Keep the T32 bit of the odd-numbered channel at "0". There is no need to set reset mode.
For the reload timer, set the upper 16-bit reload value of the 32 bits in the cycle setting register of the odd-numbered channel. Then, set the lower 16-bit reload value in the cycle setting register of the even-numbered channel.
After the writing of the T32 bit, the change to 32-bit operation mode is reflected immediately, so change the settings for both channels in the count stopped state.
To change from 32-bit mode to 16-bit mode, set the FMD2 to FMD0 bits in the TMCR register of the even-numbered channel to 0b000 for reset mode. This resets the states of both the even-numbered and odd-numbered channels. As a result, the settings for 16-bit mode can be made for each of the channels.</td></tr>

CHAPTER42: 32-bit Free-run Timer 2.Explanation of the 32-bit Free-run Timer Operation	Features of "For details" should be corrected as indicated by the shading below. (Error) ■An interrupt request flag can be masked by setting the interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10) of the timer state control register (TCCS). The interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10) are the 3-bit reload down register that reloads the value when the mask count value reaches "000B". The mask count value can also be loaded by directly writing data to the interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10). The number of mask counts is the value set in the interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10). An interrupt request flag is not masked when the mask count value (MSI2 to MSI0: bit12 to bit10) becomes "000B". (Correct) ■An interrupt request flag can be masked by setting the interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10) of the timer state control register (TCCS). The interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10) are the 3-bit reload down register that reloads the value when the mask count value reaches 0x000. The mask count value can also be loaded by directly writing data to the interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10). The number of mask counts is the value set in the interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10). An interrupt request flag is not masked when the mask count value (MSI2 to MSI0: bit12 to bit10) becomes 0x000.

CHAPTER47: QPRC(Quadrature Position/Revolution Counter) 4.Registers 4.7.Low-Order Bytes of QPRC Interrupt Control Register (QICRL)	Features of "For details" should be corrected as indicated by the shading below. (Error) This flag indicates that a position counter overflow occurs. When the position counter is counted up, this bit is set to "1" if the value of the position counter matches that of the QPRC Maximum Position Register (QMPR). This flag can only clear to "0" in write mode. Setting "1" has no effect. (Correct) This flag indicates that a position counter overflow occurs. When the set value of the QPRC Maximum Position Register(QMPR) matches the value of the position counter and the position counter is counted up, this bit is set to "1". This flag can be only cleared to "0" in write mode. Setting "1" has no effect.
CHAPTER47: QPRC(Quadrature Position/Revolution Counter) 4.Registers 4.7.Low-Order Bytes of QPRC Interrupt Control Register (QICRL)	Features of "For details" should be corrected as indicated by the shading below. (Error) [bit 5] UFDF: Underflow interrupt request flag bit This flag indicates that a position counter underflow occurs. When the position counter is counted down, this bit is set to "1" if the position counter is 0x0000. This flag can only clear to "0" in write mode. Setting "1" has no effect. (Correct) [bit5] UFDF : Underflow Interrupt Request Flag Bit This flag indicates that a position counter underflow occurs. When the position counter is 0x0000 and the position counter is counted down, this bit is set to "1". This flag can be only cleared to "0" in write mode. Setting "1" has no effect.
CHAPTER47: QPRC(Quadrature Position/Revolution Counter) 4.Registers 4.7.Low-Order Bytes of QPRC Interrupt Control Register (QICRL)	Features of "For details" should be corrected as indicated by the shading below. (Error) [bit 4] OUZIE: Overflow, underflow, or zero index interrupt enable bit This bit is used to control whether or not to issue an interrupt notification to the CPU when the overflow interrupt request flag bit (OFDF), underflow interrupt request flag bit (UFDF), or zero index interrupt request flag bit (ZIIF) is set to "1". When this bit is set to "1", an interrupt is generated if overflow is detected (OFDF="1"), underflow is detected (UFDF="1"), or zero index is detected (ZIIF="1"). (Correct) [bit4] OUZIE : Overflow, Underflow, or Zero Index Interrupt Enable Bit This bit is used to control whether or not to issue an interrupt notification to the MCU when the overflow interrupt request flag bit(OFDF), underflow interrupt request flag bit(UFDF), or zero index interrupt request flag bit(ZIIF) is set to "1". When this bit is set to "1", an interrupt is generated if overflow is detected(OFDF= 1), underflow is detected(UFDF= 1), or zero index is detected(ZIIF= 1).

CHAPTER52: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.3.TX-FIFO Control	Features of "For details" should be corrected as indicated by the shading below. (Error) (2) DDRHSSPIn_DMTRP.TRP[1:0]="11" (Only when DDRHSSPIn_MID.MID is 0x00000100) FWIDTH TRP[1:0] SDATA "00" "11" {TXDATA[7:4], TXDATA[3:0]} will be sent on {SDATA[7:4], SDATA[3:0]}. When in DDR Mode (DDRHSSPIn_DMFIFOCFG.DDRM="1"), TRP="11" is not allowed. "01" "11" {TXDATA[15:12], TXDATA[11:8]} and {TXDATA[7:4], TXDATA[3:0]} will be sequentially sent on {SDATA[7:4], SDATA[3:0]}. "11" "11" {TXDATA[31:28], TXDATA[27:24]}, {TXDATA[23:20], TXDATA[19:16]}, {TXDATA[15:12], TXDATA[11:8]} and {TXDATA[7:4], TXDATA[3:0]} will be sequentially sent on {SDATA[7:4], SDATA[3:0]}. When in TXCTRL="0", DDRHSSPI cannot transfer data at Dual Legacy Mode, since the SPI protocol is controlled just by DDRHSSPIn_DMTRP.TRP. Therefore, TX-and-RX Mode is not available for Dual Legacy Mode under this condition. (Correct) (2) DDRHSSPIn_DMTRP.TRP[1:0]= 0b11 (Only when DDRHSSPIn_MID.MID is 0x00000100 or 0x00000300) FWIDTH TRP[1:0] SDATA 0b00 0b11 {TXDATA[7:4], TXDATA[3:0]} will be sent on {SDATA[7:4], SDATA[3:0]}. When in DDR Mode (DDRHSSPIn_DMFIFOCFG.DDRM= 1), TRP= 0b11 is not allowed. 0b01 0b11 {TXDATA[15:12], TXDATA[11:8]} and {TXDATA[7:4], TXDATA[3:0]} will be sequentially sent on {SDATA[7:4], SDATA[3:0]}. 0b11 0b11 {TXDATA[31:28], TXDATA[27:24]}, {TXDATA[23:20], TXDATA[19:16]}, {TXDATA[15:12], TXDATA[11:8]} and {TXDATA[7:4], TXDATA[3:0]} will be sequentially sent on {SDATA[7:4], SDATA[3:0]}. When in TXCTRL= 0, DDRHSSPI cannot transfer data at Dual Legacy Mode, since the SPI protocol is controlled just by DDRHSSPIn_DMTRP.TRP. Therefore, TX-and-RX Mode is not available for Dual Legacy Mode under this condition.

668	CHAPTER 8:Clock Supervisor 1. Overview	Error) Two types of clock supervisors are equipped with this device. The clock supervisor to be used by the clock to be monitored is different. Correct) This device is equipped with several instances of two different types of clock supervisors. The used type of clock supervisor depends on the clock signal which is to be monitored.
668		Error) 1. Detection type of stop or frequency range abnormality of the clock. It monitors for stop or frequency range abnormality of the monitoring clock. Parameters for reference clock frequency, upper limit of the monitoring clock frequency and lower limit of the monitoring clock frequency are set to the monitoring clock counter and reference clock counter. Frequency range comparator can detect abnormalities from each counter output. Either reset or interrupt is generated when the comparator detect abnormalities. Correct) 1. Detector for stopped clock or abnormal frequency of the monitored clock. This type of clock supervisor detects two possible errors in clock operation: a stopped clock or a clock operating in an abnormal frequency range. There are clock counters for both the monitored clock and the reference clock. Parameters for each counter define the frequency of the reference clock as well as the upper and lower limit for the frequency of the monitored clock. In case the dedicated frequency range comparator detects a stopped clock or a clock outside the frequency range, an abnormal state is signalled. Then, it depends on register settings and on the way, the monitored clock is used on the device, whether a reset or an interrupt is generated.

Page	Section	Change Results
668	CHAPTER 8:Clock Supervisor 1. Overview	Error) 2. Detection type of stop of the clock. It monitors for stop of the monitoring clock. When the rising edge of the monitoring clock is not detected, the clock supervisor detects the abnormalities of oscillator. Reset is generated when the comparator detect abnormalities. Correct) 2. Detector for stopped clock only. This type of clock supervisor detects a stopped clock operation for the monitored clock. When the rising edge of the monitored clock does not occur, the clock supervisor signals an abnormal state. In this case, a reset is generated.

Page	Section	Change Results
913	CHAPTER 14:Hardware Watchdog Timer 3. Explanation of Operation	Error) The watchdog counter in RUN always operates. When the device state transitions from RUN to PSS, the processing transitions to the operation of the watchdog in PSS. For details, see The following figure shows the Hardware watchdog operation in PSS. During the operation of the watchdog counter, execute the watchdog counter clear protection trigger sequence within the range between the window upper limit value and lower limit value that have been specified beforehand. Do this to clear the watchdog counter periodically. 6. If a runaway state caused by a user program occurs and prevents periodic clearing, the watchdog counter reaches the window upper limit value. Then, processing transitions to the flow that generates the watchdog reset request or watchdog interrupt request (NMI). 7. According to the value of the IRQEN bit in the Hardware watchdog interrupt configuration register (HWDG_INT), the prior warning interrupt request is generated. At the same time, as many cycles as are set for the delay time in the Hardware watchdog reset delay counter register (HWDG_RSTDLY) are inserted. 8. After the elapse of the time corresponding to the number of cycles for the delay time, the watchdog reset request or watchdog interrupt request (NMI) is generated according to the value of the RSTEN bit in the Hardware watchdog interrupt configuration register (HWDG_INT). When the watchdog interrupt request (NMI) is generated, the processing transitions to the operation of the test function of the watchdog. For details, see Figure 3-6. Correct) 1. The watchdog counter in RUN always operates. 2. When the device state transitions from RUN to PSS, the processing transitions to the operation of the watchdog in PSS. For details, see Figure 3-5. 3. During the operation of the watchdog counter, execute the watchdog counter clear protection trigger sequence within the range between the window upper limit value and lower limit value that have been specified beforehand. Do this to clear the watchdog counter periodically. 4. If a runaway state caused by a user program occurs and prevents periodic clearing, the watchdog counter reaches the window upper limit value. Then, processing transitions to the flow that generates the watchdog reset request or watchdog interrupt request (NMI). 5. According to the value of the IRQEN bit in the Hardware watchdog interrupt configuration register (HWDG_INT), the prior warning interrupt request is generated. At the same time, as many cycles as are set for the delay time in the Hardware watchdog reset delay counter register (HWDG_RSTDLY) are inserted. 6. After the elapse of the time corresponding to the number of cycles for the delay time, the watchdog reset request or watchdog interrupt request (NMI) is generated according to the value of the RSTEN bit in the Hardware watchdog interrupt configuration register (HWDG_INT). When the watchdog interrupt request (NMI) is generated, the processing transitions to the operation of the test function of the watchdog. For details, see Figure 3-6.
916	CHAPTER 14:Hardware Watchdog Timer 3. Explanation of Operation	Error) **Note:** The notation * in The following figure shows the operation of the test function of the Hardware watchdog. Correct) ***Note:*** *The notation * in Figure 3-6 means "RUN" or "PSS".*

Page	Section	Change Results
917 to 918	CHAPTER 14:Hardware Watchdog Timer 4. Setting Procedure Example	Error) **Note:** In Figure 4-1, the setting order can be changed except for the step of setting the LOCK bit in the Hardware watchdog configuration register (HWDG_CFG) to "1". Correct) ***Note:*** − *In Figure 4-1, the setting order can be changed except for the step of setting the LOCK bit in the Hardware watchdog configuration register (HWDG_CFG) to "1".* − *Hardware watchdog timer is configured by boot program, and this is determined by value of BootROM marker. For detail of boot program and BootROM marker, see BootROM Software Interface chapter.* *Therefore, user program has to execute only "write 0x0 to HWDG_RSTCAUSE".*
942	CHAPTER 14:Hardware Watchdog Timer 6.Register List	Error) **[bit20:16] OBSSEL[4:0]: Watchdog Counter Monitor Bit Output Selection Bits** These bits are used for selecting any 1 bit in the watchdog counter (32 bits) as the output of the watchdog counter monitor bit.(Support target of this function is different depends on product specification. For details, see "3 Explanation of Operation For this product, output of the watchdog counter monitor bit of MCU output pin is supported by the Hardware watchdog timer.") Correct) **[bit20:16] OBSSEL[4:0]: Watchdog Counter Monitor Bit Output Selection Bits** These bits are used for selecting any 1 bit in the watchdog counter (32 bits) as the output of the watchdog counter monitor bit.(Support target of this function is different depends on product specification. 954	CHAPTER 15:Software Watchdog Timer 3. Explanation of Operation	Error) **Software Watchdog Timer Start by User Program** A user program starts the software watchdog timer. Specifically, operation is started by setting the LOCK bit in the software watchdog configuration register (SWDGn_CFG). **Watchdog Counter Source Clock Selection (4 Types)** The software watchdog timer sets values in the CLKSEL[1:0] bits in the software watchdog configuration register (SWDGn_CFG) to select a source clock for the watchdog counter from among 4 types of source clocks. Specifically, it selects a source clock from the high-speed CR clock, low-speed CR clock, sub clock, or main clock. (The initial setting is for the high-speed CR clock.) Correct) **Software Watchdog Timer Start by User Program** A user program starts the software watchdog timer. Specifically, operation is started by setting the LOCK bit in the software watchdog configuration register (SWDG_CFG). **Watchdog Counter Source Clock Selection (4 Types)** The software watchdog timer sets values in the CLKSEL[1:0] bits in the software watchdog configuration register (SWDG_CFG) to select a source clock for the watchdog counter from among 4 types of source clocks. Specifically, it selects a source clock from the high-speed CR clock, low-speed CR clock, sub clock, or main clock. (The initial setting is for the high-speed CR clock.)

