The master has ordered bytes from the slave and handles the data transfer from the I2C-bus to the FIFO. This means that the bits are shifted into a buffer register in the I2C kernel and afterwards are passed to the FIFO. Every time a byte was transferred to the FIFO successfully the master-receiver produces an acknowledge in the according position.

The state transitions in the master process are:

M1

The software has written the number of bytes which have to be transmitted over the I2C-bus into the control register TPSCTRL. The FIFO generates appropriate data transfer requests which transfers valid data into the FIFO. A start condition is set on the bus and the bit-field BS (bus status) in register BUSSTAT is set to 10_B (busy master). The first (the first and the second) byte is (are) the 7-bit (10-bit) address of the slave which shall be accessed.

If the master wishes to initiate a transition to high-speed mode, the transition is only valid in combination with the MCE (master code enable) bit in the ADDRCFG register. The software has to write the master code into the FIFO, this means also the value of the TPSCTRL is predetermined with 1.

M2

The master receives an acknowledge from slave and the bit RnW in the BUSSTAT register was set to 1 during the addressing phase. A slave has been addressed successfully as transmitter, the state moves to MASTER RECEIVES BYTES. An RX (Receive) request is generated to distinguish between transmit- and receive-FIFO requests in non flow controller mode.

M3

The valid data packet from the FIFO was transferred successfully to the I2C-bus and the FIFO indicates this by the EOTXP (end of transmit packet) signal. If the RnW bit was set to 0 (writing to a slave) and bit SOPE (stop on packet end) in register ADDRCFG was set to 1, the transfer is closed by putting a stop condition on the bus. After this stop condition has been detected the peripheral indicates this successful transfer to the software through the TX_END (transmission end) request. The bus status bit-field is set to 0x0 (bus free).

M4

After the master transmits a byte it releases the SDA line to allow the addressed slave to pull down the SDA line (acknowledge). If this event occurs (and RnW in register BUSSTAT was set to 0), the master can continue to transfer bytes on the I2C-bus.

M5

The SDA line level is not equal to the one that is set by the master. This means that another master also tries to control the I2C-bus. This is indicated by the AL (arbitration lost) request and the device switches to the LISTENING state. The interrupt routine has to clear bit AL in the PIRQSC register. The Arbitration lost indication is not executable when the device works in high-speed mode (no arbitration procedure in high-speed mode since there is only one master remaining). The arbitration process must be operating at

each bit which is sent by the master. Before interrupting the CPU, the bit-field BS (bus status) in register BUSSTAT is set to 01_B.

M6

If the master wants to transmit bytes but the FIFO is empty (underflow), it has to generate a TXF_UFL (TX FIFO underflow) request. The bit-field BS (bus status) in register BUSSTAT is reset to 00_B, and a TX_END (transmission end) request is generated after the master has put a stop condition on the bus.

M7

The I2C kernel wants to transfer bytes to the FIFO but without success. Then it has to produce an RXF_OFL (RX FIFO overflow) request. The current byte is not-acknowledged and a stop condition is put on the bus (bit-field BS in register BUSSTAT is set to 00 and a TX_END (transmission end) request is generated). Requests (SREQ, BREQ, LSREQ or LBREQ) are generated for the outstanding data, the target is to empty the FIFO.

M8

If master code has been transmitted by the device and a NACK (not-acknowledge) has been received, the MASTER RESTART state is entered. The clock SCL stays low as long as no further communication is requested. This is done by writing bit-field TPS in register TPSCTRL (see transition M9).

M9

A new communication in high-speed mode is started by writing bit-field TPS in register TPSCTRL when a master code has been previously transmitted (M8). The switch into high-speed mode (MC request) is done as soon as clock and data are released to high (see the figure below). State MASTER TRANSMITS BYTES is entered. During high-speed mode, all fast and standard mode devices must be disconnected from the bus. This can be done in the MC request.

M10

Bit SETRSC has been set during the transmission of the data (the software wants to change direction/slave and therefore writes to the ENDDCTRL register). The I2C kernel resets and changes to MASTER RESTART state and a TX_END (transmission end) request is generated. Therefore, the master does not lose the control of the I2C-bus after the transmission has ended. The master stops transmission after the current byte was acknowledged or not acknowledged. Valid data in the FIFO are discarded. In this situation the FIFO is flushed to produce an initial situation.

M11

If the master wants to change direction/slave immediately in this state, it has to write to bit SETRSC in the ENDDCTRL register. The master puts a not-acknowledge on the appropriate place during the current transmitted byte. This indicates the slave-transmitter to stop transmission. The master switches to MASTER RESTART state; a TX_END (transmission end) request is generated.

M12

By sending a not-acknowledge on the bus, the master indicates the slave an upcoming stop of the transmission. This is established by writing to bit SETEND in register ENDDCTRl. Stop condition and TX_END (transmission end) request are generated. Requests (SREQ, BREQ, LSREQ or LBREQ) are generated for the outstanding data, the target is to empty the FIFO. The LISTENING state is entered; the bit-field BS (bus status) in register BUSSTAT is set to 00_B.

M13

If the master is receiving a not-acknowledge and bit SONA (stop on not-acknowledge) in the ADDRCFG register is 1, it produces a stop condition, resets the bit-field BS (bus status) in register BUSSTAT and issues a NACK (not-acknowledge) request and a TX_END (transmission end) request. The FIFO is flushed; remaining data in the FIFO stages are discarded.

M14

If bit SONA (stop on not-acknowledge) in the ADDRCFG register is 0, the peripheral wants to remain the controlling master of the I2C-bus after receiving a not-acknowledge. The next state is MASTER RESTART. A NACK (not-acknowledge) request and a TX_END (transmission end) request indicate this event to the software. The FIFO transfers the valid data to the memory.

M15

The master decided to transfer data on the bus again and writes to the TPSCTRL register. The first byte is interpreted as address byte (the 8th bit indicates RnW). The appropriate data transfer requests are activated by the FIFO controller. After the SCL line is high again (slave can stretch the low period) the master is allowed to put a restart condition onto the bus and is again in the MASTER TRANSMITS BYTES state starting to transmit bytes again.

M16

The software has set the SETEND bit in the ENDDCTRL register. The peripheral stops transmission of bytes after the current byte has been written on the bus. The I2C kernel flushes the FIFO since the remaining data in the FIFO is invalid. A TX_END (transmission end) request is generated.

M17

The FIFO indicates the end of the data packet and the peripheral was configured to go into MASTER RESTART state after that event. Since the data transfer has ended as intended a TX_END (transmission end) request is produced.

M18

The master has no data to send anymore but still controls the I2C-bus. Therefore it can use the SETEND bit to give up the I2C-bus control by setting a stop condition. A TX_END (transmission end) request is generated.

M19

A value different to zero is programmed to bit-field MRPS (maximum receive packet size) of the MRPSCTRL register. If the number of received bytes is equal to the MRPS bit-field, the FIFO produces the MRPS_stop signal. When bit SOPE (stop on packet end) in the ADDRCFG register is set to 0, the master generates a not-acknowledge and changes to MASTER RESTART state, so the master does not lose the control over the I2C-bus. A TX_END (transmission end) request is generated.

M20

(See also M19.) The FIFO produces the MRPS_stop signal which indicates that the desired amount of received data bytes is reached. The peripheral generates a not-acknowledge and changes to LISTENING state because bit SOPE (stop on packet end) in the ADDRCFG register is set to 1. Of course, the interface produces a stop condition; so the I2C-bus is free again (change also the bus status bit-field). A TX_END (transmission end) request is also generated. Requests (SREQ, BREQ, LSREQ or LBREQ) are generated for the outstanding data, the target is to empty the FIFO. The LBREQ or the LSREQ indicate the completed reception of data.

31.3.1.5 FIFO operation

The I2C module uses a FIFO between its kernel and the bus, in order to adapt the character processing speed of the peripheral to the transfer rate of the bus system. The FIFO has a transmission state and a reception state. The following figure shows the bidirectional half duplex FIFO unit with the input and output lines and with the corresponding FIFO registers.

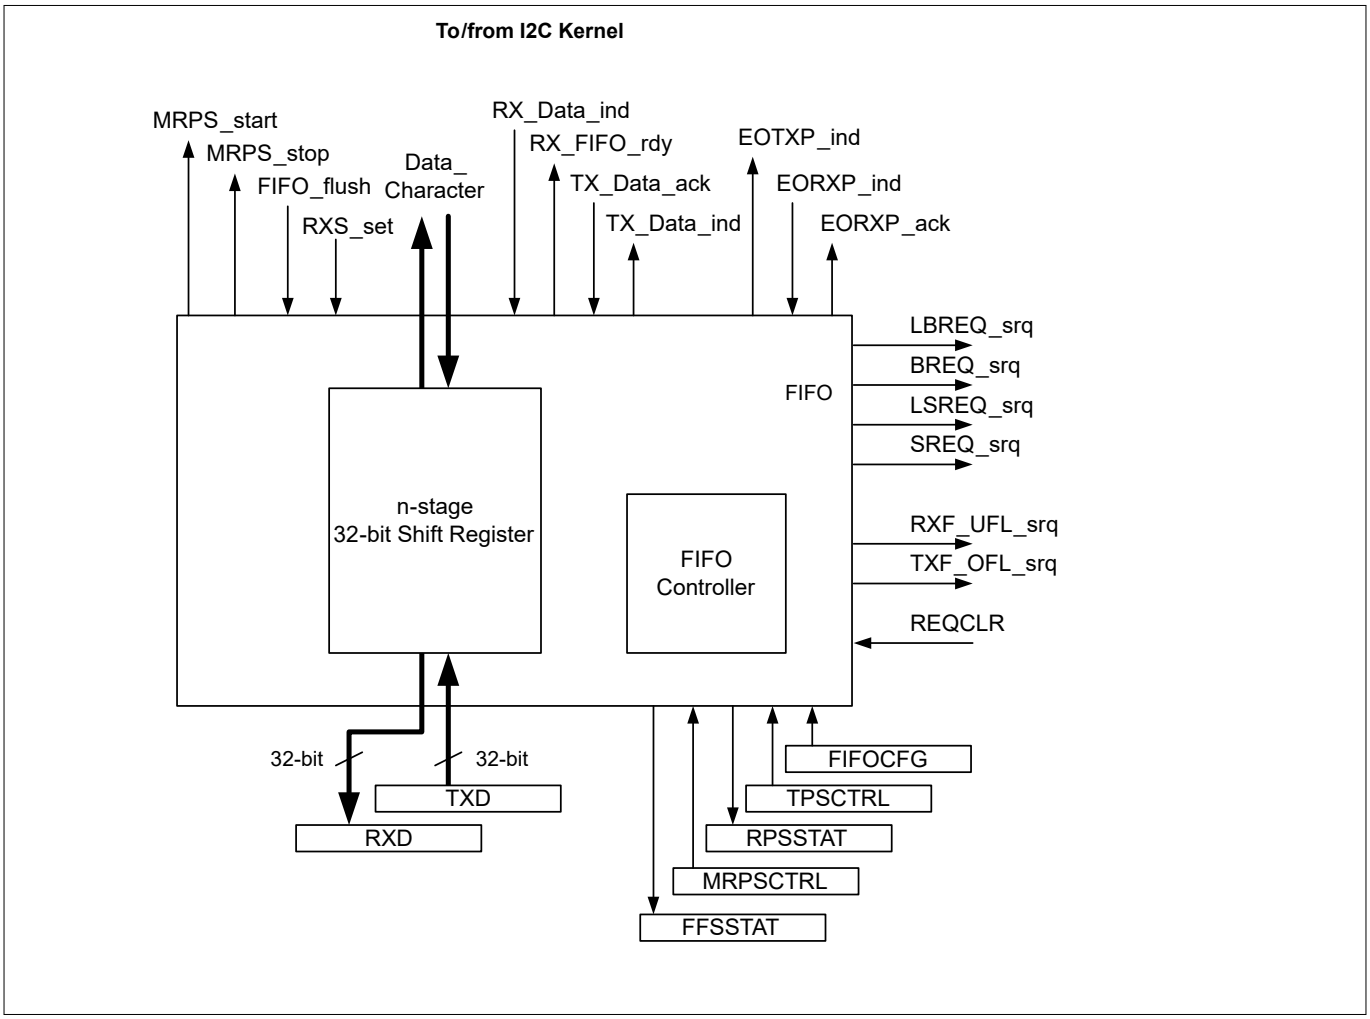

Figure 720 Bidirectional half duplex FIFO

***Notes**:*

1. *When the FIFO is not serviced in time (transmission: filled with transmit data, reception: read the received data), an underflow or overflow event will lead to abortion of the transaction. To avoid this behavior, the software shall be configured to transfer a maximum of 32 bytes per transfer. If more than 32 bytes should be transmitted, the transmissions should be divided in maximum 32 data bytes per transfer*
2. *If bit-field FIFOCFG.CRBC in register FIFOCFG is disabled, a linked list should be used to avoid that the CPU has to get active to clear the request. The DMA channel that serves I2C has to be configured with a linked list that first makes the FIFO-TX/RX transfer and second clears the interrupt by writing 0x0 to register ICR (Interrupt Clear Register)*

31.3.1.5.1 Data transmission

The software can move transmit data to the FIFO by writing to the Transmission Data Register TXD. Moving data to the FIFO can be done according to the data transfer request signals generated by the FIFO controller. But with the register FFSSTAT, which indicates the number of full FIFO stages, the data transfer to the FIFO can be handled completely without data transfer requests. The data alignment within the FIFO is described in Transmit data alignment . The FIFO shifts data to the I2C kernel by means of the handshake lines tx_data_ind and tx_data_ack.

