Every RX descriptor is fetched from the S_MEM. As for the TX path, the critical path is defined by the first RX descriptor to be fetched, once the RX FIFO Queue number is defined by the RX filter. As soon as the RX FIFO Queue is known, there is still some time required to read the corresponding RX descriptor and to write the data payload to the S_MEM. To avoid any RX DMA FIFO overflow and to limit the constraints at system level, the faster the RX descriptor is read from the S_MEM the faster the payload data can be written to the S_MEM. Nevertheless, several actions can be done to cope with high system latency:

- Align data container start address on maximum burst length (8 word of 32bit)
- Align RX FIFO Queue start address on maximum burst length (8 word of 32bit)
- Use data container size multiple of maximum burst length (8 word of 32bit)
- The usage of write outstanding transaction may not provide a significant improvement as the write accesses are somehow sequential and the RX DMA FIFO sized to support high latency. Nevertheless, it is recommended to set it to the maximum value, see Ni_AXI_PARAMS.AW_MAX_PEND[1:0] bit register
- Make use of read outstanding transaction (this is mandatory to avoid cases where DMA channel are competing against each other to read the S_MEM). The maximum value is recommended, see Ni_AXI_PARAMS.AR_MAX_PEND[1:0] bit register
- Define RX FIFO Queues (linked list of RX descriptors) in SRAM to shorter the reaction time when receiving an RX message. This is best practice to declare descriptor in SRAM whenever possible

22.5.3.32 PRT and ENABLE signal

The PRT signalizes via ENABLE whether it is active and requires message handling or not. It means a message can be received or transmitted only if the ENABLE signal is set high by the PRT.

As soon as this ENABLE signal goes low, the MH must stop its activity and goes in idle state. The MH is stopped, therefore the active TX FIFO Queue n and RX FIFO Queue m are put on hold, it means: Ni_TX_FQ_STS0.BUSY[n] = 1, Ni_RX_FQ_STS0.BUSY[m] = 1, Ni_TX_FQ_STS0.STOP[n] = 1 and Ni_RX_FQ_STS0.STOP[m] = 1. Any active TX Priority Queue slot k is discarded, Ni_TX_PQ_STS0.BUSY[k] = 0. Any RX message received or TX message transmitted at that time is discarded. Therefore, it is up to the SW to decide what to do next:

- Keep going: As soon as the ENABLE signal is back to high, the SW would need to write the Ni_MH_CTRL.START bit to 1 to set the MH in active mode. Then, the already started TX FIFO Queues would need to be started again, using the Ni_TX_FQ_CTRL0.START[7:0] bit field register, to continue their execution from where they were. Once the Ni_RX_FQ_CTRL0.START[7:0] bit field register would be set to re-started the RX FIFO Queues, they would be back to where they were before being stopped. Within such option, all the registers and internal buffers will remain the same, only start bits are used to continue MH execution at the point of time it was stopped
- Reinitialize MH partly or completely: The SW can decide to cancel the execution of an RX/TX FIFO Queue or TX Priority Queue slot. To do so, use the Ni_TX_FQ_CTRL1.ABORT[7:0], Ni_RX_FQ_CTRL1.ABORT[7:0] or Ni_TX_PQ_CTRL1.ABORT[31:0] bit field register. Only active RX/TX FIFO Queues and TX Priority Queue slots

can be aborted (see Ni_TX_FQ_STS0.BUSY[7:0], Ni_RX_FQ_STS0.BUSY[7:0] and Ni_TX_PQ_STS0.BUSY[31:0] bit field registers). Once the selected RX/TX FIFO Queue and TX Priority Queue slot are aborted, the relevant ones can be started to keep going from where they were. Nothing is preventing the SW to abort all active RX/TX FIFO Queues and TX Priority Queue slots to reinitialize completely the MH.

22.6 Protocol controller (PRT)

This document describes the PRT, the CAN XL protocol controller, and its interfaces with the host controller, a message handler frontend, and the CAN transceiver.

22.6.1 Feature list

- Classical CAN, CAN FD and CAN XL as specified in ISO 11898-1:2024
- Classical CAN bit rate up to 1 Mbps
- Arbitration phase bit rate up to 1 Mbps for CAN FD and for CAN XL
- CAN FD data phase bit rate up to 8 Mbps at a clock speed of 80 MHz or 160 MHz
- CAN XL data phase bit rate up to 20 Mbps at a clock speed of 160 MHz
- Dedicated timebase interfaces

22.6.2 Functional overview

The PRT is a CAN XL Protocol Controller that can be integrated into different CAN modules. The PRT performs CAN communication as specified in ISO 11898-1:2024. The bit-rate can be configured to values up to 20 MBit/s at a clock speed of 160 MHz, depending on the used semiconductor technology. For the connection to the physical layer, additional transceiver hardware is required, which is connected through GPIO ports or may be integrated into the CAN module (see chapter “Transceiver interface”).

The PRT does not provide internal buffering of frames, so that data has to be transferred by IP internal Message Busses in 32-bit slices in real-time while (de)-serialization on the CAN Bus. Thus single data transfers at the internal Message Busses are closely time-synchronized to the schedule at the CAN bus.

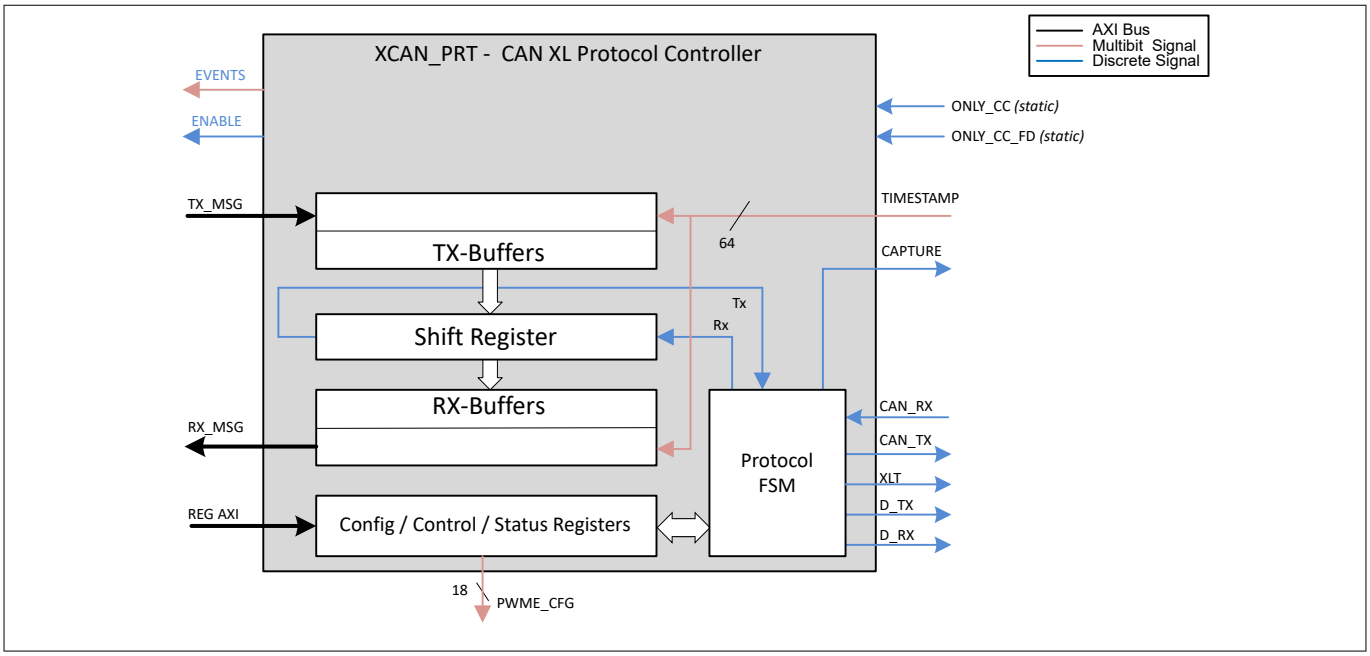

Figure 425 PRT block diagram

The figure above shows principle of the PRT’s functions. When the PRT and the message handler operate in different clock domains, they are connected through CDC modules. The time base is captured inside a CDC module, triggered by the PRT’s output signal CAPTURE.

The PRT consists of the CAN Protocol FSM, an Rx/Tx shift register, a set of interface registers for configuration, control, and status information as well as interfaces to the message handler for received messages and for messages to be transmitted. The PRT is not designed to store complete messages, there is only transient caching for two memory words for each direction during reception or transmission. A separate message handler is needed for the storage of whole messages as well as for functions like acceptance filtering, sorting of received messages into specific message buffers, and ordering the sequence of messages that are requested for transmission. Messages are streamed between message handler and PRT as sequences or 32-bit data words.

The host accesses the PRT's registers through REG_AXI, an AMBA AXI4-Lite interface, for configuration, control, and status information.

22.6.3 Functional description

The PRT does provide several interrupt outputs that signal, with a high-pulse of one CLK period length, the occurrence of specific internal events. For test purposes, the Ni_TEST register has a generate interrupt pulse function GIP so that in hardware test mode HWT an interrupt output pulse can also be triggered by writing a 0b1 to the corresponding Ni_TEST register bit.

Table 1063 Interrupts

Interrupt	TEST bit	Activated when
BUS_OFF	27	Entering Bus_Off state
BUS_ON	26	Starting CAN communication, after starting or end of Bus_Off
E_PASSIVE	25	Switching from error-active to error-passive
E_ACTIVE	24	Switching from error-passive to error-active
BUS_ERR	23	Error detected on CAN bus or protocol exception event detected
RX_EVT	22	Received a valid message
TX_EVT	21	Successfully transmitted a message
IFF_RQ	20	MH requests a message with invalid frame format in header
RX_DO	19	Data overflow condition in RX_MSG sequence detected
TX_DU	18	Data underrun condition in TX_MSG sequence detected
USOS	17	Unexpected start of sequence during TX_MSG sequence detected
ABORTED	16	TX_MSG sequence stopped by TX_MSG_WUSER code ABORT

The PRT outputs internal status information, optionally to be connected to a hardware debug port

- SAMPLE_POINT: This is the CAN sample point
- STAT_ACT: This is the actual 2-bit-value of register Ni_STAT.ACT (see register description)

22.6.3.1 Software reset

The software reset is triggered by writing 0b1 to Ni_CTRL.SRES when the CAN protocol operation is stopped. This does not require an unlocking sequence. The software reset must not be executed when Ni_CTRL.SRES is written while the CAN protocol operation is started. The software reset resets all state machines of the PRT (excluding the error-counters and the error-states) and clears the following readable registers: Ni_STAT.TDCV, Ni_STAT.FIMA, Ni_FIMC.FIP, Ni_TEST.HWT, Ni_TEST.TXC, Ni_TEST.LBCK and all flags of Ni_EVNT. The configuration registers are not changed by a software reset.

22.6.3.2 Operating mode

The operating mode is defined using the Ni_MODE register and only when the CAN communication is stopped, otherwise the register is read only. The register Ni_MODE defines separate operating mode options.

The four configuration bits FDOE, XLOE, EFDI, and XLTR, and are interrelated according the table below.

Table 1064 Frame formats

FDOE	XLOE	XLTR	EFDI	Description
0	0	X	0	When FDOE is not set, the PRT shall be to the Classical CAN frame format. In this case, when PXHD is set, the PRT shall accept both recessive and dominant bits as received reserved bits. When PXHD is not set, the PRT shall treat a recessive received first reserved bit as a Protocol Exception condition and shall enter the Protocol Exception State as defined in [1] and it shall set the flag Ni_EVNT.PXE. FDOE shall be static at 0b0 while the input signal ONLY_CC is 0b1
0	1	X	X	Invalid configuration
0	X	X	1	Invalid configuration
X	0	X	1	Invalid configuration
1	0	X	0	Operating in Classical CAN and CAN FD frame format. When FDOE is set, the PRT shall be able to transmit and to receive Classical CAN frames and CAN FD frames as defined in [1]. When XLOE is not set, the PRT shall not be able to transmit or to receive CAN XL frames as defined in [1]. When FDOE is set but not XLOE, PXHD defines the PRT's reaction on a recessive reserved bit following the recessive FDF bit in a CAN FD frame. In this case, when PXHD is set, the PRT shall treat this condition as a Form Error. When PXHD is not set, the PRT shall treat this condition as a Protocol Exception condition and shall enter the Protocol Exception State as defined in [1] and it shall set the flag Ni_EVNT.PXE. XLOE shall be static at 0b0 while the input signals ONLY_CC_FD or ONLY_CC are at 0b1
1	1	0	0	Operating in all frame formats, without XL transceiver. When FDOE and XLOE are both set and >EFDI is not set, the PRT shall be able to transmit and to receive Classical CAN frames, CAN FD frames and CAN XL frames as defined in [1]. When both FDOE and XLOE are set, PXHD defines the PRT's reaction on a recessive reserved bit following the recessive XLF bit in a CAN XL frame. In this case, when PXHD is set, the PRT shall treat this condition as a Form Error. When PXHD is not set, the PRT shall treat this condition as a Protocol Exception condition and shall enter the Protocol Exception State as defined in [1] and it shall set the flag Ni_EVNT.PXE. When EFDI is not set, the PRT shall send error flags as defined in [1]
1	1	0	1	Operating in XL frame format only, without XL transceiver, error frames are disabled for all communication. It shall be an invalid configuration to set EFDI without setting both FDOE and XLOE. When XLTR is not set, the PRT shall not control the operating mode of the transceiver
1	1	1	0	Invalid configuration

(table continues...)

Table 1064 (continued) Frame formats

FDOE	XLOE	XLTR	EFDI	Description
1	1	1	1	Operating in XL frame format only, enabling XL transceiver, error frames are disabled for all communication. When XLTR is set together with FDOE and XLOE, the PRT shall control the PWME to the transceiver in order to switch the operating mode of the transceiver at the beginning and at the end of the CAN XL data phase, as defined in [1]. When XLTR is set together with FDOE and XLOE, the PRT shall control the PWME to the transceiver in order to switch the operating mode of the transceiver at the beginning and at the end of the CAN XL data phase, as defined in [1]. When EFDI is set together with FDOE and XLOE, the PRT shall not send error flags and it shall not change its transmit error counter or its receive error counter. When an error condition occurs, the PRT shall, instead of sending an error flag, enter Protocol Exception State, like in Restricted Mode, as defined in [1]

22.6.3.3 Starting and stopping the module

The PRT is started by writing 0b1 to Ni_CTRL.STRT. This does not require an unlocking sequence. After the start command, the PRT waits for the occurrence of a sequence of 11 consecutive recessive bits (the idle condition of ISO 11898-1:1995) to finish its integration into the CAN communication on the CAN bus line. When the PRT has detected the idle condition, it switches into idle state. When it sees a recessive bit on entering idle state, the PRT is able to start a pending transmission in the following bit. When the PRT sees a dominant bit on entering idle state, it immediately becomes receiver of that frame.

There are two options to stop the CAN protocol operation under software control, one that waits for the completion of an ongoing message transfer and one that stops the operation immediately.

The two options use different variants of the Ni_CTRL.STOP command. In the first variant, only the STOP bit is written to 0b1. In the second variant, both the Ni_CTRL.STOP bit and the Ni_CTRL.IMMD bit are written to 0b1 at the same time. Both variants require the application of the unlock key sequence, followed by a write access to the Ni_CTRL register. The three consecutive write accesses may not be interrupted by other accesses through *REG_AXI*.

The first variant of the STOP command is asserted this way:

1. Write 0x1234 to Ni_LOCK.ULK 0x40
2. Write 0x4321 to Ni_LOCK.ULK 0x40
3. Write 0b1 to Ni_CTRL.STOP 0x44

The PRT's reaction to the first variant of the STOP command depends on its current activity (Ni_STAT.ACT). When the current activity of this node is Idle, it switches its activity to its inactive state immediately and stop all CAN operation. When the current activity is either Receiver or Transmitter, it continues that activity and it sets the status flag Ni_STAT.STP to show that it is waiting for end of the actual message after a Ni_CTRL.STOP command. If no TX_MSG sequence is already started, the PRT clears *TX_MSG_WREADY* and keep it cleared until all CAN operation is stopped. As soon as the current reception or transmission is finished (either successfully or in failure) the PRT reports the result of that transfer to the MH, clears the status flag Ni_STAT.STP, clears *ENABLE*, switches its activity to its inactive state, and stops all CAN operation. The PRT does not start another reception or transmission until it is started again.

The second variant of the STOP command is asserted this way:

1. Write 0x1234 to Ni_LOCK.ULK 0x40
2. Write 0x4321 to Ni_LOCK.ULK 0x44
3. Write 0b1 to Ni_CTRL.IMMD and 0b1 to Ni_CTRL.STOP 0x44
4. Write 0b1 to Ni_CTRL.SRES 0x44

The PRT's reaction to the second variant of the STOP command is to switch its activity to its inactive state immediately, to stop all CAN operation, and to set its *CAN_TX* output to 0b1 and to clear *ENABLE*. When the current activity was Transmitter, the PRT aborts that transmission. When the current activity was Receiver, it abort that reception. Both interfaces with the MH are reset, outstanding transactions are discontinued. If this happens while an RX_MSG sequence was ongoing, this sequence is discontinued with the ABORT code. The PRT does not start another reception or transmission until it is started again.

The CAN protocol operation stops automatically on the following conditions:

- When the node enters the CAN protocol's Bus-Off state
- Unexpected start of sequence during TX_MSG sequence detected

***Note**: Detecting an Unexpected Start of Sequence (USOS) indicates a mis-synchronization between PRT and MH that requires a restart.*

When the CAN protocol operation is stopped, it is started by writing 0b1 to Ni_CTRL.STRT. This does not require an unlocking sequence.

When the CAN protocol operation was stopped because the PRT entered the CAN Bus_Off state, the start command (writing 0b1 to Ni_CTRL.STRT) causes the PRT to perform the CAN Bus_Off Recovery Sequence before it is again able to participate in CAN communication.

The CAN Bus_Off Recovery Sequence (see ISO 11898-1:2024) cannot be shortened by starting or stopping the PRT. If the PRT goes Bus_Off, it will set Ni_STAT.BO bit and it will, of its own accord, stop all bus activities. Once the PRT has been started again, the PRT clears Ni_STAT.TEC, Ni_STAT.RP, Ni_STAT.REC, and Ni_STAT.EP but it will keep Ni_STAT.BO.

The PRT will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. The PRT uses the Receive Error Counter (Ni_STAT.REC) to count the occurrences of Bus Idle. Additionally, each time a sequence of 11 recessive bits has been monitored, a Bit0 Error (Ni_EVNT.B0E) is reported, enabling the host to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the progress of the Bus_Off recovery sequence. When the last-but-one sequence of 11 recessive bits has been monitored, Ni_STAT.RP, and Ni_STAT.EP are set and Ni_STAT.REC is at 0x7F. When the last sequence of 11 recessive bits has been monitored, the end of the Bus_Off recovery sequence is reached and Ni_STAT.TEC, Ni_STAT.RP, Ni_STAT.REC, Ni_STAT.EP and Ni_STAT.BO will all be reset. The PRT switches into idle state.

22.6.3.4 Reaction on exceptions at the TX_MSG and RX_MSG interfaces

22.6.3.4.1 MH requests a message with invalid frame format in header

This is detected when the requested transmit frame format is disabled in the configuration register (see Ni_MODE.FDOE, Ni_MODE.EFDI, or Ni_MODE.XLOE) or there is an internal contradiction in the header content of that frame. On the detection of this condition, the PRT ends the TX_MSG sequence with the response code HFI, generate a pulse on the IFF_RQ interrupt output and it does not transmit that message.

22.6.3.4.2 MH intentionally aborts TX_MSG sequence

If the ABORT command is given with the second transaction of the TX_MSG sequence, the PRT does not start the transmission. If the ABORT command is given after the second transaction of the TX_MSG sequence, the PRT sets an internal flag that causes the FCRC bits of that transmission to be transmitted inverted. This internal flag is cleared at the end of the transmission. In both cases, the PRT generates a pulse on the ABORTED interrupt output and the ongoing TX_MSG sequence is finished.

22.6.3.4.3 Data underrun condition in TX_MSG sequence detected

This is detected when the ongoing transmission on the CAN bus needed another TX_MSG data word but that word was not provided in time. On the detection of this condition, the PRT continues the transmission (to avoid disturbing the message schedule on the CAN bus), but the PRT generates a pulse on the TX_DU interrupt output and the PRT sets an internal flag that causes the FCRC bits of that transmission to be transmitted inverted (to avoid the acceptance of a message containing invalid data). This internal flag is cleared at the end of the transmission. In case of a Data Underrun, the ongoing TX_MSG sequence finishes with the code DU when the MH transfers the missing data word. After the end of the transmission, TX_MSG_WREADY is asserted again to accept the following TX_MSG Sequence (starting again with W0).

22.6.3.4.4 Unexpected start of sequence detected

This is detected when the PRT receives a TX_MSG transaction marked as start of sequence before a previously started TX_MSG sequence has ended. This indicates that MH and PRT operate out-of-phase. On the detection of this condition, the PRT generates a pulse on the USOS interrupt output and the PRT stops CAN protocol operation. Afterward, the PRT needs to be restarted under software control by writing 0b1 to Ni_CTRL.STRT.

22.6.3.4.5 Data overflow condition in RX_MSG sequence detected

This is detected when, during an ongoing reception, the MH has not acknowledged an RX_MSG data word in time. On the detection of this condition, the PRT generates a pulse on the RX_DO interrupt output and the PRT ends such an RX_MSG sequence through a subsequent transfer with code DO. This transfer with code DO must be acknowledged by the MH before the PRT can start a new RX_MSG sequence.

22.6.3.5 Controlling the module's clock input

The PRT has two clock inputs, CLK and CLK_AXI. CLK is the clock input of the PRT excluding its REG_AXI interface, while CLK_AXI is the clock input of the PRT's REG_AXI module. Both clocks are synchronous to each other, driven from the same source. The difference between the two clocks is that CLK_AXI must be always active (to keep the REG_AXI interface operational), but CLK may be switched off (gated) while the PRT is stopped, for example when no CAN communication is needed.

- The recommended clock frequency for CAN XL operation is 160 MHz
- The recommended clock frequency for CAN FD operation only is 80 MHz

The function of the PRT does not depend on a particular duty-cycle of the clock, that means it reacts only on rising clock edges. The duration of the clock high pulse may vary between 10% and 90% of the clock period during operation.

The PRT's input signal CLOCK_ACTIVE shows whether the clock input CLK of the PRT is active. The actual value of the CLOCK_ACTIVE input signal is always readable from the status bit Ni_STAT.CLKA, even when CLK is not active. The signal CLOCK_ACTIVE does not control the PRT's function, it provides only status information, coming from a clock multiplexer outside of the PRT.

While CLK is not active, the PRT has no function and cannot be started. CLK must be reactivated before the PRT needs to be started again.

22.6.3.6 Transceiver interface

The CAN bus is usually implemented as a twisted-pair bus line, its bus wires called CAN_H and CAN_L. An analog CAN transceiver device is connected to the CAN bus, interfacing between the bidirectional CAN bus wires and the CAN protocol controller's unidirectional, digital serial input and output signals. The future CAN XL transceivers will need to switch between two operating modes during the transmission of a CAN XL message. The switching control is coded into signals between protocol controller and transceiver. The coding is

implemented inside a separate, dedicated PWME module that is placed between protocol controller and transceiver, see block diagram.

The transceiver's RxD output is connected to the PRT's CAN_RX input. This asynchronous input signal is synchronized to the CAN clock by routing it through two synchronizer-FFs. This delay of two clock cycles is part of the input delay for the calculation of the propagation segment length of the CAN bit time. The CAN bit time configuration is only functional if the following conditions are fulfilled:

- $((NTSEG1 + 1) \times (BRP \times CLK_period))$ is larger than the transmitter loop delay
- $((DTSEG1 + 1) \times (BRP \times CLK_period))$ and $((XTSEG1 + 1) \times (BRP \times CLK_period))$ are larger than the transmitter loop delay or transmitter delay compensation is enabled

The connection from the PRT to the transceiver is routed through the PWME module (Pulse Width Modulation Encoder, specified in [1]). In CAN XL communication using a transceiver with switchable operating modes, the PWME controls the operating mode of the transceiver, to switch it into the CAN XL data phase modes for transmissions as well as receptions and back. The PWME_CFG configuration data consists of Ni_PCFG.PWMO, Ni_PCFG.PWML, and Ni_PCFG.PWMS, it is an 18-bit vector concatenating the three 6-bit vectors from Ni_PCFG.PWMO[5] downto Ni_PCFG.PWMS[0]. The appropriate switching times are signaled by the PRT via its outputs XLT, D_TX and D_RX (see [1]).

The PWME function is controlled by the following outputs of the PRT: PWME_CFG, XLT, D_TX, D_RX, and CAN_TX.

22.6.3.7 Hardware timestamping

22.6.3.7.1 Timestamping function

Timestamps are captured for each transmitted or received message, captured at either the sample point of the start of frame bit of the message or at the sample point of the bit when the message becomes valid at the end of the frame. The capture position is defined by the configuration bit Ni_MODE.SFS.

22.6.3.7.2 Time stamping offset

Due to internal propagation delays for the timestamping in the Protocol Controller (1 CAN clock cycle) and the clock domain crossing for the time capturing (n clock cycles, depending on the clock frequency ratio between the CAN and the TIMBASE domain) a certain offset has to be considered to derive the correct time.

These are the formulas for the offset:

TS_offset_max = 2 CAN_CLK period + 3 TIMEBASE_CLK period

TS_offset_min = 2 CAN_CLK period + 2 TIMEBASE_CLK period

This is the formula for the corrected timestamp:

Corrected Timestamp = Timestamp in TX/RX descriptor - TS_offset

22.6.3.8 Trace and debug

The hardware test mode functions are disabled by the software reset of the PRT. The status flag Ni_TEST.HWT shows whether the hardware test mode functions are enabled.

When the hardware test mode functions are disabled, all bits of Ni_TEST are cleared with the exception of RXD.

Enabling the hardware test mode functions (see chapter "Hardware Test Functions") requires the application of the test mode key sequence. The test mode key sequence consists of three consecutive write accesses, not interrupted by other accesses through REG_AXI:

1. Write 0x6789 to Ni_LOCK.TMK 0x40

2. Write 0x9876 to Ni_LOCK.TMK 0x40
3. Write 0b1to Ni_CTRL.TEST 0x44

The hardware test mode functions enable the host to directly control the values driven at the transceiver interface pins, to read the actual transceiver RxD output, and to transmit messages in a loop-back mode where all transmitted messages are also reported through the RX_MSG interface as received messages.

The CAN_RX input (output signal of the transceiver) is always readable at RXD.

The CAN_TX output control TXC offers four options:

- 0b00: Normal function of CAN_TX
- 0b01: Normal function of CAN_TX, CAN_RX is ignored (for message loop-back mode)
- 0b10: CAN_TX output set to 0b0 and XLT output set to 0
- 0b11: CAN_TX output set to 0b1 and XLT output set to 0

When LBCK is set, the PRT operates in the message loop-back mode. In message loop-back mode, the PRT reports transmit messages (requested through the TX_MSG interface) through RX_MSG as received messages. The transmit messages are encoded and decoded bitwise inside the PRT, but a transmitted message is treated as successfully transmitted even if it does not get ACK. When the host sets LBCK to 0b1, it also sets TXC to either 0b01 or to 0b11 to control whether messages transmitted in the message loop-back mode are visible at the transceiver pins. In the message loop-back mode with TXC set to a value > 0b00, the actual CAN_RX input (output signal of the transceiver) is ignored by the PRT.

When the host sets TXC = 0b11 in the message loop-back mode, the PRT keeps the CAN_TX output at 0b1 and loops back its internal serial output signal to its internal serial input signal.

When the host sets TXC = 0b01 in the message loop-back mode, the PRT drives the frame bits at its CAN_TX output. In this case, the PRT loops back its internal serial output signal to its internal serial input signal, so it is not able to perform an arbitration or to react on bit errors on the CAN bus.

If TXC is set as zero b00, the loop-back test may be disturbed by errors on the CAN_RX input.

If TXC is set as 0b01, the loop-back test operates independently from the CAN_RX input, the loop-back transmission can be monitored at the CAN_TX output.

If TXC is set as 0b11, the loop-back test operates independently from the CAN_RX input, the LoopBack transmision cannot be monitored at the Tx-pin. This is intended for a self-test in the field, not disturbing the CAN bus.

22.7 Pulse width modulation encoder (PWME)

This document describes the PWME, the Pulse Width Modulation Encoder, and its interfaces with the CAN XL protocol controller and the CAN transceiver.

22.7.1 Feature list

- PWM encoding as specified in [1]

22.7.2 Functional overview

The following figure shows the PWME and its interfaces with the CAN XL protocol controller and the CAN transceiver.

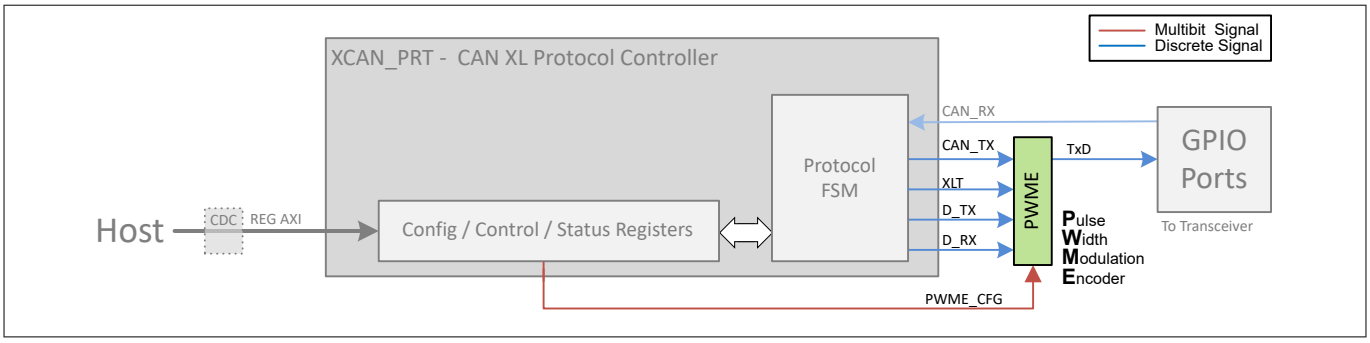

Figure 426 PWME overview

22.7.3 Functional description

PWME implements the PWM encoding as specified in [1]. When transceiver mode switching is enabled, the PWME encodes the CAN_TX input signal during a CAN XL frame's data phase and during ADH bit, to generate the PWM encoded output signal TXD.

The output of the PWM logic is registered by the Flip Flop TXD_PWME. An active reset sets this Flip Flop TXD_PWME to one. All Flip Flops in the PWME change their value with the rising edge of CLK.

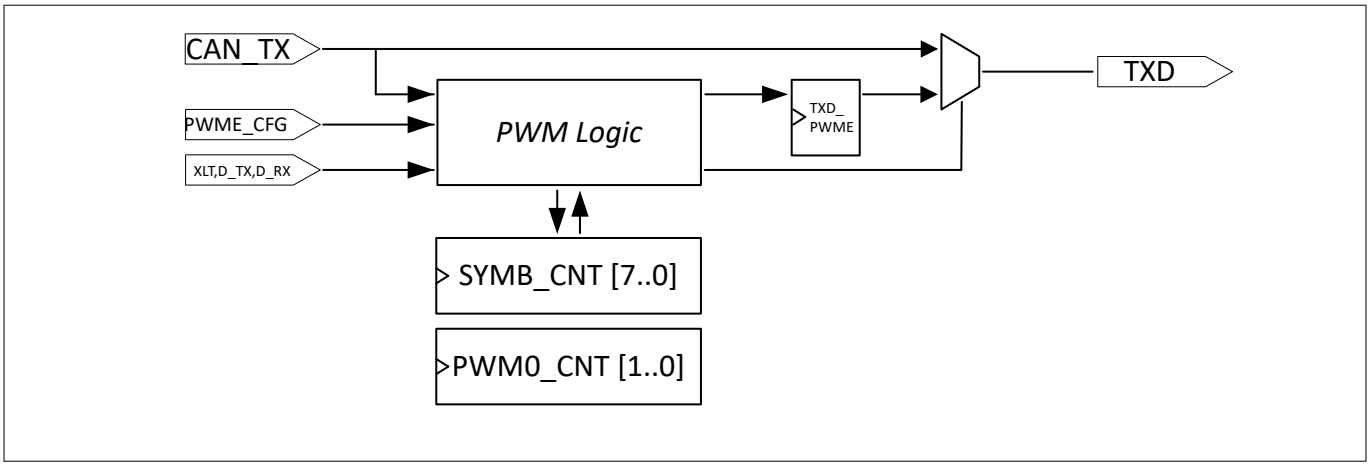

Figure 427 PWME block diagram

22.7.3.1 Transparent mode

While XLT is passive or both D_RX and D_TX are passive, the PWME interface behaves transparent between CAN_TX input and TXD output.

This mode is independent of reset.

22.7.3.2 PWM encoded mode

While XLT is active, the TXD output is PWM encoded for a transmitting node while D_TX is active and for the receiving node while D_RX active. The PWM encoded TXD output has one CLK cycle delay (internal processing delay) relative to the bit boundaries on CAN_TX input.

22.7.3.2.1 Transmitting node

When the PWME detects an edge from passive to active on D_TX and if XLT is active, then the PWME drives a LOW level on TXD for one PWM offset time.

With expiration of the PWM offset time the TXD output drives 2 consecutive PWM_0 symbols. From there onwards all following PWM symbols follow the CAN_TX input.

When D_TX is passive or XLT is passive the PWME switches back to transparent behavior regardless of the actual PWM phase.

22.7.3.2.2 Receiving node

When the PWME detects an edge from passive to active on D_RX and if XLT is active, then the PWME drives consecutive PWM_1 symbols without a leading offset time.

When D_RX is passive or XLT is passive the PWME switches back to transparent behavior regardless of the actual PWM phase.

22.7.3.3 Application information

Not applicable.

22.7.3.3.1 PWME configuration

The PWME_CFG contains the parameters needed for the PWM encoding (as defined in [1]) in the PWME module. The PWME_CFG signal may not change its value while the PRT is started, i.e. while CAN frames can be received and transmitted.

Valid values for the PWM phase Short PWMS are 00_H to $3F_H$. The actual interpretation of this value is that the PWM short phase length is (PWMS + 1) clock cycles long.

Valid values for the PWM phase Long PWML are 00_H to $3F_H$. The actual interpretation of this value is that the PWM long phase length is (PWML + 1) clock cycles long.

The PWM symbol length is the sum of PWM short phase length and PWM long phase length (PWMS + PWML + 2) clock cycles.

Valid values for the PWM Offset PWMO are 00_H to $3F_H$. PWMO shall always be smaller than the PWM symbol length (PWMO < PWMS + PWML + 2).

22.8 Interrupt Controller (IRC)

22.8.1 Feature list

- Interrupt generation for Functional events
- Interrupt generation for Error event
- Interrupt generation for Safety critical events
- Masking of individual events

22.8.2 Functional overview

The X_CAN IP is equipped with a central interrupt controller (IRC). It captures all events of the MH and PRT and can be configured for each event individually to interrupt the HOST CPU.

The events are organized in two categories, i.e. Functional Events and Error Events. Functional Events can trigger the IRC output FUNC_INT. Error Events can trigger the IRC outputs ERR_INT and SAFETY_INT.

22.8.3 Functional description

The following table lists the categories and shows the related IRC registers together with the dedicated IRC outputs:

Table 1065 Interrupt categories

Category	IRC Registers	IRC output
Functional Event	Ni_FUNC_RAW, Ni_FUNC_CLR, Ni_FUNC_ENA	FUNC_INT
Error Event	Ni_ERR_RAW, Ni_ERR_CLR, Ni_ERR_ENA	ERR_INT
	Ni_SAFETY_RAW, Ni_SAFETY_CLR, Ni_SAFETY_ENA	SAFETY_INT

For each category, three registers are implemented: xxx_RAW, xxx_CLR, and xxx_ENA. To capture the events, the xxx_RAW registers are used. These registers provide information about the occurrence of events inside the MH and the PRT. A flag is set when the related event occurred, independent of xxx_ENA. The flags remain set until the HOST CPU clears them by writing a 1 to the corresponding bit position at register xxx_CLR.

The xxx_ENA registers control on bit level, whether a certain bit in the xxx_RAW register can activate the interrupt line xxx_INT. The interrupt line xxx_INT gets active high, when at least one RAW/ENA pair is 1, e.g. ERR_INT gets active high, when Ni_ERR_RAW.MH_RX_FILTER_ERR = Ni_ERR_ENA.MH_RX_FILTER_ERR = 1.

22.9 Registers

22.9.1 Register overview - access mode glossary

Table 1066 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-PM	Protection group consisting of registers MODULE_ACCEN_WRA, MODULE_ACCEN_WRB, MODULE_ACCEN_RDA, MODULE_ACCEN_RDB, MODULE_ACCEN_VM, MODULE_ACCEN_PRS.
PM	Access protection using *APU-PM* registers.
APU-PNi (i=0-3)	Protection group consisting of registers NODEi_ACCENNODE_WRA, NODEi_ACCENNODE_WRB, NODEi_ACCENNODE_RDA, NODEi_ACCENNODE_RDB, NODEi_ACCENNODE_VM, NODEi_ACCENNODE_PRS.
PNi	Access protection using *APU-PNi* registers.
U	No access restrictions.
BE	Always returns a Bus Error.
PROT	Access restrictions as defined in the PROT register access rules.
32	Access only when using 32-bit width.

22.9.2 Registers overview - CANXL (ascending offset address)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOD_TYPE								MOD_REV							
r								r							

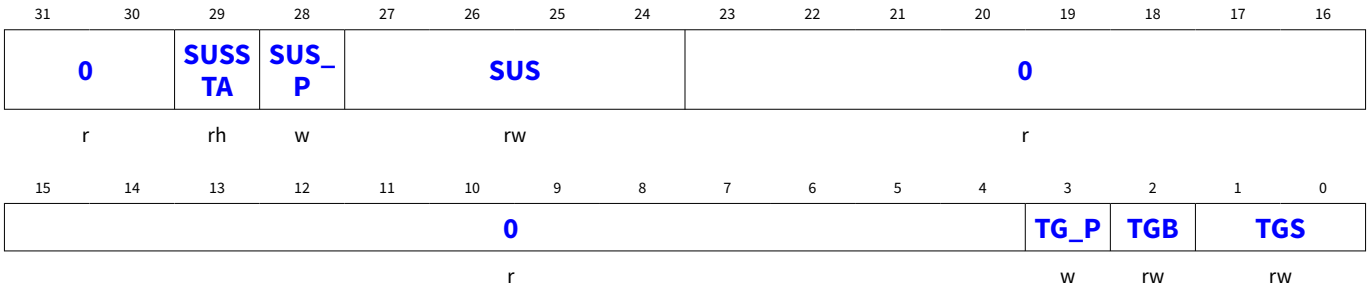
Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number.

22.9.4 OCDS Control and Status Register

The OCDS Control and Status register OCS controls the debug and trace behavior by selecting suspend modes and OTGB trigger sets. When OCDS is disabled the suspend control is ineffective.

OCS Offset address: 00004_H

OCDS Control and Status Register Debug Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TGS	1:0	rw	**Trigger Set for OTGB0/1** 00_B No Trigger Set output 01_B CANXL_HDP16 The HW signals defined by Ni_DEBUG_TEST_CTRL.HDP_SEL[1:0] are selected as OTGB triggers. 10_B Reserved 11_B Reserved
TGB	2	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1
TG_P	3	w	**TGS, TGB Write Protection** TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) Not listed combinations are reserved. 0_H Will not suspend 1_H Hard suspend. Clock is off immediately. Do not use this mode in normal CAN or CAN XL applications, this mode is meant for debugging the peripheral IP. 2_H Soft suspend mode Soft suspend of CAN-XL nodes. The clock is switched off after completion of the ongoing transmission and reception events. **others,** Reserved, do not use
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:4, 31:30	r	**Reserved**

Table 1068 Access mode restrictions of OCS sorted by descending priority

Mode name	Access mode		Description
write 1 to .**TG_P**	rw	TGB, TGS	Set TG_P during write access
write 1 to .**SUS_P**	rw	SUS	Set SUS_P during write access
otherwise	r	SUS, TGB, TGS	

22.9.5 Module Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

MODULE_CLC Offset address: 00008_H

Module Clock Control Register Application Reset value: $0000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

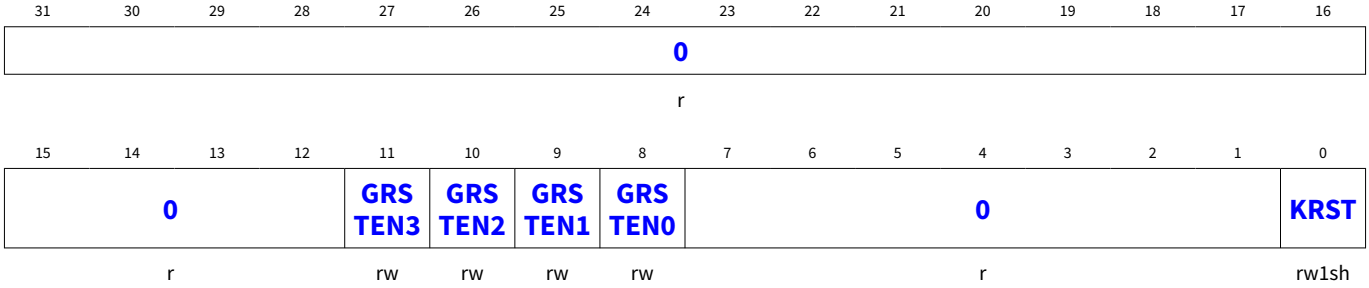
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. This also includes the Slave Interface Bridge and Master Interface Bridge 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep mode enable control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

22.9.6 Module reset control register A

MODULE_RST_CTRLA Offset address: $0000C_H$

Module reset control register A Application Reset value: $0000\ 0000_H$

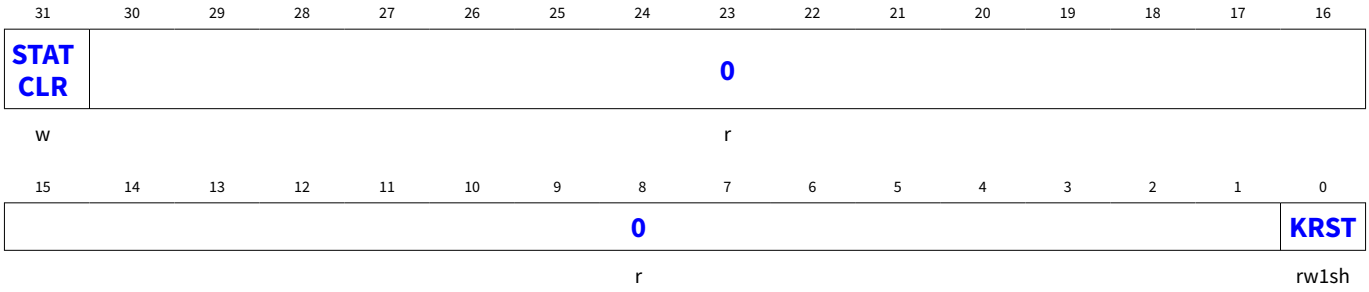


Field	Bits	Type	Description
KRST	0	rw1sh	**Kernel reset** Request a kernel reset. The requested reset is executed if MODULE_RST_CTRLA.KRST=1 and MODULE_RST_CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for global module reset group x** 0_B Global module reset group x does not have any effect 1_B Global module reset group x results in a kernel reset
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

22.9.7 Module reset control register B

MODULE_RST_CTRLB Offset address: 00010_H

Module reset control register B Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rw1sh	**Kernel reset** Request a kernel reset. The requested reset is executed if MODULE_RST_CTRLA.KRST=1 and MODULE_RST_CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested

(table continues...)

(continued)

Field	Bits	Type	Description
STATCLR	31	w	**Kernel reset status clear** Clears all status bits in MODULE_RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits MODULE_RST_STAT.GRSTx and bit MODULE_RST_STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

22.9.8 Module reset status register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

MODULE_RST_STAT Offset address: 00014_H

Module reset status register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0								RD07	RD06	RD05	RD04	RD03	RD02	RD01	RD00
r								rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
RDq (q=00-07)	q	rw	**Read access enable for PRS q** This bit enables read access to the access protected region for transactions with the PRS q. 0_B Disabled for read access 1_B Enabled for read access

(table continues...)

(continued)

Field	Bits	Type	Description
WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

22.9.15 PROT Register Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 00038_H

PROT Register Endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OWEN	ODEF	TAGID						PRSEN	PRS			VMEN	VM

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												SWEN	STATE		
r												w	rwh		

Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write

(table continues...)

(continued)

Field	Bits	Type	Description
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1069 Access mode restrictions of PROTE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
otherwise	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

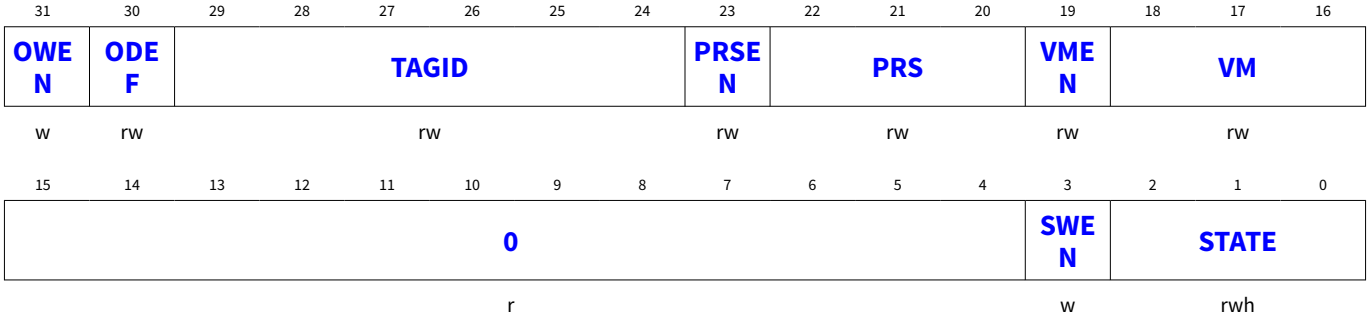
22.9.16 PROT Register Safe Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: $0003C_H$

PROT Register Safe Endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1070 Access mode restrictions of PROTSE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
otherwise	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN

Field	Bits	Type	Description
Ni_CC (i=0-3)	i	rw	**Node i clock control** This bit-field is used to enable or disable fCANXL and fCANXLH clock of CAN XL Node i. 0_B Disable Node i clocks 1_B Enable Node i clocks

(table continues...)

(continued)

Field	Bits	Type	Description
Ni_CCS (i=0-3)	i+16	rh	**Node i clock control status** This bit-field shows enable or disable status of CAN XL Node i fCANXL and fCANXLH clock. 0_B Node i clocks are disabled 1_B Node i clocks are enabled
0	15:4, 31:20	r	**Reserved, write 0, read as 0**

22.9.18 Node i reset control register A

NODEi_RST_CTRLA (i=0-3) Offset address: $00100_H+i*100_H$

Node i reset control register A Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

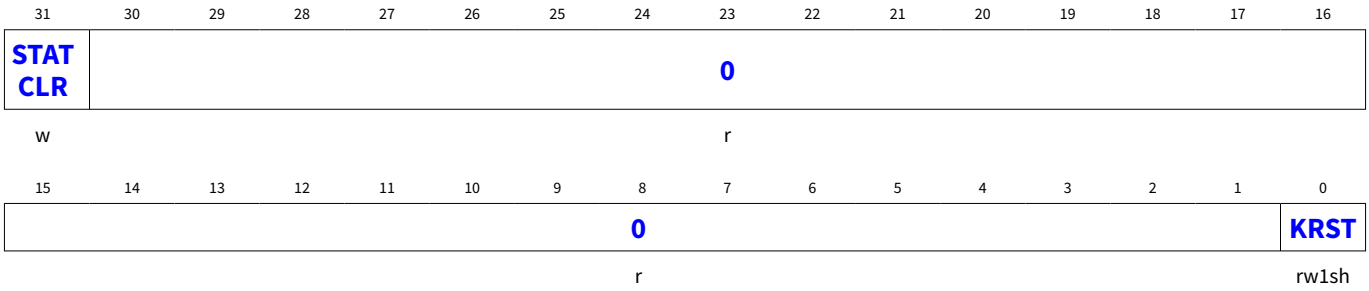
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				GRSTEN3	GRSTEN2	GRSTEN1	GRSTEN0	0							KRST
r				rw	rw	rw	rw	r							rw1sh

Field	Bits	Type	Description
KRST	0	rw1sh	**Kernel reset** Request a kernel reset. The requested reset is executed if NODEi_RST_CTRLA.KRST=1 and NODEi_RST_CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for Node reset group x** Node group reset is not supported by CANXL. Software must set this bit-field as 0. 0_B Node reset group x does not have any effect 1_B Node reset group x results in a kernel reset - Reserved
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

22.9.19 Node i reset control register B

NODEi_RST_CTRLB (i=0-3) Offset address: $00104_H+i*100_H$

Node i reset control register B Application Reset value: $0000\ 0000_H$



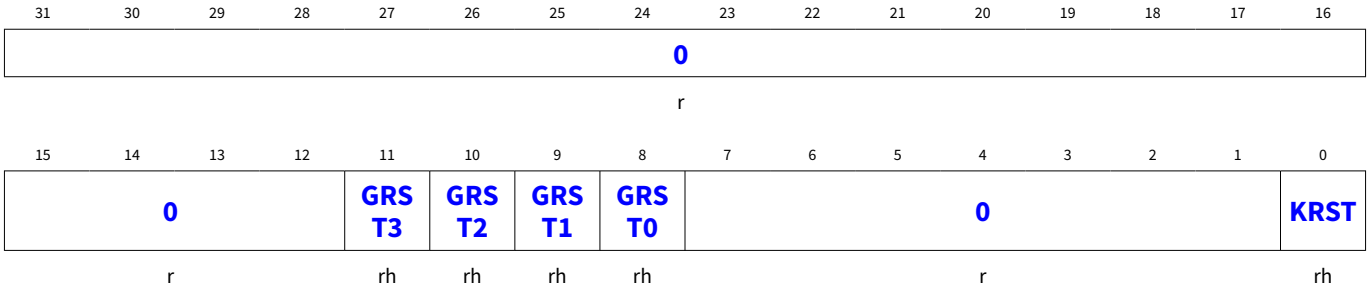
Field	Bits	Type	Description
KRST	0	rw1sh	**Kernel reset** Request a kernel reset. The requested reset is executed if NODEi_RST_CTRLA.KRST=1 and NODEi_RST_CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
STATCLR	31	w	**Kernel reset status clear** Clears all status bits in NODEi_RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits NODEi_RST_STAT.GRSTx and bit NODEi_RST_STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

22.9.20 Node i reset status register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

NODEi_RST_STAT (i=0-3) Offset address: $00108_H+i*100_H$

Node i reset status register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rh	**Kernel reset status** Indicates an executed kernel reset. NODEi_RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register NODEi_RST_CTRLB.
GRSTx (x=0-3)	x+8	rh	**Status for global module reset group x** 0_B Reset was not triggered by global reset group x 1_B Reset was triggered by global reset group x
0	7:1, 31:12	r	**Reserved** Read as 0.

22.9.21 Node i write access enable register A

Per CAN XL node SFR protection.

This register defines which master agent function TAG identifier (TAG-ID) encodings are enabled or disabled for write accesses to the access protected region.

NODEi_ACCENNODE_WRA (i=0-3) Offset address: $0010C_H+i*100_H$

Node i write access enable register A Application Reset value: $1000\ 0003_H$

ENq (q=32-39)	q-32	rw	**Write access enable for TAG-ID q** This bit enables write access to the access protected region for transactions with the TAG-ID q. 0_B Disabled for write access 1_B Enabled for write access
0	31:8	r	**Reserved** Read as 0; should be written with 0.

22.9.23 Node i read access enable register A

Per CAN XL node SFR protection.

This register defines which master agent function TAG identifier (TAG-ID) encodings are enabled or disabled for read accesses to the access protected region.

NODEi_ACCENNODE_RDA (i=0-3) Offset address: $00114_H+i*100_H$

Node i read access enable register A Application Reset value: FFFF $FFFF_H$

22.9.25 Node i VM access enable register

Per CAN XL node SFR protection.

This register defines which virtual machine encodings are enabled or disabled for accesses to the access protected region. There is one RDx and WRx bit for each VMx.

NODEi_ACCENNODE_VM (i=0-3) Offset address: $0011C_H+i*100_H$

Node i VM access enable register Application Reset value: $00FF\ 00FF_H$

22.9.26 Node i PRS access enable register

Per CAN XL node SFR protection.

This register defines which protection register set encodings are enabled or disabled for accesses to the access protected region. There is one RDx and WRx bit for each PRSx.

NODEi_ACCENNODE_PRS (i=0-3) Offset address: $00120_H+i*100_H$

Node i PRS access enable register Application Reset value: $00FF\ 00FF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

22.9.27 Node i region lower address register

Per CAN XL node SFR protection.

This register sets the lower bound of the access protected region. Addresses greater than or equal to the lower bound are considered part of the access protected region.

NODEi_ACCENNODE_RGNLA (i=0-3) Offset address: $00124_H+i*100_H$

Node i region lower address register Application Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
ADDR	31:6	rw	**Bits 31:6 of the lower bound of the access protected region**
0	5:0	r	**Reserved** Read as 0; should be written with 0.

22.9.28 Node i region upper address register

Per CAN XL node SFR protection.

This register sets the upper bound of the access protected region. Addresses stricly less than the upper bound are considered part of the access protected region.

NODEi_ACCENNODE_RGNUA (i=0-3) Offset address: $00128_H+i*100_H$

Node i region upper address register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

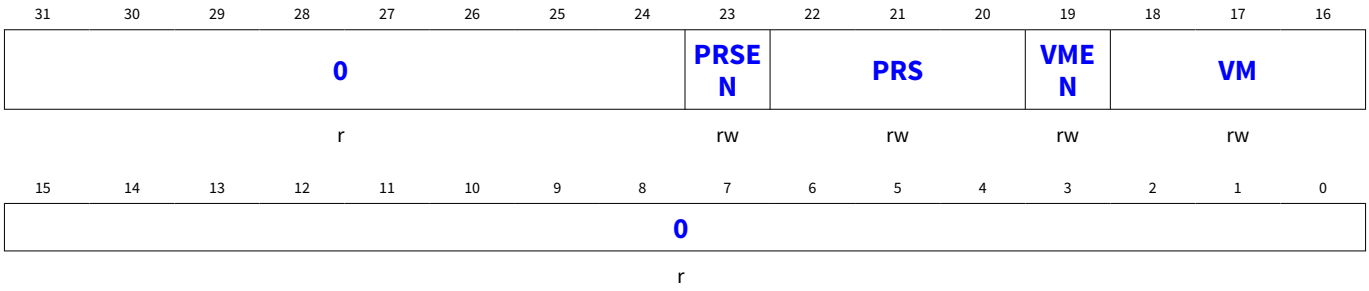
Field	Bits	Type	Description
ADDR	31:6	rw	**Bits 31:6 of the upper bound of the access protected region**
0	5:0	r	**Reserved** Read as 0; should be written with 0.

22.9.29 Node i VM and PRS configuration Register

NODEi_VMPRSCONFIG (i=0-3) Offset address: $0012C_H+i*100_H$

Node i VM and PRS configuration Register Application Reset value: $0000\ 0000_H$



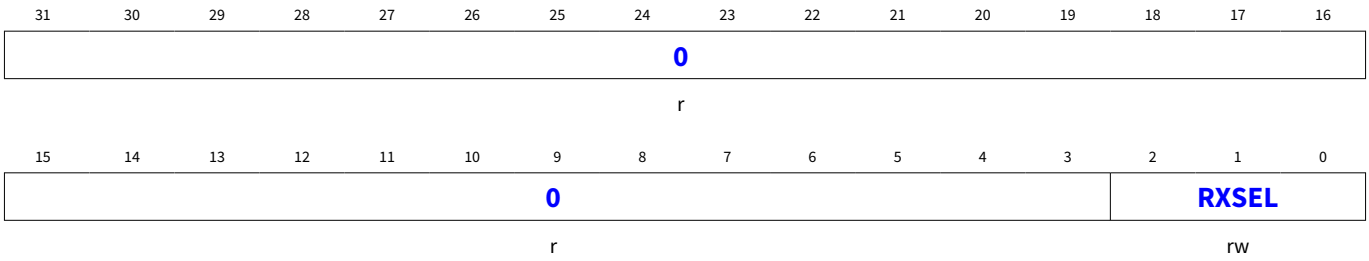
Field	Bits	Type	Description
VM	18:16	rw	**Virtual Machine** CAN-XL Node i's master interface accesses has extended VM tag ID configured in this bit-field
VMEN	19	rw	**Virtual Machine Enable** 0_B **Disable**: VM disabled 1_B **Enable**: VM enabled
PRS	22:20	rw	**Protection Set** CAN XL node i's master interface accesses with extended PRS tag ID configured in this bit-field
PRSEN	23	rw	**Protection Set Enable** 0_B **Disable**: PRS disabled 1_B **Enable**: PRS enabled
0	15:0, 31:24	r	**Reserved** Read as 0; should be written with 0.

22.9.30 Node i Port Control Register

The Node Port Control Register NODEi_PORTCTRL configures the CAN XL bus transmit/receive ports.

NODEi_PORTCTRL (i=0-3) Offset address: $00130_H+i*100_H$

Node i Port Control Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RXSEL	2:0	rw	**Receive Select** RXSEL selects one out of 8 possible receive inputs. The CAN XL receive signal is performed by the selected input. (see the device related chapter for RXSEL)

(table continues...)

(continued)

Field	Bits	Type	Description
0	31:3	r	**Reserved** Read as 0; should be written with 0.

22.9.31 Node i message transfer interrupt event register

A flag is set when the related event is detected, independent of NODEi_MTI_ENA. The flags remain set until the Host CPU clears them by writing a 1 to the corresponding bit position at register NODEi_MTI_CLR.

NODEi_MTI_RAW (i=0-3) Offset address: $00134_H+i*100_H$

Node i message transfer interrupt event register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												TS_CAPTURE	MH_RX_FILTER_IRQ	PRT_RX_EVT	PRT_TX_EVT
r												rh	rh	rh	rh

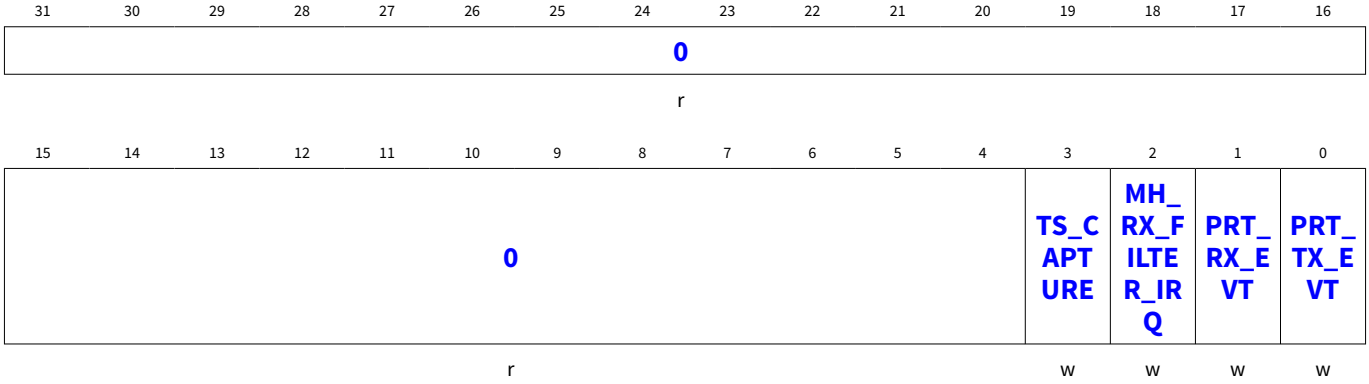
Field	Bits	Type	Description
PRT_TX_EVT	0	rh	**PRT transmitted a valid CAN message**
PRT_RX_EVT	1	rh	**PRT received a valid CAN message**
MH_RX_FILTER_IRQ	2	rh	**Receive filter event** In order to track RX filtering results an interrupt can be triggered when a match is detected on any defined RX filter element
TS_CAPTURE	3	rh	**Timestamp capture event**
0	31:4	r	**Reserved** Read as 0; should be written with 0.

22.9.32 Node i message transfer interrupt clear register

Writing a '1' to a certain bit position clears the correponding bit of register NODEi_MTI_RAW

NODEi_MTI_CLR (i=0-3) Offset address: $00138_H+i*100_H$

Node i message transfer interrupt clear register Kernel Reset value: $0000\ 0000_H$



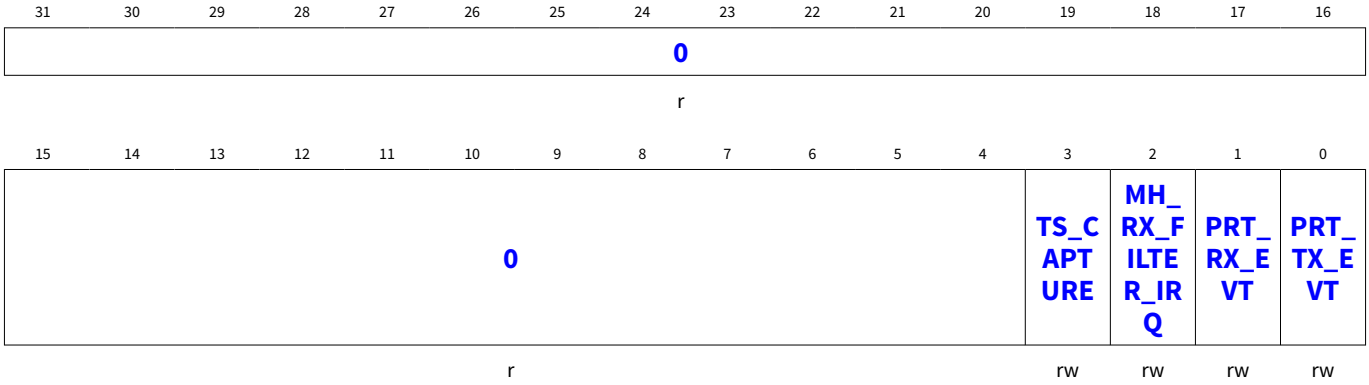
Field	Bits	Type	Description
PRT_TX_EVT	0	w	**Clear PRT transmit event** Clears NODEi_MTI_RAW.PRT_TX_EVT upon writing this bit-field with 1
PRT_RX_EVT	1	w	**Clear PRT receive event** Clears NODEi_MTI_RAW.PRT_RX_EVT upon writing this bit-field with 1
MH_RX_FILTER_IRQ	2	w	**Clear Receive filter event** Clears NODEi_MTI_RAW.MH_RX_FILTER_IRQ upon writing this bit-field with 1
TS_CAPTURE	3	w	**Timestamp capture event** Clears NODEi_MTI_RAW.TS_CAPTURE upon writing this bit-field with 1
0	31:4	r	**Reserved** Read as 0; should be written with 0.

22.9.33 Node i message transfer interrupt enable register

Writing a '1' to a certain bit position enables the correponding bit of register NODEi_MTI_RAW

NODEi_MTI_ENA (i=0-3) Offset address: $0013C_H+i*100_H$

Node i message transfer interrupt enable register Kernel Reset value: $0000\ 0000_H$

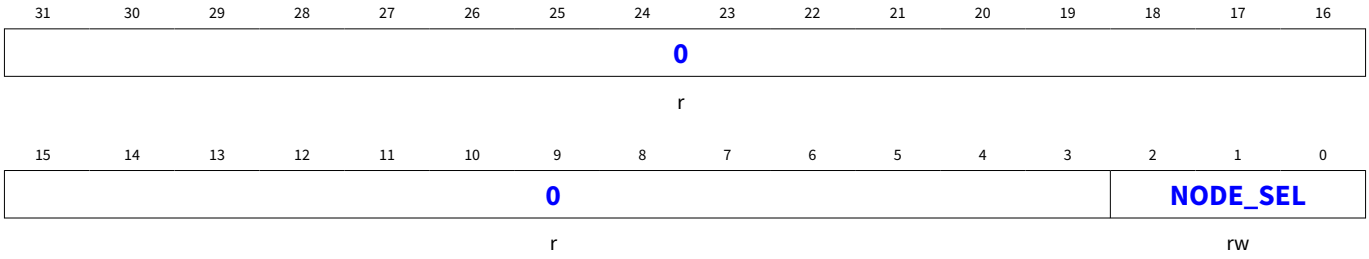


Field	Bits	Type	Description
PRT_TX_EVT	0	rw	**Enable PRT transmit event** Writing this bit-field with 1 enables MTI interrupt trigger on occurrence of corresponding event in MTI SFR. Write with 0 disables the MTI interrupt for the corresponding event.
PRT_RX_EVT	1	rw	**Enable PRT receive event** Writing this bit-field with 1 enables MTI interrupt trigger on occurrence of corresponding event in MTI SFR. Write with 0 disables the MTI interrupt for the corresponding event.
MH_RX_FILTER_IRQ	2	rw	**Enable receive filter event** Writing this bit-field with 1 enables MTI interrupt trigger on occurrence of corresponding event in MTI SFR. Write with 0 disables the MTI interrupt for the corresponding event.
TS_CAPTURE	3	rw	**Enable timestamp capture event** Writing this bit-field with 1 enables MTI interrupt trigger on occurrence of corresponding event in MTI SFR. Write with 0 disables the MTI interrupt for the corresponding event.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

22.9.34 Debug control register

DEBUG_CTL — Offset address: 10004_H

Debug control register — Kernel Reset value: $0000\ 0000_H$



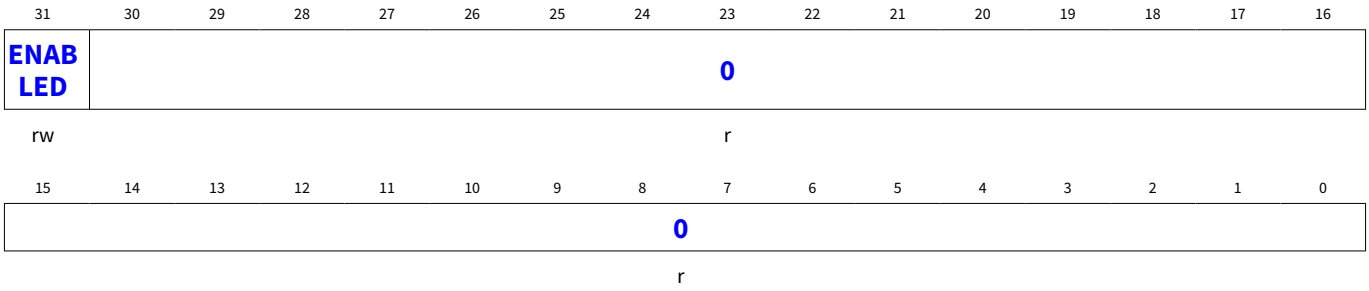
Field	Bits	Type	Description
NODE_SEL	2:0	rw	**Node select** Selection for which X_CAN debug ports are connected to the single top level ports at canxl_base for HDP[15:0], SAMPLE_POINT and STAT_ACT[1:0].
0	31:3	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.35 Node i timestamp control

This register is used to enable timstamp counters.

Ni_TS_CTL (i=0-3) — Offset address: $20010_H+i*2000_H$

Node i timestamp control — Kernel Reset value: $0000\ 0000_H$



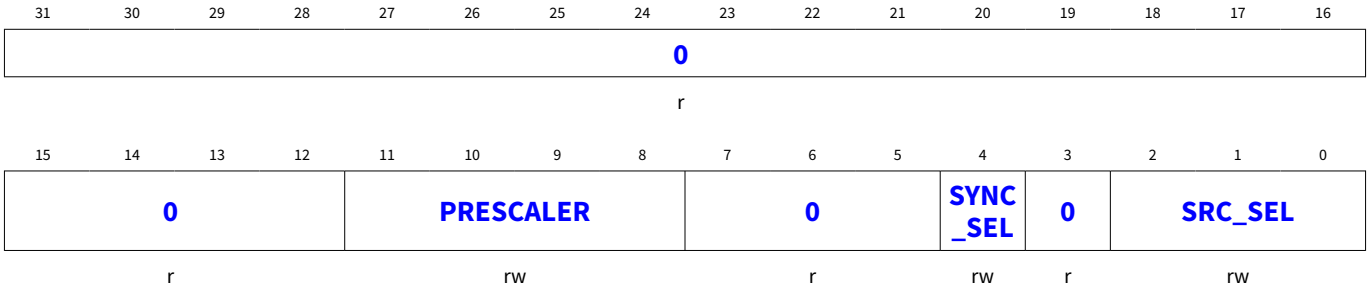
Field	Bits	Type	Description
ENABLED	31	rw	**Timestamp control** When ENABLED is 0 for instance i, TS_CNT* do not increment. Setting the bit to 1 enables incrementing. If disabling a timestamp counter, any X_CAN instance using this counter should be idle and not actively capturing from that timer.
0	30:0	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.36 Node i timestamp clock control

This register should be adjusted by software when Ni_TS_CTL register ENABLED bit = 0.

Ni_TS_CLOCK_CTL (i=0-3) Offset address: $20014_H+i*2000_H$

Node i timestamp clock control Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SRC_SEL	2:0	rw	**Clock source select for clk_timebase generation.** 000_B **HOST**: Host clock (fCANXLH) 001_B **EXT_0**: External 0 (STM Trigger) 010_B **EXT_1**: External 1 (GTM Trigger) 011_B **EXT_2**: External 2 (eGTM Trigger) **others,** External 3 (Reserved)
SYNC_SEL	4	rw	**Selection of external or local timebase** 0_B **INTERNAL**: Select internal timestamp counter and clock 1_B **EXTERNAL**: Select external timestamp counter and clock

(table continues...)

(continued)

Field	Bits	Type	Description
PRESCALER	11:8	rw	**Local pre-scaler for clk_timebase generation.** 0_H **DIV_BY_0**: Divide option 0 … F_H **DIV_BY_15**: Divide option 15
0	3, 7:5, 31:12	r	**Reserved** Read as 0; should be written with 0.

22.9.37 Node i timestamp command

Ni_TS_CMD (i=0-3) Offset address: $20020_H+i*2000_H$

Node i timestamp command Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

VALUE															
rh															

Field	Bits	Type	Description
VALUE	31:0	rh	**Bits [31:0] of 64 bit timestamp counter** Note that in the case of TS_PRESENT = 1: If SYNC_SEL = INTERNAL, Ni_TS_CNT_LO is the clk_host synchronised version of the node local timestamp counter (bits [31:0]). If SYNC_SEL = EXTERNAL, Ni_TS_CNT_LO is the clk_host synchronised version of the ext_ts_in external reference timestamp counter (bits [31:0]).

22.9.39 Node i timestamp counter MSBs

Ni_TS_CNT_HI (i=0-3) Offset address: $20034_H+i*2000_H$

Node i timestamp counter MSBs Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VALUE															
rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VALUE															
rh															

Field	Bits	Type	Description
VALUE	31:0	rh	**Bits [63:32] of timestamp counter.** Note that in the case of TS_PRESENT = 1: If SYNC_SEL = INTERNAL, Ni_TS_CNT_HI is the clk_host synchronised version of the node local timestamp counter (bits [63:32]). If SYNC_SEL = EXTERNAL, Ni_TS_CNT_HI is the clk_host synchronised version of the ext_ts_in external reference timestamp counter (bits [63:32]).

22.9.40 Node i release identification register

This register is protected by a register bank CRC defined in Ni_CRC_REG register.

Ni_VERSION (i=0-3) Offset address: $21000_H+i*2000_H$

Node i release identification register Kernel Reset value: $0560\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r				r				r				r			

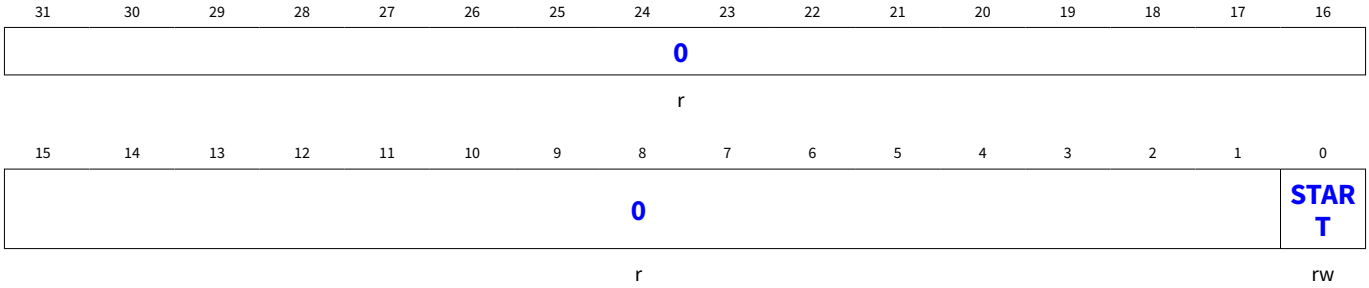
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MON								DAY							
r								r							

Field	Bits	Type	Description
DAY	7:0	r	**DAY** Define the day of the release using a binary coded decimal representation (1 being the first day of the month and so forth). This reset value is defined by the generic parameter DESIGN_TIME_STAMP_G[7:0]. If the generic parameter DESIGN_TIME_STAMP_G is not set, the default value is the one defined here
MON	15:8	r	**MON** Define the month of the release using a binary coded decimal representation (1 being January and so forth). This reset value is defined by the generic parameter DESIGN_TIME_STAMP_G[15:8]. If the generic parameter DESIGN_TIME_STAMP_G is not set, the default value is the one defined here
YEAR	19:16	r	**YEAR** Define the year of the release using a binary coded decimal representation (0 being 2020 and so forth…). This reset value is defined by the generic parameter DESIGN_TIME_STAMP_G[19:16]. If the generic parameter DESIGN_TIME_STAMP_G is not set, the default value is the one defined here
SUBSTEP	23:20	r	**SUBSTEP** Sub-Step value according to Step.
STEP	27:24	r	**STEP** Step value according to Release.
REL	31:28	r	**REL** Release value, used to identify the main release of the X_CAN.

22.9.41 Node i message handler control register

Ni_MH_CTRL (i=0-3) Offset address: $21004_H+i*2000_H$

Node i message handler control register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
START	0	rw	**START** Before starting any RX/TX FIFO Queues or TX FIFO Queue slots the MH must write 1 to this bit prior launching the PRT. At initial start, as long as the PRT is not started, this bit can be set back to 0. When set to 1, the global configuration registers are write-protected. As soon as the PRT is started, this bit cannot be set to 0. This bit can only be set to back to 0 if Ni_MH_STS.ENABLE = 0 and Ni_MH_STS.BUSY =0. For more details on starting/stopping or restarting the MH, refer to the Programming Guidelines chapter.
0	31:1	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.42 Node i message handler configuration register

This register is only accessible in write mode if the MH is not started, see Ni_MH_CTRL.START = 0. This register is protected by a register bank CRC defined in Ni_CRC_REG register.

Ni_MH_CFG (i=0-3) Offset address: $21008_H+i*2000_H$

Node i message handler configuration register Kernel Reset value: $0000\ 0700_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0													INST_NUM		
r													rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					MAX_RETRANS			0							RX_CONT_DC
r					rw			r							rw

Field	Bits	Type	Description
RX_CONT_DC	0	rw	**RX CONT DC** When set to 1, the Continuous mode is active. This mode provides the option to have a linear and continuous memory organization of the RX message data. Only one RX descriptor is used by RX message data and one single data container is required. This bit field register is only accessible in write mode if the MH is not started, see Ni_MH_CTRL.START = 0.
MAX_RETRANS	10:8	rw	**MAX RETRANS** Maximum number of TX message re-transmissions. Different configurations are possible: 0 -> no re-transmission; 1 to 6 -> 1 to 6 re-transmissions; 7-> unlimited re-transmissions; This bit field register is only accessible in write mode if the MH is not started, see Ni_MH_CTRL.START = 0.

(table continues...)

(continued)

Field	Bits	Type	Description
INST_NUM	18:16	rw	**INST NUM** In case that a cluster of X_CAN is defined, this bit field is used as a unique identifier per instance. This identifier is used by the MH to determine if the TX/RX descriptors are fetched by the right instance, see RX/TX description. This bit field register is only accessible in write mode if the MH is not started, see Ni_MH_CTRL.START = 0.
0	7:1, 15:11, 31:19	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.43 Node i message handler status register

Ni_MH_STS (i=0-3) Offset address: $2100C_H+i*2000_H$

Node i message handler status register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0							CLOCK_ACTIVE	0			ENABLE	0			BUSY
r							rh	r			rh	r			rh

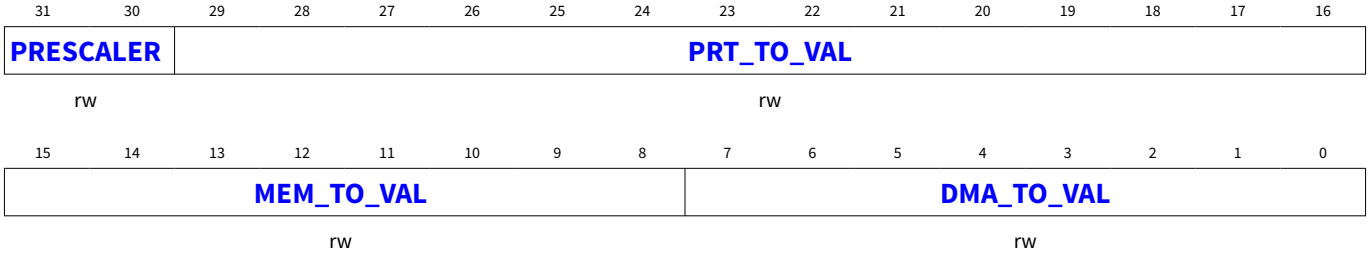
Field	Bits	Type	Description
BUSY	0	rh	**BUSY** This bit is the general busy flag, it is an ORED(RX/TX FIFO Queues and TX Priority Queue slots busy flags).
ENABLE	4	rh	**ENABLE** Value of the ENABLE signal driven by the PRT. The PRT signalizes via ENABLE whether it is active (ENABLE = 1) and requires message handling or not (ENABLE = 0).
CLOCK_ACTIVE	8	rh	**CLOCK ACTIVE** Status of MH core clock: 0 = clock off, 1 = clock on.
0	3:1, 7:5, 31:9	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.44 Node i message handler safety configuration register

This register is only accessible in write mode if the MH is not started, see Ni_MH_CTRL.START = 0. This register is protected by a register bank CRC defined in Ni_CRC_REG register.

Ni_MH_SFTY_CFG (i=0-3) Offset address: $21010_H+i*2000_H$

Node i message handler safety configuration register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DMA_TO_VAL	7:0	rw	**DMA TO VAL** This value is used by the watchdog timer for the DMA_AXI interface and defines the maximum number of timer ticks until a read or write access has to be completed. This value must be configured according to the maximum system latency, expected on the DMA_AXI interface. If this value is set to 0 and Ni_MH_SFTY_CTRL.DMA_TO_EN = 1 then the DMA_TO_ERR interrupt is triggered right away when accessing the S_MEM. This bit field register is only accessible in write mode if the MH is not started, see Ni_MH_CTRL.START = 0.
MEM_TO_VAL	15:8	rw	**MEM TO VAL** This value is used by the watchdog timer for the MEM_AXI interface and defines the maximum number of timer ticks until a read or write access has to be completed. This value must be configured to the expected maximum latency on the MEM_AXI interface. If this value is set to 0 and Ni_MH_SFTY_CTRL.MEM_TO_EN = 1 then the MEM_TO_ERR interrupt is triggered right away when accessing the L_MEM. This bit field register is only accessible in write mode if the MH is not started, see Ni_MH_CTRL.START = 0.
PRT_TO_VAL	29:16	rw	**PRT TO VAL** This value is used by the watchdog timers for the internal RX_MSG and TX_MSG interfaces. It defines the maximum number of timer ticks until a message has to be transferred from PRT to MH respective MH to PRT. The value must be configured according to the CAN frame which requires the longest time to be transported on the CAN bus. If this value is set to 0 and Ni_MH_SFTY_CTRL.PRT_TO_EN = 1 then the DP_TO_ERR interrupt is triggered right away at the beginning of an RX message or when starting a TX message. This bit field register is only accessible in write mode if the MH is not started, see Ni_MH_CTRL.START = 0.
PRESCALER	31:30	rw	**PRESCALER** Prescaler used to generate the timer ticks for the watchdogs. This bit field register is only accessible in write mode if the MH is not started, see Ni_MH_CTRL.START = 0. According to the value a different clock ratio can be selected: 0: clk divided by 32 1: clk divided by 64 2: clk divided by 128 3: clk divided by 512

22.9.45 Node i message handler safety control register

This register is only accessible in write mode if the MH is not started, see Ni_MH_CTRL.START = 0. This register is protected by a register bank CRC defined in Ni_CRC_REG register.

Ni_MH_SFTY_CTRL (i=0-3) Offset address: $21014_H+i*2000_H$

Node i message handler safety control register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
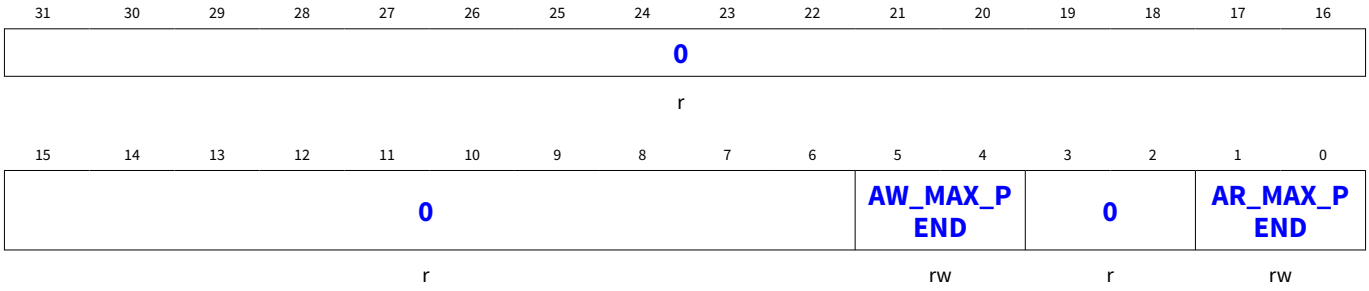
VAL	31:0	rw	**VAL** Define the MSB of the read/write AXI address bus used on the DMA_AXI interface. If not required, leave the default value and do not connect the upper part of the DMA_AXI read/write address bus. This bit field register is only accessible in write mode if the MH is not started, see Ni_MH_CTRL.START = 0.

22.9.49 Node i AXI parameter register

This register is only accessible in write mode if the MH is not started, see Ni_MH_CTRL.START = 0. This register is protected by a register bank CRC defined in Ni_CRC_REG register.

Ni_AXI_PARAMS (i=0-3) Offset address: $21024_H+i*2000_H$

Node i AXI parameter register Kernel Reset value: $0000\ 0000_H$

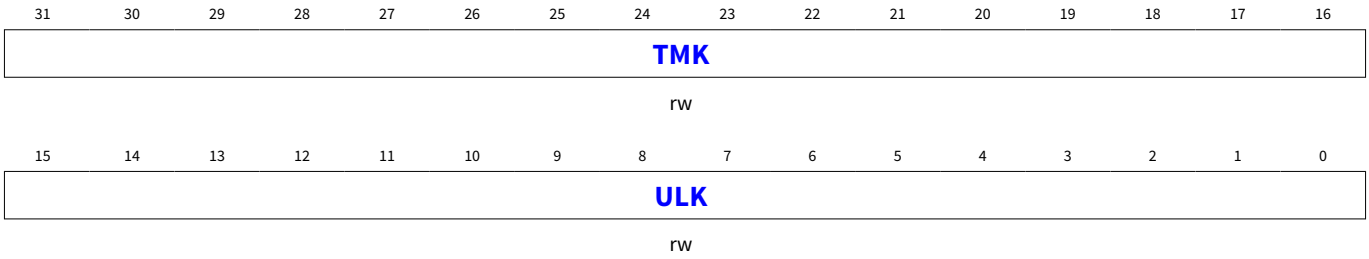


Field	Bits	Type	Description
AR_MAX_PEND	1:0	rw	**AR MAX PEND** AR_MAX_PEND[1:0] defines the maximum read pending transactions on DMA_AXI interface: 0 -> no read transfer; 1 -> 1 outstanding read transaction; 2 -> 2 outstanding read transactions, 3 -> 3 outstanding read transactions. This bit field register is only accessible in write mode if the MH is not started, see Ni_MH_CTRL.START = 0.
AW_MAX_PEND	5:4	rw	**AW MAX PEND** AW_MAX_PEND[1:0] defines the maximum write pending transactions on DMA_AXI interface: 0 -> no write transfer; 1 -> 1 outstanding write transaction allowed; 2 -> 2 outstanding write transactions, 3 -> 3 outstanding write transactions. This bit field register is only accessible in write mode if the MH is not started, see Ni_MH_CTRL.START = 0.
0	3:2, 31:6	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.50 Node i message handler lock register

Ni_MH_LOCK (i=0-3) Offset address: $21028_H+i*2000_H$

Node i message handler lock register Kernel Reset value: $0000\ 0000_H$

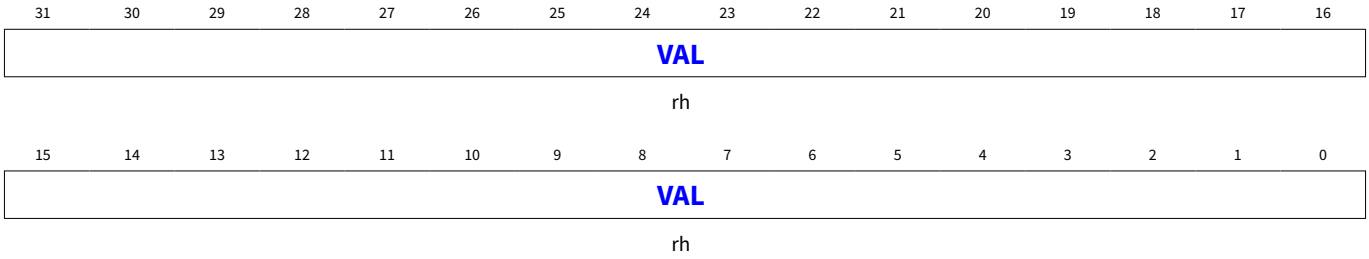


Field	Bits	Type	Description
ULK	15:0	rw	**ULK** Unlock key register. Two consecutive writes to this bit field, starting with 0x1234 and 0x04321, must be done before writing to a register being locked.
TMK	31:16	rw	**TMK** Test mode key register. Two consecutive writes to this bit field, starting with 0x6789 and 0x9876, must be done before writing to the Ni_DEBUG_TEST_CTRL register.

22.9.51 Node i TX descriptor current address pointer register

Ni_TX_DESC_ADD_PT (i=0-3) Offset address: $21100_H+i*2000_H$

Node i TX descriptor current address pointer register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
VAL	31:0	rh	**VAL** Address used to fetch a TX descriptor for the TX FIFO Queues or TX Priority Queue slots. It could be for several reasons: a new message needs to be fetched from a TX FIFO Queue or a new message is defined in a TX Priority Queue slot. This address value is always word aligned (32bit).

22.9.52 Node i TX message counter register

Ni_TX_STATISTICS (i=0-3) Offset address: $21104_H+i*2000_H$

Node i TX message counter register Kernel Reset value: $0000\ 0000_H$

0				UNSUCC											
r				rwh											

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				SUCC											
r				rwh											

Field	Bits	Type	Description
SUCC	11:0	rwh	**SUCC** Counter incremented with every successful transmission of a CAN message to the CAN bus. The counter wraps automatically to 0 and can be cleared when writing 0 to the bit field. A STATS_IRQ interrupt is generated when the counter wraps.
UNSUCC	27:16	rwh	**UNSUCC** Counter incremented with every unsuccessful transmission of a CAN message to the CAN bus. The counter wraps automatically to 0 and can be cleared when writing 0 to the bit field. A STATS_IRQ interrupt is generated when the counter wraps.
0	15:12, 31:28	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.53 Node i TX FIFO queue status register (i=0-3)

Ni_TX_FQ_STS0 (i=0-3) Offset address: $21108_H+i*2000_H$

Node i TX FIFO queue status register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								STOP							
r								rh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0								BUSY							
r								rh							

Field	Bits	Type	Description
BUSY	7:0	rh	**BUSY** When BUSY[n] = 1 the TX FIFO Queue n is active, this means the FIFO Queue is started and running (TX message defined in the TX FIFO Queue n can be processed). When the BUSY[n] = 0, the TX FIFO Queue n is stopped and would require a write to the Ni_TX_FQ_CTRL0.START[n] to make it active again. A TX FIFO Queue can go inactive if the END bit in the last TX descriptor of a TX message is set. In this case the, the BUSY[n] = 0 can occur only if the TX header descriptor of this last message has been acknowledged for the TX FIFO Queue n. When the TX FIFO Queue n is aborted, the BUSY[n] flag is set to 0 only when no acknowledge is pending.

(table continues...)

(continued)

Field	Bits	Type	Description
STOP	23:16	rh	**STOP** When STOP[n] = 1 the TX FIFO Queue n is on hold, this means the FIFO Queue is started and running but waits for the SW to keep going. The STOP[n] can be set only if the BUSY[n] = 1. Several root causes may lead to this state: an error is detected, or a TX descriptor is not valid. To identify the potential issues, refer to the Ni_TX_FQ_STS1 register. In order to keep going with the TX FIFO Queue n, a write to the Ni_TX_FQ_CTRL0.START[n] is required. When BUSY[n] = 0, this bit is automatically set to 0
0	15:8, 31:24	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.54 Node i TX FIFO queue status register (i=0-3)

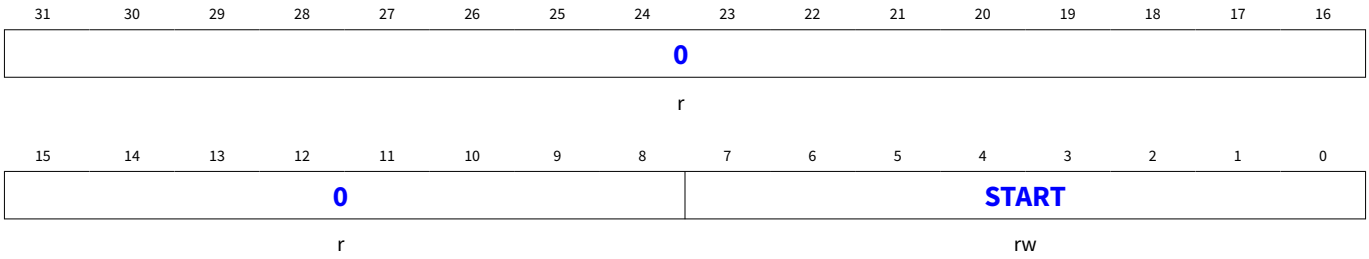
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0								UNVALID							
r								rh							

Field	Bits	Type	Description
UNVALID	7:0	rh	**UNVALID** When UNVALID[n] = 1 the TX FIFO Queue n is on hold due to an TX descriptor with VALID=0 was loaded.
ERROR	23:16	rh	**ERROR** When ERROR[n] = 1 the TX FIFO Queue n is on hold due to an inconsistent TX descriptor was loaded, see chapter Descriptor Protection.
0	15:8, 31:24	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.55 Node i TX FIFO queue control register 0

Ni_TX_FQ_CTRL0 (i=0-3) Offset address: $21110_H+i*2000_H$

Node i TX FIFO queue control register 0 Kernel Reset value: $0000\ 0000_H$



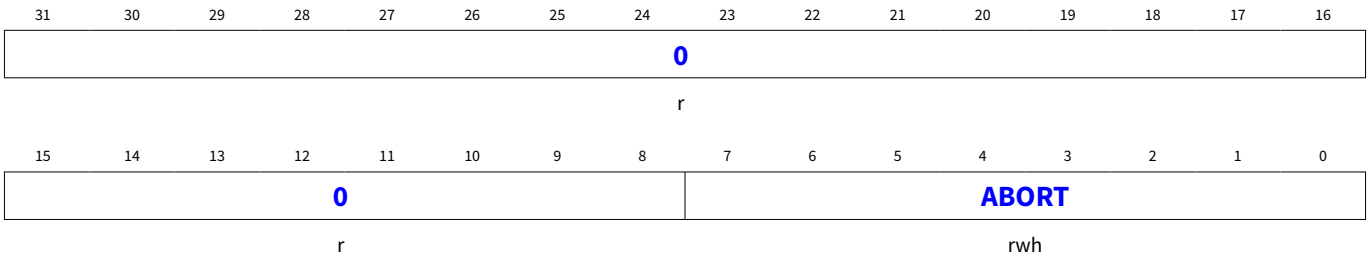
Field	Bits	Type	Description
START	7:0	rw	**START** When writing a 1 to the START[n], the TX FIFO Queue n is started. This bit is autocleared. Once started, the Ni_TX_FQ_STS0.BUSY[n] is set to 1. The MH must be started prior to any TX FIFO Queue start (Ni_MH_STS.BUSY set to 1). A TX FIFO Queue n can only be started if Ni_TX_FQ_CTRL2.ENABLE[n] is set to 1 and in order to avoid a dead lock situation with the PRT, the ENABLE signal from the PRT is high.
0	31:8	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.56 Node i TX FIFO queue control register 1

This register is only accessible in write mode if the unlock key sequence has been performed prior to write.

Ni_TX_FQ_CTRL1 (i=0-3) Offset address: $21114_H+i*2000_H$

Node i TX FIFO queue control register 1 Kernel Reset value: $0000\ 0000_H$

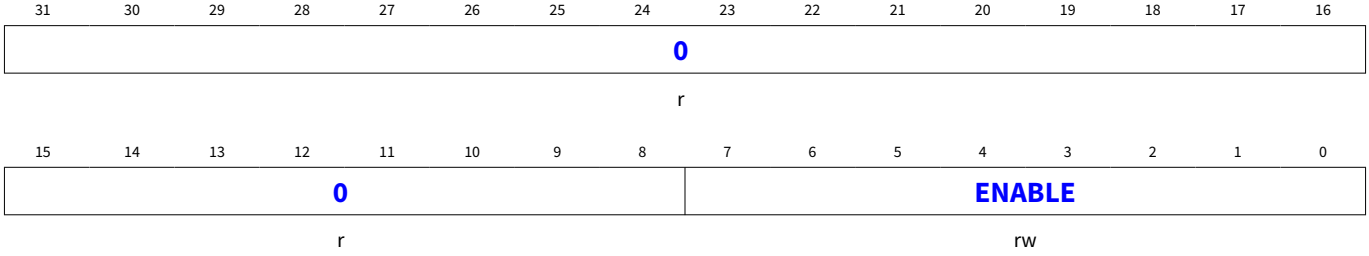


Field	Bits	Type	Description
ABORT	7:0	rwh	**ABORT** When ABORT[n] is set to 1, the TX FIFO Queue n is aborted. Once set to 1, the MH will abort all pending transaction related to the TX FIFO Queue n whenever required. This bit must be set back to 0 only when the TX FIFO Queue n is inactive, Ni_TX_FQ_STS0.BUSY[n] = 0. This bit field register is only accessible in write mode if the unlock key sequence has been performed prior to write.
0	31:8	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.57 Node i TX FIFO queue control register 2

Ni_TX_FQ_CTRL2 (i=0-3) Offset address: $21118_H+i*2000_H$

Node i TX FIFO queue control register 2 Kernel Reset value: $0000\ 0000_H$

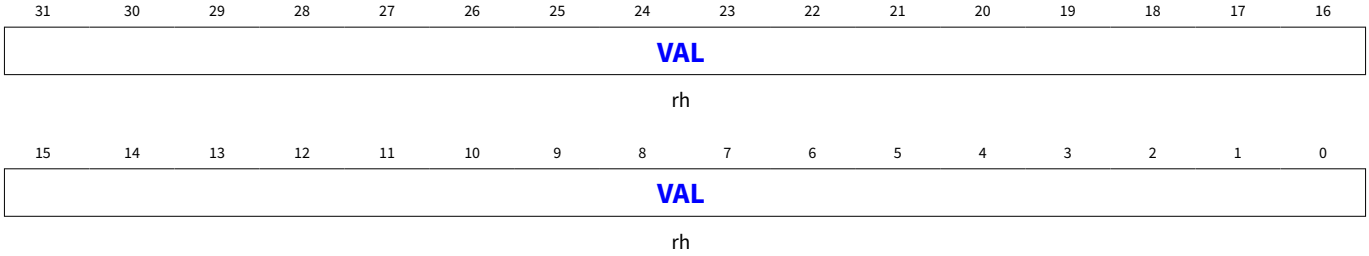


Field	Bits	Type	Description
ENABLE	7:0	rw	**ENABLE** When ENABLE[n] is set to 1, the TX FIFO Queue n is enabled. A TX FIFO Queue cannot be started if it is not enabled. Aborting a not started TX FIFO Queue has no effect.
0	31:8	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.58 Node i TX FIFO queue r current address pointer register

Ni_TX_FQ_ADD_PTr (i=0-3;r=0-7) Offset address: $21120_H+i*2000_H+r*10_H$

Node i TX FIFO queue r current address pointer register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
VAL	31:0	rh	**VAL** Provide the header descriptor address of the TX message being in used by the arbiter for the TX FIFO Queue. To follow TX descriptors over time while running TX FIFO Queues, refer to the Ni_TX_DESC_ADD_PT register. This address value is always word aligned (32bit).

22.9.59 Node i TX FIFO queue r start address register

This register is only accessible in write mode if the TX FIFO Queue r is not busy, see BUSY flag in Ni_TX_FQ_STS0 register. This register is protected by a register bank CRC defined in Ni_CRC_REG register.

Ni_TX_FQ_START_ADDr (i=0-3;r=0-7) Offset address: $21124_H+i*2000_H+r*10_H$

Node i TX FIFO queue r start address register Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VAL															
rw															

Field	Bits	Type	Description
VAL	31:0	rw	**VAL** Define the start address of the TX Priority Queue in the system memory. All TX header descriptors in the TX Priority Queue are continuously defined from this start address. The VAL[1:0] bits are always assumed to be 0b00 whatever the value written. This address value must always be word aligned (32bit). This bit field register is only accessible in write mode if the TX Priority Queue is not busy, see BUSY flag in TX_PQ_STS register

22.9.67 Node i RX descriptor current address pointer

Ni_RX_DESC_ADD_PT (i=0-3) Offset address: $21400_H+i*2000_H$

Node i RX descriptor current address pointer Kernel Reset value: $0000\ 0000_H$

VAL															
rh															

Field	Bits	Type	Description
VAL	31:0	rh	**VAL** Provide the address used to fetch the current RX descriptor. This address value is always word aligned (32bit).

22.9.68 Node i RX message counter register

Ni_RX_STATISTICS (i=0-3) Offset address: $21404_H+i*2000_H$

Node i RX message counter register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				UNSUCC											
r				rwh											

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				SUCC											
r				rwh											

Field	Bits	Type	Description
SUCC	11:0	rwh	**SUCC** Counter incremented with every successful reception of a CAN message from the CAN bus. The counter wraps automatically to 0 and can be cleared when writing 0x00 to the bit field. An interrupt is generated when the counter wraps.
UNSUCC	27:16	rwh	**UNSUCC** Counter incremented with every unsuccessful reception of a CAN message from the CAN bus. The counter wraps automatically to 0 and can be cleared when writing 0x00 to the bit field. An interrupt is generated when the counter wraps.
0	15:12, 31:28	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.69 Node i RX FIFO queue status register 0

Ni_RX_FQ_STS0 (i=0-3) Offset address: $21408_H+i*2000_H$

Node i RX FIFO queue status register 0 Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								STOP							
r								rh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0								BUSY							
r								rh							

Field	Bits	Type	Description
BUSY	7:0	rh	**BUSY** When BUSY[n] = 1 the RX FIFO Queue n is busy, this means the FIFO Queue is started and running (RX message to be written to the RX FIFO Queue can be processed). When the BUSY[n] = 0, the RX FIFO Queue n is stopped and would require a write to the Ni_RX_FQ_CTRL0.START[n] to make it active again. When the RX FIFO Queue n is aborted, the BUSY[n] flag is set to 0 only when no acknowledge is pending.
STOP	23:16	rh	**STOP** When STOP[n] = 1 the RX FIFO Queue n is on hold, it means started but waiting for the SW to react. The STOP[n] can be set only if the BUSY[n] = 1. Several root causes may lead to the RX FIFO Queue n to stop: an error is detected, or an RX descriptor is not valid, or the FIFO is full. To identify the potential issues, refer to the Ni_RX_FQ_STS1 and Ni_RX_FQ_STS2 registers. In order to keep going with the RX FIFO Queue n, a write to the Ni_RX_FQ_CTRL0.START[n] is required. When BUSY[n] = 0, this bit is automatically set to 0
0	15:8, 31:24	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.70 Node i RX FIFO queue status register 1

Ni_RX_FQ_STS1 (i=0-3) Offset address: $2140C_H+i*2000_H$

Node i RX FIFO queue status register 1 Kernel Reset value: $0000\ 0000_H$

0								UNVALID							
r								rh							

Field	Bits	Type	Description
UNVALID	7:0	rh	**UNVALID** When UNVALID[n] = 1 the RX FIFO Queue n is on hold due to an RX descriptor detected with VALID=0.
ERROR	23:16	rh	**ERROR** When ERROR[n] = 1 the RX FIFO Queue n is on hold due to an inconsistent RX descriptor being loaded, see chapter Descriptor Protection.
0	15:8, 31:24	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.71 Node i RX FIFO queue status register 2

Ni_RX_FQ_STS2 (i=0-3) Offset address: $21410_H+i*2000_H$

Node i RX FIFO queue status register 2 Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

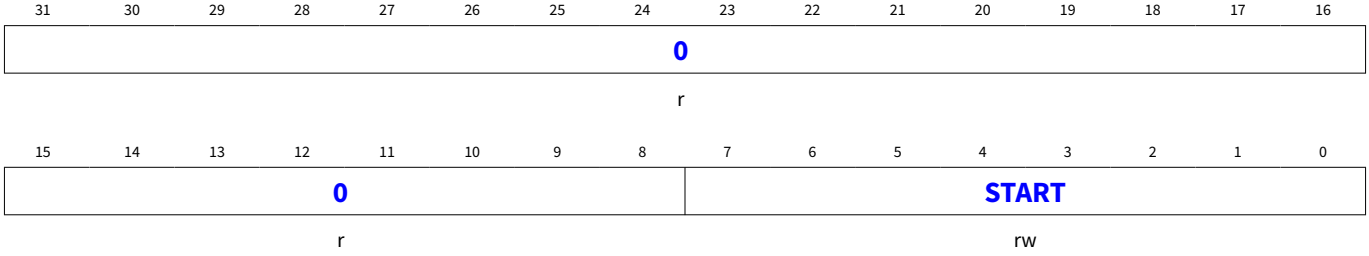
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0								DC_FULL							
r								rh							

Field	Bits	Type	Description
DC_FULL	7:0	rh	**DC FULL** When DC_FULL[n] = 1 the RX FIFO Queue n is stopped due to the RX FIFO Queue n being full. This register is relevant only for the Continuous Mode as in Normal mode, there is no need to provide such information to the MH
0	31:8	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.72 Node i RX FIFO queue control register 0

Ni_RX_FQ_CTRL0 (i=0-3) Offset address: $21414_H+i*2000_H$

Node i RX FIFO queue control register 0 Kernel Reset value: $0000\ 0000_H$



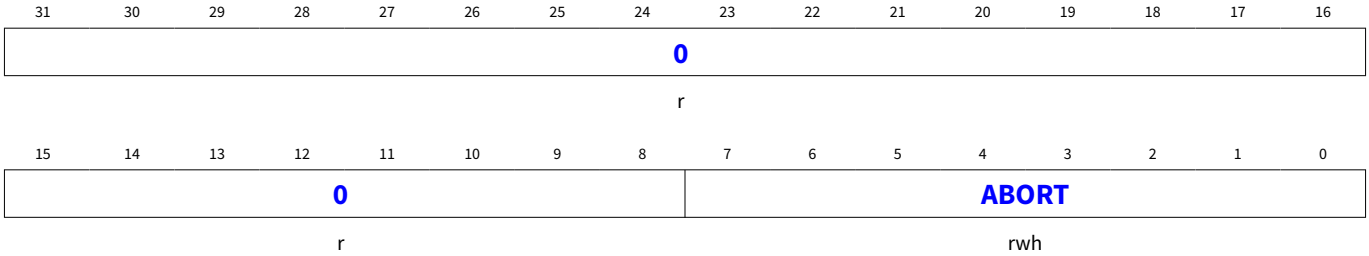
Field	Bits	Type	Description
START	7:0	rw	**START** When writing a 1 to the START[n], the RX FIFO Queue n is started. This bit is autocleared and once started, the Ni_RX_FQ_STS0.BUSY[n] is set to 1. The MH must be started prior to any RX FIFO Queue start (Ni_MH_STS.BUSY set to 1). An RX FIFO Queue n can only be started if Ni_RX_FQ_CTRL2.ENABLE[n] is set to 1.
0	31:8	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.73 Node i RX FIFO queue control register 1

This register is only accessible in write mode if the unlock key sequence has been performed prior to write.

Ni_RX_FQ_CTRL1 (i=0-3) Offset address: $21418_H+i*2000_H$

Node i RX FIFO queue control register 1 Kernel Reset value: $0000\ 0000_H$

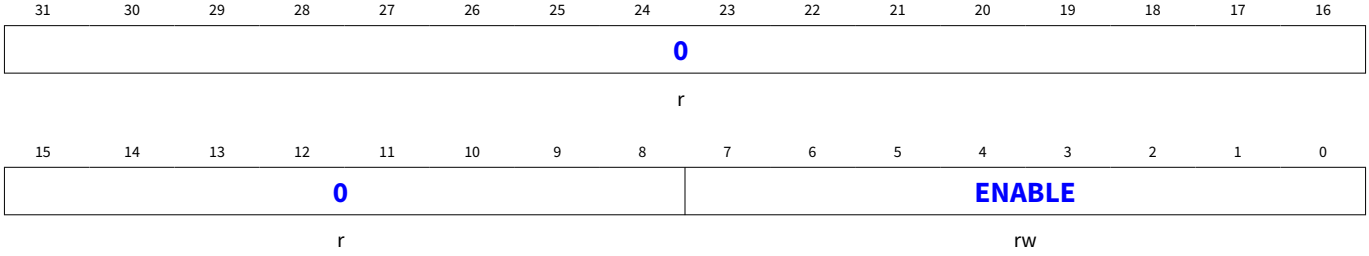


Field	Bits	Type	Description
ABORT	7:0	rwh	**ABORT** When ABORT[n] is set to 1, the RX FIFO Queue n is aborted. Once set to 1, the MH will abort all pending transactions related to the RX FIFO Queue n whenever required. The abort can be effective only if the RX FIFO Queue n is enabled. This bit must be set back to 0 only when the RX FIFO Queue n is inactive, Ni_RX_FQ_STS0.BUSY[n] = 0. This bit field register is only accessible in write mode if the unlock key sequence has been performed prior to write.
0	31:8	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.74 Node i RX FIFO queue control register 2

Ni_RX_FQ_CTRL2 (i=0-3) Offset address: $2141C_H+i*2000_H$

Node i RX FIFO queue control register 2 Kernel Reset value: $0000\ 0000_H$

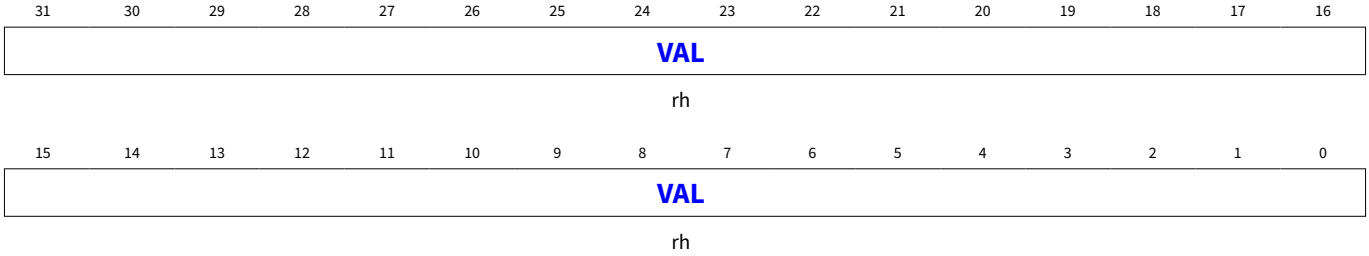


Field	Bits	Type	Description
ENABLE	7:0	rw	**ENABLE** When ENABLE[n] is set to 1, the RX FIFO Queue n is enabled. The RX FIFO Queue n cannot be started if not enabled. The abort of an RX FIFO Queue n not started would have no effect.
0	31:8	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.75 Node i RX FIFO queue s current address pointer

Ni_RX_FQ_ADD_PTs (i=0-3;s=0-7) Offset address: $21420_H+i*2000_H+s*18_H$

Node i RX FIFO queue s current address pointer Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
VAL	31:0	rh	**VAL** Provide the current RX Header Descriptor address pointer for the RX FIFO Queue 0 in the system memory. To follow RX descriptor over time, refer to the Ni_RX_DESC_ADD_PT register. This address value is always word aligned (32bit).

22.9.76 Node i RX FIFO queue s link list start address

This register is only accessible in write mode if the RX FIFO Queue is not busy, see BUSY flag in Ni_RX_FQ_STS0 register. This register is protected by a register bank CRC defined in Ni_CRC_REG register.

Ni_RX_FQ_START_ADDs (i=0-3;s=0-7) Offset address: $21424_H+i*2000_H+s*18_H$

Node i RX FIFO queue s link list start address Kernel Reset value: $0000\ 0000_H$

VAL															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VAL															
rw															

Field	Bits	Type	Description
VAL	31:0	rw	**VAL** Define the start address of the RX FIFO Queue link list descriptor in system memory. The VAL[1:0] bits are always assumed to be 0b00 whatever the value written. This address value must always be word aligned (32bit). This register is only accessible in write mode if the RX FIFO Queue 0 is not busy, see BUSY flag in Ni_RX_FQ_STS0 register

22.9.77 Node i RX FIFO queue s link list and data container size

This register is only accessible in write mode if the RX FIFO Queue is not busy, see BUSY flag in Ni_RX_FQ_STS0 register. This register is protected by a register bank CRC defined in Ni_CRC_REG register.

Ni_RX_FQ_SIZEs (i=0-3;s=0-7) Offset address: $21428_H+i*2000_H+s*18_H$

Node i RX FIFO queue s link list and data container size Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0				DC_SIZE											
r				rw											

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						MAX_DESC									
r						rw									

Field	Bits	Type	Description
MAX_DESC	9:0	rw	**MAX DESC** Define the maximum number of descriptors in the RX FIFO Queue link list. It is important to note that MAX_DESC = 0 does not prevent the RX FIFO Queue to be enabled and started. An active and running RX FIFO Queue with MAX_DESC = 0 is not allowed and will result in a DESC_ERR interrupt if no RX descriptor is defined. The size to be allocated to the link list must be equal to MAX_DESC * 16bytes for MAX_DESC >= 1. This register is only accessible in write mode if the RX FIFO Queue 0 is not busy, see BUSY flag in Ni_RX_FQ_STS0 register
DC_SIZE	27:16	rw	**DC SIZE** In Normal mode only the DC_SIZE[6:0] is used to define the maximum size of an RX data container for the RX FIFO Queue. The data container size is DC_SIZE[6:0] * 32bytes and one is attached to every RX descriptor. In continuous mode, it defines the size of the single data container used to write all RX messages. The overall data container size is DC_SIZE[11:0] * 32bytes for MAX_DESC > = 1. When set to 0, the RX FIFO Queue can be enabled but not started. This register is only accessible in write mode if the RX FIFO Queue 0 is not busy, see BUSY flag in Ni_RX_FQ_STS0 register
0	15:10, 31:28	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.78 Node i RX FIFO queue s data container start address

This register is accessible in write mode if the RX FIFO Queue is not busy, see BUSY flag in Ni_RX_FQ_STS0 register. This register is protected by a register bank CRC defined in Ni_CRC_REG register. This register is used only in Continuous Mode

Ni_RX_FQ_DC_START_ADDs (i=0-3;s=0-7) Offset address: $2142C_H+i*2000_H+s*18_H$

Node i RX FIFO queue s data container start address Kernel Reset value: $0000\ 0000_H$

rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VAL															
rw															

Field	Bits	Type	Description
VAL	31:0	rw	**VAL** Define the Data Container Start Address in system memory. This bit field is relevant only when the MH is configured in Continuous Mode. The VAL[1:0] bits are always assumed to be 0b00 whatever the value written. This address value must always be word aligned (32bit). This register is only accessible in write mode if the RX FIFO Queue 0 is not busy, see BUSY flag in Ni_RX_FQ_STS0 register

22.9.79 Node i RX FIFO queue s read address pointer

This register is used only in Continuous Mode.

Ni_RX_FQ_RD_ADD_PTs (i=0-3;s=0-7) Offset address: $21430_H+i*2000_H+s*18_H$

Node i RX FIFO queue s read address pointer Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VAL															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VAL															
rw															

Field	Bits	Type	Description
VAL	31:0	rw	**VAL** The SW uses this register to indicate the Data Read Address of the RX message being read to the MH. This address must point to the last word of the RX message considered in the data container. This bit field is relevant only when the MH is configured in Continuous mode. The MH uses this information to ensure that enough memory space is available to write the next message. For an initial start, it is mandatory to set VAL[1:0] to 0b11, to avoid Ni_RX_FQ_RD_ADD_PT0 register to be equal to the Ni_RX_FQ_START_ADDR0 registers. Excepted for the initial value, the address value must always be word aligned (32bit), VAL[1:0] must be set to 0b00.

22.9.80 Node i TX filter control register 0

This register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register. The register is accessible in write access in privileged mode only. This register is protected by a register bank CRC defined in Ni_CRC_REG register.

Ni_TX_FILTER_CTRL0 (i=0-3) Offset address: $21600_H+i*2000_H$

Node i TX filter control register 0 Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MASK								COMB							
rw								rw							

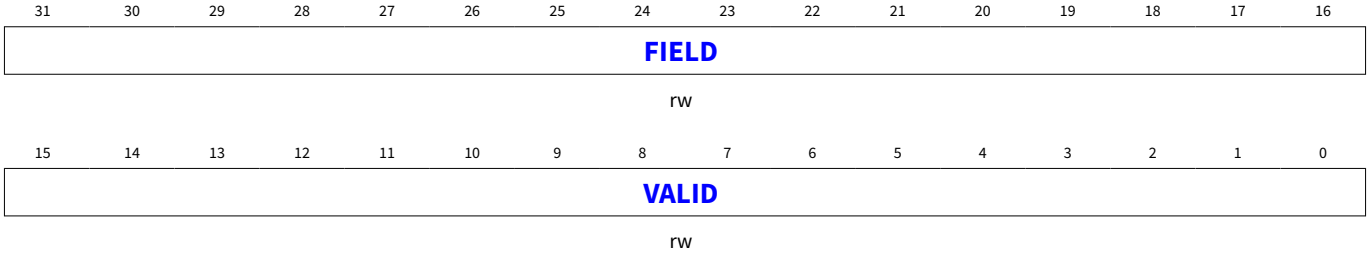
Field	Bits	Type	Description
COMB	7:0	rw	**COMB** When COMB[n] =1 the comparison attached to the reference values (REF_VAL0 and REF_VAL1) or (REF_VAL2 and REF_VAL3) are required to accept a TX message. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register
MASK	15:8	rw	**MASK** When MASK[n] =1 the reference values REF_VAL0/1 or REF_VAL2/3 are combined to define a value (REF_VAL0 or REF_VAL2) and a mask (REF_VAL1 or REF_VAL3). Otherwise, the comparison uses the REF_VAL0/1/2/3 bit field as reference value only. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register
MODE	16	rw	**MODE** When set to 1 accept on match, otherwise reject on match. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register
CAN_FD	17	rw	**CAN FD** When set to 1 reject CAN-FD messages, otherwise accept them. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register
CC_CAN	18	rw	**CC CAN** When set to 1 reject Classic CAN messages, otherwise accept them. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register
EN	19	rw	**EN** When set to 1, enable the TX filter for all TX message to be sent. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register
IRQ_EN	20	rw	**IRQ EN** When set to 1, enable the interrupt tx_filter_irq to be triggered. The interrupt is triggered when a message is rejected. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register
0	31:21	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.81 Node i TX filter control register 1

This register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register. The register is accessible in write access in privileged mode only. This register is protected by a register bank CRC defined in Ni_CRC_REG register.

Ni_TX_FILTER_CTRL1 (i=0-3) Offset address: $21604_H+i*2000_H$

Node i TX filter control register 1 Kernel Reset value: $0000\ 0000_H$



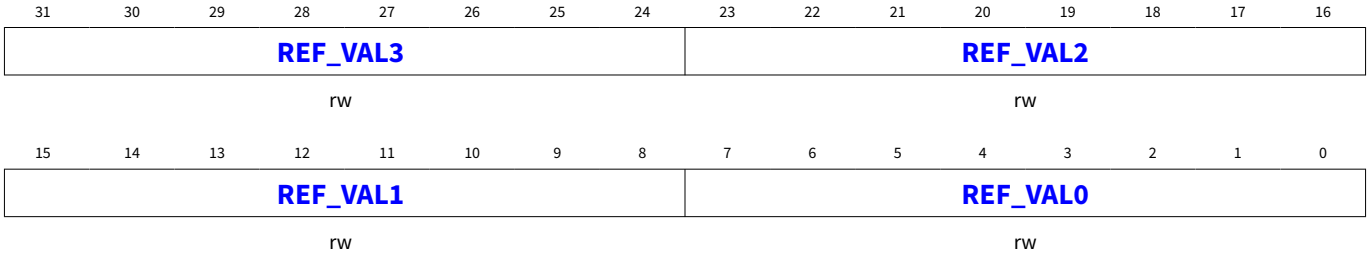
Field	Bits	Type	Description
VALID	15:0	rw	**VALID** When VALID[n] = 1 the reference value defined for the TX filter n is valid. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register. The valid reference value used is defined as follow: VALID[n] is assigned to Ni_TX_FILTER_REFVAL0.REF_VAL{n} (n € {0, 1, 2, 3}) VALID[n+4] is assigned to Ni_TX_FILTER_REFVAL1.REF_VAL{n} (n € {0, 1, 2, 3}) VALID[n+8] is assigned to Ni_TX_FILTER_REFVAL2.REF_VAL{n} (n € {0, 1, 2, 3}) VALID[n+12] is assigned to Ni_TX_FILTER_REFVAL3.REF_VAL{n} (n € {0, 1, 2, 3})
FIELD	31:16	rw	**FIELD** When FIELD[n] = 1 the TX filter element n is considering SDT, otherwise VCID, to compare with the reference value defined in Ni_TX_FILTER_REFVAL0/1/2/3. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register. The reference value to be set is defined as follow: FIELD[n] is assigned to Ni_TX_FILTER_REFVAL0.REF_VAL{n} (n € {0, 1, 2, 3}) FIELD[n+4] is assigned to Ni_TX_FILTER_REFVAL1.REF_VAL{n} (n € {0, 1, 2, 3}) FIELD[n+8] is assigned to Ni_TX_FILTER_REFVAL2.REF_VAL{n} (n € {0, 1, 2, 3}) FIELD[n+12] is assigned to Ni_TX_FILTER_REFVAL3.REF_VAL{n} (n € {0, 1, 2, 3})

22.9.82 Node i TX filter reference value register t

This register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register. The register is accessible in write access in privileged mode only. This register is protected by a register bank CRC defined in Ni_CRC_REG register.

Ni_TX_FILTER_REFVALt (i=0-3;t=0-3) Offset address: $21608_H+i*2000_H+t*4$

Node i TX filter reference value register t Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
REF_VAL0	7:0	rw	**REF VAL0** Define the reference value 0. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register
REF_VAL1	15:8	rw	**REF VAL1** Define the reference value 1. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register
REF_VAL2	23:16	rw	**REF VAL2** Define the reference value 2. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register
REF_VAL3	31:24	rw	**REF VAL3** Define the reference value 3. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register

22.9.83 Node i RX filter control register

This register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register. The register is accessible in write access in privileged mode only. This register is protected by a register bank CRC defined in Ni_CRC_REG register.

Ni_RX_FILTER_CTRL (i=0-3) Offset address: $21680_H+i*2000_H$

Node i RX filter control register Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0			THRESHOLD					NB_FE							
r			rw					rw							

Field	Bits	Type	Description
NB_FE	7:0	rw	**NB FE** Define the number of RX filter elements that are defined in the local memory. When set to 0, all RX messages are accepted and stored in the RX FIFO Queue number defined by ANMF_FQ[3:0]. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register

(table continues...)

(continued)

Field	Bits	Type	Description
THRESHOLD	12:8	rw	**THRESHOLD** THRESHOLD defines the latest point in time to wait for the result of the RX filtering process., Once this limit is reached, the MH starts fetching an RX descriptor from S_MEM. THRESHOLD value is only used when greater than 0 and ANFF bit set to 1. See chapter "RX Filter" for an explanation how to configure THRESHOLD. When the RX filtering is not providing the result before the threshold of the RX DMA FIFO is reached, the RX message is sent to the default RX FIFO Queue mentioned in the ANMF_FQ[2:0] (only enabled when ANFF set to 1). When the level is over the threshold and the RX filtering result is already known, no action is taken. Threshold is given in number of word of 32bit. This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register
ANMF_FQ	18:16	rw	**ANMF FQ** Define the default RX FIFO Queue number (from 0 to 7) when non matching frames are accepted (ANMF = 1) AND/OR when the threshold mechanism is active (ANFF = 1). This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register
ANMF	20	rw	**ANMF** When set to 1, non matching frames are accepted, otherwise rejected. It is mandatory to have the default RX FIFO Queue defined in the ANMF_FQ[2:0] bit field, enabled and started (see Ni_RX_FQ_CTRL2 and Ni_RX_FQ_CTRL0 registers). This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register
ANFF	21	rw	**ANFF** When set to 1, frames not filtered in time and over the DMA RX FIFO level defined in THRESHOLD[4:0], are routed to the default RX FIFO Queue (defined by the ANMF_FQ[2:0] bit field). It is mandatory to have the default RX FIFO Queue defined in the ANMF_FQ[2:0] bit field, enabled and started (see Ni_RX_FQ_CTRL2 and Ni_RX_FQ_CTRL0 registers). This bit field register is only accessible in write mode if the MH is not busy, see BUSY flag in Ni_MH_STS register
0	15:13, 19, 31:22	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.84 Node i TX FIFO queue interrupt status register

Ni_TX_FQ_INT_STS (i=0-3) Offset address: $21700_H+i*2000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0								RECEIVED							
r								rw1ch							

Field	Bits	Type	Description
RECEIVED	7:0	rw1ch	**RECEIVED** When RECEIVED[n] = 1, an RX message was received in the RX FIFO Queue n, writing a 1 clears the bit.
UNVALID	23:16	rwh	**UNVALID** When RX FIFO Queue n loads an RX descriptor with VALID=0, the bit UNVALID[n] will be set. Writing 1 to UNVALID[n] clears the bit.
0	15:8, 31:24	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.86 Node i TX priority queue interrupt status register 0

Ni_TX_PQ_INT_STS0 (i=0-3) Offset address: $21708_H+i*2000_H$

Node i TX priority queue interrupt status register 0 Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SENT															
rw1ch															

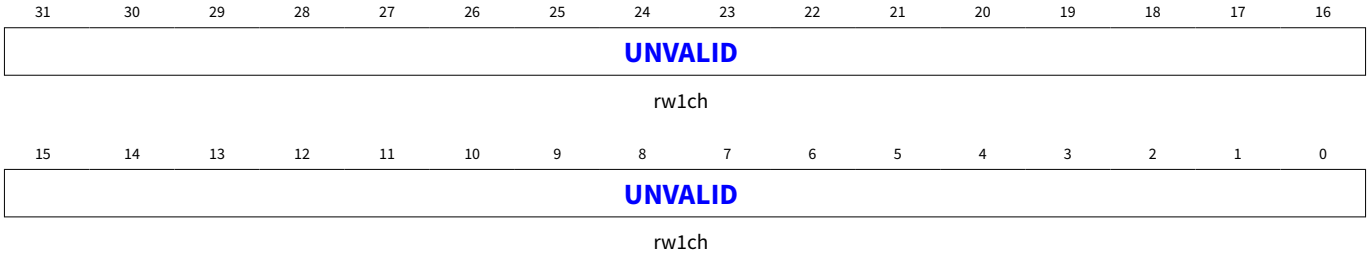
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SENT															
rw1ch															

Field	Bits	Type	Description
SENT	31:0	rw1ch	**SENT** When SENT[n] = 1 TX message was sent from the TX Priority Queue slot n, writing a 1 clears the bit.

22.9.87 Node i TX priority queue interrupt status register 1

Ni_TX_PQ_INT_STS1 (i=0-3) Offset address: $2170C_H+i*2000_H$

Node i TX priority queue interrupt status register Kernel Reset value: $0000\ 0000_H$

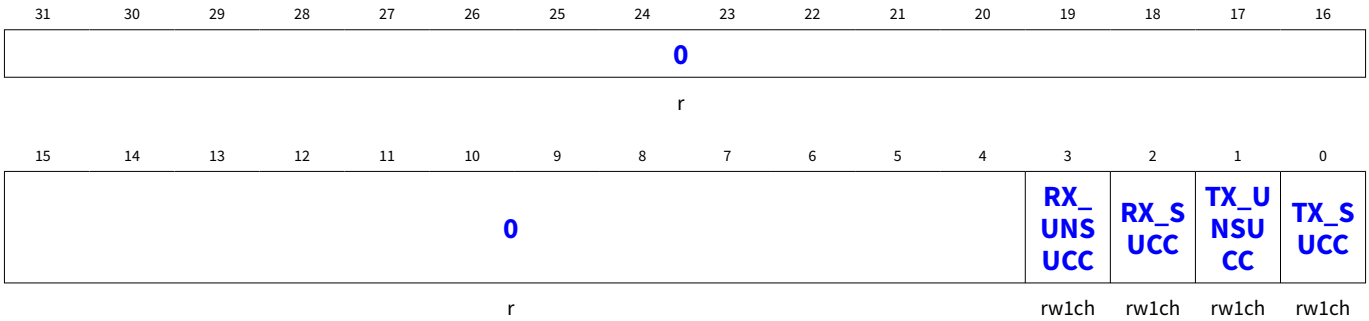


Field	Bits	Type	Description
UNVALID	31:0	rw1ch	**UNVALID** When UNVALID[n] = 1, an invalid RX descriptor is detected while running the TX Priority Queue slot n. Writing a 1 clears the bit. When set to 1, the TX Priority Queue slot n is on hold, waiting for the SW to react. As the TX message is fully defined in system memory before starting the relevant slot, there should not be any invalid TX descriptor interrupts

22.9.88 Node i statistics interrupt status register

Ni_STATS_INT_STS (i=0-3) Offset address: $21710_H+i*2000_H$

Node i statistics interrupt status register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TX_SUCC	0	rw1ch	**TX SUCC** Counter of TX message transmitted successfully has wrapped, writing a 1 clears the bit.

(table continues...)

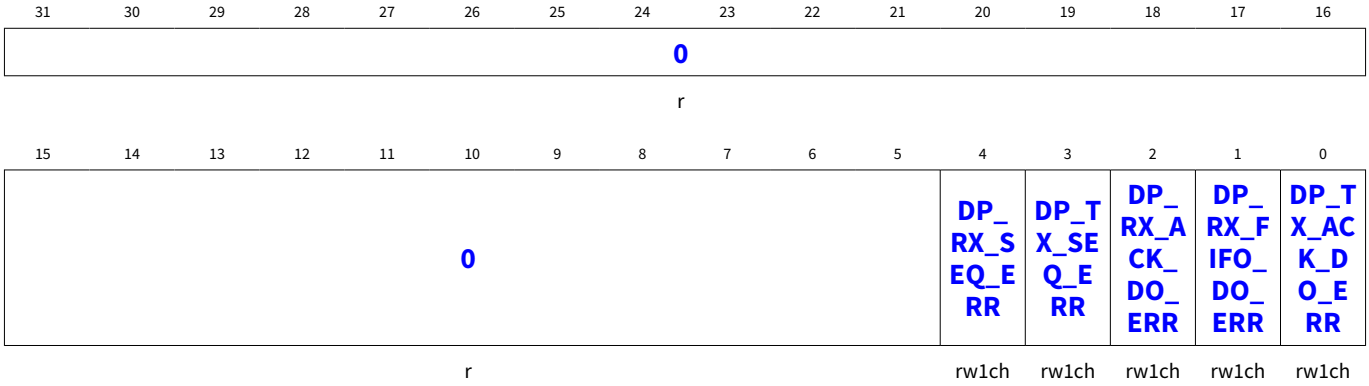
(continued)

Field	Bits	Type	Description
TX_UNSUCC	1	rw1ch	**TX UNSUCC** Counter of TX message transmitted unsuccessfully has wrapped, writing a 1 clears the bit.
RX_SUCC	2	rw1ch	**RX SUCC** Counter of RX message received successfully has wrapped, writing a 1 clears the bit.
RX_UNSUCC	3	rw1ch	**RX UNSUCC** Counter of RX message received unsuccessfully has wrapped, writing a 1 clears the bit.
0	31:4	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.89 Node i error interrupt status register

Ni_ERR_INT_STS (i=0-3) Offset address: $21714_H+i*2000_H$

Node i error interrupt status register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DP_TX_ACK_DO_ERR	0	rw1ch	**DP TX ACK DO ERR** When set to 1, a TX acknowledge data overflow is detected, writing a 1 clears the bit.
DP_RX_FIFO_DO_ERR	1	rw1ch	**DP RX FIFO DO ERR** When set to 1, an RX DMA FIFO overflow issue is detected, writing a 1 clears the bit.
DP_RX_ACK_DO_ERR	2	rw1ch	**DP RX ACK DO ERR** When set to 1, an RX acknowledge data overflow is detected, writing a 1 clears the bit.
DP_TX_SEQ_ERR	3	rw1ch	**DP TX SEQ ERR** When set to 1, a TX sequence issue is detected, writing a 1 clears the bit.
DP_RX_SEQ_ERR	4	rw1ch	**DP RX SEQ ERR** When set to 1, an RX sequence issue is detected, writing a 1 clears the bit.

(table continues...)

(continued)

Field	Bits	Type	Description
0	31:5	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.90 Node i safety interrupt status register

Ni_SFTY_INT_STS (i=0-3) Offset address: $21718_H+i*2000_H$

Node i safety interrupt status register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
DMA_AXI_WR_TO_ERR	0	rw1ch	**DMA AXI WR TO ERR** When set to 1, an AXI write access timeout issue is detected on DMA interface, writing a 1 clears the bit.
DMA_AXI_RD_TO_ERR	1	rw1ch	**DMA AXI RD TO ERR** When set to 1, an AXI read access timeout issue is detected on DMA interface, writing a 1 clears the bit.
DP_PRT_TX_TO_ERR	2	rw1ch	**DP PRT TX TO ERR** When set to 1, a TX_MSG timeout issue is detected, writing a 1 clears the bit.
DP_PRT_RX_TO_ERR	3	rw1ch	**DP PRT RX TO ERR** When set to 1, an RX_MSG timeout issue is detected, writing a 1 clears the bit.
MEM_AXI_WR_TO_ERR	4	rw1ch	**MEM AXI WR TO ERR** When set to 1, an AXI write access timeout issue is detected on local memory interface, writing a 1 clears the bit.
MEM_AXI_RD_TO_ERR	5	rw1ch	**MEM AXI RD TO ERR** When set to 1, an AXI read access timeout issue is detected on local memory interface, writing a 1 clears the bit.

(table continues...)

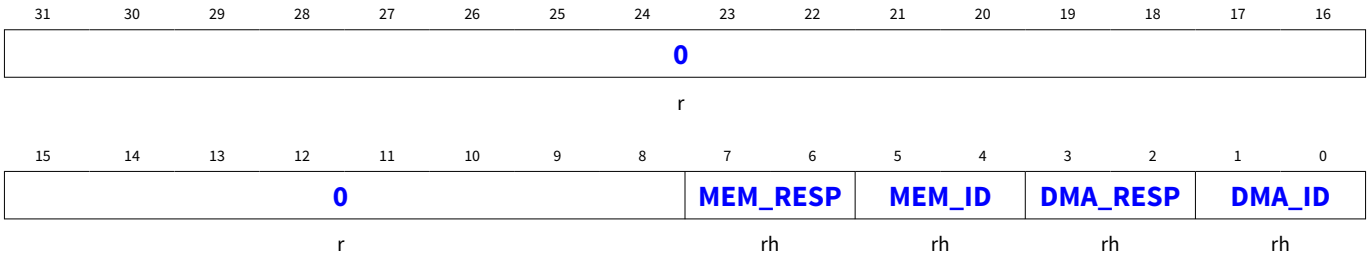
(continued)

Field	Bits	Type	Description
DP_TX_PARITY_ERR	6	rw1ch	**DP TX PARITY ERR** When set to 1, a TX data parity error is detected on datapath, writing a 1 clears the bit.
DP_RX_PARITY_ERR	7	rw1ch	**DP RX PARITY ERR** When set to 1, an RX data parity error is detected on datapath, writing a 1 clears the bit.
AP_TX_PARITY_ERR	8	rw1ch	**AP TX PARITY ERR** When set to 1, a TX address pointer parity issue is detected, writing a 1 clears the bit.
AP_RX_PARITY_ERR	9	rw1ch	**AP RX PARITY ERR** When set to 1, an RX address pointer parity issue is detected, writing a 1 clears the bit.
TX_DESC_REQ_ERR	10	rw1ch	**TX DESC REQ ERR** When set to 1, a TX descriptor fetched does not match the one expected, writing a 1 clears the bit.
TX_DESC_CRC_ERR	11	rw1ch	**TX DESC CRC ERR** When set to 1, a TX descriptor has a wrong CRC, writing a 1 clears the bit.
RX_DESC_REQ_ERR	12	rw1ch	**RX DESC REQ ERR** When set to 1, an RX descriptor fetched does not match the one expected, writing a 1 clears the bit.
RX_DESC_CRC_ERR	13	rw1ch	**RX DESC CRC ERR** When set to 1, an RX descriptor has a wrong CRC, writing a 1 clears the bit.
MEM_SFTY_UE	14	rw1ch	**MEM SFTY UE** When set to 1, an uncorrectable error is detected on the local memory interface, writing a 1 clears the bit.
MEM_SFTY_CE	15	rw1ch	**MEM SFTY CE** When set to 1, a correctable error is detected on the local memory interface, writing a 1 clears the bit.
ACK_TX_PARITY_ERR	16	rw1ch	**ACK TX PARITY ERR** When set to 1, an acknowledge data parity issue is detected on the TX path, writing a 1 clears the bit.
ACK_RX_PARITY_ERR	17	rw1ch	**ACK RX PARITY ERR** When set to 1, an acknowledge data parity issue is detected on the RX path, writing a 1 clears the bit.
0	31:18	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.91 Node i DMA error information

Ni_AXI_ERR_INFO (i=0-3) Offset address: $2171C_H+i*2000_H$

Node i DMA error information Kernel Reset value: $0000\ 0000_H$



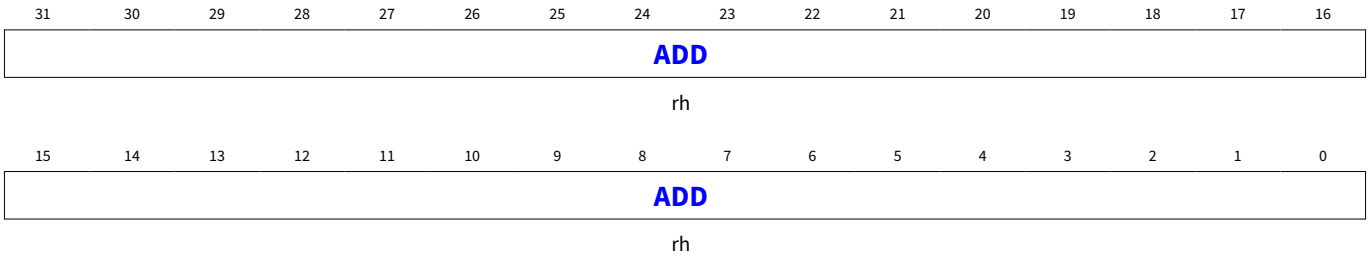
Field	Bits	Type	Description
DMA_ID	1:0	rh	**DMA ID** On DMA_AXI interface. Define the AXI ID used when a write or read error response is detected. According to the value, the DMA channel can be identified and so it is possible to define what's the effect of such issue.
DMA_RESP	3:2	rh	**DMA RESP** On DMA_AXI interface. When set to 0b10, the AXI response is SLVERR. When set to 0b11, the response is DECERR. By default, set to 0b00 (OKAY)
MEM_ID	5:4	rh	**MEM ID** On MEM_AXI interface. Define the AXI ID used when a write or read error response is detected. According to the value, the DMA channel can be identified and so it is possible to define what's the effect of such issue.
MEM_RESP	7:6	rh	**MEM RESP** On MEM_AXI interface. When set to 0b10, the AXI response is SLVERR. When set to 0b11, the response is DECERR. By default, set to 0b00 (OKAY)
0	31:8	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.92 Node i descriptor error information 0

If the Ni_DESC_ERR_INFO0.ADD[31:16] = 0 and Ni_DESC_ERR_INFO1.CRC[8:0], Ni_DESC_ERR_INFO1.RX_TX and Ni_DESC_ERR_INFO1.RC[4:0] are all equal to 0, the faulty descriptor is a TX descriptor fetched from L_MEM.

Ni_DESC_ERR_INFO0 (i=0-3) Offset address: $21720_H+i*2000_H$

Node i descriptor error information 0 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ADD	31:0	rh	**ADD** Descriptor address being used when the error is detected.

22.9.93 Node i descriptor error information 1

When the Ni_DESC_ERR_INFO1.CRC[8:0], Ni_DESC_ERR_INFO1.RX_TX and Ni_DESC_ERR_INFO1.RC[4:0] are all equal to 0, the faulty descriptor is a TX descriptor fetched from L_MEM only if the Ni_DESC_ERR_INFO0.ADD[31:16] = 0.

Ni_DESC_ERR_INFO1 (i=0-3) Offset address: $21724_H+i*2000_H$

Node i descriptor error information 1 Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

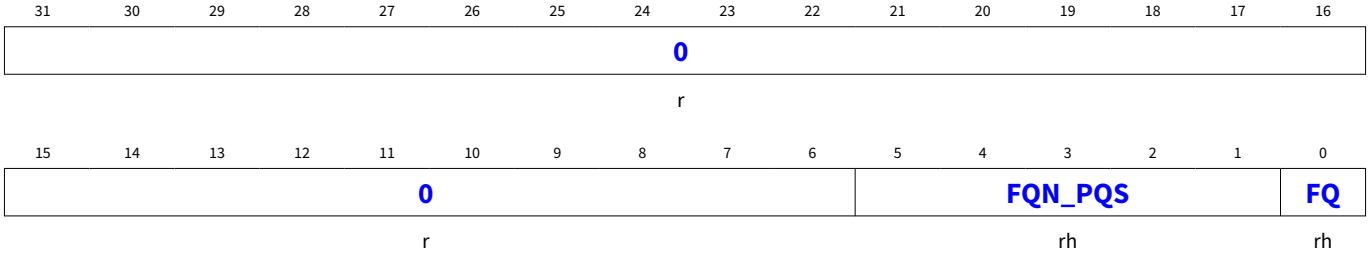
RX_TX	0	RC					PQ	IN			FQN_PQSN				
rh	r	rh					rh	rh			rh				

Field	Bits	Type	Description
FQN_PQSN	4:0	rh	**FQN PQSN** Provide the information regarding the RX/TX FIFO Queue number or the TX Priority Queue slot having an issue.
IN	7:5	rh	**IN** Provide the instance number defined in RX or TX descriptor logged in.
PQ	8	rh	**PQ** Identify which TX queue is impacted, either the TX Priority Queue (PQ set to 1) or the TX FIFO Queues.
RC	13:9	rh	**RC** Provide the information regarding the Rolling Counter defined in RX or TX descriptor impacted.
RX_TX	15	rh	**RX TX** RX descriptor has an issue (RX_TX set to 1), otherwise the same for a TX descriptor.
CRC	24:16	rh	**CRC** CRC value defined in the RX or TX descriptor logged in.
0	14, 31:25	r	**Reserved** Read as 0; should be written with 0.

22.9.94 Node i TX filter error information

Ni_TX_FILTER_ERR_INFO (i=0-3) Offset address: $21728_H+i*2000_H$

Node i TX filter error information Kernel Reset value: $0000\ 0000_H$



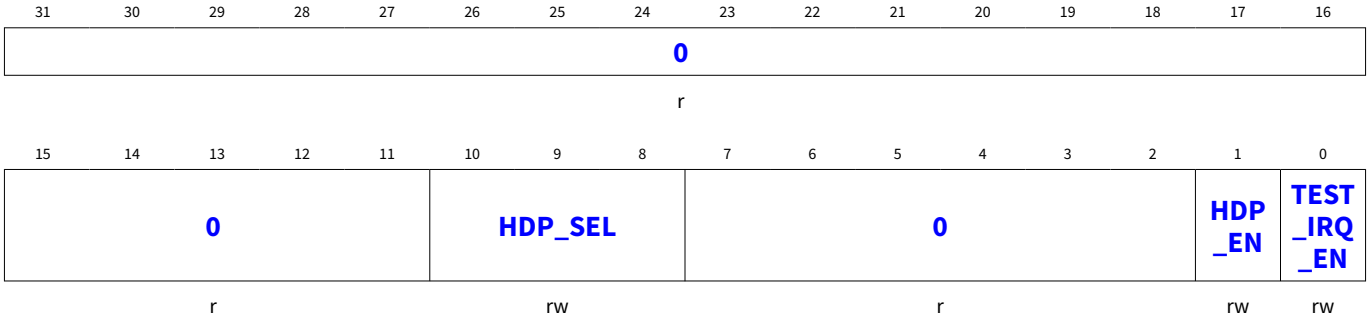
Field	Bits	Type	Description
FQ	0	rh	**FQ** When set to 1, one of the TX FIFO Queues has triggered the TX_FILTER_ERR interrupt, otherwise it is a TX Priority Queue slot.
FQN_PQS	5:1	rh	**FQN PQS** Provide the information of the TX FIFO Queue number or TX Priority Queue slot number which has triggered the TX_FILTER_ERR interrupt.
0	31:6	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.95 Node i debug control register

This register is only accessible in write mode if the Test Mode Key sequence has been performed prior to write. The register is accessible in write access in privileged mode only. This register is protected by a register bank CRC defined in Ni_CRC_REG register.

Ni_DEBUG_TEST_CTRL (i=0-3) Offset address: $21800_H+i*2000_H$

Node i debug control register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TEST_IRQ_EN	0	rw	**TEST IRQ EN** When writing 1, enable the control of the interrupt lines using the Ni_INT_TEST0 and Ni_INT_TEST1 registers. This bit field register is only accessible in write mode if the Test Mode Key sequence has been performed prior to write.
HDP_EN	1	rw	**HDP EN** When writing 1, enable the hardware debug port to monitor MH internal signals. This bit field register is only accessible in write mode if the Test Mode Key sequence has been performed prior to write.

(table continues...)

(continued)

Field	Bits	Type	Description
HDP_SEL	10:8	rw	**HDP SEL** Define the set of signals to be monitored on the HDP[15:0] bus signal interface. This bit field register is only accessible in write mode if the Test Mode Key sequence has been performed prior to write.
0	7:2, 31:11	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.96 Node i interrupt test register 0

This register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set.

Ni_INT_TEST0 (i=0-3) Offset address: $21804_H+i*2000_H$

Node i interrupt test register 0 Kernel Reset value: $0000\ 0000_H$

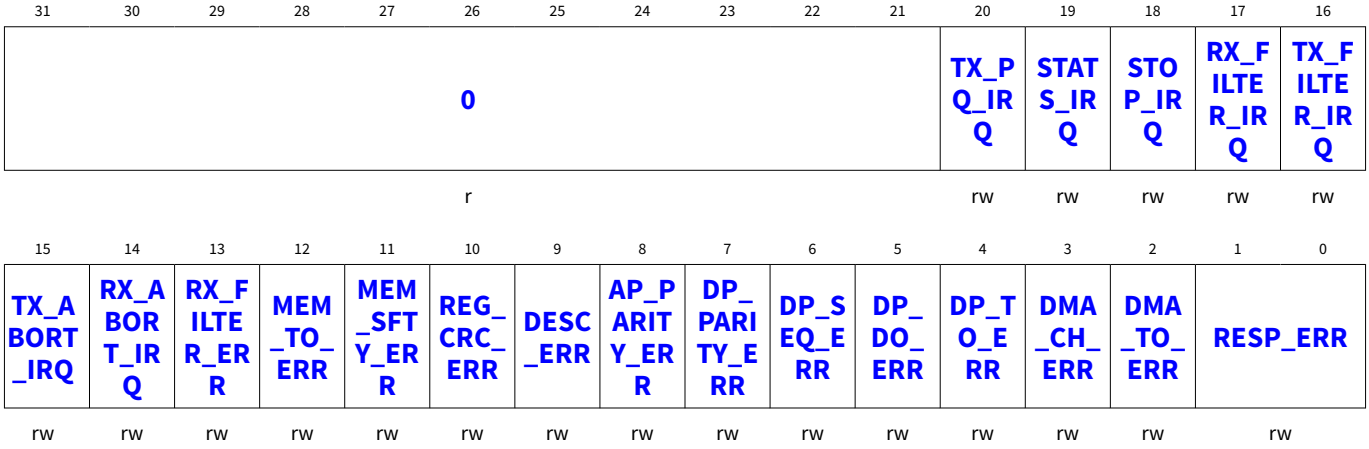
Field	Bits	Type	Description
TX_FQ_IRQ	7:0	rw	**TX FQ IRQ** When writing 1 to TX_FQ_IRQ[n], triggers the interrupt line tx_fq_irq[n], those bits are auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
RX_FQ_IRQ	23:16	rw	**RX FQ IRQ** When writing 1 to RX_FQ_IRQ[n], triggers the interrupt line rx_fq_irq[n], those bits are auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
0	15:8, 31:24	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.97 Node i interrupt test register 1

This register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set.

Ni_INT_TEST1 (i=0-3) Offset address: $21808_H+i*2000_H$

Node i interrupt test register 1 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RESP_ERR	1:0	rw	**RESP ERR** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
DMA_TO_ERR	2	rw	**DMA TO ERR** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
DMA_CH_ERR	3	rw	**DMA CH ERR** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
DP_TO_ERR	4	rw	**DP TO ERR** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
DP_DO_ERR	5	rw	**DP DO ERR** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
DP_SEQ_ERR	6	rw	**DP SEQ ERR** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
DP_PARITY_ERR	7	rw	**DP PARITY ERR** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
AP_PARITY_ERR	8	rw	**AP PARITY ERR** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set

(table continues...)

(continued)

Field	Bits	Type	Description
DESC_ERR	9	rw	**DESC ERR** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
REG_CRC_ERR	10	rw	**REG CRC ERR** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
MEM_SFTY_ERR	11	rw	**MEM SFTY ERR** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
MEM_TO_ERR	12	rw	**MEM TO ERR** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
RX_FILTER_ERR	13	rw	**RX FILTER ERR** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
RX_ABORT_IRQ	14	rw	**RX ABORT IRQ** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
TX_ABORT_IRQ	15	rw	**TX ABORT IRQ** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
TX_FILTER_IRQ	16	rw	**TX FILTER IRQ** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
RX_FILTER_IRQ	17	rw	**RX FILTER IRQ** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
STOP_IRQ	18	rw	**STOP IRQ** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
STATS_IRQ	19	rw	**STATS IRQ** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set

(table continues...)

(continued)

Field	Bits	Type	Description
TX_PQ_IRQ	20	rw	**TX PQ IRQ** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared. This bit field register is only accessible in write mode if the TEST_IRQ_EN bit in Ni_DEBUG_TEST_CTRL is set
0	31:21	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.98 Node i TX-SCAN first candidates register

This register gives the 4 best candidates evaluated by the TX-Scan. This register gives the first and second highest priority TX descriptor after a TX-Scan. It provides also the third and fourth candidates during a TX-Scan, considering the first and second candidates as already defined by a previous TX-Scan run.

Ni_TX_SCAN_FC (i=0-3) Offset address: $21810_H+i*2000_H$

Node i TX-SCAN first candidates register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0		FQN_PQSN1					FQ_PQ1	0		FQN_PQSN0					FQ_PQ0
r		rh					rh	r		rh					rh

Field	Bits	Type	Description
FQ_PQ0	0	rh	**FQ PQ0** The first candidate evaluated by TX-Scan is either a TX Priority Queue (when set to 1) or a TX FIFO Queue (when set to 0). This bit field is identical to Ni_TX_SCAN_BC.FH_PQ bit register
FQN_PQSN0	5:1	rh	**FQN PQSN0** The first candidate is coming from either the TX FIFO Queue number N (defined by FQN in TX descriptor) or the TX Priority Queue Slot number M (defined by the PQSN in TX descriptor). The meaning of this bit field depends on the PQ0. This bit field is identical to Ni_TX_SCAN_BC.FH_FQN_PQSN bit register
FQ_PQ1	8	rh	**FQ PQ1** The second candidate evaluated by TX-Scan is either a TX Priority Queue (when set to 1) or a TX FIFO Queue (when set to 0). This bit field is identical to Ni_TX_SCAN_BC.SH_PQ bit register
FQN_PQSN1	13:9	rh	**FQN PQSN1** The second candidate is coming from either the TX FIFO Queue number N (defined by FQN in TX descriptor) or the TX Priority Queue Slot number M (defined by the PQSN in TX descriptor). The meaning of this bit field depends on the PQ0. This bit field is identical to the Ni_TX_SCAN_BC.SH_FQN_PQSN bit register

(table continues...)

(continued)

Field	Bits	Type	Description
FQ_PQ2	16	rh	**FQ PQ2** The third candidate evaluated by TX-Scan is either a TX Priority Queue (when set to 1) or a TX FIFO Queue (when set to 0).
FQN_PQSN2	21:17	rh	**FQN PQSN2** The third candidate is coming from either the TX FIFO Queue number N (defined by FQN in TX descriptor) or the TX Priority Queue Slot number M (defined by the PQSN in TX descriptor). The meaning of this bit field depends on the PQ2.
FQ_PQ3	24	rh	**FQ PQ3** The fourth candidate evaluated by TX-Scan is either a TX Priority Queue (when set to 1) or a TX FIFO Queue (when set to 0).
FQN_PQSN3	29:25	rh	**FQN PQSN3** The fourth candidate is coming from either the TX FIFO Queue number N (defined by FQN in TX descriptor) or the TX Priority Queue Slot number M (defined by the PQSN in TX descriptor). The meaning of this bit field depends on the PQ3.
0	7:6, 15:14, 23:22, 31:30	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.99 Node i TX-SCAN best candidates register

This register gives the first and second highest priority TX descriptor after a TX-Scan.

Ni_TX_SCAN_BC (i=0-3) Offset address: $21814_H+i*2000_H$

Node i TX-SCAN best candidates register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SH_OFFSET										SH_FQN_PQSN					SH_PQ
rh										rh					rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FH_OFFSET										FH_FQN_PQSN					FH_PQ
rh										rh					rh

Field	Bits	Type	Description
FH_PQ	0	rh	**FH PQ** First highest priority candidate evaluated by TX-Scan. It is either a TX Priority Queue (when set to 1) or a TX FIFO Queue (when set to 0).

(table continues...)

(continued)

Field	Bits	Type	Description
FH_FQN_PQSN	5:1	rh	**FH FQN PQSN** First highest priority candidate coming from either the TX FIFO Queue number N (defined by FQN in TX descriptor) or the TX Priority Queue Slot number M (defined by the PQSN in TX descriptor). The meaning of this bit field depends on the FH_PQ.
FH_OFFSET	15:6	rh	**FH OFFSET** First highest priority candidate offset in multiple of 32bytes (TX descriptor size). This register is relevant only for the TX FIFO Queue. It provides the index of the TX descriptor in the TX FIFO Queue which is in use on the CAN bus. When FH_PQ = 1 it is set to 0.
SH_PQ	16	rh	**SH PQ** Second highest priority candidate evaluated by TX-Scan. It is either a TX Priority Queue (when set to 1) or a TX FIFO Queue (when set to 0).
SH_FQN_PQSN	21:17	rh	**SH FQN PQSN** Second highest priority candidate coming from either the TX FIFO Queue number N (defined by FQN in TX descriptor) or the TX Priority Queue Slot number M (defined by the PQSN in TX descriptor). The meaning of this bit field depends on the SH_PQ.
SH_OFFSET	31:22	rh	**SH OFFSET** Second highest priority candidate offset in multiple of 32bytes (TX descriptor size). This register is relevant only for the TX FIFO Queue. It provides the index of the TX descriptor in the TX FIFO Queue which is about to be sent on the CAN bus. When SH_PQ = 1 it is set to 0.

22.9.100 Node i valid TX FIFO queue descriptors in local memory

Ni_TX_FQ_DESC_VALID (i=0-3) Offset address: $21818_H+i*2000_H$

Node i valid TX FIFO queue descriptors in local memory Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r								rh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0								DESC_CN_VALID							
r								rh							

Field	Bits	Type	Description
DESC_CN_VALID	7:0	rh	**DESC CN VALID** When DESC_CN_VALID[n] = 1, the current/next TX descriptor for the TX FIFO Queue n is available in L_MEM.
DESC_NC_VALID	23:16	rh	**DESC NC VALID** When DESC_NC_VALID[n] = 1, the next/current TX descriptor for the TX FIFO Queue is available in L_MEM.

(table continues...)

(continued)

Field	Bits	Type	Description
0	15:8, 31:24	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.101 Node i valid TX priority queue descriptors in local memory

Ni_TX_PQ_DESC_VALID (i=0-3)

Offset address: $2181C_H+i*2000_H$

Node i valid TX priority queue descriptors in local memory

Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DESC_VALID															
rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DESC_VALID															
rh															

Field	Bits	Type	Description
DESC_VALID	31:0	rh	**DESC VALID** When DESC_VALID[n] = 1, the TX descriptor assigned to the slot n in local memory is valid.

22.9.102 Node i CRC control register

Ni_CRC_CTRL (i=0-3)

Offset address: $21880_H+i*2000_H$

Node i CRC control register

Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															START
r															w

Field	Bits	Type	Description
START	0	w	**START** Writing a 1 to this bit triggers the HW CRC check of registers. This action can be done any time for a sanity check
0	31:1	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.103 Node i CRC register

Ni_CRC_REG (i=0-3) Offset address: $21884_H+i*2000_H$

Node i CRC register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VAL															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VAL															
rw															

Field	Bits	Type	Description
VAL	31:0	rw	**VAL** CRC value of all the registers protected by CRC. Once done, a write to the START bit in the Ni_CRC_CTRL register must be done

22.9.104 Node i endianness test register

Ni_ENDN (i=0-3) Offset address: $21900_H+i*2000_H$

Node i endianness test register Kernel Reset value: $8765\ 4321_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ETV															
r															

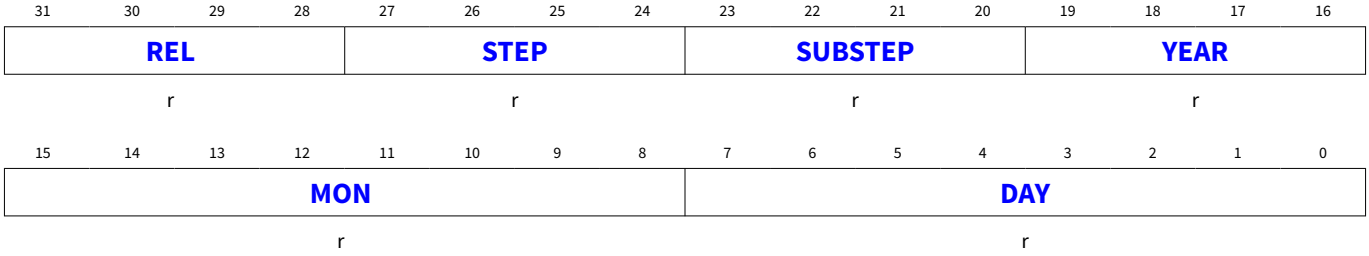
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETV															
r															

Field	Bits	Type	Description
ETV	31:0	r	**ETV** The purpose of this register is to identify the beginning of the PRT address map in a memory dump and to check the proper endianness data byte mapping when the data word is routed through different busses.

22.9.105 Node i PRT release identification register

Ni_PREL (i=0-3) Offset address: $21904_H+i*2000_H$

Node i PRT release identification register Kernel Reset value: $0540\ 0000_H$

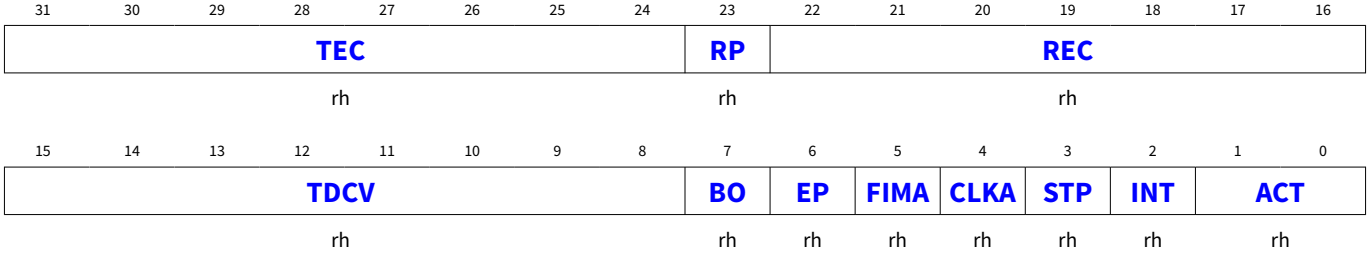


Field	Bits	Type	Description
DAY	7:0	r	**DAY** Define the day of the release using a binary coded decimal representation (1 being the first day of the month and so forth). This reset value is defined by the generic parameter DESIGN_TIME_STAMP_G[7:0]. If the generic parameter DESIGN_TIME_STAMP_G is not set, the default value is the one defined here
MON	15:8	r	**MON** Define the month of the release using a binary coded decimal representation (1 being January and so forth). This reset value is defined by the generic parameter DESIGN_TIME_STAMP_G[15:8]. If the generic parameter DESIGN_TIME_STAMP_G is not set, the default value is the one defined here
YEAR	19:16	r	**YEAR** Define the year of the release using a binary coded decimal representation (0 being 2020 and so forth…). This reset value is defined by the generic parameter DESIGN_TIME_STAMP_G[19:16]. If the generic parameter DESIGN_TIME_STAMP_G is not set, the default value is the one defined here
SUBSTEP	23:20	r	**SUBSTEP** Sub-Step value according to Step.
STEP	27:24	r	**STEP** Step value according to Release.
REL	31:28	r	**REL** Release value, used to identify the main release of the XCAN_PRT.

22.9.106 Node i PRT status register

Ni_STAT (i=0-3) Offset address: $21908_H+i*2000_H$

Node i PRT status register Kernel Reset value: $0000\ 0010_H$



Field	Bits	Type	Description
ACT	1:0	rh	**ACT** The current activity of this node: 0b00: inactive state 0b01: Idle 0b10: Receiver 0b11: Transmitter When the CAN protocol operation is stopped, ACT changes to 0b00 and INT changes to 0. When the CAN protocol operation is started, INT is set to 1, but ACT remains at 0b00 until the CAN protocol’s bus idle detection condition is met, then it changes to 0b01 and INT changes to 0. When the CAN protocol operation is started while BO is set, the PRT remains in integrating state (INT=1 and ACT=0b00) until the Bus-Off recovery sequence is finished, then it changes to 0b01 and INT changes to 0. When PRT detects a protocol exception event (see [1], chapter 10.9.5), ACT changes to 0b00 and INT changes to 1 until the CAN protocol’s bus idle detection condition is met, then ACT changes to 0b01 and INT changes to 0. ACT changes from 0b01 to 0b10 when the PRT has received a Start-of-Frame from the CAN bus. ACT changes from 0b01 to 0b11 when the PRT has sent a Start-of-Frame to the CAN bus. ACT changes from 0b11 to 0b10 when the PRT loses arbitration during a transmission. ACT changes from 0b10 to 0b01 or from 0b11 to 0b01when the PRT detects the second bit of intermission (see [1], chapter 10.4.6.2) to be recessive.
INT	2	rh	**INT** This node is integrating into CAN bus traffic.
STP	3	rh	**STP** Waiting for end of actual message after STOP command, see Starting and Stopping The Module chapter.
CLKA	4	rh	**CLKA** The actual value of the CLOCK_ACTIVE input signal, see Starting and Stopping the Module chapter. As the clock must be active when a reset is performed, the default value should be 1.
FIMA	5	rh	**FIMA** Fault Injection Module Activated, see Safety Measures chapter.
EP	6	rh	**EP** This node is in Error-Passive state. When both error counters drop below 127, or when the Bus-Off recovery sequence is finished, the EP bit is cleared.
BO	7	rh	**BO** This node is in Bus-Off state. This flag is set on an error condition that would have caused an increment of the Transmit Error Counter to a value beyond its 8 bit range. When the PRT enters Bus-Off state, BO is set to 1 and CAN protocol operation is stopped. When the Bus-Off recovery sequence is finished, BO is cleared.
TDCV	15:8	rh	**TDCV** Transmitter Delay Compensation’s delay value. A software reset clears the TDV bit field to 0x00. This register shows the sum of the measured delay plus the configured offset, giving the position of the secondary sample point. It is updated for each frame transmission that includes a data phase.

(table continues...)

(continued)

Field	Bits	Type	Description
REC	22:16	rh	**REC** The CAN protocol’s Receive Error Counter. A software reset does not change the value in this register. When the Bus-Off recovery sequence is finished, the error counter REC is cleared. The REC is a 7-bit-counter, together with the Error-Passive flag EP. When the increment REC+1 or REC+8 would result in a value > 127 (carry-flag), the REC is kept unchanged, but EP is set. When EP is set but REC is below 127 and further errors are detected with an REC+1 condition, the REC will be incremented until it reaches 127. At the reception of a valid message, the REC-1 decrements the actual value of the REC by one AND clears the Error-Passive flag EP.
RP	23	rh	**RP** The Passive flag of the CAN protocol’s Receive Error Counter. This flag is set on an error condition that would have caused an increment of the Receive Error Counter to a value beyond its 7 bit range.
TEC	31:24	rh	**TEC** The CAN protocol’s Transmit Error Counter. A software reset does not change the value in this register. When the Bus-Off recovery sequence is finished, the error counter TEC is cleared. When the increment TEC+8 would result in a value > 255 (carry-flag), the TEC is kept unchanged, but BO is set. The Transmit Error Counter is decremented by one each time a CAN message has been successfully transmitted, but it is not decremented below the value 0.

22.9.107 Node i event status flags register

The Ni_EVNT Register contains event status flags. The flags are set by the PRT when specific events occur. A software reset clears all flags. A host write access to this register, writing a 1 to a specific flag, clears that flag. When a host write access occurs concurrently with a set condition for a flag, the flag is set.

Ni_EVNT (i=0-3) Offset address: $21920_H+i*2000_H$

Node i event status flags register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r		rw1ch	rw1ch	rw1ch	rw1ch	rw1ch	rw1ch	rw1ch	rw1ch	rw1ch	rw1ch	rw1ch	rw1ch	rw1ch	rw1ch

Field	Bits	Type	Description
CRE	0	rw1ch	**CRE** CRC Error.

(table continues...)

(continued)

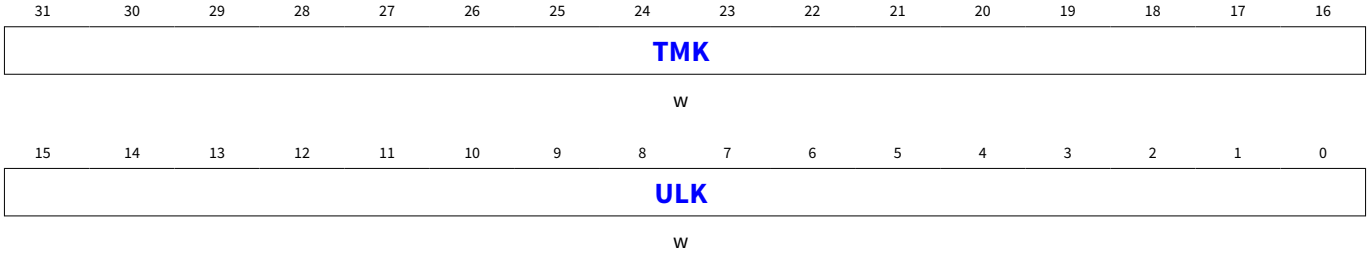
Field	Bits	Type	Description
B0E	1	rw1ch	**B0E** Bit0 Error: The PRT wanted to send a dominant bit (logical value 0), but the monitored CAN bus value was recessive. During Bus-Off recovery, B0E is also set each time a sequence of 11 recessive bits has been monitored, enabling the CPU to readily check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the Bus-Off recovery sequence.
B1E	2	rw1ch	**B1E** Bit1Error: During the transmission of a message (with the exception of the arbitration field), the PRT wanted to send a recessive bit (logical value 1), but the monitored CAN bus value was dominant.
AKE	3	rw1ch	**AKE** Acknowledge Error.
FRE	4	rw1ch	**FRE** Form Error or the condition of CAN error counting rule f).
STE	5	rw1ch	**STE** Stuff Error.
DO	6	rw1ch	**DO** Overflow condition in RX_MSG sequence detected.
RXF	7	rw1ch	**RXF** Frame received.
TXF	8	rw1ch	**TXF** Frame transmitted.
PXE	9	rw1ch	**PXE** Protocol Exception Event occurred.
DU	10	rw1ch	**DU** Underrun condition in TX_MSG sequence detected.
USO	11	rw1ch	**USO** Unexpected Start of Sequence during TX_MSG sequence detected.
IFR	12	rw1ch	**IFR** Invalid Frame Format requested in TX_MSG.
ABO	13	rw1ch	**ABO** TX_MSG sequence stopped by TX_MSG_WUSER code ABORT.
0	31:14	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.108 Node i unlock sequence register

Writing a sequence of specific data words enables the activation of control commands in the registers Ni_CTRL and Ni_FIMC.

Ni_LOCK (i=0-3) Offset address: $21940_H+i*2000_H$

Node i unlock sequence register Kernel Reset value: $0000\ 0000_H$



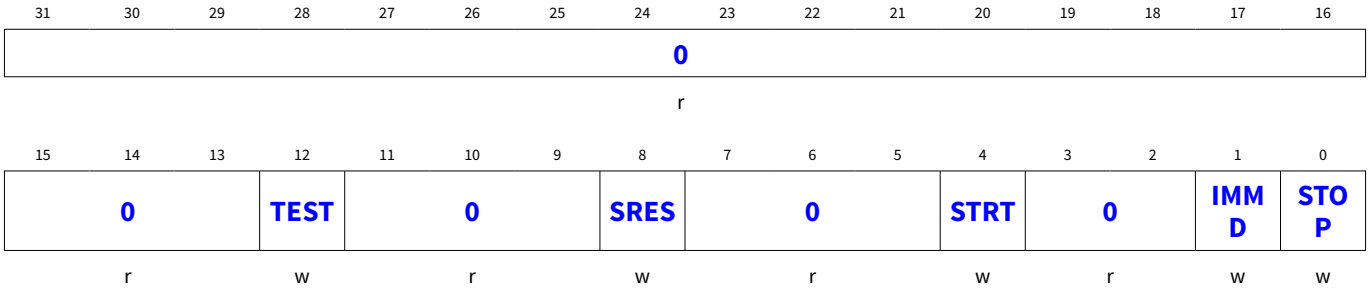
Field	Bits	Type	Description
ULK	15:0	w	**ULK** Unlock Key.
TMK	31:16	w	**TMK** Test Mode Key.

22.9.109 Node i control register

Writing to this register controls the CAN protocol operation. Reading this register gives the value 0x00000000. When writing to this register, only one of the four bits TEST, SRES , STRT, or STOP may be written to 1, otherwise the write access takes no effect. The bit IMMD may be written to 1 together with the bit STOP, but not together with one of the other bits.

Ni_CTRL (i=0-3) Offset address: $21944_H+i*2000_H$

Node i control register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STOP	0	w	**STOP** Stop CAN protocol operation. The Unlock Key must be used prior to write to this bit field. When not set together with bit IMMD the PRT waits for an ongoing CAN message to finish before stopping CAN protocol operation.
IMMD	1	w	**IMMD** Stop CAN protocol operation immediately. The Unlock Key must be used prior to write to this bit . This bit is only effective when being set together with the bit STOP.
STRT	4	w	**STRT** Start CAN protocol operation.

(table continues...)

(continued)

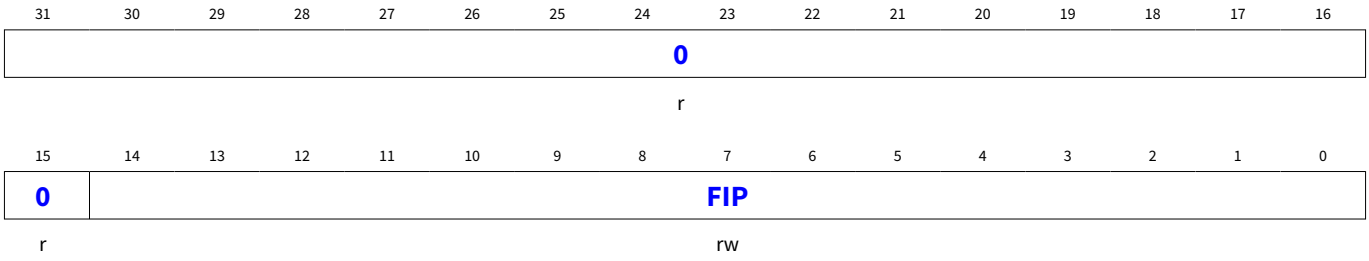
Field	Bits	Type	Description
SRES	8	w	**SRES** Software Reset. When the CAN protocol operation is stopped, the software reset of all state machines of the PRT (excluding the error-counters and the error-states) is triggered by writing 1 to Ni_CTRL.SRES. No unlocking sequence is required. A software reset will not be executed while the CAN protocol operation is started.
TEST	12	w	**TEST** Enable Test Mode. The Test Mode Key must be used prior to write to this bit field.
0	3:2, 7:5, 11:9, 31:13	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.110 Node i fault injection module control register

Writing the fault injection position number requires the application of the test mode key sequence before writing to Ni_FIMC. This register must be accessed in privileged mode when supported.

Ni_FIMC (i=0-3) Offset address: $21948_H+i*2000_H$

Node i fault injection module control register Kernel Reset value: $0000\ 0000_H$



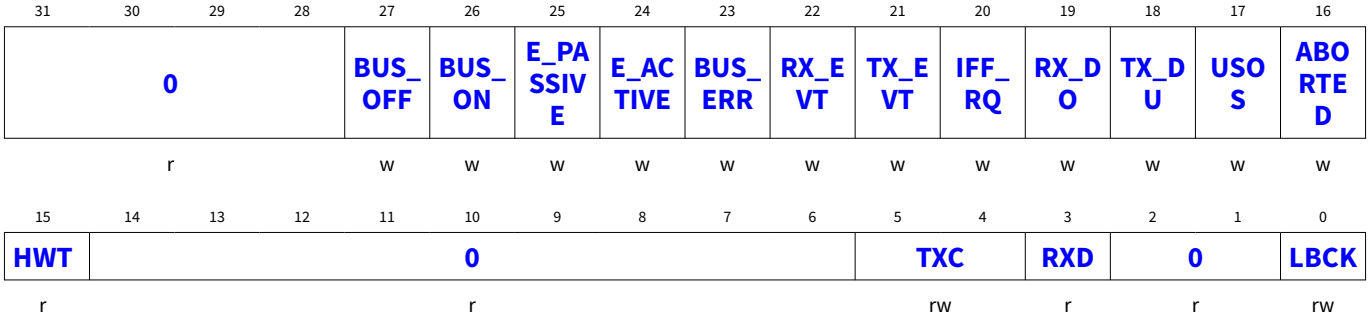
Field	Bits	Type	Description
FIP	14:0	rw	**FIP** Fault Injection Position. Writing to Ni_FIMC while Ni_MODE.FIME is set activates the Fault Injection Module FIM (see Safety Measures chapter). While the FIM is activated, the value of Ni_FIMC.FIP is protected from further write accesses until the FIM is de-activated again.
0	31:15	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.111 Node i hardware test functions register

This register is writable after the hardware test mode functions are enabled by writing the test mode key sequence to Ni_LOCK and Ni_CTRL registers. While the hardware test mode functions are not enabled, this register is read-only. This register must be accessed in privileged mode when supported. The hardware test mode functions are disabled and cleared by the software reset of the PRT.

Ni_TEST (i=0-3) Offset address: $2194C_H+i*2000_H$

Node i hardware test functions register Kernel Reset value: $0000\ 0008_H$



Field	Bits	Type	Description
LBCK	0	rw	**LBCK** Enable the Message Loop-Back mode, see chapter Trace and Debug.
RXD	3	r	**RXD** Bit value seen at CAN_RX. The CAN_RX input (output signal of the transceiver) is always readable through this bit.
TXC	5:4	rw	**TXC** Control the bit value driven at CAN_TX 0b00: Normal function of CAN TX 0b01: Normal function of CAN TX. CAN RX is ignored (for message look back mode) 0b10: CAN TX output set to 0 0b11: CAN TX output set to 1
HWT	15	r	**HWT** This status flag HWT shows whether the hardware test mode functions are enabled, set to 1 means enable.
ABORTED	16	w	**ABORTED** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared.
USOS	17	w	**USOS** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared.
TX_DU	18	w	**TX DU** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared.
RX_DO	19	w	**RX DO** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared.
IFF_RQ	20	w	**IFF RQ** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared.
TX_EVT	21	w	**TX EVT** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared.
RX_EVT	22	w	**RX EVT** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared.

(table continues...)

(continued)

Field	Bits	Type	Description
BUS_ERR	23	w	**BUS ERR** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared.
E_ACTIVE	24	w	**E ACTIVE** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared.
E_PASSIVE	25	w	**E PASSIVE** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared.
BUS_ON	26	w	**BUS ON** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared.
BUS_OFF	27	w	**BUS OFF** Writing a 1 to the bit field triggers the related interrupt line, this bit is auto-cleared.
0	2:1, 14:6, 31:28	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.112 Node i operating mode register

Configuration register that is writable while the CAN communication is stopped and that is read-only after the CAN communication is started. This register defines separate operating mode options. The four configuration bits FDOE, XLOE, EFDI, and XLTR, are interrelated according to table Frame Formats defined in Operating Mode chapter.

Ni_MODE (i=0-3) Offset address: $21960_H+i*2000_H$

Node i operating mode register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				FIME	EFDI	XLTR	SFS	RSTR	MON	TXP	EFBI	PXHD	TDCE	XLOE	FDOE
r				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rwh	rwh

Field	Bits	Type	Description
FDOE	0	rwh	**FDOE** FD Frame Format enabled. When set to 1, node is FD enabled according to ISO11898-1:2024. When set to 0, node is FD tolerant according to ISO11898-1:2024 (only Classical CAN frames used). This bit cannot be set to 1 when the static input ONLY_CC is set.

(table continues...)

(continued)

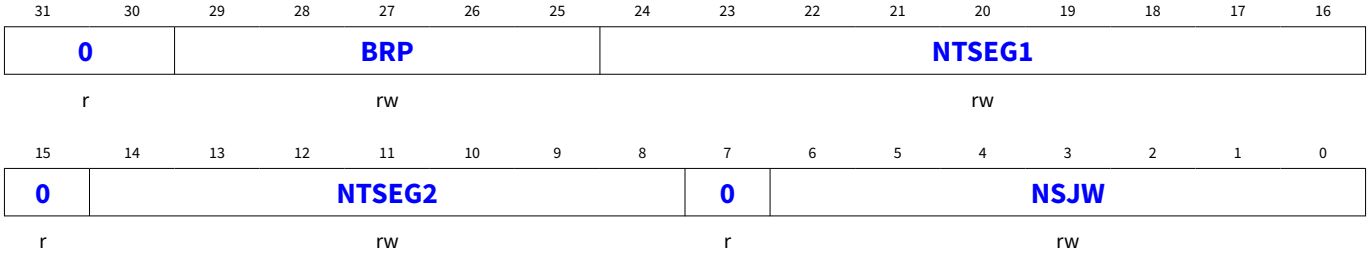
Field	Bits	Type	Description
XLOE	1	rwh	**XLOE** XL Frame Format enabled. When set to 0, node behaves according to ISO11898-1:2024, no arbitration during FDF bit. When set to 1, node behaves according to ISO11898-1:2024, arbitration during FDF bit and XLF bit. This bit cannot be set to 1 when one of the static inputs ONLY_CC or ONLY_CC_FD is set. Setting XLOE without setting FDOE is an invalid configuration.
TDCE	2	rw	**TDCE** Transmitter Delay Compensation Enabled as defined in [1].
PXHD	3	rw	**PXHD** Protocol Exception Handling Disabled.
EFBI	4	rw	**EFBI** Edge Filtering during Bus Integration. If this bit is set, the PRT requires two consecutive dominant to to detect an edge causing the reset of the bit counter for the detection of the idle condition.
TXP	5	rw	**TXP** Transmit Pause. If this bit is set, the PRT pauses for two CAN bit times before starting the next transmission after itself has successfully transmitted a frame
MON	6	rw	**MON** Monitoring Mode Enabled as defined in [1].
RSTR	7	rw	**RSTR** Restricted Mode Enabled as defined in [1].
SFS	8	rw	**SFS** Time stamp position: Start of Frame Stamping 1: Timestamps captured at the start of a frame 0: Timestamps captured at the end of a frame.
XLTR	9	rw	**XLTR** XL Transceiver Connected.
EFDI	10	rw	**EFDI** Error Flag Disable, 1 means Error Signalling is disabled as defined in [1] and the error counters REC and TEC are not incremented. When this bit is set, only CAN XL frames are transmitted and received dominant FDF or XLF bits are treated as form errors.
FIME	11	rw	**FIME** Fault Injection Module Enable, see Safety Measures chapter.
0	31:12	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.113 Node i arbitration phase nominal bit timing register

Configuration register that is writable while the CAN communication is stopped and that is read-only after the CAN communication is started. This register defines the Nominal Bit Timing as defined in [1].

Ni_NBTP (i=0-3) Offset address: $21964_H+i*2000_H$

Node i arbitration phase nominal bit timing register Kernel Reset value: $0000\ 0000_H$



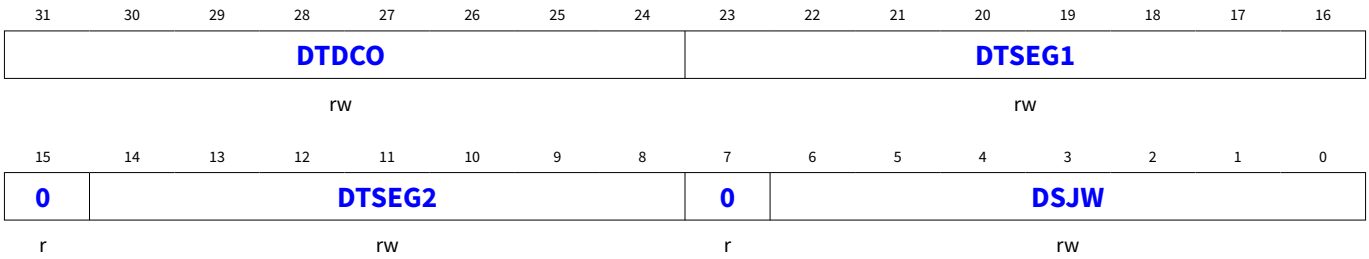
Field	Bits	Type	Description
NSJW	6:0	rw	**NSJW** Nominal SJW. Valid values for the Nominal Synchronization Jump Width NSJW are 0x00-0x7F. The actual interpretation of this value is that the Nominal Synchronization Jump Width is (NSJW + 1) TQ long.
NTSEG2	14:8	rw	**NTSEG2** Nominal Phase_Seg2. Valid values for NTSEG2 are 0x01-0x7F. This value defines the length of Phase_Seg2(N). The actual interpretation of this value is that the phase buffer segment 2 is (NTSEG2 + 1) TQ long.
NTSEG1	24:16	rw	**NTSEG1** Nominal Prop_Seg and Phase_Seg1. Valid values for NTSEG1 are 0x01-0x1FF. This value defines the sum of Prop_Seg(N) and Phase_Seg1(N). The actual interpretation of this value is that these segments together are (NTSEG1 + 1) TQ long.
BRP	29:25	rw	**BRP** Bit Rate Prescaler. Valid values for the Bit Rate Prescaler BRP are 0x00-0x1F. This value defines the length of the Time Quantum TQ for all three bit time configurations. The actual interpretation of this value is that the TQ is (BRP + 1) CLK periods long
0	7, 15, 31:30	r	**Reserved** Read as 0; should be written with 0.

22.9.114 Node i CAN FD data phase bit timing register

Configuration register that is writable while the CAN communication is stopped and that is read-only after the CAN communication is started. This register defines the FD Data Phase Bit Timing as defined in [1].

Ni_DBTP (i=0-3) Offset address: $21968_H+i*2000_H$

Node i CAN FD data phase bit timing register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DSJW	6:0	rw	**DSJW** FD data phase SJW. Valid values for the FD data phase Synchronization Jump Width DSJW are 0x00-0x7F. The actual interpretation of this value is that the FD data phase Synchronization Jump Width is (DSJW + 1) TQ long.
DTSEG2	14:8	rw	**DTSEG2** FD data phase Phase_Seg2. Valid values for DTSEG2 are 0x01-0x7F. This value defines the length of Phase_Seg2(D). The actual interpretation of this value is that the phase buffer segment 2 is (DTSEG2 + 1) TQ long.
DTSEG1	23:16	rw	**DTSEG1** FD data phase Prop_Seg and Phase_Seg1. Valid values for DTSEG1 are 0x00-0xFF. This value defines the sum of Prop_Seg(D) and Phase_Seg1(D). The actual interpretation of this value is that these segments together are (DTSEG1 + 1) TQ long
DTDCO	31:24	rw	**DTDCO** Transmitter Delay Compensation Offset for FD frames. Valid values for the FD Transmitter Delay Compensation Offset DTDCO is 0x00-0xFF. This configuration defines the distance between the measured delay from CAN_TX to CAN_RX and the secondary sample point SSP, measured in CLK periods. This value is used when transmitting a CAN FD frame
0	7, 15	r	**Reserved** Read as 0; should be written with 0.

22.9.115 Node i CAN XL data phase bit timing register

Configuration register that is writable while the CAN communication is stopped and is read-only after the CAN communication is started. This register defines the XL Data Phase Bit Timing as defined in [1].

Ni_XBTP (i=0-3) Offset address: $2196C_H+i*2000_H$

Node i CAN XL data phase bit timing register Kernel Reset value: $0000\ 0000_H$

r	rw							r	rw						

Field	Bits	Type	Description
XSJW	6:0	rw	**XSJW** XL data phase SJW. Valid values for the XL data phase Synchronization Jump Width XSJW are 0x00-0x7F. The actual interpretation of this value is that the XL data phase Synchronization Jump Width is (XSJW + 1) TQ long

(table continues...)

(continued)

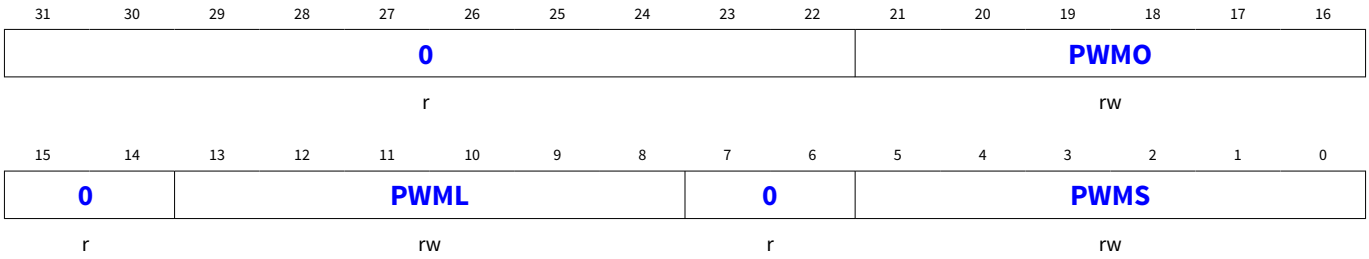
Field	Bits	Type	Description
XTSEG2	14:8	rw	**XTSEG2** XL data phase Phase_Seg2. Valid values for XTSEG2 are 0x01-0x7F. This value defines the length of Phase_Seg2(X). The actual interpretation of this value is that the phase buffer segment 2 is (XTSEG2 + 1) TQ long
XTSEG1	23:16	rw	**XTSEG1** XL data phase Prop_Seg and Phase_Seg1. Valid values for XTSEG1 are 0x00-0xFF. This value defines the sum of Prop_Seg(X) and Phase_Seg1(X). The actual interpretation of this value is that these segments together are (XTSEG1 + 1) TQ long
XTDCO	31:24	rw	**XTDCO** Transmitter Delay Compensation Offset for XL frames. Valid values for the XL Transmitter Delay Compensation Offset XTDCO is 0x00-0xFF. This configuration defines the distance between the measured delay from CAN_TX to CAN_RX and the secondary sample point SSP, measured in CLK periods. This value is used when transmitting a CAN XL frame.
0	7, 15	r	**Reserved** Read as 0; should be written with 0.

22.9.116 Node i PWME configuration register

Configuration register that is writable while the CAN communication is stopped and is read-only after the CAN communication is started. This register defines the parameters needed for the PWM coding (as described in [1]) in the PWME module for CAN XL transceivers with switchable operating modes

Ni_PCFG (i=0-3) Offset address: $21970_H+i*2000_H$

Node i PWME configuration register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PWMS	5:0	rw	**PWMS** PWM phase Short.
PWML	13:8	rw	**PWML** PWM phase Long.
PWMO	21:16	rw	**PWMO** PWM Offset.
0	7:6, 15:14, 31:22	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.117 Node i functional raw event status register

This register provides information about the occurrence of functional relevant events inside the MH and the PRT. A flag is set when the related event is detected, independent of Ni_FUNC_ENA. The flags remain set until the Host CPU clears them by writing a 1 to the corresponding bit position at register FUNC_CLR.

Ni_FUNC_RAW (i=0-3) Offset address: $21A00_H+i*2000_H$

Node i functional raw event status register Kernel Reset value: $0000\ 0000_H$

MH_TX_FQ6_IRQ	6	rh	**MH TX FQ6 IRQ** MH interrupt of the TX FIFO Queue 6. Refer to the description of the MH_TX_FQ0_IRQ

(table continues...)

(continued)

Field	Bits	Type	Description
MH_TX_FQ7_IRQ	7	rh	**MH TX FQ7 IRQ** MH interrupt of the TX FIFO Queue 7. Refer to the description of the MH_TX_FQ0_IRQ
MH_RX_FQ0_IRQ	8	rh	**MH RX FQ0 IRQ** MH interrupt of the RX FIFO Queue 0. This interrupt is triggered when an invalid RX descriptor is fetched from this RX FIFO Queue, or an RX message is received (if set in RX descriptor) in this RX FIFO Queue, see description of RX_FQ_IRQ[7:0] in MH section.
MH_RX_FQ1_IRQ	9	rh	**MH RX FQ1 IRQ** MH interrupt of the RX FIFO Queue 1. Refer to the description of the MH_RX_FQ0_IRQ
MH_RX_FQ2_IRQ	10	rh	**MH RX FQ2 IRQ** MH interrupt of the RX FIFO Queue 2. Refer to the description of the MH_RX_FQ0_IRQ
MH_RX_FQ3_IRQ	11	rh	**MH RX FQ3 IRQ** MH interrupt of the RX FIFO Queue 3. Refer to the description of the MH_RX_FQ0_IRQ
MH_RX_FQ4_IRQ	12	rh	**MH RX FQ4 IRQ** MH interrupt of the RX FIFO Queue 4. Refer to the description of the MH_RX_FQ0_IRQ
MH_RX_FQ5_IRQ	13	rh	**MH RX FQ5 IRQ** MH interrupt of the RX FIFO Queue 5. Refer to the description of the MH_RX_FQ0_IRQ
MH_RX_FQ6_IRQ	14	rh	**MH RX FQ6 IRQ** MH interrupt of the RX FIFO Queue 6. Refer to the description of the MH_RX_FQ0_IRQ
MH_RX_FQ7_IRQ	15	rh	**MH RX FQ7 IRQ** MH interrupt of the RX FIFO Queue 7. Refer to the description of the MH_RX_FQ0_IRQ
MH_TX_PQ_IRQ	16	rh	**MH TX PQ IRQ** Interrupt of TX Priority Queue. Any TX message sent from the TX Priority Queue can be configured to trigger this interrupt. The SW would then need to look at the MH register Ni_TX_PQ_INT_STS to identify which slot has generated the interrupt and for which reason.
MH_STOP_IRQ	17	rh	**MH STOP IRQ** The interrupt is triggered when the PRT is stopped. The MH finishes its task and switches to idle mode.
MH_RX_FILTER_IRQ	18	rh	**MH RX FILTER IRQ** In order to track RX filtering results, an interrupt can be triggered when the comparison between an RX message header and a defined filter is successful.
MH_TX_FILTER_IRQ	19	rh	**MH TX FILTER IRQ** The interrupt is triggered when the TX filter is enabled, and a TX message is rejected.

(table continues...)

(continued)

Field	Bits	Type	Description
MH_TX_ABORT_IRQ	20	rh	**MH TX ABORT IRQ** This interrupt line is triggered when the MH needs to abort a TX message being sent to the PRT.
MH_RX_ABORT_IRQ	21	rh	**MH RX ABORT IRQ** This interrupt line is triggered when the MH needs to abort an RX message being received from PRT.
MH_STATS_IRQ	22	rh	**MH STATS IRQ** One of the RX/TX counters have reached the threshold.
PRT_E_ACTIVE	24	rh	**PRT E ACTIVE** PRT switched from Error-Passive to Error-Active state.
PRT_BUS_ON	25	rh	**PRT BUS ON** PRT started CAN communication, after start or end of BusOff.
PRT_TX_EVT	26	rh	**PRT TX EVT** PRT transmitted a valid CAN message.
PRT_RX_EVT	27	rh	**PRT RX EVT** PRT received a valid CAN message.
0	23, 31:28	r	**Reserved** Read as 0; should be written with 0.

22.9.118 Node i error raw event status register

This register provides information about the occurrence of functional error relevant events inside the MH and the PRT. A flag is set when the related event is detected, independent of Ni_ERR_ENA. The flags remain set until the Host CPU clears them by writing a 1 to the corresponding bit position at register ERR_CLR.

Ni_ERR_RAW (i=0-3) Offset address: $21A04_H+i*2000_H$

r		rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
MH_RX_FILTER_ERR	0	rh	**MH RX FILTER ERR** MH RX filtering has not finished in time, i.e. current RX filtering has not been completed before next incoming RX message requires RX filtering.
MH_MEM_SFTY_ERR	1	rh	**MH MEM SFTY ERR** MH detected error in L_MEM. This interrupt is triggered when either the MEM_SFTY_CE or MEM_SFTY_UE input signal is active. The Message Handler provides the information, which signal was active, see flags MH:SFTY_INT_STS.MEM_SFTY_CE and MH:SFTY_INT_STS.MEM_SFTY_UE.
MH_REG_CRC_ERR	2	rh	**MH REG CRC ERR** MH detected CRC error at the register bank. See also description of REG_CRC_ERR in MH section.
MH_DESC_ERR	3	rh	**MH DESC ERR** CRC error detected on RX/TX descriptor or RX/TX descriptor not expected detected. A status flag can define if it is on TX or RX path, see Ni_SFTY_INT_STS register.
MH_AP_PARITY_ERR	4	rh	**MH AP PARITY ERR** MH detected parity error at address pointers, used to manage the MH Queues (RX/TX FIFO Queues and TX Priority Queues). See also description of AP_PARITY_ERR in MH section.
MH_DP_PARITY_ERR	5	rh	**MH DP PARITY ERR** MH detected parity error at RX message data (received from PRT and written to AXI system bus) respective parity error detected at TX message data (read from AXI system bus and transferred to PRT). Associated information provided by MH register Ni_ERR_INT_STS, e.g. if RX message or TX message was affected.
MH_DP_SEQ_ERR	6	rh	**MH DP SEQ ERR** MH detected an incorrect sequence at RX_MSG respective TX_MSG interfaces located between MH and PRT. Associated information provided by MH register Ni_ERR_INT_STS, e.g. if RX or TX interface was affected.
MH_DP_DO_ERR	7	rh	**MH DP DO ERR** MH detected a data overflow at RX buffer, see description of DP_DO_ERR in MH section.
MH_DP_TO_ERR	8	rh	**MH DP TO ERR** MH detected timeout at TX_MSG interface located between MH and PRT, see description of DP_TO_ERR in MH section.
MH_DMA_TO_ERR	9	rh	**MH DMA TO ERR** MH detected timeout at DMA_AXI interface, see description of DMA_TO_ERR in MH section.
MH_DMA_CH_ERR	10	rh	**MH DMA CH ERR** MH detected routing error, i.e. data received or sent are not properly routed to or from DMA channel interfaces, see description of DMA_CH_ERR in MH section.

(table continues...)

(continued)

Field	Bits	Type	Description
MH_RD_RESP_ERR	11	rh	**MH RD RESP ERR** MH detected a bus error caused by a read access to S_MEM respective L_MEM, see description of RESP_ERR in MH section.
MH_WR_RESP_ERR	12	rh	**MH WR RESP ERR** MH detected a bus error caused by a write access to S_MEM respective L_MEM, see description of RESP_ERR in MH section.
MH_MEM_TO_ERR	13	rh	**MH MEM TO ERR** MH detected timeout at local memory interface MEM_AXI, see description of MEM_TO_ERR in MH section.
PRT_ABORTED	16	rh	**PRT ABORTED** PRT detected stop of TX_MSG sequence by TX_MSG_WUSER code ABORT.
PRT_USOS	17	rh	**PRT USOS** PRT detected unexpected Start of Sequence during TX_MSG sequence.
PRT_TX_DU	18	rh	**PRT TX DU** PRT detected underrun condition at TX_MSG sequence.
PRT_RX_DO	19	rh	**PRT RX DO** PRT detected overflow condition at RX_MSG sequence.
PRT_IFF_RQ	20	rh	**PRT IFF RQ** PRT detected invalid Frame Format at TX_MSG.
PRT_BUS_ERR	21	rh	**PRT BUS ERR** PRT detected error on the CAN Bus.
PRT_E_PASSIVE	22	rh	**PRT E PASSIVE** PRT switched from Error-Active to Error-Passive state.
PRT_BUS_OFF	23	rh	**PRT BUS OFF** PRT entered Bus_Off state.
TOP_MUX_TO_ERR	28	rh	**TOP MUX TO ERR** Timeout at top-level multiplexer for HOST_AXI detected.
0	15:14, 27:24, 31:29	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.119 Node i safety raw event status register

This register provides information about the occurrence of safety relevant events inside the MH and the PRT. A flag is set when the related event is detected, independent of Ni_SAFETY_ENA. The flags remain set until the Host CPU clears them by writing a 1 to the corresponding bit position at register Ni_SAFETY_CLR.

Ni_SAFETY_RAW (i=0-3) Offset address: $21A08_H+i*2000_H$

Node i safety raw event status register Kernel Reset value: $0000\ 0000_H$

r		rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
MH_RX_FILTER_ERR	0	rh	**MH RX FILTER ERR** MH RX filtering has not finished in time, i.e. current RX filtering has not been completed before next incoming RX message requires RX filtering.
MH_MEM_SFTY_ERR	1	rh	**MH MEM SFTY ERR** MH detected error in L_MEM. This interrupt is triggered when either the MEM_SFTY_CE or MEM_SFTY_UE input signal is active. The Message Handler provides the information, which signal was active, see flags MH:SFTY_INT_STS.MEM_SFTY_CE and MH:SFTY_INT_STS.MEM_SFTY_UE.
MH_REG_CRC_ERR	2	rh	**MH REG CRC ERR** MH detected CRC error at the register bank. See also description of REG_CRC_ERR in MH section.
MH_DESC_ERR	3	rh	**MH DESC ERR** CRC error detected on RX/TX descriptor or RX/TX descriptor not expected detected. A status flag can define if it is on TX or RX path, see Ni_SFTY_INT_STS register.
MH_AP_PARITY_ERR	4	rh	**MH AP PARITY ERR** MH detected parity error at address pointers, used to manage the MH Queues (RX/TX FIFO Queues and TX Priority Queues). See also description of AP_PARITY_ERR in MH section.
MH_DP_PARITY_ERR	5	rh	**MH DP PARITY ERR** MH detected parity error at RX message data (received from PRT and written to AXI system bus) respective parity error detected at TX message data (read from AXI system bus and transferred to PRT). Associated information provided by MH register Ni_ERR_INT_STS, e.g. if RX message or TX message was affected.
MH_DP_SEQ_ERR	6	rh	**MH DP SEQ ERR** MH detected an incorrect sequence at RX_MSG respective TX_MSG interfaces located between MH and PRT. Associated information provided by MH register Ni_ERR_INT_STS, e.g. if RX or TX interface was affected.

(table continues...)

(continued)

Field	Bits	Type	Description
MH_DP_DO_ERR	7	rh	**MH DP DO ERR** MH detected a data overflow at RX buffer, see description of DP_DO_ERR in MH section.
MH_DP_TO_ERR	8	rh	**MH DP TO ERR** MH detected timeout at TX_MSG interface located between MH and PRT, see description of DP_TO_ERR in MH section.
MH_DMA_TO_ERR	9	rh	**MH DMA TO ERR** MH detected timeout at DMA_AXI interface, see description of DMA_TO_ERR in MH section.
MH_DMA_CH_ERR	10	rh	**MH DMA CH ERR** MH detected routing error, i.e. data received or sent are not properly routed to or from DMA channel interfaces, see description of DMA_CH_ERR in MH section.
MH_RD_RESP_ERR	11	rh	**MH RD RESP ERR** MH detected a bus error caused by a read access to S_MEM respective L_MEM, see description of RESP_ERR in MH section.
MH_WR_RESP_ERR	12	rh	**MH WR RESP ERR** MH detected a bus error caused by a write access to S_MEM respective L_MEM, see description of RESP_ERR in MH section.
MH_MEM_TO_ERR	13	rh	**MH MEM TO ERR** MH detected timeout at local memory interface MEM_AXI, see description of MEM_TO_ERR in MH section.
PRT_ABORTED	16	rh	**PRT ABORTED** PRT detected stop of TX_MSG sequence by TX_MSG_WUSER code ABORT.
PRT_USOS	17	rh	**PRT USOS** PRT detected unexpected Start of Sequence during TX_MSG sequence.
PRT_TX_DU	18	rh	**PRT TX DU** PRT detected underrun condition at TX_MSG sequence.
PRT_RX_DO	19	rh	**PRT RX DO** PRT detected overflow condition at RX_MSG sequence.
PRT_IFF_RQ	20	rh	**PRT IFF RQ** PRT detected invalid Frame Format at TX_MSG.
PRT_BUS_ERR	21	rh	**PRT BUS ERR** PRT detected error on the CAN Bus.
PRT_E_PASSIVE	22	rh	**PRT E PASSIVE** PRT switched from Error-Active to Error-Passive state.
PRT_BUS_OFF	23	rh	**PRT BUS OFF** PRT entered Bus_Off state.
TOP_MUX_TO_ERR	28	rh	**TOP MUX TO ERR** Timeout at top-level multiplexer for HOST_AXI detected.

22.9.126 Node i IRC configuration register

This register shows the hardware configuration of the IRC concerning the capturing mode of the event inputs. The IP internal events signals coming from the MH and the PRT require an 'edge sensitive' capturing. That is why the value of this register is 0x7 and cannot be changed.

Ni_CAPTURING_MODE (i=0-3) Offset address: $21A30_H+i*2000_H$

Node i IRC configuration register Kernel Reset value: $0000\ 0007_H$

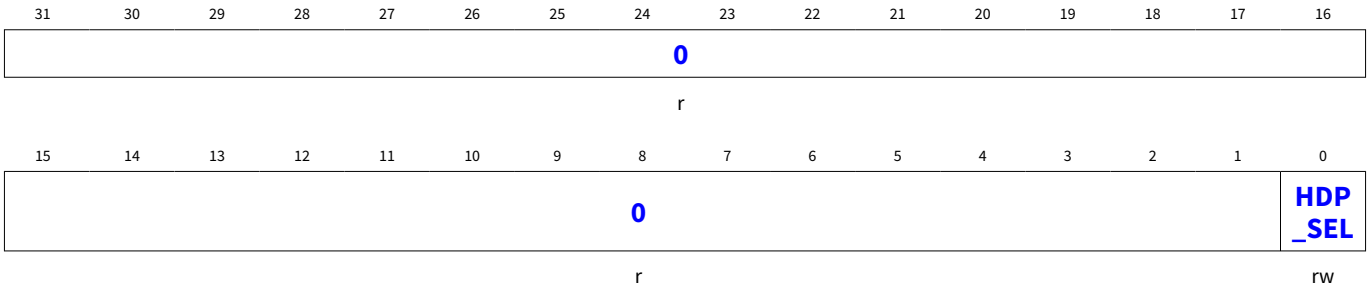
0													SAFETY	ERR	FUNC
r													r	r	r

Field	Bits	Type	Description
FUNC	0	r	**FUNC** Capturing mode of Ni_FUNC_RAW register. 0 = Level sensitive 1 = Edge sensitive
ERR	1	r	**ERR** Capturing mode of ERR RAW register. 0 = Level sensitive 1 = Edge sensitive
SAFETY	2	r	**SAFETY** Capturing mode of SAFETY RAW register. 0 = Level sensitive 1 = Edge sensitive
0	31:3	r	**Reserved** Read as all 0's; should be written with all 0's.

22.9.127 Node i hardware debug port control register

Ni_HDP (i=0-3) Offset address: $21A40_H+i*2000_H$

Node i hardware debug port control register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
HDP_SEL	0	rw	**HDP SEL** Select the driver of the Hardware Debug Port. See also chapter HDP. 0 = Message Handler 1 = Protocol Controller
0	31:1	r	**Reserved** Read as all 0's; should be written with all 0's.

22.10 Debug information

Hard suspend

Hard suspend is enabled when OCS.SUS is set to 1_B. Upon OCDS suspend trigger, both fCANXL and fCANXLH clocks are switched off immediately. The status of the suspend state can be monitored through OCS.SUSTA status bit-field. It is not recommended to use this mode in normal CAN or CAN XL applications, as they are meant only for debugging of the module.

Soft suspend

Soft suspend in enabled when OCS.SUS is set to 2_H. User must ensure that the X_CAN node's protocol controller and message handler are stopped, before entering the soft suspend mode. Upon OCDS suspend trigger, both fCANXL and fCANXLH clocks are switched off. The status of the suspend state can be monitored through OCS.SUSTA status bit-field.

OTGB trigger sets

Each X_CAN proved a set of 16 signals which can be traced using OTGB0/1 bus. X_CAN's HDP is selectable through Ni_HDP.HDP_SEL bit-field. The X_CAN node which needs to be traced is selectable through DEBUG_CTL.NODE_SEL bit-field. The OTGB bus 0 or 1 is selected through OCS.TGB bit-field.

***Note**: Limitation: "CLK" signals which are part of HDP[15] cannot be traced by user.*

22.12 CANXL revision history

Reference	Description of change(s)
Date range: 2024-08-17 to 2024-11-18	
RX FIFO queue in continuous mode	• Adding the configuration of register Ni_RX_FQ_RD_ADD_PTn to the programming instructions for continuous mode
Controller Area Network XL interface (CANXL), Feature list, Functional description, PWME, References, Feature list, X_CAN, Feature list, Functional overview, Protocol controller, Functional overview, Starting and stopping the module, Node i operating mode register, Transceiver interface , TX-SCAN	• Replacing references to CiA 610-1 and ISO 11898-1:2015 by ISO 11898-1:2024
Controller Area Network XL interface (CANXL), Feature list, Protocol controller, Feature list and Functional overview	• Updating the maximum supported CAN XL baudrate from 15 MBit/s to 20 MBit/s

22.13 TC4Dx CAN-XL information

22.13.1 TC4Dx CANXL configuration

Table 1071 TC4Dx CANXL configuration

Parameter	CANXL0
Number of CANXL nodes (N_NODES)	4
RAM size (in Kbytes)	16

22.13.2 TC4Dx CANXL features

- Supports 4 CAN XL nodes
- 16 Kbytes of shared configuration RAM

22.13.3 TC4Dx CANXL functional description

In TC4Dx device, the CANXL modules are connected to ComPB bus interface. The CANXL chapter refers to it as FPI bus.

The following restriction applies for CANXL implementation in TC4Dx

- Software must ensure that X_CAN node's Message Handler and Protocol Controller are stopped, before Kernel reset request via KRST or via module group reset trigger (when enabled through MODULE_RST_CTRLA.GRSTEN bit-field).

22.13.4 TC4Dx CANXL registers

22.13.4.1 Memory overview tables of CANXL

Table 1072 Memory overview - CANXL (ascending address)

Short name	Long name	Address

Table 1074 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register CANXL0_PROTE .
SE	Access protection using PROT register CANXL0_PROTSE .
APU-PM	Protection group consisting of registers CANXL0_MODULE_ACCEN_WRA , CANXL0_MODULE_ACCEN_WRB , CANXL0_MODULE_ACCEN_RDA , CANXL0_MODULE_ACCEN_RDB , CANXL0_MODULE_ACCEN_VM , CANXL0_MODULE_ACCEN_PRS .
PM	Access protection using *APU-PM* registers.
APU-PNi (i=0-3)	Protection group consisting of registers CANXL0_NODEi_ACCENNODE_WRA , CANXL0_NODEi_ACCENNODE_WRB , CANXL0_NODEi_ACCENNODE_RDA , CANXL0_NODEi_ACCENNODE_RDB , CANXL0_NODEi_ACCENNODE_VM , CANXL0_NODEi_ACCENNODE_PRS .
PNi	Access protection using *APU-PNi* registers.
U	No access restrictions.
BE	Always returns a Bus Error.
PROT	Access restrictions as defined in the PROT register access rules.
32	Access only when using 32-bit width.

22.13.4.4 Registers overview - CANXL0 (ascending offset address)

Table 1075 Registers overview - CANXL0 (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CANXL0_ID	Module Identification Register	00000_H	U	BE	PowerOn Reset	4310
CANXL0_OCS	OCDS Control and Status Register	00004_H	PM	SV, PM	Debug Reset	4310
CANXL0_MODULE_CLC	Module Clock Control Register	00008_H	PM	PM, SV, E	Application Reset	4312
CANXL0_MODULE_RST_CTRLA	Module reset control register A	$0000C_H$	PM	PM, SV, E	Application Reset	4312
CANXL0_MODULE_RST_CTRLB	Module reset control register B	00010_H	PM	PM, SV, E	Application Reset	4313
CANXL0_MODULE_RST_STAT	Module reset status register	00014_H	PM	BE	Application Reset	4314
CANXL0_MODULE_ACCEN_WRA	Module Write access enable register A	00018_H	U	SE, SV	Application Reset	4314
CANXL0_MODULE_ACCEN_WRB	Module Write access enable register B	$0001C_H$	U	SE, SV	Application Reset	4315
CANXL0_MODULE_ACCEN_RDA	Module Read access enable register A	00020_H	U	SE, SV	Application Reset	4315
CANXL0_MODULE_ACCEN_RDB	Module Read access enable register B	00024_H	U	SE, SV	Application Reset	4316
CANXL0_MODULE_ACCEN_VM	Module VM access enable register	00028_H	U	SE, SV	Application Reset	4316
CANXL0_MODULE_ACCEN_PRS	Module PRS access enable register	$0002C_H$	U	SE, SV	Application Reset	4317
CANXL0_PROTE	PROT Register Endinit	00038_H	U	SV, PROT	Application Reset	4318
CANXL0_PROTSE	PROT Register Safe Endinit	$0003C_H$	U	SV, PROT	Application Reset	4319
CANXL0_CLKEN	Clock enable	00040_H	clk, PM	clk, PM, SV, E	Application Reset	4321
CANXL0_NODEi_RST_CTRLA (i=0-3)	Node i reset control register A	00100_H+i *100_H	PNi	PNi, SV, E	Application Reset	4322
CANXL0_NODEi_RST_CTRLB (i=0-3)	Node i reset control register B	00104_H+i *100_H	PNi	PNi, SV, E	Application Reset	4322
CANXL0_NODEi_RST_STAT (i=0-3)	Node i reset status register	00108_H+i *100_H	PNi	BE	Application Reset	4323

(table continues...)

Table 1075 (continued) Registers overview - CANXL0 (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CANXL0_NODEi_ACCENNODE_WRA (i=0-3)	Node i write access enable register A	$0010C_H$+i*100_H	U	SE, SV	Application Reset	4324
CANXL0_NODEi_ACCENNODE_WRB (i=0-3)	Node i write access enable register B	00110_H+i*100_H	U	SE, SV	Application Reset	4324
CANXL0_NODEi_ACCENNODE_RDA (i=0-3)	Node i read access enable register A	00114_H+i*100_H	U	SE, SV	Application Reset	4325
CANXL0_NODEi_ACCENNODE_RDB (i=0-3)	Node i read access enable register B	00118_H+i*100_H	U	SE, SV	Application Reset	4326
CANXL0_NODEi_ACCENNODE_VM (i=0-3)	Node i VM access enable register	$0011C_H$+i*100_H	U	SE, SV	Application Reset	4326
CANXL0_NODEi_ACCENNODE_PRS (i=0-3)	Node i PRS access enable register	00120_H+i*100_H	U	SE, SV	Application Reset	4327
CANXL0_NODEi_ACCENNODE_RGNLA (i=0-3)	Node i region lower address register	00124_H+i*100_H	U	SE, SV	Application Reset	4328
CANXL0_NODEi_ACCENNODE_RGNUA (i=0-3)	Node i region upper address register	00128_H+i*100_H	U	SE, SV	Application Reset	4328
CANXL0_NODEi_VMPRSCONFIG (i=0-3)	Node i VM and PRS configuration Register	$0012C_H$+i*100_H	U	SE, SV	Application Reset	4328
CANXL0_NODEi_PORTCTRL (i=0-3)	Node i Port Control Register	00130_H+i*100_H	PNi	PNi	Kernel Reset	4329
CANXL0_NODEi_MTI_RAW (i=0-3)	Node i message transfer interrupt event register	00134_H+i*100_H	PNi	BE	Kernel Reset	4330
CANXL0_NODEi_MTI_CLR (i=0-3)	Node i message transfer interrupt clear register	00138_H+i*100_H	PNi	PNi	Kernel Reset	4330

(table continues...)

Table 1075 (continued) Registers overview - CANXL0 (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CANXL0_NODEi_MTI_ENA (i=0-3)	Node i message transfer interrupt enable register	$0013C_H$+i*100_H	PNi	PNi	Kernel Reset	4331
CANXL0_DEBUG_CTL	Debug control register	10004_H	PM	PM	Kernel Reset	4332
CANXL0_Ni_TS_CTL (i=0-3)	Node i timestamp control	20010_H+i*2000_H	PNi	PNi	Kernel Reset	4332
CANXL0_Ni_TS_CLOCK_CTL (i=0-3)	Node i timestamp clock control	20014_H+i*2000_H	PNi	PNi	Kernel Reset	4333
CANXL0_Ni_TS_CMD (i=0-3)	Node i timestamp command	20020_H+i*2000_H	PNi	PNi	Kernel Reset	4334
CANXL0_Ni_TS_CNT_LO (i=0-3)	Node i timestamp counter LSBs	20030_H+i*2000_H	PNi	BE	Kernel Reset	4334
CANXL0_Ni_TS_CNT_HI (i=0-3)	Node i timestamp counter MSBs	20034_H+i*2000_H	PNi	BE	Kernel Reset	4335
CANXL0_Ni_VERSION (i=0-3)	Node i release identification register	21000_H+i*2000_H	PNi, 32	BE	Kernel Reset	4335
CANXL0_Ni_MH_CTRL (i=0-3)	Node i message handler control register	21004_H+i*2000_H	PNi, 32	PNi, 32	Kernel Reset	4336
CANXL0_Ni_MH_CFG (i=0-3)	Node i message handler configuration register	21008_H+i*2000_H	PNi, 32	PNi, 32	Kernel Reset	4337
CANXL0_Ni_MH_STS (i=0-3)	Node i message handler status register	$2100C_H$+i*2000_H	PNi, 32	BE	Kernel Reset	4338
CANXL0_Ni_MH_SFTY_CFG (i=0-3)	Node i message handler safety configuration register	21010_H+i*2000_H	PNi, 32	PNi, 32	Kernel Reset	4339
CANXL0_Ni_MH_SFTY_CTRL (i=0-3)	Node i message handler safety control register	21014_H+i*2000_H	PNi, 32	PNi, 32	Kernel Reset	4340
CANXL0_Ni_RX_FILTER_MEM_ADD (i=0-3)	Node i RX filter base address register	21018_H+i*2000_H	PNi, 32	PNi, 32	Kernel Reset	4341

(table continues...)

Table 1075 (continued) Registers overview - CANXL0 (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CANXL0_Ni_TX_DESC_MEM_ADD (i=0-3)	Node i TX descriptor base address register	$2101C_H$+i*2000_H	PNi, 32	PNi, 32	Kernel Reset	4342
CANXL0_Ni_AXI_ADD_EXT (i=0-3)	Node i AXI address extension register	21020_H+i*2000_H	PNi, 32	PNi, 32	Kernel Reset	4342
CANXL0_Ni_AXI_PARAMS (i=0-3)	Node i AXI parameter register	21024_H+i*2000_H	PNi, 32	PNi, 32	Kernel Reset	4343
CANXL0_Ni_MH_LOCK (i=0-3)	Node i message handler lock register	21028_H+i*2000_H	PNi, 32	PNi, 32	Kernel Reset	4343
CANXL0_Ni_TX_DESC_ADD_PT (i=0-3)	Node i TX descriptor current address pointer register	21100_H+i*2000_H	PNi, 32	BE	Kernel Reset	4344
CANXL0_Ni_TX_STATISTICS (i=0-3)	Node i TX message counter register	21104_H+i*2000_H	PNi, 32	PNi, 32	Kernel Reset	4344
CANXL0_Ni_TX_FQ_STS0 (i=0-3)	Node i TX FIFO queue status register	21108_H+i*2000_H	PNi, 32	BE	Kernel Reset	4345
CANXL0_Ni_TX_FQ_STS1 (i=0-3)	Node i TX FIFO queue status register	$2110C_H$+i*2000_H	PNi, 32	BE	Kernel Reset	4346
CANXL0_Ni_TX_FQ_CTRL0 (i=0-3)	Node i TX FIFO queue control register 0	21110_H+i*2000_H	PNi, 32	PNi, 32	Kernel Reset	4346
CANXL0_Ni_TX_FQ_CTRL1 (i=0-3)	Node i TX FIFO queue control register 1	21114_H+i*2000_H	PNi, 32	PNi, 32	Kernel Reset	4347
CANXL0_Ni_TX_FQ_CTRL2 (i=0-3)	Node i TX FIFO queue control register 2	21118_H+i*2000_H	PNi, 32	PNi, 32	Kernel Reset	4348
CANXL0_Ni_TX_FQ_ADD_PTr (i=0-3;r=0-7)	Node i TX FIFO queue r current address pointer register	21120_H+i*2000_H+r*10_H	PNi, 32	BE	Kernel Reset	4348
CANXL0_Ni_TX_FQ_START_ADDr (i=0-3;r=0-7)	Node i TX FIFO queue r start address register	21124_H+i*2000_H+r*10_H	PNi, 32	PNi, 32	Kernel Reset	4349
CANXL0_Ni_TX_FQ_SIZEr (i=0-3;r=0-7)	Node i TX FIFO queue r size register	21128_H+i*2000_H+r*10_H	PNi, 32	PNi, 32	Kernel Reset	4349

23 FlexRay™ controller (ERAY)

The ERAY IP-module performs communication according to the FlexRay™ protocol specification v2.1, developed for automotive applications. With maximum specified clock the bit rate can be programmed to values up to 10 Mbit/s. Additional bus driver (BD) hardware is required for connection to the physical layer.

23.1 Feature list

- Conformance with the FlexRay™ protocol specification version 2.1
- Flexible functional configuration and monitoring for software
  - Configuration of message buffers with different payload lengths possible
  - Up to 128 message buffers
  - Each message buffer can be configured as receive buffer, as transmit buffer, or as part of the receive FIFO (first in first out)
  - Flag indicating which input buffer is currently accessible by the host
- Transmit frames according to the protocol
  - Data rates of up to 10 Mbit/s on each channel
  - Filtering for slot counter, cycle counter, and channel
- Receive frames according to the protocol
  - Data rates of up to 10 Mbit/s on each channel
  - Filtering for slot counter, cycle counter, and channel
- Data storage of 8 Kbyte Message RAM available for message buffers and receive FIFO (first in first out)
  - Storage of for example 128 message buffers with a maximum 48 byte data field or up to 30 message buffers with 254 byte data sections
  - One configurable receive FIFO
  - Host access to message buffers through input and output buffer
    - Input buffer holds message to be transferred to the Message RAM
    - Output buffer holds message read from the message RAM
  - Four input buffers for building up transmission frames in parallel
  - Automatically delayed read access to Input Buffer Command Request (IBCR) register if a data transfer from the input shadow buffer to the Message RAM (initiated by a previous write access to the IBCR) is ongoing
  - Automatically delayed read access to Output Buffer Command Request OBCR register if a data transfer from the message RAM to the output shadow buffer (initiated by a previous write access to the OBCR) is ongoing
- Flexible interrupt structure generation available
  - Maskable module service requests
  - Service request lines
- Time management functions
  - Synchronization to the cluster according to the protocol
  - External clock output
- Network Management support

23.2 Functional overview

The figure shows an overview of the ERAY interface.

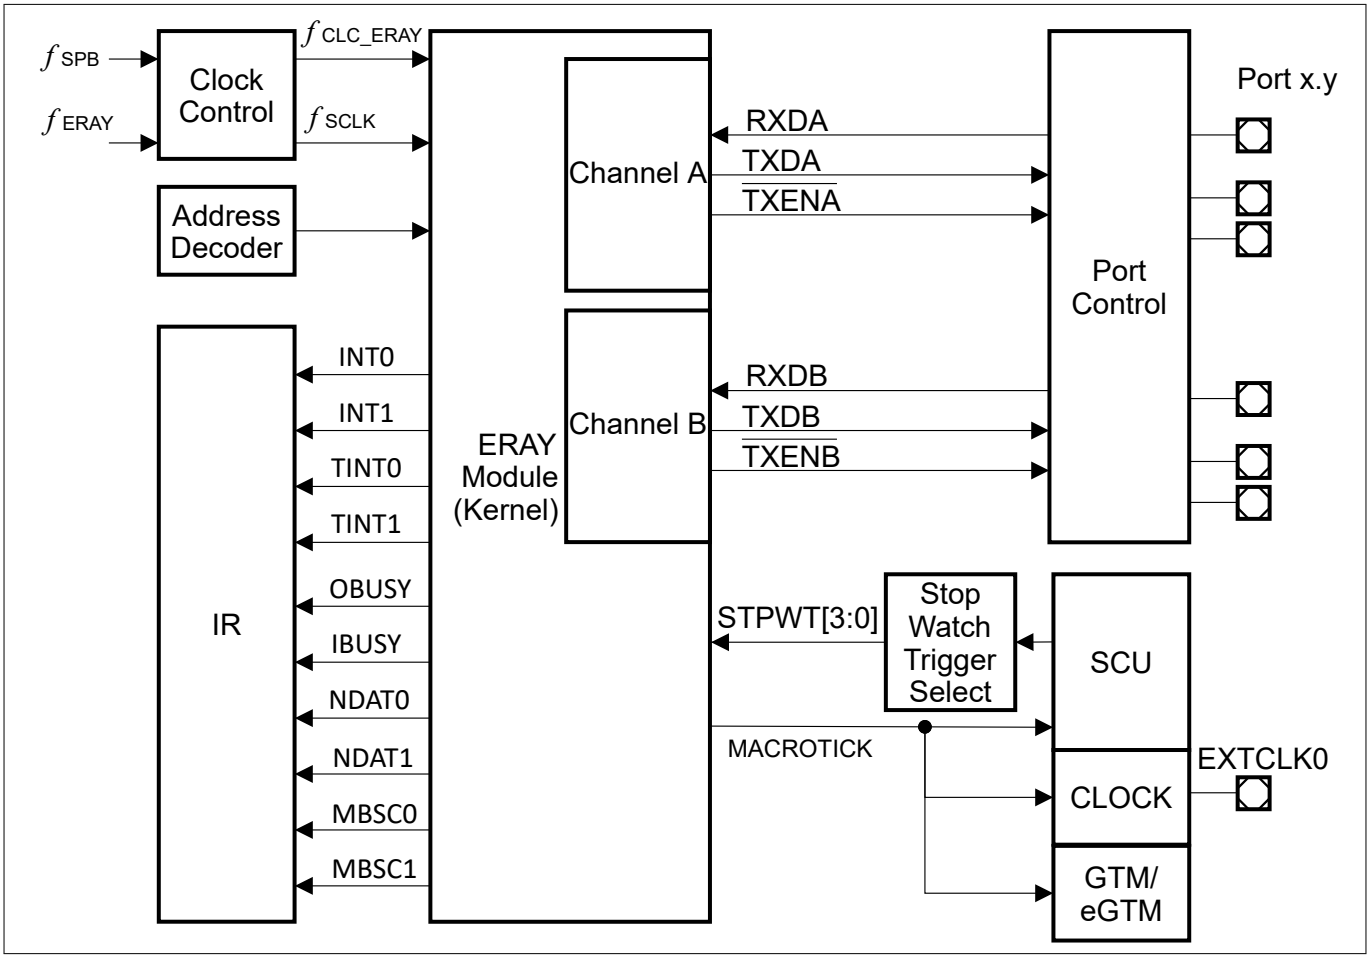

Figure 428 ERAY block diagram

The ERAY module communicates with the external world through three I/O lines on each channel. The RXDAx and RXDBx lines are the receive data input signals, the TXDA and TXDB lines are the transmit output signals, and $\overline{\text{TXENA}}$ and $\overline{\text{TXENB}}$ are the transmit enable signals.

Clock control, address decoding, and service request control are managed outside the ERAY module kernel.

The ERAY is built up of the following main sub-modules:

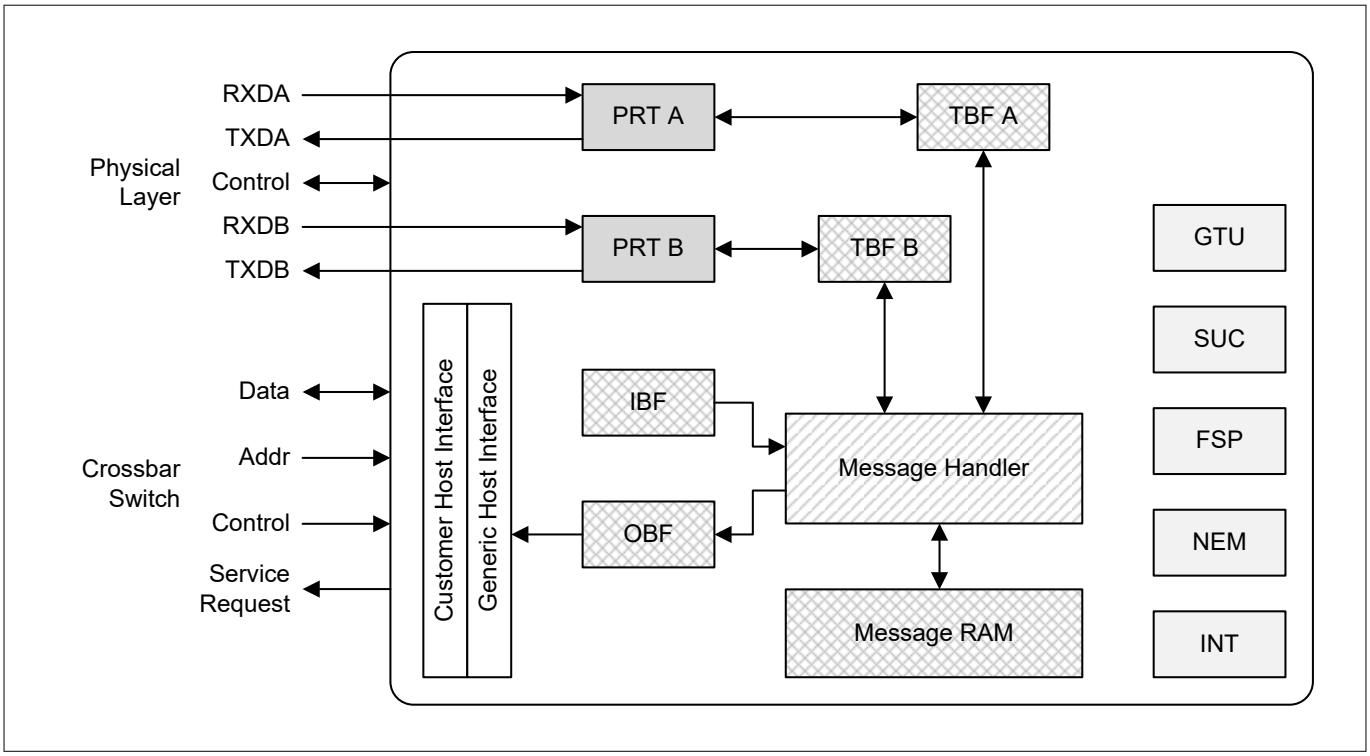

Figure 429 Main sub-modules of ERAY

Customer host interface (CIF)

Connects the FPI bus to the ERAY module through the generic host interface.

Generic host interface (GIF)

The ERAY module is provided with an 8/16/32-bit generic host interface prepared for the connection to a wide range of customer-specific Hosts. Configuration registers, status registers, and service request registers are attached to the respective blocks and can be accessed through the generic host interface.

Input buffer (IBF)

For write access to the message buffers configured in the message RAM, the host can write the header and data section for a specific message buffer to the input buffer. The message handler then transfers the data from the input buffer to the selected message buffer in the message RAM.

There are 4 IBFs. This enables to fill the buffer partly and at the end request transfer into message RAM. Two bits allow to switch between the two banks of IBF and one status bit signals the IBF currently active for host writes.

Output buffer (OBF)

For read access to a Message Buffer configured in the message RAM the message handler transfers the selected message buffer to the output buffer. After the transfer has completed, the host can read the header and data section of the transferred message buffer from the output buffer.

Message handler (MHD)

The ERAY Message Handler controls acceptance filtering, maintaining the transmission schedule, providing message status information and data transfers between the following components:

- Input/output buffer and message RAM
- Transient buffer RAMs of the two FlexRay™ protocol controllers and message RAM

Message RAM (MRAM)

The message RAM consists of a single-ported RAM that stores up to 128 FlexRay™ message buffers together with the related configuration data (header and data partition). For communication on a FlexRay™ network, individual Message Buffers with up to 254 data byte are configurable.

Transient buffer RAM (TBF 1/2)

Stores the data section of two complete messages.

FlexRay™ channel protocol controller (PRT A/B)

The FlexRay™ channel protocol controllers consist of shift register and FlexRay™ protocol FSM. They are connected to the transient buffer RAMs for intermediate message storage and to the physical layer through bus driver (BD).

They perform the following functionality:

- Control and check of bit timing
- Reception and transmission of FlexRay™ frames and symbols
- Check of header CRC
- Generation/check of frame CRC
- Interfacing to bus driver

The FlexRay™ channel protocol controllers have interfaces to:

- Physical layer (bus driver)
- Transient buffer RAM
- Message handler
- Global time unit
- System universal control
- Frame and symbol processing
- Network management
- Service request control

Global time unit (GTU)

The Global time unit performs the following functions:

- Generation of Microtick
- Generation of Macrotick
- Fault tolerant clock synchronization by Fault-Tolerant Midpoint (FTM) algorithm
  - Rate correction
  - Offset correction
- Cycle counter
- Timing control of static segment
- Timing control of dynamic segment (mini-slotting)
- Support of external clock correction

System universal control (SUC)

The System universal control controls the following functions:

- Configuration
- Wakeup
- Startup
- Normal operation

- Passive operation
- Monitor mode

Frame and symbol processing (FSP)

The frame and symbol processing controls the following functions:
- Checks the correct timing of frames and symbols
- Tests the syntactical and semantical correctness of received Frames
- Sets the slot status flags

Network management (NEM)

Handles of the network management vector

Service request control (INT)

The service request controller performs the following functions:
- Provides error and status service request flags
- Enables and disables service request sources
- Assignment of service request sources to one of the two module service request lines
- Enables and disables module service request lines
- Manages the two service request timers
- Stop watch time capturing

23.3 Functional description

This chapter describes the ERAY implementation together with the related FlexRay™ protocol features. More information about the FlexRay™ protocol itself can be found in the FlexRay™ protocol specification v2.1.

Communication on FlexRay™ networks is based on Frames and symbols. The wakeup symbol (WUS) and the collision avoidance symbol (CAS) are transmitted outside the communication cycle to setup the time schedule. Frames and media access test symbols (MTS) are transmitted inside the communication cycle.

23.3.1 Definitions

FlexRay™ Frame: Header Segment + Payload Segment

Message Buffer: Header Section + Data Section

Message RAM: Header Partition + Data Partition

Data Frame: FlexRay™ Frame that is not a NULL Frame

23.3.2 Communication cycle

A communication cycle in FlexRay™ consists of the following elements:

- Static Segment
- Dynamic Segment
- Symbol Window
- Network Idle Time (NIT)

Static segment, dynamic segment, and symbol window form the Network Communication Time (NCT). For each communication channel the slot counter starts at 1 and counts up until the end of the dynamic segment is reached. Both channels share the same arbitration grid which means that they use the same synchronized Macrotick.

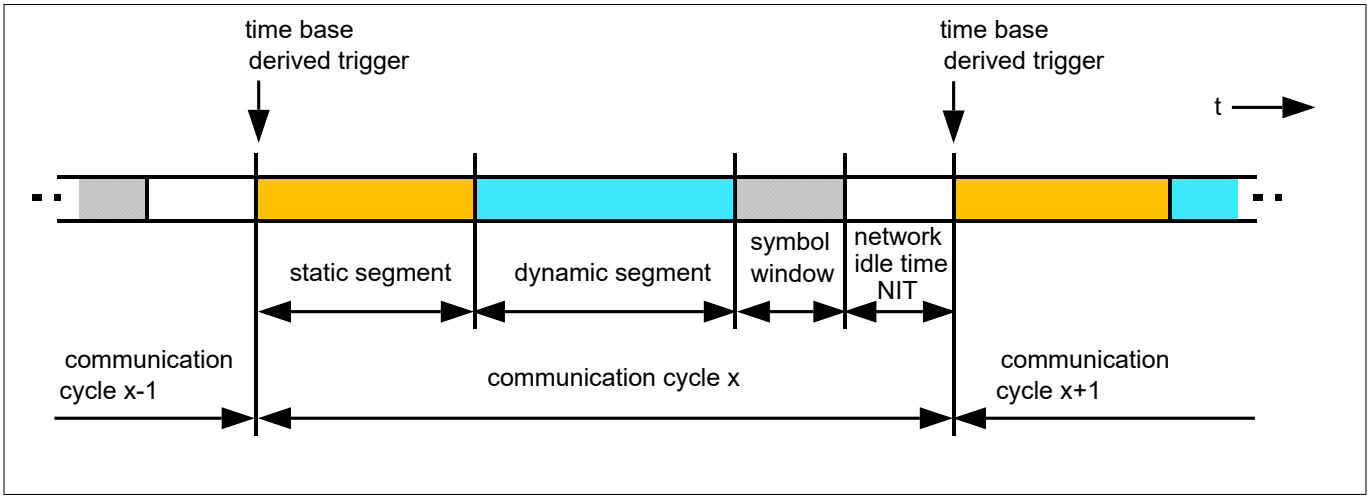

Figure 430 Structure of communication cycle

23.3.2.1 Static segment

The static segment is characterized by the following features:

- Time slots of fixed length (optionally protected by bus guardian)
- Start of Frame transmission at action point of the respective static slot
- Payload length same for all frames on both channel

Parameters: Number of Static Slots GTUC07.NSS, Static Slot Length GTUC07.SSL, Static Frame Data Length MHDC.SFDL, Action Point Offset GTUC09.APO.

23.3.2.2 Dynamic segment

The dynamic segment is characterized by the following features:

- All controllers have bus access (no bus guardian protection possible)
- Variable payload length and duration of slots, different for both channels
- Start of transmission at minislot action point

Parameters: Number of Minislots GTUC08.NMS, Minislot Length GTUC08.MSL Minislot Action Point Offset GTUC09.MAPO, Start of Latest Transmit (last minislot) MHDC.SLT.

23.3.2.3 Symbol window

During the symbol window only one media access test symbol (MTS) may be transmitted per channel. MTS symbols are send in “NORMAL_ACTIVE” state to test the bus guardian.

The symbol window is characterized by the following features:

- Send single symbol
- Transmission of the MTS symbol starts at the symbol windows action point

Parameters: Symbol Window Action Point Offset GTUC09.APO (same as for static slots), Network Idle Time Start GTUC04.NIT.

23.3.2.4 Network idle time (NIT)

During network idle time the communication controller has to perform the following tasks:

- Calculate clock correction terms (offset and rate)
- Distribute offset correction over multiple macroticks
- Perform cluster cycle related tasks

Parameters: Network Idle Time Start GTUC04.NIT, Offset Correction Start GTUC04.OCS.

23.3.2.5 Configuration of communication cycle elements

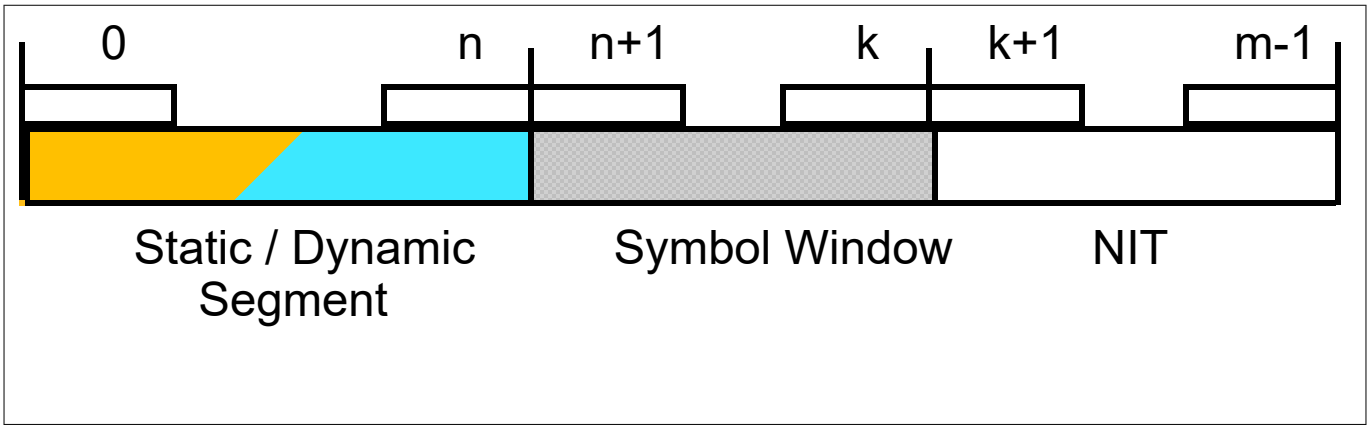

Figure 431 Configuration of network idle time (NIT) start and offset correction start

The number of Macroticks per cycle (gMacroPerCycle) is assumed to be m. It is configured by programming $\mathrm{GTUC02.MPC} = m$.

The static and dynamic segment starts with Macrotick 0 and ends with Macrotick n:

n = static segment length + dynamic segment offset + dynamic segment length − 1 Macrotick, where:

- Static segment length = gNumberOfStaticSlots × gdStaticSlot; the static segment length is configured by GTUC07.NSS and GTUC07.SSL
- Dynamic segment length = gNumberOfMinislots × gdMinislot; the dynamic segment length is configured by GTUC08.NMS and GTUC08.MSL
- The dynamic segment offset is:
  - If gdActionPointOffset ≤ gdMinislotActionPointOffset, dynamic segment offset = 0 Macrotick
  - Else if gdActionPointOffset > gdMinislotActionPointOffset,
    dynamic segment offset = gdActionPointOffset - gdMinislotActionPointOffset

The network idle time (NIT) starts with Macrotick $k + 1$ and ends with the last Macrotick of cycle $m - 1$. It is configured by setting GTUC04.NIT = k.

For ERAY the offset correction start is required to be: GTUC04.OCS ≥ GTU04.NIT + 1 = $k + 1$.

The length of symbol window results from the number of Macroticks between the end of the static and dynamic segment and the beginning of the NIT. It is calculated by: $k - n$.

23.3.3 Communication modes

The FlexRay™ protocol specification v2.1 defines the time-triggered distributed (TT-D) mode.

Time-triggered distributed (TT-D)

In TT-D mode the following configurations are possible:

- Pure static: minimum 2 static slots + symbol window (optional)
- Mixed static/dynamic: minimum 2 static slots + dynamic segment + symbol window (optional)

A minimum of two coldstart nodes need to be configured for distributed time-triggered operation. Two fault-free coldstart nodes are necessary for the cluster startup. Each Startup Frame must be a SYNC Frame, therefore all coldstart nodes are sync nodes.

23.3.4 Clock synchronization

In TT-D mode a distributed clock synchronization is used. Each node individually synchronizes itself to the cluster by observing the timing of received SYNC frames from other nodes.

23.3.4.1 Local time

Internally, nodes time their behavior with Microtick resolution. Microticks are time units derived from the oscillator clock (module clock f_{SCLK}) tick of the specific node. Therefore Microticks are controller-specific units. They may have different duration in different controllers. The precision of a node's local time difference measurements is a Microtick.

Node specific:

- Oscillator clock → prescaler → Microtick
- Microtick = basic unit of time measurement in a Communication Controller, clock correction is done in units of Microticks
- Cycle counter + Macrotick counter = nodes local view of the global time

23.3.4.2 Global time

Activities in a FlexRay™ node, including communication, are based on the concept of a global time, even though each individual node maintains its own view of it. It is the clock synchronization mechanism that differentiates

the FlexRay™ cluster from other node collections with independent clock mechanisms. The global time is a vector of two values; the cycle (cycle counter) and the cycle time (Macrotick counter).

Cluster specific:

- Macrotick = basic unit of time measurement in a FlexRay™ network, a Macrotick consists of an integer number of Microticks
- Cycle length = duration of a communication cycle in units of Macroticks

23.3.4.3 Synchronization process

Clock synchronization is performed by means of SYNC Frames. Only preconfigured nodes (sync nodes) are allowed to send SYNC Frames. In a two-channel cluster a sync node has to send its SYNC Frame on both channels.

For synchronization in FlexRay™ the following constraints have to be considered:

- Maximum one SYNC Frame per node in one communication cycle
- Maximum 15 SYNC Frames per cluster in one communication cycle
- Every node has to use all available SYNC Frames for clock synchronization
- Minimum of two sync nodes required for clock synchronization and start-up

For clock synchronization the time difference between expected and observed arrival time of SYNC Frames received during the static segment, valid on both channels (two-channel cluster), is measured. The calculation of correction terms is done during network idle time (NIT) (offset: every cycle, rate: odd cycle) by using a FTA / FTM algorithm. For details see FlexRay™ protocol specification v2.1, chapter 8.

Offset (phase) correction

- Only deviation values measured and stored in the current cycle used
- For a two channel node the smaller value will be taken
- Calculation during network idle time (NIT) of every communication cycle, value may be negative
- Offset correction value calculated in even cycles used for error checking only
- Checked against limit values (violation: NORMAL_ACTIVE → NORMAL_PASSIVE → HALT)
- Correction value is an integer number of Microticks
- Correction done in odd numbered cycles, distributed over the Macroticks beginning at offset correction start-up to cycle end (end of network idle time (NIT)) to shift nodes next start of cycle (Macroticks lengthened/shortened)

Rate (frequency) correction

- Pairs of deviation values measured and stored in even/odd cycle pair used
- For a two channel node the average of the differences from the two channels is used
- Calculated during network idle time (NIT) of odd numbered cycles, value may be negative
- Cluster drift damping is performed using global damping value
- Checked against limit values
- Correction value is a signed integer number of Microticks
- Distributed over Macroticks comprising the next even/odd cycle pair (Macroticks lengthened/shortened)

SYNC frame transmission

SYNC Frame transmission is only possible from buffer 0 and 1. Message Buffer 1 may be used for SYNC Frame transmission in case that SYNC Frames should have different payloads on the two channels. In this case bit MRC.SPLM has to be programmed to 1.

Message Buffers used for SYNC Frame transmission have to be configured with the key slot ID and can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only. For nodes transmitting SYNC Frames SUCC1.TXSY must be set to 1.

23.3.4.4 External clock synchronization

During normal operation, independent clusters can drift significantly. If synchronous operation across independent clusters is desired, external synchronization is necessary; even though the nodes within each cluster are synchronized. This can be accomplished with synchronous application of host-deduced rate and offset correction terms to the clusters.

- External offset/rate correction value is a signed integer
- External offset/rate correction value is added to calculated offset/rate correction value
- Aggregated offset/rate correction term (external + internal) is not checked against configured limits

23.3.5 Error handling

The implemented error handling concept is intended to ensure that in case of a lower layer protocol error in a single node communication between non-affected nodes can be maintained. In some cases, higher layer program command activity is required for the Communication Controller to resume normal operation. A change of the error handling state will set bit EIR.PEMC in the Error Service Request Register and may trigger an service request to the Host if enabled. The actual error mode is signaled by CCEV.ERRM in the Communication Controller Error Vector register.

Table 1077 Error modes of the Protocol Operation Control (POC) (degradation model)

Error mode	Activity
ACTIVE	Full operation, State: “NORMAL_ACTIVE” The Communication Controller is fully synchronized and supports the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers EIR and SIR
PASSIVE	Reduced operation, State: “NORMAL_PASSIVE”, Communication Controller self rescue allowed The Communication Controller stops transmitting Frames and symbols, but received Frames are still processed. Clock synchronization mechanisms are continued based on received Frames. No active contribution to the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers EIR and SIR
COMM_HALT	Operation halted, State: “HALT”, Communication Controller self rescue not allowed The Communication Controller stops Frame and symbol processing, clock synchronization processing, and the Macrotick generation. The host has still access to error and status information by reading the error and status interrupt flags from registers EIR and SIR. The bus drivers are disabled

23.3.5.1 Clock correction failed counter

When the clock correction failed counter reaches the maximum “without clock correction passive” limit defined by SUCC3.WCP, the POC transits from “NORMAL_ACTIVE” to “NORMAL_PASSIVE” state. When it reaches the “maximum without clock correction fatal” limit defined by SUCC3.WCF, it transits from “NORMAL_ACTIVE” or “NORMAL_PASSIVE” to the “HALT” state. Both limits are defined in the SUC configuration register 3.

The clock correction failed counter CCEV.CCFC allows the Host to monitor the duration of the inability of a node to compute clock correction terms after the Communication Controller passed protocol startup phase. It will be incremented by one at the end of any odd numbered communication cycle where either the Missing Offset Correction signal SFS.MOCS or the Missing Rate Correction signal SFS.MRCS flag is set. The two flags are located in the SYNC Frame Status register, while the clock correction failed counter is located in the Communication Controller Error Vector register.

The clock correction failed counter is reset to zero at the end of an odd communication cycle if neither the Missing Offset Correction signal SFS.MOCS nor the Missing Rate Correction signal SFS.MRCS flag is set.

The clock correction failed counter stops incrementing when the “maximum without clock correction fatal” value SUCC3.WCF as defined in the SUC Configuration Register 3 is reached (that is, incrementing the counter at its maximum value will not cause it to “wraparound” back to zero). The clock correction failed counter is initialized to zero when the Communication Controller enters “READY” state or when “NORMAL_ACTIVE” state is entered.

23.3.5.2 Passive to active counter

The passive to active counter controls the transition of the POC from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. SUCC1.PTA in the SUC configuration register 1 defines the number of consecutive even/odd cycle pairs that must have valid clock correction terms before the Communication Controller is allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. If SUCC1.PTA is reset to zero, the Communication Controller is not allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state.

23.3.5.3 HALT command

In case the Host wants to stop FlexRay™ communication of the local node it can bring the Communication Controller into “HALT” state by asserting the HALT command. This can be done by writing SUCC1.CMD = 0110_B in the SUC Configuration Register 1. When called in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state the POC transits to “HALT” state at the end of the current cycle. When called in any other state SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED” and bit EIR.CNA in the Error Service Request Register is set to 1. If enabled, an service request to the Host is generated.

23.3.5.4 FREEZE command

In case the Host detects a severe error condition it can bring the Communication Controller into “HALT” state by asserting the FREEZE command. This can be done by writing SUCC1.CMD = 0111_B in the SUC Configuration Register 1. The FREEZE command triggers the entry of the “HALT” state immediately regardless of the actual POC state.

The POC state from which the transition to “HALT” state took place can be read from CCSV.PSL.

23.3.6 Communication controller states

This chapter introduces the states of the communication controller.

23.3.6.1 Communication controller state diagram

State transitions are controlled by externals the application reset or RXDA/B, by the POC state machine, and by the CHI Command Vector SUCC1.CMD located in the SUC configuration register 1.

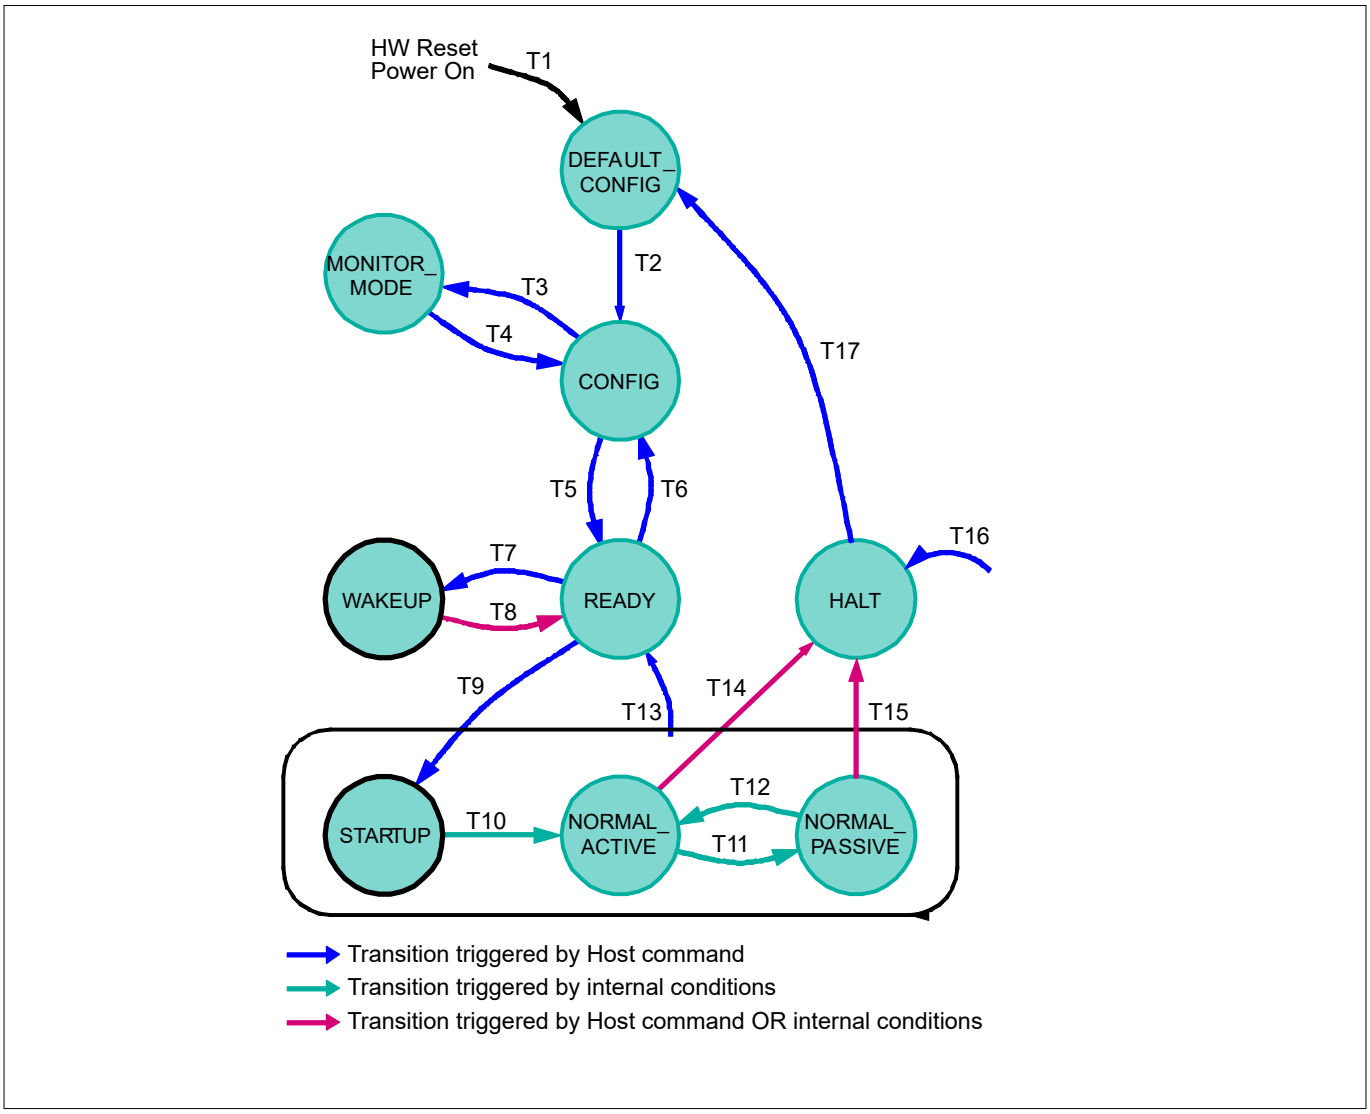

Figure 432 Overall state diagram of ERAY communication controller

The communication controller exits from all states to “HALT” state after application of the FREEZE command (SUCC1.CMD = 0111_B).

Table 1078 State transitions of ERAY overall state machine

T#	Condition	From	To
1	Application reset	Hardware reset	DEFAULT_CONFIG
2	Command CONFIG, SUCC1.CMD = 0001_B	DEFAULT_CONFIG	CONFIG

(table continues...)

Table 1078 (continued) State transitions of ERAY overall state machine

T#	Condition	From	To
3	Unlock sequence followed by command MONITOR_MODE, SUCC1.CMD = 1011_B	CONFIG	MONITOR_MODE
4	Command CONFIG, SUCC1.CMD = 0001_B	MONITOR_MODE	CONFIG
5	Unlock sequence followed by command READY, SUCC1.CMD = 0010_B	CONFIG	READY
6	Command CONFIG, SUCC1.CMD = 0001_B	READY	CONFIG
7	Command WAKEUP, SUCC1.CMD = 0011_B	READY	WAKEUP
8	Complete, non-aborted transmission of wake-up pattern OR received WUP OR received Frame Header OR command READY, SUCC1.CMD = 0010_B	WAKEUP	READY
9	Command RUN SUCC1.CMD = 0100_B	READY	STARTUP
10	Successful start-up	STARTUP	NORMAL_ACTIVE
11	Clock Correction Failed counter reached Maximum Without Clock Correction Passive limit configured by WCP in SUC Configuration Register 3	NORMAL_ACTIVE	NORMAL_PASSIVE
12	Number of valid correction terms reached the Passive to Active limit configured by PTA in SUC Configuration Register 1	NORMAL_PASSIVE	NORMAL_ACTIVE
13	Command READY, SUCC1.CMD = 0010_B	STARTUP, NORMAL_ACTIVE, NORMAL_PASSIVE	READY
14	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by WCF in SUC Configuration Register 3 AND bit HCSE in the SUC Configuration Register 1 set to 1 OR command HALT, SUCC1.CMD = 0110_B	NORMAL_ACTIVE	HALT
15	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by WCF in SUC Configuration Register 3 AND bit HCSE in the SUC Configuration Register 1 set to 1 OR command HALT, SUCC1.CMD = 0110_B	NORMAL_PASSIVE	HALT
16	Command FREEZE, SUCC1.CMD = 0111_B	All States	HALT
17	Command CONFIG, SUCC1.CMD = 0001_B	HALT	DEFAULT_CONFIG

23.3.6.2 CONFIG state

In “CONFIG” state, the communication controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state. This state is used to initialize the communication controller configuration.

The communication controller enters this state:

- When exiting from DEFAULT_CONFIG state
- When exiting from MONITOR_MODE or READY state

When the state has been entered through HALT and DEFAULT_CONFIG state, the Host can analyze status information and configuration. Before leaving CONFIG state the Host has to assure that the configuration is fault-free.

To leave “CONFIG” state, the Host has to perform the unlock sequence as described on LCK register section. Directly after unlocking the CONFIG state the Host has to write SUCC1.CMD in the SUC Configuration Register 1 to enter the next state.

Internal counters and the Communication Controller status flags are reset when the Communication Controller leaves CONFIG.

***Note**: The Message Buffer Status Registers (MHDS, TXRQ1 to TXRQ4, NDAT1 to NDAT4, MBSC1 to MBSC4) and status data stored in the Message RAM and are not affected by the transition of the POC from CONFIG to READY state.*

When the Communication Controller is in “CONFIG” state it is also possible to bring the Communication Controller into a power saving mode by halting the module clocks (f_{SCLK}, f_{CLC_ERAY}). To do this the Host has to assure that all Message RAM transfers have finished before turning off the clocks.

DEFAULT_CONFIG state

In DEFAULT_CONFIG state, the communication controller is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state.

The communication controller enters this state:

- When leaving application reset
- When exiting from HALT state

To leave DEFAULT_CONFIG state the Host has to write SUCC1.CMD = 0001_B in the SUC Configuration Register 1. The Communication Controller transits to CONFIG state.

23.3.6.3 MONITOR_MODE

After unlocking “CONFIG” state and writing SUCC1.CMD = 1011_B the Communication Controller enters “MONITOR_MODE”. In this mode the Communication Controller is able to receive FlexRay™ Frames and to detect wakeup pattern. The temporal integrity of received Frames is not checked, and therefore cycle counter filtering is not supported. It is not possible to distinguish between static and dynamic frames, because limited functions in “MONITOR_MODE” (FRF.RSS will be ignored, filtering not functional). This mode can be used for debugging purposes in case for example that startup of a FlexRay™ network fails. After writing SUCC1.CMD = 0001_B the Communication Controller transits back to “CONFIG” state.

In “MONITOR_MODE” the “pick first valid” mechanism is disabled. This means that a receive Message Buffer may only be configured to receive on one channel. Received Frames are stored into Message Buffers according to Frame ID and receive channel. NULL Frames are handled like Data Frames. After Frame reception only status bits MBS.VFRA, MBS.MLST, MBS.RCIS, MBS.SFIS, MBS.SYNS, MBS.NFIS, MBS.PPIS, MBS.RESS have valid value.

In “MONITOR_MODE” the Communication Controller is not able to distinguish between CAS and MTS symbols. In case one of these symbols is received on one or both of the two channels, the flags SIR.MTSA respectively SIR.MTSB are set. SIR.CAS has no function in “MONITOR_MODE”.

23.3.6.4 READY state

After unlocking “CONFIG” state and writing SUCC1.CMD = 0010_B the Communication Controller enters “READY” state. From this state the Communication Controller can transit to “WAKEUP” state and perform a cluster wakeup or to “STARTUP” state to perform a coldstart or to integrate into a running communication.

The Communication Controller enters this state:

- When exiting from CONFIG, WAKEUP, STARTUP, NORMAL_ACTIVE, or NORMAL_PASSIVE state by writing SUCC1.CMD = 0010_B (READY command)

The Communication Controller exits from this state:

- To CONFIG state by writing SUCC1.CMD = 0001_B (CONFIG command)
- To WAKEUP state by writing SUCC1.CMD = 0011_B (WAKEUP command)
- To STARTUP state by writing SUCC1.CMD = 0100_B (RUN command)

Internal counters and the Communication Controller status flags are reset when the Communication Controller enters “STARTUP” state.

***Note**: Status bits MHDS, registers TXRQ1 to TXRQ4, and status data stored in the Message RAM are not affected by the transition of the POC from “READY” to “STARTUP” state.*

23.3.6.5 WAKEUP state

The description below is intended to help configuring wakeup for the ERAY module. A detailed description of the wakeup procedure together with the respective Specification and Description Language (SDL) diagrams can be found in the FlexRay™protocol specification v2.1 v2.1, section 7.1.

The Communication Controller enters this state:

- When exiting from READY state by writing SUCC1.CMD = 0011_B (WAKEUP command)

The Communication Controller exits from this state to READY state:

- After complete non-aborted transmission of wakeup pattern
- After WUP reception
- After detecting a WUP collision
- After reception of a Frame Header
- By writing SUCC1.CMD = 0010_B (READY command)

The cluster wakeup must precede the communication startup in order to ensure that all mechanisms defined for the startup work properly. The minimum requirement for a cluster wakeup is that all bus drivers are supplied with power. A bus driver has the ability to wake up the other components of its node when it receives a wakeup pattern on its channel. At least one node in the cluster needs an external wakeup source.

The Host completely controls the wakeup procedure. It is informed about the state of the cluster by the bus driver and the Communication Controller and configures bus guardian (if available) and Communication Controller to perform the cluster wakeup. The Communication Controller provides to the Host the ability to transmit a special wakeup pattern on each of its available channels separately. The Communication Controller needs to recognize the wakeup pattern only during “WAKEUP” state.

Wakeup may be performed on only one channel at a time. The Host has to configure the wakeup channel while the Communication Controller is in “CONFIG” state by writing bit SUCC1.WUCS in the SUC Configuration register 1. The Communication Controller ensures that ongoing communication on this channel is not disturbed. The Communication Controller cannot guarantee that all nodes connected to the configured channel awake upon the transmission of the wakeup pattern, since these nodes cannot give feedback until the startup phase. The wakeup procedure enables single-channel devices in a two-channel system to trigger the wakeup, by only transmitting the wakeup pattern on the single channel to which they are connected. Any

coldstart node that deems a system startup necessary will then wake the remaining channel before initiating communication startup.

The wakeup procedure tolerates any number of nodes simultaneously trying to wakeup a single channel and resolves this situation such that only one node transmits the pattern. Additionally, the wakeup pattern is collision resilient, so even in the presence of a fault causing two nodes to simultaneously transmit a wakeup pattern, the resulting collided signal can still wake the other nodes.

After wakeup the Communication Controller returns to “READY” state and signals the change of the wakeup status to the Host by setting bit SIR.WST in the Status Service Request register. The wakeup status vector can be read from the Communication Controller Status Vector register CCSV.WSV. If a valid wakeup pattern was received, also either flag SIR.WUPA or flag SIR.WUPB in the Status Service Request Register is set.

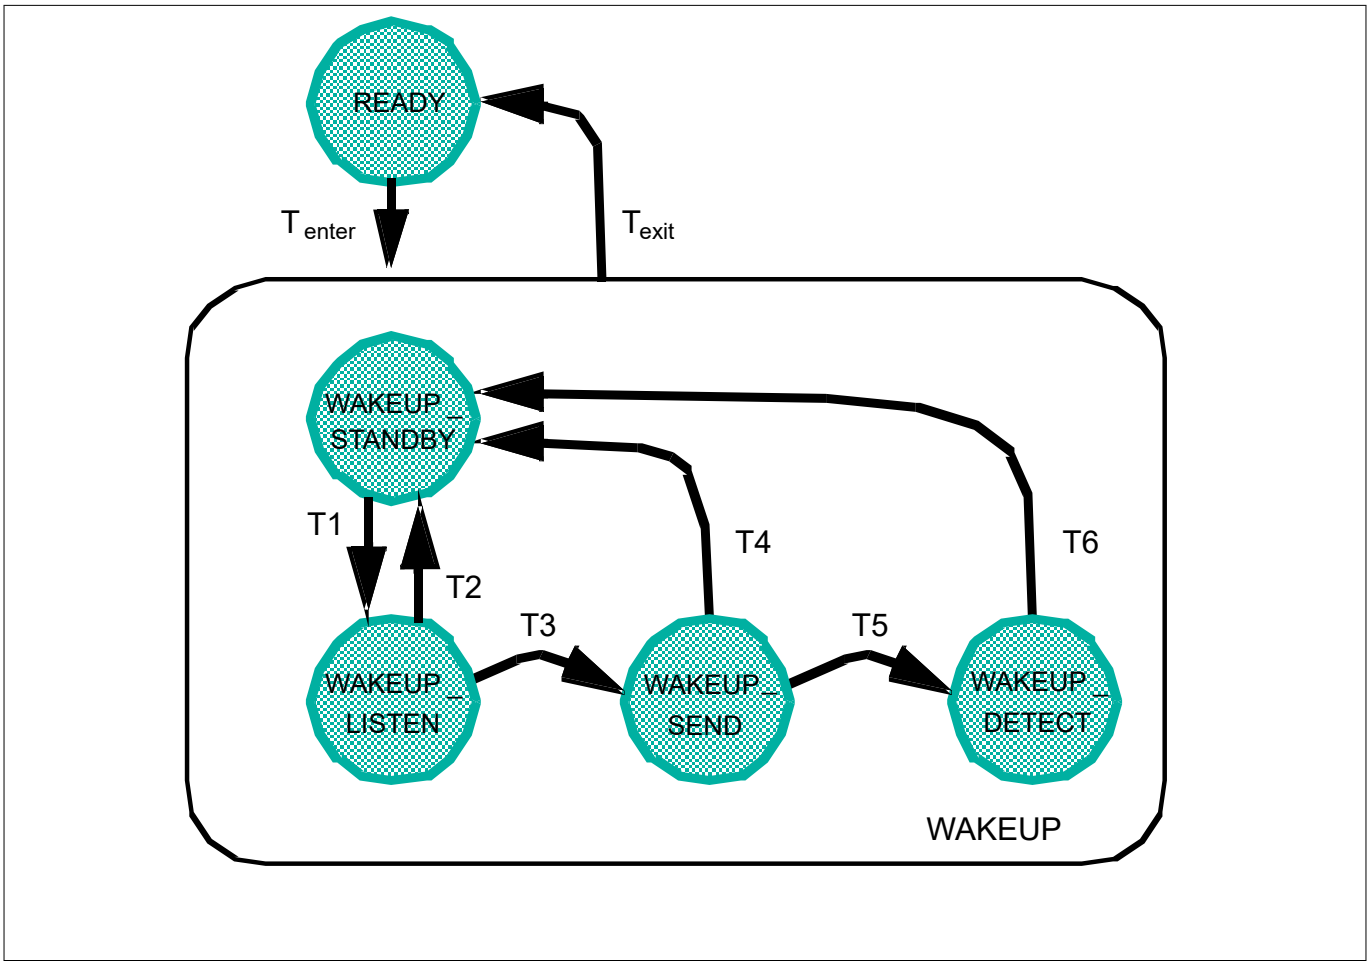

Figure 433 Structure of POC state WAKEUP

Table 1079 State transitions WAKEUP

T#	Condition	From	To
enter	Host commands change to “WAKEUP” state by writing SUCC1.CMD = 0011_B (WAKEUP command)	READY	WAKEUP
1	CHI command WAKEUP triggers wakeup FSM to transit to “WAKEUP_LISTEN” state	WAKEUP_ STANDBY	WAKEUP_LISTEN
2	Received WUP on wakeup channel selected by flag SUCC1.WUCS in the SUC Configuration Register 1 OR Frame Header on either available channel	WAKEUP_ LISTEN	WAKEUP_STAND BY

(table continues...)

