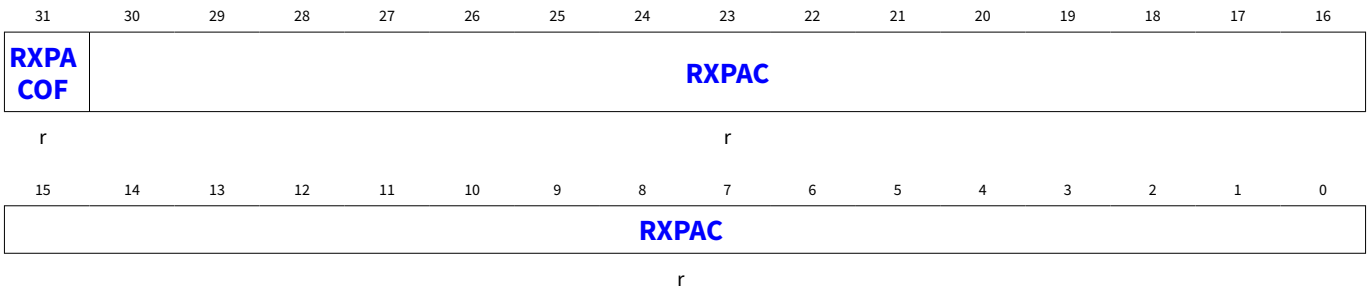
RXPACOF	31	r	**Rx-Parser Accept Counter Overflow Bit** When set, this bit indicates that the RXPAC Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0_B **INACTIVE**: Rx Parser Accept Counter overflow not occurred 1_B **ACTIVE**: Rx Parser Accept Counter overflow occurred

14.6.532 Port j MTL FRP ACNTR7

The MTL_FRP_ACNTR(#i) registers are indirect and provide the count of the number of frames accepted by FRP particular to channel. Such accept counters mapping with receive channel is static, one to one, if supported number of receive channels are less than or equal to 16. Otherwise if it is more than 16 then, FRP implements fix number of accept counters and provides programmable option to application to map it to application-specific receive channel via corresponding MTL_FRP_ACNTR_CNFG(#i) indirect registers. These indirect registers can be accessible through MTL_Indirect_Acc_Control_Status and MTL_Indirect_Acc_Data registers.

Portj_MTL_FRP_ACNTR7 (j=0-1) Offset address: $110B4_H+j*2000_H$

Port j MTL FRP ACNTR7 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RXPAC	30:0	r	**Rx-Parser Accept Counter** This 31-bit counter is incremented whenever the Rx Parser accepts a packet due to AF = 1 and RF = 0. The packet must match the Rx Parser acceptance criteria irrespective of its type (length or type) and size (undersize/runt or oversize). The counter is cleared when the register is read.
RXPACOF	31	r	**Rx-Parser Accept Counter Overflow Bit** When set, this bit indicates that the RXPAC Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0_B **INACTIVE**: Rx Parser Accept Counter overflow not occurred 1_B **ACTIVE**: Rx Parser Accept Counter overflow occurred

14.6.533 Port j MTL RXP Bypass Cnt

The MTL_RXP_Bypass_Cnt registers provides the count of the number of frames bypassed by Rx Parser. This is an indirect register which can be access through MTL_Indirect_Acc_Control_Status and MTL_Indirect_Acc_Data registers.

Portj_MTL_RXP_Bypass_Cnt (j=0-1) Offset address: $110B4_H+j*2000_H$

Port j MTL RXP Bypass Cnt Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RXPBC															
r															

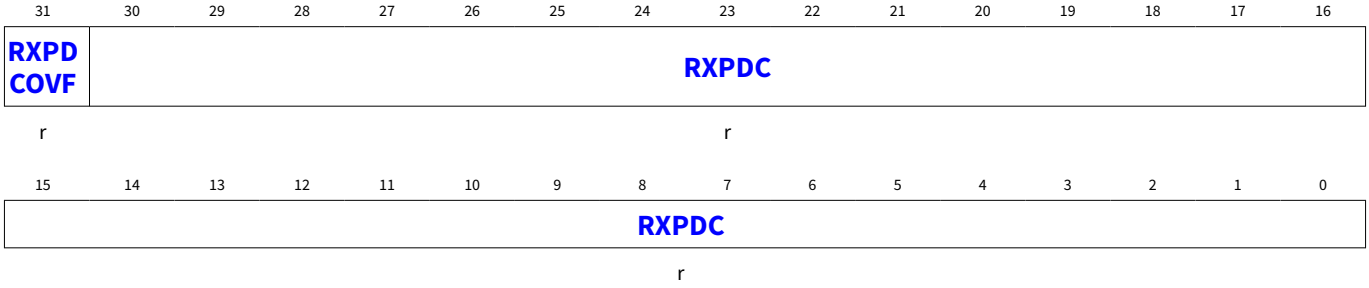
Field	Bits	Type	Description
RXPBC	30:0	r	**Rx-Parser Bypass Counter** This 31-bit counter is implemented whenever a Rx Parser Bypass a packet due to AF = 1 and RF = 1. The counter is cleared when the register is read.
RXPBCOF	31	r	**Rx-Parser Bypass Counter Overflow Bit** When set, this bit indicates that the RXPBC Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0_B **INACTIVE**: Rx Parser Bypass Counter overflow not occurred 1_B **ACTIVE**: Rx Parser Bypass Counter overflow occurred

14.6.534 Port j MTL RXP Drop Cnt

This register provides the number of packets dropped by the Flexible Receive Parser. This is an indirect register which can be accessed through MTL_Indirect_Acc_Control_Status and MTL_Indirect_Acc_Data registers.

Portj_MTL_RXP_Drop_Cnt (j=0-1) Offset address: $110B4_H+j*2000_H$

Port j MTL RXP Drop Cnt Kernel Reset value: $0000\ 0000_H$



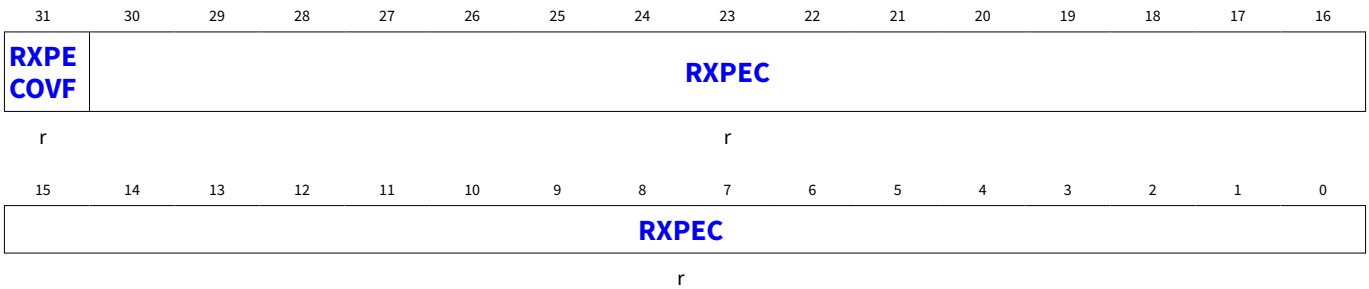
Field	Bits	Type	Description
RXPDC	30:0	r	**Rx Parser Packet Drop Count** This 31-bit counter is incremented when a Rx Parser drops a packet due to AF = 0 and RF = 1. The counter is cleared when the register is read.
RXPDCOVF	31	r	**Rx Parser Packet Drop Counter Overflow** When set, this bit indicates that the MTL_RXP_Drop_cnt (RXPDC) counter field has crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0_B **INACTIVE**: Rx Parser Drop count overflow not occurred 1_B **ACTIVE**: Rx Parser Drop count overflow occurred

14.6.535 Port j MTL RXP Error Cnt

This register provides Error Counts of the Flexible Receive Parser. This is an indirect register which can be access through MTL_Indirect_Acc_Control_Status and MTL_Indirect_Acc_Data registers.

Portj_MTL_RXP_Error_Cnt (j=0-1) Offset address: $110B4_H+j*2000_H$

Port j MTL RXP Error Cnt Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RXPEC	30:0	r	**Rx Parser Error count** This 31-bit counter is incremented when the Rx Parser encounters the following error scenarios: - Current Instruction Address is greater than NVE[] - Number of Parsed Instructions is greater than (NPE + 1) - Current Instruction's Frame offset is greater than EOF frame offset or Last Parasable Byte - Parsing is not complete even after receiving the next to next packet SOF The counter is cleared when the register is read.
RXPECOVF	31	r	**Rx Parser Error Counter Overflow Bit** When set, this bit indicates that the MTL_RXP_Error_cnt (RXPEC) counter field has crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0_B **INACTIVE**: Rx Parser Error count overflow not occurred 1_B **ACTIVE**: Rx Parser Error count overflow occurred

14.6.536 Port j MTL ECC Control

The MTL_ECC_Control register establishes the operating mode of ECC related to MAC and MTL memories.

Portj_MTL_ECC_Control (j=0-1) Offset address: $110C0_H+j*2000_H$

Port j MTL ECC Control Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
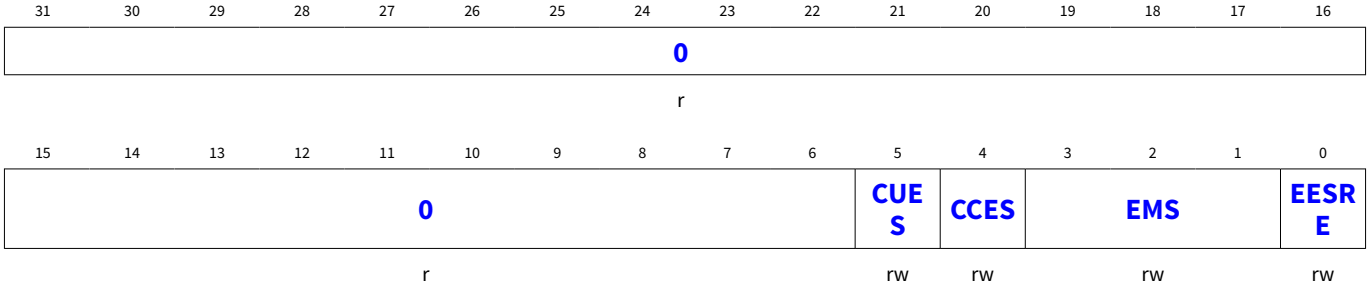
0	3, 7, 11, 15, 19, 20, 21, 22, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.540 Port j MTL ECC Err Sts Rctl

The MTL_ECC_Err_Sts_Rctl register establishes the control for ECC Error status capture.

Portj_MTL_ECC_Err_Sts_Rctl (j=0-1) Offset address: $110D0_H+j*2000_H$

Port j MTL ECC Err Sts Rctl Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EESRE	0	rw	**MAC/MTL ECC Error Status Read Enable** When this bit is set, the error status of the memory selected by EMS is captured as follows: - The correctable and uncorrectable error count values are captured in the MTL_ECC_Err_Cnt_Status register. - The address locations of correctable and uncorrectable errors are captured in the MTL_ECC_Err_Addr_Status register. Hardware resets this bit when all the status values are captured in the MTL_ECC_Err_Cnt_Status and MTL_ECC_Err_Addr_Status registers. 0_B **DISABLE**: MAC/MTL ECC Error Status Read is disabled 1_B **ENABLE**: MAC/MTL ECC Error Status Read is enabled

(table continues...)

(continued)

Field	Bits	Type	Description
EMS	3:1	rw	**MAC/MTL ECC Memory Selection** When EESRE bit of this register is set, this field indicates which memory's error status value to be read. Values: - 0x0 (TX_MEM): MTL Tx Memory - 0x1 (RX_MEM): MTL Rx Memory - 0x2 (EST_MEM): MTL GCL Memory - 0x3 (RXP_MEM): MTL Rx Parser Memory - 0x5 (DCACHE_MEM): DMA DCACHE Memory - 0x6 (SGF_MEM): MTL SGE
CCES	4	rw	**Clear Correctable Error Status** When this bit is set along with EESRE bit, correctable error address and correctable error count of the memory indicated by EMS field are cleared upon reading. Hardware resets this bit when all the error status values are cleared.
CUES	5	rw	**Clear Uncorrectable Error Status** When this bit is set along with EESRE bit, the uncorrectable error address and uncorrectable error count of the memory indicated by EMS field are cleared upon reading. Hardware resets this bit when all the error status values are cleared.
0	31:6	r	**Reserved** Read as 0; should be written with 0.

14.6.541 Port j MTL ECC Err Addr Status

The MTL_ECC_Err_Addr_Status register provides the memory addresses for the correctable and uncorrectable errors.

Portj_MTL_ECC_Err_Addr_Status (j=0-1) Offset address: $110D4_H+j*2000_H$

Port j MTL ECC Err Addr Status Kernel Reset value: $0000\ 0000_H$

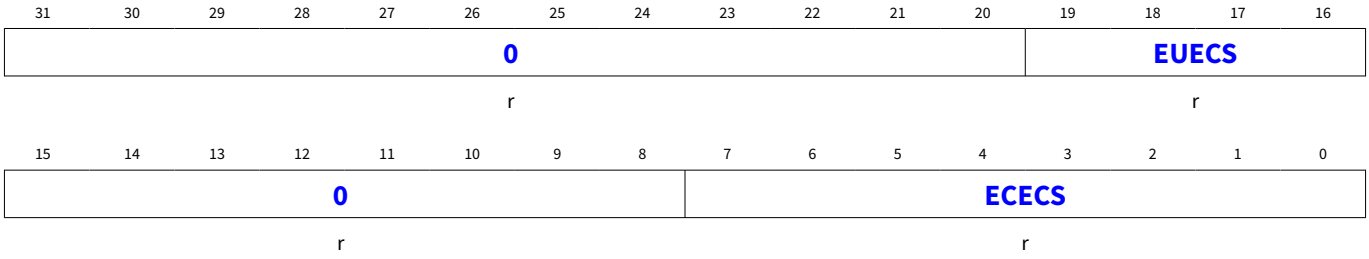
Field	Bits	Type	Description
ECEAS	15:0	r	**MAC/MTL ECC Correctable Error Address Status** Based on the EMS field of MTL_ECC_Err_Sts_Rctl register, this field holds the respective memory's address locations for which a correctable error is detected. When MEEAO bit of MTL_ECC_Control register is set, this field holds the address of memory for which correctable error or address mismatch is detected most recently. When MEEAO bit of MTL_ECC_Control register is reset, this field holds the address of the memory for which correctable error is detected for the first time.
EUEAS	31:16	r	**MAC/MTL ECC Uncorrectable Error Address Status** Based on the EMS field of MTL_ECC_Err_Sts_Rctl register, this field holds the respective memory's address locations for which an uncorrectable error or address mismatch is detected. When MEEAO bit of MTL_ECC_Control register is set, this field holds the address of memory for which either an uncorrectable error or an address mismatch is detected most recently. When MEEAO bit of MTL_ECC_Control register is reset, this field holds the address of the memory for which either an uncorrectable error or address mismatch is detected for the first time.

14.6.542 Port j MTL ECC Err Cntr Status

The MTL_ECC_Err_Cntr_Status register provides Error count for Correctable and uncorrectable ECC errors.

Portj_MTL_ECC_Err_Cntr_Status (j=0-1) Offset address: $110D8_H+j*2000_H$

Port j MTL ECC Err Cntr Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ECECS	7:0	r	**MAC/MTL ECC Correctable Error Counter Status** Based on the EMS field of MTL_ECC_Err_Cntr_Rctl register, this field holds the respective memory's correctable error count value.
EUECS	19:16	r	**MAC/MTL ECC Uncorrectable Error Counter Status** Based on the EMS field of MTL_ECC_Err_Cntr_Rctl register, this field holds the respective memory's uncorrectable error count value.
0	15:8, 31:20	r	**Reserved** Read as 0; should be written with 0.

14.6.543 Port j MTL DPP Control

The MTL_DPP_Control establishes the operating mode of Data Parity protection and error injection.

Portj_MTL_DPP_Control (j=0-1) Offset address: $110E0_H+j*2000_H$

Port j MTL DPP Control Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
IPEMRWC	13	rw	**Insert Parity error in MTL RWC data path Parity Checker** When set to 1, parity/data bit of first valid input parity/data of the MTL RWC input data (or at PC6) is flipped. Based on the EIM/BLEI field of MTL_DPP_ECC_EIC register, software can corrupt any one bit of parity/data. Hardware clears this bit after the respective parity bit is flipped. 0_B **DISABLE**: Insert Parity error in MTL RWC data path Parity checker is disabled 1_B **ENABLE**: Insert Parity error in MTL RWC data path Parity checker is enabled
IPEMRRC	14	rw	**Insert Parity Error in MTL RRC data path Parity Checker** When set to 1, parity/data bit of first valid input parity/data of the MAC RRC output data (or at PC7) is flipped. Based on the EIM/BLEI field of MTL_DPP_ECC_EIC register, software can corrupt any one bit of parity/data. Hardware clears this bit after the respective parity bit is flipped. 0_B **DISABLE**: Insert Parity error in MTL RRC data path Parity checker is disabled 1_B **ENABLE**: Insert Parity error in MTL RRC data path Parity checker is enabled
IPECW	15	rw	**Insert Parity Error in CSR Write data path Parity Checker** When set to 1, parity/data bit of first valid input parity/data of the CSR write data interface is flipped. When EPSI bit of MTL_DPP_Control register is set and this bit is set, parity/data bit of first valid input parity/data ofthe input slave parity ports(or at PC-axi) is flipped. Based on the EIM/BLEI field of MTL_DPP_ECC_EIC register, software can corrupt any one bit of parity/data. Hardware clears this bit after the respective parity bit is flipped. 0_B **DISABLE**: Insert Parity error in CSR Write data path Parity checker is disabled 1_B **ENABLE**: Insert Parity error in CSR Write data path Parity checker is enabled
IPEASR	16	rw	**Insert Parity Error in AXI Slave Read data path Parity Checker** When set to 1, parity/data bit of first valid input parity/data of the AXI Slave read data interface is flipped. Based on the EIM/BLEI field of MTL_DPP_ECC_EIC register, software can corrupt any one bit of parity/data. Hardware clears this bit after the respective parity bit is flipped. 0_B **DISABLE**: Insert Parity error in AXI Slave Read data path Parity checker is disabled 1_B **ENABLE**: Insert Parity error in AXI Slave Read data path Parity checker is enabled

(table continues...)

(continued)

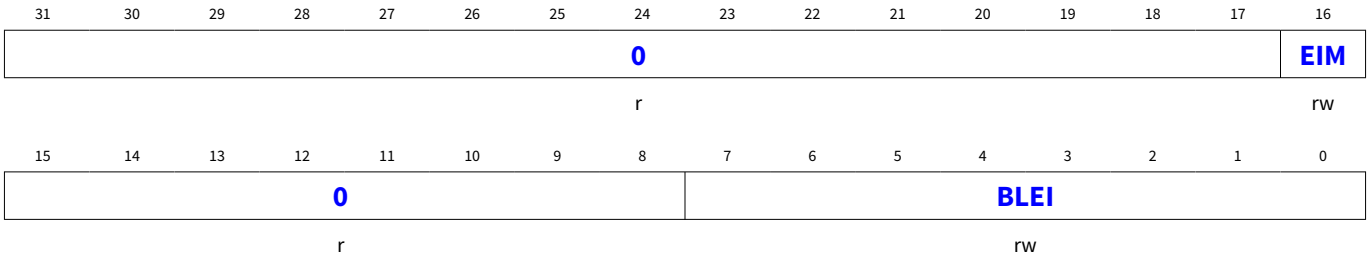
Field	Bits	Type	Description
0	2, 3, 4, 6, 7, 9, 31:17	r	**Reserved** Read as 0; should be written with 0.

14.6.544 Port j MTL DPP ECC EIC

The MTL_DPP_ECC_EIC establishes the operating mode of ECC/DPP error injection.

Portj_MTL_DPP_ECC_EIC (j=0-1) Offset address: $110E4_H+j*2000_H$

Port j MTL DPP ECC EIC Kernel Reset value: $0000\ 0000_H$



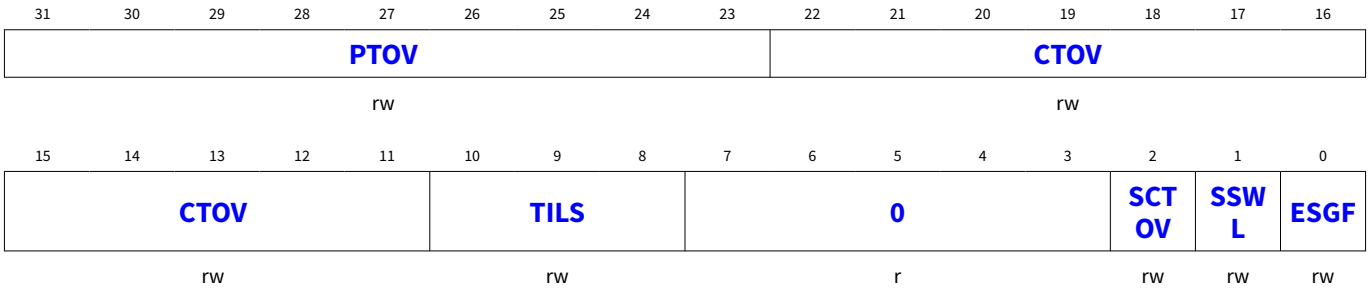
Field	Bits	Type	Description
BLEI	7:0	rw	**Bit Location of error injection** This field indicates the bit location of DPP/ECC error injection, determination of error in Parity/ECC bits or Data (being protected) depends on the Error Injection Mode (EIM field). Depending on the interface being used for error injection not all bits of this field are valid. Example, for error injection on a 64 bit data interface this field must be programmed to a value between 63 and 0. In case of 2-bit error injection bit 0 is always included in error injection and this field must represent the second bit selection for error injection.If the second bit is programed at bit 0 when 2-bit error injection is enabled, DUT inserts only a 1-bit error at bit 0.
EIM	16	rw	**Error Injection Mode - 0: Indicates error injection on data - 1: Indicates error injection on ECC/Parity bits (Check that the address error injection mode is disabled)**
0	15:8, 31:17	r	**Reserved** Read as 0; should be written with 0.

14.6.545 Port j MTL SGF Control

This register controls the operation of Stream-Gate Filtering.

Portj_MTL_SGF_Control (j=0-1) Offset address: $110E8_H+j*2000_H$

Port j MTL SGF Control Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ESGF	0	rw	**Enable Stream-Gate Filtering - 0: Indicates that the gate control list processing is halted and all gates are assumed to be in Open state** - 1: DWC_xgmac starts processing the gate control lists, only when this bit is 1. During the toggle from 0 to 1, the gate control list processing starts only after the SSWL bit is set. When ECC is selected during the configuration, if an uncorrectable error is detected in the SGF memory, DWC_xgmac resets this bit and disables the SGF function. 0_B **DISABLE**: SGF is disabled 1_B **ENABLE**: SGF is enabled
SSWL	1	rw	**Switch to software owned list - 1: Indicates that the software has programmed the list that it currently owns (SWOL) and the DWC_xgmac must switch to the new list based on the new BTR** DWC_xgmac clears this bit when it switches the SWOL, to indicate the completion of the switch or when a non-recoverable BTR error occurs (BTRL = "11111111" indicates the iterations exceeded the value of 512 and DWC_xgmac is unable to update New BTR to be equal to or greater than Current Time). When BTRE == 1, this bit is cleared. However, SWOL is not updated as the switch is unsuccessful. The write to this bit is effective only when ESGF bit is set to 1 along with it or ESGF bit is previously set to 1. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0_B **DISABLE**: Switch to S/W owned list is disabled 1_B **ENABLE**: Switch to S/W owned list is triggered
SCTOV	2	rw	**Sign bit of SGF CTOV** When reset indicates that the SGF CTOV is a negative value. When set that the SGF CTOV is a positive value. 0_B **DISABLE**: Indicates that the SGF CTOV is a negative value 1_B **ENABLE**: Indicates that the SGF CTOV is a positive value

(table continues...)

(continued)

Field	Bits	Type	Description
TILS	10:8	rw	**Time Interval Left Shift Amount** This field provides the left shift amount for the programmed Time Interval values used in the Gate Control Lists. - 000: No left shift needed (equal to x1ns) - 001: Left shift TI by 1 bit (equal to x2ns) - 010: Left shift TI by 2 bits (equal to x4ns) - ... - 111: Left shift TI by 7 bits (equal to x128ns)
CTOV	22:11	rw	**Current Time Offset Value** Provides a 12 bit time offset value in nanoseconds that is added to the current time, to compensate for all the implementation pipeline delays such as the CDC sync delay, buffering delays, data path delays, and so on.
PTOV	31:23	rw	**PTP Time Offset Value** This field must be programmed with a value of PTP Clock period multiplied by 9 in nanoseconds. This value is needed to avoid transmission overruns at the beginning of the installation of a new GCL due to sync delays between PTP clock and MAC transmitter or Application clock.
0	7:3	r	**Reserved** Read as 0; should be written with 0.

14.6.546 Port j MTL SGF Extended Control

This register controls the extended operation of Stream-Gate Filtering.

Portj_MTL_SGF_Extended_Control (j=0-1) Offset address: $110EC_H+j*2000_H$

Port j MTL SGF Extended Control Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BTRL								SWOL	0		CGCE	0		BTRE	SWLC
r								r	r		rw	r		rw	rw

Field	Bits	Type	Description
SWLC	0	rw	**Switch to Software Owned List Complete** When this field is set, indicates that DWC_xgmac has successfully switched to the SWOL, and the SWOL bit is updated to that effect. This field is cleared when the SSWL field of SGF_Control register transitions from 0 to 1, or on a software write. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears this field. Setting 0 has no effect. 0_B **INACTIVE**: Switch to S/W owned list not Complete 1_B **ACTIVE**: Switch to S/W owned list Complete

(table continues...)

(continued)

Field	Bits	Type	Description
BTRE	1	rw	**BTR Error** When this field is set, indicates a programming error in the BTR of SWOL where the programmed value is less than current time. If the BTRL = "11111111", SWOL is not updated and software must reprogram the BTR to a value greater than current time and set the SSWL bit to re-initiate the switch to SWOL. Otherwise, if the value of BTRL is less than "11111111", SWOL is updated and this field indicates the number of iterations (of + CycleTime) taken by DWC_xgmac to update the BTR to a value greater than Current Time. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0_B **INACTIVE**: BTR Error not detected 1_B **ACTIVE**: BTR Error detected
CGCE	4	rw	**Constant Gate Control Error** This error occurs when the list length (LLR) is 1 and the programmed Time Interval (TI) value after the optional Left Shifting is more than or equal to the Cycle Time (CTR). These programming guidelines imply that Gates are either always Closed or always Open based on the Gate Control values; the same effect can be achieved by other simpler (non TSN) programming mechanisms. As the implementation does not support such a programming mechanism, an error is reported. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0_B **INACTIVE**: Constant Gate Control Error not detected 1_B **ACTIVE**: Constant Gate Control Error detected
SWOL	7	r	**Software Owned List** When this field is 0, indicates that the Gate control list number 0 is owned by software. When this field is 1, indicates that the Gate Control list 1 is owned by the software. Any reads/writes by the software (using indirect access through GCL_Control) is directed to the list indicated by this value. The inverse of this value is treated as HWOL. R/W operations performed by DWC_xgmac are directed to the list pointed by HWOL. Values: - 0x0: Gate control list number "0" is owned by software - 0x1: Gate control list number "1" is owned by software
BTRL	15:8	r	**BTR Loop Count** This field provides the number of GCL cycle times after which the switch to new SWOL GCL occurs after SSWL is set. It is determined by the value N which satisfies the equation "Current Time less than or equal to New BTR + (N * 4 * New Cycle Time)". N = "11111111" indicates that the iterations exceeded the value of 512 and DWC_xgmac is unable to update New BTR to be equal to or greater than Current Time. Software intervention is needed to update the New BTR. This field is cleared when BTRE field of this register is cleared.

(table continues...)

(continued)

Field	Bits	Type	Description
0	3:2, 6:5, 31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.548 Port j MTL SGF Interrupt Enable

This register implements the Interrupt Enable bits for the various events that generate an interrupt. Bit positions have a 1- to-1 correspondence with the status bit positions in MTL_SGF_Status register.

Portj_MTL_SGF_Intr_Enable (j=0-1) Offset address: $110F4_H+j*2000_H$

Port j MTL SGF Interrupt Enable Kernel Reset value: $0000\ 0000_H$

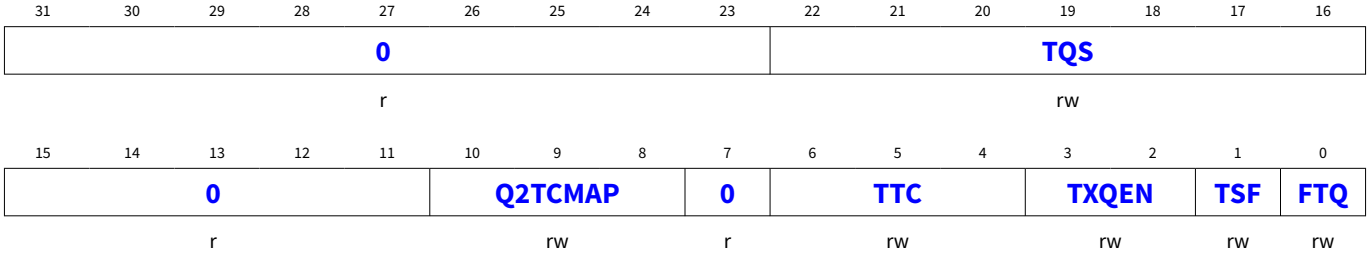
Field	Bits	Type	Description
IECC	0	rw	**Interrupt Enable for Switch List - 1: Generates interrupt when the configuration change is successful and DWC_xgmac has switched to the new list** - 0: This event does not generate an interrupt. 0_B **DISABLE**: Interrupt for Switch List is disabled 1_B **ENABLE**: Interrupt for Switch List is enabled
IEBE	1	rw	**Interrupt Enable for BTR Error - 1: Generates interrupt when the BTR Error occurs** Error is indicated in the status. - 0: This event does not generate an interrupt. 0_B **DISABLE**: Interrupt for BTR Error is disabled 1_B **ENABLE**: Interrupt for BTR Error is enabled
CGCE	4	rw	**Interrupt Enable for CGCE - 1: Generates interrupt when the Constant Gate Control Error occurs** Error is indicated in the status. - 0: This event does not generate an interrupt. 0_B **DISABLE**: Interrupt for CGCE is disabled 1_B **ENABLE**: Interrupt for CGCE is enabled
0	3:2, 31:5	r	**Reserved** Read as 0; should be written with 0.

14.6.549 Port j MTL TxQ0 Operation Mode

The Queue 0 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Portj_MTL_TxQ0_Operation_Mode (j=0-1) Offset address: $11100_H+j*2000_H$

Port j MTL TxQ0 Operation Mode Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
FTQ	0	rw	**Flush Transmit Queue** When this bit is set, the Tx Queue Controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. You must not write to this register until this bit is reset. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty. To complete this flush operation, the PHY Tx clock must be active.
TSF	1	rw	**Transmit Store and Forward** When this bit is set, the transmission starts when a full packet resides in the MTL Tx Queue. When this bit is set, the values specified in the TTC field are ignored. This bit must be changed only when the transmission is stopped.
TXQEN	3:2	rw	**Transmit Queue Enable** This field is used to enable/disable the transmit queue. - 2'b00: Not enabled - 2'b01: Audio Video Bridging - 2'b10: Enabled - 2'b11: Reserved In multiple Tx queues configuration, as the queue is disabled by default, enable the Tx Queue by programming this field in the AVB mode or default mode as desired.

(table continues...)

(continued)

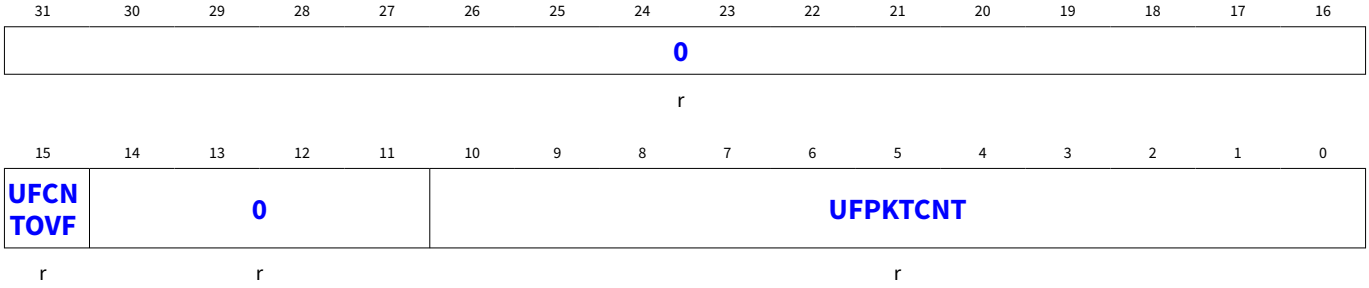
Field	Bits	Type	Description
TTC	6:4	rw	**Transmit Threshold Control** These bits control the threshold level of the MTL Tx Queue. Transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. - 3'b000: 64 - 3'b001: Reserved - 3'b010: 96 - 3'b011: 128 - 3'b100: 192 - 3'b101: 256 - 3'b110: 384 - 3'b111: 512
Q2TCMAP	10:8	rw	**Queue to Traffic Class Mapping** This field is used to map this Tx Queue to a traffic class (TC). - 3'b000: TC0 - 3'b001: TC1 - 3'b010: TC2 - 3'b011: TC3 - 3'b100: TC4 - 3'b101: TC5 - 3'b110: TC6 - 3'b111: TC7
TQS	22:16	rw	**Transmit Queue Size** This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. A value of 0 indicates 256 bytes. When this queue is enabled (TXQEN=10), a minimum value of 7 (size = 2048) is recommended so that the queue can store more than a complete max-sized Ethernet packet.
0	7, 15:11, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.550 Port j MTL TxQ0 Underflow

The Queue 0 Underflow Counter register contains the number of packets aborted because of Transmit queue underflow.

Portj_MTL_TxQ0_Underflow (j=0-1) Offset address: $11104_H+j*2000_H$

Port j MTL TxQ0 Underflow Kernel Reset value: $0000\ 0000_H$



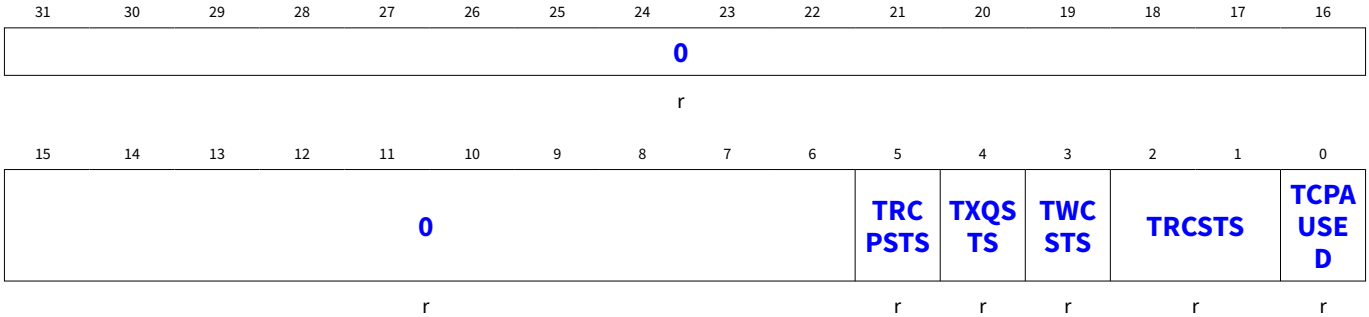
Field	Bits	Type	Description
UFPKTCNT	10:0	r	**Underflow Packet Counter** This field indicates the number of packets aborted by the controller because of Transmit Queue Underflow. This counter is incremented each time the MAC aborts an outgoing packet because of underflow. The counter is reset when this register is read with LSB of the Byte Enable for CSR access signal at 1'b1 .
UFCNTOVF	15	r	**Overflow Bit for Underflow Packet Counter** This bit is set every time the Tx Queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened.
0	14:11, 31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.551 Port j MTL TxQ0 Debug

The Queue 0 Transmit Debug register gives the debug status of various blocks related to the Transmit Queue 0 and Traffic Class 0.

Portj_MTL_TxQ0_Debug (j=0-1) Offset address: $11108_H+j*2000_H$

Port j MTL TxQ0 Debug Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TCPAUSED	0	r	**Traffic Class in Pause** - Reception of IEEE 802.3-2018 Pause packet

(table continues...)

(continued)

Field	Bits	Type	Description
TRCSTS	2:1	r	**MTL Tx Queue Read Controller Status** This field indicates the state of the Tx Queue Read Controller: - 2'b00: Idle state - 2'b01: Read state (transferring data to the MAC transmitter) - 2'b10: Waiting for pending Tx Status from the MAC transmitter - 2'b11: Flushing the Tx queue because of the Packet Abort request from the MAC
TWCSTS	3	r	**MTL Tx Queue Write Controller Status** When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.
TXQSTS	4	r	**MTL Tx Queue Not Empty Status** When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
TRCPSTS	5	r	**MTL TRC Pending Status** When this bit is high, it indicates that the MTL Tx Read Controller (TRC) has a pending status from MAC.
0	31:6	r	**Reserved** Read as 0; should be written with 0.

14.6.552 Port j MTL TC0 ETS Control

This register configures the transmission selection algorithm, for Traffic Class 0.

Portj_MTL_TC0_ETS_Control (j=0-1) Offset address: $11110_H+j*2000_H$

Port j MTL TC0 ETS Control Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QW															
rw															

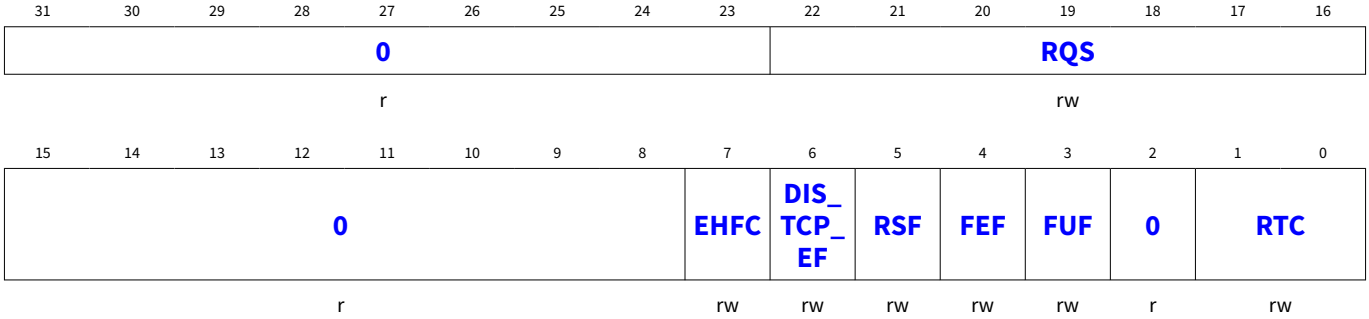
Field	Bits	Type	Description
QW	20:0	rw	**idleSlopeCredit, Quantum or Weights** - idleSlopeCredit -- When this TC is in AVB mode, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Traffic Class 0. This is the rate of change of credit in bits per cycle (3.2 ns for 2.5/10 Gbps; 8 ns for 1000 Mbps) when the credit is increasing. The software must program this field with computed credit in bits per cycle scaled by 1024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x8000 in 10 Gbps mode. Bits[20:16] must be written to zero. This field is not valid for Traffic Class 0. - Weights -- When TSA is set to ETS and ETSALG is set to WRR algorithm for Traffic Class 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits[20:7] must be written to zero. This field is reserved and RO when the number of traffic classes selected is less than two. This field is reserved in corresponding Queues 8-15 register.
0	31:21	r	**Reserved** Read as 0; should be written with 0.

14.6.554 Port j MTL RxQ0 Operation Mode

The Queue 0 Receive Operation Mode register establishes the Receive queue 0 operating modes.

Portj_MTL_RxQ0_Operation_Mode (j=0-1) Offset address: $11140_H+j*2000_H$

Port j MTL RxQ0 Operation Mode Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RTC	1:0	rw	**Receive Queue Threshold Control** These bits control the threshold level of the MTL Rx queue (in bytes): - 2'b00: 64 - 2'b01: Reserved - 2'b10: 96 - 2'b11: 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. The value of 11 is not applicable if the size of the configured Rx Queue is 128 bytes. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.
FUF	3	rw	**Forward Undersized Good Packets** - 1: Rx queue forwards the undersized good packets (with no Invalid-code/GMII/CRC/Length errors and length less than 64 bytes at Rx (X)GMII interface), including pad-bytes and CRC. - 0: Rx queue drops all packets of length less than 64 bytes.
FEF	4	rw	**Forward Error Packets** - 0: Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. - 1: All packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA.
RSF	5	rw	**Receive Queue Store and Forward** - 1: DWC_xgmac reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. - 0: Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.

(table continues...)

(continued)

Field	Bits	Type	Description
DIS_TCP_EF	6	rw	**Disable Dropping of TCP/IP Checksum Error Packets** - When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. - When this bit is reset, all error packets are dropped if the FEF bit is reset.
EHFC	7	rw	**Enable Hardware Flow Control** When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.
RQS	22:16	rw	**Receive Queue Size** This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. A value of 0 indicates 256 bytes.When this queue is used, a minimum value of 7 (size = 2048) is recommended so that the queue can store more than a complete max-sized Ethernet packet.
0	2, 15:8, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.555 Port j MTL RxQ0 Missed Pkt Overflow Cnt

The Queue 0 Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Portj_MTL_RxQ0_Missed_Pkt_Overflow_Cnt (j=0-1) Offset address: $11144_H+j*2000_H$

Port j MTL RxQ0 Missed Pkt Overflow Cnt Kernel Reset value: $0000\ 0000_H$

r												rw	rw		

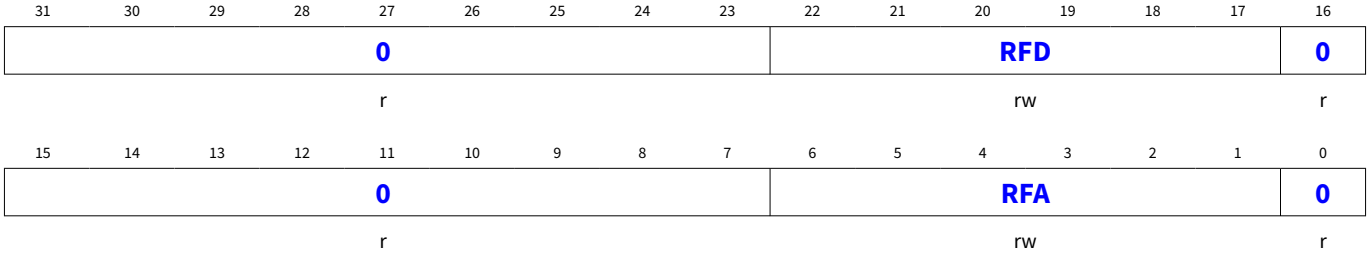
Field	Bits	Type	Description
RXQ_WEGT	2:0	rw	**Receive Queue Weight** This field indicates the weight assigned to the Rx Queue 0. The weight is used as the number of continuous PBL requests or contiguous packets (depending on the RXQ_PKT_ARBIT) allocated to the queue in one arbitration cycle.
RXQ_PKT_ARBIT	3	rw	**Receive Queue Packet Arbitration Control** - 1: MTL enables the packet-level arbitration. - 0: MTL enables the PBL based arbitration.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

14.6.558 Port j MTL RxQ0 Flow Control

This register controls the activation and de-activation threshold in the queue for triggering the generation of Flow Control packets by MAC transmitter.

Portj_MTL_RxQ0_Flow_Control (j=0-1) Offset address: $11150_H+j*2000_H$

Port j MTL RxQ0 Flow Control Kernel Reset value: $0000\ 0000_H$



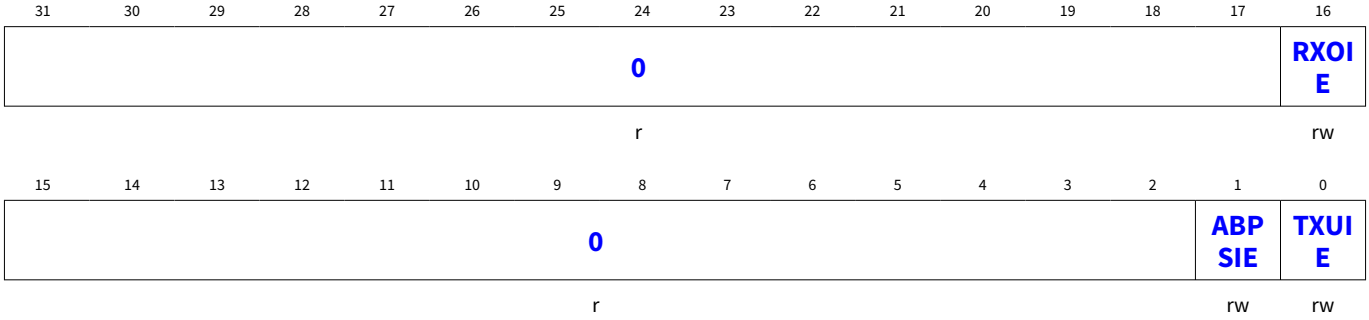
Field	Bits	Type	Description
RFA	6:1	rw	**Threshold for activating Flow Control** These bits control the threshold (fill-level of RxQ0) at which the flow control is activated - 6'b000000: RQS value minus 1 KB, that is, FULL - 1024 bytes - 6'b000001: RQS value minus 1.5 KB, that is, FULL - 1536 bytes - 6'b000010: RQS value minus 2 KB, that is, FULL - 2048 bytes. - ... - 6'b111111: RQS value minus 32.5 KB, that is, FULL - 33280 bytes The flow control is triggered when EHFC=1 and the queue size (RQS value in MTL_RxQ0_Operation Mode register) is equal to or more than 4KB. Note that the value to be programmed in RFA must be such that the threshold is positive number.
RFD	22:17	rw	**Threshold for deactivating Flow Control** These bits control the threshold (fill-level of RxQ0) at which the flow control is de-asserted once it is activated. - 6'b000000: RQS value minus 1 KB, that is, FULL - 1024 bytes - 6'b000001: RQS value minus 1.5 KB, that is, FULL - 1536 bytes - 6'b000010: RQS value minus 2 KB, that is, FULL - 2048 bytes. - ... - 6'b111111: RQS value minus 32.5 KB, that is, FULL - 33280 bytes The de-assertion is effective only after flow control is asserted as per the setting of RFA field. Note that the value to be programmed must be such that the threshold is positive number.
0	0, 16:7, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.559 Port j MTL Q0 Interrupt Enable

This register contains the interrupt enable bits for Traffic class/Queue 0.

Portj_MTL_Q0_Interrupt_Enable (j=0-1) Offset address: $11170_H+j*2000_H$

Port j MTL Q0 Interrupt Enable Kernel Reset value: $0000\ 0000_H$



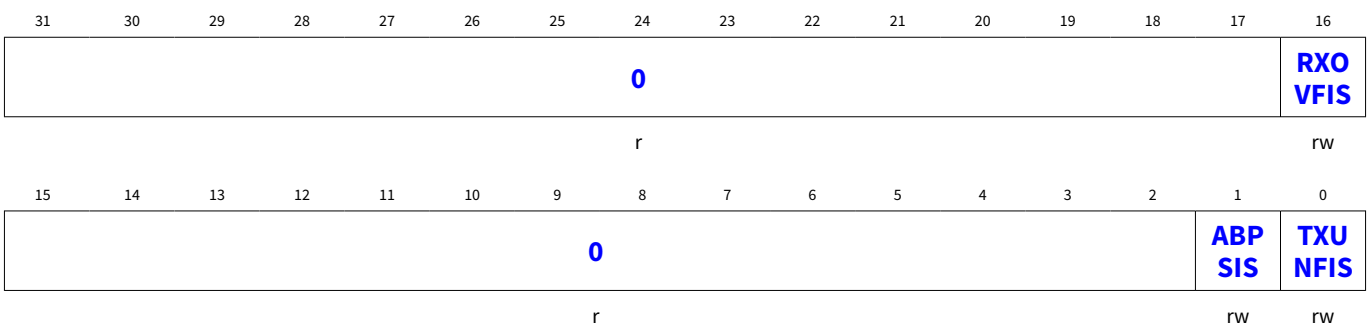
Field	Bits	Type	Description
TXUIE	0	rw	**Transmit Queue Underflow Interrupt Enable** - 1: Transmit Queue Underflow interrupt is enabled. - 0: Transmit Queue Underflow interrupt is disabled.
ABPSIE	1	rw	**Average Bits Per Slot Interrupt Enable** When this bit is set, average bits per slot interrupt is enabled for Traffic Class 0. An interrupt is generated when ABPSIS is set for this traffic class. This bit is reserved and RO when the number of traffic classes selected is less than 0.
RXOIE	16	rw	**Receive Queue Overflow Interrupt Enable** - 1: Receive Queue Overflow interrupt is enabled. - 0: Receive Queue Overflow interrupt is disabled.
0	15:2, 31:17	r	**Reserved** Read as 0; should be written with 0.

14.6.560 Port j MTL Q0 Interrupt Status

This register contains the interrupt status bits for Traffic class/Queue 0.

Portj_MTL_Q0_Interrupt_Status (j=0-1) Offset address: $11174_H+j*2000_H$

Port j MTL Q0 Interrupt Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TXUNFIS	0	rw	**Transmit Queue Underflow Interrupt Status** This bit indicates that the Transmit Queue had an Underflow during packet transmission. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes a 1 to this bit.
ABPSIS	1	rw	**Average Bits Per Slot Interrupt Status** When set, this bit indicates that the MAC has updated the ABS value for this traffic class. This bit is cleared when the application writes a 1 to this bit.
RXOVFIS	16	rw	**Receive Queue Overflow Interrupt Status** This bit indicates that the Receive Queue had an Overflow during packet reception. If partial packet is transferred to the application, the overflow status is set in the corresponding Rx status. This bit is cleared when the application writes a 1 to this bit.
0	15:2, 31:17	r	**Reserved** Read as 0; should be written with 0.

14.6.561 Port j MTL TxQ1 Operation Mode

The Queue 1 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Portj_MTL_TxQ1_Operation_Mode (j=0-1) Offset address: $11180_H+j*2000_H$

Port j MTL TxQ1 Operation Mode Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0									TQS						
r									rw						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					Q2TCMAP			0	TTC			TXQEN		TSF	FTQ
r					rw			r	rw			rw		rw	rw

Field	Bits	Type	Description
FTQ	0	rw	**Flush Transmit Queue** When this bit is set, the Tx Queue Controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. You must not write to this register until this bit is reset. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty. To complete this flush operation, the PHY Tx clock must be active.

(table continues...)

(continued)

Field	Bits	Type	Description
TSF	1	rw	**Transmit Store and Forward** When this bit is set, the transmission starts when a full packet resides in the MTL Tx Queue. When this bit is set, the values specified in the TTC field are ignored. This bit must be changed only when the transmission is stopped.
TXQEN	3:2	rw	**Transmit Queue Enable** This field is used to enable/disable the transmit queue. - 2'b00: Not enabled - 2'b01: Audio Video Bridging - 2'b10: Enabled - 2'b11: Reserved In multiple Tx queues configuration, as the queue is disabled by default, enable the Tx Queue by programming this field in the AVB mode or default mode as desired.
TTC	6:4	rw	**Transmit Threshold Control** These bits control the threshold level of the MTL Tx Queue. Transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. - 3'b000: 64 - 3'b001: Reserved - 3'b010: 96 - 3'b011: 128 - 3'b100: 192 - 3'b101: 256 - 3'b110: 384 - 3'b111: 512
Q2TCMAP	10:8	rw	**Queue to Traffic Class Mapping** This field is used to map this Tx Queue to a traffic class (TC). - 3'b000: TC0 - 3'b001: TC1 - 3'b010: TC2 - 3'b011: TC3 - 3'b100: TC4 - 3'b101: TC5 - 3'b110: TC6 - 3'b111: TC7
TQS	22:16	rw	**Transmit Queue Size** This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. A value of 0 indicates 256 bytes. When this queue is enabled (TXQEN=10), a minimum value of 7 (size = 2048) is recommended so that the queue can store more than a complete max-sized Ethernet packet.

(table continues...)

(continued)

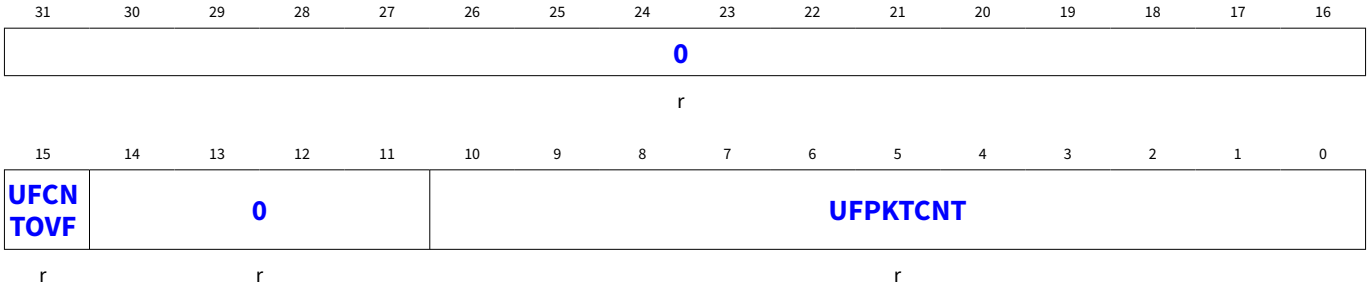
Field	Bits	Type	Description
0	7, 15:11, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.562 Port j MTL TxQ1 Underflow

The Queue 1 Underflow Counter register contains the number of packets aborted because of Transmit queue underflow.

Portj_MTL_TxQ1_Underflow (j=0-1) Offset address: $11184_H+j*2000_H$

Port j MTL TxQ1 Underflow Kernel Reset value: $0000\ 0000_H$



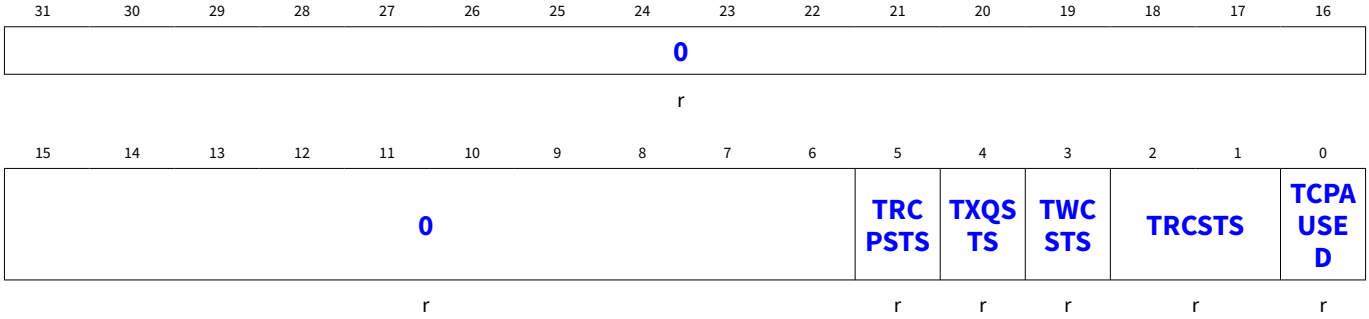
Field	Bits	Type	Description
UFPKTCNT	10:0	r	**Underflow Packet Counter** This field indicates the number of packets aborted by the controller because of Transmit Queue Underflow. This counter is incremented each time the MAC aborts an outgoing packet because of underflow. The counter is reset when this register is read with LSB of the Byte Enable for CSR access signal at 1'b1 .
UFCNTOVF	15	r	**Overflow Bit for Underflow Packet Counter** This bit is set every time the Tx Queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened.
0	14:11, 31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.563 Port j MTL TxQ1 Debug

The Queue 1 Transmit Debug register gives the debug status of various blocks related to the Transmit Queue 1 and Traffic Class 1.

Portj_MTL_TxQ1_Debug (j=0-1) Offset address: $11188_H+j*2000_H$

Port j MTL TxQ1 Debug Kernel Reset value: $0000\ 0000_H$



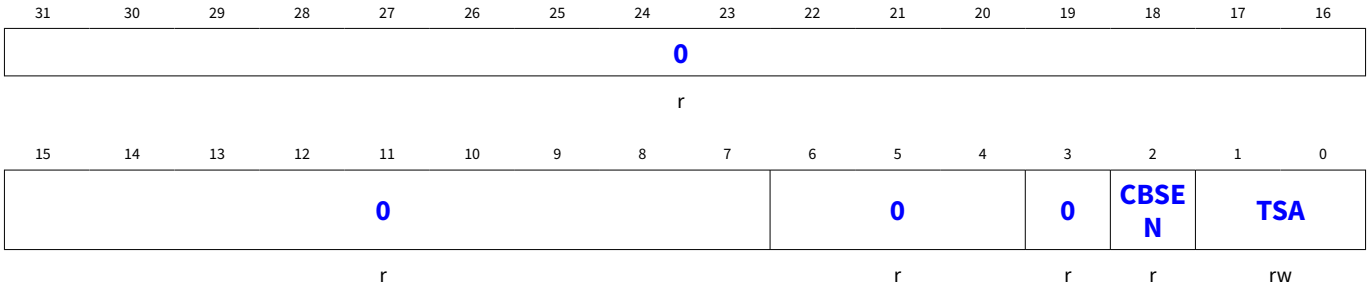
Field	Bits	Type	Description
TCPAUSED	0	r	**Traffic Class in Pause** - Reception of IEEE 802.3-2018 Pause packet
TRCSTS	2:1	r	**MTL Tx Queue Read Controller Status** This field indicates the state of the Tx Queue Read Controller: - 2'b00: Idle state - 2'b01: Read state (transferring data to the MAC transmitter) - 2'b10: Waiting for pending Tx Status from the MAC transmitter - 2'b11: Flushing the Tx queue because of the Packet Abort request from the MAC
TWCSTS	3	r	**MTL Tx Queue Write Controller Status** When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.
TXQSTS	4	r	**MTL Tx Queue Not Empty Status** When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
TRCPSTS	5	r	**MTL TRC Pending Status** When this bit is high, it indicates that the MTL Tx Read Controller (TRC) has a pending status from MAC.
0	31:6	r	**Reserved** Read as 0; should be written with 0.

14.6.564 Port j MTL TC1 ETS Control

This register configures the transmission selection algorithm, for Traffic Class 1.

Portj_MTL_TC1_ETS_Control (j=0-1) Offset address: $11190_H+j*2000_H$

Port j MTL TC1 ETS Control Kernel Reset value: $0000\ 0000_H$



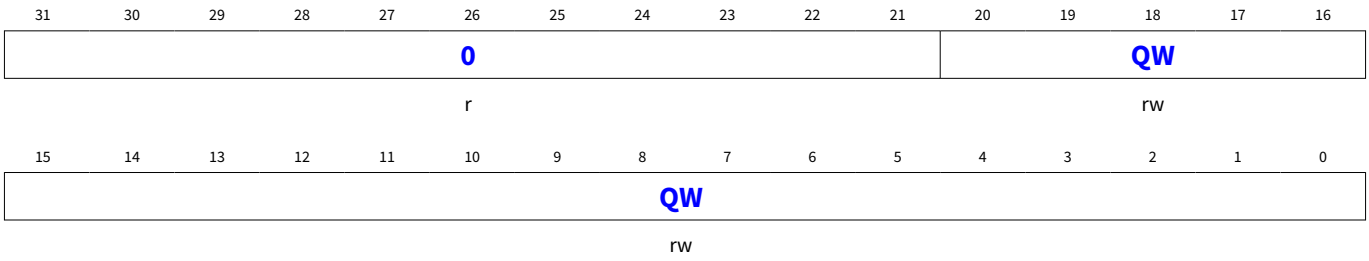
Field	Bits	Type	Description
TSA	1:0	rw	**Transmission Selection Algorithm** This field is used to assign a transmission selection algorithm for this traffic class. - 2'b00: Strict priority - 2'b01: CBS - 2'b10: ETS - 2'b11: Reserved
CBSEN	2	r	**Credit Based Shaper Enable** This field indicates that TSA field of this register is enabled for CBS
0	3, 6:4, 31:7	r	**Reserved** Read as 0; should be written with 0.

14.6.565 Port j MTL TC1 Quantum Weight

The Quantum or Weights register controls the average traffic transmitted in Traffic Class 1.

Portj_MTL_TC1_Quantum_Weight (j=0-1) Offset address: $11198_H+j*2000_H$

Port j MTL TC1 Quantum Weight Kernel Reset value: $0000\ 0000_H$



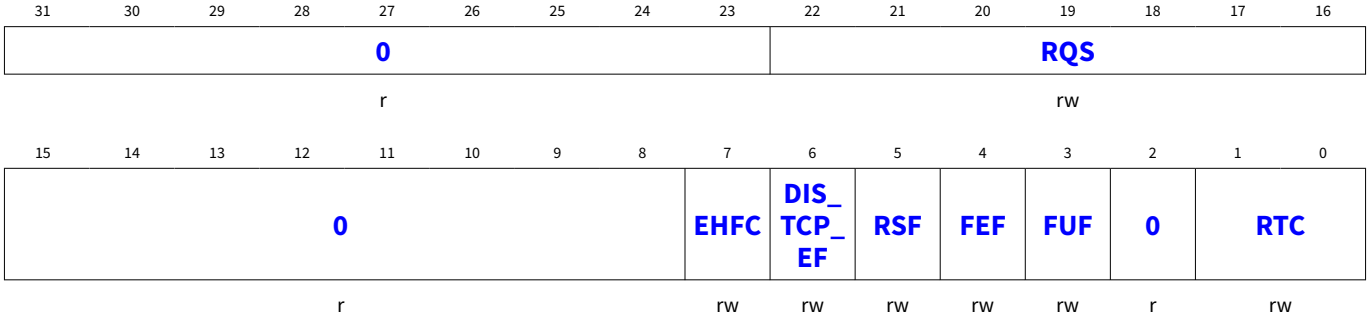
Field	Bits	Type	Description
QW	20:0	rw	**idleSlopeCredit, Quantum or Weights** - idleSlopeCredit -- When this TC is in AVB mode, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Traffic Class 1. This is the rate of change of credit in bits per cycle (3.2 ns for 2.5/10 Gbps; 8 ns for 1000 Mbps) when the credit is increasing. The software must program this field with computed credit in bits per cycle scaled by 1024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x8000 in 10 Gbps mode. Bits[20:16] must be written to zero. This field is not valid for Traffic Class 0. - Weights -- When TSA is set to ETS and ETSALG is set to WRR algorithm for Traffic Class 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits[20:7] must be written to zero. This field is reserved and RO when the number of traffic classes selected is less than two. This field is reserved in corresponding Queues 8-15 register.
0	31:21	r	**Reserved** Read as 0; should be written with 0.

14.6.566 Port j MTL RxQ1 Operation Mode

The Queue 1 Receive Operation Mode register establishes the Receive queue 1 operating modes.

Portj_MTL_RxQ1_Operation_Mode (j=0-1) Offset address: $111C0_H+j*2000_H$

Port j MTL RxQ1 Operation Mode Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RTC	1:0	rw	**Receive Queue Threshold Control** These bits control the threshold level of the MTL Rx queue (in bytes): - 2'b00: 64 - 2'b01: Reserved - 2'b10: 96 - 2'b11: 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. The value of 11 is not applicable if the size of the configured Rx Queue is 128 bytes. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.
FUF	3	rw	**Forward Undersized Good Packets** - 1: Rx queue forwards the undersized good packets (with no Invalid-code/GMII/CRC/Length errors and length less than 64 bytes at Rx (X)GMII interface), including pad-bytes and CRC. - 0: Rx queue drops all packets of length less than 64 bytes.
FEF	4	rw	**Forward Error Packets** - 0: Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. - 1: All packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA.

(table continues...)

(continued)

Field	Bits	Type	Description
RSF	5	rw	**Receive Queue Store and Forward** - 1: DWC_xgmac reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. - 0: Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.
DIS_TCP_EF	6	rw	**Disable Dropping of TCP/IP Checksum Error Packets** - When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. - When this bit is reset, all error packets are dropped if the FEF bit is reset.
EHFC	7	rw	**Enable Hardware Flow Control** When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.
RQS	22:16	rw	**Receive Queue Size** This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. A value of 0 indicates 256 bytes.When this queue is used, a minimum value of 7 (size = 2048) is recommended so that the queue can store more than a complete max-sized Ethernet packet.
0	2, 15:8, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.567 Port j MTL RxQ1 Missed Pkt Overflow Cnt

The Queue 1 Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Portj_MTL_RxQ1_Missed_Pkt_Overflow_Cnt (j=0-1) Offset address: $111C4_H+j*2000_H$

Port j MTL RxQ1 Missed Pkt Overflow Cnt Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
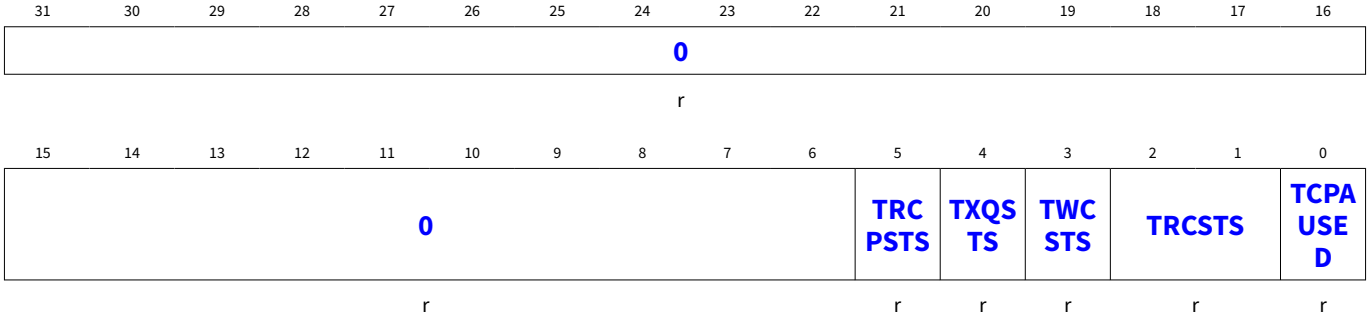
UFPKTCNT	10:0	r	**Underflow Packet Counter** This field indicates the number of packets aborted by the controller because of Transmit Queue Underflow. This counter is incremented each time the MAC aborts an outgoing packet because of underflow. The counter is reset when this register is read with LSB of the Byte Enable for CSR access signal at 1'b1 .
UFCNTOVF	15	r	**Overflow Bit for Underflow Packet Counter** This bit is set every time the Tx Queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened.
0	14:11, 31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.575 Port j MTL TxQ2 Debug

The Queue 2 Transmit Debug register gives the debug status of various blocks related to the Transmit Queue 2 and Traffic Class 2.

Portj_MTL_TxQ2_Debug (j=0-1) Offset address: $11208_H+j*2000_H$

Port j MTL TxQ2 Debug Kernel Reset value: $0000\ 0000_H$



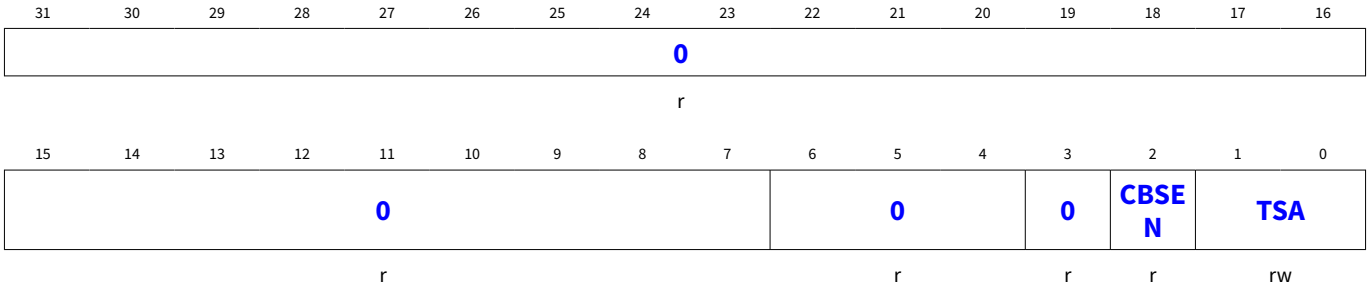
Field	Bits	Type	Description
TCPAUSED	0	r	**Traffic Class in Pause** - Reception of IEEE 802.3-2018 Pause packet
TRCSTS	2:1	r	**MTL Tx Queue Read Controller Status** This field indicates the state of the Tx Queue Read Controller: - 2'b00: Idle state - 2'b01: Read state (transferring data to the MAC transmitter) - 2'b10: Waiting for pending Tx Status from the MAC transmitter - 2'b11: Flushing the Tx queue because of the Packet Abort request from the MAC
TWCSTS	3	r	**MTL Tx Queue Write Controller Status** When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.
TXQSTS	4	r	**MTL Tx Queue Not Empty Status** When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
TRCPSTS	5	r	**MTL TRC Pending Status** When this bit is high, it indicates that the MTL Tx Read Controller (TRC) has a pending status from MAC.
0	31:6	r	**Reserved** Read as 0; should be written with 0.

14.6.576 Port j MTL TC2 ETS Control

This register configures the transmission selection algorithm, for Traffic Class 2.

Portj_MTL_TC2_ETS_Control (j=0-1) Offset address: $11210_H+j*2000_H$

Port j MTL TC2 ETS Control Kernel Reset value: $0000\ 0000_H$



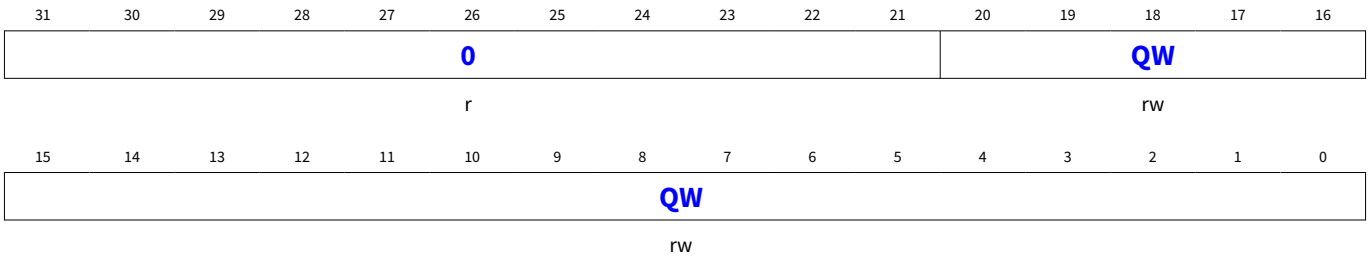
Field	Bits	Type	Description
TSA	1:0	rw	**Transmission Selection Algorithm** This field is used to assign a transmission selection algorithm for this traffic class. - 2'b00: Strict priority - 2'b01: CBS - 2'b10: ETS - 2'b11: Reserved
CBSEN	2	r	**Credit Based Shaper Enable** This field indicates that TSA field of this register is enabled for CBS
0	3, 6:4, 31:7	r	**Reserved** Read as 0; should be written with 0.

14.6.577 Port j MTL TC2 Quantum Weight

The Quantum or Weights register controls the average traffic transmitted in Traffic Class 2.

Portj_MTL_TC2_Quantum_Weight (j=0-1) Offset address: $11218_H+j*2000_H$

Port j MTL TC2 Quantum Weight Kernel Reset value: $0000\ 0000_H$



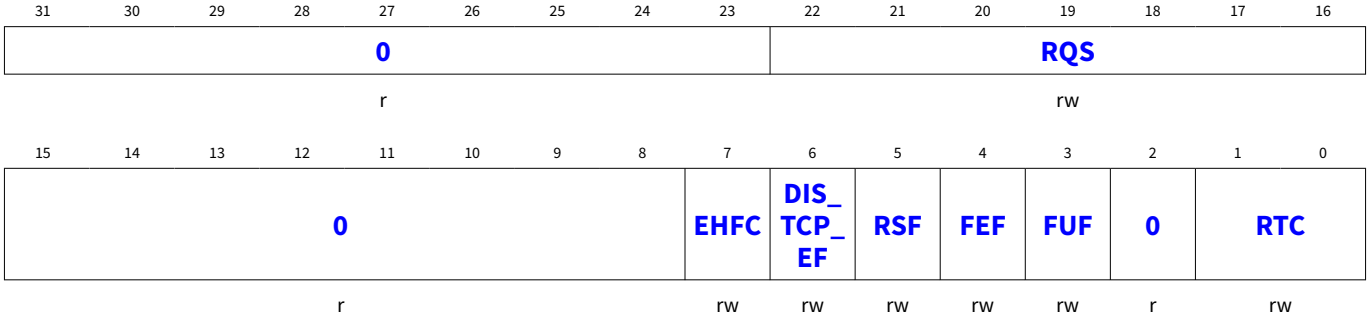
Field	Bits	Type	Description
QW	20:0	rw	**idleSlopeCredit, Quantum or Weights** - idleSlopeCredit -- When this TC is in AVB mode, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Traffic Class 2. This is the rate of change of credit in bits per cycle (3.2 ns for 2.5/10 Gbps; 8 ns for 1000 Mbps) when the credit is increasing. The software must program this field with computed credit in bits per cycle scaled by 1024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x8000 in 10 Gbps mode. Bits[20:16] must be written to zero. This field is not valid for Traffic Class 0. - Weights -- When TSA is set to ETS and ETSALG is set to WRR algorithm for Traffic Class 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits[20:7] must be written to zero. This field is reserved and RO when the number of traffic classes selected is less than two. This field is reserved in corresponding Queues 8-15 register.
0	31:21	r	**Reserved** Read as 0; should be written with 0.

14.6.578 Port j MTL RxQ2 Operation Mode

The Queue 2 Receive Operation Mode register establishes the Receive queue 2 operating modes.

Portj_MTL_RxQ2_Operation_Mode (j=0-1) Offset address: $11240_H+j*2000_H$

Port j MTL RxQ2 Operation Mode Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RTC	1:0	rw	**Receive Queue Threshold Control** These bits control the threshold level of the MTL Rx queue (in bytes): - 2'b00: 64 - 2'b01: Reserved - 2'b10: 96 - 2'b11: 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. The value of 11 is not applicable if the size of the configured Rx Queue is 128 bytes. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.
FUF	3	rw	**Forward Undersized Good Packets** - 1: Rx queue forwards the undersized good packets (with no Invalid-code/GMII/CRC/Length errors and length less than 64 bytes at Rx (X)GMII interface), including pad-bytes and CRC. - 0: Rx queue drops all packets of length less than 64 bytes.
FEF	4	rw	**Forward Error Packets** - 0: Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. - 1: All packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA.

(table continues...)

(continued)

Field	Bits	Type	Description
RSF	5	rw	**Receive Queue Store and Forward** - 1: DWC_xgmac reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. - 0: Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.
DIS_TCP_EF	6	rw	**Disable Dropping of TCP/IP Checksum Error Packets** - When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. - When this bit is reset, all error packets are dropped if the FEF bit is reset.
EHFC	7	rw	**Enable Hardware Flow Control** When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.
RQS	22:16	rw	**Receive Queue Size** This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. A value of 0 indicates 256 bytes.When this queue is used, a minimum value of 7 (size = 2048) is recommended so that the queue can store more than a complete max-sized Ethernet packet.
0	2, 15:8, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.579 Port j MTL RxQ2 Missed Pkt Overflow Cnt

The Queue 2 Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Portj_MTL_RxQ2_Missed_Pkt_Overflow_Cnt (j=0-1) Offset address: $11244_H+j*2000_H$

Port j MTL RxQ2 Missed Pkt Overflow Cnt Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OVFCNTOVF		0			OVFPKTCNT										
r		r			r										

Field	Bits	Type	Description
OVFPKTCNT	10:0	r	**Overflow Packet Counter** This field indicates the number of packets discarded by DWC_xgmac because of Receive queue overflow. This counter is incremented each time DWC_xgmac discards an incoming packet because of overflow. This counter is reset when this register bits[7:0] is read by software.
OVFCNTOVF	15	r	**Overflow Counter Overflow Bit** When set, this bit indicates that OVFPKTCNT field crossed the maximum limit.
MISPKTCNT	26:16	r	**Missed Packet Counter** This field indicates the number of packets missed by DWC_xgmac because the host asserted packet-flush for this queue. This counter is incremented each time a packet is flushed for this queue. This counter is reset when this register's bits[23:16] is read by the software.
MISCNTOVF	31	r	**Missed Packet Counter Overflow Bit** When set, this bit indicates that the MISPKTCNT field crossed the maximum limit.
0	14:11, 30:27	r	**Reserved** Read as 0; should be written with 0.

14.6.580 Port j MTL RxQ2 Debug

The Queue 2 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Portj_MTL_RxQ2_Debug (j=0-1) Offset address: $11248_H+j*2000_H$

Port j MTL RxQ2 Debug Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RWCSTS	0	r	**MTL Rx Queue Write Controller Active Status** When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue.
RRCSTS	2:1	r	**MTL Rx Queue Read Controller State** This field gives the state of the Rx queue Read controller: - 2'b00: Idle state - 2'b01: Reading packet data - 2'b10: Reading packet status (or timestamp) - 2'b11: Flushing the packet data and status

(table continues...)

(continued)

Field	Bits	Type	Description
RXQSTS	5:4	r	**MTL Rx Queue Fill-Level Status** This field gives the status of the fill-level of the Rx Queue: - 2'b00: Rx Queue empty - 2'b01: Rx Queue fill-level below flow-control deactivate threshold - 2'b10: Rx Queue fill-level above flow-control activate threshold - 2'b11: Rx Queue full
PRXQ	29:16	r	**Number of Packets in Receive Queue** This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.
0	3, 15:6, 31:30	r	**Reserved** Read as 0; should be written with 0.

14.6.581 Port j MTL RxQ2 Control

The Queue 2 Receive Control register controls the receive arbitration and passing of received packets to the application.

Portj_MTL_RxQ2_Control (j=0-1) Offset address: $1124C_H+j*2000_H$

Port j MTL RxQ2 Control Kernel Reset value: $0000\ 0000_H$

0												RXQ_PKT_ARBIT	RXQ_WEGT		
r												rw	rw		

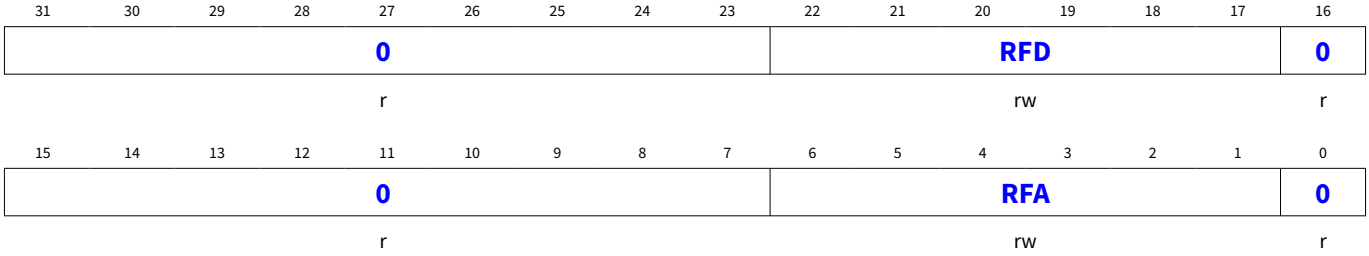
Field	Bits	Type	Description
RXQ_WEGT	2:0	rw	**Receive Queue Weight** This field indicates the weight assigned to the Rx Queue 2. The weight is used as the number of continuous PBL requests or contiguous packets (depending on the RXQ_PKT_ARBIT) allocated to the queue in one arbitration cycle.
RXQ_PKT_ARBIT	3	rw	**Receive Queue Packet Arbitration Control** - 1: MTL enables the packet-level arbitration. - 0: MTL enables the PBL based arbitration.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

14.6.582 Port j MTL RxQ2 Flow Control

This register controls the activation and de-activation threshold in the queue for triggering the generation of Flow Control packets by MAC transmitter.

Portj_MTL_RxQ2_Flow_Control (j=0-1) Offset address: $11250_H+j*2000_H$

Port j MTL RxQ2 Flow Control Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RFA	6:1	rw	**Threshold for activating Flow Control** These bits control the threshold (fill-level of RxQ0) at which the flow control is activated - 6'b000000: RQS value minus 1 KB, that is, FULL - 1024 bytes - 6'b000001: RQS value minus 1.5 KB, that is, FULL - 1536 bytes - 6'b000010: RQS value minus 2 KB, that is, FULL - 2048 bytes. - ... - 6'b111111: RQS value minus 32.5 KB, that is, FULL - 33280 bytes The flow control is triggered when EHFC=1 and the queue size (RQS value in MTL_RxQ2_Operation Mode register) is equal to or more than 4KB. Note that the value to be programmed in RFA must be such that the threshold is positive number.
RFD	22:17	rw	**Threshold for deactivating Flow Control** These bits control the threshold (fill-level of RxQ0) at which the flow control is de-asserted once it is activated. - 6'b000000: RQS value minus 1 KB, that is, FULL - 1024 bytes - 6'b000001: RQS value minus 1.5 KB, that is, FULL - 1536 bytes - 6'b000010: RQS value minus 2 KB, that is, FULL - 2048 bytes. - ... - 6'b111111: RQS value minus 32.5 KB, that is, FULL - 33280 bytes The de-assertion is effective only after flow control is asserted as per the setting of RFA field. Note that the value to be programmed must be such that the threshold is positive number.
0	0, 16:7, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.583 Port j MTL Q2 Interrupt Enable

This register contains the interrupt enable bits for Traffic class/Queue 2.

Portj_MTL_Q2_Interrupt_Enable (j=0-1) Offset address: $11270_H+j*2000_H$

Port j MTL Q2 Interrupt Enable Kernel Reset value: $0000\ 0000_H$

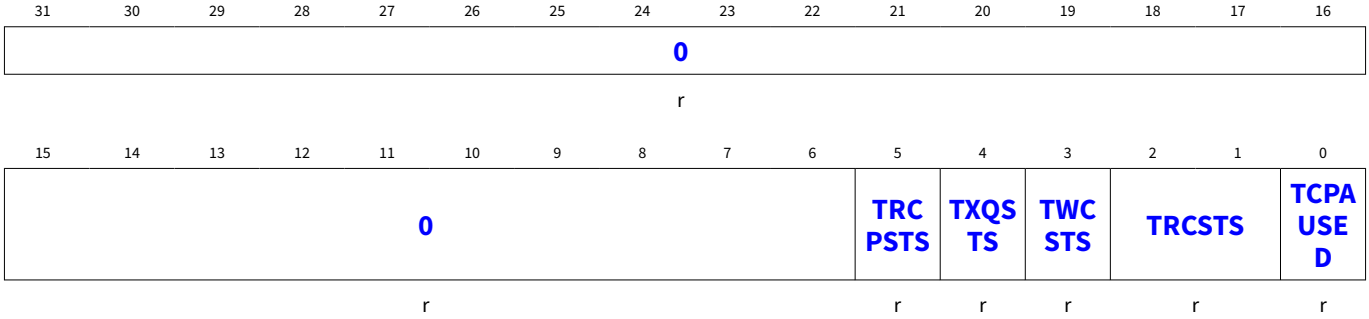
0	14:11, 31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.587 Port j MTL TxQ3 Debug

The Queue 3 Transmit Debug register gives the debug status of various blocks related to the Transmit Queue 3 and Traffic Class 3.

Portj_MTL_TxQ3_Debug (j=0-1) Offset address: $11288_H+j*2000_H$

Port j MTL TxQ3 Debug Kernel Reset value: $0000\ 0000_H$



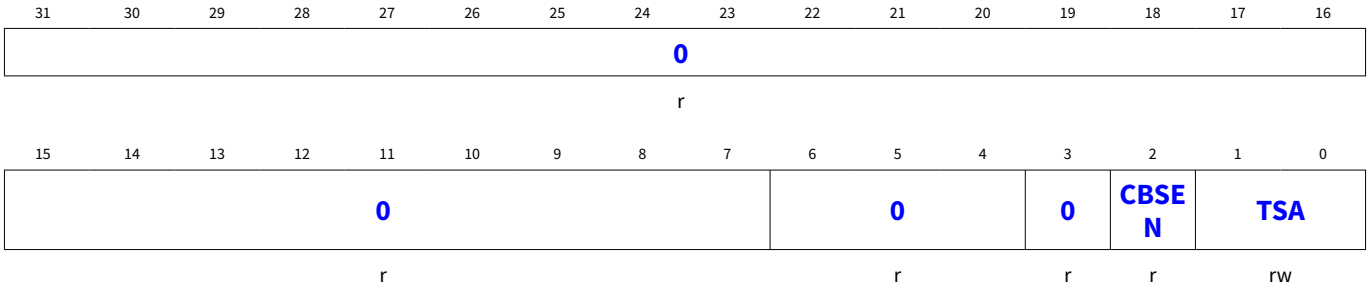
Field	Bits	Type	Description
TCPAUSED	0	r	**Traffic Class in Pause** - Reception of IEEE 802.3-2018 Pause packet
TRCSTS	2:1	r	**MTL Tx Queue Read Controller Status** This field indicates the state of the Tx Queue Read Controller: - 2'b00: Idle state - 2'b01: Read state (transferring data to the MAC transmitter) - 2'b10: Waiting for pending Tx Status from the MAC transmitter - 2'b11: Flushing the Tx queue because of the Packet Abort request from the MAC
TWCSTS	3	r	**MTL Tx Queue Write Controller Status** When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.
TXQSTS	4	r	**MTL Tx Queue Not Empty Status** When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
TRCPSTS	5	r	**MTL TRC Pending Status** When this bit is high, it indicates that the MTL Tx Read Controller (TRC) has a pending status from MAC.
0	31:6	r	**Reserved** Read as 0; should be written with 0.

14.6.588 Port j MTL TC3 ETS Control

This register configures the transmission selection algorithm, for Traffic Class 3.

Portj_MTL_TC3_ETS_Control (j=0-1) Offset address: $11290_H+j*2000_H$

Port j MTL TC3 ETS Control Kernel Reset value: $0000\ 0000_H$



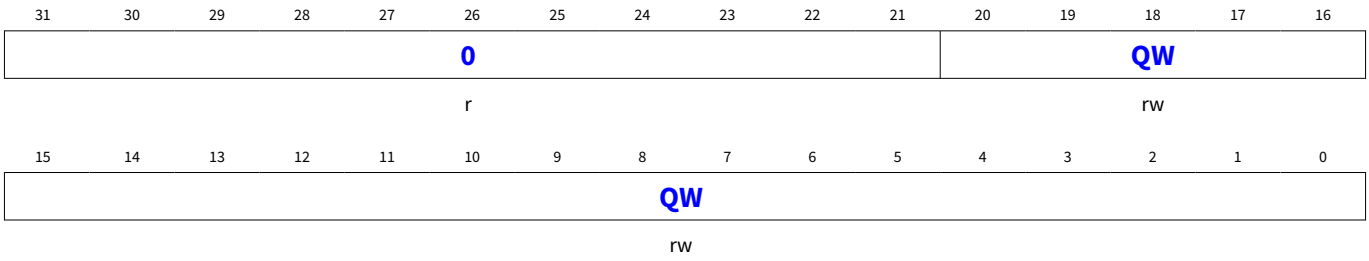
Field	Bits	Type	Description
TSA	1:0	rw	**Transmission Selection Algorithm** This field is used to assign a transmission selection algorithm for this traffic class. - 2'b00: Strict priority - 2'b01: CBS - 2'b10: ETS - 2'b11: Reserved
CBSEN	2	r	**Credit Based Shaper Enable** This field indicates that TSA field of this register is enabled for CBS
0	3, 6:4, 31:7	r	**Reserved** Read as 0; should be written with 0.

14.6.589 Port j MTL TC3 Quantum Weight

The Quantum or Weights register controls the average traffic transmitted in Traffic Class 3.

Portj_MTL_TC3_Quantum_Weight (j=0-1) Offset address: $11298_H+j*2000_H$

Port j MTL TC3 Quantum Weight Kernel Reset value: $0000\ 0000_H$



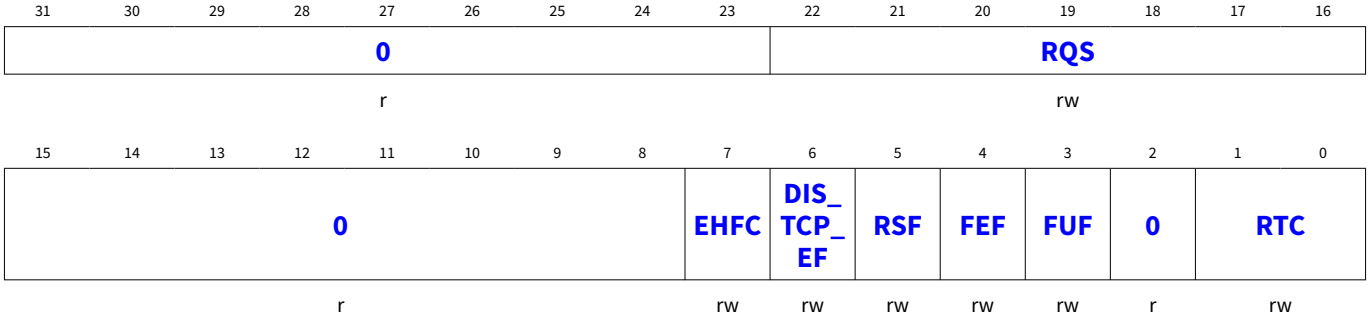
Field	Bits	Type	Description
QW	20:0	rw	**idleSlopeCredit, Quantum or Weights** - idleSlopeCredit -- When this TC is in AVB mode, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Traffic Class 3. This is the rate of change of credit in bits per cycle (3.2 ns for 2.5/10 Gbps; 8 ns for 1000 Mbps) when the credit is increasing. The software must program this field with computed credit in bits per cycle scaled by 1024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x8000 in 10 Gbps mode. Bits[20:16] must be written to zero. This field is not valid for Traffic Class 0. - Weights -- When TSA is set to ETS and ETSALG is set to WRR algorithm for Traffic Class 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits[20:7] must be written to zero. This field is reserved and RO when the number of traffic classes selected is less than two. This field is reserved in corresponding Queues 8-15 register.
0	31:21	r	**Reserved** Read as 0; should be written with 0.

14.6.590 Port j MTL RxQ3 Operation Mode

The Queue 3 Receive Operation Mode register establishes the Receive queue 3 operating modes.

Portj_MTL_RxQ3_Operation_Mode (j=0-1) Offset address: $112C0_H+j*2000_H$

Port j MTL RxQ3 Operation Mode Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RTC	1:0	rw	**Receive Queue Threshold Control** These bits control the threshold level of the MTL Rx queue (in bytes): - 2'b00: 64 - 2'b01: Reserved - 2'b10: 96 - 2'b11: 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. The value of 11 is not applicable if the size of the configured Rx Queue is 128 bytes. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.
FUF	3	rw	**Forward Undersized Good Packets** - 1: Rx queue forwards the undersized good packets (with no Invalid-code/GMII/CRC/Length errors and length less than 64 bytes at Rx (X)GMII interface), including pad-bytes and CRC. - 0: Rx queue drops all packets of length less than 64 bytes.
FEF	4	rw	**Forward Error Packets** - 0: Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. - 1: All packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA.

(table continues...)

(continued)

Field	Bits	Type	Description
RSF	5	rw	**Receive Queue Store and Forward** - 1: DWC_xgmac reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. - 0: Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.
DIS_TCP_EF	6	rw	**Disable Dropping of TCP/IP Checksum Error Packets** - When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. - When this bit is reset, all error packets are dropped if the FEF bit is reset.
EHFC	7	rw	**Enable Hardware Flow Control** When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.
RQS	22:16	rw	**Receive Queue Size** This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. A value of 0 indicates 256 bytes.When this queue is used, a minimum value of 7 (size = 2048) is recommended so that the queue can store more than a complete max-sized Ethernet packet.
0	2, 15:8, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.591 Port j MTL RxQ3 Missed Pkt Overflow Cnt

The Queue 3 Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Portj_MTL_RxQ3_Missed_Pkt_Overflow_Cnt (j=0-1) Offset address: $112C4_H+j*2000_H$

Port j MTL RxQ3 Missed Pkt Overflow Cnt Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OVFCNTOVF	0				OVFPKTCNT										
r	r				r										

Field	Bits	Type	Description
OVFPKTCNT	10:0	r	**Overflow Packet Counter** This field indicates the number of packets discarded by DWC_xgmac because of Receive queue overflow. This counter is incremented each time DWC_xgmac discards an incoming packet because of overflow. This counter is reset when this register bits[7:0] is read by software.
OVFCNTOVF	15	r	**Overflow Counter Overflow Bit** When set, this bit indicates that OVFPKTCNT field crossed the maximum limit.
MISPKTCNT	26:16	r	**Missed Packet Counter** This field indicates the number of packets missed by DWC_xgmac because the host asserted packet-flush for this queue. This counter is incremented each time a packet is flushed for this queue. This counter is reset when this register's bits[23:16] is read by the software.
MISCNTOVF	31	r	**Missed Packet Counter Overflow Bit** When set, this bit indicates that the MISPKTCNT field crossed the maximum limit.
0	14:11, 30:27	r	**Reserved** Read as 0; should be written with 0.

14.6.592 Port j MTL RxQ3 Debug

The Queue 3 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Portj_MTL_RxQ3_Debug (j=0-1) Offset address: $112C8_H+j*2000_H$

Port j MTL RxQ3 Debug Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RWCSTS	0	r	**MTL Rx Queue Write Controller Active Status** When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue.
RRCSTS	2:1	r	**MTL Rx Queue Read Controller State** This field gives the state of the Rx queue Read controller: - 2'b00: Idle state - 2'b01: Reading packet data - 2'b10: Reading packet status (or timestamp) - 2'b11: Flushing the packet data and status

(table continues...)

(continued)

Field	Bits	Type	Description
RXQSTS	5:4	r	**MTL Rx Queue Fill-Level Status** This field gives the status of the fill-level of the Rx Queue: - 2'b00: Rx Queue empty - 2'b01: Rx Queue fill-level below flow-control deactivate threshold - 2'b10: Rx Queue fill-level above flow-control activate threshold - 2'b11: Rx Queue full
PRXQ	29:16	r	**Number of Packets in Receive Queue** This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.
0	3, 15:6, 31:30	r	**Reserved** Read as 0; should be written with 0.

14.6.593 Port j MTL RxQ3 Control

The Queue 3 Receive Control register controls the receive arbitration and passing of received packets to the application.

Portj_MTL_RxQ3_Control (j=0-1) Offset address: $112CC_H+j*2000_H$

Port j MTL RxQ3 Control Kernel Reset value: $0000\ 0000_H$

0												RXQ_PKT_ARBIT	RXQ_WEGT		
r												rw	rw		

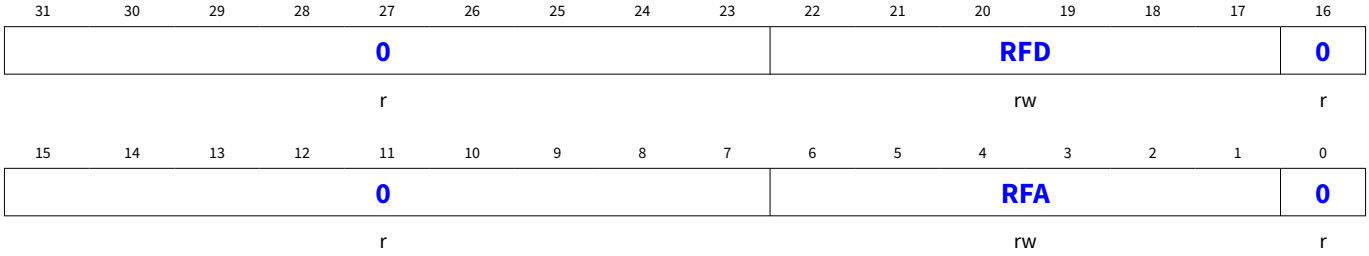
Field	Bits	Type	Description
RXQ_WEGT	2:0	rw	**Receive Queue Weight** This field indicates the weight assigned to the Rx Queue 3. The weight is used as the number of continuous PBL requests or contiguous packets (depending on the RXQ_PKT_ARBIT) allocated to the queue in one arbitration cycle.
RXQ_PKT_ARBIT	3	rw	**Receive Queue Packet Arbitration Control** - 1: MTL enables the packet-level arbitration. - 0: MTL enables the PBL based arbitration.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

14.6.594 Port j MTL RxQ3 Flow Control

This register controls the activation and de-activation threshold in the queue for triggering the generation of Flow Control packets by MAC transmitter.

Portj_MTL_RxQ3_Flow_Control (j=0-1) Offset address: $112D0_H+j*2000_H$

Port j MTL RxQ3 Flow Control Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RFA	6:1	rw	**Threshold for activating Flow Control** These bits control the threshold (fill-level of RxQ0) at which the flow control is activated - 6'b000000: RQS value minus 1 KB, that is, FULL - 1024 bytes - 6'b000001: RQS value minus 1.5 KB, that is, FULL - 1536 bytes - 6'b000010: RQS value minus 2 KB, that is, FULL - 2048 bytes. - ... - 6'b111111: RQS value minus 32.5 KB, that is, FULL - 33280 bytes The flow control is triggered when EHFC=1 and the queue size (RQS value in MTL_RxQ3_Operation Mode register) is equal to or more than 4KB. Note that the value to be programmed in RFA must be such that the threshold is positive number.
RFD	22:17	rw	**Threshold for deactivating Flow Control** These bits control the threshold (fill-level of RxQ0) at which the flow control is de-asserted once it is activated. - 6'b000000: RQS value minus 1 KB, that is, FULL - 1024 bytes - 6'b000001: RQS value minus 1.5 KB, that is, FULL - 1536 bytes - 6'b000010: RQS value minus 2 KB, that is, FULL - 2048 bytes. - ... - 6'b111111: RQS value minus 32.5 KB, that is, FULL - 33280 bytes The de-assertion is effective only after flow control is asserted as per the setting of RFA field. Note that the value to be programmed must be such that the threshold is positive number.
0	0, 16:7, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.595 Port j MTL Q3 Interrupt Enable

This register contains the interrupt enable bits for Traffic class/Queue 3.

Portj_MTL_Q3_Interrupt_Enable (j=0-1) Offset address: $112F0_H+j*2000_H$

Port j MTL Q3 Interrupt Enable Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														ABPSIS	TXUNFIS
r														rw	rw

Field	Bits	Type	Description
TXUNFIS	0	rw	**Transmit Queue Underflow Interrupt Status** This bit indicates that the Transmit Queue had an Underflow during packet transmission. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes a 1 to this bit.
ABPSIS	1	rw	**Average Bits Per Slot Interrupt Status** When set, this bit indicates that the MAC has updated the ABS value for this traffic class. This bit is cleared when the application writes a 1 to this bit. This bit is reserved and RO when the number of traffic classes selected is less than 3.
RXOVFIS	16	rw	**Receive Queue Overflow Interrupt Status** This bit indicates that the Receive Queue had an Overflow during packet reception. If partial packet is transferred to the application, the overflow status is set in the corresponding Rx status. This bit is cleared when the application writes a 1 to this bit.
0	15:2, 31:17	r	**Reserved** Read as 0; should be written with 0.

14.6.597 Port j MTL TxQ4 Operation Mode

The Queue 4 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Portj_MTL_TxQ4_Operation_Mode (j=0-1) Offset address: $11300_H+j*2000_H$

Port j MTL TxQ4 Operation Mode Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0									TQS

0					Q2TCMAP			0	TTC			TXQEN		TSF	FTQ
r					rw			r	rw			rw		rw	rw

Field	Bits	Type	Description
FTQ	0	rw	**Flush Transmit Queue** When this bit is set, the Tx Queue Controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. You must not write to this register until this bit is reset. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty. To complete this flush operation, the PHY Tx clock must be active.

(table continues...)

(continued)

Field	Bits	Type	Description
TSF	1	rw	**Transmit Store and Forward** When this bit is set, the transmission starts when a full packet resides in the MTL Tx Queue. When this bit is set, the values specified in the TTC field are ignored. This bit must be changed only when the transmission is stopped.
TXQEN	3:2	rw	**Transmit Queue Enable** This field is used to enable/disable the transmit queue. - 2'b00: Not enabled - 2'b01: Audio Video Bridging - 2'b10: Enabled - 2'b11: Reserved In multiple Tx queues configuration, as the queue is disabled by default, enable the Tx Queue by programming this field in the AVB mode or default mode as desired.
TTC	6:4	rw	**Transmit Threshold Control** These bits control the threshold level of the MTL Tx Queue. Transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. - 3'b000: 64 - 3'b001: Reserved - 3'b010: 96 - 3'b011: 128 - 3'b100: 192 - 3'b101: 256 - 3'b110: 384 - 3'b111: 512
Q2TCMAP	10:8	rw	**Queue to Traffic Class Mapping** This field is used to map this Tx Queue to a traffic class (TC). - 3'b000: TC0 - 3'b001: TC1 - 3'b010: TC2 - 3'b011: TC3 - 3'b100: TC4 - 3'b101: TC5 - 3'b110: TC6 - 3'b111: TC7
TQS	22:16	rw	**Transmit Queue Size** This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. A value of 0 indicates 256 bytes. When this queue is enabled (TXQEN=10), a minimum value of 7 (size = 2048) is recommended so that the queue can store more than a complete max-sized Ethernet packet.

(table continues...)

Field	Bits	Type	Description
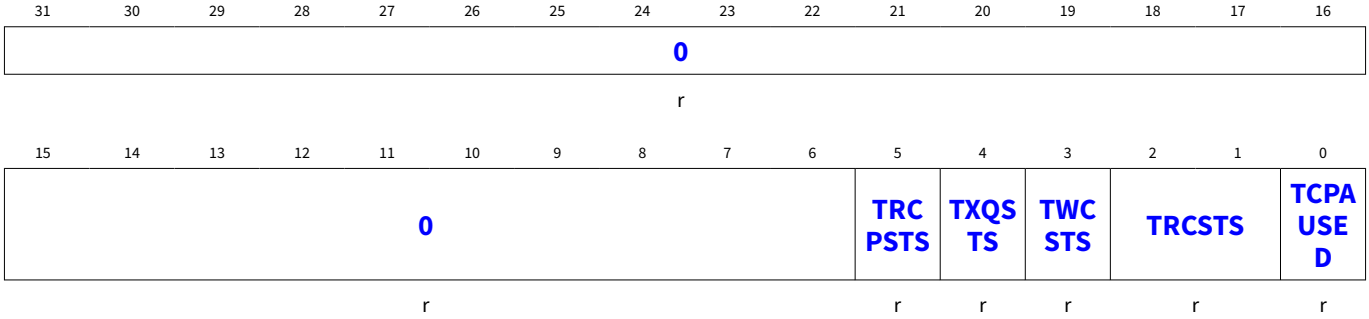
UFPKTCNT	10:0	r	**Underflow Packet Counter** This field indicates the number of packets aborted by the controller because of Transmit Queue Underflow. This counter is incremented each time the MAC aborts an outgoing packet because of underflow. The counter is reset when this register is read with LSB of the Byte Enable for CSR access signal at 1'b1 .
UFCNTOVF	15	r	**Overflow Bit for Underflow Packet Counter** This bit is set every time the Tx Queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened.
0	14:11, 31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.599 Port j MTL TxQ4 Debug

The Queue 4 Transmit Debug register gives the debug status of various blocks related to the Transmit Queue 4 and Traffic Class 4.

Portj_MTL_TxQ4_Debug (j=0-1) Offset address: $11308_H+j*2000_H$

Port j MTL TxQ4 Debug Kernel Reset value: $0000\ 0000_H$



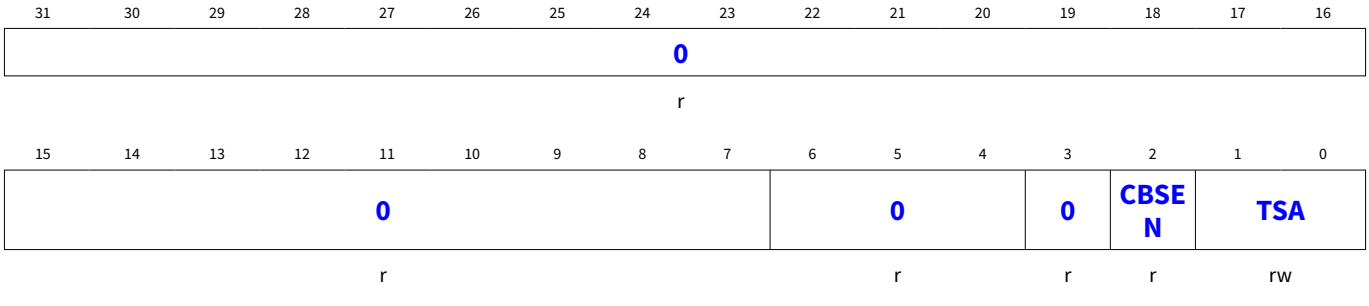
Field	Bits	Type	Description
TCPAUSED	0	r	**Traffic Class in Pause** - Reception of IEEE 802.3-2018 Pause packet
TRCSTS	2:1	r	**MTL Tx Queue Read Controller Status** This field indicates the state of the Tx Queue Read Controller: - 2'b00: Idle state - 2'b01: Read state (transferring data to the MAC transmitter) - 2'b10: Waiting for pending Tx Status from the MAC transmitter - 2'b11: Flushing the Tx queue because of the Packet Abort request from the MAC
TWCSTS	3	r	**MTL Tx Queue Write Controller Status** When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.
TXQSTS	4	r	**MTL Tx Queue Not Empty Status** When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
TRCPSTS	5	r	**MTL TRC Pending Status** When this bit is high, it indicates that the MTL Tx Read Controller (TRC) has a pending status from MAC.
0	31:6	r	**Reserved** Read as 0; should be written with 0.

14.6.600 Port j MTL TC4 ETS Control

This register configures the transmission selection algorithm, for Traffic Class 4.

Portj_MTL_TC4_ETS_Control (j=0-1) Offset address: $11310_H+j*2000_H$

Port j MTL TC4 ETS Control Kernel Reset value: $0000\ 0000_H$



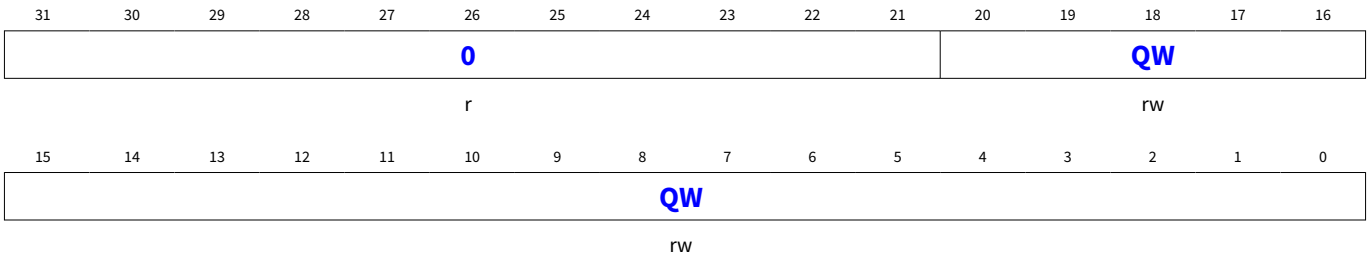
Field	Bits	Type	Description
TSA	1:0	rw	**Transmission Selection Algorithm** This field is used to assign a transmission selection algorithm for this traffic class. - 2'b00: Strict priority - 2'b01: CBS - 2'b10: ETS - 2'b11: Reserved
CBSEN	2	r	**Credit Based Shaper Enable** This field indicates that TSA field of this register is enabled for CBS
0	3, 6:4, 31:7	r	**Reserved** Read as 0; should be written with 0.

14.6.601 Port j MTL TC4 Quantum Weight

The Quantum or Weights register controls the average traffic transmitted in Traffic Class 4.

Portj_MTL_TC4_Quantum_Weight (j=0-1) Offset address: $11318_H+j*2000_H$

Port j MTL TC4 Quantum Weight Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
QW	20:0	rw	**idleSlopeCredit, Quantum or Weights** - idleSlopeCredit -- When this TC is in AVB mode, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Traffic Class 4. This is the rate of change of credit in bits per cycle (3.2 ns for 2.5/10 Gbps; 8 ns for 1000 Mbps) when the credit is increasing. The software must program this field with computed credit in bits per cycle scaled by 1024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x8000 in 10 Gbps mode. Bits[20:16] must be written to zero. This field is not valid for Traffic Class 0. - Weights -- When TSA is set to ETS and ETSALG is set to WRR algorithm for Traffic Class 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits[20:7] must be written to zero. This field is reserved and RO when the number of traffic classes selected is less than two. This field is reserved in corresponding Queues 8-15 register.
0	31:21	r	**Reserved** Read as 0; should be written with 0.

14.6.602 Port j MTL RxQ4 Operation Mode

The Queue 4 Receive Operation Mode register establishes the Receive queue 4 operating modes.

Portj_MTL_RxQ4_Operation_Mode (j=0-1) Offset address: $11340_H+j*2000_H$

Port j MTL RxQ4 Operation Mode Kernel Reset value: $0000\ 0000_H$

0								EHFC	DIS_TCP_EF	RSF	FEF	FUF	0	RTC	
r								rw	rw	rw	rw	rw	r	rw	

Field	Bits	Type	Description
RTC	1:0	rw	**Receive Queue Threshold Control** These bits control the threshold level of the MTL Rx queue (in bytes): - 2'b00: 64 - 2'b01: Reserved - 2'b10: 96 - 2'b11: 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. The value of 11 is not applicable if the size of the configured Rx Queue is 128 bytes. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.
FUF	3	rw	**Forward Undersized Good Packets** - 1: Rx queue forwards the undersized good packets (with no Invalid-code/GMII/CRC/Length errors and length less than 64 bytes at Rx (X)GMII interface), including pad-bytes and CRC. - 0: Rx queue drops all packets of length less than 64 bytes.
FEF	4	rw	**Forward Error Packets** - 0: Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. - 1: All packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA.

(table continues...)

(continued)

Field	Bits	Type	Description
RSF	5	rw	**Receive Queue Store and Forward** - 1: DWC_xgmac reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. - 0: Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.
DIS_TCP_EF	6	rw	**Disable Dropping of TCP/IP Checksum Error Packets** - When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. - When this bit is reset, all error packets are dropped if the FEF bit is reset.
EHFC	7	rw	**Enable Hardware Flow Control** When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.
RQS	22:16	rw	**Receive Queue Size** This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. A value of 0 indicates 256 bytes.When this queue is used, a minimum value of 7 (size = 2048) is recommended so that the queue can store more than a complete max-sized Ethernet packet.
0	2, 15:8, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.603 Port j MTL RxQ4 Missed Pkt Overflow Cnt

The Queue 4 Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Portj_MTL_RxQ4_Missed_Pkt_Overflow_Cnt (j=0-1) Offset address: $11344_H+j*2000_H$

Port j MTL RxQ4 Missed Pkt Overflow Cnt Kernel Reset value: $0000\ 0000_H$

OVFCNTOVF		0			OVFPKTCNT										
r		r			r										

Field	Bits	Type	Description
OVFPKTCNT	10:0	r	**Overflow Packet Counter** This field indicates the number of packets discarded by DWC_xgmac because of Receive queue overflow. This counter is incremented each time DWC_xgmac discards an incoming packet because of overflow. This counter is reset when this register bits[7:0] is read by software.
OVFCNTOVF	15	r	**Overflow Counter Overflow Bit** When set, this bit indicates that OVFPKTCNT field crossed the maximum limit.
MISPKTCNT	26:16	r	**Missed Packet Counter** This field indicates the number of packets missed by DWC_xgmac because the host asserted packet-flush for this queue. This counter is incremented each time a packet is flushed for this queue. This counter is reset when this register's bits[23:16] is read by the software.
MISCNTOVF	31	r	**Missed Packet Counter Overflow Bit** When set, this bit indicates that the MISPKTCNT field crossed the maximum limit.
0	14:11, 30:27	r	**Reserved** Read as 0; should be written with 0.

14.6.604 Port j MTL RxQ4 Debug

The Queue 4 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Portj_MTL_RxQ4_Debug (j=0-1) Offset address: $11348_H+j*2000_H$

Port j MTL RxQ4 Debug Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RWCSTS	0	r	**MTL Rx Queue Write Controller Active Status** When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue.
RRCSTS	2:1	r	**MTL Rx Queue Read Controller State** This field gives the state of the Rx queue Read controller: - 2'b00: Idle state - 2'b01: Reading packet data - 2'b10: Reading packet status (or timestamp) - 2'b11: Flushing the packet data and status

(table continues...)

(continued)

Field	Bits	Type	Description
RXQSTS	5:4	r	**MTL Rx Queue Fill-Level Status** This field gives the status of the fill-level of the Rx Queue: - 2'b00: Rx Queue empty - 2'b01: Rx Queue fill-level below flow-control deactivate threshold - 2'b10: Rx Queue fill-level above flow-control activate threshold - 2'b11: Rx Queue full
PRXQ	29:16	r	**Number of Packets in Receive Queue** This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.
0	3, 15:6, 31:30	r	**Reserved** Read as 0; should be written with 0.

14.6.605 Port j MTL RxQ4 Control

The Queue 4 Receive Control register controls the receive arbitration and passing of received packets to the application.

Portj_MTL_RxQ4_Control (j=0-1) Offset address: $1134C_H+j*2000_H$

Port j MTL RxQ4 Control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0												RXQ_PKT_ARBIT	RXQ_WEGT		
r												rw	rw		

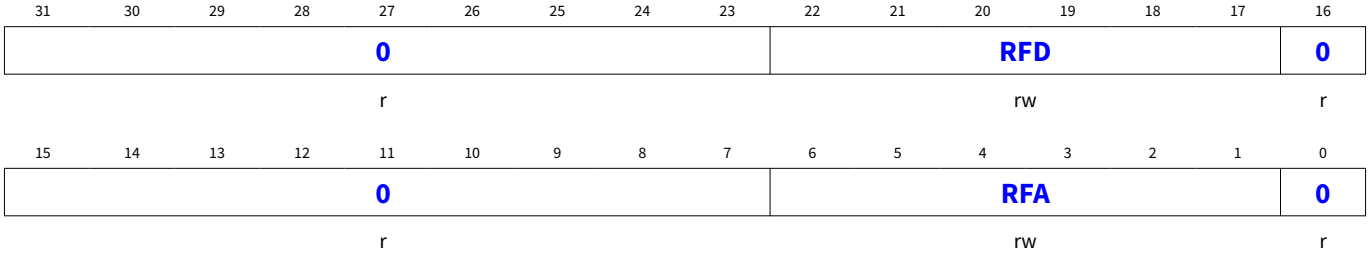
Field	Bits	Type	Description
RXQ_WEGT	2:0	rw	**Receive Queue Weight** This field indicates the weight assigned to the Rx Queue 4. The weight is used as the number of continuous PBL requests or contiguous packets (depending on the RXQ_PKT_ARBIT) allocated to the queue in one arbitration cycle.
RXQ_PKT_ARBIT	3	rw	**Receive Queue Packet Arbitration Control** - 1: MTL enables the packet-level arbitration. - 0: MTL enables the PBL based arbitration.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

14.6.606 Port j MTL RxQ4 Flow Control

This register controls the activation and de-activation threshold in the queue for triggering the generation of Flow Control packets by MAC transmitter.

Portj_MTL_RxQ4_Flow_Control (j=0-1) Offset address: $11350_H+j*2000_H$

Port j MTL RxQ4 Flow Control Kernel Reset value: $0000\ 0000_H$



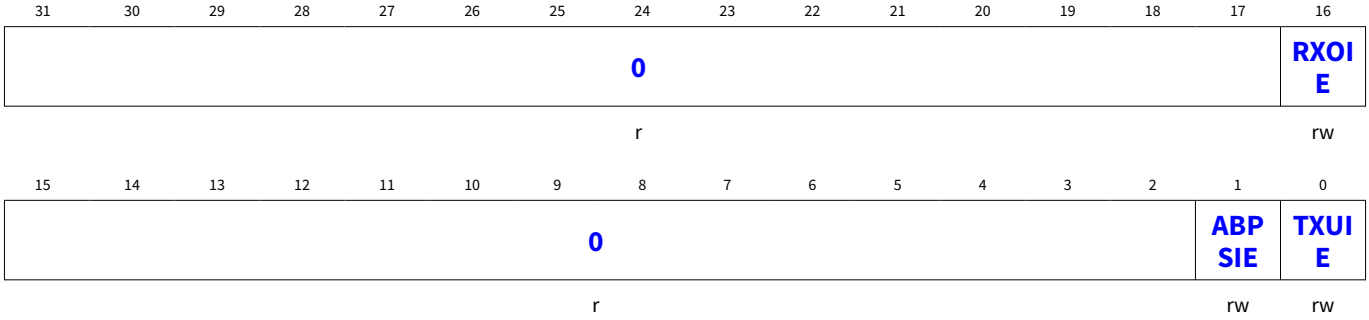
Field	Bits	Type	Description
RFA	6:1	rw	**Threshold for activating Flow Control** These bits control the threshold (fill-level of RxQ0) at which the flow control is activated - 6'b000000: RQS value minus 1 KB, that is, FULL - 1024 bytes - 6'b000001: RQS value minus 1.5 KB, that is, FULL - 1536 bytes - 6'b000010: RQS value minus 2 KB, that is, FULL - 2048 bytes. - ... - 6'b111111: RQS value minus 32.5 KB, that is, FULL - 33280 bytes The flow control is triggered when EHFC=1 and the queue size (RQS value in MTL_RxQ4_Operation Mode register) is equal to or more than 4KB. Note that the value to be programmed in RFA must be such that the threshold is positive number.
RFD	22:17	rw	**Threshold for deactivating Flow Control** These bits control the threshold (fill-level of RxQ0) at which the flow control is de-asserted once it is activated. - 6'b000000: RQS value minus 1 KB, that is, FULL - 1024 bytes - 6'b000001: RQS value minus 1.5 KB, that is, FULL - 1536 bytes - 6'b000010: RQS value minus 2 KB, that is, FULL - 2048 bytes. - ... - 6'b111111: RQS value minus 32.5 KB, that is, FULL - 33280 bytes The de-assertion is effective only after flow control is asserted as per the setting of RFA field. Note that the value to be programmed must be such that the threshold is positive number.
0	0, 16:7, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.607 Port j MTL Q4 Interrupt Enable

This register contains the interrupt enable bits for Traffic class/Queue 4.

Portj_MTL_Q4_Interrupt_Enable (j=0-1) Offset address: $11370_H+j*2000_H$

Port j MTL Q4 Interrupt Enable Kernel Reset value: $0000\ 0000_H$



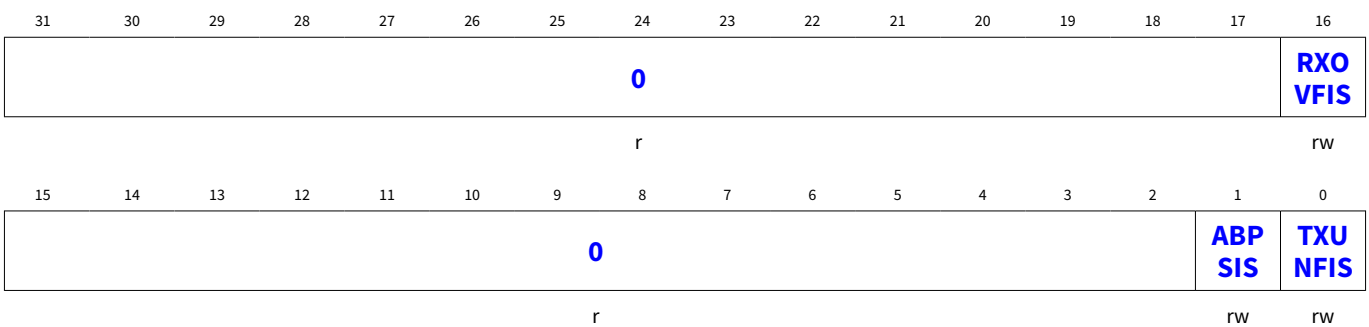
Field	Bits	Type	Description
TXUIE	0	rw	**Transmit Queue Underflow Interrupt Enable** - 1: Transmit Queue Underflow interrupt is enabled. - 0: Transmit Queue Underflow interrupt is disabled.
ABPSIE	1	rw	**Average Bits Per Slot Interrupt Enable** When this bit is set, average bits per slot interrupt is enabled for Traffic Class 4. An interrupt is generated when ABPSIS is set for this traffic class. This bit is reserved and RO when the number of traffic classes selected is less than 4.
RXOIE	16	rw	**Receive Queue Overflow Interrupt Enable** - 1: Receive Queue Overflow interrupt is enabled. - 0: Receive Queue Overflow interrupt is disabled.
0	15:2, 31:17	r	**Reserved** Read as 0; should be written with 0.

14.6.608 Port j MTL Q4 Interrupt Status

This register contains the interrupt status bits for Traffic class/Queue 4.

Portj_MTL_Q4_Interrupt_Status (j=0-1) Offset address: $11374_H+j*2000_H$

Port j MTL Q4 Interrupt Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TXUNFIS	0	rw	**Transmit Queue Underflow Interrupt Status** This bit indicates that the Transmit Queue had an Underflow during packet transmission. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes a 1 to this bit.
ABPSIS	1	rw	**Average Bits Per Slot Interrupt Status** When set, this bit indicates that the MAC has updated the ABS value for this traffic class. This bit is cleared when the application writes a 1 to this bit. This bit is reserved and RO when the number of traffic classes selected is less than 4.
RXOVFIS	16	rw	**Receive Queue Overflow Interrupt Status** This bit indicates that the Receive Queue had an Overflow during packet reception. If partial packet is transferred to the application, the overflow status is set in the corresponding Rx status. This bit is cleared when the application writes a 1 to this bit.
0	15:2, 31:17	r	**Reserved** Read as 0; should be written with 0.

14.6.609 Port j MTL TxQ5 Operation Mode

The Queue 5 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Portj_MTL_TxQ5_Operation_Mode (j=0-1) Offset address: $11380_H+j*2000_H$

Port j MTL TxQ5 Operation Mode Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0									TQS						
r									rw						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					Q2TCMAP			0	TTC			TXQEN		TSF	FTQ
r					rw			r	rw			rw		rw	rw

Field	Bits	Type	Description
FTQ	0	rw	**Flush Transmit Queue** When this bit is set, the Tx Queue Controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. You must not write to this register until this bit is reset. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty. To complete this flush operation, the PHY Tx clock must be active.

(table continues...)

(continued)

Field	Bits	Type	Description
TSF	1	rw	**Transmit Store and Forward** When this bit is set, the transmission starts when a full packet resides in the MTL Tx Queue. When this bit is set, the values specified in the TTC field are ignored. This bit must be changed only when the transmission is stopped.
TXQEN	3:2	rw	**Transmit Queue Enable** This field is used to enable/disable the transmit queue. - 2'b00: Not enabled - 2'b01: Audio Video Bridging - 2'b10: Enabled - 2'b11: Reserved In multiple Tx queues configuration, as the queue is disabled by default, enable the Tx Queue by programming this field in the AVB mode or default mode as desired.
TTC	6:4	rw	**Transmit Threshold Control** These bits control the threshold level of the MTL Tx Queue. Transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. - 3'b000: 64 - 3'b001: Reserved - 3'b010: 96 - 3'b011: 128 - 3'b100: 192 - 3'b101: 256 - 3'b110: 384 - 3'b111: 512
Q2TCMAP	10:8	rw	**Queue to Traffic Class Mapping** This field is used to map this Tx Queue to a traffic class (TC). - 3'b000: TC0 - 3'b001: TC1 - 3'b010: TC2 - 3'b011: TC3 - 3'b100: TC4 - 3'b101: TC5 - 3'b110: TC6 - 3'b111: TC7
TQS	22:16	rw	**Transmit Queue Size** This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. A value of 0 indicates 256 bytes. When this queue is enabled (TXQEN=10), a minimum value of 7 (size = 2048) is recommended so that the queue can store more than a complete max-sized Ethernet packet.

(table continues...)

(continued)

Field	Bits	Type	Description
0	7, 15:11, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.610 Port j MTL TxQ5 Underflow

The Queue 5 Underflow Counter register contains the number of packets aborted because of Transmit queue underflow.

Portj_MTL_TxQ5_Underflow (j=0-1) Offset address: $11384_H+j*2000_H$

Port j MTL TxQ5 Underflow Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
UFCNTOVF	0				UFPKTCNT										
r	r				r										

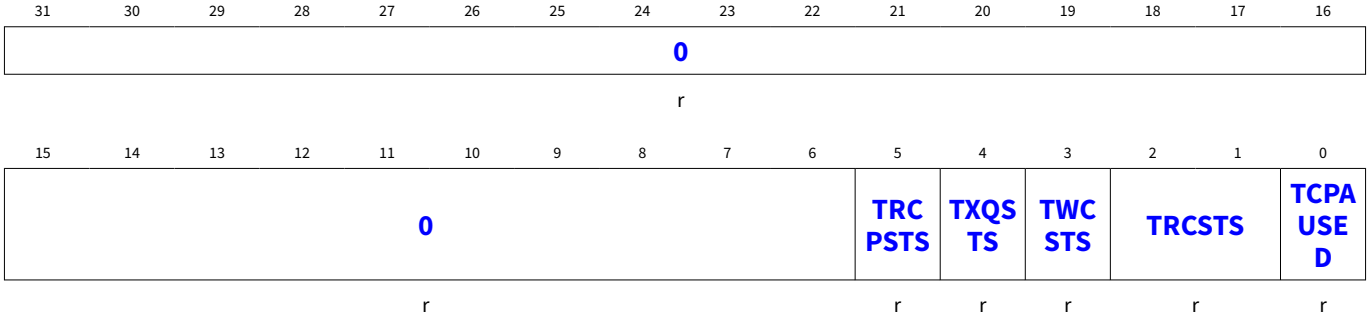
Field	Bits	Type	Description
UFPKTCNT	10:0	r	**Underflow Packet Counter** This field indicates the number of packets aborted by the controller because of Transmit Queue Underflow. This counter is incremented each time the MAC aborts an outgoing packet because of underflow. The counter is reset when this register is read with LSB of the Byte Enable for CSR access signal at 1'b1 .
UFCNTOVF	15	r	**Overflow Bit for Underflow Packet Counter** This bit is set every time the Tx Queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened.
0	14:11, 31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.611 Port j MTL TxQ5 Debug

The Queue 5 Transmit Debug register gives the debug status of various blocks related to the Transmit Queue 5 and Traffic Class 5.

Portj_MTL_TxQ5_Debug (j=0-1) Offset address: $11388_H+j*2000_H$

Port j MTL TxQ5 Debug Kernel Reset value: $0000\ 0000_H$



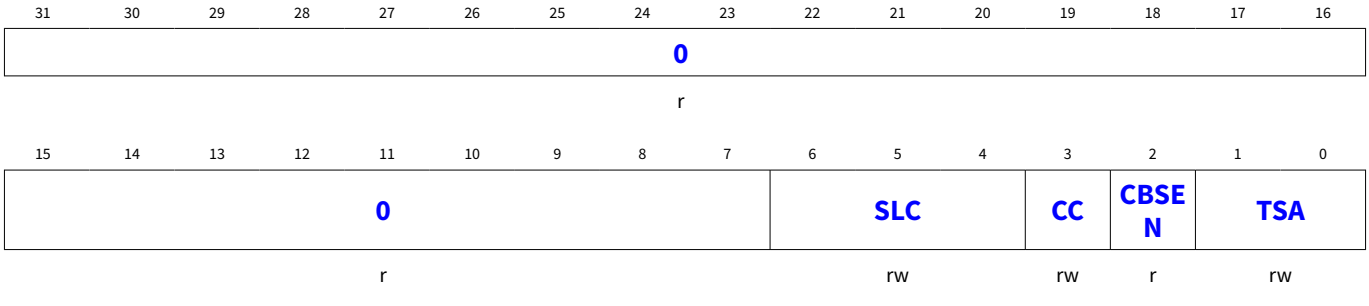
Field	Bits	Type	Description
TCPAUSED	0	r	**Traffic Class in Pause** - Reception of IEEE 802.3-2018 Pause packet
TRCSTS	2:1	r	**MTL Tx Queue Read Controller Status** This field indicates the state of the Tx Queue Read Controller: - 2'b00: Idle state - 2'b01: Read state (transferring data to the MAC transmitter) - 2'b10: Waiting for pending Tx Status from the MAC transmitter - 2'b11: Flushing the Tx queue because of the Packet Abort request from the MAC
TWCSTS	3	r	**MTL Tx Queue Write Controller Status** When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.
TXQSTS	4	r	**MTL Tx Queue Not Empty Status** When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
TRCPSTS	5	r	**MTL TRC Pending Status** When this bit is high, it indicates that the MTL Tx Read Controller (TRC) has a pending status from MAC.
0	31:6	r	**Reserved** Read as 0; should be written with 0.

14.6.612 Port j MTL TC5 ETS Control

This register configures the transmission selection algorithm, for Traffic Class 5.

Portj_MTL_TC5_ETS_Control (j=0-1) Offset address: $11390_H+j*2000_H$

Port j MTL TC5 ETS Control Kernel Reset value: $0000\ 0000_H$



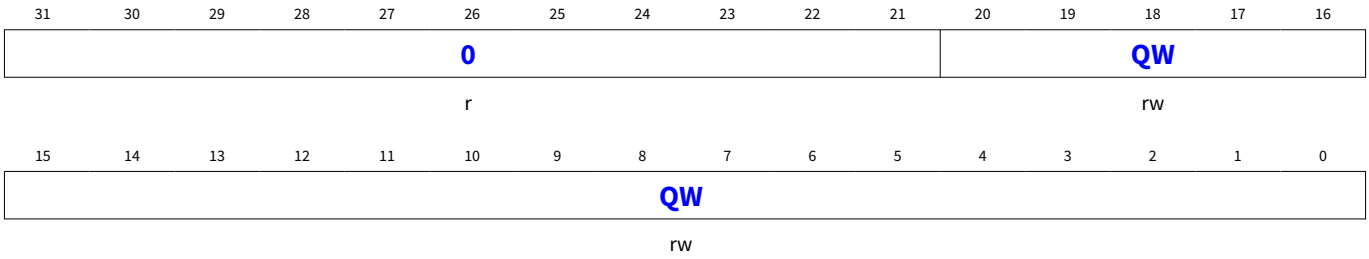
Field	Bits	Type	Description
TSA	1:0	rw	**Transmission Selection Algorithm** This field is used to assign a transmission selection algorithm for this traffic class. - 2'b00: Strict priority - 2'b01: CBS - 2'b10: ETS - 2'b11: Reserved
CBSEN	2	r	**Credit Based Shaper Enable** This field indicates that TSA field of this register is enabled for CBS
CC	3	rw	**Credit Control** When this bit is set, the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero when there is positive credit and no packet to transmit in TC(#n). The credit accumulates even when there is no packet waiting in TC(#n) and another TC is transmitting. When this bit is reset, the accumulated credit parameter in the credit-based shaper algorithm logic is set to zero when there is positive credit and no packet to transmit in TC(#n). When there is no packet waiting in TC(#n) and other TC is transmitting, no credit is accumulated.
SLC	6:4	rw	**Slot Count** If the credit-based shaper algorithm is enabled, the software can program the number of slots (of 125 us duration) over which the average transmitted bits per slot, provided in the MTL_TC(#n)_ETS_Status register, need to be computed for TC(#n). The encoding is as follows: - 3'b000: 1 Slot - 3'b001: 2 Slots - 3'b010: 4 Slots - 3'b011: 8 Slots - 3'b100: 16 Slots - 3'b101-3'b111: Reserved
0	31:7	r	**Reserved** Read as 0; should be written with 0.

14.6.613 Port j MTL TC5 Quantum Weight

The Quantum or Weights register controls the average traffic transmitted in Traffic Class 5.

Portj_MTL_TC5_Quantum_Weight (j=0-1) Offset address: $11398_H+j*2000_H$

Port j MTL TC5 Quantum Weight Kernel Reset value: $0000\ 0000_H$



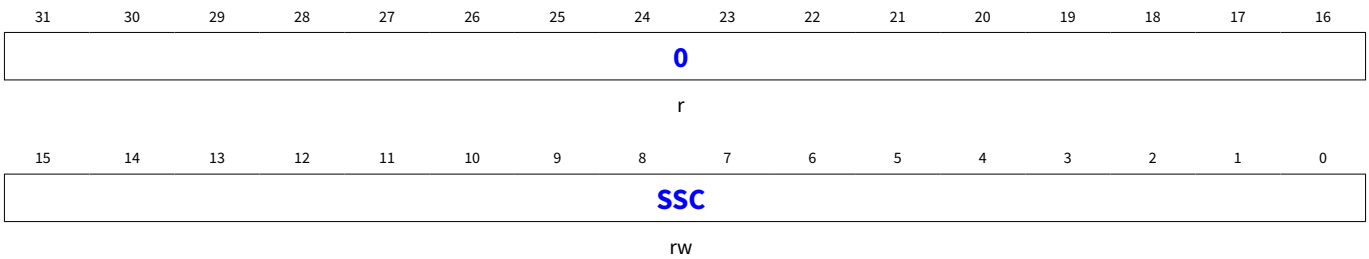
Field	Bits	Type	Description
QW	20:0	rw	**idleSlopeCredit, Quantum or Weights** - idleSlopeCredit -- When this TC is in AVB mode, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Traffic Class 5. This is the rate of change of credit in bits per cycle (3.2 ns for 2.5/10 Gbps; 8 ns for 1000 Mbps) when the credit is increasing. The software must program this field with computed credit in bits per cycle scaled by 1024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x8000 in 10 Gbps mode. Bits[20:16] must be written to zero. This field is not valid for Traffic Class 0. - Weights -- When TSA is set to ETS and ETSALG is set to WRR algorithm for Traffic Class 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits[20:7] must be written to zero. This field is reserved and RO when the number of traffic classes selected is less than two. This field is reserved in corresponding Queues 8-15 register.
0	31:21	r	**Reserved** Read as 0; should be written with 0.

14.6.614 Port j MTL TC5 SendSlopeCredit

MTL registers for traffic classes and queues 1 registers.

Portj_MTL_TC5_SendSlopeCredit (j=0-1) Offset address: $1139C_H+j*2000_H$

Port j MTL TC5 SendSlopeCredit Kernel Reset value: $0000\ 0000_H$



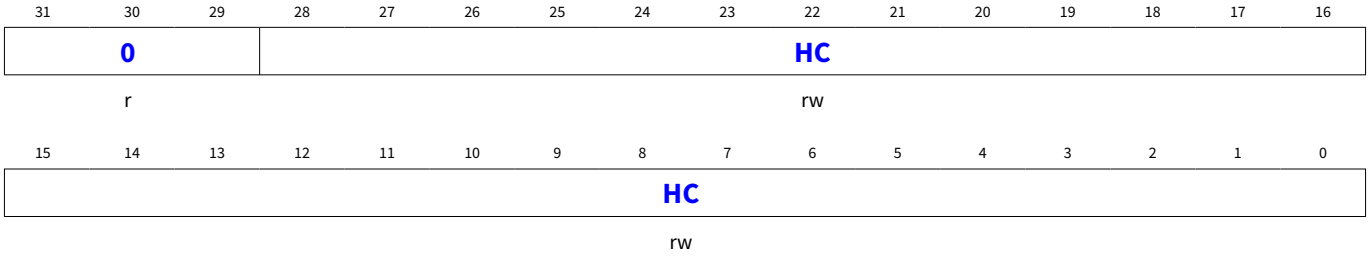
Field	Bits	Type	Description
SSC	15:0	rw	**sendSlopeCredit Value** - When Audio Video Bridging feature is enabled, this field contains the sendSlopeCredit value required for credit-based shaper algorithm for TC(#n). The software must program this field with computed credit in bits per cycle scaled by 1024. This field must be programmed with absolute sendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when TC(#n) is selected for transmission. See the application note for more details on programming this value.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.615 Port j MTL TC5 HiCredit

This register contains the hiCredit value required for the credit-based shaper algorithm for TC1.

Portj_MTL_TC5_HiCredit (j=0-1) Offset address: $113A0_H+j*2000_H$

Port j MTL TC5 HiCredit Kernel Reset value: $0000\ 0000_H$



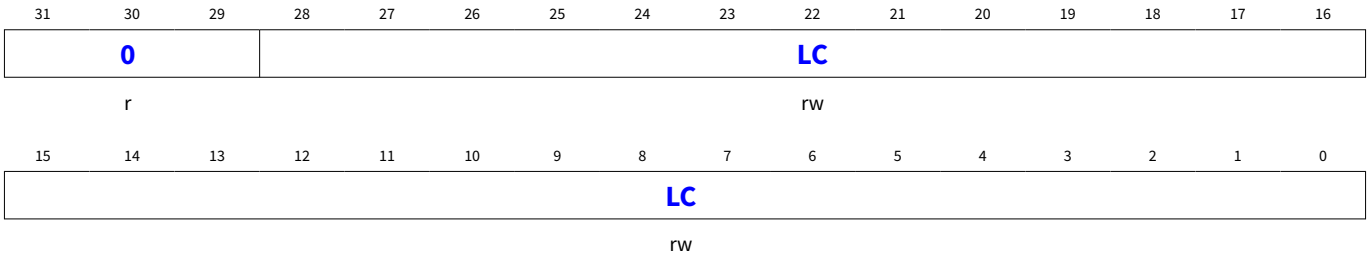
Field	Bits	Type	Description
HC	28:0	rw	**hiCredit Value** - When the Audio Video Bridging feature is enabled, this field contains the hiCredit value required for the credit-based shaper algorithm. This is the maximum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16384 bytes or 131072 bits). The value to be specified is 131072 * 1024 = 134217728 or 0x0800_0000
0	31:29	r	**Reserved** Read as 0; should be written with 0.

14.6.616 Port j MTL TC5 LoCredit

This register contains the loCredit value required for the credit-based shaper algorithm for TC1.

Portj_MTL_TC5_LoCredit (j=0-1) Offset address: $113A4_H+j*2000_H$

Port j MTL TC5 LoCredit Kernel Reset value: $0000\ 0000_H$



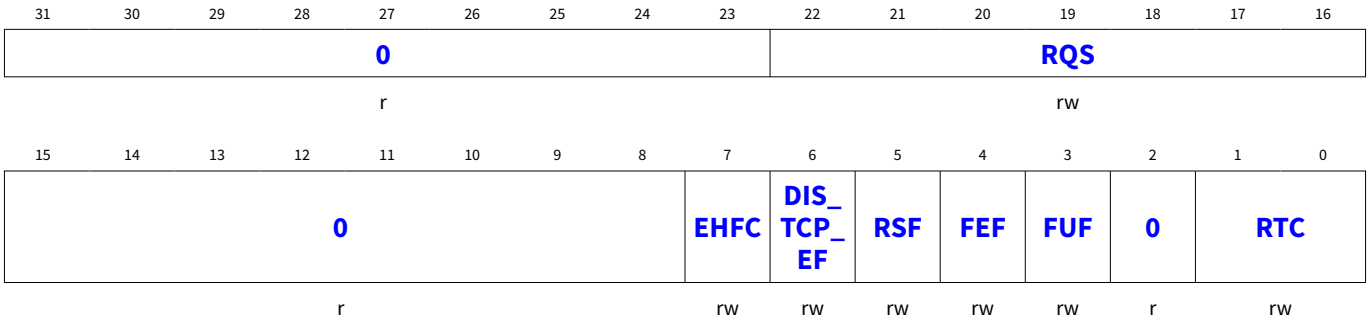
Field	Bits	Type	Description
LC	28:0	rw	**loCredit Value** - When Audio Video Bridging feature is enabled, this field contains the loCredit value required for the credit-based shaper algorithm. This is the minimum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1024. The maximum value is maxPacketSize transmitted from this queue, that is, 16384 * 8 * 1024 = 134217728 or 0x0800_0000. Because it is a negative value, the programmed value is twos complement of the value, that is, 0x1800_0000.
0	31:29	r	**Reserved** Read as 0; should be written with 0.

14.6.617 Port j MTL RxQ5 Operation Mode

The Queue 5 Receive Operation Mode register establishes the Receive queue 5 operating modes.

Portj_MTL_RxQ5_Operation_Mode (j=0-1) Offset address: $113C0_H+j*2000_H$

Port j MTL RxQ5 Operation Mode Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RTC	1:0	rw	**Receive Queue Threshold Control** These bits control the threshold level of the MTL Rx queue (in bytes): - 2'b00: 64 - 2'b01: Reserved - 2'b10: 96 - 2'b11: 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. The value of 11 is not applicable if the size of the configured Rx Queue is 128 bytes. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.
FUF	3	rw	**Forward Undersized Good Packets** - 1: Rx queue forwards the undersized good packets (with no Invalid-code/GMII/CRC/Length errors and length less than 64 bytes at Rx (X)GMII interface), including pad-bytes and CRC. - 0: Rx queue drops all packets of length less than 64 bytes.
FEF	4	rw	**Forward Error Packets** - 0: Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. - 1: All packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA.
RSF	5	rw	**Receive Queue Store and Forward** - 1: DWC_xgmac reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. - 0: Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.
DIS_TCP_EF	6	rw	**Disable Dropping of TCP/IP Checksum Error Packets** - When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. - When this bit is reset, all error packets are dropped if the FEF bit is reset.
EHFC	7	rw	**Enable Hardware Flow Control** When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.

(table continues...)

(continued)

Field	Bits	Type	Description
RQS	22:16	rw	**Receive Queue Size** This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. A value of 0 indicates 256 bytes.When this queue is used, a minimum value of 7 (size = 2048) is recommended so that the queue can store more than a complete max-sized Ethernet packet.
0	2, 15:8, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.618 Port j MTL RxQ5 Missed Pkt Overflow Cnt

The Queue 5 Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Portj_MTL_RxQ5_Missed_Pkt_Overflow_Cnt (j=0-1) Offset address: $113C4_H+j*2000_H$

Port j MTL RxQ5 Missed Pkt Overflow Cnt Kernel Reset value: $0000\ 0000_H$

r	r				r										

Field	Bits	Type	Description
OVFPKTCNT	10:0	r	**Overflow Packet Counter** This field indicates the number of packets discarded by DWC_xgmac because of Receive queue overflow. This counter is incremented each time DWC_xgmac discards an incoming packet because of overflow. This counter is reset when this register bits[7:0] is read by software.
OVFCNTOVF	15	r	**Overflow Counter Overflow Bit** When set, this bit indicates that OVFPKTCNT field crossed the maximum limit.
MISPKTCNT	26:16	r	**Missed Packet Counter** This field indicates the number of packets missed by DWC_xgmac because the host asserted packet-flush for this queue. This counter is incremented each time a packet is flushed for this queue. This counter is reset when this register's bits[23:16] is read by the software.

(table continues...)

(continued)

Field	Bits	Type	Description
MISCNTOVF	31	r	**Missed Packet Counter Overflow Bit** When set, this bit indicates that the MISPKTCNT field crossed the maximum limit.
0	14:11, 30:27	r	**Reserved** Read as 0; should be written with 0.

14.6.619 Port j MTL RxQ5 Debug

The Queue 5 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Portj_MTL_RxQ5_Debug (j=0-1) Offset address: $113C8_H+j*2000_H$

Port j MTL RxQ5 Debug Kernel Reset value: $0000\ 0000_H$

0										RXQSTS		0	RRCSTS		RWCSTS
r										r		r	r		r

Field	Bits	Type	Description
RWCSTS	0	r	**MTL Rx Queue Write Controller Active Status** When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue.
RRCSTS	2:1	r	**MTL Rx Queue Read Controller State** This field gives the state of the Rx queue Read controller: - 2'b00: Idle state - 2'b01: Reading packet data - 2'b10: Reading packet status (or timestamp) - 2'b11: Flushing the packet data and status
RXQSTS	5:4	r	**MTL Rx Queue Fill-Level Status** This field gives the status of the fill-level of the Rx Queue: - 2'b00: Rx Queue empty - 2'b01: Rx Queue fill-level below flow-control deactivate threshold - 2'b10: Rx Queue fill-level above flow-control activate threshold - 2'b11: Rx Queue full
PRXQ	29:16	r	**Number of Packets in Receive Queue** This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.
0	3, 15:6, 31:30	r	**Reserved** Read as 0; should be written with 0.

14.6.620 Port j MTL RxQ5 Control

The Queue 5 Receive Control register controls the receive arbitration and passing of received packets to the application.

Portj_MTL_RxQ5_Control (j=0-1) Offset address: $113CC_H+j*2000_H$

Port j MTL RxQ5 Control Kernel Reset value: $0000\ 0000_H$

0														ABPSIS	TXUNFIS
r														rw	rw

Field	Bits	Type	Description
TXUNFIS	0	rw	**Transmit Queue Underflow Interrupt Status** This bit indicates that the Transmit Queue had an Underflow during packet transmission. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes a 1 to this bit.
ABPSIS	1	rw	**Average Bits Per Slot Interrupt Status** When set, this bit indicates that the MAC has updated the ABS value for this traffic class. This bit is cleared when the application writes a 1 to this bit. This bit is reserved and RO when the number of traffic classes selected is less than 5.

(table continues...)

(continued)

Field	Bits	Type	Description
RXOVFIS	16	rw	**Receive Queue Overflow Interrupt Status** This bit indicates that the Receive Queue had an Overflow during packet reception. If partial packet is transferred to the application, the overflow status is set in the corresponding Rx status. This bit is cleared when the application writes a 1 to this bit.
0	15:2, 31:17	r	**Reserved** Read as 0; should be written with 0.

14.6.624 Port j MTL TxQ6 Operation Mode

The Queue 6 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Portj_MTL_TxQ6_Operation_Mode (j=0-1) Offset address: $11400_H+j*2000_H$

Port j MTL TxQ6 Operation Mode Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0									TQS						
r									rw						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					Q2TCMAP			0	TTC			TXQEN		TSF	FTQ
r					rw			r	rw			rw		rw	rw

Field	Bits	Type	Description
FTQ	0	rw	**Flush Transmit Queue** When this bit is set, the Tx Queue Controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. You must not write to this register until this bit is reset. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty. To complete this flush operation, the PHY Tx clock must be active.
TSF	1	rw	**Transmit Store and Forward** When this bit is set, the transmission starts when a full packet resides in the MTL Tx Queue. When this bit is set, the values specified in the TTC field are ignored. This bit must be changed only when the transmission is stopped.

(table continues...)

(continued)

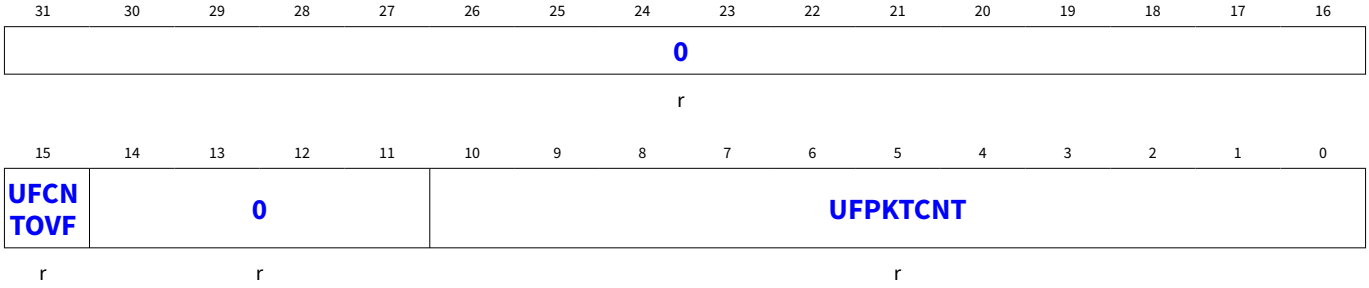
Field	Bits	Type	Description
TXQEN	3:2	rw	**Transmit Queue Enable** This field is used to enable/disable the transmit queue. - 2'b00: Not enabled - 2'b01: Audio Video Bridging - 2'b10: Enabled - 2'b11: Reserved In multiple Tx queues configuration, as the queue is disabled by default, enable the Tx Queue by programming this field in the AVB mode or default mode as desired.
TTC	6:4	rw	**Transmit Threshold Control** These bits control the threshold level of the MTL Tx Queue. Transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. - 3'b000: 64 - 3'b001: Reserved - 3'b010: 96 - 3'b011: 128 - 3'b100: 192 - 3'b101: 256 - 3'b110: 384 - 3'b111: 512
Q2TCMAP	10:8	rw	**Queue to Traffic Class Mapping** This field is used to map this Tx Queue to a traffic class (TC). - 3'b000: TC0 - 3'b001: TC1 - 3'b010: TC2 - 3'b011: TC3 - 3'b100: TC4 - 3'b101: TC5 - 3'b110: TC6 - 3'b111: TC7
TQS	22:16	rw	**Transmit Queue Size** This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. A value of 0 indicates 256 bytes. When this queue is enabled (TXQEN=10), a minimum value of 7 (size = 2048) is recommended so that the queue can store more than a complete max-sized Ethernet packet.
0	7, 15:11, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.625 Port j MTL TxQ6 Underflow

The Queue 6 Underflow Counter register contains the number of packets aborted because of Transmit queue underflow.

Portj_MTL_TxQ6_Underflow (j=0-1) Offset address: $11404_H+j*2000_H$

Port j MTL TxQ6 Underflow Kernel Reset value: $0000\ 0000_H$



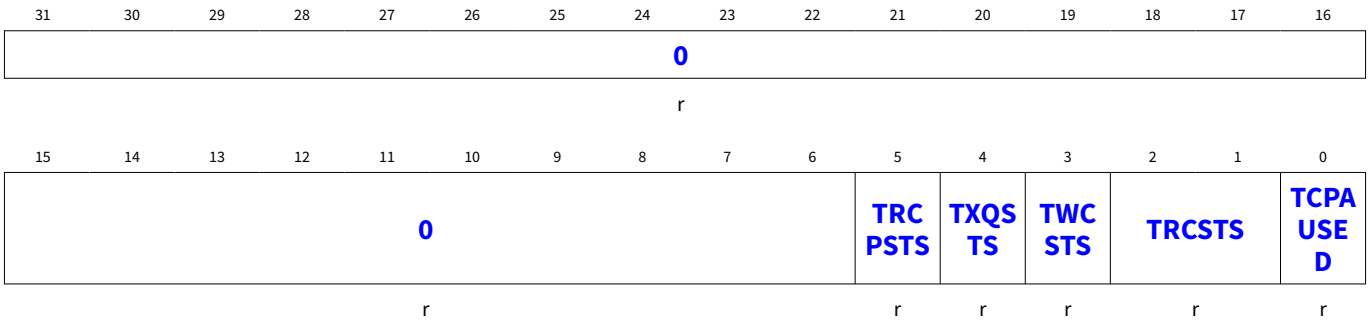
Field	Bits	Type	Description
UFPKTCNT	10:0	r	**Underflow Packet Counter** This field indicates the number of packets aborted by the controller because of Transmit Queue Underflow. This counter is incremented each time the MAC aborts an outgoing packet because of underflow. The counter is reset when this register is read with LSB of the Byte Enable for CSR access signal at 1'b1 .
UFCNTOVF	15	r	**Overflow Bit for Underflow Packet Counter** This bit is set every time the Tx Queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened.
0	14:11, 31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.626 Port j MTL TxQ6 Debug

The Queue 6 Transmit Debug register gives the debug status of various blocks related to the Transmit Queue 6 and Traffic Class 6.

Portj_MTL_TxQ6_Debug (j=0-1) Offset address: $11408_H+j*2000_H$

Port j MTL TxQ6 Debug Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TCPAUSED	0	r	**Traffic Class in Pause** - Reception of IEEE 802.3-2018 Pause packet
TRCSTS	2:1	r	**MTL Tx Queue Read Controller Status** This field indicates the state of the Tx Queue Read Controller: - 2'b00: Idle state - 2'b01: Read state (transferring data to the MAC transmitter) - 2'b10: Waiting for pending Tx Status from the MAC transmitter - 2'b11: Flushing the Tx queue because of the Packet Abort request from the MAC
TWCSTS	3	r	**MTL Tx Queue Write Controller Status** When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.
TXQSTS	4	r	**MTL Tx Queue Not Empty Status** When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
TRCPSTS	5	r	**MTL TRC Pending Status** When this bit is high, it indicates that the MTL Tx Read Controller (TRC) has a pending status from MAC.
0	31:6	r	**Reserved** Read as 0; should be written with 0.

14.6.627 Port j MTL TC6 ETS Control

This register configures the transmission selection algorithm, for Traffic Class 6.

Portj_MTL_TC6_ETS_Control (j=0-1) Offset address: $11410_H+j*2000_H$

Port j MTL TC6 ETS Control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0									SLC			CC	CBSEN	TSA	
r									rw			rw	r	rw	

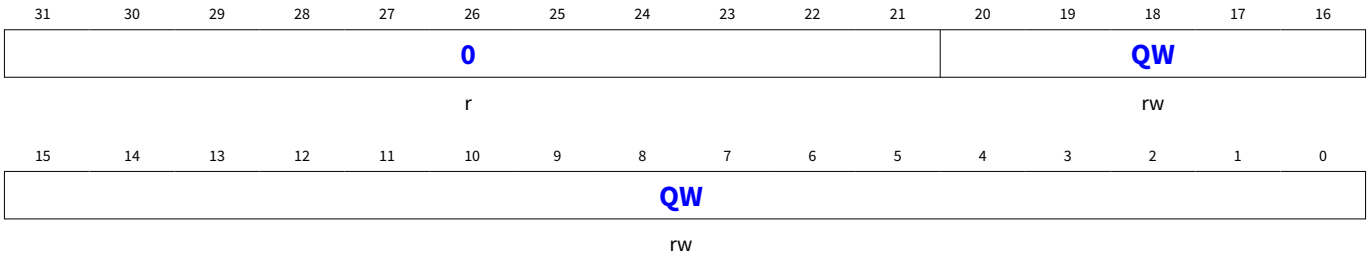
Field	Bits	Type	Description
TSA	1:0	rw	**Transmission Selection Algorithm** This field is used to assign a transmission selection algorithm for this traffic class. - 2'b00: Strict priority - 2'b01: CBS - 2'b10: ETS - 2'b11: Reserved
CBSEN	2	r	**Credit Based Shaper Enable** This field indicates that TSA field of this register is enabled for CBS
CC	3	rw	**Credit Control** When this bit is set, the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero when there is positive credit and no packet to transmit in TC(#n). The credit accumulates even when there is no packet waiting in TC(#n) and another TC is transmitting. When this bit is reset, the accumulated credit parameter in the credit-based shaper algorithm logic is set to zero when there is positive credit and no packet to transmit in TC(#n). When there is no packet waiting in TC(#n) and other TC is transmitting, no credit is accumulated.
SLC	6:4	rw	**Slot Count** If the credit-based shaper algorithm is enabled, the software can program the number of slots (of 125 us duration) over which the average transmitted bits per slot, provided in the MTL_TC(#n)_ETS_Status register, need to be computed for TC(#n). The encoding is as follows: - 3'b000: 1 Slot - 3'b001: 2 Slots - 3'b010: 4 Slots - 3'b011: 8 Slots - 3'b100: 16 Slots - 3'b101-3'b111: Reserved
0	31:7	r	**Reserved** Read as 0; should be written with 0.

14.6.628 Port j MTL TC6 Quantum Weight

The Quantum or Weights register controls the average traffic transmitted in Traffic Class 6.

Portj_MTL_TC6_Quantum_Weight (j=0-1) Offset address: $11418_H+j*2000_H$

Port j MTL TC6 Quantum Weight Kernel Reset value: $0000\ 0000_H$



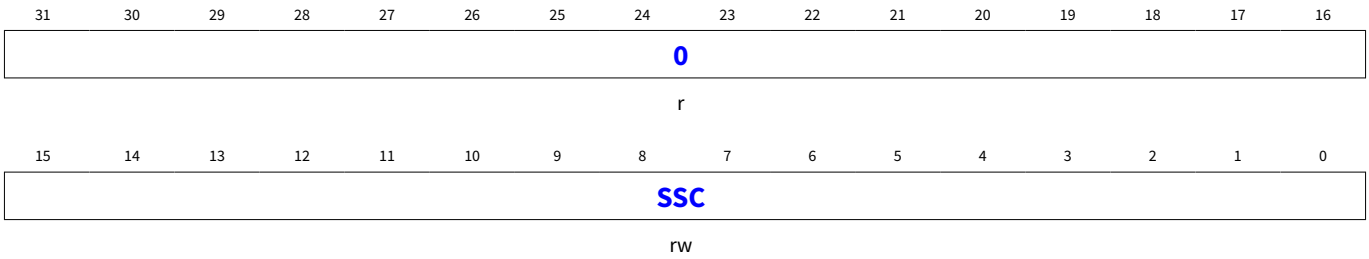
Field	Bits	Type	Description
QW	20:0	rw	**idleSlopeCredit, Quantum or Weights** - idleSlopeCredit -- When this TC is in AVB mode, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Traffic Class 6. This is the rate of change of credit in bits per cycle (3.2 ns for 2.5/10 Gbps; 8 ns for 1000 Mbps) when the credit is increasing. The software must program this field with computed credit in bits per cycle scaled by 1024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x8000 in 10 Gbps mode. Bits[20:16] must be written to zero. This field is not valid for Traffic Class 0. - Weights -- When TSA is set to ETS and ETSALG is set to WRR algorithm for Traffic Class 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits[20:7] must be written to zero. This field is reserved and RO when the number of traffic classes selected is less than two. This field is reserved in corresponding Queues 8-15 register.
0	31:21	r	**Reserved** Read as 0; should be written with 0.

14.6.629 Port j MTL TC6 SendSlopeCredit

MTL registers for traffic classes and queues 1 registers.

Portj_MTL_TC6_SendSlopeCredit (j=0-1) Offset address: $1141C_H+j*2000_H$

Port j MTL TC6 SendSlopeCredit Kernel Reset value: $0000\ 0000_H$



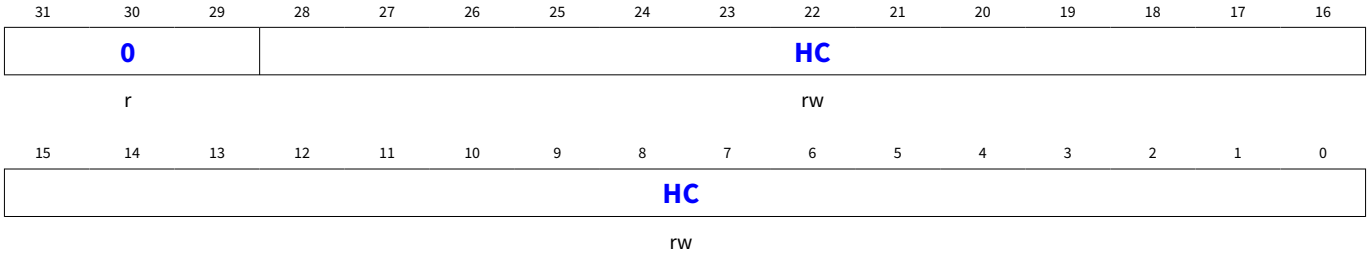
Field	Bits	Type	Description
SSC	15:0	rw	**sendSlopeCredit Value** - When Audio Video Bridging feature is enabled, this field contains the sendSlopeCredit value required for credit-based shaper algorithm for TC(#n). The software must program this field with computed credit in bits per cycle scaled by 1024. This field must be programmed with absolute sendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when TC(#n) is selected for transmission. See the application note for more details on programming this value.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.630 Port j MTL TC6 HiCredit

This register contains the hiCredit value required for the credit-based shaper algorithm for TC1.

Portj_MTL_TC6_HiCredit (j=0-1) Offset address: $11420_H+j*2000_H$

Port j MTL TC6 HiCredit Kernel Reset value: $0000\ 0000_H$



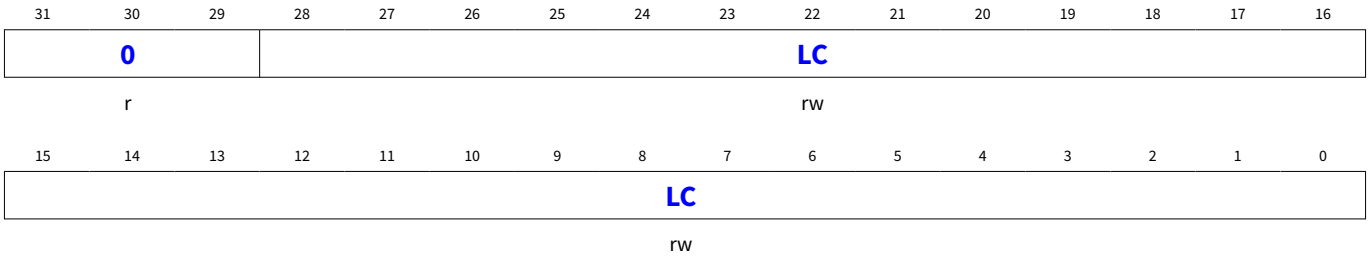
Field	Bits	Type	Description
HC	28:0	rw	**hiCredit Value** - When the Audio Video Bridging feature is enabled, this field contains the hiCredit value required for the credit-based shaper algorithm. This is the maximum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16384 bytes or 131072 bits). The value to be specified is 131072 * 1024 = 134217728 or 0x0800_0000
0	31:29	r	**Reserved** Read as 0; should be written with 0.

14.6.631 Port j MTL TC6 LoCredit

This register contains the loCredit value required for the credit-based shaper algorithm for TC1.

Portj_MTL_TC6_LoCredit (j=0-1) Offset address: $11424_H+j*2000_H$

Port j MTL TC6 LoCredit Kernel Reset value: $0000\ 0000_H$



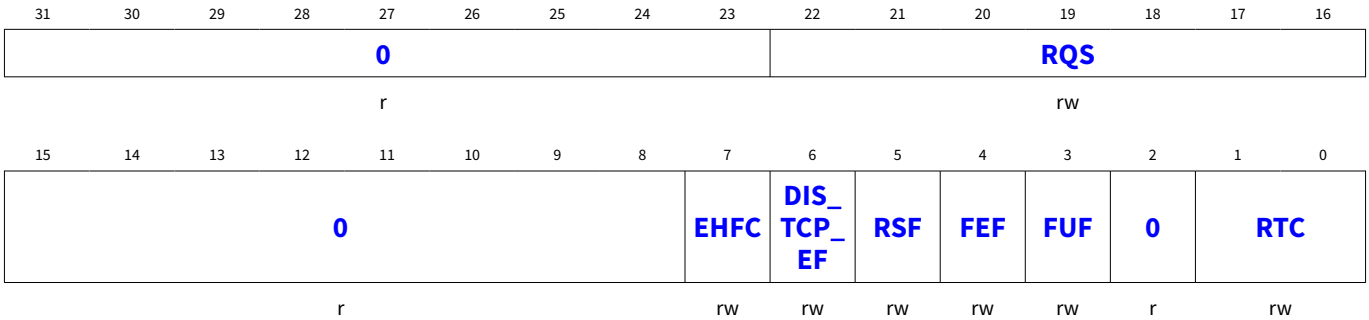
Field	Bits	Type	Description
LC	28:0	rw	**loCredit Value** - When Audio Video Bridging feature is enabled, this field contains the loCredit value required for the credit-based shaper algorithm. This is the minimum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1024. The maximum value is maxPacketSize transmitted from this queue, that is, 16384 * 8 * 1024 = 134217728 or 0x0800_0000. Because it is a negative value, the programmed value is twos complement of the value, that is, 0x1800_0000.
0	31:29	r	**Reserved** Read as 0; should be written with 0.

14.6.632 Port j MTL RxQ6 Operation Mode

The Queue 6 Receive Operation Mode register establishes the Receive queue 6 operating modes.

Portj_MTL_RxQ6_Operation_Mode (j=0-1) Offset address: $11440_H+j*2000_H$

Port j MTL RxQ6 Operation Mode Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RTC	1:0	rw	**Receive Queue Threshold Control** These bits control the threshold level of the MTL Rx queue (in bytes): - 2'b00: 64 - 2'b01: Reserved - 2'b10: 96 - 2'b11: 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. The value of 11 is not applicable if the size of the configured Rx Queue is 128 bytes. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.
FUF	3	rw	**Forward Undersized Good Packets** - 1: Rx queue forwards the undersized good packets (with no Invalid-code/GMII/CRC/Length errors and length less than 64 bytes at Rx (X)GMII interface), including pad-bytes and CRC. - 0: Rx queue drops all packets of length less than 64 bytes.
FEF	4	rw	**Forward Error Packets** - 0: Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. - 1: All packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA.
RSF	5	rw	**Receive Queue Store and Forward** - 1: DWC_xgmac reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. - 0: Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.
DIS_TCP_EF	6	rw	**Disable Dropping of TCP/IP Checksum Error Packets** - When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. - When this bit is reset, all error packets are dropped if the FEF bit is reset.
EHFC	7	rw	**Enable Hardware Flow Control** When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.

(table continues...)

(continued)

Field	Bits	Type	Description
RQS	22:16	rw	**Receive Queue Size** This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. A value of 0 indicates 256 bytes.When this queue is used, a minimum value of 7 (size = 2048) is recommended so that the queue can store more than a complete max-sized Ethernet packet.
0	2, 15:8, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.633 Port j MTL RxQ6 Missed Pkt Overflow Cnt

The Queue 6 Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Portj_MTL_RxQ6_Missed_Pkt_Overflow_Cnt (j=0-1) Offset address: $11444_H+j*2000_H$

Port j MTL RxQ6 Missed Pkt Overflow Cnt Kernel Reset value: $0000\ 0000_H$

0										RXQSTS		0	RRCSTS		RWCSTS
r										r		r	r		r

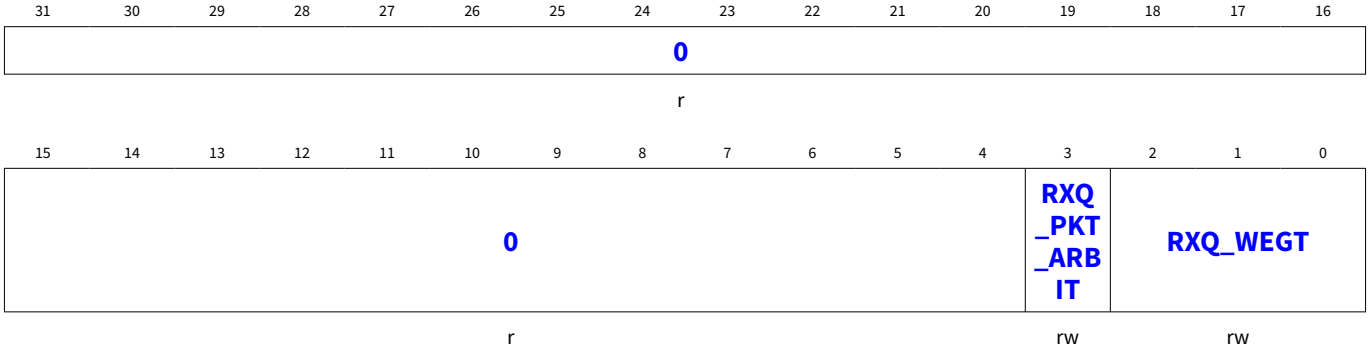
Field	Bits	Type	Description
RWCSTS	0	r	**MTL Rx Queue Write Controller Active Status** When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue.
RRCSTS	2:1	r	**MTL Rx Queue Read Controller State** This field gives the state of the Rx queue Read controller: - 2'b00: Idle state - 2'b01: Reading packet data - 2'b10: Reading packet status (or timestamp) - 2'b11: Flushing the packet data and status
RXQSTS	5:4	r	**MTL Rx Queue Fill-Level Status** This field gives the status of the fill-level of the Rx Queue: - 2'b00: Rx Queue empty - 2'b01: Rx Queue fill-level below flow-control deactivate threshold - 2'b10: Rx Queue fill-level above flow-control activate threshold - 2'b11: Rx Queue full
PRXQ	29:16	r	**Number of Packets in Receive Queue** This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.
0	3, 15:6, 31:30	r	**Reserved** Read as 0; should be written with 0.

14.6.635 Port j MTL RxQ6 Control

The Queue 6 Receive Control register controls the receive arbitration and passing of received packets to the application.

Portj_MTL_RxQ6_Control (j=0-1) Offset address: $1144C_H+j*2000_H$

Port j MTL RxQ6 Control Kernel Reset value: $0000\ 0000_H$



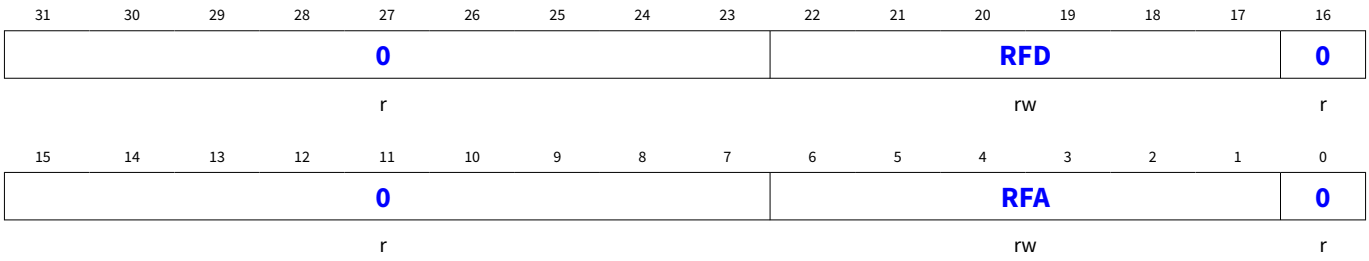
Field	Bits	Type	Description
RXQ_WEGT	2:0	rw	**Receive Queue Weight** This field indicates the weight assigned to the Rx Queue 6. The weight is used as the number of continuous PBL requests or contiguous packets (depending on the RXQ_PKT_ARBIT) allocated to the queue in one arbitration cycle.
RXQ_PKT_ARBIT	3	rw	**Receive Queue Packet Arbitration Control** - 1: MTL enables the packet-level arbitration. - 0: MTL enables the PBL based arbitration.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

14.6.636 Port j MTL RxQ6 Flow Control

This register controls the activation and de-activation threshold in the queue for triggering the generation of Flow Control packets by MAC transmitter.

Portj_MTL_RxQ6_Flow_Control (j=0-1) Offset address: $11450_H+j*2000_H$

Port j MTL RxQ6 Flow Control Kernel Reset value: $0000\ 0000_H$



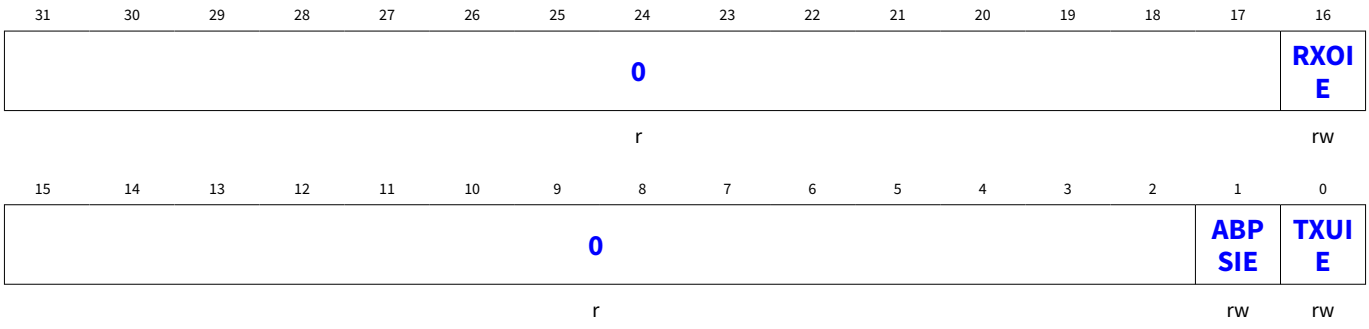
Field	Bits	Type	Description
RFA	6:1	rw	**Threshold for activating Flow Control** These bits control the threshold (fill-level of RxQ0) at which the flow control is activated - 6'b000000: RQS value minus 1 KB, that is, FULL - 1024 bytes - 6'b000001: RQS value minus 1.5 KB, that is, FULL - 1536 bytes - 6'b000010: RQS value minus 2 KB, that is, FULL - 2048 bytes. - ... - 6'b111111: RQS value minus 32.5 KB, that is, FULL - 33280 bytes The flow control is triggered when EHFC=1 and the queue size (RQS value in MTL_RxQ6_Operation Mode register) is equal to or more than 4KB. Note that the value to be programmed in RFA must be such that the threshold is positive number.
RFD	22:17	rw	**Threshold for deactivating Flow Control** These bits control the threshold (fill-level of RxQ0) at which the flow control is de-asserted once it is activated. - 6'b000000: RQS value minus 1 KB, that is, FULL - 1024 bytes - 6'b000001: RQS value minus 1.5 KB, that is, FULL - 1536 bytes - 6'b000010: RQS value minus 2 KB, that is, FULL - 2048 bytes. - ... - 6'b111111: RQS value minus 32.5 KB, that is, FULL - 33280 bytes The de-assertion is effective only after flow control is asserted as per the setting of RFA field. Note that the value to be programmed must be such that the threshold is positive number.
0	0, 16:7, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.637 Port j MTL Q6 Interrupt Enable

This register contains the interrupt enable bits for Traffic class/Queue 6.

Portj_MTL_Q6_Interrupt_Enable (j=0-1) Offset address: $11470_H+j*2000_H$

Port j MTL Q6 Interrupt Enable Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TXUIE	0	rw	**Transmit Queue Underflow Interrupt Enable** - 1: Transmit Queue Underflow interrupt is enabled. - 0: Transmit Queue Underflow interrupt is disabled.
ABPSIE	1	rw	**Average Bits Per Slot Interrupt Enable** When this bit is set, average bits per slot interrupt is enabled for Traffic Class 6. An interrupt is generated when ABPSIS is set for this traffic class. This bit is reserved and RO when the number of traffic classes selected is less than 6.
RXOIE	16	rw	**Receive Queue Overflow Interrupt Enable** - 1: Receive Queue Overflow interrupt is enabled. - 0: Receive Queue Overflow interrupt is disabled.
0	15:2, 31:17	r	**Reserved** Read as 0; should be written with 0.

14.6.638 Port j MTL Q6 Interrupt Status

This register contains the interrupt status bits for Traffic class/Queue 6.

Portj_MTL_Q6_Interrupt_Status (j=0-1) Offset address: $11474_H+j*2000_H$

Port j MTL Q6 Interrupt Status Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														ABPSIS	TXUNFIS
r														rw	rw

Field	Bits	Type	Description
TXUNFIS	0	rw	**Transmit Queue Underflow Interrupt Status** This bit indicates that the Transmit Queue had an Underflow during packet transmission. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes a 1 to this bit.
ABPSIS	1	rw	**Average Bits Per Slot Interrupt Status** When set, this bit indicates that the MAC has updated the ABS value for this traffic class. This bit is cleared when the application writes a 1 to this bit. This bit is reserved and RO when the number of traffic classes selected is less than 6.

(table continues...)

(continued)

Field	Bits	Type	Description
RXOVFIS	16	rw	**Receive Queue Overflow Interrupt Status** This bit indicates that the Receive Queue had an Overflow during packet reception. If partial packet is transferred to the application, the overflow status is set in the corresponding Rx status. This bit is cleared when the application writes a 1 to this bit.
0	15:2, 31:17	r	**Reserved** Read as 0; should be written with 0.

14.6.639 Port j MTL TxQ7 Operation Mode

The Queue 7 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Portj_MTL_TxQ7_Operation_Mode (j=0-1) Offset address: $11480_H+j*2000_H$

Port j MTL TxQ7 Operation Mode Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0									TQS

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					Q2TCMAP			0	TTC			TXQEN		TSF	FTQ
r					rw			r	rw			rw		rw	rw

Field	Bits	Type	Description
FTQ	0	rw	**Flush Transmit Queue** When this bit is set, the Tx Queue Controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. You must not write to this register until this bit is reset. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty. To complete this flush operation, the PHY Tx clock must be active.
TSF	1	rw	**Transmit Store and Forward** When this bit is set, the transmission starts when a full packet resides in the MTL Tx Queue. When this bit is set, the values specified in the TTC field are ignored. This bit must be changed only when the transmission is stopped.

(table continues...)

(continued)

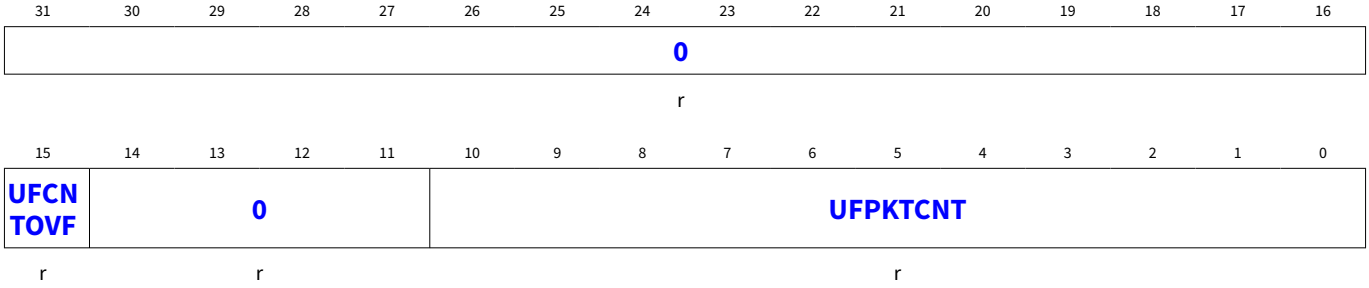
Field	Bits	Type	Description
TXQEN	3:2	rw	**Transmit Queue Enable** This field is used to enable/disable the transmit queue. - 2'b00: Not enabled - 2'b01: Audio Video Bridging - 2'b10: Enabled - 2'b11: Reserved In multiple Tx queues configuration, as the queue is disabled by default, enable the Tx Queue by programming this field in the AVB mode or default mode as desired.
TTC	6:4	rw	**Transmit Threshold Control** These bits control the threshold level of the MTL Tx Queue. Transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. - 3'b000: 64 - 3'b001: Reserved - 3'b010: 96 - 3'b011: 128 - 3'b100: 192 - 3'b101: 256 - 3'b110: 384 - 3'b111: 512
Q2TCMAP	10:8	rw	**Queue to Traffic Class Mapping** This field is used to map this Tx Queue to a traffic class (TC). - 3'b000: TC0 - 3'b001: TC1 - 3'b010: TC2 - 3'b011: TC3 - 3'b100: TC4 - 3'b101: TC5 - 3'b110: TC6 - 3'b111: TC7
TQS	22:16	rw	**Transmit Queue Size** This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. A value of 0 indicates 256 bytes. When this queue is enabled (TXQEN=10), a minimum value of 7 (size = 2048) is recommended so that the queue can store more than a complete max-sized Ethernet packet.
0	7, 15:11, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.640 Port j MTL TxQ7 Underflow

The Queue 7 Underflow Counter register contains the number of packets aborted because of Transmit queue underflow.

Portj_MTL_TxQ7_Underflow (j=0-1) Offset address: $11484_H+j*2000_H$

Port j MTL TxQ7 Underflow Kernel Reset value: $0000\ 0000_H$



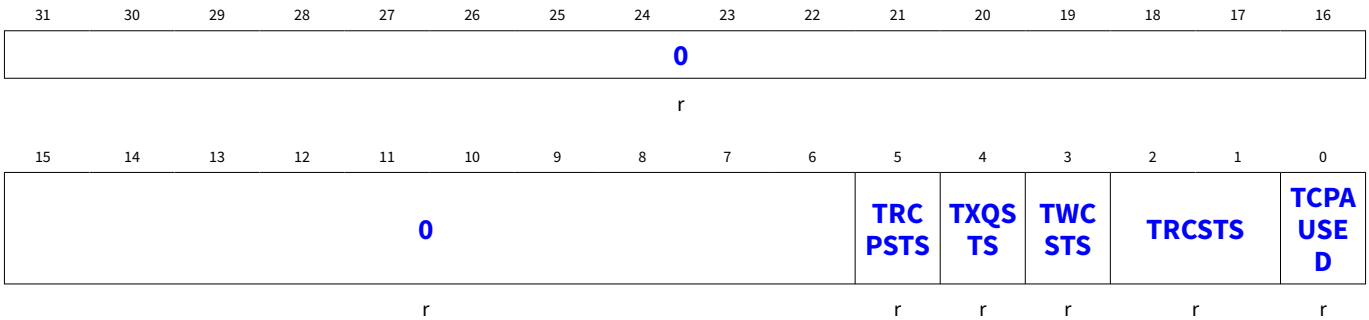
Field	Bits	Type	Description
UFPKTCNT	10:0	r	**Underflow Packet Counter** This field indicates the number of packets aborted by the controller because of Transmit Queue Underflow. This counter is incremented each time the MAC aborts an outgoing packet because of underflow. The counter is reset when this register is read with LSB of the Byte Enable for CSR access signal at 1'b1 .
UFCNTOVF	15	r	**Overflow Bit for Underflow Packet Counter** This bit is set every time the Tx Queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened.
0	14:11, 31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.641 Port j MTL TxQ7 Debug

The Queue 7 Transmit Debug register gives the debug status of various blocks related to the Transmit Queue 7 and Traffic Class 7.

Portj_MTL_TxQ7_Debug (j=0-1) Offset address: $11488_H+j*2000_H$

Port j MTL TxQ7 Debug Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TCPAUSED	0	r	**Traffic Class in Pause** - Reception of IEEE 802.3-2018 Pause packet
TRCSTS	2:1	r	**MTL Tx Queue Read Controller Status** This field indicates the state of the Tx Queue Read Controller: - 2'b00: Idle state - 2'b01: Read state (transferring data to the MAC transmitter) - 2'b10: Waiting for pending Tx Status from the MAC transmitter - 2'b11: Flushing the Tx queue because of the Packet Abort request from the MAC
TWCSTS	3	r	**MTL Tx Queue Write Controller Status** When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue.
TXQSTS	4	r	**MTL Tx Queue Not Empty Status** When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission.
TRCPSTS	5	r	**MTL TRC Pending Status** When this bit is high, it indicates that the MTL Tx Read Controller (TRC) has a pending status from MAC.
0	31:6	r	**Reserved** Read as 0; should be written with 0.

14.6.642 Port j MTL TC7 ETS Control

This register configures the transmission selection algorithm, for Traffic Class 7.

Portj_MTL_TC7_ETS_Control (j=0-1) Offset address: $11490_H+j*2000_H$

Port j MTL TC7 ETS Control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0									SLC			CC	CBSEN	TSA	
r									rw			rw	r	rw	

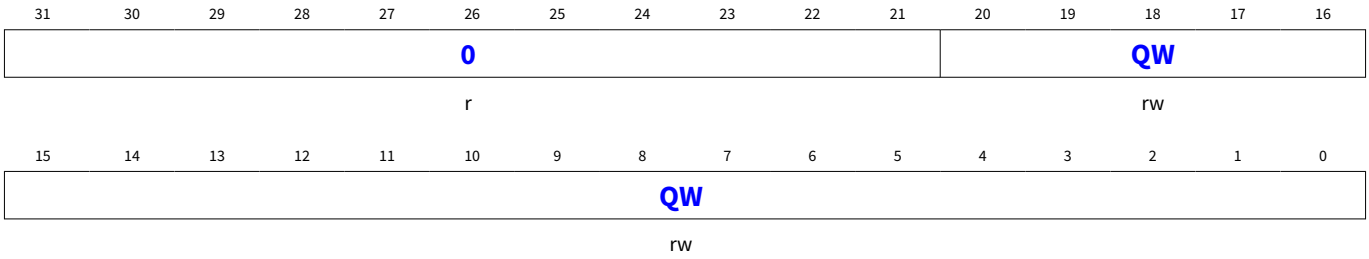
Field	Bits	Type	Description
TSA	1:0	rw	**Transmission Selection Algorithm** This field is used to assign a transmission selection algorithm for this traffic class. - 2'b00: Strict priority - 2'b01: CBS - 2'b10: ETS - 2'b11: Reserved
CBSEN	2	r	**Credit Based Shaper Enable** This field indicates that TSA field of this register is enabled for CBS
CC	3	rw	**Credit Control** When this bit is set, the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero when there is positive credit and no packet to transmit in TC(#n). The credit accumulates even when there is no packet waiting in TC(#n) and another TC is transmitting. When this bit is reset, the accumulated credit parameter in the credit-based shaper algorithm logic is set to zero when there is positive credit and no packet to transmit in TC(#n). When there is no packet waiting in TC(#n) and other TC is transmitting, no credit is accumulated.
SLC	6:4	rw	**Slot Count** If the credit-based shaper algorithm is enabled, the software can program the number of slots (of 125 us duration) over which the average transmitted bits per slot, provided in the MTL_TC(#n)_ETS_Status register, need to be computed for TC(#n). The encoding is as follows: - 3'b000: 1 Slot - 3'b001: 2 Slots - 3'b010: 4 Slots - 3'b011: 8 Slots - 3'b100: 16 Slots - 3'b101-3'b111: Reserved
0	31:7	r	**Reserved** Read as 0; should be written with 0.

14.6.643 Port j MTL TC7 Quantum Weight

The Quantum or Weights register controls the average traffic transmitted in Traffic Class 7.

Portj_MTL_TC7_Quantum_Weight (j=0-1) Offset address: $11498_H+j*2000_H$

Port j MTL TC7 Quantum Weight Kernel Reset value: $0000\ 0000_H$



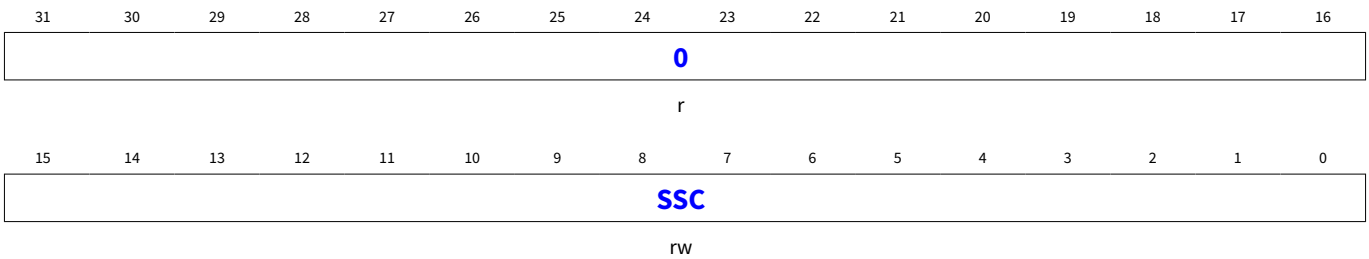
Field	Bits	Type	Description
QW	20:0	rw	**idleSlopeCredit, Quantum or Weights** - idleSlopeCredit -- When this TC is in AVB mode, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Traffic Class 7. This is the rate of change of credit in bits per cycle (3.2 ns for 2.5/10 Gbps; 8 ns for 1000 Mbps) when the credit is increasing. The software must program this field with computed credit in bits per cycle scaled by 1024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x8000 in 10 Gbps mode. Bits[20:16] must be written to zero. This field is not valid for Traffic Class 0. - Weights -- When TSA is set to ETS and ETSALG is set to WRR algorithm for Traffic Class 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits[20:7] must be written to zero. This field is reserved and RO when the number of traffic classes selected is less than two. This field is reserved in corresponding Queues 8-15 register.
0	31:21	r	**Reserved** Read as 0; should be written with 0.

14.6.644 Port j MTL TC7 SendSlopeCredit

MTL registers for traffic classes and queues 1 registers.

Portj_MTL_TC7_SendSlopeCredit (j=0-1) Offset address: $1149C_H+j*2000_H$

Port j MTL TC7 SendSlopeCredit Kernel Reset value: $0000\ 0000_H$



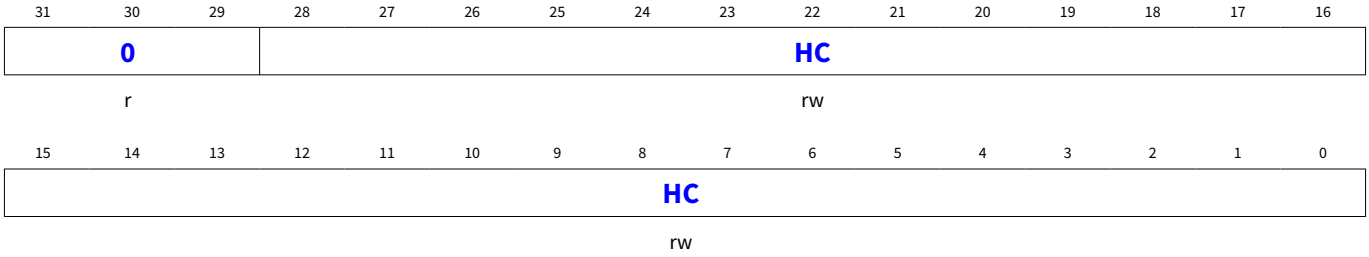
Field	Bits	Type	Description
SSC	15:0	rw	**sendSlopeCredit Value** - When Audio Video Bridging feature is enabled, this field contains the sendSlopeCredit value required for credit-based shaper algorithm for TC(#n). The software must program this field with computed credit in bits per cycle scaled by 1024. This field must be programmed with absolute sendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when TC(#n) is selected for transmission. See the application note for more details on programming this value.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.645 Port j MTL TC7 HiCredit

This register contains the hiCredit value required for the credit-based shaper algorithm for TC1.

Portj_MTL_TC7_HiCredit (j=0-1) Offset address: $114A0_H+j*2000_H$

Port j MTL TC7 HiCredit Kernel Reset value: $0000\ 0000_H$



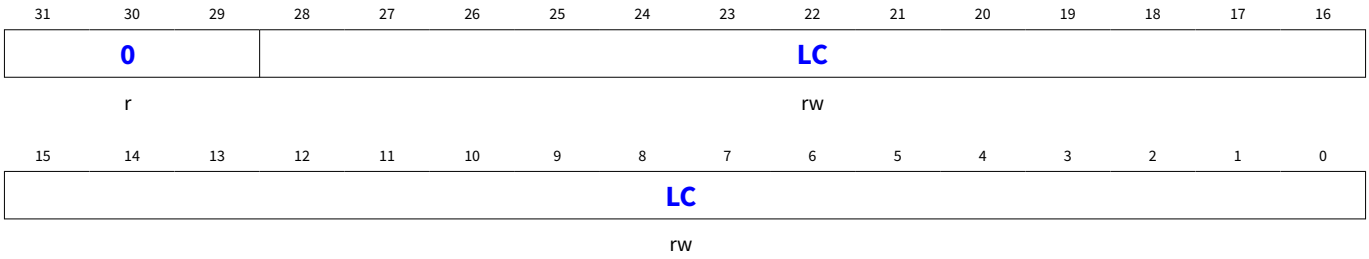
Field	Bits	Type	Description
HC	28:0	rw	**hiCredit Value** - When the Audio Video Bridging feature is enabled, this field contains the hiCredit value required for the credit-based shaper algorithm. This is the maximum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16384 bytes or 131072 bits). The value to be specified is 131072 * 1024 = 134217728 or 0x0800_0000
0	31:29	r	**Reserved** Read as 0; should be written with 0.

14.6.646 Port j MTL TC7 LoCredit

This register contains the loCredit value required for the credit-based shaper algorithm for TC1.

Portj_MTL_TC7_LoCredit (j=0-1) Offset address: $114A4_H+j*2000_H$

Port j MTL TC7 LoCredit Kernel Reset value: $0000\ 0000_H$



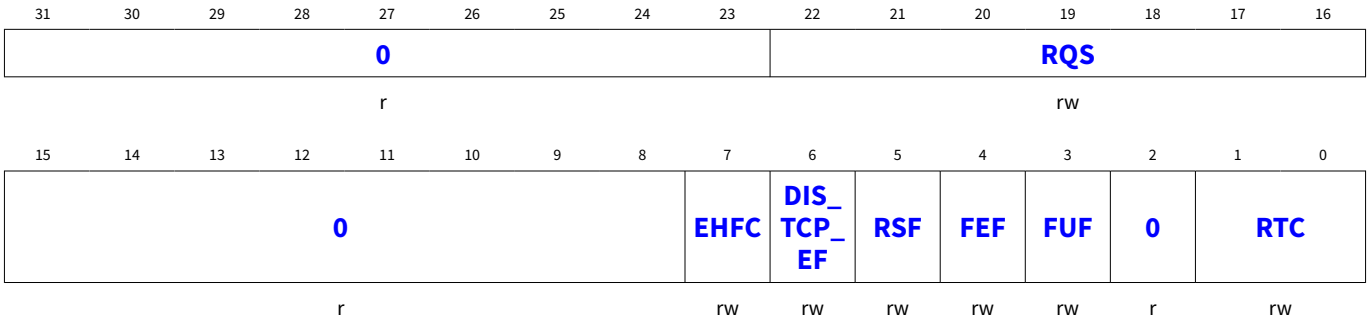
Field	Bits	Type	Description
LC	28:0	rw	**loCredit Value** - When Audio Video Bridging feature is enabled, this field contains the loCredit value required for the credit-based shaper algorithm. This is the minimum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1024. The maximum value is maxPacketSize transmitted from this queue, that is, 16384 * 8 * 1024 = 134217728 or 0x0800_0000. Because it is a negative value, the programmed value is twos complement of the value, that is, 0x1800_0000.
0	31:29	r	**Reserved** Read as 0; should be written with 0.

14.6.647 Port j MTL RxQ7 Operation Mode

The Queue 7 Receive Operation Mode register establishes the Receive queue 7 operating modes.

Portj_MTL_RxQ7_Operation_Mode (j=0-1) Offset address: $114C0_H+j*2000_H$

Port j MTL RxQ7 Operation Mode Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RTC	1:0	rw	**Receive Queue Threshold Control** These bits control the threshold level of the MTL Rx queue (in bytes): - 2'b00: 64 - 2'b01: Reserved - 2'b10: 96 - 2'b11: 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. The value of 11 is not applicable if the size of the configured Rx Queue is 128 bytes. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.
FUF	3	rw	**Forward Undersized Good Packets** - 1: Rx queue forwards the undersized good packets (with no Invalid-code/GMII/CRC/Length errors and length less than 64 bytes at Rx (X)GMII interface), including pad-bytes and CRC. - 0: Rx queue drops all packets of length less than 64 bytes.
FEF	4	rw	**Forward Error Packets** - 0: Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. - 1: All packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA.
RSF	5	rw	**Receive Queue Store and Forward** - 1: DWC_xgmac reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. - 0: Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.
DIS_TCP_EF	6	rw	**Disable Dropping of TCP/IP Checksum Error Packets** - When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. - When this bit is reset, all error packets are dropped if the FEF bit is reset.
EHFC	7	rw	**Enable Hardware Flow Control** When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled.

(table continues...)

(continued)

Field	Bits	Type	Description
RQS	22:16	rw	**Receive Queue Size** This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. A value of 0 indicates 256 bytes.When this queue is used, a minimum value of 7 (size = 2048) is recommended so that the queue can store more than a complete max-sized Ethernet packet.
0	2, 15:8, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.648 Port j MTL RxQ7 Missed Pkt Overflow Cnt

The Queue 7 Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Portj_MTL_RxQ7_Missed_Pkt_Overflow_Cnt (j=0-1) Offset address: $114C4_H+j*2000_H$

Port j MTL RxQ7 Missed Pkt Overflow Cnt Kernel Reset value: $0000\ 0000_H$

0												RXQ_PKT_ARBIT	RXQ_WEGT		
r												rw	rw		

Field	Bits	Type	Description
RXQ_WEGT	2:0	rw	**Receive Queue Weight** This field indicates the weight assigned to the Rx Queue 7. The weight is used as the number of continuous PBL requests or contiguous packets (depending on the RXQ_PKT_ARBIT) allocated to the queue in one arbitration cycle.
RXQ_PKT_ARBIT	3	rw	**Receive Queue Packet Arbitration Control** - 1: MTL enables the packet-level arbitration. - 0: MTL enables the PBL based arbitration.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

14.6.651 Port j MTL RxQ7 Flow Control

This register controls the activation and de-activation threshold in the queue for triggering the generation of Flow Control packets by MAC transmitter.

Portj_MTL_RxQ7_Flow_Control (j=0-1) Offset address: $114D0_H+j*2000_H$

Port j MTL RxQ7 Flow Control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r									rw						r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0									RFA						0
r									rw						r

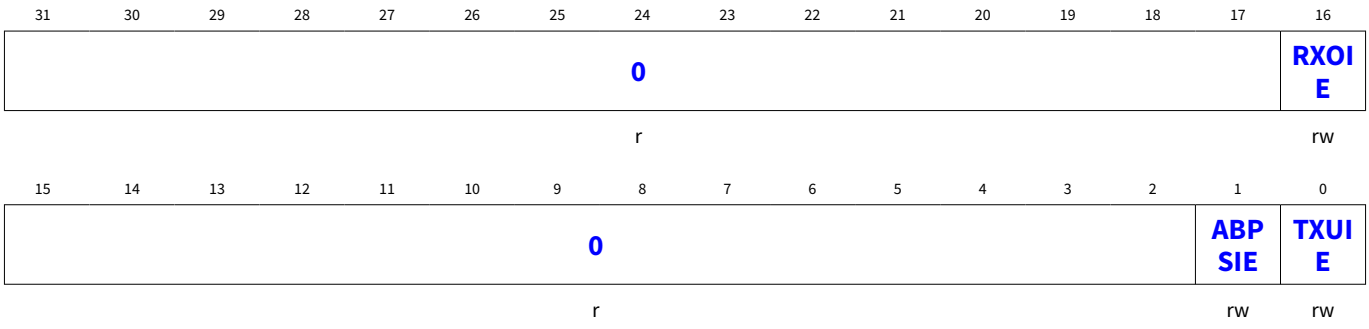
Field	Bits	Type	Description
RFA	6:1	rw	**Threshold for activating Flow Control** These bits control the threshold (fill-level of RxQ0) at which the flow control is activated - 6'b000000: RQS value minus 1 KB, that is, FULL - 1024 bytes - 6'b000001: RQS value minus 1.5 KB, that is, FULL - 1536 bytes - 6'b000010: RQS value minus 2 KB, that is, FULL - 2048 bytes. - ... - 6'b111111: RQS value minus 32.5 KB, that is, FULL - 33280 bytes The flow control is triggered when EHFC=1 and the queue size (RQS value in MTL_RxQ7_Operation Mode register) is equal to or more than 4KB. Note that the value to be programmed in RFA must be such that the threshold is positive number.
RFD	22:17	rw	**Threshold for deactivating Flow Control** These bits control the threshold (fill-level of RxQ0) at which the flow control is de-asserted once it is activated. - 6'b000000: RQS value minus 1 KB, that is, FULL - 1024 bytes - 6'b000001: RQS value minus 1.5 KB, that is, FULL - 1536 bytes - 6'b000010: RQS value minus 2 KB, that is, FULL - 2048 bytes. - ... - 6'b111111: RQS value minus 32.5 KB, that is, FULL - 33280 bytes The de-assertion is effective only after flow control is asserted as per the setting of RFA field. Note that the value to be programmed must be such that the threshold is positive number.
0	0, 16:7, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.652 Port j MTL Q7 Interrupt Enable

This register contains the interrupt enable bits for Traffic class/Queue 7.

Portj_MTL_Q7_Interrupt_Enable (j=0-1) Offset address: $114F0_H+j*2000_H$

Port j MTL Q7 Interrupt Enable Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TXUIE	0	rw	**Transmit Queue Underflow Interrupt Enable** - 1: Transmit Queue Underflow interrupt is enabled. - 0: Transmit Queue Underflow interrupt is disabled.
ABPSIE	1	rw	**Average Bits Per Slot Interrupt Enable** When this bit is set, average bits per slot interrupt is enabled for Traffic Class 7. An interrupt is generated when ABPSIS is set for this traffic class. This bit is reserved and RO when the number of traffic classes selected is less than 7.
RXOIE	16	rw	**Receive Queue Overflow Interrupt Enable** - 1: Receive Queue Overflow interrupt is enabled. - 0: Receive Queue Overflow interrupt is disabled.
0	15:2, 31:17	r	**Reserved** Read as 0; should be written with 0.

14.6.653 Port j MTL Q7 Interrupt Status

This register contains the interrupt status bits for Traffic class/Queue 7.

Portj_MTL_Q7_Interrupt_Status (j=0-1) Offset address: $114F4_H+j*2000_H$

Port j MTL Q7 Interrupt Status Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															RXOVFIS
r															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														ABPSIS	TXUNFIS
r														rw	rw

Field	Bits	Type	Description
TXUNFIS	0	rw	**Transmit Queue Underflow Interrupt Status** This bit indicates that the Transmit Queue had an Underflow during packet transmission. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes a 1 to this bit.
ABPSIS	1	rw	**Average Bits Per Slot Interrupt Status** When set, this bit indicates that the MAC has updated the ABS value for this traffic class. This bit is cleared when the application writes a 1 to this bit. This bit is reserved and RO when the number of traffic classes selected is less than 7.

(table continues...)

(continued)

Field	Bits	Type	Description
RXOVFIS	16	rw	**Receive Queue Overflow Interrupt Status** This bit indicates that the Receive Queue had an Overflow during packet reception. If partial packet is transferred to the application, the overflow status is set in the corresponding Rx status. This bit is cleared when the application writes a 1 to this bit.
0	15:2, 31:17	r	**Reserved** Read as 0; should be written with 0.

14.6.654 Forward Control

This register comprises of Forward Control settings applicable for all Bridge Ports except Host port.

Forward_Control Offset address: $1E000_H$

Forward Control Kernel Reset value: $0000\ 0040_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MAX_PKT_LENGTH															
rw															

Field	Bits	Type	Description
MAX_PKT_LENGTH	15:0	rw	**Maximum Packet Length for the Port to Port Forwarding Traffic** The maximum value of this field is 0x7FFF. Not used for 1-port and 2-port modes. Reserved for future multiple-port modes.
FW_DIS_EIN	16	rw	**Disable ATI Error Injection in the Forwarding Port for all Rx Packet Error types in the ingress port Values: - 0(ENABLE): ATI Error Injection Enabled - 1(DISABLE): ATI Error Injection Disabled**
PYLD_CHKERR_FWEI	17	rw	**Enable ATI Error Injection for the port forwarded packets which are received with IP Payload Checksum Error Status in the ingress port Values: - 0(DISABLE): ATI Error Injection Disabled for Rx packets with Payload Checksum Error - 1(ENABLE): ATI Error Injection Enabled for Rx packets with Payload Checksum Error**
IP_HDRERR_FWEI	18	rw	**Enable ATI Error Injection for the port forwarded packets which are received with IP Header Error Status in the ingress port Values: - 0(DISABLE): ATI Error Injection Disabled for Rx packets with IP Header Error - 1(ENABLE): ATI Error Injection Enabled for Rx packets with IP Header Error**

(table continues...)

(continued)

Field	Bits	Type	Description
GIANT_PKT_FWEI	19	rw	**Enable ATI Error Injection for the port forwarded packets which are received with Giant Packet Status in the ingress port** Values: - 0(DISABLE): ATI Error Injection Disabled for Rx packets with Giant Packet Status - 1(ENABLE): ATI Error Injection Enabled for Rx packets with Giant Packet Status
P2P_RUNT_PKT_FWEI	20	rw	**Enable ATI Error Injection for the port forwarded packets which are received with Good Runt Packet Status in the ingress port** Values: - 0(DISABLE): ATI Error Injection Disabled for Rx packets with Good Runt Packet Status - 1(ENABLE): ATI Error Injection Enabled for Rx packets with Good Runt Packet Status
PBL	29:22	rw	**Transmit Programmable Burst Length** These bits indicate the maximum number of beats to be transferred in one ATI/ARI data transfer in the forwarding path. This is the maximum value that is used in a single block ARI/ATI transfer. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. Note: The maximum limit is equal to half of the Tx Queue depth (Queue Depth = Queue Size / Datawidth).
PORT_SEL	30	rw	**Set to 0x1 to enable Port 1 in one-port mode Set to 0x0 to enable Port 0 in one-port mode**
Q_CH_MAPPING_EN	31	rw	**Set to 0x1 to enable TxQ/RxC mapping in two-port mode** In one-port mode, no mapping is required. This bit enables 2-port mode.
0	21	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.655 Port Flush and Loopback Control

This register provides RXQ flush enable and Port loopback mode enable.

Port_Flush_and_Loopback_Control Offset address: $1E004_H$

Port Flush and Loopback Control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RXQ_FLUSH_PORT1								RXQ_FLUSH_PORT0							
rw								rw							

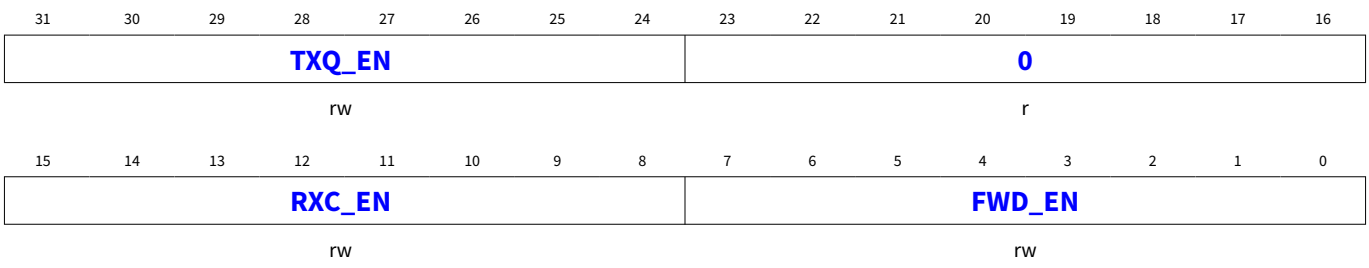
Field	Bits	Type	Description
RXQ_FLUSH_PORT0	7:0	rw	**To flush the Rx Queue corresponding to the selected RxC in Port 0 when the RxC is mapped to forwarding path** - Bit[0] : Flush the Rx queue corresponding to RxC0 of Port 0 - Bit[1] : Flush the Rx queue corresponding to RxC1 of Port 0 - Bit[2] : Flush the Rx queue corresponding to RxC2 of Port 0 - Bit[3] : Flush the Rx queue corresponding to RxC3 of Port 0 - Bit[4] : Flush the Rx queue corresponding to RxC4 of Port 0 - Bit[5] : Flush the Rx queue corresponding to RxC5 of Port 0 - Bit[6] : Flush the Rx queue corresponding to RxC6 of Port 0 - Bit[7] : Flush the Rx queue corresponding to RxC7 of Port 0
RXQ_FLUSH_PORT1	15:8	rw	**To flush the Rx Queue corresponding to the selected RxC in Port 1 when the RxC is mapped to forwarding path** - Bit[8] : Flush the Rx queue corresponding to RxC0 of Port 1 - Bit[9] : Flush the Rx queue corresponding to RxC1 of Port 1 - Bit[10] : Flush the Rx queue corresponding to RxC2 of Port 1 - Bit[11] : Flush the Rx queue corresponding to RxC3 of Port 1 - Bit[12] : Flush the Rx queue corresponding to RxC4 of Port 1 - Bit[13] : Flush the Rx queue corresponding to RxC5 of Port 1 - Bit[14] : Flush the Rx queue corresponding to RxC6 of Port 1 - Bit[15] : Flush the Rx queue corresponding to RxC7 of Port 1
PORT_LPBK_EN	17:16	rw	**To enable same-port loopback mode for port 1 (bit[17]) and port 0 (bit[16])**
PTP_PORT_NUM	24	rw	**Specifies the Port number for the PTP Timestamp Selection from Port 0/ Port 1** Values: - 0x0: Use Port 0 PTP Timestamp - 0x1: Use Port 1 PTP Timestamp Note: Software must program this field based on XGMAC's MAC_Timestamp_Control register.
0	23:18, 31:25	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.656 Port 0 Control

This register enables the queues and channels and indicate whether it is a forwarding path.

Port_0_Control Offset address: $1E00C_H$

Port 0 Control Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
FWD_EN	7:0	rw	**Indicate whether any of the TxQ[7:0] is a forwarding path**
RXC_EN	15:8	rw	**Enable any of the RxC[7:0]**
TXQ_EN	31:24	rw	**Enable any of the TxQ[7:0]**
0	23:16	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.657 TXQ Map Port 0

TxQ Map for Port 0. This register provides Port 0 TxQ connection mappings to either Tx EDMA or RxC of other Ethernet line ports in the forwarding path. When the TxQ of the Ethernet line Port is assigned to forwarding path (when FWD_EN bit of the TxQ in Port_0_Control register is set), the value of TXQ_Map_Port_0 provides the mapped RxC number of the source Ethernet line Port. When the TxQ of the Ethernet Line Port is mapped to Host traffic (when FWD_EN bit of the TxQ in Port_0_Control is zero), the value of TXQ_Map_Port_0 provides the mapped TxDMA channel number of the Host path.

TXQ_Map_Port_0 Offset address: $1E010_H$

TXQ Map Port 0 Kernel Reset value: $0000\ 0000_H$

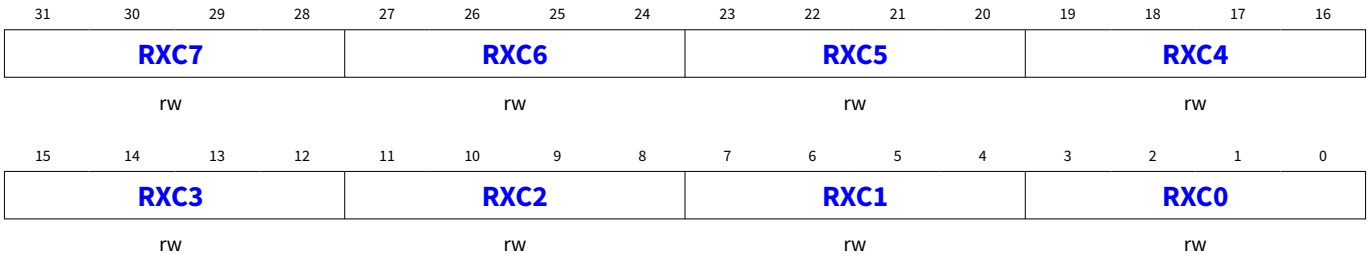
TXQ7	31:28	rw	**TxQ7 connection mappings to either Tx EDMA channel of the Host port or Rx EDMA Channels of the other Ethernet line ports** Values: - 0x0: Mapped to RxC0 (Forward path) of Port 1 or TxEDMA0 (Host traffic) - 0x1: Mapped to RxC1 (Forward path) of Port 1 or TxEDMA1 (Host traffic) - 0x2: Mapped to RxC2 (Forward path) of Port 1 or TxEDMA2 (Host traffic) - 0x3: Mapped to RxC3 (Forward path) of Port 1 or TxEDMA3 (Host traffic) - 0x4: Mapped to RxC4 (Forward path) of Port 1 or TxEDMA4 (Host traffic) - 0x5: Mapped to RxC5 (Forward path) of Port 1 or TxEDMA5 (Host traffic) - 0x6: Mapped to RxC6 (Forward path) of Port 1 or TxEDMA6 (Host traffic) - 0x7: Mapped to RxC7 (Forward path) of Port 1 or TxEDMA7 (Host traffic) - 0x8 - 0xf: Reserved

14.6.658 RXC Map Port 0

This register provides Port 0 RxC connection mappings to Rx EDMA Channels. When the RxC of Ethernet Line Port is not participating in the forwarding traffic i.e the RxC number is not mapped to the TXQ of other Ethernet Line Ports, the value programmed in RXC field corresponds to the Rx EDMA of the Host path.

RXC_Map_Port_0 Offset address: $1E014_H$

RXC Map Port 0 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RXC0	3:0	rw	**RxC0 connection mappings to Rx EDMA Channel of Host port** Values: - 0x0: Mapped to RxEDMA0. - 0x1: Mapped to RxEDMA1. - 0x2: Mapped to RxEDMA2. - 0x3: Mapped to RxEDMA3. - 0x4: Mapped to RxEDMA4. - 0x5: Mapped to RxEDMA5. - 0x6: Mapped to RxEDMA6. - 0x7: Mapped to RxEDMA7. - 0x8 - 0xf: Reserved

14.6.660 TXQ Map Port 1

TxQ Map for Port 1. This register provides Port 1 TxQ connection mappings to either Tx EDMA or RxC of other Ethernet line ports in the forwarding path. When the TxQ of the Ethernet line Port is assigned to forwarding path (when FWD_EN bit of the TxQ in Port_1_Control register is set), the value of TXQ_Map_Port_1 provides the mapped RxC number of the source Ethernet line Port. When the TxQ of the Ethernet Line Port is mapped to Host traffic (when FWD_EN bit of the TxQ in Port_1_Control is zero), the value of TXQ_Map_Port_1 provides the mapped TxDMA channel number of the Host path.

TXQ_Map_Port_1 Offset address: $1E01C_H$

TXQ Map Port 1 Kernel Reset value: $0000\ 0000_H$

(table continues...)

(continued)

Field	Bits	Type	Description
TXQ7	31:28	rw	**TxQ7 connection mappings to either Tx EDMA channel of the Host port or Rx EDMA Channels of the other Ethernet line ports** Values: - 0x0: Mapped to RxC0 (Forward path) of Port 0 or TxEDMA0 (Host traffic) - 0x1: Mapped to RxC1 (Forward path) of Port 0 or TxEDMA1 (Host traffic) - 0x2: Mapped to RxC2 (Forward path) of Port 0 or TxEDMA2 (Host traffic) - 0x3: Mapped to RxC3 (Forward path) of Port 0 or TxEDMA3 (Host traffic) - 0x4: Mapped to RxC4 (Forward path) of Port 0 or TxEDMA4 (Host traffic) - 0x5: Mapped to RxC5 (Forward path) of Port 0 or TxEDMA5 (Host traffic) - 0x6: Mapped to RxC6 (Forward path) of Port 0 or TxEDMA6 (Host traffic) - 0x7: Mapped to RxC7 (Forward path) of Port 0 or TxEDMA7 (Host traffic) - 0x8 - 0xf: Reserved

14.6.661 RXC Map Port 1

This register provides Port 1 RxC connection mappings to Rx EDMA Channels. When the RxC of Ethernet Line Port is not participating in the forwarding traffic i.e the RxC number is not mapped to the TXQ of other Ethernet Line Ports, the value programmed in RXC field corresponds to the Rx EDMA of the Host path.

RXC_Map_Port_1 Offset address: $1E020_H$

RXC Map Port 1 Kernel Reset value: $0000\ 0000_H$

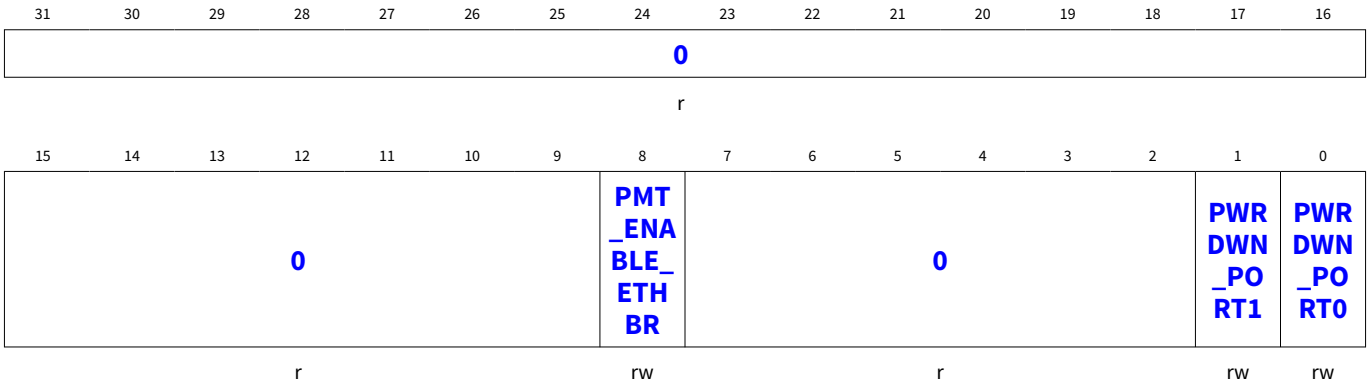
Bit[0] = 0, DMA Channel-0 is allocated to Port-0. 1, DMA channel 0 is allocated to Port 1 Bit[1] = 0, DMA Channel-1 is allocated to Port-0. 1, DMA channel 1 is allocated to Port 1 - - Bit[7] = 0, DMA Channel-7 is allocated to Port-0. 1, DMA channel 7 is allocated to Port 1 Please refer to 2.2.8 DMA Port Selection.
0	31:8	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.666 PMT Control

This register provides the power-up/power-down control of the Ethernet Bridge Port MTL/MAC switchable and always-ON logic when the port is not active.

PMT_Control Offset address: $1E114_H$

PMT Control Kernel Reset value: $0000\ 0100_H$



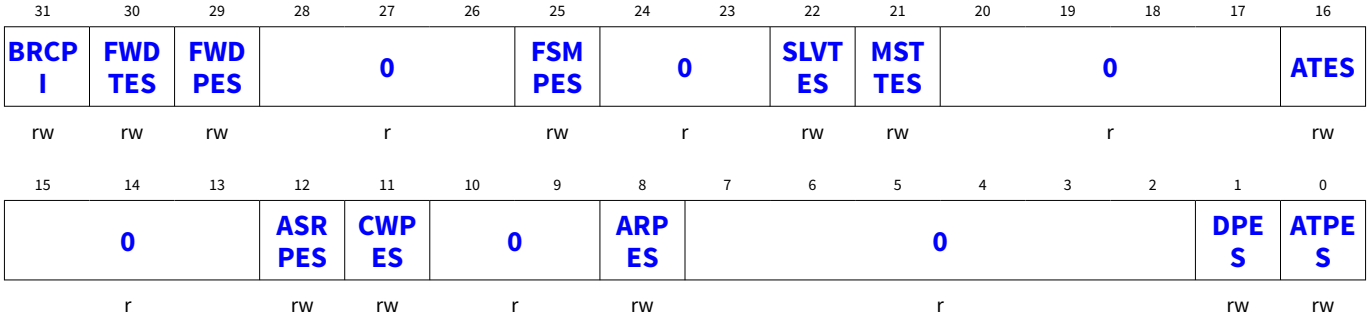
Field	Bits	Type	Description
PWRDWN_PORT0	0	rw	**Port-0 Power Down Enable When software sets this bit, both switchable and always-on logic of Port-0 is placed in the Power OFF state** When software clears this bit, both switchable and always-on logic of Port-0 is placed in the Power ON state. Values: - 0x0: Power-down Disable for Port-0 - 0x1: Power-down Enable for Port-0
PWRDWN_PORT1	1	rw	**Port 1 Power Down Enable When software sets this bit, both switchable and always-on logic of Port 1 is placed in the Power OFF state** When software clears this bit, both switchable and always-on logic of Port 1 is placed in the Power ON state. Values: - 0x0: Power-down Disable for Port 1 - 0x1: Power-down Enable for Port 1
PMT_ENABLE_ETHBR	8	rw	**PMT Enable for Ethernet Bridge switchable Power Domain** Values: - 0x0: Disable PMT for Ethernet Bridge Subsystem - 0x1: Enable PMT for Ethernet Bridge Subsystem -down Enable for Port 1
0	7:2, 31:9	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.667 DPP FSM Interrupt Status

This register contains the status of Automotive Safety related Data Path Parity Errors, Interface Timeout Errors, FSM State Parity Errors, and FSM State Timeout Errors for the Ethernet Bridge, EDMA, CSR and AXI Slave/Master Interfaces.

DPP_FSM_Interrupt_Status Offset address: $1E150_H$

DPP FSM Interrupt Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ATPES	0	rw	**Application Transmit Interface Parity Checker Error Status** This field, when set, indicates that a parity error is detected on the AXI Master read data parity checker (PC-e). This field, when set, indicates that a parity error is detected on the interface port parity checker. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: - 0x0 (INACTIVE): Application Transmit Interface Parity Checker Error Status not detected - 0x1 (ACTIVE): Application Transmit Interface Parity Checker Error Status detected
DPES	1	rw	**Descriptor Cache write data path Parity Checker Error Status This field, when set, indicates that a parity error is detected at the Descriptor Cache parity checker (or at PC-desc)** Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: - 0x0 (INACTIVE): EDMA Descriptor Cache write data path Parity Checker Error Status not detected - 0x1 (ACTIVE): EDMA Descriptor Cache write data path Parity Checker Error Status detected
ARPES	8	rw	**Application Receive interface data path Parity Error Status This field, when set, indicates that a parity error is detected at parity checker at AXI Master Interface (PC-a)** Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: - 0x0 (INACTIVE): Application Receive interface data path Parity Checker Error Status not detected - 0x1 (ACTIVE): Application Receive interface data path Parity Checker Error Status detected

(table continues...)

(continued)

Field	Bits	Type	Description
CWPES	11	rw	**CSR Write data path Parity Checker Error Status This field, when set, indicates that parity error is detected at the CSR write data interface on mci_wdata_i (or at PC8 checker)** This bit is set to 1 when EPSI bit of DPP_Control register is set and a parity mismatch is detected on the input slave parity ports (or at PC-axi/apb/mci slave checker). Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: - 0x0 (INACTIVE): CSR Write data path Parity Checker Error Status not detected - 0x1 (ACTIVE): CSR Write data path Parity Checker Error Status detected
ASRPES	12	rw	**AXI Slave Read data path Parity Checker Error Status This field, when set, indicates that parity error is detected at the AXI Slave read data interface on rdata_s_o or at PC9 checker** Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: - 0x0 (INACTIVE): AXI Slave Read data path Parity Checker Error Status not detected - 0x1 (ACTIVE): AXI Slave Read data path Parity Checker Error Status detected
ATES	16	rw	**APP FSM Timeout Error Status This field, when set, indicates that one of the APP FSM timeout has occurred** Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: - 0x0 (INACTIVE): APP FSM Timeout Error Status not detected - 0x1 (ACTIVE): APP FSM Timeout Error Status detected
MSTTES	21	rw	**Master Read/Write Timeout Error Status This field, when set, indicates that an Application/CSR timeout has occurred on the master (AXI) interface** Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: - 0x0 (INACTIVE): Master Read/Write Timeout Error Status not detected - 0x1 (ACTIVE): Master Read/Write Timeout Error Status detected

(table continues...)

(continued)

Field	Bits	Type	Description
SLVTES	22	rw	**Slave Read/Write Timeout Error Status This field, when set, indicates that an Application/CSR timeout has occurred on the AXI slave interface** Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: - 0x0 (INACTIVE): Slave Read/Write Timeout Error Status not detected - 0x1 (ACTIVE): Slave Read/Write Timeout Error Status detected
FSMPES	25	rw	**FSM State Parity Error Status Indicates that parity error is detected in one of the FSM State registers** Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: - 0x0 (INACTIVE): Slave Read/Write Timeout Error Status not detected - 0x1 (ACTIVE): Slave Read/Write Timeout Error Status detected
FWDPES	29	rw	**Ethernet Bridge Forward FSM State Parity Error Status Indicates that parity error is detected in one of the Ethernet Bridge Forward FSM State registers** Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: - 0x0 (INACTIVE): Ethernet Bridge FSM Parity Error Status not detected - 0x1 (ACTIVE): Ethernet Bridge FSM Parity Error Status detected
FWDTES	30	rw	**Ethernet Bridge Forward FSM Timeout Error Status This field, when set, indicates that an FSM timeout has occurred on the Ethernet Bridge Forwarding Path** Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_Ctrl register is set). Self-set to 1 on internal event. Values: - 0x0 (INACTIVE): Slave Read/Write Timeout Error Status not detected - 0x1 (ACTIVE): Slave Read/Write Timeout Error Status detected
BRCPI	31	rw	**Ethernet Bridge Control Register Parity Check Error This field, when set, indicates a parity check error for Ethernet Bridge and EDMA CSR registers** Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_Ctrl register is set). Self-set to 1 on internal event.

(table continues...)

(continued)

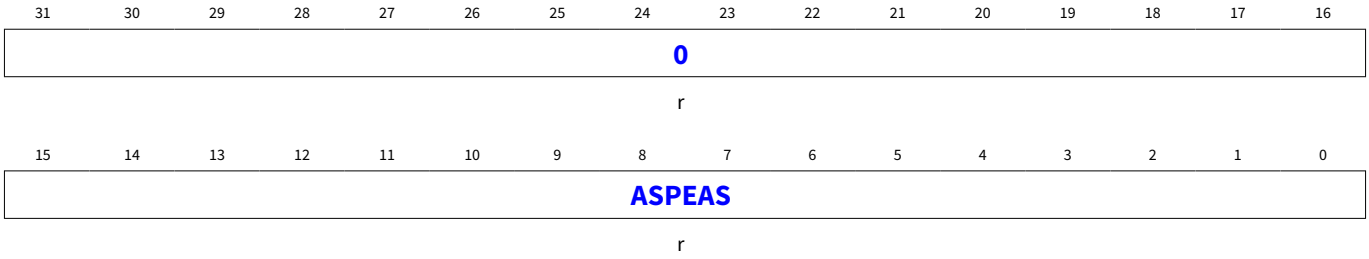
Field	Bits	Type	Description
0	7:2, 10:9, 15:13, 20:17, 24:23, 28:26	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.668 AXI Slave DPP Error Address Status

This register indicates the CSR address corresponding to the CSR write data on which parity error occurred in the Ethernet Bridge and EDMA register space.

AXI_Slave_DPP_Error_Address_Status Offset address: $1E154_H$

AXI Slave DPP Error Address Status Kernel Reset value: $0000\ 0000_H$



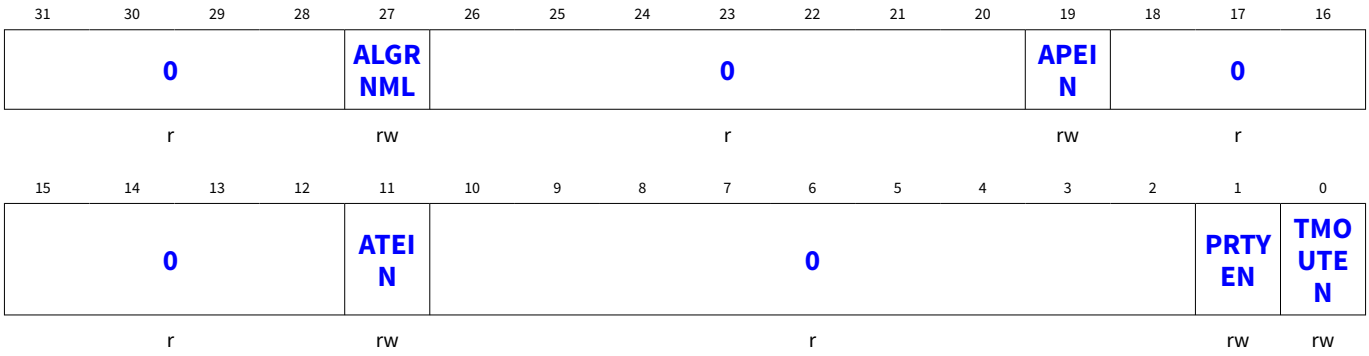
Field	Bits	Type	Description
ASPEAS	15:0	r	**AXI Slave data path Parity Error Address Status This field holds the CSR address for which parity error is detected on the CSR write data** This field holds the first address for which parity error is detected on the write data which is cleared on read.
0	31:16	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.669 FSM Control

This register controls FSM Error.