With the signal FIFO_flush the I2C kernel is able to clear the FIFO content. But if a data transfer request is pending, then the FIFO is not cleared until the corresponding signal REQCLR has been cleared.

The bit-field FIFOCFG.CRBC can be configured how to clear the FIFO request.

The I2C-bus interface should know when it is receiving the last character of a data packet from the FIFO. Therefore the software should define a transmit packet size in bit-field TPS of register TPSCTRL and then the FIFO controller indicates the last character of the packet to the I2C kernel by setting the EOTXP (end of transmit packet) signal.

Since TPS is double buffered the software can write the size of the next packet into TPSCTRL.TPS as soon as the TPSCTRL.TPS value of the current packet has been loaded into the TPS counter, that is reading TPS returns 0. It loads the new TPS value as soon as it has room in the FIFO.

Also the characters of the next packet can be moved to the FIFO immediately after the current packet characters as indicated in the following figure . If byte or half word alignment is used as described in Transmit data alignment , then the characters of two different packets must not be aligned in a single stage.

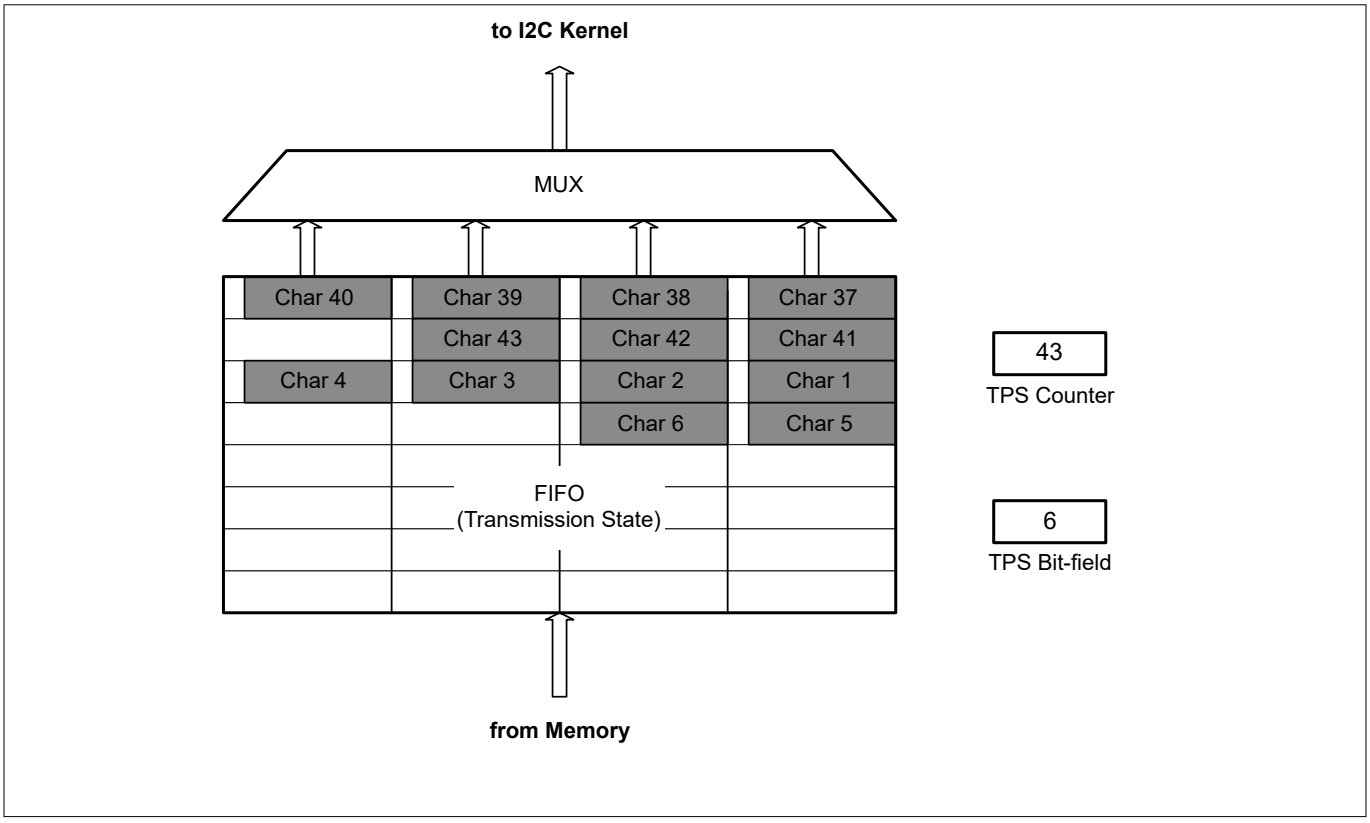

Figure 721 FIFO containing data of two different transmit packets

Error handling

- If a TX FIFO overflow occurs (that is the software writes data too fast to the FIFO), the new incoming character is discarded and a TX FIFO overflow interrupt request is generated
- If a TX FIFO underflow occurs (that is the I2C kernel tries to read from an empty FIFO), the I2C kernel generates a TX FIFO underflow interrupt request

31.3.1.5.2 Transmit request generation

For the following it is assumed that the FIFO is used as flow controller, selected through bit FIFOCFG.TXFC.

In this case the bit-field TPSCTRL.TPS is not only used for the generation of the EOTXP (end of transmit packet) signal , but also to initiate the whole data transfer. That is the software indicates that it wants to transmit a data packet by writing the packet size to the bit-field TPSCTRL.TPS. Then the FIFO unit asserts burst requests BREQ until the amount of data still to be transferred is less than or equal to the burst size set in bit-field FIFOCFG.TXBS. At this point, if the remaining data is equal to the burst size, then a last burst request LBREQ is issued. Otherwise, single requests SREQ and a last single request LSREQ will be issued.

If a data transfer (BREQ, LSBREQ, SREQ, LSREQ) request is pending, then no more request or interrupt will be done until the corresponding signal REQCLR has been cleared. The CPU (software) or DMA have to transfer the data to the FIFO and clear the generated interrupt.

***Notes**:*

1. *Preloading TPSCTRL.TPS with the packet size of the next frame, before the current packet has been transmitted completely, enables a continuous data throughput (for example of audio data)*
2. *If the FIFO is not used as flow controller, the I2C-bus interface should use bit-field TPSCTRL.TPS to set the EOTXP signal. A burst request BREQ is generated each time the number of empty FIFO stages is equal or greater than the burst size set in bit-field FIFOCFG.TXBS and the previous request was cleared. No single requests SREQ and LSREQ will be issued*

31.3.1.5.3 Transmit data alignment

Depending on bit-field TXFA (TX FIFO Alignment) in register FIFOCFG, the FIFO can deal with byte aligned, half word aligned or word aligned characters (or even more) as it is described in the following.

***Note**:* *Byte alignment is used as synonym for character alignment, half word alignment for character alignment of two data characters, and word alignment for character alignment of four characters.*

Byte aligned TX characters

If the TX characters are byte aligned, then the FIFO extracts the bytes and shifts them to the I2C kernel through a multiplexer as it is shown in the following figure .

Since the number of characters of the packet to be transmitted is not necessarily a multiple of 4, the last word must be filled up with dummy bytes if necessary. The FIFO transmits only the valid bytes of the last word depending on the setting of the bit-field TPSCTRL.TPS.

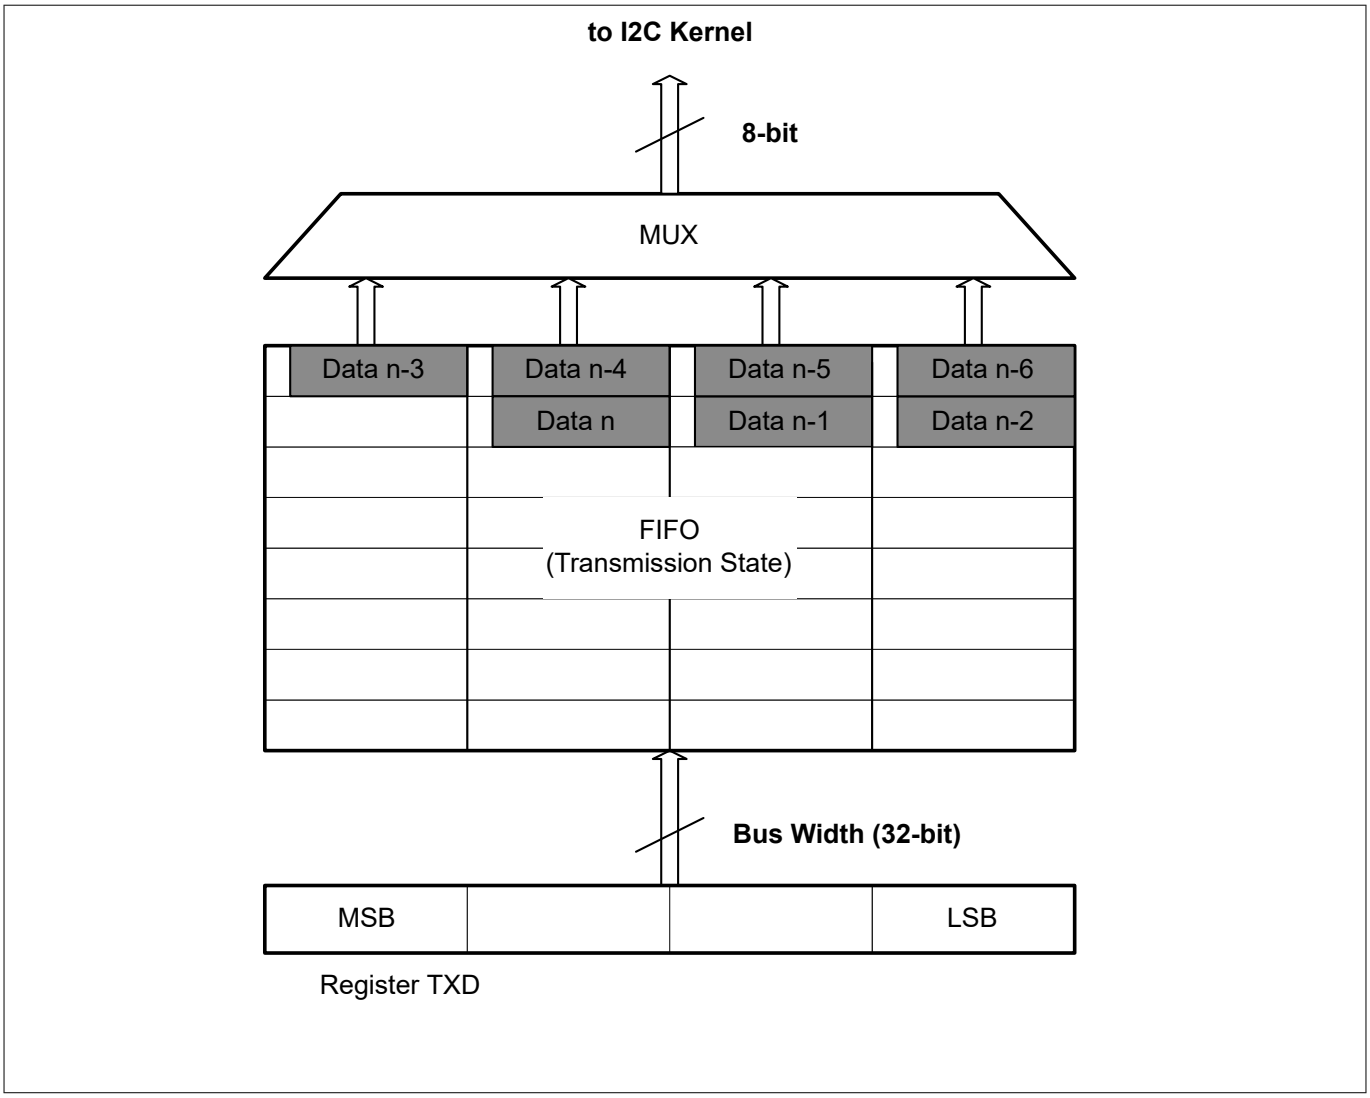

Figure 722 FIFO in transmission state with byte aligned data

Half word aligned

If the TX characters are half word aligned, then the FIFO extracts the half words and shifts them to the I2C kernel through a multiplexer as it is shown in the following figure.

***Note**: The I2C kernel extracts the right data bits from the half word it receives from the FIFO.*

Since the number of characters of the packet to be transmitted is not necessarily a multiple of 2, the last word must be filled up with a dummy half word if necessary. The FIFO transmits only the valid half words of the last word depending on the setting of the bit-field TPSCTRL.TPS .