Table 1079 (continued) State transitions WAKEUP

T#	Condition	From	To
3	Timer event	WAKEUP_ LISTEN	WAKEUP_SEND
4	Complete, non-aborted transmission of wakeup pattern	WAKEUP_ SEND	WAKEUP_STAND BY
5	Collision detected	WAKEUP_ SEND	WAKEUP_DETEC T
6	Wakeup timer expired OR WUP detected on wakeup channel selected by flag SUCC1.WUCS in the SUC Configuration register 1 OR Frame Header received on either available channel	WAKEUP_ DETECT	WAKEUP_STAND BY
exit	Wakeup completed (after T2 or T4 or T6) OR Host commands change to “READY” state by writing SUCC1.CMD = 0010_B (READY command). This command also resets the wakeup FSM to “WAKEUP_STANDBY” state	WAKEUP	READY

The “WAKEUP_LISTEN” state is controlled by the wakeup timer and the wakeup noise timer. The two timers are controlled by the parameters listen time-out SUCC2.LT and listen time-out noise SUCC2.LTN. Both values can be configured in the SUC Configuration register 2. Listen time-out enables a fast cluster wakeup in case of a noise free environment, while listen time-out noise enables wakeup under more difficult conditions regarding noise interference.

In “WAKEUP_SEND” state the Communication Controller transmits the wakeup pattern on the configured channel and checks for collisions. After return from wakeup the Host has to bring the Communication Controller into “STARTUP” state by CHI command RUN.

In “WAKEUP_DETECT” state the Communication Controller attempts to identify the reason for the wakeup collision detected in “WAKEUP_SEND” state. The monitoring is bounded by the expiration of listen time-out as configured by SUCC2.LT in the SUC Configuration Register 2. Either the detection of a wakeup pattern indicating a wakeup attempt by another node or the reception of a Frame Header indication existing communication, causes the direct transition to “READY” state. Otherwise “WAKEUP_DETECT” is left after expiration of listen time-out; in this case the reason for wakeup collision is unknown.

The Host has to be aware of possible failures of the wakeup and act accordingly. It is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal time it takes another coldstart node to become awake and to be configured.

The FlexRay™ Protocol Specification v2.1 recommends that two different Communication Controllers shall awake the two channels.

Host activities

The host must coordinate the wakeup of the two channels and must decide whether or not to wake a specific channel. The sending of the wakeup pattern is initiated by the Host and generated by the Communication Controller. The wakeup pattern is detected by the remote BDs and signalled to their local Hosts.

Wakeup procedure controlled by Host (single-channel wakeup):

- Configure the Communication Controller in CONFIG state
  - Select wakeup channel by programming bit SUCC1.WUCS
- Check local BDs whether a WUP was received
- Activate BD of selected wakeup channel

- Command Communication Controller to start wakeup on the configured channel by writing SUCC1.CMD = 0011_B
  - Communication Controller enters WAKEUP
  - Communication Controller returns to READY state and signals status of wakeup attempt to Host
- Wait predefined time to allow the other nodes to wakeup and configure themselves
- Coldstart node: wait for WUP on the other channel
  - In a dual channel cluster wait for WUP on the other channel
  - Reset coldstart inhibit flag CCSV.CSI by writing SUCC1.CMD = 1001_B (ALLOW_COLDSTART command))
- Command Communication Controller to enter startup by writing SUCC1.CMD = 0100_B (RUN command)

Wakeup procedure triggered by BD:

- Wakeup recognized by BD
- BD triggers power-up of Host (if required)
- BD signals wakeup event to Host
- Host configures its local Communication Controller
- If necessary, Host commands wakeup of second channel and waits predefined time to allow the other nodes to wakeup and configure themselves
- Host commands Communication Controller to enter STARTUP state by writing SUCC1.CMD = 0100_B (RUN command)

Wakeup pattern (WUP)

The wakeup pattern is composed of at least two wakeup symbols (WUS). Wakeup symbol and wakeup pattern are configured by the PRT configuration registers PRTC1 and PRTC2.

- Single channel wakeup, wakeup symbol may not be sent on both channels at the same time
- Wakeup symbol collision resilient for up to two sending nodes (two over-lapping wakeup symbols still recognizable)
- Wakeup symbol must be configured identical in all nodes of a cluster
- Wakeup symbol transmit low phase time configured by PRTC2.TXL
- Wakeup symbol idle time used to listen for activity on the bus, configured by PRTC2.TXI
- A wakeup pattern composed of at least two Tx wakeup symbols needed for wakeup
- Number of repetitions configurable by PRTC1.RWP (2 to 63 repetitions)
- Wakeup symbol receive window length configured by PRTC1.RXW
- Wakeup symbol receive low phase time configured by PRTC2.RXL
- Wakeup symbol receive idle time configured by PRTC2.RXI

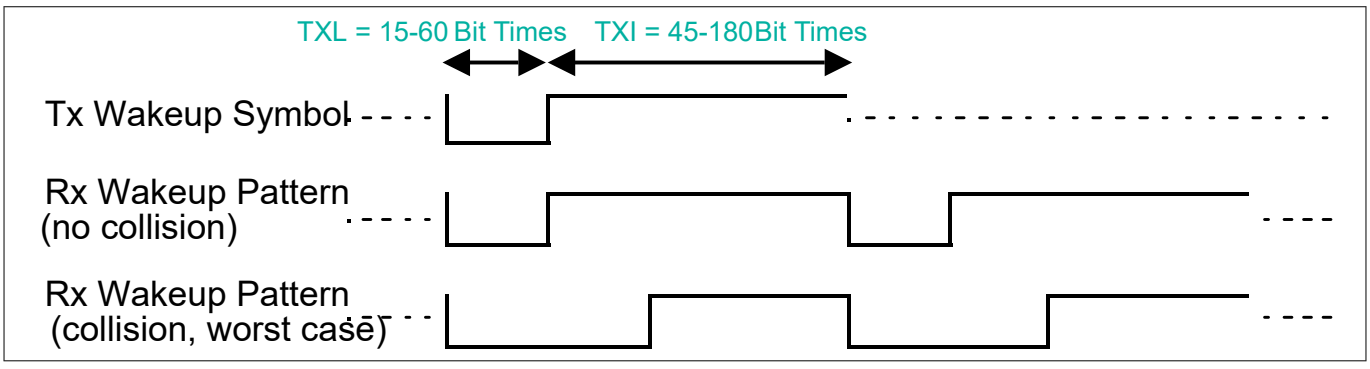

Figure 434 Timing of wakeup pattern

23.3.6.6 STARTUP state

The description here is intended to help configuring startup for the ERAY module. A detailed description of the startup procedure together with the respective SDL diagrams can be found in the FlexRay™ protocol specification v2.1, section 7.2.

Any node entering “STARTUP” state that has coldstart capability should ensure that both channels attached have been woken before initiating coldstart.

It cannot be assumed that all nodes and stars need the same amount of time to become completely awake and to be configured. Since at least two nodes are necessary to start up the cluster communication, it is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal amount of time it takes another coldstart node to become awake, to be configured and to enter startup. It may require several hundred milliseconds (depending on the hardware used) before all nodes and stars are completely awakened and configured.

Startup is performed on all channels synchronously. During startup, a node only transmits startup Frames.

A fault-tolerant, distributed startup strategy is specified for initial synchronization of all nodes. In general, a node may enter “NORMAL_ACTIVE” state through:

- Coldstart path initiating the schedule synchronization (leading coldstart node)
- Coldstart path joining other coldstart nodes (following coldstart node)
- Integration path integrating into an existing communication schedule (all other nodes)

See also figure below.

A coldstart attempt begins with the transmission of a collision avoidance symbol (CAS). Only a coldstart node that had transmitted the CAS transmits Frames in the first four cycles after the CAS, it is then joined firstly by the other coldstart nodes and afterwards by all other nodes.

A coldstart node has the Transmit Startup Frame in Key Slot bit SUCC1.TXST and Transmit SYNC Frame in Key Slot bit SUCC1.TXSY set to 1. The Message Buffer 0 holds the key slot ID which defines the slot number where the Startup Frame is send. In the Frame Header of the Startup Frame the Startup Frame indicator bit is set.

In clusters consisting of three or more nodes, at least three nodes shall be configured to be coldstart nodes. In clusters consisting of two nodes, both nodes must be coldstart nodes. At least two fault-free coldstart nodes are necessary for the cluster to startup.

Each Startup Frame must also be a SYNC Frame; therefore each coldstart node will also be a sync node. The number of coldstart attempts is configured by SUCC1.CSA in the SUC Configuration register 1.

A non-coldstart node requires at least two startup Frames from distinct nodes for integration. It may start integration before the coldstart nodes have finished their startup. It will not finish its startup until at least two coldstart nodes have finished their startup.

Both non-coldstart nodes and coldstart nodes start passive integration through the integration path as soon as they receive SYNC Frames from which to derive the schedule information. During integration the node has to adapt its own clock to the global clock (rate and offset) and has to make its cycle time consistent with the global schedule observable at the network. Afterwards, these settings are checked for consistency with all available network nodes. The node can only leave the integration phase and actively participate in communication when these checks are passed.

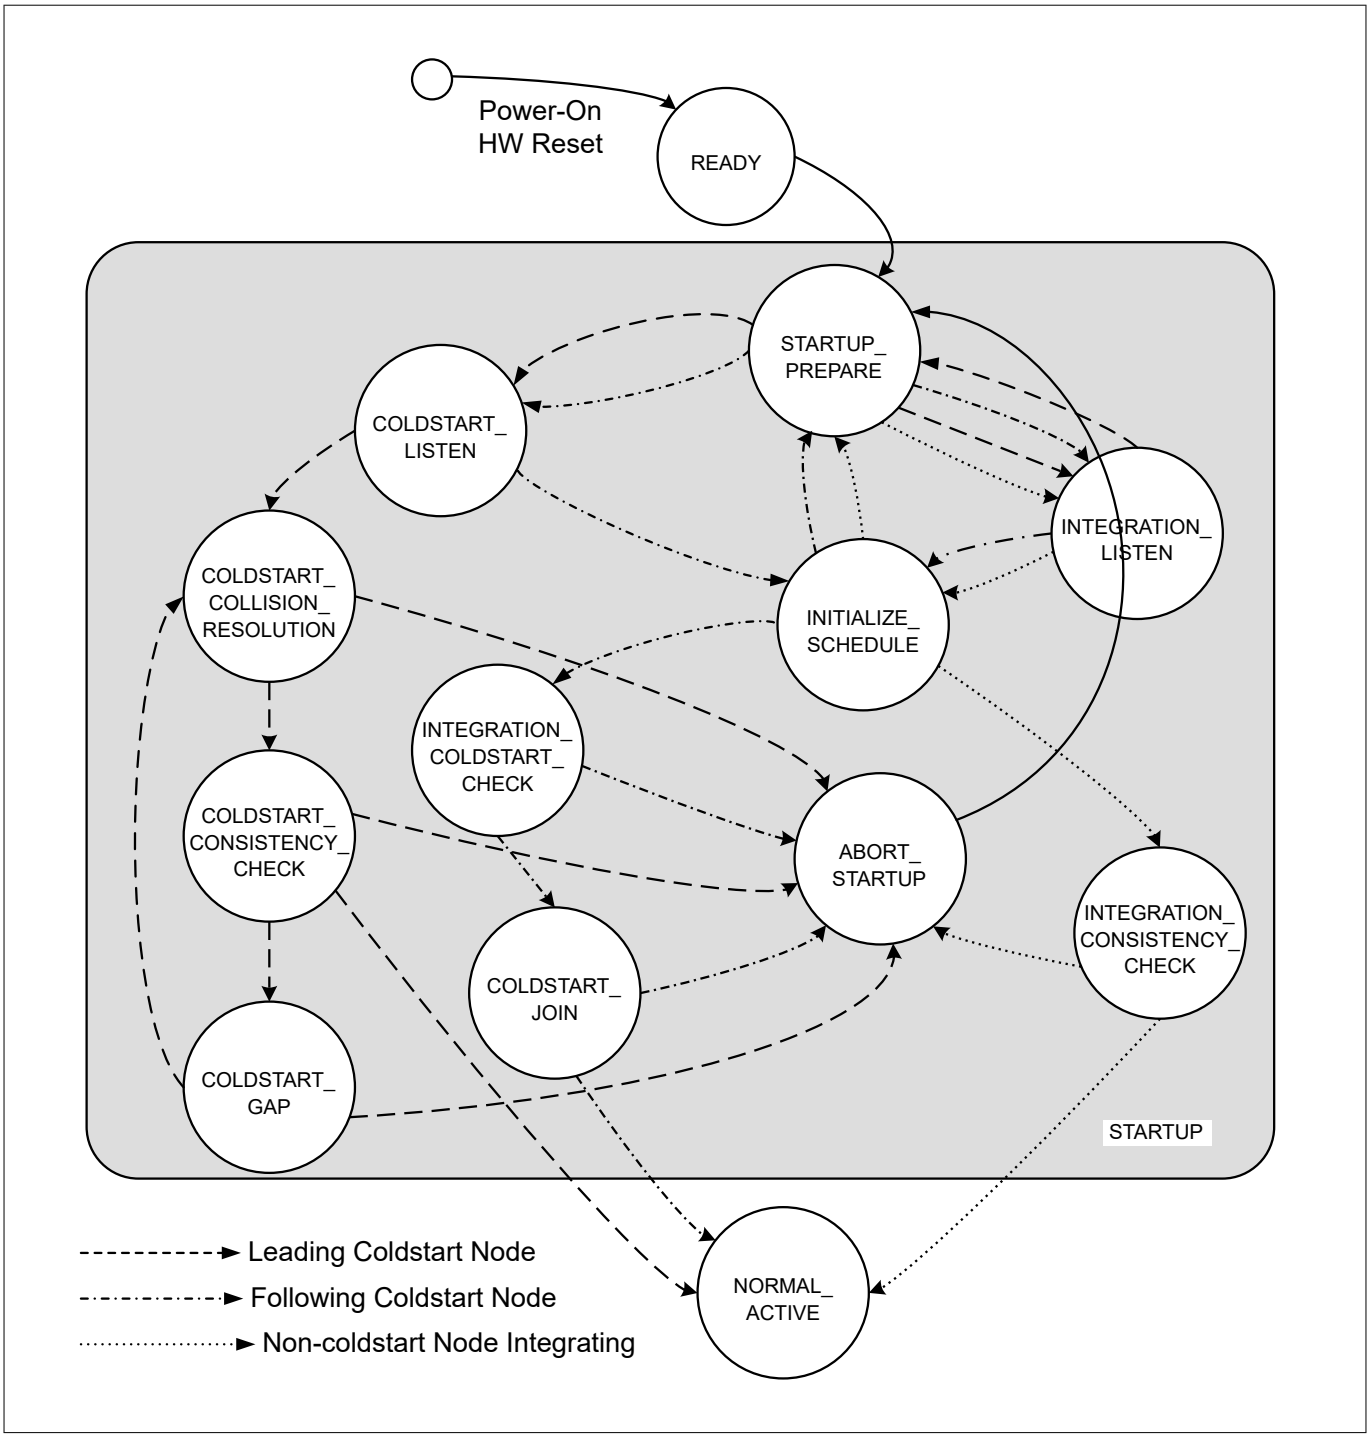

Figure 435 State diagram time-triggered startup

Coldstart inhibit mode

In coldstart inhibit mode the node is prevented from initializing the TDMA communication schedule. If bit CCSV.CSI in the Communication Controller Status Vector register is set, the node is not allowed to initialize the cluster communication, which means that entering the coldstart path is prohibited. The node is allowed to integrate to a running cluster or to transmit startup Frames after another coldstart node started the initialization of the cluster communication.

The coldstart inhibit bit CCSV.CSI is set whenever the POC enters “READY” state. The bit has to be cleared under control of the Host by CHI command ALLOW_COLDSTART (SUCC1.CMD = 1001_B)

23.3.6.6.1 Path of leading coldstart node (initiating coldstart)

When a coldstart node enters “COLDSTART_LISTEN”, it listens to its attached channels.

If no communication is detected, the node enters the “COLDSTART_COLLISION_ RESOLUTION” state and commences a coldstart attempt. The initial transmission of a CAS symbol is succeeded by the first regular cycle. This cycle has the number zero.

From cycle zero on, the node transmits its startup Frame. Since each coldstart node is allowed to perform a coldstart attempt, it may occur that several nodes simultaneously transmit the CAS symbol and enter the coldstart path. This situation is resolved during the first four cycles after CAS transmission.

As soon as a node that initiates a coldstart attempt receives a CAS symbol or a Frame Header during these four cycles, it re-enters the “COLDSTART_LISTEN” state. Thereby, only one node remains in this path. In cycle four, other coldstart nodes begin to transmit their startup Frames.

After four cycles in “COLDSTART_COLLISION_RESOLUTION” state, the node that initiated the coldstart enters the “COLDSTART_CONSISTENCY_CHECK” state. It collects all startup Frames from cycle four and five and performs the clock correction. If the clock correction does not deliver any errors and it has received at least one valid Startup Frame pair, the node leaves “COLDSTART_CONSISTENCY_CHECK” and enters “NORMAL_ACTIVE” state.

The number of coldstart attempts that a node is allowed to perform is configured by SUCC1.CSA in the SUC Configuration Register 1. The number of remaining coldstarts attempts CCSV.RCA can be read from Communication Controller Status Vector register. The number of remaining attempts is reduced by one for each attempted coldstart. A node may enter the “COLDSTART_LISTEN” state only if this value is larger than one and it may enter the “COLDSTART_COLLISION_RESOLUTION” state only if this value is larger than zero. If the number of coldstart attempts is one, coldstart is inhibited but integration is still possible.

Path of following coldstart node (responding to leading coldstart node)

When a coldstart node enters the “COLDSTART_LISTEN” state, it tries to receive a valid pair of startup Frames to derive its schedule and clock correction from the leading coldstart node.

As soon as a valid Startup Frame has been received the “INITIALIZE_SCHEDULE” state is entered. If the clock synchronization can successfully receive a matching second valid Startup Frame and can derive a schedule from this startup Frames, the “INTEGRATION_COLDSTART_CHECK” state is entered.

In “INTEGRATION_COLDSTART_CHECK” state it is assured that the clock correction can be performed correctly and that the coldstart node from which this node has initialized its schedule is still available. The node collects all SYNC Frames and performs clock correction in the following double-cycle. If clock correction does not signal any errors and if the node continues to receive sufficient Frames from the same node it has integrated on, the “COLDSTART_JOIN” state is entered.

In “COLDSTART_JOIN” state integrating coldstart nodes begin to transmit their own startup Frames. Thereby the node that initiated the coldstart and the nodes joining it can check if their schedules agree to each other. If for the following three cycles the clock correction does not signal errors and at least one other coldstart node is visible, the node leaves “COLDSTART_JOIN” state and enters “NORMAL_ACTIVE” state. Thereby it leaves “STARTUP” at least one cycle after the node that initiated the coldstart.

Path of non-coldstart node

When a non-coldstart node enters the “INTEGRATION_LISTEN” state, it listens to its attached channels and tries to receive FlexRay™ Frames.

As soon as a valid Startup Frame has been received, the “INITIALIZE_SCHEDULE” state is entered. If the clock synchronization can successfully receive a matching second valid Startup Frame and derive a schedule from this, the “INTEGRATION_CONSISTENCY_ CHECK” state is entered.

In “INTEGRATION_CONSISTENCY_CHECK” state it is verified that the clock correction can be performed correctly and that enough coldstart nodes (at least 2) send startup Frames that agree to the nodes own schedule. Clock correction is activated, and if any errors are signalled, the integration attempt is aborted.

During the first even cycle in this state, either two valid startup Frames or the Startup Frame of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

During the first double-cycle in this state, either two valid Startup Frame pairs or the Startup Frame pair of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

If after the first double-cycle less than two valid startup Frames are received within an even cycle, or less than two valid Startup Frame pairs are received within a double-cycle, the startup attempt is aborted.

Nodes in this state need to see two valid Startup Frame pairs for two consecutive double-cycles each to be allowed to leave “STARTUP” and enter “NORMAL_ACTIVE”. Consequently, they leave startup at least one double-cycle after the node that initiated the coldstart and only at the end of a cycle with an odd cycle number.

23.3.6.7 NORMAL_ACTIVE state

As soon as the node that transmitted the first CAS symbol (resolving the potential access conflict and entering STARTUP through coldstart path) and one additional node have entered the NORMAL_ACTIVE state, the startup phase for the cluster has finished. In the NORMAL_ACTIVE state, all configured messages are scheduled for transmission. This includes all Data Frames as well as the SYNC Frames. Rate and offset measurement is started in all even cycles (even/odd cycle pairs required).

In “NORMAL_ACTIVE” state the Communication Controller supports regular communication functions

- The Communication Controller performs transmissions and reception on the FlexRay™ bus as configured
- Clock synchronization is running
- The Host interface is operational

The Communication Controller exits from that state to

- HALT state by writing SUCC1.CMD = 0110_B (HALT command, at the end of the current cycle)
- HALT state by writing SUCC1.CMD = 0111_B (FREEZE command, immediately)
- HALT state due to change of the error state from ACTIVE to COMM_HALT
- NORMAL_PASSIVE state due to change of the error state from ACTIVE to PASSIVE
- READY state by writing SUCC1.CMD = 0010_B (READY command)

23.3.6.8 NORMAL_PASSIVE state

NORMAL_PASSIVE state is entered from NORMAL_ACTIVE state when the error state changes from ACTIVE (green) to PASSIVE (yellow).

In NORMAL_PASSIVE state, the node is able to receive all Frames (node is fully synchronized and performs clock synchronization). In comparison to the NORMAL_ACTIVE state the node does not actively participate in communication, that is neither symbols nor Frames are transmitted.

In NORMAL_PASSIVE state:

- The Communication Controller performs reception on the FlexRay™ bus
- The Communication Controller does not transmit any Frames or symbols on the FlexRay™ bus
- Clock synchronization is running
- The Host interface is operational

The Communication Controller exits from this state to

- HALT state by writing SUCC1.CMD = 0110_B (HALT command, at the end of the current cycle)
- HALT state by writing SUCC1.CMD = 0111_B (FREEZE command, immediately)
- HALT state due to change of the error state from PASSIVE to COMM_HALT
- NORMAL_ACTIVE state due to change of the error state from PASSIVE to ACTIVE. The transition takes place when CCEV.PTAC from the Communication Controller Error Vector register equals SUCC1.PTA - 1
- READY state by writing SUCC1.CMD = 0010_B (READY command)

23.3.6.9 HALT state

In this state all communication (reception and transmission) is stopped.

The Communication Controller enters this state:

- By writing SUCC1.CMD = 0110_B (HALT command) while the Communication Controller is in NORMAL_ACTIVE or NORMAL_PASSIVE state
- By writing SUCC1.CMD = 0111_B (FREEZE command) from all states
- When exiting from NORMAL_ACTIVE state because the clock correction failed counter reached the “maximum without clock correction fatal” limit
- When exiting from NORMAL_PASSIVE state because the clock correction failed counter reached the “maximum without clock correction fatal” limit

The Communication Controller exits from this state to DEFAULT_CONFIG state:

- By writing SUCC1.CMD = 0001_B (CONFIG command)

When the Communication Controller enters HALT state, all configuration and status data is maintained for analyzing purposes.

When the Host writes SUCC1.CMD = 0110_B (HALT command) in the SUC Configuration Register 1, the Communication Controller sets bit CCSV.HRQ in the Communication Controller Status Vector register and enters “HALT” state after the current communication cycle has finished.

When the Host writes SUCC1.CMD = 0111_B (FREEZE command) in the SUC Configuration Register 1, the Communication Controller enters “HALT” state immediately and sets the CCSV.FSI bit in the Communication Controller Status Vector register.

The POC state from which the transition to “HALT” state took place can be read from CCSV.PSL.

23.3.6.10 Startup time-outs

The Communication Controller supplies two different Microtick timers supporting two time-out values, startup time-out and startup noise time-out. The two timers are reset when the Communication Controller enters the COLDSTART_LISTEN state. The expiration of either of these timers causes the node to leave the initial sensing phase (COLDSTART_LISTEN state) with the intention of starting up communication.

***Note**: The startup and startup noise timers are identical with the wakeup and wakeup noise timers and use the same configuration values SUCC2.LT and SUCC2.LTN from the SUC Configuration Register 2.*

Startup time-out

The startup time-out limits the listen time used by a node to determine if there is already communication between other nodes or at least one coldstart node actively requesting the integration of others.

The startup timer is configured by programming SUCC2.LT (pdListenTimeout) in the SUC Configuration Register 2.

The startup timer is restarted upon:

- Entering the COLDSTART_LISTEN state
- Both channels reaching idle state while in COLDSTART_LISTEN state

The startup timer is stopped:

- If communication channel activity is detected on one of the configured channels while the node is in the COLDSTART_LISTEN state
- When the COLDSTART_LISTEN state is left

Once the startup time-out expires, neither an overflow nor a cyclic restart of the timer is performed. The timer status is kept for further processing by the startup state machine.

Startup noise time-out

At the same time the startup timer is started for the first time (transition from STARTUP_PREPARE state to COLDSTART_LISTEN state), the startup noise timer is started. This additional time-out is used to improve reliability of the startup procedure in the presence of noise.

The startup noise timer is configured by programming SUCC2.LTN ($\mathrm{gListenNoise} - 1$) in the SUC Configuration Register 2.

The startup noise time-out is: $\mathrm{pdListenTimeout} \times \mathrm{gListenNoise} = \mathrm{SUCC2.LT} \times (\mathrm{SUCC2.LTN} + 1)$

The startup noise timer is restarted upon:

- Entering the COLDSTART_LISTEN state
- Reception of correctly decoded Headers or CAS symbols while the node is in COLDSTART_LISTEN state

The startup noise timer is stopped when the COLDSTART_LISTEN state is left.

Once the startup noise time-out expires, neither an overflow nor a cyclic restart of the timer is performed. The status is kept for further processing by the startup state machine. Since the startup noise timer won't be restarted when random channel activity is sensed, this time-out defines the fall-back solution that guarantees that a node will try to start up the communication cluster even in the presence of noise.

23.3.7 Network management

The accrued Network Management (NM) vector is located in the Network Management Register 1 to Network Management Register 3 ($\mathrm{NMVx}\ (x = 1 - 3)$). The Communication Controller performs a logical OR operation over all Network Management (NM) vectors out of all received valid Network Management (NM) Frames with the Payload Preamble Indicator (PPI) bit set. Only a static Frame may be configured to hold Network Management (NM) information. The Communication Controller updates the Network Management (NM) vector at the end of each cycle.

The length of the Network Management (NM) vector can be configured from 0 to 12 byte by NML in the NEM Configuration Register. The Network Management (NM) vector length must be configured identically in all nodes of a cluster.

To configure a transmit buffer to send FlexRay™ Frames with the PPI bit set, the PPIT bit in the Header Section of the respective transmit buffer has to be set through WRHS1.PPIT. In addition the Host has to write the Network Management (NM) information to the Data Section of the respective transmit buffer.

The evaluation of the Network Management (NM) vector has to be done by the application running on the Host.

***Note**: In case a Message Buffer is configured for transmission or reception of Network Management Frames, the payload length configured in Header 2 of that Message Buffer should be equal or greater than the length of the NM Vector configured by NEMC.NML. When the Communication Controller transits to "HALT" state, the cycle count is not incremented and therefore the NM Vector is not updated. In this case NMV1 to NMV3 holds the value from the cycle before.*

23.3.8 Filtering and masking

Filtering is done by checking specific fields in a received Frame against the corresponding configuration constants of the valid Message Buffers and the actual slot and cycle counter values (acceptance filtering), or by comparing the configuration constants of the valid Message Buffers against the actual slot and cycle counter values (transmit filtering). A Message Buffer is only updated / transmitted if the required matches occur.

Filtering is done on the following fields:

- Channel ID
- Frame ID
- Cycle Counter

The following filter combinations for acceptance/transmit filtering are allowed:

- Frame ID + Channel ID
- Frame ID + Channel ID + Cycle Counter

In order to store a received message in a Message Buffer all configured filters must match.

***Note**: For the FIFO the acceptance filter is configured by the FIFO Rejection Filter and the FIFO Rejection Filter Mask.*

A message will be transmitted in the time slot corresponding to the configured Frame ID on the configured channel(s). If cycle counter filtering is enabled the configured cycle filter value must also match.

23.3.8.1 Frame ID filtering

Every transmit and receive buffer contains a Frame ID stored in the Header Section. This Frame ID is used differently for receive and transmit buffers.

Receive buffers

A received message is stored in the first receive buffer where the received Frame ID matches the configured Frame ID, provided channel ID and cycle counter criteria are also met.

Transmit buffers

For transmit buffers the configured Frame ID is used to determine the appropriate slot for message transmission. The Frame will be transmitted in the time slot corresponding to the configured Frame ID, provided channel ID and cycle counter criteria are also met.

23.3.8.2 Channel ID filtering

There is a 2-bit channel filtering field (CHA, CHB) located in the Header Section of each Message Buffer in the Message RAM. It serves as a filter for receive buffers, and as a control field for transmit buffers (see Table below).

Table 1080 Channel filtering configuration

CHA	CHB	Transmit buffer transmit frame	Receive buffer store valid receive frame
1	1	on both channels (static segment only)	received on channel A or B (store first semantically valid Frame, static segment only)
1	0	on channel A	received on channel A
0	1	on channel B	received on channel B
0	0	no transmission	ignore Frame

***Note**: If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted respectively received Frames are ignored (same function as CHA = CHB = 0).*

Receive buffers

Valid received Frames are stored if they are received on the channels specified in the channel filtering field. Only in static segment a receive buffer may be setup for reception on both channels (CHA and CHB set). Other filtering criteria must also be met.

If a valid Header Segment was stored, the respective MBC flag in the Message Buffer Status Changed register is set. If a valid Payload Segment was stored, the respective $\mathrm{NDn}\ (n = 0 - 31)$ to $\mathrm{NDn}\ (n = 96 - 127)$ flag in the New Data NDAT1 to NDAT4 register is set. In both cases, if bit RDHS1.MBI in the Header Section of the respective

Message Buffer is set, the RXI flag in the Status Service Request Register is set to 1. If enabled, an service request is generated.

Transmit buffers

The content of the buffer is transmitted only on the channels specified in the channel filtering field when the Frame ID filtering and cycle counter filtering criteria are also met. Only in static segment a transmit buffer may be setup for transmission on both channels (CHA and CHB set). After transmission has completed, and if bit WRHS1.MBI in the Header Section of the respective Message Buffer is set, the TXI flag in the Status Service Request Register is set to 1. If enabled, an service request is generated.

23.3.8.3 Cycle counter filtering

Cycle counter filtering is based on the notion of a cycle set. For filtering purposes, a match is detected if any one of the elements of the cycle set is matched. The cycle set is defined by the cycle code field in the Header Section of each Message Buffer.

If Message Buffer 0 is configured to hold the startup / SYNC Frame or the single slot Frame by bits SUCC1.TXST, SUCC1TXSY and SUCC1.TSM in the SUC Configuration Register 1, cycle counter filtering for Message Buffer 0 should be disabled.

***Note**: Sharing of a static time slot through cycle counter filtering between different nodes of a FlexRay™ network is not allowed.*

The set of cycle numbers belonging to a cycle set is determined as described in Table below.

Table 1081 Definition of cycle set

Cycle code	Matching cycle counter values		
$000000x_B$	All cycles		
$000001c_B$	Every second cycle	at (cycle count)mod2	= c
$00001cc_B$	Every fourth cycle	at (cycle count)mod4	= cc
$0001ccc_B$	Every eighth cycle	at (cycle count)mod8	= ccc
$001cccc_B$	Every sixteenth cycle	at (cycle count)mod16	= cccc
$01ccccc_B$	Every thirty-second cycle	at (cycle count)mod32	= ccccc
$1cccccc_B$	Every sixty-fourth cycle	at (cycle count)mod64	= cccccc

Table below gives some examples for valid cycle sets to be used for cycle counter filtering:

Table 1082 Examples for valid cycle sets

Cycle code	Matching cycle counter values
0000011_B	1-3-5-7- ….-63 ↵
0000100_B	0-4-8-12- ….-60 ↵
0001110_B	6-14-22-30- ….-62 ↵
0011000_B	8-24-40-56 ↵
0100011_B	3-35 ↵
1001001_B	9 ↵

Receive buffers

The received message is stored only if the received cycle counter matches an element of the receive buffer's cycle set. Channel ID and Frame ID criteria must also be met.

Transmit buffers

The content of the buffer is transmitted on the configured channels when an element of the cycle set matches the current cycle counter value and the Frame ID matches the slot counter value.

23.3.8.4 FIFO filtering

For FIFO filtering there is one rejection filter and one rejection filter mask available. The FIFO rejection filter consists of 20 bits for Channel (2 bits), Frame ID (11 bits), and Cycle Code (7 bits). Rejection filter and rejection filter mask can be configured in "DEFAULT_CONFIG" or "CONFIG" state only. The filter configuration in the Header Sections of Message Buffers belonging to the FIFO is ignored.

A valid received Frame is stored in the FIFO if channel ID, Frame ID, and cycle counter are not rejected by the configured rejection filter and rejection filter mask, and if there is no matching dedicated receive buffer.

23.3.9 Transmit process

The transmit process is described in the following sections.

23.3.9.1 Static segment

For the static segment, if there are several messages pending for transmission, the message with the Frame ID corresponding to the next sending slot is selected for transmission.

The Data Section of transmit buffers assigned to the static segment can be updated until the end of the preceding time slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

23.3.9.2 Dynamic segment

In the dynamic segment, if several messages are pending, the message with the highest priority (lowest Frame ID) is selected next. Only Frame ID's which are higher than the largest static Frame ID are allowed for the dynamic segment.

In the dynamic segment different slot counter sequences are possible (concurrent sending of different Frame ID's on both channels). Therefore pending messages are selected according to their Frame ID and their channel configuration bit.

The Data Section of transmit buffers assigned to the dynamic segment can be updated until the end of the preceding slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

The start of latest transmit configured by MHDC.SLT in the MHD Configuration Register defines the maximum minislot value allowed before inhibiting new Frame transmission in the dynamic segment of the current cycle.

23.3.9.3 Transmit buffers

A portion of the ERAY Message Buffers can be configured as transmit buffers by programming bit CFG in the Header Section of the respective Message Buffer to 1. This can be done through the Write Header Section 1 register.

There exist the following possibilities to assign a transmit buffer to the Communication Controller channels:

- Static segment
  - Channel A or channel B, channel A and channel B
- Dynamic segment
  - Channel A or channel B

Message Buffer 0 is dedicated to hold the startup Frame, the SYNC Frame, or the designated single slot Frame as configured by TXST, TXSY, and TSM in the SUC Configuration Register 1. In this case it can be reconfigured in “DEFAULT_CONFIG” or “CONFIG” state only. This ensures that any node transmits at most one startup / SYNC Frame per communication cycle. Transmission of startup / SYNC Frames from other Message Buffers is not possible.

All other Message Buffers configured for transmission in static or dynamic segment are reconfigurable during run-time. Due to the organization of the Data Partition in the Message RAM (reference by data pointer), re-configuration of the configured payload length and the data pointer in the Header Section of a Message Buffer may lead to erroneous configurations. If a Message Buffer is reconfigured during run-time, it may happen that this Message Buffer is not send out in the respective communication cycle.

The Communication Controller does not have the capability to calculate the Header CRC. The Host is supposed to provide the Header CRCs for all transmit buffers. If Network Management is required, the Host has to set the PPIT bit in the Header Section of the respective Message Buffer to 1 and write the Network Management information to the Data Section of the Message Buffer.

The payload length field configures the data payload length in 2-byte words. If the configured payload length of a static transmit buffer is shorter than the payload length configured for the static segment by SFDL in the Message Handler Configuration Register 1, the Communication Controller generates padding byte to ensure that Frames have proper physical length. The padding pattern is logical zero.

Each transmit buffer provides a transmission mode flag TXM that allows the Host to configure the transmission mode for the transmit buffer in the static segment. If this bit is set, the transmitter operates in the single-shot mode. If this bit is cleared, the transmitter operates in the continuous mode. In dynamic segment the transmitter always works in single-shot mode.

If a Message Buffer is configured in the continuous mode, the Communication Controller does not reset the transmission request flag TXR after successful transmission. In this case a Frame is sent out each time the Frame ID and cycle counter filter match. The TXR flag can be reset by the Host by writing the respective Message Buffer number to the Input Buffer Command Request register while bit STXRH in the Input Buffer Command Mask register is reset to 0.

If two or more transmit buffers are configured with the same Frame ID and cycle counter filter value, the transmit buffer with the lowest Message Buffer number will be transmitted in the respective slot.

23.3.9.4 Frame transmission

To prepare a transmit buffer for transmission the following steps are required:

- Configure the Message Buffer as transmit buffer by writing bit CFG = 1 in the Write Header Section 1 register
- Write transmit message (Header and Data Section) to the Input Buffer
- To transfer a transmit message from Input Buffer to the Message RAM, proceed as described in the “Data Transfer from Input Buffer to Message RAM” topic
- If configured in the Input Buffer Command Mask register, the Transmission Request flag for the respective Message Buffer will be set as soon as the transfer has completed and the Message Buffer is ready for transmission
- Check whether the Message Buffer has been transmitted by checking the TXR bits (TXR = 0) in the Transmission Request 1, 2, 3, 4 registers (single-shot mode only)

In single-shot mode the Communication Controller resets the TXR flag after transmission has been completed. Now the Host may update the transmit buffer with the next message. The Communication Controller does not

transmit the message before the Host has indicated that the update is completed by setting the Transmission Request flag TXR again. The Host can check the actual state of the TXR flags of all Message Buffers by reading the Transmission Request registers. After successful transmission, if bit WRHS1.MBI in the Header Section of the respective Message Buffer is set, the transmit service request flag in the Status Service Request Register is set (TXI = 1). If enabled, an service request is generated.

Data transfer from input buffer to message RAM on page 4460

23.3.9.5 NULL frame transmission

If in static segment the Host does not set the transmission request flag before transmit time, and if there is no other transmit buffer with matching filter criteria (matching Frame ID and cycle counter filter), the Communication Controller transmits a NULL Frame with the NULL Frame indication bit reset to 0 and the payload data reset to zero.

In the following cases the Communication Controller transmits a NULL Frame with the NULL Frame indication bit reset to 0, and the rest of the Frame Header and the Frame length unchanged (payload data is reset to zero):

- All transmit buffers configured for the slot have cycle counter filters that do not match the current cycle
- There are matching Frame ID's and cycle counter filters, but none of these transmit buffers has the transmission request flag TXR set

NULL Frames are not transmitted in the dynamic segment.

23.3.10 Receive process

The receive process is described in the following sections.

23.3.10.1 Frame reception

To prepare or change a Message Buffer for reception the following steps are required:

- Configure the Message Buffer as receive buffer by writing bit CFG = 0 in the Write Header Section 1 register
- Configure the receive buffer by writing the configuration data (Header Section) to the Input Buffer
- Transfer the configuration from Input Buffer to the Message RAM by writing the number of the target Message Buffer to the Input Buffer Command Request register

Once these steps are performed, the Message Buffer functions as an active receive buffer and participates in the internal acceptance filtering process, which takes place every time the Communication Controller receives a message. The first matching receive buffer is updated from the received message. If the Message Buffer holds an unprocessed Data Section (ND = 1), it is overwritten with the new message and the MLST bit in the respective Message Buffer Status register is set.

If the payload length of a received Frame PLC is longer than the value programmed by PLC in the Header Section of the respective Message Buffer, the data field stored in the Message Buffer is truncated to that length.

If no Frame, a NULL Frame, or a corrupted Frame is received in a slot, the Data Section of the Message Buffer configured for this slot is not updated. In this case only the flags in the Message Buffer Status register are updated to signal the cause of the problem. In addition the respective MBC flag in the Message Buffer Status Changed 1, 2, 3, 4 registers is set.

When the Data Section of a receive buffer has been updated from a received Frame, the respective New Data NDn $\mathrm{NDn}\,(n = 0 - 31)$ to $\mathrm{NDn}\,(n = 96 - 127)$ flag in the New Data NDAT1 to NDAT4 registers is set. When the Message Handler has updated the Message Buffer status, the respective MBC flag in the Message Buffer Status Changed 1, 2, 3, 4 registers is set. If bit RDHS1.MBI in the Header Section of the respective Message Buffer is set, the receive service request flag in the Status Service Request Register is set (RXI = 1). If enabled, an service request is generated.

To read a receive buffer from the Message RAM through the Output Buffer proceed as described on the “Data Transfer from Message RAM to Output Buffer” topic. The ND and MBC flags are automatically cleared by the Message Handler when the received message has been transferred to the Output Buffer.

Related information

Data transfer from message RAM to output buffer on page 4461

23.3.10.2 NULL frame reception

The Payload Segment of a received NULL Frame is not copied into the matching receive buffer. If a NULL Frame has been received, the Header Section of the matching Message Buffer is updated from the received NULL Frame. The NULL Frame indication bit in the Header Section 3 of the respective Message Buffer is reset (NFI = 0) and the respective MBC flag in the Message Buffer Status Changed 1, 2, 3, 4 registers is set.

In case that bit ND and / or MBC were already set before this event because the Host did not read the last received message, bit MLST in the Message Buffer Status register of the respective Message Buffer is also set.

23.3.11 FIFO function

A group of the Message Buffers can be configured as a cyclic First-In-First-Out (FIFO). The group of Message Buffers belonging to the FIFO is contiguous in the register map starting with the Message Buffer referenced by First Buffer of FIFO MRC.FFB bit field and ending with the Message Buffer referenced by Last Configured Buffer MRC.LCB in the Message RAM Configuration register. Up to 128 Message Buffers can be assigned to the FIFO.

23.3.11.1 Description

Every valid incoming message not matching with any dedicated receive buffer but passing the programmable FIFO filter is stored into the FIFO. In this case Frame ID, payload length, receive cycle count, and the status bits of the addressed FIFO Message Buffer are overwritten with Frame ID, payload length, receive cycle count, and the status from the received message and can be read by the Host for message identification. Bit RFNE in the Status Service Request Register shows that the FIFO is not empty, bit RFCL in the Status Service Request Register is set when the receive FIFO fill level FSR.RFFL is equal or greater than the critical level as configured by FSR.CL, bit RFO in the Error Service Request Register shows that a FIFO overrun has been detected. If enabled, service requests are generated.

There are two index registers associated with the FIFO. The PUT Index Register (PIDX) is an index to the next available location in the FIFO. When a new message has been received it is written into the Message Buffer addressed by the PIDX register. The PIDX register is then incremented and addresses the next available Message Buffer. If the PIDX register is incremented past the highest numbered Message Buffer of the FIFO, the PIDX register is loaded with the number of the first (lowest numbered) Message Buffer in the FIFO chain. The GET Index Register (GIDX) is used to address the next Message Buffer of the FIFO to be read. The GIDX register is incremented after transfer of the contents of a Message Buffer belonging to the FIFO to the Output Buffer. The PUT Index Register and the GET Index Register are not accessible by the Host.

The FIFO is completely filled when the PUT index (PIDX) reaches the value of the GET index (GIDX). When the next message is written to the FIFO before the oldest message has been read, both PUT index and GET index are incremented and the new message overwrites the oldest message in the FIFO. This will set FIFO overrun flag RFO in the Error Service Request Register.

A FIFO non empty status is detected when the PUT index (PIDX) differs from the GET index (GIDX). In this case flag RFNE is set. This indicates that there is at least one received message in the FIFO. The FIFO empty, FIFO not empty and the FIFO overrun states for a three Message Buffer FIFO are explained in the figure below.

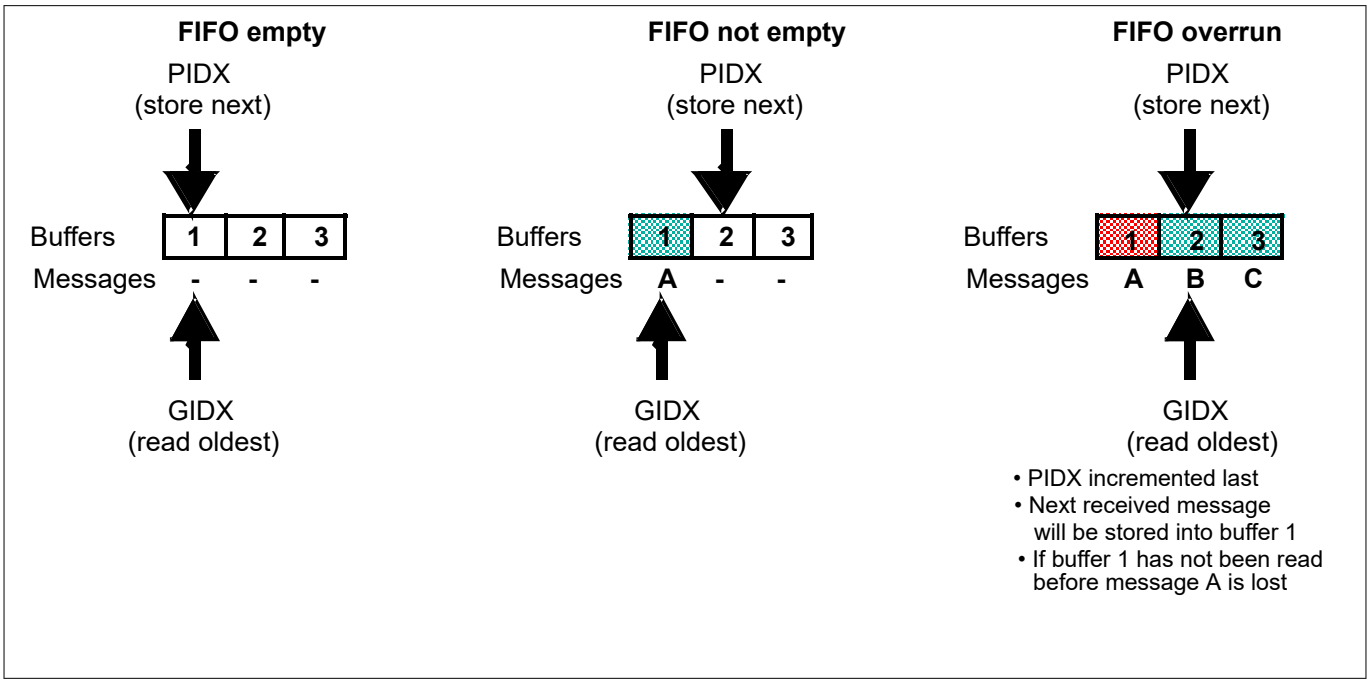

Figure 436 FIFO status: empty, not empty, overrun

There is a programmable FIFO rejection filter for the FIFO. The FIFO Rejection Filter register (FRF) defines a filter pattern for messages to be rejected. The FIFO rejection filter consists of channel filter, Frame ID filter, and cycle counter filter. If bit RSS is set to 1 (default), all messages received in the static segment are rejected by the FIFO. If bit RNF is set to 1 (default), received NULL Frames are not stored in the FIFO.

The FIFO Rejection Filter Mask register (FRFM) specifies which bits of the Frame ID filter in the FIFO Rejection Filter register are marked “do not care” for rejection filtering.

23.3.11.2 Configuration of the FIFO

For all Message Buffers belonging to the FIFO the data pointer to the first 32-bit word of the Data Section of the respective Message Buffer in the Message RAM has to be configured through the Write Header Section 3 register. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask and needs not be configured in the Header Sections of the Message Buffers belonging to the FIFO.

When programming the data pointers for the Message Buffers belonging to the FIFO, the payload length of all Message Buffers should be programmed to the same value.

***Note**: It is recommended to program the MBI bits of the Message Buffers belonging to the FIFO to 0 through WRHS1.MBI to avoid generation of RX interrupts. If the payload length of a received Frame is longer than the value programmed by WRHS2.PLC in the Header Section of the respective Message Buffer, the data field stored in a Message Buffer of the FIFO is truncated to that length.*

23.3.11.3 Access to the FIFO

To read from the FIFO the Host has to trigger a transfer from the Message RAM to the Output Buffer by writing the number of the first Message Buffer of the FIFO (referenced by FFB) to the Output Buffer Command Request register. The Message Handler then transfers the Message Buffer addressed by the GET Index Register (GIDX) to the Output Buffer. After this transfer the GET Index Register (GIDX) is incremented.

23.3.12 Message handling

The Message Handler controls data transfers between the Input or Output Buffer and the Message RAM and between the Message RAM and the two Transient Buffer RAMs. All accesses to the internal RAM’s are 32 bit accesses.

Access to the Message Buffers stored in the Message RAM is done under control of the Message Handler state machine. This avoids conflicts between accesses of the two protocol controllers and the Host to the Message RAM.

Frame IDs of Message Buffers assigned to the static segment have to be in the range from 1 to NSS as configured in the GTU Configuration Register 7. Frame IDs of Message Buffers assigned to the dynamic segment have to be in the range from $\mathrm{NSS} + 1$ to 2047 .

Received messages with no matching dedicated receive buffer (static or dynamic segment) are stored in the receive FIFO (if configured) if they pass the FIFO rejection filter.

23.3.12.1 Host access to message RAM

The message transfer between Input Buffer and Message RAM as well as between Message RAM and Output Buffer is triggered by the Host by writing the number of the target/source Message Buffer to be accessed to the Input or Output Buffer Command Request register.

The Input/Output Buffer Command Mask registers can be used to write/read Header and Data Section of the selected Message Buffer separately. If bit STXRS in the Input Buffer Command Mask register is set (STXRS = 1), the transmission request flag TXR of the selected Message Buffer is automatically set after the Message Buffer has been updated.

If bit STXRS in the Input Buffer Command Mask register is reset (STXRS = 0), the transmission request flag TXR of the selected Message Buffer is reset. This can be used to stop transmission from Message Buffers operated in continuous mode.

Input Buffer (IBF) and the Output Buffer (OBF) are build up as a double buffer structure. One half of this double buffer structure is accessible by the Host (IBF Host/OBF Host), while the other half (IBF Shadow/OBF Shadow) is accessed by the Message Handler for data transfers between IBF/OBF and Message RAM.

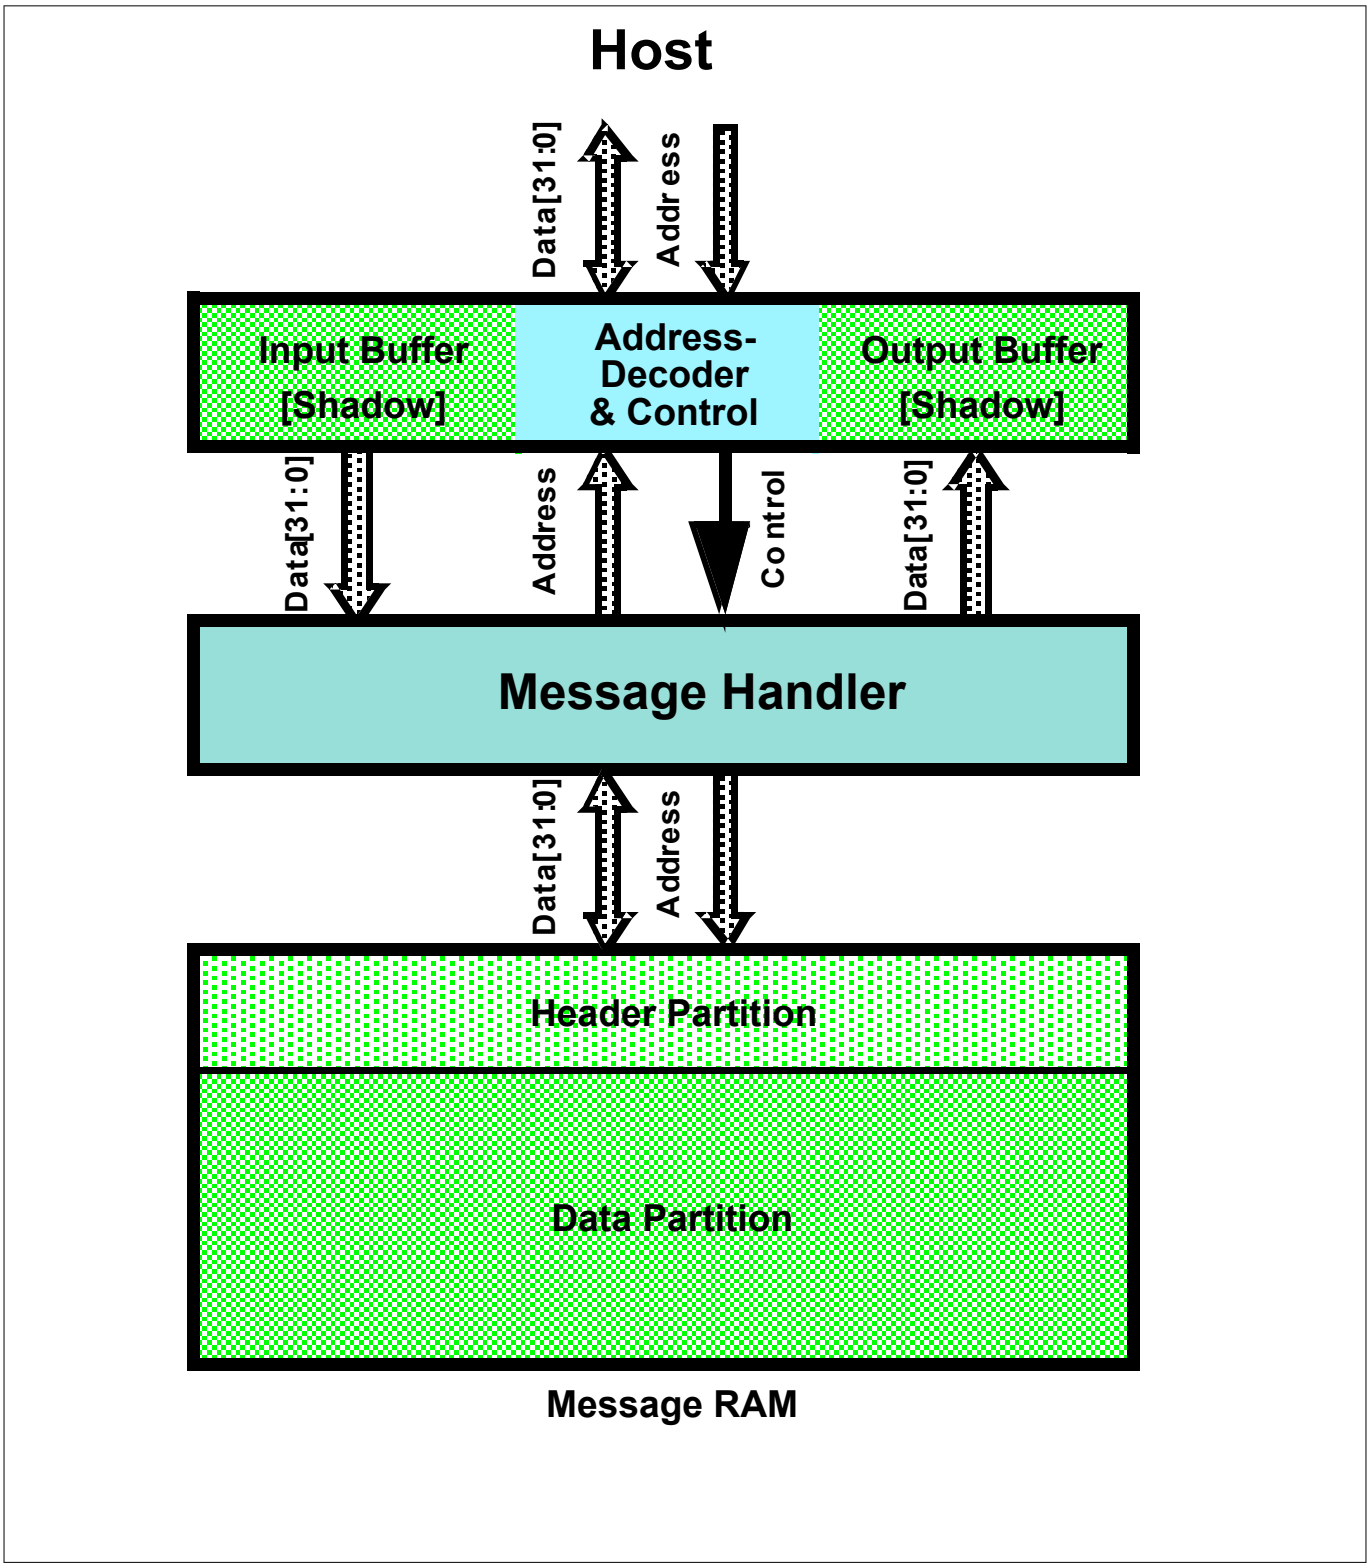

Figure 437 Host access to message RAM

23.3.12.1.1 Data transfer from input buffer to message RAM

To configure or update a Message Buffer in the Message RAM, the Host has to write the data to WRDSn $(n = 1 - 64)$ and the Header to WRHS1, WRHS2, WRHS3. Two sets of WRDSn $(n = 1 - 64)$ are available in parallel and selected by CUST1.IBF1PAG and CUST1.IBF2PAG. CUST1.IBFS shows which Input Buffer is currently used as Input Shadow Buffer and which as Input Host Buffer. WRHS1, WRHS2 and WRHS3 do only exist once. The specific action is selected by configuring the Input Buffer Command Mask IBCM.

When the Host writes the number of the target Message Buffer in the Message RAM to IBRH in the Input Buffer Command Request register IBCR, IBF Host and IBF Shadow are swapped (see figure below).

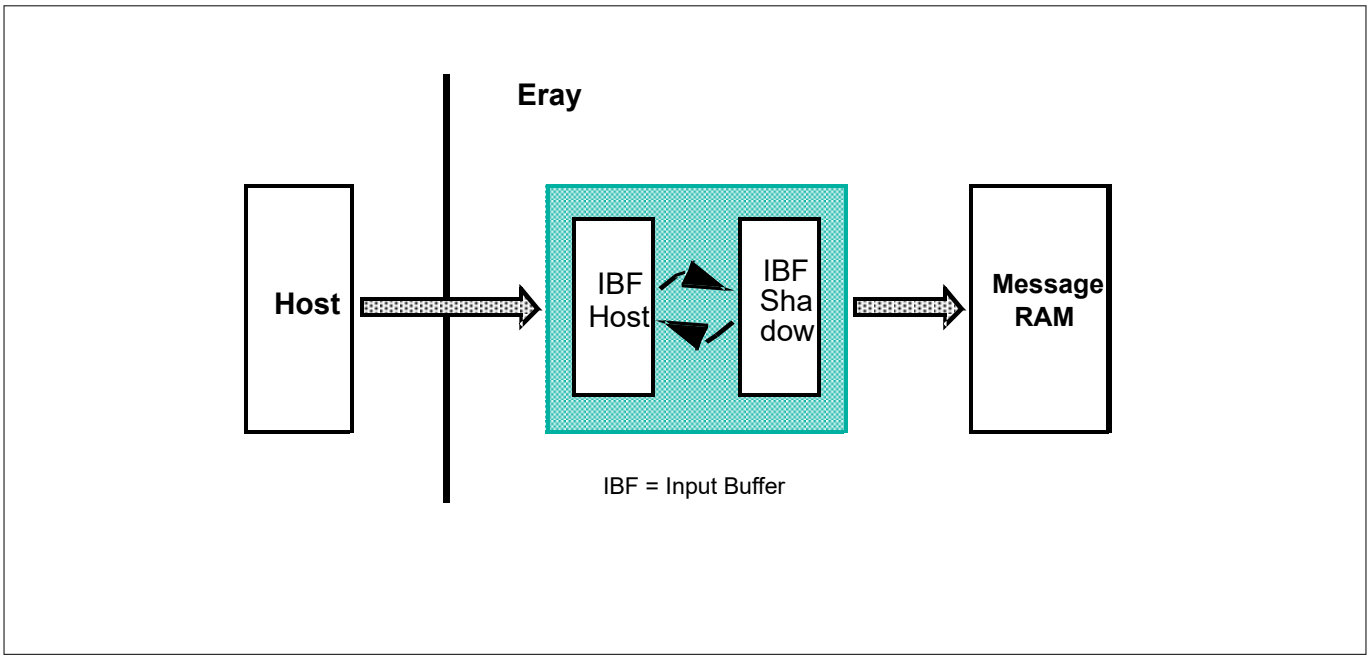

Figure 438 Swapping of IBCM and IBCR Bit

In addition the bits in the Input Buffer Command Mask and Input Buffer Command Request registers are also swapped to keep them attached to the respective IBF section (see Figure below).

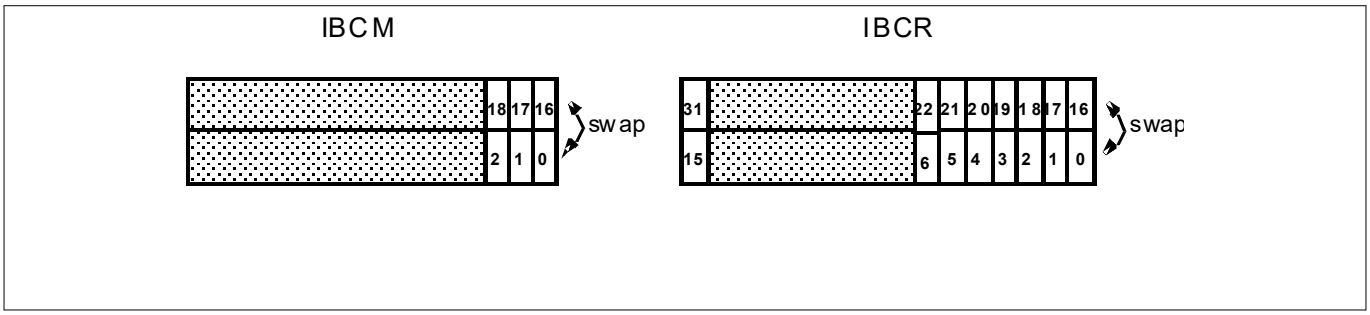

Figure 439 Swapping of IBCM and IBCR Bit

With this write operation the IBSYS bit in the Input Buffer Command Request register is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the Message Buffer in the Message RAM selected by IBRS.

While the Message Handler transfers the data from IBF Shadow to the target Message Buffer in the Message RAM, the Host may write the next message to IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, the IBSYS bit is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target Message Buffer number to IBRH in the Input Buffer Command Request register.

If a write access to IBRH occurs while IBSYS is 1, IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, IBSYH is reset to 0, IBSYS remains

set to 1, and the next transfer to the Message RAM is started. In addition the Message Buffer numbers stored under IBRH and IBRS and the Command Mask flags are also swapped.

Table 1083 Assignment of input buffer command mask bit

Pos.	Access	Bit	Function
18	rh	STXRS	Set transmission request shadow
17	rh	LDSS	Load data section shadow
16	rh	LHSS	Load header section shadow
2	rwh	STXRH	Set transmission request host
1	rwh	LDSH	Load data section host
0	rwh	LHSH	Load header section host

Table 1084 Assignment of input buffer command request bit

Pos.	Access	Bit	Function
31	rh	IBSYS	IBF Busy Shadow, signals ongoing transfer from IBF Shadow to Message RAM
22…16	rh	IBRS	IBF Request Shadow, number of Message Buffer currently or last updated
15	rh	IBSYH	IBF Busy Host, transfer request pending for Message Buffer referenced by IBRH
6-0	rwh	IBRH	IBF Request Host, number of Message Buffer to be updated next

23.3.12.1.2 Data transfer from message RAM to output buffer

To read a Message Buffer from the Message RAM, the Host has to write to Command Request register OBCR to trigger the data transfer as configured in Output Buffer Command Mask OBCM register. After the transfer has completed, the Host can read the transferred data from $\mathrm{RDDSn}\ (n = 1 - 64)$, RDHS1, RDHS2, RDHS3 and MBS.

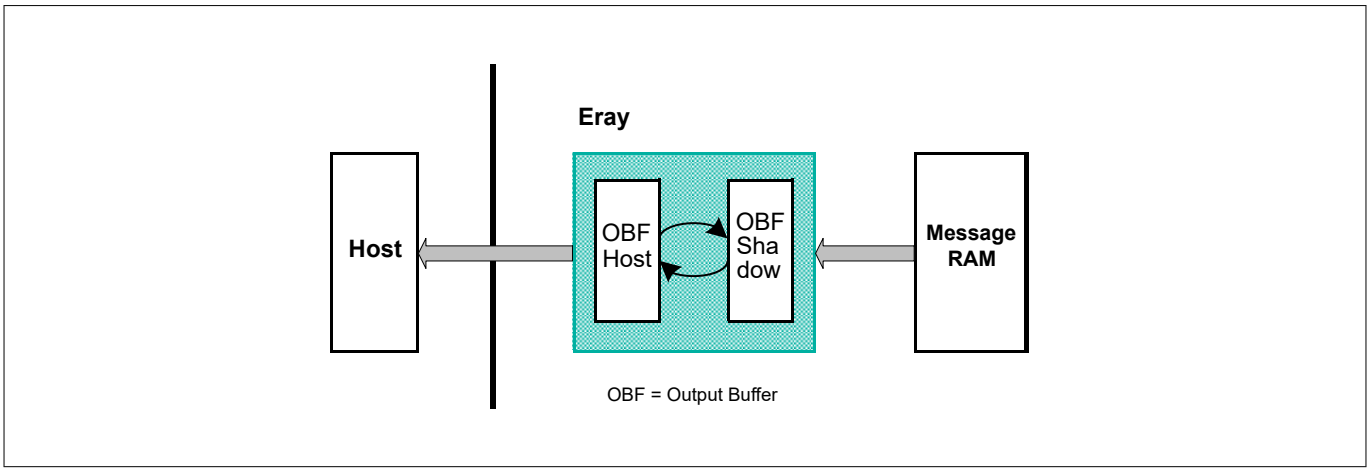

Figure 440 Double buffer structure output buffer

OBF Host and OBF Shadow as well as bits OBCM.RHSS, OBCM.RDSS, OBCM.RHSH, OBCM.RDSH and bits OBCR.OBRS, OBCR.OBRH are swapped under control of bits OBCR.VIEW and OBCR.REQ.

Writing bit OBCR.REQ to 1 copies bits OBCM.RHSS, OBCM.RDSS and bits OBCR.OBRS to an internal storage (see figure below).

After setting OBCR.REQ to 1, OBCR.OBSYS is set to 1, and the transfer of the Message Buffer selected by OBCR.OBRS from the Message RAM to OBF Shadow is started. After the transfer between the Message RAM and OBF Shadow has completed, the OBCR.OBSYS bit is set back to 0. Bits OBCR.REQ and OBCR.VIEW can only be set to 1 while OBCR.OBSYS is 0.

OBF Host and OBF Shadow are swapped by setting bit OBCR.VIEW to 1 while bit OBCR.OBSYS is 0.

In addition bits OBCR.OBRH and bits OBCM.RHSH, OBCM.RDSH are swapped with the registers internal storage thereby assuring that the Message Buffer number stored in OBCR.OBRH and the mask configuration stored in OBCM.RHSH, OBCM.RDSH matches the transferred data stored in OBF Host.

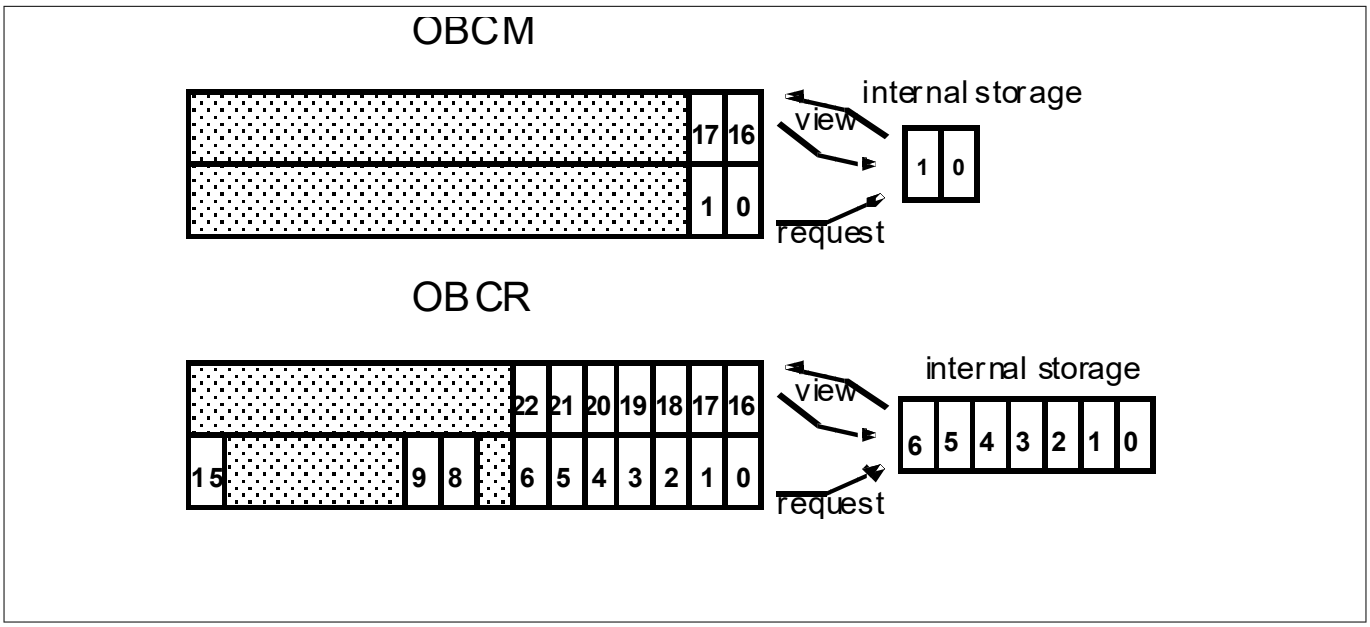

Figure 441 Swapping of OBCM and OBCR Bit

Now the Host can read the transferred Message Buffer from OBF Host while the Message Handler may transfer the next message from the Message RAM to OBF Shadow.

Table 1085 Assignment of output buffer command mask bit

Pos.	Access	Bit	Function
17	rh	RDSH	Data section available for host access
16	rh	RHSH	Header section available for host access
1	rwh	RDSS	Read data section shadow
0	rwh	RHSS	Read header section shadow

Table 1086 Assignment of output buffer command request bit

Pos.	Access	Bit	Function
22…16	rh	OBRH	OBF Request Host number of Message Buffer available for Host access
15	rh	OBSYS	OBF Busy Shadow signals ongoing transfer from Message RAM to OBF Shadow
9	rw	REQ	Request Transfer from Message RAM to OBF Shadow
8	rw	VIEW	View OBF Shadow, swap OBF Shadow, and OBF Host
6…0	rw	OBRS	OBF Request Shadow number of Message Buffer for next request

23.3.12.1.3 Automatic delay write access to OBCR and IBCR

Write and read accesses to the Output Buffer Control Register (OBCR) can be automatically stalled due to a ongoing transfer from the Message Buffer to the Output Buffer. Also write and read accesses to the Input Buffer Control Register (IBCR) may be automatically delayed due to a ongoing transfer from the Input Buffer to the Message Buffer.

This delay scheme can be controlled (enabled or disabled) by CUST1.IEN and CUST1.OEN. The maximum time to stall a write or read access is determined by a single time-out counter preluded with the 32-bit value specified in the bit field CUST3.TO_RV If the time-out counter counts down to zero before the transfer to/from the Message Buffer is completed, the access (read or write) will be canceled and a service request will be generated. A canceled read access provides a 0 value. A canceled write access does not modify any bits in the OBCR or IBCR. In addition the bit CUST1.INT0 of the service request status register will be set and must be reset by the host to disable the service request line.

The read and write access to the Output Buffer Control Register (OBCR) may be configured without automatic delay by clearing CUST1.OEN. Setting OBCR.REQ and immediately afterwards reading or writing OBCR, for example to set OBCR.VIEW will lead to a canceled read or write operation, for example OBCR.VIEW remains cleared, and an error is signaled by a set EIR.IOBA. Besides canceling the erroneous read or write operation, and setting the error bit, no further state change happens. So full operation is granted. OBCR remains read and write inaccessible until the transfer of data from the Message Buffer to the Output Buffer ($\mathrm{MBF} \Rightarrow \mathrm{OBF}$) is completed. During this time span all read and write accesses to the Output Buffer Control Register (OBCR) are canceled. The transfer is completed when OBCR.OBSYS is cleared. Additionally signal SIR.TOBC may be used, for example for service request triggering, DMA triggering, or driving a pin, to communicate the access status.

The read and write access to the Output Buffer Control Register (OBCR) may be configured to be automatic delayed by setting CUST1.OEN and configuring CUST3.TO_RV to the maximum stall time acceptable to the system. If setting OBCR.REQ and immediately afterwards reading or writing to OBCR, for example to set the OBCR.VIEW bit, this read or write will be stalled until either the maximum delay time elapsed (in this case the read or write operation is canceled after the stall time, for example OBCR.VIEW remains cleared, and an error is signaled by setting EIR.IOBA or the read or write completes normally, for example set OBCR.VIEW after the transfer of data from the Message Buffer to the Output Buffer ($\mathrm{MBF} \Rightarrow \mathrm{OBF}$) is finalized. During this time the bus is locked and no further access to the Eray module is possible due to the ongoing stalled read or write operation. Because no access is possible to the Eray module, read or write stall may only be detected through the signal SIR.TOBC or due to other not processed read or write accesses to the Eray module.

The read and write access to the Input Buffer Control Register (IBCR) may also be configured without automatic delay by clearing CUST1.IEN By writing to IBCR.IBRH the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF), the content of the shadow IBF is copied into the MBF ($\mathrm{IBF} \Rightarrow \mathrm{MBF}$), and IBCR.IBSYS is set. Writing to IBCR.IBRH a second time while IBCR.IBSYS remained set (previously initiated copy process IBF MBF ongoing) will correctly update IBCR.IBRH and set IBCR.IBSYH. This will set the signal IBUSY. A third access, read or write, to IBCR while IBCR.IBSYH remains set will cancel this third access and an error is signaled by setting EIR.IIBA. Besides canceling this last access to IBCR and setting the error bit, no further state change happens. So full operation is granted. IBCR remains read and write inaccessible until the transfer of data from the Input Shadow Buffer to the Message Buffer ($\mathrm{IBF} \Rightarrow \mathrm{MBF}$) is completed and once more the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF). During this time span all read and write accesses to the Input Buffer Control Register (IBCR) are canceled. The transfer is completed when IBCR.IBSYH is cleared. Additionally signal SIR.TIBC may be used, for example for service request triggering, DMA triggering, or driving a pin, to communicate the access status.

The read and write access to the Input Buffer Control Register (IBCR) may be configured for being automatically delayed by setting CUST1.IEN and configuring CUST3.TO_RV to the maximum stall time acceptable to the system. By writing to IBCR.IBRH the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF), the content of the shadow IBF copied into the MBF, and IBCR.IBSYS is set. Writing to IBCR.IBRH a second time while IBCR.IBSYS remains set (previously initiated copy process ongoing) will correctly update IBCR.IBRH and set IBCR.IBSYH. This will set the signal IBUSY. A third access to IBCR while IBCR.IBSYH remains set will stall this read or write until either the maximum delay time elapsed (in this case the read or write

operation is cancelled after the stall time and an error is signalled by setting EIR.IOBA or the read or write completes normally, after the transfer of data from the Input Shadow Buffer to the Message Buffer (IBF ⇒ MBF) is finalized and once more the Input Buffers are swapped (shadow IBF changes to host IBF and host IBF to shadow IBF). During this time the bus is locked and no further access to Eray module is possible due to the ongoing stalled read or write operation. Because no access is possible to the Eray module, read or write stall may only be detected through the signal SIR.TIBC or due to other not processed read or write accesses to the Eray module.

So setting CUST3.TO_RV = FFFFFFFFH, CUST1.IEN = 1, and CUST1.OEN = 1 will always grant a consistent data access of the host to the Output and Input Buffers without the need of reading and taking into account the status of OBCR.OBSYS or IBCR.IBSYH. But this simplified access may cause system latencies and system performance loss.

23.3.12.2 Data Transfers between IBF/OBF and message RAM

This document uses the following terms and abbreviations:

Table 1087 Terms and abbreviations

Term	Meaning
MHD	Message Handler
IBF	Input Buffer 1 or 2 RAM
OBF	Output Buffer 1 or 2 RAM
MBF	Message Buffer RAM
TBF	Transient Buffer RAM Channel A (TBF1) or Channel B (TBF2)
IBF ⇒ MBF	Transfer from IBF to MBF
MBF ⇒ OBF	Transfer from MBF to OBF
MBF ⇒ TBF	Transfer from MBF to TBF
TBF ⇒ MBF	Transfer from TBF to MBF
SS	Slot Status
SS ⇒ MBF	Transfer SS to MBF

Message Handler functionality

The MHD controls the access to the MBF. It manages data-transfer between MBF and IBF, OBF, TBF1, TBF2. The data-path are shown in Figure below.

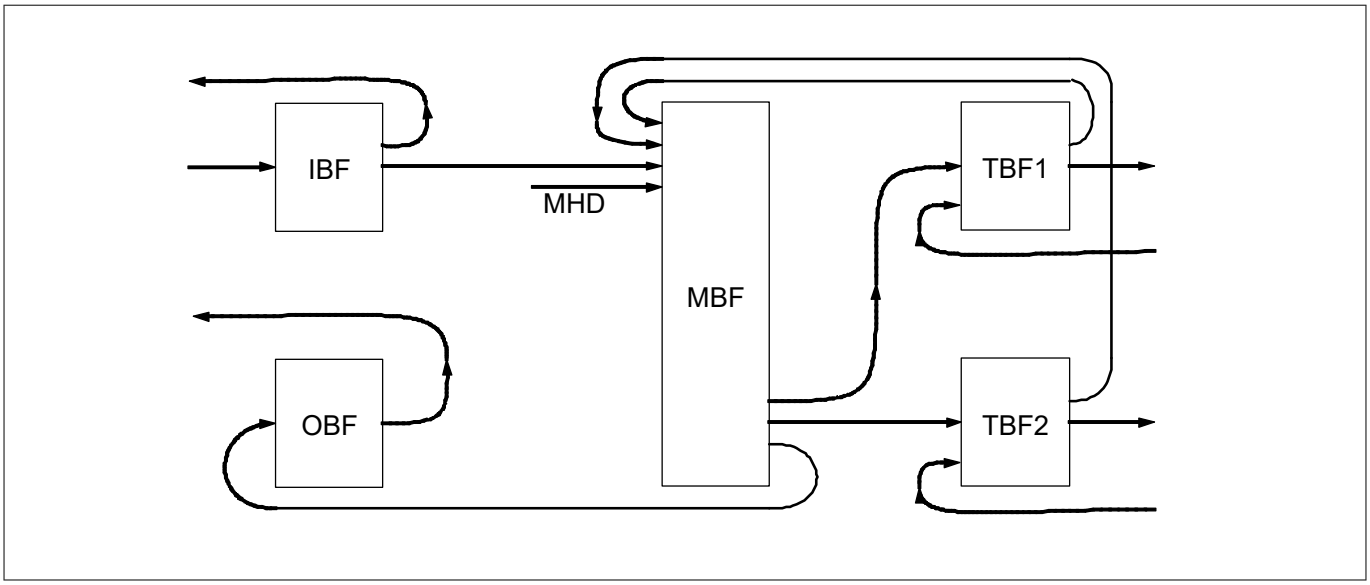

Figure 442 Interconnection of RAMs

Furthermore a search-algorithm allows to find the next valid message object in the MBF for transmission or reception.

Each transfer consists of a setup-time, four time steps to transfer the Header-section and a payload-length-dependent number of time steps to transfer the data-section. The internal data-busses have a width of 32 bits. Thereby it is possible to transfer two 2-byte words in one time step. If the payload consists of an odd number of 2-byte words, the last time step of the data-section contains only 16 bit of valid data. If the Payload-Length (PL) is for example 7, the data-section consists of 4 time steps.

The maximum length for the data-section is 64 time steps, the minimum length is zero time steps.

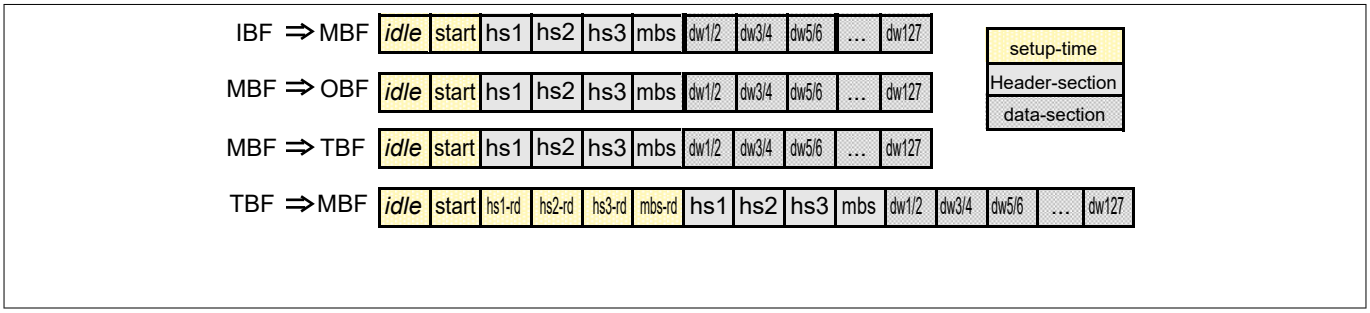

Figure 443 Different possible buffer transfers

The update of the Slot-Status consists of a setup-time and one time-step to write the new Slot-Status.

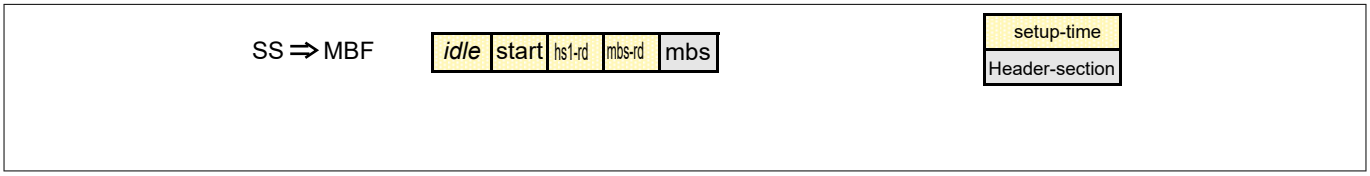

Figure 444 Update of slot status

The length of a time step depends on the number of concurrent tasks.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and MBF
- Data transfer between TBF1 and MBF, search next TX/RX Message Buffer CHA
- Data transfer between TBF2 and MBF, search next TX/RX Message Buffer CHB

Thereby the time step length can vary between one and three f_{CLC_ERAY} periods.

Under certain conditions it is possible that a transfer is stopped or interrupted for a number of time steps until it is continued.

When a IBF ⇒ MBF is started short after a TBF ⇒ MBF or SS ⇒ MBF the transfer from IBF has to wait until the setup-time of the internal transfer has finished (see Figure below)

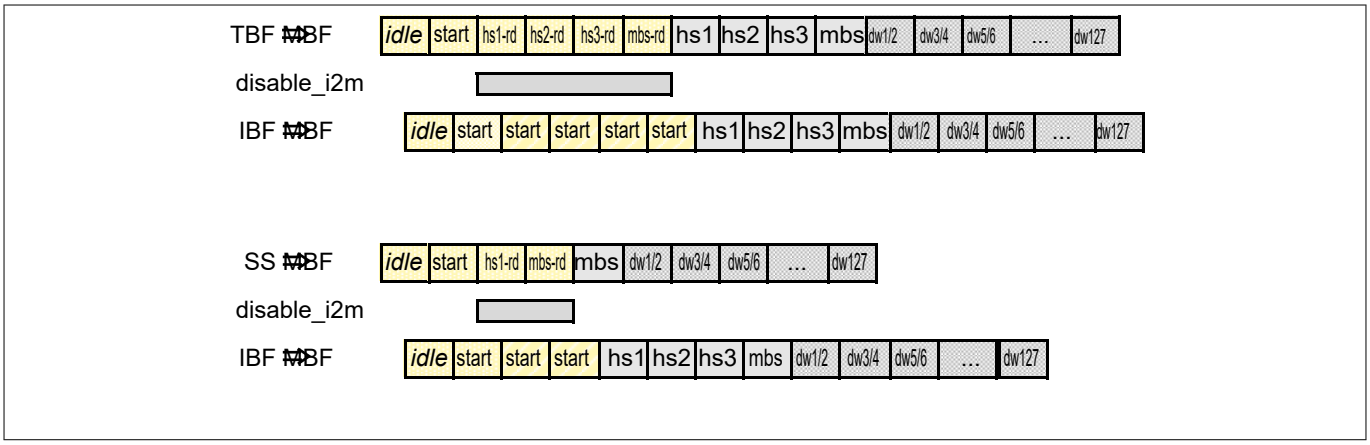

Figure 445 Delay start of IBF ⇒ MBF

The internal signal “disable_i2m” is always active when the TBF ⇒ MBF is in state “hs1-rd”, “hs2-rd”, “hs3-rd” or “mbs-rd” and when the SS ⇒ MBF is in state “hs1-rd” or “mbs-rd”.

The IBF ⇒ MBF is hold in state “start” until the internal signal “disable_i2m” gets inactive.

These additional time-steps are independent of any address-counter-values. This means, the IBF ⇒ MBF has to wait even if it writes to another buffer than the internal transfer.

Multiple requests of transfers between IBF/OBF and message RAM

The time required to transfer the contents of a Message Buffer between IBF / OBF and Message RAM depends on the number of 4-byte words to be transferred, the number of concurrent tasks to be managed by the Message Handler, and in special cases the type and address range of the internal transfer. The number of 4-byte words varies from 4 (Header Section only) to 68 (Header + maximum Data Section) plus a short setup time to start the first transfer, while the number of concurrent task varies from one to three. The 4 Header words have to be included in calculation even if only the Data Section is requested for transfer.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and MBF
- Data transfer between TBF1 and MBF, search next TX/RX Message Buffer CHA
- Data transfer between TBF2 and MBF, search next TX/RX Message Buffer CHB

Transfers between IBF and MBF respectively MBF and OBF can only be handled one after another. In case that for example a IBF ⇒ MBF has been started shortly before a MBF ⇒ OBF is requested, the MBF ⇒ OBF has to wait until the IBF ⇒ MBF has completed.

In case that for example a second IBF ⇒ MBF is requested, a MBF ⇒ OBF is requested and a IBF ⇒ MBF is ongoing, the MBF ⇒ OBF has to wait until the first IBF ⇒ MBF has completed. The second IBF ⇒ MBF has to wait until the MBF ⇒ OBF has completed (see figure below) independent whether MBF ⇒ OBF or second IBF ⇒ MBF is requested first.

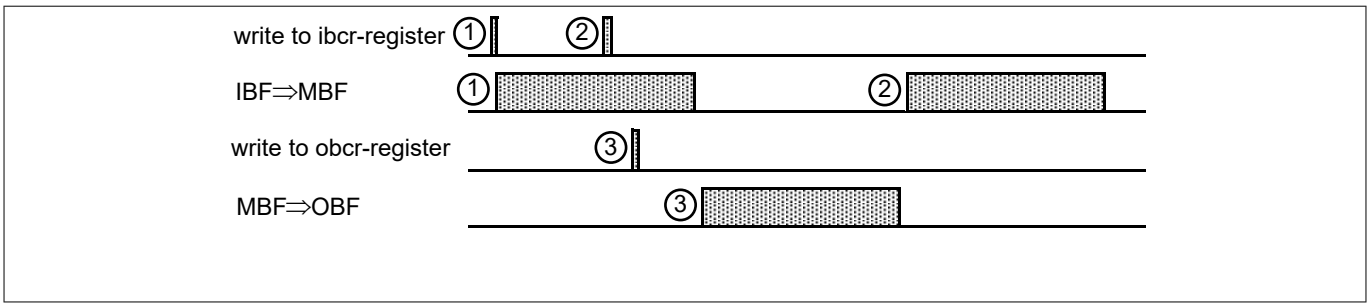

Figure 446 Multiple IBF/OBF request

Worst case for single request

When a message with a large payload length is received the TBF ⇒ MBF is started at the begin of the next slot ($n + 1$). If the next slot is a dynamic slot without transmission/reception (minislot), it may happen that the TBF ⇒ MBF has not finished until begin of the next but one slot ($n + 2$). In this case the TBF ⇒ MBF will be service requested (break) to start a transmission in the next but one slot (MBF ⇒ TBF) and/or to update the slot status (SS ⇒ MBF) for the RX-buffer corresponding with next slot ($n + 1$). After this interruption the TBF ⇒ MBF is continued.

For the transfers IBF ⇒ MBF / MBF ⇒ OBF , TBF ⇒ MBF and MBF ⇒ TBF separate address-counter are implemented, see figure below.

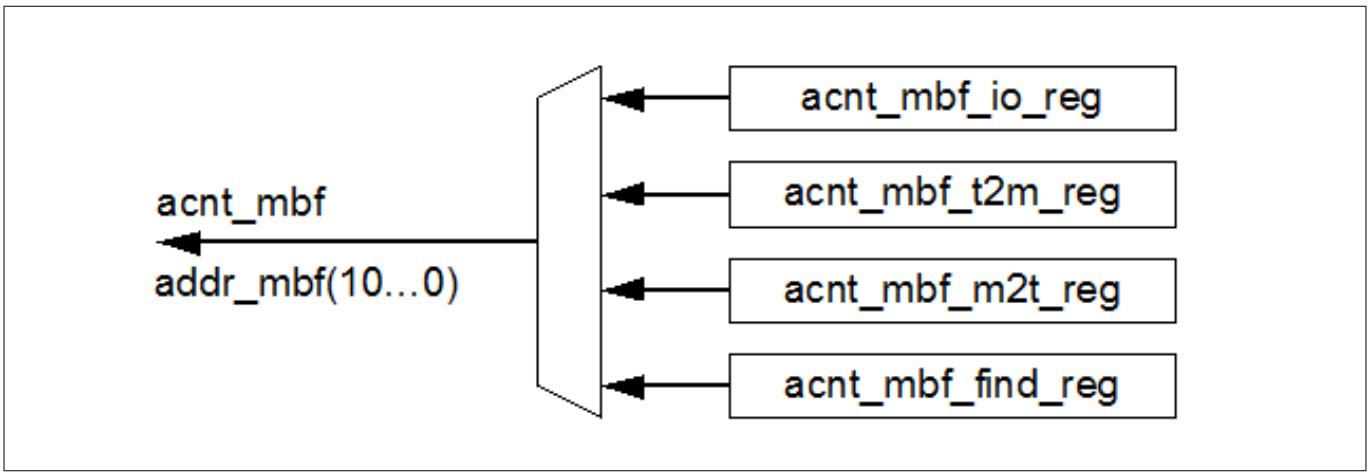

Figure 447 Address counter scheme of message RAM (simplified)

If the address-counter for IBF ⇒ MBF / MBF ⇒ OBF (acnt_mbf_io_reg) reaches the address of the interrupted TBF ⇒ MBF (acnt_mbf_t2m_reg) the IBF ⇒ MBF / MBF ⇒ OBF has to wait until the TBF ⇒ MBF is continued, see figure below.

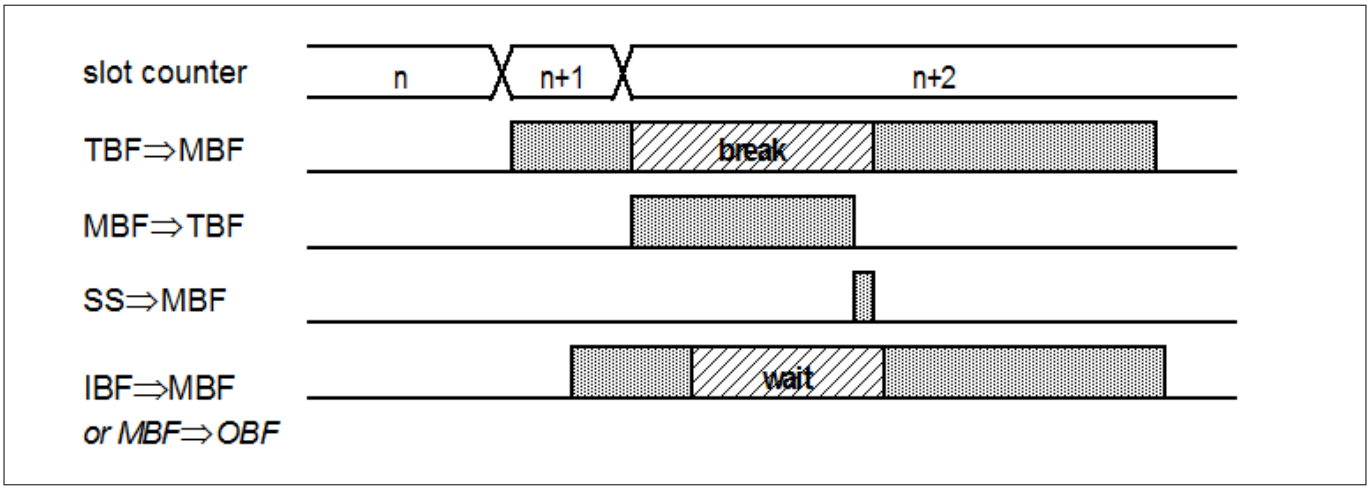

Figure 448 Interruption of TBF to MBF

The relative time is measured in f_{CLC_ERAY} cycles. Absolute time depends on the actual f_{CLC_ERAY} cycle period.

$$\text{tbf_to_mbf_breaktime}_{max} = (\text{setup time} + \text{mbf_to_tbf time}_{max}) + (\text{setup time} + \text{ss_to_mbf})$$

$$\text{cycles}_{req} = \text{number of concurrent tasks} \times \left((\text{setup time} + (\text{number of 4_byte words})_{req}\right) + \text{tbf_to_mbf_break time})$$

$$\text{setup time} = 2 f_{CLC_ERAY} \text{ cycles}$$

Worst case for one transfer

Either IBF ⇒ MBF or MFB ⇒ OBF.

Maximum break time: $\text{tbf_to_mbf_break time}_{max} = (2 + 68) + (4 + 1) = 75$

Maximum number of f_{CLC_ERAY} cycles: $\text{cycles}_{req} = 3 \times (6 + 68 + 75) = 435$

Worst case for multiple transfers

If a second IBF ⇒ MBF and a MBF ⇒ OBF is requested directly after the first IBF ⇒ MBF has started following worst case timing could appear:

$$\text{cycles}_{trans} = (\text{remaining cycles of transfer running}) + (\text{cycles of second request transfer}) + (\text{cycles of third request transfer})$$

$$\text{cycles}_{trans} = \text{cycles}_{rem} + \text{cycles}_{req_2} + \text{cycles}_{req_3}$$

$$\text{cycles}_{trans} = 447 + 435 + 447 = 1329$$

Maximum number of f_{CLC_ERAY} cycles: 1329

23.3.12.3 Minimum f_{CLC_ERAY}

To calculate the minimum f_{CLC_ERAY} the worst case scenario has to be considered.

The worst case scenario depends on the following parameters:

- Maximum payload length
- Minimum minislot length
- Number of configured Message Buffers (excluding FIFO)
- Used channels (single/dual channel)

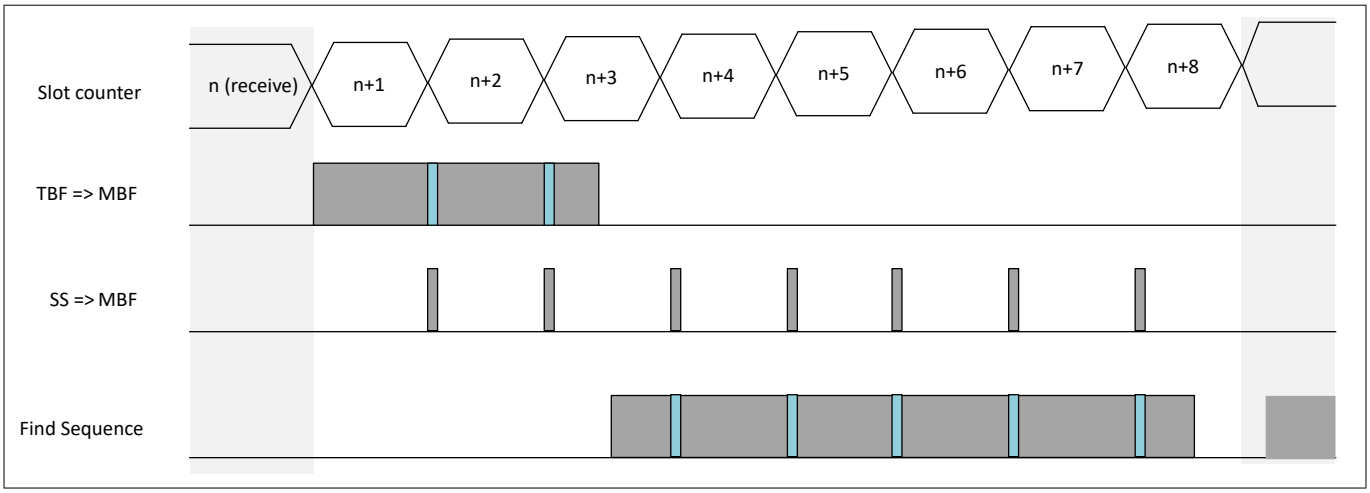

Figure 449 Worst-case scenario

Worst-case scenario:

- Reception of message with a maximum payload length in slot n (n is 7, 15, 23, 31, 39, …)
- Slot $n + 1$ to $n + 7$ are empty dynamic slots (minislot) and configured as receive buffer
- The find-sequence (usually started in slot 8, 16, 24, 32, 40, …) has to scan the maximum number of configured buffers
- The number of concurrent tasks has its maximum value of three

The find-sequence is executed each 8 Slots (slot 8, 16, 24, 32, 40, …). It has to be finished until the next find-sequence is requested.

The length of a TBF ⇒ MBF varies from 4 (Header Section only) to 68 (Header + maximum Data Section) time step plus a setup time of 6 time steps.

$$f_{\mathrm{CLC_ERAY}}\,\mathrm{cycles}_{t2m} = (\text{number of concurrent tasks}) \times (\text{setup time}_{t2m} + (\text{number of 4_byte words})_{t2m})$$

A SS ⇒ MBF has a fixed length of 1 time steps plus a setup time of 4 time steps.

$$f_{\mathrm{CLC_ERAY}}\,\mathrm{cycles}_{\mathrm{ss2}m} = (\text{number ofconcurrent tasks}) \times 5$$

The find sequence has a maximum length of 128 (maximum number of buffers) time steps plus a setup time of 2 time steps.

$$f_{\mathrm{CLC_ERAY}}\,\mathrm{cycles}_{\mathrm{find}} = (\text{number ofconcurrent tasks}) \times (\text{setup time}_{\mathrm{find}} + (\text{number of configured buffers}))$$

A minislot has a length of 2 to 63 Macrotick (gdMinislot). The minimum nominal Macrotick period (cdMinMTNom) is 1 µs. A sequence of 8 minislots has a length of

$$\mathrm{time}_{\mathrm{8minislots}} = 8 \times \mathrm{gdMinislot} \times \mathrm{cdMinMTNom}$$

The maximum period $T_{\mathrm{CLC_ERAY}} = \dfrac{1}{f_{\mathrm{CLC_ERAY}}}$ can be calculated as followed:

$$\mathrm{time}_{\mathrm{8minislots}} \geq (f_{\mathrm{CLC_ERAY}}\,\text{period in µs}) \times (f_{\mathrm{CLC_ERAY}}\,\mathrm{cycles}_{t2m}) + 7 \times (f_{\mathrm{CLC_ERAY}}\,\mathrm{cycles}_{\mathrm{ss2}m}) + (f_{\mathrm{CLC_ERAY}}\,\mathrm{cycles}_{\mathrm{find}}))$$

$$\mathrm{cycletrans} = (\text{remaining cycle of transfer running}) + (\text{cycles of requested transfer})$$

$$\mathrm{minimum} f_{\mathrm{CLC_ERAY}}\,\mathrm{cycles}_{t2m} = 3 \times (6 + 68) = 222$$

$$\mathrm{minimum}\ \mathrm{time}_{\mathrm{8minislots}} = 8 \times 2 \times 1\mu\mathrm{s} = 16\mu\mathrm{s}$$

$$\mathrm{minimum} f_{\mathrm{CLC_ERAY}}\,\mathrm{cycles}_{t2m} = 3 \times (6 + 68) = 222$$

$$\mathrm{minimum} f_{\mathrm{CLC_ERAY}}\,\mathrm{cycles}_{\mathrm{ss2}m} = 3 \times 5 = 15$$

$$\mathrm{minimum} f_{\mathrm{CLC_ERAY}}\,\mathrm{cycles}_{\mathrm{find}} = 3 \times (2 + 128) = 390$$

$$f_{CLC_ERAY}\ \text{period in ms} \leq \frac{16\mu s}{222 + 7 + 15 + 390} \approx 22.315\text{ns}$$

The minimum f_{CLC_ERAY} frequency for this worst case scenario is 44.8125 MHz.

A too low f_{CLC_ERAY} frequency can cause a malfunction of the ERAY.

The ERAY can detect several malfunctions and reports this by setting the corresponding flag in the Message Handler Constraints Flags (MHDF) register.

Minimum f_{CLC_ERAY} for various maximum payload length

Table below summarizes the minimum required f_{CLC_ERAY} frequency for various maximum payload length assuming:

- A minimum minislot length of 2 µs
- A maximum of 128 configured Message Buffers
- Dual channels in use

Table 1088 Minimum f_{CLC_ERAY} for different maximum payload length

Maximum payload length of 32 bit words	4	8	16	32	64
minimum f_{CLC_ERAY}	32.82 MHz	33.57 MHz	35.07 MHz	38.07 MHz	44.1 MHz

Minimum f_{CLC_ERAY} for various minimum minislot length

Table below summarizes the minimum required f_{CLC_ERAY} frequency for various minimum minislot length assuming:

- A maximum payload length of 254 bytes/64 four-byte-words
- A maximum 128 configured Message Buffers
- Dual channels in use

Table 1089 Minimum f_{CLC_ERAY} for different minimum minislot length

gdMinislot at dMinMTNom = 1 µs	2 µs	3 µs	4 µs	7 µs	8 µs
minimum f_{CLC_ERAY}	44.82 MHz	29.88 MHz	22.412 MHz	12.8 MHz	9.96 MHz

Minimum f_{CLC_ERAY} for various amount of configured message buffers

Table below summarizes the minimum required f_{CLC_ERAY} frequency for various amount of configured Message Buffers assuming:

- A maximum payload length of 254 bytes/64 four-byte-words
- A minimum minislot length of 2 µs
- Dual channels in use

Table 1090 Minimum f_{CLC_ERAY} for different amount of configured message buffers

Configured maximum amount of message buffers	128	64	32
minimum f_{CLC_ERAY}	44.82 MHz	32.82 MHz	26.82 MHz

Minimum f_{CLC_ERAY} for a typical configuration

The minimum required f_{CLC_ERAY} frequency for various assuming the following typical ERAY configuration:

- A maximum payload length of 32 bytes/8 four-byte-words

- A minimum minislot length of 7 µs
- A maximum 128 configured Message Buffers
- Dual channels in use

The minimum f_{CLC_ERAY} frequency for this typical example would be 10 MHz.

23.3.12.4 FlexRay™ protocol controller access to message RAM

The two Transient Buffer RAMs (TBF 1, TBF 2) are used to buffer the data for transfer between the two FlexRay™ Protocol Controllers and the Message RAM.

Each Transient Buffer RAM is build up as a double buffer, able to store two complete FlexRay™ messages. There is always one buffer assigned to the corresponding Protocol Controller while the other one is accessible by the Message Handler.

If for example the Message Handler writes the next message to be send to Transient Buffer Tx, the FlexRay™ Channel Protocol Controller can access Transient Buffer Rx to store the message it is actually receiving. During transmission of the message stored in Transient Buffer Tx, the Message Handler transfers the last received message stored in Transient Buffer Rx to the Message RAM (if it passes acceptance filtering) and updates the respective Message Buffer.

Data transfers between the Transient Buffer RAMs and the shift registers of the FlexRay™ Channel Protocol Controllers are done in words of 32 bit. This enables the use of a 32 bit shift register independent of the length of the FlexRay™ messages.

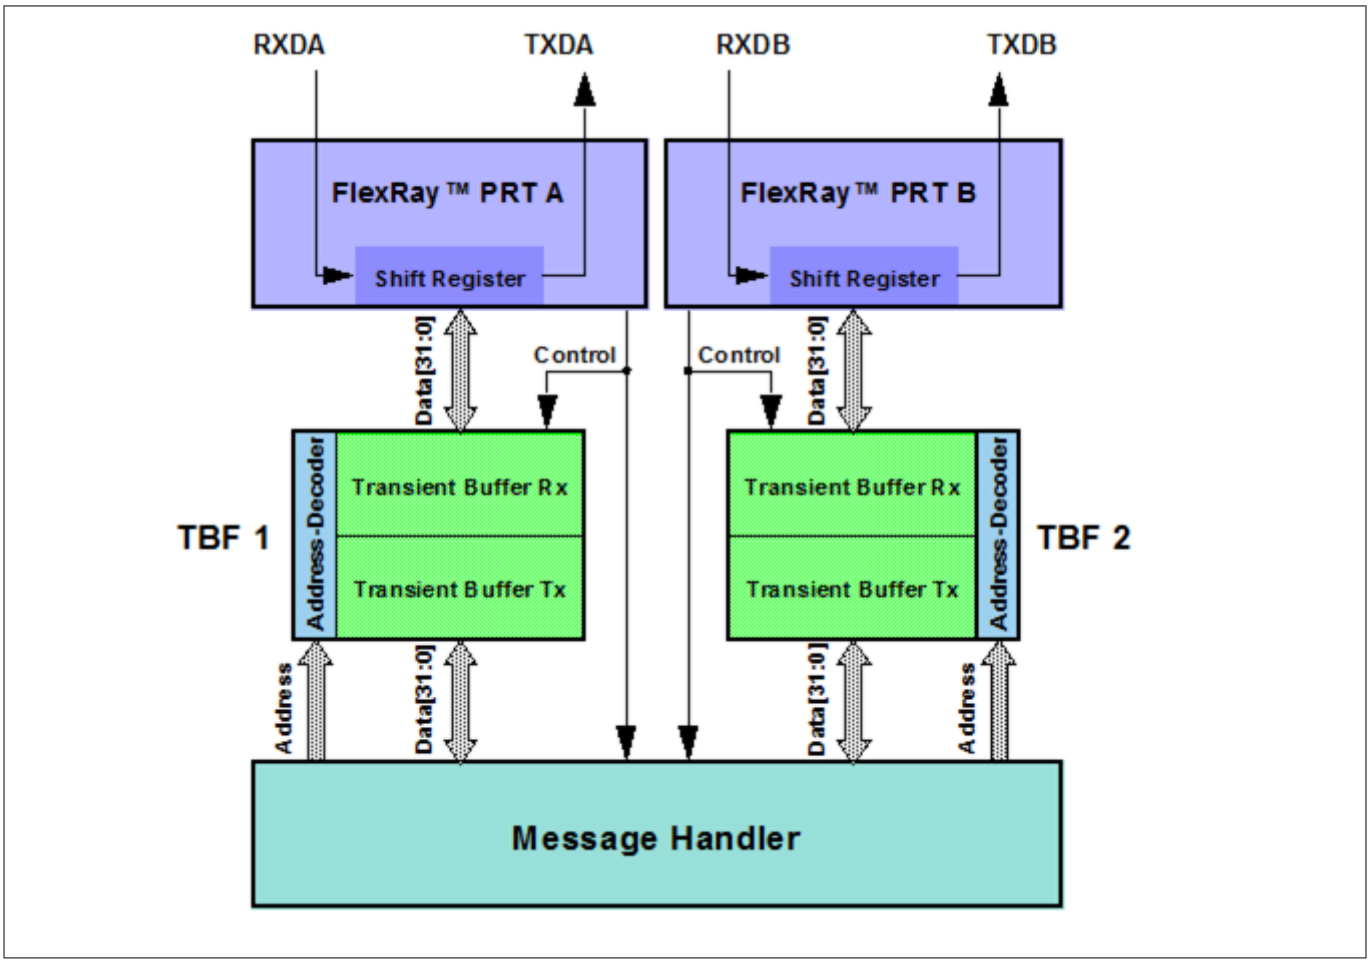

Figure 450 Access to transient buffer RAMs

23.3.13 Message RAM

To avoid conflicts between Host access to the Message RAM and FlexRay™ message reception or transmission, the Host cannot directly access the Message Buffers in the Message RAM. These accesses are handled through the Input and Output Buffers. The Message RAM is able to store up to 128 Message Buffers depending on the configured payload length.

The Message RAM is organized 2048 x 32-bit words. To achieve the required flexibility with respect to different numbers of data byte per FlexRay™ Frame (0 to 254), the Message RAM has a structure as shown in the following figure.

The Data Partition is allowed to start at Message RAM word number: $(\mathrm{MRC.LCB} + 1) \times 4$

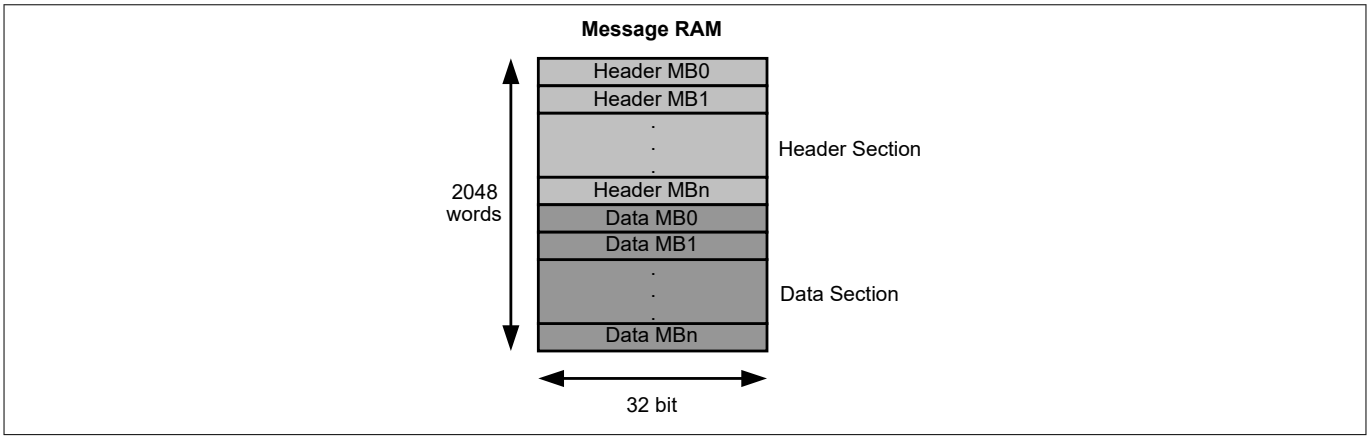

Figure 451 Structure of message RAM

Header partition

Stores Header Segments of FlexRay™ Frames:

- Supports a maximum of 128 Message Buffers
- Each Message Buffer has a Header of four 32 bit words
- Header 3 (Word 2) of each Message Buffer holds the 11 bit pointer to the respective Data Section in the Data Partition

Data partition

Flexible storage of Data Sections with different length. Some maximum values are:

- 30 Message Buffers with 254 byte Data Section each, or
- 56 Message Buffers with 128 byte Data Section each, or
- 128 Message Buffers with 48 byte Data Section each

Restriction: Header Partition + Data Partition may not occupy more than 2048 32-bit words.

23.3.13.1 Header partition

The Header of each Message Buffer occupies four 32-bit words in the Header Partition of the Message RAM. The Header of Message Buffer 0 starts with the first word in the Message RAM.

For transmit buffers the Header CRC has to be calculated by the Host.

Payload Length Received PLR, Receive Cycle Count RCC, Received on Channel Indication RCI, Startup Frame Indication bit SFI, Sync bit SYN, NULL Frame Indication bit NFI, Payload Preamble Indication bit PPI, and Reserved bit RES are only updated from received valid Frames (including valid NULL Frames).

Header word 4 of each configured Message Buffer holds the respective Message Buffer Status MBS information.

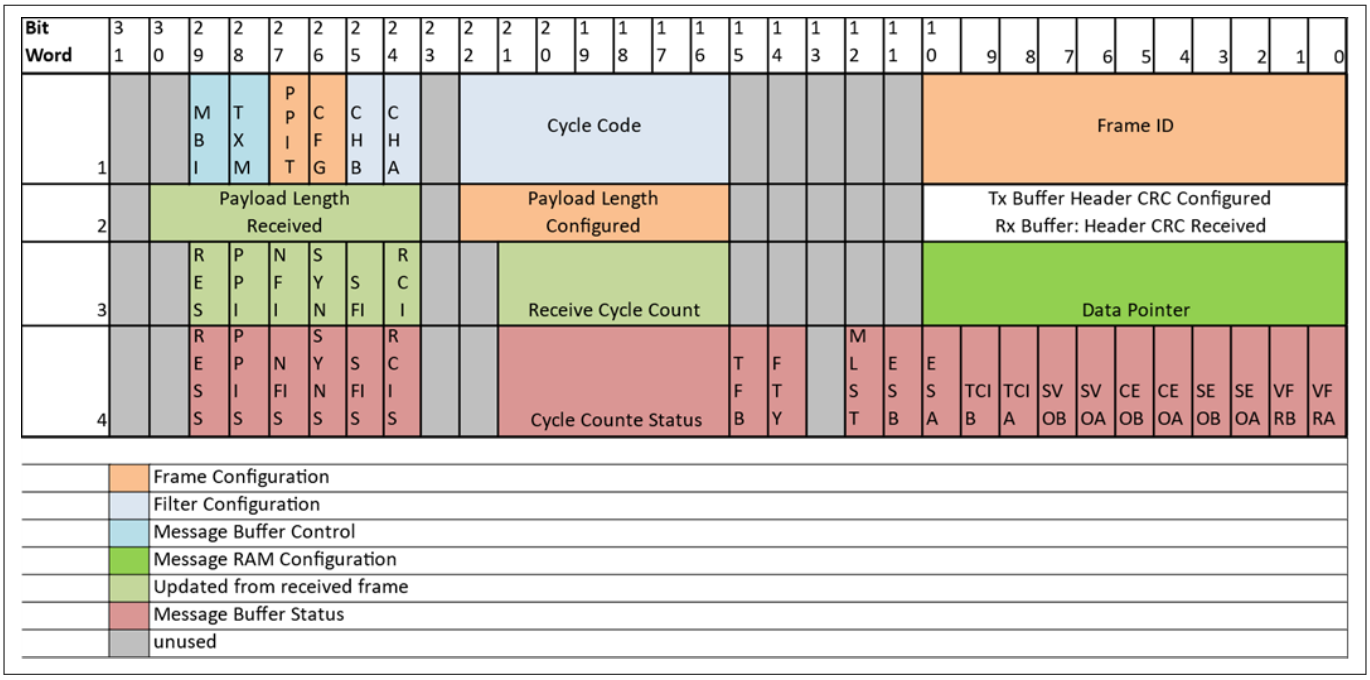

Figure 452 Header section of a message buffer in the message RAM

Header 1 (Word 0)

Write access through WRHS1, read access through RDHS1:

- Frame ID: Slot counter filtering configuration
- Cycle Code: Cycle counter filtering configuration
- CHA, CHB: Channel filtering configuration
- CFG: Message Buffer configuration: receive/transmit
- PPIT: Payload Preamble Indicator Transmit
- TXM: Transmit mode configuration: single-shot/continuous
- MBI: Message Buffer receive/transmit service request enable

Header 2 (Word 1)

Write access through WRHS2, read access through RDHS2:

- Header CRC
  - Transmit Buffer: Configured by the Host (calculated from Frame Header Segment)
  - Receive Buffer: Updated from received Frame

- Payload Length Configured
  - Length of Data Section (2-byte words) as configured by the Host
- Payload Length Received
  - Length of Payload Segment (2-byte words) stored from received Frame

Header 3 (Word 2)

Write access through WRHS3, read access through RDHS3:
- Data Pointer
  - Pointer to the beginning of the corresponding Data Section in the Data Partition

Read access through RDHS3, valid for receive buffers only, updated from received Frames:
- Receive Cycle Count: Cycle count from received Frame
- RCI: Received on Channel Indicator
- SFI: Start-up Frame Indicator
- SYN: SYNC Frame Indicator
- NFI: NULL Frame Indicator
- PPI: Payload Preamble Indicator
- RES: Reserved bit

Message buffer status MBS (Word 3)

Read access through MBS, updated by the Communication Controller at the end of the configured slot.
- VFRA: Valid Frame Received on channel A
- VFRB: Valid Frame Received on channel B
- SEOA: Syntax Error Observed on channel A
- SEOB: Syntax Error Observed on channel B
- CEOA: Content Error Observed on channel A
- CEOB: Content Error Observed on channel B
- SVOA: Slot boundary Violation Observed on channel A
- SVOB: Slot boundary Violation Observed on channel B
- TCIA: Transmission Conflict Indication channel A
- TCIB: Transmission Conflict Indication channel B
- ESA: Empty Slot Channel A
- ESB: Empty Slot Channel B
- MLST: Message LoST
- FTA: Frame Transmitted on Channel A
- FTA: Frame Transmitted on Channel B
- Cycle Count Status: Actual cycle count when status was updated
- RCIS: Received on CHannel Indicator Status
- SFIS: Startup Frame Indicator Status
- SYNS: SYNC Frame Indicator Status
- NFIS: NULL Frame Indicator Status
- PPIS: Payload Preamble Indicator Status
- RESS: Reserved Bit Status

23.3.13.2 Data partition

The Data Partition of the Message RAM stores the Data Sections of the Message Buffers configured for reception / transmission as defined in the Header Partition. The number of data bytes for each Message Buffer

can vary from 0 to 254. To optimize the data transfer between the shift registers of the two FlexRay™ Protocol Controllers and the Message RAM as well as between the Host interface and the Message RAM, the physical width of the Message RAM is set to 4 bytes.

The Data Partition starts after the last word of the Header Partition. When configuring the Message Buffers in the Message RAM the programmer has to assure that the data pointers point to addresses within the Data Partition.

The table below shows an example how the Data Sections of the configured Message Buffers can be stored in the Data Partition of the Message RAM.

The beginning and the end of a Message Buffer's Data Section is determined by the data pointer and the payload length configured in the Message Buffer's Header Section, respectively. This enables a flexible usage of the available RAM space for storage of Message Buffers with different data length.

If the size of the Data Section is an odd number of 2-byte words, the remaining 16 bits in the last 32-bit word are unused.

Table 1091 Example for structure of the data section in the message RAM

Bit Word	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
…	unused								unused								unused								unused

2046	MB0 Data3								MB0 Data2								MB0 Data2								MB0 Data0							
2047	unused								unused								MB0 Data5								MB0 Data4							

23.3.13.3 ECC check

There is an ECC checking mechanism implemented to assure the integrity of the data stored in the seven RAM blocks of the module. The RAM blocks have an ECC generator or checker attached as shown in the following figure:

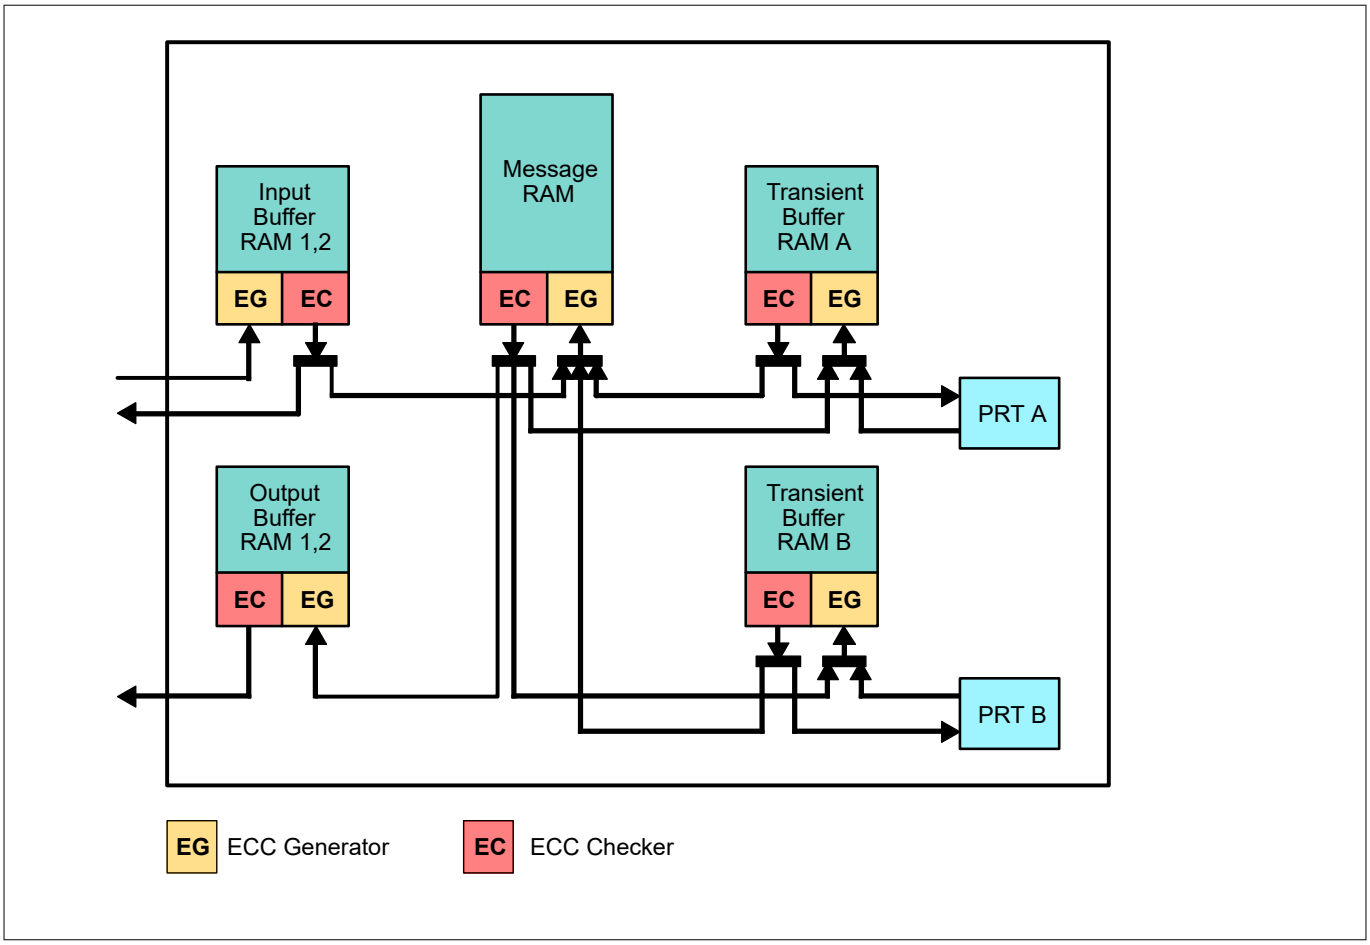

Figure 453 ECC generation and check

When data is written to a RAM block, the local ECC generator generates the ECC data. The ECC data is stored together with the respective data word. The ECC data is checked each time a data word is read from any of the RAM blocks.

If an ECC error is detected, the respective error flag is set. The ECC error flags MHDS.EIBF, MHDS.EOBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2, and the faulty Message Buffer indicators MHDS.FMBD, MHDS.MFMB, MHDS.FMB are located in the Message Handler Status register. These error flags control the error interrupt flag EIR.EERR.

When an ECC error has been detected the following actions will be performed:

In all cases

- The respective ECC error flag in the Message Handler Status MHDS register is set
- The ECC error flag EIR.EERR in the Error Service Request register is set, and if enabled, a module service request to the Host will be generated

Additionally in specific cases

1. ECC error in data transfer from Input Buffer RAM 1, 2 ⇒ Message RAM (Transfer of Header and Data Section)

a. MHDS.EIBF bit is set

b. MHDS.FMBD bit is set to indicate that MHDS.FMB has been updated

c. MHDS.FMB indicates the number of the faulty Message Buffer

d. Transmit buffer: Transmission request for the respective Message Buffer is not set

2. ECC error in data transfer from Input Buffer RAM 1, 2 ⇒ Message RAM (Transfer of Data Section only)
   a. MHDS.EMR bit is set
   b. MHDS.FMBD bit is set to indicate that MHDS.FMB points to a faulty Message Buffer
   c. MHDS.FMB indicates the number of the faulty Message Buffer
   d. The Data Section of the respective Message Buffer is not updated
   e. Transmit buffer: Transmission request for the respective Message Buffer is not set
3. ECC error during host reading Input Buffer RAM
   a. MHDS.EIBF bit is set
4. ECC error during scan of Header Sections in Message RAM
   a. MHDS.EMR bit is set
   b. MHDS.FMBD bit is set to indicate that MHDS.FMB points to a faulty Message Buffer
   c. MHDS.FMB indicates the number of the faulty Message Buffer
   d. Ignore Message Buffer (Message Buffer is skipped)
5. ECC error during data transfer from Message RAM ⇒ Transient Buffer RAM A, B
   a. MHDS.EMR bit is set
   b. MHDS.FMBD bit is set to indicate that MHDS.FMB points to a faulty Message Buffer
   c. MHDS.FMB indicates the number of the faulty Message Buffer
   d. Frame not transmitted, Frames already in transmission are invalidated by setting the Frame CRC to zero
6. ECC error during data transfer from Transient Buffer RAM A, B ⇒ Protocol Controller 1, 2
   a. MHDS.ETBF1, MHDS.ETBF2 bit is set
7. ECC error in data transfer from Transient Buffer RAM A, B ⇒ Message RAM (ECC error when reading Header Section of respective Message Buffer from Message RAM)
   a. MHDS.EMR bit is set
   b. MHDS.FMBD bit is set to indicate that MHDS.FMB points to a faulty Message Buffer
   c. MHDS.FMB indicates the number of the faulty Message Buffer
   d. The Data Section of the respective Message Buffer is not updated
8. ECC error in data transfer from Transient Buffer RAM A, B ⇒ Message RAM (ECC error when reading Transient Buffer RAM A, B)
   a. MHDS.ETBF1, MHDS.ETBF2 bit is set
   b. MHDS.FMBD bit is set to indicate that MHDS.FMB points to a faulty Message Buffer
   c. MHDS.FMB indicates the number of the faulty Message Buffer
9. ECC error during data transfer from Message RAM ⇒ Output Buffer RAM
   a. MHDS.EMR bit is set
   b. MHDS.FMBD bit is set to indicate that MHDS.FMB points to a faulty Message Buffer
   c. MHDS.FMB indicates the number of the faulty Message Buffer
10. ECC error during Host reading Output Buffer RAM
    a. MHDS.EOBF bit is set
11. ECC error during data read of Transient Buffer RAM A, B

If an ECC error occurs while the Message Handler reads a Frame with Network Management information (PPI = 1) from the Transient Buffer RAM A, B the corresponding Network Management vector registers NMV1 to NMV3 are not updated from that Frame.

23.3.13.4 Assignment of message buffers

The assignment of the Message Buffers is done according to the scheme shown in the table below. The number N of available Message Buffers depends on the payload length of the configured Message Buffers. The maximum number of Message Buffers is 128. The maximum payload length supported is 254 byte.

The Message Buffers are separated into three consecutive groups:

- Static Buffers: Transmit or Receive Buffers assigned to static segment

- Static and Dynamic Buffers: Transmit or Receive Buffers assigned to static or dynamic segment
- FIFO- Receive FIFO

Table 1092 Assignment of message buffers

Message Buffer 0	⇓ Static Buffers	
Message Buffer 1		
…		
	⇓ Static + Dynamic Buffers	⇐ FDB
	⇓ FIFO	⇐ FFB
Message Buffer N-1		
Message Buffer N		⇐ LCB

The Message Buffer separation configuration can be changed only in “DEFAULT_CONFIG” or “CONFIG” state by programming the Message RAM Configuration register (MRC).

The first group starts with Message Buffer 0 and consists of static Message Buffers only. Message Buffer 0 is dedicated to hold the startup and SYNC Frame or the single slot Frame, if node transmit one, as configured by SUCC1.TXST, SUCC1.TXSY and SUCC1.TSM in the SUC Configuration Register 1 (SUCC1). Message Buffer 1 may also be used for SYNC Frame transmission in case the SYNC Frames or single-slot Frames should have different payloads on the two channels. In this case bit MRC.SPLM has to be programmed to 1 and Message Buffers 0 and 1 have to be configured with the key slot ID and can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only.

The second group consists of Message Buffers assigned to the static or to the dynamic segment. Message Buffers belonging to this group may be reconfigured during run-time from dynamic to static or vice-versa depending on the state of MRC.SEC.

The Message Buffers belonging to the third group are concatenated to a single receive FIFO.

23.3.14 Host handling of errors

An ECC error caused by transient bit flips can be fixed by:

23.3.14.1 Self-healing

ECC errors located in

- Input Buffer RAM 1, 2
- Output Buffer RAM 1, 2
- Data Section of Message RAM
- Transient Buffer RAM A
- Transient Buffer RAM B

are overwritten with the next write access to the disturbed bit(s) caused by Host access or by FlexRay™ communication.

23.3.14.2 CLEAR_RAMS command

After Power-On Reset, the ERAY RAMs hold arbitrary values which causes ECC errors (MHDS) when a read operation is performed in a ERAY RAM location. For this reason the ERAY RAMs should be initialized always after a Power-On reset. When called in DEFAULT_CONFIG or CONFIG state POC command CLEAR_RAMS initializes all module-internal RAMs to zero. In order to perform a safe initialization of RAM blocks, the following programming sequence is suggested:

1. Enable the clock in the CLC register
2. Read the CLC register back to ensure that the clocks are enabled
3. Set the PROT state register to the required one (for example Run state)
4. Enable the test mode. Take care of the unlock sequence. Refer to description of LCK.TMK and TEST1.WRTEN
5. Check if CCSV.POCS is either 0x0 (DEFAULT_CONFIG) or 0xF (CONFIG). If not in any of these states, perform the according command to get to CONFIG state
6. Check if SUCC1.PBSY is equal to 0x0. If 0x1 wait until 0x0
7. Set SUCC1.CMD to 0xC meaning that the CLEAR_RAMS command is entered
8. Read SUCC1.CMD. If 0x0 the command has not been accepted. Repeat up from step 6. Otherwise continue
9. Wait until the status flag MHDS.CRAM is not cleared (or) wait for 1024 module cycles
10. Enable RAM Test mode: TEST1.TMC = 01b. This mode enables access of all RAM blocks in ERAY module to host
11. CUST1.IBF1PAG = 1b
12. CUST1.IBF2PAG = 1b
13. Repeat steps 6 to 9 and then proceed to step 14
14. CUST1.IBF1PAG = 0b
15. CUST1.IBF2PAG = 0b
16. Read at least one address in all the ERAY RAM blocks
17. Switch off Test Mode: TEST1.TMC = 0b and TEST1.WRTEN = 0b
18. Clear ECC error flags in MHDS and EIR registers

23.3.14.3 Temporary unlocking of header section

An ECC error in the header section of a locked message buffer can be fixed by a transfer from the Input Buffer to the locked buffer Header Section. For this transfer, the write-access to the IBCR (specifying the message buffer number) must be immediately preceded by the unlock sequence normally used to leave CONFIG state (see “Lock Register”). For that single transfer the respective message buffer header is unlocked, regardless whether it belongs to the FIFO or whether its locking is controlled by MRC.SEC[1:0], and will be updated with new data.

23.3.15 Module service request

In general, service requests provide a close link to the protocol timing as they are triggered almost immediately when an error or status change is detected by the controller, a Frame is received or transmitted, a configured timer service request is activated, or a stop watch event occurred. This enables the Host to react very quickly on specific error conditions, status changes, or timer events. On the other hand too many service requests can cause the Host to miss deadlines required for the application. Therefore the Communication Controller supports disable and enable controls for each individual service request source separately.

An service request may be triggered when:

- An error was detected
- A status flag is set
- A timer reaches a per-configured value

- A message transfer from Input Buffer to Message RAM or from Message RAM to Output Buffer has completed
- A stop watch event occurred

Tracking status and generating service requests when a status change or an error occurs are two independent tasks. Regardless of whether an service request is enabled or not, the corresponding status is tracked and indicated by the Communication Controller. The Host has access to the actual status and error information by reading the Error Service Request Register EIR and the Status Service Request SIR Register.

Table 1093 Module service request flags and service request line enable

Register	Bit	Function
SIR	WST	Wakeup Status
	CAS	Collision Avoidance Symbol
	CYCS	Cycle Start Service Request
	TXI	Transmit Service Request
	RXI	Receive Service Request
	RFNE	Receive FIFO not Empty
	RFCL	Receive FIFO Critical Level
	NMVC	Network Management Vector Changed
	TI0	Timer Service Request 0
	TI1	Timer Service Request 1
	TIBC	Transfer Input Buffer Completed
	TOBC	Transfer Output Buffer Completed
	SWE	Stop Watch Event
	SUCS	Startup Completed Successfully
	MBSI	Message Buffer Status Interrupt
	SDS	Start of Dynamic Segment
	WUPA	Wakeup Pattern Channel A
	MTSA	MTS Received on Channel A
	WUPB	Wakeup Pattern Channel B
	MTSB	MTS Received on Channel B
ILE	EINT0	Enable Service Request Line 0
	EINT1	Enable Service Request Line 1
EIR	PEMC	Protocol Error Mode Changed
	CNA	Command Not Valid
	SFBM	SYNC Frames Below Minimum
	SFO	SYNC Frame Overflow
	CCF	Clock Correction Failure
	CCL	CHI Command Locked

(table continues...)

Table 1093 (continued) Module service request flags and service request line enable

Register	Bit	Function
	EERR	ECC Error
	RFO	Receive FIFO Overrun
	EFA	Empty FIFO Access
	IIBA	Illegal Input Buffer Access
	IOBA	Illegal Output Buffer Access
	MHF	Message Handler Constraints Flag
	EDA	Error Detected on Channel A
	LTVA	Latest Transmit Violation Channel A
	TABA	Transmission Across Boundary Channel A
	EDB	Error Detected on Channel B
	LTVB	Latest Transmit Violation Channel B
	TABB	Transmission Across Boundary Channel B

The interrupt lines to the Host INT0SRC and INT1SRC are controlled by the enabled interrupts. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit ILE.EINT0/INT0SRC.SRE and ILE.EINT1/ INT1SRC.SRE.

The interrupt lines to the HostNDAT0SR and NDAT1SR are controlled by the enabled new data interrupts (NDIC1 to NDIC4). In addition each of the two interrupt lines can be enabled / disabled separately by programming bit NDAT0SRC.SRE and NDAT1SRC.SRE.

The interrupt lines to the Host MBSC0SR and MBSC1SR are controlled by the enabled message buffer status changed interrupts (MSIC1 to MSIC4). In addition each of the two interrupt lines can be enabled / disabled separately by programming bit MBSC0SRC.SRE and MBSC1SRC.SRE.

The two timer service requests generated by service request timer 0 and 1 are available on pins TINT0SR and TINT1SR. They can be configured through the Timer 0 and Timer 1 Configuration register. In addition each of the two interrupt lines can be enabled and disabled separately by programming bit TINT0SRC.SRE and TINT1SRC.SRE.

A stop watch event may be triggered through input pin STPWn.

The status of the data transfer between IBF and OBF and the Message RAM is signaled on signals IBUSY and OBUSY. When a transfer has completed bit SIR.TIBC or SIR.TOBC is set.

23.3.16 Restrictions

The following restrictions must be considered when programming the module. A violation of these restrictions may lead to an erroneous behavior.

23.3.16.1 Message buffers with the same frame ID

If two or more Message Buffers are configured with the same Frame ID, and if they have a matching cycle counter filter value for the same slot, then the Message Buffer with the lowest Message Buffer number is used.

Sharing of a static time slot through cycle counter filtering between different nodes of a FlexRay™ network is not allowed.

23.3.16.2 Data transfers between IBF, OBF and message RAM

The time required to transfer the contents of a Message Buffer between IBF, OBF and Message RAM depends on

- The setup time to start the first transfer
- The number of 4-byte words to be transferred
- The number of concurrent tasks to be managed by the Message Handler

The number of 4-byte words varies from 4 (Header Section only) to 68 (Header + maximum Data Section) while the number of concurrent task varies from one to three.

The following concurrent tasks are executed under control of the Message Handler:

- Data transfer between IBF or OBF and Message RAM
- Data transfer between TBF1 and Message RAM, search next TX/RX Message Buffer CHA
- Data transfer between TBF2 and Message RAM, search next TX/RX Message Buffer CHB

Transfers between IBF and Message RAM respectively Message RAM and OBF can only be handled one after another. In case that for example a transfer between IBF and Message RAM has been started shortly before a transfer between Message RAM and OBF is requested, the OBF transfer has to wait until the IBF transfer has completed.

The relative time is measured in f_{CLC_ERAY} cycles. Absolute time depends on the actual f_{CLC_ERAY} cycle period.

- $\text{cyclestrans} = (\text{remaining cyclesof transfer running}) + (\text{cycles of requested transfer})$,
- $\text{cyclestrans} = \text{cyclesrem} + \text{cyclesreq}$,
- $\text{cyclesrem} = (\text{number ofconcurrent tasks}) \times (\text{setuptime} + (\text{number of 4_byte words})\text{rem})$,
- $\text{cyclesreq} = (\text{number of concurrent tasks}) \times (\text{setup time} + (\text{number of 4_byte words})\text{req})$,
- setup time = 2 f_{CLC_ERAY} cycles

Under worst case conditions a transfer is requested directly after the previous transfer started:

Maximum number of f_{CLC_ERAY} cycles:

- $\text{cyclestrans} = (3 \times (2 + 68)) + (3 \times (2 + 68)) = 420$

Worst case timing:

- $\text{timetrans}(40\ \text{MHz}) = 420 \times 25\ \text{ns} = 10.5\ \mu s$

23.4 Registers

23.4.1 Register overview - access mode glossary

Table 1094 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
BE	Always returns a Bus Error.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

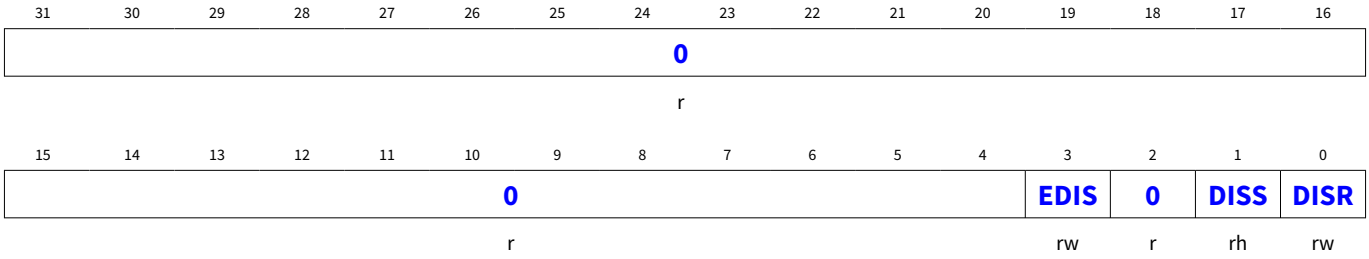
23.4.3 Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 0000_H

Clock Control Register Application Reset value: $0000\ 0003_H$



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

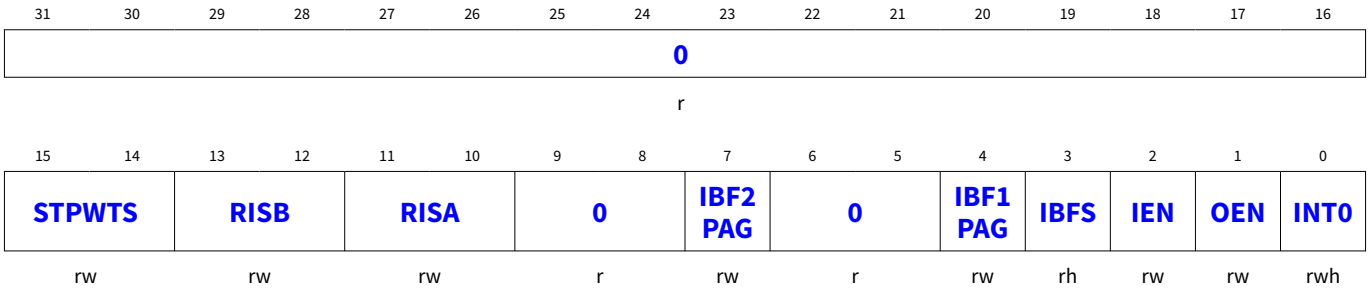
23.4.4 Busy and Input Buffer Control Register

The Busy Control Register enables the automatic delay scheme. Furthermore it signals a time-out service request for the automatic delay scheme. IBFS changes 2 clock cycles after any reset to '1'. Thus the application will read this bit as '1' already at first access after any reset.

***Note**: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all ´rwh´ bits in this register.*

CUST1 Offset address: 0004_H

Busy and Input Buffer Control Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
INT0	0	rwh	**CIF Timeout Service Request Status** INT0 will be set if a timeout has occurred during the auto delay scheme and must be reset by writing zero to INT0. Software can also set this bit field. ***Note**: In case hardware sets INT0 and at the same point of time software clears INT0, INT0 is cleared.*
OEN	1	rw	**Enable auto delay scheme for Output Buffer Control Register (OBCR)** This control bit controls the delay scheme for Output Buffer Control Register (OBCR) read accesses. 0_B Disable auto delay scheme for Output Buffer Control Register (OBCR) 1_B Enable auto delay scheme for Output Buffer Control Register (OBCR)
IEN	2	rw	**Enable auto delay scheme for Input Buffer Control Register (IBCR)** This control bit controls the auto delay scheme for Input Buffer Control Register (IBCR) read accesses. 0_B Disable auto delay scheme for Input Buffer Control Register (IBCR) 1_B Enable auto delay scheme for Input Buffer Control Register (IBCR)
IBFS	3	rh	**Input Buffer Status Register** This status bit indicates which of the two Input Buffer RAMs (IBF) is accessible by the host (through CIF) as Input Buffer. The other non accessible buffer RAM is currently used as shadow buffer RAM by the ERAY Message Handler and therefore not accessible by the host.After reset, it is set by hardware. 0_B Input Buffer RAM 2 (IBF2) is accessible as Input Buffer by the host (CIF) 1_B Input Buffer RAM 1 (IBF1) is accessible as Input Buffer by the host (CIF)

(table continues...)

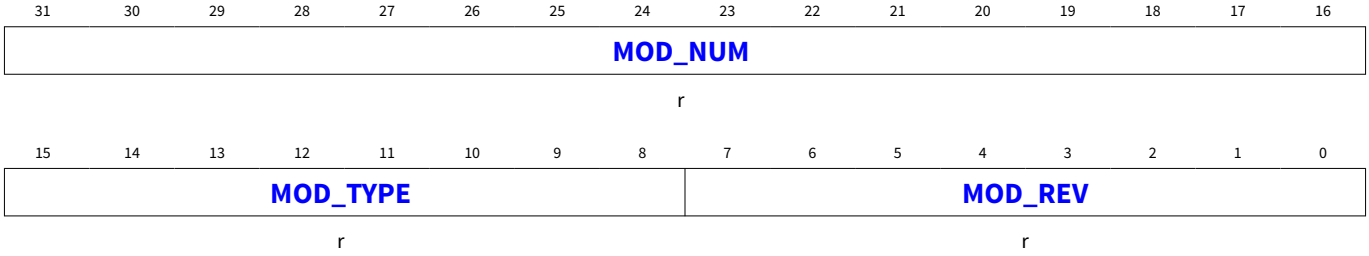
(continued)

Field	Bits	Type	Description
IBF1PAG	4	rw	**Input Buffer 1 Page Select Register** This control bit selects if the upper page or lower page of Input Buffer 1 (IBF1) currently active. ***Note**: Write is only possible, if Input Buffer RAM 1 is currently accessible by the host (through CIF) and therefore IBFS set.* 0_B Read: Lower Page (256 Bytes) of Input Buffer RAM 1 selected Write: Select Lower Page (256 Bytes) of Input Buffer RAM 1 1_B Read: Upper Page (256 Bytes) of Input Buffer RAM 1 selected Write: Select Upper Page (256 Bytes) of Input Buffer RAM 1
IBF2PAG	7	rw	**Input Buffer 2 Page Select Register** This control bit selects if the upper page or lower page of Input Buffer 2 (IBF2) currently active. ***Note**: Write is only possible, if Input Buffer RAM 2 is currently accessible by the host (through CIF) and therefore IBFS cleared.* 0_B Read: Lower Page (256 Bytes) of Input Buffer RAM 2 selected Write: Select Lower Page (256 Bytes) of Input Buffer RAM 2 1_B Read: Upper Page (256 Bytes) of Input Buffer RAM 2 selected Write: Select Upper Page (256 Byte) of Input Buffer RAM 2
RISA	11:10	rw	**Receive Input Select Channel A** 00_B Channel A receiver input RXDA0 selected 01_B Channel A receiver input RXDA1 selected 10_B Channel A receiver input RXDA2 selected 11_B Channel A receiver input RXDA3 selected
RISB	13:12	rw	**Receive Input Select Channel B** 00_B Channel B receiver input RXDB0 selected 01_B Channel B receiver input RXDB1 selected 10_B Channel B receiver input RXDB2 selected 11_B Channel B receiver input RXDB3 selected
STPWTS	15:14	rw	**Stop Watch Trigger Input Select** 00_B Stop Watch Trigger input STPWT0 selected 01_B Stop Watch Trigger input STPWT1 selected 10_B Stop Watch Trigger input STPWT2 selected 11_B Stop Watch Trigger input STPWT3 selected
0	6:5, 9:8, 31:16	r	**Reserved** Read as 0; should be written with 0.

23.4.5 Module Identification Register

ID Offset address: 0008_H

Module Identification Register PowerOn Reset value: $0044\ C009_H$



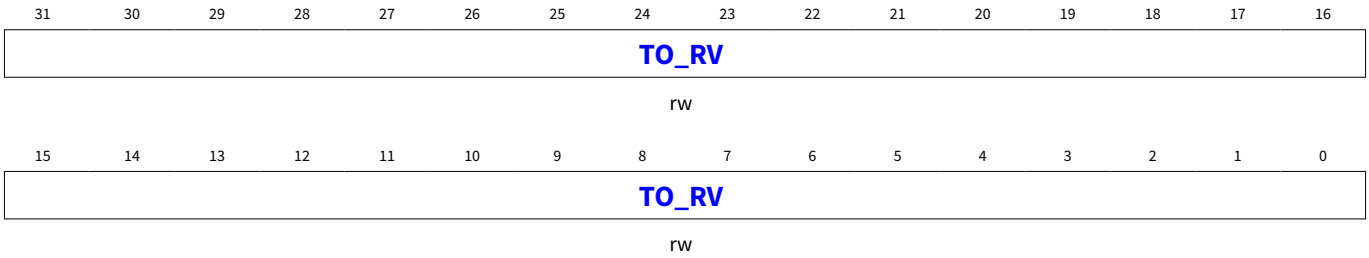
Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number.

23.4.6 Customer Interface Timeout Counter Register

The Time-out Counter Register is realizing the time-out counter reload (startup) value for the automatic delay scheme (not the time-out down counter itself).

CUST3 Offset address: $000C_H$

Customer Interface Timeout Counter Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TO_RV	31:0	rw	**CIF Timeout Reload Value - TO** The 32-bit down counter reload (start-up) value must be setup for the automatic delay scheme.

23.4.7 Test Register 1

The Test Register 1 holds the control bits to configure the test modes of the ERAY module. Write access to these bits is only possible if bit TEST1.WRTEN is set.

The Test Register 1 bits therefore can be used to test the interface to the physical layer (connectivity test) by driving / reading the respective pins.

When the ERAY IP is operated in one of its test modes that requires TEST1.WRTEN to be set (RAM Test Mode, I/O Test Mode, Asynchronous Transmit Mode, and Loop Back Mode) only the selected test mode functionality is available.

The test functions are not available in addition to the normal operational mode functions, they change the functions of parts of the ERAY module. Therefore normal operation as specified outside this chapter and as required by the FlexRay™ protocol specification and the FlexRay™ conformance test is not possible. Test mode functions may not be combined with each other or with FlexRay™ protocol functions.

The test mode features are intended for hardware testing or for FlexRay™ bus analyzer tools. They are not intended to be used in FlexRay™ applications

***Note**: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all ´rwh´ bits in this register. In CERA and CERB, coding errors are also signalled when the Communication Controller is in "MONITOR_MODE". The error codes regarding CAS / MTS symbols concern only the monitored bit pattern, irrelevant whether those bit patterns are seen in the symbol window or elsewhere.*

TEST1 Offset address: 0010_H

Test Register 1 Kernel Reset value: $0000\ 0300_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CERB				CERA				0		TXENB	TXENA	TXB	TXA	RXB	RXA
rh				rh				r		rwh	rwh	rwh	rwh	rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						AOB	AOA	0		TMC		0		ELBE	WRTEN
r						rh	rh	r		rw		r		rw	rw

Field	Bits	Type	Description
WRTEN	0	rw	**Write Test Register Enable** Enables write access to the test registers. To set the bit from 0 to 1 the test mode key has to be written as defined on “Lock Register”. The unlock sequence is not required when TEST1.WRTEN is kept at 1 while other bits of the register are changed. The bit can be reset to 0 at any time. 0_B Write access to test registers disabled. 1_B Write access to test registers enabled.

(table continues...)

(continued)

Field	Bits	Type	Description
ELBE	1	rw	**External Loop Back Enable** There are two possibilities to perform a loop back test. External loop back through physical layer or internal loop back for in-system self-test (default). In case of an internal loop back pins $\overline{\text{TXENA}}$ and $\overline{\text{TXENB}}$ are in their inactive state, pins TXDA and TXDB are set to HIGH, pins RXDA and RXDB are not evaluated. Bit ELBE is evaluated only when POC is in loop back mode and test multiplexer control is in non multiplexed mode TMC = 00. 0_B Internal loop back (default) 1_B External loop back
TMC	5:4	rw	**Test Multiplexer Control** 00_B Normal signal path (default). 01_B RAM Test Mode: Internal busses are multiplexed to make all RAM blocks of the ERAY module directly accessible by the Host. This mode is intended to enable testing of the embedded RAM blocks during production testing. 10_B I/O Test Mode: Output pins are driven to the values defined by bits TXA, TXB, $\overline{\text{TXENA}}$, $\overline{\text{TXENB}}$. The values applied to the input pins can be read from register bits RXA and RXB. 11_B Reserved; should not be used.
AOA	8	rh	**Activity on A** The channel idle condition is specified in the FlexRay™ protocol spec v2.1, chapter 3, BITSTRB process (zChannelIdle). 0_B No activity detected, channel A idle 1_B Activity detected, channel A not idle
AOB	9	rh	**Activity on B** The channel idle condition is specified in the FlexRay™ protocol spec v2.1, chapter 3, BITSTRB process (zChannelIdle). 0_B No activity detected, channel B idle 1_B Activity detected, channel B not idle
RXA	16	rh	**Read Channel A Receive Pin** This bit field shows the current logic state of RXDA. 0_B RXDA = 0 1_B RXDA = 1
RXB	17	rh	**Read Channel B Receive Pin** This bit field shows the current logic state of RXDB. 0_B RXDB = 0 1_B RXDB = 1
TXA	18	rwh	**Read or Write to Channel A Transmit Pin** A write to this bit field sets the TXDA to corresponding logic state. A read from this bit field shows the current logic state of TXDA. 0_B TXDA = 0 1_B TXDA = 1

(table continues...)

(continued)

Field	Bits	Type	Description
TXB	19	rwh	**Read or Write to Channel B Transmit Pin** A write to this bit field sets the TXDB to corresponding logic state. A read from this bit field shows the current logic state of TXDB. 0_B TXDB = 0 1_B TXDB = 1
TXENA	20	rwh	**Read or Write to Channel A Transmit Enable Pin** A write to this bit field sets the TXENA to corresponding logic state. A read from this bit field shows the current logic state of TXENA. 0_B $\overline{\text{TXENA}}$= 0 1_B $\overline{\text{TXENA}}$= 1
TXENB	21	rwh	**Read or Write to Channel B Transmit Enable Pin** A write to this bit field sets the TXENB to corresponding logic state. A read from this bit field shows the current logic state of TXENB. 0_B $\overline{\text{TXENB}}$ = 0 1_B $\overline{\text{TXENB}}$= 1
CERA	27:24	rh	**Coding Error Report Channel A** Set when a coding error is detected on channel A. Reset to zero when register TEST1 is read or written. Once the CERA is set it will remain unchanged until the Host accesses the TEST1 register. Other combinations are reserved. 0_H No coding error detected 1_H Header CRC error detected 2_H Frame CRC error detected 3_H Frame Start Sequence FSS too long 4_H First bit of Byte Start Sequence BSS seen LOW 5_H Second bit of Byte Start Sequence BSS seen HIGH 6_H First bit of Frame End Sequence FES seen HIGH 7_H Second bit of Frame End Sequence FES seen LOW 8_H CAS / MTS symbol seen too short 9_H CAS / MTS symbol seen too long

(table continues...)

(continued)

Field	Bits	Type	Description
CERB	31:28	rh	**Coding Error Report Channel B** Set when a coding error is detected on channel B. Reset to zero when register TEST1 is read or written. Once the CERB is set it will remain unchanged until the Host accesses the TEST1 register. Other combinations are reserved. 0_H No coding error detected 1_H Header CRC error detected 2_H Frame CRC error detected 3_H Frame Start Sequence FSS too long 4_H First bit of Byte Start Sequence BSS seen LOW 5_H Second bit of Byte Start Sequence BSS seen HIGH 6_H First bit of Frame End Sequence FES seen HIGH 7_H Second bit of Frame End Sequence FES seen LOW 8_H CAS / MTS symbol seen too short 9_H CAS / MTS symbol seen too long
0	3:2, 7:6, 15:10, 23:22	r	**Reserved** Read as 0; should be written with 0.

Asynchronous Transmit Mode (ATM)

The asynchronous transmit mode is entered by writing 1110_B to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1 (CHI command: ATM) while the Communication Controller is in “CONFIG” state and bit TEST1.WRTEN in the Test Register 1 is set. This write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). When called in any other state or when bit TEST1.WRTEN is not set, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. CCSV.POCS in the Communication Controller Status Vector will return 1110_B while the ERAY module is in ATM mode. Asynchronous Transmit mode can be left by writing 0001_B (CHI command: “CONFIG”) to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1.

In ATM mode transmission of a FlexRay™ Frame is triggered by writing the number of the respective Message Buffer to the Input Buffer Command Request register (IBCR.IBRH) while bit IBCM.STXRS in the Input Buffer Command Mask register is set to 1. In this mode wake-up, startup, and clock synchronization are bypassed. The CHI command SEND_MTS results in the immediate transmission of an MTS symbol.

The cycle counter value of Frames send in ATM mode can be programmed in MTCCV.CCV (writable in ATM and loop back mode only).

Loop Back Mode

The loop back mode is entered by writing 1111_B to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1 (CHI command: LOOP_BACK) while the Communication Controller is in “CONFIG” state and bit TEST1.WRTEN in the Test Register 1 is set. This write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). When called in any other state or when bit TEST1.WRTEN is not set, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. CCSV.POCS in the Communication Controller Status Vector will show $0000\ 1101_H$ while the ERAY module is in loop back mode.

Loop Back mode can be left by writing 0001_B (CHI command: “CONFIG”) to the CHI Command Vector SUCC1.CMD in the SUC Configuration Register 1.

The loop back test mode is intended to check the module’s internal data paths. Normal, time triggered operation is not possible in loop back mode.

There are two possibilities to perform a loop back test. External loop back through physical layer (TEST1.ELBE = 1) or internal loop back for in-system self-test (TEST1.ELBE = 0). In case of an internal loop back pins $\overline{\text{TXENA}}$,

$\overline{\text{TXENB}}$ are in their inactive state, pins TXDA and TXDB are set to HIGH, pins RXDAn and RXDBn are not evaluated.

When the Communication Controller is in loop back mode, a loop back test is started by the Host writing a message to the Input Buffer and requesting the transmission by writing to the Input Buffer Command Request register IBCR. The Message Handler will transfer the message into the Message RAM and then into the Transient Buffer of the selected channel. The Channel Protocol Controller (PRT) will read (in 32-bit words) the message from the transmit part of the Transient Buffer and load it into its Rx / Tx shift register. The serial transmission is looped back into the shift register; its content is written into the receive part of the channels's Transient Buffer before the next word is loaded.

The PRT and the Message Handler will then treat this transmitted message like a received message, perform an acceptance filtering on Frame ID and receive channel, and store the message into the Message RAM if it passed acceptance filtering. The loop back test ends with the Host requesting this received message from the Message RAM and then checking the contents of the Output Buffer.

Each FlexRay™ channel is tested separately. The ERAY cannot receive messages from the FlexRay™ bus while it is in the loop back mode.

The cycle counter value of Frames used in loop back mode can be programmed in MTCCV.CCV (writable in ATM and loop back mode only).

Note that in case of an odd payload the last two bytes of the looped-back payload will be shifted by 16 bits to the right inside the last 32-bit data word.

23.4.8 Test Register 2

The Test Register 2 holds all bits required for the RAM test of the seven embedded RAM blocks of the ERAY module. Write access to this register is only possible when TEST1.WRTEN in the Test Register 1 is set to 1.

TEST2 Offset address: 0014_H

Test Register 2 Kernel Reset value: $0000\ 0000_H$

(continued)

Field	Bits	Type	Description
SSEL	6:4	rw	**Segment Select** To enable access to the complete Message RAM (8192 byte addresses) the Message RAM is segmented. 000_B Access to RAM byte 0000_H to $03FF_H$ enabled 001_B Access to RAM byte 0400_H to $07FF_H$ enabled 010_B Access to RAM byte 0800_H to $0BFF_H$ enabled 011_B Access to RAM byte $0C00_H$ to $0FFF_H$ enabled 100_B Access to RAM byte 1000_H to $13FF_H$ enabled 101_B Access to RAM byte 1400_H to $17FF_H$ enabled 110_B Access to RAM byte 1800_H to $1BFF_H$ enabled 111_B Access to RAM byte $1C00_H$ to $1FFF_H$ enabled
0	3, 14:7, 15, 31:16	r	**Reserved** Read as 0; should be written with 0.

RAM Test Mode

In RAM test mode (TEST1.TMC = 1), one of the seven RAM blocks can be selected for direct RD/WR access by programming TEST2.RS.

For external access the selected RAM block is mapped to address space 400_H to $7FF_H$ (1024 byte addresses or 256 word addresses).

Because the length of the Message RAM exceeds the available address space, the Message RAM is segmented into segments of 1024 byte. The segments can be selected by programming TEST2.SSEL in the Test Register 2.

In RAM test mode the memory must be accessed with 32Bit accesses only.

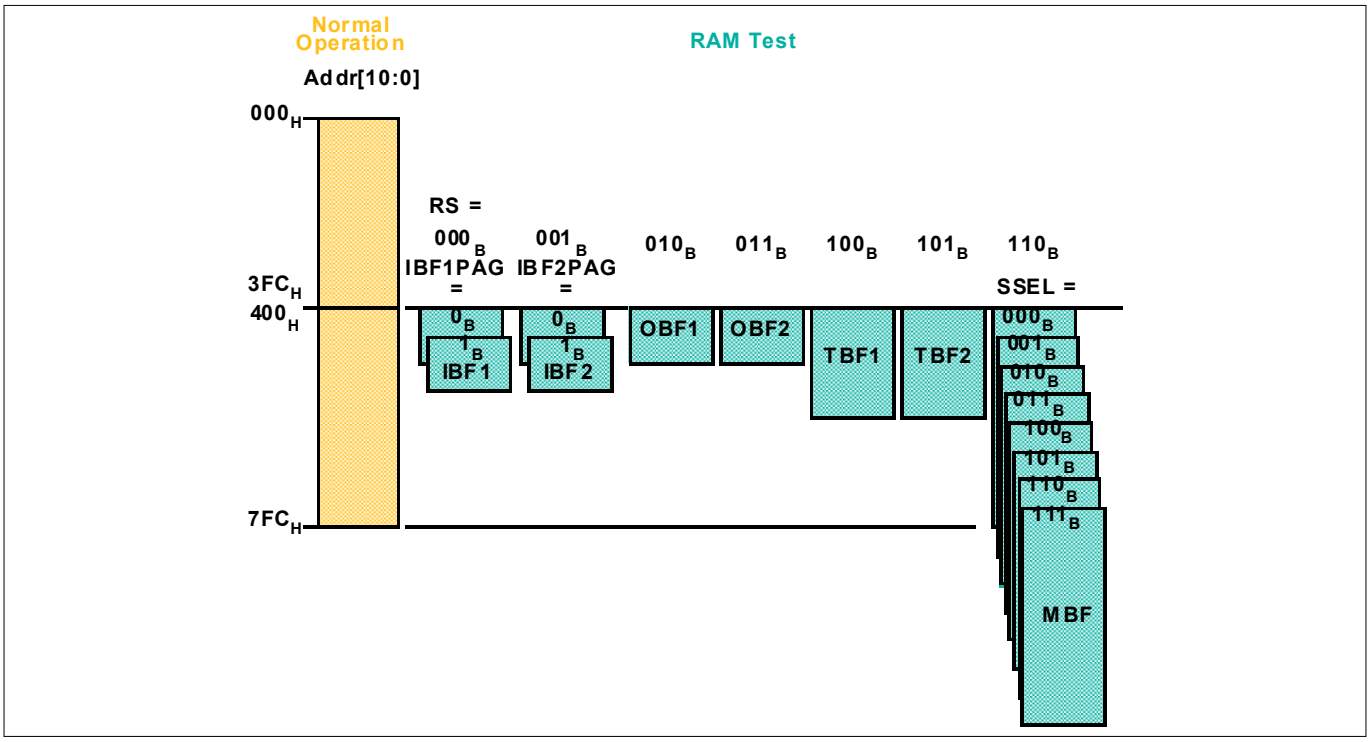

Figure 454 RAM test mode Access to ERAY RAM Blocks

23.4.9 Lock Register

The Lock Register is write-only. Reading the register will return 0000 0000$_H$.

***Note**: In case the Host uses 8/16-bit accesses to write the listed bit fields, the programmer has to ensure that no "dummy accesses" e.g. to the remaining register bytes / words are inserted by the compiler.*

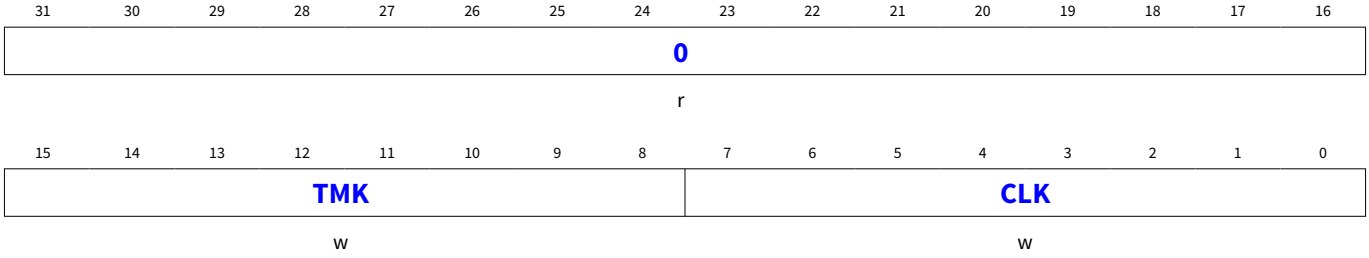
To exit "CONFIG" state by writing to SUCC1.CMD in the SUC Configuration Register 1, the write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key. If this write sequence is service requested by read accesses or write accesses to other locations, the Communication Controller remains in "CONFIG" state and the sequence has to be repeated.

First write: LCK.CLK = CE$_H$ = 1100 1110$_B$

Second write: LCK.CLK = 31$_H$ = 0011 0001$_B$

LCK Offset address: 001C$_H$

Lock Register Kernel Reset value: 0000 0000$_H$



Field	Bits	Type	Description
CLK	7:0	w	**Configuration Lock Key** To leave "CONFIG" state by writing to SUCC1.CMD (commands READY, MONITOR_MODE, ATM, LOOP_BACK) in the SUC Configuration Register 1, the write operation has to be directly preceded by two consecutive write accesses to the Configuration Lock Key (unlock sequence). If the write sequence below is interrupted by other write accesses between the second write to the Configuration Lock Key and the write access to the SUCC1 register, the Communication Controller remains in "CONFIG" state and the sequence has to be repeated. First write: LCK.CLK = CE$_H$ = 1100 1110$_B$ Second write: LCK.CLK = 31$_H$ = 0011 0001$_B$ Third write: SUCC1.CMD Returns 0 if read
TMK	15:8	w	**Test Mode Key** To set bit TEST1.WRTEN the write operation has to be directly preceded by two consecutive write accesses to the Test Mode Key. If the write sequence is interrupted by other write accesses between the second write to the Test Mode Key and the write access to the Test1 register, bit TEST1.WRTEN is not set to 1 and the sequence has to be repeated. First write: LCK.TMK = 75$_H$ = 0111 0101$_B$ Second write: LCK.TMK = 8A$_H$ = 1000 1010$_B$ Third write: TEST1.WRTEN = 1 Returns 0 if read
0	31:16	r	**Reserved** Read as 0; should be written with 0.

23.4.10 Error Service Request Select Register

The flags are set when the Communication Controller detects one of the listed error conditions. They remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

***Note**: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all ´rwh´ bits in this register.*

EIR Offset address: 0020_H

Error Service Request Select Register Kernel Reset value: $0000\ 0000_H$

r				rwh	rwh	rwh	rwh	rh	rh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
PEMC	0	rwh	**POC Error Mode Changed** This flag is set whenever the error mode signalled by CCEV.ERRM in the Communication Controller Error Vector register has changed. This flag is cleared by writing a 1. 0_B Error mode has not changed 1_B Error mode has changed
CNA	1	rwh	**Command Not Accepted** The flag signals that the write access to the CHI command vector SUCC1.CMD in the SUC Configuration Register 1 was not successful because the requested command was not valid in the actual POC state, or because the CHI command was locked (CCL = 1). This flag is cleared by writing a 1. 0_B CHI command accepted 1_B CHI command not accepted
SFBM	2	rwh	**SYNC Frames Below Minimum** This flag signals that the number of SYNC Frames received during the last communication cycle was below the limit required by the FlexRay™ protocol. May be set during startup and therefore should be cleared by the Host after the Communication Controller entered “NORMAL_ACTIVE” state. This flag is cleared by writing a 1. 0_B Sync node: 1 or more SYNC Frames received Non-sync node: 2 or more SYNC Frames received 1_B Less than the required minimum of SYNC Frames received

(table continues...)

(continued)

Field	Bits	Type	Description
SFO	3	rwh	**SYNC Frame Overflow** Set when either the number of SYNC Frames received during the last communication cycle or the total number of SYNC Frames received during the last double cycle exceeds the maximum number of SYNC Frames as defined by GTUC02.SNM in the GTU Configuration Register 2. This flag is cleared by writing a 1. 0_B Number of received SYNC Frames ≤ GTUC02.SNM 1_B More SYNC Frames received than configured by GTUC02.SNM
CCF	4	rwh	**Clock Correction Failure** This flag is set at the end of the cycle whenever one of the following errors occurred: • Missing offset and / or rate correction • Clock Correction limit reached The clock correction status is monitored in registers CCEV and SFS. A failure may occur during startup, therefore bit CCF should be cleared by the Host after the Communication Controller entered “NORMAL_ACTIVE” state. This flag is cleared by writing a 1. 0_B Clock correction successful so far 1_B Clock correction failed
CCL	5	rwh	**CHI Command Locked** The flag signals that the write access to the CHI command vector SUCC1.CMD was not successful because the execution of the previous CHI command has not yet completed. In this case bit EIR.CNA is also set to 1. This flag is cleared by writing a 1. 0_B CHI command accepted 1_B CHI command not accepted
EERR	6	rh	**ECC Error** The flag signals an ECC error to the Host. It is set whenever one of the flags MHDS.EIBF, MHDS.EOBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2 changes from 0 to 1. See also “Message Handler Status”. This bit must be cleared at initialization of the module. 0_B No error detected 1_B Error detected
RFO	7	rh	**Receive FIFO Overrun** The flag is set by the Communication Controller when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. The actual state of the FIFO is monitored in register FSR. 0_B No receive FIFO overrun detected 1_B A receive FIFO overrun has been detected

(table continues...)

(continued)

Field	Bits	Type	Description
EFA	8	rwh	**Empty FIFO Access** This flag is set by the Communication Controller when the Host requests the transfer of a message from the receive FIFO through Output Buffer while the receive FIFO is empty. 0_B No Host access to empty FIFO occurred 1_B Host access to empty FIFO occurred
IIBA	9	rwh	**Illegal Input Buffer Access** This flag is set by the Communication Controller when the Host wants to modify a Message Buffer through Input Buffer while the Communication Controller is not in “CONFIG” or “DEFAULT_CONFIG” state and one of the following conditions applies: **1.** The Host writes to the Input Buffer Command Request register to modify the: • Header Section of Message Buffer 0, 1 if configured for transmission in key slot • Header Section of static Message Buffers with buffer number < MRC.FDB while MRC.SEC = 01_B • Header Section of any static or dynamic Message Buffer while MRC.SEC = $1x_B$ • Header and / or Data Section of any message buffer belonging to the receive FIFO **2.** The Host writes to any register of the Input Buffer while IBCR.IBSYS is set. 0_B No illegal Host access to Input Buffer occurred 1_B Illegal Host access to Input Buffer occurred
IOBA	10	rwh	**Illegal Output Buffer Access** This flag is set by the Communication Controller when the Host requests the transfer of a Message Buffer from the Message RAM to the Output Buffer while OBCR.OBSYS is set to 1. 0_B No illegal Host access to Output Buffer occurred 1_B Illegal Host access to Output Buffer occurred
MHF	11	rwh	**Message Handler Constraints Flag** The flag signals a Message Handler constraints violation condition. It is set whenever one of the flags MHDF.SNUA, MHDF.SNUB, MHDF.FNFA, MHDF.FNFB, MHDF.TBFA, MHDF.TBFB, MHDF.TNSA, MHDF.TNSB, MHDF.WAHP changes from 0 to 1. 0_B No Message Handler failure detected 1_B Message Handler failure detected
EDA	16	rwh	**Error Detected on Channel A** This bit is set whenever one of the flags ACS.SEDA, ACS.CEDA, ACS.CIA, ACS.SBVA changes from 0 to 1. This flag is cleared by writing a 1. 0_B No error detected on channel A 1_B Error detected on channel A

(table continues...)

(continued)

Field	Bits	Type	Description
LTVA	17	rwh	**Latest Transmit Violation Channel A** The flag signals a latest transmit violation on channel A to the Host. This flag is cleared by writing a 1. 0_B No latest transmit violation detected on channel A 1_B Latest transmit violation detected on channel A
TABA	18	rwh	**Transmission Across Boundary Channel A** The flag signals to the Host that a transmission across a slot boundary occurred for channel A. This flag is cleared by writing a 1. 0_B No transmission across slot boundary detected on channel A 1_B Transmission across slot boundary detected on channel A
EDB	24	rwh	**Error Detected on Channel B** This bit is set whenever one of the flags ACS.SEDB, ACS.CEDB, ACS.CIB, ACS.SBVB changes from 0 to 1. This flag is cleared by writing a 1. 0_B No error detected on channel B 1_B Error detected on channel B
LTVB	25	rwh	**Latest Transmit Violation Channel B** The flag signals a latest transmit violation on channel B to the Host. This flag is cleared by writing a 1. 0_B No latest transmit violation detected on channel B 1_B Latest transmit violation detected on channel B
TABB	26	rwh	**Transmission Across Boundary Channel B** The flag signals to the Host that a transmission across a slot boundary occurred for channel B. This flag is cleared by writing a 1. 0_B No transmission across slot boundary detected on channel B 1_B Transmission across slot boundary detected on channel B
0	15:12, 23:19, 31:27	r	**Reserved** Read as 0; should be written with 0.

23.4.11 Status Service Request Register

The flags are set whenever the Communication Controller detects one of the listed events. The flags remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

***Note**: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all ´rwh´ bits in this register.*

SIR Offset address: 0024_H

Field	Bits	Type	Description
WST	0	rwh	**Wakeup Status** This flag is set when the wakeup status vector CCSV.WSV in the Communication Controller Status Vector register changes to a value other than UNDEFINED. This flag is cleared by writing a 1. 0_B Wake-up status unmodified 1_B Wake-up status modified (and not UNDEFINED)
CAS	1	rwh	**Collision Avoidance Symbol** This flag is set by the Communication Controller during STARTUP state when a CAS or potential CAS was received. This flag is cleared by writing a 1. 0_B No bit pattern matching the CAS symbol received 1_B Bit pattern matching the CAS symbol received
CYCS	2	rwh	**Cycle Start Service Request** This flag is set by the Communication Controller when a communication cycle starts This flag is cleared by writing a 1. 0_B No communication cycle started 1_B Communication cycle started
TXI	3	rwh	**Transmit Service Request** This flag is set by the Communication Controller at the end of Frame transmission if bit WRHS1.MBI in the respective Message Buffer is set. This flag is cleared by writing a 1. 0_B No Frame transmitted from a transmit buffer with WRHS1.MBI = 1 1_B At least one Frame was transmitted from a transmit buffer with WRHS1.MBI = 1
RXI	4	rwh	**Receive Service Request** This flag is set by the Communication Controller whenever the set condition of a Message Buffer ND flag is fulfilled and if bit WRHS1.MBI of that Message Buffer is set to 1. This flag is cleared by writing a 1. 0_B No ND flag of a receive buffer with WRHS1.MBI = 1 has been set to 1 1_B At least one ND flag of a receive buffer with WRHS1.MBI = 1 has been set to 1

(table continues...)

(continued)

Field	Bits	Type	Description
RFNE	5	rh	**Receive FIFO Not Empty** This flag is set by the Communication Controller when a received valid Frame was stored into the empty receive FIFO.m The actual state of the receive FIFO is monitored in register FSR 0_B Receive FIFO is empty 1_B Receive FIFO is not empty
RFCL	6	rh	**Receive FIFO Critical Level** This flag is set when a valid receive FIFO fill level FSR.RFFL is equal or greater than the critical level as configured by FCL.CL. 0_B Receive FIFO below critical level 1_B Receive FIFO critical level reached
NMVC	7	rwh	**Network Management Vector Changed** This service request flag signals a change in the Network Management Vector visible to the Host. This flag is cleared by writing a 1. 0_B No change in the Network Management vector 1_B Network Management vector changed
TI0	8	rwh	**Timer Service Request 0** This flag is set whenever timer 0 matches the conditions configured in the Timer Service Request 0 Configuration Register T0C. A Timer Service Request 0 is also signalled by TINT0SRC. This flag is cleared by writing a 1. 0_B No Timer Service Request 0 1_B Timer Service Request 0 occurred
TI1	9	rwh	**Timer Service Request 1** This flag is set whenever the conditions programmed in the Timer Service Request 1 Configuration Register T1C are met. A Timer Service Request 1 is also signalled by TINT1SRC. This flag is cleared by writing a 1. 0_B No Timer Service Request 1 1_B Timer Service Request 1 occurred
TIBC	10	rwh	**Transfer Input Buffer Completed** This flag is set whenever a transfer from Input Buffer to the Message RAM has completed and bit IBCR.IBSYS in the Input Buffer Command Request register has been reset by the Message Handler. This flag is cleared by writing a 1. 0_B No transfer completed 1_B Transfer between Input Buffer and Message RAM completed

(table continues...)

(continued)

Field	Bits	Type	Description
TOBC	11	rwh	**Transfer Output Buffer Completed** This flag is set whenever a transfer from Message RAM to the Output Buffer has completed and bit OBCR.OBSYS in the Output Buffer Command Request register has been reset by the Message Handler. This flag is cleared by writing a 1. 0_B No transfer completed 1_B Transfer between Message RAM and the Output Buffer completed
SWE	12	rwh	**Stop Watch Event** This flag is set after a stop watch activation when the current cycle counter and Macrotick value are stored in the Stop Watch Register 1 (STPW1). This flag is cleared by writing a 1. 0_B No Stop Watch Event 1_B Stop Watch Event occurred
SUCS	13	rwh	**Startup Completed Successfully** This flag is set whenever a startup completed successfully and the Communication Controller entered “NORMAL_ACTIVE” state. This flag is cleared by writing a 1. 0_B No startup completed successfully 1_B Startup completed successfully
MBSI	14	rwh	**Message Buffer Status Service Request** This flag is set by the Communication Controller when the Message Buffer status MBS has changed and if bit RDHS1.MBI of that Message Buffer is set. This flag is cleared by writing a 1. 0_B No Message Buffer status change of Message Buffer with RDHS1.MBI= 1 has changed 1_B Message Buffer status of at least one Message Buffer with RDHS1.MBI= 1 has changed
SDS	15	rwh	**Start of Dynamic Segment** This flag is set by the Communication Controller when the dynamic segment starts. 0_B Dynamic segment not yet started 1_B Dynamic segment started

23.4.19 Timer 0 Configuration

Absolute timer. Specifies in terms of cycle count and Macrotick the point in time when the timer 0 service request occurs. When the timer 0 service request is asserted, output signal TINT0SR is set to 1 for the duration of one Macrotick and SIR.TI0 is set to 1.

Timer 0 can be activated as long as the POC is either in “NORMAL_ACTIVE” state or in “NORMAL_PASSIVE” state. Timer 0 is deactivated when leaving “NORMAL_ACTIVE” state or “NORMAL_PASSIVE” state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by writing 0 to bit T0RC.

***Note**: The configuration of timer 0 is compared against the Macrotick counter value, there is no separate counter for timer 0. In case the Communication Controller leaves “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state, or if timer 0 is halted by Host command, output signal TINT0SR is reset to 0 immediately.*

T0C Offset address: 0044_H

(table continues...)

(continued)

Field	Bits	Type	Description
T0CC	14:8	rw	**Timer 0 Cycle Code** The 7-bit timer 0 cycle code determines the cycle set used for generation of the timer 0 service request. For details about the configuration of the cycle code see “Cycle Counter Filtering”.
T0MO	29:16	rw	**Timer 0 Macrotick Offset** Configures the Macrotick offset from the beginning of the cycle where the service request is to occur. The Timer 0 Service Request occurs at this offset for each cycle of the cycle set.
0	7:2, 15, 31:30	r	**Reserved** Read as 0; should be written with 0.

23.4.20 Timer 1 Configuration

Relative timer. After the specified number of Macroticks has expired, the timer 1 service request is asserted, output signal TINT1SR is set to 1 for the duration of one Macrotick and SIR.TI1 is set to 1.

Timer 1 can be activated as long as the POC is either in “NORMAL_ACTIVE” state or in “NORMAL_PASSIVE” state. Timer 1 is deactivated when leaving “NORMAL_ACTIVE” state or “NORMAL_PASSIVE” state except for transitions between the two states.

Before reconfiguration of the timer, the timer has to be halted first by resetting bit T1RC to 0.

***Note**: In case the Communication Controller leaves “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state, or if timer 1 is halted by Host command, output signal TINT1SR is reset to 0 immediately.*

T1C Offset address: 0048_H

0	15:2, 31:30	r	**Reserved** Read as 0; should be written with 0.

23.4.21 Stop Watch Register 1

The stop watch is activated by a rising or falling edge on signal STPW, by a service request 0 or 1 event (rising edge on signal INT0SR or INT1SR) or by the Host by writing bit STPW1.SSWT to 1. With the Macrotick counter increment following next to the stop watch activation the actual cycle counter and Macrotick value are captured in the Stop Watch Register 1 STPW1 while the slot counter values for channel A and B are captured in the Stop Watch Register 2 STPW2.

***Note**: Bits ESWT and SSWT cannot be set to 1 simultaneously. In this case the write access is ignored, and both bits keep their previous values. Therefore either the external stop watch triggers or the software stop watch trigger may be used.*

STPW1 Offset address: $004C_H$

Stop Watch Register 1 Kernel Reset value: $0000\ 0000_H$

23.4.23 SUC Configuration Register 1

***Note**: The protocol requires that both bits TXST and TXSY are set for coldstart nodes (For bits TXST, TXSY, MTSB).*

MTSA and MTSB may also be changed outside "DEFAULT_CONFIG" or "CONFIG" state when the write to SUCC1 register is directly preceded by the unlock sequence as described in Lock Register (LCK). This may be combined with CHI command "SEND_MTS". If both bits MTSA and MTSB are set to 1, an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000B (For MTSA).

SUCC1 Offset address: 0080_H

SUC Configuration Register 1 Kernel Reset value: $0C40\ 1000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CSA					0	TXSY	TXST	PBSY	0			CMD			
rw					r	rw	rw	rh	r			rwh			

Field	Bits	Type	Description
CMD	3:0	rwh	**CHI Command Vector** The host may write any CHI command at any time, but certain commands are only enabled in specific POC states. A disabled command will not be executed, the CHI command vector CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”, and flag EIR.CNA in the Error Service Request register will be set to 1. In case the previous CHI command has not yet completed, EIR.CCL is set to 1 together with EIR.CNA; the CHI command needs to be repeated. Except for HALT state, POC state change command applied while the Communication Controller is already in the requested POC state will be ignored. Reading SUCC1.CMD shows whether the last CHI command was accepted. CCSV.POCS monitors the actual POC state. The reserved CHI commands code hardware test functions. 0_H COMMAND_NOT_ACCEPTED 1_H CONFIG 2_H READY 3_H WAKEUP 4_H RUN 5_H ALL_SLOTS 6_H HALT 7_H FREEZE 8_H SEND_MTS 9_H ALLOW_COLDSTART A_H RESET_STATUS_INDICATORS B_H MONITOR_MODE C_H CLEAR_RAMS D_H Reserved … F_H Reserved
PBSY	7	rh	**POC Busy** Signals that the POC is busy and cannot accept a command from the Host. SUCC1.CMD is locked against write accesses. Set to 1 after hard reset during initialization of internal RAM blocks. 0_B POC not busy, SUCC1.CMD writable 1_B POC is busy, SUCC1.CMD locked
TXST	8	rw	**Transmit Startup Frame in Key Slot (pKeySlotUsedForStartup)** Defines whether the key slot is used to transmit startup Frames. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B No Startup Frame transmission in key slot, node is non-coldstarter 1_B Key slot used to transmit startup Frame, node is leading or following coldstarter

(table continues...)

(continued)

Field	Bits	Type	Description
TXSY	9	rw	**Transmit SYNC Frame in Key Slot (pKeySlotUsedForSync)** Defines whether the key slot is used to transmit SYNC Frames. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B No SYNC Frame transmission in key slot, node is neither sync nor coldstart node 1_B Key slot used to transmit SYNC Frames, node is sync node
CSA	15:11	rw	**Cold Start Attempts (gColdStartAttempts)** Configures the maximum number of attempts that a cold starting node is permitted to try to start up the network without receiving any valid response from another node. It can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Must be identical in all nodes of a cluster. Valid values are 2 to 31.
PTA	20:16	rw	**Passive to Active (pAllowPassiveToActive)** Defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the Communication Controller is allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. If set to 00000_B the Communication Controller is not allowed to transit from “NORMAL_PASSIVE” to “NORMAL_ACTIVE” state. It can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 31 even / odd cycle pairs.
WUCS	21	rw	**Wakeup Channel Select (pWakeupChannel)** With this bit the Host selects the channel on which the Communication Controller sends the Wakeup pattern. The Communication Controller ignores any attempt to change the status of this bit when not in “DEFAULT_CONFIG” or “CONFIG” state. 0_B Send wakeup pattern on channel A 1_B Send wakeup pattern on channel B
TSM	22	rw	**Transmission Slot Mode (pSingleSlotEnabled)** Selects the initial transmission slot mode. In SINGLE slot mode the Communication Controller may only transmit in the preconfigured key slot. The key slot ID is configured in the Header Section of Message Buffer 0 respectively Message Buffers 0 and 1 depending on bit MRC.SPLM. In case SUCC1.TSM = 1, Message Buffer 0 respectively Message Buffers 0, 1 can be (re)configured in “DEFAULT_CONFIG” or “CONFIG” state only. In ALL slot mode the Communication Controller may transmit in all slots. The bit can be written in “DEFAULT_CONFIG” or “CONFIG” state only. The communication controller changes to ALL slot mode when the Host successfully applied the ALL_SLOTS command by writing SUCC1.CMD = 0101_B in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE”. The actual slot mode is monitored by CCSV.SLM. 0_B ALL Slot Mode 1_B SINGLE Slot Mode (default after application reset)

(table continues...)

(continued)

Field	Bits	Type	Description
HCSE	23	rw	**Halt due to Clock Sync Error (pAllowHaltDueToClock)** Controls the transition to “HALT” state due to a clock synchronization error. The bit can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B Communication Controller will enter / remain in “NORMAL_PASSIVE” 1_B Communication Controller will enter “HALT” state
MTSA	24	rw	**Select Channel A for MTS Transmission** The bit selects channel A for MTS symbol transmission. The flag is reset by default and may be modified only in “DEFAULT_CONFIG” or “CONFIG” state. 0_B Channel A disabled for MTS transmission 1_B Channel A selected for MTS transmission
MTSB	25	rw	**Select Channel B for MTS Transmission** The bit selects channel B for MTS symbol transmission. The flag is reset by default and may be modified only in “DEFAULT_CONFIG” or “CONFIG” state. [2)] 0_B Channel B disabled for MTS transmission 1_B Channel B selected for MTS transmission
CCHA	26	rw	**Connected to Channel A (pChannels)** Configures whether the node is connected to channel A. This bit can be modified in "DEFAULT_CONFIG" or "CONFIG" state only. 0_B Not connected to channel A 1_B Node connected to channel A (default after application reset)
CCHB	27	rw	**Connected to Channel B (pChannels)** Configures whether the node is connected to channel B. This bit can be modified in "DEFAULT_CONFIG" or "CONFIG" state only. 0_B Not connected to channel B 1_B Node connected to channel B (default after application reset)
0	6:4, 10, 31:28	r	**Reserved** Read as 0; should be written with 0.

COMMAND_NOT_ACCEPTED

SUCC1.CMD is reset to 0000_B due to one of the following conditions:

- Illegal command applied by the Host
- Host writes “COMMAND_NOT_ACCEPTED”
- Host applied new command while execution of the previous Host command has not completed

When SUCC1.CMD is reset to 0000_B, bit EIR.CNA in the Error Service Request register is set, and - if enabled - an service request is generated. Commands which are not accepted are not executed.

CONFIG

Go to POC state “CONFIG” when called in POC states “DEFAULT_CONFIG“, “READY“, or in “MONITOR_MODE“. When called in “HALT” state transits to POC state “DEFAULT_CONFIG“. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

READY

Go to POC state “READY” when called in POC states “CONFIG”, “NORMAL_ACTIVE”, “NORMAL_PASSIVE”, “STARTUP”, or “WAKEUP”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

WAKEUP

Go to POC state WAKEUP when called in POC state “READY”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

RUN

Go to POC state “STARTUP” when called in POC state “READY”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

ALL_SLOTS

Leave SINGLE slot mode after successful startup / integration at the next end of cycle when called in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

HALT

Set the halt request CCSV.HRQ bit in the Communication Controller Status Vector register and go to POC state “HALT” at the next end of cycle when called in POC states “NORMAL_ACTIVE” or “NORMAL_PASSIVE“. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED“.

FREEZE

Set the freeze status indicator CCSV.FSI and go to POC state “HALT” immediately. Can be called from any state.

SEND_MTS

Send single MTS symbol during the next following symbol window on the channel configured by SUCC1.MTSA, SUCC1.MTSB, when called in POC state “NORMAL_ACTIVE”. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

ALLOW_COLDSTART

The command resets bit CCSV.CSI to enable the node to become cold starter. When called in states “DEFAULT_CONFIG“, “CONFIG”, “HALT”, or “MONITOR_MODE“. SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. To become leading coldstarter it is also required that both TXST and TXSY are set.

RESET_STATUS_INDICATORS

Resets status flags CCSV.CSNI, CCSV.CSAI, CCSV.WSV to their default values. May be called in POC state READY. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”.

MONITOR_MODE

Enter MONITOR_MODE when called in POC state CONFIG. In this mode the Communication Controller is able to receive FlexRay™ Frames and wakeup pattern. It is also able to detect coding errors. The temporal integrity of received Frames is not checked. This mode can be used for debugging purposes, e.g. in case that the startup of a FlexRay™ network fails. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. For details see “MONITOR_MODE”.

CLEAR_RAMS

Sets bit MHDS.CRAM in the Message Handler Status register when called in “DEFAULT_CONFIG” or “CONFIG” state. When called in any other state, SUCC1.CMD will be reset to 0000_B = “COMMAND_NOT_ACCEPTED”. By setting MHDS.CRAM all internal RAM blocks are initialized to zero. Note that only the currently active IBF bank is cleared. To clear the 2nd bank as well, CUST1.IBF1PAG and CUST1.IBF2PAG need to be set and command CLEAR_RAMS need to be issued again. This is required in particular after an application reset. If the 2nd bank of IBF is left unused, this procedure is not required. During the initialization of the RAMs, SUCC1.PBSY will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMS.

The initialization of the ERAY internal RAM blocks requires 2048 f_{CLC_ERAY} cycles. There should be no Host access to IBF or OBF during initialization of the internal RAM blocks after application reset or after assertion of CHI command CLEAR_RAMS. Before asserting CHI command CLEAR_RAMS the Host should make sure that no transfer between Message RAM and IBF / OBF or the Transient Buffer RAMs is ongoing. This command also resets the Message Buffer Status registers MHDS, LDTS, FSR, MHDF, TXRQ1, TXRQ2, TXRQ3, TXRQ4, NDAT1, NDAT2, NDAT3, NDAT4, MBSC1, MBSC2, MBSC3, and MBSC4.

Table below references the CHI commands from the FlexRay™ Protocol Specification v2.1 (section 2.2.1.1, Table 2-2) to the ERAY CHI command vector CMD.

Table 1096 Reference to CHI Host command summary from FlexRay™ protocol specification

CHI Command	Where processed (POC State)	CHI Command Vector CMD
ALL_SLOT	POC:NORMAL_ACTIVE, POC:NORMAL_PASSIVE	ALL_SLOTS
ALLOW_COLDSTART	All except POC:DEFAULT_CONFIG, POC:CONFIG, POC:HALT	ALLOW_COLDSTART
CONFIG	POC:DEFAULT_CONFIG, POC:READY	CONFIG
CONFIG_COMPLETE	POC:CONFIG	Unlock sequence & READY
DEFAULT_CONFIG	POC:HALT	CONFIG
FREEZE	All	FREEZE
HALT	POC:NORMAL_ACTIVE, POC:NORMAL_PASSIVE	HALT
READY	All except POC:DEFAULT_CONFIG, POC:CONFIG, POC:READY, POC:HALT	READY
RUN	POC:READY	RUN
WAKEUP	POC:READY	WAKEUP

23.4.24 SUC Configuration Register 2

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

***Note**: The wakeup / startup noise time-out is calculated as follows: The wakeup / startup noise time-out = pdListenTimeout • gListenNoise = LT • (LTN + 1)*

SUCC2 Offset address: 0084_H

SUC Configuration Register 2 Kernel Reset value: $0100\ 0504_H$

Field	Bits	Type	Description
LT	20:0	rw	**Listen Timeout (pdListenTimeout)** Configures wakeup / startup listen timeout in Microticks. The range for wakeup / startup listen timeout (pdListenTimeout) is 1284 to 1283846 (504_H to 139706_H) Microticks

(table continues...)

(continued)

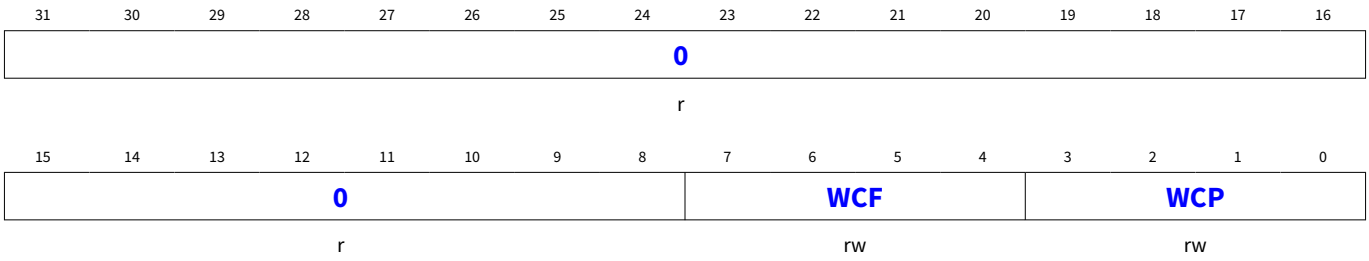
Field	Bits	Type	Description
LTN	27:24	rw	**Listen Time-out Noise (gListenNoise - 1)** Configures the upper limit for startup and wakeup listen timeout in the presence of noise expressed as a multiple of the cluster constant pdListenTimeout. The range of pdListenTimeout 2 to 16. LTN must be configured identical in all nodes of a cluster. This bit can be updated in "DEFAULT_CONFIG" or "CONFIG" state only. 1_H Listen Time-out Noise is equal 2 2_H Listen Time-out Noise is equal 3 3_H … E_H Listen Time-out Noise is equal 3 … 15 F_H Listen Time-out Noise is equal 16
0	23:21, 31:28	r	**Reserved** Read as 0; should be written with 0.

23.4.25 SUC Configuration Register 3

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

SUCC3 Offset address: 0088_H

SUC Configuration Register 3 Kernel Reset value: $0000\ 0011_H$



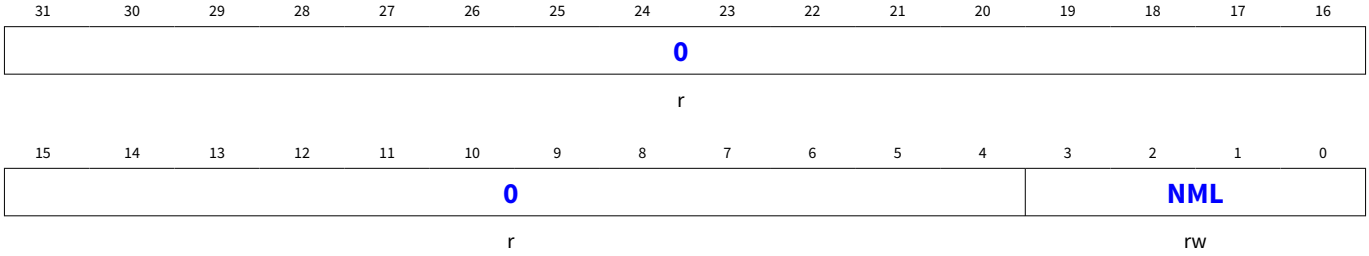
Field	Bits	Type	Description
WCP	3:0	rw	**Maximum Without Clock Correction Passive** Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from “NORMAL_ACTIVE” to “NORMAL_PASSIVE” state. Must be identical in all nodes of a cluster. Valid values are 1 to 15 (1_H to F_H) cycle pairs. (gMaxWithoutClockCorrectionPassive) - WCP
WCF	7:4	rw	**Maximum Without Clock Correction Fatal (gMaxWithoutClockCorrecti on Fatal)** Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from “NORMAL_ACTIVE” or “NORMAL_PASSIVE” to “HALT” state. Must be identical in all nodes of a cluster. Valid values are 1 to 15 (1_H to F_H) cycle pairs.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

23.4.26 NEM Configuration Register

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

NEMC Offset address: $008C_H$

NEM Configuration Register Kernel Reset value: $0000\ 0000_H$



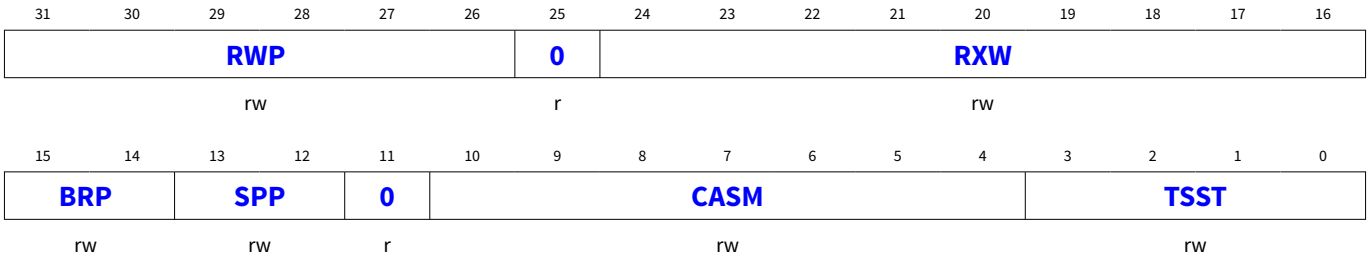
Field	Bits	Type	Description
NML	3:0	rw	**Network Management Vector Length (gNetworkManagementVectorLength)** These bits configure the length of the NM Vector. The configured length must be identical in all nodes of a cluster. Valid values are 0 to 12 (0_H to C_H) bytes.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

23.4.27 PRT Configuration Register 1

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

PRTC1 Offset address: 0090_H

PRT Configuration Register 1 Kernel Reset value: $084C\ 0633_H$



Field	Bits	Type	Description
TSST	3:0	rw	**Transmission Start Sequence Transmitter (gdTSSTransmitter)** Configures the duration of the Transmission Start Sequence (TSS) in terms of Bit Times (1 bit time = 4 Microticks = 100 ns at 10 Mbps). Must be identical in all nodes of a cluster. Valid values are 3 to 15 (3_H to F_H) Bit Times.

(table continues...)

(continued)

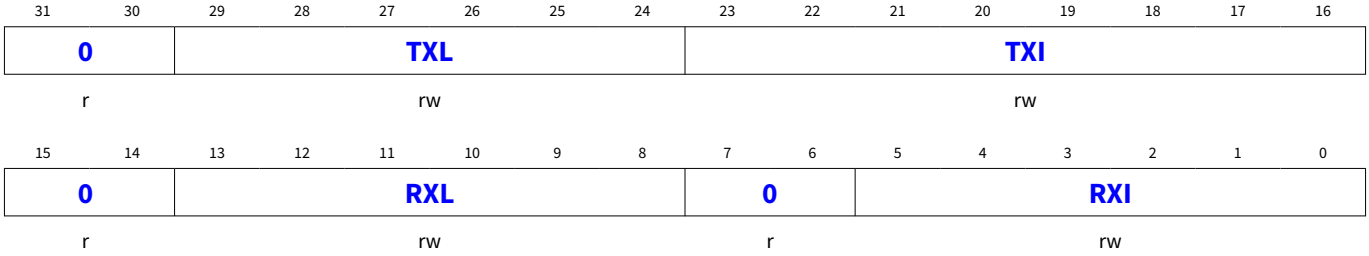
Field	Bits	Type	Description
CASM	10:4	rw	**Collision Avoidance Symbol Maximum (gdCASRxLowMax)** Configures the upper limit of the acceptance window for a collision avoidance symbol (CAS). Valid values are 67 to 99 (43_H to 63_H). Most significant bit of CASM is hard wired to 1 and can not be modified.
SPP	13:12	rw	**Strobe Point Position** Defines the sample count value for strobing. The strobed bit value is set to the voted value when the sample count is incremented to the value configured by SPP. ***Note**: The current revision 2.1 of the FlexRay™ protocol requires that SPP = 00_B. The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.* 00_B Sample 5 (default) 01_B Sample 4 10_B Sample 6 11_B Reserved; should not be used.
BRP	15:14	rw	**Baud Rate Prescaler (gdSampleClockPeriod, pSamplePerMicrotick)** The baud rate prescaler configures the baud rate on the FlexRay™ bus. The baud rates listed below are valid with a sample clock f_{SCLK} = 80 MHz. One bit time always consists of 8 samples independent of the configured baud rate. 00_B 10 Mbit/s (1 Microtick= 25 ns; twice sampled with f_{SCLK}) gdSampleClockPeriod = 12.5 ns = 1 / f_{SCLK} pSamplesPerMicrotick = 2 01_B 5 Mbit/s (1 Microtick= 25 ns; single sampled with f_{SCLK} / 2) gdSampleClockPeriod = 25 ns = 2 / f_{SCLK} pSamplesPerMicrotick = 1 10_B 2.5 Mbit/s (1 Microtick = 50 ns; single sampled with f_{SCLK} / 4) gdSampleClockPeriod = 50 ns = 4 / f_{SCLK} pSamplesPerMicrotick = 1 11_B Reserved; should not be used (2.5 Mbit/s (1 Microtick = 50 ns; single sampled with f_{SCLK} / 4) gdSampleClockPeriod = 50 ns = 4 / f_{SCLK} pSamplesPerMicrotick = 1
RXW	24:16	rw	**Wakeup Symbol Receive Window Length (gdWakeupSymbolRxWindow)** Configures the number of Bit Times used by the node to test the duration of the received wakeup pattern. Must be identical in all nodes of a cluster. Valid values are 76 to 301 ($4C_H$ to $12D_H$) Bit Times.
RWP	31:26	rw	**Repetitions of Tx Wakeup Pattern (pWakeupPattern)** Configures the number of repetitions (sequences) of the Tx wakeup symbol. Valid values are 2 to 63 (2_H to $3F_H$).
0	11, 25	r	**Reserved** Read as 0; should be written with 0.

23.4.28 PRT Configuration Register 2

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

PRTC2 Offset address: 0094_H

PRT Configuration Register 2 Kernel Reset value: $0F2D\ 0A0E_H$



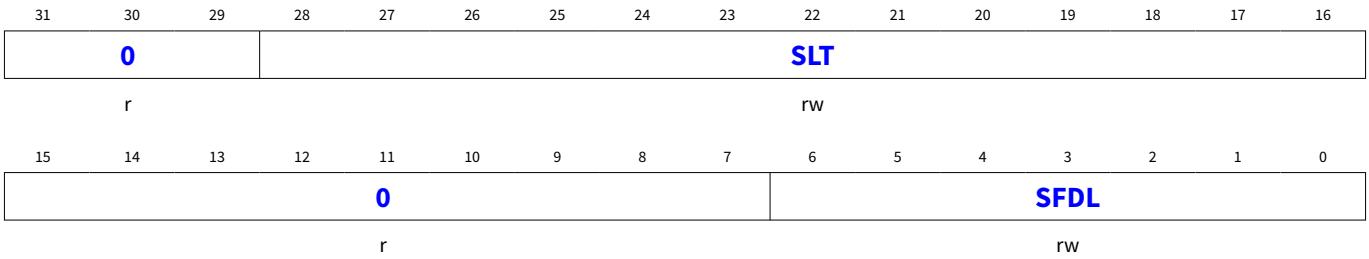
Field	Bits	Type	Description
RXI	5:0	rw	**Wakeup Symbol Receive Idle (gdWakeupSymbolRxIdle)** Configures the number of Bit Times used by the node to test the duration of the idle phase of the received wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 14 to 59 (E_H to $3B_H$) Bit Times.
RXL	13:8	rw	**Wakeup Symbol Receive Low (gdWakeupSymbolRxLow)** Configures the number of Bit Times used by the node to test the duration of the low phase of the received wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 10 to 55 (A_H to 37_H) Bit Times.
TXI	23:16	rw	**Wakeup Symbol Transmit Idle (gdWakeupSymbolTxIdle)** Configures the number of Bit Times used by the node to transmit the idle phase of the wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 45 to 180 ($2D_H$ to $B4_H$) Bit Times.
TXL	29:24	rw	**Wakeup Symbol Transmit Low (gdWakeupSymbolTxLow)** Configures the number of Bit Times used by the node to transmit the low phase of the wakeup symbol. Must be identical in all nodes of a cluster. Valid values are 15 to 60 (F_H to $3C_H$) Bit Times.
0	7:6, 15:14, 31:30	r	**Reserved** Read as 0; should be written with 0.

23.4.29 MHD Configuration Register

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

MHDC Offset address: 0098_H

MHD Configuration Register Kernel Reset value: $0000\ 0000_H$



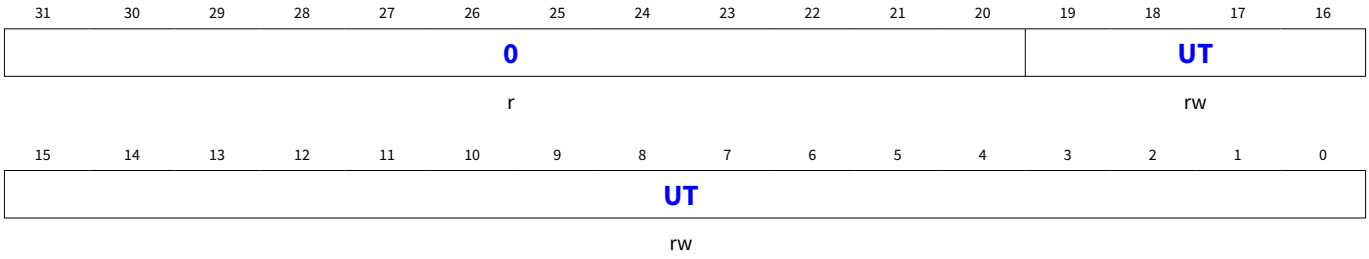
Field	Bits	Type	Description
SFDL	6:0	rw	**Static Frame Data Length (gPayloadLengthStatic)** Configures the cluster-wide payload length for all Frames sent in the static segment in double byte. The payload length must be identical in all nodes of a cluster. Valid values are 0 to 127 (0 to $7F_H$).
SLT	28:16	rw	**Start of Latest Transmit (pLatestTx)** Configures the maximum minislot value allowed before inhibiting Frame transmission in the dynamic segment of the cycle. There is no transmission dynamic segment if SLT is reset to zero. Valid values are 0 to 7981 (0 to $1F2D_H$) minislots.
0	15:7, 31:29	r	**Reserved** Read as 0; should be written with 0.

23.4.30 GTU Configuration Register 1

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC01 Offset address: $00A0_H$

GTU Configuration Register 1 Kernel Reset value: $0000\ 0280_H$



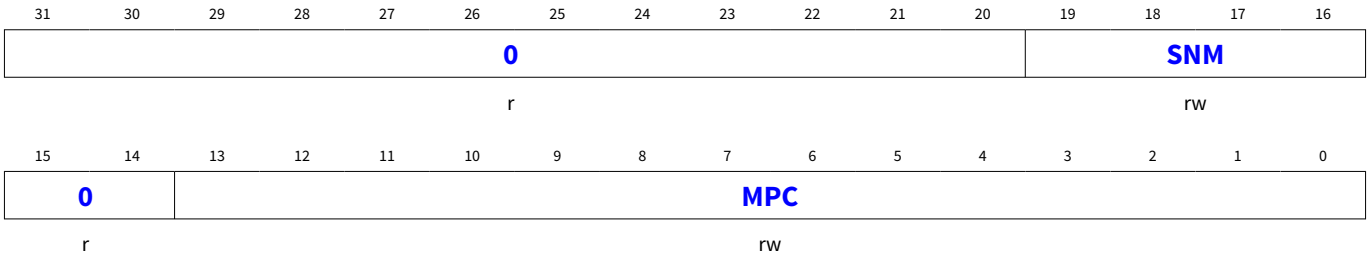
Field	Bits	Type	Description
UT	19:0	rw	**Microtick per Cycle (pMicroPerCycle)** Configures the duration of the communication cycle in Microticks. Valid values are 640 to 640000 (280_H to $9C400_H$) Microticks.
0	31:20	r	**Reserved** Read as 0; should be written with 0.

23.4.31 GTU Configuration Register 2

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC02 Offset address: $00A4_H$

GTU Configuration Register 2 Kernel Reset value: $0002\ 000A_H$



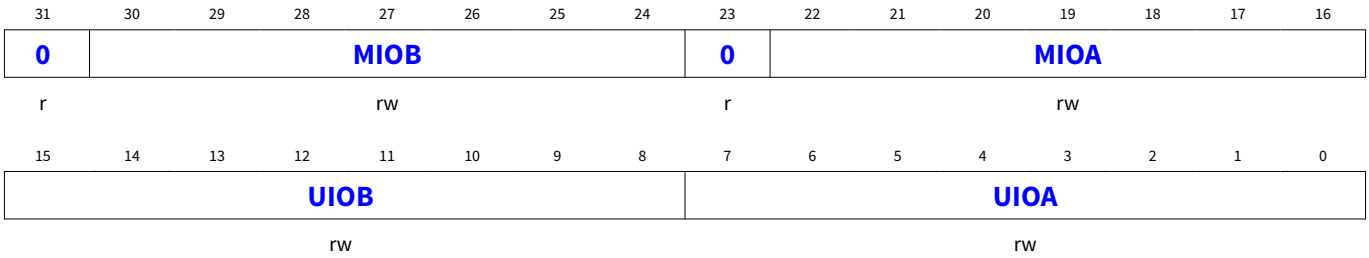
Field	Bits	Type	Description
MPC	13:0	rw	**Macrotick Per Cycle (gMacroPerCycle)** Configures the duration of one communication cycle in Macroticks. The cycle length must be identical in all nodes of a cluster. Valid values are 10 to 16000 (A_H to $3E80_H$) Macroticks.
SNM	19:16	rw	**Sync Node Max (gSyncNodeMax)** Maximum number of Frames within a cluster with SYNC Frame indicator bit SYN set to 1. Must be identical in all nodes of a cluster. Valid values are 2 to 15 (2_H to F_H).
0	15:14, 31:20	r	**Reserved** Read as 0; should be written with 0.

23.4.32 GTU Configuration Register 3

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC03 Offset address: $00A8_H$

GTU Configuration Register 3 Kernel Reset value: $0202\ 0000_H$



Field	Bits	Type	Description
UIOA	7:0	rw	**Microtick Initial Offset Channel A (pMicroInitialOffset[A])** Configures the number of Microticks between the actual time reference point on channel A and the subsequent Macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation[A] and therefore has to be set for each channel independently. Valid values are 0 to 240 (0_H to $F0_H$) Microticks.

(table continues...)

(continued)

Field	Bits	Type	Description
UIOB	15:8	rw	**Microtick Initial Offset Channel B (pMicroInitialOffset[B])** Configures the number of Microticks between the actual time reference point on channel B and the subsequent Macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation[B] and therefore has to be set for each channel independently. Valid values are 0 to 240 (0_H to $F0_H$) Microticks.
MIOA	22:16	rw	**Macrotick Initial Offset Channel A (gMacroInitialOffset[A])** Configures the number of Macroticks between the static slot boundary and the subsequent Macrotick boundary of the secondary time reference point based on the nominal Macrotick duration. Must be identical in all nodes of a cluster. Valid values are 2 to 72 (2_H to 48_H) Macroticks.
MIOB	30:24	rw	**Macrotick Initial Offset Channel B (gMacroInitialOffset[B])** Configures the number of Macroticks between the static slot boundary and the subsequent Macrotick boundary of the secondary time reference point based on the nominal Macrotick duration. Must be identical in all nodes of a cluster. Valid values are 2 to 72 (2_H to 48_H) Macroticks.
0	23, 31	r	**Reserved** Read as 0; should be written with 0.

23.4.33 GTU Configuration Register 4

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only. For details about configuration of NIT and OCS see “Configuration of Network Idle Time (NIT) Start and Offset Correction Start”.

GTUC04 Offset address: $00AC_H$

GTU Configuration Register 4 Kernel Reset value: $0008\ 0007_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		OCS													
r		rw													

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		NIT													
r		rw													

Field	Bits	Type	Description
NIT	13:0	rw	**Network Idle Time Start (gMacroPerCycle - gdNIT - 1)** Configures the starting point of the Network Idle Time (NIT) at the end of the communication cycle expressed in terms of Macroticks from the beginning of the cycle. The start of network idle time (NIT) is recognized if Macrotick = gMacroPerCycle - gdNIT -1 and the increment pulse of Macrotick is set. Must be identical in all nodes of a cluster. Valid values are 7 to 15997 (7_H to $3E7D_H$) Macroticks.

(table continues...)

(continued)

Field	Bits	Type	Description
OCS	29:16	rw	**Offset Correction Start (gOffsetCorrectionStart - 1)** Determines the start of the offset correction within the network idle time (NIT) phase, calculated from start of cycle. Must be identical in all nodes of a cluster. For cluster consisting of ERAY implementations only, it is sufficient to program OCS = NIT + 1. Valid values are 8 to 15998 (8_H to $3E7E_H$) Macroticks.
0	15:14, 31:30	r	**Reserved** Read as 0; should be written with 0.

23.4.34 GTU Configuration Register 5

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC05 Offset address: $00B0_H$

GTU Configuration Register 5 Kernel Reset value: $0E00\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw								r			rw				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DCB								DCA							
rw								rw							

Field	Bits	Type	Description
DCA	7:0	rw	**Delay Compensation Channel A (pDelayCompensation[A])** Used to compensate for reception delays on channel A. This covers assumed propagation delay up to cPropagationDelayMax for Microticks in the range of 0.0125 µs to 0.05 µs. In practice, the minimum of the propagation delays of all sync nodes should be applied. Valid values are 0 to 200 (0_H to $C8_H$) Microticks.
DCB	15:8	rw	**Delay Compensation Channel B (pDelayCompensation[B])** Used to compensate for reception delays on channel B. This covers assumed propagation delay up to cPropagationDelayMax for Microticks in the range of 0.0125 to 0.05 µs. In practice, the minimum of the propagation delays of all sync nodes should be applied. Valid values are 0 to 200 (0_H to $C8_H$) Microticks.
CDD	20:16	rw	**Cluster Drift Damping (pClusterDriftDamping)** Configures the cluster drift damping value used in clock synchronization to minimize accumulation of rounding errors. Valid values are 0 to 20 (0_H to 14_H) Microticks.
DEC	31:24	rw	**Decoding Correction (pDecodingCorrection)** Configures the decoding correction value used to determine the primary time reference point. Valid values are 14 to 143 (E_H to $8F_H$) Microticks.

(table continues...)

(continued)

Field	Bits	Type	Description
0	23:21	r	**Reserved** Read as 0; should be written with 0.

23.4.35 GTU Configuration Register 6

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC06 Offset address: $00B4_H$

GTU Configuration Register 6 Kernel Reset value: $0002\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r					rw										

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					ASR										
r					rw										

Field	Bits	Type	Description
ASR	10:0	rw	**Accepted Startup Range (pdAcceptedStartupRange)** Number of Microticks constituting the expanded range of measured deviation for startup Frames during integration. Valid values are 0 to 1875 (0_H to 753_H) Microticks.
MOD	26:16	rw	**Maximum Oscillator Drift (pdMaxDrift)** Maximum drift offset between two nodes that operate with unsynchronized clocks over one communication cycle in Microticks. Valid values are 2 to 1923 (2_H to 783_H) Microticks.
0	15:11, 31:27	r	**Reserved** Read as 0; should be written with 0.

23.4.36 GTU Configuration Register 7

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC07 Offset address: $00B8_H$

GTU Configuration Register 7 Kernel Reset value: $0002\ 0004_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						SSL									
r						rw									

Field	Bits	Type	Description
SSL	9:0	rw	**Static Slot Length (gdStaticSlot)** Configures the duration of a static slot in Macroticks. The static slot length must be identical in all nodes of a cluster. Valid values are 4 to 659 (4_H to 293_H) Macroticks.
NSS	25:16	rw	**Number of Static Slots (gNumberOfStaticSlots)** Configures the number of static slots in a cycle. At least 2 coldstart nodes must be configured to startup a FlexRay™ network. The number of static slots must be identical in all nodes of a cluster. Valid values are 2 to 1023 (2_H to $3FF_H$).
0	15:10, 31:26	r	**Reserved** Read as 0; should be written with 0.

23.4.37 GTU Configuration Register 8

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC08 Offset address: $00BC_H$

GTU Configuration Register 8 Kernel Reset value: $0000\ 0002_H$

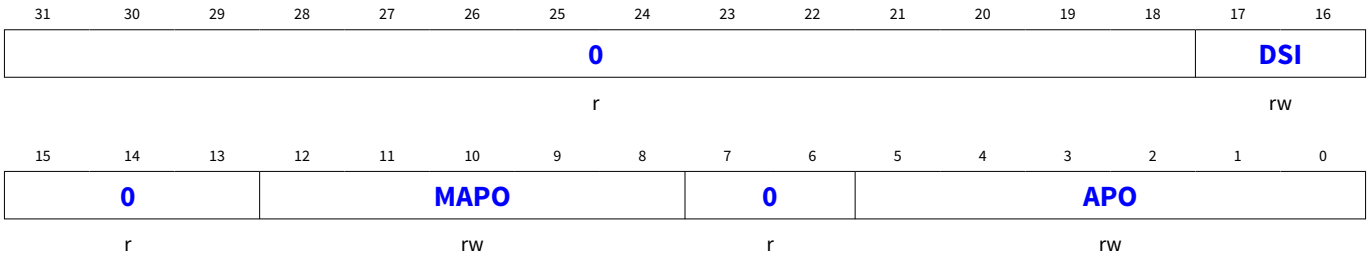
Field	Bits	Type	Description
MSL	5:0	rw	**Minislot Length (gdMinislot)** Configures the duration of a minislot in Macroticks. The minislot length must be identical in all nodes of a cluster. Valid values are 2 to 63 (2_H to $3F_H$) Macroticks.
NMS	28:16	rw	**Number of Minislots (gNumberOfMinislots)** Configures the number of minislots within the dynamic segment of a cycle. The number of minislots must be identical in all nodes of a cluster. Valid values are 0 to 7986 (0_H to $1F32_H$).
0	15:6, 31:29	r	**Reserved** Read as 0; should be written with 0.

23.4.38 GTU Configuration Register 9

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC09 Offset address: $00C0_H$

GTU Configuration Register 9 Kernel Reset value: $0000\ 0101_H$



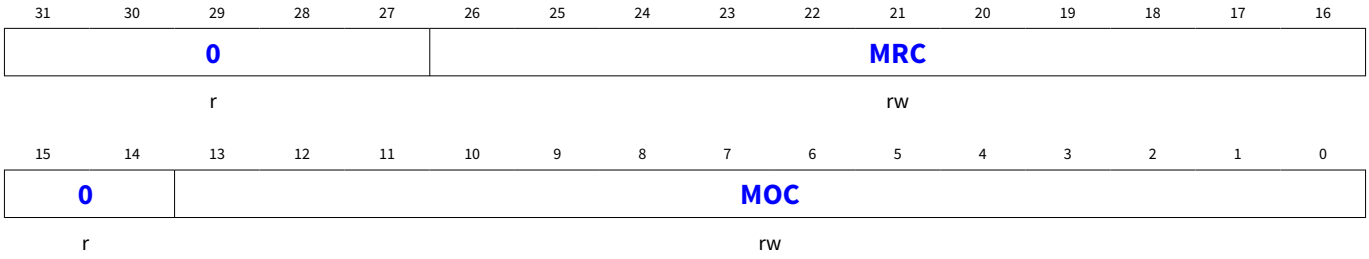
Field	Bits	Type	Description
APO	5:0	rw	**Action Point Offset (gdActionPointOffset)** Configures the action point offset in Macroticks within static slots and symbol window. Must be identical in all nodes of a cluster. Valid values are 1 to 63 (1_H to $3F_H$) Macroticks.
MAPO	12:8	rw	**Minislot Action Point Offset (gdMinislot Action Point Offset)** Configures the action point offset in Macroticks within the minislots of the dynamic segment. Must be identical in all nodes of a cluster. Valid values are 1 to 31 (1_H to $1F_H$) Macroticks.
DSI	17:16	rw	**Dynamic Slot Idle Phase (gdDynamicSlotIdlePhase)** The duration of the dynamic slot idle phase has to be greater or equal than the idle detection time. Must be identical in all nodes of a cluster. Valid values are 0 to 2 Minislot.
0	7:6, 15:13, 31:18	r	**Reserved** Read as 0; should be written with 0.

23.4.39 GTU Configuration Register 10

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

GTUC10 Offset address: $00C4_H$

GTU Configuration Register 10 Kernel Reset value: $0002\ 0005_H$



Field	Bits	Type	Description
MOC	13:0	rw	**Maximum Offset Correction (pOffsetCorrectionOut)** Holds the maximum permitted offset correction value to be applied by the internal clock synchronization algorithm (absolute value). The Communication Controller checks only the internal offset correction value against the maximum offset correction value. Valid values are 5 to 15266 (5_H to $3BA2_H$) Microticks.
MRC	26:16	rw	**Maximum Rate Correction (pRateCorrectionOut)** Holds the maximum permitted rate correction value to be applied by the internal clock synchronization algorithm. The Communication Controller checks only the internal rate correction value against the maximum rate correction value (absolute value). Valid values are 2 to 1923 (2_H to 783_H) Microticks.
0	15:14, 31:27	r	**Reserved** Read as 0; should be written with 0.

23.4.40 GTU Configuration Register 11

GTUC11 Offset address: $00C8_H$

GTU Configuration Register 11 Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
EOCC	1:0	rw	**External Offset Correction Control (pExternOffsetControl)** By writing to EOCC the external offset correction is enabled as specified below. Should be modified only outside network idle time (NIT). 00_B No external offset correction 01_B No external offset correction 10_B External offset correction value subtracted from calculated offset correction value 11_B External offset correction value added to calculated offset correction value

(table continues...)

(continued)

Field	Bits	Type	Description
ERCC	9:8	rw	**External Rate Correction Control (pExternRateControl)** By writing to ERCC the external rate correction is enabled as specified below. Should be modified only outside network idle time (NIT). 00_B No external rate correction 01_B No external rate correction 10_B External rate correction value subtracted from calculated rate correction value 11_B External rate correction value added to calculated rate correction value
EOC	18:16	rw	**External Offset Correction (pExternOffsetCorrection)** Holds the external clock offset correction value in Microticks to be applied by the internal synchronization algorithm. The value is subtracted / added from / to the calculated offset correction value. The value is applied during network idle time (NIT). May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 7 Microticks.
ERC	26:24	rw	**External Rate Correction (pExternRateCorrection)** Holds the external rate correction value in Microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated rate correction value. The value is applied during network idle time (NIT). Can be modified in “DEFAULT_CONFIG” or “CONFIG” state only. Valid values are 0 to 7 Microticks.
0	7:2, 15:10, 23:19, 31:27	r	**Reserved** Read as 0; should be written with 0.

23.4.41 Communication Controller Status Vector

CCSV Offset address: 0100_H

Communication Controller Status Vector Kernel Reset value: $0010\ 4000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	rh	rh	rh	r		rh		rh	rh	rh					

Field	Bits	Type	Description
POCS	5:0	rh	**Protocol Operation Control Status** 00_H ... 05_H, $0F_H$ Indicates the actual state of operation of the Communication Controller Protocol Operation Control 06_H … 14_H are reserved. 10_H ... 13_H Indicates the actual state of operation of the POC in the wakeup path 14_H … $1F_H$ are reserved. 20_H ... $2B_H$ Indicates the actual state of operation of the POC in the startup path $2C_H$ … $3F_H$ are reserved. 00_H “DEFAULT_CONFIG” state 01_H “READY” state 02_H “NORMAL_ACTIVE” state 03_H “NORMAL_PASSIVE” state 04_H “HALT” state 05_H “MONITOR_MODE” state $0F_H$ “CONFIG” state 10_H WAKEUP_STANDBY state 11_H “WAKEUP_LISTEN” state 12_H “WAKEUP_SEND” state 13_H “WAKEUP_DETECT” state 20_H “STARTUP_PREPARE” state 21_H “COLDSTART_LISTEN” state 22_H “COLDSTART_COLLISION_RESOLUTION state 23_H “COLDSTART_CONSISTENCY_CHECK” state 24_H “COLDSTART_GAP state 25_H “COLDSTART_JOIN” State 26_H “INTEGRATION_COLDSTART_CHECK” state 27_H “INTEGRATION_LISTEN” state 28_H “INTEGRATION_CONSISTENCY_CHECK” state 29_H “INITIALIZE_SCHEDULE” state $2A_H$ “ABORT_STARTUP” state $2B_H$ “STARTUP_SUCCESS” state
FSI	6	rh	**Freeze Status Indicator (vPOC!Freeze)** Indicates that the POC has entered the “HALT” state due to CHI command “FREEZE” or due to an error condition requiring an immediate POC halt. Reset by transition from “HALT” to “DEFAULT_CONFIG” state.
HRQ	7	rh	**Halt Request (vPOC!CHIHaltRequest)** Indicates that a request from the Host has been received to halt the POC at the end of the communication cycle. Reset by transition from “HALT” to “DEFAULT_CONFIG” state or when entering “READY” state.

(table continues...)

(continued)

Field	Bits	Type	Description
SLM	9:8	rh	**Slot Mode (vPOC!SlotMode)** Indicates the actual slot mode of the POC in states READY, WAKEUP, STARTUP, NORMAL_ACTIVE, and NORMAL_PASSIVE. Default is “SINGLE”. Changes to “ALL”, depending on configuration bit SUCC1.TSM. In “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state the CHI command “ALL_SLOTS” will change the slot mode from “SINGLE” over “ALL_PENDING” to “ALL”. Set to SINGLE in all other states. 00_B SINGLE 01_B Reserved 10_B ALL_PENDING 11_B ALL
CSNI	12	rh	**Coldstart Noise Indicator (vPOC!ColdstartNoise)** Indicates that the cold start procedure occurred under noisy conditions. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state or from “READY” to “STARTUP” state.
CSAI	13	rh	**Coldstart Abort Indicator** Coldstart aborted. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state or from “READY” to “STARTUP” state.
CSI	14	rh	**Cold Start Inhibit (vColdStartInhibit)** Indicates that the node is disabled from cold starting. The flag is set whenever the POC enters “READY” state due to CHI command “READY”. The flag has to be reset under control of the Host by CHI command “ALLOW_COLDSTART” (SUCC1.CMD = 1001_B). 0_B Cold starting of node enabled 1_B Cold starting of node disabled

(table continues...)

(continued)

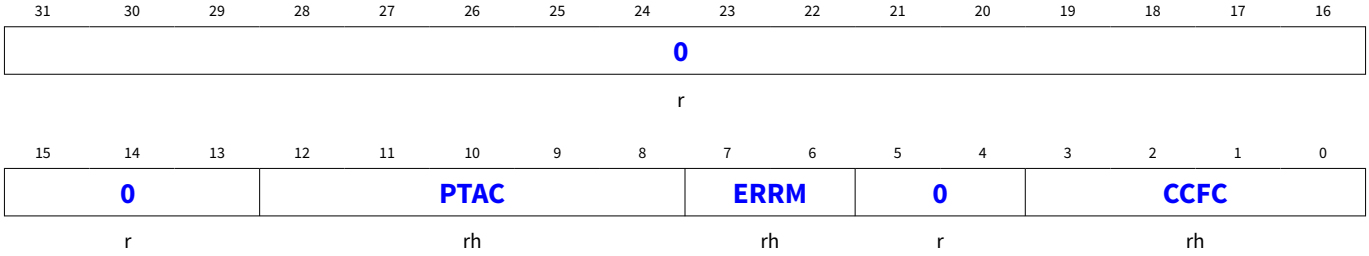
Field	Bits	Type	Description
WSV	18:16	rh	**Wakeup Status (vPOC!WakeupStatus)** Indicates the status of the current wakeup attempt. Reset by CHI command “RESET_STATUS_INDICATORS” or by transition from “HALT” to “DEFAULT_CONFIG” state. 000_B UNDEFINED. Wakeup not yet executed by the Communication Controller. 001_B RECEIVED_HEADER. Set when the Communication Controller finishes wakeup due to the reception of a Frame Header without coding violation on either channel in “WAKEUP_LISTEN” state. 010_B RECEIVED_WUP. Set when the Communication Controller finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in “WAKEUP_LISTEN” state. 011_B COLLISION_HEADER. Set when the Communication Controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid Header on either channel. 100_B COLLISION_WUP. Set when the Communication Controller stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel. 101_B COLLISION_UNKNOWN. Set when the Communication Controller stops wakeup by leaving “WAKEUP_DETECT” state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid Frame Header. 110_B TRANSMITTED. Set when the Communication Controller has successfully completed the transmission of the wakeup pattern. 111_B Reserved
RCA	23:19	rh	**Remaining Coldstart Attempts (vRemainingColdstartAttempts)** Indicates the number of remaining coldstart attempts. The RUN command resets this counter to the maximum number of coldstart attempts as configured by SUCC1.CSA.
PSL	29:24	rh	**POC Status Log** Status of CCSV.POCS immediately before entering “HALT” state. Set when entering “HALT” state. Set to “HALT” when FREEZE command is applied during “HALT” state. Reset to 000000_B when leaving “HALT” state.
0	11:10, 15, 31:30	r	**Reserved** Read as 0; should be written with 0.

23.4.42 Communication Controller Error Vector

Reset by transition from “HALT” to “DEFAULT_CONFIG” state or when entering “READY” state.

CCEV — Offset address: 0104_H

Communication Controller Error Vector — Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CCFC	3:0	rh	**Clock Correction Failed Counter (vClockCorrectionFailed)** The Clock Correction Failed Counter is incremented by one at the end of any odd communication cycle where either the missing offset correction error or missing rate correction error are active. The Clock Correction Failed Counter is reset to 0 at the end of an odd communication cycle if neither the offset correction failed nor the rate correction failed errors are active. The Clock Correction Failed Counter stops at 15.
ERRM	7:6	rh	**Error Mode (vPOC!ErrorMode)** Indicates the actual error mode of the POC. 00_B “ACTIVE” 01_B “PASSIVE” 10_B “COMM_HALT” 11_B Reserved
PTAC	12:8	rh	**Passive to Active Count (vAllowPassiveToActive)** Indicates the number of consecutive even / odd cycle pairs that have passed with valid rate and offset correction terms, while the node is waiting to transit from “NORMAL_PASSIVE” state to “NORMAL_ACTIVE” state. The transition takes place when PTAC equals SUCC1.PTA - 1.
0	5:4, 31:13	r	**Reserved** Read as 0; should be written with 0.

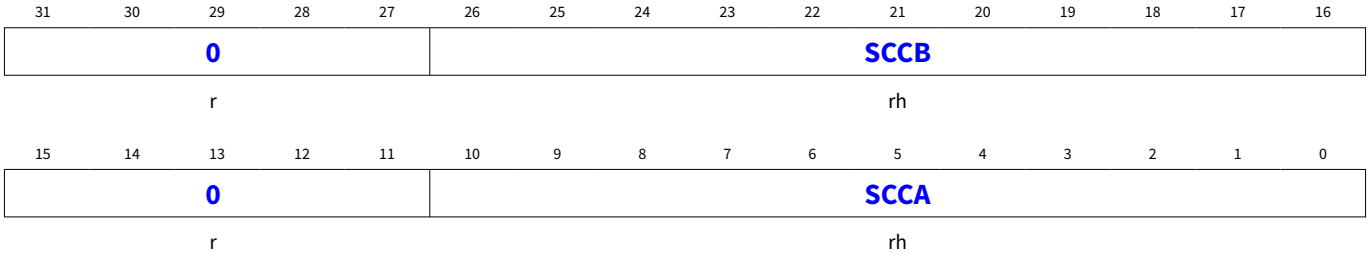
23.4.43 Slot Counter Value

SCV

Slot Counter Value

Offset address: 0110_H

Kernel Reset value: $0000\ 0000_H$

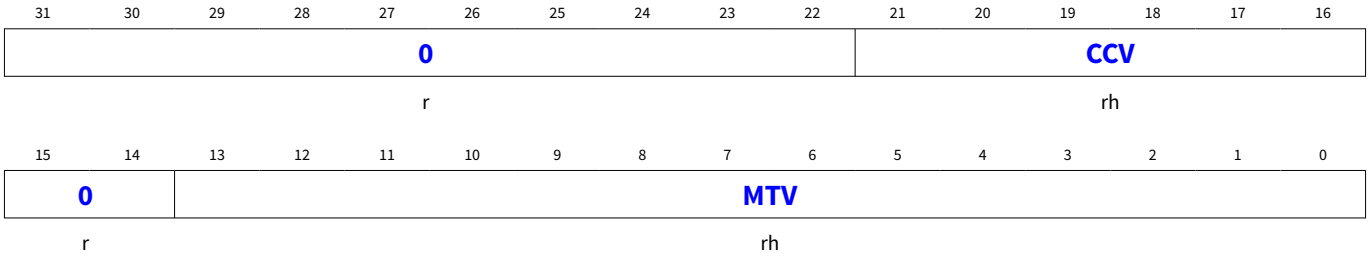


Field	Bits	Type	Description
SCCA	10:0	rh	**Slot Counter Channel A (vSlotCounter[A])** Current slot counter value on channel A. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 2047 (0_H to $7FF_H$).
SCCB	26:16	rh	**Slot Counter Channel B (vSlotCounter[B])** Current slot counter value on channel B. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 2047 (0_H to $7FF_H$).
0	15:11, 31:27	r	**Reserved** Read as 0; should be written with 0.

23.4.44 Macrotick and Cycle Counter Value

MTCCV Offset address: 0114_H

Macrotick and Cycle Counter Value Kernel Reset value: $0000\ 0000_H$

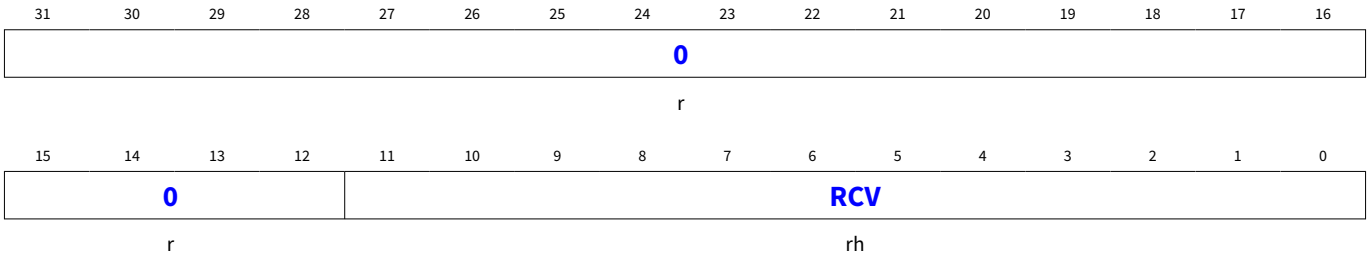


Field	Bits	Type	Description
MTV	13:0	rh	**Macrotick Value (vMacrotick)** Current Macrotick value. The value is incremented by the Communication Controller and reset at the start of a communication cycle. Valid values are 0 to 16000 (0_H to $3E80_H$).
CCV	21:16	rh	**Cycle Counter Value (vCycleCounter)** Current cycle counter value. The value is incremented by the Communication Controller at the start of a communication cycle. Valid values are 0 to 63 (0_H to $3F_H$).
0	15:14, 31:22	r	**Reserved** Read as 0; should be written with 0.

23.4.45 Rate Correction Value

RCV Offset address: 0118_H

Rate Correction Value Kernel Reset value: $0000\ 0000_H$



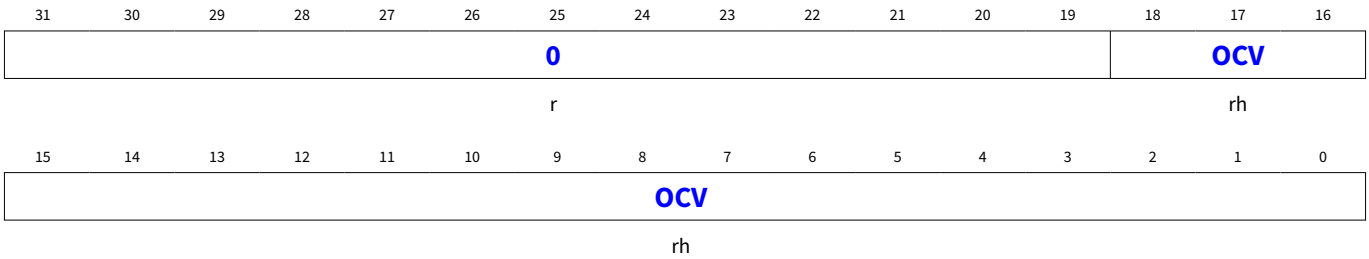
Field	Bits	Type	Description
RCV	11:0	rh	**Rate Correction Value (vRateCorrection)** Rate correction value (two's complement). Calculated internal rate correction value before limitation. If the RCV value exceeds the limits defined by GTUC10.MRC, flag SFS.RCLR is set to 1.
0	31:12	r	**Reserved** Read as 0; should be written with 0.

23.4.46 Offset Correction Value

***Note**: The external rate / offset correction value is added to the limited rate / offset correction value.*

OCV Offset address: $011C_H$

Offset Correction Value Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
OCV	18:0	rh	**Offset Correction Value (vOffsetCorrection)** Offset correction value (two's complement). Calculated internal offset correction value before limitation. If the OCV value exceeds the limits defined by GTUC10.MOC flag SFS.OCLR is set to 1.
0	31:19	r	**Reserved** Read as 0; should be written with 0.

23.4.47 SYNC Frame Status

The maximum number of valid SYNC Frames in a communication cycle is 15.

SFS Offset address: 0120_H

SYNC Frame Status Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
VSAE	3:0	rh	**Valid SYNC Frames Channel A, even communication cycle** Holds the number of valid SYNC Frames received on channel A in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY, the value is incremented by one. The value is updated during the network idle time (NIT) of each even communication cycle. This bit field is only valid if the channel A is assigned to the Communication Controller by SUCC1.CCHA.
VSAO	7:4	rh	**Valid SYNC Frames Channel A, odd communication cycle** Holds the number of valid SYNC Frames received on channel A in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY, the value is incremented by one. The value is updated during the network idle time (NIT) of each odd communication cycle. This bit field is only valid if the channel A is assigned to the Communication Controller by SUCC1.CCHA.
VSBE	11:8	rh	**Valid SYNC Frames Channel B, even communication cycle** Holds the number of valid SYNC Frames received on channel B in the even communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY, the value is incremented by one. The value is updated during the network idle time (NIT) of each even communication cycle. This bit field is only valid if the channel B is assigned to the Communication Controller by SUCC1.CCHB.
VSBO	15:12	rh	**Valid SYNC Frames Channel B, odd communication cycle** Holds the number of valid SYNC Frames received on channel B in the odd communication cycle. If transmission of SYNC Frames is enabled by SUCC1.TXSY, the value is incremented by one. The value is updated during the network idle time (NIT) of each odd communication cycle. This bit field is only valid if the channel B is assigned to the Communication Controller by SUCC1.CCHB.
MOCS	16	rh	**Missing Offset Correction Signal** The Missing Offset Correction flag signals to the Host, that no offset correction calculation can be performed because no SYNC Frames were received. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Offset correction signal valid 1_B Missing offset correction signal

(table continues...)

(continued)

Field	Bits	Type	Description
OCLR	17	rh	**Offset Correction Limit Reached** The Offset Correction Limit Reached flag signals to the Host, that the offset correction value has exceeded its limit as defined by GTUC10.MOC. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Offset correction below limit 1_B Offset correction limit reached
MRCS	18	rh	**Missing Rate Correction Signal** The Missing Rate Correction Flag signals to the Host, that no rate correction calculation can be performed because no pairs of even / odd SYNC Frames were received. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Rate correction signal valid 1_B Missing rate correction signal
RCLR	19	rh	**Rate Correction Limit Reached** The Rate Correction Limit Reached flag signals to the Host, that the rate correction value has exceeded its limit as defined by GTUC10.MRC. The flag is updated by the Communication Controller at start of offset correction phase. 0_B Rate correction below limit 1_B Rate correction limit reached
0	31:20	r	**Reserved** Read as 0; should be written with 0.

23.4.48 Symbol Window and Network Idle Time Status

Symbol window related status information. Updated by the Communication Controller at the end of the symbol window for each channel. During startup the status data is not updated.

***Note**: MTSA and MTSB may be changed outside "DEFAULT_CONFIG" or "CONFIG" state when the write to SUC Configuration Register 1 (SUCC1) register is directly preceded by the unlock sequence as described in "Lock Register". This may be combined with CHI command SEND_MTS. If both bits MTSA and MTSB are set to 1, an MTS symbol will be transmitted on both channels when requested by writing SUCC1.CMD = 1000_B*

SWNIT Offset address: 0124_H

0	31:12	r	**Reserved** Read as 0; should be written with 0.

23.4.49 Aggregated Channel Status

The aggregated channel status provides the Host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception. The aggregated channel status also includes status data from the symbol window and the network idle time. The status data is updated (set) after each slot and aggregated until it is reset by the Host. During startup the status data is not updated. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register.

***Note**: The set condition of flags CIA and CIB is also fulfilled if there is only one single Frame in the slot and the slot boundary at the end of the slot is reached during the Frames channel idle recognition phase. When one of the flags SEDB, CEDB, CIB, SBVB changes from 0 to 1, service request flag EIR.EDB is set to 1.When one of the flags SEDA, CEDA, CIA, SBVA changes from 0 to 1, service request flag EIR.EDA is set to 1. LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all rwh bits in this register.*

23.4.52 Network Management Vector x

The three Network Management Vectors n (NMVx, x=1-3) registers hold the accrued Network Management (NM) vector (configurable 0 to 12 byte). The accrued Network Management (NM) vector is generated by the Communication Controller by bit-wise ORing each Network Management (NM) vector received (valid static Frames with PPI = 1) on each channel (see “Network Management”). The Communication Controller updates the Network Management (NM) vector at the end of each communication cycle as long as the Communication Controller is either in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state. NMVx-bytes exceeding the configured Network Management (NM) vector length are not valid.

NMVx (x=1-3) Offset address: $01B0_H+(x-1)*4$

23.4.53 Message RAM Configuration

The Message RAM Configuration register defines the number of Message Buffers assigned to the static segment, dynamic segment, and FIFO. The register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

MRC Offset address: 0300_H

Message RAM Configuration Kernel Reset value: $0180\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					SPLM	SEC		LCB							
r					rw	rw		rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FFB								FDB							
rw								rw							

Field	Bits	Type	Description
FDB	7:0	rw	**First Dynamic Buffer** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00_H No group of Message Buffers exclusively for the static segment configured 01_H …$7F_H$ Message Buffers 0 to FDB-1 reserved for static segment 80_H …FF_H No dynamic Message Buffers configured
FFB	15:8	rw	**First Buffer of FIFO** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00_H …$7E_H$ Message Buffers from FFB to LCB assigned to the FIFO $7F_H$ All Message Buffers assigned to the FIFO 80_H …FF_H No Message Buffers assigned to the FIFO
LCB	23:16	rw	**Last Configured Buffer** May be only modified in “DEFAULT_CONFIG” or “CONFIG” state. 01_H …$7F_H$ Number of Message Buffers is LCB + 1 80_H …FF_H No Message Buffer configured

(table continues...)

(continued)

Field	Bits	Type	Description
SEC	25:24	rw	**Secure Buffers** Not evaluated when the Communication Controller is in “DEFAULT_CONFIG” or “CONFIG” state. For temporary unlocking see “Host Handling of Errors”. ***Note**: In nodes configured for SYNC Frame transmission or for single slot mode operation Message Buffer 0 (and if SPLM = 1, also Message Buffer 1) Reconfiguration of all Message Buffers is always locked* 00_B Reconfiguration of Message Buffers enabled with numbers < FFB enabled. 01_B Reconfiguration of Message Buffers with numbers < FDB and with numbers ≥ FFB locked and transmission of Message Buffers for static segment with numbers ≥ FDB disabled 10_B Reconfiguration of all Message Buffers locked 11_B Reconfiguration of all Message Buffers locked and transmission of Message Buffers for static segment with numbers ≥ FDB disabled
SPLM	26	rw	**SYNC Frame Payload Multiplex** This bit is only evaluated if the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1). When this bit is set to 1 Message Buffers 0 and 1 are dedicated for SYNC Frame transmission with different payload data on channel A and B. When this bit is reset to 0, SYNC Frames are transmitted from Message Buffer 0 with the same payload data on both channels. Note that the channel filter configuration for Message Buffer 0 resp. Message Buffer 1 has to be chosen accordingly. 0_B Only Message Buffer 0 locked against reconfiguration 1_B Both Message Buffers 0 and 1 are locked against reconfiguration
0	31:27	r	**Reserved** Read as 0; should be written with 0.

***Note**: In case the node is configured as sync node (SUCC1.TXSY = 1) or for single slot mode operation (SUCC1.TSM = 1), Message Buffer 0 resp. 1 is reserved for SYNC Frames or single slot Frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation Message Buffer 0 resp. 1 is treated like all other Message Buffers.*

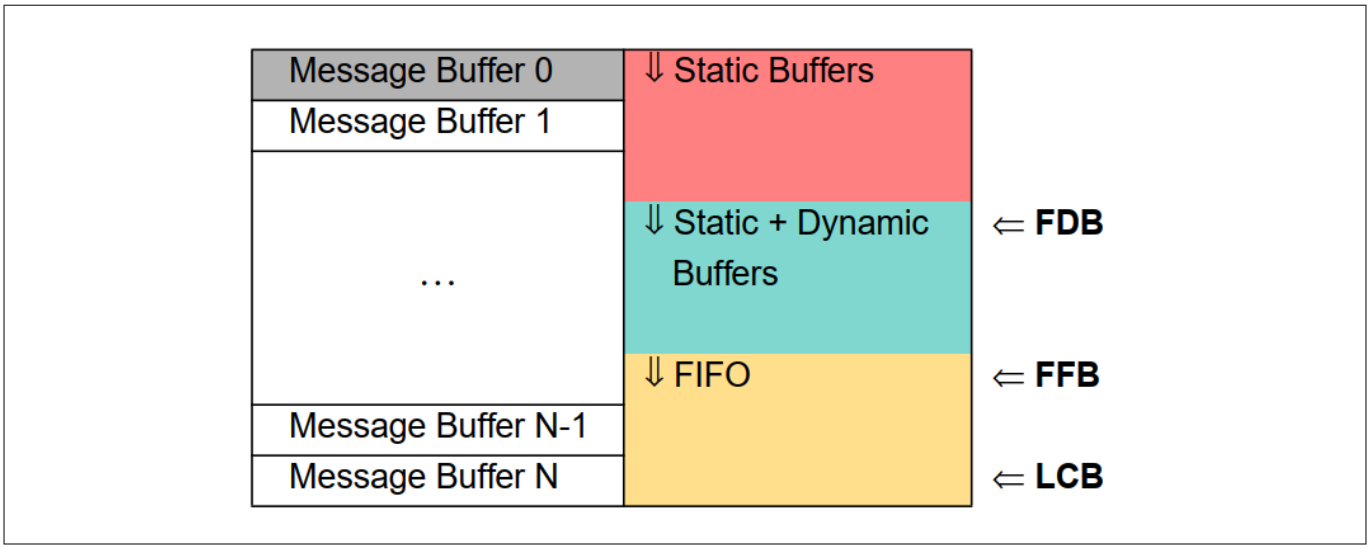

Figure 455 Assignment of message buffers

The programmer has to ensure that the configuration defined by FDB, FFB, and LCB is valid. **The Communication Controller does not check for erroneous configurations.**

The maximum number of Header Sections is 128. This means a maximum of 128 Message Buffer can be configured. The maximum length of a Data Section is 254 byte. The length of the Data Section may be configured differently for each Message Buffer. For details see “Message RAM”. In case two or more Message Buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the “Static Buffers” or at the beginning of the “Static + Dynamic Buffers” section. The payload length configured and the length of the Data Section need to be configured identically for all Message Buffers belonging to the FIFO via WRHS2.PLC and WRHS3.DP. When the Communication Controller is not in “DEFAULT_CONFIG” or “CONFIG” state reconfiguration of Message Buffers belonging to the FIFO is locked.

23.4.54 FIFO Rejection Filter

The FIFO Rejection Filter defines a user specified sequence of bits to which channel, Frame ID, and cycle count of the incoming Frames are compared. Together with the FIFO Rejection Filter Mask this register determines whether a message is rejected by the FIFO. The FRF register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

FRF Offset address: 0304_H

FIFO Rejection Filter Kernel Reset value: $0180\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0							RNF	RSS	CYF						
r							rw	rw	rw						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0			FID											CH	
r			rw											rw	

Field	Bits	Type	Description
CH	1:0	rw	**Channel Filter** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 00_B receive on both channels[1)] 01_B receive only on channel B 10_B receive only on channel A 11_B no reception
FID	12:2	rw	**Frame ID Filter** Determines the Frame ID to be rejected by the FIFO. With the additional configuration of register FRFM, the corresponding Frame ID filter bits are ignored, which results in further rejected Frame IDs. When FRFM.MFID is zero, a Frame ID filter value of zero means that no Frame ID is rejected. 000_H …$7FF_H$ Frame ID filter values
CYF	22:16	rw	**Cycle Counter Filter** The 7-bit cycle counter filter determines the cycle set to which Frame ID and channel rejection filter are applied. In cycles **not** belonging to the cycle set specified by CYF, all Frames are rejected. For details about the configuration of the cycle counter filter see “Cycle Counter Filtering”. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only.
RSS	23	rw	**Reject in Static Segment** If this bit is set, the FIFO is used only for the dynamic segment. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B FIFO also used in static segment 1_B Reject messages for static segment
RNF	24	rw	**Reject NULL Frames** If this bit is set, received NULL Frames are not stored in the FIFO. May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. 0_B NULL Frames are stored in the FIFO 1_B Reject all NULL Frames
0	15:13, 31:25	r	**Reserved** Read as 0; should be written with 0.

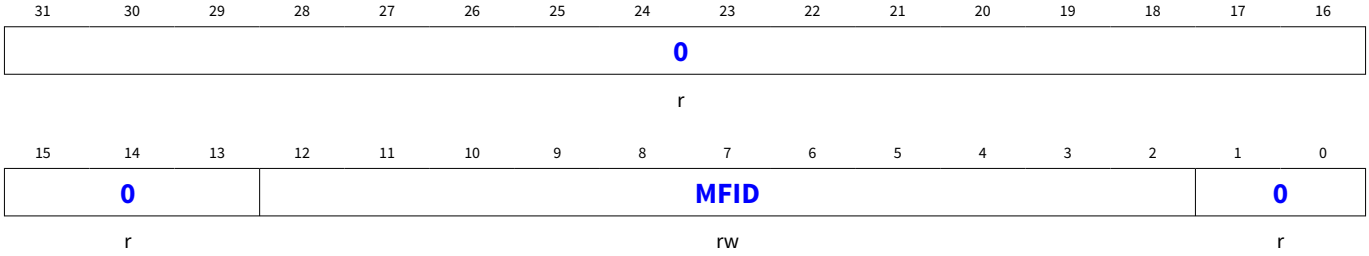
1) If reception on both channels is configured, also in static segment always both Frames (from channel A and B) are stored in the FIFO, even if they are identical.

23.4.55 FIFO Rejection Filter Mask

The FIFO Rejection Filter Mask specifies which of the corresponding Frame ID filter bits are relevant for rejection filtering. If a bit is set, it indicates that the corresponding bit in the FRF register will not be considered for rejection filtering. The FRFM register can be written during “DEFAULT_CONFIG” or “CONFIG” state only.

FRFM Offset address: 0308_H

FIFO Rejection Filter Mask Kernel Reset value: $0000\ 0000_H$



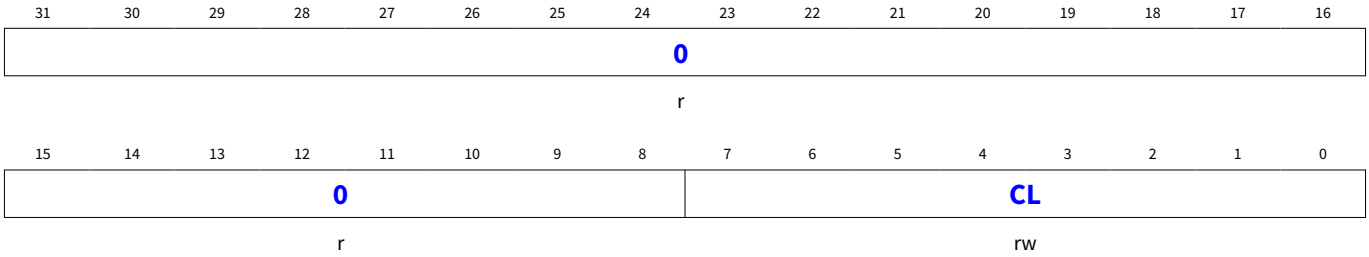
Field	Bits	Type	Description
MFID	12:2	rw	**Mask Frame ID Filter** May be modified in “DEFAULT_CONFIG” or “CONFIG” state only. When '0' written in a bit position, the corresponding Frame ID filter bit is used for rejection filtering. When '1' written in a bit position, the corresponding Frame ID filter bit is ignored. Valid values are from 0x000 - 0x3FF.
0	1:0, 31:13	r	**Reserved** Read as 0; should be written with 0.

23.4.56 FIFO Critical Level

The Communication Controller accepts modifications of the register in “DEFAULT_CONFIG” or “CONFIG” state only.

FCL Offset address: $030C_H$

FIFO Critical Level Kernel Reset value: $0000\ 0080_H$



Field	Bits	Type	Description
CL	7:0	rw	**Critical Level** When the receive FIFO fill level FSR.RFFL is equal or greater than the critical level configured by CL, the receive FIFO critical level flag FSR.RFCL is set. If CL is programmed to values > 128, bit FSR.RFCL is never set. When FSR.RFCL changes from 0 to 1, bit SIR.RFCL is set to 1, and if enabled, a service request is generated.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

23.4.57 Message Handler Status

The Message Handler Status register gives the Host access to the current state of the Message Handler. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect on the flag. An application reset will also clear the register. If one of the flags MHDS.EIBF, MHDS.EOBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2 changes from 0 to 1 EIR.EERR is set.

***Note**: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all ´rwh´ bits in this register.*

MHDS Offset address: 0310_H

Message Handler Status Kernel Reset value: $0000\ 0000_H$

ETBF1	3	rwh	**ECC Error Transient Buffer RAM A** 0_B No error 1_B Error occurred when reading Transient Buffer RAM A
ETBF2	4	rwh	**ECC Error Transient Buffer RAM B** 0_B No error 1_B Error occurred when reading Transient Buffer RAM B
FMBD	5	rwh	**Faulty Message Buffer Detected** 0_B No faulty Message Buffer 1_B Message Buffer referenced by MHDS.FMB holds faulty data due to a ECC error

(table continues...)

(continued)

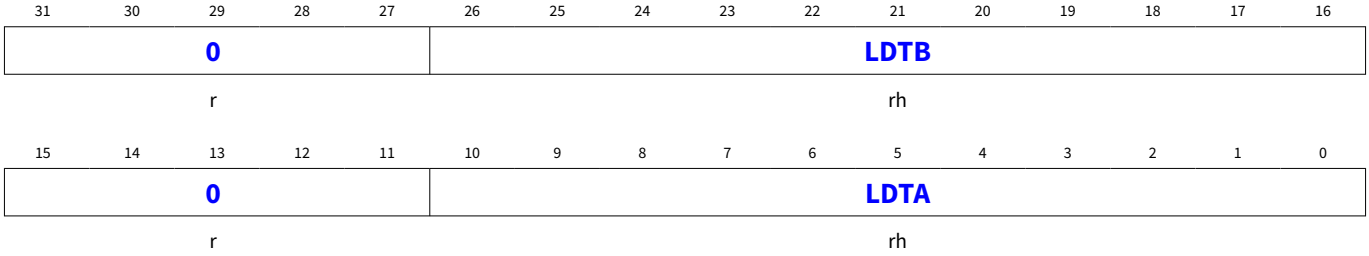
Field	Bits	Type	Description
MFMB	6	rwh	**Multiple Faulty Message Buffers detected** 0_B No additional faulty Message Buffer 1_B Another faulty Message Buffer was detected while flag MHDS.FMBD is set
CRAM	7	rh	**Clear all internal RAM's** Signals that execution of the CHI command CLEAR_RAMS is ongoing (all bits of all internal RAM blocks are written to 0). The bit is set by CHI command CLEAR_RAMS. 0_B No execution of the CHI command CLEAR_RAMS 1_B Execution of the CHI command CLEAR_RAMS ongoing
FMB	14:8	rh	**Faulty Message Buffer** ECC error occurred when reading from the Message Buffer or when transferring data from Input Buffer or Transient Buffer A or Transient Buffer B to the Message Buffer referenced by MHDS.FMB. Value only valid when one of the flags MHDS.EIBF, MHDS.EMR, MHDS.ETBF1, MHDS.ETBF2, and flag MHDS.FMBD is set. Updated only after the Host has reset flag MHDS.FMBD.
MBT	22:16	rh	**Message Buffer Transmitted** Number of last successfully transmitted Message Buffer. If the Message Buffer is configured for single-shot mode, the respective TXR flag in the Transmission Request Registers TXRQ1 to TXRQ4 was reset. MBT is reset when the Communication Controller leaves "CONFIG" state or enters "STARTUP" state.
MBU	30:24	rh	**Message Buffer Updated** Number of Message Buffer that was updated last. For this Message Buffer the respective NDn (n = 0-31) to NDn (n = 96-127)and / or MBCn (n = 0-31) to MBCn (n = 96-127) flag in the New Data Registers NDAT1 to NDAT4 and the Message Buffer Status Changed MBSC1 to MBSC4 registers are also set. MBU is reset when the Communication Controller leaves "CONFIG" state or enters "STARTUP" state.
0	15, 23, 31	r	**Reserved** Read as 0; should be written with 0.

23.4.58 Last Dynamic Transmit Slot

The Last Dynamic Transmit Slot Register stores the Slot Counter value at the time of the last Frame transmission in the dynamic segment. This register is reset when the Communication Controller leaves "CONFIG" state or enters "STARTUP" state.

LDTS Offset address: 0314_H

Last Dynamic Transmit Slot Kernel Reset value: $0000\ 0000_H$



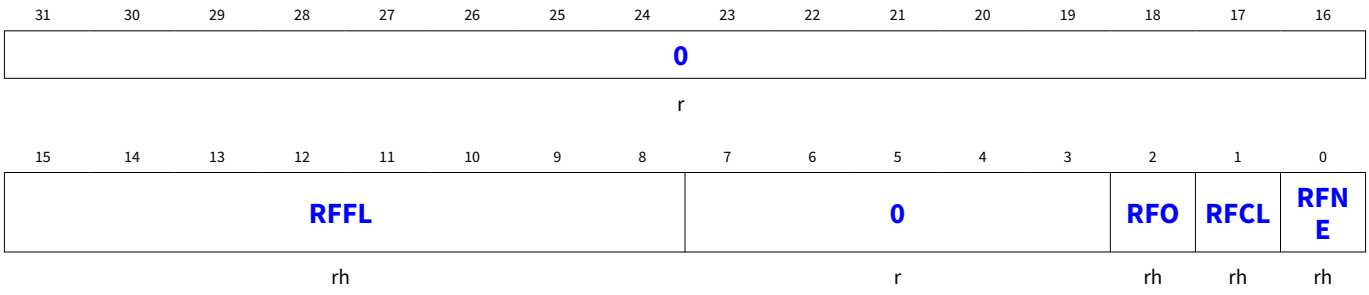
Field	Bits	Type	Description
LDTA	10:0	rh	**Last Dynamic Transmission Channel A** Value of (vSlotCounter[A]) at the time of the last Frame transmission on channel A in the dynamic segment of this node. It is updated at the end of the dynamic segment and is reset to zero if no Frame was transmitted during the dynamic segment.
LDTB	26:16	rh	**Last Dynamic Transmission Channel B** Value of (vSlotCounter[B]) at the time of the last Frame transmission on channel B in the dynamic segment of this node. It is updated at the end of the dynamic segment and is reset to zero if no Frame was transmitted during the dynamic segment.
0	15:11, 31:27	r	**Reserved** Read as 0; should be written with 0.

23.4.59 FIFO Status Register

The register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state.

FSR Offset address: 0318_H

FIFO Status Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RFNE	0	rh	**Receive FIFO Not Empty** This flag is set by the Communication Controller when a received valid Frame (data or NULL Frame depending on rejection mask) was stored in the FIFO. In addition, service request flag SIR.RFNE is set. The bit is reset after the Host has read all message from the FIFO. 0_B Receive FIFO is empty 1_B Receive FIFO is not empty

(table continues...)

(continued)

Field	Bits	Type	Description
RFCL	1	rh	**Receive FIFO Critical Level** This flag is set when the receive FIFO fill level RFFL is equal or greater than the critical level as configured by FCL.CL. The flag is cleared by the Communication Controller as soon as RFFL drops below FCL.CL. When RFCL changes from 0 to 1, bit SIR.RFCL is set to 1, and if enabled, an service request is generated. 0_B Receive FIFO below critical level 1_B Receive FIFO critical level reached
RFO	2	rh	**Receive FIFO Overrun** The flag is set by the Communication Controller when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, service request flag EIR.RFO is set. The flag is cleared by the next FIFO read access issued by the Host. 0_B No receive FIFO overrun detected 1_B A receive FIFO overrun has been detected
RFFL	15:8	rh	**Receive FIFO Fill Level** Number of FIFO buffers filled up with new data not yet read by the Host. Maximum value is 128.
0	7:3, 31:16	r	**Reserved** Read as 0; should be written with 0.

23.4.60 Message Handler Constraints Flags

Some constraints exist for the Message Handler regarding f_{CLC_ERAY} frequency, Message RAM configuration, and FlexRay™ bus traffic. To simplify software development, constraints violations are reported by setting flags in the MHDF. The register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state. A flag is cleared by setting the corresponding bit position. Clearing has no effect on the flag. Software write of '1' when a flag is already cleared has no effect. If any flag in MHDFL is set, interrupt flag EIR.MHF is set.