960	CHAPTER 15:Software Watchdog Timer 3. Explanation of Operation	Error) **Generation of Watchdog Reset Request or Watchdog Interrupt Request (NMI)** **Notes:** ■ When you generate the prior warning interrupt request, set the Software watchdog reset delay counter register (SWDG_RSTDLY) to a value other than 0x0000. The use of the watchdog interrupt request (NMI) is prohibited except when used as a test function. (This is prohibited because if such use is allowed, security will be compromised during the execution of an application.) The following figure shows the operation of the test function of the Hardware watchdog. Correct) **Generation of Watchdog Reset Request or Watchdog Interrupt Request (NMI)** ***Notes:*** — *When you generate the prior warning interrupt request, set the Software watchdog reset delay counter register (SWDG_RSTDLY) to a value other than 0x0000.* — *The use of the watchdog interrupt request (NMI) is prohibited except when used as a test function. (This is prohibited because if such use is allowed, security will be compromised during the execution of an application.) Figure 3-6 shows the operation of the test function of the Software watchdog.*
960	CHAPTER 15:Software Watchdog Timer 3. Explanation of Operation	Error) **Output of the Watchdog Counter Monitor Bit for MCU Output Pin** For This Product, Output of the Watchdog Counter Monitor Bit of MCU Output Pin is Supported by the Software Watchdog Timer. The Software watchdog timer outputs the watchdog counter monitor bit to the outside so that watchdog counter operation can be monitored from the outside. You can select any 1 bit in the watchdog counter (32 bits) by setting the OBSSEL[4:0] bits in the Software watchdog configuration register (SWDG_CFG). Correct) **Output of the Watchdog Counter Monitor Bit for MCU Output Pin** The Software watchdog timer outputs the watchdog counter monitor bit to the outside so that watchdog counter operation can be monitored from the outside. You can select any 1 bit in the watchdog counter (32 bits) by setting the OBSSEL[4:0] bits in the Software watchdog configuration register (SWDG_CFG). Support of this function is different depends on product specification.

Page	Section	Change Results
968	CHAPTER 15:Software Watchdog Timer 3. Explanation of Operation	Error) The watchdog counter in RUN always operates. When the device state transitions from RUN to PSS, the processing transitions to the operation of the watchdog in PSS. For details, see The following figure shows the Software watchdog operation in PSS. During the operation of the watchdog counter, execute the watchdog counter clear protection trigger sequence within the range between the window upper limit value and lower limit value that have been specified beforehand. Do this to clear the watchdog counter periodically. 5. If a runaway state of the software occurs and prevents periodic clearing, the watchdog counter reaches the window upper limit value. Then, processing transitions to the flow that generates the watchdog reset request or watchdog interrupt request (NMI). 6. According to the value of the IRQEN bit in the Software watchdog interrupt configuration register (SWDG_INT), the prior warning interrupt request is generated. At the same time, as many cycles as are set for the delay time in the Software watchdog reset delay counter register (SWDG_RSTDLY) are inserted. 7. After the elapse of the time corresponding to the number of cycles for the delay time, the watchdog reset request or watchdog interrupt request (NMI) is generated according to the value of the RSTEN bit in the Software watchdog interrupt configuration register (SWDG_INT). When the watchdog interrupt request (NMI) is generated, the processing transitions to the operation of the test function of the watchdog. For details, see Figure 3-6. 8. Correct) 1. The watchdog counter in RUN always operates. 2. When the device state transitions from RUN to PSS, the processing transitions to the operation of the watchdog in PSS. For details, see Figure 3-5. 3. During the operation of the watchdog counter, execute the watchdog counter clear protection trigger sequence within the range between the window upper limit value and lower limit value that have been specified beforehand. Do this to clear the watchdog counter periodically. 4. If a runaway state of the software occurs and prevents periodic clearing, the watchdog counter reaches the window upper limit value. Registers In this chapter, there is a place with two specifications, "SWP_NOMAL_type" and "SWP_LITE_type". Basically please refer to "SWP_NORMAL_type" specification, but when SWP_LITE_type is used, please refer to "SWP_LITE_type" specification and see the Product's HWM.
1355	CHAPTER 24:Security 2. Security Scope and Access Restriction by the Security 2.1. Security Scope	Added Error) The ability to execute “chip erase” always exists. The marker MK_CEER does not have any functionality. Correct) Refer to datasheet of product. If being written with "MK_CEER = Selectable", below is spec. The ability to execute “chip erase” function depends on the permission set by the marker MK_CEER. The possibility of doing chip erase can be removed, when the user intents to forbid the usage of other parties software on his system. However this removes any possibility for a recovery of a device when not implementing an unlock mechanism or forgetting the key for a device unlock. To protect the software IP only from being disassembled, debugged or copied – the normal security is enough and chip erase functionality should stay enabled. Other spec is below. The ability to execute “chip erase” always exists. The marker MK_CEER does not have any functionality.

Page	Section	Change Results
1362	CHAPTER 24:Security 3. Using and Configuring the Security 3.3. Security Marker Definition	Added Error) This section describes details of the Flash Marker which is used to configure the security setting. The security configuration is stored in the Flash Marker which is located to head of the SA0 area in small sector area of TCFlash. Correct) This section describes details of the Flash Marker which is used to configure the security setting. The security configuration is stored in the Flash Marker which is located to head of the SA0 area in small sector area of TCFlash#0.
1362	CHAPTER 24:Security 3. Using and Configuring the Security 3.3. Security Marker Definition	Error) The security markers are transferred after each RSTX_PD2H into the appropriate registers containing the security state of the device. This process is called “Security Fetch”. There is no error signaling during that hardware mechanism, since the CPU is not involved into that mechanism (no bus transfer). No errors will succeed in loading the marker values from Flash to registers. Single bit errors get corrected and will succeed in loading the marker values from Flash to registers. Fatal errors will not succeed in loading the marker values from Flash to registers. The according security register will keep its previous initial value. To check the integrity of ECC of the above marker section, it is recommended, to read the markers by the application. The normal ECC error detection by the TCFLASH interface can be utilized for that. Correct) The security markers are transferred after each RSTX_PD2H into the appropriate registers containing the security state of the device. This process is called "Security Fetch". No errors will succeed in loading the marker values from Flash to registers. Single bit errors get corrected and will succeed in loading the marker values from Flash to registers. Fatal errors will not succeed in loading the marker values from Flash to registers. The according security register will keep its previous initial value. To check detail of the integrity of ECC of the above marker section, it is recommended, to read the markers by the application. The normal ECC error detection by the TCFLASH interface can be utilized for that.

<tr><td>1364</td><td>CHAPTER 24:Security 3. Using and Configuring the Security 3.3. Security Marker Definition 3.3.3. Chip Erase Enable (MK_CEER)</td><td>Added
Correct)

Refer to datasheet of product.
If being written with "MK_CEER = Selectable", below is spec.

[31:0] CEER: Chip Erase Enable
The value controls the ability to execute the “chip erase” function.

<table><tr><th>Value</th><th>Description</th></tr><tr><td>0xFFFFFFFF</td><td>The MCU will support the “chip erase” command. As an effect a secured device can be unlocked by erasing all its internal secret content, except SHE.</td></tr><tr><td>Other</td><td>The MCU has disabled the “chip erase” command. Without knowing authentication scheme, the device cannot be erased anymore (independent from its operation mode).</td></tr></table>
The marker value is automatically copied to TCFCFG0_CEER after each RSTX_PD2H.

Other spec is below.</td></tr>
<tr><td>1369</td><td>CHAPTER 24:Security 3. Using and Configuring the Security 3.4. Gain Access in USERMODE 3.4.1. Gaining program / erase permission to Flash Sectors</td><td>Error)

Each of the bits in the above registers are controlling erase and program permissions of single Flash sectors. Lower bits reflect the permission of the lower sector number. Higher bits reflect the setting of the higher sector number.
The sector permission registers are defining accessibility of Flash during USERMODE.

Correct)

Each of the bits in the above registers control write permissions (erase and program) of single Flash sectors. Lower bits reflect the permission of the lower sector number. Higher bits reflect the setting of the higher sector number. Depending on the Flash size equipped with the device only such sector write permission registers or bits have an effect, for which the according Flash sector exists.
The sector permission registers are defining accessibility of Flash during USERMODE.</td></tr>
</table>

[31:0] CEER: Chip Erase Enable Register
Disabling chip erase is not possible by this product. Writing to that register has no effect.

Correct)

[bit31:0] CEER: Chip erase enable register
Refer to datasheet of product.
If being written with "MK_CEER = Selectable", below is spec.
Full-chip erase can be forbidden using this marker.

<table><tr><th>Value</th><th>Description</th></tr><tr><td>0xFFFFFFFF</td><td>The chip erase of a secured device is enabled.</td></tr><tr><td>Other</td><td>Any other value disables the chip erase in non-USERMODE.</td></tr></table>
Without enabling the security by TCFCFG0_SER, the Chip Erase Enable Register has no meaning.

Other spec is below.
Disabling chip erase is not possible by this product. Writing to that register has no effect.</td></tr>
</table>

Page	Section	Change Results
1382	CHAPTER 24:Security 4. Registers 4.4. Chip Erase Enable Register (TCFCFG0_CEER)	Added Error) TCFCFG0_CEER can be written by the application, when TCFCFG0_SOER indicates that overwrite is enabled. Otherwise the write access will cause a bus error. Correct) TCFCFG0_CEER can be written by the application, when TCFCFG0_SOER indicates that overwrite is enabled. Otherwise the write access will cause a bus error. Refer to datasheet of product. If being written with "MK_CEER = Selectable", below is spec. The chip erase can be triggered by JTAG equipment, writing the chip erase sequence to the general purpose registers of the security checker or transferring the chip erase sequence through serial interface when using Serial Loader equipment. It erases all sectors of the WORKFLASH and TCFLASH. Sectors used for SHE are not erased. ***Notes:*** – *A secured device without an unlock mechanism implemented by the application and without the ability to erase the full device cannot be updated or tested anymore. Not programming the unlock marker value to CEEM should be used with absolute care!* – *Single ECC errors are corrected. When double ECC errors are detected, the register is not updated from Flash and the chip erase will be disabled.*

1545	CHAPTER 27 DMA Cntroller 3.Operational Description 3.1.DMA Channels	Error) **Block of Data** A block of data is determined by the setting of Block Count (DMAi_An:BC[3:0]) and Transfer Width (DMAi_Bn:TW[1:0]). The DMA Controller will make DMAi_An:BC + 1 data transfers from source address range starting at Source Address (DMAi_SAn:SA) to destination address range starting at Destination Address (DMAi_DAn:DA). If DMAi_An:BC is set to "0" a single data transfer from Source Address (DMAi_SAn:SA) to Destination Address (DMAi_DAn:DA) will be done. The settings of Block Count (DMAi_AN:BC[3:0]), Beat Limit (DMAi_An:BL[1:0]), Alternate (DMAi_An:AL), and Transfer Width (DMAi_Bn:TW[1:0]) define how the AHB master interface issues the DMAi_An:BC + 1 data transfers. The following table shows all possible combinations between DMAi_An:BC, DMAi_An:BL, and DMAi_An:AL. Only these three influence the sequence of AHB transfers, whereas DMAi_Bn:TW only affects the data size which will be transported. Correct) **Block of Data** A block of data is determined by the setting of Block Count (DMAi_An:BC[3:0]) and Transfer Width (DMAi_Bn:TW[1:0]). Correct)
Notes:
– Attribute of the 27th bit (BEHSTPACK) of DMAi_CMICICm has "R/W" and "R0,WX" by difference of product specifications.
– DMAi_CMICICm registers are not implemeted depending on the product specification. In case of register access to those DMAi_CMICICm registers, response of bus error will occur
– About the implementation of these registers, please see the product's HWM.</td></tr>

Page	Section	Change Results
2356	CHAPTER 38: I2C Interface (I2C Communication Control Interface) 3 I2C Interface Operation 3.1 Master Mode	Error) **When DMA Mode is Enabled (SSR:DMA = 1)** ■ If the IBSR:RSA bit is "1", the interrupt flag (IBCR:INT) is set to "1" after the reserved address is received (before an acknowledgment), the SCL remains "L", and a wait is performed. After the RDR register is read, the IBCR:ACKE bit and transmission data are set, and "0" is written to the interrupt flag. This sets the interrupt flag to "0", which releases the wait. Correct) **When DMA Mode is Enabled (SSR:DMA = 1)** If the IBSR:RSA bit is "1", the interrupt flag (IBCR:INT) is set to "1" after the reserved address is received (before an acknowledgment), the SCL remains "L", and a wait is performed. After the RDR register is read, the IBCR:ACKE bit and transmission data are set, the writing "1" to the IBCRC:INTC sets the interrupt flag to "0", which releases the wait.
2390	CHAPTER 38: I2C Interface (I2C Communication Control Interface) 3 I2C Interface Operation 3.2. Slave Mode	Error) Operation is in slave mode after the (repeated) start condition is detected and an ACK response is returned when the combination of the ISBA register and the ISMK register matches the received address. **Notes:** ■ When EIBCR:BEC = 0 during address data transfer after the start condition has been detected or during transfer of bit2 to bit9 (acknowledgment bits), the start condition may be detected again. If so, a bus error is detected (IBCR:BER = 1) and reception is stopped, so the next data cannot be received. Correct) Operation is in slave mode after the start condition or the repeated start condition is detected and an ACK response is returned when the combination of the ISBA register and the ISMK register matches the received address. ***Notes:*** *− When EIBCR:BEC=0, if 2nd start condition is detected after 1st start condition is detected (during transfer of bit2 to bit9), a bus error is detected (IBCR:BER=1) and reception is stopped.*

Page	Section	Change Results
2390	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 3 I2C Interface Operation 3.2. Slave Mode	Error) **Slave Address Match Detection** After the (repeated) start condition is detected, the next data is received as a 7-bit address. With regard to the bits that are set to "1" in the ISMK register, the bits in the ISBA register are compared with the bits of the received address. If they match, ACK is output. Correct) **Slave Address Match Detection** The 1st receiving data after the start condition or the repeated start condition is detected contains 7-bit slave address and the bit that shows the direction of the data transmission. The ISMK register is set the value that masks the slave address of the ISBA register. The bit value "0" means "don't care", and "1" means that it needs that the bit value of address corresponds with the data of received slave address. That is, the bit whose the value is set to "0" in the ISMK register is not compared to the bit of the address. When SAEN is set to "1", it enables the slave address detection. The data as the address sent by a master is compared with some slave address bits(SA[6:0]) that mask bits(SM[6:0]) corresponded to is set to "1". If they match, ACK is output. If not, ACK is not output. Example of the address detection For example, a master send the slave address 0x23. **Figure 3-39 The example of the slave address detection**  Just SA5, SA1, SA0 are compared the data as the address sent by the master. Because SM[6], SM[4:2] are set to "0", those bits are "don't care". As a result, the Multi-function serial interface outputs the ACK response.