FSM_Control Offset address: $1E158_H$

FSM Control Kernel Reset value: $0000\ 0000_H$



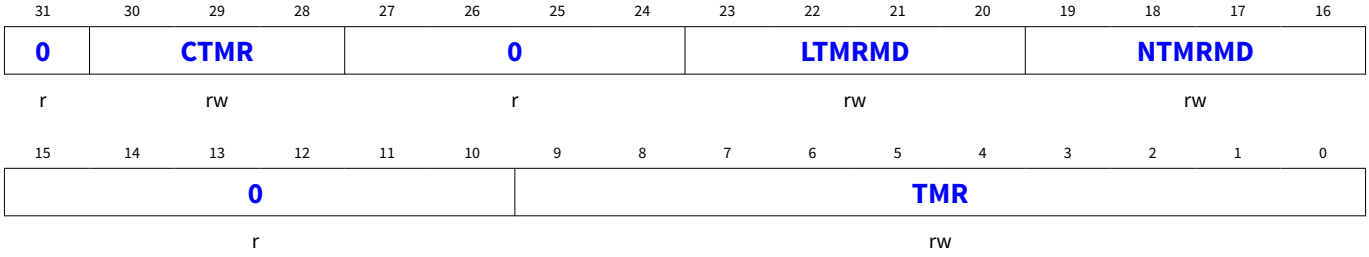
Field	Bits	Type	Description
TMOUTEN	0	rw	**This field, when set, indicates that the FSM timeout feature is enabled** Values: - 0x0 (DISABLE): FSM timeout feature is disabled - 0x1 (ENABLE): FSM timeout feature is enabled
PRTYEN	1	rw	**This field, when set, indicates that the FSM parity feature is enabled** Values: - 0x0 (DISABLE): FSM Parity feature is disabled - 0x1 (ENABLE): FSM Parity feature is enabled
ATEIN	11	rw	**APP FSM Timeout Error Injection This field, when set, indicates that Error Injection for APP FSM timeout is enabled** Values: - 0x0 (DISABLE): APP FSM Timeout Error Injection is disabled - 0x1 (ENABLE): APP FSM Timeout Error Injection is enabled
APEIN	19	rw	**APP FSM Parity Error Injection This field, when set, indicates that Error Injection for APP FSM Parity is enabled** Values: - 0x0 (DISABLE): APP FSM Parity Error Injection is disabled - 0x1 (ENABLE): APP FSM Parity Error Injection is enabled
ALGRNML	27	rw	**APP Large/Normal Mode Select This field, when set, indicates that large mode tic generation is used for APP domain; otherwise, normal mode tic generation is used** Values: - 0x0 (DISABLE): normal mode tic generation is used for APP domain - 0x1 (ENABLE): large mode tic generation is used for APP domain
0	10:2, 18:12, 26:20, 31:28	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.670 FSM ACT Timer

This register is used to select the FSM and Interface Timeout values for Ethernet Bridge.

FSM_ACT_Timer Offset address: $1E15C_H$

FSM ACT Timer Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TMR	9:0	rw	**CSR Clocks for 1us Tic This field indicates the number of CSR clocks required to generate 1us tic**
NTMRMD	19:16	rw	**Normal Mode Timeout Value This field provides the value to be used for normal mode FSM and other interface time outs** The timeout duration based on the mode value is as follows: Values: - 0x0 (DISABLE): Timer disabled - 0x1 (M_1MICRO_SEC): 1us - 0x2 (M_4MILLI_SEC): 1.024ms (~4ms) - 0x3 (M_16MILLI_SEC): 16.384ms (~16ms) - 0x4 (M_64MILLI_SEC): 65.536ms (~64ms) - 0x5 (M_256MILLI_SEC): 262.144ms (~256ms) - 0x6 (M_1SEC): 1.048sec (~1sec) - 0x7 (M_4SEC): 4.194sec (~4sec) - 0x8 (M_16SEC): 16.777sec (~16sec) - 0x9 (M_32SEC): 33.554sec (~32sec) - 0xa (M_64SEC): 67.108sec (~64sec) - 0xb (RSVD): Reserved

(table continues...)

(continued)

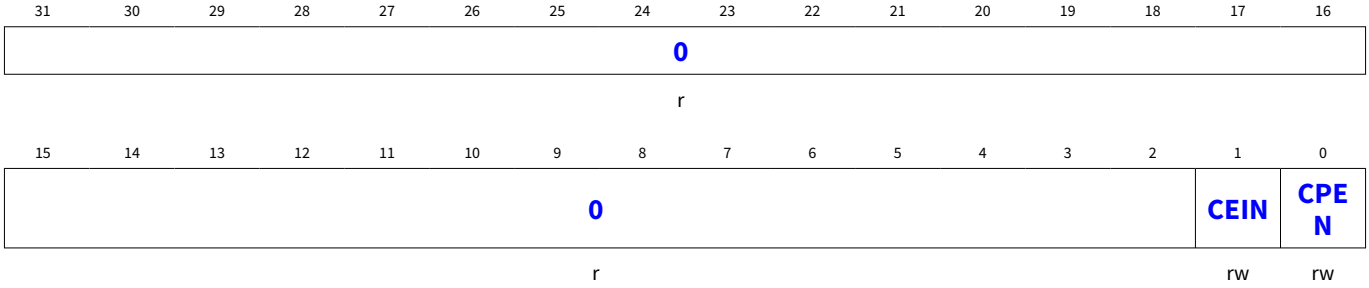
Field	Bits	Type	Description
LTMRMD	23:20	rw	**Large Mode Timeout Value This field provides the mode value to be used for large mode FSM and other interface time outs** The timeout duration based on the mode value is as follows: Values: - 0x0 (DISABLE): Timer disabled - 0x1 (M_1MICRO_SEC): 1us - 0x2 (M_4MILLI_SEC): 1.024ms (~4ms) - 0x3 (M_16MILLI_SEC): 16.384ms (~16ms) - 0x4 (M_64MILLI_SEC): 65.536ms (~64ms) - 0x5 (M_256MILLI_SEC): 262.144ms (~256ms) - 0x6 (M_1SEC): 1.048sec (~1sec) - 0x7 (M_4SEC): 4.194sec (~4sec) - 0x8 (M_16SEC): 16.777sec (~16sec) - 0x9 (M_32SEC): 33.554sec (~32sec) - 0xa (M_64SEC): 67.108sec (~64sec) - 0xb (RSVD): Reserved
CTMR	30:28	rw	**CSR Parity Check Interval Value This register is used for setting timer value for generating timer tic for CSR parity check** Values: - 0x0 (M_1MILLI_SEC): 1ms - 0x1 (M_1MICRO_SEC_CSR): 1us - 0x2 (M_4MILLI_SEC_CSR): 4.096ms (~4ms) - 0x3 (M_16MILLI_SEC_CSR): 16.384ms (~16ms) - 0x4 (M_64MILLI_SEC_CSR): 65.536ms (~64ms) - 0x5 (M_256MILLI_SEC_CSR): 262.144ms (~256ms) - 0x6 (M_1SEC_CSR): 1.048sec (~1sec) - 0x7 (ALWAYS_EN): Always Enabled
0	15:10, 27:24, 31	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.671 SCSR Control

This register is used to control safety protected CSR parity generation for Ethernet Bridge and EDMA register space.

SCSR_Control Offset address: $1E164_H$

SCSR Control Kernel Reset value: $0000\ 0000_H$



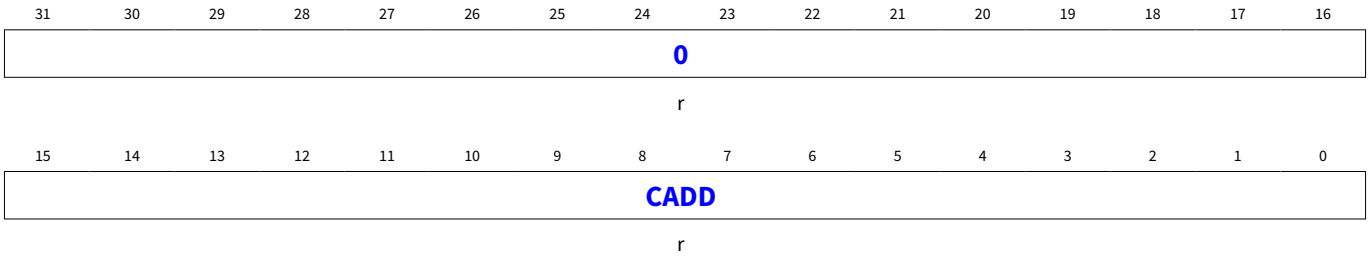
Field	Bits	Type	Description
CPEN	0	rw	**Ethernet Bridge/EDMA CSR Parity Enable This field, when set, indicates that CSR parity checking is enabled**
CEIN	1	rw	**Ethernet Bridge /EDMA CSR Error Injection Enable This field, when set, indicates that CSR error injection is enabled for the protected Ethernet Bridge and EDMA registers** Error is injected in the subsequent write operation where at the least one of the byte enable matches with byte enable indicated in CEBE. After error injection, this bit is cleared by the design.
0	31:2	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.672 SCSR Parity Status

This register indicates the offset address of the register where parity_error occurred in the Ethernet Bridge/ EDMA register space.

SCSR_Parity_Status Offset address: $1E168_H$

SCSR Parity Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CADD	15:0	r	**CSR Address with error This field indicates the offset address of the last register in which parity mismatch occurred** Self clears on read.
0	31:16	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.673 SCSR Parity Err Count

This register indicates error count associated with partity check in the Ethernet Bridge/EDMA parity protected registers.

SCSR_Parity_Err_Count Offset address: $1E16C_H$

SCSR Parity Err Count Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r						r									

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						ECCL									
r						r									

Field	Bits	Type	Description
ECCL	9:0	r	**Count of parity errors in current safety loop This field indicates the Count of parity errors in the current loop of all safety register parity check** Application read related errors are also included in the count. Value saturates at all "1"s and is cleared on read.
ECLL	25:16	r	**Count of parity errors in the previous safety loop This field indicates the Count of parity errors in previous loop of all safety register parity check** Any application read related errors are also included in the count. Value saturates at all "1"s and is cleared on read.
0	15:10, 31:26	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.674 Debug Control

This register is used to control the ECC error injection for the Descriptor Cache memory in Debug mode.

Debug_Control Offset address: $1E208_H$

Debug Control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															
r															

Field	Bits	Type	Description
EIEE	16	rw	**ECC Inject Error Enable for Descriptor Cache memories When set, enables the ECC error injection feature** If EIAEE is set, enables the ECC Address Error Injection, otherwise, enables the ECC Data/Check Bits Error Injection (See EIM and BLEI field in DPP_ECC_EIC Register). When reset, disables the ECC error injection feature.
EIAEE	17	rw	**ECC Inject Address Error Enable for Descriptor Cache memories When set, enables the ECC Address error injection feature** When reset, disables the ECC Address error injection feature. Values: - 0x0 (DISABLE): ECC Inject Address Error for Descriptor Cache memories is disabled - 0x1 (ENABLE): ECC Inject Address Error for Descriptor Cache memories is enabled
EIEC	18	rw	**ECC Inject Error Control for Descriptor Cache memories When EIEE bit of this register is set, following errors are inserted based on the value encoded in this field** Values: - 0x0 (M_1BIT): Insert 1-bit error - 0x1 (M_2BIT): Insert 2-bit errors
0	15:0, 31:19	r	**Reserved Field** Read as 0; should be written with 0.

14.6.675 ECC Control

The ECC_Control register establishes the operating mode of ECC related to Descriptor Cache memory.

ECC_Control Offset address: $1E2C0_H$

ECC Control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r							rw	r		rw	r				

Field	Bits	Type	Description
DESCED	5	rw	**DCACHE memory ECC Checker Disable When set to 1, disables the ECC Checker for DCACHE memory in DMA** When set to 0, enables the ECC Checker for DCACHE memory in DMA. Values: - 0x0 (ENABLE): Descriptor Cache memory ECC Checker is enabled - 0x1 (DISABLE): Descriptor Cache memory ECC Checker is disabled
EEAO	8	rw	**Descriptor Cache ECC Error Address Status Override When set, the following error address fields hold the last valid address where the error is detected** When reset, the following error address fields hold the first address where the error is detected. EUEAS/ECEAS of ECC_Err_Addr_Status register. Values: - 0x0 (DISABLE): ECC Error Address Status Over-ride is disabled - 0x1 (ENABLE): ECC Error Address Status Over-ride is enabled
0	4:0, 7:6, 31:9	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.676 ECC Err Sts RCtl

The ECC_Err_Sts_Rctl register establishes the control for Descriptor Cache ECC Error status capture.

ECC_Error_Status_Capture_Control Offset address: $1E2D0_H$

ECC Err Sts RCtl Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0										CUES	CCES	EMS			EESRE
r										rw	rw	rw			rw

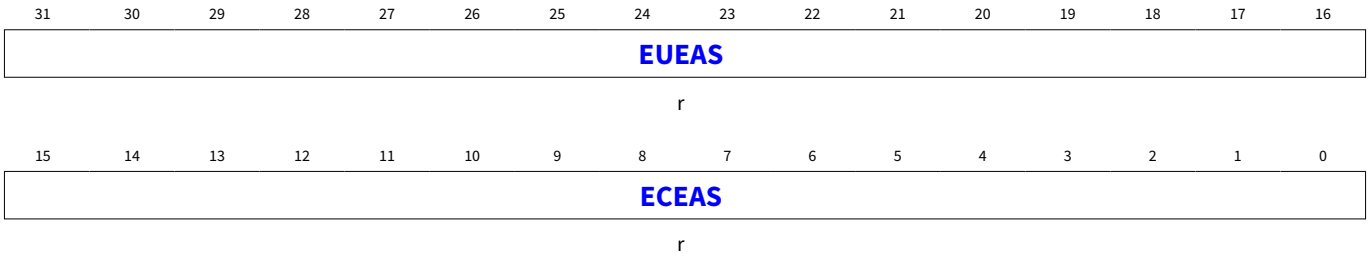
Field	Bits	Type	Description
EESRE	0	rw	**ECC Error Status Read Enable When this bit is set, based on the EMS field of this register, the Descriptor Cache memory's error status values is captured as follows: - The correctable and uncorrectable error count values are captured in the ECC_Err_Cntr_Status register** - The address locations of correctable and uncorrectable errors are captured in the ECC_Err_Addr_Status register. Hardware resets this bit when all the status values are captured in the ECC_Err_Cntr_Status and ECC_Err_Addr_Status registers. Values: - 0x0 (DISABLE): Descriptor Cache ECC Error Status Read is disabled - 0x1 (ENABLE): Descriptor Cache ECC Error Status Read is enabled
EMS	3:1	rw	**ECC Memory Selection When EESRE bit of this register is set, this field indicates which memory's error status value to be read** The memory selection encoding is as follows: Values: - 0x5 (DCACHE_MEM): DMA DCACHE memory
CCES	4	rw	**Clear Correctable Error Status When this bit is set along with EESRE bit of this register, based on the EMS field of this register, the Descriptor Cache memory's correctable error address and correctable error count values are cleared upon reading** Hardware resets this bit when all the error status values are cleared. Values: - 0x0 (INACTIVE): Clear Correctable Error Status not detected - 0x1 (ACTIVE): Clear Correctable Error Status detected
CUES	5	rw	**Clear Uncorrectable Error Status When this bit is set along with EESRE bit of this register, based on the EMS field of this register, the Descriptor Cache memory's uncorrectable error address and uncorrectable error count values are cleared upon reading** Hardware resets this bit when all the error status values are cleared. Values: - 0x0 (INACTIVE): Clear Uncorrectable Error Status not detected - 0x1 (ACTIVE): Clear Uncorrectable Error Status detected
0	31:6	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.677 ECC Err Addr Status

This register provides the Descriptor Cache memory addresses for the correctable and uncorrectable errors.

ECC_Error_Address_Status — Offset address: $1E2D4_H$

ECC Err Addr Status — Kernel Reset value: $0000\ 0000_H$



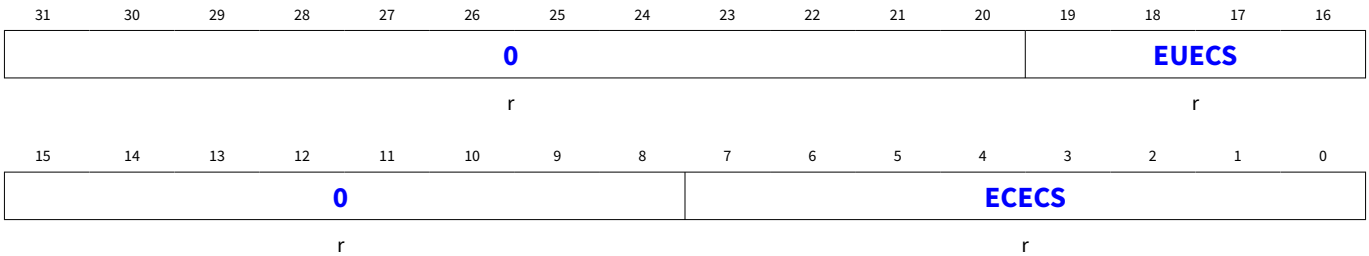
Field	Bits	Type	Description
ECEAS	15:0	r	**DCACHE Memory ECC Correctable Error Address Status Based on the EMS field of ECC_Err_Sts_Rctl register, this field holds the Descriptor Memory’s address locations for which a correctable error is detected** When EEAO bit of ECC_Control register is set, this field holds the last valid address of memory for which correctable error or address mismatch is detected. When EEAO bit of ECC_Control register is reset, this field holds the first address of the memory for which correctable error is detected.
EUEAS	31:16	r	**DCACHE Memory ECC Uncorrectable Error Address Status** Based on the EMS field of ECC_Err_Sts_Rctl register, this field holds the Descriptor Cache memory's address locations for which an uncorrectable error or address mismatch is detected. When EEAO bit of ECC_Control register is set, this field holds the last valid address of memory for which either an uncorrectable error or an address mismatch is detected. When EEAO bit of ECC_Control register is reset, this field holds the first address of the memory for which either an uncorrectable error or address mismatch is detected.

14.6.678 ECC Err Cntr Status

This register provides the Descriptor Cache memory ECC Error Count for the correctable and uncorrectable errors.

ECC_Error_Count_Status Offset address: $1E2D8_H$

ECC Err Cntr Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ECECS	7:0	r	**DCACHE Memory ECC Correctable Error Counter Status Based on the EMS field of ECC_Err_Sts_Rctl register, this field holds the Descriptor Cache memory's correctable error count value**

(table continues...)

(continued)

Field	Bits	Type	Description
EUECS	19:16	r	**DCACHE Memory ECC Uncorrectable Error Counter Status Based on the EMS field of ECC_Err_Sts_Rctl register, this field holds the Descriptor Cache memory's uncorrectable error count value**
0	15:8, 31:20	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.679 DPP Control

The DPP_Control establishes the operating mode of Data Parity protection and error injection for Ethernet Bridge, AXI Master and AXI Slave blocks.

DPP_Control Offset address: $1E2E0_H$

DPP Control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
DDPP	0	rw	**Disable Data path Parity Protection for Ethernet Bridge When set to 0, enables the parity protection for XGMAC datapath by generating and checking the parity on XGMAC datapath** When set to 1, disables the parity protection for XGMAC datapath. Values: - 0x0 (DISABLE): Data path Parity Protection is enabled - 0x1 (ENABLE): Data path Parity Protection is disabled
OPE	1	rw	**Odd Parity Enable for Ethernet Bridge When set to 1, enables odd parity protection on all the external interfaces** When set to 0, enables even parity protection on all the external interfaces. OPE default value (up on reset) is based on the DWCXG_ASP_PPE_ODD parameter, which checks if external interface parity should be odd or even). Values: - 0x0 (DISABLE): Odd Parity is disabled - 0x1 (ENABLE): Odd Parity is enabled

(table continues...)

(continued)

Field	Bits	Type	Description
ESPI	2	rw	**Enable Parity on Slave Interface port When set to 1, enables the parity check for the slave interface ports and disables the internal parity generation for the input slave data port (axi/apb/mci slave port)** When set to 0, disables the parity check for the slave interface ports and enables the internal parity generation for the input slave data port. Values: - 0x0 (DISABLE): Parity on Slave Interface port is disabled - 0x1 (ENABLE): Parity on Slave Interface port is enabled
IPEAT	4	rw	**Insert Parity Error in Application Transmit Interface Parity checker When set to 1, parity/data bit of first valid input parity/data of the Interface data parity checker is flipped** Based on the EIM/BLEI field of DPP_ECC_EIC register, software can corrupt any one bit of parity/data at Parity Checker (PC-e) at AXI Master interface. Hardware clears this bit after the respective parity bit is flipped. Values: - 0x0 (DISABLE): Insert Parity Error in Application Transmit Interface Parity checker is disabled - 0x1 (ENABLE): Insert Parity Error in Application Transmit Interface Parity checker is enabled
IPEDC	5	rw	**Insert Parity Error in Descriptor Cache data path Parity checker When set to 1, parity/data bit of first valid input parity/data of the Descriptor Cache parity checker (or at PC-desc) is flipped** Based on the EIM/BLEI field of DPP_ECC_EIC register, software can corrupt any one bit of parity/data. Hardware clears this bit after the respective parity bit is flipped. Values: - 0x0 (DISABLE): Insert Parity Error in EDMA Descriptor Cache (use different memory with TSO or TSO feature is disabled) write data path Parity checker is disabled - 0x1 (ENABLE): Insert Parity Error in EDMA Descriptor Cache (use different memory with TSO or TSO feature is disabled) write data path Parity Checker is enabled.
IPEAR	12	rw	**Insert Parity error in Insert Parity Error in Application Receive interface data path Parity Checker When set to 1, parity/data bit of first valid input parity/data of Application Receive Interface Parity Checker (PC-a) at AXI Master interface is flipped** Based on the EIM/BLEI field of DPP_ECC_EIC register, software can corrupt any one bit of parity/data. Hardware clears this bit after the respective parity bit is flipped. Values: - 0x0 (DISABLE): Insert Parity error in Application Receive interface data path Parity checker is disabled - 0x1 (ENABLE): Insert Parity error in Application Receive interface data path Parity checker is enabled

(table continues...)

(continued)

Field	Bits	Type	Description
IPECW	15	rw	**Insert Parity Error in CSR Write data path Parity Checker When set to 1, parity/data bit of first valid input parity/data of the CSR write data interface is flipped** When EPSI bit of DPP_Control register is set and this bit is set, parity/data bit of first valid input parity/data of the input slave parity ports (or at PC-axi) is flipped. Based on the EIM/BLEI field of DPP_ECC_EIC register, software can corrupt any one bit of parity/data. Hardware clears this bit after the respective parity bit is flipped. Values: - 0x0 (DISABLE): Insert Parity error in CSR Write data path Parity checker is disabled - 0x1 (ENABLE): Insert Parity error in CSR Write data path Parity checker is enabled
IPEASR	16	rw	**Insert Parity Error in AXI Slave Read data path Parity Checker When set to 1, parity/data bit of first valid input parity/data of the AXI Slave read data interface is flipped** Based on the EIM/BLEI field of DPP_ECC_EIC register, software can corrupt any one bit of parity/data. Hardware clears this bit after the respective parity bit is flipped. Values: - 0x0 (DISABLE): Insert Parity error in AXI Slave Read data path Parity checker is disabled - 0x1 (ENABLE): Insert Parity error in AXI Slave Read data path Parity checker is enabled
0	3, 11:6, 14:13, 31:17	r	**Reserved Field** Read as 0; should be written with 0.

14.6.680 DPP ECC EIC

The DPP_ECC_EIC establishes the operating mode of ETHBR ECC/DPP error injection.

DPP_ECC_Error_Injection_Control Offset address: $1E2E4_H$

DPP ECC EIC Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0								BLEI							
r								rw							

Field	Bits	Type	Description
BLEI	7:0	rw	**Bit Location of error injection This field indicates the bit location of DPP/ECC error injection, determination of error in Parity/ECC bits or Data (being protected) depends on the Error Injection Mode (EIM field)** Depending on the interface being used for error injection not all bits of this field are valid. Example, for error injection on a 64-bit data interface this field should be programmed to a value between 63 and 0. In case of 2-bit error injection bit 0 is always included in error injection and this field should represent the second bit selection for error injection. If the second bit is programed at bit 0 when 2-bit error injection is enabled, DUT only insert 1-bit error at bit 0.
EIM	16	rw	**Error Injection Mode When it set to 0, indicate error injection on data; When it set to 1, indicate error injection on ECC/Parity bits (need to check the address error injection mode is disabled)**
0	15:8, 31:17	r	**Reserved Fields** Read as 0; should be written with 0.

14.6.681 DMA Mode

The Bus Mode register establishes the bus operating modes for the DMA.

DMA_Mode Offset address: $1F000_H$

DMA Mode Kernel Reset value: $0000\ 0000_H$

r		rw		r			rw	r		rw	rw	r			rw

Field	Bits	Type	Description
SWR	0	rw	**Software Reset** When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all active clock domains. Before reprogramming any DWC_xgmac register, read a value of 0 from this bit. Note: The reset operation is complete only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock.

(table continues...)

(continued)

Field	Bits	Type	Description
TDRP	4	rw	**Tx Descriptor Read Priority** This bit controls the arbitration priority of descriptor fetches from the local cache when simultaneous requests are generated from RxDMA and TxDMA channels. By default, when this bit is 0, the RxDMA requests get higher priority. When this bit is set to 1, TxDMA descriptor fetches are serviced first by the arbiter before the RxDMA requests.
TMRP	5	rw	**Reserved**
DSPW	8	rw	**Descriptor Posted Write** - 0: By default, all Rx DMA descriptor writes are non-posted and any Rx interrupt generation mechanism can be used, that is, Descriptor IOC, Watchdog timer, Byte Counter based or any combination of these. - 1: All Rx DMA data and descriptor writes are posted and Descriptor IOC based Rx interrupt generation does not function properly and must not be used. Only Watchdog timer, Byte Counter based or any combination of these Rx interrupt generation mechanisms must be used. The Tx/Rx DMA Descriptor IOC based Tx/Rx interrupt generation mechanism does not function properly and must not be used.
INTM	13:12	rw	**Interrupt Mode** This field controls the behavior of the interrupt signal (sbd_intr_o, sbd_perch_tx_intr_o, sbd_perch_rx_intr_o) outputs for packet transfer completion events in TxDMA and RxDMA. - 00: sbd_perch_* are pulse signals for each completion events. sbd_intr_o is also asserted and cleared only when software clears the corresponding RI/TI status bits. - 01: sbd_perch_* are level signals asserted on the corresponding event and de-asserted when the software clears the corresponding RI/TI status bits. The sbd_intr_o is not asserted for these packet transfer completion events. - 10: sbd_perch_* are level signals asserted on the corresponding event and de-asserted when the software clears the corresponding RI/TI status bits. However, the signal is asserted again if the same event occurred again before it was cleared. The sbd_intr_o is not asserted for these packet transfer completion events. - 11: Reserved For more details see Table, "DWC_xgmac Transfer Complete Interrupt Behavior"
0	3:1, 7:6, 11:9, 31:14	r	**Reserved** Read as 0; should be written with 0.

14.6.682 DMA SysBus Mode

The System Bus mode register controls the behavior of the AXI master. It mainly controls burst splitting and number of outstanding requests.

DMA_SysBus_Mode Offset address: $1F004_H$

DMA SysBus Mode Kernel Reset value: $0101\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EN_LPI	LPI_XIT_PKT	ONEKBBE	AAL	0	AALE	0		BLEN256	BLEN128	BLEN64	BLEN32	BLEN16	BLEN8	BLEN4	UBL
rw	rw	rw	rw	r	rw	r		rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
UBL	0	rw	**AXI Undefined Burst Length** - 1: The AXI master can perform burst transfers that are equal to or less than the maximum allowed burst length programmed in Bits[7:4]. - 0: The AXI master performs one of the following burst transfers: -- Burst transfers of fixed burst lengths as indicated by the BLEN256, BLEN128, BLEN64, BLEN32, BLEN16, BLEN8, or BLEN4 field -- Burst transfers of length 1 When this bit is set and no BLEN bit is set, the AXI master performs bursts transfers of any length upto 16.
BLEN4	1	rw	**AXI Burst Length 4** When this bit and the UBL bit is set to 0, the AXI master can select a burst length of 4 on the AXI interface. When the UBL bit is set to 1, setting this bit has no effect.
BLEN8	2	rw	**AXI Burst Length 8** When this bit and the UBL bit is set to 0, the AXI master can select a burst length of 8 on the AXI interface. When the UBL bit is set to 1, setting this bit has no effect.
BLEN16	3	rw	**AXI Burst Length 16** When this bit and the UBL bit is set to 0, the AXI master can select a burst length of 16 on the AXI interface. When UBL is set to 1, this bit has no effect as the AXI master can always select a burst length up to 16 on the AXI interface.
BLEN32	4	rw	**AXI Burst Length 32** When this bit is set to 1, the AXI master can select a burst length of 32 on the AXI interface.
BLEN64	5	rw	**AXI Burst Length 64** When this bit is set to 1, the AXI master can select a burst length of 64 on the AXI interface.
BLEN128	6	rw	**AXI Burst Length 128** When this bit is set to 1, the AXI master can select a burst length of 128 on the AXI interface.
BLEN256	7	rw	**AXI Burst Length 256** When this bit is set to 1, the AXI master can select a burst length of 256 on the AXI interface.

(table continues...)

(continued)

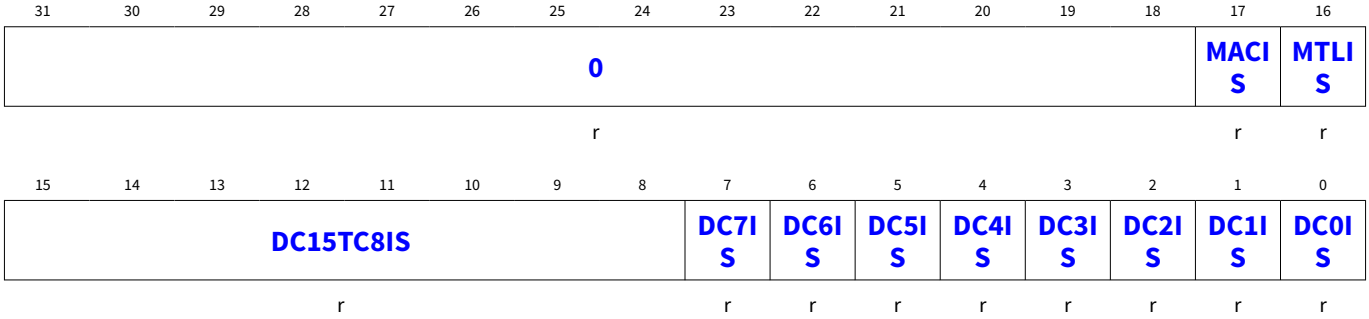
Field	Bits	Type	Description
AALE	10	rw	**Automatic AXI LPI enable** - 1: Enables the AXI master to enter into LPI state when there is no activity in DWC_xgmac for the number of system clock cycles programmed in the LPIEI field of AXI_LPI_Entry_Interval register.
AAL	12	rw	**Address-Aligned Beats** When this bit is set to 1, the AXI master performs address-aligned burst transfers on Read and Write channels.
ONEKBBE	13	rw	**1 KB Boundary Crossing Enable for the AXI Master** - 1: The burst transfers performed by the AXI master do not cross 1 KB boundary. - 0: The burst transfers performed by the AXI master do not cross 4 KB boundary.
LPI_XIT_PKT	14	rw	**Unlock on Magic Packet or Remote Wake-Up Packet** - 1: Enables the AXI master to come out of the LPI mode only when the magic packet or remote wake-up packet is received. - 0: Enables the AXI master to come out of the LPI mode when any packet is received.
EN_LPI	15	rw	**Enable Low Power Interface (LPI)** - 1: Enables the LPI mode supported by the AXI interface and accepts the LPI request from the AXI System Clock controller. - 0: Disables the LPI mode and always denies the LPI request from the AXI System Clock controller.
RD_OSR_LMT	20:16	rw	**AXI Maximum Read Outstanding Request Limit** This value limits the maximum outstanding request on the AXI read interface. Maximum outstanding requests = RD_OSR_LMT + 1
WR_OSR_LMT	28:24	rw	**AXI Maximum Write Outstanding Request Limit** This value limits the maximum outstanding request on the AXI write interface. Maximum outstanding requests = WR_OSR_LMT + 1
0	9:8, 11, 23:21, 31:29	r	**Reserved** Read as 0; should be written with 0.

14.6.683 DMA Interrupt Status

The application reads this Interrupt Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC.

DMA_Interrupt_Status Offset address: $1F008_H$

DMA Interrupt Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DC0IS	0	r	**DMA Channel 0 Interrupt Status** This bit indicates an interrupt event in DMA Channel 0. To reset this bit to 1'b0, the software must read the corresponding register in DMA Channel 0 to get the exact cause of the interrupt and clear its source.
DC1IS	1	r	**DMA Channel 1 Interrupt Status** This bit indicates an interrupt event in DMA Channel 1. To reset this bit to 1'b0, the software must read the corresponding register in DMA Channel 1 to get the exact cause of the interrupt and clear its source.
DC2IS	2	r	**DMA Channel 2 Interrupt Status** This bit indicates an interrupt event in DMA Channel 2. To reset this bit to 1'b0, the software must read the corresponding register in DMA Channel 2 to get the exact cause of the interrupt and clear its source.
DC3IS	3	r	**DMA Channel 3 Interrupt Status** This bit indicates an interrupt event in DMA Channel 3. To reset this bit to 1'b0, the software must read the corresponding register in DMA Channel 3 to get the exact cause of the interrupt and clear its source.
DC4IS	4	r	**DMA Channel 4 Interrupt Status** This bit indicates an interrupt event in DMA Channel 4. To reset this bit to 1'b0, the software must read the corresponding register in DMA Channel 4 to get the exact cause of the interrupt and clear its source.
DC5IS	5	r	**DMA Channel 5 Interrupt Status** This bit indicates an interrupt event in DMA Channel 5. To reset this bit to 1'b0, the software must read the corresponding register in DMA Channel 5 to get the exact cause of the interrupt and clear its source.
DC6IS	6	r	**DMA Channel 6 Interrupt Status** This bit indicates an interrupt event in DMA Channel 6. To reset this bit to 1'b0, the software must read the corresponding register in DMA Channel 6 to get the exact cause of the interrupt and clear its source.
DC7IS	7	r	**DMA Channel 7 Interrupt Status** This bit indicates an interrupt event in DMA Channel 7. To reset this bit to 1'b0, the software must read the corresponding register in DMA Channel 7 to get the exact cause of the interrupt and clear its source.
DC15TC8IS	15:8	r	**DMA Channel 15 Interrupt Status to DMA Channel 8 Interrupt Status** To reset a bit to 1'b0, the software must read the Channel Status register in the corresponding DMA Channel (15 to 8) to get the exact cause of the interrupt and clear its source.

(table continues...)

(continued)

Field	Bits	Type	Description
MTLIS	16	r	**MTL Interrupt Status** This bit indicates an interrupt event in the MTL. To reset this bit to 1'b0, the software must read the corresponding register in the MTL to get the exact cause of the interrupt and clear its source.
MACIS	17	r	**MAC Interrupt Status** This bit indicates an interrupt event in the MAC. To reset this bit to 1'b0, the software must read the corresponding register in the MAC to get the exact cause of the interrupt and clear its source.
0	31:18	r	**Reserved** Read as 0; should be written with 0.

14.6.684 AXI Tx AR ACE Control

This register is used to control the AXI4 Cache Coherency Signals for read transactions by all the Transmit DMA channels. The following signals of the AXI4 interface are driven with different values as programmed for corresponding type (descriptor, buffer1, buffer2) of access.

- AXI Master read control channel's cache type
- AXI Master read control channel's Domain indicator signal

AXI_Tx_AR_ACE_Control Offset address: $1F010_H$

AXI Tx AR ACE Control Kernel Reset value: $0000\ 0000_H$

THD	21:20	rw	**Transmit DMA First Packet Buffer** This field is used to drive ardomain_o[1:0] signal when Transmit DMA is accessing First Buffer of the Packet (First valid buffer with FD being set in the TDES3 of the Descriptor).
0	7:6, 15:14, 31:22	r	**Reserved** Read as 0; should be written with 0.

14.6.685 AXI Rx AW ACE Control

This register is used to control the Cache Coherency Signals of the AXI4-ACE Lite on the Receive DMA. The programmable controllability is supported on the following signals of the AXI Write channel.

- AXI Master write control channel's cache type
- AXI Master write control channel's Domain indicator signal

AXI_Rx_AW_ACE_Control Offset address: $1F018_H$

AXI Rx AW ACE Control Kernel Reset value: $0000\ 0000_H$

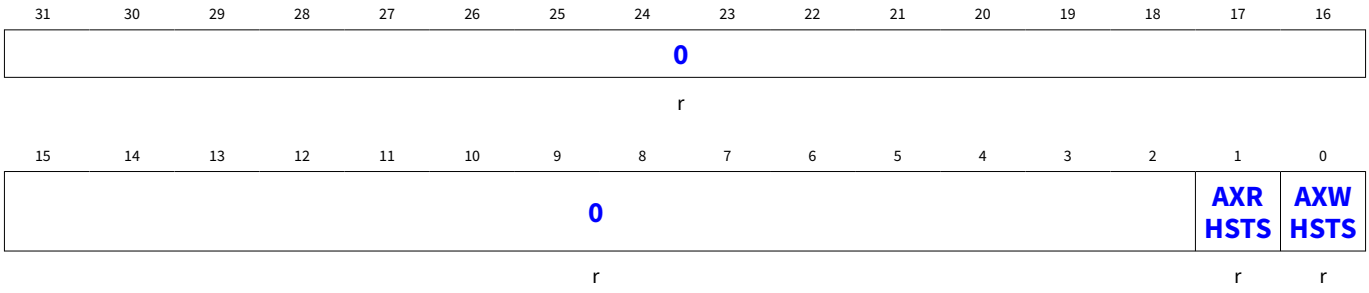
14.6.687 DMA Debug Status0

The Debug Status 0 register gives the Receive and Transmit process status for DMA Channel 0 - Channel 2 for debugging purpose.

DMA_Debug_Status0 Offset address: $1F020_H$

DMA Debug Status0 Kernel Reset value: $0000\ 0000_H$



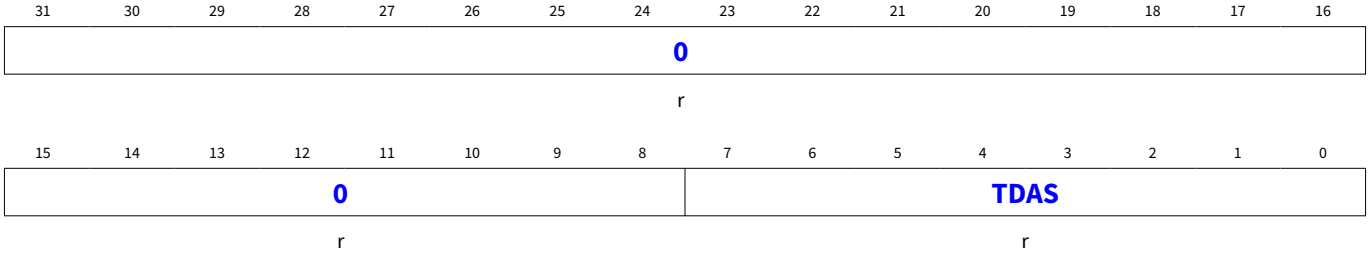
Field	Bits	Type	Description
AXWHSTS	0	r	**AXI Master Write Channel Status** - 1: Indicates that the write channel of the AXI master is active, and it is transferring data.
AXRHSTS	1	r	**AXI Master Read Channel Status** When high, this bit indicates that the read channel of the AXI master is active, and it is transferring the data.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

14.6.688 DMA Debug Status1

The Debug Status1 register gives the per Transmit DMA active status.

DMA_Debug_Status1 Offset address: $1F024_H$

DMA Debug Status1 Kernel Reset value: $0000\ 0000_H$



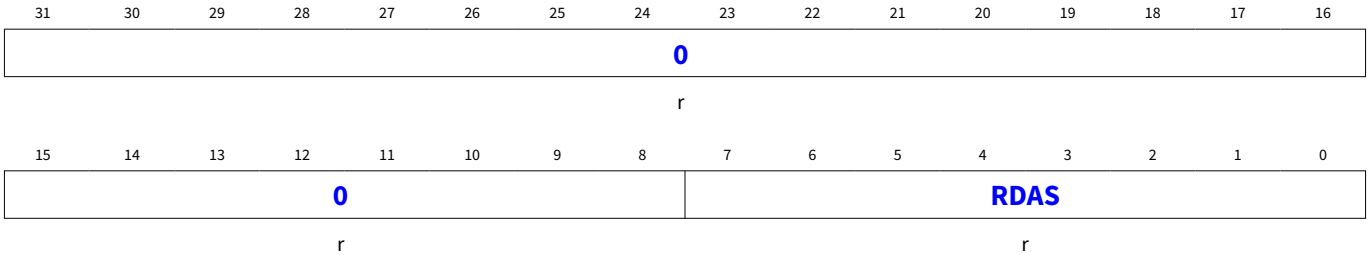
Field	Bits	Type	Description
TDAS	7:0	r	**Transmit DMA Active Status** - 1: The corresponding Transmit DMA FSMs are not idle, that is, the FSMs are actively processing the descriptors or packet data. - 0: The corresponding Transmit DMA FSMs are in idle state.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.689 DMA Debug Status3

The Debug Status3 register gives the per Receive DMA active status.

DMA_Debug_Status3 Offset address: $1F02C_H$

DMA Debug Status3 Kernel Reset value: $0000\ 0000_H$



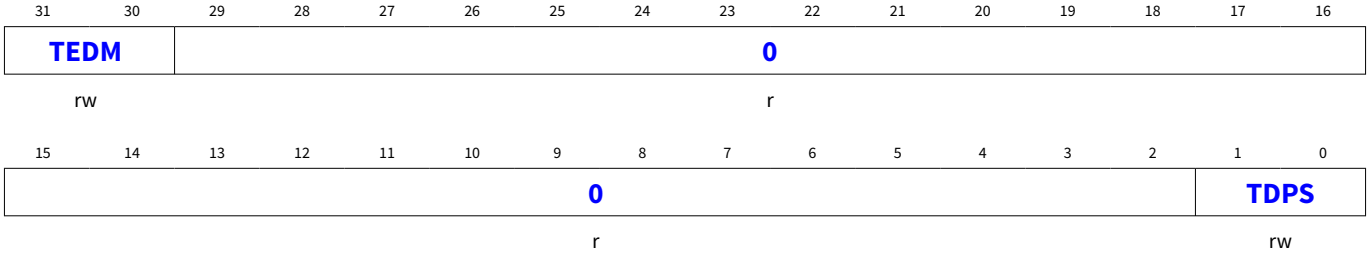
Field	Bits	Type	Description
RDAS	7:0	r	**Receive DMA Active Status** When the bit is set to 1, the corresponding Receive DMA FSMs are not idle, that is, actively processing the descriptors or packet data. When the bit is set to 0, the corresponding Receive DMA FSMs are in idle state.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.690 DMA Tx EDMA Control

The DMA_Tx_EDMA_Control register controls the sequence of all TxDMA operations with the DMA engine.

DMA_Tx_EDMA_Control Offset address: $1F040_H$

DMA Tx EDMA Control Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TDPS	1:0	rw	**Tx Descriptor Pre-fetch threshold Size** This field controls the threshold in the Descriptor cache after which the DMA starts pre-fetching the TxDMA descriptors. The DMA engine for all TxDMA channels initiate requests for the descriptor fetches as soon as the number of descriptors in the cache memory for that DMA channel, falls below or equal to the programmed threshold (each descriptor is 16 bytes). - 3'b000: Threshold of 0 descriptors. Descriptor pre-fetch is triggered only when cache is empty. - 3'b001: Threshold is 4 descriptors. Descriptor pre-fetch is triggered when 4 descriptors are left in the cache. - 3'b010: Threshold is 8 descriptors. Descriptor pre-fetch is triggered when 8 descriptors are left in the cache. - 3'b011: Threshold is 12 descriptors. Descriptor pre-fetch is triggered when 12 descriptors are left in the cache. - 3'b100: Threshold is 16 descriptors. Descriptor pre-fetch is triggered when 16 descriptors are left in the cache. - 3'b101: Threshold is 24 descriptors. Descriptor pre-fetch is triggered when 24 descriptors are left in the cache. - 3'b110 - 3'b111: Reserved. Note: Bit 2 is reserved and RO, that is TDPS value of 100 and 101 is not valid.

(table continues...)

(continued)

Field	Bits	Type	Description
TEDM	31:30	rw	**Tx DMA Mode** This field controls the sequence of descriptor and data transfers in the DMA engine for all TxDMA channels is as follows: - 2'b00: Default mode of DMA, in which all transfers are independently triggered and can occur in parallel. This gives you the best performance. Use the other modes only for debug purposes. - 2'b01: The value of TDPS field is ignored and only one Descriptor is fetched at a time from the System Memory. The next descriptor is fetched only after the current descriptor is accepted by Data Transfer Engine. The Data transfer, Descriptor close and the next descriptor fetch can still occur in parallel. - 2'b10: The value of TDPS field is ignored and only one Descriptor is fetched at a time from the System Memory. The next descriptor is fetched only after the data transfer corresponding to current descriptor is completed. The Descriptor close and the next descriptor fetch can still happen in parallel. - 2'b11: All operations are sequential. Descriptor is fetched, data transfer is completed, descriptor is closed and then only the next descriptor is fetched. The value of TDPS is ignored in this mode.
0	29:2	r	**Reserved** Read as 0; should be written with 0.

14.6.691 DMA Rx EDMA Control

The DMA_Rx_EDMA_Control register controls the sequence of all RxDMA operations with the DMA engine.

DMA_Rx_EDMA_Control Offset address: $1F044_H$

DMA Rx EDMA Control Kernel Reset value: $0000\ 0000_H$

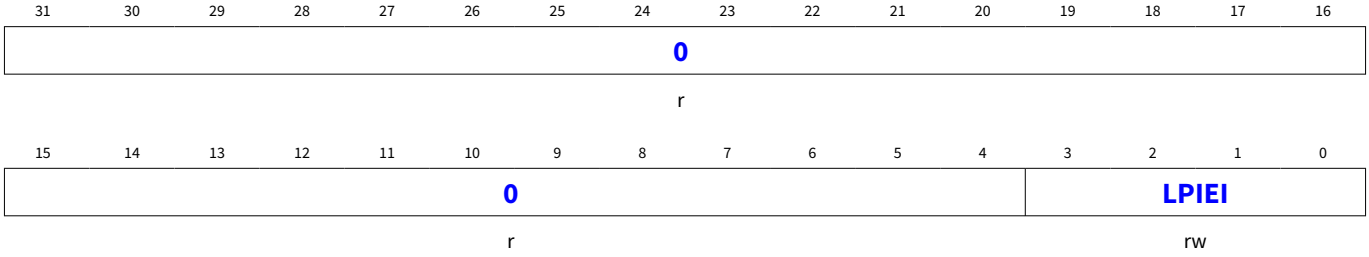
REDM	31:30	rw	**Rx DMA Mode** This field controls the sequence of descriptor and data transfers in the DMA engine for all RxDMA channels: - 2'b00: Default mode of DMA as explained in section 2.4.8 in which all transfers are independently triggered and can occur in parallel. This gives you the best performance. Use the other modes only for debug purposes. - 2'b01: The value of RDPS field is ignored and only 1 Descriptor is fetched at a time from the System Memory. The next descriptor is fetched only after the current descriptor is accepted by Data Transfer Engine. The Data transfer, Descriptor close and the next descriptor fetch can still happen in parallel. - 2'b10: The value of RDPS field is ignored and only 1 Descriptor is fetched at a time from the System Memory. The next descriptor is fetched only after the data transfer corresponding to current descriptor is completed. The Descriptor close and the next descriptor fetch can still happen in parallel. - 2'b11: All operations are sequential. Descriptor is fetched, data transfer is completed, descriptor is closed; then the next descriptor is fetched. The value of RDPS is ignored in this mode.
0	29:2	r	**Reserved** Read as 0; should be written with 0.

14.6.692 AXI LPI Entry Interval

This register is used to control the AXI LPI entry interval.

AXI_LPI_Entry_Interval Offset address: $1F050_H$

AXI LPI Entry Interval Kernel Reset value: $0000\ 0000_H$



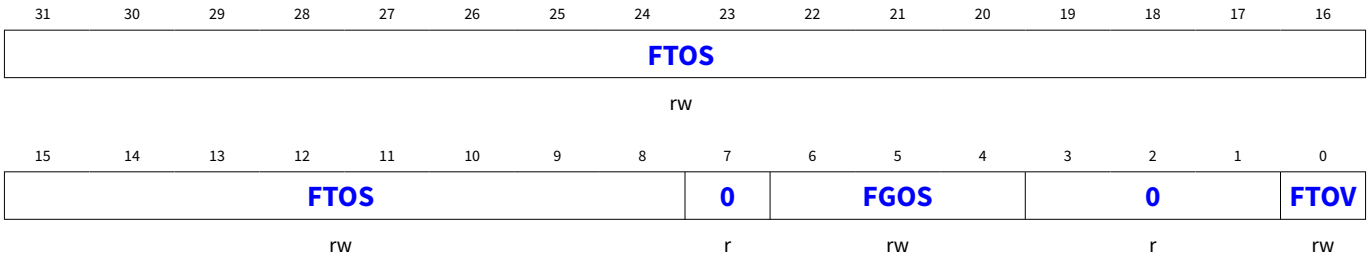
Field	Bits	Type	Description
LPIEI	3:0	rw	**LPI Entry Interval** This field contains the number of system clock cycles, multiplied by 256, to wait for an activity in DWC_xgmac to enter into the AXI low-power state, 0 indicates 256 clock cycles.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

14.6.693 DMA TBS CTRL0

This register is used to control the TBS0 attributes.

DMA_TBS_CTRL0 Offset address: $1F054_H$

DMA TBS CTRL0 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
FTOV	0	rw	**Fetch Time Offset 0 Valid** When set indicates the FTOS field is valid. When not set, indicates the Fetch Offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions. 0_B **INVALID**: Fetch Time Offset is invalid 1_B **VALID**: Fetch Time Offset is valid
FGOS	6:4	rw	**Fetch GSN Offset 0** The number of GSN slots that must be deducted from the Launch GSN to compute the Fetch GSN. Value valid only when FTOV is set.

(table continues...)

(continued)

Field	Bits	Type	Description
FTOS	31:8	rw	**Fetch Time Offset 0 - The value in units of 256 ns must be deducted from the Launch time to compute the Fetch Time** - Max value: 999,999,999 ns. Also, this must be smaller than CTR-1 value when ESTM mode is set, as this value is a modulo CTR value.
0	3:1, 7	r	**Reserved** Read as 0; should be written with 0.

14.6.694 DMA TBS CTRL1

This register is used to control the TBS1 attributes.

DMA_TBS_CTRL1 Offset address: $1F058_H$

DMA TBS CTRL1 Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

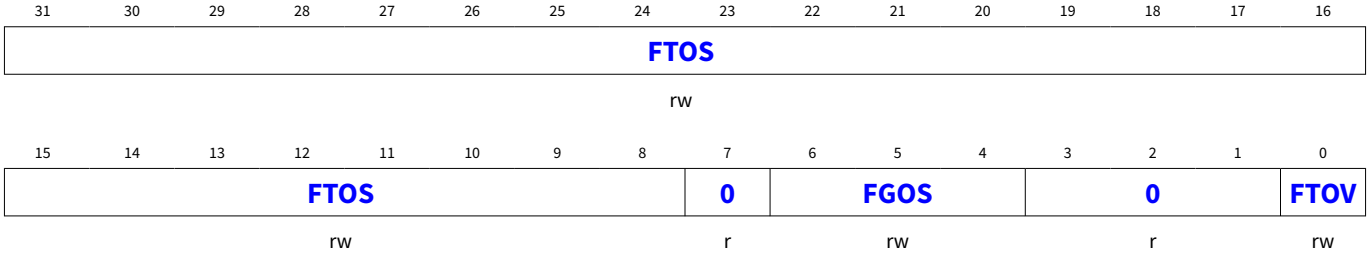
Field	Bits	Type	Description
FTOV	0	rw	**Fetch Time Offset 1 Valid** When set indicates the FTOS field is valid. When not set, indicates the Fetch Offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions. 0_B **INVALID**: Fetch Time Offset is invalid 1_B **VALID**: Fetch Time Offset is valid
FGOS	6:4	rw	**Fetch GSN Offset 1** The number of GSN slots that must be deducted from the Launch GSN to compute the Fetch GSN. Value valid only when FTOV is set.
FTOS	31:8	rw	**Fetch Time Offset 1 - The value in units of 256 ns, that must be deducted from the Launch time to compute the Fetch Time** - Max value: 999,999,999 ns. Also, this must be smaller than CTR-1 value when ESTM mode is set, as this value is a modulo CTR value.
0	3:1, 7	r	**Reserved** Read as 0; should be written with 0.

14.6.695 DMA TBS CTRL2

This register is used to control the TBS2 attributes.

DMA_TBS_CTRL2 Offset address: $1F05C_H$

DMA TBS CTRL2 Kernel Reset value: $0000\ 0000_H$



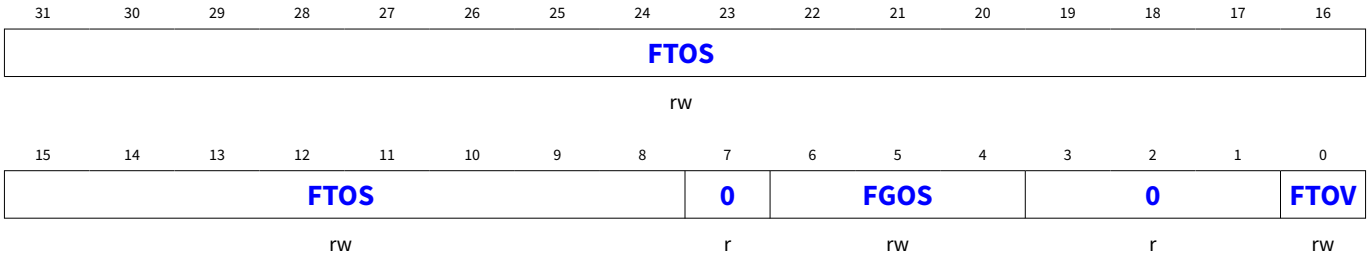
Field	Bits	Type	Description
FTOV	0	rw	**Fetch Time Offset 2 Valid** When set indicates the FTOS field is valid. When not set, indicates the Fetch Offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions. 0_B **INVALID**: Fetch Time Offset is invalid 1_B **VALID**: Fetch Time Offset is valid
FGOS	6:4	rw	**Fetch GSN Offset 2** The number of GSN slots that must be deducted from the Launch GSN to compute the Fetch GSN. Value valid only when FTOV is set.
FTOS	31:8	rw	**Fetch Time Offset 2** The value in units of 256 ns, that must be deducted from the Launch time to compute the Fetch Time. Max value: 999,999,999 ns. This must be smaller than CTR-1 value when ESTM mode is set, as this value is a modulo CTR value.
0	3:1, 7	r	**Reserved** Read as 0; should be written with 0.

14.6.696 DMA TBS CTRL3

This register is used to control the TBS3 attributes.

DMA_TBS_CTRL3 Offset address: $1F060_H$

DMA TBS CTRL3 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
FTOV	0	rw	**Fetch Time Offset 3 Valid** When set indicates the FTOS field is valid. When not set, indicates the Fetch Offset is not valid and the DMA engine can fetch the frames from host memory without any time restrictions. 0_B **INVALID**: Fetch Time Offset is invalid 1_B **VALID**: Fetch Time Offset is valid
FGOS	6:4	rw	**Fetch GSN Offset 3** The number GSN slots that must be deducted from the Launch GSN to compute the Fetch GSN. Value valid only when FTOV is set.
FTOS	31:8	rw	**Fetch Time Offset 3** The value in units of 256 ns, that has to be deducted from the Launch time to compute the Fetch Time. Max value: 999,999,999 ns. Also, this must be smaller than CTR-1 value when ESTM mode is set, as this value is a modulo CTR value.
0	3:1, 7	r	**Reserved** Read as 0; should be written with 0.

14.6.697 DMA Safety Interrupt Status

This register indicates summary (whether error occurred in DMA/MTL/MAC and correctable/uncorrectable) of the Automotive Safety related error interrupts.

DMA_Safety_Interrupt_Status Offset address: $1F064_H$

DMA Safety Interrupt Status Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

To get the exact cause of the interrupt, the application must read the DMA_ECC_Interrupt_Status register. 0_B **INACTIVE**: DMA ECC Correctable error Interrupt Status not detected 1_B **ACTIVE**: DMA ECC Correctable error Interrupt Status detected

(table continues...)

(continued)

Field	Bits	Type	Description
DEUIS	1	r	**DMA ECC Uncorrectable error Interrupt Status** This bit indicates an interrupt event in the DMA ECC safety feature. To get the exact cause of the interrupt, the application must read the DMA_ECC_Interrupt_Status register. 0_B **INACTIVE**: DMA ECC Uncorrectable error Interrupt Status not detected 1_B **ACTIVE**: DMA ECC Uncorrectable error Interrupt Status detected
AMCIS	2	r	**AXI Master interface Safety Correctable error Interrupt Status This bit indicates an interrupt event in the AXI safety feature** To get the exact cause of the interrupt, the application must read DMA_AM_Sfty_ECC_Intr_Sts. 0_B **INACTIVE**: AXI Master Interface Safety Correctable error Interrupt Status not detected 1_B **ACTIVE**: AXI Master Interface Safety Correctable error Interrupt Status detected
AMUIS	3	r	**AXI Master interface Safety Uncorrectable error Interrupt Status This bit indicates an interrupt event in the AXI safety feature** To get the exact cause of the interrupt, the application must read DMA_AM_Sfty_ECC_Intr_Sts and DMA_AM_Sfty_DPP_Intr_Sts. 0_B **INACTIVE**: AXI Master Interface Safety Uncorrectable error Interrupt Status not detected 1_B **ACTIVE**: AXI Master Interface Safety Uncorrectable error Interrupt Status detected
ASCIS	4	r	**AXI Slave interface Safety Correctable error Interrupt Status Indicates an interrupt event in the AXI safety feature** To get the cause of the interrupt, read the DMA_AS_Sfty_ECC_Intr_Sts register. 0_B **INACTIVE**: AXI Master Interface Safety Correctable error Interrupt Status not detected 1_B **ACTIVE**: AXI Master Interface Safety Correctable error Interrupt Status detected
ASUIS	5	r	**AXI Slave interface Safety Uncorrectable error Interrupt Status Indicates an interrupt event in the AXI safety feature** To get the cause of the interrupt, read the DMA_AS_Sfty_ECC_Intr_Sts and DMA_AS_Sfty_DPP_Intr_Sts. 0_B **INACTIVE**: AXI Master Interface Safety Uncorrectable error Interrupt Status not detected 1_B **ACTIVE**: AXI Master Interface Safety Uncorrectable error Interrupt Status detected
MSCIS	28	r	**MTL Safety Correctable error Interrupt Status** This bit indicates a correctable error interrupt event in MTL. To get exact cause of the interrupt, the software must read the MTL_Safety_Interrupt_Status register. 0_B **INACTIVE**: MTL Safety Correctable error Interrupt Status not detected 1_B **ACTIVE**: MTL Safety Correctable error Interrupt Status detected

(table continues...)

(continued)

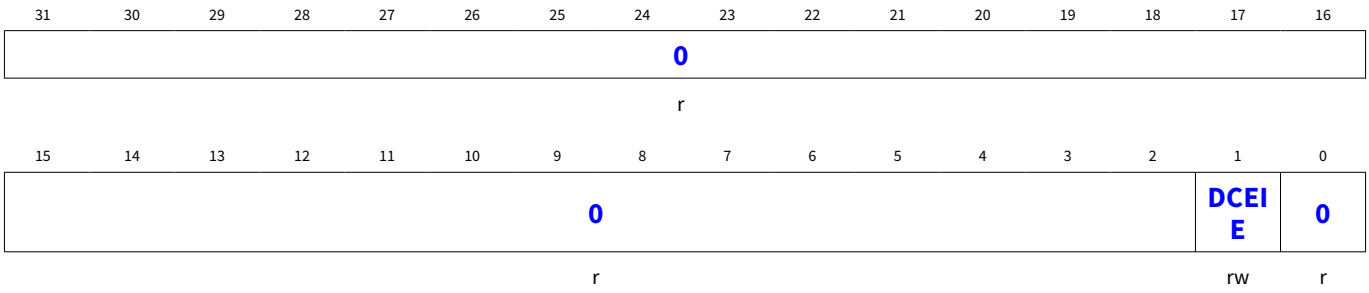
Field	Bits	Type	Description
MSUIS	29	r	**MTL Safety Unrecoverable error Interrupt Status** This bit indicates an uncorrectable error interrupt event in MTL. To get exact cause of the interrupt, the software must read the MTL_Safety_Interrupt_Status register. 0_B **INACTIVE**: MTL Safety Uncorrectable error Interrupt Status not detected 1_B **ACTIVE**: MTL Safety Uncorrectable error Interrupt Status detected
MCSIS	31	r	**MAC Safety Unrecoverable Interrupt Status** Indicates an unrecoverable Safety related Interrupt is set in the MAC module. When this bit is set, to get the cause of the safety interrupt in the MAC, read the MAC_DPP_FSM_Interrupt_Status and DMA_DPP_Interrupt_Status registers. 0_B **INACTIVE**: MAC Safety Uncorrectable Interrupt Status not detected 1_B **ACTIVE**: MAC Safety Uncorrectable Interrupt Status detected
0	27:6, 30	r	**Reserved** Read as 0; should be written with 0.

14.6.698 DMA ECC Interrupt enable

This register is used to enable the Automotive Safety related ECC error interrupt.

DMA_ECC_Interrupt_enable Offset address: $1F068_H$

DMA ECC Interrupt enable Kernel Reset value: $0000\ 0002_H$



Field	Bits	Type	Description
DCEIE	1	rw	**DCACHE memory Correctable Error Interrupt Enable** When set, generates an interrupt when a correctable error is detected at the DMA DCACHE memory interface. It is indicated in the DCES bit of DMA_ECC_Interrupt_Status register. When reset, this event does not generate an interrupt. 0_B **DISABLE**: Descriptor Cache Memory Correctable Error Interrupt is disabled 1_B **ENABLE**: Descriptor Cache Memory Correctable Error Interrupt is enabled
0	0, 31:2	r	**Reserved** Read as 0; should be written with 0.

14.6.699 DMA ECC Interrupt Status

This register indicates the Automotive Safety related ECC error interrupt status.

DMA_ECC_Interrupt_Status Offset address: $1F06C_H$

DMA ECC Interrupt Status Kernel Reset value: $0000\ 0000_H$

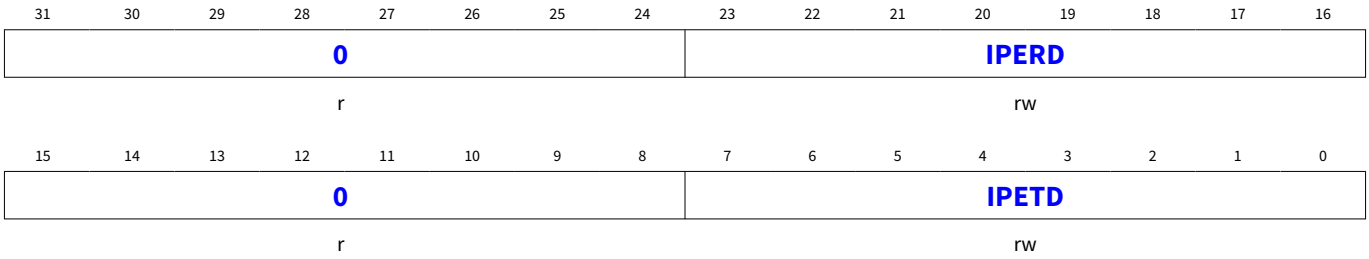
14.6.700 DMA DPP Control

The DMA_DPP_Control establishes the operating mode of Data Parity protection and error injection per channel in DMA.

DMA_DPP_Control Offset address: $1F070_H$

DMA DPP Control Kernel Reset value: $0000\ 0000_H$



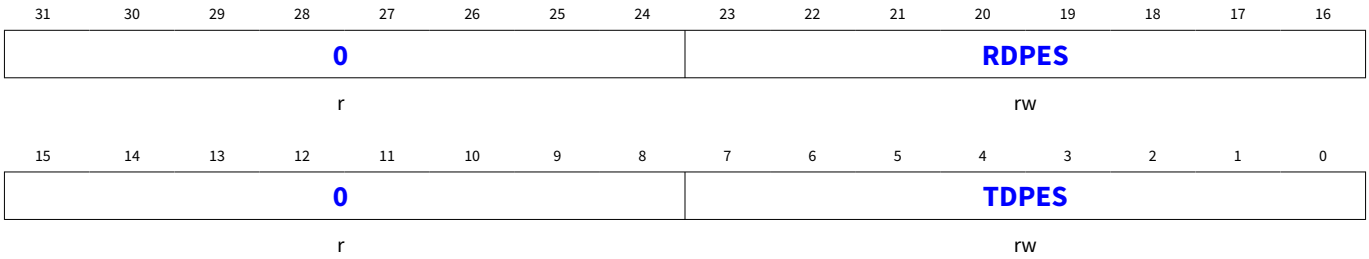
Field	Bits	Type	Description
IPETD	7:0	rw	**Insert Parity Error in DMA TD parity checker - 1: Parity/data bit of the first valid input parity/data of DMA Read Tx descriptor parity checker (or at PC1#td) is flipped** Based on the EIM/BLEI field of MTL_DPP_ECC_EIC register, software can corrupt any one bit of parity/data. DWC_xgmac clears this bit after the respective parity bit is flipped. 00_H **DISABLE**: Insert Parity Error in DMA TD Parity Checker is disabled 01_H **ENABLE**: Insert Parity Error in DMA TD Parity Checker is enabled **others,** Reserved
IPERD	23:16	rw	**Insert Parity Error in DMA RD parity checker - 1: Parity/data bit of the first valid input parity/data of DMA Read Rx descriptor parity checker (or at PC1#rd) is flipped** Based on the EIM/BLEI field of MTL_DPP_ECC_EIC register, software can corrupt any one bit of parity/data. DWC_xgmac clears this bit after the respective parity bit is flipped. 00_H **DISABLE**: Insert Parity Error in DMA RD Parity Checker is disabled 01_H **ENABLE**: Insert Parity Error in DMA RD Parity Checker is enabled **others,** Reserved
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

14.6.701 DMA DPP Interrupt Status

This register contains the status of Automotive Safety related Data Path Parity Errors per channel in DMA.

DMA_DPP_Interrupt_Status Offset address: $1F074_H$

DMA DPP Interrupt Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TDPES	7:0	rw	**Read Tx Descriptor Parity checker Error Status - 1: Indicates that a parity error is detected at the DMA Read Tx descriptor per channel parity checker (or at PC2#td) is flipped** It is cleared when written to 1. 00_H **INACTIVE**: Read Transmit Descriptor(Per Channel) Parity checker Error Status not detected 01_H **ACTIVE**: Read Transmit Descriptor(Per Channel) Parity checker Error Status detected **others,** Reserved
RDPES	23:16	rw	**Read Rx Descriptor Parity checker Error Status - 1: Indicates that a parity error is detected at the DMA Read Rx descriptor per channel parity checker (or at PC2#rd) is flipped** It is cleared when written to 1. 00_H **INACTIVE**: Read Receive Descriptor(Per Channel) Parity checker Error Status not detected 01_H **ACTIVE**: Read Receive Descriptor(Per Channel) Parity checker Error Status detected **others,** Reserved
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

14.6.702 DMA CH Ind Ctrl

This register is used to program Indirect Access DMA configuration registers.

DMA_CH_Ind_Ctrl Offset address: $1F080_H$

DMA CH Ind Ctrl Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0				AOFF				0		AUTO		0		CT	OB
r				rw				r		rw		r		rw	rw

Field	Bits	Type	Description
OB	0	rw	**Operation Busy** This bit is set along with a read or write command for initiating the indirect access to DMA_(#MSEL)_(#AOFF) register. This bit is reset when the read or write command to DMA_(#MSEL)_(#AOFF) register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into the DMA_(#MSEL)_(#AOFF) register. During a read operation, the data must be read from the DMA_CH_Ind_Data register, only after this bit is reset.

(table continues...)

(continued)

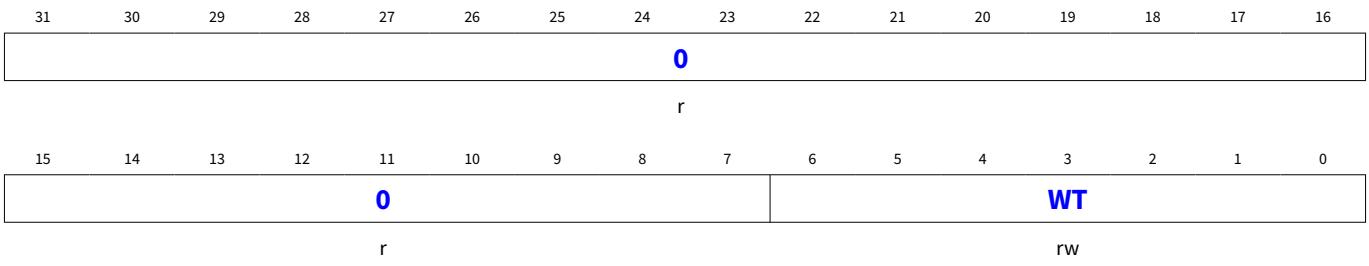
Field	Bits	Type	Description
CT	1	rw	**Command Type** This bit indicates if the current register access is a read or a write operation. - 1: Indicates a read operation. - 0: Indicates a write operation.
AUTO	5:4	rw	**Auto Increment - 00: No auto increment - 01: Auto increment MSEL only - 10: Auto increment AOFF only - 11: No auto increment**
AOFF	11:8	rw	**Address Offset This field selects the offset address of per DMA Channel registers specified by MSEL field** - 0000: CH0 - 0001: CH1 - ---- - 1111 : CH15 AOFF field is used in the indirect access of the DMA_(#MSEL)_(#AOFF) This field must be set along with initiation of read/write to the DMA_(#MSEL)_(#AOFF) register and must not be changed until the OB is reset.
MSEL	19:16	rw	**Mode Select** This field selects a group of identical registers. - 0000: DMA_CH(#i)_TxExtCfg registers - 0001-1111: reserved for future use MSEL field is used in the indirect access of the DMA_(#MSEL)_(#AOFF) This field must be set along with initiation of read/write to the DMA_(#MSEL)_(#AOFF) register and must not be changed until the OB is reset.
0	3:2, 7:6, 15:12, 31:20	r	**Reserved** Read as 0; should be written with 0.

14.6.703 DMA CH Ind Data

This register holds the read/write data for Indirect Access of the registers indicated by DMA_(#MSEL)_(#AOFF). During the read access, this field contains valid read data only after the OB bit is reset. During the write access, this field must be valid prior setting the OB bit in the DMA_CH_Ind_Data register. Once auto increment is set, application is allowed to write without setting OB bit of DMA_CH_Ind_Ctrl register.

DMA_CH_Ind_Data Offset address: $1F084_H$

DMA CH Ind Data Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
WT	6:0	rw	**Weights** This field contains the weights of the corresponding Tx DMA used for Weighted Round Robin Arbitration of Tx DMA Data Reads. The maximum value is 0x64.
0	31:7	r	**Reserved** Read as 0; should be written with 0.

14.6.704 DMA Channel j TxExtCfg

This register contains data related to per channel Tx weights used for Weighted Round Robin Arbitration of Tx DMA Data Reads.

DATA															
rw															

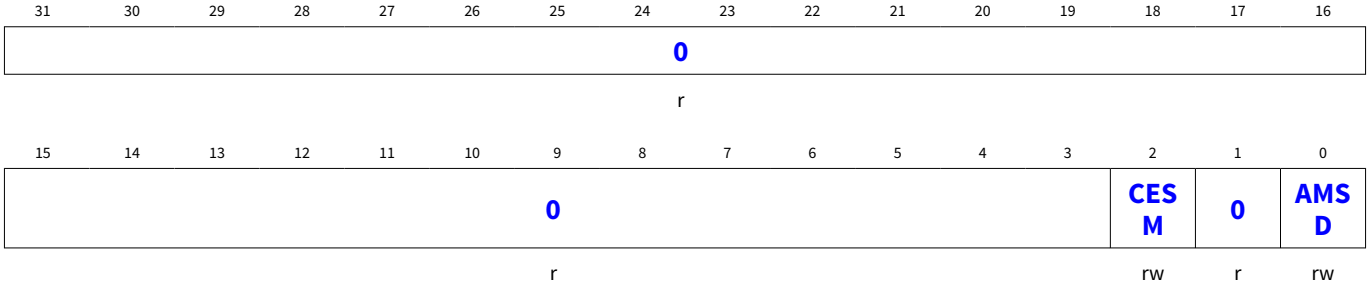
Field	Bits	Type	Description
DATA	31:0	rw	**Read or Write Data** This field contains data to read/write from DMA Safety indirect register. - Read access: This field contains valid read data after the OB bit in the DMA_Sfty_Ind_Data register is reset. - Write access: This field must be valid prior to setting the OB bit in the DMA_Sfty_Ind_Data register. When Auto Increment bit is set, the application can write new data without setting OB bit of DMA_Sfty_Ind_Data register.

14.6.714 DMA AM Sfty Ctrl

This register contains control signal for AXI Master interface safety.

DMA_AM_Sfty_Ctrl Offset address: $1F08C_H$

DMA AM Sfty Ctrl Kernel Reset value: $0000\ 0000_H$



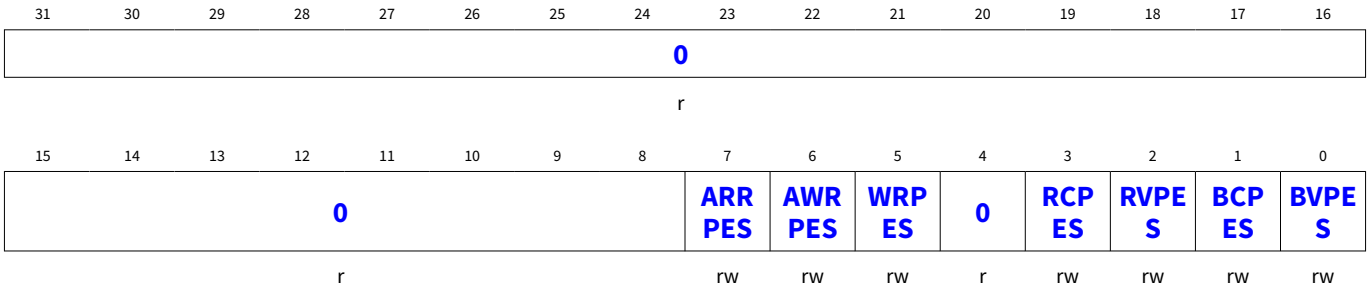
Field	Bits	Type	Description
AMSD	0	rw	**AXI Master Safety Disable - 1: Disables the safety features for all the channels of AXI Master Interface** - 0: Enables the safety features for all the channels of AXI Master Interface.
CESM	2	rw	**Clear Error Status for AXI Master Interface Safety - 1: AXI Master Interface Safety ECC uncorrectable and correctable error counters are cleared upon reading by application** The DWC_xgmac clears this bit when all the error counters are cleared.
0	1, 31:3	r	**Reserved** Read as 0; should be written with 0.

14.6.715 DMA AM Sfty DPP Intr Sts

This register contains the DPP interrupt status for AXI Master Interface safety.

DMA_AM_Sfty_DPP_Intr_Sts Offset address: $1F08C_H$

DMA AM Sfty DPP Intr Sts Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
BVPES	0	rw	**AXI Master Write Response Channel Valid Parity Error Status - 1: Indicates that a parity error is detected at the AXI Master Write Response channel valid signal**
BCPES	1	rw	**AXI Master Write Response channel Control Parity Error Status - 1: Indicates that a parity error is detected at the AXI Master Write Response channel control signals**
RVPES	2	rw	**AXI Master Read Data channel Valid Parity Error Status - 1: Indicates that a parity error is detected on the AXI Master Read Data channel valid signal**

(table continues...)

(continued)

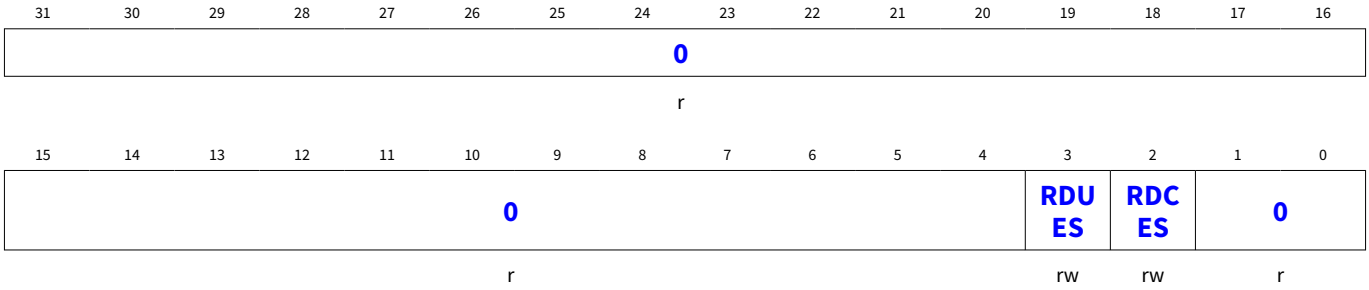
Field	Bits	Type	Description
RCPES	3	rw	**AXI Master Read Data channel Control Parity Error Status - 1: Indicates that a parity error is detected on the AXI Master Read Data channel control signals**
WRPES	5	rw	**AXI Master Write Data channel Ready Parity Error Status - 1: Indicates that a parity error is detected on AXI Master W channel Ready signal**
AWRPES	6	rw	**AXI Master Write Address channel Ready Parity Error Status - 1: Indicates that a parity error is detected on the AXI Master AW channel Ready signal**
ARRPES	7	rw	**AXI Master Read Address channel Ready Parity Error Status - 1: Indicates that a parity error is detected on the AXI Master Read Address channel Ready signal**
0	4, 31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.716 DMA AM Sfty ECC Intr Sts

This register contains the ECC interrupt status for the AXI Master Interface Safety.

DMA_AM_Sfty_ECC_Intr_Sts Offset address: $1F08C_H$

DMA AM Sfty ECC Intr Sts Kernel Reset value: $0000\ 0000_H$



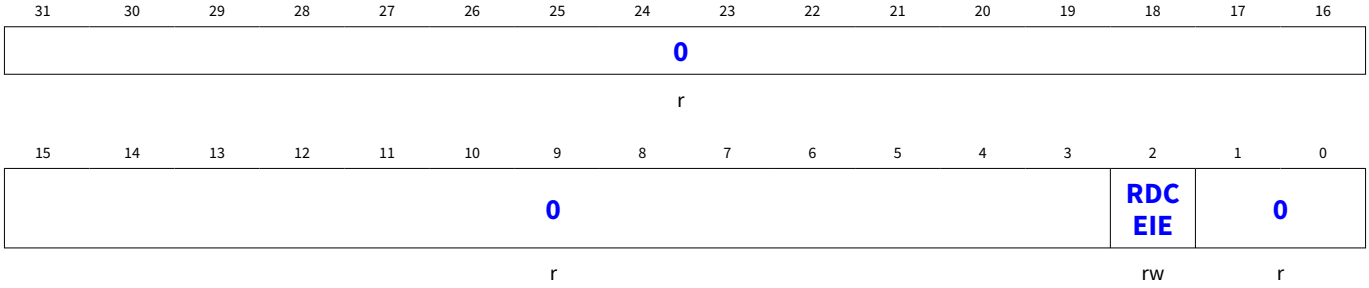
Field	Bits	Type	Description
RDCES	2	rw	**AXI Master Read Data channel data Correctable Error Status - 1: Indicates that a correctable error is detected at AXI Master Read Data channel data**
RDUES	3	rw	**AXI Master Read Data channel data Uncorrectable Error Status - 1: Indicates that an uncorrectable error is detected at AXI Master Read Data channel data**
0	1:0, 31:4	r	**Reserved** Read as 0; should be written with 0.

14.6.717 DMA AM Sfty Intr En

This register contains the interrupt enables for AXI Master Interface Safety.

DMA_AM_Sfty_Intr_En Offset address: $1F08C_H$

DMA AM Sfty Intr En Kernel Reset value: $0000\ 0000_H$



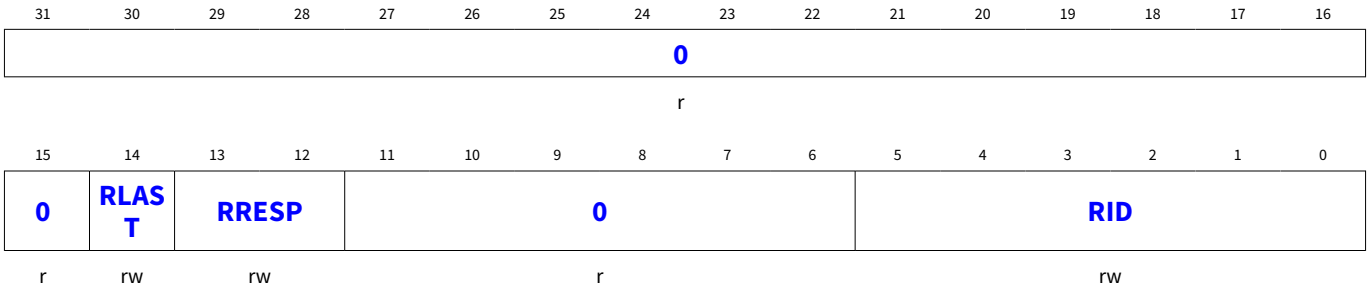
Field	Bits	Type	Description
RDCEIE	2	rw	**AXI Master Read Data channel Data Correctable Error Interrupt Enable - 1: DWC_xgmac generates an interrupt when a correctable error is detected in the AXI Master Read Data channel data and RDCES bit of DMA_AM_Sfty_ECC_Intr_Sts register is set** - 0: DWC_xgmac does not generate an interrupt when a correctable error is detected in the AXI Master Read Data channel data and RDCES bit of DMA_AM_Sfty_ECC_Intr_Sts register is set.
0	1:0, 31:3	r	**Reserved** Read as 0; should be written with 0.

14.6.718 DMA AM Sfty RDC Dbg Ctrl

This register contains the data to be driven on AXI Master Read Data channel control signals in Debug Error Injection mode.

DMA_AM_Sfty_RDC_Dbg_Ctrl Offset address: $1F08C_H$

DMA AM Sfty RDC Dbg Ctrl Kernel Reset value: $0000\ 0000_H$



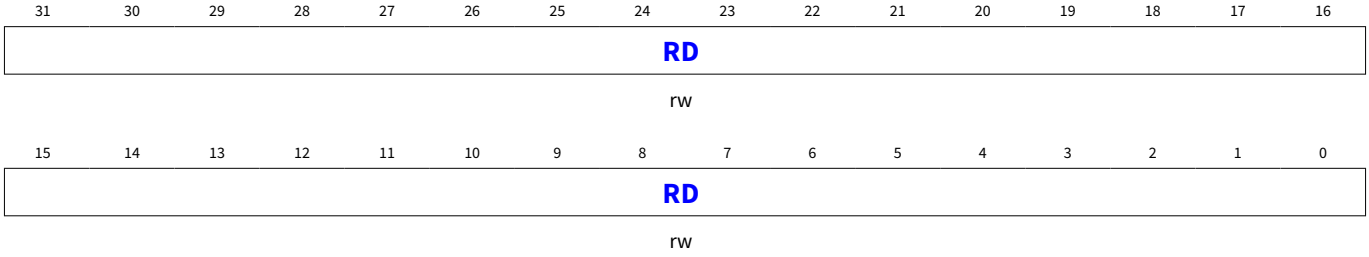
Field	Bits	Type	Description
RID	5:0	rw	**AXI Master Read Data channel RID Control Signal** This field contains the debug data to be driven on AXI Master RID signal.
RRESP	13:12	rw	**AXI Master Read Data channel RRESP Control Signal** This field contains the debug data to be driven on AXI Master RRESP signal.
RLAST	14	rw	**AXI Master Read Data channel RLAST Control Signal** This bit contains the debug data to be driven on AXI Master RLAST signal.
0	11:6, 31:15	r	**Reserved** Read as 0; should be written with 0.

14.6.719 DMA AM Sfty RDC Dbg Data

This register contains the data to be driven on AXI Master read data in Debug Error Injection mode.

DMA_AM_Sfty_RDC_Dbg_Data Offset address: $1F08C_H$

DMA AM Sfty RDC Dbg Data Kernel Reset value: $0000\ 0000_H$



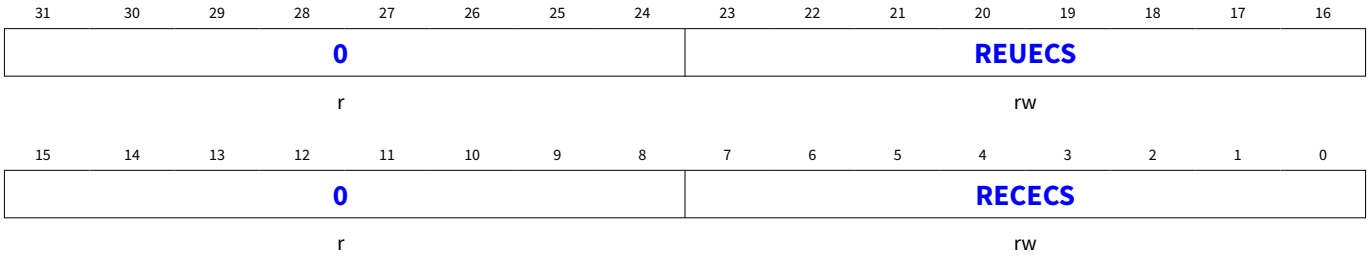
Field	Bits	Type	Description
RD	31:0	rw	**AXI Master Read Data channel Debug Data** This field contains the 32-bit debug data to be driven on AXI Master Read Data bus. The DAPS field of DMA_Sfty_Ind_Ctl register indicates which 32-bit word of read data bus this correspond to.

14.6.720 DMA AM Sfty RDC ECC Err Cntr Sts

This register contains the ECC Error counters for read data of AXI Master Interface safety.

DMA_AM_Sfty_RDC_ECC_Err_Cntr_Sts Offset address: $1F08C_H$

DMA AM Sfty RDC ECC Err Cntr Sts Kernel Reset value: $0000\ 0000_H$



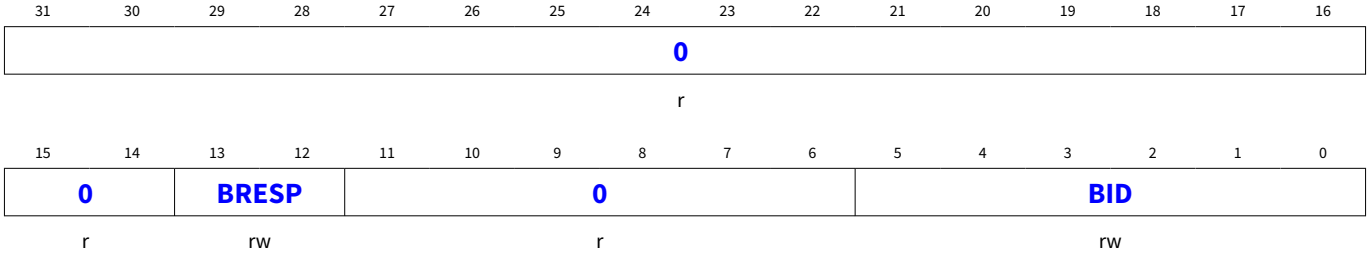
Field	Bits	Type	Description
RECECS	7:0	rw	**AXI Master Read Data channel ECC Correctable Error Counter** This field provides the number of ECC correctable errors detected in AXI Master Read Data channel. This field is cleared when the CESM bit is set to 1 and the application reads this field.
REUECS	23:16	rw	**AXI Master Read Data channel ECC Uncorrectable Error Counter** This field provides the number of ECC uncorrectable errors detected in AXI Master Read Data channel. This field is cleared when the CESM bit is set to 1 and the application reads this field.
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

14.6.721 DMA AM Sfty WRC Dbg Ctrl

This register contains the data to be driven on AXI Master write response channel control signals in Debug Error Injection mode.

DMA_AM_Sfty_WRC_Dbg_Ctrl Offset address: $1F08C_H$

DMA AM Sfty WRC Dbg Ctrl Kernel Reset value: $0000\ 0000_H$



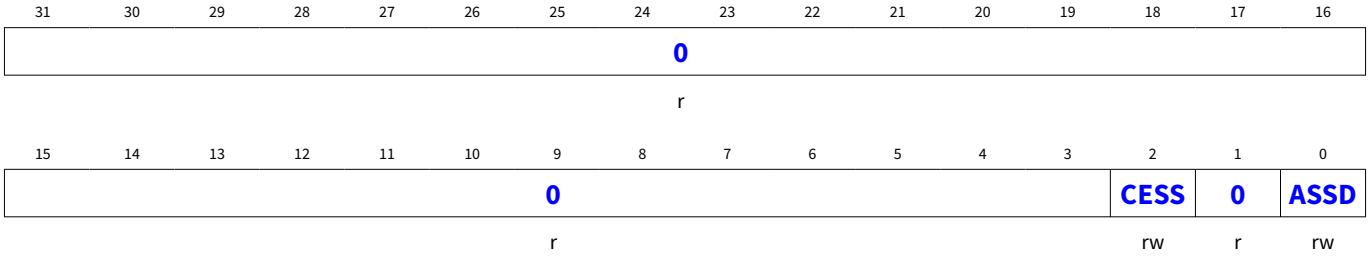
Field	Bits	Type	Description
BID	5:0	rw	**AXI Master Response Channel BID Control Signal** This field contains the debug data to be driven on AXI Master BID signal.
BRESP	13:12	rw	**AXI Master Response Channel BRESP Control Signal** This field contains the debug data to be driven on AXI Master BRESP signal.
0	11:6, 31:14	r	**Reserved** Read as 0; should be written with 0.

14.6.722 DMA AS Sfty Ctrl

This register contains control signal for AXI Slave interface safety module.

DMA_AS_Sfty_Ctrl Offset address: $1F08C_H$

DMA AS Sfty Ctrl Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ASSD	0	rw	**AXI Slave Safety Disable - 1: Disables the safety features for all the channels of AXI Slave Interface** - 0: Enables the safety features for all the channels of AXI Slave Interface.

(table continues...)

(continued)

Field	Bits	Type	Description
CESS	2	rw	**Clear Error Status for AXI Slave Interface Safety - 1: AXI Slave Interface Safety ECC uncorrectable and correctable error counters are cleared upon reading by application** The DWC_xgmac clears this bit when all the error counters are cleared.
0	1, 31:3	r	**Reserved** Read as 0; should be written with 0.

14.6.723 DMA AS Sfty DPP Intr Sts

This register contains the DPP interrupt status for AXI Slave Interface safety.

DMA_AS_Sfty_DPP_Intr_Sts Offset address: $1F08C_H$

DMA AS Sfty DPP Intr Sts Kernel Reset value: $0000\ 0000_H$

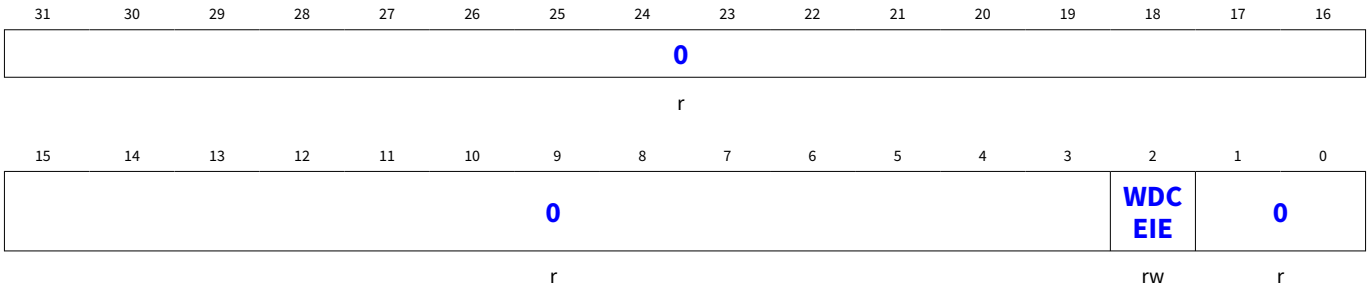
14.6.725 DMA AS Sfty Intr En

This register contains the interrupt enables for AXI Slave Interface Safety.

DMA_AS_Sfty_Intr_En Offset address: $1F08C_H$

DMA AS Sfty Intr En Kernel Reset value: $0000\ 0000_H$



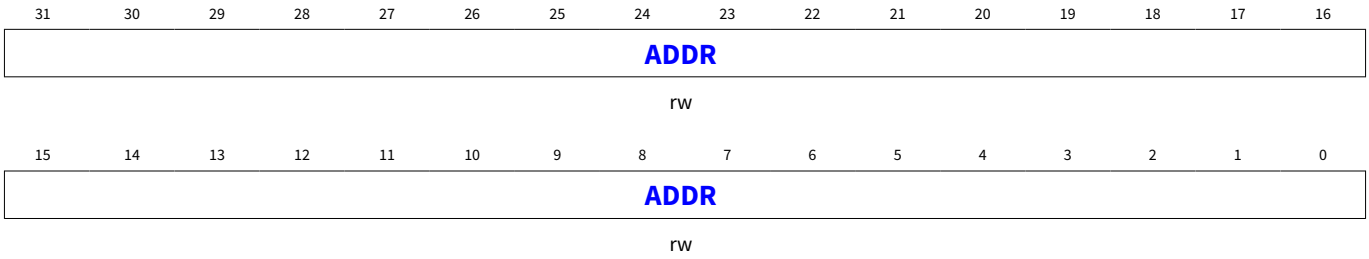
Field	Bits	Type	Description
WDCEIE	2	rw	**AXI Slave Write Data channel Data Correctable Error Interrupt Enable - 1: DWC_xgmac generates an interrupt when a correctable error is detected in the AXI Slave Write Data channel data and WDCES bit of DMA_AS_Sfty_ECC_Intr_Sts register is set** - 0: DWC_xgmac does not generate an interrupt when a correctable error is detected in the AXI Slave Write Data channel data and WDCES bit of DMA_AS_Sfty_ECC_Intr_Sts register is set.
0	1:0, 31:3	r	**Reserved** Read as 0; should be written with 0.

14.6.726 DMA AS Sfty RAC Dbg Addr

This register contains the data to be driven on address bus of AXI Slave read address channel in Debug Error Injection mode.

DMA_AS_Sfty_RAC_Dbg_Addr Offset address: $1F08C_H$

DMA AS Sfty RAC Dbg Addr Kernel Reset value: $0000\ 0000_H$



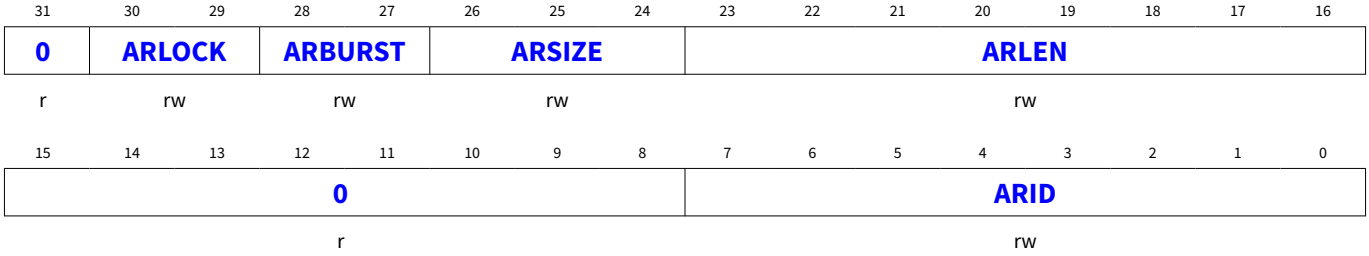
Field	Bits	Type	Description
ADDR	31:0	rw	**AXI Slave Read Address Channel Address** This field contains the 32-bit debug data to be driven on AXI Slave Read address bus. The DAPS field of DMA_Sfty_Ind_Ctl register indicates which 32-bit word of Read address bus this correspond to.

14.6.727 DMA AS Sfty RAC Dbg Ctrl

This register contains the data to be driven on control signals of AXI Slave read address channel in Debug Error Injection mode.

DMA_AS_Sfty_RAC_Dbg_Ctrl Offset address: $1F08C_H$

DMA AS Sfty RAC Dbg Ctrl Kernel Reset value: $0000\ 0000_H$



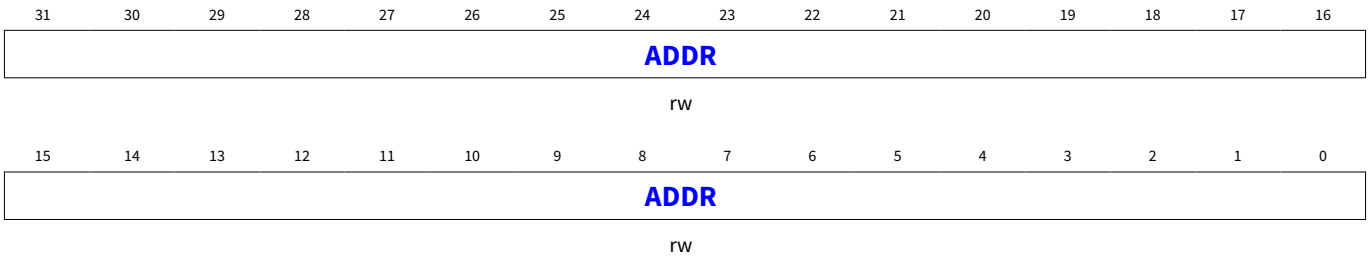
Field	Bits	Type	Description
ARID	7:0	rw	**AXI Slave Address Read Address channel ARID Control Signal** This field contains the debug data to be driven on AXI Slave ARID signal.
ARLEN	23:16	rw	**AXI Slave Address Read Address channel ARLEN Control Signal** This field contains the debug data to be driven on AXI Slave ARLEN signal.
ARSIZE	26:24	rw	**AXI Slave Address Read Address channel ARSIZE Control Signal** This field contains the debug data to be driven on AXI Slave ARSIZE signal.
ARBURST	28:27	rw	**AXI Slave Address Read Address channel ARBURST Control Signal** This field contains the debug data to be driven on AXI Slave ARBURST signal.
ARLOCK	30:29	rw	**AXI Slave Address Read Address channel ARLOCK Control Signal** This field contains the debug data to be driven on AXI Slave ARLOCK signal.
0	15:8, 31	r	**Reserved** Read as 0; should be written with 0.

14.6.728 DMA AS Sfty WAC Dbg Addr

This register contains the data to be driven on address bus of AXI Slave write address channel in Debug Error Injection mode.

DMA_AS_Sfty_WAC_Dbg_Addr Offset address: $1F08C_H$

DMA AS Sfty WAC Dbg Addr Kernel Reset value: $0000\ 0000_H$



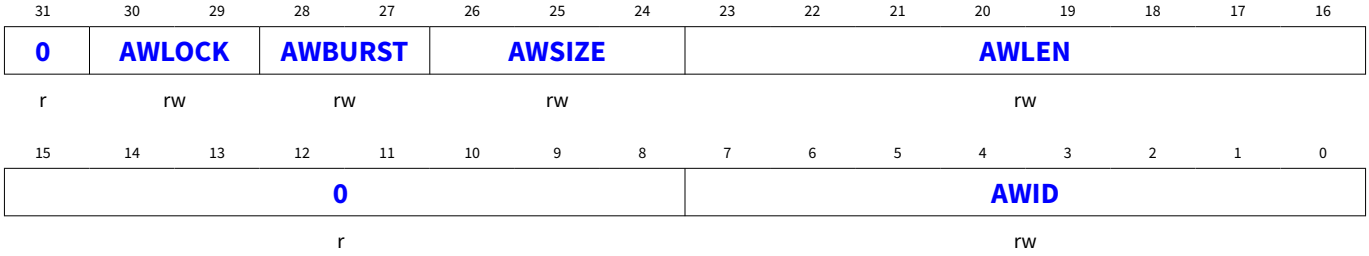
Field	Bits	Type	Description
ADDR	31:0	rw	**AXI Slave Address Write Address channel address** This field contains the 32-bit debug data to be driven on AXI Slave Write address bus. The DAPS field of DMA_Sfty_Ind_Ctl register indicates which 32-bit word of Write address bus this correspond to.

14.6.729 DMA AS Sfty WAC Dbg Ctrl

This register contains the data to be driven on control signals of AXI Slave write address channel in Debug Error Injection mode.

DMA_AS_Sfty_WAC_Dbg_Ctrl Offset address: $1F08C_H$

DMA AS Sfty WAC Dbg Ctrl Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
AWID	7:0	rw	**AXI Slave Address Write Address channel AWID Control Signal** This field contains the debug data to be driven on AXI Slave AWID signal.
AWLEN	23:16	rw	**AXI Slave Address Write Address channel AWLEN Control Signal** This field contains the debug data to be driven on AXI Slave AWLEN signal.
AWSIZE	26:24	rw	**AXI Slave Address Write Address channel AWSIZE Control Signal** This field contains the debug data to be driven on AXI Slave AWSIZE signal.
AWBURST	28:27	rw	**AXI Slave Address Write Address channel AWBURST Control Signal** This field contains the debug data to be driven on AXI Slave AWBURST signal.
AWLOCK	30:29	rw	**AXI Slave Address Write Address channel AWLOCK Control Signal** This field contains the debug data to be driven on AXI Slave AWLOCK signal.
0	15:8, 31	r	**Reserved** Read as 0; should be written with 0.

14.6.730 DMA AS Sfty WDC Dbg Ctrl

This register contains the data to be driven on AXI Slave Write Data channel control signals in Debug Error Injection mode.

DMA_AS_Sfty_WDC_Dbg_Ctrl Offset address: $1F08C_H$

DMA AS Sfty WDC Dbg Ctrl Kernel Reset value: $0000\ 0000_H$

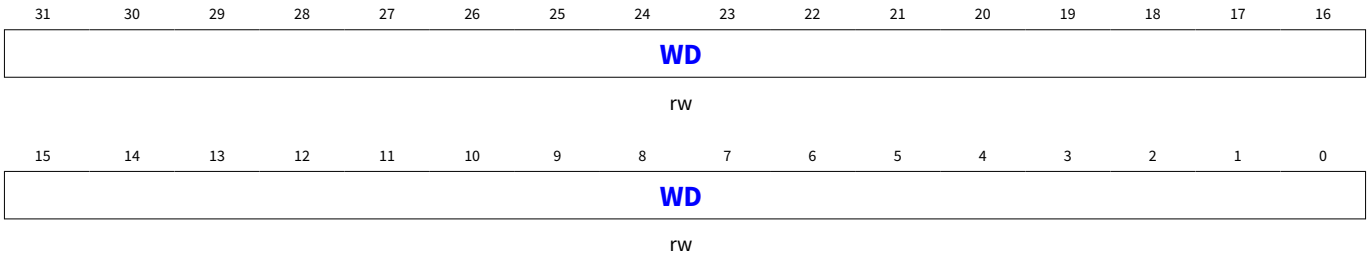
Field	Bits	Type	Description
WID	7:0	rw	**AXI Slave Write Data channel WID Control Signal** This field contains the debug data to be driven on AXI Slave WID signal.
WSTRB	19:16	rw	**AXI Slave Write Data channel WSTRB Control Signal** This field contains the debug data to be driven on AXI Slave WSTRB signal.
0	15:8, 31:20	r	**Reserved** Read as 0; should be written with 0.

14.6.731 DMA AS Sfty WDC Dbg Data

This register contains the data to be driven on AXI Slave write data in Debug Error Injection mode.

DMA_AS_Sfty_WDC_Dbg_Data Offset address: $1F08C_H$

DMA AS Sfty WDC Dbg Data Kernel Reset value: $0000\ 0000_H$



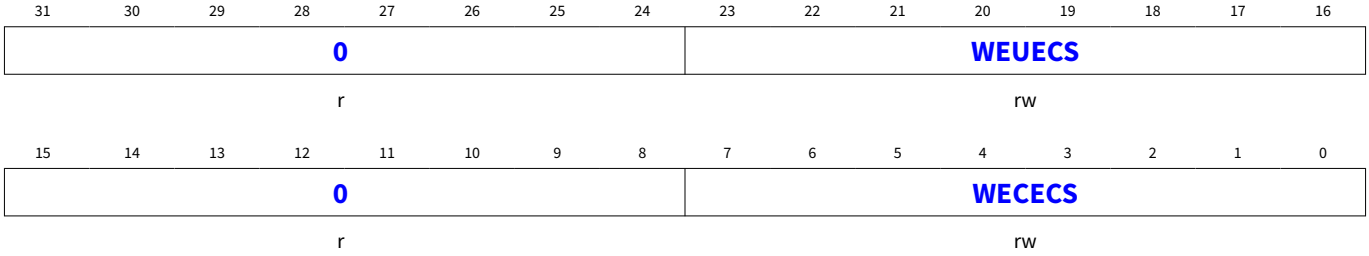
Field	Bits	Type	Description
WD	31:0	rw	**AXI Slave Write Data Channel Debug Data** This field contains the 32-bit debug data to be driven on AXI Slave write Data bus. The DAPS field of DMA_Sfty_Ind_Ctl register indicates which 32-bit word of write data bus this correspond to.

14.6.732 DMA AS Sfty WDC ECC Err Cntr Sts

This register contains the ECC Error counters for write data of AXI Slave Interface safety.

DMA_AS_Sfty_WDC_ECC_Err_Cntr_Sts Offset address: $1F08C_H$

DMA AS Sfty WDC ECC Err Cntr Sts Kernel Reset value: $0000\ 0000_H$



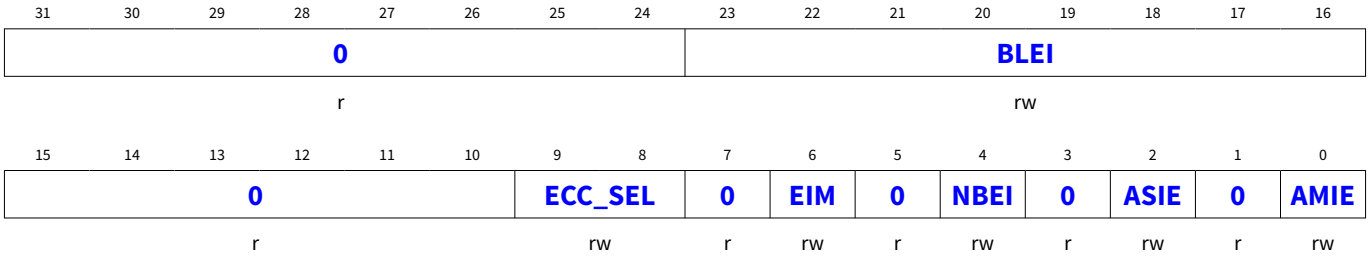
Field	Bits	Type	Description
WECECS	7:0	rw	**AXI Slave Write Data channel ECC Correctable Error Counter** This field provides the number of ECC correctable errors detected in AXI Slave Write Data channel. This field is cleared when the CESS bit is set to 1 and the application reads this field.
WEUECS	23:16	rw	**AXI Slave Write Data channel ECC Uncorrectable Error Counter** This field provides the number of ECC uncorrectable errors detected in AXI Slave Write Data channel. This field is cleared when the CESS bit is set to 1 and the application reads this field.
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

14.6.733 DMA Sfty Dbg EIC

This register contains control signals for Debug Error Injection.

DMA_Sfty_Dbg_EIC Offset address: $1F08C_H$

DMA Sfty Dbg EIC Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
AMIE	0	rw	**AXI Master Insert Error** When this bit is set to 1, parity/ECC/data bit at input of selected AXI Master channel is flipped. The error type and location is based on the EIM/BLEI field of this register. DWC_xgmac clears this bit after the respective bit is flipped.

(table continues...)

(continued)

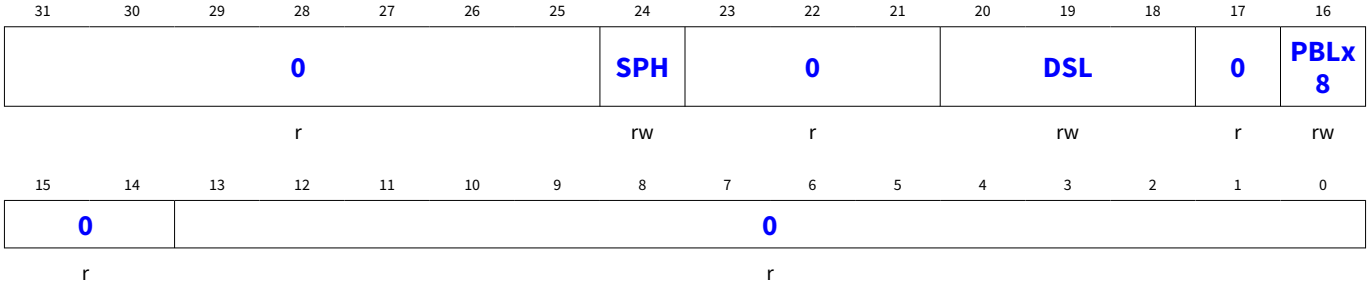
Field	Bits	Type	Description
ASIE	2	rw	**AXI Slave Insert Error - 1: Parity/ECC/data bit at the input of selected AXI Slave channel is flipped** The error type and location is based on the EIM/BLEI field of this register. DWC_xgmac clears this bit after the respective bit is flipped.
NBEI	4	rw	**Number of Bit Error Injection in ECC for AXI Interface** When ASIE or AMIE bit is set, following errors are inserted based on the value encoded in this field: - 0: Inserts 1-bit error - 1: Inserts 2-bit error
EIM	6	rw	**Debug Error Injection Mode - 0: Indicates debug error injected on data - 1: Indicates debug error injected on ECC/Parity Check-bits**
ECC_SEL	9:8	rw	**ECC Select This field selects the ECC to insert error** Depending on the configuration (input data width, ECC granularity) there can be maximum of 4 granules available. Values: - 2'b00: Insert ECC Error in 0th granule - 2'b01: Insert ECC Error in 1st granule - 2'b10: Insert ECC Error in 2nd granule - 2'b11: Insert ECC Error in 3rd granule
BLEI	23:16	rw	**Bit Location of error injection** This field indicates the bit location of DPP/ECC error injection. The EIM bit of DMA_Sfty_Dbg_EIC register indicates whether the error is injected in Data or Parity/ECC Check-bits. The channel/interface selected for debug error injection determines the number of valid bits in this field, for example, for debug error injection on a 64 bit data bus this field can be programmed to a value between 0 and 63, so only bits[21:16] are valid. When 2-bit error injection is enabled, the error is always injected in bit 0 and second error bit is indicated by this field. If the field is also programed to 0 when 2-bit error injection is enabled, DWC_xgmac inserts single bit error at bit 0.
0	1, 3, 5, 7, 15:10, 31:24	r	**Reserved** Read as 0; should be written with 0.

14.6.734 DMA Channel j Control

The DMA Channel Control register controls the common settings of both TX DMA and RX DMA channels.

DMA_CHj_Control (j=0-7) Offset address: $1F100_H+j*80_H$

DMA Channel j Control Kernel Reset value: $0000\ 0000_H$



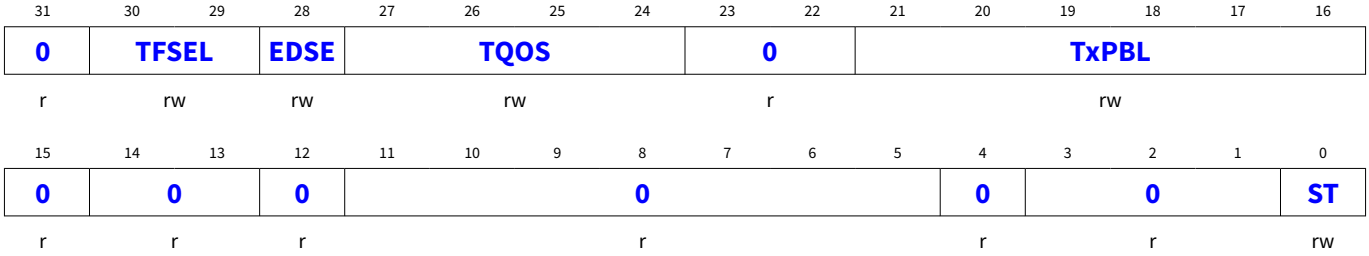
Field	Bits	Type	Description
PBLx8	16	rw	**8xPBL mode** When this bit is set, the PBL value programmed in TxPBL field of DMA_CH0_TX_Control register and RxPBL field of DMA_CH0_RX_Control is multiplied eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value.
DSL	20:18	rw	**Descriptor Skip Length** This bit specifies the number of DWord to skip between two descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor list as contiguous.
SPH	24	rw	**Header-Payload Split** When this bit is set, the DMA splits the header and payload in the Receive path. The DMA writes the header to the Buffer Address1. The DMA writes the payload to the buffer to which the Buffer Address2 is pointing. The software must ensure that the header fits into the Receive buffers. If the header length exceeds the receive buffer size, the DMA does not split the header and payload.
0	13:0, 15:14, 17, 23:21, 31:25	r	**Reserved** Read as 0; should be written with 0.

14.6.735 DMA Channel j Tx Control

The DMA Channel Transmit Control register controls the functions of the TX DMA channel.

DMA_CHj_Tx_Control (j=0-7) Offset address: $1F104_H+j*80_H$

DMA Channel j Tx Control Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ST	0	rw	**Start or Stop Transmission Command** When this bit is set,the TX DMA channel is placed in the Running state. The DMA starts fetching the transmit descriptor from either of the following locations. - The address pointed by the DMA_CHi_TxDesc_List_LAddress register if this register was updated before the ST bit is set. - The position in the Transmit List at which the DMA channel stopped last when ST bit was changed from 1 to 0. The Start Transmit command is effective only if the TX DMA is already in STOP state. The DMA checks the Transmit list at the current position for a packet to be transmitted. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, program DMA_CHi_TxDesc_List_LAddress register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state.
TxPBL	21:16	rw	**Transmit Programmable Burst Length** This field controls the maximum size of burst transaction that can be initiated by the TX DMA channel for packet data transfers. The TX DMA channel attempts to fetch the data of this burst size if available, from the Transmit Buffer pointed by the descriptor. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: - Set the PBLx8 mode in DMA_CH0_Control register. - Set the PBL. Note-1: This PBL controls the maximum burst size of the requests from this internal DMA engine. The AXI Interface block can split this PBL requests from DMA engine into multiple AXI requests based on the programmed values in DMA_SysBus_Mode register. Note-2: The maximum limit programmed must be less than or equal to half the size of the corresponding Tx Queue depth

(table continues...)

(continued)

Field	Bits	Type	Description
TQOS	27:24	rw	**Transmit QOS** This field is used to drive the values on AXI Master read control channel's QoS indicator or AXI Master write control channel's QoS indicator output signals of the AXI bus for all transactions initiated by this Tx DMA channel
EDSE	28	rw	**Enhanced Descriptor Enable** When this bit is set, the corresponding channel uses enhanced Descriptors with increased size of 32 Bytes for both Normal and Context Descriptors. When reset, the corresponding channel uses the descriptors with default size of 16 Bytes. 0_B **DISABLE**: Enhanced Descriptor is disabled 1_B **ENABLE**: Enhanced Descriptor is enabled
TFSEL	30:29	rw	**TBS Fetch Time Select** Selects the DMA_TBS_CTRLn register used to determine the settings of the TBS function applicable for the packets transferred by this TX DMA channel 00_B **DMA_TBS_CTRL0**: 01_B **DMA_TBS_CTRL1**: 10_B **DMA_TBS_CTRL2**: 11_B **DMA_TBS_CTRL3**:
0	3:1, 4, 11:5, 12, 14:13, 15, 23:22, 31	r	**Reserved** Read as 0; should be written with 0.

14.6.736 DMA Channel j Rx Control

The DMA Channel Receive Control register controls the operating modes and parameters of this RX DMA channel.

DMA_CHj_Rx_Control (j=0-7) Offset address: $1F108_H+j*80_H$

DMA Channel j Rx Control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RPF	0			RQOS				0		RxPBL					
rw	r			rw				r		rw					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	RBSZ												0		SR
r	rw												r		rw

Field	Bits	Type	Description
SR	0	rw	**Start or Stop Receive** When this bit is set, the RX DMA moves to the running state and starts to transfer packets from the MTL Rx Queues to the host memory. The RX DMA tries to first acquire RX descriptor from either of the following locations. -The address pointed by the DMA_CH0_RxDesc_List_LAddress register if this register was updated before the SR bit is set. -The position in the Receive List at which the DMA channel stopped last when SR bit was changed from 1 to 0. Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. Similarly, Start Receive command is effective only when the Receive process is in the Stopped state. So, read the corresponding channel's DMA_CH0_Debug Status register to get the current state of the RxDMA before writing the SR bit.
RBSZ	14:4	rw	**Receive Buffer size** This field indicates the size of the Rx buffers specified in bytes allocated by the software to store the packets the Rx DMA transfers to the host memory. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note-1: The buffer size must be a multiple of 8 . This is required even if the value of buffer address pointer is not aligned to bus width. If the buffer size is not a multiple of 8, it might result into undefined behavior. The LSB bits (2:0) are ignored and the DMA internally takes the LSB bits as all-zero. Therefore, these LSB bits are read-only (RO). Therefore, the maximum value that can be programmed into this field is 0x3FF8 (16376) . Note-2: It is recommended to program a minimum size of 256 bytes for better performance.

(table continues...)

(continued)

Field	Bits	Type	Description
RxPBL	21:16	rw	**Receive Programmable Burst Length** This field controls the maximum size of burst transaction that can be initiated by the RX DMA channel for packet data transfers. The RX DMA channel attempts to transfer the data of this burst size if available, to the Receive Buffer pointed by the descriptor.You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. It is recommended to use higher values (8 and higher) for better performance. A value of 0 might result in undefined behavior. To transfer more than 32 beats, perform the following steps: - Set the PBLx8 mode in the DMA_CH0_Control register. - Set the PBL. Note-1: This PBL controls the maximum burst size of the requests from this internal DMA engine. The AXI Interface block can split this PBL requests from DMA engine into multiple AXI requests based on the programmed values in DMA_SysBus_Mode register. Note-2: The maximum limit programmed must be less than or equal to half the size of the corresponding Rx Queue Depth of all the Rx Queues from which packets can be services by this RX DMA . For example, in 64-bit configuration, there are 8 bytes per location. So, when Rx Queue Size is 256 bytes, the Rx Queue Depth = 256/8 = 32. The RxPBL must be programmed is less that or equal to total no. of locations in Rx Queue/2, so RxPBL must be programmed less than 32.
RQOS	27:24	rw	**Receive QOS** This field is used to drive values on AXI Master read control channel's QoS indicator or AXI Master write control channel's QoS indicator output signals of AXI bus for all transactions inititated by this Rx DMA Channel.
RPF	31	rw	**Rx DMA Packet Flush** When this bit is set to 1, then DWC_xgmac automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped or suspended due to unavailability of descriptors. When this bit remains set and the DMA is re-started by the software driver the packets residing in the Rx Queues that were received when the DMA is stopped, still gets flushed out. The packets received by the MAC only after the DMA is re-started is routed to the Rx DMA. The flushing is done on the Read side of the Rx Queue. When the packet is duplicated to multiple Rx DMA, it is flushed by the Rx DMA to which it is routed only when it is stopped or suspended due to unavailability of descriptors to prevent head-of-line blocking. The packet duplicated to multiple Rx DMA is not flushed when the Rx DMA is re-started, irrespective of whether the packet was received during one or more Rx DMAs were stopped. When this bit is set to 0, DWC_xgmac does not flush the packet in the Rx Queue destined to this RxDMA Channel when it is in STOP state. This might cause head-of-line blocking in the corresponding RxQueue.

(table continues...)

(continued)

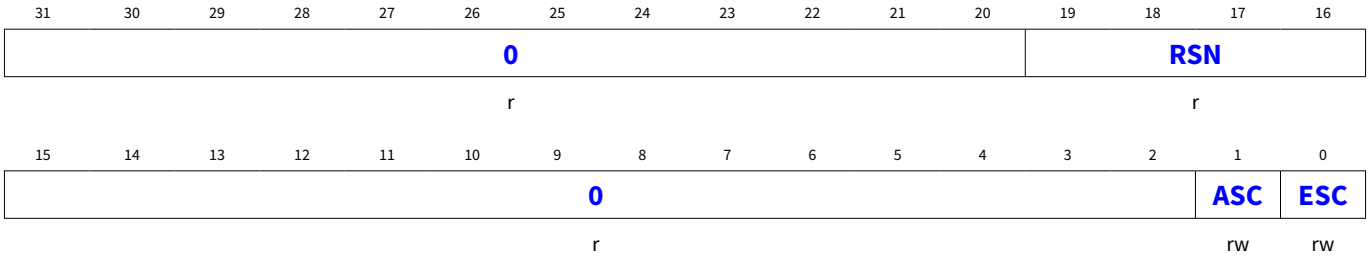
Field	Bits	Type	Description
0	3:1, 15, 23:22, 30:28	r	**Reserved** Read as 0; should be written with 0.

14.6.737 DMA Channel j Slot Function Control Status

This register contains the control and status bits of the AVB slot function in Transmit path.

DMA_CHj_Slot_Function_Control_Status (j=0-7) Offset address: $1F10C_H+j*80_H$

DMA Channel j Slot Function Control Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ESC	0	rw	**Enable Slot Comparison** When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the RSN value is equal to or less the SLOTNUM value programmed in the descriptor as determined by ASC. When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. 0_B **DISABLE**: Slot Comparison is disabled 1_B **ENABLE**: Slot Comparison is enabled
ASC	1	rw	**Advance Slot Check** When this bit is set, the TX DMA fetches data from the buffer when the RSN value is equal to or less than the SLOTNUM value programmed in that descriptor by up to 2 slots. When this bit is reset, the DMA will start fetching the the data when the RSN value is equal to or less the SLOTNUM value by one slot. This bit is applicable only when the ESC bit is set.
RSN	19:16	r	**Reference Slot Number** This field gives the current value of the reference slot number active in the DMA. It is used for slot comparison with the value programmed in SLOTNUM field of TX Descriptor before the data is fetched.
0	15:2, 31:20	r	**Reserved** Read as 0; should be written with 0.

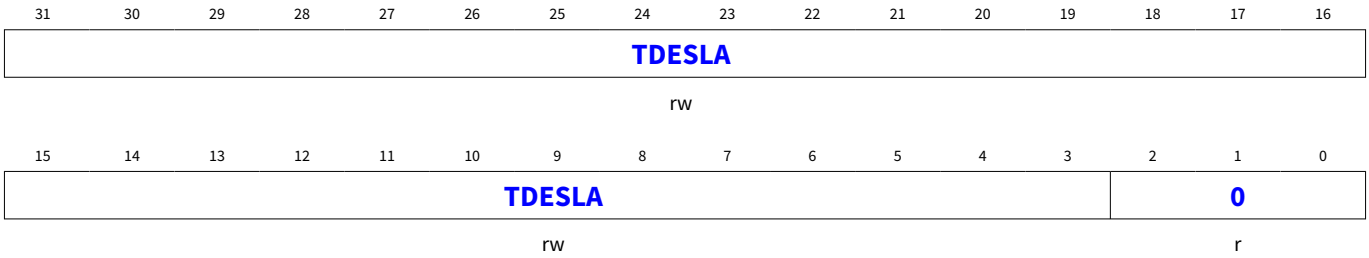
14.6.738 DMA Channel j TxDesc List LAddress

The Tx Descriptor List LAddress register has the lower 32 bits of the start address of the Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be aligned to the databus width(Dword -aligned).The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in the corresponding DMA_CH0_Tx_Control register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA on restart takes the descriptor address where it was stopped earlier.

DMA_CHj_TxDesc_List_LAddress (j=0-7) Offset address: $1F114_H+j*80_H$

DMA Channel j TxDesc List LAddress Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TDESLA	31:3	rw	**Start of Transmit List** This field contains the base address of the first descriptor in the Transmit descriptor list. The 32b address is formed by extending the TDESLA field with all-zero in the LSB bits below which are RO.
0	2:0	r	**Reserved** Read as 0; should be written with 0.

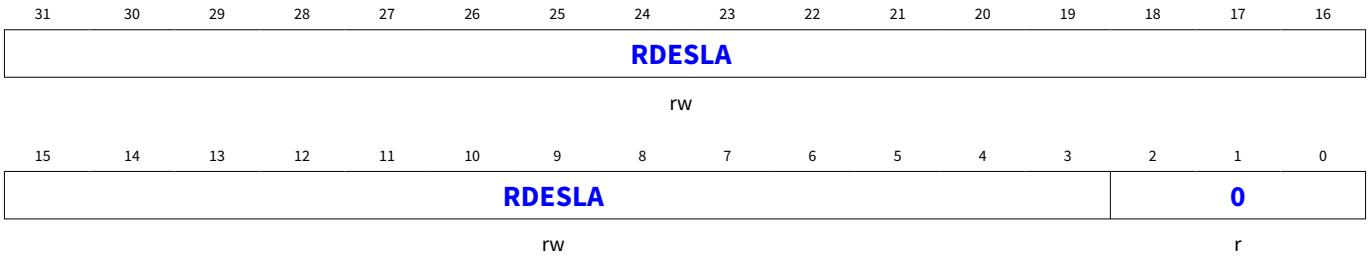
14.6.739 DMA Channel j RxDesc List LAddress

The Rx Descriptor List LAddress register has the lower 32 bits of the start address of the Receive descriptor list. This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be aligned to the databus width(Dword -aligned). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in the corresponding DMA_CH0_Rx_Control register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

DMA_CHj_RxDesc_List_LAddress (j=0-7) Offset address: $1F11C_H+j*80_H$

DMA Channel j RxDesc List LAddress Kernel Reset value: $0000\ 0000_H$



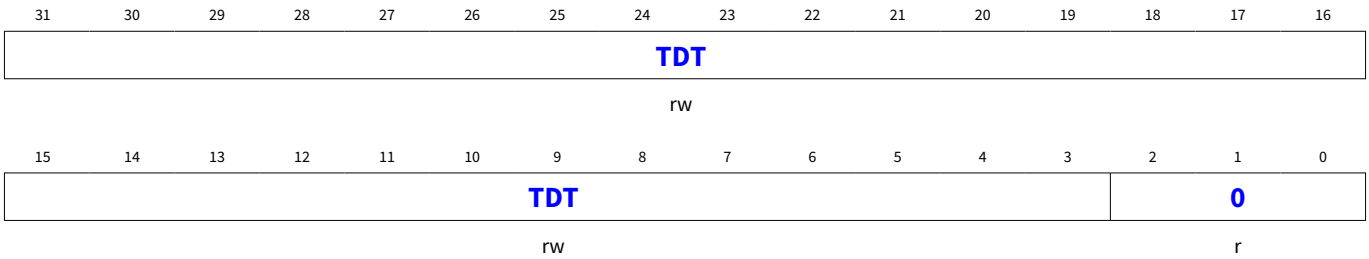
Field	Bits	Type	Description
RDESLA	31:3	rw	**Start of Receive List** This field contains the base address of the first descriptor in the Rx Descriptor list.The 32b address is formed by extending the RDESLA field with all-zero in the LSB bits below which are RO.
0	2:0	r	**Reserved** Read as 0; should be written with 0.

14.6.740 DMA Channel j TxDesc Tail LPointer

The Tx Descriptor Tail LPointer register has the 32 bits end address of the Transmit descriptor list.

DMA_CHj_TxDesc_Tail_LPointer (j=0-7) Offset address: $1F124_H+j*80_H$

DMA Channel j TxDesc Tail LPointer Kernel Reset value: $0000\ 0000_H$



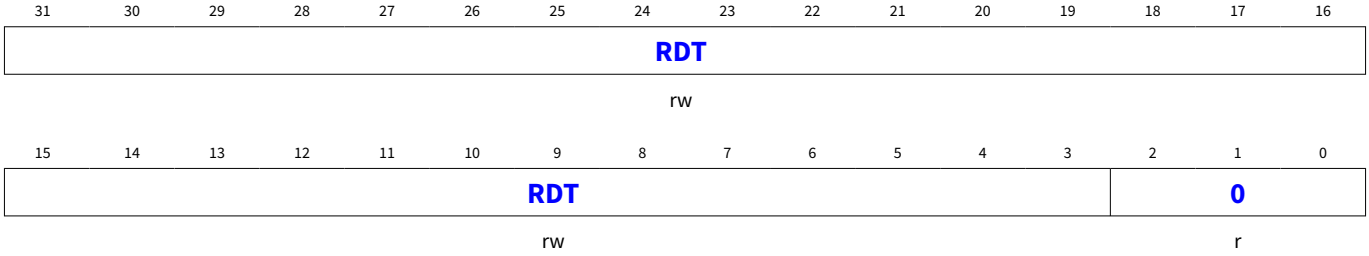
Field	Bits	Type	Description
TDT	31:3	rw	**Transmit Descriptor Tail Pointer** This field contains the tail pointer for the Tx descriptor ring. The software writes the tail pointer to add more descriptors to the Transmit List. DWC_xgmac tries to transmit all packets referenced by the descriptors between the head and the tail pointer registers.The 32b address is formed by extending the TDT field with all-zero in the LSB bits below which are RO.
0	2:0	r	**Reserved** Read as 0; should be written with 0.

14.6.741 DMA Channel j RxDesc Tail LPointer

The Rx Descriptor Tail LPointer register has the 32 bits end address of the Receive descriptor list.

DMA_CHj_RxDesc_Tail_LPointer (j=0-7) Offset address: $1F12C_H+j*80_H$

DMA Channel j RxDesc Tail LPointer Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RDT	31:3	rw	**Receive Descriptor Tail Pointer** This field contains the tail pointer for the Rx descriptor ring. The software writes the tail pointer to add more descriptors to the Rx channel. DWC_xgmac tries to write all the received packets to the descriptors referenced between the head and the tail pointer registers.The 32b address is formed by extending the RDT field with all-zero in the LSB bits below which are RO.
0	2:0	r	**Reserved** Read as 0; should be written with 0.

14.6.742 DMA Channel j Tx Control2

The Tx_Control2 register contains programmable control to Outstanding read requests per DMA and the length of the Transmit descriptor ring.

DMA_CHj_Tx_Control2 (j=0-7) Offset address: $1F130_H+j*80_H$

DMA Channel j Tx Control2 Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
TDRL	15:0	rw	**Transmit Descriptor Ring Length** This field sets the maximum number of Tx descriptors in the circular descriptor ring. . - 0 implies ring length of 1 descriptor. - 0xFFFF implies a ring length of 65536 descriptors.

(table continues...)

(continued)

Field	Bits	Type	Description
ORRQ	24	rw	**Read Outstanding Requests** When this is set to 0, the DMA can initiate the maximum number of outstanding read transactions of packet data up to 2 for each Transmit DMA channel. When this field is set to a value greater than zero, the DMA limits the number of outstanding read transactions to the value of ORRQ.
0	23:16, 31:25	r	**Reserved** Read as 0; should be written with 0.

14.6.743 DMA Channel j Rx Control2

The Channel0 Rx Control2 register contains programmable control to Outstanding Write requests and the length of the Receive descriptor circular ring.

DMA_CHj_Rx_Control2 (j=0-7) Offset address: $1F134_H+j*80_H$

DMA Channel j Rx Control2 Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RDRL	15:0	rw	**Receive Descriptor Ring Length** This field sets the maximum number of Rx descriptors in the circular descriptor ring. - 0 implies ring length of 1 descriptor. - 0xFFFF implies a ring length of 65536 descriptors.
ARBS	23:17	rw	**Alternate Receive Buffer Size** Indicates size in bytes for Buffer 1 when ARBS is programmed to a non-zero value (when split header feature is not enabled). When split header feature is enabled, ARBS indicates the buffer size for header data. The maximum alternate buffer is limited to 1016 -bytes . When ARBS=0, Rx Buffer1 and Rx Buffer2 sizes are based on RBSZ field of DMA_CH0_Rx_Control. Width of ARBS field is 7 -bits

(table continues...)

(continued)

Field	Bits	Type	Description
OWRQ	24	rw	**Write Outstanding Requests** When this is set to 0, the DMA can initiate the maximum number of outstanding write transactions of packet data, up to 2 for each Rx DMA channel. When this field is set to a value greater than zero, the DMA limits the number of outstanding write transactions to the value of OWRQ.
0	16, 31:25	r	**Reserved** Read as 0; should be written with 0.

14.6.744 DMA Channel j Interrupt Enable

The Channel0 Interrupt Enable register enables the interrupts reported by the Status register.

DMA_CHj_Interrupt_Enable (j=0-7) Offset address: $1F138_H+j*80_H$

DMA Channel j Interrupt Enable Kernel Reset value: $0000\ 0000_H$

TXSE	1	rw	**Transmit Stopped Enable** When this bit is set, AIS bit in DMA_CH0_Status register is set to high when TPS bit becomes high. When this bit is reset, setting of TPS bit does not affect the AIS bit.
TBUE	2	rw	**Transmit Buffer Unavailable Enable** When this bit is set, NIS bit in DMA_CH0_Status register is set to high when TBU bit becomes high. When this bit is reset, setting of TBU bit does not affect the NIS bit.
RIE	6	rw	**Receive Interrupt Enable** When this bit is set, NIS bit in DMA_CH0_Status register is set to high when RI bit becomes high. When this bit is reset, setting of RI bit does not affect the NIS bit.

(table continues...)

(continued)

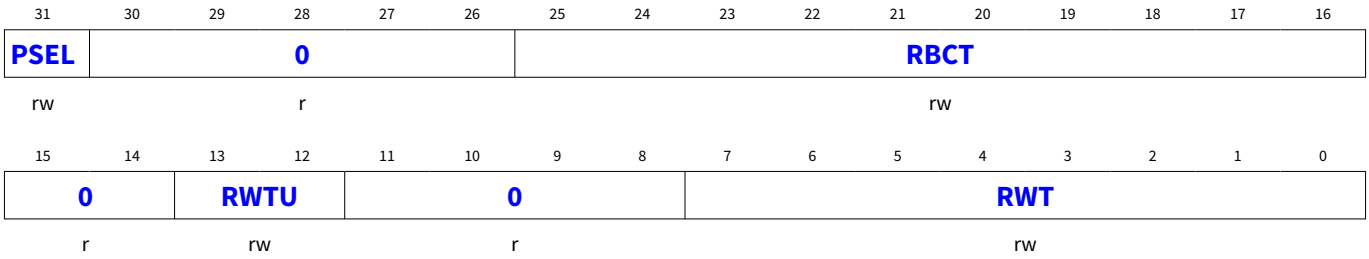
Field	Bits	Type	Description
RBUE	7	rw	**Receive Buffer Unavailable Enable** When this bit is set, AIS bit in DMA_CH0_Status register is set to high when RPS bit becomes high. When this bit is reset, setting of RPS bit does not affect the AIS bit.
RSE	8	rw	**Receive Stopped Enable** When this bit is set along with the AIE bit, the Receive Stopped Interrupt is enabled. When this bit is reset, the Receive Stopped interrupt is disabled.
DDEE	9	rw	**Descriptor Definition Error Enable** When this bit is set, AIS bit in DMA_CH0_Status register is set to high when DDE bit becomes high. When this bit is reset, setting of DDE bit does not affect the AIS bit.
FBEE	12	rw	**Fatal Bus Error Enable** When this bit is set, AIS bit in DMA_CH0_Status register is set to high when FBE bit becomes high. When this bit is reset, setting of FBE bit does not affect the AIS bit.
CDEE	13	rw	**Context Descriptor Error Enable** When this bit is set, AIS bit in DMA_CH0_Status register is set to high when CDE bit becomes high. When this bit is reset, setting of CDE bit does not affect the AIS bit.
AIE	14	rw	**Abnormal Interrupt Summary Enable** When this bit is set,interrupt is activated by XGMAC when AIS bit in DMA_CH0_Status register is set. When this bit is reset, interrupt is not activated due to setting of AIS bit.
NIE	15	rw	**Normal Interrupt Summary Enable** When this bit is set,interrupt is activated by XGMAC when NIS bit in DMA_CH0_Status register is set. When this bit is reset, interrupt is not activated due to setting of NIS bit.
0	5:3, 11:10, 31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.745 DMA Channel j Rx Interrupt Watchdog Timer

The Receive Interrupt Watchdog Timer register controls the generation of Receive Interrupt (RI) from the DMA with respect to a time window. This time-window can be in terms of number of clocks (timer of RWT) or number of transferred bytes or number of transferred packets (counter of RBCT) or a combination of both.

DMA_CHj_Rx_Interrupt_Watchdog_Timer (j=0-7) Offset address: $1F13C_H+j*80_H$

DMA Channel j Rx Interrupt Watchdog Timer Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RWT	7:0	rw	**Receive Interrupt Watchdog Timer Count** This field control the number of AXI clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CH0_Status register, because the Interrupt Enable bit in the corresponding descriptor RDES3[30] is reset. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high whenever the Interrupt Enable bit (RDES3[30]) is set in descriptor, corresponding to the RX packet transfer or due to the triggering of RBCT counter threshold. When both RWTU and RWT are set to 0, then the Rx Watchdog timer is disabled.
RWTU	13:12	rw	**Receive Interrupt Watchdog Timer Count Units** This fields indicates the number of system clock cycles corresponding to one unit in RWT field. - 2'b00: 256 - 2'b01: 512 - 2'b10: 1024 - 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.
RBCT	25:16	rw	**Receive Byte Count Threshold** This field sets the limit in number of bytes or number of RX packets (based on PSEL) transferred without the assertion of Receive Interrupt. Once this limit is crossed, Receive interrupt is asserted, and the watchdog timer (corresponding to RWT) is also reset. This function is valid only when set to a non-zero value. When RBCT = 0, RX Packet/Byte counter is inactive. When PSEL = 0, this field is multiplied by 1024, to get the actual number of byte threshold. When PSEL =1, RBCT value is directly used. Thus the maximum limit is 511 packets or 511 x 1024 bytes respectively.

(table continues...)

(continued)

Field	Bits	Type	Description
PSEL	31	rw	**Packet Count Interrupt Select** When this bit is set, RBCT indicates the number of packet threshold at which the Receive Interrupt (RI) is activated and the watchdog timer reset. When this bit is low, RBCT indicates the number of data byte threshold at which the Receive Interrupt (RI) is activated and the watchdog timer reset. - 1: RBCT field is used to generate interrupt based on number of packets received. - 0: RBCT field is used to generate interrupt based on number of bytes received.
0	11:8, 15:14, 30:26	r	**Reserved** Read as 0; should be written with 0.

14.6.746 DMA Channel j Current App TxDesc L

The Channel Current Application Transmit Descriptor Low register has the lower 32 bits of the address of the Transmit descriptor to be read by the DMA. The upper 32 address bits of the Current Transmit Descriptor are equal to the value written in the DMA_CHi_TxDesc_List_LAddress. Therefore, the upper address bits are not given in the register map.

DMA_CHj_Current_App_TxDesc_L (j=0-7) Offset address: $1F144_H+j*80_H$

DMA Channel j Current App TxDesc L Kernel Reset value: $0000\ 0000_H$

NIS	AIS	CDE	FBE	0		DDE	RPS	RBU	RI	0			TBU	TPS	TI
rw	rw	rw	rw	r		rw	rw	rw	rw	r			rw	rw	rw

Field	Bits	Type	Description
TI	0	rw	**Transmit Interrupt** This bit when set, indicates that transfer of packet to the TxQueue is completed. This is set only when the corresponding Tx packet descriptor's IOC bit (TDES2[31]) is set. This is a sticky bit and is cleared only when a "1" is written to this bit
TPS	1	rw	**Transmit Process Stopped** This bit when set, indicates that the Transmit DMA process has entered STOP state. This is a sticky bit and is cleared only when a "1" is written to this bit
TBU	2	rw	**Transmit Buffer Unavailable** This bit when set, indicates that the application owns the next descriptor in the Transmit Descriptor list, and the DMA cannot acquire it and hence is suspended. To resume the transmission, the application must do the following: - Change the ownership of the descriptor by setting Bit 31 of TDES0. - Issue a Transmit Poll Demand command by performing a write to the Transmit Descriptor Tail Pointer register. This is a sticky bit and is cleared only when a '1' is written to this bit.

(table continues...)

(continued)

Field	Bits	Type	Description
RI	6	rw	**Receive Interrupt** This bit when set, indicates that the transfer of Rx Packet to host memory is complete. This bit is set only if either of the following is true: - Corresponding Rx descriptor's IOC bit (RDES3[30]) is set - The Rx Watchdog timer or counter reaches limit set in the RWT or RBCT fields of DMA_CH0_Rx_Interrupt_Watchdog_Timer register. This is a sticky bit and is cleared only when a '1' is written to this bit.
RBU	7	rw	**Receive Buffer Unavailable** This bit when set, indicates that the software application owns the next descriptor in the Receive Descriptor list, and the DMA cannot acquire it. The Rx process is suspended. To resume the Rx process, the application must change the ownership of the descriptor and advance the DMA_CH0_RxDesc_Tail_LPointer register. If this is not done, the RxDMA remains in SUSPEND state and results in overflow of the corresponding RxQueue.This is a sticky bit and is cleared only when a 1 is written to this bit
RPS	8	rw	**Receive Process Stopped** This bit is asserted when the Rx DMA process enters the Stopped state.This is a sticky bit and is cleared only when a "1" is written to this bit.
DDE	9	rw	**Descriptor Definition Error** This bit when set, indicates that a Descriptor Definition error (Descriptor content is all-ones) occurred. When this bit is set, the corresponding DMA channel engine stops Descriptor Fetch. This is a sticky bit and is cleared only when a "1" is written to this bit. The recovery is only by issuing a Software Reset, that is setting SWR bit of DMA_Mode register, followed by reconfiguration and restarting.
FBE	12	rw	**Fatal Bus Error** This bit when set, indicates that a bus error occurred (as described in the REB and TEB fields). When this bit is set, the corresponding DMA channel engine disables all subsequent transactions and proceeds to STOP state. This is a sticky bit and is cleared only when a "1" is written to this bit.
CDE	13	rw	**Context Descriptor Error** This bit when set, indicates that the DMA Tx engine received a context descriptor in the middle of a packet (in an intermediate descriptor), and the DMA Tx engine ignored it.This is a sticky bit and is cleared only when a "1" is written to this bit.

(table continues...)

(continued)

Field	Bits	Type	Description
AIS	14	rw	**Abnormal Interrupt Summary** Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt enable bits are set in the DMA_CH0_Interrupt_Enable register: - Bit 1: Transmit Process Stopped - Bit 7: Receive Buffer Unavailable - Bit 8: Receive Process Stopped - Bit 9: Descriptor Definition Error - Bit 12: Fatal Bus Error - Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared.
NIS	15	rw	**Normal Interrupt Summary** Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt enable bits are set in the DMA_CH0_Interrupt_Enable register: - Bit 0: Transmit Interrupt - Bit 2: Transmit Buffer Unavailable - Bit 6: Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH0_Interrupt_Enable register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared.
TEB	18:16	rw	**Tx DMA Bus Error** This field indicates the type of Tx DMA transaction that resulted in Bus error response on the AXI interface. - 000 : No Bus Error response - 100 : Bus Error during data buffer write - 110 : Bus Error during Descriptor write - 111 : Bus Error during Descriptor read - others : Reserved This field is valid only when the FBE bit is set. This field does not generate an interrupt.
REB	21:19	rw	**Rx DMA Bus Error** This field indicates the type of Rx DMA transaction that resulted in a Bus error response on the AXI interface. - 000 : No Bus Error response - 100 : Bus Error during data buffer write - 110 : Bus Error during Descriptor write - 111 : Bus Error during Descriptor read - others : Reserved This field is valid only when the FBE bit is set. This field does not generate an interrupt.

(table continues...)

(continued)

Field	Bits	Type	Description
0	5:3, 11:10, 31:22	r	**Reserved** Read as 0; should be written with 0.

14.6.751 DMA Channel j Debug Status

The DMA Channel Debug Status register gives the current status of the various state machines in the TX and RX DMA channel.

DMA_CHj_Debug_Status (j=0-7) Offset address: $1F164_H+j*80_H$

DMA Channel j Debug Status Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	15, 31	r	**Reserved** Read as 0; should be written with 0.

14.6.752 DMA Channel j Desc Mem Cache Fill Level

The DMA Channel Descriptor Cache Fill Level Status register gives the fill level of the descriptor prefetch cache of the TX and RX DMA engines.

DMA_CHj_Desc_Mem_Cache_Fill_Level (j=0-7) Offset address: $1F168_H+j*80_H$

DMA Channel j Desc Mem Cache Fill Level Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0									RX_FILL_LVL						
r									r						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0									TX_FILL_LVL						
r									r						

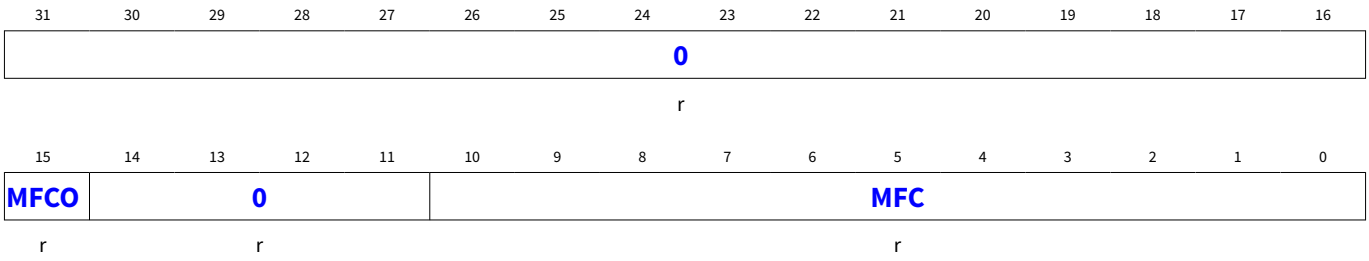
Field	Bits	Type	Description
TX_FILL_LVL	6:0	r	**TxDMA Descriptor Cache Fill Level** This field gives the fill level of the Descriptor Cache for TxDMA channel. A value of 0 implies empty and a value equal to size of Descriptor Cache implies it is full.
RX_FILL_LVL	22:16	r	**RxDMA Descriptor Cache Fill Level** This field gives the fill level of the Descriptor Cache for RxDMA Channel. A value of 0 implies empty and a value equal to size of Descriptor Cache implies it is full.
0	15:7, 31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.753 DMA Channel j Miss Packet Cnt

This register has the number of the packets that are dropped by the Receive DMA either due to Bus Error or due to programming the RPF field in the DMA_CH0_Rx_Control register.

DMA_CHj_Miss_Packet_Cnt (j=0-7) Offset address: $1F16C_H+j*80_H$

DMA Channel j Miss Packet Cnt Kernel Reset value: $0000\ 0000_H$



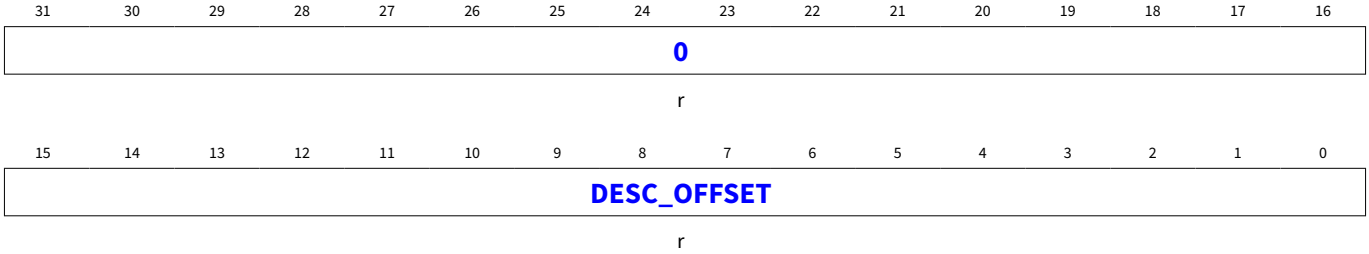
Field	Bits	Type	Description
MFC	10:0	r	**Missed Packet Counter** This counter indicates the number of packet dropped by the DMA either due to Bus Error or due to programming RPF field in DMA_CH0_Rx_Control register. (Refer RPF field of DMA_CH0_Rx_Control register for more details.) The counter gets cleared when this register is read.
MFCO	15	r	**Overflow status of MFC Counter** When this bit is set, the MFC counter reached the maximum value and wrapped around to 0. The MFC counter does not get incremented further. This bit gets cleared when this register is read.
0	14:11, 31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.754 DMA Channel j Tx Data Xfer Ring Offset

This register indicates the Offset of the Tx Descriptor List, for which the DMA engine is fetching the data.

DMA_CHj_Tx_Data_Xfer_Ring_Offset (j=0-7) Offset address: $1F170_H+j*80_H$

DMA Channel j Tx Data Xfer Ring Offset Kernel Reset value: $0000\ 0000_H$



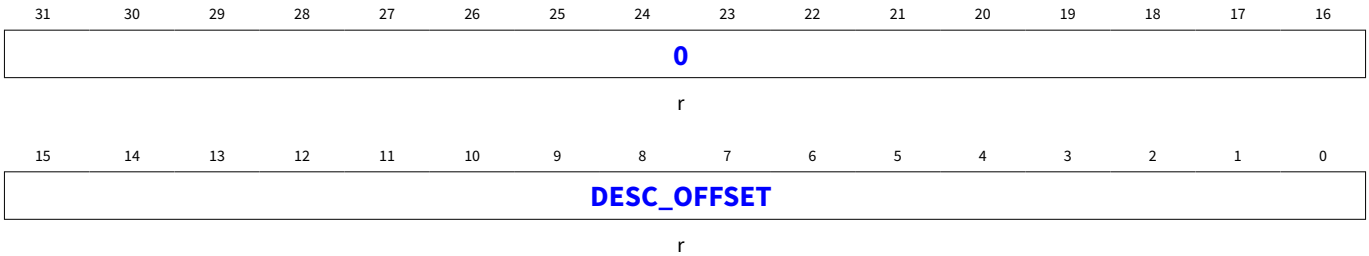
Field	Bits	Type	Description
DESC_OFFSET	15:0	r	**TxDMA channel Data Transfer ring Offset** In DMA, this field indicates the ring offset of the Descriptor DMA currently working on data transmission.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.755 DMA Channel j Rx Data Xfer Ring Offset

The DMA Channel Receive Data Transfer Ring Offset register indicates the Offset of the Rx Descriptor List, for which the DMA engine is transferring the data.

DMA_CHj_Rx_Data_Xfer_Ring_Offset (j=0-7) Offset address: $1F174_H+j*80_H$

DMA Channel j Rx Data Xfer Ring Offset Kernel Reset value: $0000\ 0000_H$



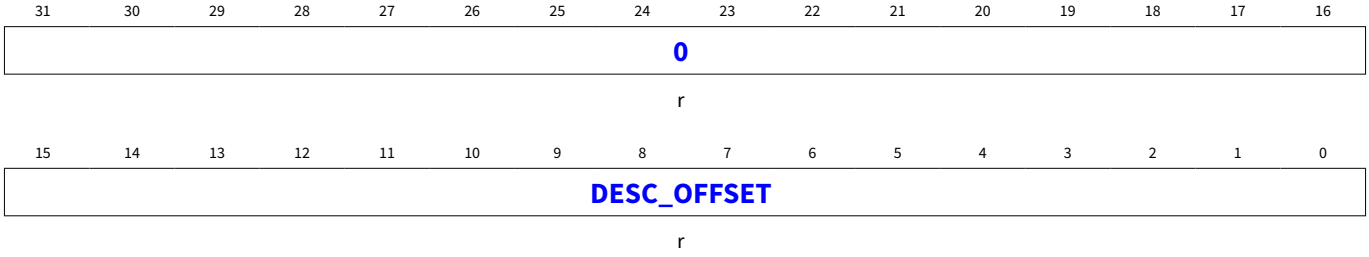
Field	Bits	Type	Description
DESC_OFFSET	15:0	r	**RxDMA Channel Data Transfer Ring Offset** In DMA, this field indicates the ring offset of the Descriptor DMA currently working on data reception.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.756 DMA Channel j Tx Desc Write Ring Offset

This register indicates the Offset of the Tx Descriptor List, for which the DMA engine is closing the descriptor.

DMA_CHj_Tx_Desc_Write_Ring_Offset (j=0-7) Offset address: $1F178_H+j*80_H$

DMA Channel j Tx Desc Write Ring Offset Kernel Reset value: $0000\ 0000_H$



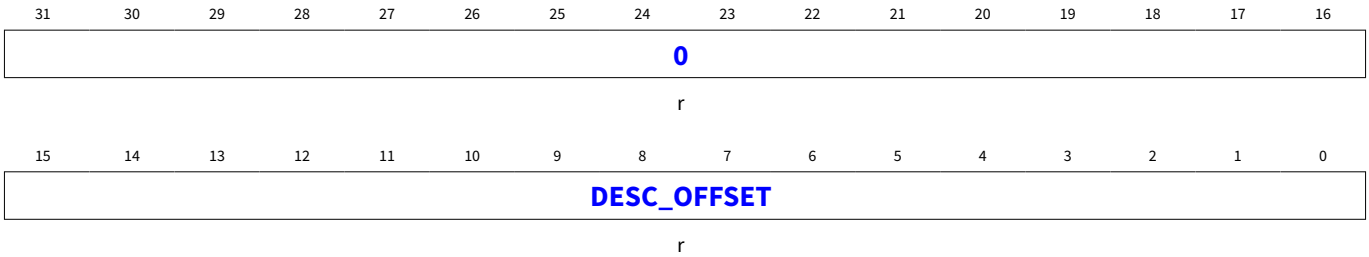
Field	Bits	Type	Description
DESC_OFFSET	15:0	r	**TxDMA Channel Descriptor Write Ring Offset** This field indicates the ring offset of the descriptor DMA posted write-back request.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.757 DMA Channel j Rx Desc Write Ring Offset

This register indicates the Offset of the Rx Descriptor List, for which the DMA engine is closing the descriptor.

DMA_CHj_Rx_Desc_Write_Ring_Offset (j=0-7) Offset address: $1F17C_H+j*80_H$

DMA Channel j Rx Desc Write Ring Offset Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DESC_OFFSET	15:0	r	**RxDMA Channel Descriptor Write Ring Offset** This field indicates the ring offset of the descriptor DMA posted write-back request.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

14.7 Debug information

This section is not applicable for the module being described.

14.9 GETH revision history

Initial release of the chapter.

14.10 TC4Dx GETH information

14.10.1 TC4Dx GETH configuration

Table 777 Device specific parameters

Parameter	GETH module
Number of MACs	2
Data rate	10M/100M - Full duplex and Half duplex 1G/2.5G (by GMII only) /5G - Full duplex only
Bridge	Yes
Number of TxQ per MAC	8
TxQ memory size per MAC	32 KBytes
Number of RxQ per MAC	8
Rx memory size per MAC	32 KBytes
Number of Rx DMA Channels	8
Number of Tx DMA Channels	8
Number of MAC filters per MAC	32
Number of VLAN filters per MAC	8
Number of Layer 3 and Layer 4 filters	8
Number of Traffic Classes (TC)	8 (TC0-7)
CBS Enabled Traffic Classes	TC5, TC6 and TC7
PHY interfaces	MII, RMII, RGMII and SGMII (UXSGMII for 5G mode)
Maximum Entries of Flexible Receive Parser (FRP) Instruction Table	256
Maximum FRP Parsable Bytes from Start of Packet	256 Bytes

14.10.2 TC4Dx GETH features

There are no deviations from the generic specification.

14.10.3 TC4Dx GETH functional description

There are no deviations from the generic specification.

14.10.4 TC4Dx GETH registers

14.10.4.1 Memory overview tables of GETH

Table 778 Memory overview - GETH (ascending address)

Short name	Long name	Address
GETH0_Memory	(10000_H Byte)	$F9020000_H$

14.10.4.2 Register address space - GETH

Table 779 Registers address space - GETH

Module	Base address	End address	Note
GETH0	$F9000000_H$	$F902FFFF_H$	

14.10.4.3 Register overview - access mode glossary

Table 780 Register overview - access mode glossary

Keyword	Description
SE	Access protection using PROT register GETH0_PROTSE .
APU-PCHy (y=0-7)	Protection group consisting of registers GETH0_ACCENCHy_WRA , GETH0_ACCENCHy_WRB , GETH0_ACCENCHy_RDA , GETH0_ACCENCHy_RDB , GETH0_ACCENCHy_VM , GETH0_ACCENCHy_PRS .
PCHy	Access protection using *APU-PCHy* registers.
APU-PG	Protection group consisting of registers GETH0_ACCENGLOBAL_WRA , GETH0_ACCENGLOBAL_WRB , GETH0_ACCENGLOBAL_RDA , GETH0_ACCENGLOBAL_RDB , GETH0_ACCENGLOBAL_VM , GETH0_ACCENGLOBAL_PRS .
PG	Access protection using *APU-PG* registers.
APU-PMy (y=0-1)	Protection group consisting of registers GETH0_ACCENMACy_WRA , GETH0_ACCENMACy_WRB , GETH0_ACCENMACy_RDA , GETH0_ACCENMACy_RDB , GETH0_ACCENMACy_VM , GETH0_ACCENMACy_PRS .
PMy	Access protection using *APU-PMy* registers.
BE	Always returns a Bus Error.
32	Access only when using 32-bit width.
PROT	Access restrictions as defined in the PROT register access rules.

14.10.4.5 Device specific registers

There are no device specific register changes.

14.10.5 TC4Dx GETH connectivity

The table below lists interfaces to and from this functional block to other blocks in the device.

Table 782 List of GETH interface signals

Interface signals	I/O	Description
SRI_GETH_SIF	In	[SRI] slave interface, that provides software access to Configuration and Monitoring function.
GETH_SRI_MIF	Out	[SRI] Master Interface
CLOCK_GETH_fSRI	In	Clock for [GETH] configuration
CLOCK_GETH_fGETH	In	Clock (aclk_i) for [GETH] Receive and Transmit function (MTL + DMA) and PTP (clk_ptp_ref_i)
SMM_GETH_ApplicationReset	In	Application Reset
SMM_GETH_DebugReset	In	Debug Reset
GETH0_IR_SRC_GETHDMA[15:0]	Out	DMA TX and Rx Interrupt event to [IR]
GETH0_IR_SRC_GETHPPS[3:0]	Out	MAC[1:0]_PPS[1:0] Interrupt event to [IR]
GETH0_IR_SRC_GETHINTR	Out	Combined MAC0 or MAC1 Side Band Interrupt event to [IR]
GETH0_EGTM_SRC_GETHPPS[3:0]	Out	MAC[1:0]_PPS[1:0] Trigger event to [eGTM]
GETH0_PORTS_PPS[3:0]	Out	MAC[1:0]_PPS[1:0] output to [PORTS]
GETH0_SMU_GETHCE_ALARM	Out	Safety alarm signals to [SMU]
GETH0_SMU_GETHNCE_ALARM	Out	Safety alarm signals to [SMU]
GETH0_SMU_GETHSE_ALARM	Out	Safety alarm signals to [SMU]
GETH0_HSPHY_P0_TXEN	Out	MAC0 Transmit Enable of MII and RMII
GETH0_HSPHY_P0_GMIITXD[7:0]	Out	MAC0 Transmit Data, GMIITXD[3:0] for MII interface and GMIITXD[7:0] for GMII interface
GETH0_HSPHY_P0_TXER	Out	MAC0 Transmit Error of MII
HSPHY_GETH0_P0_TXCLK	In	MAC0 MII transmit clock Input (clk_tx_i) from PHY (10/100 Mbps). The external PHY or oscillator provides this transmission clock. TXD[3:0] is synchronous to this clock. This is 25 MHz in 100 Mbps mode and 2.5 MHz in 10 Mbps mode.
HSPHY_GETH0_P0_COL	In	MAC0 Collision MII
HSPHY_GETH0_P0_CRS	In	MAC0 Carrier Sense MII
HSPHY_GETH0_P0_RXDV	In	MAC0 Receive Data Valid MII
HSPHY_GETH0_P0_GMIIRXD[7:0]	In	MAC0 Receive Data, GMIIRXD[3:0] for MII interface and GMIIRXD[7:0] for GMII interface

(table continues...)

Table 782 (continued) List of GETH interface signals

Interface signals	I/O	Description
HSPHY_GETH0_P0_RXER	In	MAC0 Receive Error MII
HSPHY_GETH0_P0_RXCLK	In	MAC0 Receive clock (clk_rx_i) from PHY. The external PHY provides this receive clock for MII interfaces. This clock is 25 MHz in 100 Mbps mode, 2.5 MHz in 10 Mbps mode. Needs a clock input during SW reset (GETH0_DMA_MODE.SWR).
GETH0_HSPHY_P0_TXD[3:0]	Out	MAC0 Transmit Data, TXD[3:0] for RGMII. TXD[1:0] for RMII
HSPHY_GETH0_P0_RXD[3:0]	In	MAC0 Receive Data, RXD[3:0] for RGMII. RXD[1:0] for RMII
HSPHY_GETH0_P0_CRSDV	In	MAC0 Carrier Sense / Data Valid combi-signal for RMII
HSPHY_GETH0_P0_REFCLK	In	MAC0 50-MHz clock (clk_rmii_i) used by the RMII from PHY. In 100 Mbps Mode, it is divided internally to 25 MHz and provided to the internal MII interface. If RMII is downgraded to 10 Mbps it is divided internally to 2.5 MHz. This division is controlled automatically by evaluation of mac_speed_o[1:0] and phy_intf_sel_i[2:0]. Needs a clock input during SW reset (GETH0_DMA_MODE.SWR).
GETH0_HSPHY_P0_TCTL	Out	MAC0 Transmit Control for RGMII
HSPHY_GETH0_P0_GETH_TXCLK	In	MAC0 RGMII transmission clock input (clk_tx_i) from HSPHY. TXD[3:0] is synchronous (DDR) to this 125 MHz clock to the PHY. If RGMII is downgraded to 100 Mbps it is divided internally to 25 MHz and for 10 Mbps to 2.5 MHz. In each case it is generated from clk_gref_i by respective division. TXCLK has the same on chip delay and output pad delay as the TXD signals and TCTL unless clock skew is selected in SKEW.
HSPHY_GETH0_P0_GETH_RXCLK	In	MAC0 Receive clock (clk_rx_i) from PHY. The external PHY provides this receive clock for RGMII This clock is 125 MHz in 1 Gbps mode, 25 MHz in 100 Mbps mode. Needs a clock input during SW reset (GETH0_DMA_MODE.SWR).
HSPHY_GETH0_P0_RCTL	In	MAC0 Receive Control for RGMII
HSPHY_GETH0_P0_XGMIIRX[31:0]	In	MAC0 RXD interface of XGMII
GETH0_HSPHY_P0_XGMIITX[31:0]	Out	MAC0 TXD interface of XGMII
GETH0_HSPHY_P0_MDC	Out	MAC0 MDIO clock
GETH0_HSPHY_P0_MDIO	Out	MAC0 MDIO data output for bidirectional pin
HSPHY_GETH0_P0_MDIO	In	MAC0 MDIO data input for bidirectional pin
GETH0_HSPHY_P1_TXEN	Out	MAC1 Transmit Enable of MII and RMII
GETH0_HSPHY_P1_GMIITXD[7:0]	Out	MAC1 Transmit Data, GMIITXD[3:0] for MII interface and GMIITXD[7:0] for GMII interface
GETH0_HSPHY_P1_TXER	Out	MAC1 Transmit Error of MII

(table continues...)

Table 782 (continued) List of GETH interface signals

Interface signals	I/O	Description
HSPHY_GETH0_P1_TXCLK	In	MAC1 MII transmit clock Input (clk_tx_i) from PHY (10/100 Mbps). The external PHY or oscillator provides this transmission clock. TXD[3:0] is synchronous to this clock. This is 25 MHz in 100 Mbps mode and 2.5 MHz in 10 Mbps mode.
HSPHY_GETH0_P1_COL	In	MAC1 Collision MII
HSPHY_GETH0_P1_CRS	In	MAC1 Carrier Sense MII
HSPHY_GETH0_P1_RXDV	In	MAC1 Receive Data Valid MII
HSPHY_GETH0_P1_GMIIRXD[7:0]	In	MAC1 Receive Data, GMIIRXD[3:0] for MII interface and GMIIRXD[7:0] for GMII interface
HSPHY_GETH0_P1_RXER	In	MAC1 Receive Error MII
HSPHY_GETH0_P1_RXCLK	In	MAC1 Receive clock (clk_rx_i) from PHY. The external PHY provides this receive clock for MII interfaces. This clock is 25 MHz in 100 Mbps mode, 2.5 MHz in 10 Mbps mode. Needs a clock input during SW reset (GETH0_DMA_MODE.SWR).
GETH0_HSPHY_P1_TXD[3:0]	Out	MAC1 Transmit Data, TXD[1:0] for RMII
HSPHY_GETH0_P1_RXD[3:0]	In	MAC1 Receive Data, RXD[1:0] for RMII
HSPHY_GETH0_P1_CRSDV	In	MAC1 Carrier Sense / Data Valid combi-signal for RMII
HSPHY_GETH0_P1_REFCLK	In	MAC1 50-MHz clock (clk_rmii_i) used by the RMII from PHY. In 100 Mbps Mode, it is divided internally to 25 MHz and provided to the internal MII interface. If RMII is downgraded to 10 Mbps it is divided internally to 2.5 MHz. This division is controlled automatically by evaluation of mac_speed_o[1:0] and phy_intf_sel_i[2:0]. Needs a clock input during SW reset (GETH0_DMA_MODE.SWR).
HSPHY_GETH0_P1_XGMIIRX[31:0]	In	MAC1 RXD interface of XGMII
GETH0_HSPHY_P1_XGMIITX[31:0]	Out	MAC1 TXD interface of XGMII
GETH0_HSPHY_P1_MDC	Out	MAC1 MDIO clock
GETH0_HSPHY_P1_MDIO	Out	MAC1 MDIO data output for bidirectional pin
HSPHY_GETH0_P1_MDIO	In	MAC1 MDIO data input for bidirectional pin

16 HSPHY - NDA only

Information for this functional block is only available under NDA.

17 High Speed Serial Link (HSSL)

The HSSL module provides point-to-point communication of both single data values and of large data blocks, called streams. The communicating partner can be complex microcontrollers, or a microcontroller and a device with only basic execution capabilities.

The HSSL module supports single block 8, 16, or 32-bit data write or read transfers either to or from the target device's register. Using a streaming channel it also supports transfers of long 256-bit data blocks.

The HSSL module consists of two main sub-modules:

- High Speed Serial Link (HSSL)
- High Speed Communication Tunnel (HSCT)

The HSSL sub-module implements Transport Layer tasks and hands over the data to the HSCT sub-module which provides Data Link Layer and Physical Layer services, data serialization, and transmission. All transfers are protected by safety features such as Cyclic Redundancy Check(CRC) and timeout.

17.1 Feature list

- Flexible functional configuration by application software
  - Frame formatting configuration
  - Various operation modes
  - TX-link baudrate support (10 MHz/20 MHz SysClk(System Clock)): 5 MBaud (low speed) and 320 MBaud (high speed)
  - TX-link baudrate support (25 MHz SysClk): 6.25 MBaud (low speed) and 320 MBaud (high speed)
  - RX-link baudrate support (20 MHz SysClk): 5 MBaud (low speed), 20 MBaud (medium speed) and 320 MBaud (high speed)
  - RX-link baudrate support (10 MHz SysClk): 5 MBaud (low speed) and 320 MBaud (high speed)
  - RX-link baudrate support (25 MHz SysClk): 6.25 MBaud (low speed) and 320 MBaud (high speed
- Transmit HSSL frames to external devices and handle all protocol relevant topics
  - Writing a single 8, 16, or 32-bit data value into the register of a target device
  - Supports transfers of a long 256-bit streaming data block
  - Automatic frame transfer ID (IDentity) generation for detection of dropped frames
  - Acknowledge for command and stream frames
- Receive HSSL frames from external devices and handle all protocol relevant topics
  - Reading single data from an 8, 16, or 32-bit register of a target device
  - Supports reception of a long 256-bit streaming data block
- Transfers protected by CRC16 (16 bit Cyclic Redundancy Check)
- Support of 32-bit address range
- Read and write HSSL frame data either to or from system address space
  - Support of Direct Memory Access(DMA) driven multiple register write or read transfers
  - Two stage FIFOs (First in, First Outs) for transmitting and receiving streaming data
- Flexible event signaling and interrupt structure
  - Programmable timeouts for detection of blocked answer transfers
  - Remote trigger of an event or an interrupt in the target device by the initiator
  - Total 17 interrupt lines, four types of channel specific interrupt per channel and one module interrupt
- Automatic FIFO flush when entering the run mode, for error handling
- Read and write access protection by an external Memory Protection Unit (MPU)
- Identification of the target by the JTAG ID (Joint Test Action Group Identification) number

- Multi-slave connection supports up to three slaves
- The communication interface is based on IEEE 1596.3 LVDS IOs (Low Voltage differential Signaling Input Outputs)and provides driver swing amplitude configuration

17.2 Functional overview

The block diagram of the HSSL module is shown in the following figure:

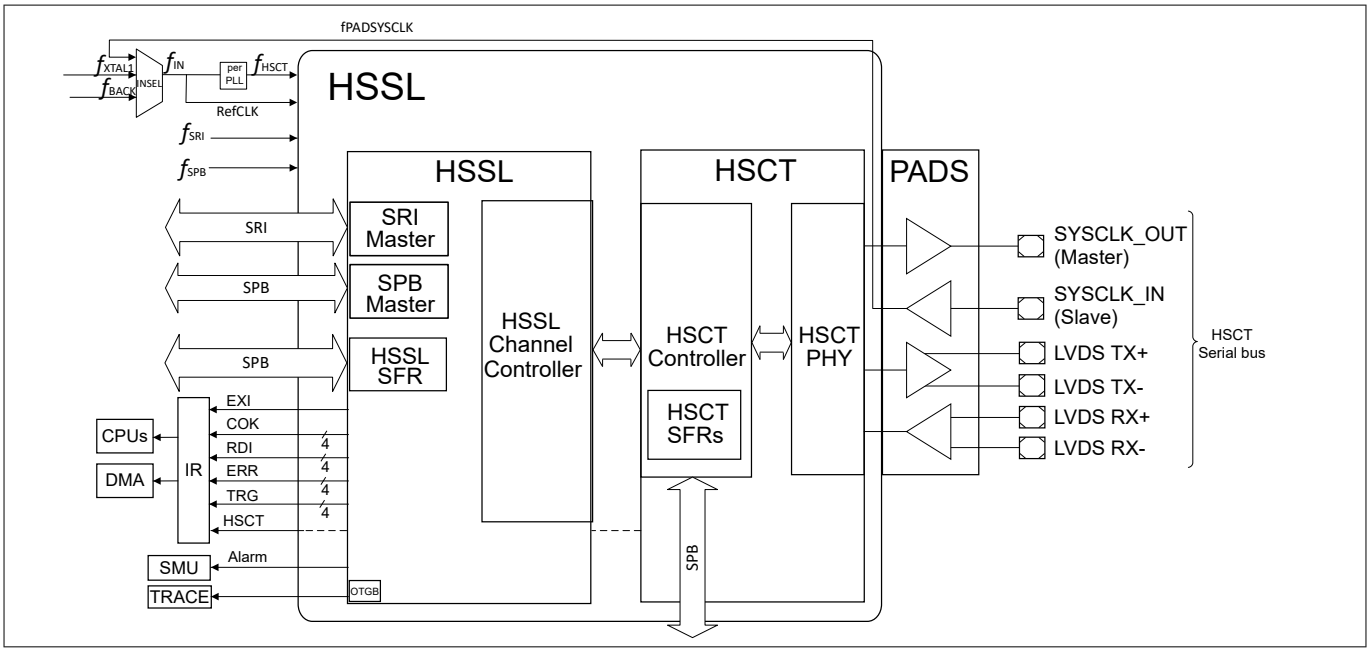

Figure 190 HSSL block diagram

***Note**: The bus interface used by the HSSL module is defined in the device specific chapter.*

The HSSL has one alarm, called 'HSSL SRI Read Data EDC Error' interfacing to the SMU (EDC stands for Error Detection and Correction). For the alarm description please refer to the alarm mapping tables in the SMU functional block and the safety manual. A set of 17 interrupts are mapped to IR(Interrupt Router), four types of channel specific interrupts per channel and one module interrupt. In order to support the debugging activities, the HSSL provides a set of internal signals to the on-chip debug system OCDS (On Chip Debug System) through OTGB (OnChip Trigger Generation Bus) trigger buses.

High Speed Serial Link (HSSL)

The HSSL sub-module provides point-to-point communication for both single data values and large data blocks, called streams. The functionality of each of these channels is further sub divided as 'transmitter and receiver' and 'Initiator and target' controllers by the HSSL channel controller. The communicating devices can be complex micro controllers, or a microcontroller and a device with only basic execution capabilities. There are four channels to transfer single values to/from target. They support direct writing of 8/16/32 bit data from the initiator into a target's local address map (e.g., registers and memory), as well as reading a value from a target, performed by a modules internal SPB/SRI bus master on the target side. For transferring large data blocks there is a channel containing FIFOs. The HSSL module implements transport layer tasks and hands over the data to another module which provides data link layer and physical layer services, data serialization and transmission. All transfers are protected by safety features like CRC and timeout. The SRI and SPB master interface on the target HSSL helps in accessing the peripherals on the corresponding bus. The SPB slave interface helps in accessing the special function registers of HSSL.

The SRI master interface is capable of performing both single and burst reads and writes on the SRI bus. The SPB slave interface is used by an SPB master (DMA, CPU, HSSL SPB Master) for writing the HSSL SFRs, so configuring the module and performing single read and write operations.

High Speed Communication Tunnel (HSCT)

The lower layer companion module and logic control the lower communication layers positioned between two devices, the data, and the physical layer. They consist of the High Speed Communication Tunnel (HSCT) and pads. For more information on the lower communication layers, see the HSCT chapter. The SPB slave interface helps in accessing the special function registers of HSCT.

The chip-to-chip interface employs a digital interface for inter chip communication between a master or a slave HSCT instance. The interface is capable of running in a master or in a slave HSCT mode. During configuration phase the role of the Interface (master or slave) has to be defined. It is not intended to change the system role after initialization and start-up. The HSCT controller consists of framer, deframer and the corresponding FSMs(finite state machines) along with the SFRs controlled via SPB slave interface.

The interface consists of a full-duplex RX and TX high-speed data interface based on double ended differential signals (in total 4 lines) and a master clock interface (SYSCLK_OUT). The master IC owns the crystal and provides the clock to the slave. The interface reset is derived from the System reset and provided by chip internal reset signaling.

17.3 Functional description

The functional description is divided into the blocks sub-functions that follow.

17.4 High Speed Serial Link (HSSL)

This chapter explains the detailed functional behavior on transport layer tasks of the HSSL sub-module.

17.4.1 Feature list

- Connecting microcontroller to microcontroller or to any digital device
- Writing a single 8, 16, or 32-bit data value into the register of a target device
- Reading single data from an 8, 16, or 32-bit register of a target device
- Supporting 32-bit address range
- Transfers protected by CRC16 (16 bit Cyclic Redundancy Check)
- Programmable time outs for detection of blocked answer transfers
- Automatic frame transfer ID (IDentity) generation for detection of dropped frames
- Supporting DMA (Direct Memory Access) driven multiple register write and read transfers
- Efficient transmission and reception of large data blocks and streams
- Acknowledge for command and stream frames
- Two stage FIFOs(First in, First Outs) for transmitting and receiving streaming data
- Automatic FIFO flush when entering the run mode, for error handling
- Write protection by an external Memory Protection Unit (MPU)
- Remote trigger of event and interrupt in the target device by the initiator
- Identification of the target by the JTAG ID(Joint Test Action Group Identification)number
- Feature set identification of the HSSL module possible by using the JTAG ID number
- Access protection from an external master

17.4.2 Functional overview

The HSSL sub-module generates all necessary protocol formats in order to enable two devices to communicate to each other. Two basic modes are supported. In register transfer mode the transmitter (sending device) provides an address and a data value by writing them into dedicated registers of the HSSL sub-module. The HSSL sub-module puts it into an envelop (called a frame) and forwards it through the HSCT protocol and physical layer to the target device. The target takes the information out of the frame and writes the received data into the address which came in the same frame as the data. If the sender wants to read the content of a register or a memory location, it simply sends only the address. The target device reads the value from the specified location and replies it to the sender by transferring it through an answer frame.

The transfer of register or memory contents is protected by several security levels. A 16-bit CRC value (called CRC16) is attached to the end of each frame. Each transfer process triggers a watchdog, which makes sure that the communication happens within a deterministic schedule. The target device itself offers the capability to define access windows, which allow reading or writing only from or into certain address ranges.

Each frame must be acknowledged by the target by sending an appropriate response frame. If the response frame does not come inside a predefined time window, the initiator module triggers a timeout interrupt.

In data stream mode data blocks of user defined size can be moved from the memory of the sending device into the memory of the target device. A DMA master, which can be configured with any source address and source length (in multiple of 256-bit frame), autonomously fetches data, breaks it into smaller blocks of programmable size, and puts it into a FIFO. The lower level companion module of the HSSL module empties the FIFO from the 'other side' to the physical lines, which connect two devices. The target device's structure is the reverse of the sender system's, in which the HSSL module's lower-level companion module , puts received data blocks into a FIFO, which is in turn emptied by a DMA master into the target memory.

All streaming data transfers are subject to the protection features which are available for the register transfer mode.

The finite state machine is taking care of the protocol's request/response pair arbitration and administration of the four virtual HSSL channels.

17.4.3 Functional description

This chapter describes in detail the HSSL sub-module functional operation.

17.4.3.1 HSSL protocol definition

The HSSL communication normally consists of two stage transactions; sending a command and receiving a response.

The communication involves two participants:

- An initiator
  - Starts a transaction by sending a command
- A target
  - Responds to the command

17.4.3.1.1 Terms and descriptions

Table 783 Common HSSL terms

Term	Description
ACK	Acknowledge frame
CRC	Cyclic redundancy check
HSSL	High speed serial link
Initiator	Device that starts a HSSL transaction by sending a command frame
lsb	Least significant bit
msb	Most significant bit
NACK	Not acknowledge frame (target error frame)
SoC	System on chip
SPB	Serial peripheral bus
Target	Device that responds to a command frame sent by an initiator
TO	Time out
TT	Transaction tag
TTERR	Transaction tag error

17.4.3.1.2 Frame types

The HSSL module generates a serial frame by:

- Taking the payload delivered by either a CPU or a DMA
- First wrapping it in a HSSL frame by adding header and CRC fields
- Wrapping the HSSL frame in a HSCT frame by adding Sync, header, and End bit-fields

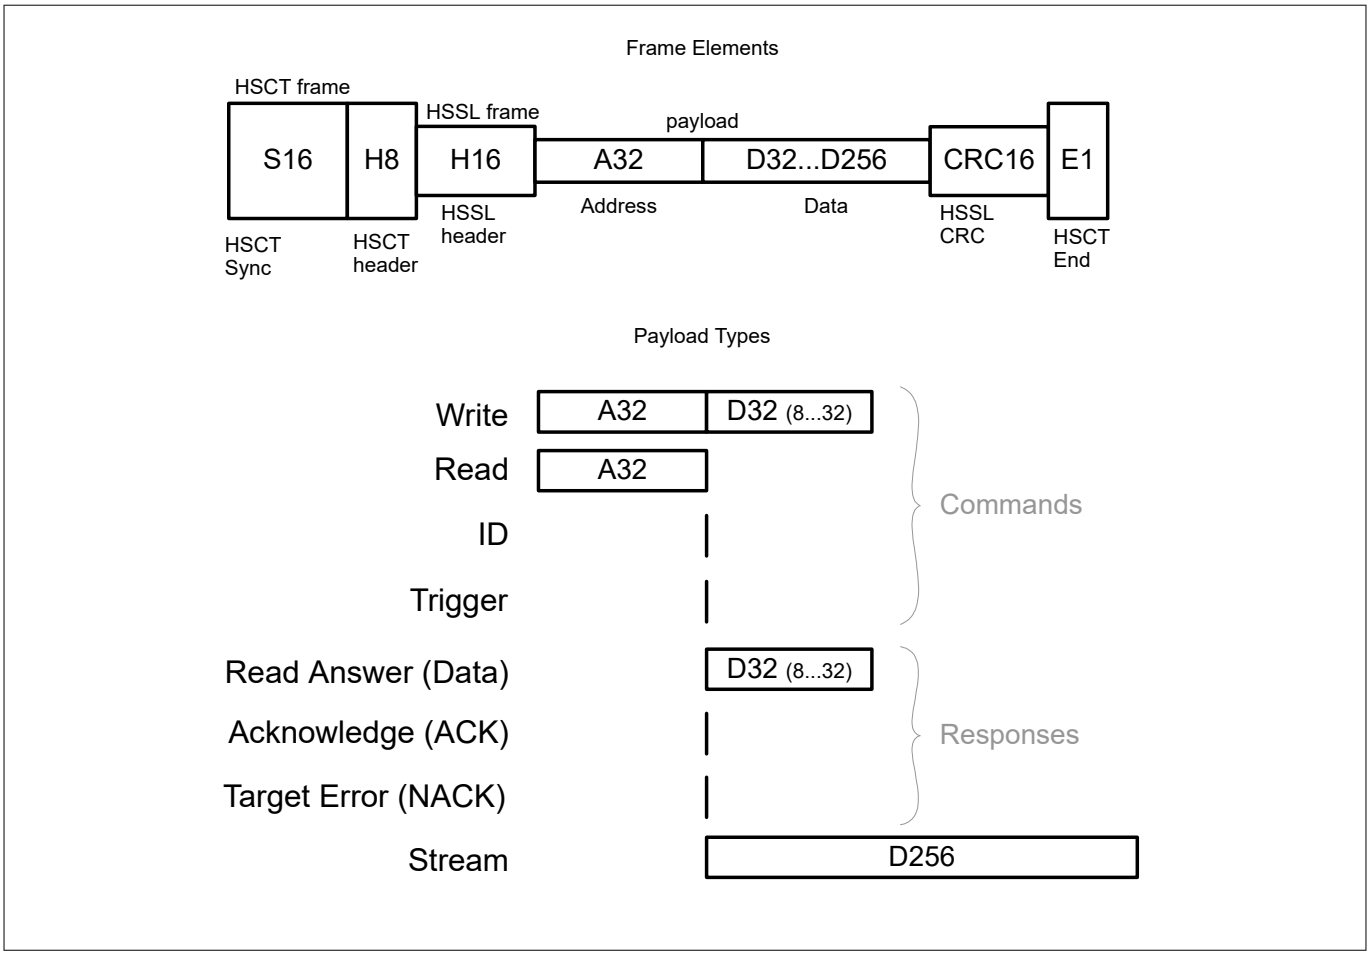

Figure 192 HSSL frame types

There are several types of frames:

- Command
- Response
- Stream

Command frames

Command frames are sent by the initiator to request an action by the target. There are four types of command frames:

- Write frame
  - Used by the initiator to request the target controller to write the data to the address, both provided by the initiator
- Read frame
  - Used by the initiator to request the target controller to read and deliver a content from an address space of target
- Read ID frame
  - Used by the initiator to request the target controller to read and deliver a content uniquely defining the target device. The answer is a standard read data answer frame
- Trigger frame
  - Used by the initiator to trigger the trigger interrupt in the target module

In this document, the command frames are sometimes referred to as WRT frames

Response frames

Response frames are sent by the target either to deliver the requested data or to report a successful or unsuccessful completion of a request. There are three types of response frames:

- Read Data Answer frame
  - Used by the target to deliver the data, requested by the initiator with a read command frame. It is frequently referred to as a Data frame
- Acknowledge frame
  - Used by the target to confirm the completion of a write or a trigger command. It is frequently referred to as an ACK frame
- Target Error frame
  - Used by the target to report the unsuccessful attempt to complete a write or a read command. It is frequently referred to as a NACK frame

Stream frame

Used by the initiator controller for sending data streams. It behaves similar to a write command frame which contains long 256-bit data block. It is acknowledged in the same way, but the acknowledge uses sliding window with depth of 2, instead of 1 as for the simple command frames.

Frame and payload lengths

Each type of frame has a single data length associated with it. The length of the frame depends on the length of the payload. Different frame types have different payload lengths, but the payload length for one type is constant for all variations of the frame type.

For example all data frames have the same length, although they can carry 8, 16, or 32-bit data. This is due to the fact that the data field in the frame is always 32 bit long, and if the data itself is shorter, it is copied several times to fill in the whole field. The same behavior is valid for the read answer frames.

The rest of the frame, consisting of sync and header fields, has always the same length.

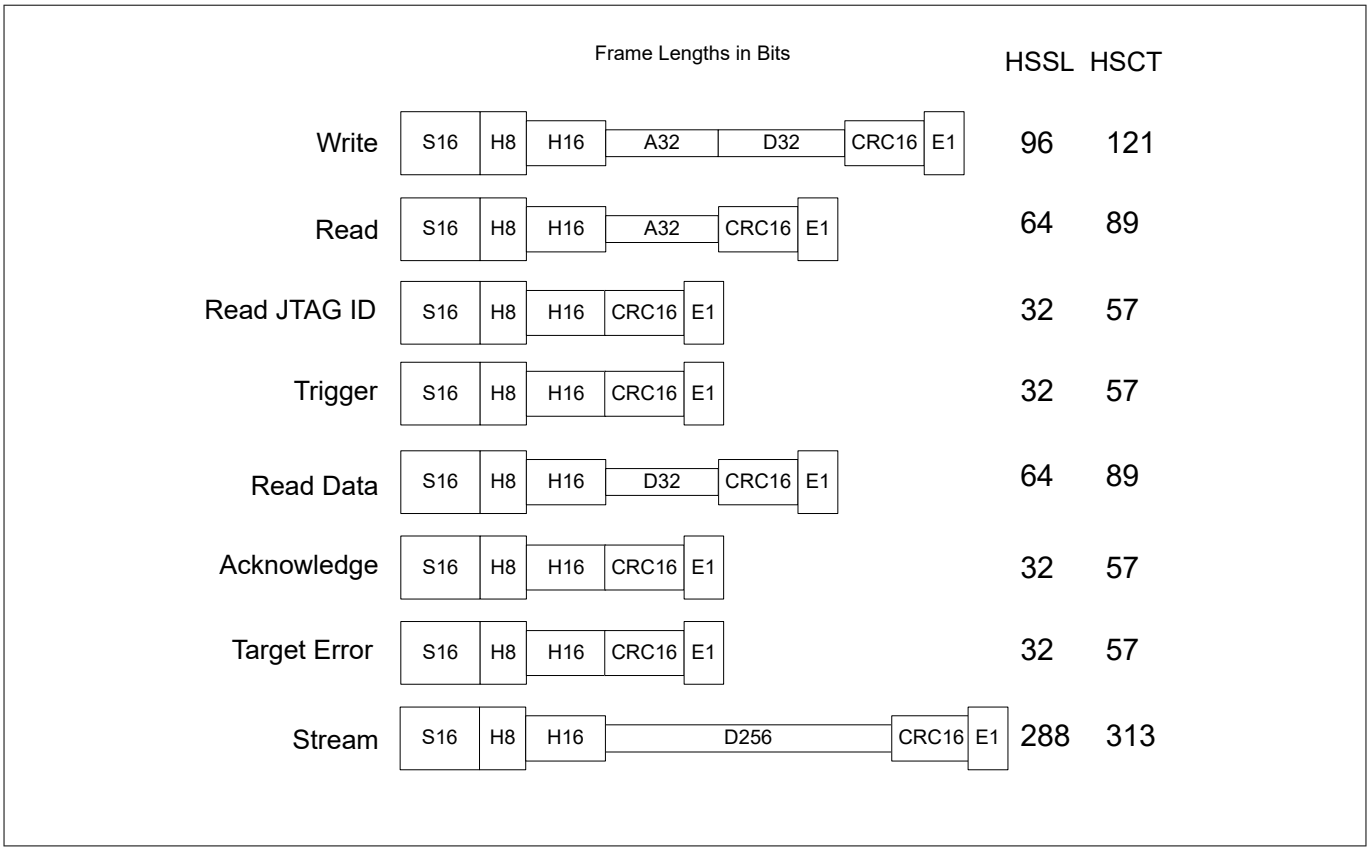

Figure 193 Frame lengths

Data types

There are four types of HSSL data:

- 8-bit
- 16-bit
- 32-bit
- 256-bit stream block

In the case of 8, 16, or 32-bit data types, the transmitted number of bits is always 32, where the shorter data types are copied several times to fill up this length. In case of 256 bit stream, each data length transmitted is of 8 bit.

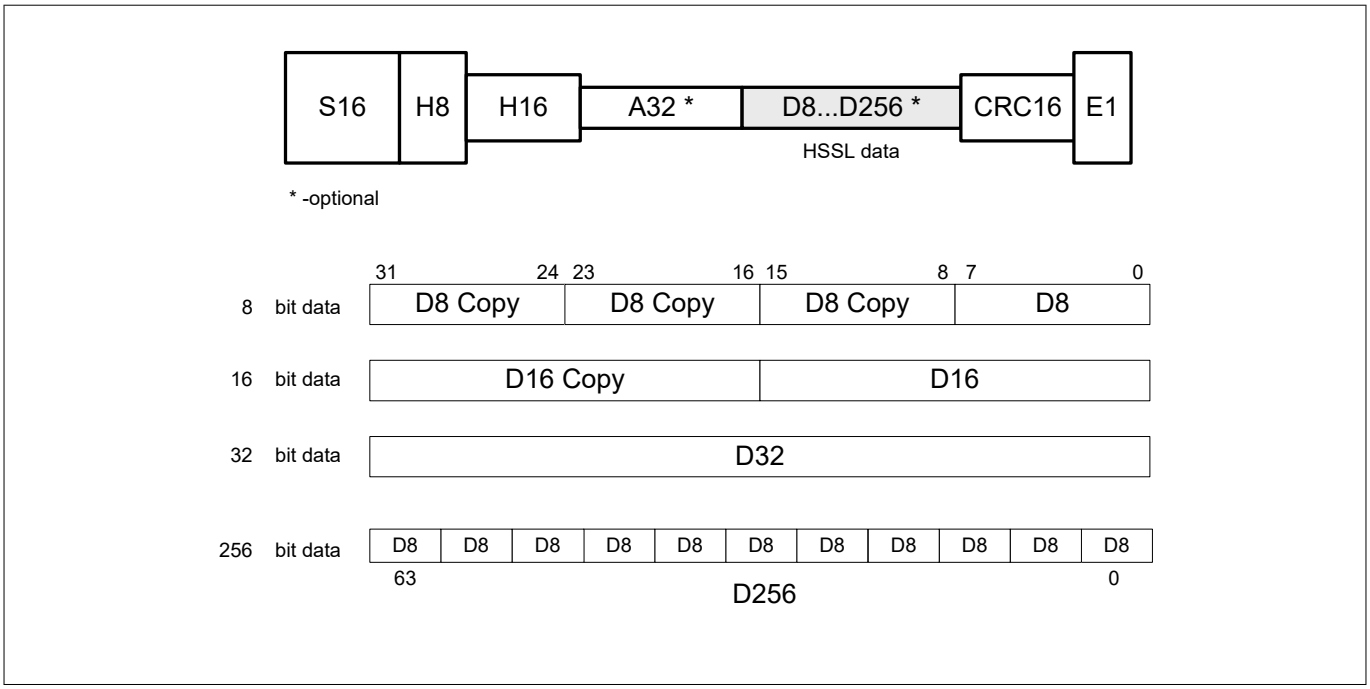

Figure 194 Data types

Cyclic redundancy check (CRC) field

The HSSL protocol uses the CRC-16-CCITT polynomial: $x^{16} + x^{12} + x^5 + 1$ with the following standard properties:

- Seed: $FFFF_H$
- Calculation direction: Msb first (header msb to lsb, then payload msb to lsb)
- CRC result direction: Msb first

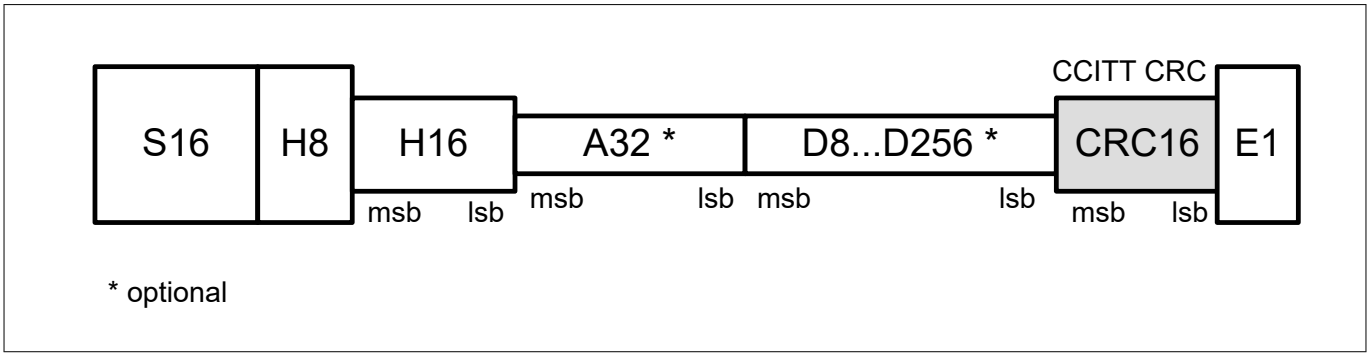

Figure 195 CRC field

Header structure

The HSSL header contains the protocol information that is required in addition to the raw payload data. The HSSL header describes the payload data in terms of the length and the type, and carries additional information such as the channel number code and transaction tag.

The header also carries stand-alone information in case of frames without payload, such as acknowledge and trigger frames.

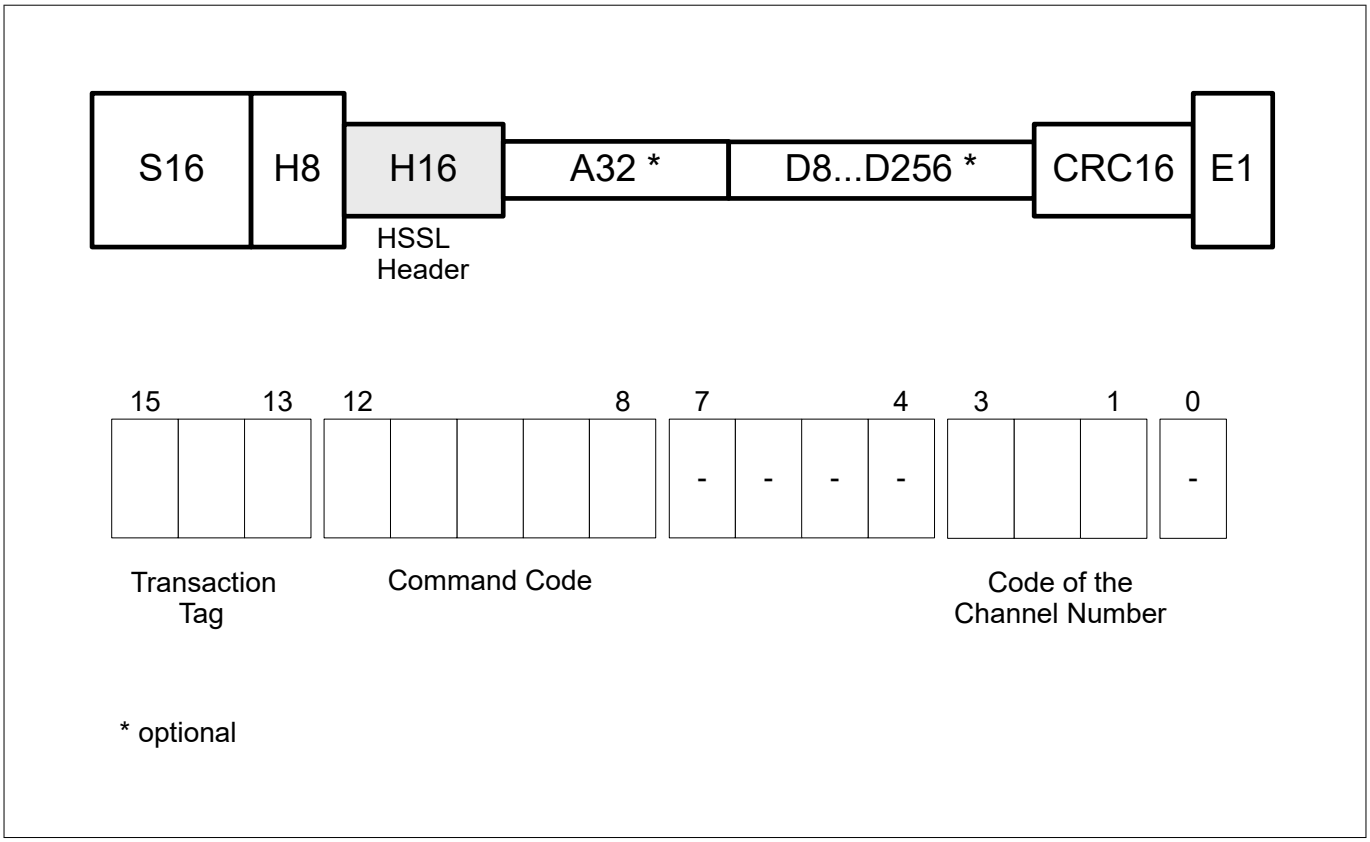

Figure 196 Header types

***Note**: The unused bits in the header are padded with 0.*

Table 784 Mapping of HSSL to HSCT channel codes

HSSL channel number	HSSL channel number, binary code	HSSL channel number, special code	HSCT channel	HSCT channel code
0	000	100	A	0100

11111	RFU	-

17.4.3.1.3 Single and block transfers

Single frame transfers are always performed expecting an acknowledgment.

17.4.3.1.4 Streaming interface

Stream frame transfers are always performed with an acknowledgment for each transfer.

There are only write streams possible. Read streams are not possible.

17.4.3.1.5 Sliding window protocol

For flow control, the HSSL module implements two variants of the 'Sliding Window' protocol depending on the sliding window depth:

- Depth of one used for command frames
  - The depth of one means that a single timer tracks the arrival of the corresponding response frame. A new command can be sent only after the response to the previous command has been received, or a timeout has occurred
- Depth of two used for streaming frames
  - The depth of two means that there are two timers tracking the acknowledgment times for the two latest streaming frames. In this case, a second stream frame can be sent although an acknowledgment or timeout to the previous stream frame has not been received yet. After the second stream frame, no third stream frame can be sent before the first one has been acknowledged

An example of communication using sliding window with depth of one protocol is shown in the next figure. Here, the initiator sends commands originating from one particular channel, for example channel 0 (labeled with the capital letter “A”), and the corresponding acknowledge frames from the target are labeled with the small letter “a”.

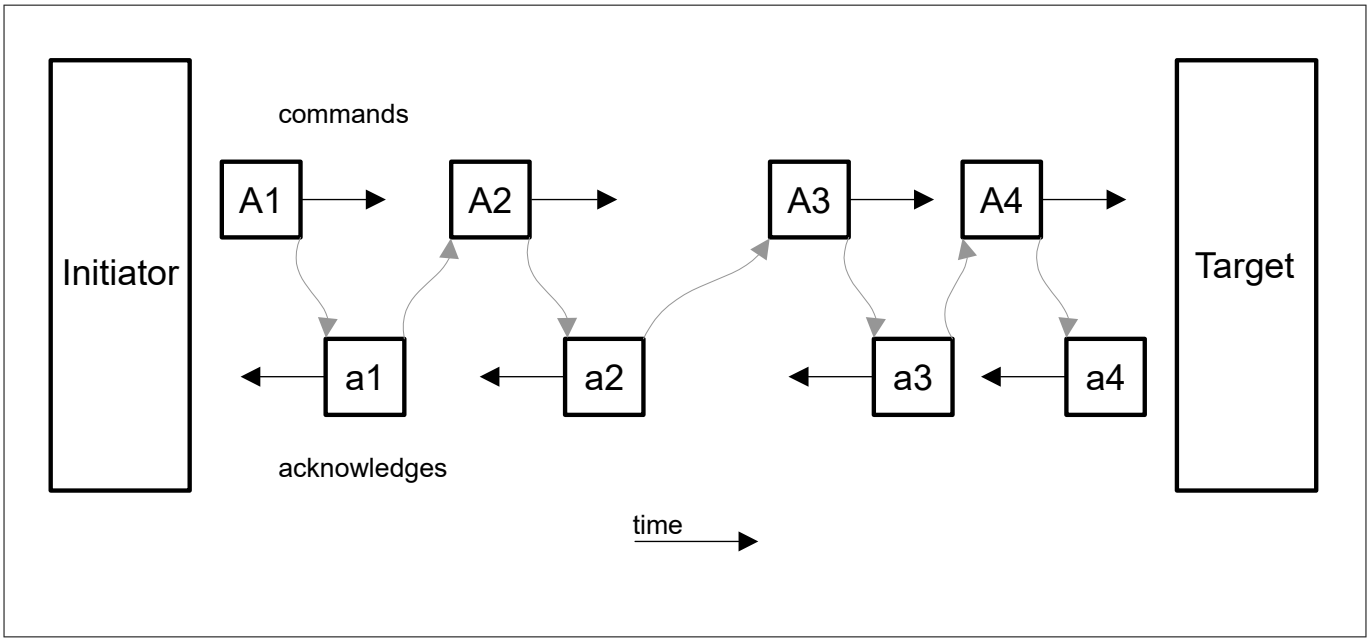

Figure 197 Flow control, single channel, sliding window with depth of one

The sliding window protocol requires the capability of sending acknowledge frames in the target, and timeout timers in the initiator.

Every time the target receives a frame without detecting an error, it sends either a response or an acknowledgment to the initiator.

If the target detects a frame with a CRC error, it does not send an acknowledgment. The missing acknowledgment causes a timeout event in the initiator channel.

If the command frames are longer than the acknowledge frames plus the reaction time, for example in the case of streaming, back-to-back transfers are easily possible, as shown in the figure below.

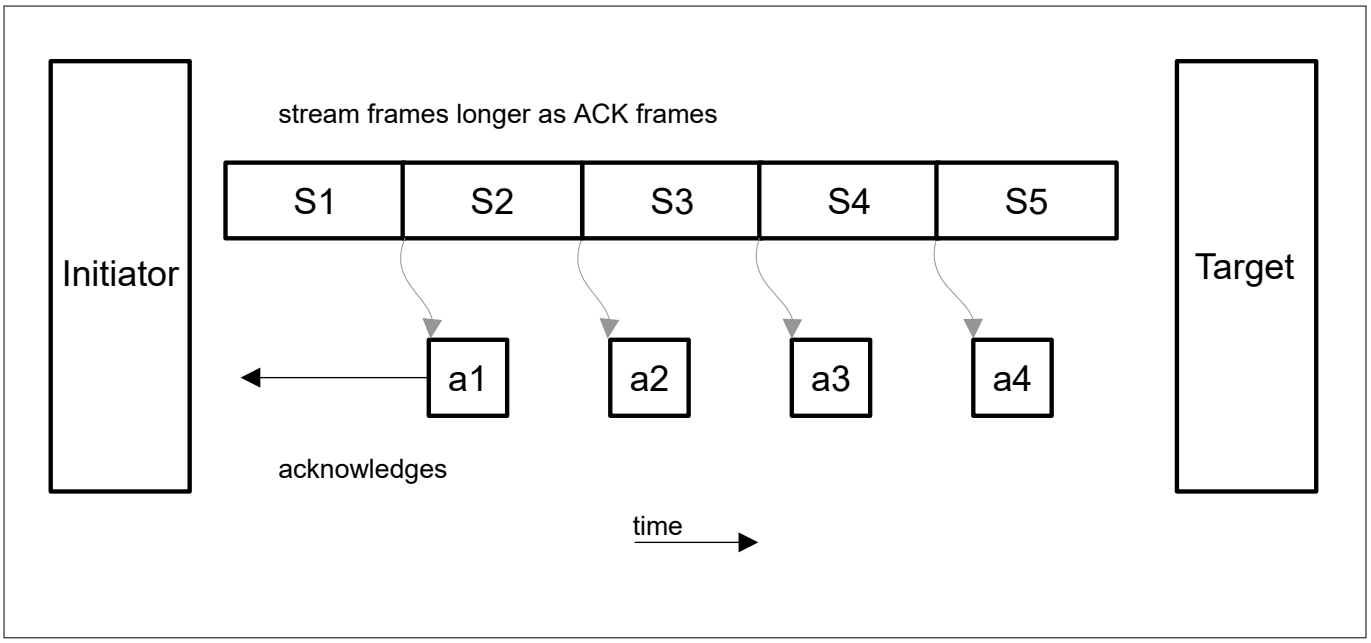

Figure 198 Flow control, streaming frames

17.4.3.1.6 Error management

The HSSL protocol defines four types of errors whose statuses can be checked in the MFLAGS register:

- Time out
- Transaction tag error
- CRC error
- Target error

Time out error

A time out error is detected at the initiator side, if the expected ACK frame was not received within the expected time window. This can occur either if a frame had been sent by the initiator, and the target detected an CRC error and did not answer with an acknowledgment, or the connection between the initiator and the target is physically damaged in one or the other direction.

Transaction tag error

A transaction tag error occurs at the initiator side, if instead the expected ACK frame with the expected TAG number, an acknowledgment with an unexpected transaction tag was received. This would indicate a missing frame or a missing acknowledgment. Transaction tag error generate frames that pass the CRC checking stage.

CRC error

A CRC error can occur:

- At the target side, in which case:
  - The CRC error flag is set
  - The received command frame with a CRC error is discarded

  - No acknowledge frame is sent
  - A channel non-specific EXI error interrupt is generated, if enabled
- At the initiator side, in which case:
  - The CRC error flag is set
  - The received response frame with a CRC error is discarded
  - A channel non-specific EXI error interrupt is generated, if enabled

Both scenarios lead to a time out at the initiator side.

In both cases the CRC error flag is set at the side receiving the erroneous frame, either initiator or target, and an interrupt is generated, if enabled.

For the purpose of CRC error injection, a bit field with an XOR mask used for toggling the bits of the calculated CRC is provided, see CRC.XORMASK. In order to switch on this feature, the XEN bit must be set by the application software. The error injection only influences the generation of the transmitted CRC.

Target error

A target error can occur while accessing the target memory. It can be a bus error or a memory protection error. In such a case, the target responds with an NACK frame indicating the error.

17.4.3.1.7 Shift direction

In general, the HSSL interface makes a copy of a memory location or block from the address space of one microcontroller into the address space of the other microcontroller.

The HSSL module delivers 32-bit parallel data.

The transfer over HSCT serial link is done by using msb first shifting at 32-bit level.

The overview of the path from the memory to the serial bus is shown in the next figure.

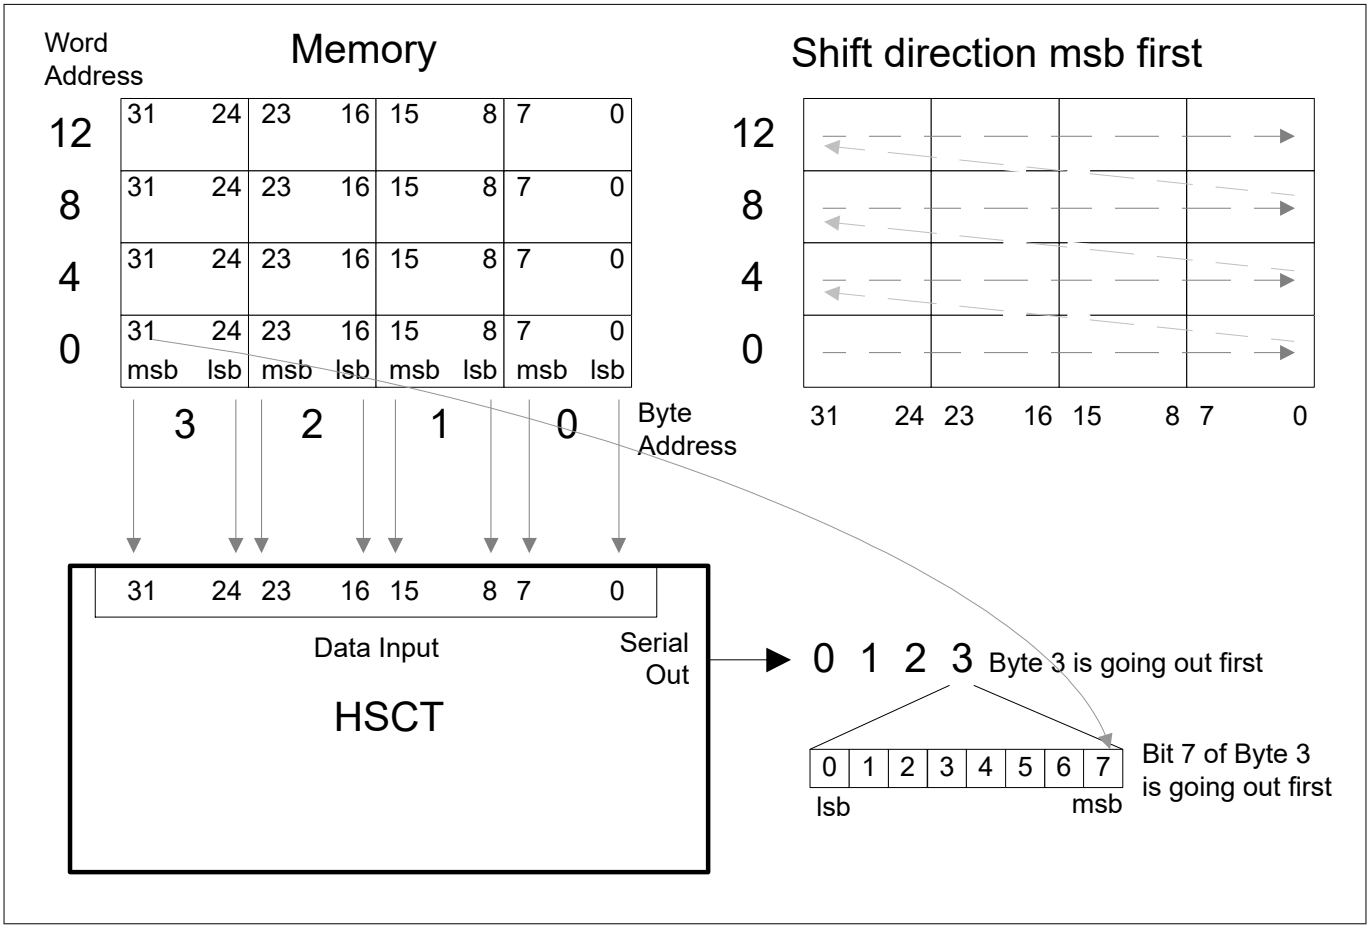

Figure 199 Shift direction in case of HSCT layer

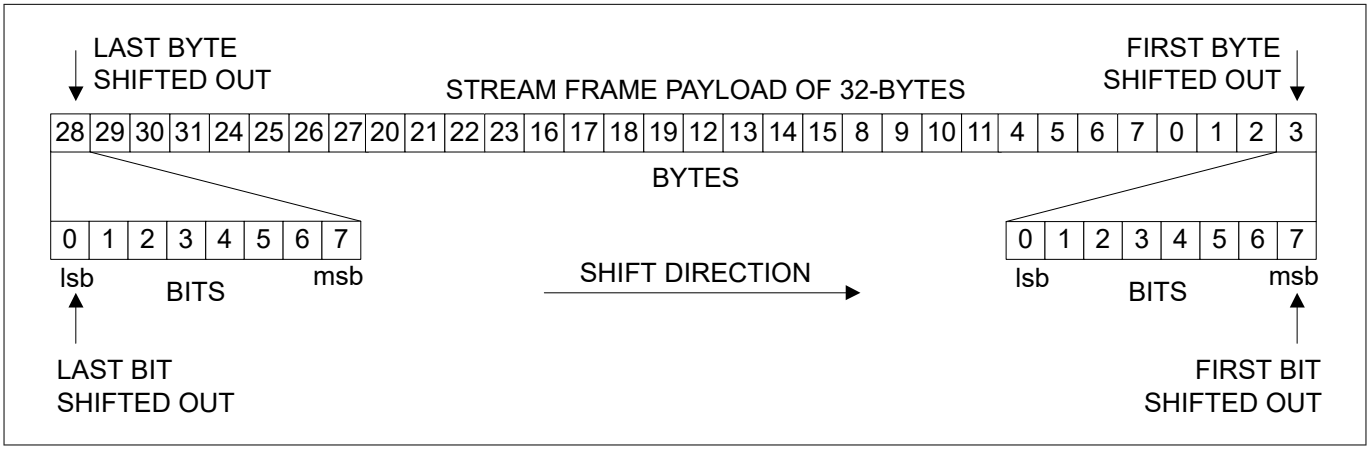

Figure 200 Stream frame in case of HSCT layer

17.4.3.2 HSSL implementation

This section describes the implementation of the HSSL protocol.

17.4.3.3 Overview

The HSSL module is connected to the SRI bus using a master interface. Additionally, the HSSL module is connected to the SPB bus with a slave and a master interface. Please refer to the System Interconnect for more details.

The SRI master interface is capable of performing both single and burst reads and writes on the SRI bus. The HSSL kernel provides logic for performing streaming communication. The write and read accesses are always performed in User Mode.

The SPB slave interface is used by an SPB master (DMA, CPU, HSSL SPB Master) for writing the HSSL registers, to configure the module and initiate the execution of streaming, read and write operations.

The SPB master interface is capable of performing single read operations, write operations, and streaming communication using BTR4 (Block Transfer Request) burst accesses on the SPB bus. The SPB master accesses are always performed in User Mode.

The HSSL module uses either the SRI master or the SPB master depending on the accessed address. The SPB address space (F000 0000_H – F3FF $FFFF_H$) is used as SPB master address window.

Accesses inside this SPB master address window are automatically routed to the SPB master, while accesses outside this SPB master address window are automatically routed to the SRI master.

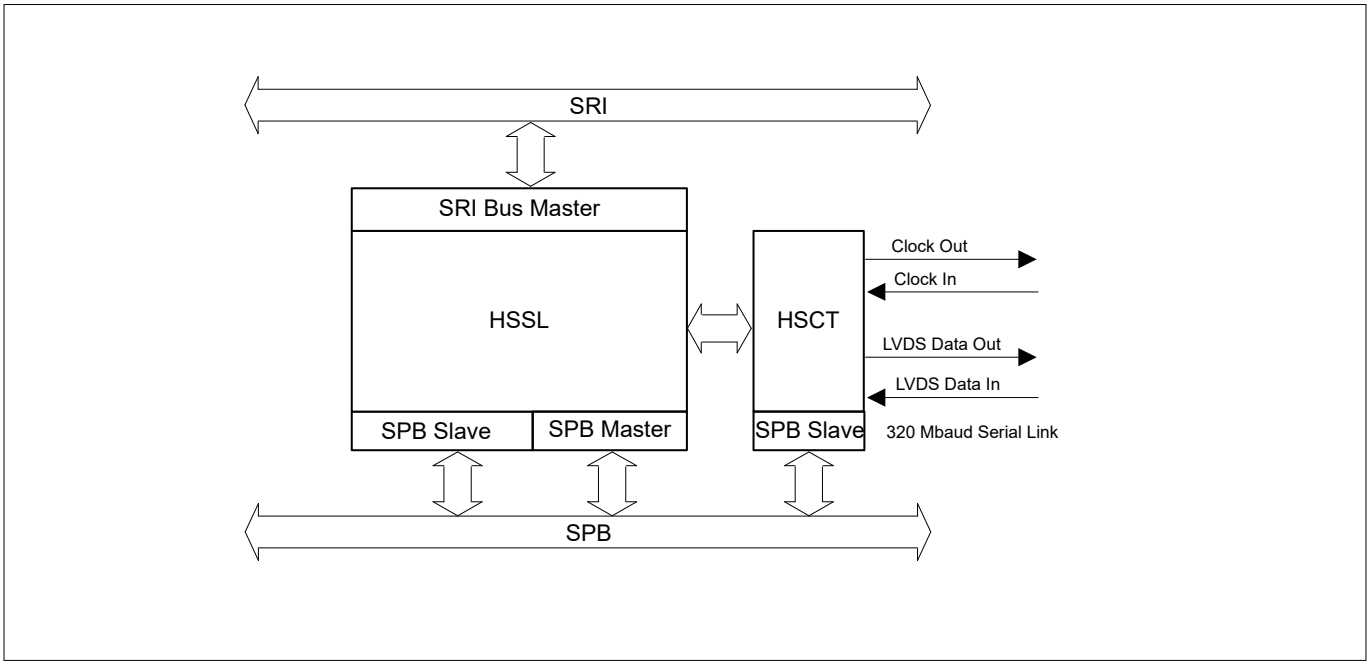

Figure 201 HSSL sub-system overview

***Note**: Any deviation from this generic description is described in the device specific chapter.*

17.4.3.3.1 HSSL operation

The HSSL module consists of separate transmitter and receiver, each containing four channels. The transmitter contains an arbiter block and a wrapper block, which are common for all channels.

17 High Speed Serial Link (HSSL)

The arbiter provides fixed arbitration between the channels which are ready to send when the serial link is available, with channel 0 having the highest priority, and channel 3 having the lowest priority. The wrapper block generates the CRC.

The receiver unwraps the HSSL frame, discards the frames with a CRC error, and distributes the error free commands and acknowledges to the channels.

A common prescaler generates the time basis for all channels, in particular for their timeout timers.

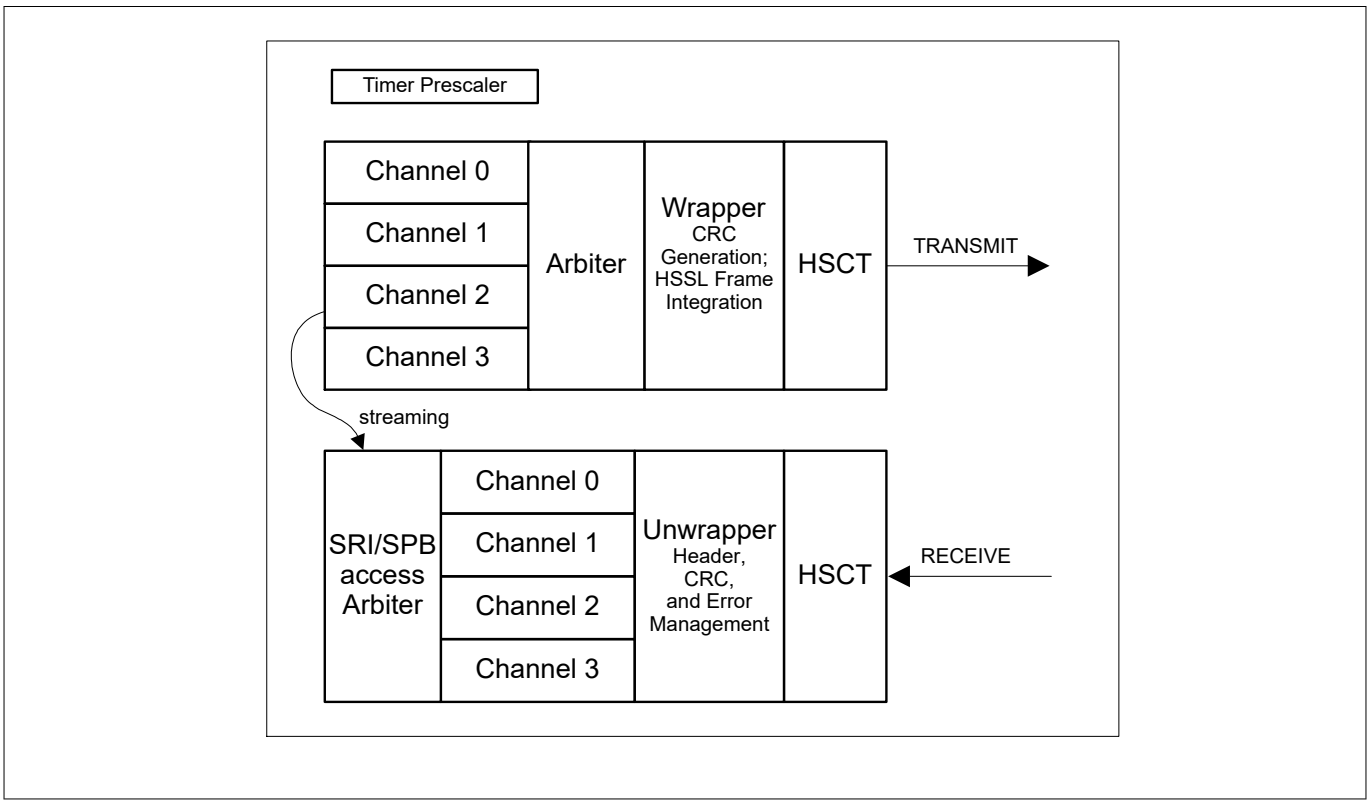

Figure 202 HSSL layer architecture

Frame transmission priorisation

When more than one frame is pending, an arbitration is performed between them. Each channel activates two flags: initiator command flag and response flag: channel 0 I0 and R0, channel 1 I1 and R1, and so on.

Between the response and command frame request types, the response request type has higher priority. Among the requests of a same type, a lower channel number has higher priority (see the figure that follows).

A pending frame is indicated with a corresponding request flag in the register QFLAGS.

The SRI/SPB bus master sets the response requests (“R” flags).

The software write accesses through the SPB bus set the initiator requests (“I” flags).

The transmit arbiter clears the “I” and “R” flags of the arbitration winner.

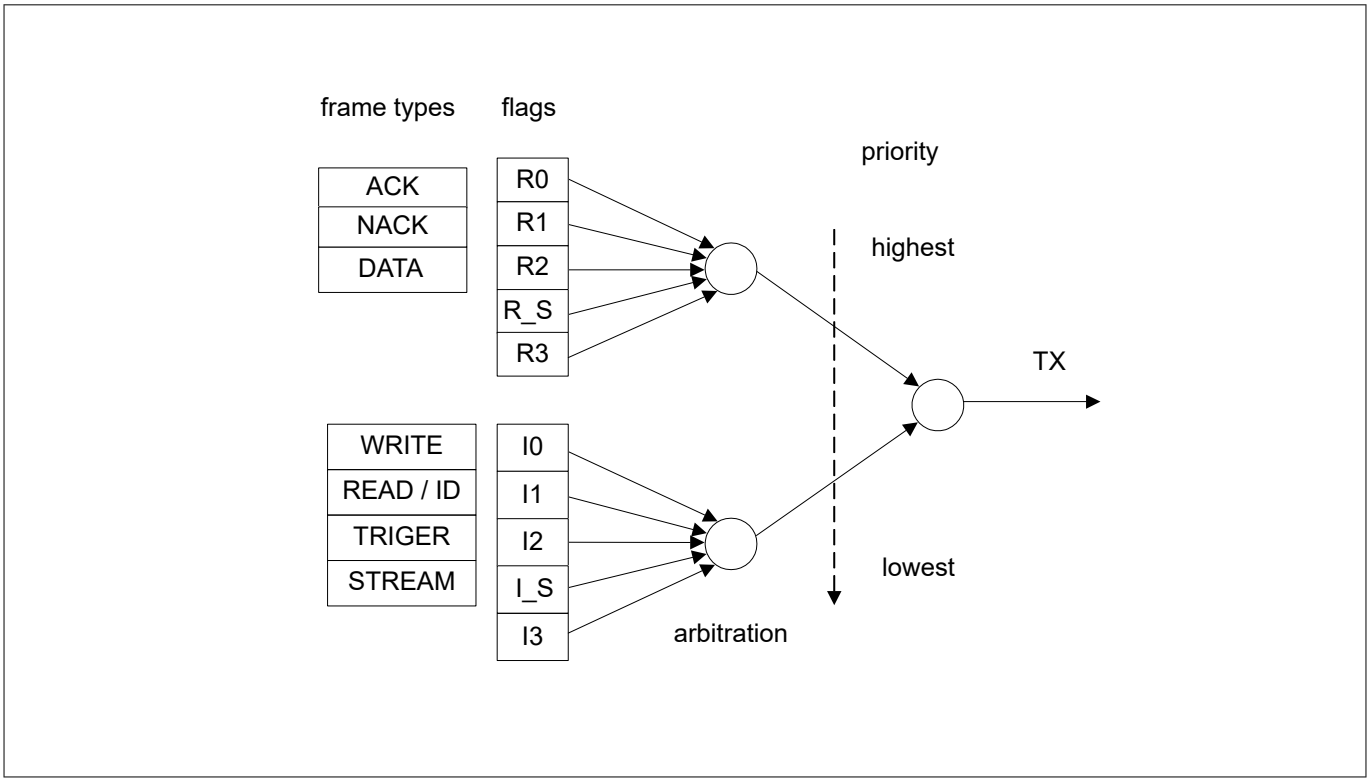

Figure 203 Frame priorities in the HSSL

Received frame management and command execution

After a frame passes the CRC check, it is checked for its type. A received command frame sets a request flag at Target for the SRI or SPB master, a received response frame resets the expect flag and stops the appropriate channel timeout,

The target flags “T” are set by the frame distributor, and cleared by the arbiter of the SRI or SPB master.

Target flags are set by the hardware according to the header information of a frame arrived at the target without a CRC error. They are used by the arbiter of the SRI/SPB master and cleared when the appropriate command is executed.

The expect flags “E” are set by the Tx arbiter, and reset by the Rx distributor.

An appropriate flag is set by the hardware when a timeout timer for a channel is started. The hardware stops the appropriate channel timeout when any response frame received resets the expect flag.

The ISB and ISF flags operate together to control the streaming process. The ISB flag (Initiator stream block flag) is set by the software to enable the streaming. The ISF flag (Initiator stream FIFO flag) is set or cleared by the TXFIFO according to its filling level.