***Note**: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all ´rwh´ bits in this register.*

MHDF Offset address: $031C_H$

Message Handler Constraints Flags Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r							rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
SNUA	0	rwh	**Status Not Updated Channel A** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to update a Message Buffer's status MBS with respect to channel A. 0_B No overload condition occurred when updating MBS for channel A 1_B MBS for channel A not updated
SNUB	1	rwh	**Status Not Updated Channel B** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to update a Message Buffer's status MBS with respect to channel B. 0_B No overload condition occurred when updating MBS for channel B 1_B MBS for channel B not updated
FNFA	2	rwh	**Find Sequence Not Finished Channel A** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching Message Buffer) with respect to channel A. 0_B No find sequence not finished for channel A 1_B Find sequence not finished for channel A
FNFB	3	rwh	**Find Sequence Not Finished Channel B** This flag is set by the Communication Controller when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching Message Buffer) with respect to channel B. 0_B No find sequence not finished for channel B 1_B Find sequence not finished for channel B
TBFA	4	rwh	**Transient Buffer Access Failure A** This flag is set by the Communication Controller when a read or write access to Transient Buffer A requested by PRT A could not complete within the available time. 0_B No TBF A access failure 1_B TBF A access failure
TBFB	5	rwh	**Transient Buffer Access Failure B** This flag is set by the Communication Controller when a read or write access to Transient Buffer B requested by PRT B could not complete within the available time. 0_B No Transient Buffer B access failure 1_B Transient Buffer B access failure
TNSA	6	rwh	**Transmission Not Started Channel A** This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel A at the action point of the configured slot. 0_B No transmission not started on channel A 1_B Transmission not started on channel A

(table continues...)

(continued)

Field	Bits	Type	Description
TNSB	7	rwh	**Transmission Not Started Channel B** This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel B at the action point of the configured slot. 0_B No transmission not started on channel B 1_B Transmission not started on channel B
WAHP	8	rwh	**Write Attempt to Header Partition** Outside “DEFAULT_CONFIG” and “CONFIG” state this flag is set by the Communication Controller when the Message Handler tries to write message data into the Header Partition of the Message RAM due to faulty configuration of a Message Buffer. The write attempt is not executed, to protect the Header Partition from unintended write accesses. 0_B No write attempt to Header Partition 1_B Write attempt to Header Partition
0	31:9	r	**Reserved** Read as 0; should be written with 0.

23.4.61 Transmission Request Register 1

This register reflect the state of the TXR flags of the configured Message Buffers 0 to 31. The flags are evaluated for transmit buffers only. If the number of configured Message Buffers is less than 31, the remaining TXRn flags have no meaning and are read as 0.

TXRQ1 Offset address: 0320_H

Transmission Request Register 1 Kernel Reset value: $0000\ 0000_H$

23.4.72 Message Buffer Status Changed 4

This register reflect the state of the MBC flags of all configured Message Buffers. If the number of configured Message Buffers is less than 127, the remaining MBCn flags have no meaning. The register is reset when the Communication Controller leaves “CONFIG” state or enters “STARTUP” state.

MBSC4 Offset address: $034C_H$

Message Buffer Status Changed 4 Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
MBCn (n=96-127)	n-96	rh	**Message Buffer Status Changed n (n = 96-127)** An MBC flags is set whenever the Message Handler changes on of the status flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB in the Header Section (see “Message Buffer Status”) of the respective Message Buffer 96 to Message Buffer 127. The flags are reset when the Header Section of the Message Buffer is reconfigured or when it has been transferred to the Output Buffer.

23.4.73 New Data Interrupt Control 1

This New Data Interrupt Control register controls the interrupt that becomes active (NDAT0SRC or NDAT1SRC) on a ND flag turning active of all configured Message Buffers 0 to Message Buffers 31.

NDIC1 Offset address: $03A8_H$

New Data Interrupt Control 1 Kernel Reset value: $0000\ 0000_H$

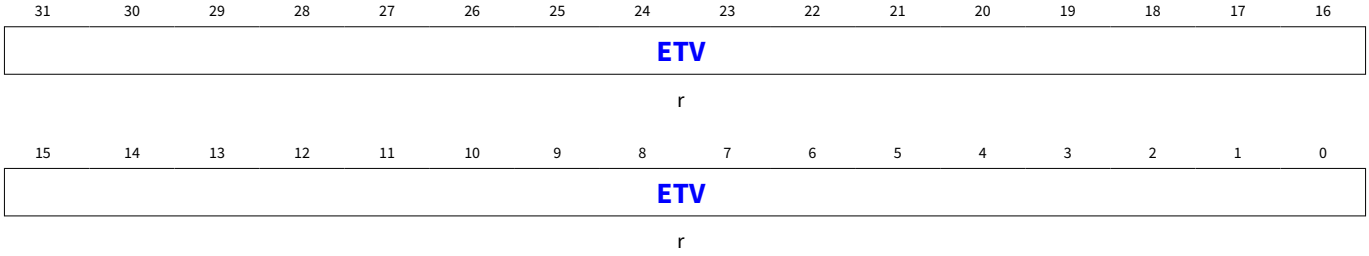
23.4.82 Endian Register

This register may be used to check, if the data of the ERAY is handled by a host with the correct endian format. It is read only.

ENDN Offset address: $03F4_H$

Endian Register Kernel Reset value: $8765\ 4321_H$



Field	Bits	Type	Description
ETV	31:0	r	**Endianness Test Value** The endianness test value.

23.4.83 Write Data Section n

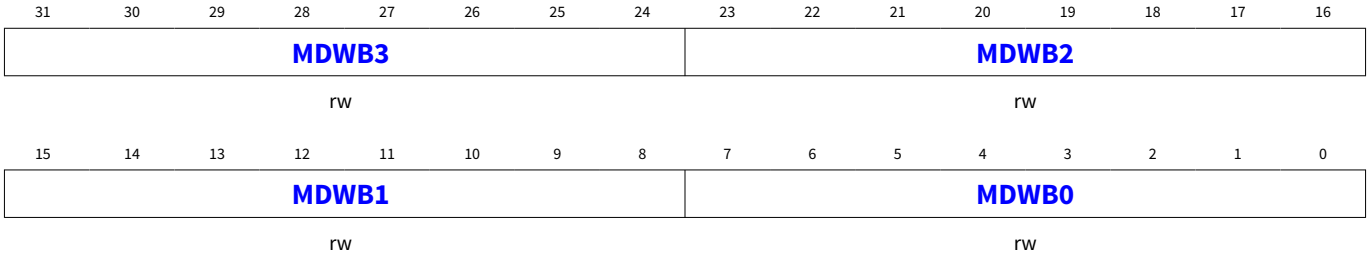
The Write Data Section (WRDSn, n = 01-64) holds the data words to be transferred to the Data Section of the addressed Message Buffer. The data words (DW_n) are written to the Message RAM in transmission order from DW1 (byte0, byte1) to DW_{PL} (PL = number of data words as defined by the payload length configured by WRHS2.PLC).

***Note**: 16-bit Word 127 is located on WRDS64.MDW. In this case WRDS64.MDW is unused (no valid data). The Input Buffer RAMs are initialized to zero by CHI command CLEAR_RAMS.*

When writing to the WRDSn (n = 01-64), each 32-bit word has to be filled up by one 32-bit access OR two consecutive 16-bit accesses OR four consecutive 8-bit accesses before the transfer from the Input Buffer to the Message RAM is started by writing the number of the target Message Buffer in the Message RAM to the Input Buffer Command Request register. If a 32-bit word of the Input Buffer has been filled with less then two consecutive 16-bit accesses OR four consecutive 8-bit accesses (less then 32-bit), random data is transferred into the Input buffer for every not written 16-bit or 8-bit of a 32-bit word.

WRDSn (n=01-64) Offset address: 0400_H+(n-1)*4

Write Data Section n Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
MDWB0	7:0	rw	**32-Bit Word n, Byte 0**
MDWB1	15:8	rw	**32-Bit Word n, Byte 1**
MDWB2	23:16	rw	**32-Bit Word n, Byte 2**
MDWB3	31:24	rw	**32-Bit Word n, Byte 3**

23.4.84 Write Header Section 1

WRHS1

Write Header Section 1

Offset address: 0500_H

Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		MBI	TXM	PPIT	CFG	CHB	CHA	0	CYC						
r		rw	rw	rw	rw	rw	rw	r	rw						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					FID										
r					rw										

Field	Bits	Type	Description
FID	10:0	rw	**Frame ID** Frame ID of the selected Message Buffer. The Frame ID defines the slot number for transmission / reception of the respective message. Message Buffers with Frame ID = 0 are considered as not valid.
CYC	22:16	rw	**Cycle Code** The 7-bit cycle code determines the cycle set used for cycle counter filtering. For details about the configuration of the cycle code see Section "Cycle Counter Filtering".
CHA	24	rw	**Channel Filter Control A** The channel filtering field A associated with the buffer serves of channel A as a filter for receive buffers, and as a control field for transmit buffers
CHB	25	rw	**Channel Filter Control B** The channel filtering field B associated with the buffer serves of channel B as a filter for receive buffers, and as a control field for transmit buffers
CFG	26	rw	**Message Buffer Direction Configuration Bit** This bit is used to configure the corresponding buffer as a transmit buffer or as a receive buffer. For Message Buffers belonging to the receive FIFO the bit is not evaluated. 0_B The corresponding buffer is configured as Receive Buffer 1_B The corresponding buffer is configured as Transmit Buffer
PPIT	27	rw	**Payload Preamble Indicator Transmit** This bit is used to control the state of the Payload Preamble Indicator in transmit Frames. If the bit is set in a static Message Buffer, the respective Message Buffer holds Network Management information. If the bit is set in a dynamic Message Buffer, the first two byte of the Payload Segment may be used for message ID filtering by the receiver. Message ID filtering of received FlexRay™ Frames is not supported by the ERAY module, but can be done by the Host. 0_B Payload Preamble Indicator not set 1_B Payload Preamble Indicator set

(table continues...)

(continued)

Field	Bits	Type	Description
TXM	28	rw	**Transmission Mode** This bit is used to select the transmission mode (see “Transmit Buffers”). 0_B Continuous mode 1_B Single-shot mode
MBI	29	rw	**Message Buffer Service Request** This bit enables the receive / transmit service request for the corresponding Message Buffer. After a dedicated receive buffer has been updated by the Message Handler, flag SIR.RXI and/or SIR.MBSI in the Status Service Request register are set. After a transmission has completed flag SIR.TXI is set. 0_B The corresponding Message Buffer service request is disabled 1_B The corresponding Message Buffer service request is enabled
0	15:11, 23, 31:30	r	**Reserved** Read as 0; should be written with 0.

***Note**: The Input Buffer RAMs are initialized to zero by CHI command CLEAR_RAMS. Note that only the currently active IBF bank is cleared. To clear the 2nd bank as well, CUST1.IBF1PAG and CUST1.IBF2PAG need to be set and command CLEAR_RAMS need to be issued again. This is required in particular after an application reset. If the 2nd bank of IBF is left unused, this procedure is not required.*

Table 1099 Channel Filter Control Bits

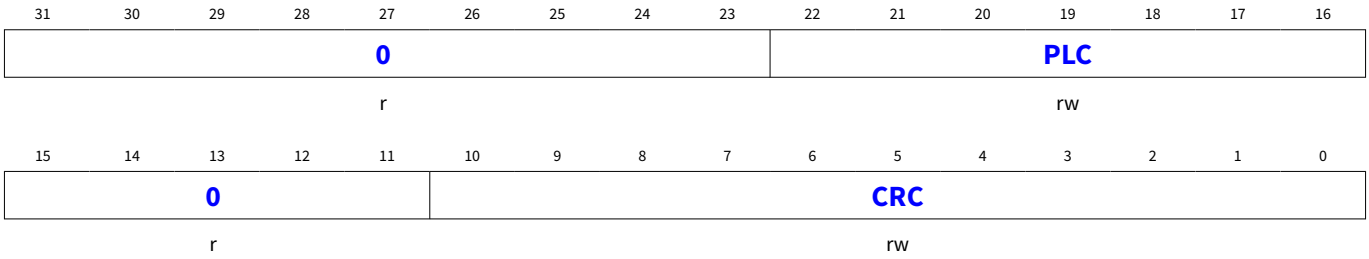
CHA	CHB	Transmit Buffertransmit Frame on	Receive Bufferstore Frame received from
1	1	Both Channels (static segment only)	Channel A or B (store first semantically valid Frame, static segment only)
1	0	Channel A	Channel A
0	1	Channel B	Channel B
0	0	No Transmission	Ignore Frame

***Note**: If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted respectively received Frames are ignored (same function as CHA = CHB = 0)*

23.4.85 Write Header Section 2

WRHS2 Offset address: 0504_H

Write Header Section 2 Kernel Reset value: $0000\ 0000_H$

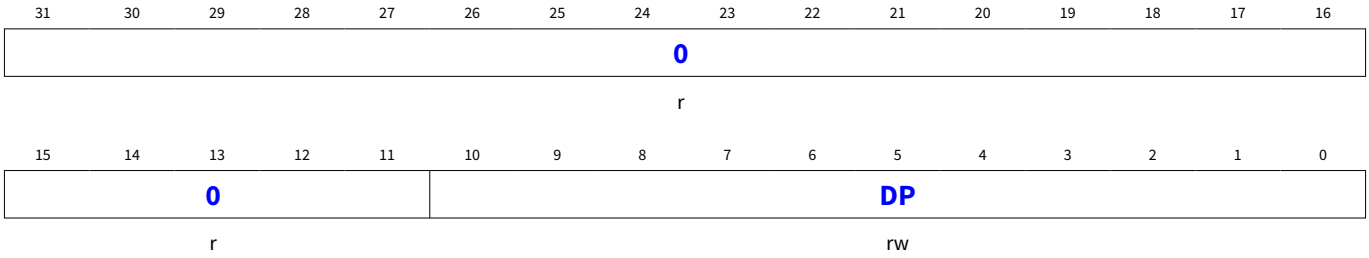


Field	Bits	Type	Description
CRC	10:0	rw	**Header CRC (vRF!Header!HeaderCRC)** Receive Buffer: Configuration not required Transmit Buffer: Header CRC calculated and configured by the Host. For calculation of the Header CRC the payload length of the Frame send on the bus has to be considered. In static segment the payload length of all Frames is configured by MHDC.SFDL.
PLC	22:16	rw	**Payload Length Configured** Length of Data Section (number of 2-byte words) as configured by the Host. During static segment the static Frame payload length as configured by MHDC.SFDL in the MHD Configuration Register defines the payload length for all static Frames. If the payload length configured by PLC is shorter than this value, padding byte are inserted to ensure that Frames have proper physical length. The padding pattern is logical zero.
0	15:11, 31:23	r	**Reserved** Read as 0; should be written with 0.

23.4.86 Write Header Section 3

WRHS3 Offset address: 0508_H

Write Header Section 3 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DP	10:0	rw	**Data Pointer** Pointer to the first 32-bit word of the Data Section of the addressed Message Buffer in the Message RAM.
0	31:11	r	**Reserved** Read as 0; should be written with 0.

23.4.87 Input Buffer Command Mask

Configures how the Message Buffer in the Message RAM selected by the Input Buffer Command Request register IBCR is updated. If IBF Host and IBF Shadow are swapped, also masked bits IBCM.LHSH, IBCM.LDSH, and IBCM.STXRH are swapped with bits IBCM.LHSS, IBCM.LDSS, and IBCM.STXRS to keep them attached to the respective Input Buffer transfer.

IBCM Offset address: 0510_H

Input Buffer Command Mask Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
STXRS	18	rh	**Transmission Request Shadow** If this bit is set to 1, the Transmission Request flag TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 96-127) for the selected Message Buffer is set in the Transmission Request Registers to release the Message Buffer for transmission. In single-shot mode the flag is cleared by the Communication Controller after transmission has completed. TXRQ1.TXRn (n = 0-31) to TXRQ4.TXRn (n = 96-127) are evaluated for transmit buffer only. 0_B Reset Transmission Request flag 1_B Set Transmission Request flag, transmit buffer released for transmission (operation is ongoing or finalized)
0	15:3, 31:19	r	**Reserved** Read as 0; should be written with 0.

23.4.88 Input Buffer Command Request

When the Host writes the number of the target Message Buffer in the Message RAM to IBRH in the Input Buffer Command Request register, IBF Host and IBF Shadow are swapped. In addition the Message Buffer numbers stored under IBRH and IBRS are also swapped (see also “Data Transfer from Input Buffer to Message RAM”).

With this write operation the IBSYS bit in the Input Buffer Command Request register is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the Message Buffer in the Message RAM selected by IBRS.

While the Message Handler transfers the data from IBF Shadow to the target Message Buffer in the Message RAM, the Host may write the next message into the IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, the IBSYS bit is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target Message Buffer number to IBRH.

If a write access to IBRH occurs while IBSYS is 1, IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, IBSYH is reset to 0. IBSYS remains set to 1, and the next transfer to the Message RAM is started. In addition the Message Buffer numbers stored under IBRH and IBRS are also swapped. Any write access to an Input Buffer register while both IBSYS and IBSYH are set will cause the error flag EIR.IIBA to be set. In this case the Input Buffer will not be changed.

IBCR Offset address: 0514_H

Input Buffer Command Request Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
IBRH	6:0	rwh	**Input Buffer Request Host** Selects the target Message Buffer in the Message RAM for data transfer from Input Buffer. Valid values are 00_H to $7F_H$ (0…127).

(table continues...)

(continued)

Field	Bits	Type	Description
IBSYH	15	rh	**Input Buffer Busy Host** Set to 1 by writing IBRH while IBSYS is still 1. After the ongoing transfer between IBF Shadow and the Message RAM has completed, the IBSYH is set back to 0. 0_B No request pending 1_B Request while transfer between IBF Shadow and Message RAM in progress
IBRS	22:16	rh	**Input Buffer Request Shadow** Number of the target Message Buffer actually updated/lately updated. Valid values are 00_H to $7F_H$ (0…127).
IBSYS	31	rh	**Input Buffer Busy Shadow** Set to 1 after writing IBRH. When the transfer between IBF Shadow and the Message RAM has completed, IBSYS is set back to 0. 0_B Transfer between IBF Shadow and Message RAM completed 1_B Transfer between IBF Shadow and Message RAM in progress
0	14:7, 30:23	r	**Reserved** Read as 0; should be written with 0.

23.4.89 Read Data Section n

The Read Data Section n (RDDSn, n = 01-64) holds the data words read from the Data Section of the addressed Message Buffer. The data words are read from the Message RAM in reception order from DW1 (byte0, byte1) to DW_{PL} (PL = number of data words as defined by the Payload Length).

***Note**: DW127 is located on RDDS64.MDW. In this case RDDS64.MDW is unused (no valid data). The Output Buffer RAMs are initialized to zero by CHI command CLEAR_RAMS.*

RDDSn (n=01-64) Offset address: 0600_H+(n-1)*4

Read Data Section n Kernel Reset value: $0000\ 0000_H$

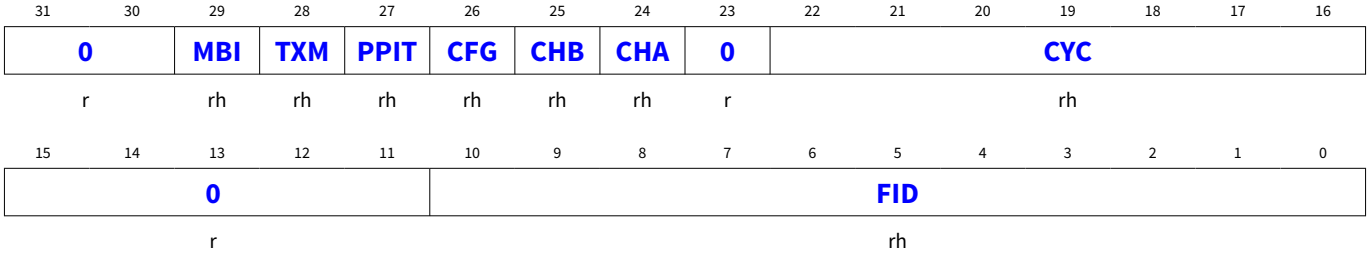
23.4.90 Read Header Section 1

Values as configured by the Host using WRHS1 Register:

RDHS1 Offset address: 0700_H

Read Header Section 1 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
FID	10:0	rh	**Frame ID**
CYC	22:16	rh	**Cycle Code**
CHA	24	rh	**Channel Filter Control A**
CHB	25	rh	**Channel Filter Control B**
CFG	26	rh	**Message Buffer Direction Configuration Bit**
PPIT	27	rh	**Payload Preamble Indicator Transmit**
TXM	28	rh	**Transmission Mode**
MBI	29	rh	**Message Buffer Service Request**
0	15:11, 23, 31:30	r	**Reserved** Read as 0; should be written with 0.

***Note**: In case that the Message Buffer read from the Message RAM belongs to the receive FIFO, FID holds the received Frame ID, while CYC, CHA, CHB, CFG, PPIT, TXM, and MBI are reset to zero.*

Table 1100 Channel Filter Control Bits

CHA	CHB	Transmit Buffertransmit Frame on	Receive Bufferstore Frame received from
1[1)]	1[1)]	Both Channels (static segment only)	Channel A or B (store first semantically valid Frame, static segment only)
1	0	Channel A	Channel A
0	1	Channel B	Channel B
0	0	No Transmission	Ignore Frame

***Note**: If a Message Buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no Frames are transmitted respecitvely received Frames are ignored (same function as CHA = CHB = 0)*

23.4.91 Read Header Section 2

***Note**: The Message RAM is organized in 4-byte words. When received data is stored into a Message Buffer's Data Section, the number of 2-byte data words written into the Message Buffer is PLC rounded to the next even value. PLC should be configured identical for all Message Buffers belonging to the receive FIFO. Header 2 is updated from Data Frames only.*

RDHS2 Offset address: 0704_H

Read Header Section 2 Kernel Reset value: $0000\ 0000_H$

0					DP										
r					rh										

Field	Bits	Type	Description
DP	10:0	rh	**Data Pointer** Pointer to the first 32-bit word of the Data Section of the addressed Message Buffer in the Message RAM.
RCC	21:16	rh	**Receive Cycle Count (vRF!Header!CycleCount)** Cycle counter value updated from received Data Frame.
RCI	24	rh	**Received on Channel Indicator (vSS!Channel)** Indicates the channel from which the received Data Frame was taken to update the respective receive buffer. 0_B Frame received on channel B 1_B Frame received on channel A
SFI	25	rh	**Startup Frame Indicator (vRF!Header!SuFIndicator)** A Startup Frame is marked by the Startup Frame indicator. 0_B The received Frame is not a startup Frame 1_B The received Frame is a startup Frame
SYN	26	rh	**SYNC Frame Indicator (vRF!Header!SyFIndicator)** A SYNC Frame is marked by the SYNC Frame indicator. 0_B The received Frame is not a SYNC Frame 1_B The received Frame is a SYNC Frame
NFI	27	rh	**NULL Frame Indicator (vRF!Header!NFIndicator)** Is set to 1 after storage of the first received Data Frame. 0_B Up to now no Data Frame has been stored into the respective Message Buffer 1_B At least one Data Frame has been stored into the respective Message Buffer

(table continues...)

(continued)

Field	Bits	Type	Description
PPI	28	rh	**Payload Preamble Indicator (vRF!Header!PPIndicator)** The payload preamble indicator defines whether a Network Management vector or message ID is contained within the Payload Segment of the received Frame. 0_B The Payload Segment of the received Frame does not contain a Network Management vector nor a message ID 1_B Static segment: Network Management vector in the first part of the payload Dynamic segment: Message ID in the first part of the payload
RES	29	rh	**Reserved (vRF!Header!Reserved)** Reflects the state of the received reserved bit. The reserved bit is transmitted as 0.
0	15:11, 23:22, 31:30	r	**Reserved** Read as 0; should be written with 0.

23.4.93 Message Buffer Status

The Message Buffer status is updated by the Communication Controller with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the Message Buffer. The flags are updated only when the Communication Controller is in “NORMAL_ACTIVE” or “NORMAL_PASSIVE” state. If only one channel (A or B) is assigned to a Message Buffer, the channel-specific status flags of the other channel are written to zero. If both channels are assigned to a Message Buffer, the channel-specific status flags of both channels are updated. The Message Buffer status is updated only when the slot counter reached the configured Frame ID and when the cycle counter filter matched. When the Host updates a Message Buffer through Input Buffer, all MBS flags are reset to zero independent of which IBCM bits are set or not. For details about receive / transmit filtering see “Filtering and Masking”, “Transmit Process”, and “Receive Process”.

Whenever the Message Handler changes one of the flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB the respective Message Buffer’s MBC flag in registers MBSC1 to MBSC4 is set

MBS Offset address: $070C_H$

Message Buffer Status Kernel Reset value: $0000\ 0000_H$

CEOB	5	rh	**Content Error Observed on Channel B (vSS!ContentErrorB)** A content error was observed in the assigned slot on channel B. 0_B No content error observed on channel B 1_B Content error observed on channel B
SVOA	6	rh	**Slot Boundary Violation Observed on Channel A (vSS!BViolationA)** A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel A. 0_B No slot boundary violation observed on channel A 1_B Slot boundary violation observed on channel A
SVOB	7	rh	**Slot Boundary Violation Observed on Channel B (vSS!BViolationB)** A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel B. 0_B No slot boundary violation observed on channel B 1_B Slot boundary violation observed on channel B
TCIA	8	rh	**Transmission Conflict Indication Channel A (vSS!TxConflictA)** A transmission conflict indication is set if a transmission conflict has occurred on channel A. 0_B No transmission conflict occurred on channel A 1_B Transmission conflict occurred on channel A

(table continues...)

(continued)

Field	Bits	Type	Description
TCIB	9	rh	**Transmission Conflict Indication Channel B (vSS!TxConflictB)** A transmission conflict indication is set if a transmission conflict has occurred on channel B. 0_B No transmission conflict occurred on channel B 1_B Transmission conflict occurred on channel B
ESA	10	rh	**Empty Slot Channel A** In an empty slot there is no activity detected on the bus. The condition is checked in static and dynamic slots. 0_B Bus activity detected in the assigned slot on channel A 1_B No bus activity detected in the assigned slot on channel A
ESB	11	rh	**Empty Slot Channel B** In an empty slot there is no activity detected on the bus. The condition is checked in static and dynamic slots. 0_B Bus activity detected in the assigned slot on channel B 1_B No bus activity detected in the assigned slot on channel B
MLST	12	rh	**Message Lost** The flag is set in case the Host did not read the message before the Message Buffer was updated from a received Data Frame. Not affected by reception of NULL Frames except for Message Buffers belonging to the receive FIFO. The flag is reset by a Host write to the Message Buffer through IBF or when a new message is stored into the Message Buffer after the Message Buffers ND flag was reset by reading out the Message Buffer through OBF. 0_B No message lost 1_B Unprocessed message was overwritten
FTA	14	rh	**Frame Transmitted on Channel A** Indicates that this node has transmitted a Data Frame in the assigned slot on channel A. ***Note**: The FlexRay™ protocol specification requires that FTA can only be reset by the Host. Therefore the Cycle Count Status CCS for these bits is only valid for the cycle where the bits are set to 1* 0_B No transmission transmitted on channel A 1_B Data Frame transmitted on channel A in cycle defined by CCS bit field

(table continues...)

(continued)

Field	Bits	Type	Description
FTB	15	rh	**Frame Transmitted on Channel B** Indicates that this node has transmitted a Data Frame in the assigned slot on channel B. ***Note:*** *The FlexRay™ protocol specification requires that FTB can only be reset by the Host. Therefore the Cycle Count Status CCS for these bits is only valid for the cycle where the bits are set to 1* 0_B No transmission transmitted on channel B 1_B Data Frame transmitted on channel B in cycle defined by CCS bit field
CCS	21:16	rh	**Cycle Count Status** Cycle Count when status (MBS register) has been updated.
RCIS	24	rh	**Received on Channel Indicator Status (vSS!Channel)** Indicates the channel on which the Frame was received. ***Note:*** *For receive buffers (CFG = 0) the RCIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.* 0_B Frame received on channel B 1_B Frame received on channel A
SFIS	25	rh	**Startup Frame Indicator Status (vRF!Header!SuFIndicator)** A Startup Frame is marked by the Startup Frame indicator. ***Note:*** *For receive buffers (CFG = 0) the SFIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.* 0_B No Startup Frame received 1_B The received Frame is a Startup Frame
SYNS	26	rh	**SYNC Frame Indicator Status (vRF!Header!SyFIndicator)** A SYNC Frame is marked by the SYNC Frame indicator. ***Note:*** *For receive buffers (CFG = 0) the SYNS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.* 0_B No SYNC Frame received 1_B The received Frame is a SYNC Frame

(table continues...)

(continued)

Field	Bits	Type	Description
NFIS	27	rh	**NULL Frame Indicator Status (vRF!Header!NFIndicator)** If reset to 0, the Payload Segment of the received Frame contains no usable data. ***Note**: For receive buffers (CFG = 0) the NFIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.* 0_B Received Frame is a NULL Frame 1_B Received Frame is not a NULL Frame
PPIS	28	rh	**Payload Preamble Indictor Status (vRF!Header!PPIndicator)** The payload preamble indicator defines whether a Network Management vector or message ID is contained within the Payload Segment of the received Frame. ***Note**: For receive buffers (CFG = 0) the PPIS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.* 0_B The Payload Segment of the received Frame does not contain a Network Management vector or a message ID 1_B Static Segment: Network Management vector at the beginning of the payload Dynamic Segment: Message ID at the beginning of the payload
RESERVED	29	rh	**Reserved (vRF!Header!Reserved) - RESS** Reflects the state of the received reserved bit. The reserved bit is transmitted as 0. ***Note**: For receive buffers (CFG = 0) the RESS is updated from both valid data and NULL Frames. If no valid Frame was received, the previous value is maintained. For transmit buffers the flags have no meaning and should be ignored.*
0	13, 23:22, 31:30	r	**Reserved** Read as 0; should be written with 0.

23.4.94 Output Buffer Command Mask

Configures how the Output Buffer is updated from the Message Buffer in the Message RAM selected by the Output Buffer Command Request register. If OBF Host and OBF Shadow are swapped, also mask bits OBCM.RDSH and OBCM.RHSH are swapped with bits OBCM.RDSS and OBCM.RHSS to keep them attached to the respective Output Buffer transfer.

***Note**: After the transfer of the Header Section from the Message RAM to OBF Shadow has completed, the Message Buffer status changed flag MBCn (n = 0-31) to MBCn (n = 96-127) of the selected Message Buffer in the Message Buffer Changed MBSC1 to MBSC4 registers is cleared. After the transfer of the Data Section from the Message RAM to OBF Shadow has completed, the New Data flag NDn (n = 0-31) to NDn (n = 96-127) of the selected Message Buffer in the New Data NDAT1 to NDAT4 registers is cleared.*

OBCM Offset address: 0710_H

Output Buffer Command Mask Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RHSS	0	rwh	**Read Header Section Shadow** 0_B Header Section is not read 1_B Header Section selected for transfer from Message RAM to Output Buffer
RDSS	1	rwh	**Read Data Section Shadow** 0_B Data Section is not read 1_B Data Section selected for transfer from Message RAM to Output Buffer
RHSH	16	rh	**Read Header Section Host** 0_B Header Section is not read 1_B Header Section selected for transfer from Message RAM to Output Buffer
RDSH	17	rh	**Read Data Section Host** 0_B Data Section is not read 1_B Data Section selected for transfer from Message RAM to Output Buffer
0	15:2, 31:18	r	**Reserved** Read as 0; should be written with 0.

23.4.95 Output Buffer Command Request

The Message Buffer selected by OBCR.OBRS is transferred from the Message RAM to the Output Buffer as soon as the Host has set OBCR.REQ. Bit OBCR.REQ can only be set while OBCR.OBSYS is 0 (see also “Data Transfer from Message RAM to Output Buffer”).

After setting OBCR.REQ, OBCR.OBSYS is automatically set, and the transfer of the Message Buffer selected by OBCR.OBRS from the Message RAM to Output Buffer Shadow is started. When the transfer between the Message RAM and OBF Shadow has completed, this is signalled by clearing OBCR.OBSYS. By setting OBCR.VIEW while OBCR.OBSYS is 0, OBF Host and OBF Shadow are swapped. When Output Buffer Host and Output Buffer Shadow are swapped, also mask bits OBCM.RDSH and OBCM.RHSH are swapped with bits OBCM.RDSS and OBCM.RHSS to keep them attached to the respective Output Buffer transfer. Now the Host can read the transferred Message Buffer from OBF Host. In parallel the Message Handler may transfer the next message from the Message RAM to OBF Shadow if OBCR.VIEW and OBCR.REQ are set at the same time.

Any write access to an Output Buffer register while OBCR.OBSYS is set will cause the error flag EIR.IOBA to be set. In this case the Output Buffer will not be changed.

OBCR Offset address: 0714_H

Output Buffer Command Request Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
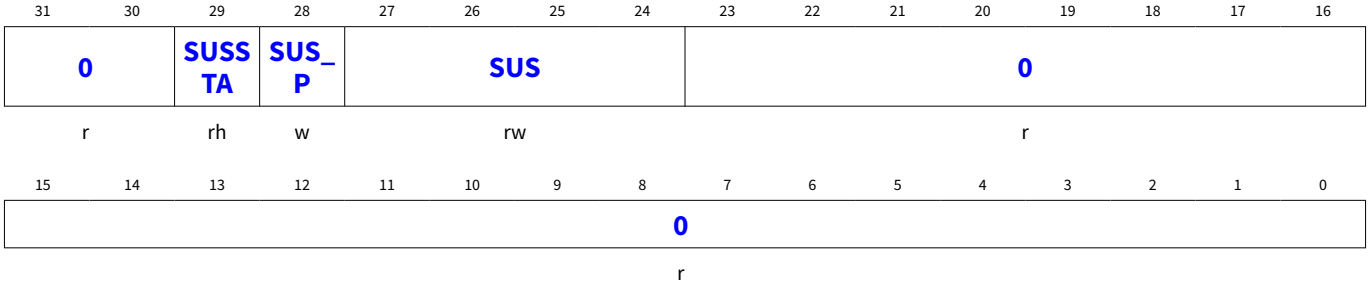
OTGB0	1:0	rw	**Trigger Set for OTGB0** 00_B No Trigger Set selected 01_B Trigger Set TS16_SEP 10_B Trigger Set TS16_MC 11_B Reserved
OTGB1	9:8	rw	**Trigger Set for OTGB1** 00_B No Trigger Set selected 01_B Trigger Set TS16_SEP 10_B Trigger Set TS16_MC 11_B Reserved
0	7:2, 15:10, 31:17	r	**Reserved** Read as 0; should be written with 0.

23.4.97 OCDS Control and Status Register

The OCDS Control and Status register OCS controls the debug and trace behavior by selecting suspend modes and OTGB trigger sets. When OCDS is disabled, the suspend control is ineffective.

OCS Offset address: $08E8_H$

OCDS Control and Status Register Debug Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) Not listed combinations are reserved. 0_H Will not suspend 1_H Hard suspend: Clock f_{CLC_ERAY} and the sampling clock f_{SCLK} are switched off immediately. Read or write access to registers is possible, it enables the clock for few cycles. 2_H Reserved 3_H Soft suspend mode: Soft suspend request forces ERAY into FREEZE/HALT state (clock remains switched on).
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:0, 31:30	r	**Reserved**

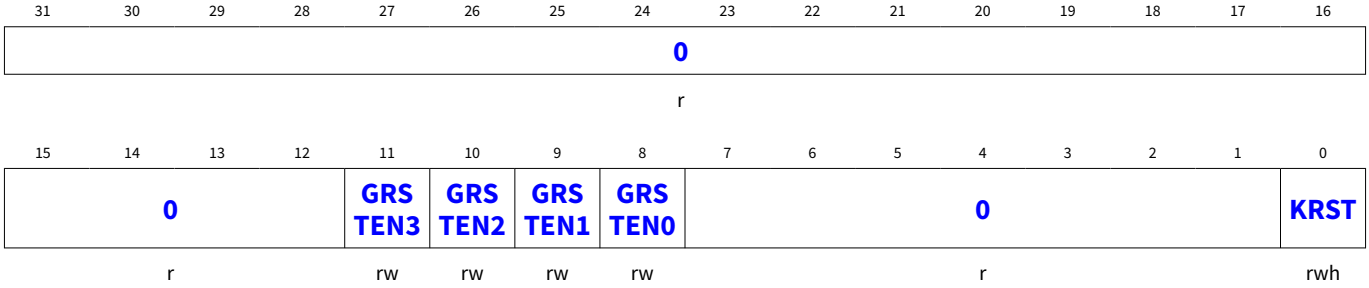
Table 1101 Access mode restrictions of OCS sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SUS_P**	rw	SUS	Set SUS_P during write access
(default)	r	SUS	

23.4.98 Reset Control Register A

RST_CTRLA Offset address: $08EC_H$

Reset Control Register A Application Reset value: $0000\ 0000_H$

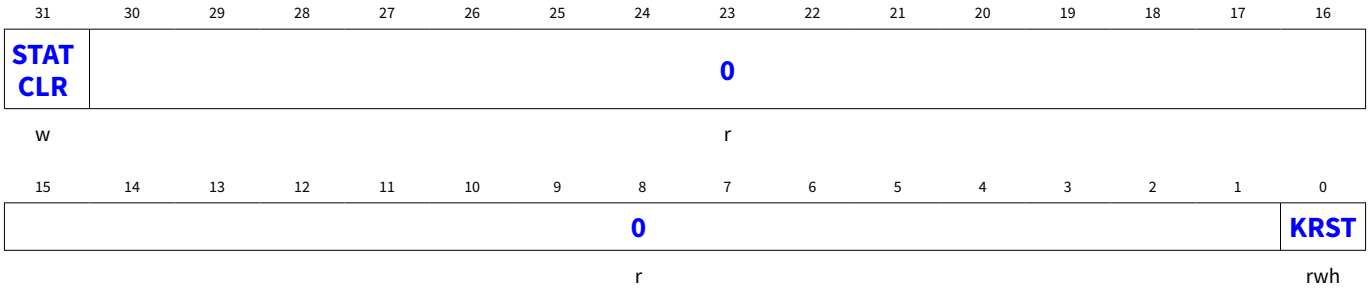


Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for Global Module Reset Group x** 0_B Global module reset group x does not have any effect 1_B Global module reset group x results in a kernel reset
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

23.4.99 Reset Control Register B

RST_CTRLB Offset address: $08F0_H$

Reset Control Register B Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested

(table continues...)

(continued)

Field	Bits	Type	Description
STATCLR	31	w	**Kernel Reset Status Clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits STAT.GRSTx and bit STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

23.4.100 Reset Status Register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: $08F4_H$

Reset Status Register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				GRST3	GRST2	GRST1	GRST0	0							KRST
r				rh	rh	rh	rh	r							rh

Field	Bits	Type	Description
KRST	0	rh	**Kernel Reset Status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.
GRSTx (x=0-3)	x+8	rh	**Status for Global Module Reset Group x** 0_B Reset was not triggered by Global Reset Group x 1_B Reset was triggered by Global Reset Group x
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

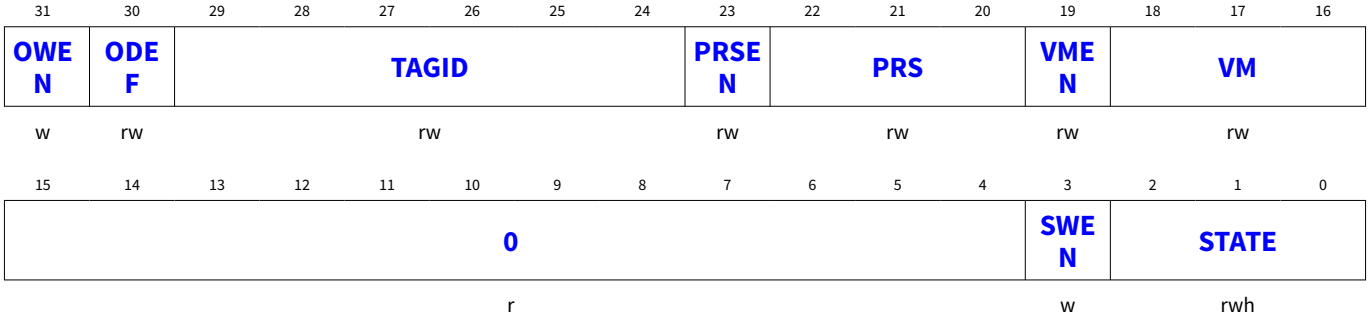
23.4.101 PROT Register Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 0900_H

PROT Register Endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1102 Access mode restrictions of PROTE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

23.4.102 PROT Register Safe Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 0904_H

PROT Register Safe Endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

23.5.2 Destructive debug

On destructive debug entry ie., when CSRM Debug configuration GP_CSRM_DBGCFG.DESTDBG= 11b and CSRM Debug mode GP_CSRM_DBGMODE.EDDM = 11b, the ERAY Transmit Data and transmit enable for Channel A and Channel B (TXDA, TXDB, TXENA and TXENB) are tied to logic ‘1b’. This blocks any further ERAY transmission when the device has entered the Destructive Debug state.

23.7 ERAY revision history

Initial release of the chapter.

23.8 TC4Dx ERAY information

23.8.1 TC4Dx ERAY configuration

TC4Dx has 2 ERAY instances: ERAY0 and ERAY1. Each of these instances has 2 channels: Channel A and Channel B.

23.8.2 TC4Dx ERAY features

There are no deviations from the generic specification.

23.8.3 TC4Dx ERAY functional description

In TC4Dx device, the ERAY modules are connected to ComPB bus interface. The ERAY chapter refers to it as FPI bus.

23.8.4 TC4Dx ERAY registers

23.8.4.1 Register address space - ERAY

Table 1108 Registers address space - ERAY

Module	Base address	End address	Note
ERAY0	$F441C000_H$	$F441CFFF_H$	FPI slave interface
ERAY1	$F441D000_H$	$F441DFFF_H$	FPI slave interface

23.8.4.2 Register overview - access mode glossary

Table 1109 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register ERAY0_PROTE or ERAY1_PROTE .
SE	Access protection using PROT register ERAY0_PROTSE or ERAY1_PROTSE .
APU-P	Protection group consisting of registers ERAY0_ACCEN_WRA , ERAY0_ACCEN_WRB , ERAY0_ACCEN_RDA , ERAY0_ACCEN_RDB , ERAY0_ACCEN_VM , ERAY0_ACCEN_PRS or ERAY1_ACCEN_WRA , ERAY1_ACCEN_WRB , ERAY1_ACCEN_RDA , ERAY1_ACCEN_RDB , ERAY1_ACCEN_VM , ERAY1_ACCEN_PRS .
P	Access protection using *APU-P* registers.
BE	Always returns a Bus Error.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

23.8.4.5 Device specific registers

There are no device specific register changes.

23.8.5 TC4Dx ERAY connectivity

The table below lists interfaces to and from this functional block to other blocks in the device.

Table 1112 List of ERAY interface signals

Interface signals	I/O	Description
CLOCK_ERAY_fSPB	In	Synchronous clock input
CLOCK_ERAY_fERAY	In	Asynchronous clock input
FPI_ERAY_SIF	In	Slave interface
ERAY0_IR_INT0	Out	Interrupt 0 Service Request
ERAY1_IR_INT0	Out	Interrupt 0 Service Request
ERAY0_IR_INT1	Out	Interrupt 1 Service Request
ERAY1_IR_INT1	Out	Interrupt 1 Service Request
ERAY0_IR_TINT0	Out	Timer Interrupt 0 Service Request
ERAY1_IR_TINT0	Out	Timer Interrupt 0 Service Request
ERAY0_IR_TINT1	Out	Timer Interrupt 1 Service Request
ERAY1_IR_TINT1	Out	Timer Interrupt 1 Service Request
ERAY0_IR_OBUSY	Out	Output Buffer Busy Service Request
ERAY1_IR_OBUSY	Out	Output Buffer Busy Service Request
ERAY0_IR_IBUSY	Out	Input Buffer Busy Service Request
ERAY1_IR_IBUSY	Out	Input Buffer Busy Service Request
ERAY0_IR_NDAT0	Out	New Data 0 Service Request
ERAY1_IR_NDAT0	Out	New Data 0 Service Request
ERAY0_IR_NDAT1	Out	New Data 1 Service Request
ERAY1_IR_NDAT1	Out	New Data 1 Service Request
ERAY0_IR_MBSC0	Out	Message Buffer Status Changed 0 Service Request
ERAY1_IR_MBSC0	Out	Message Buffer Status Changed 0 Service Request
ERAY0_IR_MBSC1	Out	Message Buffer Status Changed 1 Service Request
ERAY1_IR_MBSC1	Out	Message Buffer Status Changed 1 Service Request
PORTS_ERAY0_RXDA0	In	Receive Channel A0
PORTS_ERAY1_RXDA0	In	Receive Channel A0
PORTS_ERAY0_RXDA1	In	Receive Channel A1
PORTS_ERAY1_RXDA1	In	Receive Channel A1
PORTS_ERAY0_RXDA2	In	Receive Channel A2
PORTS_ERAY1_RXDA2	In	Receive Channel A2

(table continues...)

Table 1112 (continued) List of ERAY interface signals

Interface signals	I/O	Description
PORTS_ERAY0_RXDA3	In	Receive Channel A3
PORTS_ERAY1_RXDA3	In	Receive Channel A3
PORTS_ERAY0_RXDB0	In	Receive Channel B0
PORTS_ERAY1_RXDB0	In	Receive Channel B0
PORTS_ERAY0_RXDB1	In	Receive Channel B1
PORTS_ERAY1_RXDB1	In	Receive Channel B1

23.8.6 TC4Dx ERAY revision history

Initial release of the chapter.

24 Asynchronous/Synchronous Interface (ASCLIN)

The ASCLIN module provides asynchronous serial communication with external devices using only data-in and data-out signals. The focus of the module is for fast and flexible communication, either as fast point-to-point using ASC protocol or master-to-many slaves communication using the LIN protocol. ASCLIN supports also the synchronous SPI communication.

24.1 Feature list

General features

- Transmit ASC, LIN, and SPI frames to external devices and handle all protocol relevant topics
- Receive ASC, LIN, and SPI frames from external devices and handle all protocol relevant topics
- Data storage of 16-bytes TxFIFO (Transmit first in first out) and 16-bytes RxFIFO (Receive first in first out)
- Pack and unpack capabilities of the TxFIFO and RxFIFO
- Interrupt generation:
  - On a configurable TxFIFO level
  - On a configurable RxFIFO level
  - On an error condition (frame, parity, overrun error)
  - On various internal events (end of ASC or SPI frame, or LIN events)
- Interrupt signals capable of triggering either a CPU or a DMA
- Flexible functional configuration for software:
  - Programmable oversampling of 4 to 16 times per bit
  - Programmable sampling point position
  - Programmable digital glitch filter and median filter for incoming bit stream
  - Shift direction LSB first for LIN mode and programmable LSB or MSB first for SPI and ASC mode
- Internal loop-back mode

Standard ASC features

- Full-duplex asynchronous operating mode:
  - 7-bit, 8-bit, or 9-bit (or up to 16-bit) data frames, LSB first
  - Parity-bit generation and checking
  - One or two stop bits
  - Maximum baud rate $\frac{f_A}{16}$ (6.25 MBaud at 100 MHz f_A module clock)
  - Minimum baud rate $\frac{f_A}{268\,435\,456}$ (0.37 Baud at 100 MHz f_A module clock)
- Frame transmit on hardware or software trigger
- Circular buffer

Extended ASC features

- Programmable oversampling of 4 to 16 times per bit:
  - Module capability of up to 4 times higher baud rates ($\frac{f_A}{4}$) than the standard ASC
  - System considerations such as pad type, incoming signal quality, and accumulated PLL jitter can lead to constraints regarding the usable oversampling ratios (for example $\frac{f_A}{8} = \frac{200\,\text{MHz}}{8} = 25\,\text{MBaud}$)
- Optional RTS/CTS handshaking

LIN features

- Support of:
  - LIN version 1.3, 2.0, 2.1, and 2.2
  - J2602
- Break detection
- Break injection
- Sync field generation
- Auto baud detection based on Sync Field measurement
- Collision detection optionally (LIN2.1 mandatory)
- LIN Watchdogs:
  - Header time-out
  - Frame or Response time-out
- Stuck at zero or one monitoring
- Bus idle time monitoring
- Energy saving features (Wake-Up, Sleep)
- Minimum CPU load in master mode:
  - Single interrupt indicating the end of the frame
- Minimum CPU load in slave mode:
  - Single interrupt at the end of the header reception
  - Single interrupt at the end of the response or end of frame
- Standard operation with one interrupt per transmitted or received byte supported

SPI features

- SPI master modes (slave mode not supported):
  - Four-wire or three-wire (with or without slave select output signal)
- Up to 16-bit data width
- Full-duplex and half-duplex:
  - Maximum baud rate $\frac{f_A}{4}$ (= 25 MBaud at 100 MHz f_A module clock)
  - Minimum baud rate $\frac{f_A}{268\,435\,456}$ (= 0.37 Baud at 100 MHz f_A module clock)
- Programmable leading and trailing delays

24.2 Functional overview

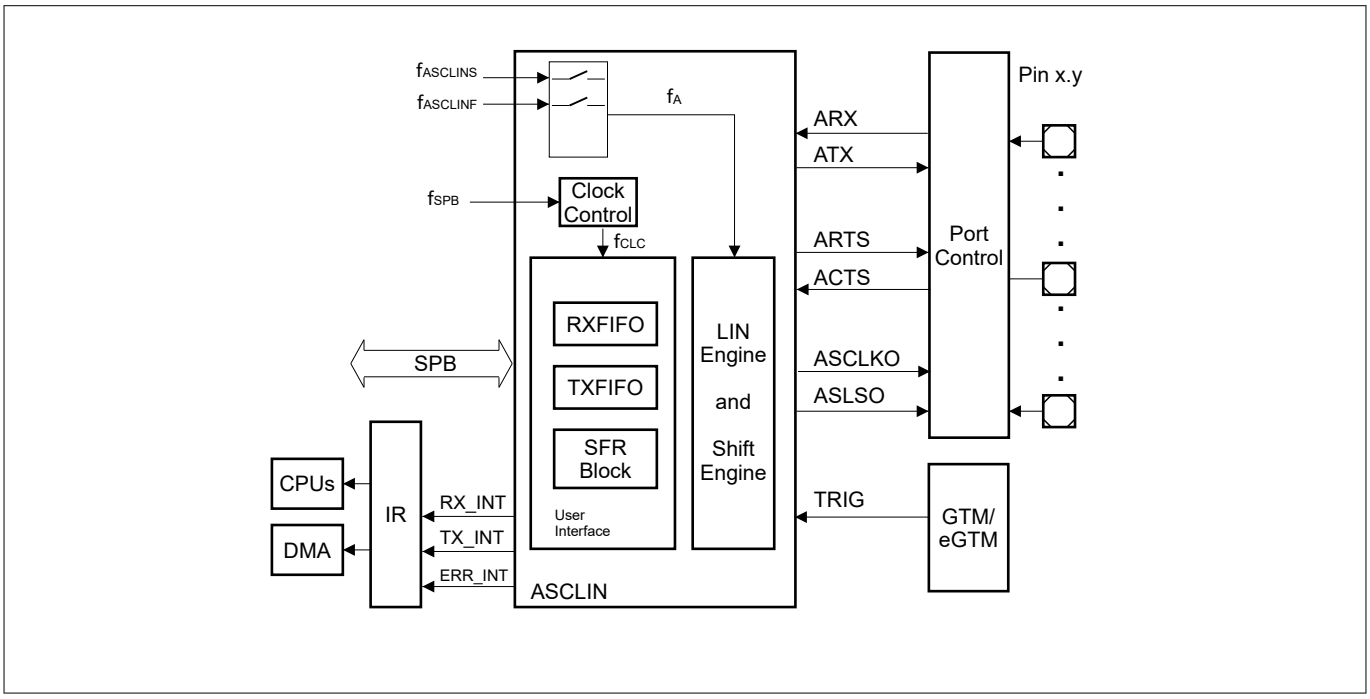

Figure 456 ASCLIN block diagram

The Shift Engine is responsible for frame transmission and reception, depending on the configured settings. For LIN communication the LIN Engine controls frame transmission and reception according to the protocol specification. This block runs on asynchronous clock.

The User Interface block is for configuration of protocol settings as well as the RxFIFO and TxFIFO and their management. The user can access the FIFOs using the registers. This block runs on synchronous clock.

24.3 Functional description

This chapter provides the description of the module and it's configuration options for functional behavior.

24.3.1 Architecture overview

The essential sub-blocks and their interactions are shown in the following image.

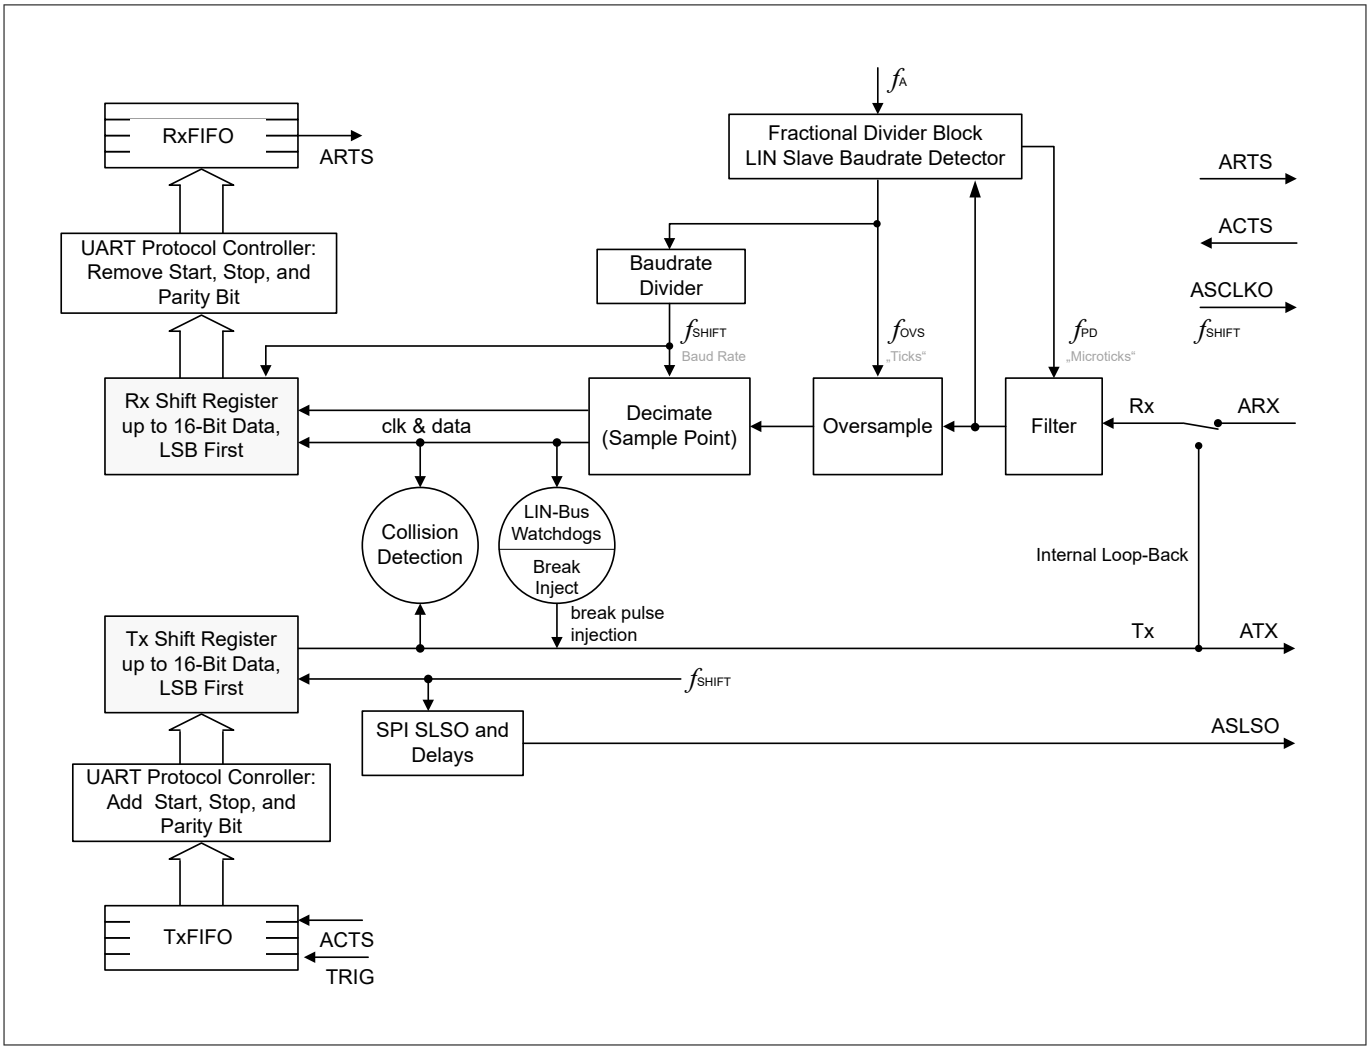

Figure 457 Architecture overview

Clocking blocks

- The Fractional Divider block and the Baudrate Divider block are used to provide the incoming and outgoing data baudrate
- The Filter, Oversample, and Sample Point blocks are used for optimizing the sampling of the incoming bit stream
- If enabled, the clocking blocks provide automatic baudrate detection in LIN slave mode

Timeouts and control blocks

- The LIN Bus Watchdogs and Break Inject are used for detecting the delays and translating them for the respective protocol
- The Collision Detection block is used to monitor the bus and report if there is any inconsistency with the outgoing bit-stream

Data receive or transmit blocks

- The RxFIFO and TxFIFO provide the user interface where the data is stored
- The protocol control machine is used to add or check protocol specific bits, for example parity bit, start bit, stop bit and shift the data

24.3.2 Supported modes

The ASCLIN module provides a number of external signals:

- ASCLKO - Serial clock output
- ARX - Receive data input (Master Receive MR in SPI mode)
- ATX - Transmit data output (Master Transmit MT in SPI mode)
- ASLSO - Slave select signal output
- ARTS - Request to send handshake output
- ACTS - Clear to send handshake input

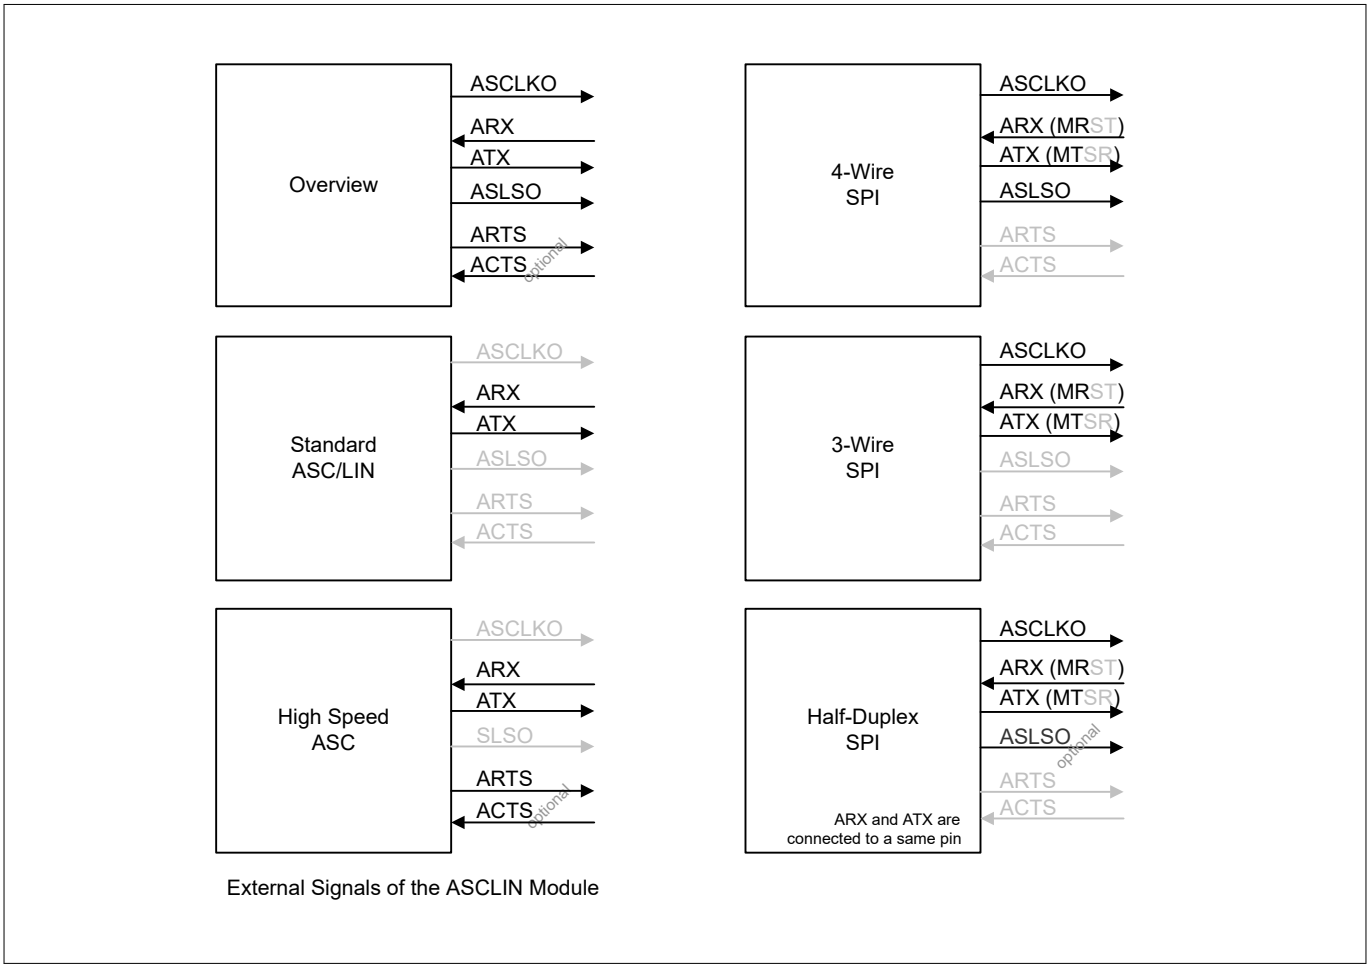

Figure 458 External signals of the ASCLIN in different modes

24.3.3 User interface

The user interface contains a TxFIFO and a RxFIFO that provide the services listed:

- Takes data packets with width optimal for the SPB bus and packs them to serial frames
- Buffers the SPB bus data
- Manages handshaking

These features are designed to optimize the use of the module in LIN, high-speed ASC, standard mode ASC, and SPI mode.

24.3.3.1 TxFIFO

The TxFIFO has the ability to pack:

- 16-bit writes from the SPB bus to two up-to-8-bit frames or one up-to-16-bit frame
- 32-bit writes from the SPB bus to four up-to-8-bit or two up-to-16-bit frames

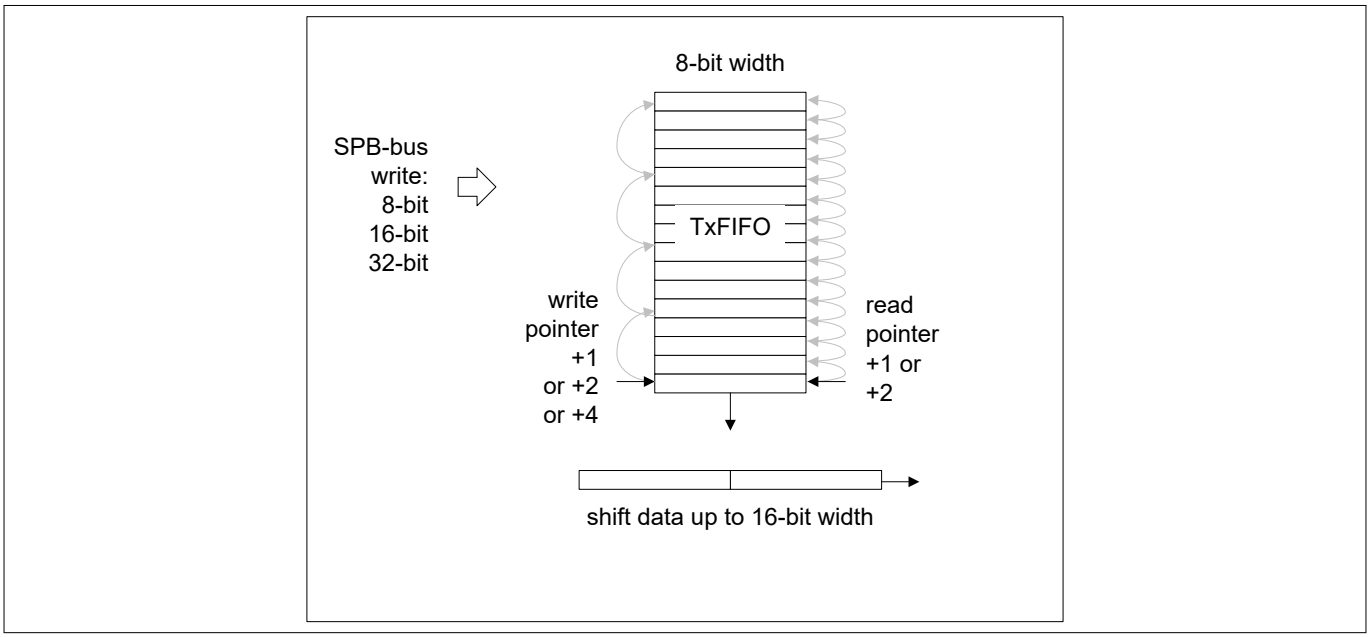

Figure 459 TxFIFO overview

The number of bytes written to the TxFIFO is always defined with the TXFIFOCON.INW register, here after referred to as Tx_Inlet_Width, and does not depend on the SPB write width. For proper functionality the SPB write width should be equal or shorter than Tx_Inlet_Width. If the SPB write width is shorter than Tx_Inlet_Width, then the missing part is padded with zeros. If the SPB-bus write width is longer then Tx_Inlet_Width, then the excessive part is lost.

On the shift register side, the TxFIFO is always emptied by a number of bytes as needed for the data width field DATCON.DATLEN register, referred to as Tx_Outlet_Width.

The table below describes all the possible write (fill) combinations. The bytes which will be filled into the TxFIFO are labeled as A, B, C, D, and 0.

Table 1113 Inlet width versus SPB write width

TxFIFO contents		SPB bus write width		
		8-bit A	**16-bit BA**	**32-bit DCBA**
Tx_Inlet_Width	8-bit	A_H	A_H	A_H
	16-bit	$0A_H$	BA_H	BA_H
	32-bit	$000A_H$	$00BA_H$	$DCBA_H$

24.3.3.1.1 Using the TxFIFO

The transmit data is written to the address TXDATA registers. Writing to any of these registers has the same effect as writing to TXDATA. The eight consecutive TXDATA registers are provided to support burst access.

Standard ASC mode

The most standard usage of the ASC module is to transmit 7 or 8-bit values, and to fill the FIFO with 8-bit wide SPB-bus accesses. The SPB bus access is 8-bit wide, and there is only BS0 (Byte Select 0) signal active.

The Tx_Inlet_Width is 8-bit and the Tx_Outlet_Width is 8-bit.

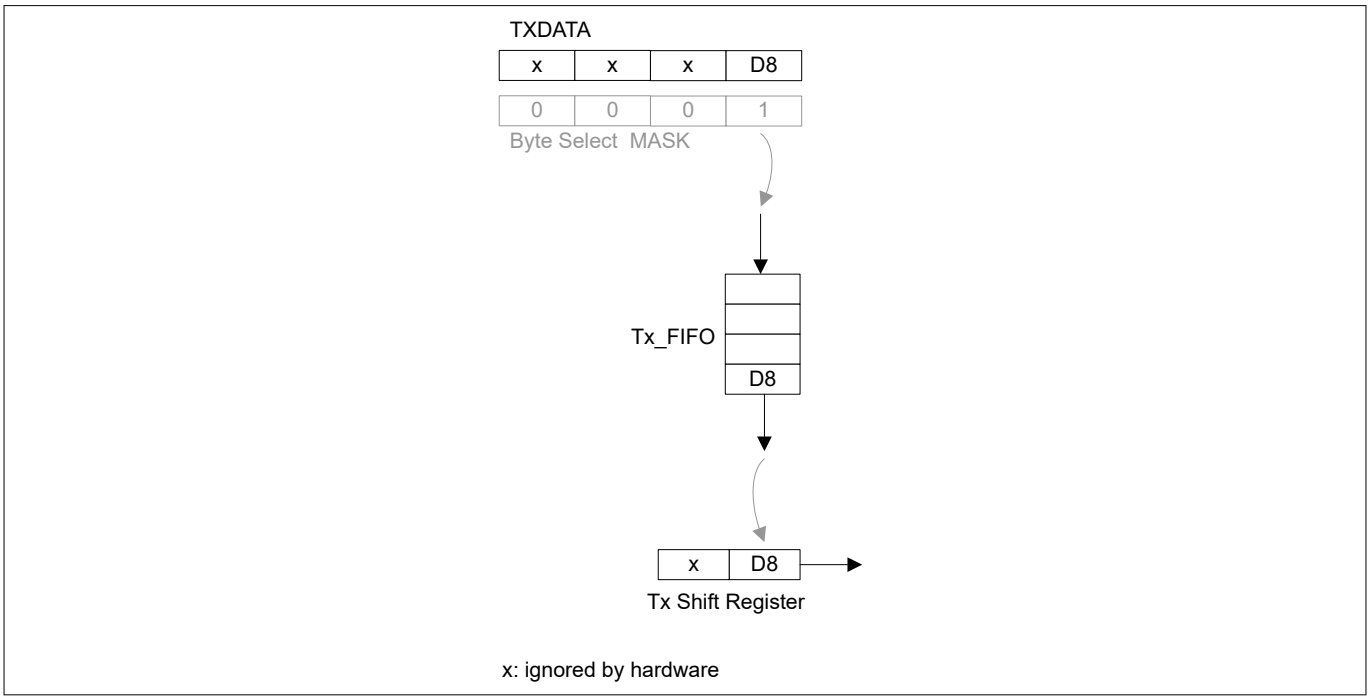

Figure 460 FIFO operation in 7- or 8-Bit ASC mode, with or without parity

A less common mode of operation of the ASC module is to transmit 9-bit values, containing either 9-bit data or 8-bit data. The SPB bus access should be 16-bit wide, and there are BS0 and BS1 (Byte Select 0 and 1) signals active. The shift register is filled with two 8-bit values at the location "read pointer" and "read pointer + 1".

The Tx_Inlet_Width is 16-bit and the Tx_Outlet_Width is 16-bit.

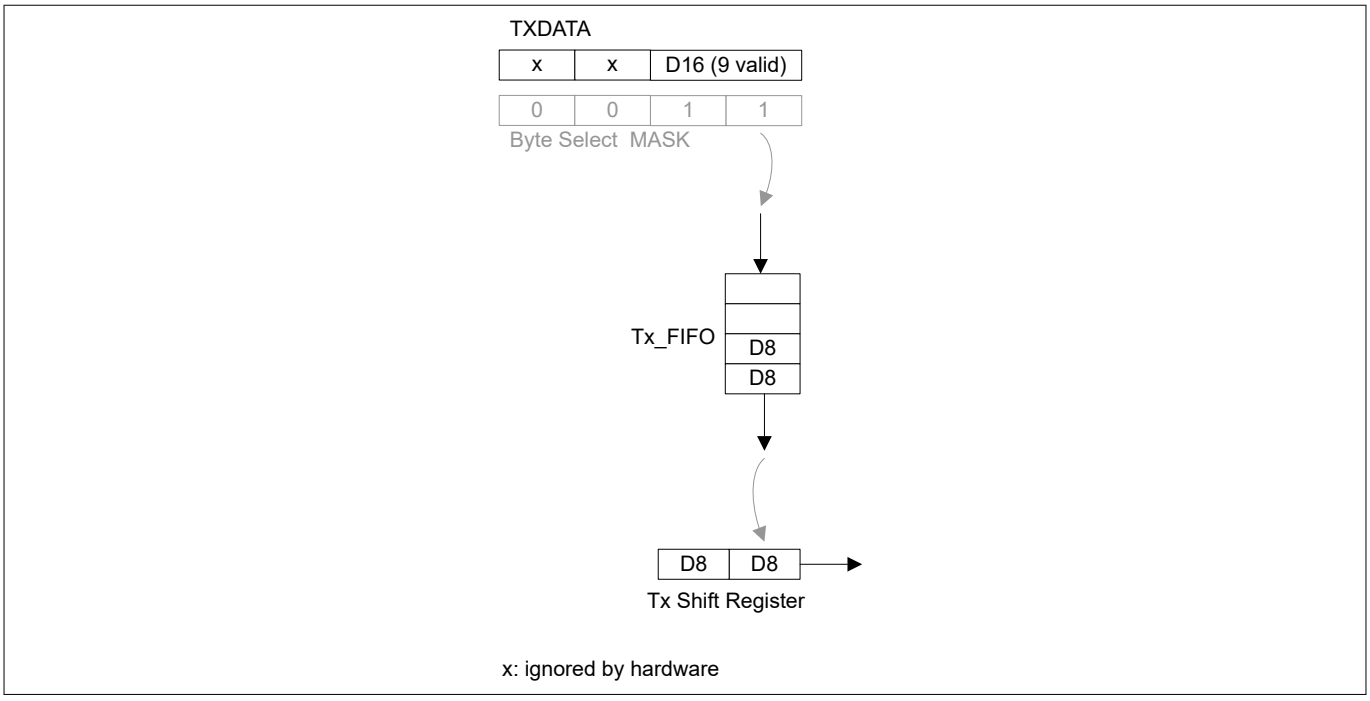

Figure 461 FIFO operation in 9-Bit ASC mode

A mode exclusive to the ASC is the circular buffer, which is selected from the TXFIFOCON.FM. The configuration settings, with the Tx_Inlet_Width and the Tx_Outlet_Width are similar to the previous description. The circulating level is defined in the configuration of the FIFO. The shifted data stays in the FIFO, only the "get-pointer" is updated. After all data, up to the circulating level, is shifted out, the pointer is reset to the first data in FIFO, thus making it a circulating FIFO. This mode is only compatible with hardware transmit trigger or software transmit trigger, but is not compatible with the traditional transmit mode.

High-speed ASC mode

In order to reduce the SPB bus load by not using a 32-bit move for 7 or 8-bit values, one option is to fill the TxFIFO with 32-bit wide accesses containing four 8-bit wide values. All Byte Select signals BS[3:0] are active, and all four bytes are written in the TxFIFO in one cycle. At the same time, the "write pointer" of the TxFIFO is incremented by four.

The Tx_Inlet_Width is 32-bit and the Tx_Outlet_Width is 8-bit.

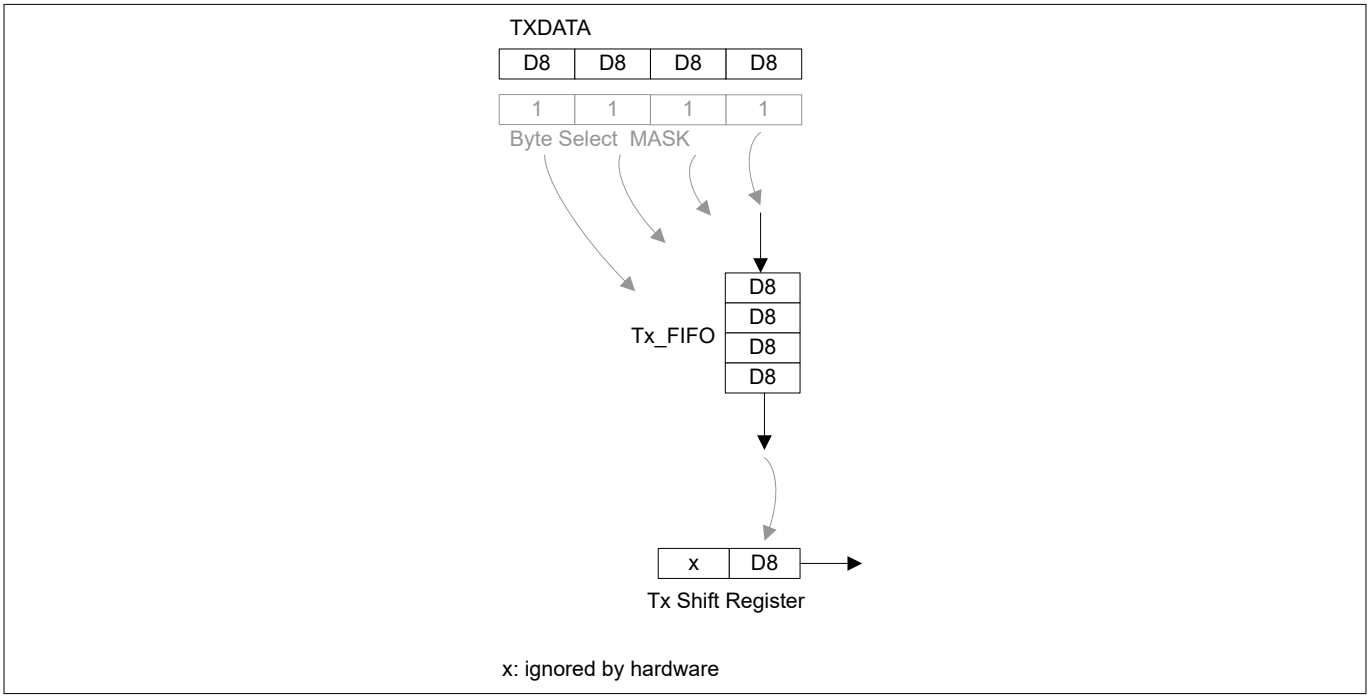

Figure 462 High-speed communication scenario

LIN mode

In LIN mode, several 8-bit frames are preceded by a low break pulse. The generation and detection of the break pulse is programmable. For more details please refer to LIN support.

The Tx_Inlet_Width can be 8-bit (or 16-bit, or 32-bit) and the Tx_Outlet_Width is 8-bit.

SPI mode

SPI mode is used most often to send or receive data of 8 up to 16-bits length.

The Tx_Inlet_Width is up to 32-bit and the Tx_Outlet_Width is up to 16-bit.

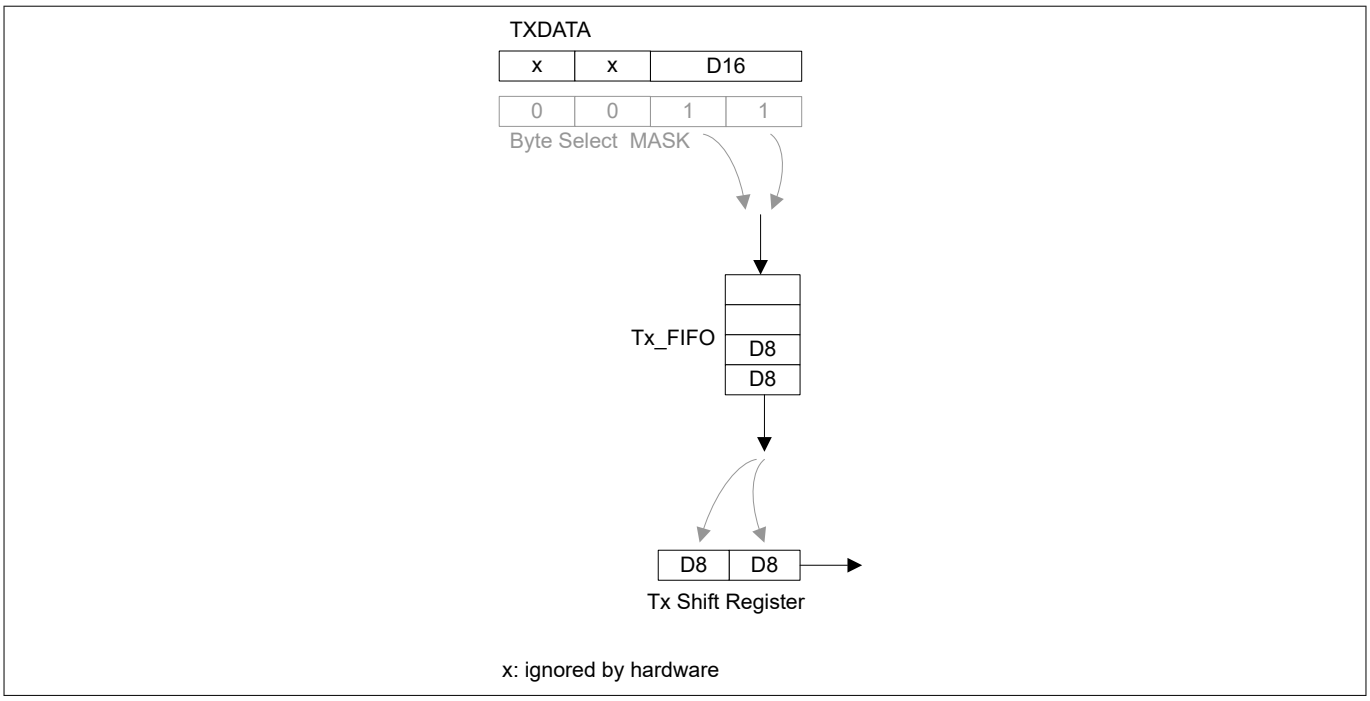

Figure 463 TxFIFO operation in SPI mode

24.3.3.1.2 TxFIFO interrupt generation

The TxFIFO provides four interrupt generation modes, selected by the bit-field TXFIFOCON.FM:

- Single Move Mode
- Batch Move Mode
- Combined Mode
- Circular Buffer Mode

The RxFIFO and the TxFIFO can use the interrupt generation modes independently of each other.

The TxFIFO interrupt flag is FLAGS.TFL. In case of an event, if the flag interrupt is enabled in FLAGSENABLE.TFLE an interrupt is generated.

Single move mode

The purpose of the Single Move Mode is to keep the TxFIFO as full as possible, refilling the TxFIFO by writing to it as soon as there is a free element.

The single move mode supports primarily a DMA operation using single move per TxFIFO interrupt. In this mode the DMA keeps the TxFIFO full. A DMA request is triggered each time a write to the TxFIFO is performed, and there is at least one empty element available.

If the write:

- Makes the TxFIFO full (no more empty elements), or
- The next write would make the TxFIFO overflow taking TXFIFOCON.INW into account

an interrupt is not generated in order to prevent overflow. It is generated later when the shift register reads one element from the TxFIFO, making it sufficiently empty to accept one Tx_Inlet_Width wide element. If TxFIFO can handle new data, it generates an interrupt but expects just one data of the defined frame width. The DMA or the user should not write multiple data at once to avoid unexpected behavior.

The following figure shows the filling levels of the TxFIFO, and the events associated with each filling level triggering an interrupt (FLAGS.TFL).

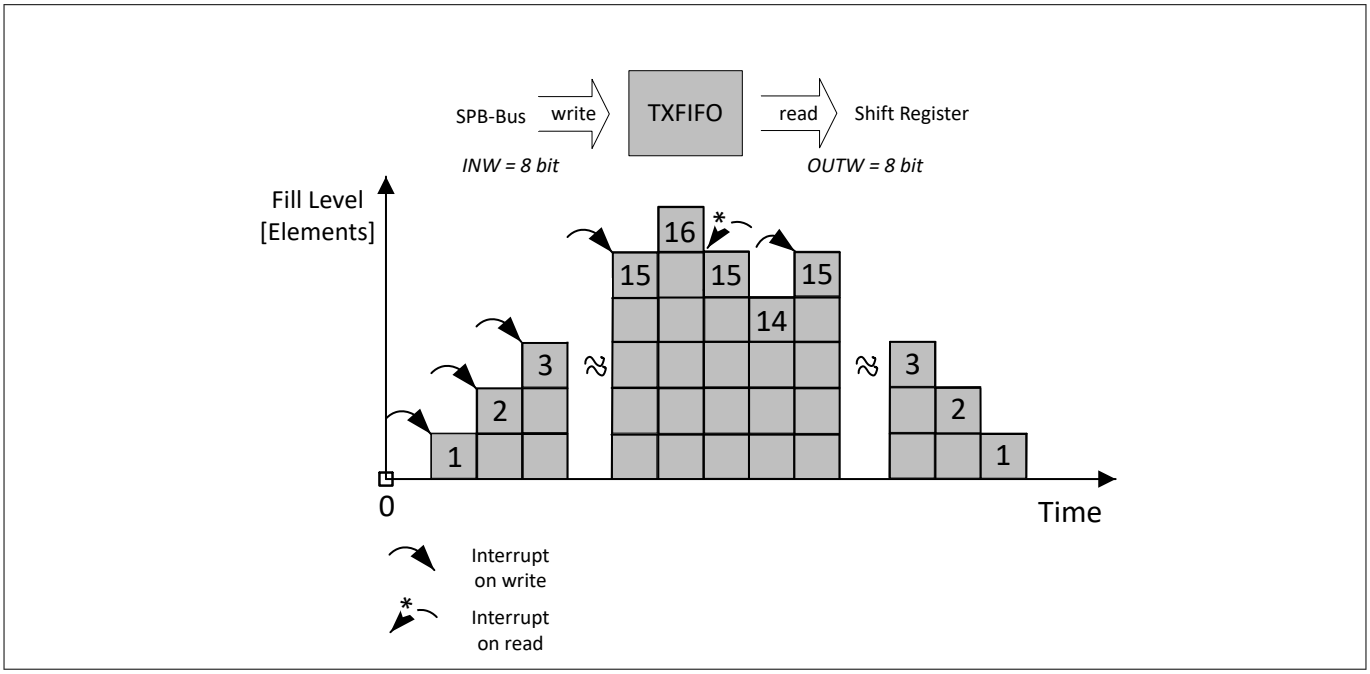

Figure 464 Interrupt generation in the single move mode

In order to initiate the very first interrupt in the chain of the refill interrupts after power-on reset, it is necessary that the software either performs one write to the TxFIFO or by setting the interrupt flag in the TxFIFO interrupt node. Afterwards, the (DMA) interrupt-chain is self sustaining until the whole transaction is over.

In Single Move Mode, when the TxFIFO is almost full (the next write operation causes the TxFIFO full) or when the TxFIFO is full, a flush on TxFIFO will trigger an interrupt (FLAGS.TFL).

Attention: ***In Single Move Mode multiple software writes or block DMA moves would lead to multiple interrupts and (false) transaction lost events. Therefore they should be avoided - only single moves should be used.***

Batch move mode

Batch Move Mode supports primarily the CPU servicing the TxFIFO use case.

The purpose of the Batch Move Mode is to reduce the number of interrupts by triggering an interrupt when more then one TxFIFO elements are empty. For example, a CPU can be interrupted less frequently and it can perform more than one moves per interrupt.

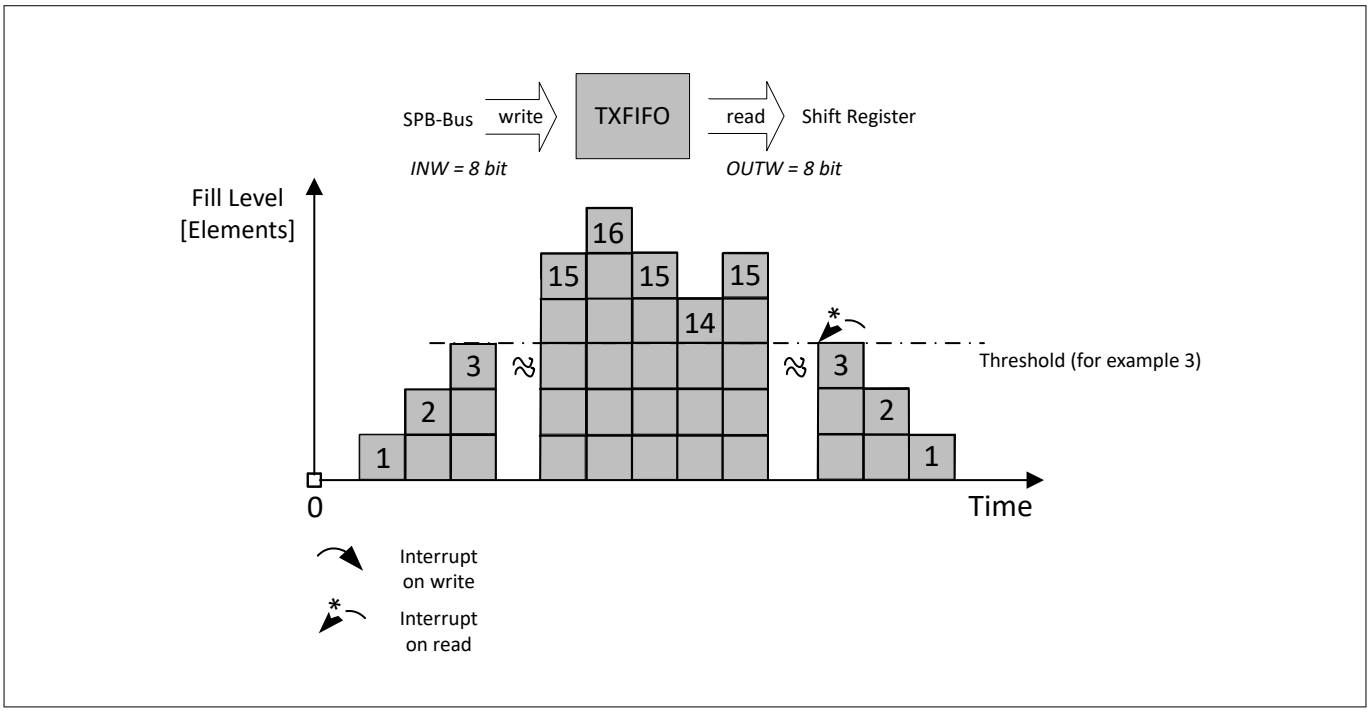

Figure 465 TxFIFO - interrupt generation in the batch move mode

In Batch Move Mode, an interrupt is generated only at one point in the TxFIFO, when the filling level falls to or below the programmed threshold, as configured in TXFIFOCON.INTLEVEL, implying that there are at least the predefined number of empty TxFIFO elements available.

Attention: ***The TxFIFO must be refilled until the filling level has risen above the interrupt threshold (ensured by polling the filling level), in order to guarantee that the next interrupt will occur.***

At high baud rates and short frames, it could be possible that a couple of frames have been transmitted until the moment the TxFIFO is refilled. For example, if the threshold is set to three full elements, then the interrupt will be set when the filling level falls below three, making two elements free. If the refill moment of the TxFIFO is delayed so long that two frames have been transmitted, the TxFIFO will become empty, and refill sequence of two will not reach the level of three. So, the next interrupt would never come unless the filling level is being polled and the CPU keeps refilling in a loop until the threshold has been passed (ideally the TxFIFO would be filled completely with each batch of moves).

Combined (compatibility) mode

An interrupt is generated when the filling level falls to INTLEVEL or below, each time when a data byte is taken out of the FIFO, as defined in the TXFIFOCON.INTLEVEL. This is the mode which is compatible with the previous versions of the ASCLIN module and described in the TXFIFOCON.INTLEVEL bit-field.

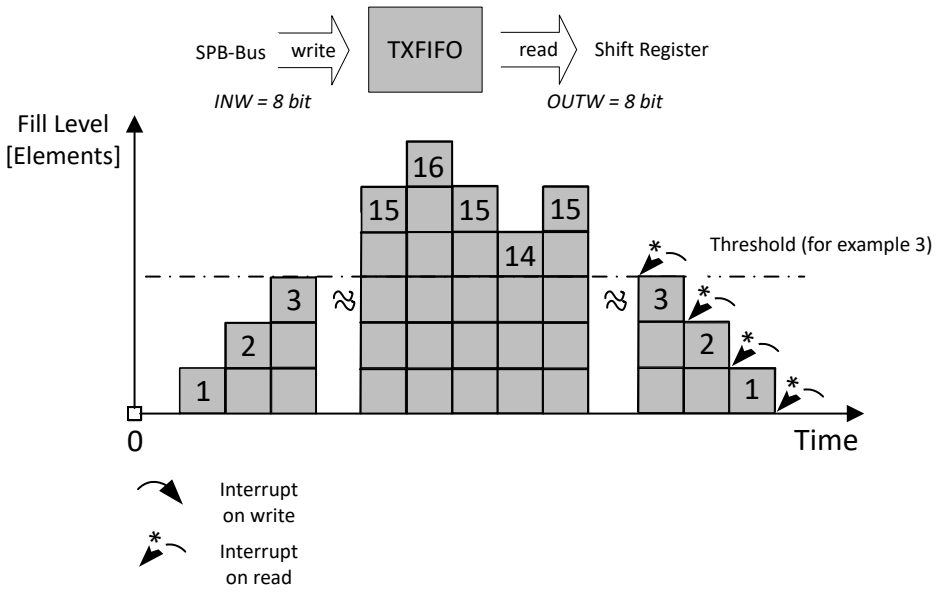

Figure 466 TxFIFO - interrupt generation in the combined mode

Circular buffer mode

This is a special mode used only when the ASCLIN is configured to run in ASC mode and the FIFO mode is circular buffer. This mode is only compatible with the hardware or software trigger transmit mode, thus an interrupt is not needed for each transmitted frame. In this mode, if enabled from FLAGSENABLE register, an interrupt in FLAGS.TFL is generated each time a full circulation is done. A full circulation means transferring of FIFO elements from the first one up to the circulation level.

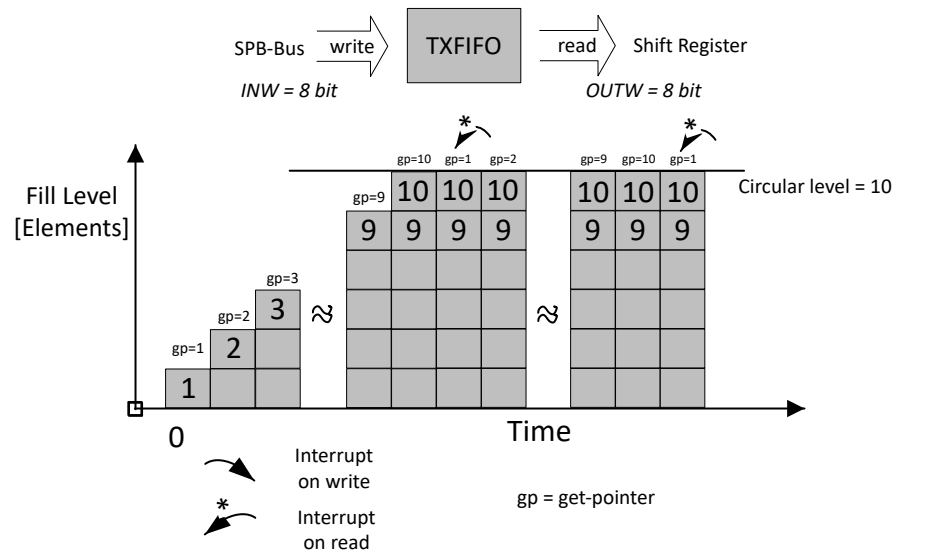

Figure 467 TxFIFO - interrupt generation in the circular buffer mode

24.3.3.2 RxFIFO

The RxFIFO has the ability to pack:

- Two up-to-8-bit frames or one up-to-16-bit frame to one 16-bit write to the SPB bus
- Four up-to-8-bit or two up-to-16-bit frames to one 32-bit write to the SPB bus

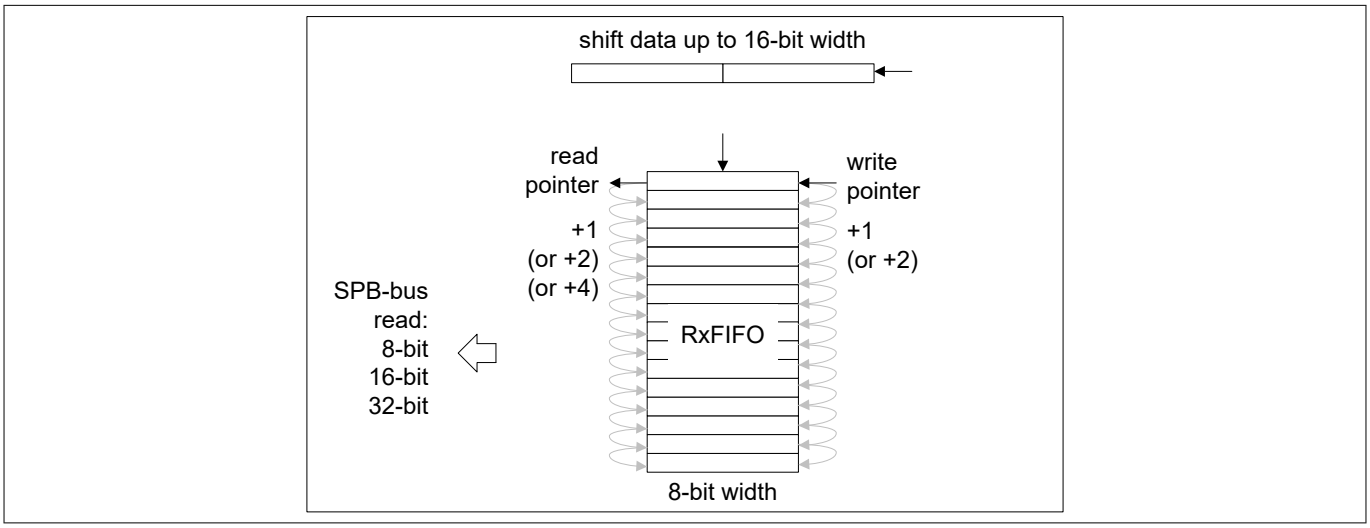

Figure 468 RxFIFO overview

The number of bytes taken out of the RxFIFO is always RXFIFOCON.OUTW, hereinafter referred as Rx_Outlet_Width and it does not depend on the SPB bus read width. For proper functionality the SPB read width should be equal or shorter than Rx_Outlet_Width.

If the SPB read width is shorter than the Rx_Outlet_Width, then the excessive part is lost.

If the SPB read width is longer then Rx_Outlet_Width, then the missing part is padded with zeros.

On the shift register side, the RxFIFO is always filled with a number of bytes as needed for the data width field DATCON.DATLEN, hereinafter referred as Rx_Inlet_Width.

The table below describes all the possible combinations. The bytes in the RxFIFO are named A, B, C and D. A being the first one to take out. The padding byte is 0.

***Note**: In case of an underflow, that is when a read access is performed to RXDATA and the number of bytes to be taken out of the FIFO as given by the setting of RXFIFOCON.OUTW exceeds the number of bytes that are actually stored in the FIFO, as indicated by RXFIFOCON.FILL, then the RxFIFO delivers the available data padded with zeros up to the read access width. However, the data remain in the FIFO and the filling level RXFIFOCON.FILL is not changed. To remove the data, the user software must flush the RxFIFO. The bit FLAGS.RFU is set.*

Table 1114 Outlet width versus SPB read width

SPB-read data, taken from the RxFIFO		SPB bus read width		
		8-bit	**16-bit**	**32-bit**
Rx_Outlet_Width	8-bit	A_H	$0A_H$	$000A_H$
	16-bit	A_H	BA_H	$00BA_H$
	32-bit	A_H	BA_H	$DCBA_H$

24.3.3.2.1 Using the RxFIFO

The received data is read from the address RXDATA registers. Reading from any of these registers has the same effect. The eight consecutive RX registers are provided to support burst access.

Standard ASC mode

In case of data width of 7 or 8 bits, one read on this address delivers one byte and empties the FIFO for one element, if the Rx_Outlet_Width is 8-bit. The Rx_Inlet_Width is 8-bit.

In case of data width of 9 bits, one read on this address delivers two bytes and empties the FIFO for two elements, if the Rx_Outlet_Width is 16-bit. The Rx_Inlet_Width is 16-bit.

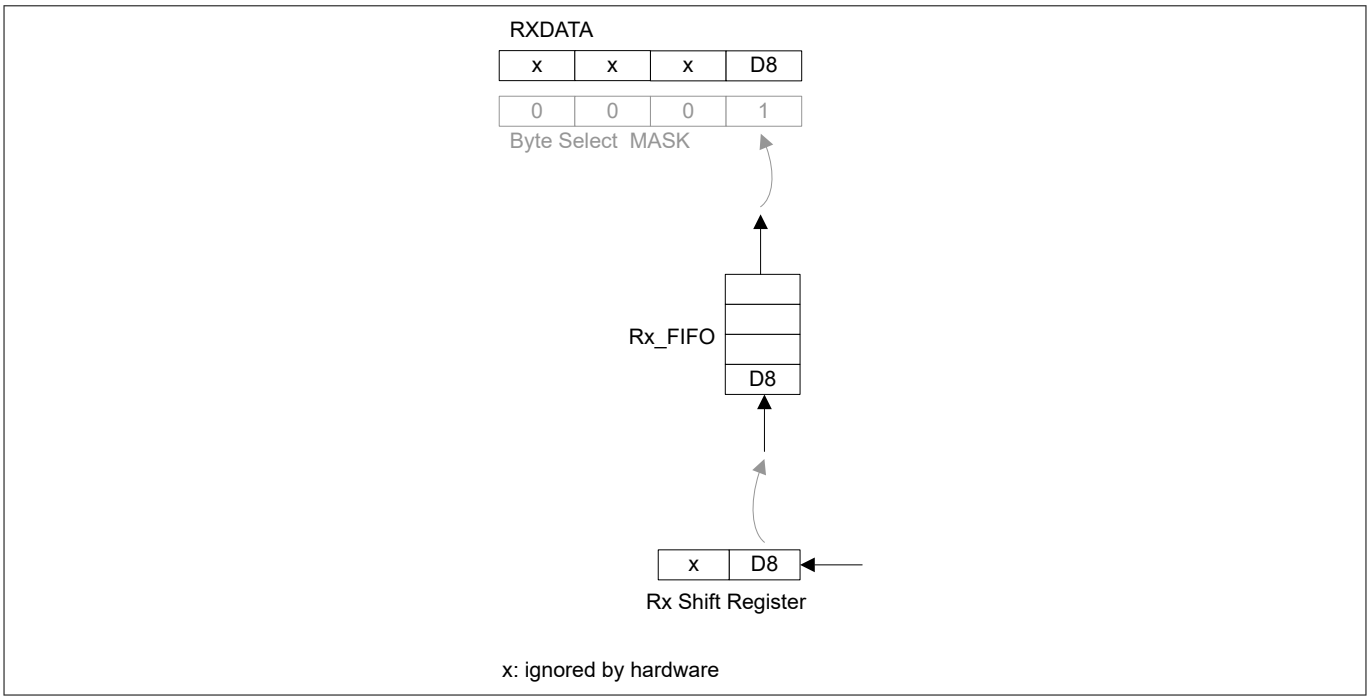

Figure 469 RxFIFO operation in 7- or 8-Bit ASC mode, with or without parity

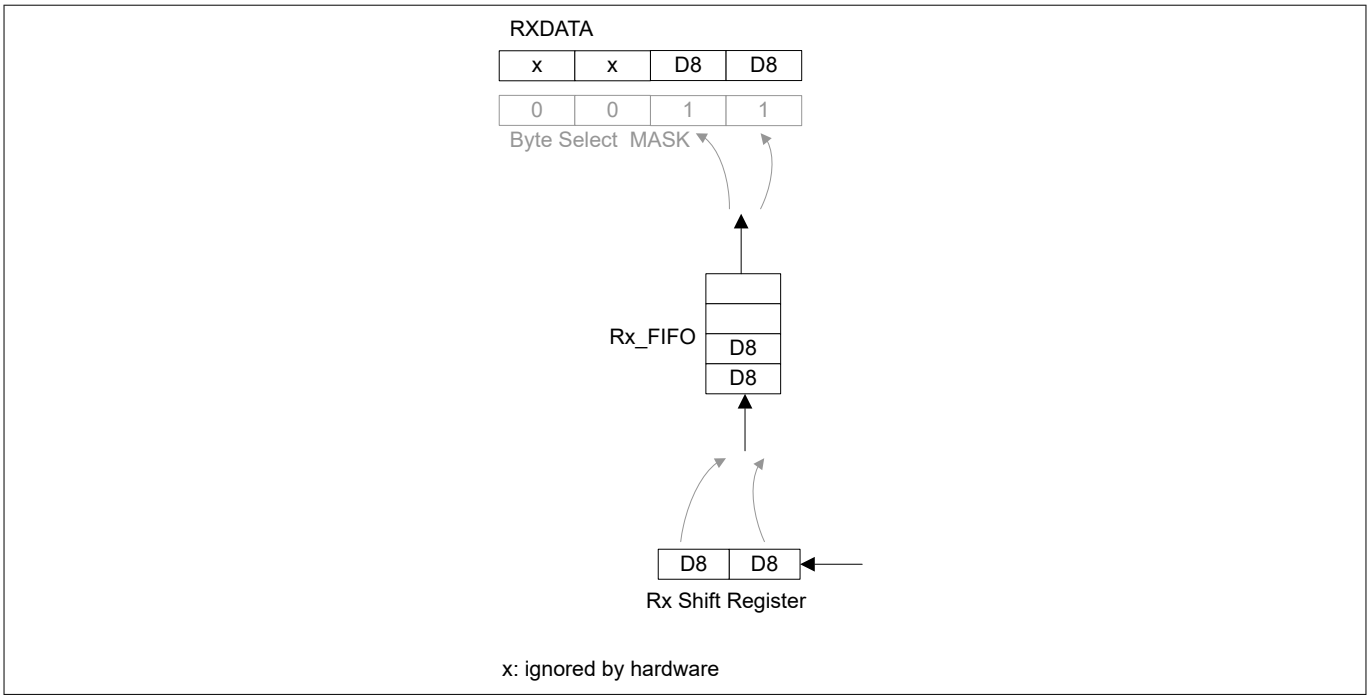

Figure 470 RxFIFO operation in 9-Bit ASC mode

High speed ASC mode

In case of data width of 7 or 8 bits, one read on this address can deliver (one or two or) four bytes and empties the FIFO by four elements, if the Rx_Outlet_Width is 32-bit. The Rx_Inlet_Width is 8-bit.

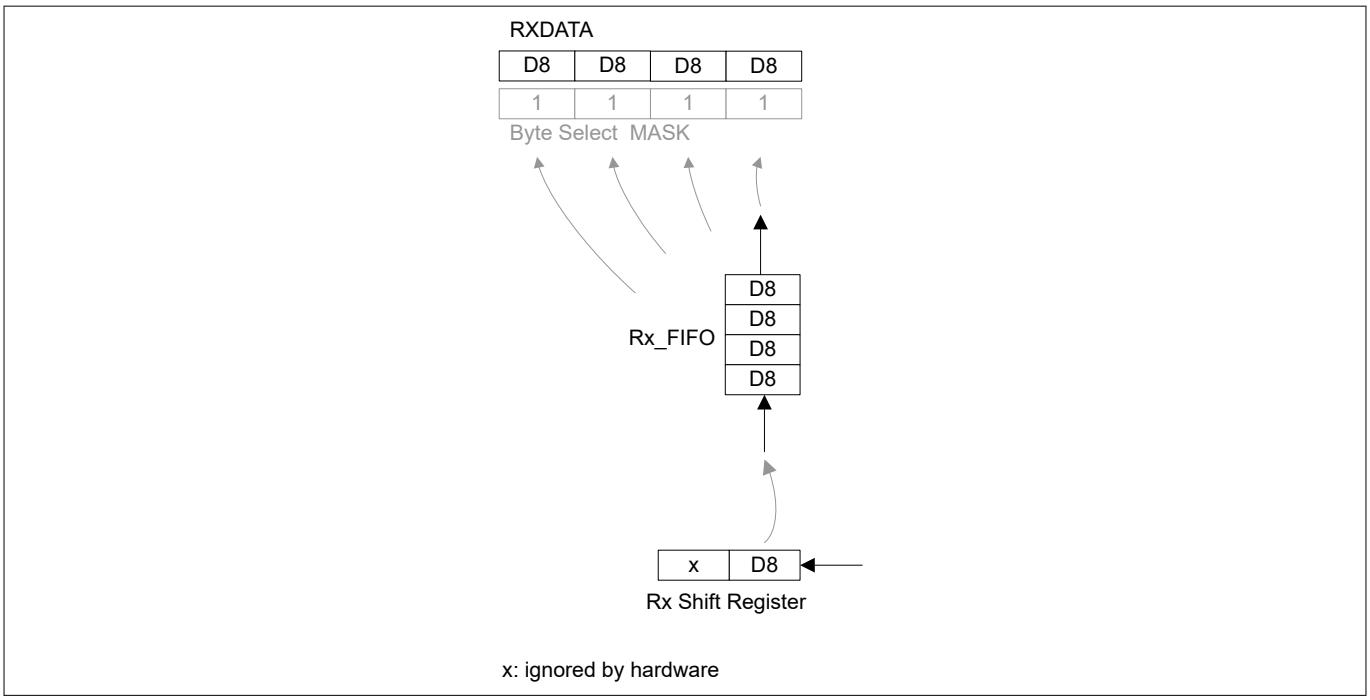

Figure 471 RxFIFO operation in high speed ASC mode

LIN mode

The read data width is 8 bits (or 16-bit or 32-bit), one read on this address delivers one byte and empties the FIFO by one element, if the Rx_Outlet_Width is 8-bit. The Rx_Inlet_Width is 8-bit.

The RxFIFO operation in LIN mode is different when using it in the slave or master mode. In slave mode first the sync break is detected. After the sync field reception the ENI bit is set by hardware to enable the transfer of the ID byte into FIFO. If response is expected, selectable from HO, then also the response is transferred into FIFO. Last field is checksum, if enabled in CSI field, this byte is transferred into FIFO.

In master mode the ENI is set by software and if enabled the response is expected from slave and it allows its transfer into FIFO. The checksum field is stored similarly to the slave mode.

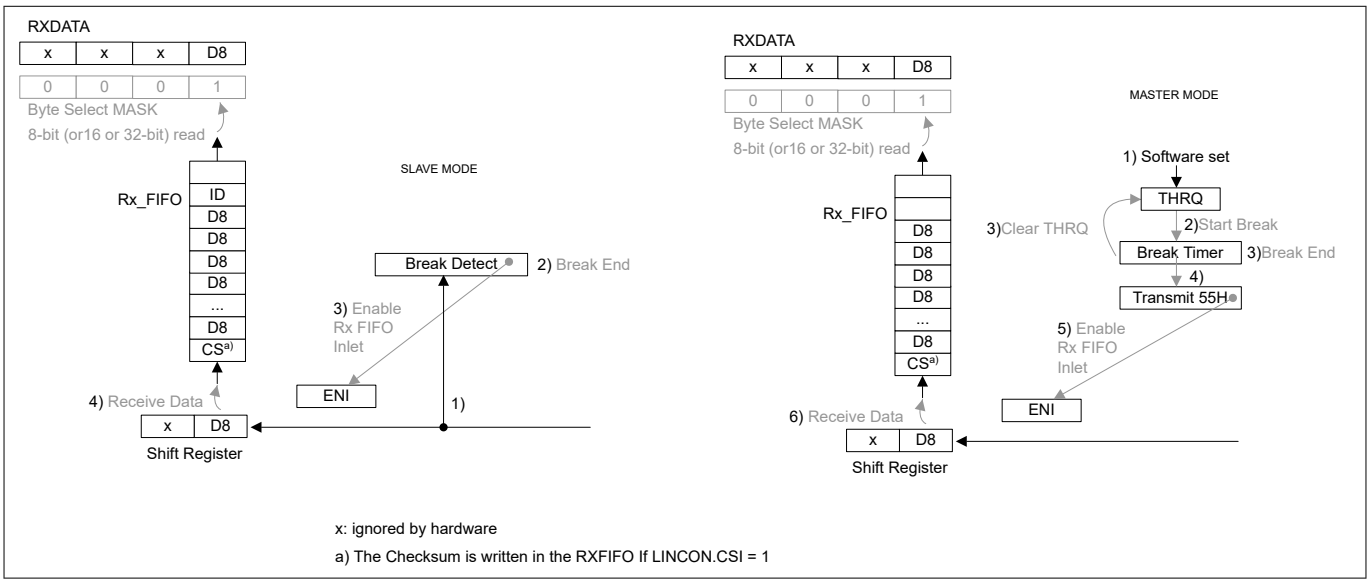

Figure 472 RxFIFO operation in LIN mode

SPI mode

In case of data width of 16 bits, one read on this address delivers two bytes and empties the FIFO by two elements, if the Rx_Outlet_Width is 16-bit. The Rx_Inlet_Width is 16-bit.

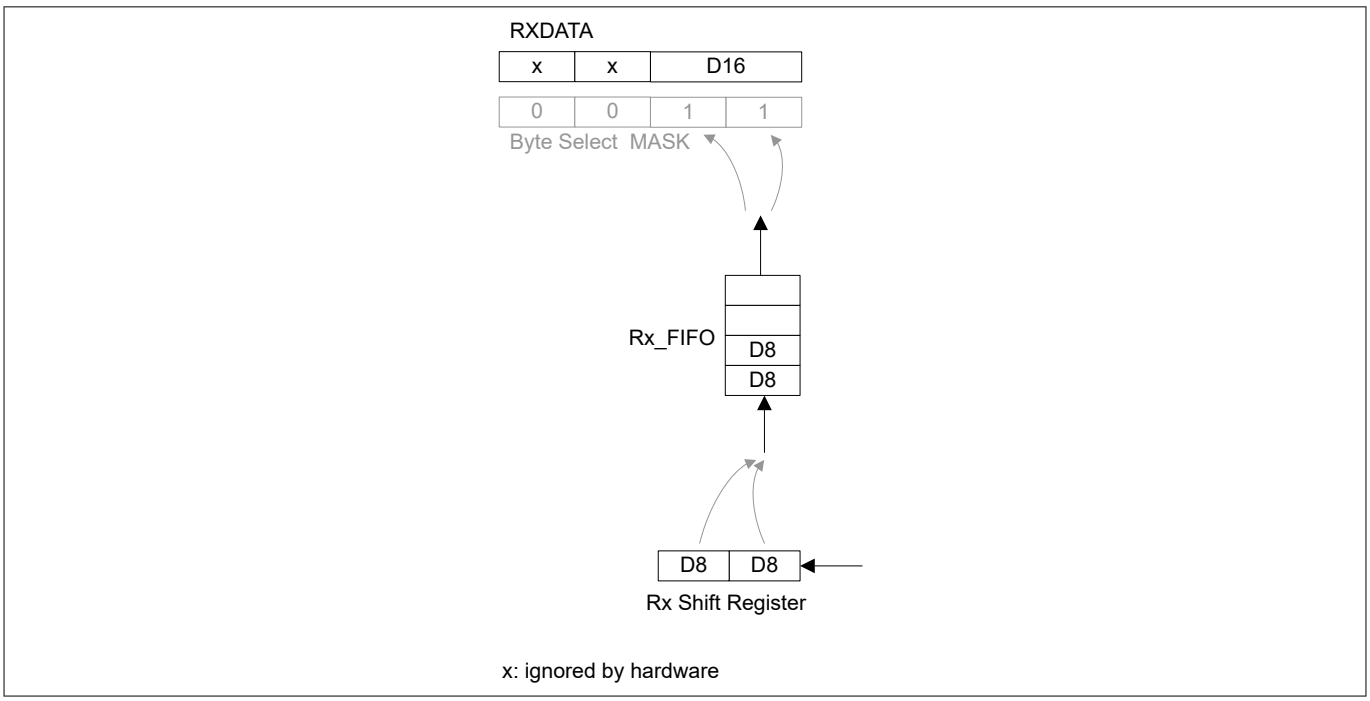

Figure 473 RxFIFO operation in SPI mode

24.3.3.2.2 RxFIFO interrupt generation

The RxFIFO provides three interrupt generation modes, selected by the bit-field RXFIFOCON.FM:

- Single Move Mode
- Batch Move Mode
- Combined (Compatibility) Mode

The RxFIFO interrupt flag is FLAGS.RFL. In case of an event (irrelevant if the event source is from read or write to the FIFO), if the flag interrupt is enabled in FLAGSENABLE.RFLE, an interrupt is generated.

Single move mode

The purpose of the Single Move Mode is to keep the RxFIFO as empty as possible, by fetching the received elements one by one as soon as possible.

The single move mode supports primarily a DMA operation using single move per RxFIFO interrupt. In this mode the DMA keeps the RxFIFO as empty as possible. A DMA request is triggered each time a read from the RxFIFO is performed, and the RxFIFO is afterwards still not empty.

If the read:

- Makes the RxFIFO empty, or
- The next read would make the RxFIFO underflow taking RXFIFOCON.OUTW into account

an interrupt is not generated in order to prevent underflow. It is generated later when the shift register writes one element to the RxFIFO, making it sufficiently full to provide one Rx_Outlet_Width wide element. If RxFIFO can handle new data, it generates an interrupt but fetches just one data of the defined frame width. The DMA or the user should not read multiple data at once to avoid unexpected behavior.

The figure below shows the filling levels of the RxFIFO, and the events associated with each filling level triggering a RxFIFO refill interrupt.

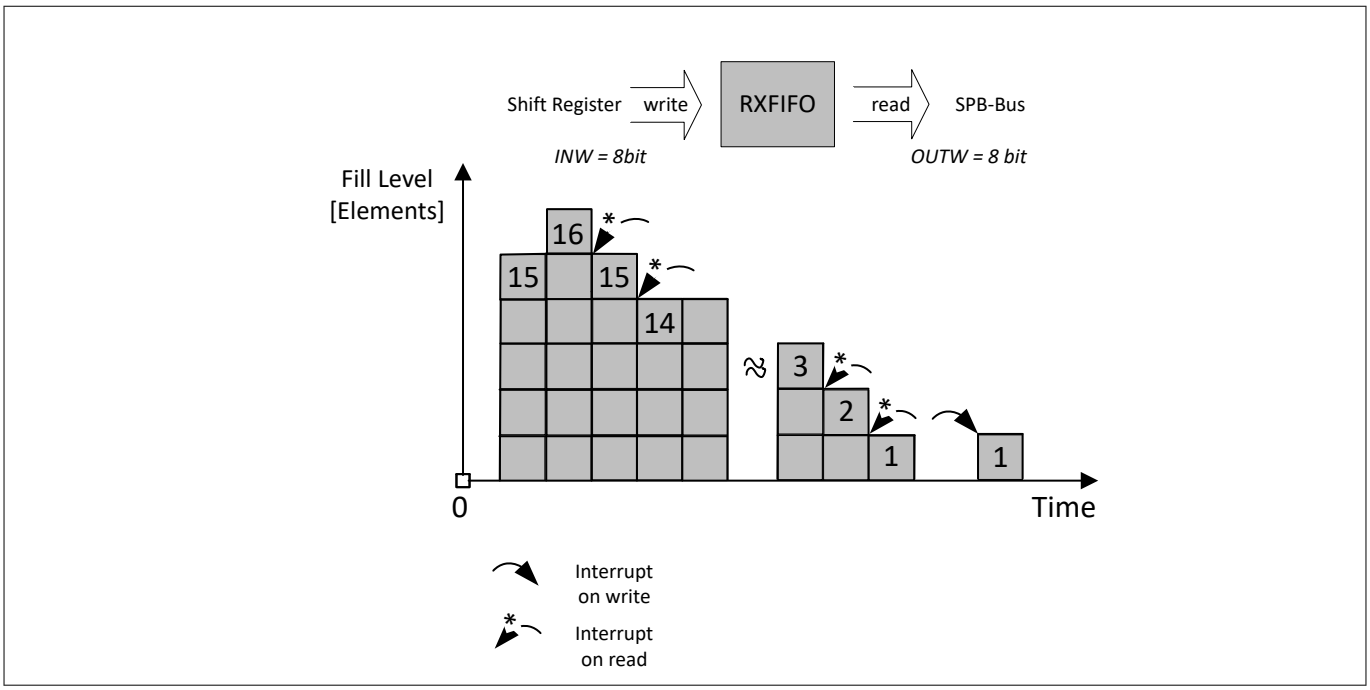

Figure 474 RxFIFO - interrupt triggering in the single move mode

The initial RxFIFO interrupt is triggered by the Shift Register, after it delivers the first received element. Afterwards, the DMA trigger-chain of re-fetch interrupts is self sustaining until the whole transaction is over. At the end of the DMA transaction, there is no service request remaining active in the service request node, due to the fact that the read of the last element in the RxFIFO does not trigger an interrupt.

Attention**: **In Single Move Mode multiple software reads or block DMA moves lead to multiple interrupts and (false) transaction lost events. Therefore they should be avoided - only single moves should be used.

Batch move mode

The purpose of the Batch Move Mode is to reduce the number of interrupts by triggering an interrupt when more then one RxFIFO elements are full. For example, a CPU can be interrupted less frequently and it can perform more than one move per interrupt.

Batch Move Mode supports primarily the CPU servicing the RxFIFO use case.

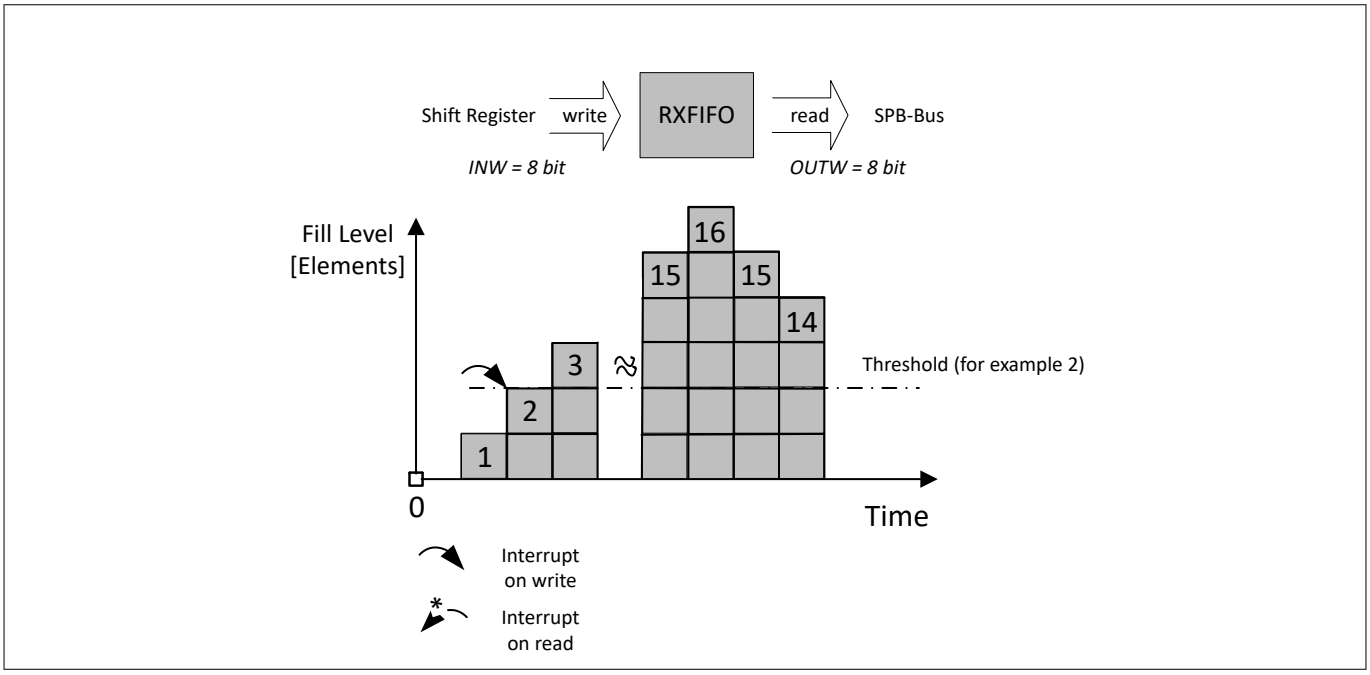

Figure 475 RxFIFO - interrupt triggering in the batch move mode

In Batch Move Mode, an interrupt is generated only at one point in the RxFIFO, when the filling level rises to or above the programmed threshold, implying that there are at least the predefined number of full RxFIFO elements available. The description refers to the interpreted value of RXFIFOCON.INTLEVEL (register value +1).

Attention**: **It must be guaranteed that the CPU keeps emptying the RxFIFO and polling the RxFIFO filling level until the filling level has fallen below the interrupt threshold (or the RxFIFO is empty), in order to guarantee that next interrupt will occur.

At high baud rates and short frames, it could be possible that more than one frames have been received until the moment the RxFIFO is re-emptied. For example, if the threshold is set to two full elements, then the interrupt will be set when the filling level rises above two. If the emptying moment of the RxFIFO is delayed so long that two additional frames have been received, the RxFIFO will become full, and re-empty sequence of two will not reach the level of two. So, the next interrupt would never come. This effect can not occur with threshold levels of 3 and 4. The threshold level of 1 is possible, but does not make much sense (use single move mode instead).

Combined (compatibility) mode

An interrupt is generated when the filling level rises to INTLEVEL or beyond, each time when a data byte is delivered to the FIFO, as defined in the RXFIFOCON.INTLEVEL. The description refers to the interpreted value of RXFIFOCON.INTLEVEL (register value +1). This is the mode which is compatible with the previous versions of the module and described in the RXFIFOCON.INTLEVEL bit-field.

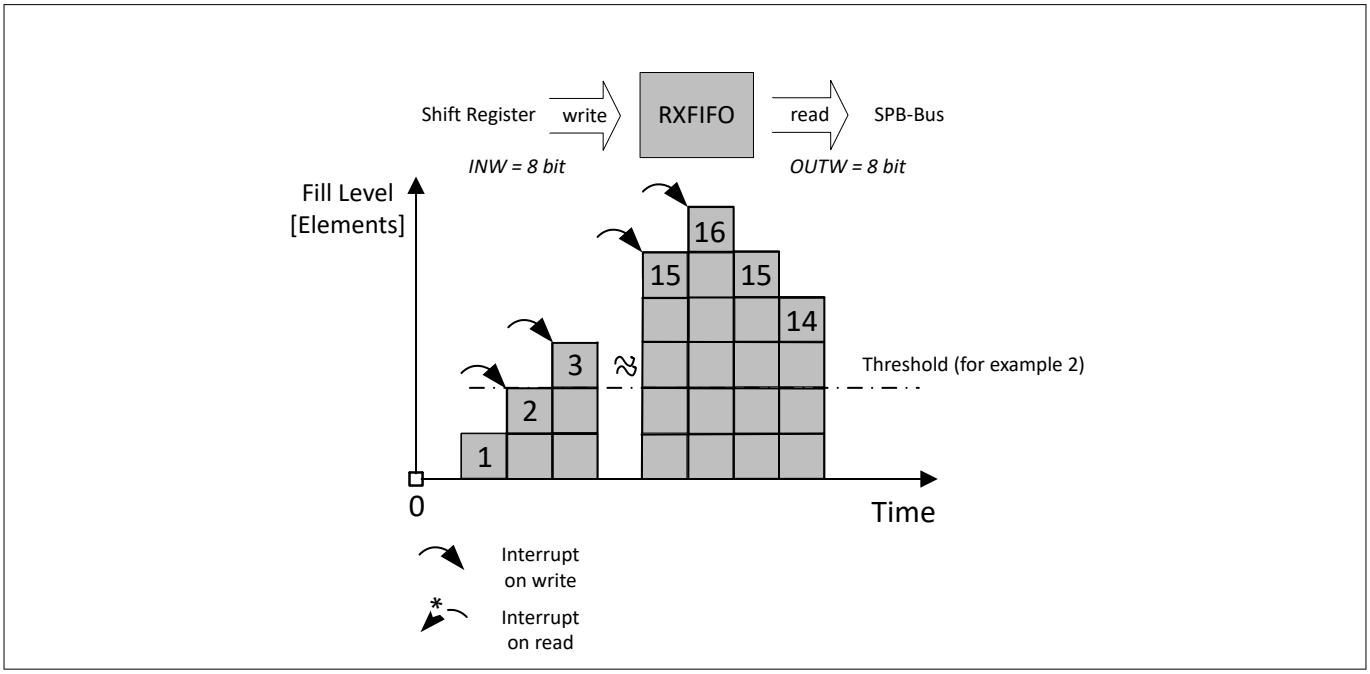

Figure 476 RXFIFO - interrupt triggering in the combined mode

24.3.3.3 RTS/CTS handshaking

The handshaking is a hardware mechanism to control the flow of communication in the ASC and High Speed ASC modes. It uses two additional signals RTS (Request to Send) and CTS (Clear to Send).

The receiver deactivates the RTS output signal when the RxFIFO is almost full, in order to avoid its overload. When the emptying of the RxFIFO starts, for example by a DMA, and the filling level falls below the threshold level, the RTS output is activated again. The transmitter receives the RTS output of the receiver on its CTS input and accordingly pauses and resumes the transmission.

The Handshaking is enabled by setting the IOCR.CTSEN bit. The threshold level is fixed to RxFIFO size minus four, in order to support byte, two bytes and four bytes DMA transfers.

ASCLIN connection with itself

The following connection is defined for each ASCLIN instance:

ARTS -> ACTSD

This connection can be useful in the SPI mode, where frequently the transmission and the reception of data are performed in parallel. If this connection is selected by using IOCR.CTS register, the TXFIFO will deliver data for transmission only if there is a free space in the RXFIFO. If not, the TXFIFO will wait for emptying of the RXFIFO by software and then automatically continue the transmission.

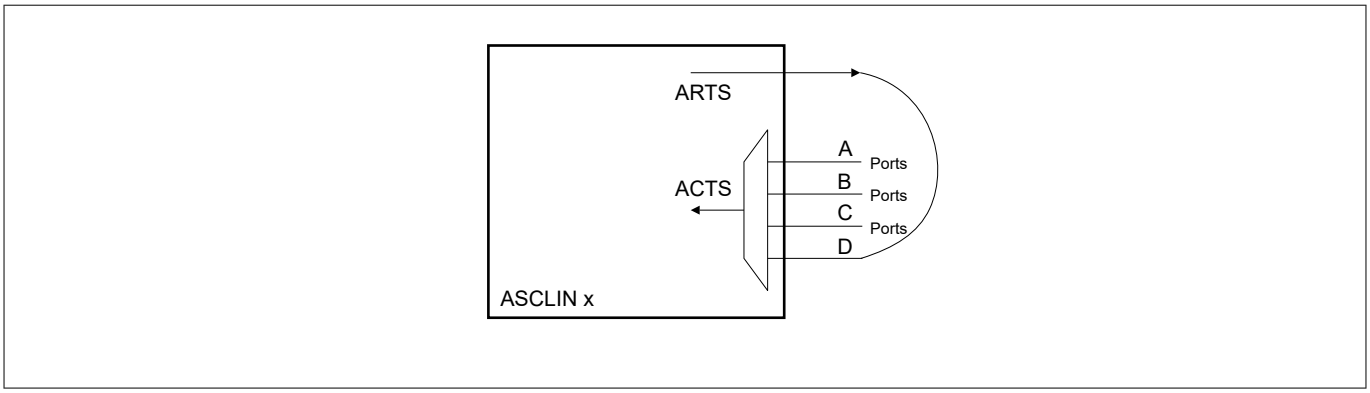

Figure 477 ASCLIN ARTS to ACTS Connection

24.3.3.4 Transmit trigger

This feature is only applicable when the ASCLIN module is configured in ASC mode.

In addition to the traditional mode, to transmit the frame once there is a full frame in TXFIFO, the ASCLIN can send frames in two additional advanced modes. The new modes are:

- Software-triggered frame transmission. It is enabled in DATCON.TRGSRC. To transmit a frame, the FLAGSSET.SWTRG bit shall be set
- Hardware-triggered frame transmission. It is enabled in the DATCON.TRGSRC bit-field, where the user selects thetimer source: GTM or eGTM for TRIG trigger input. The channel and frequency selection is configured in GTM or eGTM module
  - This mode offers transmission of frames in synchronous fashion

In case a Transmit Trigger is received but there is no data or not enough data for a full frame in the TxFIFO, the FLAGS.TFE flag is set, and an interrupt is generated, if enabled.

In case during ongoing transmission another trigger happens, this trigger is ignored and the overflow of multiple triggers (FLAGS.OMT) flag is set. The ongoing transmission is finished.

24.3.4 Clock system

The clock system generates all the clocks needed for the proper operation of the module: digital filter clock, oversampling clock, bit time and serial SPI clock.

The clock used for the clock system f_A is independent from the SPB bus clock and remains constant if the SPB bus clock changes, for example in power saving scenarios. The bit-field CSR.CLKSEL selects the clock source for the f_A frequency. There are two sources for f_A clock namely, $f_{ASCLINF}$ and $f_{ASCLINS}$. $f_{ASCLINF}$ is a fast clock typically used for SPI and extended ASC mode and $f_{ASCLINS}$ is slow clock, normally used for normal ASC mode. LIN baud rates can be derived from both clocks.

The SPB clock f_{SPB} feeds the f_{CLC} and it is enabled in CLC register.

24.3.4.1 Baud rate generation

The baud rate generation overview is shown in the figure and formula is given as follows:

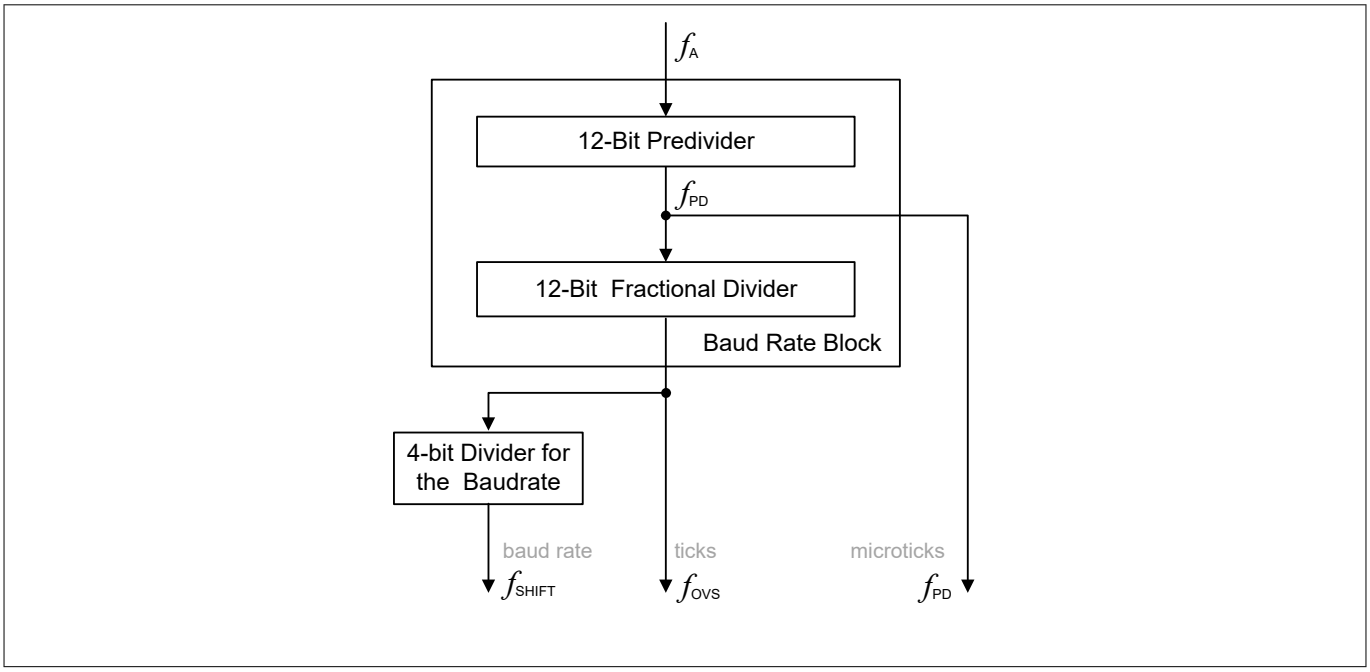

Figure 478 Baud rate generation

The chain of the generated frequencies from f_A down to the f_{SHIFT} (the baudrate) is calculated as follows:

$$f_{PD} = \frac{f_A}{\text{BITCON.PRESCALER} + 1}$$

$$f_{OVS} = f_{PD} \times \frac{\text{BRG.NUMERATOR}}{\text{BRG.DENOMINATOR}}$$

$$f_{SHIFT} = \frac{f_{OVS}}{\text{BITCON.OVERSAMPLING} + 1}$$

The following bit-fields are available for configuring of the 28-bit baud rate divider chain:

- BITCON.PRESCALER - the division ratio of the pre-divider
- BRG.NUMERATOR - the numerator of the fractional divider
- BRG.DENOMINATOR - the denominator of the fractional divider
- BITCON.OVERSAMPLING - the division ratio of the baudrate post divider

***Note**:*
- *Fractional division requires that* BRG*.NUMERATOR is less or equal than the* BRG*.DENOMINATOR*
- *Bit time is equal to the time period of* f_{SHIFT}

24.3.4.2 Bit timing properties

The ASCLIN module provides flexible programming of the bit oversampling, sampling point, digital median filter and input signal de-glitch filtering properties.

The oversampling factor for the incoming bit-stream is configurable from 4 to 16 ticks per bit.

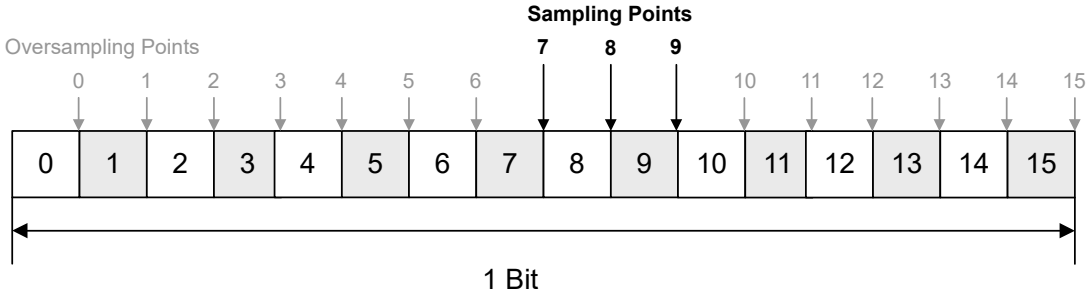
Additionally, using the oversampling frequency, a digital median filter can be enabled to filter the incoming bit stream. The filtering uses the standard majority out of three procedure. If the filter is disabled, then each bit is sampled only once.

The sampling point is also configurable and should be used in conjunction with the oversampling factor. One standard setting is 16x oversampling and using the samples 7, 8 and 9 for the data. Another possible setting could be 8x oversampling and using the samples 3, 4, and 5 for data.

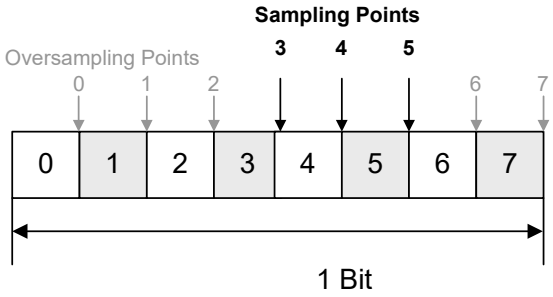
The following bit-fields are available for configuring the bit properties:

- BITCON.PRESCALER - the twelve bit integer divider defines the microtick used by the fractional divider to generate the baud rate and by the digital glitch filter for the de-glitching of the RX input signal
- BITCON.SAMPLEPOINT - the bit-field defines the sampling point position and the duty cycle in the SPI mode
- BITCON.SM - the bit enables the digital median filter (majority out of three): 1 or 3 samples per bit
- IOCR.DEPTH - the bit-field defines the floating average digital glitch filter depth: Off or 1 to 63 microticks
- BITCON.OVERSAMPLING - the bit-field defines the number of ticks per bit, in the range of 4 to 16. This is a post-divider located after the fractional divider

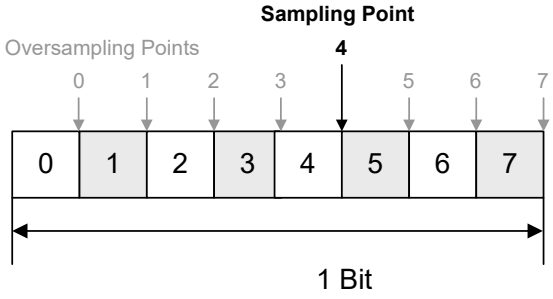
16x Oversampling, 3 sample points, revelant sample points = 7, 8, 9
(BITCON.OVERSAMPLING = 16, BITCON.SM = 1, BITCON.SAMPLEPOINT = 9)



8x Oversampling, 3 sample points, relevant sample points = 3, 4, 5
(BITCON.OVERSAMPLING = 8, BITCON.SM = 1, BITCON.SAMPLEPOINT = 5)



8x Oversampling, 1 sample point, sample point = 4
(BITCON.OVERSAMPLING = 8, BITCON.SM = 0, BITCON.SAMPLEPOINT = 4)



16x Oversampling, 1 sample point, sample point = 12
(BITCON.OVERSAMPLING = 16, BITCON.SM = 0, BITCON.SAMPLEPOINT = 12)

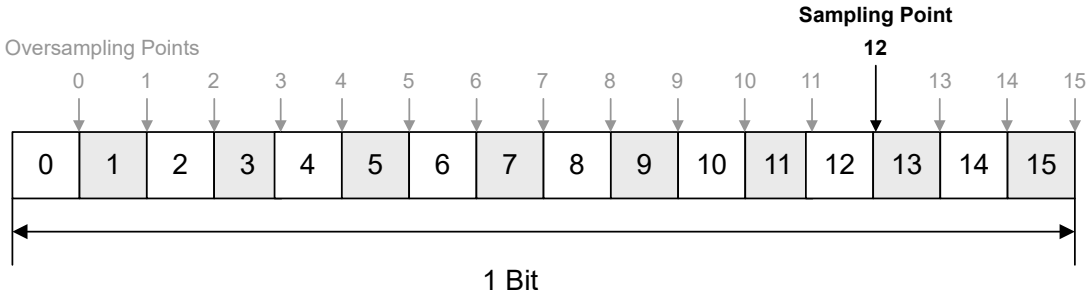


Figure 479 ASCLIN bit structure

Generally, the sampling point should be placed in the middle of the bit. This position is optimal in case the baud rate (the oscillator frequency) is not very precise and stable. However, different combinations of oscillator

precision, asymmetry of the edges, and loop delays for collision detection result in different optimal positions of the sampling point.

One example is shown in the figure below, when two microcontroller driven by quartz oscillator communicate, the oscillator precision is very high. In case the open drain half duplex connection is used, the signal edges are asymmetrical. Open drain connection usually causes the “0” bits to be longer than the “1” bits. In this case it can be of advantage to optimize the sample point by placing it in the middle of the shorter “1” bit.

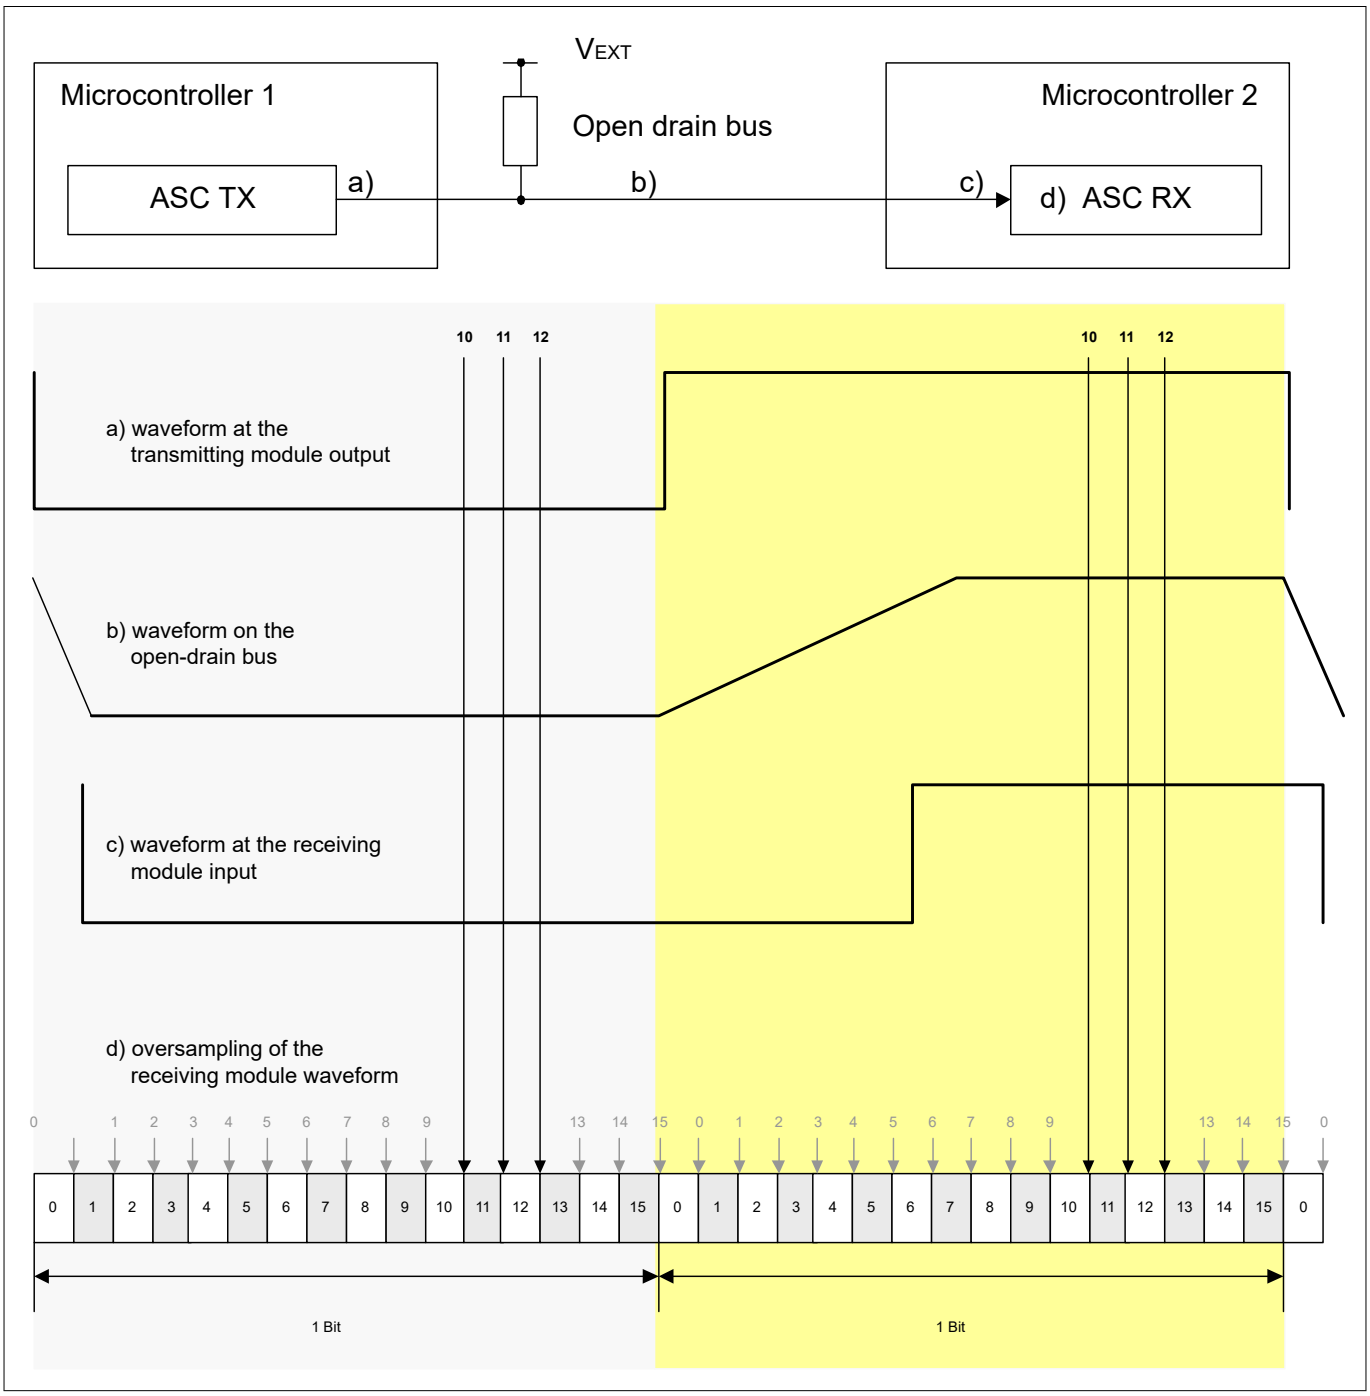

Figure 480 Bit length asymmetry and the sampling point

24.3.4.3 Auto baud rate detection

Auto baud rate detection feature is available when using the module in LIN slave mode. If the auto baud rate usage is enabled LINCON.ABD = 1, this feature is active during the reception of sync field where it measures the longest time interval between two falling edges in the sync field (55_H). The measured value (t_{AB}), is loaded in the denominator of the fractional divider and used afterward for generating the baudrate for the reminder of this frame.

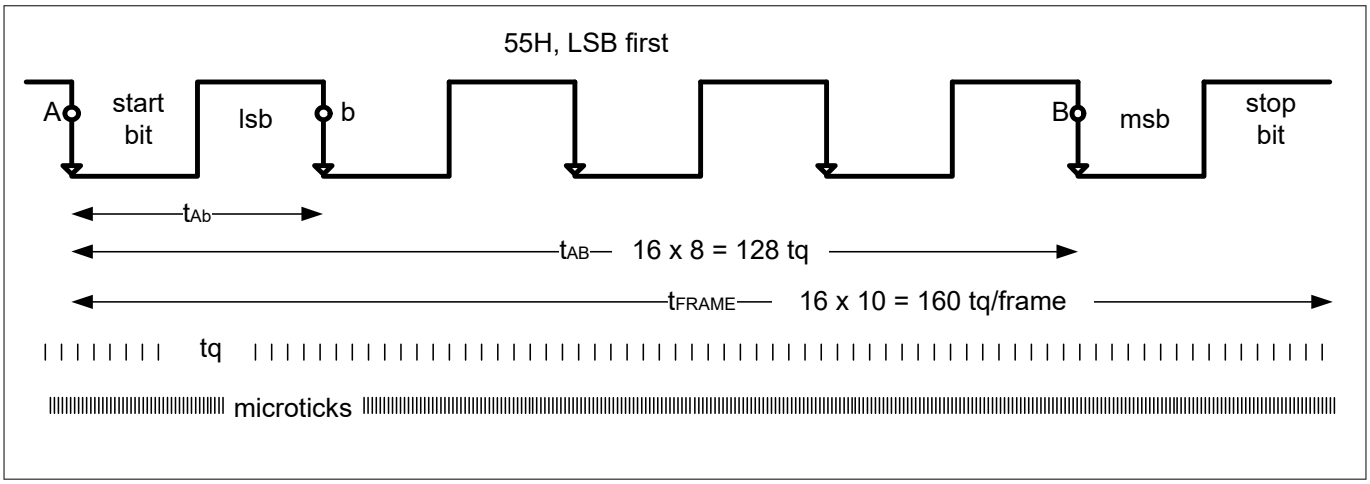

Figure 481 Measurement of the sync field

The following bitfields are available for monitoring the autobaud detection:

- BRD.MEASURED - the measured time interval between the first and the fifth falling edge of the sync byte

  ***Note**: When ABD = 1, the selected PRESCALER shall ensure, that the MEASURED (which is the measured DENOMINATOR) fits into 12 bits for the desired incoming baudate from the master.*

- BRD.UPPERLIMIT - the configured upper limit of the measured time interval
- BRD.LOWERLIMIT - the configured lower limit of the measured time interval

Auto baud rate operation

The BRD.UPPERLIMIT time interval defines the maximum allowed duration for 8 bits in microticks, in other words it defines the minimum allowed baud rate. In case the LIN autobaud detection measures a baud rate 14% lower than the nominal one, meaning it measures a time interval longer than the BRD.UPPERLIMIT, a baudrate event is triggered that, if enabled, generates an interrupt. To define 14% lower baud rate condition, the time interval duration of 16% longer than the nominal (8 bits microticks) must be entered in BRD.UPPERLIMIT bit-field.

The BRD.LOWERLIMIT defines the minimum allowed duration for 8 bits in microticks, and in other words it defines the maximum allowed baud rate. In case the LIN autobaud detection measures a baud rate 14% higher than the nominal one, meaning it measures a time interval shorter than the BRD.LOWERLIMIT, an baudrate event is triggered that, if enabled, generates an interrupt. To define 14% higher baud rate condition, the time interval duration of 12% shorter than the nominal (8 bits microticks) must be entered in BRD.LOWERLIMIT bit-field.

If the auto baud rate detection is activated, the fractional divider uses the numerator value of $8 \times (\text{BITCON.OVERSAMPLING} + 1)$ (BITCON) and ignores the bit-field BRG.NUMERATOR. For example, for the standard LIN protocol where $\text{BITCON.OVERSAMPLING} = 15$, the numerator value used is $8 \times (15 + 1) = 128$. Programming 128 in BRG.NUMERATOR may increase the clarity of the software.

Regarding the denominator of the fractional divider, defined in BRG.DENOMINATOR, its initial value is the nominal value and as set by the application software. During the operation of the module, the BRD.MEASURED value is automatically loaded into the denominator of the fractional divider, as long as it is within the limits.

***Note**: It has to be ensured that the numerator value that is, $8 \times (\text{OVERSAMPLING} + 1)$) is less than or equal to the denominator value (BRD.MEASURED) which is calculated by the Auto Baud Detection mechanism. There is no check implemented by the hardware.*

24.3.5 Data frame configuration

The following bit-fields are available for configuring the data frame, applicable for both transmitter or receiver:

- FRAMECON.ODD - the parity scheme configuration
- DATCON.DATLEN - the data length in the bit-field. Data length shall only be changed after flushing both Tx and Rx FIFOs.
- FRAMECON.STOP - the stop bits

24.3.6 Miscellaneous configuration

Loop-back mode

The loop-back mode is used for test purposes. It is enabled by setting IOCR.LB bit. It connects internally the receive signal ARX with the transmit signal ATX.

Related information

Architecture overview on page 4631

24.3.7 LIN support

The LIN (Local Interconnect Network) is a serial network communication protocol. It is a bus communication made of one master node and several slaves nodes.

A LIN frame consists of the header sent from the master and a response, send either from the master or from the slave. An overview of a LIN frame is shown in the figure below.

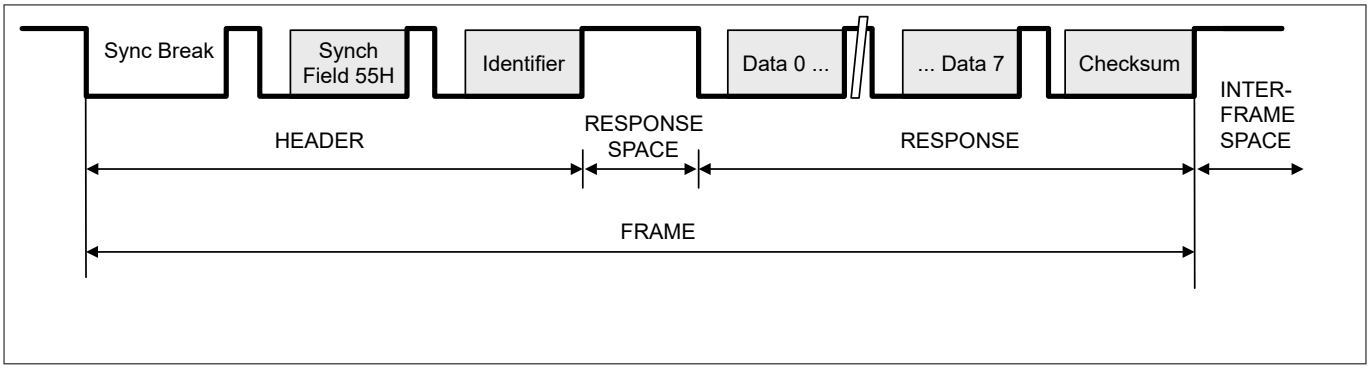

Figure 482 LIN frame format

The ASCLIN module provides hardware support for the LIN protocol. The central LIN protocol state machine is connected to the receiver and the transmitter shift registers, the TxFIFO and RxFIFO, the checksum logic and the watchdog timers. The machine takes care of generating the sync byte of 55_H, if used in master mode, and the automatic handling of the checksum. It supports all LIN use cases, sending and receiving headers and responses as LIN master or LIN slave mode.

It supports all four elementary LIN transactions:

- TxH - Transmission of Header
- TxR - Transmission of Response

- RxH - Reception of Header
- RxR - Reception of Response

A LIN master is engaged in the transactions: TxH, TxR, RxR.

A LIN slave is engaged in the transactions: RxH, TxR, RxR.

Each elementary transaction needs some hardware resources in order to be completed with minimum CPU intervention. Here is a list of tasks per transaction, supported by hardware, and the required hardware resources:

- TxH:
  - Break generation: 6 bit-field defining the break length in units of bits
  - Sync-field generation: Hard coded 55_H byte
  - ID transmission with interrupt generation
- TxR:
  - Number of bytes parameter: bit-field of length 4
  - Checksum generation: hardware engine, supporting classic and enhanced checksum, which can be enabled or disabled
- RxH:
  - Optional auto-baud detection: fractional divider with programmable nominator and denominator
  - Number of bytes parameter: bit-field of length 4
  - Interrupt at end of header (necessary to set the number of bytes for the RxR phase)
  - Timeout on overflow: 8-bit timer
  - Break detection: 8-bit timer with programmable threshold in units of bits
- RxR:
  - Number of bytes parameter: bit-field of length 4
  - Checksum detection: hardware that supports classic and enhanced checksum, which can be enabled or disabled; If enabled, a checksum error is flagged and an error interrupt can be triggered
  - Checksum: the received checksum is optionally delivered in the RXFIFO
  - Timeout on overflow: 8-bit timer

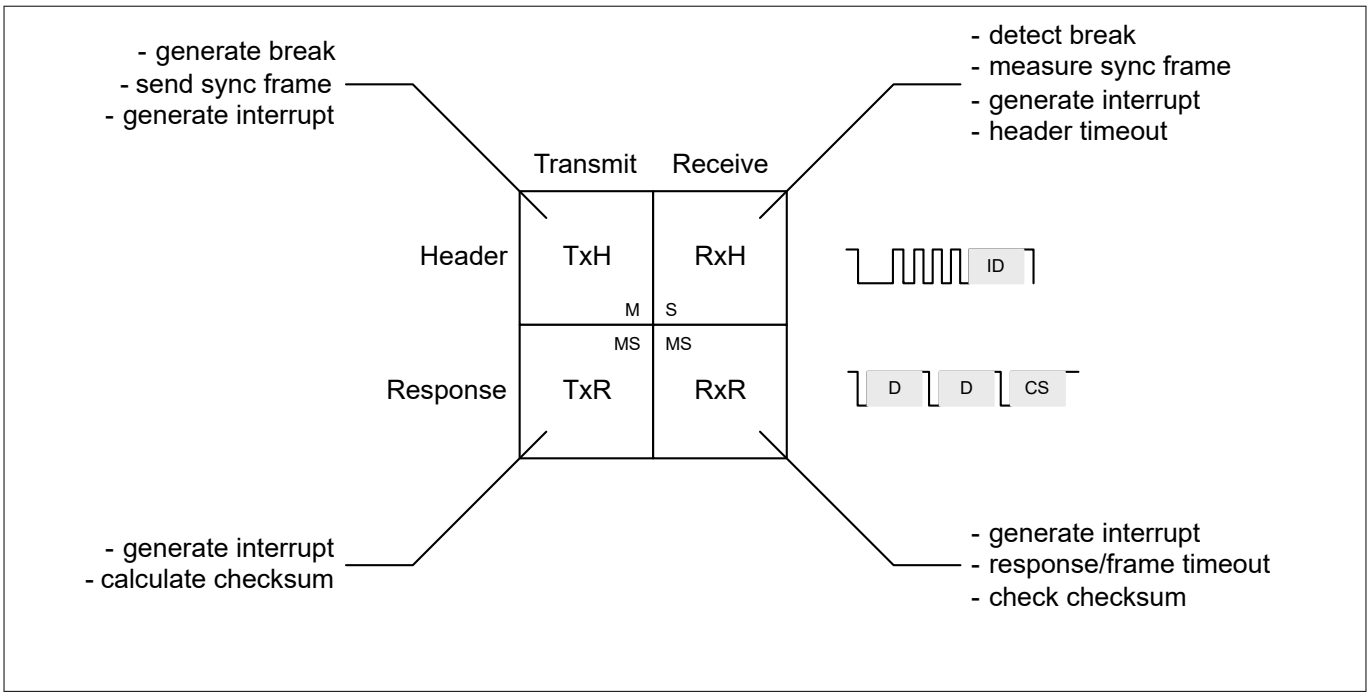

Figure 483 Overview of the elementary LIN transactions

The break detection feature is always active. Wake-up signal generation in both slave and master mode. The configuration parameters are:

- Break length
- Data width
- Break threshold
- Wake-up length
- Header, frame and response timeout
- Idle time

***Note**: For many LIN configuration parameters, the hardware of the ASCLIN module provides wider ranges than the LIN standard parameters. Therefore the application software shall take care that appropriate LIN standard values are used to configure the module.*

24.3.7.1 Using the ENI and HO Bits

The ENI (Enable Input) and HO (Header Only) bits affect the reception of the various byte types in the LIN frame.

The HO bit is normally used in cases where the response part of a frame should be ignored; the module waits for the next break signal. The ENI bit can be set by the user software, but is also set by the hardware in slave mode after the sync byte reception, in order to enable the transfer of the ID byte of the header in the RXFIFO.

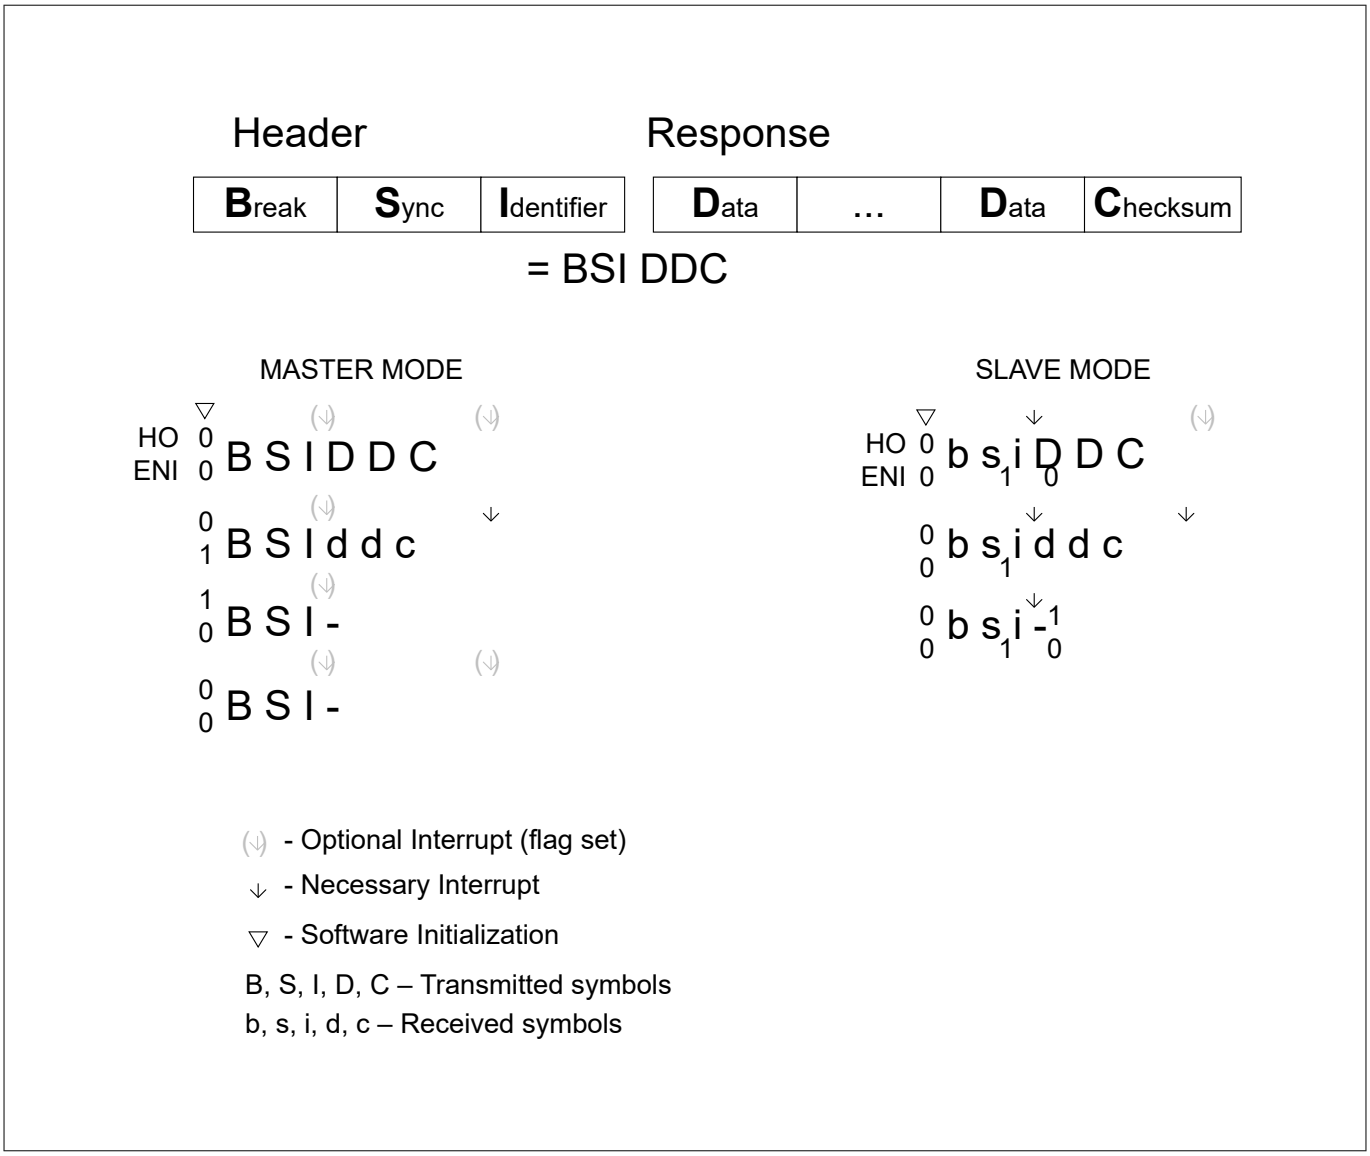

Figure 484 ENI and HO bits

24.3.7.2 LIN watchdog

The LIN watchdog monitors the duration of the header, the frame or the response, and appearance of break pulses. It checks against the pre-defined time limits. If the limits are violated, timeout interrupts are generated.

The LIN watchdog is necessary in slave mode.

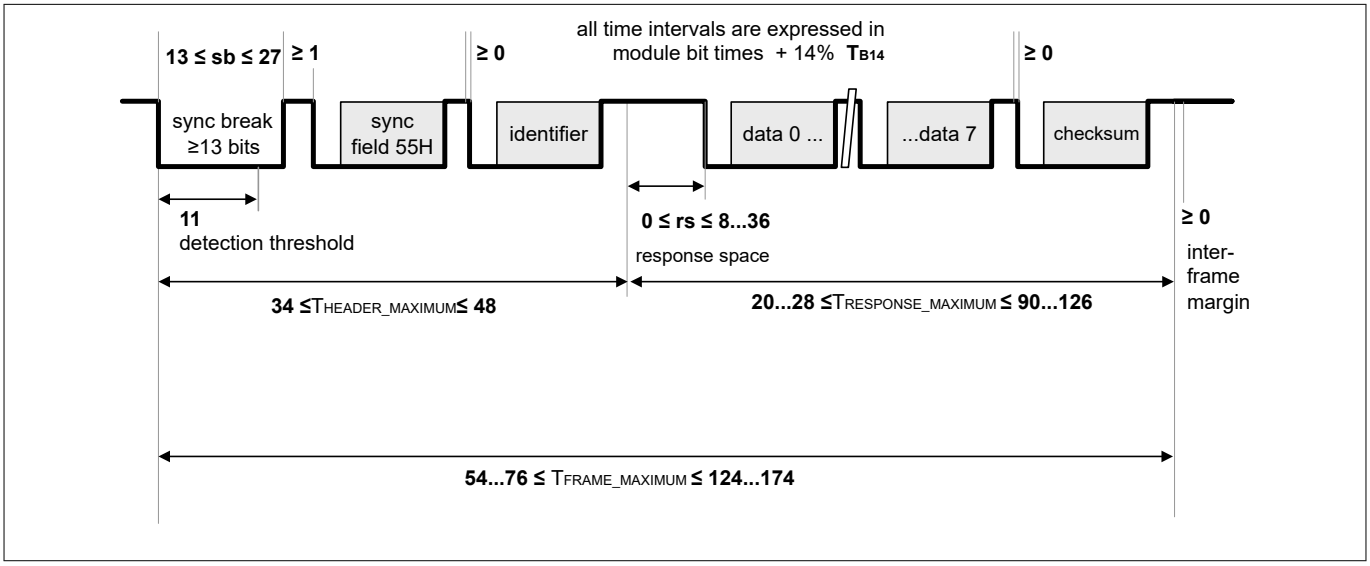

Figure 485 Duration of the elements of a LIN frame

This section describes the following watchdog monitors:

- Monitoring of the LIN Bus
- Break and Wake-up pulse detection
- Break and Wake-up pulse generation
- Header and response timeouts

Monitoring the bus

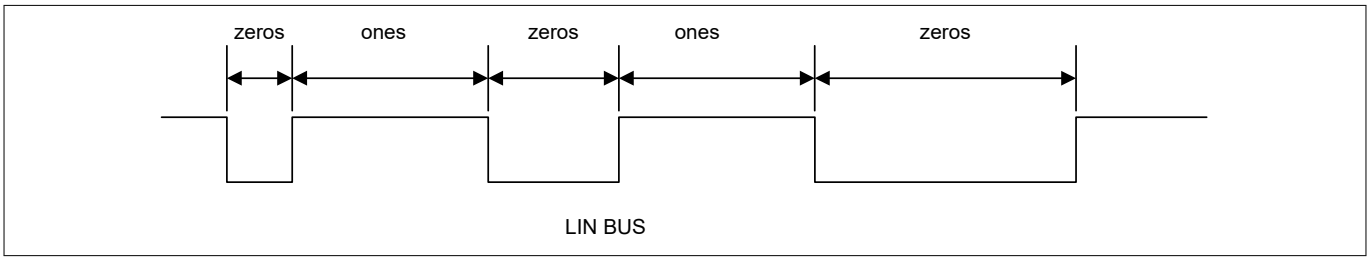

Figure 486 LIN bus view as sequence of sequences of zeros and ones

Monitoring the bus for long idle periods (or stuck periods) is supported by providing the bit-fields FLAGS.RED and FLAGS.FED. Polling these fields periodically within some defined time period by the operating system or timer for example each 1 ms or each 10 ms can be used for detecting very long inactive periods in the range, for example, of 150 ms to 10 s. Additionally, an interrupt on edge can be enabled by using the corresponding enable bits in the FLAGSENABLE registers. Setting and clearing the flags can be done by software by using the FLAGSSET and FLAGSCLEAR register.

Break and wake pulse detection

The detection of the break pulse, which is defined as low pulse with a minimum duration of 13-bit times, is performed using a threshold of either 10 or 11-bit times. The break detection threshold is set using the bit-field LINBTIMER.BREAK.

Detecting a break pulse anywhere in the frame resets the LIN state machine and the whole sequence including the watchdog timeout counting starts from the beginning. A wake-up pulse, which is also a low pulse with a duration longer than 150 µs wakes up a sleeping module. A slave which has been woken up shall be capable of receiving LIN headers after a wake-up time of maximum 100 ms.

***Note**: Detecting a break pulse anywhere in the frame could result in setting the Frame Error Flag (FE)*

Wake-up pulse detection is done by monitoring the bus for a falling edge in sleep mode. If an early wake-up shall be suppressed, the parameter IOCR.DEPTH (glitch filter) may be used.

Break and wake-up pulse generation

The generated break pulse duration is defined by the bit-field LINBTIMER.BREAK in the range of 1 to 64 bits.

Wake-up pulse is nominal 5-bits long low pulse, but can be set to any value between 1 and 9 by writing the appropriate character in the TXFIFO and requesting its transmission as the wake pulse by setting FLAGS.TWRQ (by writing 1_B to FLAGSSET.TWRQS). For a wake-up pulse of n-bit width, the appropriate character should contain "(n-1)" 0 values considering. Below are some examples for wake-up pulses of different width at a speed of 20 kBaud/s (example configurations: fA = 100 MHz, prescaler is 99, oversampling is 4, numerator is 1, denominator is 10):

- To generate the wake up pulse 9-bit long (450 µs), character written to the TXFIFO shall be 00000000_B or 00_H
- To generate the wake-up pulse 5-bit long (250 µs), character written to the TXFIFO shall be 11110000_B or $F0_H$

A master node which has received a wake-up pulse can start polling the slaves, it can start sending break pulses and headers, and send or receive the corresponding responses.

A slave issuing a wake-up pulse expects to receive a header within 150 ms to 250 ms after the end of the wake-up pulse. If the header does not come, the slave issues a wake-up pulse again.

***Note**: Injecting the low pulse disables the reception with the shift register, so that this low pulse is not detected or treated as a normal ASC frame.*

LIN header and response timers

The LIN header and response times can be monitored separately.

- Header duration measurement:
  - In master mode, the starting point of the time measurement is the falling edge of the break pulse
  - In slave mode, the starting point of the time measurement is the moment of detecting that there is a break pulse going on, that is the moment of detection of a low pulse longer than either 10 or 11-bit times, as configured in the LINBTIMER register
- Response duration measurement:
  - In master and slave mode the response duration measurement starts with the end of the header and ends with the end of the response

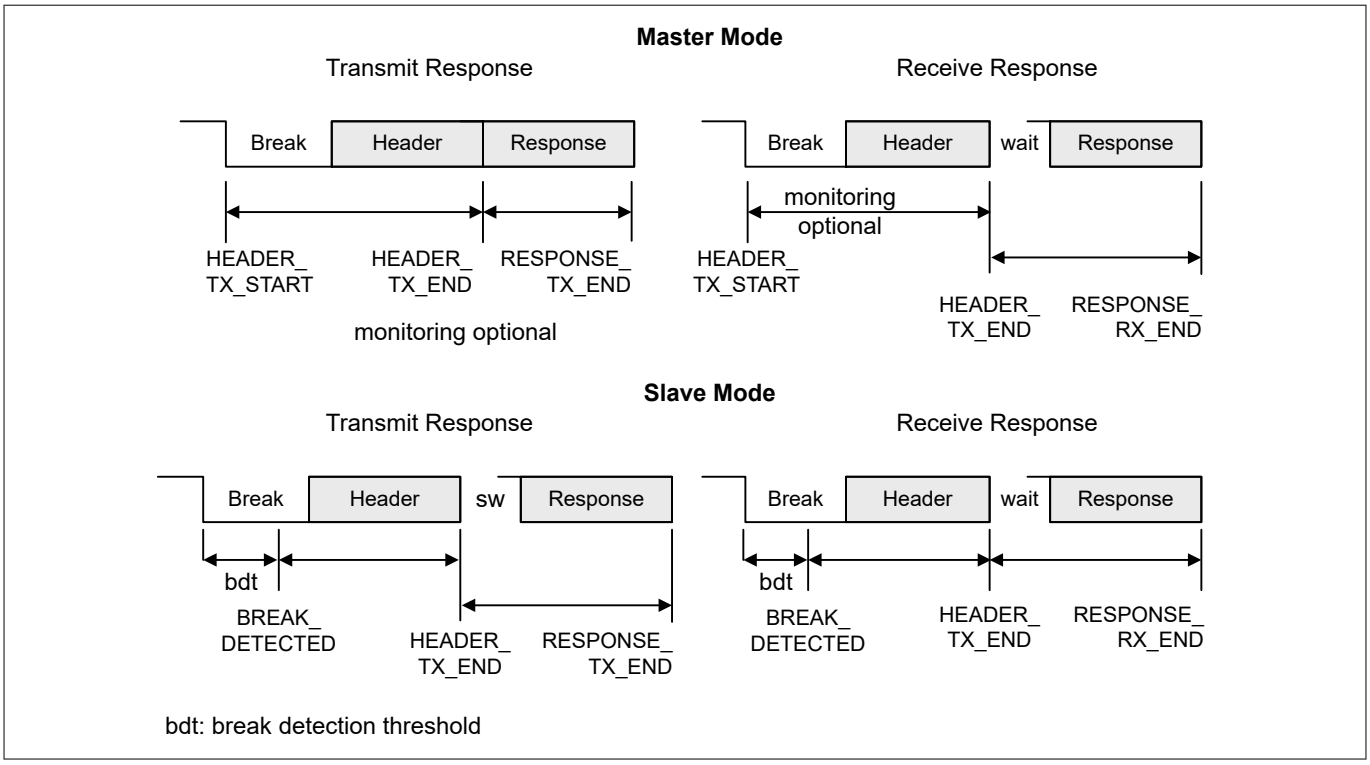

Figure 487 Duration measurement of the header and response

***Note**: Transmitting master node can optionally monitor its own header or response timeouts, in order to detect some error conditions, like TxFIFO not containing the ID or data to be transmitted. However, these error conditions can be detected also in other ways.*

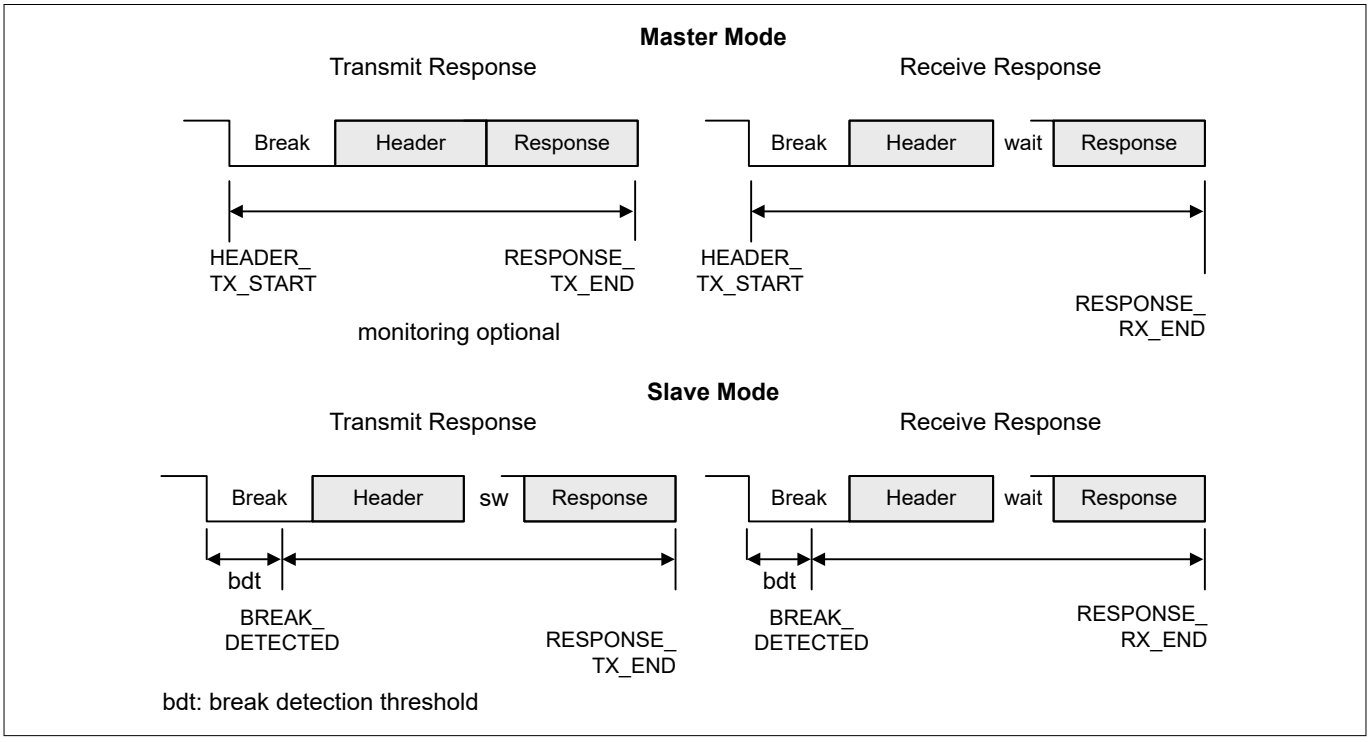

Figure 488 Duration measurement of the response or frame

According to the setting of the bit DATCON.RM, the DATCON.RESPONSE bit-field defines response or frame duration threshold.

LIN version 1.x specified the Frame Timeout Level, which includes header where as in LIN version 2.x the Response Timeout Level counter starts after the header, and does not include Header Timeout Level.

24.3.7.3 LIN checksum

In ASCLIN both the classic LIN V1.3 and the enhanced LIN V2.0/V2.1 checksum are supported. The hardware checksum feature is switchable (enable or disable), and the choice between using the classical and the enhanced checksum is done by software with the DATCON.CSM bit on a frame by frame basis. As can be seen in the figure below, for the LIN version 2.0 and 2.1, the enhanced checksum is calculated for the identifiers 0…59, and the classical checksum for the identifiers 60…63.

Additionally, the parity of the ID field is generated in master mode, and checked in slave mode. In slave mode, in case of a mismatch between the received and the calculated parity, an error interrupt is raised.

In receive case, if LINCON.CSI = 1, the received checksum byte is written to the RxFIFO after the last data byte.

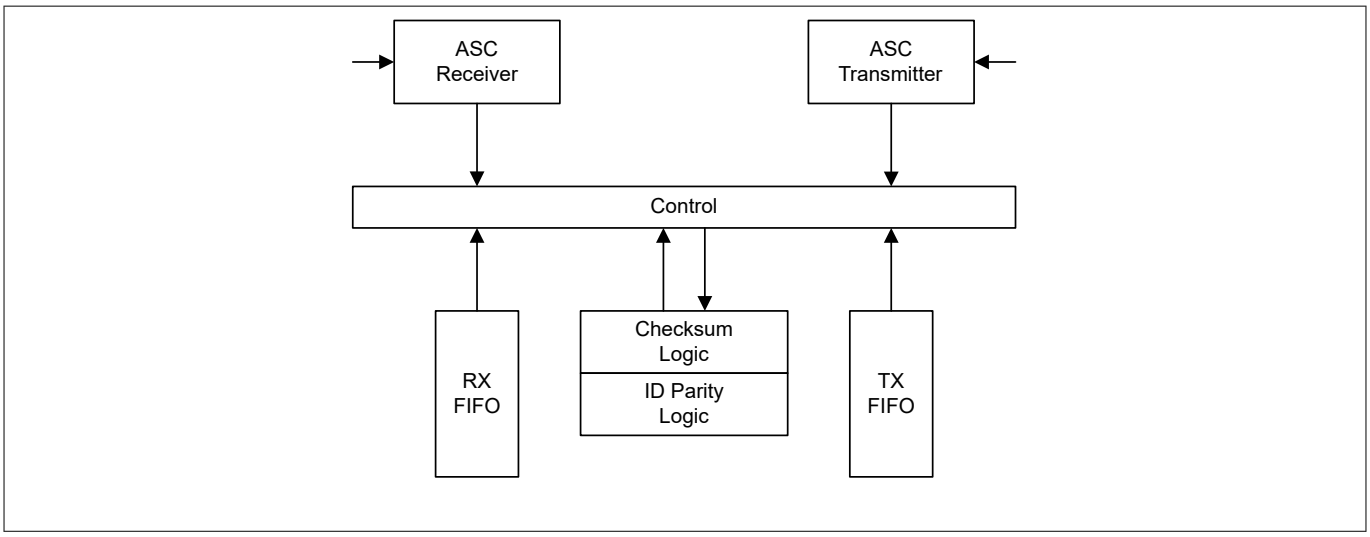

Figure 489 Block diagram of the LIN control subsystem

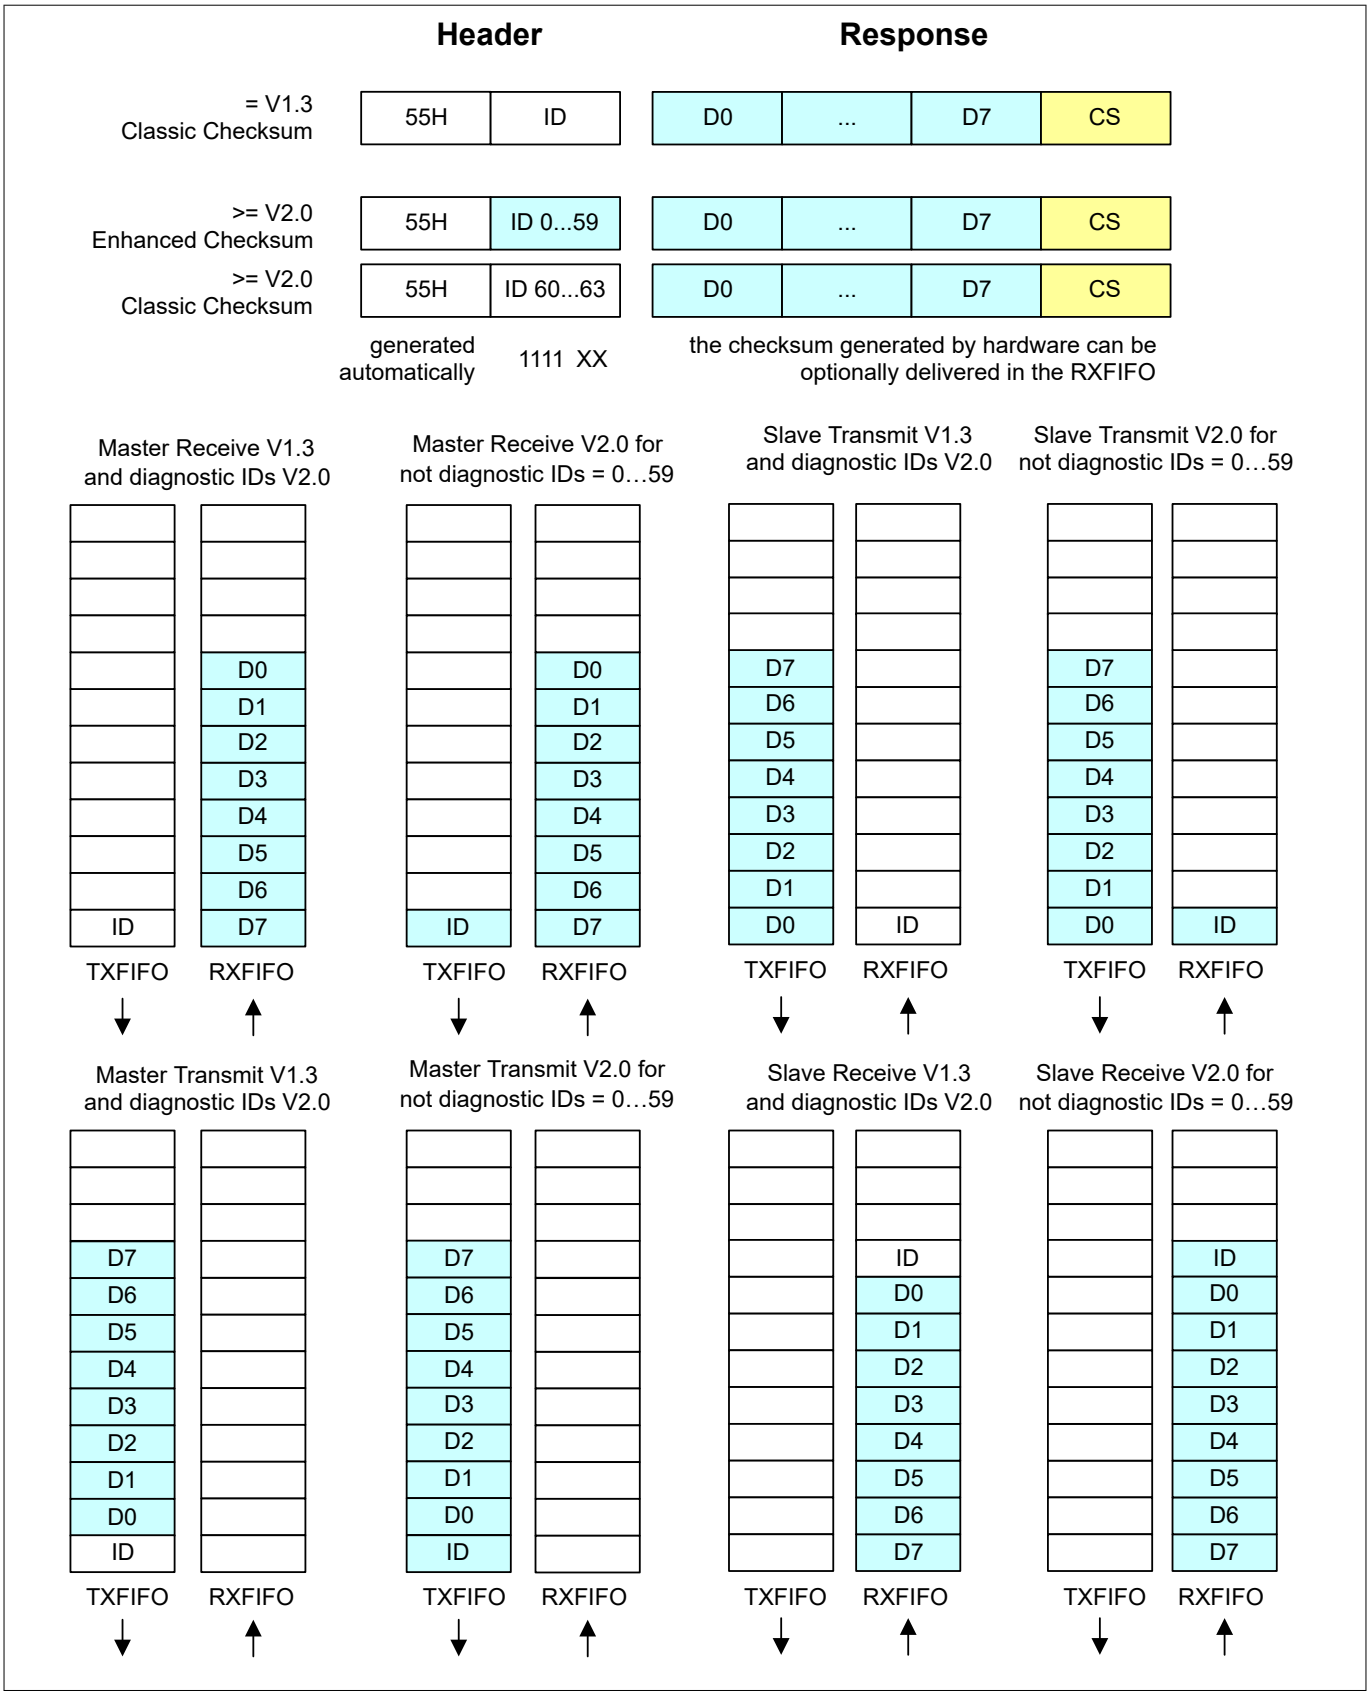

Figure 490 Coverage of the checksum in different use cases

24.3.7.4 LIN error recovery

This section describes the behavior of the module in case of errors detected during reception and during transmission of a LIN frame.

Reception related errors

The following errors are possible during the reception:

- ID Parity error (FLAGS.LP)
- Checksum error (FLAGS.LC)
- Timeout error (FLAGS.HT and FLAGS.RT)
- Framing error (FLAGS.FE)
- Baud Rate error (FLAGS.LA)

In case one of the above mentioned errors is encountered, the receive state machine goes into the state “waiting for break”, and the corresponding interrupt is triggered. In case of ID Parity or Baudrate error, data is not stored in RxFIFO. In all other cases, data received until the error condition happened is stored in RxFIFO.

Transmission related errors

During transmission it is possible to encounter collision error. If the collision detection mechanism is enabled via FLAGSSET.CES (in LIN2.1 mandatory to enable) FRAMECON.CEN, the frame will be aborted and the transmitter state machine goes to the idle state. The aborted frame is lost no longer stored in TxFIFO.

24.3.8 SPI support

The ASCLIN supports the SPI master communication in synchronous mode. The SPI setting of shift edge first, than the latch edge, see figure below. The module is set in synchronous mode by using the bit-field FRAMECON.MODE.

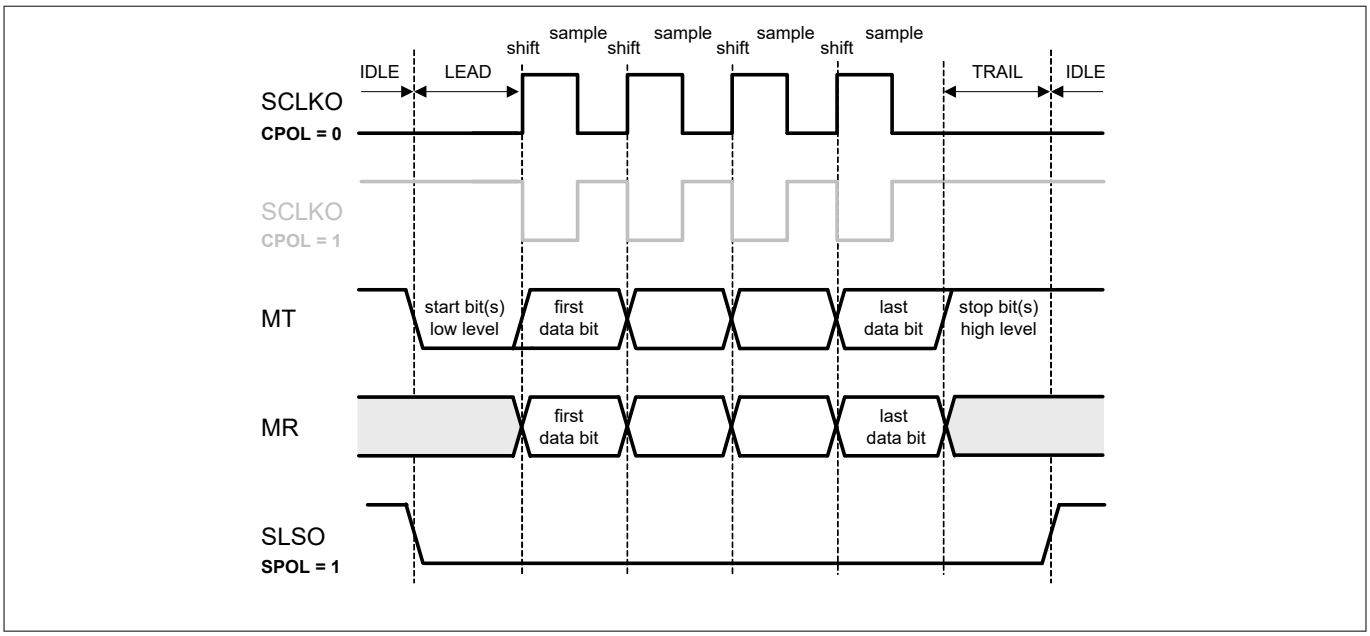

Figure 491 SPI timing

24.3.8.1 Baud rate and clock generation

The baud rate and clock generation in the synchronous mode uses generally the same counters and principles as in the asynchronous mode. It uses the same prescaler, fractional divider, and oversampling divider with configurable sample point. The only difference is that the shift clock is driven as output signal at the pin SCLKO.

If a symmetrical shift clock is required, the oversampling ratio should be an even number, and the sampling point should be set to one half of the oversampling ratio (see BITCON register).

The clock polarity is configured in the bit IOCR.CPOL.

24.3.8.2 Data frame configuration

The leading and trailing delays are configured in the bit-fields FRAMECON.LEAD and FRAMECON.STOP. The IDLE phase duration is configured using the bit-field FRAMECON.IDLE. The data length of 2 to 16-bit is defined in the bit-field DATCON.DATLEN.

24.3.8.3 Slave selects configuration

The SPI master activates automatically the slave select output signal for each data word. The polarity of the slave select can be configured by using IOCR.SPOL.

24.3.9 Collision detection

Collision detection monitors the consistency of transmitted and the echoed received bytes in LIN mode and half duplex SPI modes. Collision detection is enabled in FRAMECON.CEN bit-field.

24.3.10 Interrupts

The ASCLIN module generates three interrupts:

- TX_INT - Transmit Interrupt
  - Signals the TxFIFO level event (FLAGS.TFL)
- RX_INT - Receive Interrupt
  - Signals the RxFIFO level event (FLAGS.RFL)
- ERR_INT - Extended Error Interrupt
  - Signals every error (FLAGS.PE, FE, CE, RFO, RFU, TFO,TFE,OMT) and
  - Additional events (FLAGS.FED, RED)

The LIN events related to transmission and reception of header and response are mapped to the corresponding transmit, receive and extended error interrupts.

- TX_INT:
  - Transmission of the header in master mode completed (FLAGS.TH)
  - Transmission of a response completed (FLAGS.TR)
- RX_INT:
  - Reception of the header in a slave mode completed (FLAGS.RH)
  - Reception of the response completed (FLAGS.RR)
- ERR_INT:
  - LIN protocol (FLAGS. BD, TC) and
  - LIN error events (FLAGS.HT, RT, LP, LA, LC)

In order to determine which event is the source of a LIN interrupt, the FLAGS register must be polled.

Triggering a DMA

The interrupt signals are used also as DMA trigger signals. The interrupt signals are connected to the Interrupt Router Module, which routes the interrupts either to a CPU or to a DMA. There are no separate DMA trigger signals.

Service request and the events

There are several events mapped to each service request node.

Each service request (interrupt) node contains an SRC (Service Request Control) register containing a sticky flag bit and the associated set, clear and enable bits. The SRC registers are located in the IR (Interrupt Router) module.

One interrupt node may be triggered by more than one events. Each event which causes an interrupt also has a sticky flag bit and associated set, clear and enable bits. These bits are distributed in four registers: FLAGS, FLAGSSET, FLAGSCLEAR, and FLAGSENABLE located in the ASCLIN module. Each set of four bits associated to one event builds a virtual “event node”, see figure below.

The event flags are set by hardware and if enabled, trigger an interrupt. They are not cleared by hardware. They are cleared only by software in the corresponding interrupt service routine, which usually polls the flags to find the cause for the interrupts. The event flags can be also set by software for test purposes.

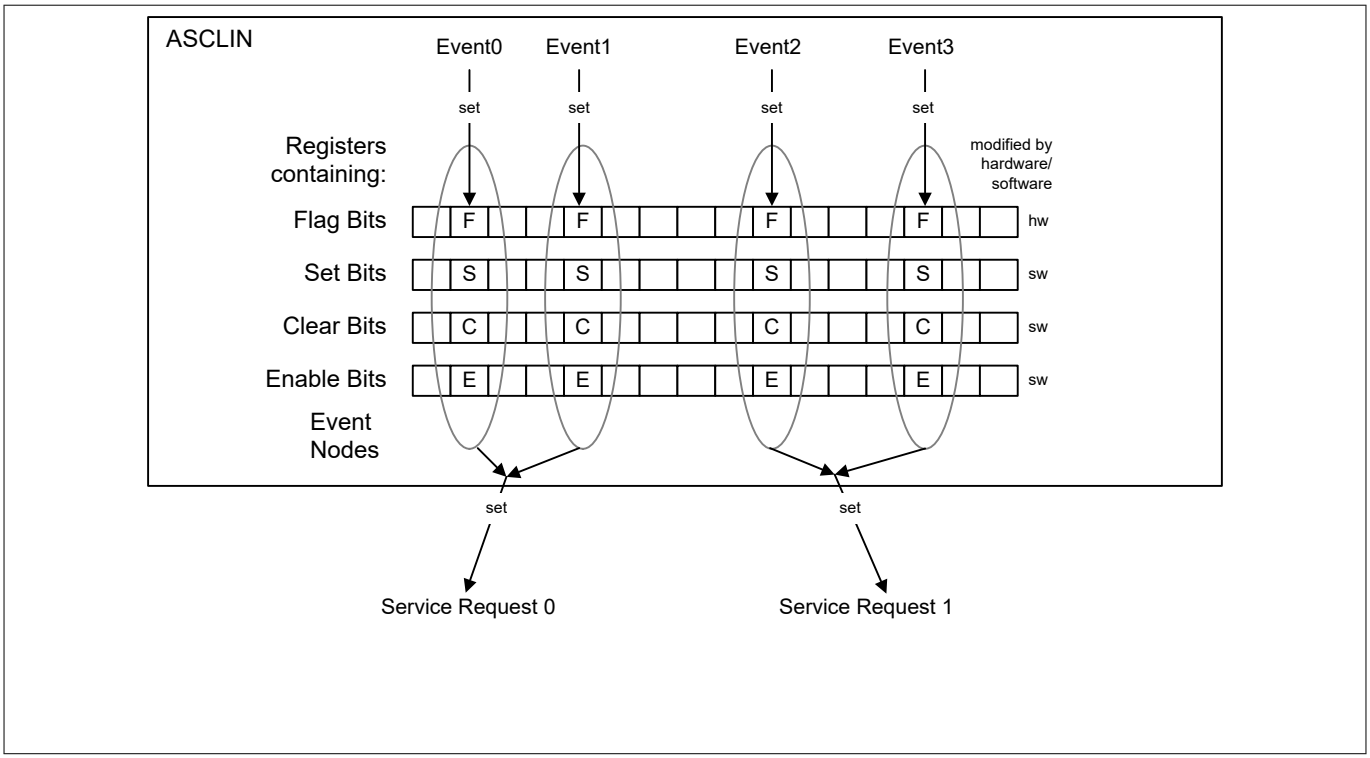

Figure 492 Relationship between event nodes and service request nodes

Some flags do not generate interrupts and do not have enable bits. They are used either for issuing requests, which are subsequently acknowledged by hardware, or only for polling by software, see figure below.

There are no pure polled only flags in the ASCLIN module, although by letting the enable bits disabled, all interrupt event flags can be used as polled only (for example idle and stuck monitoring by using FLAGS.FED, RED. Setting such bits by software in such a case is meaningless, except for test purposes).

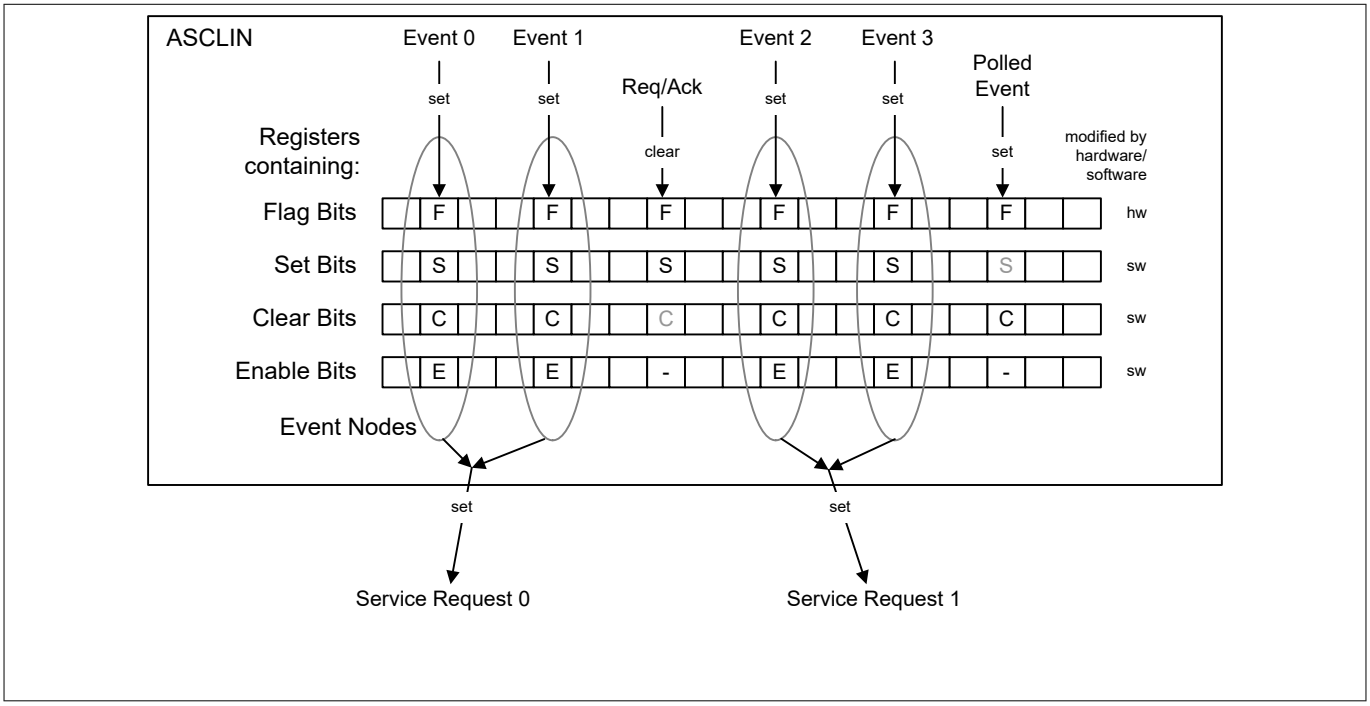

Figure 493 Acknowledge flags and polled flags

24.3.11 Digital glitch filter

The digital glitch filter removes short glitches from the input data signal by using an increment/decrement counter with programmable threshold. On the other hand, the filter introduces a delay into the signal path, depending on the digital filter sampling frequency f_{PD} and the threshold programmed in the bit-field IOCR.DEPTH. Hence the glitch filter should not be enabled in SPI mode.

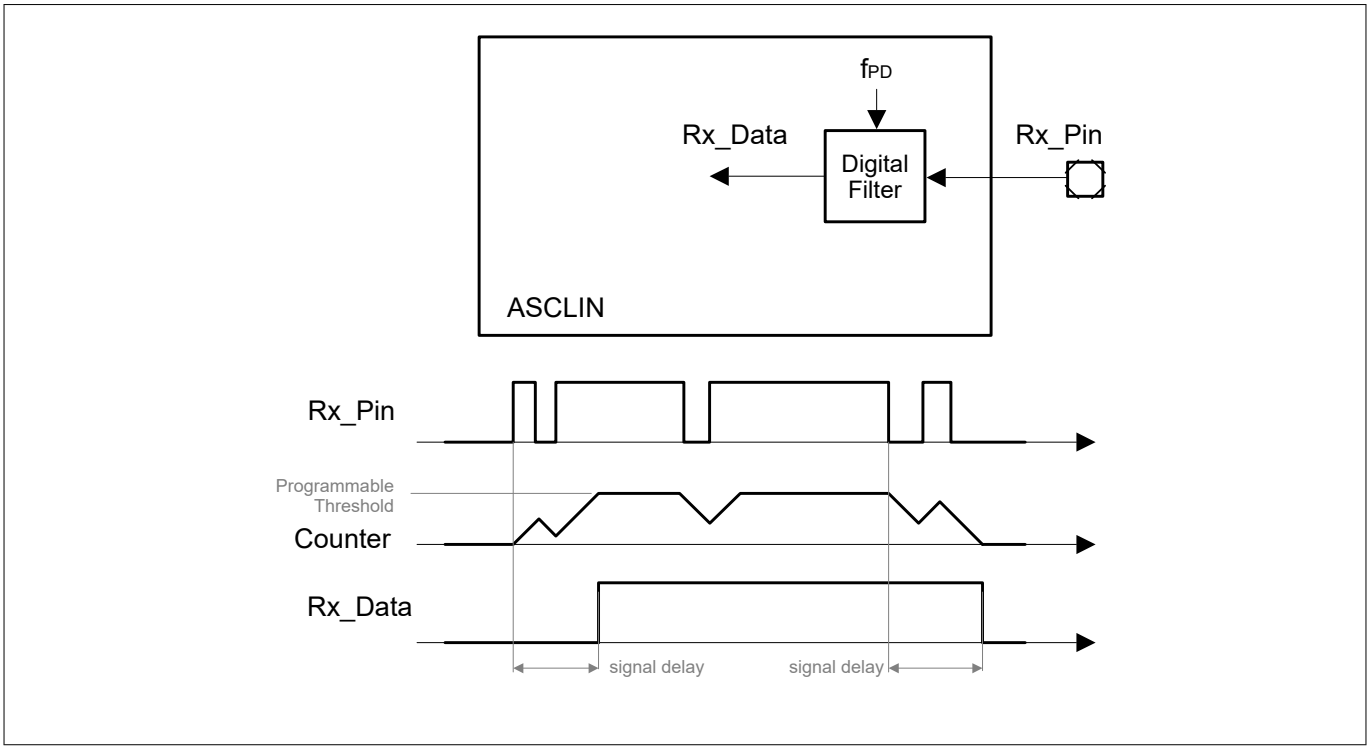

Figure 494 Digital filter

24.3.12 Sleep and power-off behavior

The ASCLIN module transmits either ASC frames (shorter frames less than 16 bits, but mostly 8 bits long) or LIN frames. Freezing the module in the middle of an asynchronous ASC frame generally results in an erroneous data at the receiver side, depending on the data content.

Freezing the module inside the LIN frame transmission, but between the transmission of single bytes, results in a timeout error at the receiver side.

If the ASCLIN module gets a request for switching off the clock, it immediately disables all request lines towards the DMA in order to stop further DMA transfers.

In order to power-down the module in a well defined way, the user software must take care that:

- The power-down request is issued when there is no ongoing single frame or LIN frame transfer
- Both FIFOs are empty

24.3.12.1 Sleep mode

Going into sleep mode implies that the ASCLIN module has finished all activities and that the TxFIFO and RxFIFO are empty. It is the responsibility of the user software to issue a sleep request in a safe time interval, where no race conditions or pipeline effects between the ASCLIN module and the DMA can occur.

The sleep mode is controlled using the CLC.EDIS register bit.

The ASCLIN module in Sleep Mode behaves the same way as in case of Disable Request.

24.3.12.2 Disable request (power-off)

Going into power off implies that the ASCLIN module has finished all activities and that the TX and RX FIFOs are empty. It is the responsibility of the user software to issue a power-off request in a safe time interval, where no race conditions or pipeline effects between the ASCLIN module and the DMA can occur. This is no issue if the power-off procedure is one-way that is no continuation of operation without re-initialization of the module is expected.

The Disable request is controller using the CLC.DISR register bit and the status can also be observed using the CLC.DISS register bit.

The ASCLIN module sets immediately all outputs to inactive, stops reacting to inputs, the internal state machines go to initial state, the registers remain unchanged, and then the module acknowledges the request. All clocks to the module are switched off.

24.4 Registers

24.4.1 Register overview - access mode glossary

Table 1115 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
BE	Always returns a Bus Error.

w								r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															KRST
r															rwh

Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
STATCLR	31	w	**Kernel Reset Status Clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits STAT.GRSTx and bit STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

24.4.8 Reset status register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: 014_H

Reset status register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				GRST3	GRST2	GRST1	GRST0	0							KRST
r				rh	rh	rh	rh	r							rh

Field	Bits	Type	Description
KRST	0	rh	**Kernel Reset Status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.
GRSTx (x=0-3)	x+8	rh	**Status for Global Module Reset Group x** 0_B Reset was not triggered by Global Reset Group x 1_B Reset was triggered by Global Reset Group x
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

24.4.9 PROT register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 020_H

PROT register endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

24.4.10 PROT register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 024_H

PROT register safe endinit Application Reset value: $0000\ 0000_H$

r								rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
RDq (q=00-07)	q	rw	**Read access enable for PRS q** This bit enables read access to the access protected region for transactions with the PRS q. 0_B Disabled for read access 1_B Enabled for read access
WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

24.4.17 Input and output control register

The Input and Output Control Register IOCRx determines several properties of the RX and TX signal path:
For the RX signal:

- The alternate input
- The filter depth

For the TX signal:

- The trigger source

Note: IOCR is only writable, if CSR.CLKSEL=0.

IOCR Offset address: 100_H

Input and output control register Reset values see: Table 1121

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TXM	RXM	CTSEN	LB	SPOL	CPOL	RCPOL	0							CTS	
rh	rh	rw	rw	rw	rw	rw	r							rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						DEPTH						0	ALTI		
r						rw						r	rw		

Field	Bits	Type	Description
ALTI	2:0	rw	**Alternate Input Select** Selects the alternate input for the RX signal: 000_B Alternate Input A selected 001_B Alternate Input B selected 010_B Alternate Input C selected 011_B Alternate Input D selected 100_B Alternate Input E selected 101_B Alternate Input F selected 110_B Alternate Input G selected 111_B Alternate Input H selected
DEPTH	9:4	rw	**Digital Glitch Filter Depth** DEPTH determines the number of port input samples clocked with microticks that are taken into account for the calculation of the floating average. The higher the DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 00_H off, default 01_H 1 … $3F_H$ 63
CTS	17:16	rw	**CTS Select** Selects the CTS input pin out of maximum four possible. 00_B ACTSA 01_B ACTSB 10_B ACTSC 11_B ACTSD
RCPOL	25	rw	**RTS CTS Polarity** RCPOL defines the active level or the RTS and CTS signals. Active means ready/clear to send. 0_B Active high 1_B Active low
CPOL	26	rw	**Clock Polarity in Synchronous Mode** CPOL defines the idle level of the clock signal if the module is set in the SPI mode. The idle level is the level outside the data transmission time intervals. Default is low level. 0_B Idle low 1_B Idle high
SPOL	27	rw	**Slave Polarity in Synchronous Mode** Defines the idle level of the SLSO signal, which is the level outside the data transmission, leading and trailing time intervals. 0_B Idle low 1_B Idle high

(table continues...)

(continued)

Field	Bits	Type	Description
LB	28	rw	**Loop Back Mode** Enables the in module connection of the transmit signal to receive signal. If Loop-back is enabled, the module can be run and tested without an external connection, in ASC and SPI modes. In LIN mode, loopback should not be used, because the module can be either master or slave. 0_B Disabled 1_B Enabled
CTSEN	29	rw	**Input Signal CTS Enable** Enables the sensitivity of the module to the external CTS signal. If disabled, the CTS signal is considered being permanently active. 0_B Disabled 1_B Enabled
RXM	30	rh	**Receive Monitor** Shows the status of the receive signal. 0_B Current signal is low. 1_B Current signal is high.
TXM	31	rh	**Transmit Monitor** Shows the status of the transmit signal. 0_B Current signal is low. 1_B Current signal is high.
0	3, 15:10, 24:18	r	**Reserved** Read as 0; should be written with 0.

Table 1121 Reset values of IOCR

Reset type	Reset value	Note
After Boot-FW Value	––00 0000 0000 0000 0000 0000 0000 0001_B	Values of RXM and TXM depend on RX and TX signal value. After ASC BSL execution.

24.4.18 TxFIFO configuration register

TXFIFOCON Offset address: 104_H

TxFIFO configuration register Reset values see: Table 1122

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0			CIRCLEVEL					0			FILL				
r			rw					r			rh				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				INTLEVEL				INW		FM		0		ENO	FLUSH
r				rw				rw		rw		r		rw	w

Field	Bits	Type	Description
FLUSH	0	w	**Flush the transmit FIFO** Write of 1 brings the TxFIFO in empty state. Write of 0 has no effect. 0_B No effect / This value will be always read back from the Bit. 1_B Empty the Tx FIFO
ENO	1	rw	**Transmit FIFO Outlet Enable** Enables the TxFIFO outlet. 0_B Disabled.In ASC and SPI, no data is transmitted.In LIN case, no data is moved to the shift register even if the protocol engine tries to fetch data. 1_B Enabled.In SPI and ASC, data transmission starts immediately when the data is available. Except in ASC mode when trigger is enabled, a frame is transmitted for each trigger. In LIN case, no data is moved to the shift register until it is fetched by the protocol engine.
FM	5:4	rw	**TxFIFO Mode** Selects between the TxFIFO Modes. 00_B Combined Move Mode 01_B Single Move Mode 10_B Batch Move Mode 11_B Circular Mode
INW	7:6	rw	**Transmit FIFO Inlet Width** Defines the number of bytes written to the TxFIFO with one SPB bus write. 00_B 0 01_B 1 10_B 2 11_B 4
INTLEVEL	11:8	rw	**FIFO Interrupt Level** Defines the filling level that triggers a re-fill interrupt or DMA access. An interrupt is generated when the filling level falls to INTLEVEL or below, each time when a data byte is taken out of the FIFO. This behavior corresponds to the Combined/Compatibility Mode of interrupt generation. See also Single Move Mode and Batch Move Mode for two additional modes. Not used with circular buffer mode. 0_H 0 … F_H 15

(table continues...)

(continued)

Field	Bits	Type	Description
FILL	20:16	rh	**FIFO Filling Level** Read only bit-field containing the current filling level of the FIFO in bytes. 00_H 0 … 10_H 16 11_H Reserved … $1F_H$ Reserved
CIRCLEVEL	28:24	rw	**FIFO Circulate Level** Defines the circulating level in data bytes. When this level is reached, the next Transmit Trigger transmits the first element of FIFO. An interrupt is generated each time one full circle of data is transmitted. This mode is used only with the hardware or software Transmit Trigger, if enabled. Note: User should make sure that CIRCLEVEL is equal with FIFO fill level. 00_H Not allowed Note: If this is selected, no trasmission is possible. 01_H 1 … 10_H 16 **others,** Reserved Note: In case this is selected the circular buffer is assumed for maximum FIFO storage (16).
0	3:2, 15:12, 23:21, 31:29	r	**Reserved** Read as 0; should be written with 0.

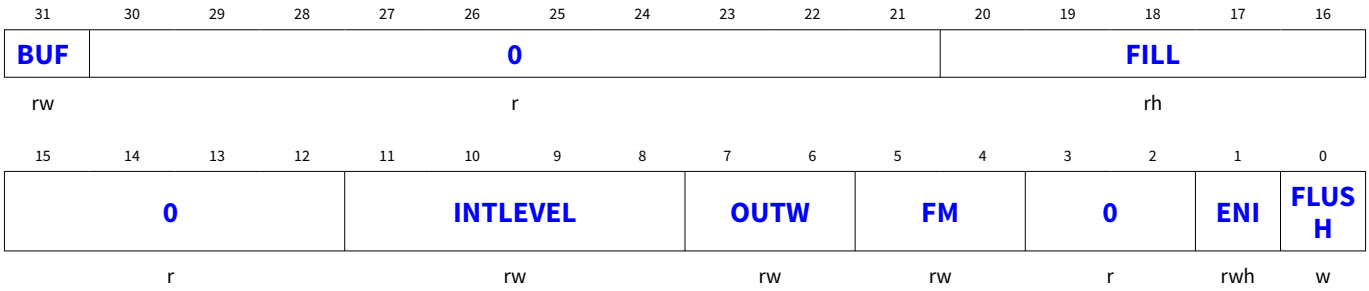
Table 1122 Reset values of TXFIFOCON

Reset type	Reset value	Note
Kernel Reset	$0000\ 0000_H$	
After Boot-FW Value	$0000\ 0142_H$	After ASC BSL execution

24.4.19 RxFIFO configuration register

RXFIFOCON Offset address: 108_H

RxFIFO configuration register Reset values see: Table 1123



Field	Bits	Type	Description
FLUSH	0	w	**Flush the receive FIFO** Write of 1 brings the RxFIFO in empty state. Write of 0 has no effect. 0_B No effect / This value will be always read back from the module. 1_B Empty the Rx FIFO
ENI	1	rwh	**Receive FIFO Inlet Enable** Enables the receiver and the filling of the RxFIFO through the shift register. In LIN slave mode, this bit is set by hardware after the correct reception of the sync byte. The software can clear this bit after reception of an foreign ID in order to suppress the reception of the following response. 0_B Disabled 1_B Enabled
FM	5:4	rw	**RxFIFO Mode** Selects between the RxFIFO Modes. 00_B Combined Move Mode 01_B Single Move Mode 10_B Batch Move Mode 11_B reserved
OUTW	7:6	rw	**Receive FIFO Outlet Width** Defines the number of bytes read to the RxFIFO with one SPB bus read. Note: If RXFIFO is configured as receive buffer mode (RXFIFOCON.BUF=1), then OUTW setting is ignored while reading data. 00_B 0 01_B 1 10_B 2 11_B 4
INTLEVEL	11:8	rw	**FIFO Interrupt Level** Defines the filling level that triggers a drain interrupt or DMA access. An interrupt is generated when the filling level rises to INTLEVEL or beyond, each time when a data byte is delivered to the FIFO. This behavior corresponds to the Combined/Compatibility Mode of interrupt generation. See also Single Move Mode and Batch Move Mode for two additional modes. 0_H 1 … F_H 16

(table continues...)

(continued)

Field	Bits	Type	Description
FILL	20:16	rh	**FIFO Filling Level** Read only bit-field containing the current filling level of the FIFO in bytes. 00_H 0 … 10_H 16 11_H Reserved … $1F_H$ Reserved
BUF	31	rw	**Receive Buffer Mode** If this bit is zero, then the RXFIFO behaves normally as described in this document. If this bit is set, the RXFIFO behaves as simple 32-bit one stage RX buffer, which is overwritten with each new received data. The received bits appear in the RXDATA register on the lowest bit locations. The upper locations are padded with zeros. 0_B RXFIFO 1_B Single Stage RX Buffer
0	3:2, 15:12, 30:21	r	**Reserved** Read as 0; should be written with 0.

0				PRESCALER											
r				rw											

Field	Bits	Type	Description
PRESCALER	11:0	rw	**Prescaling of the Fractional Divider** Prescaler bit-field with values in the range of 0 to 4095, defining division ratios from 1 to 4096. Used also as a microtick generator for the input digital filter.
OVERSAMPLING	19:16	rw	**Oversampling Factor** Defines the bit length in ticks in the range of 1 to 16. The lengths of 1 to 3 are not allowed. The position of the sampling points is shown in Bit Timing Properties chapter. 0_H 1 (not allowed) 1_H 2 (not allowed) 2_H 3 (not allowed) 3_H 4 … F_H 16
SAMPLEPOINT	27:24	rw	**Sample Point Position** Programmable in the range of 0 to 15, see the Bit Timing Properties chapter for more details. For example, if three sample points at position 7, 8, 9 are required, this bit field would contain 9. In SPI mode, this bit field + 1 defines the length of the first SCLK half period in ticks. Values equal or higher then the OVERSAMPLING value are forbidden. 0_H 0 (not allowed) 1_H 1 … F_H 15
SM	31	rw	**Sample Mode** Number of samples per bit. 0_B 1 1_B 3
0	15:12, 23:20, 30:28	r	**Reserved** Read as 0; should be written with 0.

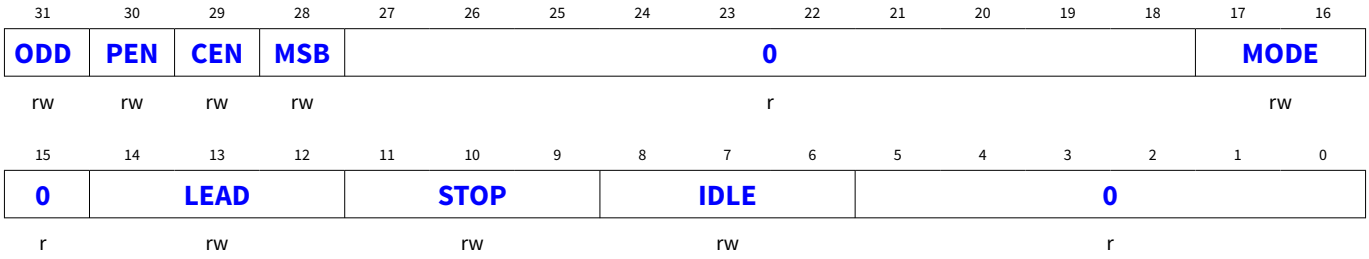
24.4.21 Frame control register

The parameters regarding the properties of the message frame of the ASC communication are controlled by the Frame Control Register FRAMECON.

Note: The register is only writable, if CSR.CLKSEL=0.

FRAMECON Offset address: 110_H

Frame control register Reset values see: Table 1125



Field	Bits	Type	Description
IDLE	8:6	rw	**Duration of the IDLE delay** Defines the duration of the IDLE delay in bit times. If more characters are available in the TxFIFO, this is the pause inserted between the characters. In the SPI mode, this is the idle time between the frames. In the ASC and LIN mode, this is the pause inserted between transmission of bytes. Idle also applies to the pause between the header and the response (response space). ***Note**: The collision detection runs in parallel to the idle delay and in LIN master mode it may extend the time between two bytes for one bit length. This effect may occur if the round trip delay including the digital filter delay is longer than the idle delay. For LIN slave task use IDLE=0.* 000_B 0 … 111_B 7
STOP	11:9	rw	**Number of Stop Bits** Defines the number of stop bits in ASC and LIN mode, or the trailing delay in SPI mode. In ASC mode, standard values are 1 and 2. In LIN mode, standard value is 1. In SPI mode there is no standard value. Nevertheless, all settings are possible in all modes. 000_B 0 (not allowed in ASC and LIN modes) 001_B 1 … 111_B 7

(table continues...)

(continued)

Field	Bits	Type	Description
LEAD	14:12	rw	**Duration of the Leading Delay** Defines the leading delay in bit times in SPI mode. Has no meaning in the ASC mode. In LIN mode, this is a delay inserted between the end of the break and the start of the sync character. 000_B 0 (not allowed in LIN mode and 4-Wire SPI mode) 001_B 1 … 111_B 7
MODE	17:16	rw	**Mode Selection** This bit field defines the basic operating mode of the module. In INIT mode, all outputs are at inactive level, and the module does not respond to the input signals. Changing the mode of the module must be done by switching first to INIT mode, and then to the other mode. The SCLK signal generated by the module is active only in the SPI mode. The CTS output generated by the module is active only in the ASC mode. 00_B INIT mode 01_B ASC mode 10_B SPI mode 11_B LIN mode
MSB	28	rw	**Shift Direction** Defines the shift direction of the shift register. Relevant for the SPI and ASC mode. In LIN mode, should be set to zero. Parity bit is shifted out last independently of the shift direction. 0_B LSB first 1_B MSB first
CEN	29	rw	**Collision Detection Enable** Enables the collision detection mechanism. 0_B Disabled 1_B Enabled
PEN	30	rw	**Parity Enable** Enables the parity bit attached to the data bits. Parity bit can be used for ASC and SPI protocols. The standard LIN bytes do not use this parity bit. 0_B Disabled 1_B Enabled
ODD	31	rw	**Parity Type** Defines the type of parity bit attached to the data bits. This setting is valid for all modes of operation (ASC, LIN, SPI). 0_B Even 1_B Odd

(table continues...)

(continued)

Field	Bits	Type	Description
0	5:0, 15, 27:18	r	**Reserved** Read as 0; should be written with 0.

24.4.22 Data configuration register

DATCON register defines the number of bits in the ASC (affecting the LIN protocol, if used) and SPI frames, data length or the number of data bytes in a LIN response (if any) and the checksum mode. It additionally defines the time window for the LIN response.

In case the whole LIN response does not fit in this time window, an error interrupt is generated. The measurement starts at the end of the last bit of the header, and ends at the end of the last bit of the response.

DATCON Offset address: 114$_H$

Data configuration register Kernel Reset value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								RESPONSE							
r								rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CSM	RM	HO	0			TRGSRC		0				DATLEN			
rw	rw	rw	r			rw		r				rw			

Field	Bits	Type	Description
DATLEN	3:0	rw	**Data Length** Defines the number of bits in a character. In the ASC mode, standard length is 7, 8, or 9 bits. In the SPI mode, there is no standard length. In ASC and SPI modes, any length from 2 to 16 bits is possible, although not standard for some protocols. In LIN mode, standard length is 8 bits per character. Therefore, this field defines the number of data bytes of the response. Allowed configuration is 0 to 7 to be compliant with LIN specification. 0_H 1 … F_H 16

(table continues...)

(continued)

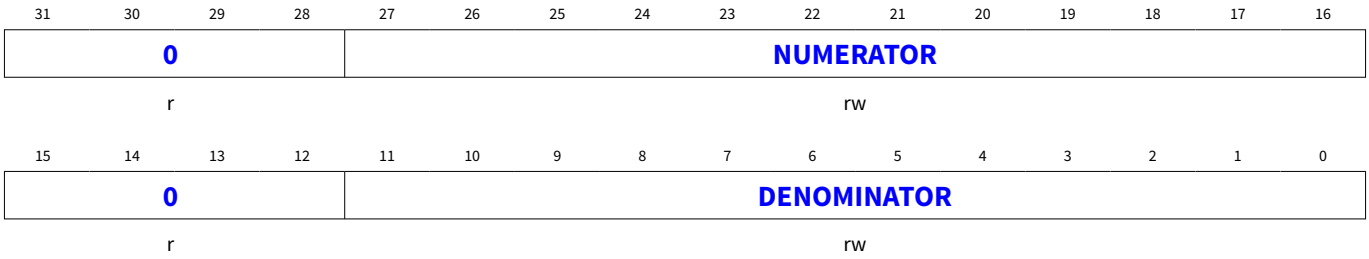
Field	Bits	Type	Description
TRGSRC	9:8	rw	**Trigger Source** This bit selects the trigger source for the triggered transmit in ASC mode. 00_B Trigger disabled. 01_B GTM trigger 10_B eGTM trigger 11_B Software trigger
HO	13	rw	**Header Only** Defines if the LIN frame shall consist of a header and response or of a header only. 0_B Header and response expected 1_B Header only expected, response ignored
RM	14	rw	**Response Mode** Defines if the RESPONSE bit field defines a LIN Frame or LIN Response timeout threshold. 0_B Frame 1_B Response
CSM	15	rw	**Checksum Mode** Defines if the classic or the enhanced checksum will be calculated by the checksum block. 0_B Classic 1_B Enhanced
RESPONSE	23:16	rw	**Response Timeout Threshold Value** Defines the timer limit in the range of 1 to 256 bit times. 00_H 1 … FF_H 256
0	7:4, 12:10, 31:24	r	**Reserved** Read as 0; should be written with 0.

24.4.23 Baud rate generation register

Configures the numerator and the denominator of the fractional divider in the baud rate generation block.
Note: The register is only writable, if CSR.CLKSEL=0.

BRG Offset address: 118_H

Baud rate generation register Reset values see: Table 1126



Field	Bits	Type	Description
DENOMINATOR	11:0	rw	**Denominator** Programmed by software, in a range of 0 to 4095. The setting of 0 is not allowed If the module is used as ASC, SPI, LIN master and LIN slave without autobaud detection, this value determines the baud rate. In slave mode with autobaud detection, it contains the nominal value. For the value measured by the autobaud detection hardware, see the BRD register.
NUMERATOR	27:16	rw	**Numerator** Defines the numerator of the fractional divider in a range of 0 to 4095. Programmed by software. The setting of 0 is not allowed.
0	15:12, 31:28	r	**Reserved** Read as 0; should be written with 0.

Table 1126 Reset values of BRG

Reset type	Reset value	Note
Kernel Reset	0000 0000$_H$	
After Boot-FW Value	0048 0–––$_H$	After ASC BSL execution

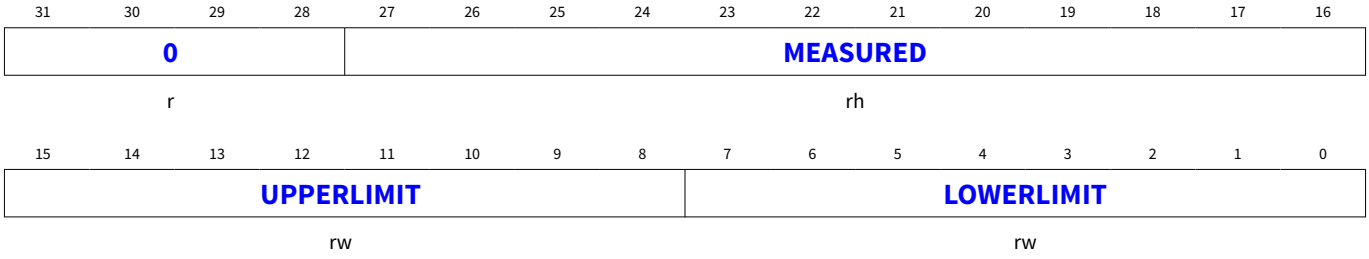
24.4.24 Baud rate detection register

The BRD defines the properties specific for the automatic baud rate detection when the module operates as a LIN slave.

Note: The register is only writable, if CSR.CLKSEL=0.

BRD Offset address: 11C$_H$

Baud rate detection register Kernel Reset value: 0000 0000$_H$



Field	Bits	Type	Description
LOWERLIMIT	7:0	rw	**Lower Limit** This field defines the 8 most significant bits of the 12 bit compare value. The lower four bits are 1000_B
UPPERLIMIT	15:8	rw	**Upper Limit** This field defines the 8 most significant bits of the 12 bit compare value. The lower four bits are 1000_B.
MEASURED	27:16	rh	**Measured Value of 8-bits from Sync Field** This bit field contains the measured value of the duration of 8-bits form the sync field of the LIN header in microticks. It is automatically loaded in the denominator of the fractional divider, in case of LIN slave operation with autobaud detection.
0	31:28	r	**Reserved** Read as 0; should be written with 0.

24.4.25 LIN control register

LINCON contains bits that control LIN specific features of the module.

Note: The register is only writable, if CSR.CLKSEL=0.

LINCON Offset address: 120_H

LIN control register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
CSI	23	rw	**Checksum Injection** Defines if the received checksum byte is written into the RXFIFO or not. 0_B Not written 1_B Written
CSEN	25	rw	**Hardware Checksum Enable** Enables the hardware checksum generation and checking. 0_B Disabled 1_B Enabled
MS	26	rw	**Master Slave Mode** Configures if the module in LIN mode operates as master or as slave. 0_B Slave 1_B Master

(table continues...)

(continued)

Field	Bits	Type	Description
ABD	27	rw	**Autobaud Detection** Enables the autobaud detection feature in LIN slave mode. In all other operating modes of the module (LIN master, ASC, SPI) not effective. If the autobaud detection is disabled (the oscillator precision of the slave is sufficient), the sync field (byte field and stop bit) is checked if correct. If not correct, a framing error is triggered. 0_B Disabled 1_B Enabled
0	22:0, 24, 31:28	r	**Reserved** Read as 0; should be written with 0.

24.4.26 LIN break timer register

This register defines

- break detection limit if the module operates as LIN slave or
- length of the generated break pulse if the module operates as LIN master.

The break timer, if enabled, monitors the bus continuously.

Note: The register is only writable, if CSR.CLKSEL=0.

LINBTIMER Offset address: 124_H

LIN break timer register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
BREAK	5:0	rw	**Break Pulse Generation and Detection** In LIN slave mode, this bit field defines the duration of the detection threshold for the break pulse. In LIN master mode, this bit field defines the duration of the transmitted break pulse. The time unit is bit time.
0	31:6	r	**Reserved** Read as 0; should be written with 0.

24.4.27 LIN header timer register

LINHTIMER register defines the time windows for the header of a LIN frame.

In master mode, the timer starts counting at the falling edge of the break pulse, and stops counting when the last bit of the header (including the stop bits) has been transmitted. If the predefined time in the HEADER bit field is violated, an error interrupt is generated (if enabled).

In slave mode, the timer starts counting when the break pulse has been detected, after a low time of 10 or 11 bit times, and stops counting when the last bit of the header has been received. If the predefined time in the HEADER bit field is violated, an error interrupt is generated (if enabled).

Note: The register is only writable, if CSR.CLKSEL=0.

LINHTIMER Offset address: 128_H

LIN header timer register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
TH	0	rh	**Transmit Header End Flag** Signals the HEADER_TX_END event. Set by hardware, clear by software. If enabled, a transmit interrupt is triggered. 0_B No HEADER_TX_END event since the last clear by software 1_B New HEADER_TX_END event since the last clear by software
TR	1	rh	**Transmit Response End Flag** Signals that RESPONSE_TX_END event. Set by hardware, clear by software. If enabled, a transmit interrupt is triggered. 0_B No RESPONSE_TX_END event since the last clear by software 1_B New RESPONSE_TX_END event since the last clear by software
RH	2	rh	**Receive Header End Flag** Signals that HEADER_RX_END event. Set by hardware, clear by software. If enabled, a receive interrupt is triggered. 0_B No HEADER_RX_END event since the last clear by software 1_B New HEADER_RX_END event since the last clear by software
RR	3	rh	**Receive Response End Flag** Signals that RESPONSE_RX_END event. Set by hardware, clear by software. If enabled, a receive interrupt is triggered. 0_B No RESPONSE_RX_END event since the last clear by software 1_B New RX_RESPONSE_END event since the last clear by software
FED	5	rh	**Falling Edge from Level 1 to Level 0 Detected** This bit is set by hardware when a falling edge is detected on the RX line. 0_B No falling edge detected 1_B Falling edge detected
RED	6	rh	**Rising Edge from Level 0 to Level 1 Detected** This bit is set by hardware when a rising edge is detected on the RX line. 0_B No rising edge detected 1_B Rising edge detected
TFE	10	rh	**Transmit FIFO Empty Flag** Signals an error whenever TxFIFO is empty or not enough data for one frame is available and a transmit request was triggered by either hardware or software. If enabled, an error interrupt is triggered. 0_B No empty error occurred 1_B TxFIFO empty error occurred

(table continues...)

(continued)

Field	Bits	Type	Description
OMT	11	rh	**Overload of Multiple Triggers** Signals that if during ongoing transmission there is one or more hardware or software trigger requests. If enabled, an error interrupt is triggered. 0_B No overload of multiple triggers 1_B Multiple trigger requested during ongoing transmission
SWTRG	12	rh	**Software Trigger Transmit Request Flag** Signals that a software trigger frame transmit has been requested. As soon as the frame transmission starts, the bit is cleared by the hardware. No interrupt is triggered. 0_B No Frame Transmit Request pending 1_B Frame Transmit Request pending.
TWRQ	13	rh	**Transmit Wake Request Flag** Signals that transmission of wake has been requested. No interrupt triggered. As soon as the wake pulse transmission starts, the bit is cleared by the hardware. 0_B No Transmit Wake Request pending 1_B Transmit Wake Request pending.
THRQ	14	rh	**Transmit Header Request Flag** Signals that transmission of header has been requested. No interrupt triggered. As soon as the header transmission starts, the bit is cleared by the hardware. 0_B No Transmit Header Request pending 1_B Transmit Header Request pending.
TRRQ	15	rh	**Transmit Response Request Flag** Signals that transmission of response has been requested. No interrupt triggered. As soon as the response transmission starts, the bit is cleared by the hardware. 0_B No Transmit Response Request pending 1_B Transmit Response Request pending.
PE	16	rh	**Parity Error Flag** Signals parity error. If enabled, an error interrupt is triggered. Parity error occurs if the internally calculated parity bit is not equal to the received parity bit. Note: This bit is only used with ASC and SPI mode. 0_B Last message received error free 1_B Last message received with parity error

(table continues...)

(continued)

Field	Bits	Type	Description
TC	17	rh	**Transmission Completed Flag** Signals an end of an ASC or SPI frame. This bit is set after the last stop bit transmission in ASC mode, or after the trailing delay in case of SPI mode. In LIN mode, if the node is transmitting a header this flag is set after each transmission break (incl lead) field, Sync field or PID field. If the node is transmitting a response, this flag is set after each byte is transmitted. If enabled, an ERR_INT interrupt is triggered. Should be cleared by software. 0_B No end of frame event occurred 1_B End of frame event occurred
FE	18	rh	**Framing Error Flag** Signals framing error. If enabled, an error interrupt is triggered. Framing error occurs if “0” is received at a stop bit position. If autobaud detection is deactivated, then the sync field is checked for framing error. 0_B Last message received error free 1_B Last message received with error
HT	19	rh	**Header Timeout Flag** Signals violation of the header duration limit. If enabled, an error interrupt is triggered. 0_B No HEADER_OVERFLOW event since the last clear by software 1_B New HEADER_OVERFLOW event since the last clear by software
RT	20	rh	**Response Timeout Flag** Signals violation of the response or frame duration limit as defined in DATCON.RM bit. If enabled, an error interrupt is triggered. 0_B No timeout event since the last clear by software 1_B New timeout event since the last clear by software
BD	21	rh	**Break Detected Flag** Signals a detection of a break pulse. If enabled, an error interrupt is triggered. Slave mode only. 0_B No Break/Wake/Stuck event since the last clear by software 1_B New Break/Wake/Stuck event since the last clear by software
LP	22	rh	**LIN Parity Error Flag** Signals parity error in the LIN identifier. If enabled, an error interrupt is triggered. Applies to LIN mode only. LIN parity error occurs if the internally calculated parity bits are not equal to the received parity bits. 0_B Last ID received error free 1_B Last ID received with parity error

(table continues...)

(continued)

Field	Bits	Type	Description
LA	23	rh	**LIN Autobaud Detection Error Flag** Signals baudrate outside the range defined by BRD.LOWERLIMIT and BRD.UPPERLIMIT. 0_B No autobaud detection error 1_B Autobaud detection error
LC	24	rh	**LIN Checksum Error Flag** Signals checksum error when receiving response, if the internally calculated checksum is different than the received checksum. If enabled, an error interrupt is triggered. 0_B Last checksum error free 1_B Last checksum shows an error
CE	25	rh	**Collision Detection Error Flag** When transmitting, signals if the transmitted data differs from the received data. If enabled, an error interrupt is triggered in case of a mismatch. Collision detection is mandatory only when supporting LIN version 2.1. 0_B No mismatch 1_B Mismatch detected
RFO	26	rh	**Receive FIFO Overflow Flag** Signals an overflow error. If enabled, an error interrupt is triggered. 0_B No overflow error occurred 1_B Overflow error occurred
RFU	27	rh	**Receive FIFO Underflow Flag** Signals an underflow error. If enabled, an error interrupt is triggered. See also RxFIFO. 0_B No underflow error occurred 1_B Underflow error occurred
RFL	28	rh	**Receive FIFO Level Flag** This flag signals whenever a RXFIFO fill interrupt is generated based on RXFIFOCON.FM mode. 0_B No receive interrupt occurred 1_B Receive interrupt occurred
TFO	30	rh	**Transmit FIFO Overflow Flag** Signals an overflow error. If enabled, an error interrupt is triggered. 0_B No overflow error occurred 1_B Overflow error occurred
TFL	31	rh	**Transmit FIFO Level Flag** This flag signals whenever a TxFIFO refill interrupt (if enabled) is generated based on TXFIFOCON.FM mode. 0_B No transmit interrupt occurred 1_B Transmit interrupt occurred

(table continues...)

(continued)

Field	Bits	Type	Description
0	4, 9:7, 29	r	**Reserved** Read as 0; should be written with 0.

24.4.29 Flags set register

The FLAGSSET register contains the write only bits used to set the corresponding bits in the FLAGS register by software. Setting a flag bit triggers an interrupt, if the corresponding interrupt enable bit is set. A read access to the register always results in 0.

FLAGSSET Offset address: 130_H

Flags set register Kernel Reset value: $0000\ 0000_H$

24.4.32 Clock selection register

This register is used to select the clock source for the baud rate generation, detection, timeouts and the SPI delays.

The reconfiguration of the clock source has to be done using two writes: first a write of zero to the CLKSEL bit-field, and then a second write defining the new clock source. Between the first and the second write a delay of minimum T_W [3] 4*(1/fA)+2*(1/fCLC) must be inserted by software, where f_A is the frequency being switched off with the first write.

Additionally, always activate the asynchronous clock for at least two f_A cycles:

- after entering the INIT state and after device reset
- after device reset

This is an example of a correct sequence:

1. CSR.CLKSEL = No_Clock (equals the reset state)
2. Wait T_W or poll for CSR.CON = 0
3. FRAMECON.MODE = INIT
4. CSR.CLKSEL = Clock_On
5. Wait T_W or poll for CSR.CON = 1
6. CSR.CLKSEL = No_Clock
7. Wait T_W or poll for CSR.CON = 0
8. FRAMECON.MODE = ASC (or SPI or LIN)
9. CSR.CLKSEL = Clock_On
10. Wait T_W or poll for CSR.CON = 1

CSR Offset address: $13C_H$

Clock selection register Reset values see: Table 1127

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA															
rh															

Field	Bits	Type	Description
DATA	31:0	rh	**Data** Reading from this bit field takes content from the RXFIFO, depending on the read width - 8, 16 or 32 bit (see RXFIFOCON.OUTW), but does not influence the read pointer of the RXFIFO. A write access to this register has no effect.

24.5 Debug information

OCDS Suspend

OCDS soft suspend request suspends the module activity at the end of the current transaction. In ASC and SPI cases, this is the end of the current frame. In LIN case, this is the end of the current LIN frame (regular end of response, header timeout, or response timeout).

OCDS hard suspend request, for debugging purposes, immediately freezes the ASCLIN module in the current register state. The SPB clock feeding the kernel clock f_{CLC} is immediately switched off and the asynchronous clock f_A remains switched on. Reading and writing of registers is possible but will enable the kernel clock f_{CLC} for a few cycles.

Attention**:* ***Register accesses with clocking in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so an ASCLIN kernel reset might not be sufficient to bring the system into a defined state.

***Note**:* *In SPI half duplex or LIN mode, when a transmission is triggered, and if soft suspend is requested before the transmission has started (first bit sent out), the CE flag might be set (if collision detection is enabled by setting bit-field FRAMECON.CEN). This flag should be ignored in this particular use-case.*

Keyword	Description
APU-P	Protection group consisting of registers ASCLIN0_ACCEN_WRA , ASCLIN0_ACCEN_WRB , ASCLIN0_ACCEN_RDA , ASCLIN0_ACCEN_RDB , ASCLIN0_ACCEN_VM , ASCLIN0_ACCEN_PRS or ASCLIN1_ACCEN_WRA , ASCLIN1_ACCEN_WRB , ASCLIN1_ACCEN_RDA , ASCLIN1_ACCEN_RDB , ASCLIN1_ACCEN_VM , ASCLIN1_ACCEN_PRS or ASCLIN2_ACCEN_WRA , ASCLIN2_ACCEN_WRB , ASCLIN2_ACCEN_RDA , ASCLIN2_ACCEN_RDB , ASCLIN2_ACCEN_VM , ASCLIN2_ACCEN_PRS or ASCLIN3_ACCEN_WRA , ASCLIN3_ACCEN_WRB , ASCLIN3_ACCEN_RDA , ASCLIN3_ACCEN_RDB , ASCLIN3_ACCEN_VM , ASCLIN3_ACCEN_PRS or ASCLIN4_ACCEN_WRA , ASCLIN4_ACCEN_WRB , ASCLIN4_ACCEN_RDA , ASCLIN4_ACCEN_RDB , ASCLIN4_ACCEN_VM , ASCLIN4_ACCEN_PRS or ASCLIN5_ACCEN_WRA , ASCLIN5_ACCEN_WRB , ASCLIN5_ACCEN_RDA , ASCLIN5_ACCEN_RDB , ASCLIN5_ACCEN_VM , ASCLIN5_ACCEN_PRS or ASCLIN6_ACCEN_WRA , ASCLIN6_ACCEN_WRB , ASCLIN6_ACCEN_RDA , ASCLIN6_ACCEN_RDB , ASCLIN6_ACCEN_VM , ASCLIN6_ACCEN_PRS or ASCLIN7_ACCEN_WRA , ASCLIN7_ACCEN_WRB , ASCLIN7_ACCEN_RDA , ASCLIN7_ACCEN_RDB , ASCLIN7_ACCEN_VM , ASCLIN7_ACCEN_PRS or ASCLIN8_ACCEN_WRA , ASCLIN8_ACCEN_WRB , ASCLIN8_ACCEN_RDA , ASCLIN8_ACCEN_RDB , ASCLIN8_ACCEN_VM , ASCLIN8_ACCEN_PRS or ASCLIN9_ACCEN_WRA , ASCLIN9_ACCEN_WRB , ASCLIN9_ACCEN_RDA , ASCLIN9_ACCEN_RDB , ASCLIN9_ACCEN_VM , ASCLIN9_ACCEN_PRS or ASCLIN10_ACCEN_WRA , ASCLIN10_ACCEN_WRB , ASCLIN10_ACCEN_RDA , ASCLIN10_ACCEN_RDB , ASCLIN10_ACCEN_VM , ASCLIN10_ACCEN_PRS or ASCLIN11_ACCEN_WRA , ASCLIN11_ACCEN_WRB , ASCLIN11_ACCEN_RDA , ASCLIN11_ACCEN_RDB , ASCLIN11_ACCEN_VM , ASCLIN11_ACCEN_PRS or ASCLIN12_ACCEN_WRA , ASCLIN12_ACCEN_WRB , ASCLIN12_ACCEN_RDA , ASCLIN12_ACCEN_RDB , ASCLIN12_ACCEN_VM , ASCLIN12_ACCEN_PRS or ASCLIN13_ACCEN_WRA , ASCLIN13_ACCEN_WRB , ASCLIN13_ACCEN_RDA , ASCLIN13_ACCEN_RDB , ASCLIN13_ACCEN_VM , ASCLIN13_ACCEN_PRS or ASCLIN14_ACCEN_WRA , ASCLIN14_ACCEN_WRB , ASCLIN14_ACCEN_RDA , ASCLIN14_ACCEN_RDB , ASCLIN14_ACCEN_VM , ASCLIN14_ACCEN_PRS or ASCLIN15_ACCEN_WRA , ASCLIN15_ACCEN_WRB , ASCLIN15_ACCEN_RDA , ASCLIN15_ACCEN_RDB , ASCLIN15_ACCEN_VM , ASCLIN15_ACCEN_PRS or ASCLIN16_ACCEN_WRA , ASCLIN16_ACCEN_WRB , ASCLIN16_ACCEN_RDA , ASCLIN16_ACCEN_RDB , ASCLIN16_ACCEN_VM , ASCLIN16_ACCEN_PRS or ASCLIN17_ACCEN_WRA , ASCLIN17_ACCEN_WRB , ASCLIN17_ACCEN_RDA , ASCLIN17_ACCEN_RDB , ASCLIN17_ACCEN_VM , ASCLIN17_ACCEN_PRS or ASCLIN18_ACCEN_WRA , ASCLIN18_ACCEN_WRB , ASCLIN18_ACCEN_RDA , ASCLIN18_ACCEN_RDB , ASCLIN18_ACCEN_VM , ASCLIN18_ACCEN_PRS or ASCLIN19_ACCEN_WRA , ASCLIN19_ACCEN_WRB , ASCLIN19_ACCEN_RDA , ASCLIN19_ACCEN_RDB , ASCLIN19_ACCEN_VM , ASCLIN19_ACCEN_PRS or ASCLIN20_ACCEN_WRA , ASCLIN20_ACCEN_WRB , ASCLIN20_ACCEN_RDA , ASCLIN20_ACCEN_RDB , ASCLIN20_ACCEN_VM , ASCLIN20_ACCEN_PRS

(table continues...)

Table 1131 (continued) Register overview - access mode glossary

Keyword	Description
	or ASCLIN21_ACCEN_WRA , ASCLIN21_ACCEN_WRB , ASCLIN21_ACCEN_RDA , ASCLIN21_ACCEN_RDB , ASCLIN21_ACCEN_VM , ASCLIN21_ACCEN_PRS or ASCLIN22_ACCEN_WRA , ASCLIN22_ACCEN_WRB , ASCLIN22_ACCEN_RDA , ASCLIN22_ACCEN_RDB , ASCLIN22_ACCEN_VM , ASCLIN22_ACCEN_PRS or ASCLIN23_ACCEN_WRA , ASCLIN23_ACCEN_WRB , ASCLIN23_ACCEN_RDA , ASCLIN23_ACCEN_RDB , ASCLIN23_ACCEN_VM , ASCLIN23_ACCEN_PRS or ASCLIN24_ACCEN_WRA , ASCLIN24_ACCEN_WRB , ASCLIN24_ACCEN_RDA , ASCLIN24_ACCEN_RDB , ASCLIN24_ACCEN_VM , ASCLIN24_ACCEN_PRS or ASCLIN25_ACCEN_WRA , ASCLIN25_ACCEN_WRB , ASCLIN25_ACCEN_RDA , ASCLIN25_ACCEN_RDB , ASCLIN25_ACCEN_VM , ASCLIN25_ACCEN_PRS or ASCLIN26_ACCEN_WRA , ASCLIN26_ACCEN_WRB , ASCLIN26_ACCEN_RDA , ASCLIN26_ACCEN_RDB , ASCLIN26_ACCEN_VM , ASCLIN26_ACCEN_PRS or ASCLIN27_ACCEN_WRA , ASCLIN27_ACCEN_WRB , ASCLIN27_ACCEN_RDA , ASCLIN27_ACCEN_RDB , ASCLIN27_ACCEN_VM , ASCLIN27_ACCEN_PRS .
P	Access protection using *APU-P* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

24.8.4.3 Register overview - ASCLIN0 (ascending offset address)

Table 1132 Register overview - ASCLIN0 (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
ASCLIN0_CLC	Clock control register	000_H	P	P, SV, E	4670	4670
ASCLIN0_OCS	OCDS control and status register	004_H	P	SV, P	Debug Reset	4671
ASCLIN0_ID	Module identification register	008_H	P	BE	PowerOn Reset	4672
ASCLIN0_RST_CTRLA	Reset control register A	$00C_H$	P	P, SV, E	Application Reset	4673
ASCLIN0_RST_CTRLB	Reset control register B	010_H	P	P, SV, E	Application Reset	4673
ASCLIN0_RST_STAT	Reset status register	014_H	P	BE	Application Reset	4674
ASCLIN0_PROTE	PROT register endinit	020_H	U	SV, PROT	Application Reset	4675
ASCLIN0_PROTSE	PROT register safe endinit	024_H	U	SV, PROT	Application Reset	4676
ASCLIN0_ACCEN_WRA	Write access enable register A	040_H	U	SE, SV	Application Reset	4678

(table continues...)

Table 1132 (continued) Register overview - ASCLIN0 (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
ASCLIN0_ACCEN_WRB	Write access enable register B	044_H	U	SE, SV	Application Reset	4678
ASCLIN0_ACCEN_RDA	Read access enable register A	048_H	U	SE, SV	Application Reset	4679
ASCLIN0_ACCEN_RDB	Read access enable register B	$04C_H$	U	SE, SV	Application Reset	4679
ASCLIN0_ACCEN_VM	VM access enable register	050_H	U	SE, SV	Application Reset	4680
ASCLIN0_ACCEN_PRS	PRS access enable register	054_H	U	SE, SV	Application Reset	4680
ASCLIN0_IOCR	Input and output control register	100_H	P	P	4681	4681
ASCLIN0_TXFIFOCON	TxFIFO configuration register	104_H	P	P	4683	4683
ASCLIN0_RXFIFOCON	RxFIFO configuration register	108_H	P	P	4685	4685
ASCLIN0_BITCON	Bit configuration register	$10C_H$	P	P	4687	4687
ASCLIN0_FRAMECON	Frame control register	110_H	P	P	4689	4689
ASCLIN0_DATCON	Data configuration register	114_H	P	P	Kernel Reset	4691
ASCLIN0_BRG	Baud rate generation register	118_H	P	P	4692	4692
ASCLIN0_BRD	Baud rate detection register	$11C_H$	P	P	Kernel Reset	4693
ASCLIN0_LINCON	LIN control register	120_H	P	P	Kernel Reset	4694
ASCLIN0_LINBTIMER	LIN break timer register	124_H	P	P	Kernel Reset	4695
ASCLIN0_LINHTIMER	LIN header timer register	128_H	P	P	Kernel Reset	4696
ASCLIN0_FLAGS	Flags register	$12C_H$	P	BE	Kernel Reset	4696
ASCLIN0_FLAGSSET	Flags set register	130_H	P	P	Kernel Reset	4701
ASCLIN0_FLAGSCLEAR	Flags clear register	134_H	P	P	Kernel Reset	4704
ASCLIN0_FLAGSENABLE	Flags enable register	138_H	P	P	Kernel Reset	4708
ASCLIN0_CSR	Clock selection register	$13C_H$	P	P	4712	4712
ASCLIN0_TXDATA	Transmit data register	140_H	P	P	Kernel Reset	4713
ASCLIN0_TXDATA # (#=0-7)	Transmit data register mirror #	140_H+#*4	P	P	Kernel Reset	4713

24.8.6 TC4Dx ASCLIN revision history

Initial release of the chapter.

25 Single Edge Nibble Transmission (SENT)

The SENT interface provides a serial communication link typically used to connect sensors or other peripheral devices.

25.1 Feature list

- Conformance with SENT specification J2716 201604
- Flexible functional configuration for software
  - Baud rate generation: Data rates of up to 65.8 kbit/s at 3 µs tick length and 6 data nibbles on each channel
  - Support of standard tick times (3 µs through 90 µs)
  - Message tick time programmable between 0.2 µs and 1024 µs
  - Configurable frame length (default is 24-bit) and maximum data size of 32 bits
  - Digital Glitch filter suppressing noise
  - Optional output inversion for use of external open drain transistor
  - Optional input inversion for use of external open transistor for level shifting
- Receive SENT frames from external devices and handle all protocol relevant topics
  - 15 SENT channels per instance implemented, all working independently in parallel
  - Programmable nibble sorting to relieve CPU
  - Transparent mode (nibble CRCs are written to the receive control register for software processing)
  - Status nibble optionally included in the checksum
  - Optional serial data processing
  - Option to enable or disable the check of the next calibration pulse before validation of received data
  - Support frequency drift analysis based on frame length for frames with pause pulse
  - Indication of system status: STOP, INITIALIZED, RUNNING, SYNCHRONIZED
  - Time stamp generation
  - Watchdog on incoming frames
  - Support of trailing pause nibble of any length (even longer than 70 ticks)
- Support of SPC (Short PWM Code)
- Flexible interrupt structure generation available
  - The receiver module will monitor the message for the following error conditions:
    - Calibration pulse length deviates more than +/-25% from the nominal 56 ticks
    - Too many or too few nibbles between calibration pulses
    - Checksum error
    - Successive calibration pulse differ by more than 1.5625%
    - Any nibble data values measured as < 0 or > 15
  - Sticky interrupt flags, error interrupt optional
  - Interrupt on status nibble violation
  - Buffer overrun detection

25.2 Functional overview

The ERAY module communicates with the external world through one IO line for each channel. The SENT Input lines are the receive data input signals. They can overlay ADC inputs. If the optional SPC mode is used, they can be used on a port configured with an open drain transistor. In this way the optional SPC data can be transmitted and the line is used bi-directionally. For an external transceiver, the receive and transmit path can be routed to two different ports.

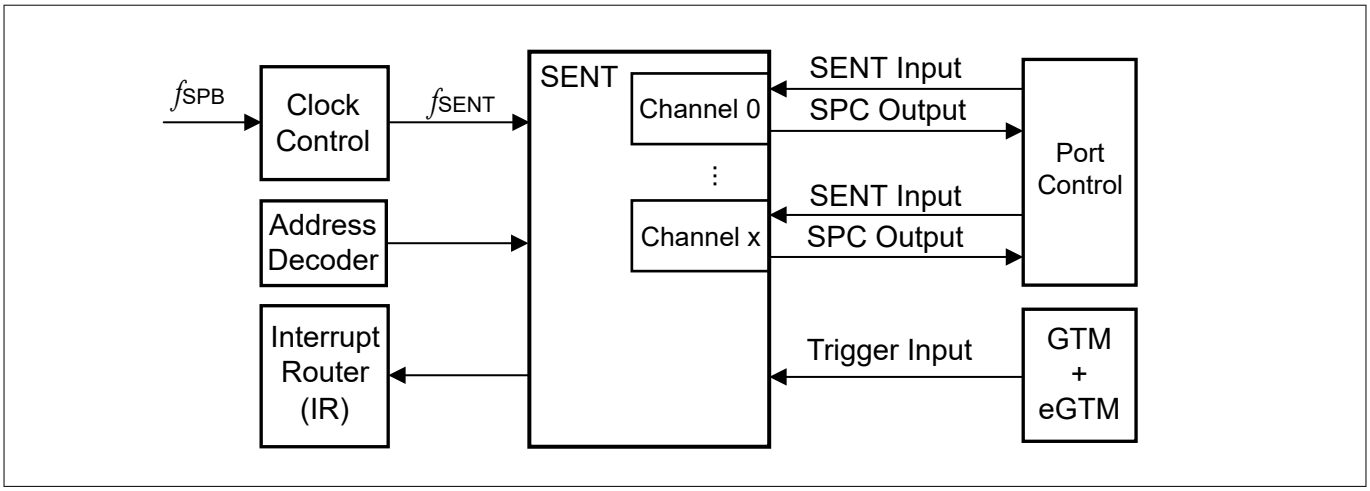

Figure 495 SENT block diagram

The ERAY interface provides a serial communication link typically used to connect sensors or other peripheral devices.

Clock control, address decoding, and service request control are managed by the ERAY module kernel.

The ERAY IP-module performs communication according to the v2.1. While staying compliant to this standard, it is able to cover as well the Short PWM Code (SPC) protocol extensions. This enhances the standardized ERAY protocol defined by v2.1. SPC enables the use of enhanced protocol functionality like “synchronous”, “range selection” and “ID selection” protocol mode.

Receive data on a ERAY channel can be set up according to the underlying application. In particular the number of nibbles forming one value is configurable.

The message storage consists of two 32-bit registers for each channel, representing a flexible double buffer system.

In SPC mode, maintaining the sample and transmission schedule as well as providing message status information is supported.

The register set of the ERAY module can be accessed directly by the CPU for configuration, GTM and eGTM for SPC pulse configuration (Trigger Input), data read out and status query.

25.3 Functional description

This section describes:

- General operation
- Standard SENT operation
- SPC operation
- Baud rate generation
- Error detection capabilities
- Support for frequency drift analysis in frames with pause pulse
- Digital glitch filter
- Interrupts
- Interface connections of the module
- Port control

25.3.1 General operation

The Single Edge Nibble Transmission encoding scheme (SENT) is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10-bit A/D converters and PWM and as a simpler low cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

The following figure shows a typical application in which a SENT interface reads a sensor device.

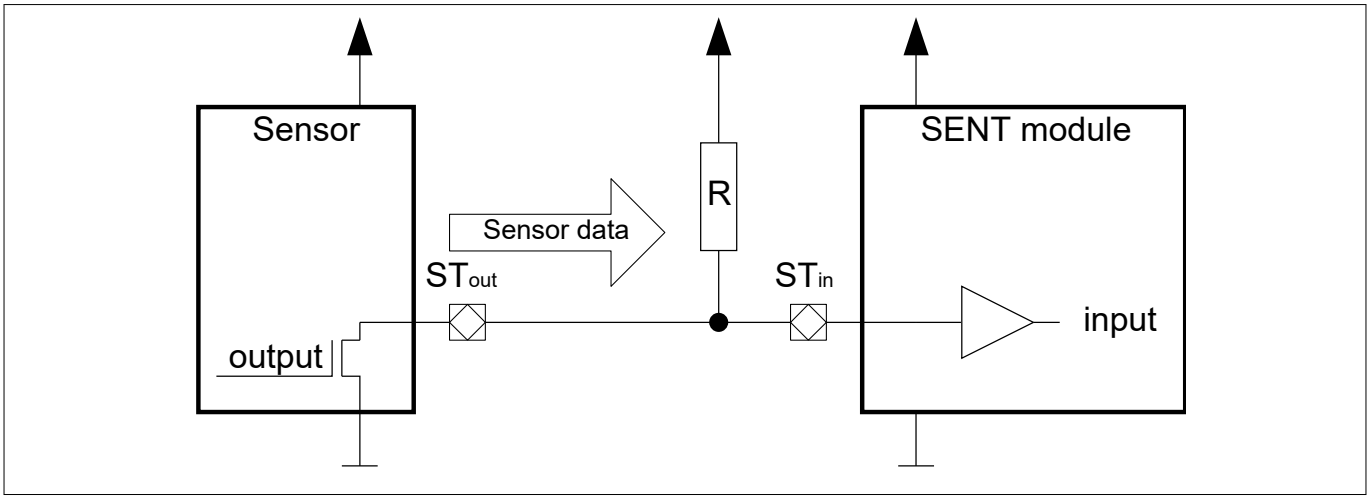

Figure 496 SENT to external device connection

SENT communication is unidirectional from sensor to controller without any synchronization. The sensor signal is transmitted as a series of PWM blocks measured as falling to falling edge times.