2393	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 3 I2C Interface Operation 3.2. Slave Mode	Error) **When DMA Mode is Disabled (SSR:DMA = 0)** ■ When the reception FIFO is enabled 2. If the interrupt flag (IBCR:INT) was set to "1", read the received data from the RDR register. After reading all the data, write "0" to the interrupt flag to release the wait for the I2C bus. If the stop condition or the repeated start condition was detected, read all the received data from the RDR register, and clear the IBSR:SPC bit or the IBSR:RSC bit to "0". Correct) **When DMA Mode is Disabled (SSR:DMA = 0)** ■ When the reception FIFO is enabled 2. If the interrupt flag (IBCR:INT) was set to "1", read the received data from the RDR register. After reading all the data, write "1" to the interrupt flag clear bit (IBCRC:INTC) to release the wait for the I2C bus. If the stop condition or the repeated start condition was detected, read all the received data from the RDR register, and clear the IBSR:SPC bit or the IBSR:RSC bit to "0".
2400	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 3 I2C Interface Operation 3.3. Bus Error	Error) Check the IBCR:BER bit when the interrupt flag (IBCR:INT) is set to "1" according to the status. If the IBCR:BER bit is "1", take action against the error. The IBCR:BER bit is cleared by the writing of "0" to the IBCR:INT bit. Correct) **When EIBCR:BEC=0** Check the IBCR:BER bit when the interrupt flag (IBCR:INT) is set to "1" according to the status. If the IBCR:BER bit is "1", take action against the error. The IBCR:BER bit is cleared by writing "1" to the interrupt flag clear bit (IBCRC:INTC).
2406	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 6. Block Transfer	Error) The block size is set in the transmission/reception block size register. Correct) The block size is set in the transmission block size register or FBYTE register(reception side).

Page	Section	Change Results
2411	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 6. Block Transfer 6.2. RW Access Mode	Error) After the reception block transfer is requested, the reception block transfer request (RIRQ) is cleared when read access to the reception FIFO occurs. The read access to the reception FIFO decrements the Read counter. Correct) After the reception block transfer is requested, the reception block transfer request (RIRQ) is cleared when a read access to the reception data occurs. The read access to the reception data decrements the Read counter.
2433	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.2. Serial Mode Register (SMR)	Error) **[bit7:5] MD[2:0] : Operation Mode Setting Bits** These bits set the operation mode. "0b000": Set operation mode 0 (asynchronous normal mode). "0b001": Set operation mode 1 (asynchronous multi-processor mode). "0b010": Set operation mode 2 (clock synchronous mode). "0b011": Set operation mode 3 (LIN communication mode). "0b100": Set operation mode 4 (I^2C mode). This section explains the register and its operations in operation mode 4 (I^2C mode). Correct) **[bit7:5] MD[2:0] : Operation Mode Setting Bits** These bits set the operation mode.
2435	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.3. I2C Bus Status Register (IBSR)	Error) **[bit7] FBT : First Byte Bit** 1. The 2nd byte is transmitted and received. Correct) **[bit7] FBT : First Byte Bit** 1. The 2nd byte starts to be transmitted and received.

Page	Section	Change Results
2442	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.4. Serial Status Register (SSR)	Error) **[bit10] RDRF : Reception Data Full Flag Bit** ■ When reading of the reception FIFO empties it during use, this bit is cleared to "0". **Notes:** ■ After RDRF becomes "1" when the reception FIFO is used, resetting the reception FIFO (FCR0:FCL2,FCL1= 1) does not cause RDRF to become "0". Therefore, to set RDRF to "0" after resetting the reception FIFO, perform a dummy read on the reception data register while reception is disabled (SCR:RXE= 0). Correct) **[bit10] RDRF : Reception Data Full Flag Bit** ■ When ECR:RXBLKEN=0 and reading of the reception FIFO empties it during use, this bit is cleared to "0". ■ When ECR:RXBLKEN=1 and using reception FIFO, this bit is clear to "0" when the number of the data in the reception FIFO is less than or equal to the value of the FBYTE register. **Notes:** − *After RDRF becomes "1" when the reception FIFO is used, resetting the reception FIFO (FCR0:FCL2,FCL1= 1) does not cause RDRF to become "0". Therefore, to set RDRF to "0" after* *resetting the reception FIFO, perform a dummy read on the reception data register while I2C mode is disabled (ISMK.I2CEN=0).*
2445	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.5. Reception Data Register/Transmission Data Register (RDR/TDR)	Error) Correct) When the FIFO mode is enabled, RDR/TDR register address is the address of reading/writing of the FIFO.

Page	Section	Change Results
2452	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.9. Noise Filter Control Register (NFCR)	Error) ***Notes:*** − *Set these bits when the ISMK:EN bit in the ISMK register is "0".* Correct) ***Notes:*** − *Set these bits when the EN bit in the ISMK register is "0".*
2457	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.12. 7-Bit Slave Address Register (ISBA)	Error) **[bit6:0] SA[6:0] : 7-Bit Slave Address** Correct) **[bit6:0] SA[6:0] : 7-Bit Slave Address** ■The 1st received data after detecting the (repeated) start condition consists of 7-bit slave address and the bit that specifies the direction of data transfer. It compares the slave address included in the received data to these bits. **Figure 8-14 The 1st byte format after detecting the (repeated) start condition**

2462	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.14. FIFO Control Register 1 (FCR1)	Error) **[bit8] FSEL : FIFO Selection Bit** ***Notes:*** Correct) **[bit8] FSEL : FIFO Selection Bit** ***Notes:*** − *Set the FIFO Selection Bit (FCR1:FSEL) before setting the FIFO byte register (FBYTE) and the Transmission FIFO Interrupt Control Register (FTICR).* − *It can not access the FIFO byte register (FBYTE) at the same access.*
2463	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.15. FIFO Control Register 0 (FCR0)	Error) **[bit6] FLST : FIFO Retransmission Data Lost Flag Bit** FLST reset conditions ■ There is a FIFO reset (writing "1" to FCL). Correct) **[bit6] FLST : FIFO Retransmission Data Lost Flag Bit** FLST reset conditions ■ Transmission FIFO reset. − When FCR1:FSEL="0", set "1" to the FCR0:FCL1. − When FCR1:FSEL="1", set "1" to the FCR0:FCL2.
2465	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.15. FIFO Control Register 0 (FCR0)	Error) **[bit3] FCL2 : FIFO2 Reset Bit** ***Notes:*** − *The valid data count of the FBYTE1 register is set to 0.* Correct) **[bit3] FCL2 : FIFO2 Reset Bit** ***Notes:*** − *The valid data count of the FBYTE2 register is set to 0.* − *TDR register and RDR register are not initialized.*

Page	Section	Change Results
2465	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.15. FIFO Control Register 0 (FCR0)	Error) **[bit2] FCL1 : FIFO1 Reset Bit** ***Notes:*** Correct) **[bit2] FCL1 : FIFO1 Reset Bit** ***Notes:*** − *TDR register and RDR register are not initialized*
2467	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.16. FIFO Byte Register (FBYTE)	Error) Correct) ■ When writing a transmission data to the TDR register one time, the FBYTE of the transmission FIFO is incremented by one ("+1"). ■ When reading a reception data from the RDR register one time, the FBYTE of the reception FIFO is decremeted by one ("-1").
2468	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.16. FIFO Byte Register (FBYTE)	Error) Correct) ***Notes:*** − *After setting the FIFO Selection Bit (FCR1:FSEL), set the FIFO byte register (FBYTE).* − *The FIFO Selection Bit and the FIFO byte register can not be set at the same time.* − *The indication of transmission FIFO data number is indicated as the valid value that is the number of writing times of the transmission data decrimented by one. This is the reason that a transmission data written is transferred to transmission FIFO when TDR register has a data not transmitted. When the data in TDR register is transmitted, the data not transmitted in transmission FIFO is transferred to TDR register.* − *The indication of reception FIFO data number is indicated the number of the data received to reception FIFO and not read from reception FIFO. The data receiving in RDR register is not included.*

Page	Section	Change Results
2470	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.17. Transmission FIFO Interrupt Control Register (FTICR)	Error) The FTICR register sets the interrupt trigger level by the valid transmission data count (remaining amount) of the transmission FIFO. The following table lists settings with the FCR1:FSEL bit. ■ Set the data count that generates a transmission interrupt in FTICR of the transmission FIFO. The interrupt flag (FDRQ) is set to "1" when the set data count matches or is smaller than the valid data count of the transmission FIFO (FTICR or FBYTE). Correct) The function of this bit is changed by the value of ECR:TXBLKEN. − ECR:TXBLKEN="0" The FTICR register sets the interrupt trigger level by the valid transmission data count (remaining amount) of the transmission FIFO. − ECR:TXBLKEN="1" The FTICR register sets the interrupt trigger level by the number of the empty data in transmission FIFO. ■ Set the data count that generates a transmission interrupt in FTICR of the transmission FIFO. ■ When ECR:TXBLKEN="0", the interrupt flag (FDRQ) is set to "1" when the set data count matches or is smaller than the valid data count of the transmission FIFO (FTICR or FBYTE). ■ When ECR:TXBLKEN="1", the interrupt flag (FDRQ) is set to "1" when the set data count matches or is smaller than the number of the empty data in transmission FIFO. When the number of data set to this register is bigger than the number of the empty data in transmission FIFO, the interrupt flag (FCR1:FDRQ) is set to "0".
2474	CHAPTER 38:I2C Interface (I2C Communication Control Interface) 8. I2C Interface Registers 8.19. Extended Status Register (ESR)	Error) **[bit11] RXUDR : Reception FIFO under Run Flag Bit** ***Notes:*** −*A software reset (SCR:UPCL= 1) resets this bit to "0".* Correct) **[bit11] RXUDR : Reception FIFO under Run Flag Bit** ***Notes:*** − *This bit is "0" when the reception FIFO is disabled.*

Table 2-1 Interrupt Control Bits and Interrupt Factors of LIN Interface (v2.1) (Manual Mode)

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Clearing of Interrupt Request Flag
Reception	RDRF	SSR	1-byte reception	SCR:RIE	- Reading of reception data (RDR) - Software reset (SCR:UPCL = 1)
			Reception of as much data as the amount set in FBYTE		- Reading of reception data until the reception FIFO becomes empty - Software reset (SCR:UPCL = 1)
			Detection of reception idle for 8-bit time or longer while the FRIIE bit is "1" and the reception FIFO contains valid data		
	ORE	SSR	Overrun error	SCR:RIE ECR:REIE	- Writing "1" to the reception error flag clear bit (SSR:REC) - Software reset (SCR:UPCL = 1)
	FRE	SSR	Framing error		
	RXUDR	ESR	Reception FIFO underrun	ECR:REIE	- Writing "1" to the reception FIFO underrun clear flag bit (ESRC:RXUDRC) - Software reset (SCR:UPCL = 1) - Disable reception FIFO - When FCR1:FSEL=0, set FCR0:FE2=0 - When FCR1:FSEL=1, set FCR0:FE1=0
	RBERR	ESR	Reception block transfer error	ECR:REIE	- Writing "1" to the reception block transfer error clear bit (ESRC:RBERRC) - Software reset(SCR:UPCL=1) - Disable Block transfer mode (ECR:RXBLKEN=0)
Transmission	TDRE	SSR	The transmission register is empty.	SCR:TIE	Writing to the transmission data (TDR), or writing "1" to the transmission FIFO operation enable bit (FCR0:FE1 or FCR0:FE2) (retransmission) while the bit value is "0" and the transmission FIFO contains valid data *1
	TBI	SSR	No transmission operation	SCR:TBIE	Writing to the transmission data (TDR), writing "1" to the LIN Break Field setting bit (LBR), or writing "1" to the transmission FIFO operation enable bit (FCR0:FE1 or FCR0:FE2) (retransmission) while the bit value is "0" and the transmission FIFO contains valid data*1
	FDRQ	FCR1	The amount of data in the transmission FIFO is equal to or smaller than the FTICR setting value or it is empty.	FCR1:FTIE	Writing "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC) , or transmission FIFO full