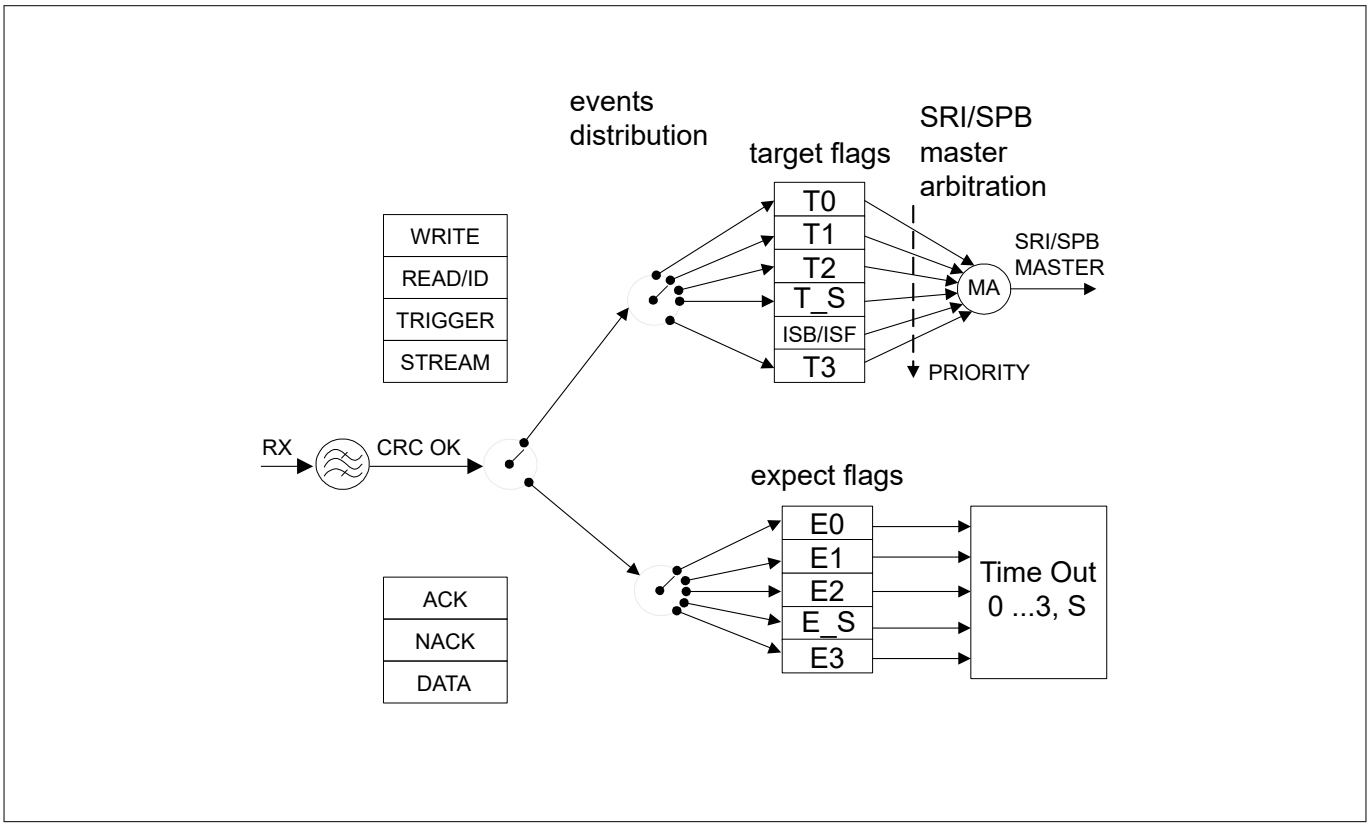

Figure 204 Received frames management

The CRC and Transaction Tag error flags are located in the MFLAGS register.

An overview of a full communication cycle over all sections of a channel (initiator, target or receive, transmit) is shown in the figure that follows, but see also the QFLAGS register description.

If the channel does not have a command pending and does not expect a response, it is ready.

***Note**: In case of at trigger command frame, the target command distributor sets the corresponding Rx flag, not the corresponding Tx flag, because the service request is triggered directly and not by the SRI or SPB master.*

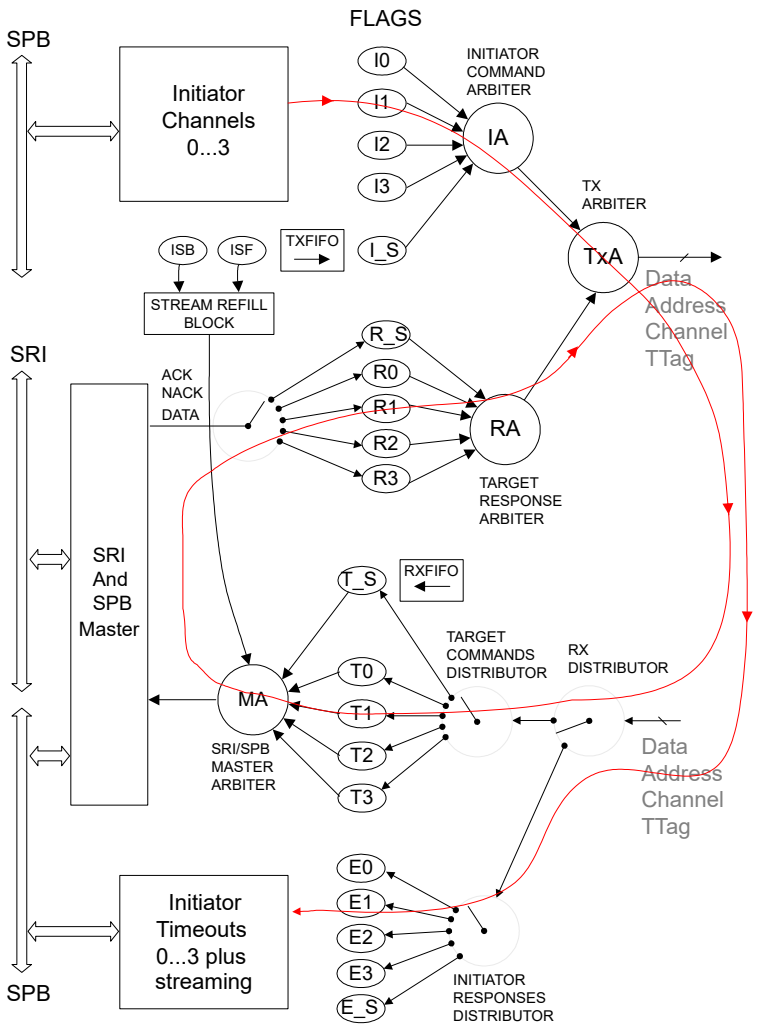

Figure 205 Request flags overview and a communication cycle example

Table 786 Set and clear of request flags

	I	R	T	E	ISB	ISF
SPB software write	set	-	-	-	set	-
Tx arbiter	clear	clear	-	set	-	-
Rx distributor	-	-[1)]	set	clear	-	-
SRI or SPB master	-	set	clear	-	-	-
Stream refill block	-	-	-	-	clear	clear
TXFIFO	-	-	-	-	-	set

1) In case of a trigger command, an R flag is set by the Rx Distributor instead of a T Flag, because a trigger command is not executed by the SRI/SPB master.

17.4.3.3.2 HSSL channel architecture

The HSSL module contains four channels. The functionality of each channel can be subdivided into four roles:

- Initiator Transmitter functionality: the channel is transmitting write, read or trigger command frames based on the arbitration described in Frame transmission priorisation, after the previous command has been responded to. It also generates an appropriate header for each frame including a transaction tag per channel to keep track of the expected response
- Initiator Receiver functionality: the channel does the comparison of the received response´s transaction tag with the one expected and do the interrupt handling

  ***Note**: The timeout management is a pure initiator functionality*

- Target Receiver functionality: the channel´s functionality is to receive commands and executes them. Interrupt handling is also a target receiver´s functionality
- Target Transmitter functionality: depending on the command type, the channel generates and transmits responses (read response, ACK, NACK) with the appropriate header for each frame. Since the reads and writes are performed by the SRI or SPB master, the module can send back a target error frame to the transmitter if an SRI or SPB bus error occurs and the transfer on the bus cannot be executed

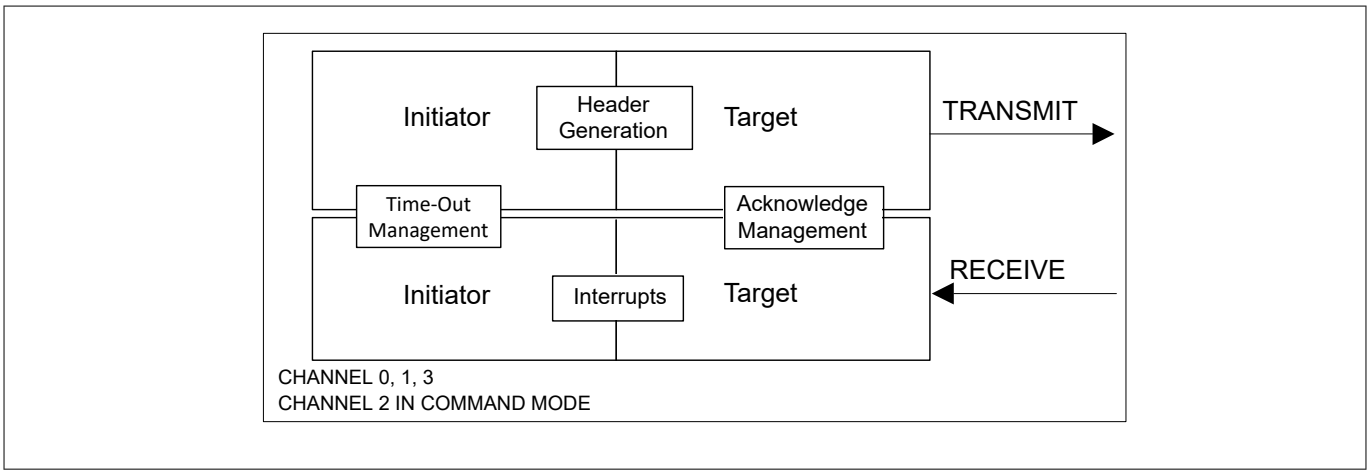

Figure 206 Architecture of channels 0,1, 3 and channel 2 in command mode

While all channels can operate in command mode using Read, Write and Trigger commands, only channel 2 can also be switched to streaming mode. Streaming mode allows to transfer a range of data from initiator to target device. In command mode a single data register is used and in streaming mode a FIFO is used.

The channel 2 contains one initiator and one target address to define the respective start address of streaming. A stream frame count register defines the size of data for the transfer.

The granularity of the start address is 256-bit.

Figure 208 Overview of channel functions

17.4.3.3.3 Acknowledge responses

A read or write command is executed by SRI or SPB master. The SRI or SPB master either reads form or writes to the SRI or SPB bus and signals either a successful transaction or an error. There are the following cases:

- When the SRI master either writes to or reads from an SRI memory space, in both cases the HSSL module receives an acknowledgment as feedback
- When the SPB master either writes to or reads from an SPB memory space, in both cases the HSSL module receives an acknowledgment as feedback

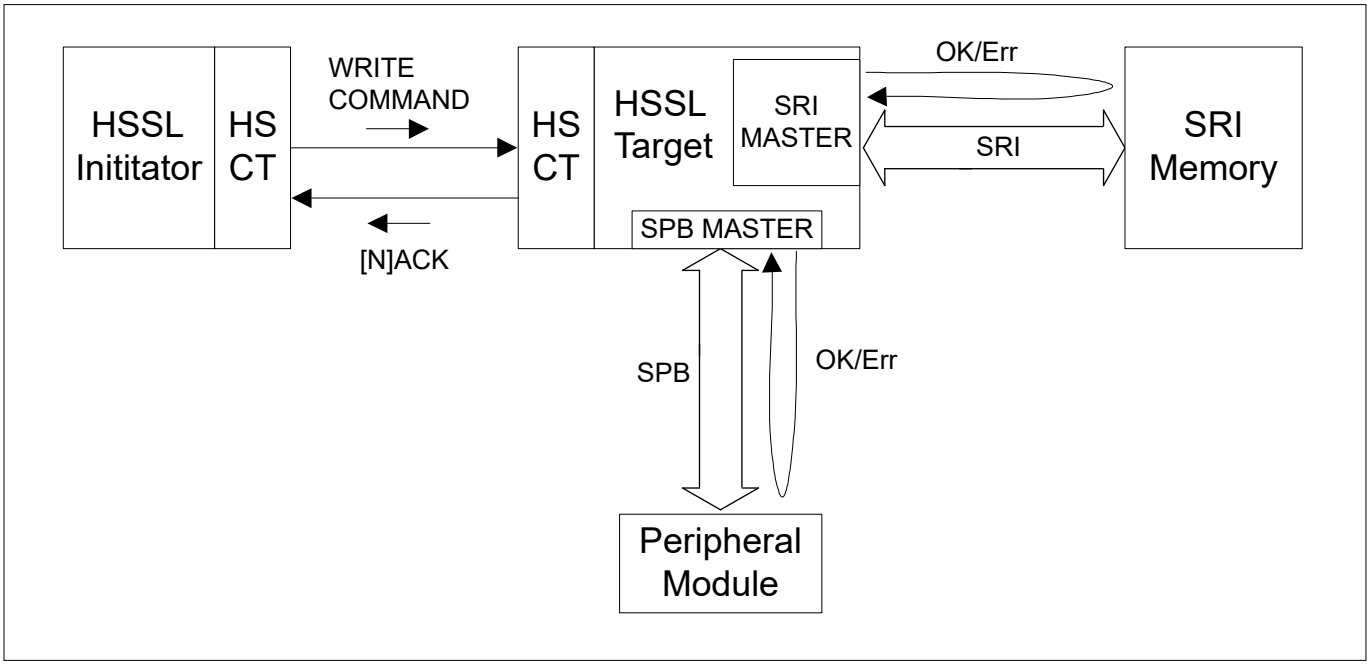

Figure 209 Bus error feedback paths

17.4.3.3.4 Cross-dependencies between the frame types

For a channel in a target role, there are cross-dependencies between a command frame arrival and triggering of an ACK or NACK frame for a channel. Each command frame received with a correct CRC of types Write, Stream or Trigger frame will result in either an ACK or a NACK (target error) response frame.

Each Read frame received with a correct CRC will result either with Data frame (Read Response frame) or with NACK (Target Error frame).

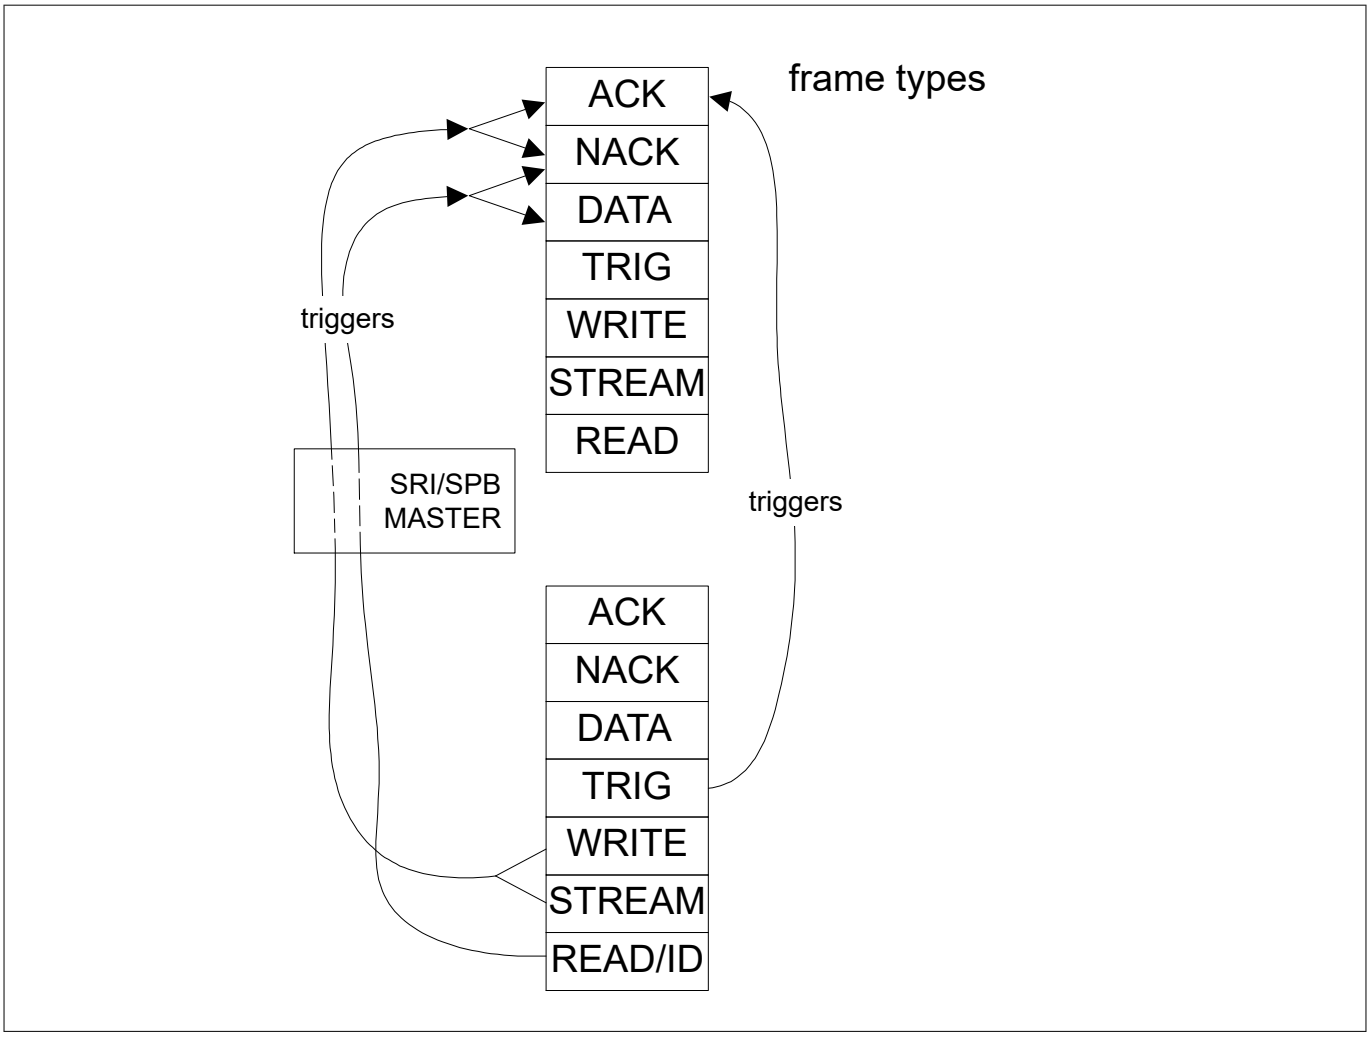

Figure 210 Channel 2 Cross-dependencies between stream and command frames and their responses in a target role

Generating a response frame involves copying the transaction tag of the command frame into the response frame. The response frame is triggered by a SRI or SPB master signalling either a successful SRI or SPB bus transaction or a SRI or SPB bus error. Only a Trigger Command frame triggers immediate acknowledgment because it results in an interrupt flag being set, and however it does not trigger a bus transaction.

On the initiator side, there is a forward looking cross-dependency between a command frame and the expected response. Setting a transmission request flag for a certain command is accompanied in parallel with:

- Capturing the current transaction tag in the bit-field ICONx.CETT
- Generating the next transaction tag by incrementing a three bit counter per channel, the ICONx.ITTAG
- Starting the timeout counter at the moment when the command wins the arbitration
- Setting an expect tag indicating that the timeout is running and a response frame is expected. See MFLAGS register

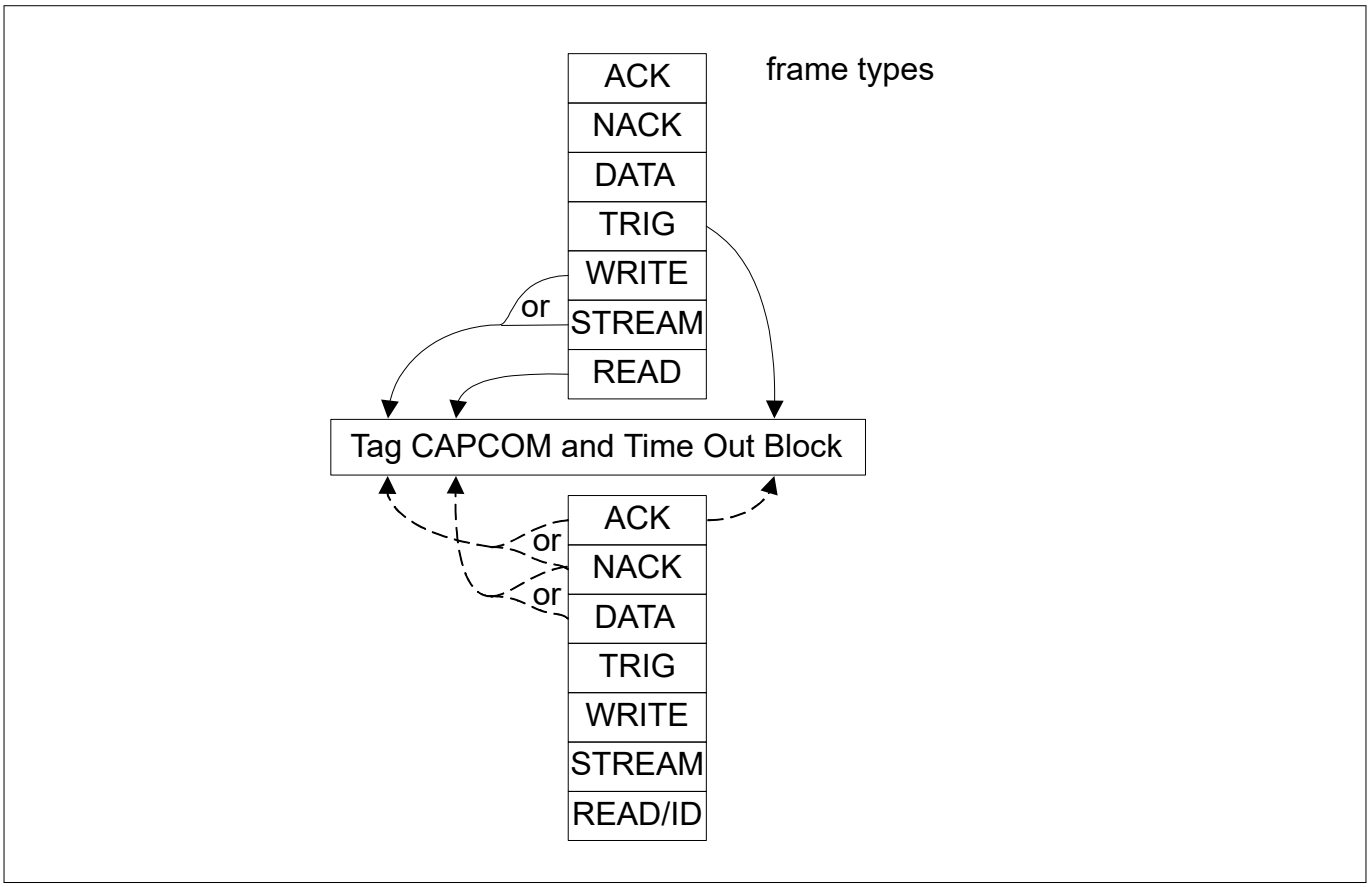

Figure 211 Channel 2 Cross-Dependencies between stream and command frames and their responses in an initiator role

17.4.3.3.5 Command timeout

A timeout timer is started when a frame wins the arbitration and is delivered by the channel for transmission. The timeout timer is stopped if an appropriate response frame without a CRC error is received in time.

If an appropriate response is not received, and the timeout timer reaches zero, then timer is stopped, a timeout error is triggered, and the expect flag is cleared.

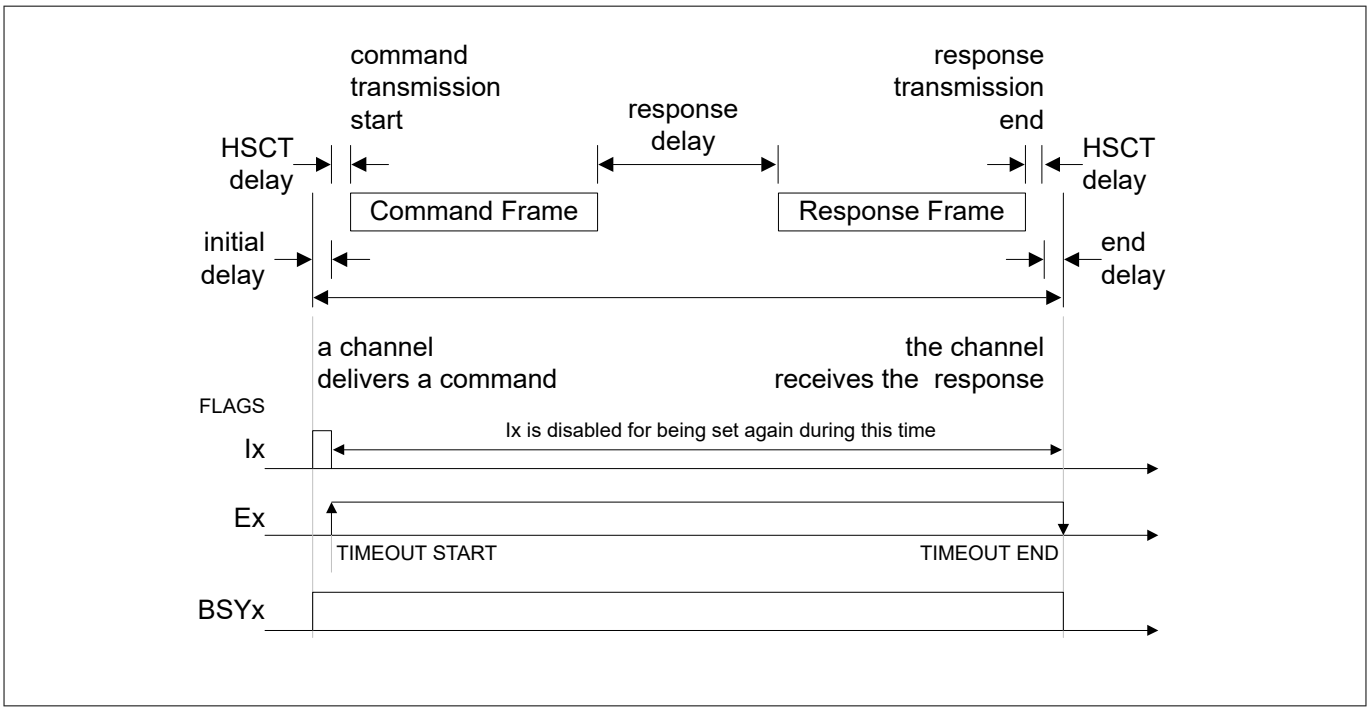

Figure 212 Command timeout measurement

Command timeout operation

The HSSL contains one prescaler common to all channels, and a channel specific timer block per channel. The timer block generates the transaction tag for the channel by incrementing a three bit counter, captures the current transaction tag, and compares it with the received response.

In case of an error sequence CRC and timeout error, the timeout block generates a timeout signal. The timeout timer is reloaded and starts down-counting when the command transmission process starts.

The current timeout timer value is indicated in the bit-field ICONx.TOCV.

The timeout reload value is configured in the bit-field ICONx.TOREL.

The current expected transaction tag is indicated in the bit-field ICONx.CETT.

The captured value of the latest erroneous transaction tag is indicated in the bit-field ICONx.LETT.

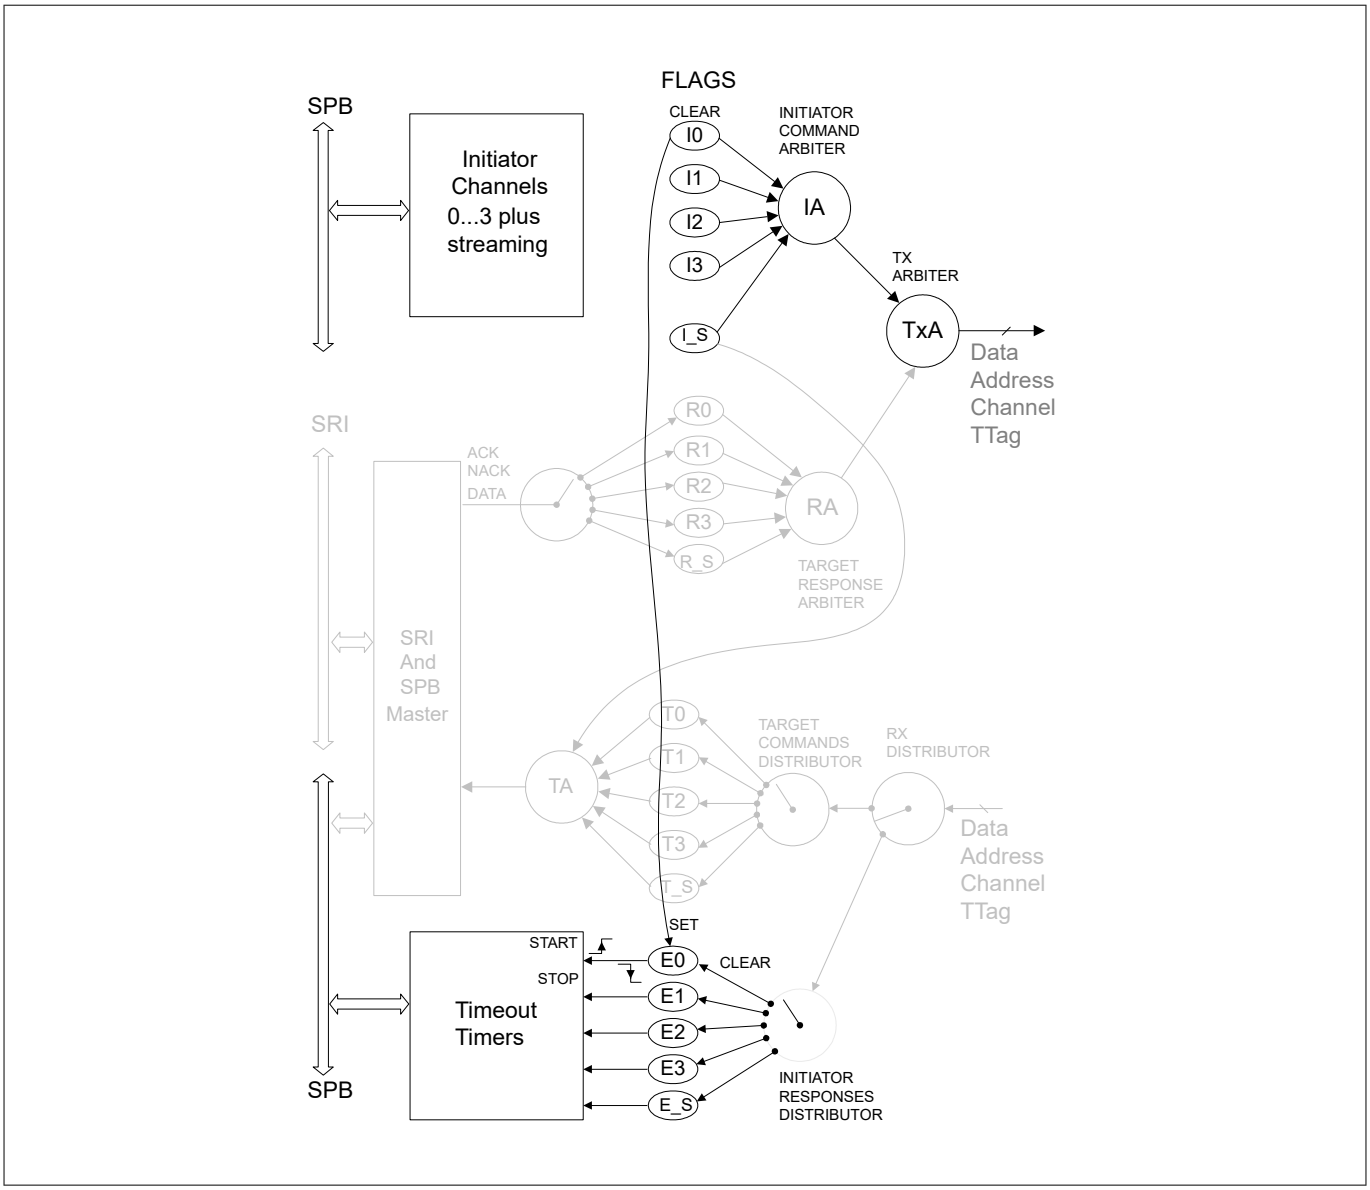

Figure 213 Request flags overview and a communication cycle example

From the flags point of view, the timeout starts with the rising edge of the QFLAGS.Ex flag and ends with its falling edge.

The Ex flag is set by the falling edge of the Ix flag, which is reset when its command request wins the transmit arbitration.

Related information

Cross-dependencies between the frame types on page 2454

17.4.3.3.6 Stream timeout

A free timeout timer block is started when a frame wins an arbitration round and is delivered by the channel for transmission. The timeout timer block is reset to zero and stopped if an appropriate response frame without a CRC error is not received in time.

If an appropriate response is not received, a timeout error is triggered and the timeout timer block is reset.

The stream initiator keeps track of the expected acknowledgements using a virtual expect FIFO having a virtual filling level .EXFL. Each new stream frame transmission increments the EXFL. Receiving a correct

acknowledgment decreases the .EXFL. As long as the 'Expect FIFO' is full (filling level 2) no new transmit request can be issued.

In order for a new stream frame request to be issued, which means the flag .I_S to be set by the module, three conditions must be met:

- EXFL<2 - the expect level must be below 2
- TXFL>0 - the TXFIFO must be not-empty
- ISB = 1 - the bit ISB must have been set by the software

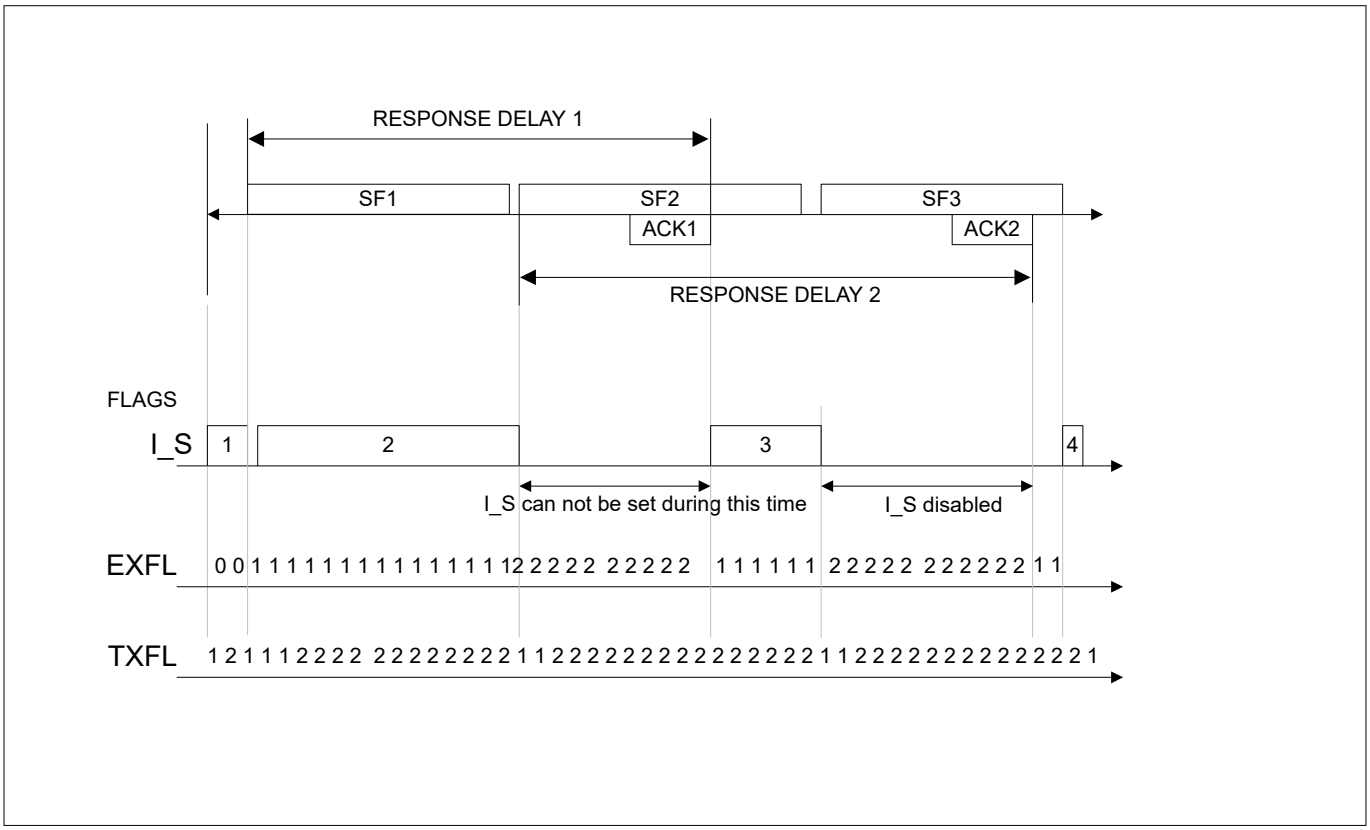

Figure 214 Stream timeout measurement

Stream timeout operation

The stream channel monitors the arrivals of the stream frame responses by using two timeout timer blocks. A single timer block is shown in the next figure.

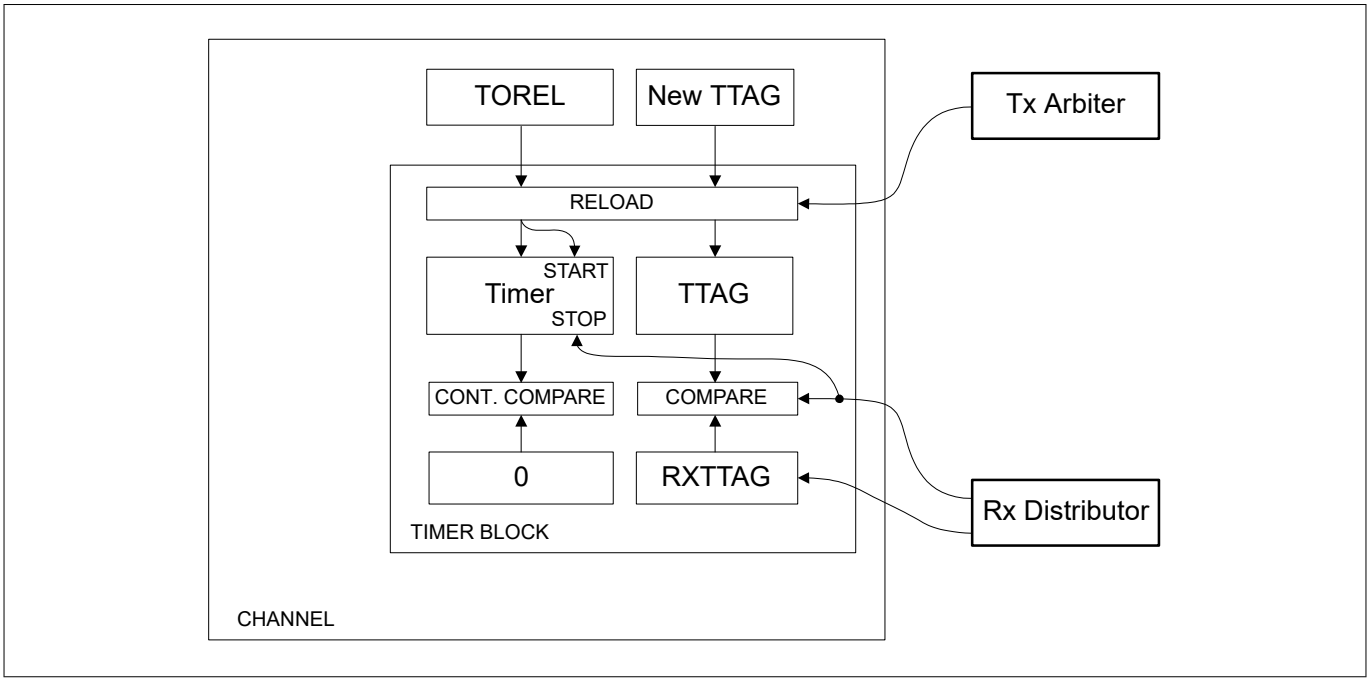

Figure 215 Single timeout block

The new initiator TTAG value which will be used for the next frame is visible in the bit-field ICONx.ITTAG. The Initiator Control Data Register x register also contains the TOREL and the TOCV bit-fields.

The streaming functionality uses two timers sharing the same reload value, as defined by the ICONx .TOREL, i=2. The timeout timer blocks simulate the behavior of a FIFO (named 'Expect FIFO'), by having additionally a “write” and “read” pointer:

- The “write” or transmit pointer points to the timer block where the next command frame will trigger the writing of the timer reload value and the transaction tag
- The “read” or receive pointer points to the block which performs the transaction tag comparison with the currently arrived stream acknowledge TTAG
- The EXFL or virtual filling level indicating how many timers are active 0, 1, or 2

The EXFL is visible in the register SFSFLAGS.

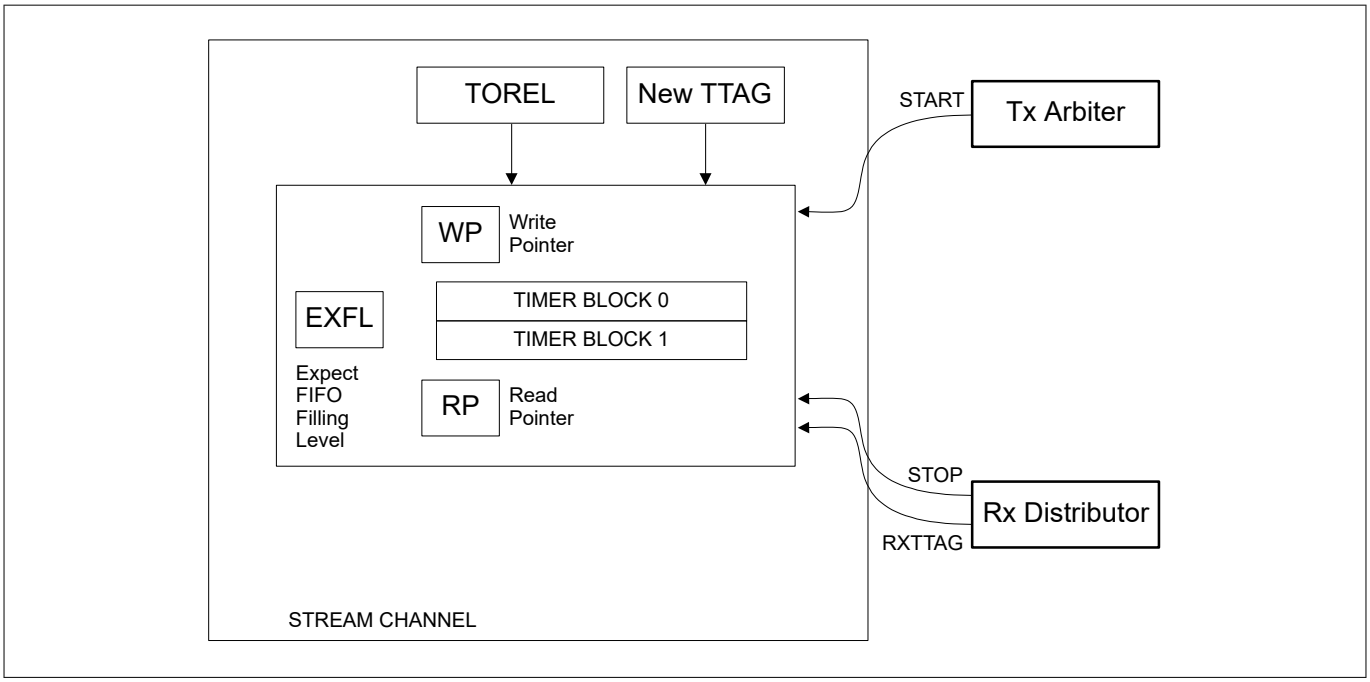

Figure 216 Stream timeout block

17.4.3.3.7 Data FIFOs of the streaming channel 2

Each stream frame delivers 256-bit data. This data is transferred by the SRI/SPB bus master in a memory by using BTR4 bursts. The start address and the end address is aligned at 256-bit block border.

Refer to:

- ISSAx
- ISFC
- TSSAx
- TSFC

The channel expects one full streaming frame of 256 bit to be delivered before triggering either the SRI or SPB master or the HSCT module for fetching the data. The streaming is full duplex capable, which means one FIFO for each direction is available. It also supports prioritization for the requests to the SRI or SPB master like emptying the RXFIFO has higher priority than filling the TXFIFO.

A service request to the SRI or SPB master is generated when the complete payload of a streaming frame is available in a FIFO.

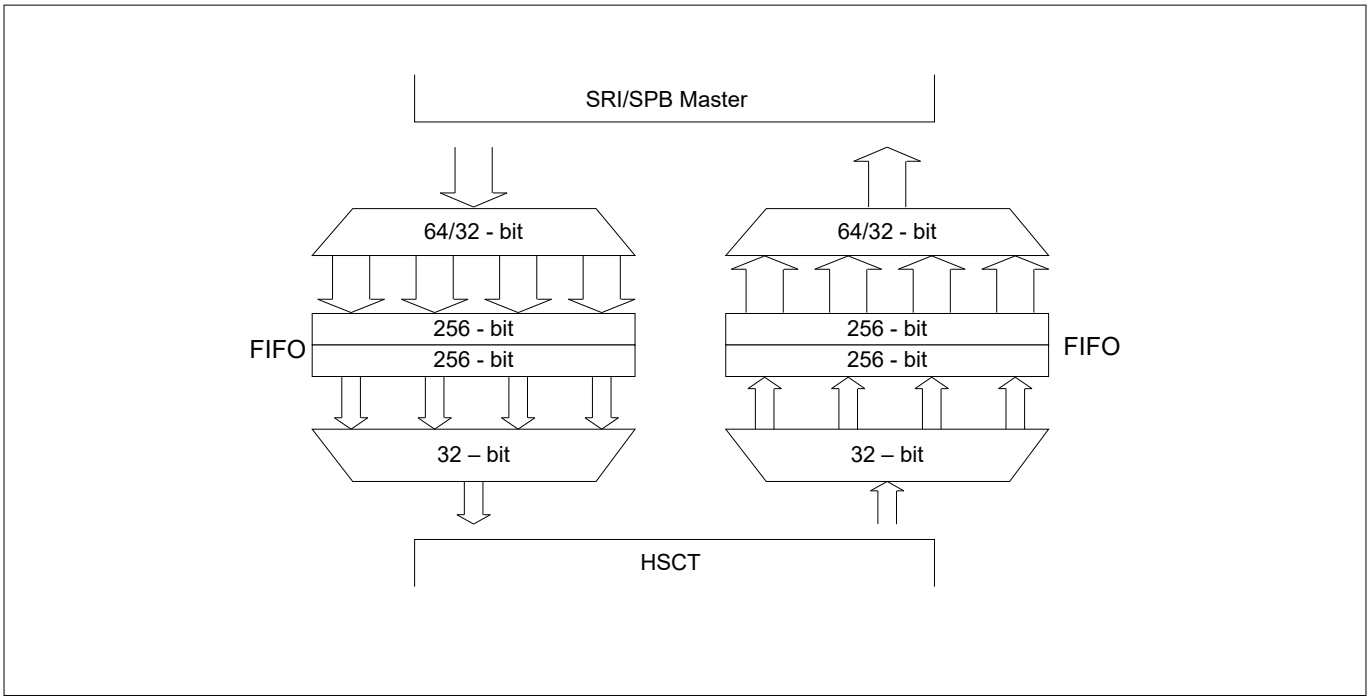

Figure 217 Streaming FIFO

17.4.3.4 Modes of operation

The HSSL module has the following modes:

- Disabled mode (software controlled through CLC.DISR bit)
- Initialize mode (software through MFLAGS.INI bit, sleep and suspend signals)
- Run mode (MFLAGS.INI bit, sleep and suspend signals)
- OCDS soft suspend mode (OCDS suspend signal)
- Sleep mode (sleep signal)

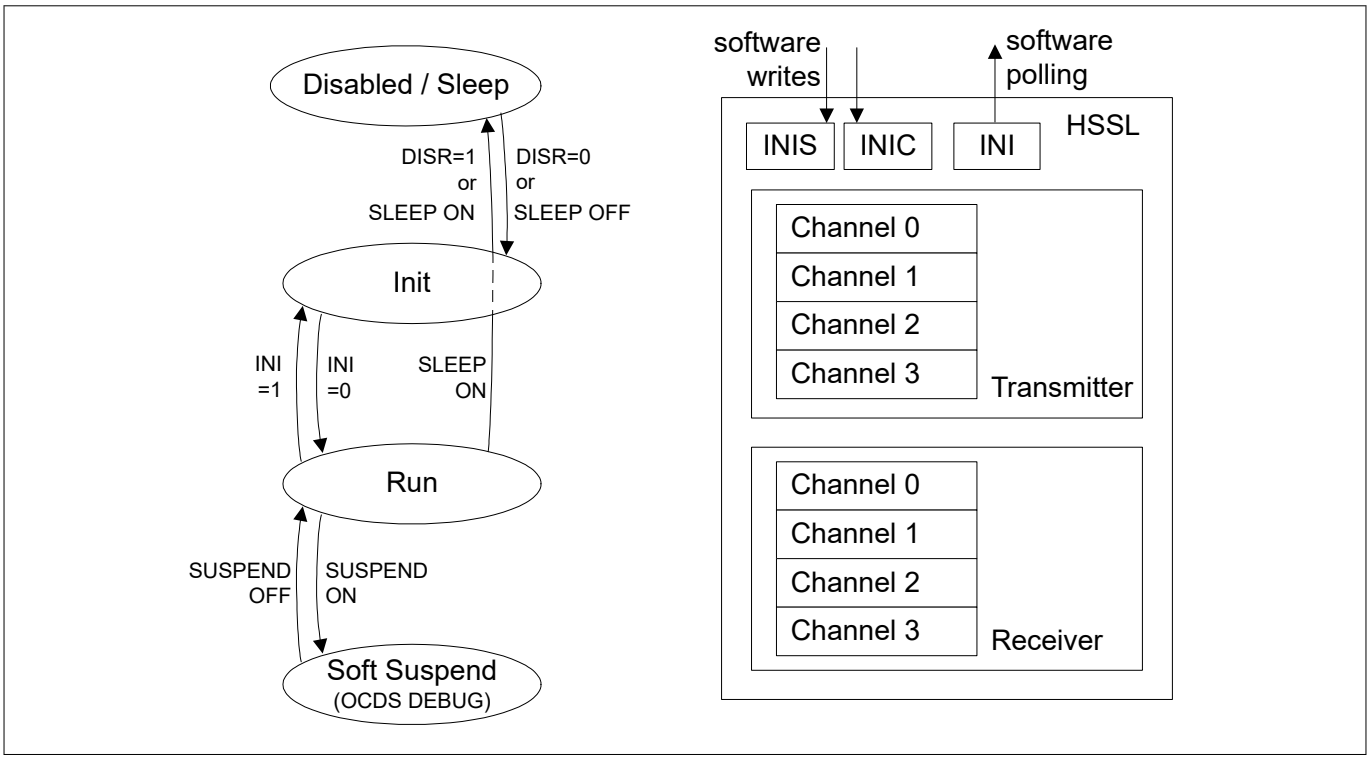

Figure 218 Modes of operation

After Init state has been requested by using the MFLAGSSET.INIS bit, the HSSL module immediately stops starting new SRI or SPB transactions and new command, response, and stream frame transmissions by resetting all request bits (I, T, and R) in the QFLAGS register, disabling these bits from being set again. Any transactions or transmissions that have already started will be finished. Afterwards, it waits for all pending response frames to arrive, or the corresponding timeout events to be raised. This condition is achieved when all 'expect bits' in the QFLAGS register has been cleared by the hardware, and there are no ongoing transmission and SRI or SPB master activities. Subsequently the module enters the Init state and the MFLAGS.INI flag is set. The Clear To Send(CTS) signal is deactivated to inform the peer module about the Init state.

During the transition from run to sleep state, triggered by the sleep signal, the MFLAGS.INI bit is automatically set by the hardware (and behaves as if the INI bit was set by software). When the sleep period is over and the sleep signal is deactivated, the module goes into the Init state and must be set to Run state by software, by writing MFLAGSCL.INIC=1.

At the state transition of Init to Run, the timeout timers and all the flags are reset. The RUN state starts with all channels inactive.

At the state transition Soft Suspend to Run, the timers are not reset but continue to run and the flags states are preserved, because the module continues operating from the point at which it was suspended.

When leaving the Run state towards Sleep, the CTS signal is deactivated and the transmission of the pending commands is stopped.

When a soft suspend is requested, the module stops the transmission of the pending command and stream frames, waits until all 'expect' flags are cleared, then deactivates the CTS signal and at the end acknowledges the soft suspend request and sets the bit OCS.SUSSTA. Incoming target frames are served until the CTS signal stops the other side from sending new command and stream frames.

A Hard Suspend request causes the module clocks to switch off immediately. After completion of the Hard Suspend state, both HSSL and HSCT modules must be reset by the application software, and communication restarted from reset state.

***Note**: The Kernel clock f_{CLC} is enabled for a few cycles, where the read from and write to registers is possible*

Attention**: **Register accesses with clocking in Hard Suspend mode can have unintended side effects such as signals becoming and staying active. This can also affect other modules so a HSSL kernel reset might not be sufficient to bring the system into a defined state.

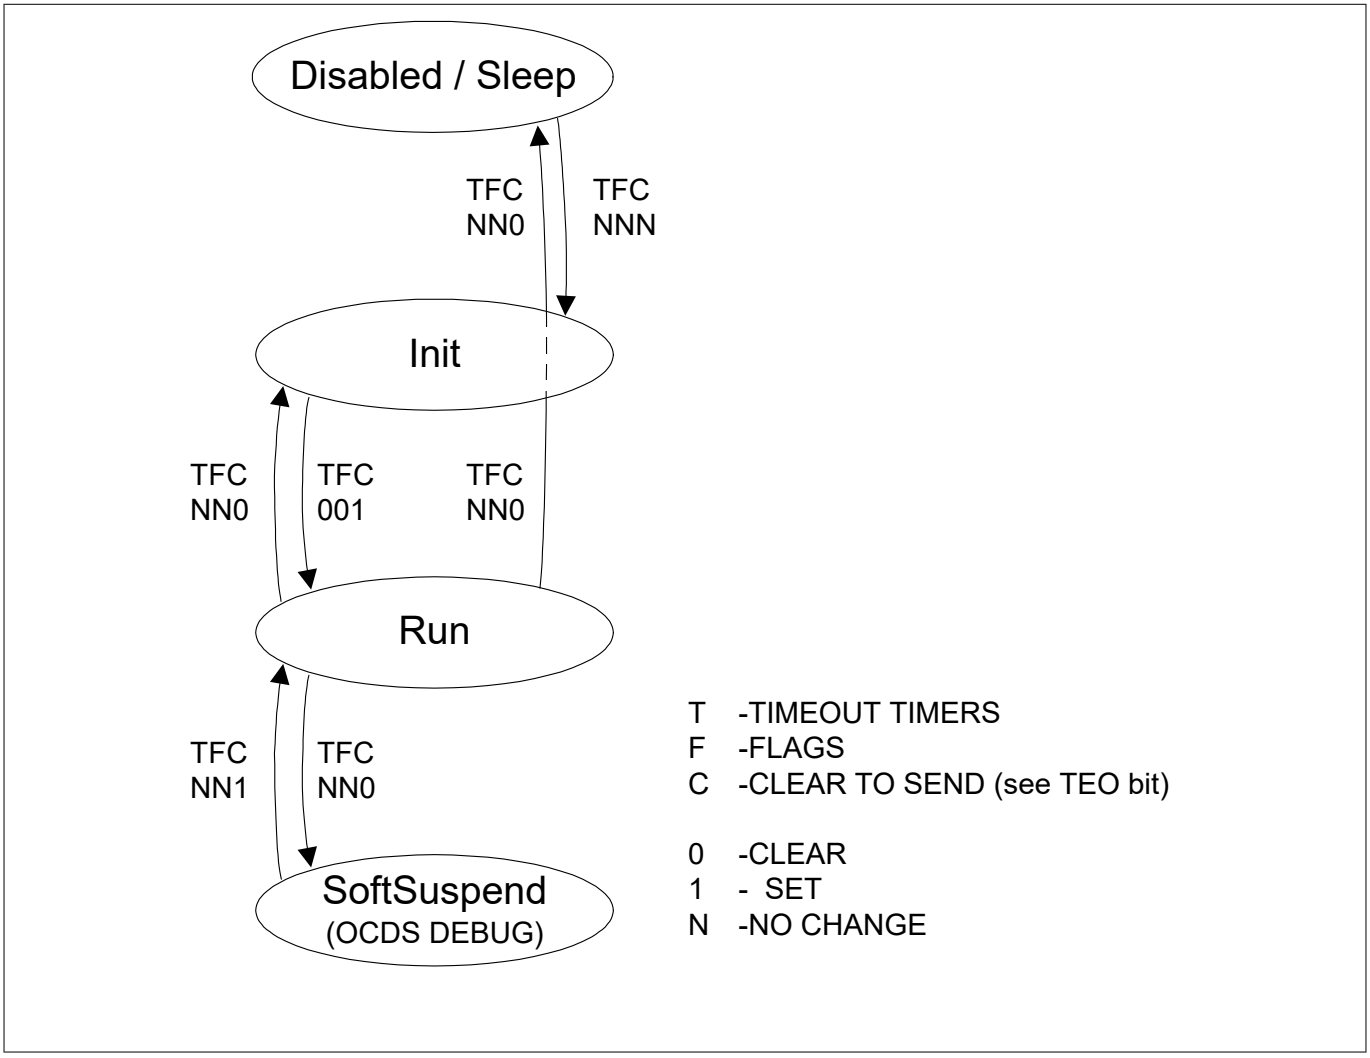

Figure 219 Actions on state transitions

17.4.3.5 Interrupts

The HSSL module generates four types of interrupts per channel and one channel unspecific module interrupt.

Command channel interrupts

Each HSSL command channel generates four interrupts:

- Command OK interrupt COK
- Read Data interrupt RDI
- Error interrupt ERR
- Trigger interrupt, triggered by a trigger command frame TRG

The names of the corresponding interrupt signals are:

- COK
- RDI
- ERR
- TRG

The arrival of an error free frame response (ACK frame) triggers a COK interrupt, otherwise an ERR interrupt is triggered. The arrival of a read response frame triggers at the initiator side, in addition to the COK interrupt, an RDI interrupt.

The arrival of a trigger frame at the target side triggers a TRG interrupt there.

ERR interrupt is disjunct to COK and RDI, which means that for one frame, either ERR or COK and optionally RDI can occur. After an ERR interrupt, normal transmission must be resumed by software, because an optional DMA would remain and not be re-triggered, and would wait for COK indefinitely. The events that trigger an ERR interrupt are indicated by the bit fields UNEXPECTED, TIMEOUT, TTE and NACK corresponding to Miscellaneous Flags Register. These bits can be enabled or masked and cleared by the registers Flags Enable Register and Miscellaneous Flags Clear Register respectively.

Stream channel interrupts

The HSSL stream transmit sub-channel generates three interrupts:

- TBE
  - Transmit Block End interrupt, shared with the COK interrupt of the command mode of the channel 2
- Error interrupt ERR
  - Shared with the ERR interrupt of the command mode of the channel 2
- RBE
  - Receive Block End interrupt, shared with the TRG interrupt of the command mode of the channel 2

Exception interrupt EXI

If the receive stage of the HSSL module detects a CRC error or any inconsistency in the received data, the global EXI Interrupt is activated, which are not channel specific. The events that trigger an EXI interrupt are indicated by the bitfields CRCE, PIE2, PIE1, SRIE and MAV corresponding to Miscellaneous Flags Register. These bits can be enabled or masked and cleared by the registers Flags Enable Register and Miscellaneous Flags Clear Register respectively.

***Note**: The HSCT module uses channels A to D for the HSSL channels 0 to 3. So, HSCT channel 0100_B corresponds to 000_B (binary code) or 100_B (special code) in the HSSL header.*

The EXI interrupt is also raised on an edge of the TEI signal (HSCT CTS output).

In total, the HSSL module provides $4 \times 4 + 1 = 17$ interrupt lines That is: number of channel(4) * channel specific interrupts(4) + module interrupt(1)

17.4.3.6 Operating a command channel

All HSSL command channel provide identical functionality.

17.4.3.6.1 Initiating a single write command

In order to initiate a write command, the software must:

- Configure the data width in ICONx.DATLEN and set the command type to write request in ICONx.RWT
- Provide the new data (often but not necessary) in IWDx register
- Provide new address in IRWAx register

Write to the address register requests the predefined type of the transfer.

17.4.3.6.2 Initiating a single read command

In order to initiate a read command, the software must:

- Configure the data width in ICONx.DATLEN and set the command type to read request in ICONx.RWT
- Skip providing the data step or provide dummy data
- Provide new address in IRWAx register

Write to the address register requests the predefined type of the transfer.

17.4.3.6.3 Initiating a single trigger command

In order to initiate a trigger command, the software can either:

- Request a trigger type of frame in ICONx.RWT and provide dummy data (optional) and address respectively in IWDx and IRWAx registers
- Directly request a trigger frame by writing to ICONx.TQ

17.4.3.6.4 DMA operated command queues

It is possible to use DMA to initiate lists of commands, by moving memory blocks containing the command lists to the HSSL module. In order to support such operation, each channel provides three registers arranged in a particular way.

The three registers are in the following order IWDx, ICONx, and IRWAx.

To execute a list of write commands all three registers must be written for each command.

To execute a list of read commands the first register IWDx is optional (dummy write possible) but the last two, ICONx and IRWAx, are mandatory.

To execute a trigger command only by writing to ICONx.TQ is mandatory, but optionally all three registers can be written: dummy write to IWDx, write to ICONx.RWT and write to IRWAx to issue the request.

The Answer data to a read command is available in the IRDx register.

***Note**: This approach relies on external peripherals like system DMA for command queuing without the intervention of the CPU. In case of a failed transaction, CPU has to be involved for recovery purposes.*

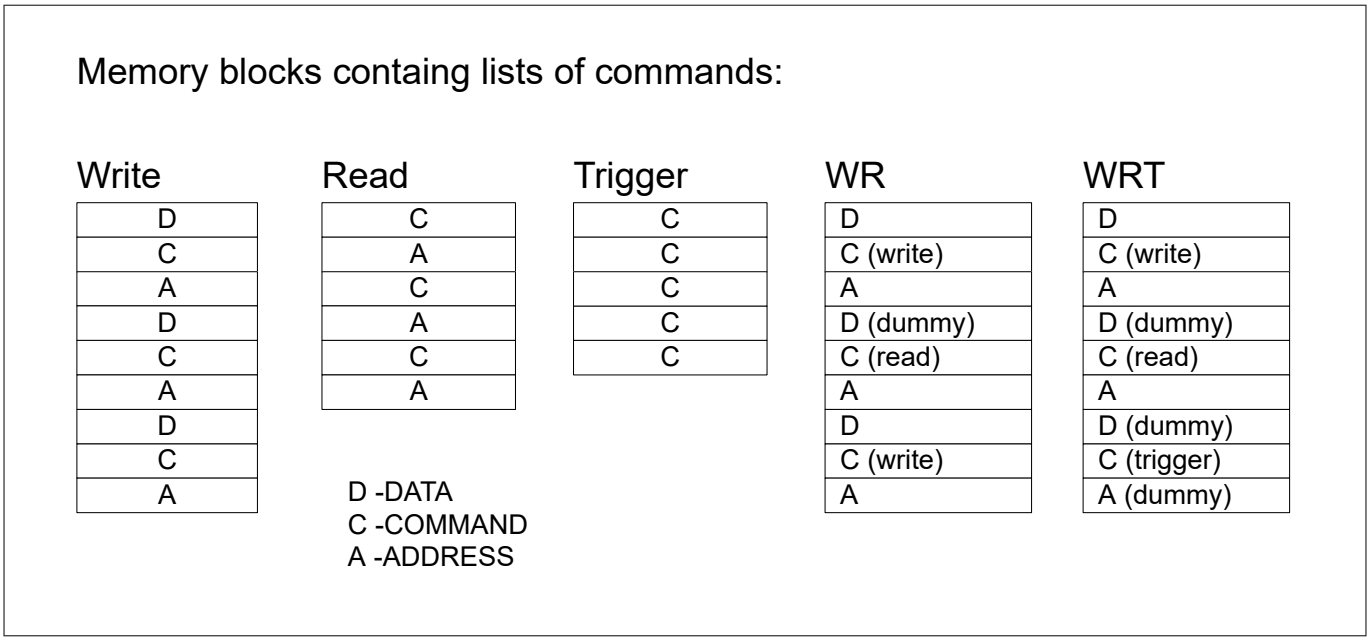

Figure 220 Command queues

17.4.3.6.5 Receiver error handling

The HSSL receiver generates three error signals, two channel specific and one general.

- Channel specific timeout and transaction tag errors
- Channel non-specific CRC error

Receiver errors are ignored in the following cases:

- Command frames, which pass the CRC check, containing an RFU command code are ignored
- Command frames, which pass the CRC check, containing invalid (greater than 3) channel number are ignored
- If a command frame is received and the acknowledgment of the previous command has not been sent yet, the new command frame is discarded
- If a response frame comes and the channel does not expect a response (the E flag is 0), an incoming response is discarded without any error interrupts in addition to the timeout interrupt. This scenario can occur if a response is received after a timeout and before the next command has been sent
- If a channel in command mode receives a stream frame, the stream frame will be ignored
- if a channel in streaming mode receives a command frame, the command frame will be ignored

Timeout error

Error triggered by the initiator.

Transaction tag error

Error is triggered by the initiator.

17.4.3.6.6 Global error

A global, non-channel specific error is triggered if a CRC error, or an inconsistency between the HSCT and HSSL header, or an SRI or SPB error occurs.

A CRC error is triggered:

- By the target when erroneous command frames are received
- By the initiator when erroneous response frames are received

There is a dedicated interrupt named EXI which signals the CRC error. There is no indication if the CRC error was caused by a command or response frame. The CRC error caused by a response frame will be followed by a timeout interrupt. The received data is discarded and it is not available for the software in any register(s).

Additionally, the CRC error interrupt signals an inconsistency between the data length and channel number code delivered by the HSCT module and the information contained in the HSSL header. The differentiation between the two types of error can be made by reading the MFLAGS.CRCE, PIE1, and PIE2 flags. All three error types can occur and are detected independent of each other, so that more than one flag can be set at the same time.

An SRI error interrupt (EXI) is triggered if there was a transaction ID error, ECC error, or SRI error acknowledgment on the SRI bus. The flag MFLAGS.SRIE indicates this type of error.

In case of an SRI read data ECC error, the HSSL SRI Read Data EDC Error signal reports this event to the SMU module.

An SPB error also triggers the global error interrupt (EXI) and sets the MFLAGS.SRIE flag.

***Note**: For one single 256-bit streaming data block, since BTR4 bursts are being used by the SRI master to transfer data, the HSSL SRI Read Data EDC Error signal could be asserted up to 4 times (once on every SRI read data ECC error occurrence in the 64-bit data transfer).*

17.4.3.7 Memory block transfer modes of the stream channel

The HSSL streaming channel is capable of transmitting one stream and receiving one stream in parallel. Streaming operates either in single block mode or continuous mode.

Single block mode

- In single block mode, after triggering or enabling the streaming by using the MFLAGS.ISB/TSE bit, the SRI or SPB master of the HSSL module transmits or receives the pre-configured memory block, generates an interrupt signal, and waits for the next trigger
- In single block mode, the hardware resets this bit after performing a block transfer

Continuous mode

- In continuous mode, after triggering or enabling the streaming by using the MFLAGS.ISB/TSE bit, the SRI or SPB master of the HSSL module transmits or receives two memory blocks of the same size in a round-robin fashion indefinitely, or after being stopped by the software
- In continuous mode, the transfer is ongoing continuously (MFLAGS.ISB or TSE remains set) and a stop of the transfer must be requested by writing one to MFLAGSCL.ISBC or TSEC bit.

Initiator and Target configuration:

- The streaming mode of the initiator or transmitter is configured by using the CFG.SMT bit
- The streaming mode of the target or receiver is configured by using the CFG.SMR bit
- Triggering or enabling a block or continuous stream is done by using the Stream Block Request bit MFLAGS.ISB or TSE bit
- On the initiator side, after completing the transfer of the current memory block, that is currently read from the memory, the transmitter will be stopped and the MFLAGS.ISB will be cleared
- On the target side, after completing the transfer of the current memory block, that is currently written to the memory, the receiver will be stopped and the MFLAGS.TSE will be cleared

Error handling:

- A SRI or SPB error on the target triggers an error interrupt and the hardware stops. The TSE bit (and the RXFIFO) will be cleared by the hardware and the incoming frames are ignored
- Any error on the initiator side, such as an SRI or SPB error, a target error, a timeout, or a transaction tag error, triggers an error interrupt and the hardware stops streaming. The bit ISB (and the TXFIFO) will be cleared by hardware. All the incoming frames will be ignored, including the acknowledge frames of the previous frames
- Error can also occur at the beginning of a new memory block, while the last frames of the previous memory block are still in the TXFIFO. These frames are also lost, and the previous memory block remains partially received
- After an error, while streaming in one direction, the software must restart the streaming in that direction at both sides. The streaming will restart with a new block
- An error while streaming in most cases leaves the target waiting in the middle of a block. The target receiver can be stopped immediately, and afterwards restarted, by clearing the MFLAGS.TSE only when TSFC.CURCOUNT equals TSFC.RELCOUNT.
- Normally, TSFC.CURCOUNT equals TSFC.RELCOUNT before the start of a transfer of a block or between block transfers. Otherwise, while waiting in the middle of a block transfer, TSFC.RELCOUNT can be made equal to TSFC.CURCOUNT by writing the TSFC.CURCOUNT value to TSFC.RELCOUNT. This can be done either locally, by the target itself, or remotely, by the initiator using HSSL command frames

Initiator configuration for stream channel:

- The two initiator start addresses are configured in ISSAx.
- The single block size is configured in the ISFC register.
- The current address being transferred is indicated in the read only (rh) ISCA register. The bit MFLAGS.IMB selects the corresponding ISSAx register. This bit is not modified by the hardware in single block mode, and is toggled by the hardware in the continuous mode. At the start of the transfer, the selected start address ISSAx is copied to the ISCA register

Target configuration for stream channel:

- The two target start addresses are configured in TSSAx
- The single block size is configured in the TSFC register
- The current address being transferred is indicated in the read only (rh) TSCA register. The bit MFLAGS.TMB selects the corresponding TSSAx register. This bit is not modified by the hardware in single block mode, and is toggled by the hardware in the continuous mode. At the start of the transfer, the selected start address TSSAx is copied to the TSCA register

Stream channel interrupts:

The HSSL stream transmitter generates one dedicated interrupt and several error events:

- Transmit block end (TBE) interrupt, generated after the acknowledgment of the last frame has been received
- Error events that can trigger a channel error interrupt: target, timeout, transaction tag, or unexpected error
- A global SRI or SPB error interrupt (check if the ISB bit is cleared by hardware)

The HSSL stream receiver generates one dedicated interrupt and several error events:

- Receive block end (RBE) interrupt event, generated after the last stream frame in a block has been written to the memory and the SRI or SPB master has received a confirmation (an acknowledgment, but not an error)
- Error event (target error that triggers an NACK frame)
- A SRI or SPB global error interrupt (check if the TSE bit is cleared by hardware)

As long as the ISB bit is low, the TXFIFO and the expect FIFO are cleared and kept in the empty state. As long as the TSE bit is low, the RXFIFO is cleared and kept in the empty state.

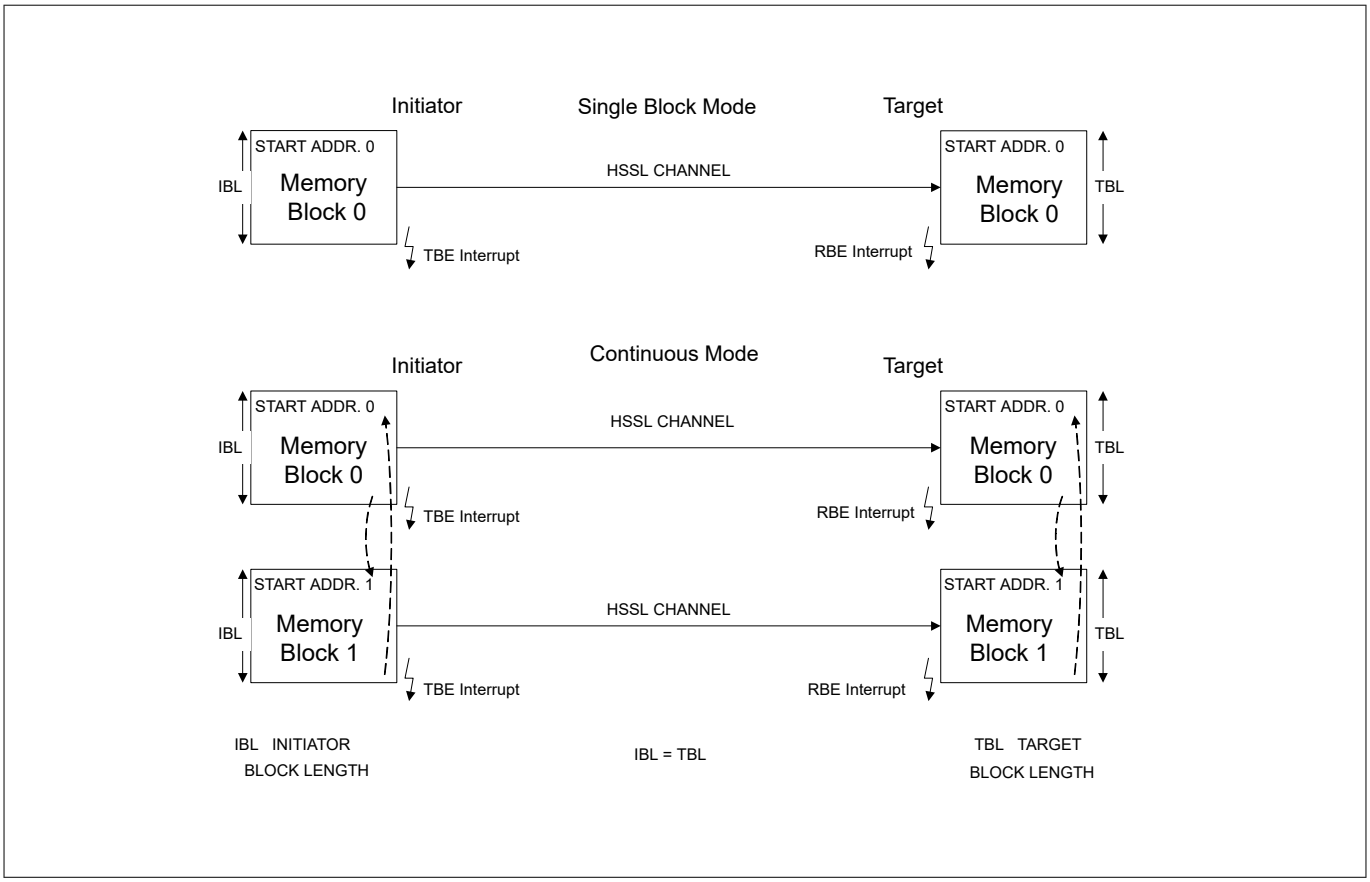

Figure 221 Stream modes of operation

17.4.3.8 HSSL reset

Both the HSCT and the HSSL modules must be reset together.

17.4.3.9 OCDS SRI or SPB master suspend

The SRI or SPB master access on the bus can be suspended by using the OCDS suspend request. When the master reaches idle state the suspend acknowledge signal is activated.

17.4.3.10 OCDS trigger sets

In order to support the debugging activities, the HSSL provides a set of internal signals to the on-chip debug system OCDS.

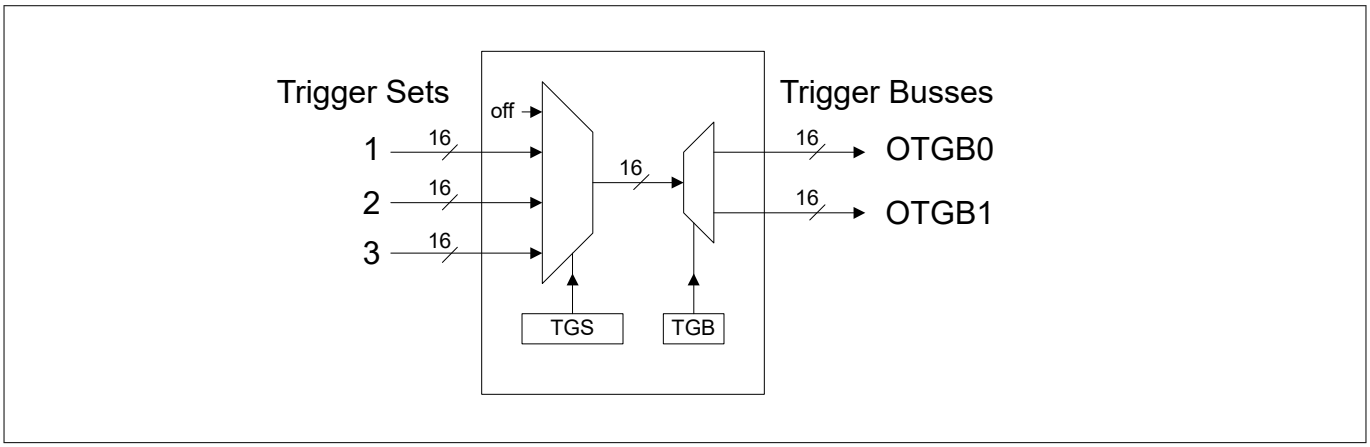

Figure 222 Overview of the trigger sets and busses

Configuration is done by using the bits OCS.TGS and TGB.

An edge on any signal, belonging to the selected set, going out on one of the two OTGB buses, triggers an action of the OCDS system. Only trigger set 1 and 2 are used and trigger set 3 is not used.

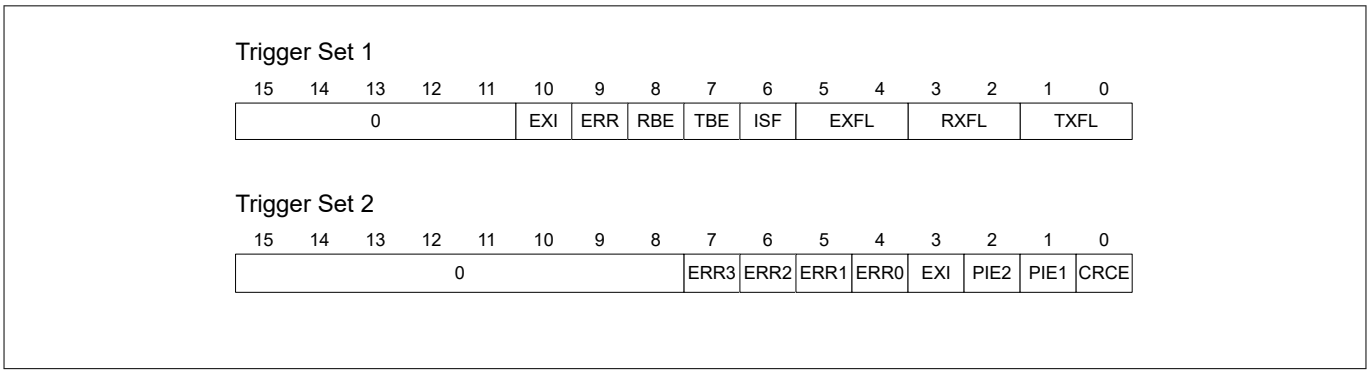

Figure 223 Overview of the trigger signal sets

Table 787 HSSL trigger sets

Name	Description
TS16_STR	Streaming channel trigger set (trigger set 1)
TS16_ERR	Error trigger set (trigger set 2)

The trigger sets 1 and 2 are used, the set 3 is not used (padded with 0).

Set 1, streaming channel debugging:

- 2 bits: TXFIFO filling level SFSFLAGS.TXFL
- 2 bits: RXFIFO filling level SFSFLAGS.RXFL
- 2 bits: Expect FIFO filling level SFSFLAGS.EXFL
- 1 bit: Initiator stream frame request SFSFLAGS.ISF
- 4 bits: streaming channel interrupt signals TBE, RBE, ERR, EXI, see the "Interrupts" section
- Others: not used

Set 2, timeout errors caused by non-specific errors debugging:

- 1 bit: CRC error MFLAGS .CRCE
- 1 bit: Phy Inconsistency error, inconsistent channel number code, MFLAGS.PIE1
- 1 bit: Phy Inconsistency error, inconsistent data length, MFLAGS.PIE2
- 5 bits: error interrupt signals 1 x EXI $1 \times \mathrm{EXI}$ and 4 x ERR $4 \times \mathrm{ERR}$. See the "Interrupts" section
- Others: not used

The signal lists are mapped to the trigger sets in the following way: First item from the list is mapped to the trigger signal 0, Second item in the list is mapped to the trigger signal 1, and so on upto 15.

Related information

Interrupts on page 2464

17.4.3.11 Access protection

The HSSL provides memory access protection in form of four memory access windows. It is the protection from external access to the address space of HSSL. Each window can be located anywhere within the address space, having an arbitrary size with the granularity of 256 bytes.

Each window defines a memory range where an access is allowed. All the four windows create a sort of access filter that protects the memory from external writing or reading. A window can be a 'read-only' (r), 'write-only'(w), or 'read and write' (rw).

Each window is defined with:

- Window start address. See register AWSTARTi
- Window end address. See register AWENDi
- Access rule: Read only, write only, or read and write. See register AR

If two access windows overlap, one read-only(r) and one write-only(w), the common address range is read and write(rw) accessible. If no access window overlaps with r, w, or rw window, the r, w, or rw window wins. No access window means the window is disabled.

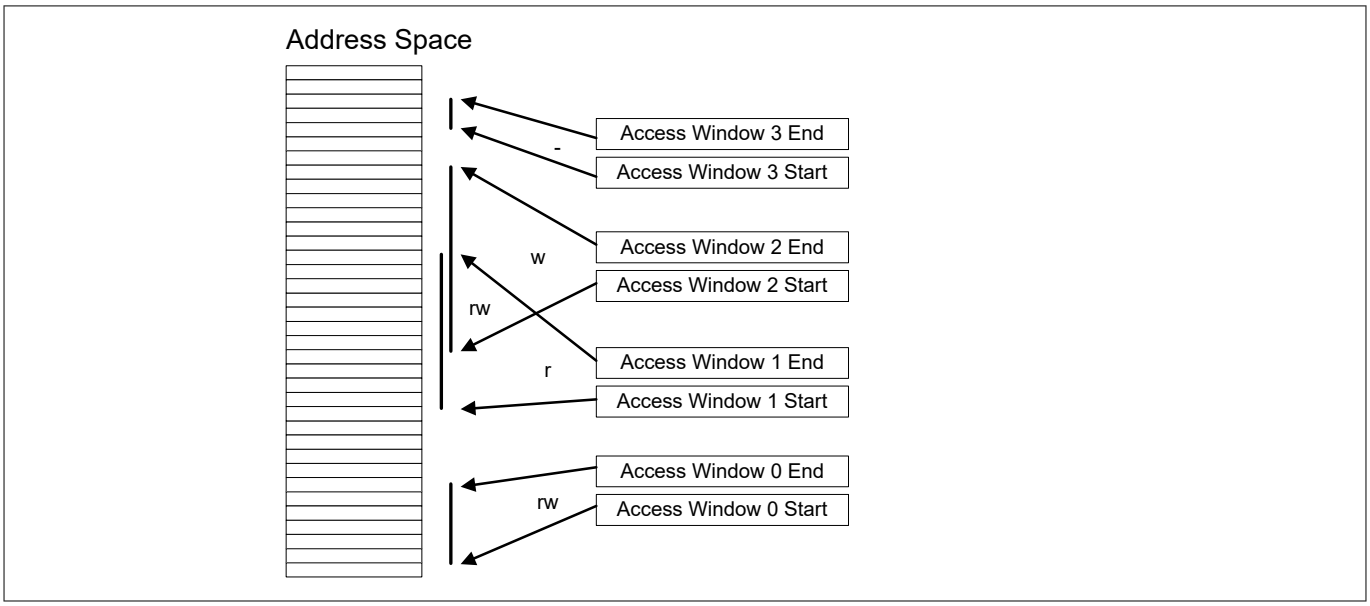

Figure 224 HSSL access windows

Normally, it is expected that the End Address is higher than or equal to the Start Address, otherwise the window is invalid and no commands can pass through the up-side-down range.

The AWSTARTi registers define the first address of the first 256-byte block of an address window.

The AWENDi registers define the first address of the last 256-byte block of an address window.

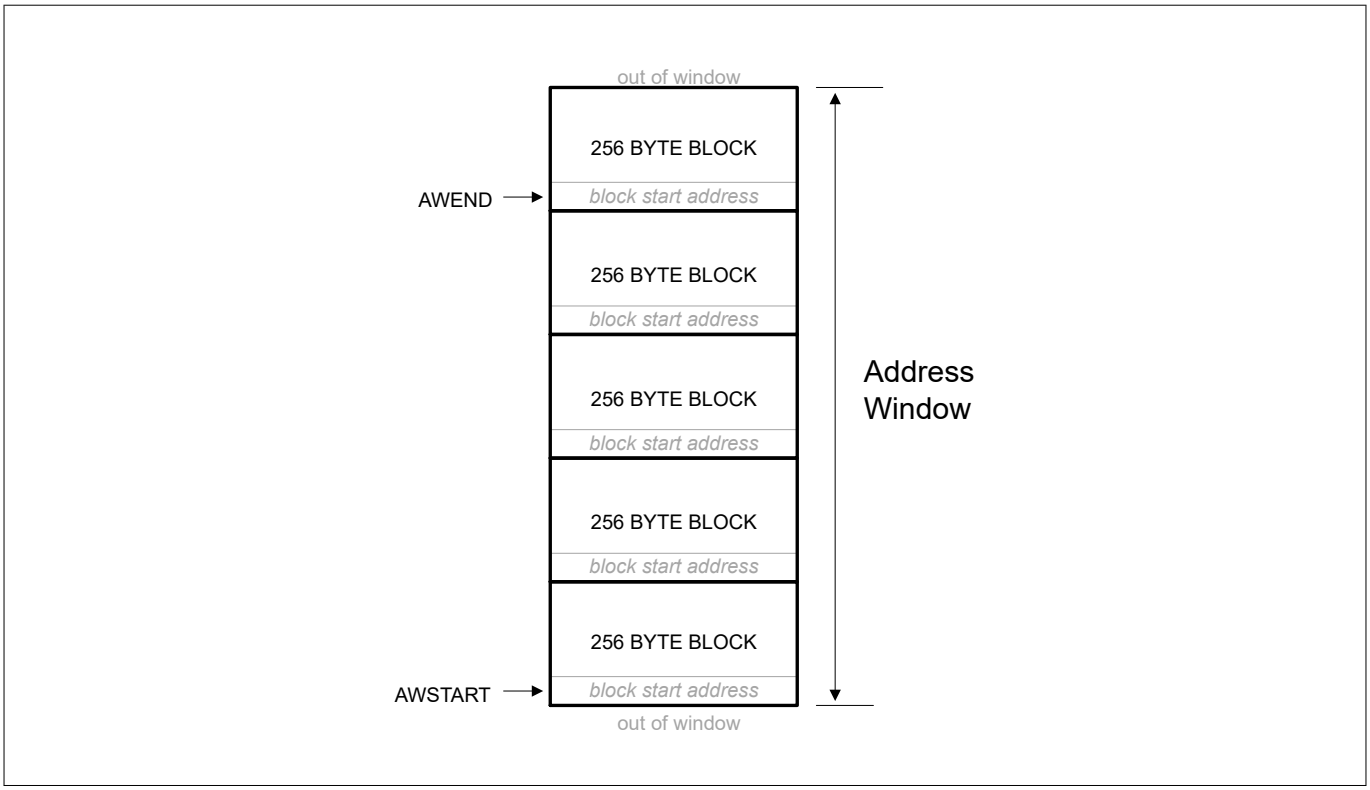

Figure 225 Access windows definition

These command frames are filtered based on the frame type:

- Register read
- Register write
- Stream Frame

These command always pass through:

- Read answer
- ACK
- NACK
- Trigger
- ID Request

17.4.3.11.1 Command frames access protection

If a HSSL target receives a read or write command frame with an address which passes through one of the windows, the command is executed and a response frame is sent back.

If a HSSL target receives a command frame with an address which does not pass through any windows, the command is not executed, a NACK response is sent back. The memory access violation flag MFLAGS.MAV is set, the access violating channel is captured in the bit field AR.MAVCH, and the EXI interrupt is triggered in the target.

17.4.3.11.2 Streaming access protection

Stream frames do not contain address information. The two distinct cases are, target side and initiator side.

Target side

At the target side, when the streaming starts, the initiator has already programmed the target addresses in the TSSAx registers by using write frames, which pass through and carry the stream address in their data field. Therefore, the memory filtering uses the current access address, visible in the TSCA register and if the current streaming address passes through the access protection filter, the read or write is executed, else a NACK frame is sent as a response.

If a HSSL target receives a stream frame and the current access address does not pass through any windows, the access is not executed, a NACK response is sent back. The MFLAGS.TSE bit will be cleared by hardware and the incoming frames will be ignored. The memory access violation flag MFLAGS.MAV is set, the access violating channel is captured in the bit-field AR.MAVCH, and the EXI interrupt is triggered in the target.

Initiator side

At the initiator side, the ISSAx registers, which are externally accessible, define the memory range to be transmitted. Therefore the access filtering at the initiator side covers the streaming read accesses by using the current access address, visible in the ISCA register.

At the initiator side, access violation stops the streaming, and the MFLAGS.ISB bit is cleared by hardware. The memory access violation flag Miscellaneous Flags Register.MAV is set, the access violating channel is captured in the bit-field AR.MAVCH, and the EXI interrupt is triggered.

17.4.3.11.3 Public and private registers

The HSSL module contains two types of registers, public and private.

- Public registers, which can be read and written by the HSSL module
- Private registers, which can only be read by the HSSL module

This behavior of the HSSL module registers is implemented by using the User Mode (U) and Supervisor Mode (SV) for writing registers. The private registers are writable in SV mode, the public registers are writable in both U and SV mode.

The memory access protection registers AWSTARTi, Access Window End Register i and AR including the TIDADD register are all writable only in Supervisor Mode, and are consequently private. The HSSL itself makes only User Mode accesses, so that it can not write these registers.

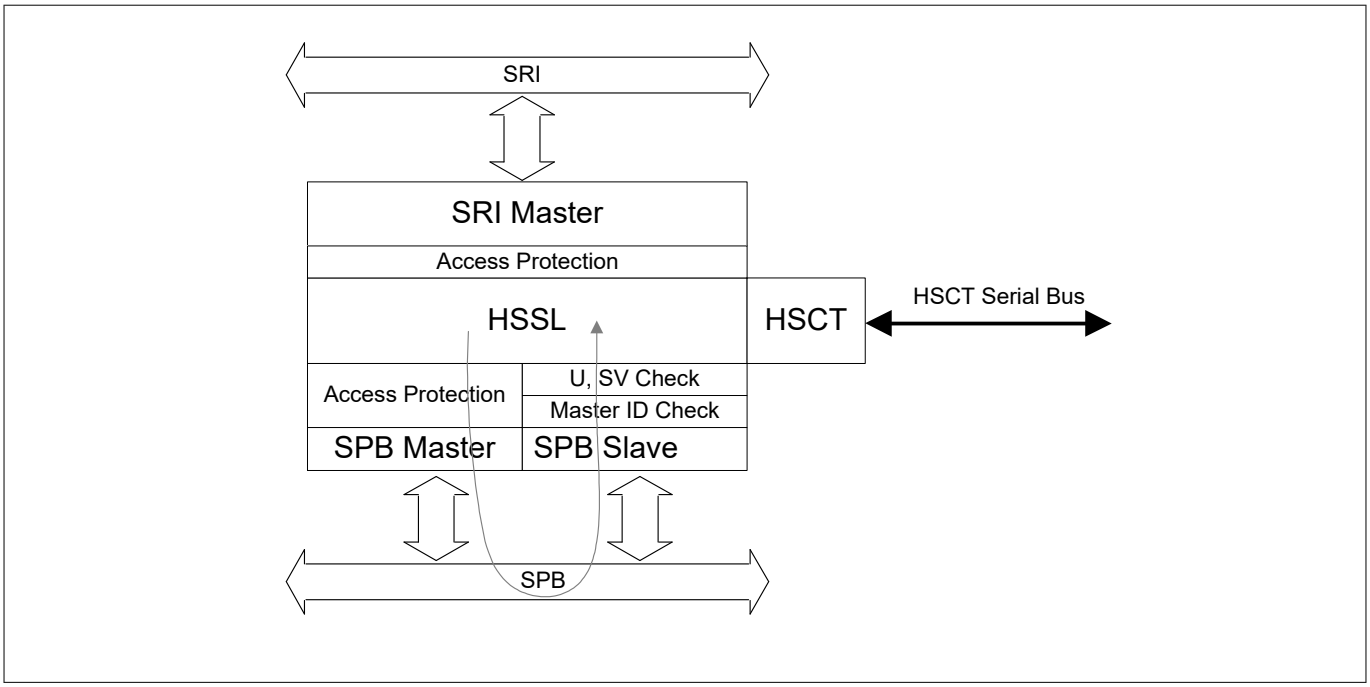

Figure 226 HSSL access to its own registers

17.4.3.12 Multi-slave operation

In multi slave use-cases, one HSSL master can communicate with up to three slaves. From the HSCT module's point of view, the master generates the reference clock and selects the active counterpart for the connection. All the slaves receive the reference clock, but the master selects one slave at a time.

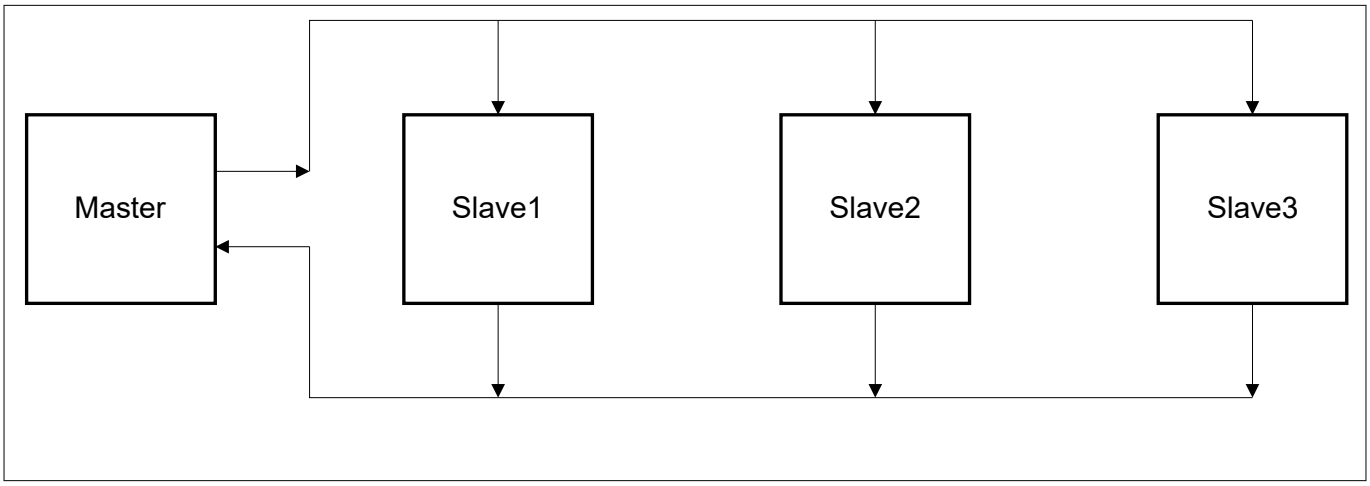

Figure 227 Three slave HSSL connection

The communication is connection based. At any point in time, there can be only one active connection (or zero) between the master and one slave. There are no broadcast or multi-cast messages on the HSSL level. There is a defined procedure for terminating a connection with one slave and activating a connection with another slave. During an active connection both master and slave can be initiators and targets.

After power-on reset, the transmit outputs of the slaves and the transmit output of the master are high impedance. Up to three slaves can be enabled for reception by the application software.

17.4.3.12.1 Slave tag and slave control

The multi-slave operation uses the identical set of command and stream frames as the standard HSSL two-device operation. The slaves are selected with a two bit slave tag in the HSSL header.

These bits are used to filter the frames which are relevant for a slave by comparing them with the two bit slave tag of the respective slave. See MSCR.SLAVETAG.

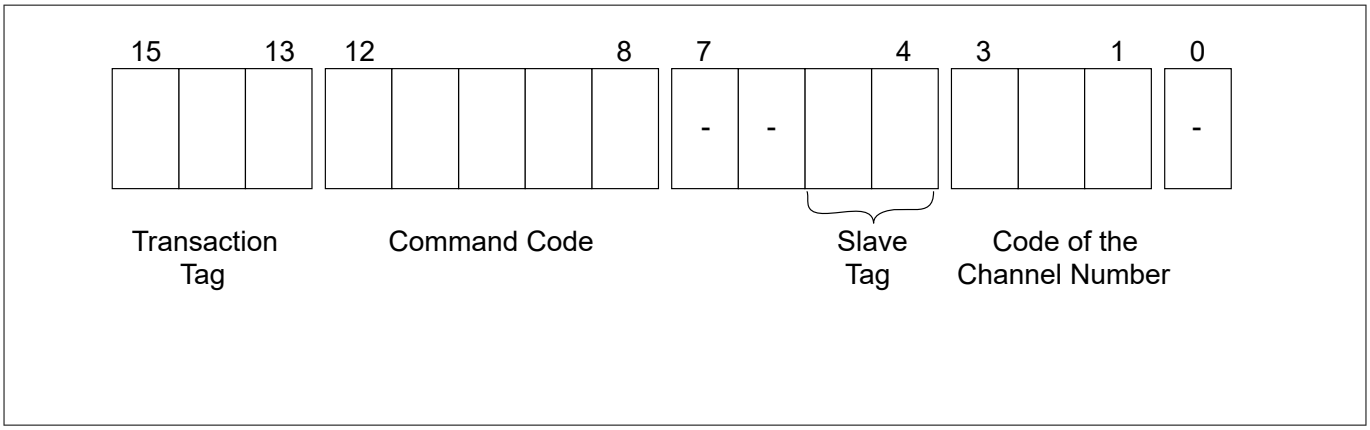

Figure 228 HSSL header with slave tag

17.4.3.12.2 Slave tag frame filter and translator

The filter is located after the CRC block. In receive direction, if there is a match, the frame is passed through and handled in a standard HSSL two-device-connection way. If there is no match, the frames are discarded.

In transmit direction, the headers of transmitted frames get the appropriate tag inserted. In case of a CRC error in a frame sent by the master, all slaves may detect the CRC error. The CRC checker discards the frames with CRC error. Even the addressed slave does not get the frame with a CRC error delivered. Frames with PIE1 and PIE2 error are also discarded. The corresponding error interrupts will be triggered if enabled.

The slaves have their tags fixed in the initialization phase and are never changed. The software of the master changes its slave tag when establishing connection with a different slave. Initially the HSCT link must be established, then the master must have its MSCR.SLAVETAG configured before starting to send HSSL commands or stream frames to the appropriate slave.

The MSCR.EN and MSCR.SLAVETAG bit fields are propagated to the HSCT module in order to ensure consistent operation of the whole communication channel.

If the multi-slave operation is disabled, by setting MSCR.EN=0, then neither the injection of the slave tag in transmit direction nor the filtering of the slave frames in the receive direction are performed. The header remains unchanged and all the incoming frames pass through.

It is not intended to set the MSCR.ITXSTOP bit in the master.

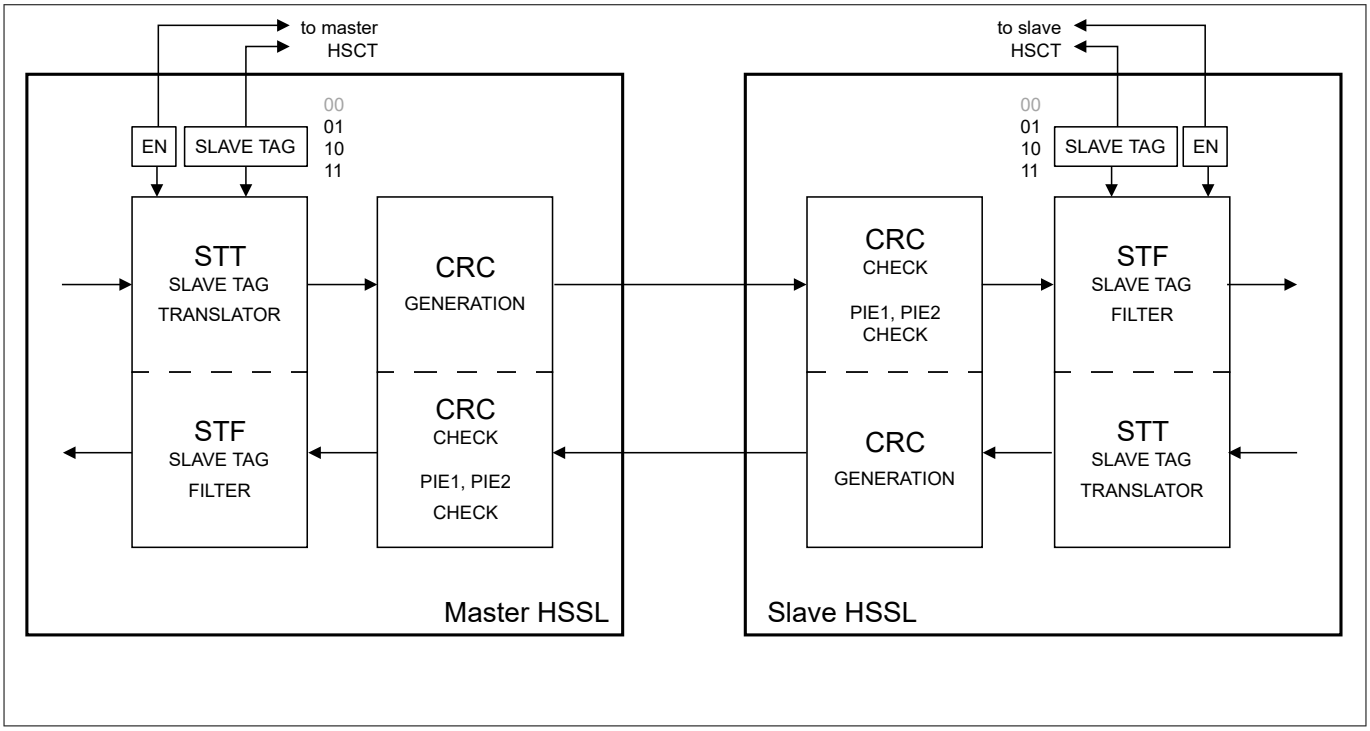

Figure 229 Slave frame filter

17.4.3.12.3 Activating a slave

A slave is activated in two steps:

- The master enables the LVDS transmitter pads of one slave by using a slave specific HSCT command. The Tx enable HSCT commands for the slaves 1, 2, and 3 have payloads 51_H, 52_H, and 53_H respectively
- The second step is either soft or hard HSSL activation:

Soft activation

The master notifies the slave by using standard HSSL commands, according to a predefined procedure. For example, the master can issue a write command to a certain location, send an interrupt trigger command frame, and a slave with a CPU can start transmitting using the HSSL module

Hard activation

The master clears the MSCR.ITXSTOP bit by using a standard HSSL 16-bit write command frame, assuming an appropriate address window for the HSSL registers has already been set up. In the next step, the master notifies the slave, for example with a trigger command, or enables the operation of the slave by setting appropriate bits. The slave continues the operation from the point its initiator transmission has been stopped

17.4.3.12.4 Deactivating a slave

The Master can deactivate a slave in two ways: soft and hard.

Soft deactivation

Soft deactivation procedure uses a software handshake procedure to bring the slave in a state where all ongoing slave initiator transactions has been completed, including streams, no new slave transactions are initiated, and the slave notifies the master that the safe deactivation state has been reached. Subsequently, the master disables the LVDS pad.

The soft deactivation sequence consists of:

- Soft HSSL deactivation:Using a software handshake with standard HSSL commands, such as writing to a memory location and triggering interrupts
- Switching off the LVDS Tx pads with a non-specific slave (broadcast) HSCT command with a payload 32_H

Hard deactivation

Hard deactivation is intended to provide faster deactivation with bounded reaction time, primarily for slaves without CPU and use-cases without streaming.

The hard deactivation sequence consists of:

- Hard HSSL deactivation
  - The master sets the MSCR.ITXSTOP bit by using a standard HSSL 16-bit write command frame. An appropriate address window for the HSSL registers must have been already set up
  - The master must assure that slave initiator commands have been processed by itself and that the acknowledge frames have been sent to the slave. For example, the master polls the slave E (expect) flags by using standard HSSL 16-bit read commands until it reads back 0
  - The master must assure that its command frames have been processed and acknowledged by the slave. For example, the master can poll its own expect flags until it reads 0
- Switching off the LVDS Tx pads with a non-specific slave (broadcast) HSCT command with a payload 32_H

The slave HSSL module initiator transmit path remains inactive and later, after being re-activated by the master, continues the operation from the point where it has been stopped. The master is not allowed to send commands to a deactivated slave.

17.4.3.12.5 MSCR HSSL to HSCT connections

The HSSL module provides the MSCR.EN and MSCR.SLAVETAG bit fields at the module border as outputs. These signals are connected to the HSCT module and provide a single point to configure the behavior of both HSSL and HSCT regarding multi-slave behavior.

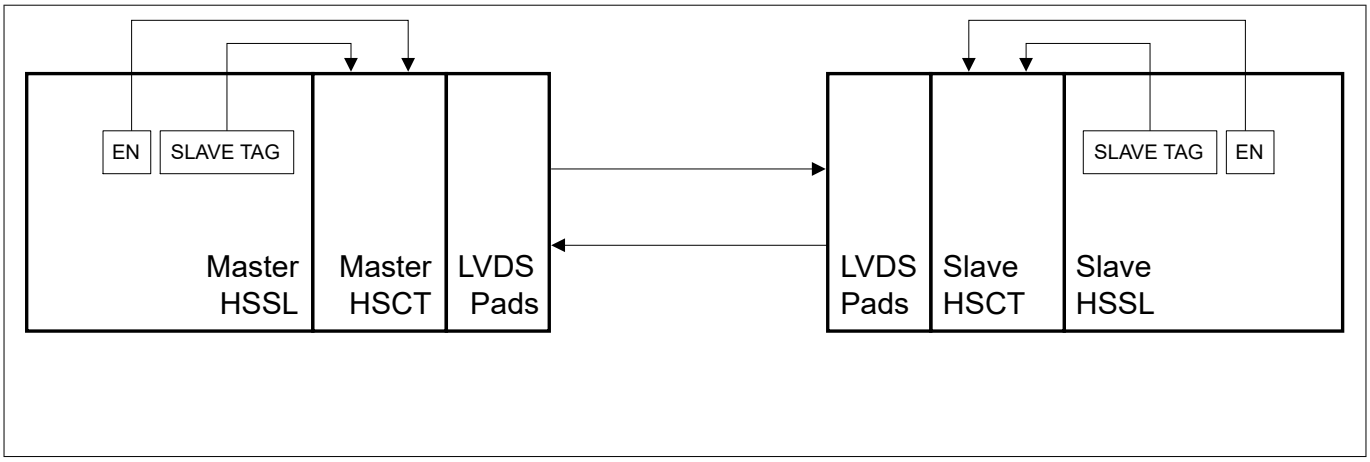

Figure 230 HSSL to HSCT connections

17.5 High Speed Communication Tunnel (HSCT)

A description of the High Speed Communication Tunnel interface for the microcontroller high speed data communication, including the physical layer and the control (link) layer.

17.5.1 Feature list

HSCT common interface basic features

- TX-link: transmit sample information from the master interface to the slave interface
- RX-link: receive sample information from the slave interface to the master interface
- System clock provided by the master interface (crystal owner) to the slave interface
- Fexible configuration of operating modes:
  - TX-link baudrate support (10 MHz/20 MHz SysClk): 5 MBaud (low speed) and 320 MBaud (high speed)
  - TX-link baudrate support (25 MHz SysClk):6.25 MBaud (low speed) and 320 MBaud (high speed)
  - RX-link data transfer speed based on f_{SYSCLK} = 20 MHz: 5 MBaud (low speed) 20 MBaud (medium speed) 320 MBaud (high speed)
  - RX-link data transfer speed based on 10 MHz SysClk: 5 MBaud (low speed) 320 MBaud (high speed)
  - RX-link baudrate support (25 MHz SysClk): 6.25 MBaud (low speed) and 320 MBaud (high speed)
- High speed data transfer rate can be reduced by implemented dividers (2, 4, 8, 16)
- The interface is based on IEEE 1596.3 LVDS IOs (Low Voltage differential Signaling Input Outputs) and provides driver swing amplitude configuration

Single slave connection features

- Control information on TX link and RX link
- Clear To Send(CTS) indication in both directions
- Unsolicited status in both directions
- Regular data transfer in both directions based on data channels

Multi-slave (maximum of 3) connection features and restrictions

- Control information on TX link only
- Multi-drop configuration (Master is addressing all slaves connected to the trace line)
- Clear to send indication not supported
- Unsolicited status not supported
- Regular data transfer in both directions based on data channel only (derived by Higher layer protocol)
- Multiple sender active or driving the RX link at the same time is prohibited (ensured by system master software)
- Slave communication channel to a selected slave by higher layer software; Only one slave can be addressed and communication must be finished before the next slave can be addressed
- Slaves driving the LVDS trace line simultaneously are prohibited
- Connection of 2 slaves to the LVDS trace line limits the maximum baud rate to 160 MBaud
- Connection of 3 slaves to the LVDS trace line limits the maximum baud rate to 80 MBaud
- Discrete termination resistor for differential receiver trace line impedance matching is required on PCB with 100 Ohm +/-5% (check PCB layout guidelines from Infineon); internal resistor is not supported

17.5.2 Functional overview

The HSCT employs an interface for inter-chip communication between a Master interface and a Slave interface. The interface is based on LVDS IO technology and developed to function as a Master or a Slave interface. During

the initialization phase the role of the Interface (Master or Slave) must to be defined. It is not intended to change the system role after initialization phase.

The interface is a full-duplex interface for TX and RX data transfer. The data transfer speed can be configured to function in low or high speed and allows to configure in each transfer direction an independent transfer speed in order to reduce power and EMI, based on transfer speed requirements.

The Master interface is defined to own the crystal and provides the clock (HSCT SysClk) to the Slave interface. The HSCT Master/Slave interface allows from system point of view one crystal only. In this scenario the HSCT SysClk input at Slave Side is used as reference clock for other PLL's like SysPLL. The interface reset is derived from System reset and supports common reset behavior, including module reset. The name of the SysClk signal driven by the Master is SYSCLK_OUT. The name of the SysClk signal received by the Slave is SYSCLK_IN.

In the next figure a system level view of the interface and interface connection is shown:

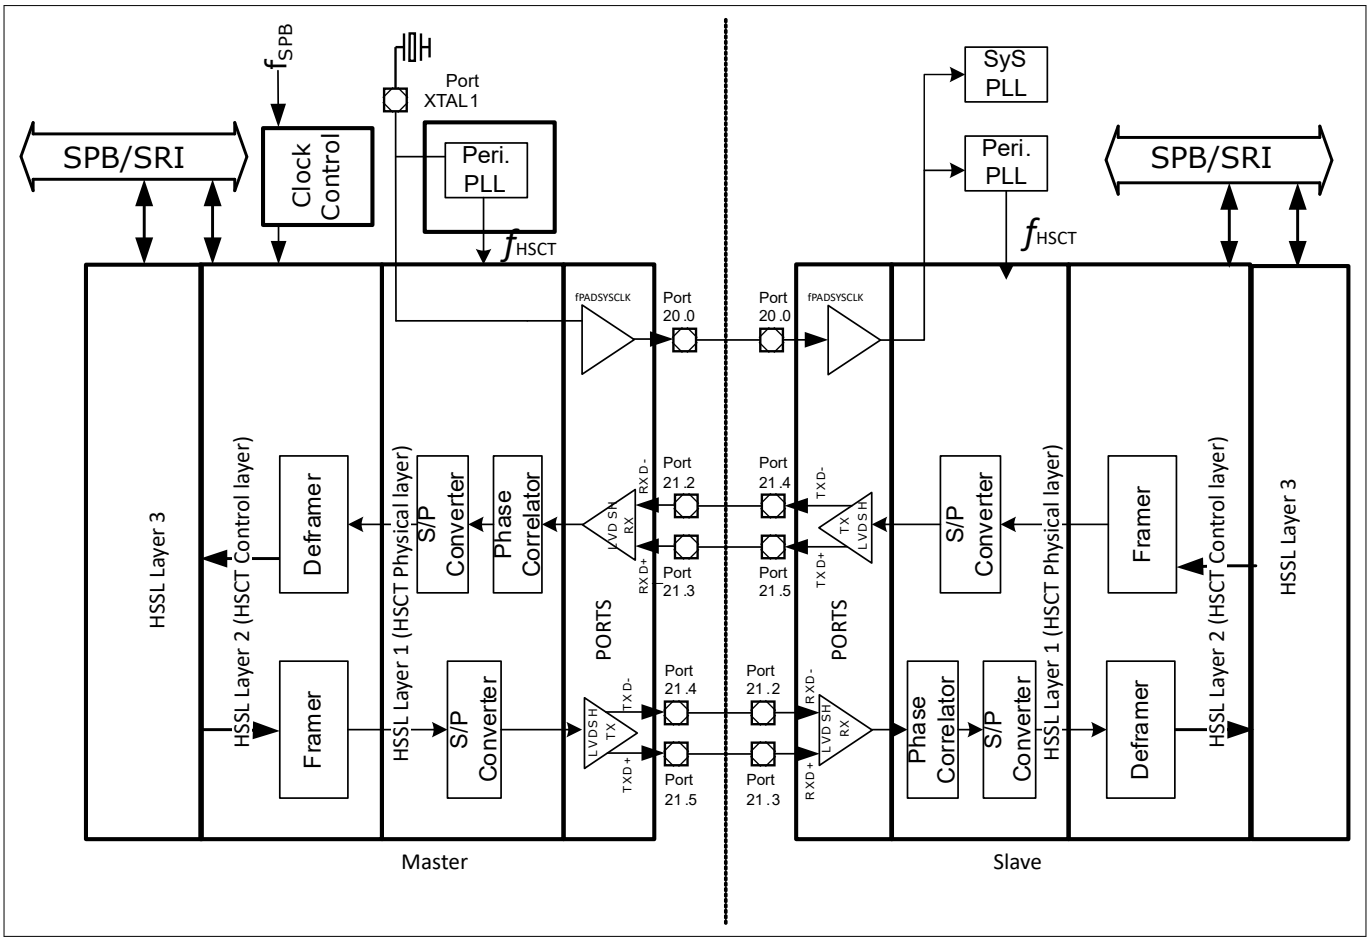

Figure 231 HSCT block diagram

17.5.3 Functional description

This chapter explains the detailed functional behavior on data-link and physical layer tasks of the HSCT sub-module.

17.5.3.1 Introduction

The initial HSCT communication is always established from master interface. The LVDS IOs are based on standard IO technology and follow the IEEE 1596.3 specification with minor limitations (see the corresponding datasheet for further information). The LVDS IO common voltage is defined to be a 1.2 V. Compared to the IEEE 1596.3 specification, the differential voltage level can be reduced through a configuration option to reduce EMI.

The intention is to implement the interface either as a master interface or as a slave interface. So the interface is able to handle both roles (master or slave). The description and definition of both the roles are as follows:

- TX line or TxData link (TX_DAT, TX_DATX) defines the data transfer from the master interface to the slave interface
- RX line or RxData link (RX_DAT, RX_DATX) defines the data transfer from the slave interface to the master interface
- Transmit direction, outbound data (or transmission) describes sending out data independent of the role of the interface
- Receive direction, inbound data (or receiving) describes receiving data independent of the role of the interface

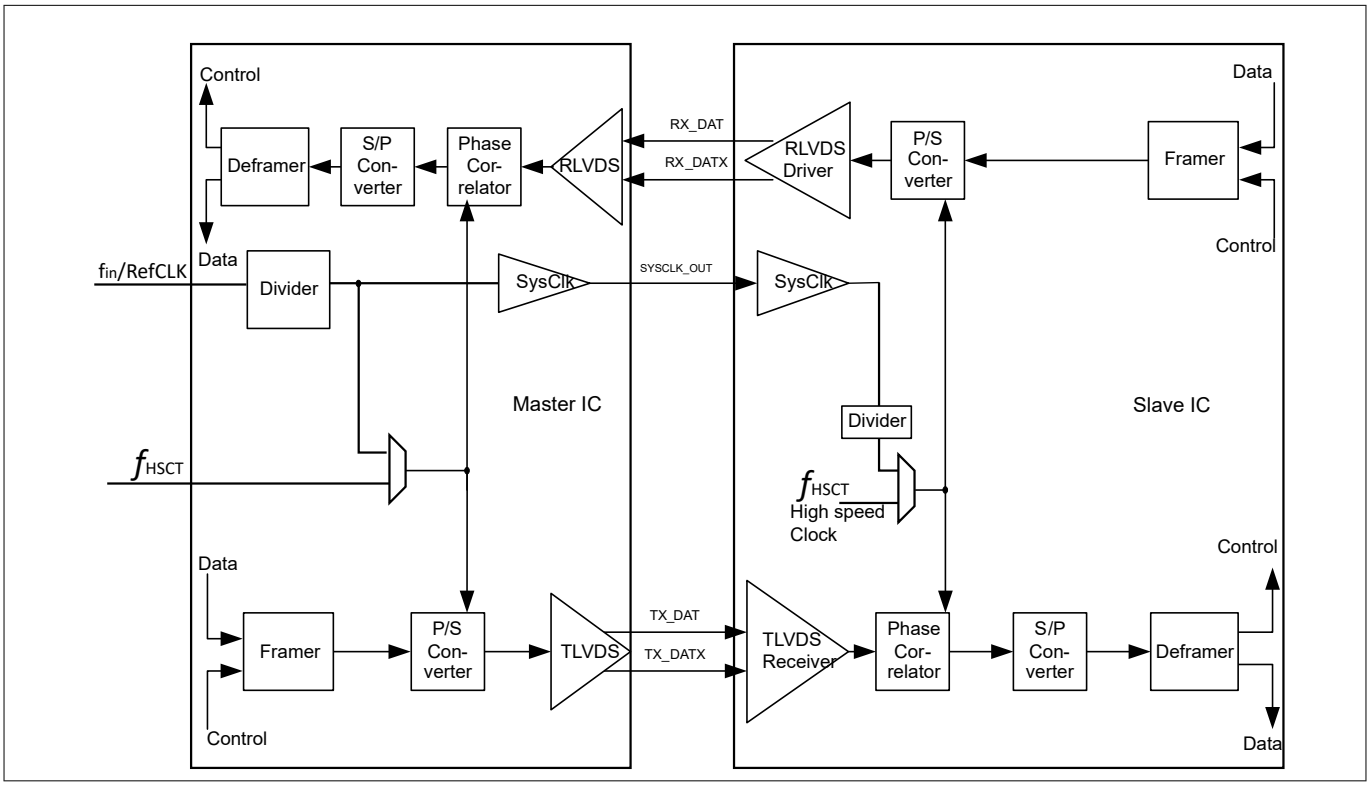

Figure 232 Internal block structure

17.5.3.2 Physical layer

This chapter explains in detail the physical layer composition of the HSCT sub-module.

17.5.3.2.1 RX/TX data communication

During initialization the associated TxData link starts in low-speed mode, with the high-speed clock not enabled or the clock generators turned off, and the RxData Link disabled. An interface control sequence, initiated by software, allows for switching the interface in high-speed mode.

The data interface can transmit with a maximum Baud rate of 320 Mbit/s in the RX and TX direction (full-duplex). The data is recovered from RX data stream (RX_DAT, RX_DATX) in the master interface and from TX data stream (TX_DAT,TX_DATX) in the slave interface. The table below shows the interconnects of the differential data lines for control and data transfers between the master and slave interface, and also shows the limitations for multi-slave connections.

Table 788 Physical interconnects

Direction	Name	Description
Transmit (single slave)	TX_DAT, TX_DATX	Channel TX data and control information at a maximum rate of 320 Mbit/s from the master interface to the slave
Receive (single slave)	RX_DAT, RX_DATX	Channel RX data and control information at a maximum rate of 320 Mbit/s from the slave interface to the master
Transmit (two slaves)	TX_DAT, TX_DATX	Channel TX data and control information at a maximum rate of 160 Mbit/s from the master interface to the slave
Receive (two slaves)	RX_DAT, RX_DATX	Channel RX data and control information at a maximum rate of 160 Mbit/s from the slave interface to the master
Transmit (three slaves)	TX_DAT, TX_DATX	Channel TX data and control information at a maximum rate of 80 Mbit/s from the master interface to the slave
Receive (three slaves)	RX_DAT, RX_DATX	Channel RX data and control information at a maximum rate of 80 Mbit/s from the slave interface to the master

The TX link differential data with the configured baud rate is transmitted from the master interface to the slave. Proper phase selection is processed at the receiver side in five different phases.

The RX link differential data is transferred from the slave interface to the master interface. A proper phase selection is required for data recovery at the master receiver path in five different phases derived from the clock generator (Peripheral PLL). The slave interface reference clock must be the HSCT SysClk, driven by the interface master. The slave must receive the SysClk from the master interface to enable reliable data transfer. A clock at the slave side derived from a crystal will lead to improper data communication, as frequency drift variation is uncontrollable and larger than if derived from a single clock source. The slave interface maximum frequency (320 MHz data clock) is generated internally from the HSCT SysClk.

The HSCT SysClk at the slave interface is also the reference clock for other PLLs on the chip.

***Note**: A local crystal at the slave interface taken as reference clock for the interface PLL is not allowed, as the data recovery based on clock phase shift works with a common reference clock source only!*

The RxDAT link (slave TX) enters shutdown mode by interface control logical channel command and exits shutdown mode again through a control command. The slave transmission line is disabled by default and must be enabled by the master. The master interface control commands are used to set the link in operation. TX or RX enable/disable shall not be changed during an active frame transmission.

Payload content is transferred most significant bit first. For example, if a 32-bit payload contains a message derived from a 32-bit register at TX side, bit31 of the register (the MSb) shall be the first bit of payload transmitted and bit0 (LSb) shall be the last. Larger payloads should be built up according to the same principle.

17.5.3.2.2 Differential signaling principle based on LVDS

The voltage at the termination resistor R_T of the receiver is either positive or negative, which depends on the direction of the current flowing through it. This is determined by the state of the switches at the transmit stage. The voltage V_{OD} should be evaluated by a comparator with hysteresis.

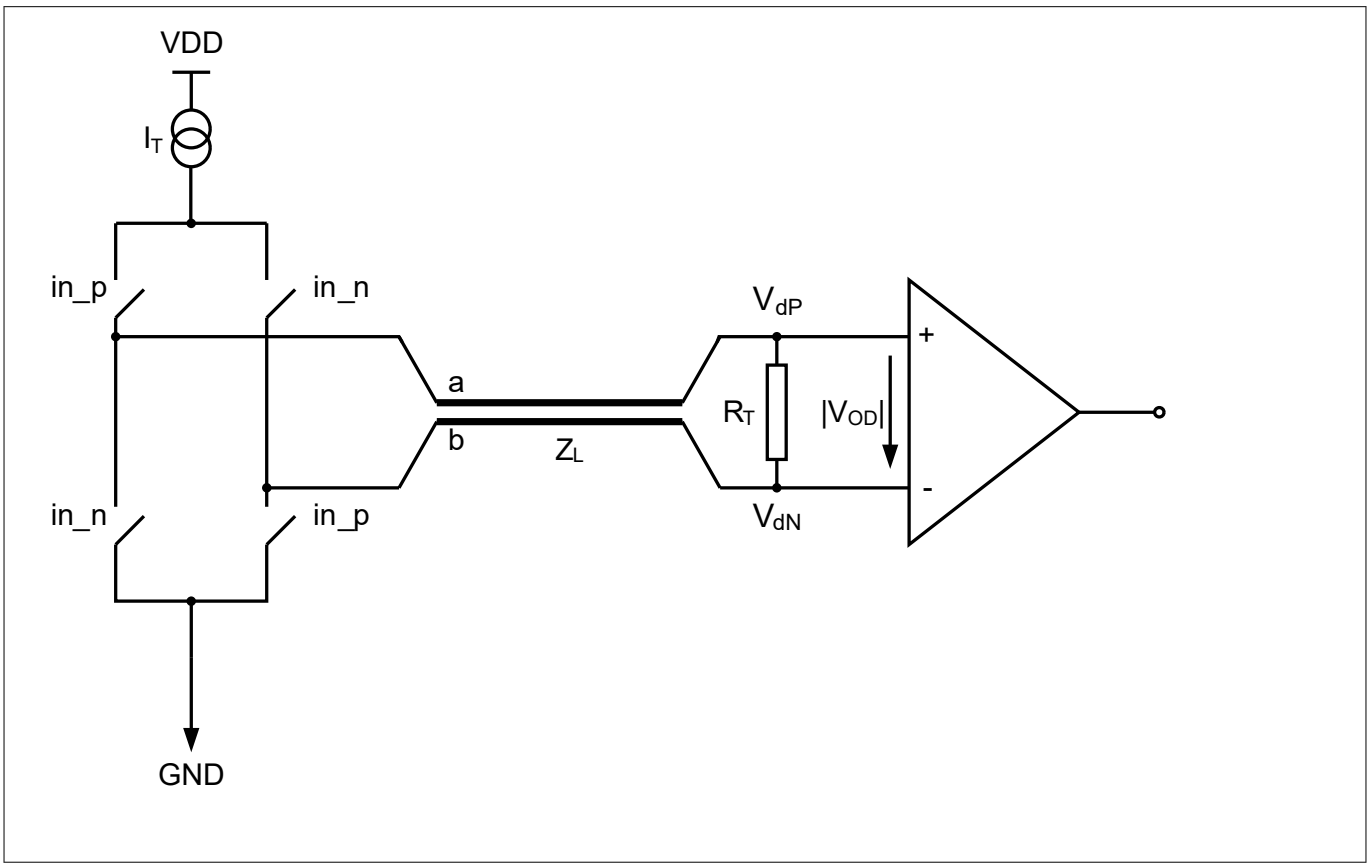

Figure 233 Pad driver and pad receive

The HSCT interface does not define any specific test for an error-free transmission, although the signal quality of course suffers from attenuation and noise, and particularly depends on proper wave propagation. Therefore the interconnect lines need to have a characteristic wave impedance Z_L equal to 100 Ω differential, corresponding to the termination resistor R_T at the receiver side.

***Note**: Due to the nature of wave propagation, a termination other than the characteristic line impedance leads to inevitable signal degradations. Therefore any operation mode other than 100 Ω termination is only supported from a functional point of view (that is the corresponding electrical configuration is possible) without any guarantee of an error-free transmission.*

***Note**: The interface receiver provides an input termination impedance of 100 Ω +/- 20% at the IO. If a more precise termination is required the design offers to disable the internal termination impedance and allow an external termination on the PCB. In a multi-slave approach the internal termination impedance must be disabled and a resistor with 100 Ω +/- 5% must be placed on the PCB instead, as close as possible to the receiver IO (exact placement can be identified based on the Infineon PCB layout guidelines).*

17 High Speed Serial Link (HSSL)

Some AURIX™ TC4xx devices may not include an internal termination resistor in the LVDS RX I/O cells. Refer to device specific chapter and Ports functional block content for related information.

The differential output voltage V_{OD} is defined as the difference of the voltages V_{dP} and V_{dN} at the receiver input pins.

$$V_{OD} = V_{dP} - V_{dN} \quad (1)$$

The common-mode voltage V_{OS} is defined as the arithmetic mean value of the voltages at the receiver input pins:

$$V_{0S} = \frac{V_{dP} + V_{dN}}{2} \quad (2)$$

V_{OD}, V_{OS}, and the corresponding minimum differential eye opening V_{eye} considering LVDS transmitter jitter are shown in the following two figures for ideal signals.

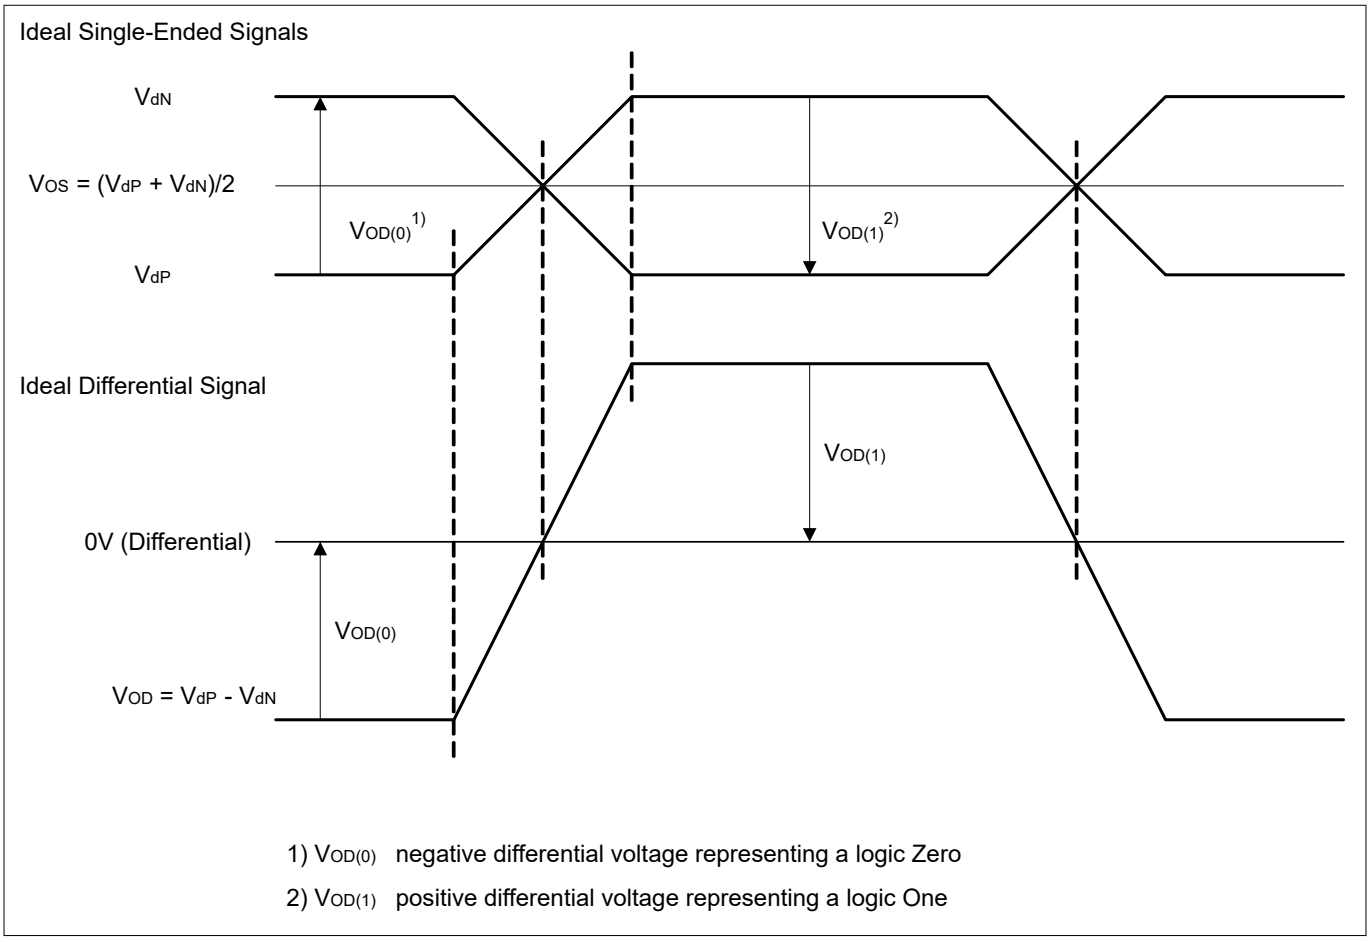

Figure 234 Ideal single-ended and ideal differential signals

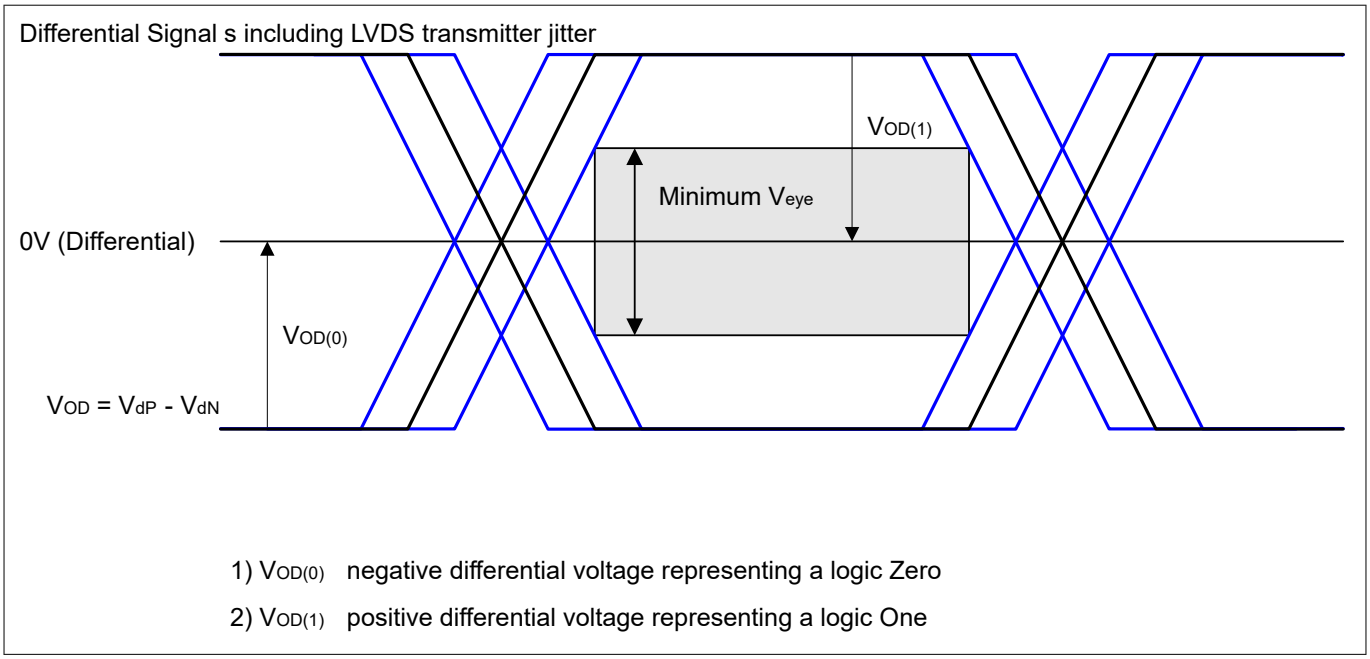

Figure 235 Differential eye opening

LVDS pads in multi-slave mode

In multi-slave mode, the procedure of changing the active slave is:

- Disabling the currently active slave LVDS transmitter
- Waiting for the LVDS pads to stabilize into Hi-Z state
- Enabling the LVDS transmitter of the next slave
- Waiting for the LVDS bus to stabilize into active state

After this, the first HSSL command can be sent to the newly activated slave.

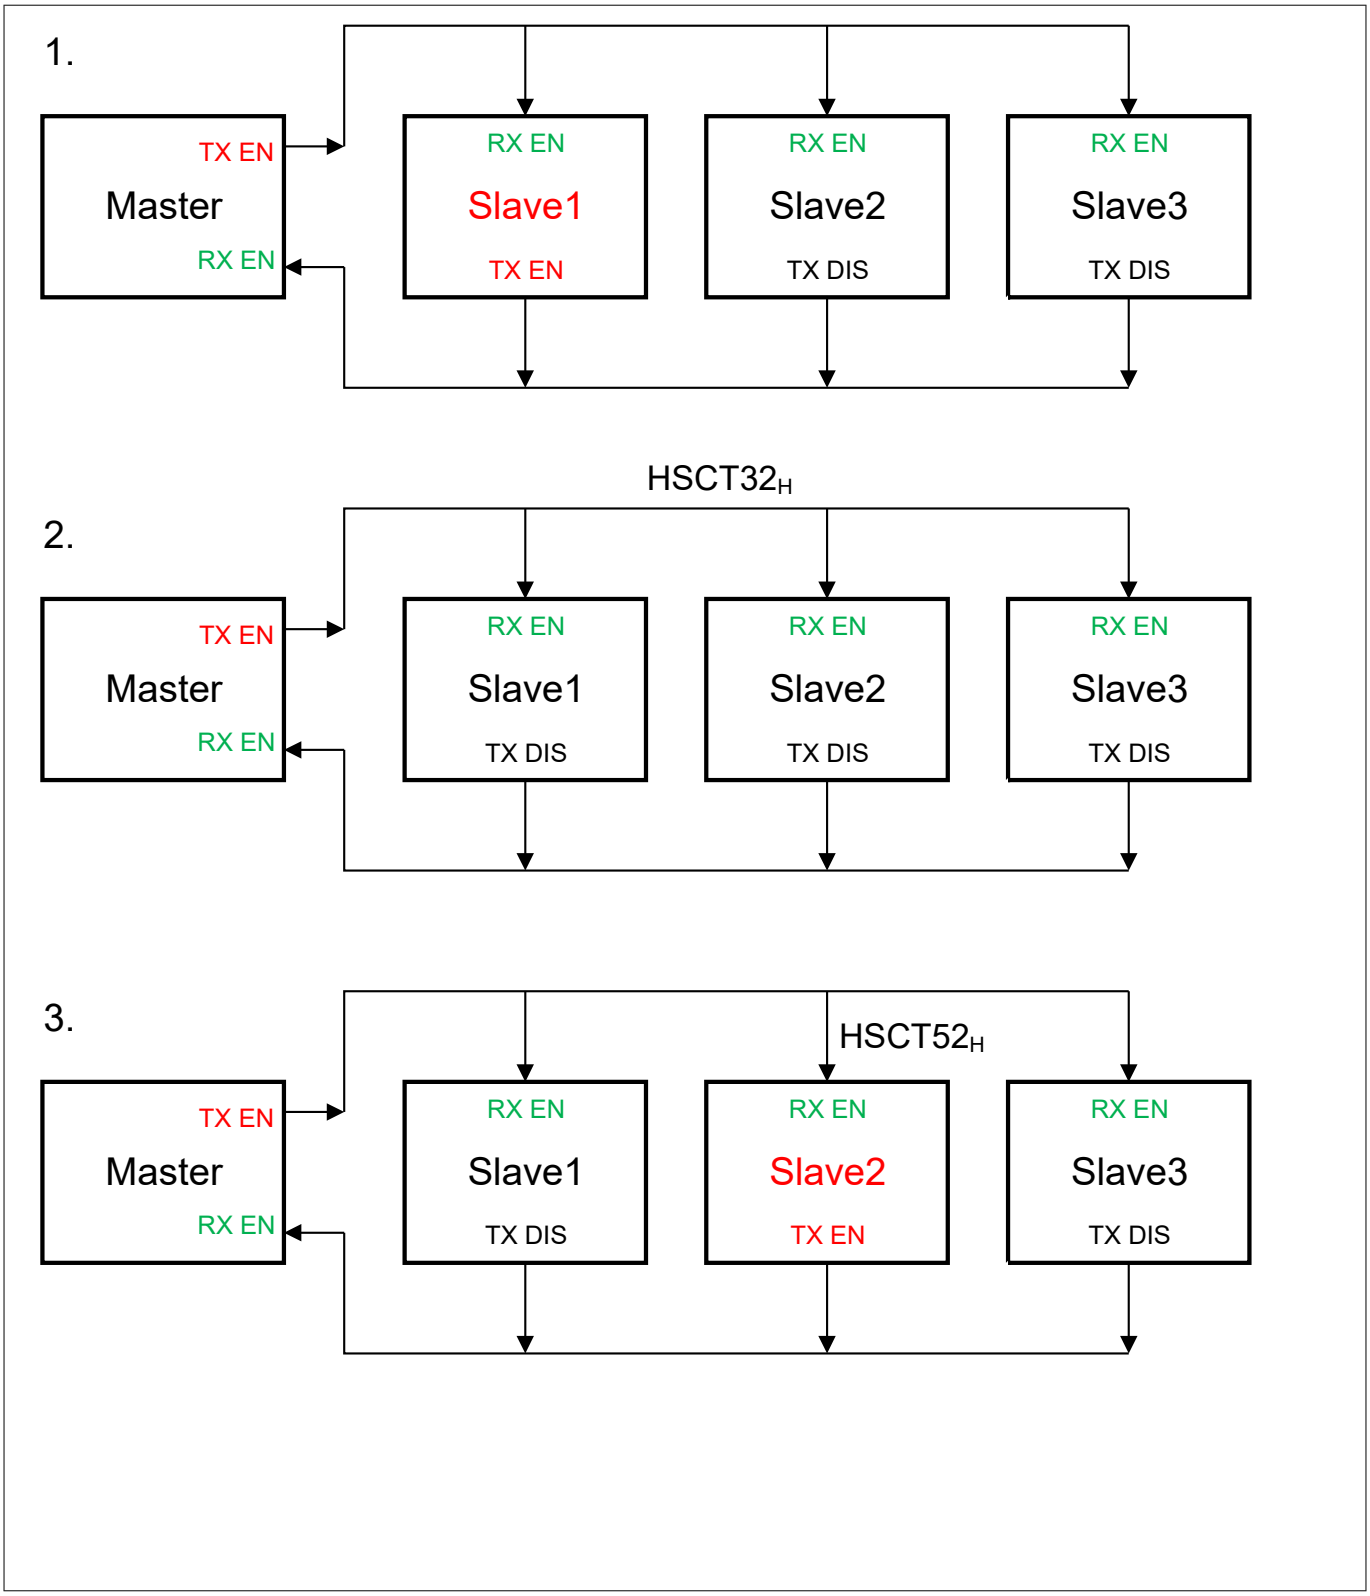

Figure 236 Changing the active slave

In step 2 of Figure 48, the output bus of the slaves is not driven by any slave and all LVDS Tx drivers are disabled. The differential voltage is equal to zero, and the offset voltage can take any value between the ground and power supply level.

The enable and disable time of the LVDS pads shown in the figure below are defined in the datasheet of the corresponding device as parameters t_{tx} (LVDS TX) and t_{trxi} (LVDS RX) $t_{LVDSDIS}$.

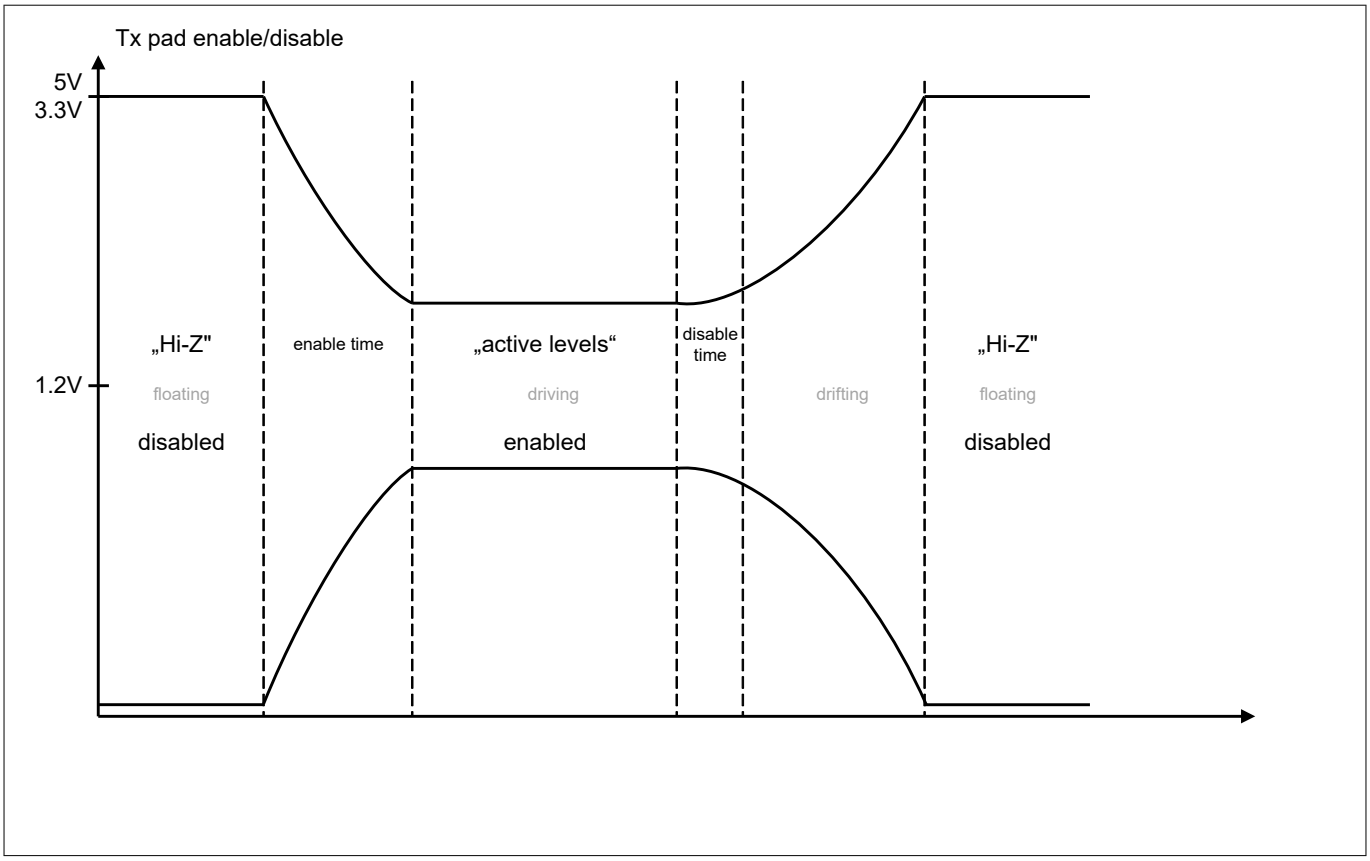

Figure 237 Voltage levels on the slave driven bus

17.5.3.2.3 Electrical characteristics based on LVDS for reduced link trace length

The characteristics are based on the LVDS standard IEEE P1596.3-1995 with some limitations as defined in the Datasheet. It is adapted for low power consumption and lower supply voltages for short ranges. It is defined that the interface supply voltages meet the common mode voltage for the differential signaling based on 1.2 V.

Operating modes

The HSCT interface comprises the following operating modes:

- Terminated Mode: The data transmitter requires a 100 Ω external termination between the pins TX_DAT and TX_DATX. The termination is given by a 100 Ω resistor at the receiver input, of the opposite LVDS device, for matching the differential characteristic impedance of the line with the impedance of the receiver. PCB design has to follow guidelines on differential signal routing. The PCB placed termination resistor can be chosen very precisely. Through configuration option, an 100 Ω LVDS receiver internal resistor can be enabled with a +/- 20% tolerance and shall not be enabled for a multi-slave scenario (PCB placed and +/- 5% tolerance according to IFX PCB guidelines)
- Power up: The line receiver is always enabled after power up and SysClk is active. The data decoder behind the receiver is not enabled at this point. It is enabled when the first transition on the data lines is detected by the line receiver (8 zeros at configured Baud rate). The line driver must be enabled on the Master side through software control. On the Slave side, the line driver must be enabled by sending interface message control commands from the Master. After power-up, the link starts in low speed mode. After line driver

enable, some time is required to power up the LVDS transmitter line. The data link in RX and TX direction is ready to transmit and receive data after the defined setup time

- Power down: When any interface driver supply voltage is removed, the driver shall provide a weak pull-down to 0 V to ensure that the signals are held in a well-defined state. It is a requirement to be free of cross current and bias current during power-down. This can be configured in the LVDS port control.

***Note**: The line driver in the Master interface shall be turned on before the line driver in the Slave interface is activated, that is before sending the transmitter activation command to the Slave interface, in order to avoid receiving undefined data in the Slave interface.*

Due to the strong dependency on link length and layout, as well as the susceptibility to noise and interference, it is recommended, to have the termination available on the PCB:

- Receiver internal termination mode not active (PCB termination): Can be programmed in register Init. The data transmitter is operated without a termination inside the differential receiver pair
- Receiver internal termination mode active: allows to have a 100 Ω resistor internally with a +/-20% tolerance (prohibited use in multi-slave scenario)

***Note**: Refer to device specific chapter to check the availability of the internal termination resistor in this particular device. In the absence of explicit reference, consider that it is available for usage.*

17.5.3.2.4 Data rates

The Slave interface shall be ready to receive frames whenever the HSCT SysClk is running. The link by default is set to low-speed mode after reset. Subsequent speed and mode changes shall be commanded by the Master interface.

Interface data rate change on both the TxData and the RxData link shall be possible without losing data. It is highly recommended to keep the link quiet during the time the interface transfer speed is changed. Changing transfer data rate on an active link does not guarantee stable data transfer.

The HSCT module provides three different data speed modes

- Low speed mode
- Medium speed mode (only available on RX link)
- High speed mode

Additionally, the HSCT module provides different data speed modes, derived from the crystal frequency. Taking the Automotive common crystal frequency of 20 MHz the following data rates can be produced based on the available multiplication factors.

SysClk; if RefClk frequency = 20 MHz

- 5 MHz = RefClk frequency/4 (low speed)
- 20 MHz = RefClk frequency (medium speed)
- 320 MHz = RefClk frequency * 16 (high speed)

Low speed mode and medium speed mode frequencies are generated directly from the refclk frequency. High speed mode frequency requires a PLL, which takes the crystal clock as reference clock. The following figure shows a frequency Scheme based on 20 MHz (refclk)crystal clock / SysClk as an example.

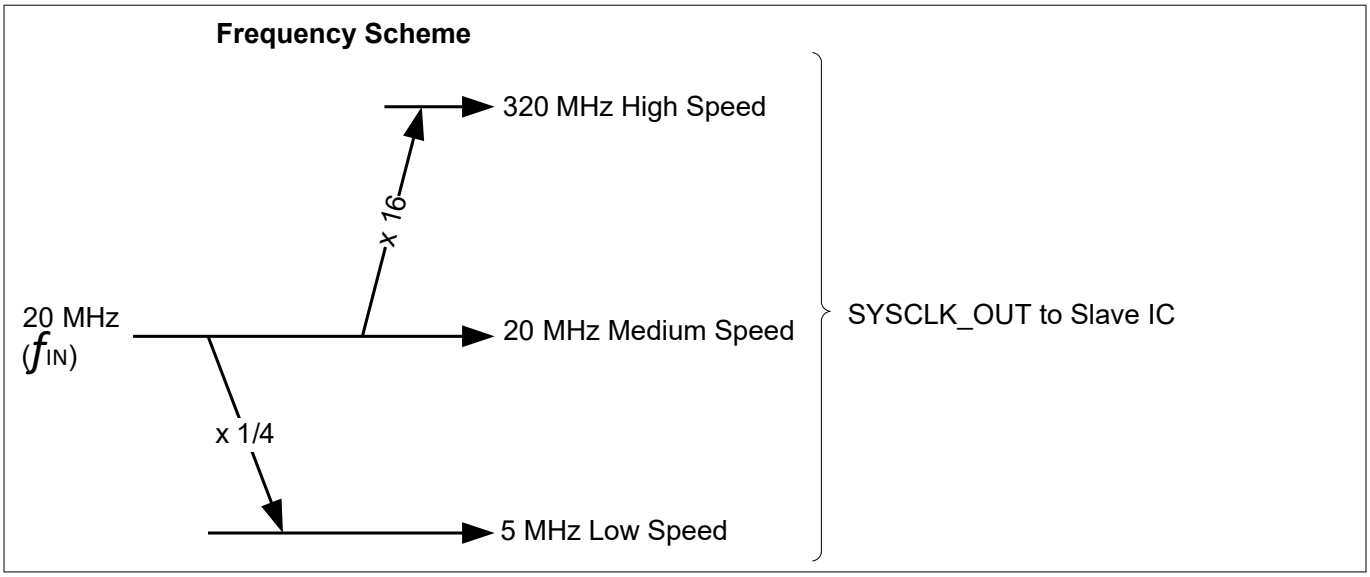

Figure 238 Frequency scheme

Connecting a 20 MHz or a 40 MHz crystal to the system, allows to generate the automotive frequency scheme.

The following table shows the data transfer direction and the available automotive transfer speed based on crystal clock frequency.

Table 789 Data rates

Direction	Data rate	Operating mode
Master interface to Slave interface	5 Mbit/s	“low speed mode” for startup/fallback
Master interface to Slave interface	320 Mbit/s	“high speed mode” (Single Slave only); Multi Slave divide
Slave interface to Master interface	5 Mbit/s	“low speed mode” for startup/fallback
Slave interface to Master interface	20 Mbit/s	“medium speed mode” ***Note**: Only available if reference clock SysClk is at 20 MHz (Crystal)*
Slave interface to Master interface	320 Mbit/s	“high speed mode” (Single Slave only); Multi Slave divide

PLL configuration and baud rates

The PLL supports different speed modes and frequency modes, which will be described in this section. Each mode and transfer direction can be configured separately.

Starting from a reference clock(REFCLK) selection in the CCU it is possible to configure a REFCLK divider (Init.SRCF) for the internal clock switches and correlator circuit as well as configure the SYSCLK divider (Init.SSCF), which divides the SysClk provided by the Master interface. The REFCLK DIV generated PHY_CLK is considered in low speed and medium speed mode. During configuration of the reference clock path the role of the interface (Master or Slave) needs to be considered.

The HSCT as Master Interface requires to enable the crystal(XTAL) path. The preferred XTAL frequency for HSCT is 20 MHz. Based on the XTAL frequency a PHY_CLK of 20 MHz shall be configured using the REFCLK DIV. In addition the Master Interface provides the SysClk having f_{SYSCLK}, which is configured using SYSCLK DIV based on the reference clock frequency. Recommended SysClk out frequency is 20 MHz

The HSCT as Slave Interface requires to enable the SYSCLK PAD path. The preferred SysCLK frequency for HSCT is 20 MHz. Based on the SysClk frequency the PHY_CLK shall be configured using REFCLK DIV. Also in this case 20 MHz is recommended. A 10 MHz PHY_CLK leads to not availability of medium speed (20 MBaud).

The data path baud rate can be configured independent per link direction using the Init.TXHD and Init.RXHD.

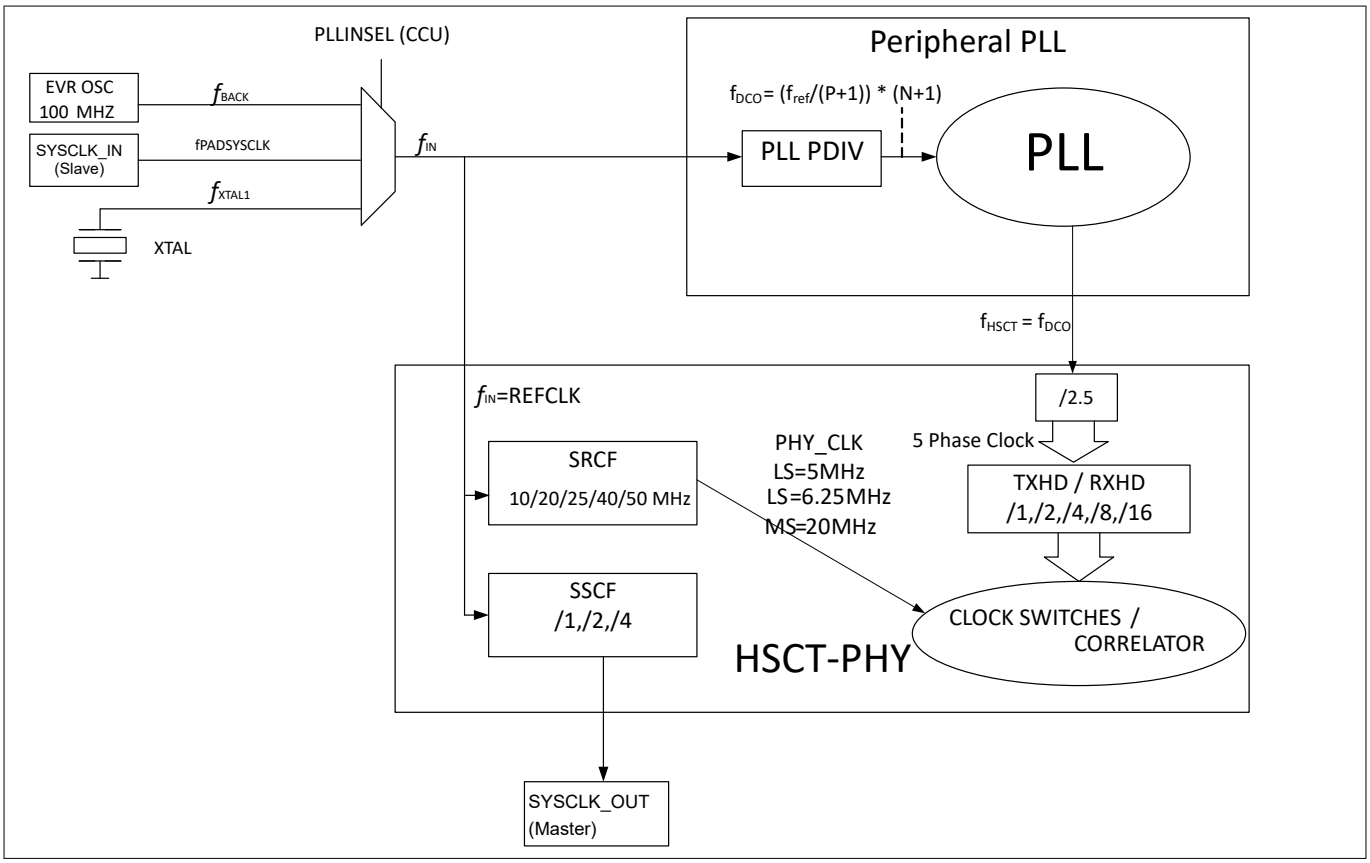

Figure 239 Frequency generation and clock divider

The following table gives more detailed information about the Baud rate configuration and the configuration bit's involved. The peripheral PLL reference frequency and their PLL frequency control word Multiplication factor (Peripheral PLL PDIV and NDIV) defines the PLL speed and are used to configure the output frequency of the PLL. The interface baud rate can be configured separately in TX direction (TXHD) and RX direction (RXHD). The table below shows the sample configuration in the TX direction.

Table 790 High speed mode selection

PLL speed fHSCT [MHz]	**800**	**800**	**800**	**800**	**800**
PLL reference frequency [MHz]	50	40	25	20	10
PLL PDIV (Peripheral PLL) [hex]	0x1	0x1	0x0	0x0	0x0
PLL NDIV (Peripheral PLL) [hex]	0x1F	0x27	0x1F	0x27	0x4F
TXHD $\frac{1}{1}$ [MBaud] (max Baud single Slave)	320	320	320	320	320
TXHD $\frac{1}{2}$ [MBaud] (max Baud two Slave)	160	160	160	160	160
TXHD $\frac{1}{4}$ [MBaud] (max Baud three Slave)	80	80	80	80	80

(table continues...)

Table 790 (continued) High speed mode selection

PLL speed fHSCT [MHz]	800	800	800	800	800
TXHD $\frac{1}{8}$ [MBaud]	40	40	40	40	40
TXHD $\frac{1}{16}$ [MBaud]	20	20	20	20	20

17.5.3.2.5 Correlator

Data transfer from the Master interface to the Slave interface can either be in “high speed mode” or “low speed mode” (for example $\frac{\text{Crystal}}{4}$ at 20 MHz HSCT SysClk or $\frac{\text{SysClk}}{2}$ at 10 MHz SysClk). A correlator is used to select the optimum sample phase for the frame based data transfer.

Phase selection

Every frame starts with a 16-bit sync field (see figure below) containing a synchronization pattern. Note that the sync pattern starts with 1, so a new frame always starts on the rising edge. In between frames, there is always at least one bit 0 in normal mode. Neither the Master interface nor the Slave interface may assume that the other side will maintain data phase relationship between frames. The receiving interface shall use the sync pattern to determine the start time of the frame relative to the local clock.

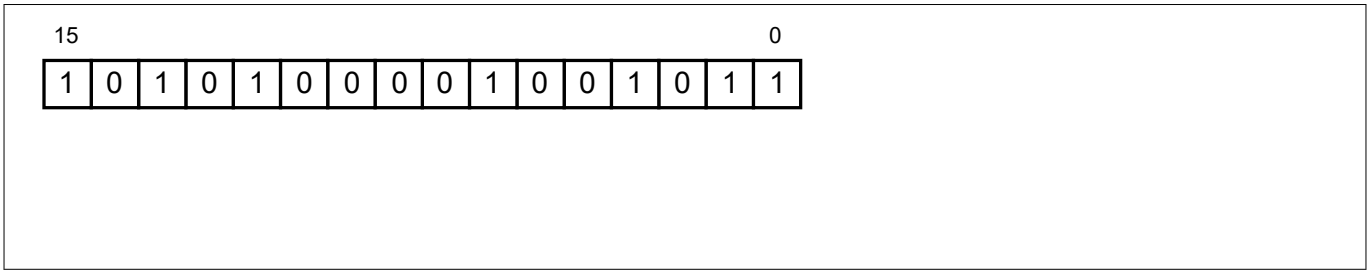

Figure 240 Synchronization pattern

The synchronization pattern is only needed for selecting the optimum sample phase, so it is not feed through to the output register of the correlator.

Payload size decoding

Every frame consists of three parts. A 16-bit synchronization pattern, an 8-bit header, and the payload field which can be 8, 32, 64, 96, 128, 256, or 288 bits. The header contains information about payload size and logical channel type. Although decoding the header is the task of the deframer, the payload size shall also be evaluated inside the correlator for finding the end of a frame.

The header is sent with MSB first. The first 3 bits (bit5, bit6, and bit7) contain the payload size of this frame.

Table 791 Payload size coding

b7:b5	Payload size (bits)	Total frame size (bits)
000	8	32
001	32	56
010	64	88

(table continues...)

Table 791 (continued) Payload size coding

b7:b5	Payload size (bits)	Total frame size (bits)
011	96	120
100	128	152
101	256	280
110	512	536 (not supported)
111	288	312

***Note**: In a harsh Automotive environment, a payload of 512 bit may cause increased error bit streams due to the long distance from one synchronization pattern to the next. This is the reason why this data transfer length is not supported.*

The correlator shall decode the payload size field and count the number of received bytes. After the last byte in a frame has been fed through to the correlator output register, the tuning of the multiplexer unit becomes invalid. In between frames at least one bit of value 0 shall be transmitted. The comparison procedure is started again as soon as there is a 1 at the MSB position in the shift registers.

The 8-bit header and the payload are used as input for the deframer block.

***Note**: The sync pattern and inter-frame bits are not passed to the deframer. An error in the sync pattern generates an error and is detected by the Physical layer.*

17.5.3.2.6 Jitter budget

The system clock is distributed directly from the Master interface to the Slave interface (see figure 56).

Subsequently, all jitter investigations considered in the following sections are referenced to the system clock f_{SYSCLK}.

Each system clock distribution has an associated filter function that incorporates the worst case combination of PLL bandwidth/peaking and equivalent jitter. The effective jitter seen at the LVDS receivers clock-data recovery inputs is a function of the difference in LVDS receiver PLL bandwidth and peaking and LVDS transmitter PLL bandwidth and peaking convolved with the jitter spectrum of the system clock.

System Clock variations contain jitter over a wide range of frequencies, some of which will be tracked by the LVDS receiver or otherwise removed by the combination of the LVDS transmitter and the LVDS receiver PLLs. Consequently, the nature of the filter functions is in part dependent on how the system clock is distributed. In general, the system clock jitter is filtered by the PLL difference function which comprehends the “mismatch” between LVDS transmitter and LVDS receiver PLL and also accounts for the impact of the transport delay.

Direct system clock distribution

This architecture provides direct distribution of the crystal clock as system clock from the Master interface to the Slave interface. Hence, the system clock is directly supplied to both LVDS transmitter PLL and LVDS receiver PLL. Hence, a major part of the clock jitter is sourced equally through LVDS transmitter and LVDS receiver PLLs. The figure below illustrates the direct system clock distribution, depicting noise sources, delay, and PLL transform sources. The amount of jitter appearing at the data recovery block is then defined by the transfer function difference of the LVDS transmitter and LVDS receiver PLLs, and by the sum of the clock jitter of the LVDS transmitter PLL, $X_{clkMaster(s)}$, and the LVDS receiver PLL, $X_{clkSlave(s)}$.

Based on the above clock architecture, a difference function may be defined that describes the “mismatch” between LVDS transmitter and LVDS receiver PLLs. As a first approximation, second order transfer functions are assumed.

The jitter of the direct system clock distribution is described by the phase noise power spectral density function as the absolute square of $X_{d(s)}$, as follows.

$$\left|X_d(s)\right|^2 = \left|X(s)\right|^2 \left|H_1(s)e^{-sT} - H_2(s)\right|^2 + \left|X_{clkMaster}(s)\right|^2 + \left|X_{clkSlave}(s)\right|^2 \quad (3)$$

where

$$H_{1(s)} = \frac{2s\,\zeta_1\omega_{n1} + \omega_{n1}^2}{s^2 + 2s\,\zeta_1\,\omega_{n1} + \omega_{n1}^2} \quad (4)$$

and

$$H_{2(s)} = \frac{2s\,\zeta_2\omega_{n2} + \omega_{n2}^2}{s^2 + 2s\,\zeta_2\,\omega_{n2} + \omega_{n2}^2} \quad (5)$$

Conversion between the natural PLL frequency ω_n and the -3 dB point is given by the following expression.

$$\omega_{3dB} = \omega_n\sqrt{1 + 2\zeta^2 + \sqrt{\left(1 + 2\,\zeta^2\right)^2 + 1}} \quad (6)$$

Under the assumption that crystal clock jitter can be ignored, that is,

$$X(s) \approx 0 \quad (7)$$

and LVDS transmitter to LVDS receiver transport delay can be neglected, that is,

$$e^{-sT} \approx 1 \quad (8)$$

the phase noise power spectral density of the direct system clock distribution can be simplified, as follows.

$$\left|X_d(s)\right|^2 = \left|X_{clkMaster}(s)\right|^2 + \left|X_{clkSlave}(s)\right|^2 \quad (9)$$

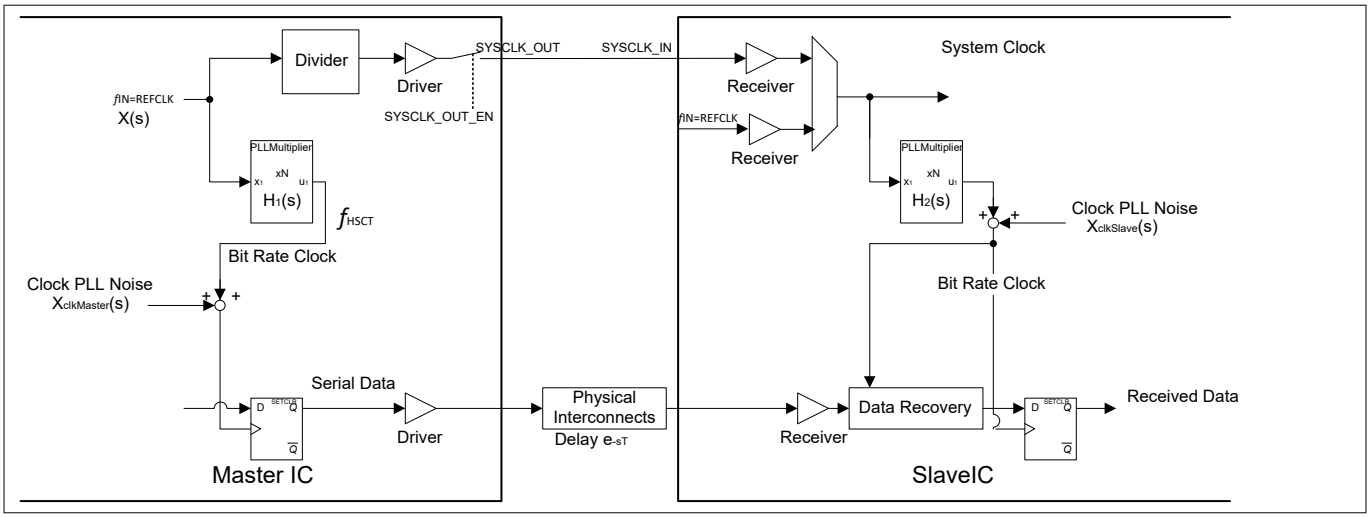

Figure 241 Direct system clock distribution

In the direct system clock distribution, the overall jitter is given by the sum of both phase noise spectral densities from the LVDS transmitter PLL, $X_{clkMaster(s)}$, and the LVDS receiver PLL, $X_{clkSlave(s)}$.

***Note**: The Slave interface requires a SysClk from the Master always as reference clock. It is not supported by the interface to have a separate crystal as reference clock at the Slave interface. The Master interface generated SysClk needs to be enabled.*

Jitter budgeting (direct system clock distribution)

To estimate the total rms jitter of LVDS transmitter PLL and LVDS receiver PLL for data recovery the following procedure has to be followed.

- Piecewise linear integration of the additive SSB (Single Sideband) phase noise for direct clock distribution to obtain the total phase noise power of the LVDS transmitter PLL
- Calculation of the rms jitter of the LVDS transmitter PLL as shown in the figure below
- Calculation of the total rms jitter *RJ* as the square root of the sum of the squares of the rms jitter from the LVDS transmitter PLL and the LVDS receiver PLL
- Calculation of total jitter that is random and deterministic, considering duty-cycle distortion and other effects to guarantee minimum eye opening at the interface

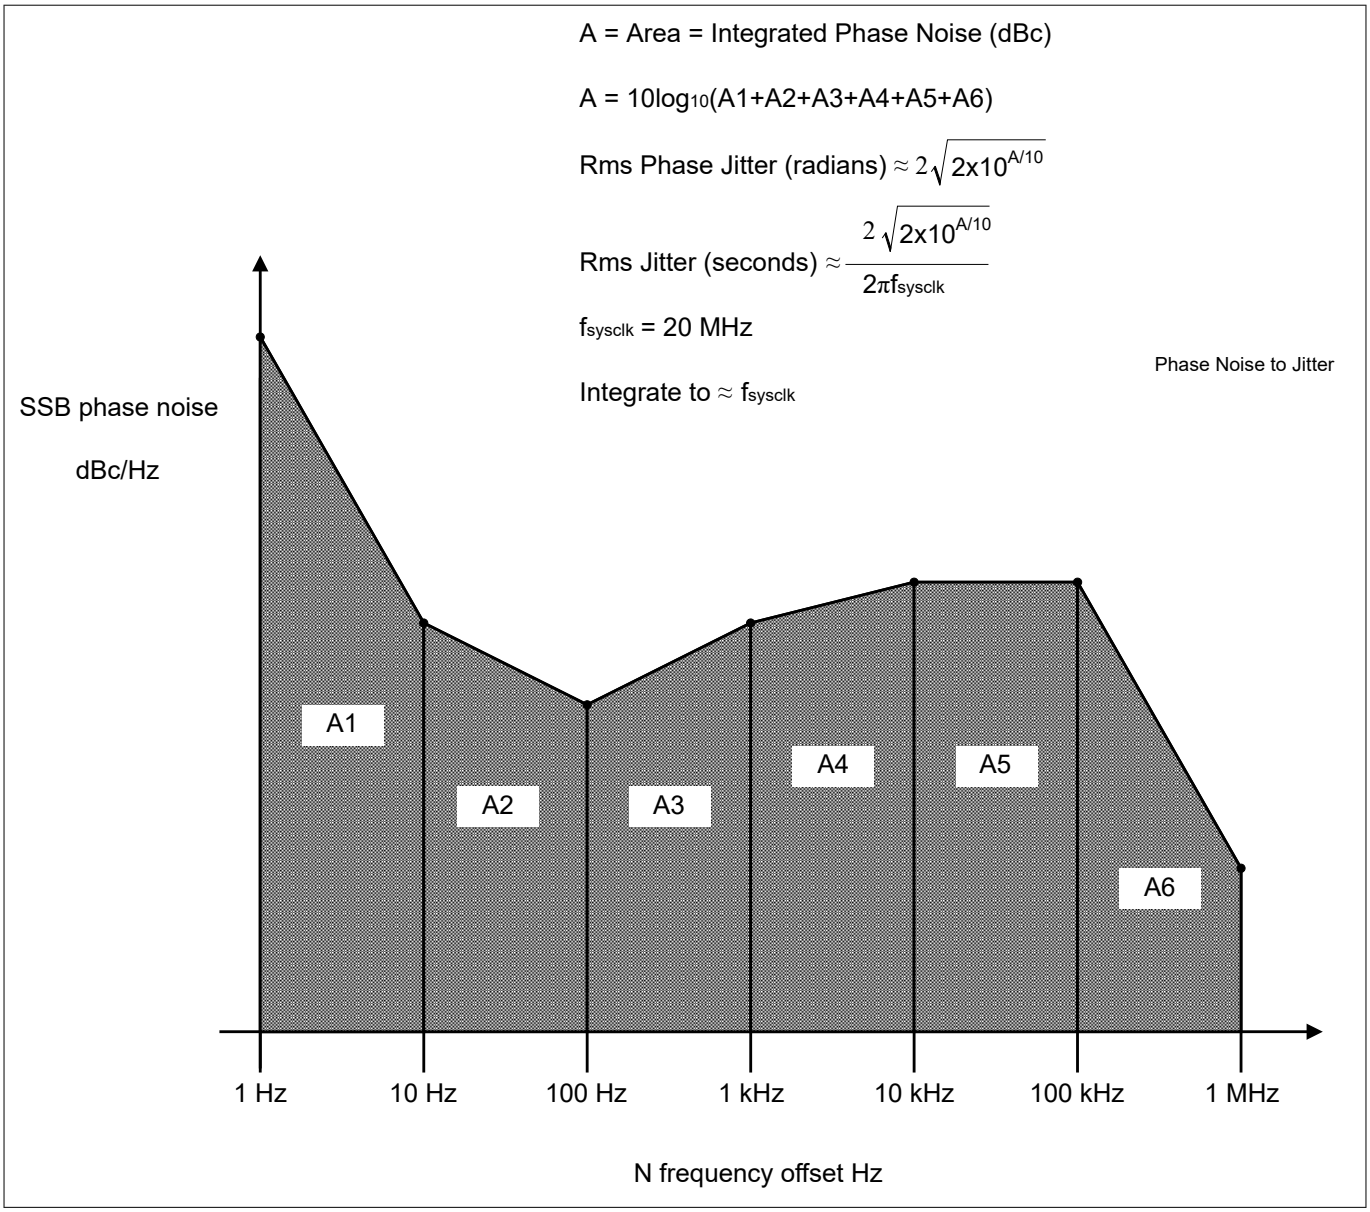

Figure 242 Calculation of jitter from SSB phase noise

Calculation of total jitter budget (direct system clock distribution)

To estimate the total jitter budget allowed for the random rms jitter *(RJ)* as described in the sections before, the following procedure for direct clock distribution has to be followed:

- Calculation of the jitter headroom available for the ideal jitter-free case given by the minimum eye opening, that is, 55% of a 320 MHz period
- Calculation of the total jitter headroom required under the assumption that the total long-term jitter *TJ* will not exceed the maximum peak-to-peak jitter specified
- Subtraction of two phases of the oversampling frequency used for data recovery taking into account the data-recovery uncertainty in multiple phases of the oversampling frequency. The data-recovery uncertainty is implementation specific and determined by the data-recovery oversampling factor DR_{OS}. The figure depicts the case where the selected sampling phase of the data recovery is almost one sample

phase away from the ideal sampling point. So the budget left for the peak jitter is reduced by almost one sample phase and the peak-to-peak jitter is reduced by almost two phases

- The remaining sum represents the jitter budget which is the upper limit for the peak-to-peak jitter calculated from the random rms jitter distribution *RJ* described in the sections before. Given a required bit error rate BER = 10^{-12} for SysClk 20 MHz and BER = 10^{-9} for SysClk 10 MHz

The jitter budget is given by the following equation.

$$TJ_{pp} = DJ_{pp} + RJ_{pp} = (DJ_{TX} + DJ_{RX}) + 2 \times Q \times \sqrt{J_{ABS}^2 + J_{ACC}^2} \quad (10)$$

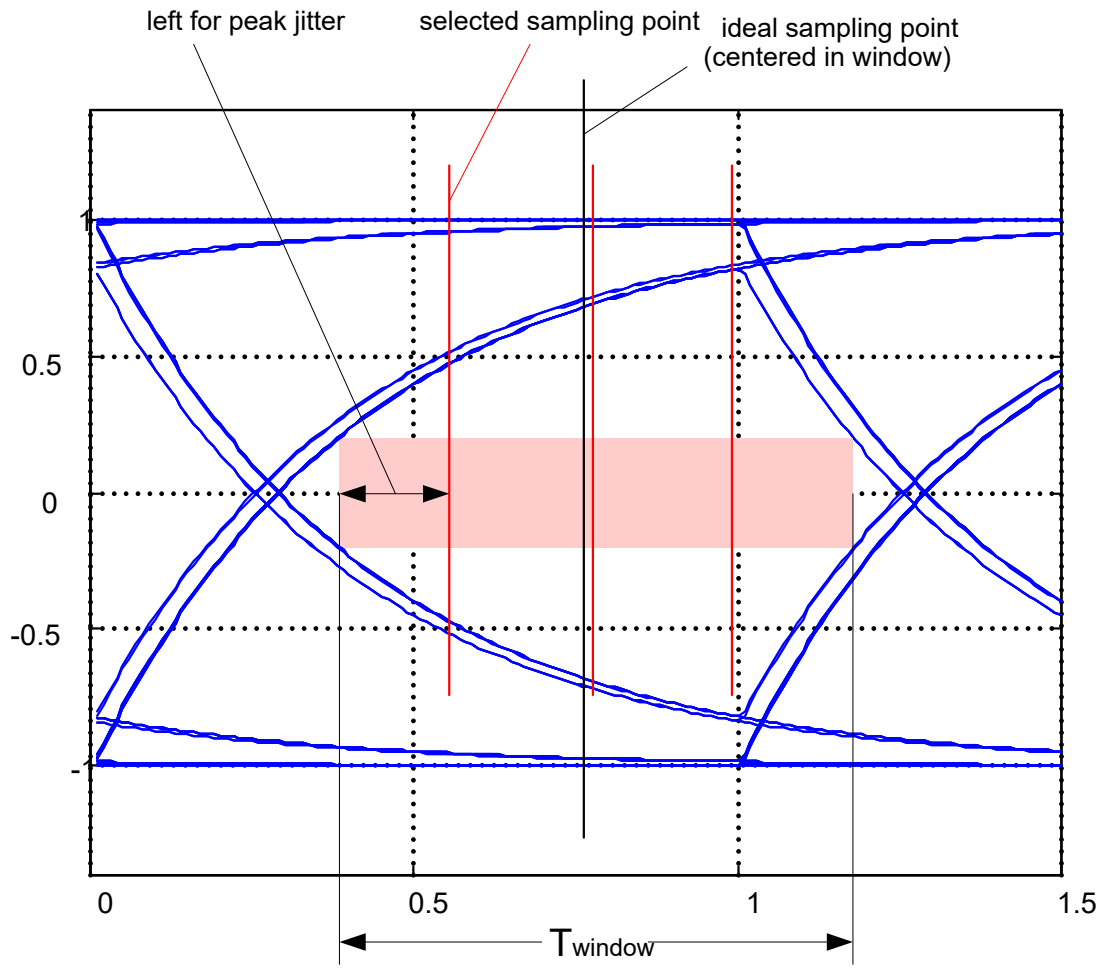

Figure 243 Sampling point selection

17.5.3.3 Protocol layer

The protocol layer is between the higher layer protocol (HSSL) and the physical layer. The protocol Layer is performing the frame generation in transmit direction and extracts the payload out of a frame in receive direction, called deframing.

17.5.3.3.1 Deframer

The deframer's tasks are, decoding the 8-bit header and separating the data stream according to the logical channel type.

During reset, the deframer shall ignore all data coming in from the correlator. This is a precaution measure to eliminate possible malfunctions due to floating HSCT lines.

Additionally the deframer checks the header for potential errors, for example, size is matching received data or size is allowed and received type is allowed. An error in the header discards the received data.

Header decoding

After the sync pattern has been filtered out by the correlator in a frame, the first 8 bits is the header or the frame type field. It contains information about the payload size and logical channel type coding. Please note again that all transfers are MSB first.

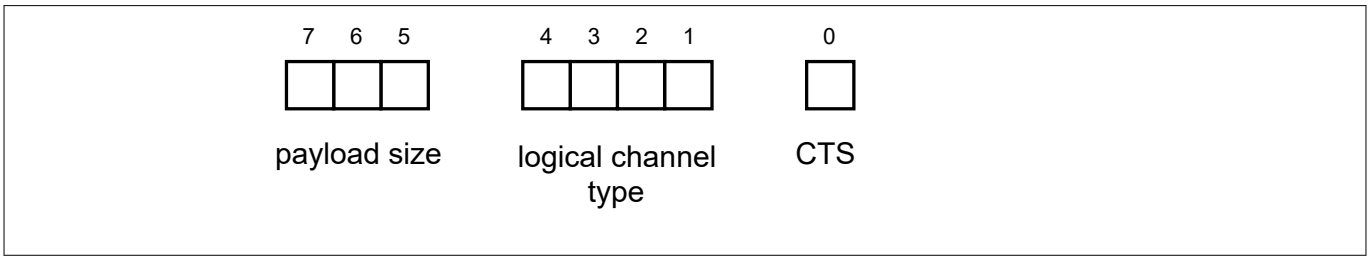

Figure 244 Header (frame type field)

- For payload size coding, refer to the Payload size decoding topic
- Bits 1 to 4 define the logical channel type. The table which follows will provide details about the logical channel type coding. Note that some kinds of transfer are exclusively used from the Master interface to the Slave interface or vice versa
- Bit 0 is used as Clear To Send bit (CTS) for transfers from the Slave interface to the Master interface (requires an enable through configuration). For transfers from the Master interface to the Slave interface also the Master interface can send CTS, which must also be enabled through configuration before. Also CTS from Master interface indicates the Master to the Slave that no more data can be accepted. This feature requires both for the Master and the Slave interface that higher layer indicates early enough in hardware that no more data can be accepted with the next frame. This needs to be send out with the frame based CTS signaling (Consider the transferred payload size for early enough CTS signaling through a frame)

Table 792 Logical channel type coding

b4:b1	Logical channel type master interface to slave interface (TX link)	Logical channel type slave interface to master interface (RX link)
0000	Interface Control; restrictions in multi-slave Mode	Interface Control (PING answer, 32-bit value; not supported in multi-slave mode)
0001	Master interface Unsolicited Status (32-bit only; not supported in multi-slave mode)	Slave interface Unsolicited Status (32-bit only; not supported in multi-slave mode)
0010	Reserved - receiver error interrupt	Reserved - receiver error interrupt
0011	CTS Transfers; not supported in multis-slave mode	CTS Transfer; not supported in multi-slave mode
0100	Data Channel A	Data Channel A
0101	Data Channel B	Data Channel B

(table continues...)

Table 792 (continued) Logical channel type coding

b4:b1	Logical channel type master interface to slave interface (TX link)	Logical channel type slave interface to master interface (RX link)
0110	Data Channel C	Data Channel C
0111	Data Channel D	Data Channel D
1000	Data Channel E (not supported, receiver generates an error interrupt)	Data Channel E (receiver error interrupt)
1001	Data Channel F (not supported, receiver error interrupt)	Data Channel F (receiver error interrupt)
1010	Data Channel G (not supported, receiver error interrupt)	Data Channel G (receiver error interrupt)
1011	Data Channel H (not supported, receiver generates an error interrupt)	Data Channel H (receiver error interrupt)
1100	Reserved - receiver error interrupt	Reserved - receiver error interrupt
1101	Reserved - receiver error interrupt	Reserved - receiver error interrupt
1110	Reserved - receiver error interrupt	Reserved - receiver error interrupt
1111	Reserved - receiver error interrupt	Reserved - receiver error interrupt

***Note**: A logical channel type TX transfer request of not supported or reserved types is not stopped or prevented to be sent out. Receiver side is expected to react with an error indication.*

***Note**: The received header information can be checked by software reading the Header status register (STAT). An error in the header is a severe error in a running system. Application software must handle the situation by interface link checks (PING. but it is not supported in multi-slave scenario). Additionally it is suggested to restart a running stream, if data loss cannot be tolerated. Received header frames are discarded, the same as the CTS information inside this error frame.*

Payload size for transmission data

For a transmission data transfer it is recommended to use a maximum 288-bit payload size.

Related information

Payload size decoding on page 2492

Logical channel separation

Reflecting the logical channel type to the higher level interface, the deframer sends the frame payload. The payload, as all other parts in a frame, is sent MSB first. The in the multi-slave scenario, it is used as a data protocol tunnel engine. Any addressing of the connected Slaves is done at a higher layer in hardware.

- All data received on and decoded as channel A to D data are sent through a 32-bit data interface to the higher layer hardware level
- Data can be sent using the 32-bit, 64-bit, 96-bit or 288-bit payload size

***Note**: Receiving a 8-bit header size on a logical channel results in an header error.*

17.5.3.3.2 Framer

The framer combines data and control information from the higher layer protocol to the frame payload. The payload is sent MSB first.

The framer codes the logical channel type and the payload size in the header according to the HSCT header format. Then a complete frame consisting of a 16-bit synchronization pattern, an 8-bit header, and a payload field, is put together.

The following logical channels are used for transmissions between Master interface and Slave interface:

- Data from the transmit unit: The frame will be sent to the receiving interface side as soon as the higher hardware layer transmit path contains enough data for the required payload size. The appropriate values will be signaled with the payload size signal and in the logical channel type field in the header. For data transfer, only the logical channel types Data Channel A to D are used. Receiving a header type reflecting the type Data Channel E to H generates an error
- Unsolicited status information can be sent by the Master interface and the Slave interface based on a 32-bit payload size. An unsolicited status can be used to send an unexpected and urgent message to the other side. Receiving an unsolicited message results in an interrupt at the receiving side. The Unsolicited status information can only be sent in a single slave scenario. In a multi-slave scenario this feature is not available

***Note**: The Slave interface in a single slave scenario (RX link) can send out a control command (channel type encoding 0h), which is the predefined PING answer with a defined 32-bit payload. No other control commands are available for the RX link to send. Receiving a header type not supported on RX link or TX link generates an error.*

The framer handles all frame parts. To determine the end of a frame, the framer counts the number of payload bits sent to the receiver side. In between frames bits 0 are transmitted.

Clear to send (CTS) for single slave scenario

The HSCT interface is able to use “data pull” in both directions (Master interface to Slave interface and Slave interface to Master interface) to perform flow control on the transmission data path.

The CTS bit in the header is asserted when the other side is allowed to send more data, and it is negated when the other side should stop transferring data.

A CTS deactivation can be sent out in a “normal” transmit frame, indicated by the header bit. The following payload is not discarded at the receiving interface side and is processed normally. CTS deactivation can be sent out in a CTS type transmit frame, if no actual transmit data is available. The clear to send information is indicated by the header CTS bit deactivation. The following payload is discarded at the receiving side. A received clear to send deactivation requires transmission to stop immediately after the actual frame that is in transmission, or the prevention from sending a new frame if no transmission is currently active. Control frames can still be sent.

The clear to send is independent of the channel having caused the back pressure (when the transmit side has sent the CTS, signaling the remote side/receiver, but the remote side is not clear to send, then this causes back pressure at the remote side/receiver). It simply stops the data channel transfer. As soon as the traffic jam is resolved the CTS bit in the next transmitted frame is activated again, or a separate CTS frame is sent with the CTS bit activated.

Higher layer software must analyze which channel caused the traffic jam and can send the information to the other side.

The use of the CTS signaling is optional. CTS signaling can be disabled by disabling the CTSCTRL.CTS_FRAME

By default the CTS bit in the header is set to 1. When the situation in the receive data path is reached, where no more data can be accepted , the CTS bit shall be reset to 0 in the header of the next frame sent. If there is currently no data in the higher layer module transmission data path to be sent in a new frame, a dedicated CTS transfer according to the logical channel type is generated. This transfer always uses the 8-bit payload size containing dummy bits. The payload in a CTS transfer will be discarded by the receiving side. Generation of dedicated CTS frames can be disabled by clearing CTSCTRL .CTS_FRAME.

The CTS bit is set to 1 again when the receive data path at the higher layer hardware protocol allows new data to be accepted. This is reflected by activating the CTS signal again.

The CTS signals are full duplex signals and are side information in the transferred data frame. The deframer filters the TXCTS information from the received frame header. The TXCTS is presented to the higher layer TX interface frame based. Changes within a frame are not intended. At the higher layer receiver side the higher layer activates the RXCTS signal if no more data can be received. The framer sends the RXCTS information with the header of the next frame.

Related information

See the Logical Channel Type Coding table on page 2498

17.5.3.3.3 Interface control

The Master interface is configured through a CPU based configuration. The Slave interface can be configured by sending an interface control command from the Master interface. The interface control command is used to configure the Slave interface into the defined mode.

The receiving Slave interface shall take no action if a reserved payload value is received. Instead it generates an error interrupt and hardware reacts on the received control command.

After start-up the interface is enabled to work at low speed (based on 20 MHz HSCT SysClk) and the PLL can be or might be off (if not used by other peripherals), regardless of the mode it had been in before. Shutting down the AURIX™ TC4xx device causes the interface to leave loopback-mode or clock test mode, if it was previously in any of these modes, and forces the receiver and transmitter into power-down mode.

The interface transmitter path is disabled by default. It is enabled by using the appropriate interface control, which is a payload command for the Slave interface and a control through software for the Master interface.

***Note**: No data can be transferred to the other side as long as the transmitter is disabled. In this case all data in the TX direction is discarded.*

The Interface control logical channel transfer command always uses the 8-bit payload size and is sent only by the Master interface. The payload is sent as MSB first. The interface control payload values are shown in the next table. All other payload values are reserved for future use. Whenever a reserved payload value is received it shall be ignored and reported by an error interrupt.

Table 793 Interface control payload values

***Note**: In multi-slave mode, it is not allowed to use the commands marked as unavailable.*

Value (hex)	Function	Multi-slave availability
00_H	“ping”. Sent by the Master interface. The Slave interface sends back a fixed 32-bit payload result.	No
01_H	Reserved	No
02_H	Slave interface clock multiplier start (in preparation for high-speed mode)[1)]	Yes

(table continues...)

Table 793 (continued) Interface control payload values

***Note**: In multi-slave mode, it is not allowed to use the commands marked as unavailable.*

Value (hex)	Function	Multi-slave availability
04_H	Slave interface clock multiplier stop[1)]	No
08_H	Select low-speed mode for transfers from the Master interface to the Slave interface	Yes
10_H	Select high-speed mode for transfers from the Master interface to the Slave interface	Yes
20_H	Select low-speed mode for transfers from the Slave interface to the Master interface	Yes
40_H	Select medium-speed mode for transfers from the Slave interface to the Master interface ***Note**: This is not allowed if SysClk = Crystal/2 (10 MHz) at Slave interface.*	Yes
80_H	Select high-speed mode for transfers from the Slave interface to the Master interface	Yes
31_H	Enable Slave interface transmitter[2)]	No
32_H	Disable Slave interface LVDS transmitter	Yes
34_H	Turn on clock test mode Send 101010… on Rx line continuously using currently configured Rx line rate; this is canceled by issuing the 'test mode off' command. Internal transmit and receive path is disabled. Received data is discarded. The only exception to this is the 'test mode off' function, which turns off the clock test mode and re-initializes for normal operation, retaining whichever interface speed mode is currently configured	No
38_H	Turn off test mode. Cancel clock test mode and payload loopback	No
51_H	Enable Slave interface LVDS transmitter of Slave 1 (only available in multi-slave mode)	Yes
52_H	Enable Slave interface LVDS transmitter of Slave 2 (only available in multi-slave mode)	Yes
53_H	Enable Slave interface LVDS transmitter of Slave 3 (only available in multi-slave mode)	Yes
FF_H	Turn on payload loopback Incoming frames at Slave interface are looped back until canceled by a Frame containing 'test mode off'. Internal transmit and receive path is disabled. Received data is discarded. The only exception to this is the 'test mode off' function, which turns off the loopback mode and re-initializes for normal operation, retaining whichever interface speed mode is currently configured ***Note**: This requires the same speed configuration for the RX and TX-link.*	No

1) The Slave PLL (Peripheral PLL) on a TC4xx device is also clock source for other modules on the SoC, and can only be switched on from the Master side using higher layer protocol commands, or with initialization software running on the Slave side. The command shows no effect on a TC4xx device at the Slave interface side. For ASICs and backward compatibility it is still supported.

2) For more details refer to the RX link state machine

***Note**: Before changing the speed mode, software has to take care that data Transmission on both links is stopped and the interface remains quiet.*

As a general principle, after a mode change the Master interface should request a data transfer from the Slave interface to stimulate a frame, which confirms the correct reception and indicates the mode change was successful. The PING function, available in the interface control logical channel in the single Slave scenario, is used to verify a successful speed change.

The Master interface generated PING has to be sent in system defined time intervals, to verify the link is still alive. Sending out a ping requires system software to activate a system timer. If the PING answer is not received within the system defined time in the single Slave scenario, then the link cannot be considered as stable and a new initialization is required. In single Slave scenario the Slave interface sends back only a fixed, known response based on a control command, at the currently configured link rate on the Rx data line.

Slow to fast data baud rate configuration

The slow to fast interface speed change can be applied to either just one of the interface's data transfer directions or to both at the same time. At both sides, clock multipliers are required when either interface is to run at high speed.

If the RXData link is not enabled, but needs to be, the Master interface sends an 'Enable Slave Interface transmitter' command.

If the Slave interface clock multiplier is not already running, the Master interface sends a 'Slave interface clock multiplier start' command to the Slave interface at low speed. The peripheral PLL register needs to be directly configured to activate the PLL through higher layer protocol commands.

The Master interface enables its own clock multiplier, if it is not already running. After a proper settling time, the Master interface sends 'select high speed' to the Slave interface at the currently configured speed for the TXData link.

- The Slave interface switches the requested interface to high speed
- The Master interface switches the requested interface to high speed
- The Master interface sends a frame to the Slave interface and expects a response at the currently configured speed for the TxData link
- The Slave interface responds with a frame to confirm the mode change has worked

In order to select high speed for both RXData and TXData links the Master interface sends 'select high speed' for the RxData link first and then for the TxData link.

In the signle slave scenario it is recommended to send the PING for verifying a successful speed change.

For the multi-slave scenario the validity of the speed transition is performed using the higher layer protocol.

Related information

Interface control on page 2501

Fast to slow data baud rate configuration

The fast to slow interface speed change is the reverse of the slow-to-fast transition. Both clock multipliers must be running for either of the interfaces to operate in high-speed mode.

Before entering high speed mode it shall be assured that the high speed clock is available. This can be achieved by reading back Peripheral PLL lock information from PLL status register through higher layer protocol register access mechanism. If a command for entering high speed mode is received and the PLL is not locked, the command is ignored and lost. Interface control command value 02_H (PLL start) or 04_H (PLL stop), are not supported as the high speed reference clock comes from a common PLL also used by many other peripherals. Switching the PLL on or off through commands might lead to safety issues. Instead, the PLL switch on or switch off must be performed by register configuration through the higher layer protocol or through software routines established in the application software. Nevertheless the command is produced and sent out if required for backward compatibility.

Interface control on page 2501

TX link state machine

The TX transmission state machine controls transfers from the Master interface to Slave interface. The interface control value (int_ctrl) represents the received interface control payload value.

***Note**: Application software has to ensure, that no data communication is active on RX-link or TX-link during the time the interface speed is changed, otherwise a safe speed change without data loss can not be guaranteed interface.*

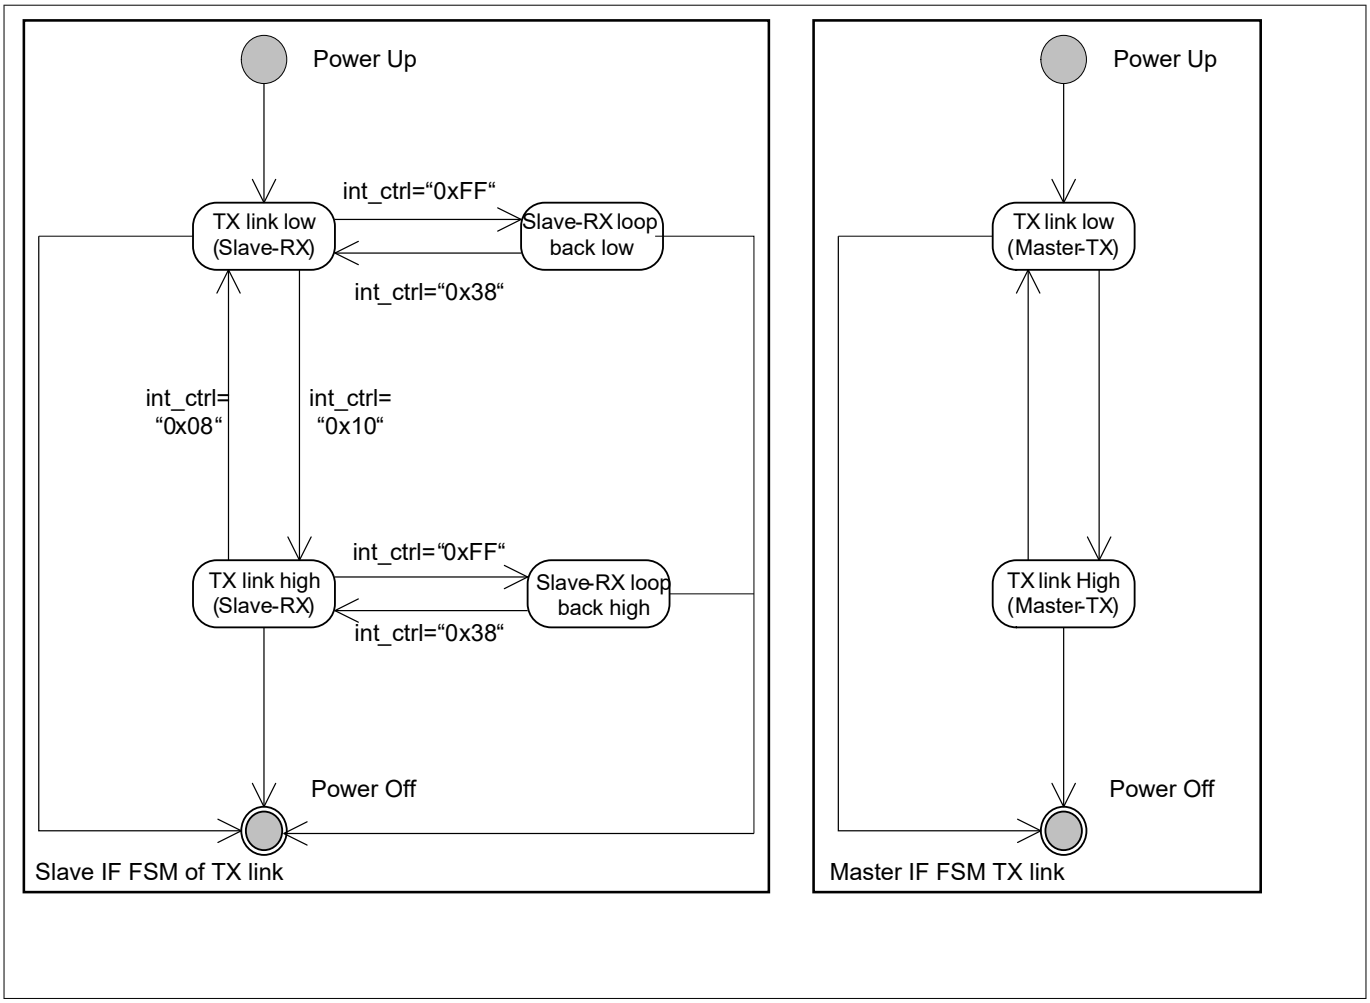

Figure 245 TX link state machine

Related information

Interface control on page 2501

Loopback mode

In the single slave scenario, loopback mode is used for test and verification to identify BER. When the Master interface demands loopback mode, the Slave interface internally loops back all received payload values in the following frames using the currently configured clock speed on the receive data link, without applying further processing internally.

Internally, transmit and receive chains shall be disabled. The header configuration is the same as in the incoming frame and the CTS bit in the header shall be asserted. Payload contents are ignored at Slave interface in loopback mode, except for the 'turn off test mode' interface control value, which ends loopback mode. The 'turn off test mode' frame is not looped back to the Master interface.

After leaving loopback mode, the interface is prepared for normal operation at the previously used clock speed.

***Note**: The 'loopback on' function has been intentionally coded at a large Hamming distance from the other codes. A minimum of 5, but usually 7, therefore requiring at least five bit-errors in the Header field for another function to be corrupted into 'loopback on'.*

Interface control on page 2501

RX link state machine

The RX link state machine is responsible for controlling transfers from a TC4xx device to the Master interface. The state machine is implemented on the Slave interface at the transmitting path.

The int_ctrl represents the received interface control payload value according to the interface control payload values.

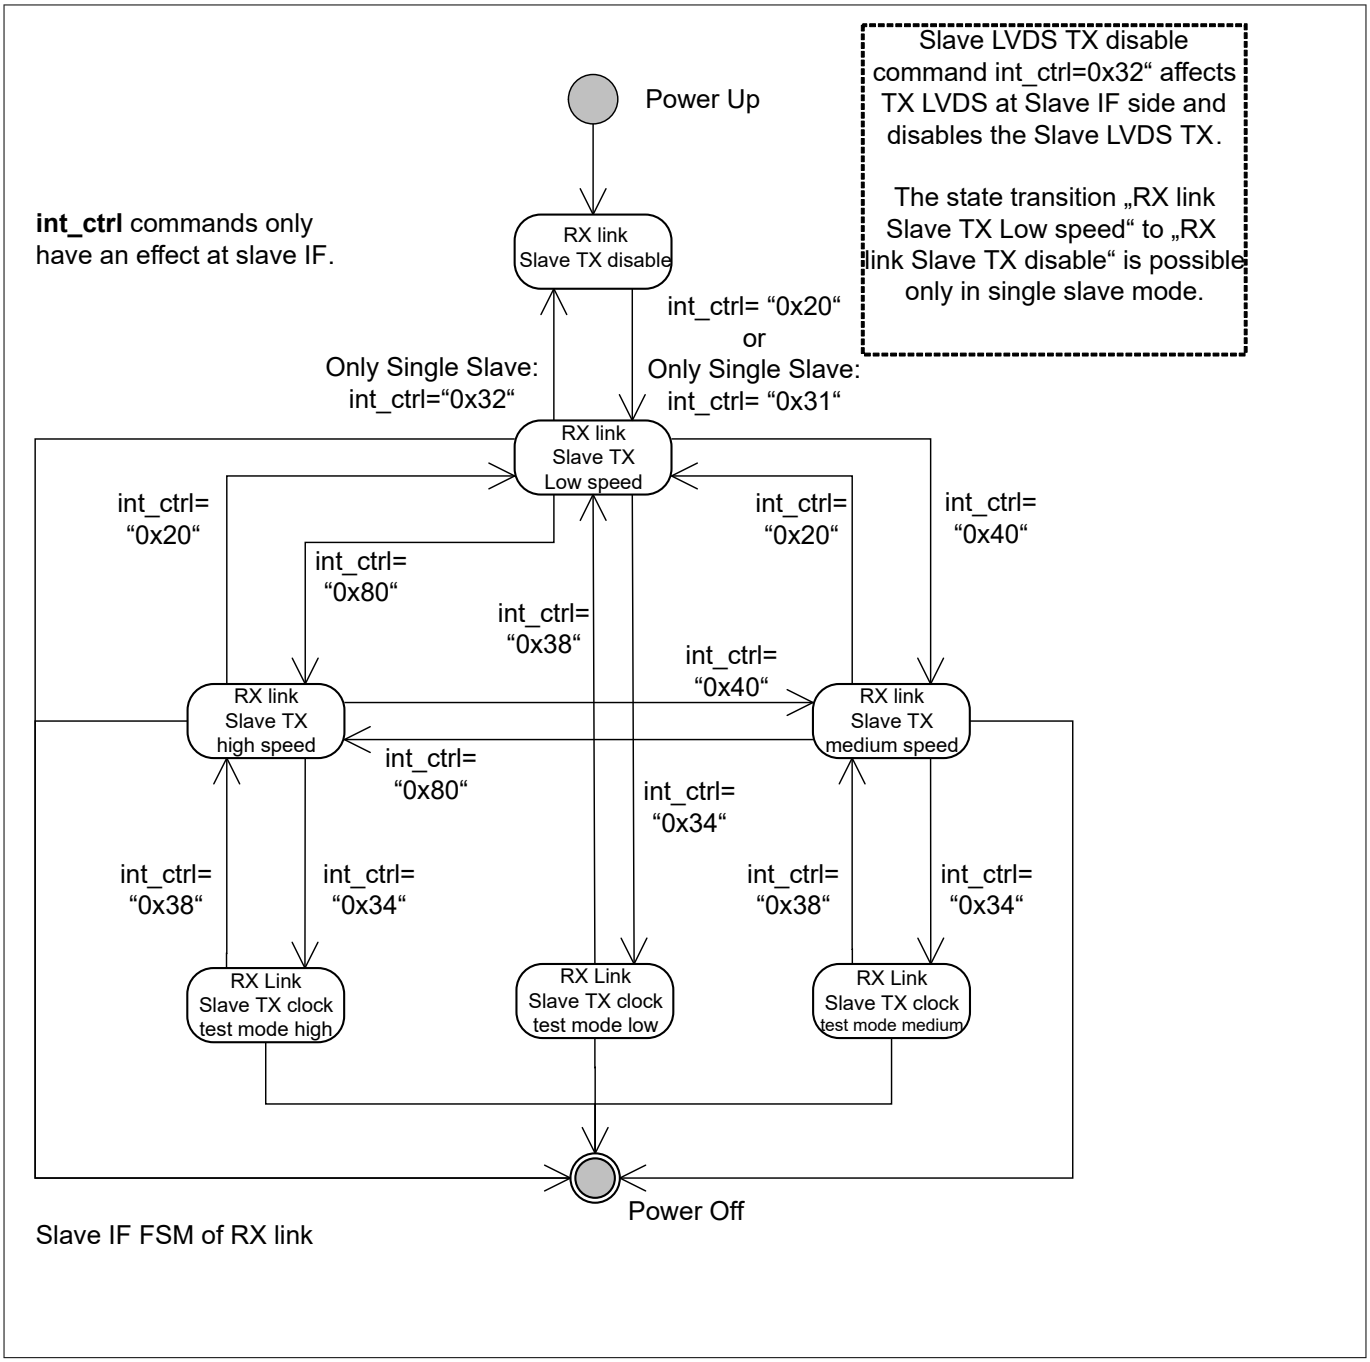

Figure 246 RX link state machine

The Slave interface TX, which is the RX link of the HSCT interfacing, can be activated from a disabled state into low-speed mode using the command "Select low-speed mode for transfers from the Slave interface to the Master interface" (20_H).

In single slave mode the command "Enable Slave interface LVDS transmitter" allows a change into "RX link Slave TX Low speed" mode.

Receiving the command "Disable Slave interface LVDS transmitter" in any of the other states disables the LVDS TX at slave side, but there is no state transition. This means for example being in high-speed mode and receiving the "Disable Slave interface LVDS transmitter" command, only the TX LVDS is disabled, but the state remains in high speed.

***Note**: The medium speed mode is only available, if the reference clock (SysClk) is running at 20 MHz.*

In clock test mode (only in single slave scenario) the transmitter sends '101010 …' continuously using the currently configured clock speed. Clock test mode can be left by sending the interface control value "turn off test mode".

Ping function

The ping function in TC4xx always uses the 32-bit payload size, sending back the value $ABCDEF01_H$ using the logical channel type Hex 0 (PING Status on RX link).

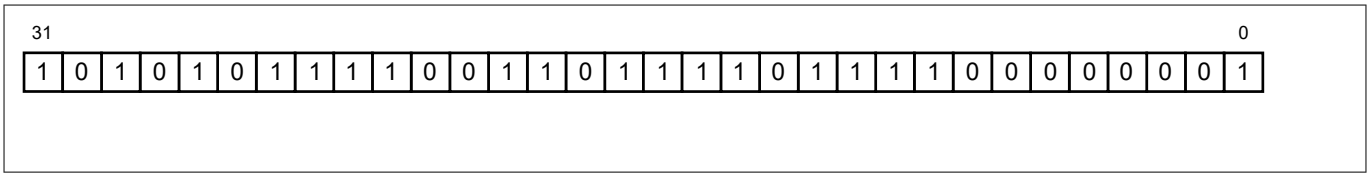

Figure 247 The Slave interface 'ping' response

Related information

Interface control on page 2501

Configuration

To configure the Slave interface, the Interface control commands have to be written into the Master interface register bits IFCTRL.IFCVS.

To send the control frame, 1b needs to be written to the register bit Interface Control Register.SIFCV to trigger the frame transfer.

The 8 register bits IFCTRL.IFCVS represent the same functionality as defined for the interface control payload values. Bit encoding is as shown in the Interface control payload values table.

The register field IFCTRL.IFCVS shall be written with the appropriate interface control payload value for every state transition shown in the TX state machine and Rx state machine figures.

The interface control in the Slave interface can alternatively be performed by programming the IFCTRL.IFCVS. This allows control of the Slave interface as well as the frame based configuration. The Master interface is only controlled by register configuration of the physical layer.

17.5.3.3.4 Power-up sequence

- The power up sequence of the HSCT Physical Layer and the LVDS IO requires to have the peripheral PLL in a locked state, a stable bandgap and bias distributor voltages before they can be enabled
  - It must also be ensured by the user that a correct clock is provided

- PLL Locked status can be read via STATPHY.PLOCK bit
- Bandgap enabling and bias distributor stabilization is automatically executed by HW after power on reset and takes t_{SET_LVDS} time

- For HSCT master, SYSCLK_OUT clock signal towards the slave is a direct output in the corresponding port. So, setting the bit PCSRx in the Selection Register for Module Port Control (PCSRSEL) is necessary for successful clock toggling (Please refer to Ports chapter for the register)
- For HSCT master, LVDS TX/RX PADS can be enabled in two possible ways depending on the value of bit TEN_CTRL/REN_CTRL set in the LVDS PAD Control register (LPCR)(Please refer to Ports chapter for these registers):
  - If TEN_CTRL/REN_CTRL =0 (port controlled condition), the LVDS TX/RX PADS are enabled in PORTS control by enabling the TX_EN/RX_EN bit in the LPCR register
  - If TEN_CTRL/REN_CTRL =1 (HSCT controlled condition), the LVDS TX/RX PADS are enabled via bit TX_DIS/RX_DIS in transmission disable register (DISABLE)
- The required time to power up LVDS TX PADS is about t_{tx} and LVDS RX PADS is t_{rxi}
- For HSCT Slave interface mode, the slave LVDS TX PADS are enabled/disabled with interface commands from master and LVDS RX PADS should always be enabled. Therefore, TEN_CTRL and REN_CTRL bits in the LVDS PAD Control register needs to be enabled by start-up software during initialization process
- After the peripheral PLL is in a locked state and LVDS is ready, the physical layer can be powered by enabling CONFIGPHY.PON
- After enabling the bit CONFIGPHY.PON, the module is ready to transfer data after t_{PON}time

***Note**: For actual values of the parameters please check the HSCT parameters section in the product specific datasheet.*

17.5.3.4 Use cases

The HSCT is as the name says a High Speed Communication Tunnel, which is used after initialization phase as high speed data transfer tunnel by higher layer protocol engines like HSSL. The interface is intended for chip to chip communication. The Micro Controller (MC) is from a system point of view intended to be the Master interface, if it owns the crystal. The connected Slave interface get's the clock (HSCT SysClk) provided by the master and can be operated without an additional reference clock for the internal PLL's. The reference clock at the Slave interface clocking the PLL is used to clock the data recovery path. The interface role definition (Master or Slave) is not allowed to change after the interface initialization phase.

There are two major UseCase scenarios in TC4xx the first one is the LVDS based point to point connection and the second is a point to multi point connection.

In both cases it is highly recommended to follow IFX PCB layout guidelines, which can be take as a reference to design a reliable PCB and meet the defined BER of 10^{-12}.

17.5.3.4.1 HSCT point-to-point LVDS based communication

The HSCT point to point LVDS based communication is a full-duplex link in TX and RX direction, which allows independent data transfer per link direction. It allows max baudrate of 320 MBaud with continuous data transfer in both directions. Subsequently some use cases are listed, which are an example of potential system scenarios.

MC to ASIC or FPGA

The MC (Master) is connected to the ASIC (Slave) and allows data streaming in both directions derived from higher layer hardware protocol (for example HSSL). In addition, the HSCT is used by the higher layer hardware

protocol to access Slave control register (read/write) and have therefore full controllability. This allows the MC to enhance it's system functions with the functions available in the connected ASIC or FPGA.

MC to MC

This use case allows to connect two MC's together. From the interface point of view, one of them is the Master function and other is the Slave function. Potential application would be register control or data streaming via higher layer hardware protocol (for example HSSL).

17.5.3.4.2 HSCT point to multi-point LVDS based communication

The is enhanced with the capability to have multiple Salves (max 3 Slaves) connected to one Master. Scenarios like MC connected to three ASICs or MC connected to two ASICs and one MC are supported. The initial Master configuration is fix and is not allowed to change during operation.

The connection of two ASICs (or ASIC and 1 MC) through LVDS allows max Baud rate of 160 MBaud.

The connection of three ASICs (or 2 ASICs and 1 MC) through LVDS additional reduces the max Baud rate to 80 MBaud.

The communication with each of the connected Slave devices is time sequential, derived by the MC. Only one Slave can be addressed (selection by Higher layer hardware protocol) and communication must be finished before the next Slave can be addressed. Rest of the Slaves stay quiet during the time one slave is addressed (selected). Higher Layer SW running on HSSL ensures this behavior and also addresses the respective slave device. Several transmitter driving the same LVDS link at once is prohibited. Electrical collisions are not allowed.

During Slave configuration phase commands are used and the Master is addressing all Slaves based on a Multi-Drop communication.

To achieve this scenario's careful high speed PCB design based on MicroStrip trace lines is required with well routed differential trace lines on PCB and good termination at the receiver input. In the multi-slave scenario the termination resistor needs to be a discrete 100 Ohm +/-5% or with less tolerance. An internal LVDS resistor is not supported in multiple Slave scenario. The location of the discrete resistor is suggested to be placed as close as possible to the Slave with a max geometrical distance from master defined (check IFX PCB layout guidelines for more details).

The LVDS IO (based on IEEE1596.3) offers several driver swing configurations, which allow application based adaptation.

17.5.3.5 Suspend and power-off behavior

Generally, the HSCT module transmits and receives data and control information through the differential signal interface.

A power down of the module can be done in any situation of the transmission. It is strongly recommended to have the transfers stopped from the higher layer protocol before sending the HSCT layer into power down state using the user software in a well defined way. Issuing an power down within a data transfer will result in data lose.

17.5.3.5.1 OCDS suspend

OCDS suspend request, for debugging purposes, simply freezes the module in the current state. This corresponds to the hard suspend of the whole module, which includes both the transmitter and the receiver. After the end of suspend state, the receive data will be most probably corrupted. Therefore, the whole interface must be reset, re-initialized and reactivated.

17.5.3.5.2 Disable request (power-off)

Going into power off requires that the module has finished all activities, which needs to be ensured by SW. It is also required that the higher level HSSL protocol has finished the transfers. It is the software responsibility to change to low speed mode and disable the transmitter and the receiver according to the application by writing the appropriate registers, as the change in speed mode and disabling of transmitter and receiver do not occur automatically. The HSCT high speed dividers need to be disabled (Init.RXHD = 0 and Init.TXHD = 0), before the physical layer is set to Power-Off mode. Power-Off mode of Physical Layer can be achieved by disabling the 5 phases with CONFIGPHY.PON. The clocks of the other parts of the HSCT module can be switched off by the CLC.DISR request bit or by the chip system sleep mode control (see CLC.EDIS).

17.5.3.6 Multi-HSCT support and restrictions

For family derivatives with two HSSL instances, the respective HSCT modules use the same peripheral PLL clock and also share the SysClk pin. The common SYSCLK output functionality is controlled by the HSCT0 register Init. Therefore, if both HSCT modules are active at the same time, they can either operate as two masters or two slaves. If both modules on one device are used as slaves, the corresponding master modules connected to these slaves must be from one device and use the same clock. For an overview of the HSSL/HSCT subsystem, see figure below.

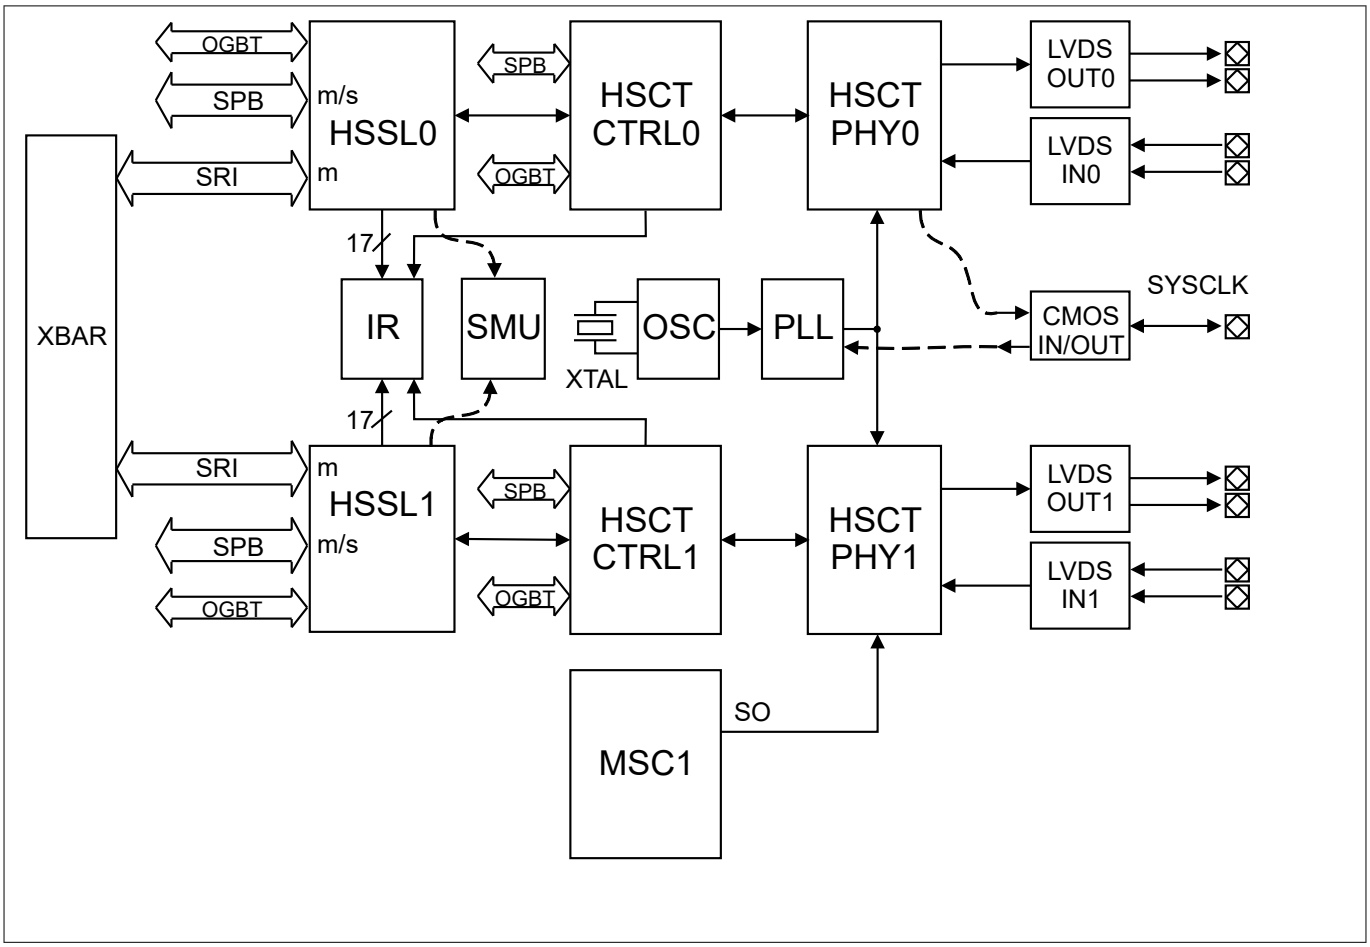

Figure 248 HSCT subsystem overview

The output LVDS Pads of the HSCT0 are shared with port signal. The port signal is either system PLL clock output or the port multiplexer output, which is selected by configuring port register PCSRSEL. The output LVDS pads of the HSCT1 are shared with an MSC and a QSPI module . The input LVDS pads are shared with QSPI. The software can select which module drives the LVDS output pad by configuring the port register LPCRx.TEN_CTRL, see figure below .

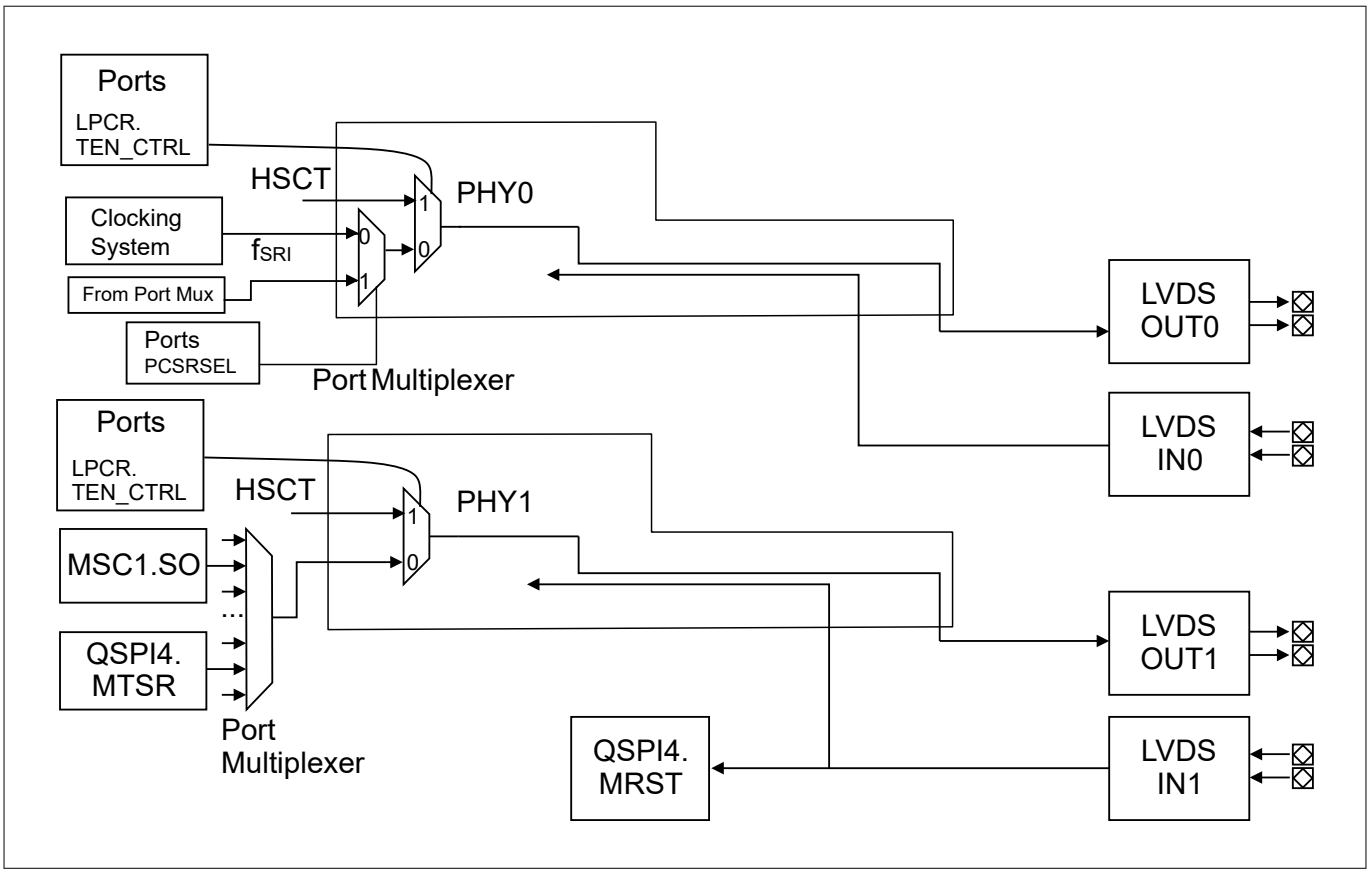

Figure 249 Pin sharing overview

17.5.3.7 Interrupts

The HSCT module generates one interrupt, called 'HSCT' towards the IR module.

The HSCT interrupt is triggered when any event represented in the register Interrupt register is triggered. These events can be masked or enabled with the help of register Interrupt Enable Register and can be cleared using the register Interrupt Clear Register.

17.6 Registers

17.6.1 HSSL registers

This section describes the registers of the HSSL module.

***Note**: The HSSL module occupies 1KByte of address space, although only the first 256 bytes are used. Accessing an address location that is not used generates a bus error.*

There are no registers in the HSSL with the destructive read property, where a read access would generate some action in the hardware.

17.6.1.1 Register overview - access mode glossary

Table 795 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
SECURE_MASTER	Description can be found in global access mode definition.