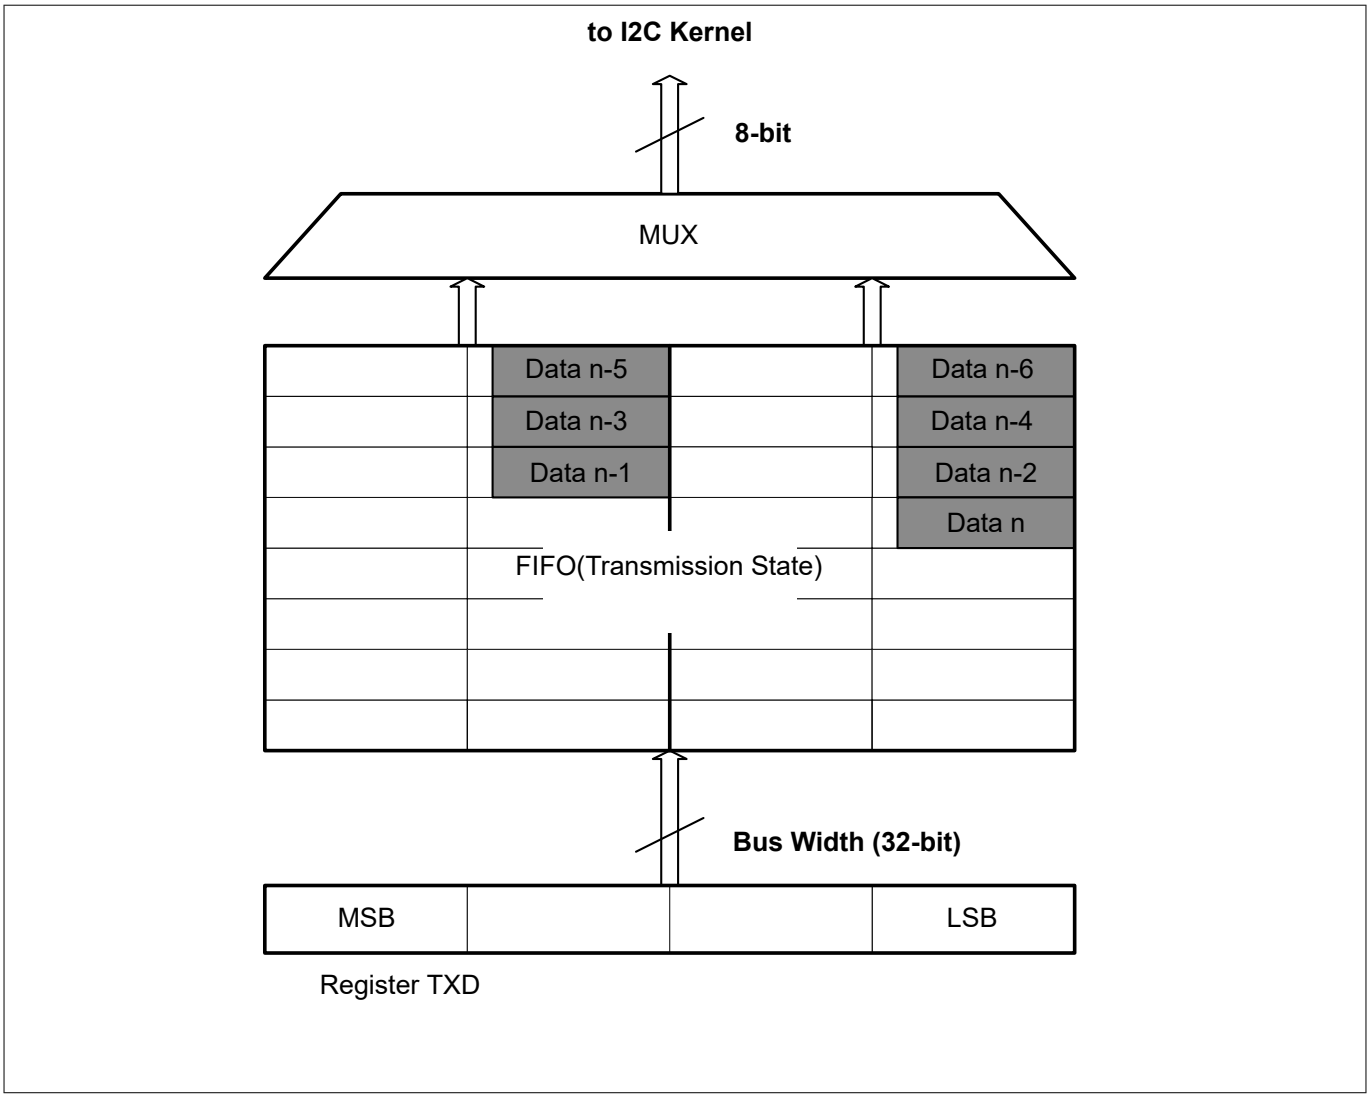

Figure 723 FIFO in transmission state with half word aligned data

Word aligned

If the TX characters are word aligned, then the FIFO shifts them to the I2C kernel as it is shown in the following figure.

***Note**: The I2C kernel extracts the right data bits from the word it receives from the FIFO.*

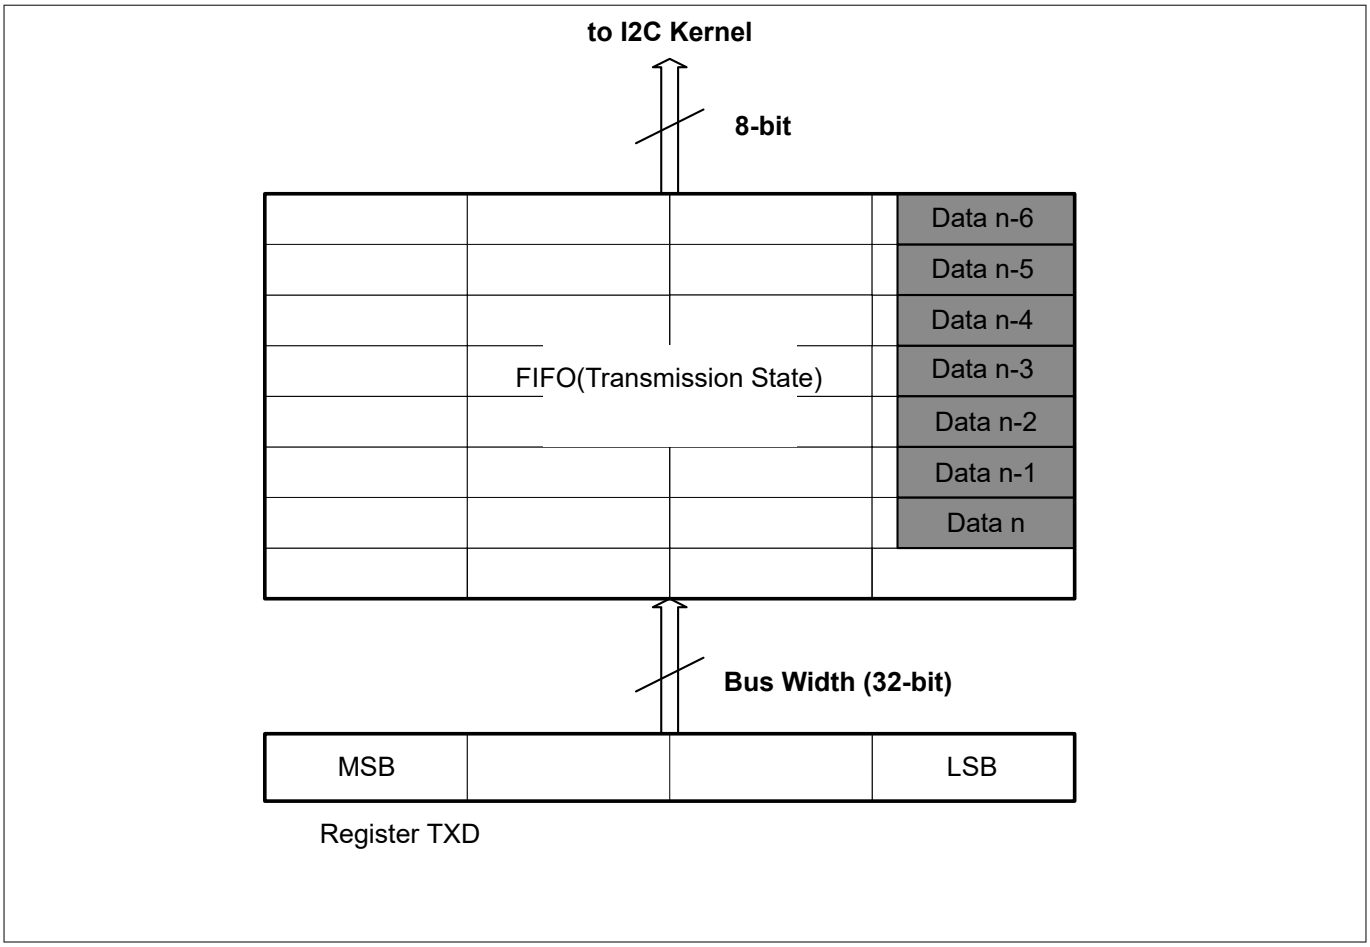

Figure 724 FIFO in transmission state with word aligned data

31.3.1.5.4 Data reception

The software can read received data from the FIFO by reading the Reception Data Register RXD. Reading data from the FIFO should be done according to the data transfer request signals generated by the FIFO controller. The register FFSSTAT indicates the number of filled FIFO stages. The data alignment within the FIFO is described in Receive data alignment . The I2C kernel shifts data into the FIFO by means of the handshake signals RX_FIFO_rdy and RX_Data_ind.

Before the first reception starts, the I2C kernel has to set the RXS_set line. This causes the assertion of RX_FIFO_rdy to indicate the I2C kernel that one data character can be written into the FIFO.

With the signal FIFO_flush the I2C kernel is able to clear the FIFO content. But if a data transfer request is pending and the FIFO is configured as flow controller, then the FIFO is not cleared until the corresponding signal REQCLR has been cleared.

Bit-field FIFOCFG.CRBC can be configured how to clear the FIFO request.

Error handling

- If the RX FIFO is completely full (that is the software reads out the data too slow), the I2C kernel generates an RX FIFO overflow interrupt request
- If an RX FIFO underflow occurs (that is the software reads from empty FIFO), an RX FIFO underflow interrupt request is generated
- If an error (including the FIFO overflow condition described above) is detected in the I2C kernel and the current reception is stopped, it has to generate an EORXP_ind signal, so that the remaining characters in the FIFO can be moved out by means of data transfer requests

Related information

Receive data alignment on page 5462

31.3.1.5.5 Receive request generation

If the whole data of the current received packet has been moved into the buffer, then the I2C kernel will set the EORXP_ind (end of receive packet indication) signal. The received characters, which are shifted in the FIFO, are counted by an RPS (received packet size) counter. If an EORXP_ind occurs, then the content of the RPS counter is moved to the register RPSSTAT and the counter is reset. If data alignment in the FIFO is used, then the RPSSTAT value can be used to check for valid characters in the last read word .

For the following it is assumed that the FIFO is used as flow controller, selected through bit RXFC of the FIFOCFG register.

The FIFO unit asserts burst requests BREQ each time the FIFO filling level is greater than the burst size set in bit-field RXBS of register FIFOCFG. An EORXP_ind causes the FIFO unit to assert burst requests BREQ until the amount of data still to be transferred is less than or equal to the burst size. At this point, if the remaining data is equal to the burst size, a last burst request LBREQ is issued. Otherwise, single requests SREQ and a last single request LSREQ will be issued.

If a data transfer (BREQ, LSBREQ, SREQ, LSREQ) request is pending, then no more request or interrupt will be done until the corresponding signal REQCLR has been cleared. The CPU (software) or DMA have to get the data from the FIFO and clear the generated interrupt.

When the packet has been shifted out of the FIFO by software, the FIFO controller provides the EORXP_ack (end of receive packet acknowledge) signal to the I2C kernel, which allows the kernel to set the next EORXP_ind.

The next received packet may be shifted into FIFO immediately after the current packet, so that the FIFO contains data of two different packets. But the EORXP_ind of the next packet must not be asserted before the EORXP_ind of the current packet has been acknowledged. The RPSSTAT.RPS counter is counting the characters of the next packet, while in the register RPSSTAT the packet size of the current packet remains readable. The first character of the new packet is always shifted in a new FIFO stage as indicated in the following figure.