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Clearing of Interrupt Request Flag
	TXOVR	ESR	Transmission FIFO overrun	ECR:TEIE	- Writing "1" to the transmission FIFO overrun flag clear bit (ESRC:TXOVRC) - Software reset (SCR:UPCL = 1) - Disable transmission FIFO - When FCR1:FSEL=0, set FCR0:FE1=0 - When FCR1:FSEL=1, set FCR0:FE2=0
	TBERR	ESR	Transmission block transfer error	ECR:TEIE	- Writing "1" to the transmission block transfer error clear bit (FSRC:TBERRC) - Software reset (SCR:UPCL=1) - Disable Block transfer mode (ECR:TXBLKEN=0)
Status (Manual Mode)	LBD	SSR	LIN Break Field detection	ESCR:LBIE	- Writing "1" to the SSRC:LBDC bit - Software reset (SCR:UPCL = 1)
	SFD	SACSR	Sync Field detection	SACSR:SFDE	- Writing "1" to the Sync Field detection flag clear bit (SACSRC:SFDC) - Software reset (SCR:UPCL=1)
	TINT	SACSR	Coincidence of the serial timer register (STMR) and the serial timer comparison register (STMCR) values	SACSR:TINTE	- Writing "1" to the timer interrupt flag clear bit (SACSRC:TINTC) - Software reset (SCR:UPCL=1)
Input Capture	ICP0	ICS0	1st falling edge of the LIN Sync Field	ICS0:ICE0	Disabling the ICP0
	ICP0	ICS0	5th falling edge of the LIN Sync Field

Table 2-4 LIN Interface (v2.1) Interrupt Control Bits and Interrupt Factors (Assist Mode)

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Clearing of Interrupt Request Flag
Reception	RDRF	SSR	1-byte reception	SCR:RIE	- Reading of reception data (RDR) - Software reset (SCR:UPCL = 1)
			Reception of as much data as the amount set in FBYTE		- Reading of reception data (RDR) until the reception FIFO becomes empty - Software reset (SCR:UPCL = 1)
			Detection of reception idle for the 8-bit time or longer while the FRIIE bit is "1" and the reception FIFO contains valid data		
	ORE	SSR	Overrun error	SCR:RIE ECR:REIE	- Writing "1" to the reception error flag clear bit (SSR:REC) - Software reset (SCr:UPCL = 1)
	FRE	SSR	Framing error		
	LBSER	LAMESR	LIN bus error detection	LAMIER: LBSERIE	- Writing "1" to LAMESRC:LBSERC - Software reset (SCr:UPCL = 1)
	LSFER	LAMESR	LIN Sync Data error detection	LAMIER: LSFERIE	- Writing "1" to LAMESRC:LSFERC - Software reset (SCr:UPCL = 1)
	LPTER	LAMESR	LIN ID parity error detection	LAMIER: LPTERIE	- Writing "1" to LAMESRC:LPTERC - Software reset (SCr:UPCL = 1)
	LCSER	LAMESR	LIN checksum error detection	LAMIER: LCSERIE	- Writing "1" to LAMESRC:LCSERC - Software reset (SCr:UPCL = 1)
	RXUDR	ESR	Reception FIFO underrun	ECR:REIE	- Writing "1" to the reception FIFO underrun flag clear bit (ESRC:RXUDRC) - Software reset (SCr:UPCL = 1) - Disable reception FIFO - When FCR1:FSEL=0, set FCR0:FE2=0 - When FCR1:FSEL=1, set FCR0:FE1=0
	RBERR	ESR	Reception block transfer error	ECR:REIE	- Writing "1" to the reception block transfer error clear bit - Software reset (SCR:UPCL=1) - Disable Block transfer mode (ECR:RXBLKEN=0)
Transmission	TDRE	SSR	The transmission register is empty.	SCR:TIE	Writing to the transmission data (TDR) , or writing "1" to the transmission FIFO operation enable bit (FCR0:FE1 or FCR0:FE2) (retransmission) when the bit value is "0" and the transmission FIFO contains valid data*1
	TBI	SSR	No transmission operation	SCR:TBIE	Writing to the transmission data (TDR), writing "1" to the LIN Break Field setting bit (LBR), or writing "1" to the transmission FIFO operation enable bit (retransmission) when the bit value is "0" and the transmission FIFO contains valid data *1
	FDRQ	FCR1	The amount of data in the transmission FIFO is equal to or less than the FTICR setting value or it is empty.	FCR1:FTIE	Writing "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC) , or the transmission FIFO is full

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Clearing of Interrupt Request Flag
	TXOVR	ESR	Transmission FIFO overrun	ECR:TEIE	- Writing "1" to the transmission FIFO overrun flag clear bit (ESRC:TXOVRC) - Software reset (SCR:UPCL=1) - Disable transmission FIFO - When FCR1:FSEL=0, set FCR0:FE1=0 - When FCR1:FSEL=1, set FCR0:FE2=0
	TBERR	ESR	Transmission block transfer error	ECR:TEIE	- Writing "1" to the transmission block transfer error clear bit (ESRC:TBERRC) - Software reset (SCR:UPCL=1) - Disable Block transfer (ECR:TXBLKEN=0)
Status (Assist Mode)	LBD	SSR	LIN Break Field detection	ESCR:LBIE	- Writing "1" to the SSRC:LBDC bit - Software reset (SCR:UPCL=1)
	SFD	SACSR	Sync Field detection	SACSR: SFDE	- Writing "1" to the Sync Field detection flag clear bit (SACSRC:SFDC) - Software reset (SCR:UPCL=1)
	TINT	SACSR	Coincidence of the value in the serial timer register (STMR) and that in the serial timer comparison register (STMCR)	SACSR: TINTE	- Writing "1" to the timer interrupt flag clear bit (SACSRC:TINTC) - Software reset (SCR:UPCL=1)
	LAHC	LAMSR	Completion of auto header	LAMIER: LAHCIE	- Writing "1" to LAMSRC:LAHCC - Reading from the ID register (LAMRID) - Software reset (SCR:UPCL = 1)
	LCSC	LAMSR	Completion of checksum calculation	LAMIER: LCSCIE	- Writing "1" to LAMSRC:LCSCC - Software reset (SCR:UPCL = 1)

2653	CHAPTER 39: LIN Interface (V2.1) 9. Interface (V2.1) Registers 9.20. FIFO Byte Register (FBYTE)	Error) ■ The initial transfer count value for the FBYTE register is 0x08. Therefore, set 0x00 as the transfer count of the FBYTE to the transmission FIFO selected by the FSEL. ■ When both of the following conditions are satisfied, the continuation of the reception idle status for 8 baud rate clocks or longer sets the interrupt flag (RDRF) to "1". ☐ Reception FIFO idle detection enable bit (FRIIE) is "1". ☐ The number of data items in the reception FIFO does not reach the transfer count. During an 8-clock count, the counter is reset to 0 when RDR is read, and the system starts counting the 8 clocks again. The counter is reset to 0 when the reception FIFO is disabled. If the reception FIFO is enabled when data remains in the reception FIFO, counting restarts. Correct) ■ The initial transfer count value for the FBYTE register is 0x08. ■ When both of the following conditions are satisfied, the continuation of the reception idle status for 8 baud rate clocks or longer sets the interrupt flag (RDRF) to "1". − - Reception FIFO idle detection enable bit (FRIIE) is "1". − - The number of data items in the reception FIFO does not reach the transfer count. During an 8-clock count, the counter is reset to 0 when RDR is read, and the system starts counting the 8 clocks again. The counter is reset to 0 when the reception FIFO is disabled. If the reception FIFO is enabled when data remains in the reception FIFO, counting restarts. − The value of FBYTE of transmission FIFO is incremented by 1 when a transmission data is written to TDR 1 time. − The value of FBYTE of reception FIFO is decremented by 1 when a reception data is read from RDR 1 time.
2655	CHAPTER 39: LIN Interface (V2.1) 9. Interface (V2.1) Registers 9.21. Transmission FIFO Interrupt Control Register (FTICR)	Error) ■ ECR:TXBLKEN = 0 The FTICR register sets the threshold for interrupts according to the valid transmission data count (remaining amount) of the transmission FIFO. The table below shows the setting conditions for different FCR1:FSEL bit values. ■ ECR:TXBLKEN = 1 The FTICR register sets the trigger level for interrupts according to the vacant data count of the transmission FIFO. Correct) ■ ECR:TXBLKEN = 0 ■ The FTICR is set the trigger level to interrupt for transmission FIFO's transmission valid data number (remained data number). ■ ECR:TXBLKEN = 1 The FTICR register sets the trigger level for interrupts according to the vacant data count of the transmission FIFO. The table below shows setting values of the FCR1:FSEL bit.

Page	Section	Change Results
2659	CHAPTER 39: LIN Interface (V2.1) 9. Interface (V2.1) Registers 9.23. Extended Status Register (ESR)	Error) **[bit11] RXUDR: Reception FIFO Underrun Flag Bit** ***Notes:*** Correct) **[bit11] RXUDR: Reception FIFO Underrun Flag Bit** ***Notes:*** − *This bit is "0" when reception FIFO is not available.*
2660	CHAPTER 39: LIN Interface (V2.1) 9. Interface (V2.1) Registers 9.23. Extended Status Register (ESR)	Error) **[bit10] TXOVR: Transmission FIFO Overrun Flag Bit** ***Notes:*** ■ When the transmission FIFO is OFF, and block transfer is performed under any one of the following conditions, this bit is set to "1" to indicate a block transfer error. ☐ A transmission interrupt is enabled (SCR:TIE = 1) and the transmission data register contains data (SSR:TDRE = 0). ☐ A transmission interrupt is disabled (SCR:TIE = 0), and a transmission bus idle interrupt is enabled (SCR:TBIE = 1) and transmission is in progress (SSR:TBI = 0). If a transmission interrupt is enabled (SCR:TIE = 1) and a transmission bus idle interrupt is enabled (SCR:TBIE = 1), the condition for enabling transmission interrupt (SCR:TIE = 1) is given priority. Correct) **[bit10] TXOVR: Transmission FIFO Overrun Flag Bit** ***Notes:*** − *This bit is "0" when transmission FIFO is not available.*

Page	Section	Change Results
2660	CHAPTER 39: LIN Interface (V2.1) 9. Interface (V2.1) Registers 9.23. Extended Status Register (ESR)	Error) **[bit9] RBERR: Reception Block Transfer Error Bit** Suppose that block transfer is performed with a value larger than the threshold specified in the FBYTE register, this bit is set to "1" to indicate a block transfer error. A reception interrupt occurs if reception interrupt is enabled (SSR:RIE = 1). ***Notes:*** − *This bit is "0" when the reception block transfer enable bit (ECR:RXBLKEN) is "0".* Correct) **[bit9] RBERR: Reception Block Transfer Error Bit** Suppose that block transfer is performed with a value larger than the threshold specified in the FBYTE register, this bit is set to "1" to indicate a block transfer error. A reception interrupt occurs if reception interrupt is enabled (SCR:RIE = 1). ***Notes:*** − *This bit is "0" when the reception block transfer enable bit (ECR:RXBLKEN) is "0" or when the reception interrupt enable bit (SCR:RIE) is "0".*
2667	CHAPTER 39: LIN Interface (V2.1) 9. Interface (V2.1) Registers 9.29. Serial Auxiliary Control Status Clear Register (SACSRC)	Error) **[bit13] SFDC: Clearing the Sync Field Detection Flag** Writing "1" to this bit resets SACSR:CSEIE to "0". **[bit12] SFDEC: Clearing the Sync Field Detection Interrupt Enable Bit** Writing "1" to this bit resets SACSR:CSE to "0". Correct) **[bit13] SFDC: Clearing the Sync Field Detection Flag** Writing "1" to this bit resets SACSR:SFD to "0". **[bit12] SFDEC: Clearing the Sync Field Detection Interrupt Enable Bit** Writing "1" to this bit resets SACSR:SFDE to "0".

3091, 3092	CHAPTER 52: DDR High Speed SPI Controller 3. Serial Interface 3.4. SPI Data Learning Pattern	Added the below: The logic related to SDATA Sampling Points and DLP is illustrated as below. The internal flag is directly invisible from the CPU, however, its status is reflected to the Bus Error and the system can detect it. **Figure 3-5SDATA Sampling Points and Related Logics**  Notes: − Once having detected a DLP error, the following Memory Read access is affected as below. (1)When a DLP error occurs, it is held on the internal flag along DDRHSSPIn_FAULTF.DLPFS bit. (2)The software clears DLP-related flags (DDRHSSPIn_FAULTF.DLPFS and DDRHSSPIn_RXF.DLPERR) and adjusts the SDATA Sampling Points to proper values. (3)This internal flag affects the next Memory Read access depending on the address. *(a)Same word-line addresses: "Error"If ("new address" >> 2) = ("previous address" >> 2), the result is as below.-Bus Error on the System Bus-Internal flag = "1"-DDRHSSPIn_FAULTF.DLPFS = "1"-DDRHSSPIn_RXF.DLPERR = "0"-DDRHSSPIn_DLPSAMPLESTATUS = 0x00000000(b)Different word-line addresses: "Success"If ("new address" >> 2) ≠("previous address" >> 2), the result is as below.-No Bus Error on the System Bus-Internal flag = "0"-DDRHSSPIn_FAULTF.DLPFS = "0"-DDRHSSPIn_RXF.DLPERR = "0"-DDRHSSPIn_DLPSAMPLESTATUS 0x00000000Figure 3-6and Figure 3-7illustrate these cases (a) and (b). Each diagram depicts two consecutive Memory Read accesses -the first one failing to sample SDATA, and the second one with successful sampling. The address of the second access determines the result.* *− The proposed Calibration sequence is described in the section 4.4.4 "Using the DDRHSSPI in Command Sequencer Mode of Operation".* **Figure 3-6Memory Read accesses from "FAIL" to "PASS" ((a) Same Word-line)** 
Page	Section	Change Results
3093	CHAPTER 52: DDR High Speed SPI Controller 3. Serial Interface 3.4. SPI Data Learning Pattern	Added the below: **Figure 3-7Memory Read accesses from "FAIL" to "PASS" ((b) Different Word-line)** 3094	CHAPTER 52: DDR High Speed SPI Controller 3. Serial Interface 3.6. Shift Direction	Error) Figure 4-7 depicts the direction in which the data in the Shift Register is shifted to/from the serial data lines, under Quad Mode. The waveforms assume DDRHSSPIn_DMFIFOCFG.FWIDTH = 0b00. The Figures depict that the transmit data is loaded into the Shift Register from the TX-FIFO. However, the source of transmit data can be other registers, such as DDRHSSPIn_RDCSDC0-11.RDCSDATA. When DDRHSSPIn_MID.MID is 0x00000100 or 0x00000300, DDRHSSPI is available for Dual Legacy Mode and Dual Quad Mode. Figure 3-6 and Figure 3-7 depict the direction in which the data in the Shift Register is shifted to/from the serial data lines, under Dual Legacy Mode and Dual Quad Mode. Correct) The following figures Figure 4-7 depict the direction in which the data in the Shift Register is shifted to/from the serial data lines. The waveforms assume DDRHSSPIn_DMFIFOCFG.FWIDTH = 0b00 in Direct Mode. The Figures depict that the transmit data is loaded into the Shift Register from the TX-FIFO. However, the source of transmit data can be other registers, such as DDRHSSPIn_RDCSDC0-11.RDCSDATA. When DDRHSSPIn_MID.MID is 0x00000100 or 0x00000300, DDRHSSPI is available for Dual Legacy Mode and Dual Quad Mode. Figure 3-14 and Figure 3-15 depict the direction in which the data in the Shift Register is shifted to/from the serial data lines, under Dual Legacy Mode and Dual Quad Mode.