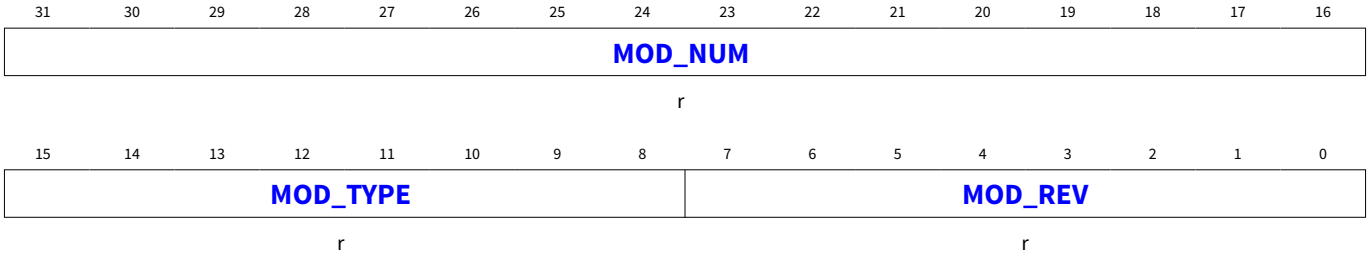
17.6.1.3 Global Registers

17.6.1.3.1 Module Identification Register

ID Offset address: 008_H

Module Identification Register PowerOn Reset value: $00CB\ C004_H$



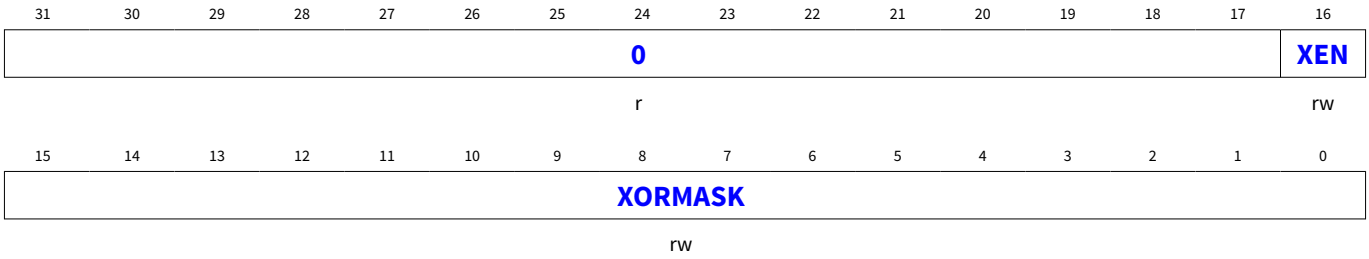
Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number

17.6.1.3.2 CRC Control Register

This register only influences the generation of the CRC in the transmit direction.

CRC Offset address: 060_H

CRC Control Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
XORMASK	15:0	rw	**Value to be XORed with the Calculated CRC** Used for error injection / test purposes.
XEN	16	rw	**Enable the Error Injection via XORMASK** 0_B disabled 1_B enabled
0	31:17	r	**Reserved** Read as 0; should be written with 0

17.6.1.3.3 Configuration Register

The CFG register is used to configure the HSSL module. It shall only be written in the Initialize Mode.

***Note**: The duration of a timeout interval may vary for an amount of one predivider clock period. Therefore the predivider should be set as low as possible, and the timeout length as many predivider periods as possible.*

CFG Offset address: 064_H

Configuration Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0												CCC	SCM	SMR	SMT
r												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		PREDIV													
r		rw													

Field	Bits	Type	Description
PREDIV	13:0	rw	**Global Predivider** Defines the down-scaled module clock to be used by all channel timeout timers. 0000_H 1 0001_H 2 0002_H 3 **others,** corresponding down-scale factor
SMT	16	rw	**Streaming Mode Transmitter** 0_B Continuous 1_B Single
SMR	17	rw	**Streaming Mode Receiver** 0_B Continuous 1_B Single
SCM	18	rw	**Streaming Channel Mode** Defines if the channel 2 is used in a streaming or command mode. 0_B Command 1_B Streaming
CCC	19	rw	**Channel Code Control** Defines the coding of the channel number in the HSSL header. 0_B Binary 1_B Special
0	15:14, 31:20	r	**Reserved** Read as 0; should be written with 0

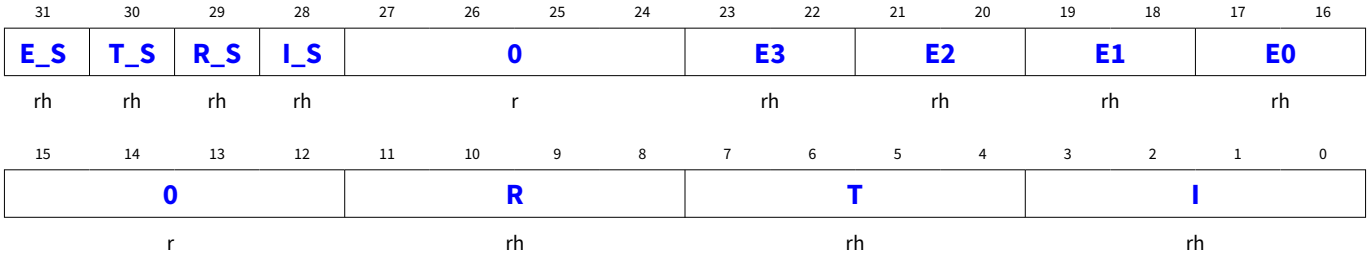
17.6.1.4 Channel Flags Registers

17.6.1.4.1 Request Flags Register

This register contains flags indicating if an appropriate action request is pending or not.

QFLAGS Offset address: 068_H

Request Flags Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
I	3:0	rh	**Request Flags for Initiated Commands** These flags are set by the corresponding channel when a WRT command is initiated. The WRT commands are initiated via the SPB bus. The S(tream) commands are initiated by the module internally, by the TXFIFO, except for the first stream frame start, which is done via the SPB bus. See MFLAGS.ISB and ISF flags. 0_H No request pending 1_H Channel 0 request pending 2_H Channel 1 request pending 4_H Channel 2 request pending 8_H Channel 3 request pending **others,** corresponding combination of requests
T	7:4	rh	**Request Flags for Commands Arrived at Target** These flags are set by the hardware according to the header information of a frame arrived at the target without a CRC error. They are used by the arbiter of the SRI/SPB master and cleared when the appropriate command is executed. 0_H No request pending 1_H Channel 0 request pending 2_H Channel 1 request pending 4_H Channel 2 request pending 8_H Channel 3 request pending **others,** corresponding combination of requests

(table continues...)

(continued)

Field	Bits	Type	Description
R	11:8	rh	**Request Flags for Response Frames at the Target** After a command has been executed by the SRI/SPB master, an appropriate flag is being set which indicates that an ACK/NACK/DATA is pending. 0_H No request pending 1_H Channel 0 request pending 2_H Channel 1 request pending 4_H Channel 2 request pending 8_H Channel 3 request pending **others,** corresponding combination of requests
E0	17:16	rh	**Expect Flags for Activated Timeout Timer 0** An appropriate two bit flag is set by the hardware when a timeout timer for a channel is started. The hardware clears the appropriate flag when any response frame arrives at the initiator. In case of an unexpected response the flag UNEXPECTED is additionally set. 00_B No request pending 01_B write request pending 10_B read request pending 11_B trigger request pending
E1	19:18	rh	**Expect Flags for Activated Timeout Timer 1**
E2	21:20	rh	**Expect Flags for Activated Timeout Timer 2**
E3	23:22	rh	**Expect Flags for Activated Timeout Timer 3**
I_S	28	rh	**I Flag for Stream Frames** See the “I” flag description above. 0_B No request pending 1_B Request pending
R_S	29	rh	**R Flag for Stream Frames** See the “R” flag description above. 0_B No request pending 1_B Request pending
T_S	30	rh	**T Flag for Stream Frames** See the “T” flag description above. 0_B No request pending 1_B Request pending
E_S	31	rh	**E Flag for Stream Frames** See the “E” flag description above. 0_B No request pending 1_B Request pending
0	15:12, 27:24	r	**Reserved** Read as 0; should be written with 0

17.6.1.4.2 Miscellaneous Flags Register

MFLAGS Offset address: $06C_H$

Miscellaneous Flags Register Kernel Reset value: $8000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INI	TEO	TEI	TSE	0		CRCE	PIE2	PIE1	SRIE	MAV	ISB	IMB	TMB	0	
rh	rh	rh	rh	r		rh	rh	rh	rh	rh	rh	rh	rh	r	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
UNEXPECTED				TIMEOUT				TTE				NACK			
rh				rh				rh				rh			

Field	Bits	Type	Description
NACK	3:0	rh	**Not Acknowledge Error - Target Error** Indicates for each channel that a target error frame has been received.
TTE	7:4	rh	**Transaction Tag Error** Indicates for each channel if a CRC correct acknowledge frame with an unexpected transaction tag number has been received.
TIMEOUT	11:8	rh	**Timeout Error** Indicates for each channel if an timeout event has occurred.
UNEXPECTED	15:12	rh	**Unexpected Type of Frame Error** Indicates for each channel if an unexpected or inappropriate response is received. For example a NACK for a Trigger frame or DATA for WRITE frame.
TMB	18	rh	**Target Memory Block** Selects the currently active memory block used by the target as a target for the streaming data, with its start address and frame counter. Switching the active block in the middle of a block transfer is not allowed. 0_B Memory block 0 1_B Memory block 1
IMB	19	rh	**Initiator Memory Block** Selects the currently active memory block used by the initiator as a source for the streaming data, with its start address and frame counter. Switching the active block in the middle of a block transfer is not allowed. 0_B Memory block 0 1_B Memory block 1

(table continues...)

(continued)

Field	Bits	Type	Description
ISB	20	rh	**Initiator Stream Block Request** Indicates if stream block request is pending. Set by the software to start a stream block transfer by using the MFLAGSSET.ISBS bit; clear by the software possible (if needed) by using the MFLAGSCL.ISBC bit; cleared by hardware at the end of the current block transfer in single mode, but not in continuous mode. 0_B No request or streaming ongoing 1_B Streaming ongoing
MAV	21	rh	**Memory Access Violation** Indicates a memory access violation. 0_B No violation 1_B Violation
SRIE	22	rh	**SRI/SPB Bus Access Error** Indicates an error on the SRI bus - transaction ID, ECC error or error acknowledge. Indicates an error on the SPB bus, error acknowledge or timeout. 0_B No error 1_B Error
PIE1	23	rh	**PHY Inconsistency Error 1(Channel Number Code Error)** Indicates if HSCT to HSSL channel number code comparator has detected an inconsistency error. 0_B No error 1_B Error
PIE2	24	rh	**PHY Inconsistency Error 2(Data Length Error)** Indicates if HSCT to HSSL data length comparator has detected an inconsistency error. 0_B No error 1_B Error
CRCE	25	rh	**CRC Error** Indicates if CRC checker has detected a CRC error. 0_B No error 1_B Error
TSE	28	rh	**Target Stream Enable** Used by the hardware to handle the single and continuous streaming. In single mode, cleared by hardware after the current block transfer ends. The module ignores afterwards the incoming steam frames. 0_B Disabled 1_B Enabled

(table continues...)

(continued)

Field	Bits	Type	Description
TEI	29	rh	**Transmit Enable Input** Indicates the state of the TEI input signal of the HSSL module, which is driven by the CTS output signal of the HSCT module. Any edge on this signal triggers an EXI interrupt. This low level signal stops the transmission of both command and response frames. Note: After kernel reset, when the HSSL module clock is enabled the TEI bit is updated with the current input value from the HSCT module.
TEO	30	rh	**Transmit Enable Output** Indicates the state of the TEO output signal of the HSSL module, which drives thee CTS input signal of the HSCT module. This bit is cleared by hardware at entering the INIT and Soft Suspend state.
INI	31	rh	**Initialize Mode** Indicates if the module is in the Initialize or Run mode. 0_B Run mode 1_B Initialize mode
0	17:16, 27:26	r	**Reserved** Read as 0; should be written with 0

17.6.1.4.3 Miscellaneous Flags Set Register

***Note**: Read access to this register returns all zero.*

MFLAGSSET Offset address: 070_H

Miscellaneous Flags Set Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	r									rh		rh		rh	

Field	Bits	Type	Description
RXFL	1:0	rh	**Stream RxFIFO Filling Level** Indicates the filling level of the FIFO with granularity of 32 bytes (one stream frame payload size). 00_B 0 01_B 1 10_B 2 11_B Reserved (not possible)

(table continues...)

(continued)

Field	Bits	Type	Description
TXFL	3:2	rh	**Stream TxFIFO Filling Level** Indicates the filling level of the FIFO with granularity of 32 bytes (one stream frame payload size). 00_B 0 01_B 1 10_B 2 11_B Reserved (not possible)
EXFL	5:4	rh	**Stream Expect FIFO Filling Level** Indicates the filling level of the FIFO with granularity of 32 bytes (one stream frame payload size). 00_B 0 01_B 1 10_B 2 11_B Reserved (not possible)
ISF	15	rh	**Initiator Stream Frame Request** Indicates if stream TXFIFO request is pending. Set and cleared by the TXFIFO. 0_B TXFIFO fill request not pending 1_B TXFIFO fill request pending
0	14:6, 31:16	r	**Reserved** Read as 0; should be written with 0

17.6.1.5 Channel Initiator Registers

This section describes the channel specific registers of the HSSL module, associated to both the initiator and the target functions. In order to support command queues, the addresses of the IWDx, ICONx, IRWAx and IRDx registers are ordered in a sequence of IWD0, ICON0, IRWA0, IRD0, IWD1, ICON1, IRWA1, IRD1, IWD2, ICON2, IRWA2, IRD2, IWD3, ICON3, IRWA3, IRD3, see chapter "DMA Operated Command Queues".

For the timeout handling description, see chapter "Command Timeout Operation".

Related information

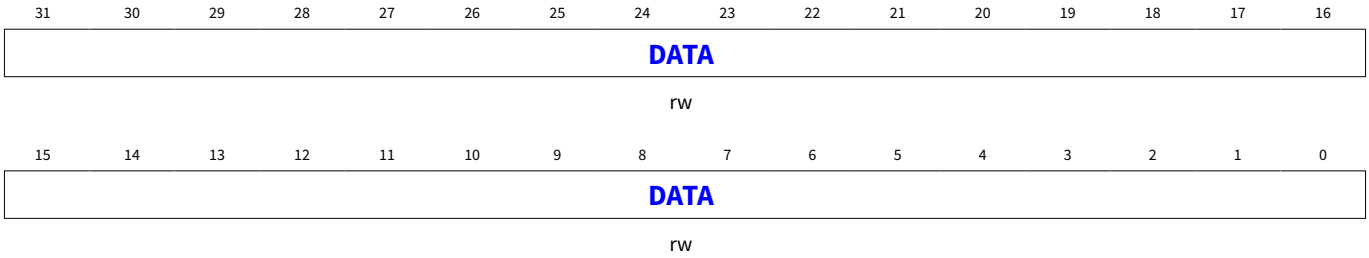
DMA operated command queues on page 2465
Command timeout operation on page 2456

17.6.1.5.1 Initiator Write Data Register x

The IWD register contains the data part of a write command.

IWDx (x=0-3) Offset address: 080_H+x*10_H

Initiator Write Data Register x Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DATA	31:0	rw	**Data Part of the Payload of a Write Frame** For 8-bit and16-bit write command frames, the whole frame payload width of 32-bit is automatically filled with copies of the lower 8-bits or 16-bits of the register.

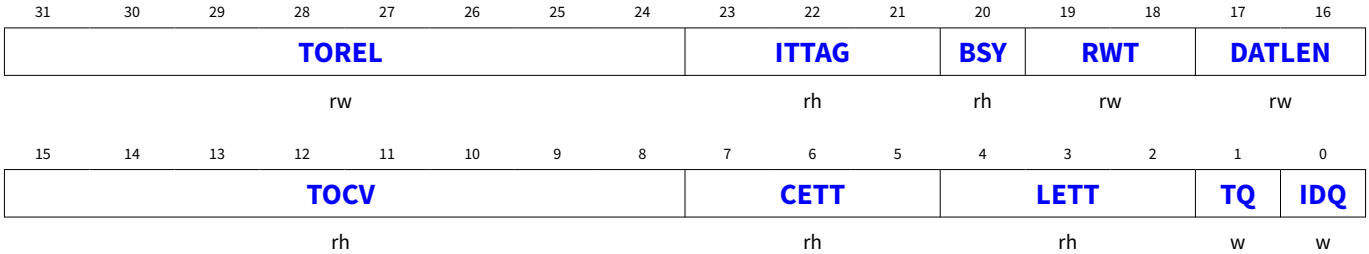
17.6.1.5.2 Initiator Control Data Register x

The ICON register contains the control and the configuration bits of a channel.

Bitfields TOREL and ITTAG are used for command frames, and also reused for streaming frames in channel 2. All other bit fields are used only for command frames.

ICONx (x=0-3) Offset address: 084_H+x*10_H

Initiator Control Data Register x Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
IDQ	0	w	**Read ID Request** This bit provides the only way to request a read ID frame. Reads always 0. Write of 1 commences a request. In case of parallel write of 1 to TQ and IDQ, the IDQ request has higher priority. 0_B No read ID request 1_B Read ID frame request
TQ	1	w	**Trigger Request** This bit provides an alternative way to request a trigger frame, without having to write to the channel address register. Reads always 0. Write of 1 commences a request. In case of parallel write of 1 to TQ and IDQ, the IDQ request has higher priority. 0_B No trigger request 1_B Trigger frame request
LETT	4:2	rh	**Last Error Transaction Tag** This bitfield indicates the latest erroneous transaction tage value.
CETT	7:5	rh	**Currently Expected Transaction Tag** This bitfield indicates the currently expected transaction tag value.
TOCV	15:8	rh	**Time Out Current Value** This bitfield indicates the timeout timer current value.
DATLEN	17:16	rw	**Data Length** Defines the length of the data in bits of the write and read command. 00_B 8-bit 01_B 16-bit 10_B 32-bit 11_B Reserved (implemented as 32-bit)
RWT	19:18	rw	**Read Write Trigger Command Type** Defines if the write to the IRWA register will trigger read, write or trigger request. 00_B No action 01_B Read Frame 10_B Write Frame 11_B Trigger Frame
BSY	20	rh	**Channel Busy** This bit indicates if the channel is busy or not.
ITTAG	23:21	rh	**Initiator Transaction Tag** This bit displays the current value of the three bit counter generating the new transaction tag value.
TOREL	31:24	rw	**Time Out Reload Value** Defines the duration of the timeout in units of prescaled clock periods. This parameter is valid both in command and stream mode of the channel 2.

17.6.1.5.3 Initiator Read Write Address Register x

The IRWA register contains the address part of a write command. Writing the IRWA register triggers a transmit request for the appropriate channel.

IRWAx (x=0-3) Offset address: 088_H+x*10_H

Initiator Read Write Address Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDRESS															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS															
rw															

Field	Bits	Type	Description
ADDRESS	31:0	rw	**Address Part of the Payload of a Write Frame** Writing to this registers triggers transmission of a Write Frame. The address must be aligned according to the data width: byte addresses for 8-bit data, half-word addresses for 16-bit data, word addresses for 32-bit data.

17.6.1.5.4 Initiator Read Data Register x

The IRD register contains the data read from the target, which has been fed back as a response to a read command.

IRDx (x=0-3) Offset address: $08C_H+x*10_H$

Initiator Read Data Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DATA															
rh															

Field	Bits	Type	Description
DATA	31:0	rh	**Data Delivered by a Read Response Frame** This bitfield indicates the data delivered by a read response frame.

17.6.1.6 Channel Target Registers

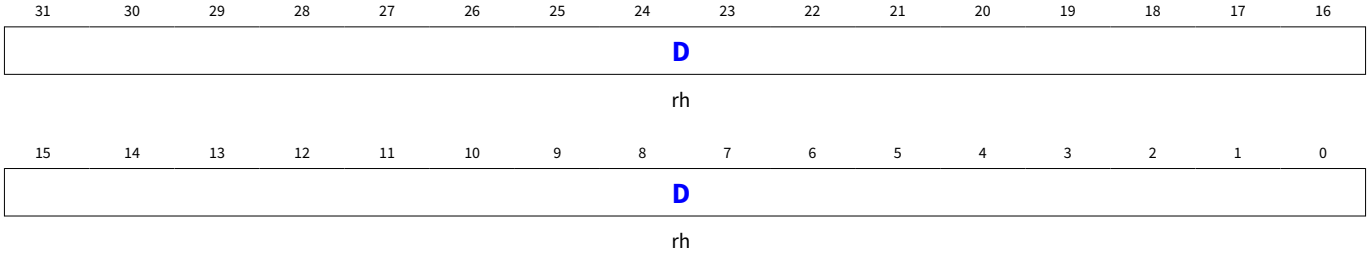
This section describes the channel specific registers of the HSSL module, associated to both the initiator and the target functions.

17.6.1.6.1 Target Current Data Register i

The TCD register contains the data part of a write command which is currently being processed by the channel on the target side, or the latest data which has been read by the SRI/SPB master in case of a read command.

TCDi (i=0-3) Offset address: $0C0_H+i*8$

Target Current Data Register i Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
D	31:0	rh	**Data Part of a WR Command Frame or RD Data of a RD Command Frame** This bitfield indicates the data part of the payload of a write command frame or read data of a read command frame.

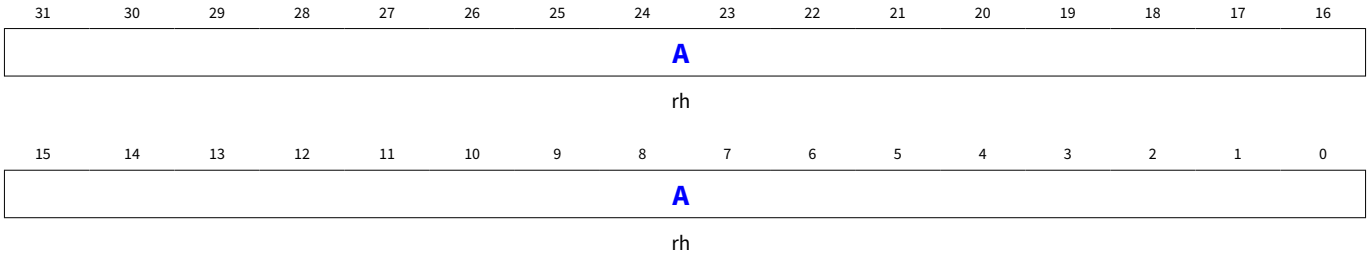
17.6.1.6.2 Target Current Address Register i

The TCA register contains the address part of a read or write command which is currently being processed by the channel on the target side.

In case of Read ID frame, the address is copied from the register TIDADD.

TCAi (i=0-3) Offset address: $0C4_H+i*8$

Target Current Address Register i Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
A	31:0	rh	**Address Part of a Write or a Read Command or ID Frame - of payload** This bitfield indicates the address part of the payload of a write command frame or a read command frame or ID frame.

17.6.1.6.3 Target Status Register

The TSTAT register contains the status bits of the common target functionality.

TSTAT Offset address: $0E0_H$

Target Status Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LASTTT1			LASTCC1					LASTTT0			LASTCC0				
rh			rh					rh			rh				

Field	Bits	Type	Description
LASTCCx (x=0-3)	8*x+4:8*x	rh	**Last Command Code** Indicates the latest command code from the header for the corresponding channel.
LASTTTx (x=0-3)	8*x+7:8*x+5	rh	**Last Transaction Tag** Indicates the transaction tag of the latest command or stream frame for the corresponding channel.

17.6.1.6.4 Target ID Address Register

The TIDADD register contains the address from which the target JTAG ID is fetched. The application software should write this register after any reset with this address of CBS_JTAGID register or some other customer defined address value.

TIDADD Offset address: $0E4_H$

Target ID Address Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CURCOUNT	31:16	rh	**Current Count Number** Displays the current count number, which is generated by down-counting from the RELCOUNT value. Bit field length depends on application requirements.

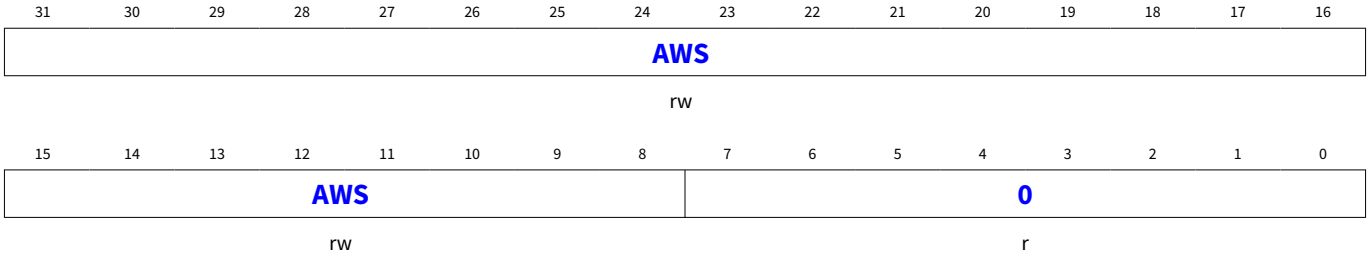
17.6.1.9 Access Protection Registers

This sub section describes the registers defining the access windows where the HSSL accesses are allowed. These registers are writable only in supervisor mode, which makes them not writable by the HSSL itself.

17.6.1.9.1 Access Window Start Register i

AWSTARTi (i=0-3) Offset address: 110_H+i*8

Access Window Start Register i Kernel Reset value: $0000\ 0000_H$

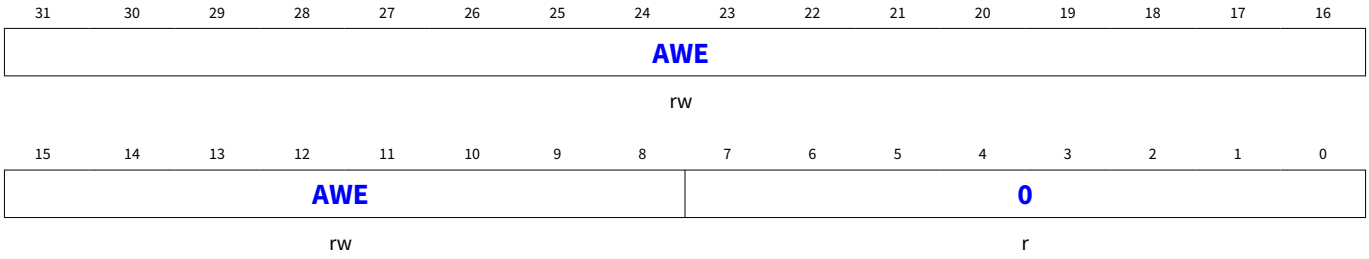


Field	Bits	Type	Description
AWS	31:8	rw	**Access Window Start Address** This bit field defines the upper 24 bits of the start address of the corresponding access window. This results in a granularity of 256 bytes for the start address.
0	7:0	r	**Reserved** Read as 0; should be written with 0

17.6.1.9.2 Access Window End Register i

AWENDi (i=0-3) Offset address: 114_H+i*8

Access Window End Register i Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
AWE	31:8	rw	**Access Window End Address** This bit field defines the upper 24 bits of the end address of the corresponding access window. This results in a granularity of 256 bytes for the end address.
0	7:0	r	**Reserved** Read as 0; should be written with 0

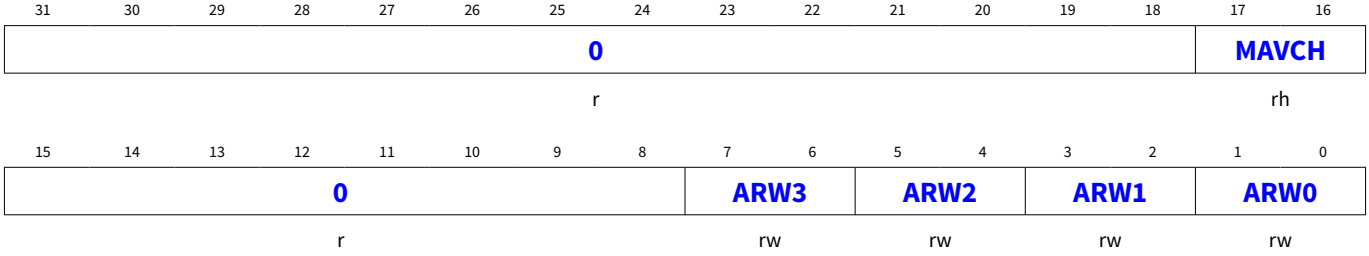
17.6.1.9.3 Access Rules Register

AR

Access Rules Register

Offset address: 130_H

Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ARWx (x=0-3)	2*x+1:2*x	rw	**Access Rule for Window x** 00_B No access (window disabled) 01_B Read access allowed 10_B Write access allowed 11_B Read and write access allowed
MAVCH	17:16	rh	**Memory Access Violation Channel** This bit field shows the number of the latest channel that attempted a not allowed access. 00_B Channel 0 01_B Channel 1 10_B Channel 2 11_B Channel 3
0	15:8, 31:18	r	**Reserved** Read as 0; should be written with 0

17.6.1.10 Security and Multi Slave Registers

This sub section describes two registers: one handling the security aspects regarding the HSSL module operation and one configuring the multi slave mode of operation.

17.6.1.10.1 Security Control Register

SEC Offset address: $0E8_H$

Security Control Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														LAW	LCK
r														rw	rw

Field	Bits	Type	Description
LCK	0	rw	**Lock the HSSL Module** Setting this bit field prevents the MFLAGS.INI bit to be cleared, that is prevents to leave the INIT state and go to RUN mode. If INIT bit has already been cleared, it is possible to set it, but not to clear it afterwards. 0_B Unlocked 1_B Locked
LAW	1	rw	**Lock the Address Windows Registers** This bit field shows if the Address Window Registers AWSTARTx, AWENDx, AR and TIDADD are locked or not. If locked, the properties of the address windows cannot be changed any more. 0_B Unlocked 1_B Locked
0	31:2	r	**Reserved** Read as 0; should be written with 0

17.6.1.10.2 Multi Slave Control Register

MSCR Offset address: $0EC_H$

Multi Slave Control Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															ITXSTOP
r															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0													SLAVETAG		EN
r													rw		rw

Field	Bits	Type	Description
EN	0	rw	**Multi Slave Mode Enable** This bit enables the multi slave mode of operation of the HSSL module. 0_B Disabled 1_B Enabled
SLAVETAG	2:1	rw	**Slave Tag** The master uses this bit field to define the current slave it sends to and receives from. The slave uses this bit field to pass through only the relevant incoming frames and to tag its own transmit frames. This tag is injected in the header by the Slave Tag Translator block and used for filtering in Slave Tag Filter Block. 00_B Reserved 01_B Slave 1 10_B Slave 2 11_B Slave 3
ITXSTOP	16	rw	**Initiator Transmission Stop** This bit is intended to be set or cleared by the master in a multi-slave operation by using 16-bit write command frames. MSCR.ITXSTOP functionality can be activated only if MSCR.EN = 1, otherwise it is ignored. Setting this bit stops the arbitration and transmission of new command and stream frames of the initiator but does not stop the ongoing frames. 0_B Initiator transmission active 1_B Initiator transmission stopped
0	15:3, 31:17	r	**Reserved** Read as 0; should be written with 0

17.6.1.11 UBS Registers

17.6.1.11.1 Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 000_H

Clock Control Register Application Reset value: $0000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

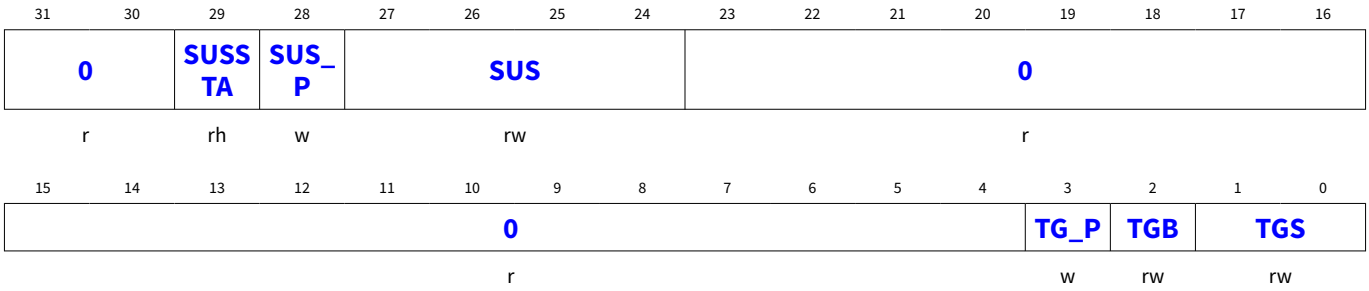
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0

17.6.1.11.2 OCDS Control and Status Register

The OCDS Control and Status register OCS controls the debug and trace behavior by selecting suspend modes and OTGB trigger sets. When OCDS is disabled the suspend control is ineffective.

OCS Offset address: 004_H

OCDS Control and Status Register Debug Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TGS	1:0	rw	**Trigger Set for OTGB0/1** 00_B No Trigger Set output 01_B TS16_STR, Streaming Channel Trigger Set 10_B TS16_ERR, Errors Trigger Set 11_B Reserved
TGB	2	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1
TG_P	3	w	**TGS, TGB Write Protection** TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) Not listed combinations are reserved. 0_H Will not suspend 1_H Hard suspend: Clocks will be disabled immediately 2_H reserved 3_H Soft suspend mode
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:4, 31:30	r	**Reserved** Read as 0; should be written with 0

Table 797 Access mode restrictions of OCS sorted by descending priority

Mode name	Access mode		Description
write 1 to .**TG_P**	rw	TGB, TGS	Set TG_P during write access
write 1 to .**SUS_P**	rw	SUS	Set SUS_P during write access
(default)	r	SUS, TGB, TGS

KRST	0	rh	**Kernel Reset Status** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed.
GRSTx (x=0-3)	x+8	rh	**Status for Global Module Reset Group x** 0_B Reset was not triggered by global reset group x 1_B Reset was triggered by global reset group x
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0

17.6.1.11.6 PROT Register Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 020_H

PROT Register Endinit Application Reset value: $0000\ 0000_H$

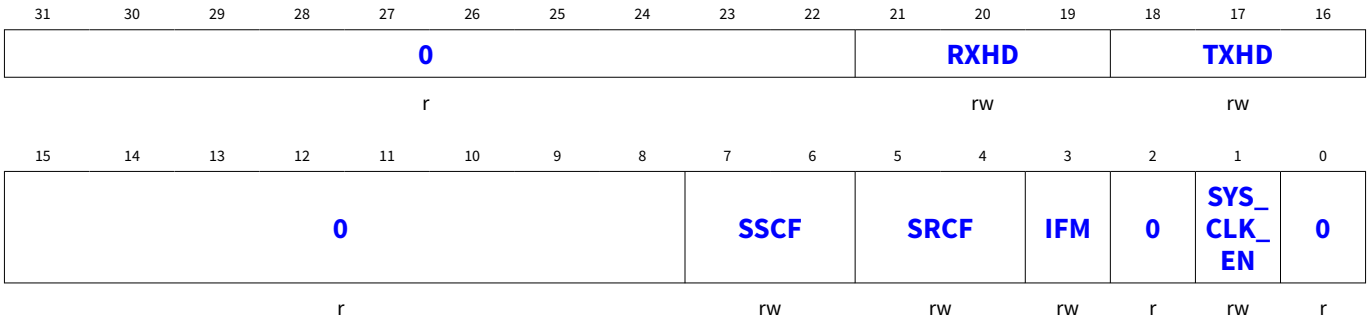
17.6.2.3 HSCT Kernel Register Definitions

17.6.2.3.1 Initialization Register

INIT Offset address: 00060_H

Initialization Register Kernel Reset value: $0000\ 0000_H$

17 High Speed Serial Link (HSSL)



Field	Bits	Type	Description
SYS_CLK_EN	1	rw	**Enable HSCT SysClk in Master interface** SysClk enable activates the SysClk. This feature is only available in the Master interface. In Slave interface mode the register setting does not have an effect. 0_B Disable (default) 1_B Enabled
IFM	3	rw	**Select Interface Mode** Select the Interface Mode (Master IF or Slave IF). 0_B Master IF 1_B Slave IF
SRCF	5:4	rw	**Select Reference Clock Frequency Divider** Defines physical layer reference frequency (PHY_CLK) and respective input frequency divider. The configuration is valid for Low speed and Medium Speed mode. 00_B REFCLK 10MHz, LS 5MBaud, MS n.a. 01_B REFCLK 20MHz, LS 5MBaud, MS=20MBaud 01_B REFCLK 25MHz, LS 6.25MBaud, MS=n.a. 10_B REFCLK 40MHz, LS 5MBaud, MS=20MBaud 10_B REFCLK 50MHz, LS 6.25MBaud, MS=n.a. 11_B Reserved; For future use
SSCF	7:6	rw	**Select SysClk Frequency Divider** For master interface defines SysClk pad output frequency. The allowed SysClk frequency is 10MHz or 20MHz or 25MHz. 00_B SYSCLK DIV 1/1 01_B SYSCLK DIV 1/2 10_B SYSCLK DIV 1/4 11_B For future use

(table continues...)

(continued)

Field	Bits	Type	Description
TXHD	18:16	rw	**Transmit High Speed Divider.** The Transmit High Speed data rate can be reduced by dividing factors. The Transmit High Speed data rate is separated from the Receive High Speed data rate. 000_B Divider 1/1 001_B Divider 1/2 010_B Divider 1/4 011_B Divider 1/8 100_B Divider 1/16 101_B For future use. … 111_B For future use.
RXHD	21:19	rw	**Receive High Speed Divider.** The Receive High Speed data rate can be reduced by dividing factors. The Receive High Speed data rate is separated from the Transmit High Speed data rate. ***Note**: For future use configuration leads to no output clock delivered to the correlator.* 000_B Divider 1/1 001_B Divider 1/2 010_B Divider 1/4 011_B Divider 1/8 100_B Divider 1/16 101_B For future use. … 111_B For future use.
0	0, 2, 15:8, 31:22	r	**Reserved** Read as 0; should be written with 0

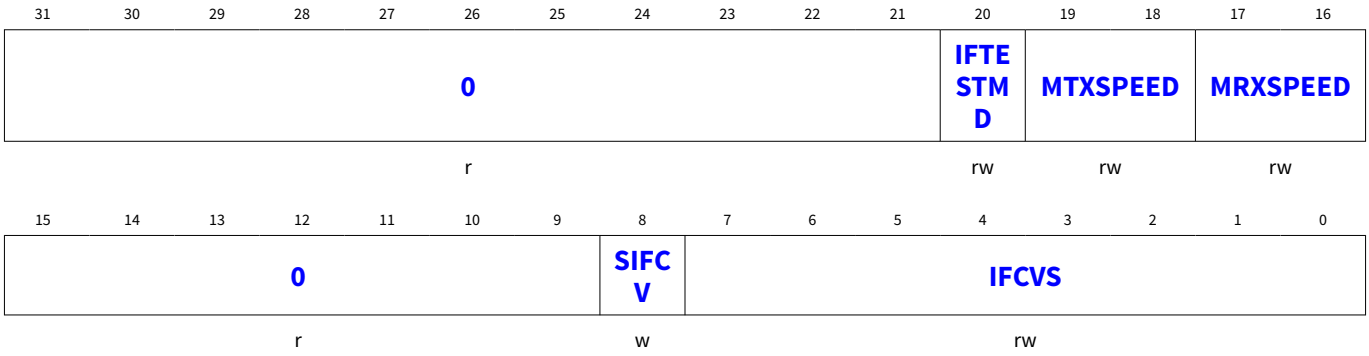
17.6.2.3.2 Interface Control Register

This register allows to configure the transfer Speed of the Master Interface and is also used to send the command frame to the Slave.

***Note**: The Master interface link speed configuration immediately takes place. Therefore the Master interface speed transition must not be changed with a Slave interface command send activity.*

IFCTRL Offset address: 00064_H

Interface Control Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
IFCVS	7:0	rw	**Master Mode - Trigger for Interface Control Value to be send to Slave interface** See the table "Interface Control Payload Values". Master IF Mode: The value is taken as control frame value send as payload to the Slave IF. Slave IF Mode: The value is a new configuration of the Slave IF (not recommended flow!!!).
SIFCV	8	w	**Master Mode - Slave IF control frame trigger** Changing the interface configuration, software must guarantee not having transfers active on the interface. This register bit always reads back zero. 0_B The IFCVS field configured value has no effect (default). 1_B Writing a one to the register bit sends the control frame configured in register field IFCVS, if the interface is configured as Master. In Slave Mode the trigger has an effect and takes the IFCTRL.IFCVS value. In Slave mode this is not the recommended control flow. A frame based configuration shall be used instead. A control frame has higher priority then a register control. At a simultaneous occurrence of both configuration source the register configuration in Slave mode is lost.
MRXSPEED	17:16	rw	**Master Mode RX speed** ***Note**: Register setting only valid in interface Master mode.* 00_B Low Speed 01_B Medium Speed 10_B High Speed 11_B For future use
MTXSPEED	19:18	rw	**Master Mode TX speed** ***Note**: Register setting only valid in interface Master mode.* 00_B Low Speed 01_B for future use 10_B High Speed 11_B For future use

(table continues...)

(continued)

Field	Bits	Type	Description
IFTESTMD	20	rw	**Interface TX Test Mode** 0_B Test Mode disabled 1_B Test Mode enabled - send out 101010101… test pattern continuously.
0	15:9, 31:21	r	**Reserved** Read as 0; should be written with 0

17.6.2.3.3 Clear To Send Control Register

The Clear To Send function is not available in multi Slave scenario. This function is an automatic HW controlled function and in multi Slave mode not easy to control. Therefore it is removed in this mode.

CTSCTRL Offset address: $0006C_H$

Clear To Send Control Register Kernel Reset value: $0000\ 0001_H$

r													rw	rw	rw

Field	Bits	Type	Description
TX_DIS	0	rw	**Disable HSCT Transmit path in Master interface** Disable the transmit path of the HSCT interface. If this bit is set to 1 - no transfer can be initiated and the LVDS driver is disabled. 0_B Enable 1_B Disable
RX_DIS	1	rw	**Disable HSCT Receive path in Master interface** Disable the receive line path of the HSCT interface. If this bit is set to 1 - no transfer from the other side can be received and the Master RX path is in a low power state. This feature is only available in the Master interface. Slave interface RX path can not be disabled and a write to the register has no effect. 0_B Enable 1_B Disable
RX_HEPD	2	rw	**Disable RX Header Error Discard Payload data.** Instead of discarding the Payload data at a header error the payload data is passed to the higher layer (HSSL). Only channel data to HSSL is affected. This function is available in Master and in Slave mode. 0_B Header error received data is discarded 1_B Header error received data is passed to the higher hardware layer.
0	31:3	r	**Reserved** Read as 0; should be written with 0

17.6.2.3.5 Status Register

STAT Offset address: 00074_H

Status Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LIFCCMDR								0				TX_CHANNEL_TYPE			
rh								r				rh

0	TX_PSIZE			0			TX_SLEEP	RX_SLEEP	RX_CHANNEL				RX_PSIZE		
r	rh			r			rh	rh	rh				rh		

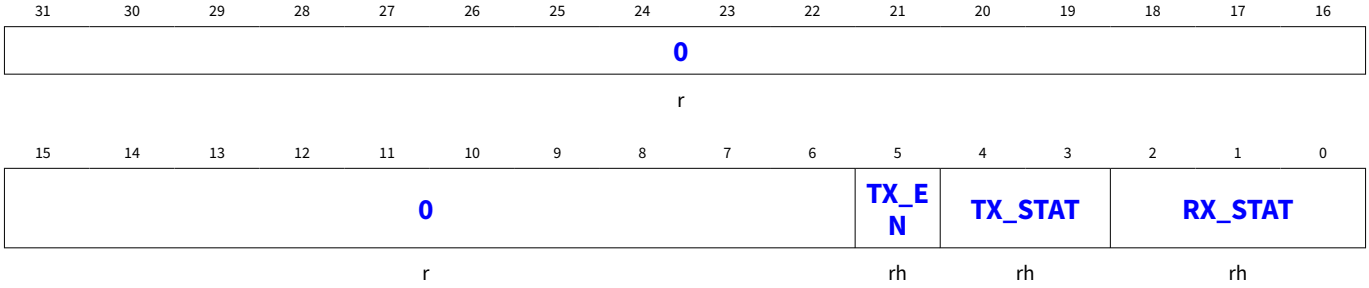
Field	Bits	Type	Description
RX_PSIZE	2:0	rh	**RX (Receiving) Payload Size** Contains the payload size of the last received frame.
RX_CHANNEL	6:3	rh	**RX (Receiving) Logical Channel Type** Contains the logical channel type of the last received frame. See Table "Logical Channel Type Coding".
RX_SLEEP	7	rh	**RX (Receiving) Sleep Mode Status** 0_B HSCT is in receive direction active 1_B HSCT is in receive direction in sleep mode
TX_SLEEP	8	rh	**TX (Transmission) Sleep Mode Status** 0_B HSCT is in transmit direction active 1_B HSCT is in transmit direction in sleep mode
TX_PSIZE	14:12	rh	**Transmission Payload Size** Coding of the logical channel type is according to the Table: Payload Size Coding. This value was used in the logical channel type field in the header for the actual transfer in transmit direction.
TX_CHANNEL_TYPE	19:16	rh	**Transmission Logical Channel Type** Coding of the logical channel type is according to the Table: Logical Channel Type Coding. This value was used in the logical channel type field in the header for the actual transfer in transmit direction.
LIFCCMDR	31:24	rh	**Last Interface Control Command Received** The bit value reflects the last control command received. The bit is active in Slave interface mode only. In Master mode it reflects logic 0 always.
0	11:9, 15, 23:20	r	**Reserved** Read as 0; should be written with 0

17.6.2.3.6 Interface Status Register

Clock test mode and Loopback mode are only available in single Slave scenario. In multi Slave scenario are not available.

IFSTAT Offset address: 00078_H

Interface Status Register Kernel Reset value: $0000\ 0000_H$

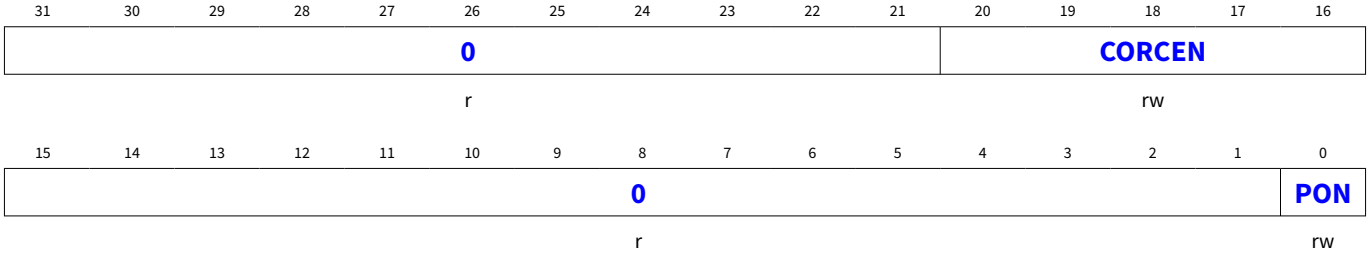


Field	Bits	Type	Description
RX_STAT	2:0	rh	**HSCT Slave interface Status for RX link** ***Note**: Slave interface transmitter only* 000_B Interface is disabled in RX link direction. 001_B Interface runs at low speed on RX link. 010_B Interface runs at medium speed on RX link. 011_B Interface runs at high speed on RX link direction. 100_B Reserved 101_B Clock test mode and low speed on RX ink 110_B Clock test mode and medium speed on RX link 111_B Clock test mode and high speed on RX link.
TX_STAT	4:3	rh	**HSCT Slave interface Status for TX link** ***Note**: Slave interface receiver only* 00_B Interface runs at low speed on TX link. 01_B Interface runs at high speed on TX link. 10_B Loopback mode low speed. 11_B Loopback mode high speed.
TX_EN	5	rh	**HSCT LVDS Slave interface TX enable** ***Note**: Slave interface only* 0_B LVDS TX disabled. 1_B LVDS TX enabled.
0	31:6	r	**Reserved** Read as 0; should be written with 0

17.6.2.3.7 Configuration Physical Layer Register

CONFIGPHY Offset address: $0007C_H$

Configuration Physical Layer Register Kernel Reset value: $001F\ 0000_H$

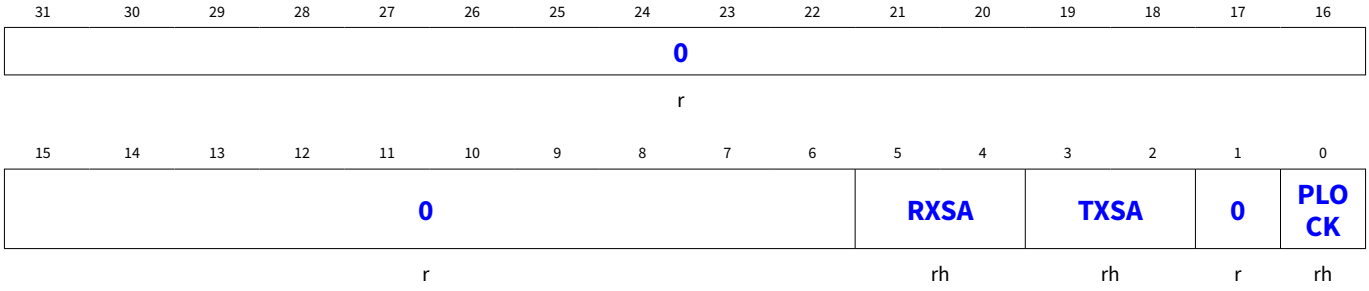


Field	Bits	Type	Description
PON	0	rw	**Physical Layer Power On.** This bit if set enables the physical layer.
CORCEN	20:16	rw	**Correlator phase enable - allows to en/dis each of the 5 Phase o/p separately.** This bit allows to enable/disable each of the 5 Phase outputs separately.
0	15:1, 31:21	r	**Reserved** Read as 0; should be written with 0

17.6.2.3.8 STATPHY

STATPHY Offset address: 00080_H

STATPHY Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PLOCK	0	rh	**PLL locked** 0_B PLL out of lock (default) 1_B PLL locked
TXSA	3:2	rh	**Transmitter speed** 00_B Transmitter in Low speed 01_B Transmitter in Medium speed 10_B Transmitter in High speed 11_B reserved

(table continues...)

(continued)

Field	Bits	Type	Description
RXSA	5:4	rh	**Receiver speed** 00_B Receiver in Low speed 01_B Receiver in Medium speed 10_B Receiver in High speed 11_B reserved
0	1, 31:6	r	**Reserved** Read as 0; should be written with 0

17.6.2.3.9 Interrupt register

Interrupt status register. Read only and updated by HW. The bit's remain active until cleared. The clear pulse is coming from the IRQCLR register. Only an interrupt source not being already active in the interrupt status register generates an interrupt pulse to the SoC interrupt controller.

IRQ Offset address: 00084_H

Interrupt register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
HER	1	rh	**Header error detected** Not supported size: • Received command at Slave interface 8-bit size only - other command sizes generate an error. • Received command ping answer at Master interface 32-bit size only - other command sizes generate an error • Unsolicited data 32-bit only • Logical data channel size 8-bit Not supported logical channel type: • 0b1xxx • 0010 (Slave interface control and Slave interface read) 0_B Header OK 1_B Header issue detected.
PYER	2	rh	**Payload error detected** Payload does not fit the header size 0_B Payload size OK 1_B Received payload size wrong

(table continues...)

(continued)

Field	Bits	Type	Description
CER	3	rh	**HSCT command error** Control command not valid or control payload size bigger than 8-bit. Single Slave specific commands received in Multi Slave Mode do not trigger CER error, but only MSCE error. 0_B No command error 1_B HSCT command error
IFCFS	4	rh	**HSCT interface control frame send** The scheduled interface control command is send. 0_B No interface control command send 1_B Interface control command send.
SMER	5	rh	**Speed Mode Switch Error (Master Mode only)** Speed mode change did not work. Received PING payload not valid. 0_B Interfaces runs at defined speed 1_B Ping payload error
USMSF	6	rh	**Unsolicited message frame send finished** Interrupt is indicated after the unsolicited message send is finished. 0_B No unsolicited message send. 1_B Unsolicited message send finished.
PLER	7	rh	**PLL lost lock error** After the PLL locked, the PLL may loose lock, which is reflected by the error 0_B PLL lock 1_B PLL lock loss
USM	8	rh	**Unsolicited Message Received** Unsolicited message received indication. Unsolicited message indicates a system event to the other interface side. 0_B no unsolicited message available 1_B unsolicited message available
PAR	9	rh	**PING Answer Received** The received message was identified as PING. 0_B No PING message available 1_B PING message received
TXTE	10	rh	**TX transfer error occurred on a disabled TX channel.** A disabled TX triggers an error interrupt, if: • TX disabled on a pending or active data transfer. • TX CTS configuration change on a active CTS frame. 0_B No error situation occurred 1_B Error situation occurred

(table continues...)

(continued)

Field	Bits	Type	Description
SFO	11	rh	**Synchronization FIFO overflow (in RX direction)** Physical layer to Controller data synchronization FIFO in RX transfer direction hit an overflow situation. ***Note**: This interrupt is an indication about a to slow SRI clock compared to Physical layer clock, which results in a overflow situation.* 0_B RX synchronization is running well. 1_B RX FIFO overflow
SFU	12	rh	**Synchronization FIFO underflow (in TX direction)** Controller to Physical layer data synchronization FIFO in TX transfer direction hit an underflow situation. ***Note**: This interrupt is an indication about a to slow SRI clock compared to Physical layer clock, which results in a underflow situation.* 0_B TX synchronization is running well. 1_B TX FIFO underflow
MSCE	13	rh	**Multi Slave scenario Command Error** This interrupt indicates a control command which is not allowed in multi Slave scenario. In Master and Slave mode a not allowed command results to an error. 0_B No multi Slave scenario command error. 1_B Multi Slave scenario command error (not allowed command used)
0	0, 31:14	r	**Reserved** Read as 0; should be written with 0

17.6.2.3.10 Interrupt Enable Register

Interrupt enable register. An enabled register generates a pulsed interrupt. On a disabled interrupt the interrupt pulse does not come through on the interrupt line.

IRQEN Offset address: 00088_H

Interrupt Enable Register Kernel Reset value: $0000\ 0000_H$

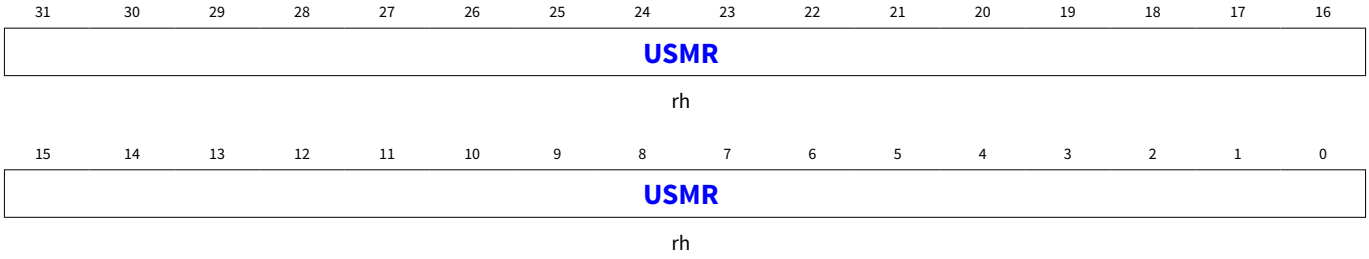
17.6.2.3.12 Unsolicited Status Message Received

The Unsolicited Status message register is available to capture unsolicited messages received with the logical channel command encoding in the header of the frame (Logical Channel Type Hex 1). This function is not available in multi Slave scenario.

USMR Offset address: 00090_H

Unsolicited Status Message Received Kernel Reset value: $0000\ 0000_H$



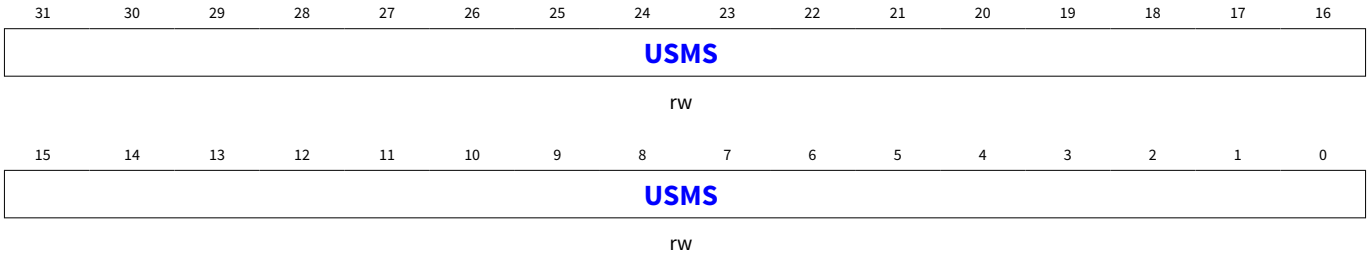
Field	Bits	Type	Description
USMR	31:0	rh	**Unsolicited status message received** The register contains the last received unsolicited status message.

17.6.2.3.13 Unsolicited Status Message Send

A write to the register activates the interface to send out an unsolicited status message to the other interface side. The Logical Channel Type reflected in the header is Hex 1 and the Payload is 32-bit always. An unsolicited frame has a higher priority then a Frame based on a data channel. In between frames the USMS gets higher priority then the data transfer requested by the HSSL. This function is not available in multi Slave scenario.

USMS Offset address: 00094_H

Unsolicited Status Message Send Kernel Reset value: $0000\ 0000_H$



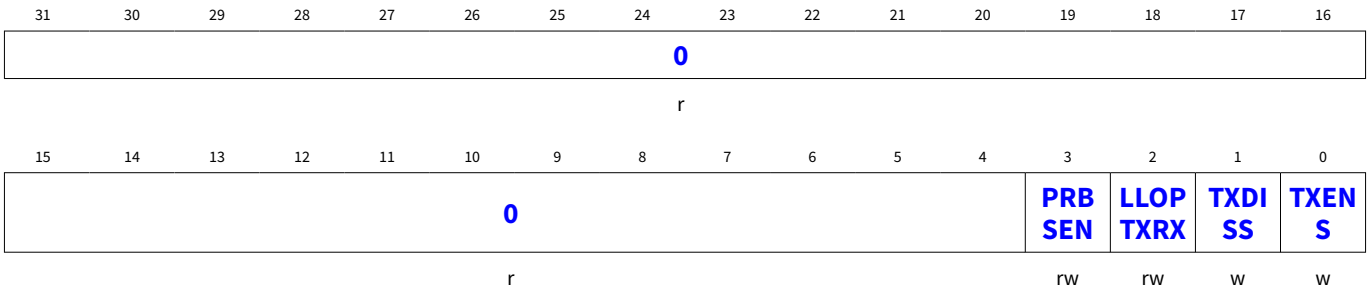
Field	Bits	Type	Description
USMS	31:0	rw	**Unsolicited status message send** Writing to the register triggers an unsolicited status message to be send to the other interface side.

17.6.2.3.14 Test Control Register

***Note**: The TESTCTRL.LLOPTXRX bit is not working with IFCTRL.IFTESTMD. Data is not transported to HSCT controller part (link layer).*

TESTCTRL Offset address: 00098_H

Test Control Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TXENS	0	w	**Enable Slave TX path (Slave interface mode only)** ***Note**: This function should be only used during interface testing the mode and SW development. In functional mode the Slave interface should only be controlled via transfer commands received from Master interface. (This trigger register reads back 0 always.) If TXENS and TXDISS are written one, TXDISS has higher priority. The status is visible in IFSTAT.TX_EN.* 0_B Writing logic 0 has no effect 1_B Triggers the Slave interface TX enable.
TXDISS	1	w	**Disable Slave TX path (Slave Interface mode only)** ***Note**: This function should be only used during interface testing mode and SW development. In functional mode the Slave interface should only be controlled via transfer commands received from Master interface. (This trigger register reads back 0 always.) If TXENS and TXDISS are written one, TXDISS has higher priority. The status is visible in IFSTAT.TX_EN.* 0_B Writing logic 0 has no effect 1_B Triggers the Slave interface TX disable.
LLOPTXRX	2	rw	**LVDS loop back TX to RX enable** Transmit data at LVDS is directly looped back to the LVDS RX. Data transfer speed is defined by the TX speed configuration. (The data path in the SoC is using the complete Transmit path through all functional layers and is looped back at LVDS from TX to RX. Also at RX data path all SoC data layers are active.) ***Note**: Requires same speed configuration for RX- and TX-link before enabled.* 0_B Disabled LVDS TX to RX data Loop back test mode 1_B Enabled TX to RX data loop back test mode.
PRBSEN	3	rw	**PRBS Pattern enable** Enable of the PRBSEN bit allows a continuos PRBS stream with the configured transfer speed Baud rate. This feature is available to measure ISI during the time other SoC functions are running in an applicative mode. This feature is for measurement purpose only. 0_B Disabled PRBS pattern generation on TX 1_B Enabled PRBS pattern generation on TX.
0	31:4	r	**Reserved** Read as 0; should be written with 0

17.6.2.4 UBS Registers

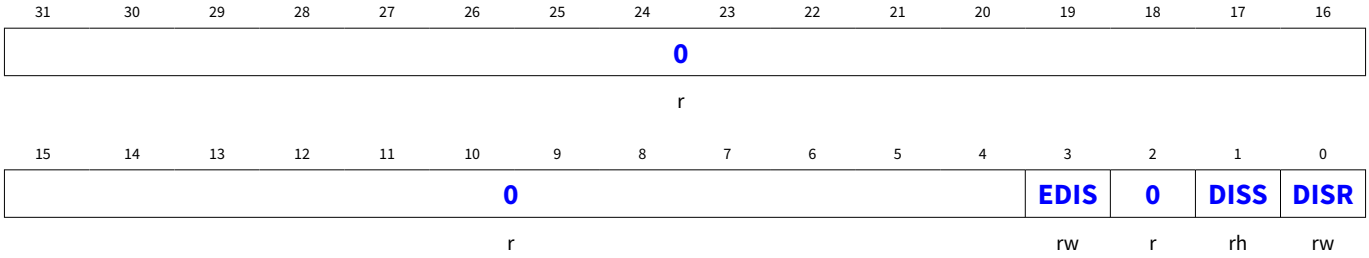
17.6.2.4.1 Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 00000_H

Clock Control Register Application Reset value: $0000\ 0003_H$



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0

17.6.2.4.2 OCDS Control and Status Register

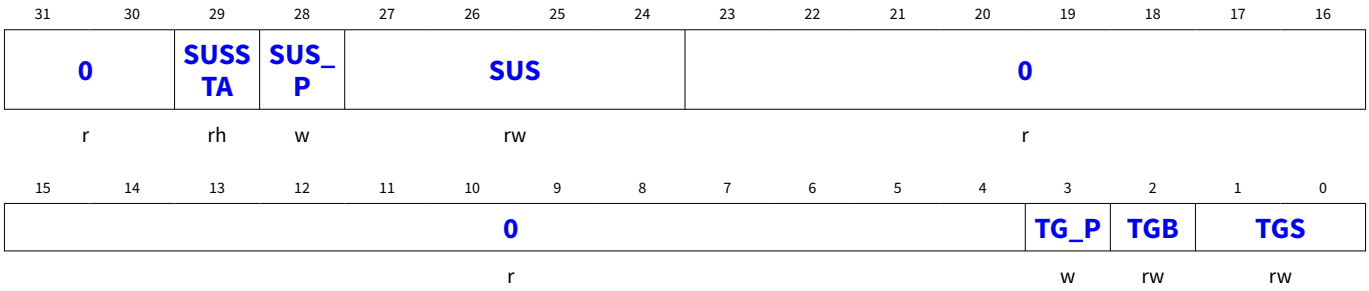
The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCDS Control and Status register OCS controls the debug and trace behavior by selecting suspend modes and OTGB trigger sets. When OCDS is disabled the suspend control is ineffective.

OCS Offset address: 00004_H

OCDS Control and Status Register Debug Reset value: $0000\ 0000_H$

17 High Speed Serial Link (HSSL)



Field	Bits	Type	Description
TGS	1:0	rw	**Trigger Set for OTGB0/1** 00_B No Trigger Set output 01_B TS16_HSCT **others,** reserved (no Trigger Set selected)
TGB	2	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1
TG_P	3	w	**TGS, TGB Write Protection** TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) Not listed combinations are reserved. ***Note**: After a Hard suspend the HSCT and higher layer protocol module must be reset. A a new initialization sequence is required afterwards* 0_H Will not suspend 1_H Hard suspend: Clocks will be disabled immediately **others,** reserved
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:4, 31:30	r	**Reserved** Read as 0; should be written with 0

Table 802 Access mode restrictions of OCS sorted by descending priority

Mode name	Access mode		Description
write 1 to .**TG_P**	rw	TGB, TGS	Set TG_P during write access
write 1 to .**SUS_P**	rw	SUS	Set SUS_P during write access
(default)	r	SUS, TGB, TGS	

17.6.2.4.3 Reset Control Register A

r				rh	rh	rh	rh	r							rh

Field	Bits	Type	Description
KRST	0	rh	**Kernel Reset Status** Indicates an executed kernel reset. RSTSTAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTLB.
GRSTx (x=0-3)	x+8	rh	**Status for Global Module Reset Group x** 0_B Reset was not triggered by global reset group x 1_B Reset was triggered by global reset group x
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0

17.6.2.4.6 Register Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 00020_H

Register Endinit Application Reset value: $0000\ 0000_H$

write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

17.6.2.4.7 PROT Register Safe Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 00024_H

PROT Register Safe Endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	rw	rw						rw	rw			rw	rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												**SWEN**	**STATE**		
r												w	rwh		

Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 804 Access mode restrictions of PROTSE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

17.6.2.4.8 Module Identification Register

0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

17.7 Debug information

HSSL module debug information on suspend can be found in section "Modes of Operation". HSSL trigger set debug information is available in section "OCDS Trigger Sets". HSCT module suspend mode information can be found in section "Suspend and power-off behavior".

The HSCT has one OCDS Trigger set available which gives a maximum of 16 triggers. The next table describes the available triggers.

Table 805 TS16_HSCT OCDS trigger set

Bits	Name	Description
0	HRXRQ	HSSL Interface RX transfer direction request
1	HRXCTS	HSSL Interface RX transfer direction CTS
2	HTXCTS	HSSL Interface TX transfer direction CTS
3	HTXRQ	HSSL Interface TX transfer direction request
4	TXF	First Byte transfer of transfer frame in TX transfer direction at controller to physical layer interface
5	TXL	Last Byte transfer of transfer frame in TX transfer direction at controller to physical layer interface
6	TXW	Transmit direction wake-up at controller to physical layer interface
7	TXS	Transmit direction sleep indication at controller to physical layer interface
8	RXFS	Receive direction frame start at physical layer to controller interface
9	DFSMI	Deframer state machine not in idle
10	IFCT	Slave interface frame command trigger
[15:11]		Reserved (value is 0)

17.10 TC4Dx HSSL information

17.10.1 TC4Dx HSSL configuration

In TC4D there are two instances of HSSL sub system being implemented.

17.10.2 TC4Dx HSSL features

There are no deviations from the generic specification.

17.10.3 TC4Dx HSSL functional description

In TC4Dx, the HSSL module is connected to the COMPB bus with a slave and a master interface. The HSSL module uses the SRI master or the COMPB master depending on the accessed address. The COMPB address space (F400 0000_H - F5FF $FFFF_H$) is used as COMPB master address window in TC4Dx.

***Note**: In the HSSL generic content, the description for SPB also applies to COMPB, except where a COMPB difference is explicitly mentioned.*

17.10.4 TC4Dx HSSL registers

There are no deviations from the generic specification.

17.10.4.2 Register overview - access mode glossary

Table 807 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register HSSL0_PROTE or HSSL1_PROTE .
SE	Access protection using PROT register HSSL0_PROTSE or HSSL1_PROTSE .
APU-P	Protection group consisting of registers HSSL0_ACCEN_WRA , HSSL0_ACCEN_WRB , HSSL0_ACCEN_RDA , HSSL0_ACCEN_RDB , HSSL0_ACCEN_VM , HSSL0_ACCEN_PRS or HSSL1_ACCEN_WRA , HSSL1_ACCEN_WRB , HSSL1_ACCEN_RDA , HSSL1_ACCEN_RDB , HSSL1_ACCEN_VM , HSSL1_ACCEN_PRS .
P	Access protection using *APU-P* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
SECURE_MASTER	Description can be found in global access mode definition.

PORTS_HSSL_SYSCLK_IN	In	System clock input when HSCT is slave

17.10.6 TC4Dx HSSL revision history

Initial release of the chapter.

18 eXpanded Serial Peripheral Interface (xSPI)

The xSPI functional block is a controller interface to enable communication with SPI slave devices compliant to the JEDEC JESD251 standard.

This master interface provides a low pin count connection to off-chip single, dual, quad, or octal SPI devices in SDR and DDR mode. The partner devices include SEMPER™ flash from Infineon (formerly Cypress), or Xccela™ from Micron and HyperBus devices such as HyperFlash (NOR flash) and HyperRAM to name a few.

18.1 Feature list

- Single, Dual, Quad, or Octal SPI and Hyperbus support over port 16
- JESD251 protocol support for Dual Data Rate (DDR) transfers with read data strobe up to 200 MHz over port 16
- Support of Single Data Rate (SDR) transfers up to 133 MHz over port 16
- Support of Quad SPI interface in SDR mode up to 25 MHz for 3 V slave devices with GPIO pads
- Option to connect two slaves in parallel using chip select
- Execute in place (XIP) support
- Internal direct memory access (DMA) support for data transfer to or from an internal memory to an external slave device
- Dynamic control of the serial bit rate
- Interrupt and alarm generation from xSPI
- Automotive safety features for register, memory, data path, and finite state machine (FSM) protection against hardware faults

18.2 Functional overview

This following figure provides a simplified system overview in the form of a block diagram.

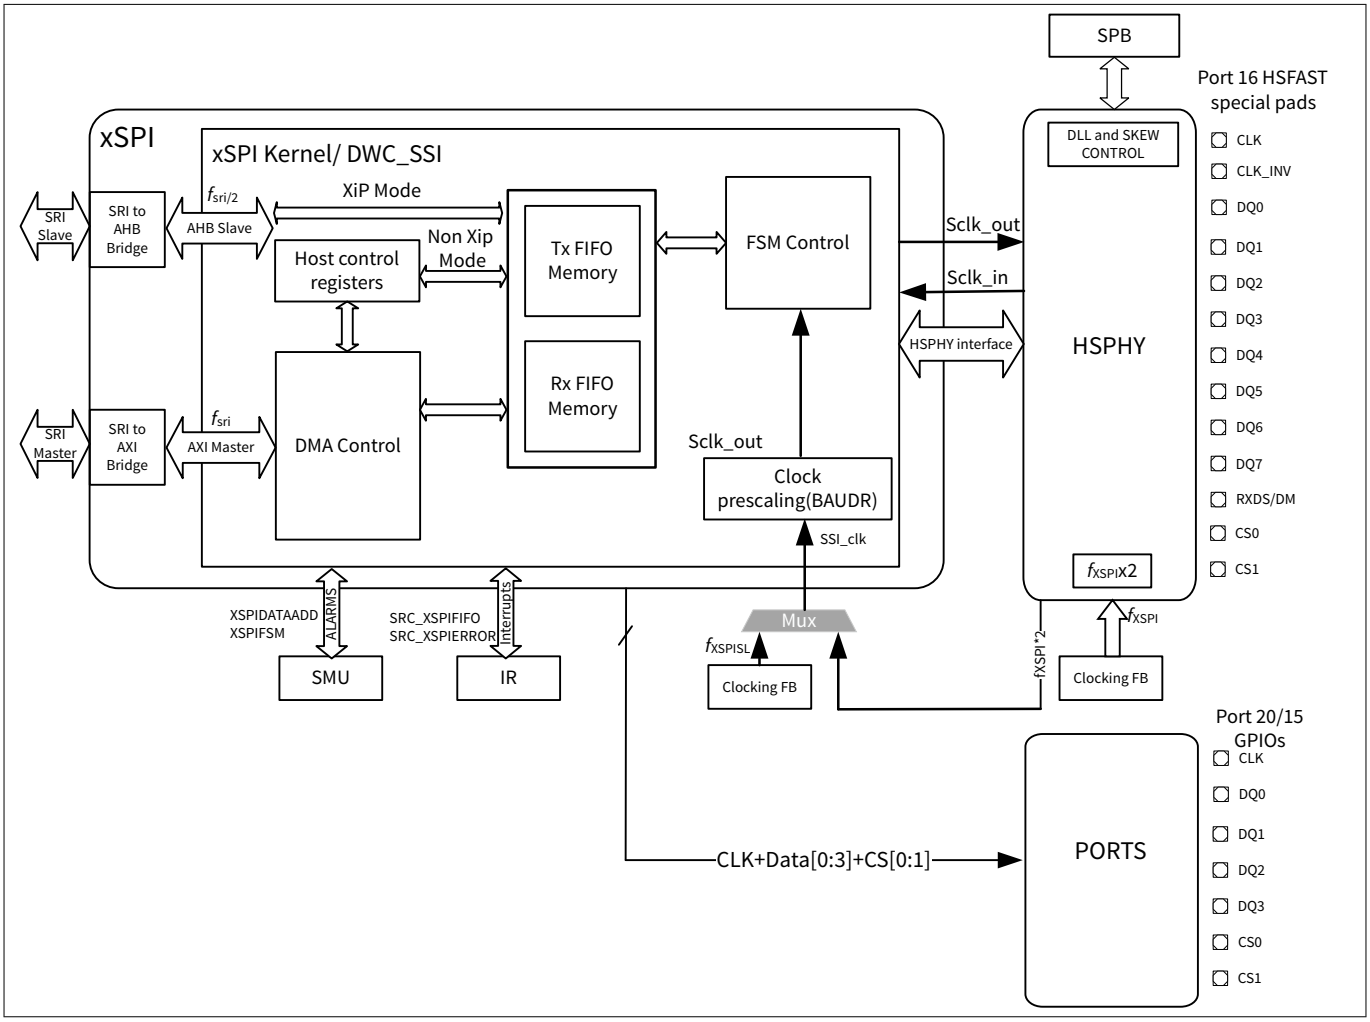

Figure 250 xSPI block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

The xSPI kernel is connected to the SRI slave via the SRI to AHB bridge and SRI master via SRI to AXI bridge. Access to host control registers and memory mapped register space via XIP takes place through SRI slave interface. Data transfers from/to external memory to/from internal memory space takes place through an internal Direct Memory Access(DMA) engine via the SRI master interface. Any type of non DMA mode data transfers takes place through the SRI slave using the internal tx and rx FIFO memory.

All the safety related interrupts are grouped under two alarms XSPIDATAADD (XSPI data address error alarm) and XSPIFSM(XSPI FSM alarm) that interfaces to SMU (Safety and security alarm Management Unit). Similarly, the non safety related interrupts are grouped under two interrupts XSPIFIFO and XSPIERROR that interface to IR (Interrupt Router).

The HSPHY functional block contains the DLL (Delay Locked Loop) along with Port 16 IO (Input Output) pad related SFRs that can be accessed via an SPB interface. The xSPI receives two times the f_{xSPI} clock called f_{XSPI*2} from the HSPHY. The SSI_clk is the internal peripheral kernel clock that is used to generate the Sclk_out. The BAUDR register helps in scaling the SSI_clk if needed, to obtain the desired output clock Sclk_out. The Sclk_in is used to sample the incoming data during data reads.

The xSPI can be used either on :

- Port 16 through the HSPHY and HSFAST pads (pads specialized for xSPI performance) at maximum performance using f_{xspi*2}
- Or over GPIO pads through the PORTS in a reduced speed mode in quad SDR mode only, using f_{XSPISL} clock

Note:
- *One of the signal (TXD3/RXD3) belonging to port 20 Quad mode implementation is routed to port 15.*
- *Since there is only one instance of xSPI in any device, the xSPI cannot be used in parallel, on both port 16 and over other ports with GPIO pads*

18.3 Functional description

This chapter describes the xSPI system overview, architecture, and various features supported in xSPI.

18.3.1 System overview

The figure below shows an application use case when two xSPI slave devices are connected to the interface.

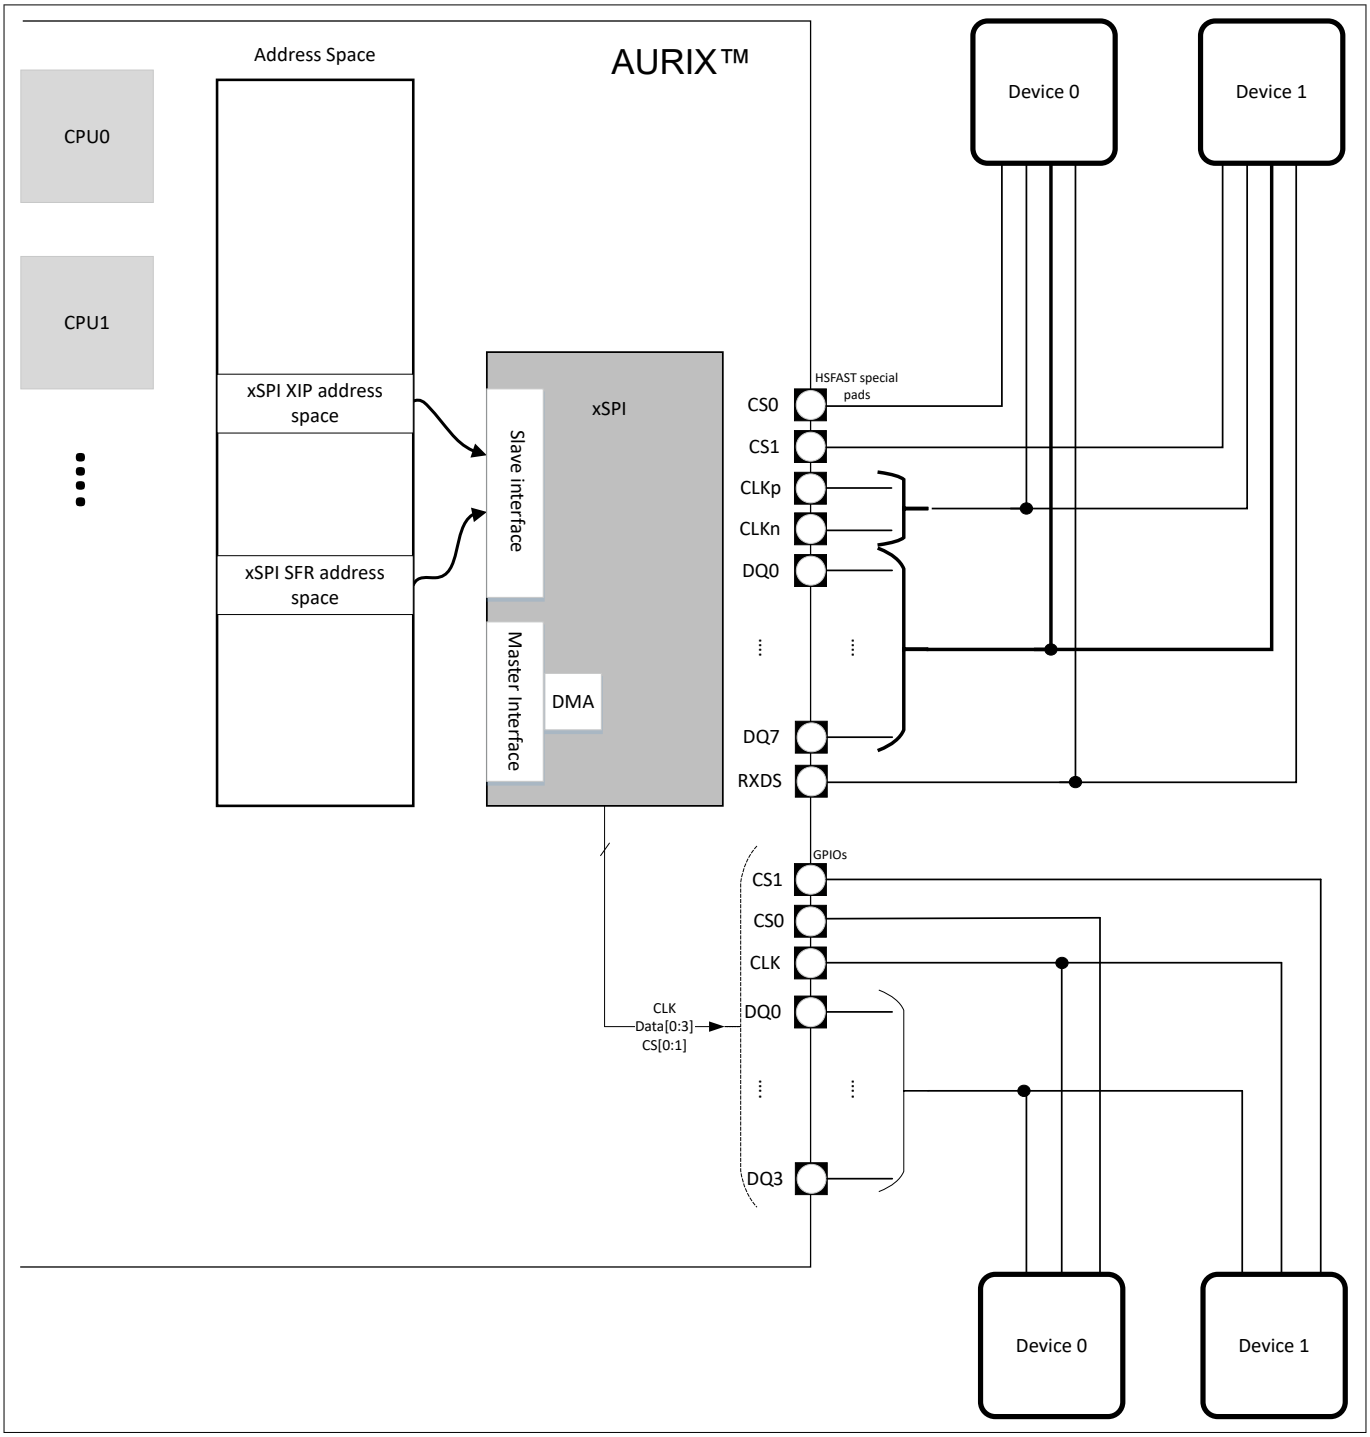

Figure 251 xSPI system overview

18.3.2 Serial Peripheral Interface (SPI)

The octal or Hyperbus, half duplex, high throughput and low pin count xSPI protocol is based on the legacy four wire, full duplex, low bandwidth SPI protocol.

xSPI is backward compatible to legacy SPI protocol along with dual and quad SPI interface protocols, which were intermediate development steps in the evolution of xSPI from the SPI protocol. The figure below shows the SPI interface and DDR octal example transaction at the xSPI interface.

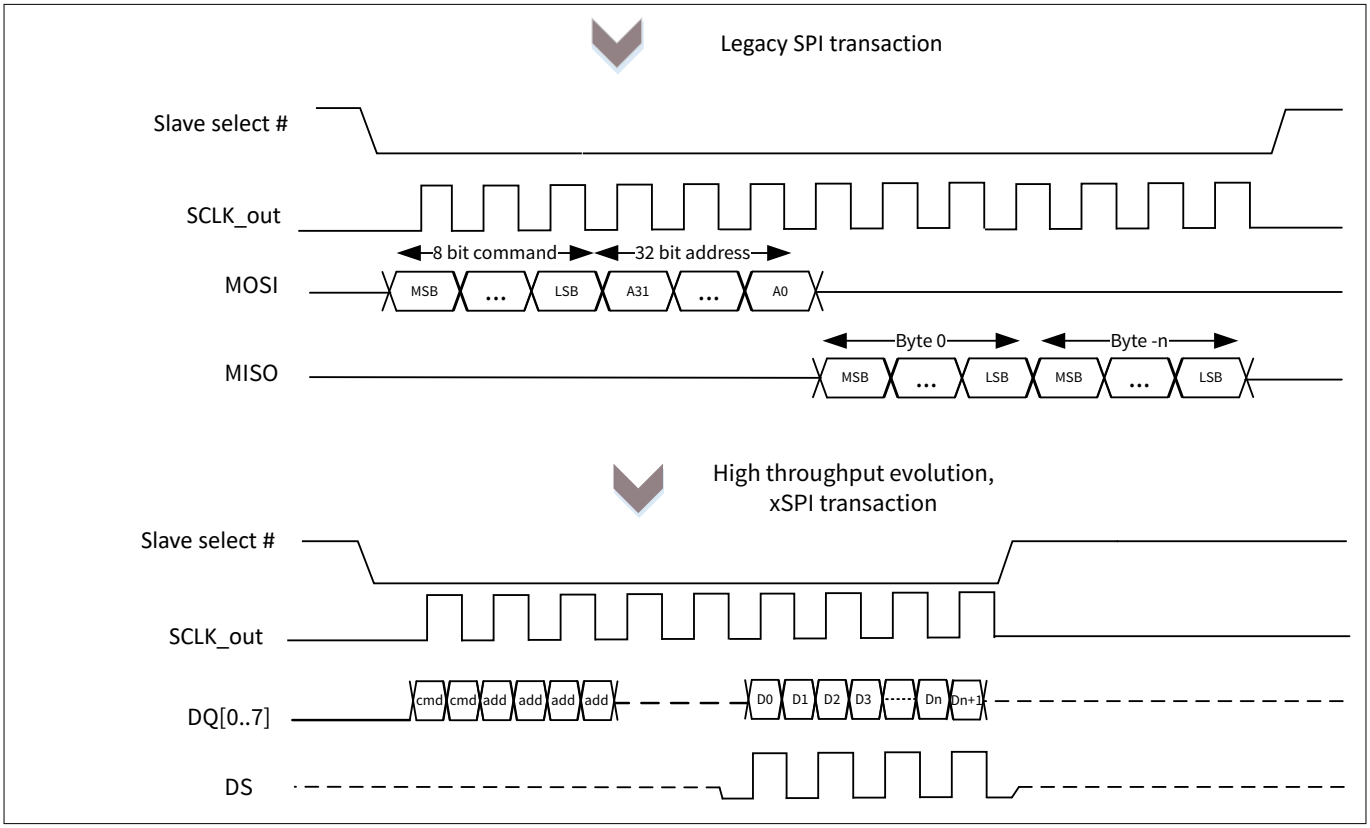

Figure 252 SPI and xSPI transaction

The following figure shows the TXD, RXD and OE signals, coming from the xSPI and HSPHY blocks, building the DQ signal. TXD is the transmit data towards the SPI slave and RXD is the receive data from the slave to the xSPI. The OE is an output enable signal which controls the IO output driver of data since this is half duplex interface.

The DLL is used to adjust the phase of the clock signal with respect to receive and transmit data signal, to generate the right set-up and hold timings for the xSPI interface. The selection of receive and transmit skew, with respect to the clock is done using the corresponding register bits TXCFG and RXCFG respectively in the HSPHY functional block

***Note**: TXD, RXD and, OE are shown here only for better understanding and are already taken care of by the host controller.*

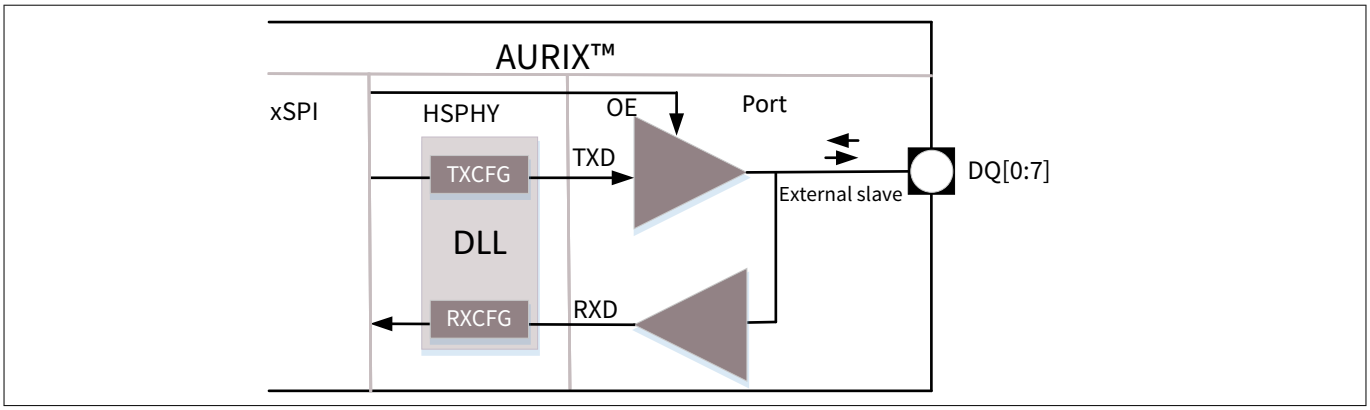

Figure 253 xSPI IO signaling

The xSPI interface provides a low pin count master-slave interface for high speed communication with JESD251 compliant non volatile memory devices, hyperbus compliant memories and is backward compliant to serial peripheral interface (SPI) devices.

In order to cater to different slave devices from different vendors available in the market, xSPI has the following configurable parameters:

- SPI Clock polarity (CTRLR0.SCPOL): Parameter determines whether the inactive state of the serial clock is high or low.
- SPI Clock Phase (CTRLR0.SCPH):
  - When CTRLR0.SCPH=0, data transmission begins on the falling edge of the slave select signal. The first data bit is captured by the master and slave peripherals on the first edge of the serial clock; therefore, valid data must be present on the TXD and RXD lines prior to the first serial clock edge. Data is driven by the master and slave peripherals on the trailing edge of the serial clock
  - When the configuration parameter CTRLR0.SCPH=1, both master and slave peripherals begin transmitting data on the first serial clock edge after the slave select line is activated. The first data bit is captured on the second (trailing) serial clock edge. Data is driven by the master and slave peripherals on the leading edge of the serial clock

The figure below shows a timing diagram for a single SPI data transfer. In the upper part of the diagram CTRLR0.SCPH = 0 (clock phase). In the lower part of the diagram CTRLR0.SCPH = 1 (clock phase). The serial clock polarity is shown for configuration parameters CTRLR0.SCPOL= 0 and CTRLR0.SCPOL= 1. To transmit data, both controller and communication partner or slave must have identical serial clock phase (CTRLR0.SCPH) and clock polarity (CTRLR0.SCPOL) values as the host. The data width can be 4 to 32 bits.

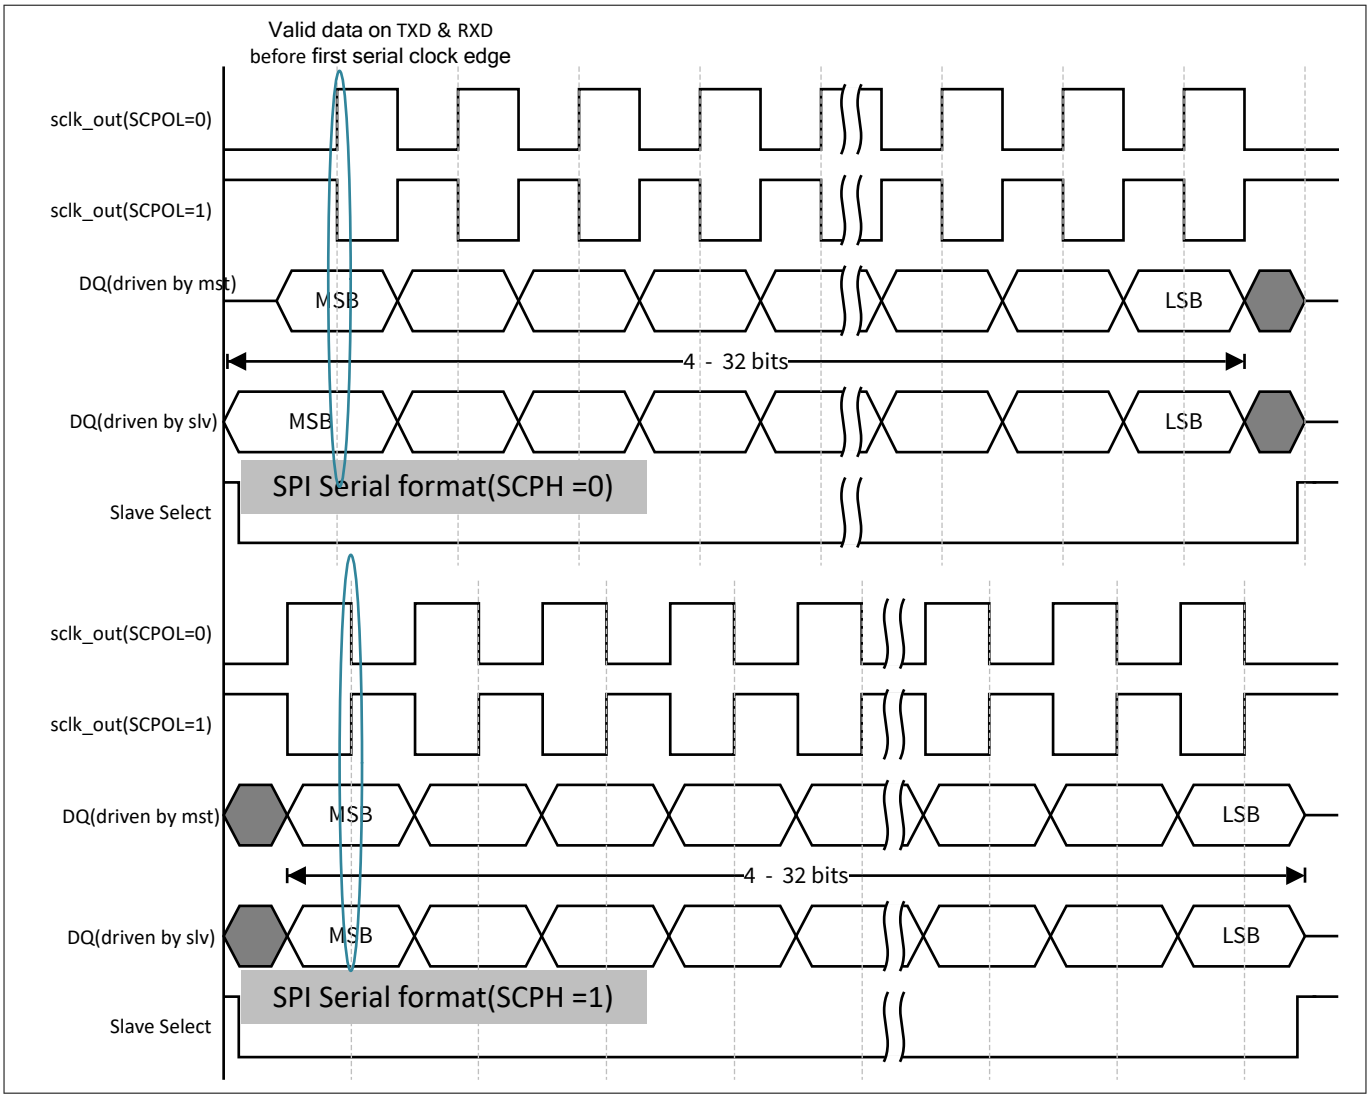

Figure 254 SPI serial format with SCPH = 0 (above) and SCPH = 1 (below)

Continuous data frames are transferred in the same way as single frames, with the MSB of the next frame following directly after the LSB of the current frame. The slave select signal is held active low for the duration of the transfer.

18.3.3 Transfer modes

This section discusses the different modes in which xSPI operates when transferring data on the serial bus. The transfer mode (TMOD) is set by writing to control register 0 (CTRLR0).

Transmit and receive

When TMOD = 00_B, both transmit and receive logic are valid. The data transfer occurs as normal, according to the selected frame format (serial protocol). Transmit data are popped from the transmit FIFO and sent through the TXD line to the target device, which replies with data on the RXD line. The receive data from the target device is moved from the receive shift register into the receive FIFO at the end of each data frame.

Transmit only

When TMOD = 01_B, the receive data is invalid and is not stored in the receive FIFO. The data transfer occurs as normal, according to the selected frame format (serial protocol). Transmit data are popped from the transmit FIFO and sent through the TXD line to the target device, which may reply with data on the RXD line. At the end of

the data frame, the receive shift register does not load its newly received data into the receive FIFO. The data in the receive shift register is overwritten by the next transfer. Interrupts originating from the receive logic should be masked when this mode is entered.

Receive only

When TMOD = 10_B, receive only mode is selected and the transmit data is invalid. The TXD outputs remain at a constant logic level during the transmission. The data transfer occurs as normal, according to the selected frame format (serial protocol). The receive data from the target device is moved from the receive shift register into the receive FIFO at the end of each data frame. Interrupts originating from the transmit logic should be masked when this mode is entered.

EEPROM read

When TMOD = 11_B, the transmit data is used to transmit an opcode and/or an address to the EEPROM device. Typically this takes three data frames (8-bit opcode followed by 8-bit upper address and 8-bit lower address). During the transmission of the opcode and address, no data is captured by the receive logic (as long as the xSPI master is transmitting data on its TXD line, data on the RXD line is ignored). The xSPI master continues to transmit data until the transmit FIFO is empty. Therefore, you should have enough data frames in the transmit FIFO to supply the opcode and address to the EEPROM. If more data frames are in the transmit FIFO than are needed, then read data is lost.

When the transmit FIFO becomes empty (all control information has been sent), data on the receive line (RXD) is valid and is stored in the receive FIFO; the TXD output is held at a constant logic level. The serial transfer continues until the number of data frames received by the xSPI master matches the value of the NDF field in the CTRLR1 register + 1.

18.3.4 Data transfers

Data transfers are started by the serial-master device when:

- xSPI is enabled (SSIENR.SSIC_EN = 1) and
- Serial-slave device is enabled (SER.SER)
- Number of data entries in transmit FIFO is greater than TXFTHR field of the TXFTLR register

While actively transferring the data, the busy flag (BUSY) in the status register (SR) is set. You must wait until the busy flag is cleared before attempting a new serial transfer.

***Note**:*

- *The SR.BUSY status is not set when the data is written into the transmit FIFO. This bit gets set only when the target slave has been selected and the transfer is underway. After writing data into the transmit FIFO, the shift logic does not begin the serial transfer until a positive edge of the `sclk_out` signal is present. The delay in waiting for this positive edge depends on the baud rate of the serial transfer. Before polling the SR.BUSY status, you should first poll the SR.TFE status (waiting for 1) or wait for `BAUDR * ssi_clk` clock cycles*
- *When DFS is greater than 8-bit, the data frame is sent and received in big endian format*

18.3.5 Enhanced SPI modes

The xSPI module supports the dual, quad, and octal modes of SPI. All four combinations of the serial clock's polarity and phase are valid in this mode and it works same as in normal SPI mode.

The mode of operation (write/read) can be selected using the CTRLR0.TMOD field.

Registers related to enhanced SPI modes

- CTRLR0
- SPI_CTRLR0

18.3.5.1 Read operation in enhanced SPI modes

A Dual, Quad, or Octal SPI read operation can be divided into four phases:

- Instruction phase
- Address phase
- Wait cycles
- Data phase

The following register fields are used for a read operation:

- CTRLR0.SPI_FRF - Specifies the format in which the transmission happens for the frame
- CTRLR1.NDF to indicate the number of data frames
- SPI_CTRLR0.TRANS_TYPE specifies the address and instruction transfer format
- SPI_CTRLR0.INST_L – Specifies length of an instruction (possible values for instruction length are 0, 4, 8, or 16 bits)
- SPI_CTRLR0.ADDR_L – Specifies address length
- CTRLR0.DFS – Specifies data length
- SPI_CTRLR0.WAIT_CYCLES field for programming the number of wait cycles. The wait cycles are introduced to provide time for the target slave device, to change its mode from input to output. The number of wait cycles can vary for different devices

For a READ-operation, xSPI sends instruction and control data once and waits until it receives NDF (CTRLR1 register) number of data frames and then de-asserts the slave select signal.

The following figure shows a typical read operation with value of N = 7 when in octal mode, N = 3 when in quad mode, and N = 1 when in dual mode.

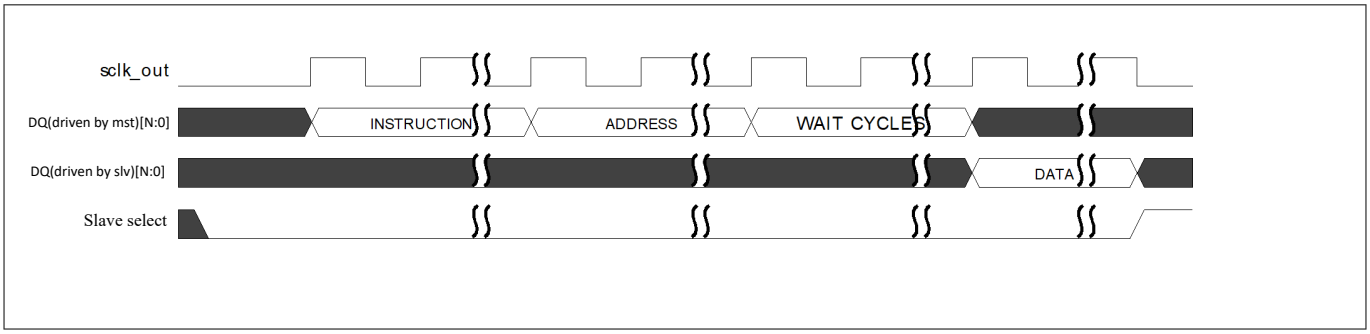

Figure 255 Typical read operation in enhanced SPI mode

Following are the possible cases of read operation in enhanced SPI modes:

1. Instruction and address both transmitted in standard SPI format: For this, SPI_CTRLR0.TRANS_TYPE field should be set to 00_B
2. Instruction transmitted in standard SPI format and address transmitted in enhanced SPI format: For this, SPI_CTRLR0.TRANS_TYPE field should be set to 01_B
3. Instruction and address both transmitted in Enhanced SPI format: For this, SPI_CTRLR0.TRANS_TYPE field must be set to 10_B
4. No Instruction, No Address READ transfer: For this, SPI_CTRLR0.ADDR_L and SPI_CTRLR0.INST_L must be set to 0 and SPI_CTRLR0.WAIT_CYCLES must be set to a non-zero value. To initiate this transfer, the software has to perform a dummy write in the data register (DRi (i=0-35).DR), xSPI waits for programmed wait cycles and fetches the amount of data specified in CTRLR1.NDF field

18.3.5.2 Write operation in enhanced SPI modes

Dual, Quad, or Octal SPI write operations can be divided into three parts:

- Instruction phase
- Address phase
- Data phase

The following register fields are used for a write operation:

- CTRLR0.SPI_FRF - Specifies the format in which the transmission happens for the frame
- SPI_CTRLR0 (SPI Control Register 0 register) – Specifies length of instruction and address
- SPI_CTRLR0.INST_L – Specifies length of an instruction (possible values for instruction length are 0, 4, 8, or 16 bits)
- SPI_CTRLR0.ADDR_L – Specifies address length
- CTRLR0.DFS – Specifies data length

An instruction takes one FIFO location and an address can take more than one FIFO location. Both the instruction and address must be programmed in the data register (DRi (i=0-35)). xSPI waits until both have been programmed to start the write operation.

The CTRLR0 and SPI_CTRLR0.TRANS_TYPE bit fields are used to control whether the instruction, address and data are transmitted in standard, dual, quad or octal mode.

***Notes**:*

1. *If CTRLR0.SPI_FRF is selected to be Standard SPI Format, everything is transmitted in Standard SPI mode and SPI_CTRLR0.TRANS_TYPE field is ignored*

2. *CTRLR0.SPI_FRF is only applicable if CTRLR0.FRF is programmed to 00_B*

The following figure shows a typical write operation with value of N = 7 when in octal mode, N = 3 when in quad mode and N = 1 when in dual mode.

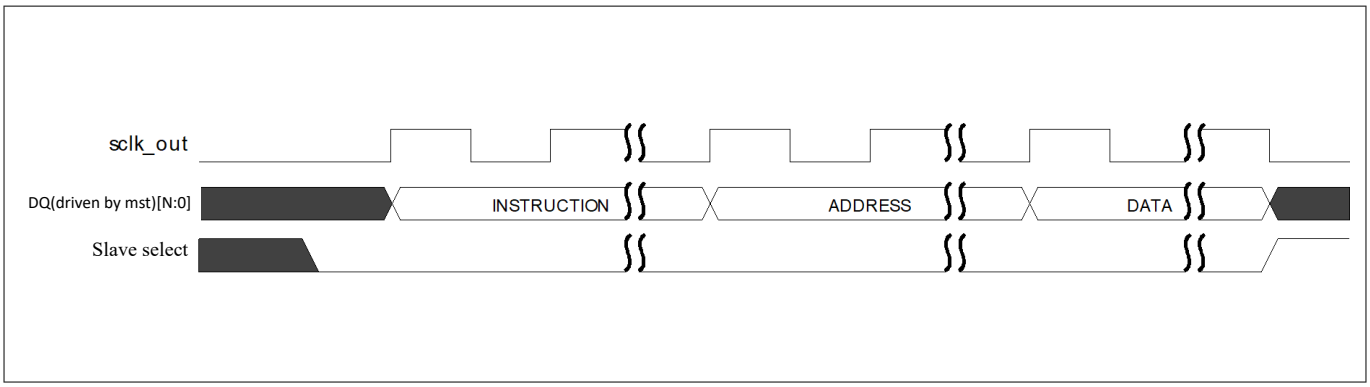

Figure 256 Typical write operation dual/quad/octal SPI mode

Following are the possible cases of write operation in enhanced SPI modes:

1. Instruction and address both transmitted in standard SPI format: For this, SPI_CTRLR0.TRANS_TYPE field must be set to 00_B

2. Instruction transmitted in standard SPI format and address transmitted in enhanced SPI format: For this, SPI_CTRLR0.TRANS_TYPE field must be set to 01_B

3. Instruction and Address both transmitted in enhanced SPI format: For this, SPI_CTRLR0.TRANS_TYPE field must be set to 10_B

4. Instruction only transfer in enhanced SPI format

***Note**:* *Some of the devices require instruction and address only transfer (without data phase). This could be achieved by skipping the address phase, and transmitting the address as data to the device. For this, SPI_CTRLR0.ADDR_L should be programmed to 0, and CTRLR0.DFS should be programmed with the required length.*

18.3.6 Clock stretching in enhanced SPI mode

xSPI includes clock stretching feature in enhanced SPI modes which can be used to prevent FIFO underflow and overflow conditions while transmitting or receiving the data respectively.

While xSPI is transmitting or receiving the data from SPI device, the software may not be able to keep up with the transfer rate due to the bandwidth issues on the slave interface. In such cases, TX FIFO becomes empty or RX FIFO overflows while transmitting and receiving the data. To avoid data corruption, CPU must discard the current operation and start a new transfer. This process is time consuming and inefficient.

To handle such scenarios, clock stretching support has been added in xSPI.

- For write transactions, whenever transmit TX FIFO becomes empty, xSPI does not de-select the slave. Instead, it masks the clock until the new data is pushed into the TX FIFO. Hence, the transfer is not broken, and CPU intervention is not required.
- For read transactions, similar to the write transaction, whenever xSPI detects that RX FIFO is full, the clock is masked until the data is read from FIFO.

The masking in this context means keeping the sclk_out at the default value, the sclk_out will remain at HIGH or LOW state based on the CTRLR0.SCPOL value. If clock stretching feature is enabled for all the write transactions, you should program the number of data frames in the CTRLR1 register. If RX_SAMPLE_DELAY register is enabled for receive transaction, then xSPI estimates when RX FIFO may become full and masks `sclk_out` accordingly.

***Note**: Clock stretching feature is applicable only for enhanced SPI transfer mode except XIP transfers.*

18.3.7 RXD sample delay

The xSPI has additional logic in order to delay the default sample time of the RXD signal(s). This additional logic can help to increase the maximum achievable frequency on the serial bus. This feature is particularly useful while working with a slave that does not support Data strobe.

Round trip routing delays on the `sclk_out` signal from the master and the RXD signal from the slave can mean that the timing of the RXD signal—as seen by the master—has moved away from the normal sampling time. The following figure illustrates this situation.

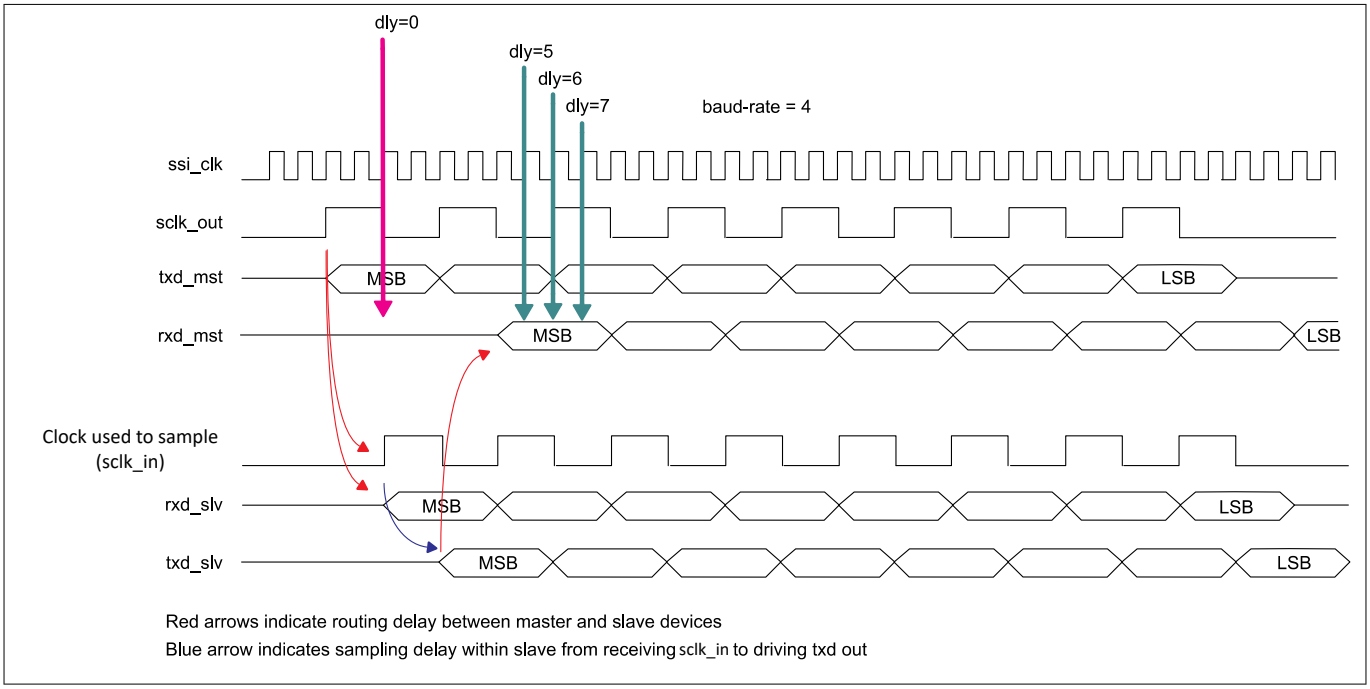

Figure 257 Effects of round-trip routing delays on the `sclk_out` signal

The slave uses the sclk_out signal from the master as a strobe in order to drive RXD signal data onto the serial bus. Routing and sampling delays on the sclk_out signal by the slave device can mean that the RXD bit has not stabilized to the correct value before the master samples the RXD signal. Figure above shows an example of how a routing delay on the RXD signal can result in an incorrect RXD value at the default time when the master samples the port.

Without the RXD Sample Delay logic, you must increase the BAUDR register value , that is increasing the dividing factor for the transfer in order to ensure that the setup times on the RXD signal are within range; this results in reducing the frequency of the serial interface.

When the RXD Sample Delay logic is used, you can dynamically program a delay value in order to move the sampling time of the RXD signal equal to a number of ssi_clk cycles from the default. The RXD sample delay logic can be configured to use positive edge of ssi_clk to sample RXD signal. This could increase the number of sampling points within a sclk_out period and help in meeting timings in higher frequencies.

xSPI uses RX_SAMPLE_DELAY register to change the sampling point of RXD signal.

- When the RX_SAMPLE_DELAY.SE is set to 0, xSPI delays the sampling point by the programmed number of ssi_clk cycles i.e, RX_SAMPLE_DELAY.RSD. Sampling is performed on the rising edge of the ssi_clk
- If RX_SAMPLE_DELAY.SE is set to 1, then xSPI delays sampling point by programmed number of ssi_clk cycles + 0.5 * (ssi_clk period). Thus, the sampling is done on negative edge of ssi_clk signal as described in the figure below. This gives user more sampling points within single sclk_out clock period.

***Note**: Using Rx sample delay it is important to arrive at a delay that covers all PVT variations. Data training during boot is also another option.*

18.3.8 Loopback clock sampling support

For the quad SPI mode of operation, there is no one standard that is guiding the behavior and signaling between the host and slave devices. A few slave devices support data strobe during quad mode and some, not. xSPI interface supports slaves with data strobe in quad mode. For the devices that support quad SPI mode with data strobe, achieving higher speeds (clock speeds of 133 MHz and more) is less of a challenge compared to devices that do not.

In cases where no data strobe support can be expected from the slave, it is already a challenge to reach frequencies above 50 MHz while reading a data. In order to stretch the achievable frequency, the incoming receive data could be sampled by two sample clocks as shown in figure below:

1. The transmit clock SCLK_out delayed by a configurable number of clock periods using the feature RXD sample delay available in xSPI kernel. The maximum frequency reachable in this case is limited to 66 MHz for 1.8 V devices and 83 MHz for 3 V devices
2. The looped back transmit clock , as shown in the figure as 'clock feedback'. This feature compensates the on-chip variations, on-chip delays, pad variations, pad delays and non-linearities introduced by Delay Lock Loop(DLL). This does not compensate non-linearities and delays due routing lines and slave device. This mode of compensation helps us achieve up to 133 MHz in SDR modes of operation when no data strobe is present

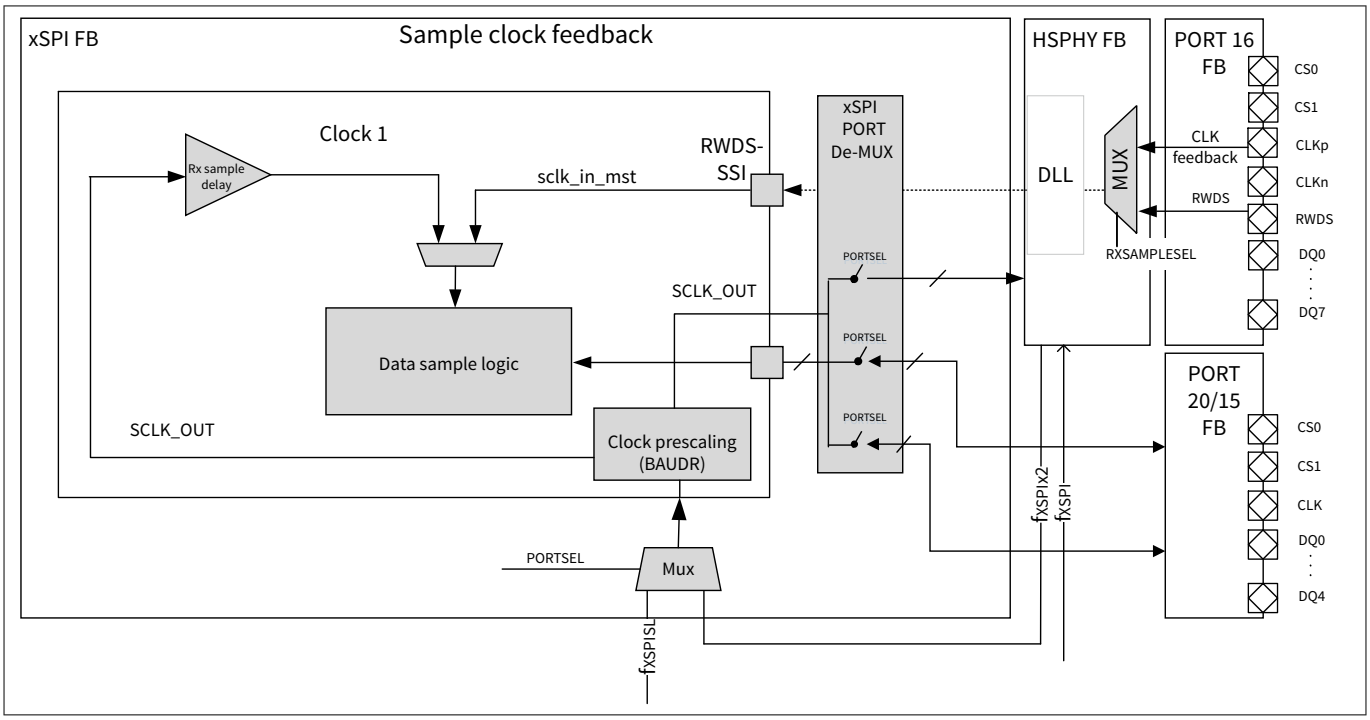

Figure 259 xSPI top level view

***Note**: When a slave with receive strobe is present, the multiplexer selection (bit RXSAMPLESEL in HSPHY register DLL_CFG) must be deactivated to avoid non-deterministic behavior*

18.3.8.1 Sampling in loopback mode

There are some slave devices that have an access time of more than half of the sclk_out period. In these cases, the user might not get an appropriate sampling window to sample the data on the positive edge of the incoming looped-back clock, Figure below shows an example for the same while using default setting, sampling with the rising edge of looped back clock, which is CTRLR0.SCPH=0.

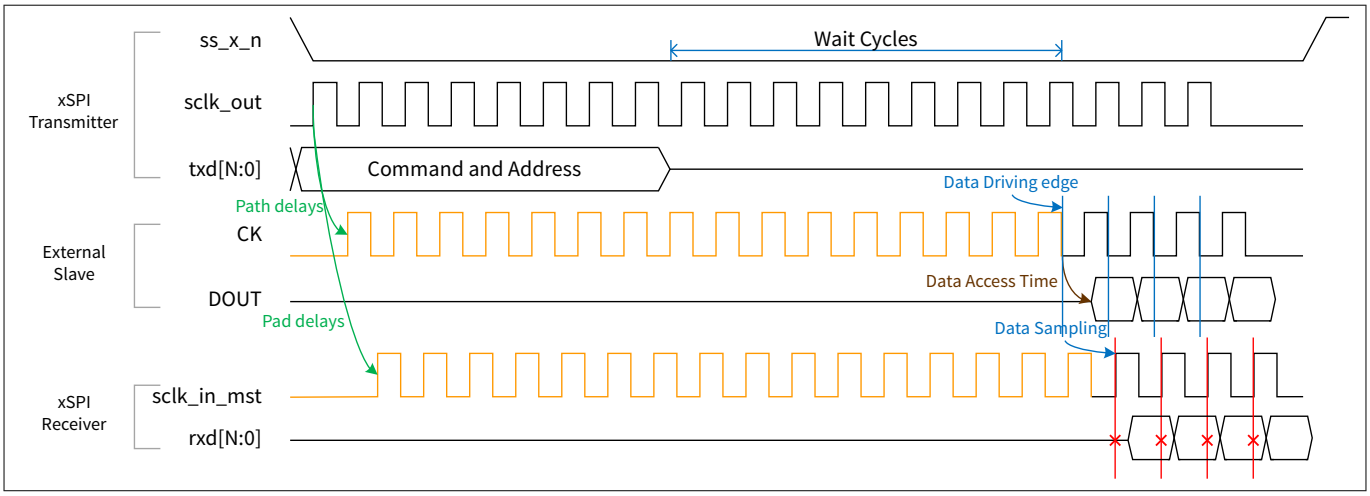

Figure 260 Clock loop back with higher access time

xSPI provides a programming option to change the sampling edge of the data in clock loopback mode as well. This enables xSPI to sample the data correctly. Figure below shows the example of the same. CTRLR0.SCPH=1 shifts the sampling to the falling edge of the looped back clock. This facilitates correct sampling of the incoming data in cases where the data access time from the slave device is more than 50% of sclk_out period. Please choose the correct sampling edge based on the access times of the slave devices.

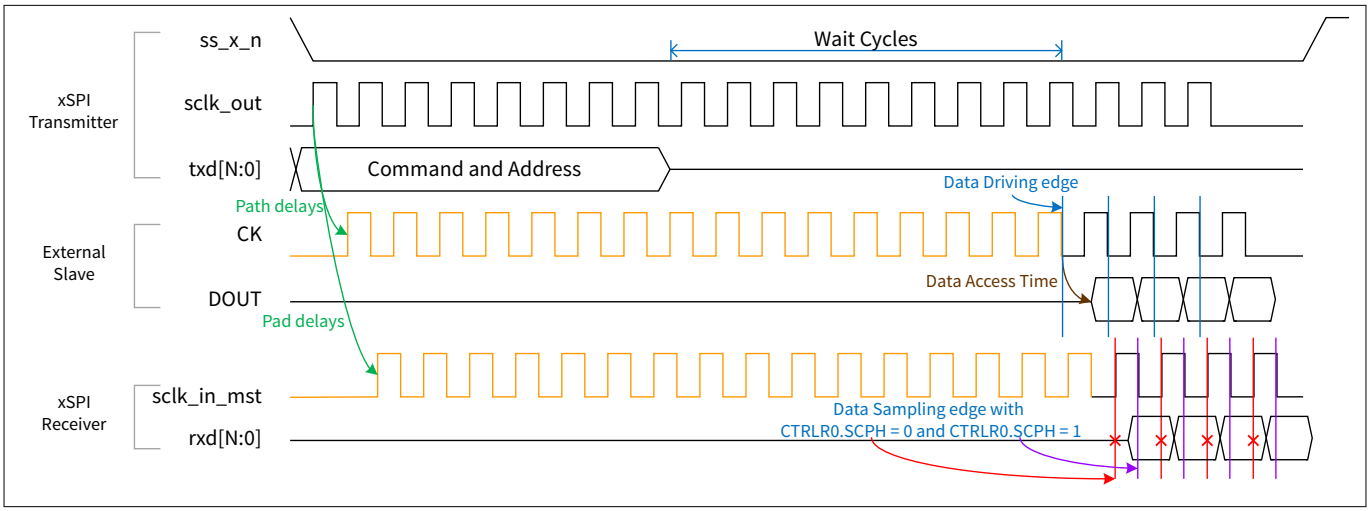

Figure 261 Clock loop back with higher access time with sampling edge variation

***Note**:*

- *The data is still transmitted in the SPI 0 format. When CTRLR0.CLK_LOOP_EN =1, CTRLR0.SCPH = 0 represents that data will be sampled with the rising edge and CTRLR0.SCPH = 1 represents that data will be sampled with the falling edge*

18.3.9 Extended quad SPI support over GPIO pads

In order to make xSPI available when high speed PORT16 is occupied by another source or FB, the xSPI functionality is extended to other standard GPIO pads as well. However, this extended xSPI support over GPIO pads has only a reduced functionality as listed below:

- support upto 25 MHz of clock
- SDR mode of operation only
- support for only 3 V external flash devices
- Only a maximum of 4 data lines are available. Octal mode of operation is not supported

In order to select the reduced functionality xSPI operation, CTRLR2.PORTSEL bit must be enabled. Since PORT16 and the DLL would be potentially occupied by RGMII, ssi_clock source must be selected to F_{XSPISL}.

***Note**:*
- *Special care must be taken to select the right clock for the right port selection*
- *xSPI cannot run in parallel on different ports. At a given time only one port can be used as we have only one instance of xSPI*

18.3.10 Dual data-rate (DDR) support

In standard operations, data transfer in SPI modes occurs on either the positive or negative edge of the clock. For improved throughput, the dual data-rate transfer can be used for reading or writing to the memories.

The DDR mode supports the following modes of the SPI protocol:

- Mode 0 – when the value of serial clock phase and serial clock polarity is 0_B (CTRLR0.SCPH = 0 and CTRLR0.SCPOL = 0)
- Mode 3 – when the value of serial clock phase and serial clock polarity is 1_B (CTRLR0.SCPH = 1 and CTRLR0.SCPOL = 1)

Description of DDR support

DDR commands enable data to be transferred on both the edges of clock. Following are the different types of DDR commands:

- Address and data are transmitted (or received in case of data) in DDR mode, while instruction is transmitted in standard format
- Instruction, address, and data are all transmitted or received in DDR mode

The SPI_CTRLR0.SPI_DDR_EN bit is used to determine if the address and data are transferred in DDR mode and the SPI_CTRLR0.INST_DDR_EN (SPI_CTRLR0[17]) bit is used to determine if instruction is transferred in DDR mode. These bits are only valid when the CTRLR0.SPI_FRF bits are set to Dual, Quad or Octal mode.

The following figure describes a DDR write transfer where instruction is transmitted in standard format. In the figure below, the value of N is 7 when CTRLR0.SPI_FRF is set to 11_B.

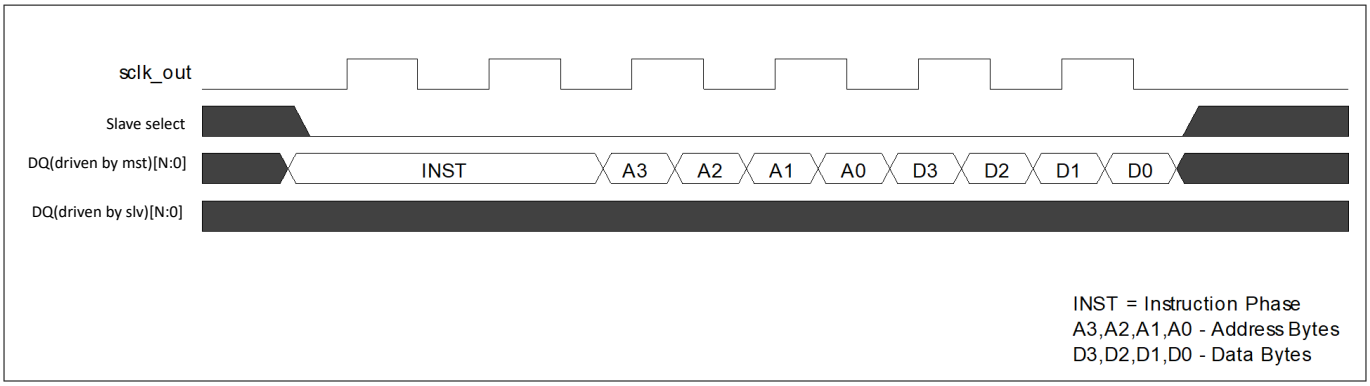

Figure 262 DDR transfer with instruction in standard format

The Figure below describes a DDR write transfer where instruction, address and data all are transferred in the DDR format.

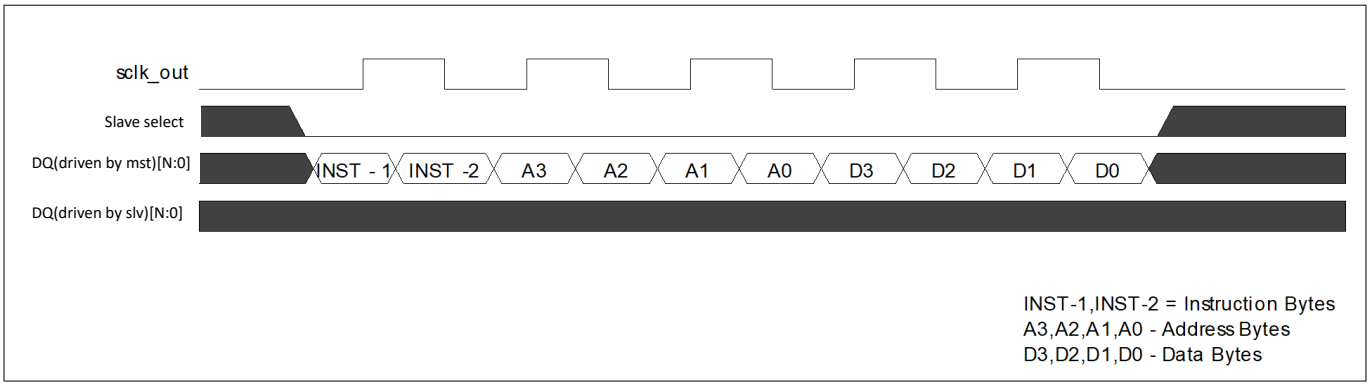

Figure 263 DDR transfer with instruction, address and data transmitted in DDR format

***Note**: In the DDR transfer, address and instruction cannot be programmed to a value of 0. The number of wait cycles cannot be 0 in a DDR read operation.*

Transmitting data in DDR mode

In DDR mode, data is transmitted on both edges. This makes it difficult to sample data correctly as the data with respect to sclk_out would have moved. xSPI uses an internal register to determine the ssi_clk edge on which the data should be transmitted. This ensures that the receiver is able to get stable data with respect to sclk_out while sampling. The internal register (DDR_DRIVE_EDGE) determines the edge on which the data is transmitted. The internal clock is divided by an integral number (ssi_clk / BAUDR) to derive the baud clock (sclk_out) which xSPI uses to send data.. The data needs to be transmitted within half clock cycle (BAUDR/2), therefore the maximum value for the DDR_DRIVE_EDGE.TDE bitfield is equal to [(BAUDR/2)-1]. Data is driven ((BAUD/2)-DDR_DRIVE_EDGE.TDE) ssi_clk before the sampling edge. If the programmed value of the DDR_DRIVE_EDGE.TDE register is set to 0 then the data is transmitted two ssi_clk before the edge of sclk_out.

The following figures show examples of how data is transmitted using different values of the DDR_DRIVE_EDGE.TDE bitfield. The green arrows in these examples represent the points where data is driven. BAUDR used in all these examples is 6.

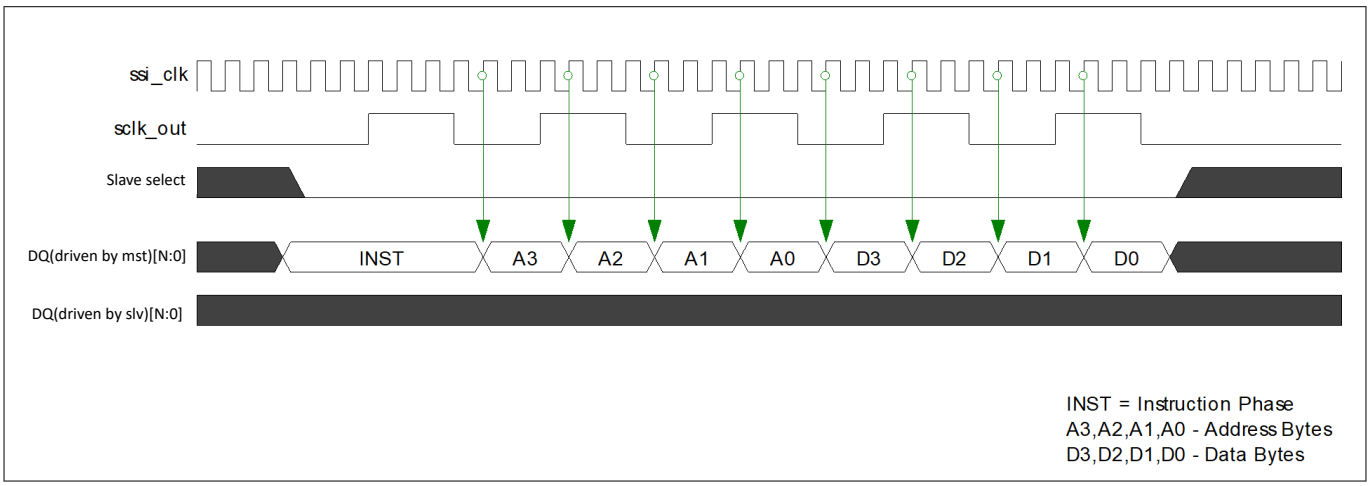

Figure 264 Transmit data with DDR_DRIVE_EDGE.TDE = 0

18.3.11 HyperBus protocol

A read or write transaction on a HyperBus interface consists of a sequential series of 16-bit, one-clock cycle, data transfers. Each 16-bit one-clock transfer consists of two 8-bit half-clock transfers, one on each clock edge.

xSPI supports the HyperBus protocol that works on the principle of the SPI DDR interface. The DDR protocol transfers two data bytes per clock cycle on the input/output (I/O) signals.

In the HyperBus protocol, read and write transactions transfer complete 16-bit words of data. Read data words always contain two valid bytes. Write data words may have one or both bytes masked to prevent writing of individual bytes within a write burst.

Command, address, and data information are transferred over the eight HyperBus (TXD[7:0]/RXD[7:0]) signals. The HyperBus slave device uses the clock to capture information while receiving the command, address, or data on the DQ signals. The Command or Address values are center aligned with clock transitions. The HyperBus uses a 48-bit command-address (CA) to convey the instruction and address information. The CA frame format is as shown in the table below.

Table 815 Command-address bit assignments

CA bit	Bit name	Bit function
47	R/W#	Identifies the transaction as a read or write. • 1 – Indicates a read transaction • 0 – Indicates a write transaction
46	Address space (AS)	Indicates whether the read or write transaction accesses the memory or register space. • 0 – Indicates the memory space • 1 – Indicates the register space

(table continues...)

Table 815 (continued) Command-address bit assignments

CA bit	Bit name	Bit function
45	Burst type	Indicates whether the burst is linear or wrapped. • 0 – Indicates a wrapped burst • 1 – Indicates a linear burst
44–16	Row and upper column address	Row and upper column component of the target address: System word address bits A31-A3 If a particular device density does not use upper row address bits, the host controller master interface must set it to 0. The size of Rows and therefore the address bit boundary between row and column address is dependent on the slave device
15–3	Reserved	Reserved for future column address expansion. Reserved bits are do not care in current HyperBus devices but the host controller must set this to 0 for future compatibility
2–0	Lower column address	Lower column component of the target address: System word address bits A2-A0 selecting the starting word within a half-page

Registers related to HyperBus protocol

- CTRLR0
- SPI_CTRLR0

18.3.11.1 HyperBus read

The HyperBus master begins a transaction by driving the slave select signal to low while the clock is idle. Then, the clock starts toggling while CA words are transferred. The HyperBus master then continues clocking for a number of cycles defined by the latency count setting in SPI_CTRLR0.WAIT_CYCLES. If the Read-Write Data Strobe (RWDS) signal, that is the slave counterpart of rxds signal for HyperBus devices, is low during the CA cycles, one latency count is inserted. If RWDS is high during the CA cycles, an additional latency count is inserted. After these latency clocks are completed, the slave transitions the RWDS and outputs the target data.

***Note**: Certain HyperBus devices can remove read data strobe signal in between transfers if a page boundary is reached. In such a situation, the master must send the clock continuously until the transfer resumes. xSPI does not support such transfer and the software must ensure that such situations do not occur before initiating the transfer by xSPI.*

18.3.11.2 HyperBus write

The HyperBus master begins a transaction by driving the slave select signal to low while the clock is idle. Then, the clock starts toggling while CA words are transferred. Further, the HyperBus master continues clocking for a number of cycles defined by the latency count setting in a configuration register SPI_CTRLR0. If RWDS is low during the CA cycles, one latency count is inserted. If RWDS is High during the CA cycles, an additional latency count is inserted. After these latency clocks are completed, the HyperBus master starts to output the target data. The Write data is center aligned with the clock edges. The first byte of data in each word is captured by the memory on the rising edge of `sclk_out` signal and the second byte is captured on the falling edge of `sclk_out` signal. The latency count can also be zero for a write transaction that is device dependent. For a HyperBus device, the read data strobe signal is driven by the slave device during the CA phase .

18.3.11.3 HyperBus enable

The CTRLR0.SPI_HyperBus_EN register bit is set to program xSPI as a HyperBus master. As the HyperBus interface has a fixed frame format, the following fields are fixed when xSPI is programmed into HyperBus mode:

- CTRLR0.SPI_FRF – 11_B (octal frame format)
- SPI_CTRLR0.TRANS_TYPE – 10_B (Address to be sent in octal format)
- SPI_CTRLR0.ADDR_L – 1100_B (address length of 48 bits)
- SPI_CTRLR0.INST_L – 00_B (no instruction phase)
- SPI_CTRLR0.SPI_DDR_EN – 1 (Address to be sent on octal-DDR mode)
- SPI_CTRLR0.SPI_RXDS_EN – 1 (enable read data strobe to sample incoming data)

Wait cycles are configured using the SPI_CTRLR0.WAIT_CYCLES field, depending on memory requirement. As the HyperBus protocol counts the wait cycles from the third CA cycle, xSPI sends SPI_CTRLR0.WAIT_CYCLES-1 wait cycles after the CA phase is complete.

If the SPI_CTRLR0.SPI_RXDS_SIG_EN bit is set to 0 or if the rxds level is 0 during CA phase, the number of wait cycles is fixed to the programmed value in the SPI_CTRLR0.WAIT_CYCLES bit-field.

You can set the type of transaction (read/write) and data frame size in CTRLR0.TMOD and CTRLR0.DFS fields, respectively. The read back value of fixed fields listed above is same as the register value but internally the hardware ignores those when CTRLR0.SPI_HyperBus_EN bit is set to 1.

After CTRLR0.SPI_HyperBus_EN is set to 1, xSPI expects a 48-bit address to start the transaction. The 48-bit data must be packed according to the HyperBus specification.

18.3.11.4 RXDS signaling

The slave HyperBus device can use for its transactions either a fixed or variable Latency.

- Variable latency: In case of variable latencies, xSPI provides an option for RXDS signaling in the CA phase as required by the HyperBus slave. One can enable this feature by programming the SPI_CTRLR0.RXDS_SIG_EN bit to 1. In this mode, if the RXDS signal is detected as high during command and address cycles, then xSPI sends (2*SPI_CTRLR0.WAIT_CYCLES-1) wait cycles after the address phase is complete. If the RXDS signal is detected low, then xSPI sends (1*SPI_CTRLR0.WAIT_CYCLES-1) wait cycles after the address phase is complete. Hence ideally, SPI_CTRLR0.WAIT_CYCLE should be programmed to the minimum latency cycles needed by slave
- Fixed latency: If the SPI_CTRLR0.RXDS_SIG_EN bit is set to 0 or if the RXDS level is 0 during CA phase, the number of wait cycles is fixed to the programmed value in the SPI_CTRLR0.WAIT_CYCLES-1) bit-field. This value should ideally be two times accounting also for the time needed for refresh latency for slaves that need them.

***Note**: The slave device has to be respectively configured in fixed or variable latency mode based on host configuration and vice versa*

18.3.12 Execute in place (XIP) mode

xSPI provides a function to directly perform memory read operation from AHB transaction. This is called execute in place mode, in which xSPI acts as memory mapped interface to an SPI memory.

XIP usage model

XIP operations are supported only in Dual, Quad, or Octal enhanced SPI modes of operation (or in hyperbus mode as described in the following section), and hence, the CTRLR0.SPI_FRF bit must not be programmed to 0. Typically, an XIP operation consists of an address phase and a data phase. The programming flow to set-up an XIP transfer is as follows:

1. Set the SPI frame format value in CTRLR0 register
2. Set the address length, wait cycles, and transaction type in SPI_CTRLR0

The instruction phase can also be included in XIP transfer by using XIP_INST_EN field of the SPI_CTRLR0 register. In this case, the following registers must be set:

1. Set length of instruction in the SPI_CTRLR0 register
2. Write the instruction opcodes in the XIP_INCR_INST and XIP_WRAP_INST registers

After the programming is completed, an XIP read transaction can be initiated by reading the xSPI memory mapped region. A read transaction is then completed using the programmed values.

When the XIP_DFS_HC field of the SPI_CTRLR0 register is set to 0, SRI control signals are used to derive the values of the data frame size and the number of data frames to be fetched by the device. Once the CTRLR0 and SPI_CTRLR0 registers are programmed with correct values for the transfer, then XIP transfers can be initiated by reading from the memory mapped xSPI address region.

Note:
- *Only a maximum of SRI BTR4 is supported at the AHB slave*
- *Memory Address regions for XIP access can be found in the device specific Memory overview table*

XIP transfers in HyperBus mode

For XIP transfers, the 32-bit address is obtained from the AHB interface and then packed to derive the 48-bit CA frame format required by the Hyperbus device. Because Hyperbus memories are word (16-bit) addressable, the least significant bit is not considered while packing the address in CA frame format.

Mode bits support

During a serial transfer, certain devices have the capability to send additional bits that are referred to as Mode bits. In xSPI, the mode bit support can be enabled by setting the XIP_MD_BIT_EN field of the SPI_CTRLR0 register. The actual value of the mode bits to be driven can be programmed by writing into the XIP_MODE_BITS register. The length of the mode bits can be programmed using XIP_MBL field of the SPI_CTRLR0 register. Mode bits occur immediately after the address phase is completed and follow the same rules as for the address bits. Therefore, serial transfers consist of following phases when mode bit support is enabled:

Instruction Phase > Address Phase > Mode Bits > Wait cycles > Data Phase

Based on the CTRLR0.SPI_FRF value, mode bits are driven as follows:

- If CTRLR0.SPI_FRF is dual, the mode bits are sent on two lanes
- If CTRLR0.SPI_FRF is quad, the mode bits are sent on four lanes
- If CTRLR0.SPI_FRF is octal, the mode bits are sent on eight lanes

XIP mode with instruction phase

Certain devices expect the instruction phase to exist during XIP transfers. xSPI supports inclusion of some fixed instruction sets during the XIP mode of operation. By default, the instruction phase feature is not enabled in XIP mode. To enable this feature, set the XIP_INST_EN bit of the SPI_CTRLR0 register. The length of instruction phase is controlled by the INST_L field of the SPI_CTRLR0 register. When the XIP_INST_EN bit of the SPI_CTRLR0 register is set to 1 and xSPI receives an XIP transfer, then the instruction opcode is also sent to the device followed by the address.

- SPI_CTRLR0
- XIP_WRAP_INST
- XIP_INCR_INST
- XIP_MODE_BITS

18.3.12.1 Continuous transfer mode in XIP

When xSPI receives a memory mapped address read request on the slave, the address is transmitted onto the SPI interface directly. Each new transfer (XIP Read) is treated in the same manner. Therefore, for every request, a new address must be sent to the device thereby contributing to the latency of the system.

If a memory device allows the stretching of slave select signal across the XIP read transfers, then xSPI can be programmed for continuous XIP mode to achieve higher performance. In this mode, the host combines two or more burst requests into a single SPI command by ensuring that the command and address are not retransmitted and the host controller need not wait for any dummy cycles in between these bursts.

xSPI can be enabled for continuous XIP mode by programming the SPI_CTRLR0.XIP_CONT_XFER_EN bit to 1. When this bit is set to 1, then xSPI functions in continuous XIP mode as soon as first XIP command is received. For the first XIP transfer, the address (and instruction if SPI_CTRLR0.XIP_INST_EN = 1) is sent on the SPI interface. After reception of requested data, xSPI continues to keep the slave selected and the clock (sclk_out) remains in the default state. For subsequent XIP transfers , xSPI resumes the clock (sclk_out) and neither the command nor the address is retransmitted onto the SPI interface. The data is fetched from the device immediately (no dummy cycles).

xSPI moves out of the continuous mode due to either of the following conditions:

- A non-XIP command (example, an SFR register space access) is received on an XIP interface
- When non-consecutive addresses are issued, the slave select is removed and xSPI initiates a new XIP request
- When the xSPI does not detect any XIP transfer for the time-period specified in XIP_CNT_TIME_OUT register the slave is de-selected

***Notes**:*

1. *In Continuous transfer mode, if SPI_CTRLR0.XIP_DFS_HC is set to 1, the XIP address must always be aligned with the DFS value programmed in the CTRLR0.DFS bit*
2. *Continuous XIP mode will not work when clock stretching is enabled*

xSPI supports the following continuous transfers:

- Continuous incremental transfer
- Continuous wrap transfer

Continuous incremental transfer

A transfer is defined as continuous incremental when the first command received in the continuous XIP (SPI_CTRLR0.SSIC_XIP_CONT_XFER_EN = 1) mode is INCR . In this mode, when the transfer is completed, the next command must also be incremental, and the address must be a contiguous address of the last burst.

Continuous wrap transfer

A transfer is defined as continuous WRAP when the first command received in continuous XIP mode is WRAP. In this mode, when the transfer is completed, the next command must start from the address of last-burst address boundary.

A continuous XIP transfer can be ended by issuing non-XIP transfer, or when a XIP read is issued to a non-consecutive address. In this case, the slave select is removed, and then xSPI initiates a new XIP request.

Data sampling in continuous transfer mode

The data sampling in continuous transfer mode depends on the SPI protocol type (SCPH and SCPOL values). The different cases for all the combinations are listed as follows:

1. Case A: CTRLR0.SCPH = 0.

In this case, when the last continuous transfer completes, the next data is sampled on the first edge of clock. The polarity of the clock during the IDLE period is dependent on the CTRLR0.SCPOL value

2. Case B: CTRLR0.SCPH = 1.

   In this case, when the last continuous transfer completes, the next data is driven at the first edge and sampled on the second edge of the clock. The polarity of the clock during the IDLE period is dependent on the CTRLR0.SCPOL value

***Note**: For dual data-rate transfers (SPI_CTRLR0.SPI_DDR_EN = 1), the continuous transfer mode is supported only for CTRLR0.SCPH = 0 and CTRLR0.SCPOL = 0 configurations, and the remaining combinations are not supported.*

Slave deselect in continuous transfer mode

During the continuous transfer, a lot of power is dissipated on the slave device since the slave is selected all the time. To reduce the slave power consumption, xSPI provides a configuration option to enable a watchdog timer to de-select the slave after the counter runs out. The counter is based on the AHB slave clock frequency, which is $f_{SRI/2}$.

When the xSPI does not detect any XIP transfer for the time-period specified in XIP_CNT_TIME_OUT register the slave is de-selected. The counter starts its operation after the last XIP transfer is completed, and then waits for a new request on AHB slave interface. Register XIP_CNT_TIME_OUT is used to set the count-down value for the IDLE period. When set to 0 the counter is disabled, and xSPI continues to wait for the next XIP request without de-selecting the slave.

- SPI_CTRLR0
- XIP_CNT_TIME_OUT

18.3.13 Read data strobe signal

To achieve high frequency, data strobe signaling is used in read operations. The slave device provides a data strobe known as read data strobe (RXDS), signal along with read data, which determines the output data valid window. The frequency of this signal follows the frequency of the peripheral clock driven by xSPI, sclk_out. xSPI must receive the read data, which is center-aligned to the edge of data strobe. The slave device normally provides an edge-aligned data with respect to the strobe. This means that the DLL in the HSPHY FB phase delays the data strobe so that read data is center aligned as shown in the following figure. This delay is introduced and controlled by the register DLL_CFG.RXCFG in the HSPHY functional block.

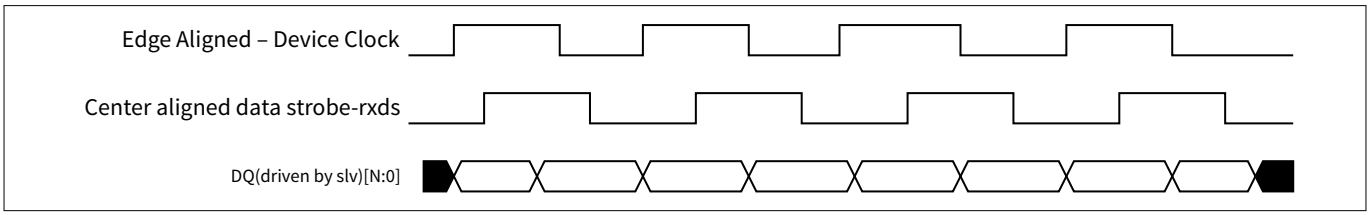

Figure 266 Center aligned data strobe for xSPI interface

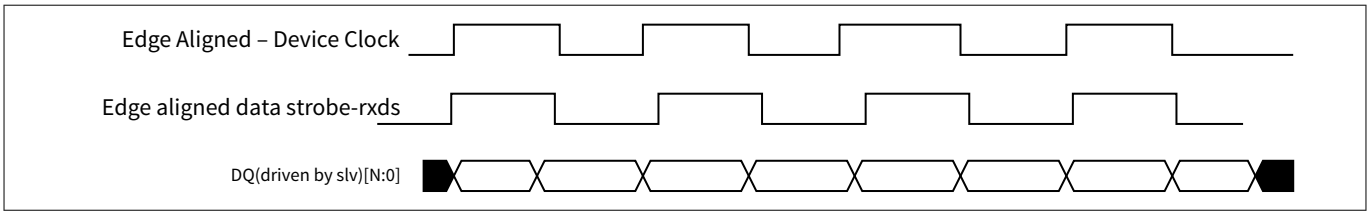

Figure 267 Edge aligned data strobe before entering DLL interface

SPI_RXDS_EN field of the SPI_CTRLR0 register is set to 1 to sample incoming data with respect to the read data strobe signal, as shown in the following figure. It is expected that the slave device uses the incoming clock, sclk_out to generate the data strobe. xSPI transmits only the minimum number of clock cycles required to complete the transfer. If the number of data frames expected is four, xSPI transmits only four clocks as shown in the following figure.

Note:

- The data must be stable around both clock edges of the data strobe. Data is sampled on both edges
- Only the SPI mode 0 is supported in this mode, that is when CTRLR0.SCPH = 0 and CTRLR0.SCPOL = 0

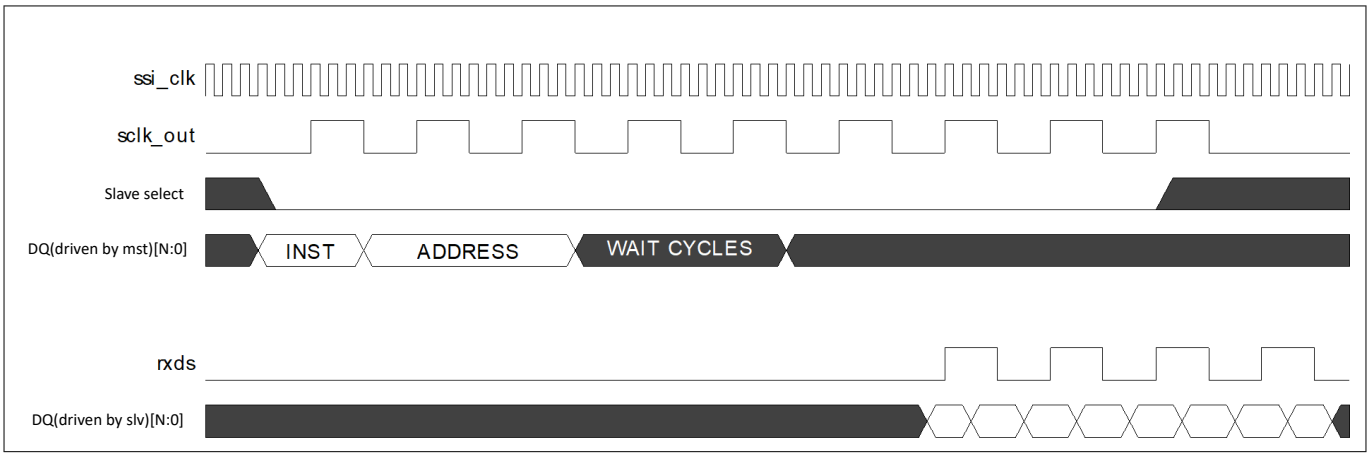

Figure 268 Example of a transfer using read data strobe signal

Registers related to read data strobe signal

- CTRLR0
- SPI_CTRLR0

18.3.14 Slave interface

The slave bus interface module or the slave bus, as referenced everywhere else in the document, implements the logic to access the internal registers of xSPI as well as perform XIP operations to the end device. This module supports only the little-endian scheme for data transfer.

***Note**: There is only one slave interface where both register accesses and XIP operations take place. Based on the addressed memory space, whether it is memory mapped external slave area or SFR register space, the transaction is either an XIP or a register access respectively.*

xSPI provides a slave error response from slave when any of the following conditions are met:

- If transmit FIFO is full and a write operation is attempted in the data register
- If receive FIFO is empty and a read operation is attempted in the data register
- If read or write operation is attempted in the data register when xSPI is not enabled (SSIENR register set to 0)
- Under XIP operation the following condition result in error response:
  - If any register write operation occurs during XIP operation

18.3.15 Data mask

xSPI supports the data mask feature that is used to mask the write data on an SPI interface. xSPI supports this feature on enhanced SPI modes. When configured in data mask mode, xSPI provides the TXD_dm signal to mask the data on the TXD line. This signal is used only during WRITE transactions in enhanced SPI DDR operations.

The SPI_DM_EN field in the register SPI_CTRLR0 is set to enable the data mask feature. The value of data mask is derived from incoming transactions on the AHB interface to data register. For example, if you want to transmit 4 bytes {D3,D2,D1,D0} (with D3 as MSB) by masking the D2 byte, you must divide the transfer into two transfers such that 16-bit transfer containing {D1,D0} is transferred and then, one 8-bit transfer with D3 being written in the data register. xSPI enables the data mask signal while transmitting the third byte in transfer.

While sending a 4 byte transfer {D3,D2,D1,D0} , that is CTRLR0=0x1f, and an AHB transfer of only one byte is received by the controller {D0} , then the remaining 3 bytes will be masked.

While sending a 2 byte transfer {D1,D0} , that is CTRLR0=0xf, when an AHB transfer of only one byte is received by the controller {D0}, then the remaining 1 byte will be masked.

Figure 269 shows a data mask used for Octal SPI write transfer. The data mask signal is active while transmitting the third byte of the data that is not written in the SPI device.

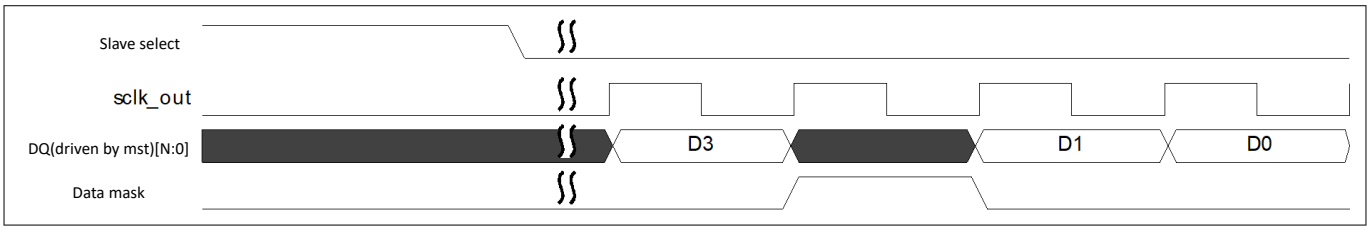

Figure 269 Octal SPI write transfer with data mask enabled

***Note**:*

- *Each FIFO location in the transmit data FIFO represents a data frame size, which can go from 4 to 32 bits. In case where the data frame size is 32, all the bits of FIFO data are valid and are sent to the SPI interface. But, if the data frame size is smaller than 32, for example 16, then, only 16 bits of each FIFO location are valid. Since the data register is 32 bits wide, all the 32 bits must be written. Among these 32 bits only 16 are valid and the data mask processing happens only for those16 bits. The reserved 16 bits must also be written and must not be skipped*
- *The data mask is only valid for the data phase of the enhanced SPI transfers. The address and instruction phases do not use the data mask. Since the address/command and the data register use the same location, you must write the address/command into the data register before starting to write the data*
- *In order to write smaller than 32 bits of data, please refer to description in CTRLR0.DFS.*

Registers related to data mask

- SPI_CTRLR0
- XIP_CTRL

18.3.16 Internal DMA feature

xSPI internal DMA feature is responsible for data transfer from an internal memory (or on chip memory) to an external slave SPI device and vice versa. xSPI uses the master interface on one side and the SPI interface on the other, acting as source or destination depending on the programming.

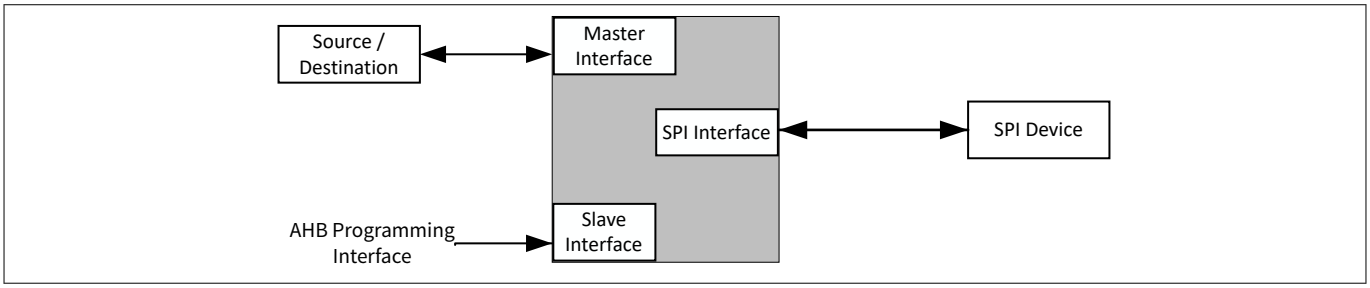

Figure 270 Block diagram for internal DMA feature for SPI operation

The programming sequence for DMA transfers can be found under the topic xSPI programming sequences. After xSPI has been programmed, it takes care of completing the transfer between the internal memory and external SPI device.

***Notes**:*

1. *The internal DMA operation is supported only in enhanced SPI (Dual/Quad/Octal and Hyperbus) mode of operation*
2. *When internal DMA is enabled, any read or write operation to Data Register (DR) results in error response from the AHB slave interface*
3. *Data Mask feature is not supported in internal DMA mode*
4. *The address length on SPI interface can be maximum of 32 bits in internal DMA mode*

18.3.16.1 AXI master interface

xSPI uses an AXI interface to perform internal DMA operations.

The AXI interface can receive an error response from a write response or a read data channel. In such a situation, xSPI immediately aborts the transfer by de-asserting the slave-select signal and asserting the `ssi_axie_intr` signal. The data present in the internal FIFO is flushed and xSPI is disabled (`SSIC_EN = 0`). Also, xSPI updates the SR.CMPLTD_DF field with the amount of data that was successfully transferred in the last DMA

transfer. This information can be used to determine where exactly the error occurred, and the amount of data transferred successfully.

***Note**: The CMPLTD_DF of status register (SR) may not represent the correct value if the transfer is aborted by the user by programming SSIENR register to 0.*

18.3.17 Receive and transmit FIFO buffers

The transmit FIFO is loaded by writing to the xSPI data register (DRi (i=0-35)). Data is popped (removed) from the transmit FIFO by the shift control logic into the transmit shift register. The transmit FIFO generates a FIFO empty interrupt request (through the `ssi_txe_intr` signal) when the number of entries in the FIFO is less than or equal to the FIFO threshold value. The threshold value, set through the programmable register TXFTLR, determines the level of FIFO entries at which an interrupt is generated. The threshold value allows you to provide an early indication to the processor that the transmit FIFO is nearly empty. A transmit FIFO overflow interrupt request (through the `ssi_txo_intr` signal) is generated if you attempt to write data into an already full transmit FIFO.

Data is popped from the receive FIFO by reading the xSPI data register (DRi (i=0-35)). The receive FIFO is loaded from the receive shift register by the shift control logic. The receive FIFO generates a FIFO-full interrupt request (through the `ssi_rxf_intr` signal) when the number of entries in the FIFO is greater than or equal to the FIFO threshold value plus 1. The threshold value, set through programmable register RXFTLR, determines the level of FIFO entries at which an interrupt is generated. The threshold value provides an early indication to the processor that the receive FIFO is nearly full.

A receive FIFO overrun interrupt request (through the`ssi_rxo_intr` signal) is generated when the receive shift logic attempts to load data into a completely full receive FIFO. This newly received data is lost. A receive FIFO underflow interrupt request (through the `sssi_rxu_intr` signal) is generated if you attempt to read from an empty receive FIFO. This alerts the processor that the read data is invalid.

***Note**: The transmit and receive FIFO buffers are cleared when the xSPI is disabled (SSIENR.SSIC_EN = 0) or when it is reset .*

18.3.18 Interrupts and alarms

This section describes the interrupts and alarms in the xSPI.

18.3.18.1 Interrupts

This section describes the interrupt grouping for xSPI.

xSPI has 2 interrupts that are routed on to the interrupt router:

- SRC_XSPIFIFO: xSPI FIFO interrupts are grouped into SRC_XSPIFIFO interrupt
- SRC_XSPIERROR: xSPI ERROR interrupts are routed to SRC_XSPIERROR interrupt

The table below shows the grouping of the corresponding interrupts.

Table 816 Interrupt multiplexing

Merged interrupt	Interrupt	Description
SRC_XSPIFIFO	ssi_txe_intr	Transmit FIFO empty active high interrupt. Active when the transmit FIFO is equal to or below the threshold value (TFT) and requires service to prevent an under-run. The threshold value, set through Transmit FIFO Threshold Level register, which determines the level of transmit FIFO entries at which an interrupt is generated. This interrupt is cleared by hardware when data is written into the transmit FIFO buffer, bringing it over the threshold level
	ssi_txo_intr	Transmit FIFO overflow active high interrupt. Set when there is an attempt to write into the transmit FIFO after it has been completely filled. When set, the data written is discarded
	ssi_txu_intr	Transmit FIFO underflow active high interrupt. Active when the transmit logic attempts to read from empty transmit FIFO
	ssi_rxf_intr	Receive FIFO full active high interrupt. Set when the receive FIFO is equal to or above its threshold value plus 1 and requires service to prevent an overflow. The threshold value, set through Receive FIFO Threshold Level register, which determines the level of receive FIFO entries at which an interrupt is generated. This interrupt is cleared by hardware when data is read from the receive FIFO buffer, bringing it below the threshold level
	ssi_rxo_intr	Receive FIFO overflow active high interrupt. Set when the receive logic attempts to place data into the receive FIFO after it has been completely filled. When set, the newly received data is discarded. This interrupt remains set until you read the receive FIFO overflow interrupt clear register (RXOICR)
	ssi_rxu_intr	Receive FIFO underflow active high interrupt. Set when an AHB access attempts to read from the receive FIFO when it is empty. When set, zeros are read back from the receive FIFO. This interrupt remains set until you read the receive FIFO underflow interrupt clear register (RXUICR)
	ssi_done_intr	Transfer done interrupt After xSPI transmits or receives the required amount of data to or from the slave respectively, the xSPI clears the SSIENR register, and interrupt ssi_done_intr is provided to software
SRC_XSPIERROR	ssi_axie_intr	AXI error interrupt

Registers related to SSI interrupts

- RXUICR
- MSTICR
- ISR , RISR, ICR
- IMR

18.3.18.2 Alarms

This section describes the alarm grouping for xSPI.

xSPI has 2 Alarms that are routed to the SMU:

- XSIPDATAADD: xSPI data address error alarm
- XSPIFSM: xSPI FSM alarm

The table below shows the grouping of the corresponding alarm.

Table 817 Alarm multiplexing

Alarm name	Interrupt	Description
XSPIDATAADD	ssi_sfty_ap_intr	AXI interface parity interrupt.
	ssi_sfty_dpe_intr	SSI data path parity interrupt. This interrupt will be asserted when xSPI encounters a parity error on internal data path
	ssi_sfty_rs_intr	SSI data register space parity interrupt. This interrupt will be asserted when xSPI encounters an inconsistency in register space programming. For more details see Register space protection.
	ssi_sfty_addr_sp_intr	SSI AHB slave address interface parity interrupt. This signal will be asserted when xSPI encounters a address parity error on AHB slave interface
	ssi_sfty_data_sp_intr	SSI AHB slave data interface parity interrupt. This signal will be asserted when xSPI encounters a data parity error on AHB slave interface
	ssi_sfty_axi_ecc_ce_intr	AXI master interface ECC correctable error
	ssi_sfty_axi_ecc_ue_intr	AXI master interface ECC uncorrectable error
	sx_alarm_s2f_aph_err	SRI to FPI bridge address phase error
	sx_alarm_s2f_dph_err	SRI to FPI bridge data phase error
	sx_alarm_a2s_aph_err	AXI to SRI bridge address phase error
	sx_alarm_a2s_dph_err	AXI to SRI bridge data phase error
	ssi_sfty_axi_vrp_intr	AXI valid/ready parity error
	sx_alarm_fpi_mst	FPI master alarm. Error related to Universal Bus Slave (UBS) in FPI master from S2F bridge. This signal is triggered when there is inconsistencies of data phase signals (ready, ack and dp_inv).
	sx_alarm_fpi_slv	FPI slave alarm. Error related to Universal Bus Slave (UBS) in FPI master from S2F bridge. This signal is triggered when there is inconsistencies of data phase signals (ready, ack and dp_inv), inconsistencies in abort signal.

(table continues...)

Table 817 (continued) Alarm multiplexing

Alarm name	Interrupt	Description
	sx_alarm_fpi_wrerr	Write error on slave interface xSPI write errors, such as, access by masters who are not enabled for writing to xSPI address or SFR space, are flagged by this alarm
XSPIFSM	ssi_sfty_fp_intr	FSM parity interrupt
	ssi_sfty_fto_intr	FSM timeout interrupt

18.3.19 Hardware safety mechanisms

This section describes the safety mechanisms provided in the xSPI kernel.

18.3.19.1 Parity protection on AHB slave interface

The parity protection feature is implemented to provide high level data integrity checks for all data transfers at the AHB slave interface.

xSPI supports parity for both address and data signals.

Address parity check

The locally computed parity for the received address is compared with the parity received from the bridges. In case of an address parity check, a failure is indicated by the `ssi_sfty_addr_sp_intr` interrupt output. The actions taken by the xSPI core in case of an address parity protection failure are explained here for the different scenarios:

- Address Parity failure in register access (read and write)
  - The current register access is ignored. In case of a write transfer, the register is not updated. In case of read transfer, the data returned is all 0's
  - `ssi_sfty_addr_sp_intr` interrupt is generated
  - The subsequent register accesses proceed normally
  - `ssi_sfty_addr_sp_intr` interrupt is deasserted when the user clears it
- Address Parity failure in data register (DRi (i=0-35)) access
  - The interrupt is generated
  - The subsequent accesses to data registers are not allowed until the interrupt `ssi_sfty_addr_sp_intr` is cleared
- Address Parity failure in XIP transfers
  - `ssi_sfty_addr_sp_intr` interrupt is generated
  - If the interrupt `ssi_sfty_addr_sp_intr` is asserted due to address parity failure, the subsequent XIP transfers goes through even if the earlier interrupt is not cleared
  - Single transfers – transfer is not started on the SPI side
  - Burst transfers:
    - Address failure in the first beat – transfer is not started on the SPI side
    - If the first beat has no address parity failure and the second beat generates an address parity failure, the xSPI slave is deselected. The xSPI internally flushes all data

The SLVIFAPES field of the Safety Interrupt Status register (SAFETYISR) indicates the address parity failure status.

Write data parity check

The locally computed parity for the received write data is compared with the parity received. The actions taken by xSPI core in case of write data parity protection failure is explained here for the different scenarios.

- Register access
  - The current register write is ignored
  - The interrupt `ssi_sfty_data_sp_intr` is asserted to indicate the write data parity failure
  - Subsequent register accesses proceed normally
- Data Register access
  - The interrupt `ssi_sfty_data_sp_intr` is asserted to indicate the write data parity failure. Subsequent data register accesses are not allowed

The SLVIFDPES field of the Safety Interrupt Status register (SAFETYISR) indicates when write data parity failure status.

Read data parity checker

xSPI provides the parity per byte during read transfers along with the read data. The receiving bridge use this read parity to check the data integrity of the read data and flag (`sx_alarm_s2f_dph_err`) safety interrupt on parity mismatch.

Registers related to parity protection on AHB slave interface

- SAFETYCR
- SAFETYISR
- SAFETYICR

18.3.19.2 ECC and parity protection on master interface

The master interface is protected with ECC and Parity protection.

ECC protection on AXI master interface

The AXI master interface monitors and validates the ECC. If ECC monitor detects a single bit error, the received payload is corrected and a correctable error interrupt is generated. If a multi-bit error is detected, then an uncorrectable error interrupt is generated; however, the received payload cannot be corrected.

xSPI provides a total of 14 ECC Check bits for a payload width of 64 bits on the AXI interface.

The ECC Monitor generates the ECC Protection interrupts to indicate the correctable and uncorrectable error.

- AXI Channel ECC Correctable Error Interrupt: `ssi_sfty_axi_ce_intr`, if single bit error is detected, ECC Monitor generates correctable error interrupt. A single bit error is detected on the payload, and it is corrected by the ECC monitor
- AXI Channel ECC Uncorrectable Error Interrupt: `ssi_sfty_axi_ue_intr`, if multi-bit error is detected, ECC Monitor generates uncorrectable error interrupt. A multi bit error is detected on the payload, and it cannot be corrected by the ECC Monitor

Parity protection on AXI master interface

The AXI Master Interface Parity Protection implements the logic to generate and check the Parity for the AXI Channels that are being driven by the AXI Master. The xSPI supports even parity. xSPI receives parity per byte from AXI read data and AXI write response channels using side-band signals. The parity is used to protect all the control signals and data signals with separate parity bits for control fields and data fields. xSPI calculates an internal parity which is compared with the received parity bits. Along with this, a separate interrupt `ssi_sfty_ap_intr` is asserted when parity failure occurs. The AXI parity error is indicated by the AXIPES field of the Safety Interrupt Status (SAFETYISR) register.

Registers related to Parity protection on AXI master interface

- SAFETYCR
- SAFETYISR
- SAFETYICR

18.3.19.3 FSM protection

The following sections describe the two mechanisms available in xSPI to protect FSMs.

FSM parity protection

xSPI implements one-hot encoding scheme for holding the state register. Odd Parity is implemented on all the FSM state register bits. Parity is monitored on every clock, after the reset is de-asserted. When a bit flips due to transient errors or permanent faults, the erroneous FSM is set to its default state and an uncorrectable error is detected.

The FSM state parity protection is enabled by setting the FSM_PAR_EN field to 1, and the error insertion is enabled by setting the field FSM_EI_TYPE to 1 in the register SAFETYCR. The FSM in which error injection should happen is selected using SAFETYCR.FSM_SEL register bitfield. The FSM state error is indicated by (SAFETYISR).FSMPES register. Also, the safety interrupt `ssi_sfty_fp_intr` is asserted when an FSM error is detected. The FSM in which the error occurred can be determined by reading the Safety Interrupt register.

Error injection mode is also supported for the FSM parity error check for all the clock domains. This can be set using dedicated register bits SAFETYCR.FSM_SEL register.

FSM timeout protection

The Finite State Machine (FSM) time out feature provides the mechanism to ensure that all FSMs in xSPI can complete transaction, and return to a known completion state within a programmed time out value.

xSPI contains FSMs in slave, SSI and master clock domains. Each clock domain has one time out register. This can be programmed using the FSM time out registers for their respective clock domains. The timer ticks are generated based on the programmable time-out value. At every timer tick, all the FSMs are monitored for being in the active state (non-IDLE state, which indicates FSM is actively processing transactions or hand-shakes) and an internal FSM active flag field is set. The internal active flag bit is implemented for every FSM that is monitored for timeout. When the FSM reaches an IDLE or transaction completion state, the internal active flag field of the FSM is reset. At subsequent timer ticks, all FSM's active flag bits are monitored and any flag that is set indicates a time out for that FSM. This process of setting the flag, and checking at subsequent timer tick is repeated at every tick.

The FSM Time out error injection can be enabled by setting the FSM_EI_EN field to 1, and the FSM_EI_TYPE field to 0 in the SAFETYCR register. The FSM in which error injection should happen is selected using the FSM_SEL programming field of the SAFETYCR register. When time out error injection is enabled for an FSM, the FSM automatically times out and generates interrupt even without traffic.

The FSM time out state error is indicated by AXIFSMTOS/SSIFSMTOS/AHBFSMTOS fields of the xSPI Safety Interrupt Status (SAFETYISR) register for master, SSI and slave clock domains respectively. Also, the safety interrupt `ssi_sfty_fto_intr` is asserted when an FSM error is detected in any of AXI, SSI or AHB clock domains.

FSM timeouts provide a mechanism to ensure all the FSMs complete transactions, and returns to a known completion state. If an FSM is hung in a state for more than a programmed amount of time, then it is indicated to the application layer through the safety interrupt `ssi_sfty_fto_intr`.

- AXIFSMTOCR

18.3.19.4 On-chip data protection with parity

The On-Chip Data Protection with Parity feature provides parity protection for the transmit and receive data paths, wherever feasible. For every byte of data, one parity bit is generated.

At the transmit side, the data from master/slave interface is protected until it reaches the shift control logic. At the receive side, the data from serial interface is protected from the serial shift register until it reaches the slave interface or master interface.

***Note**: The master interface is used in the internal DMA mode of operation, otherwise the slave interface is used for data transmission or reception. Only one of them can be active at the same time.*

Transmit data path with parity protection

For data transmission the data can come from master or the slave interface based on internal programming. Figure below describes the locations where parity generators and parity checkers are placed in the transmit data path.

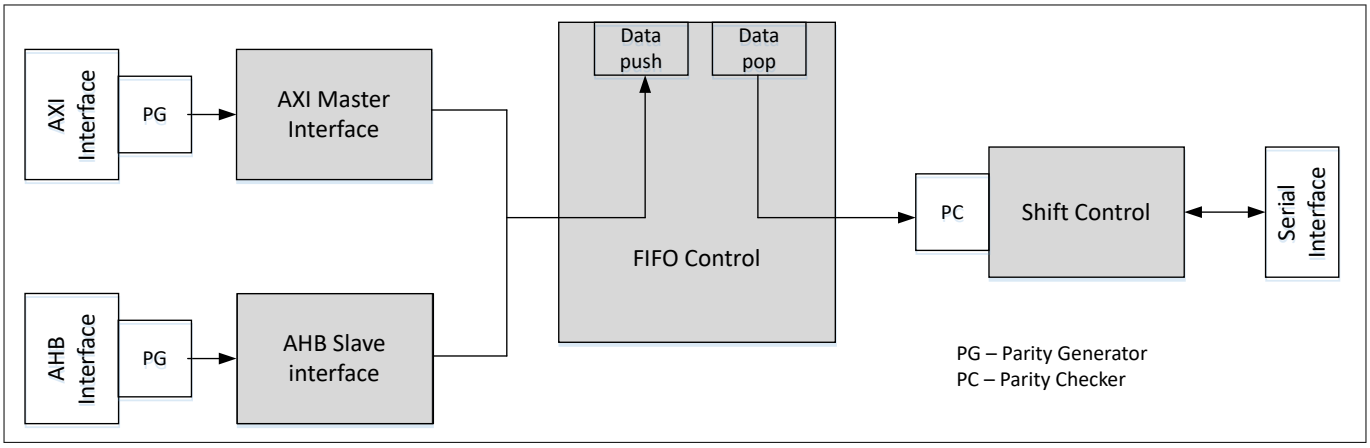

Figure 271 Data path parity protection for transmit data path

Following are the places where parity generators and checkers are present in the transmit data path:

- Parity is generated when master or slave interface has data ready to shift to the FIFO
- Parity is checked when the data is loaded into the internal shift register

Receive data path with parity protection

Figure below describes the locations where parity generators and parity checkers are placed in the receive data path.

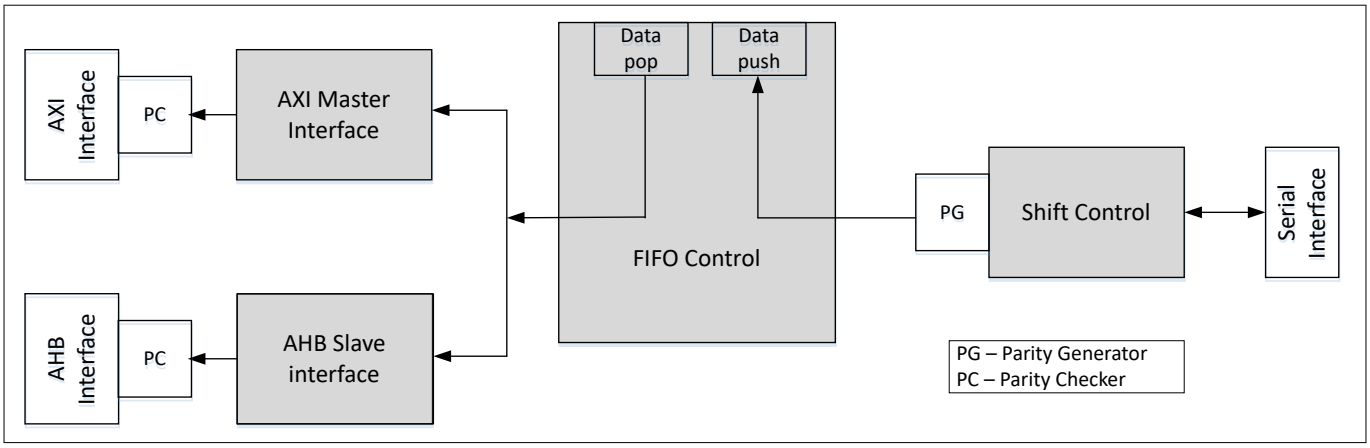

Figure 272 Data path parity protection for receive data path

Following are the places where parity generators and checkers are available in the receive data path:

- Parity is generated when the serial interface has data ready to shift to the FIFO
- Parity is checked when the data is about to be sent into the master or slave interface

Error injection in data path with parity protection

Each Parity generator supports control to inject parity errors. When enabled, the parity of the incoming data is flipped until the parity error is detected by the parity checker. The user must set the DPPG_EI_EN field of the SSI Safety Control (SAFETYCR) register. After the data path parity interrupt is detected, the hardware clears the DPPG_EI_EN. There are four possible parity error injection methods for each path. The following describes how to inject parity errors in each path:

For DMA mode:

- If the transfer mode is set to Write, an Error is injected at master interface parity generator and the error is detected at parity checker present before shift control logic
- If the transfer mode is set to Read, an Error is injected at parity generator present after shift control logic and the error is detected at the parity checker present in the master interface

For normal operation mode:

- If the transfer mode is set to Transmit Only, an Error is injected at slave interface parity generator and the error is detetced at parity checker present before shift control logic
- If the transfer mode is set to Receive Only, an Error is injected at parity generator present after shift control logic and the error is detected at the parity checker present at slave interface

After the generator inserts an error in the generated parity data, the subsequent parity checker should detect the mismatch and report the error status in SSI Safety Interrupt status (SAFETYISR) register.

For example, if xSPI needs to insert an error in the input data at parity generator, the sequence of operation is as follows:

1. Application sets the DPPG_EI_EN field of the SSI Safety Control (SAFETYCR) register
2. Application enables xSPI by setting SSIENR register to 1
3. The parity generator inserts an error in the parity generated for the data
4. As the data traverses through multiple paths, the subsequent checkers detect the parity mismatch and report the error status in the SSI Safety Interrupt (SAFETYISR) register and generate the `ssi_sfty_dpe_intr` interrupt
5. After the interrupt is detected, xSPI clears the DPPG_EI_EN bit of the SAFETYCR register

***Notes**:*

1. *For Error insertion the transfer mode field (CTRLR0.TMOD) should not be set to 00_B (transmit and receive)*
2. *Error insertion is not applicable for XIP transfers*

- SAFETYISR
- SAFETYICR

18.3.19.5 Register space protection

The Register Space Protection feature is based on a simple form of hardware redundancy, where a set of configuration registers are duplicated. The original set drives the logic, whereas the copy is used for consistency and it is not connected to any logic as shown in the figure below.

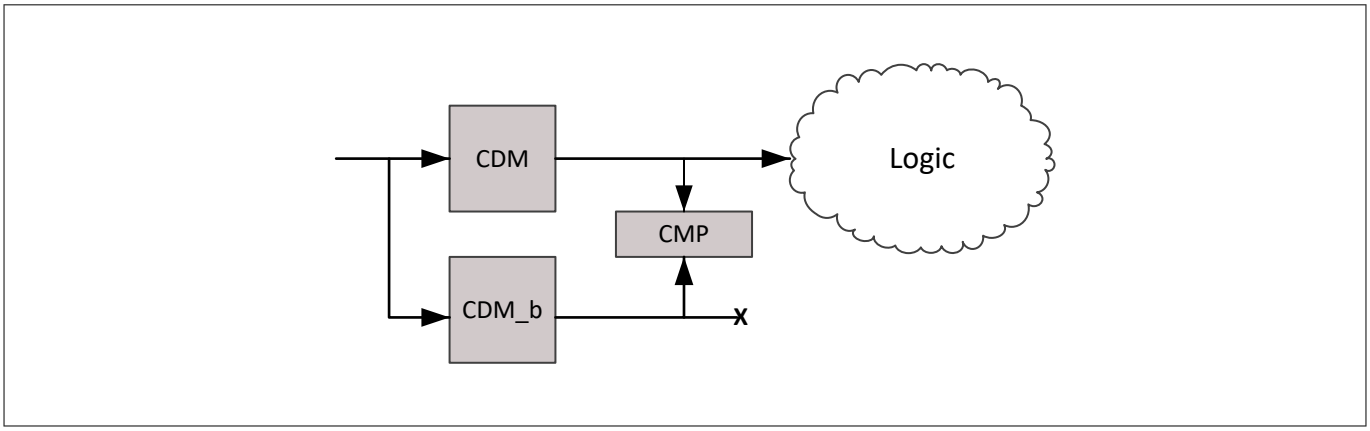

Figure 273 Register space protection architecture

Both register sets are written with the same values when any one of the registers is programmed. A state machine runs periodically traversing the register space, and comparing the values from both register sets. If a difference is detected, it is signaled to the application layer using the dedicated interrupt `ssi_sfty_rs_intr`.

Error injection capability is available for the register duplication logic. This can be enabled with the bit REGP_EI_EN of the SSI Safety Control (SAFETYCR) register. Errors can be injected in each of the registers, which are protected through this logic. The SAFETYCR.REG_SEL field is used to select the register in which error should be injected. Table below lists all the registers that are protected using this feature along with the bitfield setting for SAFETYCR.REG_SEL.

Table 818 Register protected with duplication and field decode values

Register code	Register name
0	CTRLR0: Control 0 Register
1	CTRLR1: Control 1 Register
2	SER: Slave Enable Register

18.3.20 Memory and SFR protection

The access protection unit (APU) provides granular control of the protection settings for a group of registers or memory regions. The APU consists of a set of configurable registers and access checking logic which either allows or disallows each access from the bus interface to the intended target. Disallowed accesses are terminated with an alarm or bus error.

Memory protection

In xSPI the memory mapped region is protected by a maximum of eight APUs, which are represented by set of eight configuration registers RGNx_ACCEN where x= 0 to 7. The region for each APUs is configured by writing the lower and upper addresses of the desired region into the RGNx_ACCEN_RGNLA and RGNx_ACCEN_RGNUA registers respectively. The APU allows configuration software to enable or disable access to each master agent function in the MCU through RGNx_ACCEN_WRA or RGNx_ACCEN_WRB and RGNx_ACCEN_RDA or RGNx_ACCEN_RDB registers. Each master agent function can be configured to have read-only access, write-only access, read and write access or can be disallowed access altogether.

The reset state of the APU is set to enable all master agent functions for read access, and enable only CPU0 and Cerberus for write access. The user has to configure the desired master access for XIP operation after every application reset. If overlapping regions are defined, then an access only needs to be permitted by one of the overlapping regions for it to succeed. Figure below shows APU protection scheme for memory mapped regions.

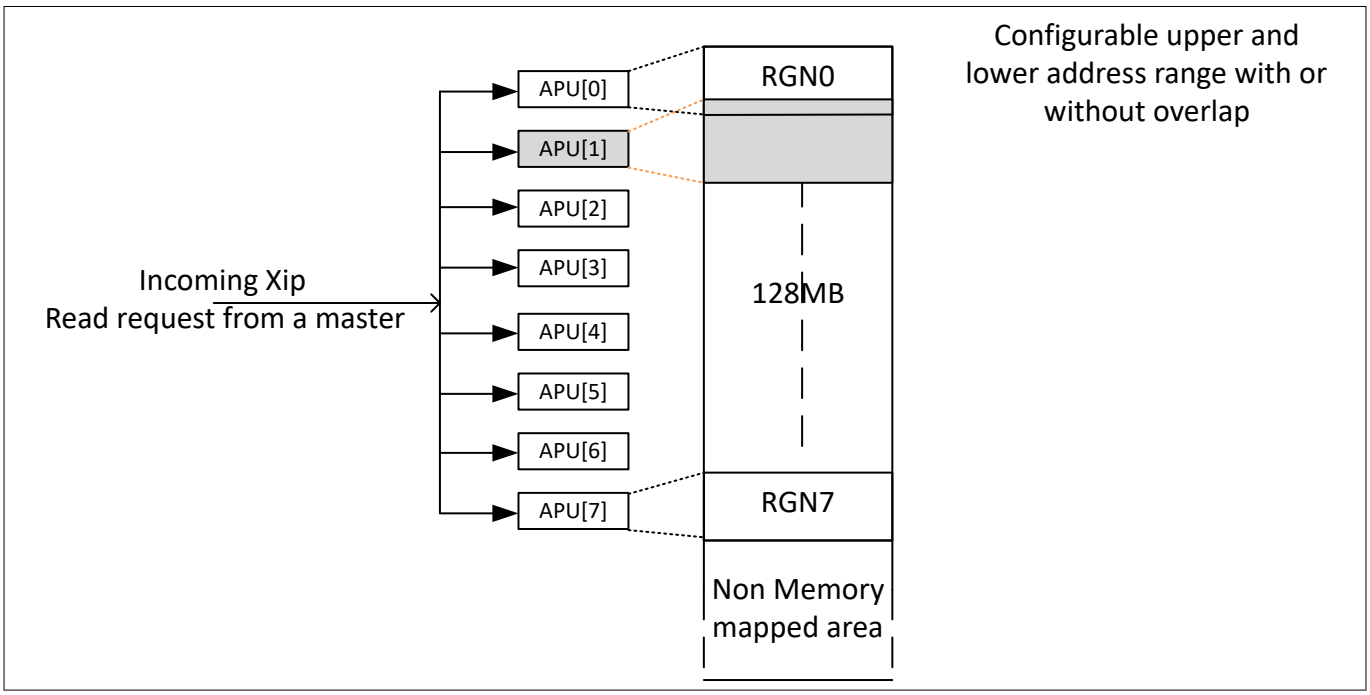

Figure 274 APU for memory mapped region

Register protection

The xSPI Special Function Registers (SFRs) are protected by one APU configuration register set ACCEN. The reset state of the APU is set to enable all master agent functions for read access, and enable only CPU0 and Cerberus for write access.

18.4.1 Register overview - access mode glossary

Table 819 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
APU-PRGNx (x=0-7)	Protection group consisting of registers RGNx_ACCEN_WRA, RGNx_ACCEN_WRB, RGNx_ACCEN_RDA, RGNx_ACCEN_RDB, RGNx_ACCEN_VM, RGNx_ACCEN_PRS, RGNx_ACCEN_RGNLA, RGNx_ACCEN_RGNUA.
PRGNx	Access protection using *APU-PRGNx* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.

18.4.3 Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 00000000_H

Clock Control Register Application Reset value: $0000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

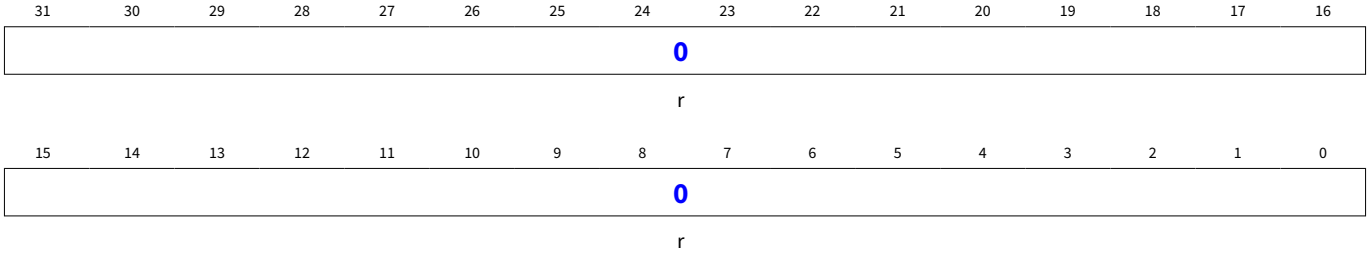
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

18.4.4 OCDS Control and Status Register

OCS Offset address: 00000004_H

OCDS Control and Status Register Debug Reset value: $0000\ 0000_H$

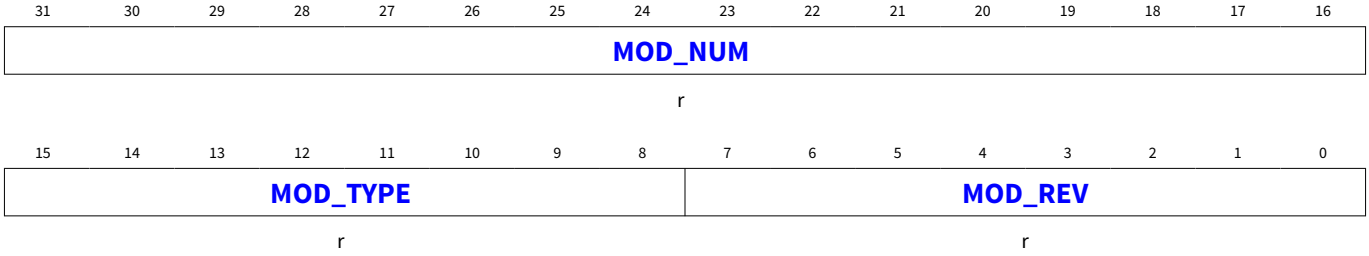


Field	Bits	Type	Description
0	31:0	r	**Reserved** Read as 0; should be written with 0.

18.4.5 Module Identification Register

ID Offset address: 00000008_H

Module Identification Register PowerOn Reset value: $0101\ C002_H$

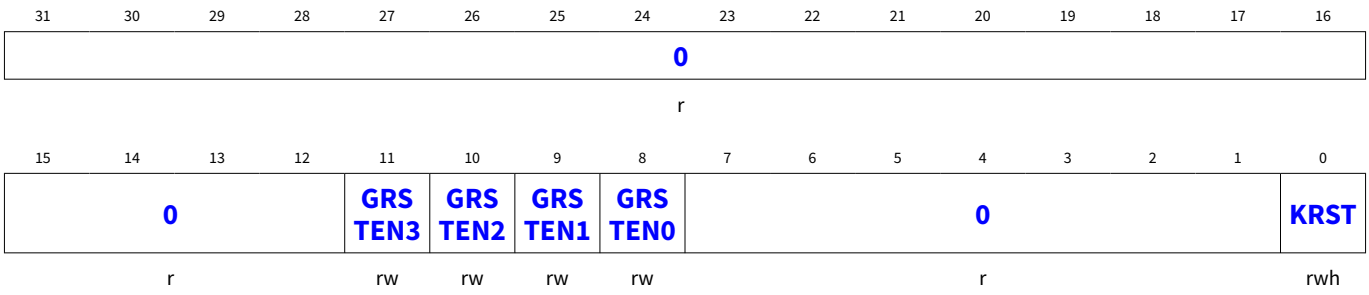


Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number

18.4.6 Reset Control Register A

RST_CTRLA Offset address: $0000000C_H$

Reset Control Register A Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for Global Module Reset Group x** 0_B Global module reset group x does not have any effect 1_B Global module reset group x results in a kernel reset
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

18.4.7 Reset Control Register B

RST_CTRLB Offset address: 00000010_H

Reset Control Register B Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
STATCLR								0							
w								r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															KRST
r															rwh

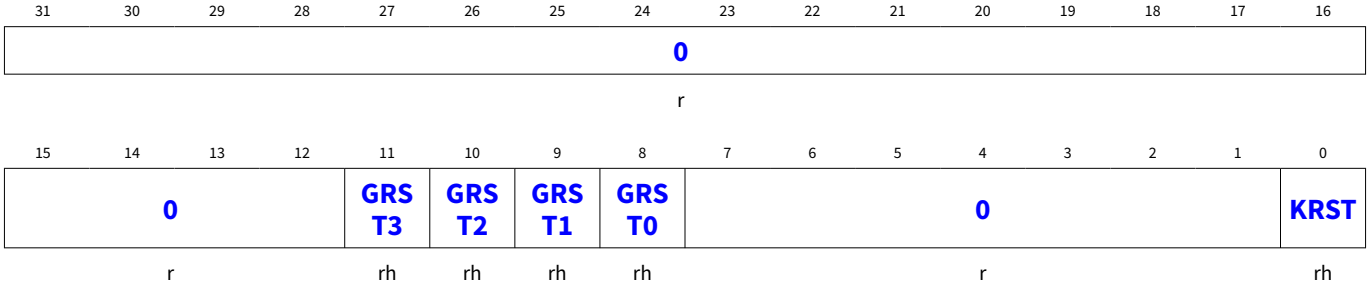
Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
STATCLR	31	w	**Kernel Reset Status Clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits STAT.GRSTx and bit STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

18.4.8 Reset Status Register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: 00000014_H

Reset Status Register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rh	**Kernel reset status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.
GRSTx (x=0-3)	x+8	rh	**Status for global module reset group x** 0_B Reset was not triggered by global reset group x 1_B Reset was triggered by global reset group x
0	7:1, 31:12	r	**Reserved** Read as 0.

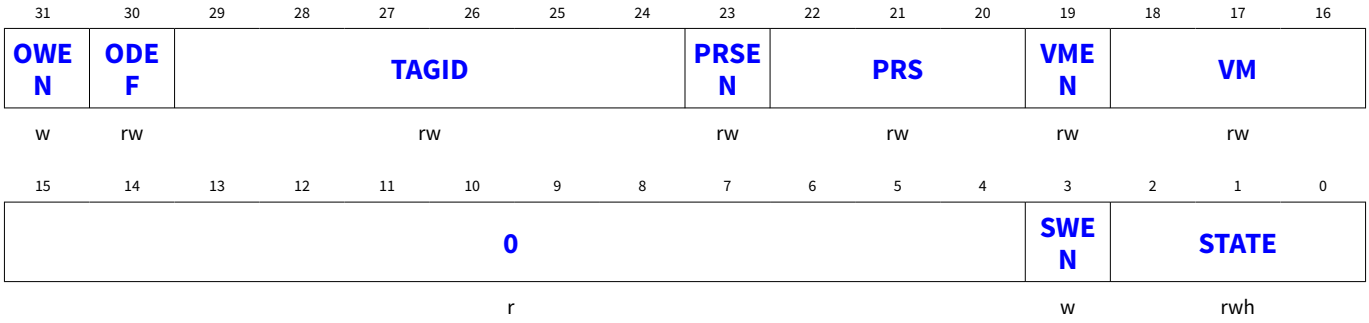
18.4.9 PROT Register Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 00000020_H

PROT Register Endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 821 Access mode restrictions of PROTE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

18.4.10 PROT Register Safe Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 00000024_H

PROT Register Safe Endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												**SWEN**	**STATE**		
r												w	rwh		

Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write

(table continues...)

(continued)

Field	Bits	Type	Description
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 822 Access mode restrictions of PROTSE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

18.4.11 Write access enable register A

This register defines which master agent function TAG identifier (TAG-ID) encodings are enabled or disabled for write accesses to the access protected region.

ACCEN_WRA Offset address: 00000040_H

Write access enable register A Application Reset value: $1000\ 0003_H$

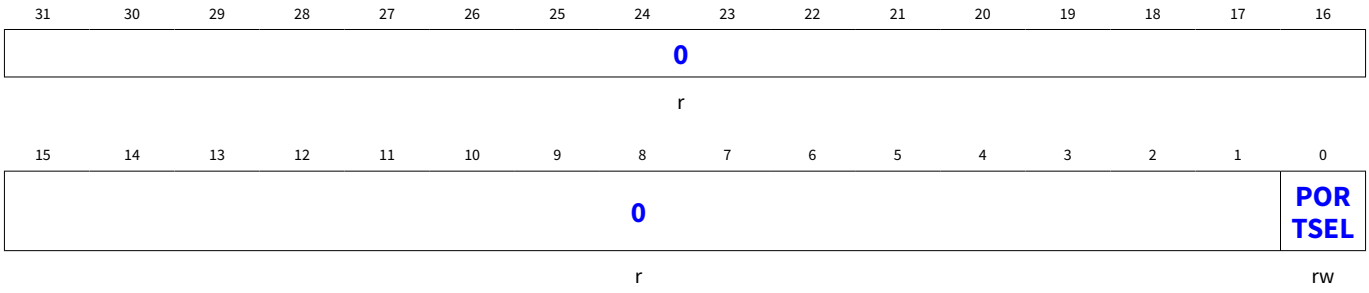
18.4.28 Control Register 2

CTRLR2 Offset address: $0000016C_H$

Control Register 2 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PORTSEL	0	rw	**Port selection** 0_B **Port16**: Port 16 selected High performant xSPI path over HSFAST pads on Port 16 is selected. Supports 1.8 V and 3 V devices in Octal, Quad, Dual and legacy SPI mode. Supports upto 200 MHz DDR/SDR in presence of data strobe and 133 MHz SDR when no data strobe is present. 1_B **GPIO**: Port with GPIO pads selected Selection of port 20. A low performant path over GPIO pads is selected. Supports 3 V devices in Quad, Dual and legacy SPI mode. Supports upto 25 MHz SDR and no data strobe. Note: RXD3/TXD3 signal is routed to port 15. Please see data sheet for exact mapping of all signals generalised as belonging to Port 20
0	31:1	r	**Reserved** Read as 0; should be written with 0.

18.4.29 Control Register 0

This register controls the serial data transfer. It is impossible to write to this register when the xSPI is enabled.

CTRLR0 Offset address: 00000200_H

Control Register 0 Kernel Reset value: $0000\ 481F_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	rw	rw	r	rw		rw	rw	rw		r	rw				

Field	Bits	Type	Description
DFS	4:0	rw	**Data Frame Size** Selects the data frame length. When the data frame size is programmed to be less than 32 bits, the receive data is automatically right-justified by the receive logic, with the upper bits of the receive FIFO zero-padded. You must right-justify transmit data before writing into the transmit FIFO. The transmit logic ignores the upper unused bits when transmitting the data. 00_H **DFS_01_BIT**: Reserved 01_H **DFS_02_BIT**: Reserved 02_H **DFS_03_BIT**: Reserved 03_H **DFS_04_BIT**: 04-bit serial data transfer 04_H **DFS_05_BIT**: 05-bit serial data transfer 05_H **DFS_06_BIT**: 06-bit serial data transfer 06_H **DFS_07_BIT**: 07-bit serial data transfer 07_H **DFS_08_BIT**: 08-bit serial data transfer 08_H **DFS_09_BIT**: 09-bit serial data transfer 09_H **DFS_10_BIT**: 10-bit serial data transfer $0A_H$ **DFS_11_BIT**: 11-bit serial data transfer $0B_H$ **DFS_12_BIT**: 12-bit serial data transfer $0C_H$ **DFS_13_BIT**: 13-bit serial data transfer $0D_H$ **DFS_14_BIT**: 14-bit serial data transfer $0E_H$ **DFS_15_BIT**: 15-bit serial data transfer $0F_H$ **DFS_16_BIT**: 16-bit serial data transfer 10_H **DFS_17_BIT**: 17-bit serial data transfer 11_H **DFS_18_BIT**: 18-bit serial data transfer 12_H **DFS_19_BIT**: 19-bit serial data transfer 13_H **DFS_20_BIT**: 20-bit serial data transfer 14_H **DFS_21_BIT**: 21-bit serial data transfer 15_H **DFS_22_BIT**: 22-bit serial data transfer 16_H **DFS_23_BIT**: 23-bit serial data transfer 17_H **DFS_24_BIT**: 24-bit serial data transfer 18_H **DFS_25_BIT**: 25-bit serial data transfer 19_H **DFS_26_BIT**: 26-bit serial data transfer $1A_H$ **DFS_27_BIT**: 27-bit serial data transfer $1B_H$ **DFS_28_BIT**: 28-bit serial data transfer $1C_H$ **DFS_29_BIT**: 29-bit serial data transfer $1D_H$ **DFS_30_BIT**: 30-bit serial data transfer $1E_H$ **DFS_31_BIT**: 31-bit serial data transfer $1F_H$ **DFS_32_BIT**: 32-bit serial data transfer
RSVD_CTRLR0_5	5	r	**Reserved bits - read as zero**
FRF	7:6	rw	**Frame Format** Selects which serial protocol transfers the data. 00_B **SPI**: Motorola SPI Frame Format 11_B **RESERVED**: Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
SCPH	8	rw	**Serial Clock Phase** Valid when the frame format (FRF) is set to Motorola SPI. The serial clock phase selects the relationship of the serial clock with the slave select signal. When SCPH = 0, data are captured on the first edge of the serial clock. When SCPH = 1, the serial clock starts toggling one cycle after the slave select line is activated, and data are captured on the second edge of the serial clock. 0_B **MIDDLE_BIT**: Serial clock toggles in middle of first bit 1_B **START_BIT**: Serial clock toggles at start of first bit
SCPOL	9	rw	**Serial Clock Polarity** Valid when the frame format (FRF) is set to Motorola SPI. Used to select the polarity of the inactive serial clock, which is held inactive when the DWC_ssi master is not actively transferring data on the serial bus. 0_B **INACTIVE_LOW**: Inactive state of serial clock is low 1_B **INACTIVE_HIGH**: Inactive state of serial clock is high
TMOD	11:10	rw	**Transfer Mode** Selects the mode of transfer for serial communication. This field does not affect the transfer duplicity. Only indicates whether the receive or transmit data are valid. In transmit-only mode, data received from the external device is not valid and is not stored in the receive FIFO memory; it is overwritten on the next transfer. In receive-only mode, transmitted data are not valid. After the first write to the transmit FIFO, the same word is retransmitted for the duration of the transfer. In transmit-and-receive mode, both transmit and receive data are valid. The transfer continues until the transmit FIFO is empty. Data received from the external device are stored into the receive FIFO memory, where it can be accessed by the host processor. 00_B **TX_AND_RX**: Transmit & Receive; Not Applicable in enhanced SPI operating mode 01_B **TX_ONLY**: Transmit only mode; Or Write in enhanced SPI operating mode 10_B **RX_ONLY**: Receive only mode; Or Read in enhanced SPI operating mode 11_B **EEPROM_READ**: EEPROM Read mode; Not Applicable in enhanced SPI operating mode
SRL	13	rw	**Shift Register Loop** Used for testing purposes only. When active, connects the transmit shift register output to the receive shift register input. Can be used in both serial-slave and serial-master modes. 0_B **NORMAL_MODE**: Normal mode operation 1_B **TESTING_MODE**: Test Mode Operation

(table continues...)

(continued)

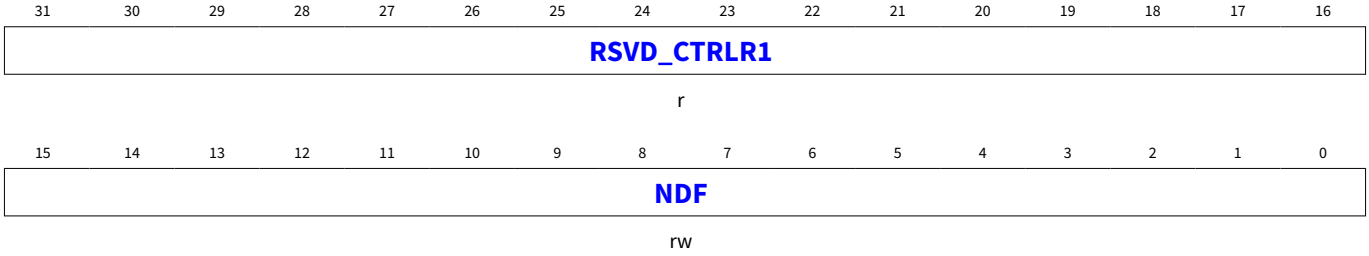
Field	Bits	Type	Description
SSTE	14	rw	**Slave Select Toggle Enable** While operating in SPI mode with clock phase (SCPH) set to 0, this register controls the behavior of the slave select line (ss_o_n) between data frames. 0_B **TOGGLE_DISABLE**: ss_*_n will stay low and sclk will run continuously for the duration of the transfer 1_B **TOGGLE_EN**: ss_*_n line will toggle between consecutive data frames, with the serial clock (sclk) being held to its default value while ss_*_n is high
RSVD_CTRLR0_15	15	r	**Reserved bits - read as zero**
RSVD_CTRLR0_20_21	21:20	r	**Reserved bits - read as zero**
SPI_FRF	23:22	rw	**SPI Frame Format** Selects data frame format for Transmitting or Receiving the data 00_B **SPI_STANDARD**: Standard SPI Format 01_B **SPI_DUAL**: Dual SPI Format 10_B **SPI_QUAD**: Quad SPI Format 11_B **SPI_OCTAL**: Octal SPI Format
SPI_HYPERBUS_EN	24	rw	**SPI Hyperbus Frame format enable** Selects if data frame format for Transmitting/Receiving the data is in Hyperbus mode. 0_B **DISABLE**: Disable Hyperbus Format 1_B **ENABLE**: Enable Hyperbus Format
CLK_LOOP_EN	26	rw	**Clock loop back enable bit** Once this bit is set to 1, xSPI will use looped back clock (mst_sclk_in) to capture read data 0_B **DISABLE**: Disable Clock Loop Back 1_B **ENABLE**: Enable Clock Loop Back
RSVD_CTRLR0_27_31	30:27	r	**Reserved bits - read as zero**
SSI_IS_MST	31	r	**Reserved** Read as 0. xSPI is always master. xSPI in slave mode is not supported.

18.4.30 Control Register 1

This register exists only when the DWC_ssi is configured as a master device. When the DWC_ssi is configured as a serial slave, writing to this location has no effect; reading from this location returns 0. Control register 1 controls the end of serial transfers when in receive-only mode. It is impossible to write to this register when the DWC_ssi is enabled.

CTRLR1 Offset address: 00000204_H

Control Register 1 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
NDF	15:0	rw	**Number of Data Frames** When TMOD = 10_B or TMOD = 11_B , this register field sets the number of data frames to be continuously received by the DWC_ssi. The DWC_ssi continues to receive serial data until the number of data frames received is equal to this register value plus 1, which enables you to receive up to 64 KB of data in a continuous transfer. When SPI_CTRLR0.CLK_STRETCH_EN=1 and TMOD = 01_B, this register field sets the number of data frames to be continously transmitted by DWC_ssi. If the Transmit FIFO goes empty in-between, DWC_ssi masks the serial clock (sclk_out), i.e, keep the sclk_out HIGH or LOW state based on the SCPOL settings and wait for rest of the data until the programmed amount of frames are transferred successfully.
RSVD_CTRLR1	31:16	r	**Reserved bits - read as zero**

18.4.31 xSPI kernel Enable Register

This register enables and disables the DWC_ssi.

SSIENR Offset address: 00000208_H

xSPI kernel Enable Register Kernel Reset value: $0000\ 0001_H$

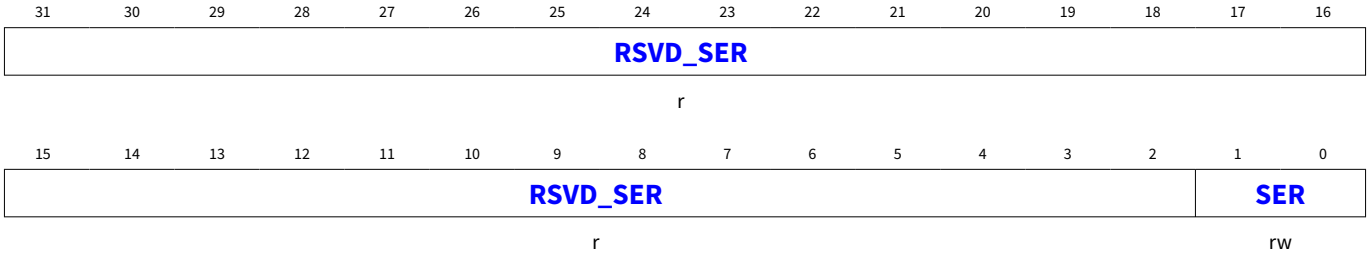
Field	Bits	Type	Description
SSIC_EN	0	rwh	**SSI Enable** Enables and disables all DWC_ssi operations. When disabled, all serial transfers are halted immediately. Transmit and receive FIFO buffers are cleared when the device is disabled. It is impossible to program some of the DWC_ssi control registers when enabled. 0_B **DISABLE**: Disables DWC_ssi 1_B **ENABLED**: Enables DWC_ssi
RSVD_SSIENR	31:1	r	**Reserved bits - read as zero**

18.4.32 Slave Enable Register

The register enables the individual slave select output lines from the DWC_ssi master. Up to 2 slave-select output pins are available on the xSPI master. You cannot write to this register when DWC_ssi is busy and when SSIC_EN = 1.

SER Offset address: 00000210_H

Slave Enable Register Kernel Reset value: $0000\ 0001_H$



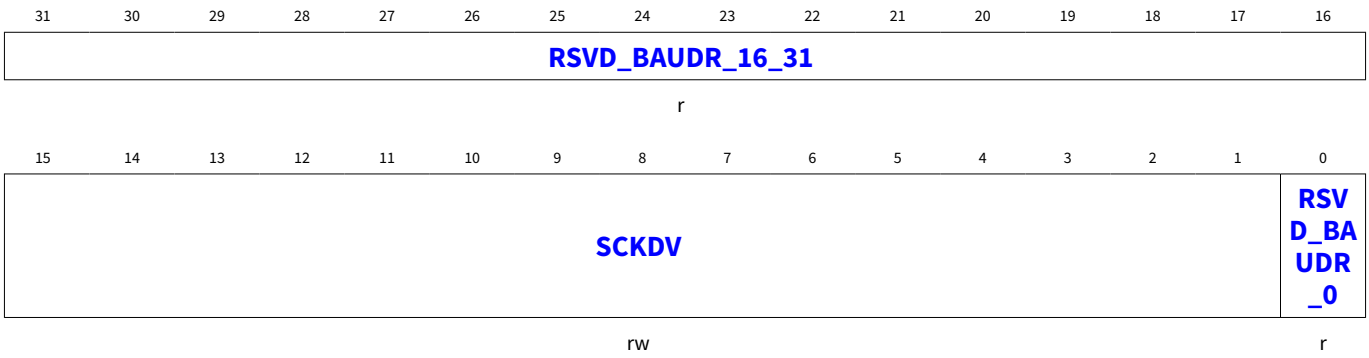
Field	Bits	Type	Description
SER	1:0	rw	**Slave Select Enable Flag** Each bit in this register corresponds to a slave select line (ss_x_n) from the DWC_ssi master. When a bit in this register is set (1), the corresponding slave select line from the master is activated when a serial transfer begins. It should be noted that setting or clearing bits in this register have no effect on the corresponding slave select outputs until a transfer is started. Before beginning a transfer, you should enable the bit in this register that corresponds to the slave device with which the master wants to communicate. When not operating in broadcast mode, only one bit in this field should be set.
RSVD_SER	31:2	r	**Reserved bits - read as zero**

18.4.33 Baud Rate Select

The register derives the frequency of the serial clock that regulates the data transfer. The 15-bit wide bit-field along with bit 0 which is always set to 0, defines the ssi_clk divider value. It is impossible to write to this register when the xSPI is enabled.

BAUDR Offset address: 00000214_H

Baud Rate Select Kernel Reset value: $0000\ 0004_H$



Field	Bits	Type	Description
RSVD_BAUDR_0	0	r	**Reserved bits - read as zero**
SCKDV	15:1	rw	**SSI Clock Divider** The LSB of the BAUDR register is always a 0, which ensures that an even value is held in this register only. If the value of this bitfield is 0, the serial output clock (sclk_out) is disabled. The frequency of the sclk_out is derived from the following equation: Fsclk_out = Fssi_clk/BAUDR where BAUDR is any even value between 2 and 65534 (BAUDR = SCKDV*2). For example: for Fssi_clk = 3.6864MHz and BAUDR =2 Fsclk_out = 3.6864/2 = 1.8432MHz
RSVD_BAUDR_16_31	31:16	r	**Reserved bits - read as zero**

18.4.34 Transmit FIFO Threshold Level

This register controls the threshold value for the transmit FIFO memory..

TXFTLR Offset address: 00000218_H

Transmit FIFO Threshold Level Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSVD_TXFTHR									TXFTHR						
r									rw						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD_TXFTLR												TFT			
r												rw			

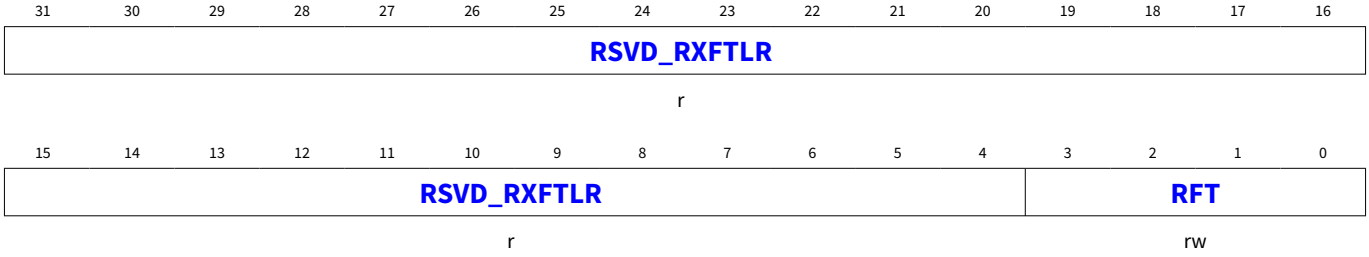
Field	Bits	Type	Description
TFT	3:0	rw	**Transmit FIFO Threshold** Controls the level of entries (or below) at which the transmit FIFO controller triggers an interrupt. The FIFO depth is 16; this register is sized to the number of address bits needed to access the FIFO. If you attempt to set this value greater than or equal to the depth of the FIFO, this field is not written and retains its current value. When the number of transmit FIFO entries is less than or equal to this value, the transmit FIFO empty interrupt is triggered.
RSVD_TXFTLR	15:4	r	**Reserved bits - read as zero**
TXFTHR	22:16	rw	**Transfer start FIFO level** Used to control the level of entries in transmit FIFO above which transfer will start on serial line. This register can be used to ensure that sufficient data is present in transmit FIFO before starting a write operation on serial line. In Internal DMA mode, this field sets the minimum amount of data entries present in the FIFO after which DWC_ssi starts the transfer. This field is valid only for Master mode of operation.
RSVD_TXFTHR	31:23	r	**Reserved bits - read as zero**

18.4.35 Receive FIFO Threshold Level

This register controls the threshold value for the receive FIFO memory..

RXFTLR Offset address: $0000021C_H$

Receive FIFO Threshold Level Kernel Reset value: $0000\ 0000_H$



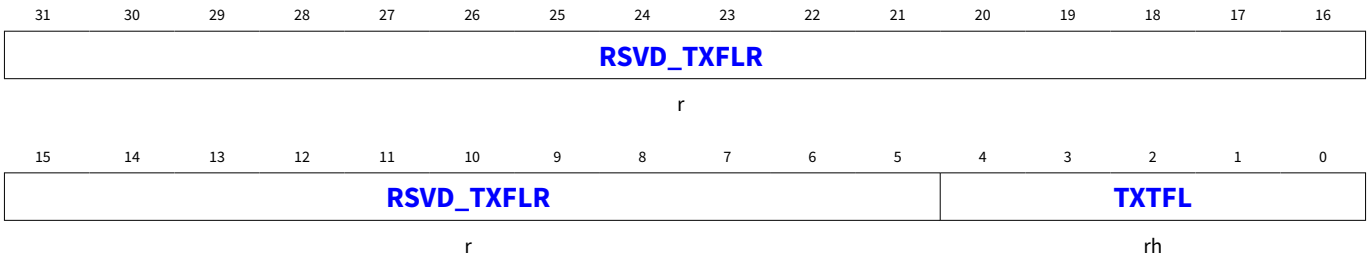
Field	Bits	Type	Description
RFT	3:0	rw	**Receive FIFO Threshold** Controls the level of entries (or above) at which the receive FIFO controller triggers an interrupt. The FIFO depth is 16. This register is sized to the number of address bits needed to access the FIFO. If you attempt to set this value greater than the depth of the FIFO, this field is not written and retains its current value. When the number of receive FIFO entries is greater than or equal to this value + 1, the receive FIFO full interrupt is triggered.
RSVD_RXFTLR	31:4	r	**Reserved bits - read as zero**

18.4.36 Transmit FIFO Level Register

This register contains the number of valid data entries in the transmit FIFO memory.

TXFLR Offset address: 00000220_H

Transmit FIFO Level Register Kernel Reset value: $0000\ 0000_H$



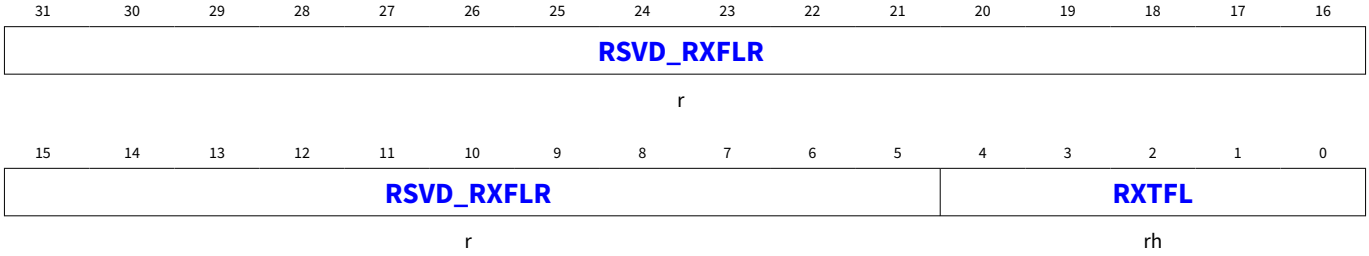
Field	Bits	Type	Description
TXTFL	4:0	rh	**Transmit FIFO Level** Contains the number of valid data entries in the transmit FIFO.
RSVD_TXFLR	31:5	r	**Reserved bits - read as zero**

18.4.37 Receive FIFO Level Register

This register contains the number of valid data entries in the receive FIFO memory. This register can be read at any time.

RXFLR Offset address: 00000224_H

Receive FIFO Level Register Kernel Reset value: $0000\ 0000_H$



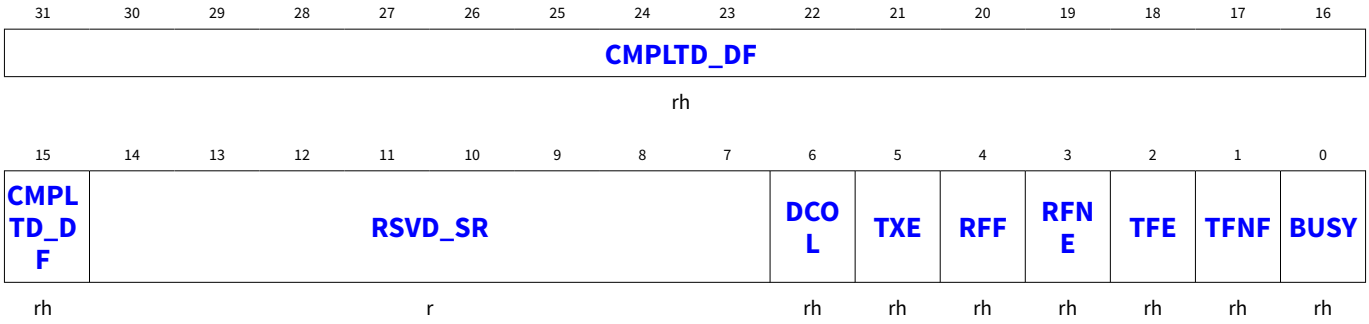
Field	Bits	Type	Description
RXTFL	4:0	rh	**Receive FIFO Level** Contains the number of valid data entries in the receive FIFO.
RSVD_RXFLR	31:5	r	**Reserved bits - read as zero**

18.4.38 Status Register

This is a read-only register used to indicate the current transfer status, FIFO status, and any transmission/ reception errors that may have occurred. The status register may be read at any time. None of the bits in this register request an interrupt.

SR Offset address: 00000228_H

Status Register Kernel Reset value: $0000\ 0006_H$



Field	Bits	Type	Description
BUSY	0	rh	**SSI Busy Flag** When set, indicates that a serial transfer is in progress; when cleared indicates that the DWC_ssi is idle or disabled. 0_B **INACTIVE**: DWC_ssi is idle or disabled 1_B **ACTIVE**: DWC_ssi is actively transferring data

(table continues...)

(continued)

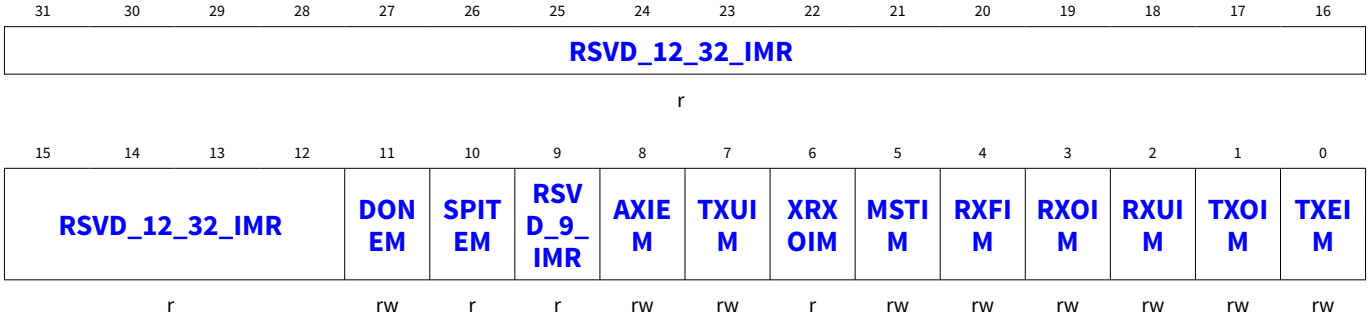
Field	Bits	Type	Description
TFNF	1	rh	**Transmit FIFO Not Full** Set when the transmit FIFO contains one or more empty locations, and is cleared when the FIFO is full. 0_B **FULL**: Tx FIFO is full 1_B **NOT_FULL**: Tx FIFO is not Full
TFE	2	rh	**Transmit FIFO Empty** When the transmit FIFO is completely empty, this bit is set. When the transmit FIFO contains one or more valid entries, this bit is cleared. This bit field does not request an interrupt. 0_B **NOT_EMPTY**: Transmit FIFO is not empty 1_B **EMPTY**: Transmit FIFO is empty
RFNE	3	rh	**Receive FIFO Not Empty** Set when the receive FIFO contains one or more entries and is cleared when the receive FIFO is empty. This bit can be polled by software to completely empty the receive FIFO. 0_B **EMPTY**: Receive FIFO is empty 1_B **NOT_EMPTY**: Receive FIFO is not empty
RFF	4	rh	**Receive FIFO Full** When the receive FIFO is completely full, this bit is set. When the receive FIFO contains one or more empty location, this bit is cleared. 0_B **NOT_FULL**: Receive FIFO is not full 1_B **FULL**: Receive FIFO is full
TXE	5	rh	**Transmission Error** Set if the transmit FIFO is empty when a transfer is started. This bit can be set only when the DWC_ssi is configured as a slave device. Data from the previous transmission is resent on the txd line. This bit is cleared when read. 0_B **NO_ERROR**: No Error 1_B **TX_ERROR**: Transmission Error
DCOL	6	rh	**Data Collision Error** Relevant only when the DWC_ssi is configured as a master device. This bit will be set if ss_in_n input is asserted by other master, when the DWC_ssi master is in the middle of the transfer. This informs the processor that the last data transfer was halted before completion. This bit is cleared when read. 0_B **NO_ERROR_CONDITION**: No Error 1_B **TX_COLLISION_ERROR**: Transmit Data Collision Error
RSVD_SR	14:7	r	**Reserved bits - read as zero**
CMPLTD_DF	31:15	rh	**Completed Data frames** This field indicates total data frames transferred in the previous internal DMA transfer

18.4.39 Interrupt Mask Register

This register masks or enables all interrupts generated by the xSPI.

IMR Offset address: 0000022C$_H$

Interrupt Mask Register Kernel Reset value: 0000 09BE$_H$



Field	Bits	Type	Description
TXEIM	0	rw	**Transmit FIFO Empty Interrupt Mask** 0_B **MASKED**: ssi_txe_intr interrupt is masked 1_B **UNMASKED**: ssi_txe_intr interrupt is not masked
TXOIM	1	rw	**Transmit FIFO Overflow Interrupt Mask** 0_B **MASKED**: ssi_txo_intr interrupt is masked 1_B **UNMASKED**: ssi_txo_intr interrupt is not masked
RXUIM	2	rw	**Receive FIFO Underflow Interrupt Mask** 0_B **MASKED**: ssi_rxu_intr interrupt is masked 1_B **UNMASKED**: ssi_rxu_intr interrupt is not masked
RXOIM	3	rw	**Receive FIFO Overflow Interrupt Mask** 0_B **MASKED**: ssi_rxo_intr interrupt is masked 1_B **UNMASKED**: ssi_rxo_intr interrupt is not masked
RXFIM	4	rw	**Receive FIFO Full Interrupt Mask0** - ssi_rxf_intr interrupt is masked 1 - ssi_rxf_intr interrupt is not masked 0_B **MASKED**: ssi_rxf_intr interrupt is masked 1_B **UNMASKED**: ssi_rxf_intr interrupt is not masked
MSTIM	5	rw	**Multi-Master Contention Interrupt Mask** 0_B **MASKED**: ssi_mst_intr interrupt is masked 1_B **UNMASKED**: ssi_mst_intr interrupt is not masked
XRXOIM	6	r	**XIP Receive FIFO Overflow Interrupt Mask** 0_B **MASKED**: ssi_xrxo_intr interrupt is masked 1_B **UNMASKED**: ssi_xrxo_intr interrupt is not masked
TXUIM	7	rw	**Transmit FIFO Underflow Interrupt Mask** 0_B **MASKED**: ssi_txu_intr interrupt is masked 1_B **UNMASKED**: ssi_txu_intr interrupt is not masked

(table continues...)

(continued)

Field	Bits	Type	Description

r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SSIC_COMP_VERSION															
r															

Field	Bits	Type	Description
SSIC_COMP_VERSION	31:0	r	**Contains the hex representation of the Synopsys component version** Consists of ASCII value for each number in the version, followed by *. For example 31_30_33_2A represents the version 1.03*.

18.4.51 xSPI Data Register i

The DWC_ssi data register is a 32-bit read/write buffer for the transmit/receive FIFOs. When the register is read, data in the receive FIFO buffer is accessed. When it is written to, data are moved into the transmit FIFO buffer; a write can occur only when SSIC_EN = 1. FIFOs are reset when SSIC_EN = 0. Note The DR register in the xSPI occupies thirty-six 32-bit address locations of the memory map to facilitate AHB burst transfers. Writing to any of these address locations has the same effect as pushing the data from the AHB bus into the transmit FIFO. Reading from any of these locations has the same effect as popping data from the receive FIFO onto the AHB bus. The FIFO buffers on the DWC_ssi are not addressable.

DRi (i=0-35) Offset address: 00000260_H+i*4

xSPI Data Register i Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD0_RX_SAMPLE_DLY								RSD							
r								rw							

Field	Bits	Type	Description
RSD	7:0	rw	**Receive Data (rxd) Sample Delay** This register is used to delay the sample of the rxd input port. Each value represents a single ssi_clk delay on the sample of rxd. Note; If this register is programmed with a value exceeding 4 (which is the depth of the internal shift registers), zero delay will be applied to the rxd sample.
RSVD0_RX_SAMPLE_DLY	15:8	r	**Reserved bits - read as zero**
SE	16	rw	**Receive Data (rxd) Sampling Edge** This register is used to decide the sampling edge for RXD signal with ssi_clk. This bit is set to 1 then negative edge of ssi_clk will be used to sample the incoming data, otherwise positive edge will be used for sampling.
RSVD1_RX_SAMPLE_DLY	31:17	r	**Reserved bits - read as zero**

18.4.53 SPI_CTRLR0 - SPI Control Register

This register is used to control the serial data transfer in enhanced SPI mode of operation. The register is relevant only when either CTRLR0.SPI_DWS_EN is set to 1 or CTRLR0.SPI_FRF is set to either 01_B or 10_B or 11_B. It is not possible to write to this register when the DWC_ssi is enabled (SSIC_EN=1).