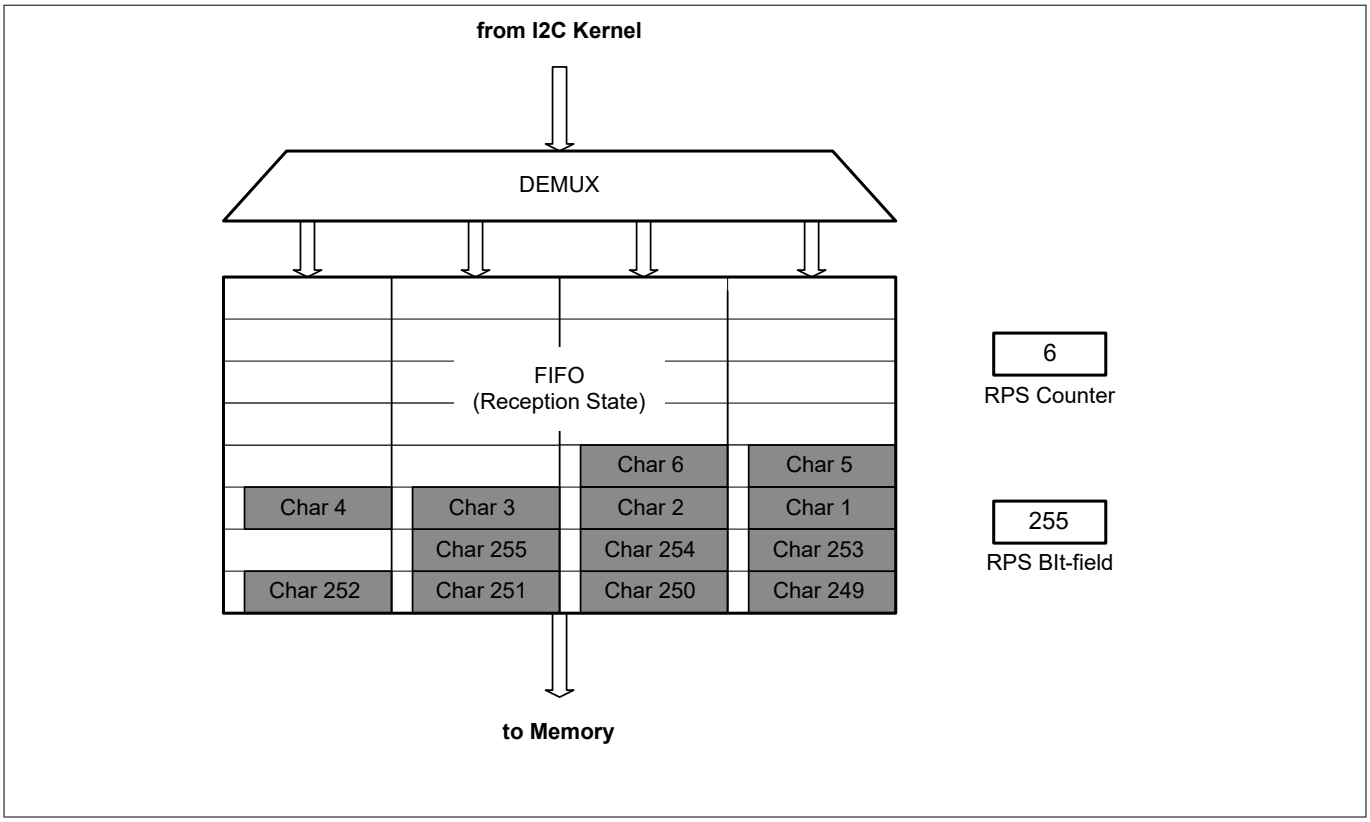

Figure 725 FIFO containing data of two different receive packets

If the number of the received characters of one packet is equal to the maximum received packet size, which is defined by bit-field MRPS in register MRPSCTRL, then the FIFO controller gets into the state, where it generates LBREQ or SREQ and LSREQ. If the I2C kernel generates an EORXP_ind in this state, then this indication is valid for the received packet and the FIFO accepts no more characters from the I2C kernel until the current packet has been moved out of the FIFO or the start of a new packet has been detected by asserting RXS_set.

The bit-field MRPSCTRL.MRPS is double buffered, that is the software can write the MRPSCTRL.MRPS value of the next packet as soon as the current MRPSCTRL.MRPS value has been loaded, that is reading MRPS returns 0. It loads the new MRPS value as soon as it has room in the FIFO. If an MRPS overflow occurs (one character before the last character is received), then the MRPS_stop trigger to the I2C kernel is generated. But if the next MRPS value is written to MRPSCTRL.MRPS before the last data character of current frame has been completely received, then no MRPS_stop is generated. The I2C-bus interface will use the MRPS_stop trigger to stop the reception of the corresponding data packet.

But the MRPSCTRL.MRPS bit-field can also be used to initiate a reception, when the peripheral is master-receiver. Therefore writing to MRPS generates a trigger MRPS_start to the I2C kernel. The next MRPS value written to the MRPS bit-field generates only an MRPS_start when an MRPS_stop was generated before.

The MRPS features can only be used if the FIFO is the flow controller.

***Notes**:*

1. *When the MRPS control feature of the FIFO is used to limit the packet size of a continuous incoming data stream (MRPS is only written once and left unchanged), characters exceeding MRPS are discarded. The FIFO can not handle more than two packets. When the FIFO is filled with data characters of two packets, a further RXS_set will be overseen by the FIFO. Additionally, the FIFO does not set the RX_FIFO_rdy*
2. *If the FIFO is not used as flow controller, a single request SREQ is always generated as soon as the readable FIFO stage is filled up with characters. Additionally, a burst request BREQ is generated as soon as the number of filled FIFO stages is equal to or greater than the burst size set in bit-field RXBS of register FIFOCFG. When the I2C kernel sets EORXP_ind, the FIFO controller provides the EORXP_ack (end of receive packet acknowledge) signal to the I2C kernel, which allows the kernel to set the next EORXP_ind*

31.3.1.5.6 Receive data alignment

Depending on bit-field FIFOCFG.RXFA (RX FIFO Alignment), the FIFO can deal with byte aligned, half word aligned or word aligned characters (or even more) as it is described in the following.

Byte aligned

If the RX data should be byte aligned, then the characters from the I2C kernel are aligned and shifted to the FIFO by a de-multiplexer as it is shown in the following figure.

Since the number of characters of the received packet is not necessarily a multiple of 4, the upper bytes of the last word can be invalid. The software has to check for invalid bytes of the last word by means of the bit-field RPSSTAT.RPS (received packet size).

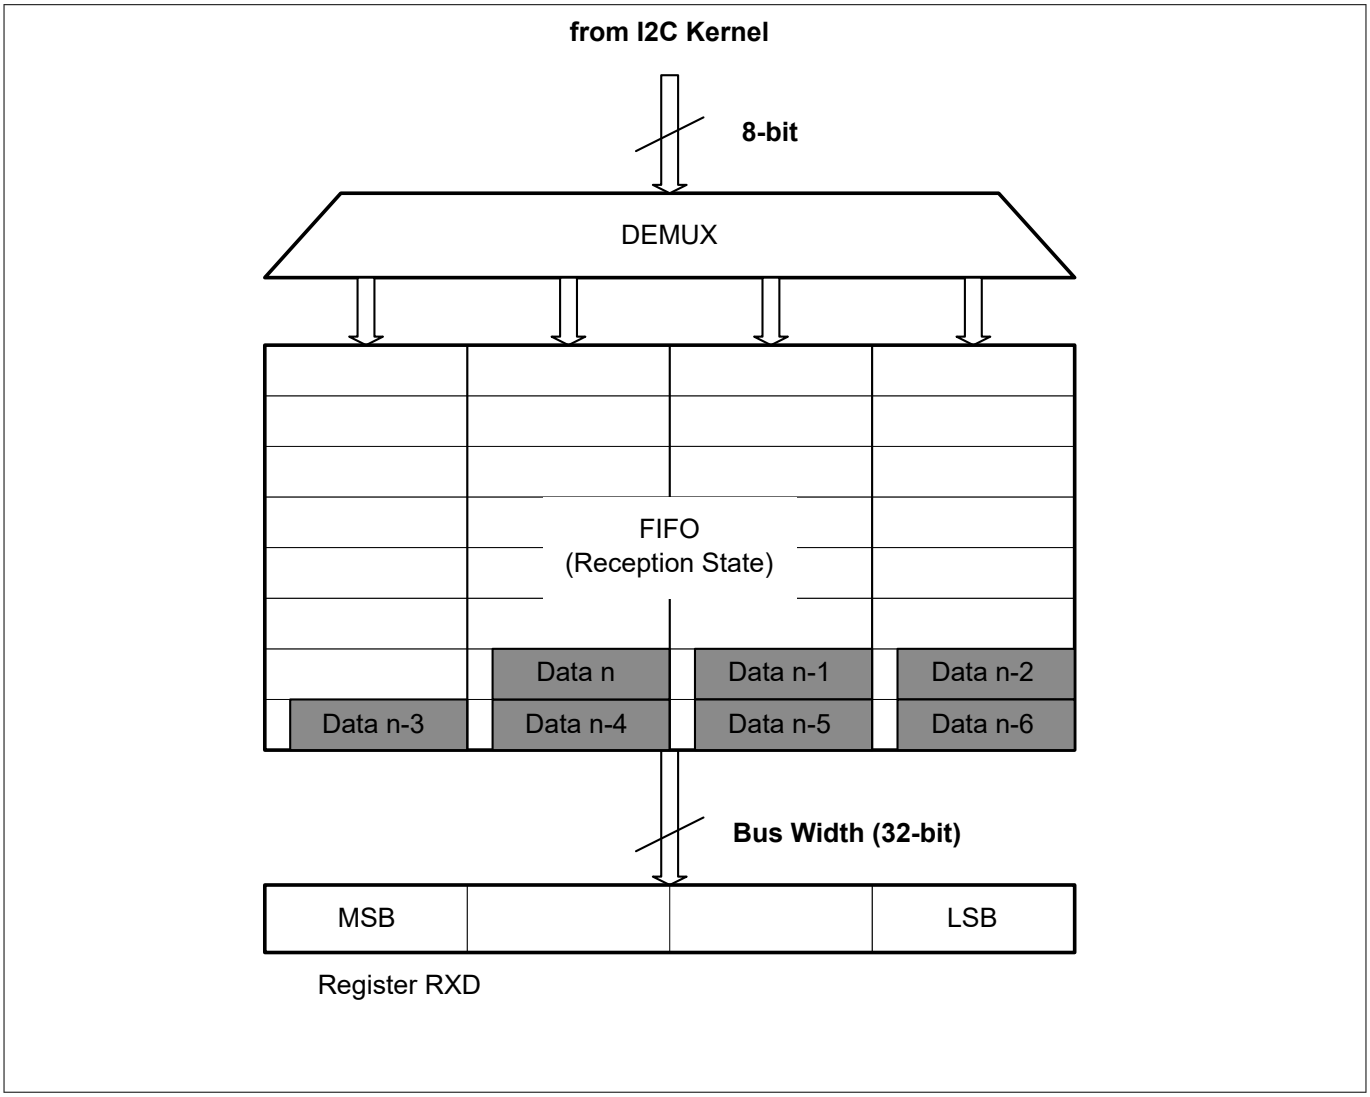

Figure 726 FIFO in reception state with byte aligned data

Half word aligned

If the RX data should be half word aligned, then the characters from the I2C kernel are aligned and shifted to the FIFO by a de-multiplexer as it is shown in the following figure .

***Note**: The I2C kernel fills up the half words with dummy bits.*

Since the number of characters of the received packet is not necessarily a multiple of 2, the upper bytes of the last word can be invalid. The software has to check for invalid half words of the last word by means of the bit-field RPS (received packet size).