3109	CHAPTER 52: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.4. Available Command Formats of Serial Flash Memory	Error) Note: − When in writing TXDATA[12:8] for SPI control on-the-fly, it is allowing regardless the setting of DDRHSSPIn_DMFIFOCFG.FWIDTH. The available command formats of Serial Flash are different according to the value of DDRHSSPIn_MID. MID. Correct) Note: − When in writing TXDATA[12:8] for SPI control on-the-fly, it is allowed regardless the setting of DDRHSSPIn_DMFIFOCFG.FWIDTH. The available command formats of Serial Flash are different according to the value of DDRHSSPIn_MID. MID bits.
3112	CHAPTER 52: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.5. FIFO Accesses in Direct Mode	Error) When in DDRHSSPIn_DMFIFOCFG.TXCTRL= 1, the setting of DDRHSSPIn_DMFIFOCFG.FWIDTH is ignored at writing into TX-FIFO, and up to 32 bits could be relevant. (please refer to the Table 4-1). Note: − In case that DDRHSSPI is configured in: − DDR Mode, AND − Dual Quad Mode setting DDRHSSPIn_DMFIFOCFG.FWIDTH to 0b00 (8-bit wide mode) is not allowed. Correct) When in DDRHSSPIn_DMFIFOCFG.TXCTRL= 1, the setting of DDRHSSPIn_DMFIFOCFG.FWIDTH is ignored at writing into TX-FIFO, and up to 32 bits could be relevant. (For details, please refer to the Table 4 1).
3112, 3113	CHAPTER 52: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.6. Service Requests	Added the below: − The DDRHSSPIn_TXF.TFES is set if the DDRHSSPIn_DMFIFOSTATUS.TXFLEVEL is 0, i.e. TX-FIFO is empty. − The DDRHSSPIn_RXF.RFFS is set if the DDRHSSPIn_DMFIFOSTATUS.RXFLEVEL is 24, i.e. RX-FIFO is full.

Page	Section	Change Results
3113	CHAPTER 52: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.6. Service Requests	Error) Each of these counters is a 5 bits down counter, which is reloaded with the DMA Block size (for the respective channel) whenever the DMA Service Request for that channel is asserted. The counters are decremented with every successful read or write accesses to the RX-FIFO or TX-FIFO. In case of the RX-FIFO accesses, the RX Block Counter is decremented only if the access was from a System Bus master other than the DAP Controller. Correct) Each of these counters is a 5 bits down counter, which is reloaded with the DMA Block size (for the respective channel) each time the DMA Service Request for that channel is asserted. The counters are decremented with every successful read or write accesses to the RX-FIFO or TX-FIFO. In case of the RX-FIFO accesses, the RX Block Counter is decremented unless the access was from the DAP Controller.
3115	CHAPTER 52: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.7. SPI Transfers	Error) When the DDRHSSPI is working in Direct Mode, it can be interfaced with up to 4 Serial Flash Memories. Correct) When the DDRHSSPI is working in Direct Mode, it can be interfaced with up to 4 Serial Flash Memories at Legacy/Quad mode (8 at Dual Legacy/Dual Quad mode).
3116	CHAPTER 52: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.1.Direct Mode 4.1.7. SPI Transfers	Deleted the below: Note: − When in TX-and-RX Mode, please avoid halting the serial transfer.

Page	Section	Change Results
3117	CHAPTER 52: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.2. Command Sequencer Mode	Error) Since the first SPI transaction is controlled under TX-Only Mode, the read data from the Serial Flash are ignored. Valid reading of Serial Flash is run at the Command Sequencer Mode. In memory reading, the bit width on the SPI from the address field should be constantly Quad. Correct) Since the first SPI transaction is controlled under TX-Only Mode, the read data from the Serial Flash are ignored in that transaction. Valid reading of Serial Flash is run at the Command Sequencer Mode. In memory reading, the bit width on the SPI from the address field should be constantly Quad (or Dual Quad).
3118	CHAPTER 52: DDR High Speed SPI Controller 4.Operations of the DDRHSSPI 4.2. Command Sequencer Mode	Error) Generation of 32-Bit Memory Address The Address Extension Mechanism allows the mapping of 256MB of the MCU address space to 4GB of address space on a Slave Select line. Every Serial Flash Memory can be visualized as entity, consisting of several memory banks. The size of each bank can be programmed in the DDRHSSPIn_CSCFG.MSEL. Each bank can be selected by changing the value in the DDRHSSPIn_CSAEXT Register. By reprogramming the DDRHSSPIn_CSAEXT Register, each time a new bank in the selected Serial Flash Memory is accessed. Through different banks, it is possible to address a Serial Flash Memory of up to 4GB size. Correct) Generation of 32-Bit Memory Address The Address Extension Mechanism allows the MCU to access each Serial Flash Memory of a size of 4GB. Each Serial Flash Memory is accessible by dividing into several memory banks. The size of each bank can be programmed in the DDRHSSPIn_CSCFG.MSEL. Each bank can be selected by changing the value in the DDRHSSPIn_CSAEXT Register. To select a new bank, the software shall program a new value to the DDRHSSPIn_CSAEXT Register. By switching banks, it is possible to address a Serial Flash Memory of 4GB size.

Page	Section	Change Results
119	CHAPTER 52: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI 4.2. Command Sequencer Mode	Error) The Least Significant Bits of the System Bus Address received by the DDRHSSPI on the System Bus are used as the offset within the bank selected by the Address Extension bits. The concatenation of the appropriate number of bits from the Address Extension Register with the appropriate number of bits from the address bus, determine the 32-bit address of the memory to be accessed on the Serial Interface. Please refer to Table 4-5. Correct) The Least Significant Bits of the System Bus Address received by the DDRHSSPI on the System Bus are used as the offset within the bank selected by the Address Extension bits. The final 32-bit address on the SPI is generated by the following concatenation: − Upper bits: Register bits DDRHSSPIn_CSAEXT.AEXT[31:m] − Lower bits: Address on the System Bus[m-1:0] (m = DDRHSSPIn_CSCFG.MSEL[3:0] + 13.) For details, please refer to Table 4-5.

Page	Section	Change Results
3120	CHAPTER 52: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI 4.2. Command Sequencer Mode	Error) Last two columns in Table 4-5 indicate which bits from the DDRHSSPIn_CSAEXT.AEXT and the address bus (i.e. HADDR) are concatenated, to get the final 32-bit address of the Serial Flash Memory. Although, the final memory address generated in this way is a 32-bit address, it must be noted, that the software can choose the number of bytes (from this 32-bit address) to be sent to the Serial Flash Memory during the address phase of a memory read Command Sequence. Internal Prefetch Buffer In Command Sequencer Mode the DDRHSSPI internally has one Prefetch Buffer for temporary storage, of the data to be received (Prefetch Buffer). This Prefetch Buffer consists of 48 locations each 32-bit wide. Prefetch Buffer shall support 32 bits, 16 bits and 8 bits reads using the following mechanism: In generation of the Command Sequence the two least significant address bits shall be ignored. When a byte or halfword is read at a random (non-sequential) address, the Command Sequence shall be generated at the aligned word address which contains this byte or halfword. In any access scenario where the required data can be read from the top most position of the Prefetch Buffer, there will be no additional Command Sequence. When the Prefetch Buffer is read (as FIFO), only if the read includes the last byte within the actual Prefetch Buffer word, it will be popped. Following are typical read scenarios with explanation when the Prefetch Buffer pops: In order to obtain maximum throughput, 32-bit access is highly recommended. Correct) Last two columns in Table 4-5 indicate which bits from the DDRHSSPIn_CSAEXT.AEXT and the address bus (i.e. HADDR) are concatenated, to get the final 32-bit address of the Serial Flash Memory. The output memory address on the SPI can be 32 or 24 bits according to the Serial Flash Memory products, and this is controlled by the register settings of DDRHSSPIn_RDCSDC0-11 (for details, refer toTable 4-6). Internal Prefetch Buffer In Command Sequencer Mode the DDRHSSPI internally has one Prefetch Buffer for a temporary storage of received data. This Prefetch Buffer consists of 48 locations, 32-bit wide. Prefetch Buffer shall support 32 bits, 16 bits and 8 bits reads using the following mechanism: − When a byte or halfword is read at a random (non-sequential) address on the System Bus, the Command Sequence is generated with the address aligned to the word boundary, which covers the required data. − In the actual Command Sequence in transmission, the two least significant address bits are fixed to "00" (i.e. these two bits from the System Bus are ignored). As long as the software reads a series of continuous data from the top most position of the Prefetch Buffer, there will be no additional Command Sequence on the SPI. When the Prefetch Buffer is read, it internally works as a FIFO, and a word data in the next location pops out only when the current read data includes the last byte in the word line. The typical cases to pop the Prefetch Buffer are as below: In order to obtain the maximum throughput, word access (i.e. 32-bit access) is highly recommended.

Page	Section	Change Results
3121	CHAPTER 52: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI 4.2. Command Sequencer Mode	Error) Initiation of Command Sequence Whenever the Command Sequencer receives a System Bus read access for the memory mapped Serial Flash Memory, it initiates a corresponding memory read command on one of the four Slave Select lines, assembles the data it has received, and responds with the memory read-data. Only Flash Memory read commands are supported in the Command Sequencer Mode. While the DDRHSSPI initiates a memory-read command and receives the read-data from the Serial Flash Memory, the System Bus Slave port of the DDRHSSPI inserts WAIT states on the System Bus. The DDRHSSPI keeps track of the previous address and the System Bus transfer type issued by the System Bus master. If the new transaction address is not contiguous, then a new serial transaction is issued on the Serial Interface. Correct) Initiation of Command Sequence Whenever the Command Sequencer detects a System Bus read access for the memory mapped Serial Flash Memory, it initiates a corresponding Memory Read Command Sequence on the SPI, assembles the received data, and responds to the System Bus with the Memory Read data. The Command Sequencer Mode supports only Memory Read commands of Serial Flash Memory. While the DDRHSSPI initiates a memory-read command and receives the read-data from the Serial Flash Memory, the DDRHSSPI inserts WAIT states on the System Bus. The DDRHSSPI keeps track of the previous address and the System Bus transfer type issued by the System Bus master. If the new transaction address is not contiguous, then a new serial transaction is issued on the Serial Interface.

Page	Section	Change Results
3122	CHAPTER 52: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI 4.2. Command Sequencer Mode	Error) **Idle Timeout** After a Serial Flash Memory is accessed in the Command Sequencer Mode, the DDRHSSPI keeps asserting the Slave Select line even if the System Bus transaction is over. And DDRHSSPI can de-assert the Slave Select automatically after waiting for a certain period of time. To use this feature, it is necessary to set DDRHSSPIn_CSCFG.ITIMEREN bit to "1". If this feature is disabled, Slave Select remains asserted after any transfer on the Serial Flash Memory. If this feature is enabled, the following part explains the Idle Timer behavior: During idle cycles on the System Bus, prefetch reads from the Serial Flash Memories to the Prefetch Buffer are performed. As soon as the Prefetch Buffer is full, the Slave Select shall be kept asserted, and the Idle Timer shall start running. If there are no subsequent System Bus accesses to the consecutive memory address during the idle time, then after the Idle Timer expires, the DDRHSSPI de-asserts the Slave Select, indicating the termination of the transfer and flushes the Prefetch Buffer. Whenever a prefetch is performed before the Idle Timer expires, the Idle Timer shall be cleared again. Within the predefined time period, defined by the DDRHSSPIn_CSITIME.ITIME, the DDRHSSPI determines whether to extend the current serial transaction. If the following conditions are satisfied: Correct) **Idle Timeout** After a Serial Flash Memory is accessed in the Command Sequencer Mode, the DDRHSSPI keeps asserting the Slave Select line even if the System Bus transaction is over. And DDRHSSPI can deassert the Slave Select automatically after waiting for a certain period of time. To use this feature, it is necessary to set DDRHSSPIn_CSCFG.ITIMEREN bit to "1". If this feature is disabled, Slave Select remains asserted after any transfer on the Serial Flash Memory. If this feature is enabled, the following part explains the Idle Timer behavior: During idle cycles on the System Bus, DDRHSSPI continues reading the Serial Flash Memory until the prefetch Buffer reaches full. After reaching full, the Slave Select shall stay asserted, and the Idle Timer shall start running. If there are no subsequent System Bus accesses to the consecutive memory address during the programmed idle time, the DDRHSSPI deasserts the Slave Select after the Idle Timer expires. The deassertion of Slave Select indicates the termination of the transfer and flushes the Prefetch Buffer. If the consecutive memory read access resumes before the Idle Timer expires, the Idle Timer shall be cleared again. Within the predefined time period, defined by the DDRHSSPIn_CSITIME.ITIME, the DDRHSSPI determines whether to extend the current serial transaction. If the following conditions are satisfied:

3129	CHAPTER 52: DDR High Speed SPI Controller 4.4. General Use Case Guidelines for DDRHSSPI 4.4.2. Steps in Programming the DDRHSSPI Module	Error) 2. The next step is to configure the Attributes related to the Peripheral Communication with the Serial Flash Memory(Memories) connected with DDRHSSPI. DDRHSSPI can be interfaced with up to 4 Serial Flash Memories. Serial communication related attributes like Transfer Frequency (i.e. Clock Division Ratio bits), etc. shall be configured in the registers: DDRHSSPIn_PCC0-3. It is very important that these attributes shall be the same as the Serial Flash Memory, which is connected with DDRHSSPI. 3. DDRHSSPI can be configured either in Direct Mode or in Command Sequencer Mode, through the DDRHSSPIn_MCTRL.CSEN bit. Depending on which mode is to be used, the software shall configure the mode-specific registers. Correct) 2. The next step is to configure the Attributes related to the Peripheral Communication with the Serial Flash Memory(Memories) connected with DDRHSSPI. DDRHSSPI can be interfaced with up to 4 Serial Flash Memories at Legacy/Quad mode (8 at Dual Legacy/Dual Quad mode). Serial communication related attributes like Transfer Frequency (i.e. Clock Division Ratio bits), etc. shall be configured in the registers: DDRHSSPIn_PCC0-3. It is very important that these attributes shall be identical among the Serial Flash Memories connected with DDRHSSPI. 3. DDRHSSPI can be configured either in Direct Mode or in Command Sequencer Mode, by the DDRHSSPIn_MCTRL.CSEN bit. Depending on which mode is to be used, the software shall configure the mode-specific registers. When DDRHSSPIn_MID.MID is 0x00000300, there are additional registers (DDRHSSPIn_SDATASAMPLEPT{CNT/LFT/RGH}0-7, DDRHSSPIn_DLP) in Command Sequencer Mode.
3131	CHAPTER 52: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI 4.4. General Use Case Guidelines for DDRHSSPI 4.4.3. Using the DDRHSSPI in Direct Mode of Operation	Error) 7. When DDRHSSPI is configured, setting the DDRHSSPIn_DMSTART.START bit triggers the start of the serial transaction. Once the serial transaction starts, if transmission is enabled in the DDRHSSPIn_DMTRP.TRP, the DDRHSSPI reads data from TX-FIFO and loads them to the Shift Register. The Shift Register is shifted left and the transmit data is shifted-out onto the Serial Interface. Correct) 7. When DDRHSSPI is configured, setting the DDRHSSPIn_DMSTART.START bit triggers the start of the serial transaction. Once the serial transaction starts, if the transmit data is available in the TX-FIFO, the DDRHSSPI reads data from TX-FIFO and loads them to the Shift Register. The Shift Register is shifted left and the transmit data is shifted-out onto the Serial Interface.

3131	CHAPTER 52: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI 4.4. General Use Case Guidelines for DDRHSSPI 4.4.3. Using the DDRHSSPI in Direct Mode of Operation	Error) 9. Service Requests are asserted by DDRHSSPI whenever the TX-FIFO level is below the threshold or whenever the DDRHSSPI RX-FIFO level is above the threshold. The software shall write TX-FIFO or read RX-FIFO, to ensure the serial data transfer of DDRHSSPI. After writing or reading the relevant FIFO, the software shall clear the Interrupt Service Requests by writing the DDRHSSPIn_TXC or the DDRHSSPIn_RXC Register. DMA Service Requests are cleared by the DMA Controller. 10. If reception is enabled in DDRHSSPIn_DMTRP Register, then the software fetches the received data from the RX-FIFO. Correct) 9. Service Requests are asserted by DDRHSSPI whenever the TX-FIFO level is below the threshold or whenever the DDRHSSPI RX-FIFO level is above the threshold. The software shall write TX-FIFO or read RX-FIFO, to ensure the serial data transfer of DDRHSSPI. After writing or reading the relevant FIFO, the software shall clear the Interrupt Service Requests by writing the DDRHSSPIn_TXC or the DDRHSSPIn_RXC Register. DMA Service Requests are cleared by the handshake responses from the DMA Controller. When the data transfer is not by DMA, the Service Requests can be asserted also by TX-FIFO's empty or RX-FIFO's full status. The software can select the conditions. 10. If reception is enabled in DDRHSSPIn_DMTRP Register (when in TX-and-RX Mode), then the software fetches the received data from the RX-FIFO.
3132	CHAPTER 52: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI 4.4. General Use Case Guidelines for DDRHSSPI 4.4.4. Using the DDRHSSPI in Command Sequencer Mode of Operation	Error) Interfacing of one Serial Flash Memory which requires 32-bit addressing and other Serial Flash Memory (also of same family, but) which requires only 24-bit addressing in Command Sequencer Mode is not possible. − On-the-fly switching of programmed Data Rate Mode (SDR Mode or DDR Mode) is not allowed in Command Sequencer Mode while module is enabled. Correct) Interfacing Serial Flash Memories mixing 32-bit addressing and 24-bit addressing is not allowed in Command Sequencer Mode. − On-the-fly switching of Data Rate Mode (SDR/DDR Mode programmed in DDRHSSPIn_CSCFG.DDRMODE) is not allowed in Command Sequencer Mode while module is enabled.

3134	CHAPTER 52: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI 4.4. General Use Case Guidelines for DDRHSSPI 4.4.4. Using the DDRHSSPI in Command Sequencer Mode of Operation	Added the below: **Calibration of SDATA Sampling Points** Before running the main process, the software shall adjust the SDATA Sampling Points by setting up registers DDRHSSPIn_SDATASAMPLEPT{LFT/CNT/RGH}0-7. To determine the best sampling points on each bit lane of SDATA[7:0], the software has to run a flow (1)~(3) as below. This flow is an example. The overview of this flow is also illustrated in Figure 4-13. (1) Calibration sequence First of all, the software needs to prepare arrays to store the result of Calibration. Each array has a size corresponding to SDATA Sampling Points (=128). It is recommended to prepare 8 arrays to store results for each bit lane of SDATA[7:0]. The software runs the following sequence: − a) Set DDRHSSPIn_MCTRL.DLPEN bit to "1". − The Calibration sequence goes with causing Bus Errors, and these errors have to be ignored by the system. Please make the settings on the system for it. − b) Set all {R/C/L} of SDATA Sampling Points to 0. − The target registers are for current bit lane of SDATA[7:0]. − E.g. If current bit lane is SDATA[0], write 0x00 to registers DDRHSSPIn_SDATASAMPLEPT{LFT/CNT/RGH}0. − c) Run a Memory Read access at 32-bits width. − From the second round in the loop, the software shall increment the address at least +8. − If any of SDATA Sampling Points is not in the valid bit range, the DLP checking results in error and causes a Bus Error. − d) Check the status of DDRHSSPIn_DLPSAMPLESTATUS register. − The software shall check the bit fields for current bit lane of SDATA[7:0], and store the result to the corresponding array. − e) Clear the DLPFS bit by writing "1" to DDRHSSPIn_FAULTC.DLPFC. − f) Increment all {R/C/L} of SDATA Sampling Points (+1 on each). − g) Repeat (c)~(f) until the max value of SDATA Sampling Points (128 rounds). − h) Repeat (b)~(g) until completing all bit lanes of SDATA[7:0] (8 rounds). − i) At this moment, DDRHSSPI is expected to be in the status as below: − SDATA Sampling Points are the max value. − The last Memory Read access has ended in Bus Error. − DDRHSSPIn_FAULTF.DLPFS="1" − DDRHSSPIn_RXF.DLPERR="1" − The software holds all arrays of "PASS"/"FAIL" results for each bit lane of SDATA[7:0].

Page	Section	Change Results
3134, 3135	CHAPTER 52: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI 4.4. General Use Case Guidelines for DDRHSSPI 4.4.4. Using the DDRHSSPI in Command Sequencer Mode of Operation	Added the below: (2) Setting SDATA Sampling Points Set the registers DDRHSSPIn_SDATASAMPLEPTCNT0-7 to the center positions in respective "PASS" ranges. If there is no "PASS" range in the array, the DDRHSSPI hereafter cannot serve Memory Read access. Else if the "PASS" range is divided by "FAIL(s)", choose the longest "PASS" range and take the center position of it. DDRHSSPIn_SDATASAMPLEPTLFT0-7 shall be set to less values than DDRHSSPIn_SDATASAMPLEPTCNT0-7 (for each bit lane of SDATA[7:0]). DDRHSSPIn_SDATASAMPLEPTRGH0-7 shall be set to greater values than DDRHSSPIn_SDATASAMPLEPTCNT0-7 (for each bit lane of SDATA[7:0]). These register settings for {"LFT", "RGH"} are actually not used in the data reception, and they are just used for detecting the violation of sampling. The degree of 'less' and 'greater' depends on the window size of "PASS" range, and these differences are used in the re-adjustment of SDATA Sampling Points afterward. (3) To the main process The software shall clear DDRHSSPIn_MCTRL.DLPEN bit to "0", if it is not allowed to lose the Memory Read data in the main process by the occurrence of DLP error. Now the DDRHSSPI is ready for the Memory Read access in the main process. During the main process, the software is required to run a periodical adjustment of SDATA Sampling Points, and this operation is described later in this section. ***Notes:*** *– If the Serial Flash Memory does not support the DLP function, please change following points.* *– DDRHSSPIn_MCTRL.DLPEN should be "0".* *– DLP-related status bits are not used.* *– All Serial Flash Memories have to store certain data in certain addresses in advance. These* *data are used for pattern matching instead of DLP, and shall have bit-toggling pattern on each bit* *lane of SDATA[7:0] as well as DLP. Please consider the "bit pattern" and "bit alignment" according to the intended SPI protocol (Quad or Dual-Quad).*

Page	Section	Change Results
3135, 3136	CHAPTER 52: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI 4.4. General Use Case Guidelines for DDRHSSPI 4.4.4. Using the DDRHSSPI in Command Sequencer Mode of Operation	Added the below: *– The software has to do pattern-matching checks with the read data, since there is no automatic checking like DLP. Please note that the read data work instead of DLP by the process of software.* *Therefore, the software shall recognize how many data to read in the DLP-like operation, and gather byte data by re-arranging bits from the read data. [e.g. Memory Read at "DDR & Dual-Quad" protocol] For the pattern matching check, it is assumed to use 8 consecutive bits on each bit lane of SDATA[7:0] as the substitute for DLP. The sum of these pattern-matching bits becomes 64 bits. In this case, the software has to read 2 words (assuming 32-bits access) to check all of these bits.* *– Although the SDATA[7:0] is sampled in parallel, the software has to check the serial bits on each bit lane of SDATA[7:0] individually. The main loop flow is basically same as the case of DLP.* *– The SPI transaction goes on regardless the sampling condition of SDATA[7:0], different from the case using DLP.* The overview of Calibration sequence is shown in the following diagram. **Figure 4-13 Calibration Sequence before the Main Process**  Before starting the main process, please read carefully the Notes of 3.4 SPI Data Learning Pattern. **Re-adjustment of SDATA Sampling Points** After setting the best position of SDATA Sampling Points, these points can gradually drift and get close to the edge of SDATA as time passes (e.g. due to the fluctuation of temperature), and the sampling may begin to fail. To avoid the miss-sampling, the software shall periodically adjust the SDATA Sampling Points. The actual interval depends on the system, however, it is expected that the software does not have to run a full Calibration sequence each time. If the periodical adjustment is frequent enough, each adjustment can change the SDATA Sampling Points +/- 1 [tap] at a time. This operation will not take time compared to the full Calibration, and it is expected that the system can insert this re-adjustment operation in the moment while the main process does not access the Serial Flash Memories. Furthermore, the system can determine the degree of adjustment not only within +/- 1 [tap]. The software runs the following sequence: a) Set DDRHSSPIn_MCTRL.DLPEN bit to "1". The handling of Bus Error is same as Calibration. Please make sure that the main process will not access Serial Flash Memories during (a)~(f) in this flow. b) Run a Memory Read access (at 32-bits width). The software shall increment the address +8 each time.

Page	Section	Change Results
3137	CHAPTER 52: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI 4.4. General Use Case Guidelines for DDRHSSPI 4.4.4. Using the DDRHSSPI in Command Sequencer Mode of Operation	Added the below: c) Check the status of following registers: DDRHSSPIn_FAULTF.DLPFS bit (optional) If this bit is "0", go to (f). DDRHSSPIn_RXF.DLPERR bit (optional) If this bit is "0", go to (f). DDRHSSPIn_DLPSAMPLESTATUS register (must) For each bit lane of SDATA[7:0], the software shall check the status of sampling and update the corresponding SDATA Sampling Point. These judgments are based on the register settings of DDRHSSPIn_SDATASAMPLEPT{LFT/CNT/RGH}0-7 in the Calibration (L < C < R). - DLPSMPLSTx{R/C/L} = "100": --> Decrease the SDATA Sampling Point. - DLPSMPLSTx{R/C/L} = "001": --> Increase the SDATA Sampling Point. - DLPSMPLSTx{R/C/L} = "000": --> No need to change the SDATA Sampling Point. If the value of DDRHSSPIn_DLPSAMPLESTATUS register is 0x00000000, go to (f). - Otherwise: --> Outside the re-adjustable range. This situation requires a full Calibration and the system shall stop the main process for a moment. When increasing/decreasing the SDATA Sampling Points, the "CNT" shall be adjusted to the center between "LFT" and "RGH", so as to ensure the PASS range as much as possible. e.g. If DLPSMPLST0{R/C/L} = "100", the software shall decrease only the value of DDRHSSPIn_SDATASAMPLEPTRGH0 registers, then calculate the "CNT" as the average value between "LFT" and "RGH". d) If DLPFS = "1", write "1" to DDRHSSPIn_FAULTC.DLPFC to clear it. If DLPERR = "1", write "1" to DDRHSSPIn_RXC.DLPERRC to clear it. e) Repeat (b)~(d) until DDRHSSPIn_DLPSAMPLESTATUS = 0x00000000. If the period to run this operation is frequent enough against the fluctuation of SDATA timing, this loop is not always necessary. f) Clear DDRHSSPIn_MCTRL.DLPEN bit to "0", if it is not allowed to lose the Memory Read data in the main process by the occurrence of DLP error. g) Main process can access Serial Flash Memories. Notes: − If the Serial Flash Memory does not support the DLP function, the software has to check the result of Memory Read access as well as Calibration sequence (please refer to its Notes). − The system has to ensure the timing for this Re-adjustment operation. Before starting the main process, please read carefully the Notes of 3.4 SPI Data Learning Pattern.