SPI_CTRLR0 Offset address: 000002F4$_H$

SPI_CTRLR0 - SPI Control Register Kernel Reset value: 0800 0A10$_H$

rw					r	rw		rw	r	rw				rw	

Field	Bits	Type	Description
TRANS_TYPE	1:0	rw	**Address and instruction transfer format** Selects whether DWC_ssi will transmit instruction/address either in Standard SPI mode or the SPI mode selected in CTRLR0.SPI_FRF field. 00_B **TT0**: Instruction and Address will be sent in Standard SPI Mode 01_B **TT1**: Instruction will be sent in Standard SPI Mode and Address will be sent in the mode specified by CTRLR0.SPI_FRF 10_B **TT2**: Both Instruction and Address will be sent in the mode specified by SPI_FRF 11_B **TT3**: Reserved
ADDR_L	5:2	rw	**This bit defines Length of Address to be transmitted** Only after this much bits are programmed in to the FIFO the transfer can begin. 0_H **ADDR_L0**: No Address 1_H **ADDR_L4**: 4 bit Address length 2_H **ADDR_L8**: 8 bit Address length 3_H **ADDR_L12**: 12 bit Address length 4_H **ADDR_L16**: 16 bit Address length 5_H **ADDR_L20**: 20 bit Address length 6_H **ADDR_L24**: 24 bit Address length 7_H **ADDR_L28**: 28 bit Address length 8_H **ADDR_L32**: 32 bit Address length 9_H **ADDR_L36**: 36 bit Address length A_H **ADDR_L40**: 40 bit Address length B_H **ADDR_L44**: 44 bit Address length C_H **ADDR_L48**: 48 bit Address length D_H **ADDR_L52**: 52 bit Address length E_H **ADDR_L56**: 56 bit Address length F_H **ADDR_L60**: 60 bit Address length
RSVD_SPI_CTRLR0_6	6	r	**Reserved bits - read as zero**

(table continues...)

(continued)

Field	Bits	Type	Description
XIP_MD_BIT_EN	7	rw	**Mode bits enable in XIP mode** If this bit is set to 1, then in XIP mode of operation DWC_ssi will insert mode bits after the address phase. These bits are set in register XIP_MODE_BITS register. The length of mode bits is always set to 8 bits.
INST_L	9:8	rw	**Dual/Quad/Octal mode instruction length in bits** 00_B **INST_L0**: No Instruction 01_B **INST_L4**: 4 bit Instruction length 10_B **INST_L8**: 8 bit Instruction length 11_B **INST_L16**: 16 bit Instruction length
RSVD_SPI_CTRLR0_10	10	r	**Reserved bits - read as zero**
WAIT_CYCLES	15:11	rw	**Wait cycles** Wait cycles in Dual/Quad/Octal mode between control frames transmit and data reception. Specified as number of SPI clock cycles.
SPI_DDR_EN	16	rw	**SPI DDR Enable bit** This will enable Dual-data rate transfers in Dual/Quad/Octal frame formats of SPI.
INST_DDR_EN	17	rw	**Instruction DDR Enable bit** This will enable Dual-data rate transfer for Instruction phase.
SPI_RXDS_EN	18	rw	**Read data strobe enable bit** Once this bit is set to 1 DWC_ssi will use Read data strobe (rxds) to capture read data.
XIP_DFS_HC	19	rw	**Fix DFS for XIP transfers** If this bit is set to 1 then data frame size for XIP transfers will be fixed to the programmed value in CTRLR0.DFS, the number of data frames to fetch will be determined by SIZE and BURST signals received on the AHB bus. If this bit is set to 0 then data frame size and number of data frames to fetch will be determined by the SIZE and BURST signals on the AHB bus
XIP_INST_EN	20	rw	**XIP instruction enable bit** If this bit is set to 1 then XIP transfers will also have instruction phase. The instruction op-codes will be chosen from XIP_INCR_INST or XIP_WRAP_INST registers bases on AHB transfer type.
SSIC_XIP_CONT_XFER_EN	21	rw	**Enable continuous transfer in XIP mode** If this bit is set to 1 then continuous transfer mode in XIP will be enabled, in this mode DWC_ssi will keep slave selected until a non-XIP transfer is detected on the AHB interface.
RSVD_SPI_CTRLR0_22_23	23:22	r	**Reserved bits - read as zero**
SPI_DM_EN	24	rw	**SPI data mask enable bit** When this bit is enabled, the txd_dm signal is used to mask the data on the txd data line.

(table continues...)

(continued)

Field	Bits	Type	Description
SPI_RXDS_SIG_EN	25	rw	**Enable rxds signaling during address and command phase of Hypebus transfer** This bit enables RXDS signaling by Hyperbus slave devices during Command-Address (CA) phase. If the rxds signal is set to 1 during the CA phase of transfer, DWC_ssi transmits (2*SPI_CTRLR0.WAIT_CYCLES-1) wait cycles after the address phase is complete.
XIP_MBL	27:26	rw	**XIP Mode bits length** Sets the length of mode bits in XIP mode of operation. These bits are valid only when SPI_CTRLR0.XIP_MD_BIT_EN is set to 1. 00_B **MBL_2**: Mode bits length equal to 2 01_B **MBL_4**: Mode bits length equal to 4 10_B **MBL_8**: Mode bits length equal to 8 11_B **MBL_16**: Mode bits length equal to 16
RSVD_SPI_CTRLR0_28	28	r	**Reserved bits - read as zero**
XIP_PREFETCH_EN	29	r	**Reserved bits - read as zero**
CLK_STRETCH_EN	30	rw	**Enables clock stretching capability in SPI transfers** In case of write, if the FIFO becomes empty DWC_ssi will stretch the clock until FIFO has enough data to continue the transfer. In case of read, if the receive FIFO becomes full DWC_ssi will stop the clock until data has been read from the FIFO.
RSVD_SPI_CTRLR0	31	r	**Reserved bits - read as zero**

18.4.54 DDR_DRIVE_EDGE - Transmit Drive Edge Register

This register is used to control the driving edge in DDR mode. It is not possible to write to this register when the DWC_ssi is enabled (SSIC_EN=1).

DDR_DRIVE_EDGE Offset address: $000002F8_H$

DDR_DRIVE_EDGE - Transmit Drive Edge Register Kernel Reset value: $0000\ 0000_H$

RSVD_DDR_DRIVE_EDGE								TDE							
r								rw							

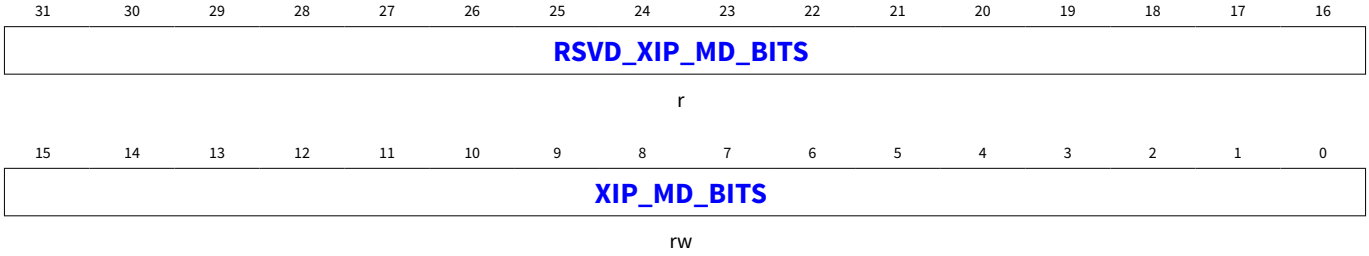
Field	Bits	Type	Description
TDE	7:0	rw	**TXD Drive edge register which decided the driving edge of transmit data** The maximum value of this register is = (BAUDR/2) -1.
RSVD_DDR_DRIVE_EDGE	31:8	r	**Reserved bits - read as zero**

18.4.55 eXecute in Place - Mode bits

This register carries the mode bits which are sent in the XIP mode of operation after address phase. This register cannot be written when xSPI is enabled, i.e, when SSIENR=1.

XIP_MODE_BITS Offset address: 000002FC$_H$

eXecute in Place - Mode bits Kernel Reset value: 0000 0000$_H$



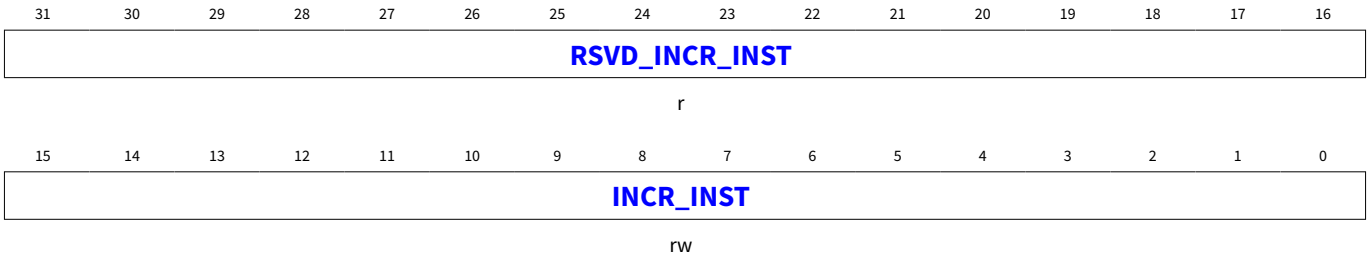
Field	Bits	Type	Description
XIP_MD_BITS	15:0	rw	**XIP mode bits to be sent after address phase of XIP transfer**
RSVD_XIP_MD_BITS	31:16	r	**Reserved bits - read as zero**

18.4.56 XIP_INCR_INST - XIP INCR transfer opcode

This register is used to store the instruction op-code to be used in INCR transactions when the same is requested on the slave interface. It is not possible to write to this register when the DWC_ssi is enabled (SSIC_EN=1).

XIP_INCR_INST Offset address: 00000300$_H$

XIP_INCR_INST - XIP INCR transfer opcode Kernel Reset value: 0000 0001$_H$



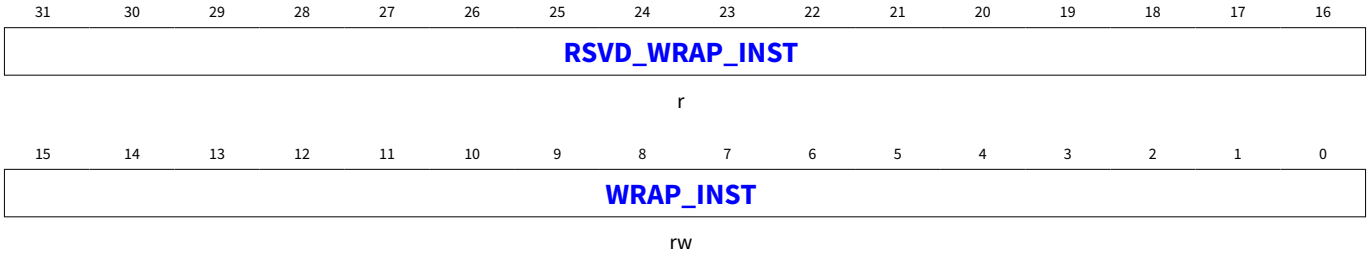
Field	Bits	Type	Description
INCR_INST	15:0	rw	**XIP INCR transfer opcode** When SPI_CTRLR0.XIP_INST_EN bit is set to 1, DWC_ssi sends instruction for all XIP transfers, this register field stores the instruction op-code to be sent when an INCR type transfer is requested on AHB bus. The number of bits to be send in instruction phase is determined by SPI_CTRL0.INST_L field.
RSVD_INCR_INST	31:16	r	**Reserved bits - read as zero**

18.4.57 XIP WRAP transfer opcode

This Register is valid only when SSIC_XIP_EN is equal to 1. This register is used to store the instruction op-code to be used in WRAP transactions when the same is requested on AHB interface. It is not possible to write to this register when the DWC_ssi is enabled (SSIC_EN=1).

XIP_WRAP_INST Offset address: 00000304_H

XIP WRAP transfer opcode Kernel Reset value: $0000\ 0002_H$



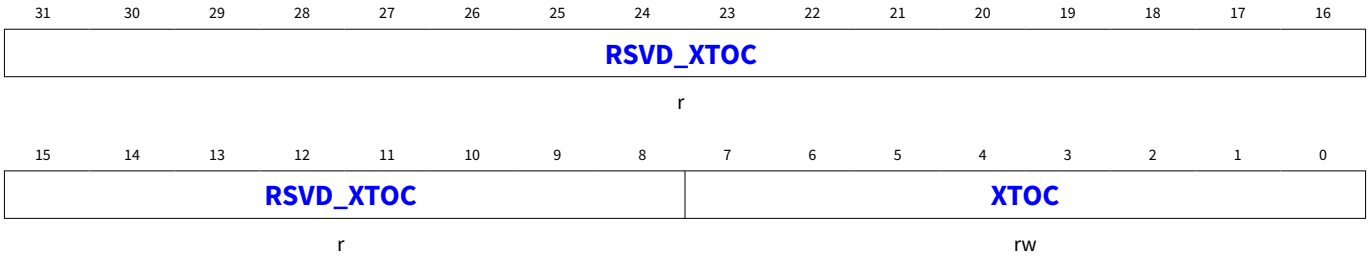
Field	Bits	Type	Description
WRAP_INST	15:0	rw	**XIP WRAP transfer opcode** When SPI_CTRLR0.XIP_INST_EN bit is set to 1, DWC_ssi sends instruction for all XIP transfers, this register field stores the instruction op-code to be sent when an WRAP type transfer is requested at the slave interface. The number of bits to be send in instruction phase is determined by SPI_CTRL0.INST_L field.
RSVD_WRAP_INST	31:16	r	**Reserved bits - read as zero**

18.4.58 XIP time out register for continuous transfers

XIP count down register for continuous mode. The counter is used to de-select the slave during continuous transfer mode. It is not possible to write to this register when the DWC_ssi is enabled (SSIC_EN=1).

XIP_CNT_TIME_OUT Offset address: 00000314_H

XIP time out register for continuous transfers Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
XTOC	7:0	rw	**XIP time out value in terms of Fsri/2** Once slave is selected in continuous XIP mode this counter will be used to de-select the slave, if there is no request for the time specified in the counter.
RSVD_XTOC	31:8	r	**Reserved bits - read as zero**

18.4.59 SPI Device Register

Field	Bits	Type	Description
RSVD_SAFETYCR_0	0	r	**Reserved bit - read as zero**
PAR_MODE	1	r	**Parity Mode** This bit selects the even or odd parity scheme for the Parity Protection feature. This covers data path, AXI Master interface and AHB slave interface parity feature. 0_B **EVEN**: Even Parity Check for Parity Protection feature 1_B **ODD**: Odd Parity Check for Parity Protection feature
FSM_PAR_EN	2	rw	**FSM Parity Enable** This bit enables parity checker for all FSM state variables in DWC_ssi. 0_B **DISABLE**: Disable FSM Parity Protection 1_B **ENABLE**: Enable FSM Parity Protection
RSVD_SAFETYCR_3_16	15:3	r	**Reserved bits - read as zero**

(table continues...)

(continued)

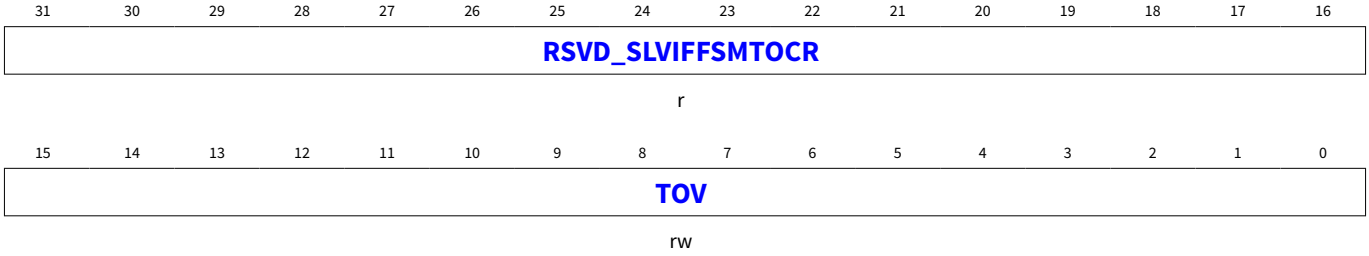
Field	Bits	Type	Description
FSM_EI_EN	16	rwh	**FSM Error Insertion Enable** This bit enables error injection in FSM selected using FSM_SEL programming field. Once this bit is enabled DWC_ssi injects error in DWC_ssi FSM safety mechanism. This bit will be cleared by hardware once the error interrupt is generated. 0_B **DISABLE**: Disable FSM Error Insertion 1_B **ENABLE**: Enable FSM Error Insertion
FSM_EI_TYPE	17	rw	**FSM Error Insertion Type** This bit selects the type of FSM safety feature should be used for error injection. 0_B **TIMEOUT**: FSM Timeout Error Insertion 1_B **PARITY**: FSM Parity Error Insertion
FSM_SEL	19:18	rw	**Select FSM in which the error injection should be enabled** 00_B **SSIM**: DWC_ssi Master FSM 01_B **SLVIF**: Slave Interface FSM 10_B **AXIM**: AXI Master FSM 11_B **DMA**: DMA FSM
RSVD_SAFETYCR_20	20	r	**Reserved bits - read as zero**
DPPG_EI_EN	21	rwh	**Data path parity Error Insertion Enable** Insert data path parity error in 1st parity generator. This bit will be cleared by hardware once the error interrupt is generated. 0_B **DISABLE**: Disable Data Path Parity Error Insertion 1_B **ENABLE**: Enable Data Path Parity Error Insertion
REGP_EI_EN	22	rwh	**Register space protection Error insertion Enable** Insert error in register space protection logic. The error will be injected in the register copy of the selected register using REG_SEL field. This bit will be cleared by hardware once the error interrupt is generated. 0_B **DISABLE**: Disable Register space Error Insertion 1_B **ENABLE**: Enable Register space Error Insertion
REG_SEL	26:23	rw	**Register select for error injection** This bit will select the register in which the error injection should be done. 0_H **CTRLR0**: Control 0 Register 1_H **CTRLR1**: Control 1 Register 2_H **SER**: Slave Enable Register 3_H **BAUDR**: Baud Rate Register 4_H **DMACR**: DMA Control Register 5_H **RX_SAMPLE_DLY**: RX Sample Delay Register 6_H **SPI_CTRLR0**: SPI Control Register 9_H **SAFETYCR**: Safety Control Register **others,** Reserved
RSVD_SAFETYCR_27_31	31:27	r	**Reserved bits - read as zero**

18.4.65 Slave interface Clock domain FSM time out register

This register contains control bits to enable AHB slave clock domain timeout features. The AHB clock domain runs on $F_{SRI/2}$. Please refer to section FSM protection for more details

SLVIFFSMTOCR Offset address: 00000384_H

Slave interface Clock domain FSM time out register Kernel Reset value: $0000\ 0000_H$



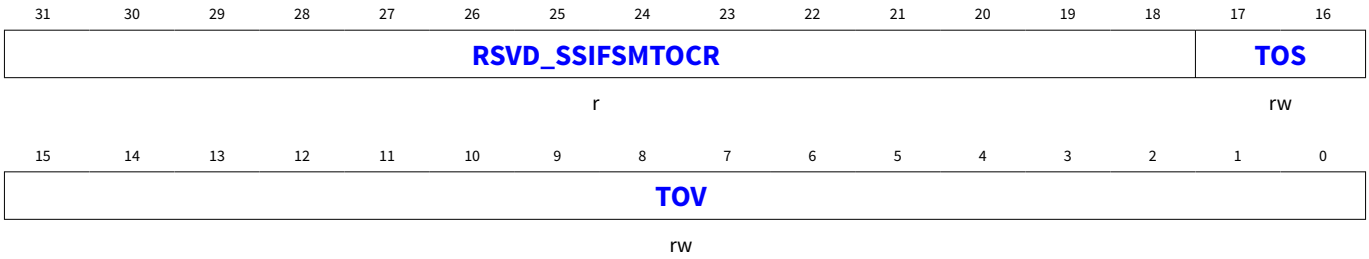
Field	Bits	Type	Description
TOV	15:0	rw	**Time Out Value** This bit sets the time out value for AHB slave clock domain FSM. If FSM state does not reach an IDLE state in given amount of AHB clock cycles, the corresponding error interrupt is asserted.
RSVD_SLVIFFSMTOCR	31:16	r	**Reserved bits - read as zero**

18.4.66 xSPI kernel Clock domain FSM time out register

This register controls the core clock domain FSM timeout features. The SSI clock domain runs on SSI_clk. Please refer to section FSM protection for more details

SSIFSMTOCR Offset address: 00000388_H

xSPI kernel Clock domain FSM time out register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TOV	15:0	rw	**Time Out Value** This bit sets the time out value for DWC_ssi core clock domain FSMs. If FSM state does not reach an IDLE state in the given time period, the corresponding error interrupt is asserted.

(table continues...)

18.6 References

1. JEDEC Expanded Serial Peripheral Interface (xSPI) for Non Volatile Memory Devices, JESD251C, May 2022

18.7 xSPI revision history

Reference	Description of change(s)
Date range: 2024-08-17 to 2025-01-31	
Data transfers	• Added note related to data frames with DFS greater than 8-bit
Registers	• Corrected bit-field access type to rh or rwh for all hardware writable register bit-fields
Safety Control register	• Removed enumerations XIP_CTRL and XIP_SER from REG_SEL bit-field description for error injection as these registers do not exist
SPI_CTRLR0 - SPI Control Register	• Set the description of XIP_PREFETCH_EN bit-field as this feature is not available

18.8 TC4Dx xSPI information

18.8.1 TC4Dx xSPI configuration

There are no deviations from the generic specification.

18.8.2 TC4Dx xSPI features

There are no deviations from the generic specification.

18.8.3 TC4Dx xSPI functional description

The TC4D device does not support XIP write feature.

Functional restrictions for back-to-back transfers

When XSPI does back-to-back transfers without disabling the IP (by programming SSIENR register to 0). Serial FSM timeout counter does not reset to value of 0 between the two transfers. Serial FSM timeout counter resumes from the previous timeout value. Due to this a spurious FSM timeout interrupt, which left unmasked, a spurious XSPIFSM alarm may occur for the serial FSM timeout if the IDLE period across multiple transfers combined goes beyond the programmed timeout period.

Consequences:

- Serial FSM timeout behavior during IDLE will not reset to 0
- System will recover itself from this interrupt by following the standard IP disable and enable procedure
- No other functional impact expected due to this behavior

Workaround:

- Program the Serial FSM controller timeout value to be more than the duration of back-to-back transfers without disabling the xSPI
- Disable the xSPI in between two transfers
- Regular software flow to disable the IP can be performed whenever the user sees an interrupt and resume the transfers

18.8.4 TC4Dx xSPI registers

There are no deviations from the generic specification.

18.8.4.1 Memory overview tables of XSPI domain SRI

Table 823 Memory overview - XSPI domain SRI (ascending address)

Short name	Long name	Address
XSPI0__CXIP	Memory mapped area (08000000_H Byte)	98000000_H
XSPI0__NCXIP	Memory mapped area (08000000_H Byte)	$B8000000_H$

18.8.4.2 Register address space - XSPI

Table 824 Registers address space - XSPI

Key: The module name in brackets () indicates a memory section name. Without brackets the reference is to a functional block.

Module	Base address	End address	Note
(XSPI0)	98000000_H	$9FFFFFFF_H$	Slave interface for XIP cached address range
	$B8000000_H$	$BFFFFFFF_H$	Slave interface for XIP non-cached address range
XSPI0	$F9040000_H$	$F904FFFF_H$	Slave interface for SFR registers

18.8.4.3 Register overview - access mode glossary

Table 825 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register XSPI0_PROTE .
SE	Access protection using PROT register XSPI0_PROTSE .
APU-P	Protection group consisting of registers XSPI0_ACCEN_WRA , XSPI0_ACCEN_WRB , XSPI0_ACCEN_RDA , XSPI0_ACCEN_RDB , XSPI0_ACCEN_VM , XSPI0_ACCEN_PRS .
P	Access protection using *APU-P* registers.
APU-PRGNx (x=0-7)	Protection group consisting of registers XSPI0_RGNx_ACCEN_WRA , XSPI0_RGNx_ACCEN_WRB , XSPI0_RGNx_ACCEN_RDA , XSPI0_RGNx_ACCEN_RDB , XSPI0_RGNx_ACCEN_VM , XSPI0_RGNx_ACCEN_PRS , XSPI0_RGNx_ACCEN_RGNLA , XSPI0_RGNx_ACCEN_RGNUA .
PRGNx	Access protection using *APU-PRGNx* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.

TC4Dx xSPI connectivity	• Corrected the direction of RXD signal as input for port20/15

19 Peripheral Component Interconnect Express (PCIe)

The PCIe is a high-speed communication interface. It is a full-duplex connection capable of sending and receiving data at the same time. The interface is compliant with PCIe Gen 5 and the data rate is up to 8 GT/s.

19.1 Feature list

- Compliant with the PCI Express™ specification, revision 5.0 Version 1.0
- Gen3 data rate, x1 lane up to 8 GT/s (giga-transfers per second)
- Dual mode: either root complex or endpoint
- Programmable Base Address Register (BAR) addressing: 32 bit or 64 bit
- Programmable BAR sizing
- 256 byte maximum payload size (MAX_PAYLOAD_SIZE)
- Requester and completer function support for PCIe transactions
- Interrupt generation and reception
  - INTx support
  - MSI support, up to 32 interrupts
  - MSI-X support, up to 64 interrupts
  - Additional support for non-standard interrupt reception in endpoint mode
- Power management
  - D0, $D3_{hot}$ and $D3_{cold}$ support
  - L0, L0s, L1, L1 sub-states, L2, and L3 support
  - Reference clock power management with CLKREQ#
  - Active-State Power Management (ASPM) support
  - PCIe beacon and wake-up (WAKE#)
- Embedded Direct Memory Access (DMA) support
  - 4 read and 4 write DMA channels
  - Linked list support
  - Remote configurable DMA channels (EP only)
- Address translation unit
  - 8 translation regions for inbound transactions
  - 8 translation regions for outbound transactions
  - Transaction type conversion
- Baseline and Advanced Error reporting (AER) support
- One physical function implemented in endpoint mode
- Optional end-to-end cyclic redundancy (ECRC) support
- Accesses to the System-on-Chip (SoC) memory and registers from wire
- Spread Spectrum Clocking (SSC) support
- Optimized Buffer Flush/Fill (OBFF) support
- Precision Time Measurement (PTM) support
- Latency Tolerance Reporting (LTR) support
- Readiness notification support
- Advanced on-chip debug support (OCDS) trigger bus (OTGB) trace support
- Safety measures for registers, memory, and data path against random hardware faults

19.2 Functional overview

PCI Express is a high performance, general purpose I/O interconnect for a wide range of applications. The interface is compatible with the PCI Express™ Base Specification, Revision 3.1a. The target of this manual is not to document the PCIe protocol. This manual describes mainly how to use the PCIe interface and only basic concept of the PCIe protocol.

The PCIe interface can be configured as a root complex or an endpoint after the power-on. Afterwards, the work mode cannot be changed without resetting the PCIe interface. The speed of the PCIe interface can be Gen1, Gen2 and Gen3. An embedded DMA is designed to offload the CPU by using DMA transfers. In addition, an address translation unit provides flexible mapping between the PCIe wire address and the SoC internal address.

The PCIe interface consists of two sub-blocks, namely the PCIe controller and the HSPHY (PCIe PHY), as shown in the following figure. An SRI master interface and an SRI slave interface are used for data transfer while two SPB slave interfaces are only for the configuration purpose. The interface connects to interrupt router (IR), safety and security alarm management unit (SMU) and TRACE for the common infrastructure functionalities.

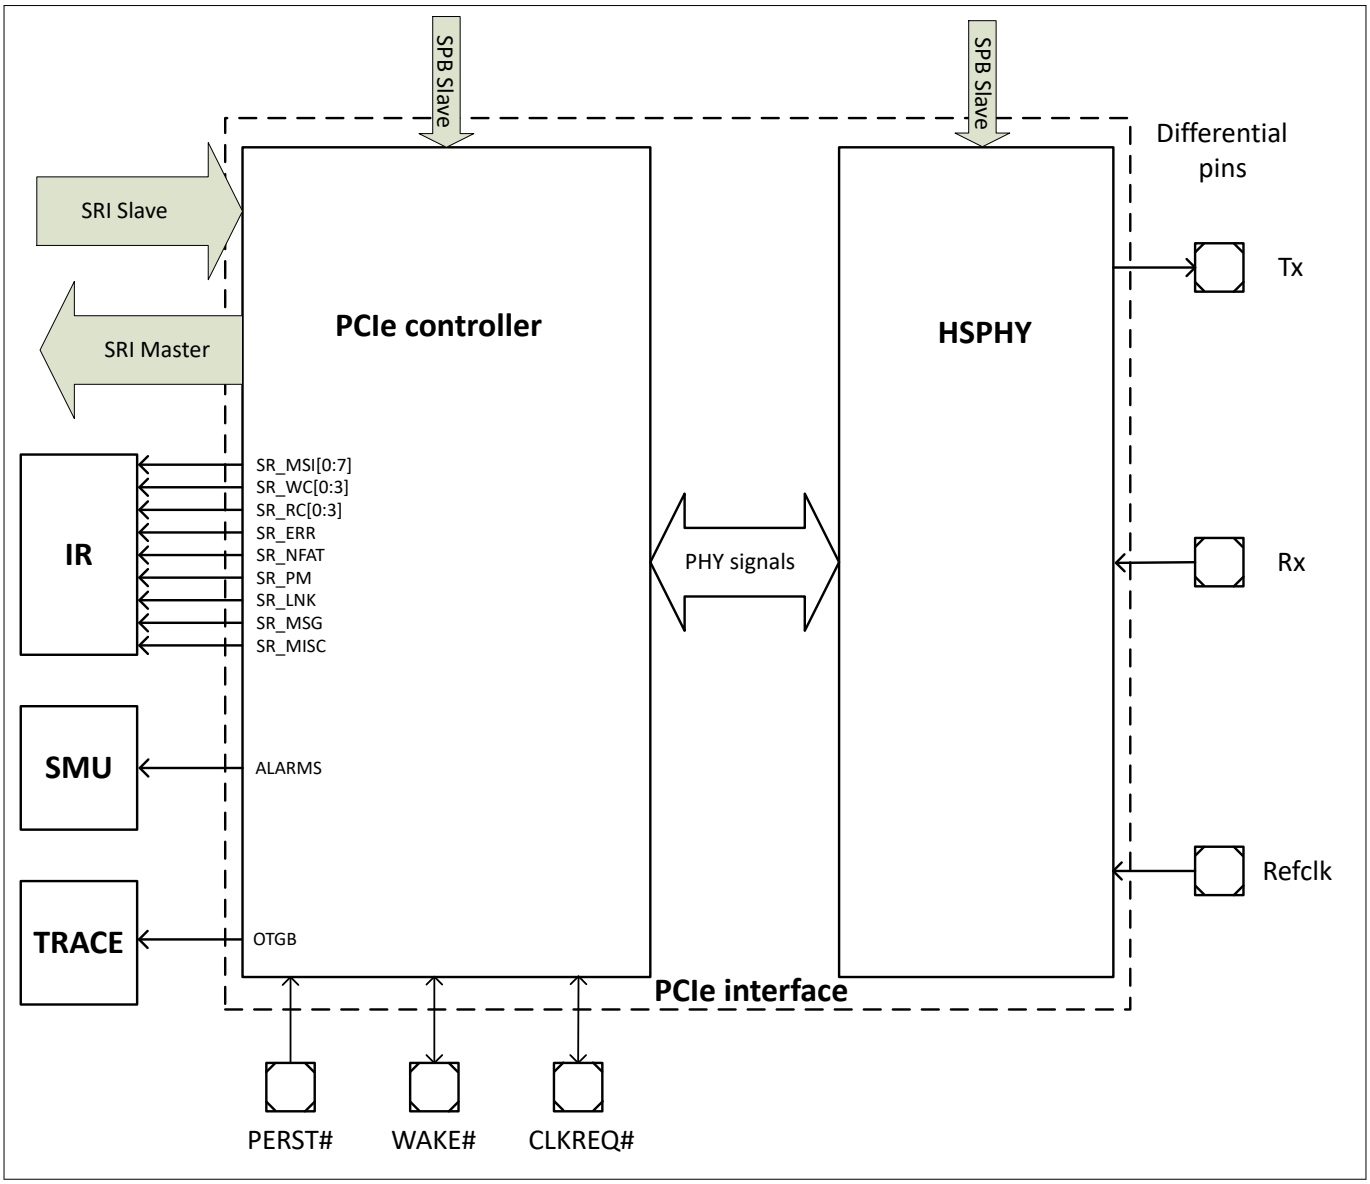

Figure 275 PCIe block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

19 Peripheral Component Interconnect Express (PCIe)

19.3 Functional description

The PCIe module described in this chapter contains both the PCIe controller and the UPCS layer, as introduced in the following figure. The blocks that are related to data stream and configuration stream are depicted. The arrows show how inbound and outbound requests are routed. The posted and the non-posted requests use different data paths.

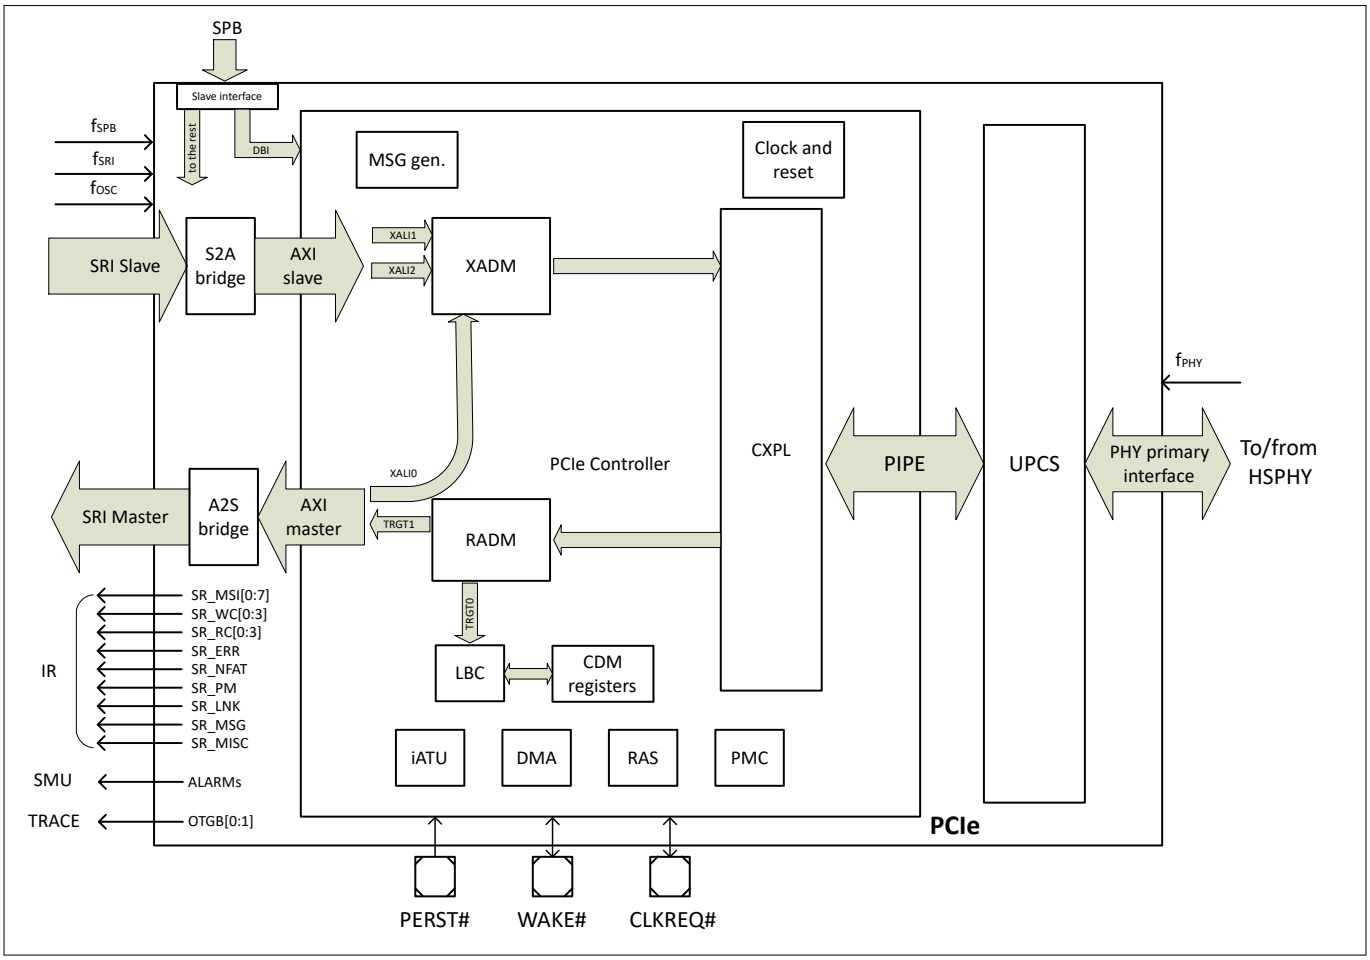

Figure 276 The overview of the PCIe module

Common Express Port Logic (CXPL) Module implements the basic functionality for the PCI Express physical, link, and transaction layers. This module implements a large part of the transaction layer logic, all of the data link layer logic, and the controller portion of the physical layer, including the link training and status state machine (LTSSM). The CXPL connects to the universal physical coding sublayer (UPCS) through the PIPE (The PHY Interface for the PCIe Express, SATA, USB, DisplayPort and Converged IO architectures), a standard PHY interface for PCIe. The UPCS provides many of the functions outlined in the PIPE 4 specification and comprises the PCS as referenced in the PIPE 4 specification.

Transmit Application-Dependent Module (XADM) implements the application-specific functionality of the PCI Express transaction layer for packet transmission. Its functions include:

- TLP Arbitration
- TLP Formation
- Flow Control (FC) Credit checking

The transmit path uses a cut-through architecture. It does not implement transmit buffering/queues (other than the retry buffer). The controller maintains an internal Target Completion Lookup Table to store certain TLP header information from the Rx request.

Receive Application-Dependent Module (RADM) implements application-specific functionality of the PCI Express transaction layer for packet reception. Its functions include:

- Sorting/filtering of received TLPs. The filtering rules and routing are configurable
- Buffering and queuing of the received TLPs
- Routing of received TLP to the controller's receive interfaces

Configuration-Dependent Module (CDM) implements:

- Standard PCI Express configuration space
- Controller-specific register space

Local Bus Controller (LBC) provides a mechanism for a link partner or a local CPU (through the SPB) to access the controller internal registers. The access to the internal registers from wire is only possible when AURIX™ is operating in EP mode.

Message Generation Module (MSG gen.) transmits messages generated by the controller.

Clock and reset block is responsible for distributing clocks to different blocks in the controller and controlling the reset of the controller.

Power management controller (PMC) implements the power management features of the controller.

PCIe system Reliability, Availability, and Serviceability (RAS) ensures that failures in the underlying processes and hardware components do not cause any interruptions in the overall system operation.

Embedded direct memory access (DMA) is designed to offload the transferring of large blocks of data and leave the CPU free to perform other tasks.

The controller uses the internal address translation unit (iATU) to implement a local address translation scheme that replaces the TLP address and TLP header fields in the current TLP request header.

The PCIe controller has the following data interfaces for various traffic.

- Receive:
  - TRGT0: the internal receive interface accesses the CDM registers and some internal registers
  - TRGT1: the internal receive interface access BAR-matched memory requests
- Transmit:
  - XALI0: the internal transmit interface for the completions
  - XALI1: the internal transmit interface for the outbound non-posted requests
  - XALI2: the internal transmit interface for the outbound posted requests

The SRI interfaces are mainly for transferring data. The SRI slave is connected to the AXI slave via the S2A bridge while the SRI master is connected to the AXI master via the A2S bridge. The PCIe controller is accessed via SRI by the CPU. The AXI interface is internal and cannot be accessed directly by software.

The SPB interface is for register configuration purpose. The SPB is connected to the DBI to access the registers located inside of the PCIe kernel. The DBI is transparent from the software point of view.

The SR_* signals are the service request signals to the IR. The details are described in the "Local interrupts" section. The ALARMS is the alarm signal to the SMU to detect errors. The OTGB signals provide diagnostic information to the TRACE for debug.

19.3.1 Link initialization

The initialization process of PCIe follows the sequence defined in the following figure.

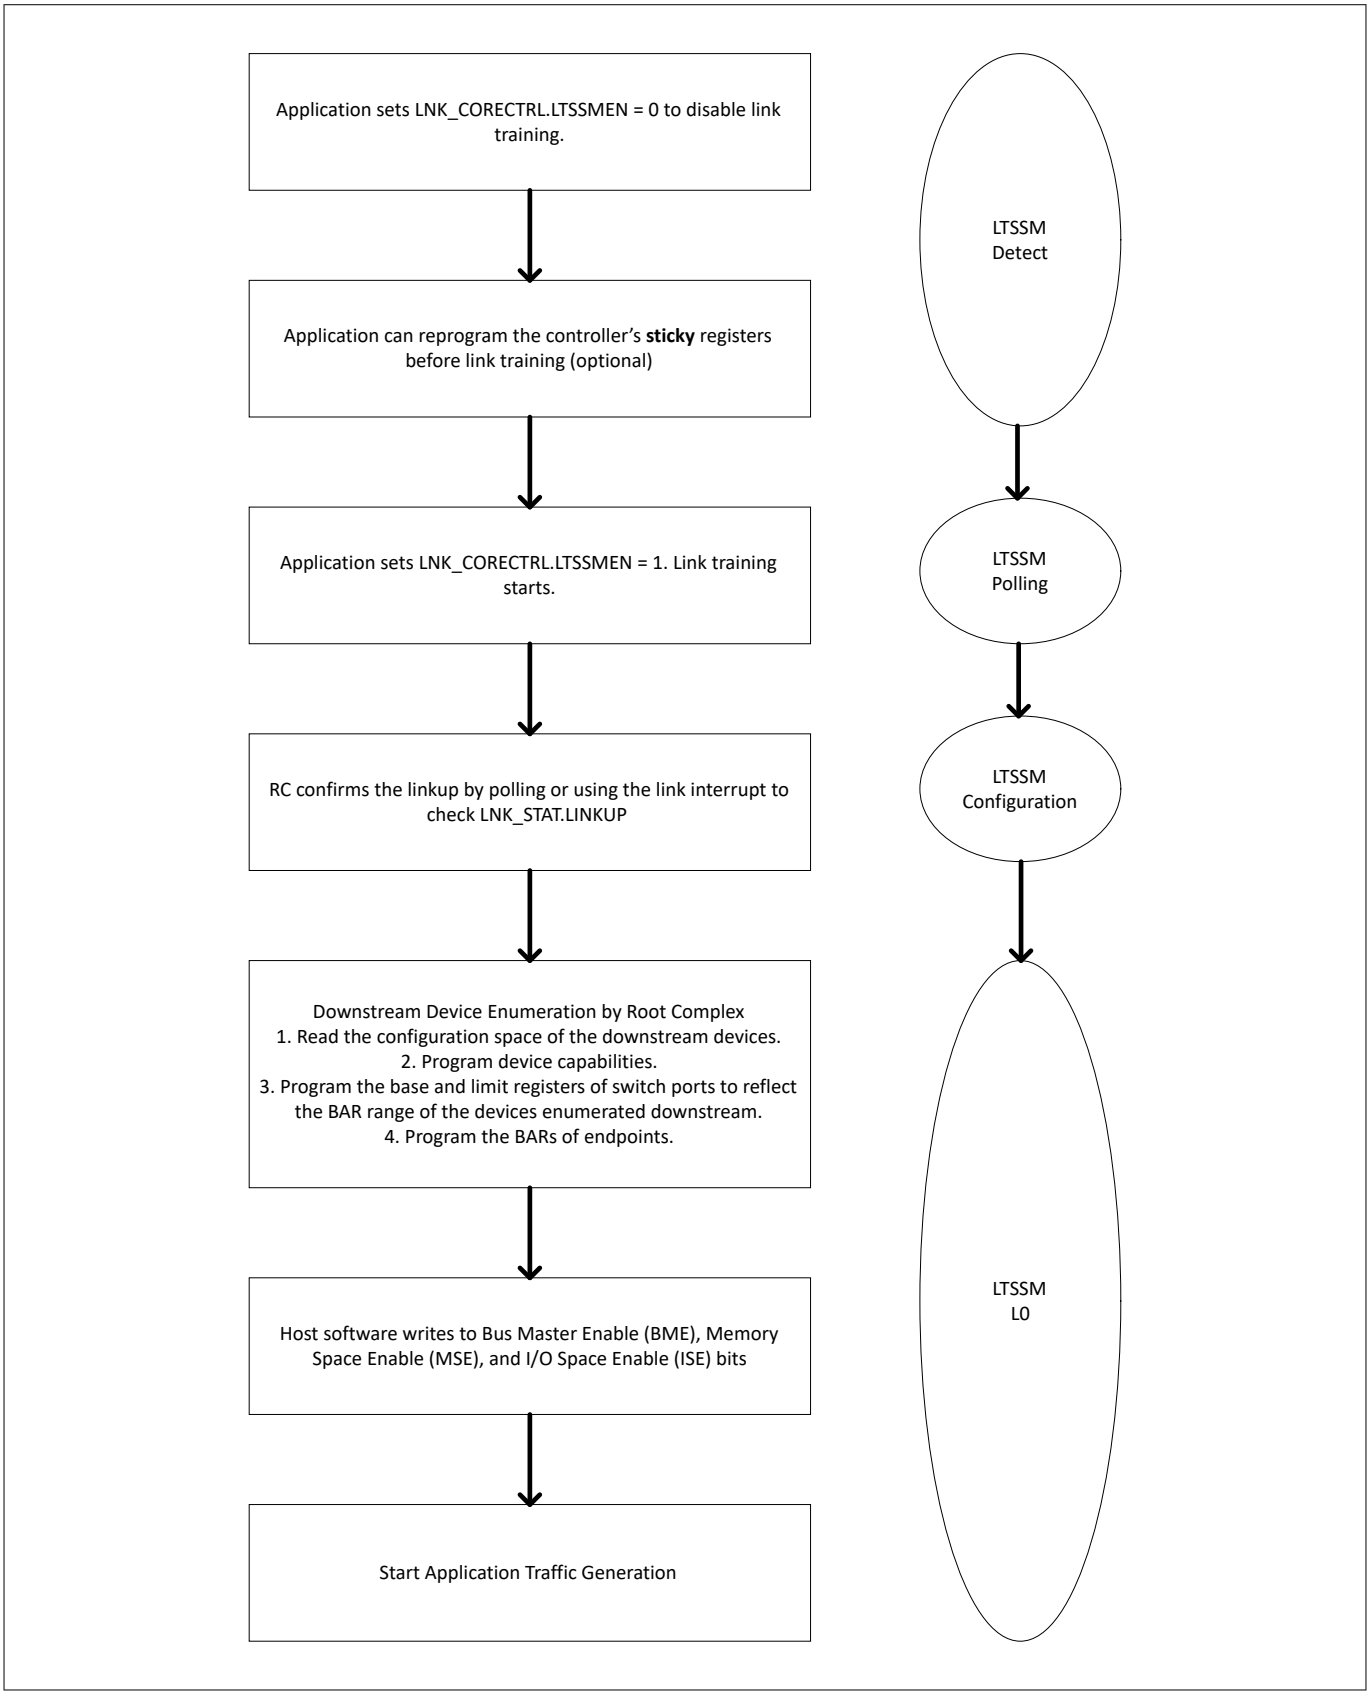

Figure 277 The steps of link establishment

Related information

iATU on page 2752

19.3.1.1 Minimum working example of RC

1. HSPHY: The HSPHY module clock shall be enabled by asserting CLC.DISR. Set the PHY_CTRL1.FSP to 1 to select the PCIe to the corresponding MP8G PHY. Select the reference clock (100 MHz refclk) from the pad by setting the PHY_CTRL1.PRS to $xx1_B$
2. After power-up, the module clock shall be enabled by using CLC.DISR. The device type shall be configured to be root complex by setting LNK_DVCTYP.TYPE = 0100_B. A PCIe module reset is needed then by applying the module reset sequences that will reset the MP8G PHY and PCIe controller together
3. After the PCIe module reset is applied, if a common reference clock is used, the PHY control signals must be overridden according to TC4Dx specific UPCS override settings for common refclk PHY settings
4. HSPHY: After the MP8G PHY reset triggered by the PCIe, there is an option to load the firmware that is executed in the MP8G PHY by the application. The PHY_CTRL1.INITDONE indicates that the MP8G PHY is ready and the application can load the firmware into the SRAM (optional). The application should assert the PHY_CTRL1.EXTLDDONE after the loading or without the loading so the MP8GPHY can continue to initialization process. During the initialization of the MP8G PHY, the clock from the MP8G PHY is not provided to the PCIe controller and no access to the controller registers should be initiated. The end of the initialization phase is indicated by the RAWCMN_DIG_AON_CMNCAL_STATUS register in the HSPHY
5. The link training can be started by asserting the LNK_CORECTRL.LTSSMEN bit. The link state is indicated in the LNK_STAT register. The software can check the current link speed by checking the LINK_CONTROL_LINK_STATUS_REG.PCIE_CAP_LINK_SPEED field, that indicates the negotiated link speed of the given PCIe link
6. The enumeration is performed with Cfg TLPs. To initiate Cfg TLPs with normal bus transfers by CPU, ATU is applied to convert the outbound accesses into Cfg TLPs. The details of how to configure ATU is described in the section iATU. The address registers of an ATU region shall follow the enhanced configuration access mechanism (ECAM) defined in the PCIe specification and be properly configured to target at the right device. The IATU_REGION_CTRL_1_OFF_OUTBOUND.TYPE must be the right TLP type
7. After the configuration of end points, the memory space or the IO space can be enabled. Please note that RC application must not generate any MEM or I/O requests until the host has enabled the PCI_TYPE0_MEM_SPACE_EN and the PCI_TYPE0_IO_EN bits in the PCIe command register (STATUS_COMMAND_REG)
8. Memory TLPs can be initiated to access EPs after the proper configuration of BAR registers in EPs

***Note**: for re-initialising the link, it has to be disabled first using the register LINK_CONTROL_LINK_STATUS_REG.PCIE_CAP_LINK_DISABLE*

19.3.1.2 Minimum working example of EP

1. HSPHY: The HSPHY module clock shall be enabled by asserting CLC.DISR. Set the PHY_CTRL1.FSP to 1 to select the PCIe to the corresponding MP8G PHY. Select the reference clock (100 MHz refclk) from the pad by setting the PHY_CTRL1.PRS to $xx1_B$
2. After power-up, the module clock shall be enabled by asserting CLC.DISR. The device type is set to endpoint by default. A PCIe module reset is needed then by applying the module sequences that will reset the MP8G PHY and PCIe controller together
3. After the PCIe module reset is applied, if a common reference clock is used, the PHY control signals must be overridden according to TC4Dx specific UPCS override settings for common refclk PHY settings
4. HSPHY: After the MP8GPHY reset triggered by the PCIe, there is an option to load the firmware that is executed in the MP8G PHY by the application. The PHY_CTRL1.INITDONE0 indicates that the MP8G PHY is ready and the application can load the firmware into the SRAM (optional). The application should assert

the PHY_CTRL1.EXTLDDONE after the loading or without the loading so the MP8G PHY can continue to initialization process. During the initialization of the MP8G PHY, the clock from the MP8G PHY is not provided to the PCIe controller and no access to the controller registers should be initiated. The end of the initialization phase is indicated by the RAWCMN_DIG_AON_CMNCAL_STATU register in the HSPHY

5. The link training can be started by asserting the LNK_CORECTRL.LTSSMEN bit. The link state is indicated in the LNK_STAT register. The software can check the current link speed by checking the LINK_CONTROL_LINK_STATUS_REG.PCIE_CAP_LINK_SPEED field, that indicates the negotiated link speed of the given PCIe link
6. After the configuration of end points by RC, the memory space or the IO space is supposed to be enabled. Memory TLPs can be initiated to access memory address space

19.3.1.3 Optional IO control

The optional pins including PERST#, WAKE# and CLKREQ# are supported by the PCIe controller. Additional software configuration is necessary to connect the signal to the right pin.

The PERST# is an input to the PCIe controller and controls the reset of the PCIe interface. One alternative pin input can be selected via LNK_CORECTRL.PERST from the possible alternatives. For more details regarding the pin assignment, refer to the corresponding data sheet.

The WAKE# acts as both input and output to the PCIe controller and supports the low power state. One alternative pin input/output can be selected via LNK_CORECTRL.WAKE from possible alternatives. For more details regarding the pin assignment, refer to the corresponding data sheet.

The CLKREQ# acts as both input and output to the PCIe controller and supports the L1 sub-states. One alternative pin input/output can be selected via LNK_CORECTRL.CLKREQ from possible alternatives. For more details regarding the pin assignment, refer to the corresponding data sheet.

19.3.2 Address spaces

PCIe supports four address spaces: configuration, memory, IO and message. Configuration address space allows software to setup and check devices in a standard way. Memory address space is the space in CPU memory address range consumed by devices for non-configuration purposes. IO address space is for data at the IO-mapped location. It is legacy from PCI and not recommended to be used according to the PCIe specification. Message address space covers event signal mechanism to general purpose messaging.

The four address spaces can be accessed from wire, meaning from a remote PCIe device. There are several restrictions regarding address space access defined in the PCIe specification. For example, only RC can access the configuration address space. The selection and switching of different address spaces mainly rely on ATU, more details introduced in the chapter iATU.

All registers in the controller can be accessed from the AURIX™ side. Part of the registers can also be accessed from wire.

Related information

iATU on page 2752

19.3.2.1 Address spaces from wire

The following table explains how memory and configuration accesses from the wire map to the local PCIe module registers.

The protocol registers including PCIe configuration header, standard and extended capability registers are registers specified by the PCIe specification while the implementation-specific registers are registers in this module but not specified by the PCIe specification.

Table 828 Register region access

Group	Register type	Local address offset[1]	Configuration space address offset	Memory space address offset (BAR0)
1	Application registers: registers related to PCIe and interactions with other modules	0_H - $2FFF_H$ (except for the locations belonging to group 2 and 3)	N.A.	N.A.
2	Request trigger registers (INT_REQTRIG and INT_TRIGSTAT)	364_H and 358_H	N.A.	000_H and 004_H
3	Mailbox registers	$3FC_H$ - $41B_H$	N.A.	008_H - 027_H
4	ATU registers	3000_H - $3FFF_H$	N.A.	N.A.
5	Protocol registers: PCIe configuration header, standard and extended capability registers	4000_H - $433F_H$	0_H - $33F_H$	N.A.
6	PCIe implementation specific registers	4700_H - $4B8F_H$	700_H - $B8F_H$	N.A.
7	MSI-X table	$5A00_H$ - $5DFF_H$	N.A.[2]	$A00_H$ - DFF_H
8	PBA table	$5E10_H$ - $5E17_H$	N.A.[2]	$E10_H$ - $E17_H$
9	Shadow registers including BAR mask registers and MSIX registers	6000_H - $6FFF_H$	N.A.	N.A.
10	DMA registers	7000_H - $791F_H$	N.A.	4000_H - $491F_H$[3]
11	Data access control registers	$3FFFE00_H$ - $3FFFF07_H$(SRI base address)	N.A.	N.A.

1) More details in Register Overview - PCIE_USP Domain FPI
2) Can be accessed depending on the value of TARGET_ABOVE_CONFIG_LIMIT_REG and CONFIG_LIMIT_REG. Possible but not recommended.
3) By default, they are not accessible. The size of BAR0 should be increased to at least 20 KB to include the DMA registers.

The register ranges in the table above are not continuous.

According to the specification, the configuration space is up to 4 KB for a function. Depending on the value of TARGET_ABOVE_CONFIG_LIMIT_REG in the MISC_CONTROL_1_OFF, the Cfg TLP with an address over CONFIG_LIMIT_REG can be routed to the TRGT1 or the internal register groups 7 and 8 that are located in the External Local Bus Interface (ELBI). Normally, CONFIG_LIMIT_REG cannot be set to less than 340_H DWORDs (equivalent to $D00_H$ bytes) which is the top of the registers. The routed TLP to TRGT1 or ELBI inherits the address offset of the Cfg TLP. For TRGT1, it uses the address as bus address. For ELBI, it uses it as the offset in the memory space referring to BAR0.

In the MEM/IO address space, the PCIe module registers and even the AURIX™ address space can be accessible, as explained in the following table. In the PCIe module, an embedded DMA is designed to facilitate data transfers between remote and local memory. The configuration registers of the DMA are addressable via BAR0 in the MEM/IO address space. The EP interrupt trigger registers can be also read/written in the same way. BAR1 to BAR5 are designed to access the internal AURIX™ address space.

The columns for the configuration space and the memory space are not applicable for RC.

Table 829 MEM/IO address space as EP

Base address register	Address offset	Access region	Note
BAR0	$A00_H \leq$ offset < DFF_H	MSI-X table (group 7)	The register layout is identical to the one from local address in the previous table.
	$E10_H \leq$ offset < $E17_H$	PBA table (group 8)	
	000_H	INT_REQTRIG (group 2)	
	004_H	INT_TRIGSTAT (group 2)	
	$008_H \leq$ offset < 027_H	mailbox registers (group 3)	
	$4000_H \leq$ offset < $491F_H$ [1)]	DMA registers (group 10)	
BAR1-5	-	AURIX™ internal address space	The addresses can be remapped by the ATU.

1) The size of BAR0 should be at least 20 KB.

19.3.2.2 Local bus accesses

The configuration of PCIe controller from the local bus is introduced in the first part of the following table. Different regions are addressed depending on the offsets. To transmit TLPs in outbound direction, the slave interface of SRI and the iATU are utilized to convert SRI transactions into PCIe TLPs. The address ranges for MEM/IO, message and configuration are configurable in the translation regions of iATU, that has eight outbound and eight inbound translation regions respectively. More details regarding addressing at address spaces can be found in the chapter iATU.

Table 830 Address map from local bus including the memory and the registers

Type	Base address	Groups	Address offset
Configuration of PCIe controller	PCIe SPB base address	1 - 10	0_H - $791F_H$
Outbound window to generate TLPs: Memory read, I/O, configuration and message	PCIe SRI base address	N.A.	0_H - $3FFFDFF_H$ (64 MB address window can be shared . The splitting is dependent on the APU and the ATU)
Configuration of data access control registers	PCIe SRI base address	11	$3FFFE00_H$ - $3FFFF07_H$

Access protection unit

The above accesses are subject to the restrictions of Access Protection Unit (APU), as shown in the below figure.

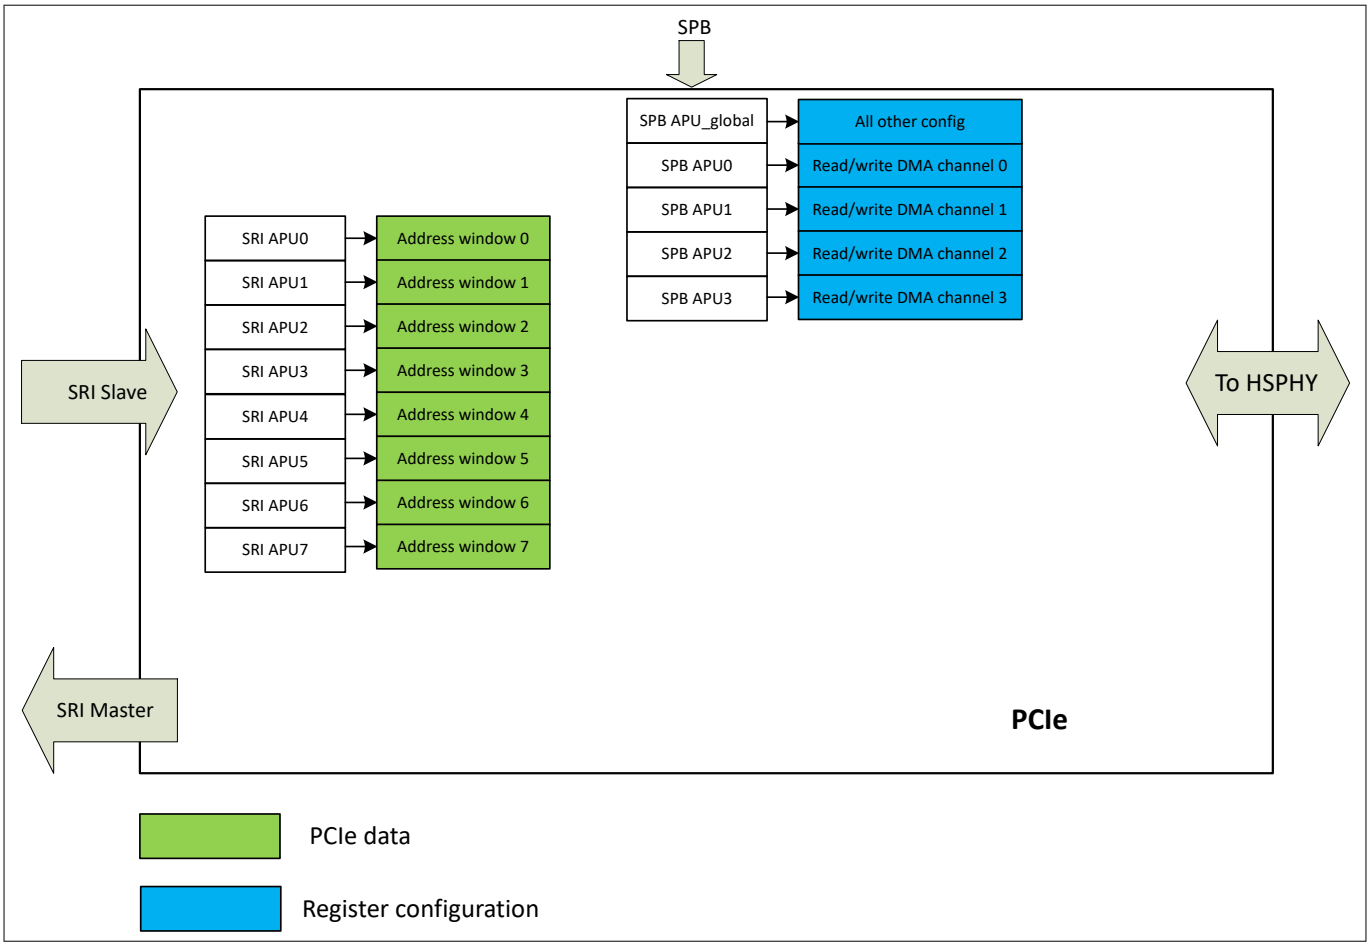

Figure 278 Access protection to the PCIe controller

For the configuration of PCIe controller, one global APU instance (APU_global) controls which bus masters are allowed to configure the PCIe controller. Four additional APUs (DMA APU0-3) protect the access to the configuration registers in the four DMA channels (including both read and write channels with the same DMA index) respectively. The configuration registers specific to DMA channels are protected by these APUs for example transfer size, doorbell and addresses. The common DMA configurations are covered by the global APU. In this way, specific virtual machines can use the assigned DMA channels without interfering each other. The details of which registers are protected by which specific APU are described in the register chapter.

To allow both dedicated control of a specific DMA channel and global control of all DMA channels, several functionality control registers appear twice, once in the common part and once in the channel specific part. For example, a DMA transfer from read channel 0 can be started by using the DMA_READ_DOORBELL_OFF that starts all read channels. It can also be started by using the DMA_CHN0_RD_DOOR that triggers only the DMA read channel 0. The DMA_READ_DOORBELL_OFF is covered by the global APU while the DMA_CHN0_RD_DOOR is protected by the DMA APU0.

The SRI bus transactions initiated by the DMA channels may have additional tag information to indicate which DMA channel is the initiator. This additional information is reflected in the VM or the PRS in an SRI transaction. The selection of the VM or the PRS is controlled by the CFG_INFO.SRITAG. Depending on the enumeration of the SRITAG, the channel ID is assigned to the corresponding VM and PRS tag. This additional tag information can help to have a better granularity of controlling the DMA accesses to the other modules.

For the region related to SRI data transactions (the second row of the previous table), eight APU instances (APU0-7) are available and each one defines an address window for data accesses. When the address of a local access falls into the address window of an APU, then this access is by this APU configuration. The APUaddress windows shall be 64 byte aligned. Every APU has independent configurations to permit accesses fromspecific b us masters. For example, each address window can be 10 MB and each window is only allowed to beaccessed b y a VMx on CPU0. More details about APU are available in the SRI chapter.

When iATU is not applied, the bus transactions in AURIX™ to the SRI slave interface of PCIe will create memory TLP for example MRd or MWr and access the memory space of remote devices.

19.3.3 Transmit/receive TLP

This section describes how TLPs are transmitted and received. The routing and the arbitration are also introduced in this section. These functionalities are performed by the XADM and the RADM.

19.3.3.1 Transmit TLP

Transmit TLP

TLPs and DLLPs have equal priorities during transmit arbitration as shown in the following figure. The priority of TLP types and DLLP types are shown in the following two tables, respectively.

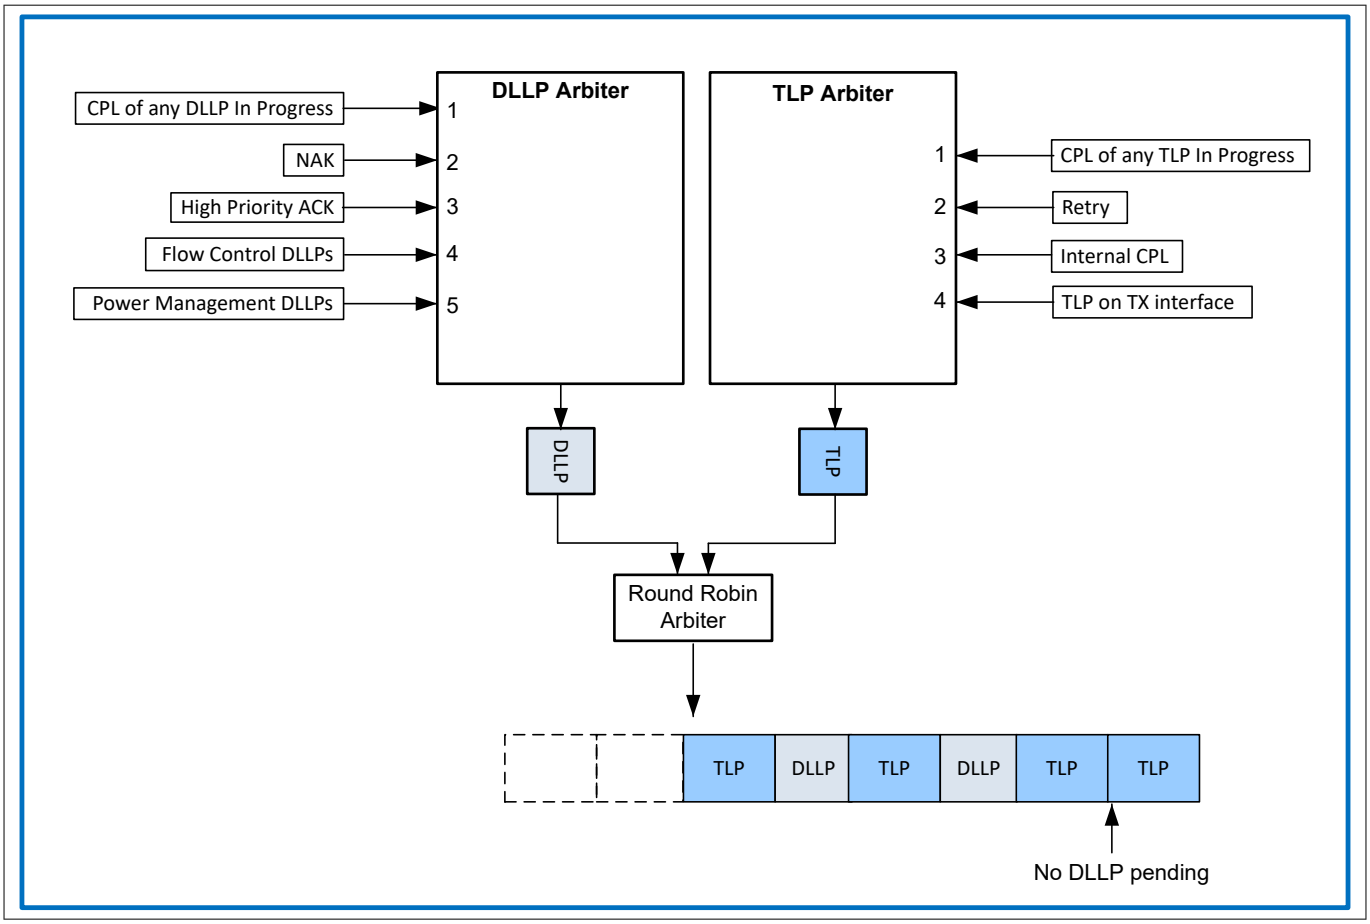

Figure 279 Transmit TLP/DLLP arbitration

Table 831 TLP arbitration priority (1 = highest, 4 = lowest)

Priority	TLP type
1	Completion (Cpl) of any TLP currently in progress
2	Retry buffer retransmissions

(table continues...)

Table 831 (continued) TLP arbitration priority (1 = highest, 4 = lowest)

Priority	TLP type
3	TLPs from the transaction layer (in the following order of priority): • Messages generated by the controller • Upstream ports: Completions generated by the controller (including memory or I/O mapped application register space) for Type 0 configuration read and write requests, or responses to error conditions (unsupported requests) Downstream ports: Completions generated by the controller for unsupported requests or completer aborts
4	TLPs on the bus interface

Table 832 DLLP arbitration priority (1= highest, 5 = lowest)

Priority	DLLP type
1	Completion of any DLLP currently in progress
2	NAK DLLP
3	High Priority ACK DLLP
4	Flow Control DLLP
5	Power management or any other Low Priority DLLP

Selecting transmit client arbitration scheme

All XALI transmit interfaces (XALI0, XALI1 and XALI2) are using round robin arbitration, when credit is available, regardless of the type of transaction. The XALI0 is responsible transmitting completions TLPs. The XALI1 transmits NP requests while the XALI2 handles P requests and messages.

Effects of flow control credits on transmit client arbitration

The controller checks that enough flow control (FC) credits are available in the remote device for the specific type of transaction (posted, non-posted, completion) before allowing a transmission of a TLP. TLPs that passed the credit check are arbitrated according to the supported arbitration method. Internally generated completions and messages are also gated by the arbitration logic, though at highest priority, and must also pass the FC credit test before they are accepted for transmission.

ACK/NAK scheduling

The following figure shows how you can reprogram the controller to influence the sending of ACK and NAK DLLPs. The registers that can be used for the same are Lane Skew Register.ACK_NAK_DISABLE, Timer Control and Max Function Number Register.TIMER_MOD_ACK_NAK, Ack Latency Timer and Replay Timer Register.ROUND_TRIP_LATENCY_TIME_LIMIT and Ack Frequency and L0-L1 ASPM Control Register.ACK_FREQ . When the link is idle, the controller sends an ACK DLLP every time it receives a good TLP. The default values are a tradeoff for performance vs. latency tolerance. If those do not fit the special custom requirements, they can be adapted.

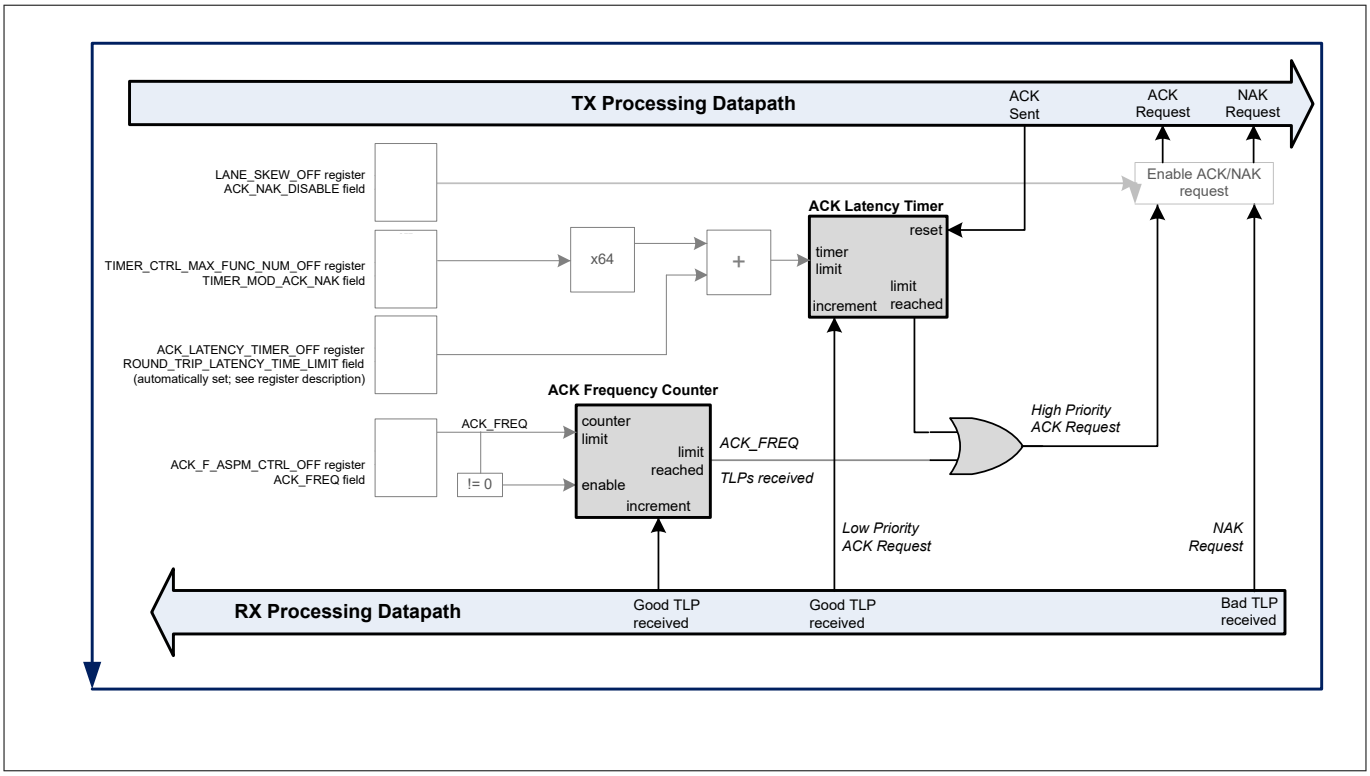

Figure 280 Ack frequency and latency timers operation (Representative)

When a low priority ACK request is scheduled for transmission to the remote link partner, the controller waits until either the ACK Latency Timer or the ACK Frequency Counter expires, then converts the low priority ACK request to a high priority ACK request, and schedules it for transmission to the remote link partner.

Transmit replay

You can modify the time-out value of the replay buffer as shown in the following figure. The default values are a tradeoff for performance vs. latency tolerance. If those do not fit your special custom requirements you can adapt them.

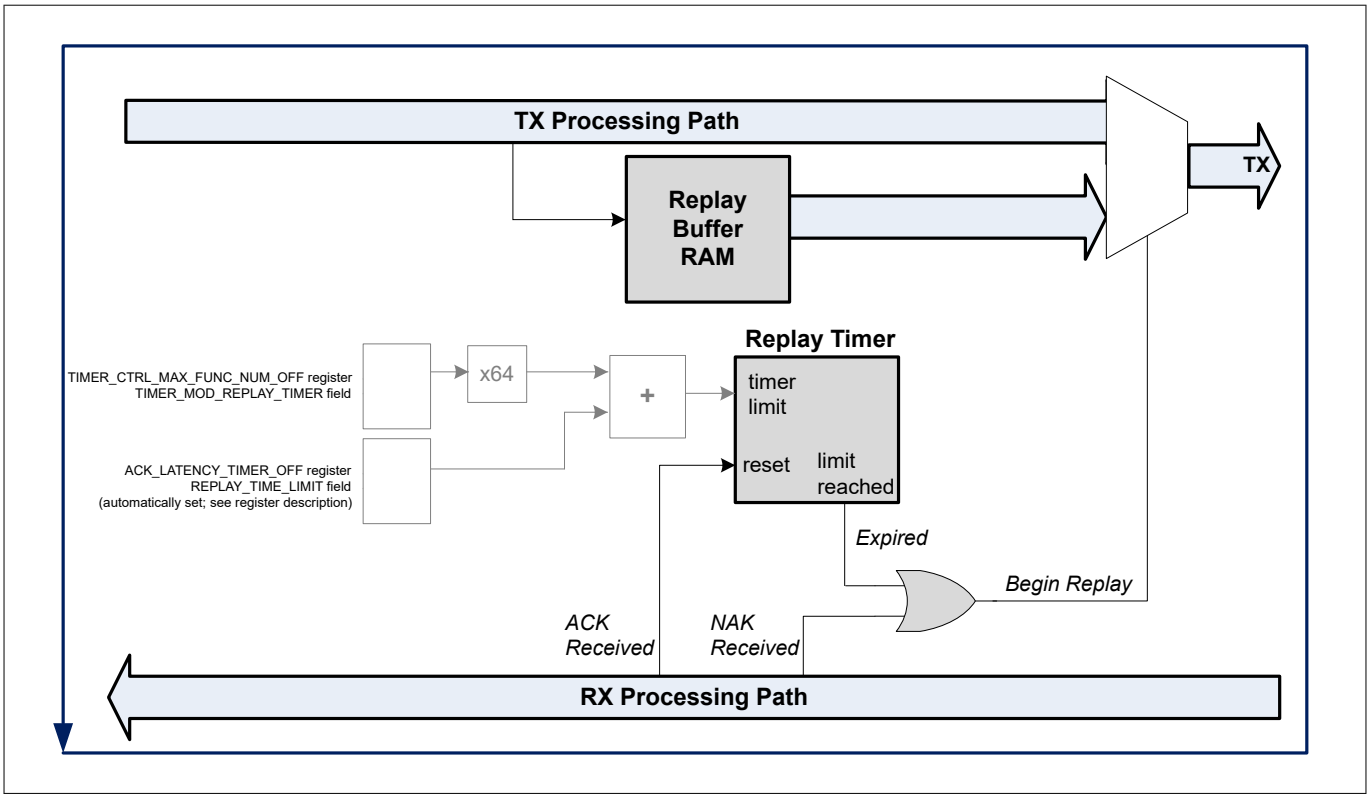

Figure 281 Replay buffer and time (representative)

Interface progression detection

This safety feature provides a mechanism for the controller to inform the application about the lack of progression on SRI/AXI slave and master interfaces. It also monitors the internal message generation interface and the configuration bus completion interface. Progression on the data transmission interfaces is not expected to halt under normal operating circumstances; it might halt if soft errors or silicon failures occur.

Tx interface progression detection features

- Timeout detection unit sets a flag (INTERFACE_TIMER_STATUS_OFF) when interface is stalling/waiting. It resets the flag when interface is not stalling/waiting
- Watchdog timer clocks the timeout detection units
- Controller automatically adjusts watchdog timer's incrementing interval when clock frequency changes after Gen1/2/3 speed change
- Controller automatically adjusts watchdog timer's incrementing interval in L1 and L2 low-power states
- Controller output if_timeout_status signal that is merged into SMU alarms to indicates a time-out event
- Programmable generation of AER message after time-out event (INTERFACE_TIMER_CONTROL_OFF.INTERFACE_TIMER_AER_EN)

The interface progression timer module instantiates a watchdog timer and timeout detection units in the interfaces to be monitored. The application software sets a window for monitoring transfer progression by programming the watchdog timer period through INTERFACE_TIMER_TARGET_OFF register. The watchdog timer signal is connected to the timeout detection units. When a change occurs in the watchdog timer signal, the timeout detection unit checks the interface signals to determine if the interface is halted, and sets a flag. This flag is reset if the interface is progressing. If the flag is found to be set on the next change to the watchdog timer signal, interface timeout status signal (if_timeout_status) is asserted. This uses an SMU alarm (PCIe uncorrectable data alarm) to indicate to the application that a progression timeout has occurred on one of the interfaces. The application can then read the INTERFACE_TIMER_STATUS_OFF register to determine which interface is causing the timeout.

19.3.3.2 Receive TLP

Receive filtering

The controller contains a filter module that is responsible for the following tasks:

- Determine the status of a received TLP using filtering rules (SYMBOL_TIMER_FILTER_1_OFF and FILTER_MASK_2_OFF)
- Determine the destination of a received TLP based on the filtering status
- Indicate the status of the received TLP
- Report Errors to AER registers in RC via error messages based on filter results. If more than one type of error is detected, Section 6.2.3.2.3 Error Pollution, of the PCI Express Base Specification, Revision 5.0, Version 1.0 is followed

The controller filters and routes the received TLPs according to a set of rules determined by the TLP type based on the PCI Express Base Specification, Revision 5.0, Version 1.0 and user-configurable filtering options. The filtering rules for a received TLP are affected by the register values (run-time options).

The following general rules apply to all incoming TLPs that are not malformed. By default:

- If the device is in power state D3hot, the controller only accepts CFG and MSG requests TLPs for that function. All other incoming request types for that function are treated as unsupported requests (UR)
- When the controller detects an error in a received TLP, it normally performs the following:
  - Discarding the TLP
  - Generating a completion (for non-posted requests) with the completion status set to CA or UR
  - Setting the status in the PCI-compatible Status register
  - Seting the status in the AER registers (when the user enables AER)
  - Generating an error message (upstream port only)
- All error-free MSG requests are decoded internally, signaled on the message interface (MSG_PAYLOADx) and then dropped

Receive routing

This section discusses how the controller routes different TLP types to different receive interfaces depending on TLP type and filter result.

EP mode routing overview

The possible destinations of a posted or non-posted request TLP are bus master interface (TRGT1), controller internal space (TRGT0) or discard[15]. By default:

- CFG requests are routed to controller internal space
- BAR-matched MEM and I/O requests are routed to the bus master interface
- MSG requests are decoded internally, signaled on the registers, and then terminated

The possible destinations of a completion TLP are bus interface and discard.

RC mode routing overview

The possible destinations of a posted or non-posted request are bus master interface (TRGT1) or discard. By default:

- MEM requests outside of the memory range and prefetchable memory range as determined by the corresponding Base and Limit fields in the Type-1 header are routed to the bus master interface
- MSG requests are decoded internally, signaled on the registers, and then terminated
- An RC does not expect to receive CFG or I/O requests
- BARs should be disabled and not used

15 Serviced internally, and then not passed to the application but dropped.

The possible destinations of a completion TLP are the bus interface or discard

19.3.4 Ordering

Inbound order enforcement

The controller only enforces ordering of TLPs that are delivered to the primary receive application interfaces TRGT1. It does not enforce ordering between these TLPs and the TLPs that are delivered to the TRGT0 or SII.

The system information interface (SII) exchanges system information between the controller and the application via the registers. It is connected to the output of the receive filter and is not subject to receive queuing. Therefore, TLPs that are routed to the SII may overtake the TLPs that are destined for the application memory. Typically, the controller sends all message TLPs including Assert_INTx/Deassert_INTx messages to the SII. An MSI interrupt received by the controller is signaled on the SII may overtake the received data destined for the application memory.

PCIe ordering :

Summary: This scheme fully obeys the producer-consumer model and deadlock is avoided. All of the PCI Express ordering rules in Table 2-34 (“2.4.1 Transaction Ordering Rules” section of the PCI Express Base Specification, Revision 5.0, Version 1.0) are obeyed.

Method: TLPs are filtered into three separate FIFO queues: posted, non-posted, and completion. The ordering controller determines which of the three queues have a TLP that is allowed to proceed.

When more than one queue has a TLP that is allowed to proceed, it uses a priority arbitration algorithm to select a transaction. This prevents starvation, which occurs when delivery rate for a particular TLP type to your application is unfairly reduced.

Rules: This scheme implements all of the PCI Express ordering rules.

Relaxed Ordering (RELAXED_ORDER_SUPPORT =1): A completion or a posted transaction with its RO header bit set to 1, can pass a previously issued posted transaction that is blocked. RO is not implemented for non-posted writes.

Outbound order enforcement

The controller does not enforce ordering between the transmit interfaces, DBI (SPB), SII, XALI0, XALI1, XALI2, and so on. Furthermore, it does not enforce ordering between transactions on any of the transmit interfaces, and internally generated messages or completions (for example, for a CFG access to internal registers).

The request arbitration priority (highest first) for transmission of TLPs at the transmit interfaces is:

1. Internally generated messages
2. Internally generated completions for received CFG requests
3. Transmit TLPs from XALI0/1/2 according to the arbitration scheme in the chapter Transmit TLP

Related information

Transmit TLP on page 2711

19.3.5 Interrupts

In this section, both the local interrupts and the PCIe interrupts (interrupt generation and reception) are introduced. The local interrupts are the interrupt signals to the system interrupt router. They include 8 PCIe interrupts (converted from PCIe interrupts namely INTX, MSI and MSI-X), 8 DMA interrupts, error interrupt, power management interrupt, link status interrupt, PCIe message interrupt and others.

All three PCIe interrupt mechanisms namely INTx, MSI and MSI-X are supported. INTx, MSI and MSI-X are mutually exclusive. Only one interrupt mechanism can be applied at a time. UpStream Port (USP) generates interrupt while DownStream Port (DSP) receives interrupts, as specified in the PCIe specification.

Message signaled interrupts (MSI or MSI-X) are the preferred interrupt mechanism in PCIe. PCI Express defines one legacy interrupt (INTA) message for a single function device and up to four legacy interrupt (INTA, INTB,

INTC and INTD) messages for a multi-Function device. Since PCIe is a single function device, only INTA can be generated in EP mode, however, can receive all the 4 interrupts, INTA, INTB, INTC and INTD in RC mode.

The following section describes the processing of interrupts in the controller. The following descriptions are based on the different types of interrupts as specified in Sections 6.1.1, “Rationale for PCI Express Interrupt Model”,6.1.4, “Message Signaled Interrupt (MSI or MSI-X) Support”, 6.1.2, “PCI Compatible INTx Emulation”, and 6.1.3, “INTx Emulation Software Model” of the PCI Express Base Specification, Revision 5.0, Version 1.0.

MSI or MSI-X uses MWr to represent interrupt Messages. The Request format used for MSI or MSI-X transactions is identical to the MWr, and MSI or MSI-X Requests are indistinguishable from memory writes with regard to ordering, flow control, and data integrity.

19.3.5.1 Interrupt reception

When used as an RC, AURIX™ is intended to service the interrupts received from USPs. The configuration of USPs must be set properly by RC.

The inbound PCIe interrupts are propagated to the IR when AURIX™ is used as an RC, as depicted in the next figure. Interrupts received by the PCIe RC are forwarded directly to the IR that is able to trigger interrupts of CPUs. All three interrupts namely INTx, MSI and MSI-X utilize this mechanism. The RC has to configure the EP properly according to the PCIe specification in order to map the interrupts correctly.

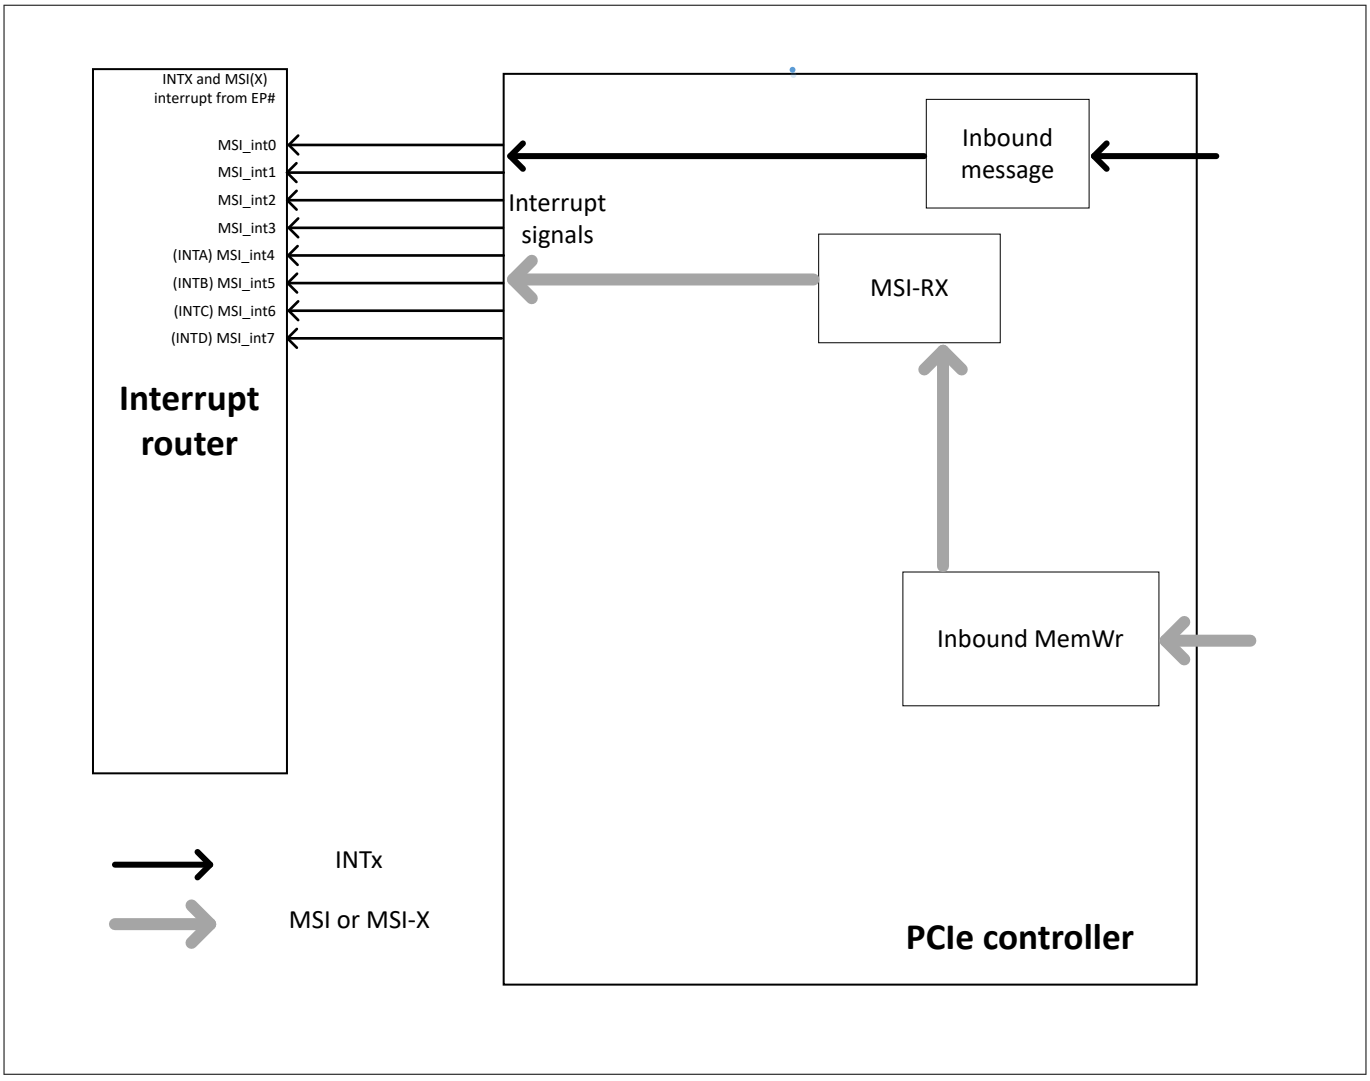

Figure 282 Interrupt reception options

PCIe controller interrupt reception

The controller decodes received Assert_INTx or Deassert_INTx messages and pulses the interrupt signals to generate a level-based interrupt to IR.

The inbound interrupts including MSI and MSI-X in the form of MWr TLP received by the controller are terminated, rather than propagating MSI MWr TLPs onto the bus through the master interface. The MSI packets are captured by the MSI-RX logic and interrupts are signaled directly to the IR. The MSI reception logic (MSI-RX) is programmed with an address (MSI_CTRL_ADDR_OFF and MSI_CTRL_UPPER_ADDR_OFF) that is used as the system MSI address. When an inbound MWr request matches this address for an MSI memory write request, an MSI interrupt is detected. Afterwards, the inbound MWr request is dropped and never appears on the bus.

The following conditions have to be fulfilled for the MSI-RX detection.

- Header attributes bits are 0_H. No snoop (NS) and relaxed ordering (RO) fields must be 0_H
- Length field is 01_H to indicate a payload of one DWORD
- First byte enable (FBE) is $xx11_B$ (enabling the first two bytes of the payload)
- Last byte enable (LBE) is 0000_B
- TLP address corresponds to systems chosen MSI address as programmed in the MSI_CTRL_ADDR_OFF and MSI_CTRL_UPPER_ADDR_OFF port logic registers. This register is a vendor specific register and is not the MSI Lower 32 Bits Address Register which is part of the PCIe MSI capability register

The MSI-RX decodes the MSI MWr data payload to determine which endpoint device sent the MSI and which interrupt vector the MSI corresponds to. When a valid interrupt has been decoded, the corresponding signal to IR is asserted. This output remains asserted when any MSI interrupt is pending. It is only de-asserted when there is no MSI interrupt pending. The detailed process is explained in the following figure.

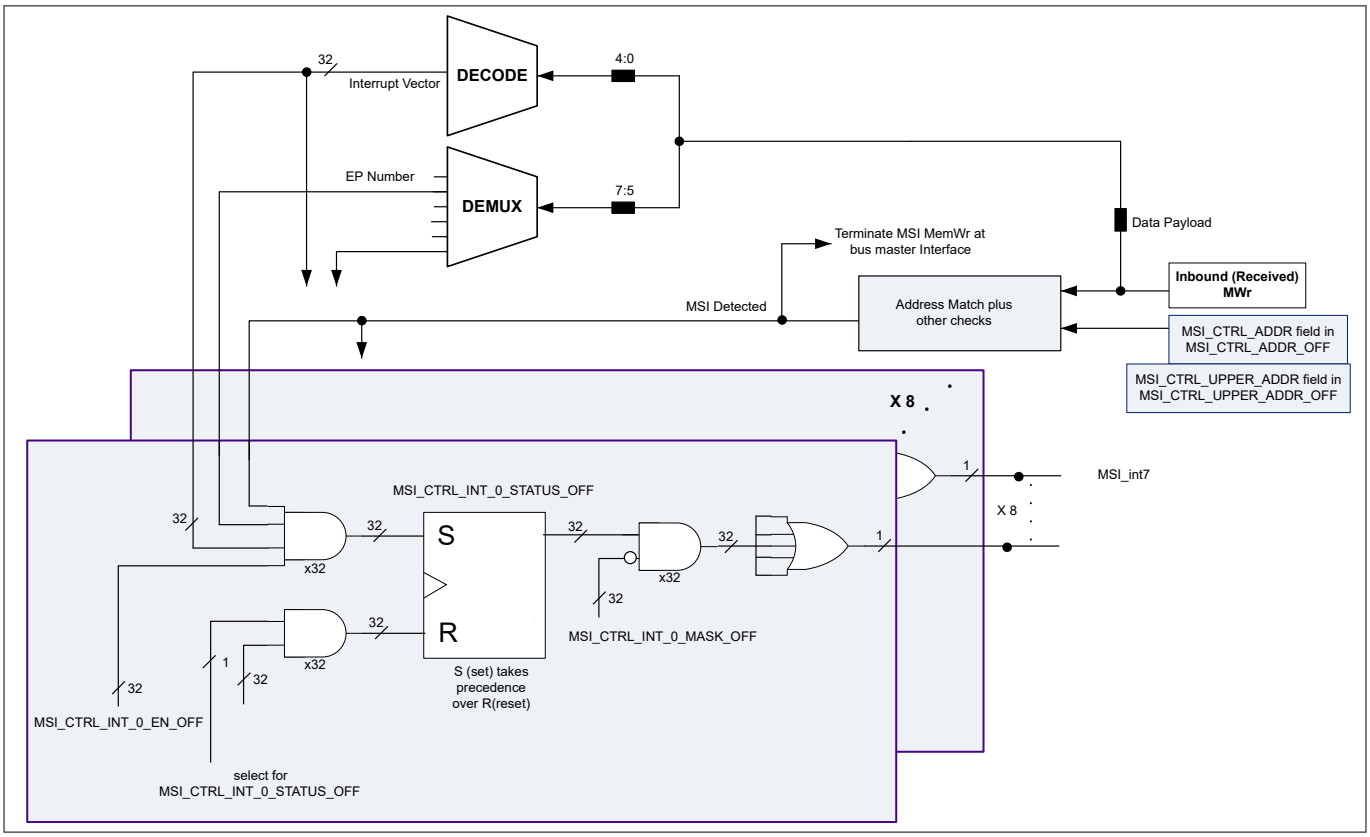

Figure 283 MSI-RX interrupt detection process

When the decoded interrupt vector is enabled (MSI_CTRL_INT_i_EN_OFF) and not masked (MSI_CTRL_INT_i_MASK_OFF), then the controller sets the corresponding bit in the MSI_CTRL_INT_i_STATUS_OFF. This bit remains asserted until the application clears the status bit by writing a 1 to the status bit. Writing a 0 has no effect.

When the decoded interrupt vector is enabled but is masked, then the controller sets the corresponding bit in the status register but it does not assert the signal to IR. When an MSI interrupt vector is received from an endpoint but that vector has not been enabled in the corresponding MSI_CTRL_INT_i_EN_OFF, then the controller does not set any bit in the interrupt status register. In addition, when no interrupts have been enabled in any of the eight interrupt enable registers, then all MSI detection logic is disabled and valid MSI MWr request TLPs are not terminated in the bridge but are passed by the bus master interface to the SRI bus.

19.3.5.1.1 Programming and usage

In order for the MSI interrupt system to work properly, the host has to configure the EP and also its own MSI-RX logic. The MSI-RX logic is responsible for the reception of MSI or MSI-X interrupts.

- The host CPU configures the MSI capabilities of all endpoints through CFG requests. Program the MSI Data Register (MSI_CAP_OFF_08H_REG or MSI_CAP_OFF_0CH_REG in the MSI capability) as introduced in the following table to allow the MSI-RX to decode the interrupt source
- Program the MSI Capability Lower 32 Bits Address Register (MSI_CAP_OFF_04H_REG) of every EP with one common MSI address
- The host CPU configures the MSI-RX through the local bus
  - It programs the MSI-RX's MSI_CTRL_ADDR_OFF and MSI_CTRL_UPPER_ADDR_OFF registers with the same value as in MSI_CAP_OFF_04H_REG
  - It reads the MSI capability of each EP to determine the number of vectors enabled in each EP and uses this information to program the MSI-RX's interrupt enable register (MSI_CTRL_INT_i_EN_OFF). This register allows up to 32 MSI interrupt vectors to be enabled within the MSI-RX for a given EP. It is the responsibility of the host CPU to read the contents of the Multiple Message Enable field in an EPs MSI capability structure and program that EPs Interrupt Enable register in the MSI-RX appropriately. For example, if the Multiple Message Enable is 100_B for endpoint #0 (which corresponds to 16 enabled interrupt vectors), the host CPU should program MSI_CTRL_INT_i_EN_OFF with $0000FFFF_H$

Table 833 MSI data register (MSI_CAP_OFF_08H_REG or MSI_CAP_OFF_0CH_REG) programming

15:8	7:5	4:0
Not used	EP number: Allows each EP to be identified within the system, For example, EP#5 is programmed with 101_B	Interrupt vector: Identifies the interrupt source within each EP. Programmed to 00000_B. Supports up to 32 Vectors

The example above shows only a possibility in a topology. The upper three bits are treated as the indication of 8 different EPs while the lower five bits are for 32 interrupts. The interpretation of data is flexible. For example, the upper 3 bits can also be used for a single EP when MSI-X is applied as MSI-X has flexible configuration of data and address.

For MSI and MSI-X reception, the data registers configuration of EPs shall follow the above rules in order to decode interrupts correctly. A software interrupt handler can read which interrupt is triggered by reading the MSI_CTRL_INT_i_STATUS register.

Related information

iATU on page 2752

19.3.5.1.2 Request trigger for EP

According to the PCIe specification, all types of interrupts, INTx, MSI and MSI-X are supposed to be received only by RC. The reception of interrupt by EP is not defined by the protocol. However, a special mechanism named Request Trigger is implemented to support interrupt reception even when AURIX™ works as an EP. The Request Trigger mechanism is not limited from RC to EP but also EP to EP. This mechanism can only be used when the device works as EP.

A special register named INT_REQTRIG is designed and it can be accessible from local bus or from wire, but can only written by wire. It is one of the EP interrupt trigger registers mentioned before and can be accessed through MEM or IO TLPs from wire. The MEM/IO TLPs shall target in the range of BAR0. The lower 5 bits of INT_REQTRIG are used by the decode logic to map them to 32 interrupt requests, as depicted in the following figure. The remaining 27 bits of the 32 bits in INT_REQTRIG are not functionally connected to hardware and can be optionally used by the application. The INT_TRIGSTAT is also readable from wire to facilitate the checking of interrupt service status. This register can only be cleared by the local software writing the INT_TRIGCLR register.

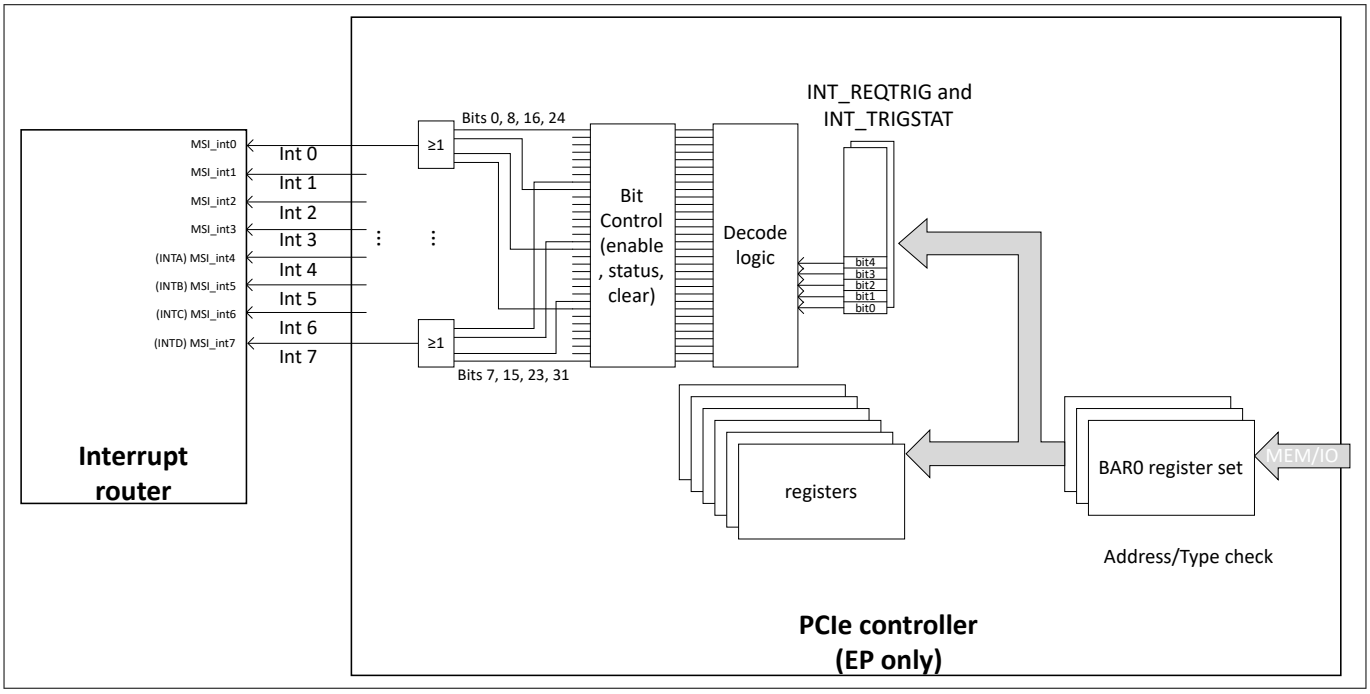

Figure 284 The request trigger mechanism for both RC and EP

After the decoding of the 5 bits, 32 interrupt requests are passed to the bit control block that consist of three different registers namely INT_REQTRIG, INT_TRIGSTAT and INT_TRIGCLR. The bit control block decides which of the 32 interrupts that will be masked, indicates the current interrupt status and clears the interrupts after service. The 32 interrupt requests will then be merged into 8 interrupts that will be handed over to IR and software interrupts triggered. The merging of interrupt requests is logical OR and is according to the following table.

Table 834 Request merging table

Interrupt	Merged request
int 0	0, 8, 16, 24
int 1	1, 9, 17, 25
int 2	2, 10, 18, 26
int 3	3, 11, 19, 27
int 4	4, 12, 20, 28
int 5	5, 13, 21, 29
int 6	6, 14, 22, 30
int 7	7, 15, 23, 31

Once a specific interrupt signal is triggered and interrupt handler starts to execute, the service handler software shall check the status of request (INT_TRIGSTAT) to see which request of the four is asserted. After which the service software shall clear the request bit by asserting the corresponding bit in INT_TRIGCLR.

If a request is not yet serviced while the same request comes again, then the second one will be missed and will not be seen by software.

19.3.5.2 Interrupt generation

As an EP, AURIX™ is supposed to trigger interrupts to RC. RC needs to configure the EP using the configuration space for matching interrupt generation on EP to interrupt reception on RC. Only one type of interrupt is allowed to be used at a time as MSI, MSI-X, and INTx are mutually exclusive.

19.3.5.2.1 INTx

To generate INTx interrupts, software needs to write INT_INTXCTRL.INTX bit-field to notify the controller that it should send an interrupt message. The controller generates two message TLPs, Assert_INTx and Deassert_INTx, in response to the assertion and the de-assertion of this bit.

Your application needs to de-assert the virtual interrupt bit-field when the link has been placed in a low power state. The controller does not automatically send a Deassert_INTx interrupt message when the power state changes.

19.3.5.2.2 MSI

An EP creates MSI interrupts using MWr requests. The application issues MSI requests through the local MSI registers; the controller then generates the corresponding memory write. Alternatively, your application can create the MSI MWr by writing to the SRI slave interface or using DMA.

The interrupts can be triggered by asserting the INTi (0 to 31) field in INT_MSICTRL register. Each bit in the INT_MSICTRL is corresponding to one of the 32 interrupts that can be supported by EP. If more than one bit is asserted at a time, the generation of MSI interrupt is processed one by one depending on the priority. The interrupt 0 has the highest priority while the interrupt 31 has the lowest. The status as to whether an interrupt has been sent is available in the INT_MSISTAT register.

INT_MSISTAT indicates whether the previous interrupt request is pending or not. A Non-pending interrupt does not mean that the interrupt is serviced but the interrupt message has been sent. If the application requests an interrupt that is still pending, this request will be lost.

MSI capability registers shall be configured by RC via Cfg TLPs. The details of these registers are specified by the PCIe protocol and not the scope of this manual.

19.3.5.2.3 MSI-X

MSI-X is an extension to basic MSI. It supports more vectors (2048) per function and independent address and data values for each interrupt compared to MSI.

Each entry in the MSI-X table corresponds to an interrupt. Each interrupt could have different message data and message address, as depicted in the following figure. The maximum number of interrupts supported by MSI-X is 64 (N=64). The 64 bits inside in the PBA table corresponds to 64 interrupts or 64 MSI-X table entries, as shown in the figure MSI-X PBA structure. When an MSI-X packet is generated, the data and the address (upper and lower addresses) in the MSI-X table are used to form the packet.

The detailed configuration process of MSI-X is described in the PCIe specification.

DWORD 3	DWORD 2	DWORD 1	DWORD 0	
Vector control	Msg data	Msg upper address	Msg lower address	entry 0
Vector control	Msg data	Msg upper address	Msg lower address	entry 1
Vector control	Msg data	Msg upper address	Msg lower address	entry 2
...	...	...	...	...
Vector control	Msg data	Msg upper address	Msg lower address	entry N-2
Vector control	Msg data	Msg upper address	Msg lower address	entry N-1

Figure 285 MSI-X table structure

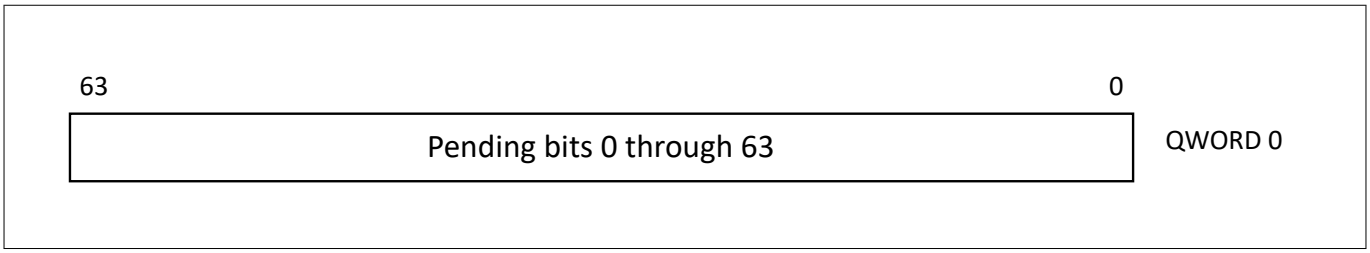

Figure 286 MSI-X PBA structure

The local application needs to configure the MSI-X logic before triggering any MSI-X interrupt. The detailed sequence of configuration as follows:

- Read the MSI-X Capability Structure registers through the local bus to get the value of MSI-X Table Size, Table BIR, Table Offset, PBA Offset, and PBA BIR. Get the starting address of the MSI-X Table as follows: MSI-X Table Start address = Start Address of BARn + Table Offset; where n = Table BIR (n = 0 in this case)
- Populate the MSI-X Table (by writing over the wire or local bus) with the required Message Address, Message Data, and Vector Control information for each entry, as explained in the figure MSI-X table structure. For example, to populate entry 0 of the MSI-X Table, perform four consecutive 32-bit writes to MSI-X Table Start Address + 0_H, 4_H,8_H and C_H with Data0 = Msg lower address, Data1 = Mag upper address, Data2 = Msg data, and Data3 = Vector control. Similarly to populate entry 2 write to "MSI-X Table Start Address + 2"
- Automatic triggering of MSI-X generation when application writes to the MSIX_DOORBELL_OFF register

MSI-X interrupt generation can be achieved by directly writing MSIX_DOORBELL_OFF by software. If the software needs to trigger a specific interrupt 'i', the index 'i' needs to be written to the vector field of MSIX_DOORBELL_OFF. Then the corresponding MSI-X table entry that contains the message data and message address is used to generate a MSI-X message to RC. The pending bits in the PBA structure indicate if a function has a pending message for the associated MSI-X table entry

MSIX_ADDRESS_MATCH_LOW_OFF and MSIX_ADDRESS_MATCH_HIGH_OFF are not supposed to be used and they shall not be modified after reset.

19.3.5.3 Local interrupts

This part describes the interrupts to the IR. It is not limited to the PCIe interrupts received but also includes local interrupts for example DMA interrupt, link state change, power management event, and errors.

Table 835 Summary of service requests to IR

Index	Service request name	Description	SRC register in IR	Relevant global interrupt control	Relevant local interrupt control
1	Remote int0	An interrupt requested from wire in RC role. It can be generated from MSI or MSI-X. In EP role int0 request trigger	SRC_PCIEwMSI0		MSI_CTRL_INT_0_STATUS_OFF[1], MSI_CTRL_INT_0_EN_OFF, MSI_CTRL_INT_0_MASK_OFF INT_TRIGSTAT, INT_TRIGCLR, INT_TRIGEN
2	Remote int1	An interrupt requested from wire in RC role. It can be generated from MSI or MSI-X. In EP role int1 request trigger	SRC_PCIEwMSI1		MSI_CTRL_INT_1_STATUS_OFF[1], MSI_CTRL_INT_1_EN_OFF, MSI_CTRL_INT_1_MASK_OFF INT_TRIGSTAT, INT_TRIGCLR, INT_TRIGEN
3	Remote int2	An interrupt requested from wire in RC role. It can be generated from MSI or MSI-X. In EP role int2 request trigger	SRC_PCIEwMSI2		MSI_CTRL_INT_2_STATUS_OFF[1], MSI_CTRL_INT_2_EN_OFF, MSI_CTRL_INT_2_MASK_OFF INT_TRIGSTAT, INT_TRIGCLR, INT_TRIGEN
4	Remote int3	An interrupt requested from wire in RC role. It can be generated from MSI or MSI-X. In EP role int3 request trigger	SRC_PCIEwMSI3		MSI_CTRL_INT_3_STATUS_OFF[1], MSI_CTRL_INT_3_EN_OFF, MSI_CTRL_INT_3_MASK_OFF INT_TRIGSTAT, INT_TRIGCLR, INT_TRIGEN

***Notes**:*

1. *These status bits are write one to clear*

2. *Both the global and local interrupt mask or enable bits have to be enabled in-order for status change to trigger an interrupt to the application software. The global mask bits are the final control to trigger the corresponding interrupt*

***Note**:* *In-order to clear an interrupt status bit, both the global and local clear bits have to cleared after it is being serviced. Please clear all the bits in case of multiple clear bits*

19.3.6 DMA

The RC system CPU, or the EP application CPU, can offload the transferring of large blocks of data to the embedded DMA controller, leaving the CPU free to perform other tasks. You can use up to four read channels and four write channels. It can simultaneously perform the following types of memory transactions:

- DMA write:
  Transfer (copy) of a block of data from local (application) memory to remote (link partner) memory
- DMA read:
  Transfer (copy) of a block of data from remote (link partner) memory to local (application) memory

Therefore the DMA supports full duplex operation, processing read and write transfers at the same time, and in parallel with normal (non-DMA) traffic. Upon completion of a DMA transfer or an error, the DMA optionally interrupts the local CPU or sends an interrupt MWr (IMWr) to the remote CPU. The DMA is highly configurable and you can program it using the local configuration bus interface or over the PCIe wire[16)].

In linked list mode, the DMA fetches the transfer control information (called channel context) for each transfer (block), from a list of DMA elements that you have constructed in local memory.

16 In EP mode the DMA registers can be accessed by wire on the default mapping of BAR0 Address spaces from wire.

19.3.6.1 DMA architecture

A DMA write and read channel operate independently to maximize the performance of the DMA read and write data transfers over the PCIe link. When you configure the DMA with multiple read channels, then it uses a weighted round robin (WRR) arbitration scheme to select the next read channel to be serviced.

The same applies when you have multiple write channels. The WRR can be programmable through DMA_CTRL_DATA_ARB_PRIOR_OFF.

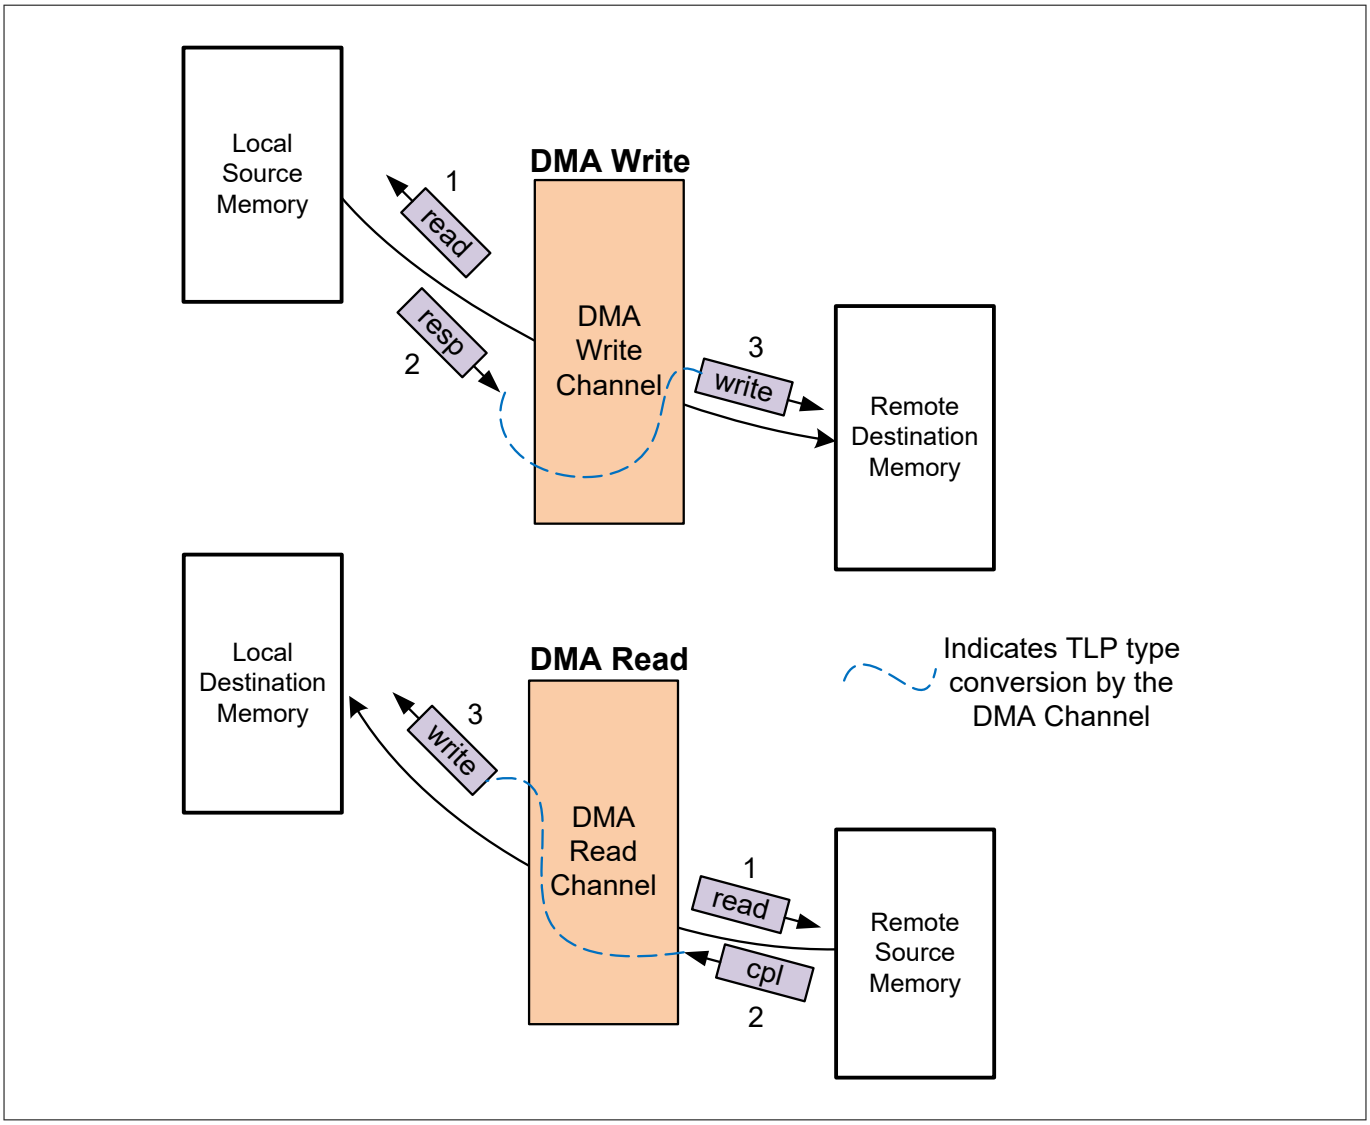

Figure 287 System level view of DMA

DMA write transfer

The DMA injects multiple MRd requests of size less than or equal to Max_Payload_Size into the inbound request path, directed toward the local application. The DMA converts the read responses into MWr TLPs, that it then transmits to the remote link partner. For a write transfer, the SAR is the address of the local memory, and the DAR is the address of the remote memory.

DMA read transfer

The DMA injects multiple MRd requests of size less than or equal to the minimum of {Max_Read_Request_Size, Max_Payload_Size} into the outbound request path, directed toward the remote link partner. The DMA converts the read responses into write requests, that it then transmits to the local SRI bus. When the DMA data transfer is

complete, the CPU is notified via interrupt. For a read transfer, the SAR is the address of the remote memory, and the DAR is the address of the local memory.

Registers and context memory

The registers that are specific to each channel are called the channel context registers. As the transfer progresses, the DMA updates these registers[17]. You program the channel context information and other DMA control registers directly with the local CPU through the configuration bus interface or remotely over the PCIe link.

19.3.6.1.1 Internal architecture

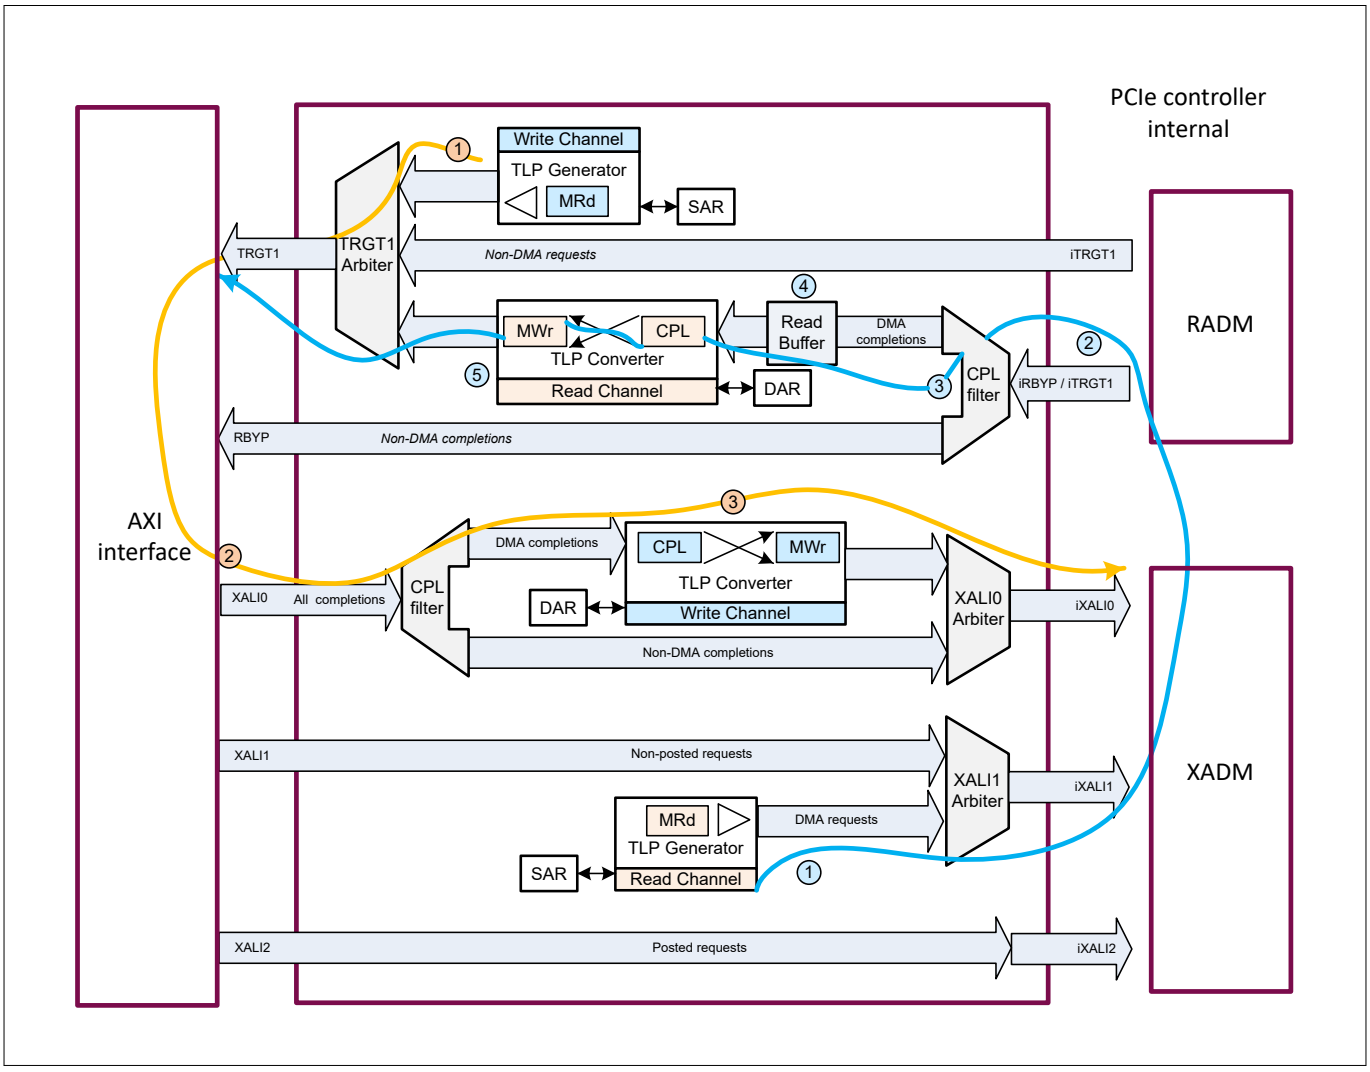

Figure 288 Operation of DMA read (blue) and write (orange) channels

DMA write transfer

The DMA injects multiple MRd requests of size less than or equal to Max_Payload_Size into the local bus. The TLP addresses are derived from the destination address. When the DMA data transfer is complete, the CPU is notified.

1. The DMA generates and sends READ requests to the local interface

17 The DMA hardware sometimes caches the context to increase performance. Therefore these registers might contain a delayed snapshot of the actual DMA channel state.

2. The local bus interface returns data on the XALI0 interface in response to these requests. Data must be returned in strict order within a single channel
3. The DMA converts the CPL TLPs to write requests and sends these to the XADM for transmission to the remote link partner

DMA read transfer

The DMA injects multiple MRd requests of a size less than or equal to the minimum of {Max_Read_Request_Size, Max_Payload_Size} into the outbound request path. The TLP addresses are derived from the source address. When the DMA data transfer is complete, the CPU is notified.

1. The DMA generates and sends read requests to the remote link partner. It uses a DMA tag
2. The link partner returns data in response to these requests on the iRBYP or iTRGT1 interface
3. The DMA module filters this data from non-DMA traffic on iRBYP or iTRGT1 and sends it to the Read Buffer. The DMA module identifies DMA traffic by looking for PCIe completion TLPs that have a DMA tag
4. The Read Buffer reorders completions that have been returned out-of-order. This is to ensure that the DMA writes data to the application in address-order
5. The DMA converts the completion TLPs to write requests and sends these to your application on TRGT1

In above figure, the XALI1 arbitration priority is Read Channel MSI (highest), Write Channel MSI, Non-DMA requests, Read Channel MRd. The XALI0 arbitration priority is Non-DMA requests (highest), Write Channel MWr. The TRGT1 arbitration priority is programmable (using the DMA_CTRL_DATA_ARB_PRIOR_OFF register) and defaults to Non-DMA requests (highest), Write Channel MRd (DMA data requests and LL element/descriptor access), Read Channel MRd (LL element/descriptor access), Read Channel MWr.

The arbitration among of DMA channels is configured through DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF for write channels and DMA_READ_CHANNEL_ARB_WEIGHT_LOW_OFF for read channels. The 5-bit channel weight specifies the maximum number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine.

19.3.6.1.2 Interrupts and error handling

The DMA generates two interrupts per channel:

- Done: The DMA successfully completes the transfer
- Abort: The DMA fails to complete the transfer or an error occurs during the transfer

The interrupts are signaled to the software on your CPU, using one or both of the following mechanisms:

- Locally through the interrupt signals to IR. The two interrupts above are merged into one (SRC_PCIERCx for read channels or SRC_PCIEWCx for write channels)
- Remotely using a posted memory write (IMWr), which can be interpreted as an MSI or MSI-X when directed toward the RC
  - There are two programmable IMWr addresses, one each for the done (DMA_WRITE_DONE_IMWR_*) and abort (DMA_WRITE_ABORT_IMWR_*) interrupts. For MSI, you must program all IMWr address registers with the same MSI address, as PCIe only supports a single MSI address per function
  - A single IMWr data register is used for both types of interrupts, so you must read DMA_READ_INT_STATUS_OFF (or DMA_WRITE_INT_STATUS_OFF) to identify the interrupt type
  - The relaxed ordering (RO) bit is automatically set to zero in the TLP header of all IMWr's so that subsequent MWr TLPs do not arrive at the remote device before the IMWr

***Note**: The IMWr address and data do not come from the MSI PCIe capability registers but from DMA registers (DMA_WRITE_ABORT_IMWR_*) or (DMA_WRITE_DONE_IMWR_*). For an upstream port, your software must program these registers with the same information that it is using to program the MSI/MSI-X capability for the function that is associated by your software with that channel in a multifunction setup.*

The interrupt handling mechanism is different for linked list (LL) mode than non LL mode, and there are also some differences between the read and write channels.

Non linked list mode interrupt handling

You enable the local and remote interrupts through the local and remote interrupt enable (LIE and RIE) bits: DMA_CH_CONTROL1_OFF_WRCH_0.LIE and DMA_CH_CONTROL1_OFF_WRCH_0.RIE.

In the write channel, there is only one error condition that results in an abort interrupt. You mask, clear, and read the status of each of the two interrupts (done and abort) through the DMA interrupt register. You can read the status of the abort error (that contribute to the abort interrupt) through the APP_READ_ERR_DETECT field of the DMA_WRITE_ERR_STATUS_OFF register.

If you want a remote interrupt and not a local interrupt, you can set LIE and RIE and mask the local interrupt using the mask register. In this way, the local error status register can still reflect the error status but no interrupt will be propagated to the IR. This allows you to poll the status register to distinguish a DONE from an ABORT.

In the read channel, there are five error conditions that results in an abort interrupt. However, you can read the status of each of the five abort errors (that contribute to the abort interrupt) through DMA_READ_ERR_STATUS_LOW_OFFand DMA_READ_ERR_STATUS_HIGH_OFF.

Linked list mode interrupt handling

The LIE and RIE bits in the LL element enable the channel done interrupts (local and remote). The LLLAIE and LLRAIE bits of the DMA_WRITE_LINKED_LIST_ERR_EN_OFF/DMA_READ_LINKED_LIST_ERR_EN_OFF registers enable the channel abort interrupts (local and remote). In the write channel, there are two error conditions that results in an abort interrupt. You can read the status of each of the two abort errors (that contribute to the abort interrupt) through the DMA_WRITE_ERR_STATUS_OFF register.

In the read channel, there are six error conditions that results in an abort interrupt. You can read the status of each of the six abort errors (that contribute to the abort interrupt) through the DMA_READ_ERR_STATUS_LOW_OFF and DMA_READ_ERR_STATUS_HIGH_OFF registers.

In non-linked list mode, LIE acts as a global switch. However when in linked list mode, LIE is just local to the current linked list element and the global switch is LLLAIE.

Setting RIE and LIE in element A followed by RIE (only) in element B is not a verified usage scenario.

19.3.6.1.3 Linked list mode

The DMA provides a linked list (LL) mode to efficiently move data from source to destination with minimal intervention from the local CPU. This mode provides an alternative to programming the DMA multiple times to transfer multiple blocks of data.

The programming information (address, size, and so on) for each block of memory is pre-programmed by your software into a LL element (also known as a descriptor) in local memory. Each element (called a data element) in the LL structure (called a transfer list) can transfer up to 4 GB of data.

You enable LL operation for a channel, by setting the LLE field of the DMA_CH_CONTROL1_OFF_WRCH_i register to 1. You can enable LL mode independently for each channel. When you enable LL for more than one channel, then you must have a separate LL structure in local memory for each channel. Your application must produce the LL element structure in local memory as shown in the following figure. Normally, all of the elements are contiguous (one after the other) in memory, and each element has six DWORDs containing the information about the block of data to be transferred. You program the channel context registers (DMA_LLP_LOW_OFF_WRCH_i and DMA_LLP_HIGH_OFF_WRCH_i) with the location of where you have placed the LL element structure in local memory. The above description also applies to read channels with RDCH instead of WRCH.

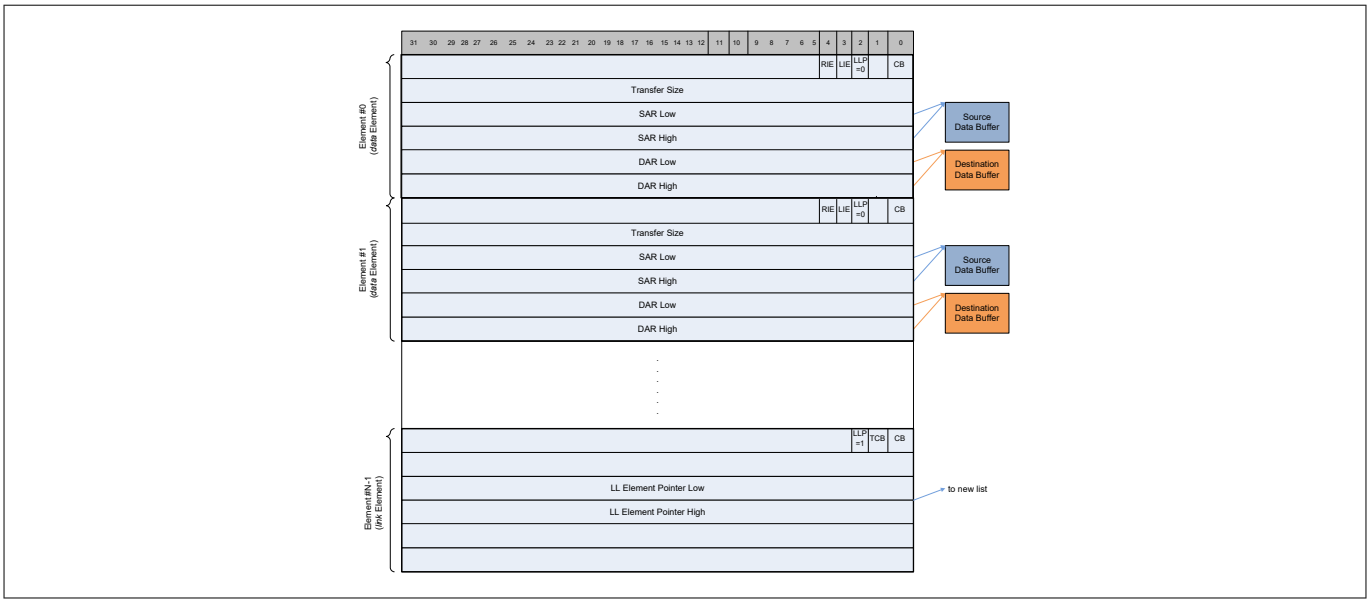

Figure 289 Linked list element/descriptor structure in local memory with N elements

When you start the DMA transfer (by writing to the DMA Write Doorbell Register DMA_WRITE_DOORBELL_OFF or DMA Read Doorbell Register DMA_READ_DOORBELL_OFF), the DMA reads (consumes) each element from local memory, and loads the information (SAR, DAR, size, and so on) from that element into the channel context registers in the DMA. These channel context registers determine the operation of the channel that the DMA controller is currently servicing. The DMA then proceeds to transfer the block of data (as defined by the element), and when it is finished, reads the next element from local memory. Normally, all of the elements are contiguous (one after the other) in memory, with the starting address defined in the channel context DMA Linked List Pointer Low Register DMA_LLP_LOW_OFF_WRCH_i. When you want to jump in local memory to another element list (or recycle the consumed elements), then you set the LLP bit in the element (for example, link element #N-1 in the previous figure), specify the location of the next element structure using the LL Element Pointer DWORDs (as indicated in the previous figure), and, set TCB to 1 (for recycling) or to 0 (to jump to another list).

Relationship Between Element DWORDs and Channel Context Registers

Notice the similarity between a data element and the DMA Channel Context registers for each channel. Each element has six DWORDs. There are eight channel context registers (DWORDs) for a channel. The DMA loads the six element DWORDs into the following channel context:

- CB, LLP, LIE, and RIE fields of the DMA Channel Control 1 register
- DMA Transfer Size
- DMA SAR Low and DMA SAR High
- DMA DAR Low and DMA DAR High

The definitions of the element DWORD bit fields are the same as the DMA Channel Context registers, with the exception of the LIE and RIE bits. The LIE and RIE bits in a LL element, only enable the done interrupt. In non-LL mode, the RIE and LIE bits (in the channel context registers) enable the done and abort interrupts.

When the LLP field of the first DWORD in the element is set to 1, the element is a link element. The DMA only loads the following information into the channel context registers:

- CB, TCB, and LLP bits of the first DWORD. The LIE and RIE bits are not defined in a link element
- LL Element Pointer (3rd and 4th DWORDs) into the DMA Linked List Pointer registers (DMA_LLP_LOW_OFF_WRCH_i and DMA_LLP_HIGH_OFF_WRCH_i)

Linked List Operation

- When enabling the linked list operation (DMA_CH_CONTROL1_OFF_WRCH_i.LLE = 1), the DMA overwrites the following DMA channel context registers with information from linked list data elements:
  - The CB, LLP, LIE, and RIE fields of the DMA Channel Control 1 register
  - DMA Transfer Size
  - DMA SAR Low and High
  - DMA DAR Low and High
- The structure of a link element is different to that of the data element. A data element has no TCB field. A link element has no LIE or RIE fields. It has no SAR, DAR, or Transfer Size DWORDs, but has LL Element Pointer DWORDs instead of the SAR DWORDs
- The LIE and RIE bits in an LL element, only enable the done interrupt. In non-LL mode, the RIE and LIE bits enable the done and abort interrupts

LL operation overview

In this section, a normal LL operation called recycling[18)] is described in detail. The process is described for a write channel, but it is possible to have duplicate processes running in parallel for other write or read channels. In this process interrupts are used to trigger the producer (software) to recycle elements. Typically a Watermark interrupt (positioned near the middle of the transfer list (TL)) and an Empty interrupt (in the last *data* element) are used by setting LIE in these two elements to '1'. The steps in this process are:

1. Software creates a LL element structure called a TL in local memory consisting of N-1 *data* elements and one *link* element:
   - The link elements "LL Element Pointer Low/High DWORDs" in the previous figure are programmed to point back to the beginning of the first data element
   - One of the data elements (near the middle of the TL) is programmed to generate a "Watermark" interrupt
   - The last data element is programmed to generate an "Empty" interrupt

2. Software programs the DMA with the location of the TL. This is done by writing to the DMA Linked List Pointer Low Register (DMA_LLP_LOW_OFF_WRCH_i) and DMA Linked List Pointer High Register (DMA_LLP_HIGH_OFF_WRCH_i)

3. Software starts the DMA process by ringing the write channel Doorbell. This is done by writing to the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF)

   The solid purple loop L1 in the following figure corresponds to steps 1-3

4. The DMA reads (consumes) each data element from local memory, and if the CB and CCS bits match it loads the information (SAR, DAR, size, and so on) from that data element into the channel context registers. These context registers determine the operation of the channel that the DMA is currently servicing. The DMA executes the check for the CB/CCS match after it has evaluated TCB and toggled CCS. The DMA always loads link elements into the channel context

   ***Note**: If the DMA stops on a link element, then your software must set the DMA Linked List Pointer registers, and restart the DMA process by ringing the doorbell.*

18 With recycling, the same LL structure is used over and over again. Another mode of operation would be to jump to a new LL element structure when the current one is consumed.

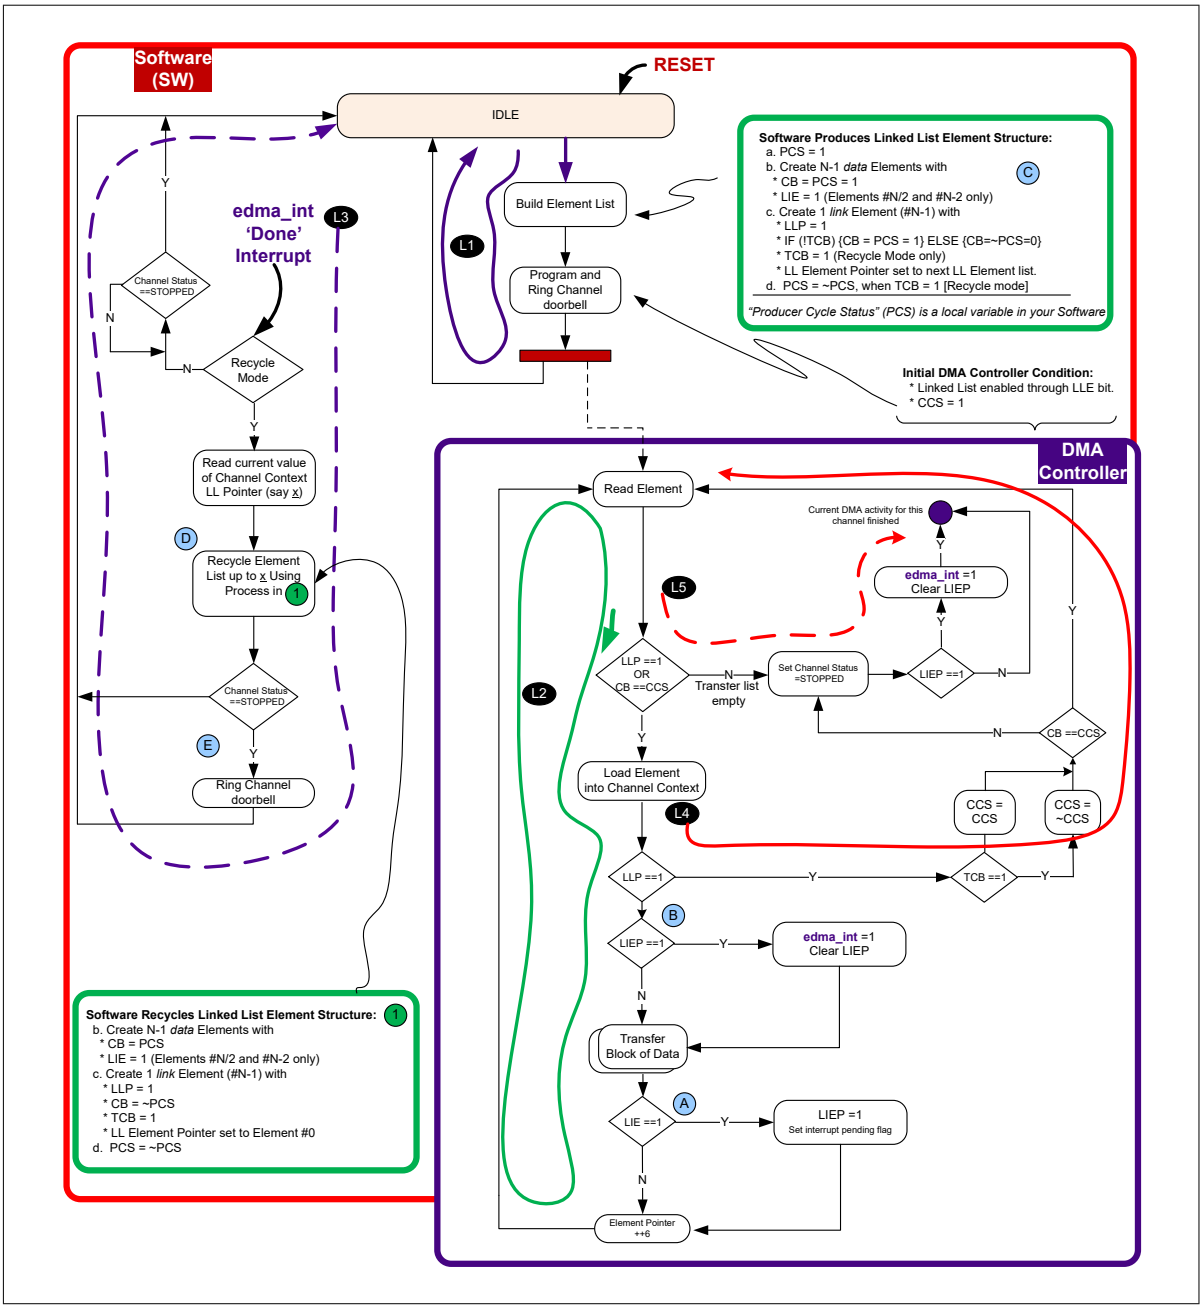

Figure 290 Linked list flow for producer and consumer

5. The DMA proceeds to transfer the block of data (as defined by the element), and when it is finished it reads the next element from local memory.

The solid green loop L2 in the figure above corresponds to steps 4-5

6. The last element in the list (called a link element, and indicated by having its LLP field set to 1) is not used to transfer a block of data.

- It causes the DMA to effectively repeat the task in step 4
- Its TCB is typically set to 1. This causes the DMA to toggle its CCS bit, and the software to toggle its PCS bit. The software and DMA use the "PCS-CCS-CB-TCB" producer-consumer synchronization mechanism to ensure that:
  - Software does not recycle elements that have not yet being consumed by the DMA
  - DMA correctly recognizes and consumes recycled elements

The solid red loop L4 in the figure above corresponds to step 6

7. Upon reception of the interrupt (mentioned in step 1), the software starts to recycle the TL
   - Software reprograms each data element with new DMA transfer information
   - The software and DMA use the “PCS-CCS-CB-TCB” producer-consumer synchronization mechanism described later in this section

   The dashed purple loop L3 in the figure above corresponds to step 7
8. At some point, the software wants to terminate the complete DMA process by not recycling any more elements. The DMA recognizes this condition when CB != CCS and sets the channel status to stopped

   The dashed red loop L5 in the figure above corresponds to step 8

Using interrupts for linked list producer-consumer synchronization

When the DMA is finished with an element, the DMA checks the LIE bit, before reading the next LL element. For more information, see circled step A in the figure above. When the LIE is set, then the DMA does not assert the “done” interrupt immediately, but sets an internal interrupt pending flag (LIEP). It asserts the actual done interrupt after the next data element has been read from system memory. For more information, see circled step B in the figure above. This automatic internal process of delaying the interrupt avoids a race condition between the DMA and software when the LIE bit is set in an element.

Your software should set the “Watermark” interrupt early to schedule the recycling of the consumed elements. Placing the Watermark interrupt too far down in the list, combined with a slow element recycling process in your application; ensures that the DMA returns to the start of the LL before your software has recycled it. The DMA channel STOPs, and you have to restart it by writing to its Doorbell. Typically a “Watermark interrupt” (positioned near the middle of the TL) and an Empty interrupt (in the last data element) are used by setting LIE in these two elements to 1. Upon reception of the interrupt, the software starts to recycle the TL.

PCS-CCS-CB-TCB producer-consumer synchronization

The software and DMA use the “PCS-CCS-CB-TCB” producer-consumer synchronization mechanism to ensure that software does not recycle elements that have not yet being consumed by the DMA, and that the DMA correctly recognizes and consumes recycled elements. This process, which is shared between the DMA and the software, is illustrated through an example producer-consumer flow in the figure below.

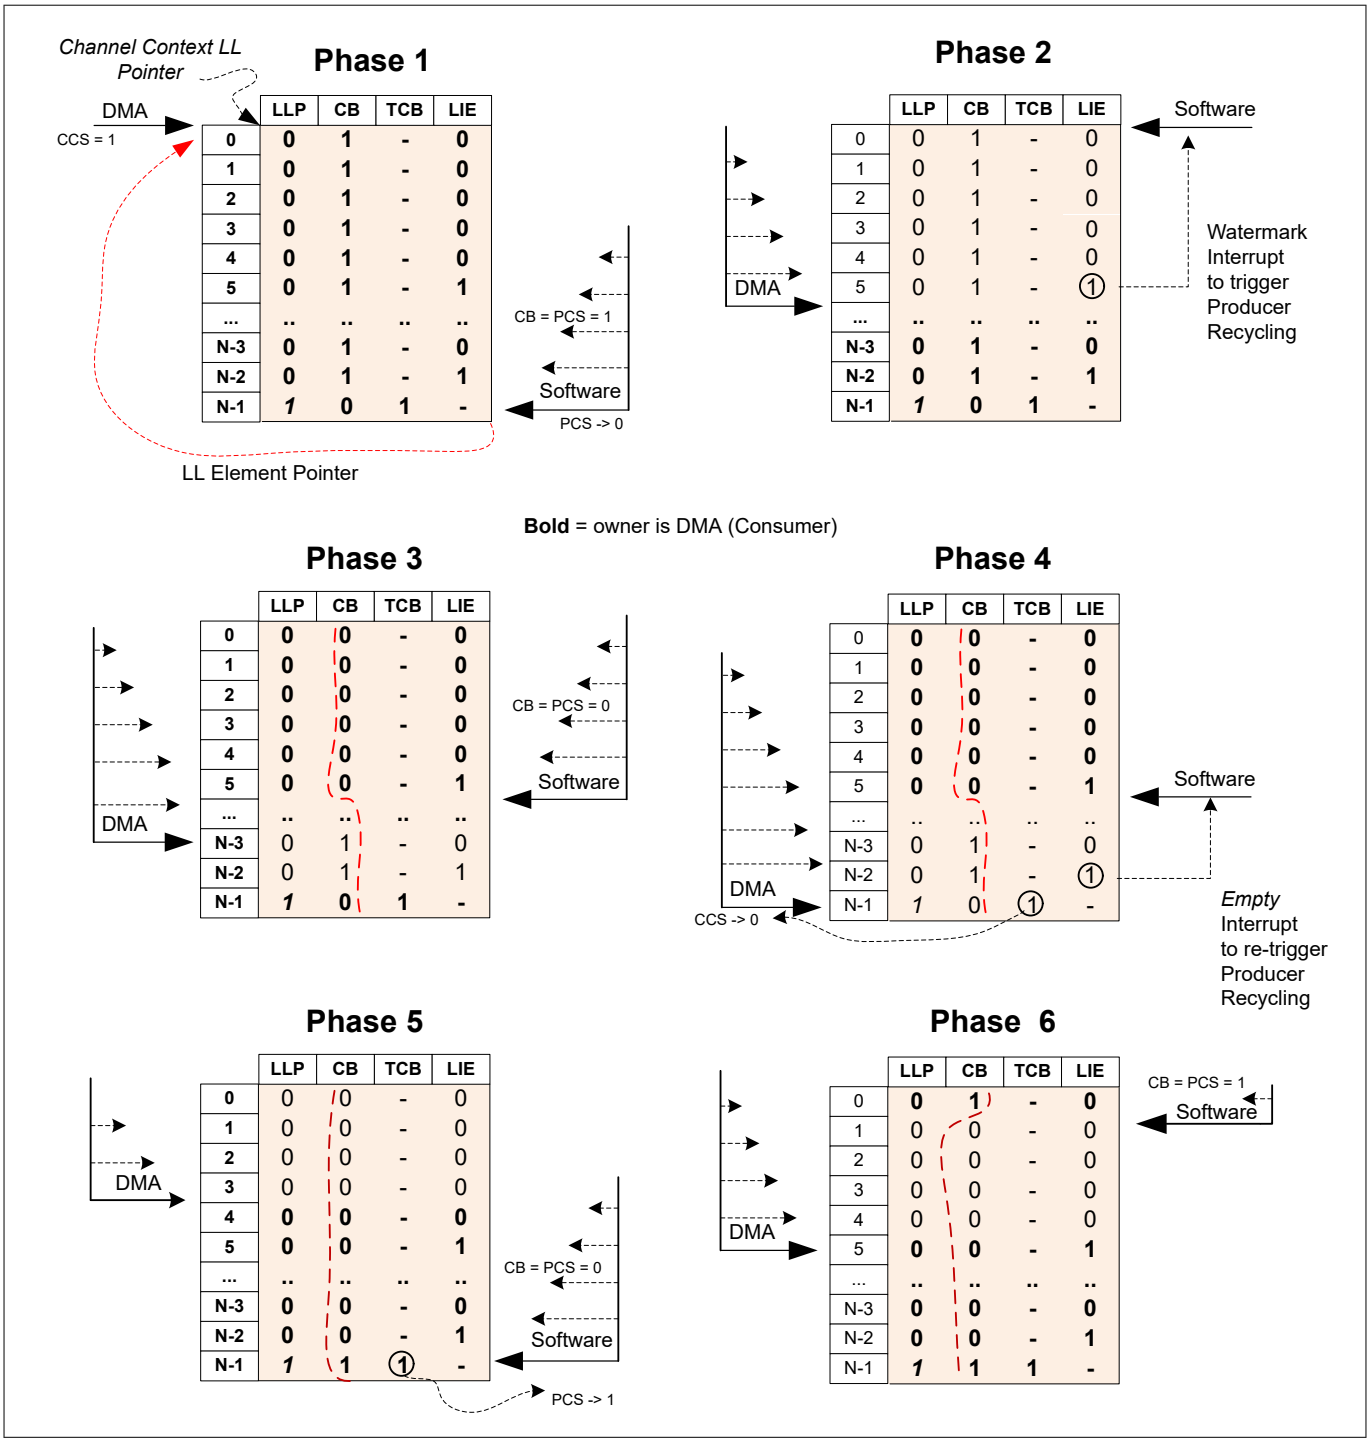

Figure 291 Example producer (software) - consumer (DMA) synchronization flow

Before looking at the example in detail, it is useful to note that the DMA performs the following two tests as part of this process:

- Consumer-Owned Element, or Transfer List (TL) Empty Test:

  The solid red loop L4 in the figure Linked List Flow for Producer and Consumer corresponds to this test. The Cycle Bit (CB) of DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_i) (which is loaded from the LL element) is tested against the DMA Consumer Cycle State (CCS) bit of the same register. When CB = CCS, the element is owned by the consumer (DMA) and the data transfer is executed. When CB != CCS, the TL is empty and the DMA sets channel Status (CS) in DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_i) to “Stopped”
- Toggle Cycle Bit (TCB) Test:

The Dashed Red Loop Marked L5 in the figure Linked List Flow for Producer and Consumer corresponds to this test. When the Toggle Cycle Bit (TCB) of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_i) (which is loaded from the LL element) is set to 1, the DMA toggles the CCS bit of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_i) to be ~ CB. The producer (software) also performs a similar action on its local variable “Producer Cycle Status” (PCS), as it sets PCS =~ PCS. The TCB field is only valid in the last LL element (the *link* element). Toggling the PCS and CCS flags in this manner synchronizes the consumer to the producer

The example in the previous figure has the following six phases:

1. The software builds the transfer list for the write (or read) channel, according to the steps outlined in the circled step C in the figure Linked List Flow for Producer and Consumer. For each element, CB = PCS = CCS = 1. The exception to this is the link element where CB is set to the next iteration value because the link element is always loaded into the channel context
   a. The link element points to the start of the TL and its TCB bit is 1. Software toggles its PCS variable
   b. Software writes the location of the TL into the channel context LL Pointer register
   c. Software rings the write channel Doorbell
2. The DMA starts processing elements. After processing element 5 (and fetching the next element), the DMA asserts a Watermark “done” interrupt to signal the software to start recycling elements
3. The software is recycling elements. It reads the channel context DMA Linked List Pointer Low Register (DMA_LLP_LOW_OFF_WRCH_i) and DMA Linked List Pointer High Register (DMA_LLP_HIGH_OFF_WRCH_i) and recycles elements up to this location[19] in the TL. It sets CB for each element to be PCS. The Dashed Purple Loop Marked L3 in figure 15 corresponds to this activity.

   The DMA continues processing (consuming) elements as before
4. The DMA then asserts an Empty “done” interrupt (from the LIE bit in the last data element at the end of TL that is set in the previous phase) to indicate to the software to start recycling elements again. The DMA reaches the end of the TL, and as the TCB is set to 1, it toggles its CCS bit to 0 (~ CB). For more information, see circled step D in the figure Linked List Flow for Producer and Consumer
5. The software reads the channel context DMA Linked List Pointer Low Register (DMA_LLP_LOW_OFF_WRCH_i) and DMA Linked List Pointer High Register (DMA_LLP_HIGH_OFF_WRCH_i) and recycles elements up to this location in the TL. It sets CB for each element to be PCS. As it recycles the link element, it detects that TCB is set to 1. It toggles its internal variable PCS to 0, and the initial TL has been fully recycled.

   The DMA starts processing the recycled elements
6. The DMA continues processing (consuming) elements as before. Software does not have to ring the Doorbell, as the first element is already recycled before the DMA started processing it.

   The software might continue recycling from the top of the list, if the DMA had already returned to the top of the list when the software read the channel context DMA Linked List Pointer Low Register (DMA_LLP_LOW_OFF_WRCH_i) and DMA Linked List Pointer High Register (DMA_LLP_HIGH_OFF_WRCH_i) in step 5. If not, it starts recycling again when the DMA processes element 4 and the DMA asserts a Watermark “done” interrupt

Element recycling

When your software is recycling elements, it should program the first DWORD (control bits) in the figure Linked List Element/Descriptor Structure in Local Memory with N Element only after the other DWORDs in the same element have been programmed. In addition, it should set the CB bit (to ~PCS) within this DWORD only after the other bits e.g. RIE in the same DWORD have been set. This programming sequence avoids the DMA incorrectly fetching an element that software is currently recycling.

When the software is finished recycling it must check the channel context status (CS). When CS is “Stopped”, the software must ring the channel Doorbell again. For more information, see circled step E in the figure Linked List Flow for Producer and Consumer. If your element recycling process is fast enough, the DMA seamlessly moves from processing the last old element to the first new element without the need for the software to ring the channel Doorbell again. To eliminate the possibility of a race condition between these two actions (read and

[19] If the consumer has moved on to another element, this is not a problem. These newly consumed elements are recycled in the next recycling phase.

write), you should first confirm the presence of the “done” interrupt bit in the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_READ_INT_STATUS_OFF) and also check the DMA Linked List Pointer Low Register (DMA_LLP_LOW_OFF_WRCH_i) to confirm that it is pointing to the correct location.

Link down recovery

During normal operation when the link goes down, the controller generates a “link reset“ interrupt (LNK_STAT.LINKRQRST) to IR. To determine the progress of the linked list operation when the link went down, you can read the contents of the channel context DMA Linked List Pointer Low Register (DMA_LLP_LOW_OFF_WRCH_i) and DMA Linked List Pointer High Register (DMA_LLP_HIGH_OFF_WRCH_i).

19.3.6.2 Using DMA

Source and destination address registers (SAR, DAR)

The DMA channel context SAR and DAR registers (DMA_SAR_LOW_OFF_WRCH_i[20] / DMA_SAR_HIGH_OFF_WRCH_i /DMA_DAR_LOW_OFF_WRCH_i / DMA_DAR_HIGH_OFF_WRCH_i) provide support for remote-to-local, and local-to-remote PCIe address mapping. You program the start of the local and remote data buffers using these registers, and the DMA increments the SAR and DAR as the DMA transfer progresses. For a write transfer, the SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in the following figure.

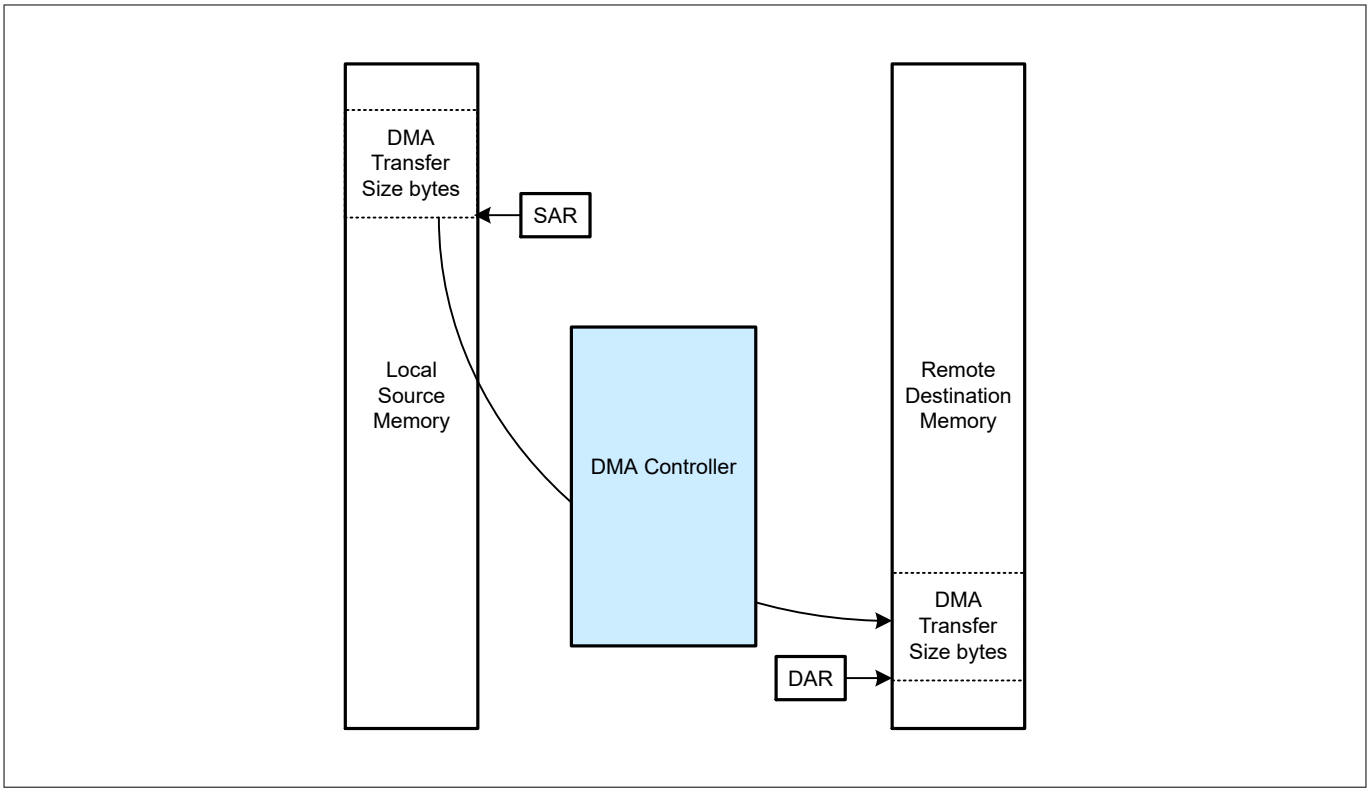

Figure 292 Write transfer: SAR and DAR for write channel 0

For a read transfer, the SAR is the address of the remote memory, and the DAR is the address of the local memory, as shown in the following figure.

[20] Replace WRCH with RDCH for a read channel.

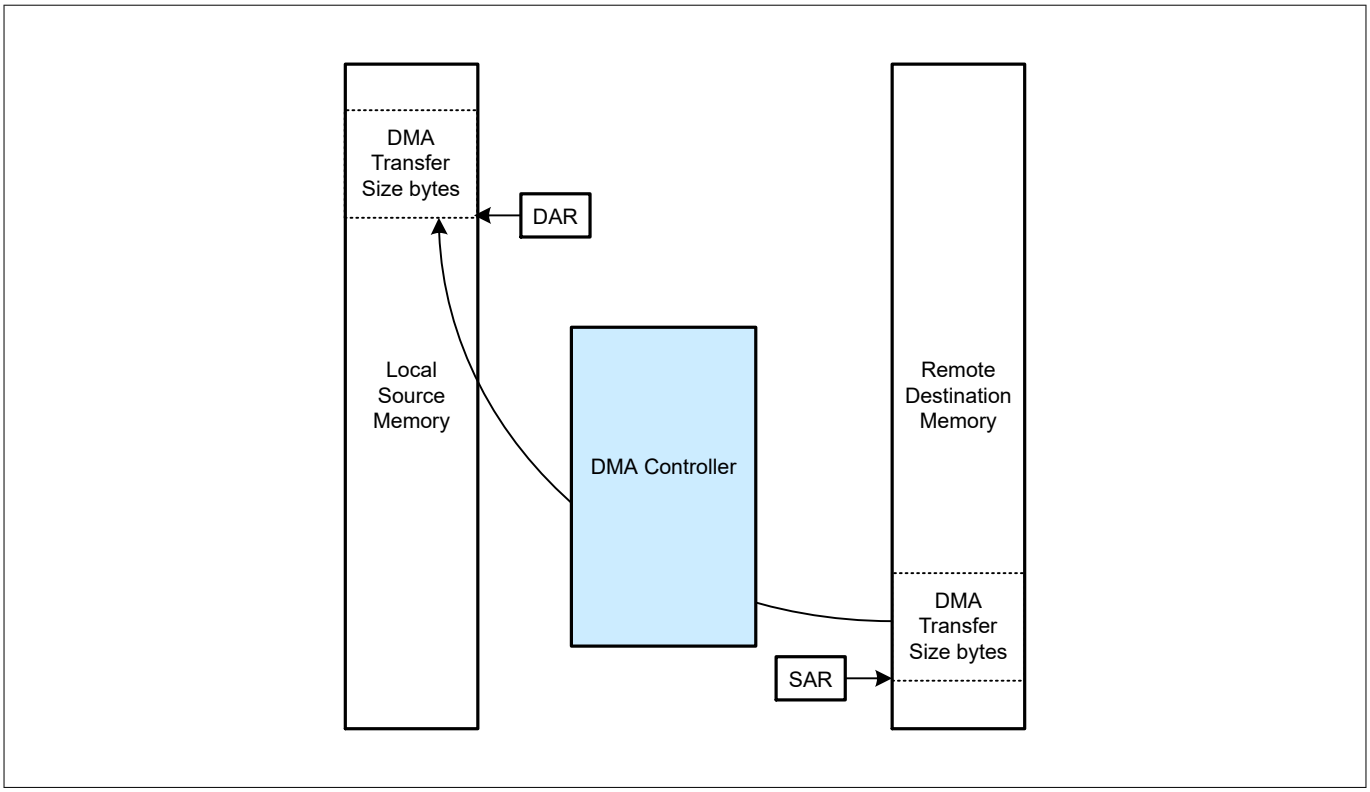

Figure 293 Read transfer: SAR and DAR for read channel 0

The presence of the DMA controller does not affect:

- Normal filtering rules for inbound TLPs (for example, BAR checking in an Endpoint)
- The operation of any internal or external address translation

When the iATU should not translate outbound requests that are generated by the internal DMA module, it is necessary to implement one of the following approaches:

- Ensuring that the combination of DMA channel programming and iATU control register programming causes no translation of DMA traffic to be done in the iATU by avoiding using the same address window
- Activating the DMA bypass mode to allow request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. It is possible to activate DMA bypass mode by setting the DMA Bypass field of the iATU Control 2 Register (IATU_REGION_CTRL_2_OFF_OUTBOUND_i)

DMA transfer size register

You program the DMA transfer size using the DMA Transfer Size Register (DMA_TRANSFER_SIZE_OFF_WRCH_ior DMA_TRANSFER_SIZE_OFF_RDCH_i). The maximum DMA transfer size is 4 GB, and the minimum transfer size is one byte (1_H). The DMA decrements the value in this register as the DMA transfer progresses. When all bytes are successfully transferred, the value in this register is zero. In LL mode, the DMA overwrites this register with the corresponding dword of the LL element. You can read this register to monitor the transfer progress. However, in some scenarios there is a delay before the controller updates this register. For example, when less than three channels are doorbelled, this register is only updated after a descriptor finishes (LL mode), or the transfer ends (non-LL mode).

Starting the DMA transfer

After you program the DMA controller registers (including writing to the DMA Read Engine Enable or DMA Write Engine Enable register), you start a DMA transfer by writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_WRITE_DOORBELL_OFF). You can program and start both a read and a write transfer at the same time. The DMA supports full duplex operation, processing read and write transfers at the same time and in parallel

with normal (non-DMA) traffic. You can program and start any number of channels in the DMA controller sequentially or simultaneously.

- Sequentially: Configuring and starting a channel, then configuring and start another channel
- Simultaneously: Configuring multiple channels, then start multiple channels

***Note**: You must not write to any of the context registers for a particular channel after you start the channel by writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF).*

Detecting the end of the DMA transfer

If a DMA transfer proceeds without any errors, it stops automatically when finished.

Detecting end of transfer without errors

The normal end of a DMA transfer is detected by any of the following methods:

- Done local interrupt asserted
- Done remote interrupt (IMWr) received
- Channel status field of the Channel Control 1 register is Stopped and the DMA Transfer Size register is 0_H
- Polling of the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF)

Detecting end of transfer with errors

The abnormal end of a DMA transfer is detected by any of the following methods:

- Abort local interrupt asserted
- Abort remote interrupt (IMWr) received
- Polling of the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF)
- Channel Status field of the Channel Control 1 register is halted. When the DMA controller detects an error, it forces the DMA to stop issuing requests for the channel. It also sets the channel status field of the Channel Control 1 register to halted, generates an abort interrupt (if enabled), and sends an abort IMWr (if enabled). The DMA Transfer Size register indicates the remaining number bytes to be transferred, except when there is an AXI write error during a DMA read transfer
- Channel Status field of the Channel Control 1 register is stopped and the DMA transfer size register is not 0_H. You have prematurely stopped this channel as described in the next section

Stopping the DMA transfer (software stop)

It is possible to manually abort (stop) the DMA transfer by writing the channel number to the Doorbell Number field and writing 1 to the Stop field in DMA_WRITE_DOORBELL_OFF. This causes the DMA to:

- Place the channel in a stopped state

  The channel Status field in DMA_CH_CONTROL1_OFF_WRCH_i is stopped and the value in DMA_TRANSFER_SIZE_OFF_WRCH_i is not 0_H
- Wait for all outstanding pending transactions
- Assert the abort interrupt (if it is enabled) in DMA_WRITE_INT_STATUS_OFF

You should not use the stop feature in operational mode. It is only a debug feature and has associated hazards

- Before setting the stop bit:
  - The user must read the channel status field (CS) of the DMA Channel Control 1 register to ensure that the corresponding channel is running (transferring data)
  - To eliminate the possibility of a race condition between these two actions (read and write), the user should confirm the presence of the abort bit in the DMA Write Interrupt Status Register

(DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_READ_INT_STATUS_OFF) and check the status of any fatal error if some other event has occurred

- After a Stop event, it is not possible to seamlessly resume the transfer again because the DMA does not resume operation exactly from the point it stopped. Therefore, it is necessary to set up and start the complete channel context again, including the:
  - Linked list pointer
  - Linked list structure in memory
  - Related PCS and CCS values
  - When operating in non-linked list mode, channel context registers mus be set up

TLP generator header control

You must program bits [31:12] of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_i/ DMA_CH_CONTROL1_OFF_RDCH_i), so that the DMA TLP generator correctly sets the TC, RO, NS, AT, and FN TLP header fields for any TLPs that it generates.

Programming examples

This section provides a programming and operation flow for each of the following scenarios:

- 1 MB Write Transfer On Write Channel #0 initiated by Local CPU (Non LL mode)
- 1 MB Read Transfer On Read Channel #0 initiated by Local CPU (Non LL mode)
- 1 MB Write Transfer On Write Channel #3 initiated by Remote CPU (Non LL mode)
- 1 MB Read Transfer On Read Channel #3 initiated by Remote CPU (Non LL mode)
- Linked List Mode Programming Example (Write Channel #0)

***Note**: You must enable the DMA before you start a DMA channel. Therefore you must write '1' to DMA Read Engine Enable or DMA Write Engine Enable register before you write '1' to the DMA Read Doorbell or DMA Write Doorbell register.*

1 MB write transfer on write channel #0 initiated by local CPU (non LL mode)

In this example, the IMWr generation is disabled, as the local CPU initiates the DMA transfer. The local CPU is interrupted using the corresponding interrupts. The SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in the following figure. The following table provides the programming information for this example transfer.

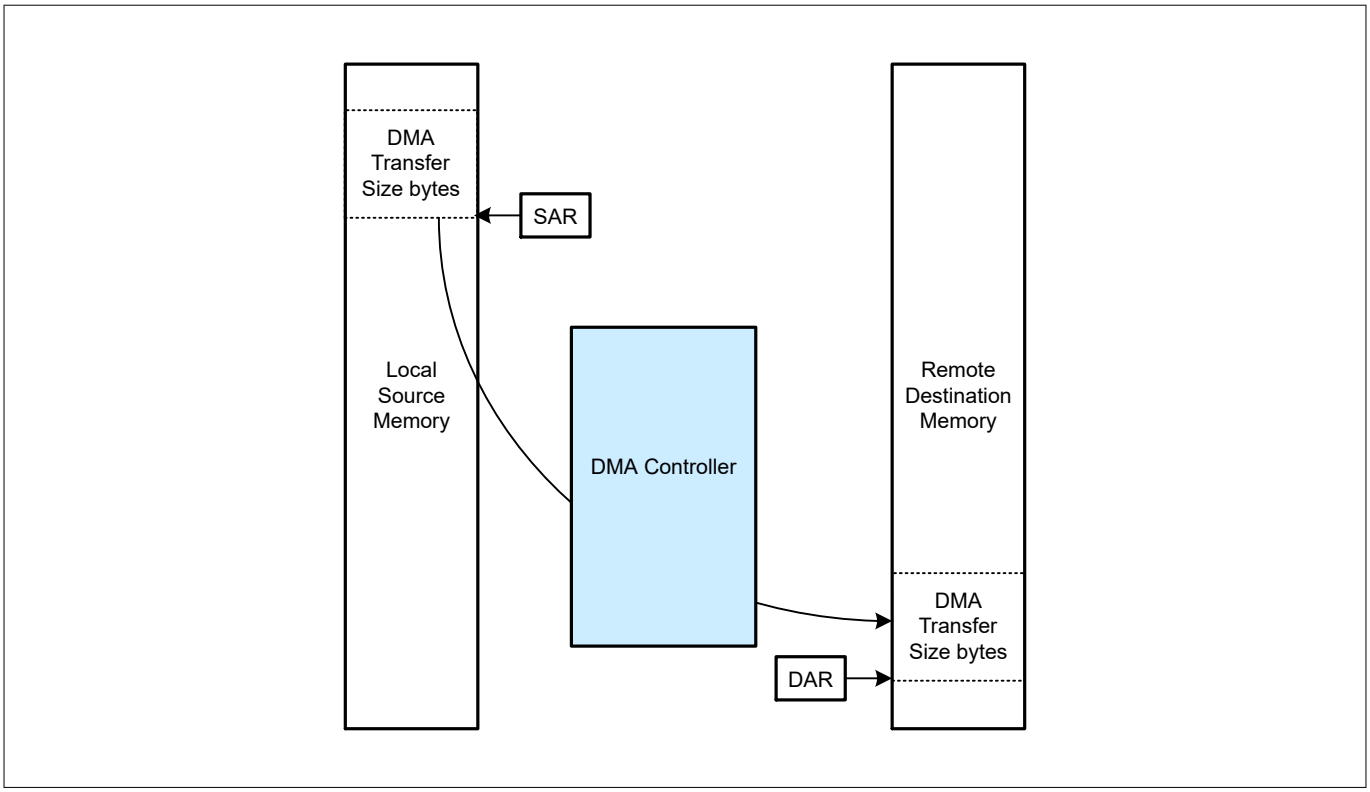

Figure 294 1 MB Write DMA Transfer from 0xBEEF_BEE0 to 0xCAFE_CAF0

Table 836 1 MB write DMA transfer from 0xBEEF_BEE0 to 0xCAFE_CAF0

Linked list mode programming example (write channel #0)

This write channel example has the following features:

- Recycled linked list (LL) of nine data elements[21] and one link element
- Transfer is initiated by local CPU
- Each data element corresponds to a 1 MB (0010_0000_H) write transfer
- The SAR for each element is separated by 2 MB (0020_0000_H). The DAR for each element is separated by 16 MB (0100_0000_H). The SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in the following figure
- The LL transfer list is located at address 0000_0200_H in local memory
- No remote interrupt is generated so the IMWr generation is disabled, as the local CPU initiates the DMA transfer. The local CPU is interrupted using the corresponding interrupts to IR
- There is a Watermark interrupt at element #5 and an Empty interrupt at element #8. Both of these interrupts are done interrupts (as opposed to abort interrupts)

You should familiarize yourself with the Linked List Flow for Producer and Consumer. These are the main steps for this process in this example:

- Step 1: Creating TL in local memory:
  - Creating the 10 elements according to the following table
    - For elements 0, 1, 2, 3, 4, 6, 7: RIE, LIE, LLP, CB = 0, 0, 0, 1
    - For element 5: RIE, LIE, LLP, CB = 0, 1, 0, 1
    - For element 8: RIE, LIE, LLP, CB = 0, 1, 0, 1
    - For element 9: LLP, TCB, CB = 1, 1, 0
- Step 2: Programming and starting DMA:
  - Configuring and starting the DMA registers as per DMA Register Setup
- Step 3: Waiting for done interrupt and recycle TL

[21] Also known as descriptors.

19.3.7 iATU

Address translation is used for mapping different address ranges to different memory spaces supported by the system. A typical example maps your application memory space to PCIe memory space. The iATU also supports type translation. Without address translation, the bus address is passed unmodified to the TLPs directly through the bus interface. You can program the iATU to implement your own outbound address translation scheme.

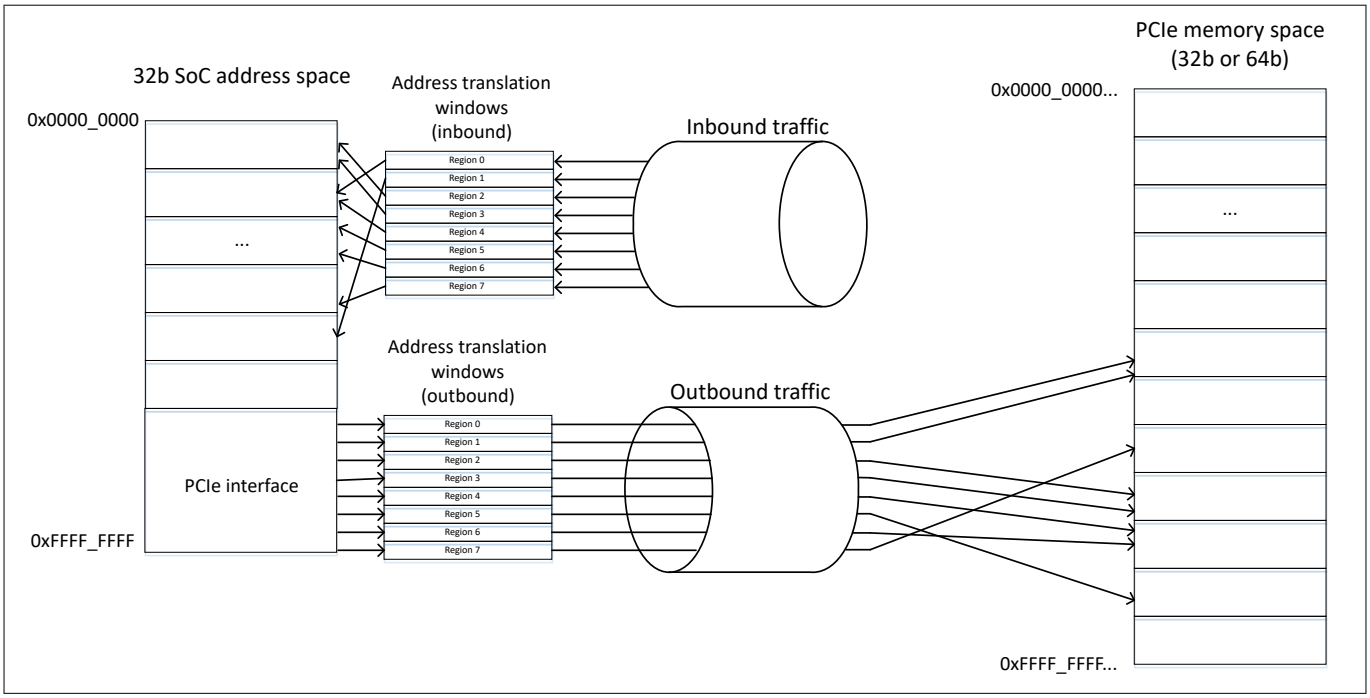

Figure 299 Memory map between PCIe memory space and SoC address (Cfg and Msg space not depicted)

19.3.7.1 Outbound features

- Address Match mode operation for MEM and I/O, CFG, and MSG TLPs
- Supports type translation through TLP type header field replacement for MEM or I/O types to MSG/CFG types
  - Includes posted to non-posted translation (for example, MWr to CfgWr0)
- Programmable TLP header field replacement
  - TYPE/TC/AT/ATTR/MSG-Code/TH/PH/ST
  - Function Number
- 8 address regions programmable for location and size
- Programmable enable/disable per region
- Automatic FMT field translation between three DWORDs and four DWORDs for 64-bit addresses
- Invert Address Matching mode to translate accesses outside of a successful address match
- Response code which defines the completion status to return for accesses matching a region
- Supports regions from 4 KB to 16 GB in size
- Payload Inhibit marks all TLPs as having no payload data
- Header Substitution replaces bytes 8 to 11 (for 3 DWORD header) or bytes 12 to 15 (for 4 DWORD header), inclusive, of the outbound TLP header
- Tag Substitution of the outbound TLP tag field
- DMA bypass mode to allow TLPs, which are initiated by the embedded DMA engine, to pass through the iATU untranslated
- TLP Header fields bypass mode to allow header information to be supplied from the bus interface

19.3.7.2 Outbound basic operation

The address field of each request MEM and I/O TLP is checked to see if it falls into any of the enabled address regions defined by the start and end addresses.

Note that when the Region Enable bit of the Region Control 2 register is '0', then that region is not used for address matching.

When an address match is found, then the TLP address field is modified as follows:

```
Translated Address = Original Address - Base Address + Target Address
```

and the TYPE, TC, AT, TH, PH, ST, Function Number, and ATTR header fields are replaced with the corresponding fields in the IATU_REGION_CTRL_1_OFF_OUTBOUND_i register. When the bus address field matches more than one of the 8 address regions, then the first (lowest of the numbers from 0 to 7) enabled region to be matched is used.

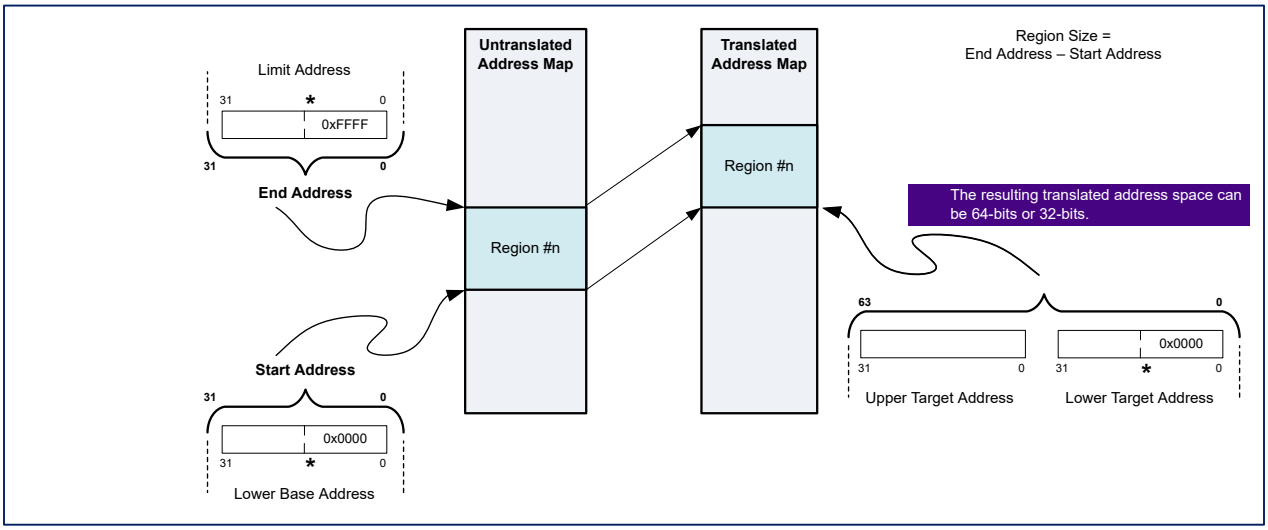

Figure 300 32-bit region mapping: outbound and inbound (address match mode)

19.3.7.3 Outbound detailed operation

Default traffic generated by the bus interface

If no regions matches, write or read accesses are converted to MWr or MRd TLPs. The generated TLP header fields such as TYPE, EP, TC and ATTR are all zeros. With ATU translation, the default memory TLPs can be translated into any TLP types.

RID BDF number replacement

Overview: When there is a successful address match on an outbound TLP, then the function number used in generating the function part of the requester ID[22)] field of the TLP is taken from the 3-bit Function Number field of the IATU_REGION_CTRL_1_OFF_OUTBOUND_i register. This feature can be bypassed by asserting the FUNC_BYPASS in IATU_REGION_CTRL_2_OFF_OUTBOUND_i.

22 Uses the 8:5:3 bit PCI Bus.Device.Function (BDF) format.

MEM to Msg/MsgD type translation

Overview: The iATU supports TYPE translation/conversion of MEM TLPs to Msg/MsgD TLPs. When there is a successful address match on an outbound MEM TLP, and the translated TLP type field is MSG (that is, the type field of the IATU_REGION_CTRL_1_OFF_OUTBOUND_i register is $10xxx_B$), then the message code field of the TLP is set to the value in the Message Code field of the IATU_REGION_CTRL_2_OFF_OUTBOUND_i register. A MWr with an effective length of '0' is converted to Msg and all other MWr TLPs are converted to MsgD. This is a way to generate messages.

MEM to CFG type translation

Overview: The iATU supports translation of MEM TLPs to CFG TLPs. The 16-bit BDF is located at bits [31:16] of the translated address where:

```
Translated Address = Original Address - Base Address + Target Address
```

As an example

```
Original Address[31:16] = {13h0,function_no[2:0]}
```

```
Base Address[31:16] = 16h0
```

```
Target Address[31:16] = {bus_no[7:0],device_no[4:0],3h0}
```

then

```
Translated Address[31:16] = BDF ={bus_no[7:0],device_no[4:0],function_no[2:0]}
```

To handle eight functions (as the previous example indicates), a 19-bit wide region size should be used. See CFG-shift feature how to limit the address range to 15 bit wide region size..

FMT translation

Overview: The iATU automatically sets the TLP format field for three DWORDs. When the original address and the translated address are of different format, the iATU ensures that the TLP header size matches the translated address format.

No address match result

Overview: When there is no address match then the address is untranslated but the TLP header information (for fields that are programmable) comes from the relevant fields on the bus interface, that is always MEM TLP.

Address match invert

Overview: In normal operation an address match on an outbound TLP occurs when the untranslated address is in the region bounded by the base address and limit address. When the invert feature is enabled, an address match occurs when the untranslated address is not in the region bounded by the base address and limit address.

Feature Configuration: To enable Invert feature, set the INVERT_MODE field of the IATU_REGION_CTRL_2_OFF_OUTBOUND_i register to '1'.

DMA bypass

Overview: When you do not want the iATU to translate outbound requests that are generated by the DMA, you must implement one of the following approaches:

- Ensure that the combination of DMA channel address programming and iATU control register programming causes no translation of DMA traffic to be done in the iATU, or
- Enable the DMA bypass mode to allow request TLPs which are initiated by the embedded DMA controller to pass through the iATU untranslated

Feature Configuration: To enable DMA bypass, set the DMA_BYPASS field of the IATU_REGION_CTRL_2_OFF_OUTBOUND_i register to '1'.

Payload inhibit

Overview: When payload inhibit is enabled and region address is matched, the iATU converts transactions with data payload to TLPs without payload data by forcing the TLP header Fmt[1] bit =0, regardless of the application inputs .

This feature must not be used for outbound transactions with data poisoning, because the EP bit is set for TLPs without data payload, this is a violation of data poisoning rules defined in section "2.7.2.2. Rules For Use of Data Poisoning" of the PCI Express Base Specification, Revision 5.0, Version 1.0.

Note: This feature is not supported for MemWr with data payload greater than 1DW.

Feature Configuration: To enable payload inhibit, set the INHIBIT_PAYLOAD field of IATU_REGION_CTRL_2_OFF_OUTBOUND_i to '1'.

Header substitution

Overview: When header substitution is enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i.

Note: For a Msg/MsgD having 4 DWORD header, when HEADER_SUBSTITUTE_EN =1, the 4th DWORD (bytes 12-15) is replaced with the contents of LWR_TARGET_RW field in the IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register. But regardless of the value of HEADER_SUBSTITUTE_EN, the 3rd DWORD is replaced with the contents of UPPER_TARGET_RW field in the IATU_UPPER_TARGET_ADDR_OFF_OUTBOUND_i register. So for a Msg, BDF (or reserved) and Vendor ID must be programmed in UPPER_TARGET_RW.

Usage Scenario: This is useful for Msg/MsgD and ATS (address translation service) transactions which is normally inefficient requiring a very large iATU region.

Feature Configuration: To enable header substitution, set the HEADER_SUBSTITUTE_EN field in IATU_REGION_CTRL_2_OFF_OUTBOUND_i register to '1'.

Tag substitution

Overview: When tag substitution is enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in IATU_REGION_CTRL_2_OFF_OUTBOUND_i.

Note: Your application must not attempt to perform TAG substitution for outgoing non-posted TLPs.

Usage Scenario: This is useful for translation from MWr to Msg/MsgD.

Feature Configuration: To enable tag substitution, set the TAG_SUBSTITUTE_EN field of the IATU_REGION_CTRL_2_OFF_OUTBOUND_i register to '1'.

19.3.7.4 Outbound programming

You can access the iATU registers through the configuration bus interface. The following registers are used for programming the iATU.

Table 842 iATU register map

Label (i = 0 to 7)	Description
IATU_REGION_CTRL_1_OFF_OUTBOUND_*i*	Region Control 1
IATU_REGION_CTRL_2_OFF_OUTBOUND_*i*	Region Control 2
ATU_LWR_BASE_ADDR_OFF_OUTBOUND_*i*	Lower Base Address
IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_*i*	Upper Base Address
IATU_LIMIT_ADDR_OFF_OUTBOUND_*i*	Limit Address
IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_*i*	Lower Target Address
IATU_UPPER_TARGET_ADDR_OFF_OUTBOUND_*i*	Upper Target Address

***Note**: You must not update the iATU registers while operations are in progress on the bus slave interface.*

Outbound programming examples

Define Outbound Region 1 as:

64 kB I/O region from 80000000_D000000$_H$ to 80000000_D000FFFF$_H$, to be mapped to 00010000$_H$ in the PCIe I/O space.

1. Setup the Region Base and Limit Address Registers.
   Write D0000000$_H$ to ATU_LWR_BASE_ADDR_OFF_OUTBOUND_*1* to set the Lower Base Address
   Write 80000000$_H$ to IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_*1* to set the Upper Base Address
   Write D000FFFF$_H$ to IATU_LIMIT_ADDR_OFF_OUTBOUND_*1* to set the Limit Address
2. Setup the Target Address Registers.
   Write 00010000$_H$ to IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_*1* to set the Lower Target Address
   Write 00000000$_H$ to IATU_UPPER_TARGET_ADDR_OFF_OUTBOUND_*i* to set the Upper Target Address
3. Configure the region through the Region Control 1 Register.
   Write 00000002$_H$ to IATU_REGION_CTRL_1_OFF_OUTBOUND_*1* to define the type of the region to be I/O
4. Enable the region.
   Write 80000000$_H$ to IATU_REGION_CTRL_2_OFF_OUTBOUND_*1* to enable the region.

Define Outbound Region 1 as 16 kB region from FC00_0000$_H$ to FC00_3FFF$_H$, to be mapped to 0113_0000$_H$ in the PCIe configuration space.

1. Setup the Region Base and Limit Address Registers.
   Write FC00_0000$_H$ to ATU_LWR_BASE_ADDR_OFF_OUTBOUND_*1* to set the Lower Base Address.
   Write FC00_3FFF$_H$ to IATU_LIMIT_ADDR_OFF_OUTBOUND_*1* to set the Limit Address
2. Setup the Target Address Registers.
   This is the lower 32 bits of the address of the start of the translated range. For configuration access translation bits 31:16 form the BDF (bus – 31:24, device – 23:19 and function – 18:16 numbers) in case the config_shift_mode bit is not set in IATU_REGION_CTRL_2_OFF_OUTBOUND_*1*. Write 0113_0000$_H$ to IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_*1* to set the Lower Target Address for bus number 1, device number 2 and function number 3 when the config shift mode is not set
3. Configure the region through the Region Control 1 Register.
   Write 0000_0004$_H$ to IATU_REGION_CTRL_1_OFF_OUTBOUND_*1* to translate to type 0 configuration TLP
4. Enable the region.

Write 80000000_H to IATU_REGION_CTRL_2_OFF_OUTBOUND_*1* to enable the region

19.3.7.5 Inbound features

- Programmable Match mode operation for MEM, I/O, CFG, and MSG TLPs. No translation for completions
- Selectable BAR Match mode operation for I/O and MEM TLPs
  - TLPs destined for the TRGT0 interface are not translated
  - TLPs that are not error-free (ECRC, malformed and so on) are not translated
- Programmable TLP header field matching
  - TYPE/TD/TC/AT/ATTR/MSG-Code/TH/PH/ST
  - Function Number
- 8 address regions programmable for location and size
- Programmable enable or disable per region
- Automatic FMT field translation between three DWORDs and four DWORDs for 64-bit addresses
- Invert Address Matching mode to translate accesses outside of a successful address match
- ECAM Configuration Shift mode to allow a 256 MB CFG1 space to be located anywhere in the 64-bit address space
- Supports regions from 4 KB to 16 GB in size
- Single Address Location to allow all TLPs to be translated to a single address location
- Msg Type Match Mode to allow matching of any TLP of type Message

***Note**: The default behavior of the ATU when there is no address match in the outbound direction or no TLP attribute match in the inbound direction, is to pass the transaction through.*

19.3.7.6 Inbound basic operations

The setting of the MATCH_MODE field in IATU_REGION_CTRL_2_OFF_INBOUND_i determines how iATU inbound matching is done for each TLP type.

Table 843 Determination of match mode

TLP type	MATCH_MODE =0	MATCH_MODE =1
CFG0	Routing ID Match Mode	Accept Mode
MEM or I/O	Address Match Mode	BAR Match Mode
MSG/MSGD	Address Match Mode	Vendor ID Match Mode

The main difference between inbound and outbound iATU operation is that the TLP type is never changed in the inbound direction. Instead, the type field is used for more precise matching. Other fields can also be optionally used to further refine the matching process.

Another difference is that for MEM and I/O TLPs, you can select between address matching (as used in outbound operation) or BAR matching. Normally, an endpoint uses BAR match mode, and a root complex uses address mode as an root complex normally does not implement BARs.

By default, the MSG and the CFG TLPs are terminated and consumed internally by the controller. No iATU translation happens.

MEM or I/O match modes

Address match mode

The address field of each request TLP is checked to see if it falls into any of the enabled regions[23]. When an address match is found then the TLP address field is modified as follows:

```
Address = Address - Base Address + Target Address
```

When the TLP address field matches more than one of the eight address regions, then the first (lowest of the numbers from 0 to 7 enabled region to be matched is used.

In address match mode, when the address range does not match one of its BAR ranges in an upstream port, then the device rejects the request with unsupported request (UR) completion status and no translation occurs. When the PCIe controller is operating with 32-bit BARs, the operation is defined as in the following figure.

BAR match mode

Looking for an address match is a two-step process.

1. The standard internal PCI Express BAR Matching mechanism checks if the address field of any MEM and I/O request TLP falls into any address region defined by the enabled BAR addresses and masks
2. When a matched BAR is found, the iATU compares the BAR ID to the BAR Number (BAR_NUM) field in the IATU_REGION_CTRL_2_OFF_INBOUND_i register for all enabled regions. The following two figures provide more information on inbound translation in BAR Match Mode

When the PCIe controller is operating with 64-bit BARs, the operation is defined as in figure below where * is $\log_2$(BAR_MASK+1).

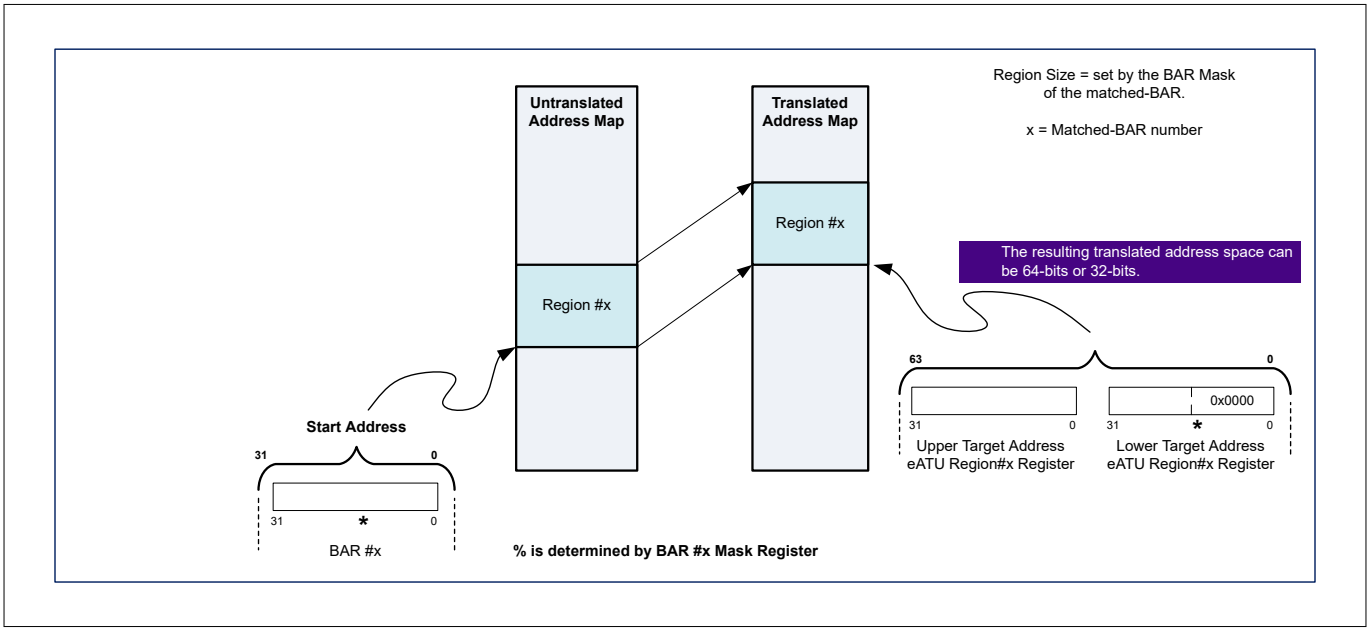

Figure 301 iATU address region mapping: inbound (BAR Match Mode), 32-bit BAR

23 When the Region Enable bit of the Region Control 2 register is 0, then that region is not used for address matching.

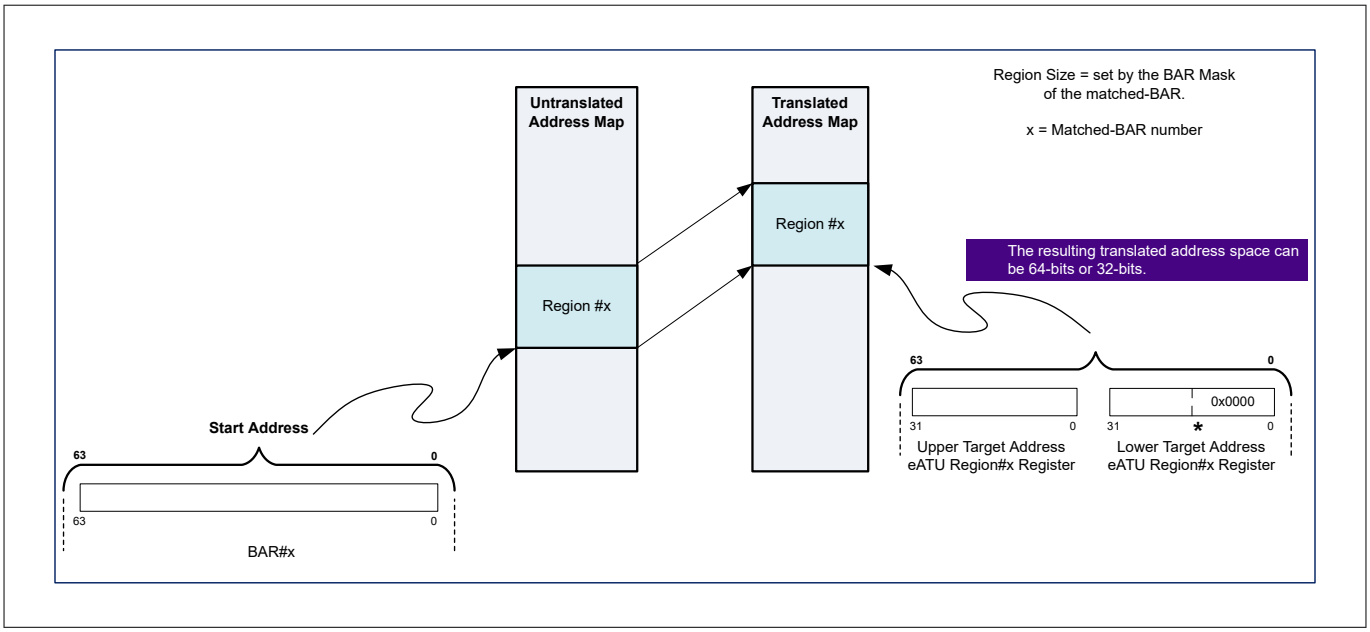

Figure 302 iATU address region mapping: inbound (BAR Match Mode), 64-bit BAR

CFG match mode

The controller normally routes CFG TLPs (to the controller internal registers) without translation. The iATU only translates CFG0 TLPs that the controller has routed to the bus master interface.

Accept mode

In Accept Mode, the controller always accepts CFG0 TLPs even when the CFG bus number does not match the current bus number of the device. The routing ID of received CFG0 TLPs are ignored when determining a match.

Routing ID match mode

The routing ID of the inbound CFG0 TLP must fall within the Base and Limit of the defined iATU region for matching to proceed. The iATU interprets the routing ID (Bytes[24)] 8-9 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM and I/O transactions.

MSG/MSGD match mode

Address match mode

The third and fourth header DWORDs are treated as an address and are compared against the iATU Region Base and Limit Address registers.

Vendor ID match mode

The iATU ignores the routing ID (BDF) in bits [31:16] of the third DWORD of the TLP header[25)], but compares it against the vendor ID in bits [15:0] of the third DWORD of the TLP header (bytes[25)] 10 and 11). This allows messages to be filtered against specific vendor IDs without needing to know the BDF number which might vary

24 For more information, see Figure 2-18 Request Header Format for Configuration Transactions in Section 2.2.7 Memory, I/O, and Configuration Request Rules of the PCI Express Base Specification, Revision 5.0, Version 1.0.

25 In Figure 2-25 Header for Vendor_Defined Messages in Section 2.2.8.6, Vendor_Defined Message of the PCI Express Base Specification, Revision 5.0, Version 1.0.

depending on the PCI topology. Bits [15:0] of the Region Upper Base register should be programmed with the required vendor ID as follows:

```
Region Upper Base[15:8] =byte 10
```

```
Region Upper Base[7:0] =byte 11
```

The lower base and limit register should be programmed to translate TLPs based on vendor-specific information in the fourth DWORD of the TLP header.

19.3.7.7 Inbound detailed operations

FMT translation

The iATU automatically sets the TLP format field for three DWORDs when it detects all zeroed in the upper 32 bits of the translated address. When the original address and the translated address are of a different format then the iATU ensures that the TLP header size matches the translated address format.

Optional matching fields

Overview: In address and BAR match modes, a successful address/BAR match can be optionally gated by successful matching of the programmable TLP header fields (per region) mentioned in table 19. When the associated Match Enable bit (see column "Field" below) is set, the TLP header field of an inbound TLP is matched to the programmed TLP header field value.

Table 844 Registers to consider for TLP header field matching

TLP header field	Match enable		Match value	
	Field	Register	Field	Register
TC	TC_MATCH_EN	IATU_REGION_CTRL_2_OFF_INBOUND_i	TC	IATU_REGION_CTRL_1_OFF_INBOUND_i
TD	TD_MATCH_EN		TD	
ATTR	ATTR_MATCH_EN		ATTR	
TH	TH_MATCH_EN		TH	
AT	AT_MATCH_EN		AT	
PH	PH_MATCH_EN		PH	
Message Code	MSG_CODE_MATCH_EN		MSG_CODE	IATU_REGION_CTRL_2_OFF_INBOUND_i

***Note**: Address translation only proceeds when compares on all enabled field are successful.*

Single address location

Overview: Single address location feature has two modes of operation, fixed and circular buffer.

Fixed: When enabled and region address matches, the TLPs translates to a single address location as determined by the target address register of the iATU region.

Circular Buffer: In this mode, the first TLP translates to a single address location as determined by the target address register of the iATU region. But, for subsequent TLPs, the target address increments by a programmable increment size (CBUF_INCR), each time a region address matches. You can program the increment size using CBUF_INCR field of the IATU_LIMIT_ADDR_OFF_INBOUND_i register (the maximum

increment size is 8192). On reaching the circular buffer window size, the target address wraps around, and resets to single location base address.

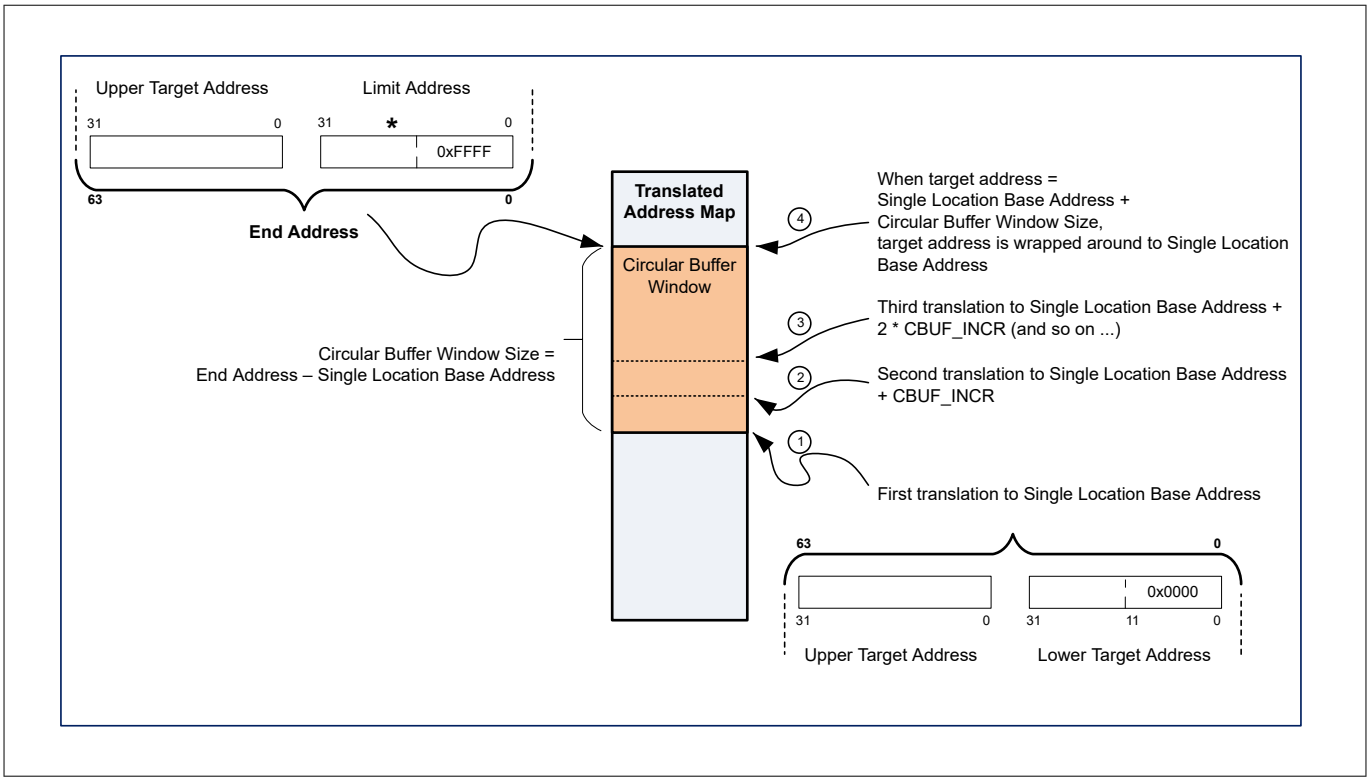

Figure 303 Circular buffer operation

Usage scenario: The main usage scenario is translation of Messages to MWr TLPs.

Feature configuration: To enable single address location feature, set the SINGLE_ADDR_LOC_TRANS_EN field of the IATU_REGION_CTRL_2_OFF_INBOUND_i register to '1'.

Steps to Program ATU Circular Buffer registers

1. Write to Upper Target Address, Lower Target Address, and Limit Address (all inbound) registers for start and end address values of Circular Buffer window for the ATU region
2. Set SINGLE_ADDR_LOC_TRANS_EN = 1 to enable single location address
3. Write the desired increment value to the CBUF_INCR field of the IATU_LIMIT_ADDR_OFF_INBOUND_i register. This enables the circular buffer feature

Table 845 Setting the single address location operation mode

Fixed	Circular buffer
IATU_LIMIT_ADDR_OFF_INBOUND_i.CBUF_INCR =0	IATU_LIMIT_ADDR_OFF_INBOUND_i.CBUF_INCR >0
	IATU_REGION_CTRL_2_OFF_INBOUND_i.SINGLE_ADDR_LOC_TRANS_EN =1

Response code

Overview: Based on the setting of the response code field of the IATU_REGION_CTRL_REG_2_INBOUND_i register (00_B: Normal RADM filter response, 01_B: UR, or 10_B: CA), the controller sets the completion status field of completion TLPs, sent in response to successfully matched non-posted TLPs. When the response code field is set to 2b00, then the normal receive filter response for this TLP is used.

***Note**: Response Code feature is not available in regions where Single Address Location Enable is set.*

Feature Configuration: To enable response code feature, set the RESPONSE_CODE field of the IATU_REGION_CTRL_2_OFF_INBOUND_i register!='00'.

Invert

Overview: Normally an address match on an inbound TLP occurs when the untranslated address is in the region bounded by the Base address and Limit address. When the invert feature is enabled, an address match occurs when the untranslated address is not in the region bounded by the Base address and Limit address.

This feature is supported only when all regions of that type are set to address match mode.

Feature Configuration: To enable invert feature, set the INVERT_MODE field of the IATU_REGION_CTRL_2_OFF_INBOUND_i register to ='1'.

19.3.7.8 Inbound programming

iATU inbound programming overview

This section discusses the register programming interface and provides details of programming examples.

You can access the iATU registers through the configuration bus interface. The following registers are used for programming the iATU.

Table 846 iATU register map

Label (i = 0 to CX_ATU_NUM_INBOUND_REGIONS-1)	Description
IATU_REGION_CTRL_1_OFF_INBOUND_*i*	Region Control 1
IATU_REGION_CTRL_2_OFF_INBOUND_*i*	Region Control 2
ATU_LWR_BASE_ADDR_OFF_INBOUND_*i*	Lower Base Address
IATU_UPPER_BASE_ADDR_OFF_INBOUND_*i*	Upper Base Address
IATU_LIMIT_ADDR_OFF_INBOUND_*i*	Limit Address
IATU_LWR_TARGET_ADDR_OFF_INBOUND_*i*	Lower Target Address

***Note**: You must not update the iATU registers while operations are in progress on the AXI bridge slave interface.*

Inbound programming examples

Address Match Mode Example

Define Inbound Region i as, MEM region matching TLPs with addresses in the range 00010000_H to $0003FFFF_H$ mapped to 90300000_H - $9032FFFF_H$ in your application memory space.

1. Setup the Region Base and Limit Address Registers.
   Write 00010000_H to ATU_LWR_BASE_ADDR_OFF_INBOUND_*i* to set the Lower Base Address.
   Write 00000000_H to IATU_UPPER_BASE_ADDR_OFF_INBOUND_*i* to set the Upper Base Address.
   Write $0003FFFF_H$ to IATU_LIMIT_ADDR_OFF_INBOUND_*i* to set the Limit Address
2. Setup the Target Address Registers.
   Write 90300000_H to IATU_LWR_TARGET_ADDR_OFF_INBOUND_i to set the Lower Target Address
3. Configure the region through the Region Control 1 Register.
   Write 00000000_H to IATU_REGION_CTRL_1_OFF_INBOUND_*i* to define the type of the region to be MEM
4. Enable the region.
   Write 80000000_H to IATU_REGION_CTRL_2_OFF_INBOUND_*i* to enable the region in address match mode

BAR Match Mode Example

Define Inbound Region i as MEM region matching BAR4 (BAR match mode) mapping to 90500000_H in your application memory space.

1. Setup the Target Address Registers.

Write 90500000_H to IATU_LWR_TARGET_ADDR_OFF_INBOUND_i to set the Lower Target Address

2. Configure the region through the Region Control 1 Register.
   Write 00000000_H to IATU_REGION_CTRL_1_OFF_INBOUND_*i* to define the type of the region to be MEM
3. Enable the region for BAR Match Mode.
   Write $C0000400_H$ to IATU_REGION_CTRL_2_OFF_INBOUND_*i* to enable the region for BAR match mode for BAR#4

***Note**: For an EP, the defined MEM or I/O regions must be inside an enabled BAR range. For a RC, the defined MEM or I/O regions must either match a BAR or be outside of the base and limit ranges defined for the port in the Type 1 configuration header.*

19.3.8 BAR details

As an EP, the PCIe controller provides six base address registers (BAR) to define the memory assignment. As a RC, two BARs are available according to the PCIe specification but they are not expected to be used and shall be disabled.

The controller provides three pairs of 32-bit BARs for each implemented function. Each pair (BARs 0 and 1, BARs 2 and 3, BARs 4 and 5) can be configured as follows:

- One 64-bit BAR: For example, BARs 0 and 1 are combined to form a single 64-bit BAR
- Two 32-bit BARs: For example, BARs 0 and 1 are two independent 32-bit BARs
- One 32-bit BAR: For example, BAR0 is a 32-bit BAR and BAR1 is either disabled

In AURIX™, BAR0 has different access regions than the other BARs, as described in table 2. When BAR0 is combined with BAR1 to have a 64-bit BAR, then this pair will inherit the access regions of BAR0.

The BAR masks (BARi_MASK_REG) are used for indicating the amount of address space that each BAR requests from host software. The BAR masks determine which bits in each BAR are non-writable by host software, which determines the size of the address space claimed by each BAR. The BAR mask values indicate the range of low-order bits, in each implemented BAR, not to use for address matching. The BAR mask value also indicates the range of low-order bits in the BAR that cannot be written from the host. The low-order bits in the BAR should be contiguous. The application can write to all BAR bits to allow setting of memory, I/O, and other standard BAR options.

You can change the mask at runtime and the BARs shall be configured again by RC. The BAR mask registers are only writable through the local bus, and not readable. They are not accessible from the PCIe wire by the remote link partner. When the BAR mask value for a BAR is less than that required for the BAR type, the controller automatically uses the minimum value for the BAR type

To disable a BAR, your application can write 0 to the LSB of the BAR mask register.

General rules for BAR setup

At run-time, software can overwrite the BAR contents to reconfigure the BARs. Software must observe the rules listed when writing to the BARs. The rules for BAR configuration are the same for all three pairs. Using BARs 0 and 1 as the example pair, the rules for BAR configuration are:

- Any pair (for example BARs 0 and 1) can be configured as one 64-bit BAR, two 32-bit BARs, or one 32-bit BAR
- BAR pairs cannot overlap to form a 64-bit BAR. For example, it is not possible to combine BARs 1 and 2 to form a 64-bit BAR
- An I/O BAR must be a 32-bit BAR and cannot be prefetchable
- When the device is configured as a PCI Express endpoint (not a Legacy endpoint), any memory that is configured as prefetchable must be assigned to a 64-bit memory BAR
- When BAR0 is configured as a 64-bit BAR:
  - BAR1 is the upper 32 bits of the combined 64-bit BAR formed by BAR0 and BAR1. Therefore, BAR1 must be disabled and cannot be configured independently

  - BAR0 must be a memory BAR and can be either prefetchable or non-prefetchable
  - The contents of the BAR0 mask register determine the number of writable bits in the 64-bit BAR, subject to the restrictions. The BAR1 mask register contains the upper 32 bits of the BAR0 mask value
  - BAR0 can be disabled by writing 0 to bit [0] of the BAR0 mask register
- When BAR0 is configured as a 32-bit BAR:
  - You can configure BAR1 as an independent 32-bit BAR
  - BAR0 can be configured as a memory BAR or an I/O BAR
  - The contents of the BAR0 mask register determine the number of writable bits in the 32-bit BAR0
  - BAR0 can be disabled by writing 0 to bit [0] of the BAR0 mask register
- When BAR0 is configured as a 32-bit BAR, BAR1 is available as an independent 32-bit BAR according to the following rules:
  - BAR1 can be configured as a memory BAR or an I/O BAR
  - The contents of the BAR1 mask register determine the number of writable bits in the 32-bit BAR1
  - BAR1 can be disabled by writing 0 to bit [0] of the BAR1 mask register

The same rules apply for pairs 2/3 and 4/5.

Memory BAR sizes

BAR bits [11:0] are always masked for a memory BAR. The controller requires each memory BAR to claim at least 4 KB. The PCI Express Base Specification, Revision 5.0, Version 1.0 states that the minimum memory address range requested by a BAR is 128 bytes. In the *PCI Local Bus Specification, rev 3.0*, it is recommended that devices that need less than 4 KB of address space should still consume 4 KB of address space in order to minimize the number of bits in the address decoder.

BAR Mask registers

Your local CPU can change the mask at runtime and the BARs shall be configured again by RC. The mask is a register that is invisible to the PCIe wire, but visible to local CPU. You cannot read the mask register but you can write to it.

Example BAR setup

The following figure shows an example configuration of the six BARs and their corresponding BAR mask registers. The example configuration includes:

- One 64-bit memory BAR (non-prefetchable)
- One 32-bit memory BAR (non-prefetchable)
- One 32-bit I/O BAR

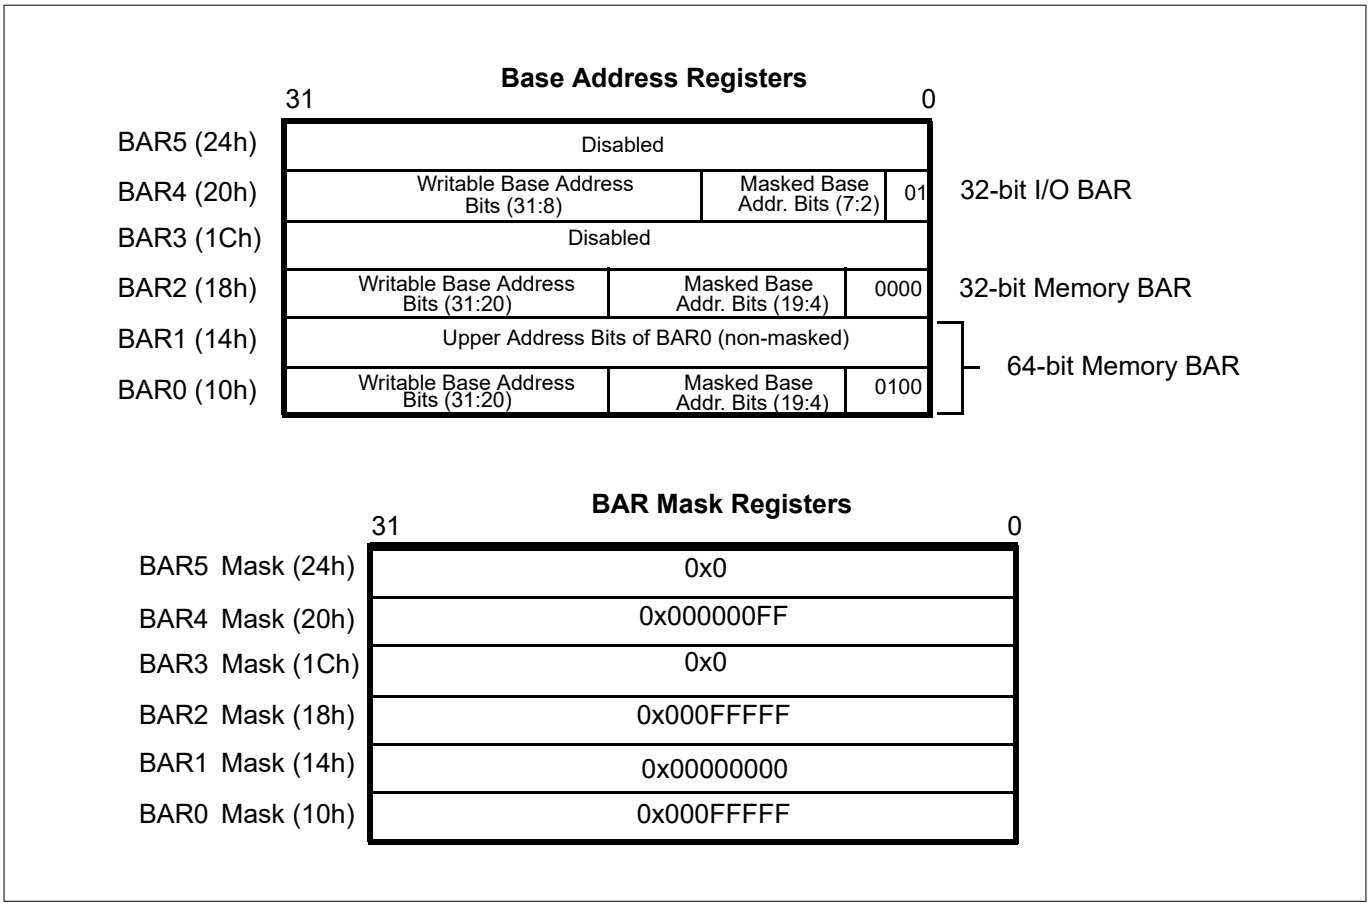

Figure 304 Example base address register configuration

Expansion ROM BAR mask register

The mask is a register that is invisible to the PCIe wire but visible to local CPU. You cannot read the mask register but you can write to it.

BARs in RC

Two BARs are present but are not expected to be used. You should disable them to avoid unnecessary memory assignment during device enumeration. If you do use a BAR, then you should program it to capture TLPs that are targeted to your local memory space residing on the bus. The BAR range must be outside of the three Base/Limit regions (three regions defined in type 1 configuration header). The controller provides one pair of 32-bit BARs (BAR0 and BAR1). The BARs can be configured as follows:

- One 64-bit BAR: BAR0 and BAR1 are combined to form a single 64-bit BAR
- Two 32-bit BARs: BAR0 and BAR1 are two independent 32-bit BARs
- One 32-bit BAR: BAR0 is a 32-bit BAR and BAR1 is either disabled or removed from controller altogether to reduce gate count

The sizing of BAR, the disabling and setup rules are similar to BARs in EP.

19.3.9 Messages

Message requests in PCIe replace many of the interrupt, error and power management sideband signals on PCI and PCI-X. They are handled as MSG TLPs and usually have fixed transmit directions.

A subset of PCIe messages is supported by AURIX™ . They are listed in the following table. The message propagation directions and brief descriptions are also introduced.

Table 847 Types of messages

Index	Message type	Message	EP mode	RC mode	Description
1	INTx	Assert_INTx, Deassert_INTx	T	R	legacy interrupt Messages
2	power management	PM_Active_State_Nak	R	T	indicates a rejection when entering L1
		PM_PME	T	R	requests a PM state change
		PME_Turn_Off	R	T	broadcasts the PME_Turn_Off Message in preparation for removing the main power source
		PME_TO_Ack	T	R	initiates the L2/L3 Ready transition protocol
3	error signaling	ERR_COR	T	R	detects a correctable error
		ERR_NONFATAL	T	R	detects a non-fatal, uncorrectable error
		ERR_FATAL	T	R	detects a fatal, uncorrectable error
4	Device readiness status	DRS or FRS	T	R	indicates that device has become configuration-ready
5	LTR	-	T	R	reports the tolerance of read or write service latencies
6	OBFF	-	R	T	reports platform central resource states to EP
7	PTM	PTM request	T	R	initiates PTM dialog
		PTM response	R	T	completes current PTM dialog – does not carry timing information
		PTM responseD	R	T	completes current PTM dialog - carries timing information

***Note**: R = Supports as Receiver; T= Supports as Transmitter*

Message generation on page 2767
Message reception on page 2768

19.3.9.1 Message generation

Various messages can be generated by AURIX™ depending on the work mode, either EP or RC. Some messages can only be generated under a specific work mode. For example, the INTx messages can be transmitted by an EP and received by a RC. These restrictions are defined by the PCIe specification.

The table below shows the message generation mechanisms under two modes. Some messages are triggered by hardware blocks autonomously. For example, the PTM messages. Some messages have to be triggered by application software directly. For example, the OBFF messages. The software uses OBFF messages to indicate the system status to other devices and provides hints how to save power. There are also messages that provide both possibilities.

Table 848 Generation sources of messages

Index	Message type	Message	EP mode	RC mode
1	INTx	Assert_INTx, Deassert_INTx	SW ()	-
2	Power management	PM_Active_State_Nak	-	HW
		PM_PME	SW ()	-
		PME_Turn_Off	-	SW ()
		PME_TO_Ack	HW	-
3	Error signaling	ERR_COR	HW;SW()	-
		ERR_NONFATAL	HW;SW()	-
		ERR_FATAL	HW;SW()	-
4	Device readiness status	DRS	HW	-
5	LTR	-	SW()	-
6	OBFF	-	-	SW()
7	PTM	PTM request	HW	-
		PTM response	-	HW
		PTM responseD	-	HW

***Note**: SW = software triggered message generation; HW = hardware autonomously triggered message generation*

There are two ways to generate a message by software. The straightforward way (Direct software triggering) is using the designated registers to trigger a specific message generation. Application software simply asserts a specific bit and then the desired message is created and transmitted. The second way (Indirect software triggering) is using the iATU to generate message TLPs. In this way, all types of messages can be created with the flexibility to control specific values in register fields. The details of how to use ATU to generate messages are described in the section iATU.

Indirect software triggering

Msg and MsgD can be generated with an indirect SW trigger. The iATU needs to be configured to translate MWr to Msg TLPs or MsgD TLPs. Msg has no payload, achieved by using the payload inhibit feature of iATU. The header and tag substitution are used to create the head for Msg by using IATU_LWR_TARGET_ADDR_OFF_OUTBOUND and IATU_UPPER_TARGET_ADDR_OFF_OUTBOUND. The address of a bus transaction triggered by application shall be DWORD aligned in order to be correctly translated to Msg.

19.3.9.2 Message reception

The reception of PCIe messages also follows rules defined by the PCIe specification. The table below indicates how various messages are handled by PCIe module under both work modes. Messages received can be handled by the hardware blocks automatically or by software interrupts.