The Short PWM Code (SPC) extension overcomes the drawback of uni-directionality while keeping conformance to the standard.

The following figure shows a typical application in which a SPC enabled SENT ECU reads a SPC enabled SENT sensor device.

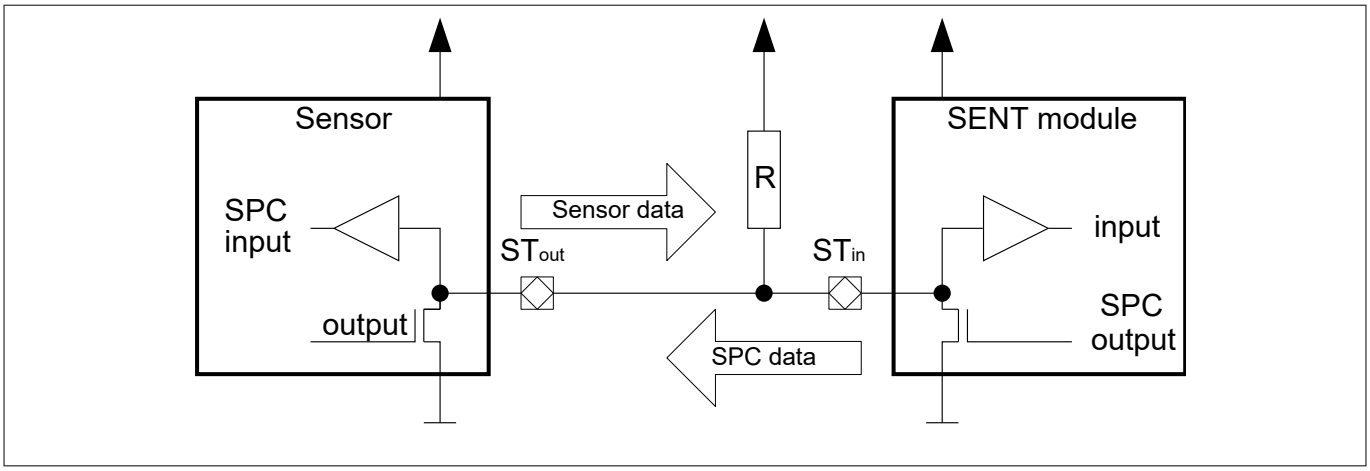

Figure 497 SENT SPC to external device connection

Some applications are:

- Read-out of the external throttle position sensor (for example: SENT enabled linear hall sensor)
- Receiving pedal position
- Synchronize sampling and read-out of up to four sensors on one single line (SPC)
- Selection of 1 out of 4 sensors connected to a single SENT channel
- Serial connections to other peripheral devices

25.3.2 Standard SENT operation

Standard SENT mode supports communication fully compliant to SENT specification J2716 201604, in which only the external device is sending and the ECU is receiving. In this unidirectional communication, both transmitter and receiver use the same data frame format and have the same baud rate. These settings are defined at system integration time and do not change for a given application. Data is received on pin ST. The following figure shows the block diagram of the SENT module when operating in standard SENT mode.

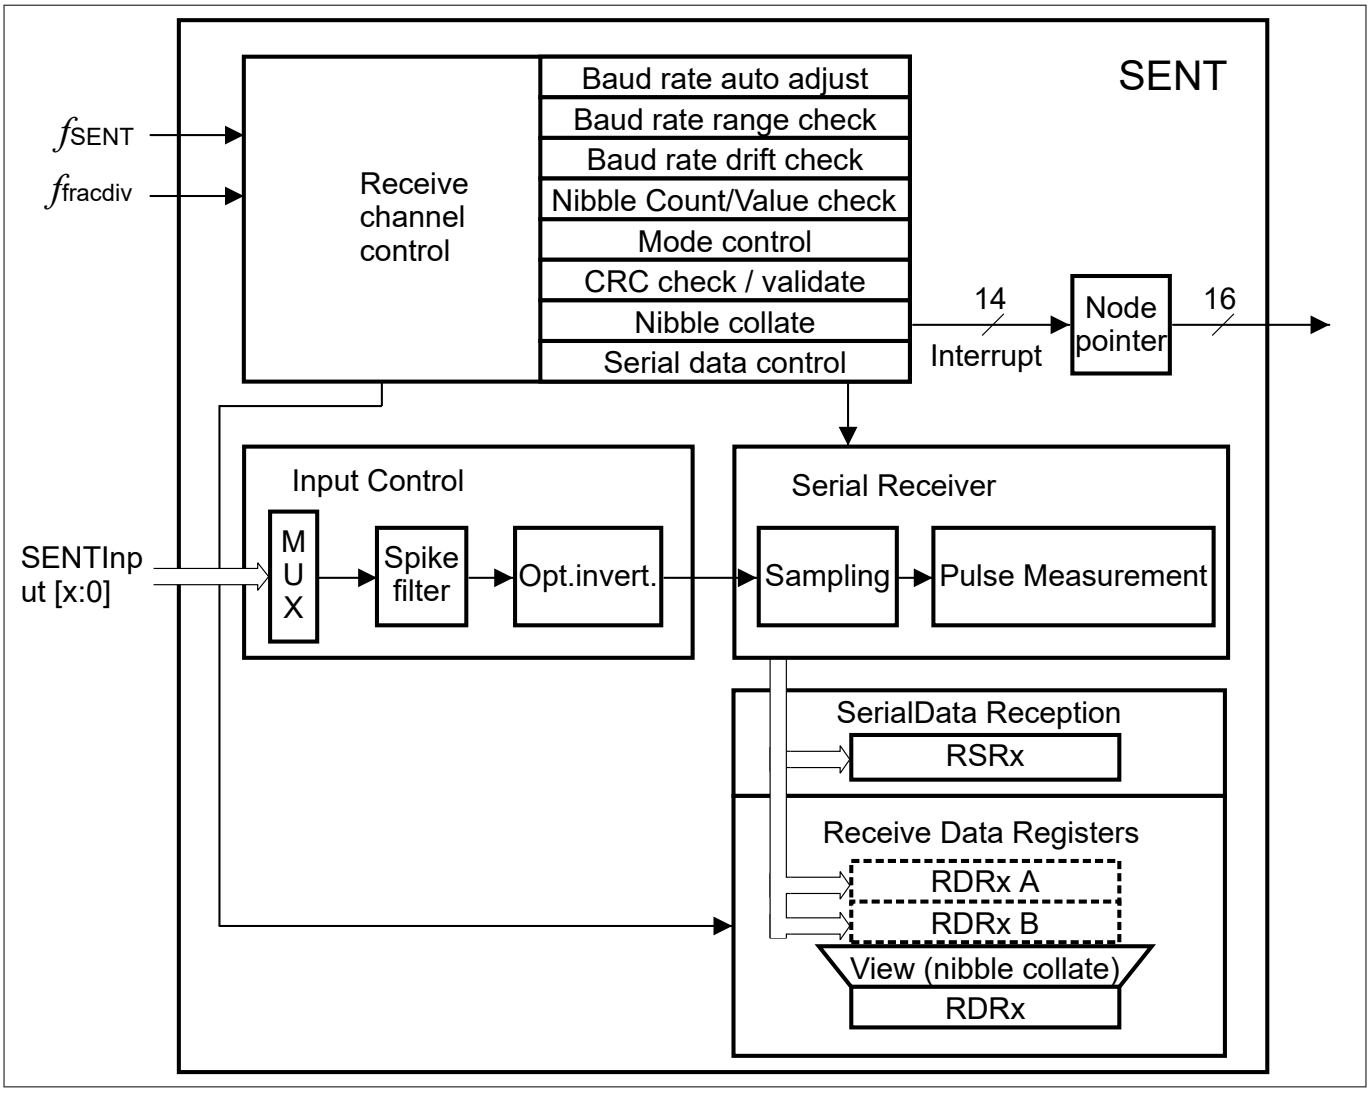

Figure 498 Standard SENT mode operation

25.3.2.1 Frame formats and definitions

This section describes the frame formats and definitions of the SENT protocol.

Basic definitions

The following figure shows the layout and definitions of a standard SENT frame. Note that the SENT standard does not specify whether the most significant nibble or the least significant nibble is sent out first.

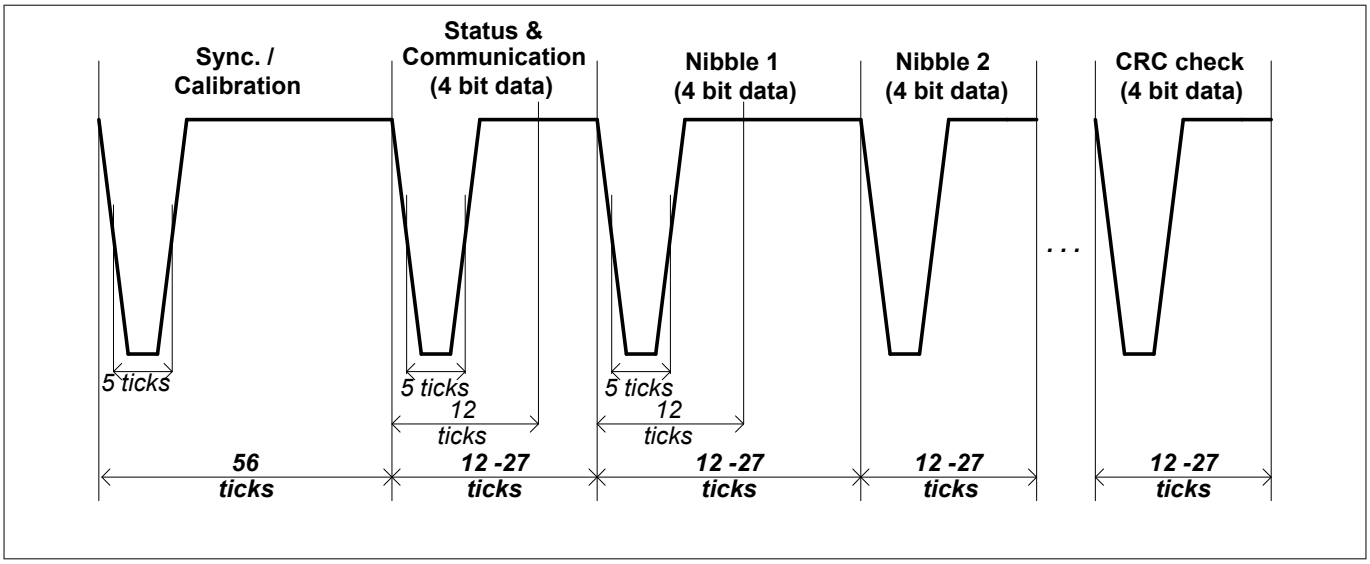

Figure 499 Standard encoding frame

Serial data encoding in status and communication nibble

The Status and Communication nibble is used by sensors that transmit extra serial data such as part numbers or diagnostic information. Data bits from this nibble are constructed across multiple SENT messages to form a Short Serial Message or an Enhanced Serial Message. These messages are alternately referred to as “Slow Channel” data in the SENT specification J2716 201604.

Table 1161 Short serial data encoding

Bit number	Bit function
0	Reserved for specific application
1	Reserved for specific application
2	Serial Data message bits
3	Message start = 1, otherwise = 0

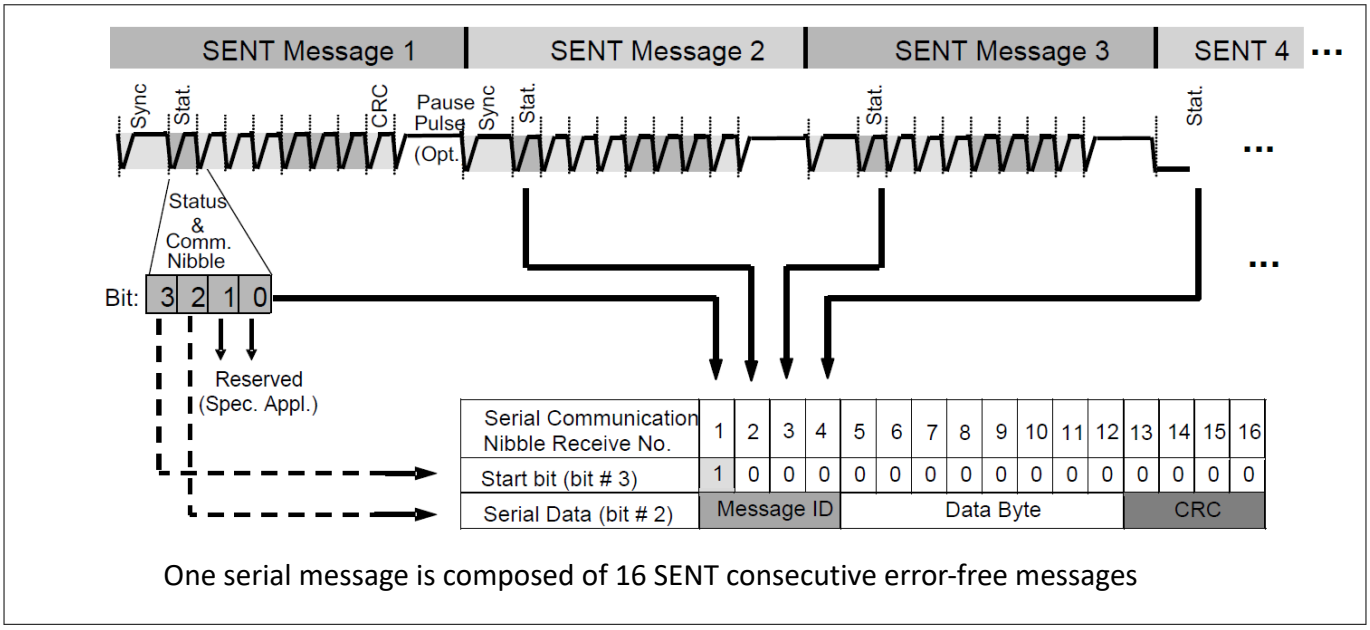

Figure 500 Short serial message, serial data encoding over 16 messages

Short serial message format

The SENT kernel supports the Short Serial Message Format defined in the SENT specification J2716 201604. The Short Serial Message Format provides 16 bits of data, constructed across 16 SENT messages. Each of the 16 messages contains one bit of Short Serial Message data in Status and Communication nibble bit 2.

Serial data is communicated in a 16-bit sequence as shown in the table below. The start of a Short Serial Message is indicated by a 1 in bit 3 of the Status and Communication nibble. That SENT message and the next 15 must be successfully received (no errors) for the Short Serial Message data to be received. The CRC generation is identical to the CRC generation on the data nibbles. Short Serial Message data is provided in the SDSx register.

Table 1162 Short serial message format

Serial communication nibble receive no.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Startbit (bit # 3)	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Serial data (bit # 2)	Message ID				Data Byte								CRC			

CRC calculation

SENT signal data and Short Serial Message data is secured with a 4-bit CRC. The standard CRC calculation method is defined in the SENT specification J2716 201604.

RCR.CRZ defines, if a zero nibble is added for calculation or not.

The alternative checksum nibble is a 4-bit CRC of the data nibbles (including the status nibble if RCR.SNI is set, as used in sensor TLE4998). The CRC is calculated using a polynomial $x^4 + x^3 + x^2 + 1$ with a seed value of 0101.

In order to facilitate CRC implementations and to avoid ambiguities, an example implementation of the alternative 4-bit CRC is given below. This is used for example in the sensor TLE4998 for the signal data. See the following figure for details.

```
//Fast way for any µC with low memory and compute capabilities
// contains input data (status nibble, 6 data nibble, CRC)
char Data[8] = {…};
// required variables and LUT
char CheckSum, i;
char CrcLookup[16] = {0, 13, 7, 10, 14, 3, 9, 4, 1, 12, 6, 11, 15, 2, 8, 5};
CheckSum= 5; // initialize checksum with seed “0101”
for (i=0; i<7; i++) {
 CheckSum = CheckSum ^ Data[i];
CheckSum = CrcLookup[CheckSum];
};
// finally check if Data[7] is equal to CheckSum
```

For the “Enhanced Serial Message Frame Format”, an own 6-bit CRC calculation method is defined by the standard.

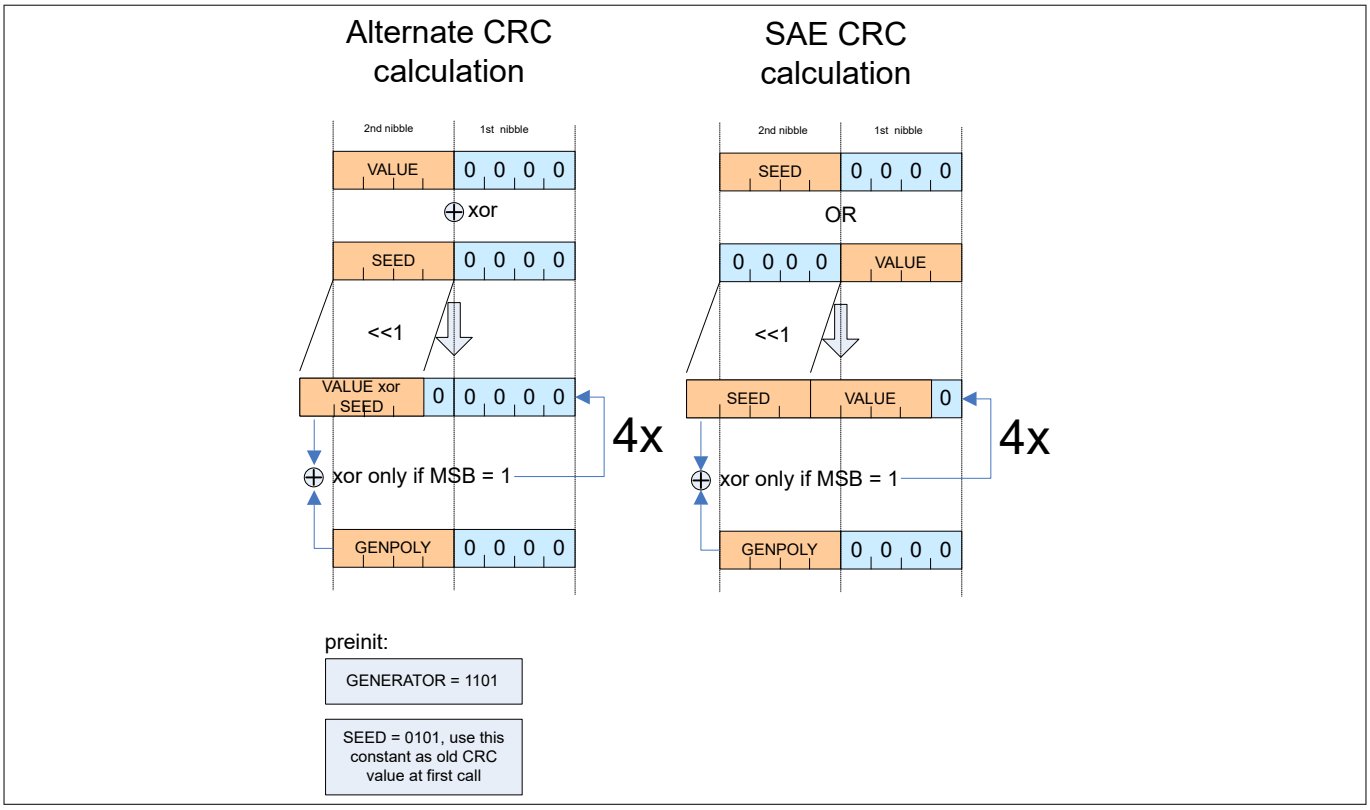

Figure 501 Alternate versus SAE CRC calculation

Enhanced serial message format

The SENT kernel supports the Enhanced Serial Message Format defined in the SENT specification J2716 201604. The Enhanced Serial Message Format provides 21 bits of message data and a 6-bit CRC, constructed across 18 SENT messages. The serial data is transmitted bit wise per frame in bits [3:2] of the Status and Communication nibbles of 18 consecutive messages from the transmitter.

Table 1163 Enhanced serial data encoding

Bit number	Bit function
0	Reserved for specific application
1	Reserved for specific application
2	Serial data message bits
3	Message start =0 1 1 1 1 1 1 0

Enhanced serial message frame

Serial data is communicated in an 18 frame sequence as shown in Table 1164. The start of an Enhanced Serial Message is indicated by the unique pattern “01111110” in bit #3 of the status and communication nibble, constructed across 8 SENT messages (SENT message 18, 1 to 7). The first “1” in a series of six ones in message 1 to 6 indicates the start of a serial message frame. In message 7, 13 and 18 they are set to “0”.

***Note**: In the start pattern of an enhanced serial message “01111110”, the "0" in SENT message 18 (first bit in the pattern) could belong either to a normal SENT frame with no enhanced serial message data or to the final message in a series of 18 consecutive SENT messages constructing the serial message.*

18 consecutive SENT messages must be successfully received (no errors) for the Enhanced Serial Message data to be received. If an error occurs in any of these 18 consecutive frames, then the SENT discard the current serial message and waits for a valid sequence of a new serial message. The 6-bit Enhanced Serial Message CRC is

different from the 4-bit CRC on SENT (fast channel) messages. (More details can be found in the SENT specification J2716 201604)

An Enhanced Serial Message contains 21 bits of message data and a 6-bit frame-check sequence. The configuration bit (serial data bit #3 of the 8th SENT message's Serial Communication Nibble) determines how the SENT module interprets the serial data.

- Configuration bit = 0: 12-bit data and 8-bit message ID
- Configuration bit = 1: 16-bit data and 4-bit message ID

Enhanced Serial Message data is provided in the SDSx register.

Table 1164 Enhanced serial message frame

Serial communication nibble receive no.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial data (bit # 3)	1	1	1	1	1	1	0	C	8-bit ID (7-4)				0	8-bit ID (3-0) or 4-bit data				0
Serial data (bit # 2)	6-bit CRC						12-bit data field											

***Note**: Messages 17-14 Status Nibble bit # 3 contain either the lower 4 bits (Bit 3-0) of 8-bit ID or 4 additional data bits.*

The following table shows in detail the frame structure for Enhanced Serial Data Frames with Configuration Bit = 0.

Table 1165 Enhanced serial message configuration - Bit = 0

Serial communication nibble receive no.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial data (bit # 3)	1	1	1	1	1	1	0	0	8-bit ID (7-4)				0	8-bit ID (3-0)				0
Serial data (bit # 2)	6-bit CRC						12-bit data field											

The following table shows in detail the frame structure for Enhanced Serial Data Frames with Configuration Bit = 1.

Table 1166 Enhanced serial message configuration Bit = 1

Serial communication nibble receive no.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Serial data (bit # 3)	1	1	1	1	1	1	0	1	4-bit ID (3-0)				0	4-bit data (15-12)				0
Serial data (bit # 2)	6-bit CRC						12-bit data field											

25.3.3 SPC operation

The module supports the SPC (Short PWM Code) protocol, which enhances the standardized SENT protocol (Single Edge Nibble Transmission) defined by SENT specification J2716 201604. SPC enables the use of enhanced protocol functionality due to the ability to select between “synchronous”, “range selection” and “ID selection” protocol mode or even “bidirectional transmit mode”.

25.3.3.1 Synchronous transmission

In the “synchronous” mode, the sensor (slave) starts to transfer a complete data frame only after a low pulse is forced by the master on the OUT pin (SPC Output). This means that the data line is bidirectional - an open drain output of the micro controller (master) sends the trigger pulse. The sensor then initiates a sync pulse and starts to calculate the new output data value. After the synchronization period, the data follows in form of a standard SENT frame, starting with the status, data and CRC nibbles. At the end, an end pulse allows the CRC nibble

decoding and indicates that the data line is idle again. The timing diagram below visualizes a synchronous transmission

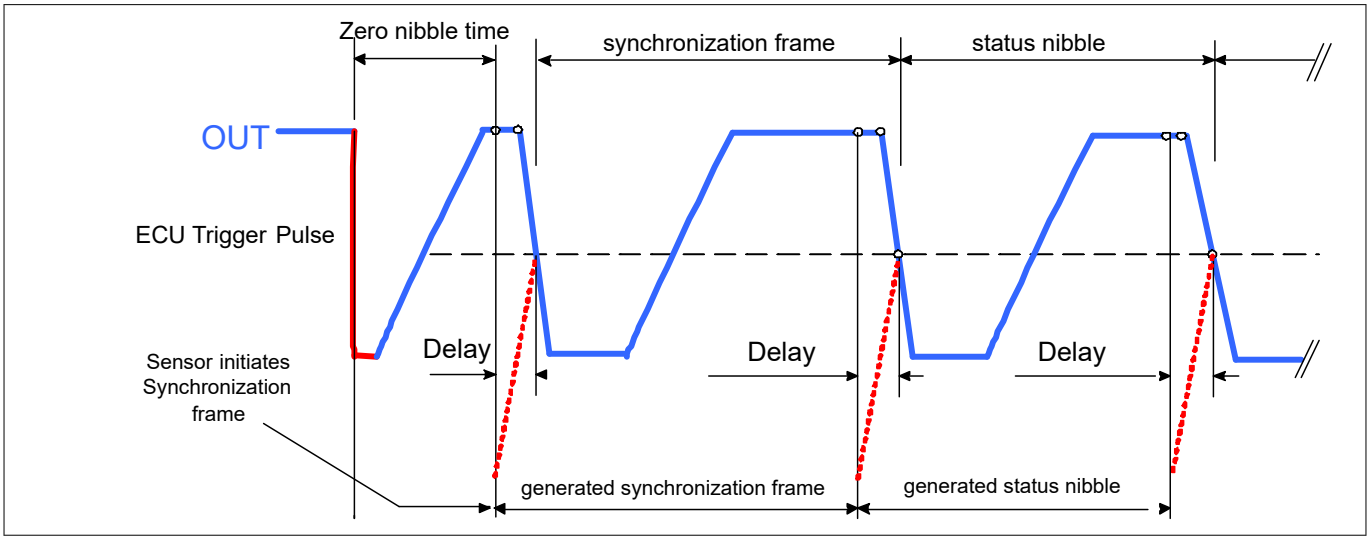

Figure 502 Synchronous transmission (SPC)

25.3.3.2 Range selection

The low time duration of the master can be used to select the range of the sensor in SPC dynamic range selection mode.

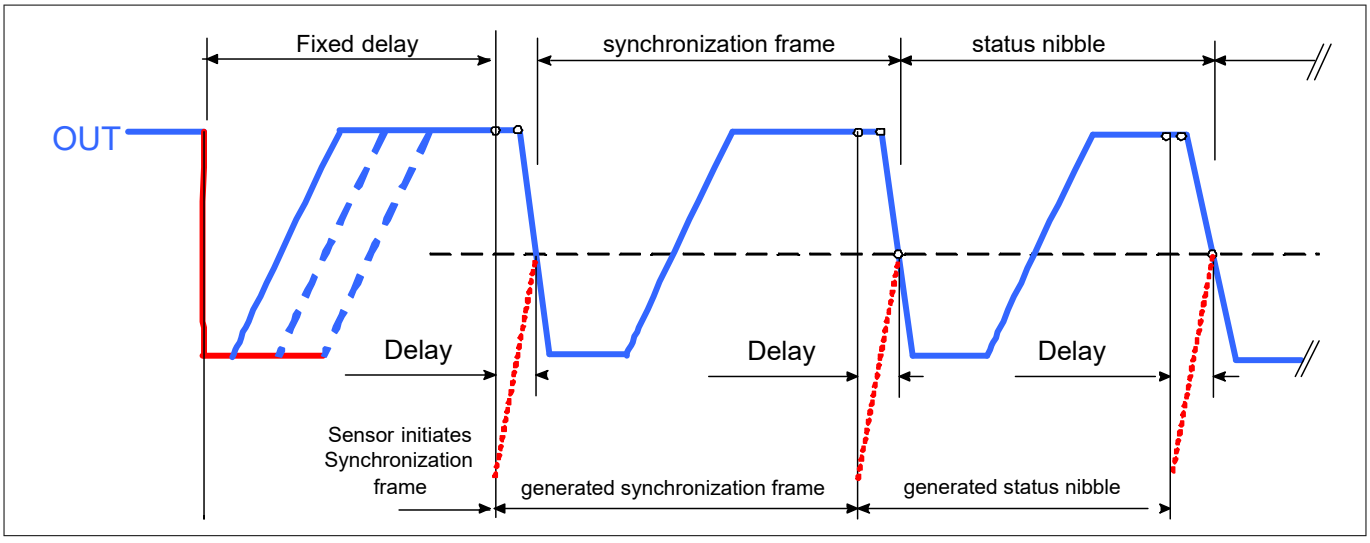

Figure 503 Range (SPC)

25.3.3.3 ID selection

This functionality is similar to the previous mode, but instead of switching the range of one sensor, one of up to four sensors are selectable on a bus (bus mode, 1 master with up to 4 slaves). This allows parallel connection of up to 4 sensors using only three lines (VDD, GND, OUT), as illustrated in the following figure.

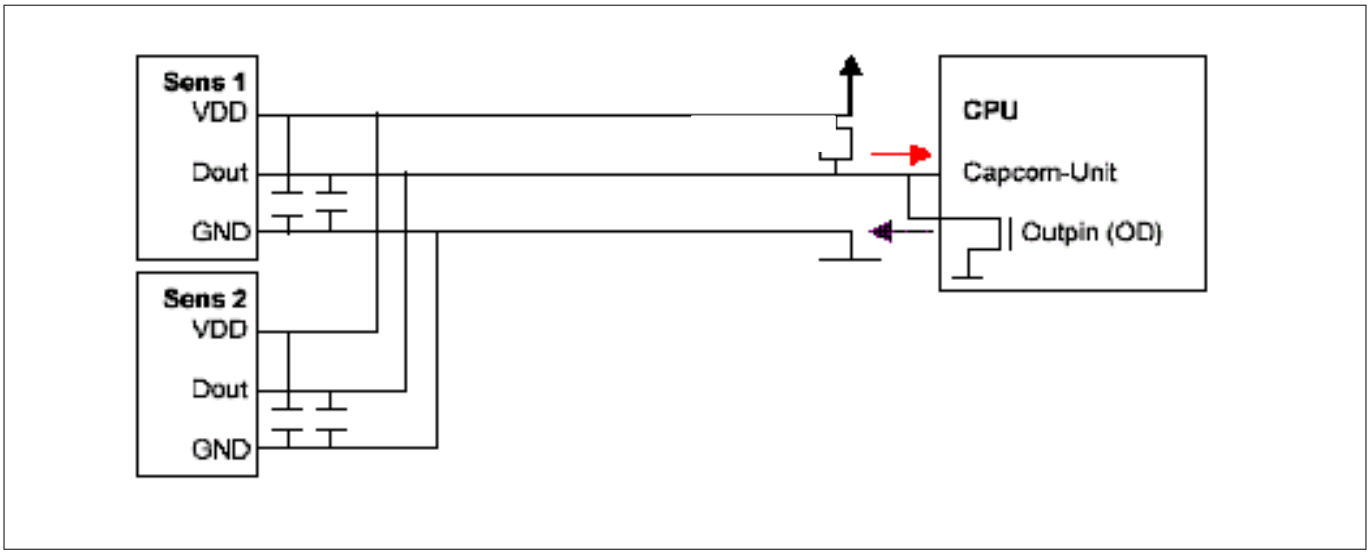

Figure 504 ID selection (SPC)

25.3.3.4 Bidirectional transmit mode

After addressing the sensor the ECU interrupts the sensor sync pulse by pulling down the line. The ECU starts to transmit own nibbles on the time base of the selected sensor. The ECU has to adapt the sensors timing from an earlier received cycle.

The sensor detects the falling edge that infringes the protocol and switches to receive mode as illustrated in the following figure.

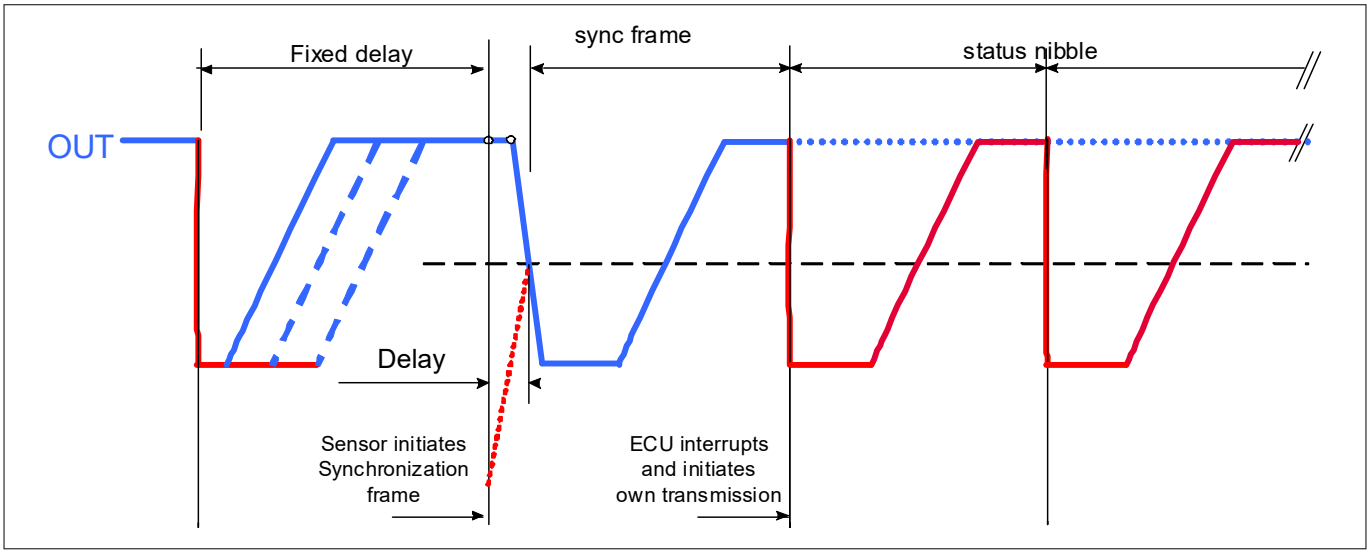

Figure 505 Bidirectional transmit mode (SPC)

25.3.3.5 SPC timing

SPC transmission is initiated by a Master pulse on the OUT pin. To detect a low level on the OUT pin, the voltage must be below a threshold V_{thf}. The sensor detects that the OUT line has been released as soon as V_{thr} is crossed. The following figure shows the timing definitions for the master pulse. The master low time t_{mlow} as well as the total trigger time t_{mtr} are individual for the different SPC modes and are given in the sensors

specifications. It is recommended to chose the typical master low time exactly between the minimum and the maximum possible time given by the connected sensor: $t_{mlow,\,typ} = \frac{(t_{mlow,\,min} + t_{mlow,\,max})}{2}$.

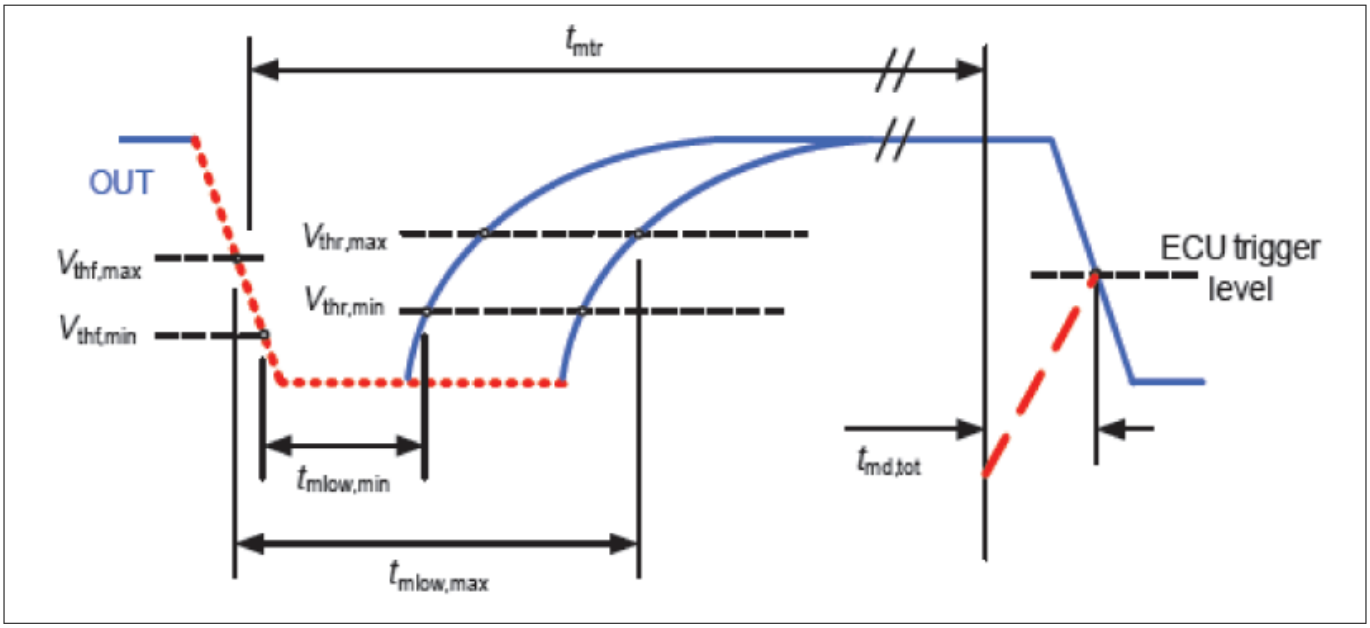

Figure 506 Timing (SPC)

25.3.3.6 Abort of frames

Only a reset condition of the device, a hard suspend or choosing Mode 0 by clearing bit-field SCRx.TRIG can abort a current SPC transmission immediately. During hard suspend, the port output drives its current value until suspend is terminated. If the receive channel becomes disabled, the soft suspend mode is requested, or the sleep mode is entered, the SENT module still does start a new frame transmission. If one of these three conditions becomes active during a running frame transmission, the frame transmission is completely finished before the requested abort state is entered. Note that in this case no frame finished interrupt is generated any more.

Received frames are aborted immediately on a disable, suspend or sleep request.

25.3.4 Baud rate generation

The nominal baud rate of each channel is individually adjustable. This is required as it is depending on the connected sensor and its current deviation from nominal frequency.

The actual baud rate of the channel follows automatically the baud rate of the connected device and its current deviation from nominal frequency. The adaptation range is +/- 25% as specified in SENT specification J2716 201604.

This chapter shows in detail how the baud rate for each channel is adjusted. $\frac{1}{f_{tick_x}}$ defines the resulting tick length.

In the first stage, a global fractional divider serves as pre divider. Its intermediate frequency $f_{fracdiv}$ can be set up as input frequency for the different SENT channels. The clock signal f_{pdiv} of a channel must always be at least 20 times the nominal tick frequency of the channel. This is to allow for the highly flexible and big tolerance of +/-25% versus the sending device. In addition the module must be able to detect a deviation in the length of 2 consecutive Synchronization and Calibration pulses of 1.5625% ($\frac{1}{64}$) and adapt the own baud rate. The tick

time is typically 3 µs but can vary by standard and take values up to 90 µs. To achieve this each channel has its own fractional divider. This allows to downscale the frequency of f_{tick} precisely to the required tick frequency.

The SENT module provides two clock signals to the channels (See the figure below):

- f_{SENT}
  This is the module clock that is used inside the SENT kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{SENT} is always identical to the system clock frequency f_{SPB}. The clock control register SENT_CLC makes it possible to enable or disable f_{SENT} under certain conditions
- $f_{fracdiv}$
  This clock is the module clock that is used inside the SENT kernel for baud rate generation of the serial channels. The fractional divider register SENT_FDR controls the frequency of $f_{fracdiv}$. DM bit-field is usually not required and set to 1

The channels generate two local clock signals:

- f_{pdiv_x}
  This clock is the channel clock that is used inside the SENT channel x for baud rate generation of the serial channel. The divider register SENT_CPDRx (x=0-14) controls the frequency of f_{pdiv_x}
- f_{tick_x}
  This clock is the channel clock that is used inside the SENT channel as the baud rate frequency. The fractional divider register SENT_CFDRx (x=0-14) controls the frequency of f_{tick_x}. The higher the value of bit-field DIV the higher the precision with which the synchronization and calibration pulse and the deviation in the length of two consecutive synchronization and calibration pulses (drift) can be measured. The bit-field DIV must be set in the range of [2200, 52428]

Each time a Synchronization and Calibration pulse starts bit-field DIVM is measured. DIVM is the result of measuring the calibration pulse duration with f_{pdiv_x}. At the end of the Synchronization and Calibration pulse this value is taken as new divider of the register CFDR.

Each time a pulse starts, the internal accumulator of the CFDR is preset with $\frac{DIVM}{2}$. This is required to center the data eye and to make the margin symmetrical.

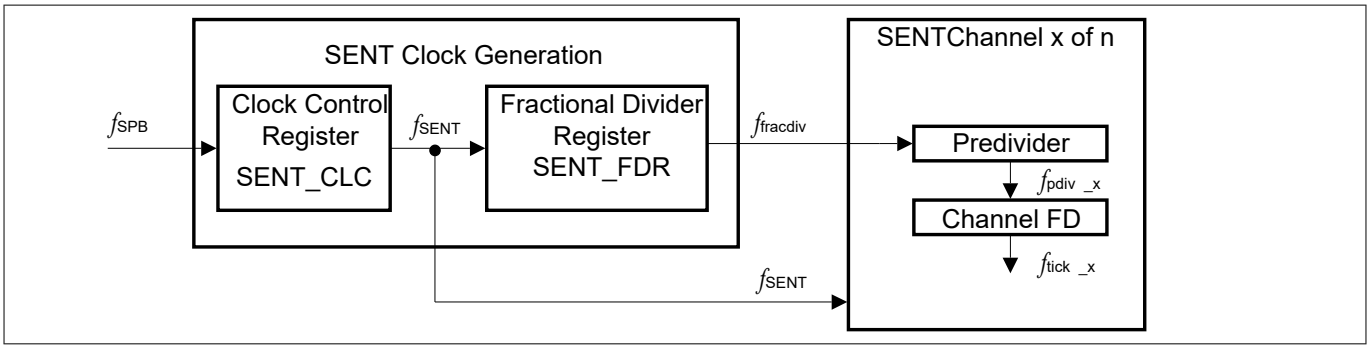

Figure 507 SENT module clock generation

The following two equations define the frequency of $f_{fracdiv}$:

$$f_{fracdiv} = f_{SENT} \div (1024 - SENT_FDR.STEP) when FDR.DM = 01_B \quad (11)$$

$$f_{fracdiv} = f_{SENT} \times SENT_FDR.STEP \div 1024 \text{ with } STEP = 0...1023 \text{ when} FDR.DM = 10_B \quad (12)$$

The following formula defines the frequency of f_{pdiv_x}:

$$f_{pdiv_x} = f_{fracdiv} \div (SENT_CPDRx.PDIV + 1) \quad (13)$$

The following formula defines the nominal frequency of f_{tick_x}. For the actual frequency of f_{tick_x} DIV is replaced by DIVM after the current sensor frequency was validly measured.

$$f_{tick_x} = \left(f_{pdiv_x} \times 56\right) \div SENT_CFDRx.DIV \text{ with } DIV = \text{from } 2200 \text{ to } 52428 \quad (14)$$

25.3.4.1 Operation outside the granted standard limits

The SENT module is granted to comply SENT specification J2716 201604. The tolerances given in this standard are valid for tick times between 3 µs and 90 µs. Nevertheless, the SENT module can operate outside this standard. A minimum tick time of 0.2 µs is programmable. In these use cases outside the standard it is in the responsibility of the system integrator to do proper jitter calculation and system design. Same holds true for tick times of greater than 90 µs. Note that the low pass filter as given in SENT specification J2716 201604 needs to be replaced by a circuit fit for the intended use case as well. Such use is not recommended, as a standard is missing for the system.

25.3.5 Error detection capabilities

Each SENT channel can detect and signal the following error conditions:

Protocol level:

- Calibration pulse length deviates more than +/-25% from the nominal 56 ticks
- Too many or too few nibbles between calibration pulses
- Checksum error
- Successive calibration pulse differ by more than 1.5625%
- Any nibble data values measured as < 0 or >15
- Wrong status and communication nibbles
- Serial communication CRC error

Any of those errors shall cause the receiver to begin searching for a valid calibration pulse to resynchronize.

Transfer Management Level:

- Receive data buffer overrun
- SPC data buffer underrun

25.3.6 Support for frequency drift analysis in frames with pause pulse (FDFL mode)

Each SENT channel supports FDFL mode, that is monitoring the following condition for messages with pause pulse and fixed message length:

Ratio of calibration pulse to message length varies by $> \frac{1}{64}$ or $< -\frac{1}{64}$ from one message to another.

The FDFL mode is entered if RCRx (x=0-14).FDFL, RCRx (x=0-14).IEP and RCRx (x=0-14).IDE are set. RCRx (x=0-14).CFC is ignored in this mode.

There is no automatic calculation or check done by hardware in this mode nor is FDI issued. Frames that have an invalid frequency drift and would cause an FDI are still accepted and not dropped by hardware. FRI is not affected by this mode. This means that the hardware still checks the sensor frequency range. The calculation of

the ratio and the comparison with the ratio of the preceding frame needs to be done in software. The software needs to decide whether or not to accept the frame based on this calculation.

The value for the calibration pulse length can be read by software from CFDRx (x=0-14).DIVM.

The value for the message length including pause pulse can be read by software from RCRx (x=0-14).FRLEN only if RCRx (x=0-14).FDFL, RCRx (x=0-14).IEP and RCRx (x=0-14).IDE are set.Both values are valid after RSI. RSI indicates the Frame Buffer valid immediately after the Pause Pulse belonging to the current frame is received if no other error occurs.

FRLEN is a 16-bit counter with saturation (stops at 0xFFFF/65.535) and is driven by f_{pdiv}. These factors limit the maximum supported length of frames including pause pulses.

For the typical use case $\frac{1}{f_{tick}} = 3\,\mu s$, a good choice for f_{pdiv} is:

16.6 MHz (PDIV = 5; f_{SENT} = 100 MHz)

The frame length can be counted up to 3.93 ms.

Note that the nominal frame length must be 20% shorter to allow the system to compensate a 20% frequency drift. This is just an example calculation and not all products may support all frequencies.

The following figure shows the two times that are measured and that need to be set in relation to each other:

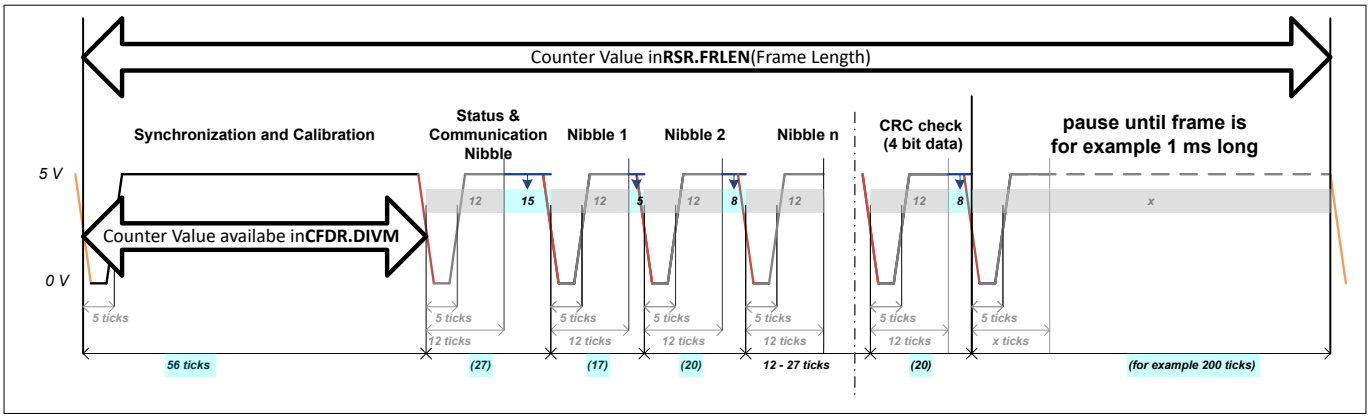

Figure 508 Frequency drift analysis in frames with pause pulse

25.3.7 Digital glitch filter

Very slow slopes and signal noise can lead to fast transitions of the input signal. These unwanted transitions are suppressed by a digital glitch filter similar to a Filter and Prescaler Cell (FPC) in Delayed Debounce Filter Mode with up and down (no reset).

It is built for filtering very fast transitions only. The filter calculates the integral of the signal. If the integral reaches a programmable saturation point, the signal change is notified to the pulse measurement unit. So it helps to find the exact pulse length for slow slopes in noisy environment.

The glitch filter is clocked with f_{pdiv}. The following conditions may apply:

- If the state of the input sample differs from the current output signal value, the internal counter is incremented by one
- If the state of the input sample matches the current output signal value and the timer is not in idle, the timer is decremented by one
- If the timer matches the compare value stored in IOCRx (x=0-14).DEPTH, the level of the output signal line is inverted. The timer will be reset and set to idle state again

The depth of the filter can be programmed to a value between 1 and 15. Typically a depth of 3 to 5 T_{pdiv} is sufficient. By default it is cleared. If IOCRx (x=0-14).DEPTH is cleared the filter is inactive. Nevertheless, the input signal is sampled with f_{pdiv}.

The internal signal after the filter will change value not before the new value was sampled DEPTH times. If during this period a spike occurs, it takes $2 \times T_{\text{pdiv}}$ times longer for the internal signal to change value. The filters principal implies a delay of the signal by ($\text{DEPTH} \times T_{\text{pdiv}}$).

Upon detection of glitch during rising or falling edge, IOCRx (x=0-14).REG or IOCRx (x=0-14).FEG is set. The rising and falling edge glitch flags must be reset by software.

The following figure shows the digital glitch filter:

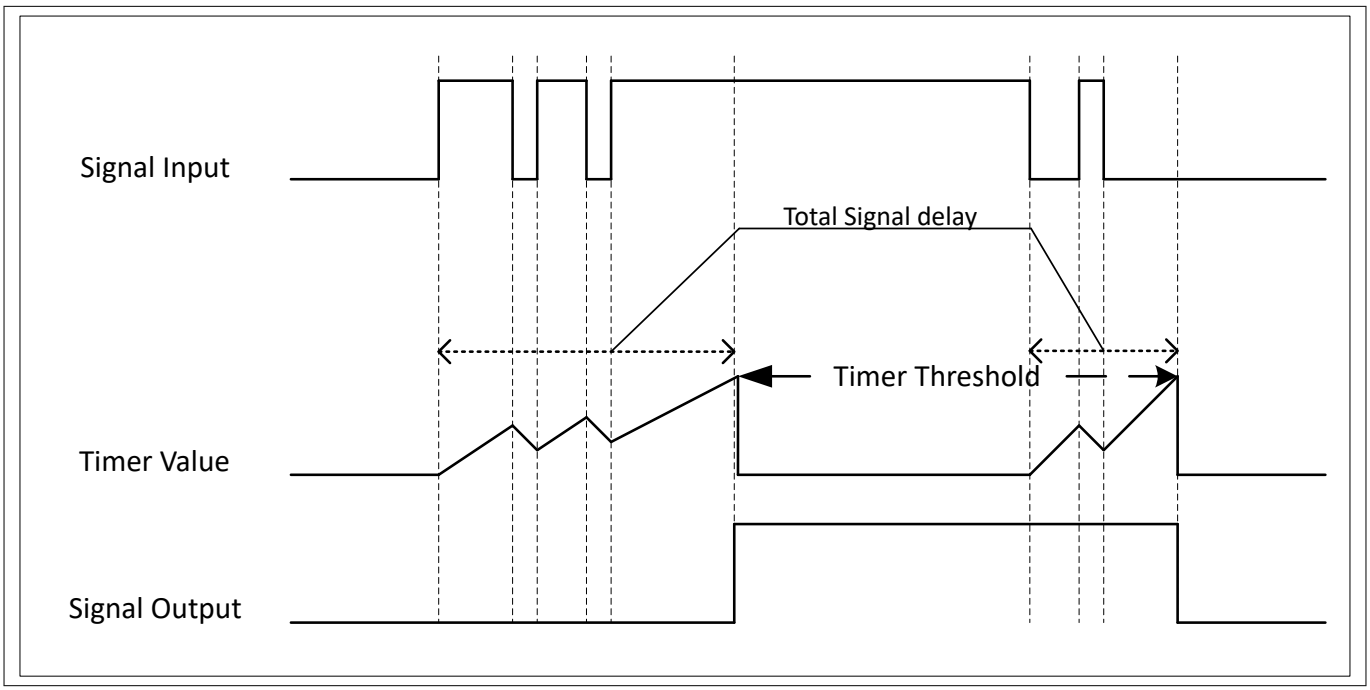

Figure 509 Digital glitch filter

25.3.8 Interrupts

For the SENT module, each channel has a total of 14 interrupts:

- RDI: Receive data interrupt is activated when a received frame is moved to the Receive Data Register RDRx (x=0-14)
- RSI: Receive frame success interrupt, that is the CRC was successful

***Note**: Both RDI and RSI will be issued together in normal use cases where the frame size is not bigger than 8 nibbles and CRC is correct. For more than 8 data nibbles, please refer to RCRx (x=0-14).FRL description.*

- RBI: Receive buffer overrun interrupt is activated when a new frame is transferred to a Receive Data Register RDRx (x=0-14) while the old value was still not read by the host (“overwrite”), that is the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set
- TDI: Transmit interrupt is activated when data is moved from a SCR to a transmit shift register
- TBI: Transfer buffer under run interrupt is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx (x=0-14)
- FRI, FDI, NNI, NVI, CRCI: Protocol error interrupts, if one of the protocol error interrupts is activated, data is to be treated as invalid according to SENT specification J2716 201604
- WSI, SDI, SCRI treat the interrupts referring to the Status and Communication nibble
- WDI: Watch Dog Error Interrupt is issued if the time between two frames is too long

For acceleration of the interrupt service routine, a Register INTOV is implemented that holds a flag for each channel. This flag is automatically set if there is an interrupt pending for the channel which is enabled. It is automatically reset, if no more enabled interrupt is pending for this channel.

The interrupt request or the corresponding interrupt set bit (in register INTSETx (x=0-14)) can trigger the interrupt generation at the selected interrupt node. The service request pulse is generated independently from the interrupt flag in registerINSTATx (x=0-14). The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLRx (x=0-14). If more than one interrupt source is connected to the same interrupt node pointer (in register INPx (x=0-14)), the requests are combined to one common line.

***Note**: Only 10 Interrupt request lines are available for the SENT module to interface with the Interrupt Router.*

25.3.9 Interface connections of the SENT module

The following figure shows a more specific implementation details and interconnections of the SENT module.

The SENT module is supplied with a separate clock control, address decoding, and interrupt control logic. Outputs of GTM timer are connected to the SENT Trigger inputs.

The inputs of the receive channels of the SENT module as well as the SPC outputs (SPCn) are connected to GPIO lines. If SPC outputs are mapped to the same port pin like the referring SENT data input line on a specific product, they can be used in a quasi bidirectional mode (that is open drain out and input on the same pin).

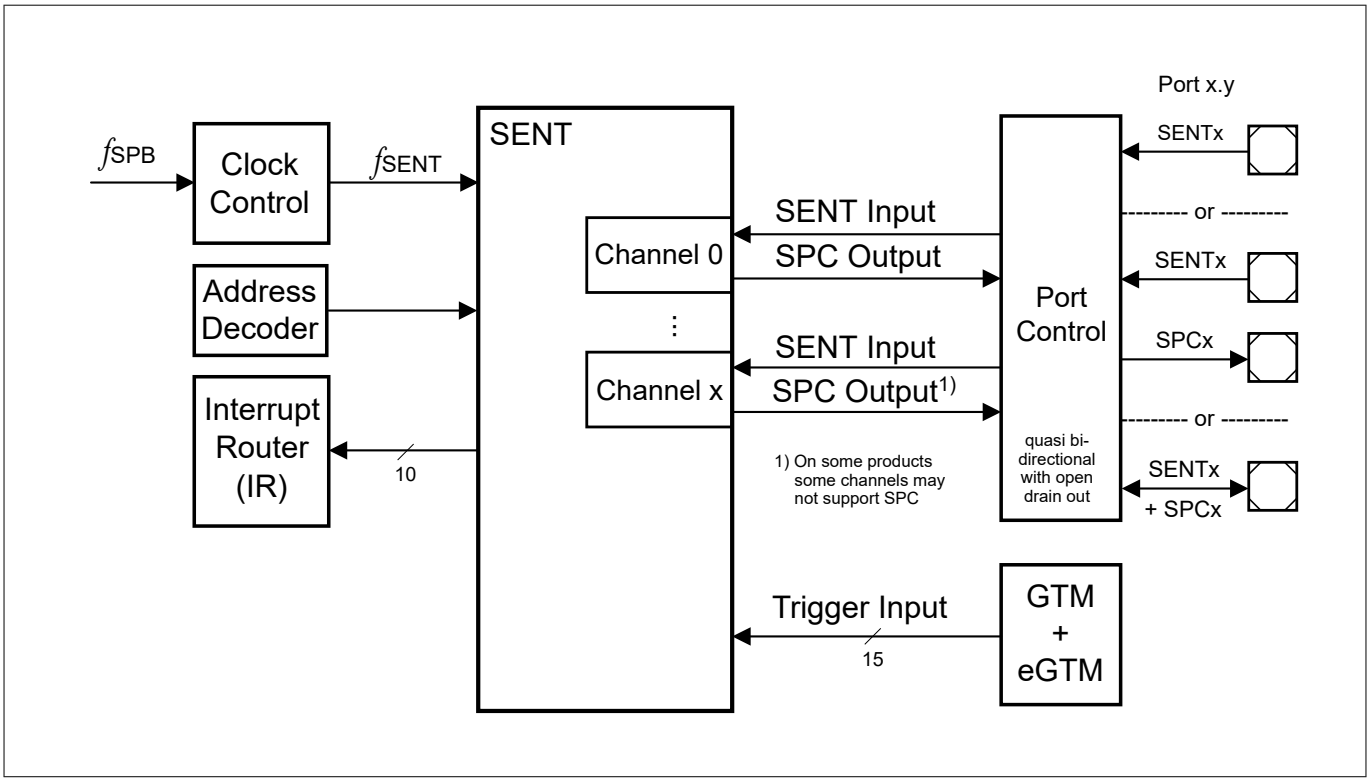

Figure 510 SENT module implementation and interconnections

25.3.9.1 Trigger inputs

The module has 15 SENT channels and the same number of trigger inputs. They can be randomly chosen by programming IOCRx (x=0-14).ETS. The trigger inputs (TRIG[14:0]) of the SENT module are connected to GTM and eGTM as shown in the SENT connectivity chapter.

25.3.10 Port control

The SENT input channels are overlain with standard ADC channels as they are replacing former analog signals. In addition each channel is connected to general purpose I/O pads as well. The selection from one of up to 4 alternate inputs per channel is done by application software by programming IOCRx (x=0-14).ALTI.

Depending on the implementation some products support SPC output as well on some of the channels.

The following port control operations must be executed for the SPC output I/O pads:

- Input/output function selection (Port IOCR registers)
- Pad driver characteristics selection for the outputs (Port PDR registers)

25.3.10.1 Input/output function selection

SENT can be used in three different ways:

- ADC input (dedicated for ADC) overlain with SENT digital input and no output option on this pad
- Standard general purpose input/output function on two different I/O pads per channel. This means that it is an input on ADC or on I/O pad while the output is chosen to be on a different I/O pad. This allows the use of external transceivers
- SPC open drain output on a digital I/O pad and SENT input from same digital I/O pad (“quasi bidirectional SENT/SPC mode”)

The SENT module overlays dedicated analog to digital converter (ADC) pads as digital input pad.

SENT physical layer uses 5 V signal voltage levels. All SENT inputs are mapped to 5 V compatible ADC pads. V_{ddm} must be supplied with 5 V for SENT operation.

The port input/output control registers contain the bit-fields that select the digital output and input driver characteristics such as port direction (input/output), alternate output selection, pull-up and pull-down devices (for pure inputs only), and open-drain selections. The I/O pads for the SENT module are controlled by the Port input/output control registers. Please see Port chapter to make conscious decisions here.

Quasi bidirectional settings are possible only, where an SPC output and a SENT input of the same channel are connected to the same pad. This configuration is not available on all SENT input pads and varies by product.

For some channels SPC outputs and SENT inputs are connected to the same I/O pad. This allows for quasi bidirectional operation: That is the output is configured as open drain (for example P00_IOCR0.PC1=11110_B) while the same pad is used as input (for example P00_IOCR0.PC1=$0XXXX_B$). The port in the example may not be present in all products.

Note that in the examples, figures and tables of this chapter, no quasi bidirectional operation is shown. Only pure inputs and pure outputs are shown for the sake of simplicity.

Alternate inputs that are not connected to any pin are connected to GND internally. For example the input selected by IOCRx (x=0-14).ALTI=0011_B (also known as: “input D”) is not present in all products.

25.3.11 Definitions

Table 1167 Definitions

Name	Description
SENT	Single Edge Nibble Transmission
Nibble	Four Bit value between 0 and 15 = half a Byte = one character in hex (0 to F)
SPC	Short PWM Code
PWM	Pulse Width Modulation

25.4.3 Clock control register

The Clock control register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 000_H

Clock control register Application Reset value: $0000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. Also the analog section is disabled by clearing ANONS. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked

(table continues...)

(continued)

Field	Bits	Type	Description
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

25.4.4 OCDS control and status register

The OCDS control and status register OCS controls the module's behavior in suspend mode (used for debugging).

Register OCS is cleared by Debug Reset.

If OCDS is being disabled, the OCS register value will not change. When OCDS is disabled the OCS suspend control is ineffective.

OCS Offset address: 004_H

OCDS control and status register Debug Reset value: $0000\ 0000_H$

r						rh									

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DM		0				STEP									
rw		r				rw									

Field	Bits	Type	Description
STEP	9:0	rw	**Step Value** Reload or addition value for RESULT.
DM	15:14	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	25:16	rh	**Result Value** Bit field for the addition result.
0	13:10, 31:26	r	**Reserved** Read as 0; should be written with 0.

25.4.18 Interrupt overview register

INTOV Offset address: 044_H

Interrupt overview register Kernel Reset value: $0000\ 0000_H$

r	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
IPCy (y=0-14)	y	rh	**Interrupt Pending on Channel y** If any interrupt requested flag is set for channel y in register INTSTATy AND the referring interrupt is enabled in INTENx then IPCy is set. It is automatically reset if all flags in INTSTATy are cleared for which the referring interrupt is enabled in INTENx.
0	31:15	r	**Reserved** Read as 0.

25.4.19 Module time stamp register

The SENT Module time stamp register contains read-only information about the current time given in clock cycles generated from TPD since last reset while module was clocked. Writing to TPD clears this register.

TSR Offset address: 048_H

Module time stamp register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CTS															
rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CTS															
rh															

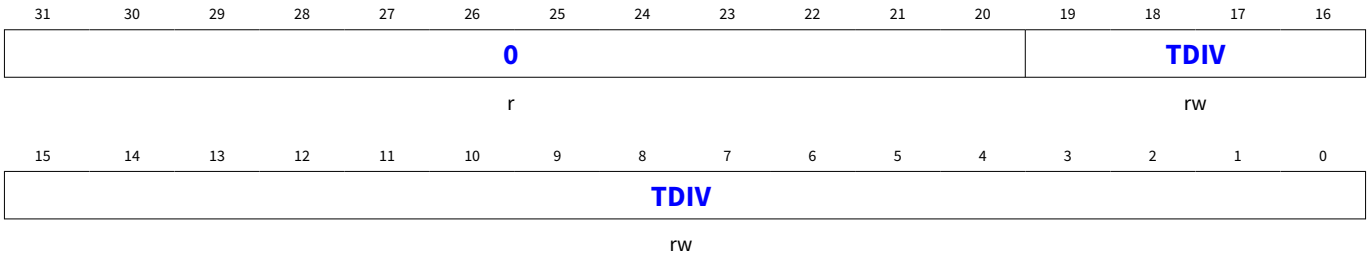
Field	Bits	Type	Description
CTS	31:0	rh	**Current Time Stamp for the Module** This bit field shows the current time stamp.

25.4.20 Time stamp predivider register

The SENT Module Time stamp predivider register contains the pre divider that defines the time resolution of TSR. Writing to TPD clears register TSR.

TPD Offset address: $04C_H$

Time stamp predivider register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TDIV	19:0	rw	**Divider Factor of Pre Divider for TSR** Divides $f_{fracdiv}$ by (TDIV + 1) and drives TSR.
0	31:20	r	**Reserved** Read as 0; should be written with 0.

25.4.21 Receive data register x

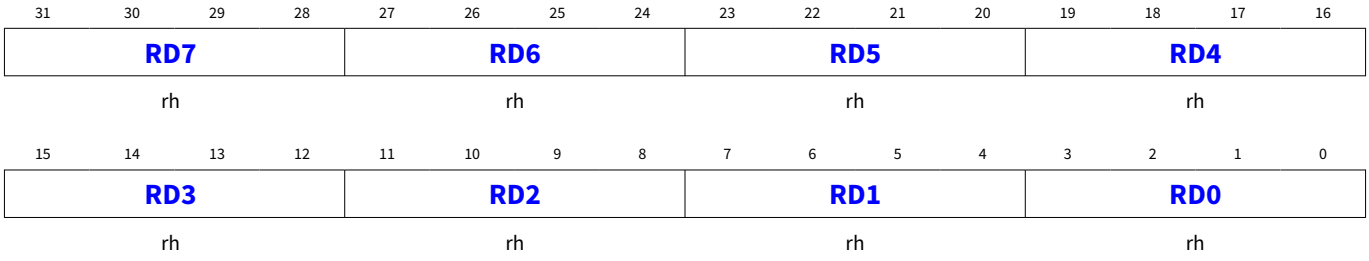
The Receive data registers RDRx for channel x shows the data content of a received data frame. Register VIEWx is used to sort the nibbles.

Register VIEW must be set up correctly to see all data nibbles of the frame. By default the application software set VIEW to 7654 3210_H.

The internal receive buffer is always cleared (0x0000 0000_H) at each frame start. Thus unused nibbles are always read as zero.

RDRx (x=0-14) Offset address: 080_H+x*4

Receive data register x Kernel Reset value: 0000 0000_H



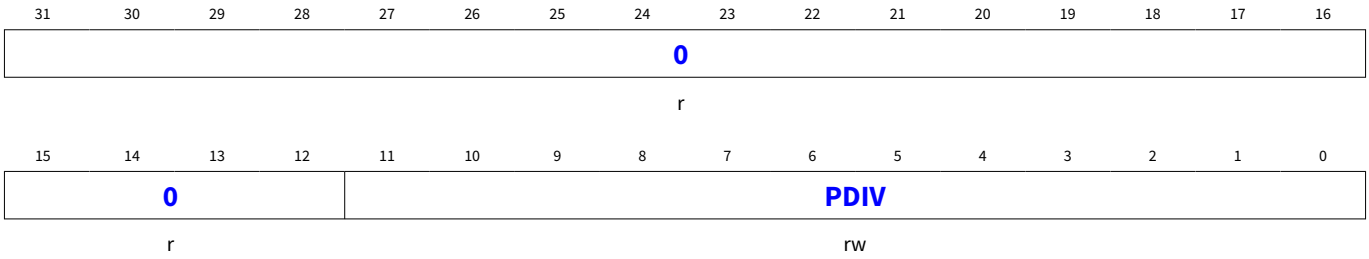
Field	Bits	Type	Description
RDy (y=0-7)	4*y+3:4*y	rh	**Receive Data Nibble y** RDy shows the nibble from the received frame that is sorted to this position. It can be selected by any of VIEWx.RDNPy (y = 0-7). By default all nibbles are sorted to RD0 as the reset value of VIEW is 0x0000 0000H. I.e. at the end of frame reception RD0 contains the last data nibble of the frame.

25.4.22 Channel pre divider register x

The Channel pre divider register CPDRx contains the pre divider that is related to the SENT channel baud rate. See

CPDRx (x=0-14) Offset address: 100_H+x*40_H

Channel pre divider register x Kernel Reset value: 0000 0000_H



Field	Bits	Type	Description
PDIV	11:0	rw	**Divider Factor of Pre Divider for Channel x** Divides $f_{fracdiv}$ by (PDIV + 1) and delivers f_{pdiv_x} to the Channel Fractional Divider. RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV.
0	31:12	r	**Reserved** Read as 0; should be written with 0.

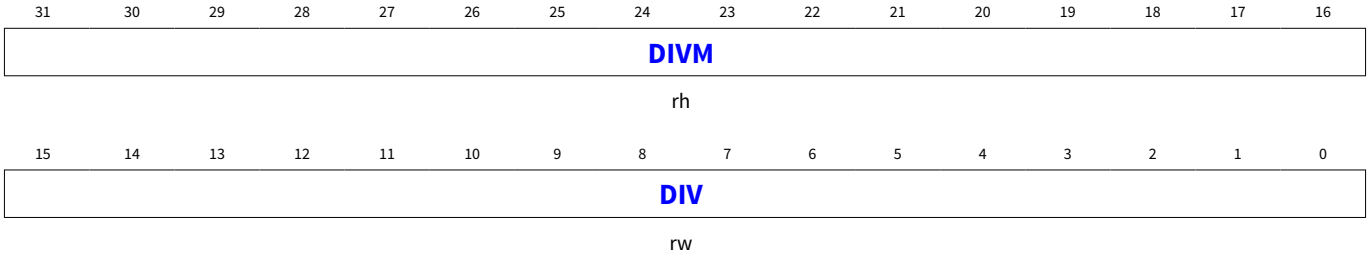
25.4.23 Channel fractional divider register x

The Channel fractional divider register CFDRx contains control bits/bit fields that are related to the SENT channel baud rate.

See in for a detailed description.

CFDRx (x=0-14) Offset address: 104_H+x*40_H

Channel fractional divider register x Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DIV	15:0	rw	**Divider Value** Initial and reference divider value for the CFDR. DIV must be programmed > 0. If cleared, DIV becomes 1. If written, DIVM is updated automatically with the same value.RCR.CEN must be cleared before changing CPDR.PDIV or CFDR.DIV. DIV must be set in the range of [2200, 52428].
DIVM	31:16	rh	**Measured Divider Value** DIVM is automatically updated by HW to adjust the receiver frequency to the current sender frequency. This value is kept automatically in the range of 75% DIV < DIVM < 125% DIV Write data is ignored.

25.4.24 Receiver control register x

The Receiver control register RCRx contains control bits/bit fields that are related to the SENT receiver operation.

RCRx (x=0-14) Offset address: 108_H+x*40_H

Receiver control register x Reset values see: Table 1173

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0											FDFL	SUSEN	IDE	ESF	CRZ
r											rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FRL								CFC	CDIS	SCDIS	SDP	SNI	ACE	IEP	CEN
rw								rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
CEN	0	rw	**Channel Enable** When CEN is set, the receiver of channel x is enabled. The internal receiver state machine can be initialized by switching the channel off and on. This does not change the current register content. 0_B channel x disabled (default) 1_B channel x enabled
IEP	1	rw	**Ignore End Pulse** When IEP is set, an end pulse is ignored. An end pulse can be generated in SPC mode or as pause pulse. For systems with an end pulse, during synchronize or re-synchronize of reception, if calibration pulses are detected one immediately following the other, the first calibration pulse shall be ignored as it may be a pause pulse with duration matching the calibration pulse range. 0_B End Pulse not ignored (default) 1_B End Pulse ignored
ACE	2	rw	**Alternative CRC Mode Enable** When ACE is set, the CRC is calculated in an alternative way for both: fast (signal) and slow (serial message) data path. If ESF is set, the standard 6 bit CRC is always used for the serial message and ACE is ignored. 0_B Serial CRC calculation as specified in SENT specification J2716 201604 (default) 1_B Alternative: 4 bit in parallel CRC calculation as used e.g. in hall sensor TLE4998C.
SNI	3	rw	**Status Nibble Included in CRC** When SNI is set, the status Nibble is included in (signal data) CRC. 0_B Status Nibble not included in CRC (default) 1_B Status Nibble included in CRC (as used e.g. in hall sensor TLE4998C).

(table continues...)

(continued)

Field	Bits	Type	Description
SDP	4	rw	**Serial Data Processing Mode** This bit switches automatic serial data processing on. 0_B Automatic Serial Data Processing is disabled. Status and Communication nibble can be read from RSRx for SW processing. (default) 1_B Automatic Serial Data Processing is enabled. Status and Communication nibble can be read from RSRx; Message ID, Serial Data and SCRC can be read from SDSx after serial data interrupt SDI is activated.
SCDIS	5	rw	**CRC for Serial Data Disabled Mode** This bit selects the CRC disabled mode. 0_B CRC is enabled (default) 1_B CRC is disabled CRC nibble can be read from SDSx. The CPU must perform the CRC on the current data by SW.
CDIS	6	rw	**CRC Disabled Mode** This bit selects the CRC disabled mode. 0_B CRC is enabled (default) 1_B CRC is disabled CRC nibble can be read from RSRx. The CPU must perform the CRC on the current data by SW.

(table continues...)

(continued)

Field	Bits	Type	Description
CFC	7	rw	**Consecutive Frame Check** This bit determines the way the most recently received frame buffer is indicated as valid. Note: If FDFL is set, CFC is ignored and the checks described here are not executed. 0_B Check against Past Sync Pulse The current Synchronization / Calibration Pulse is compared to the Synchronization / Calibration Pulse received immediately before. The whole frame is invalid if the Synchronization / Calibration Pulse length differs from the length of the Synchronization / Calibration Pulse before by more than 1.5625%. In this case of error, its length is not used as new reference. In case the check passes and no other error occurs the Frame Buffer is indicated valid (RSI) immediately after CRC calculation result is correct. Resynchronization: On the third successive calibration pulse error, the current calibration pulse value is considered as valid and the message accepted unless the message frame contains other errors. In both cases a receive data interrupt (RDI), or a referring error interrupt is issued. 1_B Check against Future Sync Pulse The current Synchronization / Calibration Pulse is compared with the Synchronization / Calibration Pulse received immediately after the current frame. The whole frame is invalid if the Synchronization / Calibration Pulse length differs from the length of the following Synchronization / Calibration Pulse by more than 1.5625%. In case the check passes and no other error occurs the Frame Buffer is indicated valid (RSI) immediately after the Synchronization / Calibration Pulse following the current frame. Resynchronization: In this case of error, the current length is used as new reference. Note: The whole frame can be indicated valid only after additionally measuring the Synchronization / Calibration Pulse of the successive frame.

(table continues...)

(continued)

Field	Bits	Type	Description
FRL	15:8	rw	**Frame Length** FRL determines the number of data nibbles per frame that the SENT channel x is setup for. Note that FRL does not include the Synchronization / Calibration Pulse, the Status and Communication nibble, the CRC nibble nor the additional zero length nibble that might be introduced by use of SPC If more than 8 nibbles are configured, please note: In addition to the receive success interrupt RSI at the successfully received end of a frame, a receive data interrupt RDI is issued each time 8 nibbles have been transferred to the Receive Data Register RDRx. At the end of a frame, RDI is issued if RSI is issued. If an error occurred, RDI is not set at the end of a frame. If no CRC has been received at the point in time where RDI is issued, the receive data interrupt is no indication whether or not the transfer was successful so far. A CRC Error Interrupt is issued at the end of the frame if Automatic CRC check is enabled and the CRC is wrong. 00_H No data nibble 01_H 1 data nibble 02_H 2 data nibbles 03_H 3 data nibbles … 07_H 7 data nibbles 08_H 8 data nibbles Maximum in normal length mode 09_H 9 data nibbles … FF_H 255 data nibbles
CRZ	16	rw	**CRC with Zero Nibble for Serial Data** This bit selects the CRC method. If CRZ is cleared, augmentation is selected, (i.e a ZERO NIBBLE is added at the end of CRC calculation (only in calculation)). E.g. as 7th nibble (in case of 6 data nibbles) The enhanced serial message (18 Frames, 6-bit CRC) is not controlled by CRZ but the 6-bit CRC is always augmented according to standard. 0_B Augmentation is selected for both 4-bit message CRC and the 4-bit CRC of the serial messages (legacy, 16 frames) (default) 1_B Augmentation is switched off for both 4-bit message CRC and the 4-bit CRC of the serial messages (legacy, 16 frames).
ESF	17	rw	**Enhanced Serial Frame Mode** This bit selects the serial frame structure. 0_B short (16 frames, 4 bit ID, 8 bit data, 4 bit CRC) 1_B enhanced (18 frames, 4 or 8 bit ID, 12 or 16 bit data, 6 bit CRC)
IDE	18	rw	**Ignore Drift Error Mode** This bit selects if drift errors lead to frame rejection and if an interrupt (INTSTAT.FDI) is generated. Used, if sensors are triggered by SPC. During a long pause period the accumulated drift could be more than 1.5625%. In this special case setting IDE is useful. 0_B Drift Errors enabled (default) 1_B Drift Errors disabled

(table continues...)

(continued)

Field	Bits	Type	Description
SUSEN	19	rw	**Suspend Enable** This bit makes it possible to set the SENT channel into Suspend Mode via OCDS (on chip debug support): Bit SUSEN is reset via OCDS Reset. 0_B An OCDS suspend trigger is ignored by this SENT channel. 1_B An OCDS suspend trigger disables the SENT channel: As soon as the SPC sender logic of the SENT channel becomes idle, the module is stopped while all registers of the channel stay readable. The receiver is stopped unconditionally. A partly received frame is discarded.
FDFL	20	rw	**Frequency Drift Check based on Frame Length** This bit is used for frames with pause pulse only. If set the drift error is not checked by HW. Instead, counter values DIVM and FRLEN are provided to the SW for checking the frequency drift. IEP (Pause Pulse expected) and IDE (no HW check of drift error) must always be set (=1) together with FDFL. Note: If FDFL is set, RCR.CFC is ignored and the checks described there are not executed. 0_B FDFL mode deactivated, RCR.CFC is valid (if IDE is cleared). 1_B FDFL mode is activated, IEP and IDE must be set too for proper function! RCR.CFC is ignored. If no other error occurs the Frame Buffer is indicated valid (RSI) immediately after the Pause Pulse belonging to the current frame.
0	31:21	r	**Reserved** Read as 0; should be written with 0.

Table 1173 Reset values of RCRx (x=0-14)

Reset type	Reset value	Note
Kernel Reset	0000 0000 0000 X000 0000 0000 0000 0000_B	
Debug Reset	XXXX XXXX XXXX 0XXX XXXX XXXX XXXX $XXXX_B$	

25.4.25 Receive status register x

The Receive status register provides the status information of channel x.

RSRx (x=0-14) Offset address: $10C_H+x*40_H$

Receive status register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0				SCN				0		CST		CRC			
r				r				r		r		r			

Field	Bits	Type	Description
CRC	3:0	r	**CRC** of last frame. CRC0 is on bit position 0.
CST	5:4	r	**Channel Status** CST shows the current status of channel x. 00_B STOP Channel is disabled and can be configured 01_B INITIALIZED Channel is configured and enabled and no Synchronization / Calibration Pulse was received since last enable. 10_B RUNNING one or more Synchronization / Calibration Pulses were received and Frequency Range or Frequency Drift not or no longer in range. Fallback status from SYNCHRONIZED. 11_B SYNCHRONIZED Frequency Range and Frequency Drift in range
SCN	11:8	r	**Status and Communication Nibble** of last frame. SCN0 is on bit position 8.
FRLEN	31:16	r	**Frame Length including Pause Nibble** of last frame. Bit FRLEN0 is on bit position 16. FRLEN is a 16 bit counter with saturation (stops at 0xFFFF / 65.535) and is driven by f_{pdiv}. This counter supports monitoring the following condition for messages with pause pulse and fixed message length: Ratio of calibration pulse to message length varies by > 1/64 or < -1/64 from one message to another. FRLEN is valid after RSI. See chapter “Support for Frequency Drift Analysis in Frames with Pause Pulse”.
0	7:6, 15:12	r	**Reserved** Read as 0; should be written with 0.

25.4.26 Serial data and status register x

The Serial (receive) data and status register provides the data and status information of channel x.

SDSx (x=0-14) Offset address: 110_H+x*40_H

Serial data and status register x Kernel Reset value: $0000\ 0000_H$

r															

Field	Bits	Type	Description
SD	15:0	r	**Serial Data** of last serial data frame. SD0 is on bit position 0. Usually all 16 data bits are used. If RCR.ESF is cleared 8 bits of data are available and bits [15:8] are zero. If RCR.ESF is set and if SDS.CON is cleared 12 bits of data are available and bits [15:12] are zero.

(table continues...)

(continued)

Field	Bits	Type	Description
MID	23:16	r	**Message ID** of last serial data frame. ID0 is on bit position 16. If RCR.ESF is cleared, or if SDS.CON is set, bits [23:20] are zero.
SCRC	29:24	r	**SCRC** CRC of last serial data frame. CRC0 is on position 24. If RCR.ESF is cleared, bits [29:28] are always zero.
CON	31	r	**Configuration bit** of last serial frame. 0_B 12-bit data and 8-bit message ID 1_B 16-bit data and 4-bit message ID
0	30	r	**Reserved** Read as 0; should be written with 0.

25.4.27 Input and output control register x

The Input and output control register IOCRx determines for the SENT channel x:
for the receiver:
- the alternate input
- the filter depth
- the input signal polarity

for the SPC Unit
- the trigger source
- the output signal polarity

IOCRx (x=0-14) Offset address: 114_H+x*40_H

Input and output control register x Reset values see: Table 1174

25.4.28 SPC control register x

The SPC control register SCR contains data to be transmitted during the sync pulse of the data frames. It contains as well the trigger control bits required for sending nibbles from the SENT module to the sensor / external SENT device.

The SPC Control Register is used to control the trigger mode and time base of the SPC channel transmission.

Data and the control bits are collected in this single register to ease transfer of multiple pulses in cases where dynamic switching of the trigger condition is required.

The SPC Control Register is used to control single pulse transfers only.

Thus it is possible to change the control settings of an individual channel from pulse to pulse as it is required in SPC mode “Bidirectional transmit”. Here it might be considered useful to change trigger mode between Mode 1 (immediately) and Mode 2 (falling edge of next Synchronization / Calibration Pulse with programmable delay).

In addition repeating transfers with the same control settings are supported. For a pulse transfer to be initiated a synchronization signal is sufficient and no further SW intervention is required. Here the data can be changed (“ID-Selection” Mode) or simply left constant (“Sync” Mode). Only a HW trigger needs to be set up.

In Mode 0, SPC is deactivated for this channel. A write access to SCRx does not initiate an SPC pulse transmission. All state transmitter machines are initialized.

In Mode 1, an SPC pulse is sent, each time SPC Control Register SCRx is written to. If a transfer is ongoing, the channel waits automatically until the internal transmission register is ready. Transmit Buffer Underflow bit TBIx is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. After the data was transferred to the internal transmission register, interrupt TDIx signals that a new value can be written. INTSTATx.TDIx must be cleared by SW. Independently from this interrupt pending bit, a new interrupt pulse is generated on each transfer of an SPC pulse. This mode is important for back to back transfers of several nibbles as in bidirectional SPC mode.

In Mode 2, an SPC pulse is sent, each time the first falling edge of any Synchronization / Calibration Pulse is received. In this mode, the programmable delay DEL is most useful. In SPC mode “Bidirectional Transmit” this mode is useful to synchronize the transmission. TDIx and TBIx work as in Mode 1.

In Mode 3, an SPC pulse is sent (with current DEL and PLEN) after each external trigger event (defined by IOCRx.ETS). This is most useful in SPC “sync” mode. TDIx and TBIx work as in Mode 1.

SCRx (x=0-14) Offset address: 118_H+x*40_H

SPC control register x Kernel Reset value: $0000\ 0000_H$

TRQ	BASE	DEL						TRIG		PLEN					
r	rw	rw						rw		rw					

Field	Bits	Type	Description
PLEN	5:0	rw	**Pulse Length** Defines the length of the pulse in tick times. The time base is the measured tick time of the latest received frame if selected so by BASE. In case this measured tick time was invalid or not already available after enable of the channel, the nominal time base of the module is used. 00_H Pulse length is 0 ticks … $3F_H$ Pulse length is 63 ticks
TRIG	7:6	rw	**Trigger Source and Mode Selection** Selects the Trigger Source and Mode. The internal sender state machine can be initialized by switching the channel off (TRIG is cleared) and on. This does not change the current register content. 00_B No Pulse is generated, OFF When cleared, an ongoing transfer is stopped immediately and the transmit output is driven recessive. 01_B Pulse starts immediately (no auto repetition) 10_B Pulse starts each time the first falling edge of any Synchronization / Calibration Pulse is received (auto repetition on next Sync. / Cal. Pulses) 11_B Pulse starts after each external trigger event. (auto repetition on next trigger) IOCRx.ETS selects the source of this event.
DEL	13:8	rw	**Delay Length** Selects how long the SPC pulse is delayed after the trigger condition. The time base is the measured tick time of the latest received frame if selected so by BASE. In case this measured tick time was invalid or not already available after enable of the channel, the nominal time base of the module is used. 00_H Pulse is not delayed 01_H Pulse is delayed by 1 tick 02_H Pulse is delayed by 2 ticks … $3F_H$ Pulse is delayed by 63 ticks
BASE	14	rw	**Time Base** Selects the Pulse Time Base 0_B Pulse is based on measured frequency of last Synchronization/ Calibration Pulse 1_B Pulse is based on nominal frequency
TRQ	15	r	**Transfer Request in Progress** While an SPC Pulse is being sent this bit is set. Write access is ignored.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

25.4.29 Receive data view register x

The Receive data view registers VIEWx stores the nibble pointers. They determine the sequence in which the received data nibbles are presented to the host. This reduces the SW effort to sort the nibbles. The data nibble that is received first in the received frame is moved to the location given in register VIEW.RDNP0, the second to VIEW.RDNP1 and so on until VIEW.RDNP7. If more than one VIEW.RDNPx point to a certain location in RDR, the last one will overwrite the previous ones. Example: two 12 bit values are transmitted. One with most significant nibble first and one with least significant nibble first. The frame looks like this: 456321_H. Note that the 1 is received as first data nibble and the 4 comes in as last data nibble. The actual signal values are $0x123_H$ and $0x456_H$. By using VIEWx this can be sorted out into two 16bit values by HW. In the example VIEWx would be set to: $73\ 654\ 012_H$. 73 is a dummy value and is not regarded if not more than 6 nibbles are received in a frame. The Register RDRx looks like this: $0x0456\ 0123_H$ to the host.

In the example RDR nibbles 3 and 7 contain $0x0000_B$ as the Receive Buffer is always cleared ($0x0000\ 0000_H$) before new data is received.

If a frame contains more than eight nibbles and the sorting can not be specified statically, VIEW can be set to e.g. $7654\ 3210_H$.

25.4.30 Interrupt status register x

The Interrupt status register INTSTATx contains status bits that show the status of any interrupt of SENT channel x.

The bits are set independently from the referring Interrupt Enable in Register INTENx. Thus they can be used as status bits as well e.g. by a SW based on polling.

On occurrence of FRI, FDI, CRCI, NVI and NNI error interrupts, the SENT state machine is reset and all corresponding received data until then is flushed and the state machine waits for a valid sync. Pulse in the input. Additionally, in case of CRCI, the RSI/RDI interrupts are skipped.

INTSTATx (x=0-14) Offset address: 120_H+x*40_H

Interrupt status register x Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RSI	0	rh	**Receive Success Interrupt Request Flag** This bit is set at the successfully received end of a frame. Depending on bit RCRx.CDIS this indicates a successful check of the CRC. This bit can be cleared by bit INTCLRx.RSI. This bit can be set by bit INTSETx.RSI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

(table continues...)

(continued)

Field	Bits	Type	Description
RDI	1	rh	**Receive Data Interrupt Request Flag** RDI is activated when a received frame is moved to a Receive Data Register RDR. Both RDI and RSI will be issued together in normal use cases where the frame size is not bigger than 8 nibbles and CRC is correct or not checked (if RCRx.CDIS is cleared). For frames with more than 8 nibbles RDI is issued after 8 nibbles. After the last nibbles of the frame are received, a last RDI and an RSI are issued together. Note that this is true independently from RCR.FDFL. This bit can be cleared by bit INTCLRx.RDI. This bit can be set by bit INTSETx.RDI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
RBI	2	rh	**Receive Buffer Overflow Interrupt Request Flag** This bit is set after a frame has been received while the old one was not read from RDRx. I.e. the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set.The old data is overwritten by the new data. This bit is NOT cleared by reading RDRx. This bit can be cleared by bit INTCLRx.RBI. This bit can be set by bit INTSETx.RBI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TDI	3	rh	**Transfer Data Interrupt Request Flag** This bit is set after the trigger condition was detected. Data to be transferred has been moved internally. Thus a new value can be written to SCRx. This can be used for back to back transfers. This bit is automatically cleared by writing SCRx. This bit can be cleared by bit INTCLRx.TDI. This bit can be set by bit INTSETx.TDI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TBI	4	rh	**Transmit Buffer Underflow Interrupt Request Flag** This bit is set after data has been completely transferred (PLEN exceeded) and no new data was written to SCRx. This bit is NOT cleared by writing SCRx. This bit can be cleared by bit INTCLRx.TBI. This bit can be set by bit INTSETx.TBI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

(table continues...)

(continued)

Field	Bits	Type	Description
FRI	5	rh	**Frequency Range Interrupt Request Flag** This bit is set after a Synchronization / Calibration pulse was received that deviates more than +/- 25% from the nominal value. The referring data is ignored. This bit can be cleared by bit INTCLRx.FRI. This bit can be set by bit INTSETx.FRI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
FDI	6	rh	**Frequency Drift Interrupt Request Flag** This bit is set after a subsequent Synchronization / Calibration pulse was received that deviates more than 1.5625% (1/64) from its predecessor. (See RCR.CFC) This bit can be cleared by bit INTCLRx.FDI. This bit can be set by bit INTSETx.FDI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
NNI	7	rh	**Number of Nibbles Wrong Request Flag** This bit is set after more nibbles have been received than expected or a Synchronization / Calibration Pulse is received too early thus too few nibbles have been received. This bit can be cleared by bit INTCLRx.NNI. This bit can be set by bit INTSETx.NNI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
NVI	8	rh	**Nibbles Value out of Range Request Flag** This bit is set after a too long or too short nibble pulse has been received. I.e. value < 0 or value > 15. This bit can be cleared by bit INTCLRx.NVI. This bit can be set by bit INTSETx.NVI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
CRCI	9	rh	**CRC Error Request Flag** This bit is set if the CRC fails. This bit can be cleared by bit INTCLRx.CRCI. This bit can be set by bit INTSETx.CRCI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

(table continues...)

(continued)

Field	Bits	Type	Description
WSI	10	rh	**Wrong Status and Communication Nibble Error Request Flag** In Short Serial Frame Mode (RCR.ESF is cleared), this bit is set if the Status and Communication nibble shows a start bit in a frame other than frame number n x 16. In Enhanced Serial Frame Mode this bit is without function. This bit can be cleared by bit INTCLRx.WSI. This bit can be set by bit INTSETx.WSI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
SDI	11	rh	**Serial Data Receive Interrupt Request Flag** This bit is set after all serial data bits have been received via the Status and Communication nibble. Depending on bit RCRx.SCDIS this indicates a successful check of the CRC. This bit can be cleared by bit INTCLRx.SDI. This bit can be set by bit INTSETx.SDI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
SCRI	12	rh	**Serial Data CRC Error Request Flag** This bit is set if the CRC of the serial message fails. In Enhanced Serial Message Format, this includes a check of the Serial Communication Nibble for correct 0 values of bit 3 in frames 7, 13 and 18. This bit can be cleared by bit INTCLRx.SCRI. This bit can be set by bit INTSETx.SCRI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
WDI	13	rh	**Watch Dog Error Request Flag** This bit is set if the Watch Dog Timer of the channel x expires. This bit can be cleared by bit INTCLRx.WDI. This bit can be set by bit INTSETx.WDI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
0	31:14	r	**Reserved** Read as 0.

25.4.31 Interrupt set register x

The Interrupt set register INTSETx contains control bits that trigger an interrupt pulse for any interrupt of SENT channel x.

INTSETx (x=0-14) Offset address: 124_H+x*40_H

Interrupt set register x Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RSI	3:0	rw	**Interrupt Node Pointer for Interrupt RSI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RSI (if enabled by bit INTENx.RSI). 0_H Trigger Output TRIGO0 is selected … F_H Trigger Output TRIGO15 is selected
RDI	7:4	rw	**Interrupt Node Pointer for Interrupt RDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RDI (if enabled by bit INTENx.RDI). For bit field definition, see RSI.
RBI	11:8	rw	**Interrupt Node Pointer for Interrupt RBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.RBI (if enabled by bit INTENx.RBI). For bit field definition, see RSI.

(table continues...)

(continued)

Field	Bits	Type	Description
TDI	15:12	rw	**Interrupt Node Pointer for Interrupt TDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.TDI (if enabled by bit INTENx.TDI). For bit field definition, see RSI.
TBI	19:16	rw	**Interrupt Node Pointer for Interrupt TBI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.TBI (if enabled by bit INTENx.TBI). For bit field definition, see RSI.
ERRI	23:20	rw	**Interrupt Node Pointer for Interrupt FRI, FDI, NNI, NVI, CRCI, WSI, SCRI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.FRI (if enabled by bit INTENx.FRI) or INTSTATx.FDI (if enabled by bit INTENx.FDI) or INTSTATx.NNI (if enabled by bit INTENx.NNI) or INTSTATx.NVI (if enabled by bit INTENx.NVI) or INTSTATx.CRCI (if enabled by bit INTENx.CRCI) or INTSTATx.WSI (if enabled by bit INTENx.WSI) or INTSTATx.SCRI (if enabled by bit INTENx.SCRI) For bit field definition, see RSI.
SDI	27:24	rw	**Interrupt Node Pointer for Interrupt SDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.SDI (if enabled by bit INTENx.SDI). For bit field definition, see RSI.
WDI	31:28	rw	**Interrupt Node Pointer for Interrupt WDI** This bit field defines the interrupt node, that is requested due to the set condition for bit INTSTATx.WDI (if enabled by bit INTENx.WDI). For bit field definition, see RSI.

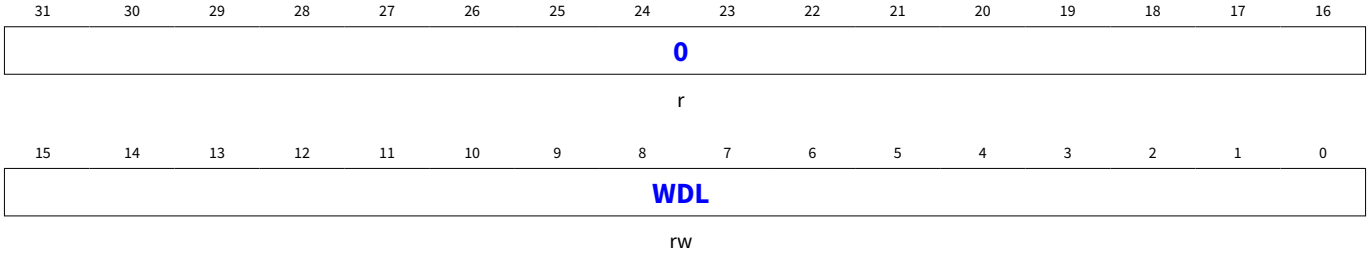
25.4.35 Watch dog timer register x

The Watch dog timer register WDTx contains the time out value for channel x. The internal Watch Dog timer is cleared and started automatically each time an RDI (Receive Data Interrupt Request Flag) is set in the INTSTAT of the referring channel and also on any write to WDL that sets WDL>0. Normally the WDTx.WDL is configured only once at module setup. However, if WDTx.WDL is written again with a value larger than 0 during frame reception, the internal Watch Dog timer is NOT cleared and restarted. Instead, the Watch Dog Timer keeps on counting and comparing to the new value. This is not recommended but offers flexibility in exceptional cases. Still, if WDTx.WDL is written with 0 during frame reception, the internal Watch Dog timer is cleared and stopped.

The value entered here defines the time in multiples of Ttick_x (defined in CFDR) from the last RDI on channel x. The internal Watch Dog Timer is compared to WDLx. A match triggers interrupt WDI and stops the internal Watch Dog Counter x. After such a match, the Watch Dog Timer will be cleared and started automatically with clearing bit WDI (by setting INTCLR.WDI). I.e. the Watch Dog Counter is running only if interrupt flag WDI is cleared. If WDL is cleared, the WDTx is stopped/disabled.

WDTx (x=0-14) Offset address: 134_H+x*40_H

Watch dog timer register x Kernel Reset value: $0000\ 0000_H$



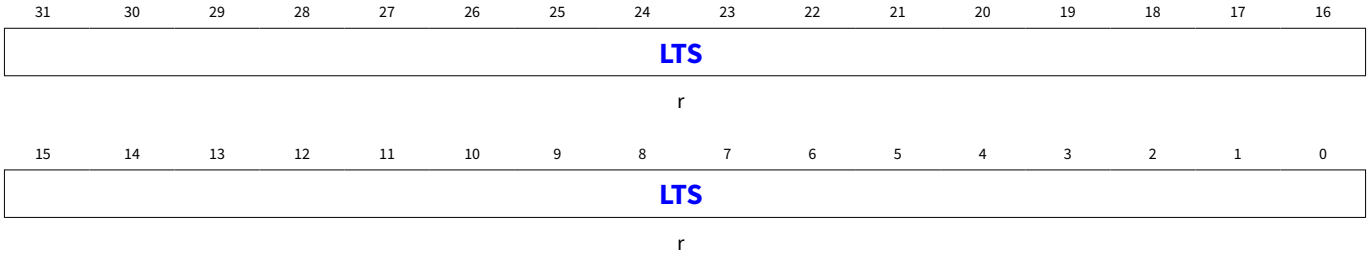
Field	Bits	Type	Description
WDL	15:0	rw	**Watch Dog Timer Limit** for channel x .
0	31:16	r	**Reserved** Read as 0; should be written with 0.

25.4.36 Receive time stamp register x

The SENT Channel x Receive time stamp register contains read-only information about the time the last frame for channel x was received. Time is captured with the second falling edge, i.e. at the Status/Communication data pulse.

RTSx (x=0-14) Offset address: $A80_H+x*4$

Receive time stamp register x Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
LTS	31:0	r	**Last Receive Time Stamp for Channel x** This bit field shows the time stamp of the last frame on channel x.

26 Peripheral Sensor Interface (PSI5)

The PSI5 module communicates with the external world through one I/O line for each channel. The PSI5RXx lines are the receive data input signals. The transmit lines PSI5TXx are on separate GPIO ports. The receive and transmit paths are always routed to two different ports.

26.1 Feature list

- According to PSI5 protocol specification V2.1 and extended powertrain substandard
- Flexibility in configuration and monitoring for software
  - Supports both Asynchronous and Synchronous data transmission modes (controlled by microcontroller in Synchronous mode)
  - Support of Enhanced Serial Messages according to SENT SAE J2716 JAN 2010
  - Three 64-bit downstream data registers for data input, data preparation and data output
  - Sticky interrupt flags, error interrupt optional (default disabled)
  - One sum interrupt for general events
  - One sum interrupt on selectable errors
  - Optional output inversion for use of external open drain transistor
  - Optional input inversion for use of external open transistor for level shifting
- Receive PSI5 frames based on the protocol standard
  - Data rates of 125 kbit/s and 189 kbit/s are supported
  - Independent and parallel PSI5 channels implemented
  - Supports 6 sensor slots per channel
  - Decoding Manchester protocol
  - Error recognition in Manchester code
  - CRC check of received sensor data implemented but CRC code transparent
  - 24-bit time stamp (resolution: 1 µs)
- Transmit PSI5 frames based on the protocol standard
  - Support of ECU to Sensor communication
  - Configurable data word length 8, 10, 16, 20, 24 bits according to standard (PSI5 V1.3)
  - Support of non-standard V1.3 frame length: 11 to 33 bits
  - Generation of 3 or 6 CRC bits for downstream data
  - Start sequence and CRC generator for downstream data
- Message Storage and FIFO access
  - Storage of up to 32 frames per channel with time stamp
  - FIFO access and management
  - Buffer overrun detection
  - Buffer memory status overview registers
- Sending sync pulses
  - Downstream data transmission by variation of pulse length (PSI5 V2.1)
  - Downstream data transmission by leaving out sync pulses (PSI5 V1.3)
  - Staggering sync pulses of all channels to avoid too many channels sending sync pulses in parallel

26.2 Functional overview

The PSI5 IP-module performs communication according to the PSI5 specification V2.1 and also supports the extended powertrain substandard. PSI5 provides high speed and high reliability data transfer.

The PSI5 kernel consists of 2 independent and parallel PSI5 channels each of which support 6 sensor slots. The IP also consists of a Manchester Decoding block that decodes the received PSI5 data frames.

The Buffer Memory holds up to 32 frames per channel along with the timestamp.

The Sync + Data Pulse Generation block generates sync pulses to trigger a data frame for data acquisition from a sensor or for ECU to sensor communication.

The Timestamp Generation block offers three time bases to select from for timestamping.

PSI5 acts as a slave on the FPI bus. The Clock Control block is driven by the system clock frequency f_{SPB}. The Clock Control block produces a total of 5 clock signals.

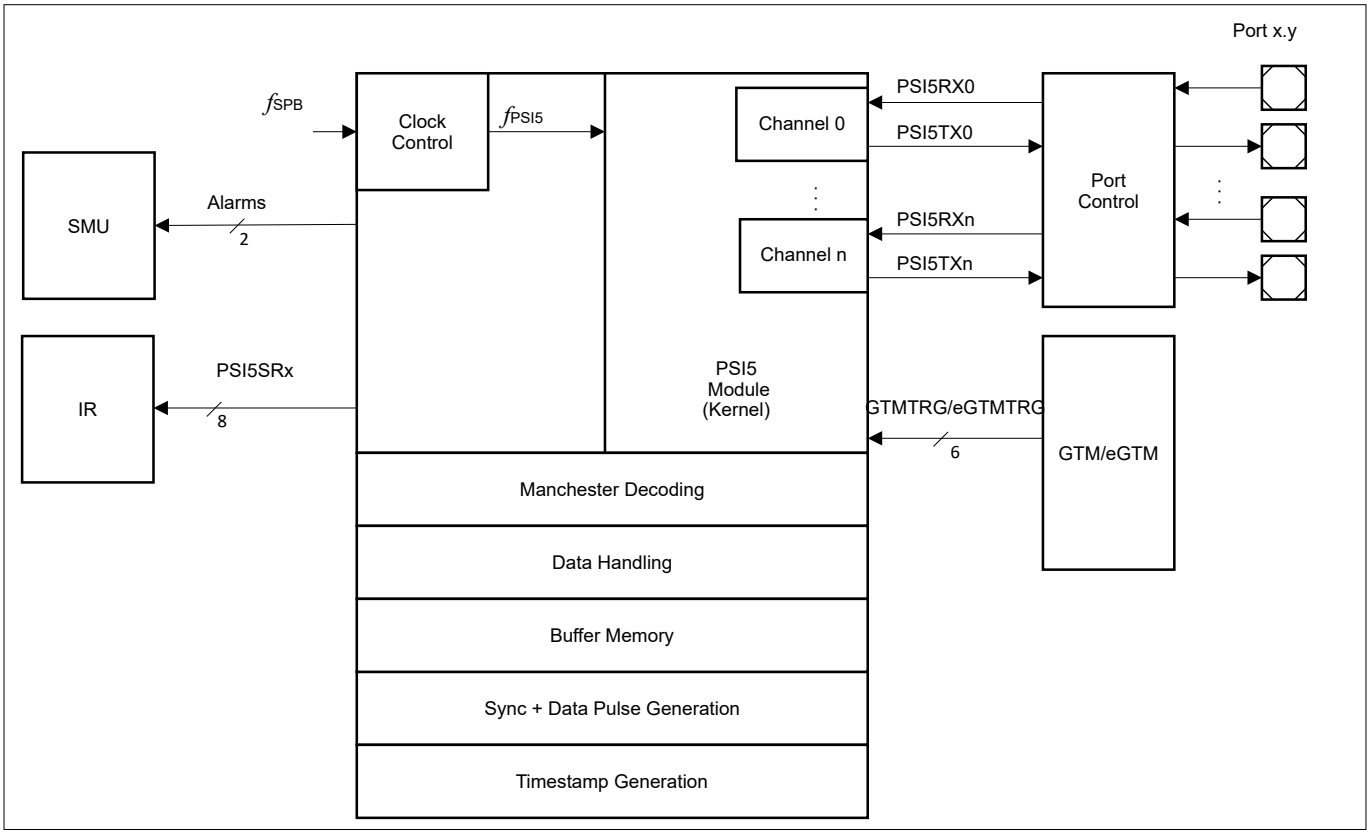

Figure 512 PSI5 block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

The Peripheral Sensor Interface is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of airbag systems.

The PSI5 interface provides a current loop-based serial communication link typically used to connect airbag sensors or other peripheral devices.

While the physical layer is done externally, this module manages protocol handling and data representation to the application. Note that there is no on-chip PHY. The current to voltage and voltage to sync pulse translation is done externally as shown in the figure below.

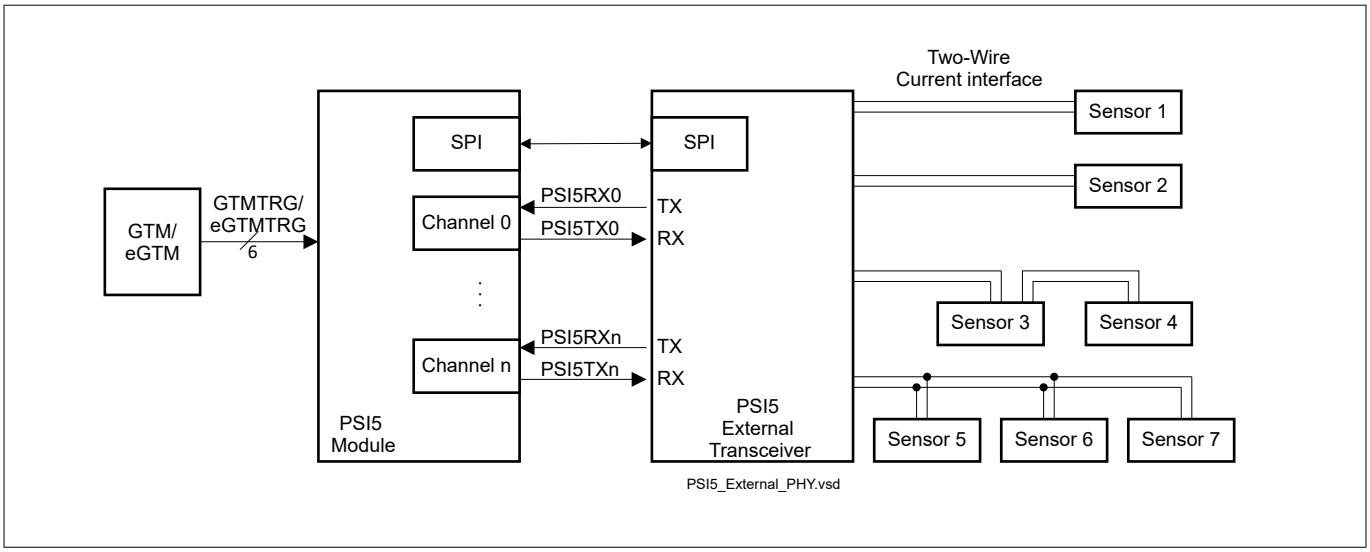

Figure 513 PSI5 module connected to external PHY

Receive data on a PSI5 channel can be set up according to the underlying application. In particular the number of bits is configurable.

The message storage consists of a 32-bit buffer register for each channel and an additional 32-bit register containing the 24-bit time stamp and additional status bits. These 64 bits per frame are additionally stored in a buffer of 32 lines per channel.

In ECU to sensor communication mode, the module can provide regular sync pulses and select between internal and external timer or trigger resources. It also supports setting up the sensor and retrieving sensor status information.

The register set of the PSI5 module can be accessed directly by the CPU for configuration, data read out and status query.

26.3 Functional description

The following section explains the different PSI5 modes of operation and frame formats.

26.3.1 General operation

PSI5 is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10-bit A/D converters and PWM and as a simpler low cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

The following figure shows a typical device application in which a PSI5 interface reads a sensor device.

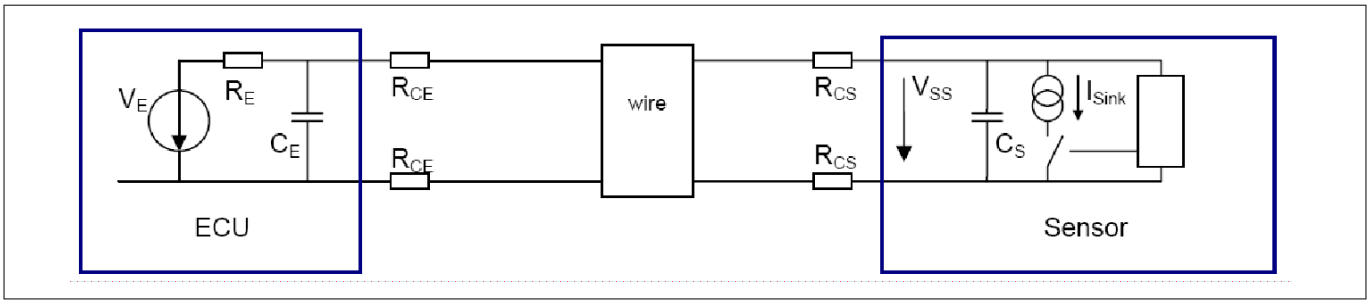

Figure 514 PSI5 to external device connection

PSI5 communication is:

- Asynchronous, unidirectional from sensor to controller without any synchronization
- Synchronous, bidirectional with a sync pulse from the ECU triggering messages
- Synchronous, bidirectional, sync pulses additionally coding data from ECU to sensor

The sensor signal is transmitted as a series of current pulses in Manchester coding.

The sync pulses are transmitted by increasing the voltage.

The following figure shows a typical device application in which a PSI5 ECU reads multiple PSI5 sensor devices on a bus.

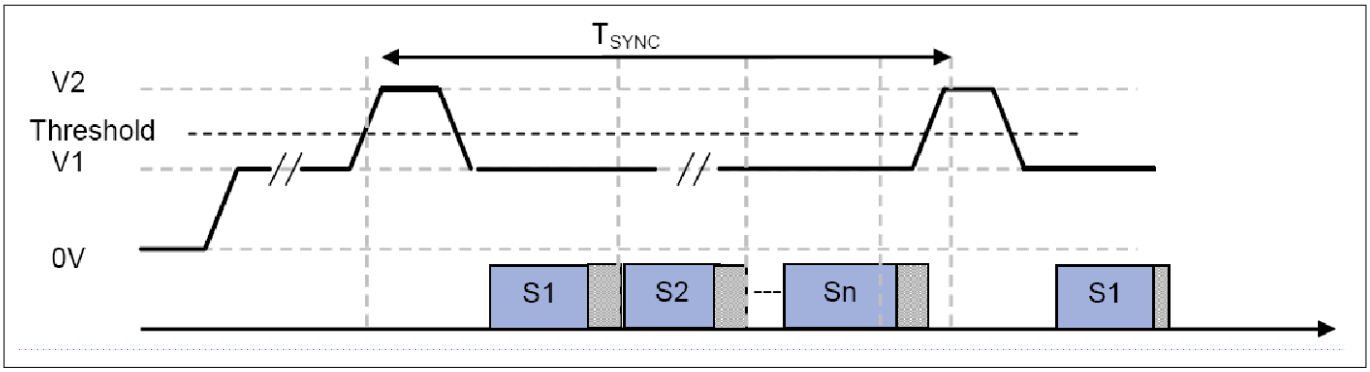

Figure 515 PSI5 frames with sync pulses

26.3.2 Definitions

Acronym	Definition
ASIC	Application specific integrated circuit
ECU	Electronic control unit

Acronym	Definition
SOF	Start of frame
EOF	End of frame
STS	Start sequence
AD	Address data (for example of ECU to Sensor frame)
SD	Send data (Payload of ECU to Sensor frame)

26.3.3 PSI5 operation

The Module supports two modes:

- Standard PSI5 mode supports communication fully compliant to V1.3
- Extended PSI5 mode supporting additional bit-fields and longer frames compliant to V2.1 (see below)

In Standard V1.3 mode, a specific start condition and a start sequence switch the sensor in ECU to Sensor Communication mode. In this mode, the sync pulses are no longer used as triggers for data frames but are interpreted as data. A pulse represents a 1 and a missing pulse represents a 0. This requires isochronous pulses.

In Extended mode (powertrain substandard), the pulse width is modulated. A standard pulse represents a 0, a longer pulse a 1. This way continuous data transmission can be achieved.

26.3.4 Frame formats and definitions

This section describes the frame formats and definitions of the PSI5 protocol.

26.3.4.1 PSI5 V1.3 frame

The following figure shows the layout and definitions of a standard PSI5 frame. Note that the PSI5 standard specifies that the least significant bit is sent out first. See standard for CRC and parity definition.

Example: 16 Bit Data Word „0xAD2C“ with 3-Bit CRC

S1	S2	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	D10	D11	D12	D13	D14	D15	C2	C1	C0
0	0	0	0	1	1	0	1	0	0	1	0	1	1	0	1	0	1	1	0	0
		C = „1100“				2 = „0010“				D = „1101“				A = „1010“						

Figure 516 Standard PSI5 frame

26.3.4.2 Extended PSI5 frame

The following figure shows the layout and definitions of an extended PSI5 frame as defined in V2.1 for automotive powertrain application. Note that the PSI5 standard specifies that the least significant bit is sent out first.

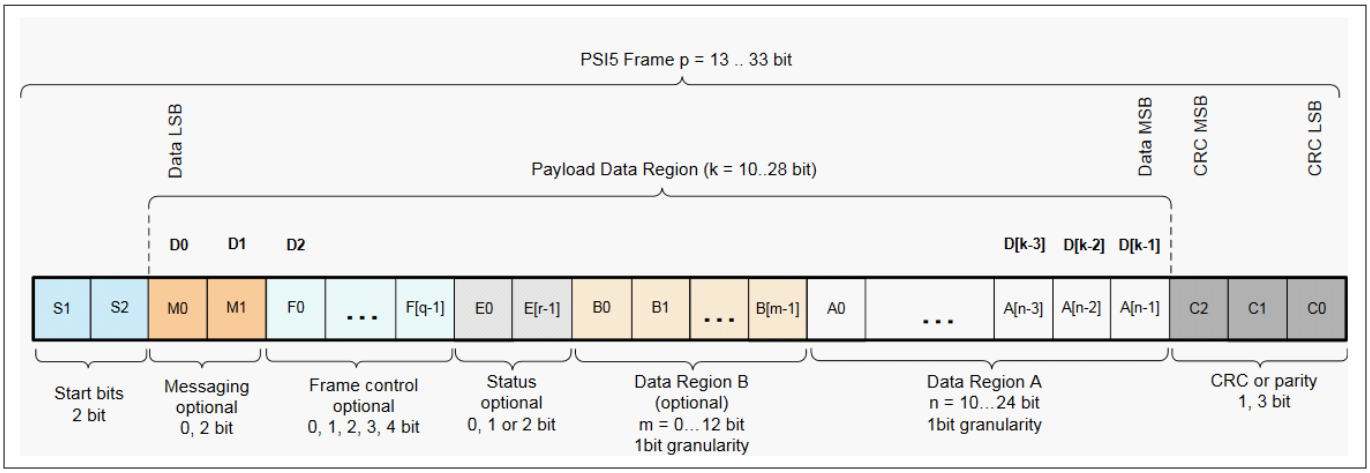

Figure 517 Extended PSI5 frame

Extended PSI5 sensor to ECU message CRC

The transmission of PSI5 data is checked by the following protection modes. The transmission error detection must be selectable:

1. 1-bit even parity
2. 3-bit CRC

The applied generator polynomial of the CRC is $g(x) = 1 + x + x^3$ with a binary start value (seed) “111”. The transmitter shall extend the data bits by three zeros (as MSBs). This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits shall be ignored in this check. When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum. These three check bits shall be transmitted in reverse order (MSB first: C2, C1, C0).

In this implementation the number of elements is configurable no longer or shorter than 8..28 bits.

26.3.4.3 Enhanced serial message (“slow channel”)

The serial data is transmitted bit-wise per frame in bits [1:0] of the Messaging bit-field of 18 consecutive messages from the transmitter.

26.3.4.3.1 Enhanced serial data frame

Serial data (“slow channel”) is communicated in an 18 frame sequence as shown in the following figure. The start of an Enhanced Serial Message is indicated by the unique pattern “1111110” in bit M1 constructed across 7 consecutive PSI5 messages. In message 1 - 6 they are set to “1”. In message 7, 13 and 18 they are set to “0”. 18 consecutive PSI5 messages must be successfully received (no errors) for the Enhanced Serial Message data to be received. The CRC generation is different from the CRC generation on the data nibbles. (See SENT SAE J2716 JAN 2010 [3])

The serial message frame contains 21 bits of message data and a 6-bit frame-check sequence. Two different configurations can be chosen:

- 12-bit data and 8-bit message ID
- 16-bit data and 4-bit message ID

A configuration bit (serial data bit M1, serial communication Messaging bits of frame No. 8) determines the configuration of the Enhanced Serial Message frame. It determines how the PSI5 module automatically interprets the serial data.

- Configuration bit = 0: 12-bit data and 8-bit message ID
- Configuration bit = 1: 16-bit data and 4-bit message ID

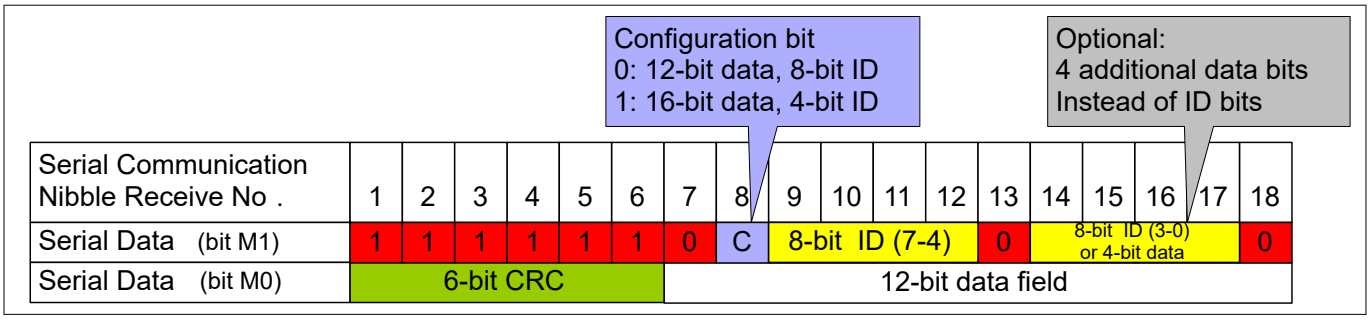

Figure 518 Enhanced serial data frame

The following figure shows in detail the frame structure for Enhanced Serial Data frames with configuration bit = 0.

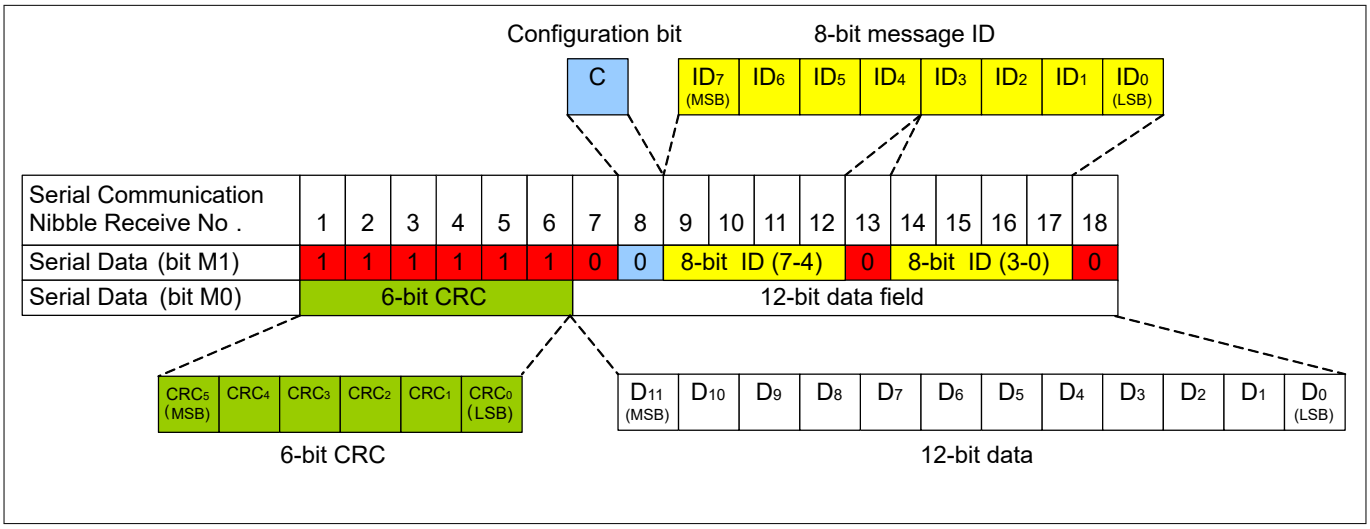

Figure 519 Configuration bit = 0

The following figure shows in detail the frame structure for Enhanced Serial Data frames with configuration bit = 1.

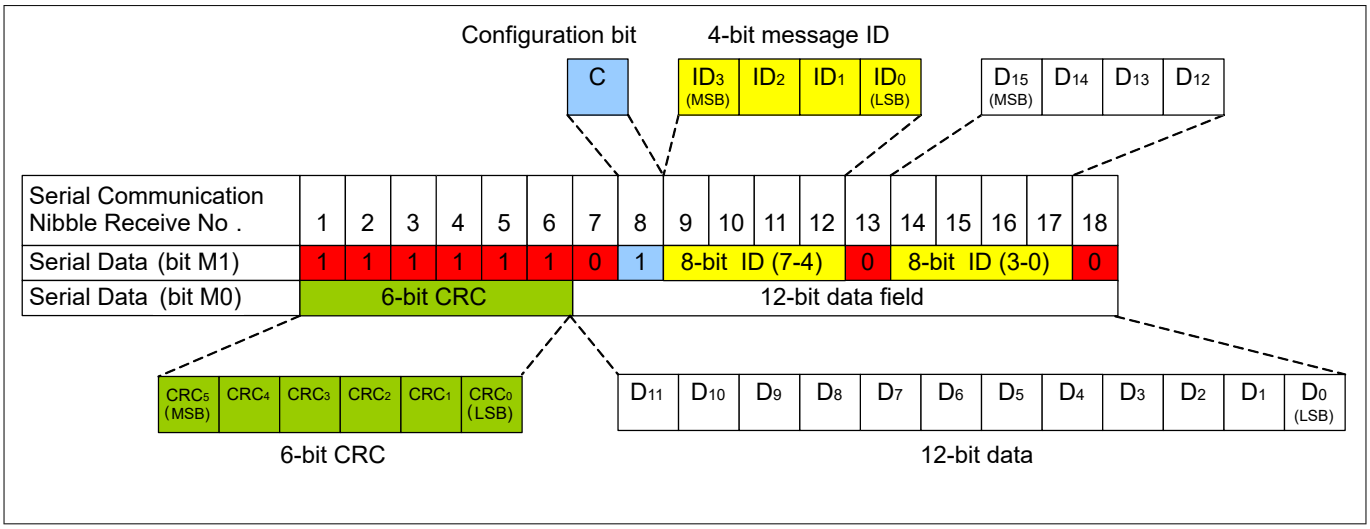

Figure 520 Configuration bit = 1

26.3.5 Sync pulses

Sync pulses are used for two different purposes:

- Triggering a data frame for data acquisition from a sensor or
- ECU to sensor communication

26.3.5.1 Synchronous transmission

In the Synchronous mode, the sensor (slave) starts to transfer a complete data frame only after a sync pulse is forced by the master on the output PSI5TXx pin. An external PHY translates this pulse into a voltage increase. The sensor then initiates a measurement and starts to calculate the new output data value. The data follows in a standard PSI5 frame, starting with the 2 start bits, data and parity or CRC. The timing diagram in the following figure visualizes a synchronous transmission.

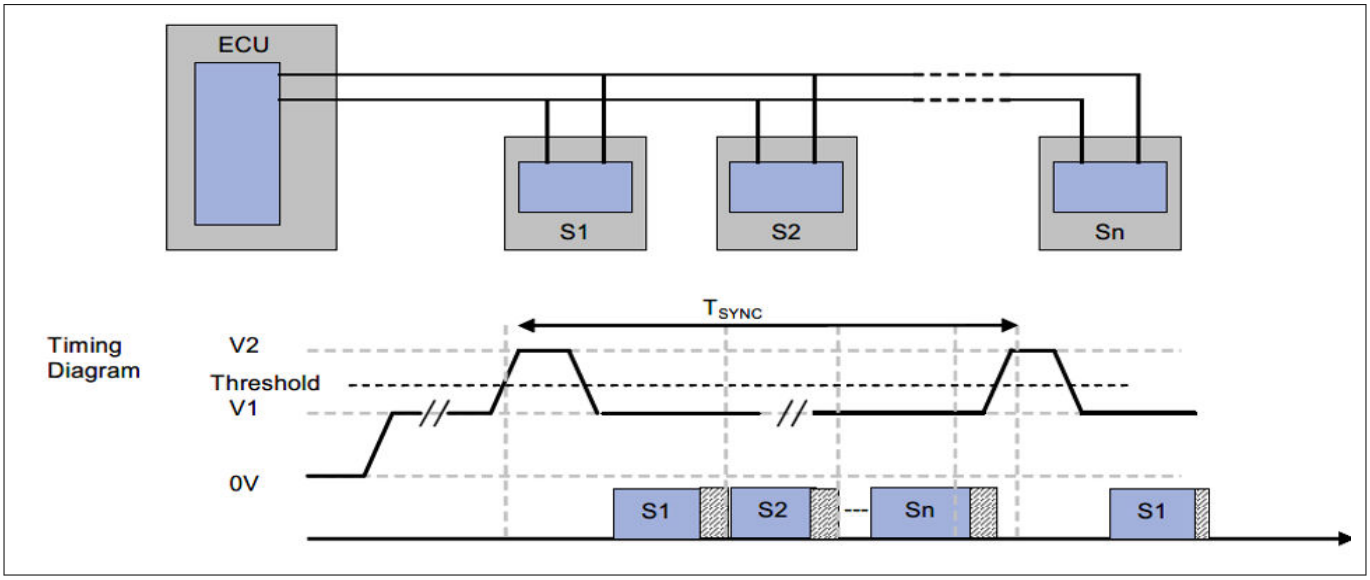

Figure 521 Synchronous transmission

26.3.5.2 ECU to sensor communication

Two versions are supported:

- Legacy PSI5 V1.3 and
- Extended powertrain substandard

Legacy version

The legacy version uses sync pulses as start condition and start bits to signal the start of the ECU to sensor communication. From this start on, the sync pulses are interpreted by the sensor as data. See standard for CRC and parity definition.

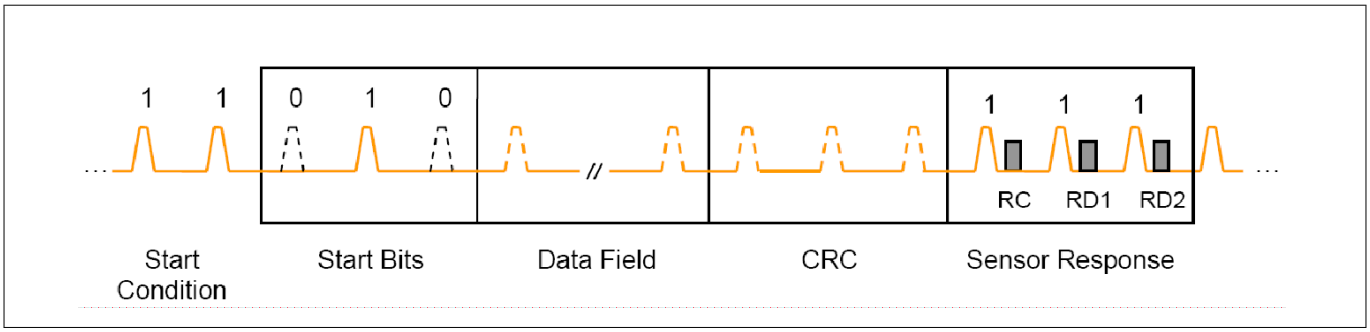

Figure 522 ECU to sensor (legacy)

Extended powertrain substandard

The revised version is the extended powertrain substandard that allows for modulation of the sync pulse duration. This way bidirectional communication is possible continuously. Every ECU to sensor frame starts with a nine-bit frame-start-sequence [0 1 1 1 1 1 1 1 0]. Synchronization is possible at the beginning of each frame.

Sync bits

A consecutive train of seven ones within the transmitted data could be misinterpreted as a frame start condition. Therefore a sync-bit (logical 0) is inserted at every seventh bit position (after every six bits of the sensor address and the payload data). With respect to the data transmission, these sync bits are treated like stuffing bits, which are removed at the receiver side.

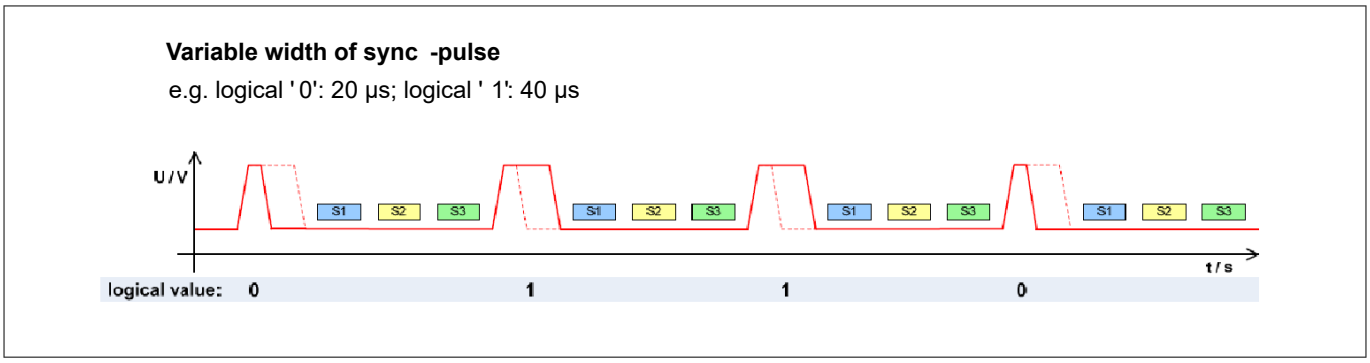

Figure 523 ECU to sensor, bit transmission (extended)

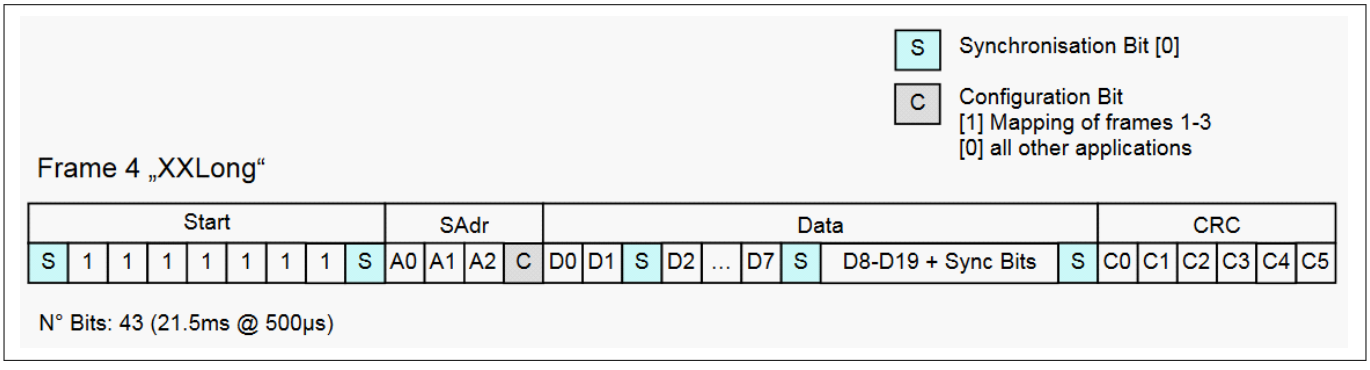

Figure 524 ECU to sensor, frame format (extended)

Extended ECU to sensor message CRC

The ECU to sensor frame has a 6-bit CRC.

The generator polynomial of the CRC is $g(x) = x^6 + x^4 + x^3 + 1$ with a binary CRC initialization value “010101”. The transmitter extends the data bits by six zeros (as MSBs). This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits and sync bits are ignored in this check. When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum. These six check

bits shall be transmitted LSB first [C0, C1…C5]. In this implementation the number of elements is configurable and no longer than 24 bits (standard is 4 address and 20 data bits)

26.3.6 Manchester decoding

Decoding of the Manchester protocol:

- The Manchester decoder uses a nominal 4 MHz/6.048 MHz sampling clock (32 samples per bit)
- A sampling counter, running at the sampling clock rate, controls the sampling of the incoming Manchester encoded data
- The Manchester signal transition occurring in the middle of the bit time resets the counter, making the counter count from 0-31 (nominally) between successive mid-bit times
- Detection of the mid-bit transitions uses three consecutive samples (011 = rising edge, 100 = falling edge)
- The maximum value of the 6-bit counter shall be 41, at which point a Manchester error is detected due to lack of a transition, and the counter rolls over to 0 (“idle time”)
- The value of a Manchester encoded input data bit is determined by proper logic levels before and after a transition and proper timing of the transition
- Bit-value determination nominally takes place at the $\frac{1}{4}$ and $\frac{3}{4}$ bit times, with the mid-bit transition occurring at the $\frac{1}{2}$ bit time. This is nominally at sampling counter values of 8 ($\frac{1}{4}$ bit time) and 24 ($\frac{3}{4}$ bit time)
- Logic levels are determined using a 2 out of 3 majority vote of consecutive samples. (samples 23, 24, 25 and 7, 8, 9)
  - The combinations 111, 011, 101, 110 indicate a 1
  - The combinations 000, 001, 010, 100 indicate a 0

Manchester-2 is used by the PSI5 standard:

- Start bits = 0 0
- Falling edge corresponds to logical 1
- Rising edge corresponds to logical 0
- Least significant bit (LSB) is sent out first

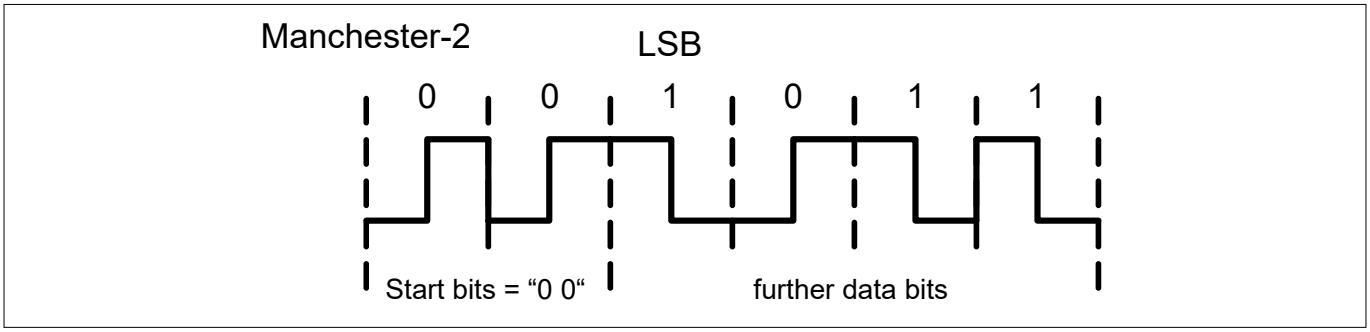

Figure 525 Manchester-2

Sampling details

- Recognition of frame start
  - Manchester decoding requires a deterministic start of frame
  - Frame separation: An idle time of at least one bit time is required
  - Idle time is the time without edges on the line that is required to safely determine that no frame is being transferred (1 bit time + tolerance = > 41 samples)

The idle counter starts counting on a falling edge, after sync pulse or after blank out time, if the channel is switched on. If the line is low, it counts up to 41 and stops and activates the idle flag until the line shows a rising edge. This clears the idle counter
  - After this idle time, a determined start bit sequence is required for synchronization of the phase of receiver and transmitter (0 0 in case of Manchester encoding)
  - If no idle time occurs at the end of a frame, bits after the configured length are dropped
  - If a second frame comes too early (collision = no idle time), the second frame is dropped. The decoder waits for an idle time for resynchronization
  - Idle time is particularly required in case of Manchester errors and frame collisions for a safe resynchronization. Otherwise, two successive zeros in a damaged frame/a second colliding frame could lead to reception of wrong data. Note that back to back transfers of correct frames are forbidden by standard (T_gap required)
  - This idle time is required as well after a regular end Of frame, sync pulse or a blank out time to avoid inadvertent synchronization inside frames under transmission
- Bit sampling
  - After the start of the protocol is detected and an edge on the line signal is detected and the sample counter is greater than 25 the sample counter value is set to 0
  - If the sample counter is 41, the counter value is set to 0 and stops
  - The sample counter will be incremented each clock cycle
  - When the sample counter has the value 9, the level is stored in cnt9_val
  - When the sample counter has the value 25, the level is stored in cnt25_val
  - cnt9_val and cnt25_val are reset if no frame is detected. Otherwise, a wrong start bit detection could occur
- Bit evaluation
  - When the sample counter value is 16, the decision is done for the new sample value:
  - Check if the last edge was detected correctly (edge detected between sample counter value 25 and sample counter value 41)
  - If true:
  - Cnt_25_lev = 0 and cnt_9_lev = 1 => new sample = 0
  - Cnt_25_lev = 1 and cnt_9_lev = 0 => new sample = 1
  - If the edge check fails or cnt_25_lev = cnt_9_lev, Manchester Error is assumed

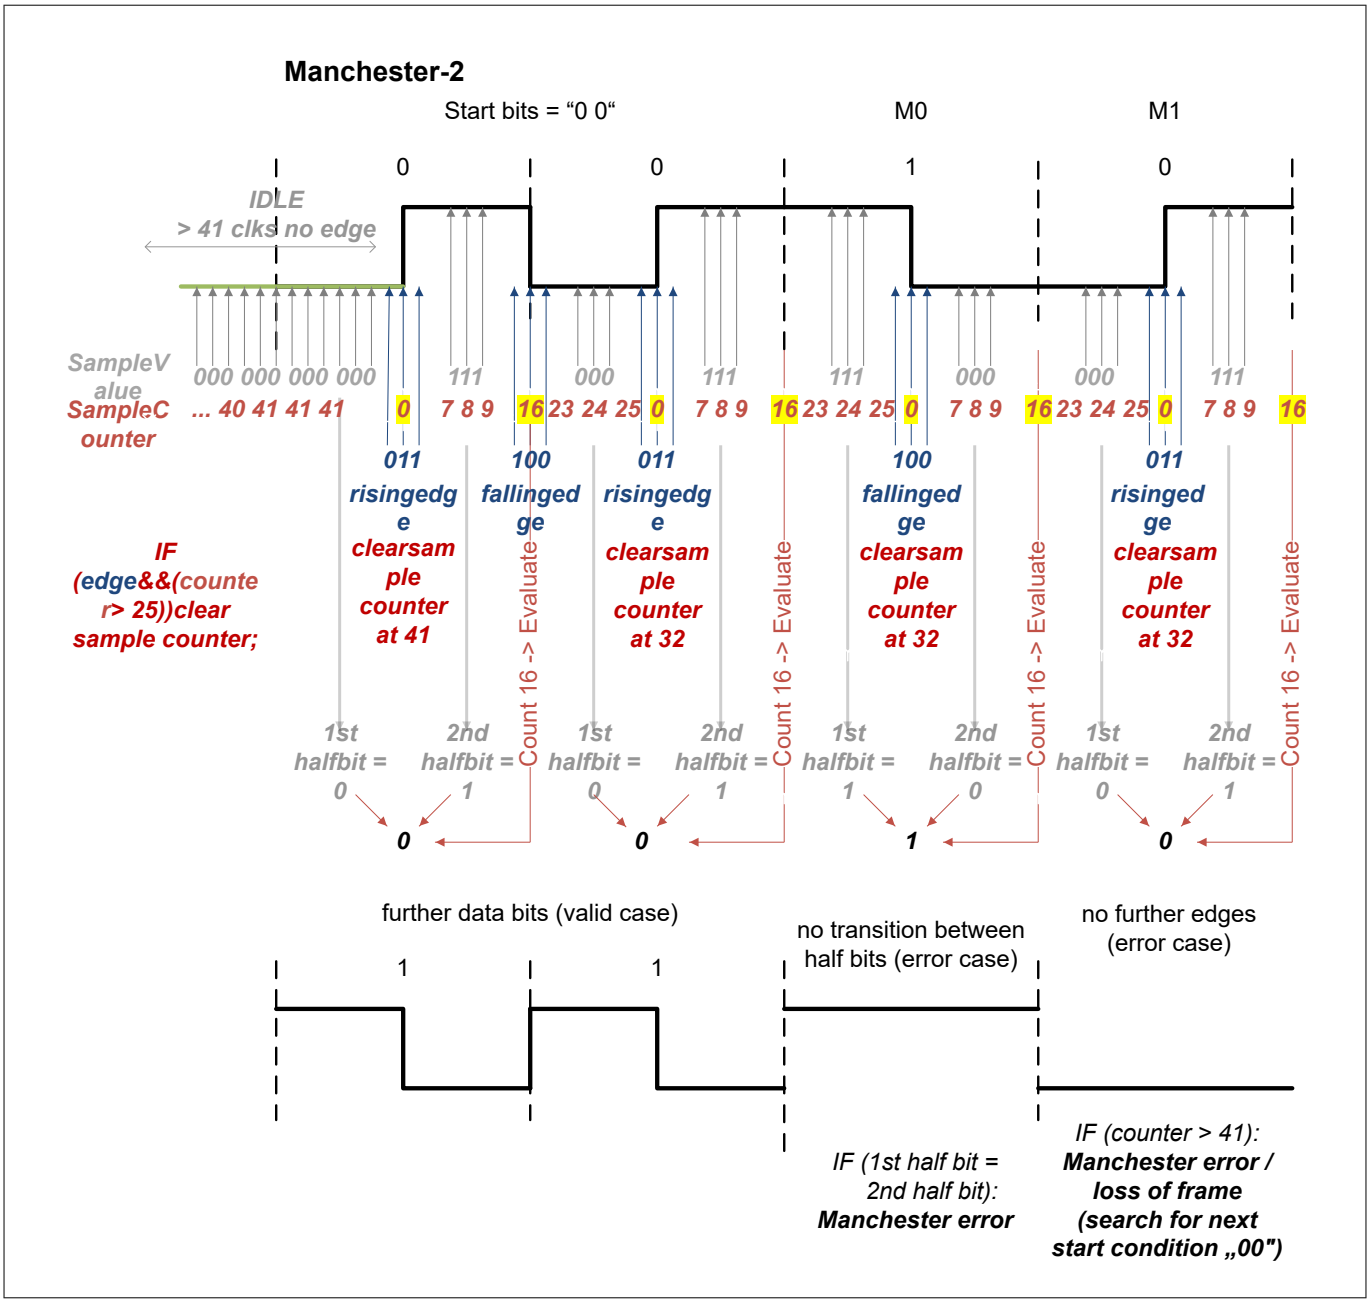

Figure 526 Manchester decoder

Definition of Manchester error (ME)

- Two half bits have the same value => ME, the decoder waits for an idle time
- > 41 sample times no edge => ME
- The ME has no dedicated interrupt but will lead to various error responses depending on where it occurs. See the following table

Table 1181 Error responses due to ME

Manchester error (ME) case	Response	Comment
First ME in start bits	Discard frame	NFI (if RCRBx.FEC is set) and empty frame stored (if RCRBx.FEC and RCRBx.VBS is set), Timestamp = end of slot where SOF happened. This is true even if these start bits should start before WDL and end after WDL
Start bits cut off by blank out time (BOT) or sync pulse (frame starts without leading idle time)	Discard frame	NFI (if RCRBx.FEC is set) and empty frame stored (if RCRBx.FEC and RCRBx.VBS is set)
First ME in Messaging bits	If MSG is set: MEI	Frame is stored, bits after error are lost (“0”)
	If MSG cleared: NBI	
First ME in data, parity or CRC / Frame ends too early	NBI	Frame is stored, bits after error are lost (“0”)
Frame ends too late (longer than PDL)	No NBI	Bits after PDL are cut off and EOF is detected. Frame is stored
Collision (idle time missing)	Discard 2nd frame	If the 1st frame was too late and running over WDL or If the 2nd frame was too early and running over WDL then for 2nd frame, NFI (if RCRBx.FEC is set) and empty frame stored (if RCRBx.FEC and RCRBx.VBS is set), Timestamp = end of 2nd slot
In all cases, the receiver waits for an idle time followed by the start bits “0 0” before a new frame is detected		

26.3.7 Bit rate generation

The bit rate of each channel is individually selectable from the 2 standard bit rates 125 kHz and 189 kHz. The two referring over sampling frequencies are generated centrally.

This chapter shows in detail how the bit rate for each channel is adjusted.

In the first stage, a global fractional divider serves as pre-divider. Its intermediate frequency $f_{fracdiv}$ can be set up so that it is handy as input frequency for the different PSI5 channels. Usually this can be left unused.

For each of the two bit rates there is an own fractional divider. Each channel can select one out of the two clock signals f_{125} and f_{189}.

The PSI5 module provides 5 clock signals centrally (see following figure):

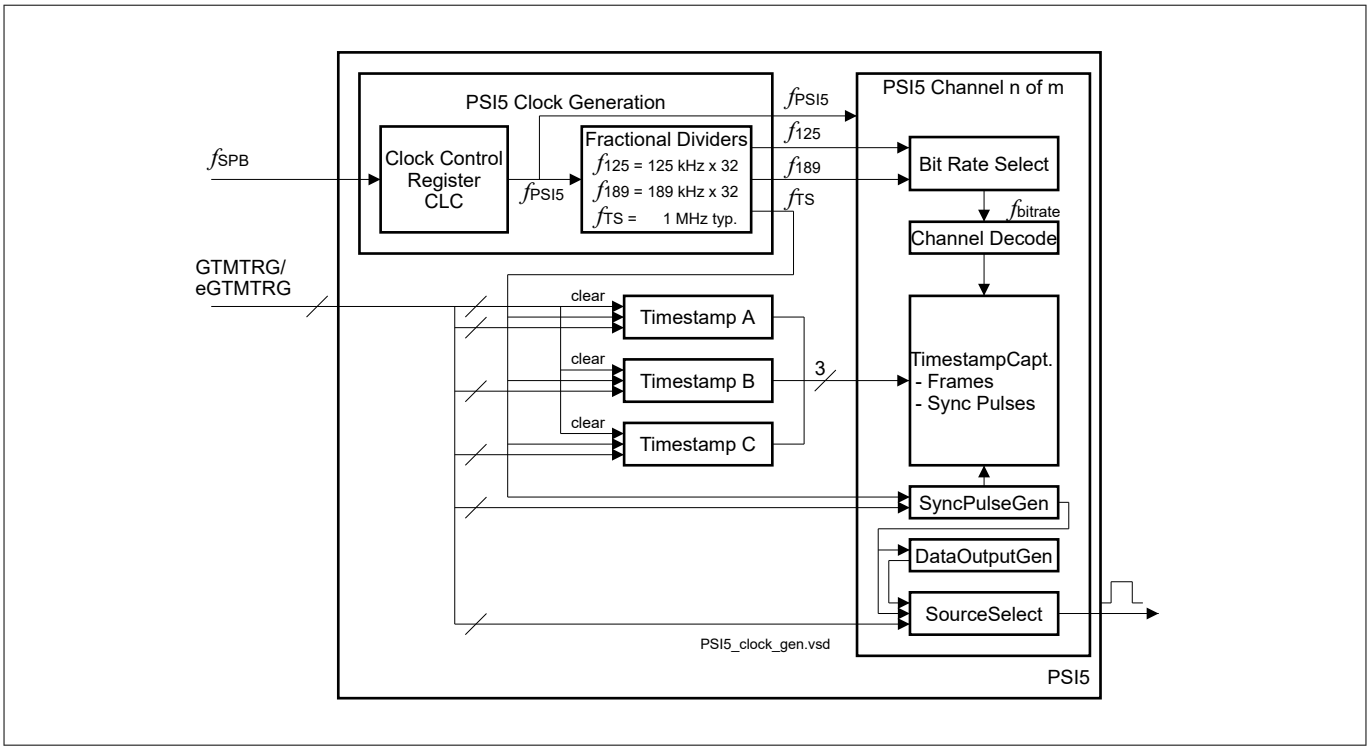

Figure 527 PSI5 module clock generation

- f_{PSI5}
  This is the module clock that is used inside the PSI5 kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{PSI5} is always identical to the system clock frequency f_{SPB}. The Clock Control register CLC makes it possible to enable/disable f_{PSI5} under certain conditions
- $f_{fracdiv}$
  This clock is the module clock that is used inside the PSI5 kernel for bit rate generation of the serial channels. The Fractional Divider register FDR controls the frequency of $f_{fracdiv}$. Usually not required and set to 1
- f_{125}
  This clock is the oversampling clock that can be selected as the bit rate frequency inside a PSI5 channel. The Fractional Divider register for Lower Bit Rate FDRL controls the frequency of f_{125}. The clock drives the Manchester decoder and needs to be 32 times faster than the nominal bus frequency
- f_{189}
  This clock is the oversampling clock that can be selected as the bit rate frequency inside a PSI5 channel. The Fractional Divider register for Higher Bit Rate FDRH controls the frequency of f_{189}. The clock drives the Manchester decoder and needs to be 32 times faster than the nominal bus frequency
- f_{TS}
  This clock is used to drive the central timestamp counter. It can be selected to drive the global sync pulse time base and inside the PSI5 channels to drive the local Watchdog timers. The Fractional Divider register for Timestamp FDRT controls the frequency of f_{TS}. This is usually adjusted to 1 MHz/1 µs period time

The following two formulas define the frequency of $f_{fracdiv}$:

$$f_{\text{fracdiv}} = f_{\text{PSI5}} \div (1024 - \text{FDR.STEP});\ \text{FDR.DM} = 01_{\text{B}} \tag{15}$$

$$f_{\text{fracdiv}} = f_{\text{PSI5}} \times \text{FDR.STEP} \div 1024 \text{ with } \text{STEP} = 0...1023; \text{FDR.DM} = 10_{\text{B}} \quad (16)$$

The following two formulas define the frequency of f_{125}:

$$f_{125} = f_{\text{fracdiv}} \div (1024 - \text{FDRL.STEP}); \text{FDRL.DM} = 01_{\text{B}} \quad (17)$$

$$f_{125} = f_{\text{fracdiv}} \times \text{FDRL.STEP} \div 1024 \text{ with } \text{STEP} = 0...1023; \text{FDRL.DM} = 10_{\text{B}} \quad (18)$$

The following two formulas define the frequency of f_{189}:

$$f_{189} = f_{\text{fracdiv}} \div (1024 - \text{FDRH.STEP}); \text{FDRH.DM} = 01_{\text{B}} \quad (19)$$

$$f_{189} = f_{\text{fracdiv}} \times \text{FDRH.STEP} \div 1024 \text{ with } \text{STEP} = 0...1023; \text{FDRH.DM} = 10_{\text{B}} \quad (20)$$

The following two formulas define the frequency of f_{TS}:

$$f_{\text{TS}} = f_{\text{PSI5}} \div (1024 - \text{FDRT.STEP}); \text{FDRT.DM} = 01_{\text{B}} \quad (21)$$

$$f_{\text{TS}} = f_{\text{PSI5}} \times \text{FDRT.STEP} \div 1024 \text{ with } \text{STEP} = 0...1023; \text{FDRT.DM} = 10_{\text{B}} \quad (22)$$

26.3.8 Digital glitch filter

Very slow slopes and signal noise can lead to fast transitions of the input signal. These unwanted transitions are suppressed by a digital glitch filter.

It is built for filtering very fast transitions only. The filter calculates the integral of the signal. If the integral reaches a programmable saturation point, the signal change is notified to the pulse measurement unit. So it helps to find the exact pulse length for said slow slopes in noisy environment.

The glitch filter is clocked with f_{PSI5}. If the state of the input sample differs from the current output signal value, the internal counter is incremented by one. When the state of the input sample matches the current output signal value and the timer is not in idle, the timer is decremented by one. When the timer matches the compare value stored in IOCRx.DEPTH, the level of the output signal line is inverted. The timer will be reset and set to idle state again.

The depth of the filter can be programmed to a value between 1 and 15. Typically a depth of 3 to 5 T_{PSI5} is sufficient. By default it is cleared. If IOCRx.DEPTH is cleared, the filter is inactive/bypassed. Nevertheless, the input signal is sampled with f_{PSI5}.

The internal signal after the filter will change value not before the new value was sampled IOCRx.DEPTH times. If during this period a spike occurs, it takes $2 \times T_{\text{PSI5}}$ times longer for the internal signal to change value. The filters principal implies a delay of the signal by (IOCRx.DEPTH x T_{PSI5}).

Upon detection of glitch during rising or falling edge, IOCRx.REG or IOCRx.FEG is set. The rising / falling edge glitch flags must be reset by software.

The following figure shows the digital glitch filter:

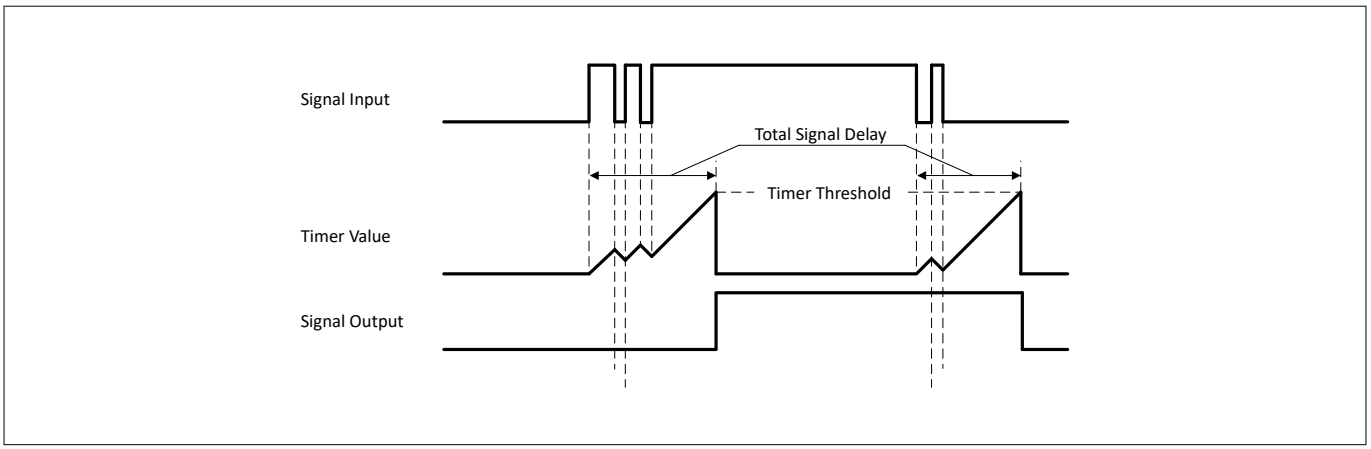

Figure 528 Digital glitch filter

26.3.9 Timestamp generation

Two time bases can be selected for timestamping:

- Internal time base (bit TBS = 0)
- External time base (bit TBS = 1) GTM/eGTM. Bit TSRA/B/C.TRIGSEL is used to select between GTM or eGTM for each of the timestamp counters. Bit TSRA/B/C.ETB is used to select the external clock line for counters CTS. ECS, if enabled by ECEA/ECEB/ECEC, selects the external trigger line that clears the timestamp counters CTS

Three timestamp counters can be selected for timestamping:

Any of the registers TSRA, TSRB and TSRC provide one timestamp counter. Each of them can be configured to be driven by either f_{TS} or by an external timer, that is, one of the GTM or eGTM inputs based on bit TRIGSEL. The frequency of f_{TS} is controllable by the fractional divider in register FDRT.

All of them can be cleared by a selectable GTM signal or by software, individually or synchronously.

Two time instances are captured for each channel:

1. The last sync pulse sent per channel is stored in the Start of Pulse Timestamp Capture register SPTSCx. Bit RCRCx.TSP is used to select from the three timestamp counters for sync pulses
2. The last start of frame (SOF) on this channel is stored in the Start of Frame (SOF) Timestamp Capture register SFTSCx. Bit RCRCx.TSF is used to select from the three timestamp counters for SOF

For each channel the capture time (SPTSC or SFTSC) can be selected using RCRCx.TSR. The selected time would be stored in the Receive Data Register (RDRLx, RDRHx) and the Receive Data Memory (RDMLxy, RDMHxy).

The following figure shows the timestamp generation:

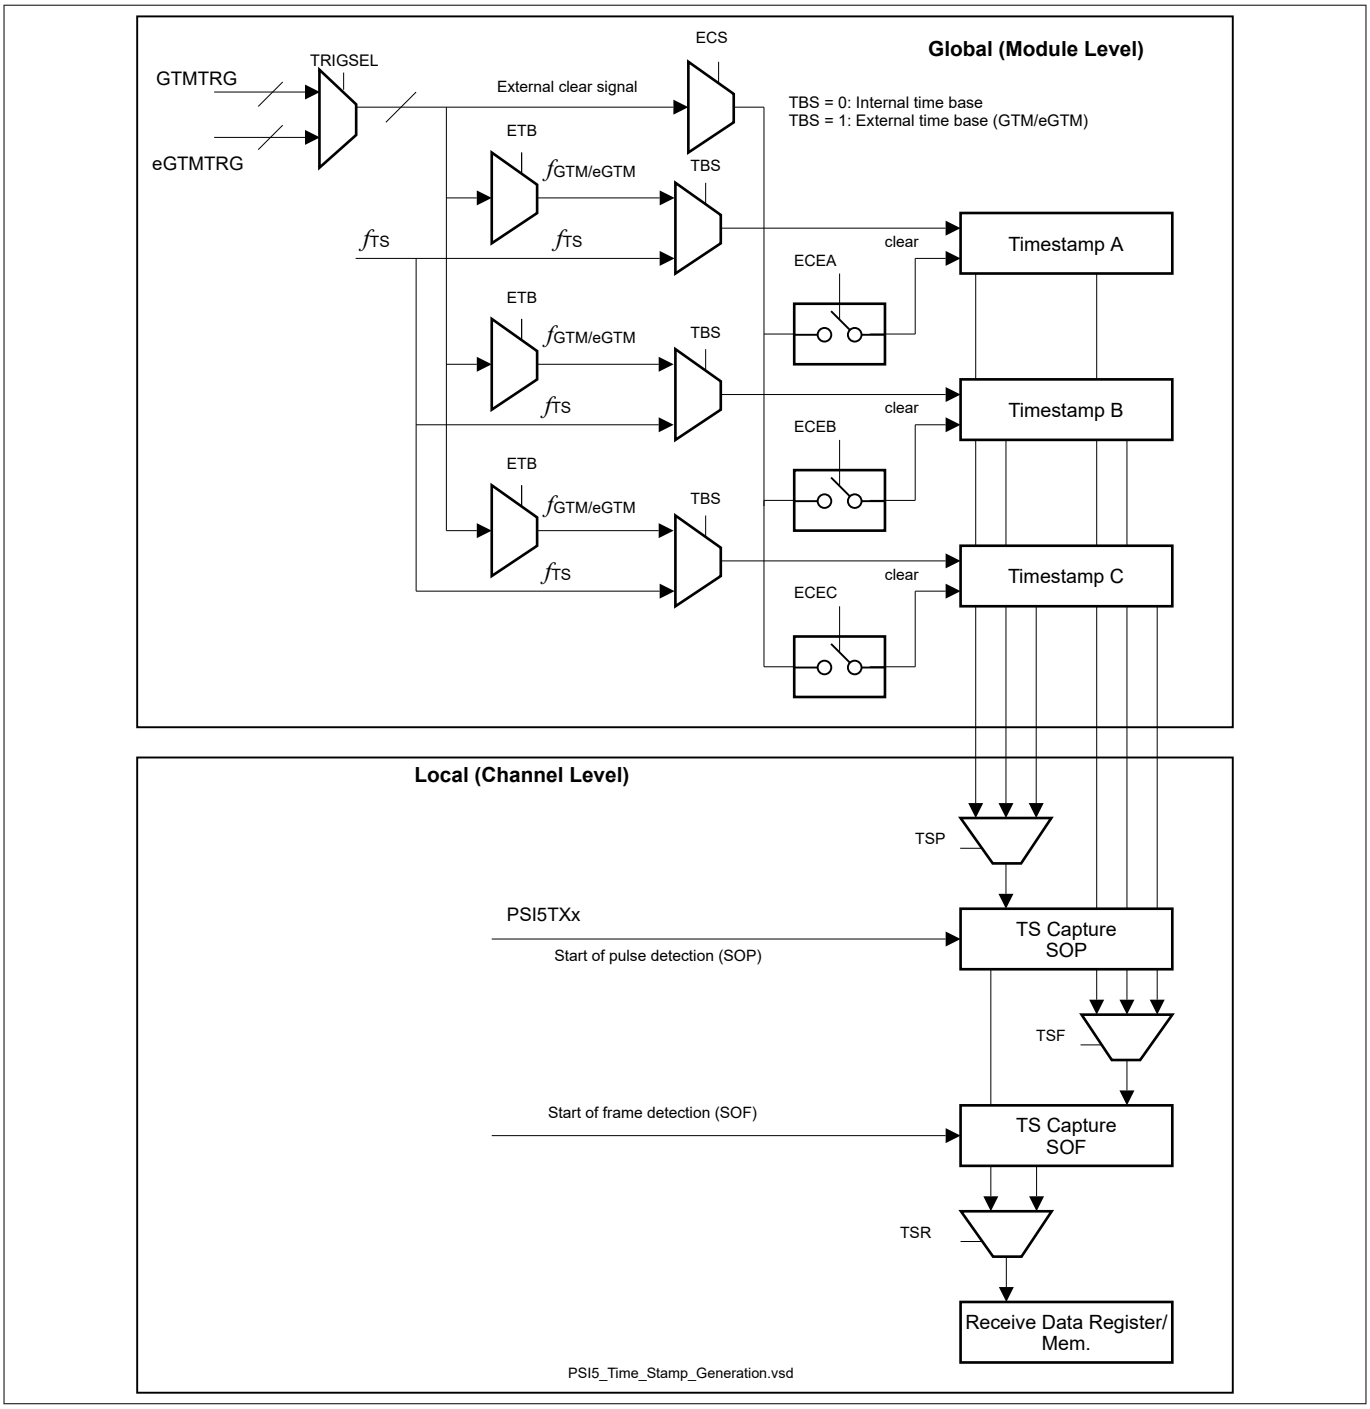

Figure 529 Timestamp generation

26.3.10 Watchdog timer

This section describes the behavior of the Watchdog timer in both Synchronous and Asynchronous modes of operation.

26.3.10.1 Synchronous mode

Selected with RCRAx.ASYN = 0.

The Watchdog Timer Registers WDTxw contain 7 time limits defining 6 frame slots per channel. The value entered here defines the time in multiples of TTS (defined in FDRT) from the last start of a sync pulse on channel x. The internal watchdog timer is started automatically at the start of a sync pulse.

The internal watchdog timer is compared to WDTxw.WDL. A match triggers:

- The automatic incrementing of slot counter RDRHx.SC
- Starting from WDTx1.WDL (channel x limit 1) on: Check if a frame with the corresponding SC y (y = slot 1 to 6) has been received or if such a frame is still being received since last WDTxw.WDL expired. If this is not the case but a frame was expected in this slot y (configured so in RCRBx.FECy (y=0-5)), “No Frame Received” interrupt NFI is issued. If configured so (in RCRBx.VBSy (y = 0-5)), an empty frame (all data fields are 0) is stored in RDRL/Hx and the referring RDML/H
- Frames that start before a slot boundary and end after this boundary (but are too short and so discarded) will result in an NFI / empty frame as well (if configured). In this scenario, Timestamps assume that RCRCx.TSR selects SFTSCx
  - If no frame was received before the SOF in this slot:

    SC = slot where SOF happened.

    Timestamp = end of slot where SOF happened
  - If a valid frame was received in this slot before a second SOF crosses WDL value, the parameters for the next slot are taken over already and if no valid frame is received in this next slot:

    SC = next slot (SC where SOF happened + 1)

    Timestamp = end of next slot (SC where SOF happened + 1)
  - If a valid frame was received in this slot before a second SOF crosses WDL value, the parameters for the next slot are taken over already and if a valid frame is received in this next slot, no NFI is issued
- A frame starting before a slot y (y = 1 to 6) and ending in slot y will not prevent NFI for slot y (y = 1 to 6)

Detection of frame boundaries:

- SOF is the first rising edge of the first start bit after an idle time, a timestamp is triggered and SC is captured for the frame at this point in time
- EOF is determined based on the configured frame length (RCRAx.PDLy and RCRCx.CRCy). An unexpected idle time or Manchester error will result in earlier EOF detection
- For each frame, the receiver checks if slot counter SC at SOF is equal to SC at EOF. If not, the interrupt TEI is issued. FEC is not relevant for TEI

If WDTxw.WDL is cleared, no check is performed but RDRH.SC is still incremented when it is its turn in the sequence of the WDLs. So such unconfigured WDTxw.WDL must appear only at the end. If an unconfigured WDTxw.WDL appears between configured WDTxw.WDL, the slot count will be incorrect

If a frame is received in a slot where no frame is expected, no dedicated flag is set but the frame is received with the parameters (PDL, SC and on) given for this slot. SW should detect this as SC for this frame is wrong.

26.3.10.2 Asynchronous mode

Selected with RCRAx.ASYN = 1.

The watchdog timers for the PSI5 channel x, limits WDL1 to WDL6 are disabled. If WDL0 (limit 0 of WDL) is not cleared, TEI is issued if the distance between two frames is longer than specified value in WDL0. Slot Counter SC is incremented with each received frame (works as frame counter) with roll over after 6. If bit RCRAx.AVBS (verbose mode) is set, an empty frame is stored in RDRL/Hx and the referring RDML/H.

Channel configuration at slot boundaries/take over of slot parameters

The receiver takes over the parameters for a frame at the beginning of a slot with 3 exceptions:

1. During SLOT0 (this is the slot after the last configured slot), after the sync pulse, the configuration of SLOT1 is already used. An internal shadow slot count value makes sure the messaging bits are routed to

slow channel for SLOT1. This way, a frame for SLOT1 that is too early will be received correctly, the messaging bits are sorted correctly. The time violation is still visible by TEI = 1 as such a frame would still start in a different slot (SLOT0) than it ends (SLOT1). SC = 1 will be stored in the receive buffer/memory

2. Frames that come too early could destroy the slow channel of the preceding slot. To prevent this, during SLOT1-SLOT5, the configuration of the next slot is loaded immediately after EOF was received. Note that an SOF must be seen first in the same slot before an EOF is looked for. This way, the hardware prevents the destruction of a good frame by a preceding frame that is too late. An internal shadow slot count value makes sure the messaging bits are routed to the slow channel for the following SLOT. This way, a frame for example on SLOT3 that is too early will be received correctly, the messaging bits are sorted correctly in SLOT3 and not in SLOT2 where the SOF of this frame is. The time violation is still visible by TEI = 1 as such a frame would still start in a different slot (SLOT2) than it ends (SLOT3). SC = 3 will be stored in the receive buffer/memory
3. If a frame does not end at the configured end of a slot, the new parameters of the following slot are taken over by the receiver only after the EOF was detected. This allows to receive a frame properly that is too late

***Note**: Orphan frames that come with a shift of one or more slots cannot be detected. They will be stored with the SC as they appear.*

Frames coming too early

A frame may come too early and will consequently start in a slot that is configured for no frame (FEC = 0). If the user wants to make sure that this frame is stored in RDR/RDM, the slot with FEC = 0 must be configured in the same way as its follower. At least, the length field PDL must be set to its maximum value (28) to allow for reception of all frame lengths. This allows to capture such a frame with referring error bits. (TEI, NBI, CRC in most cases). If this is not done and PDL is (by default) = 0, the following happens:

CASE1: SOF is too early. In the slot with FEC = 0, EOF is detected in the slot with FEC = 0.

The frame is stored in RDR/RDM with timestamp, 0 bits of data (as configured in PDL) and the slot count of the too early slot (with FEC = 0). CRCI is generated as the state machine assumes that there is no valid CRC that can be checked as there is no valid data, NBI is issued.

CASE2: SOF is too early. In the slot with FEC = 0, EOF is detected in the slot following the slot with FEC = 0 (because CRC transmission ends here. Meaning, the SOF was very close to the end of the slot)

The frame is stored in RDR/RDM with timestamp, 0 bits of data (as configured in PDL) and the slot count of the too early slot (with FEC = 0). CRCI is generated as the state machine assumes that there is no valid CRC that can be checked as there is no valid data, NBI and TEI bits are set.

Usage of the watchdog timer limits

The example below shows some use cases.

F1: “Frame too early”: Slot Count SC at SOF is 0 and 1 at EOF. Timing Error is issued (TEI). F1 is stored with configuration of slot 1 and SC = 1.

WDL2: Slot Count SC incremented by hardware, no “No Receive Frame” interrupt as no frame expected (FEC = 0)

F3: “Frame too late”: Slot Count SC at SOF is 3 and 4 at EOF. Timing Error is issued (TEI). The configuration for slot 3 is kept until the end of F3 so that it is not destroyed. Note that the EOF of frame 3 does not lead to take over the configuration of slot 5. But the EOF of F4 does. This way a F5 coming too early would be received correctly.

WDL5: “Frame missing”: No SOF or EOF received since WDL4. A frame was expected (FEC = 1), No Receive Frame interrupt is issued.

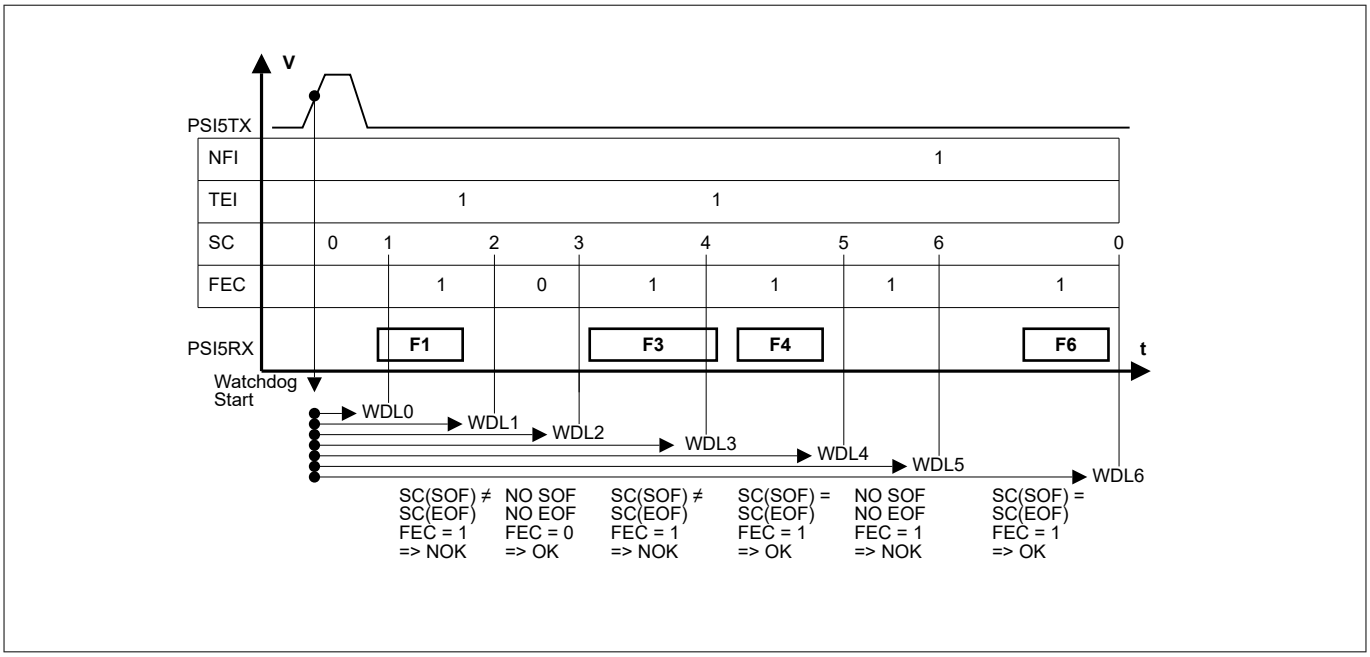

Figure 530 Watchdog timer limits

26.3.11 Receive data memory

The module design allows for usage in 2 ways without mode selection:

Ring buffer usage

The Receive Data Memory x is built as a ring buffer. That is, the first frame is stored in RDML/Hx0, the next in RDML/Hx1 and so on. At buffer 31, a wrap around is performed automatically. That is, the next frame is stored in buffer 0. RFCx.WRP shows the last location written and is automatically incremented after write.

Receive Buffer Overrun Interrupt Flag RBI is set, if a buffer is written before the SW cleared Receive Data Interrupt Overview Flag RDIOVx (unchecked or erroneous frame received or No Frame Received (NFI) message to be stored).

FIFO usage

Writing to the Receive Data Memory by the module moves the write pointer after writing.

Reading from RDFx 2 times with a 32 bit word access moves the read pointer to the next available buffer automatically after the read access. It clears as well all interrupt overview bits for this buffer line in NBIOVx, CRCIOVx, TEIOVx, RMIOVx, RSIOVx, RDIOVx, NFIOVx, MEIOVx. This allows for fully automatic DMA transfers without CPU intervention. The DMA simply needs to be set up in a way that it reads exactly the number of buffers configured with the FIFO warning level RFCx. The application SW configures “FIFO Warning Level Request Interrupt” FWI so that it is routed to the referring DMA channel as trigger source. Note that FWI does not need to be cleared to repetitively trigger the DMA.

If RFCx.WRAP is cleared and the read pointer (after the auto increment said above) equals the write pointer while reading from RDFx, a Receive Memory Underrun Interrupt INTSTATAx.RUI is flagged and the read pointer is not moved on automatically even if RDFx is read.

If RFCx.FRQ is set, the FIFO needs to be flushed by RFCx.FLU.

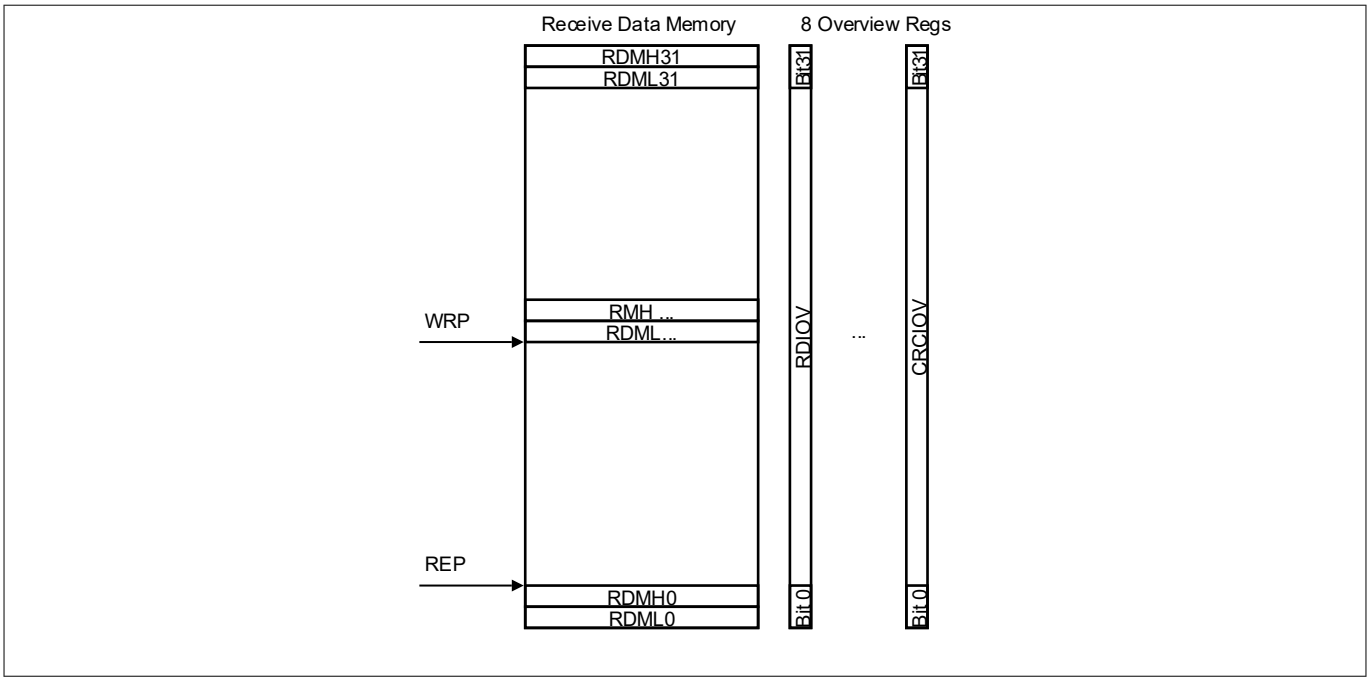

Figure 531 Receive data memory

26.3.12 Sync pulse control

The sync pulse generation provides the following functionality:

- Periodic sync pulses, driven by a common module time base (PGCx.PTE is set)
- Angle synchronous sync pulses, driven by GTM or eGTM based on PGCx.TRIGSEL (PGCx.ETE is set)
- Sync pulses for ECU to sensor communication (no pulse length extension) (SCRx.EPS is cleared)
- Sync pulses for ECU to sensor communication (with pulse length extension) (SCRx.EPS is set)
- Sync pulses provided by GTM or eGTM based on PGCx.TRIGSEL (Bypass PGCx.BYP set)
- Blank out time (switch off receiver during and after the sync pulse)

It is possible to switch on and off the periodic trigger or the angle synchronous trigger at any time. If data is available (SCRx.TOF is set), the pulses will be modulated according to the selected standard. SCRx.EPS selects between extended standard with pulse length modulation and legacy mode according to PSI5 standard V1.3 with pulse dropping (“tooth gap”). The minimum pulse length is defined by PGC.PLEN for both standards. For the extended standard, the pulses are prolonged by PGCx.DEL if a one is coded. Exception is the bypass path (BYP is set). These pulses are transmitted without any modulation.

Any combination of PTE, ETE and BYP can produce too long pulses.

An ECU to Sensor communication can be stopped at any point in time by setting the flush bit. This will clear the send register and flag TOF.

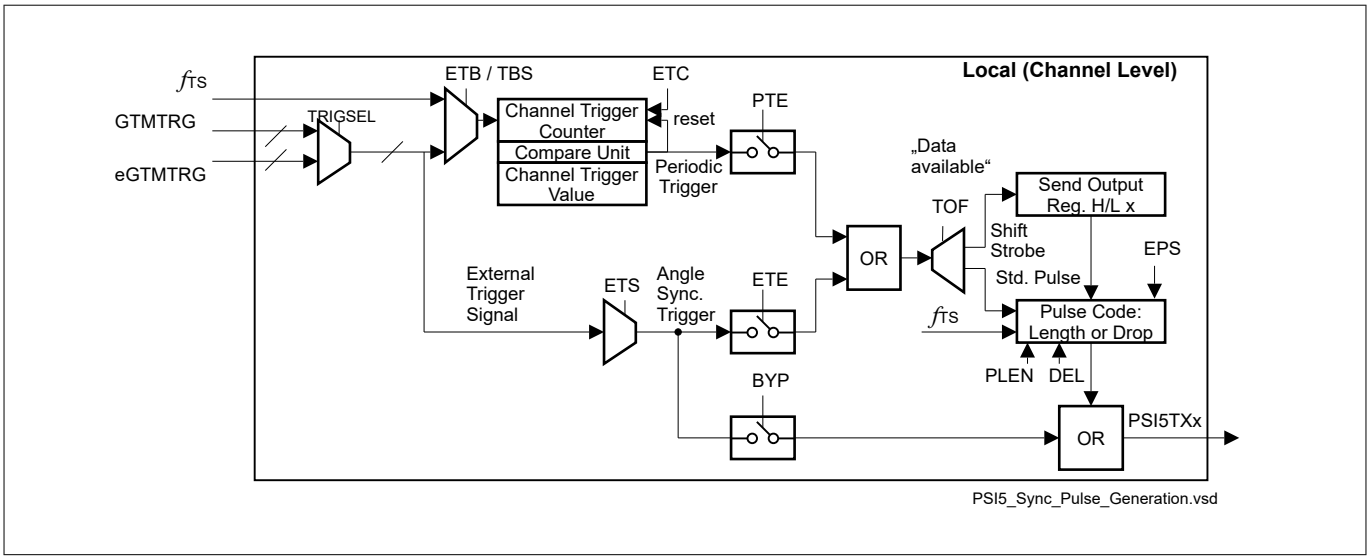

Figure 532 PSI5 sync pulse generation

Blank out time

BOT defines the length of the blank out time in TTS times (defined by FDRT) starting from the end of a sync pulse. The receiver is always switched off starting from the beginning of a sync pulse. BOT keeps the receiver switched off additionally after the sync pulse. This suppresses potential noise on the receive line after the pulse and so eases the design of the transceiver.

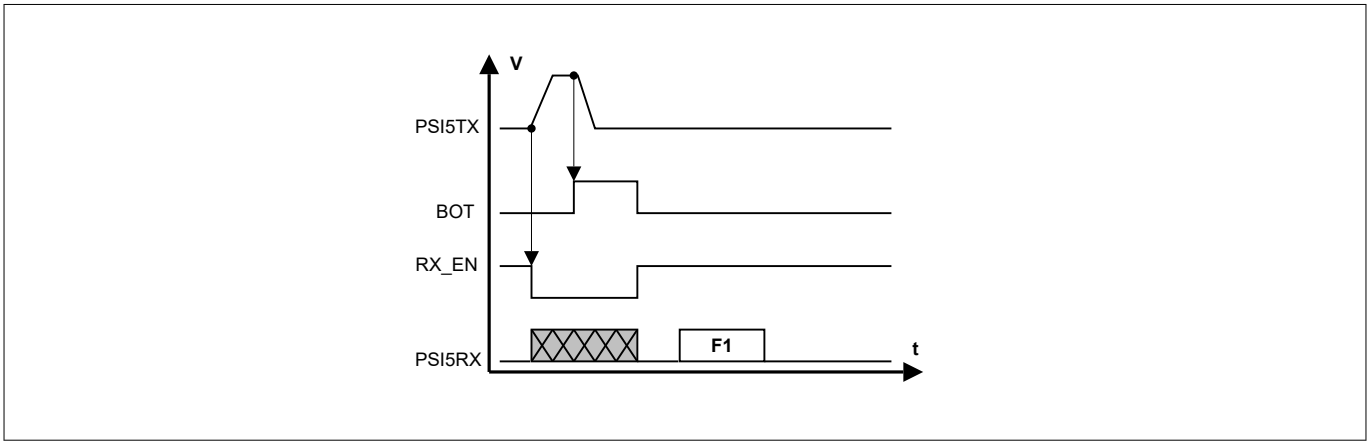

Figure 533 PSI5 blank out time

26.3.13 Channel trigger

The Channel Trigger Value Register CTVx contains a two cell reset counter CTC and CTV. CTV is the compare value of the channel trigger CTC. It allows for setting up periodic sync pulses for channel x.

The compare on equality allows to preset CTC and also configure an offset between the CTVx.CTCs. This allows for staggering periodic sync pulses that must have frequencies with common multiples (for example same frequency, double etc.). The Channel Trigger Value CTV is the compare value which clears the counter CTC on equality. At exactly this time, a sync pulse is triggered.

In this document, OFFSET = 65535 - “CTC preset value”

The Channel Trigger Value CTV is the compare value which clears the counter CTC. That is, when CTC preset is greater than CTV, the time to roll over is the offset.

When CTC preset is lesser than CTV, CTC has an advance.

Note that CTC can be written only if it is disabled by clearing GCR.ETCx.

Staggering the pulses might be required if the current source for the external PHYs can provide only limited current so that not all channels can be provided with the additional current that is required to apply the voltage increase representing a proper sync pulse.

For a synchronization of all counters CTVx.CTC, bits GCR.ETC0 can be used.

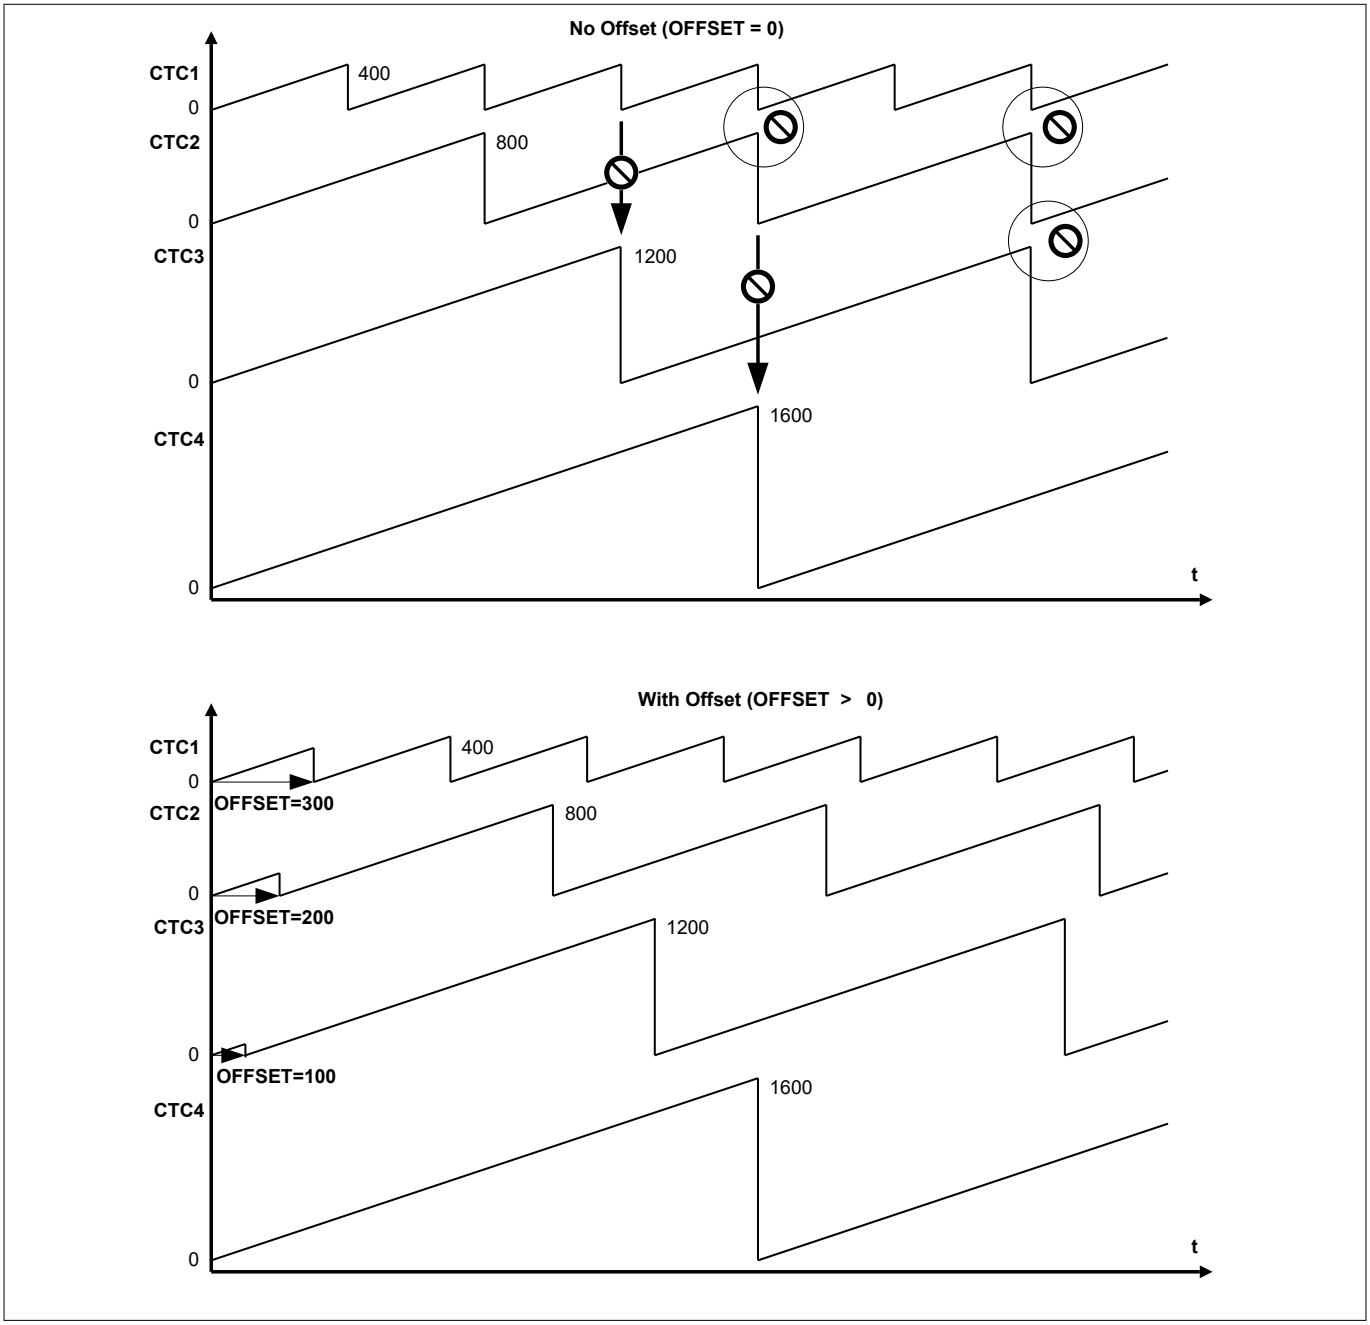

Figure 534 PSI5 pulse staggering

26.3.14 Send control

The Send Control Register SCRx contains control data bits required for sending data from the PSI5 module to the sensor / external PSI5 device.

Data is collected in SDRL/Hx (SDRLx and SDRHx) per channel and the control bits are collected in SCRx.

Send data preparation

The send control unit is built to transmit complete ECU to sensor frames. The figure below shows the send data preparation. Bit SCRx.TPF is set when send data preparation in the SDRL/Hx is in progress. Transmit Preparation Overflow Interrupt flag INTSTATAx.TPOI is set if the SDRL/Hx registers are written when the TPF bit is set. The old data is not overwritten. Send data is moved from SDRL/Hx to the Send Shift Registers. The bit INTSTATAx.TPI is set and TPF is cleared after data to be transferred has been moved from SDRL/H to SSRL/Hx. A new value can now be written to SDRL/Hx .

The Send Shift Registers SSRLX and SSRHx for channel x shows the updated send data after CRC, Stuffing and Start Sequence Insertion. Automatic CRC generation is controlled by SCRx.CRC. Bit SCRx.EPS controls the pulse length expansion. The automatic bit stuffing, depending on the EPS, is controlled by bit SCRx.BSC. When bit SCRx.STA is 0, there is no start sequence generated. Which means the payload starts from bit 0. When STA is set, there is an automatic start sequence generated. Transmit Shift Flag SCRx.TSF is set when the data in SSRL/Hx is waiting to be shifted to Send Output Registers.

Transmit Shift Overflow Interrupt flag INTSTATx.TSOI is set if SSRL/Hx registers are written when the TSF bit is set. The old data is not overwritten. The bit INTSTATAx.TSI is set and TSF is cleared after data to be transferred has been moved from SSRL/Hx to SORL/Hx. A new value can now be written to SSRL/Hx .

Send Output Registers SORLx and SORHx show the data that will be shifted to the pulse generator. Transmit Output flag SCRx.TOF is set when the data in the SORL/Hx registers are waiting to be transmitted to the sensor. Transmit Shift Overflow Interrupt flag INTSTATAx.TOOI is set if SORL/Hx registers are written when the TOF bit is set. The old data is not overwritten. The bit INTSTATAx.TOI is set and TOF is cleared after last bit to be transferred has been moved from SORL/H to the pulse generator. A new value can now be written to SORL/Hx.

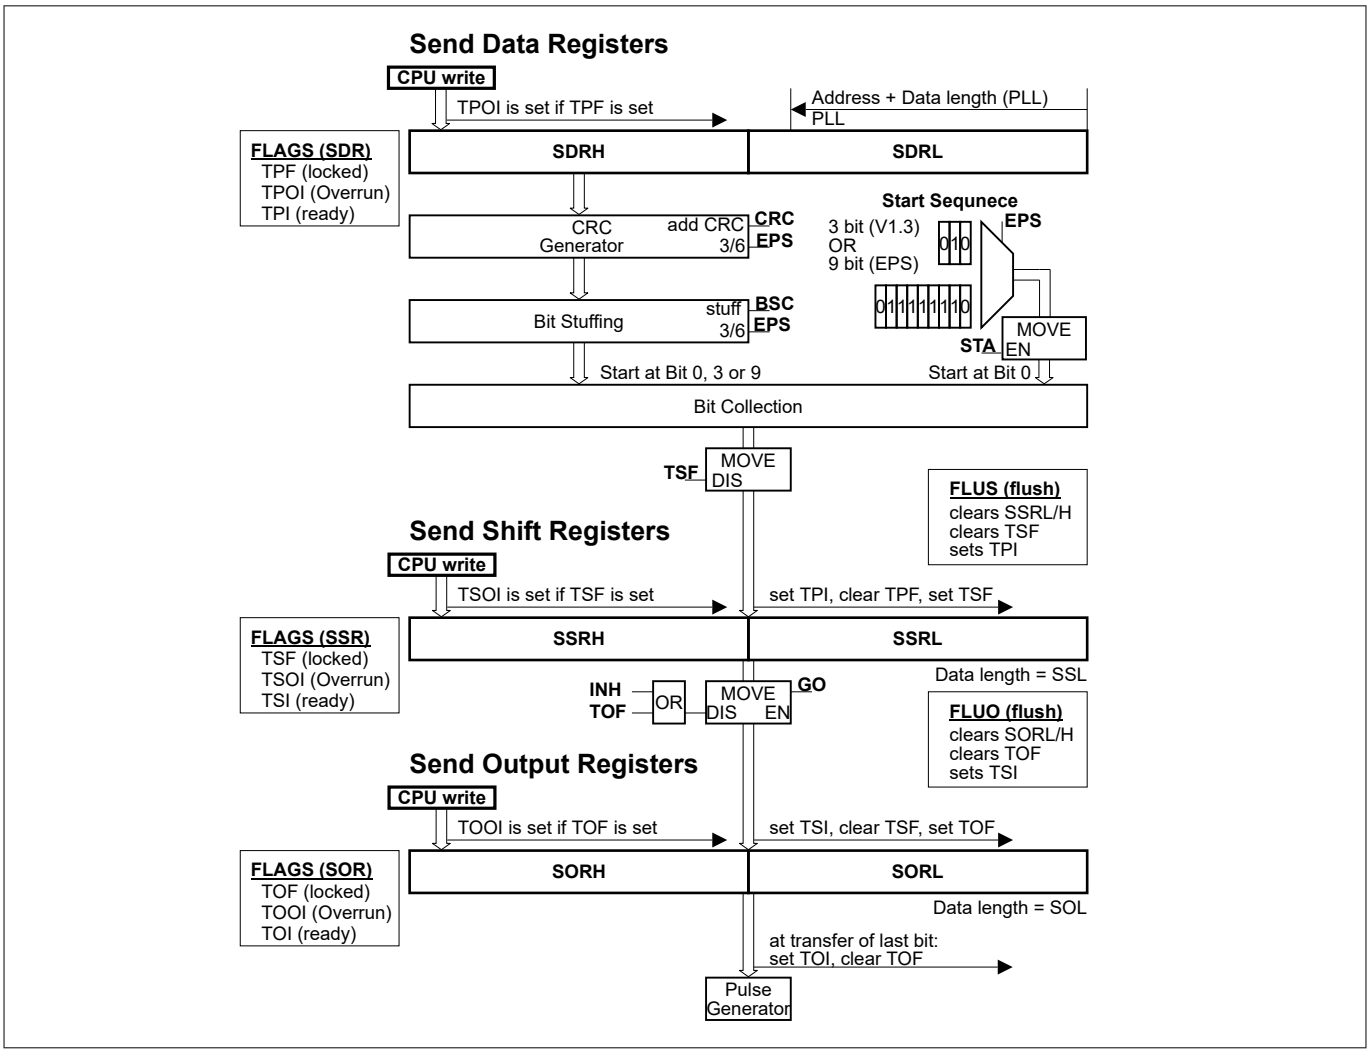

Figure 535 PSI5 send data preparation

26.3.15 Error detection capabilities

Each PSI5 channel can detect and signal the following error conditions:

Protocol level:

- No frame received/Manchester coding error in start bits (NFI)
- Messaging bits with Manchester coding error (MEI)
- Number of bits too small/Manchester coding error but messaging bits OK (NBI)
- Checksum error (CRCI)
- Frame not sent in expected time slot (TEI)
- Serial Communication: Wrong Status and Communication bit-field (WSI)
- Serial Communication: CRC error (SCRI)

Transfer Management Level:

- Receive Data Buffer Overrun (RBI)
- Receive Data Memory Overrun (RMI)
- FIFO Warning Level (FWI)
- Receive Memory Underrun (RUI)
- ECU to Sensor Data Buffer Underrun (TBI)

26.3.16 Interrupts

8 interrupt sources are available for the PSI5 module. For each trigger source of a channel x one interrupt can be selected in register INPx.

1. INPx.RDI indicates a receive data interrupt. It is activated when a received frame is moved to a Receive Data Register RDR. This happens if at least the start bits were received without Manchester coding error
2. INPx.SDI indicates a serial data receive interrupt when serial data communication is enabled
3. INPx.RSI indicates a receive frame success interrupt if none of the interrupts NFI, MEI, NBI, CRCI and TEI were detected. The referring interrupt must be enabled in GCR to be considered for RSI. This allows, for example, to use only the Receive Data Register RDRL/Hx and ignore the Receive Data Memory RDML/Hx. Both RDI and RSI will be issued together in normal use cases where reception is correct
4. INPx.RBI indicates a receive buffer overrun interrupt. It is activated when a new frame is transferred to a Receive Data Register RDR while the old value was still not read by the host (overwrite). Meaning the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set
5. INPx.FWI is set if the configured warning level of the FIFOx was reached (see RFCx)
6. INPx.TBI is a single node pointer for the overflow interrupts TPOI, TSOI, TOOI seen in the send control. TPOI, TSOI and TOOI indicate a transfer (send) register overrun interrupt. They are set if data is written to one of the registers in the transmission chain while the referring register is locked (occupied). The data written is ignored in this case
7. INPx.TDI is a single node pointer for TPI, TSI and TOI interrupts. TPI, TSI and TOI indicate a transmit interrupt. They are activated when data is moved from a SDR to SSR (TPI), from SSR to SOR (TSI) and from SOR to the pulse generator (TOI)
8. INPx.ERRI is a single node pointer for TEI, NFI, NBI, MEI, CRCI, RUI, RMI, WSI, SOI, SCRI interrupts
   a. RMI is issued if no memory buffer is available. RMI is set after a frame has been received or a No Frame Received (NFI) message is to be stored while RDIOVx.RDI[RFCx.WRP] is set. That means the kernel wants to set flag INTSTATAx.RDI[RFCx.WRP] and finds this flag already set. The old data is overwritten by the new data in the buffer memory
   b. TEI, NBI, MEI and CRCI are protocol error interrupts. If one of the protocol interrupts is activated, data is to be treated as invalid according to the PSI5 standard. The payload data received should

match the configured payload size RCRAx.PDLy (y=0-5) for channel x and slot y. Note that the wrong data is still available in all buffers. In particular, on MEI the wrong data is still fed into the serial data analyzer (slow channel)

c. NFI is set, if a frame is missing in a slot configured by the watchdog timer. The module can be configured to store a complete message anyhow with flag NFI set. The slot count and the timestamp can be helpful for debugging. This provides a method for easy data handling, for example by using DMA transfers only without checking single interrupt bits

d. WSI, SOI, SCRI treat the interrupts referring to the Status and Communication nibble for serial communication

e. RUI is issued when there is a read operation of the Receive Data FIFO while no data is available

For acceleration of the interrupt service routine, a register INTOV is implemented that shows if an interrupt class (RSI, RDI, RBI, TDI, TBI, ERRI, SDI, FWI) is active on any of the channels. It holds a flag for each class which combines the states from all channels of each node pointer in interrupt node pointer registers INPx. This flag is automatically set if there is an interrupt pending for the node pointer which is enabled. It is automatically reset, if no more enabled interrupt is pending for interrupt class.

In addition, there are 8 overview registers per channel holding the flags NBI, CRCI, TEI, RMI, RSI, RDI, NFI, MEI for each buffer line: NBIOVx, CRCIOVx, TEIOVx, RMIOVx, RSIOVx, RDIOVx, NFIOVx, MEIOVx; x = [0 - No. of PSI5 channels-1]. For example, NBIOV0 holds 32 bits, one for each buffer line of channel 0 reflecting if NBI is set in this buffer line.

The interrupt request or the corresponding interrupt set bit (in register INTSETAx or INTSETBx) can trigger the interrupt generation at the selected interrupt node. The service request pulse is generated independently from the interrupt flag in register INTSTATAx or INTSTATBx. The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLRAx or INTCLRBx.

If more than one interrupt source is connected to the same interrupt node (in register INPx), the requests are combined to one common line.

26.4 Registers

26.4.1 Register overview - access mode glossary

Table 1182 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

26.4.3 Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 000_H

Clock Control Register Application Reset value: $0000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

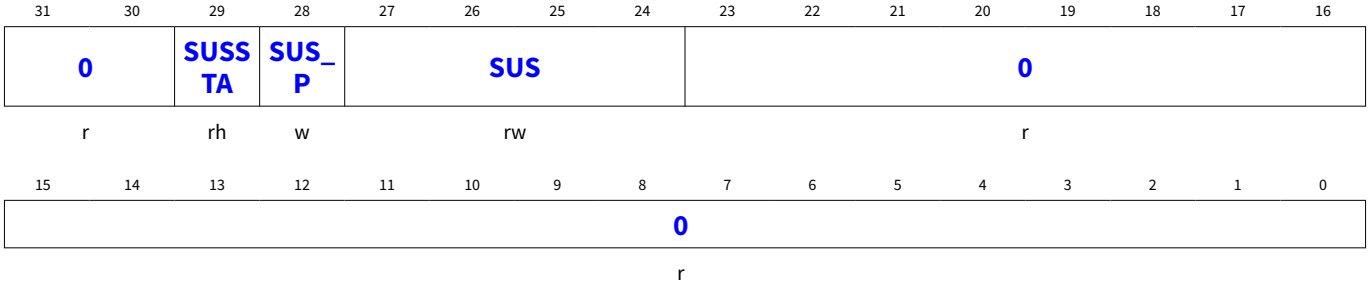
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

26.4.4 OCDS Control and Status Register

The OCDS Control and Status register OCS controls the debug and trace behavior by selecting suspend modes and OTGB trigger sets. When OCDS is disabled the suspend control is ineffective

OCS Offset address: 004_H

OCDS Control and Status Register Debug Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) Not listed combinations are reserved. 0_H Will not suspend 1_H Hard suspend: Clocks will be disabled immediately 2_H Reserved 3_H Soft suspend mode Clocks will be disabled after kernel acknowledge.
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:0, 31:30	r	**Reserved** Read as 0; should be written with 0.

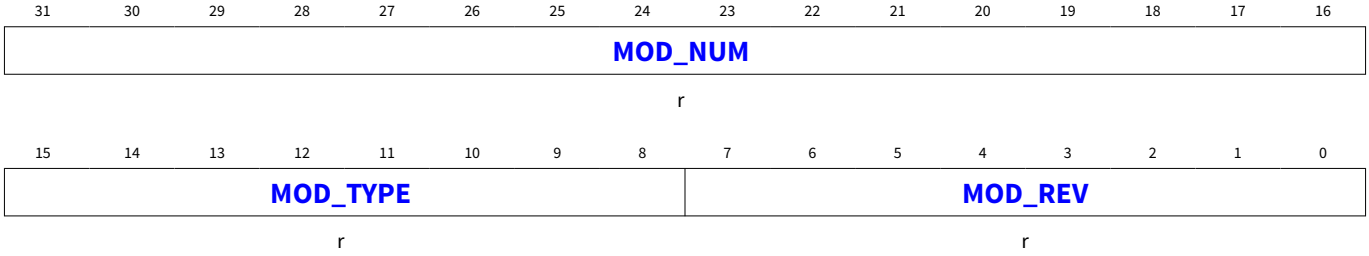
Table 1184 Access mode restrictions of OCS sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SUS_P**	rw	SUS	Set SUS_P during write access
(default)	r	SUS	

26.4.5 Module Identification Register

ID Offset address: 008_H

Module Identification Register PowerOn Reset value: $00C3\ C001_H$

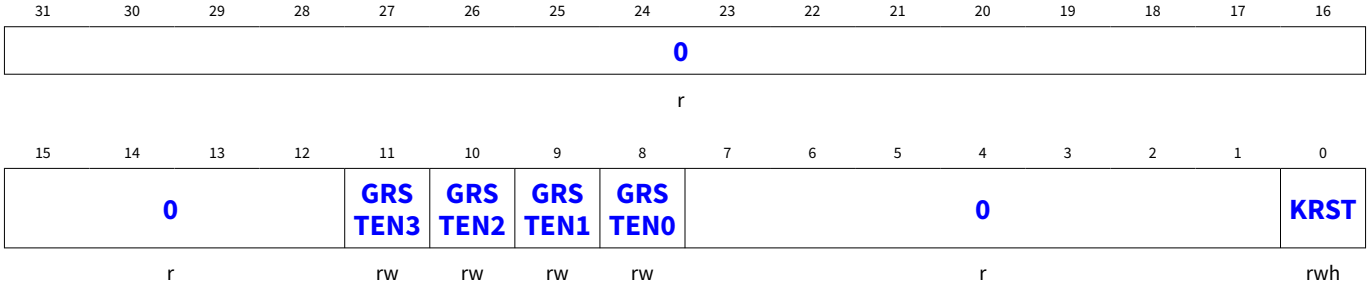


Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number.

26.4.6 Reset Control Register A

RST_CTRLA Offset address: $00C_H$

Reset Control Register A Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for Global Module Reset Group x** 0_B Global module reset group x does not have any effect 1_B Global module reset group x results in a kernel reset
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

26.4.7 Reset Control Register B

RST_CTRLB Offset address: 010_H

Reset Control Register B Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
STATCLR								0							
w								r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															KRST
r															rwh

Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
STATCLR	31	w	**Kernel Reset Status Clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits STAT.GRSTx and bit STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

26.4.8 Reset Status Register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: 014_H

Reset Status Register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r				rh	rh	rh	rh	r							rh

Field	Bits	Type	Description
KRST	0	rh	**Kernel Reset Status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.
GRSTx (x=0-3)	x+8	rh	**Status for Global Module Reset Group x** 0_B Reset was not triggered by Global Reset Group x 1_B Reset was triggered by Global Reset Group x
0	7:1, 31:12	r	**Reserved** Read as 0.

26.4.9 PROT Register Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 020_H

PROT Register Endinit Application Reset value: $0000\ 0000_H$

(table continues...)

(continued)

Field	Bits	Type	Description
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1186 Access mode restrictions of PROTSE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

26.4.11 Write access enable register A

This register defines which master agent function TAG identifier (TAG-ID) encodings are enabled or disabled for write accesses to the access protected region.

ACCEN_WRA Offset address: 040_H

Write access enable register A Application Reset value: $1000\ 0003_H$

0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

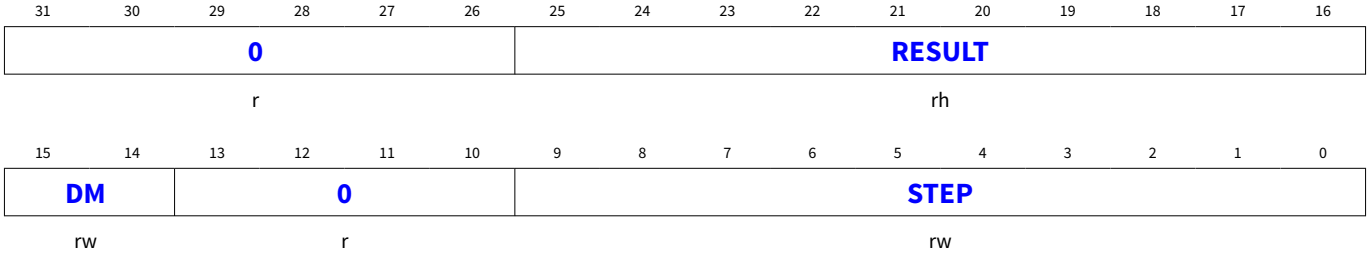
26.4.17 Fractional Divider Register

The Fractional Divider Register controls the input clock $f_{fracdiv}$.

FDR Offset address: 060_H

Fractional Divider Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STEP	9:0	rw	**Step Value** Reload or addition value for RESULT.
DM	15:14	rw	**Divider mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated 01_B Normal Divider mode selected. 10_B Fractional Divider mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	25:16	rh	**Result Value** Bit-field for the addition result.
0	13:10, 31:26	r	**Reserved** Read as 0; should be written with 0.

Related information

26.4.18 Fractional Divider Register for Lower Bit Rate

The Fractional Divider Register for Lower Bit Rate contains the divider that defines the time resolution of the f_{125} . It divides $f_{fracdiv}$ by a factor and provides f_{125} to all channels.

FDRL Offset address: 064_H

Fractional Divider Register for Lower Bit Rate Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
STEP	9:0	rw	**Step Value** Reload or addition value for RESULT.
DM	15:14	rw	**Divider mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. 01_B Normal Divider mode selected. 10_B Fractional Divider mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	25:16	rh	**Result Value** Bit-field for the addition result.
0	13:10, 31:26	r	**Reserved** Read as 0; should be written with 0.

Related information

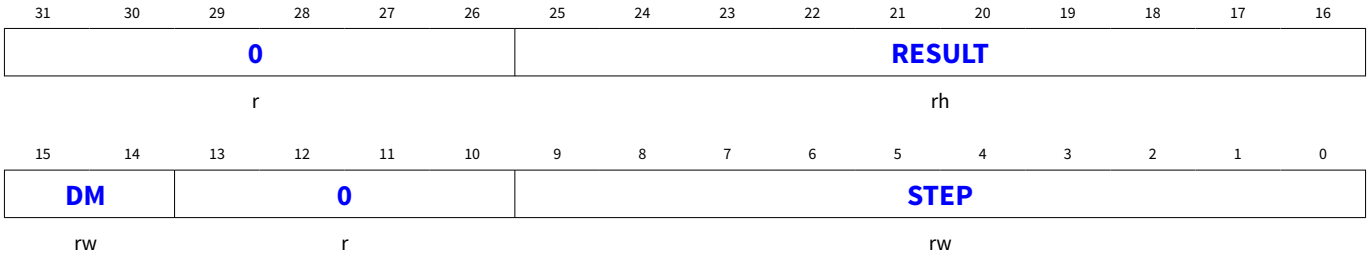
Bit rate generation on page 4867

26.4.19 Fractional Divider Register for Higher Bit Rate

The Fractional Divider Register for Higher Bit Rate contains the divider that defines the time resolution of f_{189} . It divides $f_{fracdiv}$ by a factor and provides f_{189} to all channels.

FDRH Offset address: 068_H

Fractional Divider Register for Higher Bit Rate Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STEP	9:0	rw	**Step Value** Reload or addition value for RESULT.
DM	15:14	rw	**Divider mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. 01_B Normal Divider mode selected. 10_B Fractional Divider mode selected. 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.

(table continues...)

(continued)

Field	Bits	Type	Description
RESULT	25:16	rh	**Result Value** Bit-field for the addition result.
0	13:10, 31:26	r	**Reserved** Read as 0; should be written with 0.

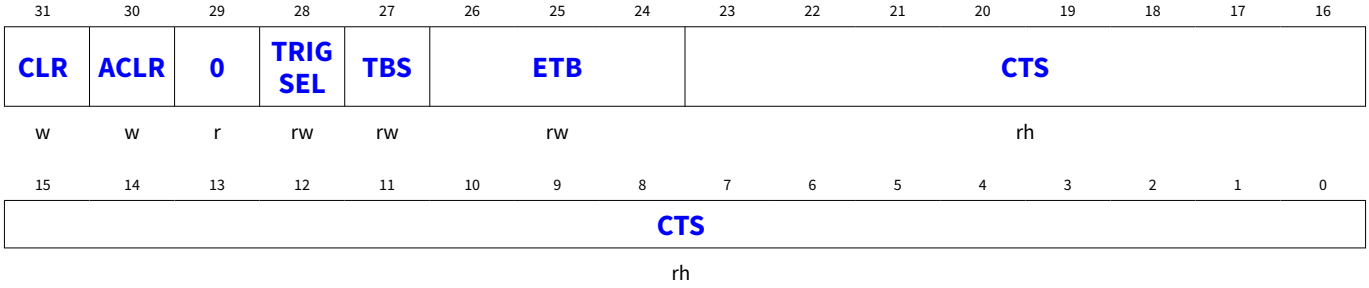
26.4.21 Timestamp Register A

This Timestamp Register contains read-only information about the current time given in clock cycles of f_{TS} or $f_{GTM/eGTM}$ since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSRA — Offset address: 070_H

Timestamp Register A — Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CTS	23:0	rh	**Current Timestamp for the Module** This bit-field shows the current timestamp.
ETB	26:24	rw	**External Time Base Select** Selects the external clock line for counter CTS. Channel must be disabled if changed (GCR.CEN = 0). 000_B TRIG0 001_B TRIG1 … 101_B TRIG5 110_B Reserved, no trigger selected 111_B Reserved, no trigger selected
TBS	27	rw	**Time Base Select** This bit selects the clock source for CTS 0_B Internal, CTS counts in clock cycles of f_{TS} 1_B External, CTS counts in clock cycles of f_{GTM} , eGTM
TRIGSEL	28	rw	**Trigger select** Trigger source selection bit 0_B **GTMTRG**: GTM GTM trigger 1_B **eGTMTRG**: eGTM eGTM trigger
ACLR	30	w	**Clear All Current Timestamp Counters** If set, this bit clears TSRA/B/C.CTS. TSRA/B/C.CTS count on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.
CLR	31	w	**Clear Current Timestamp for the Module** If set, this bit clears CTS. CTS counts on, starting from 0. This bit is automatically cleared by HW and will always be read as zero.
0	29	r	**Reserved** Read as 0; should be written with 0

26.4.22 Timestamp Register B

This Timestamp Register contains read-only information about the current time given in clock cycles of f_{TS} or $f_{GTM/eGTM}$ since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSRB Offset address: 074_H

r			rw	rw	rw	rw	rw	r			rw	rw	rw	rw	rw

Field	Bits	Type	Description
CRCI	0	rw	**CRCI** If bit is set, CRCI is selected to be checked for triggering RSI interrupt. No RSI is triggered in case of CRCI error
NBI	1	rw	**NBI** If bit is set, NBI is selected to be checked for triggering RSI interrupt. No RSI is triggered in case of NBI error
MEI	2	rw	**MEI** If bit is set, MEI is selected to be checked for triggering RSI interrupt. No RSI is triggered in case of MEI error
NFI	3	rw	**NFI** If bit is set, NFI is selected to be checked for triggering RSI interrupt. No RSI is triggered in case of NFI error
TEI	4	rw	**TEI** If bit is set, TEI is selected to be checked for triggering RSI interrupt. No RSI is triggered in case of TEI error

(table continues...)

(continued)

Field	Bits	Type	Description
ETCx (x=0-4)	x+8	rw	**Enable Channel Trigger Counter CTVx.CTC** This bit enables CTVx.CTC. The bits ETC0-ETCx can be set with one write access to synchronously start all counters. This is required for proper sync pulse staggering. If set, CTVx.CTC counts on, starting from its current value. CTVx.CTC can be written only if ETCx is cleared (stopped). In the device only ETC0-3 are available. All other must be written with 0, and always read 0.
CENx (x=0-4)	x+16	rw	**Enable Channel** This bit enables PSI5 Channel x. If cleared, all internal state machines of the receiver and the sender are forced to default idle state while all registers can be read and written. Used for configuration of a channel. In the device only CEN0…3 are available. All other must be written with 0, and always read 0.
0	7:5, 15:13, 31:21	r	**Reserved** Read as 0; should be written with 0.

26.4.25 Input and Output Control Register x

The Input and Output Control Register IOCRx determines for the PSI5 channel x:
for the receiver:

- the alternate input
- the filter depth
- the input signal polarity

for the transmitter

- the output signal polarity

IOCRx (x=0-1) Offset address: 084_H+x*90_H

Input and Output Control Register x Kernel Reset value: $0000\ 0000_H$

rw	rw					rw					rw				

Field	Bits	Type	Description
PDLy (y=0-5)	5*y+4:5*y	rw	**Payload Data Length y** PDL determines the number of data bits per frame that the PSI5 channel x is setup for in slot y. PDL does not include the start bits and the Parity/CRC bits. PDL includes the Messaging bits, the Frame Control bits and the Status bits. 00_H 0 bit data 01_H 1 bit data 02_H 2 bit data 03_H 3 bit data … $1C_H$ 28 bit data $1D_H$ 0 bit data for 29 … $1F_H$ 0 bit data for 31
ASYN	30	rw	**Asynchronous mode** If set, • The watchdog timers for the PSI5 channel x, slot WDL1 - 6 are disabled • If WDL0 is not cleared TEI is issued if the distance between two frames is longer than specified in WDL0 • Slot Counter SC is incremented with each received frame (works as frame counter) with roll over after 6. • No sync pulses generated, TX path is inactive 0_B Off 1_B On
AVBS	31	rw	**Verbose mode for Asynchronous mode** If set, and ASYN is set and WDL0 is > 0, an empty frame is stored in RDRL/Hx and the referring RDML/H each time, the watchdog timer expires for the PSI5 channel x without reception of a frame. 0_B Off 1_B On

26.4.27 Receiver Control Register B x

The Receiver Control Registers RCRBx contains control bits/bit-fields that are related to the PSI5 receiver operation. It configures up to 6 frame types in the up to 6 slots.

RCRBx (x=0-1) Offset address: $08C_H+x*90_H$

Receiver Control Register B x Kernel Reset value: $0000\ 0000_H$

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

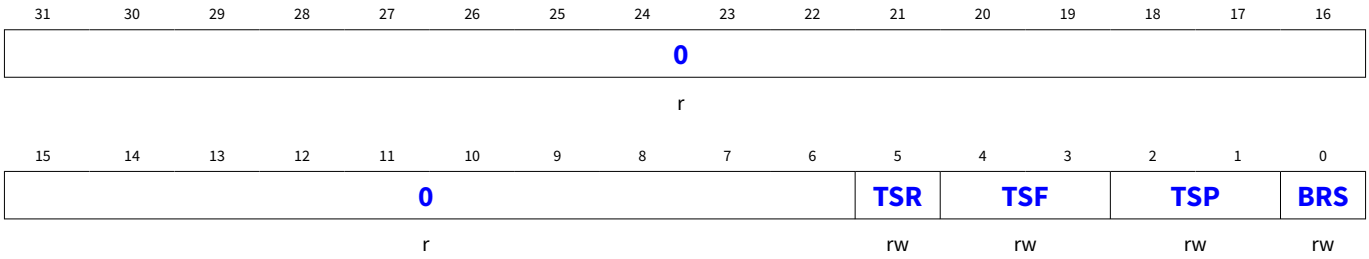
Field	Bits	Type	Description
MSGy (y=0-5)	4*y	rw	**Messaging Bits** If set, the 2 Messaging bits are configured for the PSI5 channel x in slot y. If set, Enhanced Serial Message processing on bits D[1:0] is activated. (18 frames, 4 or 8-bit ID, 12 or 16-bit data, 6-bit CRC) If Messaging bits are transmitted, they are always presented in RDRx independently from status of MSGy. That is, RDRx always stores exactly the data that was received. 0_B No Messaging bits 1_B 2 Messaging bits
CRCy (y=0-5)	4*y+1	rw	**CRC or Parity Selection** If set, a 3-bit CRC checksum is expected for the PSI5 channel x in slot y. Else, 1-bit Parity is assumed. 0_B 1 Parity Bit is configured 1_B 3 CRC bits are configured
FECy (y=0-5)	4*y+2	rw	**Frame Expectation Control** If set, a frame is expected for the PSI5 channel x in slot y. A No Frame Received error interrupt NFI is issued each time, the watchdog timer for the PSI5 channel x, slot y expires without reception of a SOF or EOF. 0_B No frame expected 1_B A frame is expected, SC is checked
VBSy (y=0-5)	4*y+3	rw	**Verbose mode** If set, and a message is expected for the PSI5 channel x in slot y (FECy) an empty frame is stored in RDRL/Hx and the referring RDML/H each time, the watchdog timer for the PSI5 channel x, slot y expires without reception of a frame. 0_B Off 1_B On
0	31:24	r	**Reserved** Read as 0; should be written with 0.

26.4.28 Receiver Control Register C x

The Receiver Control Registers RCRCx contains control bits/bit-fields that are related to the PSI5 receiver operation. Bit rate and timestamp sources are configured here.

RCRCx (x=0-1) Offset address: 090_H+x*90_H

Receiver Control Register C x Kernel Reset value: $0000\ 0000_H$



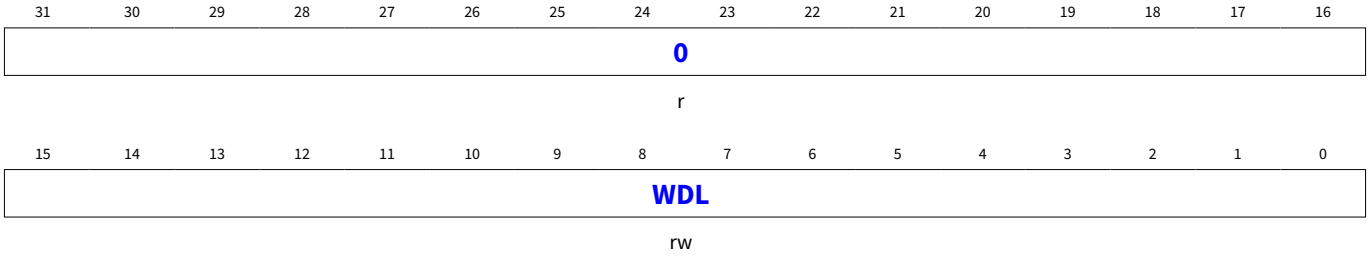
Field	Bits	Type	Description
BRS	0	rw	**Bit Rate Select** 0_B f_{125} selected for channel x 1_B f_{189} selected for channel x
TSP	2:1	rw	**Timestamp Select for Pulses** 00_B TSRA.CTS is captured in SPTSC 01_B TSRB.CTS is captured in SPTSC 10_B TSRC.CTS is captured in SPTSC 11_B not defined. Do not use
TSF	4:3	rw	**Timestamp Select for Start of Frame (SOF)** 00_B TSRA.CTS is captured in SFTSC 01_B TSRB.CTS is captured in SFTSC 10_B TSRC.CTS is captured in SFTSC 11_B not defined. Do not use
TSR	5	rw	**Timestamp Select for Receive Data Registers** 0_B SPTSC is stored in RDRHx 1_B SFTSC is stored in RDRHx
0	31:6	r	**Reserved** Read as 0; should be written with 0.

26.4.29 Watchdog Timer Register xw

For details, see chapter "Watchdog Timer".

WDTxw (w=0-6;x=0-1) Offset address: 094_H+x*90_H+w*4

Watchdog Timer Register xw Kernel Reset value: $0000\ 0000_H$



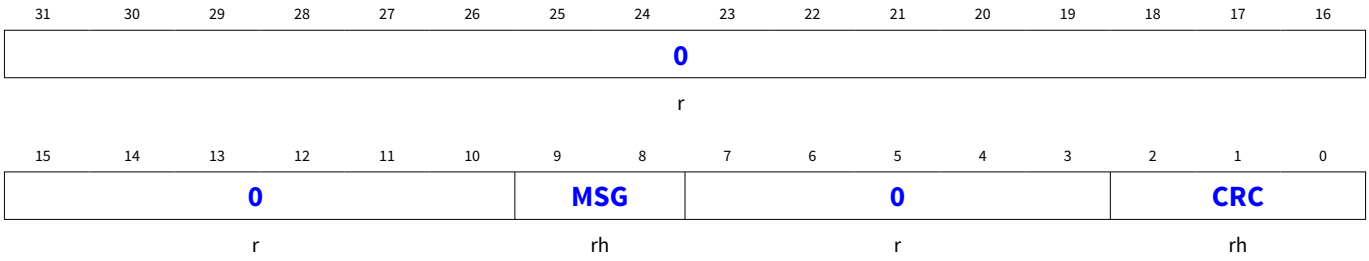
Field	Bits	Type	Description
WDL	15:0	rw	**Watchdog Timer Limit** for channel x limit w.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

26.4.30 Receive Status Register x

The Receive Status Register provides the status information of channel x.

RSRx (x=0-1) Offset address: $0B0_H+x*90_H$

Receive Status Register x Kernel Reset value: $0000\ 0000_H$



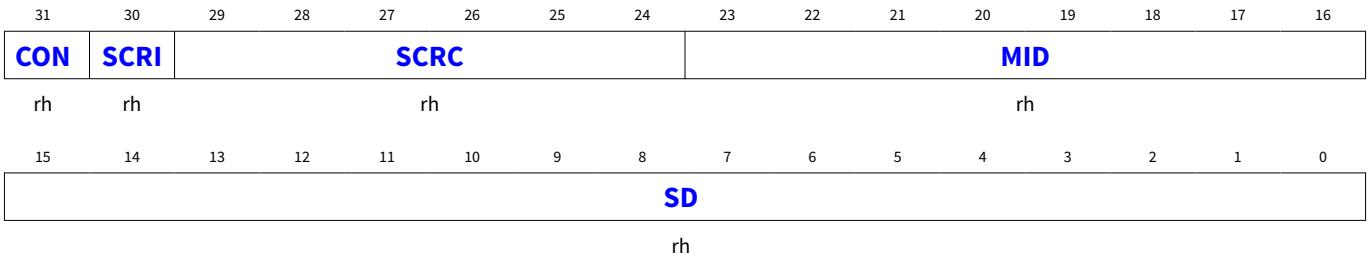
Field	Bits	Type	Description
CRC	2:0	rh	**CRC** of last frame. CRC0 is on bit position 0.
MSG	9:8	rh	**Messaging Bits** of last frame. MSG0 is on bit position 8.
0	7:3, 31:10	r	**Reserved** Read as 0; should be written with 0.

26.4.31 Serial Data and Status Register xz

The Serial (Receive) Data and Status Register provides the data and status information of channel x slot z. The data is presented in bit-field SD independent from the SCRC check result in SCRI.

SDSxz (x=0-1;z=0-5) Offset address: $0B4_H+x*90_H+z*4$

Serial Data and Status Register xz Kernel Reset value: $0000\ 0000_H$



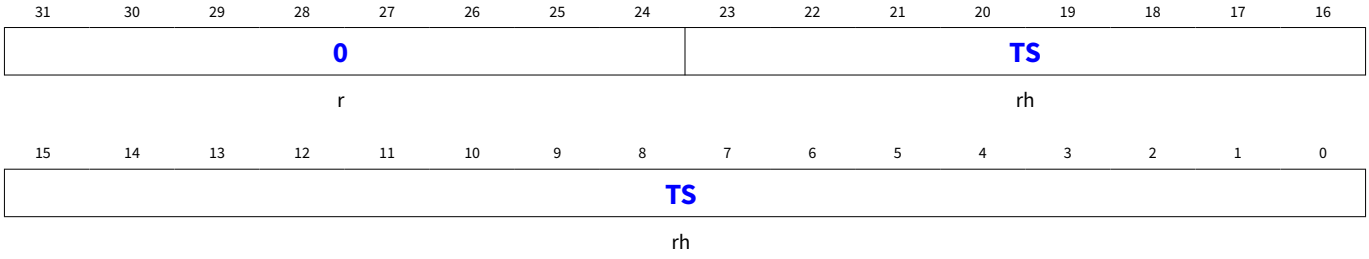
Field	Bits	Type	Description
SD	15:0	rh	**Serial Data** of last serial data frame on channel x slot z. SD0 is on bit position 0. If SDSxz.CON is not set, bits [15:12] are zero.
MID	23:16	rh	**Message ID** of last serial data frame. ID0 is on bit position 16. If SDSxz.CON is set, bits [23:20] are zero.
SCRC	29:24	rh	**SCRC** CRC of last serial data frame. SCRC0 is on position 24.
SCRI	30	rh	**CRC of Serial Message failed Interrupt Flag.** This bit is set if the CRC of the serial message fails. This includes a check of the Messaging bit-field for correct 0 values of bit 1 in frames 7, 13 and 18. See INTSTATAx.
CON	31	rh	**Configuration bit** of last serial frame. 0_B 12-bit data and 8-bit message ID 1_B 16-bit data and 4-bit message ID

26.4.32 Start of Pulse Timestamp Capture Register x

Each time a sync pulse is sent on channel x, the timestamp is captured in this register. RCRC.TSP selects if TSRA, B or C is used. RCRC.TSR determines if SPTSCx or SFTSCx is stored in RDRHx.

SPTSCx (x=0-1) Offset address: $0CC_H+x*90_H$

Start of Pulse Timestamp Capture Register x Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TS	23:0	rh	**Timestamp** of the last sync pulse sent on channel x. The Timestamp is taken at the rising edge of the pulse.
0	31:24	r	**Reserved** Read as 0; should be written with 0.

26.4.33 Start of Frame Timestamp Capture Register x

Each time a start of frame is received on channel x, the timestamp is captured in this register. The first rising edge of the first start bit is captured. Note that a preceding “Idle Time” is required for start bit detection. In case the two start bits should not be received successfully (that is, without Manchester coding errors) the frame is completely dropped and the latest captured value is overwritten with the next SOF or at the referring WDTxw.WDL for “empty messages” if configured in next SOF or at the referring WDTxw.WDL for “empty messages” if configured in RCRBx.VBSy. RCRC.TSF selects if TSRA, B or C is used. RCRCx.TSR determines if SPTSCx or SFTSCx is stored in RDRHx.

SFTSCx (x=0-1) Offset address: $0D0_H+x*90_H$

Start of Frame Timestamp Capture Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								TS							
r								rh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TS															
rh															

Field	Bits	Type	Description
TS	23:0	rh	**Timestamp** of the last frame received on channel x. The timestamp is taken at the rising edge of the first start bit S1 that was qualified by the receiver.
0	31:24	r	**Reserved** Read as 0; should be written with 0.

26.4.34 Receive Data Register Low x

The Receive Data Register RDRLx for channel x shows the data content of a received data frame.

The internal receive buffer is always cleared ($0x0000\ 0000_H$) at each frame start. Thus unused nibbles are always read as zero.

The bit CRCI reflect, wether the conditions are met to issue an interrupt signal and set the referring interrupt status bit in INTSTATA for the latest frame. Thus it is independent from the old status of the referring sticky bit in INTSTATA before latest frame reception.

RDRLx (x=0-1) Offset address: $0D4_H+x*90_H$

Receive Data Register Low x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RD												CRC			CRCI
rh												rh			rh

Field	Bits	Type	Description
CRCI	0	rh	**CRC Error Flag** This bit is set if the CRC or parity check fails. Set as well if CRC can not be calculated: PDL = 0, CRC cut off by Manchester Error, too few bits, BOT, Sync Pulse) 0_B correct CRC/parity 1_B wrong CRC/parity
CRC	3:1	rh	**CRC** CRC/parity bit of last PSI5 frame. CRC0 or parity bit is on bit position 1. In case of NFI, this field is cleared.
RD	31:4	rh	**RD** Receive data of last PSI5 frame. RD0 is on bit position 4. In case of NFI, this field is cleared.

26.4.35 Receive Data Register High x

The Receive Data Register RDRHx for channel x shows the data content of a received data frame.

The internal receive buffer is always cleared (0x0000 0000_H) at each frame start. Thus unused bits are always read as zero.

The bits RBI, RMI, RSI, NBI and TEI reflect wether the conditions are met to issue an interrupt signal and set the referring interrupt status bit in INTSTATA for the latest frame. Thus it is independent from the old status of the referring sticky bit in INTSTATA before latest frame reception.

RDRHx (x=0-1) Offset address: $0D8_H+x*90_H$

Receive Data Register High x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	rh	rh	rh			rh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TS															
rh															

Field	Bits	Type	Description
TS	23:0	rh	**Timestamp** of the last received PSI5 frame. RCRC.TSR determines if SPTSCx or SFTSCx is stored in RDRHx. (It can be selected if the timestamp of the last sync pulse is stored or the timestamp for the start of frame).

(table continues...)

(continued)

Field	Bits	Type	Description
SC	26:24	rh	**Slot Counter** In Synchronous mode (RCRAx.ASYN=0): Number of the slot the SOF of the frame was received in. In Asynchronous mode (RCRAx.ASYN=1): revolving frame number between 1 and 6. 000_B not valid (SOF too early) 001_B Slot 1 … 110_B Slot 6 111_B not valid
TEI	27	rh	**Time Slot Error Flag** In Synchronous mode (RCRAx.ASYN = 0), this bit is set if the SOF and the EOF of a frame are received in different time slots. The slots are constraint by the watchdog timer (see WDTxw). In Asynchronous mode (RCRAx.ASYN = 1), this bit is set if the distance between two frames is longer than specified in WDL0. 0_B no error 1_B error
NBI	28	rh	**Number of bits Error Flag** This bit is set if the last frame received less bits than expected but no Manchester coding error occurred until S1, S2, M0 and M1 were received. Note that the frame after the error might be completely wrong. 0_B all bits received 1_B not all bits received
MEI	29	rh	**Error in Message Bits Flag** This bit is set if a Manchester error occurred in Bit M0 or M1. (Only if configured in RCRBx.MSG) Note that the frame after the error might be completely wrong. 0_B frame is correct 1_B frame is not correct
NFI	30	rh	**No Frame Received Flag** This bit is set when the NFI condition as described in the first paragraph of INTSTATA.NFI occurs. If only the two start bits are received and no further data, this “SOF” is discarded completely and treated like no frame received as well. If RCRBx.VBS is set, an empty frame is stored anyhow and RDIx is issued as well. The content of RDRL/Hx / RDML/Hx is valid for SC and for this bit (NFI). bit-fields RD and CRC are cleared (all zero). If RCRC.VBSx is 0 then TS is cleared. If RCRC.VBSx is 1 then TS is set to either SPTSCx.TS or SFTSCx.TS depending on the value of RCRC.TSR. 0_B no error 1_B error

(table continues...)

(continued)

Field	Bits	Type	Description
RBI	31	rh	**Receive Buffer Overflow Flag** This bit is set after a frame has been received while the old one was not read from RDRHx. That is, the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set. The old data is overwritten by the new data. 0_B No overflow 1_B Overflow

26.4.36 Pulse Generation Control Register x

The Pulse Generation Control Register PGC contains control data for the sync pulse generation. It contains as well the trigger control bits required for sending data from the PSI5 module to the sensor / external PSI5 device.

PGCx (x=0-1) Offset address: $0DC_H+x*90_H$

Pulse Generation Control Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TBS	TRIG SEL	DEL						0		PLEN					
rw	rw	rw						r		rw					

Field	Bits	Type	Description
PLEN	5:0	rw	**Pulse Length** Defines the length of the pulse in TTS times (defined by FDRT). This is the standard pulse width without data coding into the pulse width or for coding a ‘0’. 00_H Pulse length is 0 TTS 01_H Pulse length is 1 TTS … $3F_H$ Pulse length is 63 TTS
DEL	13:8	rw	**Delay Length** In case data is coded into the pulse length, this defines the ADDITIONAL length of the pulse in TTS times. The resulting sum length is the pulse width for coding a ‘1’ into the pulse width. 00_H Pulse length is 0 TTS 01_H Pulse length is 1 TTS … $3F_H$ Pulse length is 63 TTS

(table continues...)

(continued)

Field	Bits	Type	Description
TRIGSEL	14	rw	**Trigger select** Trigger source selection bit 0_B **GTMTRG**: GTM GTM trigger 1_B **eGTMTRG**: eGTM eGTM trigger
TBS	15	rw	**Time Base Select** This bit selects the clock source for CTVx 0_B Internal, CTV counts in clock cycles of f_{TS} 1_B External, CTV counts in clock cycles of f_{GTM} , eGTM
ETB	18:16	rw	**External Time Base Select** Selects the external clock line for counter CTVx. 000_B TRIG0 001_B TRIG1 … 101_B TRIG5 110_B Reserved, no trigger selected 111_B Reserved, no trigger selected
PTE	19	rw	**Periodic Trigger Enable** Periodic trigger is defined by CTVx. Should be 0 if ETE or BYP is set. 0_B Disabled 1_B Enabled
ETS	22:20	rw	**External Trigger Select** Selects the external trigger line for pulse generation (e.g. angle synchronous). 000_B TRIG0 001_B TRIG1 … 101_B TRIG5 110_B Reserved, no trigger selected 111_B Reserved, no trigger selected
ETE	23	rw	**External Trigger Enable** “Angle sync. trigger”, external line is selected by ETS. Should be 0 if PTE or BYP is set. 0_B Disabled 1_B Enabled
BYP	24	rw	**Bypass Enable** An external signal, selected by ETS directly drives the output of channel x. Should be 0 if PTE or ETE is set. 0_B Disabled 1_B Enabled

(table continues...)

(continued)

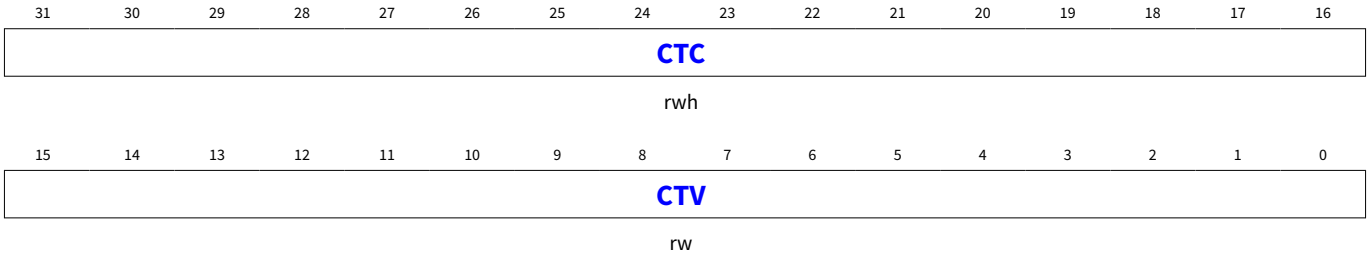
Field	Bits	Type	Description
BOT	31:25	rw	**Blank Out Time** BOT defines the length of the blank out time in TTS times (defined by FDRT) starting from the end of a Sync Pulse. The receiver is always switched off starting from the beginning of a Sync Pulse. BOT keeps the receiver switched off additionally after the Sync Pulse. This suppresses potential noise on the receive line after the pulse and thus eases the design of the transceiver. 00_H Blank Out Time is 0 TTS 01_H Blank Out Time is 1 TTS … $7F_H$ Blank Out Time is 127 TTS
0	7:6	r	**Reserved** Read as 0; should be written with 0.

26.4.37 Channel Trigger Value Register x

The Channel Trigger Value Register x contains a two cell reset counter. It allows for setting up periodic sync pulses for channel x.

CTVx (x=0-1) Offset address: $0E0_H+x*90_H$

Channel Trigger Value Register x Kernel Reset value: $0000\ 0000_H$



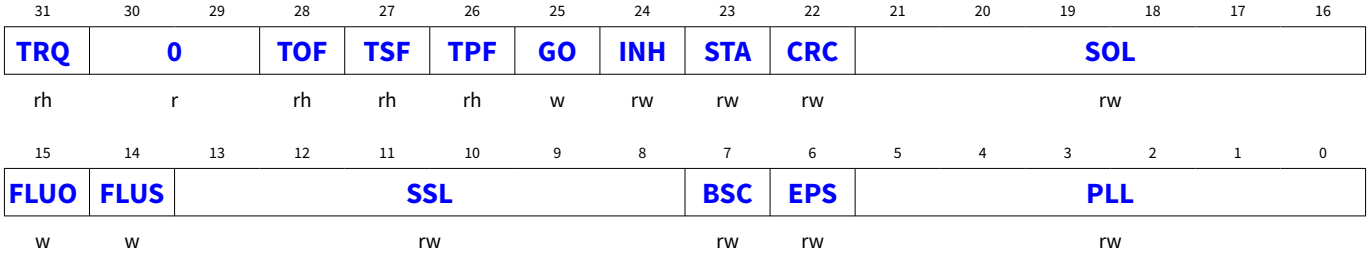
Field	Bits	Type	Description
CTV	15:0	rw	**Channel Trigger Value CTV** Contains the compare value (exact match) of Channel Trigger Counter (CTC) at which a sync pulse is triggered for channel x and the CTC value is cleared. If cleared, CTC is stopped and no pulse is generated.
CTC	31:16	rwh	**Channel Trigger Counter** This bit-field allows to read the current counter value of the reset timer cell CTVx. If GCR.ETCx is cleared, CTC can be written.

26.4.38 Send Control Register x

The Send Control Register SCR contains control data bits required for sending data from the PSI5 module to the sensor / external PSI5 device.

SCRx (x=0-1) Offset address: $0E4_H+x*90_H$

Send Control Register x Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PLL	5:0	rw	**Payload Length of Registers SDRL/H** If PLL > 31, SDRH needs to be written to trigger the HW for automatic STA, BSC or CRC generation or just moving data to SSRL/H. Else writing to SDRL is sufficient. PLL needs to written before SDRL/H is used for proper operation. If insertion of STA, BSC and CRC results in more than 64 bits, the MSBs are truncated in SSR. Defines the length that is taken into account: 00_H length is 1 01_H length is 2 … $3F_H$ length is 64
EPS	6	rw	**Enhanced Protocol Selection** 0_B PSI5 V1.3. No Pulse length extension 1_B Enhanced Protocol with Pulse length extension.
BSC	7	rw	**Bit Stuffing Control** Depending from bit EPS after 3 bits a ‘1’ is inserted (V1.3) or after 6 bits a ‘0’ is inserted (enhanced Power Train mode) Note that this makes the frame longer. 0_B No automatic bit stuffing 1_B Automatic bit stuffing is enabled.
SSL	13:8	rw	**Payload Length of Registers SSRL/H** If SSL > 31, SSRH needs to be written to trigger the HW for automatic moving data to SORL/H. Else writing to SSRL is sufficient. SSL needs to be written before SSRL/H is used for proper operation. Defines the length that is taken into account. Start Sequence, BSC and CRC need to be added to PLL by SW if SSL is calculated based on PLL. 00_H length is 1 01_H length is 2 … $3F_H$ length is 64
FLUS	14	w	**Flush SSRH/Lx** Setting this bit stops the shifting process and flushes (clears) SSRH/Lx and TSF. INTSTATAx.TPI is issued at the end of successful flushing. Reads always as zero.

(table continues...)

(continued)

Field	Bits	Type	Description
FLUO	15	w	**Flush SORH/Lx** Setting this bit stops the sending process and flushes (clears) SORH/Lx and TOF. INTSTATAx.TSI is issued at the end of successful flushing. Reads always as zero.
SOL	21:16	rw	**Payload Length of Registers SORL/H** If SOL > 31, SORH needs to be written to trigger the HW for automatic moving data to the pulse generator. Else writing to SORL is sufficient. SOL needs to written before SORL/H is used for proper operation. Defines the length that is taken into account. Start Sequence, CRC and Stuffing needs to be added by SW to PLL if SOL is calculated based on PLL. 00_H length is 1 01_H length is 2 … $3F_H$ length is 64
CRC	22	rw	**CRC Generation Control** 0_B CRC is not generated automatically. 1_B CRC is automatically generated and added to the frame by HW (according to EPS). Note that this makes the frame longer. CRC calculation is not performed, if at least 1 CRC bit does not fit into 64 bit, e.g. due to STA or BSC. In this case, one or two zero bits are inserted.
STA	23	rw	**Start Sequence Generation Control** 0_B no start sequence generated, payload starts at bit 0 1_B automatically generated and added to the frame by HW (according to EPS) payload starts at bit 3/9 (EPS = 0/1). Note that this makes the frame longer.
INH	24	rw	**Inhibit Transfer** This inhibits the automatic transfer from the shift registers SSRL/H to SORL/H after the preparation of all automatic bit-fields (STA, BSC, CRC). After a write access to SDRL/Hx, the automatic preparation is done by HW if selected. If automatic preparation of the start sequence is not selected, data is moved by HW without change to SSRL/H. When the HW is done with the transfer to the internal shift registers, interrupt TPI is activated, flag TSF is set and flag TPF is cleared automatically. Depending on INH, GO must be set after TPI before transfer to SORL/H takes place: After the transfer to SORL/H, TSI is activated, TOF is set and and TSF is cleared automatically. . INH defines the start mode: 0_B automatic transfer 1_B GO bit must be set before transfer
GO	25	w	**Release prepared Send data** This is only relevant if INH is set It allows for manual control of the transfer from SSRH/L to SORL/H. It is always read as zero and is automatically cleared. 0_B no transfer 1_B start transfer

(table continues...)

(continued)

Field	Bits	Type	Description
TPF	26	rh	**Transmit Preparation Flag** If set, preparation is in progress: start sequence and/ or CRC and/or stuffing and/or at least copying data from SDRL/H. If set, write access to SDRL/H will not change any data and issue TPOI. It is cleared automatically after preparation is finished.
TSF	27	rh	**Transmit Shift Flag** If set, data in SSRL/H is waiting to be shifted to SORL/H. This can be caused by an automatic transfer from SDRL/H or from a CPU write access to SSRL/H. If SSL < 32 it is sufficient to write SSRL. Else, only writing SSRH will set TSF. If set, write access to SSRL/H will not change any data and issue TSOI. It is cleared automatically after data was shifted to SORL/H or after flushing the register by setting bit FLUS.
TOF	28	rh	**Transmit Output Flag** If set, data in SORL/H is waiting to be transmitted to the sensor. This can be caused by an automatic transfer from SSRL/H or from a CPU write access to SORL/H. If SOL < 32 it is sufficient to write SORL. Else, only writing SDRH will set TSF. If set, write access to SORL/H will not change any data and issue TOOI. It is cleared automatically after data was transmitted to the sensor or after flushing the register by setting bit FLUO.
TRQ	31	rh	**Transfer Request in Progress** While a transfer is being sent this bit is set. Write access is ignored.
0	30:29	r	**Reserved** Read as 0; should be written with 0.

26.4.39 Send Data Register Low x

The Send Data Register SDRLx for channel x shows the data content of a data frame to be sent.

Data to be sent must be written while the channel is enabled (GCR.CEN is set). While CEN is cleared the HW can not detect the write access as all state machines are stopped.

SDRLx (x=0-1) Offset address: $0E8_H+x*90_H$

Send Data Register Low x Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
SDy (y=32-63)	y-32	rw	**SDy** Send data of next ECU to Sensor frame. The unused MSBs (bit position SCRx.PLL and higher) must be written with '0'. If PLL is < 32, SDRHx must not be written.

26.4.41 Send Shift Register Low x

The Send Shift Register SSRLx for channel x shows the data that will be shifted to the Send Output Register SORL. It contains as well the stuff bits as specified in PSI5 V1.3 or in PSI5 V2.1 frame formats 1-3. During transmission, all bits are shifted to LSB with each sync pulse. MSB is filled up with zero.

SSRLx (x=0-1) Offset address: $0F0_H+x*90_H$

It is automatically reset if all flags in INTSTATAx are cleared for which the referring interrupt is enabled in corresponding INTEN register (INTENA or INTENB).
0	31:8	r	**Reserved** Read as 0.

26.4.46 Interrupt Node Pointer Register x

The Interrupt Node Pointer Register INPx contains the node pointers of PSI5 channel x.

Node Pointer ERRI is one single node pointer for the following interrupts:

- TEI
- NFI
- NBI
- MEI
- CRCI
- RUI
- RMI
- WSIy
- SOIy
- SCRIy

Node Pointer TBI is one single node pointer for the following interrupts:

- TPOI
- TSOI
- TOOI

Node Pointer TDI is one single node pointer for the following interrupts:

- TPI
- TSI
- TOI

INPx (x=0-1) Offset address: $2C8_H+x*4$

Interrupt Node Pointer Register x Kernel Reset value: $0000\ 0000_H$

rw				rw				rw				rw			

Field	Bits	Type	Description
RSI	3:0	rw	**Interrupt Node Pointer for Interrupt RSI** This bit-field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.RSI (if enabled by bit INTENAx.RSI). 0_H Interrupt trigger PSI5SRx 0 is selected 1_H Interrupt trigger PSI5SRx 1 is selected … 7_H Interrupt trigger PSI5SRx 7 is selected 8_H reserved … F_H reserved
RDI	7:4	rw	**Interrupt Node Pointer for Interrupt RDI** This bit-field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.RDI (if enabled by bit INTENAx.RDI). For bit-field definition, see RSI.
RBI	11:8	rw	**Interrupt Node Pointer for Interrupt RBI** This bit-field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.RBI (if enabled by bit INTENAx.RBI). For bit-field definition, see RSI.
TDI	15:12	rw	**Interrupt Node Pointer for Interrupt TDI** This bit-field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.TPI, TSI, TOI (if enabled by bit INTENAx.TPI, TSI, TOI). For bit-field definition, see RSI.
TBI	19:16	rw	**Interrupt Node Pointer for Interrupt TBI** This bit-field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.TPOI, TSOI, TOOI (if enabled by bit INTENAx.TPOI, TSOI, TOOI). For bit-field definition, see RSI.
ERRI	23:20	rw	**Interrupt Node Pointer for Interrupt ERRI** This bit-field defines the interrupt node, that is requested due to the set condition for bit TEI, NFI, NBI, MEI, CRCI, RUI, RMI, CRCIy, WSIy, SOIy, SCRIy. For bit-field definition, see RSI.
SDI	27:24	rw	**Interrupt Node Pointer for Interrupt SDI** This bit-field defines the interrupt node, that is requested due to the set condition for bit INTSTATBx.SDI (if enabled by bit corresponding INTEN register (INTENA or INTENB).SDI). For bit-field definition, see RSI.
FWI	31:28	rw	**Interrupt Node Pointer for FWI** This bit-field defines the interrupt node, that is requested due to the set condition for bit INTSTATAx.FWI. For bit-field definition, see RSI.

26.4.47 Interrupt Status Register A x

The Interrupt Status Registers INTSTATA/Bx contains status bits that show the status of any interrupt of PSI5 channel x.

The bits are set independently from the referring Interrupt Enable in Register corresponding INTEN register (INTENA or INTENB). Thus they can be used as status bits as well e.g. by a SW based on polling.

INTSTATAx (x=0-1) Offset address: $2DC_H+x*4$

Interrupt Status Register A x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RSI	0	rh	**Receive Success Interrupt Request Flag** This bit is set at the successfully received end of a frame. It indicates that this frame is free of the errors NFI, TEI, NBI, MEI, CRCI if selected to be taken into account in register GCR. This bit can be cleared by bit INTCLRAx.RSI. This bit can be set by bit INTSETAx.RSI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
RDI	1	rh	**Receive Data Interrupt Request Flag** RDI is activated when a received frame is moved to a Receive Data Register RDRL/Hx. Both RDI and RSI will be issued together at correct reception. This bit can be cleared by bit INTCLRAx.RDI. This bit can be set by bit INTSETAx.RDI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

(table continues...)

(continued)

Field	Bits	Type	Description
RBI	2	rh	**Receive Buffer Overflow Interrupt Request Flag** This bit is set after a frame has been received while the old one was not read from RDRHx. That is, the kernel wants to set any of the two interrupts RSI and RDI and finds any of these two interrupts already set. The old data is overwritten by the new data. Thus, RBI can be ignored if the receive memory is used. This bit is NOT cleared by reading RDRx. This bit can be cleared by bit INTCLRAx.RBI. This bit can be set by bit INTSETAx.RBI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TEI	3	rh	**Time Slot Error Interrupt Request Flag** In Synchronous mode (RCRAx.ASYN = 0), this bit is set if the SOF and the EOF of a frame are received in different time slots. The slots are constrained by the watchdog timer (see WDTxw). In Asynchronous mode (RCRAx.ASYN = 1), this bit is set if the distance between two frames is longer than specified in WDL0. This bit can be cleared by bit INTCLRAx.TEI. This bit can be set by bit INTSETAx.TEI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
NBI	4	rh	**Number of Bits Wrong Request Flag** This bit is set if the last frame received less bits than expected but no Manchester coding error occurred until S1, S2, M0 and M1 where received. Note that the frame after the error might be completely wrong. This bit can be cleared by bit INTCLRAx.NBI. This bit can be set by bit INTSETAx.NBI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
MEI	5	rh	**Error in Message Bits Flag** This bit is set if a Manchester error occurred in bit M0 or M1 (Only if configured in RCRBx.MSG). Note that the frame after the error might be completely wrong. This bit can be cleared by bit INTCLRAx.MEI. This bit can be set by bit INTSETAx.MEI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

(table continues...)

(continued)

Field	Bits	Type	Description
CRCI	6	rh	**CRC Error Request Flag** This bit is set if the CRC fails. Set as well if CRC can not be calculated: PDL = 0, CRC cut off by Manchester Error, too few bits, Blank out time, Sync Pulse) This bit can be cleared by bit INTCLRAx.CRCI. This bit can be set by bit INTSETAx.CRCI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
FWI	7	rh	**FIFO Warning Level Request Flag** This bit is set after if the configured warning level of the FIFOx was reached. (See RFCx) This bit can be cleared by bit INTCLRAx.FWI. This bit can be set by bit INTSETAx.FWI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
RUI	8	rh	**Receive Memory Underrun Interrupt Request Flag** This bit is set after a FPI master reads from FIFO while no new data was available. (See RFCx) This bit can be cleared by bit INTCLRAx.RUI. This bit can be set by bit INTSETAx.RUI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
RMI	9	rh	**Receive Memory Overflow Flag** This bit is set after a frame has been received while RDIOVx.RDI[RFCx.WRP] is set. That is, the kernel wants to set flag RFCx.WRP and finds this flag already set. The old data is overwritten by the new data in the buffer memory. This bit can be cleared by bit INTCLRAx.RMIx. This bit can be set by bit INTSETAx.RMIx. This bit is set independently from INTENAx. 0_B No overflow 1_B Overflow

(table continues...)

(continued)

Field	Bits	Type	Description
TPI	10	rh	**Transfer Preparation Interrupt Request Flag** This bit is set after data to be transferred has been moved from SDRL/H to SSRL/H. Thus a new value can be written to SDRL/Hx and the prepared data can be checked and modified by SW. This bit is automatically cleared by writing SDRx. This is an exception. It allows for DMA transfers without CPU activity. This bit can be cleared by bit INTCLRAx.TDI. This bit can be set by bit INTSETAx.TDI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TPOI	11	rh	**Transmit Preparation Overflow Interrupt Request Flag** This bit is set after if SDRL/H is written while TPF is set. The old data is NOT overwritten. This bit can be cleared by bit INTCLRAx.TPOI. This bit can be set by bit INTSETAx.TPOI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TSI	12	rh	**Transfer Shift Interrupt Request Flag** This bit is set after data to be transferred has been moved from SSRL/H to SORL/H. Thus a new value can be written to SSRL/Hx. This bit is NOT cleared by writing SSRL/Hx. This bit can be cleared by bit INTCLRAx.TSI. This bit can be set by bit INTSETAx.TSI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TSOI	13	rh	**Transmit Shift Overflow Interrupt Request Flag** This bit is set after if SSRL/H is written while TSF is set. The old data is NOT overwritten. This bit can be cleared by bit INTCLRAx.TSOI. This bit can be set by bit INTSETAx.TSOI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

(table continues...)

(continued)

Field	Bits	Type	Description
TOI	14	rh	**Transfer Output Interrupt Request Flag** This bit is set after last bit to be transferred has been moved from SORL/H to the pulse generator. Thus a new value can be written to SORL/Hx. This bit is NOT cleared by writing SORL/Hx. This bit can be cleared by bit INTCLRAx.TOI. This bit can be set by bit INTSETAx.TOI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TOOI	15	rh	**Transmit Shift Overflow Interrupt Request Flag** This bit is set after SORL/H is written while TOF is set. The old data is NOT overwritten. This bit can be cleared by bit INTCLRAx.TOOI. This bit can be set by bit INTSETAx.TOOI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
NFI	16	rh	**No Frame Received Interrupt Flag** This bit is set at the end of a slot if a frame is expected in the slot and SOF was not received in the slot. A special case is where an SOF is received in slot 0. In this scenario, the NFI bit is only set at the end of slot 1 if a frame is expected in slot 1 and an EOF was not received in slot 1. If only the two start bits are received and no further data, this SOF is discarded completely and treated like no frame was received as well. If the SOF only frame crosses the watchdog timer limit, NFI occurs after watchdog timer limit and EOF detection. If RCRBx.VBS is set, an empty frame is stored anyhow. In this case, RDIx is issued as well. The only valid information is SC, Timestamp (captured at the end of the slot) and this bit (NFI). This bit can be cleared by bit INTCLRAx.NFI. This bit can be set by bit INTSETAx.NFI. This bit is set independently from INTENAx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
0	31:17	r	**Reserved** Read as 0.

0	31:24	r	**Reserved** Read as 0; should be written with 0.

26.4.55 Receive FIFO Control Register x

RFCx contains control bits for the FIFO and ring buffer operation.

RFCx (x=0-1) Offset address: 378_H+x*4

Receive FIFO Control Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FLU	FRQ	WRAP	0								FWL				
w	rh	rh	r								rw				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		WRP						0		REP					
r		rh						r		rh					

Field	Bits	Type	Description
REP	5:0	rh	**FIFO Read Pointer** points to the buffer to be read next. Incremented after read. The LSB bit indicates if RDMxH or RDMxL is read. This LSB is ignored for FWL comparison WRP - REP collision (RBI, RUI)
WRP	13:8	rh	**FIFO/Ring Buffer Write Pointer** points to the buffer written last. Incremented after write. The LSB indicates if RDMxH or RDMxL is written. This LSB is ignored for FWL comparison WRP - REP collision (RBI, RUI).
FWL	20:16	rw	**FIFO Warning Level** Number of new entries at which the FIFO Warning Interrupt FWIx is set automatically. For calculation WRP and REP are used.Which means, only if the memory is read from RDFx, this works properly.

(table continues...)

(continued)

Field	Bits	Type	Description
WRAP	29	rh	**Write Pointer WRAP Indicator** If set, the Write Pointer is one wrap around ahead of the Read Pointer. It is cleared, if the Read Pointer wraps around too or when FLU is set by SW.
FRQ	30	rh	**Flush Request** If set, FIFO read and write pointers are not incremented any more due to excessive RMI (too many overrun conditions). This bit is cleared when FLU is set.
FLU	31	w	**Flush** If set, FIFO read and write pointers are cleared. Bit WRAP is cleared. SW needs to clear interrupts as needed. This bit can only be set and is cleared by HW. Always read as 0.
0	7:6, 15:14, 28:21	r	**Reserved** Read as 0; should be written with 0.

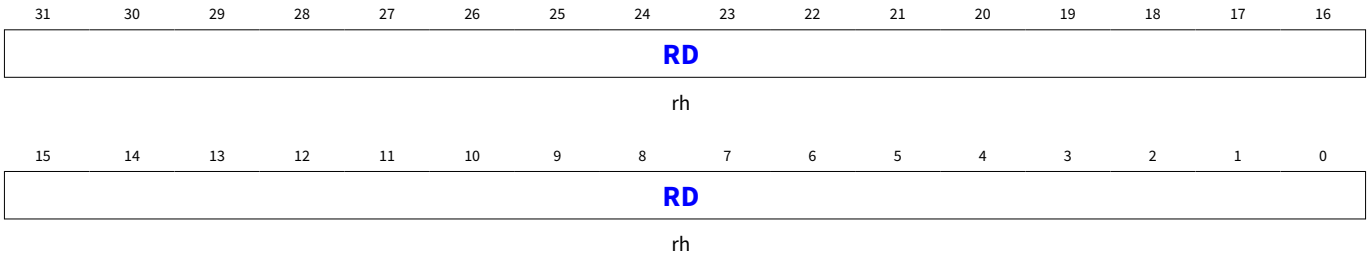
26.4.56 Receive Data FIFO x

The Receive Data FIFO RDFx for channel x shows the oldest data content of up to 32 received data frames. That is, RFCx.REP is pointing at the buffer presented.

Do not set a debugger watch point on this register as any read access will issue a hardware request for new data (move read pointer REP and present referring memory content in RDFx). A debugger watch point can be set on the RDML/Hx and RFCx to monitor the FIFO behavior.

RDFx (x=0-1) Offset address: 388_H+x*4

Receive Data FIFO x Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RD	31:0	rh	**RD** Shows the content of RDML/Hxy; y = RFCx.REP[5:1]; L/H = RFCx.REP[0]. Reading this register triggers incrementation of REP and presentation of next FIFO value at next read access. Once a complete buffer is read (64 bit, 2 accesses to RDF) all overview flags for this very buffer are cleared automatically.

26.4.57 RSI Overview Register x

The RSI Overview Register RSIOVx contains flags to manage the receive memory of PSI5 channel x.

RSIOVx (x=0-1) Offset address: 398_H+x*4

RSI Overview Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RSIy (y=0-31)	y	rh	**RSI Flag of Buffer y** Copied from INTSTATAx at frame end while RFCx.WRP pointed to buffer y. This bit can be cleared by bit RSICLRx.RSIy. This bit can be set by bit RSISETx.RSIy.

26.4.58 RMI Overview Register x

The RMI Overview Register RMIOVx contains flags to manage the receive memory of PSI5 channel x.

RMIOVx (x=0-1) Offset address: $3A8_H+x*4$

RMI Overview Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RMIy (y=0-31)	y	rh	**RMI Flag of Buffer y** Copied from INTSTATAx at frame end while RFCx.WRP pointed to buffer y. This bit can be cleared by bit RMICLRx.RMIy. This bit can be set by bit RMISETx.RMIy.