Page	Section	Change Results
3051	CHAPTER 50: I/O Port 4. Register List	Add the below: **4.13. RIC Key Code Register (RIC_KEYCDR)** **[bit14:0] RADR: Port Address Bits** ***Notes:*** − There is no effect on the key code protection release process even if registers other than this register and the applicable key code register that is in the release processing (the register set by the RADR) are accessed while writing the key code 0b00, 0b01, 0b10, and 0b11. When key code protection is released, register of protection target can be written once. If several registers are to be written, it is necessary to release the protection for each register writing.
3052	HAPTER 50: I/O Port 5. Precautions for Using This Device	Changed the below: Error) This section describes the precautions necessary when using the I/O port. A glitch may occur for a brief nanosecond (2 or 3 nanoseconds) when a general-purpose I/O port is switched (from input to output or from output to input). Correct) Notes on switching the I/O port function are shown below. A glitch may occur for a brief second (2 or 3 ns) when a general-purpose I/O port is switched (from input to output or from output to input or from port function to resource or from resource to port function). If this glitch may cause a problem for the system, please write a value to port output data register (GPIO_PODRi) in advance at a level that will not cause a problem. When a resource input is valid and its assignment is moved to another pin, a trigger which causes resource operation may occur if the pin levels before switching and after switching are different. Therefore, please switch input pins when the resource input function is stopped.
3064	CHAPTER 51: Peripheral Protection Unit 4. Registers	Deleted the below: Register map is not required because it can be extracted from each register descriptions. For the customers, they should refer DS for the I/O map.

14	CHAPTER 1: Platform Overview	Removed the shading parts as below: Error) B/B is a latest effort of the MCU platform which targets instrument cluster, graphics controller, gateway and body controller application area. Correct) B/B is the MCU platform which targets instrument cluster, graphics controller, gateway and body controller application area.
		Removed the shading parts as below: Error) To minimize design efforts of the target MCU, B/B offers rich and competitive feature sets like power saving features and IP portfolio, easy-to-use parameter option to select them, and verification suite which proves its quality.
		Revised the shading parts as below: ■Computation features Error) Cortex-R5F single core, 16K I-Cache. Targeting >240MHz with 55nm technology. Program Flash I/F which have advanced speculative prefetching algorithm. Corrrect) Cortex-R5F single core, 16K I-Cache. Main Flash I/F which have advanced speculative prefetching algorithm.
15		Removed the shading parts as below: ■Connectivity Error) CAN FD offers latest CAN protocol and highly flexible message buffering. Ext-BUS I/F supporting NAND flash

		Revised the shading parts as below: Error) - When returning from PSS mode to Run mode, Main_OSC must be valid. Therefore, be sure to enable Main_OSC setting of the RUN mode profile before entering the PSS mode. Correct) - When returning to Run mode, Main_OSC must be valid. Therefore, be sure to enable Main_OSC setting of the RUN mode profile before entering the PSS mode.
218	CHAPTER 6: 4.3. Transition from PSS to RUN	Revised the shading parts as below: Error) ■ Peripheral interrupt (PD1): External interrupt, RTC, NMI, low-voltage detection *1, HW-WDT *1, CSV *1 Correct) ■ Peripheral interrupt (PD1): External interrupt, RTC, NMI, low-voltage detection *1, HW-WDT *1
219	CHAPTER 6: 4.3. Transition from PSS to RUN	Revised the shading parts as below: Error) 2. The circuit copies the RUN profile contents to the APPLIED profile. Correct) 2. The circuit copies the RUN profile contents to the APP profile.

Page	Section	Change Results
221, 222	CHAPTER 6: 5. Registers	Revised the shading parts as below: Error) Notes: − Protection is applied to the SYSC register. To write to the register, the protection key must first be released. Invalid written data is discarded. The following shows an example of the procedure for accessing the SYSC register. 1. The accessing master releases the protection key. 2. The master that released the protection key writes to the SYSC register. 3. The hardware enables the protection key. Repeat steps 1 to 3 until completing the required settings. − The following shows protection effective conditions. 1. The protection target register was write-accessed from the master that released the protection key. 2. The protection target register was write-accessed from anything other than the master that released the protection key. Correct) Notes: − Protection is applied to the SYSC register. To write to the register, the protection key must first be unlocked. Invalid written data is discarded. The following shows an example of the procedure for accessing the SYSC register. 1. The accessing master unlocks the protection key. 2. The master that unlocked the protection key writes to the SYSC register. 3. The hardware locks the protection key. Repeat steps 1 to 3 until completing the required settings. − The following shows protection effective conditions. 1. The protection target register was write-accessed from the master that unlocked the protection key. 2. The protection target register was write-accessed from anything other than the master that unlocked the protection key.

1810	CHAPTER 31: CAN FD Controller(MCAN 3.2) 5. Registers	Add below:

Table 5-4 Register Mirror Area CAN FD CONTROLLER

Address of Register Mirror Area	Mirrored Peripheral	Mirror Area Behavior	PPU
0000_C000 to 0000_FFFF	MCU_CONFIG CAN FD ch.0	Accessing this region results to the access to MCU_CONFIG CAN FD ch.0 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #47 as well as the mirrored peripheral.
0000_C000 to 0000_FFFF	MCU_CONFIG CAN FD ch.1	Accessing this region results to the access to MCU_CONFIG CAN FD ch.1 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #48 as well as the mirrored peripheral.
0000_C000 to 0000_FFFF	MCU_CONFIG CAN FD ch.2	Accessing this region results to the access to MCU_CONFIG CAN FD ch.2 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #49 as well as the mirrored peripheral.
0000_C000 to 0000_FFFF	CommonPERI#0 CAN FD ch.0	Accessing this region results to the access to CommonPERI#0 CAN FD ch.0 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #256 as well as the mirrored peripheral.
0000_C000 to 0000_FFFF	CommonPERI#0 CAN FD ch.1	Accessing this region results to the access to CommonPERI#0 CAN FD ch.1 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #257 as well as the mirrored peripheral.
0000_C000 to 0000_FFFF	CommonPERI#0 CAN FD ch.2	Accessing this region results to the access to CommonPERI#0 CAN FD ch.2 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #258 as well as the mirrored peripheral.
0000_C000 to 0000_FFFF	CommonPERI#0 CAN FD ch.3	Accessing this region results to the access to CommonPERI#0 CAN FD ch.3 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #259 as well as the mirrored peripheral.
0000_C000 to 0000_FFFF	CommonPERI#0 CAN FD ch.4	Accessing this region results to the access to CommonPERI#0 CAN FD ch.4 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #260 as well as the mirrored peripheral.

Page	Section	Change Results
1846	CHAPTER 31: CAN FD Controller(MCAN 3.2) 5.15. Interrupt Register (MCG_CANFDx_IR, CPG_CANFDx_IR)	Revised the shading parts as below: [bit17] MRAF: Message RAM Access Failure Error) In both cases the Rx FIFO put index is not updated resp. the New Data flag for a dedicated Rx Buffer is not set, a partly stored message is overwritten when the next message is stored to this location. Correct) The data of a received frame may be incompletely stored to the Message RAM after the flag is set by the Rx Handler operation. In addition, Rx FIFO 0 Status (RXF0S), Rx FIFO 1 Status (RXF1S), or New Data 1/2 (NDAT1/2) is also updated according as the storage location (Rx FIFO0, Rx FIFO1, or an Rx Buffer). Therefore, in this case discard the received frame data.
		Removed the shading parts as below: Note: - The data of a received frame may be incompletely stored to the Message RAM after the flag is set by the Rx Handler operation. In addition, Rx FIFO 0 Status (RXF0S), Rx FIFO 1 Status (RXF1S), or New Data 1/2 (NDAT1/2) is also updated according as the storage location (Rx FIFO0, Rx FIFO1, or an Rx Buffer). Therefore, in this case discard the received frame data.
1975	CHAPTER 35: Overview of Multi-function Serial Interface 6. Registers of the Multi-Function Serial Interface	Revised the shading parts as below: **Table 6-1 Register Map of UART/CSIO/LIN/I2C in Each Modes** **UART** Error) MCU Config Group (Channel No.: 16, 17, and 18) Notes: - xx is the channel number. (16 to 18) Correct) MCU Config Group (Channel No.: 0, 1, and 2) Notes: - xx is the channel number. (0 to 2)

Page	Section	Change Results
1977	CHAPTER 35: Overview of Multi-function Serial Interface 6. Registers of the Multi-Function Serial Interface	Revised the shading parts as below: **Table 6-1 Register Map of UART/CSIO/LIN/I2C in Each Modes** **CSIO** Error) MCU Config Group (Channel No.: 16, 17, and 18) Notes: - xx is the channel number. (16 to 18) Correct) MCU Config Group (Channel No.: 0, 1, and 2) Notes: - xx is the channel number. (0 to 2)
1979	CHAPTER 35: Overview of Multi-function Serial Interface 6. Registers of the Multi-Function Serial Interface	Revised the shading parts as below: **Table 6-1 Register Map of UART/CSIO/LIN/I2C in Each Modes** **LIN** Error) MCU Config Group (Channel No.: 16, 17, and 18) Notes: - xx is the channel number. (16 to 18) Correct) MCU Config Group (Channel No.: 0, 1, and 2) Notes: - xx is the channel number (0 to 2)

Page	Section	Change Results
1981	CHAPTER 35: Overview of Multi-function Serial Interface 6. Registers of the Multi-Function Serial Interface	Revised the shading parts as below: **Table 6-1 Register Map of UART/CSIO/LIN/I2C in Each Modes** **I2C** Error) MCU Config Group (Channel No.: 16, 17, and 18) Notes: - xx is the channel number. (16 to 18) Correct) MCU Config Group (Channel No.: 0, 1, and 2) Notes: - xx is the channel number (0 to 2)
1987	CHAPTER 36: UART (Asynchronous Serial Interface)	Removed the shading parts as below: Error) Note: - ACK Mode of Block Transfer is not supported for this device.
2025	CHAPTER 36: UART (Asynchronous Serial Interface) 7. Block Transfer	Revised the shading parts as below: Error) Block transfer can be performed in that mode in which it is operated with the acknowledgment standard (ACK mode) and in that mode in which it is operated with the READ/WRITE access standard (RW access mode). Correct) Block transfer can be performed in that mode in which it is operated with the READ/WRITE access standard (RW access mode).
		Removed the shading parts as below: Error) Note: - ACK Mode of Block Transfer is not supported for this device.

Page	Section	Change Results
2026	CHAPTER 36: UART (Asynchronous Serial Interface) 7.1. ACK Mode	Removed the shading section as below: **7.1. ACK Mode**
2026	CHAPTER 36: UART (Asynchronous Serial Interface) 7.1. RW Access Mode	Revised the shading parts as below: Error) 7.2. RW Access mode Correct) 7.1. RW Access mode
2026	CHAPTER 36: UART (Asynchronous Serial Interface) 7.1. RW Access Mode	Added the shading parts as below: Correct) During application operation, if the next block transfer request occurs before the completion of the previous block transfer, this state might be reported to the system by a block transfer error. This state does not occur if you configure FBYTE=1. Completion of block transfer by DMA depends on occupation of bus transaction by application. You need to fully evaluate the application integrally, design the system, and choose the optimal number of block transfers.

Page	Section	Change Results
2026	CHAPTER 36: UART (Asynchronous Serial Interface) 7.1. RW Access Mode	Revised the shading parts as below: Figure 7.1 Reception Block Transfer in RW Access Mode Error)  Correct) 2073	CHAPTER 36: UART (Asynchronous Serial Interface) 10.13. FIFO Byte Register (FBYTE)	Removed the shading parts as below: Table 10-4 Data Count Stored in FIFO Error) Note: - Set reception FIFO FBYTE to “2” or a larger value when block transfer. At other conditions, set "1" or a larger value in the FBYTE for the reception FIFO.
2091	CHAPTER 37: CSIO (Clock Synchronous Serial Interface)	Removed the shading parts as below: Error) Note: - ACK Mode of Block Transfer is not supported for this device.

Page	Section	Change Results
2171	CHAPTER 37: CSIO (Clock Synchronous Serial Interface) 8. Block Transfer	Revised the shading parts as below: Error) Block transfer can be performed in that mode in which it is operated with the acknowledgment standard (ACK mode) and in that mode in which it is operated with the READ/WRITE access standard (RW access mode). Correct) Block transfer can be performed in that mode in which it is operated with the READ/WRITE access standard (RW access mode).
		Removed the shading parts as below: Error) Note: - ACK Mode of Block Transfer is not supported for this device.
2172	CHAPTER 37: CSIO (Clock Synchronous Serial Interface) 8.1. ACK Mode	Removed the shading section as below: Error) **8.1. ACK Mode**
2172	CHAPTER 37: CSIO (Clock Synchronous Serial Interface) 8.1. RW Access Mode	Added the shading parts as below: Added) During application operation, if the next block transfer request occurs before the completion of the previous block transfer, this state might be reported to the system by a block transfer error. This state does not occur if you configure FBYTE=1. Completion of block transfer by DMA depends on occupation of bus transaction by application. You need to fully evaluate the application integrally, design the system, and choose the optimal number of block transfers.