Table 849 Reception handling of messages

Index	Message type	Message	EP mode	RC mode
1	INTx	Assert_INTx, Deassert_INTx	-	IR
2	Power management	PM_Active_State_Nak	PMC	-
		PM_PME	-	PMC
		PME_Turn_Off	PMC	-
		PME_TO_Ack	-	PMC
3	Error signaling	ERR_COR	-	SW()
		ERR_NONFATAL	-	SW()
		ERR_FATAL	-	SW()
4	Device readiness status	DRS	-	FRS queue
5	LTR	-	-	SW()
6	OBFF	-	SW()	-
7	PTM	PTM request	-	PTM
		PTM response	PTM	-
		PTM responseD	PTM	-

***Note**: IR = interrupt router; PMC = power management controller; SW = software handling via interrupt; FRSQ= FRS queue; PTM = precise time measurement block*

19.3.10 Power management

According to PCIe specification, D states and L states are specified. D states are associated with a particular function while L states are associated with a particular link. PM defines link power management states that a PCIe physical link is permitted to enter in response to either software driven D state transitions or active state link power management activities.

PCIe has several power management protocols. In this document, two relevant ones, Active State Power Management (ASPM) and software-driven PM, are briefly introduced and applied in AURIX™. ASPM is an autonomous hardware-based, active state mechanism that enables power savings. After a period of idle link time, an ASPM protocol places the idle link into a lower power state. Software-driven PM manipulates the D states and is a PCI-PM compatible mechanism. The link state are not visible to PCI-PM legacy compatible software, and are driven from the D state of the corresponding components connected to the link or by ASPM.

19.3.10.1 Device power management state

The PCIe protocol is compatible with all PCI power management functionality. Software can direct the function to enter any of the D1, D2 or D3 low-power states from D0. This device only supports D0, $D3_{hot}$ and $D3_{cold}$. This is achieved by writing to the PMCSR in the PCI-PM capability structure.

D states:

- D0: Normal power state. In this state, no power conservation is in effect and the device is fully operational

- D1 (not supported by this device): Light sleep. Before going into this state, software must ensure that all outstanding non-posted requests have received their associated completions. This state is not supported
- D2 (not supported by this device): Deep sleep. Similar to D1, software must ensure that all outstanding non-posted requests have received their associated completions. This state is not supported
- $D3_{hot}$: Very low power state; power supply available
- $D3_{cold}$: Power-off state; power supply removed; auxiliary power supply optionally available

The transitions between different D states are described in the following figure.

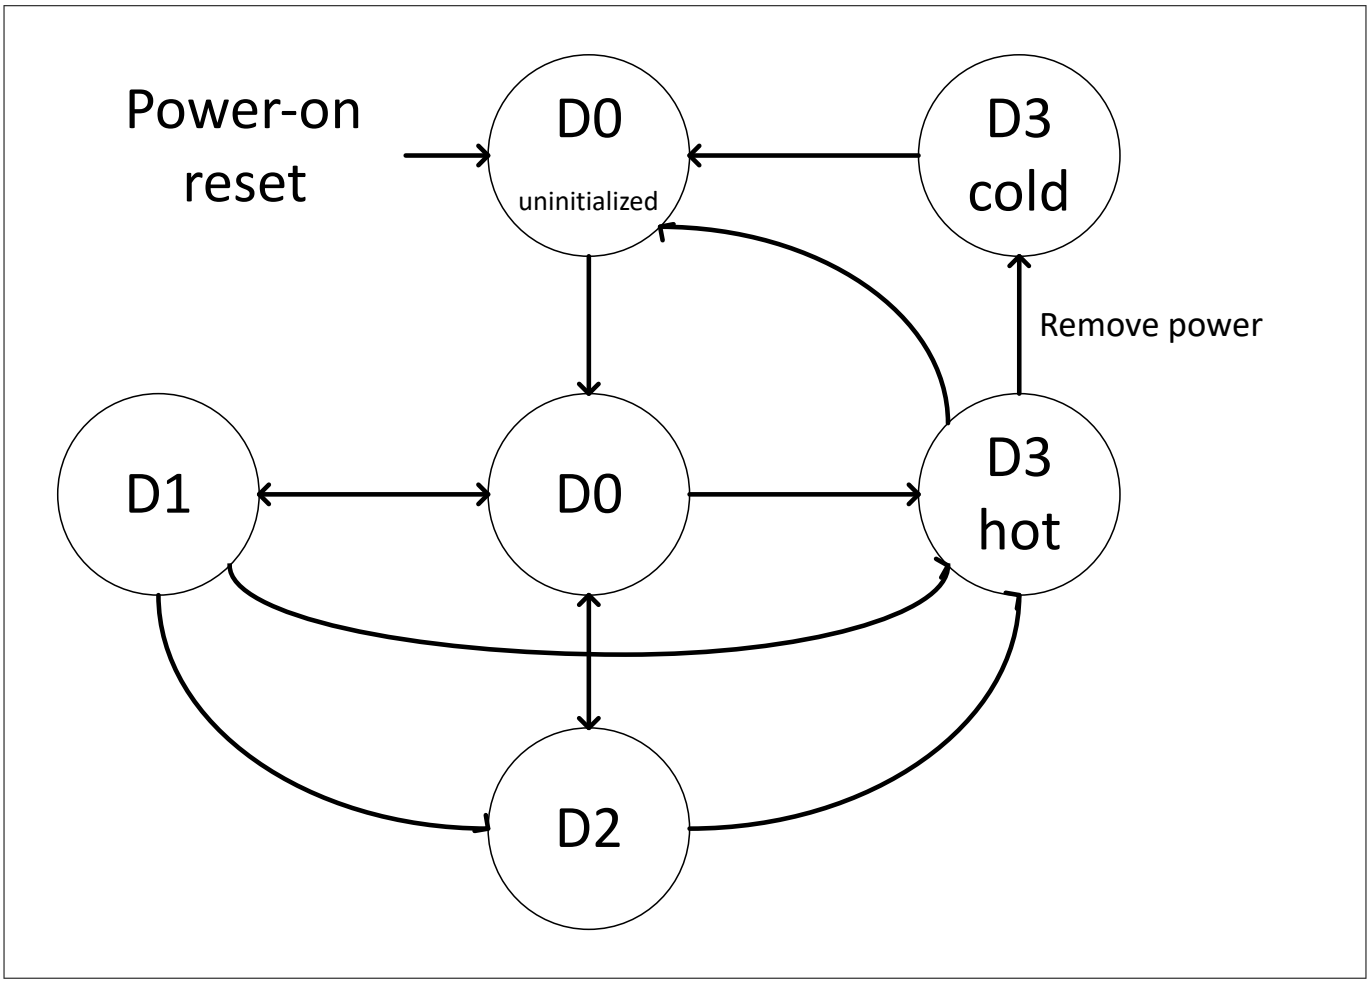

Figure 305 Device power management state flow diagram

Only the required D states: D0, $D3_{hot}$ and $D3_{cold}$ are supported in this module.

19.3.10.2 Link state power management

Several link power states are specified by the PCIe specification. PCIe controller supports all link states.

- L0s: a lower power state enabled by ASPM. The transmitters of two devices on a link are controlled separately. For example, a link works under L0s in the downstream direction while it works under L0 in the upstream direction
- L1: the L1 state is a higher latency, lower power "standby" state. L1 support is required for PCI-PM and optional for ASPM. Several substates of L1 are defined to further reduce the power consumption. L1 substates include L1.1 and L1.2
- L2/L3 ready: this is a staging point for L2 or L3
- L2: L2 is a auxiliary-powered link, deep-energy-saving state

- L3: it is a link-off state
- LDn: LDn is a transitional link down pseudo-state prior to L0

The transitions between different link states are explained by the diagram below .

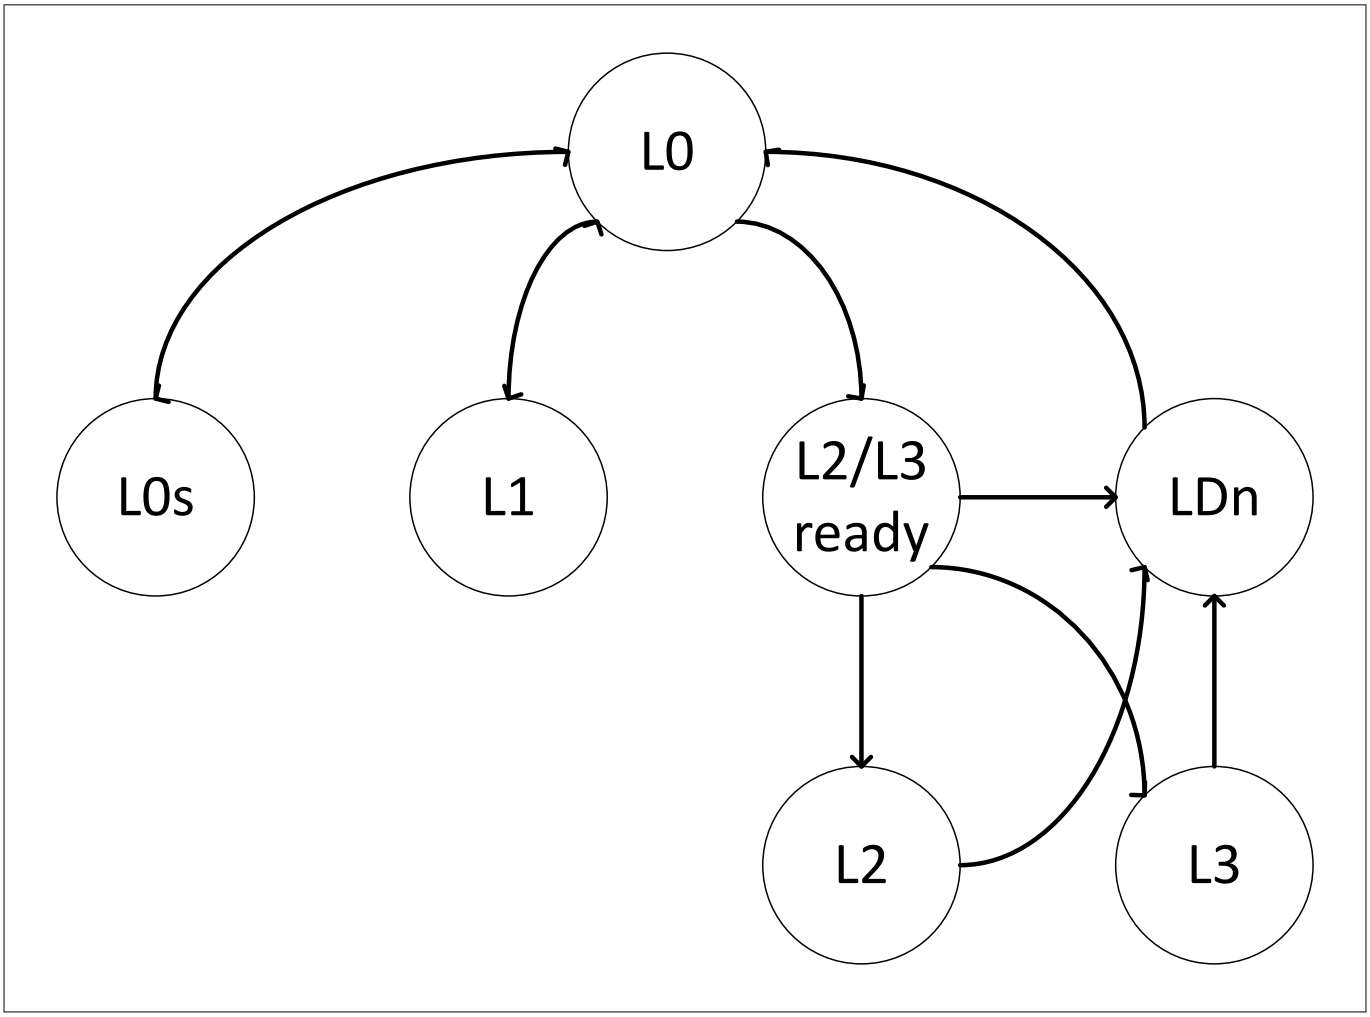

Figure 306 Link power management state flow diagram

ASPM is able to change link states autonomously.

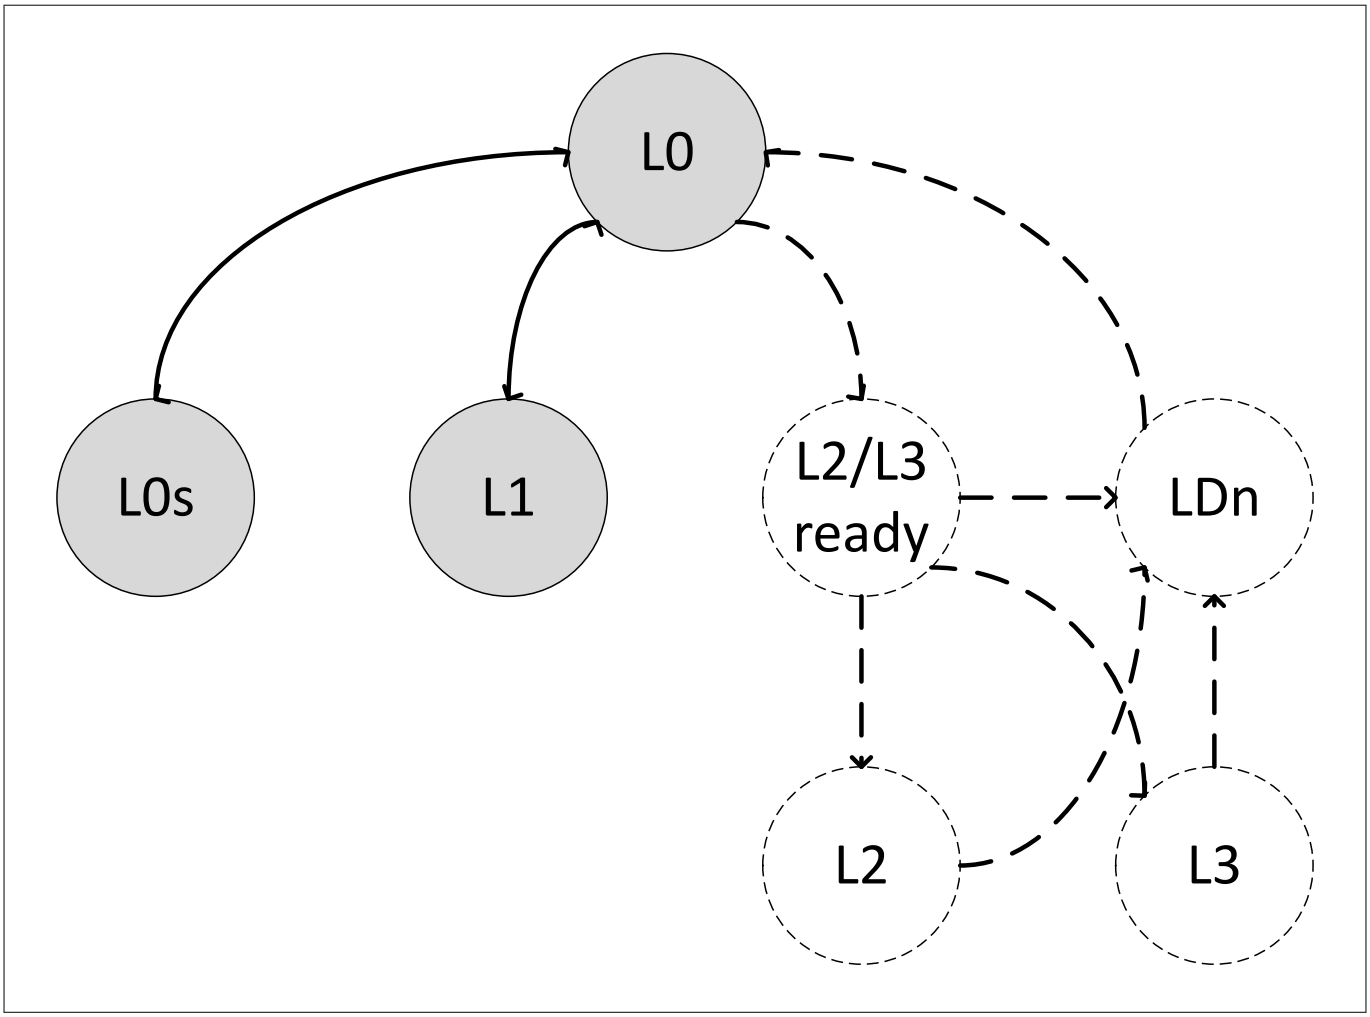

Figure 307 ASPM link state power management

The software driven mechanism can indirectly change the link state by setting the D states. The transition diagram by software driven mechanism is depicted in the diagram below.

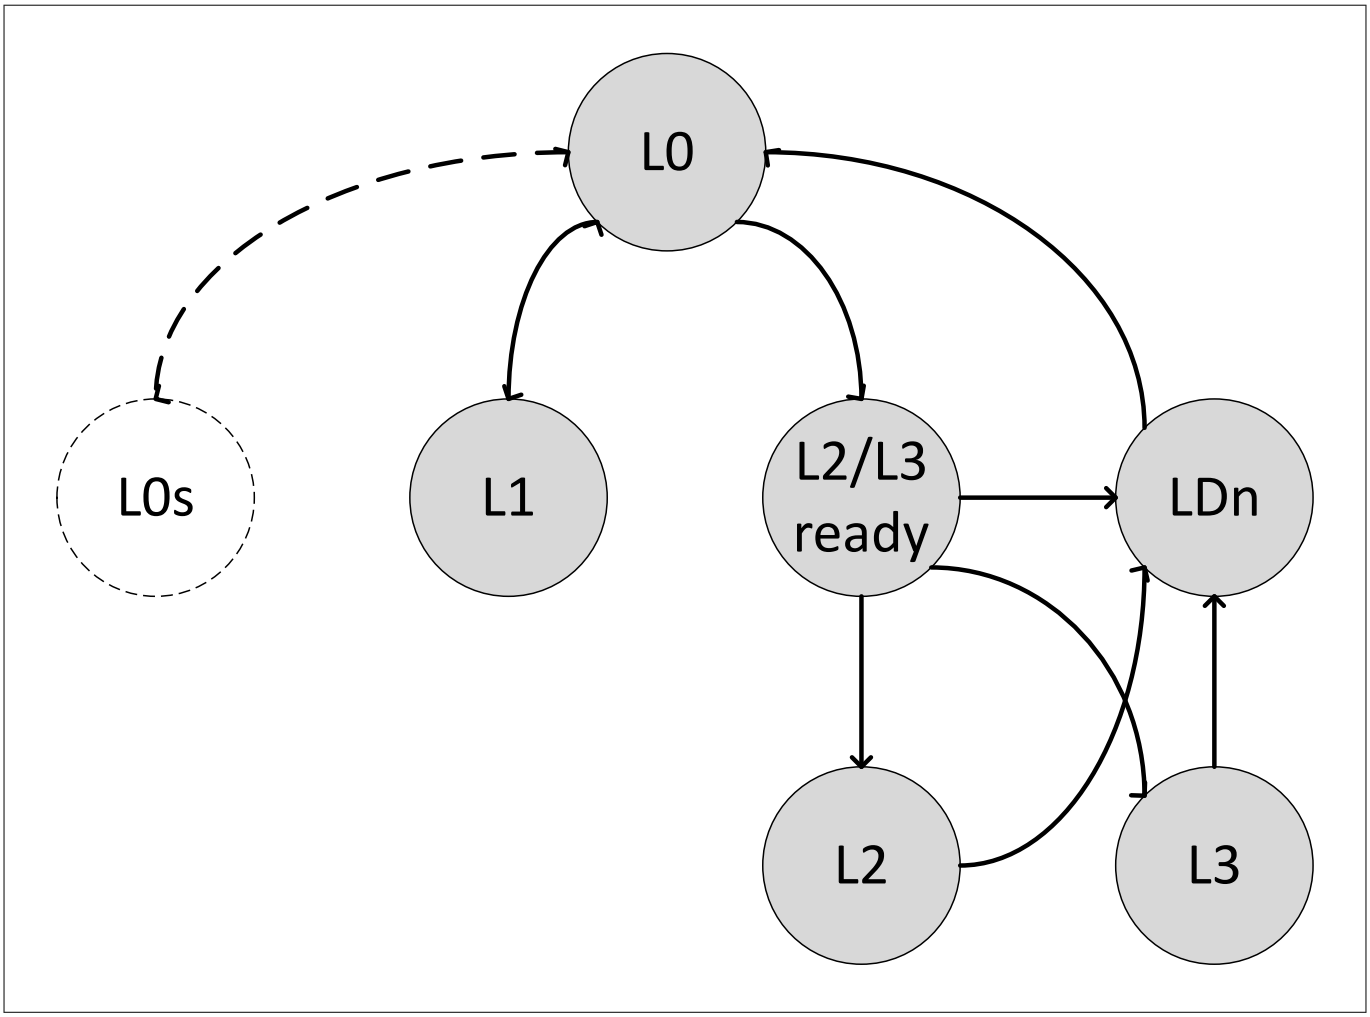

Figure 308 Software driven link state power management

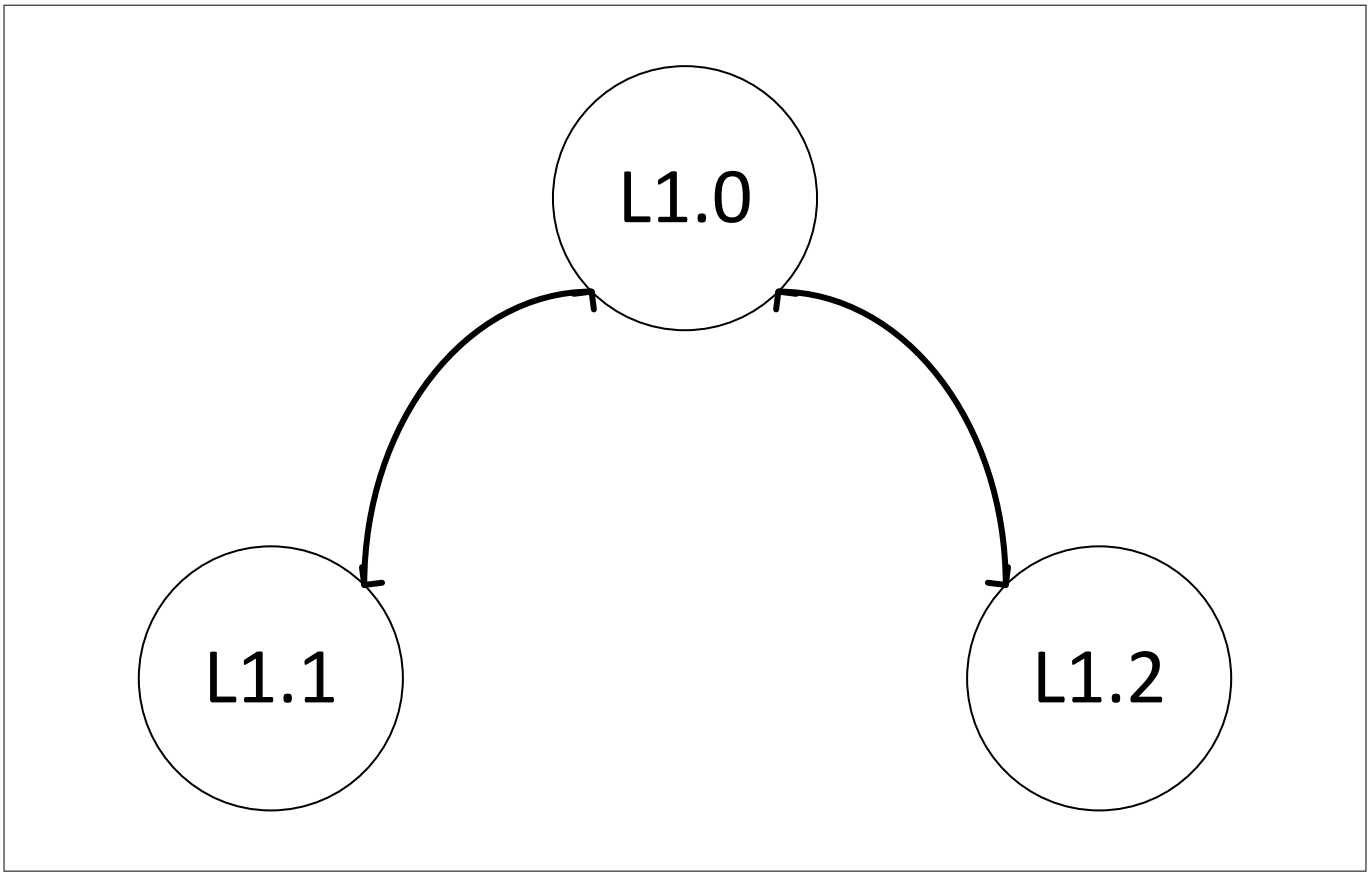

Figure 309 L1 substate power management

19.3.10.3 Impact of device states on link states

The power management state of a link is determined by the D state of it downstream component. These relationships are reflected in the following table. The link state change under D0 can only be triggered by ASPM while the link state change across D states are software driven. ASPM only applies to D0 state.

Table 850 Device and link state relationships

Downstream device state	Permissible upstream device state	Permissible link state	Link state change trigger
$D0_{uninitialized}$	-	L0	-
D0	D0	L0	ASPM
		L0s	ASPM
		L1/L1.x	ASPM
$D3_{hot}$	D0 - $D3_{hot}$	L1/L2	software-driven
$D3_{cold}$	D0 - $D3_{cold}$	L3	software-driven

According to the PCIe specification, link state transitions are allowed to be requested by certain roles, as explained in the following table.

Table 851 Link state change trigger capabilities for USP/DSP

Port type	Can trigger L0/L0s entry?	Can trigger L1 entry?	Can trigger L2/L3 entry?
USP	Yes	Yes, on any of these triggers: • Software programs non-D0 state • USPs idle timer expires (ASPM) • Application requests USP to enter L1	No
DSP	Yes	No	Yes

ASPM

When the USP is in L0 and detects idleness on the link for a specific amount of time (determined by the L0s Entrance Latency field in the “Ack Frequency and L0-L1 ASPM Control Register” ACK_F_ASPM_CTRL_OFF), it automatically transitions the link to the L0s power state. Each link direction (TX and RX) is processed separately. The controller exits L0s when there is traffic waiting to be sent.

When the USP is in L0 or L0s and it detects idleness on the link (both directions) for a specific amount of time (determined by the L1 Entrance Latency field in ACK_F_ASPM_CTRL_OFF), it automatically transitions the link to the L1 power state. The link partners must negotiate entry into the L1 link power state using PM TLPs and DLLPs. The L1 state achieves greater power savings but the exit latency from this state is higher than from L0s.

If the ASPM exit latencies from L0s or L1 are too high for the overall PCIe system data latency requirements, then the host software can disable ASPM using the ASPM Control Field of the Link Control register. The controller reports the exit latencies using the Link Capability registers.

L1 entry and exit

The power management state of a link is determined by the D-state of the USP. When the device state of the USP changes to D1, D2, or $D3_{hot}$ by writing to the PMCSR, the controller must initiate a link state transition to L1. L1 state is a bi-directional link low-power state. Both link partners must negotiate to enter this state. The L1-PM negotiation handshake uses the following DLLPs:

- PM_Enter_L1
- PM_Request_Ack

***Note**: asserting PM_CTRL.XFERPND doesn't prevent L1-PM entry, but causes immediate exit from L1-PM.*

The exit of L1-PM can be triggered by any of the below options:

- A DLLP or TLP is pending to be sent
- PM_CTRL.REQEXITL1 is asserted
- Link partner is requesting exit from L1
- PM_CTRL.XFERPND is asserted
- PM_CTRL.WKUPCMD is asserted to request the module to wake up, when the USP is programmed with capability to support PME. It can also be requested by the link partner to exit
- PM software (RC) requests a higher stage of power-down by writing to the PMCSR in the USP
- USP requests transmission of VDM, MSI/MSIX2, or LTR message
- The local software is requesting to send traffic
- The local software enables a DMA read or write channel or DMA controller is requesting data. Doorbelling any DMA read/write channel triggers L1 exit while writing to other DMA registers does not
- DSP initiates link disable or link retrain (by setting PCIE_CAP_LINK_DISABLE or PCIE_CAP_RETRAIN_LINK field in LINK_CONTROL_LINK_STATUS_REG to 1)

- DSP initiates a hot reset
- The local software requests a speed change (by setting DIRECT_SPEED_CHANGE field in GEN2_CTRL_OFF to 1)
- Clearing RADM_CLK_GATING_EN field in CLOCK_GATING_CTRL_OFF register
- Local software requests access to Configuration or Memory space mapped to the register group 6 and 7

L1 Substates

L1 Substates establish a Link power management regime that creates lower power substates of the L1 Link state.

- L1.0: The L1.0 substate corresponds to the conventional L1 Link state. This substate is entered whenever the Link enters L1
- L1.1: It uses a bidirectional open-drain clock request (CLKREQ#) signal for entry to and exit from this state. In the L1.1, the PLL and the Rx electrical idle detector are switched off
- L1.2: it uses a bidirectional open-drain clock request (CLKREQ#) signal for entry to and exit from this state. In the L1.2, the PLL, Rx electrical idle detector and Tx common mode are switched off

When the controller enters L1, the target L1 substate depends on several programming bits including PM Control/Status register bits and L1 Substates Control 1 register bits. The target L1 substate will be entered depending on the configuration according to "Entry conditions for L1 PM Substates and L1.0 Requirements" specified in the specification. A summary of these conditions are introduced in the following table. The target substate is always a deeper substate when the entry conditions of the deeper substate is fulfilled.

In order to enter the L1 substates, the application SW first sets PM_CTRL.CLKPMEN =1 and PCIE_CAP_EN_CLK_POWER_MAN field in LINK_CONTROL_LINK_STATUS_REG =1. Then it sets PM_CTRL.CLKRM =1, to indicate that the application is ready to have reference clock removed, and the controller can switch to aux_clk.

The Reported LTR is the maximum of the snoop/nosnoop latency values embedded in LTR messages transmitted by the upstream ports or received by the downstream port. The controller stores these values in the port logic LTR Latency Register (PL_LTR_LATENCY_OFF). When the requirement bit in the message is 0, the latency value is considered infinite (that is, the check with the threshold always pass).

Table 852 Target L1 sub-state

Transition trigger	ASPM PM L1.1 enabled	ASPM PM L1.2 enabled	LTR >= L1.2 threshold	PCI PM L1.1 enabled	PCI PM L1.2 enabled	Target L1 sub-state
PCI PM	-	-	-	0	0	L1
	-	-	-	1	0	L1.1
	-	-	-	-	1	L1.2
ASPM	0	0	-	-	-	L1
	1	0	-	-	-	L1.1
	0	1	0	-	-	L1
	1	1	0	-	-	L1.1
	-	1	1	-	-	L1.2

L2 and L3 entry and exit

L2/L3 entry is initiated after the RC calls power management software to initiate the removal of power and clocks. An EP must respond to the receipt of a PME_Turn_Off message by transmitting a PME_TO_Ack message. This is done by hardware automatically. Meanwhile, an interrupt (radm_pm_to_ack) is triggered when the PM_Turn_Off message is received. The application software needs to assert the PM_CTRL.RDYENTRL23 to allow the sending of PM_Enter_L23 DLLP, which will complete part of the negotiation handshake.

When the software is ready for transitioning to $D3_{cold}$, that is, loss of main power and reference clock, L2/L3_ready is entered and the downstream device begins preparation for the power and clock removal. After

main power has been removed, the link transitions to L2 if the auxiliary power is provided, or it transitions to L3 if no auxiliary power is provided.

The exit of L2/L3 is triggered by asserting the PM_CTRL.WKUPCMD bit to request the module to wakeup, when the USP is programmed with capability to support PME. It can also be requested by the link partner to exit.

Two wakeup mechanisms are implemented including Beacon (using in-band signaling) and WAKE# (using sideband signaling). Both will be triggered by the wakeup.

19.3.11 PCIe to AXI interface

There are one AXI/SRI master interface and one SRI/AXI slave interface. The AXI bus interface has the following basic properties:

- Address bus width: 32 bits
- Data bus width: 64 bits
- Maximum allowable master burst length: 16 beats

PCIe/AXI conversion

The PCIe controller provides an AXI bridging capability for directly adding a PCI Express link to an AXI system fabric. The bridge interconnects the AXI interfaces within an AXI-embedded system with a remote PCIe link. An AXI subsystem can only convey data, address and read/write information. It has no way to propagate PCIe concepts such as TLP type, posted/non-posted, function number, TLP attributes and so on.

The PCIe defines a flexible data transfer for example non-contiguous byte enable. It allows various sizes and transfers with special attributes. However, the bus protocol (AXI in this case) implemented on chip can only support a subset of possibilities. During the conversion from PCIe to AXI, several restrictions are applied. Therefore, the below section describes more about the transaction conversion from PCIe to AXI.

Inbound transfers

When the controller's AXI master wants to perform a transfer (whose length is greater than or equal to the databus width) it always uses beats of width equal to the databus size . Any unwanted data that is read is discarded. Therefore, only prefetchable[26)] memory is supported.

[26] For example, RAM where reading excess data does not prevent you from re-reading that data at a later time. Non-prefetchable memory would be a FIFO where data reads are destructive.

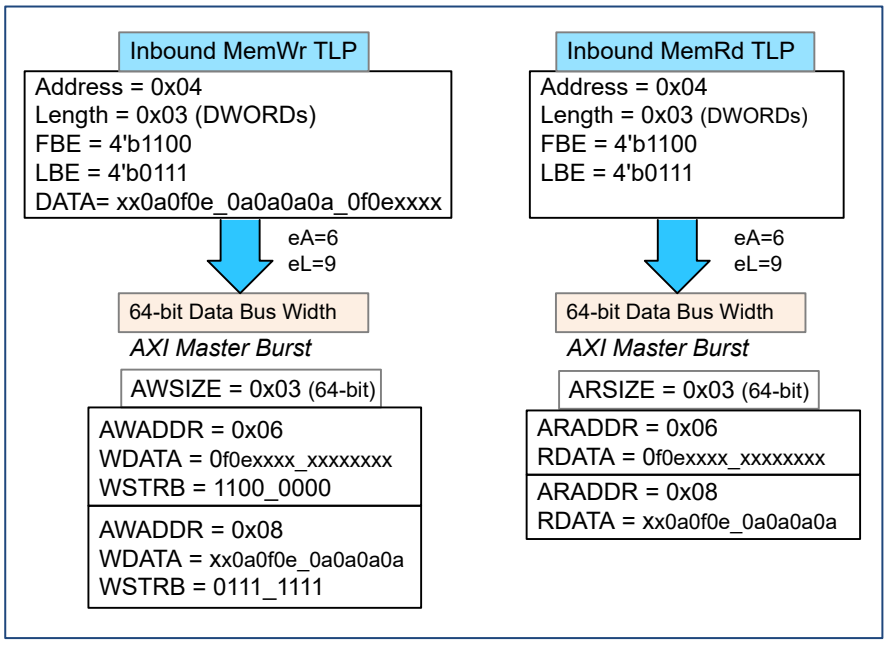

Figure 310 Examples of inbound AXI read and write transfers (eA = effective address; eL = effective length)

- Effective Length (eL): Effective PCIe TLP (byte) length excluding byte enable holes as per the first and last byte enable (FBE/LBE)
- Effective Address (eA): Effective PCIe TLP (byte) address after resolution of FBE/LBE and DWORD aligned TLP address becomes the AXI address

Inbound narrow reads

When the controllers AXI master executes a narrow (total number of read bytes < width of AXI databus) read transfer, it automatically selects one of two methods.

Table 853 Methods for executing narrow inbound reads at AXI master interface

Method and description	Automatically selected when
Approximate Full Size (Default Operation for Some Configurations) *Use for prefetchable memory.* Use an approximate byte count and perform one or more full-width accesses. With this method, the master uses the entire bus width . The controllers master reads in more bytes than the intended narrow transfer. Excess data is discarded and not forwarded to the link partner.	Single Beat Exact Size eA/eL criterion not satisfied
Single Beat Exact Size (Non-Default Operation) *Use for non-prefetchable memory (for example, FIFO).* Use an exact byte count and perform a single AXI access of width equal to the PCIe effective length (eL). A design complexity decision is taken to only support scenarios where the complete request can be completed within a single AXI beat.	Single Beat Exact Size eA/eL criterion[1)] is satisfied

1) The Single Beat Exact Size eA/eL criterion is: eL=2n and (eA is aligned to mstr_arsize).

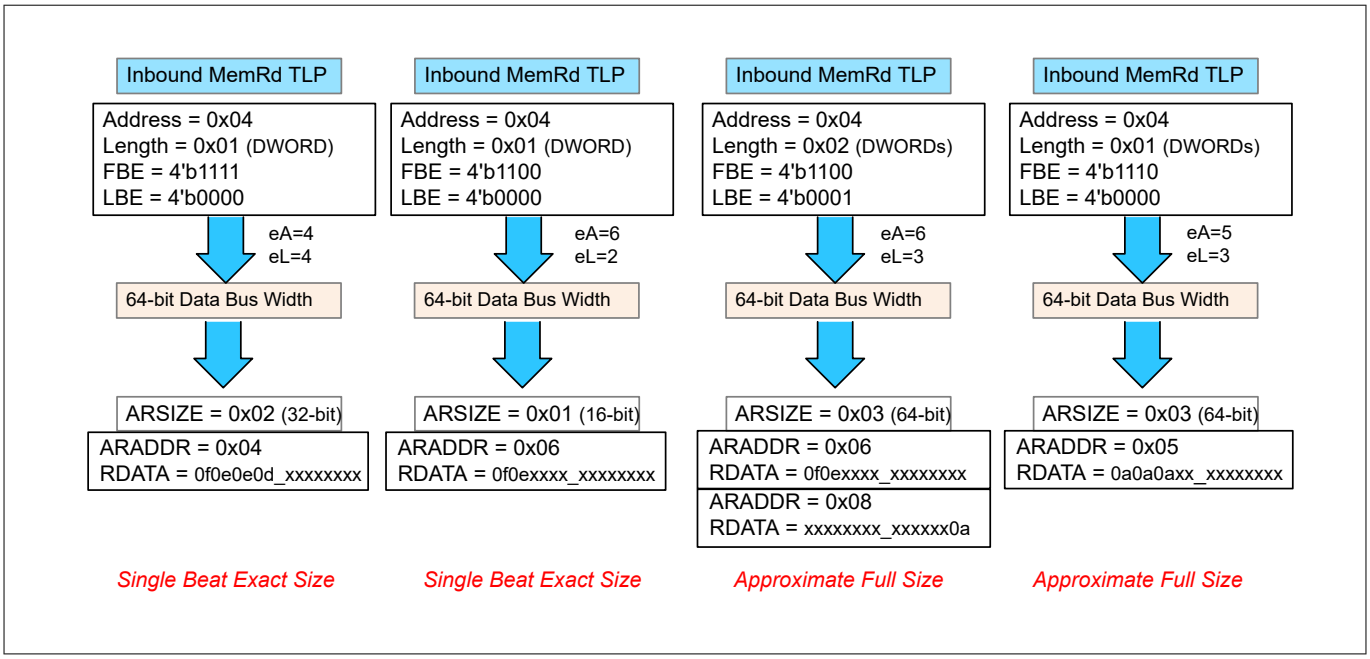

Figure 311 Examples of Inbound AXI Narrow Read Transfers (eA=effective Address; eL=effective Length)

Inbound narrow writes

When the controllers AXI master wants to perform a narrow WRITE transfer when the total number of bytes to be transferred is less than the width of the AXI data bus it uses always the full size method. It performs one or two accesses of width equal to AXI databus width. With this method, the controller master uses the entire bus width . The write strobes ensure a precise write to the intended write request address location.

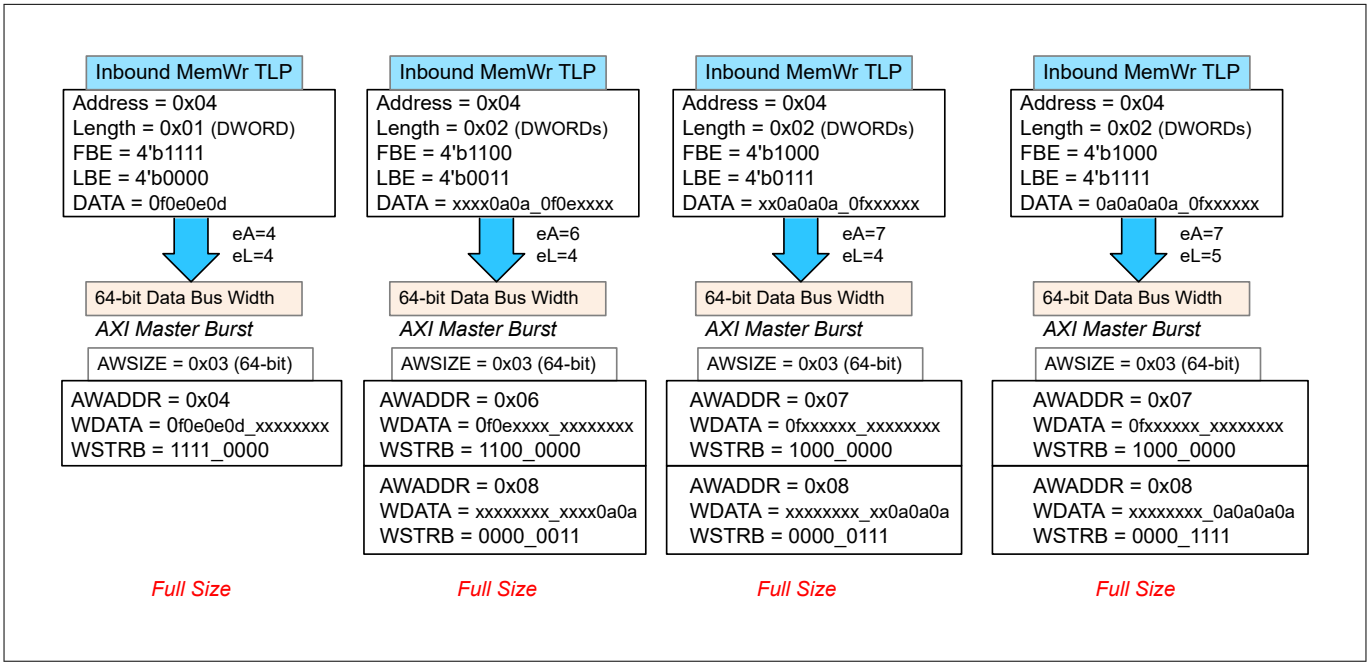

Figure 312 Examples of Inbound AXI Narrow Write Transfers (eA=effective Address; eL=effective Length)

Non-contiguous byte enable (NCBE)

The PCI Express Base Specification, Revision 5.0, Version 1.0 supports memory reads and writes with holes only when the read and write requests are one or two DWORDs long. The PCIe transaction header first and last byte

enable fields are used to signal which bytes are valid. A hole means that it is possible to have non-contiguous byte enables such as 0101_B. Non-contiguous byte enables occur when enabled bytes are separated by non-enabled bytes, for example, 0101_B. The rules for byte enables are given in Section 2.2.5 “First/Last DW Byte Enables Rules” of the PCI Express Base Specification, Revision 5.0, Version 1.0 Byte Enables are included with memory, I/O and configuration requests. The AXI protocol itself can support holes in write data as there are AXI write strobes.

Table 854 AXI inbound NCBE support for requests

	MemWr	MemRd
NCBE Supported	Yes	Yes
Size Restrictions	1,2 DWORD	1,2 DWORD

Table 855 Method and description

Method and description	
READS	The original PCIe request is first decomposed into a series of internal single byte request TLPs. These appear on the master interface according to the rules in table 28. Likewise, the responses to the individual decomposed requests are composed into a single (or double) DWORD of response data from that address. This method provides precision, but it sacrifices performance. To access n bytes, the master uses an n-beat byte-wise burst transfer.
WRITES	**Full Size** AXI write strobes are used. Perform accesses of width equal to AXI databus width. With this method, the controller master uses the entire bus width . The write strobes ensure a precise write to the intended write request address location.

Zero-length byte accesses

The PCI Express Base Specification, Revision 5.0, Version 1.0 supports zero-byte transactions as a means of flushing out previous transactions.

Rx Read/Write: Option 1 (DEFAULT_FILTER_MASK_2[3] =1)

The PCIe controller has a feature to terminate all zero-byte transactions when it is configured to do so. Enable the bit CX_FLT_MASK_HANDLE_FLUSH (default is 0) in the Filter Mask 2 register of the native controller to enable this feature. If the PCIe controller is configured to support termination of zero-byte transactions, it generates CPLs for zero-byte reads and return them automatically to the requester without sending the transaction to the AXI bridge. It also drops zero-byte writes. Transactions arriving at the PCIe receive queues are terminated with the flush function. Configuring the native PCIe controller to terminate zero-byte transactions is one way of avoiding handling zero-byte reads at the AXI interface. It has the disadvantage of not flushing out any previous transactions remaining in the AXI bridges queue buffer. In other words, the flush semantic terminates at the native PCIe controller’s receive queues.

Rx Read/Write: Option 2 (DEFAULT_FILTER_MASK_2[3] =0) - RECCOMENDED

A second possible means of handling zero-byte transactions is to let the AXI bridge receive the inbound zero-byte transaction from the native PCIe controller and present it to the AXI interface. The AXI specification (and the bridge) supports zero byte writes by setting all write strobes to 0. An inbound zero-byte read is handled as follows:

- If, AMBA_ORDERING_CTRL_OFF.AX_MSTR_ZeroLRead_FW = 0, an inbound zero-byte read is terminated at the AXI bridge master when any prior Posted transaction finishes implementing the PCIe flush semantics. When the zero-byte read terminates, it synthesizes a CPL transaction back to the requester
- If, AMBA_ORDERING_CTRL_OFF.AX_MSTR_ZeroLRead_FW = 1, an inbound zero-byte read is translated into a 1 byte read (from the original request’s address) on the AXI master and forwarded to the application. The resulting AXI response triggers the respective CPL back to the requester

19.3.12 Error handling

The controller supports the Baseline Capabilities, AER capabilities, and Advisory Non-Fatal Error Messaging as specified in Section 6.2, Error Signaling and Logging of the *PCI Express Base Specification, Revision 5.0, Version 1.0*. These include Correctable and Uncorrectable (Fatal and Non-Fatal) errors.

PCI Express errors can be classified as two types: Uncorrectable errors and Correctable errors. This classification separates those errors resulting in functional failure from those errors resulting in degraded performance. Uncorrectable errors can further be classified as Fatal or Non-Fatal.

For an RC port, it collects both the error messages from EP and the internal errors. The reporting of most errors is internal to the interrupt router or the SMU. No external error notifications are generated. One exception to this (for example) is unsupported request (UR) completion status.

EP reports error messages to the RC for reporting the detection of errors according to the severity of the error. It can also report the errors to the interrupt router or the SMU.

The error related interrupts are described in the below diagram. The additional information about the internally generated errors (SAFCORR and SAFUNCORR) can be found in the "Alarm" section.

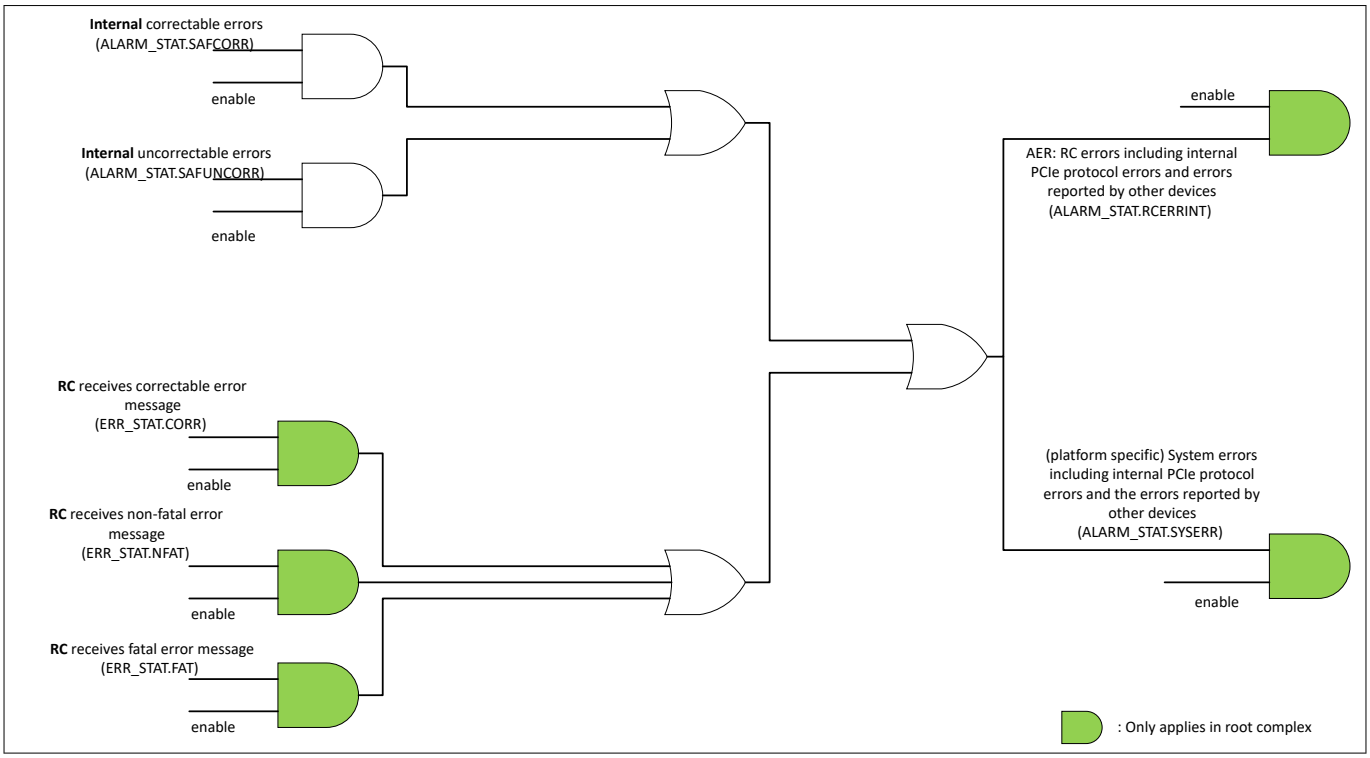

Figure 313 hierarchy of error interrupts

Error detection for received TLPs

The controller performs all mandatory error detections, the error reporting mechanism based on the *PCI Express Base Specification, Revision 5.0, Version 1.0*, and some optional error detections. When the controller detects an error in a received TLP, it performs the following by default:

- Discarding the TLP
- Generating a completion (for non-posted requests) with the completion status set to CA or UR
- Setting the status in the PCI-compatible status register
- Setting the status in the AER registers (when you enable AER)
- Generating an error MSG (upstream port only)
- For malformed TLPs credit is returned based on the buffer space which has been consumed by the TLP

AER multiple header logging

The controller supports the AER multiple header logging as specified in Section 6.2.4.2, “Multiple Error Handling (Advanced Error Reporting Capability)” of the PCI Express Base Specification, Revision 5.0, Version 1.0.

Physical Functions: by default, each physical function only logs the first header that caused an error. A valid queue entry is never overwritten. If software does not read the header log registers (HDR_LOGx) fast enough, you can miss the new header log information when the queue is full. The Completion Timeout Prefix/Header Log Capable bit is not implemented. Therefore no Header Log is stored when a Completion Timeout is received. Data Link Protocol, Surprise Link Down, Receiver Overflow, and Flow Control Protocol errors do not have TLP headers, so no Header Log is stored for those errors.

AXI and PCIe slave errors

Slave error mapping refers to what the controller (AXI) signals back to the S2A bridge that connects the SRI interconnect when it receives completion errors (CA, UR, CRS, and CPL-Timeout). The SLVERR and the DECERR are captured by the S2A bridge and will cause bus errors on SRI.

The AXI protocol provides response signaling for read transactions. The AXI responses are OKAY, SLVERR and DECERR. OKAY indicates that a normal access has been successful. SLVERR indicates slave error when the access has reached the slave successfully, but the slave wishes to return an error condition to the originating master. DECERR indicates decode error that there is no slave at the transaction address.

Table 856 AXI Slave Response for Erroneous Requests

Access Type	Transaction	Error Response to S2A
Wire	Read (Non-Posted) Write (Non-Posted)	OKAY (default) • The payload is set to 0xFFFF for reads SLVERR/DECERR • If your application sets the AMBA_ERROR_RESPONSE_GLOBAL field to ‘1’, and configures the AMBA_ERROR_RESPONSE_MAP field in the PCIEUSP_AMBA_ERROR_RESPONSE_DEFAULT_OFF register • SLVERR/DECERR will be signaled to the S2A bridge and result in a bus error
	Posted	OKAY

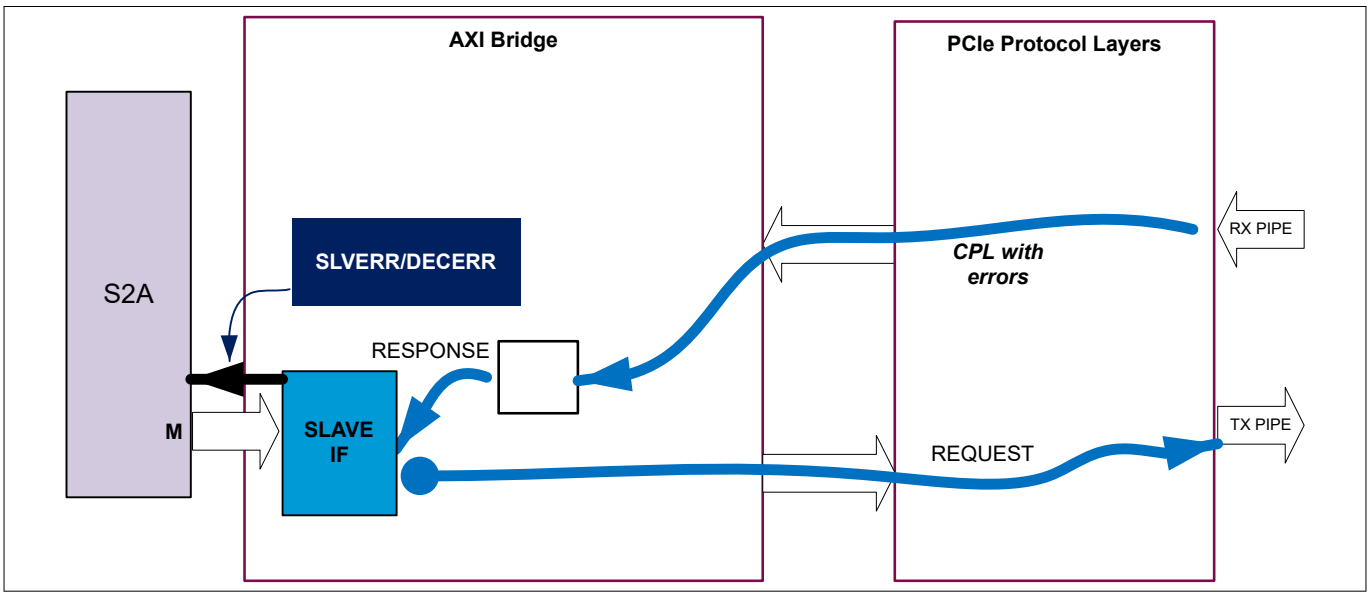

Figure 314 PCIe-to-AXI Slave Error Mapping

CRS CPL Error

A device in receipt of a Configuration Request following a valid reset condition may respond with a CRS Completion Status to terminate the Request, and thus effectively stall the Configuration Request until such time that the subsystem has completed local initialization and is ready to communicate with the host. Note that it is only legal to respond with a CRS Completion Status in response to a Configuration Request.

Receipt by the Requester of a Completion with CRS Completion Status terminates the Configuration Request on PCI Express. Root Complexes have the ability to report the receipt of CRS Completion Status to software, enabling software to attend to other tasks rather than being stalled while the device completes its self-initialization.

You can choose between different ways to handle a CRS completion error by programming AMBA_ERROR_RESPONSE_CRS field in the PCIEUSP_AMBA_ERROR_RESPONSE_DEFAULT_OFF register. The following options are available:

- 00: The AXI bridge always returns OKAY with non-FFFF data when a CRS completion is received.
- 01: The AXI bridge always returns OKAY with all-FFFF data when a CRS completion is received. This is useful when you want to detect that a completion is received with error.
- 10: The AXI bridge always returns OKAY with FFFF0001 data when a CRS completion is received for a Vendor ID read request, and OKAY with all-FFFF data for all other CRS completions. This is useful when you want to distinguish between CRS, and UR completions to Vendor ID read requests.
- 11: The AXI bridge always returns SLVERR or DECERR for all CRS completions, depending on the bit 1 value of AMBA_ERROR_RESPONSE_MAP field in the PCIEUSP_AMBA_ERROR_RESPONSE_DEFAULT_OFF register.

Reading Non-existent Vendor ID Register

The PCIe specification states that 0xFFFF is a reserved value for the Vendor ID register, to indicate that the function (containing Vendor ID register) is non-existent. An outbound CfgRd at the AXI bridge slave interface to a non-existent register (at the remote link partner) normally results in a UR response back from the PCIe wire without data. The AXI bridge slave automatically converts the completion with the UR response, to an OKAY response on the AXI slave interface, and also sets the completion data payload to 0xFFFF. This feature is supported for all CfgRd accesses (excluding byte-size accesses) to the Vendor ID register. You can modify this behavior using the AMBA_ERROR_RESPONSE_VENDORID bit of PCIEUSP_AMBA_ERROR_RESPONSE_DEFAULT_OFF.

AXI and PCIe master errors

Master error mapping refers to the AXI bus responses (for non-posted requests), and what the controller signals back to the remote link partner.

- Error-free responses (OKAY) are normally mapped to a CPL with Successful Completion (SC) status.
- Errored responses (SLVERR/DECERR) are always mapped to a CPL with CA status.

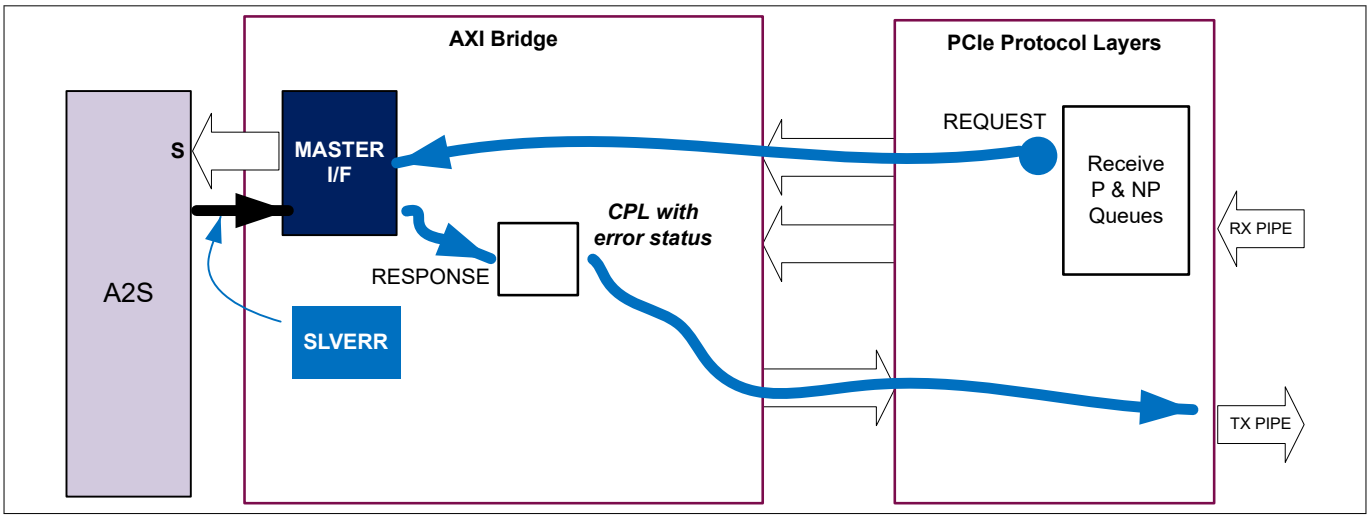

Figure 315 AXI-to-PCIe Master Error Mapping

For non-posted requests an errored master response results in the AXI bridge terminating the transmission of completions followed by a CA errored response completion. The AXI bridge master takes the following actions for each outstanding non-posted request when an errored master response data beat is detected:

1. Accepts the remaining master response beats without back pressuring the master response interface or canceling any of the remaining burst beats.
2. Sends a completion with CA status. No data is included in the completion.
3. Continues to re-format the master response packets until the last master response data beat for the last decomposed packet is detected.

19.3.13 Safety measures

This section describes the safety measures against random hardware faults for example soft errors.

19.3.13.1 Reliability, availability, and serviceability (RAS)

PCIe system Reliability, Availability, and Serviceability (RAS) ensures that failures in the underlying processes and hardware components do not cause any interruptions in the overall system operation. The PCIe RAS consists of two fundamental components:

- Reliable protocol architecture involving LCRC, ECRC, ACK and NAK handshake, and replay mechanisms
- Internal device-level Datapath and RAM protection (RAS DP) of data, header, and RAM control signals from the bus interface to LCRC extraction or generation points

19.3.13.1.1 ECRC

The controller uses the optional ECRC checksum, as defined in the PCIe specification, to protect the wire part of the link. The controller inserts the ECRC in the transmit logic and checks it in the receive logic.

Generation

The controller generates and inserts the ECRC by setting the ECRC_GEN_EN field of the ADV_ERR_CAP_CTRL_OFF register

Checking

By default, when the controller detects a TLP, with an ECRC error, it performs the following:

- Discards the TLP
- Generates a completion (for non-posted requests) with the completion status set to CA or UR
- Sets the status in the PCI-compatible status register
- Sets the status in the AER registers (when enabling AER):
  - When an ECRC error is detected by a PF, with ECRC checking enabled for any PF, ECRC error status is set for all PFs
- Generates an error message (upstream port only)

19.3.13.1.2 Data protection

For the parts of the controller outside of ECRC or LCRC protection, you can use the RAS DP feature.

Overview

- RAM Protection (ECC on data and Parity on address)

  An ECC checksum is calculated and added to data that is written to the RAM. When the data is read from the RAM, the controller recalculates the ECC and compares it against the value read from RAM. RAM ECC

protection is provided for all of the RAMs in the controller, except for the RAS-DES RAM. ECC corrects single-bit errors and reports (without correction) multi-bit errors

- Datapath Protection (ECC or Parity): for Tx traffic, the bus slave interface adds parity/ECC protection codes to traffic. Controller strips parity or ECC after LCRC Insertion on TX Path. For Rx traffic, controller inserts parity or ECC before LCRC extraction. The A2S or S2A bridges check the protection codes to check the data integrity
- AXI Interface (ECC): the standard AXI Interface Safety Block (ISB) in the AXI bridge module generates and checks ECC

Uncorrectable error handling

PCI Express defines two error reporting paradigms: the baseline capability and the Advanced Error Reporting Capability. Both are supported by this device.

PCI Express errors can be classified as two types: correctable errors and uncorrectable errors. Uncorrectable errors can further be classified as Fatal or Non-Fatal. This section describes an overview of errors. The details of standard PCIe error handling are not covered by this document.

Uncorrectable error handling

Upon detection of first Uncorrectable error (RAM and Datapath Protection), depending on value of AUTO_LINK_DOWN_EN field of the RASDP_ERROR_MODE_EN_OFF register, the controller takes one of the two actions:

- Forces the PCIe link to go down (AUTO_LINK_DOWN_EN = 1)
- Enters RASDP Error Mode (AUTO_LINK_DOWN_EN = 0)

PCIe link down

If the controller is configured to cause the link to go down upon detection of an uncorrectable error, the controller resets and resumes normal operation.

RASDP error mode

On entering RASDP error mode, the controller sets ERR_CTRL.MSTERRM or ERR_CTRL.SLVERRM. Wire access to controller registers is suspended to prevent corruption of the register configuration space.

TLP handling in RAS DP Error mode:

- Rx TLP Handling
  - Rx errored TLPs are forwarded to the bus
  - Subsequent Rx TLPs are not guaranteed to be correct; the user must discard all TLPs
- Tx TLP Handling
  - Bad TLP is nullified (EDB inserted and LCRC inverted) and transmitted
    - The controller might nullify TLPs that are received prior to the bad TLP
  - Subsequent TLPs are nullified and transmitted
  - In-progress replay is nullified and transmitted
  - Subsequent replays are silently dropped

The controller attempts a best-effort recovery in RASDP error mode (after detection of an uncorrectable error).

Credits accuracy is not retained under uncorrectable error conditions. The controller implements a best-effort approach in accounting for credits under uncorrectable error conditions. However, credit inaccuracies are unavoidable in such conditions. This might result in performance degradation or triggering of overflow protection mechanisms.

Error Logging:

- Uncorrectable error for example 2-bit ECC and all parity errors are logged
- Uncorrectable internal error reported (AER)
- The controller only reports uncorrectable errors when it exits RASDP error mode

Your application software can instruct the controller to exit RASDP error mode by writing to RASDP_ERROR_MODE_CLEAR_OFF register through SPB. Your application must perform any cleanup it may deem necessary prior to instructing the controller to exit RASDP error mode. In RASDP error mode, some uncorrectable errors can be severe enough to eventually cause the link to go down. If link down occurs, the controller resets and resumes normal operation.

Correctable error handling

The controller takes the following action to handle correctable (RAM and Datapath Protection) errors:

- Correctable[27] error is logged
- Correctable internal error reported (AER)
- TLP is modified or corrected
- Errors reported when detected (immediately)
- Error correction enable or disable control (per TX or RX direction and per-layer)[28]

19.3.13.2 CDM register check

The controller supports automatic CDM register checking to ensure that CDM registers are not corrupted. The iATU and DMA port logic registers are also checked.

The CDM registers start from 3000_H to 8000_H in the local address offset. All the physical CDM registers are checked.

CDM register check features and limitations

- The register check starts when PL_CHK_REG_CONTROL_STATUS_OFF.CHK_REG_START is set to 1
- Continuous or run once modes (PL_CHK_REG_CONTROL_STATUS_OFF.CHK_REG_CONTINUOUS)
- Programmable start and end check addresses through PL_CHK_REG_START_END_OFF register
- CHK_REG_COMPLETE field of PL_CHK_REG_CONTROL_STATUS_OFF indicates check has finished
- CHK_REG_COMPARISON_ERROR field of PL_CHK_REG_CONTROL_STATUS_OFF indicates comparison failure
- Failing address and PF of the first comparison error found is recorded in registers PL_CHK_REG_ERR_ADDR_OFF and PL_CHK_REG_ERR_PF_VF_OFF respectively

  ***Note**: Only the address of the first error found is recorded. The checking sequence proceeds until complete, unless software clears the CHK_REG_START field of PL_CHK_REG_CONTROL_STATUS_OFF register*

- The SPB or wire accesses to the CDM registers takes priority over any CDM register check sequence
- Built in self-test functionality checks the comparison logic

  CHK_REG_LOGIC_ERROR field of PL_CHK_REG_CONTROL_STATUS_OFF register indicates error in comparison logic
- The controller only reports the error (through AER: Uncorrectable Internal Error or upstream error message for EP product); it does not take any action to correct the error

CDM register check operational details

CDM register checking is controlled by a FSM which sequences checking of CDM register values against shadow registers, in CDM_B (*Register content check*). The CDM register checker's self-test functionality checks the comparison logic, by injection of an error at one particular address location (*Error Injection*). It also checks address increments during the comparison sequence (*Address Check*).

Register Content Check (CDM versus CDM_B: The CDM register checker compares CDM and CDM_B data. If a mismatch is found:

27 1-bit ECC errors.

28 If the controller is capable of single bit error correction, disabling ECC error correction does not change the nature of the errors and their reporting. A single-bit error is reported as a correctable error although correction might be disabled.

- Signal cdm_reg_chk_cmp_err is asserted, and it is connected to the SMU alarm
- CHK_REG_COMPARISON_ERROR field of PL_CHK_REG_CONTROL_STATUS_OFF register is set to 1 to indicate comparison error

The checking sequence as follows:

1. The address range specified in register PL_CHK_REG_START_END_OFF is checked for comparison errors. Check is done for each PF as well
2. If accesses to DMA registers are matched MEM/IO requests through BAR, rather than legacy indirect register addressing, DMA port logic registers are checked for all configured channels
3. If accesses to iATU registers are matched MEM/IO requests through BAR, rather than legacy indirect register addressing, iATU port logic registers are checked for all configured regions

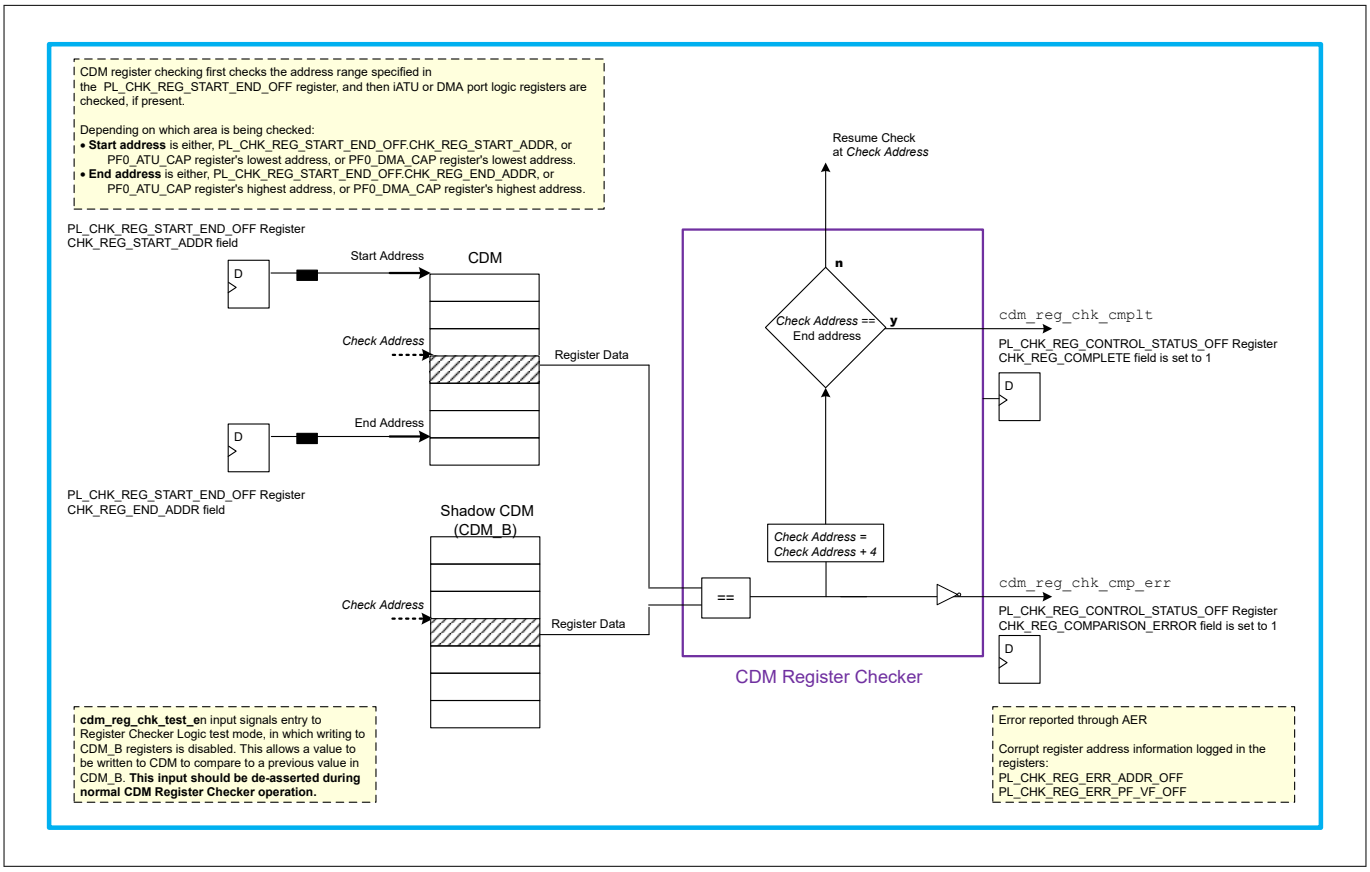

Figure 316 Register content check (CDM versus CDM_B)

Error Injection: At the end of *Register Content Check*, the comparison logic is checked by comparing data at address 100_H (offset from the beginning of CDM) in CDM against the inverted value of data in CDM_B at the same address. If the value and the inverted value do not match:

- Signal cdm_reg_chk_logic_err is asserted, and it is connected to the SMU alarm
- CHK_REG_LOGIC_ERROR field of PL_CHK_REG_CONTROL_STATUS_OFF register is set to 1 to indicate an error in comparison logic

Address Check: During *Register Content Check* and *Error Injection*, each time the address is incremented, it is checked. If the increment is not equal to 4 (corresponding to the next 32-bit register address) then:

- Signal cdm_reg_chk_logic_err is asserted, and
- CHK_REG_LOGIC_ERROR field of PL_CHK_REG_CONTROL_STATUS_OFF register is set to 1 to indicate an error in comparison logic

19.3.13.3 Tx interface progression detection

This feature provides a mechanism for the controller to inform the application about the lack of progression on AXI slave and master interfaces. It also monitors the internal MSG gen. interface and the LBC CFG completion interface. Progression on the data transmission interfaces is not expected to halt under normal operating circumstances; it might halt if soft errors or silicon failures occur, or if your application logic inadvertently hangs the TX or AXI application interfaces.

Transmit TLP on page 2711

19.3.13.4 Alarms

There are two SMU alarms, data uncorrectable alarm and configuration uncorrectable alarm. Please always refer to the device's safety manual to find out which safety mechanism of this functional block need to be considered for safety relevant applications.

PCIE data uncorrectable error alarm covers both the error signals cfg_safety_uncorr and cfg_safety_corr. The cfg_safety_uncorr includes RASDP, Tx progression detection, CDM register check and PCIe protocol uncorrectable errors. These error signals can be masked respectively and logically to cfg_safety_uncorr as shown in the following figure. The cfg_safety_corr includes both PCIe protocol correctable events and RSADP correctable events. Both signals are reported as the data uncorrectable alarm to SMU.

The controller provides dedicated functional safety interrupts (cfg_safety_uncorr and cfg_safety_corr) to route the safety related indications to your application. These interrupts report events of different severity; cfg_safety_uncorr reports uncorrectable errors and cfg_safety_corr reports correctable errors. These interrupts have independent status and mask bits in SAFETY_STATUS_OFF and SAFETY_MASK_OFF registers, respectively. The functional safety interrupt outputs provide indications from two different event categories:

- PCIe protocol defined events
- Internal safety mechanisms events
  - RAS Data Protection
  - CDM Register Check
  - Tx Interface Progression Detection

Events signaled from both the categories are recorded in the status register regardless of the specific event mask setting. The mask controls whether an event causes the safety interrupt (cfg_safety_uncorr or cfg_safety_corr) to be asserted or not.

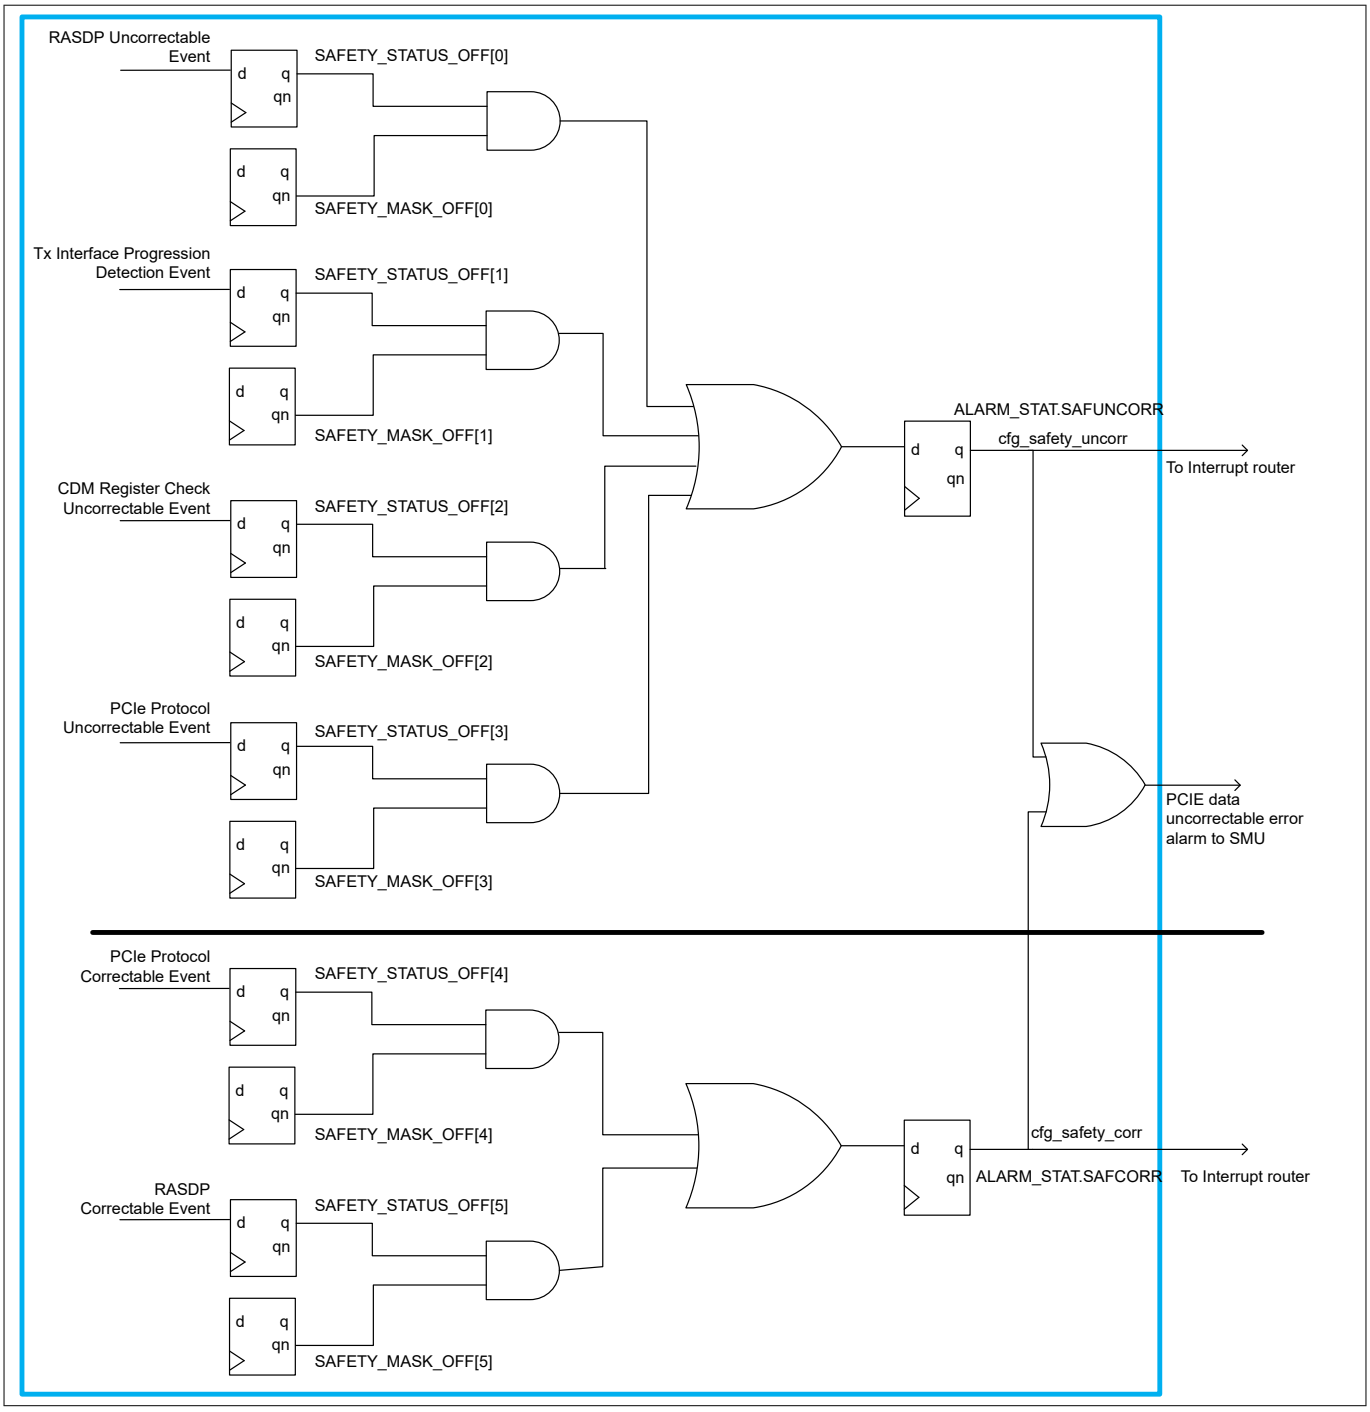

Figure 317 Events reported by cfg_safety_uncorr and cfg_safety_corr

The CDM register check feature is designed for the configuration monitoring. The errors (cdm_reg_chk_cmp_err or cdm_reg_chk_logic_err) in registers are reported as configuration uncorrectable alarm.

Additionally, errors from the S2A, A2S bridges including the data phase and address phase and FPI write error are also reported to the SMU as data uncorrectable alarm. The status and mask control are configured in ALARM_STAT, ALARM_INTCLR and ALARM_INTEN.

19.3.14 Clock and reset

The PCIe module can be reset either by local reset or PCIe reset. The local reset is the standard reset supported by AURIX™ and can only be triggered locally. The PCIe reset includes PERST# reset and hot reset.

19.3.14.1 Clocking

The clock reset module in the PCIe controller is responsible for the clock generation and distribution. It generates different reset signals for the reset of the PCIe controller.

The clock reset module receives f_{OSC} from CLOCKING and f_{PHY} from the HSPHY to generate several clocks including `core_clk`, `core_clk_ug`, `muxd_uax_clk`, and `aux_clk_g`. Normally, the controller uses the `core_clk` that is provided from the clock reset module (module reset) in normal mode. The switch selects the `aux_clk` in certain low power states, and power on reset or fundamental reset .

The clock reset module implements architectural clock gating on `core_clk`, which permits the disabling of `core_clk` in certain low power states, allowing the removal of REFCLK. In this case, the f_{PHY} disappears and the PCIe controllers uses only the f_{OSC} clock.

The HSPHY uses the standard PCIe reference clock (f_{REF_CLK}) 100Mhz to generate clock (f_{PHY}) to the PCIe controller.

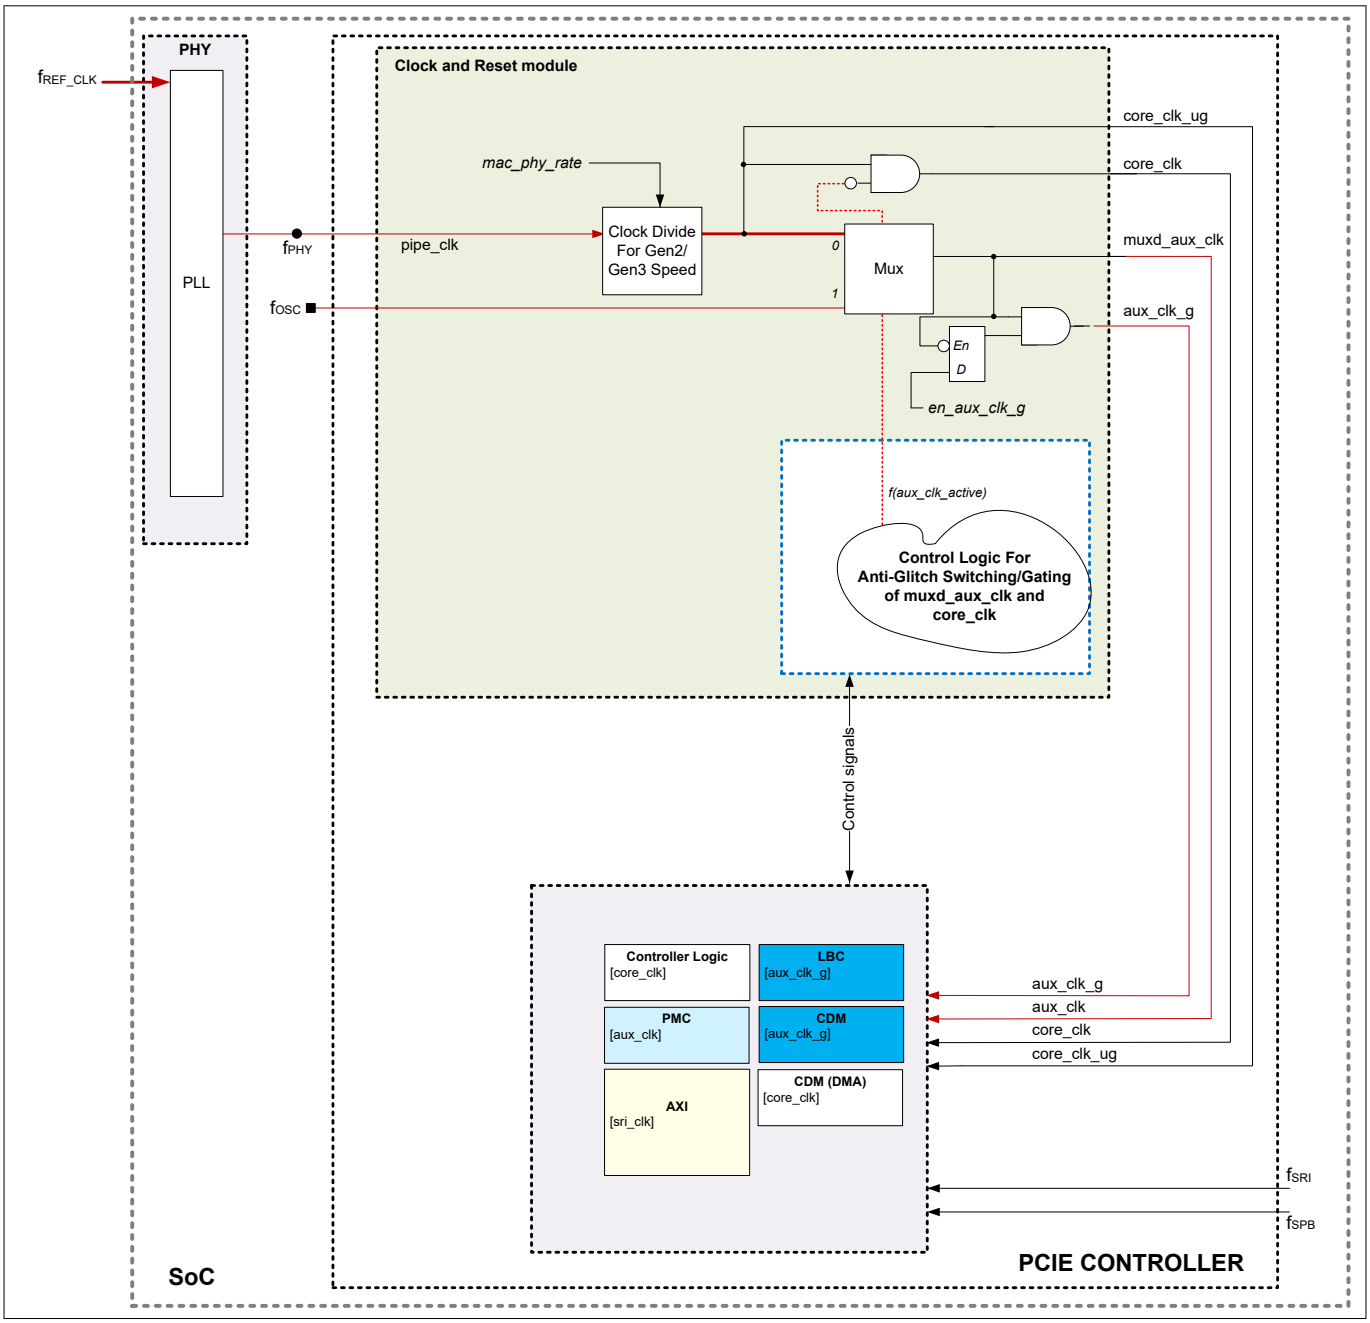

Figure 318 Clock overview of PCIe controller

Table 857 Generation of internal clock signals by the clock and reset module

Clock	Notes
core_clk	• This is the primary clock for the controller • It can have a frequency of 62.5, 125 or 250 MHz for Gen1, Gen2 and Gen3 respectively • The `core_clk` is derived from the f_{PHY} output of the HSPHY (whose TX PLL uses the platform reference clock REFCLK) • The `core_clk` signal must be gated-off when `muxd_aux_clk` is being switched to run at low frequency
core_clk_ug	• An ungated version of `core_clk` (called `core_clk_ug`) exists because a small number of controller registers must receive `core_clk` during switching to-and-from low-power states
aux_clk	• This clocks the PMC • It is derived from the f_{OSC} and it has the same frequency as the f_{OSC}
aux_clk_g	• This is a gated version of `aux_clk` that is used to clock the CDM registers and the LBC

19.3.14.2 Hot reset

A DSP can hot reset a USP controller by sending two consecutive TS1 ordered sets with the hot reset bit asserted, or by asserting the LNK_CORECTRL.HOTRST bit.

Alternatively, during normal operation, the link might fail and go down. After this link-down event, the controller requests the clock and the reset module to hot-reset the controller. There is no difference in the handling of a link-down reset or a hot reset.

To prevent application from hanging when the controller is reset, the controller must cleanly terminate all transactions that are still in-progress. The controller automatically executes the automatic flushing process before the hot reset. During this period, the access to the slave interfaces from the SRI and SPB will also be signaled as error to prevent potential bus hanging. To disable automatic flushing, set the AUTO_FLUSH_EN field in LINK_FLUSH_CONTROL_OFF to '0'.

A link reset interrupt to notify the application is available. The status is indicated by the LNK_STAT.LINKRQRST and controlled by the LNK_INTEN.LINKINTEN.

19.3.14.3 PERST# reset

The PERST# is the fundamental reset for PCIe controller but not for the SoC. The assertion of the PERST# will not lead to reset of SoC.

An unexpected assertion of the PESRT# resets the PCIe controller while other modules on the SoC run normally. This may lead to scenarios for example CPU accesses the resetting PCIe controller or on-going SRI transactions are interrupted by the reset and cannot be finished. These scenarios will cause hanging of the bus. In order to avoid this, the PERST# reset will not reset the PCIe controller immediately but be delayed until the current bus transaction completes. The bus accesses including SRI and SPB to a resetting PCIe controller will result in error signaling instead of hanging.

An interrupt is also possible to notify the SW that the PERST# is asserted.

19.3.14.4 Register accessibility during reset

On a reset event like hot reset, PERST or a link reset a link interrupt is triggered to notify the application. In such an event, PCIE controller registers are accessible until the reset sequence has completed. To check for the completion of the reset sequence, user can poll the following registers in the described order:

1. Wait until LNK_DVCTYP.PWD becomes a zero
2. Wait until PM_STAT0.LTSSMSTAT has a value greater than 0

   After the above two steps, the registers are accessible again

19.3.15 Precise time measurement

The controller supports the optional PTM feature as defined in Section 6.22, Precision Time Measurement (PTM) Mechanism of the PCI Express Base Specification, Revision 4.0, Version 1.0.

This feature enables the coordination of timing information across multiple devices with independent local time-bases. The PTM synchronization is initiated from a USP to a DSP. The controller handles the entire timestamp update process without software intervention. Each current ($t_{\#n}$) and previous timestamp ($t_{\#n-1}$) value as well as other context information can be read from the VSEC registers by software.

The controller implements 1 µs and 100 µs timers as per the requirements of the PCI Express Base Specification, Revision 5.0, Version 1.0. The controller also implements a 10 ms timer which is used for automatic update of PTM context by the Requester.

19.3.15.1 Transmit and receive latencies

A key operational goal of PTM is to stamp the time at which a message is transmitted from the physical boundary of the PCIe device.

The Tx latency is the time that it takes a message to travel from the boundary of the controller to the boundary of the PCIe device. It is added to the time at which the message left the controller.

The Rx latency is the time that it takes a message to travel from the boundary of the PCIe device to the boundary of the controller. It is subtracted from the time at which the message reaches the controller.

The Latency registers may be written to at any time with a more accurate value if required. For example:

- t1 = Local PTM Clock time when message leaves controller + PTM_REQ_TX_LATENCY_OFF.PTM_REQ_TX_LATENCY
- t3 = Local PTM Clock time when message leaves controller + PTM_RES_TX_LATENCY_OFF.PTM_RES_TX_LATENCY
- t2 = Local PTM Clock time when message received by controller - PTM_RES_RX_LATENCY_OFF.PTM_RES_RX_LATENCY
- t4 = Local PTM Clock time when message received by controller - PTM_REQ_RX_LATENCY_OFF.PTM_REQ_RX_LATENCY

***Note**:* *The Tx latency includes all delays from the moment timestamp is captured, to the time the message reaches the port pins. The Rx latency includes all delays from the time the message reaches the port pins, to the time the timestamp is captured. These delays depend on the characteristics of the PHY used, skew on the link, and deviation between the reference clocks of the two ports. There may be a dependency on link width and the current link speed also.*

For best accuracy the Tx and Rx latency values should be programmed during initialization, for each supported link speed. The controller automatically selects the Tx and Rx latency based on current link speed.

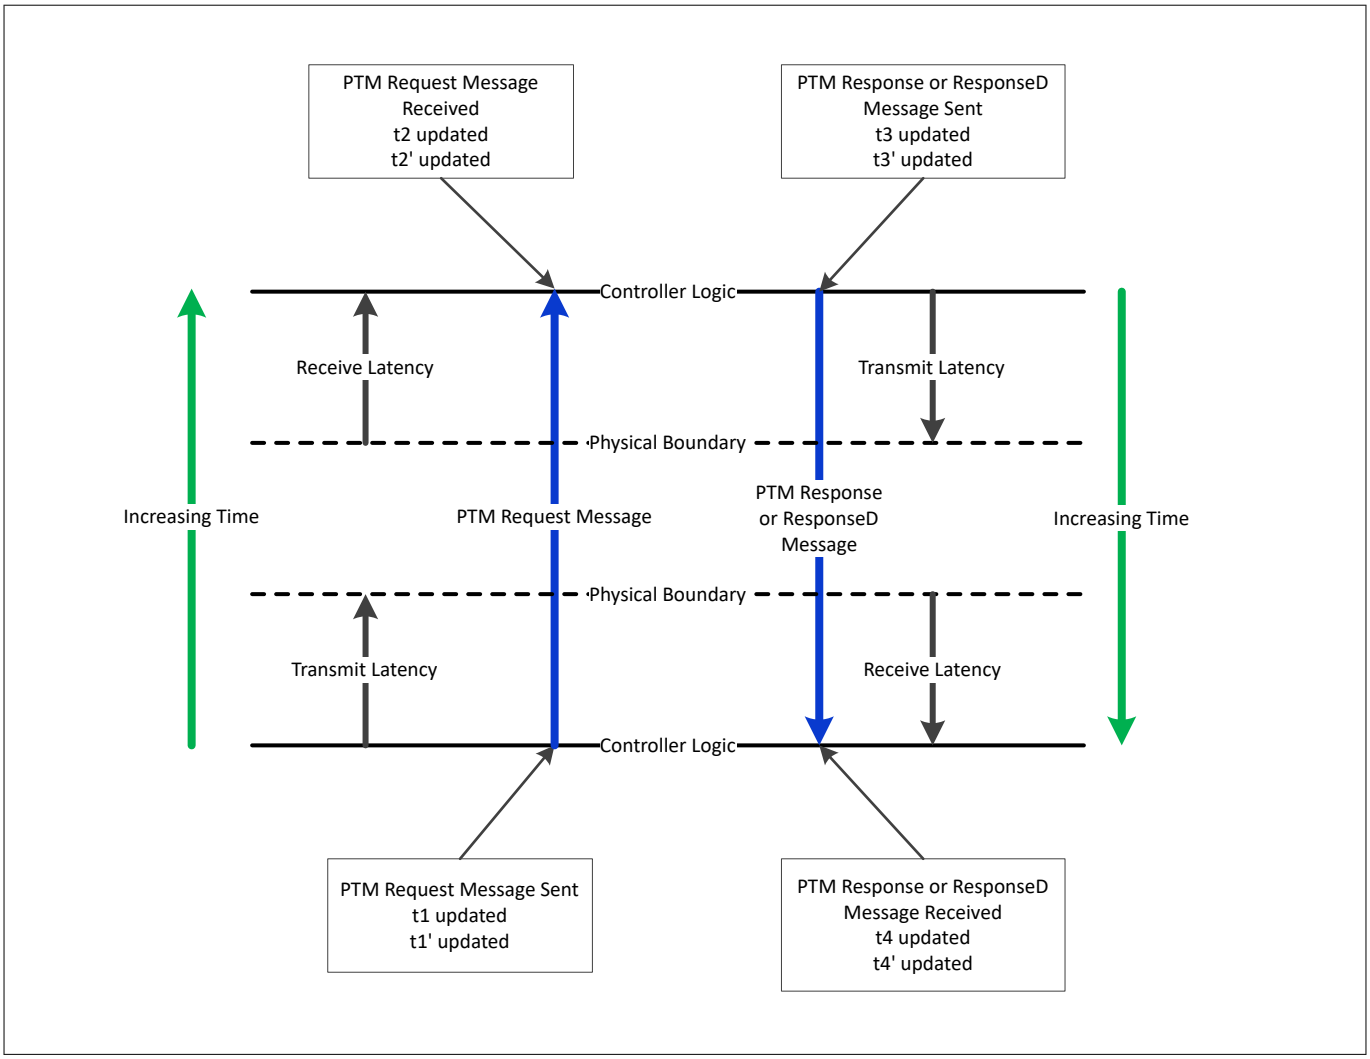

Figure 319 Tx and Rx latencies

Programming Tx and Rx latencies for each link speed

The Tx and Rx Latency registers are programmed through an indirect addressing scheme using an index register (PTM_[RES|REQ]_LATENCY_REG_SEL_OFF), to reduce the address footprint in the PCI Express extended configuration space. The index register has Responder/Requester Latency Register Write Select field (PTM_[RES|REQ]_LATENCY_REG_SEL), referred to as index, to determine which Tx or Rx Latency viewport register (PTM_RES_[TX|RX]_LATENCY_OFF) to program/read for each link speed. The following table provides the index to link speed mapping.

Table 858 Index to link speed mapping

PTM_[RES|REQ]_ESM_SEL	PTM_[RES|REQ]_LATENCY_REG_SEL	Link speed (GT/s)
PCI express speed mode		
0	0	2.5
0	1	5
0	2	8

If the Tx and Rx latency registers are not programmed, the default latency values are the same for all speeds, and are set by configuration parameters, as follows:

- Tx Latency = CX_PHY_TX_DELAY_PHY + CX_PHY_TX_DELAY_MAC
- Rx Latency = CX_PHY_RX_DELAY_PHY + CX_PHY_RX_DELAY_MAC

***Note**: The default values for Tx and Rx latency registers are defined in clock cycles. You must program the appropriate registers to set the latencies in ns.*

Programming examples

Example 1: To setup PTM Requester Tx Latency to 56 ns and Rx Latency to 334 ns for 2.5 GT/s

1. Setup speed mode

Write 0 to PTM_REQ_ESM_SEL, to set PCI Express speed mode

2. Setup the index

Write 0000_0000_H to PTM_REQ_LATENCY_REG_SEL to select 2.5 GT/s Latency viewport Tx and Rx registers

3. Write the Tx/Rx Latency values

Write 0000_0038_H to PTM_REQ_TX_LATENCY to set 2.5 GT/s Tx latency to 56 ns. Write 0000_014E_H to PTM_REQ_RX_LATENCY to set 2.5 GT/s Rx latency to 334 ns

Example 2: To setup PTM Responder Tx Latency to 24 ns and Rx Latency to 115 ns for 8 GT/s

1. Setup speed mode (PCI Express or CCIX ESM)

Write 0 to PTM_RES_ESM_SEL, to set PCI Express speed mode

2. Setup the index

Write 0000_0002_H to PTM_RES_LATENCY_REG_SEL to select 8 GT/s Latency viewport Tx and Rx registers

3. Write the Tx/Rx Latency value

Write 0000_0018_H to PTM_RES_TX_LATENCY to set 8 GT/s Tx latency to 24 ns. Write 0000_0073_H to PTM_RES_RX_LATENCY_OFF register to set 8 GT/s Rx latency to 115 ns

19.3.15.2 Requester features

- Integrated hardware for scheduling of requests to start PTM dialogs

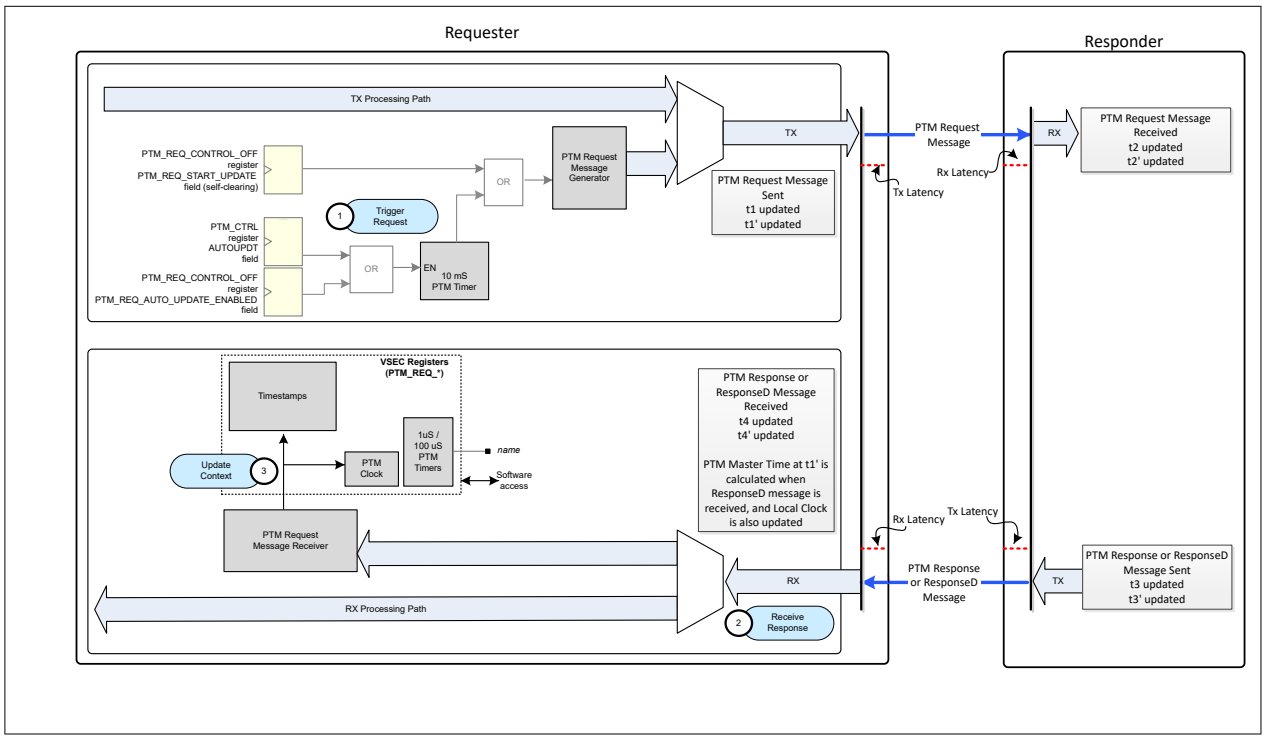

Figure 320 PTM requester (USP)

- Requester indicates PTM response timeout (through PTM_CTRL.TO interrupt) if no PTM response is received within 100 µs of sending a PTM request

  ***Note**:* *When PTM context is invalidated due to duplicates or replays, speed change, or L0 exit, the Requester waits for a PTM response or for 100 µs timeout since the previous request has been sent before allowing a new update cycle to start. If a timeout occurs while waiting, this interrupt is asserted.*

- Requester automatically updates PTM context (starting dialogs) when enabled using any or all of:
  - Automatic trigger every 10 ms (can be enabled through PTM_CTRL.AUTOUPDT)
  - Manual trigger through a register write: PTM_CTRL.TRGG is asserted or PTM_REQ_MANUAL_UPDATE_ALLOWED field in the PTM_REQ_STATUS_OFF register is set
- Requester indicates that a PTM update is in progress (through PTM_CTRL.UPDATING)
- Requester indicates reception of duplicate PTM TLPs (through PTM_CTRL.DUP interrupt) while PTM updates are in progress, or between updates when PTM context is valid
- Local PTM Clock
  - Runs on core_clk, counts time in non-integer nanoseconds, its minimum granularity is defined by the core_clk frequency
  - Auto-updated on PTM context refresh
  - Can be updated by software
  - Can be read by software
- Context automatically invalidated when:
  - core_clk stops or runs at the wrong frequency (for example, in L1 substates or when the link speed is changing), or
  - PTM is disabled by clearing the PTM_ENABLE bit in the PTM_CONTROL_OFF register, or

    ***Note**:* *If PTM is disabled by clearing the PTM_ENABLE bit, it is recommended to wait for some time to allow the PTM Responder in the link partner to complete sending a response before re-enabling PTM. The wait time depends on the maximum response time of the PTM Responder.*

  - PTM response timeouts (the requester restarts the PTM dialog when the auto update or manual update start conditions are met), or
  - A duplicate PTM TLP is received or a replay TLP is sent (if waiting for a response, the requester waits for 100 µs since the last non-duplicate request has been sent before allowing a new PTM dialog to be started)
- Context information stored in PTM Requester VSEC (PTM_REQ_*_OFF):
  - Provides access to timestamps of most recent context refresh
  - Provides notification when context is valid
  - Programmable Tx and Rx latency values for each link speed, automatically selected based on current link speed
- Requester prevents low power entry due to ASPM during PTM updates

19.3.15.3 Responder features

- Integrated hardware for scheduling of PTM responses to dialog requests when context is valid
- Timestamp generation when PTM Messages are detected

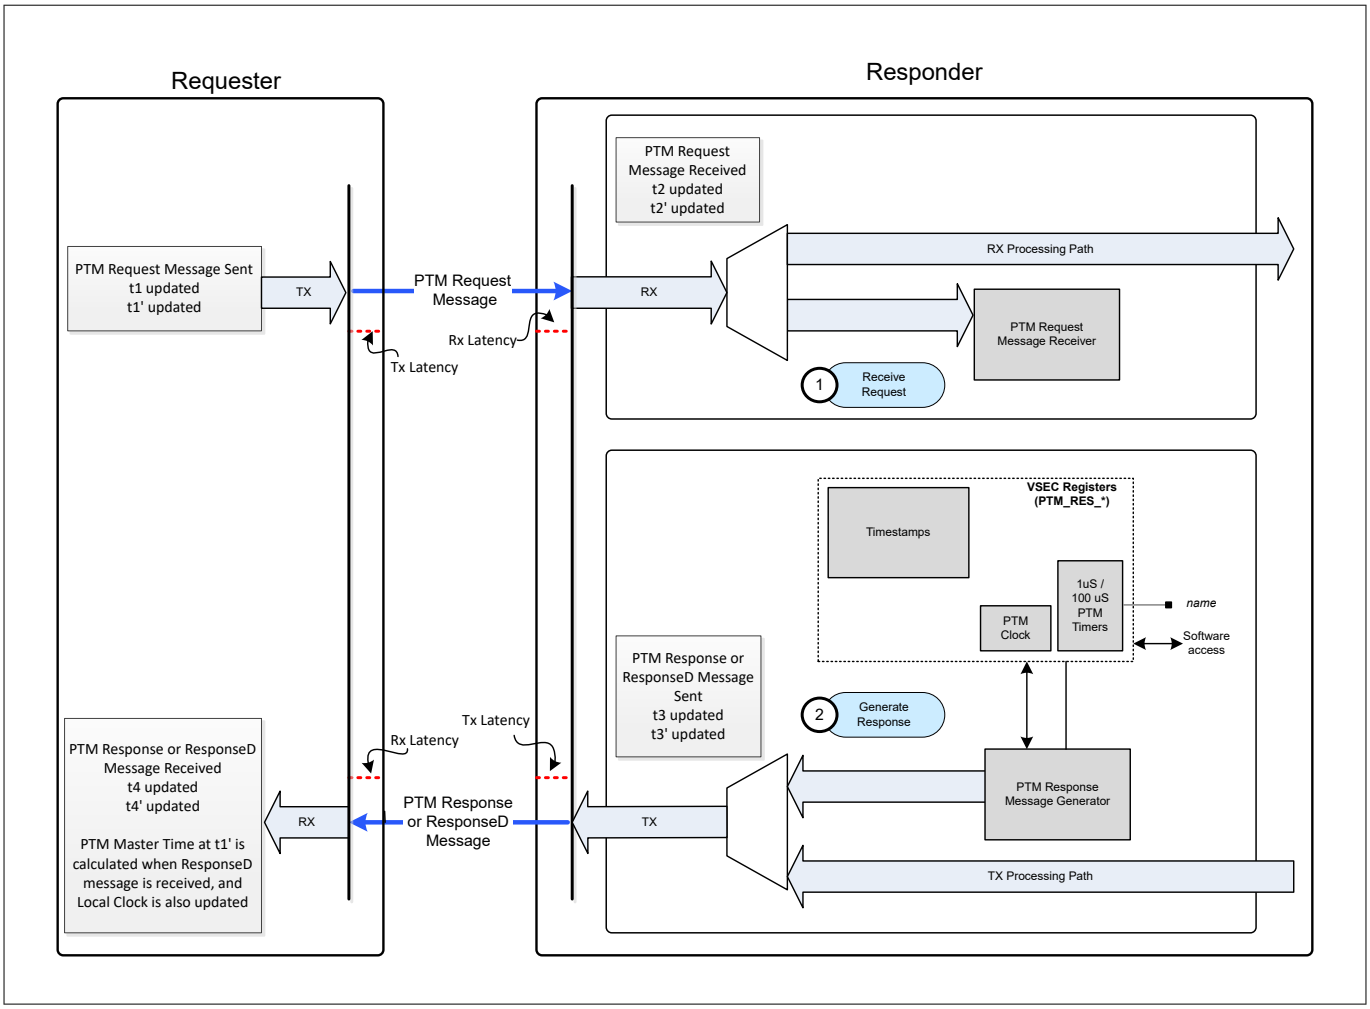

Figure 321 PTM responder (DSP)

- Local PTM Clock
  - Can also be updated by software
  - Can be read by software
- Context automatically invalidated when:
  - core_clk stops or runs at the wrong frequency (for example, in L1 substates or when the link speed is changing), or
  - When PTM is disabled by clearing the PTM_ENABLE bit in the PTM_CONTROL_OFF register

  When the controller asserts PTM_CTRL.RDYVLDT, the users application can re-validate the context by either:
  - Updating the local PTM clock using the PTM_MSKCLK.MSKCLK and PTM_CTRL.MSTSTRB bits, which automatically validates the context, or
  - Updating the local PTM clock by writing to PTM_RES_LOCAL_LSB_OFF and PTM_RES_LOCAL_MSB_OFF registers and then setting the PTM_RES_CCONTEXT_VALID field of PTM_RES_CONTROL_OFF to 1, which automatically validates the context

- Root Support
  - Ideally, a PTM root behaves like a responder with permanently valid context. However,
    - If the PTM root enters low power modes or changes link frequency, PTM context is invalidated (indicated by PTM_CTRL.CNTXTVLD)
    - Following PTM context invalidation, the application must re-validate PTM context, by using either the PTM master time interface signals or the PTM responder VSEC registers, as described in the previous list item
  - PTM messages must not contain TLP prefixes
- Context information stored in PTM Responder VSEC (PTM_RES_*_OFF):
  - Provides access to timestamps of most recent context refresh
  - Provides notification when context is valid
  - Programmable Tx and Rx latency values for each link speed, automatically selected based on current link speed
- When duplicate PTM TLP is received or a replay TLP is sent, the responder invalidates historical timestamps (t3 - t2)

19.3.15.4 Local PTM clock scaling

PTM clock scaling feature allows the local PTM clock to increment a programmable non-integer nanosecond amount in each controller clock period. This allows the PTM local time to remain coherent if there is a frequency deviation between PTM Requester and Responder.

PTM clock scaling also allows the controller to use PTM when the clock period is a non-integer nanosecond multiple.

PTM requester

To enable this feature set the PTM_REQ_SCALED_CLOCK_T_EN field of PTM_REQ_SCALED_CLOCK_T_OFF register to ‘1’ (this bit can be set only when PTM_CTRL.CNTXTVLD is set). You can set a 24-bit value consisting of an 8-bit integral part (nanoseconds) and 16-bit fractional part ($1/2^{16}$ nanoseconds) using PTM_REQ_SCALED_CLOCK_T_INT and PTM_REQ_SCALED_CLOCK_T_FRAC fields of the PTM_REQ_SCALED_CLOCK_T_OFF register, which represents the scaled local PTM clock period.

The clock scaling procedure is as follows:

- Following the second and subsequent assertions of the PTM_CTRL.UPDATED bit, while PTM_CTRL.CNTXTVLD remains asserted, your application may read the PTM Requester Clock Correction register (PTM_REQ_CLOCK_CORR_LSB_OFF)
- If the correction is below a threshold expected by your the application, your application may calculate a scaled local PTM clock period value, based on the current default clock period value, the programmed auto-update interval, and the contents of the PTM Clock Correction register (PTM_REQ_CLOCK_CORR_LSB_OFF)
- Your application may write the scaled PTM clock period to PTM Requester's Scaled PTM Clock Period register (PTM_REQ_SCALED_CLOCK_T_OFF), which represents the scaled local PTM clock period. This should happen as quickly as possible after the PTM_CTRL.UPDATEDpulse to avoid error accumulation

If the PTM context is invalidated, any pending scaled PTM clock period update should be aborted the clock scaling steps listed in this section to be restarted.

PTM responder

For the PTM Responder, your application fully controls PTM local clock updates. If the external master clock runs from the same source clock as the PCIe controller, clock scaling is not needed. However, for applications where the external master and PCIe controller run on unrelated clock sources, it may be necessary to scale the local PTM clock period.

To enable this feature set the PTM_RES_SCALED_CLOCK_T_EN field of PTM_RES_SCALED_CLOCK_T_OFF register to '1' (this bit can only be set when PTM_CTRL.CNTXTVLD is set). You can set a 24-bit value consisting of an 8-bit integral part (nanoseconds) and 16-bit fractional part ($1/2^{16}$ nanoseconds) using PTM_RES_SCALED_CLOCK_T_INT and PTM_RES_SCALED_CLOCK_T_FRAC fields of the PTM_RES_SCALED_CLOCK_T_OFF register, which represents the scaled local PTM clock period.

The clock scaling procedure is as follows:

- Your application initializes the PTM Responder with a known time from an external master
- The PTM Responder counts local PTM time using the Nominal PTM Clock Period, which your application can read from the PTM_RES_NOM_CLOCK_T_OFF register
- Your application waits for a known time and reads the local PTM clock value again
- Your application calculates the scaled PTM clock period using the deviation between the external master clock and the local PTM clock, and writes the scaled PTM clock period to PTM Responder's Scaled PTM Clock Period register (PTM_RES_SCALED_CLOCK_T_OFF), which represents the scaled local PTM clock period

If the PTM context becomes invalid your application must reiterate the steps listed in this section.

Use of scaled clock period and clock rate changes

The PTM Requester and PTM Responder scaled clock period enable bits are cleared when the core_clk rate changes, and can only be set when the clock rate change is complete. The core_clk rate is controlled by LTSSM.

19.3.16 OBFF

The optimized buffer flush/fill (OBFF) is a feature to improve overall power management. As a platform operates, each of its device does not know the power state of each of the resources in the system. Without coordination, each of the devices will go in and out of their low-power states as necessary to execute the tasks they are assigned to do.

As shown in the upper part of the following figure, asynchronous event including bus access and interrupts presents the RC going to a low power state, because the intermittent traffic keeps the system busy and unable to optimize the power management across the system.

With the help of OBFF, a host can provide information to all devices by broadcasting a message about the system power state. The devices can utilize this information to group a load of requests, wait until the system wakes up, and burst out all of the requests at the same time. By doing this, the idle windows and periods of system inactivity are prolonged, which saves overall system power, as depicted in the lower part of the following figure. More details about OBFF are described in PCIe specification.

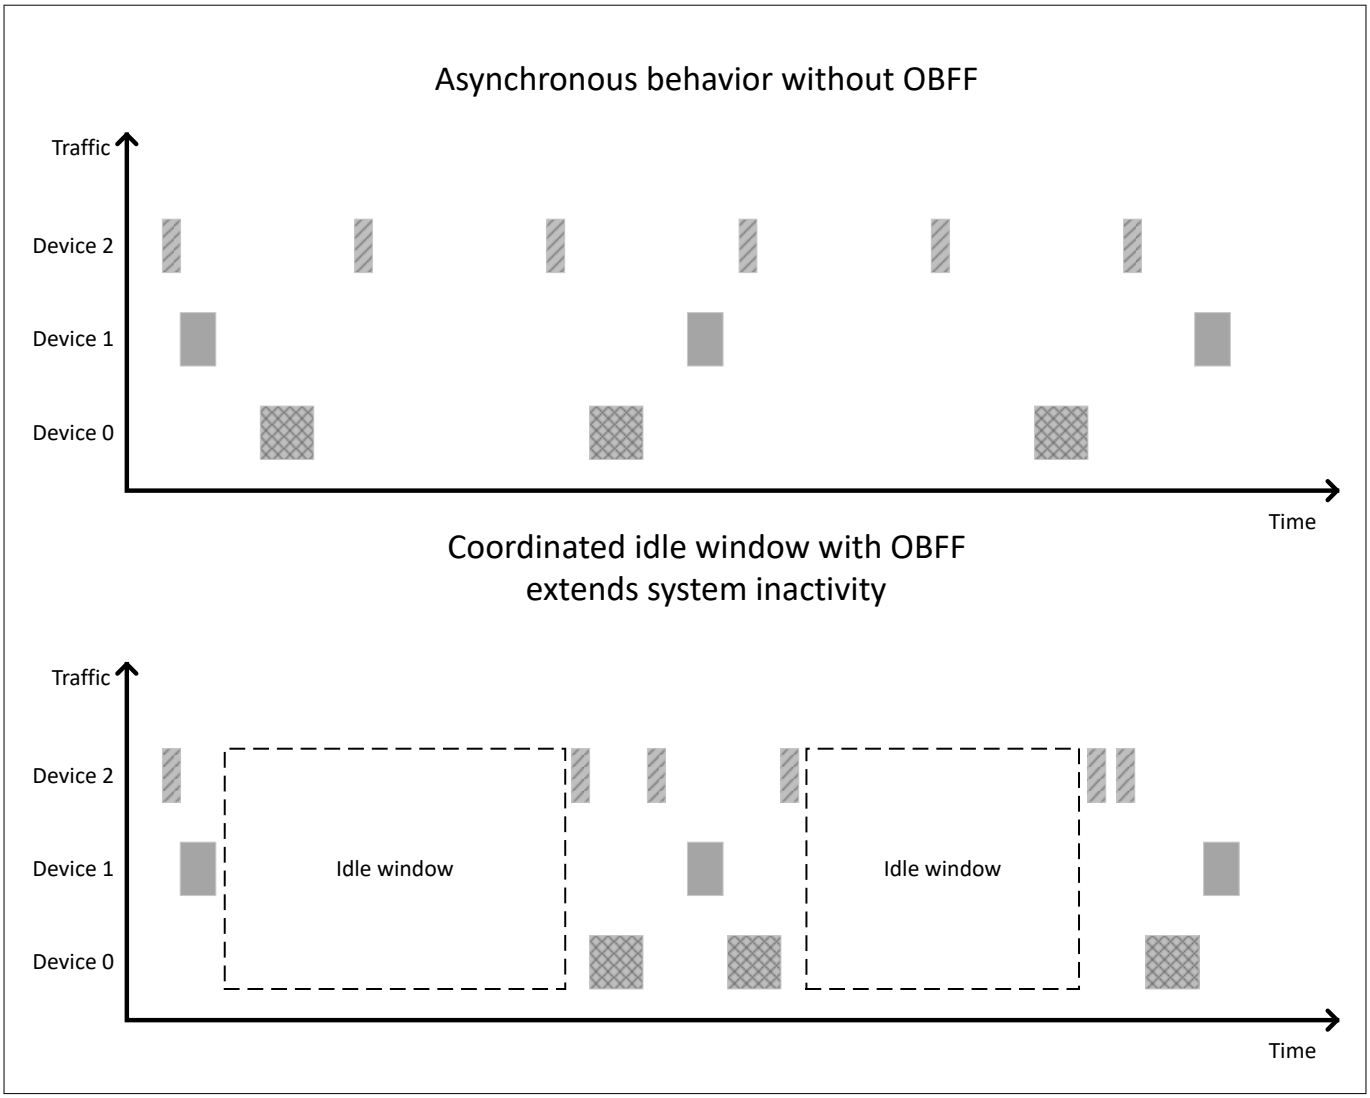

Figure 322 Optimized power consumption with OBFF

OBFF is indicated using either of the WAKE# signal or a message. The message is to be used exclusively on interconnects where the WAKE# signal is not available.

The OBFF messages shall be generated by RC and received by EP. The OBFF message generation is controlled by the OBFF register (OBFFMSG). The current OBFF hints broadcast by RC are indicated in the same register.

Another option of OBFF is using the WAKE# signal, as shown in the following figure. The original purpose of WAKE# was to wake up the system by an EP in lower power state. OBFF feature currently uses it in a compatible way such that this signal has now two functionalities. The usage of WAKE# signal is similar to the usage of messages and is controlled by the OBFFWAKE register.

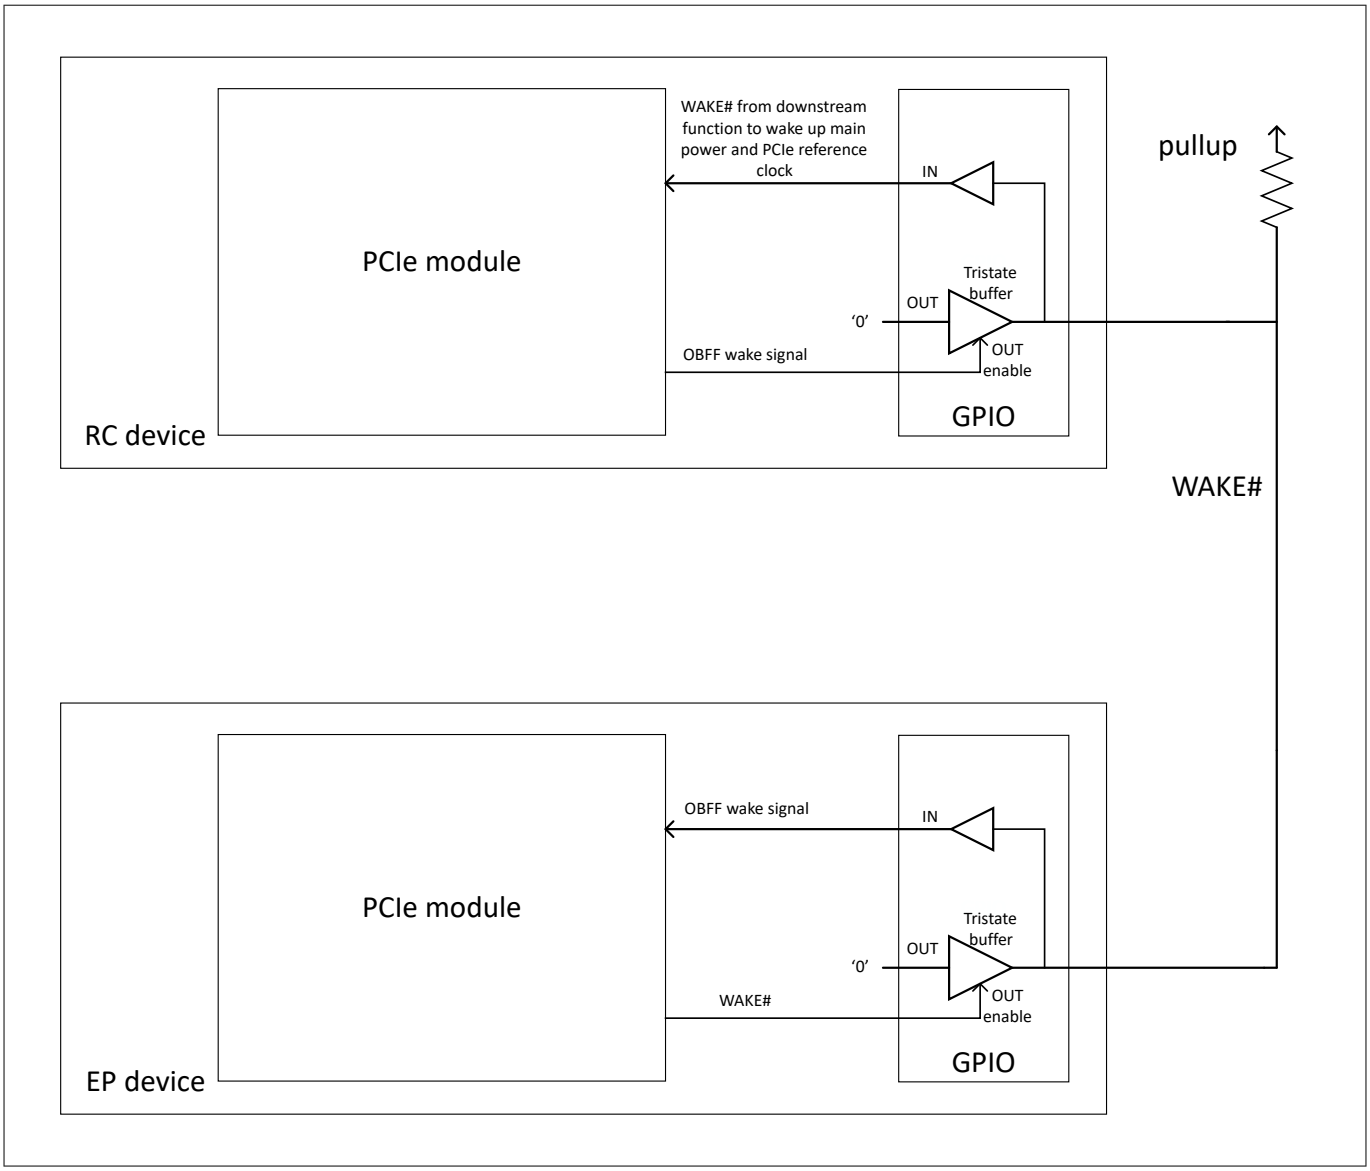

Figure 323 OBFF signaling using WAKE

In order to enable WAKE# input or output set the Controller control.WAKEN bit to 1. The generation of OBFF is triggered by asserting the corresponding OBFF registers. The reception of OBFF is indicated in the OBFF status registers and interrupt requests are also possible to notify software about the current system state. There are two OBFF registers, namely OBFFMSG and OBFFWAKE. Their functionalities are similar but one for message based OBFF and one for WAKE# pin based OBFF.

OBFF generation

You can generate OBFF messages using the following method:

- Direct software trigger: the controller generates OBFF messages in response to requests made by your application assertion of OBFFMSG.IDLEREQ, OBFFMSG.OBFFREQ and OBFFMSG.ACTREQ

You must not send an OBFF message when the OBFF Enable field of the Device Control 2 Register (DEVICE_CONTROL2_DEVICE_STATUS2_REG) is 0.

OBFF reception

When you have not enabled OBFF in the Device Control 2 register, or when the Traffic Class is non-zero, then the controller generates an UR completion when it receives an OBFF message. When the upstream port receives an OBFF message, it asserts one of the OBFFMSG.OBFF, OBFFMSG.ACT, or OBFFMSG.IDLE bit fields. Your application logic must use these outputs to control the traffic it generates. For more information, see *PCI Express Base Specification, Revision 5.0, Version 1.0*.

19.3.17 LTR

Similar to OBFF, latency tolerance reporting is another power-saving feature. The idea is to have each device in the system report its latency requirements to the host. LTR enables a device to communicate the necessary information back to the RC using an LTR message to report its required service latency.

The LTR values are used by the platform to implement an overall power management strategy that will reduce the power consumption while giving optimal performance. More details of LTR are described in the PCIe specification.

LTR generation

When you are using the direct SW triggering you should drive the contents of the LTR message header on the LTR_GNRTN.LTRLAT. It has the same format as LTR messages described in the PCIe specification. The LTR message generation is triggered by asserting LTR_CTRL.MSGREQ.

The actual values in the LTR message transmitted by this upstream port are captured in the port logic LTR Latency Register (PL_LTR_LATENCY_OFF).

The controller automatically generates a new LTR message with the Requirement bits set to 0 for both Snoop and No-Snoop latencies when:

- A function is directed to a non-D0 state through a write to the Power State field of the Power Management Control and Status register, and the LTR mechanism is active since the last DL_Down to DL_Up transition

  or
- The LTR mechanism is disabled by clearing the LTR Mechanism Enable field of the Device Control 2 register. This field is cleared through a CFG write.
- By setting DISABLE_AUTO_LTR_CLR_MSG field of the MISC_CONTROL_1_OFF register to 1, the automatic generation of the LTR clear message situations described in this section can be disabled

You must not send an LTR message when the LTR Mechanism Enable bit of the Device Control 2 Register is 0.

LTR reception

When the controller receives an LTR message, it asserts the LTR_CTRL.RLTR bit. You can access the LTR message information in the general message reception registers (PAYLOADz). The actual values in the LTR message received by this downstream port are captured in the port logic LTR Latency Register (PL_LTR_LATENCY_OFF). .

.

19.3.18 Readiness notification

The controller supports the optional Readiness Notification features. These features provide multiple mechanisms for a device or function to notify the host software that it is configuration-ready. A configuration-ready function always responds to a valid configuration request with a completion indicating successful completion status, and not CRS. For more information, see Readiness Notification in the PCI Express Base Specification, Revision 5.0, Version 1.0.

19.3.19 Limitations

- Locked transactions are not supported
- Atomic operations are not supported

Before the CLC.DISR is enabled, the SPB accesses to the PCIe module are responded with bus errors.

19.3.20 Advanced information

Advanced information that covers various topics is introduced in this part. It is not necessary for basic operations.

19.3.20.1 Separate refclk independent SSC (SRIS)

You can enable support for the Separate Refclk with Independent Spread Spectrum Clocking (SRIS) feature as defined by the PCI Express Base Specification, Revision 5.0, Version 1.0. When LNK_CORECTRL.SRISMD = 1 , then L0s is not supported and must not be advertised in the ASPM Support Capability Registers.

Table 859 SKP ordered set intervals in SRIS and non-SRIS modes

LNK_CORECTRL.SRISMD	SKP ordered set intervals (8b/10b encoding)	SKP ordered set intervals (128b/130b encoding)
0	Normal	Normal
1	Short (less than 154 Symbol times)	short (less than 38 Blocks)

19.3.21 UPCS

The PCIe 3.0 PCS block (also named universal PCS (UPCS)) provides many of the functions outlined in the PIPE 4 specification and comprises the PCS as referenced in the PIPE 4 specification. It can be used in conjunction with the HSPHY to create a PIPE4-compliant PHY solution.

The PCIe 3.0 PCS provides the following features:

- Standard PIPE 4 interface to upper layers of protocol stack (MAC layer and above)
- PCIe: 8b/10b (Gen 1/2) and 128b/130b (Gen3) encoding and decoding
- Translation of PIPE 4 power states (P0, P1, and so on) into the appropriate PHY controls, including any PHY-specific intermediate state sequencing
- Clock-rate compensation through SKP ordered sets and an elasticity buffer
- Error reporting

***Note**: Common refclk mode operation requires PHY controls to be overridden to align with PHY configuration given in the HSPHY device specific chapter.*

19.4 Registers

19.4.1 Registers of PCIE_USP

19.4.1.1 Register overview - access mode glossary

Table 860 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE or S2A_PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
APU-Py (y=0-7)	Protection group consisting of registers S2A_ACCENy_WRA, S2A_ACCENy_WRB, S2A_ACCENy_RDA, S2A_ACCENy_RDB, S2A_ACCENy_VM, S2A_ACCENy_PRS, S2A_ACCENy_RGNLA, S2A_ACCENy_RGNUA.
Py	Access protection using *APU-Py* registers.
APU-P_DMAy (y=0-3)	Protection group consisting of registers DMA_ACCENy_WRA, DMA_ACCENy_WRB, DMA_ACCENy_RDA, DMA_ACCENy_RDB, DMA_ACCENy_VM, DMA_ACCENy_PRS.
P_DMAy	Access protection using *APU-P_DMAy* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

19.4.1.4 Clock control register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 0000000$_H$

Clock control register Application Reset value: 0000 0003$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** When CLC.DISS=1_B, registers CLC, OCS, ID, PROTE, PROTSE, ACCEN_* and DMA_ACCEN_* are still accessible. Accesses to other PCIe registers are not executed and will result in a bus error 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Reserved** Used to control the module's reaction to sleep mode. Note: this bit field has no functionality implemented for PCIe. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

19.4.1.5 OCDS control and status register

OCS Offset address: 0000004_H

OCDS control and status register Debug Reset value: $0000\ 0000_H$

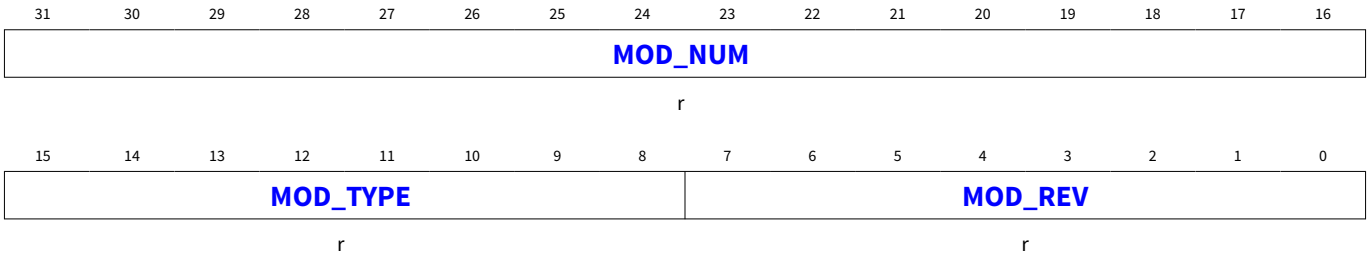
Field	Bits	Type	Description
0	31:0	r	**Reserved** Read as 0; should be written with 0.

19.4.1.6 Module identification register

ID Offset address: 0000008_H

Module identification register PowerOn Reset value: $0106\ C002_H$

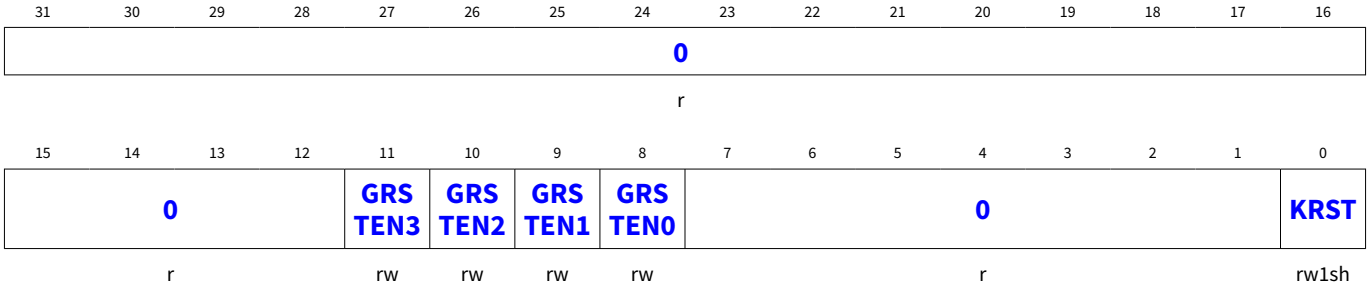


Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number. 0x0106 for PCIe.

19.4.1.7 Reset control register A

RST_CTRLA Offset address: $000000C_H$

Reset control register A Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rw1sh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for Global Module Reset Group x** 0_B Global module reset group x does not have any effect 1_B Global module reset group x results in a kernel reset
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

19.4.1.8 Reset control register B

RST_CTRLB Offset address: 0000010_H

Reset control register B Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w								r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															KRST
r															rw1sh

Field	Bits	Type	Description
KRST	0	rw1sh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
STATCLR	31	w	**Kernel Reset Status Clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits STAT.GRSTx and bit STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

19.4.1.9 Reset status register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: 0000014_H

Reset status register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				GRST3	GRST2	GRST1	GRST0	0							KRST
r				rh	rh	rh	rh	r							rh

Field	Bits	Type	Description
KRST	0	rh	**Kernel Reset Status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.
GRSTx (x=0-3)	x+8	rh	**Status for Global Module Reset Group x** 0_B Reset was not triggered by Global Reset Group x 1_B Reset was triggered by Global Reset Group x
0	7:1, 31:12	r	**Reserved** Read as 0.

19.4.1.10 PROT register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 0000020_H

PROT register endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

otherwise	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

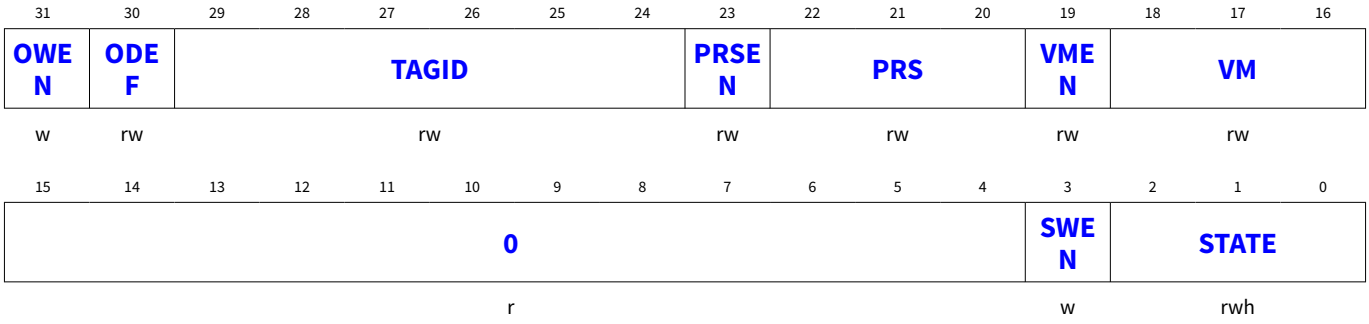
19.4.1.11 PROT register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 0000024_H

PROT register safe endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
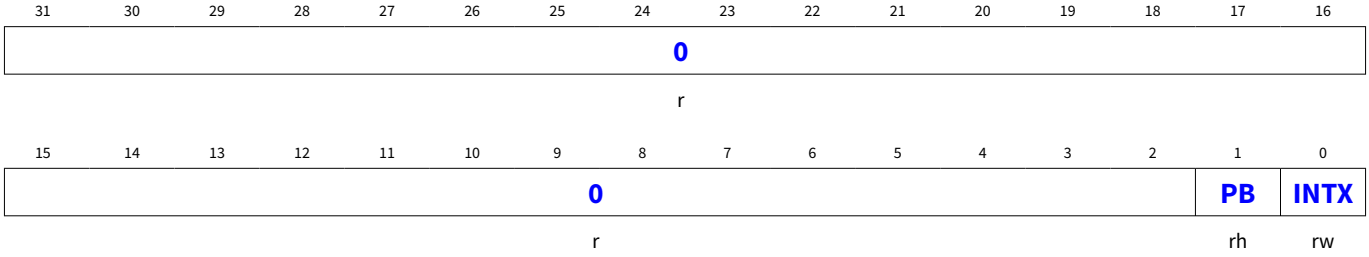
PDz (z=0-31)	z	rh	**Pending status of interrupt request** Indicates if an MSI interrupt request is pending. 1 means pending and 0 means not pending. 0_B No interrupt request pending 1_B Interrupt pending

19.4.1.43 Trigger INTX interrupt, EP only.

Legay PCI interrupt INTx support, is supposed to be connected to sys_int

INT_INTXCTRL Offset address: 0000350_H

Trigger INTX interrupt, EP only. Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
INTX	0	rw	**INTX interrupt** When this bit goes from low to high, the controller generates an Assert_INTx Message. When it goes from high to low, the controller generates a Deassert_INTx Message. The Interrupt Pin register for the corresponding function determines which INTx Message the controller generates (INTA, INTB, INTC, or INTD). Legacy and native PCIe devices capable of generating an interrupt must support both Assert_INTx/ Deassert_INTx and MSI or MSI-X.
PB	1	rh	**Pending status of INTx interrupt request** Indicates if an INTx interrupt request is pending and the message is not yet sent. 1 means pending and 0 means not pending. 0_B No interrupt request pending 1_B Interrupt pending
0	31:2	r	**Reserved** Read as 0; should be written with 0.

19.4.1.44 Trigger status

After the decoding of the 5 bits, 32 interrupt requests are passed to the Bit control block that consist of three different registers namely EN, STAT and CLR. The Bit control block decides which interrupt is masked in the 32, indicates the current interrupt status and clears the interrupts after service. The above three registers are designed for these functionalities respectively. The 32 interrupt requests will then merged into 8 interrupts that will be handed over to IR and software interrupts are then triggered.

INT_TRIGSTAT Offset address: 0000358_H

Trigger status Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
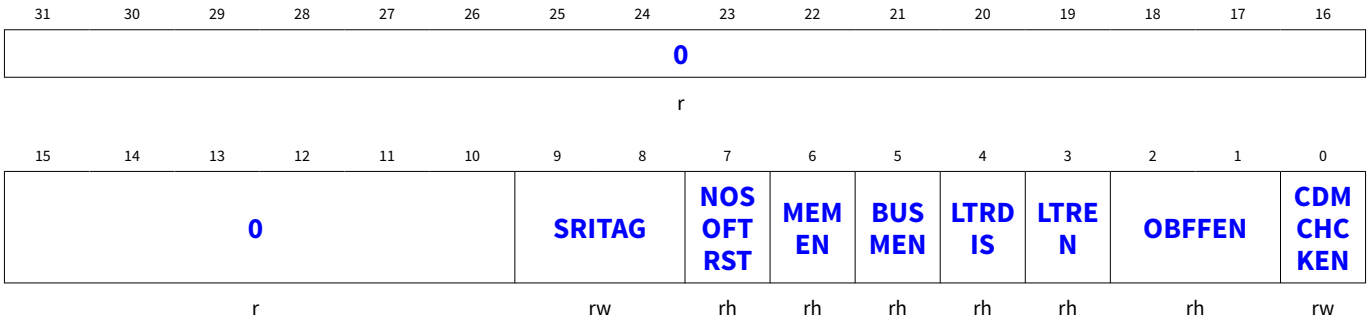
REQTRIG	4:0	rh	**Receive incoming interrupt request** This field can only be written from wire. The received value is parsed as 32 interrupt requests.
0	31:5	r	**Reserved** Read as 0; should be written with 0.

19.4.1.48 Configuration information

CFG_INFO Offset address: 0000368_H

Configuration information Kernel Reset value: $0000\ 0080_H$



Field	Bits	Type	Description
CDMCHCKEN	0	rw	**Signal to enter test mode in the Register Checking Logic.** Asserted to enter test mode in the Register Checking Logic and disable writes to shadow CDM registers. Allows a value to be written to CDM registers to compare against the previous value in shadow CDM registers. If the value written to CDM is different to the value held in shadow CDM registers, comparison error is generated when the address is checked, indicating the Register Content Check function is working correctly. Note: In normal operation mode this bit should be driven to 0.
OBFFEN	2:1	rh	**The OBFF Enable field of the Device Control 2 register of function 0** Indicates The OBFF Enable field of the Device Control 2 register of function 0.
LTREN	3	rh	**The LTR Mechanism Enable field of the Device Control 2 register of function 0.** Indicates the LTR Mechanism Enable field of the Device Control 2 register of function 0.
LTRDIS	4	rh	**Disable the autonomous generation of LTR clear message.**
BUSMEN	5	rh	**The state of the bus master enable bit in the PCI-compatible Command register.** Indicates the state of the bus master enable bit in the PCI-compatible Command register.
MEMEN	6	rh	**The state of the Memory Space Enable bit in the PCI-compatible** Indicates the state of the Memory Space Enable bit in the PCI-compatible Command register.
NOSOFTRST	7	rh	**No Soft Reset bit** This is the value of the No Soft Reset bit in the Power Management Control and Status Register. When set, you should not reset any controller registers when transitioning from D3hot to D0.
SRITAG	9:8	rw	**Selection of the VM or the PRS on the SRI** This bit selects which SRI tag (the VM or the PRS) is used to indicate the DMA index number, when an SRI bus transaction is initiated by the DMA. 00_B No VM/PRS tag used 01_B The VM tag is used in the SRI transaction 10_B The PRS tag is used in the SRI transaction 11_B Reserved, no VM/PRS tag used

(table continues...)

(continued)

0											PWD	TYP			
r											rh	rw			

Field	Bits	Type	Description
TYP	3:0	rw	**Device/port type** Indicates the specific type of this PCI Express function. It is also used to set the 'Device/Port Type' field of the 'PCI Express Capabilities Register'. The controller uses this input to determine the operating mode of the controller at run time. Encodings except for the below ones are not supported. 0_H PCIe endpoint 4_H PCIe root complex
PWD	4	rh	**Power down status of the PCIe controller** Indicate the power-down status of the PCIe controler. The power-down status can be triggered by PERST# reset, SW kernal reset, the hot reset and link reset. The S2A bridge and the SPB slave interface will refuse to accept new bus request when this bit is asserted.
0	31:5	r	**Reserved** Read as 0; should be written with 0.

19.4.1.51 Indicate link status

LNK_STAT Offset address: 0000374_H

Indicate link status Kernel Reset value: $0000\ 0004_H$

0									PERSTINT	EQINT	BWINT	LINKINT	LINKRQRST	Res	LINKUP
r									rh	rh	rh	rh	rh	r	rh

Field	Bits	Type	Description
LINKUP	0	rh	**PHY Link up/down indicator** 0_B Link is down 1_B Link is up
LINKRQRST	2	rh	**Reset request** Reset request because the link has gone down or the controller received a hot-reset request. A low level indicates that the controller is requesting external logic to reset the controller because the PHY link is down. The link reset request is delayed until all pending bus transfers have completed.

(table continues...)

(continued)

Field	Bits	Type	Description
LINKINT	3	rh	**Link Autonomous Bandwidth Interrupt. The interrupt can be triggered when the LNK_INTEN.LINKINTEN is asserted.** indicate that the Link Autonomous Bandwidth Status bit has been set. This bit is asserted when all of the following conditions are true When INTx is used • The INTx assertion disable bit in the Command register is 0, and • The Link Autonomous Bandwidth Interrupt Enable bit in the Link Control register is set to 1, and • The Link Autonomous Bandwidth Interrupt Status bit in the Link Status register is set to 1 Or when MSI is used: • MSI or MSI-X is enabled. • The Link Autonomous Bandwidth Status register (Link Status register bit 15) is updated. • The Link Autonomous Bandwidth Interrupt Enable (Link Control register bit 11) is set.
BWINT	4	rh	**Link Bandwidth Management Interrupt. The interrupt can be triggered when the LNK_INTEN.BWINTEN is asserted.** Indicate that the Link Bandwidth Management Status bit has been set. This bit is asserted when all of the following conditions are true: When INTx is used • The INTx assertion disable bit in the Command register is 0, and • The Bandwidth Management Interrupt Enable bit in the Link Control register is set to 1, and • The Bandwidth Management Interrupt Status bit in the Link Status register is set to 1. Or when MSI is used: • MSI or MSI-X is enabled. • The Link Bandwidth Management Status register (Link Control Status register bit 14) is updated • The Link Bandwidth Management Interrupt Enable (Link Control register bit 10) is set..
EQINT	5	rh	**Link Equalization Request. The interrupt can be triggered when the LNK_INTEN.EQINTEN is asserted.** Interrupt indicating to your application that the Link Equalization Request bit in the Link Status 2 Register has been set and the Link Equalization Request Interrupt Enable (Link Control 3 Register bit 1) is set.
PERSTINT	6	rh	**Interrupt status of the PERST#. The interrupt can be triggered when the LNK_INTEN.PERSTEN is asserted.** It indicates the PERST# interrupt (detecting PERST# become active 0) arrives.
0	31:7	r	**Reserved** Read as 0; should be written with 0.

19.4.1.52 Controller control

LNK_CORECTRL Offset address: 0000378_H

Controller control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0														CLKREQEN	WAKEN
r														rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CLKREQ		WAKE		PERST		PERSTCLR	PERSTOVR	PERSTVAL	PERSTSTA	HOTRST	0	PFRQRTYEN	RQRTYEN	LTSSMEN	SRISMD
rw		rw		rw		w	rw	rw	rh	w	r	rw	rw	rw	rw

Field	Bits	Type	Description
SRISMD	0	rw	**SRIS operating mode** 0_B non-SRIS mode 1_B SRIS mode
LTSSMEN	1	rw	**Start link training.** Driven low default after cold, warm or hot reset to hold the LTSSM in the Detect state until your application is ready for the link training to begin. 0_B Hold LTSSM and delay link training 1_B Start link training
RQRTYEN	2	rw	**Defer incoming configuration requests** Provides a capability to defer incoming configuration requests until initialization is complete. When this bit is asserted, the controller completes incoming configuration requests with a configuration request retry status. Other incoming requests complete normally. When the Readiness Notification mechanism is supported, DRS messaging is blocked when RQRTYEN=1. When RQRTYEN=0 and MSG_INFO.DRSRDY=1, the controller autonomously transmits a DRS message when the link transitions from DL_Down to DL_Up.

(table continues...)

(continued)

Field	Bits	Type	Description
PFRQRTYEN	3	rw	**Per Physical Function (PF) to defer incoming configuration requests** Provides a per Physical Function (PF) capability to defer incoming configuration requests until initialization is complete. When PFRQRTYEN is asserted for a certain PF, the controller completes incoming configuration requests with a configuration request retry status only for that particular PF; other incoming requests complete normally. When RQRTYEN is also asserted, the controller completes incoming configuration requests with a configuration request retry status for ALL PFs and VFs, regardless of the status of PFRQRTYEN. When the Readiness Notification mechanism is supported, DRS messaging is blocked when PFRQRTYEN =1 for at least one PF. The same applies when PFRQRTYEN =0 for all PFs, but RQRTYEN is asserted. When PFRQRTYEN =0 for a certain PF, and RQRTYEN =0, and MSG_INFO.DRSRDY=1, the controller autonomously transmits a DRS message when the link transitions from DL_Down to DL_Up.
HOTRST	5	w	**Request from your application to send a hot reset to the upstream port, RC only.** A downstream port (DSP) can hot reset an upstream port (USP) by sending two consecutive TS1 ordered sets with the hot reset bit asserted. This field requests from your application to send a hot reset to the upstream port. In an upstream port, you should not use this bit. Note: This bit is not used by the controller to set the SBR field in the BRIDGE_CTRL_INT_PIN_INT_LINE_REG register. During the transition from DL_Active to DL_inactive, assertion of this bit indicates a Surprise Down Error, but setting of SBR field in the BRIDGE_CTRL_INT_PIN_INT_LINE_REG register through FPI does not trigger a Surprise Down Error.
PERSTSTA	6	rh	**PERST# pin status** Indicate the PERST# pin status. 0_B Asserted (active low) 1_B Deasserted (active low)
PERSTVAL	7	rw	**PERST# override value** This value decides the override value of the PERST# when the PERSTOVR is enabled. 0_B Asserted (active low) 1_B Deasserted (active low)
PERSTOVR	8	rw	**PERST# override enable** When this bit is enabled, the PERSTVAL bit will override the PERST# pin value in the controller.
PERSTCLR	9	w	**Clear the interrupt status of the PERSTINT.** Clear the interrupt status of the PERSTINT. 0_B Keep the status 1_B Clear the interrupt status

(table continues...)

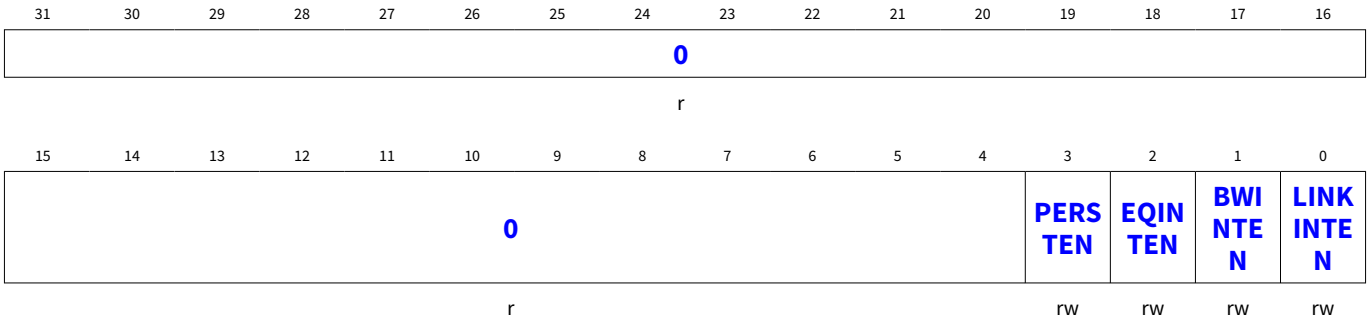
(continued)

Field	Bits	Type	Description
PERST	11:10	rw	**Alternate Input Select** Selects the alternate input for PERST#. 00_B Alternate Input A PERSTA_N 01_B Alternate Input B PERSTB_N 10_B Alternate Input A PERSTA_N 11_B Alternate Input A PERSTA_N
WAKE	13:12	rw	**Alternate input and output select** Selects the alternate input and output for WAKE#. 00_B Alternate input and output A WAKEA_IN_N 01_B Alternate input and output B WAKEB_IN_N 10_B Alternate input and output A WAKEA_IN_N 11_B Alternate input and output A WAKEA_IN_N
CLKREQ	15:14	rw	**Alternate input and output select** Selects the alternate input and output for CLKREQ#. 00_B Alternate input and output A CLKREQA_IN_N 01_B Alternate input and output B CLKREQB_IN_N 10_B Alternate input and output A CLKREQA_IN_N 11_B Alternate input and output A CLKREQA_IN_N
WAKEN	16	rw	**WAKE# enable control.** Enable the WAKE# input and output. If this bit is disabled, the alternative selection of the WAKE bit will have no effect 0_B WAKE# disable. None of the alternative pins is driven. 1_B WAKE# enable. One of the alternative pins is driven.
CLKREQEN	17	rw	**CLKREQ# enable control.** Enable the CLKREQ# input and output. If this bit is disabled, the alternative selection of the CLKREQ bit will have no effect 0_B CLKREQ# disable. None of the alternative pins is driven. 1_B CLKREQ# enable. One of the alternative pins is driven.
0	4, 31:18	r	**Reserved** Read as 0; should be written with 0.

19.4.1.53 Enable the interrupt requests to SRC_PCIELNK

LNK_INTEN Offset address: $000037C_H$

Enable the interrupt requests to SRC_PCIELNK Kernel Reset value: $0000\ 0000_H$

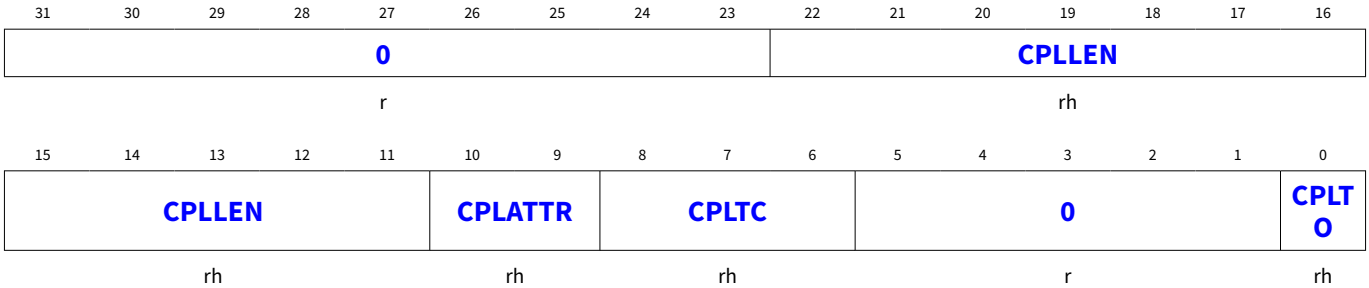


Field	Bits	Type	Description
LINKINTEN	0	rw	**Enable the LINKINT** 0_B Disable interrupt 1_B Enable interrupt
BWINTEN	1	rw	**Enable the BWINT bit.** 0_B Disable interrupt 1_B Enable interrupt
EQINTEN	2	rw	**Enable the EQINT bit.** 0_B Disable interrupt 1_B Enable interrupt
PERSTEN	3	rw	**Enable the PERSTINT bit.** 0_B Disable interrupt 1_B Enable interrupt
0	31:4	r	**Reserved** Read as 0; should be written with 0.

19.4.1.54 Rx control

TXRX_RXCTRL Offset address: 0000380_H

Rx control Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CPLTO	0	rh	**Indicates that the completion TLP for a request has not been received**
CPLTC	8:6	rh	**The Traffic Class of the timed out completion**

(table continues...)

(continued)

Field	Bits	Type	Description
CPLATTR	10:9	rh	**The Attributes field of the timed out completion**
CPLLEN	22:11	rh	**Length (in bytes) of the timed out completion.** For a split completion, it indicates the number of bytes remaining to be delivered when the completion timed out.
0	5:1, 31:23	r	**Reserved** Read as 0; should be written with 0.

19.4.1.55 Tx control 0

TXRX_TXCTRL0 Offset address: 0000384_H

Tx control 0 Kernel Reset value: $0000\ 0000_H$

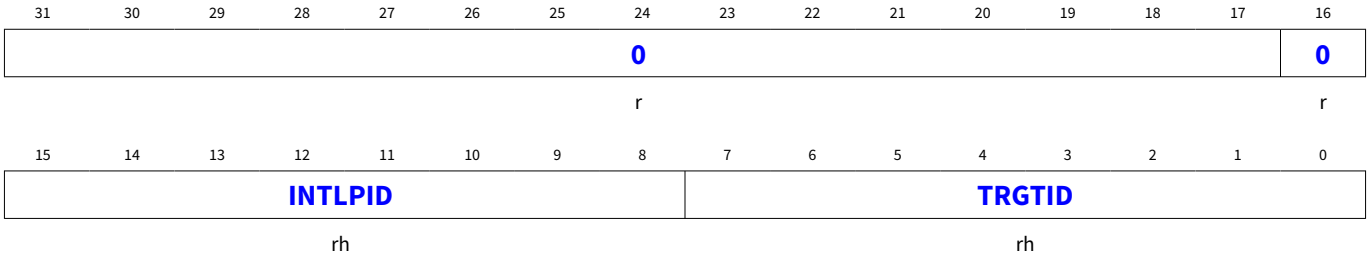
CPLLEN			CPLATTR		CPLTC			CPLFNUM			CPLTO	PRTYERR			BLCKTLP
rh			rh		rh			rh			rh	rh			rh

Field	Bits	Type	Description
BLCKTLP	0	rh	**Block TLP generation** Indicates that your application must stop generating new outgoing request TLPs due to the current power management state. Your application can continue to generate completion TLPs. This output is not used in RC mode.
PRTYERR	3:1	rh	**Indicates that the controller detected a datapath parity error** The controller handles the parity error as an uncorrectable error. • PRTYERR[0]: Parity error at front end of the transmit datapath. • PRTYERR[1]: Parity error at back end of the transmit datapath. • PRTYERR[2]: Parity error the receive datapath. They do not indicate which packet contained the parity error.
CPLTO	4	rh	**No completion for an incoming request** Information about the timed out completion is available the fields listed later. When a completion timeout occurs, the controller does not clear the corresponding entry from the completion lookup table.
CPLFNUM	7:5	rh	**The function number of the timed out completion.**
CPLTC	10:8	rh	**The TC of the timed out completion.**
CPLATTR	12:11	rh	**The Attributes value of the timed out completion.**
CPLLEN	24:13	rh	**The Length of the timed out completion.**
0	31:25	r	**Reserved** Read as 0; should be written with 0.

19.4.1.56 Tx control 1

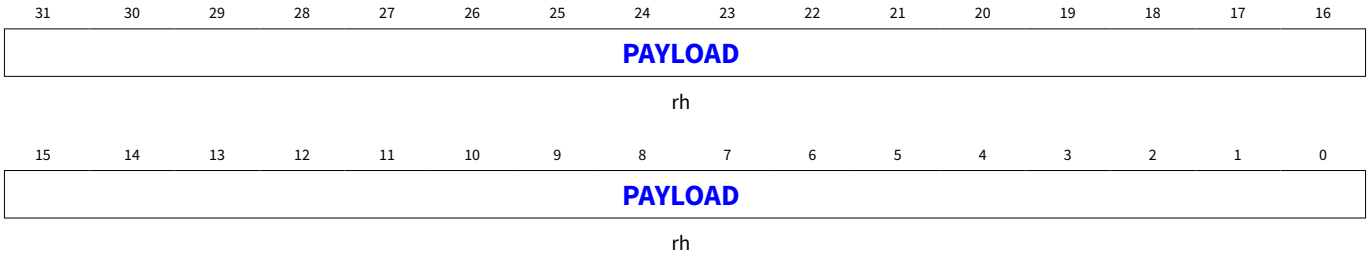


Field	Bits	Type	Description
TRGTID	7:0	rh	**The target completion LUT lookup ID of the timed out completion**
INTLPID	15:8	rh	**The target completion LUT lookup ID for the incoming request TLP.**
0	16, 31:17	r	**Reserved** Read as 0; should be written with 0.

19.4.1.57 Message payload z information

PAYLOADz (z=0-1) Offset address: $000038C_H+z*4$

Message payload z information Kernel Reset value: $0000\ 0000_H$



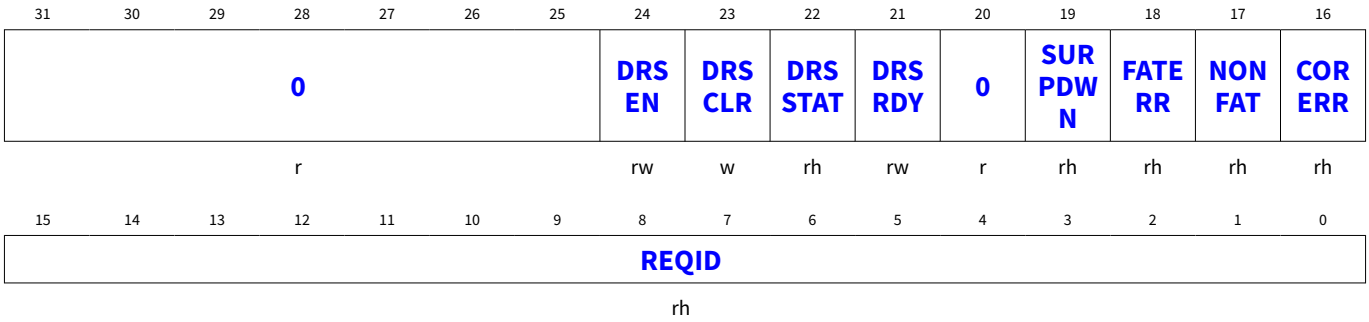
Field	Bits	Type	Description
PAYLOAD	31:0	rh	**Received message header information.** When a ltr message is received, the controller maps the message payload to the Rx TLP header dwords as follows: • PAYLOAD0 = bytes 12-15 (4th dword), where [7:0] =byte 15 • PAYLOAD1 = bytes 8-11 (3rd dword)

19.4.1.58 Message information

MSG_INFO Offset address: 0000394_H

Message information Kernel Reset value: $0000\ 0000_H$

19 Peripheral Component Interconnect Express (PCIe)



Field	Bits	Type	Description
REQID	15:0	rh	**The requester ID of the received Message.** • [2:0]: Function number • [7:3]: Device number • [15:8]: Bus number
CORERR	16	rh	**Sent Correctable Error, EP only.** Core has sent a message towards the Root Complex indicating that an Rx TLP that contained an error, and that can be corrected, was received by the EndPoint.
NONFAT	17	rh	**Sent Non-Fatal Error, EP only.** Controller has sent a message towards the Root Complex indicating that an Rx TLP that contained an non-fatal error, and that can not be corrected, was received by the EndPoint.
FATERR	18	rh	**Sent Fatal Error, EP only.** Controller has sent a message towards the Root Complex indicating that an Rx TLP that contained a fatal error, and that can not be corrected, was received by the EndPoint
SURPDWN	19	rh	**Indicates that a surprise down event is occurring in the controller.**
DRSRDY	21	rw	**Defers DRS messaging when set to '0', EP only.**
DRSSTAT	22	rh	**DRS Message Received Interrupt, RC only. The interrupt can be triggered when the DRSEN is asserted.** The DSP controller asserts this bit when all of the following are true: • It receives a DRS message • PCIE_CAP_DRS_SIGNALING_CONTROL in LINK_CONTROL_LINK_STATUS_REG is 2'b01 • MSI or MSI-X is enabled
DRSCLR	23	w	**Clear the DRS state, RC only.** 0_B Keep the status 1_B Clear the interrupt status
DRSEN	24	rw	**Enable the DRS interrupt, RC only.** 0_B Disable interrupt 1_B Enable interrupt
0	20, 31:25	r	**Reserved** Read as 0; should be written with 0.

19.4.1.59 Power management control

PM_CTRL Offset address: 0000398_H

Power management control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0														TRN	TRNACK
r														rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PMEMSG	TURNOFF	0				CLKRM	PMEINT	CLKPMEN	CLKREQ	XFERPND	REQEXITL1	RDYENTRL23	REQENTRL1	AUXPWRDET	WKUPCMD
rh	w	r				rw	rh	rw	rh	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
WKUPCMD	0	rw	**Wake Up.** Wake Up. If PME is enabled and PME support is configured for current PMCSR D-state asserting this signal causes the controller to wake from either L1 or L2 state.
AUXPWRDET	1	rw	**Auxiliary Power Detected.** Used to report to the host software that auxiliary power (Vaux) is present.
REQENTRL1	2	rw	**Application request to Enter L1 ASPM state.** This bit is for use by applications that need to control L1 entry instead of using the L1 entry timer as defined in the PCI Express Specification. It is only effective when L1 is enabled. The controller latches this request when in L0 or L0s; to be acted upon later. Note: The controller ignores this input in RC mode
RDYENTRL23	3	rw	**Application Ready to Enter L23.** Indication from your application that it is ready to enter the L23 state. This bit is provided for applications that must control L23 entry (in case certain tasks must be performed before going into L23). The controller delays sending PM_Enter_L23 (in response to PM_Turn_Off) until this signal becomes active. When this signal has been asserted by the application, it must be kept asserted until L2 entry has completed.
REQEXITL1	4	rw	**Application request to Exit L1.** Request from your application to exit L1. It is only effective when L1 is enabled.

(table continues...)

(continued)

Field	Bits	Type	Description
XFERPND	5	rw	**Indicates that your application has transfers pending** If the entry into L1 is already in progress, assertion of app_xfer_pending causes an exit from L1. This is a level signal used to inform the controller about the state of external queues and pipeline stages that contain transactions to be transmitted by the controller. The controller uses this information to determine when to enter/exit L1. When this signal is asserted, it indicates that there are transactions outside the controller that the controller needs to transmit. When de-asserted, it indicates that there are no transactions outside the controller. The controller responds to an assertion on this signal as follows: • Upstream Ports: Prevents generation of requests to enter L1. Triggers exit if already in L1. • Downstream Ports: Triggers exit if already in L1.
CLKREQ	6	rh	**Status of the CLKREQ#** Status of the CLKREQ# bidirectional CMOS board-level signal. This should be connected to the GPIO. Used by the controller to determine when to enter and exit L1 Substates when using the CLKREQ#-based mechanism. For more details, see 'L1 Substates'.
CLKPMEN	7	rw	**Clock PM feature enabled by application.** Used to inhibit the programming of the Clock PM in Link Control Register.
PMEINT	8	rh	**PME interrupt received. The interrupt can be triggered when the PM_INTEN.PMEINTEN is asserted.** The controller asserts this bit when all of the following conditions are true: • The INTx Assertion Disable bit in the Command register is 0. • The PME Interrupt Enable bit in the Root Control register is set to 1. • The PME Status bit in the Root Status register is set to 1. Or • MSI or MSI-X is enabled. • The PME Interrupt Enable bit in the Root Control register is set to 1. • The PME Status bit in the Root Status register is set to 1.
CLKRM	9	rw	**Indicates that the application is ready to have reference clock removed.** The application should set this bit to 1'b1 if it supports reference clock removal. If the application does not want to remove reference clock it should set this bit to 1'b0. This bit should be asserted or de-asserted when L1 CPM or L1 Sub-states are being configured, it should not be changed dynamically during L1.
TURNOFF	14	w	**Request from your application to generate a PM_Turn_Off message.** You must assert this signal for one clock cycle. You must not assert the same bit again, until the previous message has been transmitted.
PMEMSG	15	rh	**The controller received a PM_PME message.The interrupt can be triggered when the PM_INTEN.PMEMSGEN is asserted.**

(table continues...)

(continued)

Field	Bits	Type	Description
TRNACK	16	rh	**The controller received a PME_TO_Ack message. Upstream port: Reserved. The interrupt can be triggered when the PM_INTEN.TOACKEN is asserted.**
TRN	17	rh	**The controller received a PME Turnoff message. The interrupt can be triggered when the PM_INTEN.TOEN is asserted.**
0	13:10, 31:18	r	**Reserved** Read as 0; should be written with 0.

0												HPINTCLR	HPINTEN	HPINT	HPPME
r												w	rw	rh	rh

Field	Bits	Type	Description
HPPME	0	rh	**The controller asserts hp_pme when all of the following conditions are true:** • The PME Enable bit in the Power Management Control and Status register is set to 1. • Any bit in the Slot Status register transitions from 0 to 1 and the associated event notification is enabled in the Slot Control register. The controller does not check if the PM state is D1, D2, or D3hot. It is up to your application to check the value pm_dstate to make sure the device is in D1, D2, or D3hot. There is one bit of HPPME for each configured function. The controller pulses this bit output only when any hot plug status bit changes from 0 to 1 (as is HPINT). hp_int stays asserted as long as the status bit is set. In addition, it asserts HPPME only if PME is enabled, but it does not matter if hot-plug interrupts are enabled.
HPINT	1	rh	**The controller asserts hp_int when all of the following conditions are true:** • The INTx Assertion Disable bit in the Command register is 0. • Hot-Plug interrupts are enabled in the Slot Control register. • Any bit in the Slot Status register is equal to 1, and the associated event notification is enabled in the Slot Control register. Or • MSI or MSI-X is enabled. • Hot-Plug interrupts are enabled in the Slot Control register. • Any bit in the Slot Status register transitions from 0 to 1 and the associated event notification is enabled in the Slot Control register.
HPINTEN	2	rw	**Hot plug enable** 0_B Disable interrupt 1_B Enable interrupt
HPINTCLR	3	w	**Clear the HPINT bit.** 0_B Keep the status 1_B Clear the interrupt status
0	31:4	r	**Reserved** Read as 0; should be written with 0.

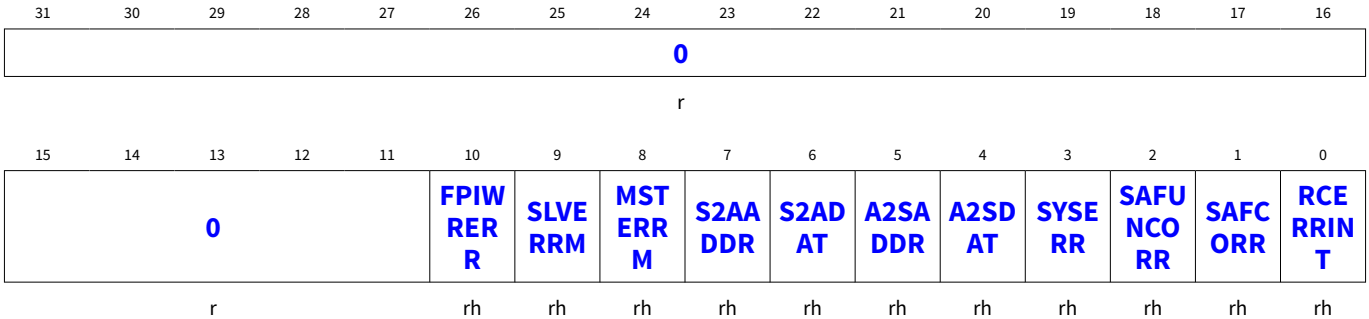
19.4.1.82 Interrupt/alarm status

ALARM_STAT Offset address: 0000424_H

Interrupt/alarm status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RCERRINT	0	rh	**Error reported. The interrupt can be triggered when the ALARM_INTEN.RCERREN is asserted.** Asserted when a reported error condition causes a bit to be set in the Root Error Status register and the associated error message reporting enable bit is set in the Root Error Command register. This bit is set when the RC internally generates an error or when an error message is received by the RC. Because the RC itself generates it, this needs to be propagated up to the system software which would then need to read the error registers to see which error occurred.
SAFCORR	1	rh	**Indicate correctable error. The interrupt can be triggered when the ALARM_INTEN.SAFCORREN is asserted.** The controller asserts this bit when a PCIe protocol correctable error or a Data Path protection correctable error is indicated and the associated mask for that event is not set.
SAFUNCORR	2	rh	**Indicate uncorrectable error. The interrupt can be triggered when the ALARM_INTEN.SAFUNCORR is asserted.** The controller asserts this bit when any of the internal safety mechanisms reports an uncorrectable error and the associated mask for that event is not set.
SYSERR	3	rh	**System error detected. The interrupt can be triggered when the ALARM_INTEN.SYSERREN is asserted.** Assertion of this bit indicates if any device in the hierarchy reports any of the following errors and the associated enable bit is set in the Root Control register: ERR_COR, ERR_FATAL, ERR_NONFATAL. Also asserted when an internal error is detected.
A2SDAT	4	rh	**Error detected during the data phase in the A2S bridge. The interrupt can be triggered when the ALARM_INTEN.A2SDEN is asserted.**
A2SADDR	5	rh	**Error detected during the address phase in the A2S bridge. The interrupt can be triggered when the ALARM_INTEN.A2SAEN is asserted.**
S2ADAT	6	rh	**Error detected during the data phase in the S2A bridge. The interrupt can be triggered when the ALARM_INTEN.S2ADEN is asserted.**
S2AADDR	7	rh	**Error detected during the address phase in the S2A bridge. The interrupt can be triggered when the ALARM_INTEN.S2AAEN is asserted.**
MSTERRM	8	rh	**The controller has entered RASDP error mode at the master interface of AXI.** The controller enters RASDP error mode (if the ERROR_MODE_EN register field =1) upon detection of the first uncorrectable error. During this mode: • Controller sets SLVERRM=1 • Controller sets MSTERRM=1 • Rx TLPs that are forwarded to your application are not guaranteed to be correct; you must discard them.

(table continues...)

(continued)

Field	Bits	Type	Description
SLVERRM	9	rh	**The controller has entered RASDP error mode at the slave interface of AXI.** The controller enters RASDP error mode (if the ERROR_MODE_EN register field =1) upon detection of the first uncorrectable error. During this mode: • Controller sets SLVERRM=1 • Controller sets MSTERRM=1 • Rx TLPs that are forwarded to your application are not guaranteed to be correct; you must discard them.
FPIWRERR	10	rh	**FPI write error status** Status to indicate write returned an error on the FPI interface
0	31:11	r	**Reserved** Read as 0; should be written with 0.

19.4.1.83 Interrupt/alarm clear

0		Res	0		ATTR		TD	TC			TYPE				
r		r	r		rw		rw	rw			rw				

Field	Bits	Type	Description
TYPE	4:0	rw	**When the address of an outbound TLP is matched to this region, then the TYPE field of the TLP is changed to the value in this register** Note: This register field is sticky.
TC	7:5	rw	**When the address of an outbound TLP is matched to this region, then the TC field of the TLP is changed to the value in this register** Note: This register field is sticky.
TD	8	rw	**This is a reserved field** Do not use. Note: This register field is sticky.
ATTR	10:9	rw	**When the address of an outbound TLP is matched to this region, then the ATTR field of the TLP is changed to the value in this register** Note: This register field is sticky.
CTRL_1_FUNC_NUM	22:20	rw	**Function Number** The value in this register must be 0x0 as only one function is supported by this controller. . When the address of an outbound TLP is matched to this region and the FUNC_BYPASS field in the "iATU Region Control 2 Register" is '0', then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register. This field is swapped before AXI decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used. Note: This register field is sticky
0	12:11, 19:14, 31:23	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.1.86 iATU Region i Control 2 Register Outbound

Using this register you can enable/disable the outbound iATU optional features.

IATU_REGION_CTRL_2_OFF_OUTBOUND_i (i=0-7) Offset address: $0003004_H+i*200_H$

iATU Region i Control 2 Register Outbound Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REGION_EN	0	INVERT_MODE	Res	DMA_BYPASS	0			HEADER_SUBSTITUTE_EN	INHIBIT_PAYLOAD	Res		FUNC_BYPASS	0		TAG_SUBSTITUTE_EN
rw	r	rw	r	rw	r			rw	rw	r		rw	r		rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAG								MSG_CODE							
rw								rw							

Field	Bits	Type	Description
MSG_CODE	7:0	rw	**MSG TLPs (Message Code)** When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. Note: This register field is sticky.
TAG	15:8	rw	**TAG** The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. Note: This register field is sticky.
TAG_SUBSTITUTE_EN	16	rw	**TAG Substitute Enable** When enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
FUNC_BYPASS	19	rw	**Function Number Translation Bypass** In this mode, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "iATU Region Control 1 Register" Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
INHIBIT_PAYLOAD	22	rw	**Inhibit TLP Payload Data for TLP's in Matched Region; assign iATU region to be TLP without data** When enabled and region address is matched, the iATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0b. Encoding are define as above. Note: This register field is sticky. 0_B **SUPPORT_DATA_TLP**: Fmt[1] =0/1 so that TLPs with or without data can be sent 1_B **NO_SUPPORT_FOR_DATA_TLP**: Fmt[1] =0 so that only TLP type without data is sent For example, a Msg instead of MsgD will be sent.
HEADER_SUBSTITUTE_EN	23	rw	**Header Substitute Enable** When enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i. Encodings are as above. Note: This register field is sticky. 0_B **FORM_ADDR**: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register forms the new address of the translated region 1_B **FILL_BYTES**: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header

(table continues...)

(continued)

Field	Bits	Type	Description
DMA_BYPASS	27	rw	**DMA Bypass Mode** Allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
INVERT_MODE	29	rw	**Invert Mode** When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
REGION_EN	31	rw	**Region Enable** This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
0	18:17, 26:24, 30	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.1.87 iATU i Lower Base Address Register Outbound

.

IATU_LWR_BASE_ADDR_OFF_OUTBOUND_i (i=0-7) Offset address: $0003008_H+i*200_H$

iATU i Lower Base Address Register Outbound Kernel Reset value: $0000\ 0000_H$

rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LWR_TARGET_RW_OUTBOUND															
rw															

Field	Bits	Type	Description
LWR_TARGET_RW_OUTBOUND	31:0	rw	**Containing the Lower Target part of the new address of the translated region, or the outbound TLP header information** When HEADER_SUBSTITUTE_EN is 0, for lower target address, the start address must be aligned to a 4 kB boundary, so the lower bits of the start address of the new address of the translated region (bits 11:0) are always '0'. When HEADER_SUBSTITUTE_EN in IATU_REGION_CTRL_2_OFF_OUTBOUND_i is '1': - this field forms bytes 8-11 (for 3 dword header) or bytes 12-15 (for 4 dword header) of the outbound TLP header. Note: This register field is sticky.

19.4.1.91 iATU i Upper Target Address Register Outbound

This register holds the upper 32 bits of the start address (Upper Target part) of the new address of the translated region.

IATU_UPPER_TARGET_ADDR_OFF_OUTBOUND_i (i=0-7) Offset address: $0003018_H+i*200_H$

iATU i Upper Target Address Register Outbound Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UPPER_TARGET_RW															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
UPPER_TARGET_RW															
rw															

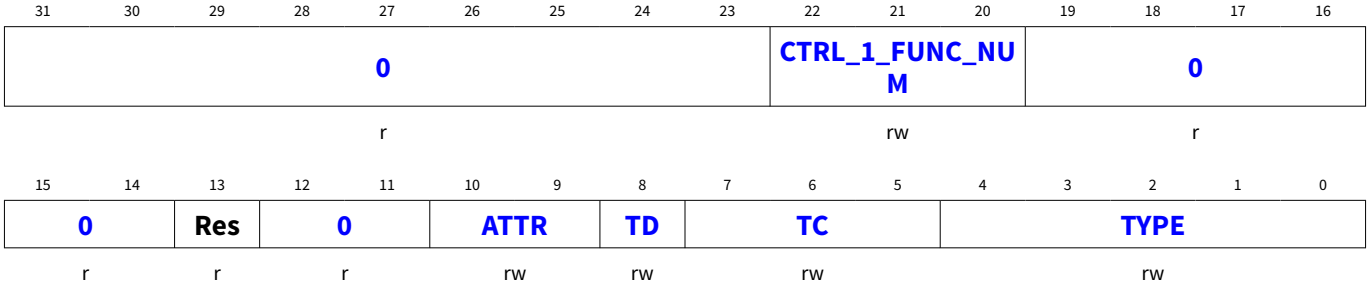
Field	Bits	Type	Description
UPPER_TARGET_RW	31:0	rw	**Forms bits [63:32] of the start address (Upper Target part) of the new address of the translated region** Note: This register field is sticky.

19.4.1.92 iATU Region i Control 1 Register Inbound

This register controls the iATU inbound region access based on the optional iATU inbound features enabled using iATU Region Control 2 Register.

IATU_REGION_CTRL_1_OFF_INBOUND_i (i=0-7) Offset address: $0003100_H+i*200_H$

iATU Region i Control 1 Register Inbound Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TYPE	4:0	rw	**When the TYPE field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful)** Note: This register field is sticky.
TC	7:5	rw	**When the TC field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful)** This check is only performed if the "TC Match Enable" bit of the "iATU Region Control 2 Register" is set. Note: This register field is sticky.
TD	8	rw	**When the TD field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful)** This check is only performed if the "TD Match Enable" bit of the "iATU Region Control 2 Register" is set. Note: This register field is sticky.
ATTR	10:9	rw	**When the ATTR field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful)** This check is only performed if the "ATTR Match Enable" bit of the "iATU Region Control 2 Register" is set. Note: This register field is sticky.
CTRL_1_FUNC_NUM	22:20	rw	**Function Number** - MEM-I/O: When the Address and BAR matching logic in the controller indicate that a MEM-I/O transaction matches a BAR in the function corresponding to this value, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Region Control 2 Register" is set. - CFG0/CFG1: When the destination function number as specified in the routing ID of the TLP header matches the function, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Region Control 2 Register" is set. Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
MSG_CODE	7:0	rw	**MSG TLPs: (Message Code)** When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Message Code Match Enable" bit of the "iATU Region Control 2 Register" is set. Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
BAR_NUM	10:8	rw	**BAR Number** When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "iATU Region Control 2 Register" is set. IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. Note: This register field is sticky. 000_B **BAR0**: BAR0 001_B **BAR1**: BAR1 010_B **BAR2**: BAR2 011_B **BAR3**: BAR3 100_B **BAR4**: BAR4 101_B **BAR5**: BAR5 110_B **ROM**: ROM 111_B **RSVD**: reserved
MSG_TYPE_MATCH_MODE	13	rw	**Message Type Match Mode** When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the IATU_REGION_CTRL_1_OFF_INBOUND_i register (TYPE[4:3]=2'b10) will be translated. Message type match mode overrides any value of MATCH_MODE field in this register. Usage scenarios for this are translation of VDM or ATS messages when AXI bridge is configured on client interface. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
TC_MATCH_EN	14	rw	**TC Match Enable** Ensures that a successful TC TLP field comparison match (see TC field of the "iATU Region Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky. 0_B **DISABLE**: TC Match Disable 1_B **ENABLE**: TC Match Enable
TD_MATCH_EN	15	rw	**TD Match Enable** Ensures that a successful TD TLP field comparison match (see TD field of the "iATU Region Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky. 0_B **DISABLE**: TD Match Disable 1_B **ENABLE**: TD Match Enable
ATTR_MATCH_EN	16	rw	**ATTR Match Enable** Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "iATU Region Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky. 0_B **DISABLE**: ATTR Match Disable 1_B **ENABLE**: ATTR Match Enable

(table continues...)

(continued)

Field	Bits	Type	Description
FUNC_NUM_MATCH_EN	19	rw	**Function Number Match Enable** Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "iATU Region Control 1 Register") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. Note: This register field is sticky. 0_B **DISABLE**: Function Number Match Disable 1_B **ENABLE**: Function Number Match Enable
MSG_CODE_MATCH_EN	21	rw	**Message Code Match Enable (Msg TLPS)** Ensures that a successful message Code TLP field comparison match (see Message Code field of the "iATU Region Control 2 Register") occurs (in MSG transactions) for address translation to proceed. Note: This register field is sticky. 0_B **DISABLE**: Virtual Function Number Match Disable 1_B **ENABLE**: Message Code Match Enable (for Msg TLPS) or ST Match Enable (for Mem TLPs)
SINGLE_ADDR_LOC_TRANS_EN	23	rw	**Single Address Location Translate Enable** When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the iATU region. The main usage scenario is translation of Messages to MWr TLPs when the AXI bridge is enabled. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
RESPONSE_CODE	25:24	rw	**Response Code** Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. Note: This register field is sticky. 00_B **NORMAL_RADM**: Normal RADM filter response is used 01_B **UNSUP_REQ**: Unsupported request (UR) 10_B **COMPL_ABORT**: Completer abort (CA) 11_B **NOT_USED**: Not used / undefined / reserved
INVERT_MODE	29	rw	**Invert Mode Enable** When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). When set all regions of that type must use address match mode. Note: This register field is sticky. 0_B **DISABLE**: Invert Mode Disable 1_B **ENABLE**: Invert Mode Enable

(table continues...)

(continued)

Field	Bits	Type	Description
MATCH_MODE	30	rw	**Match Mode** Determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received as follows: For MEM-I/O TLPs, this field is interpreted as follows: • 0: Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. • 1: BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as follows: • 0: Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed • 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number For MSG/MSGD TLPs, this field is interpreted as follows: • 0: Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers • 1: Vendor ID Match Mode. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1 AND MSG_TYPE_MATCH_MODE =1, then Match Mode is ignored. Note: This register field is sticky. 0_B **ZERO**: The interpretation is dependent on TLP type, that is, MEM/IO, CFG0, or MSG/MSGD TLPs 1_B **ONE**: The interpretation is dependent on TLP type, that is, MEM/IO, CFG0, or MSG/MSGD TLPs
REGION_EN	31	rw	**Region Enable** This bit must be set to '1' for address translation to take place. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable

(table continues...)

(continued)

Field	Bits	Type	Description
0	12:11, 18:17, 20, 22, 26	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.1.94 iATU i Lower Base Address Register Inbound

IATU_LWR_BASE_ADDR_OFF_INBOUND_i (i=0-7) Offset address: $0003108_H+i*200_H$

iATU i Lower Base Address Register Inbound Kernel Reset value: $0000\ 0000_H$

r					rw	r	rw	r	rw	r	r	r	rw	rwh	rwh

Field	Bits	Type	Description
PCI_TYPE0_IO_EN	0	rwh	**IO Space Enable** Controls a Function's response to I/O Space accesses. • When this bit is set, the Function is enabled to decode the address and further process I/O Space accesses • When this bit is clear, all received I/O accesses are caused to be handled as Unsupported Requests. For a Function that does not support I/O Space accesses, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: • Wire: !has_io_bar ? RO : RW • Dbi: !has_io_bar ? RO : RW
PCI_TYPE0_MEM_SPACE_EN	1	rwh	**Memory Space Enable** Controls a Function's response to Memory Space accesses. • When this bit is set, the Function is enabled to decode the address and further process Memory Space accesses • When this bit is clear, all received Memory Space accesses are caused to be handled as Unsupported Requests. For a Function does not support Memory Space accesses, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: RW - Dbi: RW
PCI_TYPE0_BUS_MASTER_EN	2	rw	**Bus Master Enable** Controls the ability of a Function to issue Memory and I/O Read/Write requests. • When this bit is set, the Function is allowed to issue Memory or I/O Requests • When this bit is clear, the Function is not allowed to issue any Memory or I/O Requests Requests other than Memory or I/O Requests are not controlled by this bit. Note: MSI/MSI-X interrupt Messages are in-band memory writes, setting the Bus Master Enable bit to 0b disables MSI/MSI-X interrupt Messages as well. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
PCI_TYPE0_SPECIAL_CYCLE_OPERATION	3	r	**Special Cycle Enable** This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
PCI_TYPE_MWI_ENABLE	4	r	**Memory Write and Invalidate** This bit was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge architecture specification. Its functionality does not apply to PCI Express, the controller hardwires this bit to 0b.
PCI_TYPE_VGA_PALETTE_SNOOP	5	r	**VGA Palette Snoop** This bit was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge architecture specification. Its functionality does not apply to PCI Express, the controller hardwires this bit to 0b.

(table continues...)

(continued)

Field	Bits	Type	Description
PCI_TYPE0_PARITY_ERR_EN	6	rw	**Parity Error Response** This bit controls the logging of poisoned TLPs in the Master Data Parity Error bit in the Status register.
PCI_TYPE_IDSEL_STEPPING	7	r	**IDSEL Stepping/Wait Cycle Control** This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
PCI_TYPE0_SERREN	8	rw	**SERR# Enable** When set, this bit enables reporting upstream of Non-fatal and Fatal errors detected by the Function. Note: The errors are reported if enabled either through this bit or through the PCI Express specific bits in the Device Control register.
RSVDP_9	9	r	**Reserved for future use**
PCI_TYPE0_INT_EN	10	rw	**Interrupt Disable** Controls the ability of a Function to generate INTx emulation interrupts. • When set, Functions are prevented from asserting INTx interrupts. • Any INTx emulation interrupts already asserted by the Function must be de-asserted when this bit is Set. INTx interrupts use virtual wires that must, if asserted, be de-asserted using the appropriate Deassert_INTx message(s) when this bit is set • Only the INTx virtual wire interrupt(s) associated with the Function(s) for which this bit is set are affected • For functions that generate INTx interrupts, this bit is required. For functions that do not generate INTx interrupts, this bit is optional
PCI_TYPE_RESERV	15:11	r	**Reserved**
RSVDP_17	18:17	r	**Reserved for future use**
INT_STATUS	19	rh	**Emulation interrupt pending** When set, indicates that an INTx emulation interrupt is pending internally in the Function. Setting the Interrupt Disable bit has no effect on the state of this bit. For Functions that do not generate INTx interrupts, the controller hardwires this bit to 0b.
CAP_LIST	20	r	**Capabilities List** Indicates the presence of an Extended Capability list item. Since all PCI Express device Functions are required to implement the PCI Express Capability structure, the controller hardwires this bit to 1b.
FAST_66MHZ_CAP	21	r	**66MHz Capable** This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
RSVDP_22	22	r	**Reserved for future use**
FAST_B2B_CAP	23	r	**Fast Back to Back Transaction Capable** This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.

(table continues...)

(continued)

Field	Bits	Type	Description
MASTER_DPE	24	rw1ch	**Master Data Parity Error** This bit is set by a Function if the Parity Error Response bit in the Command register is 1b and either of the following two conditions occurs: • Function receives a Poisoned Completion • Function transmits a Poisoned Request If the Parity Error Response bit is 0b, this bit is never set
DEV_SEL_TIMING	26:25	r	**DEVSEL Timing** This field was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this field to 00b.
SIGNALED_TARGET_ABORT	27	rw1ch	**Signaled Target Abort** Software write with 1 clears this bit-field.. 1_B **SET**: This bit is set when a Function completes a Posted or Non-Posted Request as a Completer Abort error The controller hardwires this bit to 0b for Functions that do not signal Completer Abort.
RCVD_TARGET_ABORT	28	rw1ch	**Received Target Abort** Software write with 1 clears this bit-field.. 1_B **SET**: This bit is set when a Requester receives a Completion with Completer Abort Completion Status For Functions that do not make Non-Posted Requests on their own behalf, the controller hardwires this bit to 0b.
RCVD_MASTER_ABORT	29	rw1ch	**Received Master Abort** Software write with 1 clears this bit-field.. 1_B **SET**: This bit is set when a Requester receives a Completion with Unsupported Request Completion Status For Functions that do not make Non-Posted Requests on their own behalf, the controller hardwires this bit to 0b.
SIGNALED_SYS_ERR	30	rw1ch	**Signaled System Error** Software write with 1 clears this bit-field.. 1_B **SET**: This bit is set when a Function sends an ERR_FATAL or ERR_NONFATAL message, and the SERR# Enable bit in the Command register is 1b For Functions that do not send ERR_FATAL or ERR_NONFATAL messages, the controller hardwires this bit to 0b.
DETECTED_PARITY_ERR	31	rw1ch	**Detected Parity Error** Software write with 1 clears this bit-field.. 1_B **SET**: This bit is set by a Function whenever it receives a Poisoned TLP, regardless of the state the Parity Error Response bit in the Command register
0	16	r	**Reserved** Read as 0; should be written with 0.

Table 865 Reset values of STATUS_COMMAND_REG

Reset	Reset value	Note
Kernel Reset	0000 0000 0001 X000 0000 0000 0000 0000$_B$	

19.4.1.100 Class Code and Revision ID Register

This register specifies the class code and revision ID of a function.

CLASS_CODE_REVISION_ID Offset address: 0004008$_H$

Class Code and Revision ID Register Kernel Reset value: 0000 0001$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BASE_CLASS_CODE								SUBCLASS_CODE							
rw								rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PROGRAM_INTERFACE								REVISION_ID							
rw								rw							

Field	Bits	Type	Description
REVISION_ID	7:0	rw	**Revision ID** The value in this register specifies a Function specific revision identifier. The value is chosen by the vendor. Zero is an acceptable value. The Revision ID should be viewed as a vendor defined extension to the Device ID. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
PROGRAM_INTERFACE	15:8	rw	**Programming Interface** This field identifies a specific register-level programming interface (if any) so that device independent software can interact with the Function. Encodings for interface are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are Reserved. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
SUBCLASS_CODE	23:16	rw	**Sub-Class Code** Specifies a base class sub-class, which identifies more specifically the operation of the Function. Encodings for sub-class are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are Reserved. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
BASE_CLASS_CODE	31:24	rw	**Base Class Code** A code that broadly classifies the type of operation the Function performs. Encodings for base class, are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are Reserved. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.1.101 BIST, Header Type, Latency Timer, and Cache Line Size Register

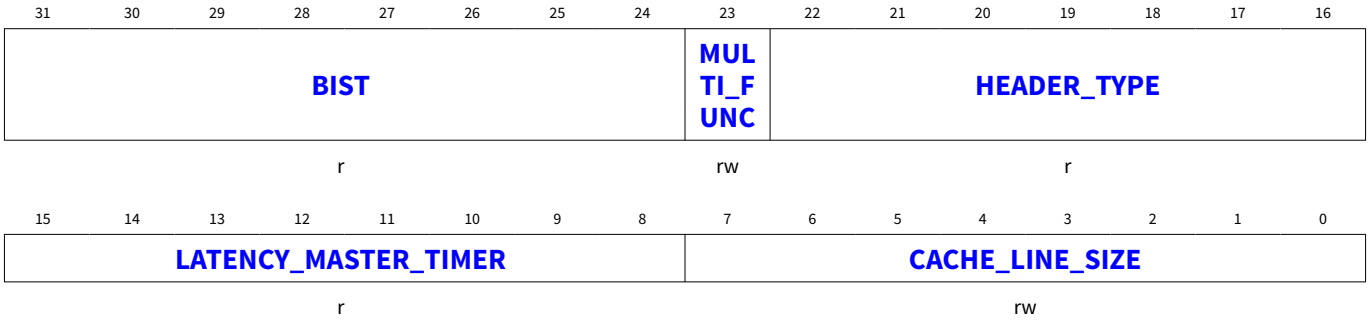
This register provides the status and controls BIST. It also holds information regarding the header layout, latency timer, and cache line size.

BIST_HEADER_TYPE_LATENCY_CACHE_LINE_SIZE_REG

Offset address: $000400C_H$

BIST, Header Type, Latency Timer, and Cache Line Size Register

Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CACHE_LINE_SIZE	7:0	rw	**Cache Line Size** The Cache Line Size register is programmed by the system firmware or the operating system to system cache line size. However, legacy conventional PCI software may not always be able to program this register correctly especially in the case of Hot-Plug devices. This read-write register is implemented for legacy compatibility purposes but has no effect on any PCI Express device behavior.
LATENCY_MASTER_TIMER	15:8	r	**Latency Timer** The Latency Timer was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this register to 00h.
HEADER_TYPE	22:16	r	**Header Layout** This field identifies the layout of the second part of the predefined header. The controller uses 000 0000b encoding.
MULTI_FUNC	23	rw	**Multi-Function Device** Except where stated otherwise, it is recommended that this bit be set if there are multiple Functions, and clear if there is only one Function. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_B **CLEAR**: Software must not probe for Functions other than Function 0 1_B **SET**: Indicates that the Device may contain multiple Functions, but not necessarily Software is permitted to probe for Functions other than Function 0

(table continues...)

(continued)

Field	Bits	Type	Description
BIST	31:24	r	**BIST** This register is used for control and status of BIST. For Functions that do not support BIST the controller hardwires the register to 00h. A Function whose BIST is invoked must not prevent normal operation of the PCI Express Link. Bit descriptions: • [31]: BIST Capable. When Set, this bit indicates that the Function supports BIST. When Clear, the Function does not support BIST • [30]: Start BIST. If BIST Capable is Set, Set this bit to invoke BIST. The Function resets the bit when BIST is complete. Software is permitted to fail the device if this bit is not Clear (BIST is not complete) 2 seconds after it had been Set. Writing this bit to 0b has no effect. This bit must be hardwired to 0b if BIST Capable is Clear • [29:28]: Reserved • [27:24]: Completion Code. This field encodes the status of the most recent test. A value of 0000b means that the Function has passed its test. Non-zero values mean the Function failed. Function-specific failure codes can be encoded in the non-zero values. This field's value is only meaningful when BIST Capable is Set and Start BIST is Clear. This field must be hardwired to 0000b if BIST Capable is clear

19.4.1.102 BAR0 Register i

System software must build a consistent address map before booting the machine to an operating system. This means it has to determine how much memory is in the system, and how much address space the Functions in the system require. After determining this information, system software can map the Functions into reasonable locations and proceed with system boot. In order to do this mapping in a device-independent manner, the base registers for this mapping are placed in the predefined header portion of Configuration Space. It is strongly recommended that power-up firmware/software also support the optional Enhanced Configuration Access Mechanism (ECAM).

BARi_REG (i=0-5) Offset address: 0004010_H+i*4

BAR0 Register i Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BAR0_START

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BAR0_START												BAR0_PREFETCH	BAR0_TYPE		BAR0_MEM_IO
rwh												rwh	rwh		rwh

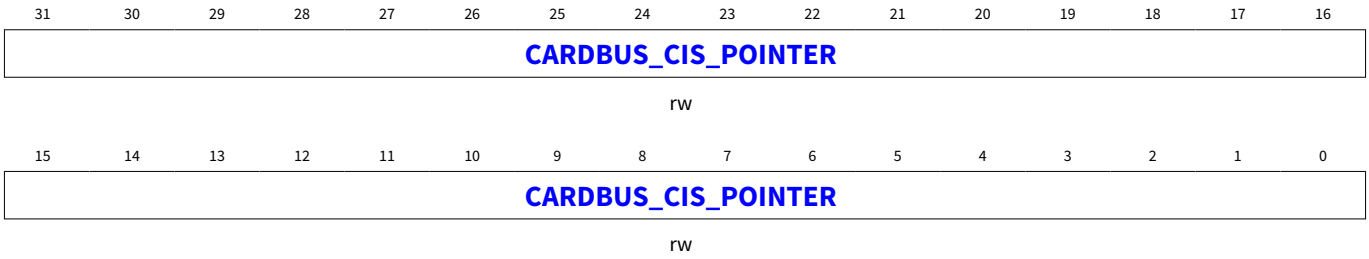
Field	Bits	Type	Description
BAR0_MEM_IO	0	rwh	**BAR0 Memory Space Indicator** This bit is used to determine whether the register maps into Memory or I/O Space. Base Address registers that map to Memory Space must return a 0b. Base Address registers that map to I/O Space must return a 1b. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (BAR_ENABLED == 1) then (if [DBI_RO_WR_EN == 1] then R(Sticky)/W(Sticky) else R(Sticky)) else RO(Sticky) Note: This register field is sticky.
BAR0_TYPE	2:1	rwh	**BAR0 Type** - Memory Space: Base Address registers that map into Memory Space can be 32 bits or 64 bits wide (to support mapping into a 64-bit address space). The encodings defined in Values: apply. - IO Space: Bit 1 is reserved and must return 0b on reads. Bits[31:2] are used to map the function into IO space. The encodings defined in Values: do not apply. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (BAR_ENABLED == 1) then (if [DBI_RO_WR_EN == 1] then R(Sticky)/W(Sticky) else R(Sticky)) else RO(Sticky) Note: This register field is sticky. 00_B **BAR_32**: Base register is 32 bits wide and can be mapped anywhere in the 32 address bit Memory Space 01_B **RSVD_1**: Reserved 10_B **BAR_64**: Base register is 64 bits wide and can be mapped anywhere in the 64 address bit Memory Space 11_B **RSVD_2**: Reserved
BAR0_PREFETCH	3	rwh	**BAR0 Prefetchable** - Memory Space: Set to one if data is prefetchable. A Function is permitted to mark a range as prefetchable. If there are no side effects on reads, the function returns all bytes on reads regardless of the byte enables, and host bridges can merge processor writes into this range without causing errors. Bit must me clear otherwise. - IO Space: Not applicable Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (BAR_ENABLED == 1) then (if [DBI_RO_WR_EN == 1] then R(Sticky)/W(Sticky) else R(Sticky)) else RO(Sticky) Note: This register field is sticky.
BAR0_START	31:4	rwh	**BAR0 Base Address** - Memory Space: Base Address. - IO Space: bits[31:2] are used to map the function into IO space/Base. Address. Note: The access attributes of this field are as follows: - Wire: R(Sticky)/W(Sticky) if (BAR_ENABLED == 1) then (if [DBI_RO_WR_EN == 1] enabled else R(Sticky) - Dbi: R(Sticky)/W(Sticky) if enabled else R(Sticky) Note: This register field is sticky.

19.4.1.103 CardBus CIS Pointer Register

This register holds the CardBus CIS pointer.

CARDBUS_CIS_PTR_REG Offset address: 0004028_H

CardBus CIS Pointer Register Kernel Reset value: $0000\ 0000_H$



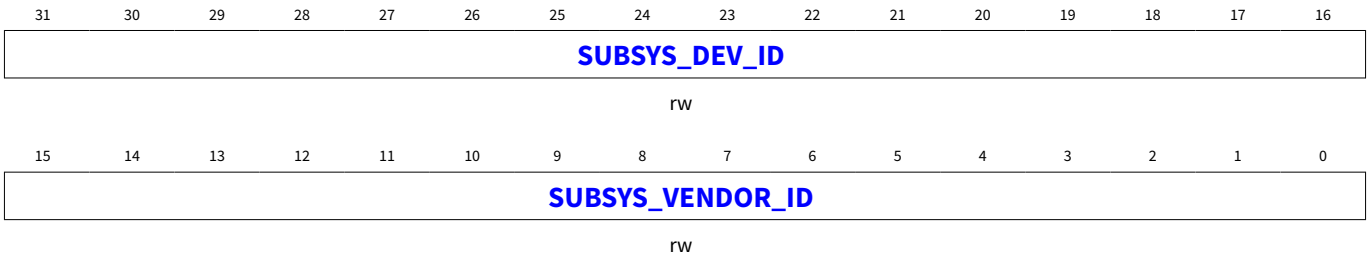
Field	Bits	Type	Description
CARDBUS_CIS_POINTER	31:0	rw	**CardBus CIS Pointer** Its functionality does not apply to PCI Express. It must be hardwired to 0000 0000h. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.1.104 Subsystem ID and Subsystem Vendor ID Register

These registers are used to uniquely identify the add-in card or subsystem where the PCI Express component resides. They provide a mechanism for vendors to distinguish their products from one another even though the assemblies may have the same PCI Express component on them (and, therefore, the same Vendor ID and Device ID).

SUBSYSTEM_ID_SUBSYSTEM_VENDOR_ID_REG Offset address: $000402C_H$

Subsystem ID and Subsystem Vendor ID Register Kernel Reset value: $0000\ 0000_H$



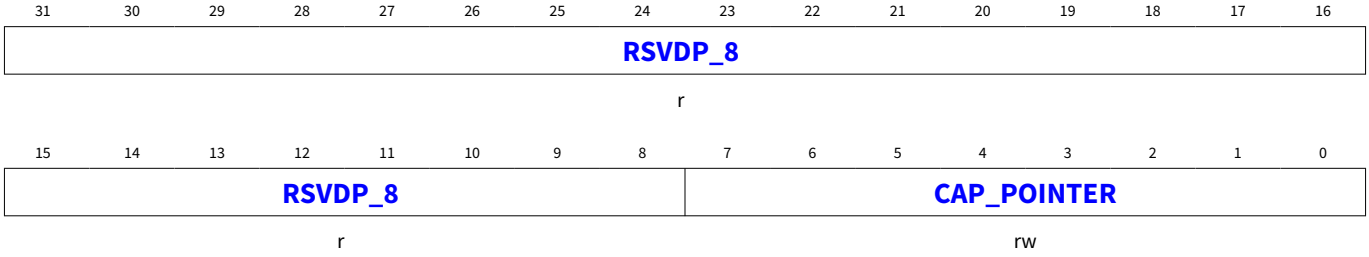
Field	Bits	Type	Description
SUBSYS_VENDOR_ID	15:0	rw	**Subsystem Vendor ID** Subsystem Vendor IDs can be obtained from the PCI SIG and are used to identify the vendor of the add-in card or subsystem. Values for the Subsystem ID are vendor-specific. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
SUBSYS_DEV_ID	31:16	rw	**Subsystem ID** Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.1.105 Capabilities Pointer Register

This register is used to point to a linked list of capabilities implemented by a Function.

PCI_CAP_PTR_REG Offset address: 0004034_H

Capabilities Pointer Register Kernel Reset value: $0000\ 0040_H$



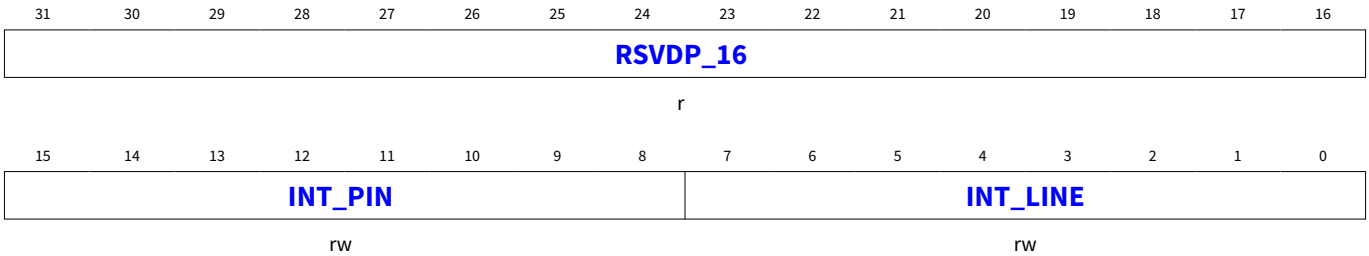
Field	Bits	Type	Description
CAP_POINTER	7:0	rw	**Capabilities Pointer** This register points to a valid capability structure. Either this structure is the PCI Express Capability structure, or a subsequent list item points to the PCI Express Capability structure. The bottom two bits are reserved, the controller sets it to 00b. Software must mask these bits off before using this register as a pointer in Configuration Space to the first entry of a linked list of new capabilities. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
RSVDP_8	31:8	r	**Reserved for future use**

19.4.1.106 Max_Lat, Min_Gnt, Interrupt Pin, and Interrupt Line Register

The Interrupt Line register communicates interrupt line routing information. The Interrupt Pin register identifies the legacy interrupt Message(s) the Function uses.

MAX_LATENCY_MIN_GRANT_INTERRUPT_PIN_INTERRUPT_LINE_REG Offset address: $000403C_H$

Max_Lat, Min_Gnt, Interrupt Pin, and Interrupt Line Register Kernel Reset value: $0000\ 01FF_H$



Field	Bits	Type	Description
INT_LINE	7:0	rw	**Interrupt Line** The Interrupt Line register communicates interrupt line routing information. The register must be implemented by any Function that uses an interrupt pin. Values in this register are programmed by system software and are system architecture specific. The Function itself does not use this value; rather the value in this register is used by device drivers and operating systems.
INT_PIN	15:8	rw	**Interrupt Pin** The Interrupt Pin register identifies the legacy interrupt Message(s) the Function uses. All encodings other than the defined encodings are reserved. PCI Express defines one legacy interrupt Message for a single Function device and up to four legacy interrupt Messages for a multi-Function device. For a single Function device, only INTA may be used. Any Function on a multi-Function device can use any of the INTx Messages. If a device implements a single legacy interrupt Message, it must be INTA; if it implements two legacy interrupt Messages, they must be INTA and INTB; and so forth. For a multi-Function device, all Functions may use the same INTx Message or each may have its own (up to a maximum of four Functions) or any combination thereof. A single Function can never generate an interrupt request on more than one INTx Message. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 00_H **NO_INT**: Indicates that the Function uses no legacy interrupt Message(s) 01_H **INTA**: Map to legacy interrupt Messages for INTA 02_H **INTB**: Map to legacy interrupt Messages for INTB 03_H **INTC**: Map to legacy interrupt Messages for INTC 04_H **INTD**: Map to legacy interrupt Messages for INTD **others,** Reserved
RSVDP_16	31:16	r	**Reserved for future use**

19.4.1.107 Power Management Capabilities Register

This register provides information refarding the Power Management Capabilities.

CAP_ID_NXT_PTR_REG Offset address: 0004040_H

Power Management Capabilities Register Reset values see: Table 866

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PME_SUPPORT					D2_SUPPORT	D1_SUPPORT	AUX_CURR			DSI	0	PME_CLK	PM_SPEC_VER		
rwh					rw	rw	rw			rw	r	r	rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PM_NEXT_POINTER								PM_CAP_ID							
rw								r							

Field	Bits	Type	Description
PM_CAP_ID	7:0	r	**Capability ID** This field returns 01h to indicate that this is the PCI Power Management Capability. Each function may have only one item in its capability list with Capability ID set to 01h.
PM_NEXT_POINTER	15:8	rw	**Next Capability Pointer** This field provides an offset into the function's configuration space pointing to the location of next item in the capabilities list. If there are no additional items in the capabilities list, this field is set to 00h. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
PM_SPEC_VER	18:16	rw	**Version** This field provides the Power Management specification version. The controller hardwires this field to 011b for functions compliant to PCI Express Base Specification, Revision 4.0, Version 1.0>. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
PME_CLK	19	r	**PME Clock** Does not apply to PCI Express, the controller hardwires it to 0b. Note: This register field is sticky.
DSI	21	rw	**Device Specific Initialization** The DSI bit indicates whether special initialization of this function is required. When set, indicates that the function requires a device specific initialization sequence following a transition to the D0uninitialized state. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. DSI capability is not supported in this implementation

(table continues...)

(continued)

Field	Bits	Type	Description
AUX_CURR	24:22	rw	**Aux_Current** This 3 bit field reports the Vaux auxiliary current requirements for the function. If this function implements the Data Register, the controller hardwires this field to 000b. If PME_Support is 0 xxxxb (PME assertion from D3cold is not supported), the controller hardwires this field to 0000b. For functions where PME_Support is 1 xxxxb (PME assertion from D3cold is supported), and which do not implement the Data field, the encodings defined in Values: apply: Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 000_B **SELF_**: 0 self powered 001_B **_055mA_**: 55mA Vaux Max Current Required 010_B **_100mA_**: 100mA Vaux Max Current Required 011_B **_160mA_**: 160mA Vaux Max Current Required 100_B **_220mA_**: 220mA Vaux Max Current Required 101_B **_270mA_**: 270mA Vaux Max Current Required 110_B **_320mA_**: 320mA Vaux Max Current Required 111_B **_370mA_**: 375mA Vaux Max Current Required
D1_SUPPORT	25	rw	**D1_Support** If this bit is set, this function supports the D1 Power Management state. Functions that do not support D1 must always return a value of 0b for this bit. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. D1-support capability is not supported in this implementation
D2_SUPPORT	26	rw	**D2_Support** If this bit is set, this function supports the D2 Power Management state. Functions that do not support D2 must always return a value of 0b for this bit. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. D2-support capability is not supported in this implementation

(table continues...)

(continued)

Field	Bits	Type	Description
PME_SUPPORT	31:27	rwh	**PME_Support** This 5-bit field indicates the power states in which the function may generate a PME and/or forward PME messages. A value of 0b for any bit indicates that the function is not capable of asserting PME while in that power state. • bit(27) X XXX1b - PME can be generated from D0 • bit(28) X XX1Xb - PME can be generated from D1 • bit(29) X X1XXb - PME can be generated from D2 • bit(30) X 1XXXb - PME can be generated from D3hot • bit(31) 1 XXXXb - PME can be generated from D3cold Bit 31 (PME can be asserted from D3cold) represents a special case. Functions that set this bit require some sort of auxiliary power source. Implementation specific mechanisms are recommended to validate that the power source is available before setting this bit. Each bit that corresponds to a supported D-state must be set for PCI-PCI Bridge structures representing Ports on Root Complexes/Switches to indicate that the Bridge will forward PME Messages. Bit 31 must only be set if the Port is still able to forward PME Messages when main power is not available. The read value from this field is the write value && (sys_aux_pwr_det, 1'b1, D2_SUPPORT, D1_SUPPORT, 1'b1), where D1_SUPPORT and D2_SUPPORT are fields in this register. The reset value PME_SUPPORT_n && (sys_aux_pwr_det, 1'b1, D2_SUPPORT, D1_SUPPORT, 1'b1), where PME_SUPPORT_n is a configuration parameter. Note: The access attributes of this field are as follows: - Wire: R - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
0	20	r	**Reserved** Read as 0; should be written with 0.

Table 866 Reset values of CAP_ID_NXT_PTR_REG

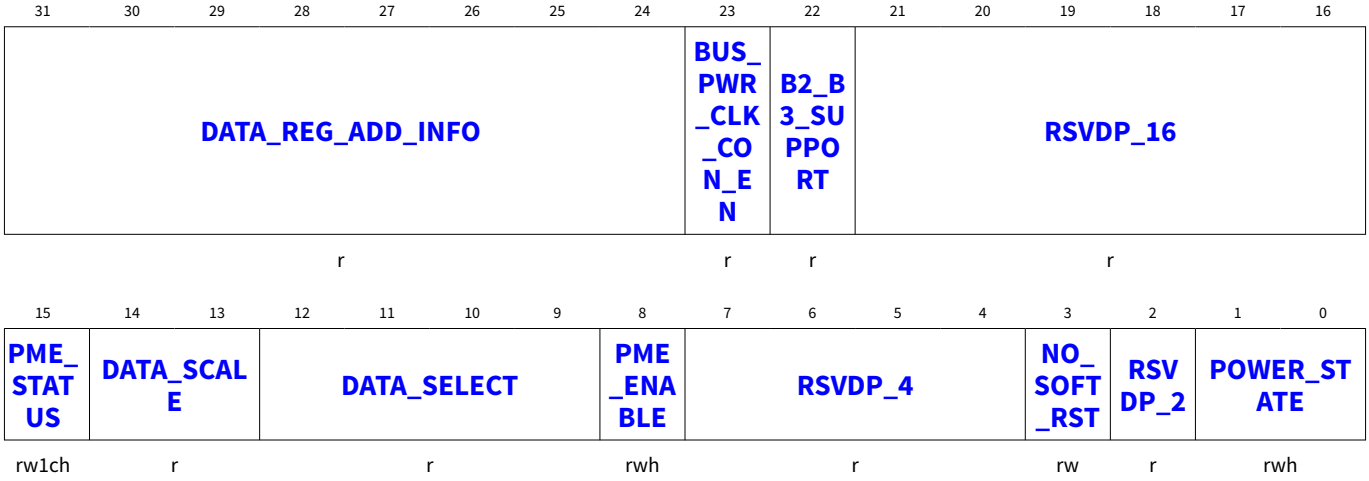
19.4.1.108 Power Management Control and Status Register

This register is used to manage the PCI function's power management state as well as to enable/monitor PMEs.

CON_STATUS_REG Offset address: 0004044_H

Power Management Control and Status Register Reset values see: Table 867

19 Peripheral Component Interconnect Express (PCIe)



Field	Bits	Type	Description
POWER_STATE	1:0	rwh	**PowerState** This 2-bit field is used both to determine the current power state of a function and to set the function into a new power state. You can write to this register; however, the read-back value is the actual power state, not the write value. If you attempt to write an unsupported, optional state to this field, the write operation completes normally; however, the data is discarded and no state change occurs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 00_B **D0**: D0 power state 01_B **D1**: D1 power state 10_B **D2**: D2 power state 11_B **D3hot**: D3hot D3hot power state
RSVDP_2	2	r	**Reserved for future use**
NO_SOFT_RST	3	rw	**No_Soft_Reset** This bit indicates the state of the function after writing the PowerState field to transition the function from D3hot to D0. • When set, this transition preserves internal function state. The function is in D0Active and no additional software intervention is required • When clear, this transition results in undefined internal function state Regardless of this bit, functions that transition from D3hot to D0 by Fundamental Reset will return to D0Uninitialized with only PME context preserved if PME is supported and enabled. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
RSVDP_4	7:4	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
PME_ENABLE	8	rwh	**PME_En** • When set, the function is permitted to generate a PME • When clear, the function is not permitted to generate a PME. If PME_Support is 1 xxxxb (PME generation from D3cold) or the function consumes Aux power and Aux power is available this bit is RWS and the bit is not modified by Conventional Reset If PME_Support is 0 xxxxb, this field is not sticky (RW). If PME_Support is 0 0000b, the controller hardwires this bit to 0b. Note: This register field is sticky.
DATA_SELECT	12:9	r	**Data_Select** This 4-bit field is used to select which data is to be reported through the Data and Data_Scale field. If the Data field is not implemented, this field must be hardwired to 0000b.
DATA_SCALE	14:13	r	**Data_Scale** This field indicates the scaling factor to be used when interpreting the value of the Data field. The value and meaning of this field varies depending on which data value has been selected by the Data_Select field. For more details, see 7.5.2.3 section of PCI Express Base Specification.
PME_STATUS	15	rw1ch	**PME_Status** This bit is set when the function normally generates a PME signal. The value of this bit is not affected by the value of the PME_En bit. If PME_Support bit 31 of the Power Management Capabilities register is clear, this bit is permitted to be hardwired to 0b. Functions that consume Aux power must preserve the value of this sticky register when Aux power is available. In such functions, this register value is not modified by Conventional Reset Note: This register field is sticky. Software write with 1 clears this bit-field.
RSVDP_16	21:16	r	**Reserved for future use**
B2_B3_SUPPORT	22	r	**B2B3 Support for D3hot** If this field is set, B2B3 support for D3hot is available.
BUS_PWR_CLK_CON_EN	23	r	**Bus Power/Clock Control Enable** If this field is set, Bus Power/Clock Control is Enable.
DATA_REG_ADD_INFO	31:24	r	**Data** This field is used to report the state dependent data requested by the Data_Select field. The value of this field is scaled by the value reported by the Data_Scale field.

PCI_MSI_CAP_NEXT_OFFSET								PCI_MSI_CAP_ID							
rw								r							

Field	Bits	Type	Description
PCI_MSI_CAP_ID	7:0	r	**Capability ID** Indicates the MSI Capability structure. This field returns a Capability ID of 05h indicating that this is an MSI Capability structure.
PCI_MSI_CAP_NEXT_OFFSET	15:8	rw	**Next Capability Pointer** This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of Capabilities. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
PCI_MSI_ENABLE	16	rw	**MSI Enable** • If set and the MSI-X Enable bit in the MSI-X Message Control register is clear, the function is permitted to use MSI to request service and is prohibited from using INTx interrupts. System configuration software sets this bit to enable MSI. A device driver is prohibited from writing this bit to mask a function's service request. For more details on control of INTx interrupts, see section 7.5.1.1 of PCI Express Base Specification. • If clear, the function is prohibited from using MSI to request service Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
PCI_MSI_MULTIPLE_MSG_CAP	19:17	rw	**Multiple Message Capable** System software reads this field to determine the number of requested vectors. The number of requested vectors must be aligned to a power of two (if a function requires three vectors, it requests four by initializing this field to 010b). All encodings other than the defined encodings are reserved. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 000_B **_1_VECTOR**: 1 vector requested 001_B **_2_VECTOR**: 2 vectors requested 010_B **_4_VECTOR**: 4 vectors requested 011_B **_8_VECTOR**: 8 vectors requested 100_B **_16_VECTOR**: 16 vectors requested 101_B **_32_VECTOR**: 32 vectors requested **others,** Reserved
PCI_MSI_MULTIPLE_MSG_EN	22:20	rw	**Multiple Message Enable** Software writes to this field to indicate the number of allocated vectors (equal to or less than the number of requested vectors). The number of allocated vectors is aligned to a power of two. If a function requests four vectors (indicated by a Multiple Message Capable encoding of 010b), system software can allocate either four, two, or one vector by writing a 010b, 001b, or 000b to this field, respectively. When MSI is enabled, a function will be allocated at least 1 vector. All encodings other than the defined encodings are reserved. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 000_B **_1_VECTOR**: 1 vector allocated 001_B **_2_VECTOR**: 2 vectors allocated 010_B **_4_VECTOR**: 4 vectors allocated 011_B **_8_VECTOR**: 8 vectors allocated 100_B **_16_VECTOR**: 16 vectors allocated 101_B **_32_VECTOR**: 32 vectors allocated **others,** Reserved
PCI_MSI_64_BIT_ADDR_CAP	23	rw	**64 bit address capable** • If set, the function is capable of sending a 64-bit message address • If clear, the function is not capable of sending a 64-bit message address. This bit must be set if the function is a PCI Express Endpoint Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
PCI_PVM_SUPPORT	24	r	**Per-Vector Masking Capable** • If set, the function supports MSI Per-Vector Masking • If clear, the function does not support MSI Per-Vector Masking

(table continues...)

(continued)

Field	Bits	Type	Description
PCI_MSI_EXT_DATA_CAP	25	rw	**Extended Message Data Capable** • If set, the function is capable of providing Extended Message Data • If clear, the function does not support providing Extended Message Data Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. Extended Message Data Capability is not supported in the current implementation
PCI_MSI_EXT_DATA_EN	26	rw	**Extended Message Data Enable** • If set, the function is enabled to provide Extended Message Data • If clear, the function is not enabled to provide Extended Message Data Note: The access attributes of this field are as follows: • Wire: PCI_MSI_CAP_ID_NEXT_CTRL_REG.PCI_MSI_EXT_DATA_CAP ? RW : RO • Dbi: PCI_MSI_CAP_ID_NEXT_CTRL_REG.PCI_MSI_EXT_DATA_CAP ? RW : RO
RSVDP_27	31:27	r	**Reserved for future use**

19.4.1.110 Message Address Register for MSI (Offset 04h)

This register holds the system specified message address for an MSI transaction.

MSI_CAP_OFF_04H_REG Offset address: 0004054_H

Message Address Register for MSI [Offset 04h) Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RSVDP_0	1:0	r	**Reserved for future use**
PCI_MSI_CAP_OFF_04H	31:2	rw	**Message Address - System-specified message address** If the Message Enable bit (bit 16 of the PCI_MSI_CAP_ID_NEXT_CTRL_REG register) is set, the contents of this field specify the DWORD-aligned address (Address[31:02]) for the MSI transaction. Address[1:0] are set to 00b. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.1.111 Message Address Register for MSI (Offset 08h)

This register represents the Message Upper Address Register for MSI (Offset 08h). It specifies the Message Upper Address (System-specified message upper address). This register is required for PCI Express Endpoints and is optional for other function types. If the Message Enable bit (bit 0 of the Message Control register) is set, the contents of this register (if non-zero) specify the upper 32-bits of a 64-bit message address (Address[63:32]). If the contents of this register are zero, the Function uses the 32 bit address specified by the Message Address register.

MSI_CAP_OFF_08H_REG Offset address: 0004058_H

Message Address Register for MSI [Offset 08h) Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PCI_MSI_CAP_OFF_08H															
rw															

Field	Bits	Type	Description
PCI_MSI_CAP_OFF_08H	15:0	rw	**For a function that supports a 32-bit message address, this field contains Message Data (System-specified message data)** If the Message Enable bit (bit 16 of the PCI_MSI_CAP_ID_NEXT_CTRL_REG) is set, the function sends a DWORD Memory Write transaction using Message Data for the lower 16 bits. All 4 Byte Enables are set. The Multiple Message Enable field (bits 22:20 of the PCI_MSI_CAP_ID_NEXT_CTRL_REG) defines the number of low order message data bits the function is permitted to modify to generate its system software allocated vectors. For example, a Multiple Message Enable encoding of 010b indicates the function has been allocated four vectors and is permitted to modify message data bits 1 and 0 (a function modifies the lower message data bits to generate the allocated number of vectors). If the Multiple Message Enable field is 000b, the Function is not permitted to modify the message data. For a function that supports a 64-bit message address, it contains lower 16 bits of the Message Upper Address. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(continued)

Field	Bits	Type	Description
PCI_MSI_CAP_OFF_0AH	31:16	rw	**For a function that supports a 32-bit message address, this field contains Extended Message Data (System-specified message data)** Extended Message Data Capability is not supported in the current implementation For the MSI Capability structures without per-vector masking, it must be implemented if the Extended Message Data Capable bit is set; otherwise, it is outside the MSI Capability structure and undefined. For the MSI Capability structures with Per-vector Masking, it must be implemented if the Extended Message Data Capable bit is set; otherwise, it is RsvdP. If the Extended Message Data Enable bit (bit 26 of the PCI_MSI_CAP_ID_NEXT_CTRL_REG) is set, the DWORD Memory Write transaction uses Extended Message Data for the upper 16 bits; otherwise, it uses 0000h for the upper 16 bits. For a function that supports a 64-bit message address, it contains upper 16 bits of the Message Upper Address. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.1.112 Message Address Register for MSI (Offset 0Ch)

This register contains Message Data.