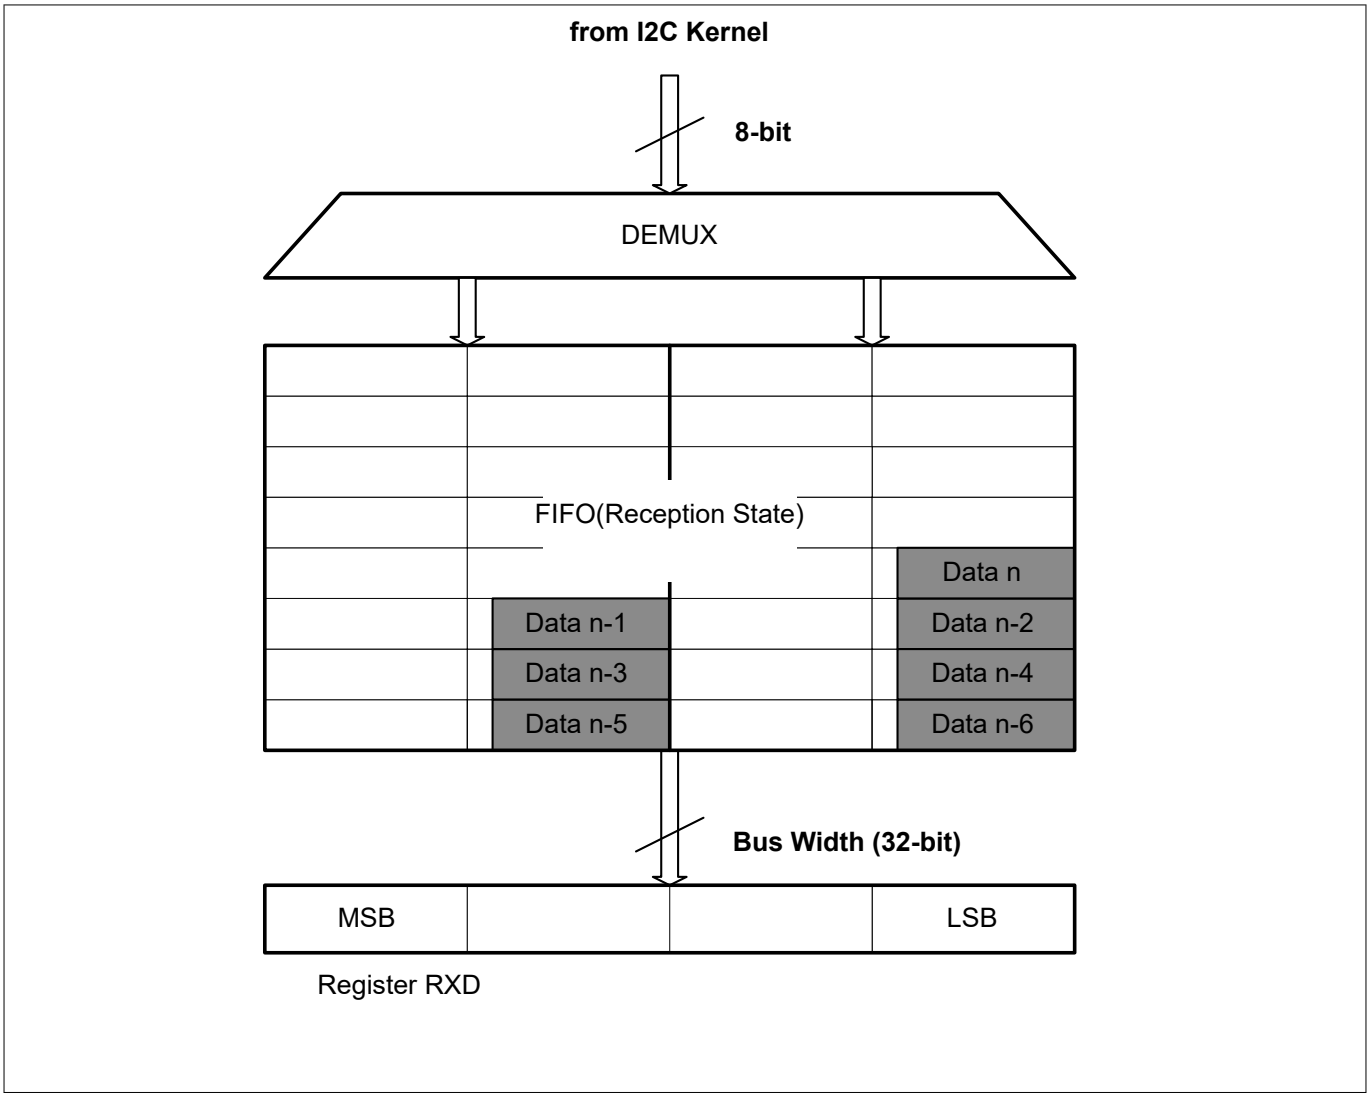

Figure 727 FIFO in reception state with half word aligned data

Word aligned

If the RX data should be word aligned, then the characters from the I2C kernel are shifted to the FIFO as it is shown in the following figure.

***Note**: The I2C kernel fills up the words with dummy bits.*

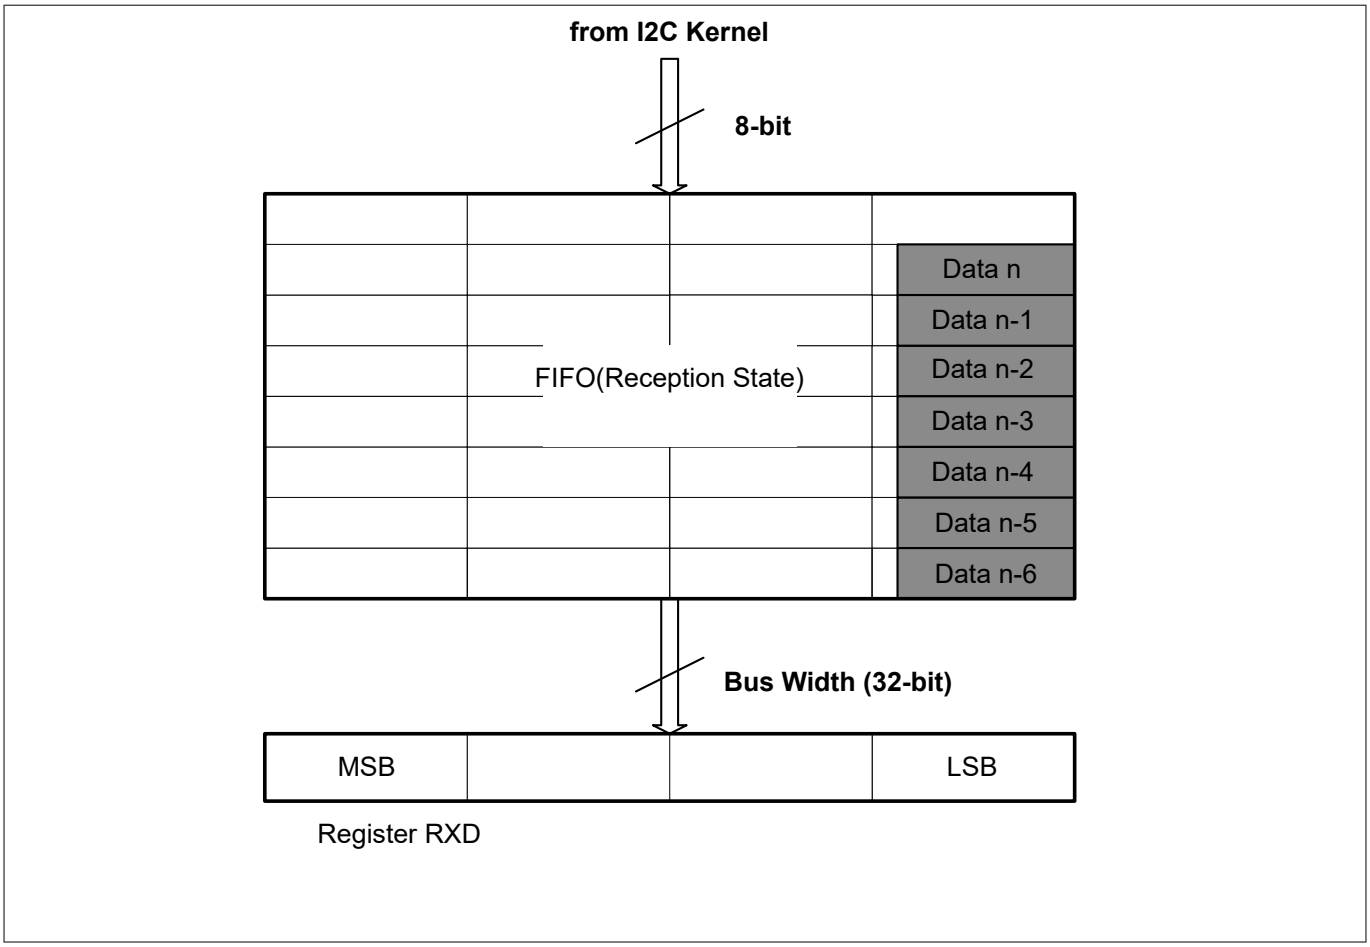

Figure 728 FIFO in reception state with word aligned receive data

31.3.1.5.7 Switching between transmission and reception

Initially, the FIFO is in the TX state, so that the software can initiate a TX transfer simply by writing data to the bit-field TXD.TXD . If the I2C kernel wants the FIFO to switch to the RX state in the meantime, then it can set the RXS_set line and even if transmission is ongoing the TX transfer is aborted. This causes the FIFO to flush its content, switch to the RX state and reset the received packet size counter. If the software wants to write to the register TXD when the FIFO is in RX state, then this causes a bus error. As soon as the FIFO has received an EORXP_ind signal from the kernel and the software has moved all RX characters out of the FIFO through the register RXD, the FIFO automatically switches back into the TX state.

If the software writes to the register TPSCTRL when the FIFO is in the RX state, the TPS value is pending until the FIFO returns to the TX state. Then the transmission is initiated, if the FIFO is the flow controller.

If the FIFO is flow controller and the software writes to the register MRPSCTRL, then an MRPS_start is generated independent of the state of the FIFO.

With the signal FIFO_flush the I2C kernel is able to clear the FIFO content. But if a data transfer request (xREQ) is pending, then the FIFO is not cleared until the corresponding signal REQCLR has been cleared.

If the FIFO has been cleared in the RX state, then it switches back to the TX state afterwards.

31.3.1.5.8 Switching between reception and transmission

When the I2C kernel is changing from RX state to TX state the FIFO is flushed. In order to avoid loosing data when the FIFO is flushed, the software should proceed in the right sequence. In a scenario where the device is addressed as slave and is asked to return data, this new data must be entered in the FIFO only after detection of

the address and TX_END interrupt requests and then can transfer the data to the FIFO or can trigger the DMA that fills the FIFO for the TX transfer.

31.3.1.6 Service request block operation

The SRB (Service Request Block) of the I2C module is used to prepare the interrupt and data transfer requests for the interrupt controller.

31.3.1.6.1 Overview of service requests

The I2C service requests are partially combined in the SRB (see ERRIRQSM, ERRIRQSS and ERRIRQSC as well as PIRQSM, PIRQSS and PIRQSC). The figure below shows an overview of the service requests. The following table provides a list of all service requests of the I2C module.

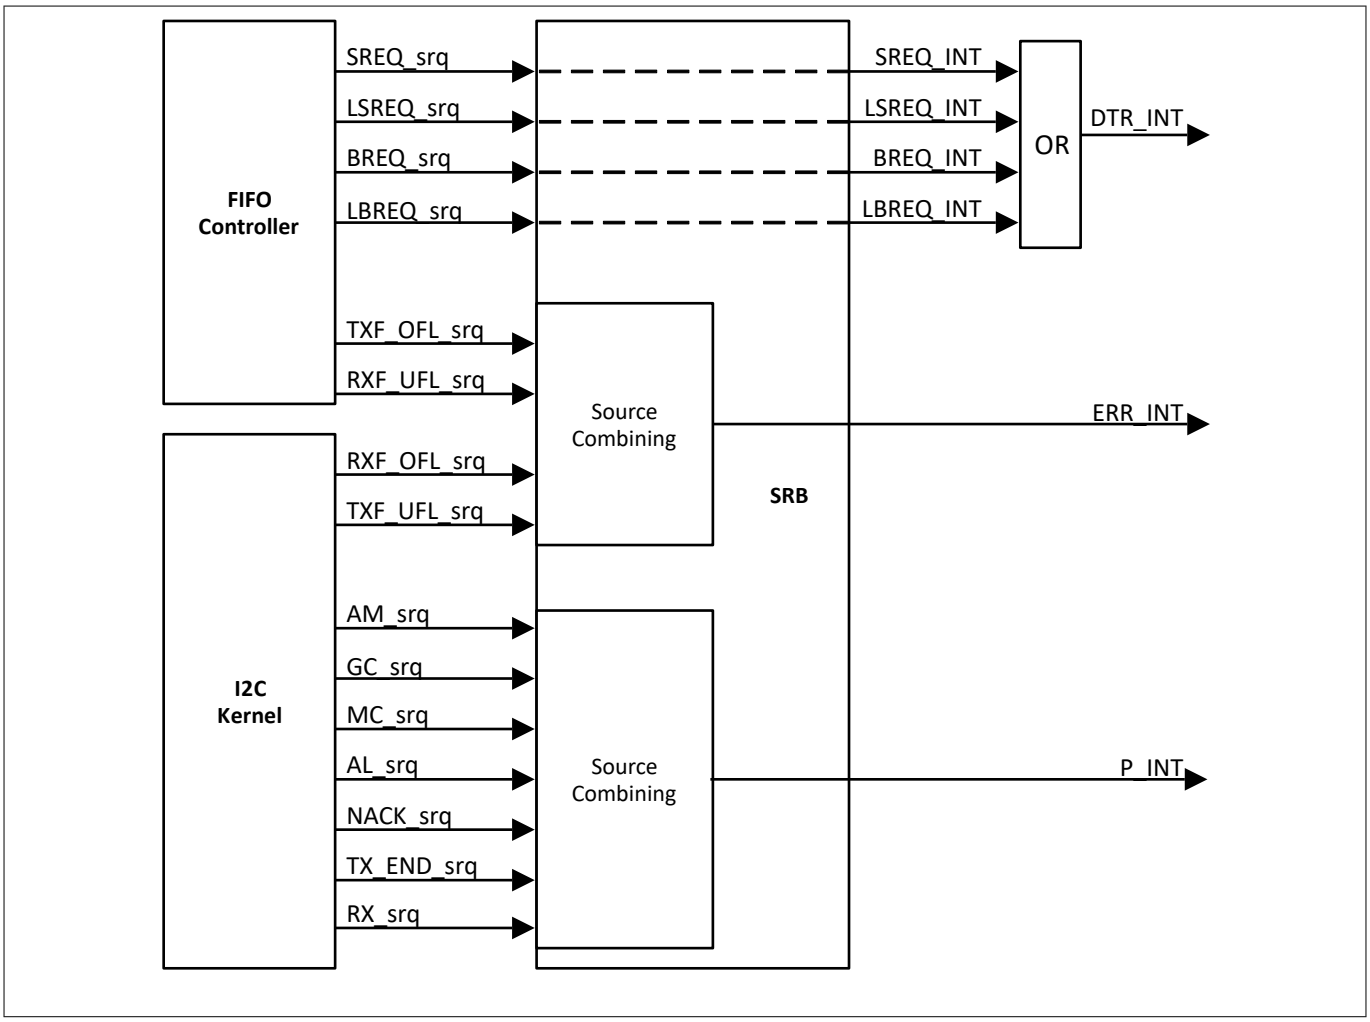

Figure 729 Overview of I2C module service requests

Table 1261 I2C module service requests

Service request	Interrupt request	Description
BREQ_srq	DTR_INT	Burst Data Transfer Request FIFO requests a transfer of a programmed burst number of words from or to the memory.

(table continues...)