26.4.59 NBI Overview Register x

The NBI Overview Register NBIOVx contains flags to manage the receive memory of PSI5 channel x.

NBIOVx (x=0-1) Offset address: $3B8_H+x*4$

NBI Overview Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RDIy (y=0-31)	y	rh	**RDI Flag of Buffer y** Copied from INTSTATAx at frame end while RFCx.WRP pointed to buffer y. This bit can be cleared by bit RDICLRx.RDIy. This bit can be set by bit RDISETx.RDIy.

26.4.63 NFI Overview Register x

The NFI Overview Register NFIOVx contains flags to manage the receive memory of PSI5 channel x.

NFIOVx (x=0-1) Offset address: $3F8_H+x*4$

NFI Overview Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
NFIy (y=0-31)	y	rh	**NFI Flag of Buffer y** Copied from INTSTATAx at frame end while RFCx.WRP pointed to buffer y. This bit can be cleared by bit NFICLRx.NFIy. This bit can be set by bit NFISETx.NFIy.

26.4.64 MEI Overview Register x

The MEI Overview Register MEIOVx contains flags to manage the receive memory of PSI5 channel x.

MEIOVx (x=0-1) Offset address: 408_H+x*4

MEI Overview Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MEI31	MEI30	MEI29	MEI28	MEI27	MEI26	MEI25	MEI24	MEI23	MEI22	MEI21	MEI20	MEI19	MEI18	MEI17	MEI16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
MEIy (y=0-31)	y	rh	**MEI Flag of Buffer y** Copied from INTSTATAx at frame end while RFCx.WRP pointed to buffer y. This bit can be cleared by bit MEICLRx.MEIy. This bit can be set by bit MEISETx.MEIy.

26.4.65 RSI Overview Set Register x

The RSI Overview Set Register RSISETx contains bits to set the status flags of RSIOVx.

RSISETx (x=0-1) Offset address: 418_H+x*4

RSI Overview Set Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSI31	RSI30	RSI29	RSI28	RSI27	RSI26	RSI25	RSI24	RSI23	RSI22	RSI21	RSI20	RSI19	RSI18	RSI17	RSI16

RSI15	RSI14	RSI13	RSI12	RSI11	RSI10	RSI9	RSI8	RSI7	RSI6	RSI5	RSI4	RSI3	RSI2	RSI1	RSI0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
RSIy (y=0-31)	y	w	**Set RSI Flag of Buffer y** Setting this bit sets bit RSIOVx.RSIy Clearing this bit has no effect. Reading this bit returns always zero.

26.4.66 RMI Overview Set Register x

The RMI Overview Set Register RMISETx contains bits to set the status flags of RMIOVx.

RMISETx (x=0-1) Offset address: 428_H+x*4

RMI Overview Set Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RMI31	RMI30	RMI29	RMI28	RMI27	RMI26	RMI25	RMI24	RMI23	RMI22	RMI21	RMI20	RMI19	RMI18	RMI17	RMI16

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
RMIy (y=0-31)	y	w	**Set RMI Flag of Buffer y** Setting this bit sets bit RMIOVx.RMIy Clearing this bit has no effect. Reading this bit returns always zero.

26.4.67 NBI Overview Set Register x

The NBI Overview Set Register NBISETx contains bits to set the status flags of NBIOVx.

NBISETx (x=0-1) Offset address: 438_H+x*4

NBI Overview Set Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NBI31	NBI30	NBI29	NBI28	NBI27	NBI26	NBI25	NBI24	NBI23	NBI22	NBI21	NBI20	NBI19	NBI18	NBI17	NBI16
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

NBI15	NBI14	NBI13	NBI12	NBI11	NBI10	NBI9	NBI8	NBI7	NBI6	NBI5	NBI4	NBI3	NBI2	NBI1	NBI0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
NBIy (y=0-31)	y	w	**Set NBI Flag of Buffer y** Setting this bit sets bit NBIOVx.NBIy Clearing this bit has no effect. Reading this bit returns always zero.

26.4.68 TEI Overview Set Register x

The TEI Overview Set Register TEISETx contains bits to set the status flags of TEIOVx.

TEISETx (x=0-1) Offset address: 448_H+x*4

TEI Overview Set Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TEI31	TEI30	TEI29	TEI28	TEI27	TEI26	TEI25	TEI24	TEI23	TEI22	TEI21	TEI20	TEI19	TEI18	TEI17	TEI16
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TEI15	TEI14	TEI13	TEI12	TEI11	TEI10	TEI9	TEI8	TEI7	TEI6	TEI5	TEI4	TEI3	TEI2	TEI1	TEI0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
TEIy (y=0-31)	y	w	**Set TEI Flag of Buffer y** Setting this bit sets bit TEIOVx.TEIy Clearing this bit has no effect. Reading this bit returns always zero.

26.4.69 CRCI Overview Set Register x

The CRCI Overview Set Register CRCISETx contains bits to set the status flags of CRCIOVx.

CRCISETx (x=0-1) Offset address: 458_H+x*4

CRCI Overview Set Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRCI 31	CRCI 30	CRCI 29	CRCI 28	CRCI 27	CRCI 26	CRCI 25	CRCI 24	CRCI 23	CRCI 22	CRCI 21	CRCI 20	CRCI 19	CRCI 18	CRCI 17	CRCI 16
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
CRCIy (y=0-31)	y	w	**Set CRCI Flag of Buffer y** Setting this bit sets bit CRCIOVx.CRCIy Clearing this bit has no effect. Reading this bit returns always zero.

26.4.70 RDI Overview Set Register x

The RDI Overview Set Register RDISETx contains bits to set the status flags of RDIOVx.

RDISETx (x=0-1) Offset address: 468_H+x*4

RDI Overview Set Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDI31	RDI30	RDI29	RDI28	RDI27	RDI26	RDI25	RDI24	RDI23	RDI22	RDI21	RDI20	RDI19	RDI18	RDI17	RDI16
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
NFIy (y=0-31)	y	w	**Set NFI Flag of Buffer y** Setting this bit sets bit NFIOVx.NFIy Clearing this bit has no effect. Reading this bit returns always zero.

26.4.72 MEI Overview Set Register x

The MEI Overview Set Register MEISETx contains bits to set the status flags of MEIOVx.

MEISETx (x=0-1) Offset address: 488_H+x*4

MEI Overview Set Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MEI31	MEI30	MEI29	MEI28	MEI27	MEI26	MEI25	MEI24	MEI23	MEI22	MEI21	MEI20	MEI19	MEI18	MEI17	MEI16
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

MEIy (y=0-31)	y	w	**Clear MEI Flag of Buffer y** Setting this bit clears bit MEIOVx.MEIy Clearing this bit has no effect. Reading this bit returns always zero.

26.4.81 Receive Data Memory Low xy

The Receive Data Memory RDMLx for channel x shows the data content of up to 32 received data frames.

The internal receive buffer is always cleared (0x0000 0000$_H$) at each frame start. Thus unused nibbles are always read as zero.

RDMLxy (x=0-1;y=0-31) Offset address: $600_H+x*100_H+y*8$

Receive Data Memory Low xy Kernel Reset value: 0000 0000$_H$

26.7 PSI5 revision history

Initial release of the chapter.

26.8 TC4Dx PSI5 information

26.8.1 TC4Dx PSI5 configuration

Table 1187 TC4Dx PSI5 configuration

Parameters	PSI5
Number of channels	2
RAM size (in Kbytes)	0.5

26.8.2 TC4Dx PSI5 features

There are no deviations from the generic specification.

26.8.3 TC4Dx PSI5 functional description

1. PSI5 acts as a slave on the ComPB bus. The Clock Control block is driven by the system clock frequency f_{SPB} as in TC4Dx, the ComPB also uses this clock
2. There is no GTM trigger available. Only eGTM trigger signals are used for Time stamp generation and Sync pulse control

26.8.4 TC4Dx PSI5 registers

There are no deviations from the generic specification.

26.8.4.1 Register address space - PSI5

26.8.4.4 Device specific registers

There are no device specific register changes.

26.8.5 TC4Dx PSI5 connectivity

The table below lists interfaces to and from this functional block to other blocks in the device.

Table 1191 List of PSI5 interface signals

Interface signals	I/O	Description
CLOCK_PSI5_fSPB	In	FPI clock input
PSI5_IR_PSI5SRx[7:0]	Out	Interrupt trigger output
EGTM_PSI5_TRIG[5:0]	In	eGTM trigger
PORTS_PSI5_PSI5RX[1:0]	In	Receive data per PSI5 module
PSI5_PORTS_PSI5TX[1:0]	Out	Transmit data per PSI5 module

26.8.6 TC4Dx PSI5 revision history

Initial release of the chapter.

27 Peripheral Sensor Interface with Serial Interface to PHY (PSI5-S)

The PSI5-S module performs communication according to the PSI5 specification. It communicates with the external world using one ASC interface for all channels. This ASC interface is built into the PSI5-S module. If the optional bidirectional mode is used, the commands to the external Physical Layer Interface (PHY) are transmitted through this interface.

27.1 Feature list

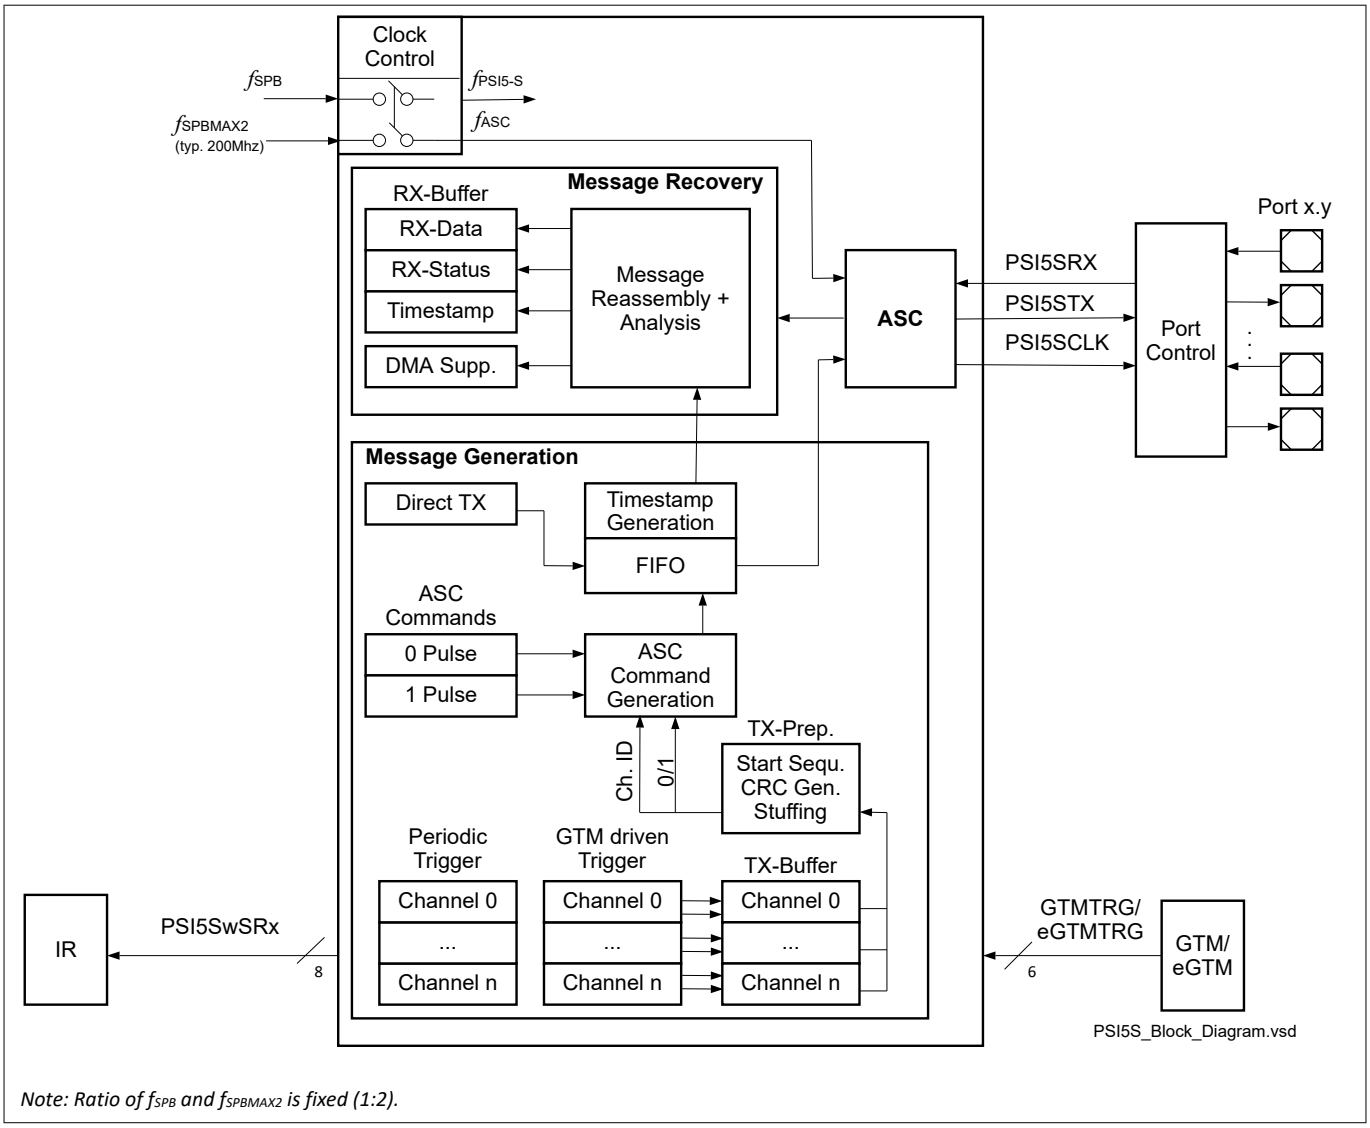
- According to PSI5 protocol specification v2.1
- Flexible configuration and monitoring using software
  - Asynchronous/synchronous serial communication (ASC interface) with compatible PSI5-S physical-layer (PHY)
  - Baud rate generator up to 12,5 MBaud at 200 MHz ASC sub-module clock
  - Clock out generator to supply external PHY
  - Data rates of 125 kbit/s and 189 kbit/s supported
  - 8 PSI5-S channels sharing one common ASC interface (channel 0 frame 1 special use)
  - Asynchronous and Synchronous PSI5 data transmission modes
  - Supports 6 sensor slots per channel
  - 8 interrupts or direct memory access (DMA) triggers
- Receive data processing using Message Recovery block:
  - 10-bit ASC format: 1 Start bit, 8 Data bits, 1 Stop bit (upstream)
  - Each PSI5 frame is transported in a packet frame consisting of 3 to 6 UART frames transmitted back to back with exactly one Stop bit. There is no additional delay
  - Packet frames are separated by a programmable idle time (with 1 to 16 idle bits)
  - Assembly and decoding of packet frames (envelope)
  - Routing of PSI5 frames to their referring channel receive buffer in system memory by hardware DMA support
  - Checking CRC of packet frames (XCRC)
  - Frames with XCRC error will be routed to channel 0 frame 1
  - The external PHY sends all frames of an asynchronous channel with frame ID (FID) = 1. All frames of this channel have the same length and structure as defined for FID 1. Therefore it is sufficient to configure frame 1 for asynchronous channels
  - Configurable data length from 8 to 28 bits and 3-bit PSI5 CRC or 1-bit PSI5 parity
  - CRC check of received PSI5 sensor data, CRC code still transparent
  - No hardware support of extended serial data messaging according to SENT SAE J2716 JAN 2010. Messaging bits are transported fully transparent for software decoding
  - 24-bit timestamp on sync pulse request through ASC (resolution: 1 µs)
  - Two independent time bases for timestamp: clocked by GTM or eGTM (1 out of n GTM or eGTM signals is selectable) or internal periodic trigger generator
  - PHY answers to CPU commands with standard frames of fixed predefined length in channel 0 frame 0
  - Error bits in packet frame are presented fully transparent and an interrupt is issued
  - One interrupt for error free packet frame. Relevant errors are selectable
  - One interrupt for packet frame reception disregarding any error
- Transmit message data preparation using Message Generation block
  - Support of ECU to sensor communication
  - One 32-bit send data register per channel for downstream data input
  - Data is shifted out LSB first. MSB is filled with ‘0’ or ‘1’ with each shift, depending on the bit coding method: Tooth Gap or Pulse Width

- 11-bit ASC format: 1 Start bit, 8 Data bits, 1 Parity, 1 Stop bit (downstream)
- Downstream commands of fixed format (3 MSB = Channel ID. 5 LSB = Command)
- All commands are randomly programmable and are therefore not interpreted by PSI5-S
- Downstream data transmission by 2 different ASC commands (short/no, and long pulse)
- 8 common lines of FIFO for all channels, writable by:
  - PSI5 message generation
  - Sync pulse generation. Pre-programmed bytes for 0 and 1
  - CPU commands:
    - CPU direct write registers (CDW) allow for insertion of commands into the FIFO for configuration and debugging
- 8 GTM or eGTM inputs for sync pulse triggering
- Software configurable staggering of sync pulse generation
- Generation of 3 or 6-bit CRC for downstream data
- Start sequence generator for downstream data. This can also be switched off
- Bit stuffing generator for downstream data. This can also be switched off
- CRC generator for downstream data. This can also be switched off
- Internal Loop-Back mode for a check of the CRC generator and for software development

27.2 Functional overview

The Peripheral Sensor Interface is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of airbag systems.

The following block diagram shows a global view of the PSI5-S interface.



Note: Ratio of f_{SPB} and $f_{SPBMAX2}$ is fixed (1:2).

Figure 536 PSI5-S block diagram

PSI5 defines a current loop based serial communication link typically used to connect airbag sensors or other peripheral devices. PSI5 provides high speed and high reliability data transfer. The PSI5-S acts as a slave on the SPB bus. The PSI5-S kernel is composed of the clock control block that is driven by the system clock frequency f_{SPB}.

The PSI5-S consists of three main blocks that are shared between 8 channels :

- Message Generation block that is used for preparing the transmit data
- Message Recovery block that processes the received messages
- Common ASC module

While the physical layer is done externally, this module manages communication with this PHY and the presentation of the data to the application. Note that there is no on chip PHY, therefore the current to voltage and voltage to sync pulse translation is done externally.

Receive data on a PSI5-S channel can be set up according to the underlying application. In particular the number of bits is configurable.

The message storage consists of a set of 3 32-bit registers for all channels: one receive data register containing the received sensor data, one timestamp register containing the 24-bit value and one additional register containing status bits.

For Synchronous Communication mode, the module can consume sync pulses from the external GTM/eGTM or generate periodic sync pulses by itself. It supports as well ECU to sensor communication by offering a 32-bit

register, where messages can be set up by the CPU. All kinds of sync pulses are translated into a referring, programmable byte to be sent through ASC.

The register set of the PSI5-S module can be accessed directly by the CPU for configuration, data read out and status query.

27.3 Functional description

The following section explains the different PSI5-S modes of operation and frame formats

27.3.1 PSI5 ECU to sensor operation

ECU to sensor communication is defined in the PSI5 protocol specification v2.1. Data transmission and configuration of the sensor is made by modulation of the sync pulses.

Two modes are supported:

- Tooth Gap method
  - With the Tooth Gap method, a specific start condition and a start sequence switch the sensor in ECU to sensor communication mode. In this mode, the sync pulses are no longer used as triggers for PSI5 frames but are interpreted as data for the sensor. A pulse represents a 1 and a missing pulse represents a 0. This requires isochronous pulses.
- Pulse Width method
  - With the Pulse Width method a standard length pulse represents a 0, and a longer pulse a 1. In this way, continuous data transmission can be achieved. The pulses can be non-isochronous. They can for example, be dependent from the angle position of a rotating axis.

27.3.2 Frame formats and definitions

This section describes the frame formats and definitions of the PSI5-S protocol.

27.3.2.1 Communication between PSI5-S and PHY through UART

This chapter covers the communication on the UART connection.

27.3.2.1.1 Packet frames received from PHY

Packet frames are 3 to 6 UART frames carrying one PSI5 frame. The format accepted by PSI5-S is explained here.

A UART frame is one transmission unit over the ASC interface. On the receive path it consists of one Start bit, 8 Data bits, and one Stop bit. Parity can be optionally chosen, for loop-back tests for example.

The figures show the minimum and maximum packet frame population with data. Where the figures show ‘Res0’ bits, these bits can be crowded by more data bits if configured.

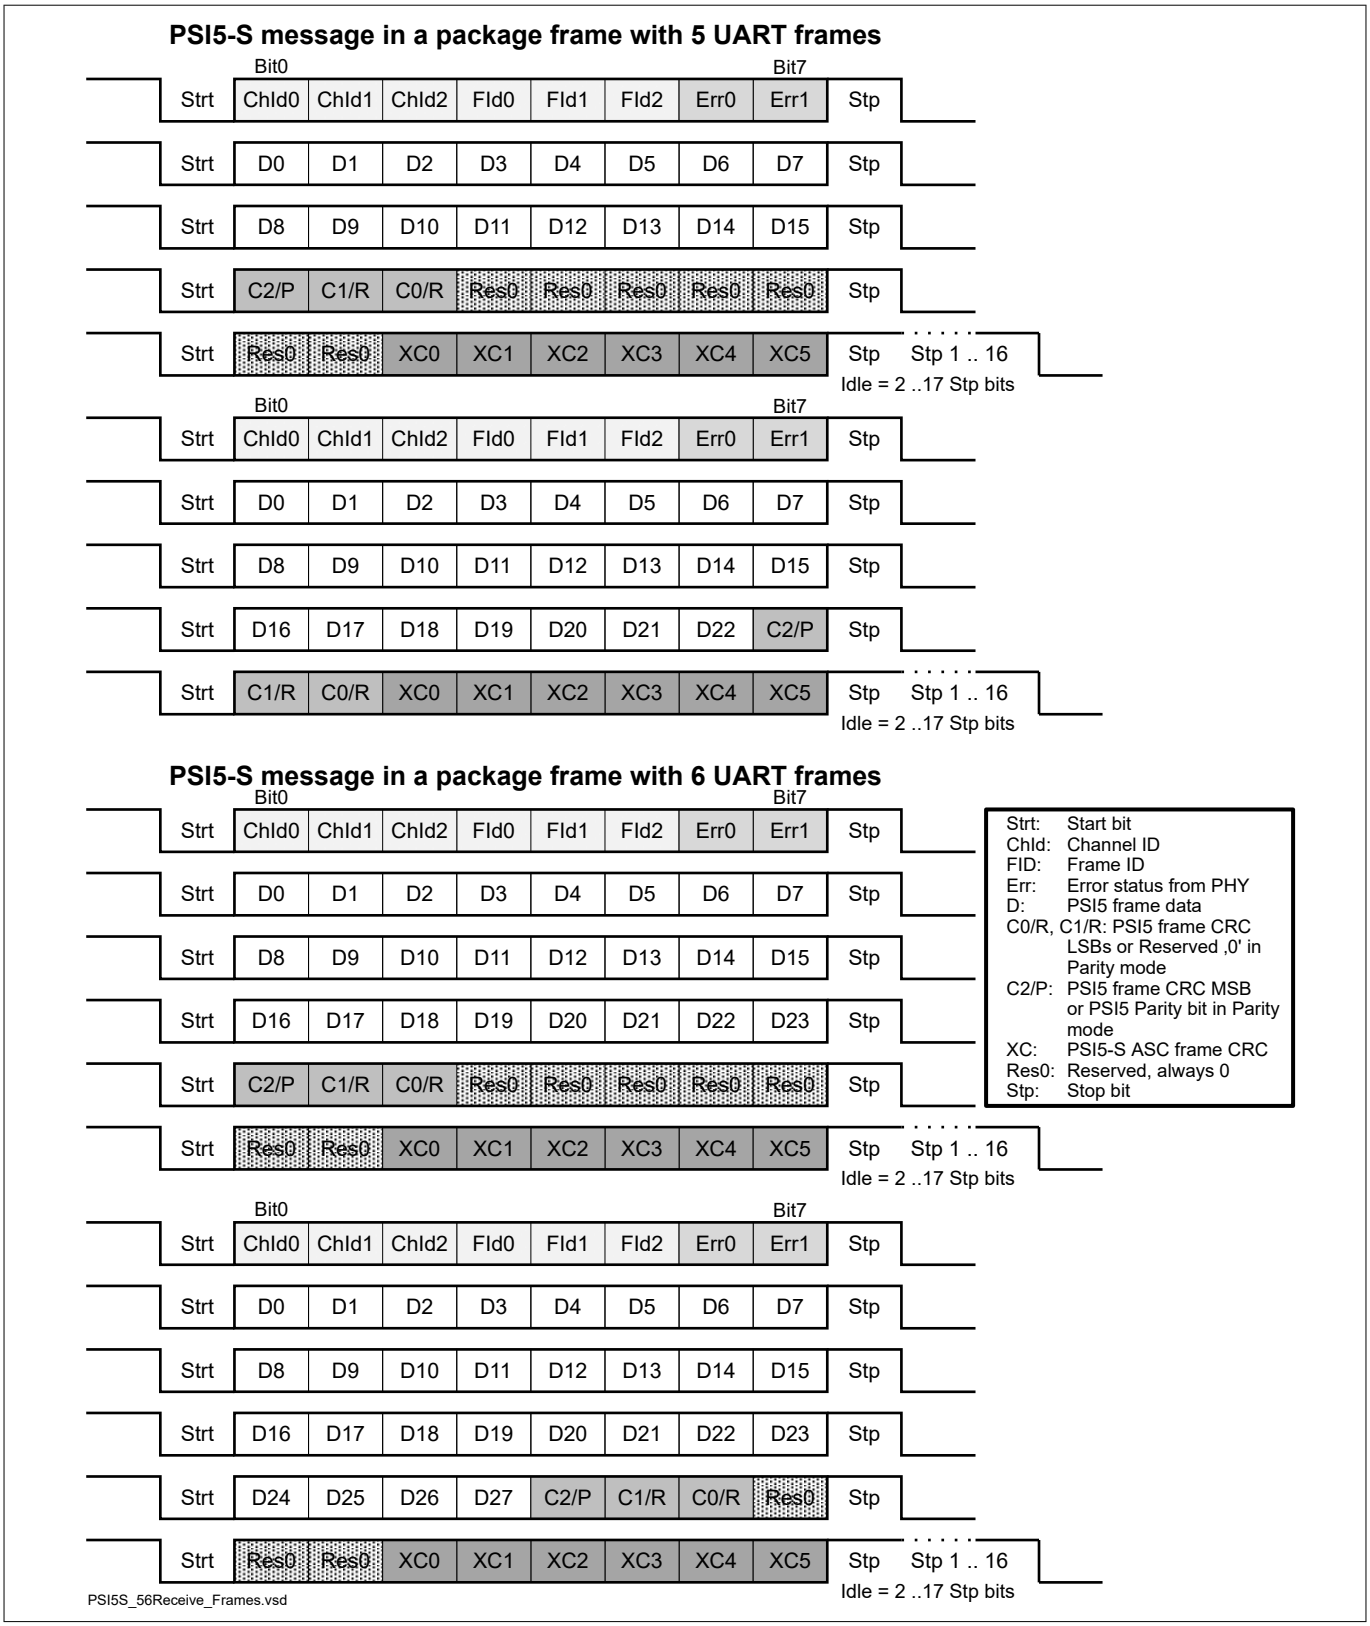

Figure 537 PSI5-S 5 and 6 UART frames per package frame received from PHY

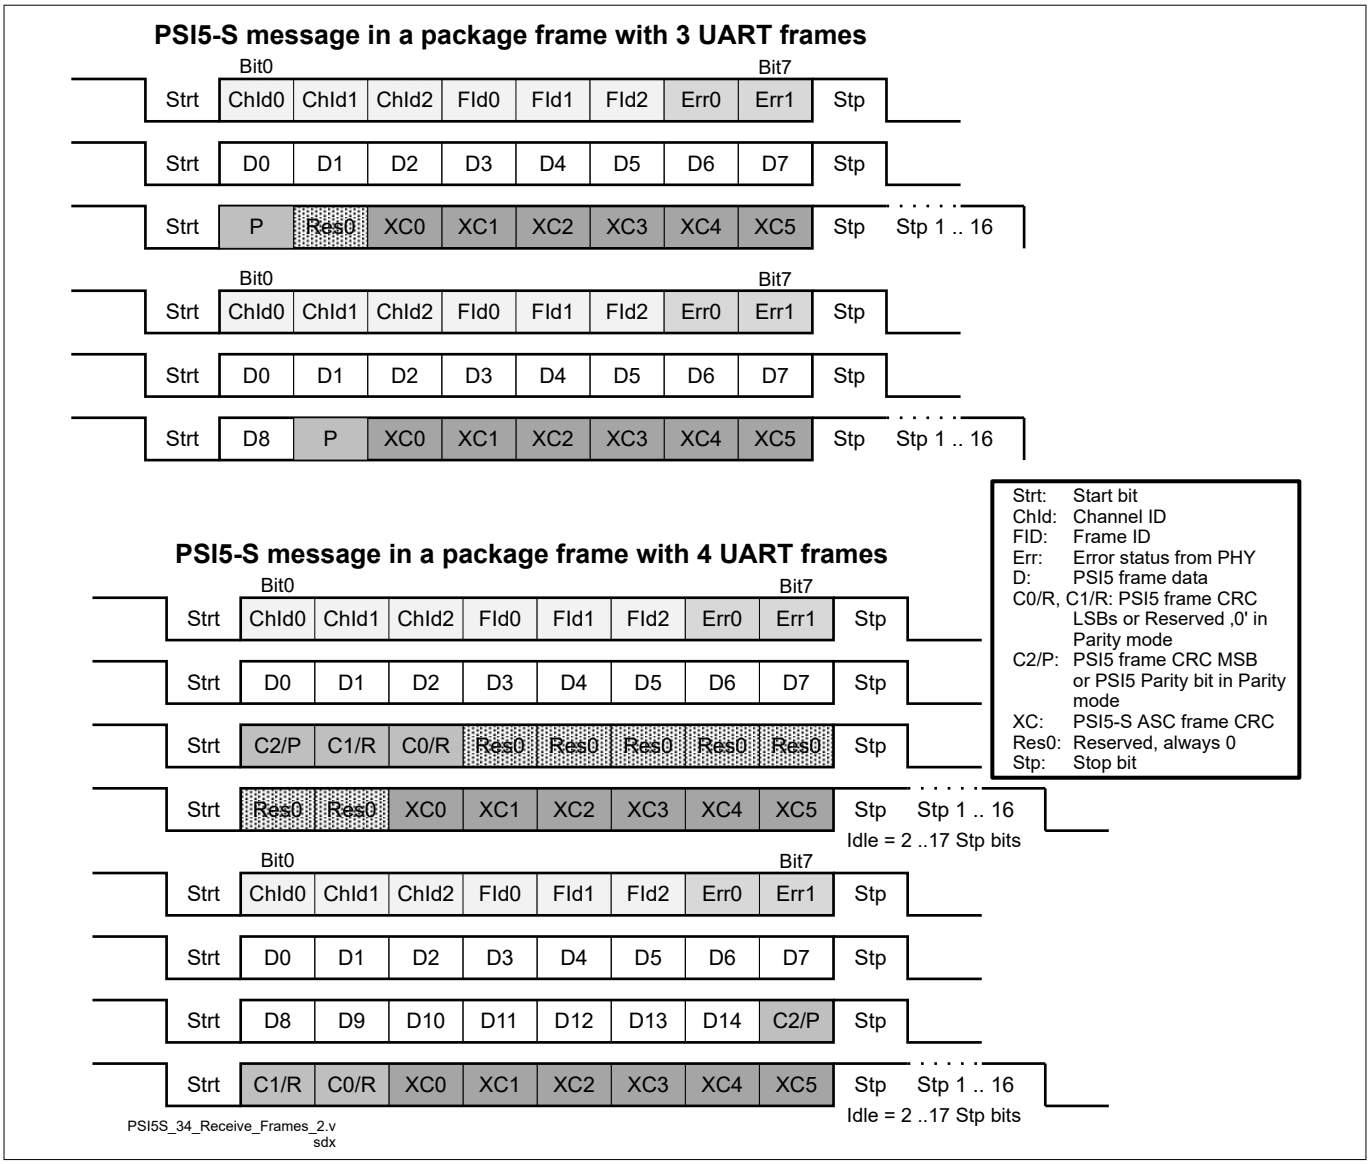

Figure 538 PSI5-S 3 and 4 UART frames per package frame received from PHY

Detection of frame boundaries and packet frame processing

- SOF (start of frame) is defined by a Start bit detected after idle on ASC interface
- Idle equals at least two Stop bits:
  - The required idle time can be configured between 1 and 16 additional Stop bits
  - An idle state signal is provided internally by the ASC module to the reassembly unit
  - The idle signal starts on detection of the first Stop bit and ends when the first slope of the next Start bit has passed the two out of three majority vote input filter
- If idle is detected before the minimum of 3 UART frames were received, these UART frames are copied to channel 0 frame 1 (non-recoverable frames)
- Based on the RDS.ChID and RDS.FID received in the first UART frame, the module checks:
  - If the referring channel is enabled
  - If the FID is valid and configured (PDLy > 0)
  - The expected number of UART frames configured in RCRAx.UFCy
  - If at least this number of UART frames is received without idle
  - If the XCRC is correct

- If these checks pass:
  - EOF is detected after the correct number of UART frames
  - Data is copied to RDR, interrupts and the status are updated in RDS. In particular CRC/parity check is executed. Timestamp (TSM) and target address (TAR) are updated. Depending from bit RCRAx.FIDS, the FID might be manipulated
  - The message recovery unit does not wait for idle to execute the steps above
- If these checks fail (non-recoverable frames):
  - EOF is detected after idle or a maximum of 6 UART frames
  - The 1 to 6 UART frames are stored in channel 0 frame 1
- If more UART frames follow a passing or failing packet frame without idle:
  - EOF is detected after idle or a maximum of 6 UART frames
  - The 1 to 6 UART frames are stored in channel 0 frame 1
  - Reception is stopped
  - The next UART frames following without idle time are ignored
  - Reception starts only after the idle time programmed in GCR.IDT is detected (so-called babbling-idiot protection)

Non-recoverable frame presentation in RDR and RDS

- RDS.FID and ChID are derived from the first UART frame received
- RDR.RD[27:0] contains all bits of each UART frame received after the header. That is:
  - 0 bits for 1 UART frame
  - 8 bits for 2 UART frames
  - 16 bits for 3 UART frames
  - 24 bits for 4 UART frames
  - 28 bits for 5 and 6 UART frames
- RDS.CRC is determined as follows:
  - If 6 UART frames were received: bits [6:4] of the 5th UART frame
  - If 1 to 5 UART frames where received: determined by RCRBx.PDLy
  - RCRBx.PDLy may not be reliable, but this way all data is covered either in the data field or in the XCRC field. In case RCRBx.PDLy was correct, CRC is shown correctly
- RDS.XCRC contains always the bits [7:2] of the last UART frame received. Also if only 1 UART frame was received
- Note that XCRCI is always set as either XCRC was wrong, or the number of UART frames received was wrong, or it could not be determined

Loop-back support

- Parity and number of Stop bits need to be configured the same for sender and receiver in Loop-Back mode. Parity control and polarity of parity can be configured separately each for TX and RX. This can be done before switching on Loop-Back mode. Alternatively, the parity control can be adjusted as well in one single register access together with switching the ASC part to Loop-Back mode
- Both ways are supported: Add parity bit to the receiver, or use the transmitter without parity. The standard use case is to use transmitter with parity
- Data to be transmitted can be written directly to the CDW register
- In this way a synthetic Packet frame can be sent to the reassembly unit for test purposes
- The received loop-back data is treated in the same way as the normal receive data. Good frames are received in their referring channel and slot. Frames with the wrong XCRC, idle time, or RCRAx.UFCy, are stored in channel 0 frame 1

XCRC content

XCRC is always sent at the end of the last UART Packet. For XCRC calculation, all bits of the preceding UART frames that belong to the packet frame are relevant, including potential stuffing bits (Res0). UART Start or Stop bits are excluded.

In detail the XCRC shall contain the header (ChID, FID, Err0, Err1), PSI5 frame data (D0 … Dx, PSI5 frame parity bit or CRC bits) and potential stuffing bits (Res0) between P/CRC and XCRC. Not included are Start and Stop bits of the UART packets and the 2 Start bits (S0, S1) of the PSI5 frame.

The LSB of the first byte (ChId0) is fed first into the XCRC polynomial.

XCRC calculation method

XCRC equals the CRC defined in the PSI5 standard v2.1 “Frame format 4 ECU to Sensor Message CRC”.

The following figure shows the layout and definitions of the UART frames sent by PSI5-S.

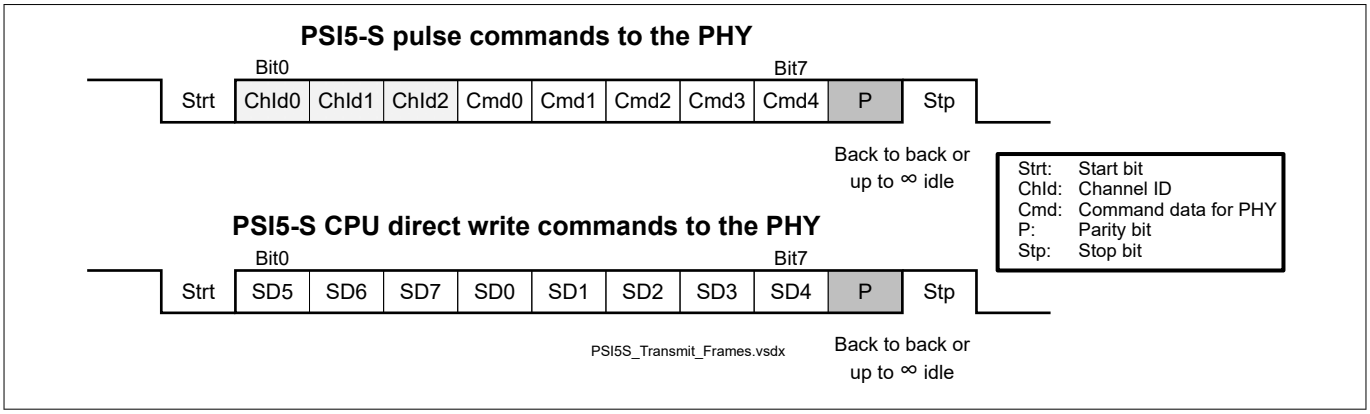

Figure 539 PSI5-S UART frames transmitted to the PHY

27.3.2.2 Communication between PHY and sensor (PSI5 standard)

This chapter treats the frame formats on the PSI5 bus as short reference.

27.3.2.2.1 PSI5 standard frame format

The following figure shows the principal layout and definitions of a PSI5 frame. Note that the PSI5 standard specifies that the least significant bit is sent out first. See standard for CRC and parity definition.

Example: 16 Bit Data Word „0xAD2C“ with 3-Bit CRC

S1	S2	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	D10	D11	D12	D13	D14	D15	C2	C1	C0
0	0	0	0	1	1	0	1	0	0	1	0	1	1	0	1	0	1	1	0	0
		C = „1100“				2 = „0010“				D = „1101“				A = „1010“						

Figure 540 Standard PSI5 frame format

27.3.2.2.2 PSI5 extended frame format

The following figure shows the layout and definitions of an Extended PSI5 Frame. Note that the PSI5 standard specifies that the least significant bit is sent out first.

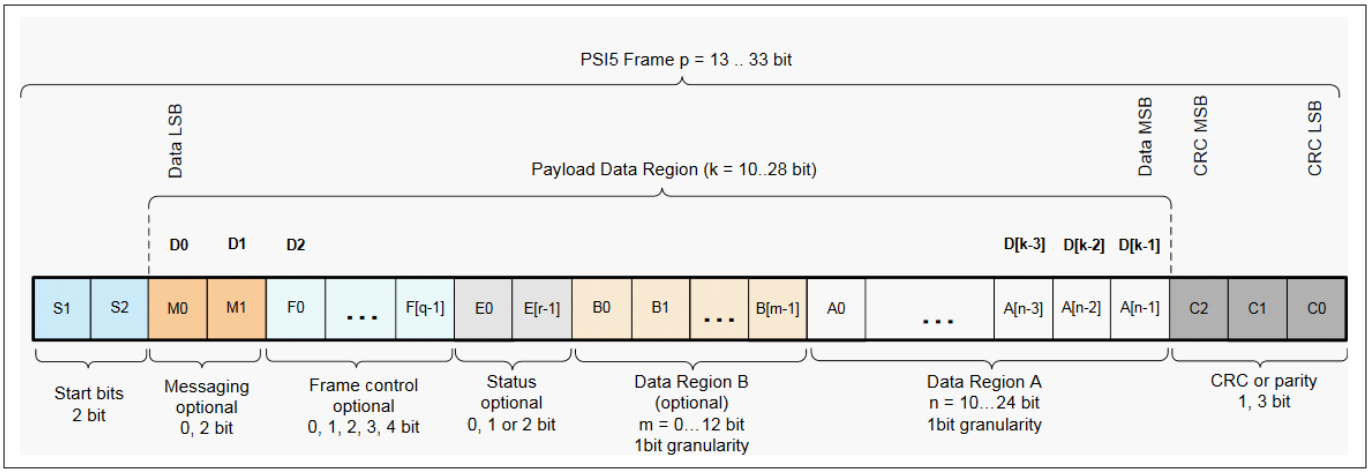

Figure 541 PSI5 extended frame format

PSI5 Sensor to ECU Message CRC

The transmission of PSI5 data is checked by the following protection modes. The transmission error detection must be selectable:

1. 1-bit even parity
2. 3-bit CRC

The applied generator polynomial of the CRC is $g(x) = 1 + x + x^3$ with a binary start value (seed) “111”. The transmitter shall extend the data bits by three zeros (as MSBs). This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits shall be ignored in this check. When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum. These three check bits shall be transmitted in reverse order (MSB first: C2, C1, C0).

27.3.2.2.3 Sync pulses

Sync pulses are used for two different purposes:

- Triggering a data frame for data acquisition from a sensor or
- ECU to sensor communication

Synchronous transmission

In the “Synchronous” mode, the sensor (slave) starts to transfer a complete data frame only after a sync pulse is transmitted through ASC to the external PHY. The external PHY translates this ASC command into a voltage increase. The sensor then initiates a measurement and starts to calculate the new output data value. The data follows in a standard PSI5 frame, starting with the 2 Start bits, data and parity or CRC. The timing diagram in the following figure visualizes a synchronous transmission

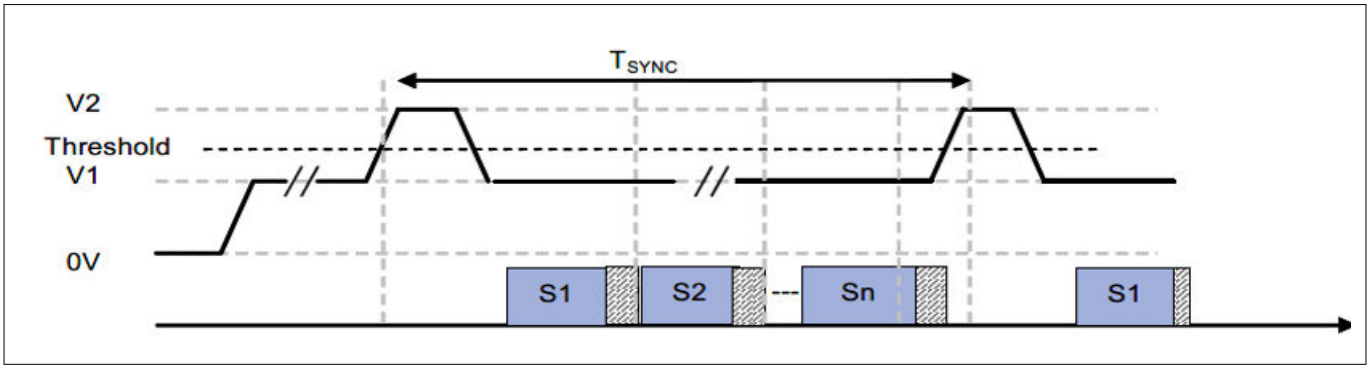

Figure 542 Synchronous transmission

ECU to sensor communication

PSI5 v2.1 defines 4 principle frame formats. Please refer to this standard document for more details. As the main target application is powertrain, only frame format 4 is cited here. This is the format for the powertrain substandard.

Two methods for the ECU to sensor communication are supported:

- Tooth Gap method
- Pulse Width method

Tooth gap method

Tooth gap method uses usually 31 sync pulses as start condition and start bits (0 1 0) to signal the start of the ECU to sensor communication. From this start on, the sync pulses are interpreted by the sensor as data. See standard for CRC and parity definition.

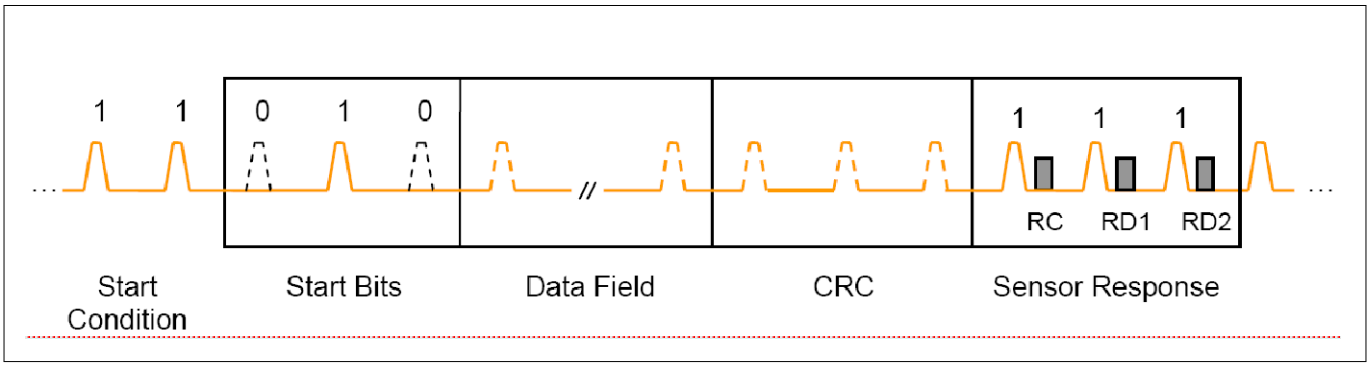

Figure 543 ECU to sensor (tooth gap method)

Pulse width method

Pulse width method allows for modulation of the sync pulse duration. This way bidirectional communication is possible continuously.

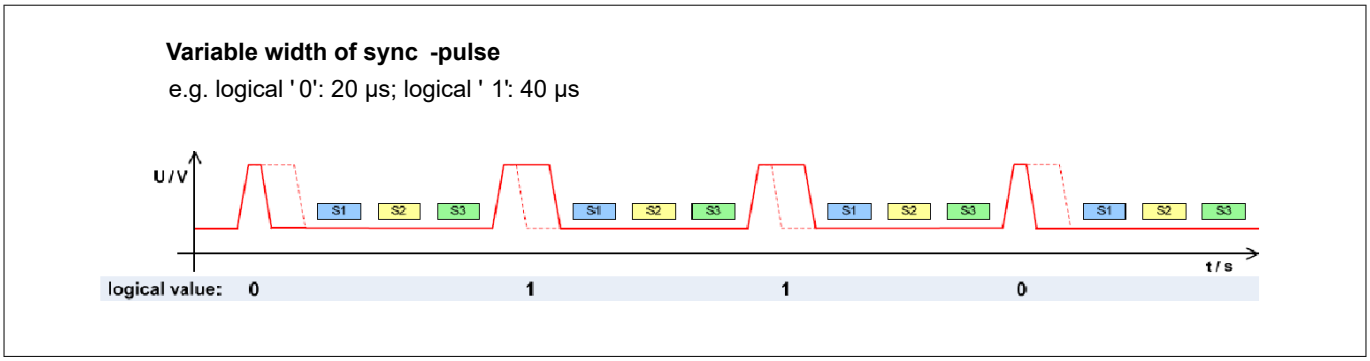

Figure 544 ECU to sensor, bit transmission (pulse width method)

The extended powertrain substandard frame format 4 "XXLong" follows the Pulse Width method.

Frame format 4 (power train)

Sync bits

Seven consecutive ones within the transmitted data could be misinterpreted as a frame start condition. Therefore a “sync bit” (logical 0) is inserted after every six bits of the sensor address and the payload data. With respect to the data transmission, these sync bits are treated like stuffing bits, which are removed at the receiver side.

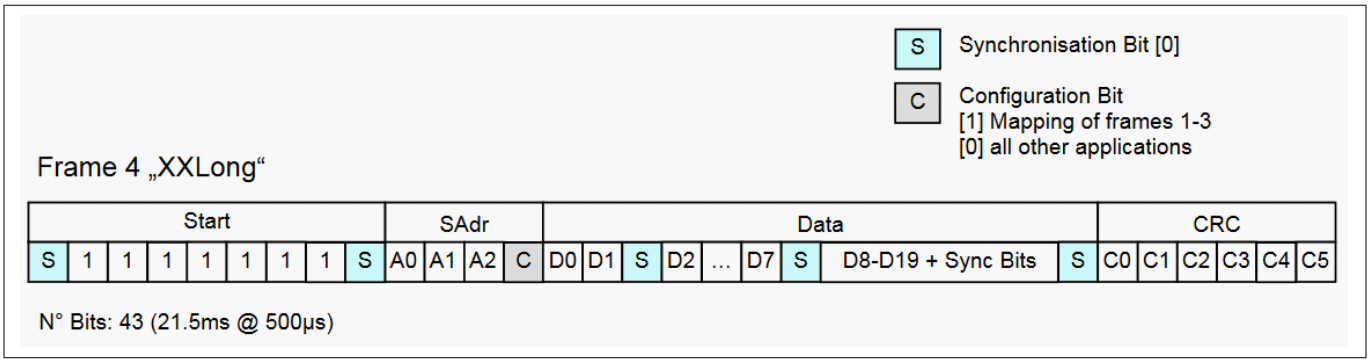

Figure 545 ECU to Sensor, frame format 4 (power train)

ECU to sensor message CRC

The ECU-to-Sensor frame has a 6-bit CRC. The generator polynomial of the CRC is $g(x) = x^6 + x^4 + x^3 + 1$ with a binary CRC initialization value “010101”.

The transmitter extends the data bits by six zeros (as MSBs). This augmented data word shall be fed (LSB first) into the shift registers of the CRC check. Start bits and sync bits are ignored in this check. When the last zero of the augmentation is pending on the input adder, the shift registers contain the CRC checksum. These six check bits shall be transmitted LSB first [C0, C1 … C5]. This CRC value is computed as a function of the contents of all Address and Data bits and sync bits (“0” bits). For purposes of the CRC calculation, the bits shall be ordered: m = [A0 A1 … A3 D0 D1 0 D2 … D19 0]. In this implementation the number of elements is configurable. While the standard is 4 Address and 20 Data bits, the module allows longer or shorter messages too.

27.3.3 Clock generation

The PSI5-S module provides 2 Timestamp Counters (TSCNTA and TSCNTB) and the timestamp clock f_{TS} to each channel as shown in the following figure. The clock of each timestamp counter is individually selectable: either f_{TS} or any of the GTM/eGTM inputs can be selected to drive them.

The PSI5-S module provides 2 internal clock signals

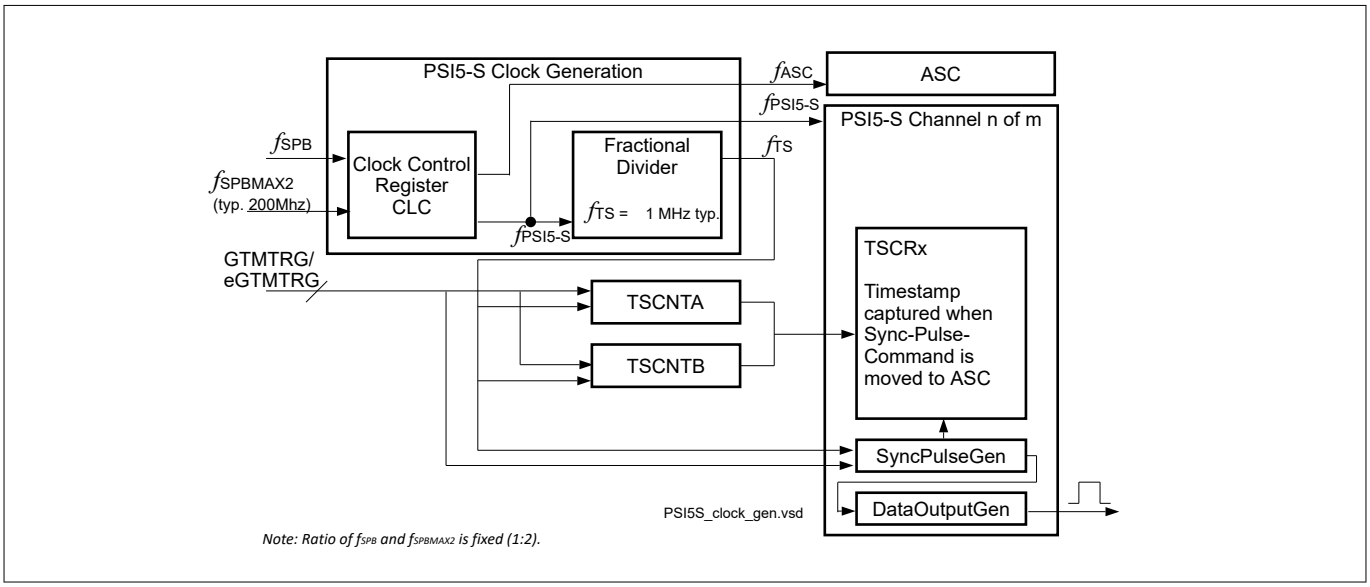

Figure 546 PSI5-S module clock generation

- f_{PSI5-S}
  This is the module clock that is used inside the PSI5-S kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{PSI5-S} is controlled by register FDR and derived from the system clock frequency f_{SPB}. The Clock Control register CLC makes it possible to enable/disable f_{PSI5-S} under certain conditions.
  The following two formulas define the frequency of f_{PSI5-S}:

$$f_{PSI5-S} = f_{SPB} \div (1024 - FDR.STEP); FDR.DM = 01_B \quad (23)$$

$$f_{PSI5-S} = f_{SPB} \times FDR.STEP \div 1024 \text{ with } STEP = 0...1023; FDR.DM = 10_B \quad (24)$$

- f_{TS}
  This clock is usually used to drive the timestamp counters. It can be selected to drive the global sync pulse time base and inside the PSI5-S channels to drive the local sync pulse generators and watchdog timers. The Fractional Divider register FDRT controls the frequency of f_{TS}. This is usually adjusted to 1 MHz/1 µs period time.
  The following two formulas define the frequency of f_{TS}:

$$f_{TS} = f_{PSI5-S} \div (1024 - FDRT.STEP); FDRT.DM = 01_B \quad (25)$$

$$f_{TS} = f_{PSI5-S} \times FDRT.STEP \div 1024 \text{ with } STEP = 0...1023; FDRT.DM = 10_B \quad (26)$$

27.3.3.1 Overview on clocks in the system

To reduce system cost, the external PHY can be supplied with a clock from this module by PSI5SCLK pin. The range is limited to 20-25 MHz for proper clock transmission. The PHY needs to provide 3 clocks from this: sample clock for 189 kHz, 125 kHz and the ASC oversampling clock.

$f_{PSISCLK}$

This clock is used to drive the external PHY as shown in the following figure.

The Fractional Divider register FDO controls the frequency of $f_{PSISCLK}$.

The following formula defines the frequency of $f_{PSISCLK}$:

$$f_{PSISCLK} = f_{ASC} \div (2048 - FDO.STEP) \div 2; DM = 01_B \quad (27)$$

$$f_{PSISCLK} = f_{ASC} \times FDO.STEP \div 2048 \div 2 \text{ with } STEP = 0...2047; DM = 10_B \quad (28)$$

In order to relax the requirements with respect to ASC communication while allowing for high bit rates, some additional provisions have been made. The ASC submodule is supplied with a higher frequency (f_{ASC}) to allow for very high precision at high baud rates (4 - 12,5 MBaud). As a second measure to achieve this, the fractional divider in ASC submodule is longer than in the standard module. The following figure illustrates the situation. Refer to the ASC subchapter for baud rate calculations.

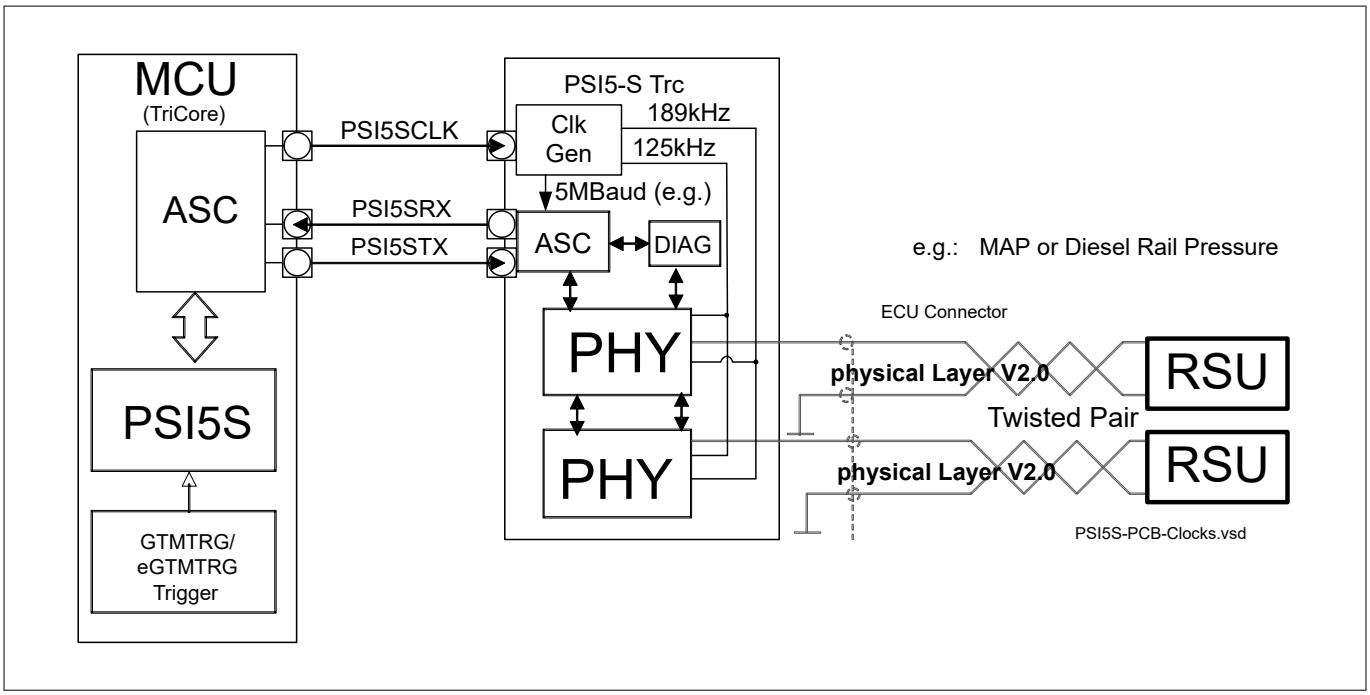

Figure 547 PSI5-S clock requirements of PHY

27.3.4 Timestamp generation

Two time bases can be selected for timestamping:

- Internal time base (Bit TSCNTA.TBS = 0 or TSCNTB.TBS = 0)
- External time base (Bit TSCNTA.TBS = 1 or TSCNTB.TBS = 1) GTM or eGTM
  - Bit TSCNTB.TRIGSELA and TSCNTB.TRIGSELB are used to select between GTM or eGTM for TSCNTA and TSCNTB respectively. Bit TSCNTA.ETB or TSCNTB.ETB are used to select the external clock line for counters CTS. Bit ECS, if enabled by FDRT.ECEA or ECEB, selects the external trigger line that clears the timestamp counters CTS

There are two Timestamp Counters TSCNTA.CTS and TSCNTB.CTS . Bits TSCNTA.TBEA and TSCNTA.TBEB start or stop the counters. Bit RCRAx.TSP is used to select between the two timestamp counters. Each of them can be

configured to be driven by either f_{TS} or by an external timer(GTM or eGTM). The frequency of f_{TS} is controllable by the fractional divider in the FDRT register.

All of the counters can be cleared by software synchronously.

The last sync pulse sent on a channel is stored in the sync pulse Timestamp Capture register TSCRx. Note that if RCRAx.TSTS is set, the sync pulses do not trigger the timestamp capture. In this case, the packet frame reception triggers the capture. Non-recoverable packet frames will be stored with the current value of TSCNTA or B copied directly to the TSM register. See RCRAx for more details.

For each channel the capture time (TSCRx) is stored.

The following figure shows the timestamp generation:

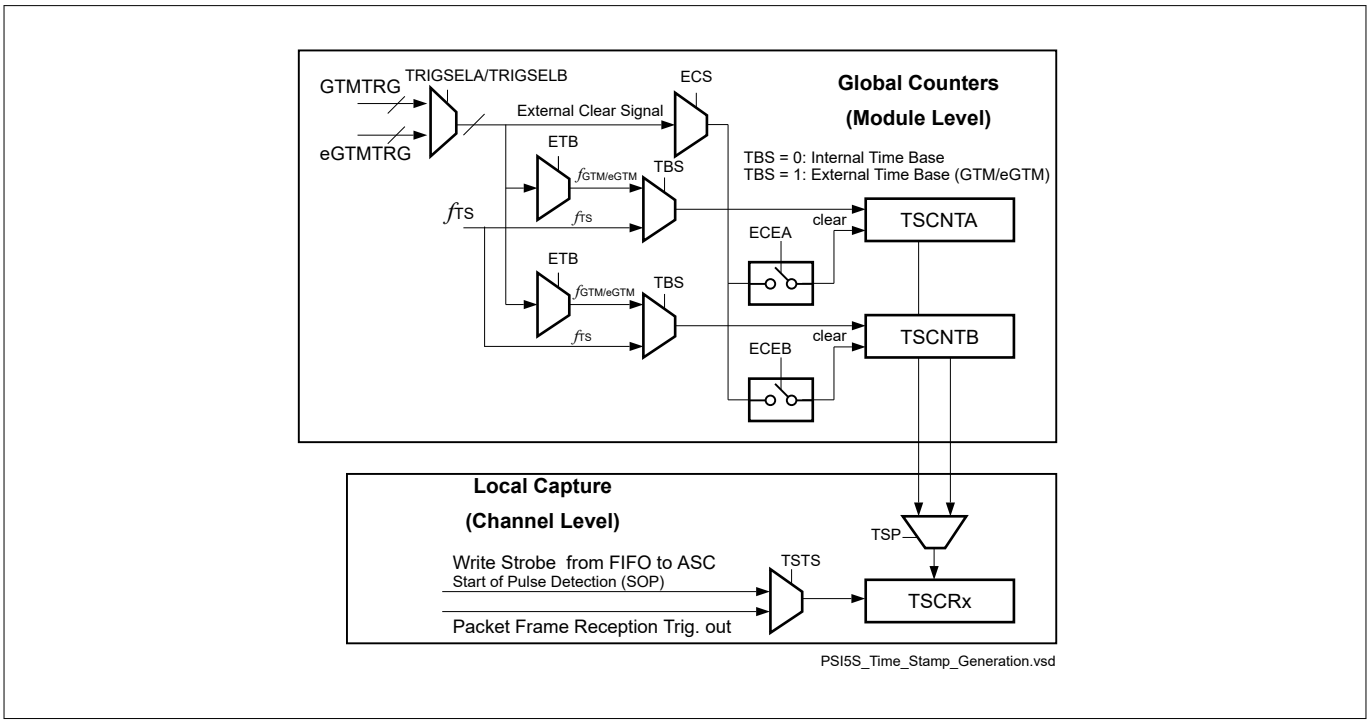

Figure 548 Timestamp generation

27.3.5 Watchdog timers

The value entered in WDTx.WDL defines the time in multiples of TTS (time resolution defined in FDRT) until expiry of the watchdog timer.

There are two modes of operation that can be selected with bit RCRAx.WDMS.

In Asynchronous mode an interrupt (TEI) is issued if the time between two RDIs is longer than specified in WDL. In this mode, the internal watchdog timer is started automatically when the channel is enabled.

In Synchronous mode, TEI is issued if the watchdog timer expires without reception of interrupt CHCI in time. Which means that the time from issuing the sync pulse to reception of the last expected frame configured in NFC.NFx was too long.

In both modes, only completely and correctly received packet frames with no XCRC error on channel x can qualify. Otherwise, the channel number cannot be determined as the referring WDTx.WDL will not be selected.

The internal watchdog timer is compared to WDTx.WDL. A match:

- Triggers a TEI
- Restarts the watchdog timer. It clears the internal watchdog timer and it counts on from zero. TEI is repeated if non-recoverable frames are received

If no watchdog timer is needed, WDL is cleared, the internal watchdog timer is stopped and no check is performed.

Asynchronous mode of the watchdog timers

If RCRAx.WDMS is cleared, the internal watchdog timer is restarted on reception of a new recoverable frame (RDIx is set) for the referring channel, as shown in the following figure. The frame is considered to be valid when the timing between two consecutive received frames (RDIx is set) is less than WDL. Otherwise, a TEI interrupt is triggered. It is not restarted by a sync pulse and not stopped by a certain number of received packet frames.

The example below shows the usage of the watchdog timer. The sync pulse is completely ignored by the watchdog timer system.

F2 is the only frame coming too late. All others start before the expiry of the watchdog.

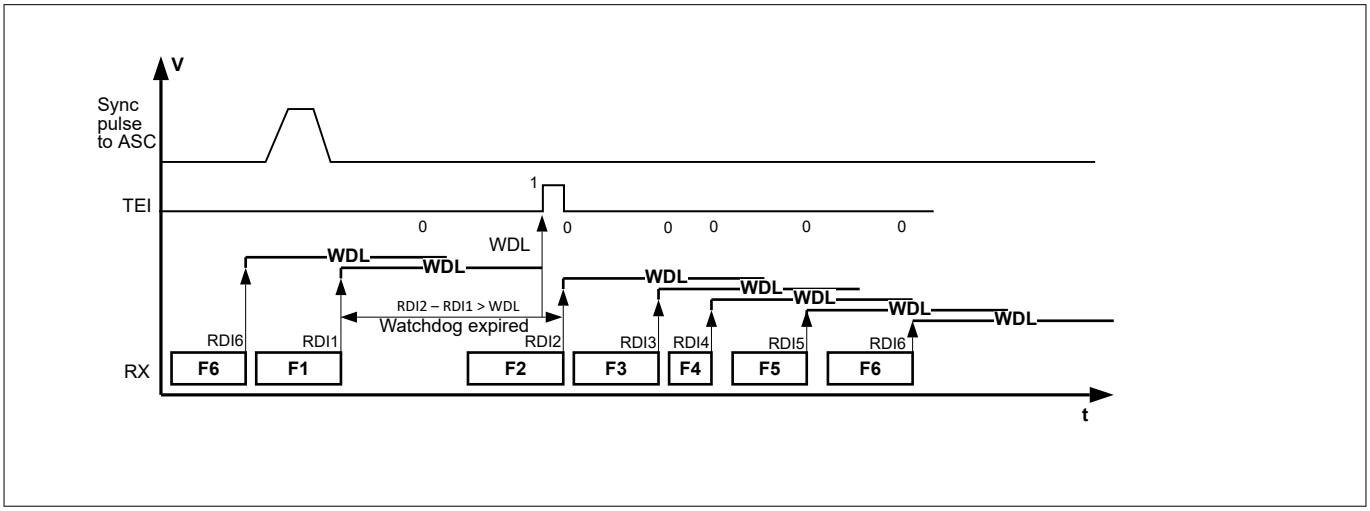

Figure 549 Watchdog timers in asynchronous mode

Synchronous mode of the watchdog timers

If RCRAx.WDMS is set, the watchdog timer is restarted on sync pulse and stopped at reception of the last frame configured in NFC.NFx. Register NFC contains the bit fields NFx which configure the number of packet frames expected after the sync pulse.

The watchdog timer is restarted (cleared and set to run), each time a sync pulse is transferred for the referring channel from FIFO to ASC. The watchdog timer of this channel is forced to stop if the number of a received packet frames (counted in FCNT.FCx) matches the number configured in NFC.NFx. This supports in particular angle synchronous channels where the distance of packets can vary strongly.

The watchdog timer cannot stop in time if a non-recoverable (and thus not counted) packet frame is received. If more than the configured number of packet frames are received, no dedicated interrupt is issued for this but the frames are still received correctly.

RCRAx.WDMS should be 0 on asynchronous channels. Otherwise, the internal watchdog timer will be stopped after reception of the number of configured frames but never be restarted due to the lack of a sync pulse.

If a sensor is not present in its configured slot, NFC.NFx must be reduced accordingly. For example, if out of F1-F6 the F2 is missing, only 5 frames are configured.

Please refer to register NFC on page 5033 for detailed description.

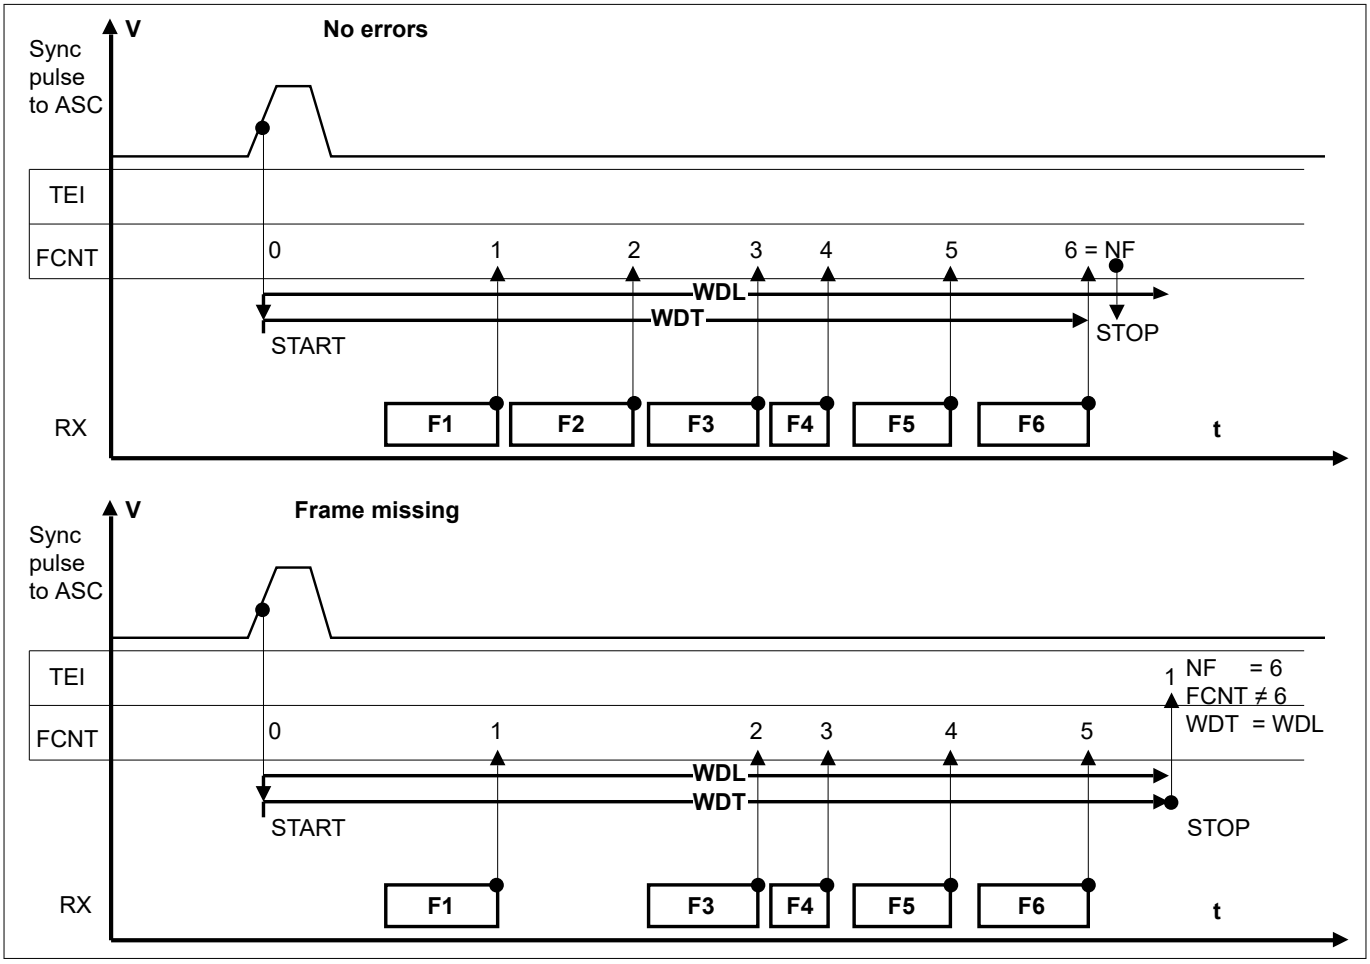

Figure 550 Watchdog timers in synchronous mode

27.3.6 Send data

This chapter contains the details on how data to be sent is prepared. The scope extends to:

- Periodic triggers
- Angle synchronous triggers
- ECU to sensor communication

27.3.6.1 Channel trigger

The channel trigger value register CTVx contains a reset counter. It allows for setting up periodic sync pulses for channel x.

The channel trigger value CTV is the compare value which restarts the counter CTC on equality. At exactly this time, a sync pulse is triggered.

The compare on equality allows to preset CTC and thus configure an offset between the CTVx.CTCs. This allows for staggering periodic sync pulses that must have frequencies with common multiples (for example same frequency, double etc.).

The PSI5-S sync pulse staggering is done based on the offset.

$$\text{Offset} = 65535 - \text{CTC preset value}$$

Which means, if the CTC preset is greater than CTV and the time to roll over is the offset. When the CTC preset is lesser than CTV, the CTC has some lead. This is shown in the following figure.

Note that CTC can be written only if it is disabled by clearing GCR.ETCx.

Staggering the pulses might be required if the current source for the external PHYs can provide only limited current so that not all channels can be provided with the additional current that is required to apply the voltage increase representing a proper sync pulse.

For a synchronization of all counters CTVx.CTC, bits GCR.ETCx can be used.

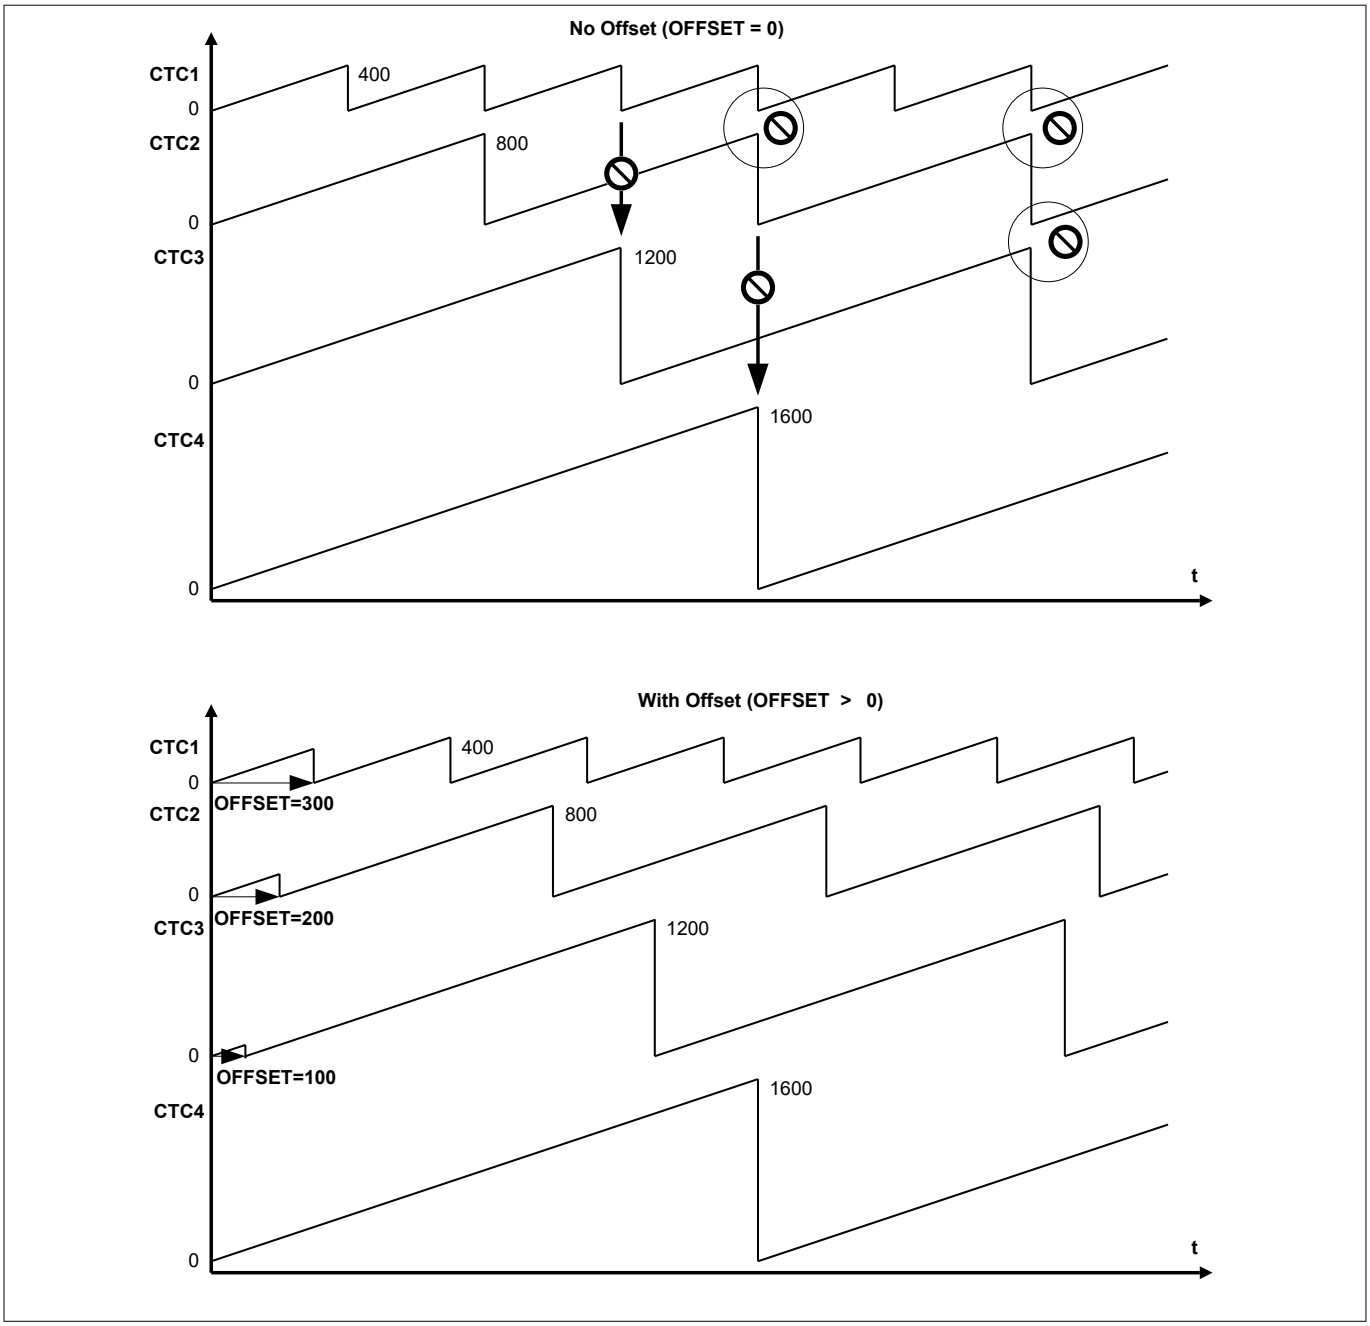

Figure 551 PSI5-S pulse staggering

27.3.6.2 Sync pulse control

The sync pulse generation provides the following functionality:

- Periodic sync pulses, driven by a common module time base (PGCx.PTE is set)
- Angle synchronous sync pulses, driven by GTM or eGTM based on bit FDRT.TRIGSEL (PGCx.ETE is set)
- Sync pulses for ECU to sensor communication (Tooth Gap method, SCRx.EPS[0]=0)
- Sync pulses for ECU to sensor communication (Pulse Width method, SCRx.EPS[0]=1)

It is possible to switch on and off the periodic trigger or the angle synchronous trigger at any time. The pulses will be modulated according to the selected standard. EPS selects between Pulse Width method and Tooth Gap method with pulse dropping.

An ECU to sensor communication can be stopped at any point in time by setting the flush bit SCRx.FLUS. This will clear the send register and flag SCRx.TPF.

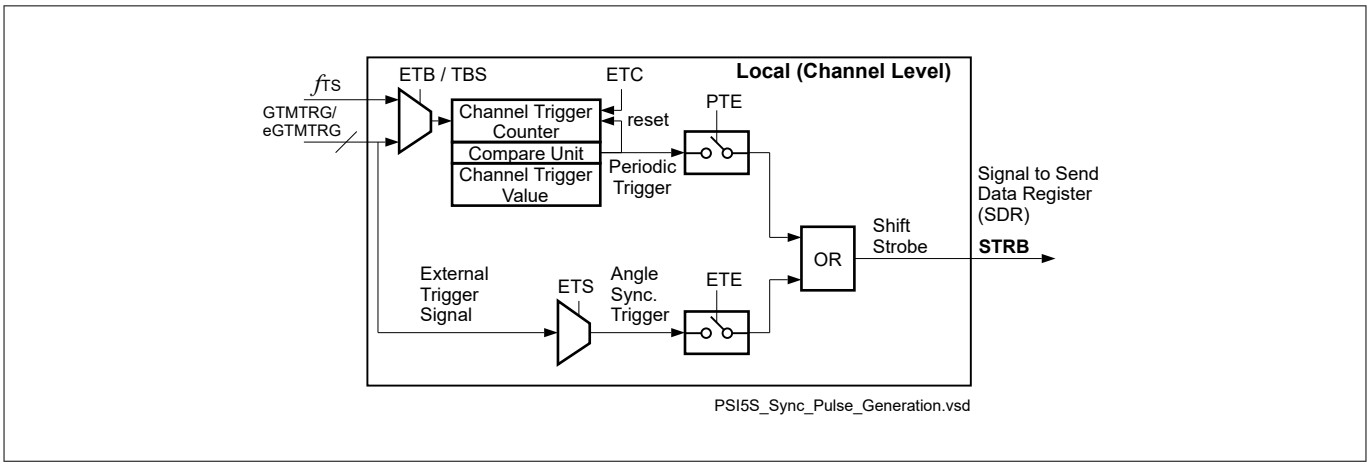

Figure 552 PSI5-S sync pulse generation

27.3.6.3 Send data preparation

The data frame to be sent is prepared in the SDRx register. The Send Data Register can be cleared and initialized by setting the SCRx.FLUS bit. The Send Control Register SCRx contains control bits that are required to send the data from the PSI5-S module to an external PHY. The following figure shows the mechanisms for how ECU to sensor communication data is treated:

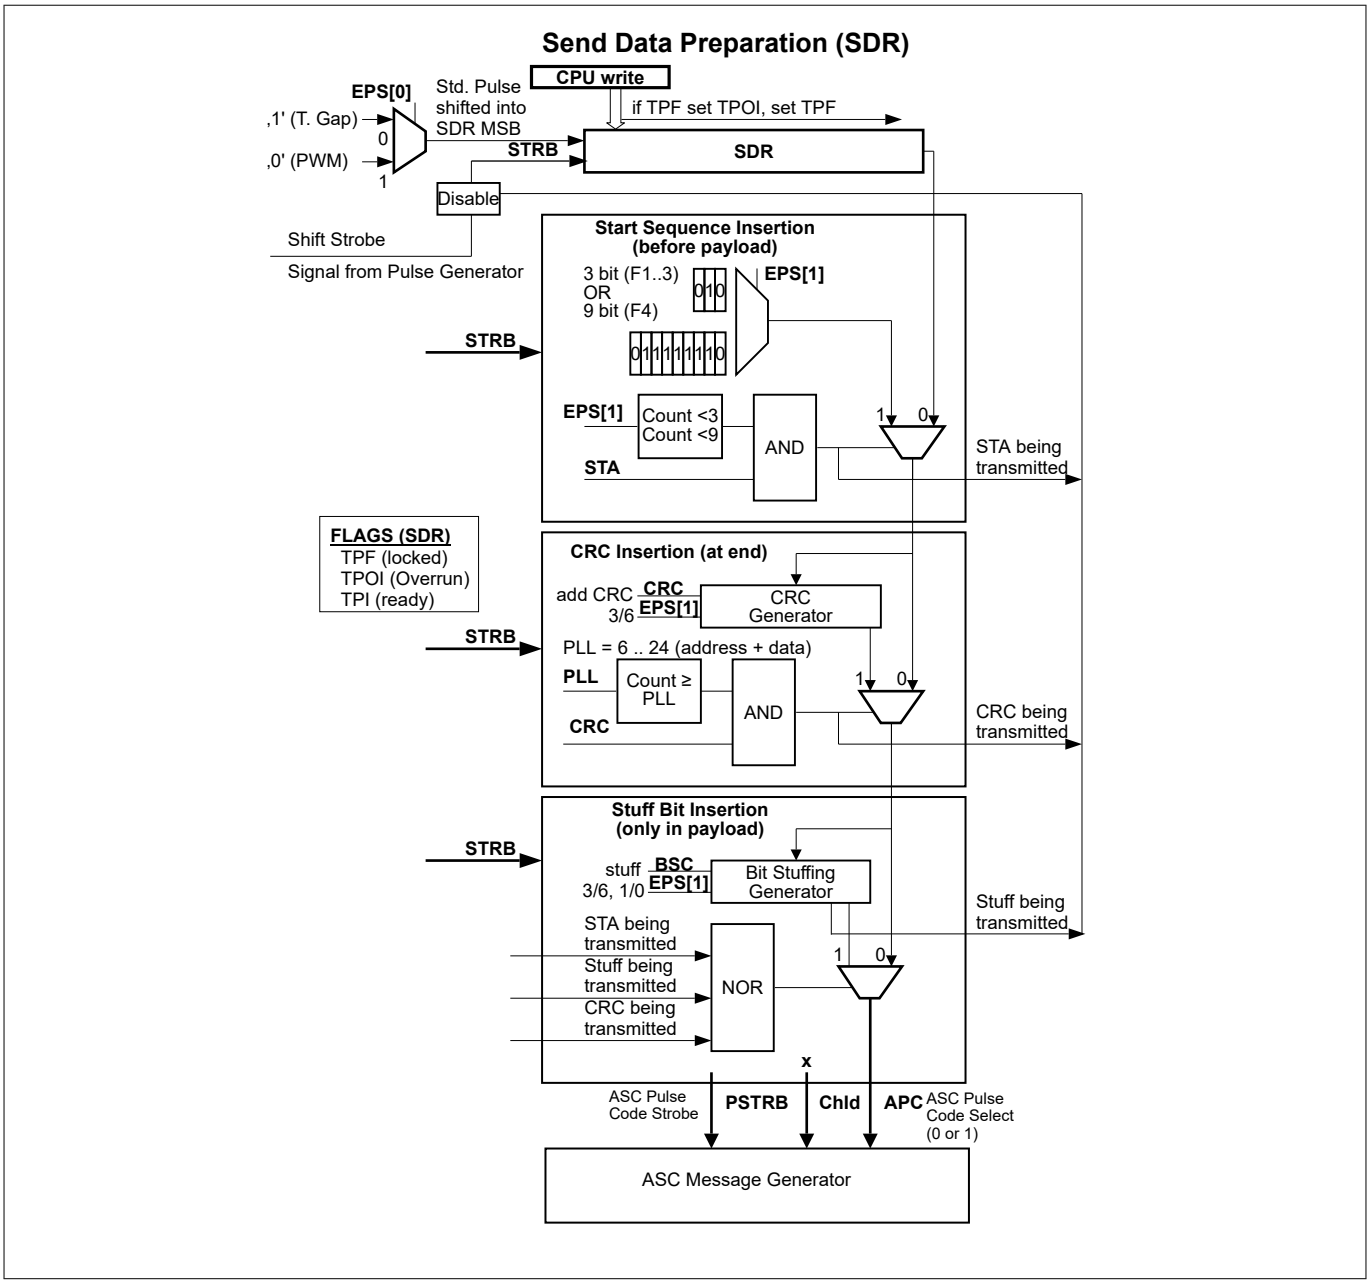

Figure 553 PSI5-S send data preparation

Bit EPS is used to select between the two methods of ECU to sensor communication. The bit is also used to set the frame format (format 1-3 or format 4). SCRx.PLL defines the payload length that is taken into account. SCRx.PLL needs to be configured before SDRx is issued for send data preparation. The send data preparation involves:

- Start sequence insertion (before the payload)
- CRC insertion (at the end)
- Stuff bit insertion (in the payload)

All three processes are driven by the shift strobe signal from pulse generator STRB. The start sequence insertion is controlled by the SCRx.STA bit. When STA is cleared, no start sequence is generated. When STA is set, the start sequence is automatically generated by the hardware. Similarly, the CRC insertion is controlled by the SCRx.CRC bit. When CRC is cleared, there is no automatic generation of CRC. It can still be written by software along with the data. When CRC bit is set, the CRC is automatically generated by the hardware. Bit BSC controls the stuff bit insertion. The SCRx.TPF flag is set when there is a data preparation in progress. At this moment, when the SDRx register is written, the old data is not overwritten and TPOI interrupt request flag is set. Once the send data has been moved completely and when the SDRx register is ready to be written with a new value, TPI interrupt request flag is set.

27.3.7 Message generation

The following figure shows the message generation logic.

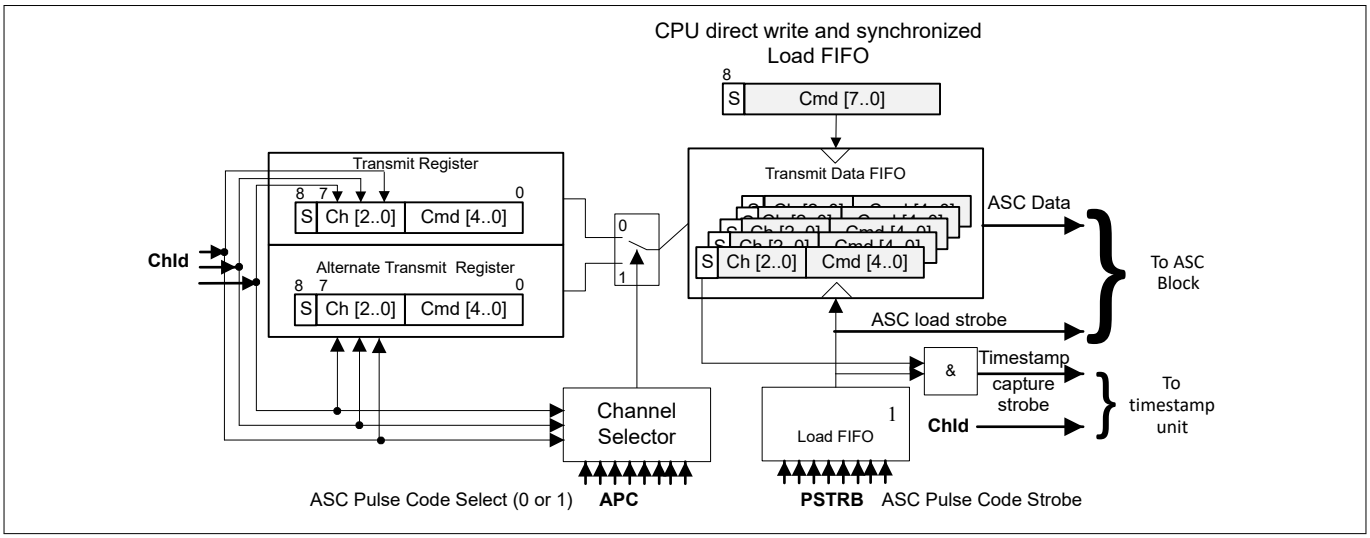

Figure 554 PSI5-S message generation logic

ASC Pulse Code Strobe PSTRB, channel ID ChId, and ASC Pulse Code Select APC are the signals from the send data preparation that are used for the ASC message generation (UART). The generated ASC commands are sorted into an internal FIFO of 8 entries of 9 bits width. The MSB stores the information, if a command is generated from the sync pulse generation (ASC Pulse Code Strobe PSTRB issued the write into FIFO) or if the CPU wrote a command.

The APC Pulse Code Select signal from the send data preparation, selects between the pulse code 0 or 1. This is important for the timestamp generation. Usually the timestamp is captured when a sync pulse command leaves the FIFO. That is, it is copied to the ASC TX buffer. Commands stored in the FIFO can only trigger a timestamp capture if they are marked as sync pulse in bit 8. Nevertheless the CPU can set bit CDW.TSI if the command is to be treated like a sync pulse command and a timestamp should be captured. Note that if RCRAx.TSTS is set, the sync pulses do not trigger the timestamp capture. In this case, the packet frame reception triggers the capture and bit 9 is ignored.

There is no further arbitration of the CPU and Message Generation Unit. The PHY answers CPU commands with standard frames of fixed predefined length in channel 0 frame 0.

Interrupt FOI is issued if a transfer to the FIFO was generated by the Message Generation Unit or by CPU direct write register (CDW) and if the FIFO was full. In a correct setup this will never be the case as the bandwidth of the ASC is assumed to be by far higher than the write bandwidth in order to have short delays. In most cases too many write accesses to CDW will be the root cause. This exceptional condition can be handled either by waiting until the FIFO has transferred at least one command or by a module reset by software. It should not occur in the application but FOI should help software generation and debugging.

The transfer path of a command to the ASC block could add jitter to sync pulses.

In case several channels request a pulse at exactly the same time, as shown in the figure above by two transmit registers (Transmit and Alternate Transmit), the channel with the lower channel number is served first and CDW has highest priority.

27.3.8 DMA support

The received frames come in sequentially and are XCRC checked. The complete re-assembled frame including channel Id (ChId), frame ID (FId), and status are available at RDR and RDS. TSM shows the latest timestamp of the currently received frame.

RDR, RDS, and TSM are located in 3 sequentially addressed registers. In this way they are easily readable by DMA.

Related information

Dedicated DMA channels on page 4989

27.3.8.1 Dedicated DMA channels

With one single DMA channel, one common frame buffer in the system memory can be built up. All frames can be collected from RDR, RDS and TSM registers. The DMA source address is programmed to be always RDS, block transfer is set to 3 words with auto address increment. The target is set to be automatically incremented. This results in one buffer in system memory with all frames from all channels.

Individual buffers for each channel can be built up if more DMA channels are used. Each channel can generate its own receive triggers RDI and RSI. Thus individual DMAs can be set up for each of the 8 channels similarly to the single DMA use case but with individual target addresses for each channel.

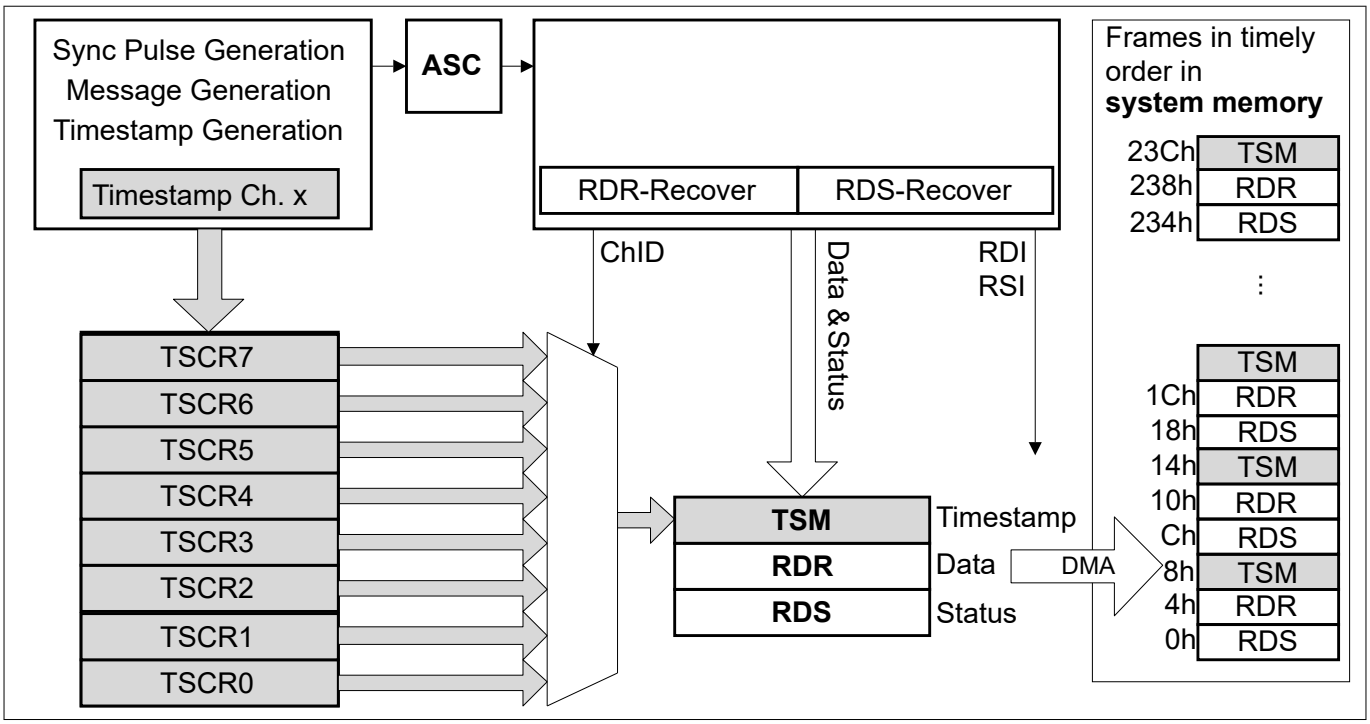

Figure 555 PSI5-S single DMA channel

27.3.8.2 Two daisy-chained DMAs

The PSI5-S supports sorting by channel with only two DMA channels. The register TAR contains the target address that is to be copied by the first DMA channel into the target address register of the second DMA channel. Source and target of the first DMA are fixed (DMA register SADR and DADR). The target address offered in TAR is calculated by PSI5-S by adding an offset value to the programmable base address defined in register BAR. This allows for locating the channel buffers at any location in system memory.

The resulting base + offset is presented in the register TAR. The target address depends on:

- Base address defined in the BAR register
- ChID: Offset of channel number currently received (6 buffer lines, 3 words per frame and 4 bytes per word gives 72 bytes times channel number). This allows to receive 6 frames per channel which equals the maximum number of PSI5 frames per sync pulse
- FID: Offset of frame ID currently received (3 words or 12 bytes per frame)

  Note that the frame ID used for this sorting depends on RCRAx.FIDS. Particularly in Asynchronous mode, RCRAx.FIDS needs to be set so that the FID from the packet frame is replaced by a rolling number 0 to 5.
- Note that the Message Reassembly unit forces non-recoverable messages to be stored at the address for ChID = 0, FID = 1, but with original ChID and FID. That is, RDS contains the ChID and FID as received in the first UART frame for better debugging
- The source address of the second DMA channel needs to be programmed to be fixed to the address of RDS. Use shadow control to “wrap around” the source address. (MEmADICR.SHCT must be set to 0x0101b).

  Block transfer with address auto incrementing must be selected and the number of transactions programmed to 3 (see the SDMA chapter, MEmCHCR.BLKM) 32-bit (the data width is defined in MEmCHCR.CHDW) accesses.

  Use shadow control to wrap around the source address. (MEmADICRSHCT must be set to 0x0101b)

The second DMA must be of the next lower priority than the first. Selecting hardware request input through CHCRxz.PRSEL allows for daisy chaining the two DMA channels. See following figure.

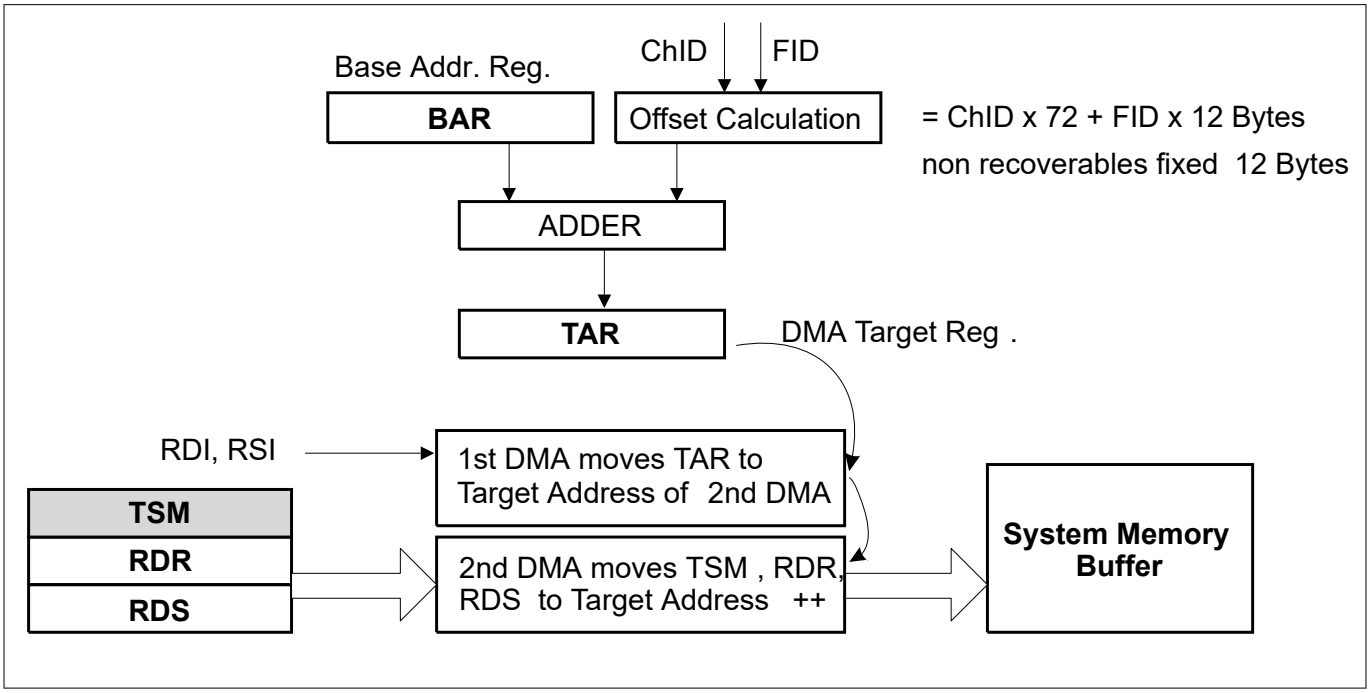

Figure 556 PSI5-S dual DMA support (daisy chained)

The following table shows the detailed mapping of the received frames resulting from the described calculation rules:

Table 1192 Frame mapping

Offset (dec)	Offset (hex)	Channel/frame	Content
0	0_H	Channel 0 frame 0	Status (Reserved for transceiver messages)
4	4_H	Channel 0 frame 0	Data (Reserved for transceiver messages)
8	8_H	Channel 0 frame 0	Timestamp (Reserved for transceiver messages)
12	C_H	Channel 0 frame 1	Status (Reserved for non-recoverable messages)

27.3.8.3 Interrupts for DMA support

Interrupts for single DMA channel usage.

Interrupts RDI or RSI can be used as trigger for the DMA transfer from TSM/RDS/RDR.

Interrupts for two daisy chained DMA usage.

If one of the buffers is full, this is signaled to the software by the interrupt INTSTATx.CHCI. The “status buffer full” is defined as follows: current number of received frames counted in FCNT.FCx equals the number of expected frames configured in NFC.NFx. In Synchronous mode this is the case if all expected PSI5 frames after a sync pulse are received by PSI5-S. The number of expected frames is looked up in the register NFC.NFx for channel x. In Asynchronous mode, NFC.NFx should be programmed to 6 while RCRAx.FIDS is set. This way the FID for an asynchronous channel is a rolling number 0 to 5 and the 6 buffer locations are used completely before INTSTATx.CHCI is issued. See following figure.

There is a delay between INTSTATx.CHCI and the completion of the DMA transfer of the last set of RDS, RDR and TSM to the system memory. The software needs special checks to grant data consistency, for example evaluating the DMA interrupts or comparison of the timestamps in the system memory.

CHCI is not granting that all data is completely moved to system memory by the DMA.

Improved data consistency with packet frame count (PFC)

For data consistency, RDR, RDS and TSM are tagged with a packet frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise, they need to be read again until PFC is identical.

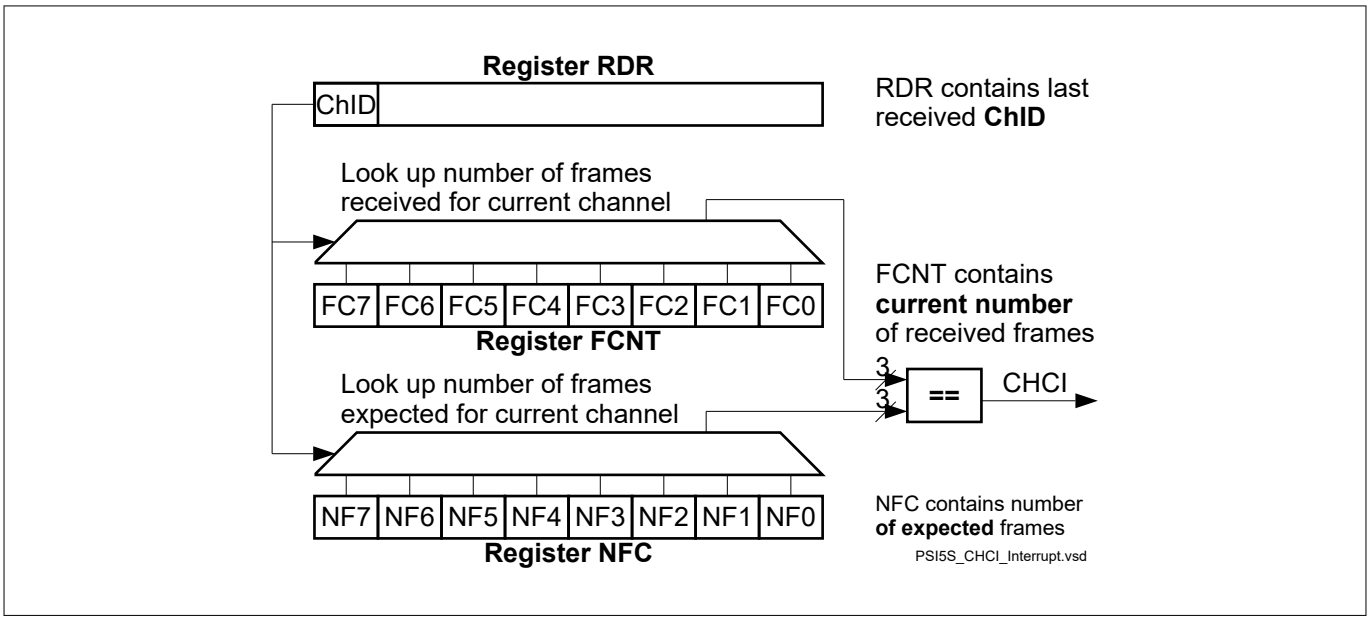

Figure 557 PSI5-S generation of interrupt CHCI

27.3.9 Error detection capabilities

Each PSI5-S channel can detect and signal the following error conditions:

Protocol Level:

- Packet frame CRC error (XCRCI)
- PSI5 frame checksum error (CRCI)
- Frame not sent in time/UART frames missing (TEI)
- Error bits set in packet frame (HDI)
- Errors signaled by ASC sub module (that is PE, FE, OE)

Transfer management level:

- Receive data buffer overrun (RBI)
- ECU to sensor data buffer underrun (TBIR)

27.3.10 Special use of channel 0

Note that data that is received in incomplete or too long packet frames is always copied - as is - to channel 0 frame ID 1. This can happen, if UART frames are lost, the PHY sends non allowed data or idle before the actual end of the packet frame. See related information.

This is the only actual reservation/limitation in functionality of channel 0. I.e. all frames can be received and sorted correctly in channel 0 as long as the packet frame is configured with: ChID = 0. It is recommended not to use ChID = 0 and FID = 1 for normal sensor frames but to keep FID = {2, 3 ,4 ,5}.

The target application assumes, that the PHY sends messages for its own house keeping with ChID = 0, FID = 0. This is assumed in this document and for example shown in the table in the Two daisy-chained DMAs chapter. Nevertheless, a different application may not have this functionality or may use a different ChID/FID configuration.

27.3.11 ASC kernel description

The following figure shows a global view of the ASC interface. The ASC interface is fully integrated into the PSI5-S module. It can be switched to dedicated internal use of the PSI5-S module or to ASC-only mode where all PSI5-S functionality is disabled. In the last case, the whole PSI5-S module represents one additional ASC interface in the system.

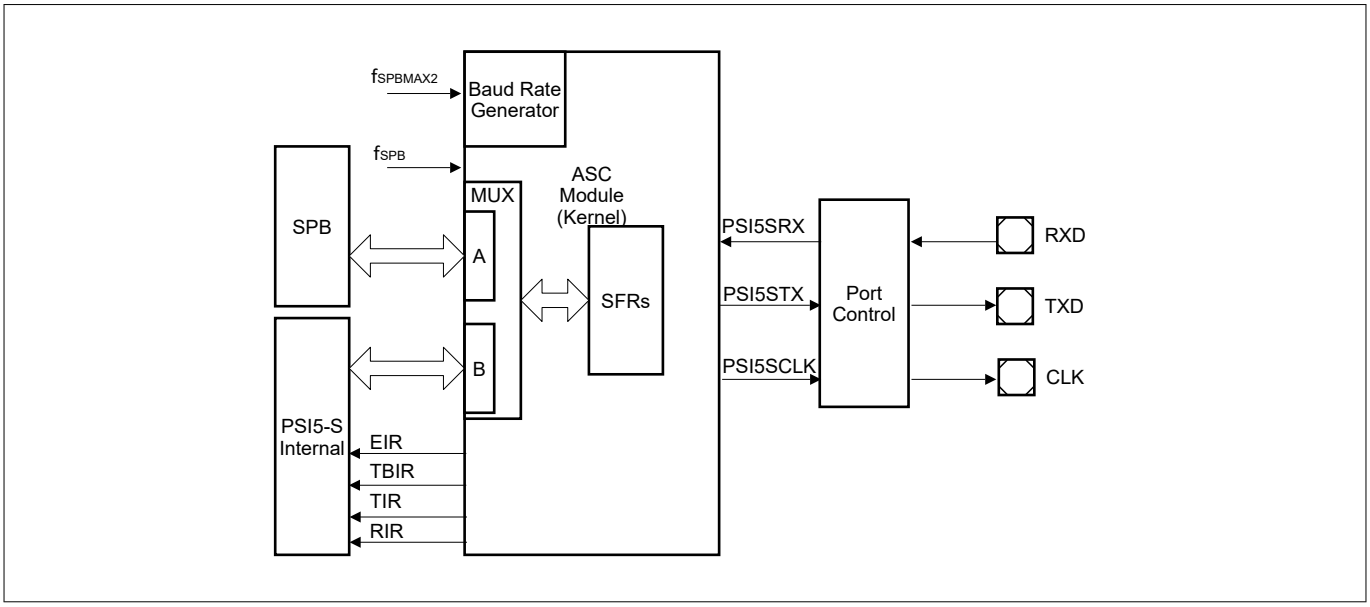

Figure 558 General block diagram of the ASC interface

The ASC module communicates with the external world through two I/O lines. The RXD line is the receive data input signal (and also output signal in Synchronous mode), and TXD is the transmit output signal.

Clock control, address decoding and interrupt service request control are managed outside the ASC module kernel.

27.3.11.1 ASC kernel overview

The ASC provides serial communication between this device and other micro controllers, microprocessors, or external peripherals.

The ASC supports full-duplex asynchronous communication and half-duplex synchronous communication. In Synchronous mode, data is transmitted or received synchronous to a shift clock that is generated by the ASC internally. In Asynchronous mode, 8-bit or 9-bit data transfer, parity generation, and the number of Stop bits can be selected. Parity, framing, and overrun error detection are provided to increase the reliability of data transfers. Transmission and reception of data is double-buffered in ASC-only mode. During internal PSI5-S mode, double-buffering is switched off for the transmitter. The receiver stays double buffered. For multiprocessor communication, a mechanism is included to distinguish address bytes from data bytes. Testing is supported by a Loop-Back option. A 13-bit baud rate generator provides the ASC with a separate serial clock signal, which can be accurately adjusted by a prescaler implemented as fractional divider.

Features

- Full-duplex asynchronous operating modes
  - 8-bit or 9-bit data frames, LSB first
  - Parity-bit generation/checking
  - Separate parity control for receive and transmit
  - One or two Stop bits
  - Baud rate from 12,5 Mbit/s to 3 bit/s (at 200 MHz module clock)

  - Multiprocessor mode for automatic address/data byte detection
  - Loop-back capability
- Half-duplex 8-bit synchronous operating mode
  - Baud rate from 25 Mbit/s to 2034,5 bit/s (at 200 MHz module clock)
- Double-buffered transmitter (in ASC-only mode)/receiver
- Interrupt generation
  - On a transmit buffer empty condition
  - On a transmit last bit of a frame condition
  - On a receive buffer full condition
  - On an error condition (frame, parity, overrun error)
- Implementation features
  - Connections to DMA controller
  - Connections from GTM

27.3.11.2 ASC kernel general operation

The ASC supports full-duplex asynchronous communication and half-duplex synchronous communication. In Synchronous mode, data is transmitted or received synchronously to a shift clock generated by the microcontroller. In Asynchronous mode, 8-bit or 9-bit data transfer, parity generation, and the number of Stop bits can be selected. Parity, framing, and overrun error detection are provided to increase the reliability of data transfers. Transmission and reception of data are double-buffered. For multiprocessor communication, a mechanism is included to distinguish address bytes from data bytes. Testing is supported by a Loop-Back option. A 13-bit baud rate generator provides the ASC with a separate serial clock signal, which can be accurately adjusted by a prescaler implemented as fractional divider.

A transmission is started by writing to the Transmit Buffer Register, TBUF. Only the number of data bits determined by the selected operating mode will actually be transmitted; that is, bits written to positions 9 through 15 of register TBUF are always insignificant. Data transmission is double-buffered, so a new character may be written to TBUF before the transmission of the previous character is complete. This allows a back-to-back transmission of characters to take place without gaps.

Data reception is enabled by the receiver enable bit CON.REN. After a reception has been completed, the received data and, if provided by the selected operating mode, the received parity bit can be read from the (read-only) Receive Buffer Register RBUF. Unused bits in the upper half of RBUF that are not required in the selected operating mode will be read as zeros.

Data reception is double-buffered, so that reception of a second character may already begin before the previously received character has been read out of the receive buffer register. During the exclusive use by the PSI5-S, double buffering is switched off. The PSI5-S internal output FIFO is used instead. As commands for sync pulses are timestamped inside PSI5-S as they leave the internal FIFO, the double buffering would add unwanted jitter. In all modes, receive buffer overrun error detection can be selected through bit CON.OEN. When enabled, the overrun error status flag CON.OE and the error interrupt request line INTOV.EIR will be activated when the receive buffer register has not been read by the time reception of a second character is complete. In this case, the previously received character in the receive buffer is overwritten.

The Loop-Back option (selected by bit CON.LB) allows the data currently being transmitted to be received simultaneously in the receive buffer. This may be used to test serial communication routines at an early stage without having to provide an external network. In Loop-Back mode, the alternate input/output function of port pins is not required.

27.3.11.3 Asynchronous operation

Asynchronous mode supports full-duplex communication, in which both transmitter and receiver use the same data frame format and have the same baud rate. Data is transmitted on pin TXD and received on pin RXD. The following figure shows the block diagram of the ASC when operating in Asynchronous mode.

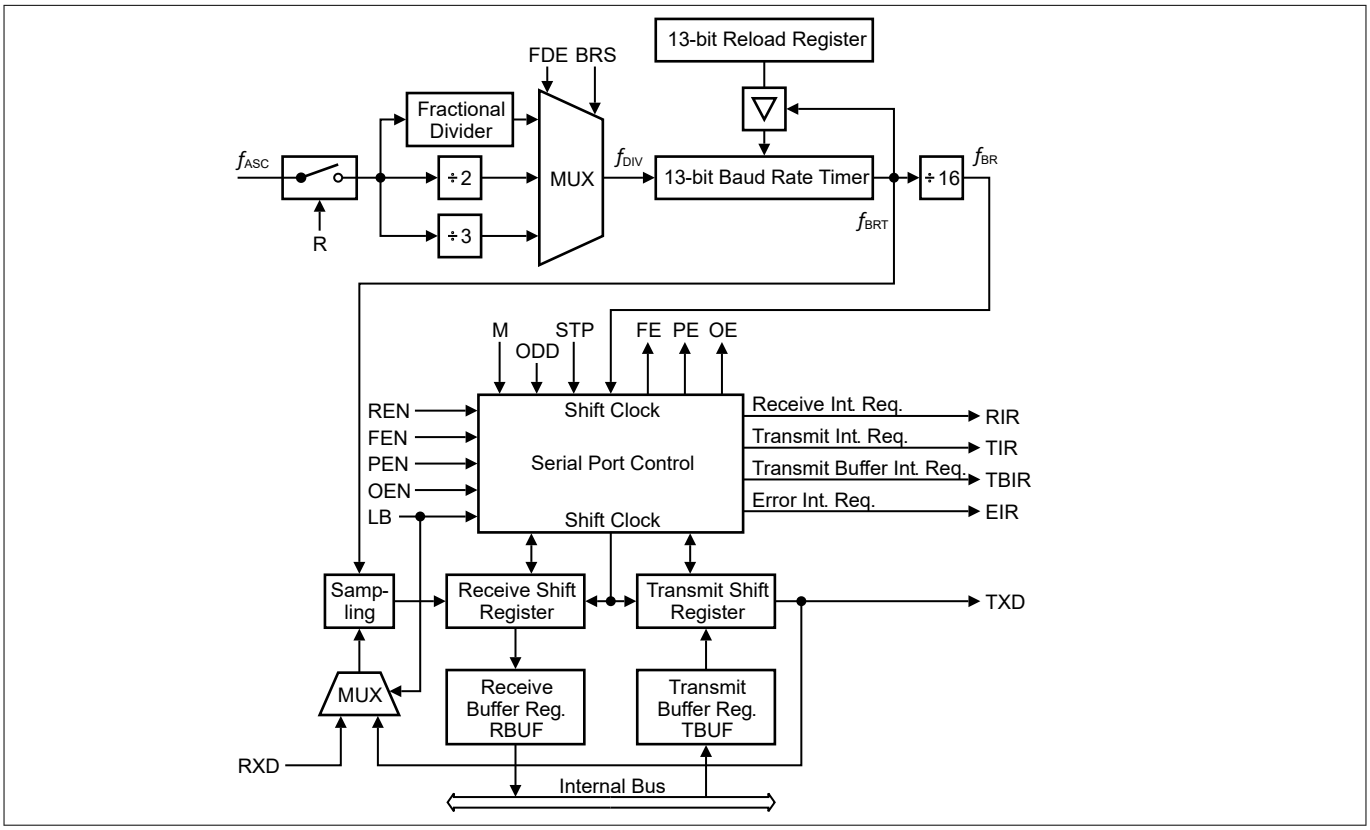

Figure 559 Asynchronous mode of the ASC

27.3.11.3.1 Asynchronous data frames

Asynchronous data frames can consist of 8-bit or 9-bit data frames.

8-bit data frames

The 8-bit data frames consist of either eight Data bits D7…D0 (CON.M=001_B), or of seven Data bits D6…D0 plus an automatically generated Parity bit (CON.M=011_B). Parity may be odd or even, depending on bit CON.ODD. An even Parity bit will be set if the modulo-2 sum of the seven data bits is 1. An odd Parity bit will be cleared in this case. Parity checking is enabled by bit CON.PEN (always OFF in 8-bit data mode). The parity error flag CON.PE will be set, along with the error interrupt request flag, if a wrong Parity bit is received. The received Parity bit itself will be stored in RBUF too.

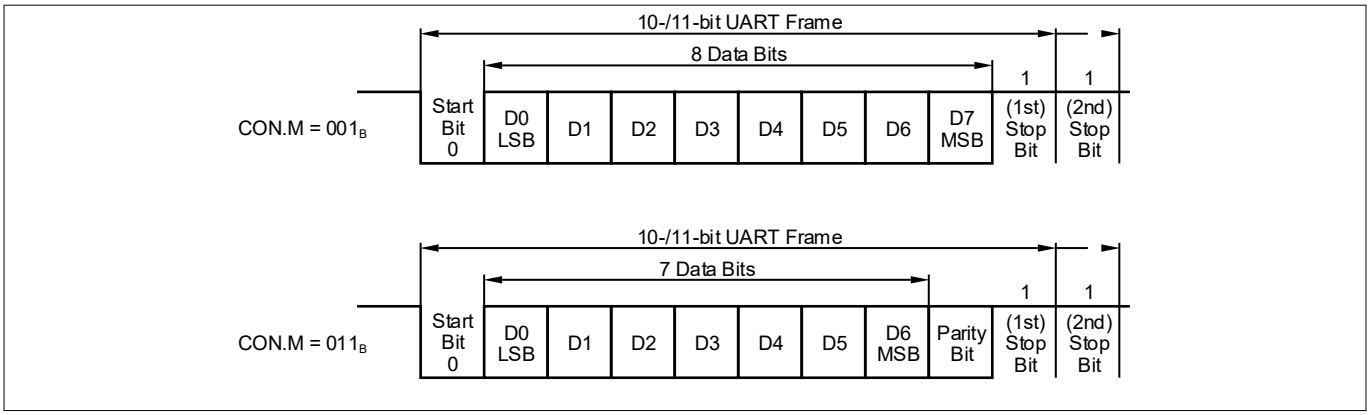

Figure 560 Asynchronous 8-bit frames

9-bit data frames

The 9-bit data frames consist of nine Data bits D8…D0 (CON.M=100_B), or of eight Data bits D7…D0 plus an automatically generated Parity bit (CON.M=111_B) or of eight Data bits D7…D0 plus Wake-up bit (CON.M=101_B). Parity may be odd or even, depending on bit CON.ODD. An even Parity bit will be set if the modulo-2-sum of the eight data bits is 1. An odd Parity bit will be cleared in this case. Parity checking is enabled by bit CON.PEN (always OFF in 9-bit data and Wake-up mode). The parity error flag CON.PE will be set along with the error interrupt request flag if a wrong parity bit is received. The received Parity bit itself will be stored in RBUF too.

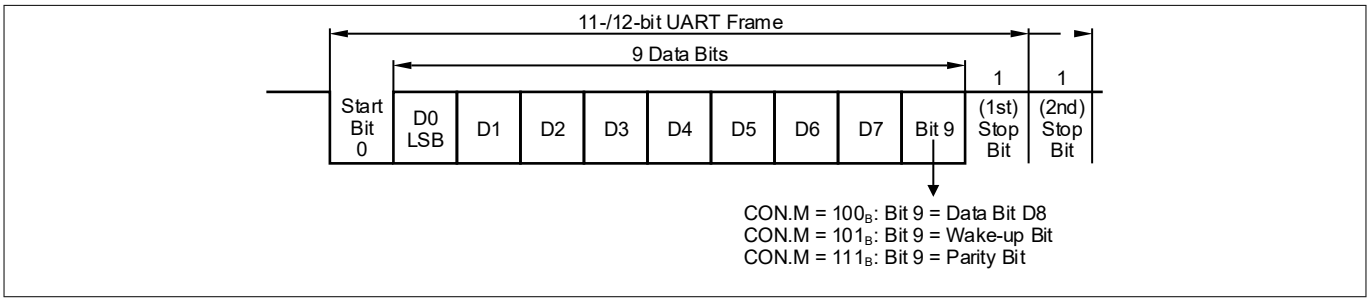

Figure 561 Asynchronous 9-bit frames

In Wake-up mode (CON.M=101_B), received frames are transferred to the receive buffer register only if the 9^{th} bit (the Wake-up bit) of the frame is 1. If this bit is 0, no receive interrupt request will be activated and no data will be transferred.

This feature can be used to control communication in multi-processor systems, for example:

When the master processor aims to transmit a block of data to one of several slaves, it first sends out an address ‘Byte’ (in this case, a ‘Byte’ consists of nine bits) that identifies the target slave. An address ‘Byte’ differs from a data ‘Byte’ in that the additional 9^{th} bit is a 1 for an address ‘Byte’ but is a 0 for a data ‘Byte’, so, no slave will be interrupted by a data ‘Byte’. An address ‘Byte’ will interrupt all slaves (operating in 8-bit data + Wake-up bit mode), so each slave can examine the eight LSBs of the received character (the address). The addressed slave will switch to 9-bit data mode (for example, by clearing bit CON.M[0]), which enables it to also receive the data 'Bytes' that will be coming (having the Wake-up bit cleared). The slaves that were not being addressed remain in 8-bit data + Wake-up bit mode, ignoring the following data ‘Bytes’.

27.3.11.3.2 Asynchronous transmission

Asynchronous transmission begins when the next overflow of the divide-by-16 baud rate timer (transition of the baud rate clock f_{BR}) occurs, if bit CON.R is set and data has been loaded into TBUF. The transmitted data frame consists of three elements:

1. The Start bit
2. The data field (8 or 9 bits, LSB first, including a Parity bit, if selected)
3. The delimiter (1 or 2 Stop bits)

Data transmission is double-buffered. When the transmitter is idle, the transmit data loaded into TBUF is immediately moved to the transmit shift register; thus, freeing TBUF for the next transmit data to be loaded. This is indicated by the transmit buffer interrupt request line INTOV.TBIR being activated. TBUF may then be loaded with the next transmit data while transmission of the previous one continues.

The transmit interrupt request line INTOV.TIR will be activated before the last bit of a frame is transmitted, that is, before the first or the second Stop bit is shifted out of the transmit shift register.

***Note**: A dedicated GPIO device pin which is connected to the module output pin TXD must be configured by software as alternate data output for asynchronous transmission.*

27.3.11.3.3 Asynchronous reception

Asynchronous reception is initiated by a falling edge (1-to-0 transition) on pin RXD, on the condition that bits CON.R and CON.REN are set. The receive data input pin RXD is sampled at sixteen times the rate of the selected baud rate. A majority decision of the 7^{th}, 8^{th} and 9^{th} sample determines the effective sampled bit value. This avoids erroneous results that may be caused by noise.

If the detected value is not a 0 when the Start bit is sampled, the receive circuit is reset and waits for the next 1-to-0 transition at pin RXD. If the Start bit proves valid, the receive circuit continues sampling and shifts the incoming data frame into the receive shift register.

When the last Stop bit has been received, the contents of the receive shift register are transferred to the Receive Data Buffer Register RBUF. Simultaneously, the receive interrupt request line INTOV.RIR is activated after the 9^{th} sample in the last stop bit time-slot (as programmed), regardless whether valid Stop bits have been received or not. The receive circuit then waits for the next Start bit (1-to-0 transition) at the receive data input line.

***Note**: A dedicated GPIO pin that is connected to the module input pin RXD must be configured by software as input for asynchronous reception.*

Asynchronous reception is stopped by clearing bit CON.REN. A currently received frame is completed including generation of the receive interrupt request and an error interrupt request, if appropriate. Start bits that follow this frame will not be recognized.

***Note**: In Wake-up mode, received frames are transferred to the receive buffer register only if the 9^{th} bit (the Wake-up bit) is 1. If this bit is 0, no receive interrupt request will be activated and no data will be transferred.*

27.3.11.3.4 RXD/TXD data path selection in asynchronous modes

The data paths for the serial input and output data in Asynchronous modes are affected by control bit CON.LB (loop-back) as shown in the following figure.

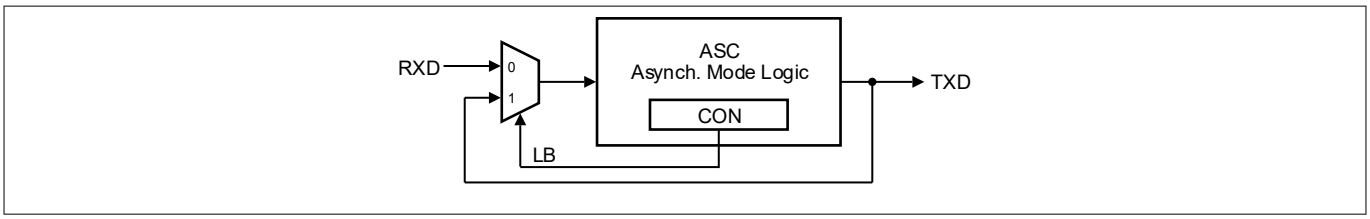

Figure 562 RXD/TXD data path selection in asynchronous modes

27.3.11.4 Synchronous operation

Synchronous mode supports half-duplex communication, usable for simple I/O expansion by shift registers. Data is transmitted and received by pin RXD while pin TXD outputs the shift clock. These signals are typically connected as alternate functions with GPIO port pins. Synchronous mode is selected with CON.M=000_B.

Eight data bits are transmitted or received synchronous to a shift clock generated by the internal baud rate generator. The shift clock is active only as long as data bits are transmitted or received.

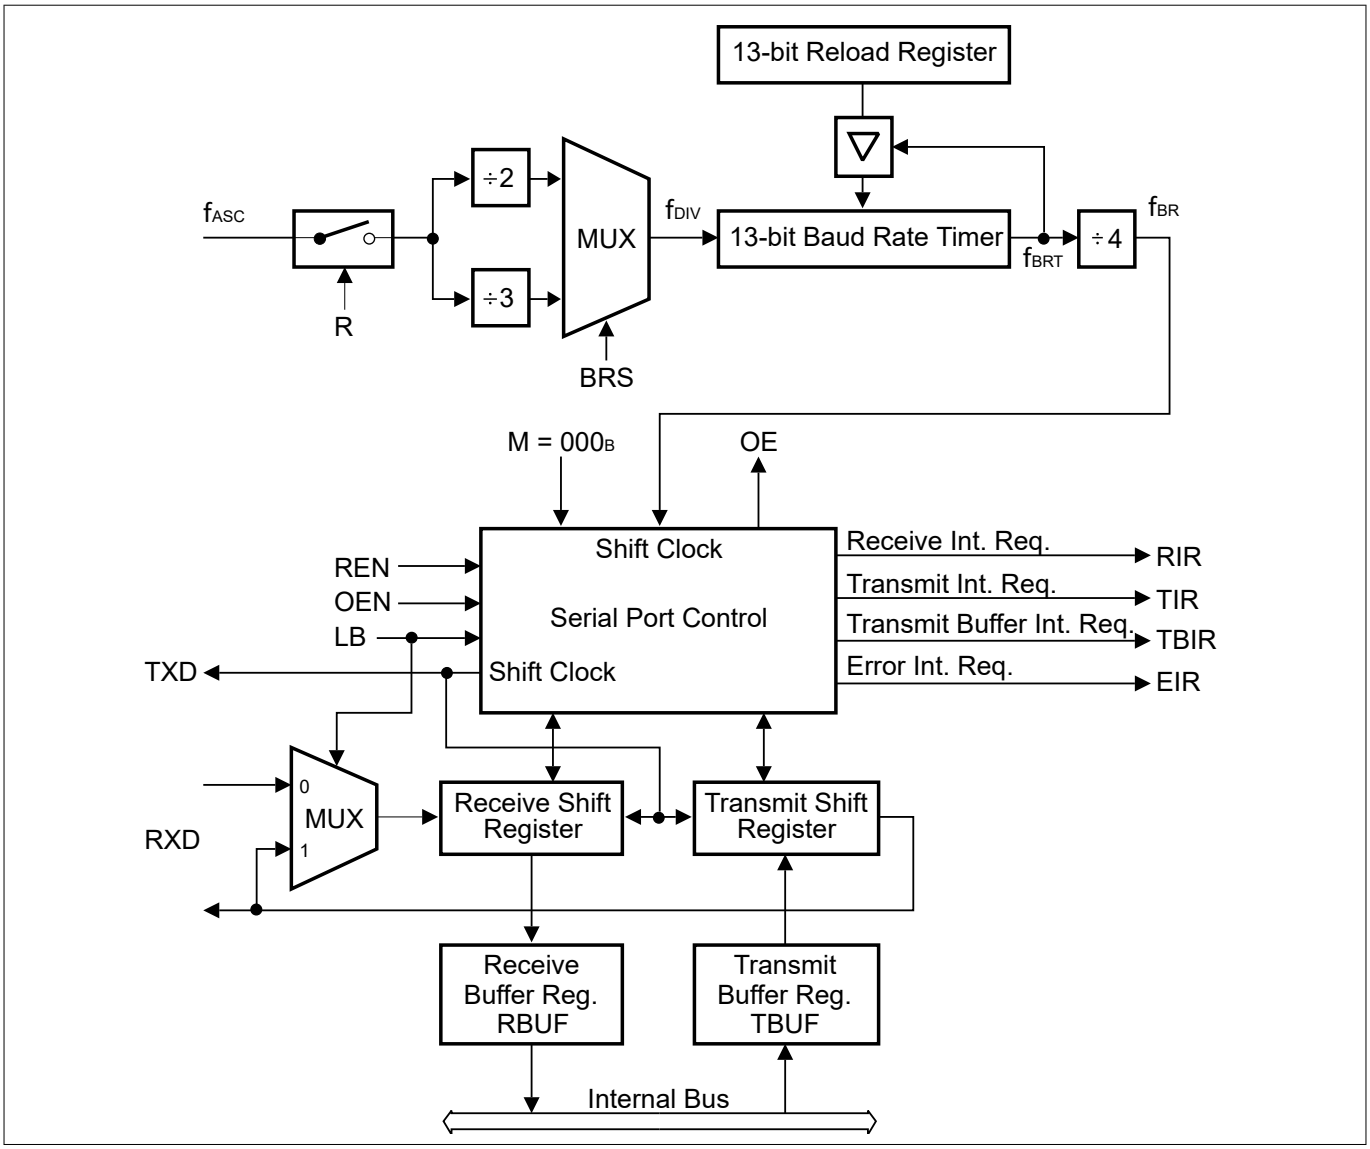

Figure 563 Synchronous mode of serial channel ASC

27.3.11.4.1 Synchronous transmission

Synchronous transmission begins after data has been loaded into TBUF, provided that CON.R is set and CON.REN=0 (half-duplex, no reception), with one exception: in asynchronous Loop-Back mode (bit CON.LB set), CON.REN must be set for reception of the transmitted byte. In synchronous Loop-Back mode, the transmitted byte can still be received if CON.REN=0. Data transmission is double-buffered. When the transmitter is idle, the transmit data loaded into TBUF is immediately moved to the transmit shift register, thus freeing TBUF for the next data to be sent. This is indicated by the transmit buffer interrupt request line INTOV.TBIR being activated. TBUF may now be loaded with the next data, while transmission of the previous one continues. The data bits are transmitted synchronously with the shift clock. After the bit time for the 8th data bit, both TXD and RXD will be set to high level, the transmit interrupt request line INTOV.TIR is activated, and serial data transmission stops.

***Note**: The dedicated GPIO device pins that are connected to TXD and RXD must be configured by software as alternate data outputs in order to provide the shift clock and the output data during synchronous transmission.*

27.3.11.4.2 Synchronous reception

Synchronous reception is initiated by setting bit CON.REN=1. If bit CON.R=1, the data applied at RXD is clocked into the receive shift register synchronously to the clock which is output at TXD. After the 8th bit has been shifted in, the contents of the receive shift register are transferred to the receive data buffer RBUF, the receive interrupt request line INTOV.RIR is activated, the receiver enable bit CON.REN is reset, and serial data reception stops.

Synchronous reception is stopped by clearing bit CON.REN. Any byte that is currently being received is completed, including the generation of the receive interrupt request and an error interrupt request, if appropriate. Writing to the transmit buffer register while a reception is in progress has no effect on reception and will not start a transmission.

If a previously received byte has not been read out of the receive buffer register by the time the reception of the next byte is complete, both the error interrupt request line INTOV.EIR and the overrun error status flag CON.OE will be activated/set, provided that the overrun check has been enabled by bit CON.OEN.

***Note**: The dedicated GPIO device pin that is connected to TXD must be configured by software as alternate data output in order to provide the shift clock. The dedicated GPIO device pin that is connected to RXD must be configured by software as input during synchronous reception.*

27.3.11.4.3 Synchronous timing

The following figure shows timing diagrams of the ASC Synchronous mode data reception and data transmission. In idle state, the shift clock is at high level. With the beginning of a synchronous transmission of a data byte, the data is shifted out at RXD with the falling edge of the shift clock. If a data byte is received through RXD, data is latched with the rising edge of the shift clock.

One shift clock cycle (f_{BR}) delay is inserted between two consecutive receive or transmit data bytes.

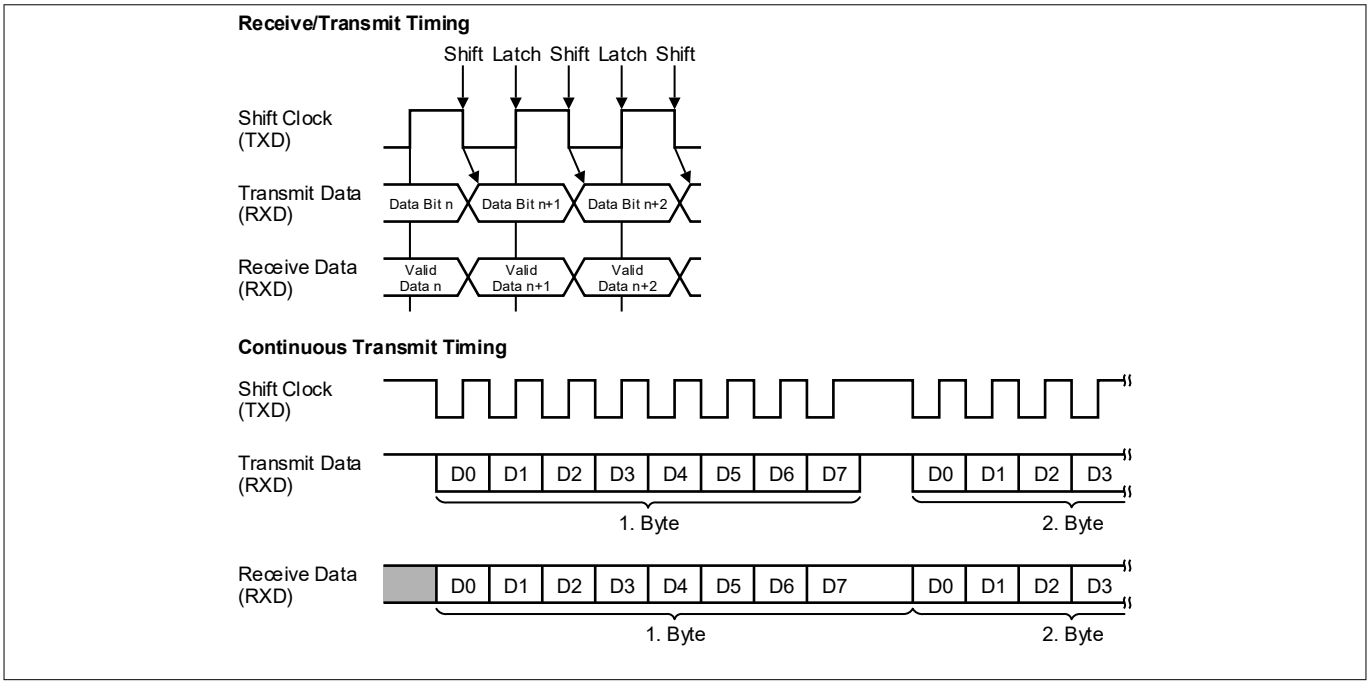

Figure 564 ASC synchronous mode waveforms

27.3.11.5 Baud rate generation

The ASC has its own dedicated 13-bit baud rate generator with 13-bit reload capability, allowing baud rate generation independent of other timers.

The baud rate generator is clocked with a clock (f_{DIV}) which is derived by a prescaler from the ASC module clock f_{ASC}. The baud rate timer is counting downwards and can be started or stopped through the baud rate generator run bit CON.R. Each underflow of the timer generates one clock pulse to the serial channel. The timer is reloaded with the value stored in its 13-bit reload register at each underflow. The resulting clock f_{BRT} is again divided by a factor for the baud rate clock ($\frac{f_{BRT}}{16}$ in Asynchronous operating modes and $\frac{f_{BRT}}{4}$ in Synchronous operating mode). The prescaler is selected by the bits CON.BRS and CON.FDE. In the Asynchronous operating modes, a fractional divider prescaler unit is available (in addition to the two fixed dividers) that allows selection of prescaler divider ratios of $\frac{n}{2048}$ with n=0-2047. Therefore, the baud rate of ASC is determined by the module clock, the content of register FDV, the reload value in register BG, and the operating mode (Asynchronous or Aynchronous).

Register BG is the dual-function baud rate generator/reload register. Reading BG returns the contents of the timer in bit field BR_VALUE (bits 31:13 return zero), while writing to BG always updates the reload register (bits 31:13 are insignificant).

An auto-reload of the timer with the contents of the reload register is performed each time BG is written to. However, if CON.R=0 at the time the write operation to BG is performed, the timer will not be reloaded until the first instruction cycle after CON.R=1. For a clean baud rate initialization, BG should only be written if CON.R=0. If BG is written with CON.R=1, an unpredictable behavior of the ASC may occur during running transmit or receive operations.

27.3.11.5.1 Baud rates in asynchronous mode

For asynchronous operation, the baud rate generator provides a clock f_{BRT} with sixteen times the rate of the established baud rate. Every received bit is sampled on the 7th, 8th and 9th cycle of this clock. The clock divider circuitry, which generates the input clock f_{DIV} for the 13-bit baud rate timer, is extended by a fractional divider circuitry that allows the adjustment of more accurate baud rates and the extension of the baud rate range.

The baud rate of the baud rate generator depends on the settings of the following bits and register values:

- Input clock f_{ASC}
- Selection of the baud rate timer input clock f_{DIV} by bits CON.FDE and CON.BRS
- If bit CON.FDE=1 (fractional divider): value of register FDV
- Value of the 13-bit reload register BG

The output clock of the baud rate timer with the reload register is the sample clock in the Asynchronous operating modes of the ASC. For baud rate calculations, this baud rate clock f_{BR} is derived from the sample clock f_{BRT} by a division of sixteen.

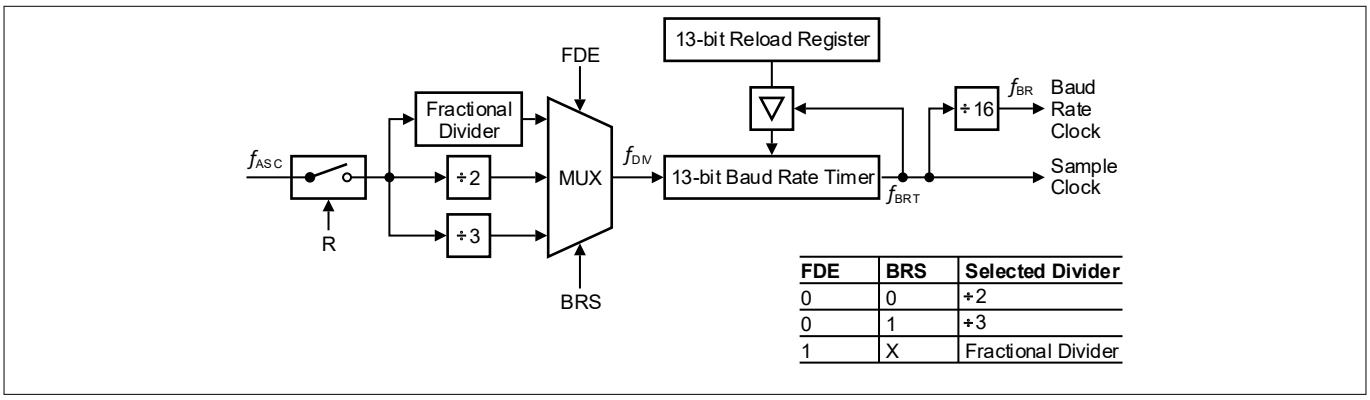

Figure 565 ASC baud rate generator circuitry in asynchronous modes

Using the fixed input clock divider

The baud rate for asynchronous operation of the serial channel ASC when using the fixed input clock divider ratios (CON.FDE=0) and the required BG reload value for a given baud rate can be determined by the following formulas:

Table 1193 Asynchronous baud rate formulas using the fixed input clock dividers

FDE	BRS	BG	Formula
0	0	0 … 8191	$\text{Baud rate} = \frac{f_{ASC}}{(32 \times (BG + 1))}$ $BG = \frac{f_{ASC}}{(32 \times \text{Baud rate}) - 1}$
	1		$\text{Baud rate} = \frac{f_{ASC}}{(48 \times (BG + 1))}$ $BG = \frac{f_{ASC}}{(48 \times \text{Baud rate}) - 1}$

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer.

The maximum baud rate that can be achieved for the Asynchronous operating modes when using the two fixed clock dividers and a module clock of 200 MHz is 6.25 Mbit/s.

Using the fractional divider

When the fractional divider is selected, the input clock f_{DIV} for the baud rate timer is derived from the module clock f_{ASC} by a programmable fractional divider. If CON.FDE=1, the fractional divider is activated. It divides f_{ASC} by a fraction of $\frac{n}{2048}$ for any value of n from 0 to 2047. If n=0, the divider ratio is 1, which means that f_{DIV}=f_{ASC}. In general, the fractional divider allows the baud rate to be programmed with much better accuracy than with the two fixed prescaler divider stages.

***Note**: In fractional divider mode, the clock f_{DIV} can have a maximum period jitter of one f_{ASC} clock period.*

Table 1194 Asynchronous baud rate formulas using the fractional input clock divider

FDE	BRS	BG	FDV	Formula
1	–	0 … 8191	1 … 2047	$\text{Baud rate} = \frac{\text{FDV}}{2048} \times \frac{f_{\text{ASC}}}{16 \times (\text{BG} + 1)}$
			0	$\text{Baud rate} = \frac{f_{\text{ASC}}}{16 \times (\text{BG} + 1)}$

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer. FDV represents the contents of the fractional divider register bit field FDV.FD_VALUE, taken as an unsigned 11-bit integer.

27.3.11.5.2 Baud rates in synchronous mode

For synchronous operation, the baud rate generator provides a clock f_{BRT} that runs with four times the established baud rate, see following figure.

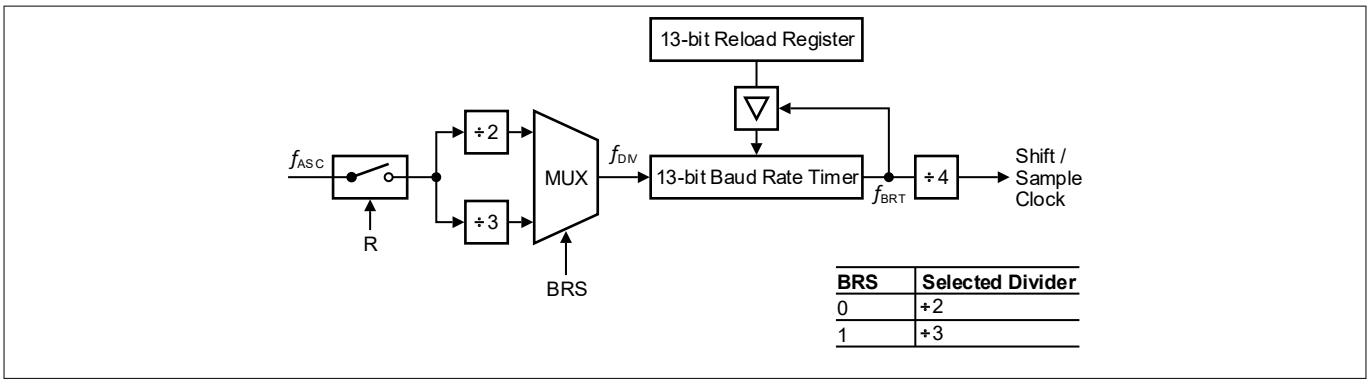

Figure 566 ASC baud rate generator circuitry in synchronous mode

The baud rate for synchronous operation of the serial channel ASC can be determined by the formulas as shown in the following table.

Table 1195 Synchronous baud rate formulas

BRS	BG	Formula
0	0 … 8191	$\text{Baud rate} = \frac{f_{ASC}}{8 \times (BG + 1)}$ $BG = \frac{f_{ASC}}{(8 \times \text{Baud rate}) - 1}$
1		$\text{Baud rate} = \frac{f_{ASC}}{12 \times (BG + 1)}$ $BG = \frac{f_{ASC}}{(12 \times \text{Baud rate}) - 1}$

BG represents the content of the reload register bit field BG.BR_VALUE, taken as an unsigned 13-bit integer.

27.3.11.6 Hardware error detection capabilities

To improve the reliability of serial data exchange, the serial channel ASC provides an error interrupt request flag that indicates the presence of an error and three (selectable) error status flags in register CON that indicate which error has been detected during reception. Upon completion of a reception, the error interrupt request line INTOV.EIR will be activated simultaneously with the receive interrupt request line INTOV.RIR, if one or more of the following conditions are met:

- If the framing error detection enable bit CON.FEN is set and any of the expected Stop bits is not high, the framing error flag CON.FE is set, indicating that the error interrupt request is due to a framing error (Asynchronous operating modes only)
- If the parity error detection enable bit CON.PEN is set in the modes where a Parity bit is received and the parity check on the received data bits proves false, the parity error flag CON.PE is set, indicating that the error interrupt request is due to a parity error (asynchronous operating modes only)
- If the overrun error detection enable bit CON.OEN is set and the last character received was not read out of the receive buffer by software or DMA transfer is complete at the time the reception of a new frame, the overrun error flag CON.OE is set, indicating that the error interrupt request is due to an overrun error (Asynchronous and Synchronous modes)

27.3.11.7 ASC Interrupts

Four interrupt sources are provided for serial channel ASC.

- INTOV.TIR indicates a transmit interrupt
- INTOV.TBIR indicates a transmit buffer interrupt
- INTOV.RIR indicates a receive interrupt
- INTOV.EIR indicates an error interrupt of the serial channel

The interrupt output lines INTOV.TBIR, INTOV.TIR, INTOV.RIR, and INTOV.EIR are synchronized to the PSI5-S kernel and routed by the INPx to the trigger output lines.

The cause of an error interrupt request EIR (framing, parity, overrun error) can be identified by the error status flags CON.FE, CON.PE, and CON.OE.

***Note**: By contrast to the error interrupt request line EIR, the error status flags CON.FE/CON.PE/CON.OE are not reset automatically and must be cleared by software.*

For normal operation (that is, other than error interrupt), the ASC provides three interrupt requests to control data exchange by this serial channel:

- TBIR is activated when data is moved from TBUF to the transmit shift register
- TIR is activated before the last bit of an asynchronous frame is transmitted or after the last bit of a synchronous frame has been transmitted
- RIR is activated when the received frame is moved to RBUF

While the task of the receive interrupt handler is quite clear, the transmitter is serviced by two interrupt handlers. This provides advantages for the servicing software.

For single transfers, it is sufficient to use the transmit interrupt (TIR), which indicates that the previously loaded data has been transmitted, except for the last bit of an asynchronous frame.

For multiple back-to-back transfers, it is necessary to load the following piece of data at least before the last bit of the previous frame has been transmitted. In Asynchronous mode, this leaves just one bit-time for the handler to respond to the transmitter interrupt request; in Synchronous mode, it is entirely impossible.

Using the transmit buffer interrupt (TBIR) to reload transmit data provides the time necessary to transmit a complete frame for the service routine, as TBUF may be reloaded while the previous data is still being transmitted.

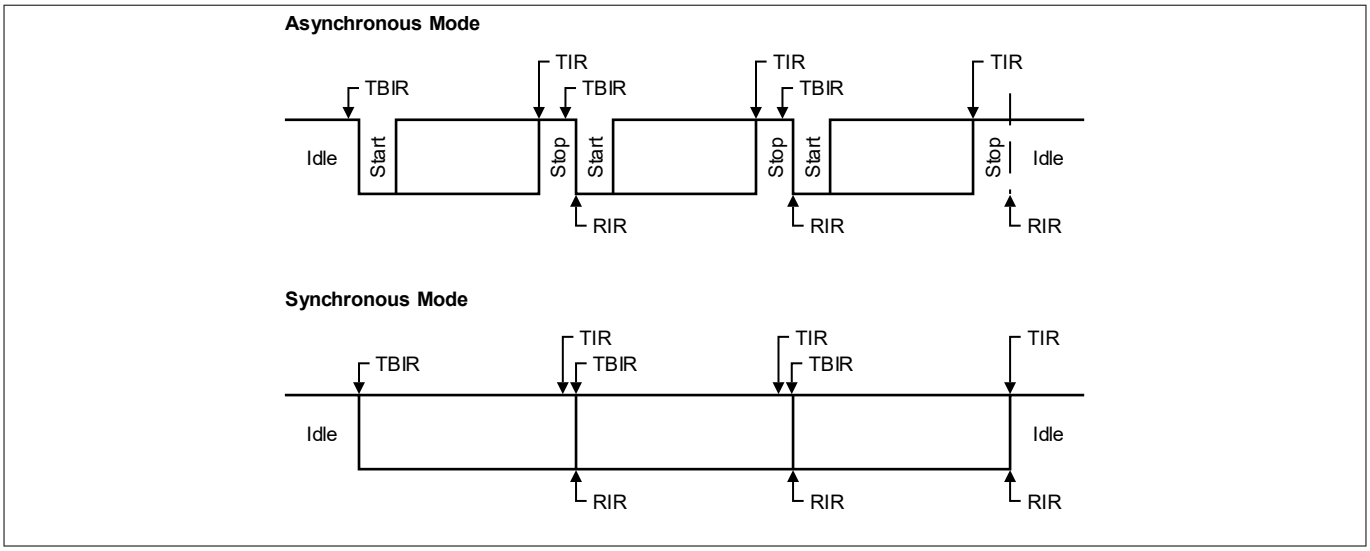

Figure 567 ASC interrupt generation

As shown in the figure above, TBIR is an early trigger for the reload routine, while TIR indicates the completed transmission. Software using handshake should, therefore, rely on TIR at the end of a data block to ensure that all data has been transmitted.

27.3.12 PSI5-S interrupts

8 Interrupt sources are available for the PSI5-S module. For each trigger source of a channel x one interrupt can be selected in register INPx.

1. INTSTATx.RDI indicates a receive data interrupt. It is activated when a received frame is moved to Receive Data Register RDR
2. INTSTATx.RSI indicates a receive frame success interrupt, i.e. non of the interrupts/errors XCRCI, CRCI, TEI, PE, FE, OE, RBI or HDI was detected. The referring interrupt must be enabled in GCR to be considered for RSI. Both RDI and RSI will be issued together in normal use cases where reception is correct
3. INTSTATx.RBI indicates a receive buffer overrun interrupt. It is activated when a new frame is transferred to a Receive Data Register RDR while the old value was still not read by the host (“overwrite”), i.e. the kernel wants to set interrupt RDI and finds RDI already set
4. INTSTATx.TPI indicates a transmit interrupt. It is activated when data is completely moved from a SDR to ASC (INTSTATx.TPI). Thus it can be used to trigger the next write access to SDRx
5. INTSTATx.TPOI indicates a transfer (send) register (SDRx) overrun interrupt. It is set if data is written to SDRx while the referring register is locked (occupied), signaled by SCRx.TPF. The data written is ignored in this case. INTOV.FOI indicates that the output FIFO was overrun

   In addition the protocol error interrupts are available:
6. INTSTATx.CRCI, XCRC. If CRC interrupt is activated, data is to be treated as invalid according to standard v2.1. Note that the wrong data is still available in all buffers. For XCRCI, these frames are always stored in channel 0 frame 1
7. INTSTATx.TEI is issued by the watchdog timer if the timely distance between two frames is too long
8. INTSTATx.CHCI indicates that the last frame expected for a channel is received

The interrupt request or the corresponding interrupt set bit (in register INTSET) can trigger the interrupt generation at the selected interrupt node. The service request pulse is generated independently from the interrupt flag in register INTSTATx. The interrupt flag can be cleared by software by writing to the corresponding bit in register INTCLR.

If more than one interrupt source is connected to the same interrupt node pointer (in register INPx all node pointer point to the same line), the requests are combined to one common line.

27.4 Registers

27.4.1 Register overview - access mode glossary

Table 1196 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

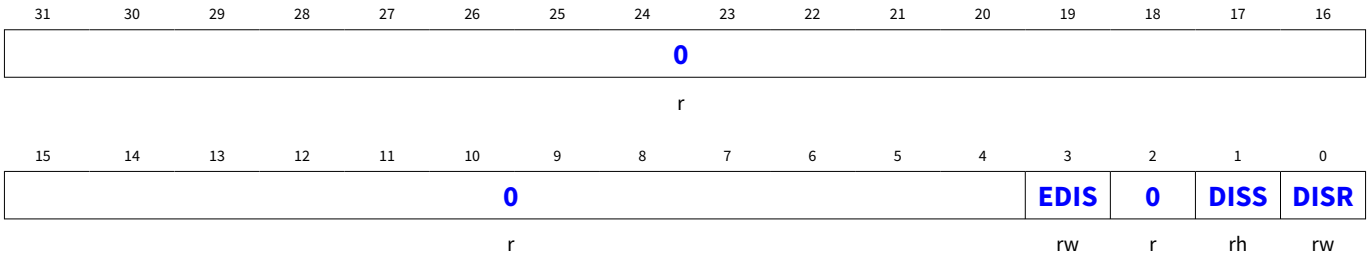
27.4.3 Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 0000_H

Clock Control Register Application Reset value: $0000\ 0003_H$



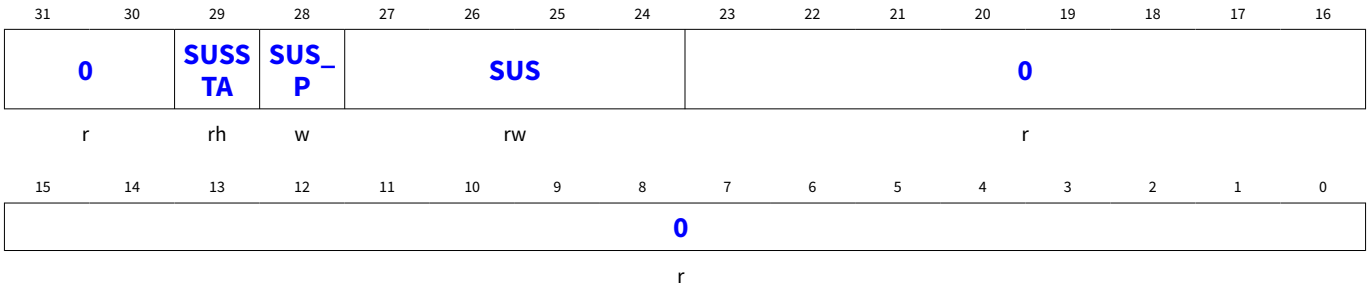
Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B On: Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

27.4.4 OCDS Control and Status Register

The OCDS Control and Status register OCS controls the debug and trace behavior by selecting suspend modes and OTGB trigger sets. When OCDS is disabled the suspend control is ineffective

OCS Offset address: 0004_H

OCDS Control and Status Register Debug Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) Not listed combinations are reserved. 0_H Will not suspend 1_H Hard suspend: Clocks will be disabled immediately 2_H Soft suspend mode Clock will be disabled after kernel acknowledge 3_H Soft suspend mode Kernel clock will not be disabled after acknowledge
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:0, 31:30	r	**Reserved** Read as 0; should be written with 0.

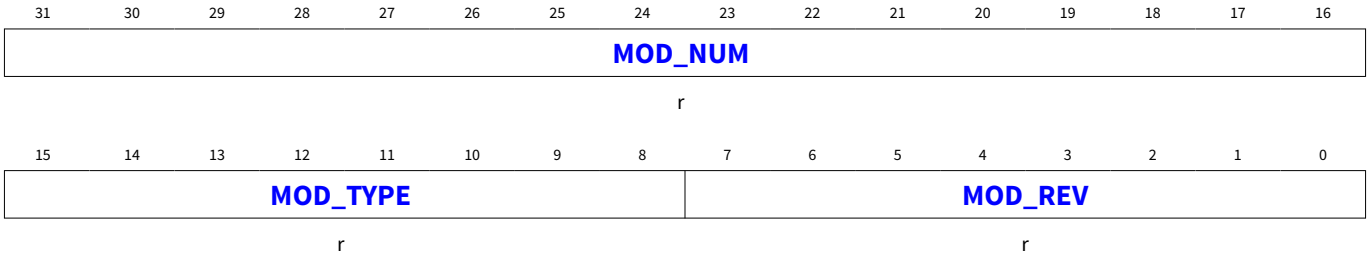
Table 1198 Access mode restrictions of OCS sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SUS_P**	rw	SUS	Set SUS_P during write access
(default)	r	SUS	

27.4.5 Module Identification Register

ID Offset address: 0008_H

Module Identification Register PowerOn Reset value: $00D3\ C001_H$



Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number.

27.4.6 Reset Control Register A

RST_CTRLA Offset address: $000C_H$

Reset Control Register A Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0				GRSTEN3	GRSTEN2	GRSTEN1	GRSTEN0	0							KRST
r				rw	rw	rw	rw	r							rwh

Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for Global Module Reset Group x** 0_B Global module reset group x does not have any effect 1_B Global module reset group x results in a kernel reset
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

27.4.7 Reset Control Register B

RST_CTRLB Offset address: 0010_H

Reset Control Register B Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
STATCLR								0							
w								r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															KRST
r															rwh

Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
STATCLR	31	w	**Kernel Reset Status Clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits STAT.GRSTx and bit STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

27.4.8 Reset Status Register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: 0014_H

Reset Status Register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0				GRST3	GRST2	GRST1	GRST0	0							KRST
r				rh	rh	rh	rh	r							rh

Field	Bits	Type	Description
KRST	0	rh	**Kernel Reset Status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.
GRSTx (x=0-3)	x+8	rh	**Status for Global Module Reset Group x** 0_B Reset was not triggered by Global Reset Group x 1_B Reset was triggered by Global Reset Group x
0	7:1, 31:12	r	**Reserved** Read as 0.

27.4.9 PROT Register Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 0020_H

PROT Register Endinit Application Reset value: $0000\ 0000_H$

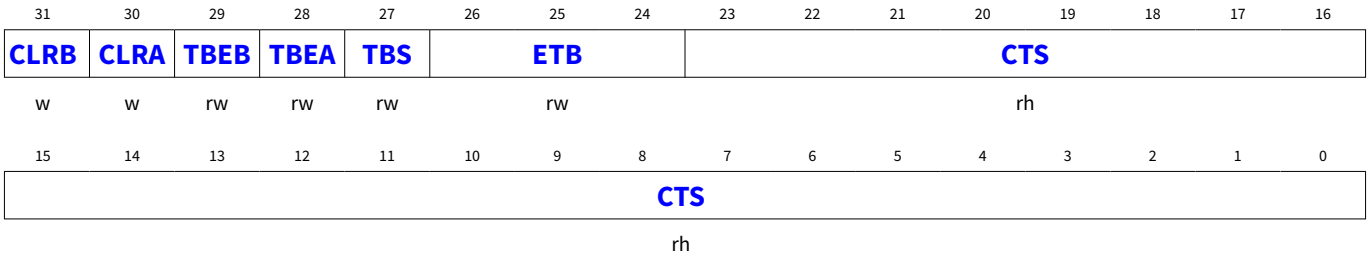
27.4.19 Timestamp Count Register A

The Timestamp Counter Register contains read-only information about the current time given in clock cycles of f_{TS} or $f_{GTM/eGTM}$ since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSCNTA Offset address: 0068_H

Timestamp Count Register A Kernel Reset value: $0000\ 0000_H$



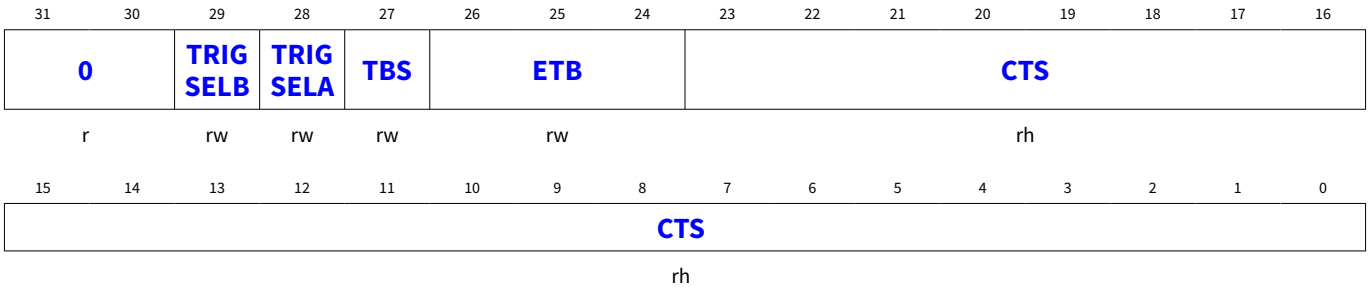
Field	Bits	Type	Description
CTS	23:0	rh	**Current Timestamp for the Module** This bit field shows the current timestamp.
ETB	26:24	rw	**External Time Base Select** Selects the external clock line for counter CTS if TBS is set. 000_B TRIG0 001_B TRIG1 … 111_B TRIG7
TBS	27	rw	**Time Base Select** This bit selects the clock source for CTS 0_B Internal, CTS counts in clock cycles of f_{TS} 1_B External, CTS counts in clock cycles received on external clock line selected by ETB
TBEA	28	rw	**Time Base Enable TSCNTA** This bit starts/stops TSCNTA.CTS 0_B CTS stopped (without clear of CTS) 1_B CTS started (without clear of CTS)
TBEB	29	rw	**Time Base Enable TSCNTB** This bit starts/stops TSCNTB.CTS 0_B CTS stopped (w/o clear of CTS) 1_B CTS started (w/o clear of CTS)
CLRA	30	w	**Clear Timestamp Counter A** This bit clears TSCNTA.CTS. TSCNTA.CTS counts on, starting from 0.
CLRB	31	w	**Clear Timestamp Counter B** This bit clears TSCNTB.CTS. TSCNTB.CTS counts on, starting from 0.

27.4.20 Timestamp Count Register B

The Timestamp Counter Register contains read-only information about the current time given in clock cycles of f_{TS} or $f_{GTM/eGTM}$ since last reset while module was clocked. It also contains the control bits for selection of input clock and reset of this counter.

TSCNTB Offset address: $006C_H$

Timestamp Count Register B Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CTS	23:0	rh	**Current Timestamp for the Module** This bit field shows the current timestamp.
ETB	26:24	rw	**External Time Base Select** Selects the external clock line for counter CTS. 000_B TRIG0 001_B TRIG1 … 111_B TRIG7
TBS	27	rw	**Time Base Select** This bit selects the clock source for CTS 0_B Internal, CTS counts in clock cycles of f_{TS} 1_B External, CTS counts in clock cycles received on external clock line selected by ETB
TRIGSELA	28	rw	**Trigger select** Trigger source selection bit for TSCNTA 0_B **GTMTRG**: GTM GTM trigger 1_B **eGTMTRG**: eGTM eGTM trigger
TRIGSELB	29	rw	**Trigger select** Trigger source selection bit for TSCNTB 0_B **GTMTRG**: GTM GTM trigger 1_B **eGTMTRG**: eGTM eGTM trigger
0	31:30	r	**Reserved** Read as 0; should be written with 0.

27.4.21 Global Control Register

The Global Control Register defines module wide settings.

The first 8 bits define, which error flags are regarded at RSI. RSI indicates that the referring frame is free of the selected errors. Each of these errors can be selected: CRCI, XCRCI, TEI, PE, FE, OE, RBI, HDI.

GCR Offset address: 0070_H

Global Control Register Kernel Reset value: $0000\ 001F_H$

27 Peripheral Sensor Interface with Serial Interface to PHY (PSI5-S)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
CRCI	0	rw	**CRCI** If bit is set, CRCI is selected to be checked for triggering RSI interrupt. No RSI is triggered in case of CRCI error
XCRCI	1	rw	**XCRCI** If bit is set, XCRCI is selected to be checked for triggering RSI interrupt. No RSI is triggered in case of XCRCI error
TEI	2	rw	**TEI** If bit is set, TEI is selected to be checked for triggering RSI interrupt. No RSI is triggered in case of TEI error
PE	3	rw	**PE** If bit is set, PE is selected to be checked for triggering RSI interrupt. No RSI is triggered in case of PE error
FE	4	rw	**FE** If bit is set, FE is selected to be checked for triggering RSI interrupt. No RSI is triggered in case of FE error
OE	5	rw	**OE** If bit is set, OE is selected to be checked for triggering RSI interrupt. No RSI is triggered in case of OE error
RBI	6	rw	**RBI** If bit is set, RBI is selected to be checked for triggering RSI interrupt. No RSI is triggered in case of RBI error
HDI	7	rw	**HDI** If bit is set, HDI is selected to be checked for triggering RSI interrupt. No RSI is triggered in case of HDI error
ETCx (x=0-7)	x+8	rw	**Enable Channel Trigger Counter CTVx.CTC** This bit enables CTVx.CTC. The bits ETC0 - x can be set with one write access to synchronously start all counters. This is required for proper sync pulse staggering. If set, CTVx.CTC counts on, starting from its current value. CTVx.CTC can be written only if ETCx is cleared (stopped).
CENx (x=0-7)	x+16	rw	**Enable Channel x** This bit enables PSI5-S channel x. If cleared, all internal state machines of the receiver and the sender are forced to default idle state while all registers can be read and written. Used for configuration of a channel. Frames received for a disabled channel are copied to ChID 0, FID 1 with original IDs.

(table continues...)

(continued)

Field	Bits	Type	Description
IDT	27:24	rw	**Idle Time (GLOBAL VALUE FOR ALL CHANNELS)** determines the number of stop bits in addition to the stop bit of the last UART frame that is required for SOF detection. (IDT-1) idle bit times are allowed/tolerated within one Packet frame. Default is IDT = 0, that is, back to back transfer. 0_H 1 bit time idle … F_H 16 bit time idle
ASC	31	rw	**ASC only Mode** is selected if bit is set. The ASC registers are fully controllable by software via SPB bus. If cleared, the ASC is controlled by the message reassembly unit and the message generation unit. RBUF and TBUF are no longer writable by software and interrupts are handled by the message reassembly block automatically.
0	30:28	r	**Reserved** Read as 0; should be written with 0.

27.4.22 Number of Frames Control Register

This register contains the number of Packet frames expected after a Sync Pulse.
It stores the compare values for the counters in register FCNT.
See FCNT.

NFC Offset address: 0074_H

Number of Frames Control Register Kernel Reset value: $0024\ 9249_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

NF5		NF4		NF3			NF2			NF1			NF0		
rw		rw		rw			rw			rw			rw		

Field	Bits	Type	Description
NFx (x=0-7)	3*x+2:3*x	rw	**Number of expected frames on Channel x** 000_B reserved, do not use. Reads back 1. 001_B 1 … 110_B 6 111_B reserved, do not use. Reads back 6.
0	31:24	r	**Reserved** Read as 0; should be written with 0.

27.4.23 Frame Counter Register

This register contains the number of Packet frames actually received after the last sync pulse. A sync pulse on channel x will clear FCx.

If FCNT.FCx equals NFC.NFx, interrupt CHCI is issued and FCNT.FCx will roll over to '1' with the reception of the next recoverable message on channel x. The roll over happens in any case, even if no sync pulse clears FCx after CHCI.

If RCRAx.WDMS is set, NFC and FCNT affect the operation of the watchdog timer. See Watchdog Timer chapter.

NFC and FCNT also affect the generation of interrupt CHCI. See Interrupts for DMA support chapter.

FCNT Offset address: 0078_H

Frame Counter Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Watchdog timers on page 4980

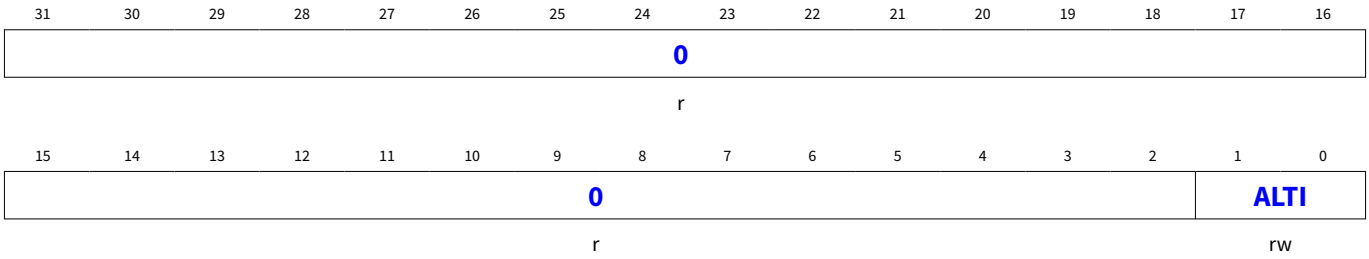
Interrupts for DMA support on page 4996

27.4.24 Input and Output Control Register

The Input and Output Control Register IOCR determines for the PSI5-S, the alternate input for the receiver

IOCR Offset address: $007C_H$

Input and Output Control Register Kernel Reset value: $0000\ 0000_H$



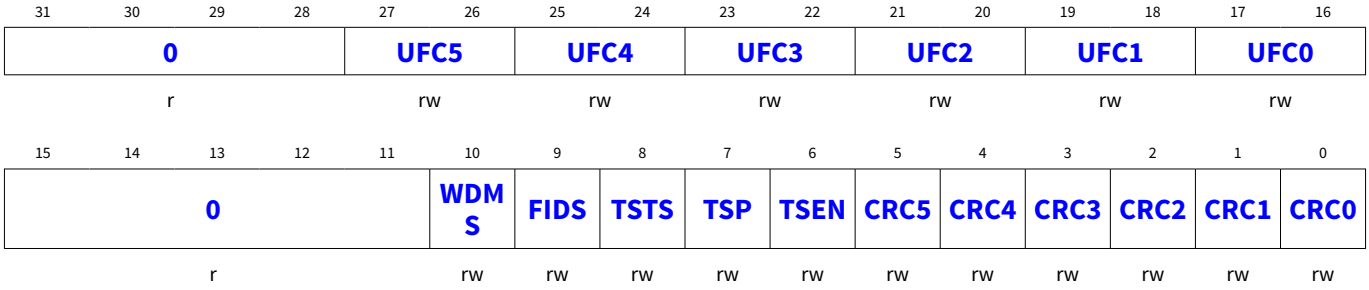
Field	Bits	Type	Description
ALTI	1:0	rw	**Alternate Input Select** Selects the alternate input for RX of the ASC: 00_B Alternate Input 0 selected … 11_B Alternate Input 3 selected
0	31:2	r	**Reserved** Read as 0; should be written with 0.

27.4.25 Receiver Control Register Ax

The Receiver Control Registers RCRAx contain control bits/bit fields that are related to the PSI5-S receiver operation. It enables the channel and determines the use of CRC or parity. GCR.CENx must be clear for write access.

RCRAx (x=0-7) Offset address: 0080_H+x*4

Receiver Control Register Ax Kernel Reset value: 0000 0000_H



Field	Bits	Type	Description
CRCy (y=0-5)	y	rw	**CRC or Parity Selection y** If set, a 3 bit CRC checksum is expected for the PSI5-S channel x in slot y. Else, 1 bit Parity is assumed. This bit field is looked up before potential modification of FID according to FIDS. 0_B 1 Parity Bit is configured 1_B 3 CRC bits are configured
TSEN	6	rw	**Timestamp Enable** Enables the timestamping for channel x 0_B Off TSCRx and thus TSM are forced to 0x0000 0000 1_B On, see TSP and TSTS bit fields

(table continues...)

(continued)

Field	Bits	Type	Description
TSP	7	rw	**Timestamp Select** For non-recoverable Packets (stored in ChID ‘0’, FID ’1’ with original IDs); TSCNTA is captured in TSM and not in TSCR0 (independent from TSP). 0_B TSCNTA.CTS is captured in TSCRx 1_B TSCNTB.CTS is captured in TSCRx
TSTS	8	rw	**Timestamp Trigger Select** 0_B On sync pulse. TSCRx is updated on sync pulse. TSM is updated from TSCRx on Packet Frame reception after ChID extraction. For non-recoverable Packets (stored in ChID ‘0’, FID ’1’ with original IDs); TSCR0 is not updated and TSM is updated with the current value of TSCNTA (independent from TSP). This happens at the time the FSM assumes the Packet Frame to be non-recoverable. This allows following good packets to be timestamped correctly. 1_B On any Frame. TSCRx and TSM are updated simultaneously with the current value of TSCNTA/B depending from RCRAx.TSP on Packet Frame reception after ChID extraction. (RDI) This allows software to read the time of reception on the referring channel from TSCRx. For non-recoverable Packets (stored in ChID ‘0’, FID ’1’ with original IDs), TSM is updated with the current value of TSCNTA (independent from TSP and TSEN). This happens at the time the FSM assumes the Packet Frame to be non-recoverable. TSCR0 is updated only if RCRA0.TSTS is set (‘1’)
FIDS	9	rw	**Frame ID Select** 0_B Frame ID is updated from Packet Frame Header (sync mode). Channel 0 should have FIDS cleared. This avoids that the module overwrites non-recoverable messages with transceiver messages. Note that non-recoverable messages are always stored in ChID ‘0’, FID ’1’ with original IDs. 1_B Frame ID is a rolling number 0-5 copied from FCNT.FC(x-1) (async mode) non-recoverable messages are still stored in ChID ‘0’, FID ’1’ with original IDs.
WDMS	10	rw	**Watchdog Timer Mode Select** 0_B Watchdog Timer is restarted on reception of each recoverable frame on Channel x (async mode). 1_B Watchdog Timer is restarted on sync pulse and stopped at reception of the last frame configured in NFC.NFx.(sync mode)
UFCy (y=0-5)	2*y+17:2*y +16	rw	**UART frame Count per Packet Frame in Slot y** This bit field defines the number of UART frames per Packet frame that are expected for Slot y. This bit field is looked up before potential modification of FID according to FIDS. 00_B 3 UART frames 01_B 4 UART frames 10_B 5 UART frames 11_B 6 UART frames
0	15:11, 31:28	r	**Reserved** Read as 0; should be written with 0.

27.4.26 Receiver Control Register Bx

The Receiver Control Registers RCRBx configures the number of payload bits and implicitly the number of UART frames (Bytes) each of the up to 6 slots in channel x. GCR.CENx must be clear for write access.

RCRBx (x=0-7) Offset address: $00A0_H$+x*4

Receiver Control Register Bx Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		PDL5					PDL4					PDL3

PDL3		PDL2				PDL1					PDL0				
rw		rw				rw					rw				

Field	Bits	Type	Description
PDLy (y=0-5)	5*y+4:5*y	rw	**Payload Data Length y** PDL determines the number of bits in a Packet frame for Slot y. It also determines the position of the CRC/Parity bit. For exmaple, 8 defines 8 data bits on position [7:0]. On bit position 8 the CRC/Parity is located. See Packet frames received from PHY chapter. If PDLy is cleared (‘0’) no frame is expected for this slot. Packet frames received for a slot with PDL = ‘0’ are copied to ChID 0, FID 1 with original IDs without further processing. This bit field is looked up before potential modification of FID according to RCRAx.FIDS 00_H No Frame expected 01_H 8 bits for 1 … 08_H 8 bits for 8 09_H 9 bits … $1B_H$ 27 bits $1C_H$ 28 bits for 28 … $1F_H$ 28 bits for 31
0	31:30	r	**Reserved** Read as 0; should be written with 0.

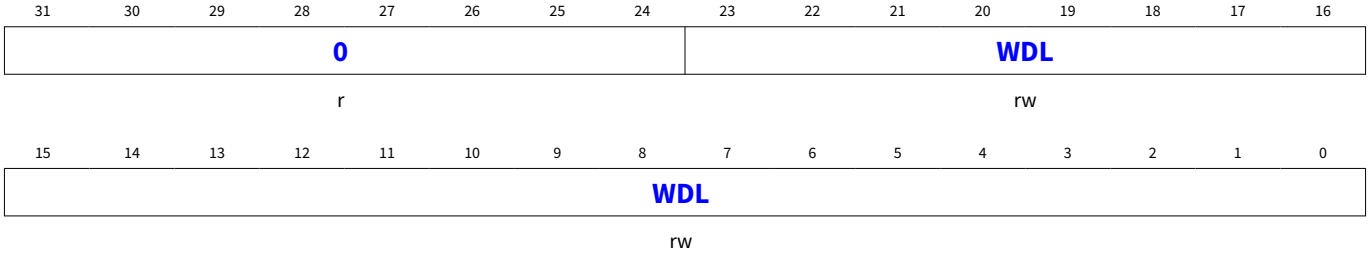
Related information

Packet frames received from PHY on page 4970

27.4.27 Watchdog Timer Register x

WDTx (x=0-7) Offset address: $00C0_H$+x*4

Watchdog Timer Register x Kernel Reset value: $0000\ 0000_H$



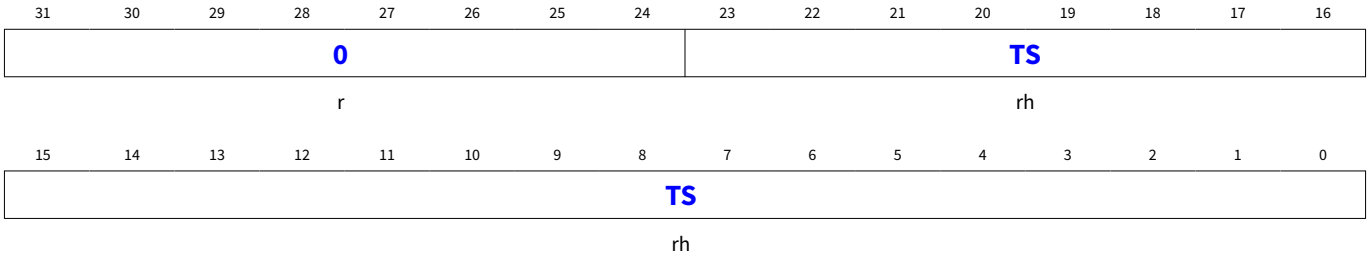
Field	Bits	Type	Description
WDL	23:0	rw	**Watchdog Timer Limit** for channel x. If no watchdog is needed, WDL is cleared, the internal watchdog timer is stopped and no check is performed. GCR.CENx must be clear for write access.
0	31:24	r	**Reserved** Read as 0; should be written with 0.

27.4.28 Timestamp Capture Register x

If RCRAx.TSEN is set, the timestamp is captured in this register each time a sync pulse is sent from the ASC FIFO to the ASC TX buffer for channel x. RCRAx.TSP selects, if TSCNTA or B is used.

TSCRx (x=0-7) Offset address: $00E0_H+x*4$

Timestamp Capture Register x Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TS	23:0	rh	**Timestamp** of the last sync pulse sent for channel x.
0	31:24	r	**Reserved** Read as 0; should be written with 0.

27.4.29 Receive Status Register

The Receive Status Register RDS shows the status of a received data frame.

The internal receive buffer is always cleared (0x0000 0000$_H$) at each frame start. Thus unused bits are always read as zero.

The bits CRCI, XCRCI, HDI, PE, FE, OE, TEI and RBI reflect, wether the conditions are met to issue an interrupt signal and set the referring interrupt status bit in INTSTAT or CON (ASC sub module) for the latest frame. Thus it is independent from the old status of the referring sticky bit in INTSTAT or CON before latest frame reception.

RDS Offset address: 0100$_H$

Receive Status Register Kernel Reset value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PFC				AFC			CID			FID			RBI	TEI	OE

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
XCRCy (y=0-5)	y	rh	**XCRC** CRC of last Packet frame. XCRC0 is on bit position 0.
XCRCI	6	rh	**XCRC Error Flag** This bit is set if the CRC check on the enveloping Packet frame fails including the case where XCRC check can not be performed (non-recoverable frames). Refer to Packet Frames received from PHY chapter 0_B correct XCRC 1_B wrong XCRC
CRCy (y=0-2)	y+7	rh	**CRC** of last frame. CRC0 / Parity is on bit position 7. If Parity is used, CRC1/2 are always 0.
CRCI	10	rh	**CRC Error Flag** This bit is set if the CRC or Parity check on the transported PSI5 frame fails. 0_B correct CRC/Parity 1_B wrong CRC/Parity
ERR0	11	rh	**Error signalling Flag 0** This bit represents the status of the error signalling flag Err0 in the enveloping Packet frame.
ERR1	12	rh	**Error signalling Flag 1** This bit represents the status of the error signalling flag Err1 in the enveloping Packet frame.

(table continues...)

(continued)

Field	Bits	Type	Description
HDI	13	rh	**Header Error Signalled Flag** This bit is set if at least one of the error signalling flags in the enveloping Packet Frame Err0 and Err1 is set. 0_B (Err0 OR Err1) = false (0) 1_B (Err0 OR Err1) = true (1)
PE	14	rh	**ASC Parity Error Flag** This bit is set if the error flag signalling a parity error was set during reception of one of the ASC bytes transporting this PSI5 frame.
FE	15	rh	**ASC Framing Error Flag** This bit is set if the error flag signaling a framing error was set during reception of one of the ASC bytes transporting this PSI5 frame.
OE	16	rh	**ASC Overrun Error Flag** This bit is set if the error flag signaling an overrun error was set during reception of one of the ASC bytes transporting this PSI5 frame.
TEI	17	rh	**Time Error Flag** This bit is set if the watchdog timer expired. Depending from RCRAx.WDMS either the distance between two RDIs is longer than specified in WDL or it expired without reception of CHCI in time. That is, the time from issuing the sync pulse to reception of the last expected frame configured in NFC.NFx was too long. If WDMS is in synchronous mode, all frames after TEI have TEI set in RDS until either CHCI is issued or INSTATx.TEI is cleared by software. RDS.TEI flag is independently from INTENx.TEI. 0_B no error 1_B error
RBI	18	rh	**Receive Buffer Overflow Flag** This bit is set after a frame has been received while the old one was not read from RDR. I.e. the kernel wants to set interrupt RDI and finds RDI already set. The old data is overwritten by the new data. 0_B No overflow 1_B Overflow
FID	21:19	rh	**Frame ID (Frame Number)** See bit RCRAx.FIDS for actual content. 000_B Slot0 … 101_B Slot5 110_B not valid, frame is copied to ChID 0, FID 1 with original IDs 111_B not valid, frame is copied to ChID 0, FID 1 with original IDs
CID	24:22	rh	**Channel ID (Channel Number)** 000_B channel 0 001_B channel 1 … 111_B channel 7

(table continues...)

(continued)

Field	Bits	Type	Description
AFC	27:25	rh	**Actual UART frame Count** This bit field shows the number of UART frames actually received. This is used to further analyze non-recoverable frames by software or during debugging.
PFC	31:28	rh	**Packet Frame Count** For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.

27.4.30 Receive Data Register

The Receive Data Register RDR shows the data content of a received data frame. If Messaging bits are used, they are located on bit position [1:0].

The internal receive buffer is always cleared (0x0000 0000$_H$) at each frame start. Thus unused bits are always read as zero.

RDR Offset address: 0104$_H$

Receive Data Register Kernel Reset value: 0000 0000$_H$

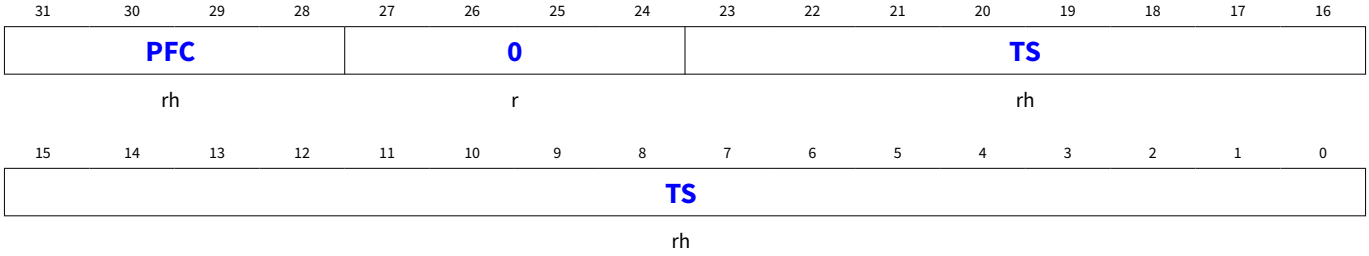
Field	Bits	Type	Description
RDy (y=0-27)	y	rh	**PSI5 Receive Data** of last frame. D0 is on bit position 0.
PFC	31:28	rh	**Packet Frame Count** For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.

27.4.31 Timestamp Mirror Register

Each time a new frame is received, the value from TSCRx for the referring channel is mirrored here. This register is updated, after XCRC was checked ok, as the referring channel number can not be securely determined before.

TSM Offset address: 0108_H

Timestamp Mirror Register Kernel Reset value: $0000\ 0000_H$



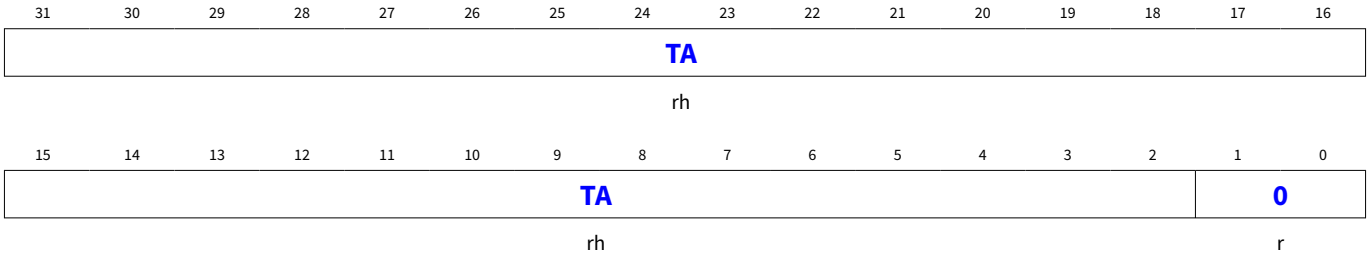
Field	Bits	Type	Description
TS	23:0	rh	**Timestamp** of the last sync pulse sent on channel x.
PFC	31:28	rh	**Packet Frame Count** For data consistency, RDR, RDS and TSM are tagged with a Packet Frame count value. For each channel there is a separate internal packet counter. This allows to read a triplet of RDR, RDS and TSM from the system memory without looking at interrupts. If the PFC is identical all three values belong together. Otherwise they need to be read again until PFC is identical.
0	27:24	r	**Reserved** Read as 0; should be written with 0.

27.4.32 Target Address Register

TAR contains the address that is to be copied by the first DMA into the target address register of the second DMA. This is required for the use case with 2 DMAs. See DMA Support chapter.

TAR Offset address: $010C_H$

Target Address Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TA	31:2	rh	**Target Address** Contains the upper 30 bit of the target address for the next DMA transfer. The 32 bit target address must be word aligned. Thus the 2 LSBs are fixed to 0. It is updated each time a new Packet Frame is received completely.
0	1:0	r	**Reserved** Read as 0; should be written with 0.

Related information

DMA support on page 4989

27.4.33 Base Address Register

BAR contains the address in the system memory where the PSI5-S buffer for all channels is built up.

BAR must be configured by the application for an address space that is big enough for all channels that are enabled. TAR will wrap around after the upper limit (0xFFFF FFFF) if adding the offsets (based on ChID and FID) exceeds this limit.

BAR Offset address: 0110_H

Base Address Register Kernel Reset value: $0000\ 0000_H$

CTV															
rw															

Field	Bits	Type	Description
CTV	15:0	rw	**Channel Trigger Value CTV** Contains the compare value (exact match) of Channel Trigger Counter CTC at which a sync pulse is triggered for channel x and the counter CTC is cleared. If cleared, CTC is stopped and no pulse triggered.
CTC	31:16	rwh	**Channel Trigger Counter** This bit field allows to read the current counter value of the reset timer cell CTVx. If GCR.ETCx is cleared, CTC can be written.

27.4.36 Send Control Register x

The Send Control Register SCRx contains control data bits required for sending data from the PSI5-S module to the sensor / external PHY.

Data is collected in SDRx and the control bits are collected in SCRx.

The send control unit is build to transmit complete ECU to sensor frames.

SCRx (x=0-7) Offset address: 0154_H+x*4

Send Control Register x Kernel Reset value: $0000\ 0000_H$

27 Peripheral Sensor Interface with Serial Interface to PHY (PSI5-S)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	FLUS	0					BSC	EPS		0	PLL				
r	w	r					rw	rw		r	rw				

Field	Bits	Type	Description
PLL	4:0	rw	**Payload Length of Registers SDRx** Defines the length that is taken into account. PLL needs to written before SDRx is used for proper operation. 00_H length is 6 for 0 … 06_H length is 6 for 6 07_H length is 7 … 17_H length is 23 18_H length is 24 for 24 … $1F_H$ length is 24 for 31
EPS	7:6	rw	**Enhanced Protocol Selection** EPS[0] controls the Bit Format and MSB Fill bit. (0: Tooth Gap, MSB Fill 1) (1: Pulse Width method, MSB Fill 0) EPS[1] controls the Frame Format (0: Frame Format 1 - 3) (1: Frame Format 4) 00_B Tooth Gap method, ‘1’ for filling the shift register from MSB; Frame format 1 -3 (3 bit start sequence, 3 bit stuffing distance, ‘1’ for stuffing, 3 bit CRC). 01_B Pulse Width method, ‘0’ for filling the shift register from MSB; Frame format 1 -3 (3 bit start sequence, 3 bit stuffing distance, ‘1’ for stuffing, 3 bit CRC). 10_B Reserved, do not use 11_B Pulse Width method, ‘0’ for filling the shift register from MSB; Frame Format 4 (9 bit start sequence, 6 bit stuffing distance, ‘0’ for stuffing, 6 bit CRC).
BSC	8	rw	**Bit Stuffing Control** Depending from bit EPS[1] after 3 bits a ‘1’ is inserted (Frame Format 1 -3) or after 6 bits a ‘0’ is inserted (Frame Format 4) 0_B No automatic bit stuffing 1_B Automatic bit stuffing is enabled.
FLUS	14	w	**Flush SDRx** Setting this bit stops shifting out the data in SDRx, the start sequence or CRC if any and clears the referring FSMs and counters. If EPS[0] is 0, SDRx is flushed by setting all bits of EPS[0] to 1 and clears TPF. TPIx is issued at the end of successful flushing. Reads always as zero.

(table continues...)

(continued)

Field	Bits	Type	Description
CRC	22	rw	**CRC Generation Control** 0_B CRC is not generated automatically, it still can be written by software together with the data (for example, to test the remote CRC) 1_B CRC is automatically generated by hardware (according to EPS[1])
STA	23	rw	**Start Sequence Generation Control** 0_B no start sequence generated, shifting out payload starts at bit 0! 1_B automatically generated by hardware (according to EPS[1]) shifting out payload starts after 3/9 bits (EPS[1] = 0/1)
TPF	26	r	**Transmit in Progress Flag** If set, data preparation and transmission is in progress: start sequence or CRC or stuffing bits or data from SDRx are being transferred. It is cleared automatically after preparation and transmitting is finished. If set, write access to SDRx will not change any data and issue TPOI.
0	5, 13:9, 21:15, 25:24, 31:27	r	**Reserved** Read as 0; should be written with 0.

27.4.37 Send Data Register x

The Send Data Register SDRx shows the data content of a data frame to be sent.
GCR.CENx must be set for write access. For initialization SCRx.FLUS can be used.

SDRx (x=0-7) Offset address: 0174_H+x*4

Send Data Register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								SD23	SD22	SD21	SD20	SD19	SD18	SD17	SD16
r								rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
SDy (y=0-23)	y	rwh	**SDy** Send data of next ECU to Sensor frame. Each time a bit is shifted out, the whole content is shifted right by 1 position and the MSB is filled with '1' or '0' depending from EPS[0]. This allows to read back SDR and determine the status of the shift process by software. The unused MSBs (bit position SCRx.PLL and higher) must be written with '0' if EPS[0] is set (Pulse width method) and with '1' if EPS[0] is cleared (Tooth Gap method). This is required, as the respective standard value is shifted into the register from MSB during shift out operation. SDRx will be filled with this value after shift out process.
0	31:24	r	**Reserved** Read as 0.

27.4.38 CPU Direct Write Register

The CPU Direct Write Register CDW allows the CPU to insert a command into the ASC FIFO. Note that Bits SD[7:5] select the channel for which the timestamp is captured. These bits are copied to the UART frame Bit positions [2:0] (ChID) while SD[4:0] are copied to UART frame Bit positions [7:3] (Command). See Figure PSI5-S UART frames transmitted to the PHY .

CDW Offset address: 0194_H

CPU Direct Write Register Kernel Reset value: $0000\ 0000_H$

(table continues...)

(continued)

Field	Bits	Type	Description
ODDTX	28	rw	**Parity Selection TX direction** While bit field ODD controls the RX path, ODDTX controls the mode for the TX path. 0_B Even parity selected (parity bit = 1 on odd number of 1s in data, parity bit = 0 on even number of 1s in data) 1_B Odd parity selected (parity bit = 1 on even number of 1s in data, parity bit = 0 on odd number of 1s in data)
0	27:19, 31:29	r	**Reserved** Read as 0; should be written with 0.

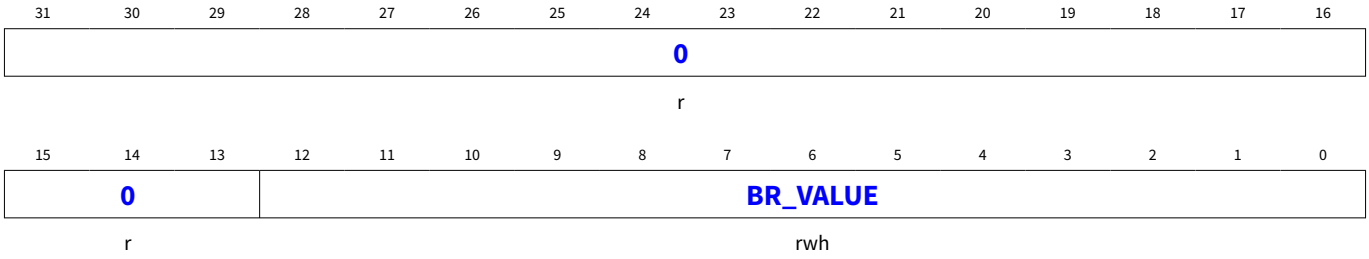
Serial data transmission or reception is possible only when the run bit CON.R is set to 1. Otherwise, the serial interface is idle. To avoid unpredictable behavior of the serial interface, do not program the mode control field CON.M to one of the reserved combinations.

27.4.40 Baud Rate Timer/Reload Register

The Baud Rate Timer Reload Register BG of the ASC module contains the 13-bit reload value for the baud rate timer in Asynchronous and Synchronous Modes.

BG Offset address: $019C_H$

Baud Rate Timer/Reload Register Kernel Reset value: $0000\ 0000_H$



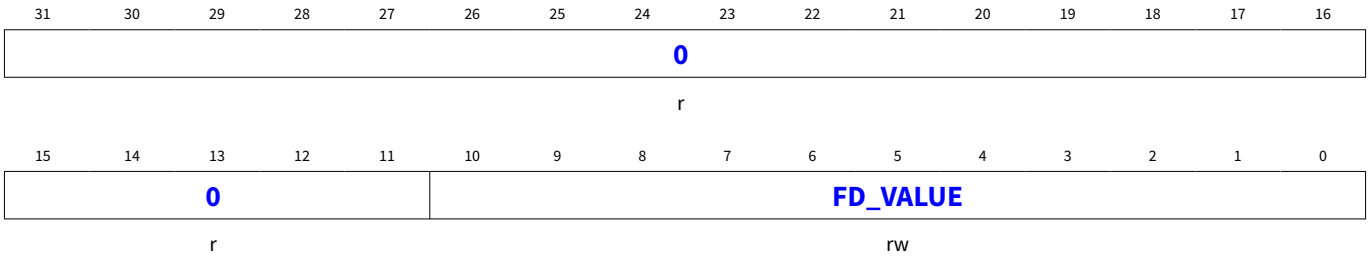
Field	Bits	Type	Description
BR_VALUE	12:0	rwh	**Baud Rate Timer/Reload Register Value** Reading BR_VALUE returns the 13-bit content of the baud rate timer. Writing BR_VALUE loads the baud rate timer reload register. BG should only be written if CON.R = 0.
0	31:13	r	**Reserved** Read as 0; should be written with 0.

27.4.41 Fractional Divider Register

The Fractional Divider Register FDV of the ASC module contains the 11-bit divider value for the fractional divider (asynchronous mode only).

FDV Offset address: $01A0_H$

Fractional Divider Register Kernel Reset value: $0000\ 0000_H$



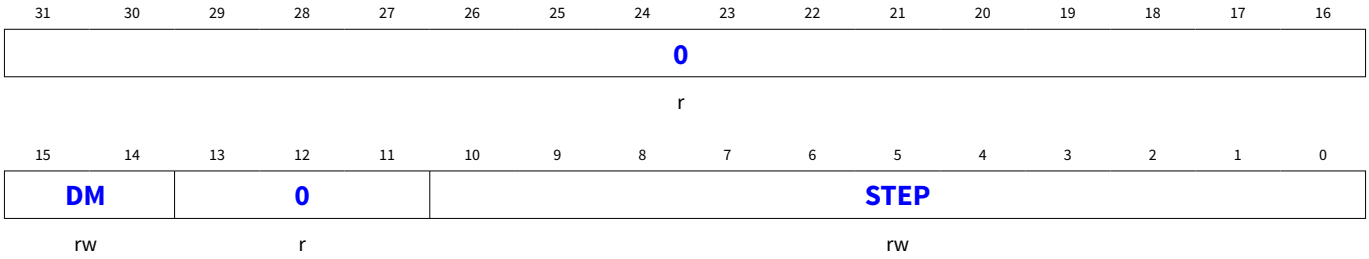
Field	Bits	Type	Description
FD_VALUE	10:0	rw	**Fractional Divider Register Value** FD_VALUE contains the 11-bit value n of the fractional divider which determines the fractional divider ratio n/2048 (n = 0-2047). With n = 0, the fractional divider is switched off (divider ratio = 1).
0	31:11	r	**Reserved** Read as 0; should be written with 0.

27.4.42 Fractional Divider for Output CLK Register

The Fractional Divider Register FDO contains the 11-bit divider value for the fractional divider that is generating $f_{PSISCLK}$ from f_{ASC} . PSISCLK is a clock that can be used on a pin to drive the external PHY.

FDO Offset address: $01A4_H$

Fractional Divider for Output CLK Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STEP	10:0	rw	**Step Value** Reload or addition value for internal accumulator.
DM	15:14	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. 01_B Normal Divider Mode selected. 10_B Fractional Divider Mode selected. 11_B Fractional divider is switched off; no output clock is generated.
0	13:11, 31:16	r	**Reserved** Read as 0; should be written with 0.

Related information

Clock generation on page 4977

27.4.43 Transmit Buffer Register

The Transmit Buffer Register TBUF of the ASC module contains the transmit data value in Asynchronous And Synchronous Modes. If GCR.ASC is cleared, TBUF is no longer writable by software and interrupts are handled by the message reassembly block automatically.

TBUF Offset address: $01A8_H$

Transmit Buffer Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0							TD_VALUE								
r							rwh								

Field	Bits	Type	Description
TD_VALUE	8:0	rwh	**Transmit Data Register Value** TBUF contains the data to be transmitted in the asynchronous and synchronous operating modes of the ASC. Data transmission is double-buffered; therefore, a new value can be written to TBUF before the transmission of the previous value is complete.
0	31:9	r	**Reserved** Read as 0; should be written with 0.

27.4.44 Receive Buffer Register

The receive buffer register RBUF of the ASC module contains the receive data value in Asynchronous and Synchronous Modes.

RBUF Offset address: $01AC_H$

Receive Buffer Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0							RD_VALUE								
r							rh								

Field	Bits	Type	Description
RD_VALUE	8:0	rh	**Receive Data Register Value** RD_VALUE contains the received data bits and, depending on the selected mode, the parity bit in the asynchronous and synchronous operating modes of the ASC. In Asynchronous Mode, with CON.M = 011_B (7-bit data + parity), the received parity bit is written into RD_VALUE[7]. In Asynchronous Mode, with CON.M = 111_B (8-bit data + parity), the received parity bit is written into RD_VALUE[8].
0	31:9	r	**Reserved** Read as 0.

27.4.45 Write Hardware Bits Control Register

The three error flags in register CON and the REN bit can be set or cleared by software by register WHBCON. WHBCON is a write-only register. Reading WHBCON always returns 0000 0000_H.

***Note**: When the set and clear bits for an error flag are set at the same time during a WHBCON write operation (for example, SETPE = CLRPE = 1), the error flag in CON is not affected.*

WHBCON Offset address: $01B0_H$

Write Hardware Bits Control Register Kernel Reset value: 0000 0000_H

0							HDI	TPOI	TPI	CRCI	CHCI	TEI	RBI	RDI	RSI
r							rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
RSI	0	rh	**Receive Success Interrupt Request Flag** This bit is set at the successfully received end of a frame. It indicates that this frame is free of the errors CRCI, XCRCI, TEI, PE, FE, OE, RBI, HDI if selected to be taken into account in register GCR. This bit can be cleared by bit INTCLRx.RSI. This bit can be set by bit INTSETx.RSI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
RDI	1	rh	**Receive Data Interrupt Request Flag** RDI is activated when a received frame is moved to a Receive Data Register RDR. Both RDI and RSI will be issued together at correct reception. This bit can be cleared by bit INTCLRx.RDI. This bit can be set by bit INTSETx.RDI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
RBI	2	rh	**Receive Buffer Overflow Interrupt Request Flag** This bit is set after a frame has been received while the old one was not read from RDR. That is, the kernel wants to set interrupt RDI and finds this interrupt already set. The old data is overwritten by the new data. This bit is NOT cleared by reading RDR. This bit can be cleared by bit INTCLRx.RBI. This bit can be set by bit INTSETx.RBI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TEI	3	rh	**Timing Error Interrupt Request Flag** This bit is set if the watchdog timer expired. Depending from RCRAx.WDMS either the distance between two RDIs is longer than specified in WDL or it expired without reception of CHCI in time. That is, the time from issuing the sync pulse to reception of the last expected frame configured in NFC.NFx was too long. Note that the root cause might be a non-recoverable frame! This bit can be cleared by bit INTCLRx.TEI. This bit can be set by bit INTSETx.TEI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

(table continues...)

(continued)

Field	Bits	Type	Description
CHCI	4	rh	**Channel Completed Interrupt Request Flag** This bit is set if FCNT.FCx equals NFC.NFx. This bit can be cleared by bit INTCLRx.CHCI. This bit can be set by bit INTSETx.CHCI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
CRCI	5	rh	**CRC Error Request Flag** This bit is set if the CRC fails. This bit can be cleared by bit INTCLRx.CRCI. This bit can be set by bit INTSETx.CRCI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TPI	6	rh	**Transfer Preparation Interrupt Request Flag** This bit is set after data to be transferred has been moved completely. Thus a new value can be written to SDRx. This bit can be cleared by bit INTCLRx.TPI. This bit can be set by bit INTSETx.TPI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TPOI	7	rh	**Transmit Preparation Overflow Interrupt Request Flag** This bit is set if SDR is written while TPF is set. The old data is NOT overwritten. This bit can be cleared by bit INTCLRx.TPOI. This bit can be set by bit INTSETx.TPOI. This bit is set independently from INTENx. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
HDI	8	rh	**Header Error Signalled Flag** This bit is set if at least one of the error signalling flags in the enveloping Packet frame Err0 and Err1 is set. 0_B (Err0 OR Err1) = false (0) 1_B (Err0 OR Err1) = true (1)
0	31:9	r	**Reserved** Read as 0.

27.4.47 Interrupt Set Register x

The Interrupt Set Registers INTSETx contain control bits that trigger an interrupt pulse for any interrupt of PSI5-S channel x.

INTSETx (x=0-7) Offset address: $01D4_H+x*4$

Interrupt Set Register x Kernel Reset value: $0000\ 0000_H$

0	31:15	r	**Reserved** Read as 0.

27.4.52 Interrupt Status Register Global

The Interrupt Status Registers Global INTSTATG contains status bits that show the status of any global interrupt of the ASC inside PSI5-S and XCRCI indicating a non-recoverable message is received. On XCRCI, the non-recoverable message is stored in ChID ‘0’, FID ’1’ with original IDs. INTSTATG contains as well FOI indicating a FIFO overrun condition. In a correct setup, this will never be set as the bandwidth of the ASC is assumed to be by far higher than the write bandwidth in order to have short delays.

The bits are set independently from the referring Interrupt Enable in Register INTENG. Thus they can be used as status bits as well. For example, by a software based on polling.

INTSTATG Offset address: 0258_H

Interrupt Status Register Global Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0										FOI	XCRCI	TBIR	EIR	RIR	TIR
r										rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
TIR	0	rh	**Transmit Interrupt Request Flag** This bit can be cleared by bit INTCLRG.TIR. This bit can be set by bit INTSETG.TIR. This bit is set independently from INTENG. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
RIR	1	rh	**Receive Interrupt Request Flag** This bit can be cleared by bit INTCLRG.RIR. This bit can be set by bit INTSETG.RIR. This bit is set independently from INTENG. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
EIR	2	rh	**Error Interrupt Request Flag** The cause of an error interrupt request EIR (framing, parity, overrun error) can be identified by the error status flags CON.FE, CON.PE, and CON.OE, This bit can be cleared by bit INTCLRG.EIR. This bit can be set by bit INTSETG.EIR. This bit is set independently from INTENG. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
TBIR	3	rh	**Transmit Buffer Interrupt Request Flag** This bit can be cleared by bit INTCLRG.TBIR. This bit can be set by bit INTSETG.TBIR. This bit is set independently from INTENG. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
XCRCI	4	rh	**XCRC Error Request Flag** This bit is set if the CRC check on the enveloping Packet frame fails including the case where XCRC check can not be performed (non-recoverable frames). Refer Packet frames received from PHY chapter. The received data is not reliable and stored in ChID ‘0’, FID ’1’ with original IDs. This bit can be cleared by bit INTCLRG.XCRCI. This bit can be set by bit INTSETG.XCRCI. This bit is set independently from INTENG. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time

(table continues...)

(continued)

Field	Bits	Type	Description
FOI	5	rh	**FIFO Error Request Flag** This bit is set if the Transmit FIFO of the message generation is overrun, that is, a transfer to the FIFO was generated by the message generation unit or by CDW (CPU Direct Write Register) while the FIFO was already full. This bit can be cleared by bit INTCLRG.FOI. This bit can be set by bit INTSETG.FOI. This bit is set independently from INTENG. 0_B No interrupt was requested since this bit was cleared the last time 1_B An interrupt was requested since this bit was cleared the last time
0	31:6	r	**Reserved** Read as 0.

27.4.55 Interrupt Enable Register Global

The Interrupt Enable Register Global INTENG contain control bits that enable the interrupt source of any interrupt of the ASC integrated in PSI5-S and for XCRCI and FOI.

The Interrupt Status bits in register INTSTATG are set independently from the Interrupt Enable in Register INTENG.

INTENG Offset address: 0264_H

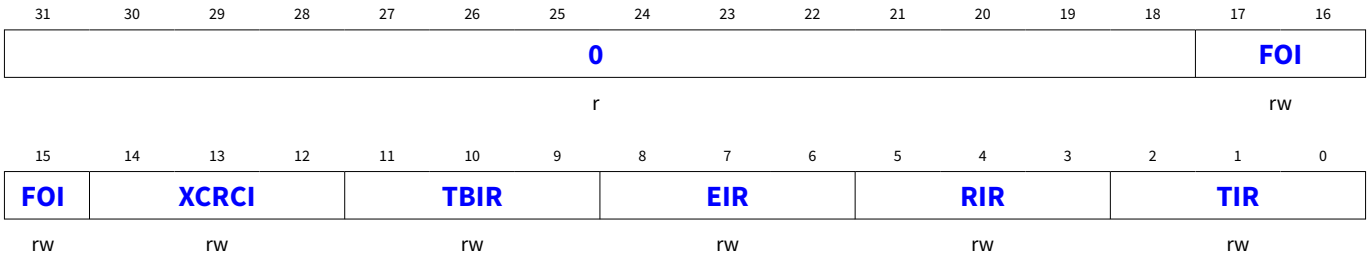
27.4.56 Interrupt Node Pointer Register Global

The Interrupt Node Pointer Register Global INPG contains the node pointers of PSI5-S ASC and for XCRCI and FOI.

INPG Offset address: 0268_H

Interrupt Node Pointer Register Global Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TIR	2:0	rw	**Interrupt Node Pointer for Interrupt TIR** This bit field defines the interrupt node that is requested due to the set condition for bit INTSTATG.TIR (if enabled by bit INTENG.TIR). 000_B Trigger Output PSI5SwSRx 0 is selected ... 111_B Trigger Output PSI5SwSRx 7 is selected
RIR	5:3	rw	**Interrupt Node Pointer for Interrupt RIR** This bit field defines the interrupt node that is requested due to the set condition for bit INTSTATG.RIR (if enabled by bit INTENG.RIR). For bit field definition, see INPGx.TIR.
EIR	8:6	rw	**Interrupt Node Pointer for Interrupt EIR** This bit field defines the interrupt node that is requested due to the set condition for bit INTSTATG.EIR (if enabled by bit INTENG.EIR). For bit field definition, see INPGx.TIR.
TBIR	11:9	rw	**Interrupt Node Pointer for Interrupt TBIR** This bit field defines the interrupt node that is requested due to the set condition for bit INTSTATG.TBIR (if enabled by bit INTENG.TBIR). For bit field definition, see INPGx.TIR.
XCRCI	14:12	rw	**Interrupt Node Pointer for Interrupt XCRCI** This bit field defines the interrupt node that is requested due to the set condition for bit INTSTATG.XCRCI (if enabled by bit INTENG.XCRCI). For bit field definition, see INPGx.TIR.
FOI	17:15	rw	**Interrupt Node Pointer for Interrupt FOI** This bit field defines the interrupt node that is requested due to the set condition for bit INTSTATG.FOI (if enabled by bit INTENG.FOI). For bit field definition, see INPGx.TIR.
0	31:18	r	**Reserved** Read as 0; should be written with 0.

27.8.6 TC4Dx PSI5-S revision history

Initial release of the chapter.

28 Micro Second Channel (MSC)

The MSC is a serial interface that is especially designed to connect external power switch devices. The serial data transmission capability minimizes the number of pins required to connect such external power switch devices. Parallel data information (coming from the timer units) or command information is sent out to the power switch device using a high-speed synchronous serial data stream (downstream channel). The MSC receives data and status back from the power switch device through a low-speed asynchronous serial data stream (upstream channel).

Parallel requests from on chip bus masters to a module will be executed sequentially through the on-chip bus system. A read-modify-write feature provides an atomic read/write sequence where no other master can access the module in between. Module hardware semaphores are not supported.

The following figure shows a typical application in which an MSC interface controls two power switch devices. Output data is provided by the module.

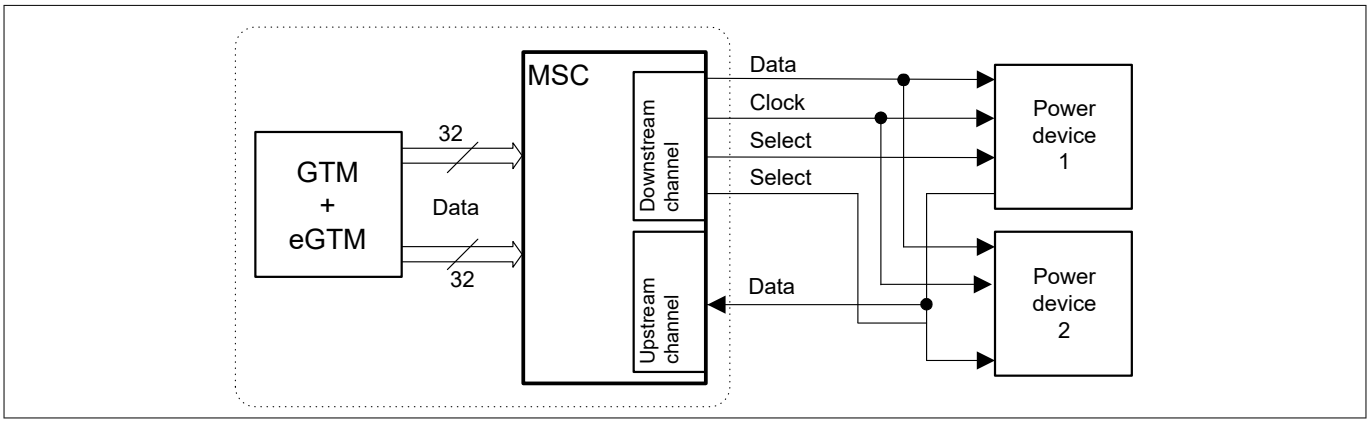

Figure 568 MSC to external power device connection

Some MSC applications are:

- Control of the external power switching unit through the downstream channel
- Receiving information back from power switching unit
- Serial connections to other peripheral devices

28.1 Feature list

- Flexible functional configuration for software
  - Baud rate configuration
- Transmit MSC frames to external devices and handle all protocol relevant topics
  - Supports 64-bit data frames and 32-bit data frames transmission
  - Asynchronous baud rate adjustment block
  - Supports command frame transmission through slow channel
  - Selectable MSC Manchester code transmission: combination of downstream data, clock and enable signals transmitted in the same line
- Receive MSC frames from external devices and handle all protocol relevant topics
  - Programmable upstream data frame length (16 or 12 bits)
  - Programmable delay of the receive interrupt after the last stop bit (0 or 1-bit time)
- Flexible interrupt structure generation available
- Selectable pin types of downstream channel interface: four low-voltage differential signaling (LVDS) output drivers or four digital general purpose input output (GPIO) pins
- Additional clock input selection is available, f_{SRI} = 500 MHz. This clock selection with an additional clock divider offers the possibility to provide a MSC baud rate configuration up to 50 MHz (and frequencies

divided as describe in the Baud rate configuration section) without asynchronous baud rate adjustment (ABRA) usage

28.2 Functional overview

The MSC interface provides a serial communication link typically used to connect power switches or other peripheral devices. The serial communication link includes a fast synchronous downstream channel and a slow asynchronous upstream channel.

The following block diagram of the MSC interface shows a global view of the MSC interface signals.

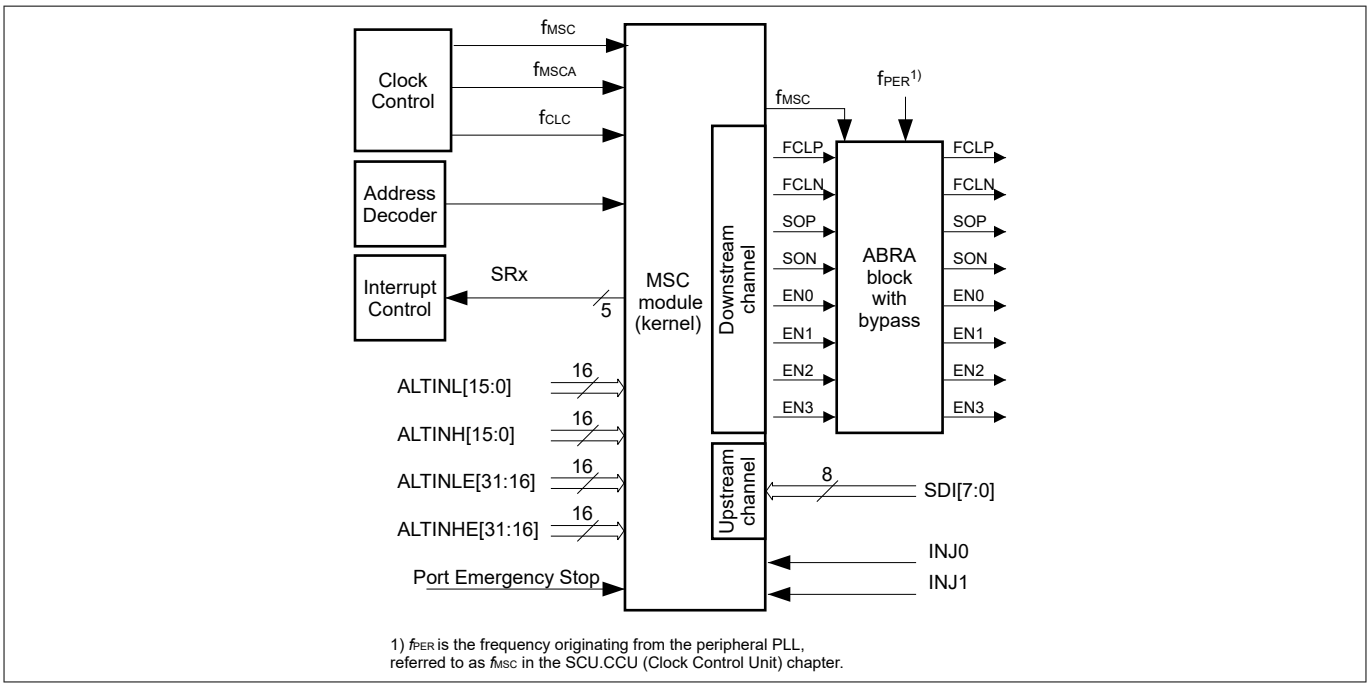

Figure 569 MSC block diagram

The MSC module features functional extensions, but is backward compatible with the previous microcontroller generations.

The downstream and upstream channels of the MSC module communicate with the external world through nine I/O lines. Eight output lines are required for the serial communication of the downstream channel (clock, data and enable signals). One out of the eight input lines SDI[7:0] is used as serial data input signal for the upstream channel. The source of the serial data to be transmitted by the downstream channel can be MSC register contents or data that is provided at the ALTINL/ALTINH input lines. These input lines are typically connected to other on-chip peripheral units (for example with a timer unit like the GTM). A Port Emergency Stop input signal makes it possible to set bits of the serial data stream to dedicated values in case of emergency.

Clock control, address decoding and interrupt service request control are managed outside the MSC module kernel. Service request outputs are able to trigger an interrupt or a DMA request.

In MSC+ mode 2 lines are required for the serial communication of the downstream channel (since clock, data and enable are embedded in one pair line).

28.3 Functional description

This section describes:

- MSC kernel
- The extension mode
- Asynchronous baud rate adjustment block
- Slow channel
- MSC+ transmission
- Module implementation

28.3.1 MSC kernel description

This section describes the functionality of the MSC kernel.

***Note**: The configuration should not be changed on run-time.*

28.3.1.1 Downstream channel

The downstream channel performs a high-speed synchronous serial transmission of data to external devices. Its 64-bit shift register is divided into two 32-bit parts, SRL and SRH.

Each bit of SRL and SRH can be selected to be delivered by the Downstream Data Register DD, by the Downstream Command Register DC or by two 16-bit wide input signal buses, ALTINL and ALTINH.

In the 64-bit extended mode, set with the bit DSCE.EXEN=1, the MSC module provides two 16-bit extension buses, ALTINLE and ALTINHE.

The figure below shows a diagram of the MSC downstream channel.

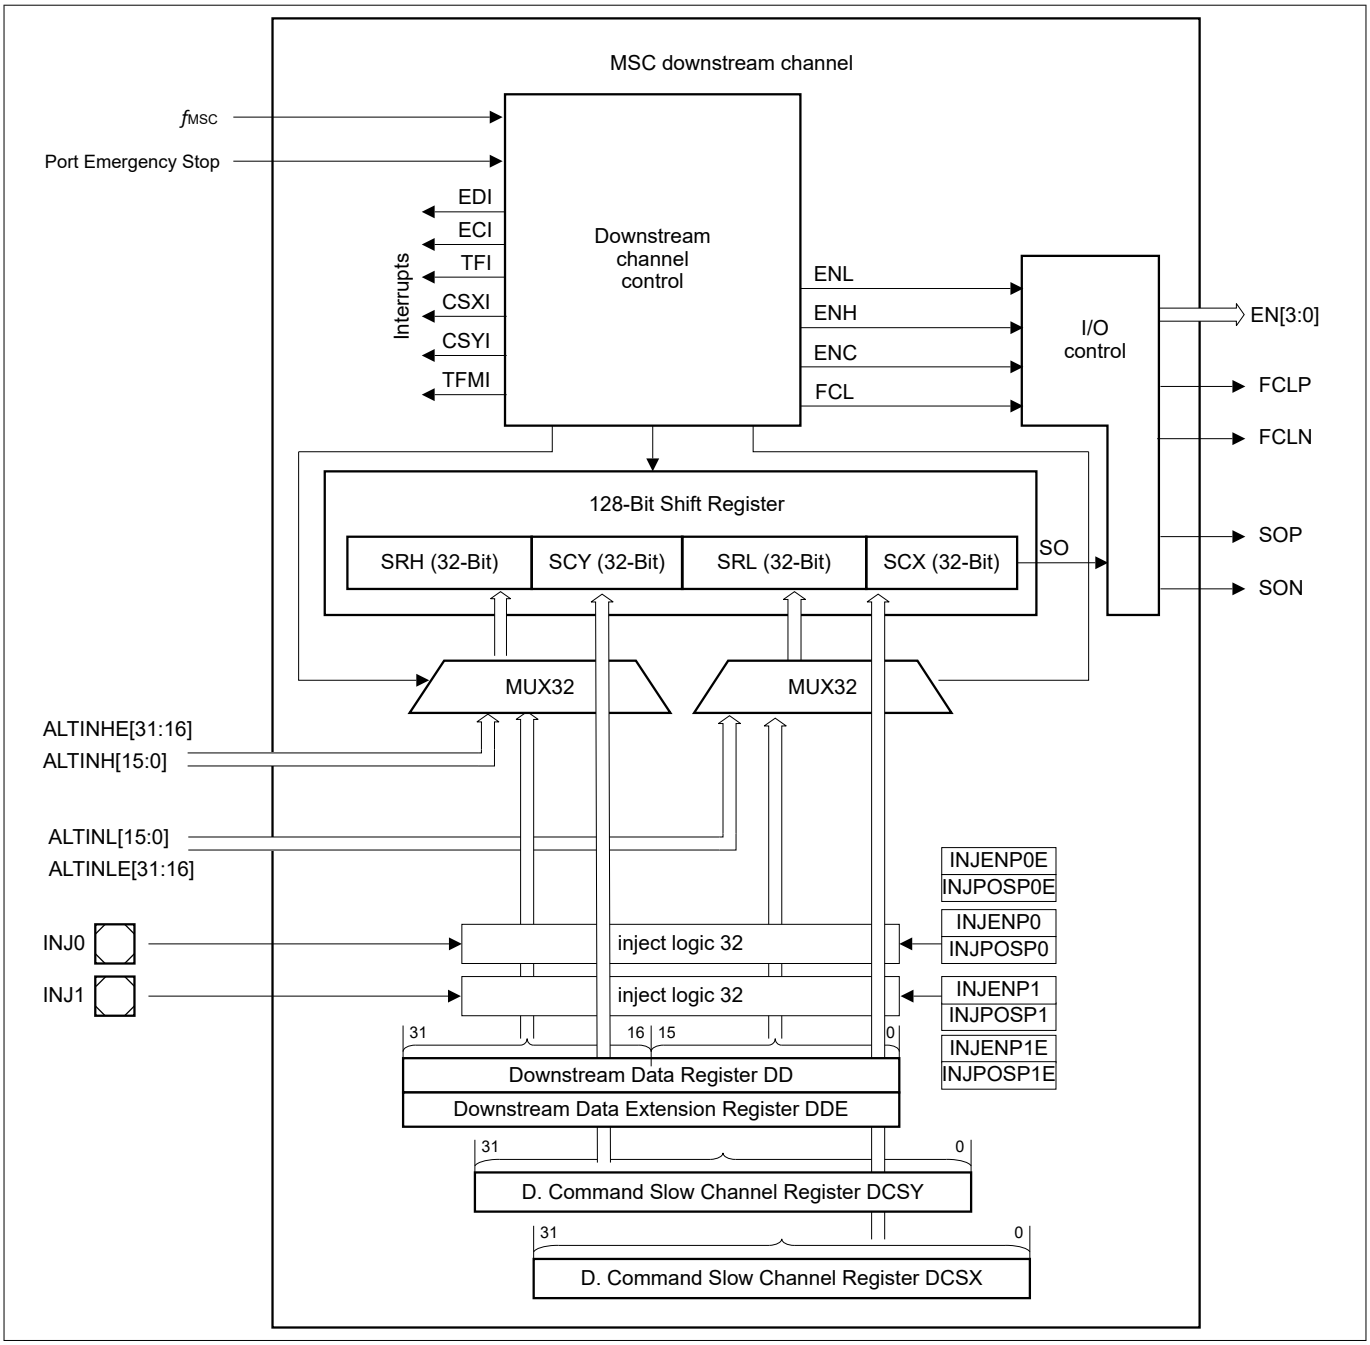

Figure 570 Downstream channel block diagram

***Note**: Refer to the block diagram in the Downstream channel with slow channel feature chapter when operating with slow channel.*

The enable signals ENL, ENH and ENC indicate certain phases of the serial transmission in relation to the serial clock FCL. In the I/O control logic, these signals can be combined to four enable/select outputs EN[3:0]. For supporting differential output drivers, the serial clock output FCL and the serial data output SO are available in both polarities, indicated by the signal name suffix “P” and “N”.

The Port Emergency Stop input is used to indicate an emergency stop condition of a power switch device. In an emergency case, shift register bits can be loaded bit-wise from the downstream data register instead from the ALTINL, ALTINH, ALTINLE and ALTINHE buses.

Downstream channel with slow channel feature on page 5110

28.3.1.1.1 Frame formats and definitions

This section describes the frame formats and definitions of the MSC.

Basic definitions

A downstream frame is composed of:

- An active phase
  - During the active phase data transmission takes place
- A passive phase
  - During the passive phase no data is transmitted at SO

The active phase is split into two parts:

- The SRL active phase in which the content of the shift register low part SRL is transmitted
- The SRH active phase in which the content of the shift register high part SRH is transmitted

At the beginning of the SRL and SRH active phase, a Selection bit (SELL) can be optionally inserted into the serial data stream. In the frame shown in the figure below, SELL is generated at the beginning of the SRL active phase (not for the SRH active phase). The least significant bits of SRL and SRH are sent out first.

The figure below shows the layout and definitions of a downstream frame.

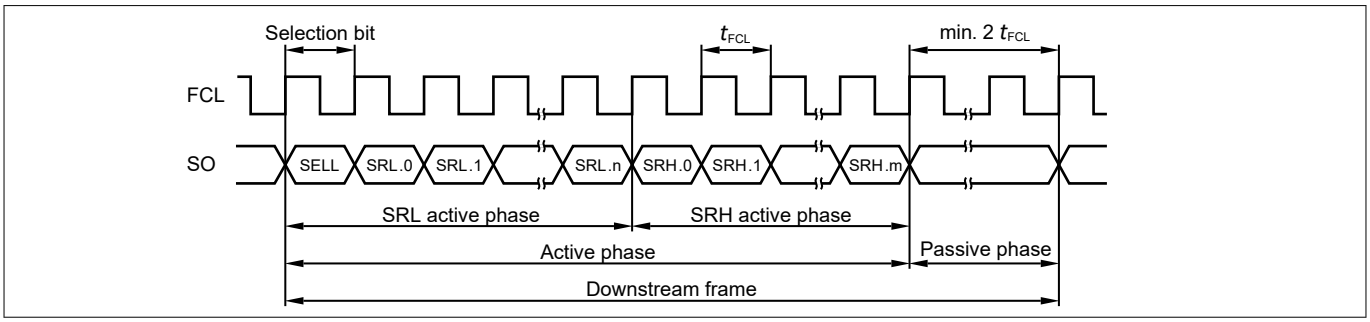

Figure 571 Downstream channel frame

The MSC downstream channel uses three types of frame formats for operation:

- Command frames, indicated by SELL = 1
- Data frames, indicated by SELL = 0 or SELL bit insertion disabled
- Passive time frame, indicated by ENL=ENH = 0

Command frames

A command frame has two active phase parts:

- SRL active phase
- SRH active phase

The command frame always starts with a High-level Selection bit, independently of whether the Selection bit insertion (as defined by bit DSC.ENSELL) is enabled or not. The number of bits transmitted during SRL and SRH active phases (except the Selection bit) is defined by bit-field DSC.NBC. SRL and SRH bits combined length can be selected from 0 upto 32 bits. SRH bits transmission starts only after SRL bits transmission is completed. In Command Extension mode, activated with the DSTE.CX bit, the commands can be up to 64-bit long (see CX (command extension) mode section).

During the active phase of a command frame the enable output signal ENC becomes active. The enable output signals ENL and ENH remain inactive.

The passive phase of a command frame always has a fixed length of $2 \times t_{FCL}$. The diagram shown in the figure below assumes that the FCL clock is only generated during the active phase of the command frame (OCR.CLKCTRL=0).

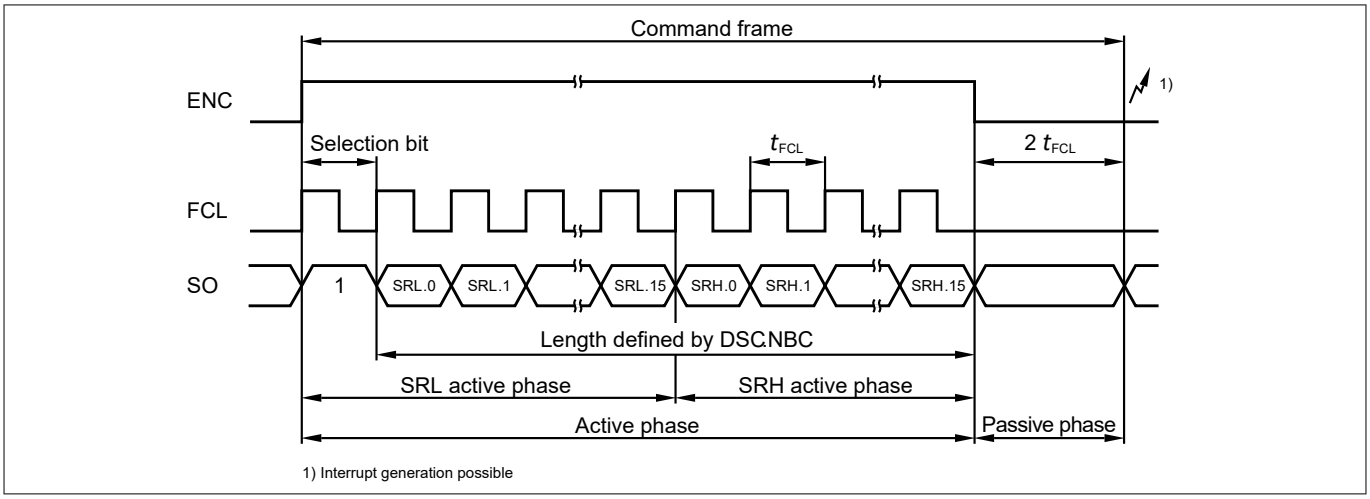

Figure 572 Command frame layout

The following table shows the programming of the bits to be transmitted and the resulting length of the complete command frame.

Table 1206 Command frame length

DSC.NBC	SRL/SRH bits transmitted in active phase	Command frame length in t_{FCL} periods
000000_B	No bit shifted out	1+0+2=3
000001_B	SRL[0] shifted out	1+1+2=4
000010_B	SRL[1:0] shifted out	1+2+2=5
000011_B	SRL[2:0] shifted out	1+3+2=6
…	…	…
001111_B	SRL[14:0] shifted out	1+15+2=18
010000_B	SRL[15:0] shifted out	1+16+2=19
010001_B	SRL[15:0] and SRH[0] shifted out	1+17+2=20
010010_B	SRL[15:0] and SRH[1:0] shifted out	1+18+2=21
010011_B	SRL[15:0] and SRH[2:0] shifted out	1+19+2=22
…	…	…
011111_B	SRL[15:0] and SRH[14:0] shifted out	1+31+2=34
100000_B	SRL[15:0] and SRH[15:0] shifted out	1+32+2=35
Other NBC combinations	Reserved; do not use these bit combinations	

Data frames

A data frame has two active phase parts:

- SRL active phase
- SRH active phase

The number of bits that are transmitted can be programmed separately for each of these two phases.

- Bit-field DSC.NDBL determines the number of SRL bits that are transmitted during the SRL active phase
- Bit-field DSC.NDBH determines the number of SRH bits that are transmitted during the SRH active phase

SRL and SRH active phases can start with a Low-level Selection bit when enabled by bits DSC.ENSELL or DSC.ENSELH.

During the SRL active phase of a data frame the enable output signal ENL becomes active and during the SRH active phase of a data frame, the enable output signal ENH becomes active. The enable output signal ENC remains inactive.

The length of the data frame's passive phase is variable and is defined by the bit-field DSC.PPD. It can be within a range of $2 \times t_{FCL}$ up to $31 \times t_{FCL}$. The diagram shown in the figure below assumes that the FCL clock is only generated during the active phase of the data frame (OCR.CLKCTRL=0).

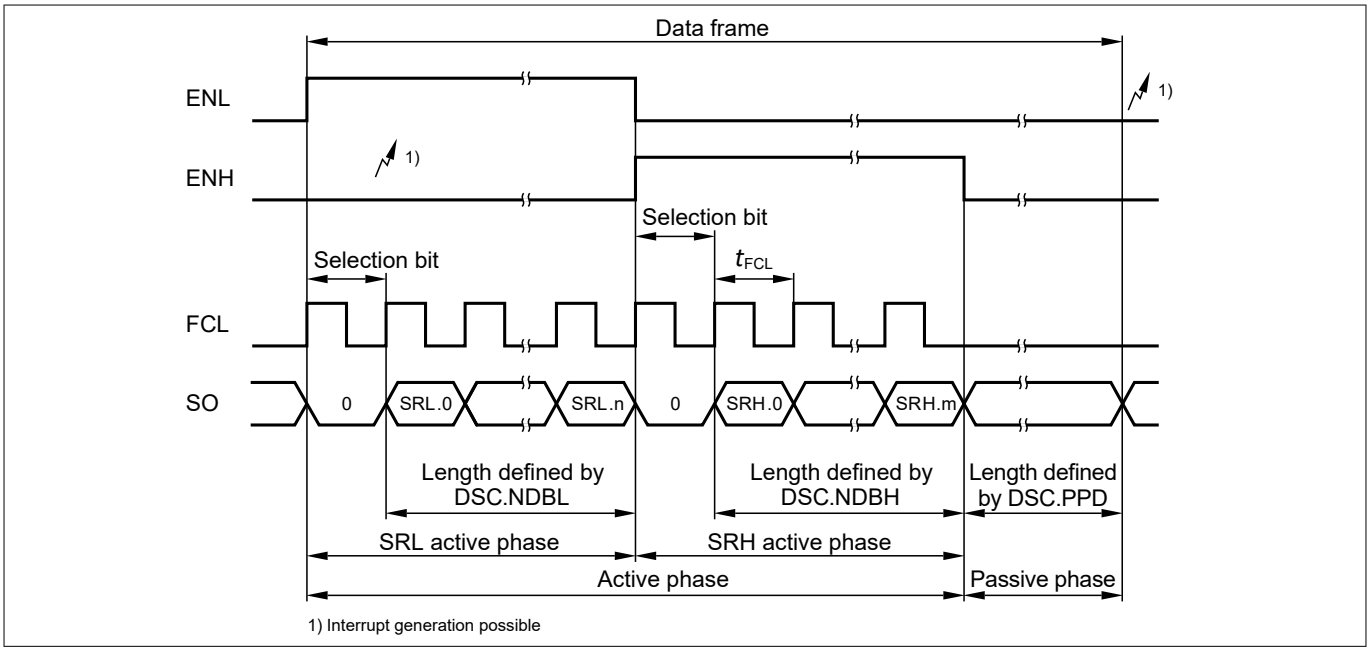

Figure 573 Data frame layout

The following tables show the definitions of the five data frame parameters that determine the layout of the data frame.

Table 1207 Data frame selection bit parameters

DSC.ENSELL	Selection bit	DSC.ENSELH	Selection bit
0	No Selection bit inserted at the beginning of the SRL active phase	0	No Selection bit inserted at the beginning of the SRH active phase
1	A Low-level Selection bit is inserted at the beginning of the SRL active phase	1	A Low-level selection bit is inserted at the beginning of the SRH active phase

***Note**: The MSC module can operate in two modes: Standard (up to 32 data bits) or Extended (up to 64 data bits). The mode is selected by using the bit-field DSCE.EXEN.*

Table 1208 Data frame SRL/SRH length parameters, Standard mode

Table 1210 Data frame passive phase length

DSC.PPD	Passive phase length
00000_B	$2 \times t_{FCL}$
00001_B	$2 \times t_{FCL}$
00010_B	$2 \times t_{FCL}$
00011_B	$3 \times t_{FCL}$
…	…
11110_B	$30 \times t_{FCL}$
11111_B	$31 \times t_{FCL}$

The following formula determines the number of t_{FCL} cycles of data frame up to 32-bit in size (all parameters, bits and bit-fields, are located in register DSC):

$$N_{CYCLES} = \text{ENSELL} + \text{NDBL} + \text{ENSELH} + \text{NDBH} + \text{PPD} \quad (29)$$

***Note**: In the formula above, PPD must be set to 2 when DSC.PPD ≤ 00010_B.*

The following formula determines the number of t_{FCL} cycles of an extended, up to 64-bit data frame, in case DSC.NDBL and DSC.NDBH are not equal to zero:

$$N_{CYCLES}=ENSELL + NDBL + NDBLE \times EXEN \times 16 + ENSELH + NDBH + NDBHE \times EXEN \times 16 + PPD + PPDE \times EXEN \times 32 \quad (30)$$

Otherwise, the corresponding factor $NDBLE \times EXEN \times 16$ or $NDBHE \times EXEN \times 16$ must be taken as zero.

***Note**: In the formula above, PPD must be set to 2 when DSC.PPD ≤ 00010_B.*

The parameters (bits and bit-fields) are located in the registers DSC and DSCE.

Attention**: **In order to calculate the time between two consecutive TRPs (time reference points), always use ENSELL=1 in the formulas above. ENSELL does not influence the time between two consecutive TRPs, but only the length of a data frame. The difference in the starting point of a frame with ENSELL=0 and 1 is shown in related information.

***Note**: Refer to the Slow channel or Manchester code transmission mode sections when operating in these modes. The equation to calculate the time reference point differs from the one operating in legacy mode.*

Passive time frames

A passive time frame has the length defined by the five data frame parameters according to the equations above. They are generated only in Data Repetition mode. Under special conditions (command frame insertion), passive time frames can be shortened.

During passive time frames, the data output SO has to be considered as invalid at the receiving device and the clock output FCL may toggle or not (as selected by bit OCR.CLKCTRL). The ENL and ENH enable signals remain at low level during a passive time frame.

***Note**: A passive time frame and a passive phase are different from each other. A passive phase is part of a downstream frame whereas a passive time frame(PTF) is a type of frame which is transmitted after the transmission of downstream frame is finished.*

28.3.1.1.2 Transmission modes

The downstream channel of the MSC makes it possible to select between two transmission modes:

- Triggered mode, selected by DSC.TM=0 or
- Data Repetition mode, selected by DSC.TM=1

  ***Note**: The behavior is undefined when the configuration is changed in between an ongoing transaction*

Triggered mode

In Triggered mode, command frames or data frames are sent out as a result of a software event. When a frame transmission has been finished and no further frame transmission has been requested, the downstream channel returns to idle state and waits for the next frame transmission to be triggered by software.

When the Downstream Command Register DC is written, the command pending bit DSC.CP becomes set and a command frame will be immediately started and sent out if the downstream channel is idle. If a data or

command frame is currently processed and output, the command frame transmission is delayed and started when the active downstream frame has been finished. The command pending bit DSC.CP will be cleared by hardware.

If the downstream channel is idle and the data pending bit DSC.DP is set by writing bit ISC.SDP with 1, a data frame will be immediately started and sent out if the downstream channel is idle. If a data frame or a command frame is currently processed and output, the data frame transmission is delayed and started when the active downstream frame has been finished. The data pending bit DSC.DP will be cleared by hardware.

If the MSC configuration is set for command frame prioritization over data frame (DSCE.DFP = 0) then both frame pending bits are set (DSC.DP=DSC.CP=1), the command frame will always be sent first. Therefore, a pending data frame transmission will be delayed as long as no further command frame transmission is running or requested.

The following figure is a flow diagram of the Triggered mode. This diagram especially shows the behavior of the data and command pending bits DSC.DP and DSC.CP. If both frame pending bits are set (DSC.DP=DSC.CP=1), the command frame will always (if DSCE.DFP = 0) be sent first, followed by the data frame (assuming no further command frame has been requested).

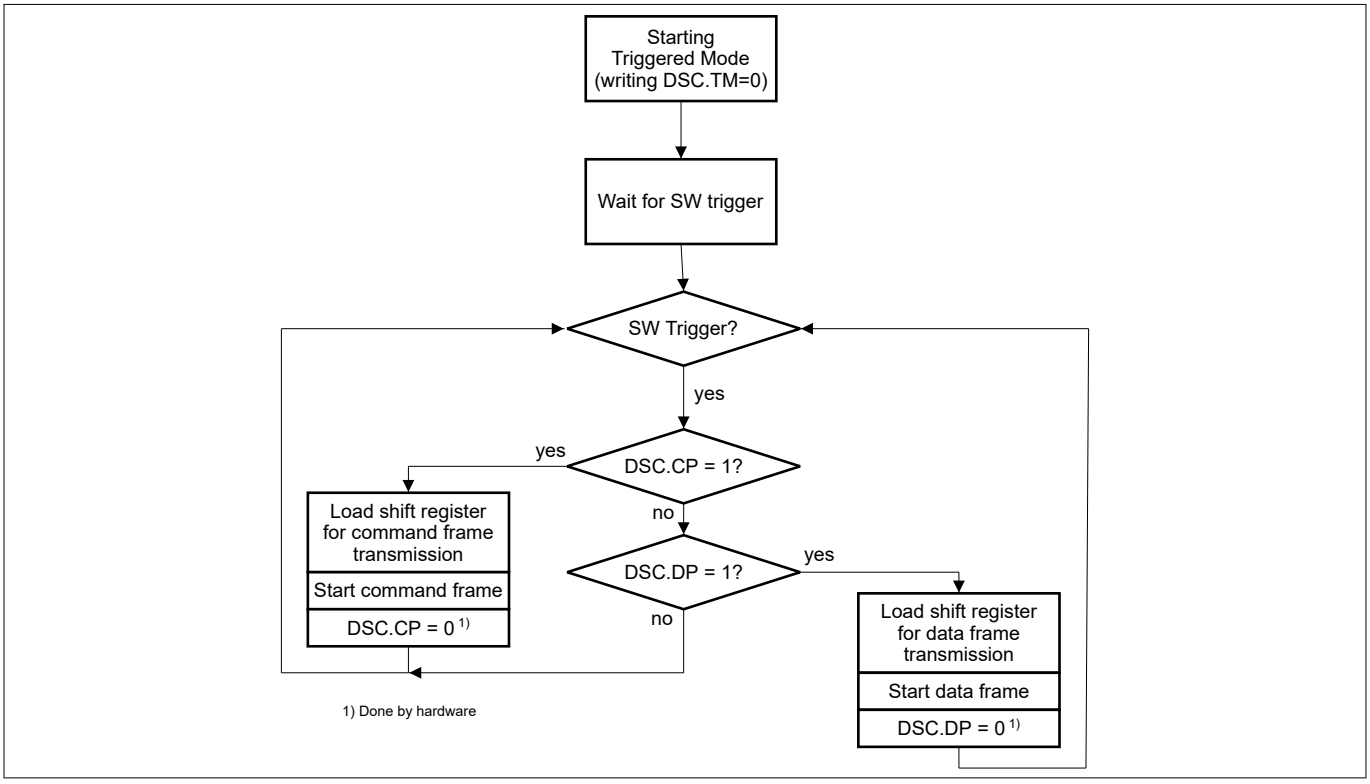

Figure 574 Triggered mode flow diagram

The type of the active frame that is currently processed and output is indicated by two status flags: DSS.DFA is set during a data frame transmission and DSS.CFA is set during a command frame transmission. Further, the downstream counter DSS.DC indicates the number of shift clock periods that have been elapsed since the start of the current frame.

In Triggered mode, the shift register loading event, as described in the SRL and SRH shift register loading chapter, occurs just before a command or data frame transmission is started.

Data repetition mode

Setting the DSC.TM bit selects Data Repetition mode. In Data Repetition mode, data frames are sent out continuously without any software interaction. In the time gap between two consecutive data frames, passive time frames can be inserted. The number of passive time frames to be inserted (0 to 15) is defined by bit-field DSS.NPTF. The duration of data frame (t_{DF}) and passive time frames (t_{PTF}) is determined by the data frame parameters as described in the previous chapter. These parameters determine the time reference points (TRP)

at which a data, command or passive time frame is started (see diagram A in the following figure and the Attention note in the Frame formats and definitions chapter).

The automatic data frame generation is controlled by the data pending bit DSC.DP. This bit is set at the end of the last passive time frame if a command frame is running or starts at this TRP, overruling a data frame. DSC.DP is cleared by hardware when the pending data frame starts with transmission at the next TRP. Data frames are always aligned to time reference points. This means they always start at a TRP. Passive time frames can be shortened. This is especially the case when command frames are inserted.

Continuous data frame transmission can be interrupted by insertion of command frames. Command frames are initiated by software. When the downstream command register DC is written, the command pending bit DSC.CP is set by hardware. CP=1 indicates that the MSC starts a command frame at the next TRP, independently of whether a data frame (indicated by DSC.DP=1) or passive time frame should be started with the next TRP. This means also that command frames are always aligned to time reference points.

The bit-field DSCE.CDCM provides an option for automatic insertion of data frame between two consecutive command frames.

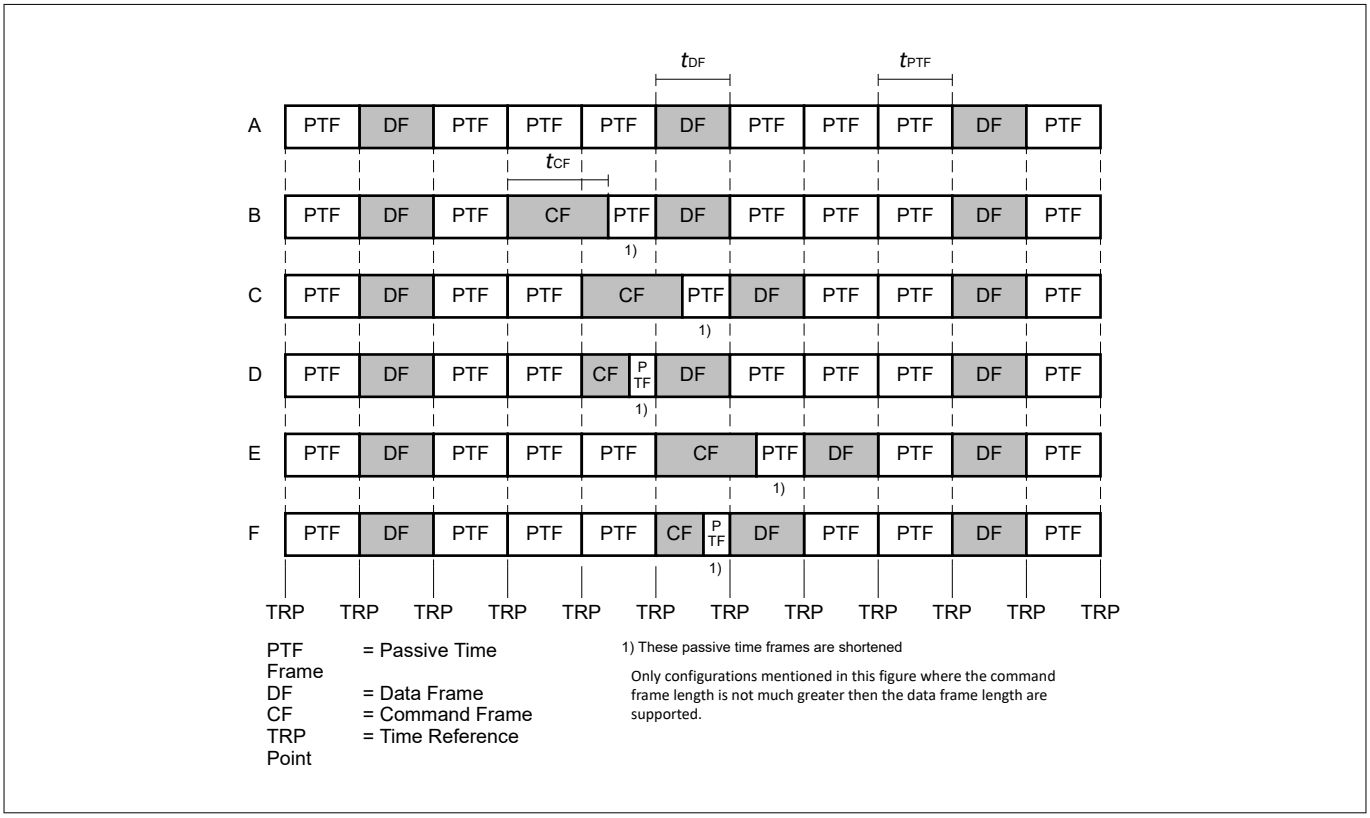

Figure 575 Data repetition mode frame examples with DSS.NPTF=0011$_B$

Diagrams B to F in the figure above show the command frame insertion in Data Repetition mode.

In diagram B, a command frame has been requested during the first passive time frame after the data frame and is inserted at the next TRP. In diagrams C and D, a command frame has been requested during the second passive time frame and is inserted at the time reference point of the last nominal passive time frame.

When the command frame and data frame is not of the same length (this is the case in diagram B to F), a shortened passive time frame is inserted until the next TRP is reached. This ensures that the next data or normal passive time frame is again aligned to a TRP.

When the last passive frame is transmitted and in case of a conflict with command frame, DSC.DP becomes set by hardware. This triggers the start of a data frame when the next TRP is reached.

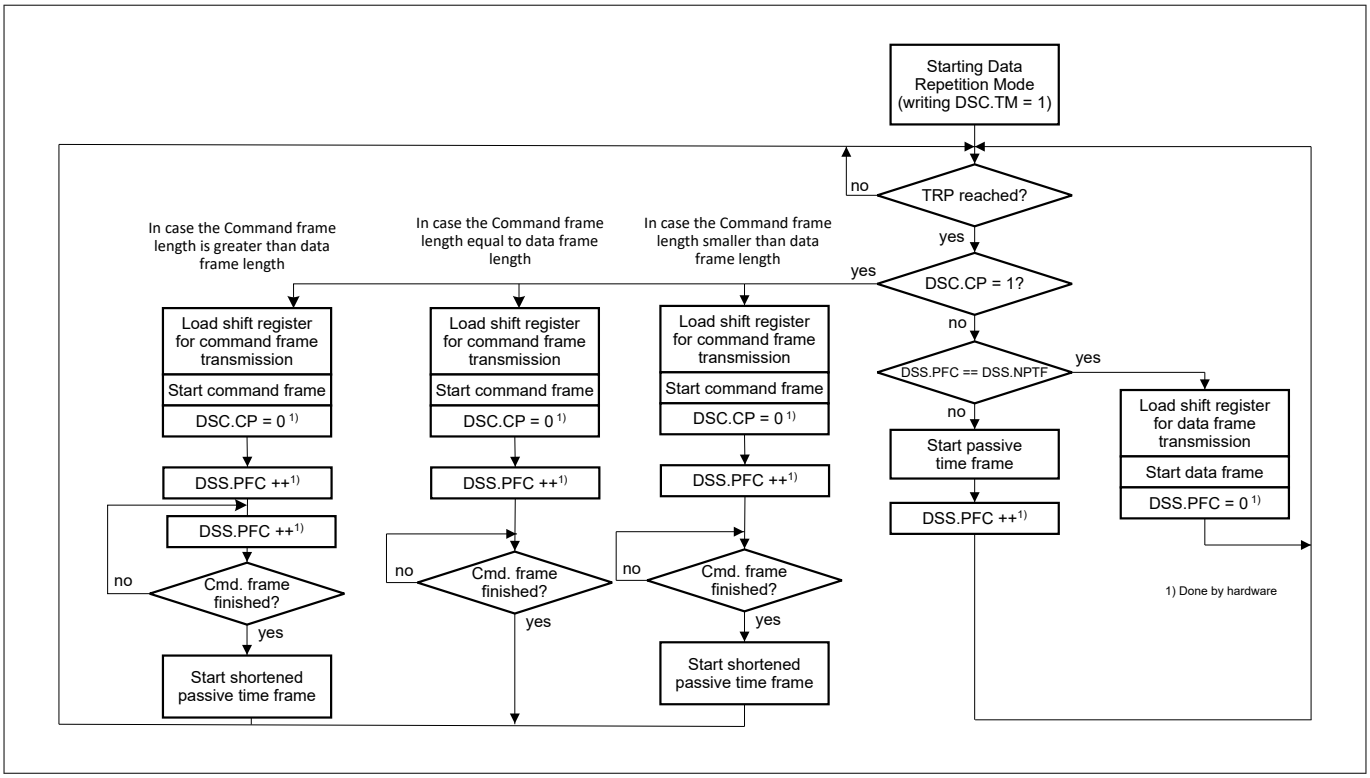

Figure 576 Data repetition mode flow diagram

The type of the active frame (data or command frame) that is currently processed and output is indicated by two status flags: DSS.DFA is set during a data frame transmission and DSS.CFA is set during a command frame transmission. Further, the downstream counter DSS.DC indicates the number of shift clock periods that have been elapsed since the start of the current data, command or passive time frame.

As in Triggered mode, the shift register loading event as described in related information occurs in Data Repetition mode just before a TRP, this means shortly before a command or data frame transmission is started.

Data frame prioritization over command frame

The bit-field DSCE.DFP provides an option to prioritize the data frame over the command frame.

This change is illustrated in diagram C, E and F by enabling this feature in bit field DSCE.DFP.

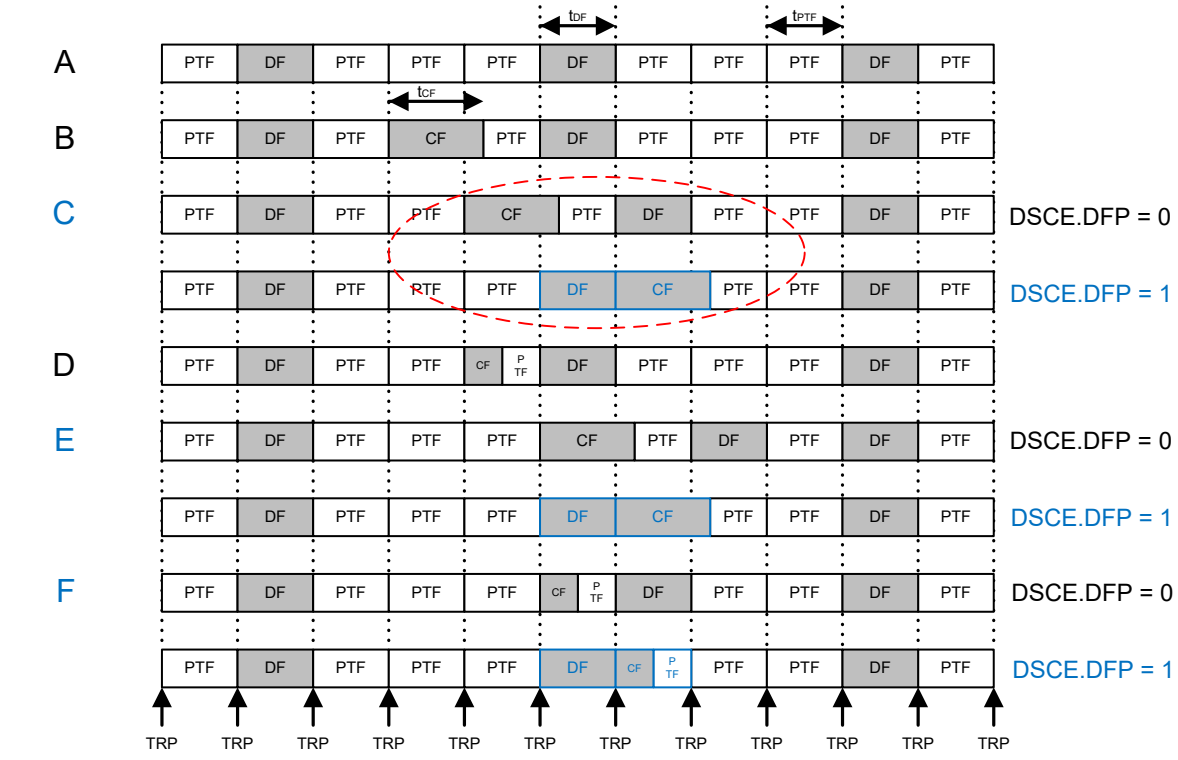

Figure 577 Data frame prioritization over command frame

If there is a request to send a command frame at a TRP where a data frame should be sent and DSCE.DFP is enabled, the data frame is prioritized over the command frame. This means the transmission of the command frame is delayed until the next TRP and the data frame is sent. This allows to guarantee equidistant data frames.

This feature, data frame prioritization over command frame can be used in both transmission modes: Triggered mode and Data Repetition mode.

The MSC does not provide protection against misconfiguration, when a command frame is longer than the longest passive time frame (PTF).

The following figure is a flow diagram of the Triggered mode when the data frame prioritization over command frame is active.