MSI_CAP_OFF_0CH_REG Offset address: $000405C_H$

Message Address Register for MSI [Offset 0Ch) Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PCI_MSI_CAP_OFF_0CH															
rw															

Field	Bits	Type	Description
PCI_MSI_CAP_OFF_0CH	15:0	rw	**For a function that supports a 32-bit message address, this field contains the lower Mask Bits when the Per Vector Masking Capable bit (PCI_MSI_CAP_ID_NEXT_CTRL_REG.PCI_PVM_SUPPORT) is set** This field contains Message Data (System-specified message data). If the Message Enable bit (bit 16 of the PCI_MSI_CAP_ID_NEXT_CTRL_REG) is set, the function sends a DWORD Memory Write transaction using Message Data for the lower 16 bits. All 4 Byte Enables are set. The Multiple Message Enable field (bits 22:20 of the PCI_MSI_CAP_ID_NEXT_CTRL_REG) defines the number of low order message data bits the function is permitted to modify to generate its system software allocated vectors. For example, a Multiple Message Enable encoding of 010b indicates the function has been allocated four vectors and is permitted to modify message data bits 1 and 0 (a function modifies the lower message data bits to generate the allocated number of vectors). If the Multiple Message Enable field is 000b, the Function is not permitted to modify the message data. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

Field	Bits	Type	Description
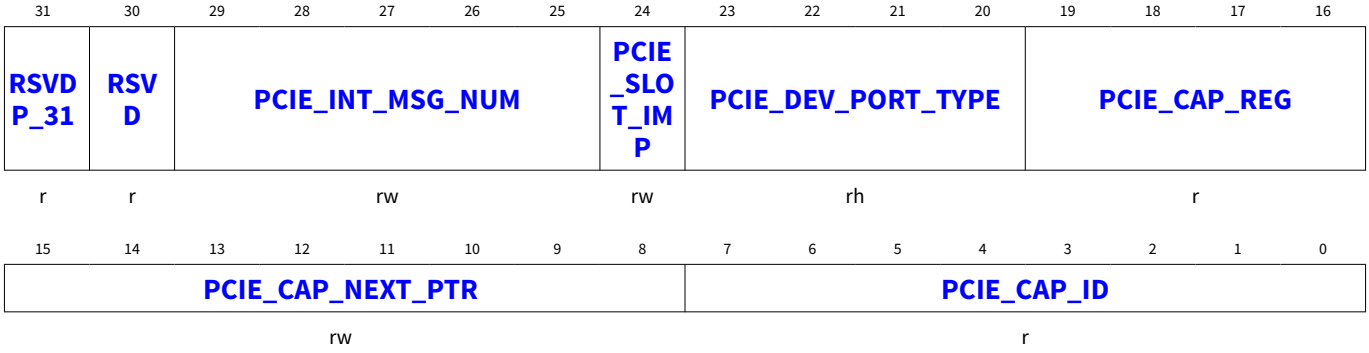
PCI_MSI_CAP_OFF_14H	31:0	r	**Pending Bits** For each pending bit that is set, the function has a pending associated message.

19.4.1.115 PCI Express Capabilities, ID, Next Pointer Register

This is the PCI Express Capabilities, ID, and Next Pointer Register.

PCIE_CAP_ID_PCIE_NEXT_CAP_PTR_PCIE_CAP_REG Offset address: 0004070_H

PCI Express Capabilities, ID, Next Pointer Register Kernel Reset value: $0002\ B010_H$



Field	Bits	Type	Description
PCIE_CAP_ID	7:0	r	**Capability ID** Indicates the PCI Express Capability structure. This field must return a Capability ID of 10h indicating that this is a PCI Express Capability structure.
PCIE_CAP_NEXT_PTR	15:8	rw	**Next Capability Pointer** This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of Capabilities. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
PCIE_CAP_REG	19:16	r	**Capability Version** Indicates PCI-SIG defined PCI Express Capability structure version number. A version of the specification that changes the PCI Express Capability structure in a way that is not otherwise identifiable (for example, through a new Capability field) is permitted to increment this field. All such changes to the PCI Express Capability structure must be software-compatible. Software must check for Capability Version numbers that are greater than or equal to the highest number defined when the software is written, as functions reporting any such Capability Version numbers will contain a PCI Express Capability structure that is compatible with that piece of software. The controller hardwires this field to 2h for functions compliant to PCI Express Base Specification, Revision 4.0, Version 1.0. Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_DEV_PORT_TYPE	23:20	rh	**Device/Port Type** Indicates the specific type of this PCI Express function. Note: Different functions in a Multi-Function Device can generally be of different types. Defined encodings for functions that implement a Type 00h PCI Configuration Space header are: Defined encodings for functions that implement a Type 01h PCI Configuration Space header are: All other encodings are Reserved. Note: Different Endpoint types have notably different requirements in Section 1.3.2 of PCI Express Base Specification regarding I/O resources, Extended Configuration Space, and other capabilities. 0_H **PCIE_EP**: PCI Express Endpoint 1_H **PCIE_LEGACY_EP**: Legacy PCI Express Endpoint 4_H **ROOT_PORT_PCIE_RC**: Root Port of PCI Express Root Complex 5_H **USP_PCIE_SWITCH**: Upstream Port of PCI Express Switch 6_H **DSP_PCIE_SWITCH**: Downstream Port of PCI Express Switch **others,** Reserved
PCIE_SLOT_IMP	24	rw	**Slot Implemented** When set, this bit indicates that the Link associated with this Port is connected to a slot (as compared to being connected to a system-integrated device or being disabled). This bit is valid for Downstream Ports. This bit is undefined for Upstream Ports. Note: The access attributes of this field are as follows: - Wire: HWINIT - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
PCIE_INT_MSG_NUM	29:25	rw	**PCIE Interrupt Message Number** Interrupt Message Number. This field indicates which MSI/MSI-X vector is used for the interrupt message generated in association with any of the status bits of this Capability structure. For MSI, the value in this field indicates the offset between the base Message Data and the interrupt message that is generated. Hardware is required to update this field so that it is correct if the number of MSI Messages assigned to the Function changes when software writes to the Multiple Message Enable field in the MSI Message Control register. For MSI-X, the value in this field indicates which MSI-X Table entry is used to generate the interrupt message. The entry must be one of the first 32 entries even if the Function implements more than 32 entries. For a given MSI-X implementation, the entry must remain constant. If both MSI and MSI-X are implemented, they are permitted to use different vectors, though software is permitted to enable only one mechanism at a time. If MSI-X is enabled, the value in this field must indicate the vector for MSI-X. If MSI is enabled or neither is enabled, the value in this field must indicate the vector for MSI. If software enables both MSI and MSI-X at the same time, the value in this field is undefined. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
RSVD	30	r	**Reserved**
RSVDP_31	31	r	**Reserved for future use**

19.4.1.116 Device Capabilities Register

The Device Capabilities register identifies PCI Express device function specific capabilities.

DEVICE_CAPABILITIES_REG Offset address: 0004074_H

Device Capabilities Register Reset values see: Table 868

Field	Bits	Type	Description
PCIE_CAP_PHANTOM_FUNC_SUPPORT	4:3	rw	**Phantom Functions Supported** For functions that do not implement this capability (Phantom function capability is not available in this implementation), this bit will be hardwired to 0b. This field indicates the support for use of unclaimed function numbers to extend the number of outstanding transactions allowed by logically combining unclaimed function numbers (called Phantom Functions) with the Tag identifier (see Section 2.2.6.2 of PCI Express Base Specification for a description of Tag Extensions). With every Function in an ARI Device, the Phantom Functions Supported field must be set to 00b. The remainder of this field description applies only to non-ARI Multi-Function Devices. This field indicates the number of most significant bits of the Function Number portion of Requester ID that are logically combined with the Tag identifier. Note: Phantom Function support for the function must be enabled by the Phantom Functions Enable field in the Device Control register before the Function is permitted to use the Function Number field in the Requester ID for Phantom Functions. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 00_B **NO_PHNATOM_FUNC**: No Function Number bits are used for Phantom Functions Multi-Function Devices are permitted to implement up to 8 independent functions. 01_B **MAX_1_PHANTOM_PER_FUNC**: The most significant bit of the Function number in Requester ID is used for Phantom Functions; a Multi-Function Device is permitted to implement Functions 0-3 Functions 0, 1, 2, and 3 are permitted to use Function Numbers 4, 5, 6, and 7 respectively as Phantom Functions. 10_B **MAX_3_PHANTOM_PER_FUNC**: The two most significant bits of Function Number in Requester ID are used for Phantom Functions; a Multi-Function Device is permitted to implement Functions 0-1 Function 0 is permitted to use Function Numbers 2, 4, and 6 for Phantom Functions. Function 1 is permitted to use Function Numbers 3, 5, and 7 as Phantom Functions. 11_B **SINGLE_FUNC_MAX_7_PHANTOM_FUNC**: All 3 bits of Function Number in Requester ID used for Phantom Functions The device must have a single Function 0 that is permitted to use all other Function Numbers as Phantom Functions.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_EXT_TAG_SUPP	5	rw	**Extended Tag Field Supported** This bit, in combination with the 10-Bit Tag Requester Supported bit in the Device Capabilities 2 register, indicates the maximum supported size of the Tag field as a Requester. This bit must be set if the 10-Bit Tag Requester Supported bit is set. Note: 8-bit Tag field generation must be enabled by the Extended Tag Field Enable bit in the Device Control register of the Requester Function before 8-bit Tags can be generated by the Requester. See Section 2.2.6.2 of PCI Express Base Specification for interactions with enabling the use of 10-Bit Tags. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 0_B **_5b_TAG**: 5-bit Tag field supported 1_B **_8b_TAG**: 8-bit Tag field supported
PCIE_CAP_EP_L0S_ACCPT_LATENCY	8:6	rw	**Endpoint L0s Acceptable Latency** This field indicates the acceptable total latency that an Endpoint can withstand due to the transition from L0s state to the L0 state. It is essentially an indirect measure of the Endpoint's internal buffering. Power management software uses the reported L0s Acceptable Latency number to compare against the L0s exit latencies reported by all components comprising the data path from this Endpoint to the Root Complex Root Port to determine whether ASPM L0s entry can be used with no loss of performance. For functions other than Endpoints, this field is Reserved and the controller hardwires it to 000b. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 000_B **MAX_64NS**: Maximum of 64 ns 001_B **MAX_128NS**: Maximum of 128 ns 010_B **MAX_256NS**: Maximum of 256 ns 011_B **MAX_512NS**: Maximum of 512 ns 100_B **MAX_1US**: Maximum of 1 µs 101_B **MAX_2US**: Maximum of 2 µs 110_B **MAX_4US**: Maximum of 4 µs 111_B **NO_LIMIT**: No limit

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_EP_L1_ACCPT_LATENCY	11:9	rw	**Endpoint L1 Acceptable Latency** This field indicates the acceptable latency that an Endpoint can withstand due to the transition from L1 state to the L0 state. It is essentially an indirect measure of the Endpoint's internal buffering. Power management software uses the reported L1 Acceptable Latency number to compare against the L1 Exit Latencies reported (see below) by all components comprising the data path from this Endpoint to the Root Complex Root Port to determine whether ASPM L1 entry can be used with no loss of performance. For functions other than Endpoints, this field is Reserved and the controller hardwires it to 000b. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W (Sticky) else R(Sticky) Note: This register field is sticky. 000_B **MAX_1US**: Maximum of 1 µs 001_B **MAX_2US**: Maximum of 2 µs 010_B **MAX_4US**: Maximum of 4 µs 011_B **MAX_8US**: Maximum of 8 µs 100_B **MAX_16US**: Maximum of 16 µs 101_B **MAX_32US**: Maximum of 32 µs 110_B **MAX_64US**: Maximum of 64 µs 111_B **NO_LIMIT**: No limit
RSVDP_12	14:12	r	**Reserved for future use**
PCIE_CAP_ROLE_BASED_ERR_REPORT	15	rw	**Role-Based Error Reporting** When set, this bit indicates that the function implements the functionality originally defined in the Error Reporting ECN for PCI Express Base Specification, Revision 1.0a, and later incorporated into PCI Express Base Specification, Revision 1.1. This bit must be set by all functions conforming to the ECN, PCI Express Base Specification, Revision 1.1., or subsequent PCI Express Base Specification revisions. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
RSVDP_16	17:16	r	**Reserved for future use**
PCIE_CAP_CAP_SLOT_PWR_LMT_VALUE	25:18	rh	**Captured Slot Power Limit Value** Captured Slot Power Limit Value (Upstream Ports only). In combination with the Captured Slot Power Limit Scale value, specifies the upper limit on power available to the adapter. Power limit (in Watts) is calculated by multiplying the value in this field by the value in the Captured Slot Power Limit Scale field except when the Captured Slot Power Limit Scale field equals 00b (1.0x) and the Captured Slot Power Limit Value exceeds EFh, then alternative encodings are used (for more details, see section 7.5.3.9 of PCI Express Base Specification). This value is set by the Set_Slot_Power_Limit Message or hardwired to 00h (for more details, see section 6.9 of PCI Express Base Specification).

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_CAP_SLOT_PWR_LMT_SCALE	27:26	rh	**Captured Slot Power Limit Scale** Captured Slot Power Limit Scale (Upstream Ports only). Specifies the scale used for the Slot Power Limit Value. This value is set by the Set_Slot_Power_Limit Message or hardwired to 00b (for more details, see section 6.9 of PCI Express Base Specification). 00_B **_1_0X**: 1.0x 01_B **_0_1X**: 0.1x 10_B **_0_01X**: 0.01x 11_B **_0_001X**: 0.001x
PCIE_CAP_FLR_CAP	28	rw	**Function Level Reset Capability** A value of 1b indicates the function supports the optional Function Level Reset mechanism described in section 6.6.2 of the PCI Express Base Specification. This bit applies to Endpoints only. For all other function types the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. Function Level Reset mechanism is not supported in this implementation
RSVDP_29	31:29	r	**Reserved for future use**

Field	Bits	Type	Description
PCIE_CAP_CORR_ERR_REPORT_EN	0	rw	**Correctable Error Reporting Enable** This bit, in conjunction with other bits, controls sending ERR_COR Messages (for more details, see section 6.2.5, section 6.2.6, and section 6.2.10.2 of PCI Express Base Specification). For a Multi-Function device, this bit controls error reporting for each function from point-of-view of the respective function. For a Root Port, the reporting of correctable errors is internal to the root. No external ERR_COR Message is generated.
PCIE_CAP_NON_FATAL_ERR_REPORT_EN	1	rw	**Non-Fatal Error Reporting Enable** This bit, in conjunction with other bits, controls sending ERR_NONFATAL Messages (for more details, see section 6.2.5 and Section 6.2.6 of PCI Express Base Specification). For a Multi-Function Device, this bit controls error reporting for each function from point-of-view of the respective Function. For a Root Port, the reporting of Non-fatal errors is internal to the root. No external ERR_NONFATAL Message is generated.
PCIE_CAP_FATAL_ERR_REPORT_EN	2	rw	**Fatal Error Reporting Enable** This bit, in conjunction with other bits, controls sending ERR_FATAL Messages (for more details, see section 6.2.5 and section 6.2.6 of of PCI Express Base Specification). For a Multi-Function device, this bit controls error reporting for each function from point-of-view of the respective function. For a Root Port, the reporting of Fatal errors is internal to the root. No external ERR_FATAL Message is generated.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_UNSUPPORT_REQ_REP_EN	3	rw	**Unsupported Request Reporting Enable** This bit, in conjunction with other bits, controls the signaling of Unsupported Request Errors by sending error Messages (for more details, see section 6.2.5 and section 6.2.6 of PCI Express Base Specification). For a Multi-Function Device, this bit controls error reporting for each Function from point-of-view of the respective Function.
PCIE_CAP_EN_REL_ORDER	4	rw	**Enable Relaxed Ordering** If this bit is set, the function is permitted to set the Relaxed Ordering bit in the Attributes field of transactions it initiates that do not require strong write ordering (for more details, see section 2.2.6.4 and section 2.4 of PCI Express Base Specification). For a function that never sets the Relaxed Ordering attribute in transactions it initiates as a Requester, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
PCIE_CAP_MAX_PAYLOAD_SIZE_CS	7:5	rw	**Max_Payload_Size** This field sets maximum TLP payload size for the Function. As a Receiver, the Function must handle TLPs as large as the set value. As a Transmitter, the Function must not generate TLPs exceeding the set value. Permissible values that can be programmed are indicated by the Max_Payload_Size Supported field (PCIE_CAP_MAX_PAYLOAD_SIZE) in the Device Capabilities (DEVICE_CAPABILITIES_REG) register (for more details, see section 7.5.3.3 of PCI Express Base Specification). This field sets the maximum Read Request size for the function as a Requester. The function must not generate Read Requests with a size exceeding the set value. For Functions that support only the 128-byte max payload size, the controller hardwires this field to 000b. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 000_B **MAX_128B_SIZE**: 128 bytes maximum Read Request size 001_B **MAX_256B_SIZE**: 256 bytes maximum Read Request size 010_B **MAX_512B_SIZE**: 512 bytes maximum Read Request size 011_B **MAX_1024B_SIZE**: 1024 bytes maximum Read Request size 100_B **MAX_2048B_SIZE**: 2048 bytes maximum Read Request size 101_B **MAX_4096B_SIZE**: 4096 bytes maximum Read Request size 110_B **RESERVED1**: RESERVED 111_B **RESERVED2**: RESERVED

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_EXT_TAG_EN	8	rh	**Extended Tag Field Enable** This bit, in combination with the 10-Bit Tag Requester Enable bit in the Device Control 2 register, determines how many Tag field bits a Requester is permitted to use. When the 10-Bit Tag Requester Enable bit is clear, • If the Extended Tag Field Enable bit is set, the function is permitted to use an 8-bit Tag field as a Requester • If the Extended Tag Field Enable bit is clear, the Function is to a 5-bit Tag field See section 2.2.6.2 of PCI Express Base Specification for required behavior when the 10-Bit Tag Requester Enable bit is set. If software changes the value of the Extended Tag Field Enable bit while the function has outstanding Non-Posted Requests, the result is undefined. For functions that do not implement this capability, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: DEVICE_CAPABILITIES_REG.PCIE_CAP_EXT_TAG_SUPP ? RW : RO - Dbi: DEVICE_CAPABILITIES_REG.PCIE_CAP_EXT_TAG_SUPP ? RW : RO
PCIE_CAP_PHANTOM_FUNC_EN	9	rh	**Phantom Functions Enable** For functions that do not implement this capability (Phantom function capability is not available in this implementation), this bit will be hardwired to 0b. This bit, in combination with the 10-Bit Tag Requester Enable bit in the Device Control 2 register, determines how many Tag field bits a Requester is permitted to use. When the 10-Bit Tag Requester Enable bit is clear, • If this bit is set, it enables a function to use unclaimed functions as Phantom functions to extend the number of outstanding transaction identifiers • If this bit is clear, the function is not allowed to use Phantom functions For more details, see section 2.2.6.2 of PCI Express Base Specification. Software should not change the value of this bit while the function has outstanding Non-Posted Requests; otherwise, the result is undefined. For functions that do not implement this capability, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: • Wire: DEVICE_CAPABILITIES_REG.PCIE_CAP_PHANTOM_FUNC_SUPPORT ? RW : RO • Dbi: DEVICE_CAPABILITIES_REG.PCIE_CAP_PHANTOM_FUNC_SUPPORT ? RW : R

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_AUX_POWER_PM_EN	10	rwh	**Aux Power PM Enable** This bit is derived by sampling the sys_aux_pwr_det input. When set this bit, enables a function to draw Aux power independent of PME Aux power. Functions that require Aux power on legacy operating systems should continue to indicate PME Aux power requirements. Aux power is allocated as requested in the Aux_Current field of the Power Management Capabilities register (PMC), independent of the PME_En bit in the Power Management Control/Status register (PMCSR). For Multi-Function devices, a component is allowed to draw Aux power if at least one of the functions has this bit set. Note: Functions that consume Aux power must preserve the value of this sticky register when Aux power is available. In such functions, this bit is not modified by Conventional Reset. For functions that do not implement this capability, the controller hardwires this bit to 0b. Note: This register field is sticky.
PCIE_CAP_EN_NO_SNOOP	11	rw	**Enable No Snoop** If this bit is set, the function is permitted to Set the No Snoop bit in the Requester Attributes of transactions it initiates that do not require hardware enforced cache coherency (see section 2.2.6.5 in PCI Express Base Specification). Note: Setting this bit to 1b should not cause a function to set the No Snoop attribute on all transactions that it initiates. Even when this bit is set, a function is only permitted to set the No Snoop attribute on a transaction when it can guarantee that the address of the transaction is not stored in any cache in the system. The controller hardwires this bit 0b if a function would never set the No Snoop attribute in transactions it initiates. Note: The access attributes of this field are as follows: - Wire: R - Dbi: R
PCIE_CAP_MAX_READ_REQ_SIZE	14:12	rw	**Max_Read_Request_Size** This field sets the maximum Read Request size for the function as a Requester. The function must not generate Read Requests with a size exceeding the set value. For functions that do not generate Read Requests larger than 128 bytes and functions that do not generate Read Requests on their own behalf, the controller implements this field as Read Only (RO) with a value of 000b. 000_B **MAX_128B_SIZE**: 128 bytes maximum Read Request size 001_B **MAX_256B_SIZE**: 256 bytes maximum Read Request size 010_B **MAX_512B_SIZE**: 512 bytes maximum Read Request size 011_B **MAX_1024B_SIZE**: 1024 bytes maximum Read Request size 100_B **MAX_2048B_SIZE**: 2048 bytes maximum Read Request size 101_B **MAX_4096B_SIZE**: 4096 bytes maximum Read Request size 110_B **RESERVED1**: RESERVED 111_B **RESERVED2**: RESERVED
PCIE_CAP_CORR_ERR_DETECTED	16	rw1ch	**Correctable Error Detected** This bit indicates status of correctable errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For functions supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the Correctable Error Mask register. Software write with 1 clears this bit-field.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_NON_FATAL_ERR_DETECTED	17	rw1ch	**Non-Fatal Error Detected** This bit indicates status of Non-fatal errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For functions supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the Uncorrectable Error Mask register. Software write with 1 clears this bit-field.
PCIE_CAP_FATAL_ERR_DETECTED	18	rw1ch	**Fatal Error Detected** This bit indicates status of Fatal errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For Functions supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the Uncorrectable Error Mask register. Software write with 1 clears this bit-field.
PCIE_CAP_UNSUPPORTED_REQ_DETECTED	19	rw1ch	**Unsupported Request Detected** This bit indicates that the function received an Unsupported Request. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. Software write with 1 clears this bit-field.
PCIE_CAP_AUX_POWER_DETECTED	20	rh	**AUX Power Detected** Functions that require Aux power report this bit as set if Aux power is detected by the function. .
PCIE_CAP_TRANS_PENDING	21	rh	**Transactions Pending** Endpoints: When set, this bit indicates that the function has issued Non-Posted Requests that have not been completed. A Function reports this bit cleared only when all outstanding Non-Posted Requests have completed or have been terminated by the Completion Timeout mechanism. Root and Switch Ports: The controller hardwires this bit to 0b.
RSVDP_22	31:22	r	**Reserved for future use**
0	15	r	**Reserved** Read as 0; should be written with 0.

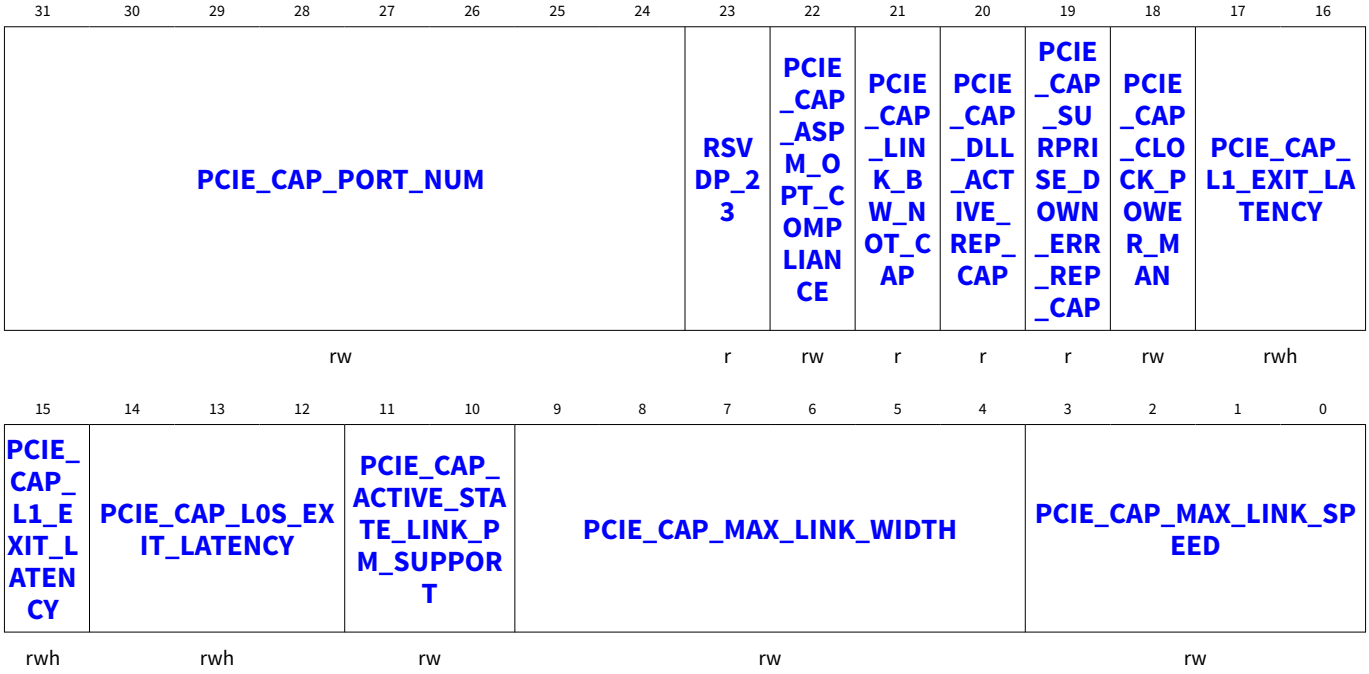
19.4.1.118 Link Capabilities Register

The Link Capabilities register identifies PCI Express Link specific capabilities.

LINK_CAPABILITIES_REG Offset address: $000407C_H$

Link Capabilities Register Kernel Reset value: $0047\ 6813_H$



Field	Bits	Type	Description
PCIE_CAP_MAX_LINK_SPEED	3:0	rw	**Max Link Speed** This field indicates the maximum Link speed of the associated Port. The encoded value specifies a bit location in the Supported Link Speeds Vector (in the Link Capabilities 2 register) that corresponds to the maximum Link speed. All encodings other than the defined encodings are reserved. Multi-Function Devices associated with an Upstream Port must report the same value in this field for all functions. In M-PCIe mode, the reset and dynamic values of this field are calculated by the controller. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 1_H **SUP_LINK_SPEED_FIELD_BIT_0**: Supported Link Speeds Vector field bit 0 2_H **SUP_LINK_SPEED_FIELD_BIT_1**: Supported Link Speeds Vector field bit 1 3_H **SUP_LINK_SPEED_FIELD_BIT_2**: Supported Link Speeds Vector field bit 2 4_H **SUP_LINK_SPEED_FIELD_BIT_3**: Supported Link Speeds Vector field bit 3 5_H **SUP_LINK_SPEED_FIELD_BIT_4**: Supported Link Speeds Vector field bit 4 6_H **SUP_LINK_SPEED_FIELD_BIT_5**: Supported Link Speeds Vector field bit 5 7_H **SUP_LINK_SPEED_FIELD_BIT_6**: Supported Link Speeds Vector field bit 6 **others,** Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_MAX_LINK_WIDTH	9:4	rw	**Maximum Link Width** This field indicates the maximum Link width (xN - corresponding to N Lanes) implemented by the component. This value is permitted to exceed the number of Lanes routed to the slot (Downstream Port), adapter connector (Upstream Port), or in the case of component-to-component connections, the actual wired connection width. All encodings other than the defined encodings are reserved. Multi-Function devices associated with an Upstream Port must report the same value in this field for all functions. In M-PCIe mode, the reset and dynamic values of this field are calculated by the controller. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 01_H **X1**: x1 02_H **X2**: x2 04_H **X4**: x4 08_H **X8**: x8 $0C_H$ **X12**: x12 10_H **X16**: x16 20_H **X32**: x32 **others,** Reserved
PCIE_CAP_ACTIVE_STATE_LINK_PM_SUPPORT	11:10	rw	**Active State Power Management (ASPM) Support** This field indicates the level of ASPM supported on the given PCI Express Link. For more details on ASPM support requirements, see section 5.4.1 of PCI Express Base Specification. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 00_B **NO_ASPM_SUP**: No ASPM Support 01_B **L0S_SUP**: L0s Supported 10_B **L1_SUP**: L1 Supported 11_B **L0S_L1_SUP**: L0s and L1 Supported

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_L0S_EXIT_LATENCY	14:12	rwh	**L0s Exit Latency** This field indicates the L0s exit latency for the given PCI Express Link. The value reported indicates the length of time this Port requires to complete transition from L0s to L0. If L0s is not supported, the value is undefined; however, see the Implementation Note "Potential Issues With Legacy Software When L0s is Not Supported" in section 5.4.1.1 of PCI Express Base Specification for the recommended value. Note: Exit latencies may be influenced by PCI Express reference clock configuration depending upon whether a component uses a common or separate reference clock. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 000_B **LESS_THAN_64NS**: Less than 64 ns 001_B **_64NS_TO_128NS**: 64 ns to less than 128 ns 010_B **_128NS_TO_256NS**: 128 ns to less than 256 ns 011_B **_256NS_TO_512NS**: 256 ns to less than 512 ns 100_B **_512NS_TO_1US**: 512 ns to less than 1 µs 101_B **_1US_TO_2US**: 1 µs to less than 2 µs 110_B **_2US_TO_4US**: 2 µs to 4 µs 111_B **GREATER_THAN_4US**: More than 4 µs
PCIE_CAP_L1_EXIT_LATENCY	17:15	rwh	**L1 Exit Latency** This field indicates the L1 exit latency for the given PCI Express Link. The value reported indicates the length of time this Port requires to complete transition from ASPM L1 to L0. If ASPM L1 is not supported, the value is undefined. Note: Exit latencies may be influenced by PCI Express reference clock configuration depending upon whether a component uses a common or separate reference clock. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 000_B **LESS_THAN_1US**: Less than 1 µs 001_B **_1US_TO_2US**: 1 µs to less than 2 µs 010_B **_2US_TO_4US**: 2 µs to less than 4 µs 011_B **_4US_TO_8US**: 4 µs to less than 8 µs 100_B **_8US_TO_16US**: 8 µs to less than 16 µs 101_B **_16US_TO_32US**: 16 µs to less than 32 µs 110_B **_32US_TO_64US**: 32 µs to 64 µs 111_B **GREATER_THAN_64US**: More than 64 µs

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_CLOCK_POWER_MAN	18	rw	**Clock Power Management** For Upstream Ports, a value of 1b in this bit indicates that the component tolerates the removal of any reference clock(s) via the "clock request" (CLKREQ#) mechanism when the Link is in the L1 and L2/L3 Ready Link states. A value of 0b indicates the component does not have this capability and that reference clock(s) must not be removed in these Link states. L1 PM Substates defines other semantics for the CLKREQ# signal, which are managed independently of Clock Power Management. This Capability is applicable only in form factors that support "clock request" (CLKREQ#) capability. The reset value of this bit field is decided by the value of PM_CTRL.CLKPMEN. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
PCIE_CAP_SURPRISE_DOWN_ERR_REP_CAP	19	r	**Surprise Down Error Reporting Capable** For a Downstream Port, this bit must be set if the component supports the optional capability of detecting and reporting a Surprise Down error condition. For Upstream Ports and components that do not support this optional capability, the controller hardwires this bit to 0b. Note: This register field is sticky.
PCIE_CAP_DLL_ACTIVE_REP_CAP	20	r	**Data Link Layer Link Active Reporting Capable** For a Downstream Port, the controller hardwires this bit to 1b if the component supports the optional capability of reporting the DL_Active state of the Data Link Control and Management State Machine. For a hot-plug capable Downstream Port (as indicated by the Hot-Plug Capable bit of the Slot Capabilities register) or a Downstream Port that supports Link speeds greater than 5.0 GT/s, the controller hardwires this bit to 1b. For Upstream Ports and components that do not support this optional capability, the controller hardwires this bit to 0b.
PCIE_CAP_LINK_BW_NOT_CAP	21	r	**Link Bandwidth Notification Capability** A value of 1b indicates support for the Link Bandwidth Notification status and interrupt mechanisms. This capability is required for all Root Ports and Switch Downstream Ports supporting Links wider than x1 and/or multiple Link speeds. This field is not applicable and is Reserved for Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches. For functions that do not implement the Link Bandwidth Notification Capability the controller hardwires this bit to 0b. Note: This register field is sticky.
PCIE_CAP_ASPM_OPT_COMPLIANCE	22	rw	**ASPM Optionality Compliance** This field must be set to 1b in all functions. Components implemented against certain earlier versions of this specification will have this bit set to 0b. Software is permitted to use the value of this bit to help determine whether to enable ASPM or whether to run ASPM compliance tests. Note: The access attributes of this field are as follows: - Wire: HWINIT (hardware initialized) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
RSVDP_23	23	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_PORT_NUM	31:24	rw	**Port Number** This field indicates the PCI Express Port number for the given PCI Express Link. Multi-Function Devices associated with an Upstream Port must report the same value in this field for all functions. Note: The access attributes of this field are as follows: - Wire: HWINIT - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

19.4.1.119 Link Control and Link Status Register

This register controls and provides information about PCI Express Link specific parameters.

LINK_CONTROL_LINK_STATUS_REG Offset address: 0004080_H

Field	Bits	Type	Description
PCIE_CAP_ACTIVE_STATE_LINK_PM_CONTROL	1:0	rw	**Active State Power Management (ASPM) Control** This field controls the level of ASPM enabled on the given PCI Express Link. See section 5.4.1.3 of PCI Express Base Specification for requirements on when and how to enable ASPM. Note: "L0s Entry Enabled" enables the Transmitter to enter L0s. If L0s is supported, the Receiver must be capable of entering L0s even when the Transmitter is disabled from entering L0s (00b or 10b). ASPM L1 must be enabled by software in the Upstream component on a Link prior to enabling ASPM L1 in the Downstream component on that Link. When disabling ASPM L1, software must disable ASPM L1 in the Downstream component on a Link prior to disabling ASPM L1 in the Upstream component on that Link. ASPM L1 must only be enabled on the Downstream component if both components on a Link support ASPM L1. Software must not enable L0s in either direction on a given Link unless components on both sides of the Link each support L0s; otherwise, the result is undefined. 00_B **DISABLED**: Disabled 01_B **L0S_ENTRY_EN**: L0s Entry Enabled 10_B **L1_ENTRY_En**: L1 Entry Enabled 11_B **L0S_L1_ENTRY_EN**: L0s and L1 Entry Enabled
RSVDP_2	2	r	**Reserved for future use**
PCIE_CAP_RCB	3	rw	**Read Completion Boundary (RCB)** Root Ports: Indicates the RCB value for the Root Port. Refer to section 2.3.1.1 of PCI Express Base Specification for the definition of the parameter RCB. The controller hardwires this bit for a Root Port and returns its RCB support capabilities. Endpoints and Bridges: Optionally set by configuration software to indicate the RCB value of the Root Port Upstream from the Endpoint or Bridge. Refer to Section 2.3.1.1 of PCI Express Base Specification for the definition of the parameter RCB is same as Root Port. Configuration software must only set this bit if the Root Port Upstream from the Endpoint or Bridge reports an RCB value of 128 bytes (a value of 1b in the Read Completion Boundary bit). For functions that do not implement this feature, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_B **_64B**: 64 byte 1_B **_128B**: 128 byte
PCIE_CAP_LINK_DISABLE	4	rwh	**Link Disable** This bit disables the Link by directing the LTSSM to the Disabled state when set; this bit is Reserved on Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches. Writes to this bit are immediately reflected in the value read from the bit, regardless of actual Link state. After clearing this bit, software must honor timing requirements defined in Section 6.6.1 with respect to the first Configuration Read following a Conventional Reset. Note: The access attributes of this field are as follows: - Wire: dsp=1 ? RW : RO - Dbi: dsp=1? RW : RO

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_RETRAIN_LINK	5	rwh	**Retrain Link** A write of 1b to this bit initiates Link retraining by directing the Physical Layer LTSSM to the Recovery state. If the LTSSM is already in Recovery or Configuration, re-entering Recovery is permitted but not required. Reads of this bit always return 0b. It is permitted to write 1b to this bit while simultaneously writing modified values to other fields in this register. If the LTSSM is not already in Recovery or Configuration, the resulting Link training must use the modified values. If the LTSSM is already in Recovery or Configuration, the modified values are not required to affect the Link training that's already in progress. This bit is not applicable and is Reserved for Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches. This bit always returns 0b when read.
PCIE_CAP_COMMON_CLK_CONFIG	6	rw	**Common Clock Configuration** When set, this bit indicates that this component and the component at the opposite end of this Link are operating with a distributed common reference clock. A value of 0b indicates that this component and the component at the opposite end of this Link are operating with asynchronous reference clock. Components utilize this common clock configuration information to report the correct L0s and L1 Exit Latencies. After changing the value in this bit in both components on a Link, software must trigger the Link to retrain by writing a 1b to the Retrain Link bit of the Downstream Port.
PCIE_CAP_EXTENDED_SYNCH	7	rwh	**Extended Synch** When set, this bit forces the transmission of additional Ordered Sets when exiting the L0s state (see section 4.2.4.5 of PCI Express Base Specification) and when in the Recovery state (see section 4.2.6.4.1 of PCI Express Base Specification). This mode provides external devices (for example, logic analyzers) monitoring the Link time to achieve bit and Symbol lock before the Link enters the L0 state and resumes communication. For Multi-Function devices if any function has this bit set, then the component must transmit the additional Ordered Sets when exiting L0s or when in Recovery.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_EN_CLK_POWER_MAN	8	rwh	**Enable Clock Power Management** Applicable only for Upstream Ports and with form factors that support a "Clock Request" (CLKREQ#) mechanism, this bit operates as follows: . For Downstream Ports and components that do not support Clock Power Management (as indicated by a 0b value in the Clock Power Management bit of the Link Capabilities register), the controller hardwires this bit to 0b. The write value is gated with the PCIE_CAP_CLOCK_POWER_MAN field in LINK_CAPABILITIES_REG. Note: The access attributes of this field are as follows: • Wire: LINK_CAPABILITIES_REG.PCIE_CAP_CLOCK_POWER_MAN ? RWS : ROS • Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_CLOCK_POWER_MAN ? RWS : ROS Note: This register field is sticky 0_B **PM_DISABLE_LOW_CLKREQ**: Clock power management is disabled and device must hold CLKREQ# signal low 1_B **CLKREQ_IN_USE**: When this bit is set, the device is permitted to use CLKREQ# signal to power manage Link clock according to protocol defined in appropriate form factor specification
PCIE_CAP_HW_AUTO_WIDTH_DISABLE	9	rw	**Hardware Autonomous Width Disable** When set, this bit disables hardware from changing the Link width for reasons other than attempting to correct unreliable Link operation by reducing Link width. For components that do not implement the ability autonomously to change Link width, the ciontroller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
PCIE_CAP_LINK_BW_MAN_INT_EN	10	rwh	**Link Bandwidth Management Interrupt Enable** When set, this bit enables the generation of an interrupt to indicate that the Link Bandwidth Management Status bit has been set. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG. This bit is not applicable and is Reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges, and Upstream Ports of Switches. For functions that do not implement the Link Bandwidth Notification Capability, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: • Wire: LINK_CAPABILITIES_REG.PCIE_CAP_LINK_BW_NOT_CAP ? RW : RO • Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_LINK_BW_NOT_CAP ? RW : RO

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_LINK_AUTO_BW_INT_EN	11	rwh	**Link Autonomous Bandwidth Management Interrupt Enable** When set, this bit enables the generation of an interrupt to indicate that the Link Autonomous Bandwidth Status bit has been set. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG. This bit is not applicable and is Reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges, and Upstream Ports of Switches. For functions that do not implement the Link Bandwidth Notification Capability, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: • Wire: LINK_CAPABILITIES_REG.PCIE_CAP_LINK_BW_NOT_CAP ? RW : RO • Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_LINK_BW_NOT_CAP ? RW : RO
RSVDP_12	13:12	r	**Reserved for future use**
PCIE_CAP_DRS_SIGNALING_CONTROL	15:14	r	**DRS Signaling Control** Indicates the mechanism used to report reception of a DRS message. Must be implemented for Downstream Ports with the DRS Supported bit Set in the Link Capabilities 2 Register. Encodings are: • If DRS Supported is set, receiving a DRS Message will set DRS Message Received in the Link Control 2 and Status 2 Register Register but will otherwise have no effect • If the DRS Message Received bit in the Link Control 2 and Status 2 Register Register transitions from 0 to 1, and either MSI or MSI-X is enabled, an MSI or MSI-X interrupt is generated using the vector in Interrupt Message Number (section 7.5.3.2) Behavior is undefined if this field is set to 10b as the FRS capability is not Supported. Behavior is undefined if this field is set to 11b. For Downstream Ports with the DRS Supported bit clear in the Link Capabilities 2 register, the controller hardwires this field to 00b. This field is Reserved for Upstream Ports. 00_B **DRS_NOT_REPORTED**: DRS not Reported 01_B **DRS_INTRRUPT_EN**: DRS Interrupt Enabled 10_B **FRS_EN**: DRS to FRS Signaling Enabled **others,** Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_LINK_SPEED	19:16	rh	**Current Link Speed** This field indicates the negotiated Link speed of the given PCI Express Link. The encoded value specifies a bit location in the Supported Link Speeds Vector (in the Link Capabilities 2 register) that corresponds to the current Link speed. All encodings other than the defined encodings are reserved. The value in this field is undefined when the Link is not up. 1_H **SUP_LINK_SPEED_FIELD_BIT_0**: Supported Link Speeds Vector field bit 0 2_H **SUP_LINK_SPEED_FIELD_BIT_1**: Supported Link Speeds Vector field bit 1 3_H **SUP_LINK_SPEED_FIELD_BIT_2**: Supported Link Speeds Vector field bit 2 4_H **SUP_LINK_SPEED_FIELD_BIT_3**: Supported Link Speeds Vector field bit 3 5_H **SUP_LINK_SPEED_FIELD_BIT_4**: Supported Link Speeds Vector field bit 4 6_H **SUP_LINK_SPEED_FIELD_BIT_5**: Supported Link Speeds Vector field bit 5 7_H **SUP_LINK_SPEED_FIELD_BIT_6**: Supported Link Speeds Vector field bit 6 **others,** Reserved
PCIE_CAP_NEGO_LINK_WIDTH	25:20	rh	**Negotiated Link Width** This field indicates the negotiated width of the given PCI Express Link. All encodings other than the defined encodings are reserved. The value in this field is undefined when the Link is not up. 01_H **X1**: x1 02_H **X2**: x2 04_H **X4**: x4 08_H **X8**: x8 $0C_H$ **X12**: x12 10_H **X16**: x16 20_H **X32**: x32 **others,** Reserved
RSVDP_26	26	r	**Reserved for future use**
PCIE_CAP_LINK_TRAINING	27	rh	**Link Training** This read-only bit indicates that the Physical Layer LTSSM is in the Configuration or Recovery state, or that 1b was written to the Retrain Link bit but Link training has not yet begun. Hardware clears this bit when the LTSSM exits the Configuration/Recovery state. This bit is not applicable and Reserved for Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches, and the controller hardwires it to 0b. Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: R

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_SLOT_CLK_CONFIG	28	rw	**Slot Clock Configuration** This bit indicates that the component uses the same physical reference clock that the platform provides on the connector. If the device uses an independent clock irrespective of the presence of a reference clock on the connector, this bit must be clear. For a Multi-Function Device, each Function must report the same value for this bit. Note: The access attributes of this field are as follows: - Wire: HWINIT - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
PCIE_CAP_DLL_ACTIVE	29	r	**Data Link Layer Link Active** This bit indicates the status of the Data Link Control and Management State Machine. It returns a 1b to indicate the DL_Active state, 0b otherwise. This bit must be implemented if the Data Link Layer Link Active Reporting Capable bit is 1b. Otherwise, the controller hardwires it to 0b.
PCIE_CAP_LINK_BW_MAN_STATUS	30	r	**Link Bandwidth Management Status** This bit is set by hardware to indicate that either of the following has occurred without the Port transitioning through DL_Down status: • A Link retraining has completed following a write of 1b to the Retrain Link bit. Note: This bit is set following any write of 1b to the Retrain Link bit, including when the Link is in the process of retraining for some other reason • Hardware has changed Link speed or width to attempt to correct unreliable Link operation, either through an LTSSM timeout or a higher level process. This bit must be set if the Physical Layer reports a speed or width change was initiated by the Downstream component that was not indicated as an autonomous change. This bit is not applicable and is Reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges, and Upstream Ports of Switches. The default value of this bit is 0b. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: R
PCIE_CAP_LINK_AUTO_BW_STATUS	31	r	**Link Autonomous Bandwidth Status** This bit is set by hardware to indicate that hardware has autonomously changed Link speed or width, without the Port transitioning through DL_Down status, for reasons other than to attempt to correct unreliable Link operation. This bit must be set if the Physical Layer reports a speed or width change was initiated by the Downstream component that was indicated as an autonomous change. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG. This bit is not applicable and is Reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges, and Upstream Ports of Switches. For functions that do not implement the Link Bandwidth Notification Capability, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: R

Table 870 Reset values of LINK_CONTROL_LINK_STATUS_REG

r		r	r	rw	r	r	r	r	r	r	r	r			

Field	Bits	Type	Description
PCIE_CAP_CPL_TIMEOUT_RANGE	3:0	r	**Completion Timeout Ranges Supported** This field indicates device Function support for the optional Completion Timeout programmability mechanism. This mechanism allows system software to modify the Completion Timeout value. This field is applicable only to Root Ports, Endpoints that issue Requests on their own behalf, and PCI Express to PCI/PCI-X Bridges that take ownership of Requests issued on PCI Express. For all other Functions this field is Reserved and must be hardwired to 0000b. Four time value ranges are defined: • Range A: 50 µs to 10 ms • Range B: 10 ms to 250 ms • Range C: 250 ms to 4 s • Range D: 4 s to 64 s Bits are set according to the list below to show timeout value ranges supported. All encodings other than the defined encodings are reserved. It is strongly recommended that the Completion Timeout mechanism not expire in less than 10 ms. 0_H **NOT_SUP**: Completion Timeout programming not supported, the Function must implement a timeout value in the range 50 µs to 50 ms 1_H **RANGE_A**: Range A 2_H **RANGE_B**: Range B 3_H **RANGE_A_B**: Ranges A and B 6_H **RANGE_B_C**: Ranges B and C 7_H **RANGE_A_B_C**: Ranges A, B, and C E_H **RANGE_B_C_D**: Ranges B, C, and D F_H **RANGE_A_B_C_D**: Ranges A, B, C, and D
PCIE_CAP_CPL_TIMEOUT_DISABLE_SUPPORT	4	r	**Completion Timeout Disable Supported** A value of 1b indicates support for the Completion Timeout Disable mechanism. The Completion Timeout Disable mechanism is required for Endpoints that issue Requests on their own behalf and PCI Express to PCI/PCI-X Bridges that take ownership of Requests issued on PCI Express. This mechanism is optional for Root Ports. For all other Functions this field is Reserved and the controller hardwires this bit to 0b.
PCIE_CAP_ARI_FORWARD_SUPPORT	5	r	**ARI Forwarding Supported** Alternate routing ID capability is not available in this implementation. Applicable only to Switch Downstream Ports and Root Ports; must be 0b for other Function types. This bit must be set to 1b if a Switch Downstream Port or Root Port supports this optional capability. For more details, see section 6.13 of PCI Express Base Specification.
PCIE_CAP_ATOMIC_ROUTING_SUPP	6	r	**AtomicOp Routing Supported** Applicable only to Switch Upstream Ports, Switch Downstream Ports, and Root Ports; must be 0b for other Function types. This bit must be set to 1b if the Port supports this optional capability. For more details, see section 6.15 of PCI Express Base Specification.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_32_ATOMIC_CPL_SUPP	7	r	**32-bit AtomicOp Completer Supported** Applicable to Functions with Memory Space BARs as well as all Root Ports; must be 0b otherwise. Includes FetchAdd, Swap, and CAS AtomicOps. This bit must be set to 1b if the Function supports this optional capability. For more details on additional RC requirements, see section 6.15.3.1 of PCI Express Base Specification.
PCIE_CAP_64_ATOMIC_CPL_SUPP	8	r	**64-bit AtomicOp Completer Supported** Applicable to Functions with Memory Space BARs as well as all Root Ports; must be 0b otherwise. Includes FetchAdd, Swap, and CAS AtomicOps. This bit must be set to 1b if the Function supports this optional capability. For more details on additional RC requirements, see section 6.15.3.1 of PCI Express Base Specification.
PCIE_CAP_128_CAS_CPL_SUPP	9	r	**128-bit CAS Completer Supported** Applicable to Functions with Memory Space BARs as well as all Root Ports; must be 0b otherwise. This bit must be set to 1b if the Function supports this optional capability. For more details, see section 6.15 of PCI Express Base Specification.
PCIE_CAP_NO_RO_EN_PR2PR_PAR	10	r	**No RO-enabled PR-PR Passing** If this bit is set, the routing element never carries out the passing permitted by Table 2-39 of PCI Express Base Specification entry A2b that is associated with the Relaxed Ordering Attribute field being Set. This bit applies only for Switches and RCs that support peer-to-peer traffic between Root Ports. This bit applies only to Posted Requests being forwarded through the Switch or RC and does not apply to traffic originating or terminating within the Switch or RC itself. All Ports on a Switch or RC must report the same value for this bit. For all other functions, this bit must be 0b.
PCIE_CAP_LTR_SUPP	11	rw	**LTR Mechanism Supported** A value of 1b indicates support for the optional Latency Tolerance Reporting (LTR) mechanism. Root Ports, Switches and Endpoints are permitted to implement this capability. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(Sticky) else R(Sticky) Note: This register field is sticky.
PCIE_CAP_TPH_CMPLT_SUPPORT_0	12	r	**TPH Completer Supported Bit 0** TLP Processing Hints(TPH) is not supported in this implementation. Value of this bit along with TPH Completer Supported Bit 1 indicates Completer support for TPH or Extended TPH. Applicable only to Root Ports and Endpoints. For all other Functions, this field is Reserved. For more details, see section 6.17 of PCI Express Base Specification. 0_B **TPH_EXT_TPH_CMPL_NOT_SUP_OR_RSVD**: TPH and Extended TPH Completer not supported (if TPH Completer Supported Bit is 0) or Reserved ((if TPH Completer Supported Bit is 1) 1_B **TPH_SUP_EXT_TPH_NOT_SUP_OR_BOTH_SUPP**: TPH Completer supported; Extended TPH Completer not supported(if TPH Completer Supported Bit is 0) or Both TPH and Extended TPH Completer supported ((if TPH Completer Supported Bit is 1)
PCIE_CAP_TPH_CMPLT_SUPPORT_1	13	r	**TPH Completer Supported Bit 1** TLP Processing Hints(TPH) is not supported in this implementation

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP2_LN_SYS_CLS	15:14	r	**LN System CLS** Applicable only to Root Ports and RCRBs; must be 00b for all other Function types. This field indicates if the Root Port or RCRB supports LN protocol as an LN Completer, and if so, what cacheline size is in effect. All encodings other than the defined encodings are reserved. The above feature is not supported in this implementation Note: This register field is sticky. 00_B **LN_COMPLETER_NO_SUP**: LN Completer either not supported or not in effect 01_B **LN_COMPLETER_64B_CACHE**: LN Completer with 64-byte cachelines in effect 10_B **LN_COMPLETER_128B_CACHE**: LN Completer with 128-byte cachelines in effect **others,** Reserved
PCIE_CAP2_10_BIT_TAG_COMP_SUPPORT	16	r	**10-Bit Tag Completer Supported** If this bit is set, the Function supports 10-Bit Tag Completer capability; otherwise, the Function does not. For more details, see section 2.2.6.2. of PCI Express Base Specification.
PCIE_CAP2_10_BIT_TAG_REQ_SUPPORT	17	r	**10-Bit Tag Requester Supported** If this bit is set, the Function supports 10-Bit Tag Requester capability; otherwise, the Function does not. This bit must not be set if the 10-Bit Tag Completer Supported bit is clear. Note: 10-Bit Tag field generation must be enabled by the 10-Bit Tag Requester Enable bit in the Device Control 2 register of the Requester Function before 10-Bit Tags can be generated by the Requester. For more details, see section 2.2.6.2. of PCI Express Base Specification.
PCIE_CAP_OBFF_SUPPORT	19:18	rw	**OBFF Supported** This field indicates if OBFF is supported and, if so, what signaling mechanism is used. The value reported in this field must indicate support for WAKE# signaling only if: • for a Downstream Port, driving the WAKE# signal for OBFF is supported and the connector or component connected Downstream is known to receive that same WAKE# signal • for an Upstream Port, receiving the WAKE# signal for OBFF is supported and, if the component is on an add-in-card, that the component is connected to the WAKE# signal on the connector. Root Ports, Switch Ports, and Endpoints are permitted to implement this capability. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(Sticky) else R(Sticky) Note: This register field is sticky. 00_B **NOT_SUP**: OBFF Not Supported 01_B **SUP_USING_MSG**: OBFF supported using Message signaling only 10_B **SUP_USING_WAKE**: OBFF supported using WAKE# signaling only 11_B **SUP_USING_MSG_AND_WAKE**: OBFF supported using WAKE# and Message signaling
RSVDP_24	30:24	r	**Reserved for future use**

r	rw		r		rw	r				r	rw	rw			

Field	Bits	Type	Description
PCIE_CAP_CPL_TIMEOUT_VALUE	3:0	rw	**Completion Timeout Value** In device Functions that support Completion Timeout programmability, this field allows system software to modify the Completion Timeout value. This field is applicable to Root Ports, Endpoints that issue Requests on their own behalf. Functions that support Completion Timeout programmability must support the values given below corresponding to the programmability ranges indicated in the Completion Timeout Ranges Supported field. All encodings other than the defined encodings are reserved. It is strongly recommended that the Completion Timeout mechanism not expire in less than 10 ms. Software is permitted to change the value in this field at any time. For Requests already pending when the Completion Timeout Value is changed, hardware is permitted to use either the new or the old value for the outstanding Requests, and is permitted to base the start time for each Request either on when this value was changed or on when each request was issued. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_H **DEFAULT**: Default range: 50 µs to 50 ms 1_H **_50_TO_100_US**: 50 µs to 100 µs 2_H **_1_TO_10_MS**: 1 ms to 10 ms 5_H **_16_TO_55_MS**: 16 ms to 55 ms 6_H **_65_TO_210_MS**: 65 ms to 210 ms 9_H **_260_TO_900_MS**: 260 ms to 900 ms A_H **_1_TO_3_5_S**: 1 s to 3.5 s D_H **_4_TO_13_S**: 4 s to 13 s E_H **_17_TO_64_S**: 17 s to 64 s **others,** Reserved
PCIE_CAP_CPL_TIMEOUT_DISABLE	4	rw	**Completion Timeout Disable** When set, this bit disables the Completion Timeout mechanism. This bit is required for all Functions that support the Completion Timeout Disable Capability. Functions that do not support this optional capability are permitted to hardwire this bit to 0b Software is permitted to set or clear this bit at any time. When set, the Completion Timeout detection mechanism is disabled. If there are outstanding Requests when the bit is cleared, it is permitted but not required for hardware to apply the completion timeout mechanism to the outstanding Requests. If this is done, it is permitted to base the start time for each Request on either the time this bit was cleared or the time each Request was issued.
PCIE_CAP_ARI_FORWARD_SUPPORT_CS	5	r	**ARI Forwarding Enable** Alternate routing ID capability is not available in this implementation. When set, the Downstream Port disables its traditional Device Number field being 0 enforcement when turning a Type 1 Configuration Request into a Type 0 Configuration Request, permitting access to Extended Functions in an ARI Device immediately below the Port. For more details, see Section 6.13 of PCI Express Base Specification.

(table continues...)

(continued)

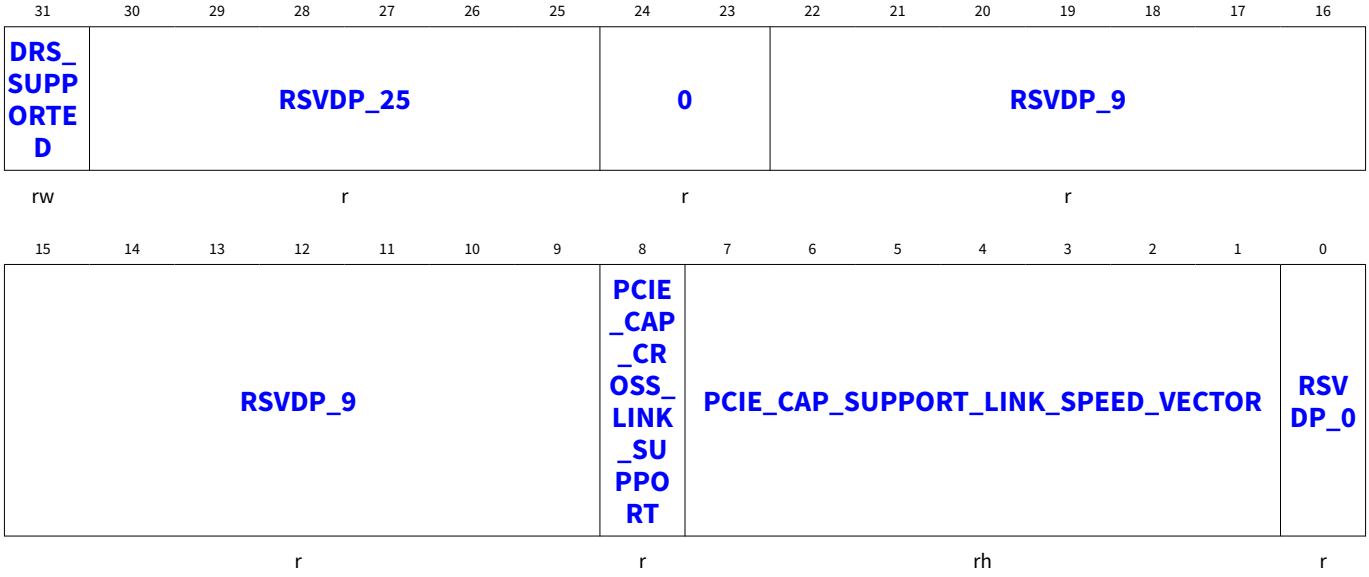
Field	Bits	Type	Description
PCIE_CAP_LTR_EN	10	rw	**LTR Mechanism Enable** When set to 1b, this bit enables Upstream Ports to send LTR messages and Downstream Ports to process LTR Messages. For Downstream Ports, this bit must be reset to the default value if the Port goes to DL_Down status. The write value is gated with the PCIE_CAP_LTR_SUPP field of DEVICE_CAPABILITIES2_REG. Note: RW for function #0 and RsdvP for all other functions. Note: The access attributes of this field are as follows: - Wire: if (pf=0 && DEVICE_CAPABILITIES2_REG.PCIE_CAP_LTR_SUPP) then R/W else R - Dbi: if (pf=0 && DEVICE_CAPABILITIES2_REG.PCIE_CAP_LTR_SUPP) then R/W else R
PCIE_CAP_OBFF_EN	14:13	rw	**OBFF Enable** This field enables the OBFF mechanism and selects the signaling method. For more details on these encodings, see section 6.19 of PCI Express Base Specification. This field is required for all Ports that support the OBFF Capability. Note: RW for function #0 and RsdvP for all other functions. Note: The access attributes of this field are as follows: • Wire: if (DEVICE_CAPABILITIES2_REG.PCIE_CAP_OBFF_SUPPORT) then R/W else R • Dbi: if (DEVICE_CAPABILITIES2_REG.PCIE_CAP_OBFF_SUPPORT) then R/W else R 00_B **DISABLED**: Disabled 01_B **EN_USING_MSG_SIG_A**: Enabled using Message signaling [Variation A] 10_B **EN_USING_MSG_SIG_B**: Enabled using Message signaling [Variation B] 11_B **EN_USING_WAKE_SIG**: Enabled using WAKE# signaling
0	9:6, 12:11, 31:15	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.1.122 Link Capabilities 2 Register

This register identifies PCI Express Link specific capabilities; in addition to the Link Capabilities Register.

LINK_CAPABILITIES2_REG Offset address: $000409C_H$

Link Capabilities 2 Register Reset values see: Table 871



Field	Bits	Type	Description
RSVDP_0	0	r	**Reserved for future use**
PCIE_CAP_SUPPORT_LINK_SPEED_VECTOR	7:1	rh	**Supported Link Speeds Vector** This field indicates the supported Link speed(s) of the associated Port. For each bit, a value of 1b indicates that the corresponding Link speed is supported; otherwise, the Link speed is not supported. For more details, see section 8.2.1 of PCI Express Base Specification. Bit definitions within this field are: • Bit 0 2.5 GT/s • Bit 1 5.0 GT/s • Bit 2 8.0 GT/s • Bit 3 16.0 GT/s • Bit 4 32.0 GT/s • Bits 6:5 RsvdP This field has a default of (PCIE_CAP_MAX_LINK_SPEED == 0101) ? 0011111 : (PCIE_CAP_MAX_LINK_SPEED == 0100) ? 0001111 : (PCIE_CAP_MAX_LINK_SPEED == 0011) ? 0000111 : (PCIE_CAP_MAX_LINK_SPEED == 0010) ? 0000011 : 0000001 where PCIE_CAP_MAX_LINK_SPEED is a field in the LINK_CAPABILITIES_REG register.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_CROSS_LINK_SUPPORT	8	r	**Crosslink Supported** When set to 1b, this bit indicates that the associated Port supports crosslinks (for more details, see section 4.2.6.3.1 of PCI Express Base Specification). When set to 0b on a Port that supports Link speeds of 8.0 GT/s or higher, this bit indicates that the associated Port does not support crosslinks. When set to 0b on a Port that only supports Link speeds of 2.5 GT/s or 5.0 GT/s, this bit provides no information regarding the Port's level of crosslink support. It is recommended that this bit be Set in any Port that supports crosslinks even though doing so is only required for Ports that also support operating at 8.0 GT/s or higher Link speeds. Note: Software should use this bit when referencing fields whose definition depends on whether or not the Port supports crosslinks (for more details, see section 7.7.3.4 of PCI Express Base Specification). Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions. No crosslink capability in this implementation
RSVDP_9	22:9	r	**Reserved for future use**
RSVDP_25	30:25	r	**Reserved for future use**
DRS_SUPPORTED	31	rw	**DRS Supported** When set, indicates support for the optional Device Readiness Status (DRS) capability. Must be Set in Downstream Ports that support DRS. Must be Set in Downstream Ports that support FRS. For Upstream Ports that support DRS, it is strongly recommended that this bit be Set in Function 0. For all other Functions associated with an Upstream Port, this bit must be Clear.127 Must be Clear in Functions that are not associated with a Port. RsvdP in all other Functions. Note: The access attributes of this field are as follows: - Wire: HWINIT - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
0	24:23	r	**Reserved** Read as all 0's; should be written with all 0's.

rwh				rwh	rw	rwh			r	rw	rwh	rw			

Field	Bits	Type	Description
PCIE_CAP_TARGET_LINK_SPEED	3:0	rw	**Target Link Speed** For Downstream Ports, this field sets an upper limit on Link operational speed by restricting the values advertised by the Upstream component in its training sequences. The encoded value specifies a bit location in the Supported Link Speeds Vector (in the Link Capabilities 2 register) that corresponds to the desired target Link speed. All encodings other than the defined encodings are reserved. . If a value is written to this field that does not correspond to a supported speed (as indicated by the Supported Link Speeds Vector), the result is undefined. If either of the Enter Compliance or Enter Modified Compliance bits are implemented, then this field must also be implemented. The default value of this field is the highest Link speed supported by the component (as reported in the Max Link Speed field of the Link Capabilities register) unless the corresponding platform/form factor requires a different default value. For both Upstream and Downstream Ports, this field is used to set the target compliance mode speed when software is using the Enter Compliance bit to force a Link into compliance mode. For Upstream Ports, if the Enter Compliance bit is Clear, this field is permitted to have no effect. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky 1_H **SUP_LINK_SPEED_VECTOR_BIT_0**: Supported Link Speeds Vector field bit 0 2_H **SUP_LINK_SPEED_VECTOR_BIT_1**: Supported Link Speeds Vector field bit 1 3_H **SUP_LINK_SPEED_VECTOR_BIT_2**: Supported Link Speeds Vector field bit 2 4_H **SUP_LINK_SPEED_VECTOR_BIT_3**: Supported Link Speeds Vector field bit 3 5_H **SUP_LINK_SPEED_VECTOR_BIT_4**: Supported Link Speeds Vector field bit 4 6_H **SUP_LINK_SPEED_VECTOR_BIT_5**: Supported Link Speeds Vector field bit 5 7_H **SUP_LINK_SPEED_VECTOR_BIT_6**: Supported Link Speeds Vector field bit 6 **others,** Reserved
PCIE_CAP_ENTER_COMPLIANCE	4	rwh	**Enter Compliance** Software is permitted to force a Link to enter Compliance mode (at the speed indicated in the Target Link Speed field and the de-emphasis/ preset level indicated by the Compliance Preset/De-emphasis field) by setting this bit to 1b in both components on a Link and then initiating a hot reset on the Link. Default value of this bit following Fundamental Reset is 0b. Components that support only the 2.5 GT/s speed are permitted to hardwire this bit to 0b. This bit is intended for debug, compliance testing purposes only. System firmware and software is allowed to modify this bit only during debug or compliance testing. In all other cases, the system must ensure that this bit is set to the default value. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_HW_AUTO_SPEED_DISABLE	5	rw	**Hardware Autonomous Speed Disable** When set, this bit disables hardware from changing the Link speed for device-specific reasons other than attempting to correct unreliable Link operation by reducing Link speed. Initial transition to the highest supported common link speed is not blocked by this bit. Functions that do not implement the associated mechanism are permitted to hardwire this bit to 0b. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky.
PCIE_CAP_SEL_DEEMPHASIS	6	r	**Selectable De-emphasis** When the Link is operating at 5.0 GT/s speed, this bit is used to control the transmit de-emphasis of the link in specific situations. For more details, see section 4.2.6 of PCI Express Base Specification. When the Link is not operating at 5.0 GT/s speed, the setting of this bit has no effect. Components that support only the 2.5 GT/s speed are permitted to hardwire this bit to 0b. This bit is not applicable and Reserved for Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches. Note: This register field is sticky. 0_B **_6_DB**: -6 dB 1_B **_3_5_DB**: -3.5 dB
PCIE_CAP_TX_MARGIN	9:7	rwh	**Transmit Margin, This field controls the value of the non-deemphasized voltage level at the Transmitter pins** This field is reset to 000b on entry to the LTSSM Polling.Configuration substate (see Chapter 4 of PCI Express Base Specification for details of how the Transmitter voltage level is determined in various states). - 001b-111b: As defined in Section 8.3.4 not all encodings are required to be implemented. For components that support only the 2.5 GT/s speed, the controller hardwires this bit to 000b. This field is intended for debug, compliance testing purposes only. System firmware and software is allowed to modify this field only during debug or compliance testing. In all other cases, the system must ensure that this field is set to the default value. Note: This register field is sticky. 000_B **NORMAL_RANGE**: Normal operating range **others,** Reserved
PCIE_CAP_ENTER_MODIFIED_COMPLIANCE	10	rw	**Enter Modified Compliance** When this bit is set to 1b, the device transmits Modified Compliance Pattern if the LTSSM enters Polling.Compliance substate. Components that support only the 2.5 GT/s speed are permitted to hardwire this bit to 0b. This bit is intended for debug, compliance testing purposes only. System firmware and software is allowed to modify this bit only during debug or compliance testing. In all other cases, the system must ensure that this bit is set to the default value. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_COMPLIANCE_SOS	11	rwh	**Compliance SOS** When set to 1b, the LTSSM is required to send SKP Ordered Sets between sequences when sending the Compliance Pattern or Modified Compliance Pattern. This bit is applicable when the Link is operating at 2.5 GT/s or 5.0 GT/s data rates only. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky.
PCIE_CAP_COMPLIANCE_PRESET	15:12	rwh	**Compliance Preset/De-emphasis** • For 8.0 GT/s and higher Data Rate: This field sets the Transmitter Preset in Polling.Compliance state if the entry occurred due to the Enter Compliance bit being 1b. The encodings are defined in section 4.2.3.2 of PCI Express Base Specification . Results are undefined if a reserved preset encoding is used when entering Polling.Compliance in this way. • For 5.0 GT/s Data Rate: This field sets the de-emphasis level in Polling.Compliance state if the entry occurred due to the Enter Compliance bit being 1b • When the Link is operating at 2.5 GT/s, the setting of this field has no effect. Components that support only 2.5 GT/s speed are permitted to hardwire this field to 0000b This field is intended for debug and compliance testing purposes. System firmware and software is allowed to modify this field only during debug or compliance testing. In all other cases, the system must ensure that this field is set to the default value. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_H **_6_DB**: -6 dB (for 5.0 GT/s Data Rate) 1_H **_3_5_DB**: -3.5 dB (for 5.0 GT/s Data Rate) **others,** Reserved
PCIE_CAP_CURR_DEEMPHASIS	16	rh	**Current De-emphasis Level** When the Link is operating at 5.0 GT/s speed, this bit reflects the level of de-emphasis. The value in this bit is undefined when the Link is not operating at 5.0 GT/s speed. 0_B **_6DB**: -6 dB 1_B **_3_5DB**: -3.5 dB
PCIE_CAP_EQ_CPL	17	rh	**Equalization 8.0 GT/s Complete** When set to 1b, this bit indicates that the Transmitter Equalization procedure at the 8.0 GT/s data rate has completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in section 4.2.6.4.2 of PCI Express Base Specification. For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. For components that only support speeds below 8.0 GT/s, the controller hardwires this bit to 0b. Note: This register field is sticky.

(continued)

Field	Bits	Type	Description
PCIE_CAP_EQ_CPL_P1	18	rh	**Equalization 8.0 GT/s Phase 1 Successful** When set to 1b, this bit indicates that Phase 1 of the 8.0 GT/s Transmitter Equalization procedure has successfully completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in section 4.2.6.4.2 of PCI Express Base Specification. Note: This register field is sticky.
PCIE_CAP_EQ_CPL_P2	19	rh	**Equalization 8.0 GT/s Phase 2 Successful** When set to 1b, this bit indicates that Phase 2 of the 8.0 GT/s Transmitter Equalization procedure has successfully completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in section 4.2.6.4.2 of PCI Express Base Specification. Note: This register field is sticky.
PCIE_CAP_EQ_CPL_P3	20	rh	**EEqualization 8.0 GT/s Phase 3 Successful** When set to 1b, this bit indicates that Phase 3 of the 8.0 GT/s Transmitter Equalization procedure has successfully completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in section 4.2.6.4.2 of PCI Express Base Specification. Note: This register field is sticky.
PCIE_CAP_LINK_EQ_REQ	21	rw1ch	**Link Equalization Request 8.0 GT/s** This bit is set by hardware to request the 8.0 GT/s Link equalization process to be performed on the Link. For more details, see sections 4.2.3 and 4.2.6.4.2 of PCI Express Base Specification. Note: This register field is sticky. Software write with 1 clears this bit-field.
RSVDP_26	27:26	r	**Reserved for future use**

(table continues...)

(continued)

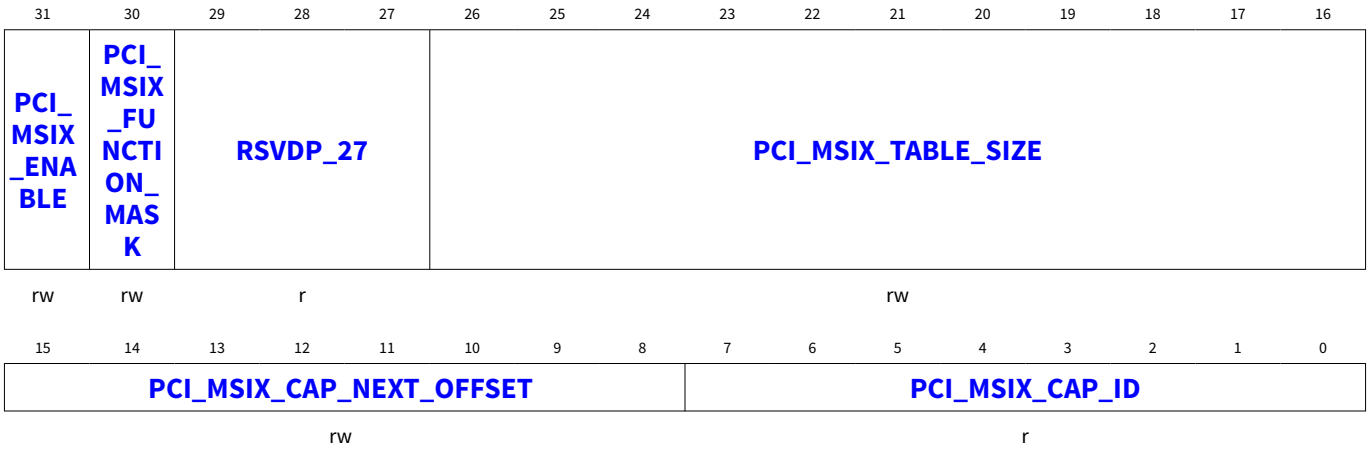
Field	Bits	Type	Description
DOWNSTREAM_COMPO_PRESENCE	30:28	r	**Downstream Component Presence** This field indicates the presence and DRS status for the Downstream Component, if any, connected to the Link. All encodings other than the defined encodings are reserved. Component Presence state must be determined by the logical "OR" of the Physical Layer in-band presence detect mechanism and, if present, any out-of-band presence detect mechanism implemented for the Link. If no out-of-band presence detect mechanism is implemented, then Component Presence state must be determined solely by the Physical Layer in-band presence detect mechanism. This field must be implemented in any Downstream Port where the DRS Supported bit is Set in the Link Capabilities 2 register. This field is RsvdZ for all other Functions. 000_B **LINK_DN_NOT_DETERMINED**: Link Down - Presence Not Determined 001_B **LINK_DN_DSP_NOT_PRESENT**: Link Down - Component Not Present indicates the Downstream Port (DP) has determined that a Downstream Component is not present 010_B **LINK_DN_DLL_NOT_ACTIVE**: Link Down - Component Present indicates the DP has determined that a Downstream Component is present, but the Data Link Layer is not active 100_B **LINK_UP_DRS_NOT_RECEIVED**: Link Up - Component Presentindicates the DP has determined that a Downstream Component is present, but no DRS Message has been received since the Data Link Layer became active 101_B **LINK_UP_DRS_RECEIVED**: Link Up - Component Present and DRS Received indicates the DP has received a DRS Message since the Data Link Layer became active **others,** Reserved
DRS_MESSAGE_RECEIVED	31	r	**DRS Message Received** This bit must be set whenever the Port receives a DRS Message. This bit must be cleared in DL_Down. This bit must be implemented in any Downstream Port where the DRS Supported bit is Set in the Link Capabilities 2 register. This bit is RsvdZ for all other Functions.
0	25:22	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.1.124 MSI-X Capability ID, Next Pointer, Control Register

This Register holds MSI-X Capability ID, Next Capability pointer. It also controls the MSI-X behaviour.

PCI_MSIX_CAP_ID_NEXT_CTRL_REG Offset address: $00040B0_H$

MSI-X Capability ID, Next Pointer, Control Register Kernel Reset value: $0040\ 0011_H$



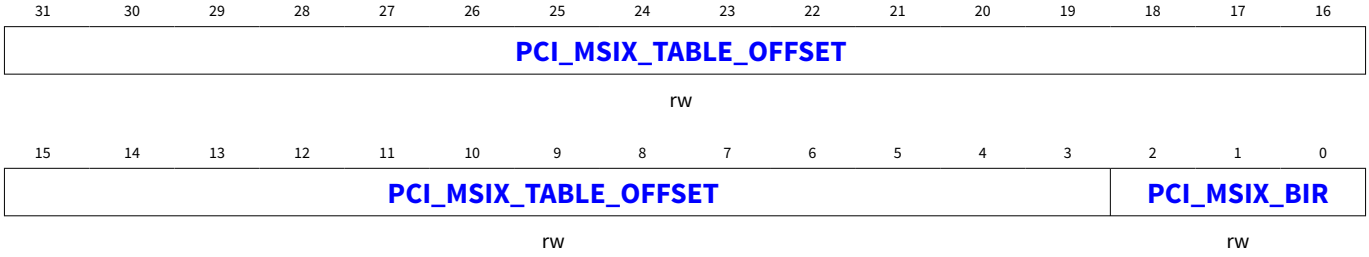
Field	Bits	Type	Description
PCI_MSIX_CAP_ID	7:0	r	**MSI-X Capability ID** This field indicates the MSI-X Capability structure. This field must return a Capability ID of 11h indicating that this is an MSI-X Capability structure.
PCI_MSIX_CAP_NEXT_OFFSET	15:8	rw	**MSI-X Next Capability Pointer** This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of Capabilities. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
PCI_MSIX_TABLE_SIZE	26:16	rw	**MSI-X Table Size** System software reads this field to determine the MSI-X Table Size N, which is encoded as N-1. For example, a returned value of 000 0000 0011b indicates a table size of 4. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
RSVDP_27	29:27	r	**Reserved for future use**
PCI_MSIX_FUNCTION_MASK	30	rw	**Function Mask** If Set, all of the vectors associated with the Function are masked, regardless of their per-vector Mask bit values. If Clear, each vector's Mask bit determines whether the vector is masked or not. Setting or Clearing the MSI-X Function Mask bit has no effect on the value of the per-vector Mask bits. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
PCI_MSIX_ENABLE	31	rw	**MSI-X Enable** If Set and the MSI Enable bit in the MSI Message Control Register for MSI is Clear, the Function is permitted to use MSI-X to request service and is prohibited from using INTx interrupts (if implemented). System configuration software Sets this bit to enable MSI-X. A device driver is prohibited from writing this bit to mask a Function's service request. If Clear, the Function is prohibited from using MSI-X to request service.

19.4.1.125 MSI-X Table Offset and BIR Register

This register provides Table BIR and MSI-x Table offset select.

MSIX_TABLE_OFFSET_REG Offset address: $00040B4_H$

MSI-X Table Offset and BIR Register Kernel Reset value: $0000\ 0A00_H$



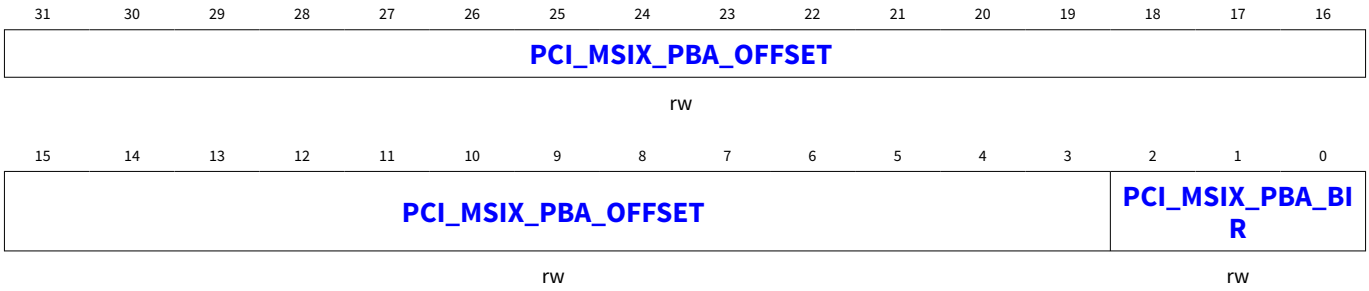
Field	Bits	Type	Description
PCI_MSIX_BIR	2:0	rw	**MSI-X Table BAR Indicator Register Field** This field indicates which one of a Function's Base Address Registers , located beginning at 10h in Configuration Space, or entry in the Enhanced Allocation capability with a matching BEI , is used to map the Function's MSI-X Table into Memory Space. All encodings other than the defined encodings are reserved. For a 64-bit Base Address Register , the Table BIR indicates the lower DWORD. For Functions with Type 1 Configuration Space headers, BIR values 2 through 5 are also Reserved. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 000_B **BAR_10**: Base Address Register 10h 001_B **BAR_14**: Base Address Register 14h 010_B **BAR_18**: Base Address Register 18h 011_B **BAR_1C**: Base Address Register 1Ch 100_B **BAR_20**: Base Address Register 20h 101_B **BAR_24**: Base Address Register 24h **others,** Reserved
PCI_MSIX_TABLE_OFFSET	31:3	rw	**MSI-X Table Offset** Used as an offset from the address contained by one of the Function's Base Address Registers to point to the base of the MSI-X Table. The lower 3 Table BIR bits are masked off (set to zero) by software to form a 32-bit QWORD-aligned offset. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

19.4.1.126 MSI-X PBA Offset and BIR Register

This register provides PBA Offset and PBA BIR value.

MSIX_PBA_OFFSET_REG Offset address: $00040B8_H$

MSI-X PBA Offset and BIR Register Kernel Reset value: $0000\ 0E10_H$



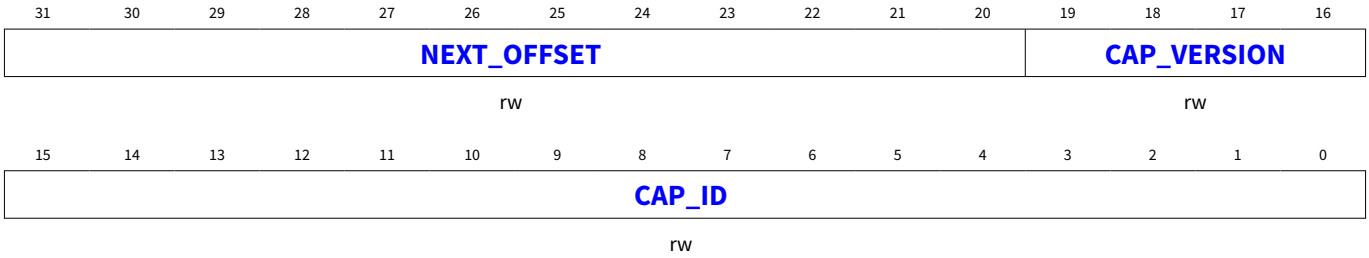
Field	Bits	Type	Description
PCI_MSIX_PBA_BIR	2:0	rw	**MSI-X PBA BIR** This field indicates which one of a Function's Base Address Registers , located beginning at 10h in Configuration Space, or entry in the Enhanced Allocation capability with a matching BEI, is used to map the Function's MSI-X PBA into Memory Space. The PBA BIR value definitions are identical to those for the Table BIR . Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
PCI_MSIX_PBA_OFFSET	31:3	rw	**MSI-X PBA Offset** Used as an offset from the address contained by one of the Function's Base Address Registers to point to the base of the MSI-X PBA. The lower 3 PBA BIR bits are masked off (set to zero) by software to form a 32-bit QWORD-aligned offset. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

19.4.1.127 Advanced Error Reporting Extended Capability Header

Advanced Error Reporting Extended Capability Header provides information about Capability ID, Version, and next offset.

AER_EXT_CAP_HDR_OFF Offset address: 0004100_H

Advanced Error Reporting Extended Capability Header Kernel Reset value: $1482\ 0001_H$



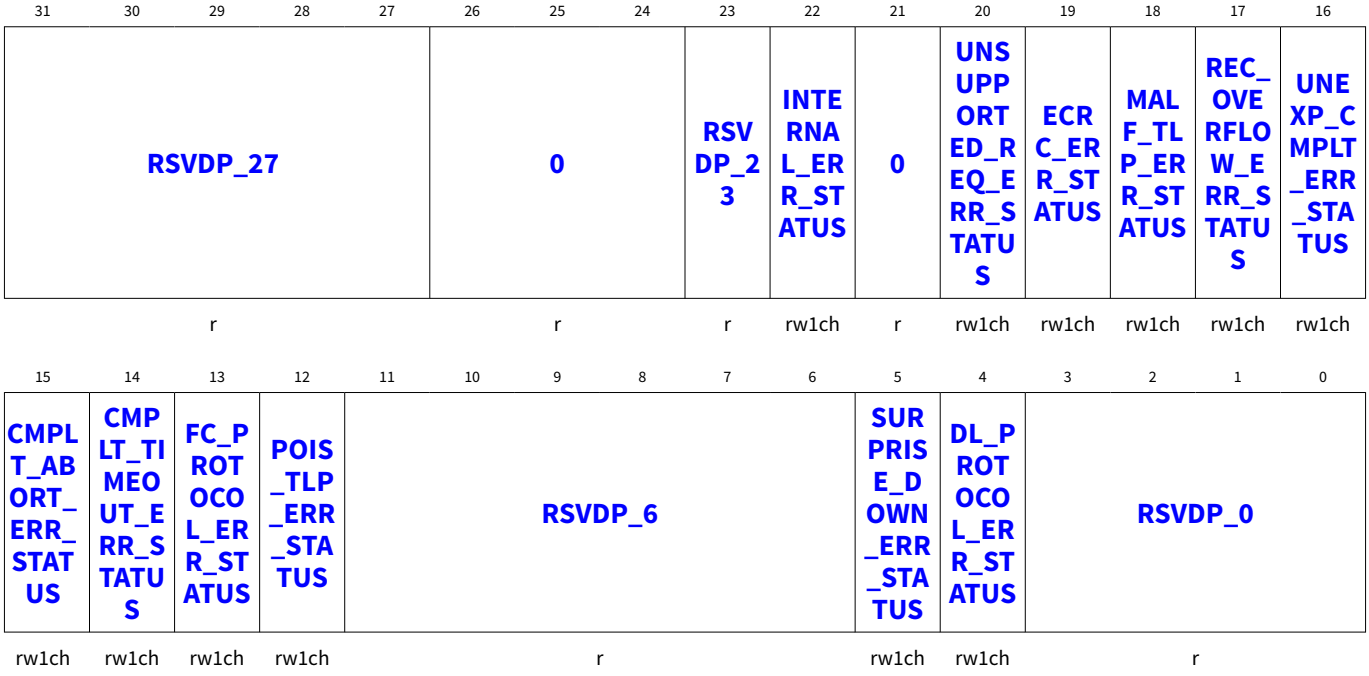
Field	Bits	Type	Description
CAP_ID	15:0	rw	**AER Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. The Extended Capability ID for the Advanced Error Reporting Capability is 0001h. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
CAP_VERSION	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. This field must be 2h if the End-End TLP Prefix Supported bit is set and must be 1h or 2h otherwise. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.1.128 Uncorrectable Error Status Register

The Uncorrectable Error Status Register (Offset 04h) indicates error detection status of individual errors on a PCI Express device Function. An individual error status bit that is Set indicates that a particular error was detected; software may clear an error status by writing a 1b to the respective bit. Register bits not implemented by the Function are hardwired to 0b.

UNCORR_ERR_STATUS_OFF Offset address: 0004104_H

Uncorrectable Error Status Register Reset values see: Table 872



Field	Bits	Type	Description
RSVDP_0	3:0	r	**Reserved for future use**
DL_PROTOCOL_ERR_STATUS	4	rw1ch	**Data Link Protocol Error Status** Status bit for Data Link Protocol Error. Note: This register field is sticky. Software write with 1 clears this bit-field.
SURPRISE_DOWN_ERR_STATUS	5	rw1ch	**Surprise Down Error Status (Optional)** Status bit for Surprise Down Error. Note: This register field is sticky. Software write with 1 clears this bit-field.
RSVDP_6	11:6	r	**Reserved for future use**
POIS_TLP_ERR_STATUS	12	rw1ch	**Poisoned TLP Status** Status bit for Poisoned TLP. Note: This register field is sticky. Software write with 1 clears this bit-field.
FC_PROTOCOL_ERR_STATUS	13	rw1ch	**Flow Control Protocol Error Status** Status bit for Flow Control Protocol Error. Note: This register field is sticky. Software write with 1 clears this bit-field.
CMPLT_TIMEOUT_ERR_STATUS	14	rw1ch	**Completion Timeout Status** Status for Completion Timeout. Note: This register field is sticky. Software write with 1 clears this bit-field.
CMPLT_ABORT_ERR_STATUS	15	rw1ch	**Completer Abort Status** Status bit for Completer Abort. Note: This register field is sticky. Software write with 1 clears this bit-field.
UNEXP_CMPLT_ERR_STATUS	16	rw1ch	**Unexpected Completion Status** Status bit for Unexpected Completion. Note: This register field is sticky. Software write with 1 clears this bit-field.

(table continues...)

(continued)

Field	Bits	Type	Description
REC_OVERFLOW_ERR_STATUS	17	rw1ch	**Receiver Overflow Status** Status bit for Receiver Overflow. Note: This register field is sticky. Software write with 1 clears this bit-field.
MALF_TLP_ERR_STATUS	18	rw1ch	**Malformed TLP Status** This field represents status of Malformed TLP. Note: This register field is sticky. Software write with 1 clears this bit-field.
ECRC_ERR_STATUS	19	rw1ch	**ECRC Error Status** This field represents status of ECRC Error. Note: This register field is sticky. Software write with 1 clears this bit-field.
UNSUPPORTED_REQ_ERR_STATUS	20	rw1ch	**Unsupported Request Error Status** This field represents status of Unsupported Request Error. Note: This register field is sticky. Software write with 1 clears this bit-field.
INTERNAL_ERR_STATUS	22	rw1ch	**Uncorrectable Internal Error Status** This field gives status of the Uncorrectable Internal Error.Note: This register field is sticky. Software write with 1 clears this bit-field.
RSVDP_23	23	r	**Reserved for future use**
RSVDP_27	31:27	r	**Reserved for future use**
0	21, 26:24	r	**Reserved** Read as 0; should be written with 0.

19.4.1.129 Uncorrectable Error Mask Register

The Uncorrectable Error Mask Register controls reporting of individual errors by the device Function to the PCI Express Root Complex through a PCI Express error Message. A masked error (respective bit Set in the mask register) is not recorded or reported in the Header Log, TLP Prefix Log, or First Error Pointer, and is not reported to the PCI Express Root Complex by this Function. There is a mask bit per error bit of the Uncorrectable Error Status register. Register fields for bits not implemented by the Function are hardwired to 0b.

19.4.1.131 Correctable Error Status Register

The Correctable Error Status register reports error status of individual correctable error sources on a PCI Express device Function. When an individual error status bit is Set, it indicates that a particular error occurred; software may clear an error status by writing a 1b to the respective bit. Register bits not implemented by the Function are hardwired to 0b by the controller.

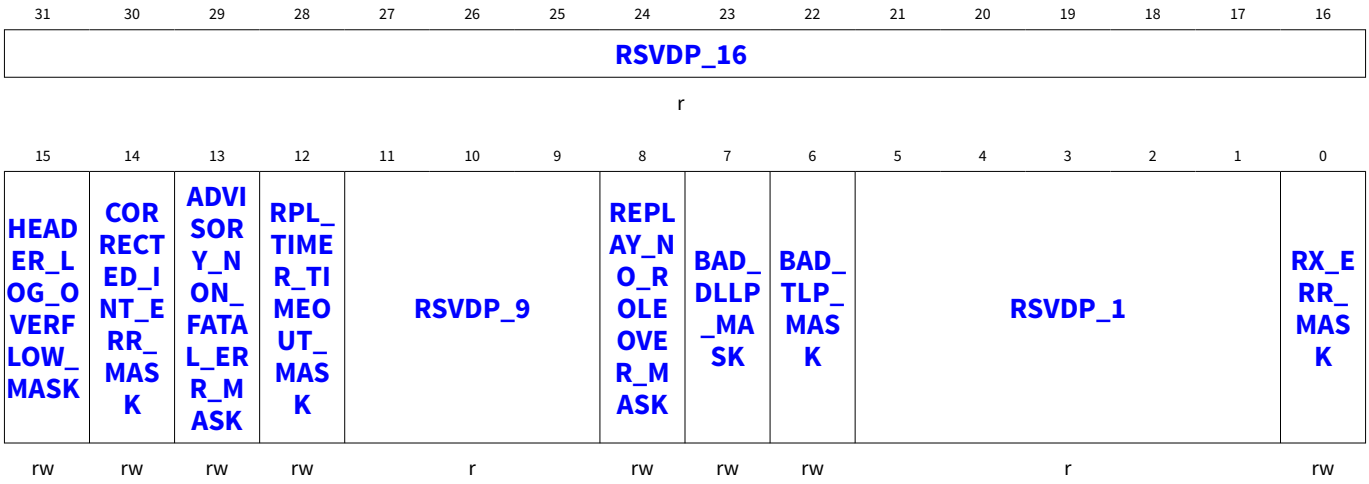
19.4.1.132 Correctable Error Mask Register

The Correctable Error Mask Register controls reporting of individual correctable errors by this Function to the PCI Express Root Complex through a PCI Express error Message. A masked error (respective bit Set in the mask register) is not reported to the PCI Express Root Complex by this Function. There is a mask bit per error bit in the Correctable Error Status register. Register fields for bits not implemented by the Function are hardwired to 0b by the controller.

CORR_ERR_MASK_OFF Offset address: 0004114_H

Correctable Error Mask Register Kernel Reset value: $0000\ E000_H$



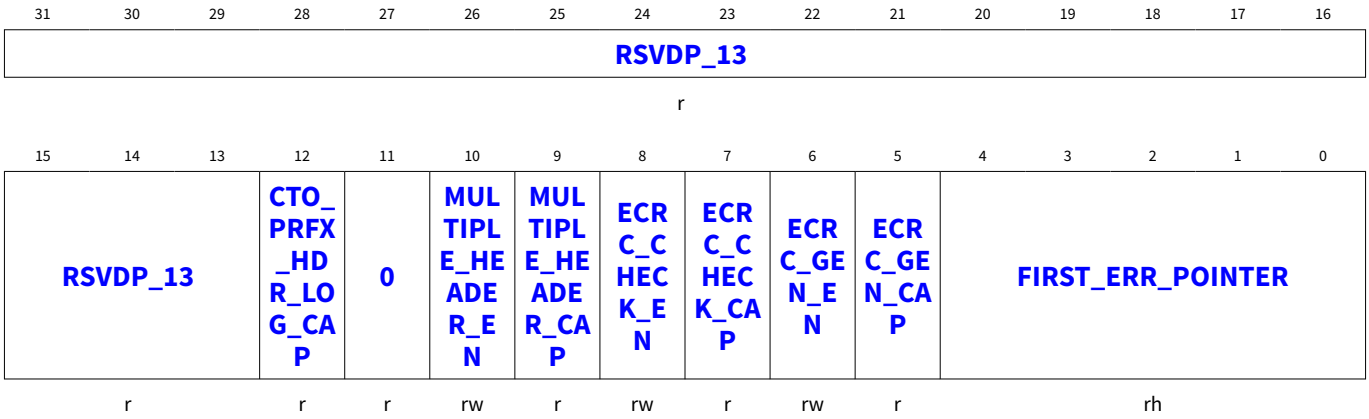
Field	Bits	Type	Description
RX_ERR_MASK	0	rw	**Receiver Error Mask (Optional)** Masking bit for Receiver Error. Note: This register field is sticky.
RSVDP_1	5:1	r	**Reserved for future use**
BAD_TLP_MASK	6	rw	**Bad TLP Mask** Masking bit for Bad TLP. Note: This register field is sticky.
BAD_DLLP_MASK	7	rw	**Bad DLLP Mask** Masking bit for Bad DLLP. Note: This register field is sticky.
REPLAY_NO_ROLEOVER_MASK	8	rw	**REPLAY_NUM Rollover Mask** Masking bit for REPLAY_NUM Rollover. Note: This register field is sticky.
RSVDP_9	11:9	r	**Reserved for future use**
RPL_TIMER_TIMEOUT_MASK	12	rw	**Replay Timer Timeout Mask** Masking bit for Replay Timer Timeout. Note: This register field is sticky.
ADVISORY_NON_FATAL_ERR_MASK	13	rw	**Advisory Non-Fatal Error Mask** Masking bit for Advisory Non-Fatal Error. Note: This register field is sticky.
CORRECTED_INT_ERR_MASK	14	rw	**Corrected Internal Error Mask (Optional)** Masking bit for Corrected Internal Error Mask. Note: This register field is sticky.
HEADER_LOG_OVERFLOW_MASK	15	rw	**Header Log Overflow Error Mask (Optional)** Masking bit for Header Log Overflow Error. Note: This register field is sticky.
RSVDP_16	31:16	r	**Reserved for future use**

19.4.1.133 Advanced Error Capabilities and Control Register

Advanced Error Capabilities and Control Register provides information whether the individual capability is supported or not. If the capability is supported then it is enabled or not.

ADV_ERR_CAP_CTRL_OFF Offset address: 0004118_H

Advanced Error Capabilities and Control Register Kernel Reset value: $0000\ 02A0_H$



Field	Bits	Type	Description
FIRST_ERR_POINTER	4:0	rh	**First Error Pointer** The First Error Pointer is a field that identifies the bit position of the first error reported in the Uncorrectable Error Status register. Note: This register field is sticky.
ECRC_GEN_CAP	5	r	**ECRC Generation Capable** If Set, this bit indicates that the Function is capable of generating ECRC. Note: This register field is sticky.
ECRC_GEN_EN	6	rw	**ECRC Generation Enable** When Set, ECRC generation is enabled. Functions that do not implement the associated mechanism are permitted to hardwire this bit to 0b. Default value of this bit is 0b. Note: This register field is sticky.
ECRC_CHECK_CAP	7	r	**ECRC Check Capable** If Set, this bit indicates that the Function is capable of checking ECRC. Note: This register field is sticky.
ECRC_CHECK_EN	8	rw	**ECRC Check Enable** When Set, ECRC checking is enabled. Functions that do not implement the associated mechanism are permitted to hardwire this bit to 0b. Default value of this bit is 0b. Note: This register field is sticky.
MULTIPLE_HEADER_CAP	9	r	**Multiple Header Recording Capable** If Set, this bit indicates that the Function is capable of recording more than one error header. Note: This register field is sticky.
MULTIPLE_HEADER_EN	10	rw	**Multiple Header Recording Enable** When Set, this bit enables the Function to record more than one error header. Functions that do not implement the associated mechanism are permitted to hardwire this bit to 0b. Default value of this bit is 0b. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: R (sticky) Note: This register field is sticky.
CTO_PRFX_HDR_LOG_CAP	12	r	**Completion Timeout Prefix/Header Log Capable** If Set, this bit indicates that the Function records the prefix/header of Request TLPs that experience a Completion Timeout error.
RSVDP_13	31:13	r	**Reserved for future use**
0	11	r	**Reserved** Read as 0; should be written with 0.

19.4.1.134 Header i Log Register 0

The Header Log Register 0 contains the header for the TLP corresponding to a detected error; The header is captured such that, when read using DW accesses, the fields of the header are laid out in the same way the headers are presented in the specification. Therefore, byte 0 of the header is located in byte 3 of the Header Log Register 0, byte 1 of the header is in byte 2 of the Header Log Register 0, and so forth. For 12-byte headers, only bytes 0 through 11 of the Header Log Register are used and values in bytes 12 through 15 are undefined. In certain cases where a Malformed TLP is reported, the Header Log Register may contain TLP Prefix information.

HDR_LOG_i_OFF (i=0-3) Offset address: $000411C_H+i*4$

Header i Log Register 0 Kernel Reset value: $0000\ 0000_H$

FIRST_DWORD_SECOND_BYTE								FIRST_DWORD_FIRST_BYTE							
rh								rh							

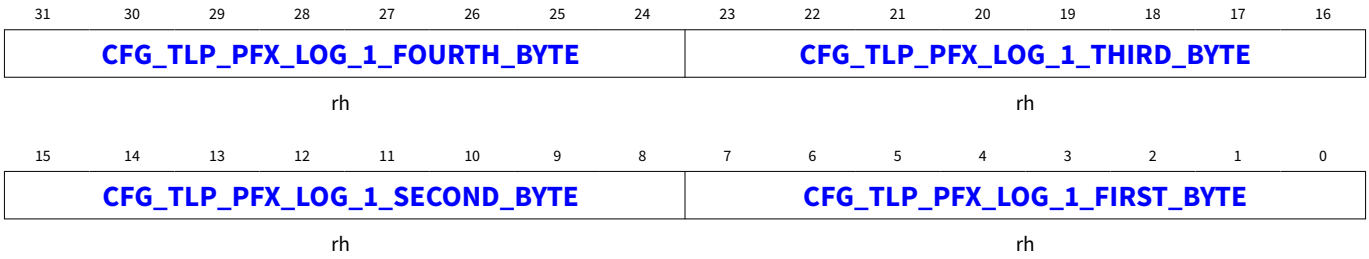
Field	Bits	Type	Description
FIRST_DWORD_FIRST_BYTE	7:0	rh	**Byte 0 of Header log register of First 32-bit Data Word** This field represents first byte of First DW of Header. Note: This register field is sticky.
FIRST_DWORD_SECOND_BYTE	15:8	rh	**Byte 1 of Header log register of First 32-bit Data Word** This field represents second byte of First DW of Header. Note: This register field is sticky.
FIRST_DWORD_THIRD_BYTE	23:16	rh	**Byte 2 of Header log register of First 32-bit Data Word** This field represents third byte of First DW of Header. Note: This register field is sticky.
FIRST_DWORD_FOURTH_BYTE	31:24	rh	**Byte 3 of Header log register of First 32-bit Data Word** This field represents fourth byte of First DW of Header. Note: This register field is sticky.

19.4.1.135 TLP Prefix i Log Register 1

The First TLP Prefix Log Register contains the first End-End TLP Prefix from the TLP corresponding to the detected error. The TLP Prefix Log Register is only meaningful when the TLP Prefix Log Present bit is Set. The TLP Prefixes are captured such that, when read using DW accesses, the fields of the TLP Prefix are laid out in the same way the fields of the TLP Prefix are described. Therefore, byte 0 of a TLP Prefix is located in byte 3 of the associated TLP Prefix Log Register; byte 1 of a TLP Prefix is located in byte 2; and so forth. The TLP Prefix Log Registers beyond the number supported by the Function are hardwired to zero by controller. If the End-End TLP Prefix Supported bit is Clear, the TLP Prefix Log Register is not required to be implemented.

TLP_PREFIX_LOG_i_OFF (i=0-3) Offset address: 0004138_H+i*4

TLP Prefix i Log Register 1 Kernel Reset value: $0000\ 0000_H$



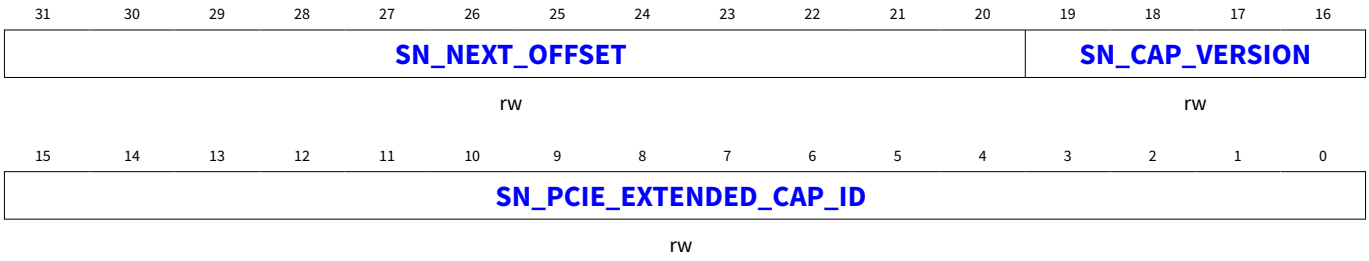
Field	Bits	Type	Description
CFG_TLP_PFX_LOG_1_FIRST_BYTE	7:0	rh	**Byte 0 of Error TLP Prefix Log 1** This field contains first byte of First DW of TLP Prefix. Note: This register field is sticky.
CFG_TLP_PFX_LOG_1_SECOND_BYTE	15:8	rh	**Byte 1 of Error TLP Prefix Log 1** This field contains second byte of First DW of TLP Prefix. Note: This register field is sticky.
CFG_TLP_PFX_LOG_1_THIRD_BYTE	23:16	rh	**Byte 2 of Error TLP Prefix Log 1** This field contains third byte of First DW of TLP Prefix. Note: This register field is sticky.
CFG_TLP_PFX_LOG_1_FOURTH_BYTE	31:24	rh	**Byte 3 of Error TLP Prefix Log 1** This field contains fourth byte of First DW of TLP Prefix. Note: This register field is sticky.

19.4.1.136 Device Serial Number Extended Capability Header

The Device Serial Number Extended Capability is an optional Extended Capability that may be implemented by any PCI Express device Function. This register provides Capability Id, Capability version, and Next offset of Capability structure.

SN_BASE Offset address: 0004148_H

Device Serial Number Extended Capability Header Kernel Reset value: $1581\ 0003_H$



Field	Bits	Type	Description
SN_PCIE_EXTENDED_CAP_ID	15:0	rw	**Serial Number Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for the Device Serial Number Extended Capability is 0003h. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

(table continues...)

(continued)

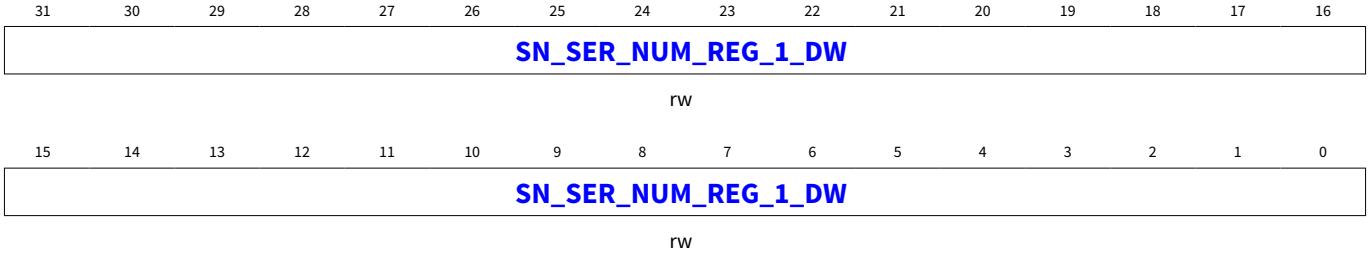
Field	Bits	Type	Description
SN_CAP_VERSION	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. This field is depends on the version of specification. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
SN_NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.1.137 Serial Number 1 Register

The Serial Number register is a 64-bit field that contains the IEEE defined 64-bit extended unique identifier.

SER_NUM_REG_DW_1 Offset address: $000414C_H$

Serial Number 1 Register Kernel Reset value: $0000\ 0000_H$



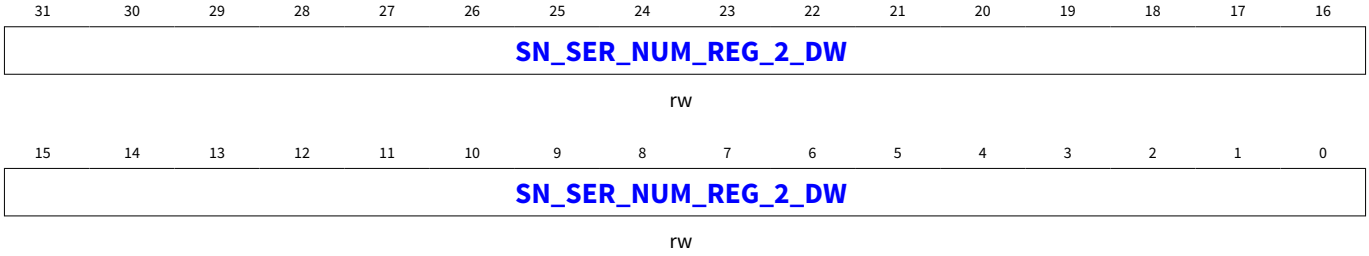
Field	Bits	Type	Description
SN_SER_NUM_REG_1_DW	31:0	rw	**IEEE 64 bit Device Serial Number (DW 1)** This field contains the IEEE defined 64-bit Extended Unique Identifier [EUI-64]. This identifier includes a 24-bit company id value assigned by IEEE registration authority and a 40-bit extension identifier assigned by the manufacturer. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.1.138 Serial Number 2 Register

The Serial Number register is a 64-bit field that contains the IEEE defined 64-bit extended unique identifier.

SER_NUM_REG_DW_2 Offset address: 0004150_H

Serial Number 2 Register Kernel Reset value: $0000\ 0000_H$



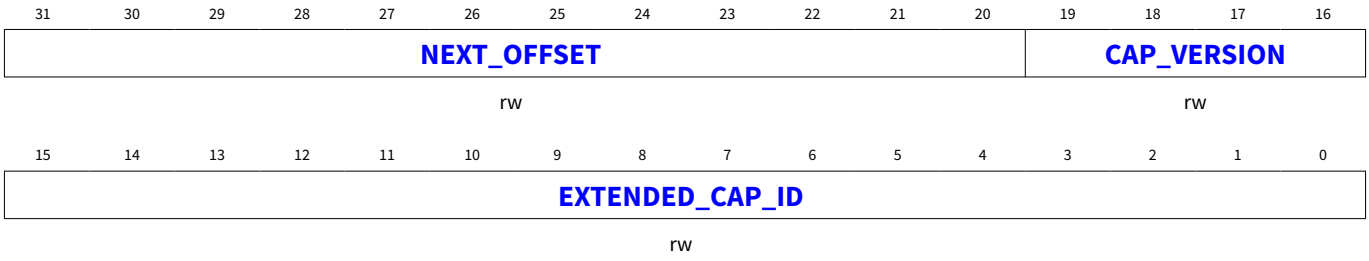
Field	Bits	Type	Description
SN_SER_NUM_REG_2_DW	31:0	rw	**IEEE 64 bit Device Serial Number (DW 2)** This field contains the IEEE defined 64-bit Extended Unique Identifier [EUI-64]. This identifier includes a 24-bit company id value assigned by IEEE registration authority and a 40-bit extension identifier assigned by the manufacturer. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.1.139 SPCIE Capability Header

This Register provides Capability Id, Capability Version, and next Offset of SPCIE Structure.

SPCIE_CAP_HEADER_REG Offset address: 0004158_H

SPCIE Capability Header Kernel Reset value: $1681\ 0019_H$



Field	Bits	Type	Description
EXTENDED_CAP_ID	15:0	rw	**Secondary PCI Express Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. PCI Express Extended Capability ID for the Secondary PCI Express Extended Capability is 0019h. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value

(table continues...)

(continued)

Field	Bits	Type	Description
CAP_VERSION	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of Capabilities. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value

19.4.1.140 Link Control 3 Register

This Register controls equilization and equilization interrupt.

LINK_CONTROL3_REG Offset address: $000415C_H$

Link Control 3 Register Reset values see: Table 873

r	r			r				r	r			r			

Field	Bits	Type	Description
DSP_TX_PRESET0	3:0	r	**Downstream Port 8.0 GT/s Transmitter Preset 0** Transmitter preset 0 value used for 8.0 GT/s equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. For an Upstream Port if Crosslink Supported is 0b, this field is RsvdP. Otherwise, this field is HwInit. Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: RSVDP
DSP_RX_PRESET_HINT0	6:4	r	**Downstream Port 8.0 GT/s Receiver Preset Hint 0** Receiver preset hint 0 value that may be used as a suggested setting for 8.0 GT/s receiver equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. For an Upstream Port if Crosslink Supported is 0b, this field is RsvdP. Otherwise, this field is HwInit. Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: RSVDP
RSVDP_7	7	r	**Reserved for future use**

(table continues...)

(continued)

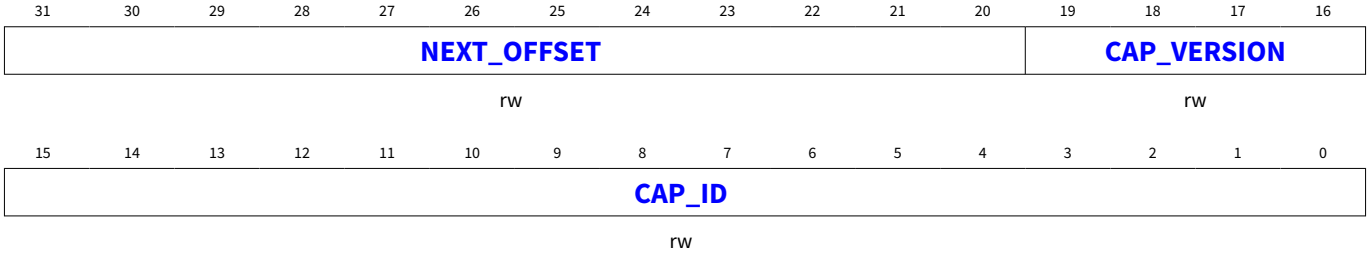
Field	Bits	Type	Description
USP_TX_PRESET0	11:8	r	**Upstream Port 8.0 GT/s Transmitter Preset 0** The write value is gated with the PCIE_CAP_CROSS_LINK_SUPPORT field of LINK_CAPABILITIES2_REG. Field contains the Transmitter preset 0 value sent or received during 8.0 GT/s Link Equalization. • Case A: When Operating port is Downstream port and whether the Crosslink is supported or not, this field representss the value sent on Lane 0 during 8.0 GT/s equalization • Case B: When Operating port is Upstream port and Crosslink Supported bit is 0, this field is intended for debug and diagnostics. It contains the value captured from Lane 0 during Link Equalization • Case C: When Operating port is Upstream port and Crosslink Supported bit is 1, Field is not used or affected by the current Link Equalization. Field value will be used if a future crosslink negotiation switches the Operating Port Direction so that case A applies For case A and C, Field is HwInit. For case B, Field is RO. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: R (sticky) Note: This register field is sticky.
USP_RX_PRESET_HINT0	14:12	r	**Upstream Port 8.0 GT/s Receiver Preset Hint 0** The write value is gated with the PCIE_CAP_CROSS_LINK_SUPPORT field of LINK_CAPABILITIES2_REG. Field contains the Receiver preset hint 0 value sent or received during 8.0 GT/s Link Equalization. • Case A: When Operating port is Downstream port and whether the Crosslink is supported or not, this field representss the value sent on Lane 0 during 8.0 GT/s equalization • Case B: When Operating port is Upstream port and Crosslink Supported bit is 0, this field is intended for debug and diagnostics. It contains the value captured from Lane 0 during Link Equalization • Case C: When Operating port is Upstream port and Crosslink Supported bit is 1, Field is not used or affected by the current Link Equalization. Field value will be used if a future crosslink negotiation switches the Operating Port Direction so that case A applies For case A and C, Field is HwInit. For case B, Field is RO. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: R (sticky) Note: This register field is sticky.
RSVDP_15	15	r	**Reserved for future use**
RSVDP_23	23	r	**Reserved for future use**
RSVDP_31	31	r	**Reserved for future use**
0	22:16, 30:24	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.1.143 LTR Extended Capability Header

This register provides capbility ID, capability version and next offset value for LTR(Latency Tolerance Reporting).

LTR_CAP_HDR_REG Offset address: 0004168_H

LTR Extended Capability Header Kernel Reset value: $1701\ 0018_H$



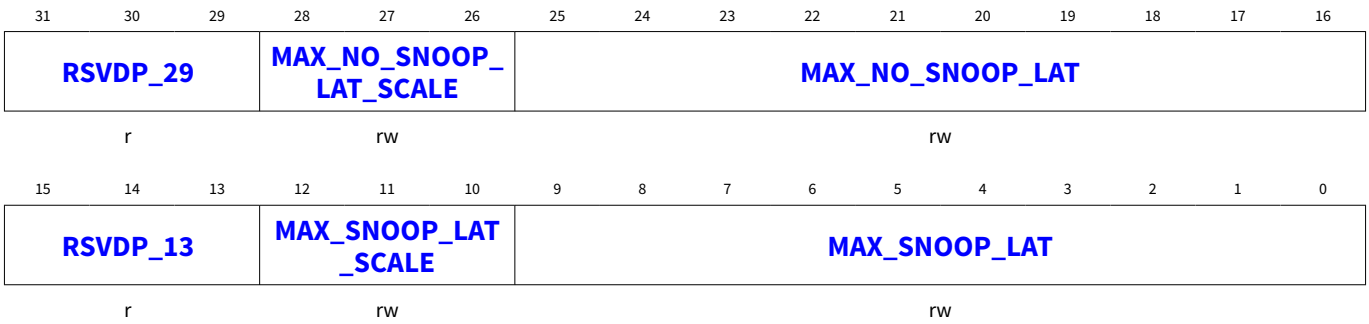
Field	Bits	Type	Description
CAP_ID	15:0	rw	**LTR Extended Capacity ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. PCI Express Extended Capability for the LTR Extended Capability is 0018h. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
CAP_VERSION	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. This field is depends on version of the specification. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of Capabilities. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.1.144 LTR Max Snoop and No-Snoop Latency Register

This register indicates Latency scale and vlaue for Max Snoop and No-Snoop.

LTR_LATENCY_REG Offset address: $000416C_H$

LTR Max Snoop and No-Snoop Latency Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
MAX_SNOOP_LAT	9:0	rw	**Max Snoop Latency Value** Along with the Max Snoop LatencyScale field,this register specifies the maximum snoop latency that a device is permitted to request. Software should set this to the maximum supported latency or less. It is strongly recommended that any updates to this field are reflected in LTR Message(s) sent by the device within 1 ms.
MAX_SNOOP_LAT_SCALE	12:10	rw	**Max Snoop Latency Scale** This register provides a scale for the value contained within the Max Snoop LatencyValue field. Encoding is the same as the LatencyScale fields in the LTR Message. It is strongly recommended that any updates to this field are reflected in LTR Message(s) sent by the device within 1 ms. Hardware operation is undefined if software writes a Not Permitted value to this field.
RSVDP_13	15:13	r	**Reserved for future use**
MAX_NO_SNOOP_LAT	25:16	rw	**Max No-Snoop Latency Value** Along with the Max No-Snoop LatencyScale field, this register specifies the maximum no-snoop latency that a device is permitted to request. Software should set this to the maximum supported latency or less. It is strongly recommended that any updates to this field are reflected in LTR Message(s) sent by the device within 1 ms.
MAX_NO_SNOOP_LAT_SCALE	28:26	rw	**Max No-Snoop Latency Scale** This register provides a scale for the value contained within the Max No-Snoop LatencyValue field. Encoding is the same as the LatencyScale fields in the LTR Message. It is strongly recommended that any updates to this field are reflected in LTR Message(s) sent by the device within 1 ms. Hardware operation is undefined if software writes a Not Permitted value to this field.
RSVDP_29	31:29	r	**Reserved for future use**

19.4.1.145 L1 Substates Extended Capability Header

L1 Substates Extended Capability Header provides capability ID, capability version and next offset value for L1 Substates.

L1SUB_CAP_HEADER_REG Offset address: 0004170_H

L1 Substates Extended Capability Header Kernel Reset value: $1801\ 001E_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

EXTENDED_CAP_ID															
rw															

Field	Bits	Type	Description
EXTENDED_CAP_ID	15:0	rw	**L1SUB Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for L1 PM Substates is 001Eh. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
CAP_VERSION	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. This field is depends on version of the specification. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Capability structure or 000h, if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. The bottom 2 bits of this offset are Reserved and must be implemented as 00b although software must mask them to allow for future uses of these bits. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.1.146 L1 Substates Capability Register

This register provides extended capability of L1 Substates.

L1SUB_CAPABILITY_REG Offset address: 0004174_H

L1 Substates Capability Register Kernel Reset value: $0038\ 0A1F_H$

RSVDP_18	18	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
PWR_ON_VALUE_SUPPORT	23:19	rw	**Port T Power On Value** Along with the Port T_POWER_ON_SCALE field in the L1 PM Substates Capabilities register sets the time (in µs) that this Port requires the port on the opposite side of Link to wait in L1.2.Exit after sampling CLKREQ# asserted before actively driving the interface. The value of Port T_POWER_ON is calculated by multiplying the value in this field by the scale value in the Port T_POWER_ON_SCALE field in the L1 PM Substates Capabilities register. Required for all Ports for which either the PCI-PM L1.2 Supported bit is Set, ASPM L1.2 Supported bit is Set, or both are Set, otherwise this field is of type RsvdP. Note: The access attributes of this field are as follows: • Wire: HWINIT • Dbi: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT|| L1SUB_CAPABILITY_REG.L1_2_PCIPM_SUPPORT ? RWS : RSVDP
RSVDP_24	31:24	r	**Reserved for future use**

19.4.1.147 L1 Substates Control 1 Register

This register Controls that the individual extended capability is enabled ot not.

L1SUB_CONTROL1_REG Offset address: 0004178_H

L1 Substates Control 1 Register Kernel Reset value: $0000\ 0000_H$

r								r				rw	rw	rw	rw

Field	Bits	Type	Description
L1_2_PCIPM_EN	0	rw	**PCI-PM L12 Enable** When Set this field, enables PCI-PM L1.2. For Ports for which the PCI-PM L1.2 Supported bit is clear, this bit is permitted to be hardwired to 0. Required for both Upstream and Downstream Ports. For compatibility with possible future extensions, software must not enable L1 PM Substates unless the L1 PM Substates Supported field in the L1 PM Substates Capabilities Register is Set.
L1_1_PCIPM_EN	1	rw	**PCI-PM L11 Enable** When Set this field, enables PCI-PM L1.1. Required for both Upstream and Downstream Ports. For compatibility with possible future extensions, software must not enable L1 PM Substates unless the L1 PM Substates Supported field in the L1 PM Substates Capabilities Register is Set.

(table continues...)

(continued)

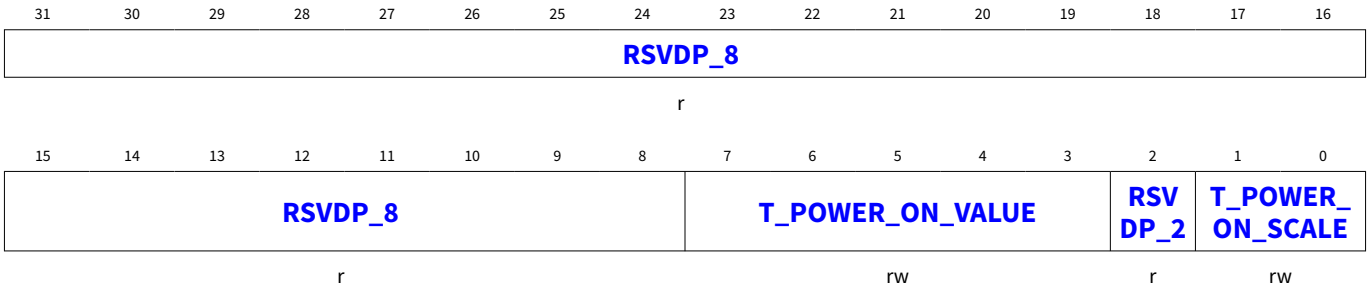
Field	Bits	Type	Description
L1_2_ASPM_EN	2	rw	**ASPM L12 Enable** When Set this field, enables ASPM L1.2. For Ports for which the ASPM L1.2 Supported bit is clear, this bit is permitted to be hardwired to 0. Required for both Upstream and Downstream Ports. For compatibility with possible future extensions, software must not enable L1 PM Substates unless the L1 PM Substates Supported field in the L1 PM Substates Capabilities Register is Set.
L1_1_ASPM_EN	3	rw	**ASPM L11 Enable** When Set this field, enables ASPM L1.1. For Ports for which the ASPM L1.1 Supported bit is clear, this bit is permitted to be hardwired to 0. Required for both Upstream and Downstream Ports. For compatibility with possible future extensions, software must not enable L1 PM Substates unless the L1 PM Substates Supported field in the L1 PM Substates Capabilities Register is Set.
RSVDP_4	7:4	r	**Reserved for future use**
T_COMMON_MODE	15:8	r	**Common Mode Restore Time** Sets value of TCOMMONMODE (in µs), which must be used by the Downstream Ports for timing the re-establishment of common mode. This field is of type RsvdP for Upstream Ports.
L1_2_TH_VAL	25:16	rw	**LTR L12 Threshold Value** Along with the LTR_L1.2_THRESHOLD_Scale, this field indicates the LTR threshold used to determine if entry into L1 results in L1.1 (if enabled) or L1.2 (if enabled). Required for all Ports for which the ASPM L12 Supported bit is Set, otherwise this field is of type RsvdP. Note: The access attributes of this field are as follows • Wire: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT ? RW : RSVDP • Dbi: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT ? RW : RSVDP
RSVDP_26	28:26	r	**Reserved for future use**
L1_2_TH_SCA	31:29	rw	**LTR L12 Threshold Scale** This field provides a scale for the value contained within the LTR_L1.2_THRESHOLD_Value. Hardware operation is undefined if software writes a Not-Permitted value to this field. Required for all Ports Ports for which the ASPM L12 Supported bit is Set, otherwise this field is of type RsvdP. Note: The access attributes of this field are as follows: • Wire: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT ? RW : RSVDP • Dbi: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT ? RW : RSVD

19.4.1.148 L1 Substates Control 2 Register

This register Controls that the individual extended capability is enabled ot not.

L1SUB_CONTROL2_REG Offset address: $000417C_H$

L1 Substates Control 2 Register Kernel Reset value: $0000\ 0028_H$



Field	Bits	Type	Description
T_POWER_ON_SCALE	1:0	rw	**T Power On Scale** Specifies the scale used for T_POWER_ON_VALUE. Range of values are given below. Required for all Ports that support L1.2, otherwise this field is of type RsvdP. This field must only be modified when the ASPM L1.2 Enable and PCI-PM L1.2 Enable bits are both Clear. The Port behavior is undefined if this field is modified when either the ASPM L1.2 Enable and/or PCI-PM L1.2 Enable bit(s) are set. Note: The access attributes of this field are as follows: • Wire: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT|| L1SUB_CAPABILITY_REG.L1_2_PCIPM_SUPPORT ? RSVDP_8	31:8	r	**Reserved for future use**

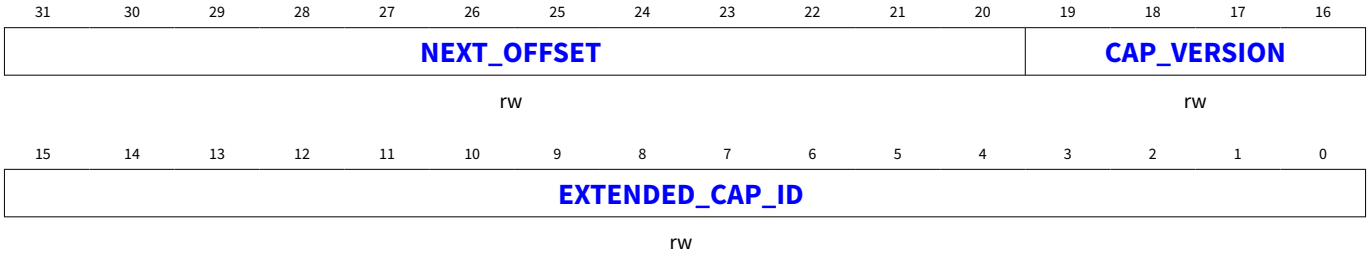
19.4.1.149 Vendor-Specific Extended Capability Header

The Vendor-Specific Extended Capability (VSEC Capability) is an optional Extended Capability that is permitted to be implemented by any PCI Express Function or RCRB. This Register contains Capability Id, Capability Version and Next Offset value for Vendor-Specific Extended Capability.

RAS_DES_CAP_HEADER_REG Offset address: 0004180_H

Vendor-Specific Extended Capability Header Kernel Reset value: $2801\ 000B_H$



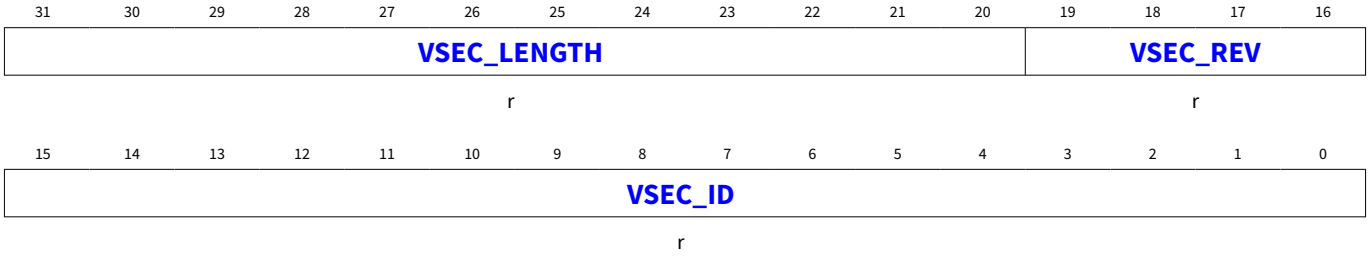
Field	Bits	Type	Description
EXTENDED_CAP_ID	15:0	rw	**PCI Express Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for the Vendor-Specific Extended Capability is 000Bh. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
CAP_VERSION	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Value of this field is depends on the version of the specification. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value

19.4.1.150 Vendor-Specific Header

This Register field provides VSEC Length, VSEC ID and VSEC Rev(Version Number). Vendor-specific software must qualify the associated Vendor ID of the PCI Express Function or RCRB before attempting to interpret the values in the VSEC ID or VSEC Rev fields.

VENDOR_SPECIFIC_HEADER_REG Offset address: 0004184_H

Vendor-Specific Header Kernel Reset value: $1004\ 0002_H$



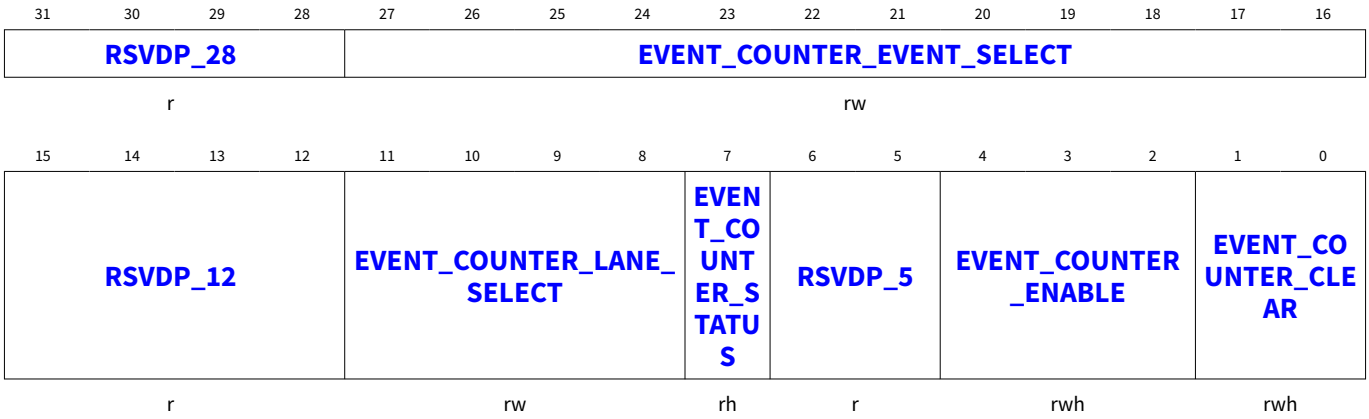
Field	Bits	Type	Description
VSEC_ID	15:0	r	**VSEC ID** This field is a vendor-defined ID number that indicates the nature and format of the VSEC structure. Software must qualify the Vendor ID before interpreting this field. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
VSEC_REV	19:16	r	**VSEC Rev** This field is a vendor-defined version number that indicates the version of the VSEC structure. Software must qualify the Vendor ID and VSEC ID before interpreting this field. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
VSEC_LENGTH	31:20	r	**VSEC Length** This field indicates the number of bytes in the entire VSEC structure, including the Vendor-Specific Extended Capability Header, the Vendor-Specific Header, and the vendor-specific registers. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value

19.4.1.151 Event Counter Control

This is a viewport control register. - Setting the EVENT_COUNTER_EVENT_SELECT and EVENT_COUNTER_LANE_SELECT fields in this register determine the Event Counter data returned by the EVENT_COUNTER_DATA_REG viewport register. - Setting the EVENT_COUNTER_ENABLE field in this register enables the Event Counter selected by the EVENT_COUNTER_EVENT_SELECT and EVENT_COUNTER_LANE_SELECT fields in this register. - Setting the EVENT_COUNTER_CLEAR field in this register clears the Event Counter selected by the EVENT_COUNTER_EVENT_SELECT and EVENT_COUNTER_LANE_SELECT fields in this register. - Reading the EVENT_COUNTER_STATUS field in this register returns the Enable status of the Event Counter selected by the EVENT_COUNTER_EVENT_SELECT and EVENT_COUNTER_LANE_SELECT fields in this register.

EVENT_COUNTER_CONTROL_REG Offset address: 0004188_H

Event Counter Control Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EVENT_COUNTER_CLEAR	1:0	rwh	**Event Counter Clear** Clears the Event Counter selected by the EVENT_COUNTER_EVENT_SELECT and EVENT_COUNTER_LANE_SELECT fields in this register. You can clear the value of a specific Event Counter by writing the 'per clear' code and you can clear all event counters at once by writing the 'all clear' code. The read value is always '0'. Other values are reserved. 00_B **NO_CHANGE**: no change 01_B **PER_CLEAR**: per clear 10_B **NO_CHANGE_2**: no change 11_B **ALL_CLEAR**: all clear
EVENT_COUNTER_ENABLE	4:2	rwh	**Event Counter Enable** Enables/disables the Event Counter selected by the EVENT_COUNTER_EVENT_SELECT and EVENT_COUNTER_LANE_SELECT fields in this register. By default, all event counters are disabled. You can enable/disable a specific Event Counter by writing the 'per event off' or 'per event on' codes. You can enable/disable all event counters by writing the 'all on' or 'all off' codes. The read value is always '0'. For other values no change. 001_B **PER_EVENT_OFF**: per event off 011_B **PER_EVENT_ON**: per event on 101_B **ALL_OFF**: all off 111_B **ALL_ON**: all on
RSVDP_5	6:5	r	**Reserved for future use**
EVENT_COUNTER_STATUS	7	rh	**Event Counter Status** This register returns the current value of the Event Counter selected by the following fields: - EVENT_COUNTER_EVENT_SELECT - EVENT_COUNTER_LANE_SELECT Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Set

(table continues...)

(continued)

Field	Bits	Type	Description
EVENT_COUNTER_LANE_SELECT	11:8	rw	**Event Counter Lane Select** This field in conjunction with EVENT_COUNTER_EVENT_SELECT indexes the Event Counter data returned by the EVENT_COUNTER_DATA_REG register. Note: This register field is sticky. 0_H **MIN_VAL**: Lane0 F_H **MAX_VAL**: Lane15
RSVDP_12	15:12	r	**Reserved for future use**
EVENT_COUNTER_EVENT_SELECT	27:16	rw	**Event Counter Data Select** This field in conjunction with the EVENT_COUNTER_LANE_SELECT field indexes the Event Counter data returned by the EVENT_COUNTER_DATA_REG register • 27-24: Group number(4-bit: 0..0x7) • 23-16: Event number(8-bit: 0..0x13) within the Group Note: This register field is sticky. 000_H **EBUF_OVERFLOW**: Ebuf Overflow 001_H **EBUF_UNDERRUN**: Ebuf Underrun 700_H **TX_MEM_WRITE**: Tx Memory Write 713_H **RX_MSG_TLP**: Rx Message TLP **others,** Reserved
RSVDP_28	31:28	r	**Reserved for future use**

19.4.1.152 Event Counter Data

This viewport register returns the data selected by the following fields: - EVENT_COUNTER_EVENT_SELECT in EVENT_COUNTER_CONTROL_REG - EVENT_COUNTER_LANE_SELECT in EVENT_COUNTER_CONTROL_REG

EVENT_COUNTER_DATA_REG Offset address: $000418C_H$

Event Counter Data Kernel Reset value: $0000\ 0000_H$

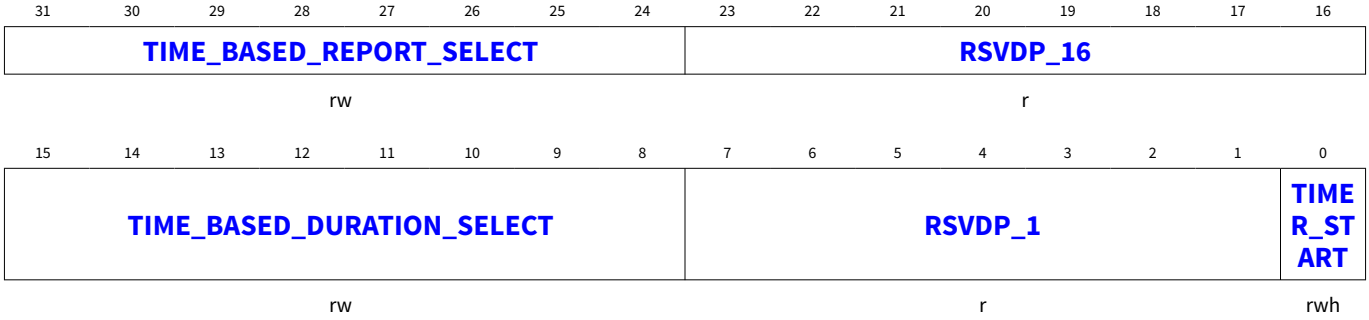
19.4.1.153 Time-based Analysis Control

Used for controlling the measurement of RX/TX data throughput and time spent in each low-power LTSSM state.

TIME_BASED_ANALYSIS_CONTROL_REG Offset address: 0004190_H

Time-based Analysis Control Kernel Reset value: $0000\ 0100_H$



Field	Bits	Type	Description
TIMER_START	0	rwh	**Timer Start** This bit will be cleared automatically when the measurement is finished. Note: This register field is sticky. 0_B **STOP**: Stop 1_B **START_RESTART**: Start/Restart
RSVDP_1	7:1	r	**Reserved for future use**
TIME_BASED_DURATION_SELECT	15:8	rw	**Time-based Duration Select** Selects the duration of time-based analysis. When "manual control" is selected and TIMER_START is set to '1', this analysis never stops until TIMER_STOP is set to '0'. All encodings other than the defined encodings are reserved. Note: This register field is sticky. 00_H **MANUAL**: Manual control 01_H **_1_MS**: 1ms 02_H **_2_MS**: 10ms 03_H **_100_MS**: 100ms 04_H **_1_S**: 1s 05_H **_2_S**: 2s 06_H **_4_S**: 4s FF_H **_4_US**: 4 µs (Debug purpose)
RSVDP_16	23:16	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
TIME_BASED_REPORT_SELECT	31:24	rw	**Time-based Report Select** Selects what type of data is measured for the selected duration (TIME_BASED_DURATION_SELECT), and returned in TIME_BASED_ANALYSIS_DATA. Each type of data is measured using one of three types of units: • Core_clk Cycles for 2.5GT/s, 5.0GT/s, 8.0GT/s. Total time in ps is [Value of TIME_BASED_ANALYSIS_DATA returned when TIME_BASED_REPORT_SELECT=0x00] * TIME_BASED_ANALYSIS_DATA. Values 0x0-0x4 and 0x7-0x8 correspond to Core_clk Cycles for 2.5GT/s, 5.0GT/s, 8.0GT/s. • Aux_clk Cycles. Total time in ps is [Period of platform specific clock] * TIME_BASED_ANALYSIS_DATA. Values 0x5, 0x6, and 0x9 correspond to aux_clk Cycles • Data Bytes. Actual amount of bytes is 16 * TIME_BASED_ANALYSIS_DATA. Values 0x20-0x23 correspond to data bytes All encodings other than the defined encodings are reserved. Note: This register field is sticky. 00_H **ONE_CYCLE**: Duration of 1 cycle 01_H **TX_L0S**: TxL0s 02_H **RX_L0S**: RxL0s 03_H **L0**: L0 04_H **L1**: L1 05_H **L1_1**: L1.1 06_H **L1_2**: L1.2 07_H **CFG_RCVRY**: Configuration/Recovery 08_H **TX_RX_L0S**: TxL0s and RxL0s 09_H **L1_AUX**: L1 aux 20_H **TX_PCIE_TLP**: Tx PCIe TLP data payload Bytes 21_H **RX_PCIE_TLP**: Rx PCIe TLP data payload Bytes 22_H **TX_CCIX_TLP**: Tx CCIX TLP data payload Bytes 23_H **RX_CCIX_TLP**: Rx CCIX TLP data payload Bytes **others,** Reserved

19.4.1.154 Time-based Analysis Data

Contains the measurement results of RX/TX data throughput and time spent in each low-power LTSSM state. This viewport register returns the data selected by the TIME_BASED_REPORT_SELECT field in TIME_BASED_ANALYSIS_CONTROL_REG.

TIME_BASED_ANALYSIS_DATA_REG Offset address: 0004194_H

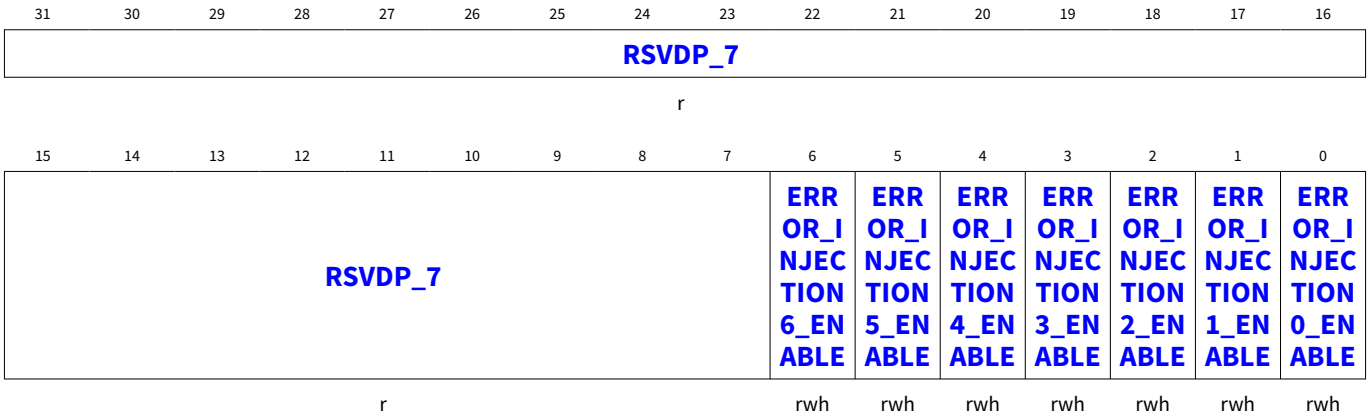
19.4.1.156 Error Injection Enable

Each type of error insertion is enabled by the corresponding bit in this register. The specific injection controls for each type of error are defined in the following registers: - 0: CRC Error: EINJ0_CRC_REG - 1: Sequence Number Error: EINJ1_SEQNUM_REG - 2: DLLP Error: EINJ2_DLLP_REG - 3: Symbol DataK Mask Error or Sync Header Error: EINJ3_SYMBOL_REG - 4: FC Credit Update Error: EINJ4_FC_REG - 5: TLP Duplicate/Nullify Error: EINJ5_SP_TLP_REG - 6: Specific TLP Error: EINJ6_COMPARE_*_REG/EINJ6_CHANGE_*_REG/EINJ6_TLP_REG After the errors have been inserted by controller, it will clear each bit here.

EINJ_ENABLE_REG Offset address: $00041B0_H$

Error Injection Enable Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ERROR_INJECTION0_ENABLE	0	rwh	**Error Injection0 Enable (CRC Error)** Enables insertion of errors into various CRC. For more details, see the EINJ0_CRC_REG register. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
ERROR_INJECTION1_ENABLE	1	rwh	**Error Injection1 Enable (Sequence Number Error)** Enables insertion of errors into sequence numbers. For more details, see the EINJ1_SEQNUM_REG register. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
ERROR_INJECTION2_ENABLE	2	rwh	**Error Injection2 Enable (DLLP Error)** Enables insertion of DLLP errors. For more details, see the EINJ2_DLLP_REG register. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
ERROR_INJECTION3_ENABLE	3	rwh	**Error Injection3 Enable (Symbol DataK Mask Error or Sync Header Error)** Enables DataK masking of special symbols or the breaking of the sync header. For more details, see the EINJ3_SYMBOL_REG register. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
ERROR_INJECTION4_ENABLE	4	rwh	**Error Injection4 Enable (FC Credit Update Error)** Enables insertion of errors into UpdateFCs. For more details, see the EINJ4_FC_REG register. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
ERROR_INJECTION5_ENABLE	5	rwh	**Error Injection5 Enable (TLP Duplicate/Nullify Error)** Enables insertion of duplicate/nullified TLPs. For more details, see the EINJ5_SP_TLP_REG register. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable

(table continues...)

(continued)

Field	Bits	Type	Description
ERROR_INJECTION6_ENABLE	6	rwh	**Error Injection6 Enable (Specific TLP Error)** Enables insertion of errors into the packets that you select. For more details, see the EINJ6_COMPARE_*_REG/EINJ6_CHANGE_*_REG/ EINJ6_TLP_REG registers. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
RSVDP_7	31:7	r	**Reserved for future use**

19.4.1.157 Error Injection Control 0 (CRC Error)

Controls the insertion of errors into the CRC, and parity of ordered sets for the selected type of the packets as follows: - LCRC. Bad TLP will be detected at the receiver side; receiver responds with NAK DLLP; Data Link Retry starts. - 16-bit CRC of ACK/NAK DLLPs. Bad DLLP occurs at the receiver side; Replay NUM Rollover occurs. - 16-bit CRC of UpdateFC DLLPs. Error insertion continues for the specific time; LTSSM transitions to the Recovery state because of the UpdateFC timeout (if the timeout is implemented at the receiver of the UpdateFCs). - ECRC. If ECRC check is enabled, ECRC error is detected at the receiver side. - FCRC. Framing error will be detected, TLP is discarded, and the LTSSM transitions to Recovery state. - Parity of TSOS. Error insertion continues for the specific time; LTSSM Recovery/Configuration timeout will occur. - Parity of SKPOS. Lane error will be detected at the receiver side.

EINJ0_CRC_REG Offset address: $00041B4_H$

Error Injection Control 0 [CRC Error) Kernel Reset value: $0000\ 0000_H$

RSVDP_12				EINJ0_CRC_TYPE				EINJ0_COUNT							
r				rw				rwh							

Field	Bits	Type	Description
EINJ0_COUNT	7:0	rwh	**Error injection count** Indicates the number of errors. This register is decremented when the errors have been inserted. - If the counter value is 0x01 and error is inserted, ERROR_INJECTION0_ENABLE in EINJ_ENABLE_REG returns 0b. - If the counter value is 0x00 and ERROR_INJECTION0_ENABLE=1, the errors are inserted until ERROR_INJECTION0_ENABLE is set to '0'. Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
EINJ0_CRC_TYPE	11:8	rw	**Error injection type** Selects the type of CRC error to be inserted. All encodings other than the defined encodings are reserved. Note: This register field is sticky. 0_H **TLP_LCRC_ERR**: (TX Path) New TLP's LCRC error injection 1_H **_16b_CRC_ERR_ACK_NAK_DLLP**: (TX Path) 16bCRC error injection of ACK/NAK DLLP 2_H **_16b_CRC_ERR_UPD_FC**: (TX Path) 16bCRC error injection of Update-FC DLLP 3_H **TLP_ECRC_ERR**: (TX Path) New TLP's ECRC error injection 4_H **FCRC_ERR_TLP**: (TX Path) TLP's FCRC error injection (128b/130b) 5_H **PARITY_TSOS_ERR**: (TX Path) Parity error of TSOS (128b/130b) 6_H **PARITY_SKPOS_ERR**: (TX Path) Parity error of SKPOS (128b/130b) 8_H **LCRC_ERR**: (RX Path) LCRC error injection B_H **ECRC_ERR**: (RX Path) ECRC error injection **others,** Reserved
RSVDP_12	31:12	r	**Reserved for future use**

19.4.1.158 Error Injection Control 1 (Sequence Number Error).

Controls the sequence number of the specific TLPs and ACK/NAK DLLPs. Data Link Protocol Error will be detected at the Rx side of ACK/NAL DLLPs when one of these conditions is true: - ((NEXT_TRANSMIT_SEQ -1) - AckNak_Seq_Num) mod 4096 > 2048 - (AckNak_Seq_Num - ACKD_SEQ) mod 4096 >= 2048 TLP is treated as Duplicate TLP at the Rx side when all these conditions are true: - Sequence Number != NEXT_RCV_SEQ - (NEXT_RCV_SEQ - Sequence Number) mod 4096 <= 2048 TLP is treated as Bad TLP at the Rx side when all these conditions are true: - Sequence Number != NEXT_RCV_SEQ and - (NEXT_RCV_SEQ - Sequence Number) mod 4096 > 2048

EINJ1_SEQNUM_REG Offset address: $00041B8_H$

Error Injection Control 1 [Sequence Number Error).
 Kernel Reset value: $0000\ 0000_H$

RSVDP_9							EINJ1_SEQNUM_TYPE	EINJ1_COUNT							
r							rw	rwh							

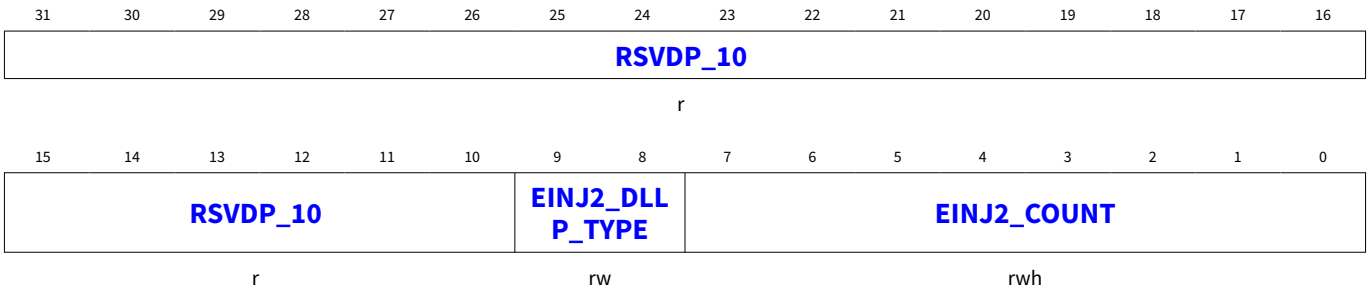
Field	Bits	Type	Description
EINJ1_COUNT	7:0	rwh	**Error injection count** Indicates the number of errors. This register is decremented as the errors are being inserted. - If the counter value is 0x01 and error is inserted, ERROR_INJECTION1_ENABLE in EINJ_ENABLE_REG returns '0'. - If the counter value is 0x00 and ERROR_INJECTION1_ENABLE=1, the errors are inserted until ERROR_INJECTION1_ENABLE is set to '0'. Note: This register field is sticky.
EINJ1_SEQNUM_TYPE	8	rw	**Sequence number type** Selects the type of sequence number. Note: This register field is sticky. 0_B **TLP_ERR**: Insertion of New TLP's SEQ# error 1_B **ACK_NAK_DLLP_ERR**: Insertion of ACK/NAK DLLP's SEQ# Error
RSVDP_9	15:9	r	**Reserved for future use**
EINJ1_BAD_SEQNUM	28:16	rw	**Bad sequence number** Indicates the value to add/subtract from the naturally-assigned sequence numbers. This value is represented by two's complement. For example: - Set Type, SEQ# and Count -- EINJ1_SEQNUM_TYPE =0 (Insert errors into new TLPs) -- EINJ1_BAD_SEQNUM =0x1FFD (represents -3) -- EINJ1_COUNT =1 - Enable Error Injection -- ERROR_INJECTION1_ENABLE =1 - Send a TLP From the Core's Application Interface -- Assume SEQ#5 is given to the TLP. - The SEQ# is Changed to #2 by the Error Injection Function in Layer2. -- 5 + (-3) = 2 - The TLP with SEQ#2 is Transmitted to PCIe Link. Note: This register field is sticky. $0FFF_H$ **MAX_VAL**: +4095 1001_H **MIN_VAL**: -4095 **others,** Reserved
RSVDP_29	31:29	r	**Reserved for future use**

19.4.1.159 Error Injection Control 2 (DLLP Error)

Controls the transmission of DLLPs and inserts the following errors: - If "ACK/NAK DLLP's transmission block" is selected, replay timeout error will occur at the transmitter of the TLPs and then Data Link Retry will occur. - If "Update FC DLLP's transmission block" is selected, LTSSM will transition to the Recovery state because of the UpdateFC timeout (if the timeout is implemented at the receiver of the UpdateFCs). - If "Always Transmission for NAK DLLP" is selected, Data Link Retry will occur at the transmitter of the TLPs. Furthermore, Replay NUM Rollover will occur when the transmitter has been requested four times to send the TLP with the same sequence number.

EINJ2_DLLP_REG Offset address: $00041BC_H$

Error Injection Control 2 [DLLP Error) Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EINJ2_COUNT	7:0	rwh	**Error injection count** Indicates the number of errors. This register is decremented as the errors are being inserted. - If the counter value is 0x01 and the error is inserted, ERROR_INJECTION2_ENABLE in EINJ_ENABLE_REG returns '0'. - If the counter value is 0x00 and ERROR_INJECTION2_ENABLE =1, the errors are inserted until ERROR_INJECTION2_ENABLE is set to '0'. This register is affected only when EINJ2_DLLP_TYPE =2'10b. Note: This register field is sticky.
EINJ2_DLLP_TYPE	9:8	rw	**DLLP Type** Selects the type of DLLP errors to be inserted. Note: This register field is sticky. 00_B **ACK_NACK_DLLP**: ACK/NAK DLLP's transmission block 01_B **UPD_FC_DLLP**: Update FC DLLP's transmission block 10_B **NAK_DLLP**: Always Transmission for NAK DLLP 11_B **RSVD**: Reserved
RSVDP_10	31:10	r	**Reserved for future use**

19.4.1.160 Error Injection Control 3 (Symbol Error)

When 8b/10b encoding is used, this register controls error insertion into the special (K code) symbols. - If TS1/TS2/FTS/E-Idle/SKP is selected, it affects whole of the ordered set. It might cause timeout of the LTSSM. - If END/EDB/STP/SDP is selected, TLP/DLLP will be discarded at the receiver side. When 128b/130b encoding is used, this register controls error insertion into the sync-header.

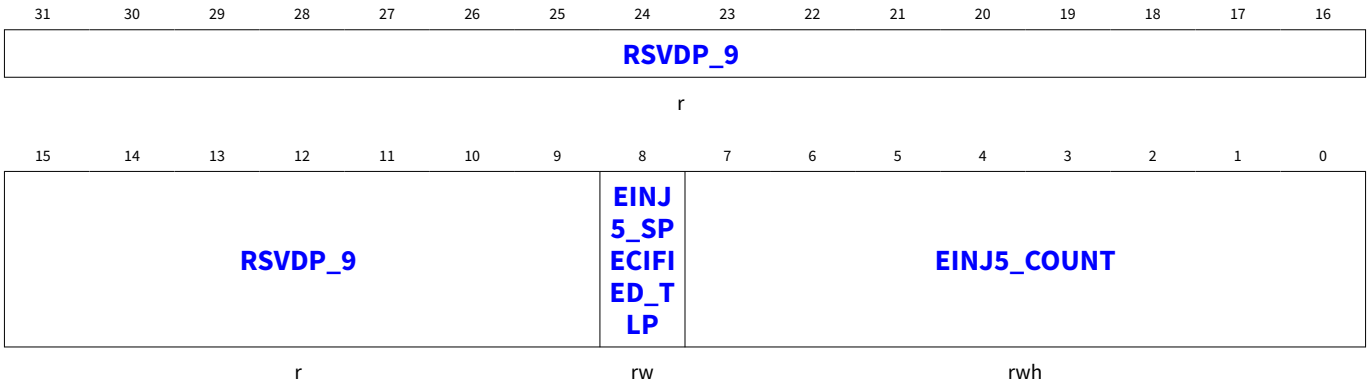
19.4.1.162 Error Injection Control 5 (Specific TLP Error)

Controls the generation of specified TLPs. Correctable errors will occur which will be fixed by the PCIe protocol. - For Duplicate TLP, the controller initiates Data Link Retry by handling ACK DLLP as NAK DLLP. These TLPs will be duplicate TLPs at the receiver side. - For Nullified TLP, the TLPs that the controller transmits are changed into nullified TLPs and the original TLPs are stored in the retry buffer. The receiver of these TLPs will detect the lack of seq# and send NAK DLLP at the next TLP. Then the original TLPs are sent from retry buffer and the data controls are recovered. For 128 bit controller or more than 128 bit, the controller inserts errors the number of times of EINJ5_COUNT but doesn't ensure that the errors are continuously inserted into TLPs.

EINJ5_SP_TLP_REG Offset address: $00041C8_H$

Error Injection Control 5 [Specific TLP Error) Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EINJ5_COUNT	7:0	rwh	**Error injection count** Indicates the number of errors. This register is decremented as the errors are being inserted. - If the counter value is 0x01 and error is inserted, ERROR_INJECTION5_ENABLE in EINJ_ENABLE_REG returns '0'. - If the counter value is 0x00 and ERROR_INJECTION5_ENABLE =1, the errors are inserted until ERROR_INJECTION5_ENABLE is set to '0'. RSVDP_9	31:9	r	**Reserved for future use**

19.4.1.163 Error Injection Control 6 (Compare Point Header DWORD #0) i

Program this register for the 1st DWORD of TLP header/prefix. It is necessary to carefully consider the endianness when you program this register. Bits [31:0] = TLP_DW0[7:0], TLP_DW0[15:8], TLP_DW0[23:16], TLP_DW0[31:24] The Packet Compare Point registers (EINJ6_COMPARE_POINT*) specify which Tx TLP header bits to compare with the corresponding bits in the Packet Compare Value registers (EINJ6_COMPARE_VALUE*). When all specified bits (in the Tx TLP header and EINJ6_COMPARE_VALUE*) match, the controller inserts errors into the TLP. The type and number of errors are specified by the EINJ6_TLP_REG register.

EINJ6_COMPARE_POINT_Hi_REG (i=0-3) Offset address: $00041CC_H+i*4$

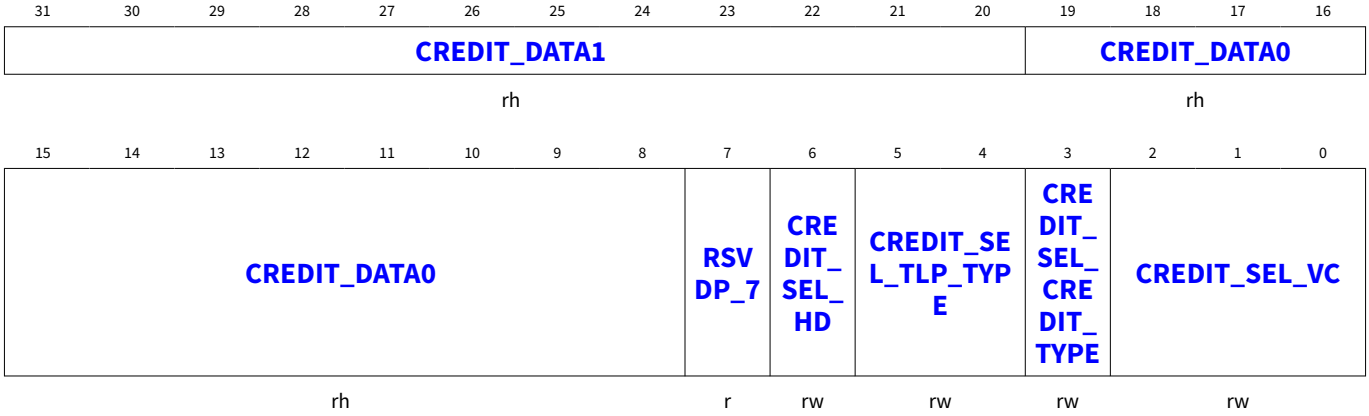
19.4.1.174 Silicon Debug Status(Layer3 FC)

The CREDIT_DATA[0/1] fields in this viewport register return the data for the VC and TLP Type selected by the following fields: - CREDIT_SEL_VC - CREDIT_SEL_CREDIT_TYPE - CREDIT_SEL_TLP_TYPE - CREDIT_SEL_HD

SD_STATUS_L3FC_REG Offset address: 0004240$_H$

Silicon Debug Status[Layer3 FC) Kernel Reset value: 0000 0000$_H$



Field	Bits	Type	Description
CREDIT_SEL_VC	2:0	rw	**Credit Select(VC)** This field in conjunction with the CREDIT_SEL_CREDIT_TYPE, CREDIT_SEL_TLP_TYPE, and CREDIT_SEL_HD viewport-select fields determines that data that is returned by the CREDIT_DATA0 and CREDIT_DATA1 data fields. Note: This register field is sticky. 000_B **MIN_VAL**: VC0 111_B **MAX_VAL**: VC7
CREDIT_SEL_CREDIT_TYPE	3	rw	**Credit Select(Credit Type)** This field in conjunction with the CREDIT_SEL_VC, CREDIT_SEL_TLP_TYPE, and CREDIT_SEL_HD viewport-select fields determines that data that is returned by the CREDIT_DATA0 and CREDIT_DATA1 data fields. Note: This register field is sticky. 0_B **RX**: Rx 1_B **TX**: Tx
CREDIT_SEL_TLP_TYPE	5:4	rw	**Credit Select(TLP Type)** This field in conjunction with the CREDIT_SEL_VC, CREDIT_SEL_CREDIT_TYPE, and CREDIT_SEL_HD viewport-select fields determines that data that is returned by the CREDIT_DATA0 and CREDIT_DATA1 data fields. Note: This register field is sticky. 00_B **POSTED**: Posted 01_B **NON_POSTED**: Non-Posted 10_B **COMPLETION**: Completion **others,** Reserved
CREDIT_SEL_HD	6	rw	**Credit Select(HeaderData)** This field in conjunction with the CREDIT_SEL_VC, CREDIT_SEL_CREDIT_TYPE, and CREDIT_SEL_TLP_TYPE viewport-select fields determines that data that is returned by the CREDIT_DATA0 and CREDIT_DATA1 data fields. Note: This register field is sticky. 0_B **HEADER_CREDIT**: Header Credit 1_B **DATA_CREDIT**: Data Credit
RSVDP_7	7	r	**Reserved for future use**

(table continues...)

(continued)

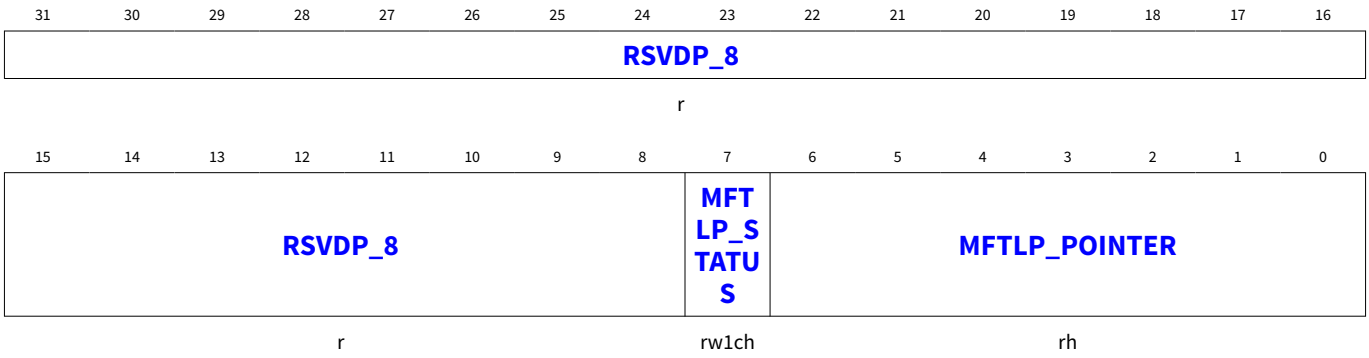
Field	Bits	Type	Description
CREDIT_DATA0	19:8	rh	**Credit Data0** Current FC credit data selected by the CREDIT_SEL_VC, CREDIT_SEL_CREDIT_TYPE, CREDIT_SEL_TLP_TYPE, and CREDIT_SEL_HD viewport-select fields. - Rx: Credit Received Value - Tx: Credit Consumed Value Note: This register field is sticky.
CREDIT_DATA1	31:20	rh	**Credit Data1** Current FC credit data selected by the CREDIT_SEL_VC, CREDIT_SEL_CREDIT_TYPE, CREDIT_SEL_TLP_TYPE, and CREDIT_SEL_HD viewport-select fields. - Rx: Credit Allocated Value - Tx: Credit Limit Value. This value is valid when DLCMSM=0x3(DL_ACTIVE). Note: This register field is sticky.

19.4.1.175 Silicon Debug Status(Layer3)

Silicon Debug Status(Layer3).

SD_STATUS_L3_REG Offset address: 0004244_H

Silicon Debug Status[Layer3] Kernel Reset value: $0000\ 0000_H$



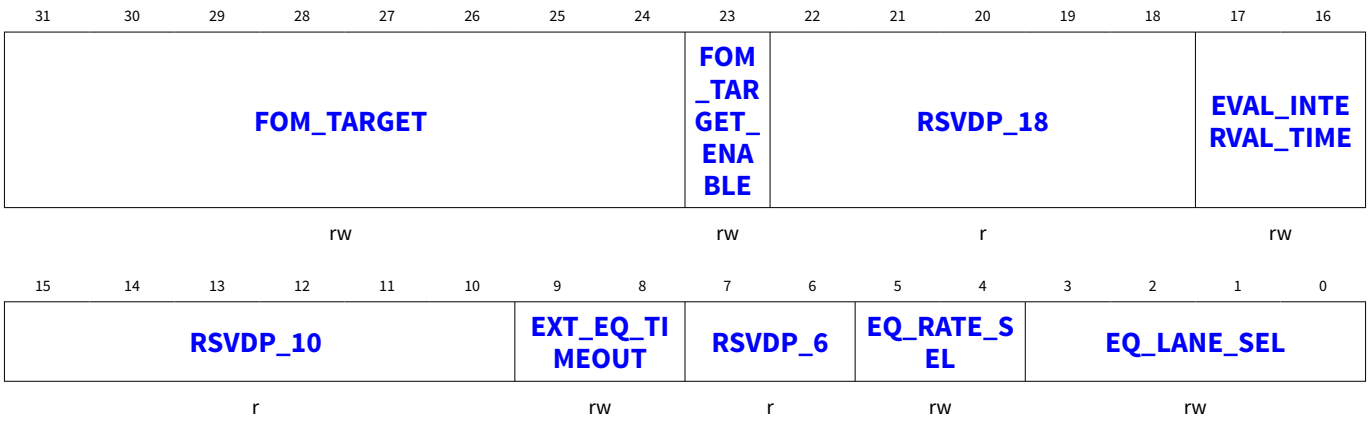
Field	Bits	Type	Description
MFTLP_POINTER	6:0	rh	**First Malformed TLP Error Pointer** Indicates the element of the received first malformed TLP. This pointer is validated by MFTLP_STATUS. All encodings other than the defined encodings are reserved. Note: This register field is sticky. 01_H **ATMC_OP_ALIGN**: AtomicOp address alignment 02_H **ATMC_OP_OPERAND**: AtomicOp operand 03_H **ATMC_OP_BYTE_EN**: AtomicOp byte enable 04_H **TLP_LENGTH_MISMATCH**: TLP length miss match 05_H **MAX_PAYLOAD_SIZE**: Max payload size 06_H **TLP_WITHOUT_TC0**: Message TLP without TC0 07_H **INVALID_TC**: Invalid TC 08_H **UNXPCTD_ROUTE_BIT_MSG_TLP**: Unexpected route bit in Message TLP 09_H **UNXPCTD_CRS_STATUS_CMPL_TLP**: Unexpected CRS status in Completion TLP $0A_H$ **BYTE_ENABLE**: Byte enable $0B_H$ **MEM_ADDR_4KB_BOUNDARY**: Memory Address 4KB boundary $0C_H$ **TLP_PREFIX_RULES**: TLP prefix rules $0D_H$ **TRANSLATION_RULES**: Translation request rules $0E_H$ **INVALID_TLP_TYPE**: Invalid TLP type $0F_H$ **CMPL_RULES**: Completion rules $7F_H$ **APPLICATION**: Application
MFTLP_STATUS	7	rw1ch	**Malformed TLP Status** Indicates malformed TLP has occurred. Note: This register field is sticky. Software write with 1 clears this bit-field.
RSVDP_8	31:8	r	**Reserved for future use**

19.4.1.176 Silicon Debug EQ Control 1

This is a viewport control register. Setting the EQ_RATE_SEL and EQ_LANE_SEL fields in this register determine the per-lane Silicon Debug EQ Status data returned by the SD_EQ_STATUS[1/2/3] viewport registers.

SD_EQ_CONTROL1_REG Offset address: 0004250_H

Silicon Debug EQ Control 1 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EQ_LANE_SEL	3:0	rw	**EQ Status Lane Select** Setting this field in conjunction with the EQ_RATE_SEL field determines the per-lane Silicon Debug EQ Status data returned by the SD_EQ_CONTROL[2/3] and SD_EQ_STATUS[1/2/3] viewport registers. Note: This register field is sticky. 0_H **MIN_VAL**: Lane0 F_H **MAX_VAL**: Lane15
EQ_RATE_SEL	5:4	rw	**EQ Status Rate Select** Setting this field in conjunction with the EQ_LANE_SEL field determines the per-lane Silicon Debug EQ Status data returned by the SD_EQ_CONTROL[2/3] and SD_EQ_STATUS[1/2/3] viewport registers. Note: This register field is sticky. 00_B **_8GT**: 8.0GT/s Speed (include ESM data rate) 01_B **_16GT**: 16.0GT/s Speed (include ESM data rate) 10_B **_32GT**: 32.0GT/s Speed **others,** Reserved
RSVDP_6	7:6	r	**Reserved for future use**
EXT_EQ_TIMEOUT	9:8	rw	**Extends EQ Phase2/3 Timeout** This field is used when the LTSSM is in Recovery.EQ2/3. When this field is set, the value of EQ2/3 timeout is extended. Note: This register field is sticky. 00_B **_24MS_OR_32MS**: [EQ Master(DSP in EQ Phase3/USP in EQ Phase2)] 24ms (default) or [EQ Slave(DSP in EQ Phase2/USP in EQ Phase3)] 32ms (default) 01_B **_48MS_OR_56MS**: [EQ Master(DSP in EQ Phase3/USP in EQ Phase2)] 48ms (x2) or [EQ Slave(DSP in EQ Phase2/USP in EQ Phase3)] 56ms (32ms+24ms) 10_B **_240MS_OR_248MS**: [EQ Master(DSP in EQ Phase3/USP in EQ Phase2)] 240ms (x10) or [EQ Slave(DSP in EQ Phase2/USP in EQ Phase3)] 248ms (32ms +9*24ms) 11_B **NO_TIMEOUT**: [EQ Master(DSP in EQ Phase3/USP in EQ Phase2)] No timeout or [EQ Slave(DSP in EQ Phase2/USP in EQ Phase3)] No timeout
RSVDP_10	15:10	r	**Reserved for future use**
EVAL_INTERVAL_TIME	17:16	rw	**Eval Interval Time** Indicates interval time of RxEqEval assertion. This field is used for EQ Master(DSP in EQ Phase3/USP in EQ Phase2). Note: This register field is sticky. 00_B **_500NS**: 500 ns 01_B **_1US**: 1 µs 10_B **_2US**: 2 µs 11_B **_4US**: 4 µs
RSVDP_18	22:18	r	**Reserved for future use**
FOM_TARGET_ENABLE	23	rw	**FOM Target Enable** Enables the FOM_TARGET fields. Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
FOM_TARGET	31:24	rw	**FOM Target** Indicates figure of merit target criteria value of EQ Master(DSP in EQ Phase3/USP in EQ Phase2). This field is only valid when GEN3_EQ_FB_MODE is 0001b(Figure Of Merit). Note: This register field is sticky.

19.4.1.177 Silicon Debug EQ Control 2

This viewport register returns the value for the rate and lane selected by the EQ_RATE_SEL and EQ_LANE_SEL fields in the SD_EQ_CONTROL1_REG register.

SD_EQ_CONTROL2_REG Offset address: 0004254_H

Silicon Debug EQ Control 2 Kernel Reset value: $0000\ 0000_H$

r								rh	rh	rh	rh	r	rh		rh

Field	Bits	Type	Description
EQ_SEQUENCE	0	rh	**EQ Sequence** Indicates that the controller is starting the equalization sequence. Note: This register field is sticky.

(table continues...)

(continued)

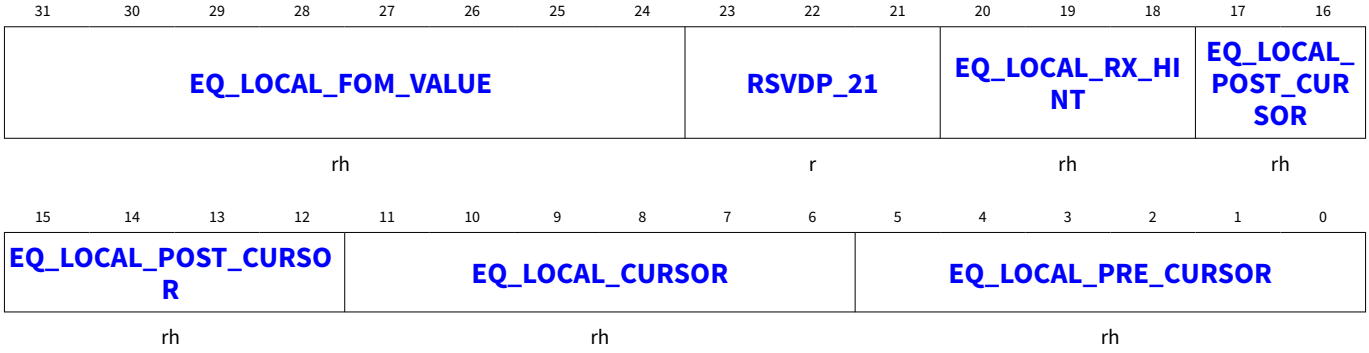
Field	Bits	Type	Description
EQ_CONVERGENCE_INFO	2:1	rh	**EQ Convergence Info** Indicates equalization convergence information. This bit is automatically cleared when the controller starts EQ Master phase again. Note: This register field is sticky. 00_B **EQ_NOT_ATTEMPTED**: Equalization is not attempted 01_B **EQ_SUCCESSFUL**: Equalization finished successfully 10_B **EQ_UNSUCCESSFUL**: Equalization finished unsuccessfully 11_B **RSVD**: Reserved
RSVDP_3	3	r	**Reserved for future use**
EQ_RULEA_VIOLATION	4	rh	**EQ Rule A Violation** Indicates that coefficients rule A violation is detected in the values provided by PHY using direction change method during EQ Master phase(DSP in EQ Phase3/USP in EQ Phase2). The coefficients rules A correspond to the rules a) from section "Rules for Transmitter Coefficents" in the PCI Express Base Specification. This bit is automatically cleared when the controller starts EQ Master phase again. Note: This register field is sticky.
EQ_RULEB_VIOLATION	5	rh	**EQ Rule B Violation** Indicates that coefficients rule B violation is detected in the values provided by PHY using direction change method during EQ Master phase(DSP in EQ Phase3/USP in EQ Phase2). The coefficients rules B correspond to the rules b) from section "Rules for Transmitter Coefficents" in the PCI Express Base Specification. This bit is automatically cleared when the controller starts EQ Master phase again. Note: This register field is sticky.
EQ_RULEC_VIOLATION	6	rh	**EQ Rule C Violation** Indicates that coefficients rule C violation is detected in the values provided by PHY using direction change method during EQ Master phase(DSP in EQ Phase3/USP in EQ Phase2). The coefficients rule C correspond to the rules c) from section "Rules for Transmitter Coefficents" in the PCI Express Base Specification. This bit is automatically cleared when the controller starts EQ Master phase again. Note: This register field is sticky.
EQ_REJECT_EVENT	7	rh	**EQ Reject Event** Indicates that the controller receives two consecutive TS1 OS w/ Reject=1b during EQ Master phase(DSP in EQ Phase3/USP in EQ Phase2). This bit is automatically cleared when the controller starts EQ Master phase again. Note: This register field is sticky.
RSVDP_8	31:8	r	**Reserved for future use**

19.4.1.180 Silicon Debug EQ Status 2

This viewport register returns the second of three words of Silicon Debug EQ Status data for the rate and lane selected by the EQ_RATE_SEL and EQ_LANE_SEL fields in the SD_EQ_CONTROL1_REG register. Each field is available when Equalization finished successfully(EQ_CONVERGENCE_INFO=1).

SD_EQ_STATUS2_REG Offset address: 0004264_H

Silicon Debug EQ Status 2 Kernel Reset value: $0000\ 0000_H$



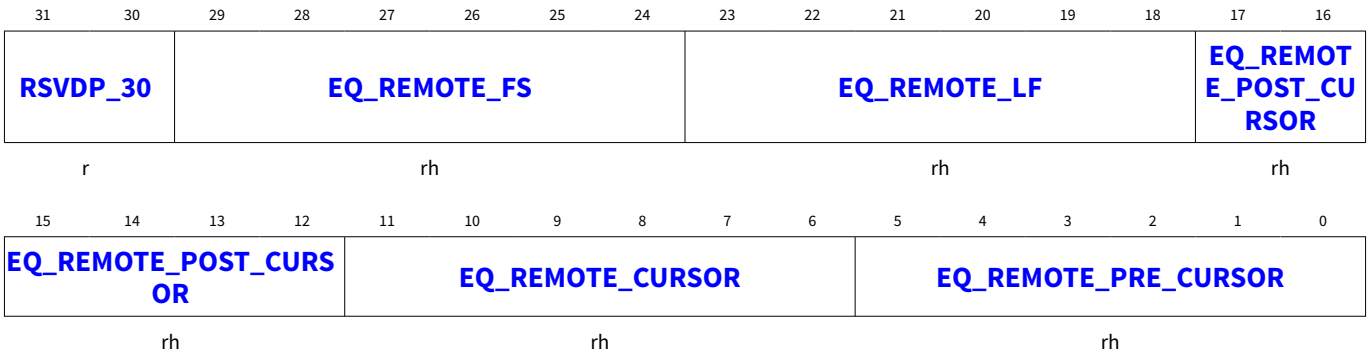
Field	Bits	Type	Description
EQ_LOCAL_PRE_CURSOR	5:0	rh	**EQ Local Pre-Cursor** Indicates Local pre cursor coefficient value. Note: This register field is sticky.
EQ_LOCAL_CURSOR	11:6	rh	**EQ Local Cursor** Indicates Local cursor coefficient value. Note: This register field is sticky.
EQ_LOCAL_POST_CURSOR	17:12	rh	**EQ Local Post-Cursor** Indicates Local post cursor coefficient value. Note: This register field is sticky.
EQ_LOCAL_RX_HINT	20:18	rh	**EQ Local Receiver Preset Hint** Indicates Local Receiver Preset Hint value. If select rate in the EQ_RATE_SEL field is other than 8.0GT/s Speed, this feature is not available. Note: This register field is sticky.
RSVDP_21	23:21	r	**Reserved for future use**
EQ_LOCAL_FOM_VALUE	31:24	rh	**EQ Local Figure of Merit** Indicates Local maximum Figure of Merit value. Note: This register field is sticky.

19.4.1.181 Silicon Debug EQ Status 3

This viewport register returns the third of three words of Silicon Debug EQ Status data for the rate and lane selected by the EQ_RATE_SEL and EQ_LANE_SEL fields in the SD_EQ_CONTROL1_REG register. Each field is available when Equalization finished successfully(EQ_CONVERGENCE_INFO=1).

SD_EQ_STATUS3_REG Offset address: 0004268_H

Silicon Debug EQ Status 3 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EQ_REMOTE_PRE_CURSOR	5:0	rh	**EQ Remote Pre-Cursor** Indicates Remote pre cursor coefficient value. Note: This register field is sticky.
EQ_REMOTE_CURSOR	11:6	rh	**EQ Remote Cursor** Indicates Remote cursor coefficient value. Note: This register field is sticky.
EQ_REMOTE_POST_CURSOR	17:12	rh	**EQ Remote Post-Cursor** Indicates Remote post cursor coefficient value. Note: This register field is sticky.
EQ_REMOTE_LF	23:18	rh	**EQ Remote LF** Indicates Remote LF value. Note: This register field is sticky.
EQ_REMOTE_FS	29:24	rh	**EQ Remote FS** Indicates Remote FS value. Note: This register field is sticky.
RSVDP_30	31:30	r	**Reserved for future use**

19.4.1.182 PCIe Extended capability ID, Capability version and Next capability offset

This Register provides capability ID, Capability version, and Next capability offset for PCIe Extended capability stucture.

RASDP_EXT_CAP_HDR_OFF

PCIe Extended capability ID, Capability version and Next capability offset

Offset address: 0004280_H

Kernel Reset value: $2B81\,000B_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NEXT_OFFSET												CAP			
rw												rw			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ID															
rw															

Field	Bits	Type	Description
ID	15:0	rw	**PCI Express Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value

(table continues...)

(continued)

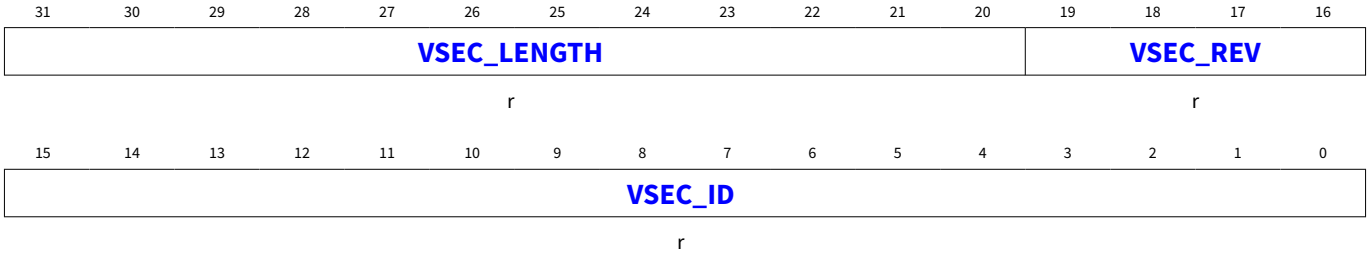
Field	Bits	Type	Description
CAP	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. A version of the specification that changes the Extended Capability in a way that is not otherwise identifiable (e.g., through a new Capability field) is permitted to increment this field. All such changes to the Capability structure must be software-compatible. Software must check for Capability Version numbers that are greater than or equal to the highest number defined when the software is written, as Functions reporting any such Capability Version numbers will contain a Capability structure that is compatible with that piece of software. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. The bottom 2 bits of this offset are Reserved and must be implemented as 00b although software must mask them to allow for future uses of these bits. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value

19.4.1.183 Vendor Specific Header

This Register provides VSEC Length, VSEC ID and VSEC Rev (Version Number). Vendor-specific software must qualify the associated Vendor ID of the PCI Express Function or RCRB before attempting to interpret the values in the VSEC ID or VSEC Rev fields.

RASDP_VENDOR_SPECIFIC_HDR_OFF Offset address: 0004284_H

Vendor Specific Header Kernel Reset value: $0381\ 0001_H$



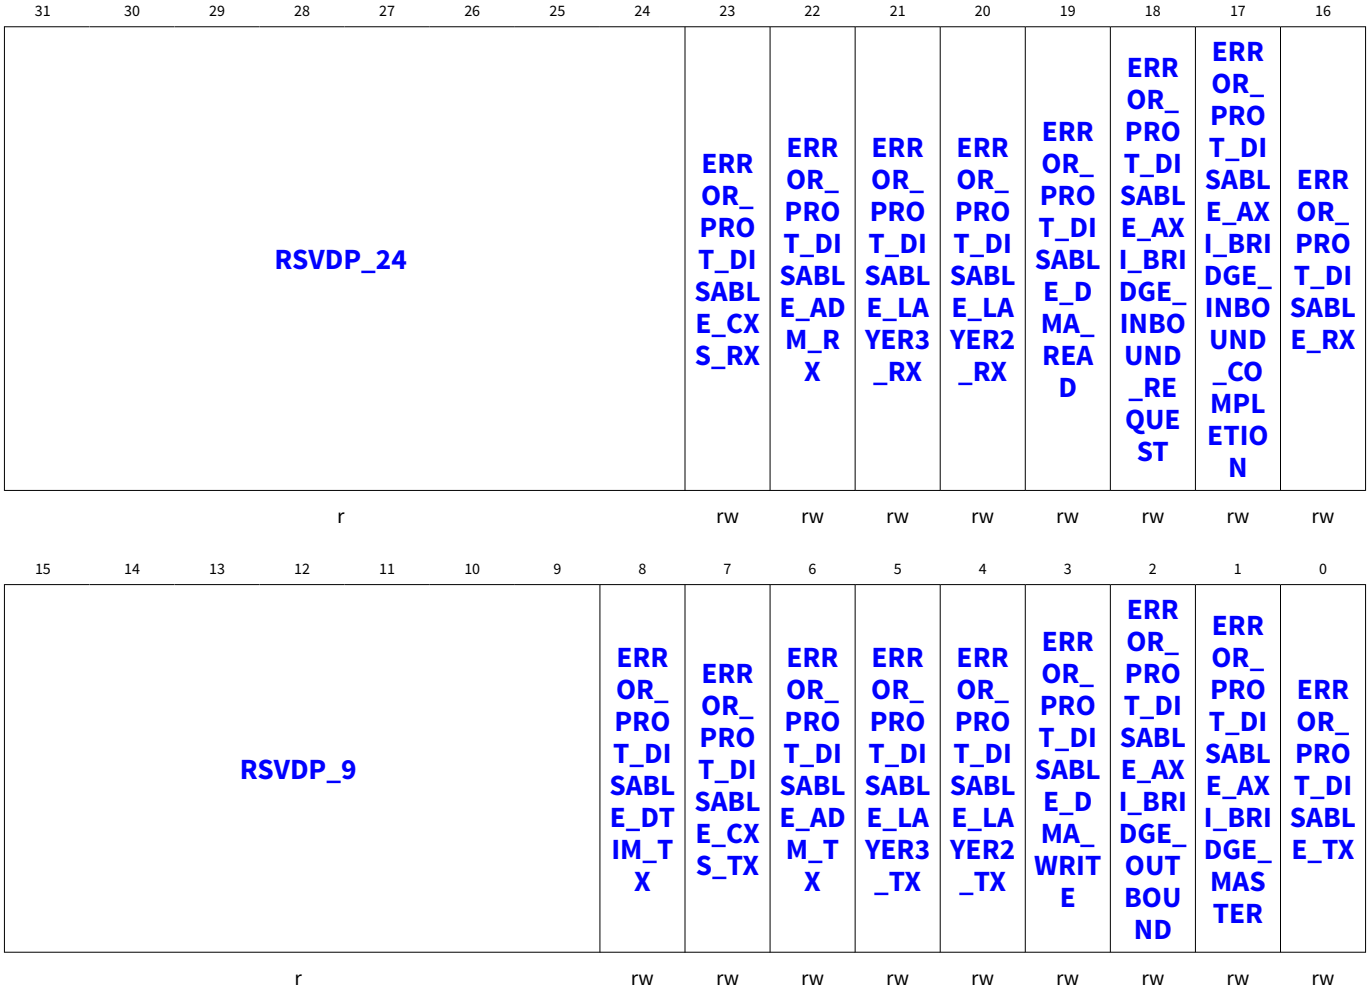
Field	Bits	Type	Description
VSEC_ID	15:0	r	**VSEC ID** This field is a vendor-defined ID number that indicates the nature and format of the VSEC structure. Software must qualify the Vendor ID before interpreting this field. Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
VSEC_REV	19:16	r	**VSEC Rev** This field is a vendor-defined version number that indicates the version of the VSEC structure. Software must qualify the Vendor ID and VSEC ID before interpreting this field. Note: This register field is sticky. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
VSEC_LENGTH	31:20	r	**VSEC Length** This field indicates the number of bytes in the entire VSEC structure, including the Vendor-Specific Extended Capability Header, the Vendor-Specific Header, and the vendor-specific registers. Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value

19.4.1.184 ECC Error Correction and Control Register

Allows you to disable ECC error correction for RAMs and datapath. When the AXI Bridge Module is implemented and the master / slave clocks are asynchronous to the PCIe native controller clock (core_clk), you must not write this register while operations are in progress in the AXI master / slave interface.

RASDP_ERROR_PROT_CTRL_OFF Offset address: 0004288_H

ECC Error Correction and Control Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ERROR_PROT_DISABLE_TX	0	rw	**Global error correction disable for all Tx layers** Does not disable the error detection reporting for 1-bit and 2-bit ECC errors. Note: This register field is sticky.
ERROR_PROT_DISABLE_AXI_BRIDGE_MASTER	1	rw	**Error correction disable for AXI bridge master completion buffer** Note: This register field is sticky.
ERROR_PROT_DISABLE_AXI_BRIDGE_OUTBOUND	2	rw	**Error correction disable for AXI bridge outbound request path** Note: This register field is sticky.
ERROR_PROT_DISABLE_DMA_WRITE	3	rw	**Error correction disable for DMA write engine** Note: This register field is sticky.
ERROR_PROT_DISABLE_LAYER2_TX	4	rw	**Error correction disable for layer 2 Tx path** Note: This register field is sticky.

(table continues...)

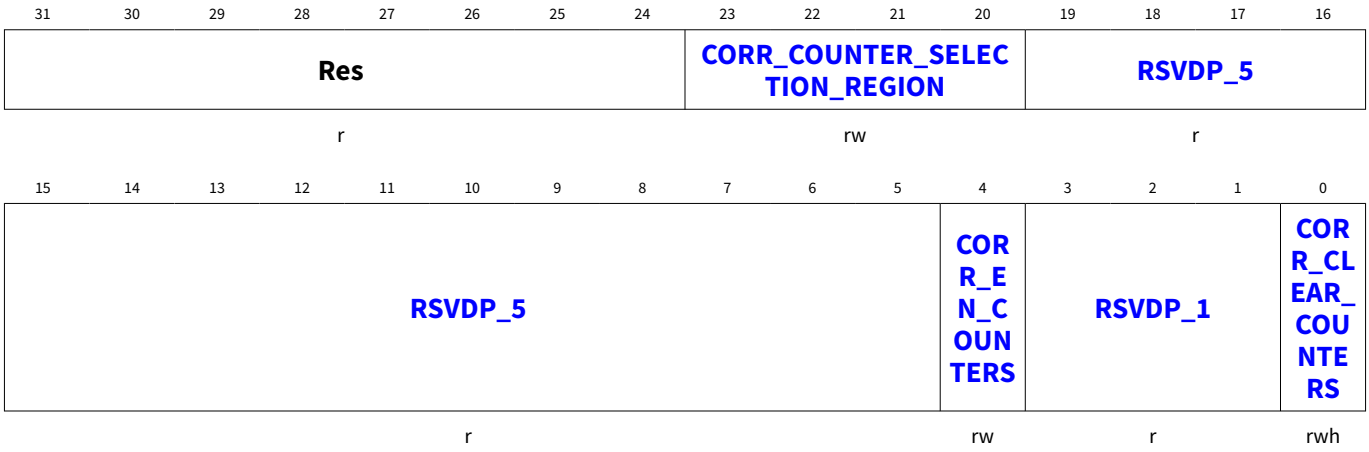
(continued)

Field	Bits	Type	Description
ERROR_PROT_DISABLE_LAYER3_TX	5	rw	**Error correction disable for layer 3 Tx path** Note: This register field is sticky.
ERROR_PROT_DISABLE_ADM_TX	6	rw	**Error correction disable for Adm Tx path** Note: This register field is sticky.
ERROR_PROT_DISABLE_CXS_TX	7	rw	**Error correction disable for CXS Rx path (PCIe Tx path)** Note: This register field is sticky.
ERROR_PROT_DISABLE_DTIM_TX	8	rw	**Error correction disable for DTIM Tx path** Note: This register field is sticky.
RSVDP_9	15:9	r	**Reserved for future use**
ERROR_PROT_DISABLE_RX	16	rw	**Global error correction disable for all Rx layers** Note: This register field is sticky.
ERROR_PROT_DISABLE_AXI_BRIDGE_INBOUND_COMPLETION	17	rw	**Error correction disable for AXI bridge inbound completion composer** Does not disable the error detection reporting for 1-bit and 2-bit ECC errors. Note: This register field is sticky.
ERROR_PROT_DISABLE_AXI_BRIDGE_INBOUND_REQUEST	18	rw	**Error correction disable for AXI bridge inbound request path** Note: This register field is sticky.
ERROR_PROT_DISABLE_DMA_READ	19	rw	**Error correction disable for DMA read engine** Note: This register field is sticky.
ERROR_PROT_DISABLE_LAYER2_RX	20	rw	**Error correction disable for layer 2 Rx path** Note: This register field is sticky.
ERROR_PROT_DISABLE_LAYER3_RX	21	rw	**Error correction disable for layer 3 Rx path** Note: This register field is sticky.
ERROR_PROT_DISABLE_ADM_RX	22	rw	**Error correction disable for ADM Rx path** Note: This register field is sticky.
ERROR_PROT_DISABLE_CXS_RX	23	rw	**Error correction disable for CXS Tx path (PCIe Rx path)** Note: This register field is sticky.
RSVDP_24	31:24	r	**Reserved for future use**

19.4.1.185 Corrected Error (1-bit ECC) Counter Selection and Control Register

This is a viewport control register. Setting the CORR_COUNTER_SELECTION_REGION and CORR_COUNTER_SELECTION fields in this register determine the counter data returned by the RASDP_CORR_COUNT_REPORT_OFF viewport data register.

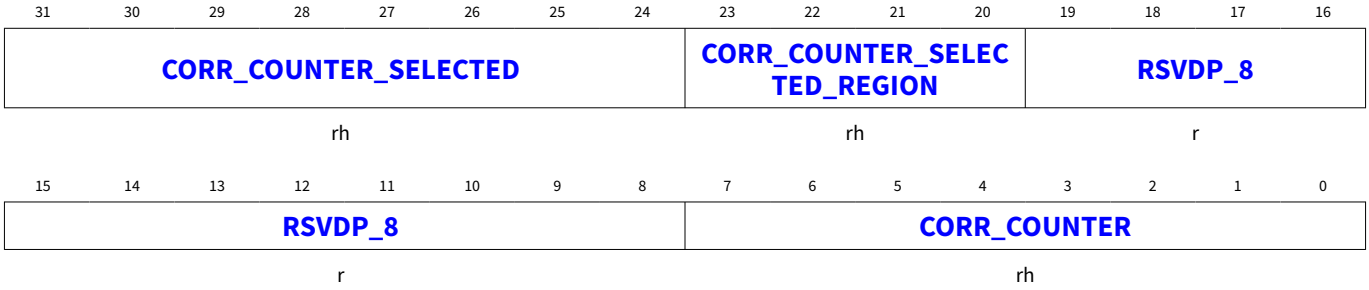
19 Peripheral Component Interconnect Express (PCIe)



Field	Bits	Type	Description
CORR_CLEAR_COUNTERS	0	rwh	**Clear all correctable error counters** Reading register field always returns a '0'.
RSVDP_1	3:1	r	**Reserved for future use**
CORR_EN_COUNTERS	4	rw	**Enable correctable errors counters** The counters are enabled by default. Note: This register field is sticky. 0_B **COUNTER_FROZEN**: Counters are frozen 1_B **COUNTER_EN**: Counters increment when the controller detects a correctable error
RSVDP_5	19:5	r	**Reserved for future use**
CORR_COUNTER_SELECTION_REGION	23:20	rw	**Select correctable counter region** All encodings other than the defined encodings are reserved. Note: This register field is sticky. 0_H **ADM_RX_PATH**: Region select for Adm Rx path 1_H **L3_RX_PATH**: Region select for layer 3 Rx path 2_H **L2_RX_PATH**: Region select for layer 2 Rx path 3_H **DMA_INBOUND_PATH**: Region select for DMA inbound path 4_H **AXI_INBOUND_REQ_PATH**: Region select for AXI bridge inbound request path 5_H **AXI_INBOUND_CMPL_PATH**: Region select for AXI bridge inbound completion composer path 6_H **ADM_TX_PATH**: Region select for Adm Tx path 7_H **L3_TX_PATH**: Region select for layer 3 Tx path 8_H **L2_TX_PATH**: Region select for layer 2 Tx path 9_H **DMA_OUTBOUND_PATH**: Region select for DMA outbound path A_H **AXI_OUTBOUND_REQ_PATH**: Region select for AXI bridge outbound request path B_H **AXI_OUTBOUND_CMPL_PATH**: Region select for AXI bridge outbound master completion buffer path C_H **CXS_TX_RX_PATH**: Region select for CXS Tx/Rx path D_H **DTIM_TX_RX_PATH**: Region select for DTIM Tx/Rx path **others,** Reserved

19.4.1.186 Corrected Error (1-bit ECC) Counter Data Register

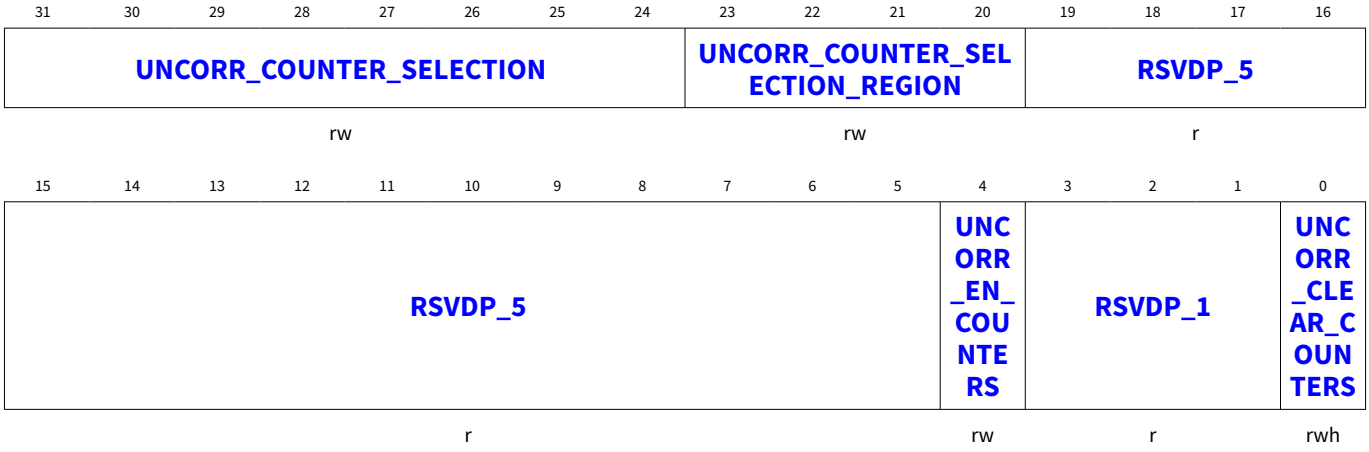
This viewport register returns the counter data selected by the CORR_COUNTER_SELECTION_REGION and CORR_COUNTER_SELECTION fields in the RASDP_CORR_COUNTER_CTRL_OFF register.



Field	Bits	Type	Description
CORR_COUNTER	7:0	rh	**Current corrected error count for the selected counter** Note: This register field is sticky.
RSVDP_8	19:8	r	**Reserved for future use**
CORR_COUNTER_SELECTED_REGION	23:20	rh	**Selected correctable counter region** All encodings other than the defined encodings are reserved. Note: This register field is sticky. 0_H **ADM_RX_PATH**: Region select for Adm Rx path 1_H **L3_RX_PATH**: Region select for layer 3 Rx path 2_H **L2_RX_PATH**: Region select for layer 2 Rx path 3_H **DMA_INBOUND_PATH**: Region select for DMA inbound path 4_H **AXI_INBOUND_REQ_PATH**: Region select for AXI bridge inbound request path 5_H **AXI_INBOUND_CMPL_PATH**: Region select for AXI bridge inbound completion composer path 6_H **ADM_TX_PATH**: Region select for Adm Tx path 7_H **L3_TX_PATH**: Region select for layer 3 Tx path 8_H **L2_TX_PATH**: Region select for layer 2 Tx path 9_H **DMA_OUTBOUND_PATH**: Region select for DMA outbound path A_H **AXI_OUTBOUND_REQ_PATH**: Region select for AXI bridge outbound request path B_H **AXI_OUTBOUND_CMPL_PATH**: Region select for AXI bridge outbound master completion buffer path C_H **CXS_TX_RX_PATH**: Region select for CXS Tx/Rx path D_H **DTIM_TX_RX_PATH**: Region select for DTIM Tx/Rx path **others,** Reserved
CORR_COUNTER_SELECTED	31:24	rh	**Counter selection** Returns the value set in the CORR_COUNTER_SELECTION field of the RASDP_CORR_COUNTER_CTRL_OFF register. Note: This register field is sticky.

19.4.1.187 Uncorrected Error (2-bit ECC and parity) Counter Selection and Control Register

This is a viewport control register. Setting the UNCORR_COUNTER_SELECTION_REGION and UNCORR_COUNTER_SELECTION fields in this register determine the counter data returned by the RASDP_UNCORR_COUNT_REPORT_OFF viewport data register.



Field	Bits	Type	Description
UNCORR_CLEAR_COUNTERS	0	rwh	**Clear uncorrectable errors counters** When asserted causes all counters tracking the uncorrectable errors to be cleared. Reading register field always returns a '0'.
RSVDP_1	3:1	r	**Reserved for future use**
UNCORR_EN_COUNTERS	4	rw	**Enable uncorrectable errors counters** The counters are enabled by default. Note: This register field is sticky. 0_B **COUNTER_FROZEN**: Counters are frozen 1_B **ENABLE_COUNTER**: Enables the counters to increment on detected correctable errors
RSVDP_5	19:5	r	**Reserved for future use**

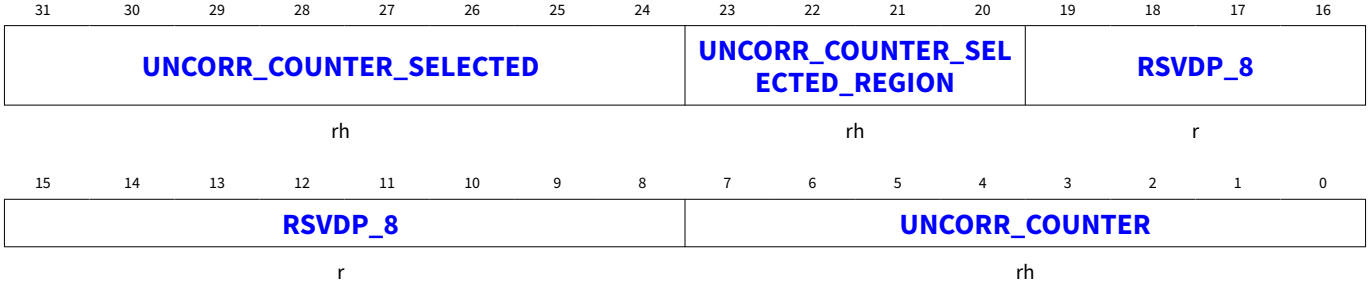
(table continues...)

(continued)

Field	Bits	Type	Description
UNCORR_COUNTER_SELECTION_REGION	23:20	rw	**Select uncorrectable counter region** All encodings other than the defined encodings are reserved. Note: This register field is sticky. 0_H **ADM_RX_PATH**: Region select for Adm Rx path 1_H **L3_RX_PATH**: Region select for layer 3 Rx path 2_H **L2_RX_PATH**: Region select for layer 2 Rx path 3_H **DMA_INBOUND_PATH**: Region select for DMA inbound path 4_H **AXI_INBOUND_REQ_PATH**: Region select for AXI bridge inbound request path 5_H **AXI_INBOUND_CMPL_PATH**: Region select for AXI bridge inbound completion composer path 6_H **ADM_TX_PATH**: Region select for Adm Tx path 7_H **L3_TX_PATH**: Region select for layer 3 Tx path 8_H **L2_TX_PATH**: Region select for layer 2 Tx path 9_H **DMA_OUTBOUND_PATH**: Region select for DMA outbound path A_H **AXI_OUTBOUND_REQ_PATH**: Region select for AXI bridge outbound request path B_H **AXI_OUTBOUND_CMPL_PATH**: Region select for AXI bridge outbound master completion buffer path C_H **CXS_TX_RX_PATH**: Region select for CXS Tx/Rx path D_H **DTIM_TX_RX_PATH**: Region select for DTIM Tx/Rx path **others,** Reserved
UNCORR_COUNTER_SELECTION	31:24	rw	**Counter selection** This field selects the counter ID (within the region defined by UNCORR_COUNTER_SELECTION_REGION) whose contents can be read from the RASDP_UNCORR_COUNT_REPORT_OFF register. You can cycle this field value from 0 to 255 to access all counters according to the detailed report of check points at http://www.synopsys.com/dw/doc.php/iip/DWC_pcie/latest/doc/RASDP_CheckPoints.pdf Note: This register field is sticky.

19.4.1.188 Uncorrected Error (2-bit ECC and parity) Counter Data Register

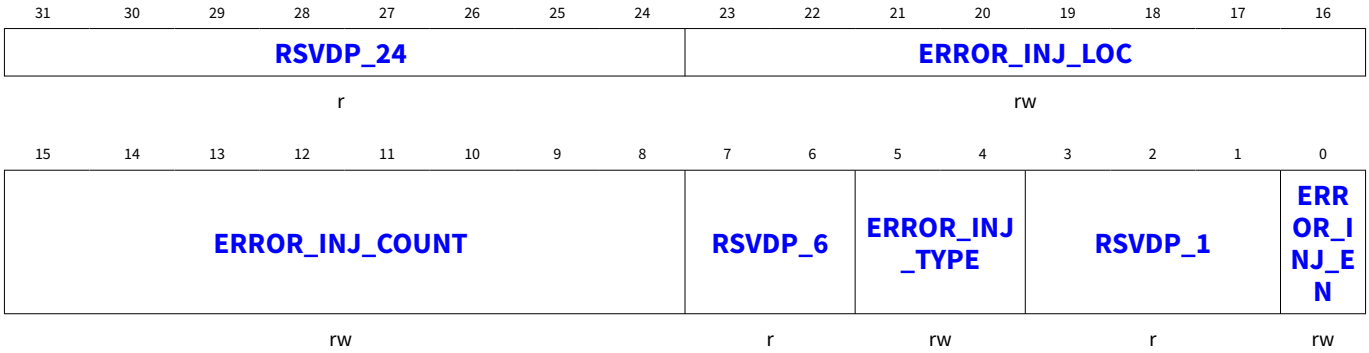
This viewport register returns the counter data selected by the UNCORR_COUNTER_SELECTION_REGION and UNCORR_COUNTER_SELECTION fields in the RASDP_UNCORR_COUNTER_CTRL_OFF register.



Field	Bits	Type	Description
UNCORR_COUNTER	7:0	rh	**Current uncorrected error count for the selected counter** Note: This register field is sticky.
RSVDP_8	19:8	r	**Reserved for future use**
UNCORR_COUNTER_SELECTED_REGION	23:20	rh	**Selected uncorrectable counter region** All encodings other than the defined encodings are reserved. Note: This register field is sticky. 0_H **ADM_RX_PATH**: Region select for Adm Rx path 1_H **L3_RX_PATH**: Region select for layer 3 Rx path 2_H **L2_RX_PATH**: Region select for layer 2 Rx path 3_H **DMA_INBOUND_PATH**: Region select for DMA inbound path 4_H **AXI_INBOUND_REQ_PATH**: Region select for AXI bridge inbound request path 5_H **AXI_INBOUND_CMPL_PATH**: Region select for AXI bridge inbound completion composer path 6_H **ADM_TX_PATH**: Region select for Adm Tx path 7_H **L3_TX_PATH**: Region select for layer 3 Tx path 8_H **L2_TX_PATH**: Region select for layer 2 Tx path 9_H **DMA_OUTBOUND_PATH**: Region select for DMA outbound path A_H **AXI_OUTBOUND_REQ_PATH**: Region select for AXI bridge outbound request path B_H **AXI_OUTBOUND_CMPL_PATH**: Region select for AXI bridge outbound master completion buffer path C_H **CXS_TX_RX_PATH**: Region select for CXS Tx/Rx path D_H **DTIM_TX_RX_PATH**: Region select for DTIM Tx/Rx path **others,** Reserved
UNCORR_COUNTER_SELECTED	31:24	rh	**Counter selection** Returns the value set in the UNCORR_COUNTER_SELECTION field of the RASDP_UNCORR_COUNTER_CTRL_OFF register. Note: This register field is sticky.

19.4.1.189 Error Injection Control Register

Error injection control for the following features: - 1-bit or 2-bit injection - Continuous or fixed-number (n) injection modes - Global enable/disable - Selectable location where injection occurs



Field	Bits	Type	Description
ERROR_INJ_EN	0	rw	**Error injection global enable** When set, enables the error insertion logic.
RSVDP_1	3:1	r	**Reserved for future use**
ERROR_INJ_TYPE	5:4	rw	**Error injection type** Note: This register field is sticky. 00_B **NONE**: none 01_B **_1_BIT**: 1-bit 10_B **_2_BIT**: 2-bit **others,** Reserved
RSVDP_6	7:6	r	**Reserved for future use**
ERROR_INJ_COUNT	15:8	rw	**Error injection count** If value is n, n amount of errors injected. Note: This register field is sticky. 00_H **ERR_INJ_EVERY_TLP**: Errors are inserted in every TLP until you clear ERROR_INJ_EN 01_H **ERR_INJ_1**: One errors injected 02_H **ERR_INJ_2**: Two errors injected **others,** Reserved
ERROR_INJ_LOC	23:16	rw	**Error injection location** Selects where error injection takes place. You can cycle this field value from 0 to 255 to access all locations according to the detailed report of check points at RASDP_CheckPoints.pdf Note: This register field is sticky.
RSVDP_24	31:24	r	**Reserved for future use**

19.4.1.190 Corrected Errors Location Register

Corrected errors locations.

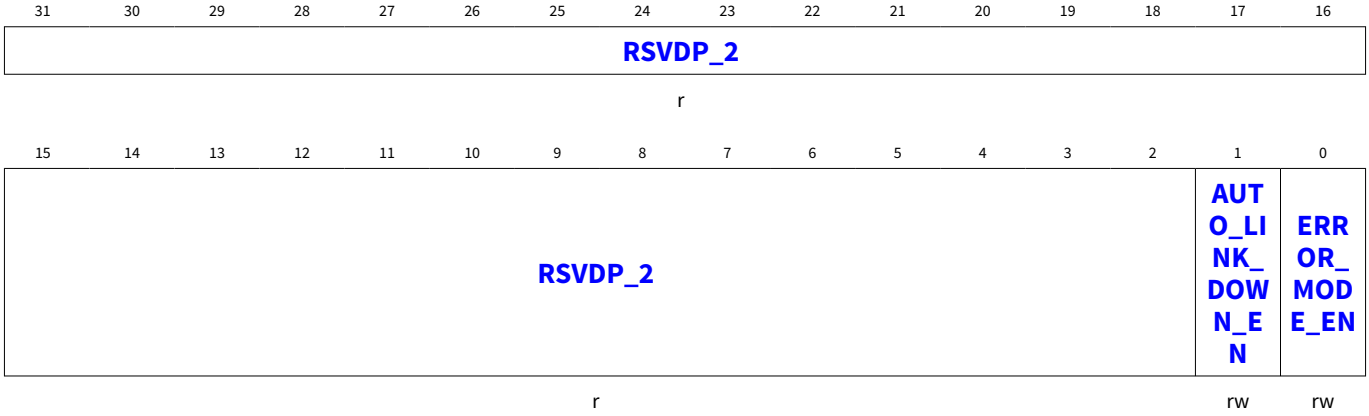
19.4.1.192 RASDP error mode enable.

RASDP error mode enable. The controller enters RASDP error mode (if ERROR_MODE_EN =1) upon detection of the first uncorrectable error. During this mode: - Rx TLPs that are forwarded to your application are not guaranteed to be correct; you must discard them. For more details, see the RAS Data Protection (DP) section in the Core Operations chapter of the user manual.

RASDP_ERROR_MODE_EN_OFF Offset address: $00042A8_H$

RASDP error mode enable. Kernel Reset value: $0000\ 0001_H$



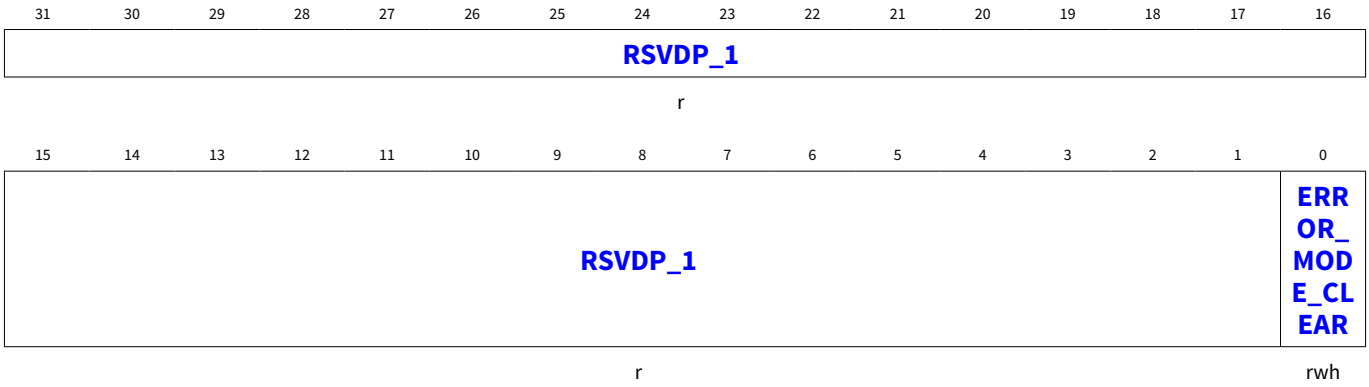
Field	Bits	Type	Description
ERROR_MODE_EN	0	rw	**Write '1' to enable the controller enter RASDP error mode when it detects an uncorrectable error** Note: This register field is sticky.
AUTO_LINK_DOWN_EN	1	rw	**Write '1' to enable the controller to bring the link down when the controller enters RASDP error mode** Note: This register field is sticky.
RSVDP_2	31:2	r	**Reserved for future use**

19.4.1.193 RASDP Error Mode Clear Register

Exit RASDP error mode. For more details, see the RAS Data Protection (DP) section in the Core Operations chapter of the user manual.

RASDP_ERROR_MODE_CLEAR_OFF Offset address: $00042AC_H$

RASDP Error Mode Clear Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ERROR_MODE_CLEAR	0	rwh	**Write '1' to take the controller out of RASDP error mode** The controller will then report uncorrectable errors (through AER internal error reporting) and also stop nullifying/discarding TLPs. Reading register field always returns a '0'.
RSVDP_1	31:1	r	**Reserved for future use**

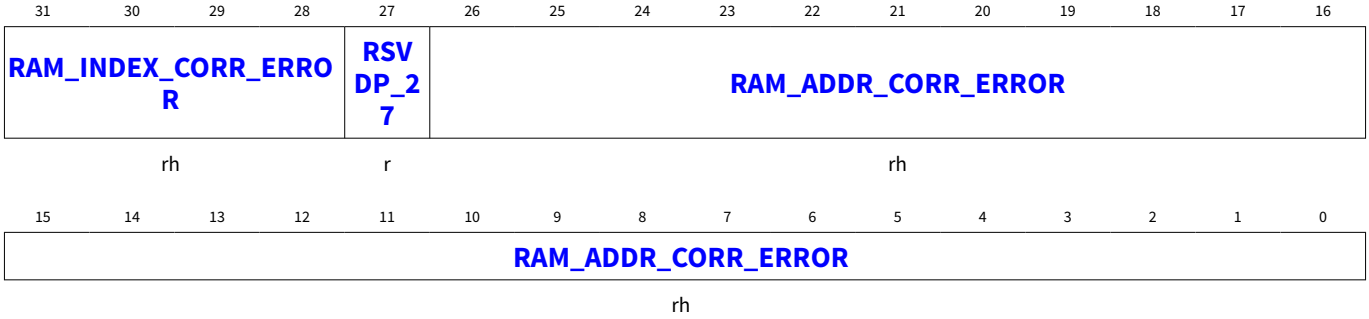
19.4.1.194 RAM Address where a corrected error (1-bit ECC) is detected

For more details, see the RAS Data Protection (DP) section in the Core Operations chapter of the user manual.

RASDP_RAM_ADDR_CORR_ERROR_OFF Offset address: $00042B0_H$

RAM Address where a corrected error [1-bit ECC) is detected

Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RAM_ADDR_CORR_ERROR	26:0	rh	**RAM Address where a corrected error (1-bit ECC) is detected** Note: This register field is sticky.
RSVDP_27	27	r	**Reserved for future use**
RAM_INDEX_CORR_ERROR	31:28	rh	**RAM index where a corrected error (1-bit ECC) is detected** Note: This register field is sticky.

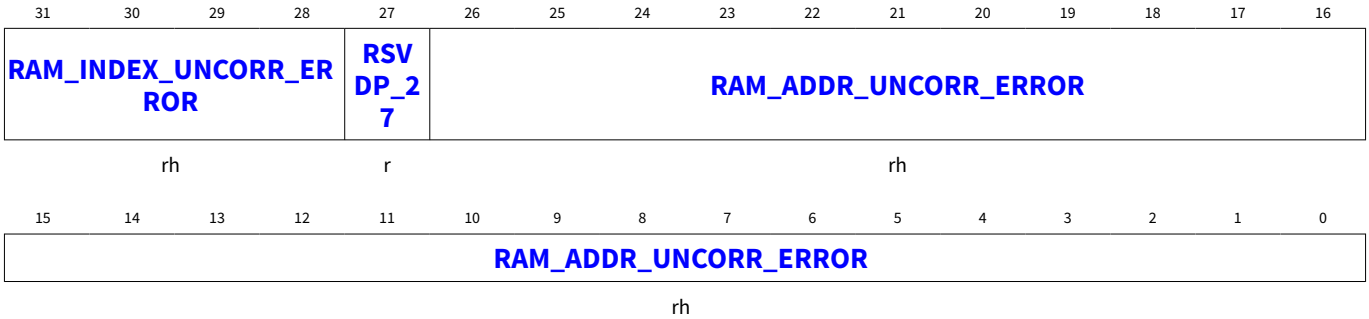
19.4.1.195 RAM Address where an uncorrected error (2-bit ECC) is detected

For more details, see the RAS Data Protection (DP) section in the Core Operations chapter of the user manual.

RASDP_RAM_ADDR_UNCORR_ERROR_OFF Offset address: $00042B4_H$

RAM Address where an uncorrected error [2-bit ECC) is detected

Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RAM_ADDR_UNCORR_ERROR	26:0	rh	**RAM Address where an uncorrected error (2-bit ECC) is detected** Note: This register field is sticky.
RSVDP_27	27	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
RAM_INDEX_UNCORR_ERROR	31:28	rh	**RAM index where an uncorrected error (2-bit ECC) is detected** Note: This register field is sticky.

19.4.1.196 Precision Time Measurement Capability Header

This Register provides Capability ID, Cabability Version, and Next Offset of Precision Time Measurement Capability structure.

PTM_EXT_CAP_HDR_OFF Offset address: $00042B8_H$

Precision Time Measurement Capability Header Kernel Reset value: $2C41\ 001F_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PTM_NEXT_OFFSET												PTM_CAP_VERSION			
rw												rw			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PTM_CAP_ID															
rw															

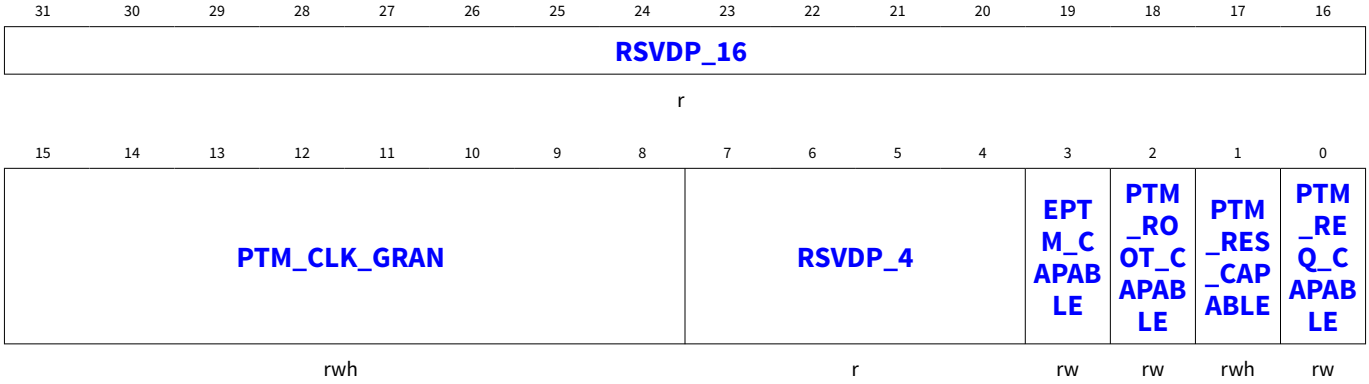
Field	Bits	Type	Description
PTM_CAP_ID	15:0	rw	**Precision Time Measurement PCI Express Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. PCI Express Extended Capability ID for the Precision Time Measurement Capability is 001Fh. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
PTM_CAP_VERSION	19:16	rw	**Precision Time Measurement PCI Express Extended Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. This bit depends on the version of the specification. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
PTM_NEXT_OFFSET	31:20	rw	**Precision Time Measurement PCI Express Extended Capability Next Offset** This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of Capabilities. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value

19.4.1.197 PTM Capability Register

This register describes a Function's support for Precision Time Measurement. Not all fields within this register apply to all Functions capable of implementing PTM.

PTM_CAP_OFF Offset address: $00042BC_H$

PTM Capability Register Kernel Reset value: $0000\ 040F_H$



Field	Bits	Type	Description
PTM_REQ_CAPABLE	0	rw	**PTM Requester Capable** Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Endpoints and RCiEPs are permitted to, and Switches supporting PTM must, set this bit to 1b to indicate they implement the PTM Requester role
PTM_RES_CAPABLE	1	rwh	**PTM Responder Capable** Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Root Ports and RCRB's are permitted to, and Switches supporting PTM must, set this bit to 1b to indicate they implement the PTM Responder role If PTM Root Capable is Set, this bit must be Set to 1b.
PTM_ROOT_CAPABLE	2	rw	**PTM Root Capable** Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Root Ports, RCRBs and Switches are permitted to set this bit to 1b, if they implement a PTM Time Source Role and are capable of serving as the PTM Root

(table continues...)

(continued)

Field	Bits	Type	Description
EPTM_CAPABLE	3	rw	**ePTM Capable** Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Indicates Enhanced Precision Time Management (ePTM) is supported Defaults to 0x1.
RSVDP_4	7:4	r	**Reserved for future use**
PTM_CLK_GRAN	15:8	rwh	**PTM Local Clock Granularity** For other than this value (between b00000001-b111111110) indicates the period of this Time Source's local clock in ns. If the PTM Root Select bit is Set, this local clock is used to provide PTM Master Time. Otherwise, the Time Source uses this local clock to locally track PTM Master Time received from further Upstream within a PTM Hierarchy. This field is reserved for Functions that do not implement the PTM Time Source role. Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) 00_H **No_local_clock**: Time Source does not implement a local clock It simply propagates timing information obtained from further Upstream in the PTM Hierarchy when responding to PTM Request messages. FF_H **Greater_than_254ns**: Indicates the period of this Time Source's local clock is greater than 254 ns
RSVDP_16	31:16	r	**Reserved for future use**

19.4.1.198 PTM Control Register

This register controls a Function's participation in the Precision Time Measurement mechanism. Not all fields within this register apply to all Functions capable of implementing PTM.

PTM_CONTROL_OFF Offset address: $00042C0_H$

PTM Control Register Kernel Reset value: $0000\ 0000_H$

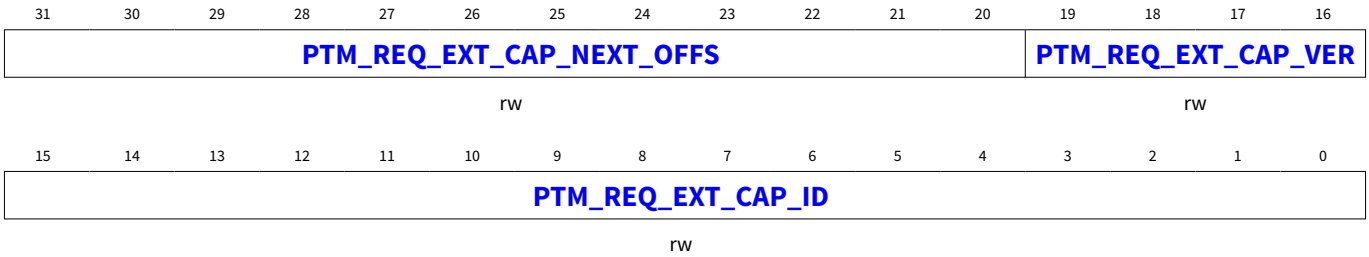
Field	Bits	Type	Description
PTM_ENABLE	0	rw	**PTM Enable** 0_B **CLEAR**: Clear 1_B **SET**: When Set, this Function is permitted to participate in the PTM mechanism according to its selected role(s)
ROOT_SELECT	1	rw	**PTM Root Select** If the value of the PTM Root Capable bit is 0b, this bit is permitted to be hardwired to 0b by the controller. Within each PTM Hierarchy, it is recommended that system software select only the furthest Upstream Time Source to be the PTM Root. Note: The access attributes of this field are as follows: - Wire: HWINIT - Dbi: HWINIT 0_B **CLEAR**: Clear 1_B **SET**: When Set, if the PTM Enable bit is also Set, this Time Source is the PTM Root
RSVDP_2	7:2	r	**Reserved for future use**
EFF_GRAN	15:8	rh	**PTM Effective Granularity** For Functions implementing the PTM Requester Role, this field provides information relating to the expected accuracy of the PTM clock, but does not otherwise affect the PTM mechanism. For Endpoints, system software must program this field to the value representing the maximum Local Clock Granularity reported by the PTM Root and all intervening PTM Time Sources. For RCiEPs, system software must set this field to the value reported in the Local Clock Granularity field by the associated PTM Time Source. For other than this value (between b00000001-b111111110) indicates the effective PTM granularity in ns. Note: The access attributes of this field are as follows: - Wire: HWINIT - Dbi: HWINIT 00_H **No_local_clock**: Unknown PTM granularity - one or more Switches between this Function and the PTM Root reported a Local Clock Granularity value of 0000 0000b FF_H **Greater_than_254ns**: Indicates the effective PTM granularity is greater than 254 ns
RSVDP_16	31:16	r	**Reserved for future use**

19.4.1.199 Precision Time Measurement Requester Capability Header (VSEC)

This Register provides Capability ID, Cabability Version, and Next Offset of Precision Time Measurement Capability structure.

PTM_REQ_CAP_HDR_OFF — Offset address: $00042C4_H$

Precision Time Measurement Requester Capability Header [VSEC) — Kernel Reset value: $32C1\ 000B_H$



Field	Bits	Type	Description
PTM_REQ_EXT_CAP_ID	15:0	rw	**Precision Time Measurement Requester VSEC ID** For more details, see the PTM section in the user manual. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
PTM_REQ_EXT_CAP_VER	19:16	rw	**Precision Time Measurement Requester VSEC Version** For more details, see the PTM section in the user manual. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
PTM_REQ_EXT_CAP_NEXT_OFFS	31:20	rw	**Precision Time Measurement Requester VSEC Next Pointer** For more details, see the PTM section in the user manual. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value

19.4.1.200 Precision Time Measurement Requester Vendor Specific Header

For more details, see the PTM section in the user manual.