Table 1261 (continued) I2C module service requests

Service request	Interrupt request	Description
LBREQ_srq	DTR_INT	Last Burst Data Transfer Request FIFO requests a last burst transfer from or to the memory.
SREQ_srq	DTR_INT	Single Data Transfer Request FIFO requests a single transfer of a word from or to the memory.
LSREQ_srq	DTR_INT	Last Single Data Transfer Request FIFO requests a last single transfer from or to the memory.
TXF_OFL_srq	ERR_INT	TX FIFO Overflow Request FIFO has detected a TX FIFO overflow
TXF_UFL_srq	ERR_INT	TX FIFO Underflow Request I2C kernel has detected a TX FIFO underflow. The transmission is finished after the current byte. A stop condition is generated if the kernel works as master. The kernel changes to listening state
RXF_OFL_srq	ERR_INT	RX FIFO Overflow Request I2C kernel has detected an RX FIFO overflow and the incoming character is discarded. The kernel puts a not-acknowledge on the bus and changes to listening state. A stop condition is generated if the kernel works as master
RXF_UFL_srq	ERR_INT	RX FIFO Underflow Request FIFO has detected an RX FIFO underflow
AM_srq	P_INT	Address Match Request Device (master or slave) has been addressed by a remote master (also indicated in bit-field BS in register BUSSTAT)
GC_srq	P_INT	General Call Request When the general call matching process is activated this interrupt indicates that another master has put a general call on the I2C-bus
MC_srq	P_INT	Master Code Request When the master code matching process is activated this interrupt indicates the appearing of a master code on the I2C-bus issued by a remote master. The request is generated after a not-acknowledge and the clock is released to high again
AL_srq	P_INT	Arbitration Lost Request Arbitration is lost after the device has tried to start a transmission on the I2C_bus
NACK_srq	P_INT	Not-acknowledge Received Request Not-acknowledge received when working as transmitter (that is RnW bit is 0)

(table continues...)

Table 1261 (continued) I2C module service requests

Service request	Interrupt request	Description
TX_END_srq	P_INT	Transmission End Request In master mode this event is produced by the I2C kernel to indicate that the transmission of the current packet has ended properly after the stop condition has been put on the I2C-bus or MASTER RESTART state has been entered. At this point, a restart condition can be generated or the connection can be finished by generating a stop condition. This request is created in master mode at any stop condition to indicate that the bus is free again and it could be obtained. In slave mode this event is produced by the I2C kernel if it was addressed by a master and the current transmission was terminated by a stop or restart condition
RX_srq	P_INT	Receive Mode Request I2C kernel indicates to the FIFO switching from transmit to receive mode. When FIFO is operating in non flow controller mode, this service request can be used to distinguish between transmit and receive FIFO data requests

The generation of these events is visualized in the Top-level state machine. The timing is shown in I2C kernel control logic.

Related information

I2C kernel control logic on page 5443

31.3.1.6.2 Interrupt service request structure

The I2C module provides level based service request lines, which can be processed by an interrupt controller. The service requests must be cleared in the interrupt service routine. For test purposes, all service requests can also be set by SW through a register bit. All service requests can be masked within the peripheral. Furthermore, requests that are not necessarily mutually exclusive are combined in order to reduce the number of request lines.

Flow of data transfer requests

The following figure shows the flow of a data transfer request, which comes from the FIFO controller.

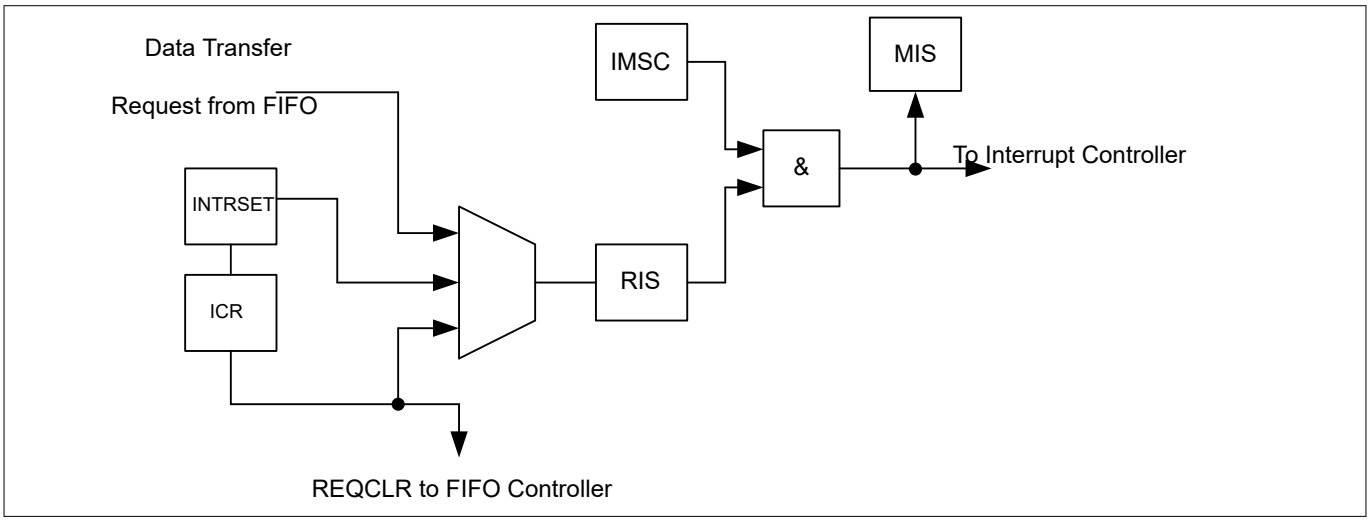

Figure 730 Data transfer request flow

A data transfer request sets the corresponding status bit in the Raw Interrupt Status Register RIS. The status bit can also be set by writing 1 to the corresponding bit in the Interrupt Set Register INTRSET. It will be cleared by writing 1 to the corresponding bit in the Interrupt Clear Register ICR.

The Interrupt Mask Control Register IMSC enables or disables the requests to the interrupt controller. The Masked Interrupt Status Register MIS contains the current masked values of the requests.

If a request is disabled through register IMSC while the request is active, the request will be removed but only until the IMSC bit is set again, unless the request has been cleared in the meantime.

If a request is disabled through register IMSC and the source becomes active, then the request bit will only be set in the RIS register. If the corresponding IMSC bit is later enabled, the request will consequently become active in the MIS register.

Before enabling a request, it is good practice to always first clear the corresponding bit in the RIS register through ICR.

Multiple source interrupt requests

For error and protocol interrupt requests which have multiple sources, the interrupt structure is extended. Additional register sets are implemented within the SRB.

The following figure gives an overview of the combining of several request sources to a single request.

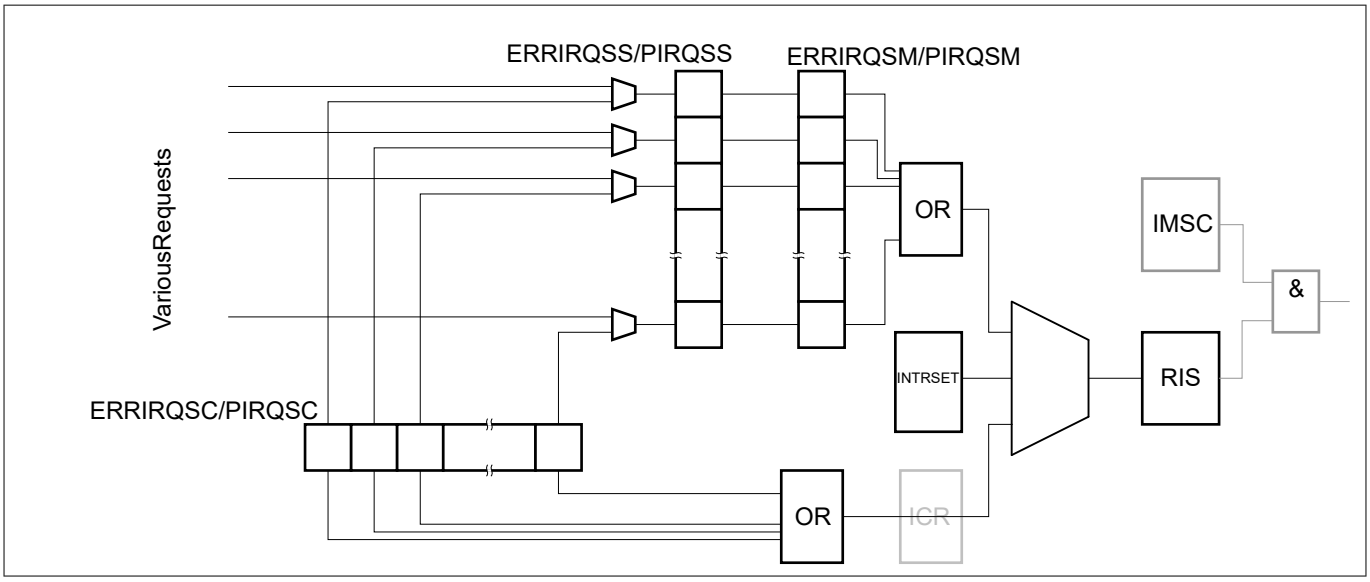

Figure 731 Interrupt request with multiple sources

An interrupt request sets the corresponding raw status bit in the Interrupt Request Source Status Register ERRIRQSS (for error) or PIRQSS (for protocol).

The status bits can be cleared through the Interrupt Request Source Clear Register ERRIRQSC (for error) or PIRQSC (for protocol). If no further error or protocol request sources are active, the whole error or protocol interrupt request is cleared. This register replaces the functionality of the bit I2C_ERR_INT (for error) or bit I2C_P_INT (for protocol) in the Interrupt Clear Register ICR.

The Interrupt Request Source Mask Register ERRIRQSM (for error) or PIRQSM (for protocol) enables or disables the interrupt requests. The request lines from the enabled sources are combined (OR) to a single level sensitive request line, which acts as input for the corresponding bit I2C_ERR_INT (for error) or I2Cm_bit I2C_P_INT (for protocol) in the Raw Interrupt Status Register RIS.

31.3.2 I2C module implementation

This section describes I2C module interfaces with the clock control, port control and interrupt control.

31.3.2.1 Interfaces of the I2C module(s)

The following figure shows the specific implementation details and interconnections of the I2C module(s):

- A clock control block generates the clock signals required for the module
- For the I2C-bus lines SCL and SDA, different I/O lines can be selected
- The interrupt outputs of the module are connected to the interrupt control unit

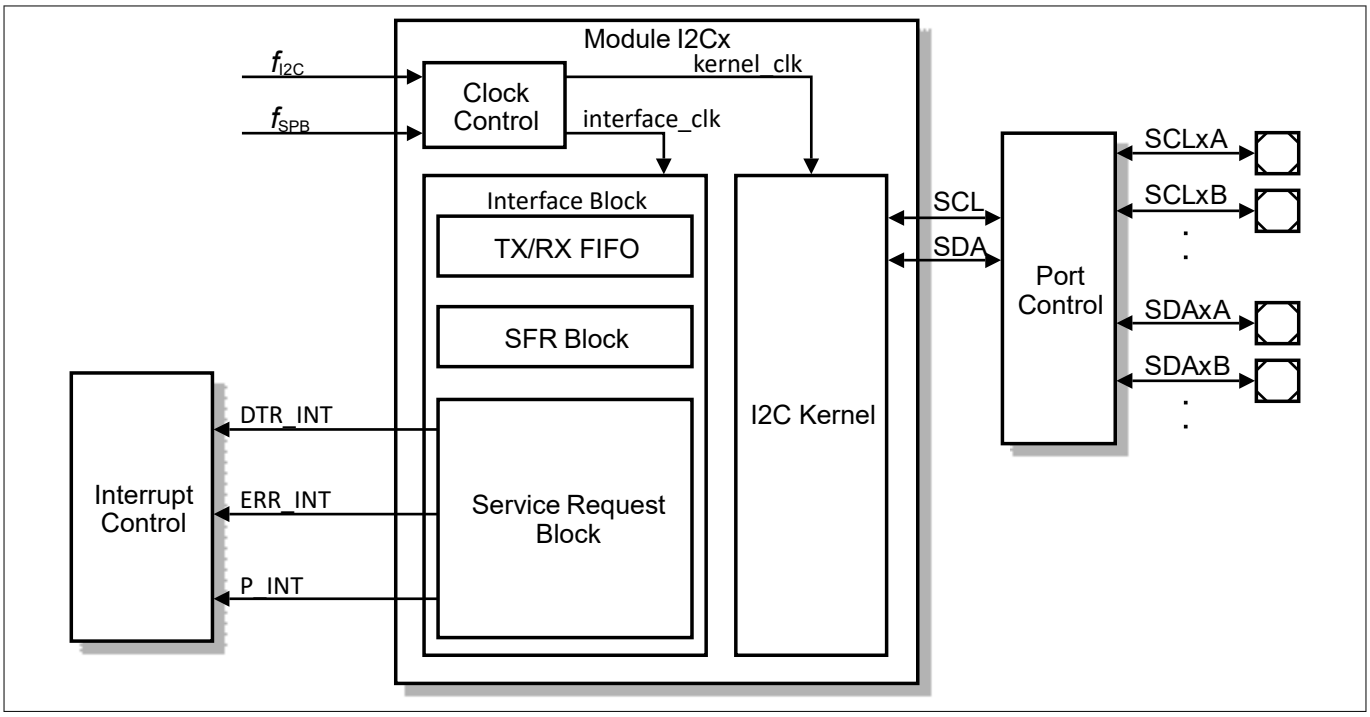

Figure 732 I2C module implementation and interconnections

31.3.2.2 Module clock control

The clock control allows the programmer to adapt the peripheral's functionality and power consumption to the application’s requirement. By programming the kernel’s operating frequency, an optimal ratio between power consumption, EMC behavior and functionality can be achieved. Furthermore, for power saving reasons the peripheral can be disabled as a whole by switching off the peripheral’s clocks through clock gating cells.