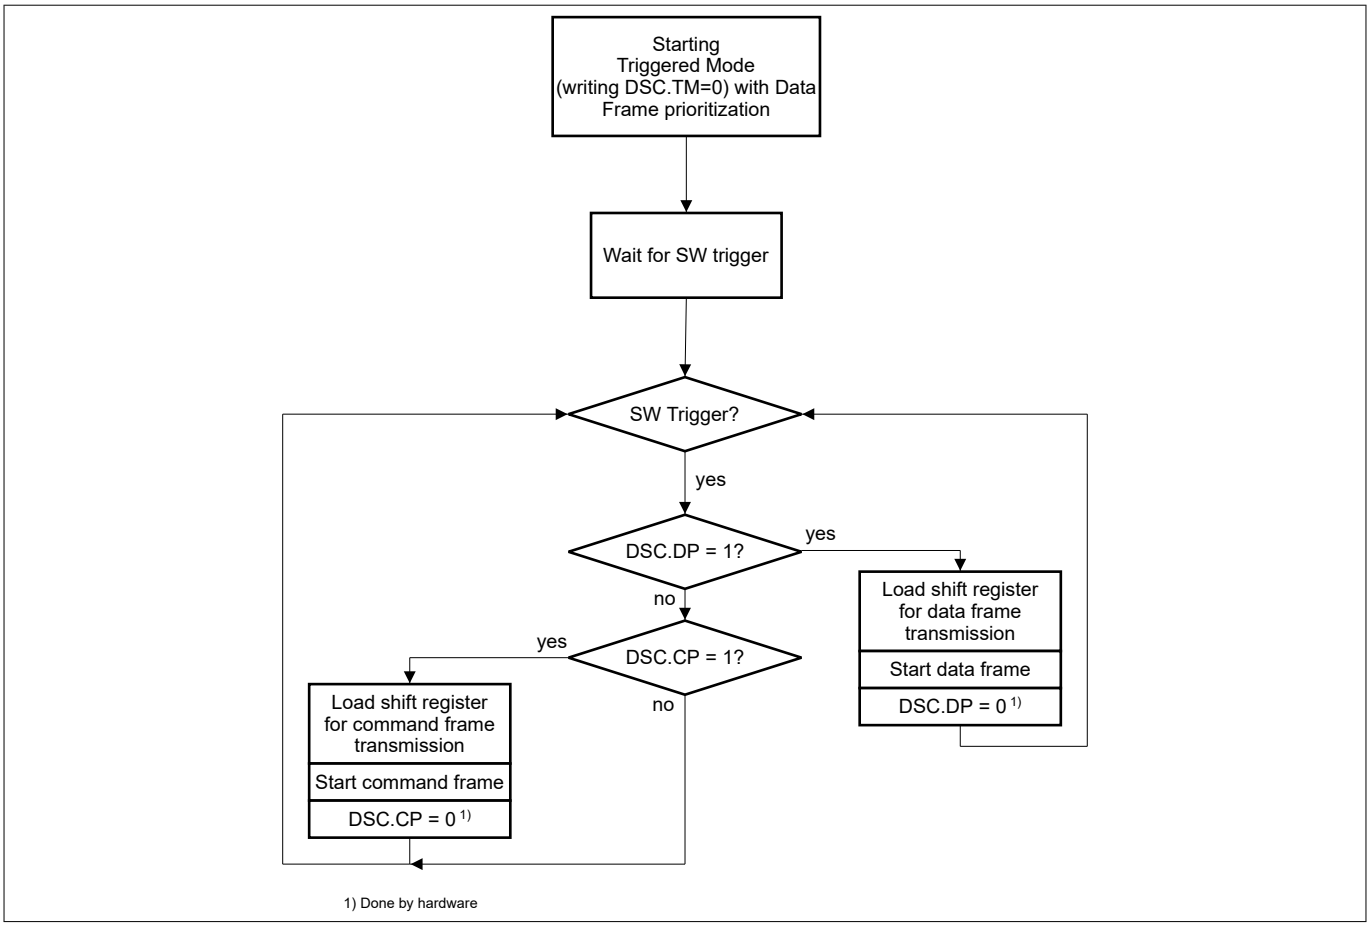

Figure 578 Triggered mode flow diagram with data frame prioritization

The following figure is a flow diagram of the Data Repetition mode when the data frame prioritization over command frame is active.

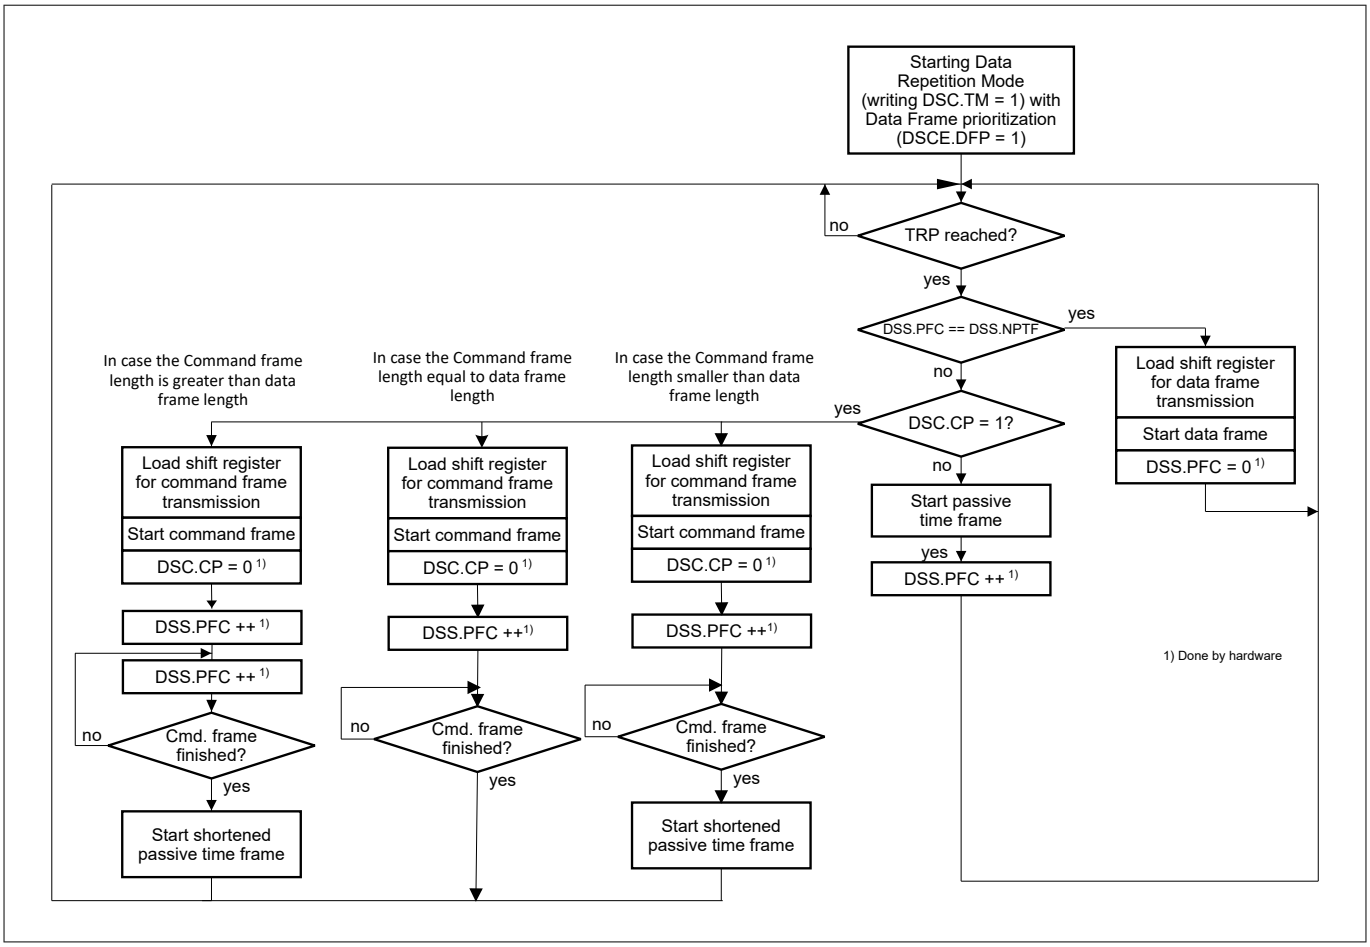

Figure 579 Data repetition mode flow diagram with data frame prioritization

Passive frame counter in data repetition mode

In Data Repetition mode, a passive time frame counter DSS.PFC indicates how many time frames have been already transmitted after the last regular data frame occurrence. The passive time frame counter counts up from 0000_B to the value which has been written into bit field DSS.NPTF (number of passive time frames). DSS.PFC=0000_B indicates that a data frame is requested for transmission.

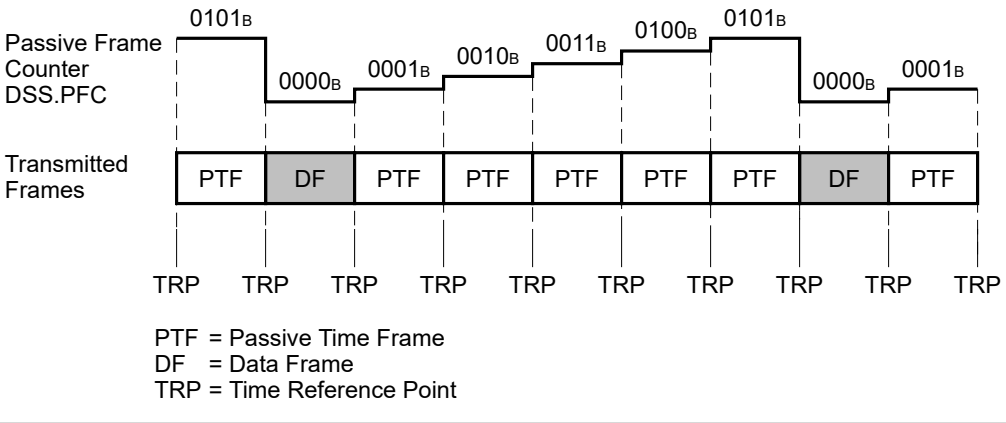

Figure 580 Passive frame counter operation (with DSS.NPTF=0101_B)

SRL and SRH shift register loading on page 5093

Frame formats and definitions on page 5082

28.3.1.1.3 SRL and SRH shift register loading

During the SRL and SRH shift register load operation at the beginning of each downstream frame transmission, several parameters determine which information is loaded into the bits of the shift register.

SRL shift register loading

The following figure shows the logic that is implemented for the SRL shift register loading operation. The logic for the SRH shift register loading operation is equivalent to the one for the SRL register. Its differences in data sources and register controls are described below.

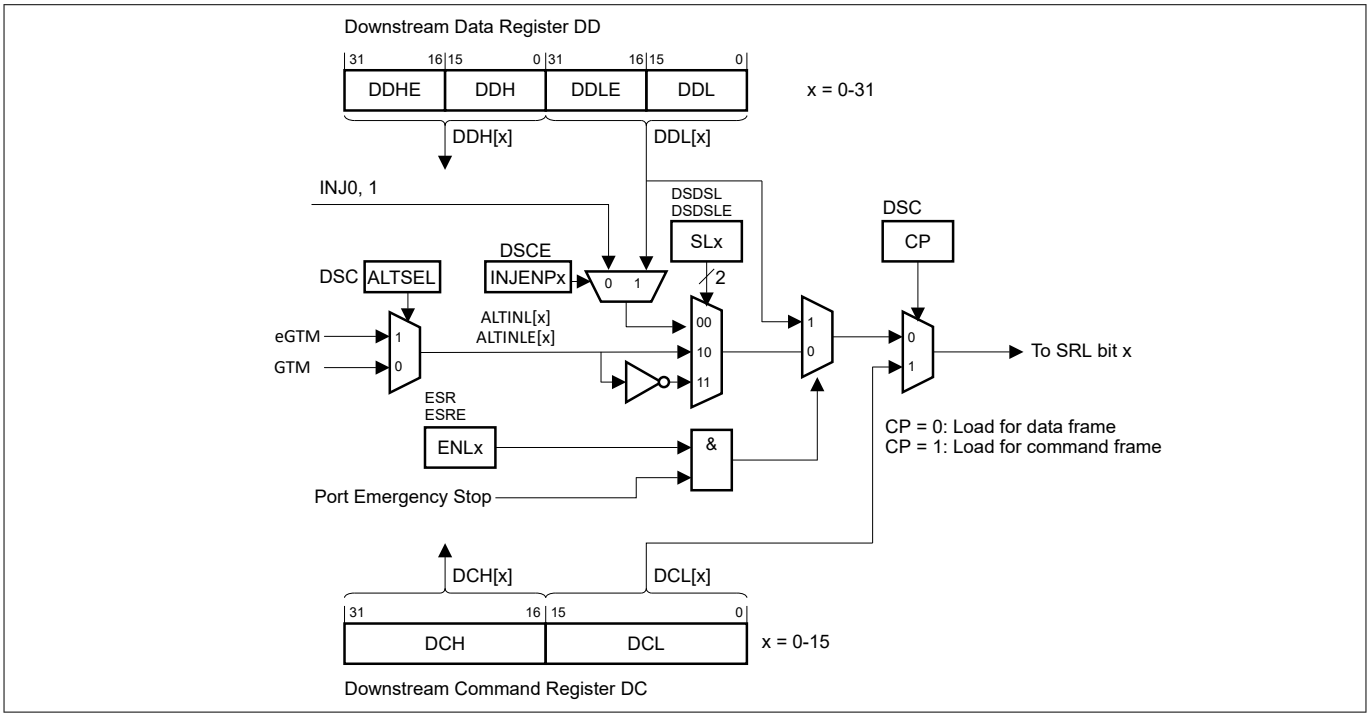

Figure 581 SRL shift register data loading control

Four data sources can be selected for each SRL bit by using several control bits and one control signal:

- ALTINL, ALTINLE input line (non-inverted)
- ALTINL, ALTINLE input line (inverted)
- Bit of DD.DDL, DDLE (Downstream Data Register)
- Bit of DC.DCL (Downstream Control Register)

GTM or eGTM can be selected (DSC.ALTSEL) as data source for ALTINL and ALTINLE.

When SRL is loaded for data frame transmission (DSC.CP=0), bit-fields DSDSL.SLx determine bit-wise which data is loaded into SRL bit x. The data source selection as controlled by DSDSL.SLx, will only be effective when Port Emergency Stop is inactive (at low level). When Port Emergency Stop=1 (active) during the load operation, all SRL[x] bits that are enabled for the emergency stop feature (bit ESR.ENLx=1) are loaded directly with the corresponding bit DDL[x] of the Downstream Data Register DD.

When SRL is loaded for command frame transmission (DSC.CP=1), always the lower 16-bit part DCL of the downstream control register is loaded completely into SRL.

The following table summarizes all SRL data source selection capabilities $(x = 0 - 31)$:

- In Standard mode, DSCE.EXEN = 0, the selection configuration of up to 16 bits $(x = 0 - 15)$ is taken into account
- In Extended mode, DSCE.EXEN = 1, the selection configuration of up to 32 bits $(x = 0 - 31)$ is taken into account

Table 1211 SRL data source selection capabilities

DSC. CP	DSDSL.SLx DSDSLE.SLx	ESR. ENLx	Port emergency stop	Selection
0	00_B	0	–	Bit DD.DDL[x] is loaded into SRL[x]
	01_B			Reserved
	10_B			State of ALTINL[x] input is loaded into SRL[x]
	11_B			Inverted state of ALTINL[x] input is loaded into SRL[x]
	XX_B	1	1	Bit DD.DDL[x] is loaded into SRL[x]
1	XX_B	X	X	Bit-fields DCL and DCH are completely loaded into SRL and SRH, respectively

***Note**: The data signals can be overruled by injected pin signals INJ0 and INJ1. See DSCE register.*

SRH shift register loading

The SRH operation is equivalent to the SRL shift register load operation, but the following differences must be taken into account for SRH shift register loading:

- Input lines ALTINH/ALTINHE are connected instead of ALTINL/ALTINLE input lines
- DSDSH register bits control data source selection instead of the DSDSL register
- Emergency stop is enabled by ESR.ENHx bits instead of ESR.ENLx bits
- Bits of the Downstream Data Register high part DDH are selected instead of DDL
- Downstream Control Register high part DCH is selected instead of DCL

28.3.1.1.4 External signal injection

Input signals from two pins can be independently injected at two data bit positions in a data frame. The injection takes place both in Normal and in Extended mode. The external signals are always injected at the defined position and if the data frame is shorter than this position, than these signals remain unused. For example, if DSCE.INJPOS0 defines injection at the position 14 of the SRL and the DSC.NBDL=12, then all the data bits from position 12 and up remain unused, including the injected signal.

In Normal mode the bits are counted from 0 to 31 from LSB to MSB and in Extended mode the bits are counted from 0 to 63 from LSB to MSB (see following figure). The injection position is always counted as if the frame has the maximum length. In the first step of the preparation for a transmission the injection takes place and then in the second step, if some fields are configured to be shorter or omitted (for example DDLE or DDH or any other), the unused bits are discarded and only the remaining valid bits are shifted out.

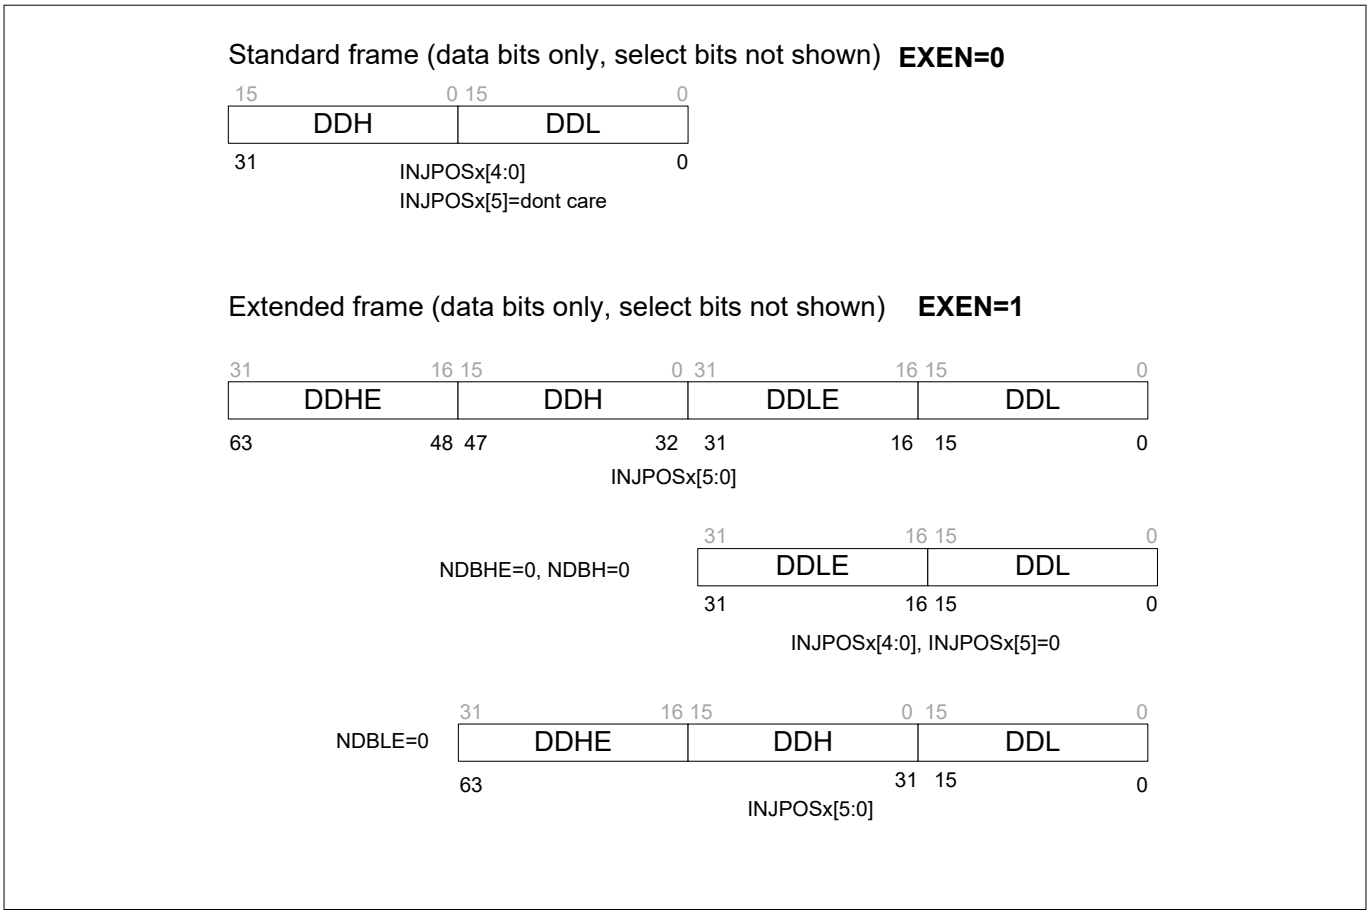

Figure 582 External signal injection

28.3.1.1.5 Downstream counter and enable signals

During downstream channel operation, a 8-bit downstream counter DSS.DC is counting FCL shift clock periods. With the loading of the shift register, the downstream counter is reset to 00_H and started for counting up to the end of the downstream frame (end of passive phase).

- Triggered mode
  - The downstream counter stops counting at the end of the passive phase and waits until a new downstream frame is started
- Data Repetition mode
  - The downstream counter does not stop at the end of the passive phase but is reset and starts counting up again with the next frame, independently of whether a data frame, command frame or passive time frame is started as the next frame

The following figure shows an example of downstream channel data frame transmission. In this example, the Selection bit for the SRL active frame is enabled (ENSELL=1) and the Selection bit for the SRH active frame is disabled (ENSELH=0). With loading of the shift register SRL/SRH, the downstream counter is reset and then starts counting up with each FCL clock until the end of the passive phase. ENL is set to high level at the beginning of the SRL active frame Selection bit.

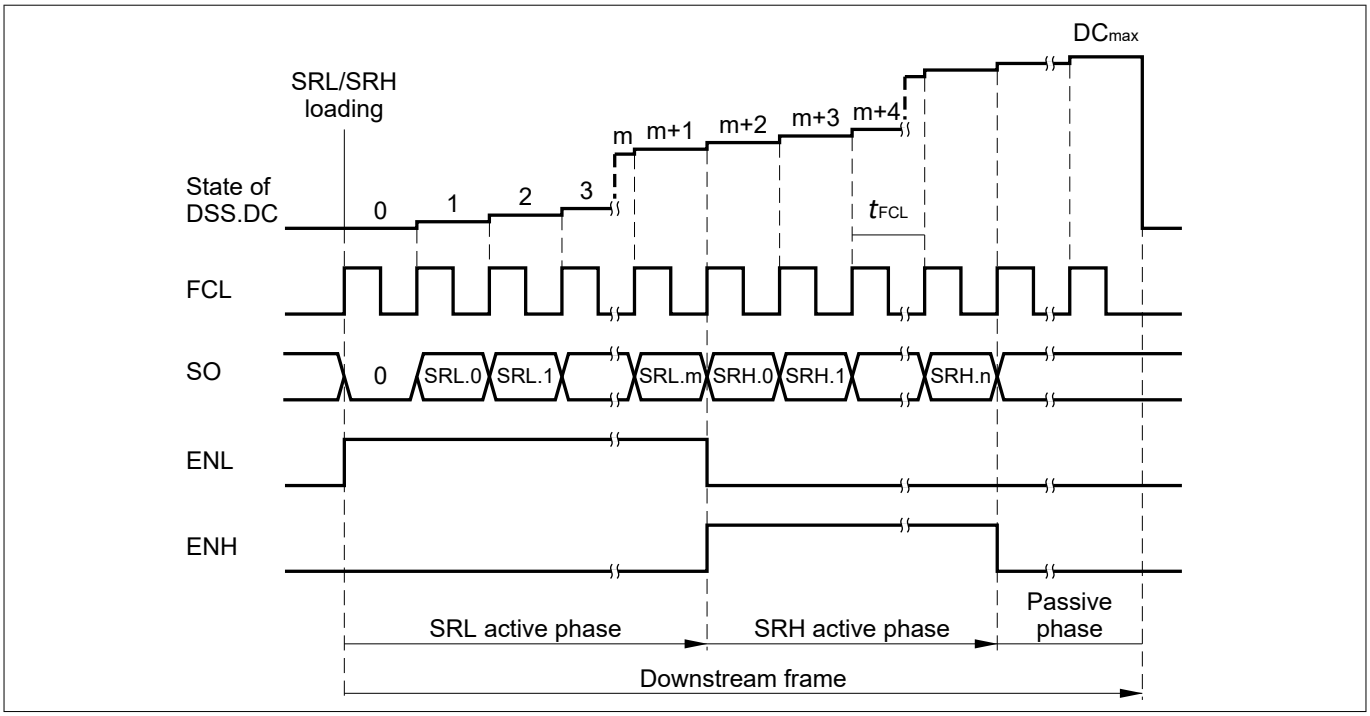

Figure 583 Shift clock counting: Data frame with ENSELL=1 and ENSELH=0

When the Selection bit for the SRL active frame is disabled (ENSELL=0, see following figure), the loading of the shift register SRL/SRH (and reset of the downstream counter) occurs one FCL clock cycle before the first data bit SRL.0 is output. ENL is set to high level with the beginning of the first data bit SRL.0.

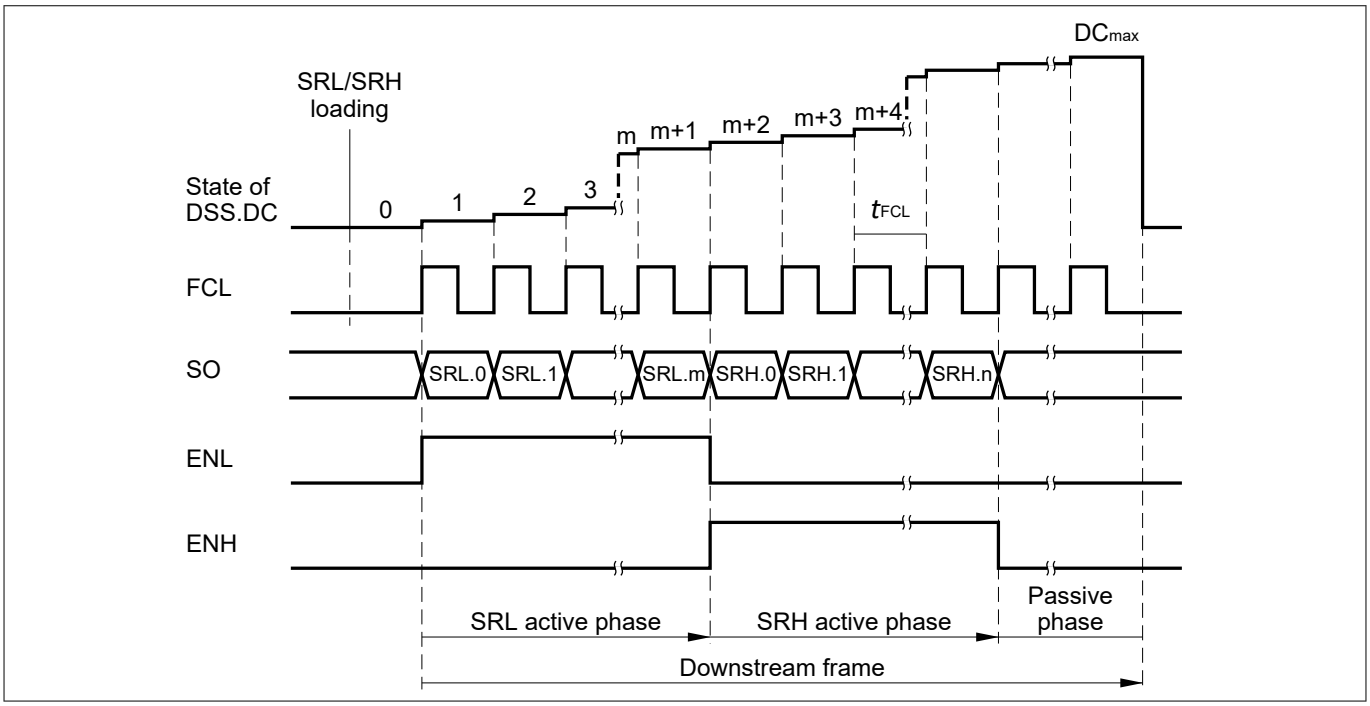

Figure 584 Shift clock counting: Data frame with ENSELL=0 and ENSELH=0

28.3.1.1.6 Downstream channel baud rate

The baud rate of the downstream channel's serial transmission is defined by the frequency of the serial clock output (FCL) and is always $\frac{f_{MSC}}{2}$.

The f_{MSC} generation is device specific and depends on the implementation of the MSC module.

Related information

Clock control on page 5132

28.3.1.1.7 Aborting frames

Only a reset condition of the device can abort a current transmission. The MSC module will not start a new frame transmission when:

- The downstream channel becomes disabled
- The Suspend mode is requested
- Sleep mode is entered

If one of these three conditions becomes active during a running frame transmission, the frame transmission is completely finished before the requested abort state is entered. Note that in this case no Time Frame Finished interrupt is generated.

***Note**: In case of a hard suspend, the abort state is entered immediately after being requested.*

28.3.1.2 Upstream channel

The MSC upstream channel is an asynchronous serial receiver based on the standard asynchronous data transfer protocol. It is dedicated to receive a serial data stream from a peripheral device through its serial data input SDI, using two specific data frame formats.

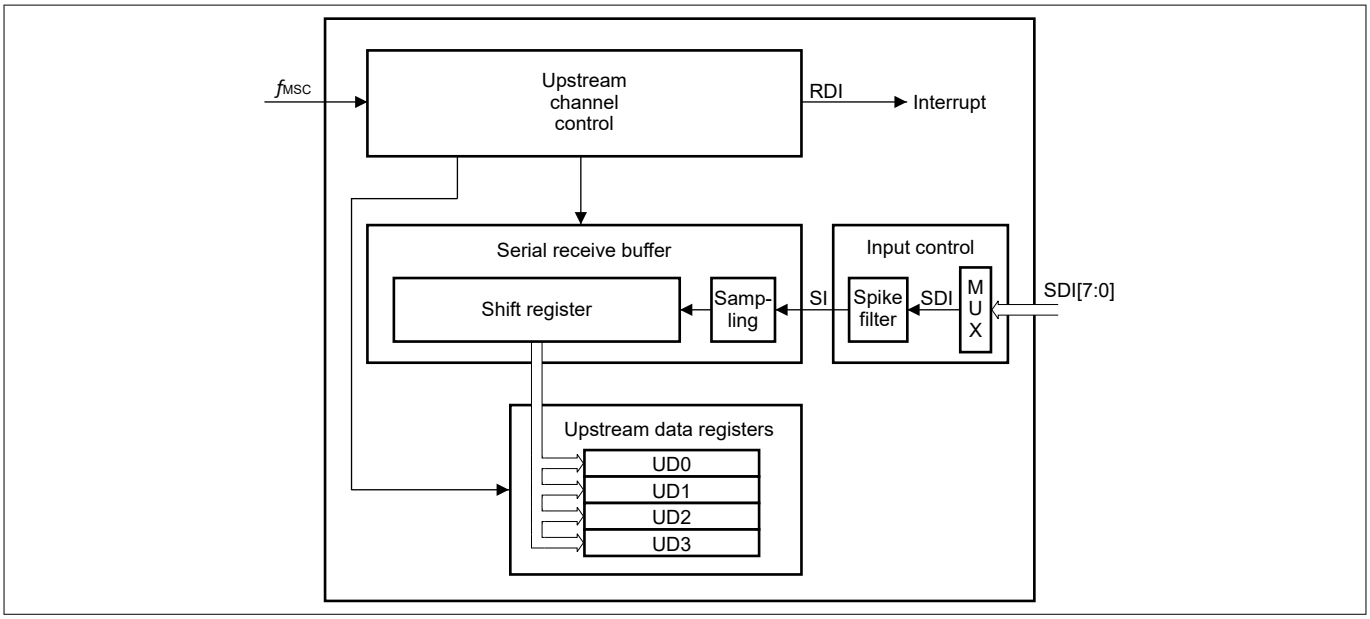

Figure 585 Upstream channel block diagram

The incoming data at SI is sampled after it has been filtered for spikes. The detected logic states of the serial input are clocked into a shift register.

After the complete reception of the serial data frame, the content of the shift register is transferred into one of the four data registers and an interrupt can be optionally generated.

The reception baud rate is directly coupled to the module clock f_{MSC} and can be within a range of $\frac{f_{MSC}}{4}$ down to $\frac{f_{MSC}}{256}$.

***Note**: If the ABRA block is used, a fractional divider with a fractional ratio generates the upstream sampling rate and in order to compensate the additional fractional divider jitter, the reception baud rate must be less than* $\frac{f_{MSC}}{10}$ *or* $\frac{f_{MSC}}{(8 \text{ to } 256)} \times \frac{n}{1024} < \frac{f_{MSC}}{10}$

28.3.1.2.1 Data frames

The asynchronous data frames used by the upstream channel include four basic parts:

1. One Start bit, always at low level
2. An optional 4-bit address field A[3:0] with LSB first
3. An 8-bit data field D[7:0] with LSB first
4. One Parity bit and two Stop bits that are always at high level

The receive interrupt is generated after the second Stop bit, but its generation can be delayed by one bit time by setting the bit-field USR.SRDC.

As shown in the following figure, the 16-bit upstream data frame includes an additional 4-bit address field. The upstream frame type is selected by bit-field USR.UFT.

- USR.UFT = 0:12-bit upstream data frame selected
- USR.UFT = 1:16-bit upstream data frame with 4-bit address field selected

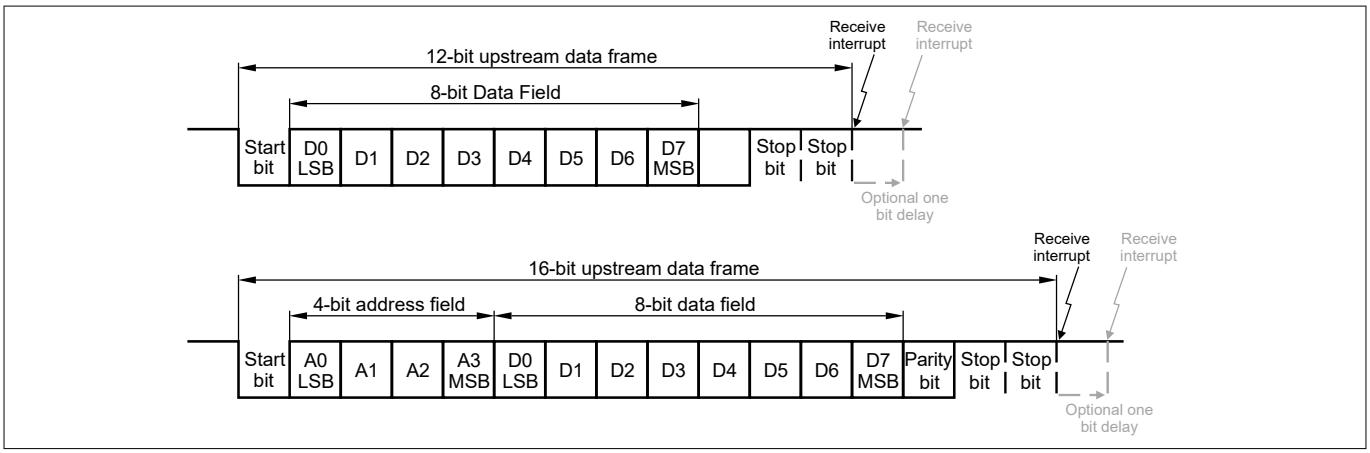

Figure 586 Upstream channel frame types

28.3.1.2.2 Parity checking

The incoming Parity bit of the data frames can be checked by the upstream channel. When a Parity error is detected, the Parity error flag PERR in the related Upstream Data Register UDx is set. Note that a setting of the Parity error flag PERR does not generate an interrupt. The PERR bits must be checked by software, data will be stored regardless of a detected Parity error. The UDx registers also store the Parity bit of the incoming data frame (UDx.P) and the Parity bit that is generated internally (UDx.IPF).

Bit USR.PCTR determines the Parity mode, even or odd, that is selected for parity checking.

- USR.PCTR = 0
  - Even Parity mode is selected. Even parity means that the Parity bit is set on an odd number of 1 s in the data field (12-bit upstream data frame) or in the address plus data field (16-bit upstream data frame)
- USR.PCTR = 1
  - Odd Parity mode is selected. In Odd Parity mode, the Parity bit is set on an even number of 1 s of the related data

The parity checking logic in the upstream channel also controls whether the Start bit and the two Stop bits of the upstream data frame are at the correct logic level. If the Start bit is not at a low level and the two Stop bits are not at a high level at the end of the frame reception, the Parity error flag UDx.PERR is set.

28.3.1.2.3 Data reception

The reception of the upstream frame is started with a falling edge (1-to-0 transition) on the SI line. When the Start bit is detected, serial reception is enabled and the receive circuit begins to sample the incoming serial data and to buffer it in the receive buffer.

After the second Stop bit has been detected, the content of the receive buffer is transferred to one of four upstream data registers UDx. The receive circuit then waits for the next Start bit (1-to-0 transition) at the SI line. When the content of the receive buffer has been transferred to UDx, the Valid bit UDx.V is set by hardware and a receive interrupt can be generated, independently of whether PERR occurred or not.

The data reception mechanism does not involve destructive read mechanisms. This means, reading the UDx registers does not change any bits automatically.

***Note**: The SI input line is the filtered non-inverted (OCR.ILP=0) or inverted (OCR.ILP=1) SDI input signal. The SI input signal selection is described in related information).*

Frame reception with address field

Frame reception for a 16-bit data frame is selected by USR.UFT=1. When the content of the receive buffer has been received completely, it is transferred to one of the four UDx registers. The two most significant address bits A[3:2] of the received 4-bit address field select the number x of register UDx in which the received frame content is stored.

Register UDx is loaded with:

- The two least significant address bits A0 and A1 (UDx.LABF)
- The 8-bit data (UDx.DATA)
- The received Parity bit (UDx.P)
- The calculated Parity bit (UDx.IPF)
- The parity checking result (UDx.PERR)

Finally, the Valid bit UDx.V is set to indicate that the UDx register contains valid data.

The current state of the frame reception is indicated by the content of an upstream counter that is readable through bit-field USR.UC. The upstream counter is a 5-bit counter that counts the upstream frame bits during reception. As shown in the following figure, the upstream counter is loaded with 10000_B at the detection of a Start bit. It counts down and is again at 00000_B when the second Stop bit has been detected and the frame reception is finished.

The state of the serial input data line SI is sampled in the middle of a bit cell and shifted into the receive buffer at the end of the bit cell. The frequency of the shift clock f_{BR} depends on the selected baud rate.

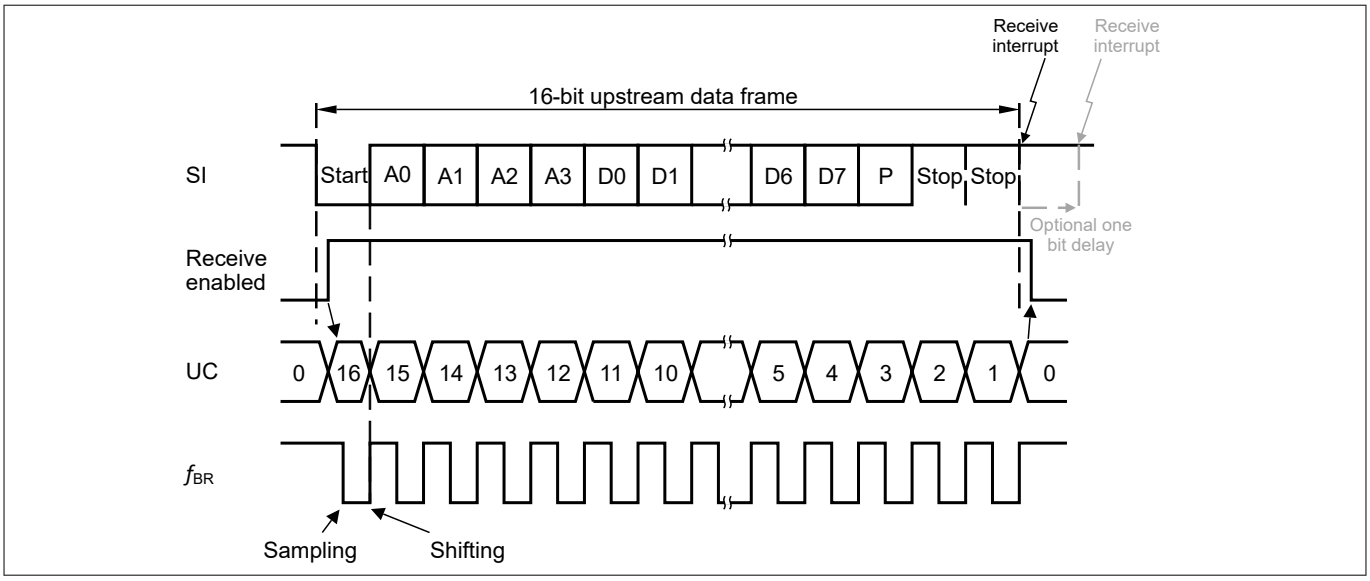

Figure 587 16-bit upstream reception

Data reception without address field

Frame reception for a 12-bit data frame is selected by USR.UFT=0.

The reception scheme is comparable with that of the 16-bit data frame reception but there are a few differences:

- The upstream counter is initially loaded with 01100_B
- The received frame content is always stored in register UD0
- Bit-field UD0.LABF is always loaded with 00_B when the frame is stored

Related information

Upstream channel baud rate on page 5100

Upstream channel input control on page 5107

28.3.1.2.4 Upstream channel baud rate

The baud rate of the upstream channel is derived from the MSC module clock f_{MSC}.

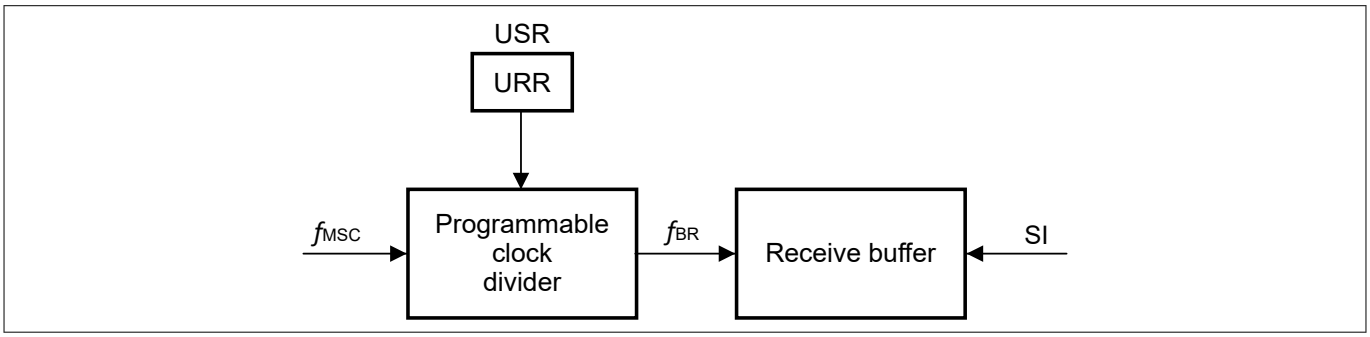

Figure 588 Upstream channel clock circuitry

The serial data input SI is evaluated with the baud rate clock f_{BR} in the middle of each bit element and latched in case of a data bit.

The baud rate clock f_{BR} is derived from f_{MSC} by a programmable clock divider. The frequency of f_{BR} determines the width of a received bit element and therefore the baud rate for the received data.

The content of bit-field USR.URR selects the baud rate according to the table below. The resulting baud rate formula is:

$$\text{Baud rate}_{\text{MSC Upstream Channel}} = \frac{f_{\text{MSC}}}{\text{DF}} \tag{31}$$

Table 1212 Upstream channel divide factor (DF) selection and baud rate

USR.URR	Divide factor (DF)	Baud rate
000_B	Reception disabled	–
001_B	4	$\frac{f_{\text{MSC}}}{4}$
010_B	8	$\frac{f_{\text{MSC}}}{8}$
011_B	16	$\frac{f_{\text{MSC}}}{16}$
100_B	32	$\frac{f_{\text{MSC}}}{32}$
101_B	64	$\frac{f_{\text{MSC}}}{64}$
110_B	128	$\frac{f_{\text{MSC}}}{128}$
111_B	256	$\frac{f_{\text{MSC}}}{256}$

***Note**: When USR.URR=000_B the upstream channel is disabled and data reception is not possible.*

The content of bit-field USR.URR determines the operation of an internal sampling reload counter that is clocked with f_{MSC}. The following figure shows the operation of the sampling counter at the beginning of an upstream frame with a divide factor DF of 8 (USR.URR=010_B is equal to DF=8) which means eight sampling clocks per each frame bit cell.

When the upstream channel is in idle state, it waits for a falling edge (1-to-0 transition) at SI. Therefore the sample counter starts counting up and is reset when the selected divide factor DF as shown in the table above is reached. In the middle of the sampling counter's count range, the logic state at SI is evaluated and, in case of a data bit, latched in the receive buffer's shift register. With the reload of the sampling counter, the shift register is shifted by one bit position.

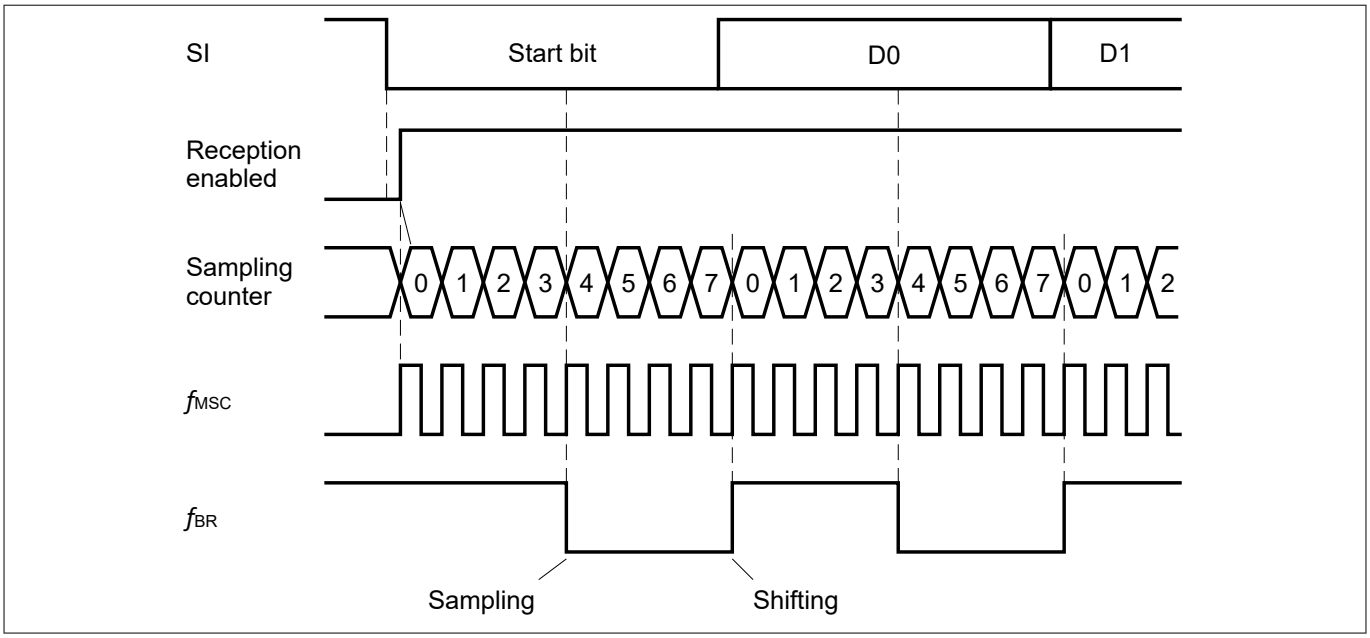

Figure 589 Upstream channel sampling with URR=010$_B$

28.3.1.2.5 Spike filter

The upstream channel input line SDI is sampled using a built-in spike filter with synchronization stage, both clocked with f_{MSC}. The spike filter is a chain of flip-flops with a majority decision logic (2 out of 3). A sampled value that is found at least twice in three samples is taken as data input value for SI.

28.3.1.2.6 Upstream timer

The upstream timer monitors the time interval between two subsequent upstream frames. The timer reloads its starting values from the register USCE and starts counting downwards. If the time interval between two frames is longer than allowed, the counter reaches the value of zero, raises an upstream timer interrupt and stops counting.

The counter reloads and starts counting on four events:

- Enabling of the MSC module after reset through CLC.DISR
- A module reset
- Writing the bit-fields USCE.USTOPRE or USCE.USTOVAL by software
- Detecting the falling edge of the start bit of a frame

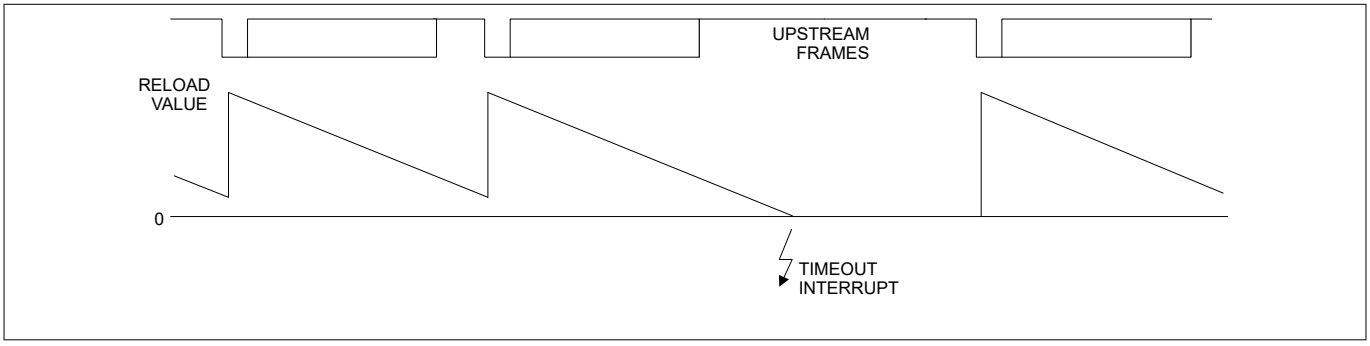

Figure 590 Upstream timer operation

The upstream watchdog timer counts bit times. The time window in which the next upstream frame must occur can be calculated according to the formula:

$$\text{Time-out} = \text{BitTime} \times 2^{(\text{USTOPRE}+1)} \times (\text{USTOVAL}+1) \quad (32)$$

28.3.1.3 CX (command extension) mode

Command Extension mode overrides the following standard features of the MSC protocol:

- Command frames:
  - Instead of 32 bits, command frames contain up to 2×32 bits and two select bits set to 1, one before each 32-bit block. One command frame now contains two commands, both with same length
  - The bit-field DSC.NBC is reused as it is and defines the length of both commands
  - The command chip select ENC is active during the whole active phase of the frame
  - The passive phase extension is extended to cover 2 to 127-bit times, see bit-field DSTE.PPCE and DSTE.PPCEM. This is valid only in ABRA active mode. When ABRA bypassed, the command passive phase is constant and fixed to two. The PPCEM bit is needed and extends the command passive phase only in the CX mode (CX = 1), where a command can be up to 64-bit long. If CX = 0, PPCEM bit is ignored and treated as always 0
- Data frames:
  - Instead of activating two enable signals ENL and ENH, data frames activate only one enable signal, ENL
  - It is the responsibility of the user to mandatory activate the select bits in the data frames with DSC.ENSELL and ENSELH in order to ensure the same frame structure of the command and the data frames
  - The existing data frame length bit-fields are reused as they are: DSC.NDBL, DSC.NDBH, DSCE.NDBLE and DSCE.NDBHE. It is the responsibility to the user to program them symmetrically if required and program the DSCE.EXEN, for example to set the same data frame length as the command frame length, which is the standard use case
  - The passive phase of the data frames is reused as it is
- Baud rate: It is possible to configure the MSC module to drive with maximal speed of 80 MBaud. The divider DSTE.NDD divides the module kernel frequency. When NDD = 0, the module runs with 100 MHz. When NDD = 2, the module runs with 33 MHz

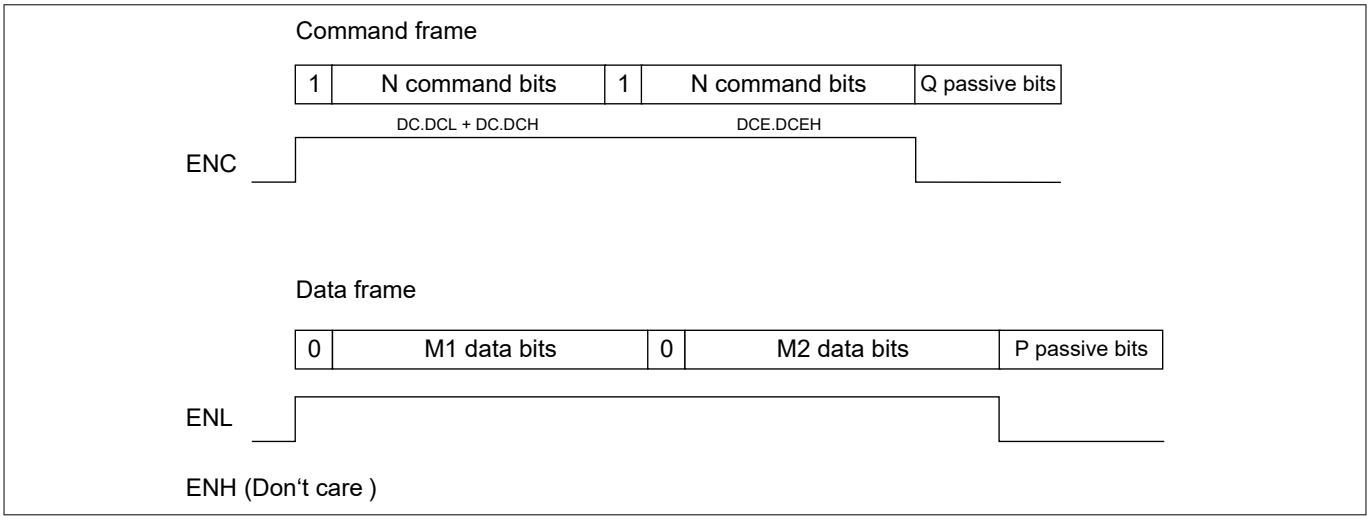

Figure 591 MSC frames in CX mode

This is the list of the additional bit-fields and registers correlated to CX mode.

- DSTE.CX bit, activating the CX mode

- DSTE.FM bit, activating the fast mode (up to 80 MBaud)
- DSTE.UL1 protection bit, for unlocking the CX and FM bits for one clock cycle
- DSTE.PPCE extended by one bit, in order to lengthen the passive phase of the command frame
- DCM, Downstream Command Mirror Register, providing convenient way to send more than 32-bit long commands by using DMA with memory address wrap around
- DCE, Downstream Command Extension Register, defining the second half of the command frame. In CX mode, always write first the DCE register and then DC or DCM, because write to the DC or DCM triggers the command transmission

28.3.1.4 I/O control

The types of I/O control logic for the MSC module I/O lines are shown in the following figure:

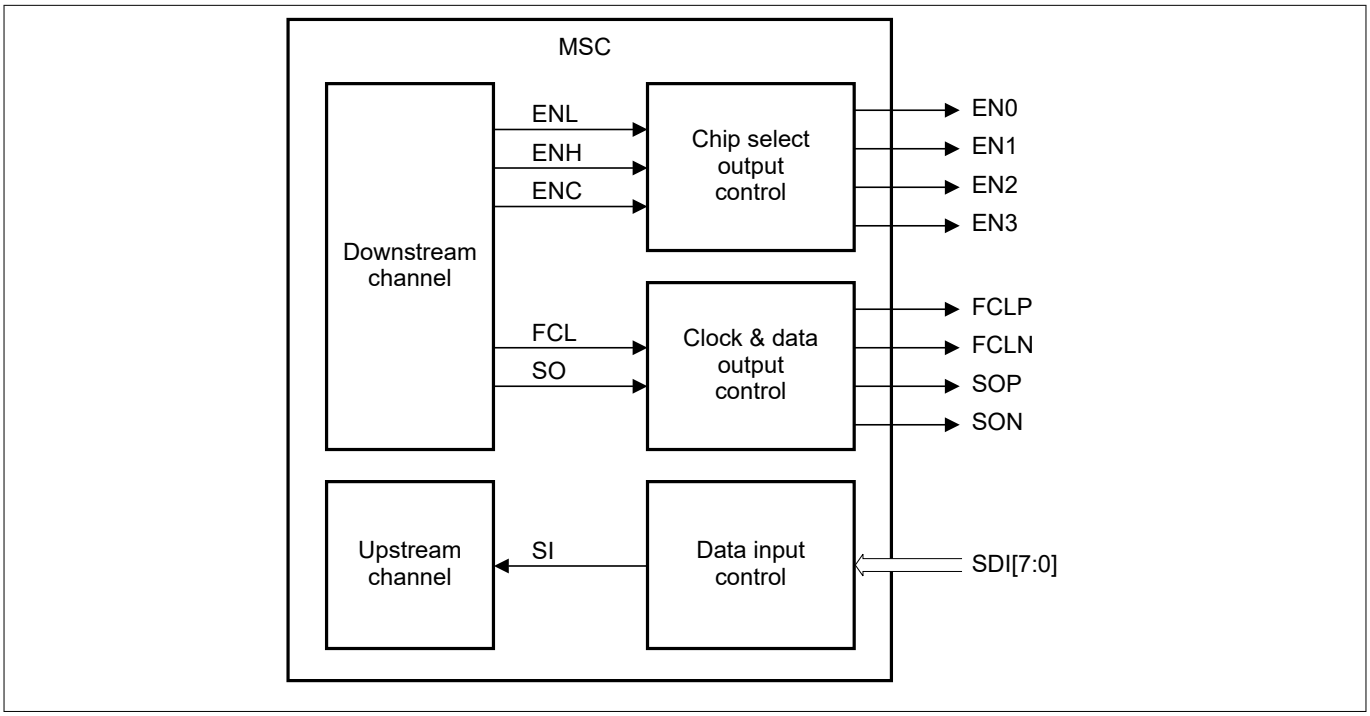

Figure 592 I/O control

The downstream channel generates five output signals that control eight MSC module outputs, split into four chip select outputs, two clock outputs and two serial data outputs.

The upstream channel has one input signal.

The MSC module I/O signals are controlled by bit-fields located in the Output Control Register (OCR).

28.3.1.4.1 Downstream channel output control

As described in the Frame and formats and definitions section, the active phases during downstream channel operation are indicated by three enable signals:

- ENL indicates the SRL active phase of a data frame
- ENH indicates the SRH active phase of a data frame
- ENC indicates the active phase of a command frame

The chip select output control logic of the MSC uses a signal compressing scheme (similar to the scheme described in the Interrupt request compressor section) that allows each of the three enable signals to be directed through a 2-bit selector to one of the four chip enable outputs EN[3:0]. This also makes it possible to connect more than one internal enable signal (ENL, ENH, ENC) to one chip enable output ENx. Three bit-fields

in the register OCR (CSL, CSH and CSC) determine which chip enable output becomes active on a valid internal enable signal.

In the MSC, enable signals are high-level active signals. If required in a specific application, all chip enable outputs ENx can be assigned for low-level active polarity by setting bit OCR.CSLP.

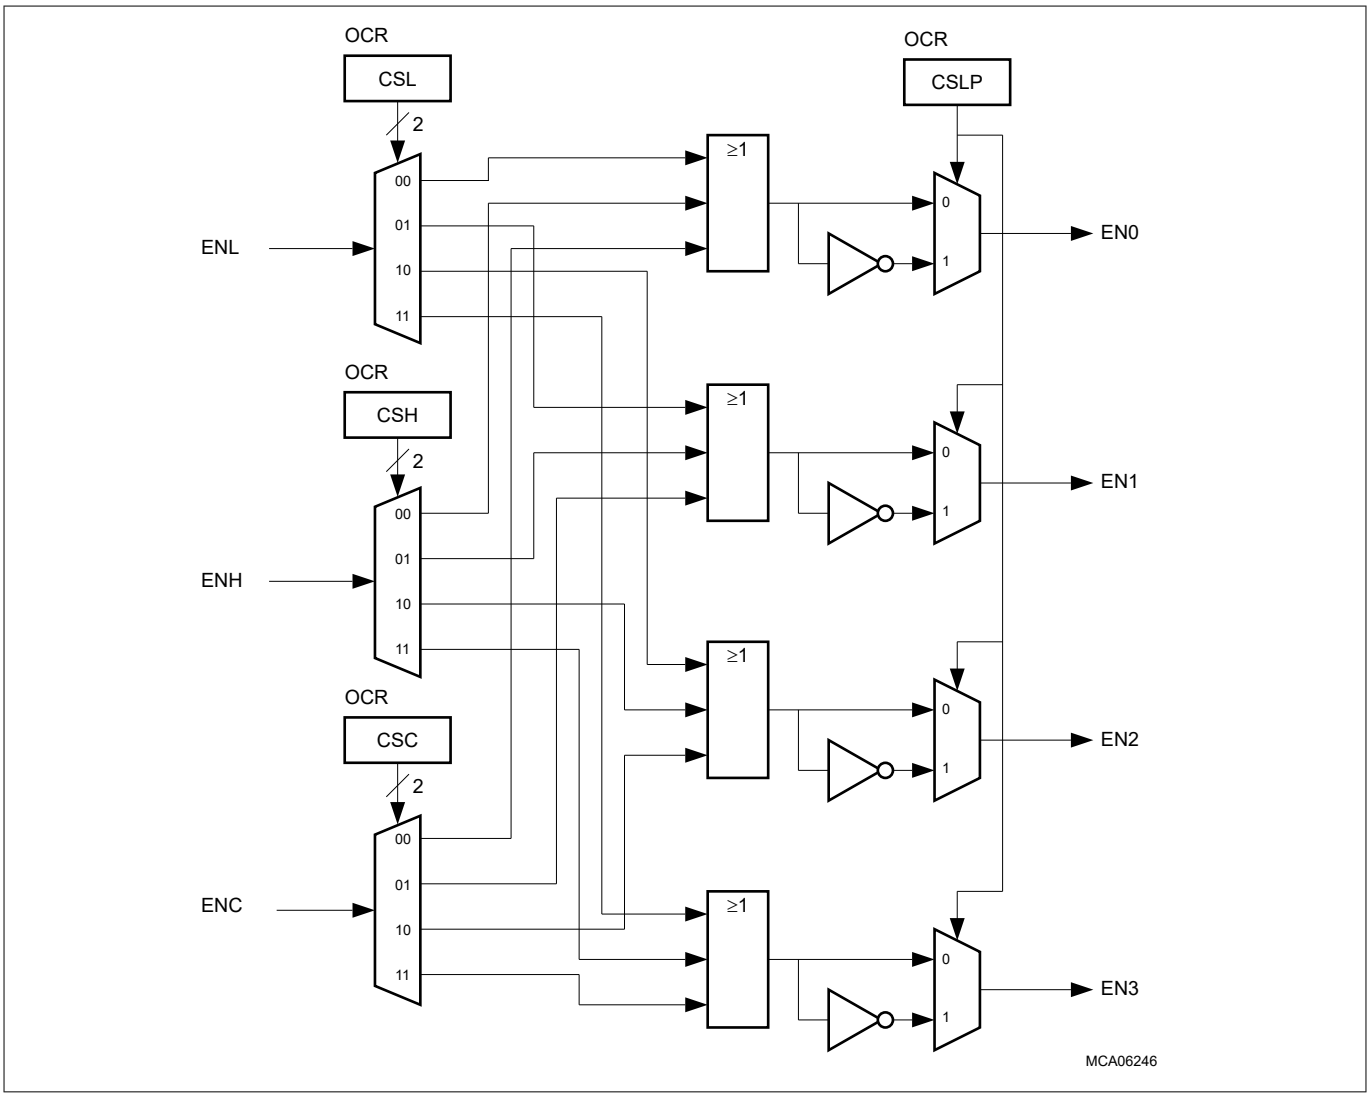

Figure 593 Downstream channel: Chip enable output control

At the MSC downstream channel, the internal serial clock output FCL and data output line SO are available outside the MSC module as two signal pairs with inverted signal polarity, FCLP/FCLN and SOP/SON. Both, clock and data outputs, are generated from the module internal signals FCL and SO according to the following figure.

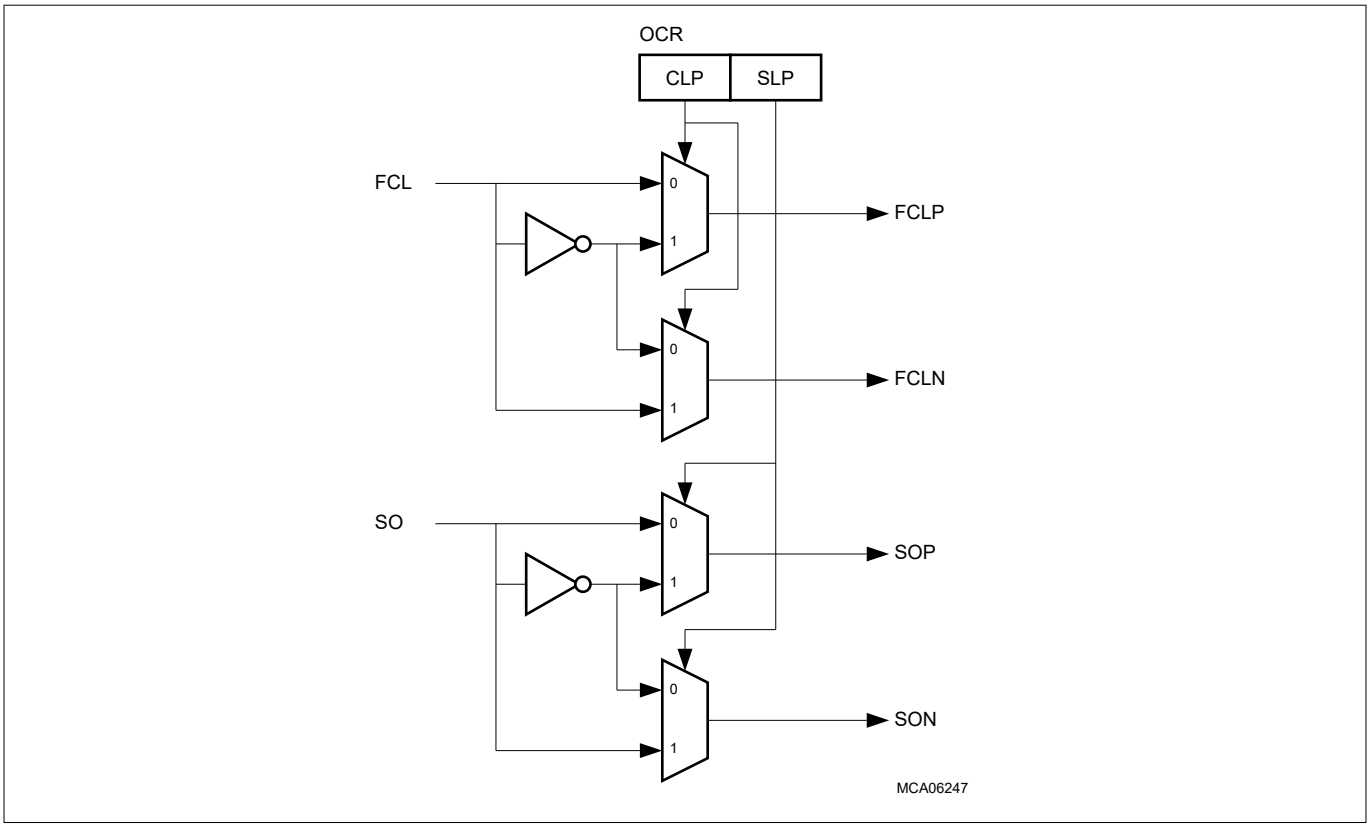

Figure 594 Downstream channel: Clock and data output control

With OCR.CLP=0, FCLP has identical and FCLN has inverted polarity compared to FCL. Setting OCR.CLP, exchanges the signal polarities of FCLP and FCLN. An equivalent control capability is available for the SOP and SON data outputs (controlled by OCR.SLP).

One additional control capability not shown in the previous figure is available for the FCL signal:

- OCR.CLKCTRL=1
  - The FCL clock signal will always be generated, independently of whether a downstream frame is currently transmitted or not
- OCR.CLKCTRL=0
  - FCL becomes active only during the active phases of data or command frames (not during passive time frames)

Enable Signal Time Adjustment

The enable signal can be adjusted in steps of ½ FCL clock time period.

Each enable signal has the possibility to be configured 0, 1 or 2 steps of ½ clock time-period adjustment at assertion and deassertion independently, as shown in the figure below. This functionality can be programmed in the OECR register.

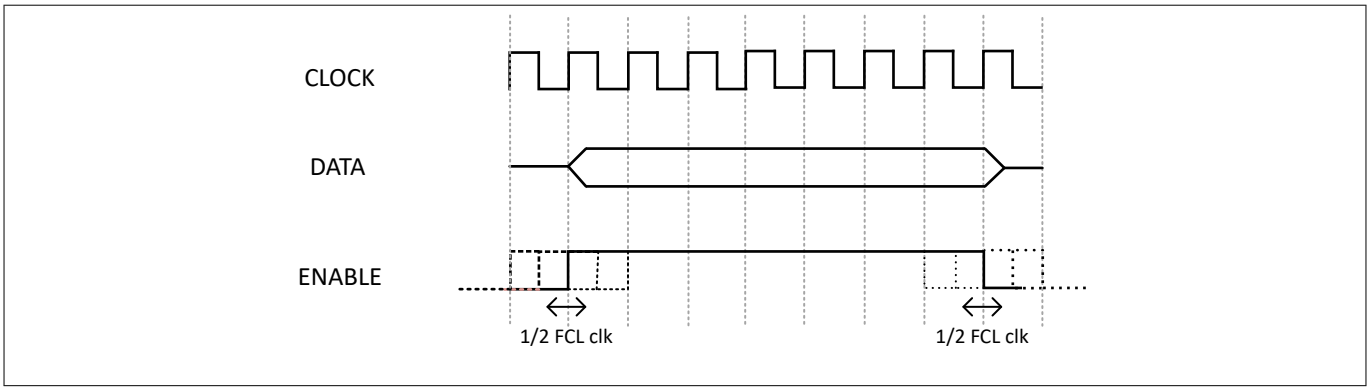

Figure 595 Halb bit enable signal adjustment

When using this option the passive phase needs to be taken into account. The passive phase is min. $2 \times t_{FCL}$. If a time adjustment is configured for the enable signal, the passive phase has to be adjusted accordingly (minimum $2 \times t_{FCL}$). The length of the passive phase can be programed accordingly in DSC.PPD for data frame and in DSTE.PPCE/DSTE. PPCEM for command frame.

28.3.1.4.2 Upstream channel input control

As shown in the figure below, the MSC upstream channel can be connected to up to eight SDI[7:0] serial inputs. Bit-field OCR.SDISEL selects one out of these input lines (input signal SDI).

- OCR.ILP = 0
  - SDI is directly connected to the serial receive buffer input SI
- OCR.ILP = 1
  - SDI is connected to input SI through an inverter

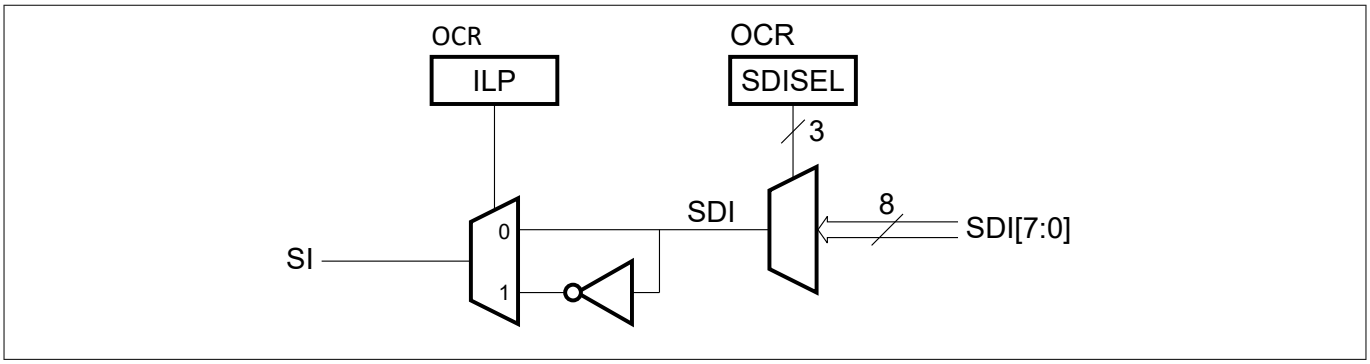

Figure 596 Upstream channel serial data input control

28.3.1.5 Slow channel

This section describes the Slow Channel feature for the MSC downstream transmission.

The main use case of the Slow Channel feature is the transmission of command frames without interrupting the continuous data frame traffic (for example equidistant update of data).

Slow Channel mode overrides the following standard features of the MSC protocol:

- No Selection bits are used

- The enable signals ENH and ENL are used as are used in legacy
- The enable signal ENC is not used
- There is no possibility to send command frames as in legacy, they can be only send embedded through the slow channel
- It is not compatible with CX (Command Extension) mode
- The registers DD and DDE are reused and contain the data to be transmitted in the data frames
- The existing data frame length bit fields are reused as they are: DSC.NDBL, DSC.NDBH, DSCE.NDBLE and DSCE.NDBHE. It is the user responsibility to program them symmetrically if required and program the DSCE.EXEN
- The passive phase of the data frames is reused as is
- Interrupts (see interrupt section)

This is the list of the additional bit-fields and registers correlated to the slow channel mode:

- The bit-field SCC.SC enables the Slow Channel mode
- The bit-fields SCC.SCLX and SCC.SCLY define the bit length of the slow channels
- The bit-fields SCC.CFLX and SCCCFLY define the length of the command frames
- The bit-fields SCC.PCX and SCC.PCY enable and select the parity to be used for the command frame transmission
- The registers DCSX and DCSY are used for defining the command frame data
- The bit-fields SCC.CFSTOPX and SCC.CFSTOPY define the Stop bits configuration for the command frame
- The bit-fields ISR.CSXI and ISR.CSYI for the interrupt status flag for the corresponding command frame slave X or slave Y and the related bit-fields in registers ICR and ISC

***Note**: The behavior is undefined when the configuration is changed in between an ongoing transaction*

28.3.1.5.1 Overview

The main difference to the standard downstream transmission is that at every MSC downstream frame some bits are reserved for including a slow channel for sending the command frame in small parts.

In the block diagram below the behavior of the downstream channel when enabling the Slow Channel feature is shown. The Slow Channel feature is set in bit-field SCC.SC.

One slow channel is supported per slave without CPU interaction in Data Repetition and Triggered mode by using this feature. A maximum of 2 slaves are supported.

The data source for the command frame are the Downstream Command Register DCSX for Slave X and the Downstream Command Register DCSY for Slave Y. The length of the command frame is configurable between 1 and 32 bits in bit-fields SCC.CFLX and SCC.CFLY.

The command frame is split into small parts and each of these parts is transferred as slow channel payload in the data frame. The bit width of the slow channel (number of slow channel bits) per data frame is configurable independently for each slave in the bit-fields SCC.SCLX and SCC.SCLY. The slow channel width possible configuration is: 0, 1, 2, 4, 8, 16 or 32-bits. The slow channel is always transmitted in the payload before the data frame of each slave.

The transmitted payload through the MSC interface is built as follows: The slow channel data is transmitted with the configured bit length and the data frame is sent directly after the slow channel as indicated in the picture below.

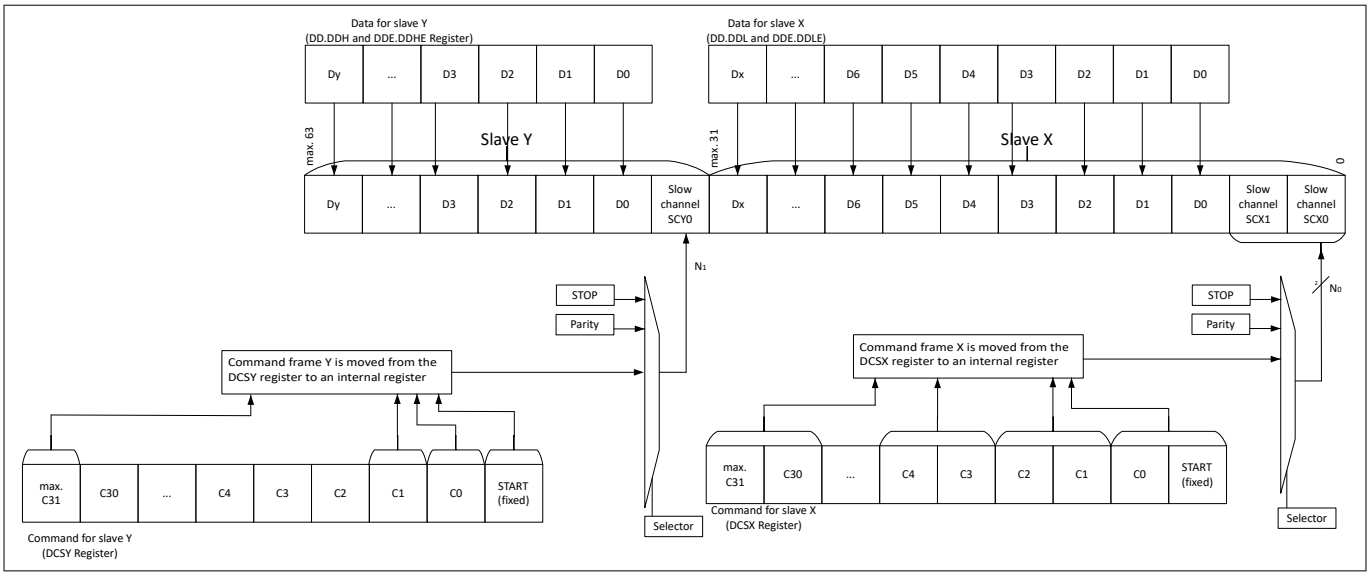

Figure 597 MSC transmitted payload with slow channel

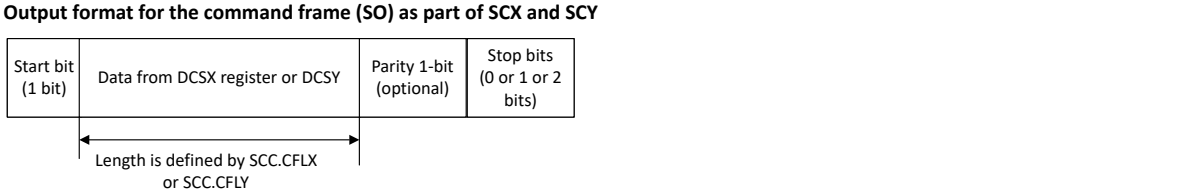
The command frame transmission for both slaves is completely independent.

If there is no command data to be transmitted the slow channel will transmit Stop bits (logical 1).

If command data is being transmitted though the slow channel and a next command is pending, the next command frame is transmitted directly after the current one is finished.

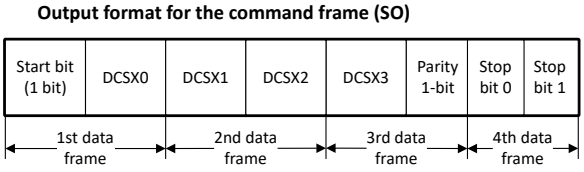
Command frame data is encoded in a UART fashion frame (Start, Data, Parity optional and configurable 1 or 2 Stop bits). The Start bit is fixed and coded with a logical 0. The parity for the command frame is optional and the type of parity can be configured in the bit-field SCC.PCX and SCC.PCY. The number of Stop bits to be used can be programmed in SCC.CFSTOPX and SCC.CFSTOPY bit-fields. 0, 1 or 2 Stop bits can be programmed. More Stop bits can be programmed by software as part of the command frame (in registers DCSX and DCSY). The Stop bit is coded with a logical 1. The exact format of the output command frame is shown in the figure below along with an example.



Whether the entire command frame is sent out or if it is sent out in parts depends on the ratio of the value configured for SCC.SCLX or SCC.SCLY and the complete number of bits in the command frame (Start bit, Data, optional Parity bit and optional Stop bits)

Figure 598 Output format for command frame

Example configuration
SCC.SCLX = 010 => 2 bits
SCC.CFLX = 4 bits
SCC.PCX = 01 => Even parity ON
SCC.CFSTOPX = 10 => 2 Stop bits



Write into the DCSX register triggers the next command frame to be sent with new data. Otherwise default bits are sent out

Figure 599 Example command frame

***Note**: No Selection bit is used in this mode. While using slow channel in legacy mode the Selection bit has to be disabled (DSC.ENSELL=0 and DSC.ENSELH=0).*

***Note**: The number of bits of the command frame to be transmitted through the slow channel are the width programmed in SCC.CFLX and SCC.CFLY.*

***Note**: Without any data frame to be transmitted, no command bits will be sent out in Slow Channel mode.*

28.3.1.5.2 Downstream channel with slow channel feature

The downstream channel performs a high-speed synchronous serial transmission of data to external devices. Its 128-bit shift register is divided into four 32-bit parts, SRH, SCY, SRL and SCX.

Each 32-bits of SRL and SRH can be selected to be delivered by the Downstream Data Register DD and DDE or by four 16-bit wide input signal buses, ALTINL, ALTINH.ALTINLE and ALTINHE if the Extended mode is activated (DSCE.EXEN=1).

The figure below is a diagram of the MSC downstream channel with the Slow Channel feature activated.

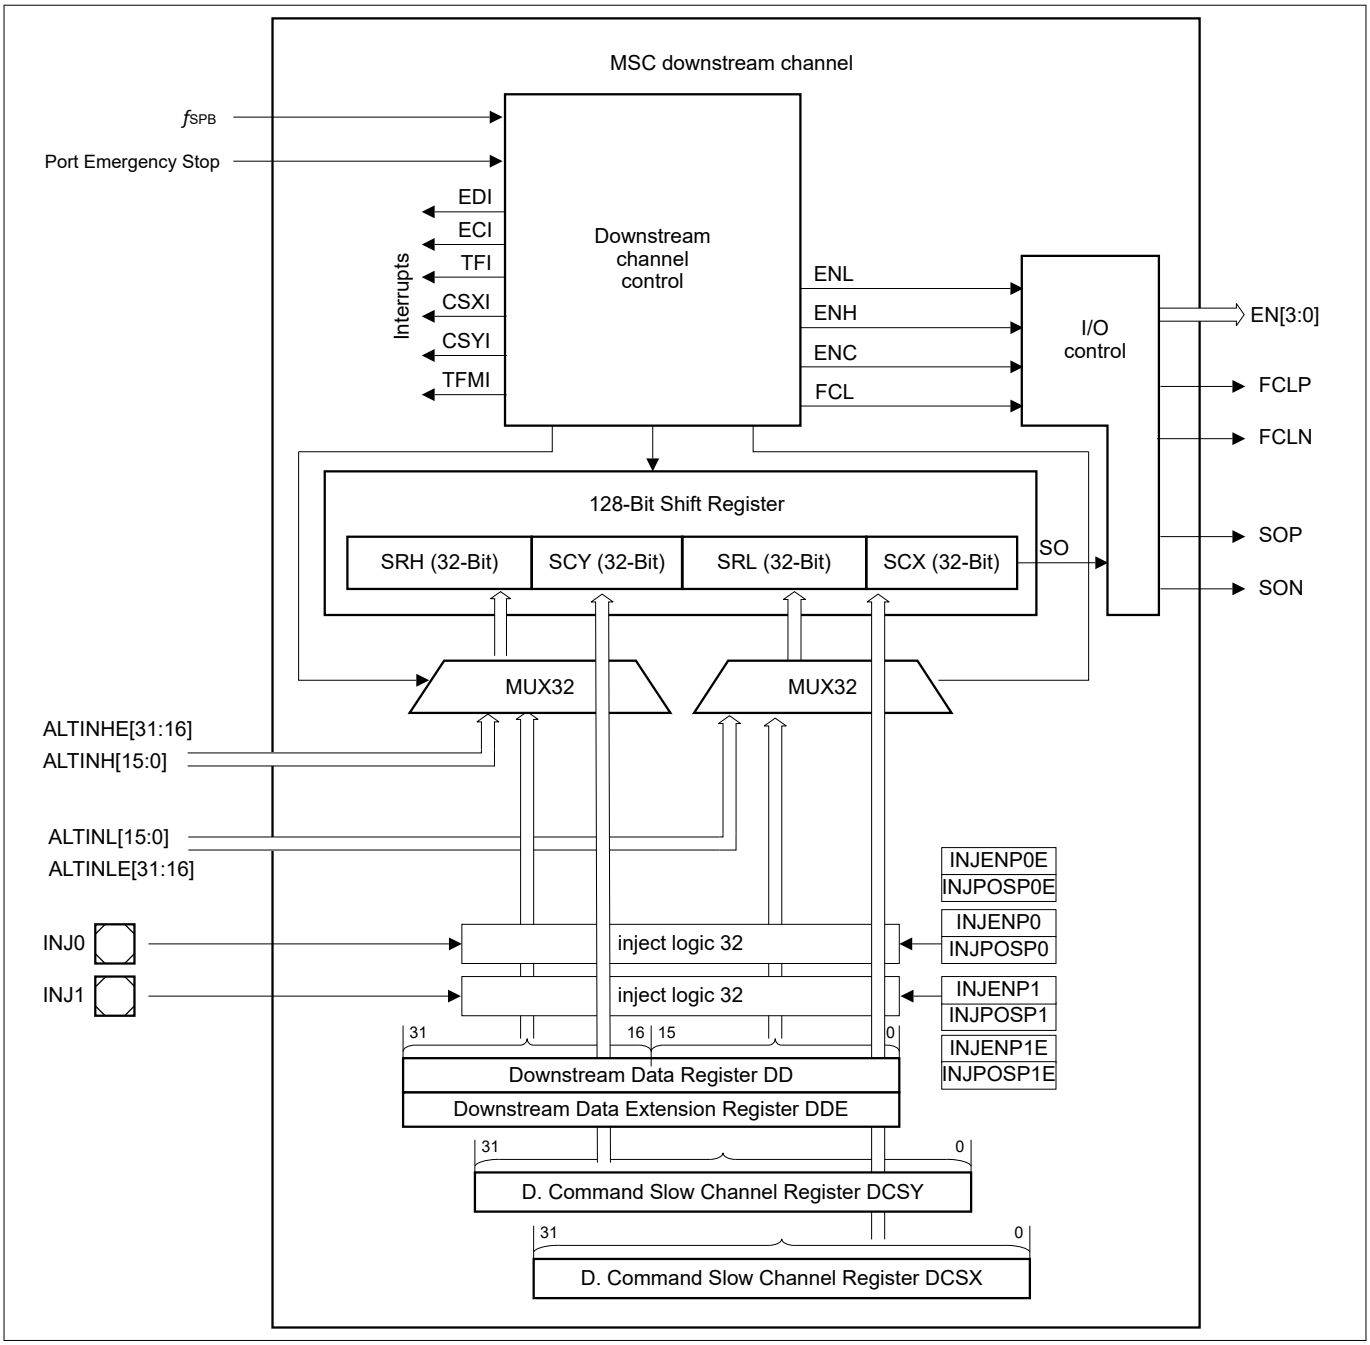


Figure 600 Downstream channel with slow channel feature

The enable signals ENL and ENH indicate the low and high phases of the serial transmission in relation to the serial FCL. The enable signal ENC is not used while Slow Channel feature is enabled.

The Port Emergency Stop input is used to indicate an emergency stop condition of a power device. In the case of an emergency, shift register bits can be loaded bit-wise from the downstream data register instead from the ALTINL, ALTINH, ALTINLE and ALTINHE buses. This behavior does not change when the slow channel is activated since these bits can be mapped only to data frame bits and the slow channel bits are extra bits in the MSC downstream payload.

28.3.1.5.3 Frame format using slow channel for command frame transmission

A downstream frame is composed of:

- An active phase
  - During the active phase data and slow channel transmission take place
- A passive phase
  - During the passive phase no data is transmitted at SO

The active phase is split into four parts:

- SRL active phase, which is further two parts:
  - The content of the shift register slow channel X and
  - Low part SRL is transmitted
- SRH active phase , which has further two parts:
  - The content of the shift register slow channel Y and
  - High part SRH is transmitted

The least significant bits of SRL, SRH, slow channel X and slow channel Y are sent out first.

The figure below shows the layout and definitions of the downstream frame using slow channel for the command frame transmission.

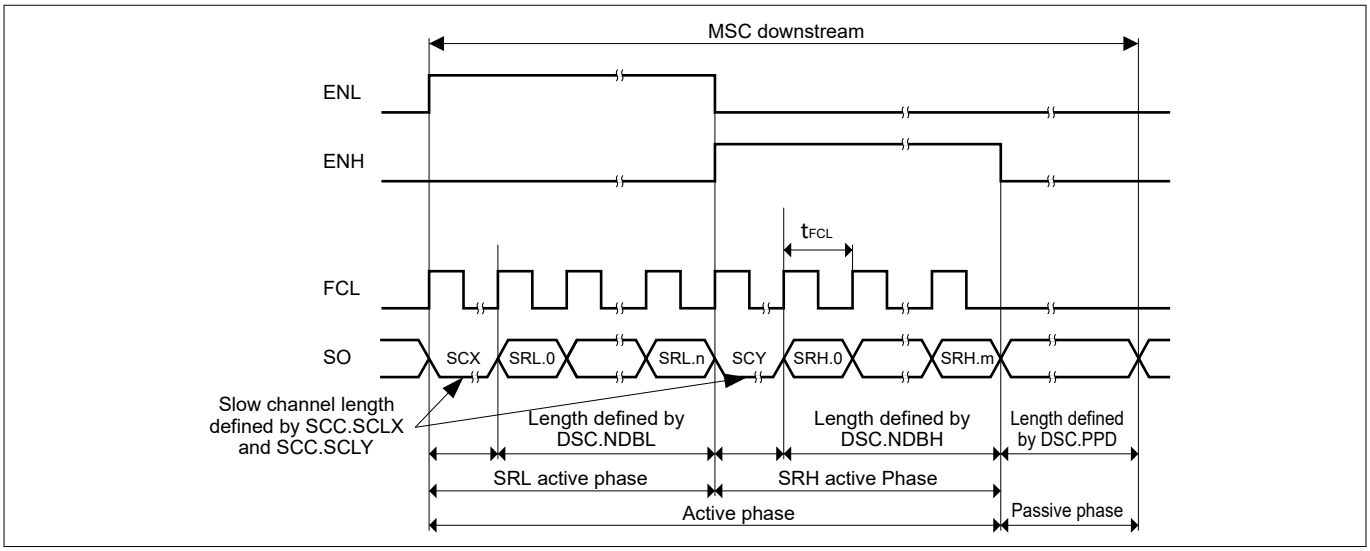

Figure 601 Downstream channel frame using slow channel

28.3.1.5.4 Interrupts in slow channel mode

The interrupts available in slow channel:

- Command frame Interrupts for slow channels X and Y (special implementation only for slow channel mode)

28.3.1.5.5 Time reference point in slow channel, data repetition mode

A passive time frame has the length defined by the parameters according to the following equation. The passive time frame is only generated in Data Repetition mode as shown in the picture below. Running in slow channel mode, there is no possibility to shorten the passive time frames.

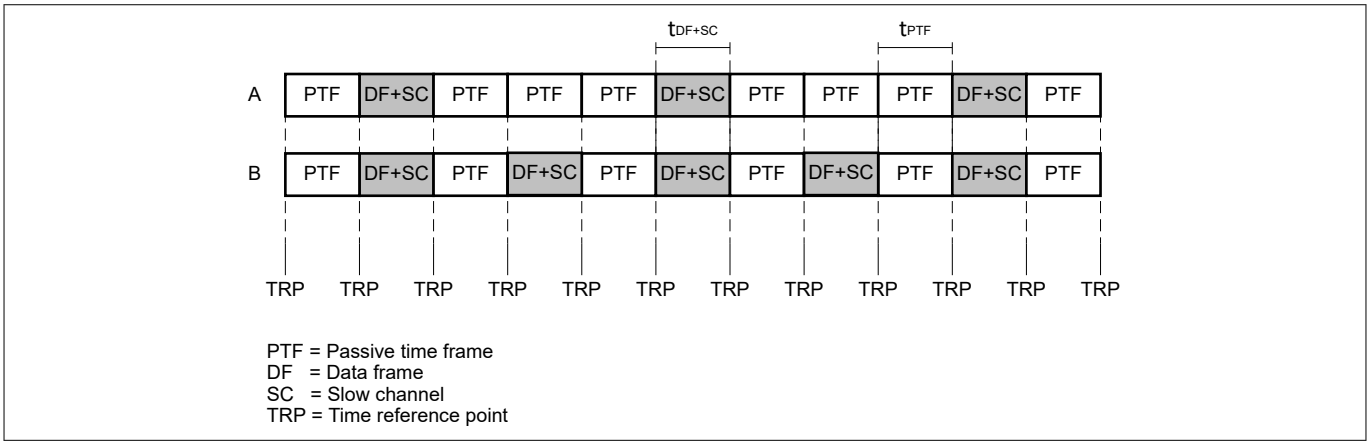

Figure 602 Passive time frame and time reference point using slow channel

The time reference point in slow channel mode is calculated with the following formula:

$$N_{CYCLES} = SCC.SCLX + NDBL + NDBLE \times EXEN \times 16 + SCC.SCLY + NDBH + NDBHE \times EXEN \times 16 + PPD + PPDE \times EXEN \times 32 \quad (33)$$

t_{PTF} calculation using slow channel

***Note**: In the formula above, PPD must be set to 2 when DSC.PPD<= 00010_B.*

28.3.1.5.6 Slow channel and ABRA block

While combining the ABRA block and the slow channel, the formulas explained in chapter Adjusting the passive phase of a frame can be used. ND needs to be calculated as follow:

$$N_D = SCC.SCLX + SCC.SCLY + DSC.NDBH + DSC.NDBL + DSCE.NDBHE + DSCE.NDBLE \quad (34)$$

N_D calculation

***Note**: While combining the slow channel and ABRA block, note that only 64 bit length downstream frames are considered to be used.*

28.3.1.6 Manchester code transmission mode

This section describes the Manchester Code transmission mode for the downstream channel. This transmission mode is only compatible with the Slow Channel feature, also when the slow channel is combined with ABRA block . No legacy downstream transmission is possible with Manchester code.

In order to reduce the pin count on the downstream channel all following signals are embedded in one:

- Enable signal
- Clock
- Data

This is the list of the additional bit-fields and registers correlated to Manchester Code transmission mode:

- The bit-field SCC.MCT enables the Manchester encoding transmission
- The bit-field ISR.TFMI flags for time frame Manchester code interrupt and corresponding bit-fields in ICR and ISC registers

The Manchester encoding transmission is enabled in bit-field SCC.MCT = 1.

The data and clock signals are sent through the MSC output line encoded in Manchester code, while the enable signals are represented by 2 idle bits without Manchester encoding. The level of these idle bits is used for addressing the slave. There can be either IDLE 0 or IDLE 1 between the Data frames.

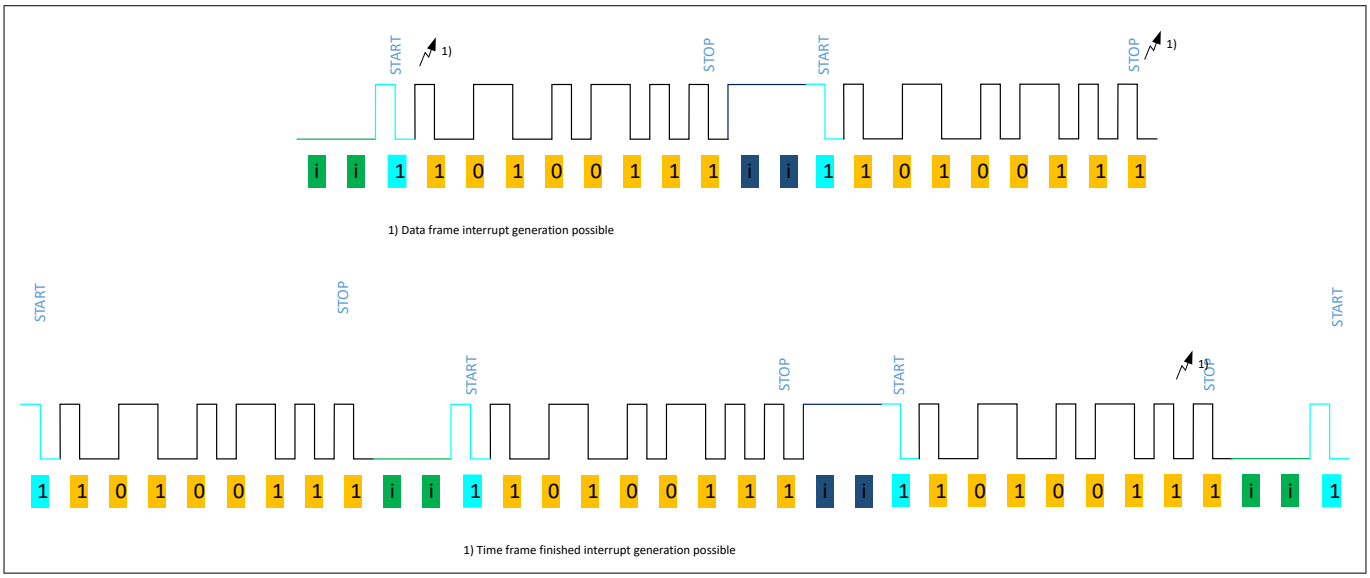

Figure 603 MSC frame Manchester encoded

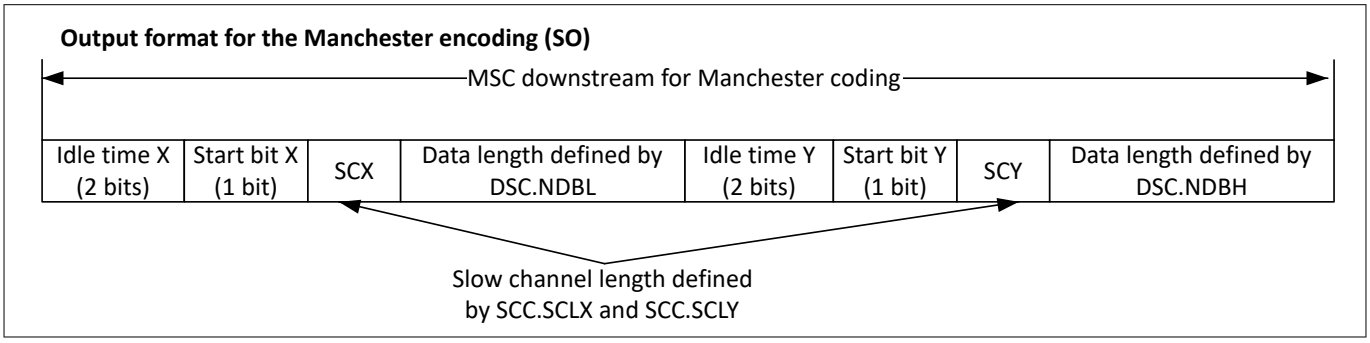

Figure 604 Output format for Manchester encoding (SO)

Both Manchester encoding are supported: IEEE and G.E. Thomas. This can be configured in bit-field OCR.SLP. Transmission in G.E. Thomas when OCR.SLP=0. To transmit in IEEE 802.3 the polarity of the SOP line has to be inverted, by setting OCR.SLP=1. Note that transmitting in IEEE encoding the slaves are swapped.

This transmission mode supports 2 slaves addressing. The slaves are addressed with the idle time:

- Idle time with level low, addresses slave X
- Idle time with level high, addresses slave Y

***Note**: This description and all figures in this document represent the G.E. Thomas Manchester encoding.*

28.3.1.6.1 Interrupts in Manchester code

The interrupts available in Manchester code are:

- Time frame finished interrupt in Manchester code mode (special for Manchester code - no passive phase available)

28.3.1.6.2 Time reference point in Manchester code - data repetition mode

A passive time frame has the length defined by the parameters according to the following equation in Manchester code. The passive time frame is only generated in Data Repetition mode (refer to figure "Passive time frame and time reference point using slow channel").

The time reference point in Manchester Code mode has to be calculated with the following formula:

$$N_{CYCLES} = 2(\text{idle time length}) + 1(\text{start bit}) + SCC.SCLX + NDBL + NDBLE \times EXEN \times 16 + 2(\text{idle time length}) + 1(\text{start bit}) + SCC.SCLY + NDBH + NDBHE \times EXEN \times 16 \quad (35)$$

t_{PTF} calculation in Manchester code

Time reference point in slow channel, data repetition mode on page 5113

28.3.2 Asynchronous baud rate adjustment (ABRA)

The ABRA block takes as input a serial MSC stream with one baud rate and outputs the same serial stream with another baud rate, asynchronous to the input one. The input signal bundle consists of serial clock, data and select signal. The output signal bundle consists of the same signals.

The output clock of an MSC without ABRA can only be set to 50% duty cycle, while with the ABRA block other duty cycles are also possible.

***Note**: The ABRA feature and Manchester encoding are not compatible with each other, therefore they can not be used together.*

28.3.2.1 Overview

The ABRA block is located between the MSC kernel and the output pins.

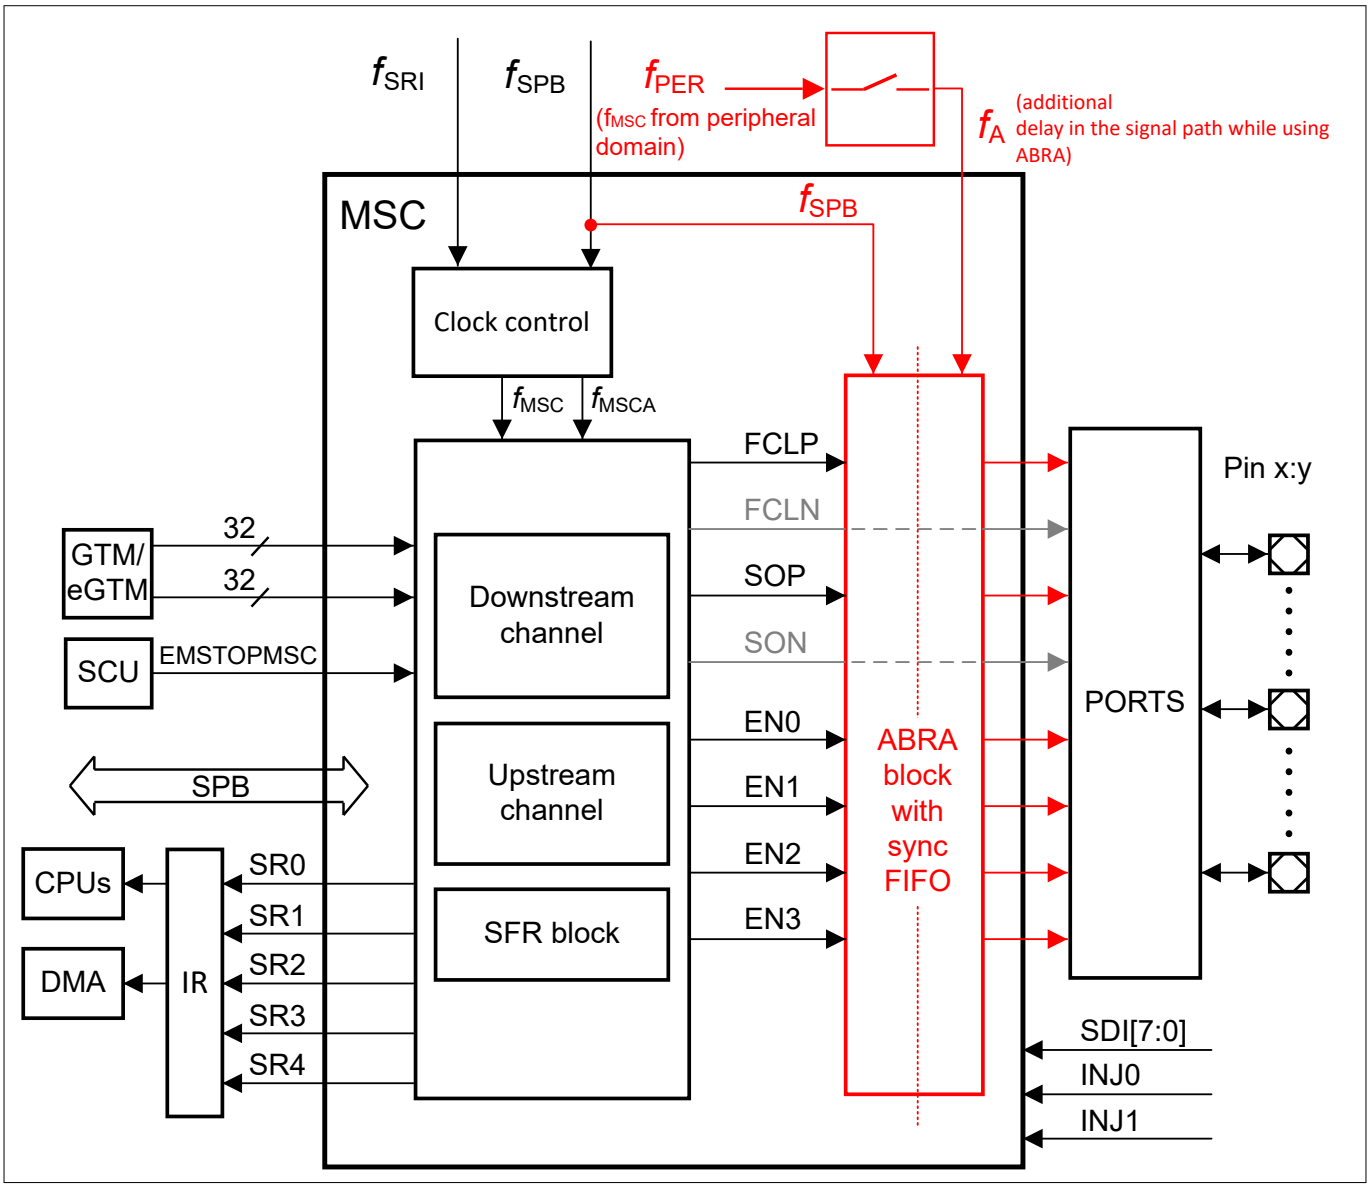

Figure 605 ABRA overview

The user has two possibilities: either to use the ABRA block or to bypass it. In case of using ABRA, additional delay in the signal path between the module and the pins of up to three f_A periods is to be taken into account. Additionally, some margin between the input frame length and the output frame length must be guaranteed by the customer, in order to avoid overflow of the ABRA block.

If the ABRA is not used, the behavior of the MSC module is identical with previous implementations. The user can also choose between using the 64-bit extension or not, which makes 4 combinations in total, as shown in the figure below.

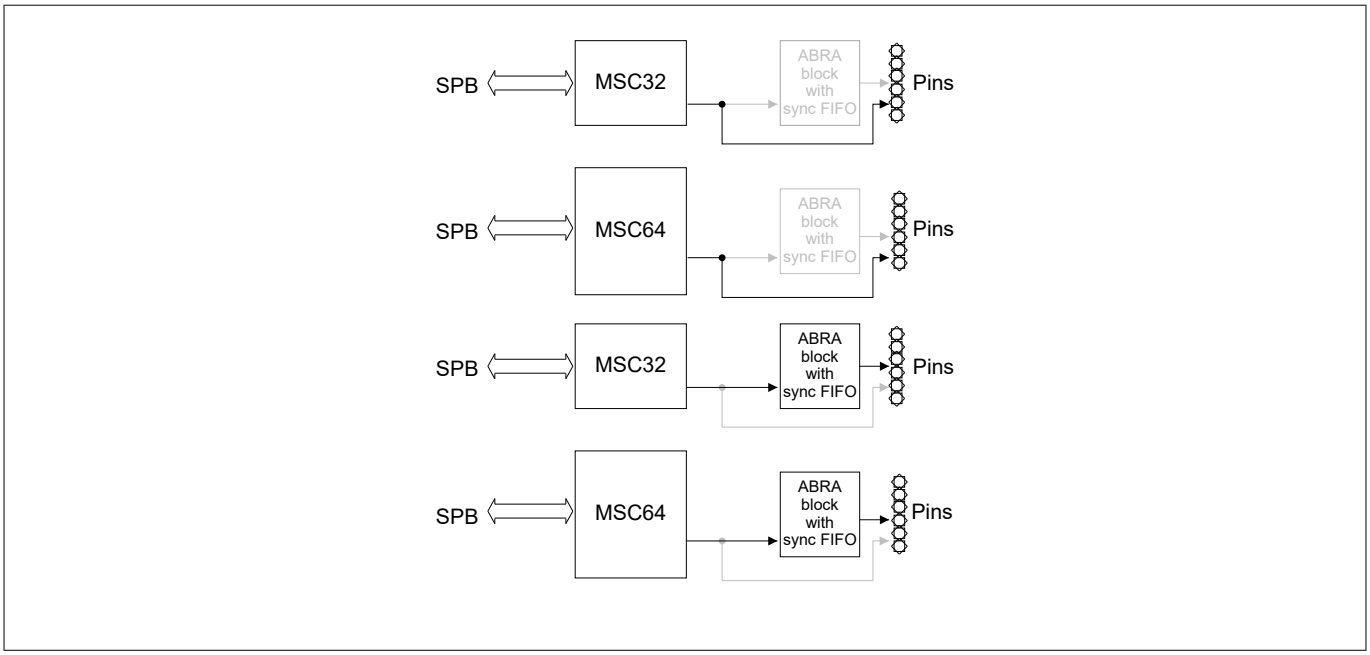

Figure 606 Use-case combinations

All configuration parameters related to the ABRA block are located in the ABC (Asynchronous Block Configuration) register.

28.3.2.2 Timing issues

The ABRA block introduces a delay in the signal path from the MSC module to the pins. However it does not significantly influence the timings between the signals themselves.

The output delays between the shift clock, data, and enable signals remain approximately the same as if the ABRA block is not used. These are covered in the timings of the MSC module as defined in the respective datasheet.

28.3.2.3 Adjusting the passive phase of a frame

The main purpose of the ABRA block is to transform a frame going in with a higher baud rate (for example 50 MBaud), to a frame going out with a lower baud rate (for example 40 MBaud). Therefore, the duration of the outgoing frame is longer then the duration of the incoming frame. In order not to overflow the ABRA block with too many incoming frames, there must be a pause between them, which is adjusted by configuring the passive phase of the frames. This pause plus the incoming frame duration must be longer or equal to the outgoing frame duration plus some margin.

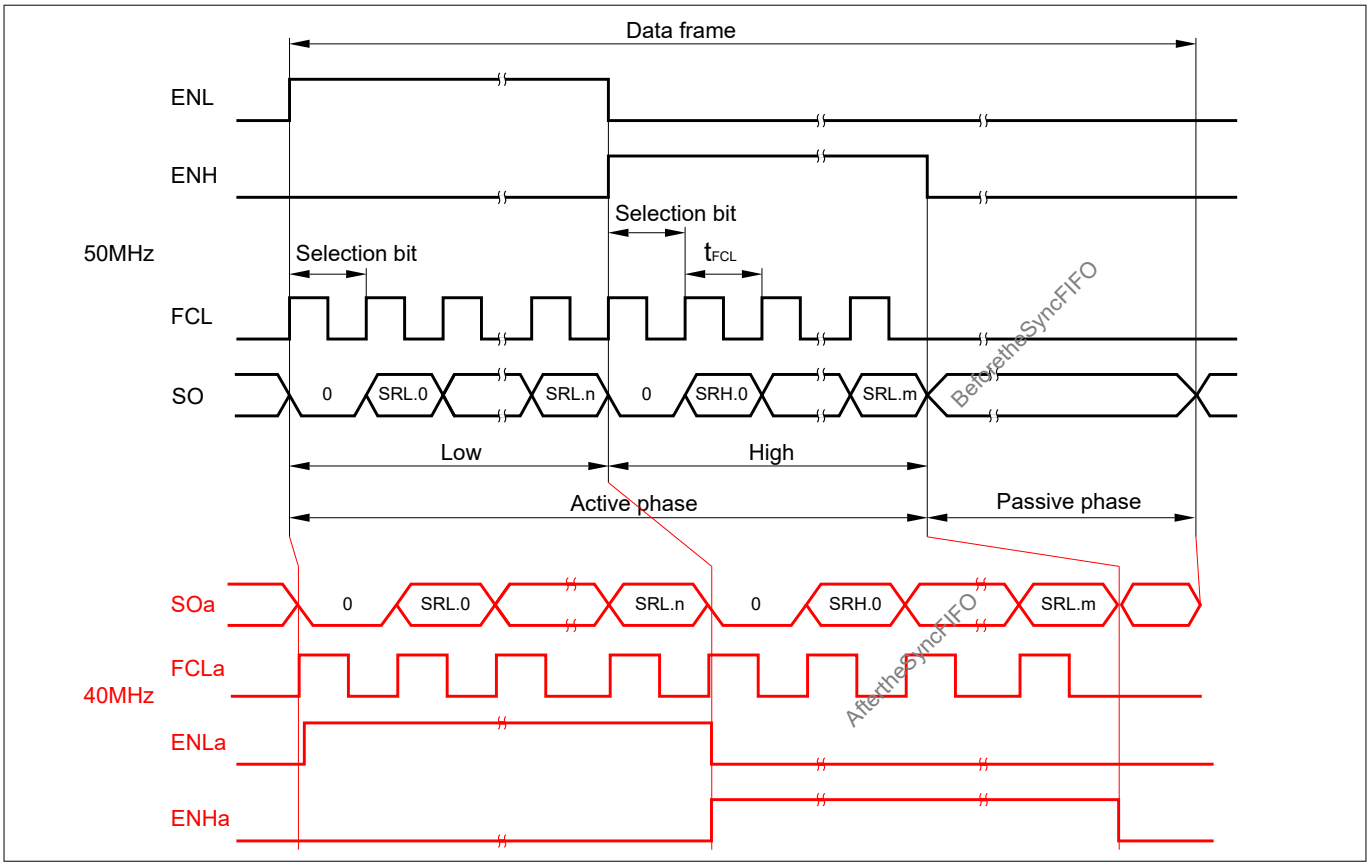

Figure 607 Passive phase adjustment

In order to allow for frame length adjustments:

- For command frames, the bit-field DSTE.PPCE defines a programmable passive phase in a range of 2 to 65 input frequency cycles and for data frames, the bit-field DSTE.PPDE extends the passive phase from 2 to 31 to 2 to 127-bit times

The length of the frame in the MSC domain (data and passive bits) must be longer than the length of the frame in the asynchronous domain, in order to prevent overload in case of back to back transmission:

$(N_D + N_P) \times T_{\mathrm{FCL}} > (N_D + N_{\mathrm{PA}}) \times T_{\mathrm{FCLA}}$

which results to the following inequality for setting the length of the passive phase in the MSC domain:

$N_P > \frac{(N_D + N_{\mathrm{PA}}) \times T_{\mathrm{FCLA}}}{T_{\mathrm{FCL}}} - N_D$ or equivalently $N_P > \frac{(N_D + N_{\mathrm{PA}}) \times f_{\mathrm{FCL}}}{f_{\mathrm{FCLA}}} - N_D$

for example if $f_{\mathrm{FCL}} = 50\ \mathrm{MBaud}$, $f_{\mathrm{FCLA}} = 40\ \mathrm{MBaud}$, $N_D = 32$ and $N_{\mathrm{PA}} = 3$, then $N_P > (32 + 3) \times 1.25 - 32$, $N_P > 12$

Where:

T_{FCL}: serial clock period in the MSC domain with activated ABRA: $T_{\mathrm{FCL}} = \frac{1}{\mathrm{BaudRate}_{\mathrm{MSCA}}}$,

$\mathrm{BaudRate}_{\mathrm{MSCA}} = \frac{f_{\mathrm{SPB}}}{(2 \times m)}$, see the Clock control when using the ABRA block section.

T_{FCLA}: serial clock period of the ABRA block $T_{\mathrm{FCLA}} = \frac{1}{\mathrm{BaudRate}_{\mathrm{ABRA}}}$,

$\mathrm{BaudRate}_{\mathrm{ABRA}} = \frac{f_A}{(\mathrm{ABC.NDA} + 1) \times (\mathrm{ABC.LOW} + 1 + \mathrm{ABC.HIGH} + 1)}$

N_{P}: number of the passive bits in the MSC domain (see DSTE.PPDE and DSC.PPD)

N_{PA}: number of the targeted passive bits in the asynchronous domain

N_D: number of data bits DSC.NDBH + NDBL + SELH + SELL + DSCE.NDBLE + NDBHE in both domains.

***Note**: If the passive phase settings in the MSC module are not correctly configured in such a way that two frames merge, that is, there is no passive phase on the pins at all, an overflow interrupt is triggered. If the passive phase is wrongly shorter, no error signal is generated.*

Input/output baud rate ratio

The ABRA output baud rate going to the pins must be lower than the input baud rate coming from the MSC module and higher than roughly half of the input baud rate (more precisely higher than 57% of the input baud rate in worst-case, due to the fact that in worst-case MSC data frame can contain 64 data bits plus additionally two select bits).

Related information

Clock control when using the ABRA block on page 5134

28.3.2.4 Jitter of the downstream frames

This section describes the jitter effects affecting the starting point of the downstream frames, depending on the setting of the serial clock - serial clock only during the active phase of a frame or continuous clock.

28.3.2.4.1 Jitter in active phase clock mode

The active phase clock mode is set when OCR.CLKCTRL = 0. In this mode the serial clock is generated only during the transmission of the data bits. The ABRA outgoing frame passive phase duration jitters for +- one f_A cycle.

The example in the following figure assumes 50 MBaud input and 40 MBaud output baud rate, f_A = 80 MHz, back to back frames.

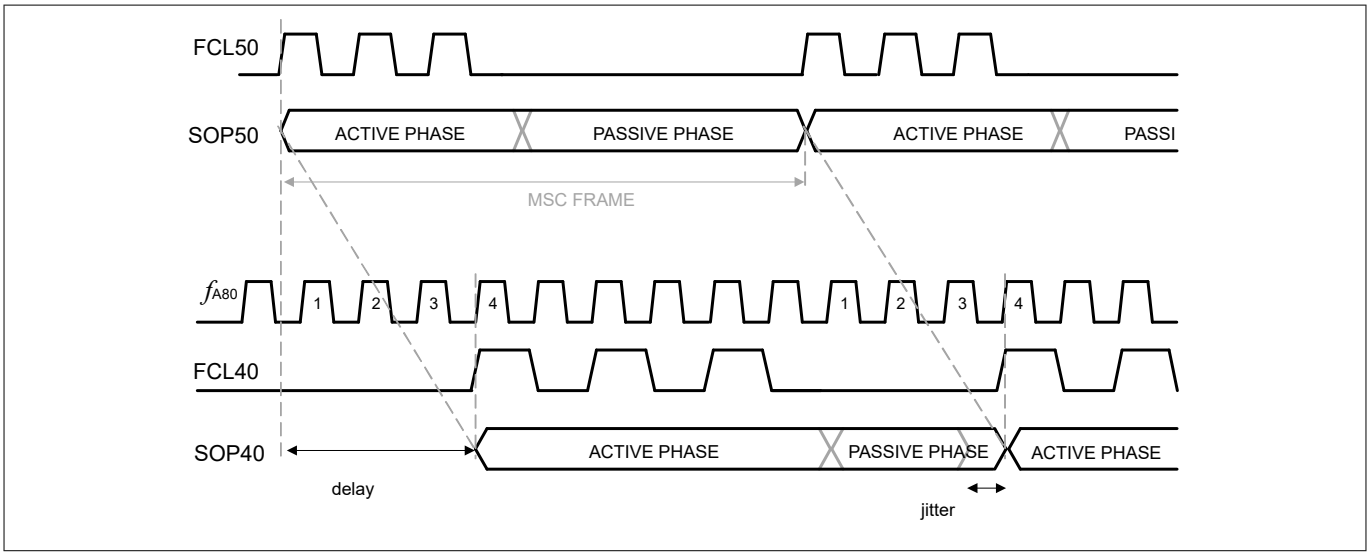

Figure 608 Frame jitter in active phase clock mode

28.3.2.4.2 Jitter in continuous clock mode

Continuous Clock mode is set when OCR.CLKCTRL = 1. In this mode the serial clock is always on. The jitter is one output bit time.

The average length of the output frames is equal to the length of the input frames. The ABRA block generates an averaging effect similar to that of a fractional divider. It introduces occasionally jitter of one bit time in the output frame length, in the passive phase of the frame, in order to adjust the average output time raster to the ideal input time raster.

The granularity of the input time raster is one input bit time (for example 20 ns at 50 MBaud).

The granularity of the output time raster is one output bit time (for example 25 ns at 40 MBaud).

The example in the following figure assumes 50 MBaud input baud rate and 40 MBaud output baud rate, f_A = 80 MHz, back to back frames.

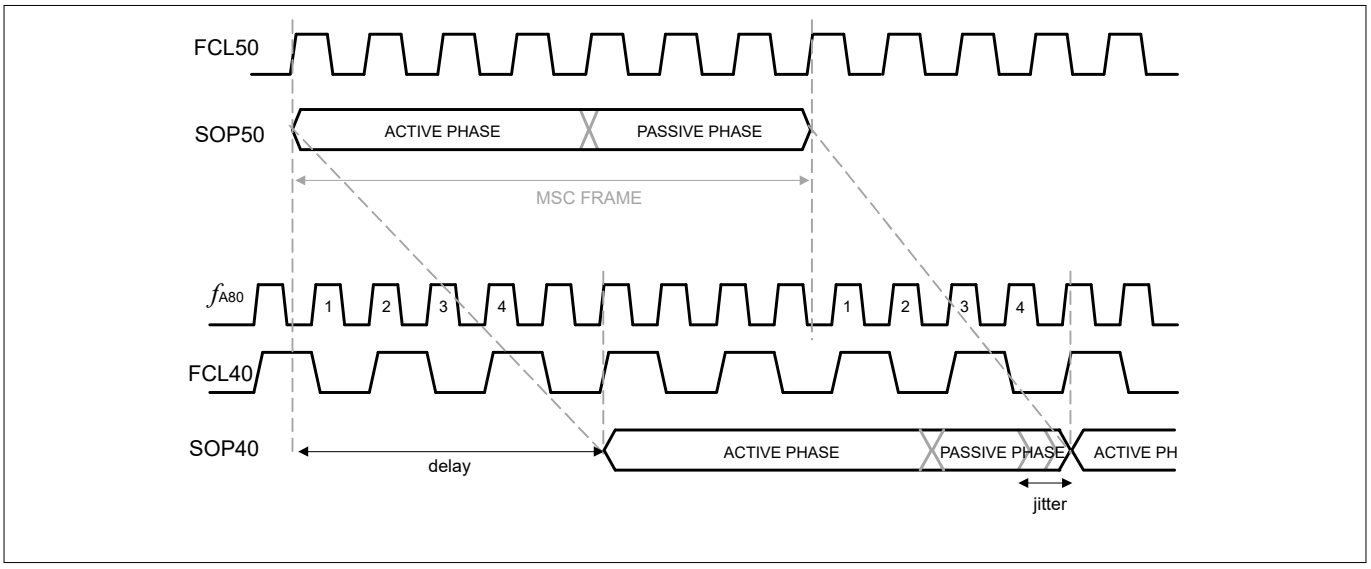

Figure 609 Frame jitter in continuous clock mode

28.3.2.5 Interrupt position with the ABRA block

The position of the MSC interrupts within a frame depends only on the internal time schedule of the MSC module in both use cases with and without the ABRA block. Therefore the interrupt position in the internal time raster is constant and is the same as in the previous versions of the MSC module and does not depend on the asynchronous baud rate which is seen on the pins.

This behavior affects only the downstream interrupts, which are:

- Data frame interrupt
- Command frame interrupt
- Time frame finished interrupt

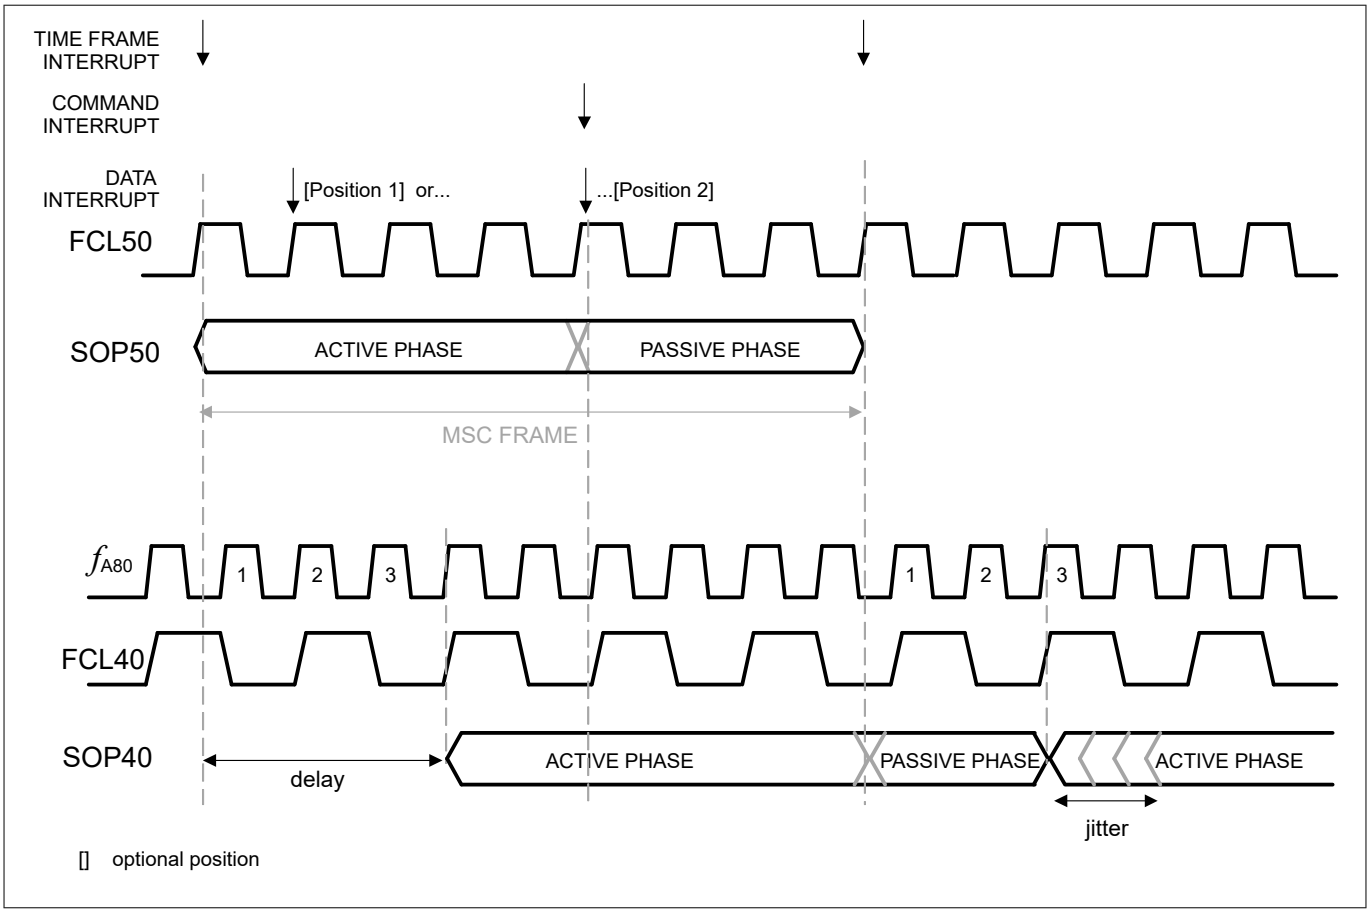

Figure 610 Interrupt position with the ABRA block

The downstream interrupts can be used for updates of the shadowed rw bit-fields for the next frame transmission. Such bit-fields are located in:

- Data register DD
- Command register DC
- Data control DSC
- Data status DSS

Due to the next-frame-update effect, the small jitter and delay effects of the frames as seen on the pins is not relevant, as well as the position of the interrupt in the asynchronous frame.

28.3.2.6 Configuring the ABRA block

This section describes all the configurable parameters of the ABRA block. They are located in the Asynchronous Block Configuration Register ABC.

Output baud rate

The ABRA block shifts out the data with a baud rate generated by dividing the clock f_A and using the bit-fields ABC.HIGH, ABC.LOW and ABC.NDA.

The high and the low time of the shift clock are generated by a separate 4-bit n-divider, each operating in the range of 1 to 16. Therefore the duty cycle can be finely configured to be 50% or any other ratio. This may provide some advantages when the communicating devices have asymmetrical timings (output delays or set-up/hold times). See the description of the bit-fields ABC.HIGH and ABC.LOW.

The output baud rate of the ABRA block is defined with the formula:

$$\text{BaudRate} = \frac{f_A}{(\text{ABC.NDA} + 1) \times (\text{ABC.LOW} + 1 + \text{ABC.HIGH} + 1)}$$

Committed baud rates

The following table defines the settings for the baud rates that are mandatory for the ABRA block for various devices. The ABRA ABC.LOW and HIGH are equal in the range of 0 to 7 and divide the f_A with 2, 4, 6, 8, 10, 12, 14, 16. The clock pre divider ABC.NDA=000_B.

The planned f_A frequencies for the various devices are the following:

160 MHz (80 MHz) and 200 MHz without FMPLL, 100 MHz with FMPLL.

This results in the following table (* baud rates above 40 MBaud are beyond the standard MSC specification):

Table 1213 Committed baud rates in MBaud

Division ratio	200 MHz	160 MHz	100 MHz	80 MHz
2	-	80,00[1)]	50,00*	40,00
4	50,00*	40,00	25,00[1)]	20,00
6	33,33	26,67[1)]	16,67	13,33
8	25,00[1)]	20,00	12,50	10,00
10	20,00	16,00	10,00	8,00
12	16,67	13,33	8,33	6,67
14	14,29	11,43	7,14	5,71
16	12,50	10,00	6,25	5,00

1) For baud rate of 80 MBaud, FM mode with NDD=0 must be used. For baud rates of 25 MBaud and 26,67 MBaud, it is recommended to use FM mode with NDD=2, so that the MSC module fills the ABRA FIFO with baud rate of 33.3 MBaud.

Continuous shift clock

As defined in the bit-field OCR.CLKCTRL, the shift clock signal can be active either:

- Only during the data transmission time
- Continuously

Overflow and underflow interrupts

If the input and the output timings of the ABRA block are not adjusted to each other, an overflow of the ABRA block will occur and an error interrupt will be triggered on line X.

Overflow occurs either if the input data rate is too high or the output data rate is too low.

The corresponding bit-fields are ABC.OVF, OFM, OIE.

Underflow occurs either if the input data rate is too low or the output data rate is too high.

The corresponding bit-fields are ABC.UNF, UFM, UIE

See also the Interrupt request compressor section.

This feature can not guarantee protection against software errors like reconfigure the baud rates in the middle of a frame.

The configuration of the ABRA block and the MSC kernel is static and the time behavior is deterministic and calculable. Therefore, an overflow/underflow event always signals some configuration error resulting in unadjusted input/output baud rate ratio (see the Adjusting the passive phase of a frame section). In normal operation and with correctly configured baud rates (clocks and clock dividers) these events do not occur.

In case of underflow/overflow event the output frame will be corrupt. The simplest solution to a sporadic event caused by a transient (noise, alpha particle) is to reset the module, reconfigure and restart the communication.

Bypass mode

If the ABRA block is not used, it is disabled and bypassed through the bit-field ABC.ABB.

Adjusting the passive phase of a frame on page 5117
Interrupt request compressor on page 5130

28.3.2.7 Implementation issues

The ABRA block operates using synchronization FIFO. The MSC module writes its serial stream to the synchronization FIFO with its serial shift clock and the same data is read out of the FIFO by using the ABRA serial shift clock, generating out of the f_A.

Three signals are being transformed: the serial shift clock, the serial data stream and the enable (chip select) signals.

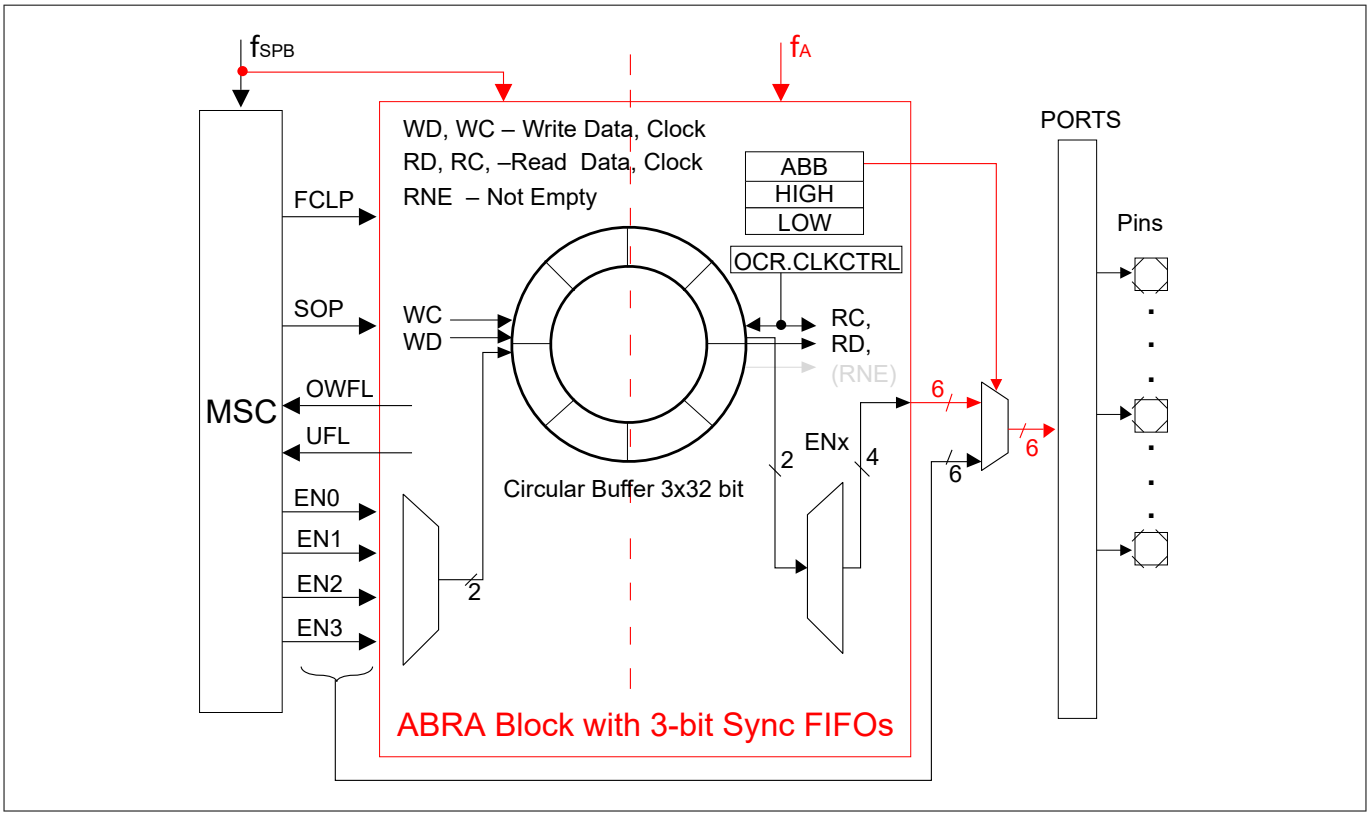

Figure 611 Implementation details of the ABRA block

28.3.2.8 ABRA disable and sleep

This section describes the behavior of the MSC module in case of:

- Switching the module on/off - disable behavior
- Power saving - Sleep mode

The main concept is to provide behavior as similar as the behavior of the MSC module without the ABRA block, as much as possible.

28.3.2.8.1 Disable and sleep behavior

There is no difference in the behavior of the module in case of entering/leaving the disable and sleep state. Disable state is controlled by a bit set/cleared by software, sleep state is controlled by a hardware signal which can be disabled or enabled.

On disable/sleep state request, the module finishes the possibly ongoing frames (downstream or upstream), then acknowledges the request and the module clock is switched off.

On leaving the disable/sleep state, the module continues with the operation at the same point where it entered the corresponding state.

Refer to the chapter Debug information for suspend behavior.

Debug information on page 5186

28.3.3 MSC interrupts

The MSC module has seven interrupt sources and five service request outputs. A service request output is able to generate interrupts or DMA requests(controlled by a service request control register). The service request output assignment, interrupt or DMA request, is specific for each microcontroller that is using the MSC. In this section, the term “interrupt request” has the meaning of “service request” that is able to handle interrupt or DMA requests.

Each interrupt source is provided with a status flag, enable bit(s) with software set/clear capability and an interrupt node pointer. An interrupt event, internally generated as a request pulse, is always stored in an interrupt status flag that is located in the Interrupt Status Register ISR. All interrupt status flags can be set or cleared individually by software through the interrupt Set Clear Register ISC. Software-controlled interrupt generation can be initiated by setting the interrupt status flag of the corresponding interrupt. Each interrupt source can be enabled or disabled individually. When an interrupt event is enabled, a 2-bit interrupt node pointer determines which of the service request outputs will be activated. See the Interrupt request compressor section.

The following table shows the seven MSC interrupt sources.

Table 1214 MSC interrupt sources

Interrupt type	Generated by
Data frame interrupt	Downstream channel
Command frame interrupt	
Time frame finished interrupt	
Receive data interrupt	Upstream channel
Upstream time-out Interrupt	
Sync FIFO overflow	ABRA block
Sync FIFO underflow	

Related information

Interrupt request compressor on page 5130

28.3.3.1 Data frame interrupt

A data frame interrupt can be generated when either the first or the last data bit of the downstream channel is shifted out and becomes available at the SO output line (see also related information). Bit ICR.EDIE selects which case is selected.

***Note**: If ICR.EDIE=10_B, an interrupt at the first data bit is only generated if DSC.NDBL is not equal 00000_B. This means, at least one SRL bit must be shifted out for the first data bit shifted interrupt to become active.*

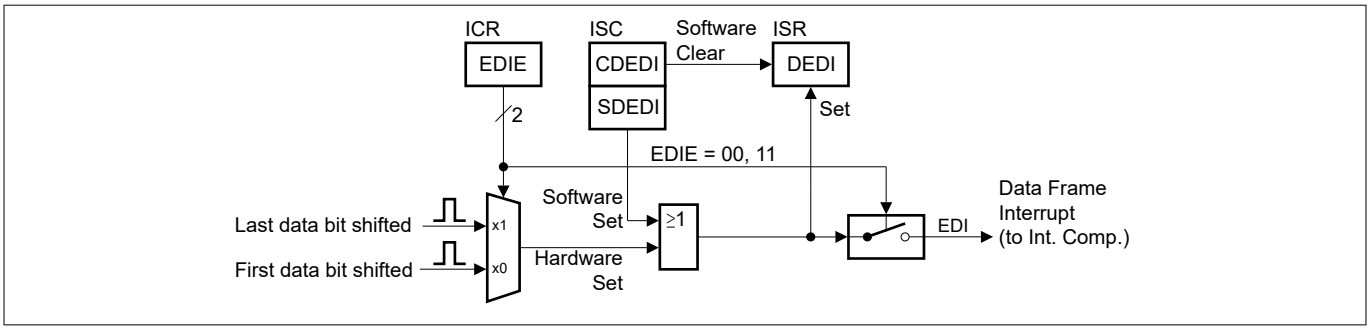

Figure 612 Data frame interrupt control

Slow Channel mode

This interrupt can also be used in Slow Channel mode.

In the figure below the behavior of the data frame interrupt in Slow Channel mode is represented.

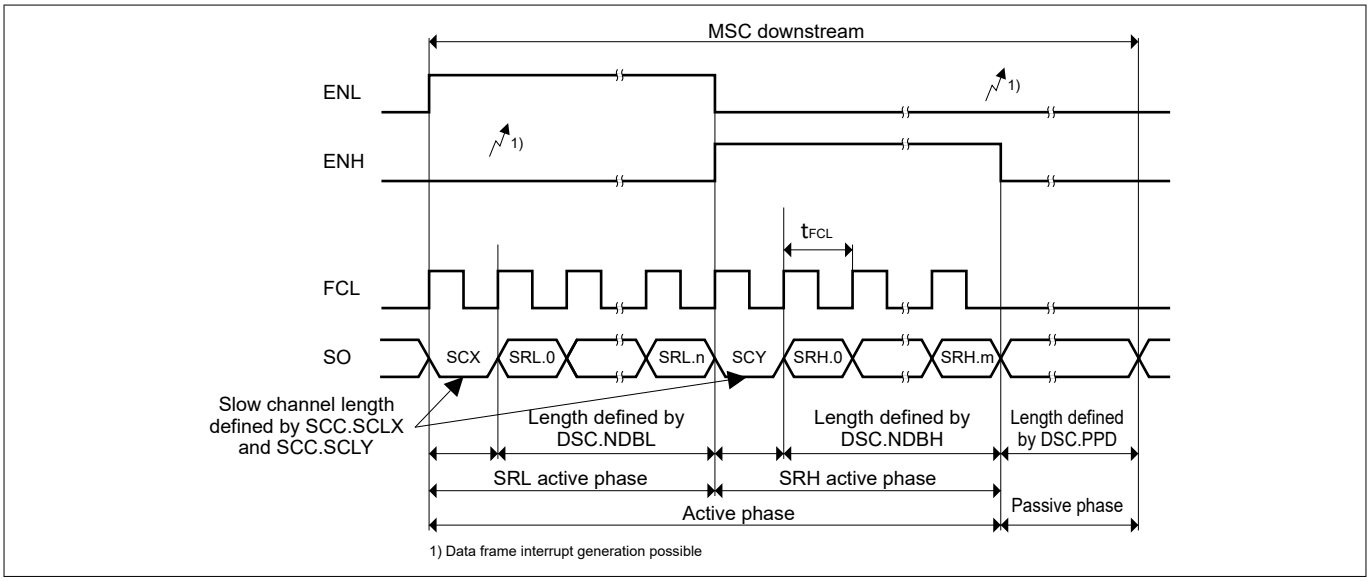

Figure 613 Data frame interrupt diagram (slow channel)

Manchester Code mode

This interrupt can also be used in Manchester Code mode.

In the figure below the behavior of the data frame interrupt in Manchester Code mode is explained. Note that Manchester Code mode can only be used in combination with slow channel.

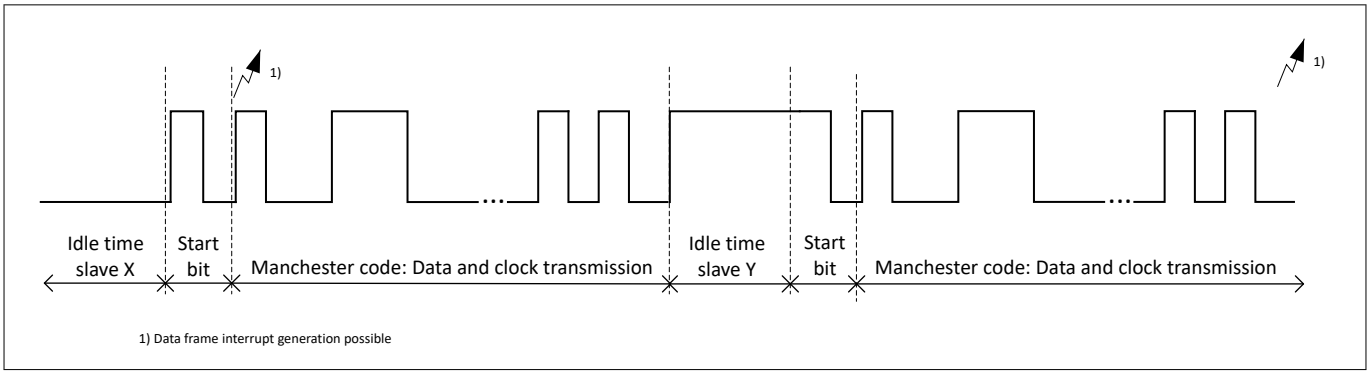

Figure 614 Data frame interrupt behavior in Manchester code mode

Related information

Frame formats and definitions on page 5082

28.3.3.2 Command frame interrupt

A command frame interrupt can be generated at the end of a downstream channel command frame, directly after the active phase, see also related information.

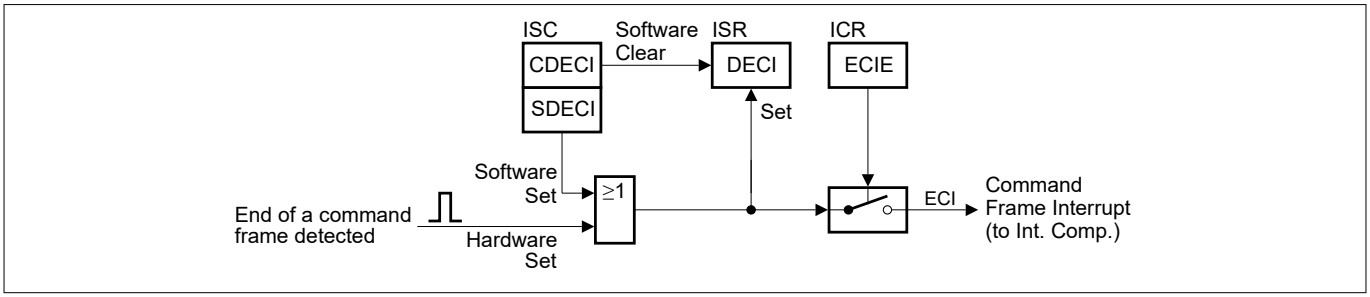

Figure 615 Command frame interrupt control

Command frame interrupts for slow channel X and Y

A command frame interrupt for slow channel X can be generated when the command frame X is moved from the DCSX register to an internal register to be shifted on the SO output and the DCSX register can be written again. This interrupt can be enabled in bit-field ICR.CSXIE. The same behavior applies to the command frame interrupt for slow channel Y, this interrupt is generated when the command frame Y is moved from the DCSY register to an internal register to be shifted on the SO output and the DCSY register can be written again. This interrupt can be enabled in bit-field ICR.CSYIE.

When the system is configured to run with only one slave, the interrupts can be configured accordingly.

In the diagrams below both interrupt generation are explained.

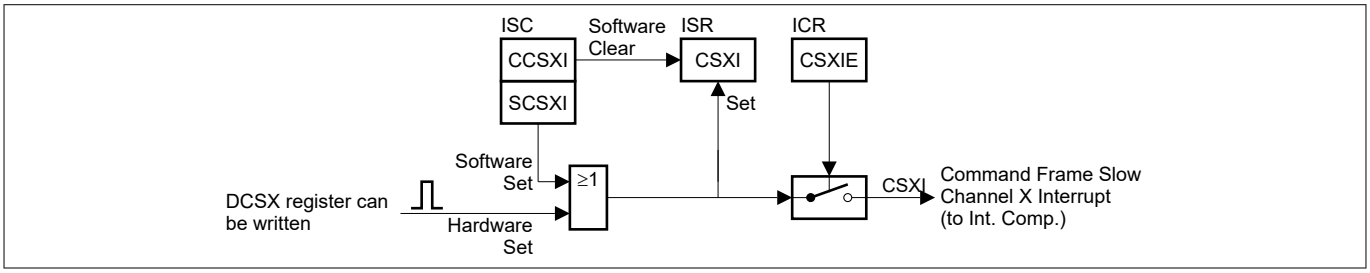

Figure 616 Command frame interrupt for slow channel X

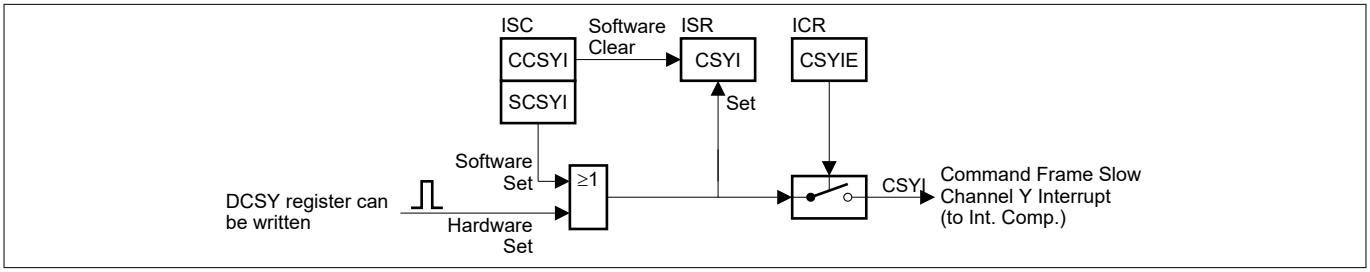

Figure 617 Command frame interrupt for slow channel Y

***Note**: This interrupt can be used in all modes that allow slow channel, in legacy with slow channel and Manchester code transmission.*

Frame formats and definitions on page 5082

28.3.3.3 Time frame finished interrupt

A time frame finished interrupt can be generated at the end of a downstream channel passive phase.

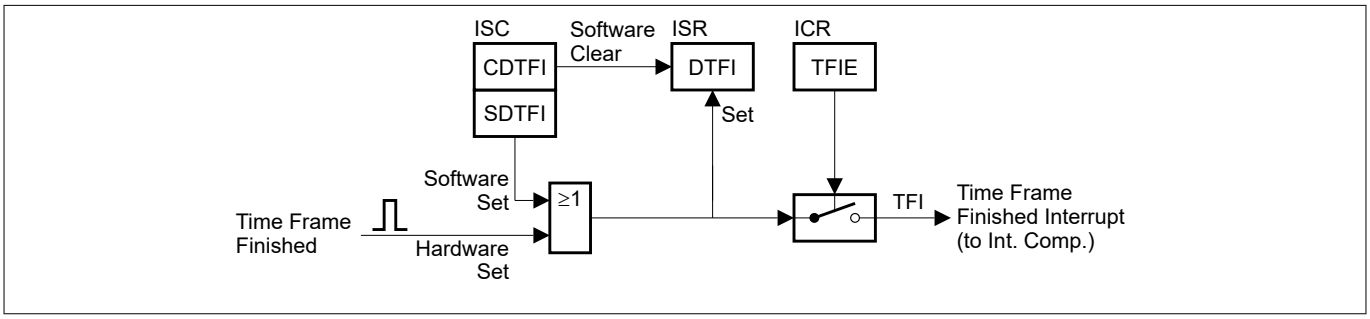

Figure 618 Time frame finished interrupt control

Slow channel mode

This interrupt can also be used in slow channel mode.

In the figure below the behavior of the time frame finished interrupt in Slow Channel mode is represented.

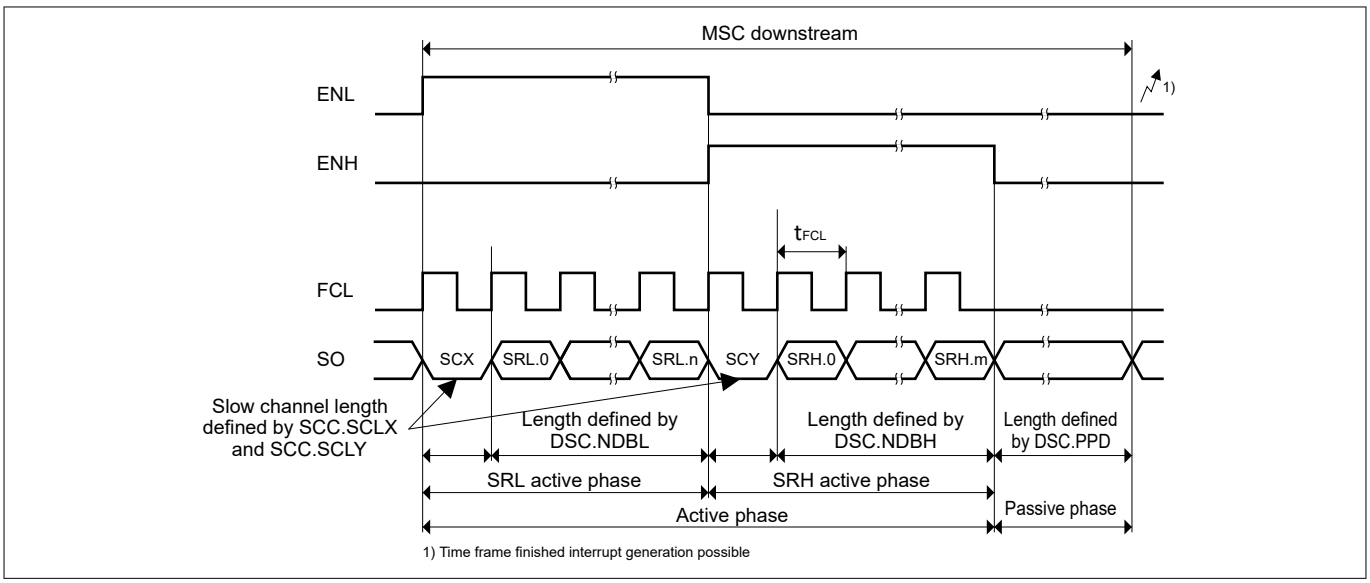

Figure 619 Time frame finished interrupt (slow channel)

Time frame finished interrupt in Manchester code mode

A time frame finished interrupt can be generated at the end of a downstream channel frame when the last bit of the downstream frame is shifted out and becomes available at the SO output.

Since the time frame finished interrupt in legacy mode is based on the passive phase and in Manchester Code mode there is no passive phase available, a new interrupt has been added for indicating the end of the frame in this mode, time frame finished Manchester code Interrupt (TFMI).

In the diagram below the interrupt generation is explained.

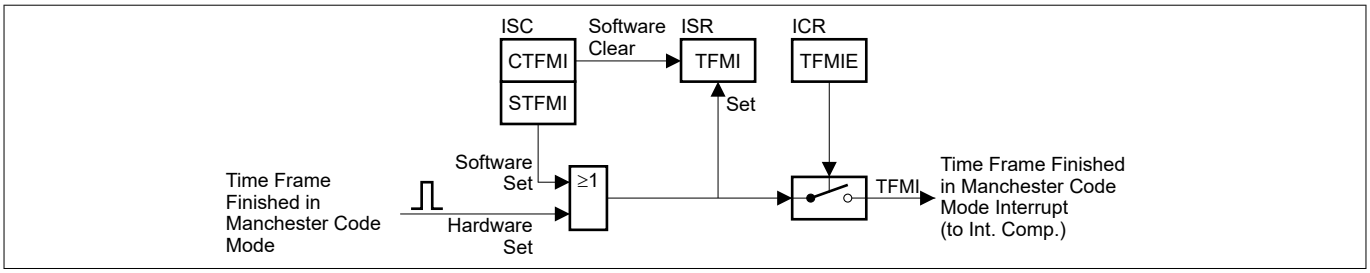

Figure 620 Time frame finished Manchester code interrupt

In the figure below the behavior of the Interrupt is explained.

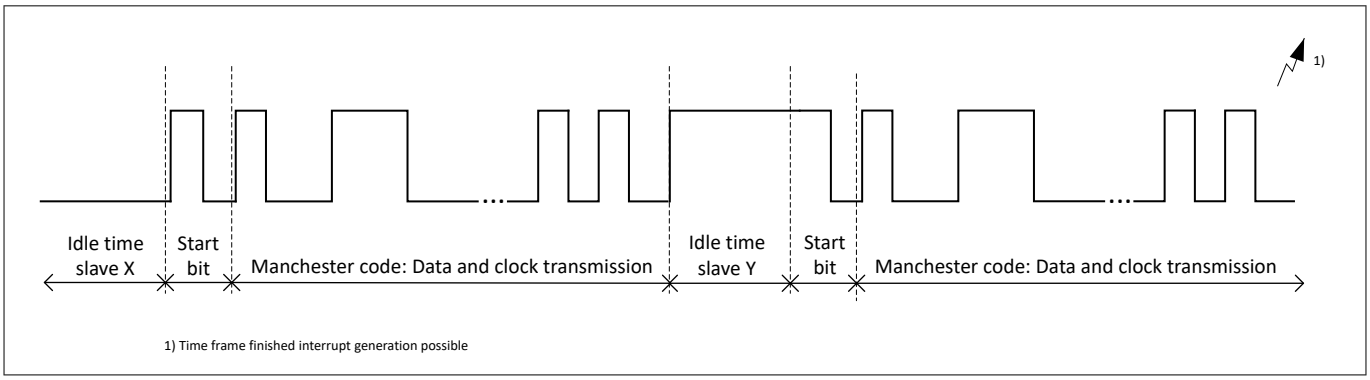

Figure 621 Time frame finished Manchester code interrupt behavior

28.3.3.4 Receive data interrupt

Whenever the upstream channel receives data in the UDx $(x = 0 - 3)$ registers, the MSC is able to generate an interrupt. Three interrupt generation conditions can be selected for the receive data interrupt:

- Each update of UDx $(x = 0 - 3)$ generates a receive data interrupt
- Each update of UDx $(x = 0 - 3)$ generates a receive data interrupt when the updated value is not equal 00_H
- Only an update of register UD3 generates a receive data interrupt

The selection of the interrupt generation condition is controlled by bit-field ICR.RDIE. Setting ICR.RDIE=0 disables the receive data interrupt in general. ISR.URDI is the interrupt status flag that can be set or cleared when writing bits ISC.SURDI or ISC.CURDI with a 1. If the fractional divider is used, then the software should clear the URDI flag by using ISC.CURDI with a delay of one bit time after the interrupt signal has been generated. The same applies to clearing the UDx.V flag via UDx.C. Otherwise, due to the latencies introduced by the fractional divider, the clear may fail.

The receive interrupt is generated either after the second Stop bit or delayed for one bit time by setting the USR.SRDC, as shown in related information.

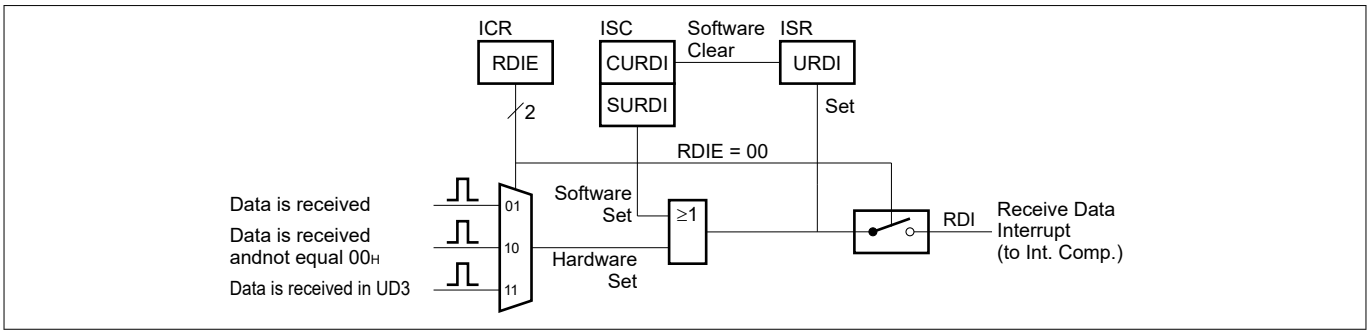

Figure 622 Receive data interrupt control

28.3.3.5 Interrupt request compressor

The interrupt control logic of the MSC uses an interrupt compressing scheme that allows high flexibility in interrupt processing. The seven interrupt sources can be directed to five service request outputs SR[4:0] as shown in the figure below. This makes it possible to connect more than one interrupt source to one interrupt output SRx.

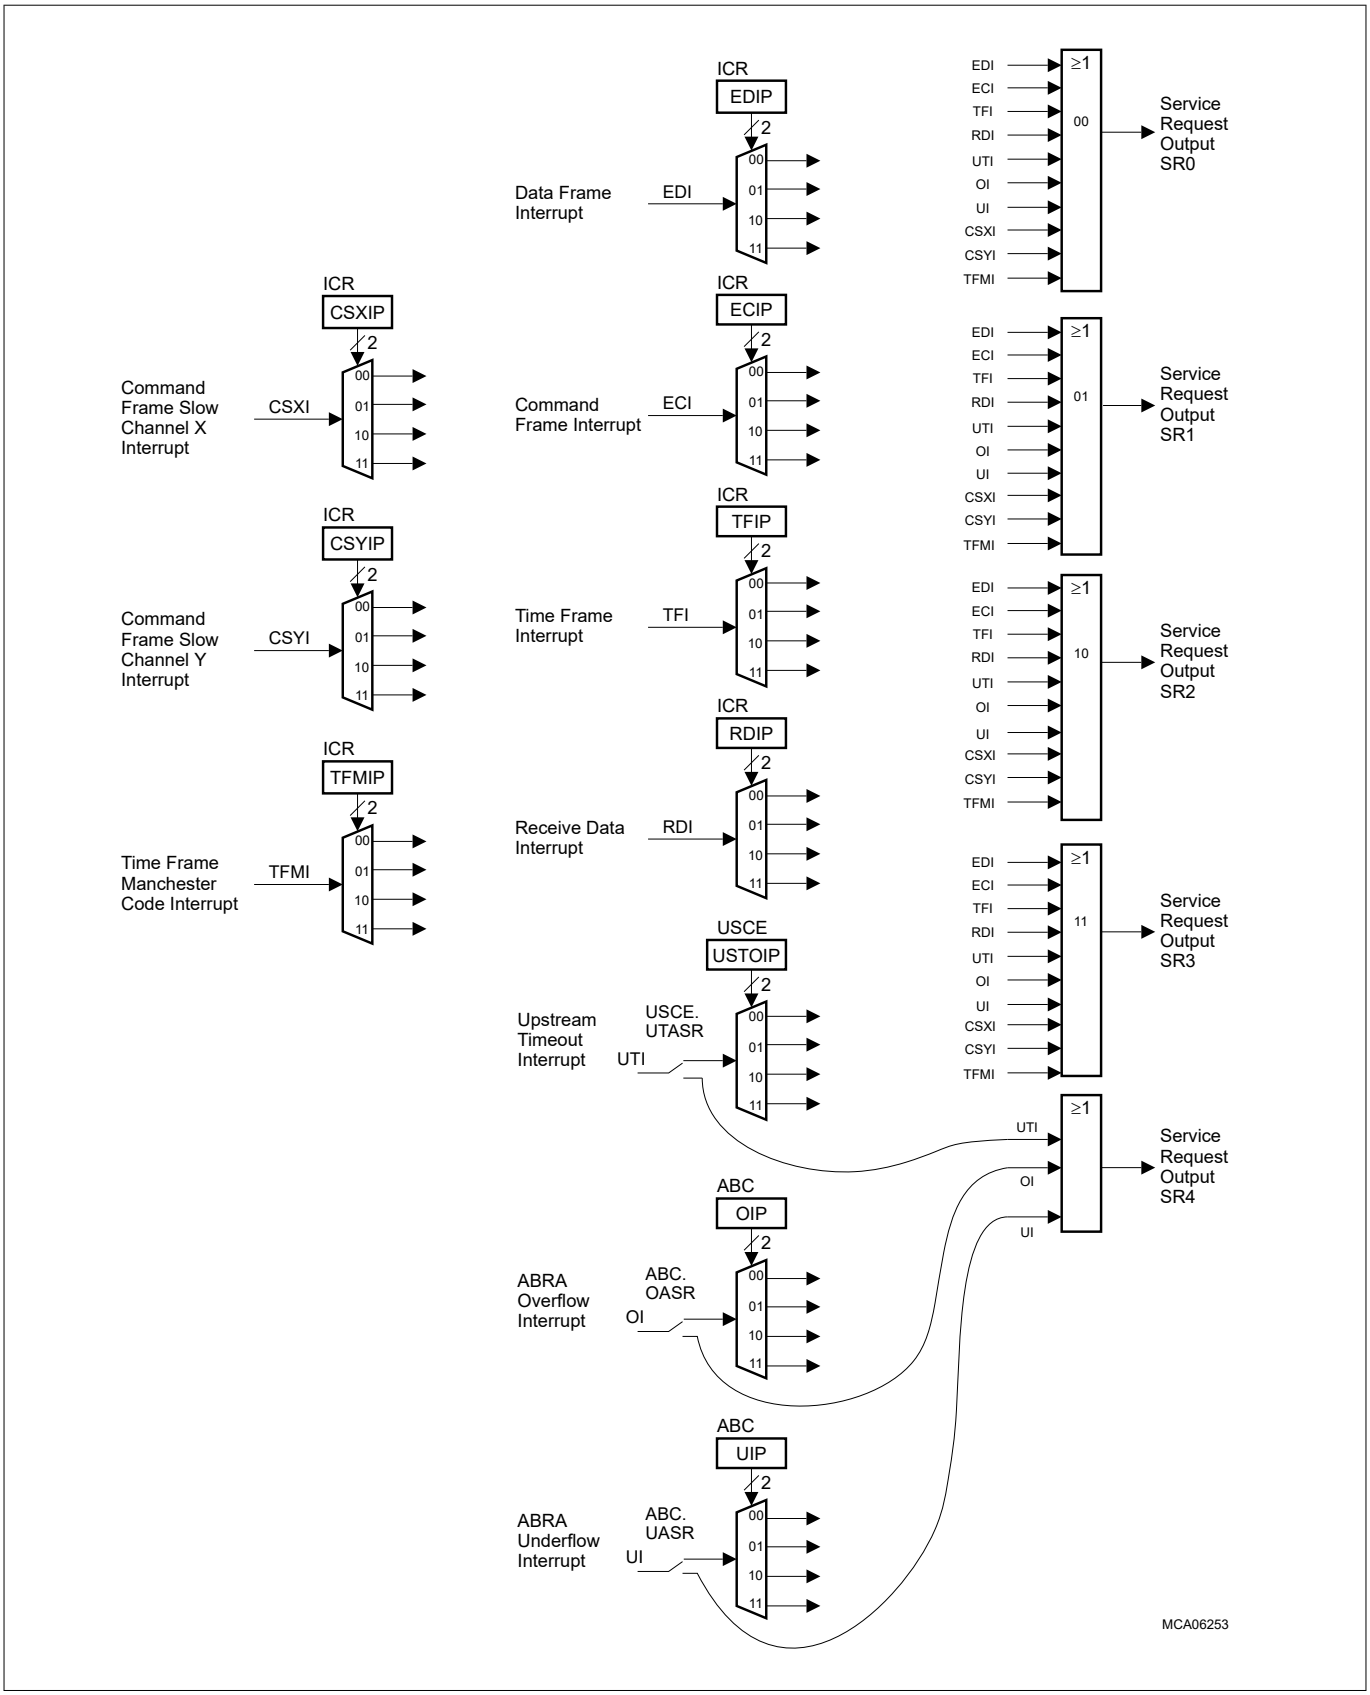

Figure 623 MSC interrupt request compressor

28.3.4 Clock control

The following section describes the clock control and the baud rate generation of the MSC module.

The MSC module is provided with two independent clock signals (see following figure):

- f_{CLC}
  This is the module clock that is used inside the MSC kernel for control purposes such as clocking of control logic and register operations. The frequency of f_{CLC} is always identical to the system clock frequency f_{SPB}. The clock control register MSC_CLC makes it possible to enable/disable f_{CLC} under certain conditions
- f_{MSC}
  This clock is the module clock that is used inside the MSC for baud rate generation of the serial upstream and downstream channel. The fractional divider register MSC_FDR controls the frequency of f_{MSC} and makes it possible to enable/disable it independent of f_{CLC}
- f_{MSCA}
  This clock is the downstream clock which is used together with the ABRA block. In this case, the upstream baud rate can be fine-tuned with the fractional divider and the downstream channel frequency is configured with an N-divider

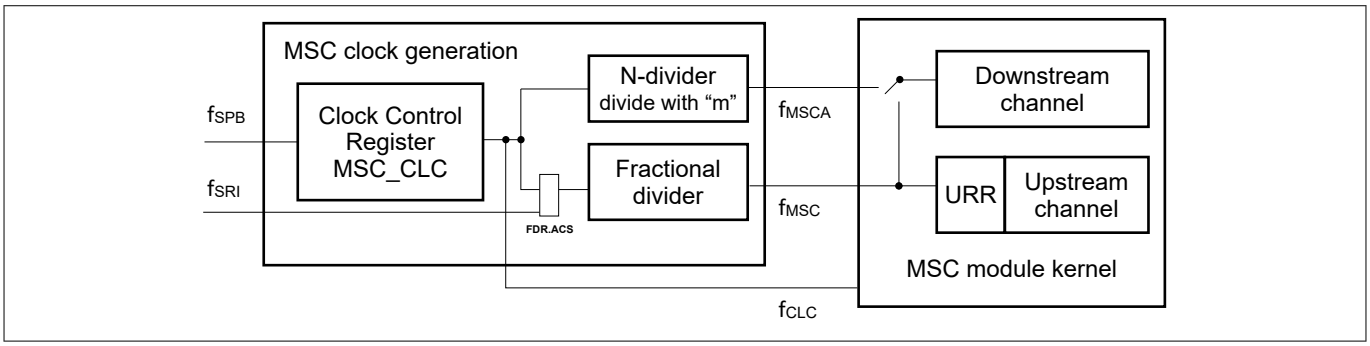

Figure 624 MSC module clock generation

28.3.4.1 Clock control without the ABRA block

Not using the ABRA block is the standard, compatibility use-case, which guarantees the full compatibility with the standard MSC module not containing the ABRA block. The clock generation is therefore identical with the standard MSC clock generation. The additional N-divider (dividing with the division factor named “m”) is not used. Only the fractional divider is used (using the factor named “n” in the formulas below).

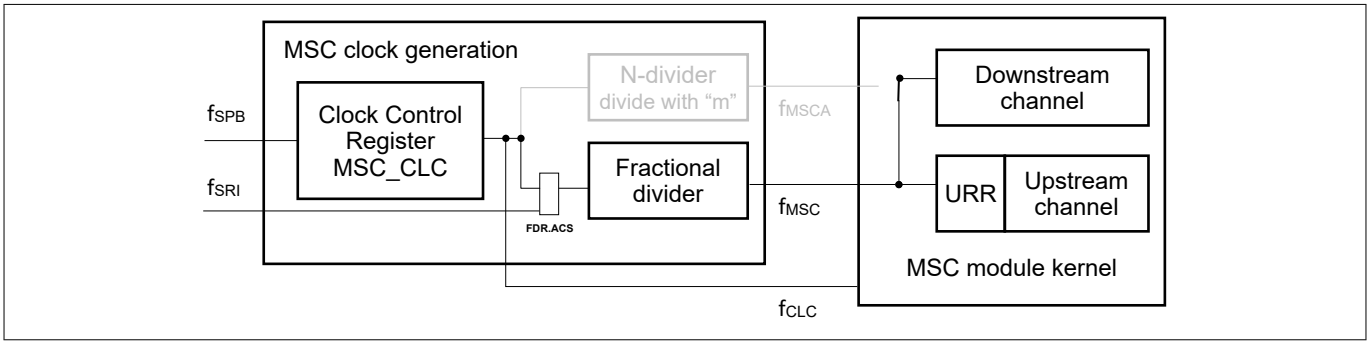

Figure 625 MSC module clock generation

To use the f_{SPB} clock source for the MSC output the bit-field FDR.ACS has to be set to 0 (default value). The following two formulas define the frequency of f_{MSC}:

$$f_{MSC} = f_{SPB} \times \frac{1}{n} \quad \text{with } n = 1024 - \text{MSC.FDR.STEP} \tag{36}$$

Valid for normal divider mode (FDR.DM=01_B)

$$f_{MSC} = f_{SPB} \times \frac{n}{1024} \quad \text{with } n = 0\text{-}1023 \tag{37}$$

Valid for fractional divider mode (FDR.DM=10_B)

The f_{SRI} clock source is synchronous to the f_{SPB} clock. To use the f_{SRI} clock source for the MSC output the bit-field FDR.ACS has to be activated and set to 1. The following two formulas define the frequency of f_{MSC}:

$$f_{MSC} = f_{SRI} \times \frac{1}{n} \quad \text{with } n = 1024 - \text{MSC.FDR.STEP} \tag{38}$$

Valid for normal divider mode (FDR.DM=01_B) and f_{SRI} clock source

$$f_{MSC} = f_{SRI} \times \frac{n}{1024} \quad \text{with } n = 0\text{-}1023 \tag{39}$$

Valid for fractional divider mode (FDR.DM=10_B) and f_{SRI} clock source

***Note**: The behavior is undefined when the configuration of FDR.ACS is changed in between an ongoing transaction*

Downstream channel baud rate

As the clock signal FCL of the synchronous downstream channel is always half the frequency of f_{MSC}, the resulting downstream channel baud rate is defined by:

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{1}{2 \times (1024 - \text{MSC.FDR.STEP})} \tag{40}$$

Valid for normal divider mode (FDR.DM=01_B)

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{\text{MSC.FDR.STEP}}{2 \times 1024} \tag{41}$$

Valid for fractional divider mode (FDR.DM=10_B)

$$\text{Baud rate}_{MSC} = f_{SRI} \times \frac{1}{2 \times (1024 - \text{MSC.FDR.STEP})} \tag{42}$$

Valid for normal divider mode (FDR.DM=01_B) and f_{SRI} clock source

$$\text{Baud rate}_{MSC} = f_{SRI} \times \frac{\text{MSC.FDR.STEP}}{2 \times 1024} \tag{43}$$

Valid for fractional divider mode (FDR.DM=10_B) and f_{SRI} clock source

Upstream channel baud rate

The baud rate of the asynchronous upstream channel is derived from the module clock f_{MSC} by a programmable clock divider selected by bit-field USR.URR (see also the equation in the Upstream channel baud rate section). The divide factor DF can be at minimum 4 and at maximum 256. The following formulas can be used for both configurations FDR.ACS set to 0 and FDR.ACS set to 1. In case FDR.ACS set to 1, f_{SRI} clock source is used as a substitute for f_{SPB}.

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{1}{DF \times (1024 - \text{MSC.FDR.STEP})} \quad (44)$$

Valid for normal divider mode (FDR.DM=01_B)

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{\text{MSC.FDR.STEP}}{DF \times 1024} \quad (45)$$

Valid for fractional divider mode (FDR.DM=10_B)

Related information

Upstream channel baud rate on page 5100

28.3.4.2 Clock control when using the ABRA block

Using the ABRA block makes additional considerations regarding the baud-rate adjustments necessary.

An additional N-divider DSTE.NDD is used for configuring the intermediate downstream baud rate the MSC module is using for writing to the ABRA block (dividing the f_{SPB} with the integer division factor named “m” in the formulas below). The final output downstream baud rate is configured in the ABRA block itself. The following restriction applies: the ABRA output downstream baud rate is between half and whole intermediate baud rate.

When the ABRA block is active, the fractional divider FDR.STEP is used only for adjusting the upstream baud rate (using the factor named “n” in the formulas below).

In case FDR.ACS set to 1, f_{SRI} clock source is used as a substitute for f_{SPB}.

Attention*: *The following restriction applies: the upstream baud rate must be less than one tenth of the f_{SPB}. See also related information.

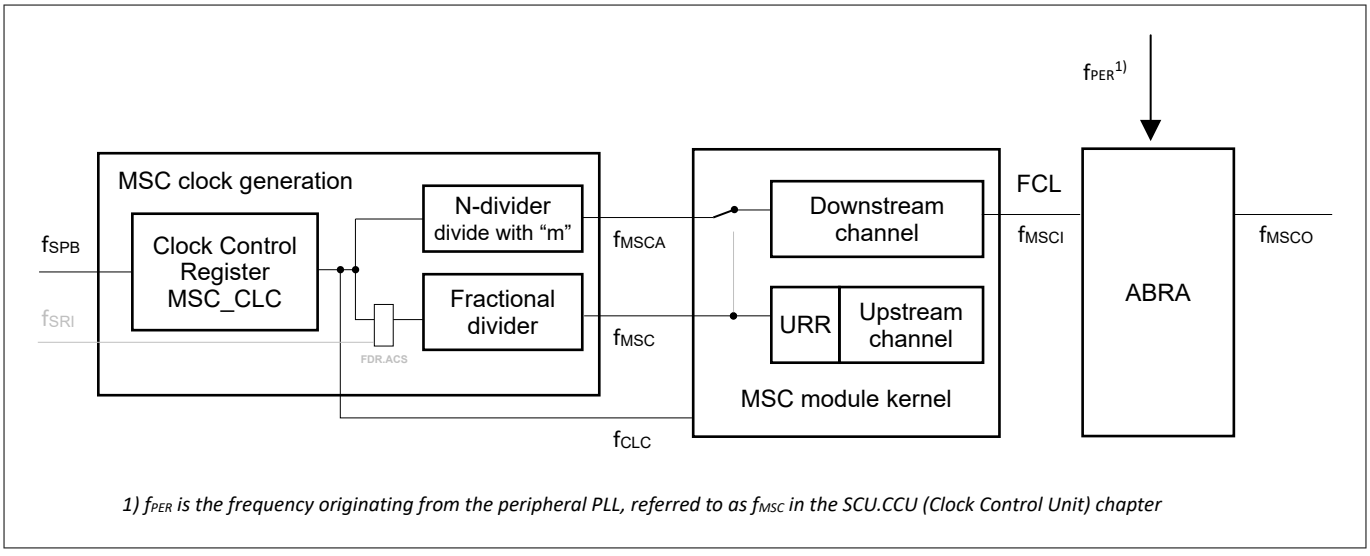

Figure 626 MSC module clock generation

The following two formulas define the frequency of f_{MSC}:

$$f_{MSC} = f_{SPB} \times \frac{1}{n} \quad \text{with } n = 1024 - \text{MSC.FDR.STEP} \tag{46}$$

Valid for normal divider mode (FDR.DM=01_B)

$$f_{MSC} = f_{SPB} \times \frac{n}{1024} \quad \text{with } n = 0\text{-}1023 \tag{47}$$

Valid for fractional divider mode (FDR.DM=10_B)

The following formula defines the frequency of f_{MSCA}:

$$f_{MSCA} = f_{SPB} \times \frac{1}{m} \quad \text{with } m = 1 - 16 \tag{48}$$

Intermediate downstream channel baud rate

When the ABRA block and the downstream N-divider are enabled with ABC.ABB, the intermediate clock signal FCL with frequency f_{MSCI} of the synchronous downstream channel going into the ABRA block is always half the frequency of f_{MSCA}:

$$\text{Baud rate}_{MSCI} = f_{SPB} \times \frac{1}{2 \times m} \tag{49}$$

The final output baud rate f_{MSCO} can be calculated as described in Output baud rate.

Upstream channel baud rate

The baud rate of the asynchronous upstream channel is derived from the module clock f_{MSC} by a programmable clock divider selected by bit-field USR.URR (see also equation 3 in related information, chapter upstream channel baud rate). The divide factor DF can be at minimum 4 and at maximum 256. Nevertheless, the minimum DF factor when using ABRA block should be 8. See the note in the chapter Upstream channel (related information).

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{1}{\text{DF} \times (1024 - \text{MSC.FDR.STEP})} \tag{50}$$

Valid for normal divider mode (FDR.DM=01_B)

$$\text{Baud rate}_{MSC} = f_{SPB} \times \frac{\text{MSC.FDR.STEP}}{\text{DF} \times 1024} \tag{51}$$

Valid for fractional divider mode (FDR.DM=10_B)

Example for setting the fractional divider

This example shows how to receive upstream frames generated from 40 MHz downstream clock, when the module baud-rate frequency is $\frac{100\,\text{MHz}}{2} = 50\,\text{MHz}$. The fractional divider is used to adjust the FCL clock of 50 MHz to FCL clock of 40 MHz, that is, it multiplies with $\frac{4}{5}$. The best approximation of $\frac{4}{5}$ with $\frac{x}{1024}$ is for $x = 819$, giving an error of 0.025%. So in this case, the optimal setting for FDR.STEP is 819. In the next stage of

the divider cascade, the DF power-of-two-divider divides the clock further to the final baud rate, matching the baud rate generated by the MSC slave device.

28.3.4.3 Baud rate configuration

This section describes the available baud rates for the various devices.

The planned f_{MSC} frequencies are the following:

- f_{SPB} (The f_{SPB} depends on the system configuration and this is 100 MHz)
- f_{SRI}. (The f_{SRI} depends on the system configuration and this is 400 MHz or 500 MHz)

This results in the following table:

Table 1215 Baud rate configuration

Division ratio	f_{SRI} = 500 MHz	f_{SRI} = 400 MHz	f_{SPB} = 100 MHz
2	-	-	50.00
4	-	-	25.00
6	-	-	16.67
8	-	50	12.50
10	50	40	10.00
12	41.6	33.34	8.33
14	35.71	28.57	7.14
16	31.25	25	6.25

These baud rates are bypassing ABRA. The available baud rates using ABRA are already listed in the related chapter.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DM		0			ACS	STEP									
rw		r			rw	rw									

Field	Bits	Type	Description
STEP	9:0	rw	**Step Value** Reload or addition value for RESULT.
ACS	10	rw	**Alternate Clock Source** ACS selects the clock source for the MSC Output. 0_B Source clock for MSC Output f_{SPB}. 1_B Source clock for MSC Output f_{SRI}.
DM	15:14	rw	**Divider Mode** DM selects normal or fractional divider mode. 00_B Fractional divider is switched off; no output clock is generated. The Reset External Divider signal is 1. RESULT is not updated (default after System Reset). 01_B Normal divider mode 10_B Fractional divider mode 11_B Fractional divider is switched off; no output clock is generated. RESULT is not updated.
RESULT	25:16	rh	**Result Value** Bit field for the addition result.

(table continues...)

(continued)

Field	Bits	Type	Description
DISCLK	31	rwh	**Disable Clock** Hardware controlled disable for f_{MSC} signal. 0_B Enable 1_B Disable
0	13:11, 30:26	r	**Reserved** Read as 0; should be written with 0.

28.4.18 Upstream status register

The Upstream Status Register is used to configure the upstream channel data format, baud rate and parity type. It also provides the status information of the upstream counter (UC).

USR Offset address: 044_H

Upstream status register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0											UC				
r											rh

0										SRDC	PCTR	URR			UFT
r										rw	rw	rw			rw

Field	Bits	Type	Description
UFT	0	rw	**Upstream Channel Frame Type** This bit determines the frame type used by the upstream channel for data reception. 0_B 12-bit upstream frame selected 1_B 16-bit upstream frame selected (with 4-bit address field)
URR	3:1	rw	**Upstream Channel Receiving Rate** This bit field determines the baud rate for the upstream channel. 000_B Upstream channel disabled; no reception is possible 001_B Baud rate = f_{MSC} /4 010_B Baud rate = f_{MSC} /8 011_B Baud rate = f_{MSC} /16 100_B Baud rate = f_{MSC} /32 101_B Baud rate = f_{MSC} /64 110_B Baud rate = f_{MSC} /128 111_B Baud rate = f_{MSC} /256

(table continues...)

(continued)

Field	Bits	Type	Description
PCTR	4	rw	**Parity Control** This bit determines the parity mode used by the upstream channel for data reception. 0_B Even parity mode is selected. A parity bit is set on an odd number of 1s in the serial address/data stream. 1_B Odd parity mode is selected. A parity bit is set on an even number of 1s in the serial address/data stream.
SRDC	5	rw	**Service Request Delay Control** This bit determines the additional delay inserted by the upstream channel when triggering the receive interrupt. Only the hardware generated interrupt can be delayed. The software generated interrupt by writing the ISC.SURDI bit is never delayed. 0_B No delay 1_B Delay of 1 bit time
UC	20:16	rh	**Upstream Counter** This bit field indicates the content of the upstream counter that counts the bits during upstream channel reception.
0	15:6, 31:21	r	**Reserved** Read as 0; should be written with 0.

28.4.19 Downstream control register

The Downstream Control Register is used to control the operation mode and frame layout of the downstream channel transmission. It also contains the two pending status bits.

The “rw” bits in the DSC register are buffered in a shadow buffer at the start of a corresponding frame transmission.

If the asynchronous mode (ABC.ABB=1) is enabled and no data-bit (zero data-bits) in a data frame is configured (DSC.NDBL=DSC.NDBH=00000), then the first select-bit must be set to active (DSC.ENSELL=1).

DSC Offset address: 048_H

Downstream control register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		ALTSEL	PPD					0		NBC					
r		rw	rw					r		rw					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DSDIS	ENSELH	ENSELL	NDBH					NDBL					DP	CP	TM
rh	rw	rw	rw					rw					rh	rh	rw

Field	Bits	Type	Description
TM	0	rw	**Transmission Mode** This bit selects the transmission mode of the downstream channel. 0_B Triggered Mode selected 1_B Data Repetition Mode selected
CP	1	rh	**Command Pending** This bit is set when the downstream command register DC is written. CP is cleared when the first bit of the related command frame is sent out.
DP	2	rh	**Data Pending** In Triggered Mode, this bit is set when the set data pending bit ISC.SDP is set by software. In Data Repetition Mode, this bit is set by hardware at the last passive time frame. At the start of the data frame, DP is cleared by hardware.
NDBL	7:3	rw	**Number of SRL Bits Shifted at data frames** NDBL determines the number of shift register low part (SRL) bits that are shifted out on SO during a data frame. Other bit combinations are reserved; do not use these bit combinations. 00_H No SRL bit shifted 01_H SRL[0:0] shifted … 10_H SRL[15:0] shifted **others,** reserved
NDBH	12:8	rw	**Number of SRH Bits Shifted at data frames** NDBH determines the number of shift register high part (SRH) bits that are shifted out on SO during a data frame. Other bit combinations are reserved; do not use these bit combinations. 00_H No SRH bit shifted; no selection bit is generated, the SRH active phase is completely skipped. 01_H SRH[0:0] shifted … 10_H SRH[15:0] shifted **others,** reserved
ENSELL	13	rw	**Enable SRL Active Phase Selection Bit** This bit determines whether a low level selection bit is inserted at the beginning of a data frame's SRL active phase. 0_B No selection bit inserted. 1_B Low level selection bit inserted.
ENSELH	14	rw	**Enable SRH Active Phase Selection Bit** This bit determines whether a low level selection bit is inserted at the beginning of a data frame's SRH active phase. 0_B No selection bit inserted. 1_B Low level selection bit inserted.

(table continues...)

(continued)

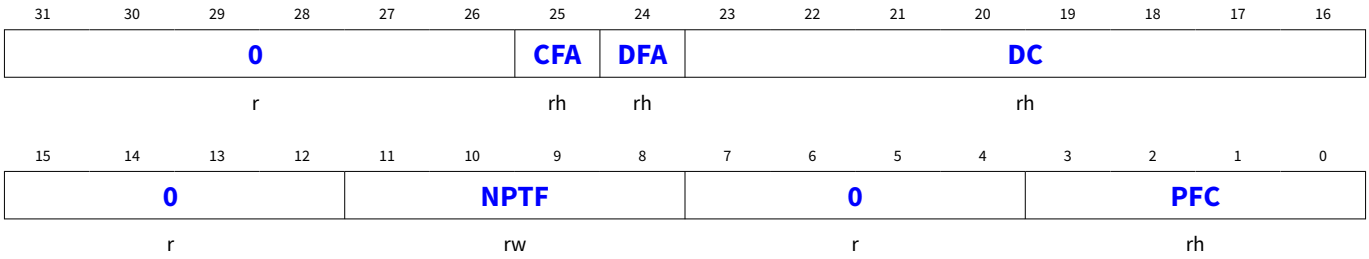
Field	Bits	Type	Description
DSDIS	15	rh	**Downstream Disable** This bit indicates the state of the downstream channel operation. 0_B The downstream channel is enabled. A frame transmission can take place (Triggered Mode) or takes place (Data Repetition Mode). 1_B Downstream Counter becomes disabled. No new frame transmission is started. A running frame transmission is always completed.
NBC	21:16	rw	**Number of Bits Shifted at command frames** This bit field determines how many bits of the SRL/SRH shift registers are shifted out during transmission of a command frame. 00_H No bit shifted 01_H SRL[0:0] shifted … 10_H SRL[15:0] shifted 11_H SRL[15:0] and SRH[0:0] shifted … 20_H SRL[15:0] and SRH[15:0] shifted **others,** reserved
PPD	28:24	rw	**Passive Phase Length at data frames** This bit field determines the length of the passive phase of a data frame. 00_H Passive phase length is 2 x t_FCL for value 0 … 02_H Passive phase length is 2 x t_FCL for value 2 03_H Passive phase length is 3 x t_FCL … $1F_H$ Passive phase length is 31 x t_FCL
ALTSEL	29	rw	**Alternative Input Timer Selection** This bit-field selects the input source, GTM or eGTM, for the ALTINL, ALTINH, ALTINLE and ALTINHE. 0_B GTM input selected. 1_B eGTM input selected.
0	23:22, 31:30	r	**Reserved** Read as 0; should be written with 0.

28.4.20 Downstream status register

The Downstream Status Register DSS contains counter bit fields, status bits and indicates the number of passive time frames.

DSS Offset address: $04C_H$

Downstream status register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PFC	3:0	rh	**Passive Time Frame Counter** In Data Repetition Mode, this bit field indicates the count of passive time frames that are currently transmitted. In Triggered Mode PFC remains at 0000_B. 0_H Data frame is transmitted. 1_H 1st passive time frame is transmitted. 2_H 2th passive time frame is transmitted. … F_H 15th passive time frame is transmitted.
NPTF	11:8	rw	**Number Of Passive Time Frames** This bit field indicates the number of passive time frames that are inserted in Data Repetition Mode between two data frames. 0_H No passive time frame inserted. 1_H 1 passive time frame inserted. 2_H 2 passive time frames inserted. … F_H 15 passive time frames inserted.
DC	23:16	rh	**Downstream Counter** This bit field indicates the number of downstream shift clock periods that have been elapsed since the start of the current frame. DC is reset at the end of a downstream frame. 00_H No shift clock elapsed (after counter reset). 01_H 1 shift clock elapsed. 02_H 2 shift clocks elapsed. … FF_H 255 shift clocks elapsed.
DFA	24	rh	**Data Frame Active** This bit indicates if a data frame is currently sent out, active phase only. 0_B No data frame is currently sent out. 1_B A data frame is currently sent out.
CFA	25	rh	**Command Frame Active** This bit indicates if a command frame is currently sent out, active phase only. 0_B No command frame is currently sent out. 1_B A command frame is currently sent out.

(table continues...)

(continued)

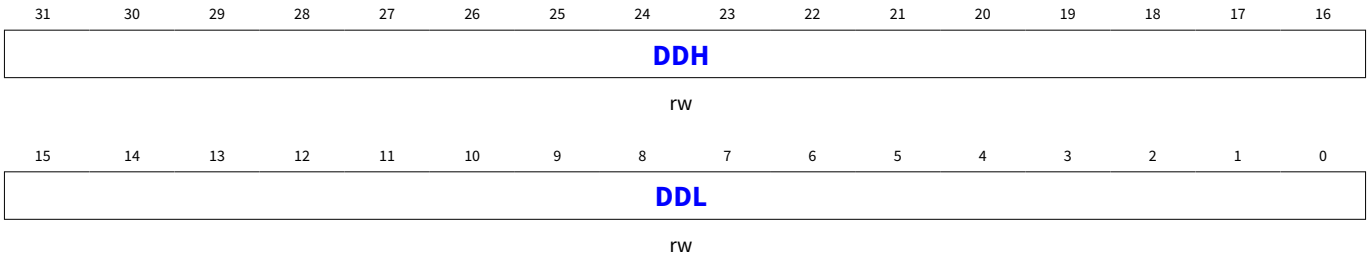
Field	Bits	Type	Description
0	7:4, 15:12, 31:26	r	**Reserved** Read as 0; shall be written with 0.

28.4.21 Downstream data register

The Downstream Data Register DD contains data to be transmitted during data frames.

DD Offset address: 050_H

Downstream data register Kernel Reset value: $0000\ 0000_H$



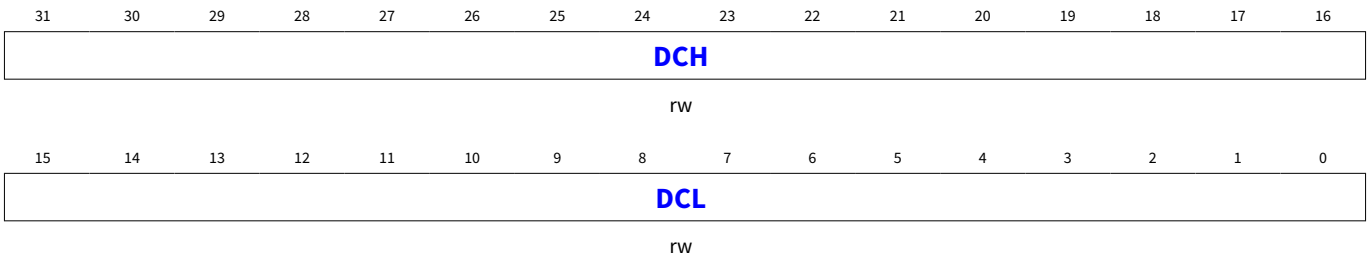
Field	Bits	Type	Description
DDL	15:0	rw	**Downstream Data for SRL Shift Register** Contains the data bits to be transmitted during the SRL active phase of a data frame.
DDH	31:16	rw	**Downstream Data for SRH Shift Register** Contains the data bits to be transmitted during the SRH active phase of a data frame.

28.4.22 Downstream command register

The Downstream Command Register DC contains command information to be transmitted during command frames. Every write access to the DC register triggers a transmission of a command frame.

DC Offset address: 054_H

Downstream command register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DCL	15:0	rw	**Downstream Command for SRL Shift Register** Contains the data bits to be transmitted during the SRL active phase of a command frame.
DCH	31:16	rw	**Downstream Command for SRH Shift Register** Contains the data bits to be transmitted during the SRH active phase of a command frame.

28.4.23 Downstream select data source low register

The bit fields of the Downstream Select Data Source Low Register DSDSL determine the data source for each bit in shift register SRL.

DSDSL Offset address: 058_H

Downstream select data source low register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
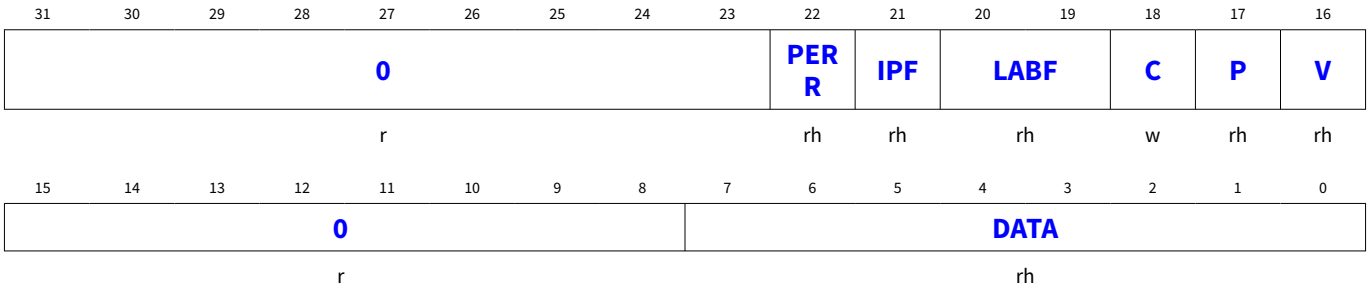
ENLx (x=0-15)	x	rw	**Emergency Stop Enable for Bit x in SRL** This bit enables the emergency stop feature selectively for each SRL bit. If the emergency stop condition is met and enabled (ENLx = 1), the SRL[x] bit of the data register DD.DDL[x] is used for the shift register load operation. 0_B Emergency stop feature for bit SRL[x] is disabled. 1_B The emergency stop feature for bit SRL[x] is enabled.
ENHx (x=0-15)	x+16	rw	**Emergency Stop Enable for Bit x in SRH** This bit enables the emergency stop feature selectively for each SRH bit. If the emergency stop condition is met and enabled (ENHx = 1), the SRH[x] bit of the data register DD.DDH[x] is used for the shift register load operation. 0_B Emergency stop feature for bit SRH[x] is disabled. 1_B The emergency stop feature for bit SRH[x] is enabled.

28.4.26 Upstream data register x

The four Upstream Data Registers UDx store the content (data, addresses, received and calculated parity bit, parity error bit) of a received upstream channel data frame.

UDx (x=0-3) Offset address: 070_H+x*4

Upstream data register x Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DATA	7:0	rh	**Received Data** This bit field contains the 8-bit receive data.
V	16	rh	**Valid Bit** This bit is set by hardware when the received data is written to UDx. Writing bit C = 1 clears V. If hardware setting and software clearing of the valid bit occur simultaneously, bit V will be cleared.
P	17	rh	**Parity Bit** This flag contains the parity bit that has been received with the data frame.
C	18	w	**Clear Bit** C is always read as 0. 0_B No operation. 1_B Bit V is cleared.
LABF	20:19	rh	**Lower Address Bit Field** This bit field contains the two address bits A[1:0] of the 4-bit address field (16-bit data frame). If 12-bit data frame is selected, LABF is always set to 00_B.
IPF	21	rh	**Internal Parity Flag** This bit contains the parity bit that has been calculated in the MSC during data frame reception.
PERR	22	rh	**Error bit- PERR** This bit indicates if a start bit error, parity error or stop bit error occurred during frame reception. 0_B No error detected. 1_B Error detected.
0	15:8, 31:23	r	**Reserved** Read as 0; should be written with 0.

28.4.27 Interrupt control register

The Interrupt Control Register ICR holds the interrupt enable bits and interrupt pointers of all seven MSC interrupts.

ICR Offset address: 080_H

Interrupt control register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r									rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
DEDI	0	rh	**Data Frame Interrupt Flag** This flag is always set by hardware when a downstream channel data frame interrupt is generated. DEDI can be set or cleared by software when writing to register ISC with the appropriate bits ISC.SDEDI or ISC.CDEDI set.

(table continues...)

(continued)

Field	Bits	Type	Description
DECI	1	rh	**Command Frame Interrupt Flag** This flag is always set by hardware when a downstream channel command frame interrupt is generated, whether or not it is enabled. DECI can be set or cleared by software when writing to register ISC with the appropriate bits SDECI or CDECI set.
DTFI	2	rh	**Time Frame Interrupt Flag** This flag is always set by hardware when a downstream channel time frame interrupt is generated, whether or not it is enabled. DTFI can be set or cleared by software when writing to register ISC with the appropriate bits SDTFI or CDTFI set.
URDI	3	rh	**Receive Data Interrupt Flag** This flag is always set by hardware when an upstream channel receive data interrupt is generated, whether or not it is enabled. URDI can be set or cleared by software when writing to register ISC with the appropriate bits SURDI or CURDI set.
CSXI	4	rh	**Command Frame Slow Channel X Interrupt Flag** This flag is always set by hardware when a downstream channel command frame interrupt in Slow Channel mode is generated. CSXI can be set or cleared by software when writing to register ISC with the appropriate bits ISC.SCSXI or ISC.CCSXI set.
CSYI	5	rh	**Command Frame Slow Channel Y Interrupt Flag** This flag is always set by hardware when a downstream channel command frame interrupt in Slow Channel mode is generated. CSYI can be set or cleared by software when writing to register ISC with the appropriate bits ISC.SCSYI or ISC.CCSYI set.
TFMI	6	rh	**Time Frame Manchester Code Interrupt Flag** This flag is always set by hardware when a downstream channel command frame interrupt in Slow Channel mode is generated. TFMI can be set or cleared by software when writing to register ISC with the appropriate bits ISC.STFMI or ISC.CTFMI set.
0	31:7	r	**Reserved** Read as 0.

28.4.29 Interrupt set clear register

The Interrupt Set Clear Register ISC is used to set or clear the MSC interrupt flags located in the Interrupt Status Register ISR. Reading ISC always returns 0000 0000_H.

***Note**: When the ISC register is written with both bits (set and clear bit) for a specific interrupt flag, the clear operation takes place and the set operation is ignored.*

ISC Offset address: 088_H

Interrupt set clear register Kernel Reset value: 0000 0000_H

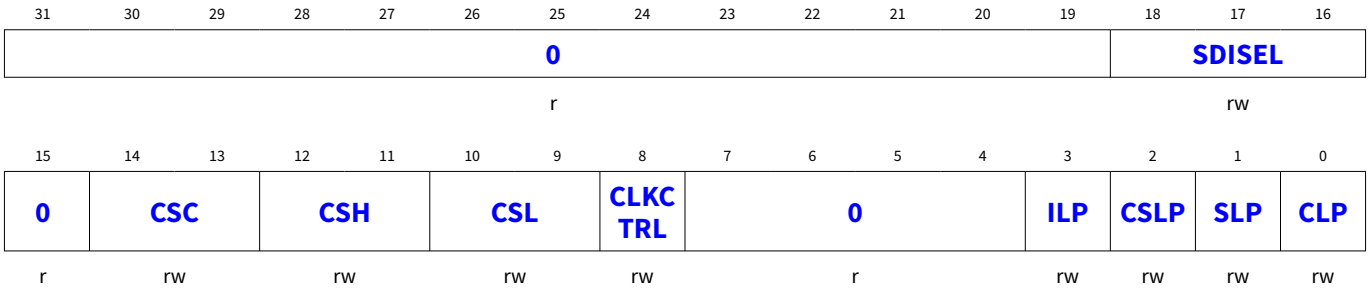
28.4.30 Output control register

The Output Control Register OCR determines the MSC input/output signal polarities, the chip select output signal assignment and the serial output clock generation.

OCR Offset address: $08C_H$

Output control register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CLP	0	rw	**FCLP Line Polarity** 0_B FCLP and FCL signal polarity is identical. FCLN signal has inverted FCL signal polarity. 1_B FCLP signal has inverted FCL signal polarity. FCLN and FCL signal polarities are identical.
SLP	1	rw	**SOP Line Polarity** This bit determines the polarity configuration of SON, SOP and SO. Also determines the Manchester encoding method to be used. 0_B SOP and SO signal polarity is identical. SON signal has inverted SO signal polarity. G.E. Thomas manchester encoding is used. 1_B SOP signal has inverted SO signal polarity. SON and SO signal polarities are identical. IEEE enconding is used.
CSLP	2	rw	**Chip Selection Lines Polarity** Bit CSLP is buffered during a frame transmission. This means that any change of CSLP becomes valid first with the start of the next frame transmission. 0_B EN[3:0] and ENL, ENH, ENC signal polarities are identical (high active). 1_B EN[3:0] signal polarities are inverted (low active) to the ENL, ENH, ENC signal polarities.
ILP	3	rw	**SDI Line Polarity** 0_B SDI and SI signal polarities are identical. 1_B SDI and SI signal polarities are inverted.
CLKCTRL	8	rw	**Clock Control** This bit determines the activation of clock output FCL. 0_B FCL is activated only during the active phases of data or command frames (not during passive time frames). 1_B FCL is always active whether or not a downstream frame is currently transmitted.

(table continues...)

(continued)

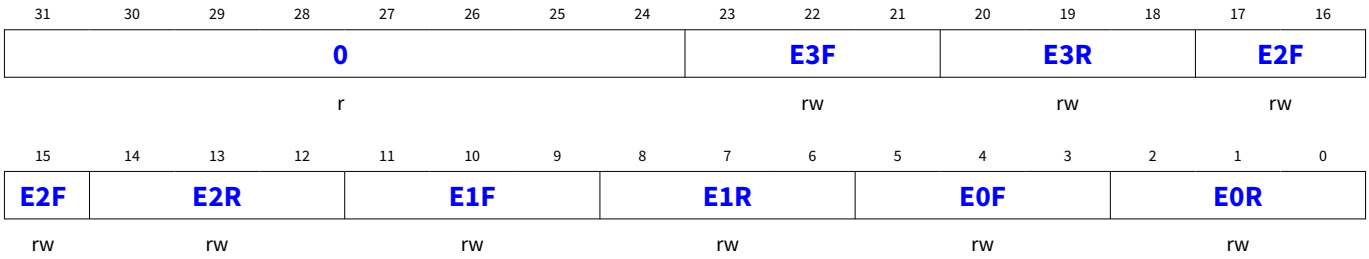
Field	Bits	Type	Description
CSL	10:9	rw	**Chip Enable Selection for ENL** This bit field selects the chip enable output ENx that becomes active during the SRL active phase (ENL = 1) of a data frame. The active level of ENx is defined by bit CSLP. 00_B EN0 line is selected for ENL. 01_B EN1 line is selected for ENL. 10_B EN2 line is selected for ENL. 11_B EN3 line is selected for ENL.
CSH	12:11	rw	**Chip Enable Selection for ENH** This bit field selects the chip enable output ENx that becomes active during the SRH active phase (ENH = 1) of a data frame. The active level of ENx is defined by bit CSLP. 00_B EN0 line is selected for ENH. 01_B EN1 line is selected for ENH. 10_B EN2 line is selected for ENH. 11_B EN3 line is selected for ENH.
CSC	14:13	rw	**Chip Enable Selection for ENC** This bit field selects the chip enable output ENx that becomes active during the active phase (ENC = 1) of a command frame. The active level of ENx is defined by bit CSLP. 00_B EN0 line is selected for ENC. 01_B EN1 line is selected for ENC. 10_B EN2 line is selected for ENC. 11_B EN3 line is selected for ENC.
SDISEL	18:16	rw	**Serial Data Input Selection** This bit field selects the source for the serial data input SDI of the upstream channel. 000_B SDI0 input is selected for SDI. 001_B SDI1 input is selected for SDI. 010_B SDI2 input is selected for SDI. 011_B SDI3 input is selected for SDI. 100_B SDI4 input is selected for SDI. 101_B SDI5 input is selected for SDI. 110_B SDI6 input is selected for SDI. 111_B SDI7 input is selected for SDI.
0	7:4, 15, 31:19	r	**Reserved** Read as 0; should be written with 0.

28.4.31 Output extended control register

The Output Extended Control Register OCER determines the MSC enable output signal adjustment.

OECR Offset address: 090_H

Output extended control register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
E0R	2:0	rw	**Downstream Enable 1/2 Clock Time Adjustment Assertion (Rising Edge, EN0)** This bit field selects the configuration adjustment of 0, 1 or 2 steps of ½ clock time-period at assertion. 000_B 0 Step of ½ clock period before edge adjustment. 001_B 1 Step of ½ clock period before edge adjustment. 010_B 2 Step of ½ clock period before edge adjustment. 011_B 1 Step of ½ clock period after edge adjustment. 100_B 2 Steps of ½ clock period after edge adjustment. **others,** reserved
E0F	5:3	rw	**Downstream Enable 1/2 Clock Time Adjustment Deassertion (Falling Edge,EN0)** This bit field selects the configuration adjustment of 0, 1 or 2 steps of ½ clock time-period at deassertion. 000_B 0 Step of ½ clock period before edge adjustment. 001_B 1 Step of ½ clock period before edge adjustment. 010_B 2 Step of ½ clock period before edge adjustment. 011_B 1 Step of ½ clock period after edge adjustment. 100_B 2 Steps of ½ clock period after edge adjustment. **others,** reserved
E1R	8:6	rw	**Downstream Enable 1/2 Clock Time Adjustment Assertion (Rising Edge, EN1)** This bit field selects the configuration adjustment of 0, 1 or 2 steps of ½ clock time-period at assertion. 000_B 0 Step of ½ clock period before edge adjustment. 001_B 1 Step of ½ clock period before edge adjustment. 010_B 2 Step of ½ clock period before edge adjustment. 011_B 1 Step of ½ clock period after edge adjustment. 100_B 2 Steps of ½ clock period after edge adjustment. **others,** reserved

(table continues...)

(continued)

Field	Bits	Type	Description
E1F	11:9	rw	**Downstream Enable 1/2 Clock Time Adjustment Deassertion (Falling Edge,EN1)** This bit field selects the configuration adjustment of 0, 1 or 2 steps of ½ clock time-period at deassertion. 000_B 0 Step of ½ clock period before edge adjustment. 001_B 1 Step of ½ clock period before edge adjustment. 010_B 2 Step of ½ clock period before edge adjustment. 011_B 1 Step of ½ clock period after edge adjustment. 100_B 2 Steps of ½ clock period after edge adjustment. **others,** reserved
E2R	14:12	rw	**Downstream Enable 1/2 Clock Time Adjustment Assertion (Rising Edge, EN2)** This bit field selects the configuration adjustment of 0, 1 or 2 steps of ½ clock time-period at assertion. 000_B 0 Step of ½ clock period before edge adjustment. 001_B 1 Step of ½ clock period before edge adjustment. 010_B 2 Step of ½ clock period before edge adjustment. 011_B 1 Step of ½ clock period after edge adjustment. 100_B 2 Steps of ½ clock period after edge adjustment. **others,** reserved
E2F	17:15	rw	**Downstream Enable 1/2 Clock Time Adjustment Deassertion (Falling Edge,EN2)** This bit field selects the configuration adjustment of 0, 1 or 2 steps of ½ clock time-period at deassertion. 000_B 0 Step of ½ clock period before edge adjustment. 001_B 1 Step of ½ clock period before edge adjustment. 010_B 2 Step of ½ clock period before edge adjustment. 011_B 1 Step of ½ clock period after edge adjustment. 100_B 2 Steps of ½ clock period after edge adjustment. **others,** reserved
E3R	20:18	rw	**Downstream Enable 1/2 Clock Time Adjustment Assertion (Rising Edge, EN3)** This bit field selects the configuration adjustment of 0, 1 or 2 steps of ½ clock time-period at assertion. 000_B 0 Step of ½ clock period before edge adjustment. 001_B 1 Step of ½ clock period before edge adjustment. 010_B 2 Step of ½ clock period before edge adjustment. 011_B 1 Step of ½ clock period after edge adjustment. 100_B 2 Steps of ½ clock period after edge adjustment. **others,** reserved

Field	Bits	Type	Description
SC	0	rw	**Slow Channel** This bit field enables the Slow Channel (embedded command frame into data frame) for 2 slaves. 0_B Slow Channel is disabled. 1_B Slow Channel is enabled for both slaves.
MCT	1	rw	**Manchester Code Transmission MSC+** This bits enables the Manchester Encoding transmission. Note that the Manchester code transmission can only be set in combination with an active Slow Channel. 0_B Manchester code transmission is disabled. 1_B Manchester code transmission is enabled.

(table continues...)

(continued)

Field	Bits	Type	Description
SCLX	4:2	rw	**Slow Channel Length for Slave X** This bit field determines the number of slow channel X bits which precede the data frame. This bit field has no effect if the Slow Channel is not enabled (SCC.SC). 000_B Slow Channel length is 0 bits. 001_B Slow Channel length is 1 bit. 010_B Slow Channel length is 2 bits. 011_B Slow Channel length is 4 bits. 100_B Slow Channel length is 8 bits. 101_B Slow Channel length is 16 bits. 110_B Slow Channel length is 32 bits. **others,** reserved
SCLY	7:5	rw	**Slow Channel Length for Slave Y** This bit field determines the number of slow channel Y bits which precede the data frame. This bit field has no effect if the Slow Channel is not enabled (SCC.SC). 000_B Slow Channel length is 0 bits. 001_B Slow Channel length is 1 bit. 010_B Slow Channel length is 2 bits. 011_B Slow Channel length is 4 bits. 100_B Slow Channel length is 8 bits. 101_B Slow Channel length is 16 bits. 110_B Slow Channel length is 32 bits. **others,** reserved
CFLX	13:8	rw	**Command Frame Length for Slave X** This bit field determines the length of the command frame data (excluding start, parity and stop bits). This bit field has no effect if the Slow Channel is not enabled (SCC.SC). 00_H Slow channel command frame length is 0 bits 01_H Slow channel command frame length is 1 bits … 20_H Slow channel command frame length is 32 bits **others,** reserved
CFLY	19:14	rw	**Command Frame Length for Slave Y** This bit field determines the length of the command frame data (excluding start, parity and stop bits). This bit field has no effect if the Slow Channel is not enabled (SCC.SC). 00_H Slow channel command frame length is 0 bits 01_H Slow channel command frame length is 1 bits … 20_H Slow channel command frame length is 32 bits **others,** reserved

(table continues...)

(continued)

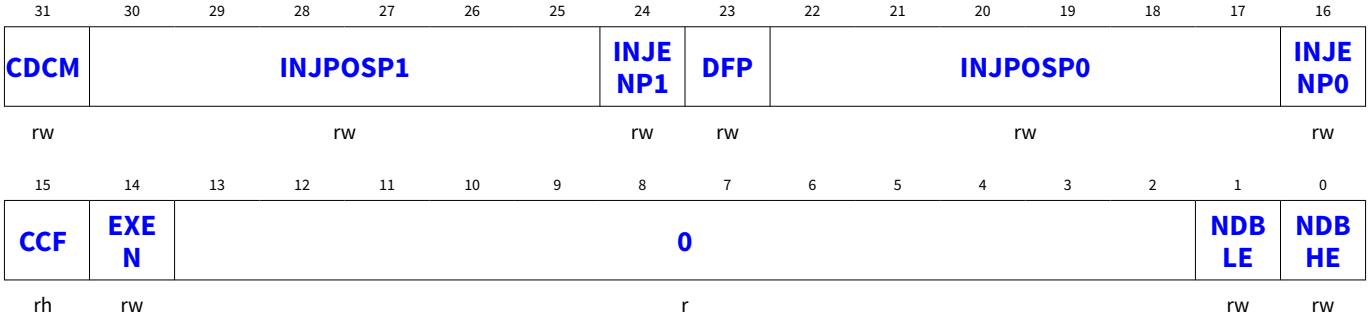
Field	Bits	Type	Description
PCX	21:20	rw	**Paritiy Control for command frame Slave X** This bit field enables the parity for the command frame transmission on Slave X when Slow Channel mode is enabled. This bit field has no effect if the Slow Channel is not enabled (SCC.SC). 00_B Parity OFF. 01_B Even parity ON. 10_B Odd parity ON. **others,** reserved
PCY	23:22	rw	**Paritiy Control for command frame Slave Y** This bit field enables the parity for the command frame transmission on Slave Y when Slow Channel mode is enabled. This bit field has no effect if the Slow Channel is not enabled (SCC.SC). 00_B Parity OFF. 01_B Even parity ON. 10_B Odd parity ON. **others,** reserved
CFSTOPX	25:24	rw	**Command Frame Stop Bits Slave X** This bit field enables and selects the stop bit options for the command frame transmission on Slave X. 00_B no stop bits 01_B 1 stop bit 10_B 2 stop bits **others,** reserved
CFSTOPY	27:26	rw	**Command Frame Stop Bits Slave Y** This bit field enables and selects the stop bit options for the command frame transmission on Slave Y. 00_B no stop bits 01_B 1 stop bit 10_B 2 stop bits **others,** reserved
0	31:28	r	**Reserved** Read as 0; should be written with 0.

28.4.33 Downstream control enhanced register

The Downstream Control Enhanced Register is used to control the enhanced operation mode and frame layout of the downstream channel transmission.

DSCE Offset address: 098_H

Downstream control enhanced register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
NDBHE	0	rw	**Number of SRH Bits Shifted at data frames Extension** Additional MSB bit extension of the DSC.NDBH bit field. Adds 16 to the resulting DSC.NDBH value if set.
NDBLE	1	rw	**Number of SRL Bits Shifted at data frames Extension** Additional MSB bit extension of the DSC.NDBL bit field. Adds 16 to the resulting DSC.NDBL value if set.
EXEN	14	rw	**Extension Enable** Enables the extension bit fields. 0_B Disabled 1_B Enabled
CCF	15	rh	**Command-Command Flag** This bit flags that a second command frame has been written without data frame to be sent in between. It is active only if CDCM=1. Otherwise it is always low. 0_B no second command 1_B second command frame pending
INJENP0	16	rw	**Injection Enable of the Pin 0 Signal** This bit selects if an external signal is injected in a data frame. 0_B Disabled 1_B Enabled
INJPOSP0	22:17	rw	**Injection Position of the Pin 0 Signal** This bit selects the position of the injected external one bit signal, at the bit position in range of 0 to 63 in the data frame. If both INJPOSP0 and INJPOSP1 point to a same bit, INJPOSP0 has the higher priority, that is only INJ0 level will be visible in the data frame.
DFP	23	rw	**Data Frame over command frame Prioritization** This bits selects if the data frame has priority over command frame, in both modes: Triggered mode and Data Repetition mode. In Manchester Code transmission mode, while using the Slow Channel for transmiting the command frame this bit-filed has no effect. 0_B Data Frame prioritization over command frame disabled. 1_B Data Frame prioritization over command frame enabled.

(table continues...)

(continued)

Field	Bits	Type	Description
INJENP1	24	rw	**Injection Enable of the Pin 1 Signal** This bit selects if an external signal is injected in a data frame. 0_B Disabled 1_B Enabled
INJPOSP1	30:25	rw	**Injection Position of the Pin 1 Signal** This bit selects the position of the injected external one bit signal, at the bit position in range of 0 to 63 in the data frame. If both INJPOSP0 and INJPOSP1 point to a same bit, INJPOSP0 has the higher priority, that is INJ0 level will be visible in the data frame.
CDCM	31	rw	**Command-Data-Command in Data Repetition Mode** This bit selects if a data frame is automatically inserted between two consecutive command frame requests. 0_B Automatic data insertion disabled 1_B Automatic data insertion enabled
0	13:2	r	**Reserved** Read as 0; should be written with 0.

28.4.34 Upstream control enhanced register

The Upstream Control Enhanced Register is used to control the upstream channel time-out feature.

USCE Offset address: $09C_H$

Upstream control enhanced register Kernel Reset value: $0000\ 00FF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USTOIP		UTASR	0	USTS	USTC	USTF	USTOEN	USTOVAL				USTOPRE			
rw		rw	r	w	w	rh	rw	rw				rw			

Field	Bits	Type	Description
USTOPRE	3:0	rw	**Upstream Time-out Prescaler** Prescaler for the upstream time-out limit. Expressed in upstream bit times. 2^n divider in the range of 1 to 16384. Write to this bit field triggers new start of the watchdog timer. 0_H 1 … E_H 16384 F_H reserved

(table continues...)

(continued)

Field	Bits	Type	Description
USTOVAL	7:4	rw	**Upstream Time-out Value** Upstream time-out value for the N-divider in the range of 1 to 16, expressed in number of upstream bit time lengths (the upstream bit time is the reciprocal value of the upstream baud rate). Time-out = BitTime * $2^{(USTOPRE+1)}$ * (USTOVAL+1). Write to this bit field triggers new start of the watchdog timer.
USTOEN	8	rw	**Upstream Time-out Interrupt Enable** Enable bit for the upstream time-out interrupt. The Time-out counter runs continuously independently of the USTOEN bit. The USTOEN enables only the interrupt generation. 0_B Disabled 1_B Enabled
USTF	9	rh	**Upstream Time-out Flag** Signals an upstream timer event. If set by software, the interrupt is also triggered, if enabled. The watchdog timer runs continuously and sets the USTF flag at overflow, independently from the enable bit. Therefore this bit must be cleared with the same write access which enables the interrupt. 0_B Disabled 1_B Enabled
USTC	10	w	**Upstream Time-out Clear** Clears the USTF flag. Write only bit, reads as 0. 0_B No action 1_B Clear
USTS	11	w	**Upstream Time-out Set** Sets the USTF flag. Write only bit, reads as 0. 0_B No action 1_B Set
UTASR	13	rw	**Upstream Time-out Alternate Service Request** Selects if the interrupt signal is routed to the alternate service request node. Refer to interrupt request compressor. 0_B SR Multiplexer selected 1_B Alternate Service Request Node (SR4) selected
USTOIP	15:14	rw	**Upstream Time-out Interrupt Node Pointer** USTOIP selects the service request output line SRn (n = 0-3) for the time-out interrupt. 00_B Service request output SR0 selected 01_B Service request output SR1 selected 10_B Service request output SR2 selected 11_B Service request output SR3 selected
0	12, 31:16	r	**Reserved** Read as 0; should be written with 0.

28.4.35 Downstream select data source low extension register

The bit fields of the Downstream Select Data Source Low Extension Register DSDSLE determine the data source for the upper 16 bits in the shift register SRL.

DSDSLE Offset address: $0A0_H$

Downstream select data source low extension register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
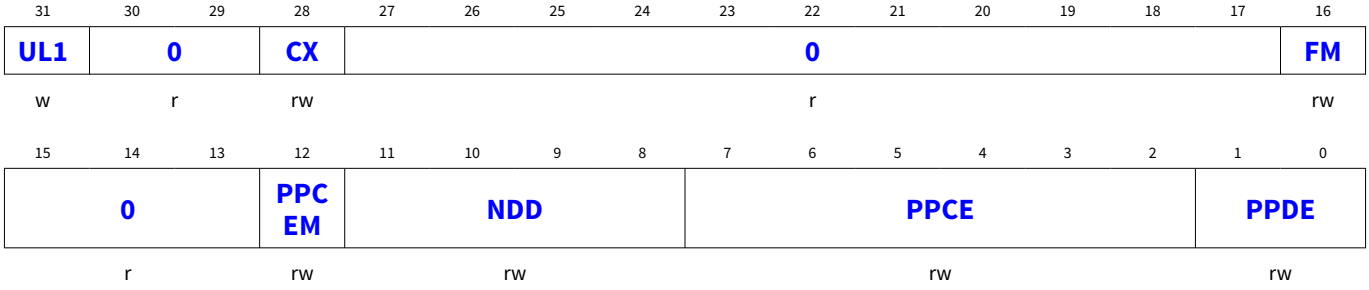
ENLx (x=16-31)	x-16	rw	**Emergency Stop Enable for Bit x in SRL** This bit enables the emergency stop feature selectively for each SRL bit. If the emergency stop condition is met and enabled (ENLx = 1), the SRL[x] bit is of the data register DDE.DDLE[x] is used for the shift register load operation. 0_B Emergency stop feature for bit SRL[x] is disabled. 1_B The emergency stop feature for bit SRL[x] is enabled.
ENHx (x=16-31)	x	rw	**Emergency Stop Enable for Bit x in SRH** This bit enables the emergency stop feature selectively for each SRH bit. If the emergency stop condition is met and enabled (ENHx = 1), the SRH[x] bit of the data register DDE.DDHE[x] is used for the shift register load operation. 0_B Emergency stop feature for bit SRH[x] is disabled. 1_B The emergency stop feature for bit SRH[x] is enabled.

28.4.38 Downstream timing extension register

The Downstream Timing Extension Register is used to control the enhanced operation mode and frame layout of the downstream channel transmission.

DSTE Offset address: $0AC_H$

Downstream timing extension register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PPDE	1:0	rw	**Passive Phase Length at data frames Extension** Additional MSB bits extension of the DSC.PPD bit field.
PPCE	7:2	rw	**Passive Phase Length at Control Frames Extension** Additional MSB bits extension of the fixed length of 2 of the command frames passive phase. The final length is 2 + PPCE resulting in a range of 2 to 65. 00_H 2 … $3F_H$ 65
NDD	11:8	rw	**N Divider Downstream** Defines the division ratio in the range of 1 to 16. 0_H 1 … F_H 16
PPCEM	12	rw	**PPCE Extension Bit on the MSB Side** This bit is the MSB extension bit for the PPCE bit field, extending command frame passive phase to the value of 127. The values of 128 and 129 are not allowed. 0_B MSB value of 0 1_B MSB value of 1
FM	16	rw	**Fast Mode** Activates the fast mode and writing to the ABRA FIFO with 100 MBaud input baud rate, in order to provide 80MBaud output baud rate. It is also recommended for baud rate of 26,67 MBaud, as defined in the committed baud rates. FM=0 is the compatibility setting with the previous generations of the MSC. 0_B Fast Mode deactivated 1_B Fast Mode activated

(table continues...)

(continued)

Field	Bits	Type	Description
CX	28	rw	**Command Extension Mode** Activates 64 bit command frame feature. 0_B CX mode deactivated 1_B CX mode activated
UL1	31	w	**Unlock CX and FM for one write access** Write access with UL1 = 1 unlocks the CX and FM bit fields for the current write access. Write accesses to these bit fields with UL1 = 0 do not have any effect. Returns zero on read.
0	15:13, 27:17, 30:29	r	**Reserved** Read as 0; should be written with 0.

28.4.39 Downstream data mirror register

The Downstream Data Mirror Register DDM provides alternative address for the DD register. The purpose of this alternative address is to provide convenient way to write up to 64 bit data blocks (32 bitwise) to the MSC module by using DMA with automatic address increment and wrap around. The DMA writes first to the DDE register and then to the DDM register, which behaves in the same way as a write to the DD register.

DDM Offset address: $0B0_H$

Downstream data mirror register Kernel Reset value: $0000\ 0000_H$

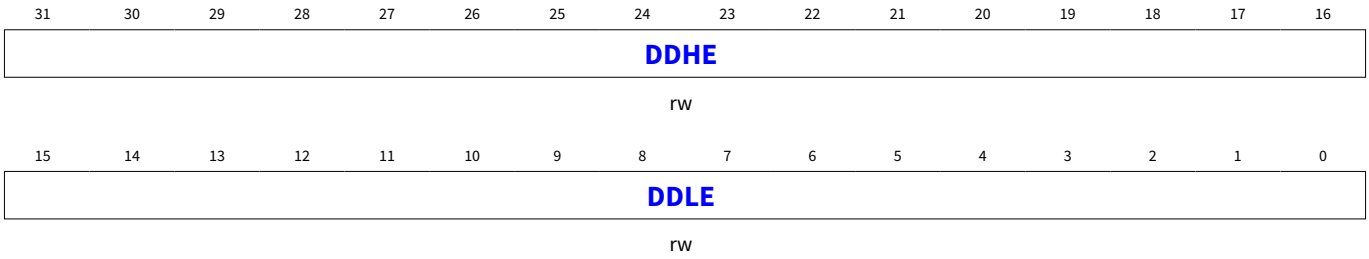
Field	Bits	Type	Description
DDLM	15:0	w	**Downstream Data Mirror for SRL Shift Register** Contains the data bits to be transmitted during the SRL active phase of a data frame.
DDHM	31:16	w	**Downstream Data Mirror for SRH Shift Register** Contains the data bits to be transmitted during the SRH active phase of a data frame.

28.4.40 Downstream data extension register

The Downstream Data Extension Register DDE contains data to be transmitted during data frames.

DDE Offset address: $0B4_H$

Downstream data extension register Kernel Reset value: $0000\ 0000_H$



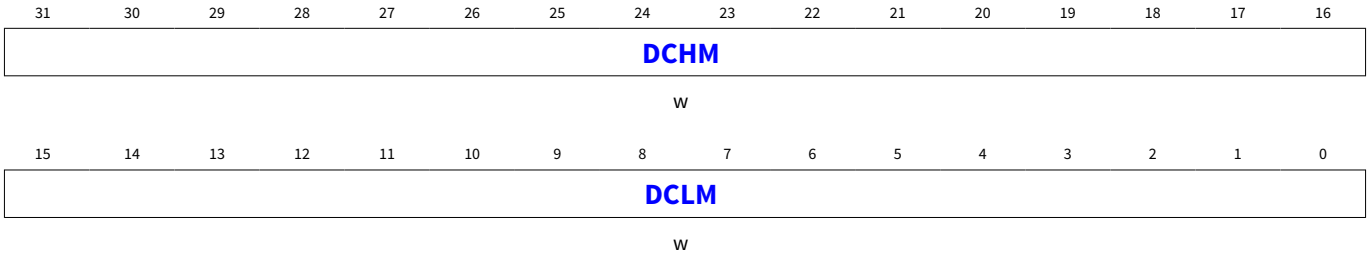
Field	Bits	Type	Description
DDLE	15:0	rw	**Downstream Data Extension for SRL Shift Register** Contains the data bits to be transmitted during the SRL active phase of a data frame.
DDHE	31:16	rw	**Downstream Data Extension for SRH Shift Register** Contains the data bits to be transmitted during the SRH active phase of a data frame.

28.4.41 Downstream command mirror register

The Downstream Command Mirror Register DCM provides alternative address for the DC register. This alternative address provides convenient way to write up to 64 bit data blocks (32 bitwise) to the MSC module by using DMA with automatic address increment and wrap around. The DMA writes first to the DCE register and then to the DCM register. Every write to DCE triggers a command transmission the same way as a write to the DC register.

DCM Offset address: $0B8_H$

Downstream command mirror register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DCLM	15:0	w	**Downstream Command Mirror of the DC.DCL Bit Field** Contains alternate write location for the command bits to be transmitted during the SRL active phase of a command frame.
DCHM	31:16	w	**Downstream Command Mirror of the DC.DCH Bit Field** Contains the alternate write location for the command bits to be transmitted during the SRH active phase of a command frame.

28.4.42 Downstream command extension register

The Downstream Command Extension Register DCE contains data to be transmitted during data frames, which are concatenated to the standard 32-bit commands, after the second select bit.

DCE Offset address: $0BC_H$

Downstream command extension register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
DCEH	31:0	rw	**Downstream Command Extension for SRH Shift Register** Contains the data bits to be transmitted during the second half of the command frame in CX mode.

28.4.43 Asynchronous block configuration register

The Asynchronous Block Configuration register ABC contains all the bit fields related to the ABRA block.

***Note**: Switching the peripheral clock off and on is done by using two writes: first a write of zero to the CLKSEL bitfield and then a second write switching on the clock source. Between the first and the second write a delay of minimum 4 * (1/f_{PER}) + 2 * (1/f_{CLC}) must be inserted by software, where f_{PER} is the frequency being switched off with the first write. This also applies if in-between the writes the clock frequency is changed in the CCU.*

ABC Offset address: $0C0_H$

Asynchronous block configuration register Kernel Reset value: $0000\ 0000_H$

28.5 Debug information

28.5.1 OCDS suspend behavior

In case of hard suspend, the clock is switched off immediately. A running frame will not be finished.

In case of soft suspend, the state is entered after the following two conditions are met:

- Any ongoing upstream reception is completed and
- Any ongoing downstream frame transmission is completed, both from the MSC kernel and the ABRA block side

28.6 References

This section is not applicable for the module being described.

28.7 MSC revision history

Initial release of the chapter.

28.8 TC4Dx MSC information

28.8.1 TC4Dx MSC configuration

There are no deviations from the generic specification.

28.8.2 TC4Dx MSC features

There are no deviations from the generic specification.

28.8.3 TC4Dx MSC functional description

1. MSC acts as a slave on the ComPB bus. The Clock Control block is driven by the system clock frequency f_{SPB}. As in TC4Dx, the ComPB also uses this clock
2. There is no GTM trigger available. Only eGTM trigger signals are to be selected

28.8.4 TC4Dx MSC registers

There are no deviations from the generic specification.

28.8.4.4 Device specific registers

There are no device specific register changes.

28.8.5 TC4Dx MSC connectivity

The table below lists interfaces to and from this functional block to other blocks in the device.

Table 1224 List of MSC interface signals

Interface signals	I/O	Description
CLOCK_MSC_fSPB	In	SPB clock input
CLOCK_MSC_fSRI	In	SRI clock input
CLOCK_MSC_fMSC	In	Peripheral clock input
MSC0_IR_SR[4:0]	Out	Service Requests
EGTM_MSC0_MSCSELIN_INLCON	In	eGTM timer output vector [15:0]- low part
EGTM_MSC0_MSCSELIN_INLECON	In	eGTM timer output vector [15:0] - low extension part
EGTM_MSC0_MSCSELIN_INHCON	In	eGTM timer output vector [31:16]- high part
EGTM_MSC0_MSCSELIN_INHECON	In	eGTM timer output vector [31:16] - high extension part
PORTS_MSC0_SDI[7:0]	In	Upstream asynchronous input signal
PORTS_MSC0_INJ[1:0]	In	Injection signal from port
MSC0_PORTS_EN[3:0]	Out	Chip Select
SMU_MSC_PORTSEmergencyStop	In	Emergency stop signal from SMU
MSC0_PORTS_FCL[P,N]	Out	Shift-clock signal pairs with inverted signal polarities FCLP/FCLN
MSC0_PORTS_SO[P,N]	Out	Data output signal pairs with inverted signal polarities SOP/SON
MSC0_SCU_FCLP	Out	MSC0 FCLP output to ERU

28.8.6 TC4Dx MSC revision history

Initial release of the chapter.

29 Secure Digital Multi-Media Card (SDMMC)

The purpose of the SDMMC module is to enable communication to external managed NAND flashes and SDIO (Secure Digital Input Output) devices using the SD (Secure Digital) or eMMC(embedded Multi-Media Card) interface. The focus of the module is communication with a single eMMC memory device, SD-card or a SDIO device.

29.1 Feature list

- Communication to eMMC (embedded multi-media card) memories
  - Communication using 1, 4, or 8-data lines
  - Legacy MMC (multi-media Card) and High-speed SDR (single data rate) mode supported
- Communication to SD-cards
  - Communication using 1 or 4-data lines
  - Default- and High Speedmode supported
- Communication to SDIO cards
- Communication support using different levels of direct memory access (DMA) support
  - Programmed Input Output (PIO) - operation without DMA
  - Single operation DMA (SDMA)
  - Advanced DMA-2 (ADMA2)
  - Advanced DMA-3 (ADMA3)
- Provides 1 KB SRAM for buffering up to two 512-Byte blocks
- Compliant to "Embedded Multi-Media Card (eMMC) Standard (5.1)" with the following exceptions:
  - No dual voltage eMMC support, only high voltage (3.3 V)
  - No high clock frequencies for HS200/HS400, only 0-50 MHz
  - No large 4-kB sector device support, only 512-B sectors
  - No DDR (Double Data Rate) signaling only SDR (Single Data Rate) signaling
  - No data strobe support
  - No high speed DDR, HS200 or HS400 speed mode support, only Legacy MMC card and High Speed SDR
  - No “Interrupt” mode, only “device identification”, “data transfer” and “inactive” mode
  - No clock tuning support
  - No multi device support
  - No Command Queuing Engine (CQE)
- Compliant to “SD Specifications Part A2 SD Host Controller Standard Specification v4.20” with the following exceptions:
  - No Multi Slot Support , only single cards
  - No suspend and resume functionality
  - No Sampling Clock Tuning supported, only Default Speed mode and High Speed mode supported
  - No Suspend or Resume operation in an SDIO card
- Compliant to “SD Specifications Part 1 Physical Layer Specification v6.00” with the following exceptions:
  - No UHS-II (Ultra High Speed) voltages, only high voltage SD memory card
  - No UHS-I and UHS-II speed modes, only Default Speed mode and High Speed mode
  - No physical write protection switch support
  - No card insertion detection, only sensing of pull-up on DAT line
  - No SPI card support
- Compliant to SD Specifications Part E1 SDIO Specification Version 4.10

29.2 Functional overview

The SDMMC controller supports SD-card, eMMC and SDIO interfaces. It contains a DMA engine for data transfer, a registers unit, and a FIFO controller.

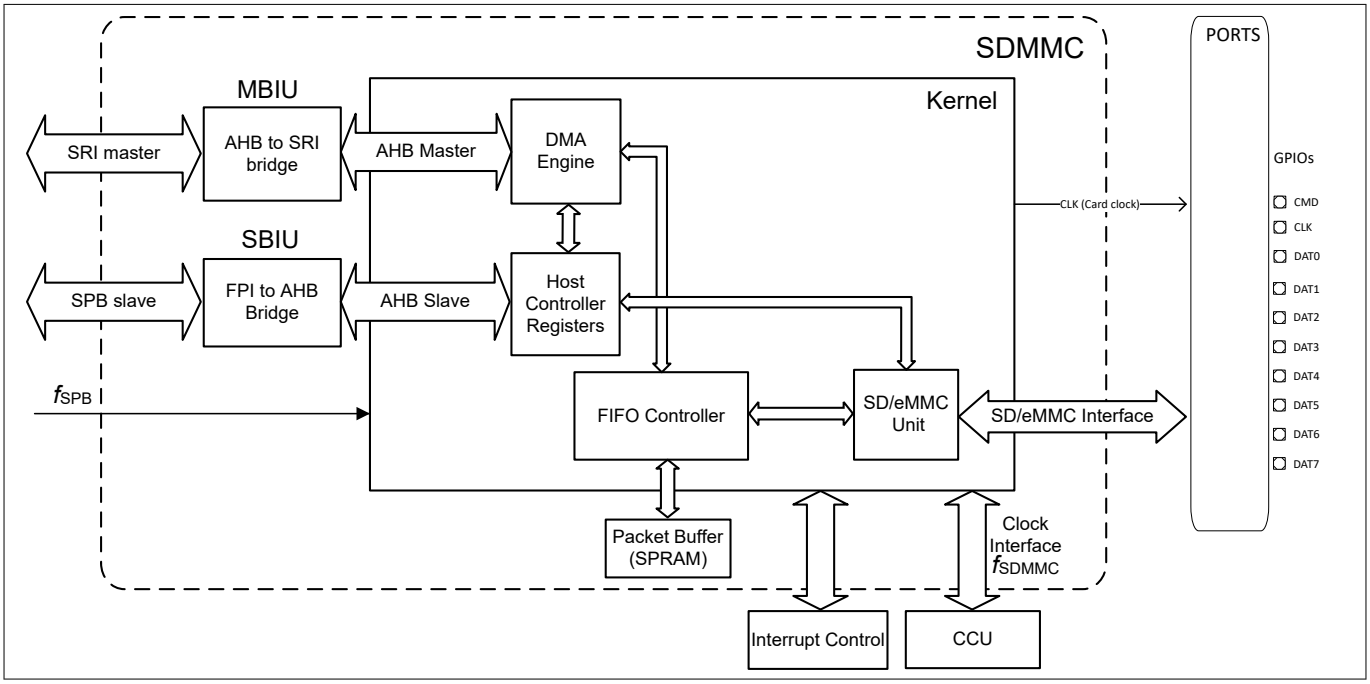

Figure 627 SDMMC block diagram

The figure above provides a simplified overview of SDMMC in the form of a block diagram.

The SDMMC kernel is connected to the SPB slave through the FPI to AHB bridge and SRI master via AHB to SRI bridge. Access to host control registers takes place through slave interface. Data transfers from or to external NAND memory to or from internal system memory space takes place through an internal Direct Memory Access(DMA) engine through the master interface. The slave and master clock domain runs at a frequency of f_{SPB} The card clock domain runs at the peripheral frequency of f_{SDMMC}. The Host controller accesses the external memory device over the GPIO pads belonging to the PORTS functional block. SDMMC has a single port RAM for packet buffering interfacing the FIFO controller.

29.3 Functional description

The following sections describes briefly the protocol overview, SDMMC programming sequences and Error handling.

29.3.1 Architecture overview

The following are the various modules in the SDMMC functional block:

***Note**: Only a brief description of the blocks are given below, please refer to the standards and specifications listed in References section for more details.*

Master bus interface unit

The master bus interface unit (MBIU) transfers data to and from the system memory through the system resource interconnect (SRI) master.

Slave bus interface unit

The slave bus interface unit (SBIU) implements the logic to access the SDMMC registers through the system peripheral bus (SPB) slave.

DMA engine

The DMA engine unit handles data transfer between SDMMC and system memory. The key features of this unit are as follows:

- Supports: SDMA,ADMA2 and ADMA3 modes (for more details on DMA programming then please refer to Application layer data flow section)
- Write back the received data packets to the system memory
- Write data from system memory to the FIFO for SD or SDIO or eMMC transfer
- Support of SINGLE and burst (INCR4 and INCR8) transfers

  ***Note**: In order to achieve optimal performance with burst transfers, data should be aligned to 256-bit for INCR8 and 128-bit for INCR4. For example, in case of INCR8 and non 256-bit aligned data, the DMA engine will use SINGLE and INCR4 transfers until 256-bit alignment is achieved*

- Pre-fetches data for back-to-back eMMC write commands
- 32-bit addressing support
- 32-bit data width

SDMMC registers

The host controller register unit comprises of the standard SD host controller registers as specified in the SD Specifications Part A2 SD Host Controller Standard specification version 4.20a.

For the following registers the internal clock controlled by CLK_CTRL.INTERNAL_CLK_EN must be enabled before accessing them:

- BLOCKSIZE
- BLOCKCOUNT
- ARGUMENT
- XFER_MODE
- CMD

FIFO controller

The data FIFO controller interfaces the internal FIFO that transport data To/From Packet Buffer (External Memory) and the DMA Engine.

SD/eMMC unit

This unit is responsible for managing SD/eMMC interface protocols. The key features of this unit are to:

- Generate command and data packets
- Generate Cyclic redundancy Check (CRC) to check command and data packets
- Handle packet timeouts
- Support 1-bit DAT, 4-bit DAT, and 8-bit DAT modes

SD/eMMC interface signals

SD/eMMC interface signals to the pads are

- SDMMC_DAT0-7: data lines
- SDMMC_CMD: command line
- SDMMC_CLK: clock line

For the different data widths 1, 4, and 8-wire communication different enable signals for the corresponding data pins are required to activate and deactivate these lines according to the output width selection.

SPRAM (single port RAM)

SRAM that is internal to the SDMMC functional block is used as a packet buffer to store data packets while carrying out data transfer to and from the card. The size of the SRAM is 1 KB that supports buffering of two 512-bytes blocks.

In the unlikely scenario when the packet buffer may become full or empty during card read, the clock to the card is stopped in SD/eMMC mode to prevent card from sending the next data block.

The single port RAM is not initialized after reset. Reading the RAM should only be done after the uninitialized values got overwritten (either data was received by the card, or the RAM was written by application software to prepare a write to the card). This is to avoid Checksum errors (safety alerts) when the software accesses uninitialized RAM cells.

As write and read transfers to the cards do not occur simultaneously, a single shared buffer is used for read and write operations. During the data transfer command handshake, the read/write bit of the command register is sampled and stored. This read/write bit defines whether the SDMMC is in read or write mode. The figure below shows how data flows from the card interface to the AHB master interface unit through the packet buffer for a card read transfer.

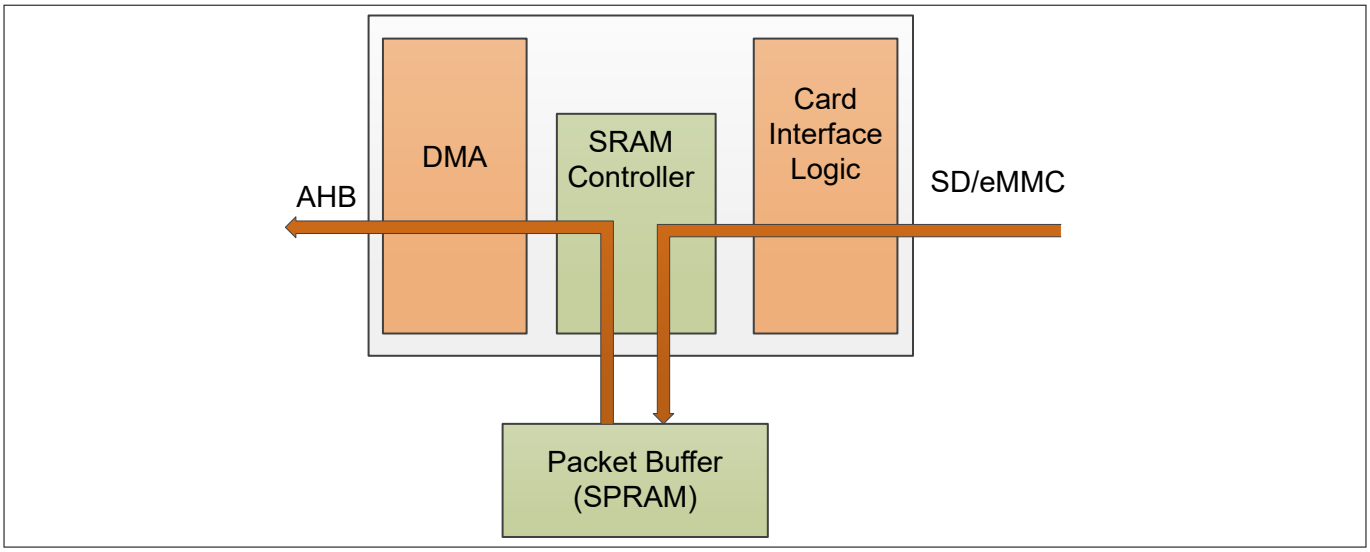

Figure 628 Data flow for card read

Received data from the card interface is written into the packet buffer. When one block of data (512 bytes) is received, DMA starts transmitting that data to the system memory by reading it from the packet buffer. For a card write transfer, data flows in the reverse direction. DMA writes data into a packet buffer that is subsequently read by the card interface logic. DMA and card interface logic can work simultaneously because read and write to packet buffer can be interleaved.

For card read, DMA can send out the previous block while card interface logic is receiving the current block. For card write, DMA can write the current block into packet buffer while card interface logic is sending out the previous block. When the packet buffer becomes full in card read, the clock to the card is stopped to prevent the card from sending the next data block. When packet buffer is empty, data block is not sent. In both cases, card interface logic is idle. SDMMC does not support SDIO Read Wait signaling through DAT[2]. Therefore, the I/O command (CMD52) cannot be performed during a multiple read cycle because the card clock is stopped.

Interrupts

The SDMMC supports the following interrupts:

- Normal Interrupt signal
  - Used as interrupt for different events during active mode. The Interrupt Status Registers (NORMAL_INT_STAT) indicate the events that caused the interrupt generation. Each event can be prevented from asserting the interrupt on the interrupt signal by setting the corresponding mask bits NORMAL_INT_SIGNAL_EN. When an interrupt event occurs, it will be captured in the Interrupt Status Registers (NORMAL_INT_STAT) only if the corresponding interrupt bit is enabled in the NORMAL_INT_STAT_EN register. The interrupt line gets active high only when the interrupt status in (NORMAL_INT_STAT) register and the corresponding interrupt signal enable in NORMAL_INT_SIGNAL_EN register are set to 1
- Wake-up Interrupt signal
  - During standby mode, Wake-up Interrupt Signal must be used to identify any wake-up event, such as an SD-card insertion and removal. The corresponding register is WUP_CTRL. As card insertion and removal is not applicable to an embedded device, wake-up interrupt should not be used in this case. However it can still be used for SDIO card interrupt
- Error Interrupts
  - Used as interrupt for errors arising from different events during active mode captured in register SDMMC_ERROR_INT_STAT and enabled bySDMMC_ERROR_INT_STAT_EN and ERROR_INT_SIGNAL_EN(similar to normal interrupts)

The interrupts are signaled to the Interrupt Router (IR) by using a single pulse using a pulse shaper.

SDMMC host driver is responsible for enabling wake-up signals and disabling interrupt signals when the host system enters its standby mode, and for disabling wake-up signals and enabling interrupt signals when host

system goes into active mode. The host driver must not enable both at same time. Interrupt signals are enabled using interrupt signal enable and wake-up signals are enabled using wake-up event enable.

Table 1225 Interrupt grouping towards IR

Interrupt grouping towards interrupt router(IR)	Interrupts in SDMMC
SRC_SDMMCERR	Normal interrupt signal
	Error interrupts
SRC_SDMMCDMA	Wake-up interrupt signal

Clock interface

The clock interface is the interface to the CCU (clock control unit) in order to derive a 100 MHz peripheral PLL clock f_{SDMMC}. The card clock 'SDCLK' is subsequently derived from f_{SDMMC} using the controls in the register CLK_CTRL.

29.3.2 Error handling

SDMMC is capable of detecting different types of error in SD and eMMC. An error can be detected in either the command or data portion of the transaction. When an error is detected, the error interrupt in the normal interrupt status register (NORMAL_INT_STAT) is set.

When an error occurs in the SD or eMMC mode, one of the bits is set in the error interrupt status register(ERROR_INT_STAT). To recover from an error detected during data transfer, predefined commands are used.

There are two more error status registers supported in both SD and eMMC modes

- AUTO_CMD_STAT
- ADMA_ERR_STAT

Table 1226 Error types and categories for SD or eMMC mode

Categories	Error type	Bit field
Command errors	• Command timeout error • Command CRC error • Command end bit error • Command index error • Response error	• ERROR_INT_STAT.CMD_TOUT_ERR • ERROR_INT_STAT.CMD_CRC_ERR • ERROR_INT_STAT.CMD_END_BIT_ERR • ERROR_INT_STAT.CMD_IDX_ERR • ERROR_INT_STAT.RESP_ERR

(table continues...)

Table 1226 (continued) Error types and categories for SD or eMMC mode

Categories	Error type	Bit field
Auto command errors	• Auto CMD12 Not Executed • Command not issued by auto CMD12 error • Auto command timeout error • Auto command CRC error • Auto command end bit error • Auto command index error • Auto CMD response error	• AUTO_CMD_STAT.AUTO_CMD12_NOT_EXEC • AUTO_CMD_STAT.CMD_NOT_ISSUED_AUTO_CMD12 • AUTO_CMD_STAT.AUTO_CMD_TOUT_ERR • AUTO_CMD_STAT.AUTO_CMD_CRC_ERR • AUTO_CMD_STAT.AUTO_CMD_EBIT_ERR • AUTO_CMD_STAT.AUTO_CMD_IDX_ERR • AUTO_CMD_STAT.AUTO_CMD_RESP_ERR
Data errors	• Data timeout error • Data CRC error • Data end bit error • ADMA error	• ERROR_INT_STAT.DATA_TOUT_ERR • ERROR_INT_STAT.DATA_CRC_ERR • ERROR_INT_STAT.DATA_END_BIT_ERR • ERROR_INT_STAT.ADMA_ERR
Other errors	• Current Limit Error • Boot Acknowledgment Error	• ERROR_INT_STAT.CUR_LMT_ERR • ERROR_INT_STAT.BOOT_ACK_ERR

29.3.3 Protocol overview

This section provides an overview of protocols that are supported in SDMMC. For detailed information about the protocols, refer to the applicable standard documents.

The SDMMC block operates in eMMC mode when the EMMC_CTRL.CARD_IS_EMMC bit is set; otherwise, it operates in SD/SDIO mode. The speed mode is configured through HOST_CTRL1 and HOST_CTRL2 registers as per following table.

Table 1227 Bus Speed Mode Configuration

Bus speed mode	HOST_CTRL1.**HIGH_SPEED_EN**	HOST_CTRL2.**SIGNALING_EN**	Preset register
SD default speed (DS)	0	0	PRESET_DS
SD high speed (HS)	1	0	PRESET_HS

29.3.3.1 SD bus protocol

The bus communication in SD mode is based on command and data bit streams each bounded by a start bit and a stop bit. A command is a token that starts an operation and is sent by the Host to the card. The command is transferred through the CMD line.

Response is a token that is sent by the addressed card to the host as a reply to the previous command. The response is also transferred serially through the CMD line.

Data can be set either by the Host (Write operation) or by the card (Read operation) and can be transferred through the data lines.

Data transfers in either direction are made in blocks. Each block has a CRC succeeding it. The transfers can either happen as a single or multiple block. Multiple block transmissions are terminated by the issue of a stop command on the command line.

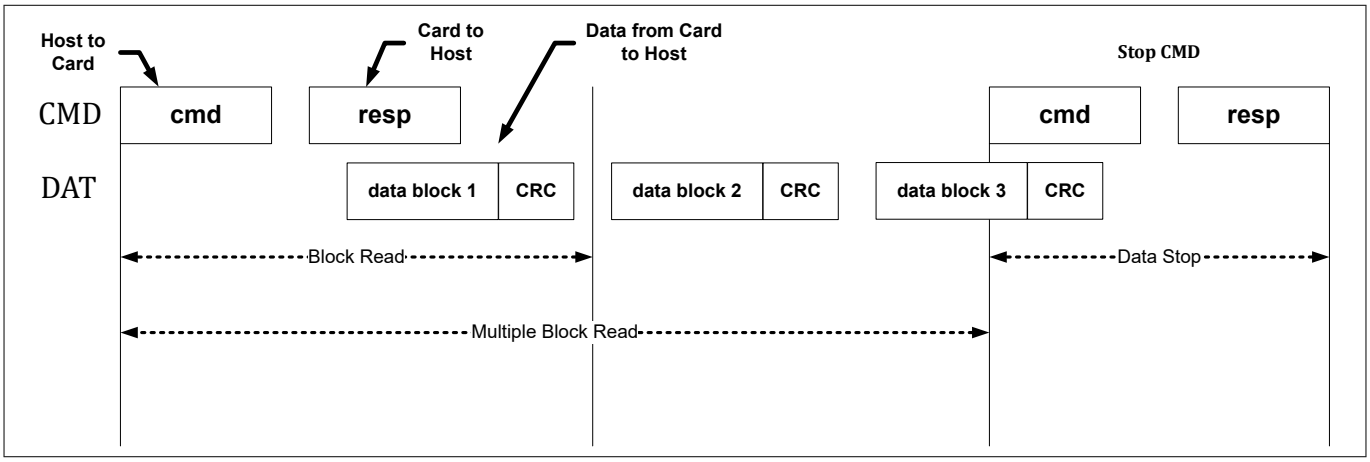

Figure 629 SD bus protocol; Command and data bit streams in the SD mode

29.3.3.2 SDIO bus protocol

An embedded SDIO device or card utilizes the SD bus and SD commands. Several commands required for SD Memory cards, example erase, are not supported by SDIO-only cards. In addition, there are several commands for SD cards that have different commands when used with the SDIO section of a card. [29)]

A host device controls the SDCLK (card clock) to stop the read data block output from a card executing a multiple read commands when the host cannot accept more data. The duration of time when the host has stopped the SDCLK, a CMD52 cannot be issued. This limitation causes a problem in that a host device cannot perform the I/O command during a multiple read cycle.

To overcome this limitation, the read wait feature is introduced to signal a card that is executing multiple read operations to temporarily pause data transfer while allowing the host to send commands to any other function within the card. Read wait feature is not supported by SDMMC. The read wait function is optional for SDIO cards.

SDIO Card Interrupt

An SD interface supports the interrupt function to allow an SDIO card to interrupt the host. This interrupt is used:

- To Inform the host about error status and also about normal information, such as function ready.
- As a source of wakeup event to inform the host to resume from standby mode

The card interrupt is cleared when the card/device stops asserting the interrupt, that is, when the application services the interrupt condition. For SD 1-bit mode, there are no timing constraints for interrupt. For 4-bit mode, the SDMMC samples the card interrupt only during the interrupt period that is defined as follows:

- Interrupt period ends from the end bit of a command that transfers the data block, 1 to 3 clocks for SDR50 mode
- Resume two clocks after the completion of last data block transfer, 2 to 4 for SDR50
- Within the data block gap, 2-clock Interrupt period begins 2 clocks after the end bit of data blocks. Block Gap card interrupt is disabled in SDR50

29 refer toSD Specifications Part E1 SDIO Specification Version document described in References section for more information about SDIO cards and differences between them and D-Card commands

- The SDMMC does not distinguish between synchronous and asynchronous interrupt periods
- In case of abort CMD, the interrupt period ends 2 clocks after the end bit of abort CMD and resumes 2 clocks after the end bit of the response

29.3.3.3 eMMC bus protocol

An eMMC bus data transfer contains a command, response and data block tokens. Each data transfer is considered as a bus operation that always contains a command and a response token. Additionally, certain bus operations also contain a data token.

Data sent on the data line can be transferred one bit (single data rate) or two bits (dual data rate, not supported) per clock cycle. Similar to the SD bus protocol, command and data bit streams are bound by a start bit and a stop bit.

Data transfer occurs in the form of blocks that are followed by CRC bits and data is transferred in single or multiple blocks. While a single or multiple read block is terminated by a stop command on the CMD line, a single or multiple write block is terminated by a busy signal on the data (DAT[0]) line.

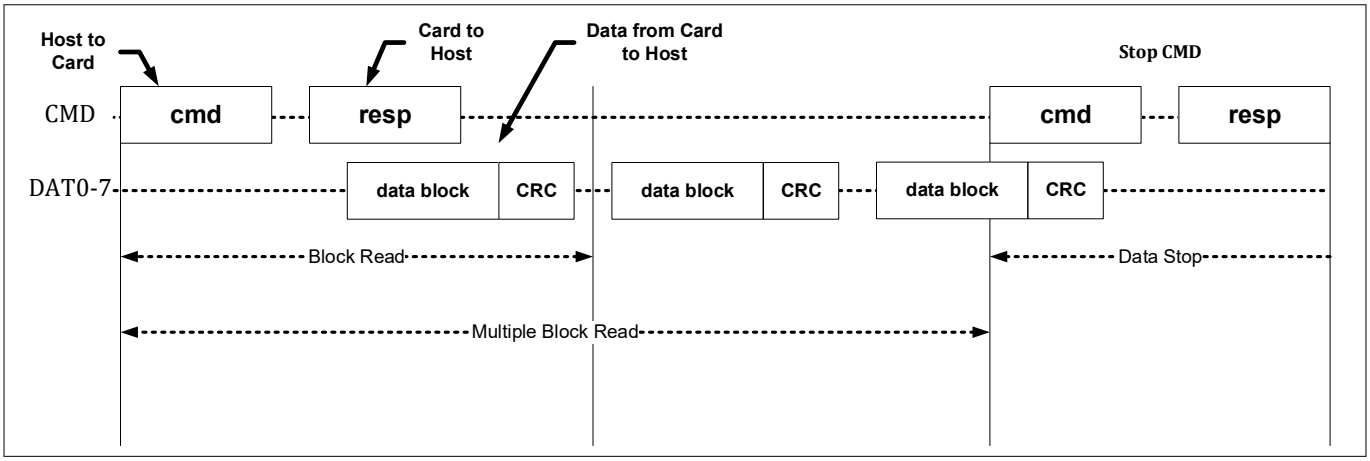

Figure 630 eMMC block read operation

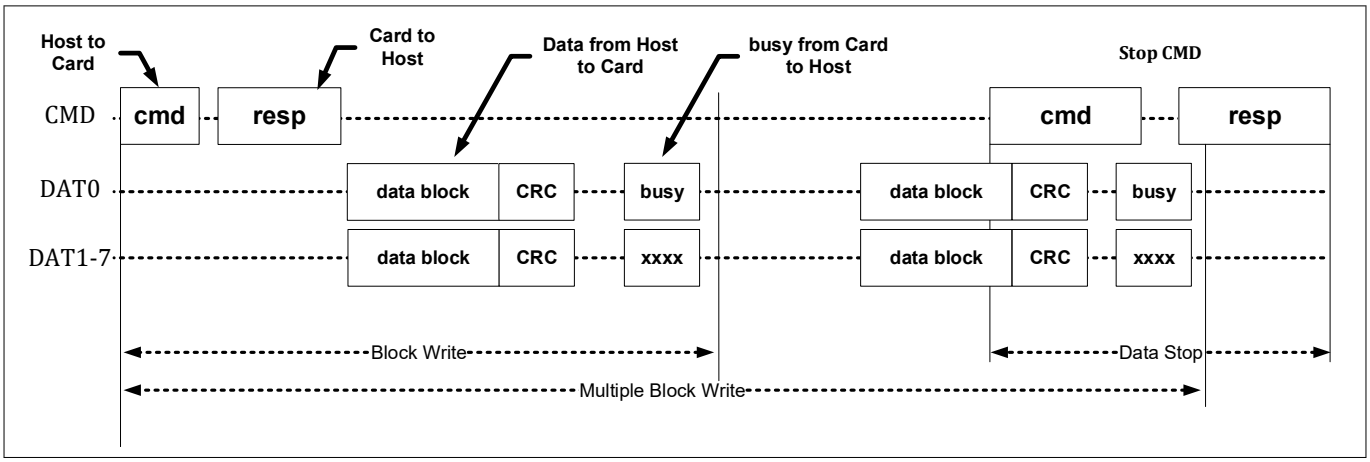

Figure 631 eMMC block write operation

29.3.4 Application layer data flow

The host controller communicates to the software driver using the system bus interface and to the card using the SD Bus interface.

The following figure shows the high level data flow through the Host controller.

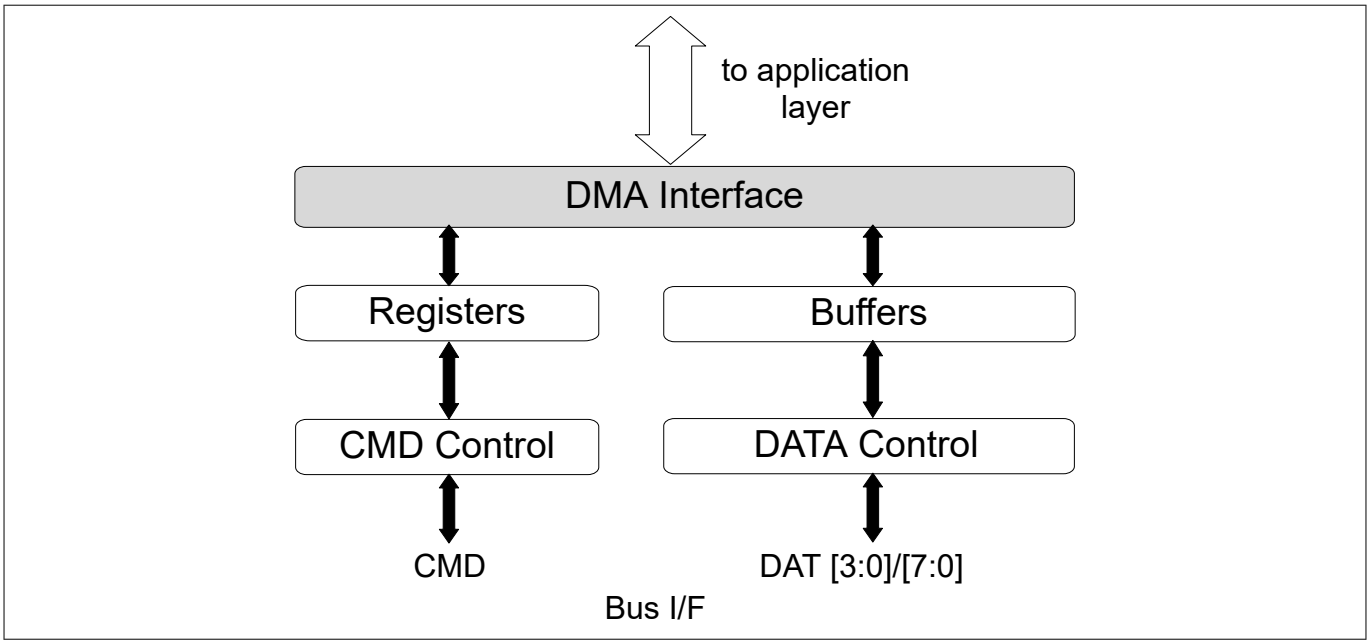

Figure 632 Host controller data flow

The host driver can transfer data using either a programmed I/O method or using any of the defined DMA methods.

Programmed Input/Output (PIO)

In the Programmed Input/Output (PIO) method of data transfer, data is transferred to the system memory by the host driver. It is done on the basis of block size, a maximum of 512 bytes. In a card write, the controller provides Buffer Write ready interrupt when it has space for one block. Based on this interrupt, the host driver must transfer one block of data from system memory to the SDMMC buffer through the Buffer data port register BUF_DATA. After that block is sent to the card by the controller, the same mechanism is used in the reverse direction in the case of a card read using the Buffer read ready interrupt. PIO mode is much slower and burdens the processor.