PTM_REQ_LONG_TIMER								RSVDP_3					PTM_REQ_FAST_TIMERS	PTM_REQ_START_UPDATE	PTM_REQ_AUTO_UPDATE_ENABLED
rw								r					rw	rw1ch	rw

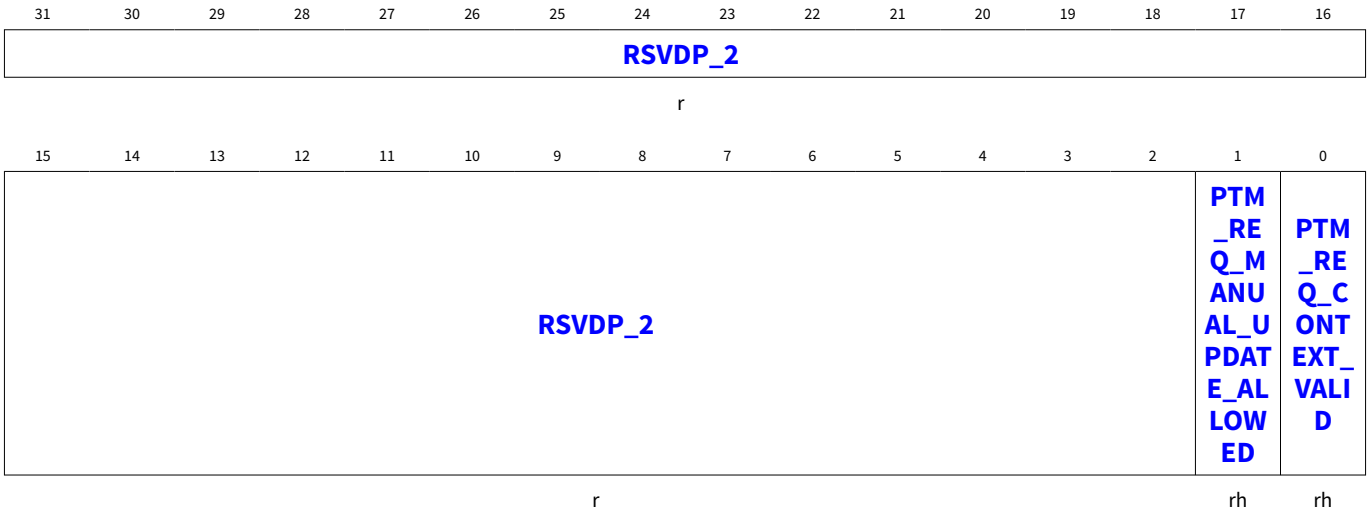
Field	Bits	Type	Description
PTM_REQ_AUTO_UPDATE_ENABLED	0	rw	**PTM Requester Auto Update Enabled** For more details, see the PTM section in the user manual. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: When enabled PTM Requester will automatically atempt to update its context every 10ms
PTM_REQ_START_UPDATE	1	rw1ch	**PTM Requester Start Update** For more details, see the PTM section in the user manual. Software write with 1 clears this bit-field. 0_B **CLEAR**: Clear 1_B **SET**: When set, the PTM Requester will attempt a PTM Dialogue to update its context; This bit is self clearing
PTM_REQ_FAST_TIMERS	2	rw	**PTM Fast Timers (Debug mode for PTM Timers)** The 100 µs timer output will go high at 30 µs and the 10 ms timer output will go high at 100 µs (the Long Timer Value is ignored). There is no change to the 1 µs timer. The requester operation will otherwise remain the same. For more details, see the PTM section in the user manual. Note: This register field is sticky.
RSVDP_3	7:3	r	**Reserved for future use**
PTM_REQ_LONG_TIMER	15:8	rw	**PTM Requester Long Timer** Determines the period between each auto update PTM Dialogue in miliseconds. Update period is the register value +1 milisecond. For the Switch product this value must not be set larger than 0x9 for spec compliance. For more details, see the PTM section in the user manual. Note: This register field is sticky.
PTM_REQ_PDEL_BYTE_REV	16	rw	**PTM Requester Propagation Delay Byte Reversal** Reverse the order of bytes in the PTM Propagation Delay data word of the PTM ResponseD Message, for compatibility with previous revisions. For more details, see the PTM section in the user manual. Note: This register field is sticky.
RSVDP_17	31:17	r	**Reserved for future use**

19.4.1.202 PTM Requester Vendor Specific Status Register

For more details, see the PTM section in the user manual.

PTM_REQ_STATUS_OFF Offset address: $00042D0_H$

PTM Requester Vendor Specific Status Register Kernel Reset value: $0000\ 0000_H$



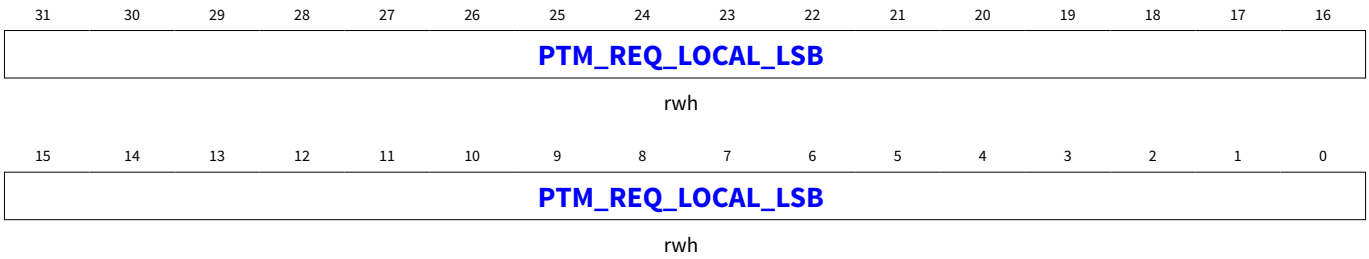
Field	Bits	Type	Description
PTM_REQ_CONTEXT_VALID	0	rh	**PTM Requester Context Valid** Indicate that the Timing Context is valid. For more details, see the PTM section in the user manual.
PTM_REQ_MANUAL_UPDATE_ALLOWED	1	rh	**PTM Requester Manual Update Allowed** Indicates whether or not a Manual Update can be signalled. For more details, see the PTM section in the user manual.
RSVDP_2	31:2	r	**Reserved for future use**

19.4.1.203 PTM Requester Local Clock LSB

For more details, see the PTM section in the user manual.

PTM_REQ_LOCAL_LSB_OFF Offset address: $00042D4_H$

PTM Requester Local Clock LSB Kernel Reset value: $0000\ 0000_H$



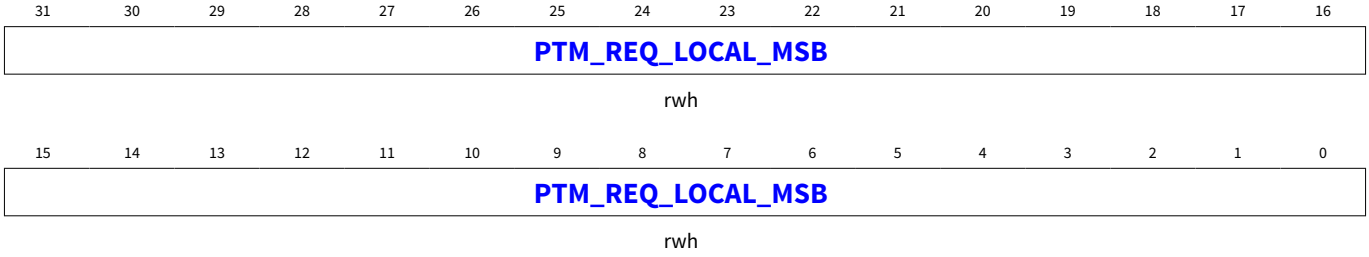
Field	Bits	Type	Description
PTM_REQ_LOCAL_LSB	31:0	rwh	**PTM Requester Local Clock LSB** Lower 32 bits of local timer value. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.1.204 PTM Requester Local Clock MSB

For more details, see the PTM section in the user manual.

PTM_REQ_LOCAL_MSB_OFF Offset address: $00042D8_H$

PTM Requester Local Clock MSB Kernel Reset value: $0000\ 0000_H$



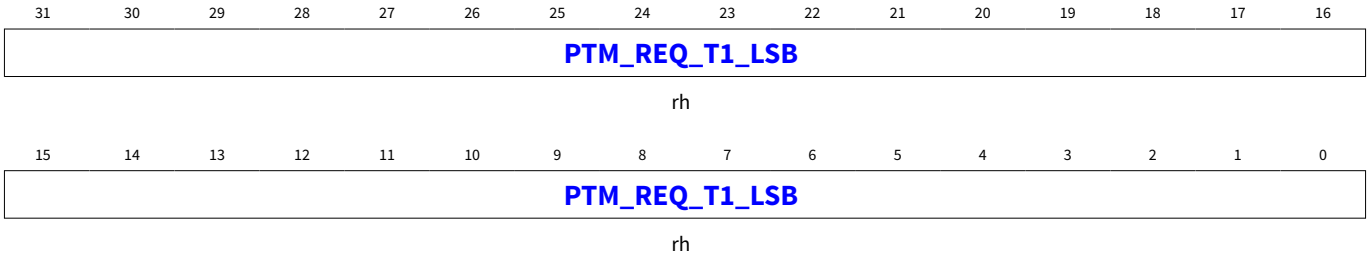
Field	Bits	Type	Description
PTM_REQ_LOCAL_MSB	31:0	rwh	**PTM Requester Local Clock MSB** Upper 32 bits of local timer value. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.1.205 PTM Requester T1 Timestamp LSB

For more details, see the PTM section in the user manual.

PTM_REQ_T1_LSB_OFF Offset address: $00042DC_H$

PTM Requester T1 Timestamp LSB Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PTM_REQ_T1_LSB	31:0	rh	**PTM Requester T1 Timestamp LSB** Lower 32 bits of the T1 Timestamp value. Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.1.206 PTM Requester T1 Timestamp MSB

For more details, see the PTM section in the user manual.

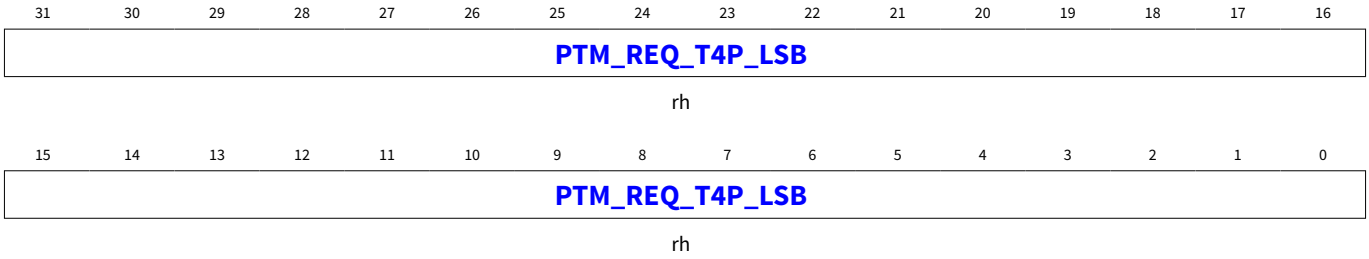
PTM_REQ_T4P_LSB_OFF Offset address: $00042F4_H$

PTM Requester T4 Previous Timestamp LSB Kernel Reset value: $0000\ 0000_H$



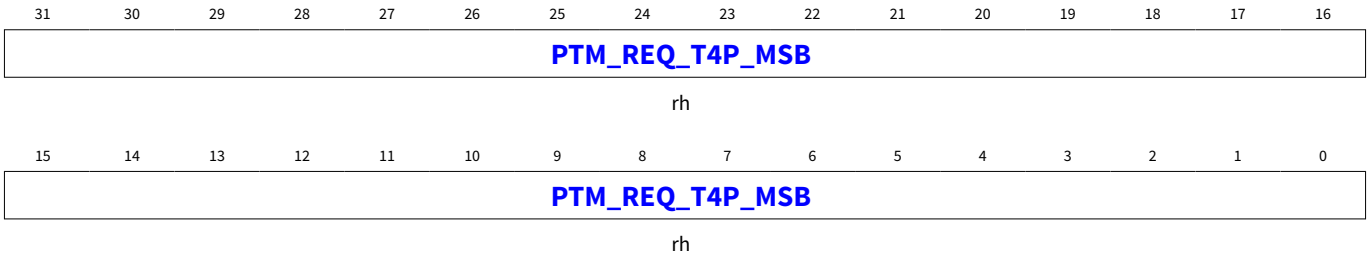
Field	Bits	Type	Description
PTM_REQ_T4P_LSB	31:0	rh	**PTM Requester T4 Previous Timestamp LSB** Lower 32 bits of the previously stored T4 Timestamp value. Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.1.212 PTM Requester T4 Previous Timestamp MSB

For more details, see the PTM section in the user manual.

PTM_REQ_T4P_MSB_OFF Offset address: $00042F8_H$

PTM Requester T4 Previous Timestamp MSB Kernel Reset value: $0000\ 0000_H$



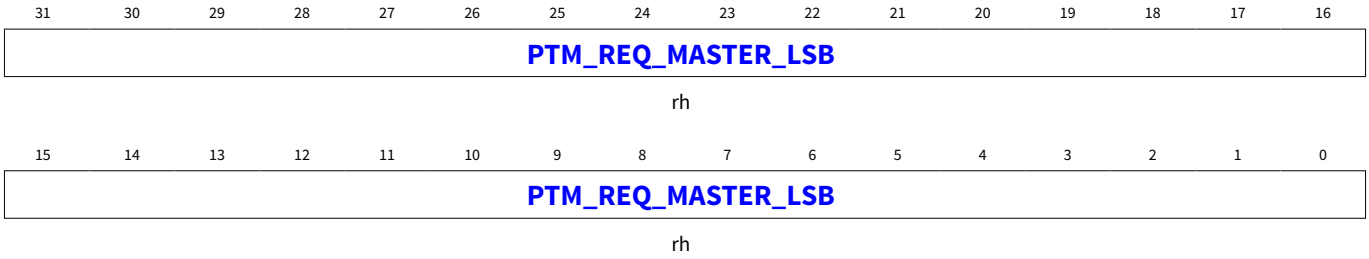
Field	Bits	Type	Description
PTM_REQ_T4P_MSB	31:0	rh	**PTM Requester T4 Previous Timestamp MSB** Upper 32 bits of the previously stored T4 Timestamp value. Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.1.213 PTM Requester Master Time LSB

For more details, see the PTM section in the user manual.

PTM_REQ_MASTER_LSB_OFF Offset address: $00042FC_H$

PTM Requester Master Time LSB Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PTM_REQ_MASTER_LSB	31:0	rh	**PTM Requester Master Time LSB** Lower 32 bits of Master Time value sent from PTM Responder. Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.1.214 PTM Requester Master Time MSB

For more details, see the PTM section in the user manual.

PTM_REQ_MASTER_MSB_OFF Offset address: 0004300_H

PTM Requester Master Time MSB Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PTM_REQ_PROP_DELAY															
rh															

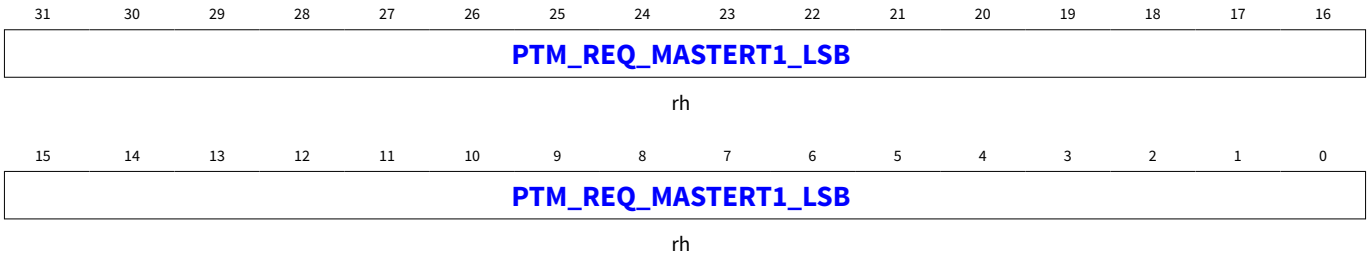
Field	Bits	Type	Description
PTM_REQ_PROP_DELAY	31:0	rh	**PTM Requester Propagation Delay** Propagation Delay sent from the PTM Responder. Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.1.216 PTM Requester Master Time at T1 LSB

For more details, see the PTM section in the user manual.

PTM_REQ_MASTERT1_LSB_OFF Offset address: 0004308_H

PTM Requester Master Time at T1 LSB Kernel Reset value: $0000\ 0000_H$



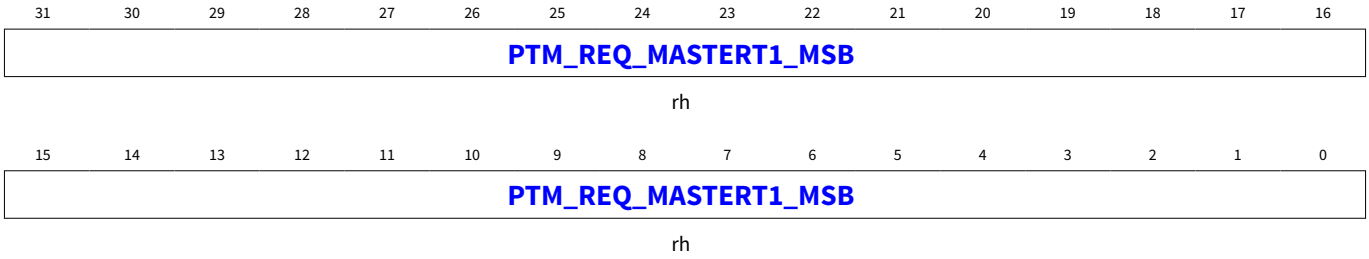
Field	Bits	Type	Description
PTM_REQ_MASTERT1_LSB	31:0	rh	**PTM Requester Master Time at T1 LSB** Lower 32 bits of the calculated Master Time at T1 prime. Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.1.217 PTM Requester Master Time at T1 MSB

For more details, see the PTM section in the user manual.

PTM_REQ_MASTERT1_MSB_OFF Offset address: $000430C_H$

PTM Requester Master Time at T1 MSB Kernel Reset value: $0000\ 0000_H$



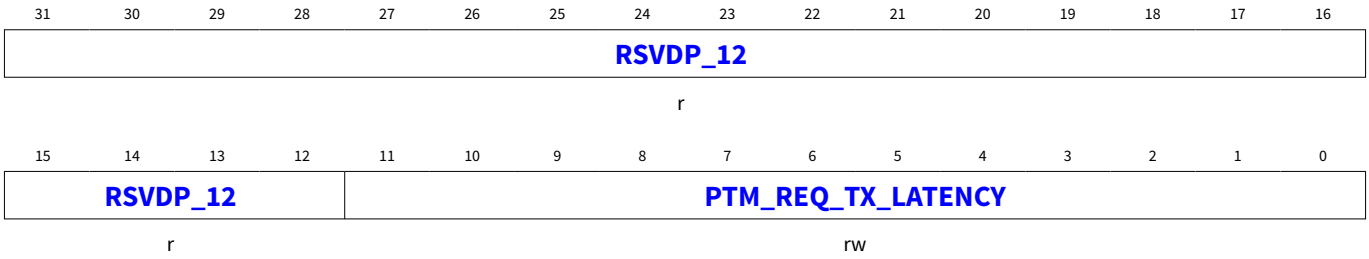
Field	Bits	Type	Description
PTM_REQ_MASTERT1_MSB	31:0	rh	**PTM Requester Master Time at T1 MSB** Upper 32 bits of the calculated Master Time at T1 prime. Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.1.218 PTM Requester TX Latency

For more details, see the PTM section in the user manual.

PTM_REQ_TX_LATENCY_OFF Offset address: 0004310_H

PTM Requester TX Latency Kernel Reset value: $0000\ 000E_H$



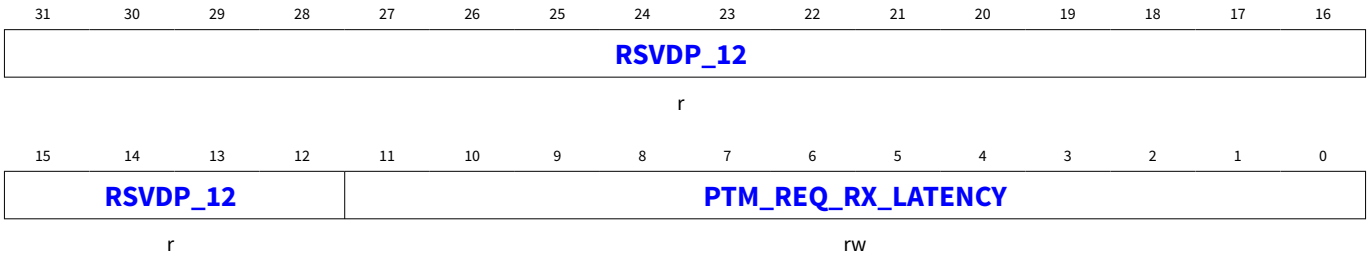
Field	Bits	Type	Description
PTM_REQ_TX_LATENCY	11:0	rw	**PTM Requester TX Latency** Requester Transmit path latency viewport register. A register is provided for each supported link speed, and the value used for timestamp adjustment is automatically selected based on the current speed. The PTM Requester Latency Register Select register specifies the register to be written or read. For more details, see the PTM section in the user manual. Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value
RSVDP_12	31:12	r	**Reserved for future use**

19.4.1.219 PTM Requester RX Latency

For more details, see the PTM section in the user manual.

PTM_REQ_RX_LATENCY_OFF Offset address: 0004314_H

PTM Requester RX Latency Kernel Reset value: $0000\ 002A_H$



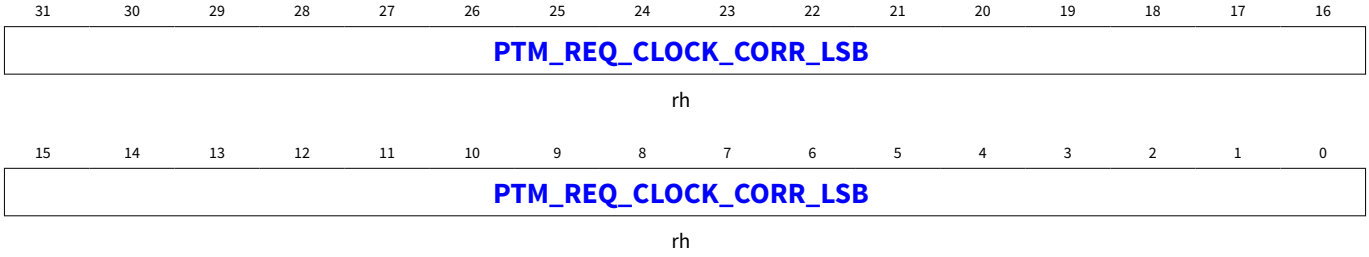
Field	Bits	Type	Description
PTM_REQ_RX_LATENCY	11:0	rw	**PTM Requester RX Latency - Requester Receive path latency viewport register** A register is provided for each supported link speed, and the value used for timestamp adjustment is automatically selected based on the current speed. The PTM Requester Latency Register Select register specifies the register to be written or read. For more details, see the PTM section in the user manual. Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value
RSVDP_12	31:12	r	**Reserved for future use**

19.4.1.220 PTM Requester Clock Correction LSB

For more details, see the PTM section in the user manual.

PTM_REQ_CLOCK_CORR_LSB_OFF Offset address: 0004318_H

PTM Requester Clock Correction LSB Kernel Reset value: $0000\ 0000_H$



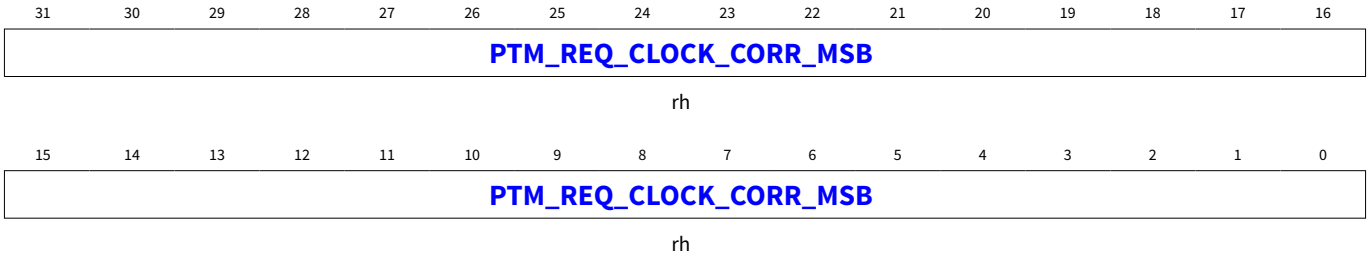
Field	Bits	Type	Description
PTM_REQ_CLOCK_CORR_LSB	31:0	rh	**PTM Requester Clock Correction LSB** Lower 32 bits of amount by which PTM Requester Local Clock has been corrected. For more details, see the PTM section in the user manual. Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.1.221 PTM Requester Clock Correction MSB

For more details, see the PTM section in the user manual.

PTM_REQ_CLOCK_CORR_MSB_OFF Offset address: $000431C_H$

PTM Requester Clock Correction MSB Kernel Reset value: $0000\ 0000_H$



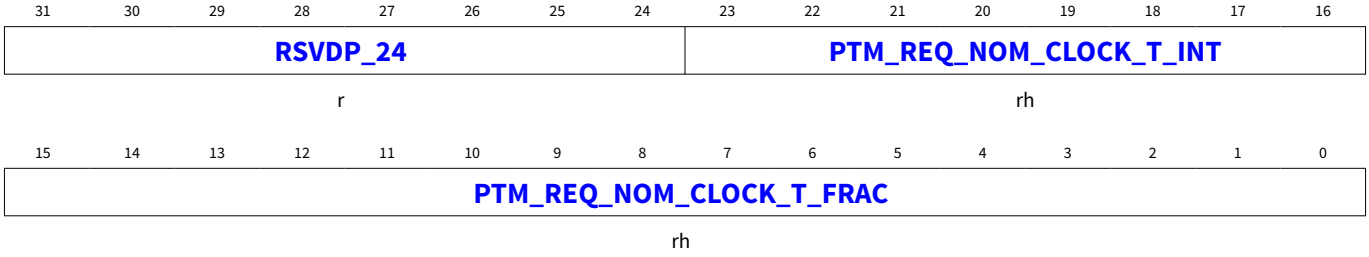
Field	Bits	Type	Description
PTM_REQ_CLOCK_CORR_MSB	31:0	rh	**PTM Requester Clock Correction MSB** Upper 32 bits of amount by which PTM Requester Local Clock has been corrected. For more details, see the PTM section in the user manual. Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.1.222 PTM Requester Nominal Clock Period

For more details, see the PTM section in the user manual.

PTM_REQ_NOM_CLOCK_T_OFF Offset address: 0004320_H

PTM Requester Nominal Clock Period Kernel Reset value: $0000\ 0000_H$



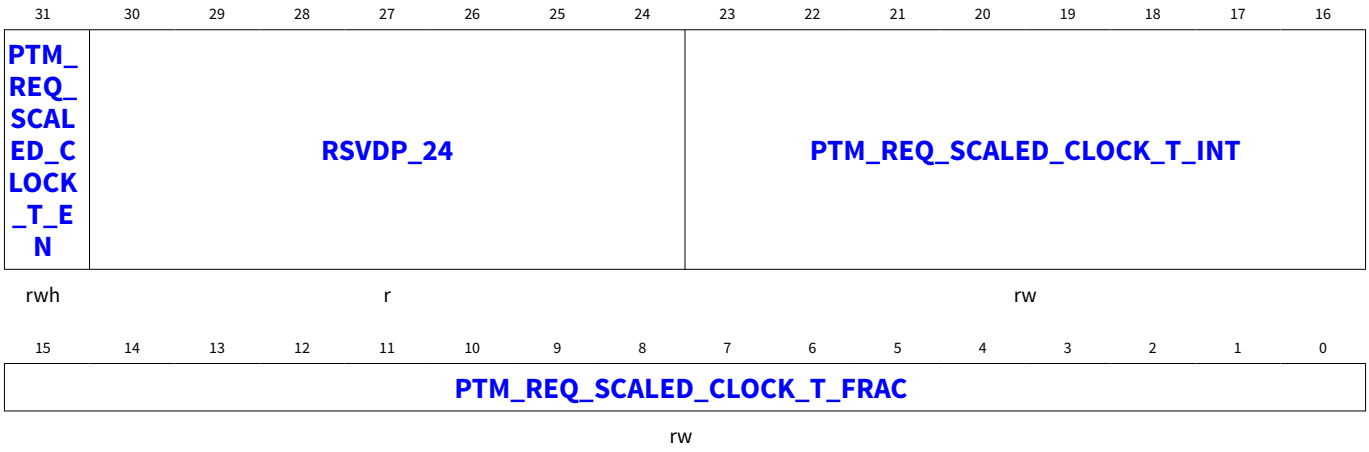
Field	Bits	Type	Description
PTM_REQ_NOM_CLOCK_T_FRAC	15:0	rh	**PTM Requester Nominal Clock Period Fractional** Fractional part of the nominal PTM local clock period, in nanoseconds. For more details, see the PTM section in the user manual. Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
PTM_REQ_NOM_CLOCK_T_INT	23:16	rh	**PTM Requester Nominal Clock Period Integral** Integral part of the nominal PTM local clock period. LSB is 1/(2^16) nanoseconds. For more details, see the PTM section in the user manual. Note: This register field is sticky. 00_H **MIN_VAL**: Min value FF_H **MAX_VAL**: Max value
RSVDP_24	31:24	r	**Reserved for future use**

19.4.1.223 PTM Requester Scaled Clock Period

For more details, see the PTM section in the user manual.

PTM_REQ_SCALED_CLOCK_T_OFF Offset address: 0004324_H

PTM Requester Scaled Clock Period Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PTM_REQ_SCALED_CLOCK_T_FRAC	15:0	rw	**PTM Requester Scaled Clock Period Fractional** Fractional part of the nominal PTM local clock period. LSB is 1/(2^16) nanoseconds. For more details, see the PTM section in the user manual. Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
PTM_REQ_SCALED_CLOCK_T_INT	23:16	rw	**PTM Requester Scaled Clock Period Integral** Integral part of the nominal PTM local clock period, in nanoseconds. For more details, see the PTM section in the user manual. Note: This register field is sticky. 00_H **MIN_VAL**: Min value FF_H **MAX_VAL**: Max value
RSVDP_24	30:24	r	**Reserved for future use**
PTM_REQ_SCALED_CLOCK_T_EN	31	rwh	**PTM Requester Scaled Clock Period Enable** This bit is cleared when the core_clk rate starts to change and can only be set when the clock period change is complete. For more details, see the PTM section in the user manual. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Use the programmed scaled PTM clock period rather than the nominal values

19.4.1.224 PTM Requester Latency Viewport Register Select

For more details, see the PTM section in the user manual.

PTM_REQ_LATENCY_REG_SEL_OFF Offset address: 0004328_H

PTM Requester Latency Viewport Register Select Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r								rw	r			rw			

Field	Bits	Type	Description
PTM_REQ_LATENCY_REG_SEL	3:0	rw	**Selects the PTM Requester Tx and Rx Latency Viewport register to be written or read, together with the PTM_REQ_ESM_SEL field** For more details, see the PTM section in the user manual. Note: This register field is sticky. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
RSVDP_4	6:4	r	**Reserved for future use**
PTM_REQ_ESM_SEL	7	rw	**Selection Mode for PTM Requester Tx and Rx Latency Viewport register to be written or read** For more details, see the PTM section in the user manual. Note: This register field is sticky. 0_B **SEL_PCIE_REGS**: write or read latency registers for PCIe rates 1_B **SEL_CCIX_ESM_REGS**: write or read latency registers for additional ESM rates
RSVDP_8	31:8	r	**Reserved for future use**

19.4.1.225 PCIe Extended Capability ID, Capability Version, and Next Capability Offset Register

This register provides capability ID, capability version, and next capability offset for PCIe extended capability structure.

VSECDMA_EXT_CAP_HDR_OFF Offset address: $000432C_H$

PCIe Extended Capability ID, Capability Version, and Next Capability Offset Register — Kernel Reset value: $0001\ 000B_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NEXT_OFFSET												CAP			
rw												rw			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ID															
rw															

Field	Bits	Type	Description
ID	15:0	rw	**PCI Express Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

(table continues...)

(continued)

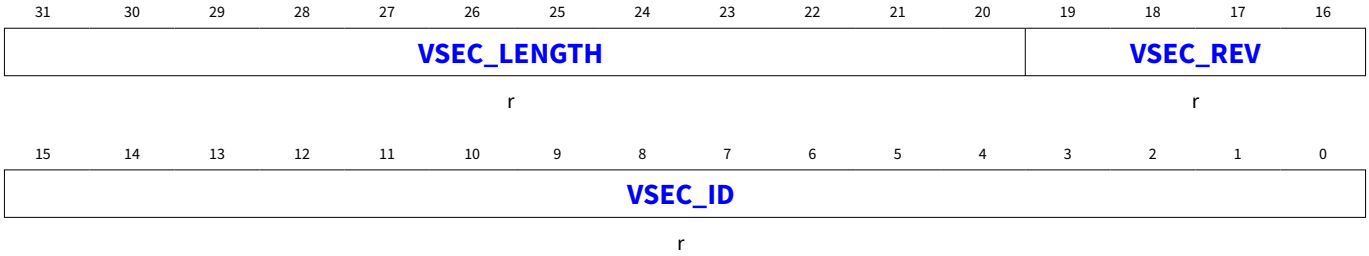
Field	Bits	Type	Description
CAP	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. A version of the specification that changes the Extended Capability in a way that is not otherwise identifiable (that is, through a new Capability field) is permitted to increment this field. All such changes to the Capability structure must be software-compatible. Software must check for Capability Version numbers that are greater than or equal to the highest number defined when the software is written, as Functions reporting any such Capability Version numbers will contain a Capability structure that is compatible with that piece of software. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. The bottom 2 bits of this offset are Reserved and must be implemented as 00b although software must mask them to allow for future uses of these bits. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.1.226 Vendor Specific Header Register

This Register provides VSEC Length, VSEC ID, and VSEC Rev(Version Number). Vendor-specific software must qualify the associated Vendor ID of the PCI Express Function or RCRB before attempting to interpret the values in the VSEC ID or VSEC Rev fields.

VSECDMA_VENDOR_SPECIFIC_HDR_OFF Offset address: 0004330_H

Vendor Specific Header Register Kernel Reset value: $0180\ 0006_H$



Field	Bits	Type	Description
VSEC_ID	15:0	r	**VSEC ID** This field is a vendor-defined ID number that indicates the nature and format of the VSEC structure. Software must qualify the Vendor ID before interpreting this field.

(table continues...)

(continued)

Field	Bits	Type	Description
VSEC_REV	19:16	r	**VSEC Rev** This field is a vendor-defined version number that indicates the version of the VSEC structure. Software must qualify the Vendor ID and VSEC ID before interpreting this field.
VSEC_LENGTH	31:20	r	**VSEC Length** This field indicates the number of bytes in the entire VSEC structure, including the Vendor-Specific Extended Capability Header, the Vendor-Specific Header, and the vendor-specific registers.

19.4.1.227 DMA and related AXI Bridge Implementation Information

This register provides DMA and AXI Bridge implementation-specific information: - DMA Architecture: Legacy DMA or Hyper DMA (HDMA). - Register Location: Port-logic or Mapped to a Function and BAR. - Register Map: Legacy DMA or HDMA. - Channel Separation: Address distance between read and write channels. - AXI Bridge: Used or Not Used - AXI Master Bus Specification: AXI Master Bus Width, Burst Length, and Boundary Pointer Width You must use this information along with the IP version registers: - PCIE_VERSION_NUMBER_OFF - PCIE_VERSION_TYPE_OFF

VSECDMA_DEVICE_INFORMATION_OFF Offset address: 0004334_H

DMA and related AXI Bridge Implementation Information Kernel Reset value: $3498\ 0001_H$

Field	Bits	Type	Description
MAP_FORMAT	2:0	r	**Defines the register map format and features to be one of the following values: Other values are reserved** 000_B **EDMA_LEGACY_PL**: Legacy DMA register map accessed by the port-logic registers 001_B **EDMA_LEGACY_UNROLL**: Legacy DMA register map, mapped to a PF/BAR 101_B **HDMA_COMPATIBILITY_MODE**: HDMA compatibility mode (CC_LEGACY_DMA_MAP =1) register map, mapped to a PF/BAR 111_B **HDMA_NATIVE**: HDMA native (CC_LEGACY_DMA_MAP =0) register map, mapped to a PF/BAR
RSVDP_3	7:3	r	**Reserved for future use**
BARN	10:8	r	**Bar Number** This field provides information regarding the DMA register and BAR number mapping.

(table continues...)

(continued)

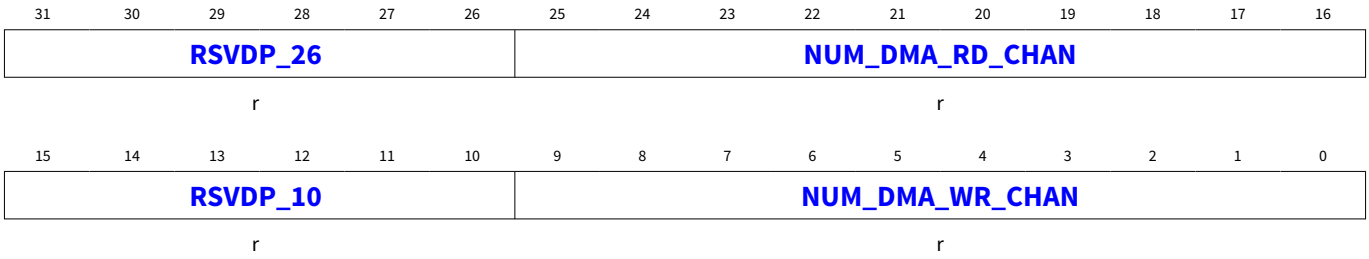
Field	Bits	Type	Description
PFN	15:11	r	**Physical Function Number** This field provides information regarding the DMA register and physical function mapping.
CHANNEL_SEPARATION	18:16	r	**If the MAP_FORMAT is set to HDMA_NATIVE, this field specifies the read write channel address separation** Other values are reserved. 000_B **CHSEP_256**: 256 separated 001_B **CHSEP_512**: 512 separated 010_B **CHSEP_1K**: 1k separated 011_B **CHSEP_2K**: 2k separated 100_B **CHSEP_4K**: 4k separated 101_B **CHSEP_8K**: 8k separated 110_B **CHSEP_16K**: 16k separated 111_B **CHSEP_32K**: 32k separated
AXI	19	r	**This field provides information about AXI interface usage** It reports the value of AXI_POPULATED configuration parameter.
MASTER_BUS_WIDTH	22:20	r	**This field provides information regarding the AXI master data bus width** It reports the value of width of the AXI master databus. 000_B **MSTR_BUSWD_32**: 32 bits 001_B **MSTR_BUSWD_64**: 64 bits 010_B **MSTR_BUSWD_128**: 128 bits 011_B **MSTR_BUSWD_256**: 256 bits 100_B **MSTR_BUSWD_512**: 512 bits **others,** Reserved
MASTER_BURST_LENGTH	25:23	r	**Reports the maximum burst length (in beats) of an AXI transfer at the master interface** 000_B **MSTR_BRSTLEN_8**: 8 bits 001_B **MSTR_BRSTLEN_16**: 16 bits 010_B **MSTR_BRSTLEN_32**: 32 bits 011_B **MSTR_BRSTLEN_64**: 64 bits 100_B **MSTR_BRSTLEN_128**: 128 bits 101_B **MSTR_BRSTLEN_256**: 256 bits **others,** Reserved
MASTER_PAGE_BOUNDARY_POINTER_WIDTH	29:26	r	**This field provides address page boundary information** It reports the value of the page boundary of 128, 256, 512, 1K, 2K or 4K (bytes). .
RSVDP_30	31:30	r	**Reserved for future use**

19.4.1.228 Number of Implemented Channels Register

This register specifies the number of read and write channels implemented.

VSECDMA_NUM_CHAN_OFF Offset address: 0004338_H

Number of Implemented Channels Register Kernel Reset value: $0004\ 0004_H$



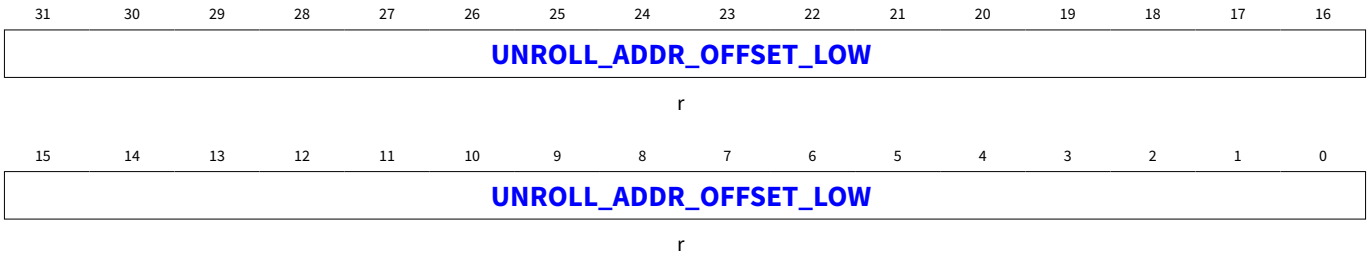
Field	Bits	Type	Description
NUM_DMA_WR_CHAN	9:0	r	**This field provides information regarding the number of implemented write channels** It reports the value of the number of write channels implemented in the DMA logic.
RSVDP_10	15:10	r	**Reserved for future use**
NUM_DMA_RD_CHAN	25:16	r	**This field provides information regarding the number of implemented read channels** It reports the value of the number of read channels implemented in the DMA logic.
RSVDP_26	31:26	r	**Reserved for future use**

19.4.1.229 DMA Register Map Start Address Offset Low Register

This register specifies the lower 32 bits of the offset of the start address of the DMA register map.

VSECDMA_UNROLL_ADDR_OFFSET_LOW_OFF Offset address: $000433C_H$

DMA Register Map Start Address Offset Low Register Kernel Reset value: $0000\ 4000_H$



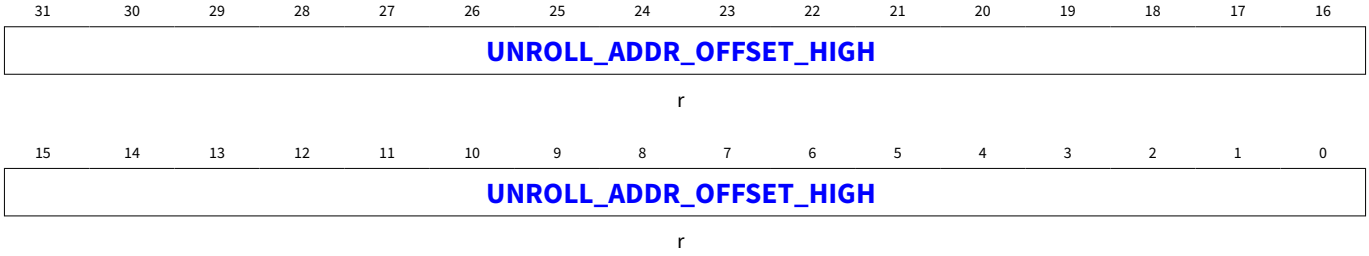
Field	Bits	Type	Description
UNROLL_ADDR_OFFSET_LOW	31:0	r	**BAR address offset, 32-bit LSB**

19.4.1.230 DMA Register Map Start Address Offset High Register

This register specifies the upper 32 bits of the offset of the start address of the DMA register map.

VSECDMA_UNROLL_ADDR_OFFSET_HIGH_OFF Offset address: 0004340_H

DMA Register Map Start Address Offset High Register Kernel Reset value: $0000\ 0000_H$



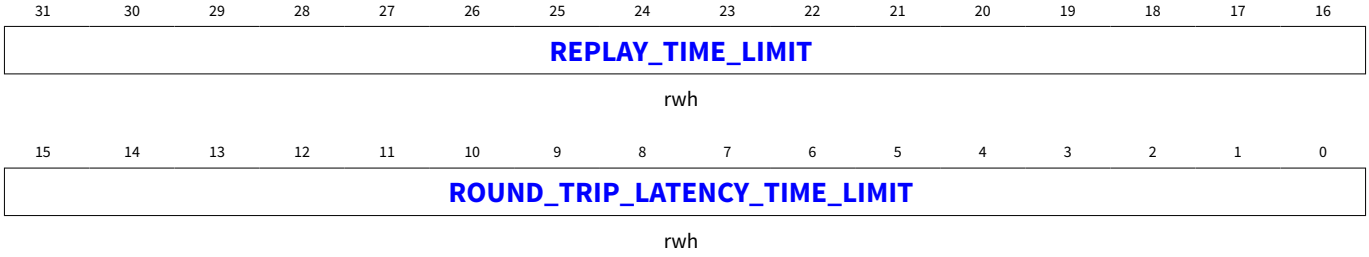
Field	Bits	Type	Description
UNROLL_ADDR_OFFSET_HIGH	31:0	r	**BAR address offset, 32-bit MSB**

19.4.1.231 Ack Latency Timer and Replay Timer Register

This register holds the ack latency timer limit and replay timer limit values.

ACK_LATENCY_TIMER_OFF Offset address: 0004700_H

Ack Latency Timer and Replay Timer Register Kernel Reset value: $0C23\ 040B_H$



Field	Bits	Type	Description
ROUND_TRIP_LATENCY_TIME_LIMIT	15:0	rwh	**Ack Latency Timer Limit** The Ack latency timer expires when it reaches this limit. - You can modify the effective timer limit through the TIMER_MOD_ACK_NAK field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register. - After reset, the controller updates the default according to the Negotiated Link Width, Max_Payload_Size, and speed. The value is determined from Tables 3-7, 3-8, and 3-9 of the PCI Express Base Specification. - The limit must reflect the round trip latency from requester to completer. - If there is a change in the payload size or link width, the controller overrides any value that you have written to this register field, and resets the field back to the specification-defined value. The controller does not change the value in the TIMER_MOD_ACK_NAK field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register.

(table continues...)

(continued)

Field	Bits	Type	Description
REPLAY_TIME_LIMIT	31:16	rwh	**Replay Timer Limit** The replay timer expires when it reaches this limit. The controller initiates a replay upon reception of a NAK or when the replay timer expires. - You can modify the effective timer limit through the TIMER_MOD_REPLAY_TIMER field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register. - After reset, the controller updates the default according to the Negotiated Link Width, Max_Payload_Size, and speed. The value is determined from Tables 3-4, 3-5, and 3-6 of the PCI Express Base Specification. - If there is a change in the payload size or link speed, the controller overrides any value that you have written to this register field, and resets the field back to the specification-defined value. The controller does not change the value in the TIMER_MOD_REPLAY_TIMER field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register.

19.4.1.232 Vendor Specific DLLP Register

This register holds the vendor specific DLLP.

VENDOR_SPEC_DLLP_OFF Offset address: 0004704_H

Vendor Specific DLLP Register Kernel Reset value: $FFFF\ FFFF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VENDOR_SPEC_DLLP															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VENDOR_SPEC_DLLP															
rw															

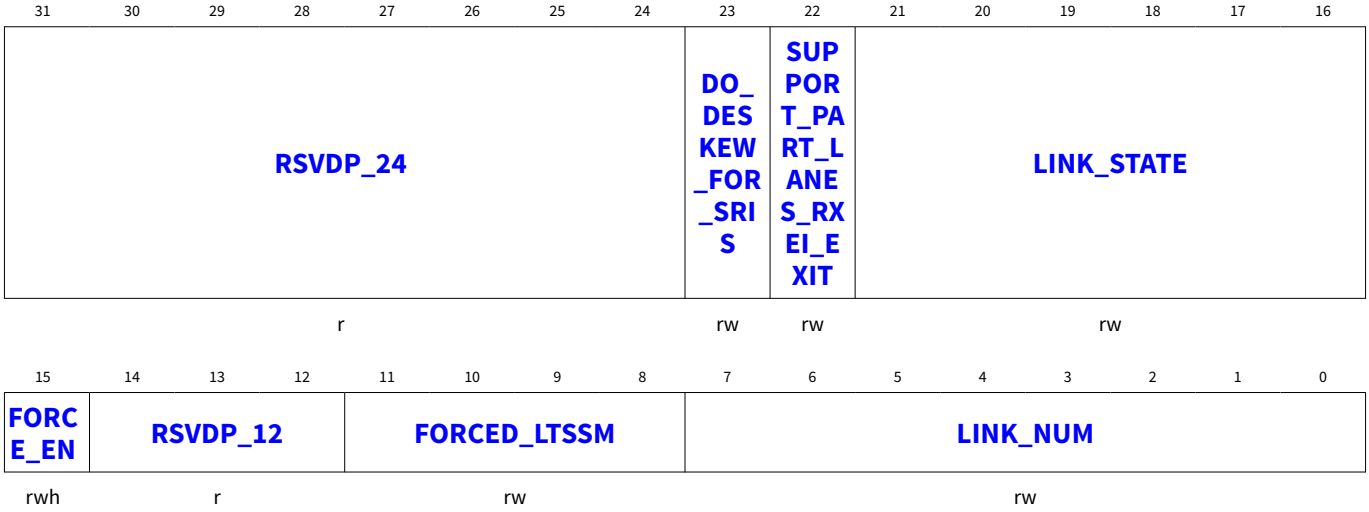
Field	Bits	Type	Description
VENDOR_SPEC_DLLP	31:0	rw	**Vendor Specific DLLP Register** You can use this register to send a specific PCI Express DLLP. Your application can write 8-bit DLLP Type and 24-bit Payload data into this register, and set the VENDOR_SPECIFIC_DLLP_REQ field of the PORT_LINK_CTRL_OFF, to send the DLLP. - Bits[7:0]: DLLP Type - Bits[31:8]: Vendor Defined Payload (24 bits) Note: This register field is sticky. 00000000_H **ZERO**: Zero value $FFFFFFFF_H$ **MAX**: Max value

19.4.1.233 Port Force Link Register

This register can be used for testing and debugging the link.

PORT_FORCE_OFF Offset address: 0004708_H

Port Force Link Register Kernel Reset value: $0080\ 0001_H$



Field	Bits	Type	Description
LINK_NUM	7:0	rw	**Link Number** Not used for endpoint. Note: This register field is sticky.
FORCED_LTSSM	11:8	rw	**Forced Link Command** The link command that the controller is forced to transmit when you set FORCE_EN bit (Force Link). Link command encoding is defined by the ltssm_cmd variable in workspace/src/Layer1/smlh_ltssm.v. Note: This register field is sticky.
RSVDP_12	14:12	r	**Reserved for future use**
FORCE_EN	15	rwh	**Force Link** The controller supports a testing and debug capability to allow your software to force the LTSSM state machine into a specific state, and to force the controller to transmit a specific Link Command. Asserting this bit triggers the following actions: • Forces the LTSSM to the state specified by the Forced LTSSM State field • Forces the controller to transmit the command specified by the Forced Link Command field This is a self-clearing register field. Reading from this register field always returns a '0'. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
LINK_STATE	21:16	rw	**Forced LTSSM State** The LTSSM state that the controller is forced to when you set the FORCE_EN bit (Force Link). . Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
SUPPORT_PART_LANES_RXEI_EXIT	22	rw	**Support LTSSM transition from Polling.Active to Polling.Config based on Rx 8 TSs on any lanes which are Rx EI exit too from base spec after 24ms timeout** This prevents some lanes detected but not Rx EI exit and LTSSM cannot move to Polling.Config. Note: This register field is sticky. 0_B **UNSUPPORT**: Any lanes receives 8 consecutive TS OS and all predetermined lanes have Rx ElecIdle exit, LTSSM moves from Polling.Active to Polling.Config This is legacy mode from Base Spec. Any predetermined lanes are still on Rx ElecIdle, LTSSM moves from Polling.Active to Polling.Compliance. 1_B **SUPPORT**: Any lanes receives 8 consecutive TS OSs, LTSSM moves from Polling.Active to Polling.Config If all lanes do not receive 8 consecutive TS OSs and any predetermined lanes are still on Rx ElecIdle, LTSSM moves from Polling.Active to Polling.Compliance.
DO_DESKEW_FOR_SRIS	23	rw	**Use the transitions from TS2 to Logical Idle Symbol, SKP OS to Logical Idle Symbol, EIEOS to Logical Idle Symbol, and FTS Sequence to SKP OS to do deskew instead of using received SKP OS or TS1 to TS2 transition if DO_DESKEW_FOR_SRIS is set to '1'** Note: This register field is sticky.
RSVDP_24	31:24	r	**Reserved for future use**

19.4.1.234 Ack Frequency and L0-L1 ASPM Control Register

This register is used to control ack frequency and L0-L1 ASPM behaviour.

ACK_F_ASPM_CTRL_OFF Offset address: 000470C$_H$

Ack Frequency and L0-L1 ASPM Control Register Kernel Reset value: 09B4 B400$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSVDP_31	ENTER_ASPM	L1_ENTRANCE_LATENCY			L0S_ENTRANCE_LATENCY			COMMON_CLK_N_FTS							
r	rw	rw			rw			r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ACK_N_FTS								ACK_FREQ							
rw								rw							

Field	Bits	Type	Description
ACK_FREQ	7:0	rw	**Ack Frequency** The controller accumulates the number of pending ACKs specified here (up to 255) before scheduling an ACK DLLP • 0: Indicates that this Ack Frequency Counter feature is turned off. The controller generates a low-priority ACK request for every TLP that it receives. The controller waits until the ACK Latency Timer expires, then converts the current low-priority ACK request to a high-priority ACK request and schedules the DLLP for transmission to the remote link partner • 1-255: Indicates that the controller will schedule a high-priority ACK after receiving this number of TLPs. It might schedule the ACK before receiving this number of TLPs if the ACK Latency Timer expires, but never later For a typical system, you do not have to modify the default setting. For more details, see "ACK/NAK Scheduling" in the user manual. Note: This register field is sticky. 00_H **MIN_VAL**: The value '0' indicates that this Ack Frequency Counter feature is turned off FF_H **MAX_VAL**: Any value between 1 and 255 indicates that the controller will schedule a high-priority ACK after receiving the specified number of TLPs
ACK_N_FTS	15:8	rw	**The number of Fast Training Sequence(N_FTS) ordered sets to be transmitted when transitioning from L0s to L0** Note: This register field is sticky. 00_H **ZERO**: The controller does not support a value of zero; a value of zero can cause the LTSSM to go into the recovery state when exiting from L0s FF_H **MAX_VAL**: The maximum number of FTS ordered-sets that a component can request is 255
COMMON_CLK_N_FTS	23:16	r	**Common Clock N_FTS** This is the N_FTS when common clock is used. The number of Fast Training Sequence ordered sets to be transmitted when transitioning from L0s to L0. Note: The access attributes of this field are as follows: - Wire: R - Dbi: R 00_H **ZERO**: The controller does not support a value of zero; a value of zero can cause the LTSSM to go into the recovery state when exiting from L0s FF_H **MAX_VAL**: The maximum number of FTS ordered-sets that a component can request is 255

r				rw				r	rw	rw	r	rw	rw	rw	rw1ch

Field	Bits	Type	Description
VENDOR_SPECIFIC_DLLP_REQ	0	rw1ch	**Vendor Specific DLLP Request** Reading from this self-clearing register field always returns a '0'. Software write with 1 clears this bit-field. 0_B **CLEAR**: This is a self clearing register 1_B **SET**: When software writes a '1' to this bit, the controller transmits the DLLP contained in the VENDOR_SPEC_DLLP field of VENDOR_SPEC_DLLP_OFF
SCRAMBLE_DISABLE	1	rw	**Scramble Disable** Turns off data scrambling. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
LOOPBACK_ENABLE	2	rw	**Loopback Enable** Turns on loopback. For more details, see "Loopback" in the user manual. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
RESET_ASSERT	3	rw	**Reset Assert** Triggers a recovery and forces the LTSSM to the hot reset state (downstream port only). Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Set
RSVDP_4	4	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
DLL_LINK_EN	5	rw	**DLL Link Enable** Note: This register field is sticky. 0_B **DISABLE**: The controller does not transmit InitFC DLLPs and does not establish a link 1_B **ENABLE**: Enables link initialization
LINK_DISABLE	6	rw	**LINK_DISABLE is an internally reserved field** Do not use. Note: This register field is sticky.
LINK_RATE	11:8	rw	**LINK_RATE is an internally reserved field** Do not use. Note: This register field is sticky.
RSVDP_12	15:12	r	**Reserved for future use**
LINK_CAPABLE	21:16	rw	**Link Mode Enable** Sets the number of lanes in the link that you want to connect to the link partner.Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 01_H **X1**: x1 03_H **X2**: x2 07_H **X4**: x4 $0F_H$ **X8**: x8 $1F_H$ **X16**: x16 $3F_H$ **X32**: x32 (not supported)
BEACON_ENABLE	24	rw	**BEACON_ENABLE is an internally reserved field** Do not use. Note: This register field is sticky.
CORRUPT_LCRC_ENABLE	25	rw	**CORRUPT_LCRC_ENABLE is an internally reserved field** Do not use. Note: This register field is sticky.
EXTENDED_SYNCH	26	rw	**EXTENDED_SYNCH is an internally reserved field** Do not use. Note: This register field is sticky.
TRANSMIT_LANE_REVERSALE_ENABLE	27	rw	**TRANSMIT_LANE_REVERSALE_ENABLE is an internally reserved field** Do not use. Note: This register field is sticky.
RSVDP_28	31:28	r	**Reserved for future use**
0	23:22	r	**Reserved** Read as all 0's; should be written with all 0's.

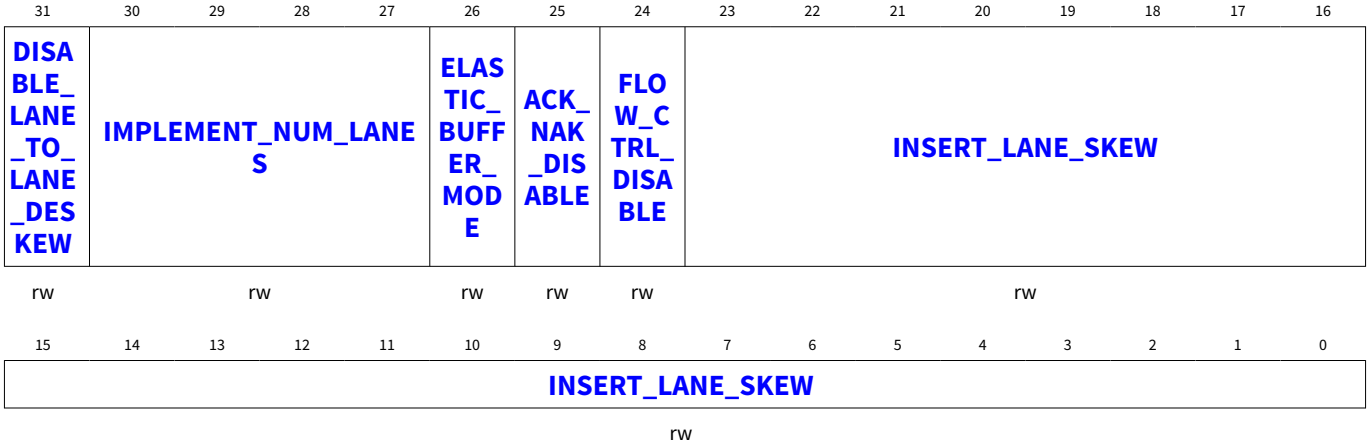
19.4.1.236 Lane Skew Register

This register is used to control the lane skew behaviour.

LANE_SKEW_OFF Offset address: 0004714_H

Lane Skew Register Kernel Reset value: $0400\ 0000_H$

19 Peripheral Component Interconnect Express (PCIe)



Field	Bits	Type	Description
INSERT_LANE_SKEW	23:0	rw	**INSERT_LANE_SKEW is an internally reserved field** Do not use. Note: This register field is sticky. 000000_H **MIN**: Zero value $0000FF_H$ **MAX**: Max value **others,** Reserved
FLOW_CTRL_DISABLE	24	rw	**Flow Control Disable** Prevents the controller from sending FC DLLPs. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
ACK_NAK_DISABLE	25	rw	**Ack/Nak Disable** Prevents the controller from sending ACK and NAK DLLPs. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
ELASTIC_BUFFER_MODE	26	rw	**Selects Elasticity Buffer operating mode:** Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **HALF_FULL**: Nominal Half Full Buffer mode 1_B **EMPTY**: Nominal Empty Buffer Mode

(table continues...)

(continued)

Field	Bits	Type	Description
IMPLEMENT_NUM_LANES	30:27	rw	**Implementation-specific Number of Lanes** Set the implementation-specific number of lanes. The number of lanes to be used when in Loopback Master. The number of lanes programmed must be equal to or less than the valid number of lanes set in LINK_CAPABLE field. You must configure this field before initiating Loopback by writing in the LOOPBACK_ENABLE field. The controller will transition from Loopback.Entry to Loopback.Active after receiving two consecutive TS1 Ordered Sets with the Loopback bit asserted on the implementation specific number of lanes configured in this field. Note: This register field is sticky. 0_H **_1_LANE**: 1 lane 1_H **_2_LANE**: 2 lanes 3_H **_4_LANE**: 4 lanes 7_H **_8_LANE**: 8 lanes F_H **_16_LANE**: 16 lanes
DISABLE_LANE_TO_LANE_DESKEW	31	rw	**Disable Lane-to-Lane Deskew** Causes the controller to disable the internal Lane-to-Lane deskew logic. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable

19.4.1.237 Timer Control and Max Function Number Register

This register holds the ack frequency, latency, replay, and max function number values.

TIMER_CTRL_MAX_FUNC_NUM_OFF Offset address: 0004718_H

Timer Control and Max Function Number Register Reset values see: Table 874

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSVDP_31	Res		UPDATE_FREQ_TIMER					TIMER_MOD_ACK_NAK					TIMER_MOD_REPLAY_TIMER		
r	r		rw					rw					rwh		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIMER_MOD_REPLAY_TIMER			RSVDP_8					MAX_FUNC_NUM							
rwh			r					rw							

Field	Bits	Type	Description
MAX_FUNC_NUM	7:0	rw	**Maximum function number that can be used in a request** Configuration requests targeted at function numbers above this value are returned with UR (unsupported request). Note: This register field is sticky. 00_H **MIN**: Zero value FF_H **MAX**: Max value
RSVDP_8	13:8	r	**Reserved for future use**
TIMER_MOD_REPLAY_TIMER	18:14	rwh	**Replay Timer Limit Modifier** Increases the time-out value for the replay timer in increments of 64 clock cycles at Gen1 or Gen2 speed, and in increments of 256 clock cycles at Gen3 speed. A value of '0' represents no modification to the timer limit. For more details, see the REPLAY_TIME_LIMIT field of the ACK_LATENCY_TIMER_OFF register. At Gen3 speed, the controller automatically changes the value of this field to DEFAULT_GEN3_REPLAY_ADJ. Note: This register field is sticky.
TIMER_MOD_ACK_NAK	23:19	rw	**Ack Latency Timer Modifier** Increases the timer value for the Ack latency timer in increments of 64 clock cycles. A value of '0' represents no modification to the timer value. For more details, see the ROUND_TRIP_LATENCY_TIME_LIMIT field of the ACK_LATENCY_TIMER_OFF register. Note: This register field is sticky.
UPDATE_FREQ_TIMER	28:24	rw	**UPDATE_FREQ_TIMER is an internally reserved field** Do not use. Note: This register field is sticky.
RSVDP_31	31	r	**Reserved for future use**

Table 874 Reset values of TIMER_CTRL_MAX_FUNC_NUM_OFF

Reset	Reset value	Note
Kernel Reset	0100 0000 0000 0XXX XX00 0000 0000 0000_B	

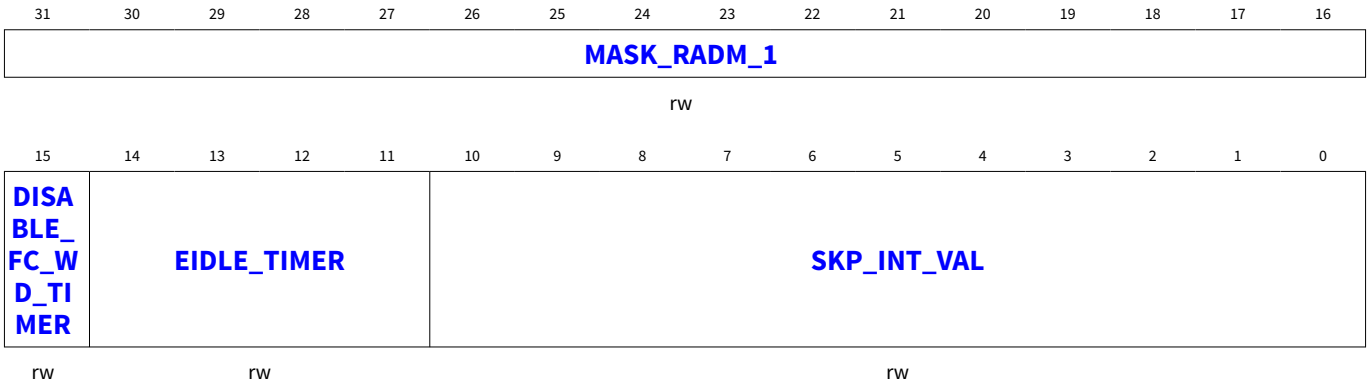
19.4.1.238 Symbol Timer Register and Filter Mask 1 Register

The Filter Mask 1 Register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule.

SYMBOL_TIMER_FILTER_1_OFF Offset address: $000471C_H$

Symbol Timer Register and Filter Mask 1 Register Kernel Reset value: $0000\ 0140_H$

19 Peripheral Component Interconnect Express (PCIe)



Field	Bits	Type	Description
SKP_INT_VAL	10:0	rw	**SKP Interval Value** The number of symbol times to wait between transmitting SKP ordered sets. The controller waits the number of symbol times in this register plus 1, between transmitting SKP ordered sets. Your application must program this register accordingly. For example, if 384 were programmed into this register (62.5 MHz for GEN 1, 4 symbols/cycle), then the controller actually transmits SKP ordered sets once every 1537 (384*4+1) symbol times. The value programmed to this register is actually clock ticks and not symbol times. Note: This value is not used at Gen3 speed; the skip interval is hardcoded to 370 blocks. Note: This register field is sticky.
EIDLE_TIMER	14:11	rw	**EIDLE_TIMER is an internally reserved field** Do not use. Note: This register field is sticky.
DISABLE_FC_WD_TIMER	15	rw	**Disable FC Watchdog Timer** Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable

(table continues...)

(continued)

Field	Bits	Type	Description
MASK_RADM_1	31:16	rw	**Filter Mask 1** The Filter Mask 1 Register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule. • [31]: CX_FLT_MASK_RC_CFG_DISCARD - 0: For RADM RC filter to not allow CFG transaction being received - 1: For RADM RC filter to allow CFG transaction being received • [30]: CX_FLT_MASK_RC_IO_DISCARD - 0: For RADM RC filter to not allow IO transaction being received - 1: For RADM RC filter to allow IO transaction being received • [29]: CX_FLT_MASK_MSG_DROP - 0: Drop MSG TLP (except for Vendor MSG). Send decoded message on the SII - 1: Do not Drop MSG (except for Vendor MSG). Send message TLPs to your application on TRGT1 and send decoded message on the SII - The default for this bit is the inverse of FLT_DROP_MSG. That is, if FLT_DROP_MSG =1, then the default of this bit is '0' (drop message TLPs). This bit only controls message TLPs other than Vendor MSGs. Vendor MSGs are controlled by Filter Mask Register 2, bits [1:0]. The controller never passes ATS Invalidate messages to the SII interface regardless of this filter rule setting. The controller passes all ATS Invalidate messages to TRGT1 (or AXI bridge master), as they are too big for the SII • [28]: CX_FLT_MASK_CPL_ECRC_DISCARD - Only used when completion queue is advertised with infinite credits and is in store-and-forward mode. - 0: Discard completions with ECRC errors - 1: Allow completions with ECRC errors to be passed up - Reserved field for SW • [27]: CX_FLT_MASK_ECRC_DISCARD - 0: Discard TLPs with ECRC errors - 1: Allow TLPs with ECRC errors to be passed up • [26]: CX_FLT_MASK_CPL_LEN_MATCH - 0: Enforce length match for completions; a violation results in cpl_abort, and possibly AER of unexp_cpl_err - 1: Mask length match for completions • [25]: CX_FLT_MASK_CPL_ATTR_MATCH - 0: Enforce attribute match for completions; a violation results in a malformed TLP error, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask attribute match for completions • [24]: CX_FLT_MASK_CPL_TC_MATCH - 0: Enforce Traffic Class match for completions; a violation results in a malformed TLP error, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask Traffic Class match for completions • [23]: CX_FLT_MASK_CPL_FUNC_MATCH - 0: Enforce function match for completions; a violation results in cpl_abort, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask function match for completions • [22]: CX_FLT_MASK_CPL_REQID_MATCH - 0: Enforce Req. Id match for completions; a violation result in cpl_abort, and possibly AER of

(table continues...)

(continued)

Field	Bits	Type	Description
			unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask Req. Id match for completions • [21]: CX_FLT_MASK_CPL_TAGERR_MATCH - 0: Enforce Tag Error Rules for completions; a violation result in cpl_abort, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask Tag Error Rules for completions • [20]: CX_FLT_MASK_LOCKED_RD_AS_UR - 0: Treat locked Read TLPs as UR for EP; Supported for RC - 1: Treat locked Read TLPs as Supported for EP; UR for RC • [19]: CX_FLT_MASK_CFG_TYPE1_REQ_AS_UR - 0: Treat CFG type1 TLPs as UR for EP; Supported for RC - 1: Treat CFG type1 TLPs as Supported for EP; UR for RC • [18]: CX_FLT_MASK_UR_OUTSIDE_BAR - 0: Treat out-of-bar TLPs as UR - 1: Do not treat out-of-bar TLPs as UR • [17]: CX_FLT_MASK_UR_POIS - 0: Treat poisoned request TLPs as UR - 1: Do not treat poisoned request TLPs as UR - The native controller always passes poisoned completions to your application except when you are using the DMA read channel • [16]: CX_FLT_MASK_UR_FUNC_MISMATCH - 0: Treat Function MisMatched TLPs as UR - 1: Do not treat Function MisMatched TLPs as UR. CX_FLT_MASK_UR_FUNC_MISMATCH is not allowed to be set unless CONFIG_LIMIT_REG =0 and TARGET_ABOVE_CONFIG_LIMIT_REG =2 in MISC_CONTROL_1_OFF register or CFG_TLP_BYPASS_EN_REG =1 and TARGET_ABOVE_CONFIG_LIMIT_REG =2 in MISC_CONTROL_1_OFF register Note: This register field is sticky.

19.4.1.239 Filter Mask 2 Register

This register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule.

FILTER_MASK_2_OFF Offset address: 0004720_H

Filter Mask 2 Register Kernel Reset value: $0000\ 0000_H$

r								rw	rw	rw	rw	rw	r	rwh	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PRE_DET_LANE			NUM_OF_LANES					FAST_TRAINING_SEQ							
rw			rw					rw							

Field	Bits	Type	Description
FAST_TRAINING_SEQ	7:0	rw	**Sets the Number of Fast Training Sequences (N_FTS) that the controller advertises as its N_FTS during Gen2 or Gen3 link training** This value is used to inform the link partner about the PHY's ability to recover synchronization after a low power state. Do not set N_FTS to zero; doing so can cause the LTSSM to go into the recovery state when exiting from L0s. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky.
NUM_OF_LANES	12:8	rw	**Predetermined Number of Lanes** Defines the number of lanes which are connected and not bad. Used to limit the effective link width to ignore 'broken" or "unused" lanes that detect a receiver. Indicates the number of lanes to check for exit from Electrical Idle in Polling.Active and L2.Idle. It is possible that the LTSSM might detect a receiver on a bad or broken lane during the Detect Substate. However, it is also possible that such a lane might also fail to exit Electrical Idle and therefore prevent a valid link from being configured. This value is referred to as the "Predetermined Number of Lanes" in section 4.2.6.2.1 of the PCI Express Base Specification. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 01_H **_1_LANE**: 1 lane 02_H **_2_LANE**: 2 lanes 03_H **_3_LANE**: 3 lanes **others,** Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
PRE_DET_LANE	15:13	rw	**Predetermined Lane for Auto Flip** This field defines which physical lane is connected to logical Lane0 by the flip operation performed in Detect. This field is used to restrict the receiver detect procedure to a particular lane when the default detect and polling procedure performed on all lanes cannot be successful. A notable example of when it is useful to program this field to a value different from the default, is when a lane is asymmetrically broken, that is, it is detected in Detect LTSSM state but it cannot exit Electrical Idle in Polling LTSSM state. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 000_B **LANE0**: Connect logical Lane0 to physical lane 0, depending on which lane is detected 001_B **LANE1**: Connect logical Lane0 to physical lane 1 010_B **LANE3**: Connect logical Lane0 to physical lane 3 011_B **LANE7**: connect logical lane0 to physical lane 7 100_B **LANE15**: Connect logical Lane0 to physical lane 15 **others,** Reserved
AUTO_LANE_FLIP_CTRL_EN	16	rw	**Enable Auto flipping of the lanes** This feature is not supported by hardware. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
DIRECT_SPEED_CHANGE	17	rwh	**Directed Speed Change** When the speed change occurs, the controller will clear the contents of this field; and a read to this field by your software will return a '0'. To manually initiate the speed change: • Write to LINK_CONTROL2_LINK_STATUS2_REG.PCIE_CAP_TARGET_LINK_SPEED in the local device • Deassert this field • Assert this field If you set the default of this field using the DEFAULT_GEN2_SPEED_CHANGE configuration parameter to '1', then the speed change is initiated automatically after link up, and the controller clears the contents of this field. If you want to prevent this automatic speed change, then write a lower speed value to the Target Link Speed field of the Link Control 2 register (LINK_CONTROL2_LINK_STATUS2_OFF.PCIE_CAP_TARGET_LINK_SPEED) through the DBI before link up. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_B **CLEAR**: Clear 1_B **SET**: Writing '1' to this field instructs the LTSSM to initiate a speed change to Gen2 or Gen3 after the link is initialized at Gen1 speed

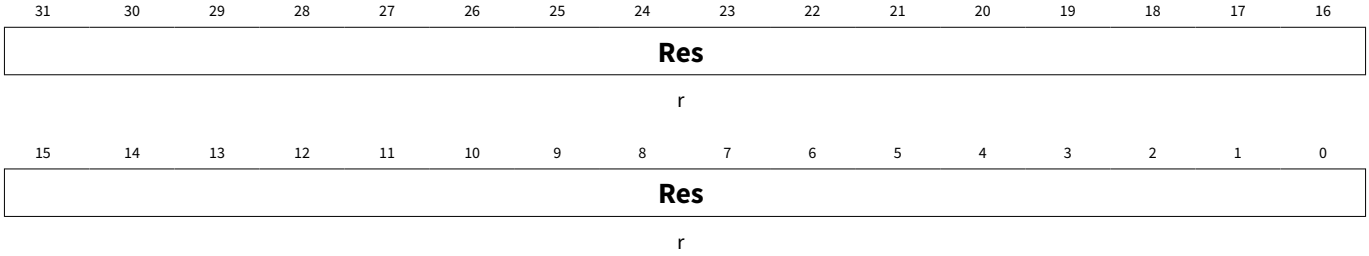
(table continues...)

(continued)

Field	Bits	Type	Description
CONFIG_TX_COMP_RX	19	rw	**Config Tx Compliance Receive Bit** Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: When set to 1, signals LTSSM to transmit TS ordered sets with the compliance receive bit assert (equal to '1')
SEL_DEEMPHASIS	20	rw	**Used to set the de-emphasis level for upstream ports** This bit selects the level of de-emphasis the link operates at. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **N_6DB**: -6 dB 1_B **N_3_5DB**: -3.5 dB
GEN1_EI_INFERENCE	21	rw	**Electrical Idle Inference Mode at Gen1 Rate** Programmable mode to determine inferred electrical idle (EI) in Recovery.Speed or Loopback.Active (as slave) state at Gen1 speed by looking for a '1' value on RxElecIdle instead of looking for a '0' on RxValid. If the PHY fails to deassert the RxValid signal in Recovery.Speed or Loopback.Active (because of corrupted EIOS for example), then EI cannot be inferred successfully in the controller by just detecting the condition RxValid=0. Note: This register field is sticky. 0_B **RXELECIDLE_TO_INFER**: Use RxElecIdle signal to infer Electrical Idle 1_B **RXVALID_TO_INFER**: Use RxValid signal to infer Electrical Idle
SELECT_DEEMPH_VAR_MUX	22	rw	**The select_deemphasis variable for DSP on entry to Recovery.RcvrCfg state is muxed between the Selectable De-emphasis field in the Link Control 2 register and the value requested by the Upstream Port in the eight consecutive TS1 Ordered Sets it received** Note: This register field is sticky. 0_B **REQUESTED_BY_USP**: The value requested by USP in Recovery.RcvrLock state through Tx TS1s from USP 1_B **FROM_LINK_CTRL_2_REG**: The value from the Selectable De-emphasis field in the Link Control 2 register
SELECTABLE_DEEMPH_BIT_MUX	23	rw	**The selectable deemphasis bit (Symbol 4 bit 6) of the transmitted TS2 Ordered Sets for DSP in Recovery.RcvrCfg state is muxed between the Selectable De-emphasis field in the Link Control 2 register and the value requested by USP in Recovery.RcvrLock state through Tx TS1s from USP** Note: This register field is sticky. 0_B **FROM_LINK_CTRL_2_REG**: The value from the Selectable De-emphasis field in the Link Control 2 register 1_B **REQUESTED_BY_USP**: The value requested by USP in Recovery.RcvrLock state through Tx TS1s from USP
0	31:24	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.1.253 PHY Status Register

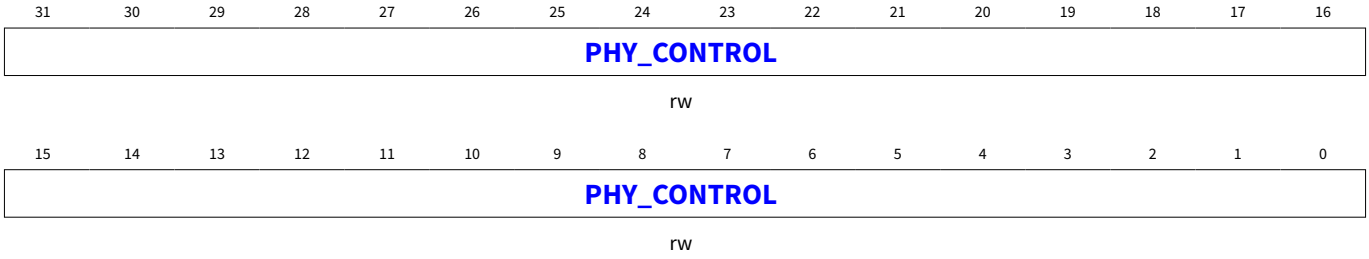
Memory mapped register from phy_cfg_status GPIO input pins.



Field	Bits	Type	Description

19.4.1.254 PHY Control Register

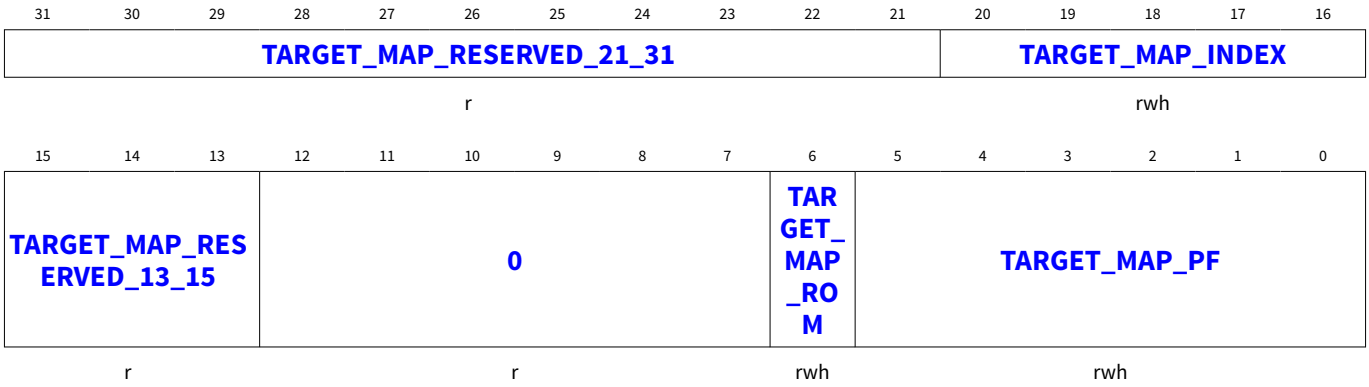
Memory mapped register to cfg_phy_control GPIO output pins.



Field	Bits	Type	Description
PHY_CONTROL	31:0	rw	**PHY Control** Data sent directly to the cfg_phy_control bus. This is a GPIO register driving the values on the static cfg_phy_control output signals, and does not in any way influence controller functionality. It can be used for any static sideband control signaling requirements that you have for your PHY. Usage of this register and the associated GPIO bus is RESERVED when the controller is connected to a Synopsys PHY. Note: This register field is sticky. 00000000_H **MIN_VAL**: Zero value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.1.255 Programmable Target Map Control Register

This register controls the target map.



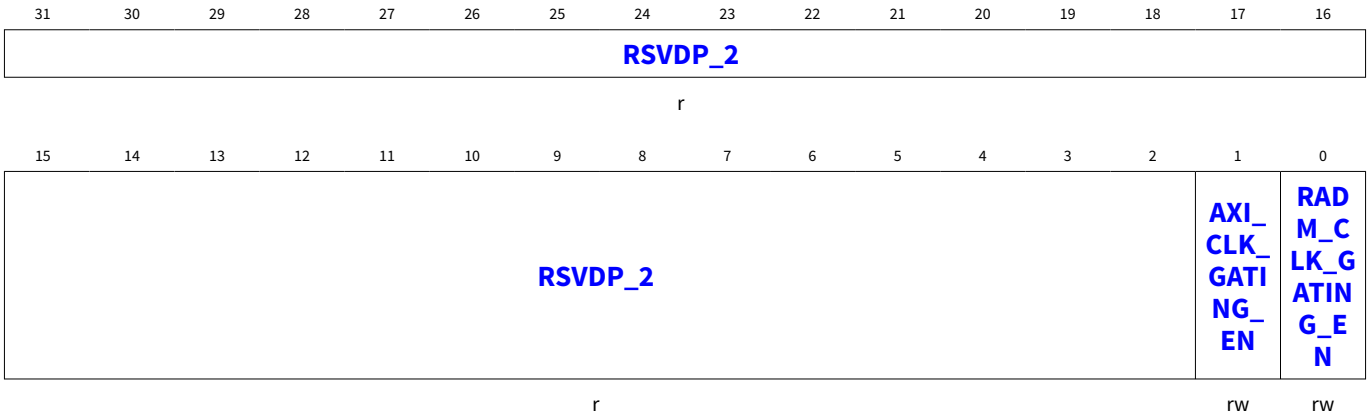
Field	Bits	Type	Description
TARGET_MAP_PF	5:0	rwh	**Target Values for each BAR on the PF Function selected by the index number** This register does not respect the Byte Enable setting, any write will affect all register bits.
TARGET_MAP_ROM	6	rwh	**Target Value for the ROM page of the PF Function selected by the index number** This register does not respect the Byte Enable setting, any write will affect all register bits.
TARGET_MAP_RESERVED_13_15	15:13	r	**Reserved** Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: R (sticky)
TARGET_MAP_INDEX	20:16	rwh	**The number of the PF Function on which the Target Values are set** This register does not respect the Byte Enable setting, any write will affect all register bits.
TARGET_MAP_RESERVED_21_31	31:21	r	**Reserved** Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: R (sticky)
0	12:7	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.1.256 Clock Gating Control Register

This register enables you to disable dynamic clock gating. By default dynamic clock gating is on, allowing the controller to autonomously enable and disable its clocks. The clock gating is performed in the clock and reset module, and is initiated by the controllers clock enable signals. The following modules support dynamic clock gating: - AXI Bridge - RADM

CLOCK_GATING_CTRL_OFF Offset address: $000488C_H$

Clock Gating Control Register Kernel Reset value: $0000\ 0003_H$



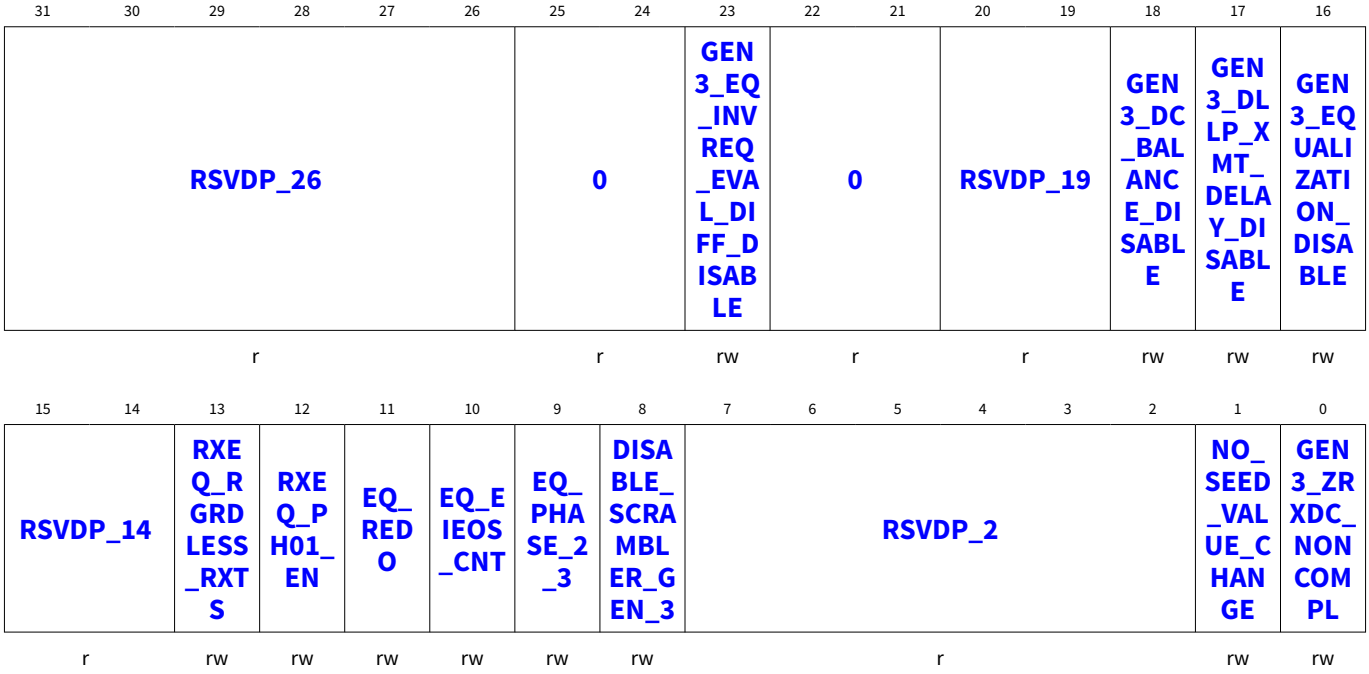
Field	Bits	Type	Description
RADM_CLK_GATING_EN	0	rw	**RADM Clock Gating Enable** This register, if set, enables the RADM to autonomously enable and disable its clock. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable (default)
AXI_CLK_GATING_EN	1	rw	**AXI Clock Gating Enable** This register enables the AXI Bridge to autonomously enable and disable the AXI Master clock, the AXI Slave clock and the AXI DBI slave clock. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable (default)
RSVDP_2	31:2	r	**Reserved for future use**

19.4.1.257 Gen3 Control Register

There is no Gen3-specific N_FTS field. The N_FTS field in the "Link Width and Speed Change Control Register" is used for both Gen2 and Gen3 speed modes. There is no Gen3-specific "Directed Speed Change" field. The "Directed Speed Change" field in the "Link Width and Speed Change Control Register" is used to change to Gen2 or Gen3 speed. A speed change to Gen3 occurs if (1) the "Directed Speed Change" field is set to '1' and (2) the "Target Link Speed" field in the Link Control 2 Register is set to Gen3. Gen3 support is advertised by both sides of the link during link training.

GEN3_RELATED_OFF Offset address: 0004890_H

Gen3 Control Register Kernel Reset value: $0000\ 2001_H$



Field	Bits	Type	Description
GEN3_ZRXDC_NONCOMPL	0	rw	**Gen3 Receiver Impedance ZRX-DC Not Compliant** Receivers that operate at 8.0 GT/s with an impedance other than the range defined by the ZRX-DC parameter for 2.5 GT/s (40-60 Ohms) must meet additional behavior requirements in the following LTSSM states: Polling, Rx_L0s, L1, L2, and Disabled. Note: This register field is sticky. 0_B **RCVR_COMPLIES**: The receiver complies with the ZRX-DC parameter for 2.5 GT/s when operating at 8 GT/s or higher 1_B **RCVR_NOT_COMPLIES**: The receiver does not comply with the ZRX-DC parameter for 2.5 GT/s when operating at 8 GT/s or higher
NO_SEED_VALUE_CHANGE	1	rw	**If this bit is set to 1, the seed value of LFSR for scrambler at Gen3 rate does not change after LinkUp = 1** This feature is not supported. Note: this register is shared for Gen3 and Gen4/Gen5 data rates. Note: This register field is sticky. 1_B **NO_CHANGE**: Not Change
RSVDP_2	7:2	r	**Reserved for future use**
DISABLE_SCRAMBLER_GEN_3	8	rw	**Disable Scrambler for Gen3 and Gen4 Data Rate** The Gen3 and Gen4 scrambler/descrambler within the controller needs to be disabled when the scrambling function is implemented outside of the controller (for example within the PHY). Note: This register field is sticky.
EQ_PHASE_2_3	9	rw	**Equalization Phase 2 and Phase 3 Disable** This applies to downstream ports only. Note: The access attributes of this field are as follows: - Wire: see description - Dbi: see description Note: This register field is sticky. 0_B **NO_TX_EQ_RX_EQ_PH01**: Rx equalization in phase 0/1 1_B **TX_EQ_23_RX_EQ_PH01**: No Rx equalization

(table continues...)

(continued)

Field	Bits	Type	Description
EQ_EIEOS_CNT	10	rw	**Equalization EIEOS Count Reset Disable** Disable requesting reset of EIEOS count during equalization. Note: This register field is sticky. 1_B **DISABLE**: Disable
EQ_REDO	11	rw	**Equalization Redo Disable** Disable autonomous mechanism for requesting to redo the equalization process. The received presets or coefficients mismatch in Recovery.RcvrLock after Recovery EQ phases causes the EQ redo requests. If the EQ redo is infinite or you do not want eq requests and redo, setting this bit to 1 will stop the EQ requests and EQ redo so that the link can go ahead to L0 state for packet trasmissions. Note: This register field is sticky.
RXEQ_PH01_EN	12	rw	**Rx Equalization Phase 0/Phase 1 Hold Enable** When this bit is set the upstream port holds phase 0 (the downstream port holds phase 1) for 10ms. Holding phase 0 or phase 1 can be used to allow sufficient time for Rx Equalization to be performed by the PHY. This bit is used during Virtex-7 Gen3 equalization. The programmable bits [RXEQ_PH01_EN, EQ_PHASE_2_3] can be used to obtain the following variations of the equalization procedure: Note: The access attributes of this field are as follows: - Wire: see description - Dbi: see description Note: This register field is sticky. 0_B **TX_EQ_23**: Tx equalization only in phase 2/3 1_B **NO_TX_EQ_NO_RX_EQ**: No Tx equalization
RXEQ_RGRDLESS_RXTS	13	rw	**When set to '1', the controller as Gen3 EQ master asserts RxEqEval to instruct the PHY to do Rx adaptation and evaluation after a 500ns timeout from a new preset request** . Note: The access attributes of this field are as follows: - Wire: see description - Dbi: see description Note: This register field is sticky. 0_B **ASSERT_1US**: mac_phy_rxeqeval asserts after 1 µs and 2 TS1 received from remote partner 1_B **ASSERT_500NS**: mac_phy_rxeqeval asserts after 500ns regardless of TS's received or not
RSVDP_14	15:14	r	**Reserved for future use**
GEN3_EQUALIZATION_DISABLE	16	rw	**Equalization Disable** Disable equalization feature. This bit cannot be changed once the LTSSM starts link training. Note: This register field is sticky.
GEN3_DLLP_XMT_DELAY_DISABLE	17	rw	**DLLP Transmission Delay Disable** Disable delay transmission of DLLPs before equalization. Note: This register field is sticky.
GEN3_DC_BALANCE_DISABLE	18	rw	**DC Balance Disable** Disable DC Balance feature. Note: This register field is sticky.
RSVDP_19	20:19	r	**Reserved for future use**
GEN3_EQ_INVREQ_EVAL_DIFF_DISABLE	23	rw	**Eq InvalidRequest and RxEqEval Different Time Assertion Disable** Disable the assertion of Eq InvalidRequest and RxEqEval at different time. Note: This register field is sticky.

(continued)

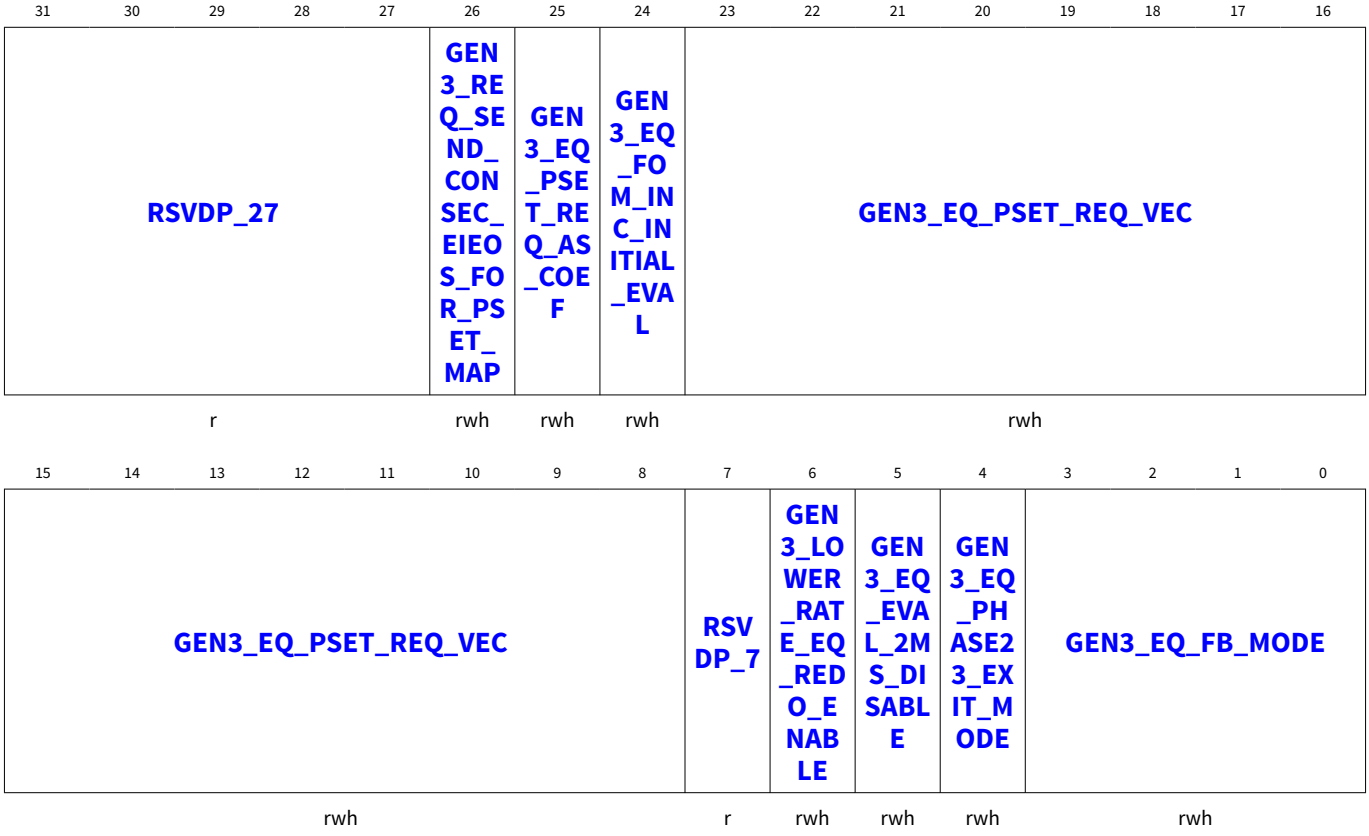
Field	Bits	Type	Description
RSVDP_26	31:26	r	**Reserved for future use**
0	22:21, 25:24	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.1.258 Gen3 EQ Control Register

This register controls equalization for Phase2 in an upstream port (USP), or Phase3 in a downstream port (DSP).

GEN3_EQ_CONTROL_OFF Offset address: $00048A8_H$

Gen3 EQ Control Register Kernel Reset value: $0501\ 7271_H$



Field	Bits	Type	Description
GEN3_EQ_FB_MODE	3:0	rwh	**Feedback Mode** Other values are reserved. Note: This register field is sticky. 0_H **DIR_CHG**: Direction Change 1_H **FOM**: Figure Of Merit **others,** Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
GEN3_EQ_PHASE23_EXIT_MODE	4	rwh	**Behavior After 24 ms Timeout (when optimal settings are not found)** For a USP: Determine next LTSSM state from Phase2 after 24ms Timeout • 0: Recovery.Speed • 1: Recovery.Equalization.Phase3 When optimal settings are not found then: • Equalization Phase 2 Successful status bit is not set in the "Link Status Register 2" when GEN3_EQ_PHASE23_EXIT_MODE = 0 • Equalization Phase 2 Successful status bit is set in the "Link Status Register 2" when GEN3_EQ_PHASE23_EXIT_MODE = 1 • Equalization Phase 2 Complete status bit is set in the "Link Status Register 2" For a DSP: Determine next LTSSM state from Phase3 after 24ms Timeout • 0: Recovery.Speed • 1: Recovery.Equalization.RcvrLock When optimal settings are not found then: • Equalization Phase 3 Successful status bit is not set in the "Link Status Register 2" when GEN3_EQ_PHASE23_EXIT_MODE = 0 • Equalization Phase 3 Successful status bit is set in the "Link Status Register 2" when GEN3_EQ_PHASE23_EXIT_MODE = 1 • Equalization Phase 3 Complete status bit is set in the "Link Status Register 2" Note: GEN3_EQ_PHASE23_EXIT_MODE = 1 affects Direction Change feed back mode. EQ requests for Figure Of Merit mode complete before 24 ms timeout. Please see GEN3_EQ_PSET_REQ_VEC Register for more. Note: This register field is sticky. 0_B **RCVRY_SPEED**: Recovery.Speed 1_B **RCVRY_EQ**: USP: Recovery.Equalization.Phase3; DSP: Recovery.Equalization.RcvrLock
GEN3_EQ_EVAL_2MS_DISABLE	5	rwh	**Phase2_3 2 ms Timeout Disable** Determine behavior in Phase2 for USP (Phase3 if DSP) when the PHY does not respond within 2ms to the assertion of RxEqEval. Note: This register field is sticky. 0_B **ABORT_CURRENT_EVA**: Abort the current evaluation, stop any attempt to modify the remote transmitter settings, Phase2 is terminated by the 24ms timeout 1_B **IGNORE_2MS_TIMEOUT**: Ignore the 2ms timeout and continue as normal This is used to support PHYs that require more than 2ms to respond to the assertion of RxEqEval.
GEN3_LOWER_RATE_EQ_REDO_ENABLE	6	rwh	**Support EQ redo and lower rate change** To access this field, RATE_SHADOW_SEL should be set to 0. Note: This register field is sticky. 0_B **NO_SUP**: Not supported 1_B **SUP**: Supported
RSVDP_7	7	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
GEN3_EQ_PSET_REQ_VEC	23:8	rwh	**Preset Request Vector** Requesting of Presets during the initial part of the EQ Master Phase. Encoding scheme is as follows: Bit [15:0] =0x0: No preset is requested and evaluated in EQ Master Phase. Bit [i] =1: "Preset=i" is requested and evaluated in EQ Master Phase. • 0000000000000000: No preset be requested and evaluated in EQ Master Phase • 000000xxxxxxxxx1: Preset 0 is requested and evaluated in EQ Master Phase • 000000xxxxxxxx1x: Preset 1 is requested and evaluated in EQ Master Phase • 000000xxxxxxx1xx: Preset 2 is requested and evaluated in EQ Master Phase • 000000xxxxxx1xxx: Preset 3 is requested and evaluated in EQ Master Phase • 000000xxxxx1xxxx: Preset 4 is requested and evaluated in EQ Master Phase • 000000xxxx1xxxxx: Preset 5 is requested and evaluated in EQ Master Phase • 000000xxx1xxxxxx: Preset 6 is requested and evaluated in EQ Master Phase • 000000xx1xxxxxxx: Preset 7 is requested and evaluated in EQ Master Phase • 000000x1xxxxxxxx: Preset 8 is requested and evaluated in EQ Master Phase • 00000x1xxxxxxxxx: Preset 9 is requested and evaluated in EQ Master Phase • 000001xxxxxxxxxx: Preset 10 is requested and evaluated in EQ Master Phase • All other encodings: Reserved Note: This register field is sticky.
GEN3_EQ_FOM_INC_INITIAL_EVAL	24	rwh	**Include Initial FOM** Include or not the FOM feedback from the initial preset evaluation performed in the EQ Master, when finding the highest FOM among all preset evaluations. Note: This register field is sticky. 0_B **DO_NOT_INCLUDE**: Do not include 1_B **INCLUDE**: Include
GEN3_EQ_PSET_REQ_AS_COEF	25	rwh	**GEN3_EQ_PSET_REQ_AS_COEF is an internally reserved field** Do not use. Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
GEN3_REQ_SEND_CONSEC_EIEOS_FOR_PSET_MAP	26	rwh	**Request controller to send back-to-back EIEOS in Recovery.RcvrLock state until presets to coefficients mapping is complete** Note: Gen3 and Gen4 share the same register bit and have the same feature. Note: This register field is sticky. 0_B **DO_NOT_REQ**: Do not request 1_B **REQ**: Request
RSVDP_27	31:27	r	**Reserved for future use**

19.4.1.259 Gen3 EQ Direction Change Feedback Mode Control Register

Equalization controls to be used in Phase2 (USP) or Phase 3 (DSP), when you set the Feedback Mode in "Gen3 EQ Control Register" to "Direction Change." These fields allow control over the initial starting point for the search of optimal coefficient settings, and allow control over the criteria used to determine when the optimal settings have been achieved. The values are applied to all the lanes.

GEN3_EQ_FB_MODE_DIR_CHANGE_OFF — Offset address: $00048AC_H$

Gen3 EQ Direction Change Feedback Mode Control Register — Kernel Reset value: $0000\ 0040_H$

Field	Bits	Type	Description
DBI_RO_WR_EN	0	rwh	**Write to RO Registers Using DBI** This bit field protects the access to the registers to avoid intended modifications.. Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Your application can write to some RO and HwInit register fields through the DBI when you set this field to '1'
DEFAULT_TARGET	1	rw	**Default target for an IO or MEM request with UR/CA/CRS received** Based on the value of this field the controller either drops or forwards these requests to your application. Note: This register field is sticky. 0_B **DROP_IO_MEM_REQ**: The controller drops all incoming I/O or MEM requests (after corresponding error reporting) A completion with UR status is generated for non-posted requests. 1_B **FWD_IO_MEM_UR_CA_CRS**: The controller forwards all incoming I/O or MEM requests with UR/CA/CRS status to your application
UR_CA_MASK_4_TRGT1	2	rw	**When this field is set to '1', the controller suppresses error logging, error message generation, and CPL generation for non-posted requests TLPs (with UR filtering status) forwarded to your application (that is, when DEFAULT_TARGET =1)** Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Set

(table continues...)

(continued)

Field	Bits	Type	Description
SIMPLIFIED_REPLAY_TIMER	3	rw	**Enables Simplified Replay Timer (Gen4)** Simplified Replay Timer can have the following Values: • A value from 24,000 to 31,000 Symbol Times when Extended Synch is 0b • A value from 80,000 to 100,000 Symbol Times when Extended Synch is 1b The Simplified Replay Timer value must not be changed while the link is in use. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
DISABLE_AUTO_LTR_CLR_MSG	4	rw	**Disable the autonomous generation of LTR clear message in upstream port** This field can have the following values. Note: This register field is sticky. 0_B **ALLOW**: Allow the autonomous generation of LTR clear message 1_B **DISABLE**: Disable the autonomous generation of LTR clear message
ARI_DEVICE_NUMBER	5	rw	**When ARI is enabled, this field enables use of the device ID** Note: This register field is sticky. ARI capability is not available in this implementation 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
CPLQ_MNG_EN	6	rw	**This field enables the Completion Queue Management feature** Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
CFG_TLP_BYPASS_EN_REG	7	rw	**Setting of this field defines how to decide the destination of Configuration requests** Note: When LNK_CORECTRL.RQRTYEN is asserted, the setting of this field is ignored. Note: This register field is sticky. 0_B **ZERO**: Configuration TLPs are routed according to the setting of TARGET_ABOVE_CONFIG_LIMIT_REG, depending on the setting of CONFIG_LIMIT_REG Refer to the definition of CONFIG_LIMIT_REG for details. 1_B **ONE**: Configuration TLPs are routed according to the setting of TARGET_ABOVE_CONFIG_LIMIT_REG, regardless the value of CONFIG_LIMIT_REG

(table continues...)

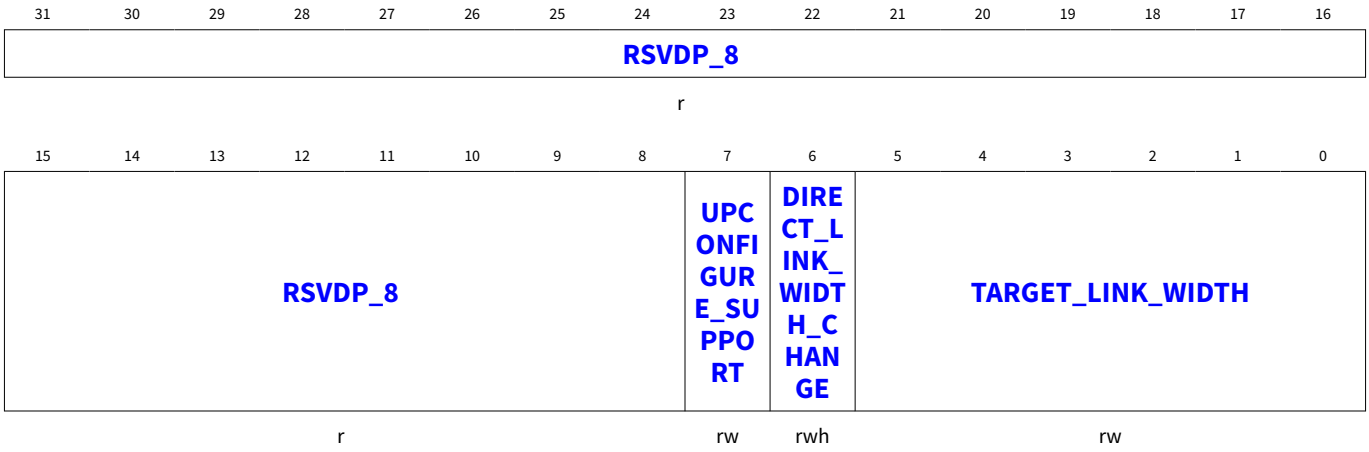
(continued)

Field	Bits	Type	Description
CONFIG_LIMIT_REG	17:8	rw	**Configuration requests are directed either to CDM or ELBI/RTRGT1 based on the value of this field** • Configuration requests with an address less CONFIG_LIMIT_REG are directed to the CDM • Configuration requests with an address greater than CONFIG_LIMIT_REG are directed to either ELBI or TRGT1 interface based on the setting of TARGET_ABOVE_CONFIG_LIMIT_REG field Your application must set a proper value for this field based on your extended configuration registers. Note: This register field is sticky.
TARGET_ABOVE_CONFIG_LIMIT_REG	19:18	rw	**Configuration requests with an address greater than CONFIG_LIMIT_REG are directed to either ELBI or TRGT1 interface based on the setting of this field** This field can have the following values: Note: This register field is sticky. 01_B **ELBI**: ELBI 10_B **TRGT1**: TRGT1 **others,** Reserved
P2P_TRACK_CPL_TO_REG	20	rw	**Determines whether to track completion of transmitted Non-Posted TLPs in P2P mode** Note: This register field is sticky. 0_B **DO_NOT_TRACk**: Do not track completion 1_B **TRACK**: Track completion
P2P_ERR_RPT_CTRL	21	rw	**Determines whether to enable Peer to Peer (P2P) error reporting** Note: This register field is sticky. 0_B **DISABLE**: Disable P2P error reporting 1_B **ENABLE**: Enable P2P error reporting
PORT_LOGIC_WR_DISABLE	22	rw	**Disable port logic register write from wire side** Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: R/W (sticky) Note: This register field is sticky.
RSVDP_23	31:23	r	**Reserved for future use**

19.4.1.263 UpConfigure Multi-lane Control Register

Used when upsizing or downsizing the link width through Configuration state without bringing the link down.

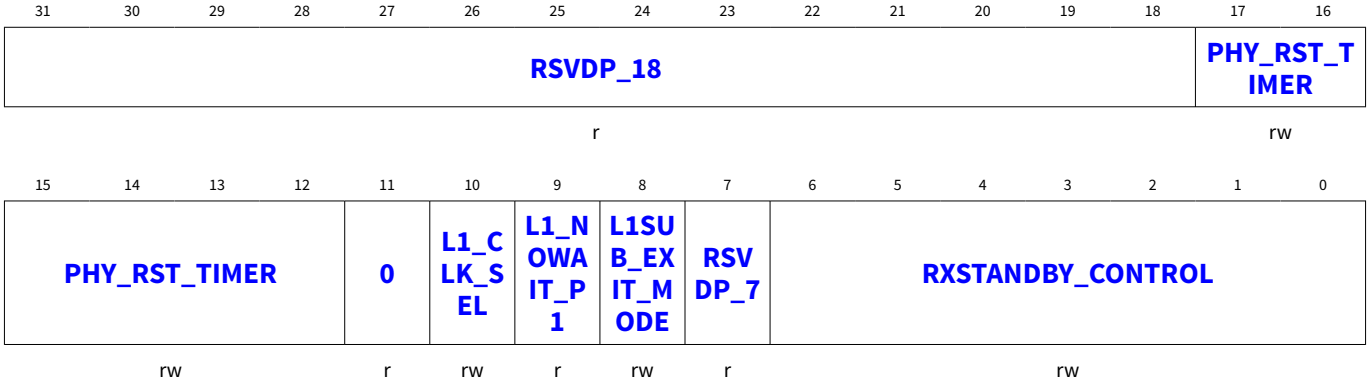
19 Peripheral Component Interconnect Express (PCIe)



Field	Bits	Type	Description
TARGET_LINK_WIDTH	5:0	rw	**Target Link Width** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 00_H **NOT_START**: Controller does not start upconfigure or autonomous width downsizing in the Configuration state 01_H **X1**: x1 02_H **X2**: x2 04_H **X4**: x4 08_H **X8**: x8 10_H **X16**: x16 20_H **X32**: x32 **others,** Reserved
DIRECT_LINK_WIDTH_CHANGE	6	rwh	**Directed Link Width Change** • If the upconfigure_capable variable is '1' and the PCIE_CAP_HW_AUTO_WIDTH_DISABLE bit in LINK_CONTROL_LINK_STATUS_REG is '0', the controller starts upconfigure or autonomous width downsizing (to the TARGET_LINK_WIDTH value) in the Configuration state • If TARGET_LINK_WIDTH value is 0x0, the controller does not start upconfigure or autonomous width downsizing in the Configuration state The controller self-clears this field when the controller accepts this request. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_B **CLEAR**: Clear 1_B **SET**: The controller always moves to Configuration state through Recovery state when this bit is set to '1'
UPCONFIGURE_SUPPORT	7	rw	**Upconfigure Support** The controller sends this value as the Link Upconfigure Capability in TS2 Ordered Sets in Configuration.Complete state. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky.
RSVDP_8	31:8	r	**Reserved for future use**

19.4.1.264 PHY Interoperability Control Register

This register controls the PHY interoperability.



Field	Bits	Type	Description
RXSTANDBY_CONTROL	6:0	rw	**Rxstandby Control** Bits 0..5 determine if the controller asserts the RxStandby signal (mac_phy_rxstandby) in the indicated condition. Bit 6 enables the controller to perform the RxStandby/RxStandbyStatus handshake. This field is reserved for internal use. You should not write to this field and change the default unless specifically instructed by Synopsys support. • [0]: Rx EIOS and subsequent T TX-IDLE-MIN • [1]: Rate Change • [2]: Inactive lane for upconfigure/downconfigure • [3]: PowerDown=P1orP2 • [4]: RxL0s.Idle • [5]: EI Infer in L0 • [6]: Execute RxStandby/RxStandbyStatus Handshake Note: This register field is sticky.
RSVDP_7	7	r	**Reserved for future use**
L1SUB_EXIT_MODE	8	rw	**L1 Exit Control Using phy_mac_pclkack_n** This field is reserved for internal use. You should not write to this field and change the default unless specifically instructed by Synopsys support. If PCLK as PHY input is selected, you should not write to this field and change the default value since PCLK as PHY input doesn't support any value other than the default. Note: This register field is sticky. 0_B **WAIT_FOR_PCLKACK**: Controller waits for the PHY to assert phy_mac_pclkack_n before exiting L1 1_B **NO_WAIT_FOR_PCLKACK**: Controller exits L1 without waiting for the PHY to assert phy_mac_pclkack_n

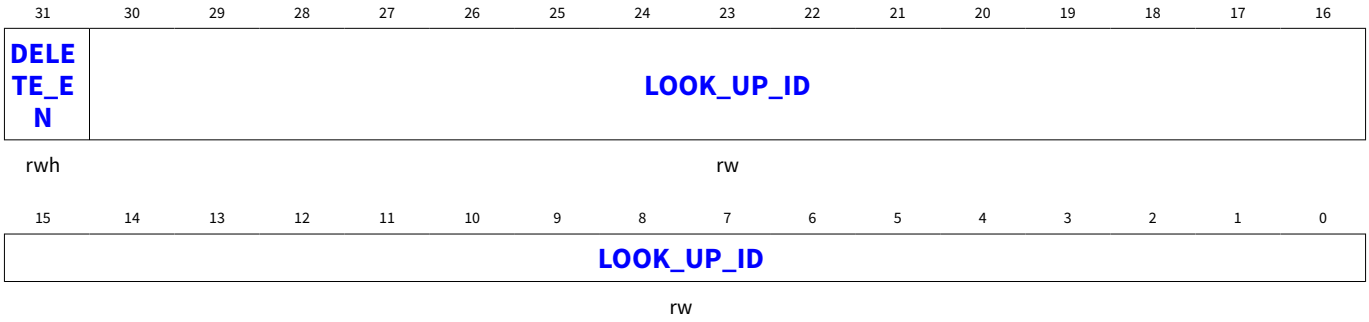
(table continues...)

(continued)

Field	Bits	Type	Description
L1_NOWAIT_P1	9	r	**L1 entry control bit** This field is reserved for internal use. You should not write to this field and change the default unless specifically instructed by Synopsys support. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **WAIT_FOR_ACK**: Controller waits for the PHY to acknowledge transition to P1 before entering L1 1_B **NO_WAIT_FOR_ACK**: Controller does not wait for PHY to acknowledge transition to P1 before entering L1
L1_CLK_SEL	10	rw	**L1 Clock control bit** This field is reserved for internal use. You should not write to this field and change the default unless specifically instructed by Synopsys support. Note: This register field is sticky. 0_B **CAN_REQ**: Controller requests aux_clk switch and core_clk gating in L1 1_B **NO_REQ**: Controller does not request aux_clk switch and core_clk gating in L1
PHY_RST_TIMER	17:12	rw	**Decide how many aux clock cycles the PHY reset lasts (0 to 63 aux clock cycles)** Note: This register field is sticky. 00_H **MIN_VAL**: Zero value $3F_H$ **MAX_VAL**: Max value
RSVDP_18	31:18	r	**Reserved for future use**
0	11	r	**Reserved** Read as 0; should be written with 0.

19.4.1.265 TRGT_CPL_LUT Delete Entry Control register

Using this register you can delete one entry in the target completion LUT. You should only use this register when you know that your application will never send the completion because of an FLR or any other reason. Note:: The target completion LUT (and associated target completion timeout event) is watching for completions (from your application on XALI0/1/2 or AXI master read channel) corresponding to previously received non-posted requests from the PCIe wire.



Field	Bits	Type	Description
LOOK_UP_ID	30:0	rw	**This number selects one entry to delete of the TRGT_CPL_LUT**

(table continues...)

(continued)

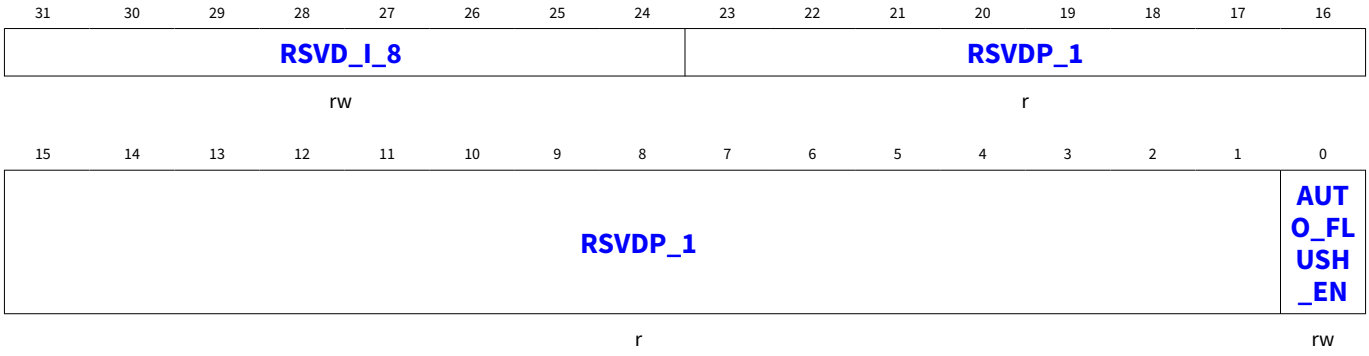
Field	Bits	Type	Description
DELETE_EN	31	rwh	**This is a one-shot bit** This is a self-clearing register field. Reading from this register field always returns a '0'. 0_B **CLEAR**: Clear 1_B **SET**: A '1' write to this bit triggers the deletion of the target completion LUT entry that is specified in the LOOK_UP_ID field

19.4.1.266 Link Reset Request Flush Control Register

This register controls link reset request flush behaviour.

LINK_FLUSH_CONTROL_OFF Offset address: $00048CC_H$

Link Reset Request Flush Control Register Kernel Reset value: $FF00\ 0001_H$



Field	Bits	Type	Description
AUTO_FLUSH_EN	0	rw	**Enables automatic flushing of pending requests before sending the reset request to the application logic to reset the PCIe controller and the AXI Bridge** The flushing process is initiated if any of the following events occur: • Hot reset request. A downstream port (DSP) can "hot reset" an upstream port (USP) by sending two consecutive TS1 ordered sets with the hot reset bit asserted • Warm (Soft) reset request. Generated when exiting from D3 to D0 and CFG_INFO.NOSOFTRST=0 • Link down reset request. A high to low transition on LNK_STAT.LINKRQRST indicates the link has gone down and the controller is requesting a reset If you disable automatic flushing, your application is responsible for resetting the PCIe controller and the AXI Bridge. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
RSVDP_1	23:1	r	**Reserved for future use**
RSVD_I_8	31:24	rw	**This is an internally reserved field** Do not use. Note: This register field is sticky.

19.4.1.267 AXI Bridge Slave Error Response Register

This register holds the AXI bridge slave error responses.

AMBA_ERROR_RESPONSE_DEFAULT_OFF Offset address: $00048D0_H$

AXI Bridge Slave Error Response Register Kernel Reset value: $0000\ 9C00_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

AMBA_ERROR_RESPONSE_MAP						RSVDP_5					AMBA_ERROR_RESPONSE_CRS		AMBA_ERROR_RESPONSE_VENDORID	RSVDP_1	AMBA_ERROR_RESPONSE_GLOBAL
rw						r					rw		rw	r	rw

Field	Bits	Type	Description
AMBA_ERROR_RESPONSE_GLOBAL	0	rw	**Global Slave Error Response Mapping** Determines the AXI slave response for all error scenarios on non-posted requests. Note: This register field is sticky. 0_B **OK_**: OKAY (with FFFF data for non-posted requests) 1_B **ERR_**: SLVERR/DECERR (the AMBA_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping)
RSVDP_1	1	r	**Reserved for future use**
AMBA_ERROR_RESPONSE_VENDORID	2	rw	**Vendor ID Non-existent Slave Error Response Mapping** Determines the AXI slave response for errors on reads to non-existent Vendor ID register. Note: This register field is sticky. 0_B **_OK_**: OKAY (with FFFF data) 1_B **_ERR_**: SLVERR/DECERR (the AMBA_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping)
AMBA_ERROR_RESPONSE_CRS	4:3	rw	**CRS Slave Error Response Mapping** Determines the AXI slave response for CRS completions. Note: This register field is sticky. 00_B **OK_**: OKAY 01_B **OK_CRS_CMPL**: OKAY with all FFFF_FFFF data for all CRS completions 10_B **OK_READ_REQ**: OKAY with FFFF_0001 data for CRS completions to vendor ID read requests, OKAY with FFFF_FFFF data for all other CRS completions 11_B **SLVERR_DECERR**: SLVERR/DECERR (the AMBA_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping)
RSVDP_5	9:5	r	**Reserved for future use**

(table continues...)

(continued)

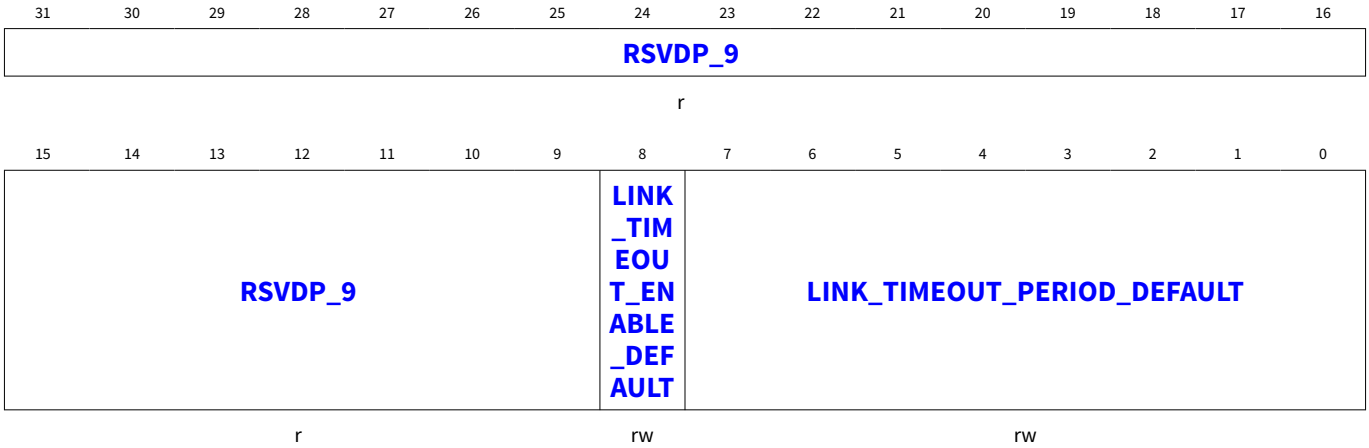
Field	Bits	Type	Description
AMBA_ERROR_RESPONSE_MAP	15:10	rw	**AXI Slave Response Error Map** Allows you to selectively map the errors received from the PCIe completion (for non-posted requests) to the AXI slave responses, slv_rresp or slv_bresp. The recommended setting is SLVERR. CRS is always mapped to OKAY. • [0] -- 0: UR (unsupported request) -> DECERR -- 1: UR (unsupported request) -> SLVERR • [1] -- 0: CRS (configuration retry status) -> DECERR -- 1: CRS (configuration retry status) -> SLVERR • [2] -- 0: CA (completer abort) -> DECERR -- 1: CA (completer abort) -> SLVERR • [3]: RESERVED (0x0) • [4]: RESERVED (0x0) • [5] -- 0: Completion Timeout -> DECERR -- 1: Completion Timeout -> SLVERR. The AXI bridge internally drops (processes internally but not passed to your application) a completion that has been marked by the Rx filter as UC or MLF, and does not pass its status directly down to the slave interface. It waits for a timeout and then signals "Completion Timeout" to the slave interface. The controller sets the AXI slave read databus to 0xFFFF for all error responses. Note: This register field is sticky.
RSVDP_16	31:16	r	**Reserved for future use**

19.4.1.268 Link Down AXI Bridge Slave Timeout Register

If your application issues outbound requests to the AXI bridge slave interface before the PCIe link is operational, the controller starts a "flush" timer. The timeout value of the timer is set by this register. If the timer times out before the PCIe link is operational, the bridge TX request queues are flushed.

AMBA_LINK_TIMEOUT_OFF Offset address: $00048D4_H$

Link Down AXI Bridge Slave Timeout Register Kernel Reset value: $0000\ 0032_H$



Field	Bits	Type	Description
LINK_TIMEOUT_PERIOD_DEFAULT	7:0	rw	**Timeout Value (ms)** The timer will timeout and then flush the bridge TX request queues after this amount of time. The timer counts when there are pending outbound AXI slave interface requests and the PCIe TX link is not transmitting any of these requests. The timer is clocked by core_clk. Note: This register field is sticky.
LINK_TIMEOUT_ENABLE_DEFAULT	8	rw	**Disable Flush** Note: This register field is sticky. 0_B **ENABLE**: Enable 1_B **DISABLE**: You can disable the flush feature by setting this field to '1'
RSVDP_9	31:9	r	**Reserved for future use**

19.4.1.269 AXI Bridge Ordering Control

This register controls the AXI Bridge Ordering.

AMBA_ORDERING_CTRL_OFF Offset address: $00048D8_H$

AXI Bridge Ordering Control Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RSVDP_0	0	r	**Reserved for future use**
AX_SNP_EN	1	rw	**AXI Serialize Non-Posted Requests Enable** This field enables the AXI Bridge to serialize same ID Non-Posted Read/Write Requests on the wire. Serialization implies one outstanding same ID NP Read or Write on the wire and used to avoid AXI RAR and WAW hazards at the remote link partner. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
RSVDP_2	2	r	**Reserved for future use**

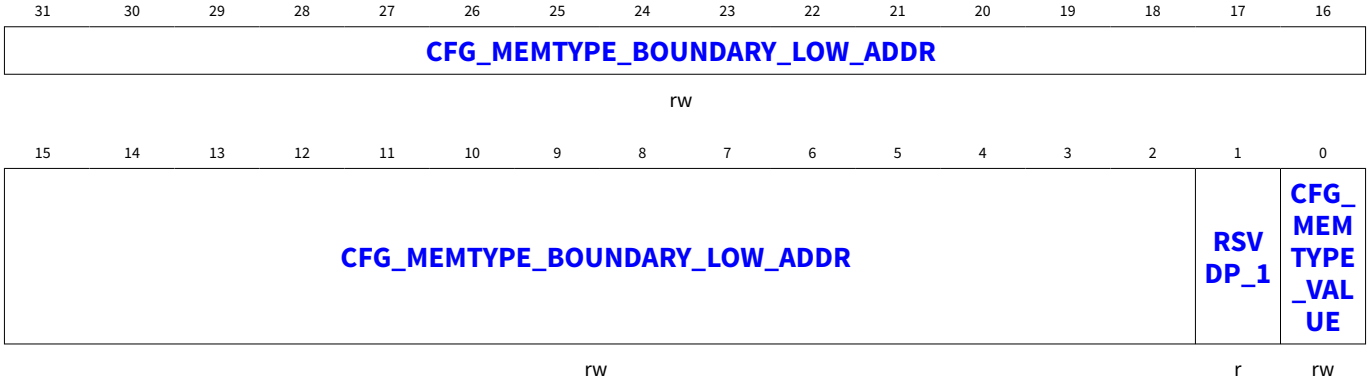
(table continues...)

(continued)

Field	Bits	Type	Description
AX_MSTR_ORDR_P_EVENT_SEL	4:3	rw	**AXI Master Posted Ordering Event Selector** This field selects how the master interface determines when a P write is completed when enforcing the PCIe ordering rule, "NP must not pass P" at the AXI Master Interface. The AXI protocol does not support ordering between channels. Therefore, NP reads can pass P on your AXI bus fabric. This can result in an ordering violation when the read overtakes a P that is going to the same address. Therefore, the bridge master does not issue any NP requests until all outstanding P writes reach their destination. It does this by waiting for the all of the write responses on the B channel. This can affect the performance of the master read channel. For scenarios where the interconnect serializes the AXI master "AW", "W" and "AR" channels,you can increase the performance by reducing the need to wait until the complete Posted transaction has effectively reached the application slave. Note: This setting will not affect: • MSI interrupt catcher and P data ordering. This is always driven by the B'last event • DMA read engine TLP ordering. This is always driven by the B'last event • NP write transactions which are always serialized with P write transactions 00_B **B**: B'last event: wait for the all of the write responses on the B channel thereby ensuring that the complete Posted transaction has effectively reached the application slave (default) 01_B **AW**: AW'last event: wait until the complete Posted transaction has left the AXI address channel at the bridge master 10_B **W**: W'last event: wait until the complete Posted transaction has left the AXI data channel at the bridge master 11_B **RSVD**: Reserved
RSVDP_5	6:5	r	**Reserved for future use**
AX_MSTR_ZEROLREAD_FW	7	rw	**AXI Master Zero Length Read Forward to the application** The AXI bridge is able to terminate in order with the Posted transactions the zero length read, implementing the PCIe express flush semantics of the Posted transactions. 0_B **_0_LN_RD_TERMINATE**: The zero length Read is terminated at the DW PCIe AXI bridge master 1_B **_0_LN_RD_FWD**: The zero length Read is forward to the application
RSVDP_8	31:8	r	**Reserved for future use**

19.4.1.270 ACE Cache Coherency Control Register 1

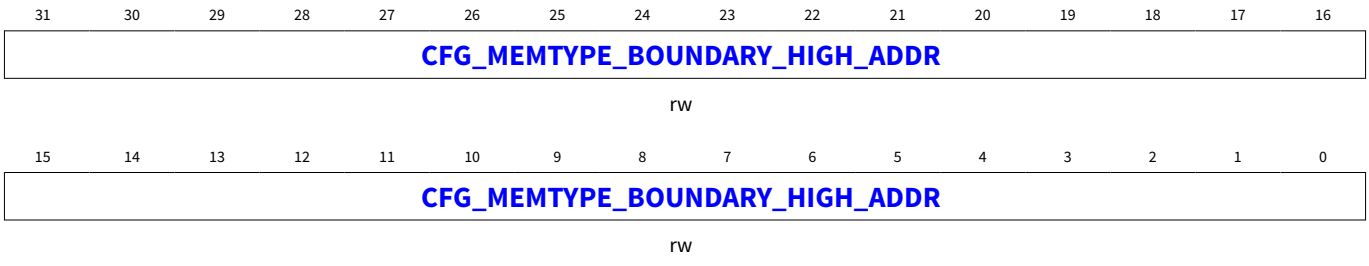
This register controls the ACE cache coherency operation.



Field	Bits	Type	Description
CFG_MEMTYPE_VALUE	0	rw	**Sets the memory type for the lower and upper parts of the address space:** Note: This register field is sticky. 0_B **LOWER_PREPH**: lower = Peripheral; upper = Memory 1_B **LOWER_MEM**: lower = Memory type; upper = Peripheral
RSVDP_1	1	r	**Reserved for future use**
CFG_MEMTYPE_BOUNDARY_LOW_ADDR	31:2	rw	**Boundary Lower Address For Memory Type** Bits [31:0] of dword-aligned address of the boundary for Memory type. The two lower address LSBs are '00'. Addresses up to but not including this value are in the lower address space region; addresses equal or greater than this value are in the upper address space region. Note: This register field is sticky.

19.4.1.271 ACE Cache Coherency Control Register 2

This register controls the ACE cache coherency operation.



Field	Bits	Type	Description
CFG_MEMTYPE_BOUNDARY_HIGH_ADDR	31:0	rw	**Boundary Upper Address For Memory Type** Bits [63:32] of the 64-bit dword-aligned address of the boundary for Memory type. Note: This register field is sticky.

19.4.1.272 ACE Cache Coherency Control Register 3

This register controls the ACE cache coherency operation.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	CFG_MSTR_AWCACHE_VALUE				0				CFG_MSTR_ARCACHE_VALUE				0

r	rw				r				rw				r		

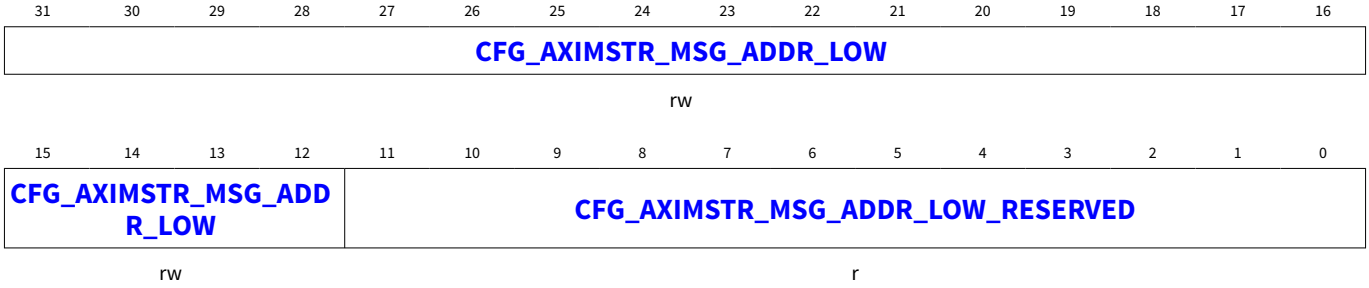
Field	Bits	Type	Description
CFG_MSTR_ARCACHE_MODE	6:3	rw	**Master Read CACHE Signal Behavior** Defines how the individual bits in mstr_arcache are controlled. Note: This register field is sticky. 0_H **SET_BY_AXI_MASTER**: set automatically by the AXI master 1_H **SET_BY_FIELD**: set by the value of the corresponding bit of the CFG_MSTR_ARCACHE_VALUE field **others,** Reserved
CFG_MSTR_AWCACHE_MODE	14:11	rw	**Master Write CACHE Signal Behavior** Defines how the individual bits in mstr_awcache are controlled. Note: for message requests the value of mstr_awcache is always "0000" regardless of the value of this bit. Note: This register field is sticky. 0_H **SET_BY_AXI_MASTER**: set automatically by the AXI master 1_H **SET_BY_FIELD**: set by the value of the corresponding bit of the CFG_MSTR_AWCACHE_VALUE field **others,** Reserved
CFG_MSTR_ARCACHE_VALUE	22:19	rw	**Master Read CACHE Signal Value** Value of the individual bits in mstr_arcache when CFG_MSTR_ARCACHE_MODE is '1'. Note: This register field is sticky.
CFG_MSTR_AWCACHE_VALUE	30:27	rw	**Master Write CACHE Signal Value** Value of the individual bits in mstr_awcache when CFG_MSTR_AWCACHE_MODE is '1'. Note: Not applicable to message requests; for message requests the value of mstr_awcache is always '0000'. Note: This register field is sticky.
0	2:0, 10:7, 18:15, 26:23, 31	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.1.273 Lower 32-bits of the Programmable AXI Address

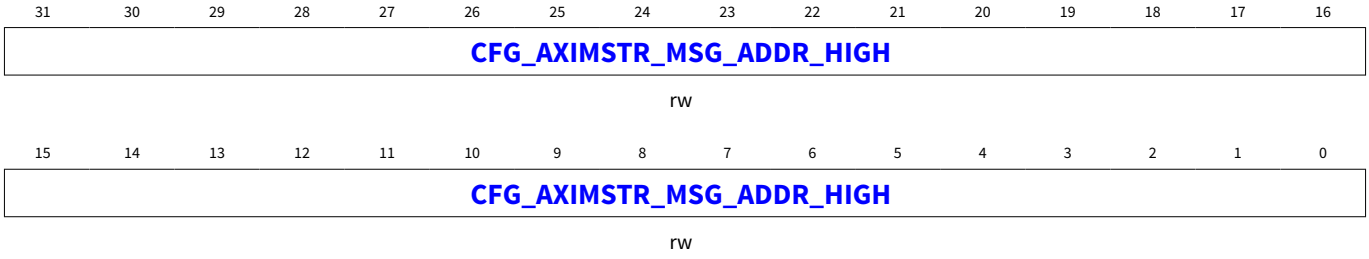
Lower 20 bits of the programmable AXI address to which Messages coming from wire are mapped. Bits [11:0] of the register are tied to zero for the address to be 4k-aligned. In previous releases, the third and fourth DWORDs of a message (Msg/MsgD) TLP header were delivered though the AXI master address bus (mstr_awaddr). These DWORDS are now supplied through the mstr_awmisc_info_hdr_34dw[63:0] output; and the value on mstr_awaddr is driven to the value you have programmed into the AXI_MSTR_MSG_ADDR_LOW_OFF and AXI_MSTR_MSG_ADDR_HIGH_OFF registers.



Field	Bits	Type	Description
CFG_AXIMSTR_MSG_ADDR_LOW_RESERVED	11:0	r	**Reserved for future use** Note: This register field is sticky.
CFG_AXIMSTR_MSG_ADDR_LOW	31:12	rw	**Lower 20-bits of the programmable AXI address for Messages** Note: This register field is sticky.

19.4.1.274 Upper 32-bits of the Programmable AXI Address

Upper 32 bits of the programmable AXI address to which Messages coming from wire are mapped.



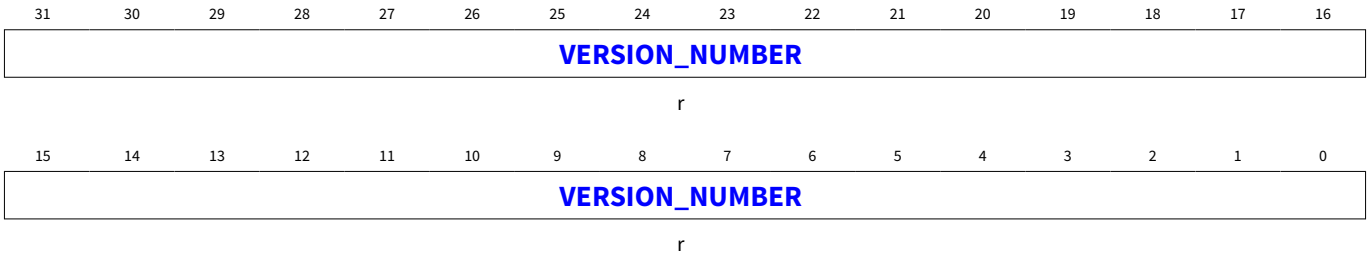
Field	Bits	Type	Description
CFG_AXIMSTR_MSG_ADDR_HIGH	31:0	rw	**Upper 32 bits of the programmable AXI address for Messages** Note: This register field is sticky.

19.4.1.275 PCIe Controller IIP Release Version Number

The version number is given in hex format. You should convert each pair of hex characters to ASCII to interpret. Using 4.70a (GA) as an example: - VERSION_NUMBER = 0x3437302a which translates to 470* - VERSION_TYPE = 0x67612a2a which translates to ga** Using 4.70a-ea01 as an example: - VERSION_NUMBER = 0x3437302a which translates to 470* - VERSION_TYPE = 0x65613031 which translates to ea01 GA is a general release available on www.designware.com EA is an early release available on a per-customer basis.

PCIE_VERSION_NUMBER_OFF Offset address: $00048F8_H$

PCIe Controller IIP Release Version Number Kernel Reset value: $3537\ 312A_H$



Field	Bits	Type	Description

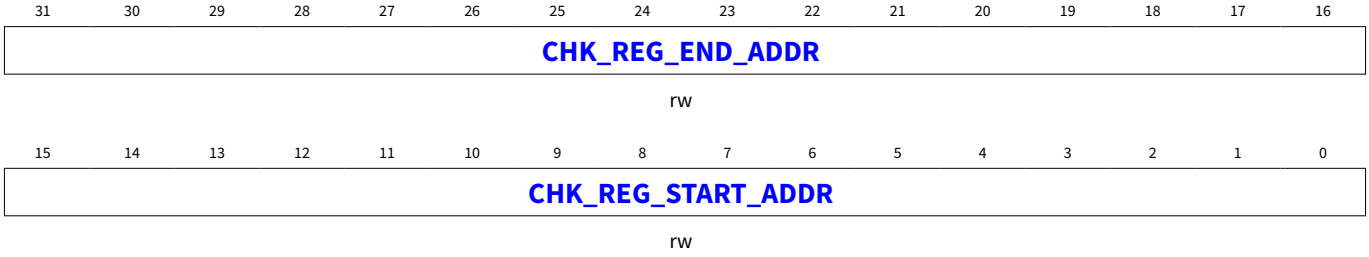
CHK_REG_LOGIC_ERROR	17	rw1ch	**The system has detected an error in its own checking logic** Note: This register field is sticky. Software write with 1 clears this bit-field. 0_B **CLEAR**: Clear 1_B **SET**: Indicates an error in comparison logic
CHK_REG_COMPLETE	18	rw1ch	**The system has completed a checking cycle** Note: This register field is sticky. Software write with 1 clears this bit-field. 0_B **CLEAR**: Clear 1_B **SET**: Indicates the system has completed a checking cycle
RSVDP_19	31:19	r	**Reserved for future use**

19.4.1.289 CDM Register Checking First and Last address to check

This register holds the first and last address to check.

PL_CHK_REG_START_END_OFF Offset address: $0004B24_H$

CDM Register Checking First and Last address to check Kernel Reset value: $0BFF\ 0000_H$



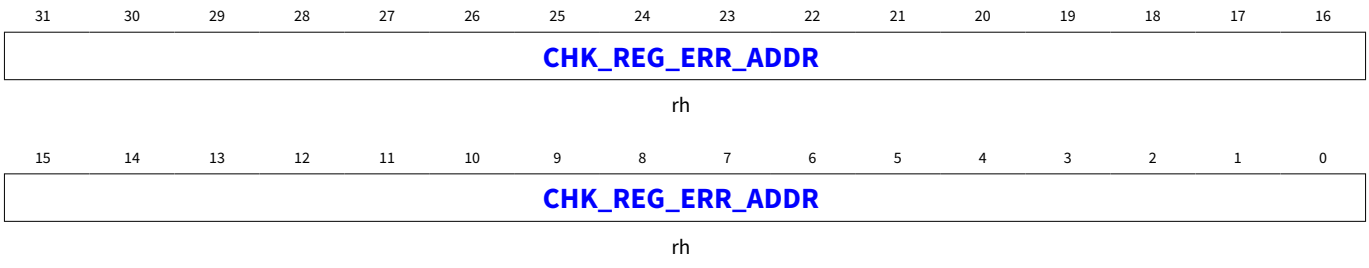
Field	Bits	Type	Description
CHK_REG_START_ADDR	15:0	rw	**The first address that is checked by the system** Note: This register field is sticky. 0000_H **MIN_VAL**: Zero value $FFFF_H$ **MAX_VAL**: Max value
CHK_REG_END_ADDR	31:16	rw	**The last address that is checked by the system** Note: This register field is sticky. 0000_H **MIN_VAL**: Zero value $FFFF_H$ **MAX_VAL**: Max value

19.4.1.290 CDM Register Checking Error Address

This register holds the CDM register checking error address.

PL_CHK_REG_ERR_ADDR_OFF Offset address: $0004B28_H$

CDM Register Checking Error Address Kernel Reset value: $0000\ 0000_H$



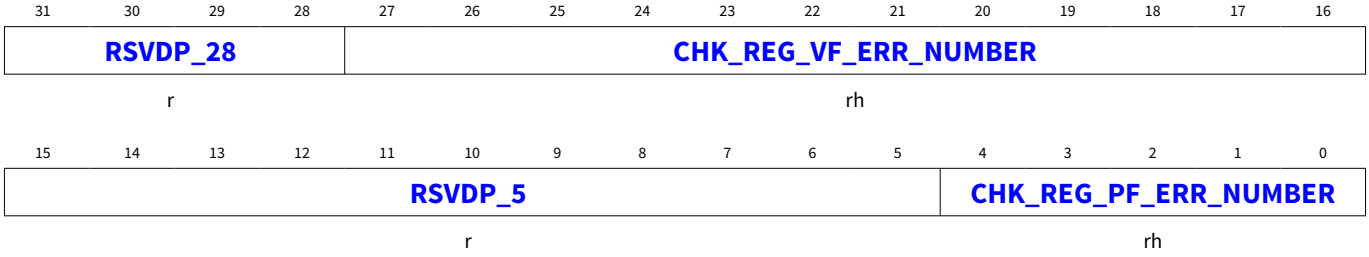
Field	Bits	Type	Description
CHK_REG_ERR_ADDR	31:0	rh	**The address at which an error has been detected** Valid only when the CDM Register Checker Comparison Error bit is set in the status register. Note: This register field is sticky. 00000000_H **MIN_VAL**: Zero value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.1.291 CDM Register Checking error PF Numbers

This register holds the CDM Register checking error PF numbers.

PL_CHK_REG_ERR_PF_VF_OFF Offset address: $0004B2C_H$

CDM Register Checking error PF Numbers Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CHK_REG_PF_ERR_NUMBER	4:0	rh	**The PF number at which the error was detected** Valid only when the CDM Register Checker Comparison Error bit is set in the status register. Note: This register field is sticky. 00_H **MIN_VAL**: Zero value $1F_H$ **MAX_VAL**: Max value
RSVDP_5	15:5	r	**Reserved for future use**
CHK_REG_VF_ERR_NUMBER	27:16	rh	**The VF number at which the error was detected** Valid only when the CDM Register Checker Comparison Error bit is set in the status register. Note: This register field is sticky. 000_H **MIN_VAL**: Zero value $7FF_H$ **MAX_VAL**: Max value **others,** Reserved
RSVDP_28	31:28	r	**Reserved for future use**

19.4.1.292 LTR Latency Register

The function of this register field (and all other fields in this register) differs between an upstream port and a downstream port. For an upstream port, the register fields capture the corresponding fields in the LTR messages that are transmitted by the port. For a downstream port, the register fields capture the corresponding fields in the LTR messages that are received by the port.

PL_LTR_LATENCY_OFF Offset address: $0004B30_H$

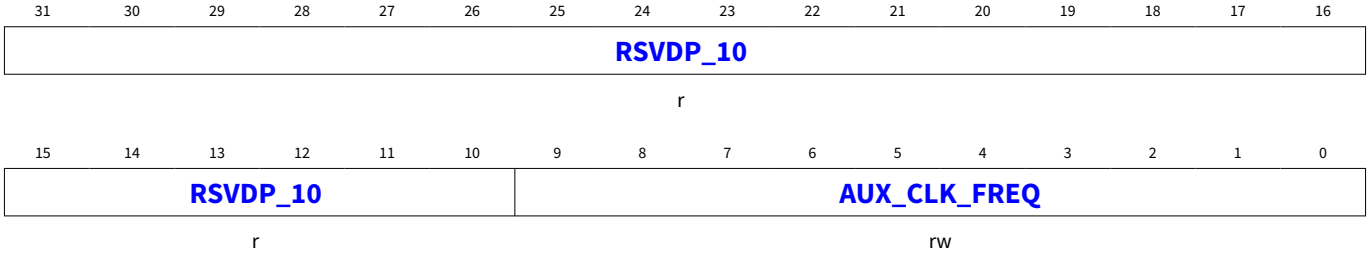
19.4.1.293 Auxiliary Clock Frequency Control Register

This register controls the auxiliary clock frequency.

AUX_CLK_FREQ_OFF Offset address: $0004B40_H$

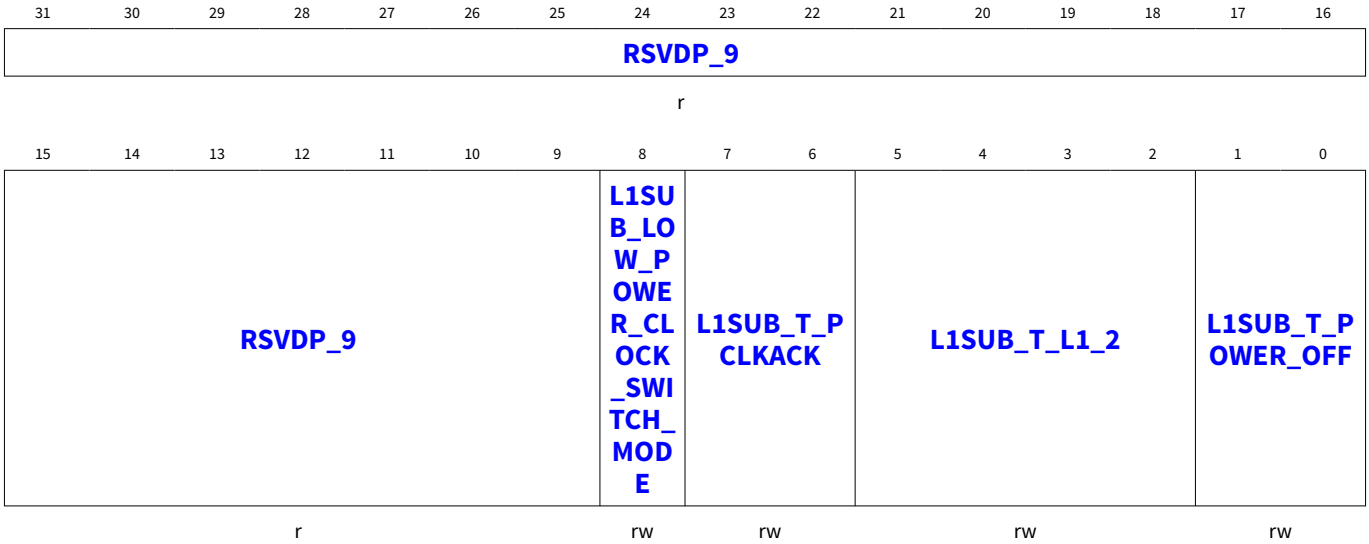
Auxiliary Clock Frequency Control Register Kernel Reset value: $0000\ 000A_H$



Field	Bits	Type	Description
AUX_CLK_FREQ	9:0	rw	**The aux_clk frequency in MHz** This value is used to provide a 1 µs reference for counting time during low-power states with aux_clk when the PHY has removed the pipe_clk. If the actual frequency (f) of aux_clk does not exactly match the programmed frequency (f_prog), then there is an error in the time counted by the controller that can be expressed in percentage as: err% = (f_prog/f-1)*100. For example if f=2.5 MHz and f_prog=3 MHz, then err% =(3/2.5-1)*100 =20%, meaning that the time counted by the controller on aux_clk will be 20% greater than the time in µs programmed in the corresponding time register (for example T_POWER_ON). Note: This register field is sticky.
RSVDP_10	31:10	r	**Reserved for future use**

19.4.1.294 L1 Substates Timing Register

This register holds L1 substates timing information.



Field	Bits	Type	Description
L1SUB_T_POWER_OFF	1:0	rw	**Duration (in 1 µs units) of L1.2.Entry** Range is 1..4. Note: This register field is sticky. 00_B **MIN_VAL**: Min value 11_B **MAX_VAL**: Max value

(table continues...)

(continued)

Field	Bits	Type	Description
L1SUB_T_L1_2	5:2	rw	**Duration (in 1 µs units) of L1.2** Range is 1..16. Note: This register field is sticky. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
L1SUB_T_PCLKACK	7:6	rw	**Max delay (in 1 µs units) between a MAC request to remove the clock and a PHY response** If the PHY does not respond within this time the request is aborted. Range is 1..4 Note: This register field is sticky. 00_B **MIN_VAL**: Min value 11_B **MAX_VAL**: Max value
L1SUB_LOW_POWER_CLOCK_SWITCH_MODE	8	rw	**If the bit is set to 1'b1 the controller will delay the switching of aux_clk to the slow platform clock until it detects that the link partner has de-asserted CLKREQ#** Note: This register field is sticky. 0_B **CLEAR**: The reference clock may be gated off when CLKREQ# is de-asserted 1_B **SET**: The reference clock shall be kept running regardless of the CLKREQ# setting
RSVDP_9	31:9	r	**Reserved for future use**

19.4.1.295 Powerdown Control and Status Register

This is the Powerdown Control and Status register.

19.4.1.302 BAR i Mask Register

This register is the mask for BAR_REG. Normally, the BAR masks are used for indicating the amount of address space that each BAR requests from host software. The BAR masks determine which bits in each BAR are non-writable by host software, which determines the size of the address space claimed by each BAR. The BAR mask values indicate the range of low-order bits, in each implemented BAR, not to use for address matching. The BAR mask value also indicates the range of low-order bits in the BAR that cannot be written from the host. The application can write to all BAR bits to allow setting of memory, I/O, and other standard BAR options. Your local CPU can change the mask at runtime using the DBI. The mask register is invisible to the PCIe wire but visible to your local CPU through the DBI. The reset value of BARMASK_REG0 is 0x3FFF instead of 0xFFFF. You cannot read the mask register but you can write to it.

BARi_MASK_REG (i=0-5) Offset address: 0006010_H+i*4

BAR i Mask Register Kernel Reset value: $0000\ FFFF_H$

Field	Bits	Type	Description
PCI_MSIX_PBA_BIR	2:0	rwh	**MSI-X PBA BIR** This field indicates which one of a Function's Base Address Registers , located beginning at 10h in Configuration Space, or entry in the Enhanced Allocation capability with a matching BEI, is used to map the Function's MSI-X PBA into Memory Space. The PBA BIR value definitions are identical to those for the Table BIR . Note: The access attributes of this field are as follows: • Wire: No access • Dbi: if (DBI_RO_WR_EN == 1 && MSIX_CAP_ENABLE=1) then R/W else R Note: This register field is sticky.
PCI_MSIX_PBA_OFFSET	31:3	rwh	**MSI-X PBA Offset** Used as an offset from the address contained by one of the Function's Base Address Registers to point to the base of the MSI-X PBA. The lower 3 PBA BIR bits are masked off (set to zero) by software to form a 32-bit QWORD-aligned offset. Note: The access attributes of this field are as follows: • Wire: No access • Dbi: if (DBI_RO_WR_EN == 1 && MSIX_CAP_ENABLE=1) then R/W else R Note: This register field is sticky.

19.4.1.306 DMA Arbitration Scheme for TRGT1 Interface

This register is used to control traffic priorities among various sources that are delivered to your application through TRGT1 where 0x0 represents the highest priority. - Non-DMA Rx Requests - DMA Write Channel MRd Requests (DMA data requests and LL element/descriptor access) - DMA Read Channel MRd Requests (LL element/descriptor access) - DMA Read Channel MWr Requests Concurrent traffic from channels with same priority are sorted according to Round-Robin arbitration rules. The arbitration priority defaults to Non-DMA requests (highest), Write Channel MRd, Read Channel MRd, Read Channel MWr.

RSVDP_1															DMA_WRITE_ENGINE
r															rwh

Field	Bits	Type	Description
DMA_WRITE_ENGINE	0	rwh	**DMA Write Engine Enable** For normal operation, you must initially set this bit to '1', before any other software setup action. You do not need to toggle or rewrite to this bit during normal operation. You should set this bit to '0' when you want to "Soft Reset" the DMA controller write logic. There are three possible reasons for resetting the DMA controller write logic • The "Abort Interrupt Status" bit is set in the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF), and any of the bits in the DMA Write Error Status Register (DMA_WRITE_ERR_STATUS_OFF) are set. Resetting the DMA controller write logic re-initializes the control logic, ensuring that the next DMA write transfer is executed successfully. • You have executed the procedure outlined in "Stop Bit", after which, the "Abort Interrupt Status" bit is set and the Channel Status(CS) field of the DMA Write Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_i) is set to "Stopped". Resetting the DMA controller write logic re-initializes the control logic ensuring that the next DMA write transfer is executed successfully • During software development, when you incorrectly program the DMA write engine To "Soft Reset" the DMA controller write logic, you must: • De-assert the DMA write engine enable bit. • Wait for the DMA to complete any in-progress TLP transfer, by waiting until a read on the DMA write engine enable bit returns a '0'. • Assert the DMA write engine enable bit. This "Soft Reset" does not clear the DMA configuration registers. The DMA write transfer does not start until you write to the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_B **DISABLE**: Disable (Soft Reset) 1_B **ENABLE**: Enable
RSVDP_1	15:1	r	**Reserved for future use**

19.4.1.309 DMA Write Doorbell Register

This register controls the DMA write channel doorbell.

DMA_WRITE_DOORBELL_OFF Offset address: 0007010_H

DMA Write Doorbell Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WR_STOP	RSVDP_3														
rwh	r														

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVDP_3													WR_DOORBELL_NUM		
r													rwh		

Field	Bits	Type	Description
WR_DOORBELL_NUM	2:0	rwh	**Doorbell Number** You must write the channel number to this register to start the DMA write transfer for that channel. The DMA detects a write to this register field even if the value of this field does not change. You do not need to toggle or write any other value to this register to start a new transfer. The range of this field is 0x0 to 0x7, where 0x0 corresponds to channel 0. Note: A write to this field triggers the controller to exit L1 substates. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_3	30:3	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
WR_STOP	31	rwh	**Stop** Set in conjunction with the Doorbell Number field. The DMA write channel stops issuing requests, sets the channel status to "Stopped", and asserts the "Abort" interrupt if it is enabled. Before setting the Stop bit, you must read the channel Status field (CS) of the DMA Write Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) to ensure that the write channel is "Running" (transferring data). For more information, see "Stopping the DMA Transfer (Software Stop)". Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.1.310 DMA Write Engine Channel Arbitration Weight Low Register

The 5-bit channel weight (for write channels 0-3) specifies the maximum number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached or DMA channel request transfer size reaches zero, the WWR arbiter selects the next channel to be processed. Your software must initialize this register before ringing the doorbell. Value range is (0-0x1F) corresponding to (1-32) transaction requests.

DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF Offset address: 0007018_H

DMA Write Engine Channel Arbitration Weight Low Register — Kernel Reset value: $0000\ 8421_H$

Field	Bits	Type	Description
WRITE_CHANNEL0_WEIGHT	4:0	rw	**Channel 0 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
WRITE_CHANNEL1_WEIGHT	9:5	rw	**Channel 1 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

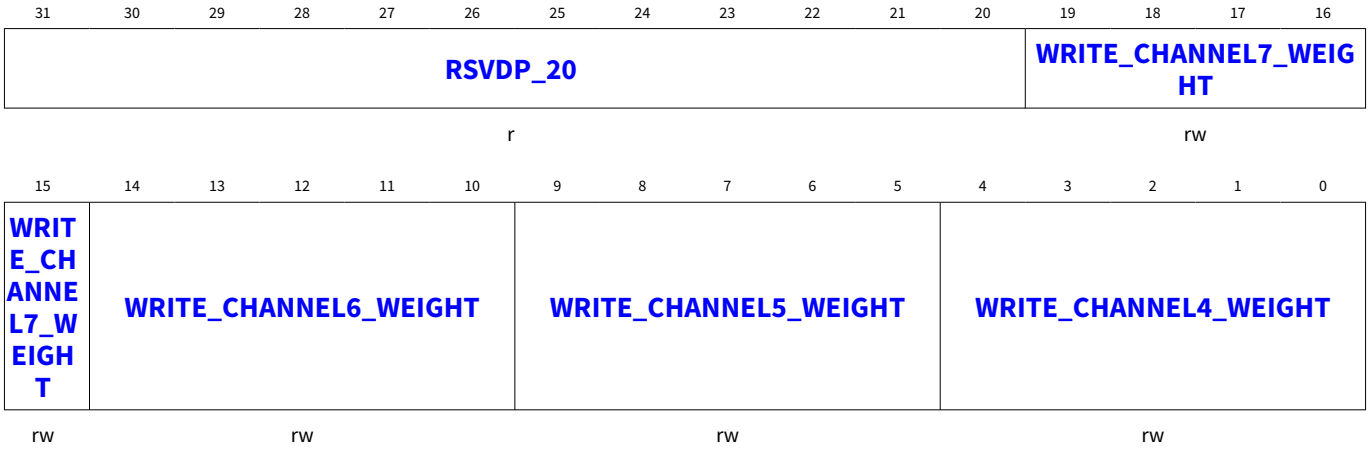
(table continues...)

(continued)

Field	Bits	Type	Description
WRITE_CHANNEL2_WEIGHT	14:10	rw	**Channel 2 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
WRITE_CHANNEL3_WEIGHT	19:15	rw	**Channel 3 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_20	31:20	r	**Reserved for future use**

19.4.1.311 DMA Write Engine Channel Arbitration Weight High Register

The 5-bit channel weight (for write channels 4-7) specifies the maximum number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached or DMA channel request transfer size reaches zero, the WWR arbiter selects the next channel to be processed. Your software must initialize this register before ringing the doorbell. For more details, see "Multichannel Arbitration". Value range is (0-0x1F) corresponding to (1-32) transaction requests.



Field	Bits	Type	Description
WRITE_CHANNEL4_WEIGHT	4:0	rw	**Channel 4 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
WRITE_CHANNEL5_WEIGHT	9:5	rw	**Channel 5 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
WRITE_CHANNEL6_WEIGHT	14:10	rw	**Channel 6 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
WRITE_CHANNEL7_WEIGHT	19:15	rw	**Channel 7 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. 19.4.1.315 DMA Read Engine Channel Arbitration Weight High Register

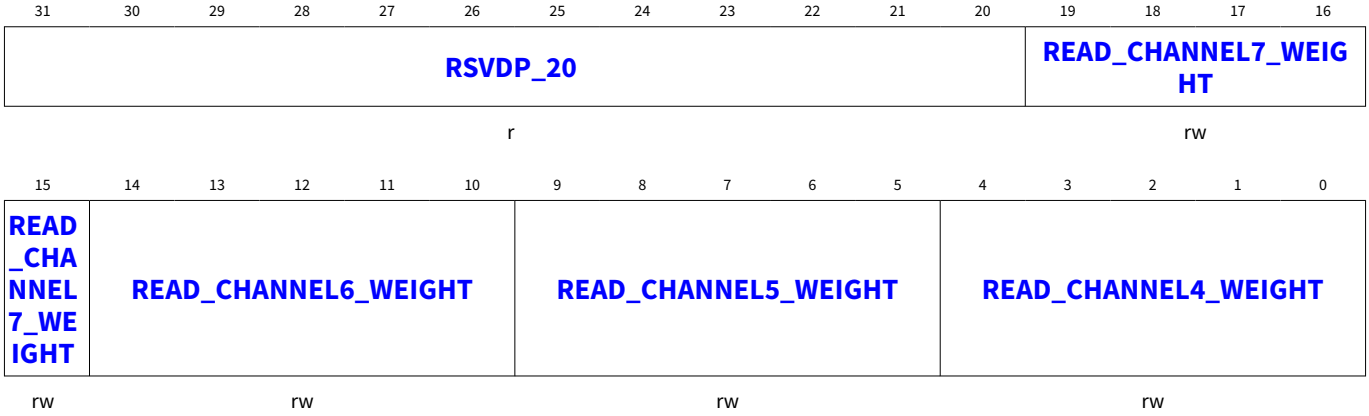
The 5-bit channel weight (for read channels 4-7) specifies the maximum number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached or DMA channel request transfer size reaches zero, the WWR arbiter selects the next channel to be processed. Your software must initialize this register before ringing the doorbell. For more details, see "Multichannel Arbitration". Value range is (0-0x1F) corresponding to (1-32) transaction requests.



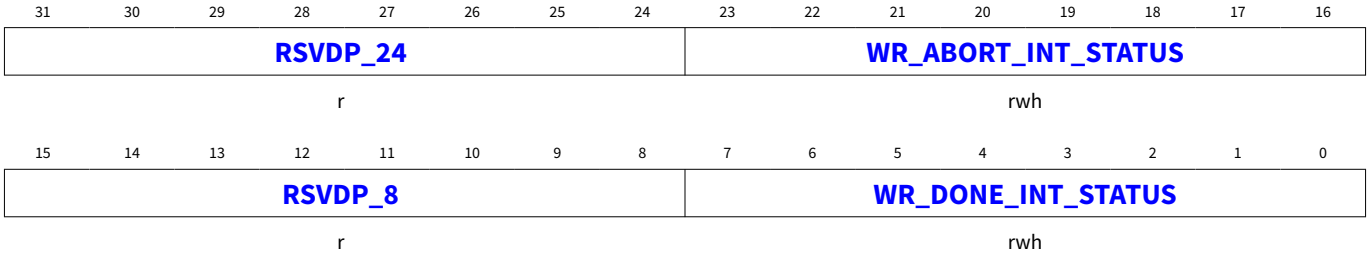
Field	Bits	Type	Description
READ_CHANNEL4_WEIGHT	4:0	rw	**Channel 4 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
READ_CHANNEL5_WEIGHT	9:5	rw	**Channel 5 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
READ_CHANNEL6_WEIGHT	14:10	rw	**Channel 6 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
READ_CHANNEL7_WEIGHT	19:15	rw	**Channel 7 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_20	31:20	r	**Reserved for future use**

19.4.1.316 DMA Write Interrupt Status Register

This register indicates the status of Abort and Done interrupts for the DMA write channels.

DMA_WRITE_INT_STATUS_OFF Offset address: $000704C_H$

DMA Write Interrupt Status Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
WR_DONE_INT_STATUS	7:0	rwh	**Done Interrupt Status** The DMA write channel has successfully completed the DMA transfer. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA write interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA write interrupt Clear register to clear this interrupt bit. Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register . Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_8	15:8	r	**Reserved for future use**
WR_ABORT_INT_STATUS	23:16	rwh	**Abort Interrupt Status** The DMA write channel has detected an error, or you manually stopped the transfer as described in "Error Handling Assistance by Remote Software". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA write interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA write interrupt Clear register to clear this interrupt bit Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_24	31:24	r	**Reserved for future use**

19.4.1.317 DMA Write Interrupt Mask Register

This register holds the Abort and Done DMA write interrupt mask.

DMA_WRITE_INT_MASK_OFF Offset address: 0007054_H

DMA Write Interrupt Mask Register Kernel Reset value: $000F\ 000F_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RSVDP_8								APP_READ_ERR_DETECT							
r								rh							

Field	Bits	Type	Description
APP_READ_ERR_DETECT	7:0	rh	**Application Read Error Detected** The DMA write channel has received an error response from the AXI bus while reading data from it. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA write interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the DMA Write Interrupt Clear Register (DMA_WRITE_INT_CLEAR_OFF) to clear this error bit.
RSVDP_8	15:8	r	**Reserved for future use**
LINKLIST_ELEMENT_FETCH_ERR_DETECT	23:16	rh	**Linked List Element Fetch Error Detected** The DMA write channel has received an error response from the AXI bus while reading a linked list element from local memory. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA write interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the DMA Write Interrupt Clear Register (DMA_WRITE_INT_CLEAR_OFF) to clear this error bit.
RSVDP_24	31:24	r	**Reserved for future use**

19.4.1.320 DMA Write Done IMWr Address Low Register

This register holds the lower 32 bits of the Done IMWr TLP address.

DMA_WRITE_DONE_IMWR_LOW_OFF Offset address: 0007060$_H$

DMA Write Done IMWr Address Low Register Kernel Reset value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RSVDP_8								0				WR_CHANNEL_LLRAIE			
r								r				rw			

Field	Bits	Type	Description
WR_CHANNEL_LLRAIE	3:0	rw	**Write Channel LL Remote Abort Interrupt Enable (LLRAIE)** You enable the write channel remote abort interrupt through this bit. The LIE and RIE bits in the LL element enable the write channel done interrupts. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only. For more details, see "Interrupt Handling". Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_8	15:8	r	**Reserved for future use**
WR_CHANNEL_LLLAIE	19:16	rw	**Write Channel LL Local Abort Interrupt Enable (LLLAIE)** You enable the write channel local abort interrupt through this bit. The LIE and RIE bits in the LL element enable the write channel done interrupts. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only. For more details, see "Interrupt Handling". Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_24	31:24	r	**Reserved for future use**
0	7:4, 23:20	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.1.329 DMA Read Interrupt Status Register

This register indicates the status of Abort and Done interrupts for the DMA read channels.

DMA_READ_INT_STATUS_OFF Offset address: $00070A0_H$

DMA Read Interrupt Status Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVDP_8								RD_DONE_INT_STATUS							
r								rwh							

Field	Bits	Type	Description
RD_DONE_INT_STATUS	7:0	rwh	**Done Interrupt Status** The DMA read channel has successfully completed the DMA read transfer. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA read interrupt Clear register to clear this interrupt bit Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_8	15:8	r	**Reserved for future use**
RD_ABORT_INT_STATUS	23:16	rwh	**Abort Interrupt Status** The DMA read channel has detected an error, or you manually stopped the transfer as described in "Stopping the DMA Transfer (Software Stop)". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. You can read the DMA Read Error Status Low Register (DMA_READ_ERR_STATUS_LOW_OFF) and DMA Read Error Status High Register (DMA_READ_ERR_STATUS_HIGH_OFF) to determine the source of the error. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA read interrupt Clear register to clear this interrupt bit. Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_24	31:24	r	**Reserved for future use**

19.4.1.330 DMA Read Interrupt Mask Register

This register holds the Abort and Done DMA read interrupt mask.

DMA_READ_INT_MASK_OFF Offset address: $00070A8_H$

DMA Read Interrupt Mask Register Kernel Reset value: $000F\ 000F_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RSVDP_8								0				RD_DONE_INT_MASK			
r								r				rw			

Field	Bits	Type	Description
RD_DONE_INT_MASK	3:0	rw	**Done Interrupt Mask** Prevents the Done interrupt status field in the DMA read interrupt status register from asserting the edma_int output. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_8	15:8	r	**Reserved for future use**
RD_ABORT_INT_MASK	19:16	rw	**Abort Interrupt Mask** Prevents the Abort interrupt status field in the DMA read interrupt status register from asserting the edma_int output. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_24	31:24	r	**Reserved for future use**
0	7:4, 23:20	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.1.331 DMA Read Interrupt Clear Register

You can write to this register to clear the Abort and Done read interrupts.

DMA_READ_INT_CLEAR_OFF Offset address: $00070AC_H$

DMA Read Interrupt Clear Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVDP_8								APP_WR_ERR_DETECT							
r								rh							

Field	Bits	Type	Description
APP_WR_ERR_DETECT	7:0	rh	**Application Write Error Detected** The DMA read channel has received an error response from the AXI bus while writing data to it. This error is fatal. You must restart the transfer from the beginning, as the channel context is corrupted, and the transfer is not rolled back. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit Note, this clears all bits in this register, and also the DMA Read Error Status High register (DMA_READ_ERR_STATUS_HIGH_OFF).
RSVDP_8	15:8	r	**Reserved for future use**
LINK_LIST_ELEMENT_FETCH_ERR_DETECT	23:16	rh	**Linked List Element Fetch Error Detected** - The DMA read channel has received an error response from the AXI bus while reading a linked list element from local memory. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the DMA Read Interrupt Clear Register (DMA_READ_INT_CLEAR_OFF) to clear this error bit Note, this clears all bits in this register, and also the DMA Read Error Status High register (DMA_READ_ERR_STATUS_HIGH_OFF).
RSVDP_24	31:24	r	**Reserved for future use**

19.4.1.333 DMA Read Error Status High Register

This register provides information pertaining to completion errors.

DMA_READ_ERR_STATUS_HIGH_OFF Offset address: $00070B8_H$

DMA Read Error Status High Register Kernel Reset value: $0000\ 0000_H$

rh								rh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CPL_ABORT								UNSUPPORTED_REQ							
rh								rh							

Field	Bits	Type	Description
UNSUPPORTED_REQ	7:0	rh	**Unsupported Request** The DMA read channel has received a PCIe unsupported request completion status from the remote device in response to the MRd request. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the DMA Read Interrupt Clear Register (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
CPL_ABORT	15:8	rh	**Completer Abort** The DMA read channel has received a PCIe completer abort completion status from the remote device in response to the MRd request. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the DMA Read Interrupt Clear Register (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.

(table continues...)

(continued)

Field	Bits	Type	Description
CPL_TIMEOUT	23:16	rh	**Completion Time Out** The DMA read channel has timed-out while waiting for the remote device to respond to the MRd request, or a malformed CplD has been received. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the DMA Read Interrupt Clear Register (DMA_READ_INT_CLEAR_OFF) to clear this error bit Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
DATA_POISIONING	31:24	rh	**Data Poisoning** The DMA read channel has detected data poisoning in the completion from the remote device (in response to the MRd request). The DMA read channel will drop the completion and then be halted. The CX_FLT_MASK_UR_POIS filter rule does not affect this behavior. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the DMA Read Interrupt Clear Register (DMA_READ_INT_CLEAR_OFF) to clear this error bit Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.

19.4.1.334 DMA Read Linked List Error Enable Register

The LIE and RIE bits in the LL element enable the channel "done" interrupts (local and remote). The LLLAIE and LLRAIE bits enable the channel "abort" interrupts (local and remote).

DMA_READ_LINKED_LIST_ERR_EN_OFF Offset address: $00070C4_H$

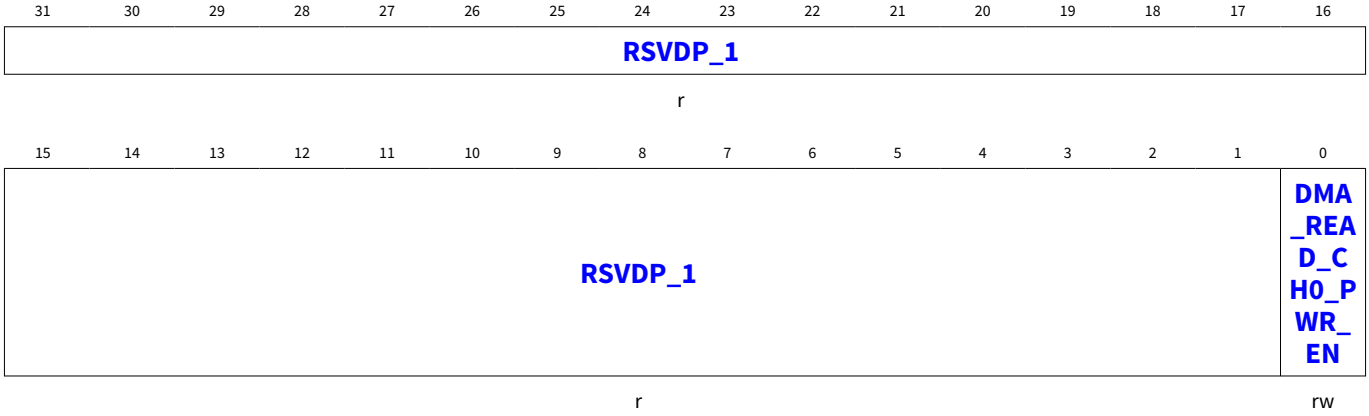
RSVDP_1	31:1	r	**Reserved for future use**

19.4.1.348 DMA Read Channel i Power Enable Register

This register controls power enable/disable for read channel 0.

DMA_READ_CHi_PWR_EN_OFF (i=0-3) Offset address: 0007168_H+i*4

DMA Read Channel i Power Enable Register Kernel Reset value: $0000\ 0000_H$



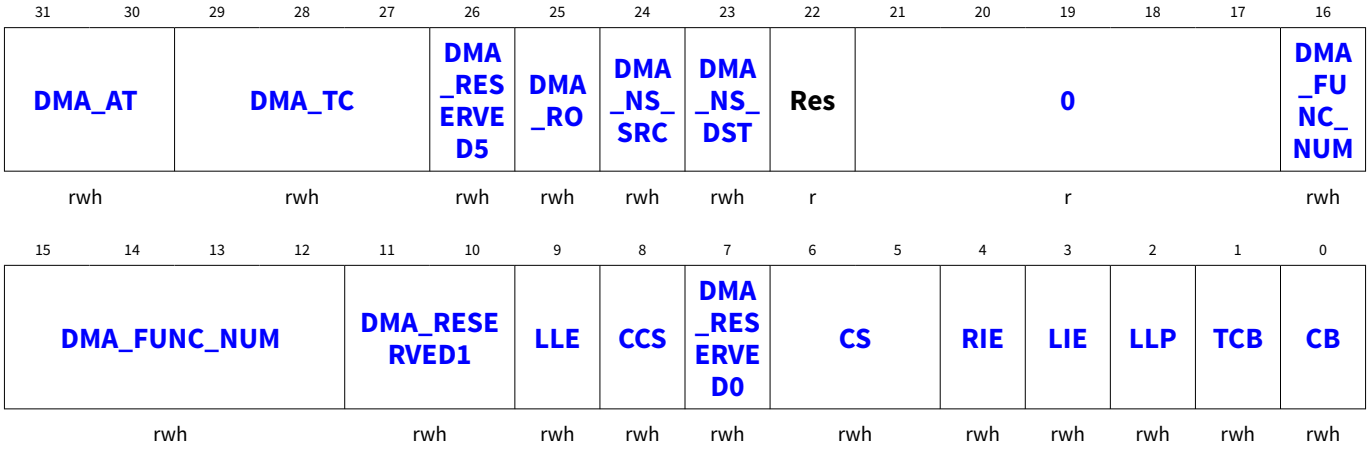
Field	Bits	Type	Description
DMA_READ_CH0_PWR_EN	0	rw	**DMA Read Channel 0 Power enable/disable** 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
RSVDP_1	31:1	r	**Reserved for future use**

19.4.1.349 DMA Write Channel i Control 1 Register

This register controls the DMA write channel operation.

DMA_CH_CONTROL1_OFF_WRCH_i (i=0-3) Offset address: 0007200_H+i*200_H

DMA Write Channel i Control 1 Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CB	0	rwh	**Cycle Bit (CB)** Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the CB of the linked list element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
TCB	1	rwh	**Toggle Cycle Bit (TCB)** Indicates to the DMA to toggle its interpretation of the CB. Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the TCB of the linked list element. this field is not defined in a data LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
LLP	2	rwh	**Load Link Pointer (LLP)** Used in linked list mode only. Indicates that this linked list element is a link element, and its LL element pointer dwords are pointing to the next (non-contiguous) element. The DMA loads this field with the LLP of the linked list element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
LIE	3	rwh	**Local Interrupt Enable (LIE)** You must set this bit to enable the generation of the Done or Abort Local interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the LIE of the LL element. The LIE bit in a LL element only enables the Done interrupt. In non-LL mode, the LIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RIE	4	rwh	**Remote Interrupt Enable (RIE)** You must set this bit to enable the generation of the Done or Abort Remote interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the RIE of the LL element. The RIE bit in a LL element only enables the Done interrupt. In non-LL mode, the RIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
CS	6:5	rwh	**Channel Status (CS)** The channel status bits identify the current operational state of the DMA channel. The operation state encoding for each DMA channel is a s follows: 00_B **RESERVED**: Reserved 01_B **RUNNING**: This channel is active and transferring data 10_B **HALTED**: An error condition has been detected, and the DMA has stopped this channel 11_B **STOPPED**: The DMA has transferred all data for this channel, or you have prematurely stopped this channel by writing to the Stop field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF)
DMA_RESERVED0	7	rwh	**Reserved** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
CCS	8	rwh	**Consumer Cycle State (CCS)** Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". You must initialize this bit. The DMA updates this bit during linked list operation. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
LLE	9	rwh	**Linked List Enable (LLE)** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_B **DISABLE**: Disable linked list operation 1_B **ENABLE**: Enable linked list operation
DMA_RESERVED1	11:10	rwh	**Reserved** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_FUNC_NUM	16:12	rwh	**DMA Channel Physical Function Number** This field indicates the physical function associated with the DMA channel. The controller uses this field to form the requester ID of the generated MRd/MWr DMA TLPs. Note: The behavior is undefined if any value outside of the valid range is set for this field Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 00_H **Min_Val**: Physical Channel Function Number starts at 0 $1F_H$ **Max_Val**: The maximum number of Physical Functions, so the maximum value of this field is 0
DMA_NS_DST	23	rwh	**Destination No Snoop TLP Header Bit** The DMA uses this TLP header field when generating MWr (DAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_NS_SRC	24	rwh	**Source No Snoop TLP Header Bit** The DMA uses this TLP header field when generating MRd (SAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_RO	25	rwh	**Relaxed Ordering TLP Header Bit (RO)** DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_RESERVED5	26	rwh	**Reserved** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_TC	29:27	rwh	**Traffic Class TLP Header Bit (TC)** The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
DMA_AT	31:30	rwh	**Address Translation TLP Header Bit (AT)** The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
0	21:17	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.1.350 DMA CH i Write Transfer Size Register

This register holds the DMA write transfer size.

DMA_TRANSFER_SIZE_OFF_WRCH_i (i=0-3) Offset address: $0007208_H+i*200_H$

DMA CH i Write Transfer Size Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMA_TRANSFER_SIZE															
rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DMA_TRANSFER_SIZE															
rwh															

Field	Bits	Type	Description
DMA_TRANSFER_SIZE	31:0	rwh	**DMA Transfer Size** You program this register with the size of the DMA transfer. The maximum DMA transfer size is 4Gbytes. The minimum transfer size is one byte (0x1). This field is automatically decremented by the DMA as the DMA write channel transfer progresses. This field indicates the number bytes remaining to be transferred. When all bytes are successfully transferred the current transfer size is zero. In LL mode, the DMA overwrites this register with the corresponding dword of the LL element. You can read this register to monitor the transfer progress, however in some scenarios this register is updated after a delay. For example, when less than 3 channels are doorbelled, this register is updated only after a descriptor finishes(linked list mode), or the transfer ends (non-linked list mode). Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.1.351 DMA CH i Write SAR Low Register

This register holds the lower 32 bits of the Source Address Register (SAR).

DMA_SAR_LOW_OFF_WRCH_i (i=0-3) Offset address: $000720C_H+i*200_H$

DMA CH i Write SAR Low Register Kernel Reset value: $0000\ 0000_H$

rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SRC_ADDR_REG_LOW															
rwh															

Field	Bits	Type	Description
SRC_ADDR_REG_LOW	31:0	rwh	**Source Address Register (lower 32 bits)** Indicates the next address to be read from. The DMA increments the SAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding dword of the LL element. - DMA Read: The SAR is the address of the remote memory. - DMA Write: The SAR is the address of the local memory. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.1.352 DMA CH i Write SAR High Register

This register holds the higher 32 bits of the Source Address Register (SAR).

DMA_SAR_HIGH_OFF_WRCH_i (i=0-3) Offset address: $0007210_H+i*200_H$

DMA CH i Write SAR High Register Kernel Reset value: $0000\ 0000_H$

rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SRC_ADDR_REG_HIGH															
rwh															

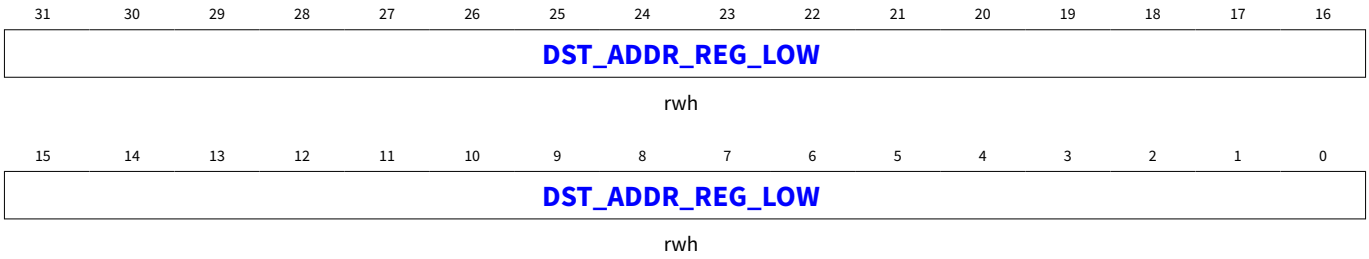
Field	Bits	Type	Description
SRC_ADDR_REG_HIGH	31:0	rwh	**Source Address Register (higher 32 bits)** In LL mode, the DMA overwrites this with the corresponding dword of the LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.1.353 DMA CH i Write DAR Low Register

This register holds the lower 32 bits of the Destination Address Register (DAR).

DMA_DAR_LOW_OFF_WRCH_i (i=0-3) Offset address: $0007214_H+i*200_H$

DMA CH i Write DAR Low Register Kernel Reset value: $0000\ 0000_H$



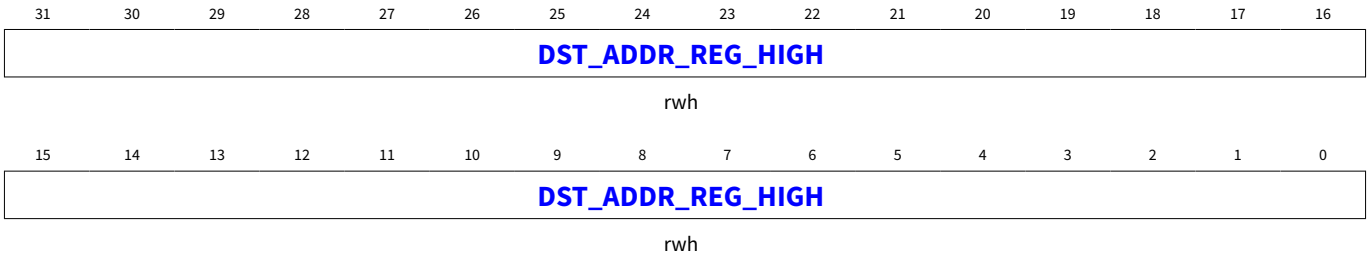
Field	Bits	Type	Description
DST_ADDR_REG_LOW	31:0	rwh	**Destination Address Register (lower 32 bits)** Indicates the next address to be written to. The DMA increments the DAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding dword of the LL element. - DMA Read: The DAR is the address of the local memory. - DMA Write: The DAR is the address of the remote memory. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.1.354 DMA CH i Write DAR High Register

This register holds the higher 32 bits of the Destination Address Register (DAR).

DMA_DAR_HIGH_OFF_WRCH_i (i=0-3) Offset address: $0007218_H+i*200_H$

DMA CH i Write DAR High Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DST_ADDR_REG_HIGH	31:0	rwh	**Destination Address Register (Higher 32 bits)** In LL mode, the DMA overwrites this with the corresponding dword of the LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.1.355 DMA CH i Write Linked List Pointer Low Register

This register holds the lower 32 bits of the DMA write linked list pointer.

DMA_LLP_LOW_OFF_WRCH_i (i=0-3) Offset address: $000721C_H+i*200_H$

DMA CH i Write Linked List Pointer Low Register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
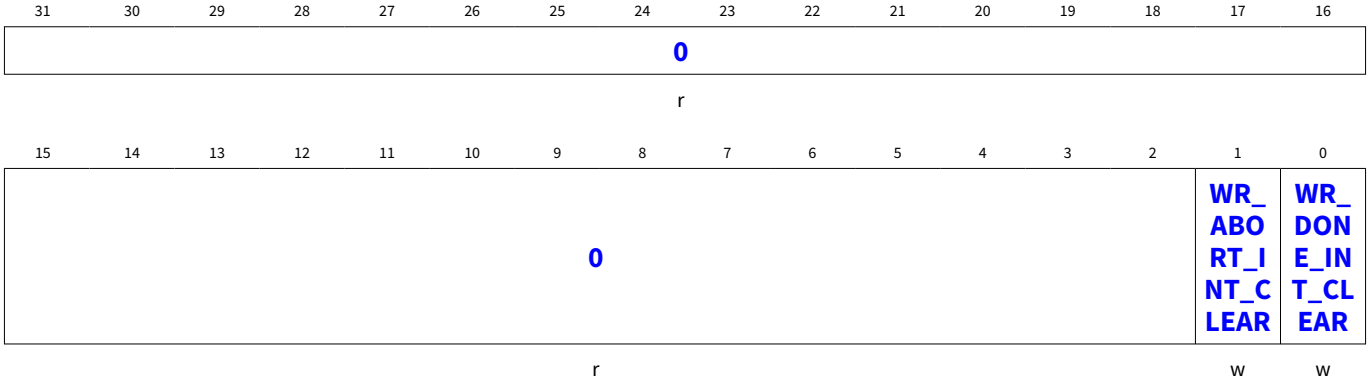
LLP_HIGH	31:0	rwh	**Higher 32 bits of the address of the linked list transfer list in local memory** Used in linked list mode only. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.1.357 Interrupt clear for DMA write channel i

This register has dedicated control over a DMA channel and it has the same functionality as DMA Write Interrupt Clear Register.

DMACAP_CHi_WRCHN_WR_INT_CLEAR (i=0-3) Offset address: $0007224_H+i*200_H$

Interrupt clear for DMA write channel i Kernel Reset value: $0000\ 0000_H$



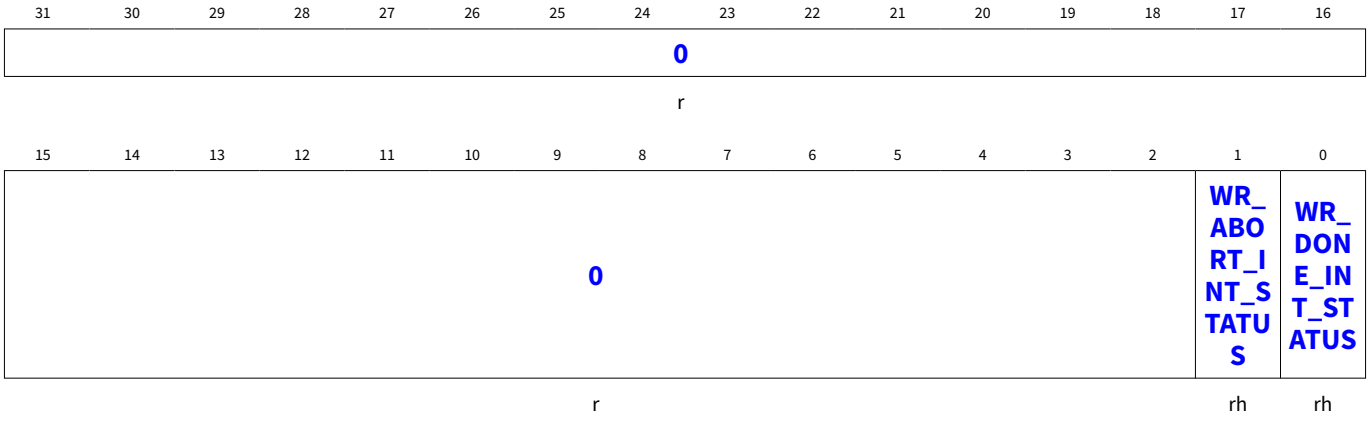
Field	Bits	Type	Description
WR_DONE_INT_CLEAR	0	w	**Done Interrupt Clear for the DMA channel i** You must write a 1'b1 to clear the corresponding bit in the Done interrupt status field of the DMA write interrupt status register. Note: Reading from this self-clearing register field always returns a '0'. 0_B No effect 1_B Clear status
WR_ABORT_INT_CLEAR	1	w	**Abort Interrupt Clear for the DMA channel i** You must write a 1'b1 to clear the corresponding bit in the Abort interrupt status field of the DMA write interrupt status register. Note: Reading from this self-clearing register field always returns a '0'. 0_B No effect 1_B Clear status
0	31:2	r	**Reserved** Read as 0; should be written with 0.

19.4.1.358 Interrupt status for DMA write channel i

This register has dedicated control over a DMA channel and it has the same functionality as DMA Write Interrupt Status Register.

DMACAP_CHi_WRCHN_WR_INT_STATUS (i=0-3) Offset address: $0007228_H+i*200_H$

Interrupt status for DMA write channel i Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
WR_DONE_INT_STATUS	0	rh	**Done Interrupt Status for the DMA channel i** The DMA write channel has successfully completed the DMA transfer.
WR_ABORT_INT_STATUS	1	rh	**Abort Interrupt Status for the DMA channel i** The DMA write channel has detected an error, or you manually stopped the transfer.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

19.4.1.359 Error status for DMA write channel i

This register has dedicated control over a DMA channel and it has the same functionality as DMA Write Error Status Register.

DMACAP_CHi_WRCHN_WR_ERR_STATUS (i=0-3) Offset address: $000722C_H+i*200_H$

Error status for DMA write channel i Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0														LINKLIST_ELEMENT_FETCH_ERR_DETECT	APP_READ_ERR_DETECT
r														rh	rh

Field	Bits	Type	Description
APP_READ_ERR_DETECT	0	rh	**Application Read Error Detected for the DMA channel i** The DMA write channel has received an error response from the AXI bus while reading data from it. . - Clearing: You must write a 1'b1 to the WR_ABORT_INT_CLEAR to clear this error bit.
LINKLIST_ELEMENT_FETCH_ERR_DETECT	1	rh	**Linked List Element Fetch Error Detected for the DMA channel i** The DMA write channel has received an error response from the AXI bus while reading a linked list element from local memory.- Clearing: You must write a 1'b1 to the corresponding channel bit in the WR_ABORT_INT_CLEAR to clear this error bit.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

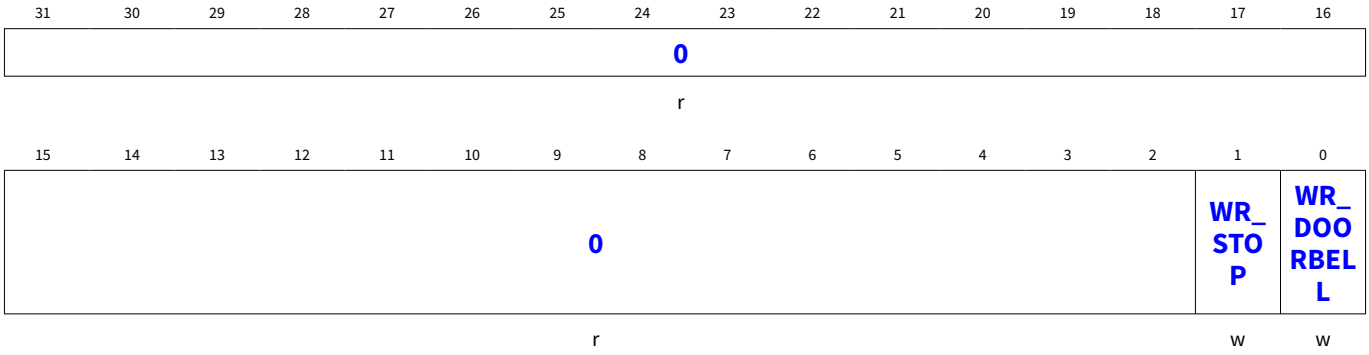
19.4.1.360 Doorbell for DMA write channel i

This register has dedicated control over a DMA channel and it has the same functionality as DMA Write Doorbell Register.

Note: This register is strictly a write only register. Reading this register may result in undefined behavior.

DMACAP_CHi_WRCHN_WR_DOORBELL (i=0-3) Offset address: $0007230_H+i*200_H$

Doorbell for DMA write channel i Kernel Reset value: $0000\ 0000_H$



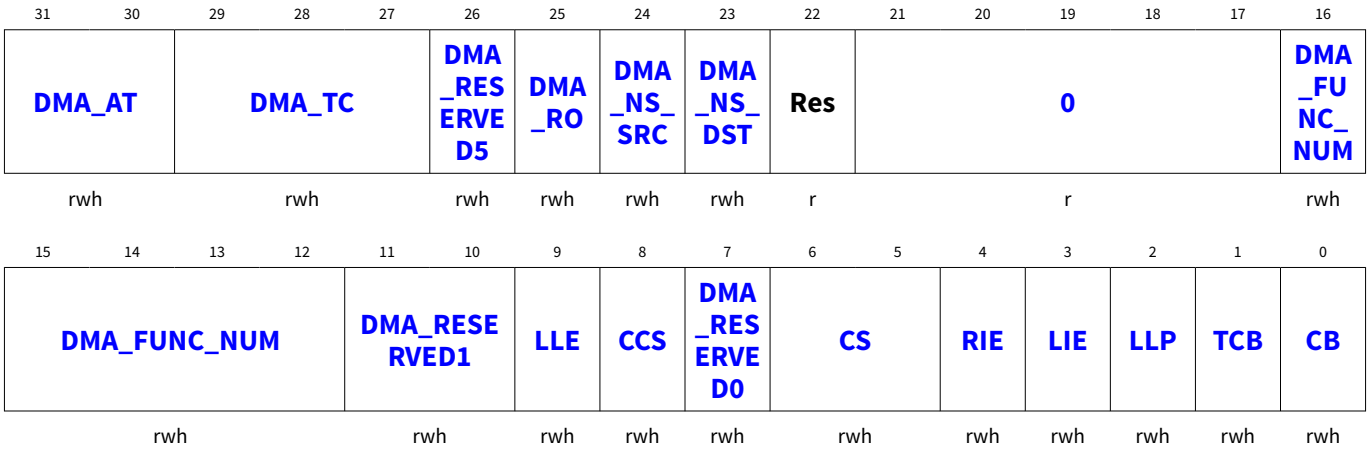
Field	Bits	Type	Description
WR_DOORBELL	0	w	**Doorbell Number for the DMA channel i** You must write the channel number 1'b1 to this register to start the DMA write transfer for that channel. Note: A write to this field triggers the controller to exit L1 substates 0_B No effect 1_B Start DMA transfer
WR_STOP	1	w	**Stop for the DMA channel i** The DMA write channel stops issuing requests, sets the channel status to "Stopped", and asserts the "Abort" interrupt if it is enabled. Before setting the Stop bit, you must read the channel Status field (CS) of the DMA Write Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) to ensure that the write channel is "Running" (transferring data). Note: Use this feature with caution. DMA stop feature is not meant to be used in operational mode. It is only a debug feature and has associated hazards. 0_B No effect 1_B Stop the DMA
0	31:2	r	**Reserved** Read as 0; should be written with 0.

19.4.1.361 DMA Read Channel i Control 1 Register

This register controls the DMA read channel operation.

DMA_CH_CONTROL1_OFF_RDCH_i (i=0-3) Offset address: $0007300_H+i*200_H$

DMA Read Channel i Control 1 Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CB	0	rwh	**Cycle Bit (CB)** Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the CB of the linked list element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
TCB	1	rwh	**Toggle Cycle Bit (TCB)** Indicates to the DMA to toggle its interpretation of the CB. Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the TCB of the linked list element. This field is not defined in a data LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
LLP	2	rwh	**Load Link Pointer (LLP)** Used in linked list mode only. Indicates that this linked list element is a link element, and its LL element pointer dwords are pointing to the next (non-contiguous) element. The DMA loads this field with the LLP of the linked list element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
LIE	3	rwh	**Local Interrupt Enable (LIE)** You must set this bit to enable the generation of the Done or Abort Local interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the LIE of the LL element. The LIE bit in a LL element only enables the Done interrupt. In non-LL mode, the LIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
RIE	4	rwh	**Remote Interrupt Enable (RIE)** You must set this bit to enable the generation of the Done or Abort Remote interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the RIE of the LL element. The RIE bit in a LL element only enables the Done interrupt. In non-LL mode, the RIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
CS	6:5	rwh	**Channel Status (CS)** The channel status bits identify the current operational state of the DMA channel. The operation state encoding for each DMA channel is a s follows: 00_B **RSVD**: Reserved 01_B **RUN**: Running This channel is active and transferring data. 10_B **HALT**: Halted An error condition has been detected, and the DMA has stopped this channel. 11_B **STOP**: Stopped The DMA has transferred all data for this channel, or you have prematurely stopped this channel by writing to the Stop field of the DMA Read Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF).
DMA_RESERVED0	7	rwh	**Reserved** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
CCS	8	rwh	**Consumer Cycle State (CCS)** Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". You must initialize this bit. The DMA updates this bit during linked list operation. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
LLE	9	rwh	**Linked List Enable (LLE)** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_B **DISABLE**: Disable linked list operation 1_B **ENABLE**: Enable linked list operation
DMA_RESERVED1	11:10	rwh	**Reserved** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

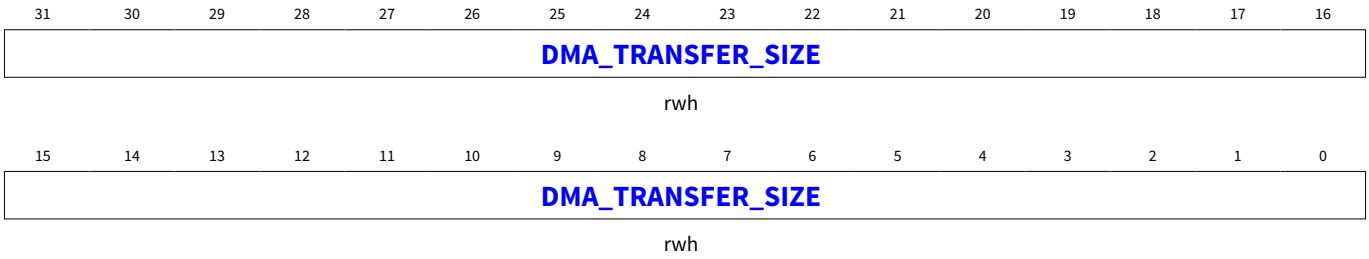
Field	Bits	Type	Description
DMA_FUNC_NUM	16:12	rwh	**DMA Channel Physical Function Number** This field indicates the physical function associated with the DMA channel. The controller uses this field to form the requester ID of the generated MRd/MWr DMA TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 00_H **Min_Val**: Physical Channel Function Number starts at 0 $1F_H$ **Max_Val**: The maximum number of Physical Functions, so the maximum value of this field is 0
DMA_NS_DST	23	rwh	**Destination No Snoop TLP Header Bit** The DMA uses this TLP header field when generating MWr (DAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_NS_SRC	24	rwh	**Source No Snoop TLP Header Bit** The DMA uses this TLP header field when generating MRd (SAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_RO	25	rwh	**Relaxed Ordering TLP Header Bit (RO) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_RESERVED5	26	rwh	**Reserved** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_TC	29:27	rwh	**Traffic Class TLP Header Bit (TC)** The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_AT	31:30	rwh	**Address Translation TLP Header Bit (AT)** The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
0	21:17	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.1.362 DMA CH i Read Transfer Size Register

This register holds the DMA read transfer size.

DMA_TRANSFER_SIZE_OFF_RDCH_i (i=0-3) Offset address: $0007308_H+i*200_H$

DMA CH i Read Transfer Size Register Kernel Reset value: $0000\ 0000_H$



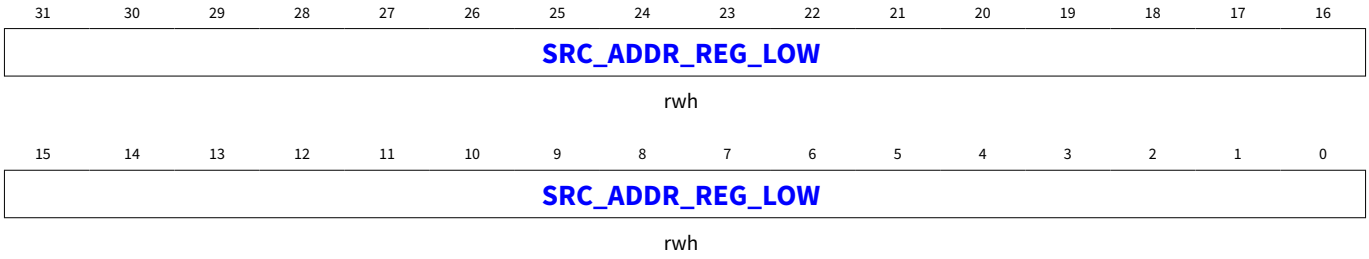
Field	Bits	Type	Description
DMA_TRANSFER_SIZE	31:0	rwh	**DMA Transfer Size** You program this register with the size of the DMA transfer. The maximum DMA transfer size is 4Gbytes. The minimum transfer size is one byte (0x1). This field is automatically decremented by the DMA as the DMA read channel transfer progresses. This field indicates the number bytes remaining to be transferred. When all bytes are successfully transferred the current transfer size is zero. In LL mode, the DMA overwrites this register with the corresponding dword of the LL element. You can read this register to monitor the transfer progress, however in some scenarios this register is updated after a delay. For example, when less than 3 channels are doorbelled, this register is updated only after a descriptor finishes(linked list mode), or the transfer ends (non-linked list mode). Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.1.363 DMA CH i Read SAR Low Register

This register holds the lower 32 bits of the Source Address Register (SAR).

DMA_SAR_LOW_OFF_RDCH_i (i=0-3) Offset address: $000730C_H+i*200_H$

DMA CH i Read SAR Low Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SRC_ADDR_REG_LOW	31:0	rwh	**Source Address Register (Lower 32 bits)** Indicates the next address to be read from. The DMA increments the SAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding dword of the LL element. • DMA Read: The SAR is the address of the remote memory • DMA Read: The SAR is the address of the local memory Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.1.364 DMA CH i Read SAR High Register

This register holds the higher 32 bits of the Source Address Register (SAR).

DMA_SAR_HIGH_OFF_RDCH_i (i=0-3) Offset address: $0007310_H+i*200_H$

DMA CH i Read SAR High Register Kernel Reset value: $0000\ 0000_H$

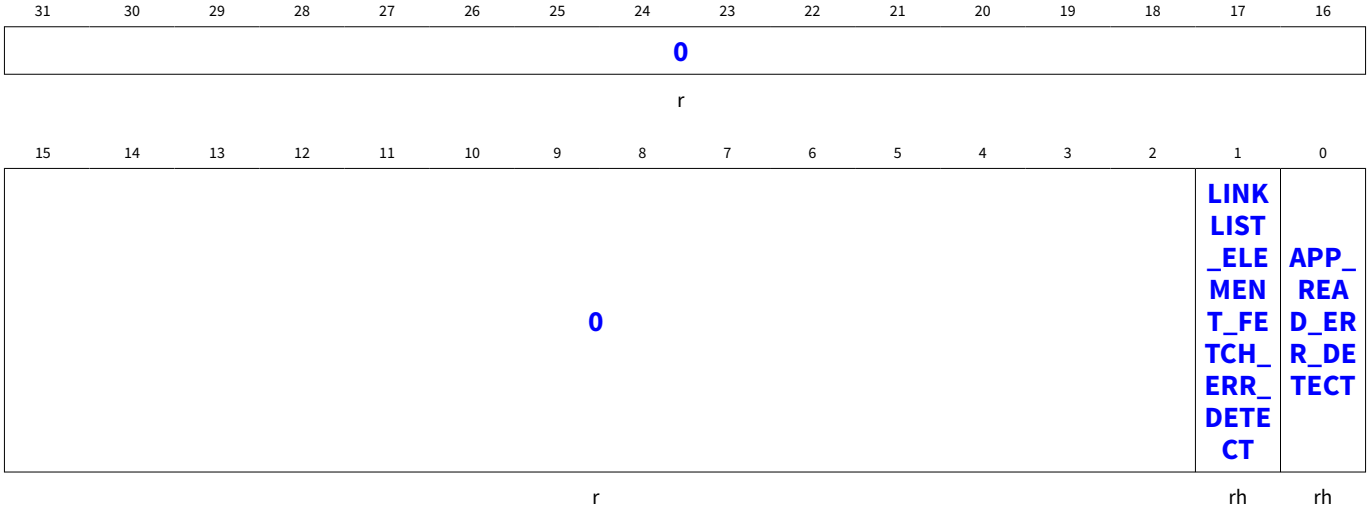
RD_ABORT_INT_STATUS	1	rh	**Abort Interrupt Status for the DMA channel i** The DMA read channel has detected an error, or you manually stopped the transfer.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

19.4.1.371 Error status for DMA read channel i

This register has dedicated control over a DMA channel and it has the same functionality as DMA Read Error Status Low Register.

DMACAP_CHi_RDCHN_RD_ERR_STATUS (i=0-3) Offset address: $000732C_H+i*200_H$

Error status for DMA read channel i Kernel Reset value: $0000\ 0000_H$



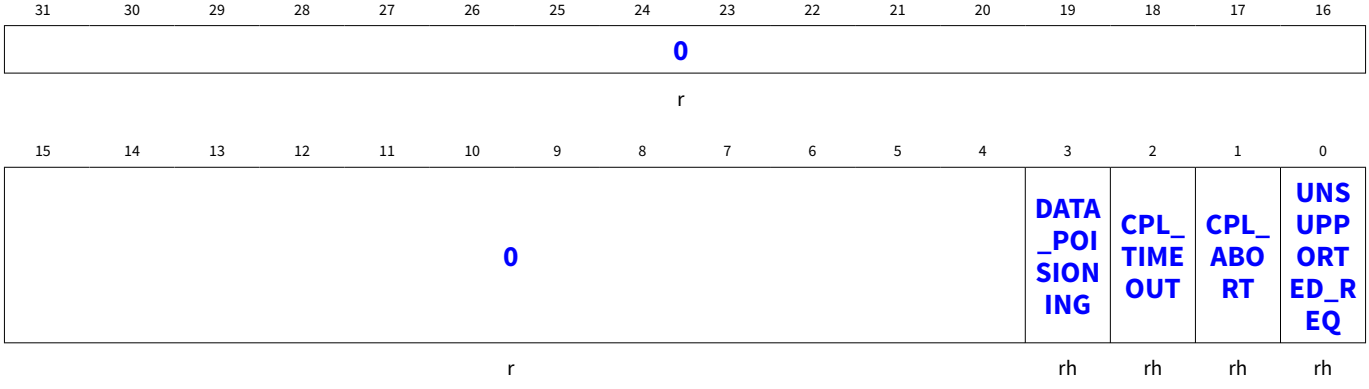
Field	Bits	Type	Description
APP_READ_ERR_DETECT	0	rh	**Application Read Error Detected for the DMA channel i** The DMA read channel has received an error response from the AXI bus while reading data from it. . - Clearing: You must write a 1'b1 to the RD_ABORT_INT_CLEAR to clear this error bit.
LINKLIST_ELEMENT_FETCH_ERR_DETECT	1	rh	**Linked List Element Fetch Error Detected for the DMA channel i** The DMA read channel has received an error response from the AXI bus while reading a linked list element from local memory.- Clearing: You must write a 1'b1 to the corresponding channel bit in the RD_ABORT_INT_CLEAR to clear this error bit.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

19.4.1.372 Higher error status for DMA read channel i

This register has dedicated control over a DMA channel and it has the same functionality as DMA Read Error Status High Register.

DMACAP_CHi_RDCHN_RD_ERR_STATUS_HIGH (i=0-3) Offset address: $0007330_H+i*200_H$

Higher error status for DMA read channel i Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
UNSUPPORTED_REQ	0	rh	**Unsupported Request for the DMA channel i** The DMA read channel has received a PCIe unsupported request completion status from the remote device in response to the MRd request. . - Clearing: You must write a 1'b1 to RD_ABORT_INT_CLEAR to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
CPL_ABORT	1	rh	**Completer Abort for the DMA channel i** The DMA read channel has received a PCIe completer abort completion status from the remote device in response to the MRd request.- Clearing: You must write a 1'b1 to the corresponding channel bit in the RD_ABORT_INT_CLEAR to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
CPL_TIMEOUT	2	rh	**Completion Time Out for the DMA channel i** The DMA read channel has timed-out while waiting for the remote device to respond to the MRd request, or a malformed CplD has been received. - Clearing: You must write a 1'b1 to the RD_ABORT_INT_CLEAR to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
DATA_POISIONING	3	rh	**Data Poisoning for the DMA channel i** The DMA read channel has detected data poisoning in the completion from the remote device (in response to the MRd request). The DMA read channel will drop the completion and then be halted. - Clearing: You must write a 1'b1 to the RD_ABORT_INT_CLEAR to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

19.4.1.373 Doorbell for DMA read channel i

This register has dedicated control over a DMA channel and it has the same functionality as DMA Read Doorbell Register.

Note: This register is strictly a write only register. Reading this register may result in undefined behavior.

DMACAP_CHi_RDCHN_RD_DOORBELL (i=0-3) Offset address: $0007334_H+i*200_H$

Doorbell for DMA read channel i Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RD_DOORBELL	0	w	**Doorbell Number for the DMA channel $ii** You must write the channel number 1'b1 to this register to start the DMA write transfer for that channel. Note: A write to this field triggers the controller to exit L1 substates 0_B No effect 1_B Start DMA transfer
RD_STOP	1	w	**Stop for the DMA channel $ii** The DMA read channel stops issuing requests, sets the channel status to "Stopped", and asserts the "Abort" interrupt if it is enabled. Before setting the Stop bit, you must read the channel Status field (CS) of the DMA Write Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) to ensure that the write channel is "Running" (transferring data). Note: Use this feature with caution. DMA stop feature is not meant to be used in operational mode. It is only a debug feature and has associated hazards. 0_B No effect 1_B Stop the DMA
0	31:2	r	**Reserved** Read as 0; should be written with 0.

19.4.1.374 Write access enable register A

This register defines which master agent function TAG identifier (TAG-ID) encodings are enabled or disabled for write accesses to the access protected region.

S2A_ACCENy_WRA (y=0-7) Offset address: $3FFFE00_H+y*20_H$

Write access enable register A Application Reset value: $1000\ 0003_H$

Field	Bits	Type	Description
RDq (q=00-07)	q	rw	**Read access enable for VM ID q** This bit enables read access to the access protected region for transactions with the VM ID q. 0_B Disabled for read access 1_B Enabled for read access

(table continues...)

(continued)

Field	Bits	Type	Description
WRq (q=00-07)	q+16	rw	**Write access enable for VM ID q** This bit enables write access to the access protected region for transactions with the VM ID q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

19.4.1.379 PRS access enable register

This register defines which protection register set encodings are enabled or disabled for accesses to the access protected region. There is one RDx and WRx bit for each PRSx.

S2A_ACCENy_PRS (y=0-7) Offset address: $3FFFE14_H+y*20_H$

PRS access enable register Application Reset value: $00FF\ 00FF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0								RD07	RD06	RD05	RD04	RD03	RD02	RD01	RD00
r								rw	rw	rw	rw	rw	rw	rw	rw

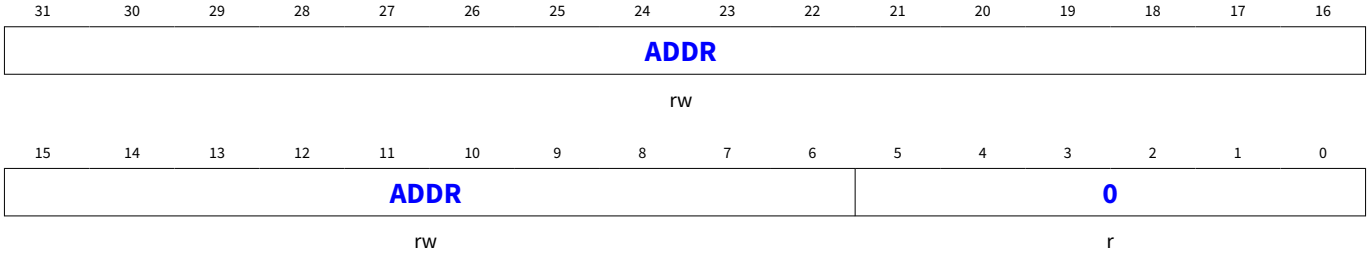
Field	Bits	Type	Description
RDq (q=00-07)	q	rw	**Read access enable for PRS q** This bit enables read access to the access protected region for transactions with the PRS q. 0_B Disabled for read access 1_B Enabled for read access
WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

19.4.1.380 Region lower address register

This register sets the lower bound of the access protected region. Addresses greater than or equal to the lower bound are considered part of the access protected region.

S2A_ACCENy_RGNLA (y=0-7) Offset address: $3FFFE18_H+y*20_H$

Region lower address register Application Reset value: $0000\ 0000_H$



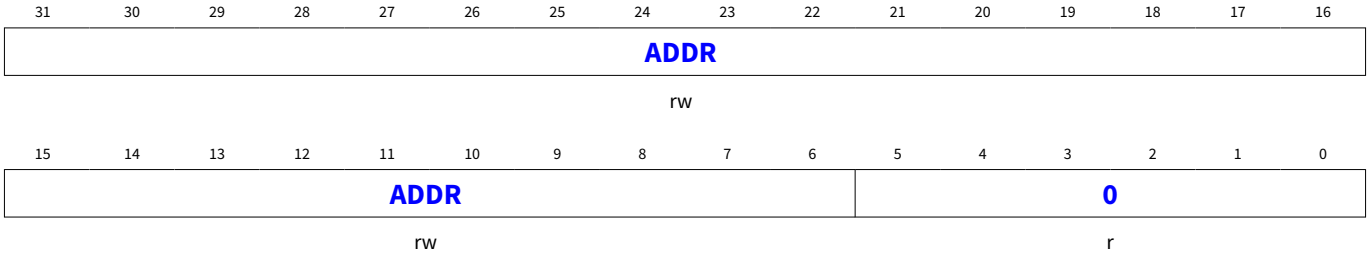
Field	Bits	Type	Description
ADDR	31:6	rw	**Bits 31:6 of the lower bound of the access protected region**
0	5:0	r	**Reserved** Read as 0; should be written with 0.

19.4.1.381 Region upper address register

This register sets the upper bound of the access protected region. Addresses stricly less than the upper bound are considered part of the access protected region.

S2A_ACCENy_RGNUA (y=0-7) Offset address: $3FFFE1C_H+y*20_H$

Region upper address register Application Reset value: $FFFF\ FFC0_H$



Field	Bits	Type	Description
ADDR	31:6	rw	**Bits 31:6 of the upper bound of the access protected region**
0	5:0	r	**Reserved** Read as 0; should be written with 0.

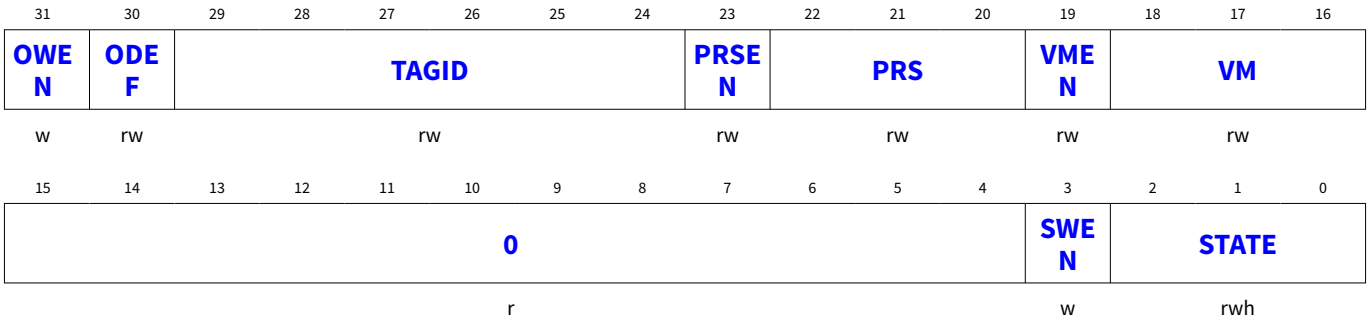
19.4.1.382 PROT Register Safe Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

S2A_PROTSE Offset address: $3FFFF04_H$

PROT Register Safe Endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 876 Access types of S2A_PROTSE in order of evaluation

Condition	Type		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
otherwise	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

19.4.2 Registers of PCIE_DSP

19.4.2.1 Register overview - access mode glossary

Table 877 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE or S2A_PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
APU-Py (y=0-7)	Protection group consisting of registers S2A_ACCENy_WRA, S2A_ACCENy_WRB, S2A_ACCENy_RDA, S2A_ACCENy_RDB, S2A_ACCENy_VM, S2A_ACCENy_PRS, S2A_ACCENy_RGNLA, S2A_ACCENy_RGNUA.
Py	Access protection using *APU-Py* registers.
APU-P_DMAy (y=0-3)	Protection group consisting of registers DMA_ACCENy_WRA, DMA_ACCENy_WRB, DMA_ACCENy_RDA, DMA_ACCENy_RDB, DMA_ACCENy_VM, DMA_ACCENy_PRS.
P_DMAy	Access protection using *APU-P_DMAy* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

19.4.2.2 Register overview - PCIE_DSP domain FPI (ascending offset address)

Table 878 Register overview - PCIE_DSP domain FPI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CLC	Clock control register	0000000 H	P	P, SV, E	Application Reset	3218
OCS	OCDS control and status register	0000004 H	P	SV, P	Debug Reset	3219

19.4.2.4 Clock control register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 0000000$_H$

Clock control register Application Reset value: 0000 0003$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** When CLC.DISS=1_B, registers CLC, OCS, ID, PROTE, PROTSE, ACCEN_* and DMA_ACCEN_* are still accessible. Accesses to other PCIe registers are not executed and will result in a bus error. 0_B Module clock is enabled 1_B Off: module is not clocked

(table continues...)

(continued)

Field	Bits	Type	Description
EDIS	3	rw	**Reserved** Used to control the module's reaction to sleep mode. Note: this bit field has no functionality implemented for PCIe. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

19.4.2.5 OCDS control and status register

OCS Offset address: 0000004_H

OCDS control and status register Debug Reset value: $0000\ 0000_H$

MOD_TYPE								MOD_REV							
r								r							

Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.

(table continues...)

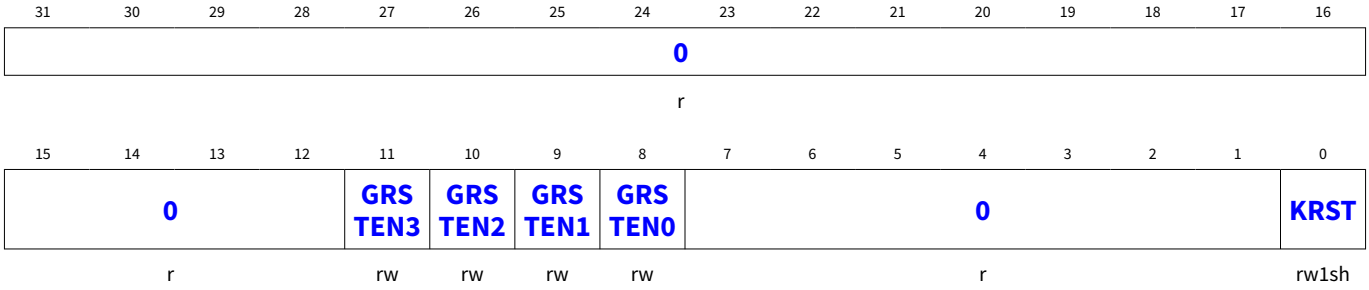
(continued)

Field	Bits	Type	Description
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number. 0x0106 for PCIe.

19.4.2.7 Reset control register A

RST_CTRLA Offset address: $000000C_H$

Reset control register A Application Reset value: $0000\ 0000_H$

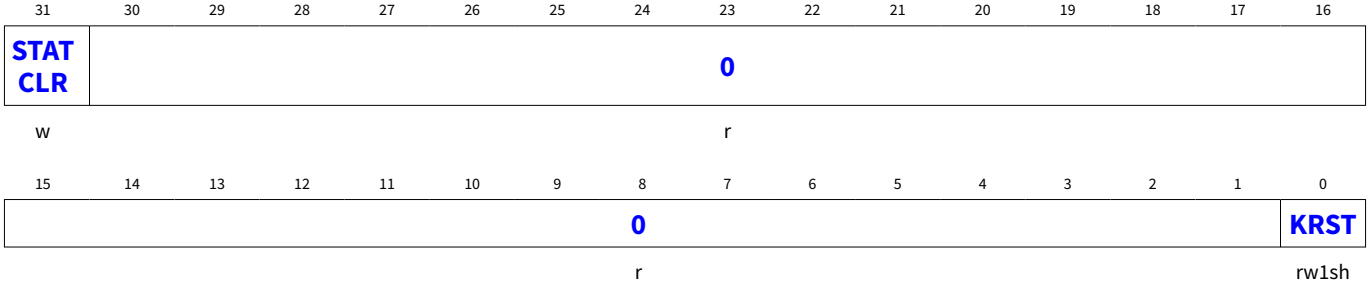


Field	Bits	Type	Description
KRST	0	rw1sh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for Global Module Reset Group x** 0_B Global module reset group x does not have any effect 1_B Global module reset group x results in a kernel reset
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

19.4.2.8 Reset control register B

RST_CTRLB Offset address: 0000010_H

Reset control register B Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rw1sh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
STATCLR	31	w	**Kernel Reset Status Clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits STAT.GRSTx and bit STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

19.4.2.9 Reset status register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: 0000014_H

Reset status register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				GRST3	GRST2	GRST1	GRST0	0							KRST
r				rh	rh	rh	rh	r							rh

Field	Bits	Type	Description
KRST	0	rh	**Kernel Reset Status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.
GRSTx (x=0-3)	x+8	rh	**Status for Global Module Reset Group x** 0_B Reset was not triggered by Global Reset Group x 1_B Reset was triggered by Global Reset Group x
0	7:1, 31:12	r	**Reserved** Read as 0.

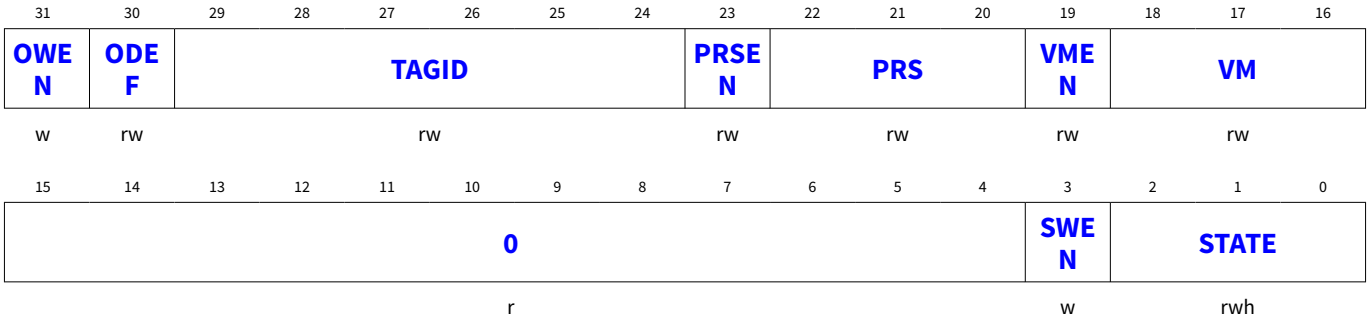
19.4.2.10 PROT register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 0000020_H

PROT register endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.

(table continues...)

(continued)

Field	Bits	Type	Description
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 880 Access types of PROTE in order of evaluation

Condition	Type		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
otherwise	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN

19.4.2.11 PROT register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 0000024_H

PROT register safe endinit Application Reset value: $0000\ 0000_H$