A simplified description of the clock control is shown in the following figure . See register CLC1 for a description of the clock control parameters.

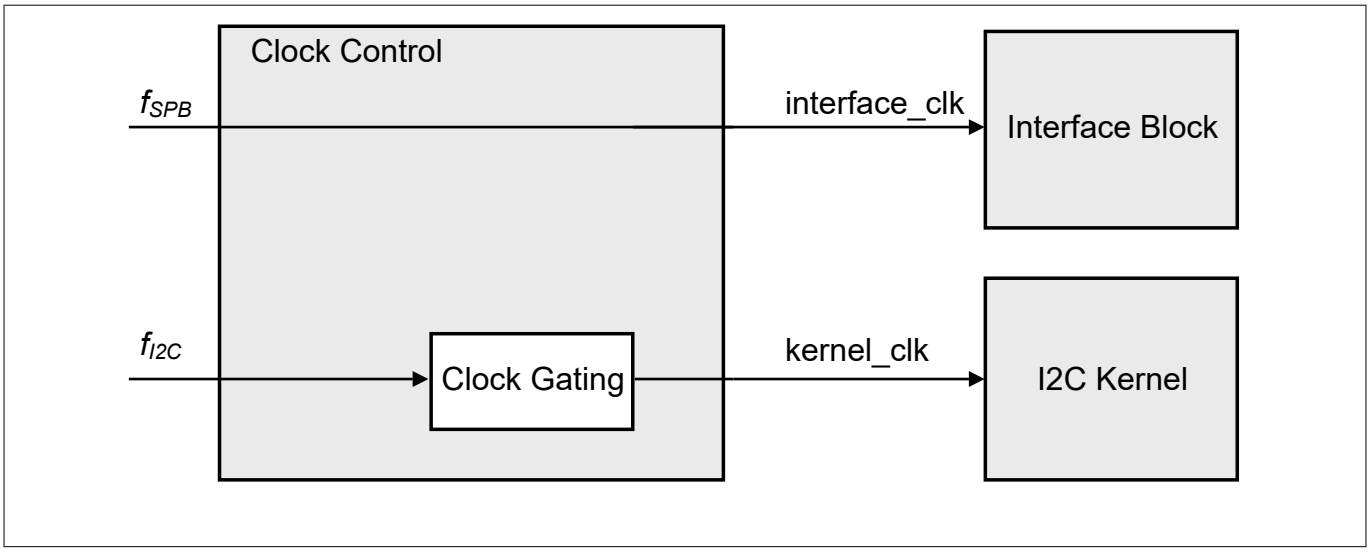

Figure 733 Module clock control

The following clocking modes are supported for the peripheral:

- Disabled mode
- OCDS suspend mode

Disabled mode

In Disabled Mode, the clocks are stopped and register write accesses are not possible (except access to CLC1 register itself).

There are several ways possible to bring the module into disabled mode:

- Software disable
  Set CLC1.DISR = 1 (software disable request)
- Hardware disable
  Must be enabled through CLC1.EDIS = 0
  Drive input signal sleep_n_i = 0(active low: 0= disable; 1 = enable)

In all cases, current bus accesses are finished and a kernel handshake is issued to make sure that the state machine is in a safe state (same as CLC1.FSOE = 0 in OCDS Suspend Mode; see description below).

Module is in Disabled Mode after reset and must be enabled by setting CLC1.DISR = 0 and CLC1.RMC > 0.

OCDS suspend mode

In this mode the clocks are disabled. If bit SPEN in register CLC1 is set, the suspend mode can be entered.

In OCDS suspend mode, all registers of the suspended module can be read. Note that each read during disabled clock can not affect hardware. For example multiple reads to FIFO port registers always return the same value as the FIFO control is not working.

No write access to the registers is supported during suspend mode, except writes to the CLC1 register. For writing other registers the suspend mode for the module has to be removed first by clearing bit SPEN. After the write access is executed, bit SPEN should be set again.

OCDS suspend mode supports two different disable features, selectable by bit FSOE in register CLC1:

***Note**: To write to SPEN or FSOE, bit SBWE in register CLC1 must also be set in the same write access.*

- Secure clock switch off
  Disabling the clock through secure clock switch off additionally activates the handshake mechanism with the peripheral. The peripheral is switched to a secure state before disabling the clock

With secure clock switch off:

- Internal state machine will wait until a safe state is reached
- SCL_out will be tied to 0 to delay I2C bus operation

***Note**: This feature is only available in slave mode. In master mode, there is no difference and I2C will always perform "fast clock switch off"*

- Fast clock switch off

  Selecting the fast clock switch off stops the clock immediately after all pending read and write accesses are finished (including synchronization mechanisms with the I2C kernel)

  With fast clock switch off:

  - I2C will go into the suspend mode immediately after the current register access operation is finished. FSM will remain in the latest state. In master mode, all clocks will be stopped, SCL will hold latest level. In slave mode, SCL_out will be tied 0 to delay I2C bus operation
  - Depending on timing of the input signal of OCDS_suspend_i I2C bus protocol may be violated

  ***Notes**:*

  ***1.** This also applies when I2C is programmed as master but accessed as slave from another master*

  ***2.** SCL = 0 is only driven when bus operation was detected by a start condition*

31.3.2.3 Port and I/O line control

Not only the interconnections between the I2C module and the port I/O lines have to be configured, but also the function and the characteristics of the port pins. The following control operations must be executed for the used port pins:

- Selection of I2C module through output port multiplexer
- Configuration of output port function with open drain
- Configuration of pad driver characteristics
- Selection of I2C input lines

31.3.2.4 Interrupt control

The interrupt functionality is described in more detail under the chapter interrupt router (IR).

The signal names used in the interrupt router description are explained in the following table .

Table 1262 Interrupt router signal names for I2Cm module (m is the instance number)

Signal name	Name in module	Explanation
SRC_I2CmDTR	DTR_INT	Data transfer
SRC_I2CmERR	ERR_INT	Error
SRC_I2CmP	P_INT	Protocol

31.3.3 Module integration overview

This section describes the topics regarding the integration of the module on chip. The I2C module consists of a delivery providing an AHB bus interface integrated into the FPI bus system by using abridge between FPI and AHB.

The bridge contains a slave bus interface providing translation between the FPI and the AHB bus protocols. The module supports additionally the following features:

- Power saving (sleep mode)
- Debug suspend
- Local module reset
- PISEL - port input selection regarding the serial data input

***Note**:* *The FPI slave interface has support for read modify write (RMW) transactions. This type of transaction shall not be used for I2C module and kernel registers which can be written by the kernel, indicated by bit-fields of type rwh . The reason for this limitation is a potential modification of the register content during the transaction.*

The power saving and debug suspend features are supported by the AHB based I2C module itself, and the local module reset and PISEL features are supported by the bridge between FPI and AHB, see the following figure.

31.4 Registers

31.4.1 Registers overview

This section describes the internal registers of the I2C module. All register names described in this section are also referenced in other parts of the I2C by the module name prefix “I2Cm_”. For an overview of all internal module registers, please refer to the Registers overview table.

Special I2C register access conditions

Besides the general register protection, the I2C module has two main modes that must be considered when programming the peripheral:

- Configuration Mode: In this mode, the peripheral can be prepared for transmission and reception through the configuration registers, which are only writable in this mode. The peripheral is in the configuration mode when bit RUN is set to 0
- Run Mode: In this mode, the peripheral is ready to transmit or receive data. Its configuration registers are locked for write access which will generate a bus error. The peripheral is in the run mode when bit RUN is set to 1

I2C registers overview

The I2C registers are grouped in to the following blocks (see figure below):

- Bus Peripheral Interface Registers
- Global Module Control Registers
- FIFO Registers
- Basic Interrupt Registers
- Error Interrupt Source Registers
- Protocol Interrupt Source Registers

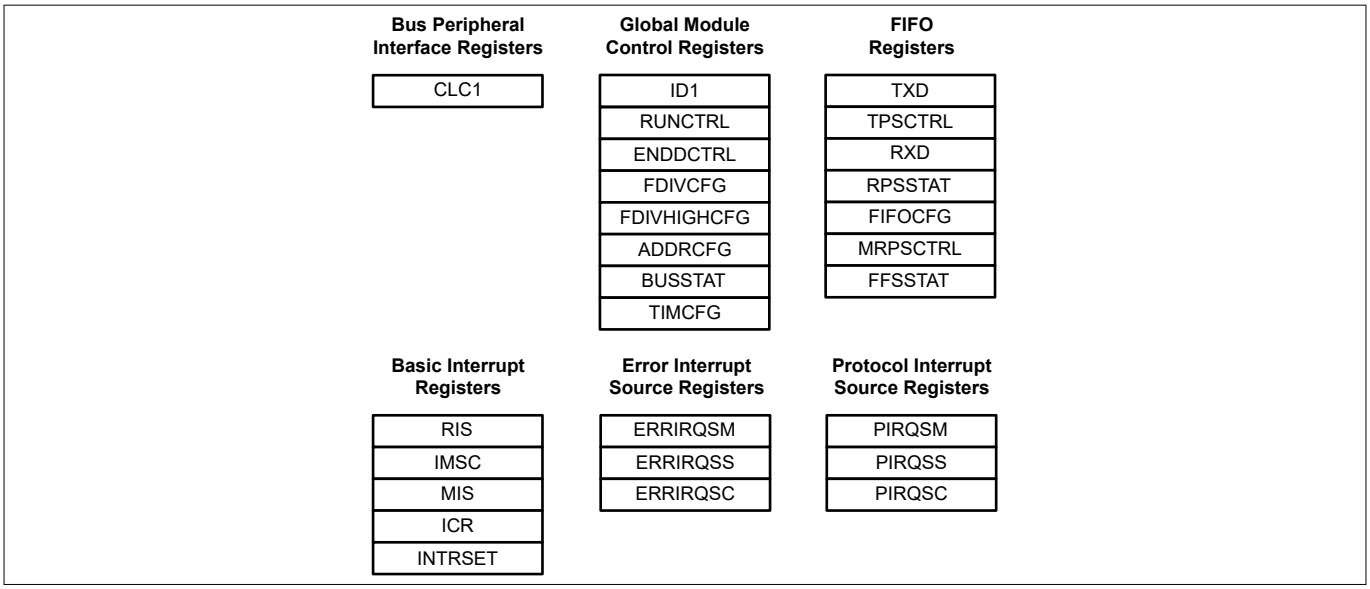

Figure 735 I2C registers

System registers overview

Figure 736 provides an overview of the remaining system registers of the I2C.

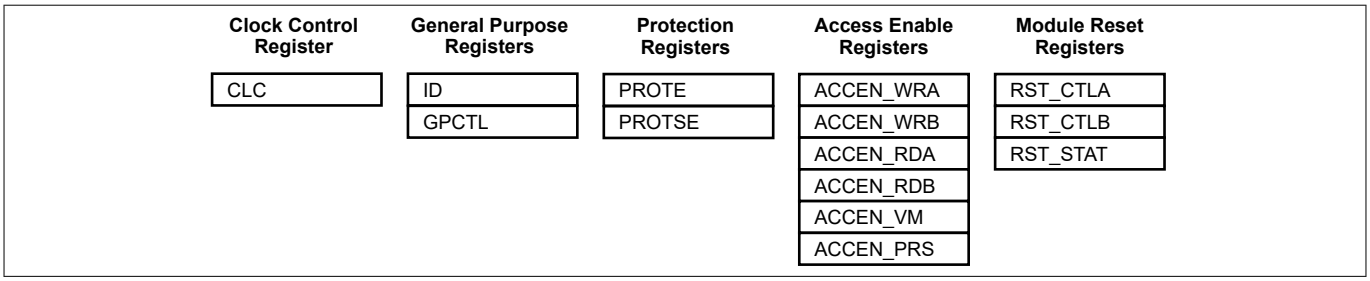

Figure 736 System registers

31.4.1.1 Register overview - access mode glossary

Table 1263 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
U	No access restrictions.
BE	Always returns a Bus Error.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.
PROT	Access restrictions as defined in the PROT register access rules.

(table continues...)