***Note**:*
- *It is not recommended to use the PIO mode for large transfers*
- *All bus accesses by the DMA engine are executed in user mode*

DMA

The following are the different DMA methods described in the SD standards:

1. SDMA: Single operation DMA is suitable for short data transfer because it requires address update at page boundary of system memory (256bit for Pflash and 64bit for Dflash). An interrupt is generated at every page boundary. Writing to the command register CMD triggers SDMA transfer. The Configuration registers for SDMA transfer are:
- System Memory Address or Block Count SDMASA.BLOCKCNT
- Data Block Size BLOCKSIZE.XFER_BLOCK_SIZE
- Size of Contiguous Buffer BLOCKSIZE.SDMA_BUF_BDARY

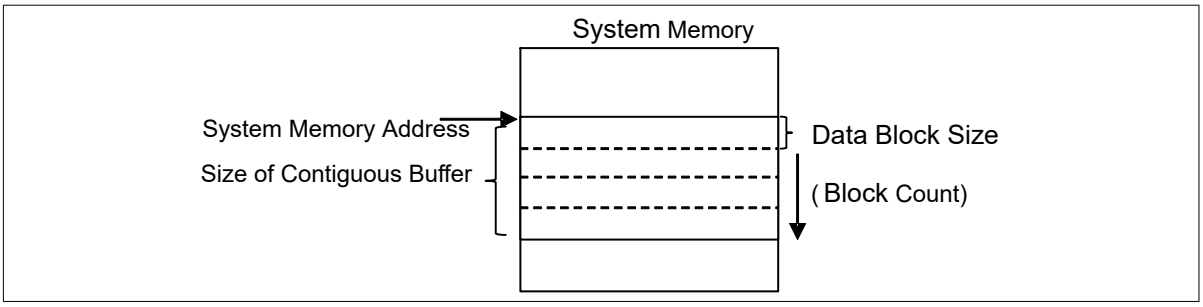

Figure 633 System Memory

2. ADMA2: Advanced DMA-2, supports multiple SDMA transfers allowing a single read or write operation across page boundaries. The configuration registers for ADMA2 transfers are:
   - Setting ADMA System Memory Address in ADMA system address register low for Descriptor table start address
   - Writing to the command register Command register triggers ADMA2 transfer
   - ADMA2 fetches one descriptor line and executes it in the Descriptor Table. This step is repeated until the end of the descriptor is found

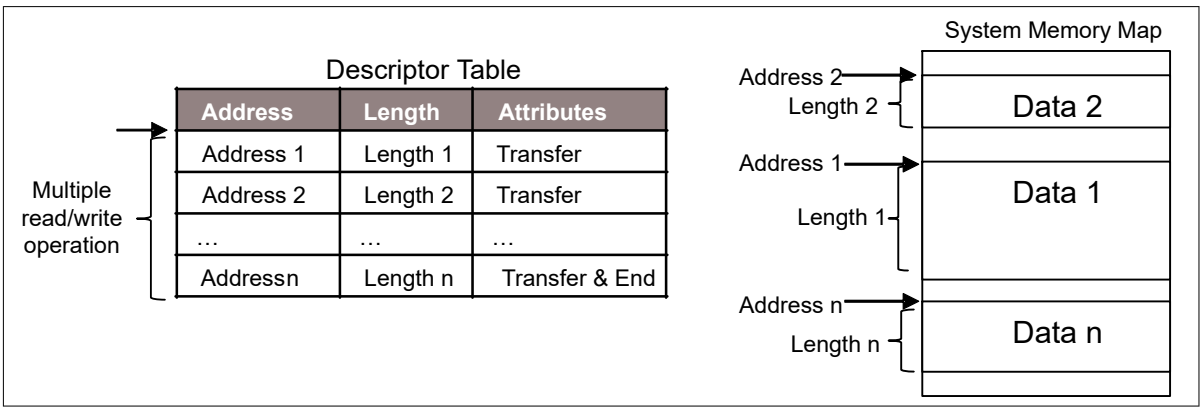

Figure 634 ADMA2 Descriptor table

3. ADMA3: Advanced DMA-3, supports multiple read or write commands to be programmed in the descriptor table. It performs multiple ADMA2 operations.
   a. Writing to the ADMA3 integrated descriptor address register ADMA_ID_LOW triggers the DMA operation as depicted in figure below

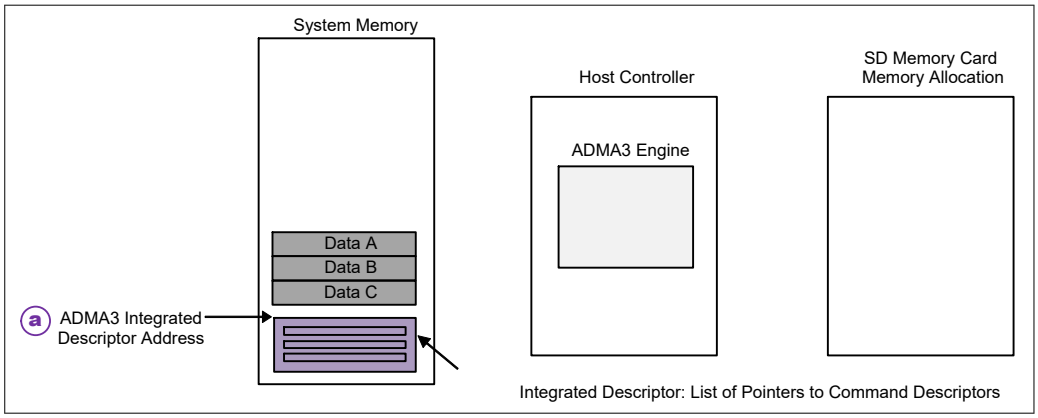

Figure 635 ADMA3 writing to Integrated Address Register

   b. ADMA3 fetches pointers one by one in the Integrated Descriptor and executes descriptors designated by the pointer as in figure below

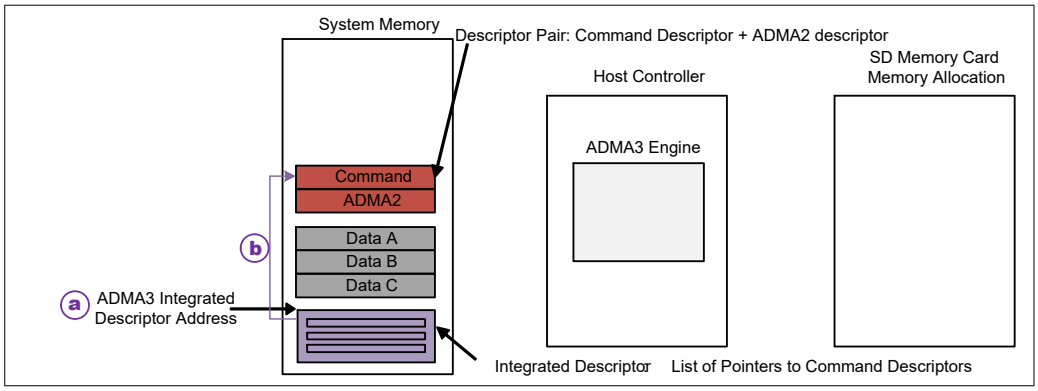

Figure 636 ADMA3 pointer fetch

c. ADMA3 writes the Command Descriptor contents to the Host Controller registers to issue a command and then executes the ADMA2 Descriptor

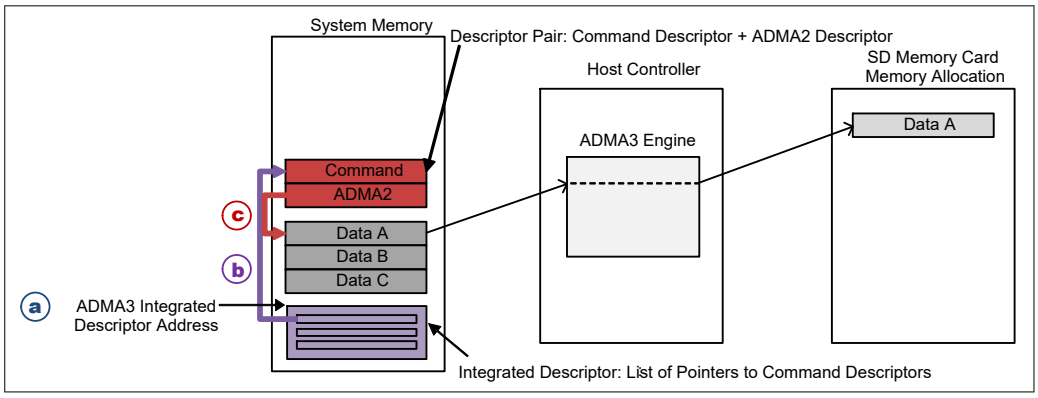

Figure 637 Issuing a Command

d. ADMA3 fetches the next pointer in the Integrated Descriptor and executes descriptors designated by the pointer

e. ADMA3 writes the next Command Descriptor contents to the Host Controller registers to issue a command and then executes the ADMA2 descriptor as shown below

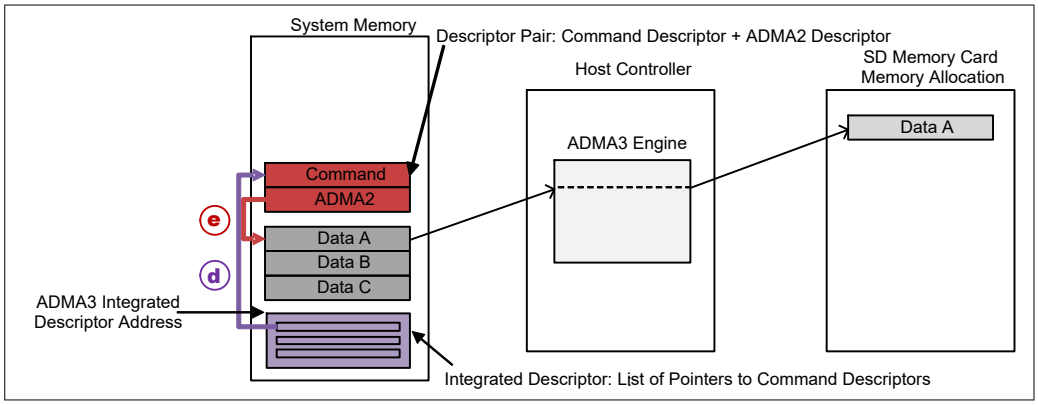

Figure 638 : Executing Next Descriptor

f. ADMA3 fetches the next pointer in the Integrated Descriptor and executes descriptors designated by the pointer until the end of the Command Descriptor

g. ADMA3 writes the end of the Command Descriptor contents to the Host Controller registers to issue a command and then executes the ADMA2 descriptor as shown below

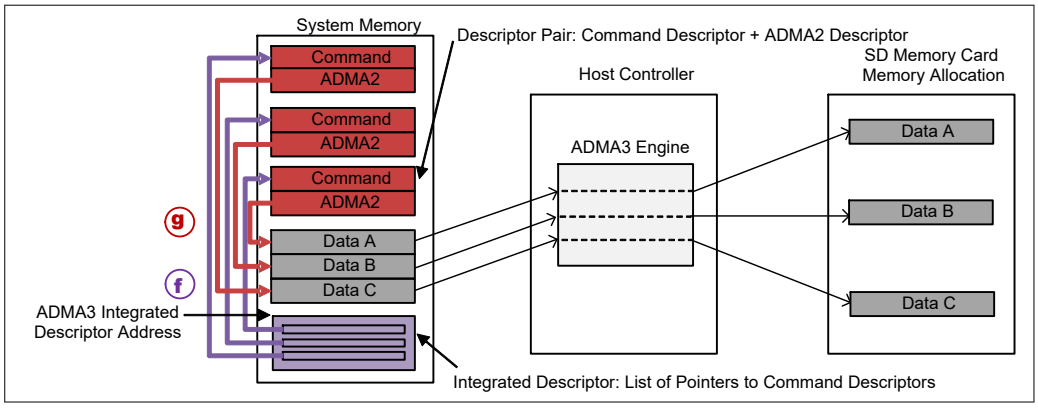

Figure 639 Executing until the end of Descriptor

***Note**: The control bits in the Block Gap Control(BGAP_CTRL) register are used to Stop and Restart a DMA operation*

***Note**: When HOST_CTRL2.HOST_VER4_EN = 1, SDMA uses ADMA_SA_LOW as system address register and SDMASA is reassigned to 32-bit block count*

29.3.5 SDMMC programming sequences

This section describes the SDMMC programming sequences.

29.3.5.1 Pin enabling

The direction control of the data and command pins(half duplex) are managed by the SDMMC peripheral through controlling the output enable signals. During start-up, the pins can be configured as inputs. The direction of the clock pin is set to 1 using the DIR bit in register PADCFGp_DRVCFG (p=00-15). Other pin configurations, such as pulls and driver strength, are also selected according to the application needs using the same register. For more details please refer to the Ports chapter.

29.3.5.2 Programming overview

A certain programming sequence is required for SDMMC and the card sub-system before starting data transfer with a connected card.

The following is the programming sequence required before starting the data transfer with the card:

1. Enable SDMMC peripheral clock,f_{SDMMC} using PERCCUCON1.SDMMCPERON (please refer to Clocking chapter)
2. Enabled clock for SDMMC module if not already enabled by configuring CLC.DISR after applying a module reset. Check if CLC.DISS!=0
3. Set up basic settings for SDMMC as described in Host Controller Setup Sequence. It involves settings such as the bus power voltage level for the card, timeout counter value, setting clock generation parameters. Different setup sequences for SD card (“Host controller setup sequence for an SD interface”) and eMMC card (“Host controller setup sequence for an eMMC interface”) are required
4. Enable other input clocks like the card clock that are available in SDMMC. Further details are as discussed in the programming sequence in Host controller clock setup sequence. At this stage, SDMMC is ready to communicate with the card
5. Identify the type of card that is connected to SDMMC as explained in the programming sequence in “SD Card Interface Detection”[30]. If SDMMC is connected to an eMMC card, then programming sequence described in “eMMC Card Interface Setup”[31] must be executed. This is a simplified sequence especially for an eMMC card as the type of card is always known. Both the programming sequences provide power and clock to the card
6. After powering up the card, the card is initialized. Appropriate sequence as shown below must to be executed based on type of the connected card

Table 1228 Card initialization sequence for different cards

Type of card	Card initialization sequence
SD	SD card initialization and identification[1]
eMMC	Initializing and identifying an eMMC card[2]

1) refer to SD Specifications Part A2 Host Controller document in References section for the sequence
2) refer to JEDEC eMMC 5.1 Specification - JESD84-B51 document in References section for the sequence

7. As both host controller and card are initialized, the host can start sending commands to the card to perform the data transfer. Control and data commands are two types of commands that can be issued to

30 refer to SD Specifications Part A2 Host Controller document in References section for the sequence
31 refer to SD Specifications Part A2 Host Controller document in References section for the sequence

the card. The control command is used to read or write any register in the card. The data command is used for writing or reading data to or from the card.

a. Data transfer can be aborted using abort command

b. If errors are detected during the transfer, recovery should be done using the Error Recovery sequence

Table 1229 Command sequence for SD and eMMC cards

Type of card	Control and data command sequences for SD and eMMC cards	
SD/eMMC	Control CMD	Issuing CMD without data transfer[1)]
	Data CMD	Issuing CMD with data transfer[2)]

1) refer to SD Specifications Part A2 Host Controller document in References section for the sequence

2) refer to SD Specifications Part A2 Host Controller document in References section for the sequence

The figure below shows the programming overview. Subsequent sections describe the steps in detail.

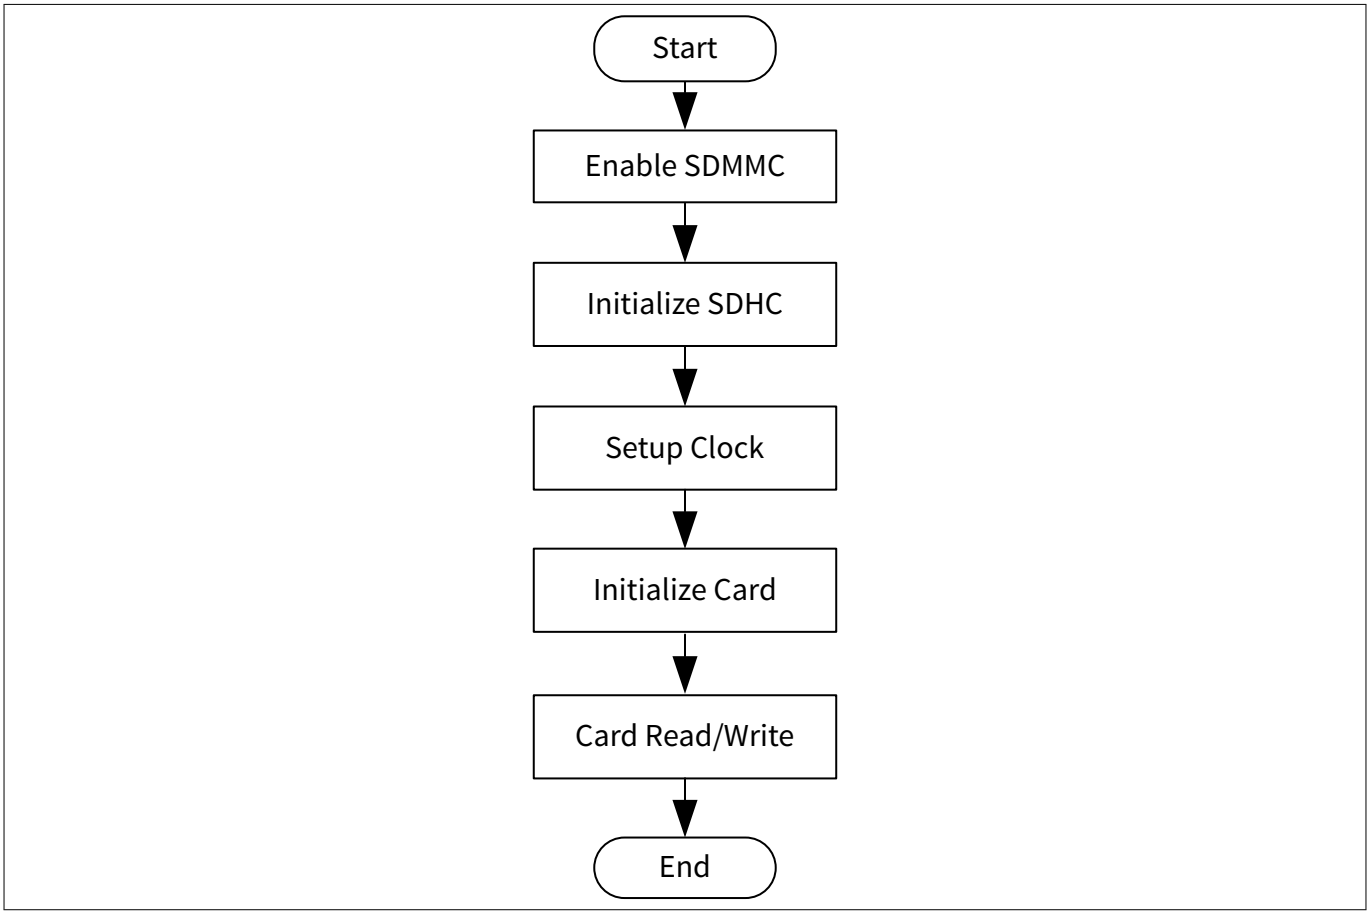

Figure 640 Programming sequence overview

29.3.5.3 Host controller setup sequence

This section discusses the host controller setup sequence for SD device and an eMMC device.

29.3.5.3.1 Host controller setup sequence for an SD interface

The host controller setup sequence for an SD interface involves some basic settings for SDMMC, such as the bus power voltage level for the card, timeout counter value, and setting clock generation parameters.

The following figure shows the host controller setup sequence. The register parameters set in this sequence retain their values irrespective of bus speed mode changes.

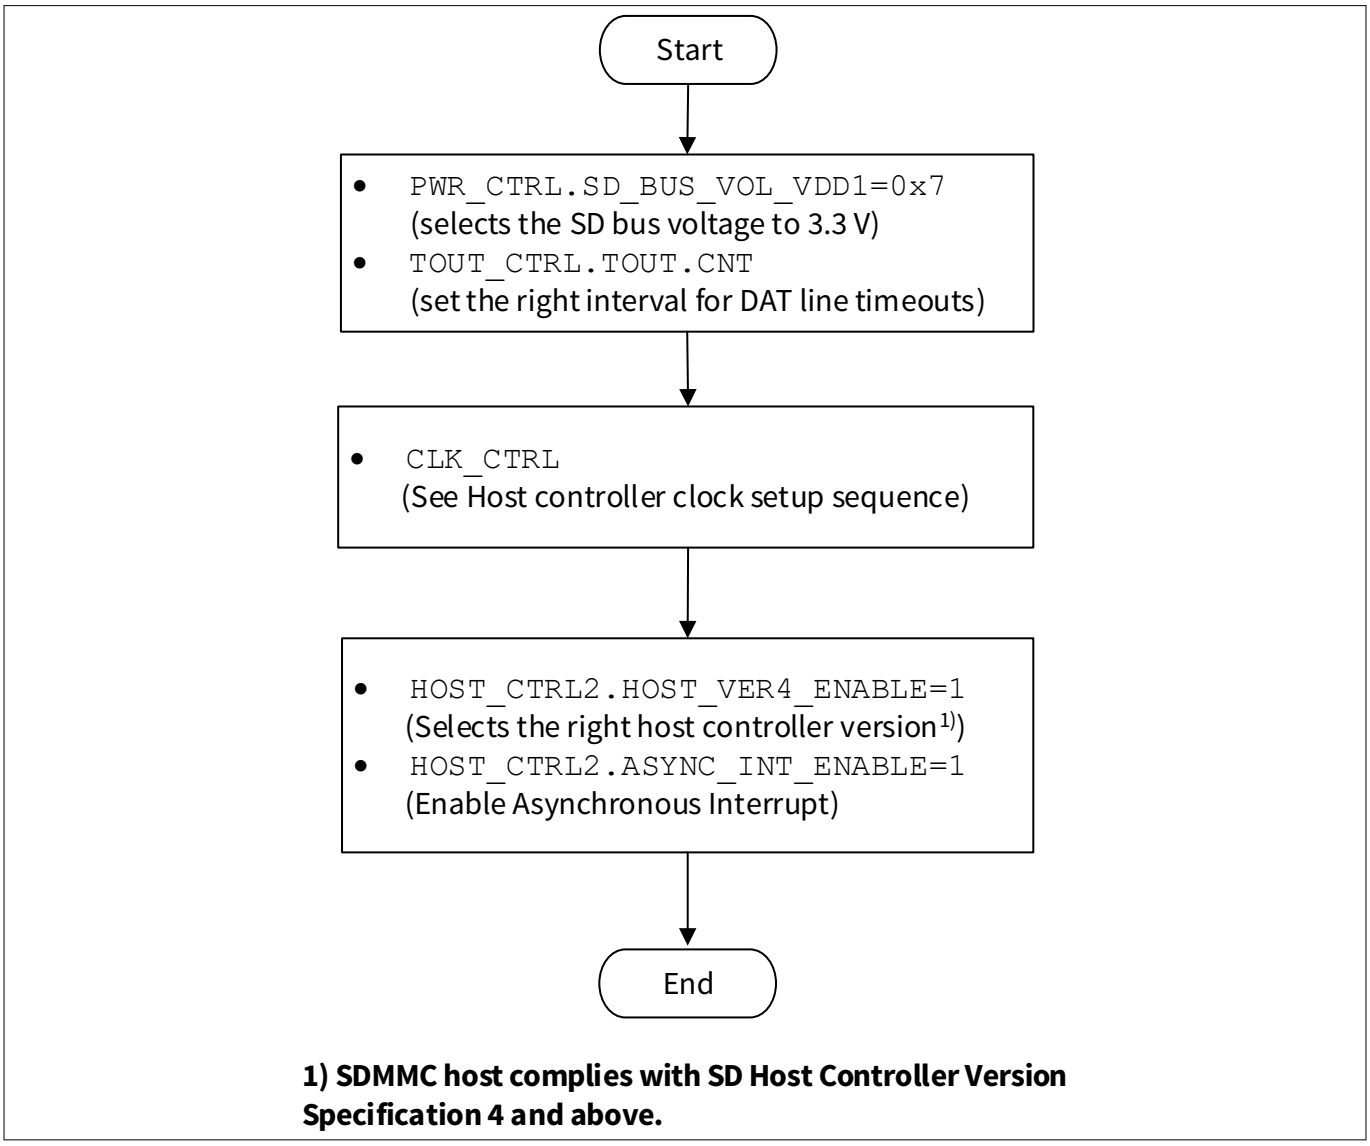

Figure 641 Host controller setup sequence for SD interface

29.3.5.3.2 Host controller setup sequence for an eMMC interface

The host controller setup sequence for an eMMC device requires some basic settings for SDMMC. The procedure involves setting certain parameters common to both version 3 and 4, clock control kernel register, and version 4 parameters.

The following figure shows the host controller setup sequence for an eMMC device. In addition to completing the programming sequence you must set the parameter EMMC_CRTL.CARD_IS_EMMC = 1.

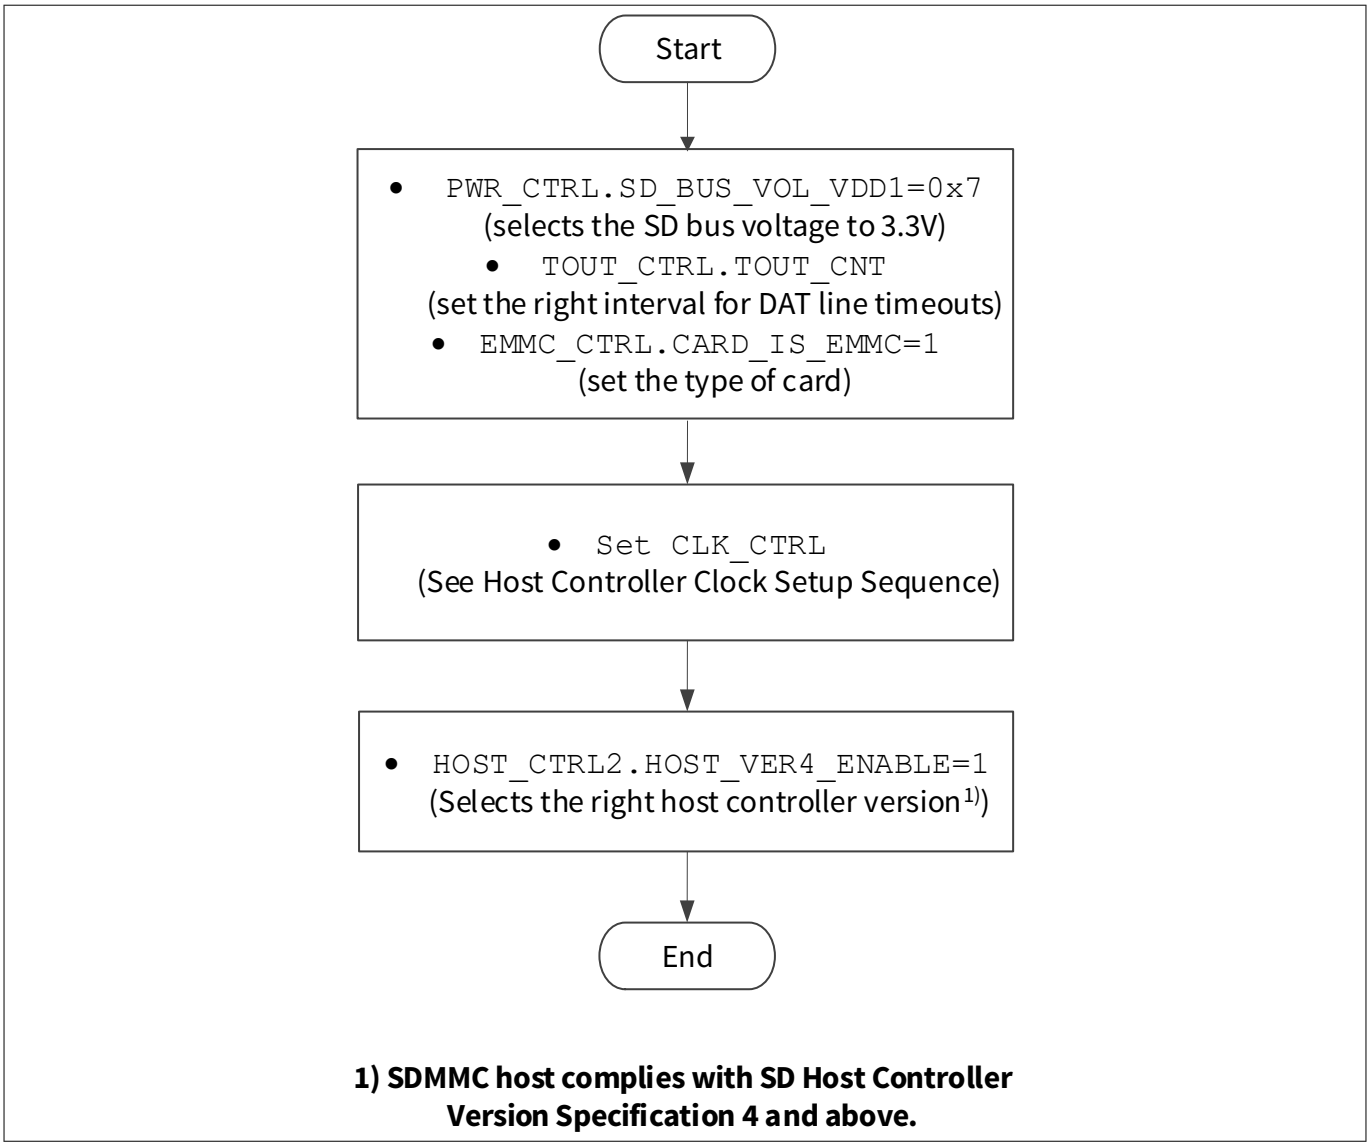

Figure 642 Host controller setup sequence for eMMC interface

29.3.5.4 Clock control

This section discusses the programming sequence for setting up the internal clocks and card clock provided to SDMMC, for supplying and setting up a clock provided to the card, and for changing the card clock frequency.

This section includes the following sequences:

- Host controller clock setup sequence
- Card clock supply and stop sequence

29.3.5.4.1 Host controller clock setup sequence

The SDMMC requires a master domain clock, slave domain clock and peripheral clock (f_{SDMMC}) from the system. All the input clocks are asynchronous to each other. Based on the controls available for enabling clocks required for SDMMC, they are categorized into two types, namely Internal clock and Card clock.

The following figure shows the sequence for setting up clocks for SDMMC.

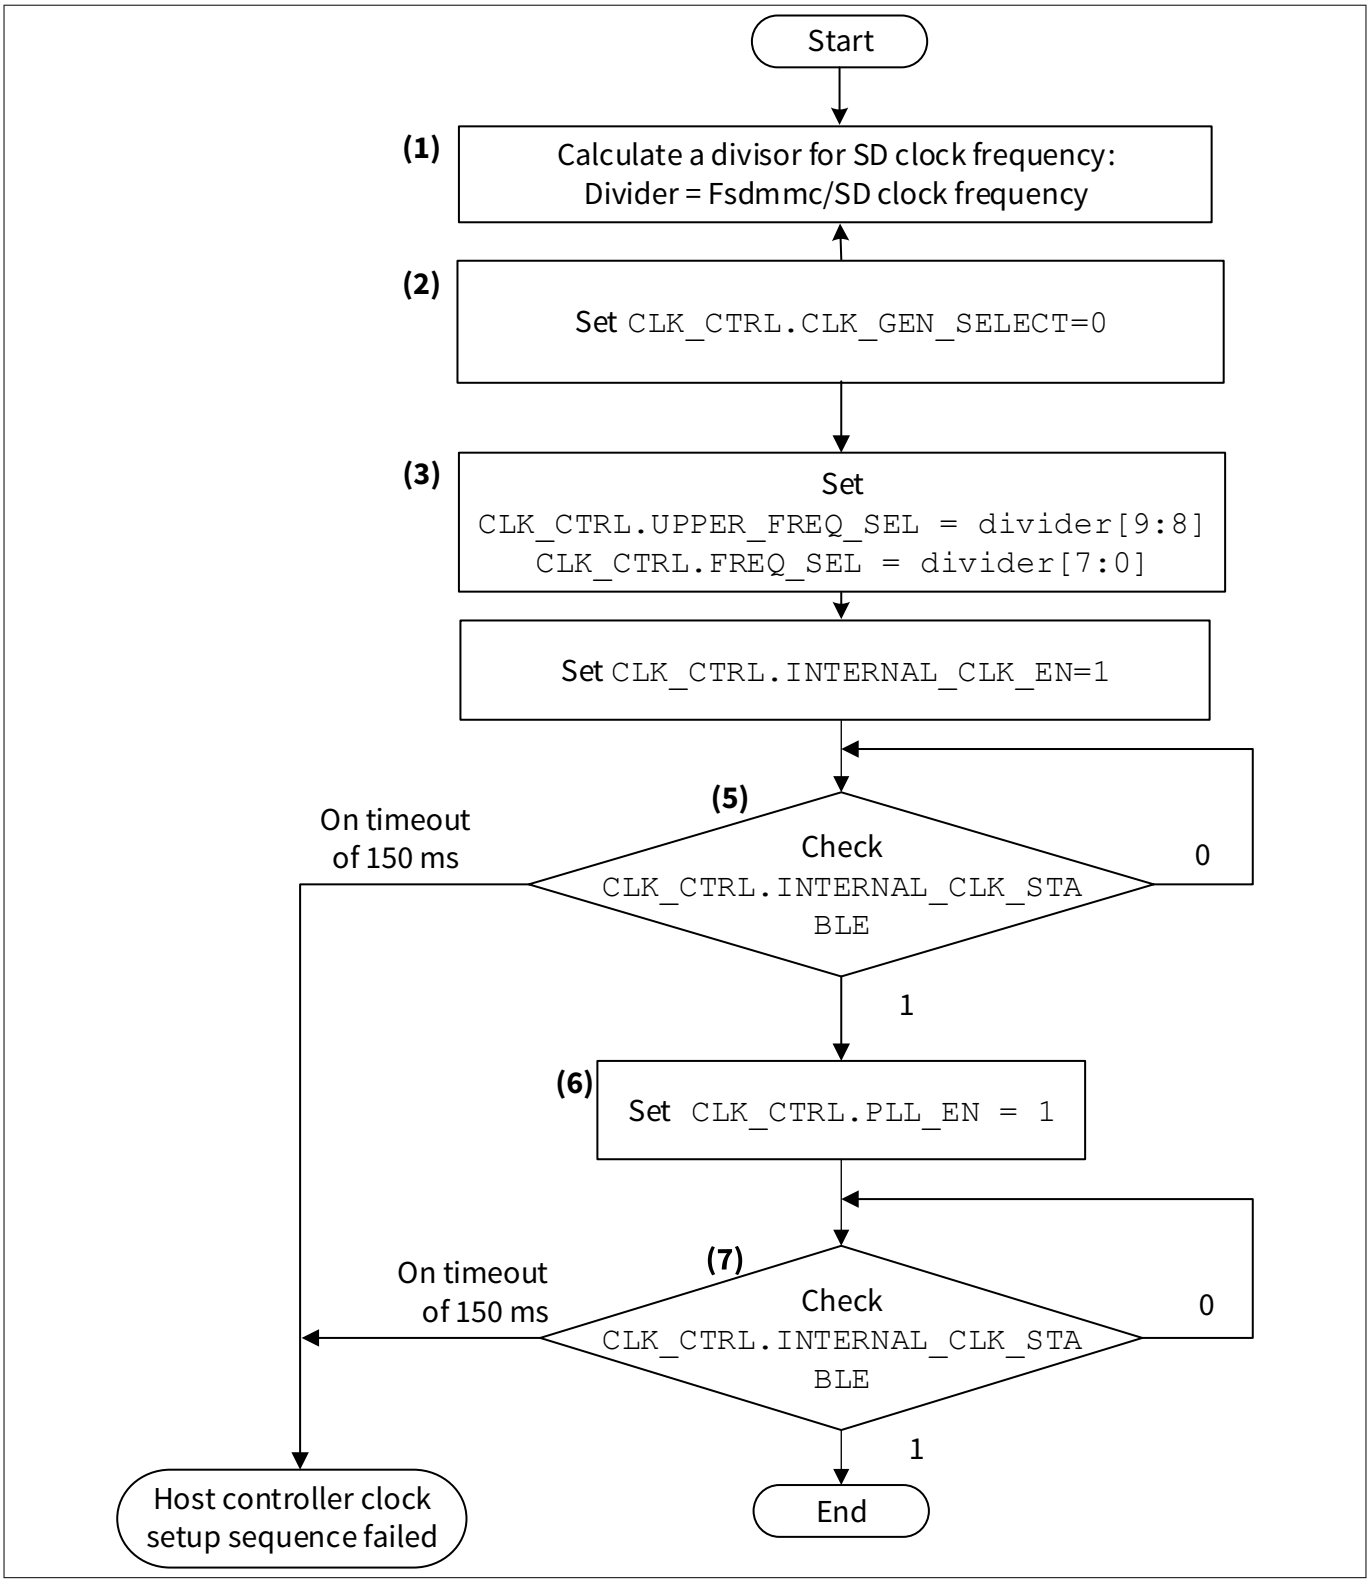

Figure 643 Host controller clock setup sequence

29.3.5.4.2 Card clock supply and stop sequence

The following figure shows the flow chart for stopping the clock to card. The procedure outlined in the figure applies to both SD and eMMC cards.

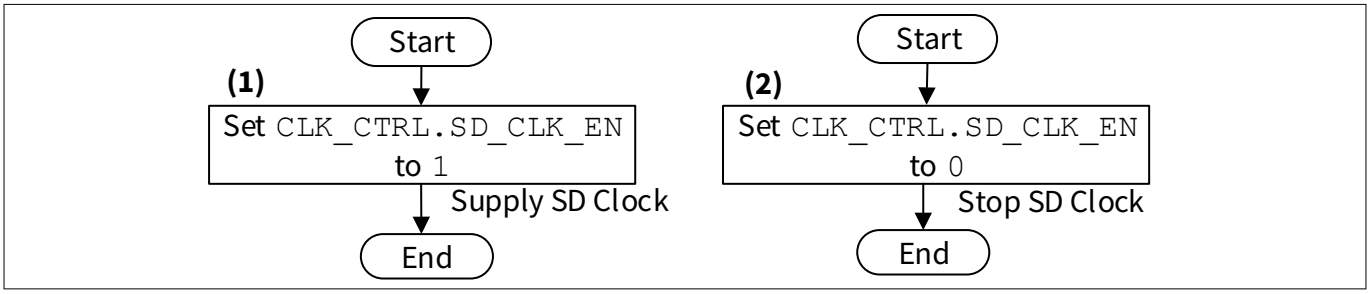

Figure 644 Card clock supply and stop sequence

29.4.3 Clock control register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 000_H

Clock control register Application Reset value: $0000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0				GRST3	GRST2	GRST1	GRST0	0							KRST
r				rh	rh	rh	rh	r							rh

Field	Bits	Type	Description
KRST	0	rh	**Kernel reset status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.
GRSTx (x=0-3)	x+8	rh	**Status for global module reset group x** 0_B Reset was not triggered by global reset group x 1_B Reset was triggered by global reset group x
0	7:1, 31:12	r	**Reserved** Read as 0.

29.4.9 PROT register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 020_H

PROT register endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0												SWEN	STATE		
r												w	rwh		

Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.

(table continues...)

(continued)

Field	Bits	Type	Description
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1232 Access mode restrictions of PROTE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

29.4.10 PROT register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 024_H

PROT register safe endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RDq (q=00-07)	q	rw	**Read access enable for PRS q** This bit enables read access to the access protected region for transactions with the PRS q. 0_B Disabled for read access 1_B Enabled for read access
WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

29.4.17 SDMA system address register

This register is used to configure 32-bit Block Count or SDMA System Address based on the Host Version 4 Enable bit in the Host Control 2 register. This register is applicable for both SD and eMMC modes.

SDMASA Offset address: 400_H

SDMA system address register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BLOCKCNT_SDMASA															
rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BLOCKCNT_SDMASA															
rwh															

Field	Bits	Type	Description
BLOCKCNT_SDMASA	31:0	rwh	**32-bit Block Count (SDMA System Address)** • SDMA System Address (Host Version 4 Enable = 0) - This register contains the system memory address for SDMA transfer in the 32-bit addressing mode. When the Host Controller stops an SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing. Reading this register during data transfers may return invalid value. • 32-bit Block Count (Host Version 4 Enable = 1) - From Host Controller Version 4.10, this register is redefined as 32-bit Block Count. The Host Controller decrements the block count of this register for every block transfer and the data transfer stops when the count reaches zero. This register should be accessed when no transaction is executing. Reading this register during data transfers may return invalid value. • FFFF_FFFFh - 4G - 1 block • ... - ... • 0000_0002h - 2 blocks • 0000_0001h - 1 block • 0000_0000h - Stop Count ***Note**: For Host Version 4 Enable = 0, Host driver shall not program system address in this register while operating in ADMA mode. It should be programmed in ADMA System Address register.* ***Note**: For Host Version 4 Enable = 0, Host driver shall program 32-bit block count in this register when Auto CMD23 is enabled for non-DMA and ADMA mode.*

29.4.18 Block size register

This register is used to configure SDMA buffer boundary and number of bytes in a data block. This register is applicable for both SD and eMMC modes.

BLOCKSIZE Offset address: 404_H

Block size register Kernel Reset value: 0000_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD_BLOCKSIZE15	SDMA_BUF_BDARY			XFER_BLOCK_SIZE											
r	rw			rw											

Field	Bits	Type	Description
XFER_BLOCK_SIZE	11:0	rw	**Transfer Block Size** This register specifies the block size of data transfers. In case of memory, it shall be set up to 512 bytes. It can be accessed only if no transaction is executing. Read operations during transfers may return an invalid value, and write operations shall be ignored. 000_H No Data Transfer 001_H 1 Byte 002_H 2 Bytes … 200_H 512 Bytes 201_H reserved … FFF_H reserved
SDMA_BUF_BDARY	14:12	rw	**SDMA Buffer Boundary** These bits specify the size of contiguous buffer in system memory. The SDMA transfer shall wait at every boundary specified by these fields and the Host Controller generates the DMA interrupt to request the Host Driver to update the SDMA System Address register. 000_B 4K Bytes 001_B 8K Bytes 010_B 16K Bytes 011_B 32K Bytes 100_B 64K Bytes 101_B 128K Bytes 110_B 256K Bytes 111_B 512K Bytes
RSVD_BLOCKSIZE15	15	r	**Reserved** This bit is reserved. It will always return 0.

29.4.19 16-bit block count register

This register is used to configure the number of data blocks. This register is applicable for both SD and eMMC modes.

BLOCKCOUNT Offset address: 406_H

16-bit block count register Kernel Reset value: 0000_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BLOCK_CNT															
rwh															

Field	Bits	Type	Description
BLOCK_CNT	15:0	rwh	**16-bit Block Count** • If Host Version 4 Enable is set 0 or 16-bit Block Count register is set to non-zero, 16-bit Block Count register is selected. • If Host Version 4 Enable is set 1 and 16-bit Block Count register is set to zero, 32-bit Block Count register is selected. ***Note**: For Host Version 4 Enable = 0, this register should be set to 0000h before programming 32-bit block count register when Auto CMD23 is enabled for non-DMA and ADMA mode.* 0000_H Stop Count 0001_H 1 Block 0002_H 2 Blocks … $FFFF_H$ 65535 Blocks

29.4.20 Argument register

This register is used to configure the SD/eMMC command argument.

ARGUMENT Offset address: 408_H

Argument register Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARGUMENT															
rw															

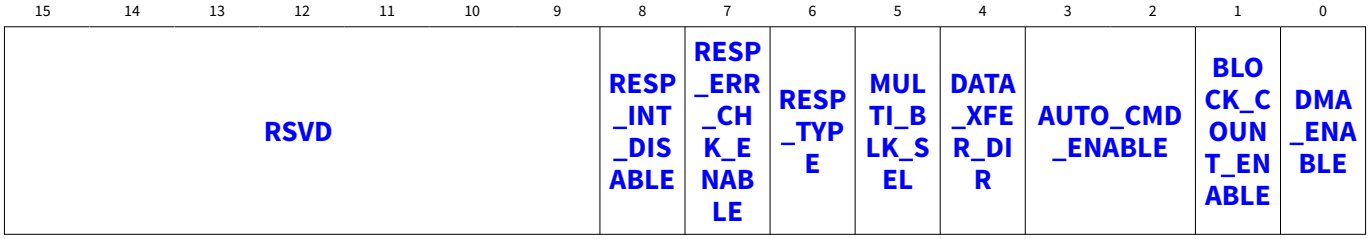
Field	Bits	Type	Description
ARGUMENT	31:0	rw	**Command Argument** The SD/eMMC command argument is specified as bit 39-8 of the command format.

29.4.21 Transfer mode register

This register is used to control the operation of data transfers for an SD/eMMC mode. The Host driver shall set this register before issuing a command that transfers data.

XFER_MODE Offset address: $40C_H$

Transfer mode register Kernel Reset value: 0000_H



Field	Bits	Type	Description
DMA_ENABLE	0	rw	**DMA Enable** This bit enables the DMA functionality. If this bit is set to 1, a DMA operation begins when Host Driver writes to Command register. You can select one of the DMA modes by using DMA Select in the Host Control 1 register. The DMA supports only transfers of 32bit data. The addresses have to be 32bit aligned for 32bit addressing. 0_B No data transfer or Non DMA data transfer 1_B DMA Data transfer
BLOCK_COUNT_ENABLE	1	rw	**Block Count Enable** This bit is used to enable the Block Count register, which is relevant for multiple block transfers. When this bit is 0, the Block Count register is disabled, which is useful in executing an infinite transfer. Host Driver should set this bit to 0 when ADMA is used. 0_B Disable 1_B Enable
AUTO_CMD_ENABLE	3:2	rw	**Auto Command Enable** This field determines use of auto command functions. ***Note**: In SDIO, this field should be set as 00b (Auto Command Disabled).* 00_B Auto Command Disabled 01_B Auto CMD12 Enable 10_B Auto CMD23 Enable 11_B Auto CMD Auto Select
DATA_XFER_DIR	4	rw	**Data Transfer Direction Select** This bit defines the direction of DAT line data transfers. This bit is set to 1 by the Host Driver to transfer data from the SD/eMMC card to the Host Controller and it is set to 0 for all other commands. 0_B Write (Host to Card) 1_B Read (Card to Host)

(table continues...)

(continued)

Field	Bits	Type	Description
MULTI_BLK_SEL	5	rw	**Multi/Single Block Select** This bit is set when issuing multiple-block transfer commands using DAT line. If this bit is set to 0, it is not necessary to set Block Count register. 0_B Write (Single Block) 1_B Read (Multiple Block)
RESP_TYPE	6	rw	**Response Type R1/R5** When response error check is enabled, this bit selects either R1 or R5 response types. Error statuses checked in R1: • OUT_OF_RANGE • ADDRESS_ERROR • BLOCK_LEN_ERROR • WP_VIOLATION • CARD_IS_LOCKED • COM_CRC_ERROR • CARD_ECC_FAILED • CC_ERROR • ERROR Response Flags checked in R5: • COM_CRC_ERROR • ERROR • FUNCTION_NUMBER • OUT_OF_RANGE 0_B R1 (Memory) 1_B R5 (SDIO)
RESP_ERR_CHK_ENABLE	7	rw	**Response Error Check Enable** Host Controller supports response check function to avoid overhead of response error check by Host driver. Only R1 and R5 can be checked by the controller. If Host Controller checks the response error, set this bit to 1 and set Response Interrupt Disable to 1. If an error is detected, Response Error interrupt is generated in the Error Interrupt Status register. ***Note**: Response error check should not be enabled for any reponse type other than R1 and R5.* ***Note**: Response check should not be enabled for tuning command.* 0_B Response Error Check is disabled 1_B Response Error Check is enabled

(table continues...)

(continued)

Field	Bits	Type	Description
RESP_INT_DISABLE	8	rw	**Response Interrupt Disable** Host Controller supports response check function to avoid overhead of response error check by Host driver. Only R1 and R5 can be checked by the controller. If Host Driver checks response error, set this bit to 0 and wait for Command Complete Interrupt and then check the response register. If Host Controller checks response error, set this bit to 1 and set Response Error Check Enable to 1. Command Complete Interrupt is disabled by this bit regardless of Command Complete Signal Enable. ***Note**: While carrying out tuning (When Execute Tuning bit in Host Control2 register is set), command complete interrupt is not generated irrespective of Response Interrupt Disable setting.* 0_B Response Interrupt enabled 1_B Response Interrupt is disabled
RSVD	15:9	r	**Reserved** These bits are reserved. They will always return 0.

29.4.22 Command register

This register is used to provide the information related to command and response packet. This register is applicable for an SD/eMMC mode.

CMD Offset address: $40E_H$

Command register Kernel Reset value: 0000_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD		CMD_INDEX						CMD_TYPE		DATA_PRESENT_SEL	CMD_IDX_CHK_ENABLE	CMD_CRC_CHK_ENABLE	SUB_CMD_FLAG	RESP_TYPE_SELECT	
r		rw						rw		rw	rw	rw	rw	rw	

Field	Bits	Type	Description
RESP_TYPE_SELECT	1:0	rw	**Response Type Select** These bits indicate the type of response expected from the card. 00_B No Response 01_B Response Length 136 10_B Response Length 48 11_B Response Length 48 (check Busy after response)
SUB_CMD_FLAG	2	rw	**Sub Command Flag** This bit distinguishes a main command or a sub command. 0_B Main Command 1_B Sub Command

(table continues...)

(continued)

Field	Bits	Type	Description
CMD_CRC_CHK_ENABLE	3	rw	**Command CRC Check Enable** If this bit is set, Host Controller shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC error. ***Note**: CRC Check enable should be set to 0 for the command with no response, R3 response and R4 response.* 0_B Disable 1_B Enable
CMD_IDX_CHK_ENABLE	4	rw	**Command Index Check Enable** If this bit is set, Host Controller shall check the index field in the response to verify if it has the same value as the command index. If it is not, it is reported as a Command Index error. ***Note**: Index Check enable should be set to 0 for the command with no response, R2 response, R3 response and R4 response.* 0_B Disable 1_B Enable
DATA_PRESENT_SEL	5	rw	**Data Present Select** This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. This bit is set to 0 in the following instances: • Command using CMD line • Command with no data transfer but using busy signal on DAT[0] line • Resume Command 0_B No Data Present 1_B Data Present
CMD_TYPE	7:6	rw	**Command Type** These bits indicate the command type. 00_B Normal Command 01_B Suspend Command 10_B Resume Command 11_B Abort Command
CMD_INDEX	13:8	rw	**Command Index** These bits shall be set to the command number that is specified in bits 45-40 of the Command Format.
RSVD	15:14	r	**Reserved** These bits are reserved. They will always return 0.

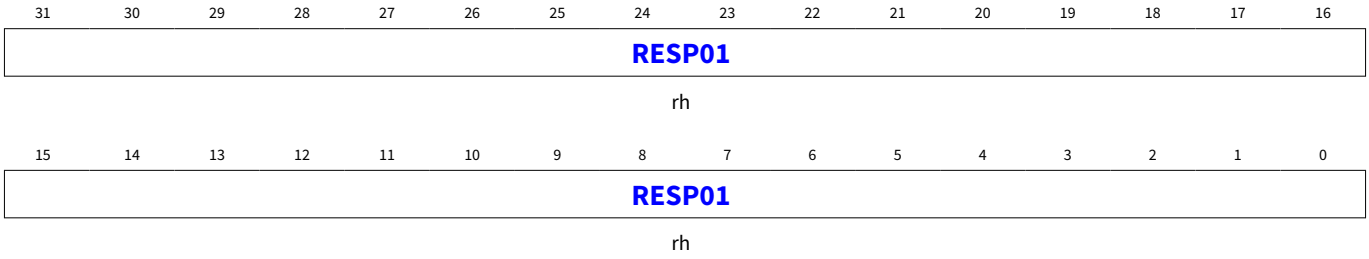
29.4.23 Response register 01

This register is used to store the response from the cards. The response can be a maximum of 128 bits. These 128 bits are segregated into four 32-bit registers: RESP01_R, RESP23_R, RESP45_R and RESP67_R.

RESP01_R stores 39-08 bits of Response Field for an SD/eMMC mode. Writing this register has no effect.

RESP01 Offset address: 410_H

Response register 01 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RESP01	31:0	rh	**Command Response** These bits reflect bits 39-8 of the Response Field. ***Note**: For Auto CMD, the 32-bit response (bits 39-8 of the Response Field) is updated in RESP67_R register.*

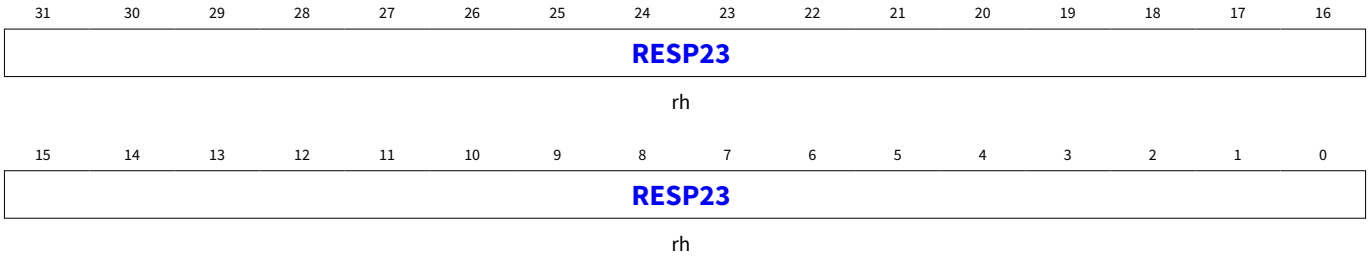
29.4.24 Response register 23

This register is used to store the response from the cards. The response can be of maximum 128 bits. These 128 bits are segregated into four 32-bit registers RESP01_R, RESP23_R, RESP45_R and RESP67_R.

RESP23_R stores 71-40 bits of Response Field for an SD/eMMC mode. Writing this register has no effect.

RESP23 Offset address: 414_H

Response register 23 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RESP23	31:0	rh	**Command Response** These bits reflect bits 71-40 of the Response Field.

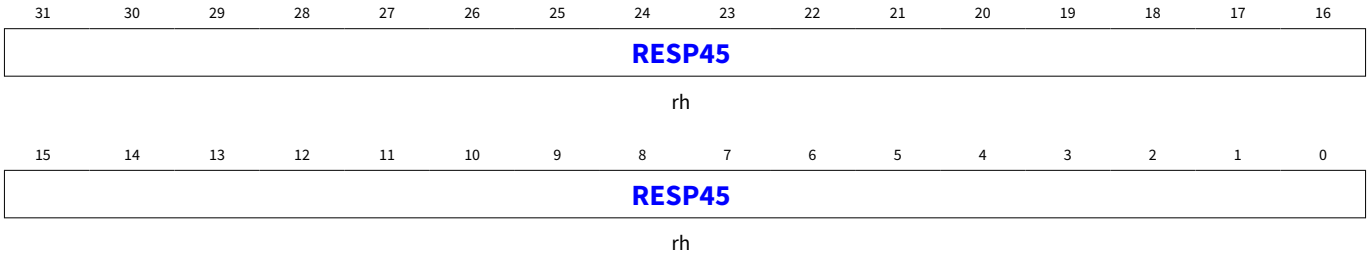
29.4.25 Response register 45

This register is used to store the response from the cards. The response can be of maximum 128 bits. These 128 bits are segregated into four 32-bit registers RESP01_R, RESP23_R, RESP45_R and RESP67_R.

RESP45_R stores 103-72 bits of Response Field for an SD/eMMC mode. Writing this register has no effect.

RESP45 Offset address: 418_H

Response register 45 Kernel Reset value: $0000\ 0000_H$



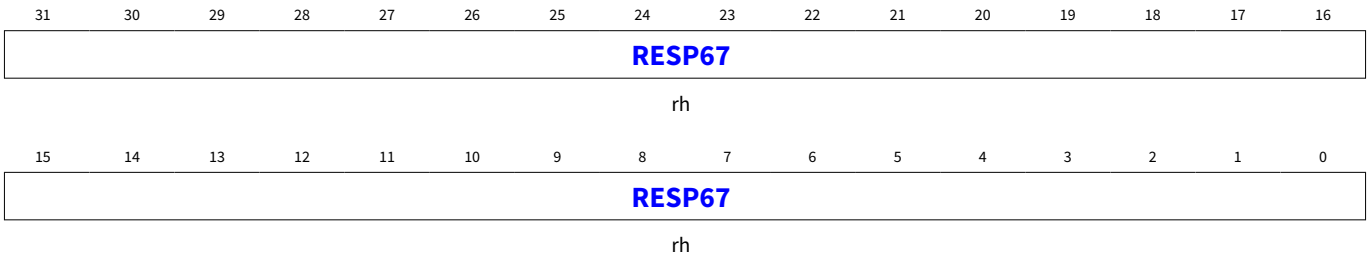
Field	Bits	Type	Description
RESP45	31:0	rh	**Command Response** These bits reflect bits 103-72 of the Response Field.

29.4.26 Response register 67

This register is used to store the response from the cards. The response can be of maximum 128 bits. These 128 bits are segregated into four 32-bit registers RESP01_R, RESP23_R, RESP45_R and RESP67_R. RESP67_R stores 135-104 bits of Response Field for an SD/eMMC mode. Writing this register has no effect.

RESP67 Offset address: $41C_H$

Response register 67 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RESP67	31:0	rh	**Command Response** These bits reflect bits 135-104 of the Response Field. ***Note**: For Auto CMD, this register also reflects the 32-bit response (bits 39-8 of the Response Field).*

29.4.27 Buffer data port register

This register is used to access the packet buffer. This register is applicable for an SD/eMMC mode.

BUF_DATA Offset address: 420_H

Buffer data port register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BUF_DATA															
rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BUF_DATA															
rwh															

Field	Bits	Type	Description
BUF_DATA	31:0	rwh	**Buffer Data** The Host Controller packet buffer can be accessed through this 32-bit Buffer Data Port register.

29.4.28 Present state register

This register indicates the present status of the Host Controller. This register is applicable for an SD/eMMC mode. Writing this register has no effect.

PSTATE_REG Offset address: 424_H

Present state register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UHS2_IF_DETECT	LANE_SYNC	IN_DORMANT_ST	SUB_CMD_STAT	CMD_ISSUE_ERR	RSVD_26	HOST_REG_VOL	CMD_LINE_LVL	DAT_3_0				WR_PROTECT_SW_LVL	CARD_DETECT_LEVEL	CARD_STABLE	CARD_INSERTED
rh	rh	rh	rh	rh	r	rh	rh	rh				rh	rh	rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD_15_12				BUF_RD_ENABLE	BUF_WR_ENABLE	RD_XFER_ACTIVE	WR_XFER_ACTIVE	DAT_7_4				RE_TUNE_REQ	DAT_LINE_ACTIVE	CMD_INHIBIT_DAT	CMD_INHIBIT
r				rh	rh	rh	rh	rh				rh	rh	rh	rh

Field	Bits	Type	Description
CMD_INHIBIT	0	rh	**Command Inhibit (CMD)** In an SD/eMMC mode, if this bit is 0, it indicates that the CMD line is not in use and the Host controller can issue an SD/eMMC command using the CMD line. This bit is set when the command register is written. This bit is cleared when the command response is received. This bit is not cleared by the response of auto CMD12/23 but cleared by the response of read/write command. 0_B Host Controller is not ready to issue a command 1_B Host Controller is ready to issue a command
CMD_INHIBIT_DAT	1	rh	**Command Inhibit (DAT)(SD/eMMC Mode only)** This status bit is generated if either DAT line active or Read transfer active is set to 1. If this bit is 0, it indicates that Host Controller can issue subsequent SD/eMMC commands. 0_B Can issue command which used DAT line 1_B Cannot issue command which used DAT line
DAT_LINE_ACTIVE	2	rh	**DAT Line Active (SD/eMMC Mode only)** This bit indicates whether one of the DAT lines on the SD/eMMC bus is in use. In the case of read transactions, this status indicates whether a read transfer is executing on the SD/eMMC bus. In the case of write transactions, this status indicates whether a write transfer is executing on the SD/eMMC bus. For command with busy, this status indicates whether command executing busy is executing on the SD/eMMC bus. 0_B DAT Line Inactive 1_B DAT Line Active
RE_TUNE_REQ	3	rh	**Re-Tuning Request** This bit can be ignored.
DAT_7_4	7:4	rh	**DAT[7:4] Line Signal Level (Embedded only)** This status is used to check the DAT line level to recover from errors and for debugging.
WR_XFER_ACTIVE	8	rh	**Write Transfer Active (SD/eMMC Mode only)** This status indicates whether a write transfer is active. 0_B No valid data 1_B Transferring data
RD_XFER_ACTIVE	9	rh	**Read Transfer Active (SD/eMMC Mode only)** This status indicates whether a read transfer is active. 0_B No valid data 1_B Transferring data

(table continues...)

(continued)

Field	Bits	Type	Description
BUF_WR_ENABLE	10	rh	**Buffer Write Enable** This status is used for non-DMA transfers. This bit is set if space is available for writing data. 0_B Write disable 1_B Write enable
BUF_RD_ENABLE	11	rh	**Buffer Read Enable** This status is used for non-DMA transfers. This bit is set if valid data exists in Host buffer. 0_B Read disable 1_B Read enable
RSVD_15_12	15:12	r	**Reserved** These bits are reserved. They will always return 0.
CARD_INSERTED	16	rh	**Card Inserted** This bit indicates whether a card has been inserted. The Host Controller shall debounce this signal so that Host Driver will not need to wait for it to stabilize. 0_B Reset or Debouncing or No card 1_B Card Inserted
CARD_STABLE	17	rh	**Card Stable** If this bit is set, it means the Card Detect Level is stable. No card is detected if this bit is set to 1 and card inserted is 0 0_B Reset or Debouncing 1_B No Card or Inserted
CARD_DETECT_LEVEL	18	rh	**Card Detect Pin Level - CARD_DETECT_PIN_LEVEL** This bit usually reflects the card detect stats. I.e, it reflects the inverse synchronized value of **card_detect_n** pin. But, this is not truly reflected in the bitfield because there is no pin connection. The user will need to use other means, i.e. by CMD timeout and checking CARD registers, to check whether a CARD is present and if it is write protected. 0_B No card present 1_B Card Present
WR_PROTECT_SW_LVL	19	rh	**Write Protect Switch Pin Level** The write Protect Switch is supported only for memory and combo card. This bit usually reflects the synchronized value of **card_write_prot**pin. But, this is not truly reflected in the bitfield because there is no pin connection. The user will need to use other means, i.e. by CMD timeout and checking CARD registers, to check whether a CARD is present and if it is write protected. 0_B Write protected 1_B Write enabled

(table continues...)

(continued)

Field	Bits	Type	Description
DAT_3_0	23:20	rh	**DAT[3:0] Line Signal Level (SD/eMMC Mode only)** This status is used to check the DAT line level to recover from errors and for debugging.
CMD_LINE_LVL	24	rh	**Command Line Signal Level (SD/eMMC Mode only)** This status is used to check the CMD line level to recover from errors and for debugging.
HOST_REG_VOL	25	rh	**Host Regulator Voltage Stable** This bit can be ignored.
RSVD_26	26	r	**Reserved** This bit is reserved. It will always return 0.
CMD_ISSUE_ERR	27	rh	**Command Not Issued by Error** This bit is set if a command cannot be issued after setting the command register due to error except Auto CMD12 error 0_B No error for issuing a command 1_B Command cannot be issued
SUB_CMD_STAT	28	rh	**Sub Command Status** This status is used to distinguish main command and sub command status. 0_B Main Command Status 1_B Sub Command Status
IN_DORMANT_ST	29	rh	**In Dormant Status** This bit can be ignored.
LANE_SYNC	30	rh	**Lane Synchronization** This bit can be ignored.
UHS2_IF_DETECT	31	rh	**UHS-II IF Detection** This bit can be ignored.

29.4.29 Host control 1 register

This register is used to control the operation of Host Controller. This register is applicable for an SD/eMMC mode.

HOST_CTRL1 Offset address: 428_H

Host control 1 register Kernel Reset value: 00_H

7	6	5	4	3	2	1	0

rw	rw	rw	rw		rw	rw	rw

Field	Bits	Type	Description
LED_CTRL	0	rw	**LED Control** This bit can be ignored. Must be written with '0'. 0_B LED off 1_B LED on
DAT_XFER_WIDTH	1	rw	**Data Transfer Width (SD/eMMC Mode only)** This bit selects the data width of the Host Controller. The Host Driver shall set it to match the data width of the SD/eMMC card. 0_B 1-bit mode 1_B 4-bit mode
HIGH_SPEED_EN	2	rw	**High Speed Enable (SD/eMMC Mode only)** Before setting this bit, the Host Driver shall check the High Speed Support in the Capabilities register. This bit is used to determine the selection of preset value for High Speed mode. ***Note**: SDMMC always outputs the **sd_cmd_out and sd_dat_out** lines at the rising edge of card clock irrespective of this bit.* 0_B Normal Speed mode 1_B High Speed mode
DMA_SEL	4:3	rw	**DMA Select** This field is used to select the DMA type. When Host Version 4 Enable is 1 in Host Control 2 register: • 00b - SDMA is selected • 01b - Reserved • 10b - ADMA2 is selected • 11b - ADMA2 or ADMA3 is selected When Host Version 4 Enable is 0 in Host Control 2 register: • 00b - SDMA is selected • 01b - Reserved • 10b - 32-bit Address ADMA2 is selected • 11b - Reserved 00_B SDMA is selected 01_B Reserved 10_B ADMA2 is selected (+32 bit address if Host Version 4 enable is 1 in Host Control 2 register) 11_B ADMA2 or ADMA3 is selected
EXT_DAT_XFER	5	rw	**Extended Data Transfer Width (Embedded and an SD/eMMC Mode only)** This bit controls 8-bit bus width mode of embedded device. 0_B Bus Width is selected by Data Transfer Width 1_B 8-bit Bus Width

(table continues...)

(continued)

Field	Bits	Type	Description
CARD_DETECT_TEST_LVL	6	rw	**Card Detect Test Level** This bit is enabled while the Card Detect Signal Selection is set to 1 and it indicates card inserted or not 0_B No Card 1_B Card Inserted
CARD_DETECT_SIG_LVL	7	rw	**Card Detect Signal Selection** This bit selects source for card detection 0_B SDCD# is selected (for normal use) 1_B The Card Detect Test Level is selected (for test purpose)

29.4.30 Power control register

Control the bus power for the Card. This register is applicable for an SD/eMMC mode.

PWR_CTRL Offset address: 429_H

Power control register Kernel Reset value: 00_H

7	6	5	4	3	2	1	0
SD_BUS_VOL_VDD2			SD_BUS_PWR_VDD2	SD_BUS_VOL_VDD1			SD_BUS_PWR_VDD1
rw			rw	rw			rw

Field	Bits	Type	Description
SD_BUS_PWR_VDD1	0	rw	**SD Bus Power for VDD1** Before setting this bit, the SD Host Driver shall set SD Bus Voltage Select. If the Host Controller detects the No Card state, this bit shall be cleared. In SD mode, if this bit is cleared, the Host Controller shall stop SD Clock by clearing SD_CLK_IN bit in CLK_CTRL_R register. 0_B Power off 1_B Power on
SD_BUS_VOL_VDD1	3:1	rw	**SD Bus Voltage Select for VDD1/eMMC Bus Voltage Select for VDD.** By setting these bits, the Host Driver selects the voltage level for the SD/eMMC card. Before setting this register, the Host Driver shall check the Voltage Support bits in the capabilities register. If an unsupported voltage is selected, the Host System shall not supply SD Bus voltage. The value set in this field is available on the SDMMC output signal (sd_vdd1_sel), which will be used by the voltage switching circuitry. 000_B Reserved … 110_B Reserved 111_B SD 3.3 V (Typ.) / eMMC 3.0 V (Typ.)
SD_BUS_PWR_VDD2	4	rw	**SD Bus Power for VDD2.** This bit needs to be written with '1'

(table continues...)

(continued)

Field	Bits	Type	Description
SD_BUS_VOL_VDD2	7:5	rw	**SD Bus Voltage Select for VDD2.** This field needs to be written with 0b000 000_B VDD2 Not Supported 001_B Reserved … 101_B Reserved 110_B Not used 111_B Not used

29.4.31 Block gap control register

The host driver shall use this register to control any operation related to Block Gap. This register is applicable for an SD/eMMC mode.

BGAP_CTRL Offset address: $42A_H$

Block gap control register Kernel Reset value: 00_H

7	6	5	4	3	2	1	0
RSVD_7_4				INT_AT_BGAP	RD_WAIT_CTRL	CONTINUE_REQ	STOP_BG_REQ
r				rw	rw	rwh	rw

Field	Bits	Type	Description
STOP_BG_REQ	0	rw	**Stop At Block Gap Request** This bit is used to stop executing read and write transaction at the next block gap for non-DMA, SDMA and ADMA transfers. 0_B Transfer 1_B Stop
CONTINUE_REQ	1	rwh	**Continue Request** This bit is used to restart the transaction, which was stopped using the Stop At Block Gap Request. The Host Controller automatically clears this bit when the transaction re-starts. If stop at block gap request is set to 1, any write to this bit is ignored. 0_B Not Affected 1_B Restart
RD_WAIT_CTRL	2	rw	**Read Wait Control (SD Mode only)** This bit is used to enable the read wait protocol to stop read data using DAT[2] line if the card supports read wait. Otherwise, the Host Controller has to stop the card clock to hold the read data. Read wait feature is not supported by SDMMC. Software must set this bitfield to 0. 0_B Disable Read Wait Control 1_B Enable Read Wait Control

(table continues...)

(continued)

Field	Bits	Type	Description
INT_AT_BGAP	3	rw	**Interrupt At Block Gap (SD Mode only)** This bit is valid only in 4-bit mode of SDIO card and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. 0_B Disabled 1_B Enabled
RSVD_7_4	7:4	r	**Reserved** These bits of Block Gap Control register are reserved. They will always return 0.

29.4.32 Wakeup control register

This register is mandatory for the Host Controller, but wakeup functionality depends on the Host Controller system hardware and software. The Host Driver shall maintain voltage on the SD Bus, by setting SD Bus Power to 1 in the Power Control Register, when wakeup event through Card Interrupt is desired.

WUP_CTRL Offset address: $42B_H$

Wakeup control register Kernel Reset value: 00_H

7	6	5	4	3	2	1	0
RSVD_7_3					CARD_REMOVAL	CARD_INSERT	CARD_INT
r					rw	rw	rw

Field	Bits	Type	Description
CARD_INT	0	rw	**Wakeup Event Enable on Card Interrupt** This bit enables wakeup event through Card Interrupt assertion in the Normal Interrupt Status register. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. 0_B Disable 1_B Enable
CARD_INSERT	1	rw	**Wakeup Event Enable on SD Card Insertion** This bit enables wakeup event through Card Insertion assertion in the Normal Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not affect this bit. 0_B Disable 1_B Enable
CARD_REMOVAL	2	rw	**Wakeup Event Enable on SD Card Removal** This bit enables wakeup event through Card Removal assertion in the Normal Interrupt Status register.FN_WUS (Wake Up Support) in CIS does not affect this bit. 0_B Disable 1_B Enable
RSVD_7_3	7:3	r	**Reserved** These bits are reserved. They will always return 0.

29.4.33 Clock control kernel register

This register controls SDCLK (card clock) in an SD/eMMC mode. This register is applicable for an SD/eMMC mode.

CLK_CTRL Offset address: $42C_H$

Clock control kernel register Kernel Reset value: 0000_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rwh								rwh		rwh	r	rw	rw	rh	rw

Field	Bits	Type	Description
INTERNAL_CLK_EN	0	rw	**Internal Clock Enable** This bit must be set to 1 to enable the internal clock before programming the SDMMC registers. It is set to 0 when the Host Driver is not using the Host Controller or the Host Controller awaits a wakeup interrupt. The Host Controller should stop its internal clock in-order to enter low power state. However, registers, belonging to hclk domain can still be capable of read and write. There are other registers belonging to bclk domain like BLOCKSIZE, BLOCKCOUNT, ARGUMENT, XFER_MODE_CMD, that cannot be read and written to when there is no internal clock 0_B Stop 1_B Oscillate
INTERNAL_CLK_STABLE	1	rh	**Internal Clock Stable** Host Driver checks clock stability by this status twice after Internal Clock Enable is set and after PLL Enable is set. 0_B Not Ready 1_B Ready
SD_CLK_EN	2	rw	**SD/eMMC Clock Enable** This bit stops the SDCLK or RCLK when this bit is set to 0. SDCLK/RCLK Frequency Select can be changed when this bit is 0. 0_B Disable 1_B Enable
PLL_ENABLE	3	rw	**PLL Enable** This bit can be ignored. Must be written with '0'. 0_B PLL is in low power mode 1_B PLL is enabled
RSVD_4	4	r	**Reserved** This bit is reserved. It will always return 0.

(table continues...)

(continued)

Field	Bits	Type	Description
CLK_GEN_SELECT	5	rwh	**Clock Generator Select** This bit is used to select the clock generator mode in SDCLK/RCLK Frequency Select. If Preset Value Enable = 0, this field is set by Host Driver. If Preset Value Enable = 1, this field is automatically set to a value specified in one of the Preset Value registers. 0_B Divided Clock Mode 1_B Programmable Clock Mode
UPPER_FREQ_SEL	7:6	rwh	**SDCLK/RCLK Upper Frequency Select -** These bits specify the upper 2 bits of 10-bit SDCLK/RCLK Frequency Select control. The value is reflected on the upper 2 bits of the card_clk_freq_sel signal
FREQ_SEL	15:8	rwh	**SDCLK/RCLK Frequency Select** These bits together with UPPER_FREQ_SEL are used to select the frequency of the SDCLK pin. This field depends on setting of Preset Value Enable in Host Control 2 register. If Preset Value Enable = 0, this field is set by Host Driver. If Preset Value Enable = 1, this field is automatically set to a value specified in one of the Preset Value register. frequency of the SDCLK pin is calculated with the formula =Fsdmmc * 1/((N+1)*2). Here Fsdmmc= 100MHz **10-bit Divided Clock Mode:** • 3FFh - 1/2048 Fsdmmc • ... - ... • N - 1/2(N+1) Fsdmmc • ... - ... • 002h - 1/6 Fsdmmc • 001h - 1/4 Fsdmmc • 000h - 1/2 Fsdmmc

29.4.34 Timeout control register

At the initialization of the Host Controller, the Host Driver shall set the Data Timeout Counter value for an SD/eMMC mode according to the timer clock defined in the Capabilities register.

TOUT_CTRL Offset address: $42E_H$

Timeout control register Kernel Reset value: 00_H

7	6	5	4	3	2	1	0
RSVD_7_4				TOUT_CNT			
r				rw			

Field	Bits	Type	Description
TOUT_CNT	3:0	rw	**Data Timeout Counter Value.** This value determines the interval by which DAT line timeouts are detected. The Timeout is based on the base clock TMCLK, which is fSPB devided by 32. Timeout clock frequency will be generated by dividing the base clock TMCLK value by this value. When setting this register, prevent inadvertent timeout events by clearing the Data Timeout Error Status Enable (in the Error Interrupt Status Enable register) ***Note**: During a boot operating in an eMMC mode, an application should configure the boot data timeout value (approximately 1 sec) in this field.* 0_H TMCLK * 2^13 1_H TMCLK * 2^14 2_H TMCLK * 2^15 … E_H TMCLK * 2^27 F_H Reserved
RSVD_7_4	7:4	r	**Reserved** These bits are reserved. They will always return 0.

29.4.35 Software reset register

A reset pulse is generated when writing 1 to each bit of this register. After completing the reset, the Host Controller shall clear each bit. As it takes some time to complete software reset, the Host Driver shall confirm that these bits are 0. This register is applicable for an SD/eMMC mode.

SW_RST Offset address: $42F_H$

Software reset register Kernel Reset value: 00_H

7	6	5	4	3	2	1	0

Field	Bits	Type	Description
CMD_COMPLETE	0	rwh	**Command Complete** In an SD/eMMC Mode, this bit is set when the end bit of a response except for Auto CMD12 and Auto CMD23. This interrupt is not generated when the Response Interrupt Disable in Transfer Mode Register is set to 1. A write of 1 clears this register field. 0_B No command complete 1_B Command Complete
XFER_COMPLETE	1	rwh	**Transfer Complete** This bit is set when a read/write transfer and a command with status busy is completed. A write of 1 clears this register field. 0_B Not complete 1_B Command execution is completed
BGAP_EVENT	2	rwh	**Block Gap Event** This bit is set when both read/write transaction is stopped at block gap due to Stop at Block Gap Request. A write of 1 clears this register field. 0_B No Block Gap Event 1_B Transaction stopped

(table continues...)

(continued)

Field	Bits	Type	Description
DMA_INTERRUPT	3	rwh	**DMA Interrupt** This bit is set if the Host Controller detects the SDMA Buffer Boundary during transfer. In case of ADMA, by setting Int field in the descriptor table, Host controller generates this interrupt. This interrupt shall not be generated after Transfer Complete. A write of 1 clears this register field. 0_B No DMA Interrupt 1_B DMA Interrupt is generated
BUF_WR_READY	4	rwh	**Buffer Write Ready** This bit is set if the Buffer Write Enable changes from 0 to 1. A write of 1 clears this register field. 0_B Not ready to write buffer 1_B Ready to write buffer
BUF_RD_READY	5	rwh	**Buffer Read Ready** This bit is set if the Buffer Read Enable changes from 0 to 1. A write of 1 clears this register field. 0_B Not ready to read buffer 1_B Ready to read buffer
CARD_INSERTION	6	rwh	**Card Insertion** This bit is set if the Card Inserted in the Present State register changes from 0 to 1. A write of 1 clears this register field. 0_B Card state stable or Debouncing 1_B Card Inserted
CARD_REMOVAL	7	rwh	**Card Removal** This bit is set if the Card Inserted in the Present State register changes from 1 to 0. A write of 1 clears this register field. 0_B Card state stable or Debouncing 1_B Card Removed
CARD_INTERRUPT	8	rh	**Card Interrupt** This bit reflects the synchronized value of: DAT[1]. ***Note**: This reflection changes after the interrupt ocurred. Clearing the interrupt is only possible by clearing it inside the card while the CARD_INTERRUPT is disabled inside SDMMC.* 0_B No Card Interrupt 1_B Generate Card Interrupt

(table continues...)

(continued)

Field	Bits	Type	Description
INT_A	9	rh	**INT_A (Embedded)** This bit is set if INT_A is enabled. 0_B No Interrupt is detected 1_B INT_A is detected
INT_B	10	rh	**INT_B (Embedded)** This bit is set if INT_B is enabled. 0_B No Interrupt is detected 1_B INT_B is detected
INT_C	11	rh	**INT_C (Embedded)** This bit is set if INT_C is enabled. 0_B No Interrupt is detected 1_B INT_C is detected
RE_TUNE_EVENT	12	r	**Re-tuning Event** This bit can be ignored.
FX_EVENT	13	rh	**FX Event** This status is set when r[14] of response register is set to 1 and Response Type R1/R5 is set to 0 in Transfer Mode register. This interrupt is used with response check function. 0_B No Event 1_B FX Event is detected
CQE_EVENT	14	rwh	**Command Queuing Event** This bit can be ignored. 0_B No Event 1_B Command Queuing Event is detected
ERR_INTERRUPT	15	rh	**Error Interrupt** If any of the bits in the Error Interrupt Status register are set, then this bit is set. 0_B No Error 1_B Error

29.4.37 Error interrupt status register

Signals defined in this register can be enabled by the Error Interrupt Status Enable register, but not by the Error Interrupt Signal Enable register. The interrupt is generated when the Error Interrupt Status Enable is enabled and at least one of the statuses is set to 1. Writing to 1 clears the bit and writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. This register is applicable for an SD/eMMC mode.

ERROR_INT_STAT Offset address: 432_H

Error interrupt status register Kernel Reset value: 0000_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VENDOR_ERR3	VENDOR_ERR2	VENDOR_ERR1	BOOT_ACK_ERR	RESP_ERR	TUNING_ERR	ADMA_ERR	AUTO_CMD_ERR	CUR_LMT_ERR	DATA_END_BIT_ERR	DATA_CRC_ERR	DATA_TOUT_ERR	CMD_IDX_ERR	CMD_END_BIT_ERR	CMD_CRC_ERR	CMD_TOUT_ERR
rw	rw	rw	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
CMD_TOUT_ERR	0	rwh	**Command Timeout Error (SD/eMMC Mode only)** This bit is set only if no response is returned within 64 SD clock cycles from the end bit of the command. If the Host Controller detects a CMD line conflict, clock cycles. A write of 1 clears this register field. 0_B No Error 1_B Time out
CMD_CRC_ERR	1	rwh	**Command CRC Error (SD/eMMC Mode only)** Command CRC Error is generated in two cases. If a response is returned and the Command Timeout Error is set to 0 (indicating no timeout), this bit is set to 1 when detecting a CRC error in the command response. The Host Controller detects a CMD line conflict by monitoring the CMD line when a command is issued. If the Host Controller drives the CMD line to 1 level, but detects 0 level on the CMD line at the next SD clock edge, then the Host Controller shall abort the command (stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict. A write of 1 clears this register field. 0_B No Error 1_B CRC Error Generated
CMD_END_BIT_ERR	2	rwh	**Command End Bit Error (SD/eMMC Mode only)** This bit is set when detecting that the end bit of a command response is 0. A write of 1 clears this register field. 0_B No Error 1_B End Bit Error Generated
CMD_IDX_ERR	3	rwh	**Command Index Error (SD/eMMC Mode only)** This bit is set if a Command Index error occurs in the command response. A write of 1 clears this register field. 0_B No Error 1_B Error

(table continues...)

(continued)

Field	Bits	Type	Description
DATA_TOUT_ERR	4	rwh	**Data Timeout Error (SD/eMMC Mode only)** This bit is set when detecting one of the following timeout conditions: - Busy timeout for R1b, R5b type - Busy timeout after Write CRC status - Write CRC Status timeout - Read Data timeout A write of 1 clears this register field. 0_B No Error 1_B Time out
DATA_CRC_ERR	5	rwh	**Data CRC Error (SD/eMMC Mode only).** This error occurs when detecting CRC error when transferring read data which uses the DAT line, when detecting the Write CRC status having a value of other than 010 or when write CRC status timeout. A write of 1 clears this register field. 0_B No Error 1_B Error
DATA_END_BIT_ERR	6	rwh	**Data End Bit Error (SD/eMMC Mode only)** This error occurs either when detecting 0 at the end bit position of read data that uses the DAT line or at the end bit position of the CRC status. A write of 1 clears this register field. 0_B No Error 1_B Error
CUR_LMT_ERR	7	rwh	**Current Limit Error** By setting the SD Bus Power bit in the Power Control register, the Host Controller is requested to supply power for the SD Bus. If the Host Controller supports the Current Limit function, it can be protected from an illegal card by stopping power supply to the card in which case this bit indicates a failure status. A reading of 1 for this bit means that the Host Controller is not supplying power to the SD card due to some failure. A reading of 0 for this bit means that the Host Controller is supplying power and no error has occurred. The Host Controller may require some sampling time to detect the current limit. If the Host Controller does not support this function, this bit shall always be set to 0. A write of 1 clears this register field. 0_B No Error 1_B Power Fail

(table continues...)

(continued)

Field	Bits	Type	Description
AUTO_CMD_ERR	8	rwh	**Auto CMD Error (SD/eMMC Mode only)** This error status is used by Auto CMD12 and Auto CMD23. This bit is set when detecting that any of the bits D00 to D05 in Auto CMD Error Status register has changed from 0 to 1. D07 is effective in case of Auto CMD12. Auto CMD Error Status register is valid while this bit is set to 1 and may be cleared by clearing of this bit (another implementation is also allowed). A write of 1 clears this register field. 0_B No Error 1_B Error
ADMA_ERR	9	rwh	**ADMA Error** This bit is set when the Host Controller detects error during ADMA-based data transfer. The error could be due to following reasons: • Error response received from System bus (Master I/F) • ADMA3,ADMA2 Descriptors invalid • CQE Task or Transfer descriptors invalid When the error occurs, the state of the ADMA is saved in the ADMA Error Status register. In eMMC CQE mode: The Host Controller generates this Interrupt when it detects an invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error has occurred in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. A write of 1 clears this register field. 0_B No Error 1_B Error
TUNING_ERR	10	rwh	**Tuning Error** This bit can be ignored and needs to be written to with '0'.
RESP_ERR	11	rwh	**Response Error (SD Mode only)** Host Controller Version 4.00 supports response error check function to avoid overhead of response error check by Host Driver during DMA execution. If Response Error Check Enable is set to 1 in the Transfer Mode register, Host Controller Checks R1 or R5 response. If an error is detected in a response, this bit is set to 1. A write of 1 clears this register field. 0_B No Error 1_B Error

(table continues...)

(continued)

Field	Bits	Type	Description
BOOT_ACK_ERR	12	rwh	**Boot Acknowledgement Error (eMMC Mode only)** This bit is set when there is a timeout for boot acknowledgement or when detecting boot ack status having a value other than 010. This is applicable only when boot acknowledgement is expected and boot feature in SDMMC is enabled with DWC_MSHC_EMMC_BOOT_EN = 1. A write of 1 clears this register field. 0_B No Error 1_B Error
VENDOR_ERR1	13	rw	**Reserved** This bit can be ignored. Must be written with '0'. 0_B No Error 1_B Error
VENDOR_ERR2	14	rw	**Reserved** This bit can be ignored. Must be written with '0'. 0_B No Error 1_B Error
VENDOR_ERR3	15	rw	**Reserved** This bit can be ignored. Must be written with '0'. 0_B No Error 1_B Error

29.4.38 Normal interrupt status enable register

This register enables the Interrupt Status for Normal Interrupt Status register (NORMAL_INT_STAT_R) when NORMAL_INT_STAT_R is set to 1. This register is applicable for an SD/eMMC mode.

NORMAL_INT_STAT_EN Offset address: 434_H

29.4.41 Error interrupt signal enable register

This register is used to select the interrupt status that is notified to the Host System as an interrupt. All these status bits share the same 1-bit interrupt line. Setting any of these bits to 1 enables interrupt generation. This register is applicable for an SD/eMMC mode.

ERROR_INT_SIGNAL_EN Offset address: $43A_H$

29.4.42 Auto CMD status register

This register is used to indicate the CMD12 response error of Auto CMD12, and the CMD23 response error of Auto CMD23. The Host driver can determine the kind of Auto CMD12/CMD23 errors that can occur in this register. Auto CMD23 errors are indicated in bit 04-01. This register is valid only when Auto CMD Error is set. This register is applicable for an SD/eMMC mode. Writing this register has no effect.

AUTO_CMD_STAT Offset address: $43C_H$

Auto CMD status register Kernel Reset value: 0000_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

CMD23_ENABLE	11	rw	**CMD23 Enable** If the card supports CMD23, this bit is set to 1. This bit is used to select Auto CMD23 or Auto CMD12 for ADMA3 data transfer. 0_B Auto CMD23 is disabled 1_B Auto CMD23 is enabled

(table continues...)

(continued)

Field	Bits	Type	Description
HOST_VER4_ENABLE	12	rw	**Host Version 4 Enable** This bit selects either Version 3.00 compatible mode or Version 4 mode. Functions of following fields are modified for Host Version 4 mode: • SDMA Address: SDMA uses ADMA System Address ($05F_H$-058_H) instead of SDMA System Address register (003_H-000_H) • ADMA2/ADMA3 selection: ADMA3 is selected by DMA select in Host Control 1 register • 32-bit Block Count: SDMA System Address register (003_H-000_H) is modified to 32-bit Block Count register ***Note**: It is recommended not to program ADMA3 Integrated Descriptor Address registers while operating in Host version less than 4 mode (Host Version 4 Enable = 0).* 0_B Version 3.00 compatible mode 1_B Version 4 mode
ADDRESSING	13	rw	**64-bit Addressing** This bit is effective when Host Version 4 Enable is set to 1. 0_B 32 bits addressing 1_B Reserved
ASYNC_INT_ENABLE	14	rw	**Asynchronous Interrupt Enable** This bit can be set if a card supports asynchronous interrupts and Asynchronous Interrupt Support is set to 1 in the Capabilities register. 0_B Disabled 1_B Enabled
PRESET_VAL_ENABLE	15	rw	**Preset Value Enable** This bit enables automatic selection of SDCLK frequency and Driver strength Preset Value registers. When Preset Value Enable is set, SDCLK frequency generation (Frequency Select and Clock Generator Select) amd driver strength selection is performed by the controller. These values are selected from set of Preset Value registers based on selected speed mode. During initialization, the host driver needs to manually set the clock preset value to SDCLK/Rclk frequency select. Preset value enable can be set after intialization completed, in accordance with PartA2_SD Host_controller_simplified_specification. 0_B SDCLK and Driver Strength are controlled by Host Driver 1_B Automatic Selection of SDCLK frequency and Driver Strength as Preset Values are Enabled

29.4.44 Capabilities 1 register 0 to 31

This register provides the Host Driver with information specific to the Host Controller implementation. The host controller implements these values as fixed. Capabilities register is segregated into two 32-bit registers: CAPABILITIES1_R and CAPABILITIES2_R. The CAPABILITIES1_R register is the lower part of Capabilities register. Writing this register has no effect.

CAPABILITIES1 Offset address: 440_H

Capabilities 1 register 0 to 31 Kernel Reset value: $216C\ 6483_H$

29.4.48 Force event register for auto CMD error status register

The register is not physically implemented, but is an address at which the Auto CMD Error Status register can be written. This register is applicable for an SD/eMMC mode.

- 1 : Sets each bit of the Auto CMD Error Status register
- 0 : No effect

FORCE_AUTO_CMD_STAT Offset address: 450_H

Force event register for auto CMD error status register Kernel Reset value: 0000_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD_15_8								FORCE_CMD_NOT_ISSUED_AUTO_CMD12	RSVD_6	FORCE_AUTO_CMD_RESP_ERR	FORCE_AUTO_CMD_IDX_ERR	FORCE_AUTO_CMD_EBIT_ERR	FORCE_AUTO_CMD_CRC_ERR	FORCE_AUTO_CMD_TOUT_ERR	FORCE_AUTO_CMD12_NOT_EXEC
w								w	w	w	w	w	w	w	w

Field	Bits	Type	Description
FORCE_AUTO_CMD12_NOT_EXEC	0	w	**Force Event for Auto CMD12 Not Executed** 0_B Not Affected 1_B Auto CMD12 Not Executed Status is set
FORCE_AUTO_CMD_TOUT_ERR	1	w	**Force Event for Auto CMD Timeout Error** 0_B Not Affected 1_B Force Event for Auto CMD Timeout Error Status is set
FORCE_AUTO_CMD_CRC_ERR	2	w	**Force Event for Auto CMD CRC Error** 0_B Not Affected 1_B Force Event for Auto CMD CRC Error Status is set
FORCE_AUTO_CMD_EBIT_ERR	3	w	**Force Event for Auto CMD End Bit Error** 0_B Not Affected 1_B Force Event for Auto CMD End Bit Error Status is set
FORCE_AUTO_CMD_IDX_ERR	4	w	**Force Event for Auto CMD Index Error** 0_B Not Affected 1_B Force Event for Auto CMD Index Error Status is set
FORCE_AUTO_CMD_RESP_ERR	5	w	**Force Event for Auto CMD Response Error** 0_B Not Affected 1_B Force Event for Auto CMD Response Error Status is set
RSVD_6	6	w	**Reserved** This bit is reserved. It will always return 0.
FORCE_CMD_NOT_ISSUED_AUTO_CMD12	7	w	**Force Event for Command Not Issued By Auto CMD12 Error** 0_B Not Affected 1_B Command Not Issued By Auto CMD12 Error Status is set
RSVD_15_8	15:8	w	**Reserved** These bits are reserved. They will always return 0.

29.4.49 Force event register for error interrupt status

This register is not physically implemented, but is an address at which the Error Interrupt Status register can be written. The effect of a write to this address will be reflected in the Error Interrupt Status register if the corresponding bit of the Error Interrupt Status Enable register is set. This register is applicable for an SD/eMMC mode.

- 1 - Sets each bit of the Error Interrupt Status register
- 0 - No effect

FORCE_ERROR_INT_STAT Offset address: 452_H

Force event register for error interrupt status Kernel Reset value: 0000_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FORCE_VENDOR_ERR3	FORCE_VENDOR_ERR2	FORCE_VENDOR_ERR1	FORCE_BOOT_ACK_ERR	FORCE_RESP_ERR	FORCE_TUNING_ERR	FORCE_ADMA_ERR	FORCE_AUTO_CMD_ERR	FORCE_CUR_LMT_ERR	FORCE_DATA_END_BIT_ERR	FORCE_DATA_CRC_ERR	FORCE_DATA_TOUT_ERR	FORCE_CMD_IDX_ERR	FORCE_CMD_END_BIT_ERR	FORCE_CMD_CRC_ERR	FORCE_CMD_TOUT_ERR
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
FORCE_CMD_TOUT_ERR	0	w	**Force Event for Command Timeout Error (SD/eMMC Mode only)** 0_B Not Affected 1_B Command Timeout Error Status is set
FORCE_CMD_CRC_ERR	1	w	**Force Event for Command CRC Error (SD/eMMC Mode only)** 0_B Not Affected 1_B Command CRC Error Status is set
FORCE_CMD_END_BIT_ERR	2	w	**Force Event for Command End Bit Error (SD/eMMC Mode only)** 0_B Not Affected 1_B Command End Bit Error Status is set
FORCE_CMD_IDX_ERR	3	w	**Force Event for Command Index Error (SD/eMMC Mode only)** 0_B Not Affected 1_B Command Index Error Status is set
FORCE_DATA_TOUT_ERR	4	w	**Force Event for Data Timeout Error (SD/eMMC Mode only)** 0_B Not Affected 1_B Data Timeout Error Status is set
FORCE_DATA_CRC_ERR	5	w	**Force Event for Data CRC Error (SD/eMMC Mode only)** 0_B Not Affected 1_B Data CRC Error Status is set
FORCE_DATA_END_BIT_ERR	6	w	**Force Event for Data End Bit Error (SD/eMMC Mode only)** 0_B Not Affected 1_B Data End Bit Error Status is set

(table continues...)

(continued)

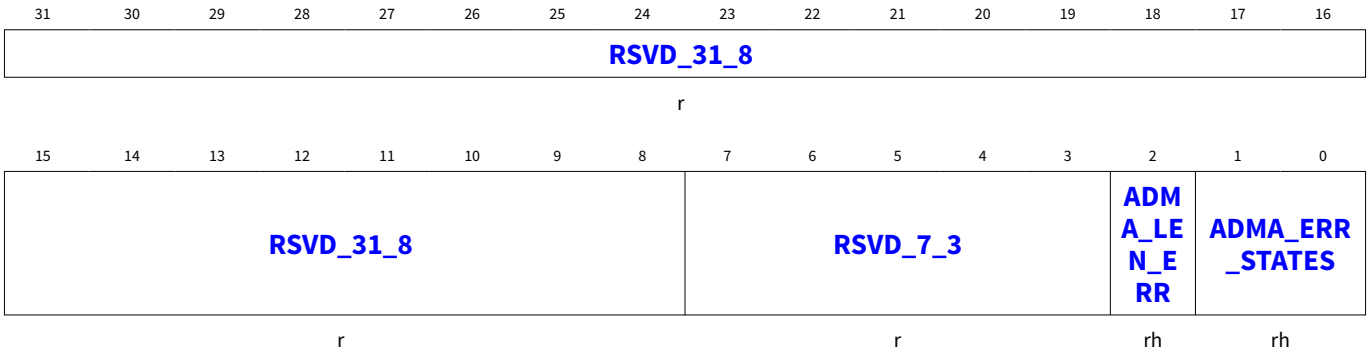
Field	Bits	Type	Description
FORCE_CUR_LMT_ERR	7	w	**Force Event for Current Limit Error** 0_B Not Affected 1_B Current Limit Error Status is set
FORCE_AUTO_CMD_ERR	8	w	**Force Event for Auto CMD Error (SD/eMMC Mode only)** 0_B Not Affected 1_B Auto CMD Error Status is set
FORCE_ADMA_ERR	9	w	**Force Event for ADMA Error** 0_B Not Affected 1_B ADMA Error Status is set
FORCE_TUNING_ERR	10	w	**Force Event for Tuning Error** This bit must remain '0'.
FORCE_RESP_ERR	11	w	**Force Event for Response Error (SD Mode only)** 0_B Not Affected 1_B Response Error Status is set
FORCE_BOOT_ACK_ERR	12	w	**Force Event for Boot Ack error.** 0_B Not Affected 1_B Vendor Specific Error Status is set
FORCE_VENDOR_ERR1	13	w	**Reserved** This bit is reserved. It will always return 0. 0_B Not Affected 1_B Vendor Specific Error Status is set
FORCE_VENDOR_ERR2	14	w	**Reserved** This bit is reserved. It will always return 0. 0_B Not Affected 1_B Vendor Specific Error Status is set
FORCE_VENDOR_ERR3	15	w	**Reserved** This bit is reserved. It will always return 0. 0_B Not Affected 1_B Vendor Specific Error Status is set

29.4.50 ADMA error status register

This register holds the ADMA state during ADMA error. This register is applicable for an SD/eMMC mode. Writing this register has no effect.

ADMA_ERR_STAT Offset address: 454_H

ADMA error status register Kernel Reset value: $0000\ 0000_H$



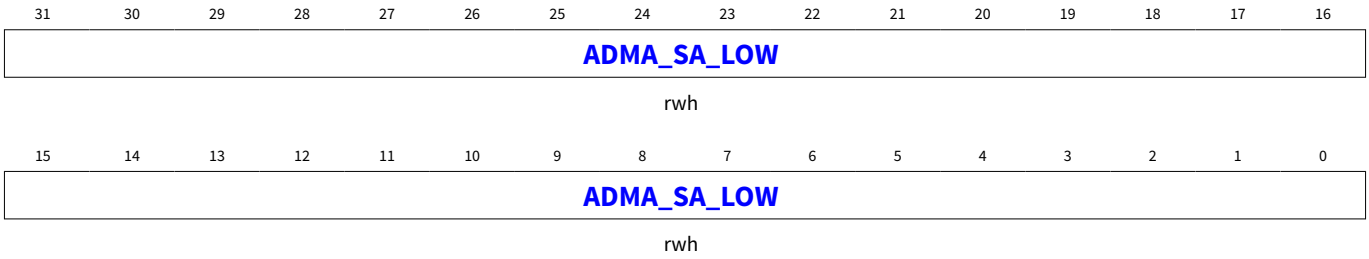
Field	Bits	Type	Description
ADMA_ERR_STATES	1:0	rh	**ADMA Error States** These bits indicate the state of ADMA when an error occurs during ADMA data transfer. 00_B Stop DMA (SYS_ADR register points to a location next to the error descriptor) 01_B Fetch Descriptor (SYS_ADR register points to the error descriptor) 10_B Never set this state (Not used) 11_B Transfer Data (SYS_ADR register points to a location next to the error descriptor)
ADMA_LEN_ERR	2	rh	**ADMA Length Mismatch Error States** This error occurs in the following instances: • While Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length • Total data length cannot be divided by the block length 0_B No Error 1_B Error
RSVD_7_3	7:3	r	**Reserved** These bits are reserved. Read operations may return nonzero values. They shall be ignored.
RSVD_31_8	31:8	r	**Reserved** These bits are reserved. They will always return 0. Volatile: true

29.4.51 ADMA system address register low

This register holds the lower 32-bit system address for DMA transfer. This register is applicable for an SD/eMMC mode.

ADMA_SA_LOW Offset address: 458_H

ADMA system address register low Kernel Reset value: $0000\ 0000_H$



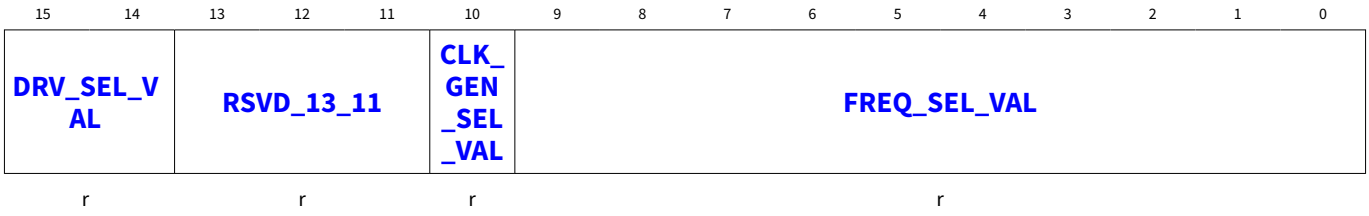
Field	Bits	Type	Description
ADMA_SA_LOW	31:0	rwh	**ADMA System Address** These bits indicate the lower 32 bits of the ADMA system address. • SDMA If Host Version 4 Enable is set to 1, this register holds the system address of the data location • ADMA2 This register holds byte address of executing command of the descriptor table • ADMA3 This register is set by ADMA3. ADMA2 increments the address of this register that points to the next line, every time a Descriptor line is fetched.

29.4.52 Preset value for initialization

This register defines Preset Value for Initialization in SD/eMMC mode. Writing this register has no effect.

PRESET_INIT Offset address: 460_H

Preset value for initialization Kernel Reset value: $007F_H$



Field	Bits	Type	Description
FREQ_SEL_VAL	9:0	r	**SDCLK/RCLK Frequency Select Value** 10-bit preset value to be set in SDCLK/RCLK frequency select field of the clock control kernel register described by a Host System.
CLK_GEN_SEL_VAL	10	r	**Clock Generator Select Value** This bit is effective when the Host Controller supports a programmable clock generator. 0_B Host Controller Ver2.0 Compatible Clock Generator 1_B Programmable Clock Generator

(table continues...)

(continued)

Field	Bits	Type	Description
RSVD_13_11	13:11	r	**Reserved** These bits are reserved. They will always return 0.
DRV_SEL_VAL	15:14	r	**Driver Strength Select Value** Driver strength is supported by 1.8V signaling bus speed modes. This field is meaningless for 3.3V signaling. 00_B Driver Type B is selected 01_B Driver Type A is selected 10_B Driver Type C is selected 11_B Driver Type D is selected

29.4.53 Preset value for default speed

This register defines Preset Value for Default Speed mode in SD mode. Writing this register has no effect.

PRESET_DS Offset address: 462_H

Preset value for default speed Kernel Reset value: 0001_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DRV_SEL_VAL		RSVD_13_11			CLK_GEN_SEL_VAL	FREQ_SEL_VAL									
r		r			r	r									

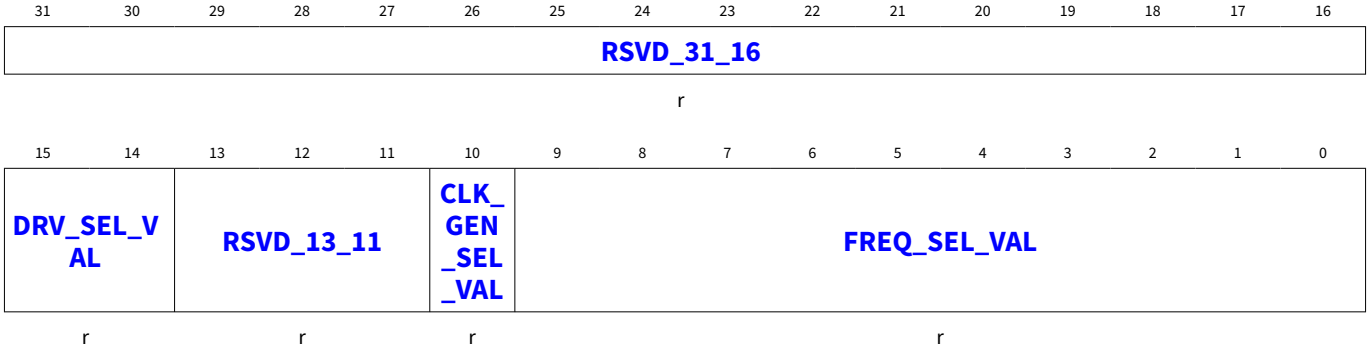
Field	Bits	Type	Description
FREQ_SEL_VAL	9:0	r	**SDCLK/RCLK Frequency Select Value** 10-bit preset value to be set in SDCLK/RCLK frequency select field of the clock control kernel register described by a host System.
CLK_GEN_SEL_VAL	10	r	**Clock Generator Select Value** This bit is effective when Host Controller supports programmable clock generator. 0_B Host Controller Ver2.0 Compatible Clock Generator 1_B Programmable Clock Generator
RSVD_13_11	13:11	r	**Reserved** These bits are reserved. They will always return 0.
DRV_SEL_VAL	15:14	r	**Driver Strength Select Value** Driver strength is supported by 1.8 V signaling bus speed modes. This field is meaningless for 3.3 V signaling. **Value After Reset:** 0_H 00_B Driver Type B is selected 01_B Driver Type A is selected 10_B Driver Type C is selected 11_B Driver Type D is selected

29.4.54 Preset value for high speed

This register defines Preset Value for High Speed mode in SD mode. Writing this register has no effect.

PRESET_HS Offset address: 464_H

Preset value for high speed Kernel Reset value: $0000\ 0000_H$



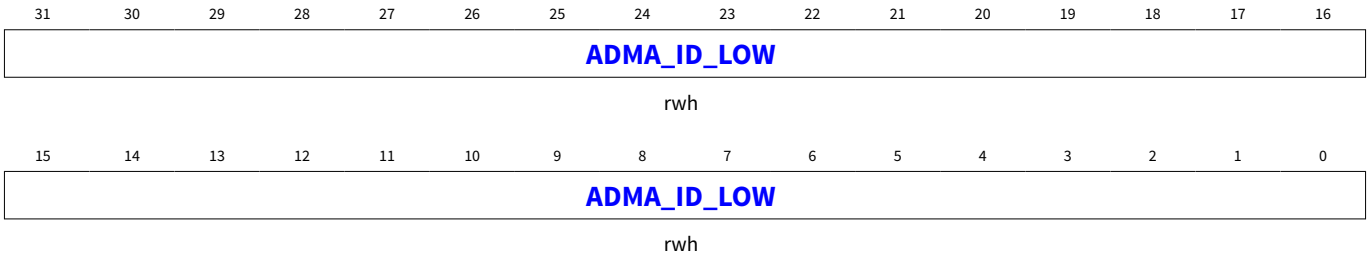
Field	Bits	Type	Description
FREQ_SEL_VAL	9:0	r	**SDCLK/RCLK Frequency Select Value** 10-bit preset value to be set in SDCLK/RCLK frequency select field of the clock control kernel register described by a Host System.
CLK_GEN_SEL_VAL	10	r	**Clock Generator Select Value** This bit is effective when Host Controller supports programmable clock generator. 0_B Host Controller Ver2.0 Compatible Clock Generator 1_B Programmable Clock Generator
RSVD_13_11	13:11	r	**Reserved** These bits are reserved. They will always return 0.
DRV_SEL_VAL	15:14	r	**Driver Strength Select Value** Driver strength is supported by 1.8 V signaling bus speed modes. This field is meaningless for 3.3 V signaling. 00_B Driver Type B is selected 01_B Driver Type A is selected 10_B Driver Type C is selected 11_B Driver Type D is selected
RSVD_31_16	31:16	r	**Reserved** These bits are reserved. They will always return 0.

29.4.55 ADMA3 integrated descriptor address register - low

This register holds the lower 32-bit Integrated Descriptor address.This register is applicable for an SD/eMMC mode.

ADMA_ID_LOW Offset address: 478_H

ADMA3 integrated descriptor address register - low Kernel Reset value: $0000\ 0000_H$



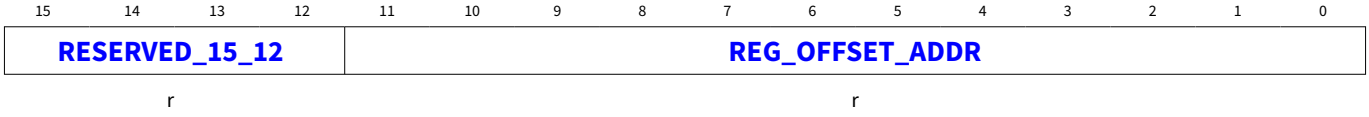
Field	Bits	Type	Description
ADMA_ID_LOW	31:0	rwh	**ADMA Integrated Descriptor Address** This bit indicates the lower 32-bit of the ADMA Integrated Descriptor address. The start address of Integrated Descriptor is set to this register. The ADMA3 fetches one Descriptor Address and increments this field to indicate the next Descriptor address.

29.4.56 Pointer for vendor specific area 1

This register used as a pointer for the Vendor Specific Area 1. Writing this register has no effect.

P_VENDOR_SPECIFIC_AREA Offset address: $4E8_H$

Pointer for vendor specific area 1 Kernel Reset value: 0180_H



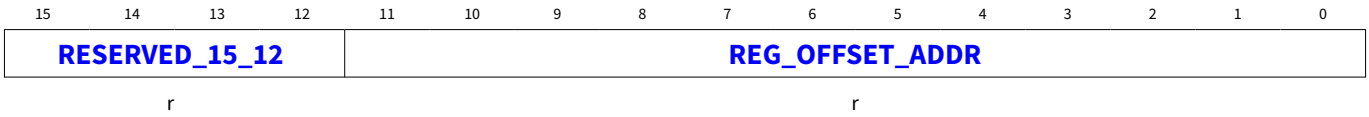
Field	Bits	Type	Description
REG_OFFSET_ADDR	11:0	r	**Base offset Address for Vendor Specific registers.**
RESERVED_15_12	15:12	r	**Reserved** These bits are reserved. They will always return 0.

29.4.57 Pointer for vendor specific area 2

This register is used as a pointer for the Vendor Specific Area 2. Writing this register has no effect.

P_VENDOR2_SPECIFIC_AREA Offset address: $4EA_H$

Pointer for vendor specific area 2 Kernel Reset value: 0300_H



Field	Bits	Type	Description
REG_OFFSET_ADDR	11:0	r	**Base offset Address for Command Queuing registers.**

(table continues...)

(continued)

Field	Bits	Type	Description
RESERVED_15_12	15:12	r	**Reserved** These bits are reserved. They will always return 0.

29.4.58 Slot interrupt status register

This register indicate the Interrupt status of each slot. Writing this register has no effect.

SLOT_INTR_STATUS Offset address: $4FC_H$

Slot interrupt status register Kernel Reset value: 0000_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED_15_8								INTR_SLOT							
r								rh							

Field	Bits	Type	Description
INTR_SLOT	7:0	rh	**Interrupt signal for each Slot** These status bits indicate the logical OR of Interrupt signal and Wakeup signal for each slot. A maximum of 8 slots can be defined. If one interrupt signal is associated with multiple slots, the Host Driver can know which interrupt is generated by reading these status bits. By a power on reset or by setting Software Reset For All, the interrupt signal are de-asserted and this status reads 00h. 01_H Bit 0 - Slot 1 02_H Bit 1 - Slot 2 04_H Bit 2 - Slot 3 08_H Bit 3 - Slot 4 10_H Bit 4 - Slot 5 20_H Bit 5 - Slot 6 40_H Bit 6 - Slot 7 80_H Bit 7 - Slot 8
RESERVED_15_8	15:8	r	**Reserved** These bits are reserved. They will always return 0. **Volatile:** true

29.4.59 Host controller version

This register is used to indicate the Host Controller Version number. Writing this register has no effect.

HOST_CNTRL_VERS Offset address: $4FE_H$

Host controller version Kernel Reset value: 1005_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VENDOR_VERSION_NUM								SPEC_VERSION_NUM							
r								r							

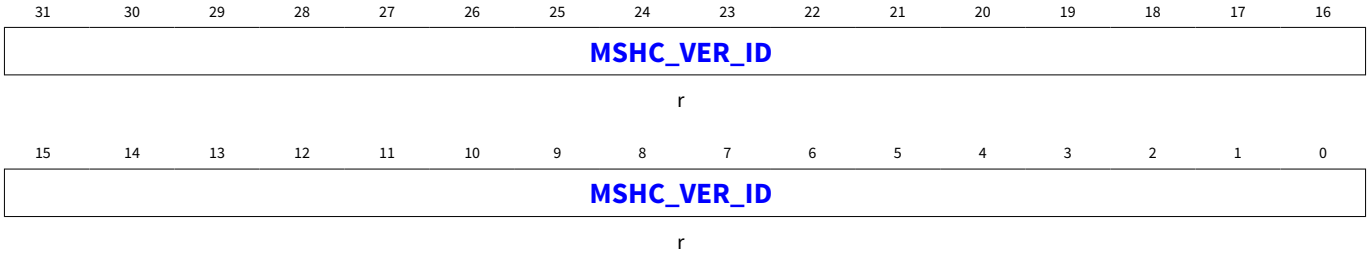
Field	Bits	Type	Description
SPEC_VERSION_NUM	7:0	r	**Specification Version Number** This field indicates Host controller specification version. The upper and lower 4-bits indicate the version. 00_H SD Host Controller Specification Version 1.00 01_H SD Host Controller Specification Version 2.00 02_H SD Host Controller Specification Version 3.00 03_H SD Host Controller Specification Version 4.00 04_H SD Host Controller Specification Version 4.10 05_H SD Host Controller Specification Version 4.20 **others,** Reserved
VENDOR_VERSION_NUM	15:8	r	**Vendor Version Number** This field is reserved for the vendor version number. Host Driver should not use this status.

29.4.60 MSHC version

This register reflects the current release number of SDMMC.

MSHC_VER_ID Offset address: 580_H

MSHC version Kernel Reset value: $3139\ 302A_H$



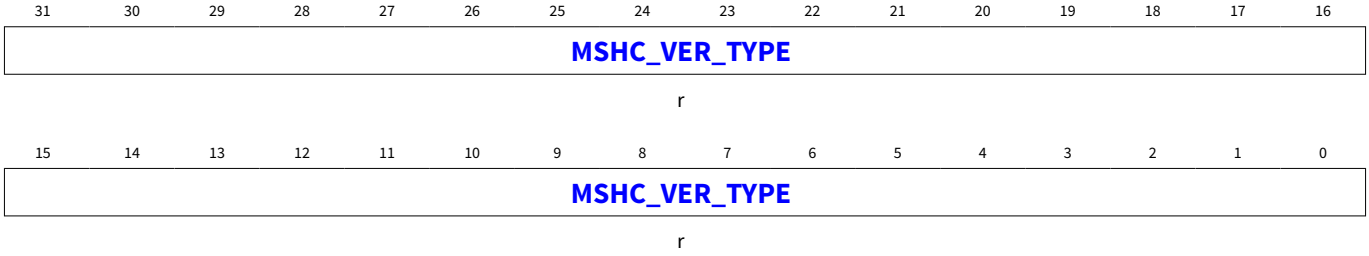
Field	Bits	Type	Description
MSHC_VER_ID	31:0	r	**Current release number** This field indicates the Synopsys DesignWare Cores SDMMC current release number that is read by an application. Current release is 1.80a which is represented in ASCII as 0x313830. Lower 8 bits read from this register can be ignored by the application. Application reading this register in conjunction with MSHC_VER_TYPE_R will gather details of the current release.

29.4.61 MSHC version type

This register reflects the current release type of SDMMC.

MSHC_VER_TYPE Offset address: 584_H

MSHC version type Kernel Reset value: $6561\ 3030_H$



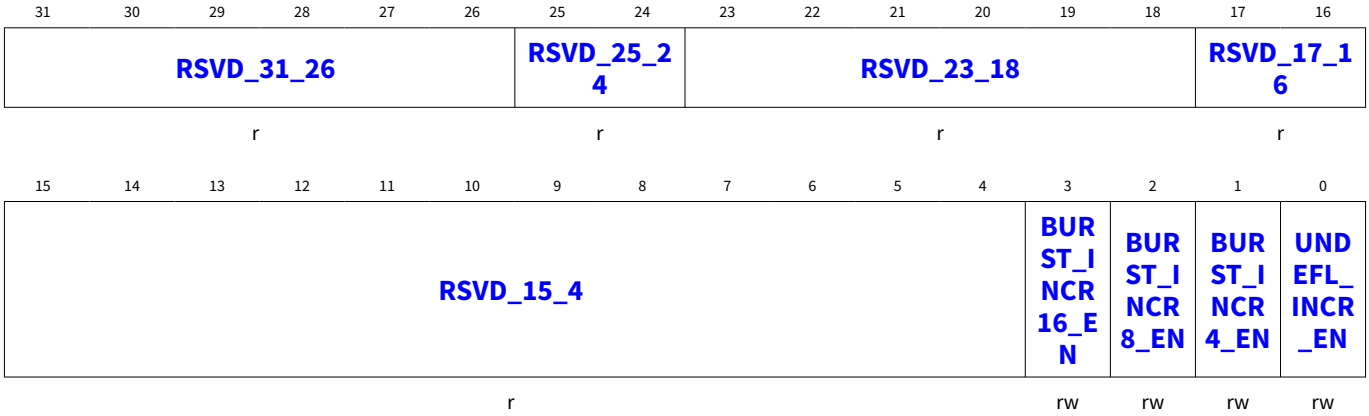
Field	Bits	Type	Description
MSHC_VER_TYPE	31:0	r	**Current release type** This field indicates the Synopsys DesignWare Cores SDMMC current release type that is read by an application. Current release is of type "ga", which is represented in ASCII as 0x6761. Lower 16 bits read from this register can be ignored by the application. Application reading this register in conjunction with MSHC_VER_ID_R will gather details of the current release.

29.4.62 DMA burst control register

This register is used to control the Master bus interface.

MBIU_CTRL Offset address: 590_H

DMA burst control register Kernel Reset value: $0303\ 0007_H$



Field	Bits	Type	Description
UNDEFL_INCR_EN	0	rw	**Controls the generation of undefined length INCR transfer on master interface** Must be disabled for usage of INCR4 and INCR8 bursts. 0_B INCR type bursts are not preferrend on AHB Master interface 1_B INCR type bursts are preferrend on AHB Master interface
BURST_INCR4_EN	1	rw	**Controls generation of INCR4 transfers on master interface** 0_B INCR bursts of length 4 are not generated on the master interface 1_B INCR bursts of length 4 can be generated on the master interface

(table continues...)

(continued)

Field	Bits	Type	Description
BURST_INCR8_EN	2	rw	**Controls generation of INCR8 transfers on master interface** 0_B INCR bursts of length 8 are not generated on the master interface 1_B INCR bursts of length 8 can be generated on the master interface
BURST_INCR16_EN	3	rw	**Controls generation of INCR16 transfers on master interface** Not supported. Must be disabled. 0_B INCR bursts of length 16 are not generated on the master interface 1_B INCR bursts of length 16 can be generated on the master interface
RSVD_15_4	15:4	r	**Reserved - RSVD_7_4** These bits are reserved. They will always return 0.
RSVD_17_16	17:16	r	**Reserved** Write '1' to read '1'.
RSVD_23_18	23:18	r	**Reserved - RSVD_31_8** These bits are reserved. They will always return 0.
RSVD_25_24	25:24	r	**Reserved - RSVD_7_4** Write '1' to read '1'.
RSVD_31_26	31:26	r	**Reserved - RSVD_31_8** These bits are reserved. They will always return 0.

29.4.63 eMMC control register

This register is used to control the eMMC operation.

EMMC_CTRL Offset address: $5AC_H$

eMMC control register Kernel Reset value: $000C_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD												RSVD_3	RSVD_2	DISABLE_DATA_CRC_CHK	CARD_IS_EMMC
r												rw	rw	rw	rw

Field	Bits	Type	Description
CARD_IS_EMMC	0	rw	**eMMC Card present** This bit indicates the type of card connected. An application program this bit based on the card connected to SDMMC. 0_B **NON_EMMC_CARD**: Card connected to is not eMMC card 1_B **EMMC_CARD**: Card connected is eMMC card

(table continues...)

(continued)

Field	Bits	Type	Description
DISABLE_DATA_CRC_CHK	1	rw	**Disable Data CRC Check** This bit controls masking of CRC16 error for Card Write in eMMC mode. This is useful in bus testing (CMD19) for an eMMC device. In bus testing, an eMMC card does not send CRC status for a block, which may generate CRC error. This CRC error can be masked using this bit during bus testing. 0_B **ENABLE**: DATA CRC check is enabled 1_B **DISABLE**: DATA CRC check is disabled
RSVD_2	2	rw	**Reserved** This bit is reserved. Read as 1 and shall be written with 1.
RSVD_3	3	rw	**Reserved** This bit is reserved. Read as 1 and shall be written with 1.
RSVD	15:4	r	**Reserved** These bits (RSVD) of the EMMC_CTRL_R register are reserved. They always return 0.

29.4.64 eMMC boot control register

This register is used to control the eMMC Boot operation.

BOOT_CTRL Offset address: $5AE_H$

eMMC boot control register Kernel Reset value: 0000_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOT_TOUT_CNT				RSVD_11_9			BOOT_ACK_ENABLE	VALIDATE_BOOT	RSVD_6_1						MAN_BOOT_EN
rw				r			rw	w	r						rwh

Field	Bits	Type	Description
MAN_BOOT_EN	0	rwh	**Mandatory Boot Enable** This bit is used to initiate the mandatory boot operation. The application shall set this bit along with VALIDATE_BOOT bit. Writing 0 is ignored. The SDMMC clears this bit after the boot transfer is completed or terminated. **Testable:** readOnly 0_B Mandatory boot disable 1_B Mandatory boot enable
RSVD_6_1	6:1	r	**Reserved** These bits are reserved. They will always return 0.

(table continues...)

(continued)

Field	Bits	Type	Description
VALIDATE_BOOT	7	w	**Validate Mandatory Boot Enable bit** This bit is used to validate the MAN_BOOT_EN bit. 0_B Ignore Mandatory boot Enable bit 1_B Validate Mandatory boot enable bit
BOOT_ACK_ENABLE	8	rw	**Boot Acknowledge Enable** When this bit set, SDMMC checks for boot acknowledge start pattern of 0-1-0 during boot operation. This bit is applicable for both mandatory and alternate boot mode. 0_B Boot Ack disable 1_B Boot Ack enable
RSVD_11_9	11:9	r	**Reserved** These bits are reserved. They will always return 0.
BOOT_TOUT_CNT	15:12	rw	**Boot Ack Timeout Counter Value.** This value determines the interval by which boot ack timeout (50 ms) is detected when boot ack is expected during boot operation. 0_H TMCLK * 2^13 1_H TMCLK * 2^14 2_H TMCLK * 2^15 … E_H TMCLK * 2^27 F_H Reserved

29.4.65 Embedded control register

This register is control embedded device. When host controller is connected to removable device this register is not used.

EMBEDDED_CTRL Offset address: 680_H

Embedded control register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSVD_31	BACK_END_PWR_CTRL							RSVD_23	INT_PIN_SEL			RSVD_19	CLK_PIN_SEL		
r	rw							r	rw			r	rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD_15	BUS_WIDTH_PRESET							RSVD_7_6		NUM_INT_PIN		RSVD_3	NUM_CLK_PIN		
r	r							r		r		r	r		

Field	Bits	Type	Description
NUM_CLK_PIN	2:0	r	**Number of Clock Pins (SD Mode)** This field is not used and can be ignored.

(table continues...)

(continued)

Field	Bits	Type	Description
RSVD_3	3	r	**Reserved** This bit is reserved. It will always return 0.
NUM_INT_PIN	5:4	r	**Number of Interrupt Input Pins** This field is not used and can be ignored.
RSVD_7_6	7:6	r	**Reserved** These bits are reserved. They will always return 0.
BUS_WIDTH_PRESET	14:8	r	**Bus Width Preset (SD Mode)** This field is not used and can be ignored.
RSVD_15	15	r	**Reserved** This bit is reserved. It will always return 0.
CLK_PIN_SEL	18:16	rw	**Clock Pin Select (SD Mode)** This field is not used and should not be changed.
RSVD_19	19	r	**Reserved** This bit is reserved. It will always return 0.
INT_PIN_SEL	22:20	rw	**Interrupt Pin Select** This field is not used and should not be changed.
RSVD_23	23	r	**Reserved** This bit is reserved. It will always return 0.
BACK_END_PWR_CTRL	30:24	rw	**Back-End Power Control (SD Mode)** This field is not used and should not be changed.
RSVD_31	31	r	**Reserved** This bit is reserved. It will always return 0.

29.5 Debug information

The SDMMC module does not include debug feature. Correct functionality of SDMMC is not guaranteed if suspend is enabled in other relevant blocks, with which the SDMMC is transacting.

Initial release of the chapter.

30 Queued Synchronous Peripheral Interface (QSPI)

QSPI provides synchronous serial communication with external devices using clock, data-in, data-out, and slave select signals. Operation as both master and slave, with flexible configurations and timing options are also supported.

30.1 Feature list

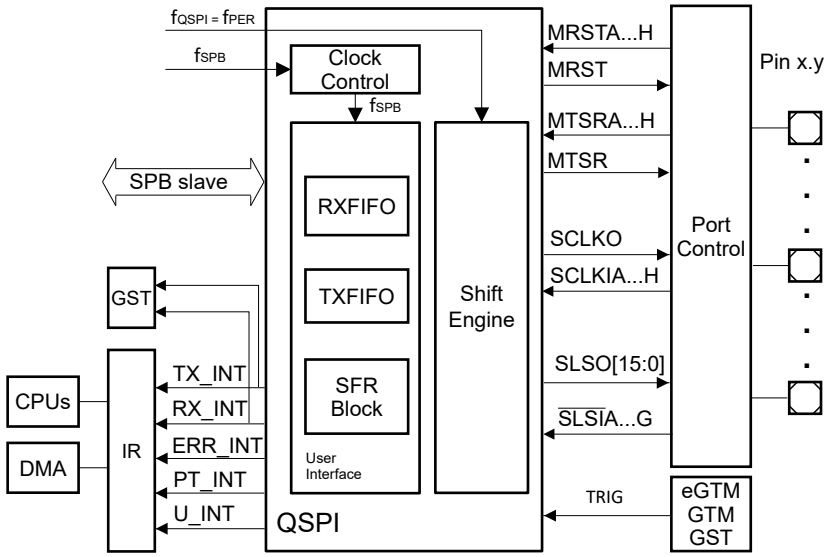
- Master and Slave mode operation
  - Full-duplex operation
  - Half-duplex operation
  - Automatic slave select control
  - Four-wire and three-wire types of connection
- Flexible data format
  - Programmable number of data bits: 2 to 32 data bits (plus parity: 3 to 33 bits)
  - Programmable shift direction: least significant bit (LSB) or most significant bit (MSB) shift first
  - Programmable clock polarity: Idle low or idle high state for the shift clock
  - Programmable clock phase: data shift with leading or trailing edge of the shift clock
- Baud rate generation
  - Baud rates generated from high precision phase locked loop (PLL) clock, asynchronous to the system PLL
- Interrupt generation
  - On a transmitter first-in first-out memory (FIFO) event
  - On a receiver FIFO event
  - On an error condition (receive, baud rate, transmit error, parity error)
  - On a phase transition (At the start of frame for example, or the end of frame)
- Supports control and data handling by the direct memory access (DMA) controller
- Flexible QSPI pin configuration
- Hardware supported parity mode
  - Odd, even, or no parity
- Seven slave select inputs $\overline{\text{SLSIA...G}}$ in Slave mode
- Sixteen programmable slave select outputs SLSO[15:0] in Master mode
  - Automatic SLSO generation with programmable timing
  - Programmable active level and enable control
  - External de-multiplexing of the slave select outputs support
  - Multiple slave select activation (up to 4 slave select outputs)
- Transmission triggering from external timer
- Several module reset options
  - State machine reset per software (only the state machine)
  - Module reset per software (both FIFOs, all registers, and the state machine)
  - Automatic stop option of the state machine in slave mode after baud rate error
- Loop-Back mode
- Interoperability with SSC (Synchronous Serial Channel) and USIC (Universal Serial Interface Channel) modules of Infineon microcontroller families, and with popular (Q)SPI interfaces of multiple suppliers
- Communication stop on RxFIFO full
  - Shift register full and RxFIFO full can pause the communication
  - Interrupt generation

***Note**: Baud rate generation: The maximum baud rate achievable in a particular connection is limited by the timings of both the master and the slave chips, as defined in the corresponding data sheets. Important considerations are the type of Input/Output (I/O) pads used, for example Low Voltage Differential Signalling (LVDS) or Complementary Metal Oxide Semiconductor (CMOS) pads, the I/O power supply voltage, the configured output driver strength, and the allowed electromagnetic radiation and temperature. Due to temperature and voltage change there is variation in loop delay. To compensate that run-time adjustment of sampling point by application software might be required for baud rate higher than 20 Mbit/s*

30.2 Functional overview

The main purpose of the QSPI module is to provide synchronous serial communication with external devices using clock, data-in, data-out and slave select signals. The focus of the module is fast and flexible communication. This can be either point-to-point or master-to-many slaves communication.

Parallel requests from on-chip bus masters to a module will be executed sequentially through the on-chip bus system. A read-modify-write feature provides an atomic read and write sequence where no other master can access the module in between operations. Module hardware semaphores are not supported.



***Note**: In CLOCK chapter this f_{PER} is referenced to as f_{QSPI} for overview purposes*

Figure 645 QSPI block diagram

The figure above shows a high level overview of the QSPI module. The two clock domains of register interface and shift engine are shown, the connection to ports and interrupts. The latter has independent request lines for TX-interrupt (TX_INT), RX-interrupt (RX_INT), Error-interrupt (ERR_INT), Phase transition-interrupt (PT_INT) and User-interrupt (U_INT). These interrupts are connected to the following inputs of the IR: SRC_QSPIwTX, SRC_QSPIwRX, SRC_QSPIwERR, SRC_QSPIwPT, SRC_QSPIwU.

30.2.1 Abstract overview

An abstract overview of the QSPI module is shown in the below picture. This document describes the QSPI module according to this view: the State Machine with its configuration and status capabilities, the User Interface, and the Interrupts.

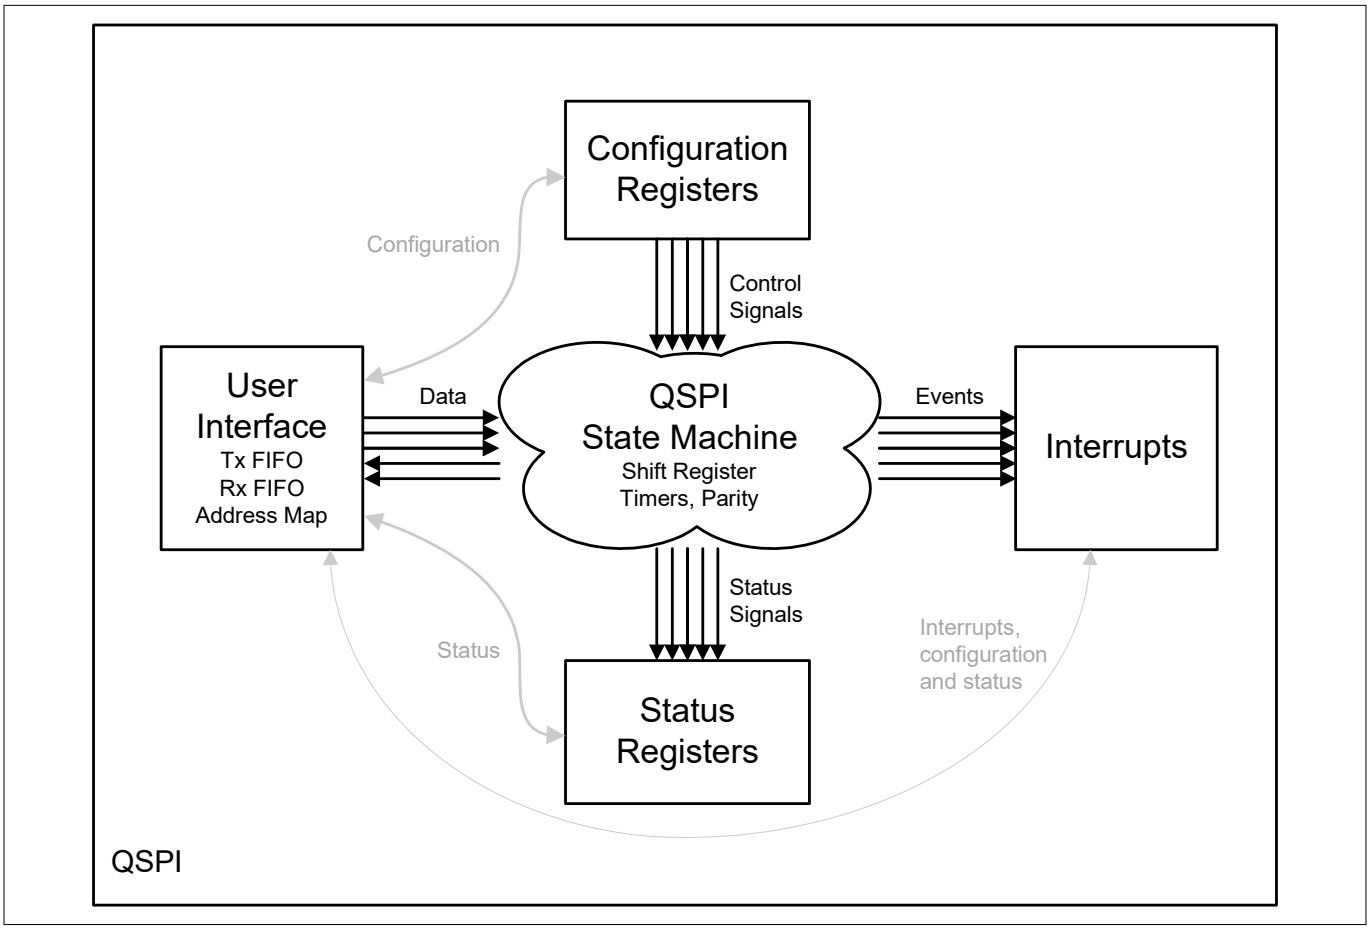

Figure 646 QSPI - abstract overview

30.2.2 Operating modes

The QSPI operates in one of two modes regarding the generation of the serial clock and slave select signals: master or slave mode. The master generates and drives the clock and select signals, the slave receives these signals.

The QSPI operates in one of three modes regarding the direction of the communication and depending whether the transmission and the reception appear simultaneously or not: duplex, half-duplex and simplex mode.

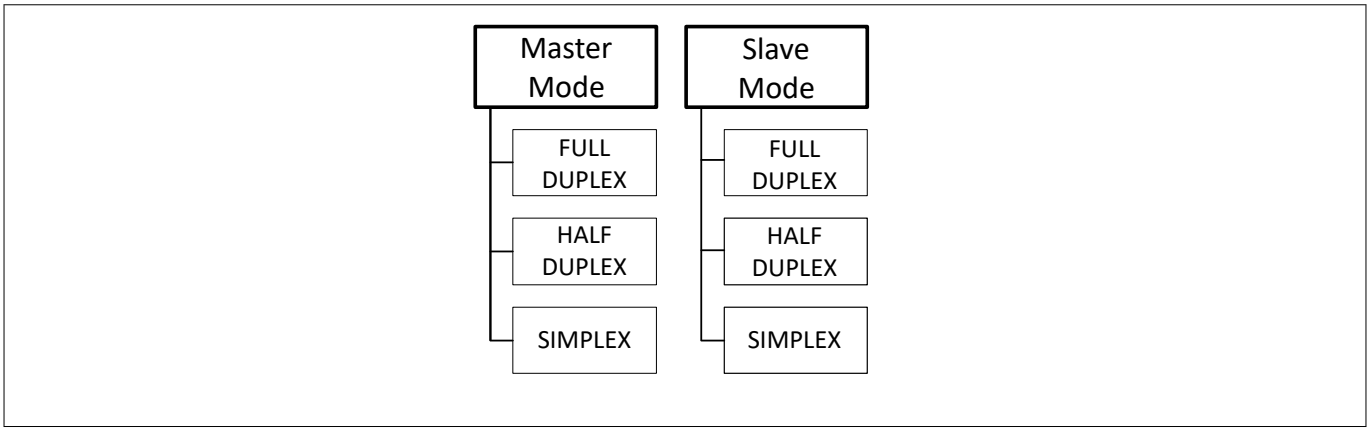

Figure 647 Operating modes overview

This gives six possible combinations for the operating mode of the QSPI: master duplex, half-duplex, and simplex; slave duplex, half-duplex, and simplex.

***Note**: The half-duplex mode can be implemented either by direct connection between two different pins on the pcb, one data output and one data input pin, or by using single pins mapped to both data input and data output signals. See the pinning and port chapters for the pinning definition of a particular product. The module itself does not differentiate between the full-duplex, half-duplex or simplex connection.*

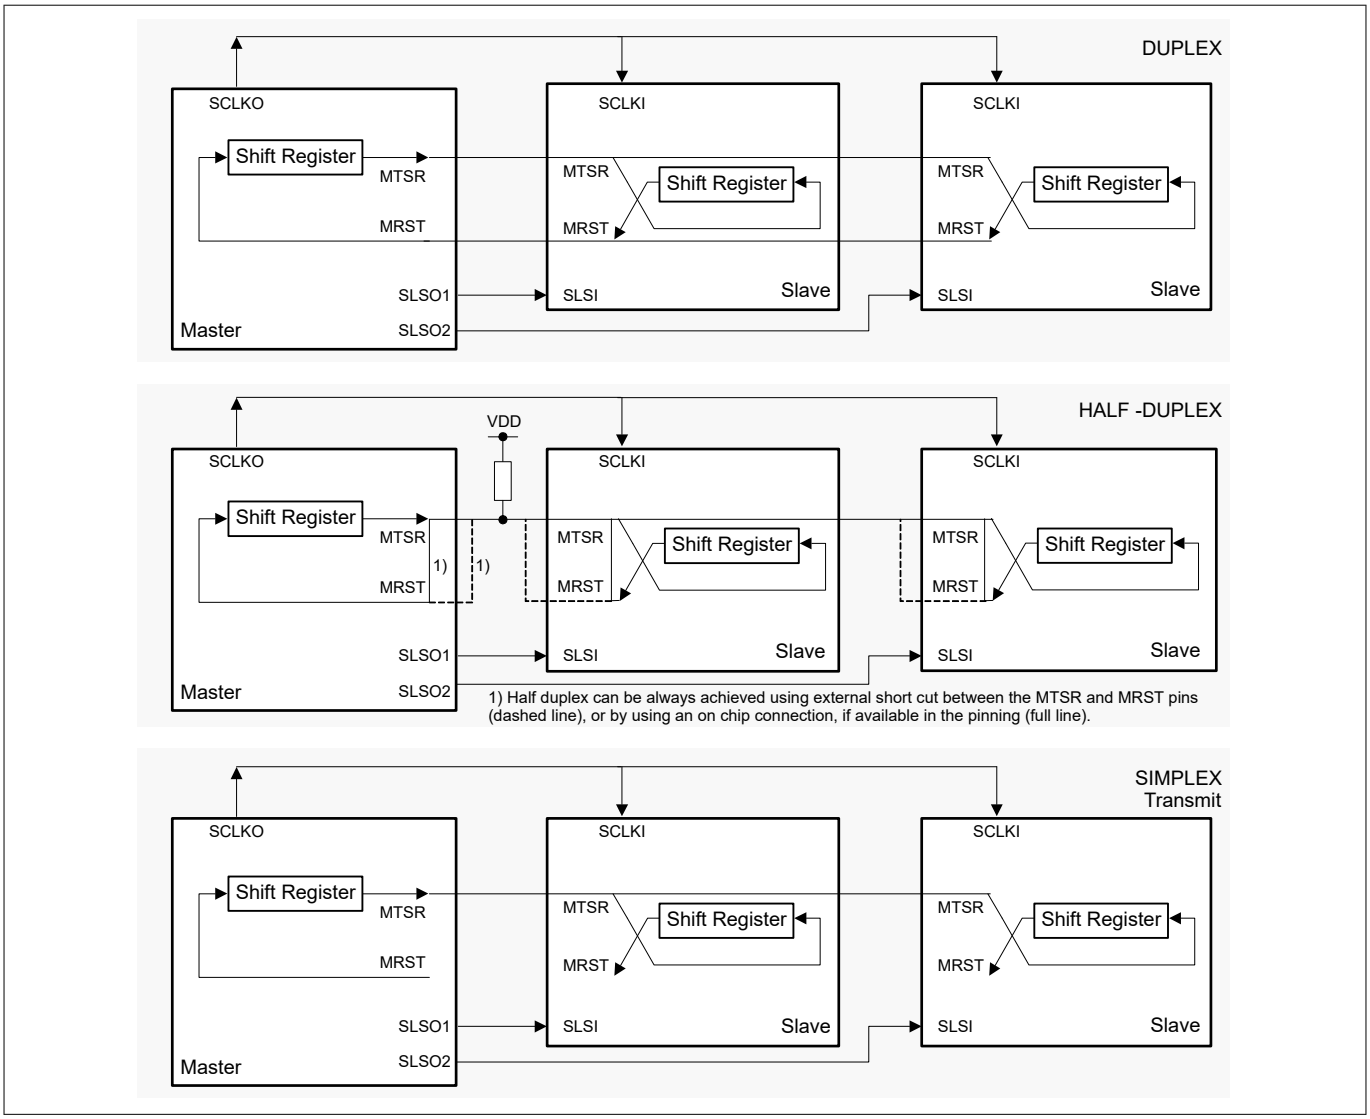

Figure 648 Operating modes and types of connections

30.2.3 Queue support overview

The term “Queue Support” is used in this context to describe the functionality implemented for comfortable switching of the timing configuration of the QSPI frames, depending on the slave select signal which is to be activated. The main feature of the module is the possibility to take both the configuration and data to the TXFIFO, and to track down which TXFIFO entry is configuration, and which data. The QSPI module expects 32 basic configuration bits to be moved with one move (for example DMA move) from some on-chip general purpose RAM to the TXFIFO. These 32 configuration bits from the TXFIFO and the configuration bits from the 8 configuration extension registers ECONz contained in the QSPI module, define together the full configuration of the module. One extension register is used for two slave selects: ECON0 for SLSO0 and SLSO8, ECON1 for SLSO1 and SLSO9...

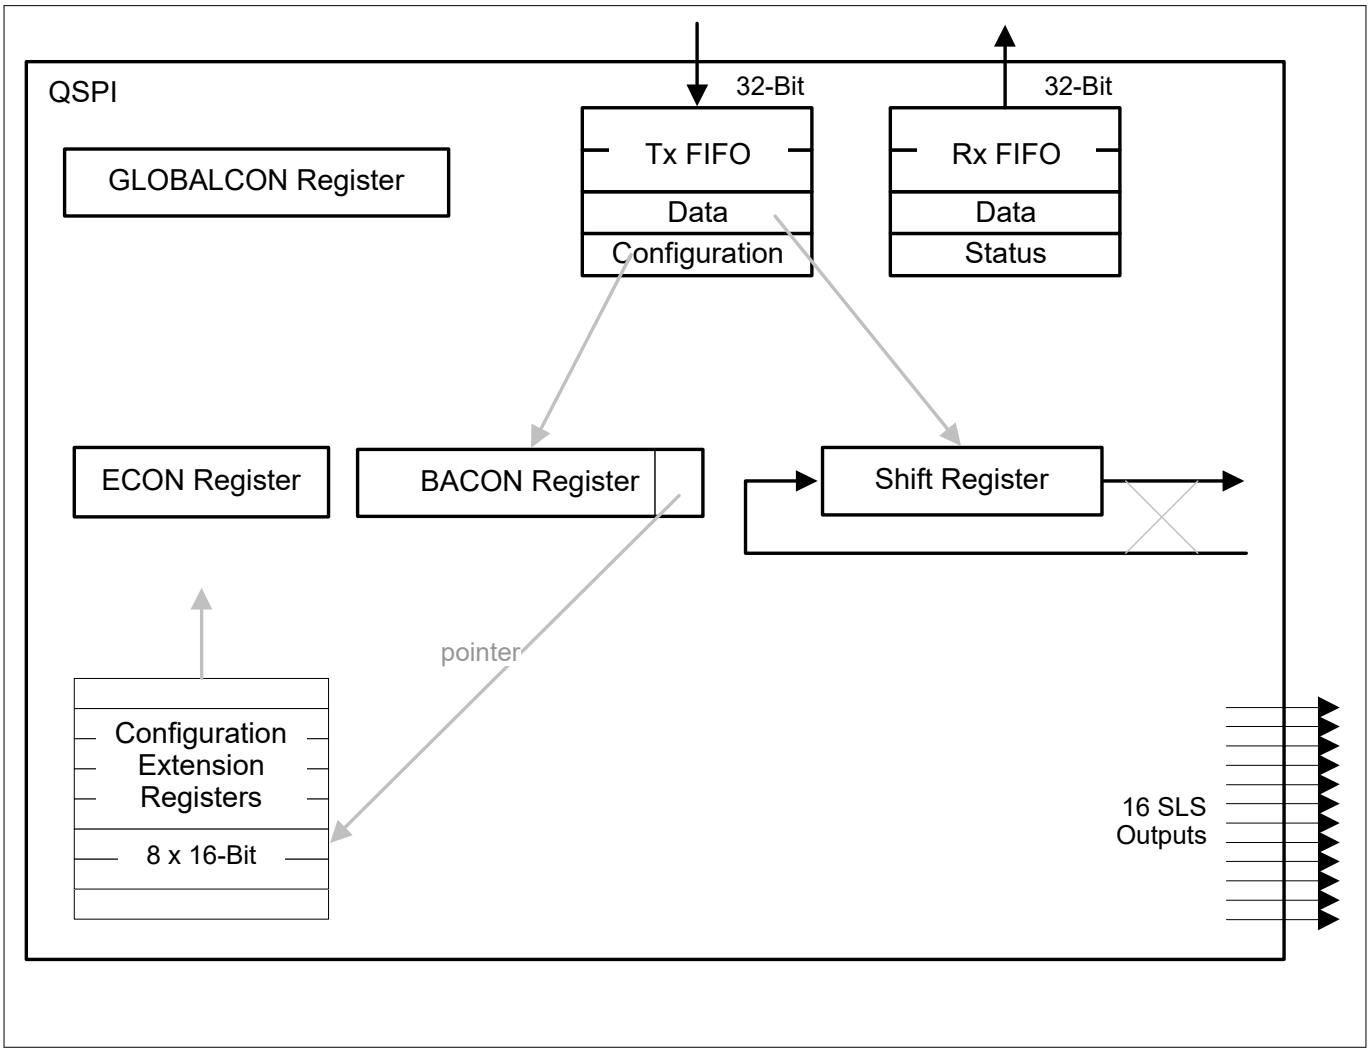

Figure 649 Queue support overview

30.2.4 Architecture overview

The below figure shows the main blocks of the QSPI module. The TxFIFO and RxFIFO provide the user interface. The Shift Register and the “Miscellaneous Logic” block build the state machine of the module. The “Configuration Extensions” block provides comprehensive capabilities for configuring the QSPI frames.

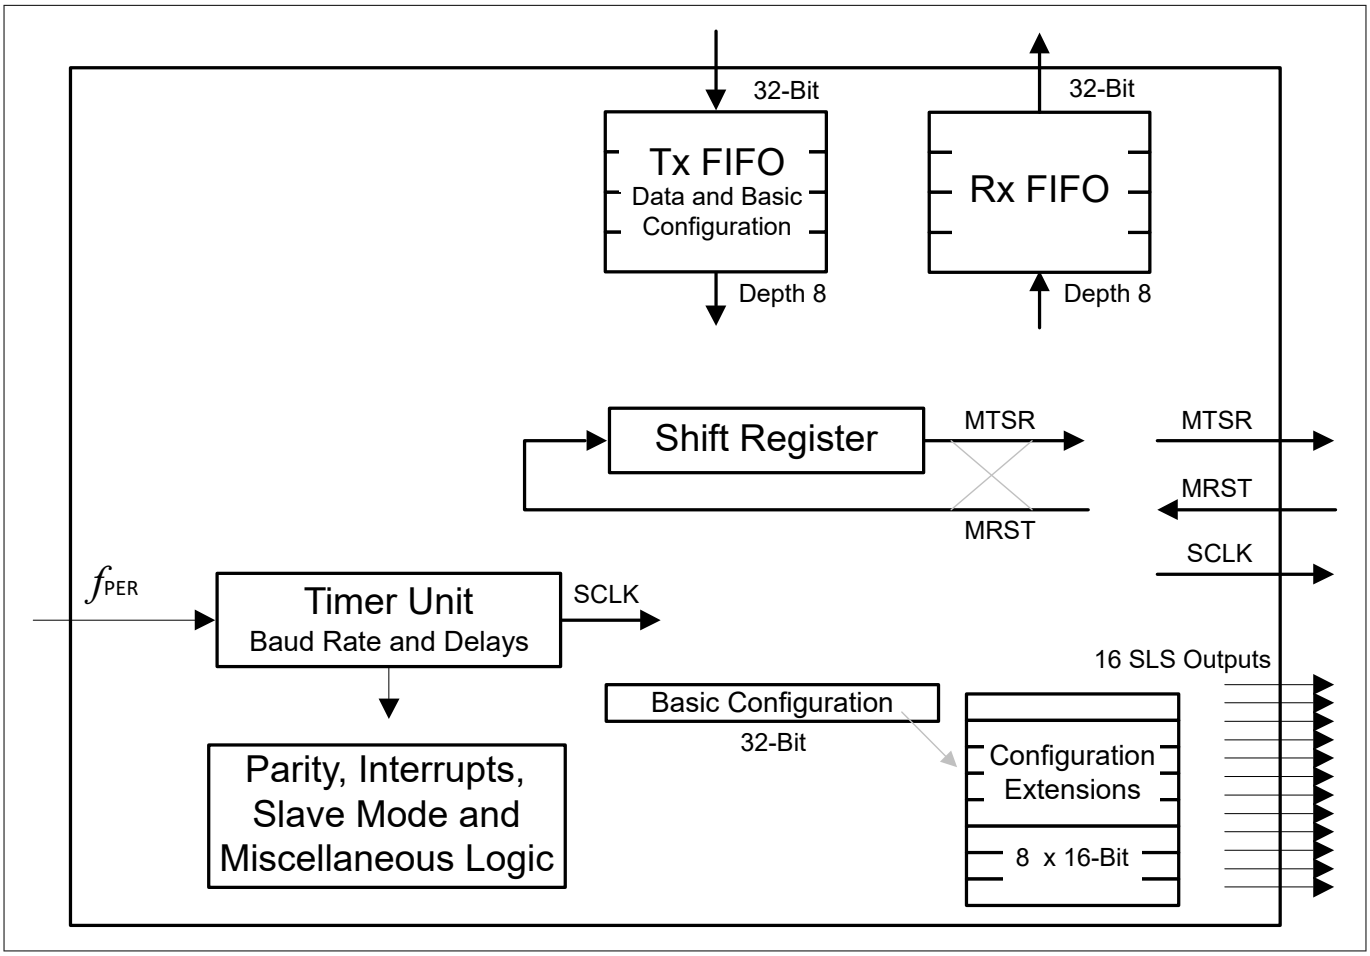

Figure 650 QSPI - architecture overview

30.2.5 Three wire connection

The term “Three Wire Connection” is used in this context to describe a connection without slave select signal. This connection relies solely on counting bits for determining the end of the current frame and resetting the shift register state machine, instead of using the slave select signal for this purpose. This way of communication is less robust than communication with slave select, but it saves a pin on both master and slave device.

The name “three wire connection” is true only in case of full-duplex connection, where exactly three signals (clock, data-in, data-out) are needed. In case of half-duplex and simplex connections only two signals (clock, data-in/data-out common data line) are necessary.

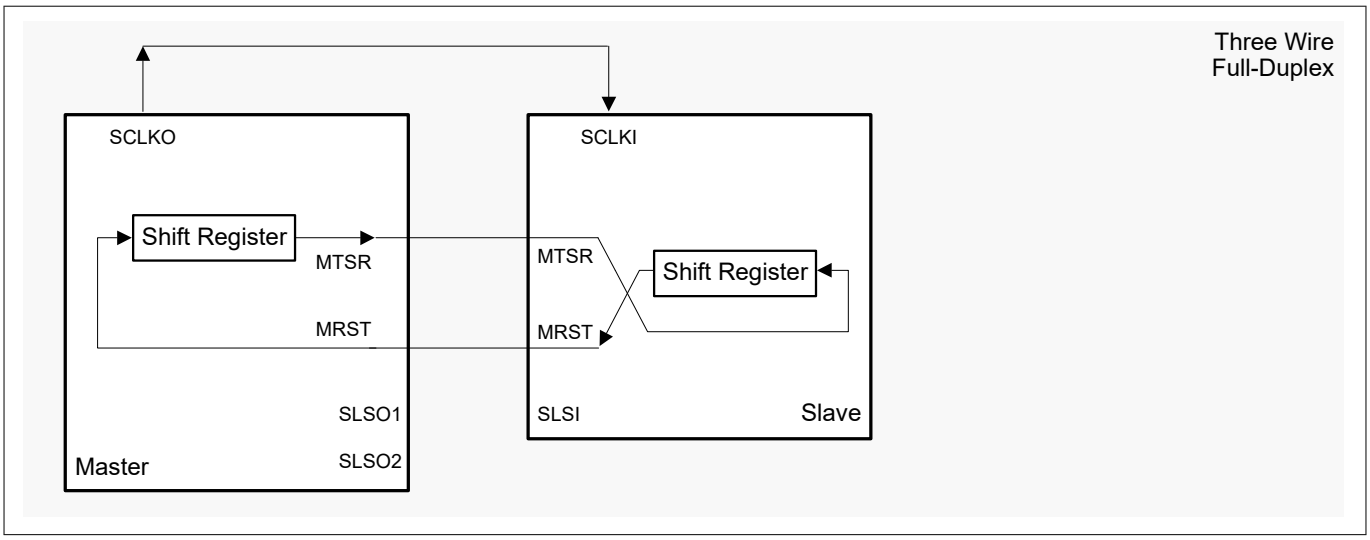

Figure 651 Three wire connection

30.3 Functional description

This chapter provides the description of the module and it's configuration options for functional behavior.

30.3.1 Frequency domains

The state machine of the QSPI is placed in a separate frequency domain operating with a frequency f_{PER} which is generated by the peripheral PLL. This clock is completely asynchronous to f_{SPB}.

In Chapter CLOCK this f_{PER} is referenced to as f_{QSPI} for overview purposes.

The baud rate is determined by the f_{PER} frequency divided by an integer equal to or greater than four.

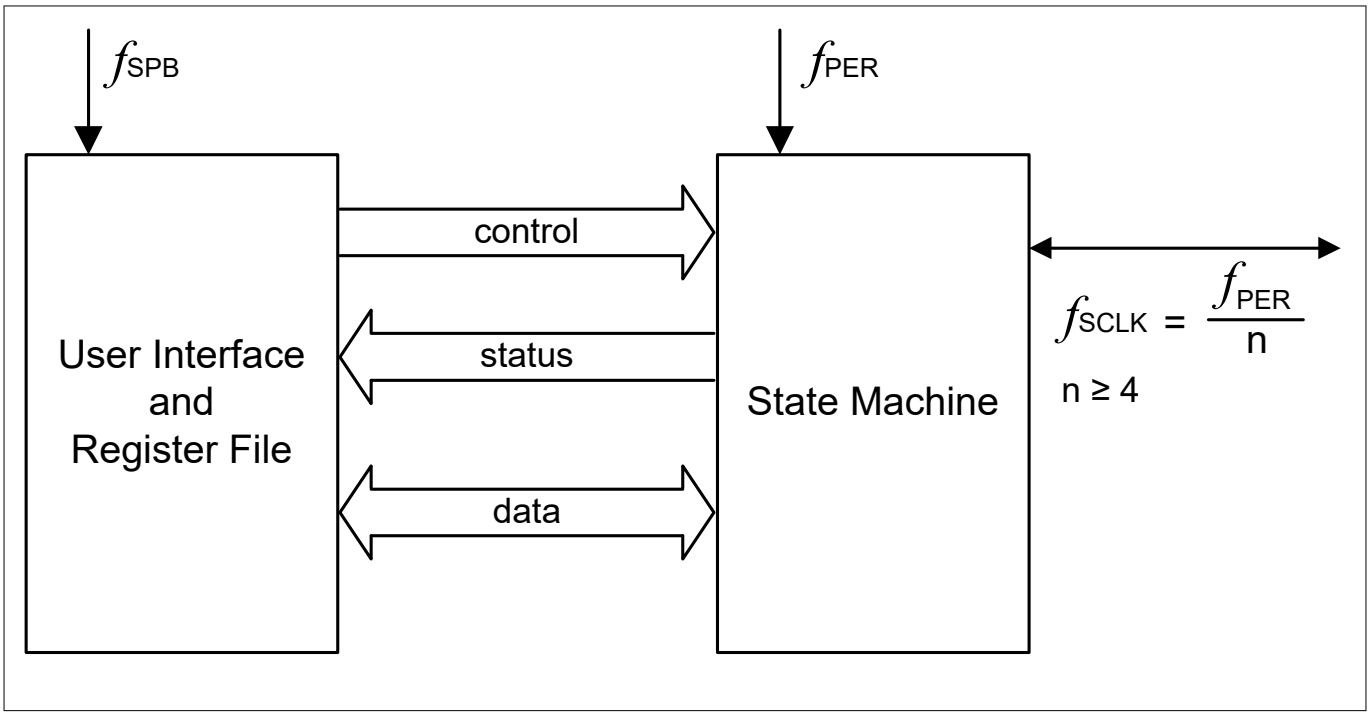

Figure 652 QSPI - frequency domains

30.3.2 Master mode

In master mode, the QSPI module generates the timings, the serial clock, and the slave select signals.

30.3.2.1 Phases of one communication cycle

This section describes the possibilities available for configuring the length of the phases of the QSPI communication: timing delays, data length, duty cycle and data sampling.

A QSPI frame starts with activating a slave select signal SLSO (at transition from idle to leading delay phase), and ends with its deactivation (at transition from trailing delay to wait or idle phase). It is a sequence of five phases: idle delay, leading delay, data, trailing delay and an optional wait. The idle phase is subdivided in two phases of equal length: idle A and idle B.

The following figure shows a full and a compressed view of a QSPI frame and its phases. The full view shows all four signals needed for a QSPI connection. The compressed view represents the phases in a single row, in a way suitable to discuss their properties.

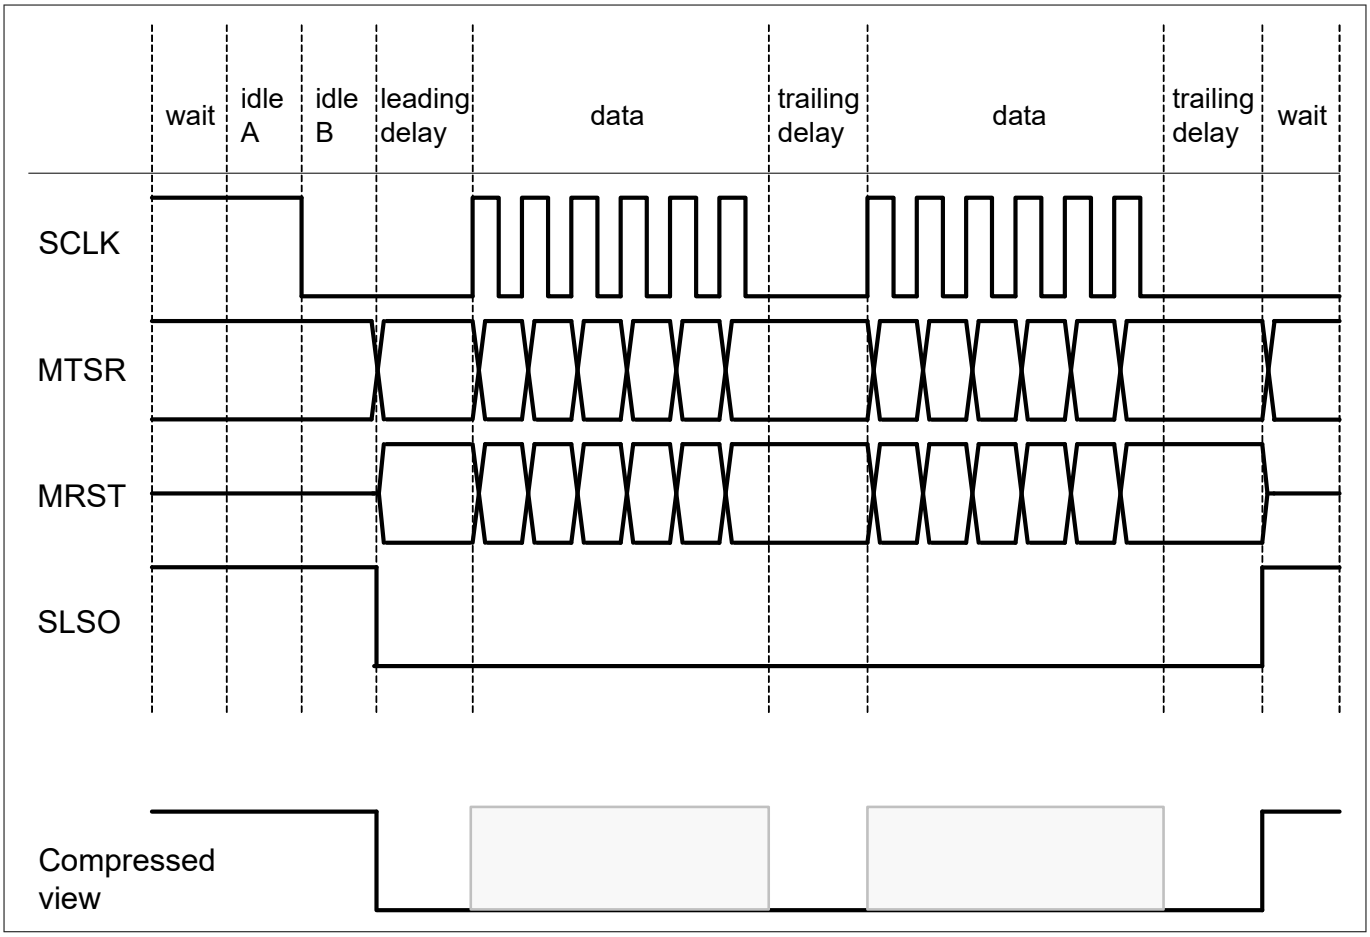

Figure 653 Phases of a QSPI frame (example for data length of 5 bits)

The flexible timing control of the QSPI allows to program each phase in a very wide time range, with sufficient precision. Some examples of QSPI frames, in compressed view, with different lengths of the phases, are shown in the following figure.

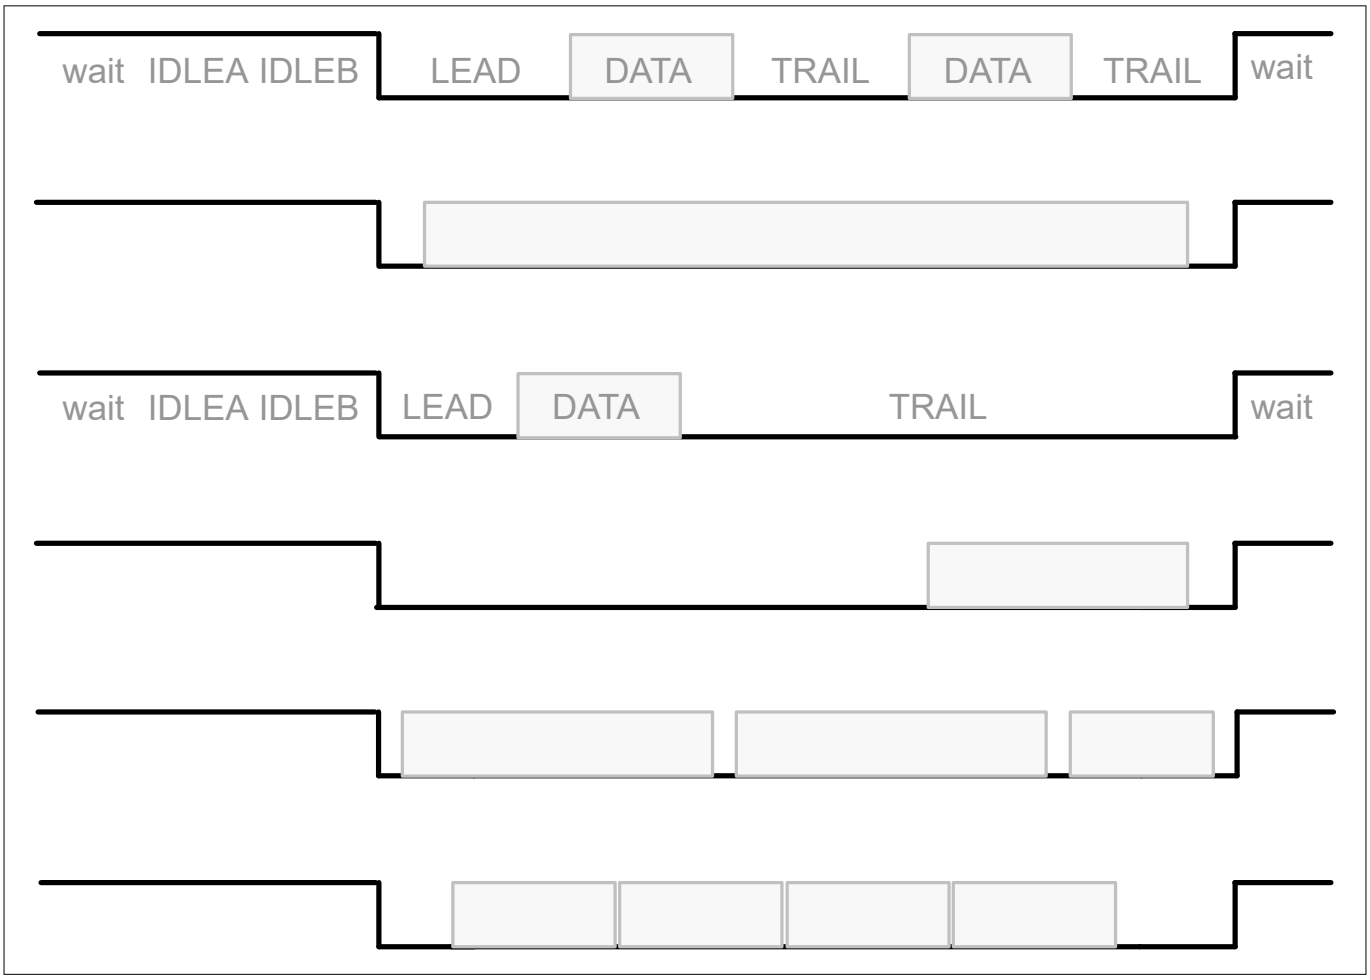

Figure 654 Examples of QSPI frames in compressed view

The length of the phases is programmed using the corresponding bit-fields in the register BACON. There are four main bit-fields defining the length of the phases in t_Q units and several modifier bit-fields defining their range and granularity:

- IDLE
- LEAD
- DATA
- TRAIL

The WAIT phase is simply a loop waiting for a write to the Tx FIFO, without predefined duration, and consequently without a defining bit-field.

The IDLE bit-field defines two sub-phases with the same length IDLEA and IDLEB. At the transition between them the polarity of the serial clock signal for the next slave is set.

In addition, the flexible timing control allows to program the duty cycle and the sampling point properties of the serial clock. This allows to improve to a certain extent the achievable baud rate taking into account the clock asymmetries and the loop-delay.

The ECONz (z=0-7) bit-fields A, B and C define the length of the corresponding bit segments. The sampling point is always at the transition between phases B and C, and the clock duty cycle is defined by the phases A and B+C.

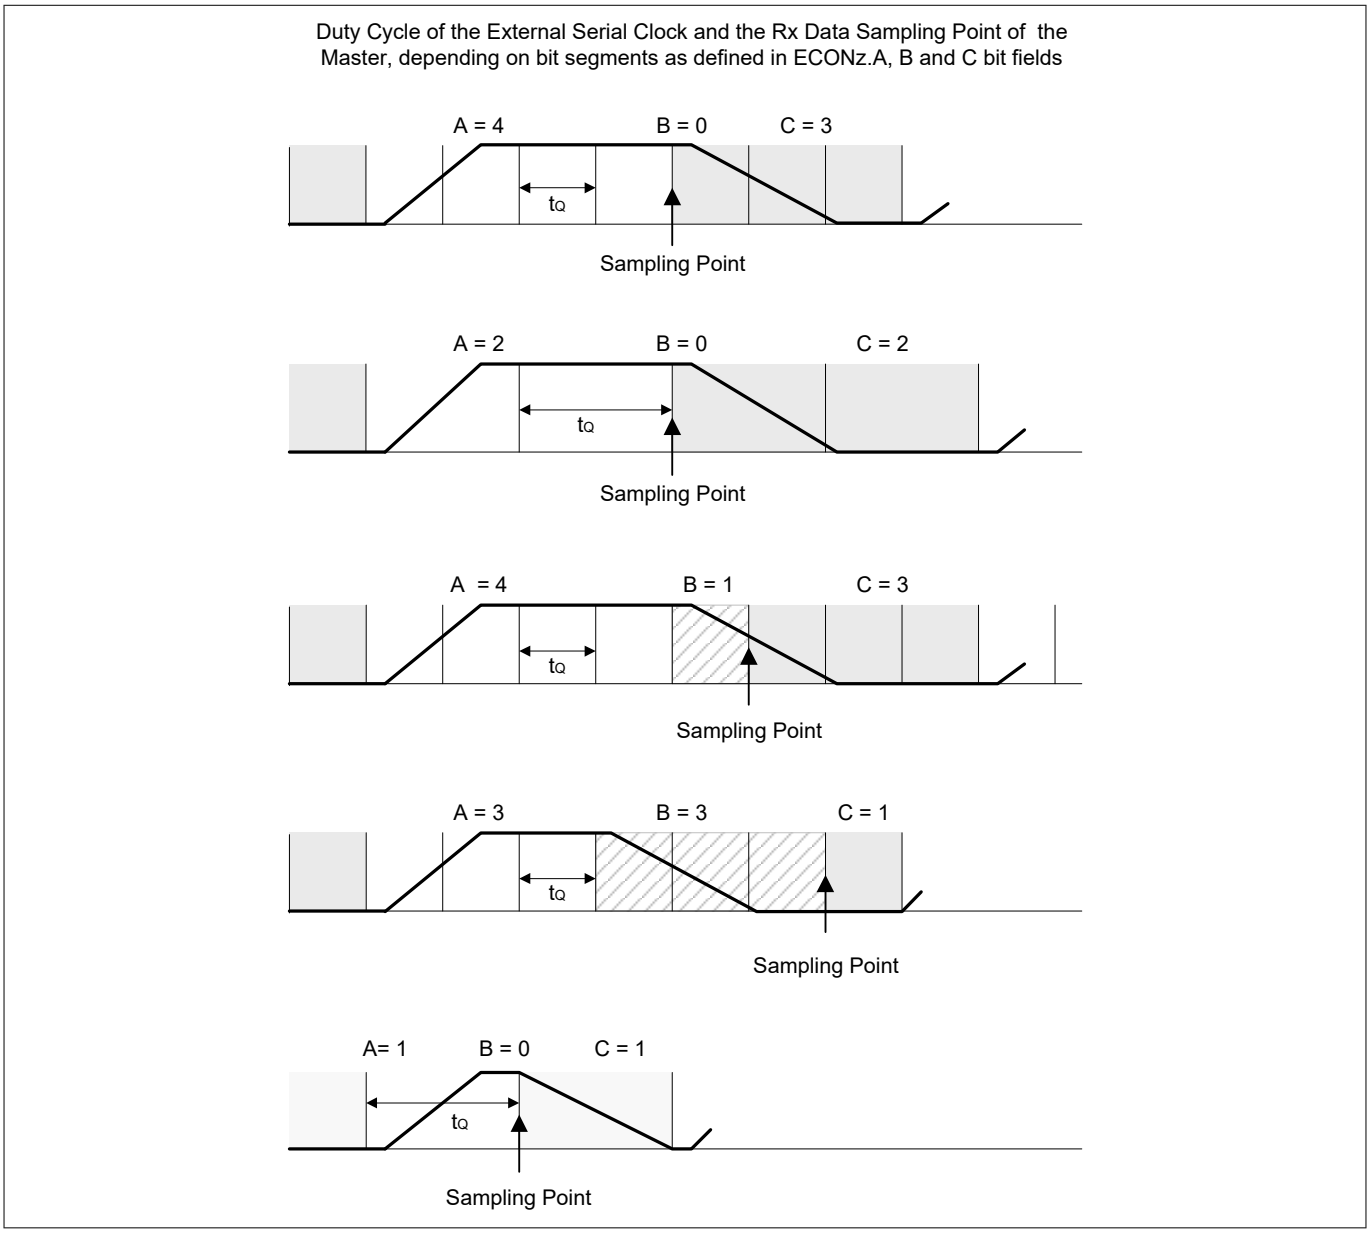

Figure 655 SCLKO duty cycle and the Rx data sampling point relative to SCLKO in master mode

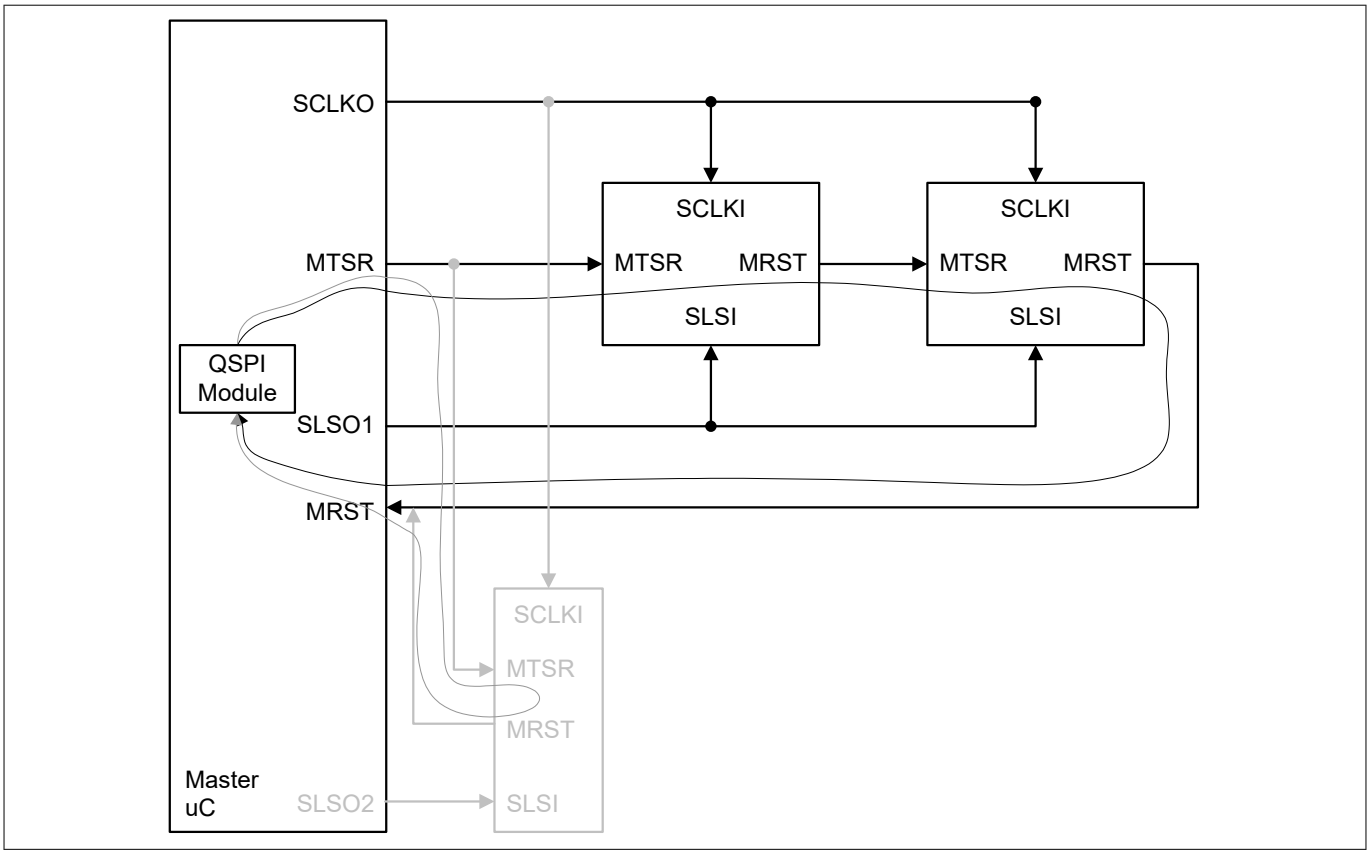

Figure 656 Closed-loop delays in a simple network consisting of one daisy-chain and one point to point connection in parallel

The purpose of the duty cycle control is:

- Compensating the influence of the path and pad asymmetry on the duty cycle
- Compensating the considerable asymmetry of the edges in case of half-duplex connection implemented as open-drain driver with pull-up resistor
- Adjusting the duty cycle optimally to the timing properties of the master and slave and to the properties of the connection (distance and capacitive load)
- Helping to achieve optimal baud rate, especially at higher baud rates which need an odd division factor (for example $5 = 3$ high time $+ 2$ low time or $5 = 2$ high time $+ 3$ low time)

The purpose of the sampling point control is to allow reliable reception of the data transmitted by the slave, at high baud rates. A further improvement on achievable baud rates is possible using High Speed Mode, see related information.

In master receive direction the slave transmitted data reaches the master considerably late relative to the shift edge of the serial clock. This is caused by the loop delay consisting of:

- The propagation delay of the shift clock edge from the master to the slave
- The response delay of the slave
- The propagation delay of the data from the slave to the master

Last but not least, the flexible timing control allows to configure the phase and the polarity of the shift clock.

The clock polarity is configured by bit-field ECONz (z=0-7).CPOL. This bit-field sets the clock idle polarity to low or high.

The clock phase is configured by bit-field ECONz (z=0-7).CPH. This bit-field sets the initial clock delay to 0 or Bit Segment A, as defined by the bit-field ECONz (z=0-7).A.

The CPOL and CPH settings control the master mode. The slave mode timing behavior is fixed to CPOL=0 and CPH=1, and these values must be programmed in the ECONz (z=0-7) register pointed by BACON.CS. The ECONz (z=0-7).A, B and C do not influence the sampling point in the slave mode, the sampling is at the falling edge of the SCLKI.

The following figure shows the QSPI timings for clock phase CPH = 0.

ECONz (z=0-7).CPH = 0 is used when communicating with a slave that delivers a valid value of the first bit immediately after being selected with an SLS signal. In such a case the first clock edge in a frame is used to latch the first bit. The second edge delivers the second bit value, and so on. The last edge in a frame delivers a bit with a to be ignored value.

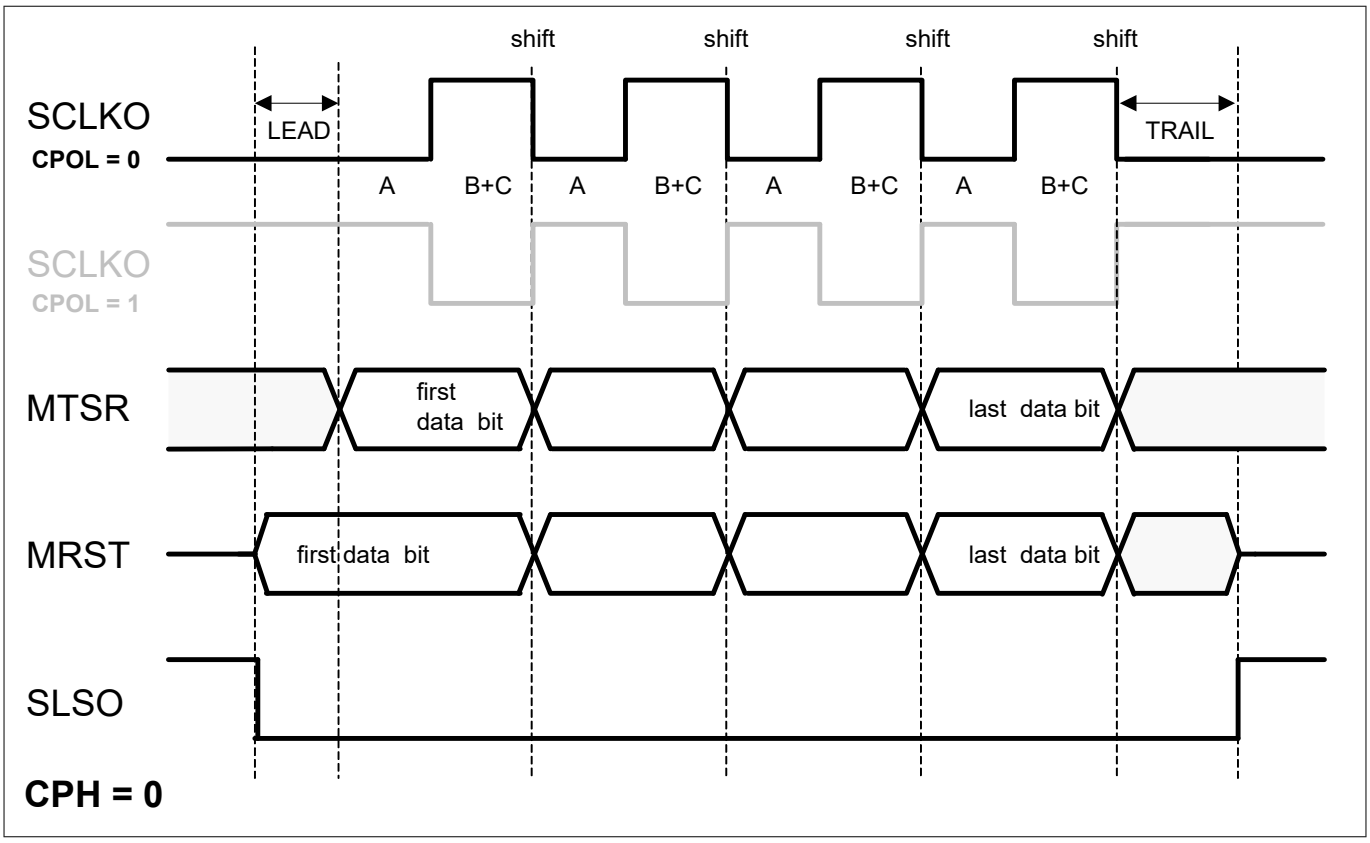

Figure 657 Timing of a transfer with CPH = 0 (example for data length of 4 bits)

The trailing delay starts after the last shift clock period of a data block and is followed either by the deactivating edge of SLSO, or a new data block in continuous mode.

***Attention**: If CPH = 0, then the total delay between the SLSO activating edge and the first edge of the serial clock SCLKO is LEAD + ECONz (z=0-7).A*

The following figure shows the QSPI timings for clock phase CPH = 1.

ECONz (z=0-7).CPH = 1 is used when communicating with a slave that delivers a bit with a random or to be ignored value immediately after being selected with the SLSO signal. In such a case the first clock edge in a frame is used by the slave to shift out the first valid data bit. The second edge latches this bit value, and so on. The last edge in a frame is used to latch the last valid data bit, which normally remains driven until the end of the frame.

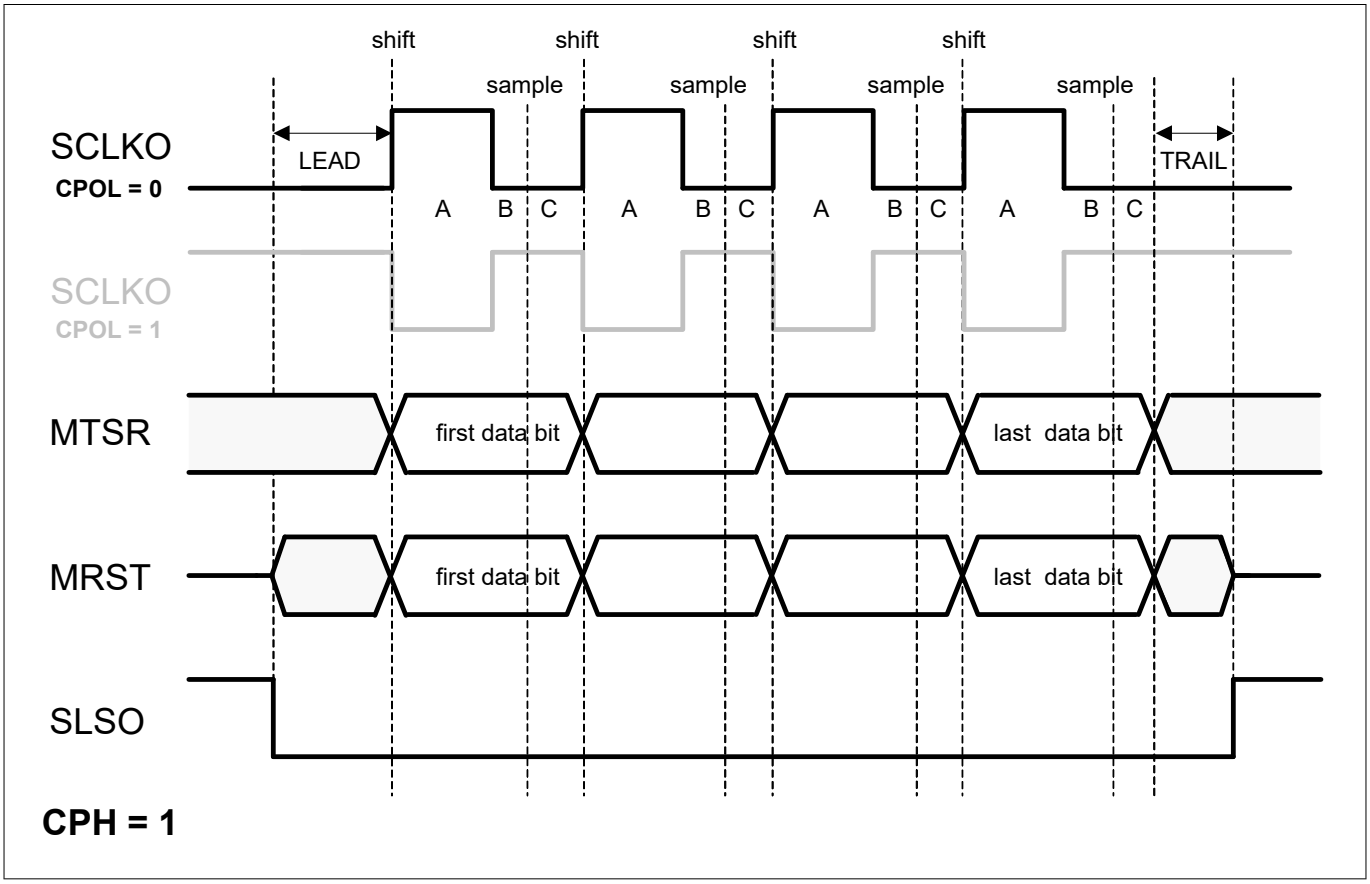

Figure 658 Timing of a transfer with CPH = 1 (example for data length of 4 bits)

The leading delay lasts between the active edge of the SLSO and the first shift clock edge.

***Attention**: If CPH = 1, then the total delay between the last edge of the SCLKO and the SLSO deactivating edge is TRAIL + ECONz (z=0-7).B + ECONz (z=0-7).C*

***Attention**: When 3 wire mode is used, and the polarity of CPH or CPOL is changing, a dummy frame is required. The pad enable to be after the dummy frame. The values of the clock and data signals are not defined before the first data is transmitted.*

30.3.2.2 Configuration extensions

This section describes the possibilities available for configuring the phases of the QSPI communication: timing delays, data lengths, their ranges and granularity.

The QSPI module controls 16 communication channels, which are individually programmable. Each channel is associated to one slave select output and to the corresponding timing and other properties (baud rate, delays, data width, parity...).

The 16 slave select channels of the QSPI module are subdivided in two groups of 8 slave select channels:

- Channels 0 to 7
- Channels 8 to 15, channel 8 having the same ECONz (z=0-7) settings as channel 0, channel 9 as channel 1, and so on

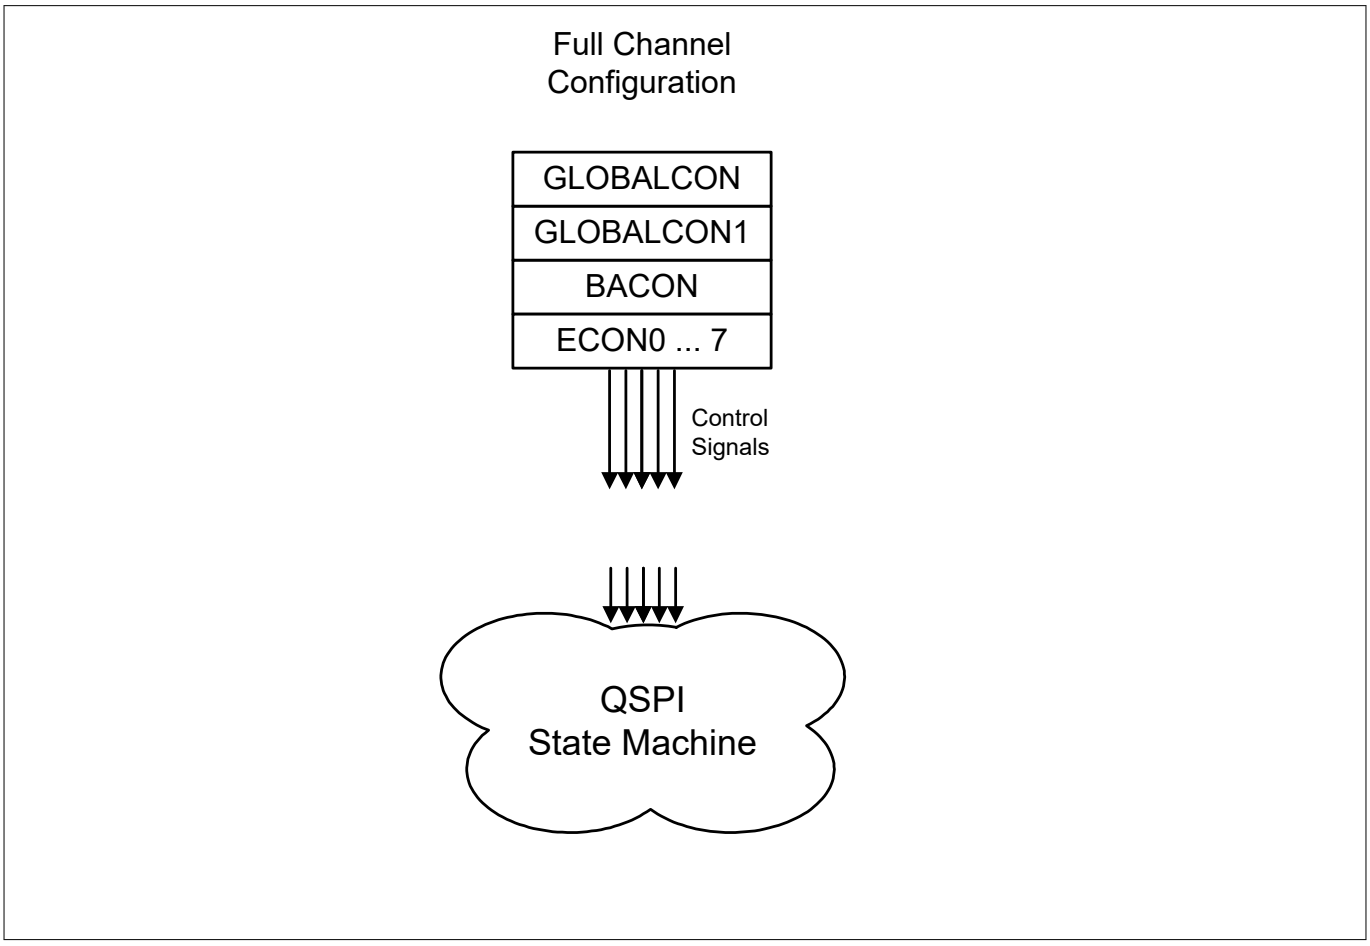

Figure 659 Flexible configuration concept

30.3.2.3 Details of the baud rate and phase duration control

The QSPI phases correspond to states of a simple state machine defining a sequence of simple states and loops. Due to the strict sequential nature of the communication cycle one timer is enough to define the length of each phase. The length of each phase is defined in time quanta, and the length of a time quantum is defined by a time quantum timer. Each QSPI slave select channel has its own time quantum length, based on the module time quantum length: T_{PER} clock period -> one module time quantum -> one channel time quantum

Each QSPI module generates a module time quantum which is further downscale to a channel quantum. This affects both the delays and the baud rates. The assumption is that the pad strength setting, the capacitive load and the corresponding QSPI network layout properties do not allow extreme differences in the baud rates for the different slaves connected to one module. They all have similar speed range: high speed, or medium speed, or low speed. Mixing very high speed and very low speed slaves does not make much sense. Many slaves produce high accumulated capacitive load on the clock and data outputs, which influences the possible baud rates for all slaves. Variations in the baud rates of slaves of one module are supported by the ECONz.Q and the ECONz.A/B/C bitfield settings allowing for a flexible bit time variation between the channels in one module.

Each QSPI slave select channel has its own set of phase lengths, depending on $T_{PER} = \frac{1}{f_{PER}}$.

- $T_{SCLKz} = T_{PER} \times$ GLOBALCON.TQ $\times$ ECONz (z=0-7).Q $\times$ (A + B + C)
- $t_{LEAD} = T_{PER} \times$ BACON.LPRE $\times$ BACON.LEAD
- $t_{TRAIL} = T_{PER} \times$ BACON.TPRE $\times$ BACON.TRAIL
- $t_{IDLEA,B} = T_{PER} \times$ BACON.IPRE $\times$ BACON.IDLE
- $t_{STROBE_DELAY} = T_{PER} \times$ GLOBALCON.TQ $\times$ ECONz (z=0-7).Q $\times$ GLOBALCON.STROBE

***Note**: The equations above contain the representative decimal values of the bit-fields in corresponding units, not their actual binary bit-value. For the formulas using the actual binary values of the bit-fields, see figures in related information.*

The subsequent figure summarizes the above formulas, especially the upper part of the picture shows the fact how T_{PER} is transferred to T_Q and subsequently to T_{Qx}. The lower part shows how different parts of the BACON registers, such as IDLE, LEAD, A, B, C, TRAIL are connected to different source clocks to produce the different timings of a SPI communication.

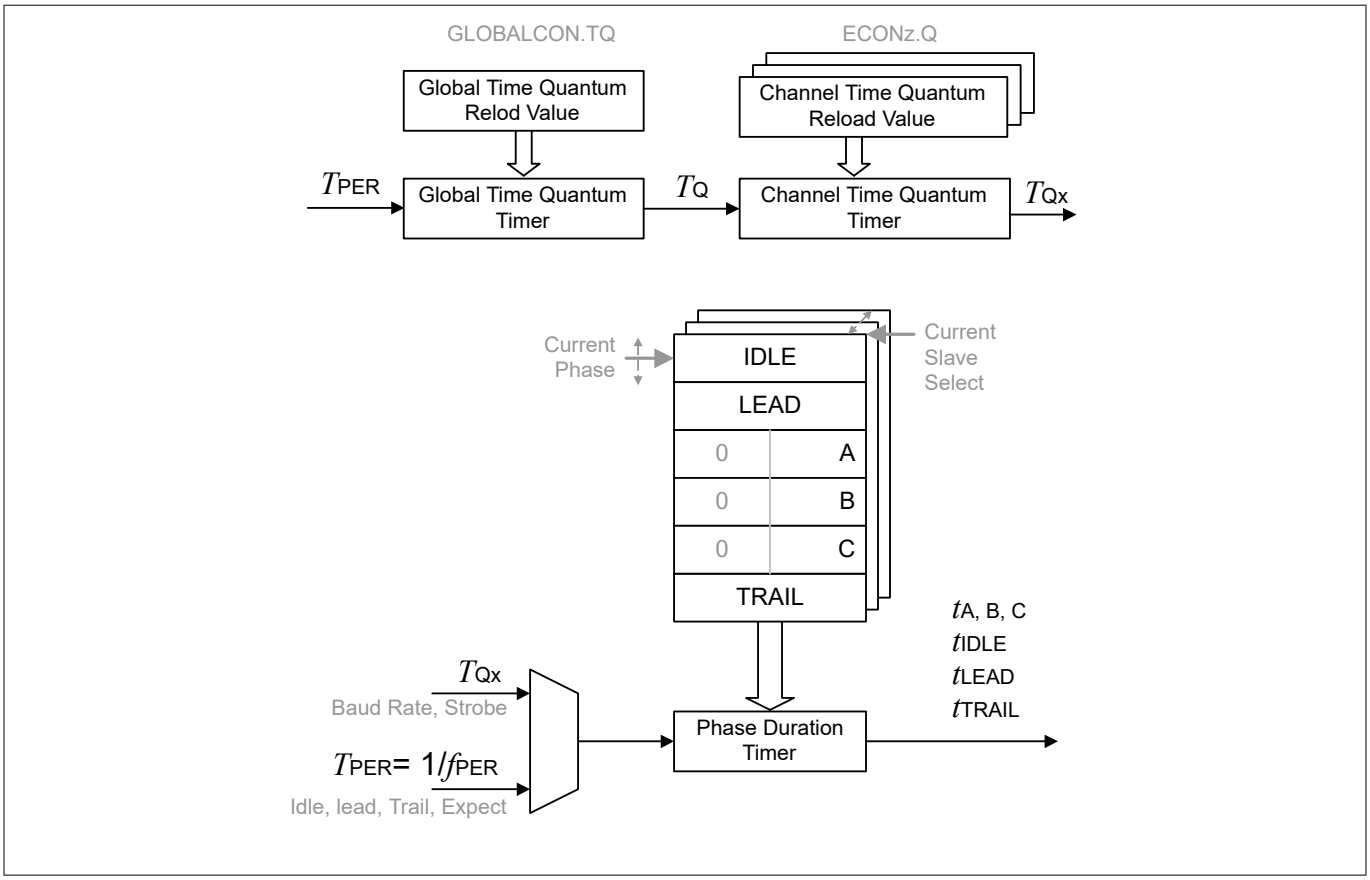

Figure 660 Overview of phase duration control

Related information

Calculation of the baud rates and the delays on page 5313

30.3.2.4 Calculation of the baud rates and the delays

This section gives another alternative view to the calculation of the baud rate and the duration of the delays.

The baud rate generation chain for a channel starts with a common TQ divider. The resulting global time quantum is used by the dedicated Q and A,B,C dividers to generate the baud rates per channel (slave select). See following figure.

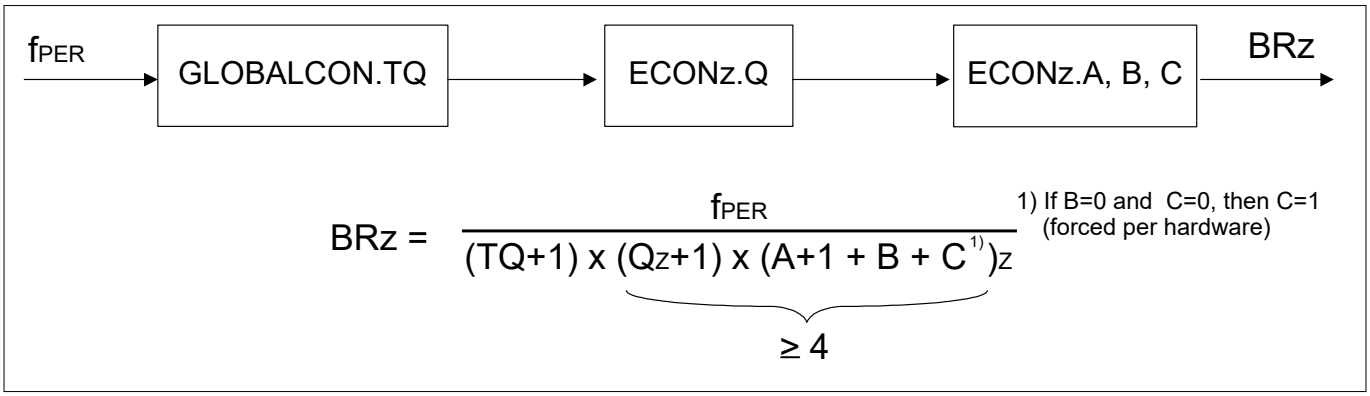

Figure 661 Baud rate calculation

Attention: ***The following condition must be satisfied:*** $(Q+1)\times(A+B+C+1)\geq 4$***. Or alternatively formulated: bit length must be at least*** $4\times T_Q$***.***

Each delay of an active channel (slave select) has a separate and independent divider chain starting with a power-of-four prescaler and an n-divider. See following figure.

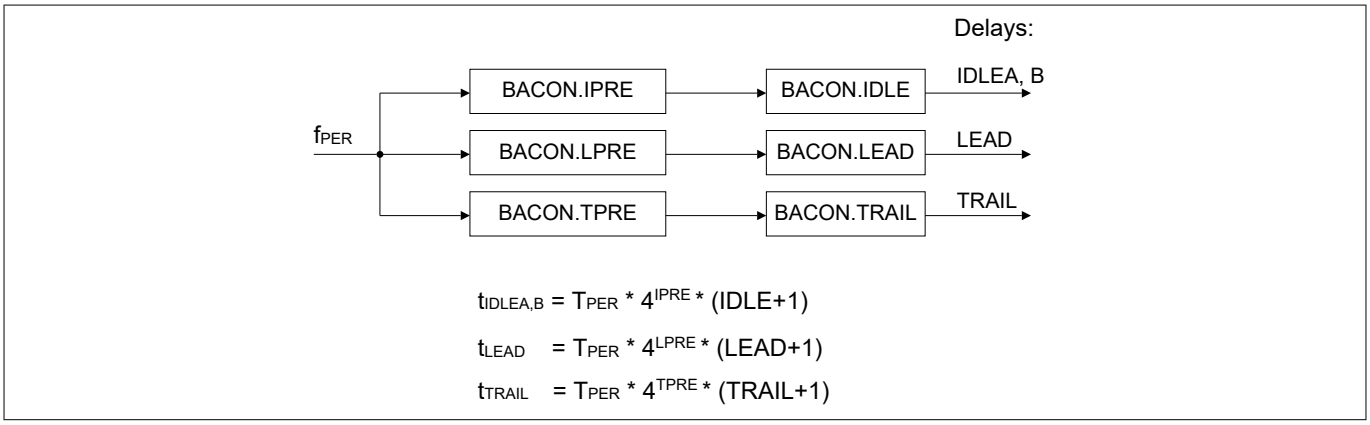

Figure 662 Calculation of the delays

30.3.2.5 State diagram of standard communication cycle

Figure "Standard communication cycle of the state machine (short data)" shows the top view of the standard communication cycle of the QSPI state machine in a hierarchical way. The “Data” state consists of a loop of several “Bit” states, where the number of repetitions is defined with the data width bit-field. Each “Bit” state consists of a simple sequence of “A”, “B”, and “C” states.

A complete (or standard) communication cycle containing all phases, starting with activating the slave select and ending with its deactivation, is executed only if the bit BACON.LAST = 1. Otherwise, the slave select remains active and the module waits for more FIFO data entries.

In Master Mode, the Phase Transition Interrupt events, PT1 and PT2 , each of them can signal one of the phase transitions which are shown in Figure 663 . The events are flagged through STATUS.PT1F and STATUS.PT2F. The values of GLOBALCON1.PT1 and GLOBALCON1.PT2 determine which of the transitions cause the events. The events will also cause interrupts if GLOBALCON1.PT1EN and GLOBALCON1.PT2EN are set to 1. The event flags are cleared through the programming of the FLAGSCLEAR register.

For the Move Counter Mode, see related information.

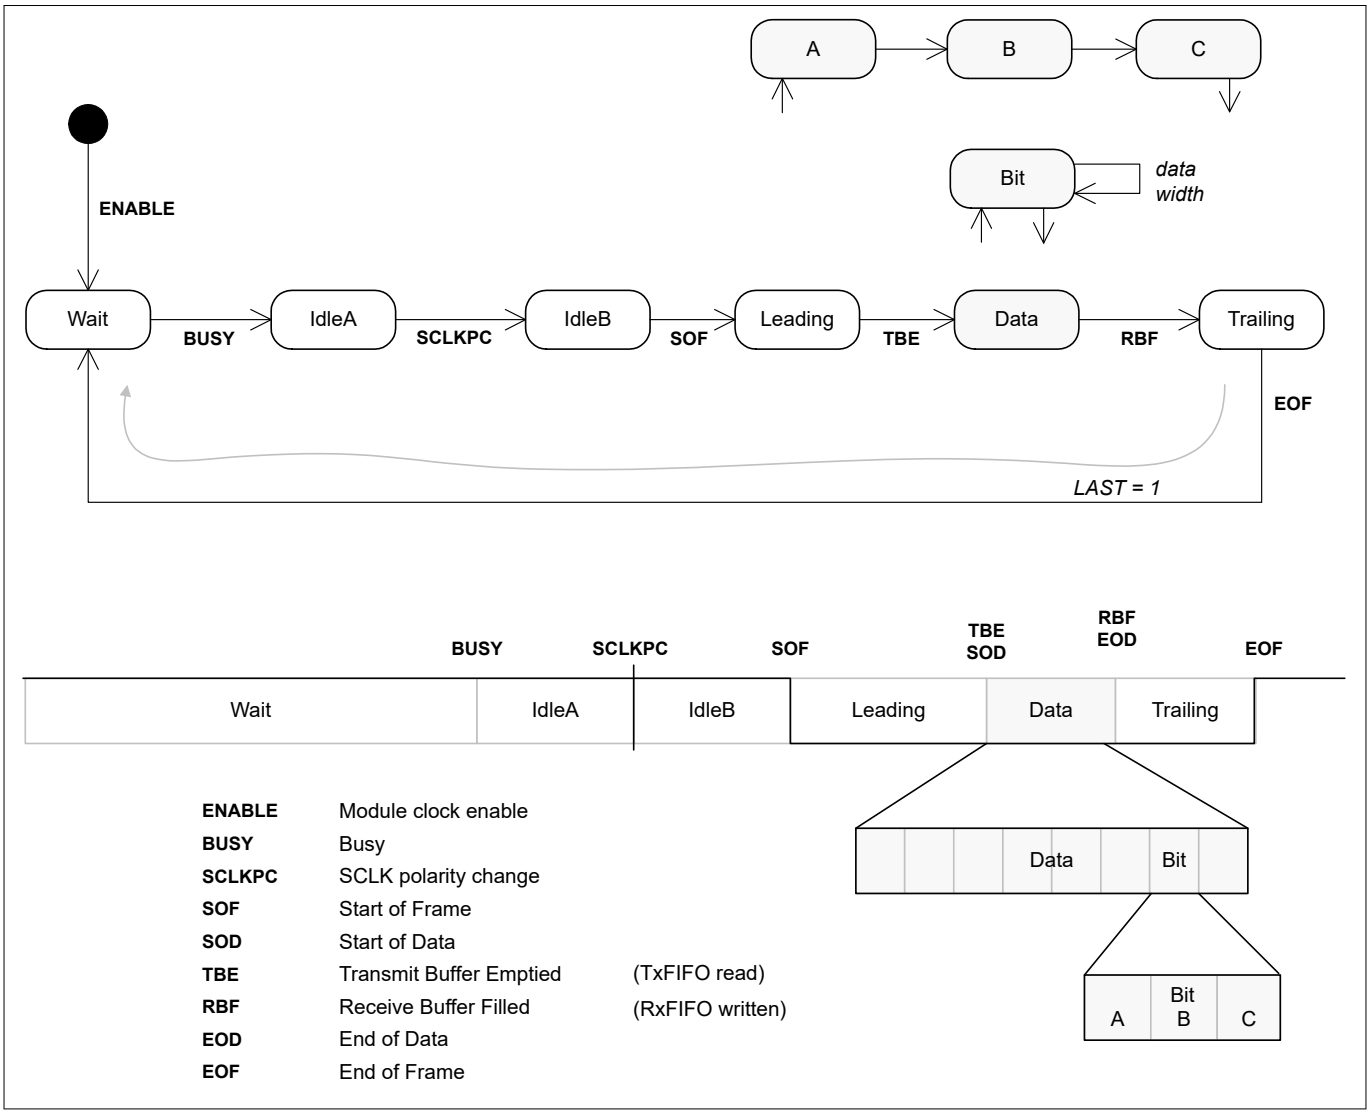

Figure 663 Standard communication cycle of the state machine (short data)

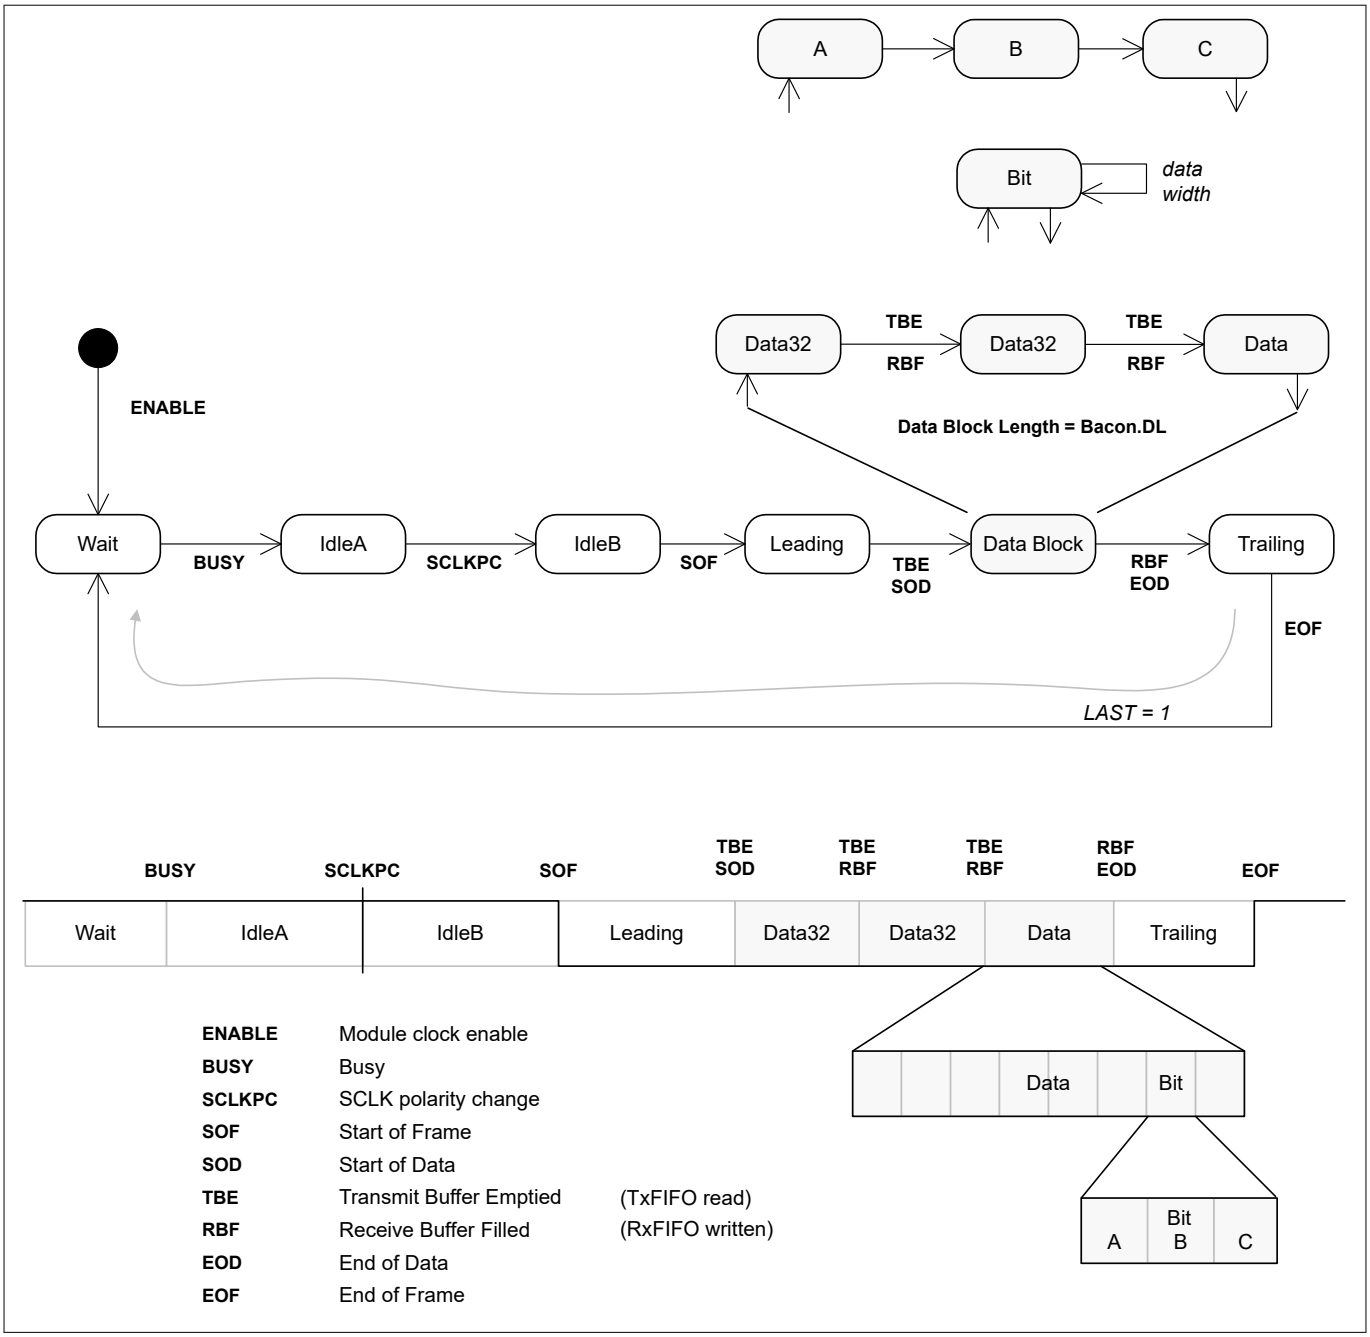

Figure 664 Standard communication cycle of the state machine (long data)

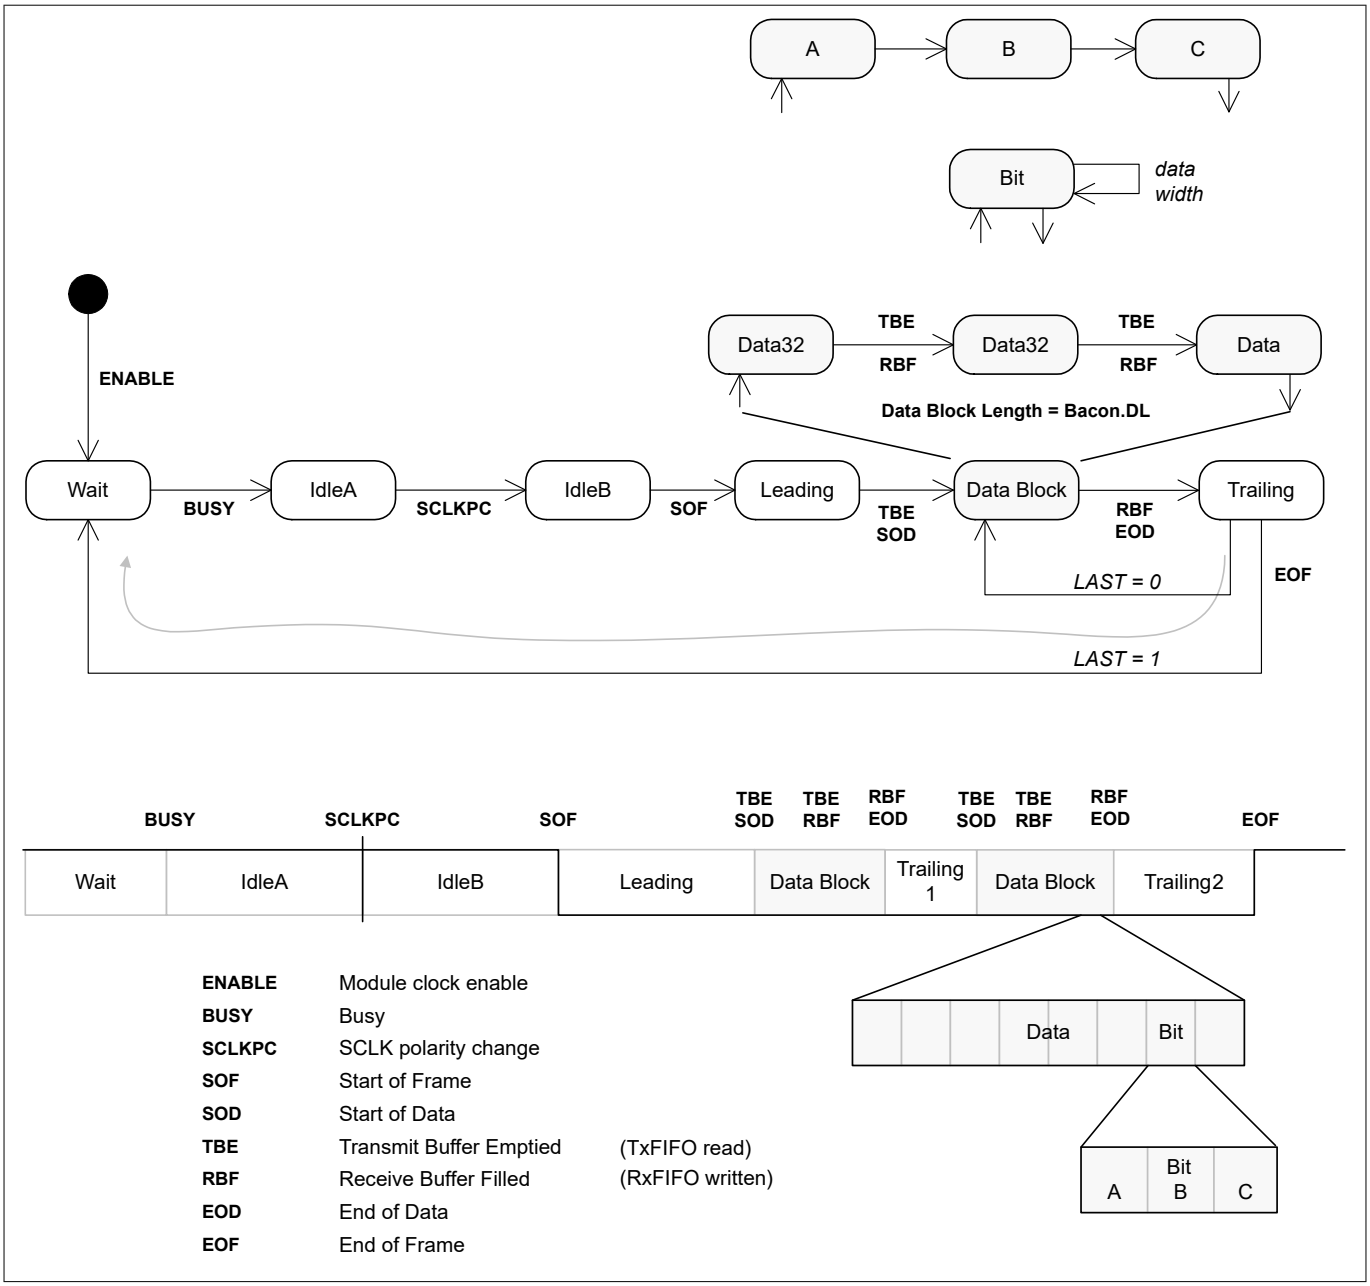

Figure 665 Standard communication cycle of the state machine (continuous)

"Data Block" in the figure above refers to either short data or long data block. When concatenating data blocks in continuous mode, each block can be configured independently as short or long, according to its BACON configuration.

Related information

Move counter mode on page 5342

30.3.2.6 Expect phase

The following figure shows the EXPECT state in the QSPI state machine diagram. This state can be entered in the long data mode and in the continuous mode, where one frame consists of more than one TXFIFO entries. Its purpose is to provide monitoring of the latencies on the FPI bus. In this case, after one FIFO entry has been shifted out and the module expects more bits to shift, according to the BACON.DL, a time-out counting starts. If the expected FIFO entry does not come in time, a time-out occurs.

The duration of the EXPECT state is zero if at the end of the current DATA state the new data is already available in the FIFO.

The maximum allowed duration for EXPECT phase before time-out occurs can be programmed in GLOBALCON.EXPECT. The duration of the EXPECT state can be anywhere between zero and the programmed upper limit, if the next data is written into the TXFIFO any time within the allowed time window. In this case the current frame continues with the SLSO signal remaining active.

The duration of the EXPECT state is exactly maximum if the data did not come in time. Then the current frame is stopped, but the SLSO is not deactivated. A TO (Time - Out) interrupt is raised. The state machine continues the EXPECT state in a loop, waiting for the software intervention, generating an interrupt signal after each expect time interval.

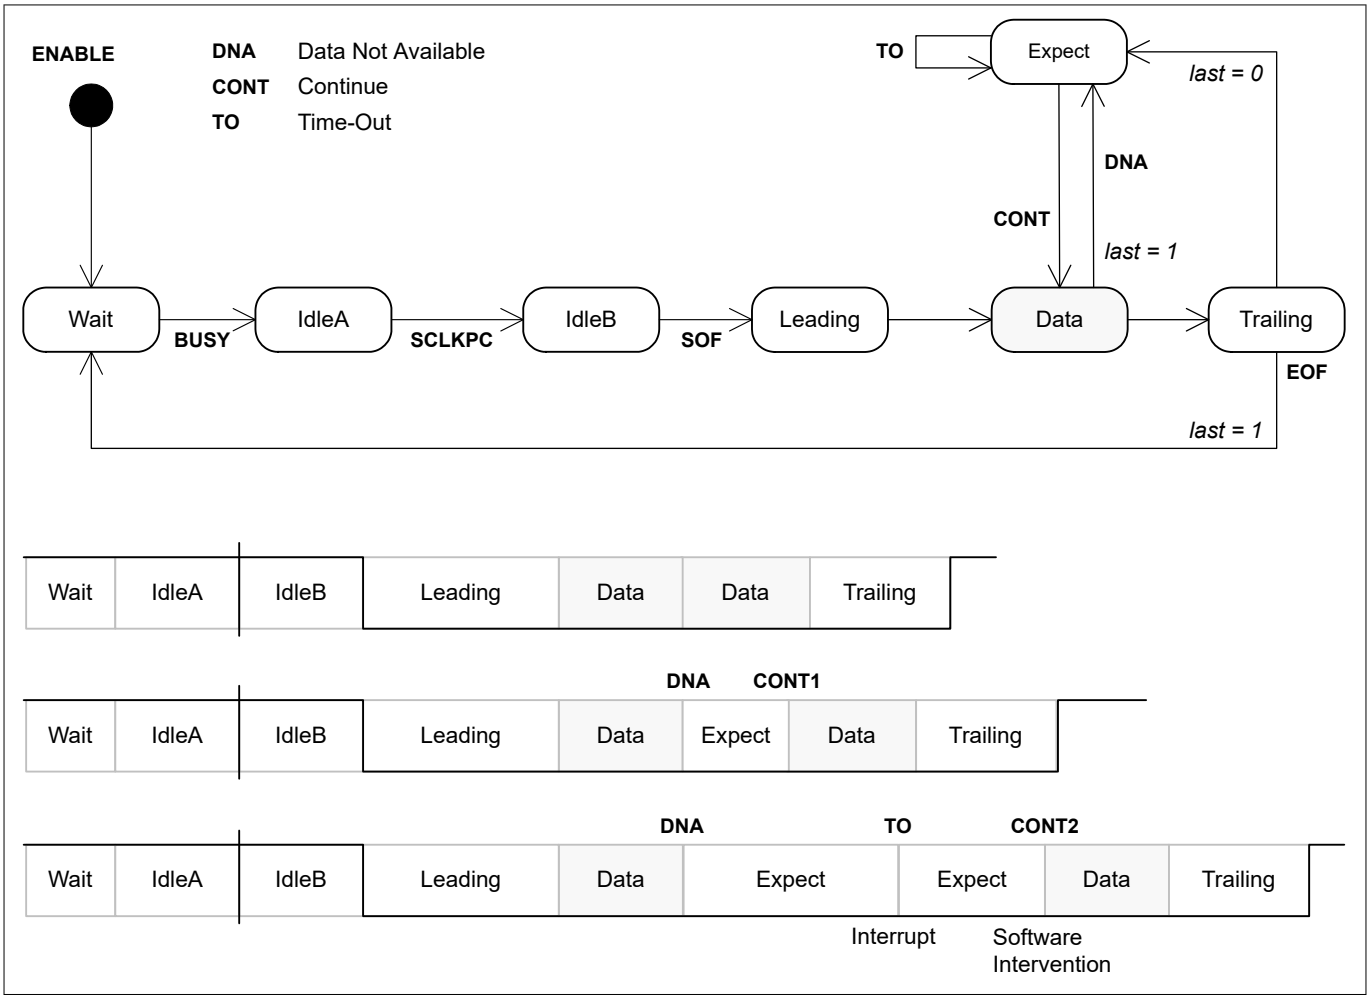

Figure 666 EXPECT cycles of the QSPI state machine

30.3.2.7 External slave select expansion

The external slave select expansion mode (delayed mode) is activated with the bit GLOBALCON.DEL0. This mode enables the connection of an external multiplexer for communication with up to 16 slaves using a single QSPI module while only utilizing 4+1 SLSO outputs pins of the device.

In this mode the binary coding of the bit-field BACON.CS (bits 0 to 3) drives up to four SLSO pins, not demultiplexed by the QSPI, but connected to the selection input of an external demultiplexer. The SSOC.AOL bits can invert the SLSO0...15 signal levels individually; SSOC.OEN bits enable the signals to the output pins.

Using the standard reset values of the register MSSMUX defaults to a similar behavior to previous QSPI generations (shown in the following figure), where BACON.CS drives directly the SLSO1 to SLSO4 signals, and SLSO0 is used for the strobe signal.

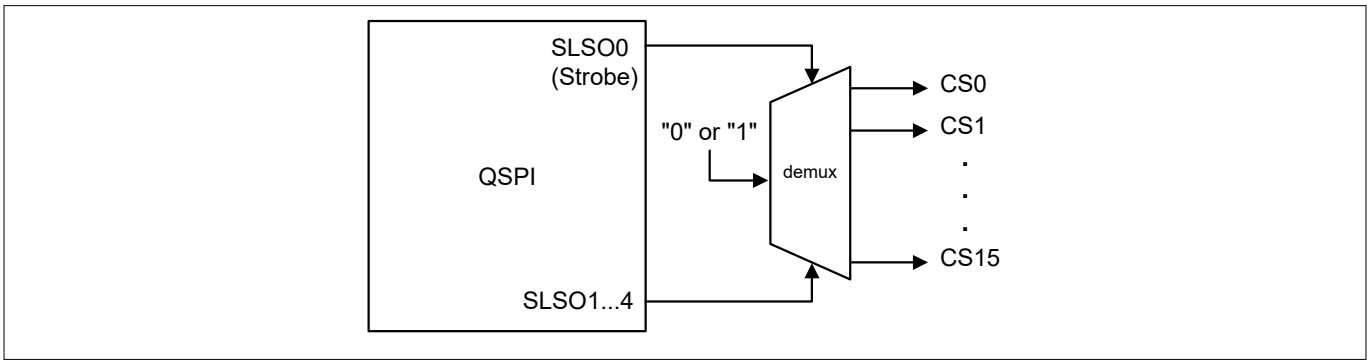

Figure 667 Demultiplexing the slave select signals externally

The External slave select expansion mode is not to the usage of the pins SLSO0-4, but any SLSOs canbe used. I n applications some of the pins corresponding to SLSO0-4 might be used by other features. The figureabove sh ows how to select up to four slave select outputs for the external MUX selection bits using the bits MSSOUT0-3 and how to select the slave select the pin for outputting the strobe signal using the MSSOUTS bitfield.

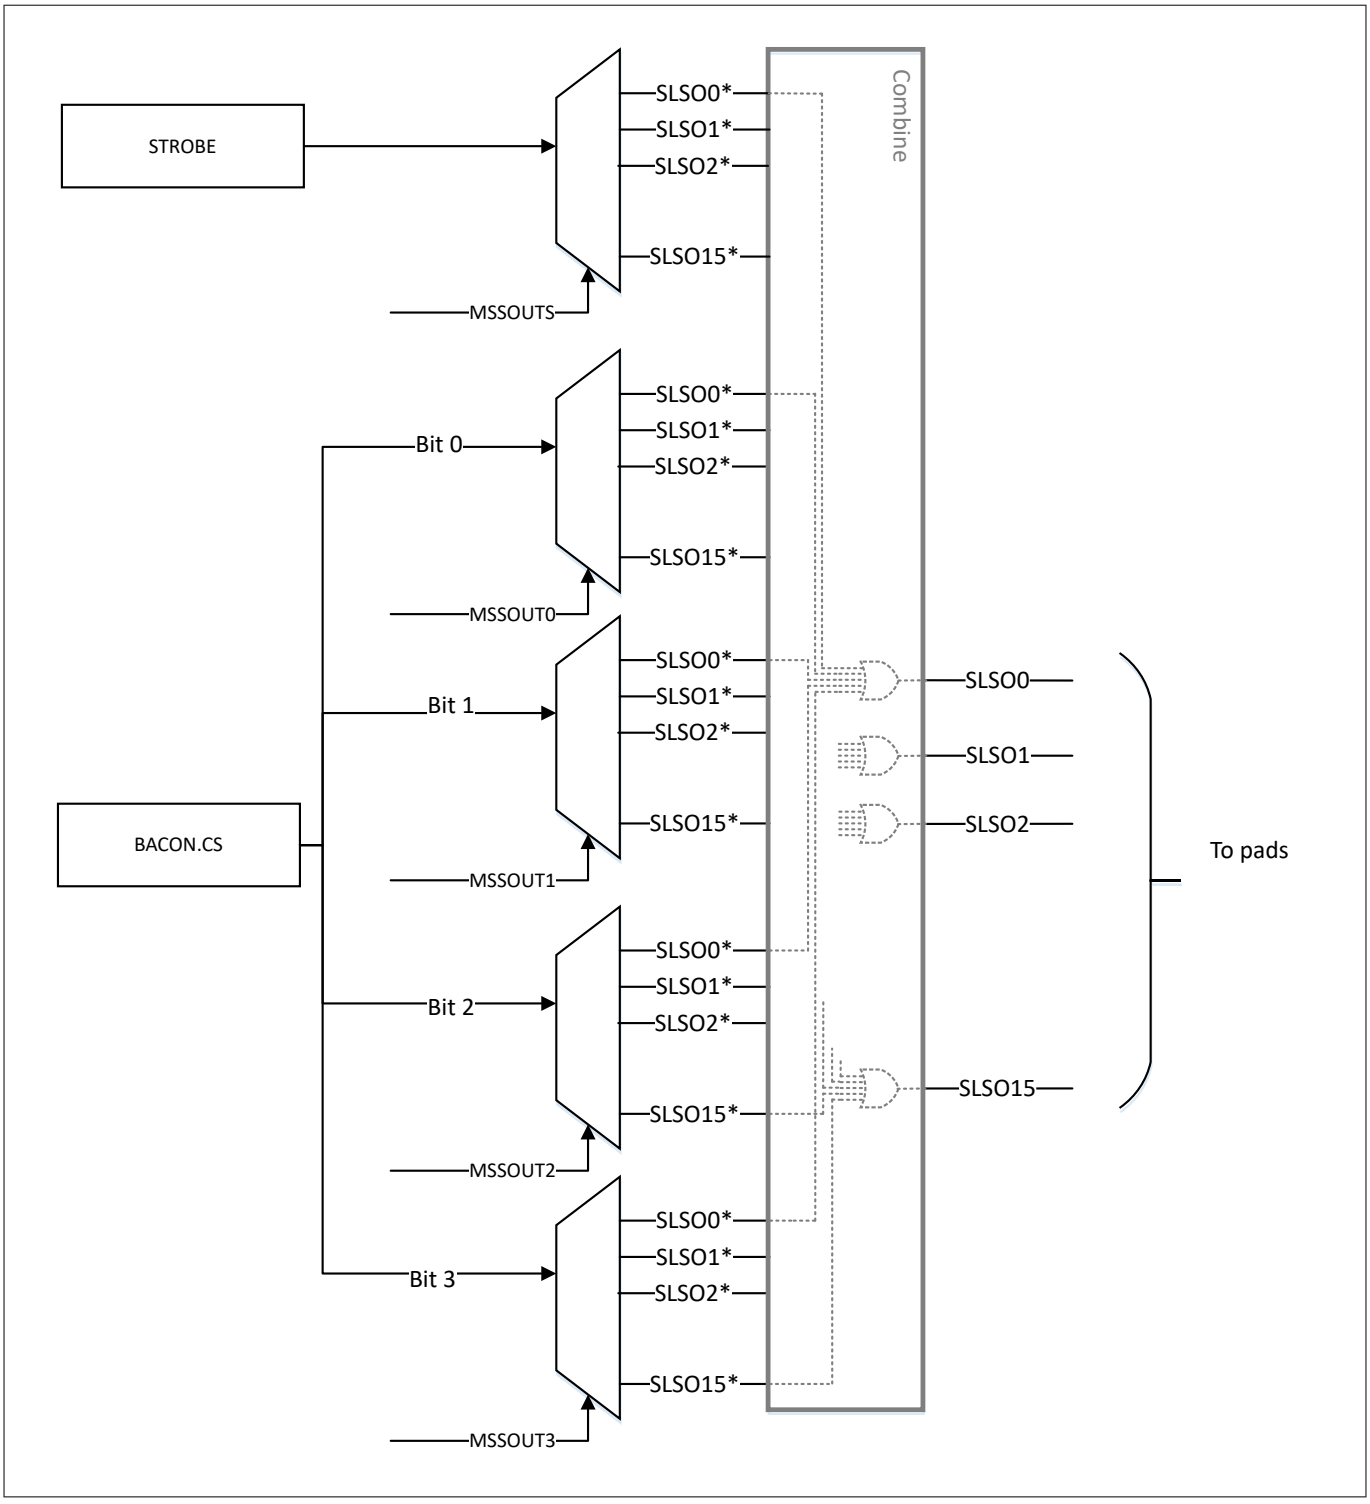

Figure 668 Selecting arbitrary SLSOs for external slave select expansion

In order to ensure glitch free selection, a strobe signal is provided, driven at strobe pin selected by MSSMUXS.MSSOUTS. This signal is delayed relative to the SLSO signals used for external MUX selection bits. This delay is by LS (Lead_Strobe) and TS (Trail_Strobe), equal in duration and can be calculated using the formula for t_{STROBE_DELAY}. The duration of LS and TS can be configured in the GLOBALCON.STROBE in multiples of channel time-quanta units T_Q.

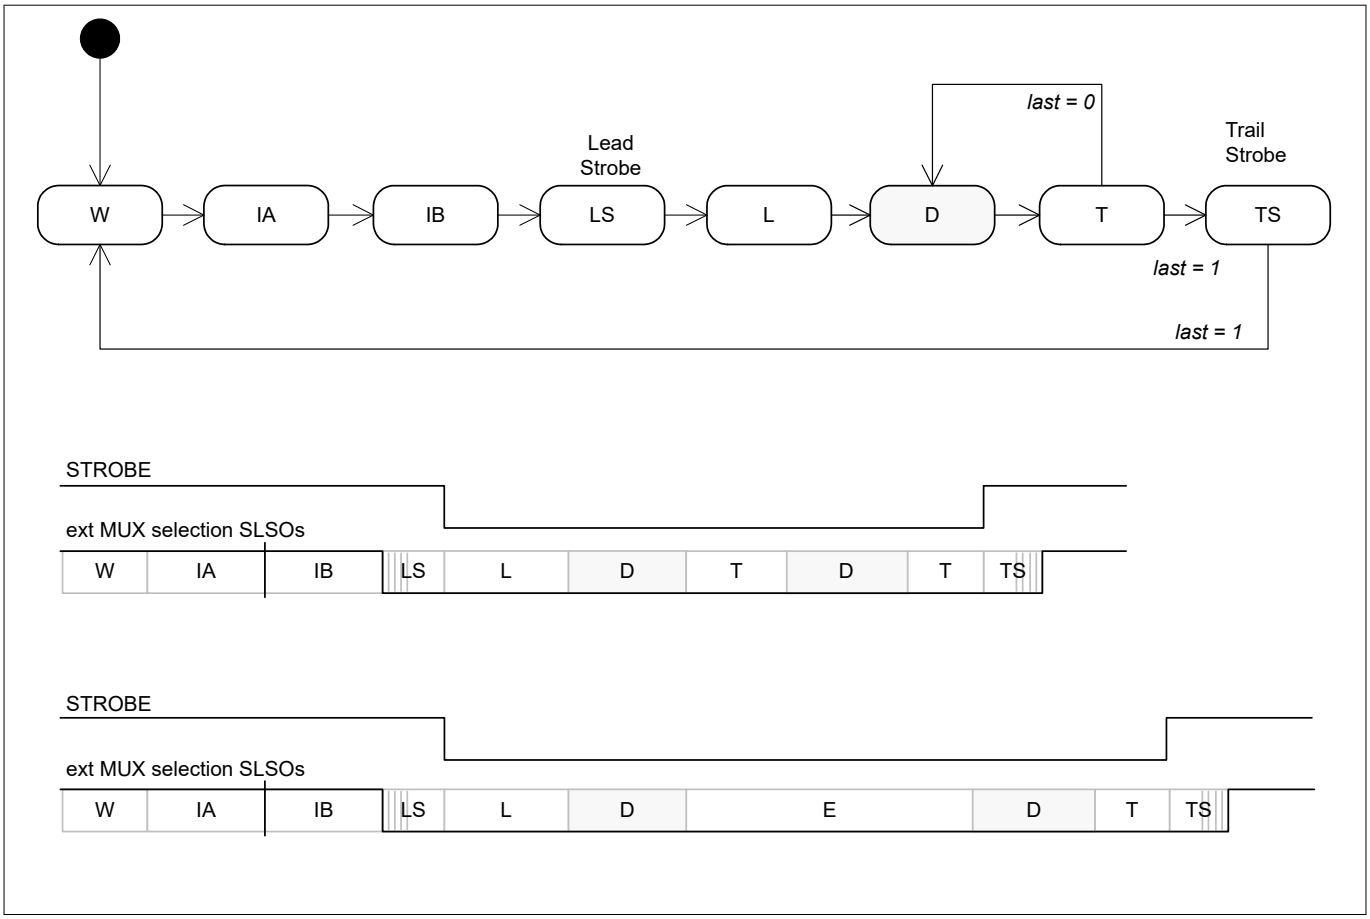

Figure 669 State machine and SLS signals in strobed mode

When using External slave select expansion, all the SLSO signals will be inactive (as per SSOC.AOL), while no communication is ongoing. If a communication is started, the SLSO will change to their corresponding level during "LS" and will go back to inactive during "TS".

Selecting multiple slave simultaneously

It is possible to use the External slave select expansion mode to send messages to multiple slaves simultaneously, as in this mode the SLSO outputs are driven by the binary value of BACON.CS. So if one communication should be received by two slaves, then this can be achieved by using BACON.CS=0b11 for the communication and by mapping the outputs *bit0* and *bit1* to the corresponding SLSO outputs to these slaves. This is done using MSSOUT0 and MSSOUT1. The selected SLSOs will only be active during the ongoing communication (enabled during LS, disabled during TS), as shown in the previous figures.

***Note**: Reception of data from multiple slaves simultaneously is not supported.*

30.3.2.8 High speed mode

The bit-fields A, B and C in ECONz provide means to compensate for the loop delay in SPI communications. But for very high speed communications, these settings of A, B and C might not be sufficient, because they only allow shifting the data sampling point within the current clock cycle. If the loop delay of the system is higher than the period of the envisioned baud-rate, a different approach is needed.

Enabling the High Speed Mode (GLOBALCON.HS=1) allows setting the effective sampling point of the input data on MRST to a point in time after the current clock cycle. For achieving this, an additional parameter D is introduced, which defines an additional phase D. This phase starts after phase B and concurrently with phase

C. The RX data sampling point is then after phases A+B+D in this mode. The phase D has no impact on period or duty cycle of the serial clock.

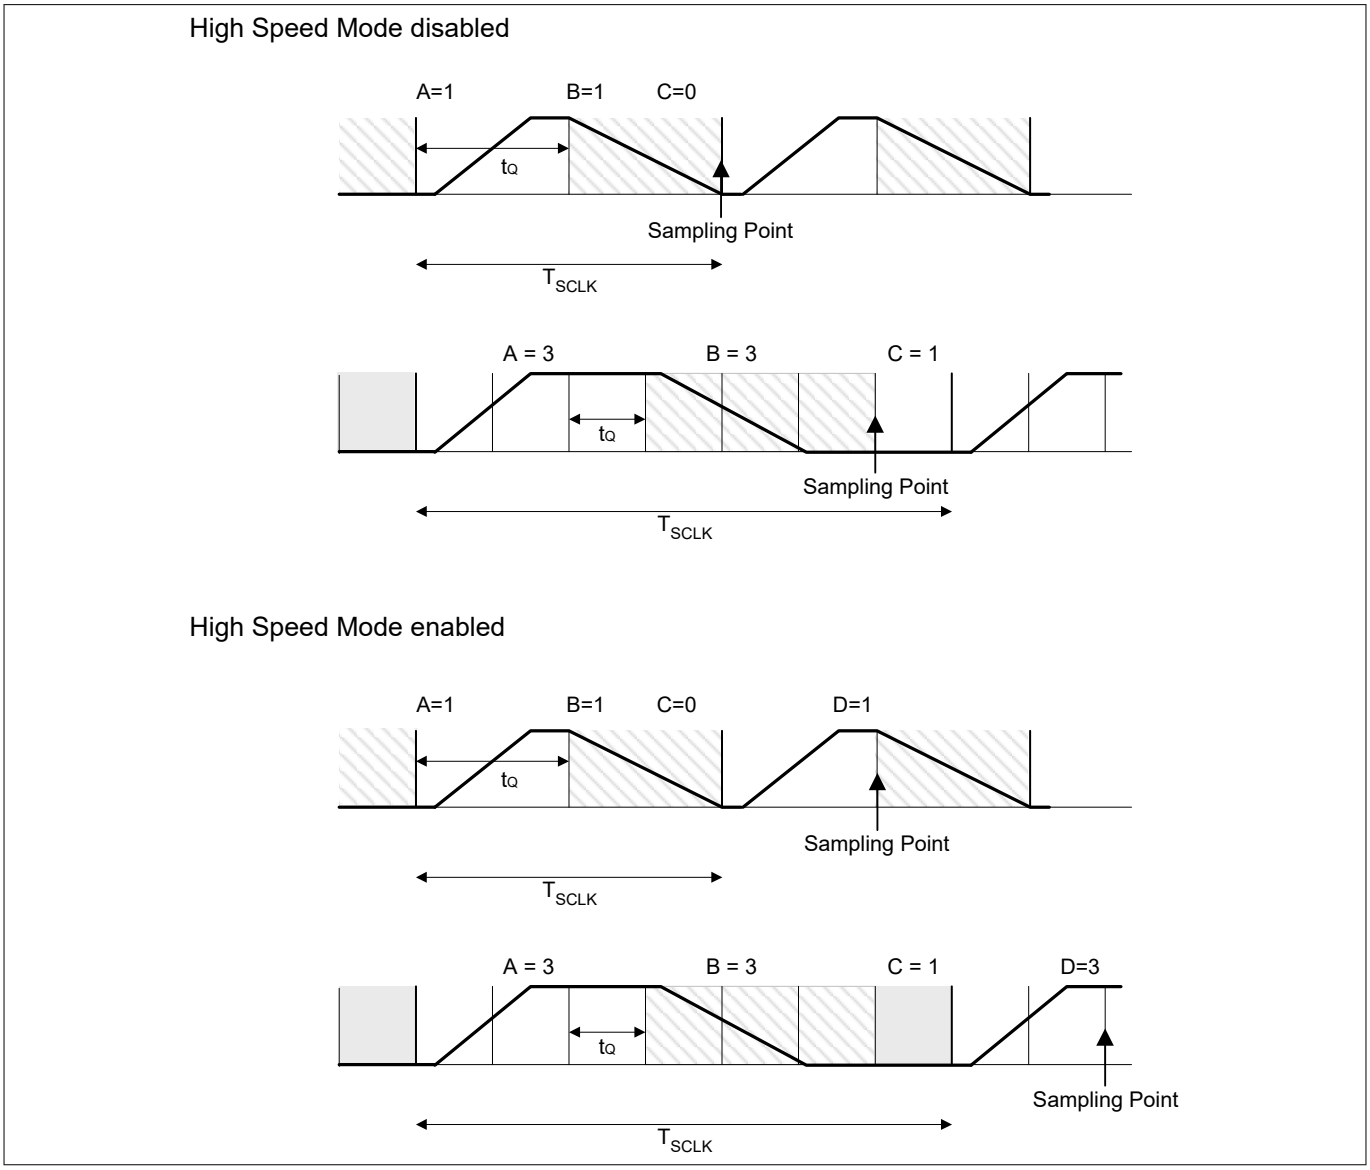

Figure 670 Rx data sampling point in high speed master mode

The figure above visualizes the High Speed Mode. The first two waveforms show two different settings of A, B and C in GLOBALCON.HS = 0. Then the subsequent two waveforms visualize the same settings of A, B and C (same serial clock), but with GLOBALCON.HS=1 and D > 0. In all four waveforms one clock cycle is marked as T_{SLCK} and the corresponding sampling point is given. The waveforms for High Speed Mode show a sampling point outside of the current clock cycle, enabling higher SPI clock frequencies since the compensated loop delay is the sum of phases A+B+D. The last waveform additionally shows the concurrency of phases C and D.

The user must make sure that the TRAIL delay is as least as long as the time corresponding to the length of phase D minus phase C, meaning:

$$(D - C) \times \text{ECONz.}Q \times \text{GLOBALCON.TQ} \leq \text{BACON.TPRE} \times \text{BACON.TRAIL}$$

***Note**: The equations above contain the representative decimal values of the bit-fields in corresponding units, not their actual binary bit-value.*

30.3.2.9 Hardware trigger mode

A QSPI hardware triggered **HWT** mode is enabled by setting GLOBALCON.HWTREN=1. In this mode, the CPU writes first the configuration and data in the BACON_ENTRY and DATA_ENTRYx address, respectively and the QSPI module initiates the data transmission on reception of a hardware trigger signal. Different sources for the trigger are selectable in GLOBALCON1.HWTRSEL. The hardware trigger is detected and processed only in the WAIT state. If a trigger signal is received in any other state, then it will be discarded and the corresponding error is flagged in STATUS.ERRORFLAGS and will trigger an interrupt if it is enabled in GLOBALCON1.ERRORENS.

The **HWT** mode is operated in two different ways based on the value of GLOBALCON1.FD bit-field. This bit-field may only be set only when GLOBALCON.HWTREN=1 and Short data mode is used. Setting GLOBALCON1.FD=1 freezes the 32-bit data, which will be sent, so that the same data entry is shifted out on the SPI bus whenever a hardware trigger is received. Setting GLOBALCON1.FD=0, provides the normal QSPI data transmission behavior on every trigger reception. An example illustrating the difference between the two settings is shown in the following figure, here 32-bit data frames are sent with the same configuration on every trigger.

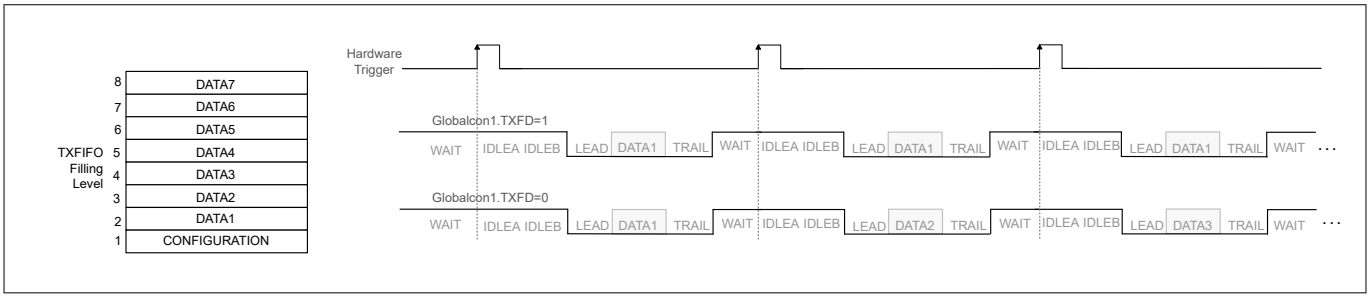

Figure 671 QSPI hardware trigger mode

An empty TXFIFO at the instant of hardware trigger arrival would result in no transaction and the raising of the Trigger Ignored Error. The TXFIFO must be reset by the software whenever switching from a freeze TXFIFO state to an unfreeze TXFIFO state. The selection of the hardware trigger source is configurable based on the GLOBALCON1.HWTRSEL bit-field.

GTM, eGTM and GST trigger inputs

There are two trigger inputs that you can select from by programming GLOBALCON1.HWTRSEL:

- 0 selects GTM

  ***Note**: In products that do not contain GTM, this input is connected to GST.*

- 1 selects eGTM

  ***Note**: In products that do not contain GTM, this input is tied to inactive. It can not be used in these products..*

30.3.3 Slave mode

The slave mode is entered by setting the bit-field GLOBALCON.MS to value 0x1Xb. Before entering the slave mode, the related parameters must be configured, including pin selection for SCLKI, SLSI and MTSR, pin input level, and pull-up/pull-down configuration. The configuration should be done before data transmission starts. Reconfiguration is only allowed when the module is in a wait state. Subsequently a state machine reset should be performed and then the slave mode should be entered.

In slave mode data is being pushed into or out of the module through the serial pins by an external master. The RXFIFO must be regularly emptied by the system in order to avoid data loss, and the TXFIFO must be regularly fed by the system to avoid delivering all “1” data in case of an empty TXFIFO.

If the slave mode relies on a slave select signal to mark the start and, in parallel to the bit counting, the end of a frame, then deactivating the slave signal by the master automatically resets the shift register state machine to wait state.

If the slave mode relies solely on bit counting for determining the frame end, then any SCLKI clock period longer than two bit times is treated as an end of a frame and simultaneously as a baud rate error.

In slave mode, the module simply immediately responds to external clock edges. Therefore the settings for the leading, trailing, idle delays, and duty cycle and sampling point are irrelevant. From all timing settings, only the data length and the baud rate divider setting are relevant. The baud rate setting is important because of its role of watchdog timer of the incoming serial clock.

Generally, the slave mode supports the same user interface as the master mode. This means the BACON-Data sequences remain the same. The SRF bit is ignored.

Limit the data length setting in the slave mode to the range of 2 to 32 bits. The byte setting BACON.BYTE is to be set to zero, that is, it always defines bits.

In case of receive only (simplex receive) the user software must reset the module in order to switch to transmit and receive mode (full duplex). Generally, mode reconfiguration (slave mode to master mode) requires module reset which resets the internal state machines and counters.

In case of slave transmit, the user software must write data to the TXFIFO before the first SCLKI edge of a frame arrives. If the TXFIFO is empty at this point of time, an underflow occurs, all “1” data is delivered, and underflow error interrupt is triggered if enabled. If the TXFIFO is written at the same time when the first SCLKI edge starts the shifting, the underflow occurs, interrupt will be triggered and data from the TXFIFO will be transmitted possibly corrupted. The first bit will be “1”.

In the event of TXFIFO or RXFIFO underflow the FIFOs deliver all “1” data.

In the event of TXFIFO or RXFIFO overflow, the last data is lost. In this case, data or status in the RXFIFO can be lost.

The bit counting in the slave mode operates according to the following rules:

- The incoming bits (or shift clock shift edges) are counted and when the number defined in the BACON.DL is reached, the bits are transferred in the RXFIFO
- If the SLSI input is deactivated, the internal bit counter is reset

In slave mode, sleep requests may be enabled only when there is no pending transmit queue and no pending transmission, and the TXFIFO is empty.

Phase interrupts in slave mode

PT1 interrupt signals the following events:

- BUSY
  - Option 000 from GLOBALCON1.PT1
  - Transmit data is present and is waiting for the shift clock
- SOF
  - Option 010 from GLOBALCON1.PT1
  - Transmission of the first data bit started. It is not connected to SLSI active edge, but to the first clock pulse received
- TBE
  - Option 011 from GLOBALCON1.PT1
  - Data is taken from the TXFIFO by the QSPI shift engine. It will be transmitted with the first shift clock pulse

- RBF
  - Option 100 from GLOBALCON1.PT1
  - Received data is written to the RXFIFO
- EOF
  - Option 101 from GLOBALCON1.PT1
  - The last data bit has been received
- DNA
  - Option 110 from GLOBALCON1.PT1
  - Transmit data not available at the first shift clock edge reception

PT2 interrupt signals the following events:

- EOF
  - Option 101 from GLOBALCON1.PT2
  - SLSI deactivated (rising edge on the SLSI pin)

30.3.3.1 Shift clock phase and polarity in slave mode

In slave mode the shift clock phase and polarity are fixed to CPH=1 and CPOL=0 (have to be programmed accordingly in the ECONz (z=0-7) register selected by BACON.CS) and slave select polarity is fixed to low active. The baud rate that the slave expects is defined in the ECONz (z=0-7) register pointed at by the BACON.CS.

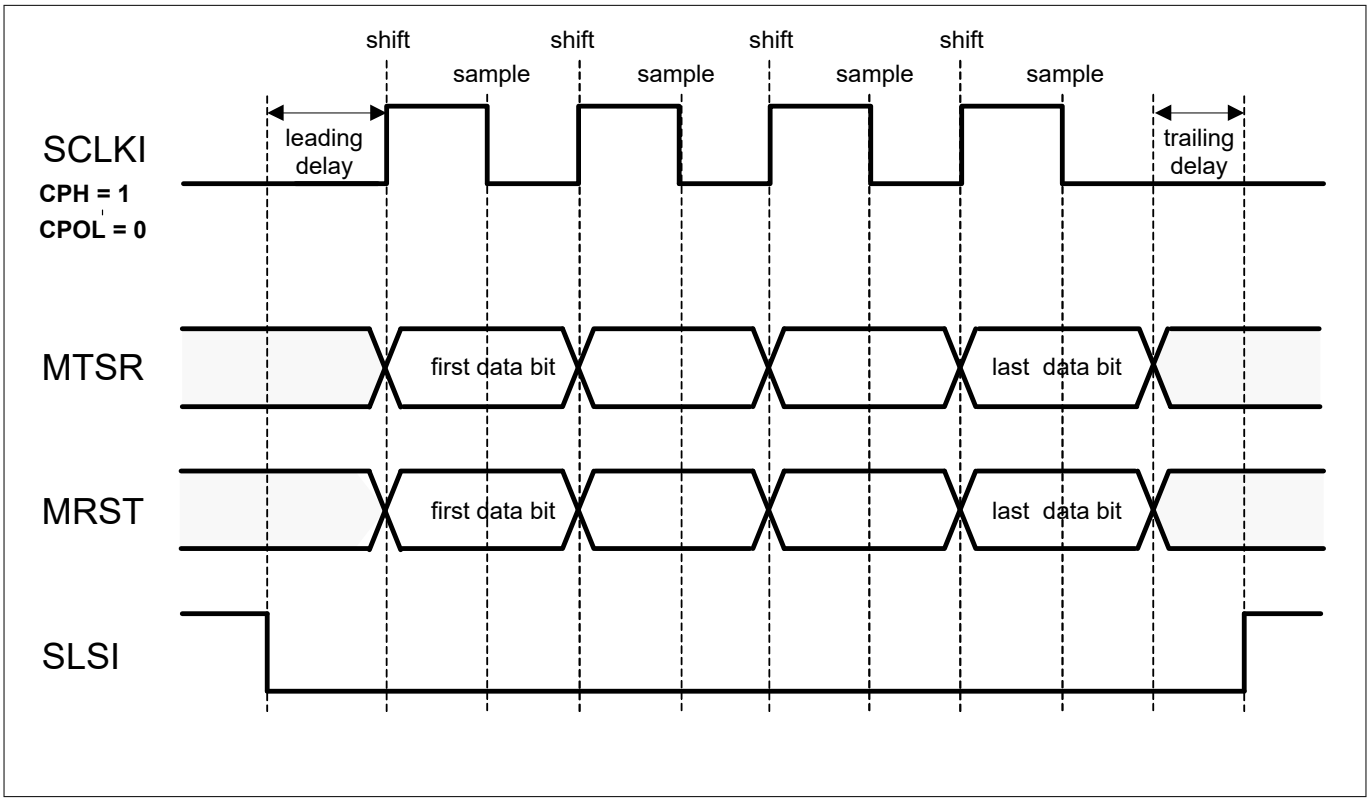

Figure 672 Slave transfer, CPH = 1, CPOL = 0

***Attention**: Slave re-configuration must only be performed in a gap between the frames. However, as a general recommendation, slave mode configuration should be done once only and before the transition starts.*

30.3.3.2 Shift clock monitoring

The QSPI module provides two mechanisms for monitoring the shift clock input signal in slave mode. These mechanisms monitor:

- If the receiving shift clock frequency (baud rate) lies within a certain range and
- If there are spikes on the shift clock input

In case such disturbances are detected, the reaction is always the same:

- The corresponding error flags in STATUS.ERRORFLAGS are set, which can be cleared with FLAGSCLEAR.ERRORCLEARS
- The common error interrupt is raised if enabled in GLOBALCON1.ERRORENS and
- The bit GLOBALCON.EN is automatically cleared, if this feature is enabled by the bit GLOBALCON.AREN. The user software can activate a reset afterward

In case of too high baud rate error, baud rate detection and spike detection both react, where spike detection is more effective. Spike detection reacts immediately, baud rate detection requires several bits with higher baud rate. Baud rate detection uses a window two nominal bit times wide and counts the real bit times: double baud rate error requires at least four real shift clock pulses to be detected, triple baud rate error requires six and so

on. Baud rate detection does not react to all spikes smaller than one kernel clock period. In case of too low baud rate, baud rate error detection reacts immediately, spike detection ignores this case.

30.3.3.2.1 Baud rate error detection

If the shift clock has less than half or more than double the expected baud rate, then:

- The corresponding flag is set in STATUS.ERRORFLAGS
- Error interrupt is raised if enabled in GLOBALCON1.ERRORENS
- Automatic clear of GLOBALCON.EN follows, if enabled by GLOBALCON.AREN

30.3.3.2.2 Spike detection

Short spikes on the clock line due to ground bouncing or clock ringing due to over/undershoots would cause one or more extra bits to be written to the front end receive FIFO of the slave. This extra bit, if no measures are taken by the software, would cause all the subsequent received frames to be corrupted (shifted).

The spike detection mechanism operates up to 50 MBaud and checks if a bouncing spike has occurred on the clock line near to the correct receiving clock edges.

If a spike is detected, the software should use GLOBALCON.RESET bit-field, and should clear the corresponding status flags. Alternatively a complete module reset may be performed through registers RST_CTRLA and RST_CTRLB.

The spike detection is based on two mechanisms:

- Detection of two close writes to the front end receive FIFO by detecting filling level of two
- Using an inverted watchdog set to approximately 75% to 80% SCLKI clock period, which is the optimal range

The inverted watchdog is a timer which starts to count triggered on the write event to the front-end receive FIFO of the slave. During the time the watchdog counts, no edge is allowed to occur. An edge in the forbidden time raises a spike error event.

If a spike occurs in the last 25% of the SCLKI period, when the watchdog has stopped counting, the watchdog will be triggered to count by the spike. The next regular edge will violate the forbidden time and raise a spike event.

The watchdog counts $\mathrm{ECONz}.B + \mathrm{ECONz}.C$ time quantas. The following constraint applies:
$50\,\% \times T_{\mathrm{SCLKI}} < \mathrm{ECONz}.B + \mathrm{ECONz}.C < 100\,\% \times T_{\mathrm{SCLKI}}$.

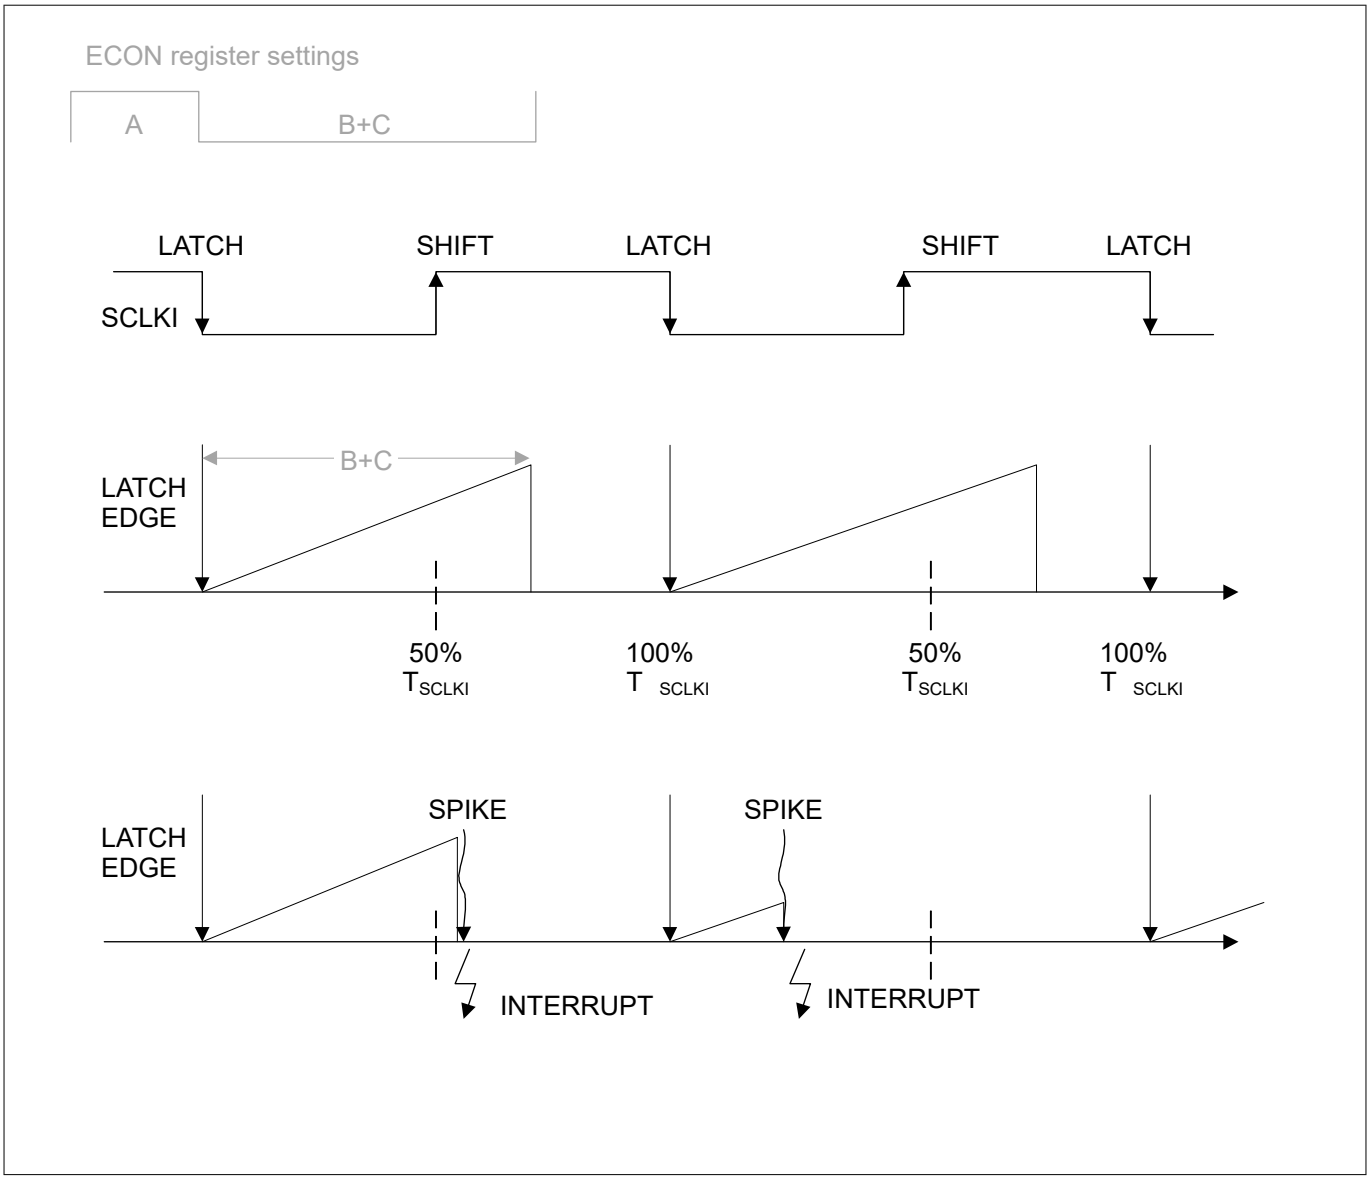

Figure 673 Spike watchdog

30.3.3.2.3 Shift clock monitor flags

The spike detection mechanism sets the flag STATUS1.SPD, if it has detected a spike. The baud rate error detection mechanism sets the flag STATUS1.BRD, if it has detected excessive baud rate deviation.