Page	Section	Change Results
2172	CHAPTER 37: CSIO (Clock Synchronous Serial Interface) 8.1. RW Access Mode	Revised the shading parts as below: Figure 8-1 Reception Block Transfer in RW Access Mode Error)  Correct) 2172	CHAPTER 37: CSIO (Clock Synchronous Serial Interface) 8.1. RW Access Mode	Revised the shading parts as below: Error) 8.2. RW Access mode Correct) 8.1. RW Access mode

Page	Section	Change Results
2229	CHAPTER 37: CSIO (Clock Synchronous Serial Interface) 9.16. FIFO Byte Register (FBYTE)	Removed the shading parts as below: Table 9-4 Data Count Stored in FIFO Error) Note: - Set reception FIFO FBYTE to “2” or a larger value when block transfer. At other conditions, set "1" or a larger value in the FBYTE for the reception FIFO.
2312	CHAPTER 38: I^2C Interface (I^2C Communication Control Interface) 6.Block Transfer	Removed the shading parts as below: 6. Block Transfer Error) Block transfer has two modes: ACK mode and RW access mode. ACK mode operates based on acknowledgment. RW access mode operates based on READ/WRITE access.
2313	CHAPTER 38: I^2C Interface (I^2C Communication Control Interface) 6.1. ACK Mode	Removed the shading section as below: Error) **6.1. ACK Mode**
2313	CHAPTER 38: I^2C Interface (I^2C Communication Control Interface) 6.1. RW Access Mode	Added the shading parts as below: Correct) During application operation, if the next block transfer request occurs before the completion of the previous block transfer, this state might be reported to the system by a block transfer error. This state does not occur if you configure FBYTE=1. Completion of block transfer by DMA depends on occupation of bus transaction by application. You need to fully evaluate the application integrally, design the system, and choose the optimal number of block transfers.

2313	CHAPTER 38: I²C Interface (I²C Communication Control Interface) 6.1. RW Access Mode	Revised the shading parts as below: Figure 6-1 Reception Block Transfer in RW Access Mode Error)  Correct) 2313	CHAPTER 38: I²C Interface (I²C Communication Control Interface) 6.1. RW Access Mode	Revised the shading parts as below: Error) 6.2. RW Access mode Correct) 6.1. RW Access mode

Page	Section	Change Results
2335	CHAPTER 38: I²C Interface (I²C Communication Control Interface) 8.2. Serial Mode Register (SMR)	Added the shading parts as below: **[bit4] WUCR: WAKE UP Control Bit** Note: − The WAKE UP function is not supported.
2369	CHAPTER 38: I²C Interface (I²C Communication Control Interface) 8.16. FIFO Byte Register (FBYTE)	Removed the shading parts as below: Table 8-4 Data Count Stored in FIFO Error) Note: - Set reception FIFO FBYTE to “2” or a larger value when block transfer. At other conditions, set "1" or a larger value for FBYTE of the reception FIFO.
2397	CHAPTER 39: LIN Interface (V2.1) (LIN Communication Control Interface (V2.1))	Removed the shading parts as below: Error) Note: - ACK Mode of Block Transfer is not supported for this device.
2397	CHAPTER 39: LIN Interface (V2.1) (LIN Communication Control Interface (V2.1))	Deleted the shading parts as below: Error) This chapter describes the LIN communication function supported by operation mode 3 of the multi-function serial interface functions. The LIN communication function has the following 2 modes: Manual mode, which allows the transmission/reception of the LIN header section using interrupt functions, and the assist mode, which allows automatic transmission/reception of the LIN header.
2416	CHAPTER 39: LIN Interface (V2.1) (LIN Communication Control Interface (V2.1)) 2.2.1. Occurrence of Reception Interrupts and Flag Set Timing in Assist Mode	Revised the shading parts as below: Error) Occurrence of Framing Error Iterrupt and Flag Set Timing Correct) Occurrence of Framing Error Interrupt and Flag Set Timing

Page	Section	Change Results
2447	CHAPTER 39: LIN Interface (V2.1) (LIN Communication Control Interface (V2.1)) 6. Block Transfer	Revised the shading parts as below: Error) Block transfer can be performed in that mode in which it is operated with the acknowledgment standard (ACK mode) and in that mode in which it is operated with the READ/WRITE access standard (RW access mode). Correct) Block transfer can be performed in that mode in which it is operated with the READ/WRITE access standard (RW access mode).
		Removed the shading parts as below: Error) Note: - ACK Mode of Block Transfer is not supported for this device.
2448	CHAPTER 39: LIN Interface (V2.1) (LIN Communication Control Interface (V2.1)) 6.1. ACK Mode	Removed the shading section as below: Error) **6.1. ACK Mode**
2448	CHAPTER 39: LIN Interface (V2.1) (LIN Communication Control Interface (V2.1)) 6.1. RW Access Mode	Added the shading parts as below: Correct) During application operation, if the next block transfer request occurs before the completion of the previous block transfer, this state might be reported to the system by a block transfer error. This state does not occur if you configure FBYTE=1. Completion of block transfer by DMA depends on occupation of bus transaction by application. You need to fully evaluate the application integrally, design the system, and choose the optimal number of block transfers.

3008	CHAPTER 52: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI	Changed the below: **4.2. Command Sequencer Mode** **Figure 4-6 Addressing 4GB Serial Flash Memories on Each Slave Select, Through Different Bank (DDRHSSPIn_CSCFG.MSEL= 0b0000)** Error)  Correct) 
Page	Section	Change Results
3023	CHAPTER 52: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI	Revised the shading parts as below: **4.4.4. Using the DDRHSSPI in Command Sequencer Mode of Operation** Error) 2.The next step is to configure the transfer protocol (i.e. whether the DDRHSSPI serial transfers use the Quad or Octal Protocol in the DDRHSSPIn_CSCFG.MBM). The DDRHSSPIn_CSCFG. DDRMODE bit shall be set same as DDRHSSPIn_DMFIFOCFG.DDRM bit. Correct) 2.The next step is to configure the transfer protocol (i.e. whether the DDRHSSPI serial transfers use the Quad or Octal Protocol in the DDRHSSPIn_CSCFG.MBM). The DDRHSSPIn_CSCFG. DDRMODE bit shall be set same as DDRHSSPIn_DMTRP.DDRM bit.
3030	CHAPTER 52: DDR High Speed SPI Controller 4. Operations of the DDRHSSPI	Deleted the below: **4.4. General Use Case Guidelines for DDRHSSPI** 4.4.5. Notice On Document Designations Cypress issues documents and data sheets with Advance Information or Preliminary designations to advise readers of product information or intended specifications throughout the product life cycle,including development, qualification, initial production, and full production. In all cases, however, readers are encouraged to verify that they have the latest information before finalizing their design. The following descriptions of Cypress data sheet designations are presented here to highlight their presence and definitions 4.4.6. Advance Information The Advance Information designation indicates that Cypress Semiconductor Corp. is developing one or more specific products, but has not committed any design to production. Information presented in a document with this designation is likely to change, and in some cases, development on the product may discontinue. Cypress Semiconductor Corp. therefore places the following conditions upon Advance Information content: This document contains information on one or more products under development at Cypress Semiconductor Corp. The information is intended to help you evaluate this product. Do not design in this product without contacting the Cypress Semiconductor Corp. Cypress Semiconductor Corp. reserves the right to change or discontinue work on this proposed product without notice.

153	CHAPTER 5: Clock System 5. Registers 5.1. Common Configuration Registers 5.1.2. Main Oscillator Control Register(SYSC_MOSCCNTR)	Added the shading parts as below: **[bit31] MCMODE : Main Clock Amplifier Oscillation Mode Bit** Correct) ***Note:*** *The initial value (value "0") of this bit specifies High drive mode.* *To reduce noise, set the mode to low drive mode (value "1") after transition to the user program.*
154		Added the shading parts as below: **[bit27:26] MCMODE : MCGAIN[1:0] : Main Clock GAIN Bit** Correct) ***Note:*** *These frequency values are just reference value.* *Set optimum value according to oscillator matching evaluation.* *Generally, MCMODE should be "1" (Stop mode) to optimize by MCGAIN setting.*

126	CHAPTER 5: 2. Configuration and Block Diagram 2.2. Clock Generator Configuration and Block Diagram 2.2.1. PLL Clock Generator Configuration and Bloack Diagram	Revised the below figure: **Figure 2-3 PLLx (x=0,1,2,3)Clock Generator Block Diagram** Error)  Correct) 
Page	Section	Change Results
138	CHAPTER 5: Clock System 3.4. Clock Gear	Revised the shading parts as below: ***Note:*** Error) *STEP 0 to 63:* *STEP 0 to 63: Clock output patterns of Gear operation.* *As the number of step increases, the clock output increases.* *STEP 0 to 1: clock/loop* *STEP 1 to 2: clock/loop* *:* *:* *:* *STEP 63 to 64 clock/loop (Clock output for all cycles in loop)* Correct) *STEP 0 to 63: Clock output patterns of Gear operation.* *As the number of step increases, the clock output increases.* *STEP 0 : 1 clock/loop* *STEP 1 : 2 clock/loop* *:* *:* *:* *STEP 63 : 64 clock/loop (Clock output for all cycles in loop)*

Page	Section	Change Results
140	CHAPTER 5: Clock System 3.4. Clock Gear	Added Figure 3-2 and Figure 3-3. Correct) Figure.3-2(Gear Up) and Figure.3-3(Gear Down) show the relationship between the register configuration and the Clock Gear STEP. **Figure 0-1 Clock Gear STEP by register configuration (Gear Up)**  Transition time of clock gear = total loop number * 64cycle * (PLL or SSCG period) = (xxxCGLP + 1) * (64 − xxxCGSSN) / (xxxCGSTP + 1) * 64cycle * (PLL or SSCG period) Note: The number is rounded up after the decimal point in "(64 − xxxCGSSN) / (xxxCGSTP + 1)". **Figure 0-2 Clock Gear STEP by register configuration (Gear Down)**  Transition time of clock gear = Same as gear up (Figure.3-2)

Page	Section	Change Results
994	CHAPTER 17: TCFLASH 3. Explanation of Operation 3.2. Programming and Erasing	Added the shading parts as below: Correct) ■After erase operation completed, all the values of the flash memory cells in the target sectors are "1".
1055	CHAPTER 18: WorkFLASH 3. Explanation of Operation 3.2. Write and Erase	Revised the shading parts as below: Error) Overwriting of the same data bit is prohibited. (Even overwriting of 1 -> 0, 0 -> 0, or 1 -> 1 is also prohibited.) The Flash security function does not allow writing and erasing of protected sectors. For details, see the security specifications. Correct) Overwriting of the same data bit is prohibited. (Even overwriting of 1 -> 0, 0 -> 0, or 1 -> 1 is also prohibited.) After erase operation completed, all the values of the flash memory cells in the target sectors are "1". The Flash security function does not allow writing and erasing of protected sectors. For details, see the security specifications.
1605	CHAPTER 30: CAN FD Controller(MCAN 3.2) 3.5: Tx Handling 3.5.2. Dedicated Tx Buffers	Added the shading parts as below: Correct) Dedicated Tx Buffers are intended for message transmission under complete control of the CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first. These Tx buffers shall be requested in ascending order with lowest buffer number first. Alternatively all Tx buffers configured with the same Message ID can be requested simultaneously by a single write access to TXBAR.

Page	Section	Change Results
1606	CHAPTER 30: CAN FD Controller(MCAN 3.2) 3.5: Tx Handling 3.5.4. Tx Queue	Revised the shading parts as below: Error) Tx Queue operation is configured by programming the Tx FIFO/Queue Mode bit TXBC.TFQM to "1". Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first. Correct) Tx Queue operation is configured by programming the Tx FIFO/Queue Mode bit TXBC.TFQM to "1". Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). If multiple Tx Queue buffers are configured with the same Message ID, the transmission order depends on numbers of the buffers where the messages were stored for transmission. As these buffer numbers depend on the then current states of the PUT index, a prediction of the transmission order is not possible.
1606	CHAPTER 30: CAN FD Controller(MCAN 3.2) 3.5: Tx Handling 3.5.4. Tx Queue	Revised the shading parts as below: Error) **Adding Messages and Requesting Transmissions** New messages have to be written to the Tx Buffer referenced by the Tx FIFO/Queue Put Index TXFQS.TFQPI[4:0]. An Add Request cyclically increments the Put Index to the next free Tx Buffer. Correct) **Adding Messages and Requesting Transmissions** New messages have to be written to the Tx Buffer referenced by the Tx FIFO/Queue Put Index TXFQS.TFQPI[4:0]. The PUT Index always points to that free buffer of the Tx Queue with the lowest buffer number.
2041	CHAPTER 36: UART (Asynchronous Serial Interface) 10.Registers of UART (Asynchronous Serial Interface) 10.2. Serial Mode Register (SMR)	Added the shading parts as below: Correct) [bit4] WUCR: WAKE UP Control Bit WUCR is not supported This bit selects a pin used for external interrupts.

Page	Section	Change Results
2179	CHAPTER 37: CSIO (Clock Synchronous Serial Interface) 9. Registers of the CSIO (Clock Synchronous Serial Interface) 9.2. Serial Mode Register (SMR)	Added the shading parts as below: Correct) [bit4] WUCR: WAKE UP Control Bit WUCR is not supported This bit selects a pin used for external interrupts.
2332	CHAPTER 38: I2C Interface (I2C Communication Control Interface) 8. I^2C Interface Registers 8.2. Serial Mode Register (SMR)	Added the shading parts as below: Correct) [bit4] WUCR: WAKE UP Control Bit WUCR is not supported This bit selects a pin used for external interrupts.
2503	CHAPTER 39: LIN Interface (V2.1) (LIN Communication Control Interface (V2.1)) 9. Interface (V2.2) Registers 9.2. Serial Mode Register (SMR)	Added the shading parts as below: Correct) [bit4] WUCR: WAKE UP Control Bit WUCR is not supported This bit selects a pin used for external interrupts.