Writing 1 to SPD and BRD sets the bit and causes an interrupt, if enabled. Writing 0 has no effect.

Both signals are ORed. This combined signal is shown in STATUS.ERRORFLAGS and raises an interrupt, if enabled in GLOBALCON1.ERRORENS. Automatic clear of GLOBALCON.EN follows, if enabled by GLOBALCON.AREN.

If the STATUS.ERRORFLAGS[2] bit is cleared through FLAGSCLEAR.ERRORCLEARS[2], both flags SPD and BRD are automatically cleared.

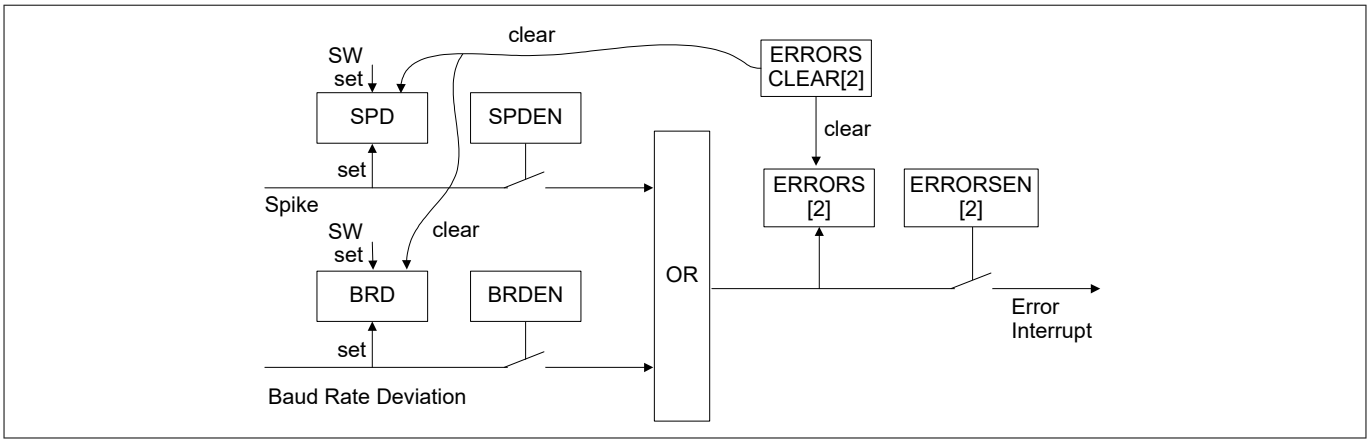

Figure 674 Shift clock monitor flags

30.3.3.3 Parity

Parity settings for transmit and receive are defined by the corresponding bit-fields in the BACON register.

The parity bit is concatenated to the data bits at transmission time. This means that a frame containing 16-bit data is 17 bits long (data + 1 parity). The transmitted parity bit can be read from the STATUS.TPV bit.

The parity bit is removed from the received bits at receive time automatically. The received parity bit can be read from the STATUS.RPV bit.

Attention**: **Parity is available only in short mode, that is, only for data of up to 32 bits length.

Attention**: **The parity bit is concatenated to the data at the LSB location. If the bit-field BACON.MSB = 0 it is shifted out first, else the parity bit is shifted out last.

30.3.4 Operation modes

Generally, the QSPI module transmits a RAM queue of an arbitrary length, fed by a DMA module, and makes pauses between the queues. The QSPI module does not know anything about the queue length or the current position within the queue or the future schedule of the messages that may come.

If the QSPI module gets a request for switching off the clock or pausing the module, it disables all service request lines.

The QSPI module provides two options for switching off the clocks or pausing the module: hard suspend (as soon as possible regarding for example the length of interrupt request pulses), and soft suspend (transition to the PAUSE state after reaching predefined state). The requests can be triggered by hardware signals (disable, suspend, sleep) or by software write to GLOBALCON.EN bit.

Disable, pause and run

After being enabled by clearing the CLC.DISR bit, the QSPI enters the PAUSE state. In this state, the QSPI module can be initialized, the TXFIFO pre-filled, and then, by setting the GLOBALCON.EN bit, put into a RUN state.

The software requests PAUSE state of the running module by clearing the GLOBALCON.EN bit. The software can detect that the QSPI module has reached the PAUSE state by polling for the GLOBALCON.EN=0 and STATUS.PHASE=0 (indicating WAIT state, master mode only).

In PAUSE state, the user interface of the module is active. The registers and the FIFOs can be read and written. However, both the receive and transmit state machines are inactive, in master as well as in the slave mode. This allows for reconfiguration of the module without affecting the serial bus.

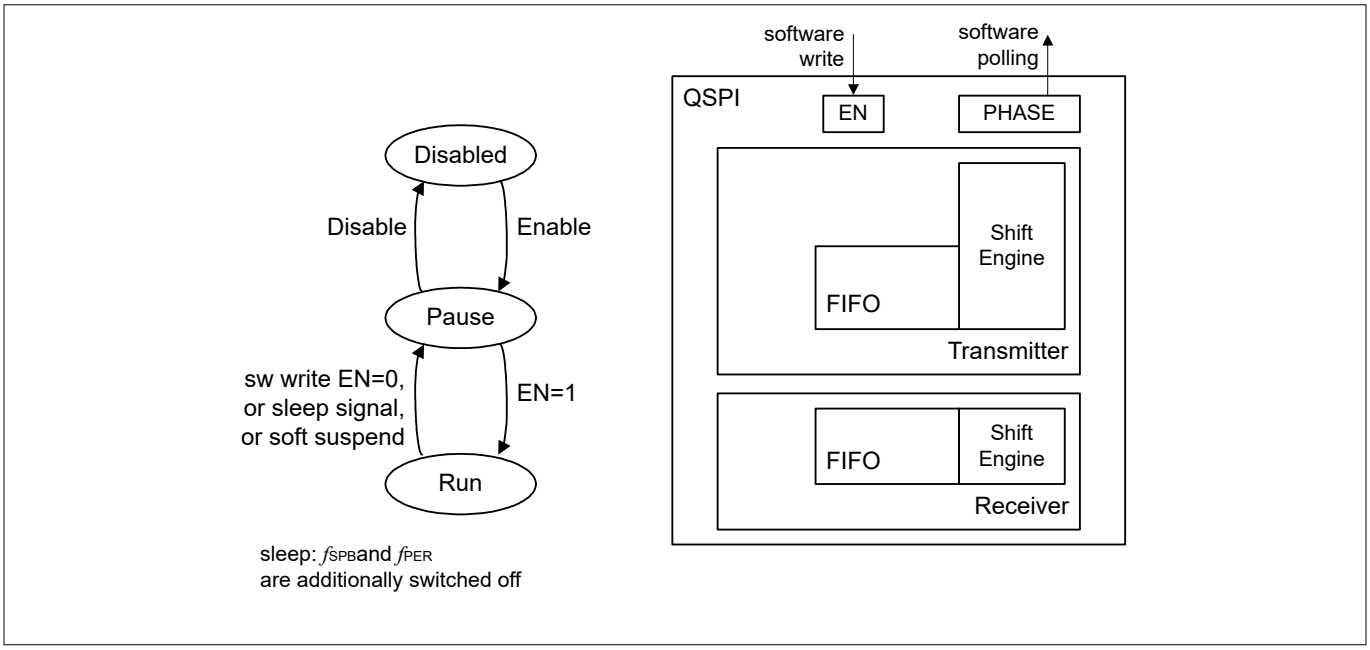

Figure 675 Pause and run overview

The concept of the PAUSE state is reused for handling the soft OCDS suspend and Sleep requests. In contrast to active Pause state and OCDS suspend, the sleep state has the special property that (due to the low power requirement) both FPI and QSPI clocks are switched off.

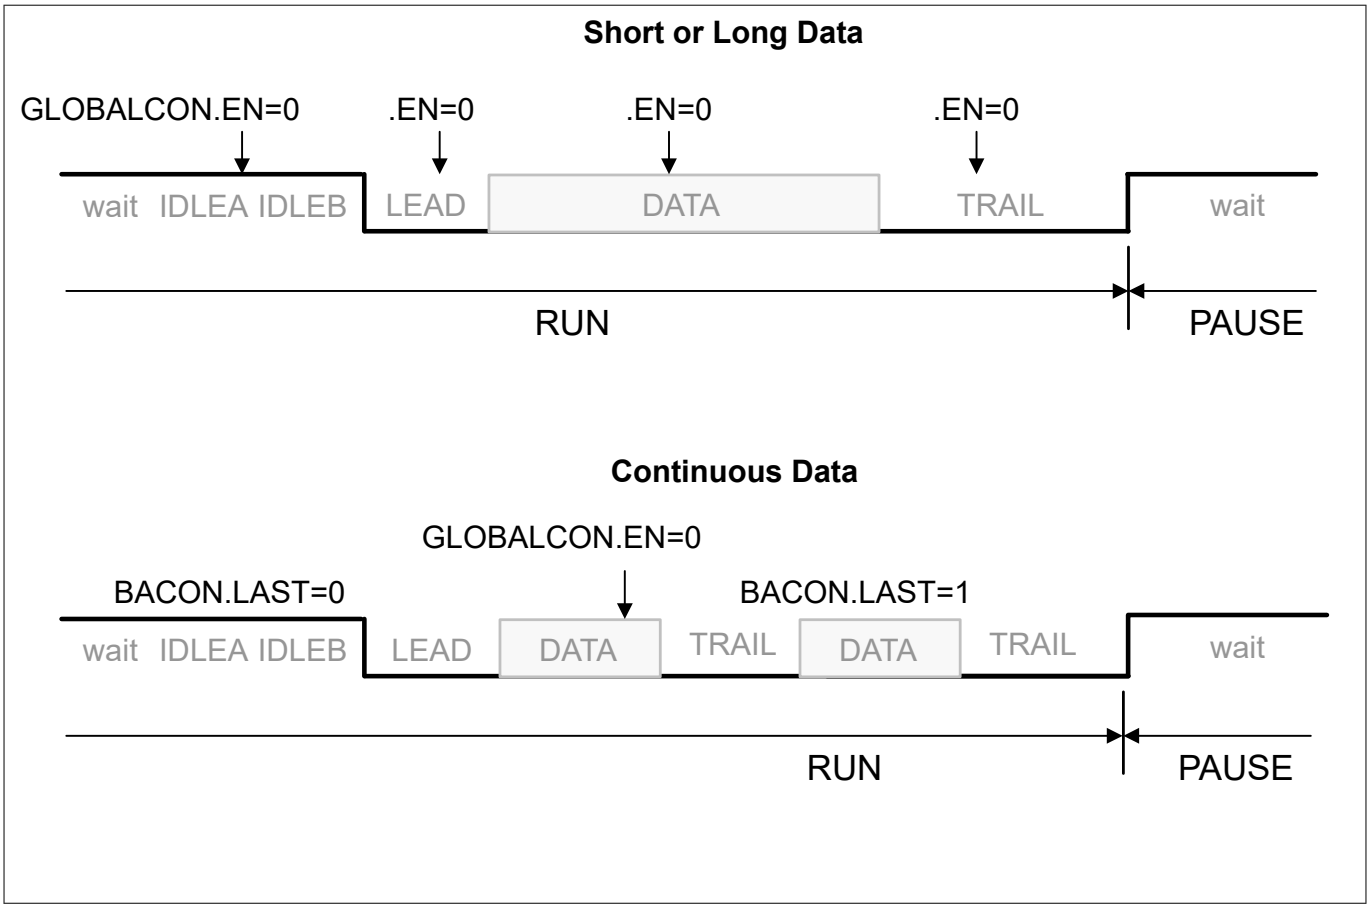

Figure 676 Entering the pause state with GLOBALCON.EN = 0

If a running module receives a request to PAUSE, it waits for the end of the last TRAIL phase of a frame.

For all modes (Short, Long and Continuous), the PAUSE state is indicated by GLOBALCON.EN=0 and STATUS.PHASE=0, master mode only.

30.3.4.1 OCDS suspend

See debug information.

Debug information on page 5402

30.3.4.2 Sleep mode

Sleep signal is a system wide hardware signal requesting from all modules to go to low power saving state as soon as possible. For the QSPI module, going to sleep mode can be disabled or enabled by setting or clearing the CLC.EDIS bit. The module enters the sleep as soon as possible and remains in this state as long as the hardware sleep signal is active. Upon deactivation of the sleep signal, the QSPI wakes in PAUSE state (GLOBALCON.EN bit is cleared by the QSPI module) and waits for the software to enable the GLOBALCON.EN bit.

If CLC.EDIS bit is cleared, the sleep mode is enabled and the module enters the sleep state:

In master mode:

- After ending the TRAIL delay if a transmission is in progress
- Or immediately if the module is in WAIT state

In slave mode:

- After the bit counter has counted the full predefined number of bits as defined in BACON.DL field
- Immediately if the module is in wait state, no transmission ongoing and shift register empty and TXFIFO empty
- Or immediately if the SLSI is inactive (the one selected by PISEL)

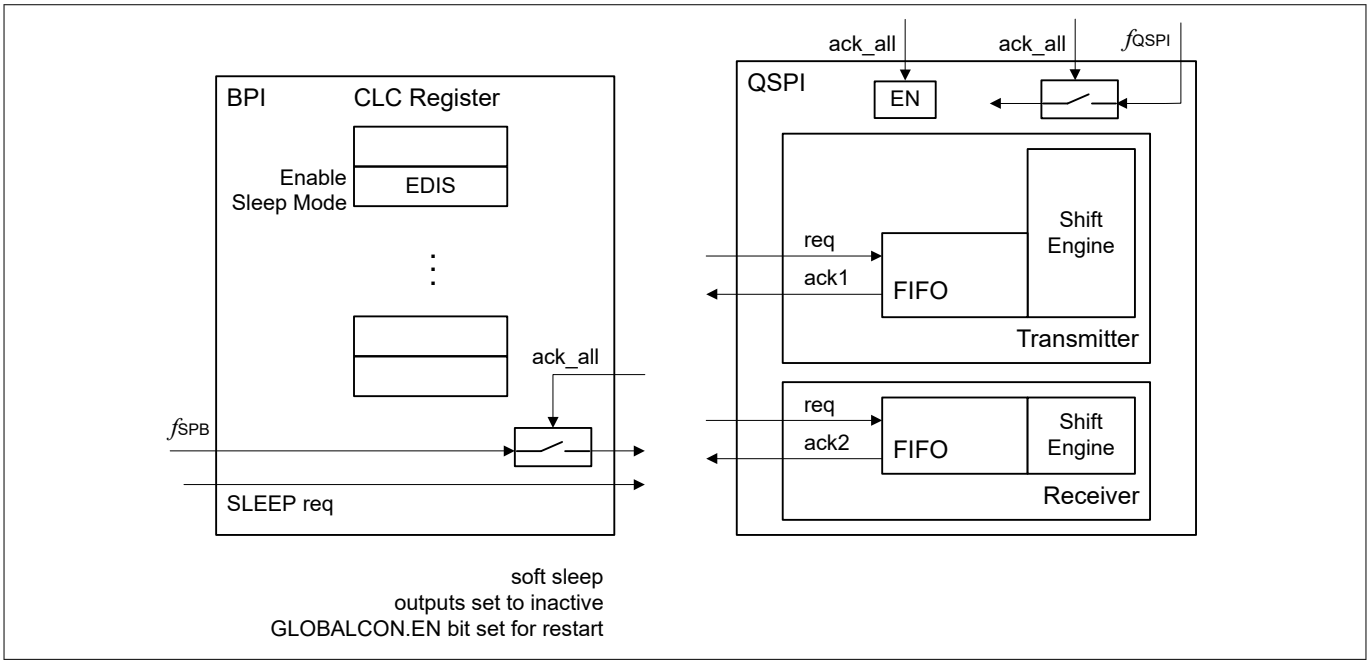

Figure 677 Sleep overview

It is responsibility of the user software to have the sleep enabled in a safe time intervals, where no race conditions or pipeline effects between the QSPI module and the DMA can occur in case of sleep request.

***Note**: CLC disable request and sleep request block immediately kernel register write accesses. This includes also the TXFIFO access. Therefore if the module expects more data (like in long or continuous mode), it will enter the expect phase and remain there and never do an acknowledge and enter the required state. Periodic timeout interrupts will be generated. Therefore it is not recommended to request a sleep or disable during an ongoing long or continuous transfer.*

30.3.4.3 Disabling the QSPI

The software can switch off the QSPI module by setting the CLC.DISR bit. It is responsibility of the user software to issue a disable request in a safe time interval, where no race conditions or pipeline effects between the QSPI

module and the DMA can occur. This is no issue if the switch-off procedure is one-way, that is no continuation of operation without reinitialization or reset of the module is expected. GLOBALCON.EN bit is cleared.

The QSPI module itself behaves in the following way.

In master mode, like entering the sleep mode:

- After ending the TRAIL delay, if a transmission is in progress
- Immediately, if the module is in WAIT state

In slave mode:

- After the bit counter has counted the full predefined number of bits as defined in BACON.DL and BYTE bit-fields, if a transmission is ongoing
- Immediately, if the module is in wait state. No transmission ongoing and shift register empty and TXFIFO empty

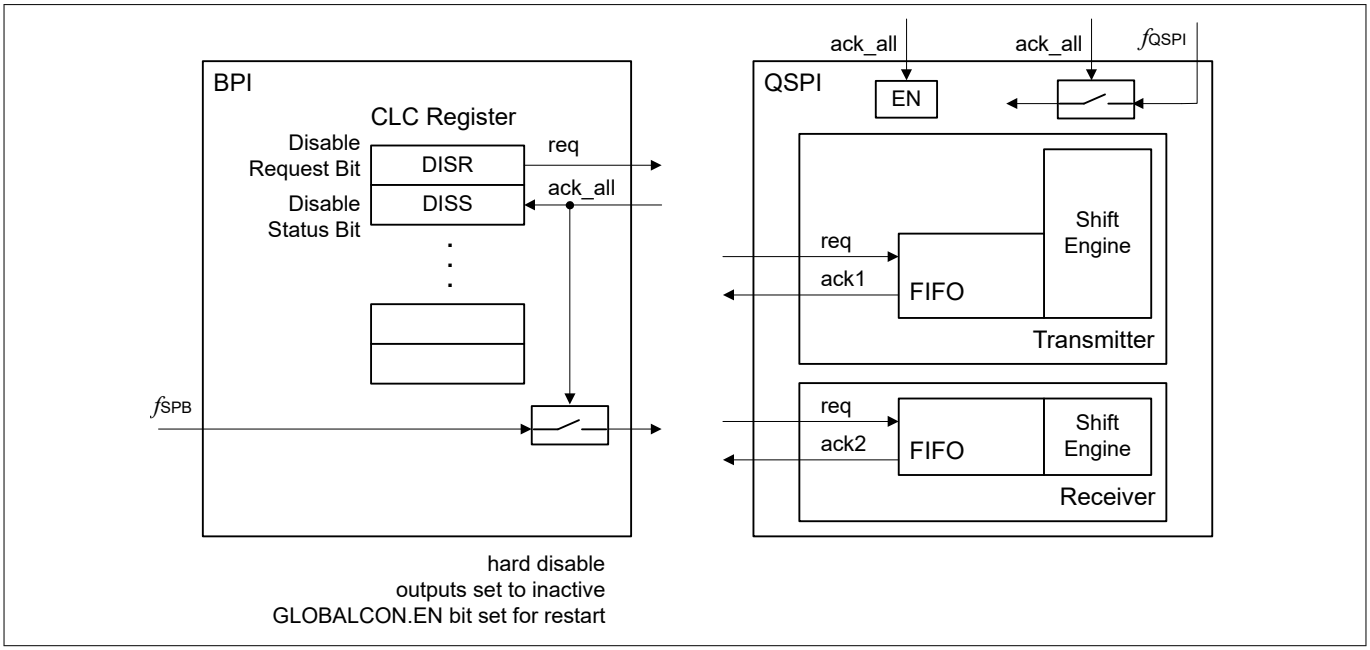

Figure 678 Disable overview

30.3.5 User interface

This section describes the possibilities available for transferring data between the on-chip RAM memories and the QSPI module using the transmit and receive FIFOs. The QSPI features one $8 \times 32 - \text{bit Tx FIFO}$ and one $8 \times 32 - \text{bit Rx FIFO}$. The address ranges for writing data and configuration to the Tx FIFO and for reading data and status from the Rx FIFO consist of address locations with special properties:

- Tx FIFO
  - DATA_ENTRY - writes to any of these eight functionally identical locations are always interpreted as data
  - BACON_ENTRY - writes to this location are always interpreted as configuration
  - MIX_ENTRY - writes to this location are interpreted as data or configuration, based on a set of rules
- Rx FIFO
  - RX_EXIT - reads from this location deliver either data or optionally status, based on a set of rules

Use either MIX_ENTRY or the combination DATA_ENTRY/BACON_ENTRY for sending a frame. Do not combine DATA_ENTRY/BACON_ENTRY and MIX_ENTRY for sending a frame.

The following list gives an overview of the operating modes of QSPI and usage of the TxFIFO entry addresses:

- Short Mode: MIX_ENTRY, DATA_ENTRY/BACON_ENTRY
- Long Mode: MIX_ENTRY, DATA_ENTRY/BACON_ENTRY
- Continuous Mode: MIX_ENTRY, DATA_ENTRY/BACON_ENTRY
- Single Configuration Multiple Frames: MIX_ENTRY
- XXL Mode: DATA_ENTRY/BACON_ENTRY
- Move Counter Mode: DATA_ENTRY/BACON_ENTRY

30.3.5.1 Transmit and receive FIFOs

The Tx_FIFO is filled with both configuration and data entries, which are distributed to the BACON and the shift register at the exit of the Tx_FIFO. The TxFIFO keeps track if an entry is configuration or data. The control and the data elements are automatically distributed to the BACON and shift register. If no data is available, the new BACON is pending.

If a frame is finished and there is data in the TXFIFO:

- In short mode, a new frame starts automatically with the same configuration as the previous one
- In long mode, the extra data is ignored

TXFIFO error conditions:

- FPI bus write to a full TXFIFO generates an overflow interrupt. The write is ignored
- In case of slave mode, $(\mathrm{GLOBALCON.MS} = 1X)$, in case of an underflow, only 1 are delivered

RXFIFO error conditions:

- FPI bus read from an empty RXFIFO generates an underflow interrupt, and delivers only 1 bits
- Hardware attempt to write a full RXFIFO with data or status generates an overflow interrupt. The write attempt is ignored by the RXFIFO
- If the GLOBALCON.SRF bit is set, the communication is stopped in case of full FIFO in master mode. In slave mode, the bit is ignored, no stop can be done
- If the FPI bus frequency is very slow, and the baud rate very high, it can happen that some data is lost on the way between the shift register and a not full RXFIFO. In this case, an overflow interrupt is generated, although the RXFIFO is not full

The Rx_FIFO can be filled with both status and received data entries, depending on GLOBALCON.SI.

***Note**: If a 8-bit or 16-bit write is executed to the TXFIFO entry addresses, the data is mapped 1:1 to its location within the 32-bit wide TXFIFO entry, and the rest is padded with zeros.*

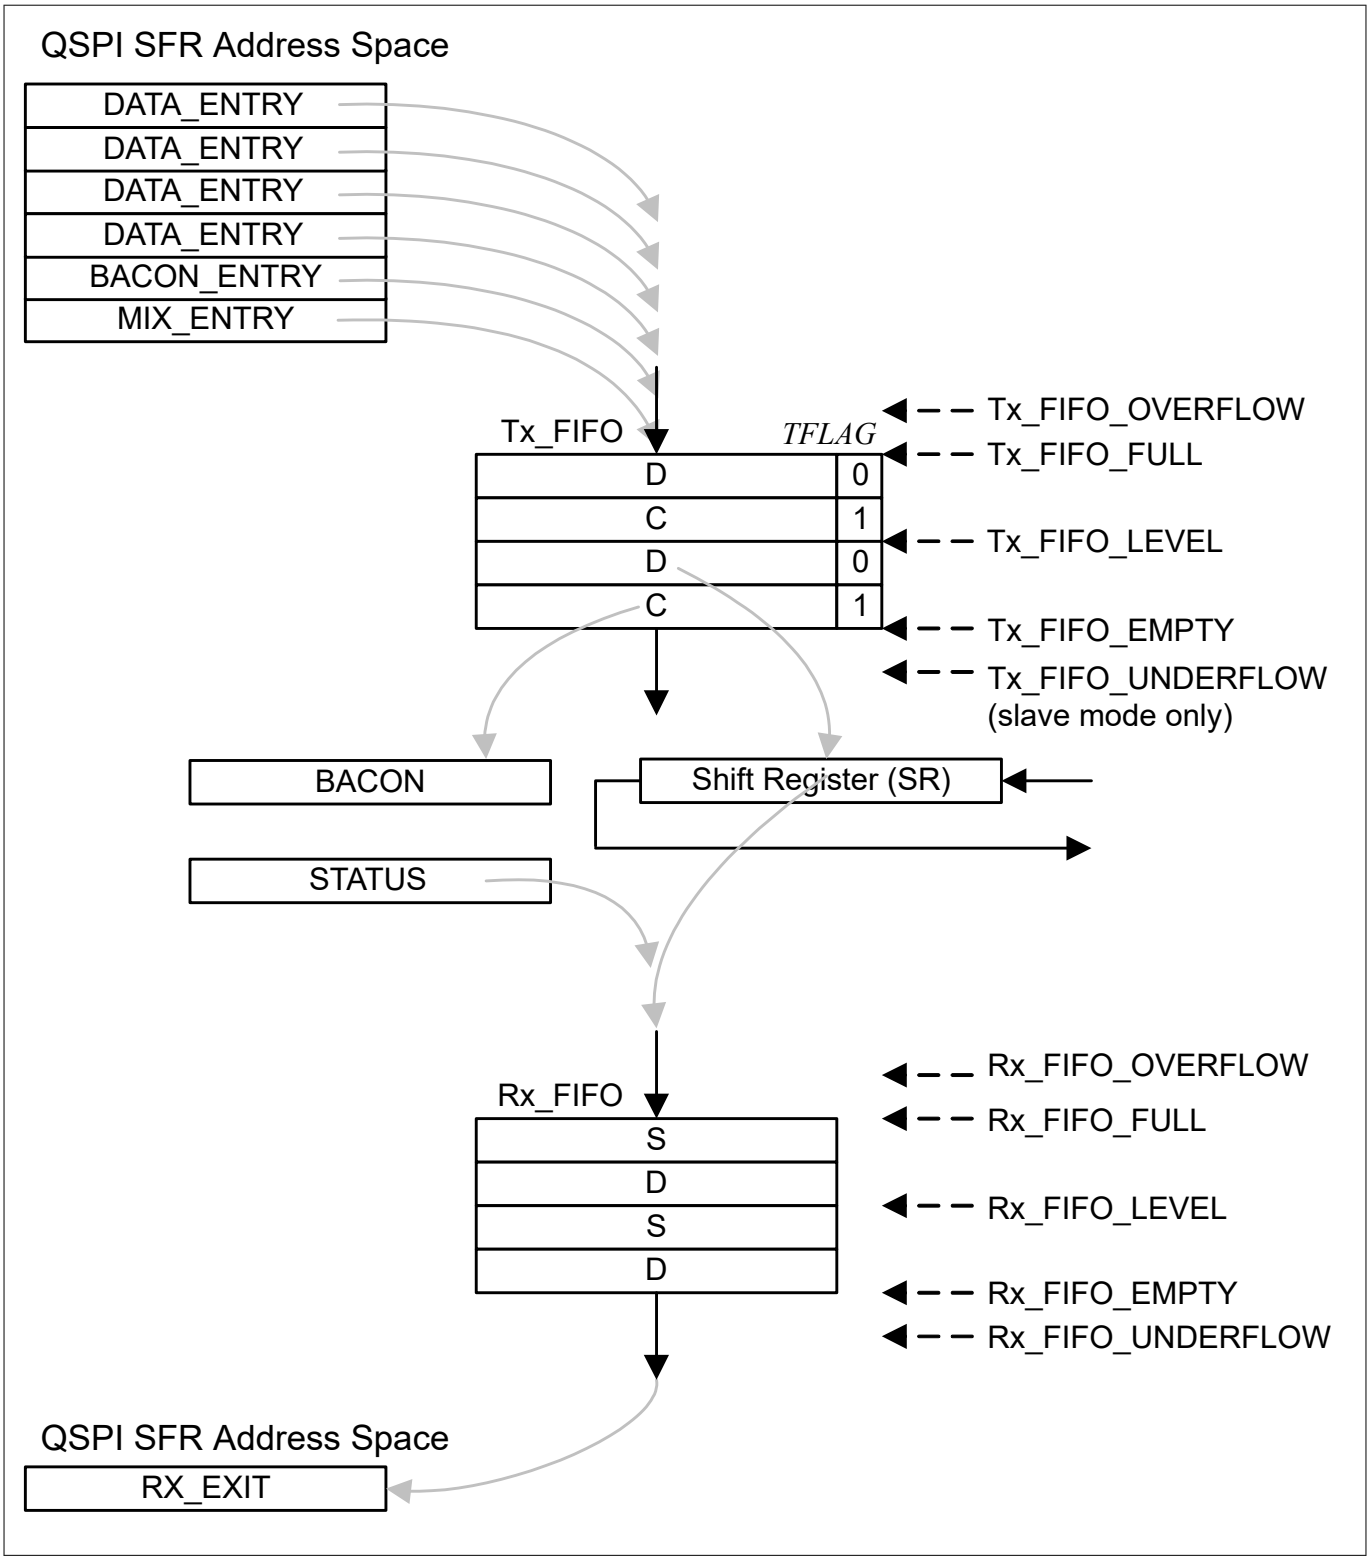

Figure 679 Architecture of the Tx and Rx FIFOs

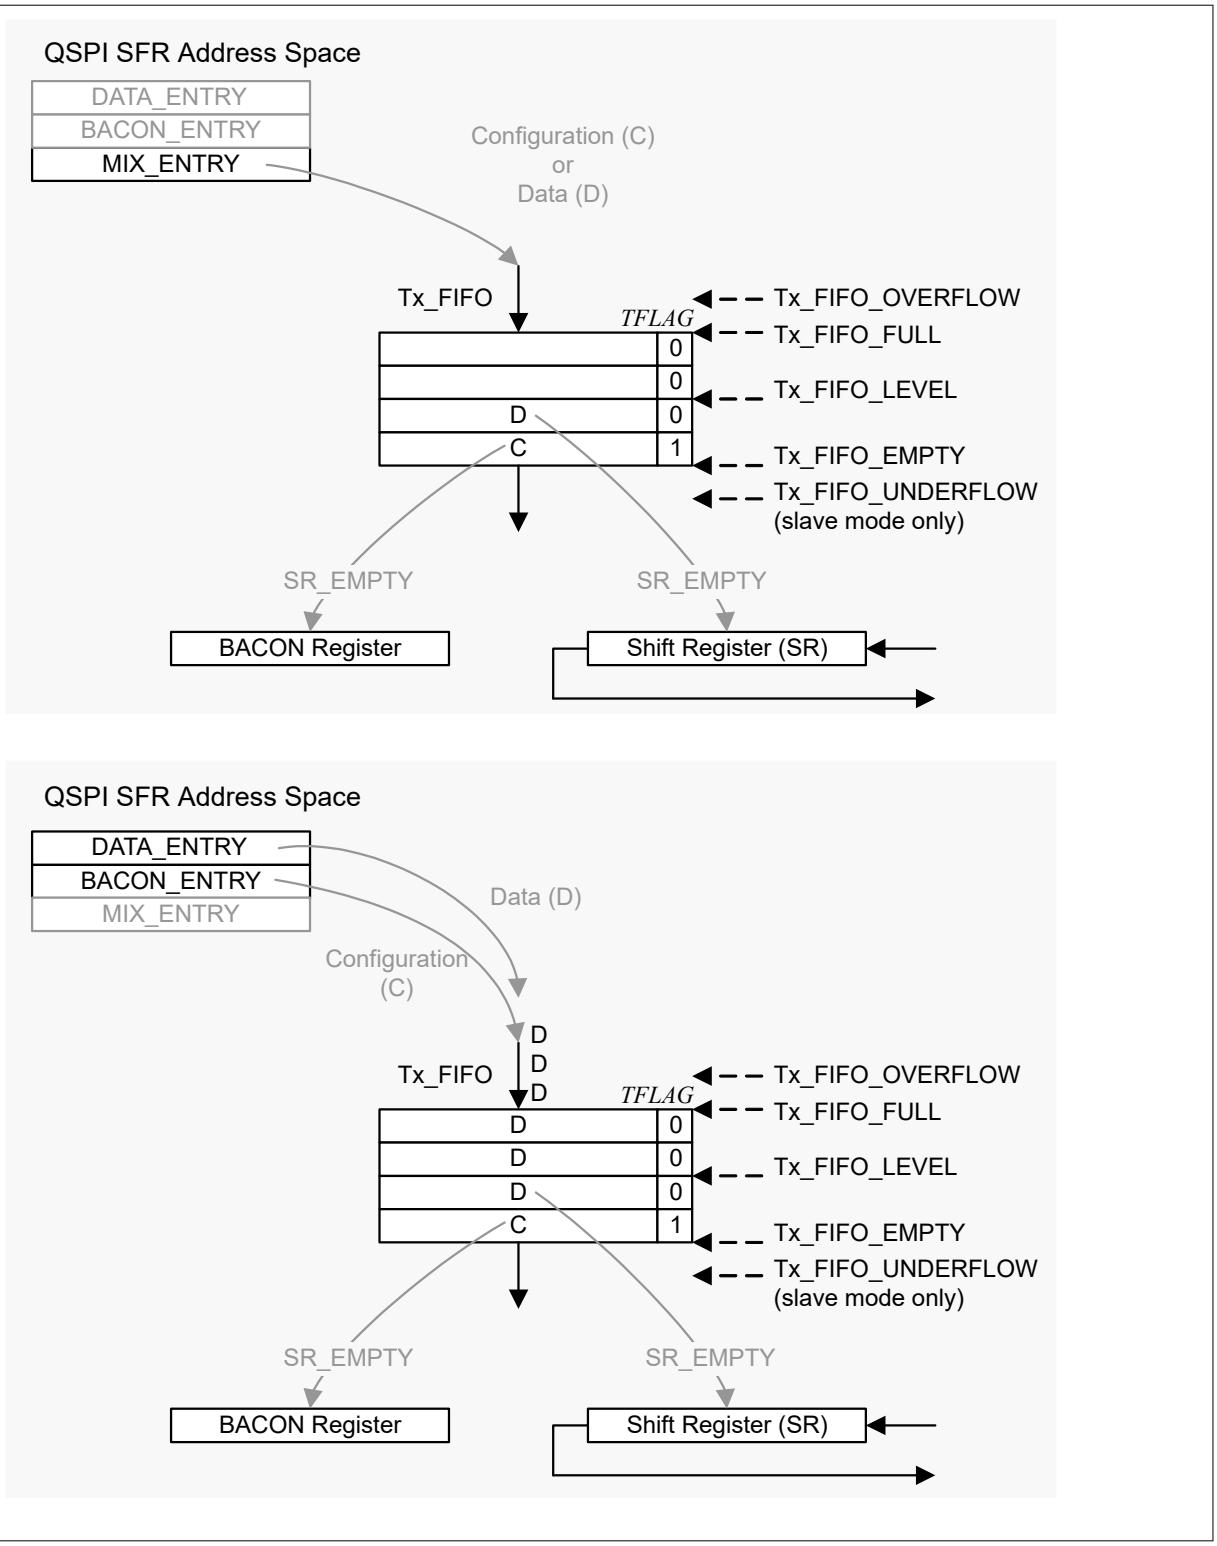

Figure 680 Using Tx FIFO mix and bacon/data entries

30.3.5.1.1 Short data mode

In Short Data Mode, the QSPI module transmits single data with a length of 2 to 32 bits in one frame. This mode is defined by BACON.LAST = 1 and BACON.BYTE = 0.

The transfer cycle is a sequence of the following phases: W?_I_L_D_T. The symbol "?" means that the phase is optional (duration of 0 allowed).

For example, a Tx_FIFO event can be used to trigger one DMA transfer (consisting of two 32-bit moves) to transfer both the BACON and DATA entries from an on-chip RAM memory to the QSPI module.

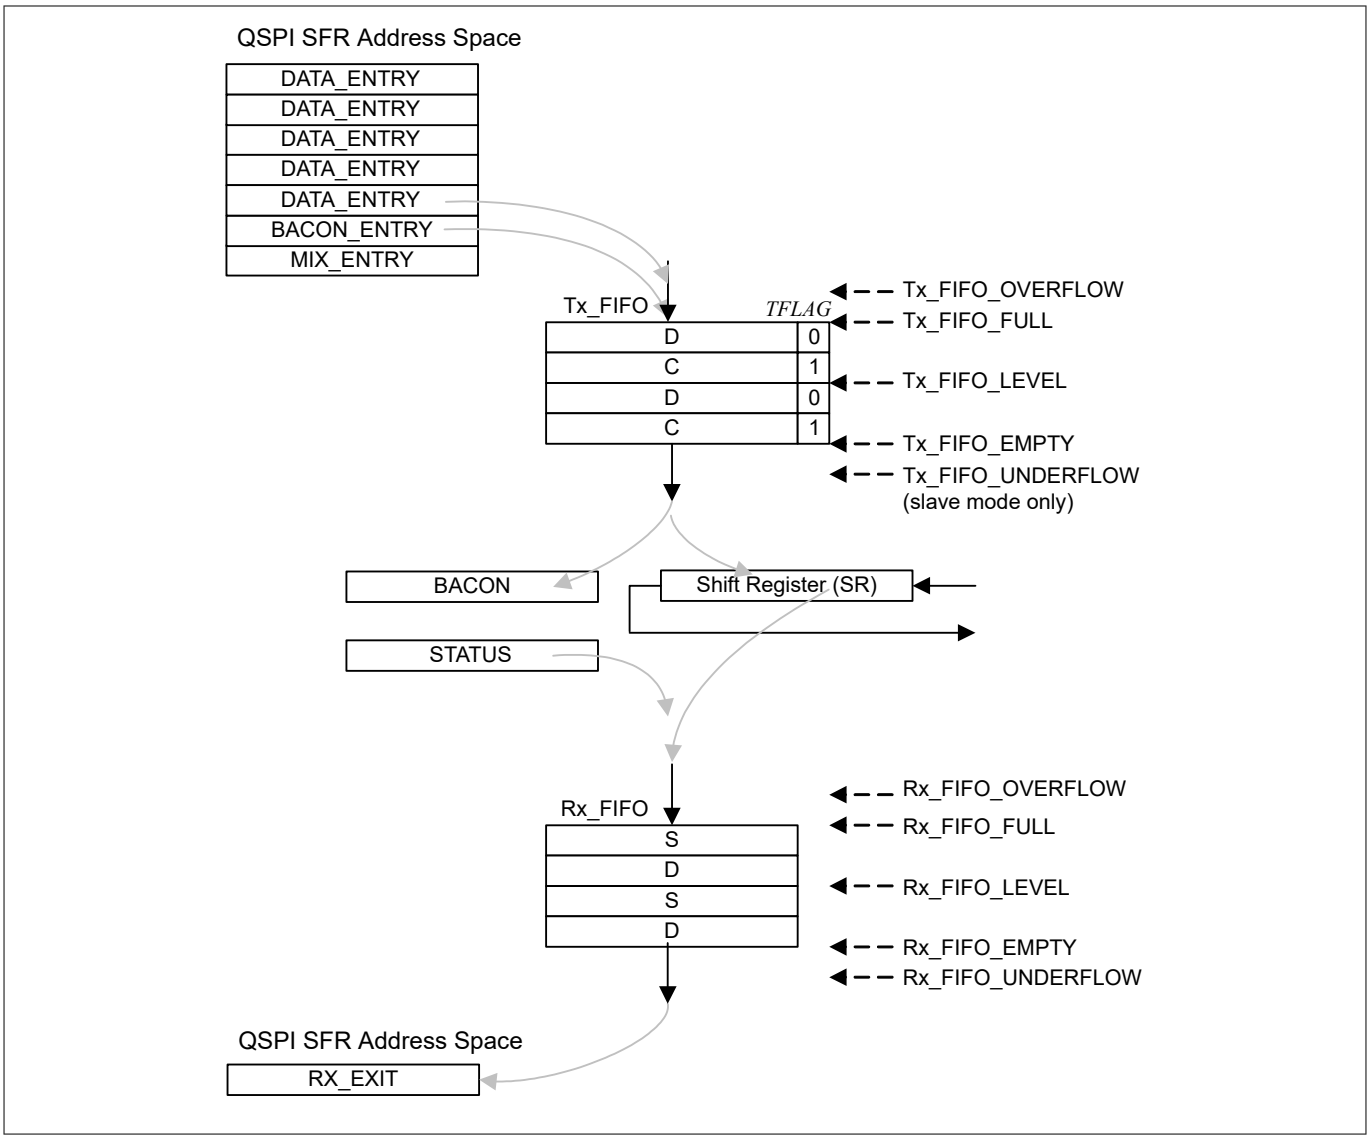

Figure 681 User interface in short data mode

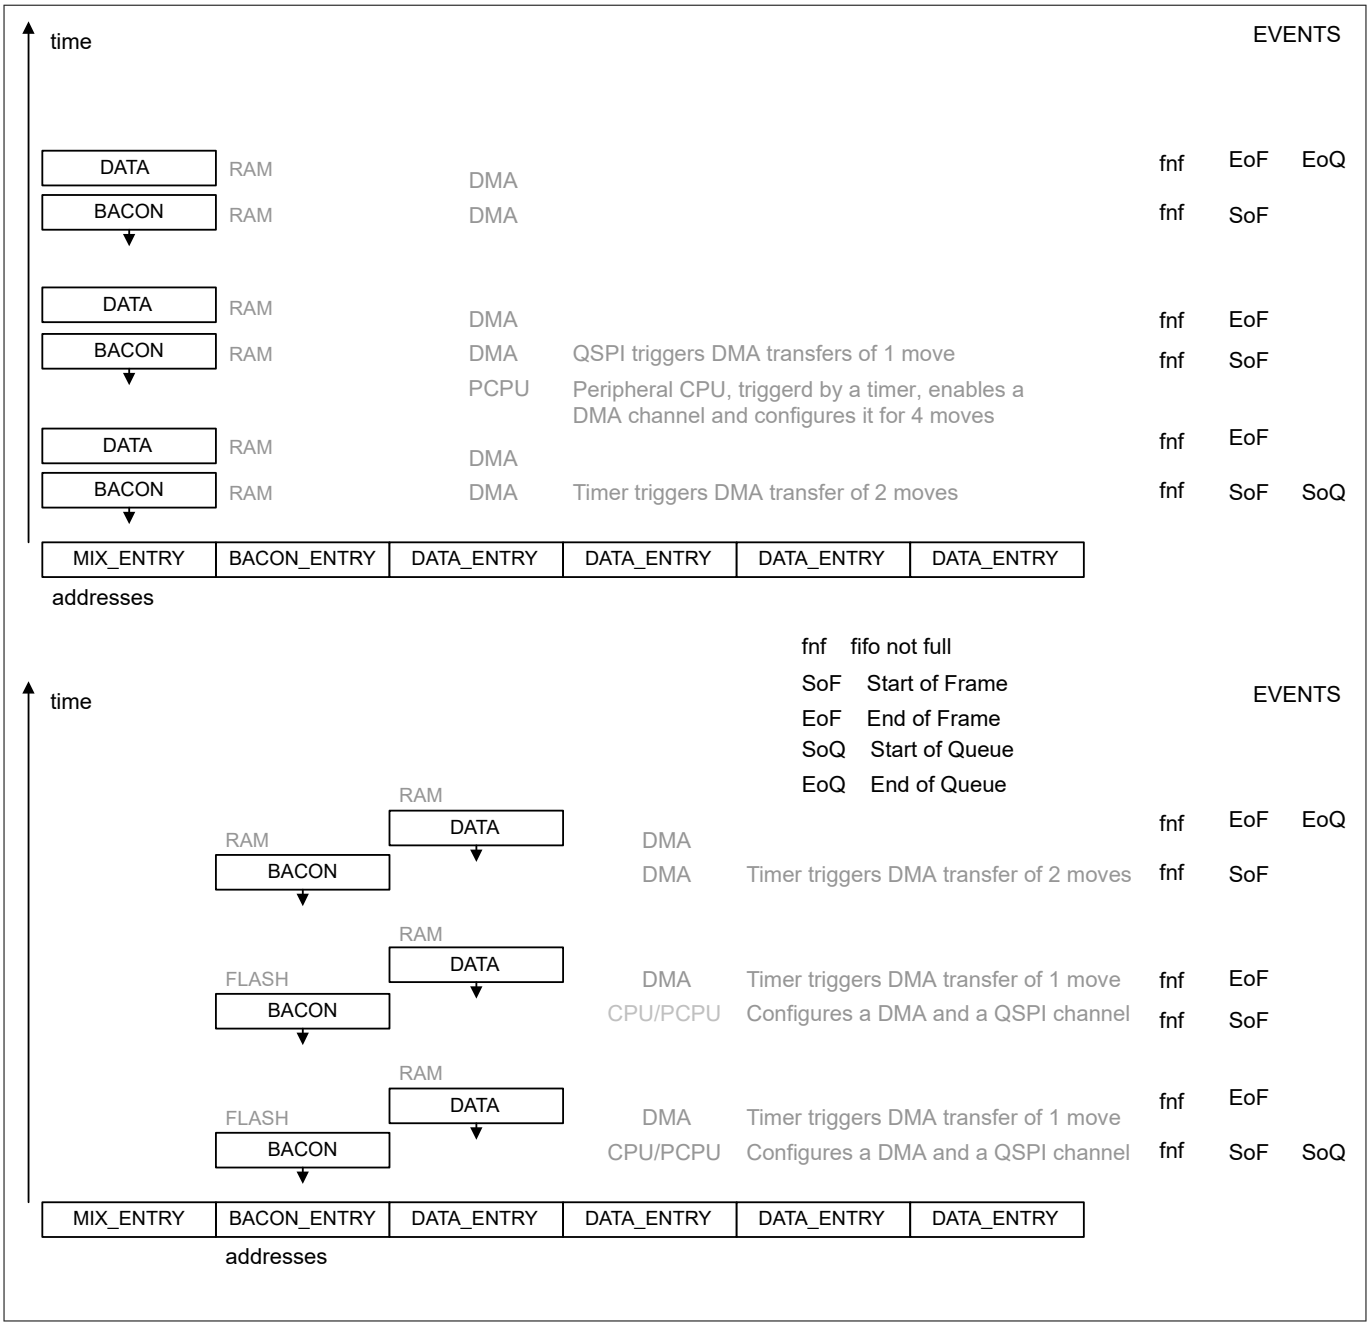

Figure 682 Use diagram of the user interface in short data mode

30.3.5.1.2 Long data mode

In Long Data Mode, the QSPI module transmits bursts of up to 32 bytes (256 bits) in one frame. This mode is defined by programming BACON.LAST = 1 and BACON.BYTE = 1.

One transfer cycle in long data mode is a sequence of the following phases: W?_I_L_D_T. The W_I_L_D_T_I_L_D_T sequence is possible. The symbol "?" indicates that the phase is optional (duration of 0 allowed). Each "D" indicates a data length as defined with BACON.DL and BACON.BYTE, that is, up to 32 bytes. One "D" is made of a number of 32-bit TXFIFO entries "d" and one rest at the end "b", which can be written as D=ddddddb.

The Long Data Mode can be extended by using the XXLCON register.

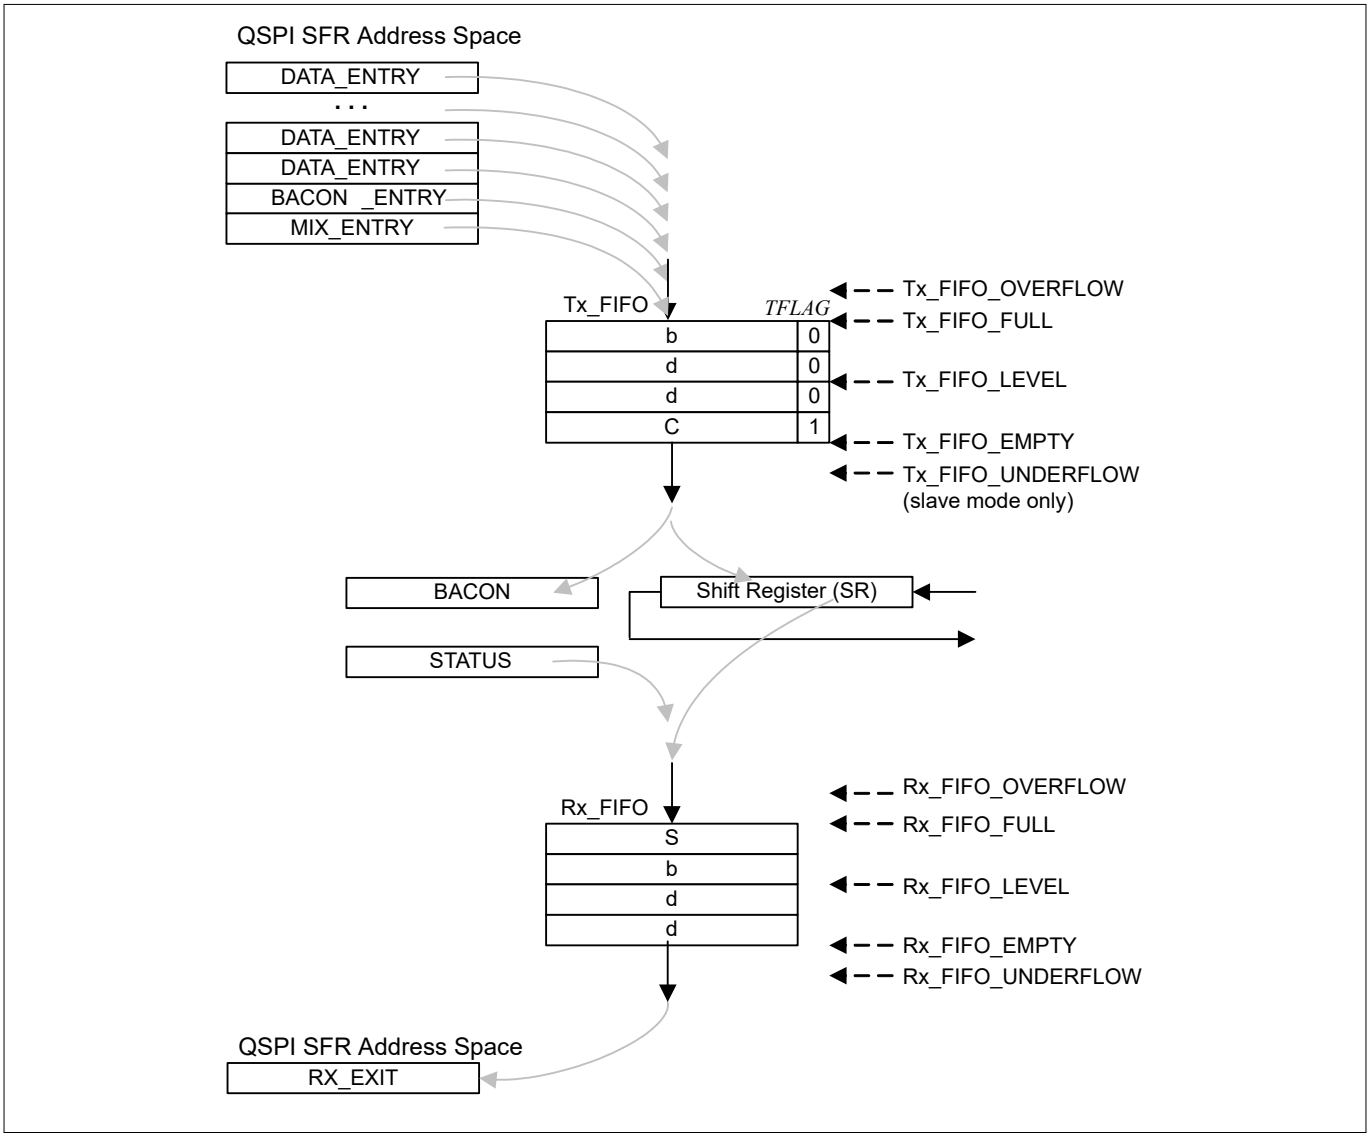

Figure 683 User interface in long data mode

In a DMA transfer example, a Tx_FIFO_EMPTY event can be used to trigger one DMA transfer (consisting of, for example, four 32-bit moves) to transfer the BACON and three DATA entries from RAM memory to the QSPI module. The three data words could contain 80 bits (10 bytes) of data. The three data words could also contain 40 bits (5 bytes), 64 bits (8 bytes) plus one dummy word. In this way short bursts of up to 96 bits can be transmitted.

In such 4 words DMA transfer example, the Tx_FIFO event can be used to transfer two 32-bit words per transfer.

If a configuration word is written when a data word is expected, the configuration word is ignored, and an Unexpected Configuration Error is raised.

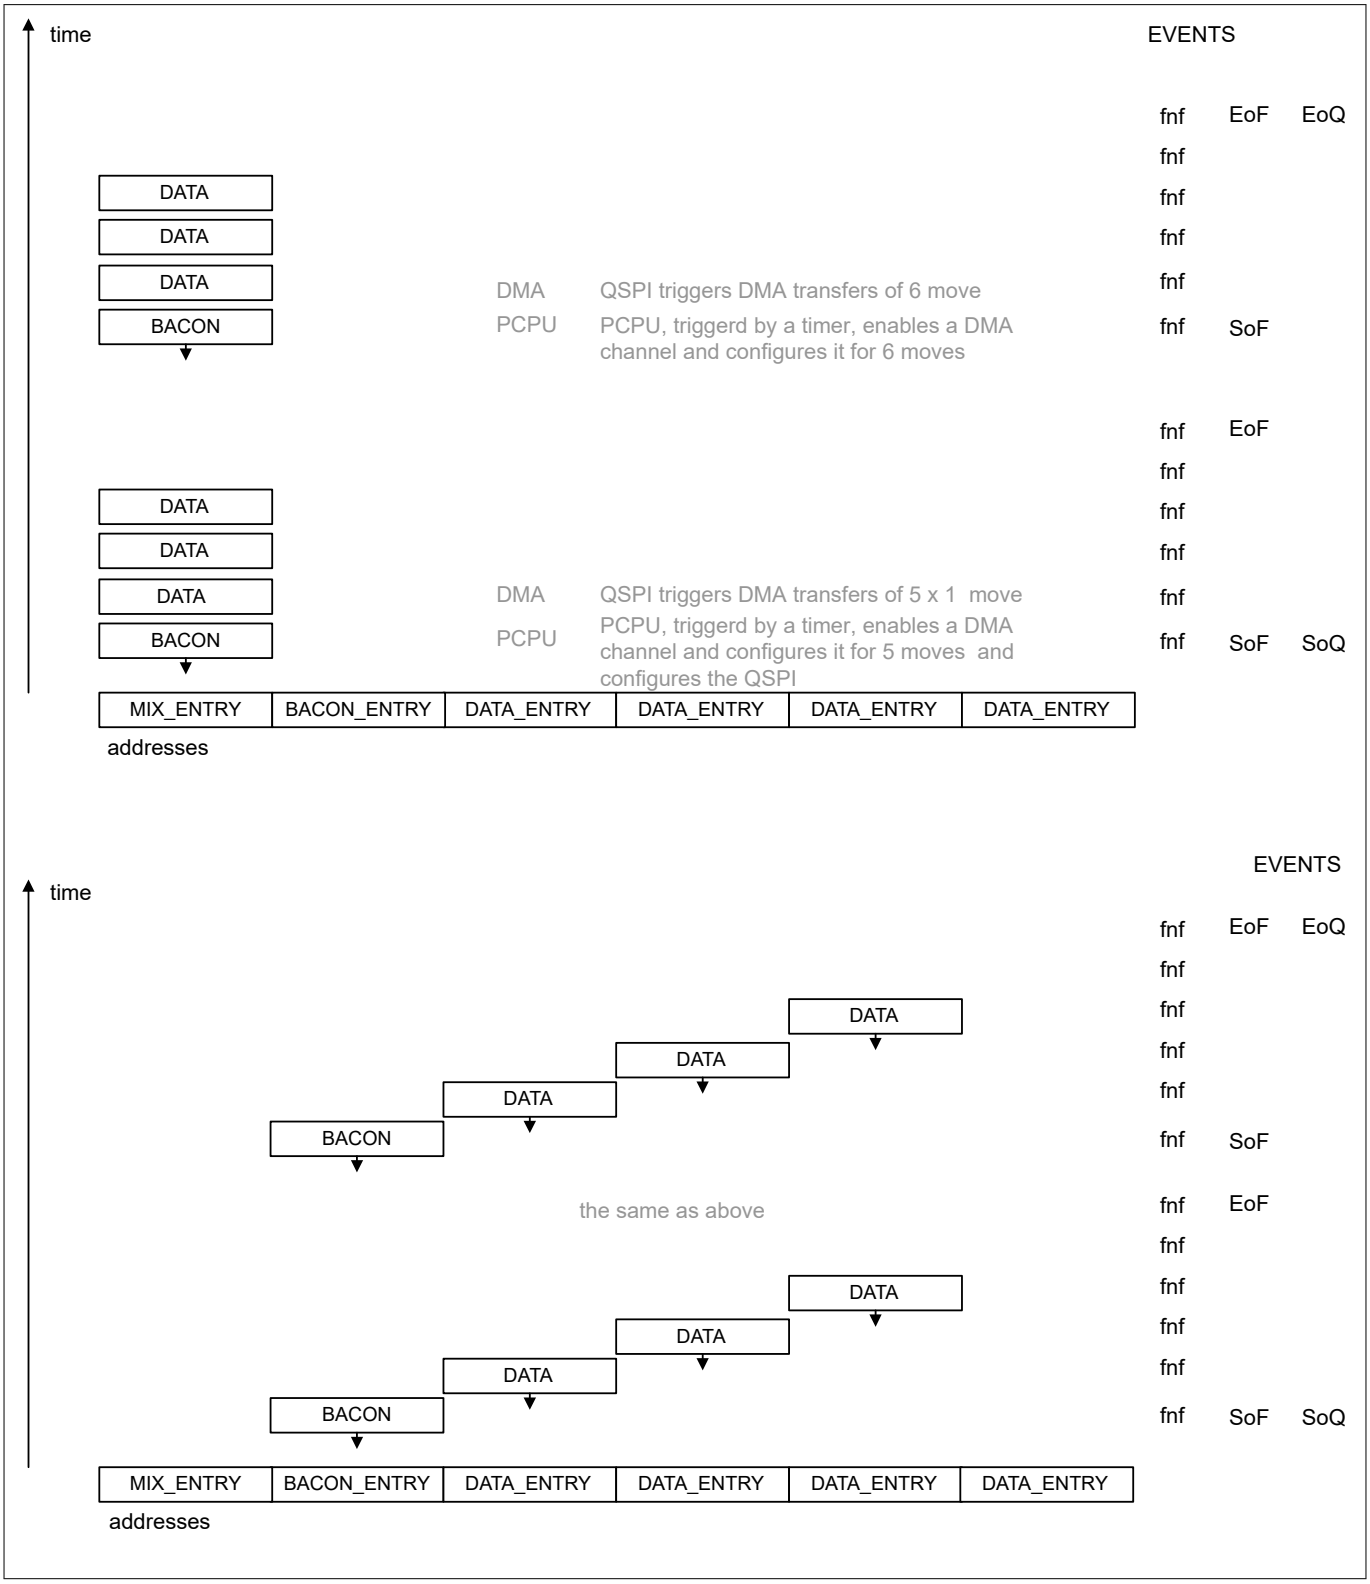

Figure 684 Diagram of the user interface in long data mode

30.3.5.1.3 Move counter mode

The Move Counter (MC) mode enables sending of multiple short frames by extending the short data mode. This mode is enabled when MCCON.MCEN=1 and BACON.BYTE = 0. Two different types are possible:

- BACON.LAST = 0: In this mode, the slave select signal SLSO remains active during the time of MC.MCOUNT write accesses (for example DMA moves) to the TXFIFO are being executed. After the frame has been completed, SLSO is automatically deactivated. After this completion, the software should clear the MCEN if the move counter is not needed anymore
- BACON.LAST = 1: In this mode, the slave select signal SLSO is deactivated after each frame transfer until all the MC.MCOUNT frames have been transmitted

The move counter is a down-counter that triggers an interrupt (if enabled):

- After the move before last has been shifted out
- After the last move has been shifted out

The range of counting is 65535 to 1. The bit field MC.CURRENT shows the currently transmitted frame, the last one being 1. The update of the MC.CURRENT bit field takes place with a couple of cycles delay due to the asynchronous frequency domain of the shift engine. The decrementing is done after shifting the last bit of each data. MC.CURRENT= 0 means no data pending, the complete data of the frame has been shifted out.

The enable, flag, set and clear bits for the Interrupt Before Last (IBL) and Interrupt After Last (IAL) are defined in MCCON register. The interrupt signals are mapped to the User Interrupt line, but have separate enable bits in the MCCON register and do not depend on BACON.UINT. Therefore on user interrupt in MC mode, the software must also check the MCCON.IALF and IBLF flags. All other standard QSPI phase interrupts are triggered as usual. If the data is not fed to the TXFIFO in time, EXPECT phase is activated.

An example sequence of using MC mode is: CPU writes the configuration for the frame once at the start in the BACON_ENTRY address, afterwards DMA writes DATA in DATA_ENTRY. MIX_ENTRY shall not be used. The TXFIFO interrupts trigger the DMA, which itself counts the moves in parallel to the MC register.

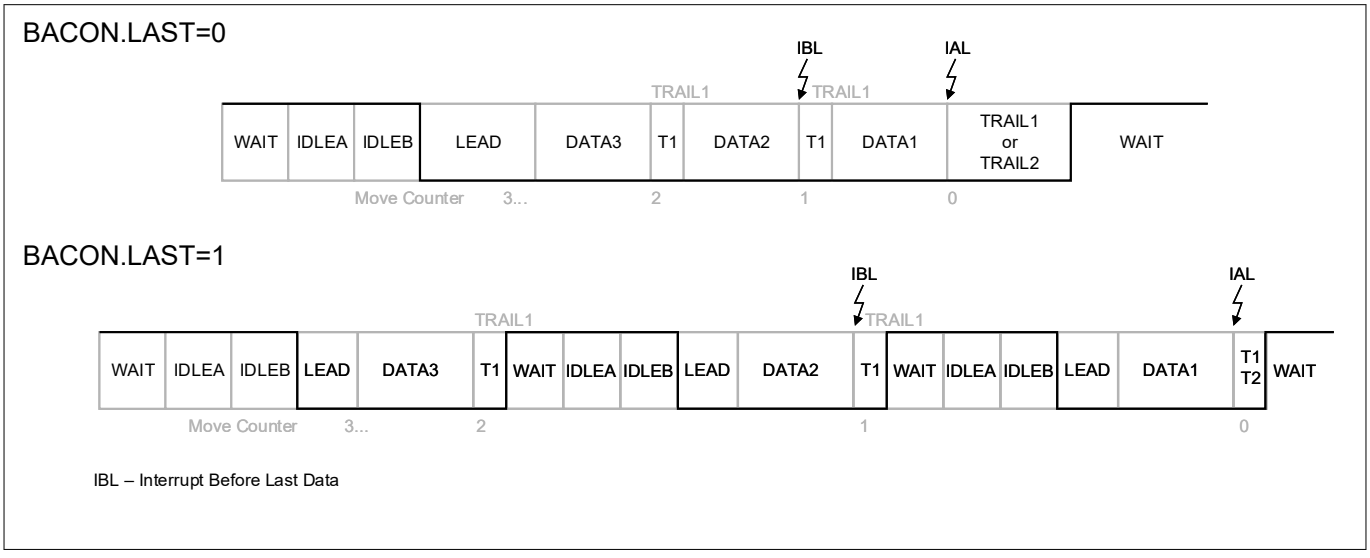

Figure 685 Frame sequence of phases in short move counter continuous mode

Another usage example of using MC mode is daisy-chaining: Here the CPU writes the number of frames for all slaves to the MC register. Afterwards it writes the configuration for the frame of the first slave (BACON3 in the figure) in the BACON_ENTRY address, afterwards DMA writes the data for the first slave (DATA3_2 and DATA3_1) in DATA_ENTRY. MIX_ENTRY shall not be used. The TXFIFO interrupts trigger the DMA, which until all data for the first slave has been written. Then the configuration of the second slave (BACON2) needs to be written to BACON_ENTRY, followed by its data (DATA2_3, DATA2_2 and DATA2_1). This process may be repeated until the whole daisy-chain is filled (in the figure this is an additional BACON1 and DATA1_1). The different BACONs may only vary in the BACON.DL and (or) BACON.MSB setting.

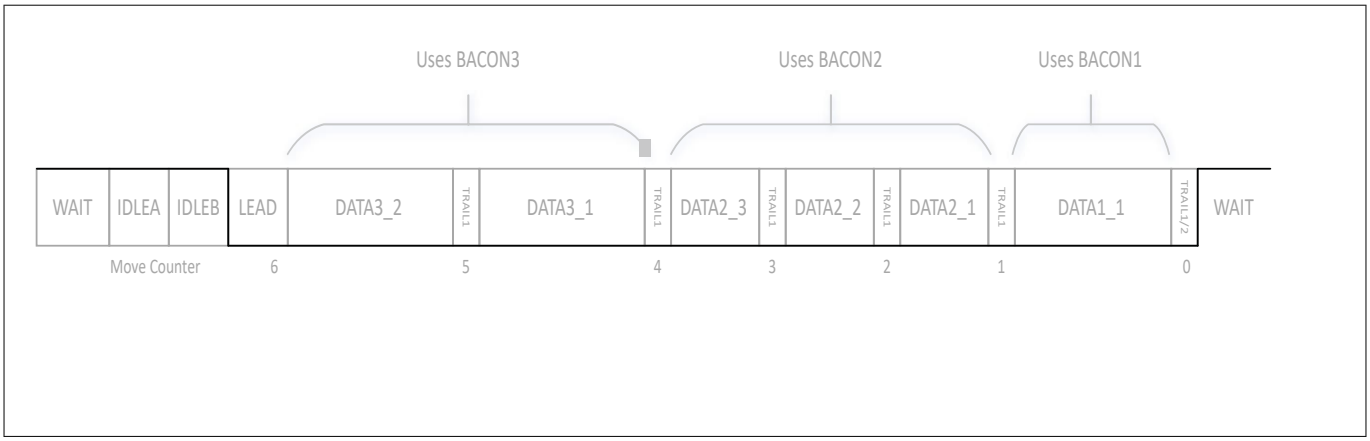

Figure 686 Frame sequence of phases in move counter implementing daisy-chaining

It is possible to combine Continuous Long Mode with Move Counter Mode so that a frame starts with one or more Continuous Long Mode transmissions and ends with one Move Counter Mode transmission.

30.3.5.1.4 Continuous data mode

In Continuous Data Mode, the QSPI transmits a stream of data with an arbitrary length and an active slave select signal. It can be used with both short and long data.

This mode starts by programming a control word containing BACON.LAST = 0 and the first data. The communication continues with the subsequent data entries written. The mode ends with a control word containing BACON.LAST = 1 and the last data. If LAST = 0, then TRAIL is a delay between data blocks. The W_I_L_D_T_D_T_D_T sequence appears. Each “D” represents data block as defined with BACON.DL and BACON.BYTE (up to 256 bits). If LAST = 1 then TRAIL is trailing delay, see related information.

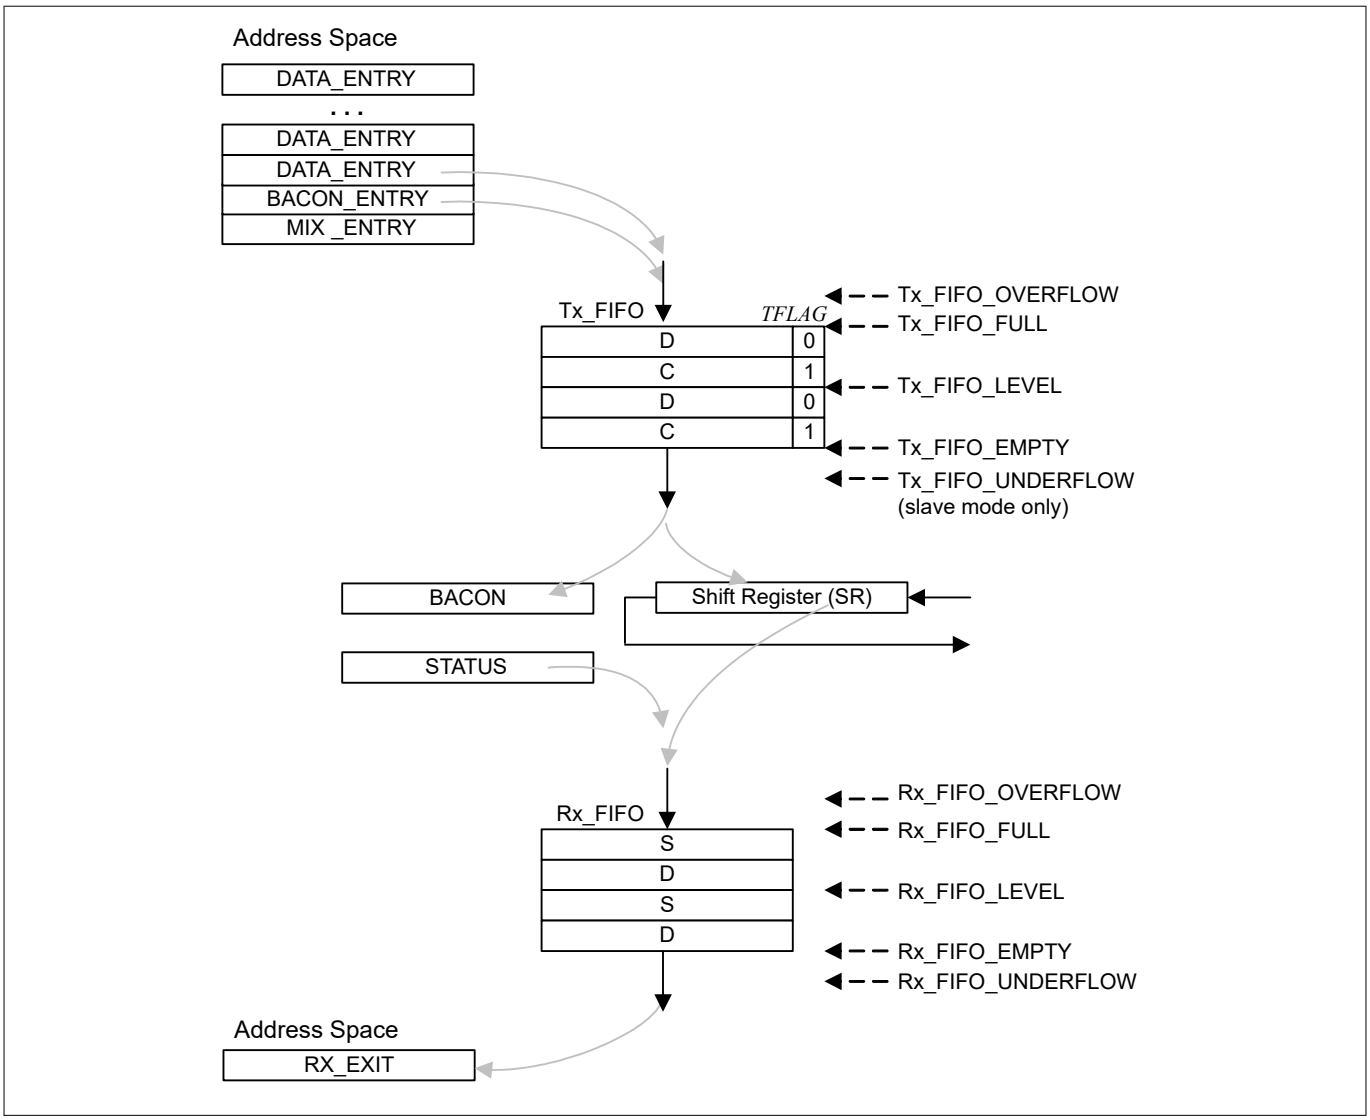

Figure 687 User interface in continuous data mode

The following figure shows an example of continuous data mode using short data. Here, the CPU starts the stream by writing BACON to the BACON_ENTRY address, and afterwards a DMA transfers the whole stream except the last BACON and DATA.

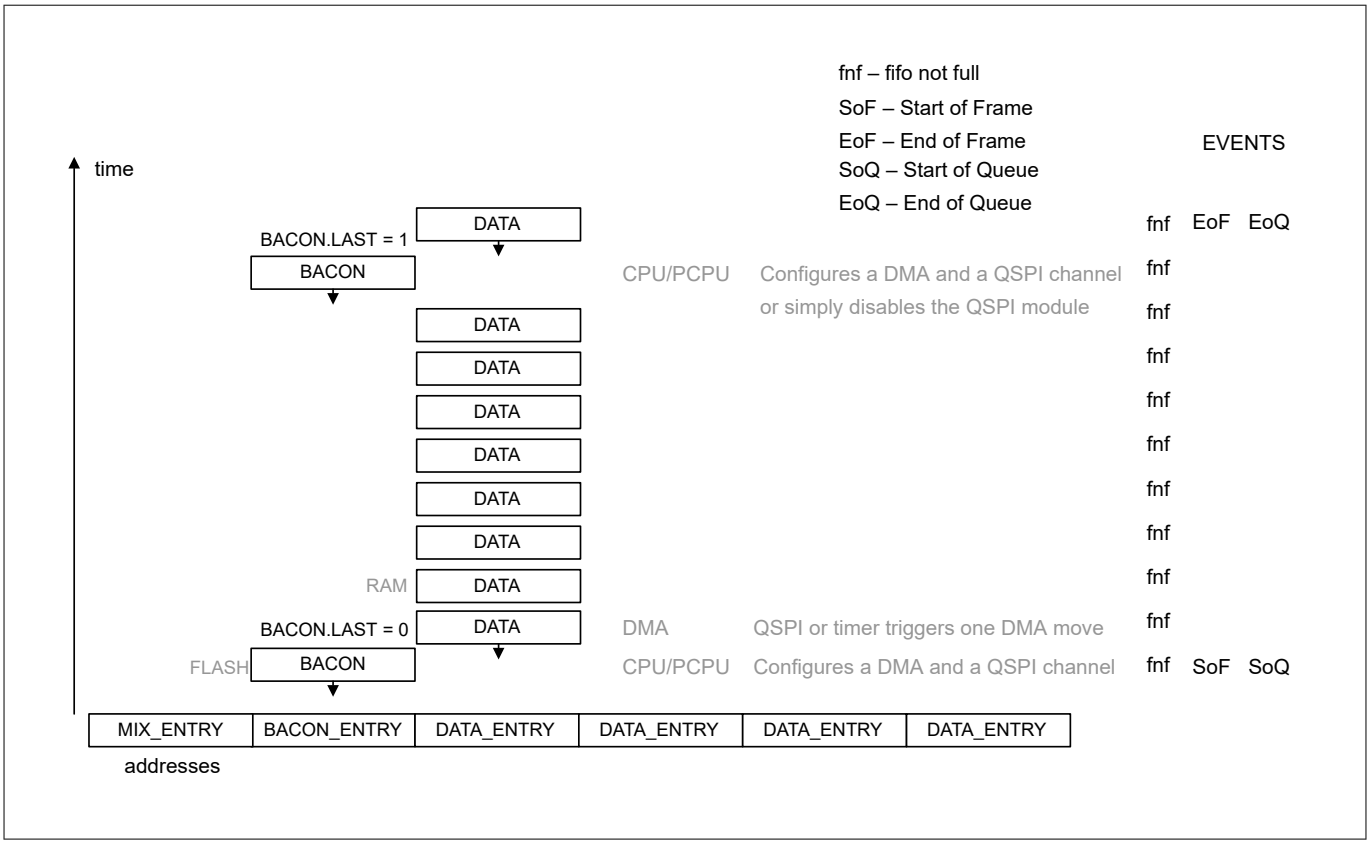

Figure 688 Use diagram of continuous data mode with short data

The following figure shows an example of continuous data mode using long data. Here, the first BACON must be repeated after each data block, but on the other hand, the whole transfer can be done using only the MIX entry and one single DMA channel, without CPU involvement. The loss of efficiency because of the unnecessary extra BACONs can be minimized by using long data blocks.

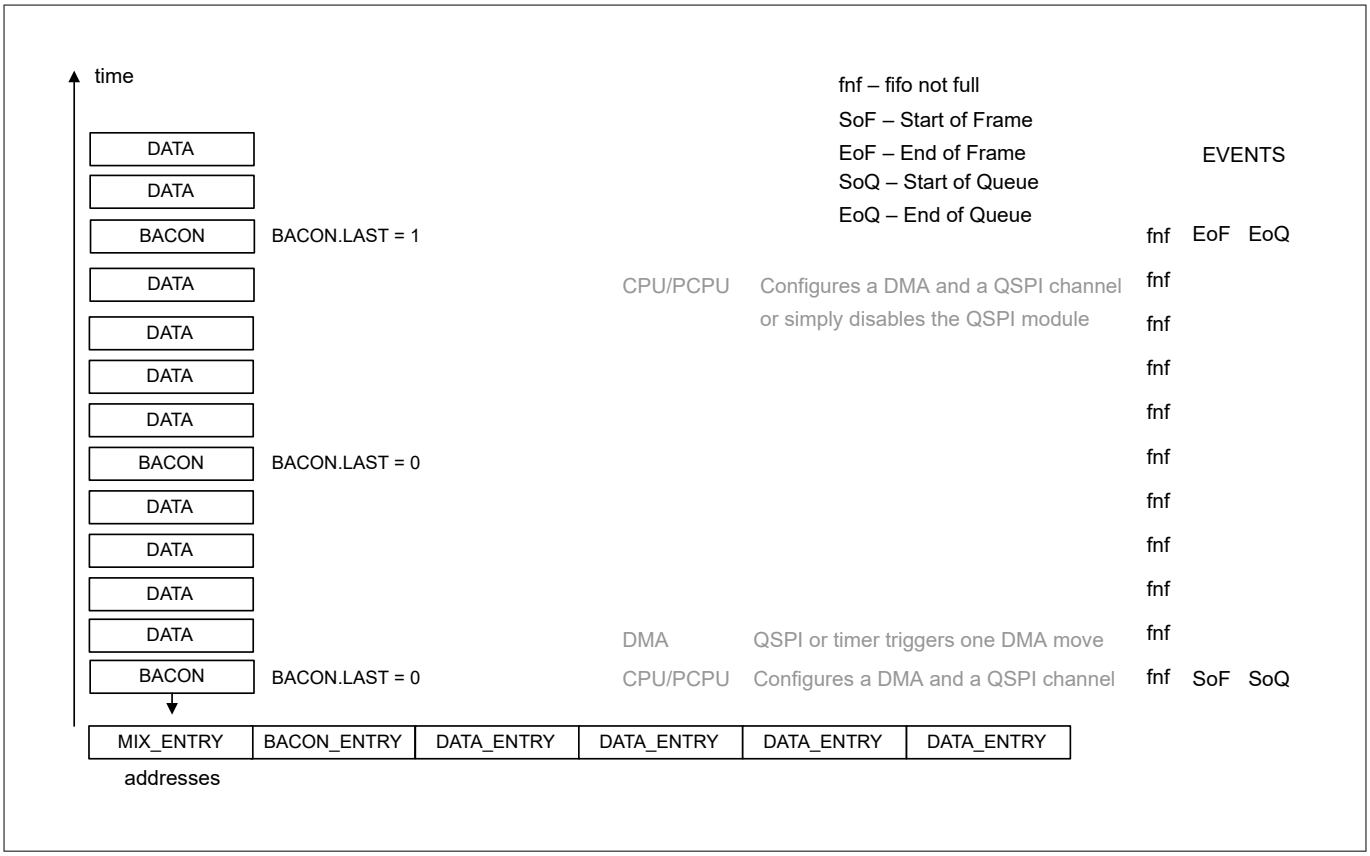

Figure 689 Use diagram of continuous cata mode with long data

30.3.5.1.5 Single configuration - multiple frames behavior

If longer sequences of data with length of up to 16-bit have to be sent to single slave in separate frames, then the DMA move for the repeating configuration word can be saved. An example of a TxFIFO contents and the resulting message sequence is shown in the following figure.

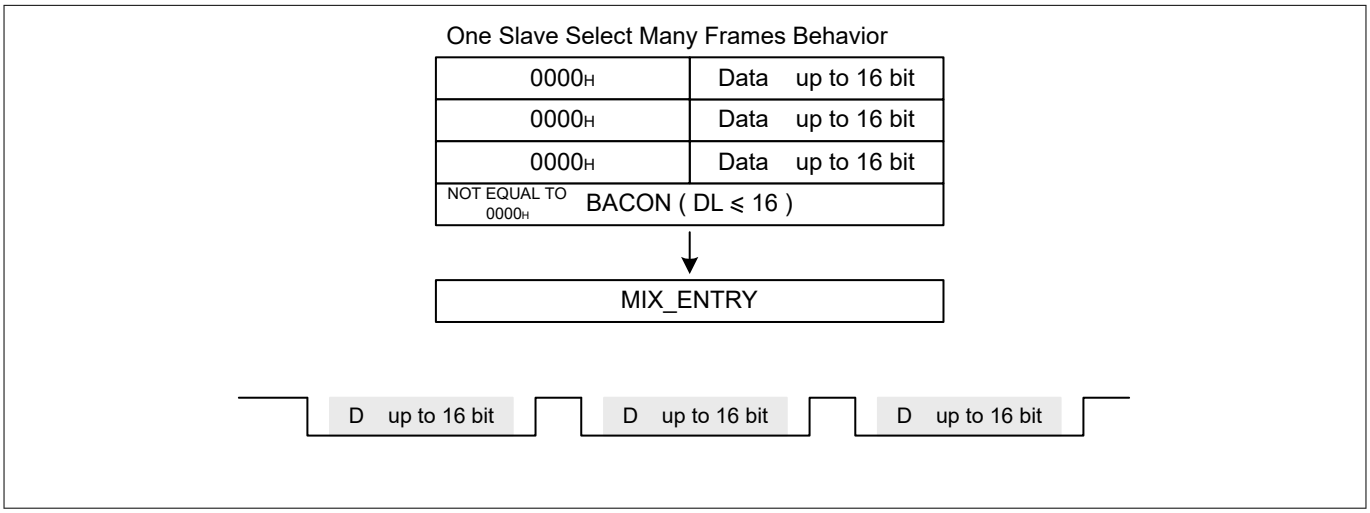

Figure 690 Multiple frames to one channel (example of up to 16-bit data)

In order to support sending short multiple frames to single channel without having to send the same configuration each time, the TXFIFO follows this rule:

- If BACON.DL is less or equal 15 (up to 16-bit data length)
- If MIX_ENTRY address is used
- Then if the upper 16-bit of a 32-bit MIX_ENTRY are 0, the entry is considered data, else configuration

  ***Note**: There is no valid configuration word with upper 16 bits equal to 0.*

- In this case, the TXFIFO marks the entry as data

***Note**: In case the BACON.LAST = 0, the slave select remains active between the frames. The behavior is equal to the continuous mode. The disadvantage of this method is that only up to 16 bits data can be transferred with one FPI bus move. The advantage is that continuous mode is possible using the mix entry.*

30.3.5.1.6 Big endian data format

The bit-field ECONz (z=0-7).BE activates the permutation of the data bytes written to the shift register and read from it to the big endian format and back.

ECONz (z=0-7).BE allows for switching between big and little endian per slave (SLSO signal).

See following figures.

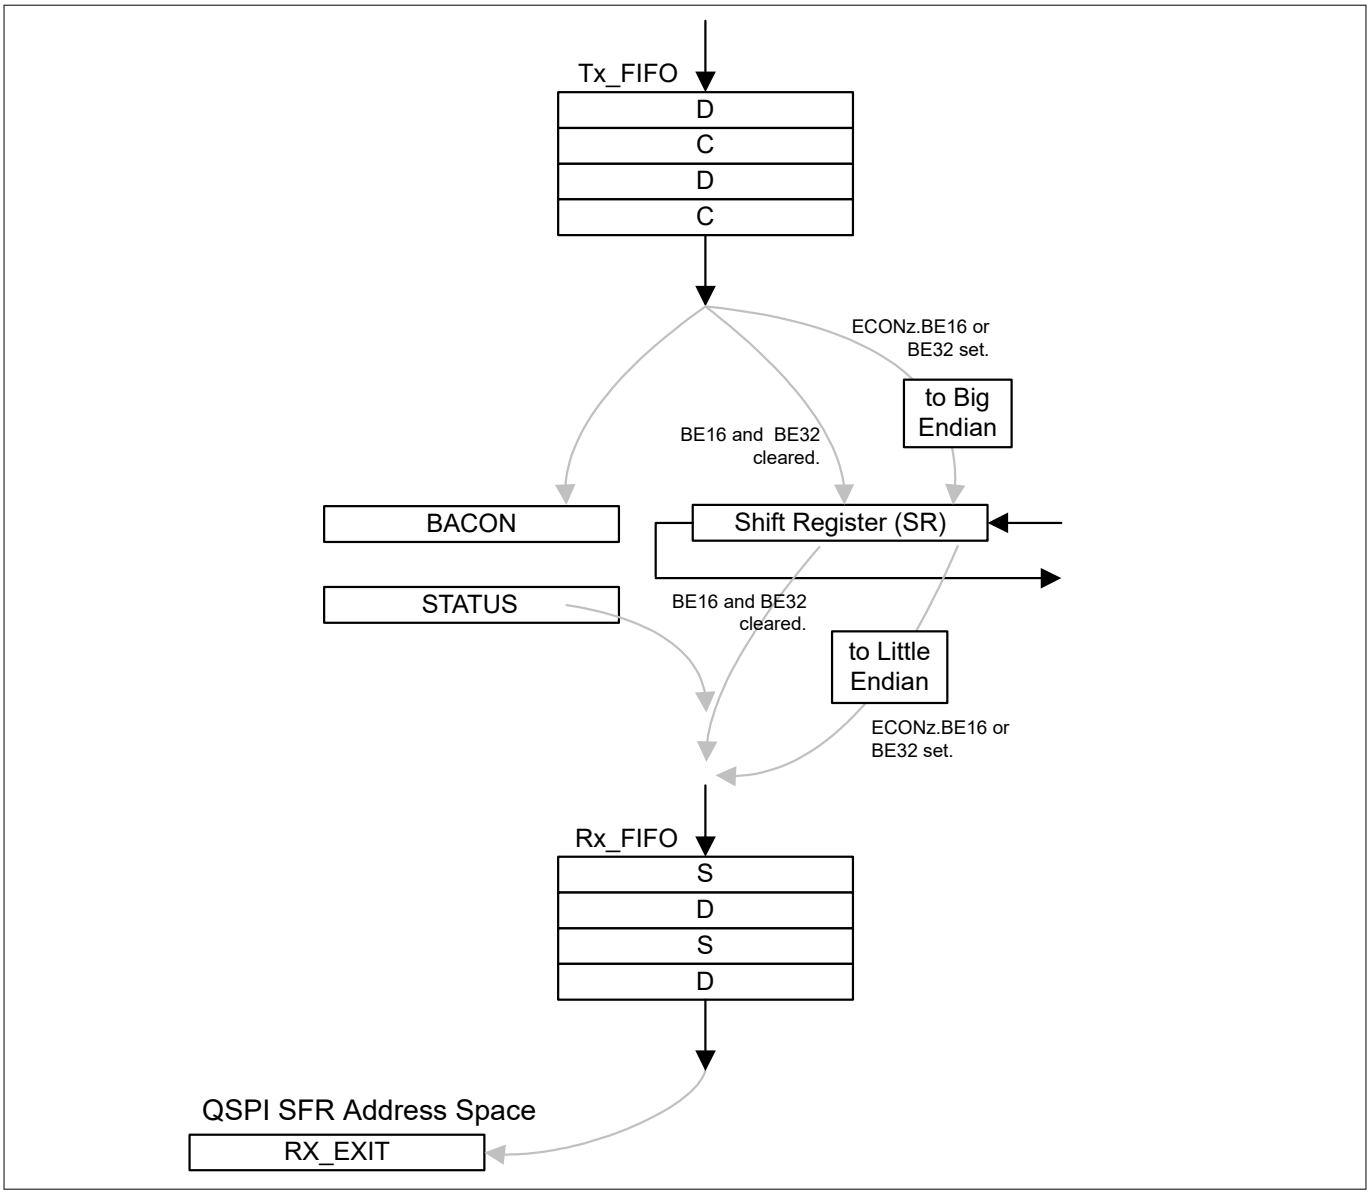

Figure 691 Big endian data path

Converting data from little to big endian and other way around requires one and the same permutation of the data bytes, as shown in the figure above, one permutation block is located before and one after the shift register, so that only data can be permutated, and not BACON or STATUS.

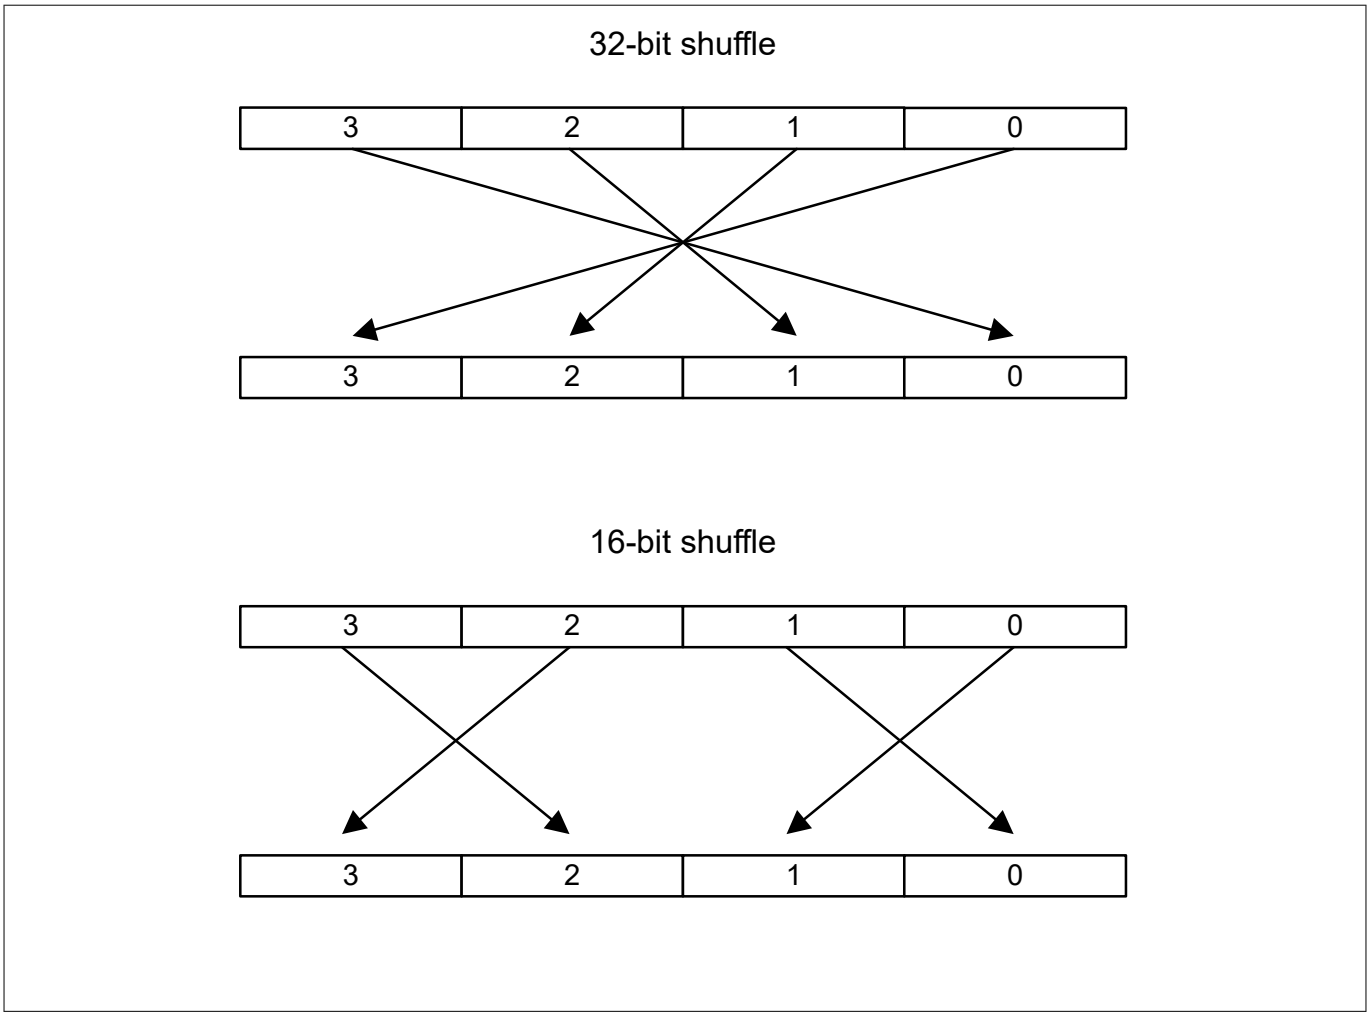

Figure 692 Endianness byte permutation

The endianness byte permutation should be used only for 16-bit and 32-bit data (and multiples of it), and not for other data lengths.

30.3.5.2 Loop-back mode

Loop-Back mode is a master mode test feature used for establishing a module internal connection between the transmit and the receive signal, the same as if the transmit and receive pins would be short connected. It is activated by setting the GLOBALCON.LB bit.

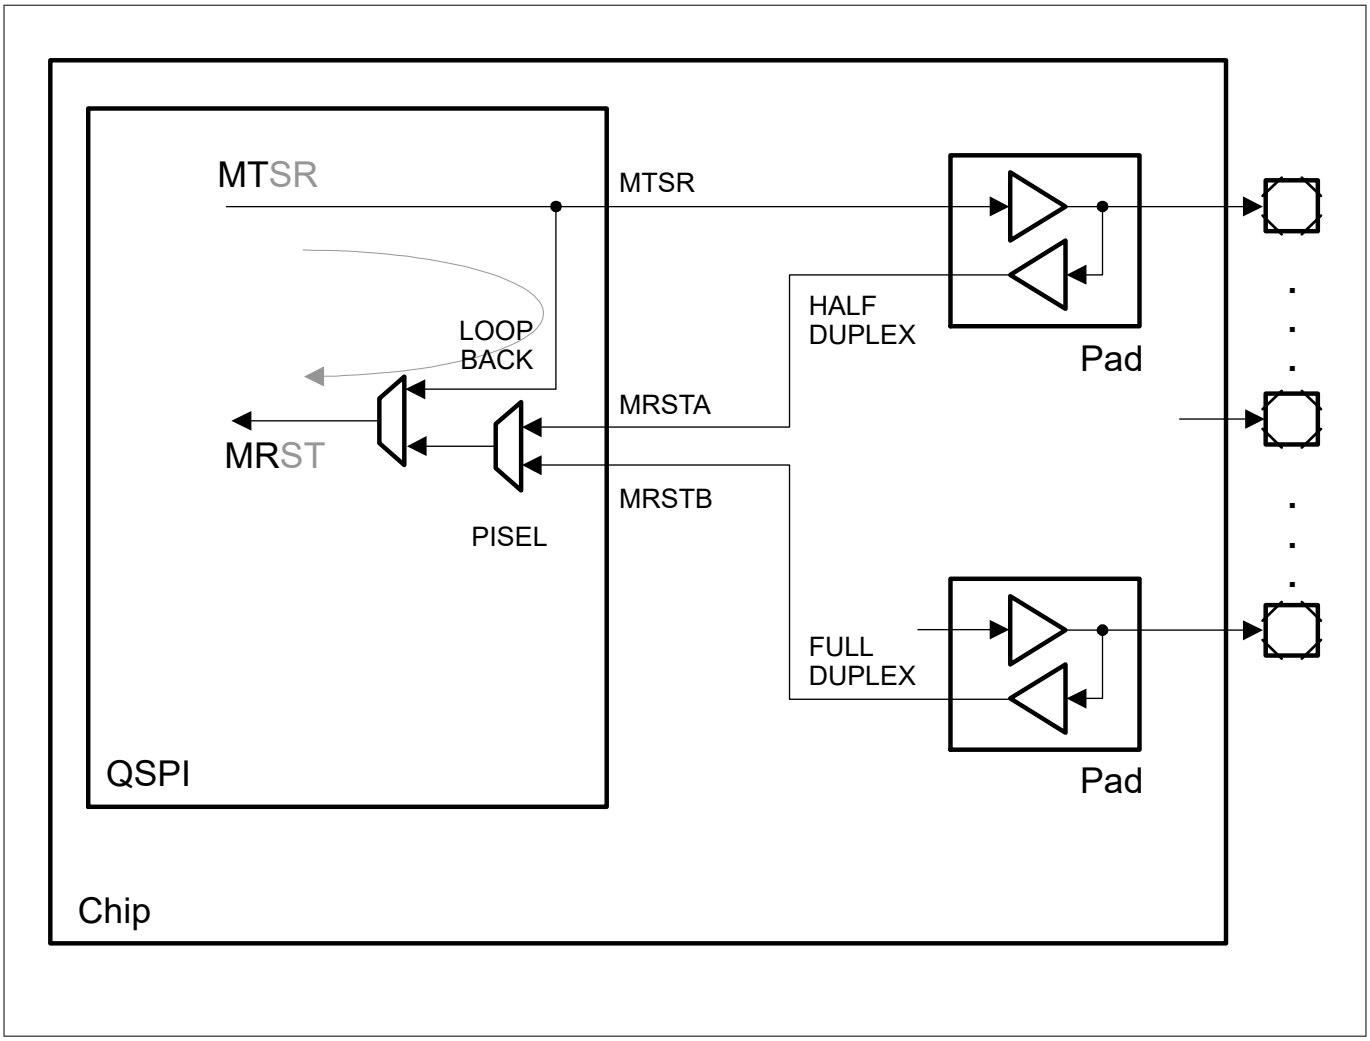

Figure 693 Loop-back mode

30.3.6 Interrupts

There are several types of interrupts:

- Interrupts related to the user interface
- FIFO related interrupts
- Interrupts related to the shift engine (state machine)
  - Error interrupts
  - Phase transition interrupts

According to this classification, here follows the complete list of all the interrupts:

- FIFO related interrupts
  - TX Transmit FIFO Interrupt, requests feeding of the TXFIFO, but does not signal the error events of overflow and underflow (see figure Architecture of the Tx and Rx FIFOs, related information)
  - RX Receive FIFO Interrupt, requests emptying of the RxFIFO, but does not signal the error events of overflow and underflow (see figure Architecture of the Tx and Rx FIFOs, related information)
- ERR Error Interrupt
  - Signals every error condition (see GLOBALCON1.ERRORENS)
  - Signals TX_FIFO_OVERFLOW, TX_FIFO_UNDERFLOW
  - Signals RX_FIFO_OVERFLOW, RX_FIFO_UNDERFLOW
- PT Phase transition interrupt, signaling two out of all phase transitions in the QSPI communication cycle (see figures Standard Communication Cycle of the State Machine (Short Data) and EXPECT Cycles of the QSPI State Machine, related information)
  - PT1 event
  - PT2 event
- U User Interrupt
  - Triggered by the PT1 event during the time BACON.UINT bit keeps this event enabled
- MC Move Counter Mode Interrupts
  - Interrupt before last-triggered when move counter was decremented to 1
  - Interrupt after last-triggered when move counter was decremented to 0

The Transmit event (TX_INT) and Receive event (RX_INT) are also connected to GST, if present in device, for time capture purpose.

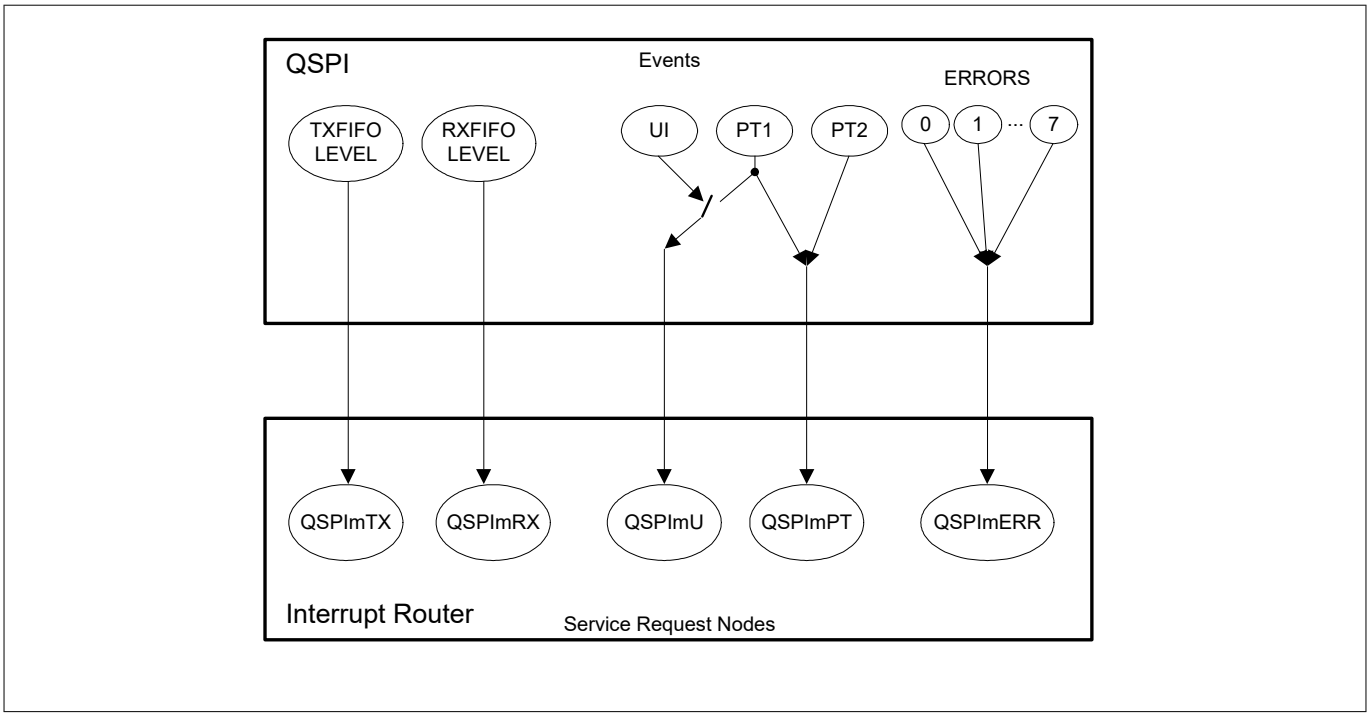

Figure 694 Events and interrupts overview

Related information

State diagram of standard communication cycle on page 5314
Expect phase on page 5317

30.3.6.1 Slave mode SLSI interrupt

In slave mode, deactivating the SLSI signal (SLSI rising edge) triggers the PT interrupt, if PT2 enabled.

30.3.6.2 Interrupt flags behavior

A state of an event flag (low or high) does not influence the flow of its event signal. If an event occurs recurrently, and the event flag remains set (if not cleared by the software interrupt handler), then in that case the interrupt flag (which is cleared by hardware, by an interrupt control unit (ICU), when the interrupt wins an arbitration round) would receive recurrent triggers, and the interrupt flag would be constantly set all the time.

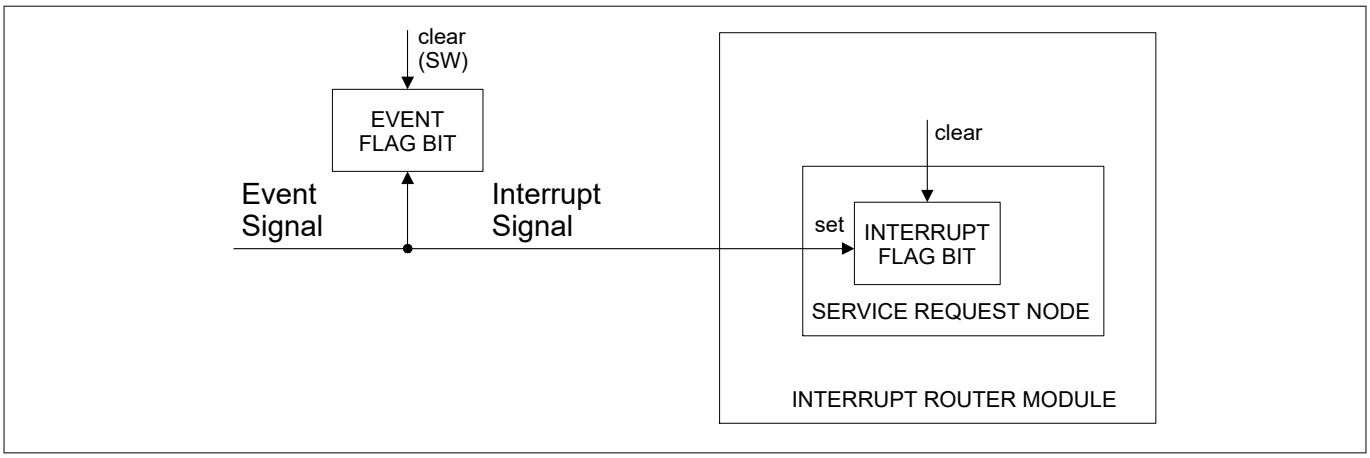

Figure 695 Events and interrupts overview

30.3.6.3 TXFIFO interrupt generation

The TXFIFO provides four interrupt generation modes, selected by the bit-field GLOBALCON1.TXFM:

- Single Move Mode
- Batch Move Mode-1
- Batch Move Mode-2
- Combined Mode

The RXFIFO and the TXFIFO can use the interrupt generation modes independently of each other.

Single move mode

The purpose of the Single Move Mode is to keep the TXFIFO as full as possible, refilling the TXFIFO by writing to it as soon as there is a free element.

An example use case could be using single move mode with a DMA performing single move per TXFIFO interrupt. In this mode the DMA keeps the TXFIFO full. A DMA request is triggered each time a write to the TXFIFO is performed, and there is at least one empty element available. If the write makes the TXFIFO full (no more empty elements), an interrupt is not generated in order to prevent overflow. It is generated later when the shift register (or BACON) reads one element from the TXFIFO, making it not full.

The following figure shows the filling levels of the TXFIFO, and the events associated with each filling level triggering a TXFIFO refill interrupt.

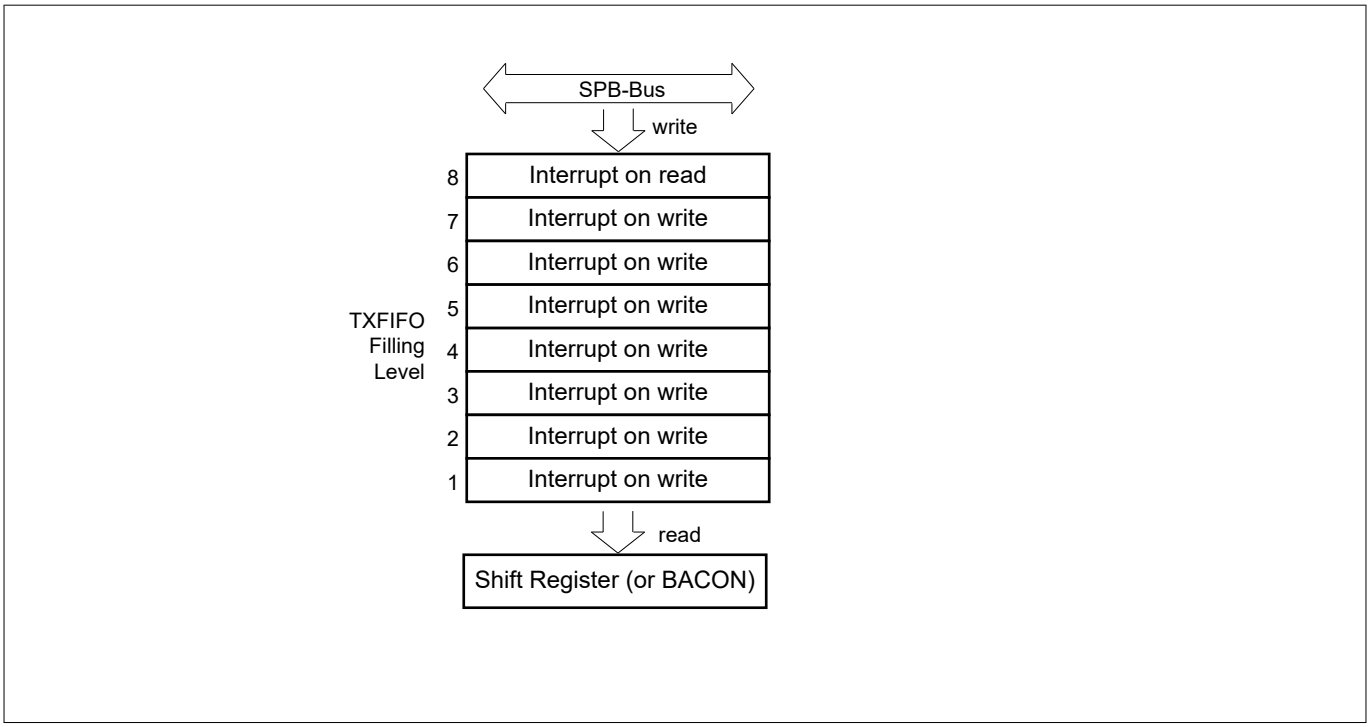

Figure 696 Interrupt generation in the single move mode

In order to initiate the very first chain of the refill interrupts after power-on reset, it is necessary that the software either performs one write to the TXFIFO, or sets the interrupt flag in the TXFIFO interrupt node. Afterwards, the (DMA) interrupt-chain is self sustaining until the whole transaction is over.

Attention**: **In Single Move Mode multiple software writes or block DMA moves would lead to multiple interrupts and (false) transaction lost events. Therefore they should be avoided - only single moves should be used.

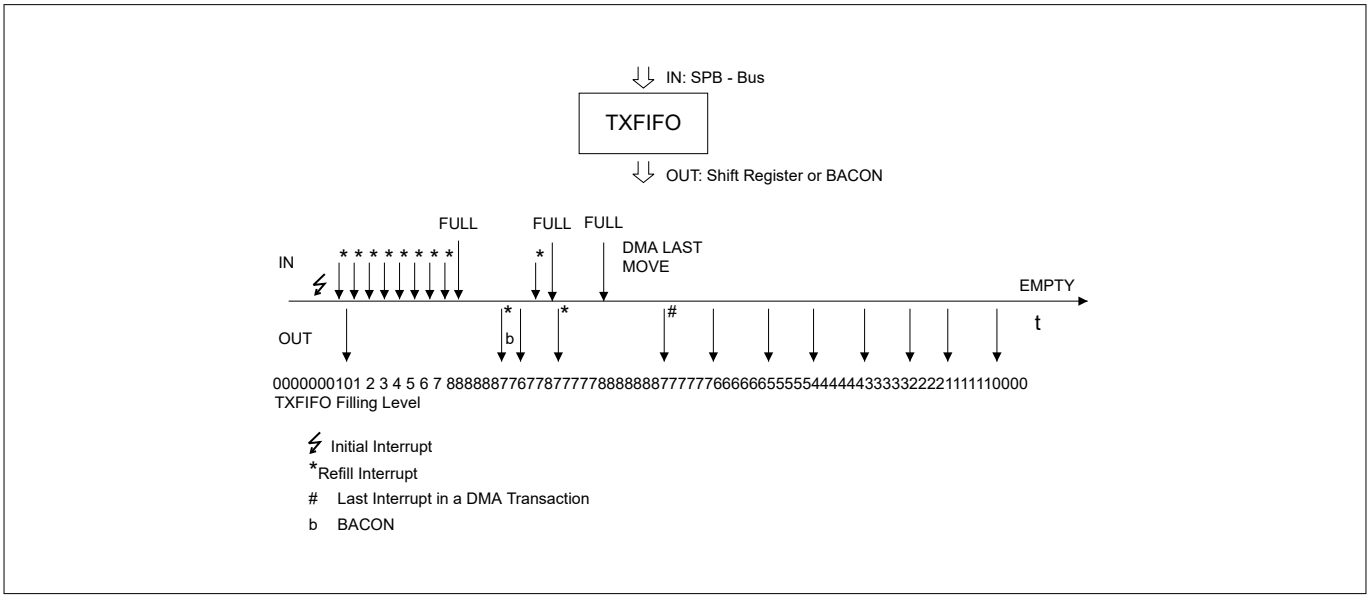

Figure 697 TXFIFO - interrupt operation in single move mode

Batch move mode-1

The purpose of this mode is to reduce the number of interrupts by triggering an interrupt when more than one TXFIFO element is empty. For example, a CPU can be interrupted less frequently and it can perform more than one moves per interrupt.

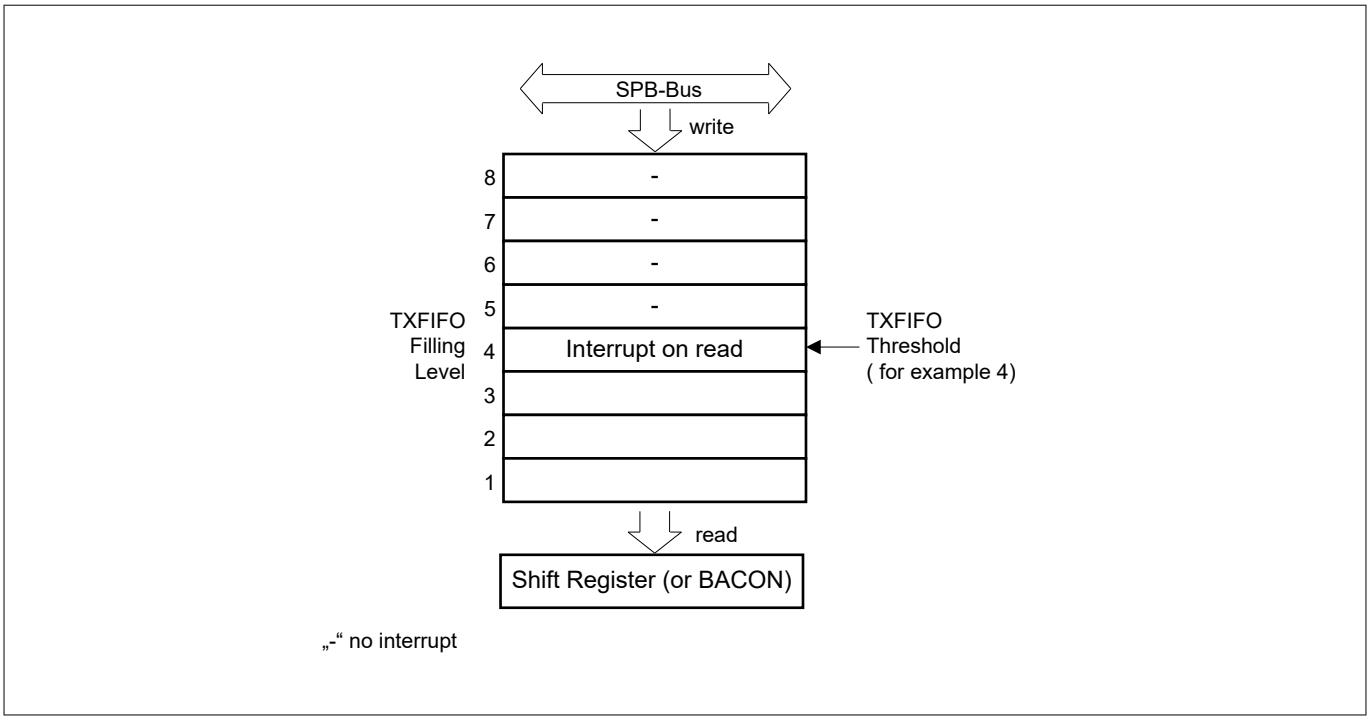

Figure 698 TXFIFO - interrupt generation in the batch move mode-1

In this mode, an interrupt is generated only at one point in the TXFIFO, when the filling level falls below the programmed threshold, implying that there are at least the predefined number of empty TXFIFO elements available.

***Attention**: The TXFIFO must be refilled until the filling level has risen above the interrupt threshold (ensured by polling the filling level), in order to guarantee that the next interrupt will occur.*

At high baud rates and short frames, it could be possible that a couple of frames have been transmitted until the moment the TXFIFO is refilled. For example, if the threshold is set to three full elements, then the interrupt will be set when the filling level falls below three, making two elements free. If the refill moment of the TXFIFO is delayed so long that two frames have been transmitted (or frame and BACON), the TXFIFO will become empty, and refill sequence of two will not reach the level of three. So, the next interrupt would never come unless the filling level is being polled and the CPU keeps refilling in a loop until the threshold has been passed (ideally the TXFIFO would be filled completely with each batch of moves).

Batch move mode-2

Batch Move Mode-2 is a combination of the Batch Move Mode-1 and Single Move Mode in a way such that, an interrupt is generated not only when the filling level falls below the programmed threshold but also on each write to the TXFIFO when the filling level is less than the programmed threshold.

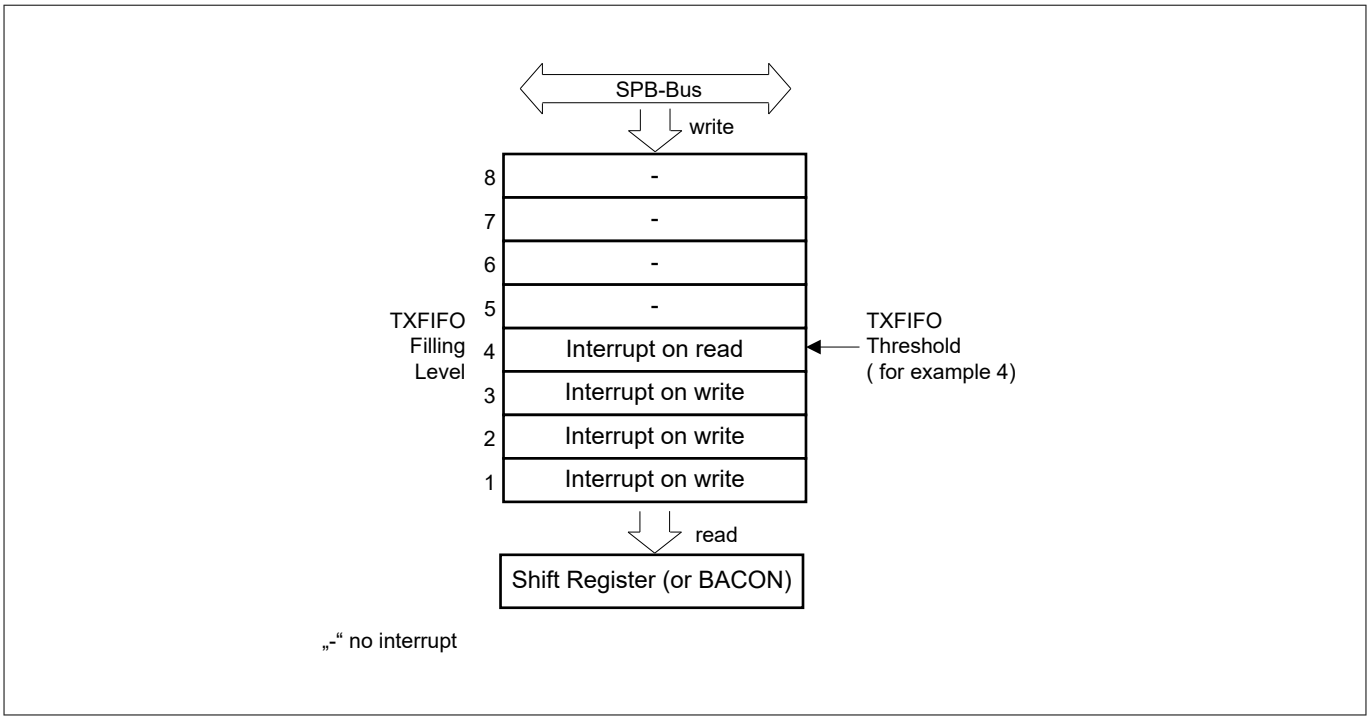

Figure 699 TXFIFO - interrupt generation in the batch move mode-2

Combined mode

TXFIFO generates interrupt each time a data is fetched from it below the pre-programmed threshold, as defined in the GLOBALCON1.TXFIFOINT. Consequently, it generates two close interrupts when delivering BACON and the first following data. If the BACON TX interrupt is not serviced until the DATA1 TX interrupt comes, which will always be the case due to their time proximity, the BACON TX interrupt will be lost. Therefore, it is recommended that a DMA should always perform two moves per interrupt trigger (transfer size of two). Otherwise, the TXFIFO average filling level will go down with the time and at the end remain oscillating between zero and one (except in continuous mode). The DMA transaction loss event that may be raised by the DMA should be ignored.

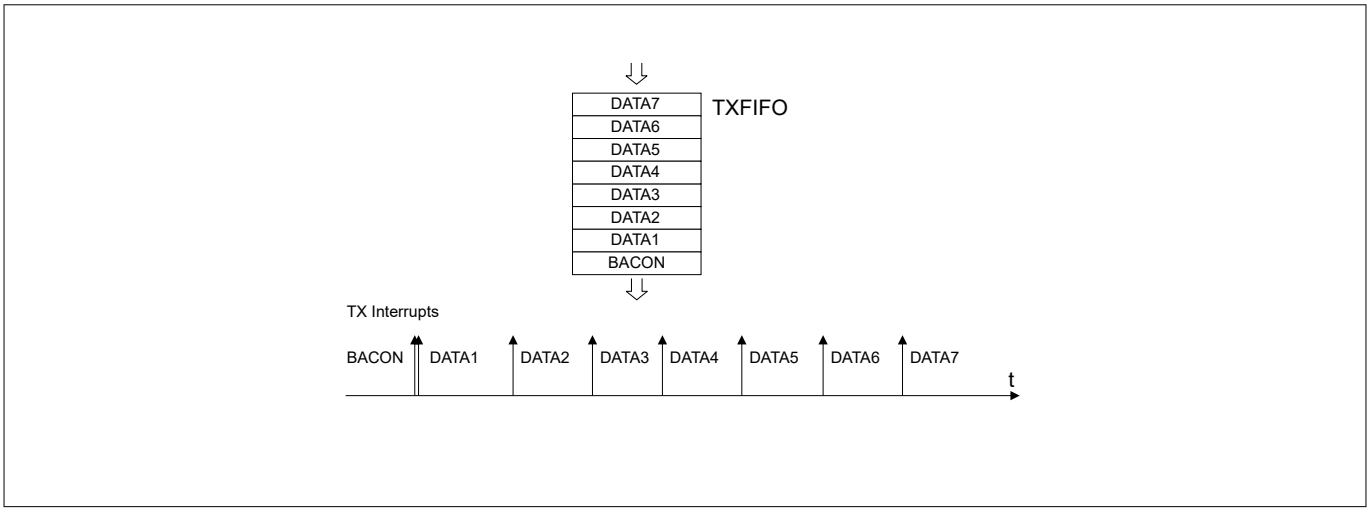

Figure 700 Events and interrupts overview

30.3.6.4 RXFIFO interrupt generation

The RXFIFO provides four interrupt generation modes, selected by the bit-field GLOBALCON1.RXFM:

- Single move mode
- Batch move mode-1
- Batch Move Mode-2
- Combined mode

Single move mode

The purpose of the Single Move Mode is to keep the RXFIFO as empty as possible, by fetching the received elements one by one as soon as possible.

An example use case could be using single move mode with a DMA performing single move per RXFIFO interrupt. In this mode the DMA keeps the RXFIFO as empty as possible. A DMA request is triggered each time a read from the RXFIFO is performed, and the RXFIFO is afterwards still not empty. If the read makes the RXFIFO empty, an interrupt is not generated in order to prevent underflow. It is generated later when the shift register (or STATUS) writes new element to the empty RXFIFO.

The following figure shows the filling levels of the RXFIFO, and the events associated with each filling level triggering a RXFIFO refill interrupt.

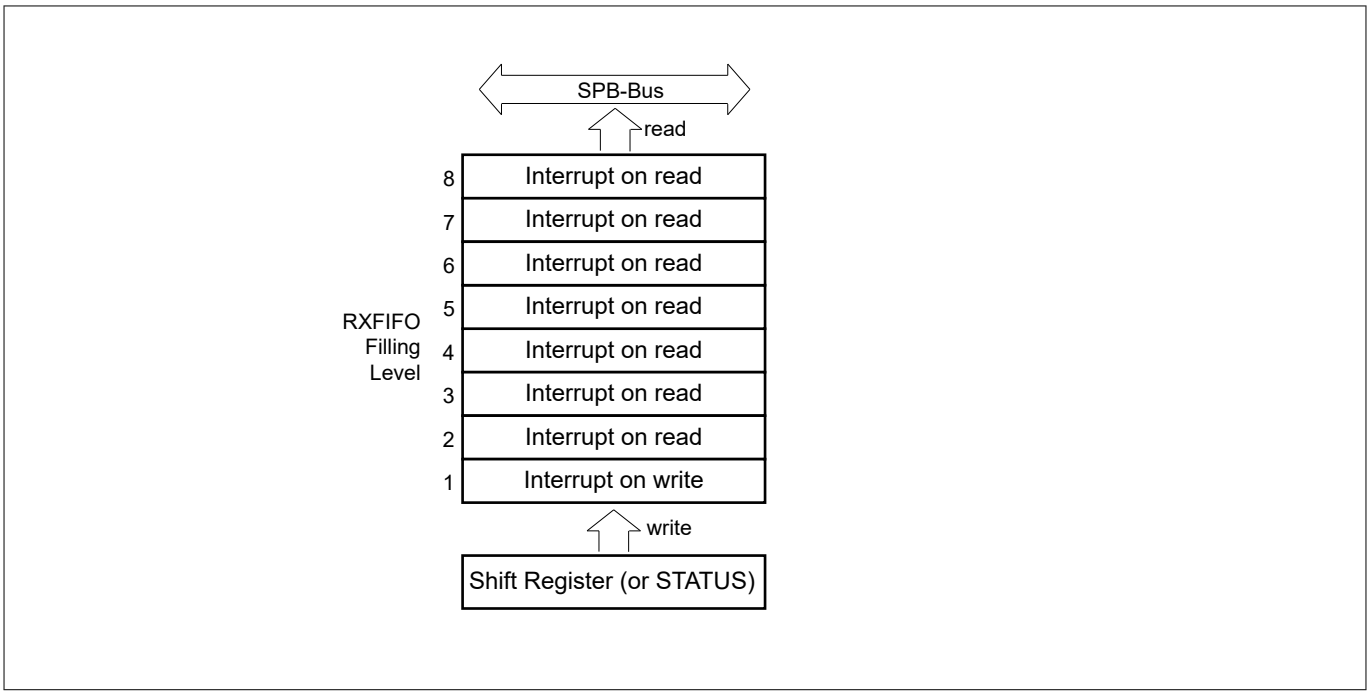

Figure 701 RXFIFO - interrupt triggering in the single move mode

The initial RXFIFO interrupt is triggered by the Shift Register, after it delivers the first received element. Afterwards, the DMA trigger-chain of re-fetch interrupts is self sustaining until the whole transaction is over. At the end of the DMA transaction, there is no service request remaining active in the service request node, due to the fact that the read of the last element in the RXFIFO does not trigger an interrupt.

Attention**: **In Single Move Mode multiple software reads or block DMA moves lead to multiple interrupts and (false) transaction lost events. Therefore they should be avoided - only single moves should be used.

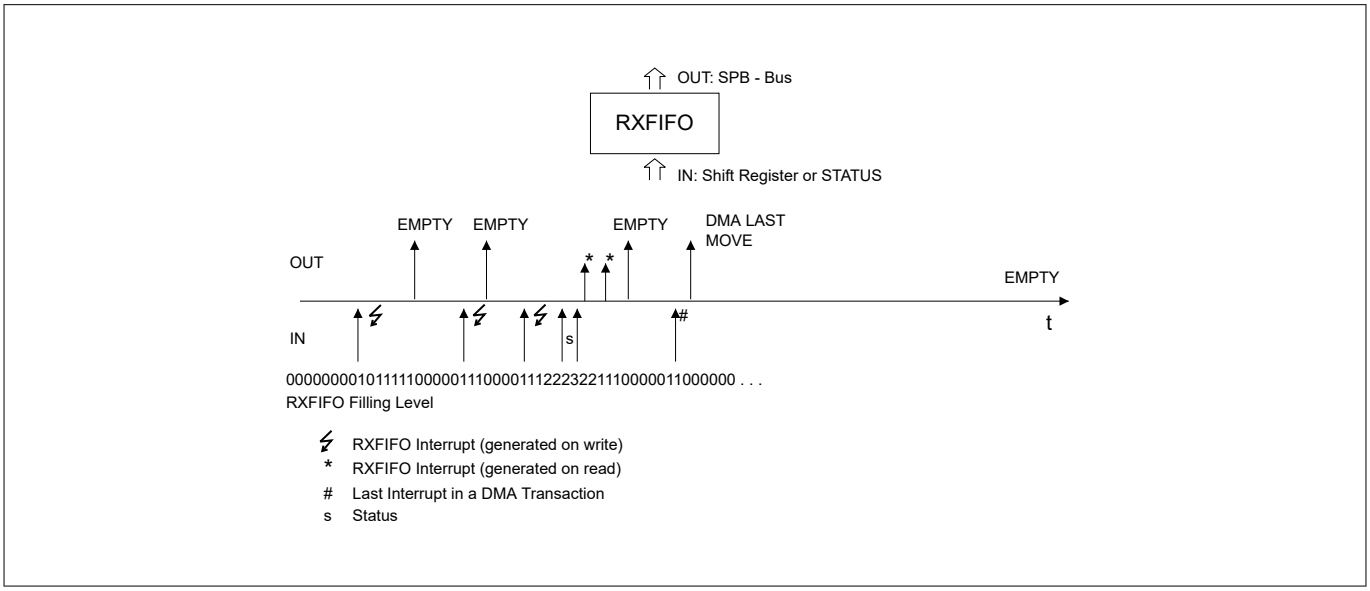

Figure 702 RXFIFO - interrupt operation in single move mode

Batch move mode-1

The purpose of this mode is to reduce the number of interrupts by triggering an interrupt when more than one RXFIFO element is full. For example, a CPU can be interrupted less frequently and it can perform more than one move per interrupt.

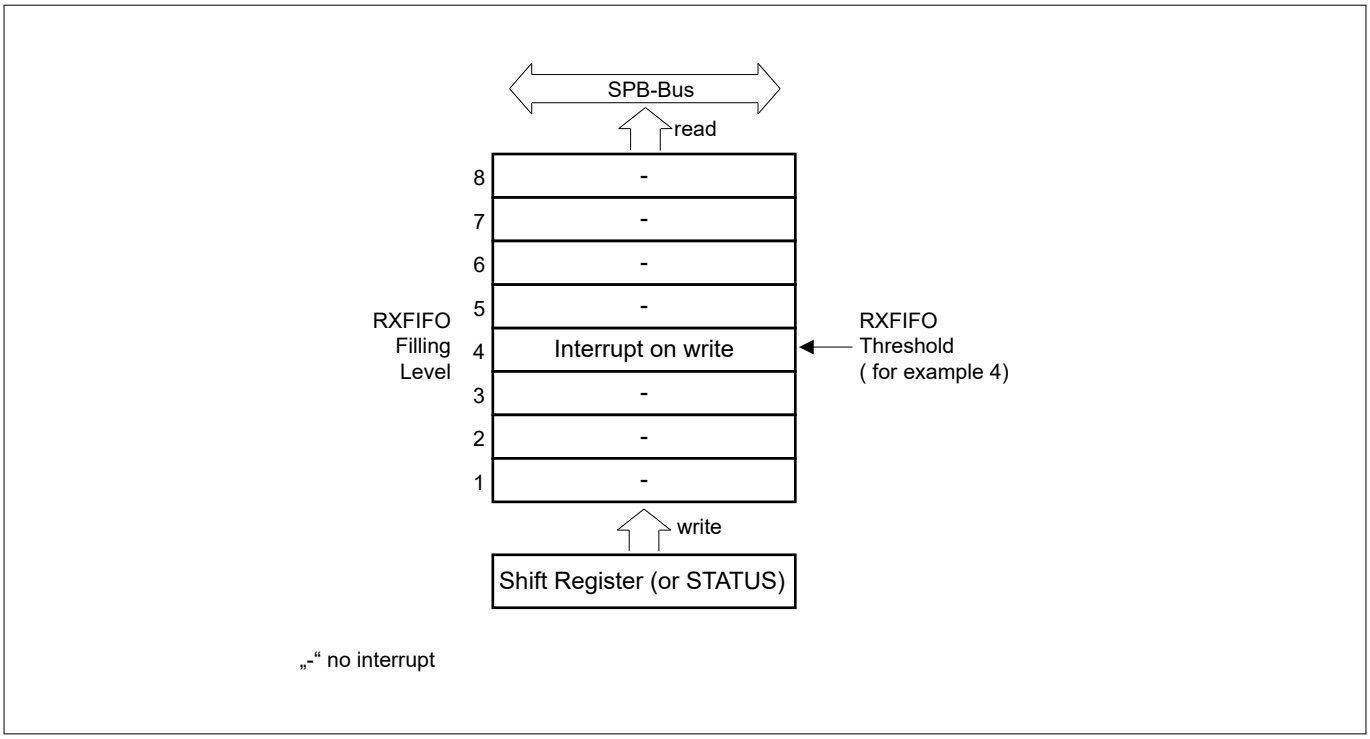

Figure 703 RXFIFO - interrupt triggering in the batch move mode-1

In Batch Move Mode-1, an interrupt is generated only at one point in the RXFIFO, when the filling level rises above the programmed threshold, implying that there are at least the predefined number of full RXFIFO elements available.

Attention*: *It must be guaranteed that the CPU keeps emptying the RXFIFO and polling the RXFIFO filling level until the filling level has fallen below the interrupt threshold (or the RXFIFO is empty), in order to guarantee that next interrupt will occur.

At high baud rates and short frames, it could be possible that more than one frame has been received until the moment the RXFIFO is re-emptied. For example, if the threshold is set to two full elements, then the interrupt will be set when the filling level rises above two. If the emptying moment of the RXFIFO is delayed so long that two additional frames have been received (or a frame and STATUS), the RXFIFO will become full, and re-empty sequence of two will not reach the level of two. So, the next interrupt would never come. This effect cannot occur with threshold levels of 3 and 4. The threshold level of 1 is possible, but does not make much sense (use single move mode instead).

Batch move mode-2

Batch Move Mode-2 is a combination of the Batch Move Mode-1 and Single Move Mode in a way such that, an interrupt is generated not only when the filling level rises above the programmed threshold but also on each read from the RXFIFO when the filling level is higher than the programmed threshold.

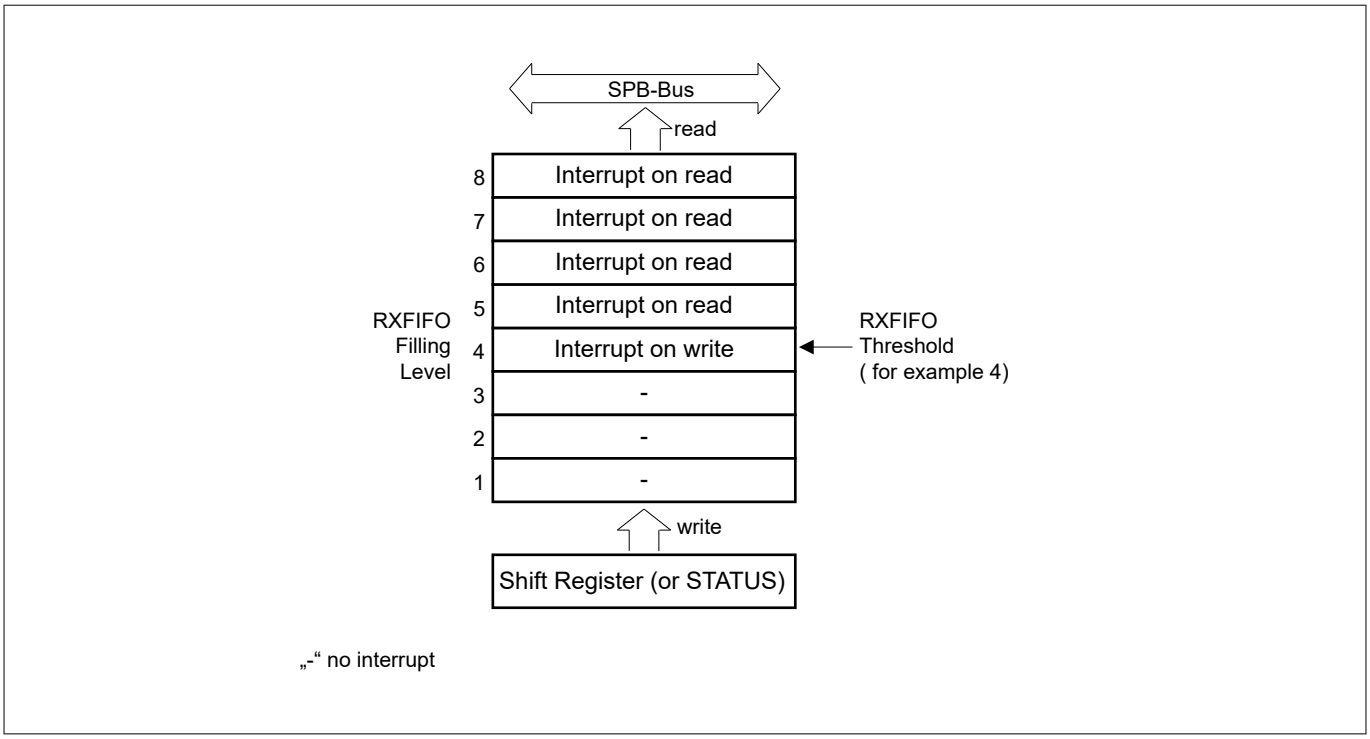

Figure 704 TXFIFO - interrupt generation in the batch move mode-2

Combined mode

RXFIFO generates interrupt each time a data is written to it above the preprogrammed level, as defined in the GLOBALCON1.RXFIFOINT. Consequently, it generates two close interrupts when filled with data and STATUS. If the data RX interrupt is not serviced until the STATUS RX interrupt comes, which will always be the case due to their time proximity, the STATUS RX interrupt will be lost. In such a case, it is recommended that the DMA performs two moves per interrupt trigger (transfer size of two). Otherwise, the RXFIFO average filling level will go up with the time and at the end overflow.

30.3.7 Reset behavior

There are two sources of reset provided by the module for it’s operation:

- KRST bit-field of registers RST_CTRLA/B
- Reset bits in the register GLOBALCON.RESETS

The KRST bit-field puts the whole QSPI module in reset state. All outputs get the reset value.

Software writing the GLOBALCON.RESETS bit will select what will be Reset (TX_FIFO, RX_FIFO, protocol statemachine, registers).

KRSTx resets the whole Module while GLOBALCON.RESETS=0b11 resets only a subset of all the available registers in the module.

30.4 Registers

30.4.1 Register overview - access mode glossary

Table 1238 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

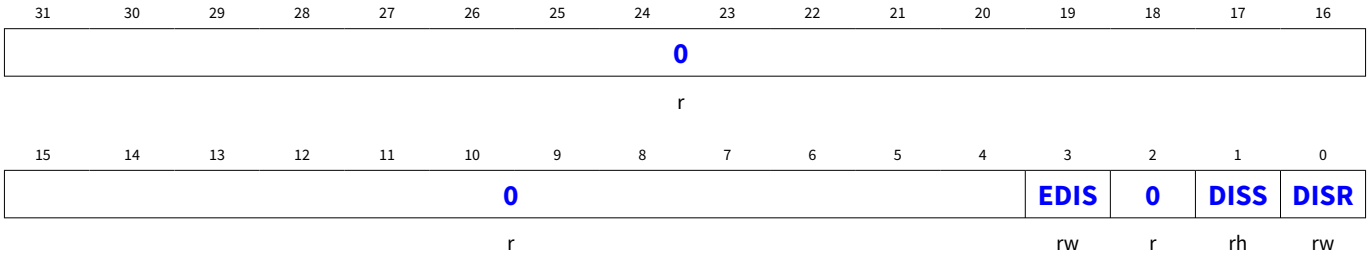
30.4.3 Clock control register

The clock control register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 000_H

Clock control register Application Reset value: $0000\ 0003_H$



Field	Bits	Type	Description
DISR	0	rw	**Module disable request bit** Used for enable and disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module disable status bit** 0_B Module clock is enabled 1_B Module is not clocked
EDIS	3	rw	**Sleep mode enable control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

30.4.4 OCDS control and status register

The OCDS control and status register OCS controls the debug behavior by selecting suspend modes. When OCDS is disabled the suspend control is ineffective.

OCS Offset address: 004_H

OCDS control and status register Debug Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
SUS	27:24	rw	**OCDS suspend control** Controls the sensitivity to the suspend signal coming from the OCDS trigger switch (OTGS) Not listed combinations are reserved. 0_H Will not suspend 1_H Hard suspend Clocks will be disabled immediately 2_H Reserved 3_H Soft suspend mode
SUS_P	28	w	**SUS write protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend state** 0_B Module is not (yet) suspended 1_B Module is suspended
0	1:0, 2, 3, 23:4, 31:30	r	**Reserved** Read as 0; should be written with 0.

Table 1240 Access mode restrictions of OCS sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SUS_P**	rw	SUS	Set SUS_P during write access
(default)	r	SUS	

30.4.5 Module identification register

ID Offset address: 008_H

Module identification register PowerOn Reset value: $00C0\ C006_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MOD_TYPE								MOD_REV							
r								r							

Field	Bits	Type	Description
MOD_REV	7:0	r	**Module revision** Indicates the revision number of the implementation.

(table continues...)

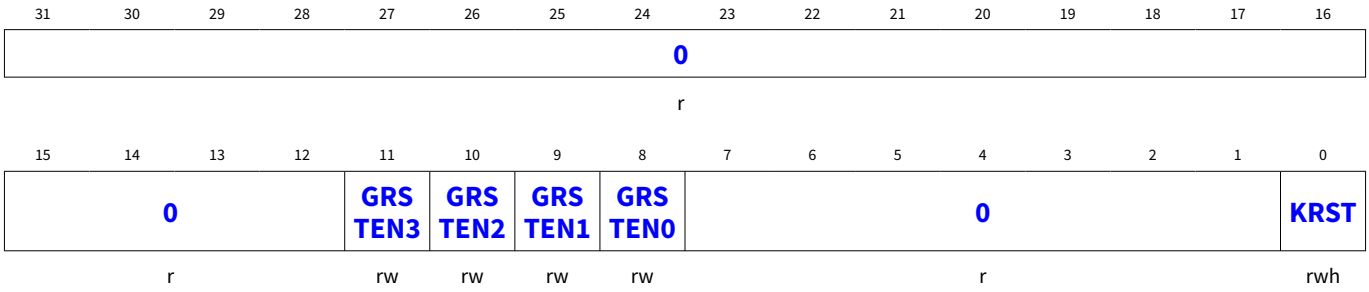
(continued)

Field	Bits	Type	Description
MOD_TYPE	15:8	r	**Module type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module number** Indicates the module identification number.

30.4.6 Reset control register A

RST_CTRLA Offset address: $00C_H$

Reset control register A Application Reset value: $0000\ 0000_H$

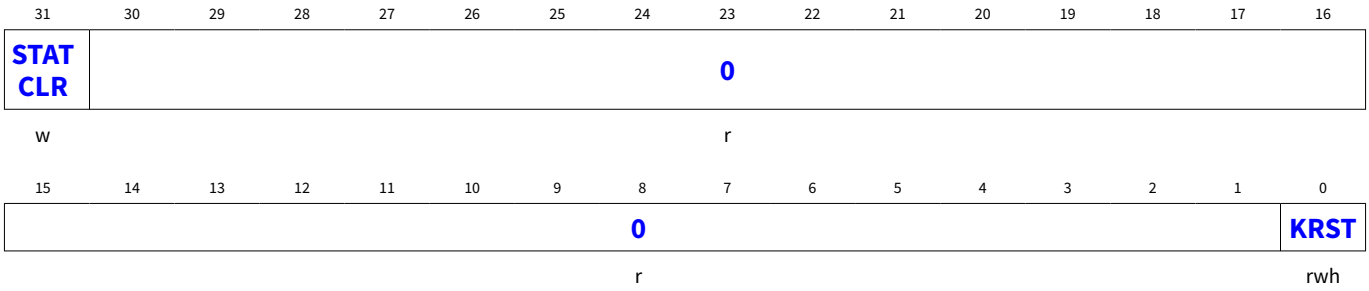


Field	Bits	Type	Description
KRST	0	rwh	**Kernel reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for global module reset group x** 0_B Global module reset group x does not have any effect 1_B Global module reset group x results in a kernel reset
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

30.4.7 Reset control register B

RST_CTRLB Offset address: 010_H

Reset control register B Application Reset value: $0000\ 0000_H$



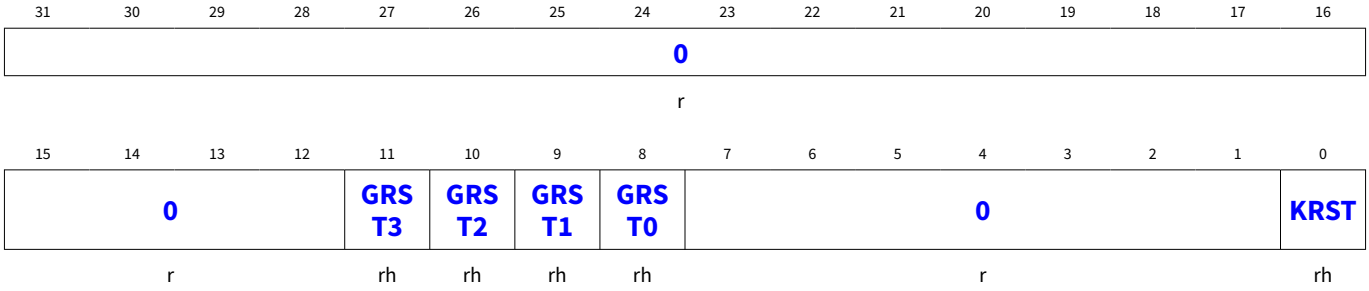
Field	Bits	Type	Description
KRST	0	rwh	**Kernel reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
STATCLR	31	w	**Kernel reset status clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits STAT.GRSTx and bit STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

30.4.8 Reset status register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: 014_H

Reset status register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rh	**Kernel reset status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.

(table continues...)

(continued)

Field	Bits	Type	Description
GRSTx (x=0-3)	x+8	rh	**Status for global module reset group x** 0_B Reset was not triggered by global reset group x 1_B Reset was triggered by global reset group x
0	7:1, 31:12	r	**Reserved** Read as 0.

30.4.9 PROT register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock and unlock of the local endinit (E) protected control registers.

PROTE Offset address: 020_H

PROT register endinit Application Reset value: $0000\ 0000_H$

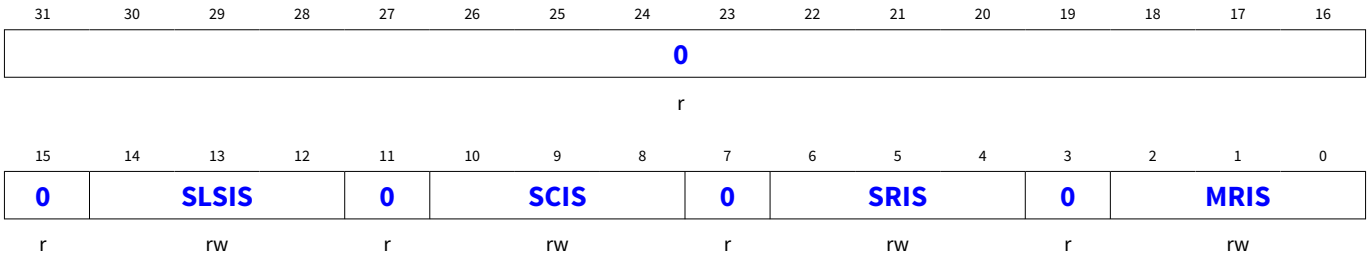
30.4.17 Port input select register

The PISEL register controls the input signal selection of the QSPI module.

PISEL Offset address: 104_H

Port input select register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
MRIS	2:0	rw	**Master Mode Receive Input Select** MRIS selects one out of eight MRST receive input lines, used in Master Mode. Note that not all inputs are used in every device of the family. Selecting an unused input returns a continuous low value. 000_B MRST input line A is selected for operation 001_B MRST input line B is selected for operation 010_B MRST input line C is selected for operation 011_B MRST input line D is selected for operation 100_B MRST input line E is selected for operation 101_B MRST input line F is selected for operation 110_B MRST input line G is selected for operation 111_B MRST input line H is selected for operation
SRIS	6:4	rw	**Slave Mode Receive Input Select** SRIS selects one out of eight MTSR receive input lines, used in Slave Mode. Note that not all inputs are used in every device of the family. Selecting an unused input returns a continuous low value. 000_B MTSR input line A is selected for operation 001_B MTSR input line B is selected for operation 010_B MTSR input line C is selected for operation 011_B MTSR input line D is selected for operation 100_B MTSR input line E is selected for operation 101_B MTSR input line F is selected for operation 110_B MTSR input line G is selected for operation 111_B MTSR input line H is selected for operation
SCIS	10:8	rw	**Slave Mode Clock Input Select** SCIS selects one out of eight module kernel SCLK input lines that is used as clock input line in slave mode. Note that not all inputs are used in every device of the family. Selecting an unused input returns a continuous low value. 000_B SCLK input line A is selected for operation 001_B SCLK input line B is selected for operation 010_B SCLK input line C is selected for operation 011_B SCLK input line D is selected for operation 100_B SCLK input line E is selected for operation 101_B SCLK input line F is selected for operation 110_B SCLK input line G is selected for operation 111_B SCLK input line H is selected for operation

(table continues...)

(continued)

Field	Bits	Type	Description
SLSIS	14:12	rw	**Slave Mode Slave Select Input Selection** The SLSIS must be programmed properly before the slave mode is set with GLOBALCON.MODE and the module is set to RUN mode. 000_B Slave select input lines are deselected QSPI is operating without slave select input functionality. 001_B SLSI input line A is selected for operation 010_B SLSI input line B is selected for operation 011_B SLSI input line C is selected for operation 100_B SLSI input line D is selected for operation 101_B SLSI input line E is selected for operation 110_B SLSI input line F is selected for operation 111_B SLSI input line G is selected for operation
0	3, 7, 11, 31:15	r	**Reserved** Read as 0; should be written with 0.

30.4.18 Global configuration register

GLOBALCON contains configuration parameters which affect all channels.

***Note**: If the EN bit is cleared first, and then the partial state machine reset activated, then the state machine goes into PAUSE state.*

***Note**: Switching the peripheral clock off and on is done by using two writes: first a write of zero to the CLKSEL bit field, and then a second write switching on the clock source. Between the first and the second write a delay of minimum 4 x (1/f_{PER}) + 2 x (1/f_{CLC}) must be inserted by software, where f_{PER} is the frequency being switched off with the first write. This also applies if between the writes the clock frequency is changed in the CCU.*

GLOBALCON Offset address: 110_H

Global configuration register Kernel Reset value: $000F\ 30FF_H$

Field	Bits	Type	Description
TQ	7:0	rw	**Global Time Quantum Length** Common n-divider scaling the baud rates of all channels in direction of higher or lower baud rates. Must not be changed during a running transaction. 00_H division by 1 01_H division by 2 … FF_H division by 256
SI	9	rw	**Status Injection** Selects if the status register content injection into the RxFIFO is enabled or disabled. The status injections, if enabled, is performed after each data block, depending on the BACON.DL and BACON.BYTE setting. 0_B Disabled 1_B Enabled
EXPECT	13:10	rw	**Time-Out Value for the Expect Phase** expressed in T_{QSPI} units 0_H 64 (2^6) 1_H 128 (2^7) … F_H 2097152 (2^21)
LB	14	rw	**Loop-Back Control** Selects if the transmit output is internally connected to the receive input for test purposes. For detailed description, see the Loop-Back Mode section. 0_B Loop-Back inactive 1_B Loop-Back active
DEL0	15	rw	**Delayed Mode** Switches the delayed mode (external slave select expansion mode) on and off 0_B Delayed mode off 1_B Delayed mode on
STROBE	20:16	rw	**Strobe Delay in Delayed Mode** Defines the length of the delay of the strobe signal for the external multiplexer in T_Q time units as defined for channel z (T_Q units) selected by the current BACON.CS, if GLOBALCON.DEL0 = 1. 00_H 1 01_H 2 … $1F_H$ 32

(table continues...)

(continued)

Field	Bits	Type	Description
SRF	21	rw	**Stop on RxFIFO Full** If this bit is set, the data fetching out of the TxFIFO by the shift register stops when the RxFIFO is full, in order to prevent RxFIFO overflow. Master mode only. 0_B Feature disabled 1_B *Feature enabled*
STIP	22	rw	**Slave Transmit Idle State Polarity** This bit determines the logic level of the Slave Mode transmit signal MRST when the QSPI slave select input signals are inactive (PISEL.SLSIS != 000_B). 0_B MRST = 0 when QSPI is deselected in Slave Mode. 1_B MRST = 1 when QSPI is deselected in Slave Mode
HS	23	rw	**High Speed Mode** Enables high speed QSPI mode. 0_B Feature disabled 1_B Feature enabled
EN	24	rwh	**Enable Bit** Used to request transition between PAUSE and RUN mode per software. Cleared by hardware automatically at leaving the following states: disabled, suspend and sleep. In order to determine if the requested state has actually been reached, the STATUS.PHASE bit field should be polled. See also Operation Modes. 0_B PAUSE requested 1_B RUN requested
MS	26:25	rw	**Master Slave Mode** Selects if the module operates in master or slave mode. This bit field must be configured before the first write to the TXFIFO. 00_B Master Transmit and Receive 01_B Reserved 10_B Slave Transmit and Receive 11_B Slave Transmit and Receive
AREN	27	rw	**Automatic Reset Enable** Enables the reset of the GLOBALCON.EN on baud rate and spike error in slave mode. 0_B Disabled 1_B Enabled
HWTREN	28	rw	**Hardware Trigger Enable** If this bit is set, the data fetching out of the TXFIFO by the shift register starts on the reception of a hardware trigger signal. 0_B Feature disabled 1_B *Feature enabled*

(table continues...)

(continued)

Field	Bits	Type	Description
CLKSEL	29	rw	**Clock Select** Selects the clock source for the asynchronous block. 0_B no clock 1_B f_{PER}
RESETS	31:30	w	**Bits for resetting sub-modules per software** Read as 0. Write to this bit field triggers a reset operation. The duration of reset operation depends on the used clock setups. It is 10 times of the slowest clock between SPB and Kernel. ***Note**: CLOCKSEL shall be enabled to use GLOBALCON.RESETS. After the Reset the CLOCKSEL will be also cleared in case of 10 11.* For resetting the whole module kernel, use alternatively the registers KRST reset mechanism. 00_B No reset triggered 01_B State Machine, TXFIFO and RXFIFO reset, registers not reseted. Only control structures shall be reset. It avoids a re-configuration of the whole IP. After this reset Communication can be restarted. 10_B Registers reset. Clears the configuration of the QSPI registers. New setup have to be programmed. 11_B State Machine, TXFIFO and RXFIFO reset and registers reset
0	8	r	**Reserved** Read as 0; should be written with 0.

30.4.19 Global configuration register 1

GLOBALCON1 contains bit fields for control of the extension of the slave select signals by using an external demultiplexer.

GLOBALCON1 Offset address: 114_H

Global configuration register 1 Kernel Reset value: $001B\ 0000_H$

30.4.20 Basic configuration register

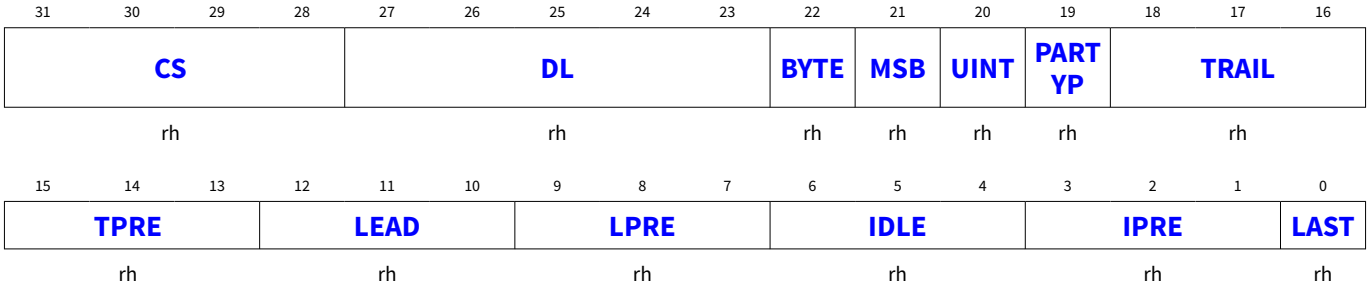
Defines the basic configuration parameters for the current slave select. It can be read by software, or written through a write to the TXFIFO.

If an application does not use the SLSO signals of the QSPI module, but uses software channel selection, then the alternate function multiplexer in the ports must be configured so that the signal SLSO is not selected, but the corresponding bit Pn.OUT.

Alternatively, to emulate SLSO functionality, the software can disable (low) all the SSOC.OEN bits, and then toggle the SSOC.AOL bits.

BACON Offset address: 118_H

Basic configuration register Kernel Reset value: $0F87\ 1C71_H$



Field	Bits	Type	Description
LAST	0	rh	**Last Word in a Frame** Defines if the following data word is last in the current frame or not 0_B Not Last 1_B Last
IPRE	3:1	rh	**Prescaler for the Idle Delay** Length in T_{PER} units 000_B 1 001_B 4 010_B 16 … 111_B 16384
IDLE	6:4	rh	**Idle Delay Length** Defines the length of both idle delays, IDLEA and IDLEB, in T_{PER} units pre scaled with IPRE 000_B 1 unit 001_B 2 units … 111_B 8 units

(table continues...)

(continued)

Field	Bits	Type	Description
LPRE	9:7	rh	**Prescaler for the Leading Delay** Length in T_{PER} units 000_B 1 001_B 4 010_B 16 … 111_B 16384
LEAD	12:10	rh	**Leading Delay Length** Defines the length of the leading delay, in T_{PER} units pre scaled with LPRE 000_B 1 unit 001_B 2 units … 111_B 8 units
TPRE	15:13	rh	**Prescaler for the Trailing Delay** Length in T_{PER} units 000_B 1 001_B 4 010_B 16 … 111_B 16384
TRAIL	18:16	rh	**Trailing Delay Length** Defines the length of the trailing delay, in T_{PER} units pre scaled with TPRE 000_B 1 unit 001_B 2 units … 111_B 8 units
PARTYP	19	rh	**Parity Type** Valid for both receive and transmit direction 0_B Even parity 1_B Odd parity
UINT	20	rh	**User Interrupt at the PT1 Event in the Subsequent Frames** This bit is an enable signal for the PT1 event routed to the User Interrupt Service Request. The interrupt signals are generated until disabled with the next BACON. 0_B Disabled 1_B Enabled

(table continues...)

(continued)

Field	Bits	Type	Description
MSB	21	rh	**Shift MSB or LSB First** This bit sets the shift direction of the shift register. If the MSB option is set, and the data is a block longer than 32 bits, the block must be fed into the TXFIFO in reverse direction, from the end of the block until its beginning. 0_B Shift LSB first 1_B Shift MSB first
BYTE	22	rh	**Byte** Defines if data length is expressed in bits or bytes. In Slave Mode BYTE must be '0'. 0_B DL defines the data length in bits 1_B DL defines the data length in bytes
DL	27:23	rh	**Data Length** Defines the data length in bits or bytes of one data block, depending on the setting of the bit field BYTE. For the maximum baud rate of 50 MBaud, the minimum data length possible is four. 00_H 2 bits if BYTE=0; XXL mode if BYTE=1 01_H 2 bits or bytes … $1F_H$ 32 bits or bytes
CS	31:28	rh	**Channel Select** Selects the channel to which the subsequent data entry belongs (channel = the SLSO signal to be activated and the corresponding ECON configuration extension) This bit field selects one slave in a range of 0 to 15, by driving one SLSO signal out of 16 available. In case of an external demux mode, this bit field appears on the selected SLSO lines as it is, additionally inverted or not, as defined in the SSOC register.

30.4.21 Configuration extension z

Configuration extensions for channels 0 to 15. Register z defines several timing characteristics for two channels: z and z+8.

ECONz (z=0-7) Offset address: 120_H+z*4

Configuration extension z Kernel Reset value: $0000\ 1450_H$

0	15, 29:18	r	**Reserved**

30.4.22 Status register

Status register contains bits flagging the current status of the module and its sub-modules.

***Note**: It is not recommended to set the STATUS register flags per software for purposes other than testing. In such cases, use write instructions only, not read-modify-write instructions or bit instructions which compile to read-modify-write instructions.*

When using the RXFIFO status injection feature, only bits 22 to 31 reflect the status at the moment of injection, that is for the latest frame. Due to pipeline effects, the other bits contain not-latest information.

Slave TXFIFO underflow error is activated if the transmission has been started by the master at the time when the slave FIFO was empty, or at the same moment updated. In the second case inconsistent data will be transmitted.

Reading the TXFIFO filling level bit field returns a value which can be used to calculate how many writes can be performed by a CPU without causing an overflow (in case no DMA is programmed to access the TXFIFO in parallel). For example, if the TXFIFO level was one, maximum seven (TXFIFO depth of eigth minus one) write accesses are possible. Due to the volatility of the bit field, the filling level can go down in some nanoseconds after the read.

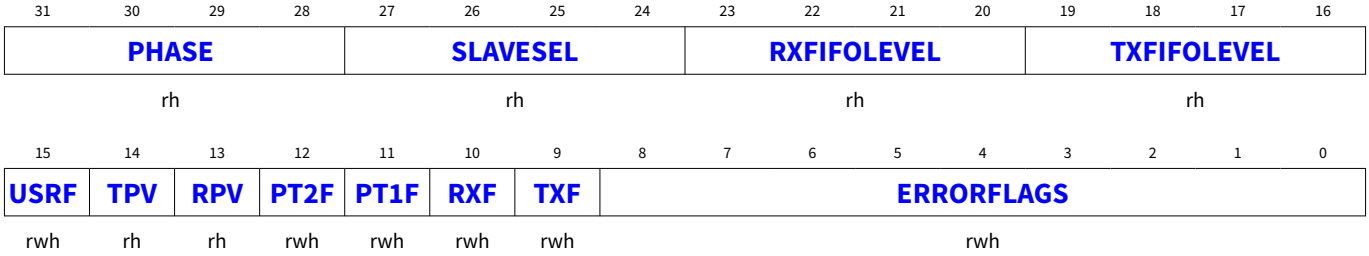
Reading the RXFIFO filling level bit field returns a value which shows directly how many reads can be performed by a CPU without causing an underflow. Due to the volatility of the bit field, the filling level can go up in some nanoseconds after the read.

Reading the PHASE bit field shows a previous phase of the frame, and a PT1F and PT2F flags indicate previous phase transitions. If the communication speed is not too high or the phases duration not very short compared to the software latency delays, which would normally be the case, these would be the latest completed phase and the latest phase transitions. Nevertheless, in case of high baud rates, the duration of the phases must be taken into consideration, but only if these bit fields are used in an application, and not only for debugging purposes.

SLSI misplaced inactivation error interrupt is raised when SLSI is deactivated by the master while the data transfer is still ongoing.

STATUS Offset address: 140_H

Status register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ERRORFLAGS	8:0	rwh	**Sticky Flags Signalling Errors** Writing 1 sets the error Flag and triggers an error interrupt, if enabled. Writing 0 has no effect. 000_H No Error 001_H Parity Error 002_H Unexpected Configuration Error 004_H Trigger Ignored Error (master mode), Baud Rate Error (slave mode) 008_H TXFIFO overflow (software error) 010_H TXFIFO underflow (slave mode) 020_H RXFIFO overflow 040_H RXFIFO underflow (software error) 080_H EXPECT time out error 100_H SLSI misplaced inactivation (slave mode)
TXF	9	rwh	**Transmit Interrupt Request Flag** Flags an occurrence of a request to feed the TXFIFO, which is generated when an element is fetched from the FIFO, and the FIFO filling level is equal or less than the set threshold level. Writing 1 sets the flag and triggers an interrupt if GLOBALCON1.TXEN = 1. Writing 0 has no effect.
RXF	10	rwh	**Receive Interrupt Request Flag** Flags an occurrence of a request to empty the RXFIFO, which is generated when an element is written into the FIFO, and the FIFO filling level is equal or greater than the set threshold level. Writing 1 sets the flag and triggers an interrupt if GLOBALCON1.RXEN = 1. Writing 0 has no effect.
PT1F	11	rwh	**Phase Transition 1 Flag** Flags an occurrence of a PT1 event, as selected with the GLOBALCON1.PT1, and triggers an interrupt if GLOBALCON1.PT1EN = 1. Writing 1 sets the flag and triggers an error interrupt. Writing 0 has no effect.

(table continues...)

(continued)

Field	Bits	Type	Description
PT2F	12	rwh	**Phase Transition 2 Flag** In master mode, flags an occurrence of a PT2 event, as selected with the GLOBALCON1.PT2, and triggers an interrupt if GLOBALCON1.PT2EN = 1. In slave mode, set by the SLSI deactivated event. Writing 1 sets the flag and triggers an error interrupt. Writing 0 has no effect.
RPV	13	rh	**Received Parity Value** Displays the last received parity bit, if parity was enabled. Else if the parity is disabled, reads 0.
TPV	14	rh	**Transmitted Parity Value** Displays the last transmitted parity bit, if parity was enabled. Else 0.
USRF	15	rwh	**User Interrupt Request Flag** Flags an occurrence of an USR event. Writing 1 sets the flag and triggers an interrupt if GLOBALCON1.USREN = 1. Writing 0 has no effect.
TXFIFOLEVEL	19:16	rh	**TXFIFO Filling Level** Shows how many entries in the TXFIFO are waiting for transmission 0_H 0 1_H 1 2_H 2 3_H 3 4_H 4 5_H 5 6_H 6 7_H 7 8_H 8 **others,** reserved
RXFIFOLEVEL	23:20	rh	**RXFIFO Filling Level** Shows how many entries in the RXFIFO are waiting for software to move them to RAM 0_H 0 1_H 1 2_H 2 3_H 3 4_H 4 5_H 5 6_H 6 7_H 7 8_H 8 **others,** reserved
SLAVESEL	27:24	rh	**Currently Active Slave Select Flag** Displays the currently active slave select.

(table continues...)

(continued)

Field	Bits	Type	Description
PHASE	31:28	rh	**Flags the ongoing phase** Displays the current phase number. Relevant only in master mode. In slave mode this bit field indicates always 0. Not 0 means busy. 0_H Wait 1_H Idle A 2_H Idle B 3_H Lead 4_H Data 5_H Trail 6_H Expect 7_H Lead Strobe 8_H Trail Strobe

30.4.23 Status register 1

If the STATUS.ERRORFLAGS[2] bit is cleared through FLAGSCLEAR.ERRORCLEARS[2], the both flags SPD and BRD are automatically cleared.

STATUS1 Offset address: 144_H

Status register 1 Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0								BITCOUNT							
r								r							

Field	Bits	Type	Description
BITCOUNT	7:0	r	**Number of bits shifted out** Supports up to 256 bits. A BITCOUNT value of greater than 0 indicates that a transmission is in progress. The value is not accurate; it may be lower than the number of bits shifted. After transmission of the last bit, BITCOUNT is set to zero.
BRDEN	28	rw	**Baud Rate Deviation Enable** Enables the signal path. 0_B Disabled 1_B Enabled

(table continues...)

(continued)

Field	Bits	Type	Description
BRD	29	rwh	**Baud Rate Deviation Flag** Shows if baud rate deviation has been detected. Write of 1 sets the bit and raises the event per software. Write of 0 has no effect. 0_B no event 1_B event detected
SPDEN	30	rw	**Spike Detection Enable** Enables the signal path. 0_B Disabled 1_B Enabled
SPD	31	rwh	**Spike Detection Flag** Shows if spike has been detected. Write of 1 sets the bit and raises the event per software. Write of 0 has no effect. 0_B No event 1_B Event detected
0	27:8	r	**Reserved** Read as 0; should be written with 0.

30.4.24 Slave select output control register

SSOC controls the level of each slave select and enables/disables each one individually.

SSOC Offset address: 148_H

Slave select output control register Kernel Reset value: $0000\ 0000_H$

0	13, 14, 31:16	r	**Reserved** Read as 0; should be written with 0.

30.4.26 Extra large data configuration register

The XXLCON register provides counter for sending frames with very long blocks of data by extending the long data mode. It avoids a need for further BACON entries, like those needed in continuous mode.

Data length in this register overrides the BACON.DL setting in XXL mode, when BACON.BYTE=1 and BACON.DL=0. The data is sent to the corresponding slave as defined by BACON.CS bit field.

XXLCON Offset address: 154_H

Extra large data configuration register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
MCOUNT	15:0	rw	**Move Count** Defines the number of moves to be performed in short mode, in range of 1 to 65535.
CURRENT	31:16	rh	**Current Status of the Move Counter** Shows the current status of the Move Counter, that is, how many data blocks are to be transmitted until the end of the frame. The value is in the range of 0 to 65535.

30.4.33 Move counter control register

Contains the control bits for the Move Counter Mode. See the description MC register.

MCCON Offset address: $1B8_H$

Move counter control register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
TPRE2	2:0	rw	**Prescaler for the Trailing Delay 2** Trailing delay injected in the configuration register for the last data if T2EN is set. Length in units T_{PER} 000_B 1 001_B 4 010_B 16 … 111_B 16384
TRAIL2	5:3	rw	**Last Trailing Delay** Trailing delay injected in the configuration register for the last data if T2EN is set. Defines the length of the leading delay, in T_{PER} units pre scaled with TPRE 000_B 1 unit 001_B 2 units … 111_B 8 units
IBLEN	16	rw	**Interrupt Before Last Enable** Enable bit for this event. 0_B Disabled 1_B Enable
IBLF	17	rh	**Interrupt Before Last Flag** Flag bit for this event. 0_B No event 1_B Event occurred
IBLC	18	w	**Clear Bit for IBLF** Writing 1 clears the IBLF. Writing 0 has no effect. Returns 0 on read.

(table continues...)

(continued)

Field	Bits	Type	Description
IBLS	19	w	**Set Bit for IBLF** Writing 1 sets the IBLF and triggers an interrupt (if enabled). Writing 0 has no effect. Returns 0 on read.
IALEN	20	rw	**Interrupt After Last Enable** Enable bit for this event. 0_B Disabled 1_B Enable
IALF	21	rh	**Interrupt After Last Flag** Flag bit for this event. 0_B No event 1_B Event occurred
IALC	22	w	**Clear Bit for IALF** Writing 1 clears the IALF. Writing 0 has no effect. Returns 0 on read.
IALS	23	w	**Set Bit for IALF** Writing 1 sets the IALF and triggers an interrupt (if enabled). Writing 0 has no effect. Returns 0 on read.
T2EN	30	rw	**TRAIL 2 Injection Enable** This bit has to be configured before the transmission of the frame starts. If set, a new value for the last trailing delay will be injected for the last data block, as defined with the bit field TRAIL2. If not set, the TRAIL value from the latest BACON will be valid also as the last trailing delay.
MCEN	31	rw	**Move Counter Enable** Enables the Move Counter feature. If enabled, the MCOUNT value is taken in consideration, otherwise the standard continuous mode is active.
0	15:6, 29:24	r	**Reserved** Read as 0; should be written with 0.

30.4.34 Multiple slave select register

This registers enables and configures the multiple slave select mode.

0	27:16	r	**Reserved** Read as 0; should be written with 0.

30.5 Debug information

OCDS suspend

The OCDS hard suspend request, for debugging purposes, simply freezes the QSPI module in the current state. No signal is changed including the service request lines, which remain frozen in the current state.

***Attention**: On chips where hard OCDS suspend simply switches the clock off immediately, without waiting on acknowledge from the module, all output signals are simply frozen.*

The QSPI responds to an OCDS soft suspend request by entering the PAUSE state immediately after the subsequent end of a trail phase, and then sending acknowledge (see below Figure). The behavior is the same as for entering the Sleep mode.

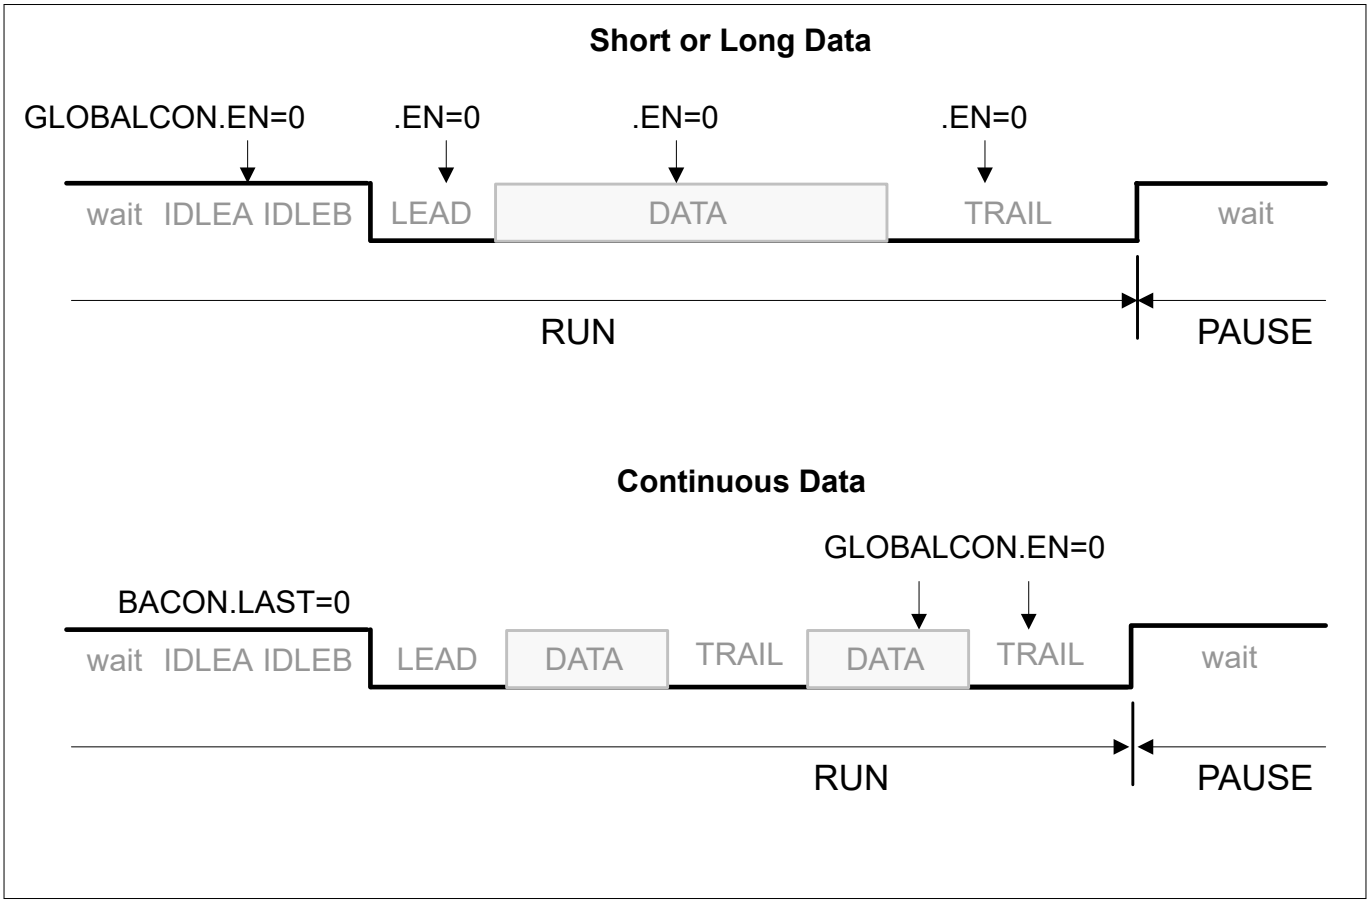

Figure 705 Entering the sleep, soft suspend, and disable state

Reading the FIFO entries by the Cerberus (detected by the FPI master tag) does not modify the FIFO content nor the read and write pointers.

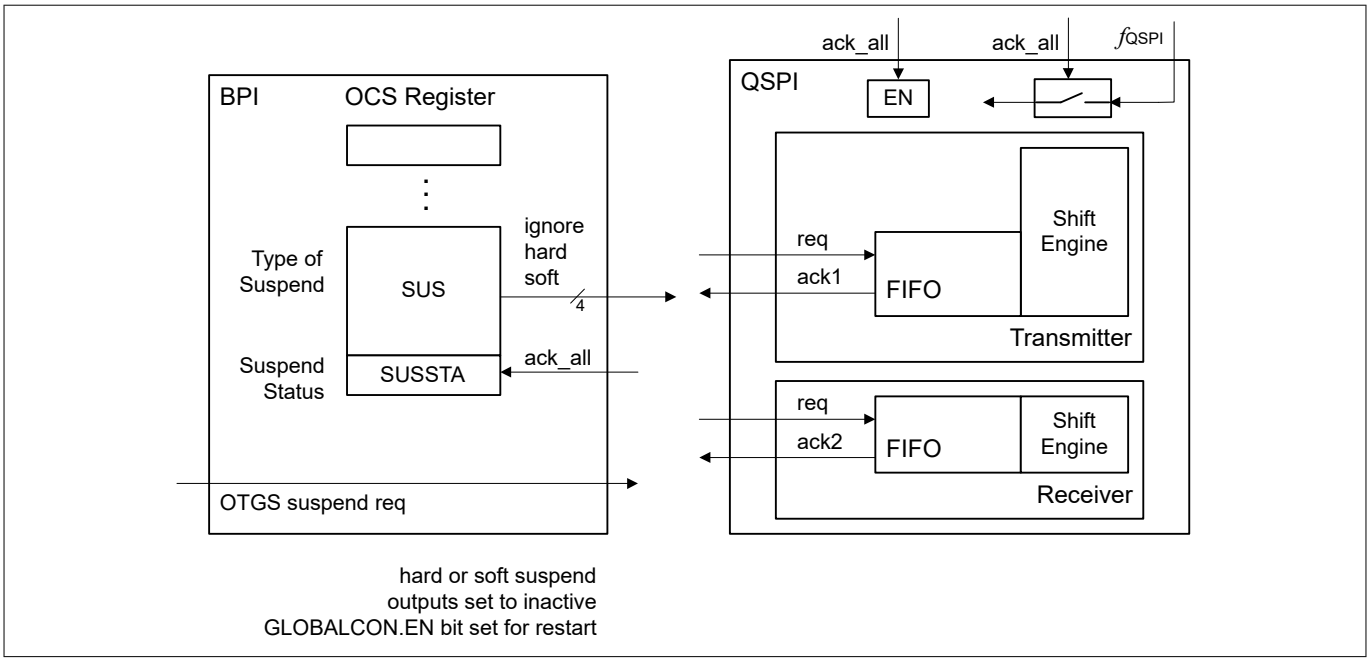

Figure 706 Suspend overview

Please note the following:

- In Hard Suspend Mode:
  - The QSPI kernel clock is switched off immediately
  - Writing to registers is possible but will enable the kernel clock for a few cycles(see note below)
  - Read access to a register does not let any clock cycles through, but is done in combinatorial way. Therefore, RXFIFO pointer does not move

Attention*: *These clock pulses in Hard Suspend Mode can have unintended side effects like signals becoming and staying active. This can affect also other modules, so a QSPI kernel reset might not be sufficient to bring the system into a defined state

- In Soft Suspend Mode:
  - The QSPI kernel clock is switched on, the module is only paused
  - Each read and write can cause state transition in some state machine in the module. Therefore, RXFIFO reacts to the read accesses

Keyword	Description
E	Access protection using PROT register QSPI0_PROTE or QSPI1_PROTE or QSPI2_PROTE or QSPI3_PROTE or QSPI4_PROTE or QSPI5_PROTE or QSPI6_PROTE or QSPI7_PROTE .
SE	Access protection using PROT register QSPI0_PROTSE or QSPI1_PROTSE or QSPI2_PROTSE or QSPI3_PROTSE or QSPI4_PROTSE or QSPI5_PROTSE or QSPI6_PROTSE or QSPI7_PROTSE .
APU-P	Protection group consisting of registers QSPI0_ACCEN_WRA , QSPI0_ACCEN_WRB , QSPI0_ACCEN_RDA , QSPI0_ACCEN_RDB , QSPI0_ACCEN_VM , QSPI0_ACCEN_PRS or QSPI1_ACCEN_WRA , QSPI1_ACCEN_WRB , QSPI1_ACCEN_RDA , QSPI1_ACCEN_RDB , QSPI1_ACCEN_VM , QSPI1_ACCEN_PRS or QSPI2_ACCEN_WRA , QSPI2_ACCEN_WRB , QSPI2_ACCEN_RDA , QSPI2_ACCEN_RDB , QSPI2_ACCEN_VM , QSPI2_ACCEN_PRS or QSPI3_ACCEN_WRA , QSPI3_ACCEN_WRB , QSPI3_ACCEN_RDA , QSPI3_ACCEN_RDB , QSPI3_ACCEN_VM , QSPI3_ACCEN_PRS or QSPI4_ACCEN_WRA , QSPI4_ACCEN_WRB , QSPI4_ACCEN_RDA , QSPI4_ACCEN_RDB , QSPI4_ACCEN_VM , QSPI4_ACCEN_PRS or QSPI5_ACCEN_WRA , QSPI5_ACCEN_WRB , QSPI5_ACCEN_RDA , QSPI5_ACCEN_RDB , QSPI5_ACCEN_VM , QSPI5_ACCEN_PRS or QSPI6_ACCEN_WRA , QSPI6_ACCEN_WRB , QSPI6_ACCEN_RDA , QSPI6_ACCEN_RDB , QSPI6_ACCEN_VM , QSPI6_ACCEN_PRS or QSPI7_ACCEN_WRA , QSPI7_ACCEN_WRB , QSPI7_ACCEN_RDA , QSPI7_ACCEN_RDB , QSPI7_ACCEN_VM , QSPI7_ACCEN_PRS .
P	Access protection using *APU-P* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

30.8.4.3 Register overview - QSPI0 (ascending offset address)

Table 1247 Register overview - QSPI0 (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
QSPI0_CLC	Clock control register	000_H	P	P, SV, E	Application Reset	5364
QSPI0_OCS	OCDS control and status register	004_H	P	SV, P	Debug Reset	5364
QSPI0_ID	Module identification register	008_H	P	BE	PowerOn Reset	5365
QSPI0_RST_CTRLA	Reset control register A	$00C_H$	P	P, SV, E	Application Reset	5366
QSPI0_RST_CTRLB	Reset control register B	010_H	P	P, SV, E	Application Reset	5366
QSPI0_RST_STAT	Reset status register	014_H	P	BE	Application Reset	5367
QSPI0_PROTE	PROT register endinit	020_H	U	SV, PROT	Application Reset	5368
QSPI0_PROTSE	PROT register safe endinit	024_H	U	SV, PROT	Application Reset	5369
QSPI0_ACCEN_WRA	Write access enable register A	040_H	U	SE, SV	Application Reset	5371
QSPI0_ACCEN_WRB	Write access enable register B	044_H	U	SE, SV	Application Reset	5372
QSPI0_ACCEN_RDA	Read access enable register A	048_H	U	SE, SV	Application Reset	5372
QSPI0_ACCEN_RDB	Read access enable register B	$04C_H$	U	SE, SV	Application Reset	5373
QSPI0_ACCEN_VM	VM access enable register	050_H	U	SE, SV	Application Reset	5373
QSPI0_ACCEN_PRS	PRS access enable register	054_H	U	SE, SV	Application Reset	5374
QSPI0_PISEL	Port input select register	104_H	P	SV, P	Kernel Reset	5374
QSPI0_GLOBALCON	Global configuration register	110_H	P	SV, P	Kernel Reset	5376
QSPI0_GLOBALCON1	Global configuration register 1	114_H	P	SV, P	Kernel Reset	5379
QSPI0_BACON	Basic configuration register	118_H	P	BE	Kernel Reset	5383
QSPI0_ECONz (z=0-7)	Configuration extension z	120_H+z*4	P	SV, P	Kernel Reset	5385
QSPI0_STATUS	Status register	140_H	P	P	Kernel Reset	5387
QSPI0_STATUS1	Status register 1	144_H	P	P	Kernel Reset	5390

(table continues...)

Table 1247 (continued) Register overview - QSPI0 (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
QSPI0_SSOC	Slave select output control register	148_H	P	SV, P	Kernel Reset	5391
QSPI0_FLAGSCLEAR	Flags clear register	150_H	P	P	Kernel Reset	5392
QSPI0_XXLCON	Extra large data configuration register	154_H	P	P	Kernel Reset	5393
QSPI0_MIXENTRY	MIX_ENTRY register	158_H	P	P	Kernel Reset	5394
QSPI0_BACONENTRY	BACON_ENTRY register	$15C_H$	P	P	Kernel Reset	5394
QSPI0_DATAENTRYx (x=0-7)	DATA_ENTRY register x	160_H+x*4	P	P	Kernel Reset	5397
QSPI0_RXEXIT	RX_EXIT register	180_H	P	BE	Kernel Reset	5397
QSPI0_RXEXIT# (#=0-7)	RX_EXIT register mirror #	180_H+#*4	P	BE	Kernel Reset	5397
QSPI0_RXEXITD	RX_EXIT debug register	$1A0_H$	P	BE	Kernel Reset	5398
QSPI0_MC	Move counter register	$1B4_H$	P	P	Kernel Reset	5398
QSPI0_MCCON	Move counter control register	$1B8_H$	P	P	Kernel Reset	5399
QSPI0_MSSMUX	Multiple slave select register	$1BC_H$	P	P	Kernel Reset	5400

QSPI5_MC	Move counter register	$1B4_H$	P	P	Kernel Reset	5398
QSPI5_MCCON	Move counter control register	$1B8_H$	P	P	Kernel Reset	5399
QSPI5_MSSMUX	Multiple slave select register	$1BC_H$	P	P	Kernel Reset	5400

30.8.4.9 Register overview - QSPI6 (ascending offset address)

Table 1253 Register overview - QSPI6 (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
QSPI6_CLC	Clock control register	000_H	P	P, SV, E	Application Reset	5364
QSPI6_OCS	OCDS control and status register	004_H	P	SV, P	Debug Reset	5364
QSPI6_ID	Module identification register	008_H	P	BE	PowerOn Reset	5365
QSPI6_RST_CTRLA	Reset control register A	$00C_H$	P	P, SV, E	Application Reset	5366
QSPI6_RST_CTRLB	Reset control register B	010_H	P	P, SV, E	Application Reset	5366
QSPI6_RST_STAT	Reset status register	014_H	P	BE	Application Reset	5367
QSPI6_PROTE	PROT register endinit	020_H	U	SV, PROT	Application Reset	5368
QSPI6_PROTSE	PROT register safe endinit	024_H	U	SV, PROT	Application Reset	5369
QSPI6_ACCEN_WRA	Write access enable register A	040_H	U	SE, SV	Application Reset	5371
QSPI6_ACCEN_WRB	Write access enable register B	044_H	U	SE, SV	Application Reset	5372
QSPI6_ACCEN_RDA	Read access enable register A	048_H	U	SE, SV	Application Reset	5372
QSPI6_ACCEN_RDB	Read access enable register B	$04C_H$	U	SE, SV	Application Reset	5373
QSPI6_ACCEN_VM	VM access enable register	050_H	U	SE, SV	Application Reset	5373
QSPI6_ACCEN_PRS	PRS access enable register	054_H	U	SE, SV	Application Reset	5374
QSPI6_PISEL	Port input select register	104_H	P	SV, P	Kernel Reset	5374
QSPI6_GLOBALCON	Global configuration register	110_H	P	SV, P	Kernel Reset	5376
QSPI6_GLOBALCON1	Global configuration register 1	114_H	P	SV, P	Kernel Reset	5379
QSPI6_BACON	Basic configuration register	118_H	P	BE	Kernel Reset	5383
QSPI6_ECONz (z=0-7)	Configuration extension z	120_H+z*4	P	SV, P	Kernel Reset	5385
QSPI6_STATUS	Status register	140_H	P	P	Kernel Reset	5387
QSPI6_STATUS1	Status register 1	144_H	P	P	Kernel Reset	5390

(table continues...)

Table 1253 (continued) Register overview - QSPI6 (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
QSPI6_SSOC	Slave select output control register	148_H	P	SV, P	Kernel Reset	5391
QSPI6_FLAGSCLEAR	Flags clear register	150_H	P	P	Kernel Reset	5392
QSPI6_XXLCON	Extra large data configuration register	154_H	P	P	Kernel Reset	5393
QSPI6_MIXENTRY	MIX_ENTRY register	158_H	P	P	Kernel Reset	5394
QSPI6_BACONENTRY	BACON_ENTRY register	$15C_H$	P	P	Kernel Reset	5394
QSPI6_DATAENTRYx (x=0-7)	DATA_ENTRY register x	160_H+x*4	P	P	Kernel Reset	5397
QSPI6_RXEXIT	RX_EXIT register	180_H	P	BE	Kernel Reset	5397
QSPI6_RXEXIT# (#=0-7)	RX_EXIT register mirror #	180_H+#*4	P	BE	Kernel Reset	5397
QSPI6_RXEXITD	RX_EXIT debug register	$1A0_H$	P	BE	Kernel Reset	5398
QSPI6_MC	Move counter register	$1B4_H$	P	P	Kernel Reset	5398
QSPI6_MCCON	Move counter control register	$1B8_H$	P	P	Kernel Reset	5399
QSPI6_MSSMUX	Multiple slave select register	$1BC_H$	P	P	Kernel Reset	5400

30.8.4.10 Register overview - QSPI7 (ascending offset address)

Table 1254 Register overview - QSPI7 (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
QSPI7_CLC	Clock control register	000_H	P	P, SV, E	Application Reset	5364
QSPI7_OCS	OCDS control and status register	004_H	P	SV, P	Debug Reset	5364
QSPI7_ID	Module identification register	008_H	P	BE	PowerOn Reset	5365
QSPI7_RST_CTRLA	Reset control register A	$00C_H$	P	P, SV, E	Application Reset	5366
QSPI7_RST_CTRLB	Reset control register B	010_H	P	P, SV, E	Application Reset	5366

30.8.4.11 Device specific registers

There are no device specific register changes.

30.8.5 TC4Dx QSPI connectivity

The table below lists interfaces to and from this functional block to other blocks in the device.

Table 1255 List of QSPI interface signals

Interface signals	I/O	Description
CLOCK_QSPI_fSPB	In	SPB clock input
CLOCK_QSPI_fQSPI	In	QSPI clock input (fQSPI is referred as fPER in QSPI chapter description)
FPI_QSPI_SIF	In	QSPI slave interface
QSPI0_IR_RX_INT	Out	QSPI0 Receive Service Request
QSPI1_IR_RX_INT	Out	QSPI1 Receive Service Request
QSPI2_IR_RX_INT	Out	QSPI2 Receive Service Request
QSPI3_IR_RX_INT	Out	QSPI3 Receive Service Request
QSPI4_IR_RX_INT	Out	QSPI4 Receive Service Request
QSPI5_IR_RX_INT	Out	QSPI5 Receive Service Request
QSPI6_IR_RX_INT	Out	QSPI6 Receive Service Request
QSPI7_IR_RX_INT	Out	QSPI7 Receive Service Request
QSPI0_IR_TX_INT	Out	QSPI0 Transmit Service Request
QSPI1_IR_TX_INT	Out	QSPI1 Transmit Service Request
QSPI2_IR_TX_INT	Out	QSPI2 Transmit Service Request
QSPI3_IR_TX_INT	Out	QSPI3 Transmit Service Request
QSPI4_IR_TX_INT	Out	QSPI4 Transmit Service Request
QSPI5_IR_TX_INT	Out	QSPI5 Transmit Service Request
QSPI6_IR_TX_INT	Out	QSPI6 Transmit Service Request
QSPI7_IR_TX_INT	Out	QSPI7 Transmit Service Request
QSPI0_IR_ERR_INT	Out	QSPI0 Error Service Request
QSPI1_IR_ERR_INT	Out	QSPI1 Error Service Request
QSPI2_IR_ERR_INT	Out	QSPI2 Error Service Request
QSPI3_IR_ERR_INT	Out	QSPI3 Error Service Request
QSPI4_IR_ERR_INT	Out	QSPI4 Error Service Request
QSPI5_IR_ERR_INT	Out	QSPI5 Error Service Request
QSPI6_IR_ERR_INT	Out	QSPI6 Error Service Request
QSPI7_IR_ERR_INT	Out	QSPI7 Error Service Request
QSPI0_IR_PT_INT	Out	QSPI0 Phase Transition Service Request

(table continues...)

Table 1255 (continued) List of QSPI interface signals

Interface signals	I/O	Description
QSPI1_IR_PT_INT	Out	QSPI1 Phase Transition Service Request
QSPI2_IR_PT_INT	Out	QSPI2 Phase Transition Service Request
QSPI3_IR_PT_INT	Out	QSPI3 Phase Transition Service Request
QSPI4_IR_PT_INT	Out	QSPI4 Phase Transition Service Request
QSPI5_IR_PT_INT	Out	QSPI5 Phase Transition Service Request
QSPI6_IR_PT_INT	Out	QSPI6 Phase Transition Service Request
QSPI7_IR_PT_INT	Out	QSPI7 Phase Transition Service Request
QSPI0_IR_U_INT	Out	QSPI0 User Defined Service Request
QSPI1_IR_U_INT	Out	QSPI1 User Defined Service Request
QSPI2_IR_U_INT	Out	QSPI2 User Defined Service Request
QSPI3_IR_U_INT	Out	QSPI3 User Defined Service Request
QSPI4_IR_U_INT	Out	QSPI4 User Defined Service Request
QSPI5_IR_U_INT	Out	QSPI5 User Defined Service Request
QSPI6_IR_U_INT	Out	QSPI6 User Defined Service Request
QSPI7_IR_U_INT	Out	QSPI7 User Defined Service Request
EGTM_QSPI0_TRIG	In	eGTM Trigger Input
EGTM_QSPI1_TRIG	In	eGTM Trigger Input
EGTM_QSPI2_TRIG	In	eGTM Trigger Input

30.8.6 TC4Dx QSPI revision history

Initial release of the chapter.

31 Inter-Integrated Circuit (I2C)

The I2C module is a functional block that offers communication functionality according to the I2C-bus specification version 2.1. I2C is either connected to the SPB bus or the COMPB bus with a slave interface including a set of special function registers (SFRs). The bus interface used by the I2C module is defined in the device specific chapter.

31.1 Feature list

- Compatible with I2C-bus specification version 2.1
- Master mode supported
- Multi-master mode supported
- Slave mode supported
- Different speed ranges available for data transfer:
  - Standard mode up to 100 kbit/s (20 kbit/s - 100 kbit/s)
  - Fast mode up to 400 kbit/s (100 kbit/s - 400 kbit/s)
  - High-speed mode up to 3.4 Mbit/s (500 kbit/s - 3.4 Mbit/s)
- 7-bit and 10-bit I2C-bus addressing supported
- Automatic execution of low-level tasks such as:
  - (De)Serialization of the bus data
  - Generation or detection of start and stop signal
  - Generation or detection of acknowledge signal
  - Bus state detection
  - Bus access arbitration in multi-master mode
  - Recognition of device address in slave mode
  - Configurable detection of general call address
  - Configurable repeated start in master mode
- Flexible clock and timing control:
  - Prescaler for I2C kernel clock (from 0 to 255)
  - Bit rate generation through fractional divider
  - I2C-bus signal timing adjustment
- FIFO for buffering data from or to CPU with following features:
  - 8 FIFO stages based on 32-bit width
  - Configurable data alignment (byte, half word, word)
  - Configurable sizes for burst, transmit and receive package
  - FIFO usable as flow controller (seamless DMA flow)
- Advanced interrupt handling:
  - 4 data transfer interrupt requests (burst, last burst, single, last single) resulting in one single data transfer interrupt
  - Protocol interrupt with 7 sources (address match, general call, master code, arbitration lost, not-acknowledge received, transmission end, receive mode)
  - Error interrupt with 4 sources (overflow or underflow of FIFO for transmit or receive)
- Pretended Networking:
  - High-speed mode, fast mode and standard mode work with the system clock frequency f_{I2C}. that can reach a minimum of 5 MHz

31.2 Functional overview

The I2C module communicates with the external world through a pair of I/O lines. A serial data line (SDA) and a serial clock line (SCL) carry the information between the devices.

The SDA and SCL are connected to a positive supply voltage through pull-up resistors. In quiescent state, when the bus is free, both lines are high. During communication the lines are alternatively pulled to low. The output stages of devices connected to the bus must have an open-drain (CMOS) or open-collector (bipolar) to perform a wired-AND function.

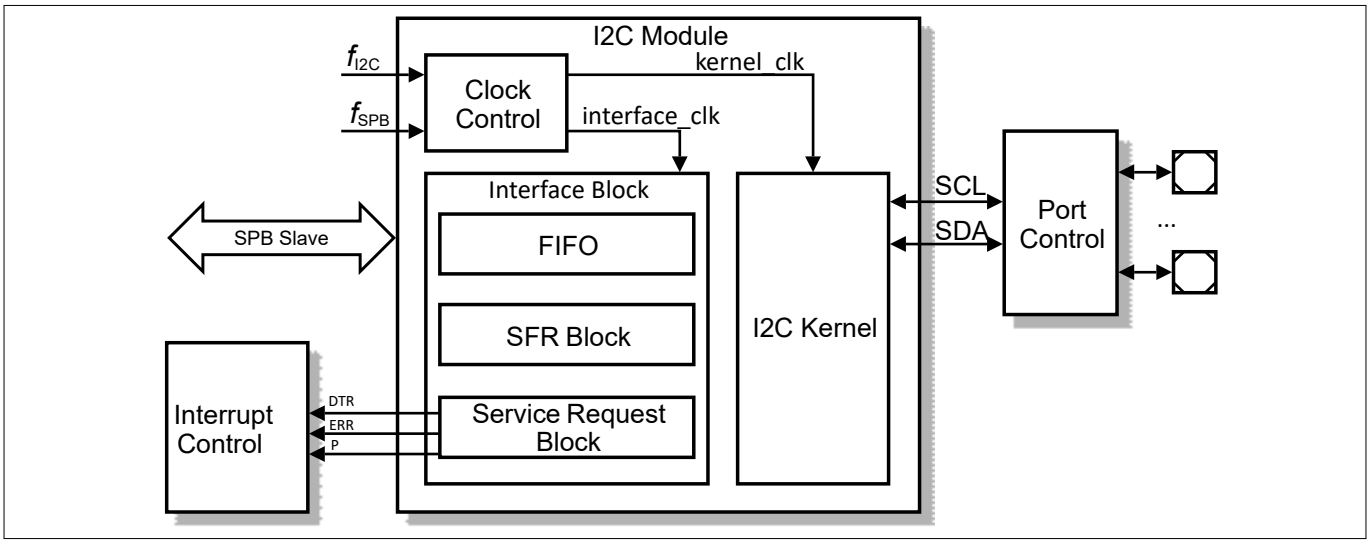

Figure 707 I2C block diagram

The I2C protocol was developed to provide a simple and efficient data transfer between multiple devices over a short distance. It uses a bidirectional serial bus with two wires.

The device can work as master or as slave. The master initiates the transfer, generates the clock pulses, and terminates the transfer; it addresses a slave through a 7-bit or 10-bit address. Data can flow in either direction. In many applications there is only one master, typically a single-chip microcontroller, which communicates with several slaves, for example general purpose peripherals or application specific circuits. However multi-master systems with arbitration and collision detection are also possible.

Data on the I2C-bus can be transferred at rates of up to 100 kbit/s in standard mode, up to 400 kbit/s in fast mode, and up to 3.4 Mbit/s in high-speed mode. A slow slave may stretch the clock period. The number of devices connected to the same I2C-bus is limited by a maximum bus capacitance of 400 pF.

The module relieves the CPU from many time-critical tasks.

The clock for the kernel of the I2C module is derived from the system clock through a pre-scaler. An additional fractional divider generates the desired bit rate. The exact timing of the I2C-bus signals can be adjusted.

A FIFO is used for data transfer between the CPU and the I2C module during transmission and reception. This allows writing and reading of multiple bytes. Data alignment and data sizes can be configured.

Six separate interrupt requests are available: for filling or emptying the FIFO, for reacting on certain protocol events, and for handling errors.

31.3 Functional description

This section gives a description of the kernel, module implementation, and module integration.

31.3.1 I2C kernel description

Functional description of the I2C kernel.

31.3.1.1 I2C protocol

Data is transmitted bit-by-bit on line SDA in conjunction with the clock on line SCL. To start communication, a master device generates a so called start condition. Subsequently data transfer starts. Therefore the data on the SDA line must be stable during the high period of the clock and may only change during SCL low phase. After all data have been transferred, the master closes transmission with a stop condition (see the figure below).

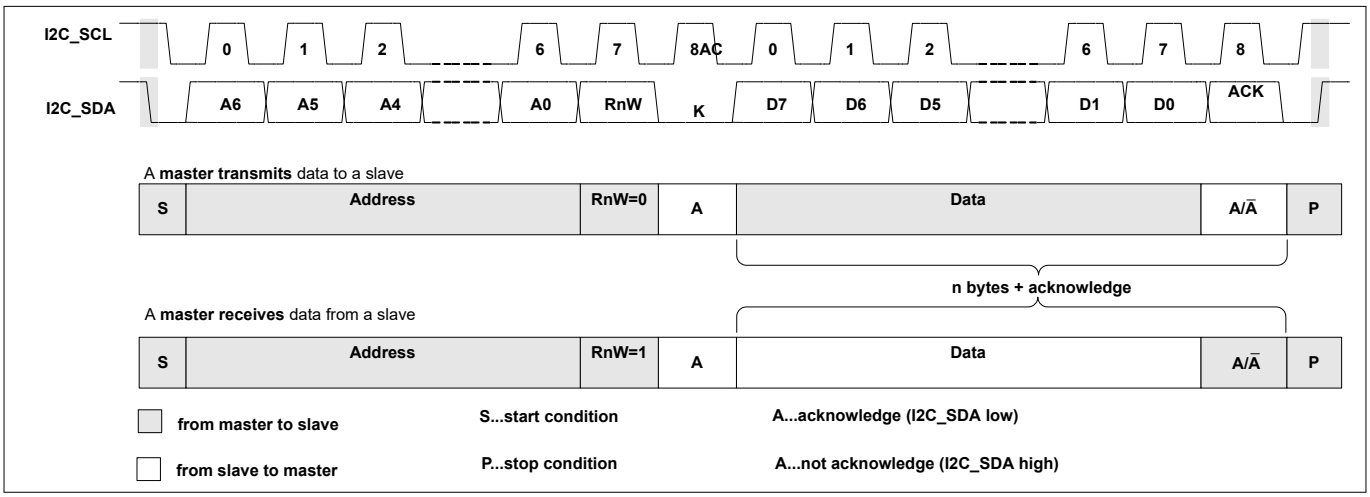

Figure 708 A complete I2C data transfer

Start, restart and stop conditions

A start condition is indicated by a high to low transition on line SDA while SCL remains high, a stop condition is defined by low to high transition under the same condition of high level on line SCL. The bus is considered to be busy after a start condition and to be free again after a stop condition. To allow continuous data transmission or reception without first generating a stop condition, a third condition has been introduced - the restart condition. The bus stays busy if this condition is generated and the same or another slave can be addressed. Start and restart condition are functionally identical.

Address transmission

After the start condition a slave address is sent. Normally, the address is 7 bits long followed by an 8th bit that is a data direction bit (Read/not Write see the figure below). A zero indicates a transmission (write operation); a one indicates a request to data (read operation). Following the address transmission the addressed device responds with an acknowledge (low on line SDA). If no acknowledge is returned, the master can then generate either a stop condition to abort the transfer or a repeated start condition to start another new transfer.

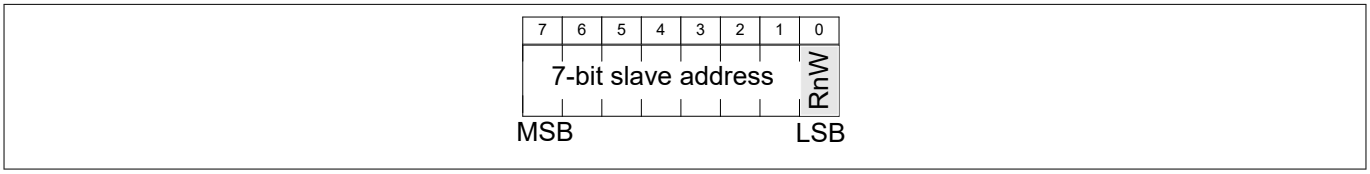

Figure 709 Address byte composition

Two groups of eight addresses (0000 XXX and 1111 XXX) are reserved for purposes, as shown in the table below . For example the bit combination “11110XX” is reserved for 10-bit addressing mode.

Table 1256 Reserved I2C-bus addresses

Address	RnW	Description
0000000	0	General call address
0000000	1	Start byte - no device is allowed to acknowledge
0000001	x	CBUS address - I2C-bus devices may not respond
0000010	x	Reserved for different bus format
0000011	x	Reserved for future use
00001XX	x	High-speed mode master code
11111XX	x	Reserved for future use
11110XX	x	10-bit slave addressing mode

General call

A general call is characterized by transmission of address “0000000” and RnW bit = 0. It is used for addressing every device connected to the I2C-bus. However, if a device does not need any of the data supplied within the general call structure, it can ignore this address by not issuing an acknowledgment. Otherwise it acknowledges this general call and the following data bytes (if required) and behaves like a slave-receiver. The received data (for example programmable part of slave address, address of I2C-bus master) has to be handled by software.

Data transmission

Each byte transferred over the I2C-bus has to be 8 bits long whereby the number of bytes transmitted per transfer is unrestricted. Bytes are transferred MSB (Most Significant Bit) first. If the slave cannot receive or transmit a data byte until it has performed another function, it can hold the clock line SCL low (wired AND connection) to force the master into a wait state. Data transfer continues when the slave releases the clock line.

Acknowledge

Each transferred respectively received byte has to be followed by an acknowledge bit that is set by the recipient (master or slave depending on the transmission direction) onto the data line SDA. The acknowledge-related clock pulse is generated by the master. The device that has to set the acknowledge bit must pull down the SDA line during the acknowledge clock pulse so that it remains stable low during the high period of this clock pulse. Therefore in case of a slave the clock line may be held low until an acknowledge is released.

When the recipient of data does not acknowledge the data, for example because it was unable to receive the data or to transmit any data, the data line must be left high. A master-receiver that does not acknowledge the data from a transmitting slave device thereby tells the slave to stop transmission. The master then generates a stop condition to abort transfer or a repeated start condition to continue.

Clock synchronization

To transfer messages a master generates its own clock on the SCL line. Data is only valid during the high period of the clock. Therefore data on line SDA has to be stable during this period and may only be changed during the low period of clock.

Two special cases must be considered. First, slave devices (or master devices operating as slaves) never generate clocks but are permitted to delay them. According to the following figure, if device 1 as master device for example sets line SCL to low, device 2 as slave device may extend the low phase by setting its SCL output to low. A device such as a microcontroller with limited hardware for the I2C-bus can thereby slow down the bus clock and adapt the master to the internal operating rate of this device.

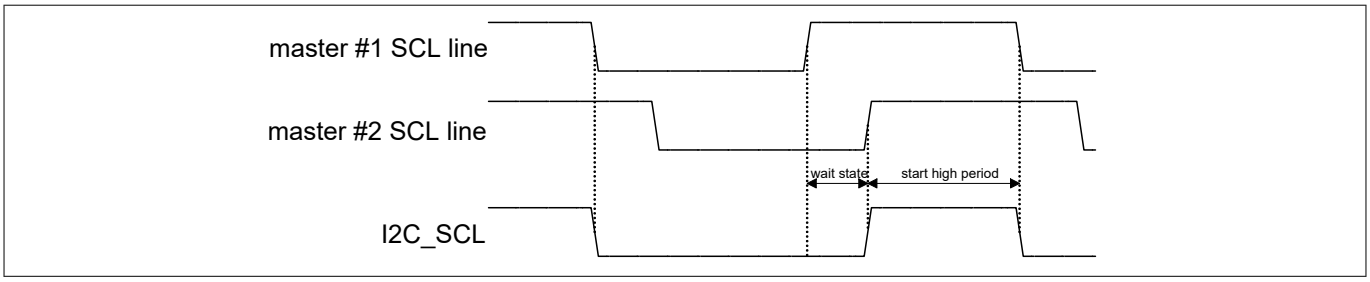

Figure 710 Clock synchronization

Second, if several master devices access the I2C-bus at the same time, the SCL line is influenced by more than one device. As shown in the previous example, the SCL line will be held low by the device with the longest SCL low period. Devices with shorter periods enter a wait state during this time. In this way a synchronized SCL clock is generated.

Arbitration

To allow multi-master mode operation, bus arbitration is required. A master may start a transfer only if the bus is free. Two or more masters may generate a defined start condition simultaneously within a minimum hold time.

Arbitration takes place on the SDA line while SCL line is high, when one master transmits a high level while another master transmits a low level. Because of the wired AND functionality, the low level dominates the high level. As result the device that was trying to transmit a high level recognizes a different level on the SDA line and switches off its SDA and SCL output (see the figure below).

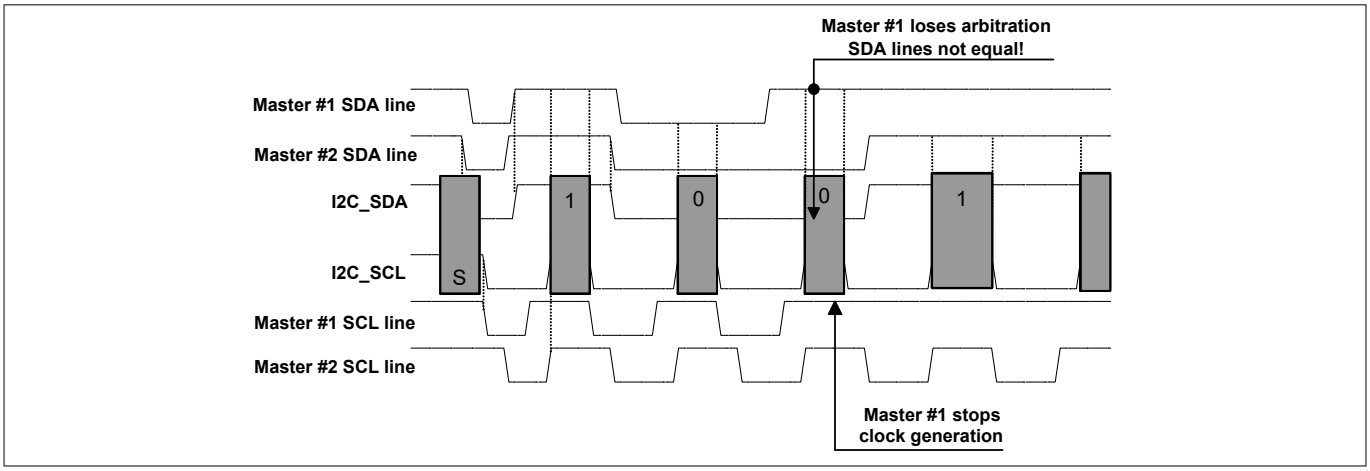

Figure 711 Example of an arbitration procedure

Arbitration may occur in different stages of transmission. A different level may potentially first appear during comparison of the address bits. If each of the masters are trying to address the same device, arbitration continues with comparison of the RnW bit and subsequent data bits (if the masters are transmitting) or acknowledge bits (if the masters are receiving). Because information on the I2C-bus is determined by the winning master, no information is lost during the arbitration process. Since control of the I2C-bus is decided only by comparison of the data transmission stream over line SDA, there is no central master or any order of priority on the bus.

I2C-bus formats

With the described rule types the formats shown in the following figure are possible.

- Master-transmitter transmits to slave-receiver and stops after not-acknowledge

- Master reads slave immediately after transmission of the RnW bit (high level) and the acknowledge from the slave, whereas the master becomes master-receiver and the slave becomes slave-transmitter
- In combined format the regular sequences described above are handled, except for the repeated start condition instead of the stop condition between two sequences

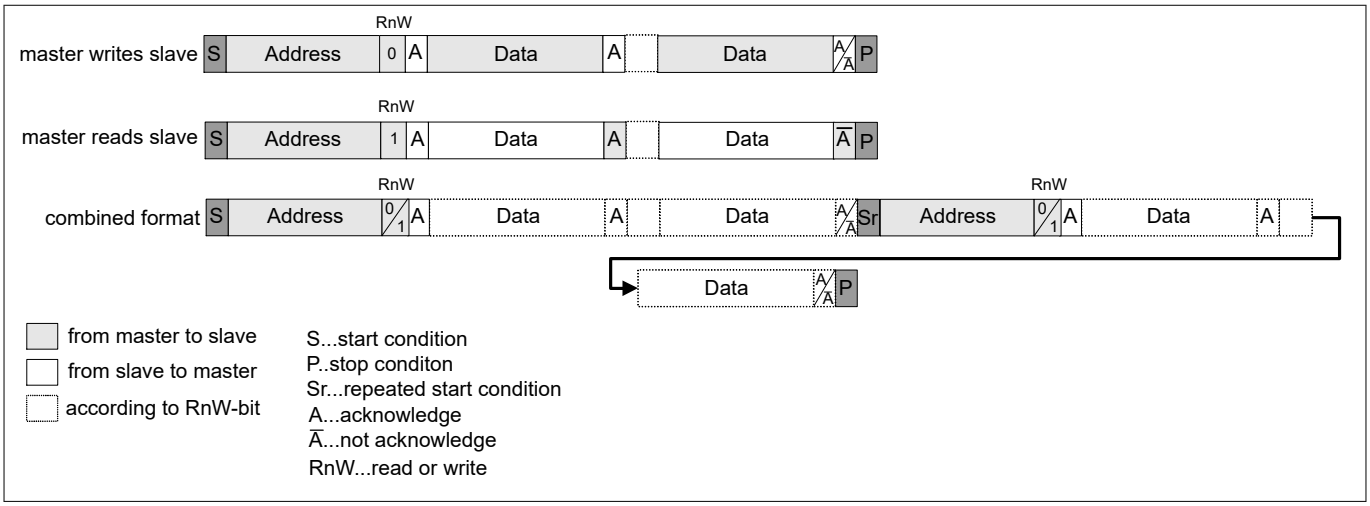

Figure 712 Types of I2C-bus formats

10-bit addressing mode

The I2C address area is to 112 applicable addresses with the 7-bit address mechanism describedabove. It tu rned out, that more combinations were required to prevent problems with the allocation of slaveaddresses for new devices. This problem was resolved with the 10-bit addressing scheme that is compatiblewith 7-bit addressing. Both modes may be used simultaneously.

To use 10 bits for addressing, the preamble address “11110XX” with RnW bit = 0 has to be used, including the two most significant bits “XX” of the 10-bit address, followed by an acknowledge from at least one 10-bit address matching slave and the second address byte containing the eight least significant bits. Only the (combined) 10-bit address matching slave now acknowledges. Data packages may now be transmitted to the addressed slave until stop condition or restart condition. If the master needs to read the slave, a combined format with a restart condition is necessary to

- First transmit the 10-bit address (first data package after preamble address contains second address byte, RnW bit is 0) after the restart condition
- Receive the requested data packages. Note that after the restart condition the preamble address “11110XX” has to be sent one more time, now with RnW bit = 1; the matching slave remembers that it was addressed before (see the following figure). In case of a non matching preamble address, a not-acknowledge is returned

The slave remains active as slave-transceiver until a stop condition or a restart condition occurs. According to the value of the following RnW bit a new slave may be addressed or the same slave is requested to transmit more data. Additionally the following combined formats (and mixtures of these formats) are allowed:

- A master transmits data to a slave and then reads back data from the same slave. The transfer direction is changed after the restart condition
- A master transmits data to one slave and then transmits data to another slave
- 10-bit and 7-bit addressing combined in one serial transfer. After restart condition the new addressing mode is selected by the address itself

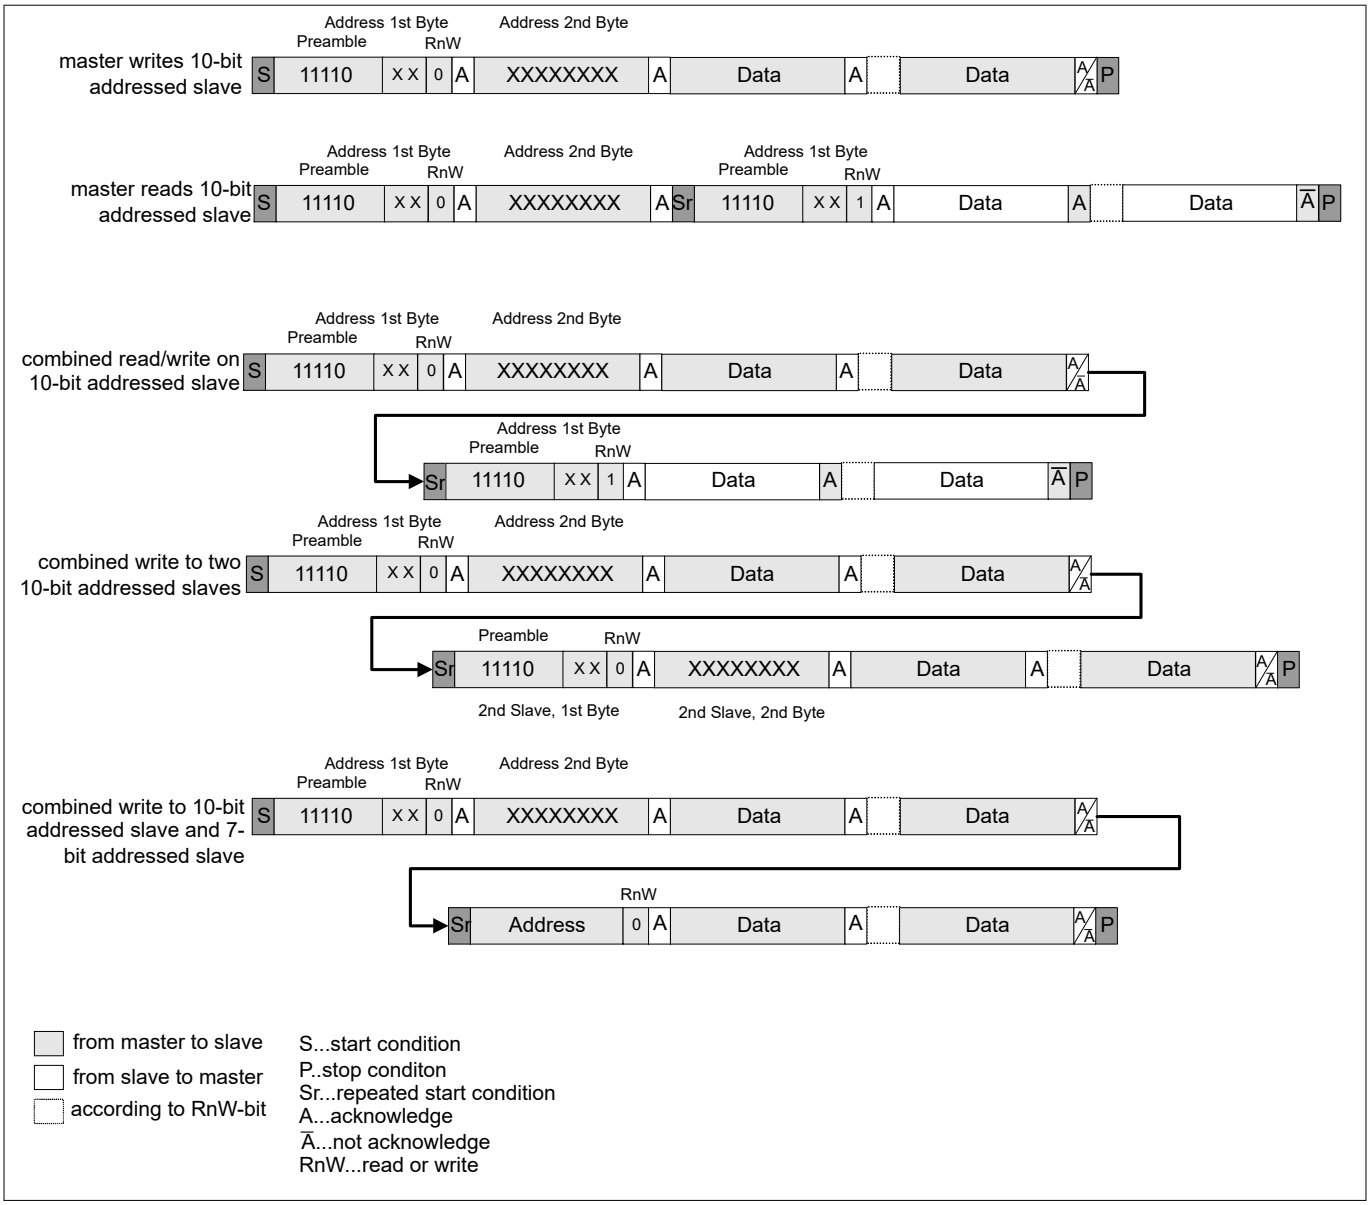

Figure 713 Types of I2C-bus 10-bit address formats

High-speed mode

To support higher baud rates on the I2C-bus (up to 3.4 MBaud) the specification introduces the high-speed mode. To communicate at this higher baud rate the protocol uses a so called master code in place of the address byte to indicate that a master wants to change to the high-speed mode.

Special attention must be paid to meet the requirements of rise and fall times of the signal edges and other timing characteristics when working in high-speed mode. Also it is necessary to disconnect I2C-bus devices which are not able to follow the fast communication.

After the master sends this master code, no device is allowed to acknowledge it. The involved devices change to high-speed mode and the master starts the communication. The high-speed mode transmission behavior is the same as at lower baud rates with the exception that only restart conditions and stop conditions appear (no start condition). Since the master code determines a unique master device to control the bus, the arbitration process is finished after the master code sequence is put on the bus and must not be continued when working at the new communication speed.

Improvements to the regular I2C-bus specification for high-speed mode are given in section 13.1 of the I2C-bus specification version 2.1.

For high-speed mode there exists a separate configuration register FDIVHIGHCFG to program the baud rate. .

31.3.1.2 Functional restrictions

There are some functional restrictions in this I2C module.

Multi-master mode - master collision

The Multi-master mode is supported with a limitation or restriction in the following situation:

- The I2C module operates in master mode
- Another master wants to access or address the I2C module as slave

The resulting "master collision (problem)" cannot be handled correctly because the incoming address sent by the other master cannot be evaluated. So, if collision occurs second master has to restart access and retransmit the data.

Multi-master mode - hold time for the (repeated) start condition

In the above special situation, this design step of the I2C module violates the timing specification by ~30% for Standard mode and by ~18.6% for Fast mode (minimum 2.8 µs instead 4.0 µs for Standard mode and minimum 0.488 µs instead 0.6 µs for Fast mode). This occurs when data is written into TX FIFO, the I2C module is ready to start transmission and another master starts driving its startbit shortly before the I2C module starts driving. In this case the I2C Finite State Machine tries to win arbitration by reloading approximately half period in baud rate generator, so next SCL clock edge of the I2C module comes earlier than defined by t_7 (refer to datasheet for definition of t_7).

High-speed mode

The standard for the clock duty cycle ratio of the I2C high speed mode is 1:2. See Clocking and timing control in order to achieve the best duty cycle ratio for high speed mode. Note that not for every f_{I2C} frequencies 0% duty cycle ratio deviation can be achieved.

Related information

Clock and timing control on page 5439

31.3.1.3 Clock and timing control

The I2C module offers the following features to control clock and timing:

- Module clock control for integration logic clock and I2C kernel clock
- Baud rate generation
- I2C signal timing adjustment

31.3.1.3.1 Baud rate generation for master mode

A baud rate generation unit in the I2C kernel generates the SCL signal from the kernel_clk, controlled by the settings of parameters FDIVCFG.INC , FDIVCFG.DEC , and TIMCFG.FS_SCL_LOW in registers FDIVCFG for normal and fast mode, FDIVHIGHCFG in high-speed mode, and TIMCFG.

The I2C standard has some special requirements for the clock, such as:

- Asymmetric duty cycle
- Slave or other masters are allowed to delay the clock by extending the low period. For this reason, a master must check if any slave holds the clock line low after the master set the clock line to high. This implies that the state machine of a master needs at least 1 internal clock cycle delay between setting the clock

to high and reading it back to check if it reached high level already. In addition, more delay cycles can be introduced by the time constant of the pull up resistor and the line capacity. In any case, this protocol has the consequence that the actual baud rate will always be lower than the nominal baud rate

Table 1257 I2C baud rate generation configuration for master mode

Mode	EN_SCL_LOW_LEN	FS_SCL_LOW	f_{SCL}	Low time correction	Duty cycle
Standard	0	0	$fSCL = \frac{INC}{2DEC + 3INC} \times fI2C$	-	-
Fast	0	1		-	-
	1	X		1) $SCL_LOW_LEN = \frac{3INC}{2}$	-
High speed	X	X	$fSCL = \frac{INC}{5DEC + 2INC} \times fI2C$	-	1:2

1) This formula can be use to achieve a 50% duty cycle.TIMCFG.SCL_LOW_LEN can be program with other values, but not greater than FDIVCFG.DEC .

TIMCFG.EN_SCL_LOW_LEN, TIMCFG.FS_SCL_LOW and TIMCFG.SCL_LOW_LEN used in the above table are bit-fields in register TIMCFG .

In Table 1258 some example settings to program FDIVCFG.INC , FDIVCFG.DEC and LTC (bit-field TIMCFG.SCL_LOW_LEN) are given and information about the duty cycle is shown.

Table 1258 I2C INC and DEC settings for master mode

I2C mode	f_{I2C} [MHz]	INC	DEC	SCL_LOW_LEN	Duty cycle [%]	f_{SCL} [MHz]
Standard	66.6	1	332	-	56.3	0.099
Fast	66.6	2	170	3	50	0.384
High speed	66.6	46	162	-	30.6	3.399

If a slave device is sensitive for violation of maximum frequency according I2C standard (for example 3.4 MHz in high-speed mode) it is recommended to select a target SCL frequency with some margin to this limit.

31.3.1.3.2 Baud rate generation for slave mode

Baud rate generation is mainly used for master mode, but there is one corner case where a support of the baud rate generation is required in slave mode: when I2C is in slave mode with a pending transmit data request and FIFO is currently empty then SCL is kept low until FIFO is filled after some time. Then transmit data is sent out immediately. SCL is kept low for a minimum time of t_4 as shown in the table below .

In order to keep the set-up time, t_4 , according to the I2C standard, the baud rate generation is used to guarantee the delay on SCL. The formulas in the 3rd and the 4th column of the following table shows how to configure FDIVCFG.DEC and FDIVCFG.INC for a given f_{I2C} and the intended set-up time. The formulas in column four define the real value of t_4 with the selected FDIVCFG.DEC and FDIVCFG.INC values.

It is not recommended to use the same value for FDIVCFG.DEC and FDIVCFG.INC as in master mode, and would lead to additional delay, as defined by the standard, in most cases.

Table 1259 I2C baud rate generation configuration for slave mode

MODE	min t_4[µs]	DEC, INC	Resulting t_4 [µs][1) 2)]
Standard	0.25	$\mathrm{DEC} = \frac{8}{9}((\mathrm{fI2C}) \times (t_4) \times \mathrm{INC} + \mathrm{INC})$	$C = \mathrm{INT}\left(\frac{\mathrm{DEC} + \mathrm{DEC(div)8}}{\mathrm{INC}} - 1\right)$ $\frac{C}{\mathrm{fI2C}} = t_4$
Fast	0.1	3) $\mathrm{DEC} = \frac{4}{5}((\mathrm{fI2C}) \times (t_4) \times \mathrm{INC} + \mathrm{INC})$	$C = \mathrm{INT}\left(\frac{\mathrm{DEC} + \mathrm{DEC(div)4}}{\mathrm{INC}} - 1\right)$ $\frac{C}{\mathrm{fI2C}} = t_4$
High speed	0.01	$\mathrm{DEC} = \mathrm{INC} + 1$	$C = \mathrm{INT}\left(\frac{\mathrm{DEC}}{\mathrm{INC}} + 1\right)$ $\frac{C}{\mathrm{fI2C}} = t_4$

1) The used abbreviation INT is the integer function.
2) The operator div denotes the integer division: a div b = greatest integer not greater than a divided by b.
3) SCL_LOW_LEN can not be greater than DEC.

In the following table some example settings are given to program FDIVCFG.INC and FDIVCFG.DEC. The used abbreviation INT is the integer function.

Table 1260 I2C INC and DEC settings for slave mode

I2C MODE	f_{I2C} [MHz]	INC	DEC	t_4 [ns]
Standard	66.6	20	314	250
Fast	66.6	25	160	105.1
High speed	66.6	250	251	30

The minimum kernel frequency is 8 MHz for standard and fast mode and 55 MHz for high speed mode.

31.3.1.3.3 I2C timing adjustment

The I2C standard includes a number of requirements for the SCL and the SDA timing. These cannot always be fulfilled by the timing of the pads. Therefore, additional timing adjustment options are provided in the controller logic.

Various timings of signals can be shifted by multiples of kernel_clk cycles, as defined in registerTIMCFG .

These settings offer a wide range of timing compensation. Not all of the values can be used and will result in a valid I2C timing, even clock or data hang-up is possible. Detailed analyses should be done - for example during chip evaluation - taking actual kernel_clk and external timing into account.

SDA_DEL_HD_DAT

- Delays SDA output data starting from SCL falling edge for a defined number of kernel_clks
- Must not exceed SCL low period to keep setup time for collision detection at next SCL rising edge

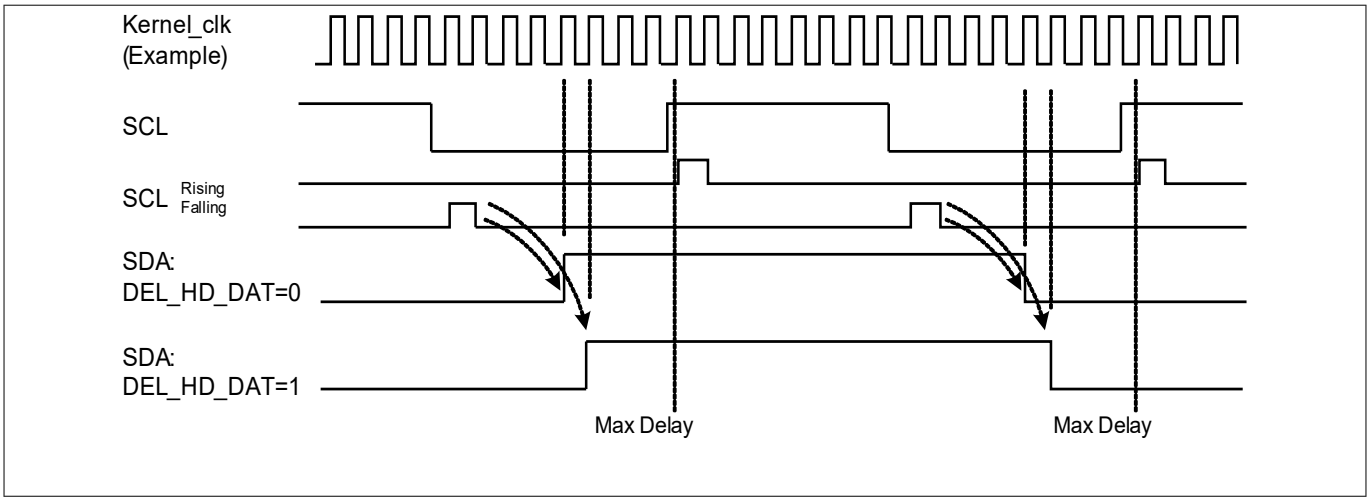

Figure 714 SDA_DEL_HD_DAT

High speed mode corrections

In the following figure, the base period and delay corrections are shown for the entering and stop phases of HS mode.

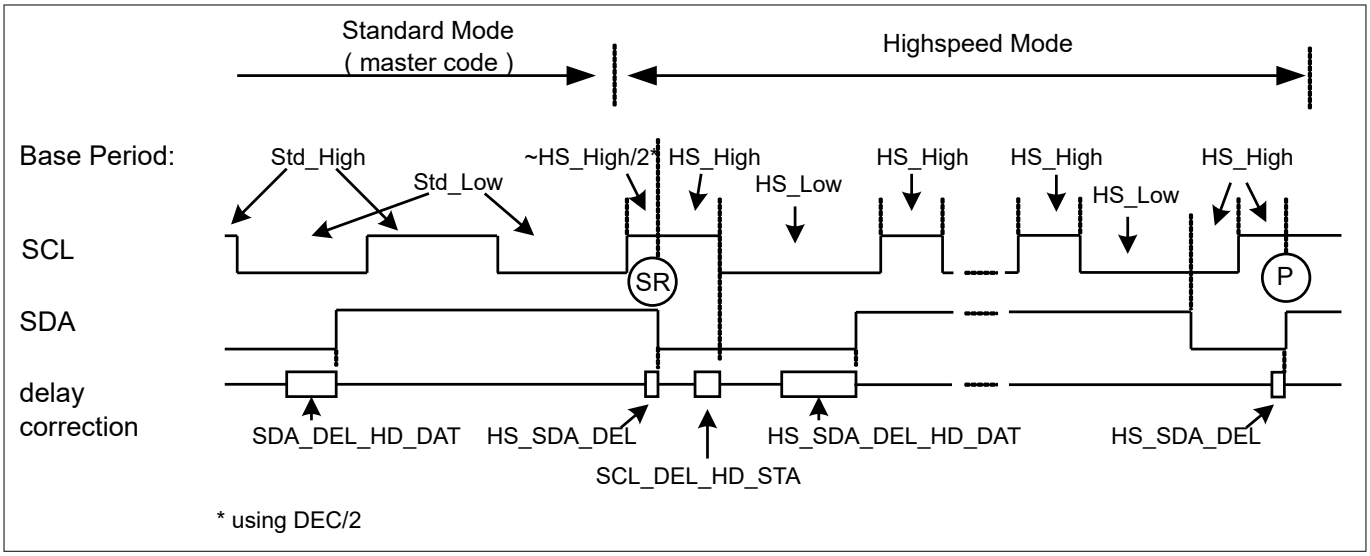

Figure 715 High speed mode corrections

31.3.1.4 I2C kernel control logic

The I2C kernel can work in four different modes:

- Master-transmitter
- Master-receiver
- Slave-transmitter
- Slave-receiver

A state machine description can give a good and fast overview of the functionality. Also nearly all possible conditions can be rebuilt by stepping through the state machine and most of the error handling is covered by it. So this method is used to describe the I2C kernel.

Beginning with the top-level state machine, the starting up procedure is covered and together with the slave process and the master process sub-state machines, the active operations are understood. These three state machines and their state transitions are described in the following sections.

As the I2C-bus working principle is packet orientated, the FIFO is typically configured as flow controller and so it issues the burst- and single-requests. This configuration is established by programming the bits FIFOCFG.RXFC and FIFOCFG.TXFC of the FIFOCFG register. Writing to the TXD register after writing to the TPSCTRL.TPS bit-field of register TPSCTRL starts the transfer.

***Notes**:*

1. *Peripheral is flow controller. The principle is as described before*

2. *Peripheral is not flow controller. In principle it is possible to use the FIFO in non flow controller mode. When the FIFO is not configured to operate as flow controller, the behavior of the FIFO operation has to be considered. The update of the FIFO fill level is only done when a stage is filled completely. In case of a (not protocol compliant) stopped transfer of the transmitter, the device is not able to evaluate the valid bytes since the FIFO issues interrupts and updates fill level only when a stage is filled completely. To prevent this behavior, the FIFO can be, for example, programmed to word alignment, so every received byte issues an interrupt and update. In any case the software has to take care of such upcoming not protocol compliant data transmission stops, and has to handle this for example by programming an appropriate time-out*

The top-level state machine

The following figure shows the top-level state machine. There are four states in the top-level state machine:

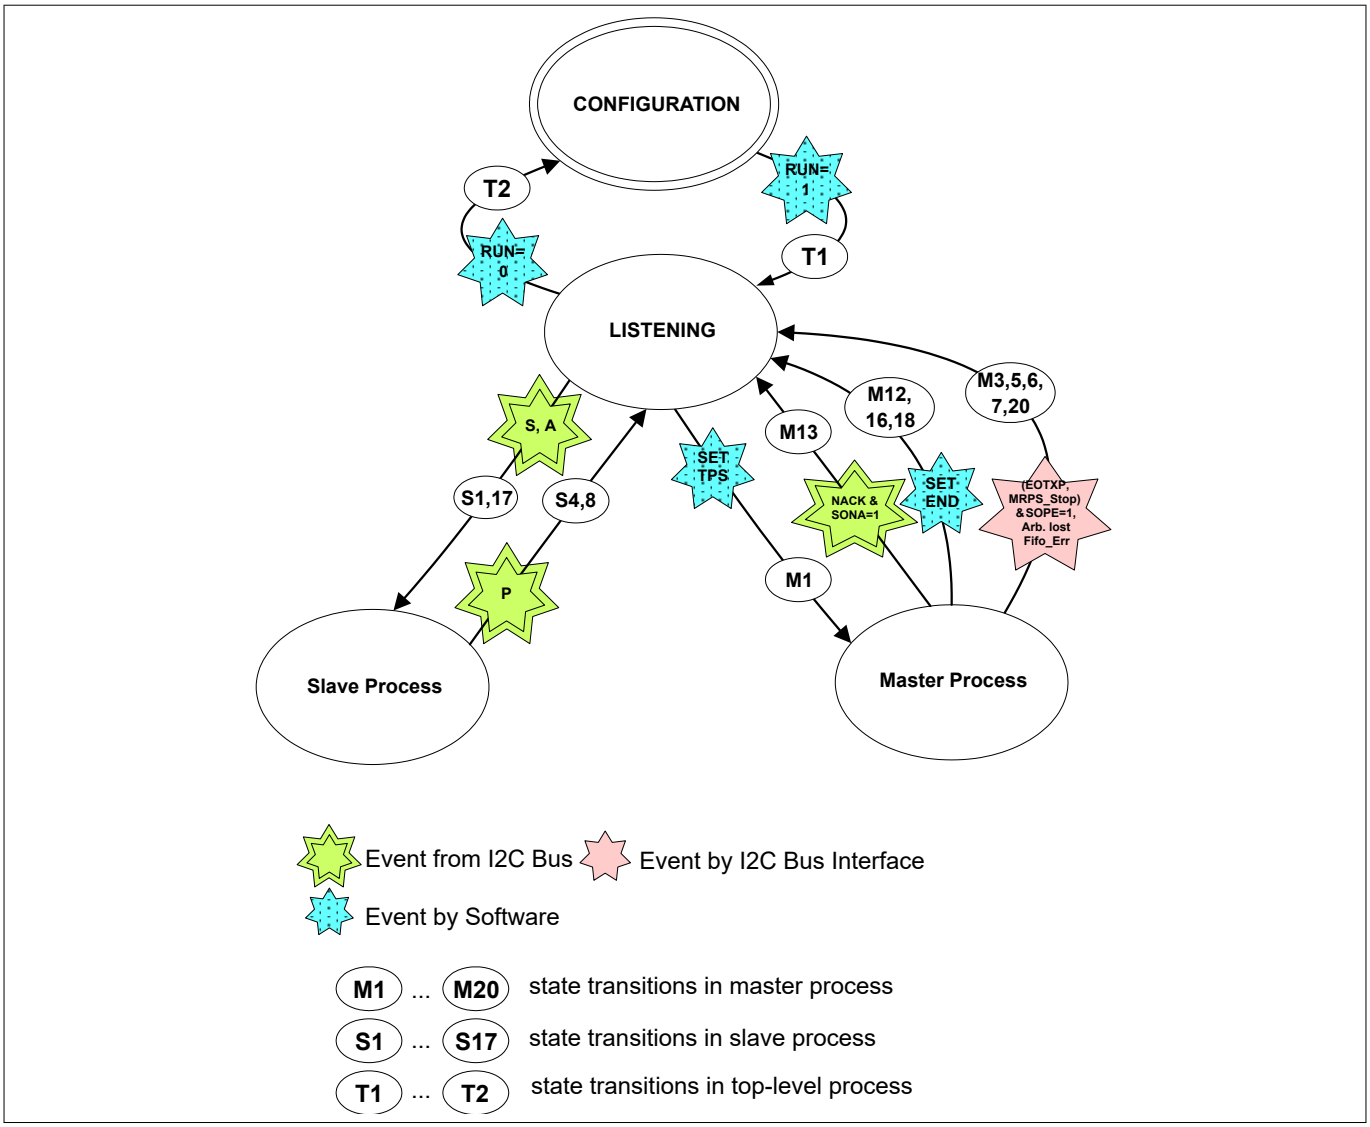

Figure 716 Top-level state machine

CONFIGURATION

The peripheral is inactive. This is indicated by the RUNCTRL.RUN bit in the RUNCTRL register, which is set to 0. In this state the peripheral should be configured by software by writing appropriate data words to the ADDRCFG, FDIVCFG, and FIFOCFG registers. This determines the following features:

- Peripheral is master or slave
- Address when accessed by another device
- Answering behavior to master calls and general calls
- Operating speed on the I2C-bus
- FIFO behavior

LISTENING

The peripheral has been activated by software. This state is entered in master and slave mode. The peripheral has to observe the bus for a certain time (one period of 1/100 kHz should be sufficient), which has to be programmed in software, to ensure that there is no running transmission on the bus after this state has been entered. If no transitions on the I2C-bus are detected during this time period, the bus is supposed to be free. Otherwise the bit-field BUSSTAT.BS (bus status) in register BUSSTAT is set to 01_B (bus busy). Further functionality depends on the configuration: If the peripheral is configured as slave, only the slave process can be entered. If the device works as master, slave and master processes can be entered.

SLAVE PROCESS

A Start condition has been detected. The device is waiting for commands from the I2C-bus. This state represents the operation when acting as slave-transmitter or slave-receiver and is itemized in an own sub state machine.

MASTER PROCESS

The device is able to control the bus and work either as master-receiver or master-transmitter. Before the master can control the bus it has to set its clock frequency by programming its fractional divider with the appropriate value by writing it to the FDIVCFG register (when the I2C-bus is also operating in high-speed mode the appropriate values for INC and DEC have to be written to FDIVHIGHCFG). The master process state is itemized in an own sub state machine.

The transition between the three states on the top-level are:

T1

The RUNCTRL.RUN bit has been set to 1 by software. The peripheral is activated and ready to observe the I2C-bus or react on transmission start commands.

T2

The RUNCTRL.RUN bit has been set to 0 again. This means that because of new configuration effort, the peripheral is switched back to CONFIGURATION mode.

Attention**:* ***When turning off the peripheral it must be assured that no I2C-bus control responsibility is owned by the interface. Therefore the shut off process has to change the peripheral into a "secure" state and free the I2C-bus if necessary (generate a stop condition if in master mode). There are signals provided by the interface block which can be used to guarantee a secure shut off when turning off the I2C kernel.

Slave process sub-state machine

The following figure shows the slave process sub-state machine. There are 5 plus 1 (the listening state belongs to master and slave) different states in this sub-state machine:

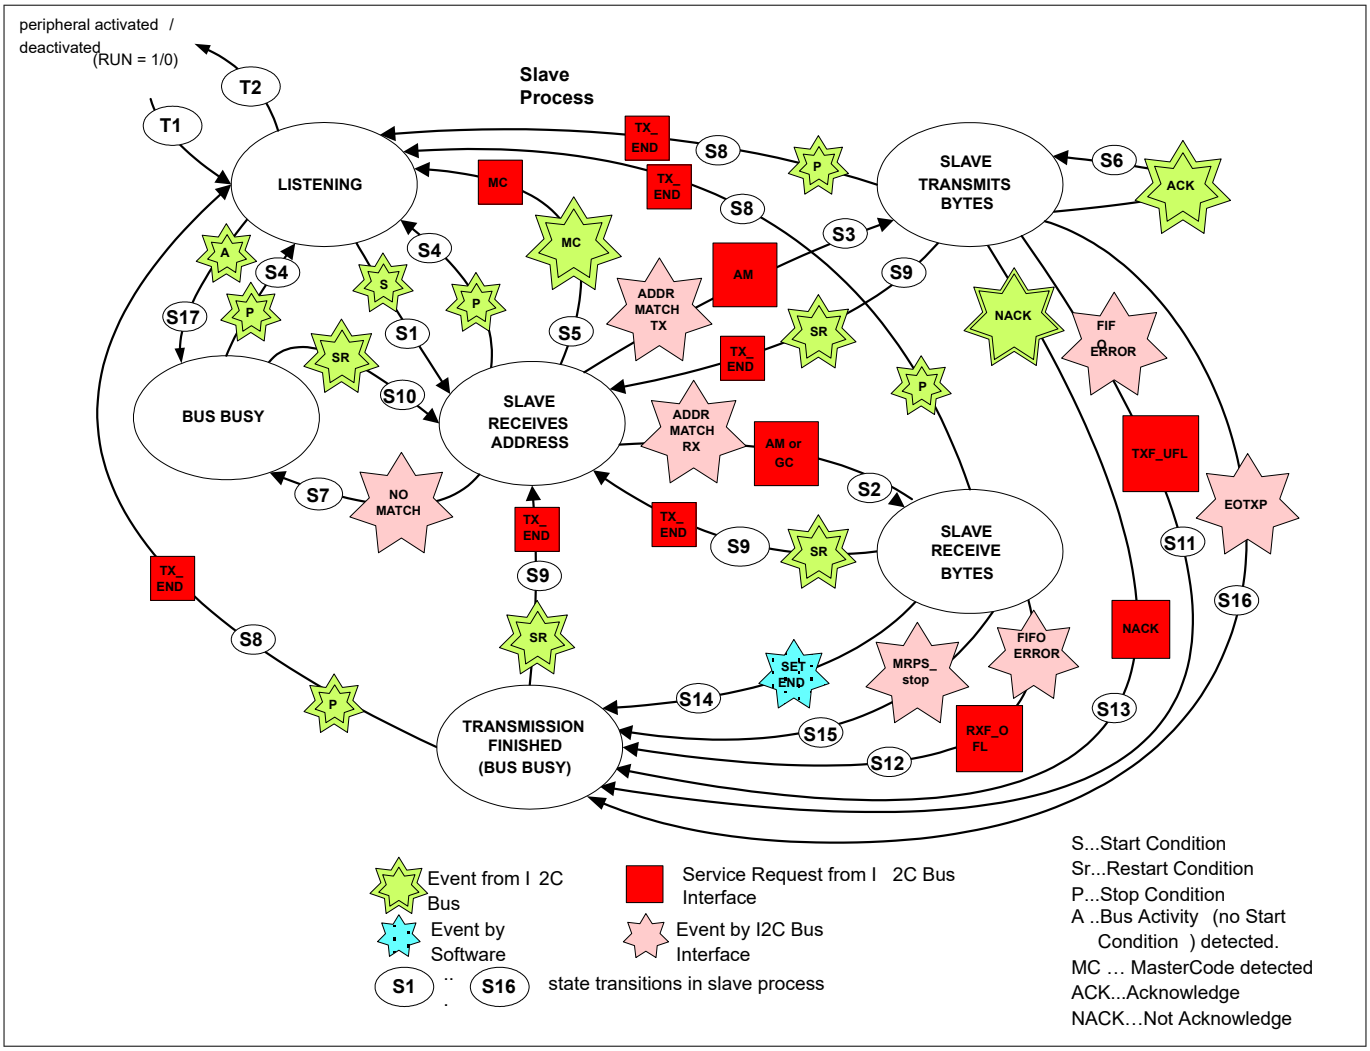

Figure 717 Slave process sub-state machine

LISTENING

This state has been previously described (in figure Top-level state machine). If the device is configured as slave, the module is listening only to the bus activity.

SLAVE RECEIVES ADDRESS

The module is shifting in the serial bits from the I2C-bus and acknowledges if the received byte(s) (first one in 7-bit address mode, first and second one in 10-bit address mode) match the adjusted address. During address matching the slave-receiver has the possibility to slow down the master clock by holding the SCL line low after each bit, since this can be used as a bit-by-bit handshake procedure.

***Note**: The address byte(s) is (are) not shifted into the FIFO.*

SLAVE RECEIVES BYTES

The module is shifting in the serial bits from the I2C-bus and acknowledges when the whole data byte has been transported to the FIFO. The slave-receiver has the possibility to slow down the master clock by holding the SCL line low after each bit since this can be used as a bit-by-bit handshake procedure.

SLAVE TRANSMITS BYTES

The slave is allowed to hold down the SCL line when preparing the data for transmission. When valid data is available the slave releases the SCL line and waits for the clock cycles from the master. The interrupt routine which proceeds when entering this state may write to the TPSCTRL register to initiate a transmission. This is only allowed if the bit-field BUSSTAT.BS (bus status) in register BUSSTAT

in combination with the BUSSTAT.RnW clearly identifies the slave-transmitter mode of the peripheral. Otherwise writing to this register has no effect. First the I2C kernel gets a byte from the FIFO and puts it into a shift register. The module is then putting single data bits onto the I2C-bus and releases the SDA line after the 8th bit is sent.

***Note**: Since the data flow control responsibility is task of the master device the slave should not stop transmitting bytes until the master tells it to do so. Therefore the TPSCTRL.TPS value in register TPSCTRL should be large enough to not run out of data bytes. In case of running out of data, the TRANSMISSION FINISHED state is reentered. The I2C data line is released to high level. The master continues receiving wrong values (0xFF).*

BUS BUSY

The bus is busy and the module is not involved in any data transfer. This is also the entry state when the bus is not free when starting up procedure is taking place (see state S17).

TRANSMISSION FINISHED (BUS BUSY)

The module was involved in any data transfer. In distinction to the BUS BUSY state, the slave is still addressed by a master. Every time this state is left, caused due to a stop/restart condition, a TX_END request is generated as indication that the previous transmission has been closed.

The transitions which are connecting the several states are in detail:

S1

The module is detecting a start condition on the bus. It has to set the bit-field BUSSTAT.BS (bus status)to 01_B. When this situation is occurring the I2C kernel is initialized since this indicates a new data transmission.

S2

The address which has been received matches the one stored in the address field of register ADDRCFG. The BUSSTAT.RnW bit (8th bit in the first received byte) was set to 0. This means that the master wants to write to the slave. The corresponding bit BUSSTAT.RnW is set to 1, that is the device continues working as slave-receiver. Also an acknowledge has to be set on the I2C-bus in the appropriate place (9th clock cycle). The I2C kernel sets the bit-field BUSSTAT.BS (bus status) to 11_B and generates an AM (address match) request.

If the general call (GC) address matching is enabled by setting bit ADDRCFG.GCE , the device has to react also when it receives a general call (0x00). The GC request is issued and also an acknowledge has to be set on the I2C-bus when the GC is detected.

S3

The address which has been received matches the one stored in the address field in the ADDRCFG register and the SDA line was at a high level when the BUSSTAT.RnW bit was sent. This means that the remote master wants to read from the slave. The corresponding bit BUSSTAT.RnW has to be set to 0 (write). Also an acknowledge has to be set on the I2C-bus in the appropriate place (9th clock cycle). The I2C kernel sets the bit-field BUSSTAT.BS (bus status) to 11_B and generates an AM (address match) request. The device is now working as a slave-transmitter.

S4

The device detects a stop condition on the I2C-bus and switches back to SLAVE LISTENING state. No interrupt is generated after the device was not addressed. The bit-field BUSSTAT.BS (bus status) is set to 00_B (bus free).

S5

If the device is configured through bit MCE (master code enable) in the ADDRCFG register to react on a master code, the device can change baud rate to high-speed (Hs) mode when a remote master sends a master code. No device is allowed to acknowledge this master call. The interrupt routine which is called (MC request issued), has to handle the clearing of the interrupt bit in register PIRQSC. The LISTENING state is reentered. From now on the device works as slave in high-speed mode until a stop condition occurs.

S6

The slave-transmitter has received an acknowledge from the master-receiver and continues transmission.

S7

After the reception of the address bytes has been finished and no address match has taken place, the device changes to BUS BUSY state.

S8

The device has detected a stop condition on the I2C-bus after/while it was addressed. A TX_END (transmission end) request is generated, the bus is free again respectively the bit-field BS (bus status) in register BUSSTAT has to be set to 00_B again. The slave is now in LISTENING state.

S9

The slave has received a restart condition (repeated start condition) after/while it was addressed. A TX_END (transmission end) request is generated, the state switches back to SLAVE RECEIVES ADDRESS. The slave is reset again to a new transmission pending state (bit-field BS in register BUSSTAT = 01_B.). When the TBAM is activated (configuration register) the slave has to remember that it was addressed before because this event may be followed by a read access of the master to this device. So the address procedure after reset can be shortened and the transition S3 occurs one byte earlier (master sends 10-bit address mode byte with RnW bit = 1 (read)).

S10

A running transmission is ended by a remote master and this device wants to continue without losing control of the I2C-bus. The slave was not in transmission and resets to receive address bytes again since the new data transmission is concerning all connected slaves.

S11

The peripheral has problems to read data bytes from the FIFO (underflow/not ready). This is indicated by generating a TXF_UFL (TX FIFO underflow) request. It also changes to TRANSMISSION FINISHED state.

***Note**:* *The device is still addressed by a master (bit-field BS in register BUSSTAT = 11_B.) until a stop or restart condition occurs.*

S12

The peripheral has problems to write the received byte into the FIFO (overflow/not ready). This is indicated by generating a RXF_OFL (RX FIFO overflow) request. The slave-transmitter puts a not-acknowledge on the I2C-bus to indicate its situation to the controlling master. This byte is not valid and will be discarded.

***Note**:* *The device is still addressed by a master (bit-field BS in register BUSSTAT = 11_B.) until a stop or restart condition occurs.*

S13

The remote master wishes to close the connection to this slave and sets a not-acknowledge on the I2C-bus. The device generates a NACK (not-acknowledge) request and changes to TRANSMISSION FINISHED state (bit-field BS in register BUSSTAT = 01_B.). The interrupt routine can clear the appropriate bit through the corresponding bit in the PIRQSC register.

S14

The slave wants to stop the transmission and sets the ENDDCTRL.SETEND bit. It puts a not-acknowledge on the I2C-bus after the next received byte. With this the slave gets the possibility to cancel the transmission through software intervention.

S15

The value of received bytes is equal to bit-field MRPS (maximum receive packet size) of the FIFO register MRPSCTRL. The FIFO part of the interface generates the signal MRPS_stop to the I2C kernel, which indicates the end of the received packet capacity. The slave produces a not-acknowledge to the master and changes to TRANSMISSION FINISHED.

S16

The number of transmitted bytes is equal to the TPS bit-field of the FIFO register TPSCTRL. The FIFO controller generates the EOTXP (end of transmit packet) signal to the I2C kernel, which indicates the last byte to transmit. After the last byte the device changes to TRANSMISSION FINISHED.

***Note**: The master is not informed about this situation. Since the data flow control responsibility is task of the master device, it may continue receiving wrong values (0xFF).*

S17

The module detects bus activity; no start condition has been detected before. A transmission may be currently in progress. The device changes to BUS BUSY state. This transition is performed if a start condition has been missed because the device was not activated (CONFIGURATION state).

Master process sub-state machine

The following figure shows the master process sub-state machine. There are four different states in this sub-state machine:

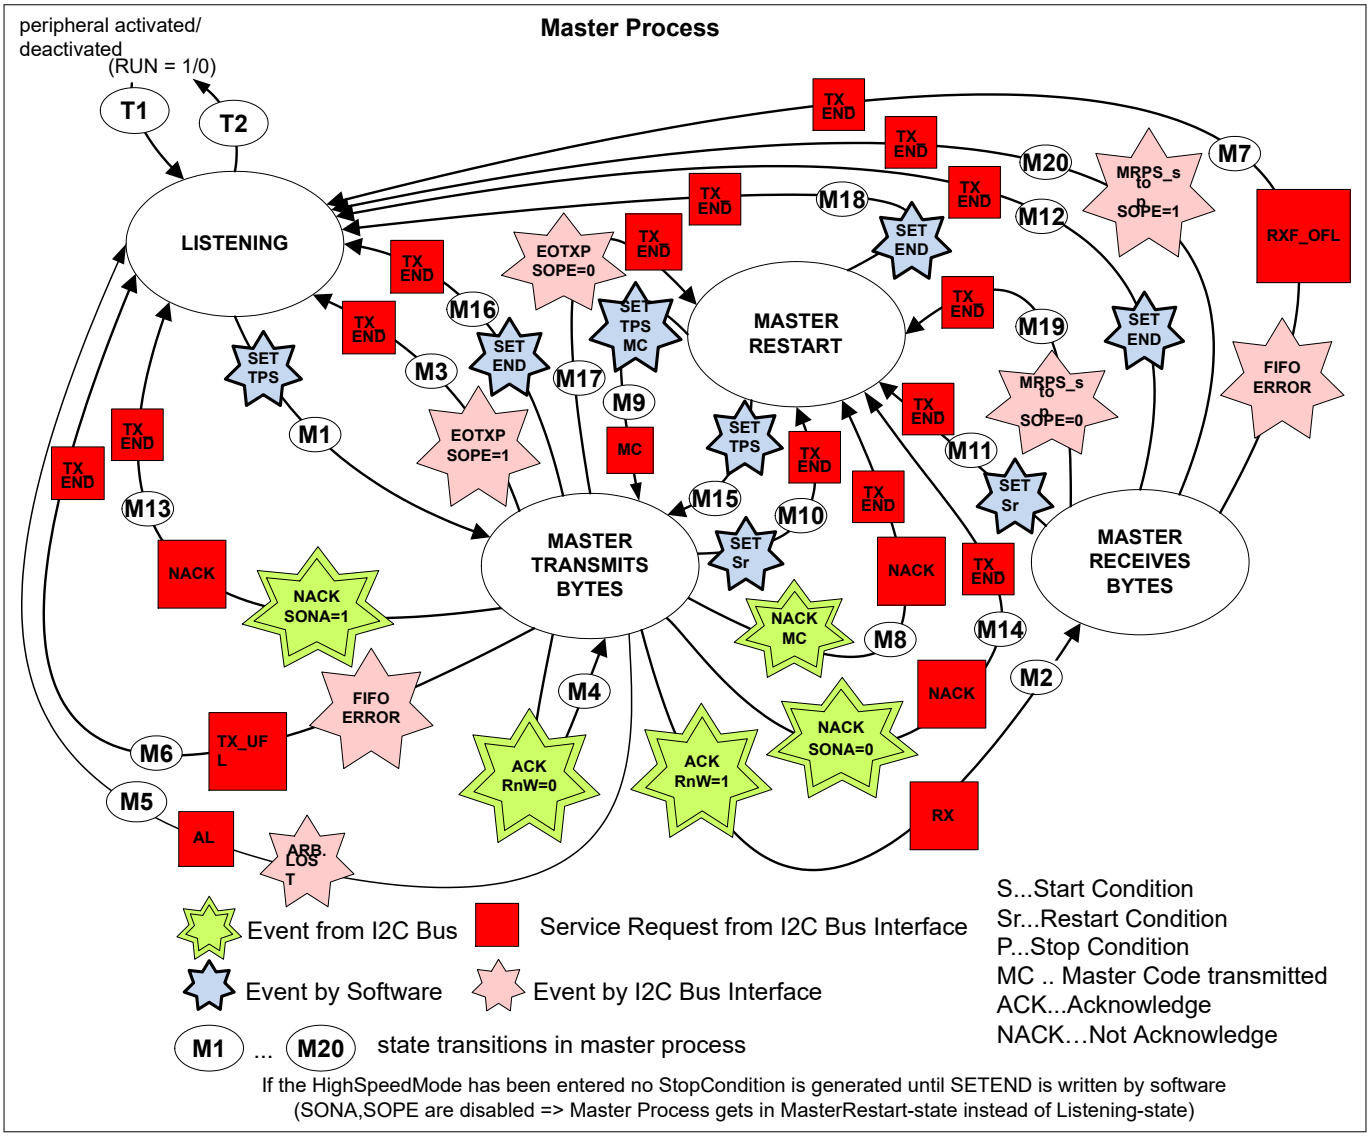

Figure 718 Master process sub-state machine

LISTENING

This state has been previously described (in the figure Top-level state machine). If the device is configured as master, it is listening to events either from software (writing to TPSCTRL register) or from the I2C-bus.

MASTER TRANSMITS BYTES

The device has started a transmission on the I2C-bus by software. The first byte after a start condition contains the address byte including the RnW bit. According to this bit (RnW bit in BUSSTAT register is set by hardware) the direction of the following transfer is determined. Bytes are transmitted on the I2C-bus until the FIFO is empty or a stop is initiated by software.

If bit MCE (master code enable) is set in the ADDRCFG register, the device has to check if the transmitted address byte is a master code.

MASTER RESTART

The device wants to restart a transmission without losing the control over the I2C-bus. The clock SCL stays low as long as no further communication is requested. The only event that should occur in this state is writing to the TPSCTRL register. Nevertheless the device can give up the I2C-bus control by writing to bit SETEND in the ENDDCTRL register. Of course, when this situation occurs, the peripheral produces a stop condition on the I2C-bus.

If bit MCE (master code enable) is set in the ADDRCFG register, the device has to check if the transmitted address byte is a master code.

MASTER RECEIVES BYTES