(continued)

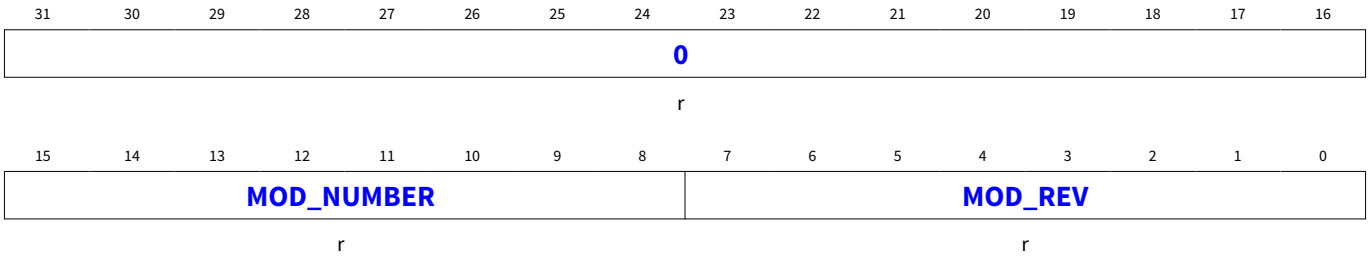
Field	Bits	Type	Description
DISS	1	rh	**Module Disable Status Bit** Bit indicates the current status of the module. 0_B Module enabled 1_B Module disabled
SPEN	2	rw	**Module Suspend Enable Bit for OCDS** 0_B Module suspend disabled 1_B Module suspend enabled
EDIS	3	rw	**External Request Disable** ***Note:*** *This bit is not used in TC4Dx and should always be written with 0.* 0_B External clock disable request is enabled 1_B External clock disable request is disabled
SBWE	4	w	**Module Suspend Bit Write Enable for OCDS** This bit is always read as 0. 0_B Bits SPEN and FSOE are write protected 1_B Bits SPEN and FSOE are overwritten by respective value of SPEN or FSOE
FSOE	5	rw	**Fast Switch Off Enable** 0_B FSOE Clock switch off in OCDS suspend mode via Disable Control Feature (Secure Clock Switch Off) 1_B Fast clock switch off in OCDS suspend mode
RMC	15:8	rwh	**Clock Divider for Standard Run Mode** Max. 8-bit divider value If RMC is set to 0 the module is disabled. ***Note:*** *As long as the new divider value RMC is not valid, reading register returns 0000 00XX$_H$*
RESERVED	23:16,	r	**Reserved** Read as 0; shall be written with 0.
0	7:6, 31:24	r	**Reserved** Read as 0; should be written with 0.

31.4.1.4 Module identification register

This register contains read-only information about the module and its revision.

ID1 Offset address: 00008_H

Module identification register Kernel Reset value: $0000\ 5705_H$



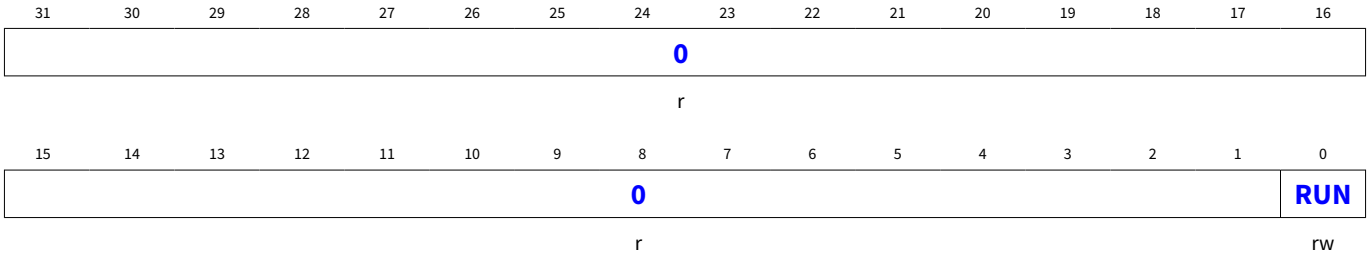
Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision Number** This bit-field defines the revision number.
MOD_NUMBER	15:8	r	**Module Number** This bit-field defines the module identification number.
0	31:16	r	**Reserved** Read as 0.

31.4.1.5 RUN control register

This register selects configuration mode or run mode.

RUNCTRL Offset address: 00010_H

RUN control register Kernel Reset value: $0000\ 0000_H$



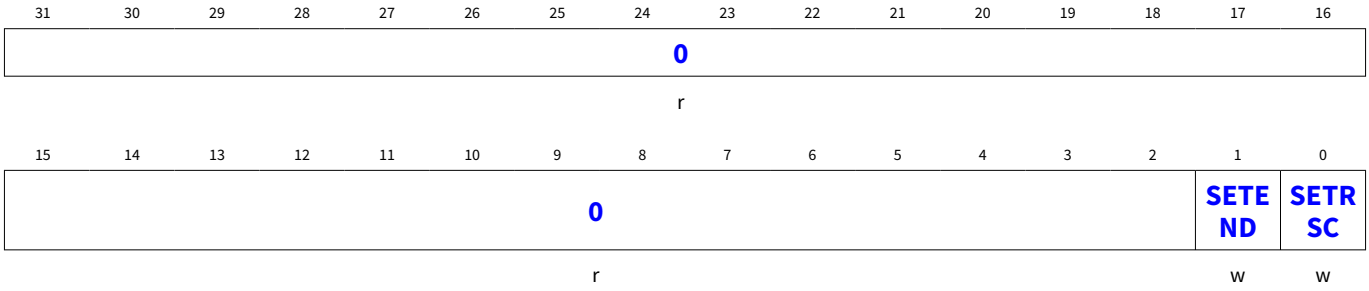
Field	Bits	Type	Description
RUN	0	rw	**Enable I2C-bus Interface** 0_B I2C-bus interface disabled; write access to configuration registers enabled 1_B Participation in I2C-bus communication enabled (if properly configured); write access to configuration registers disabled
0	31:1	r	**Reserved** Read as 0; should be written with 0.

31.4.1.6 End data control register

This register is used to either turn around the data transmission direction or address another slave without sending a stop condition. Also the software can stop the slave-transmitter by sending a not-acknowledge when working as master-receiver or even stop data transmission immediately when operating as master-transmitter. The writing to the bits of this control register is only effective in certain states.

ENDDCTRL Offset address: 00014_H

End data control register Kernel Reset value: $0000\ 0000_H$



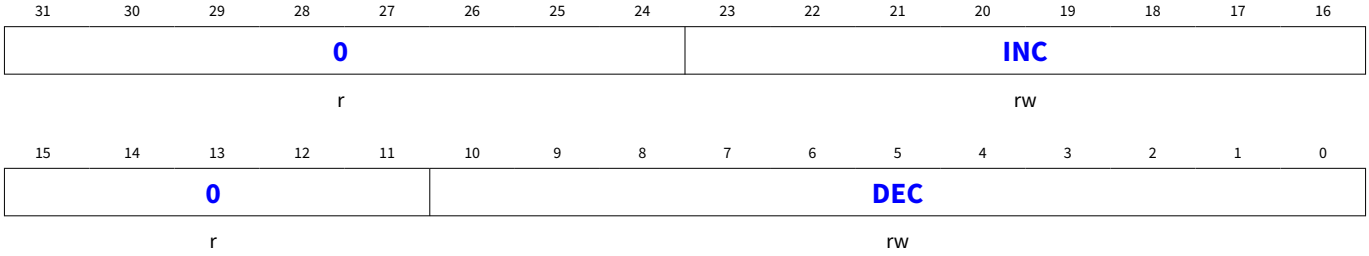
Field	Bits	Type	Description
SETRSC	0	w	**Set Restart Condition** This bit is always read as 0. 0_B Has no effect. 1_B The master wants to restart a data transmission (changing slave/ direction). The effect depends on the current state. MASTER RECEIVES BYTES: The master puts a not-acknowledge on the bus and switches to MASTER RESTART state. MASTER TRANSMITS BYTES: After the current byte has been sent, the master switches to MASTER RESTART state.
SETEND	1	w	**Set End of Transmission** This bit is always read as 0. ***Note**: Do not write 1 to this bit when bus is free. This will cause an abort after the first byte when a new transfer is started.* 0_B Has no effect. 1_B The effect depends on the current state. MASTER RECEIVES BYTES: After receiving the current byte, the master puts a not-acknowledge on the bus to indicate the transmission end to the slave-transmitter. Next it produces a stop condition on the bus and changes its state to LISTENING. MASTER TRANSMITS BYTES: After sending the current byte and receiving an acknowledge or not-acknowledge from the slave-receiver, the master puts a stop condition on the bus to close the data transmission and changes its state to LISTENING. MASTER RESTART: The master puts a stop condition on the bus to close the data transmission and changes its state to LISTENING. SLAVE RECEIVES BYTES: The slave-receiver puts a not-acknowledge on the bus after the received byte and changes its state to TRANSMISSION FINISHED.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

31.4.1.7 Fractional divider configuration register

This configuration register is used to program the fractional divider of the I2C-bus for standard and fast mode. Before the peripheral is switched on by setting the RUN bit, the register should be configured.

FDIVCFG Offset address: 00018_H

Fractional divider configuration register Kernel Reset value: $0000\ 0000_H$



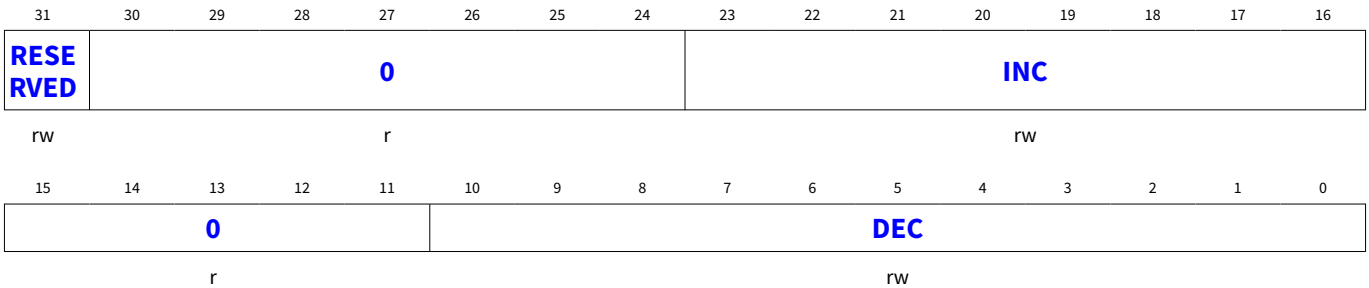
Field	Bits	Type	Description
DEC	10:0	rw	**Decrement Value of Fractional Divider** For standard/fast mode, see Clock and timing control section
INC	23:16	rw	**Increment Value of Fractional Divider** For standard/fast mode, see Clock and timing control section.
0	15:11, 31:24	r	**Reserved** Read as 0; should be written with 0.

31.4.1.8 Fractional divider high-speed mode configuration register

This configuration register is used to program the fractional divider of the I2C-bus for high-speed mode. Before the peripheral is switched on by setting the RUN bit, the register should be configured if high-speed mode is used.

FDIVHIGHCFG Offset address: $0001C_H$

Fractional divider high-speed mode configuration register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DEC	10:0	rw	**Decrement Value of Fractional Divider** For high-speed mode, see Clock and timing control section.
INC	23:16	rw	**Increment Value of Fractional Divider** For high-speed mode, see Clock and timing control section

(table continues...)

(continued)

Field	Bits	Type	Description
RESERVED	31	rw	**Reserved** Read as 0; shall be written with 0.
0	15:11, 30:24	r	**Reserved** Read as 0; should be written with 0.

31.4.1.9 Address configuration register

This configuration register contains the I2C-address (when addressed as a slave) and some bits that control the basic operation of the peripheral.

ADDRCFG Offset address: 00020_H

Address configuration register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						ADR									
r						rw									

Field	Bits	Type	Description
ADR	9:0	rw	**I2C-bus Device Address** This bit-field determines the address of the device when addressed as a slave. (Watch out for reserved addresses by referring to I2C-bus spec V2.1.) Depending on setting of TBAM, this is either a 7-bit address (bits [7:1]) or a 10-bit address (bits [9:0]).
TBAM	16	rw	**Ten Bit Address Mode** ***Note**: When this bit is zero, only bits 7 down to 1 of the ADR field are valid.* 0_B 7-bit address mode enabled. 1_B 10-bit address mode enabled.
GCE	17	rw	**General Call Enable** 0_B Ignore general call occurrence. 1_B Enable general call detection; when detected, an acknowledge will be put on the bus
MCE	18	rw	**Master Code Enable** 0_B Device is not able to get along with high-speed mode 1_B Device is able to handle master code
MnS	19	rw	**Master / not Slave** 0_B Peripheral is configured as slave 1_B Peripheral is configured as master

(table continues...)

(continued)

Field	Bits	Type	Description
SONA	20	rw	**Stop on Not-acknowledge** ***Note**: After successful transmission of a master code (during high-speed mode) SONA is not considered till a stop condition is manually generated by SETEND.* 0_B Device changes to MASTER RESTART state. 1_B Device puts a stop condition on the bus and changes to LISTENING state.
SOPE	21	rw	**Stop on Packet End** ***Notes**:* ***1.** This bit-field should be used only in Master Mode. In slave mode should always be 0.* ***2.** If device works as receiver a not-acknowledge is always generated on package end.* ***3.** After successful transmission of a master code (during high-speed mode) SOPE is not considered till a stop condition is manually generated by SETEND.* 0_B Device enters MASTER RESTART state when the data packet end is indicated by the FIFO. 1_B Device puts a stop condition on the bus when the data packet end is indicated by the FIFO and changes to MASTER LISTENING state.
0	15:10, 31:22	r	**Reserved** Read as 0; should be written with 0.

31.4.1.10 Bus status register

This register contains status information of the I2C-bus. This additional information can be used by software to start appropriate actions.

BUSSTAT Offset address: 00024_H

Bus status register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TXBS	5:4	rw	**TX Burst Size** 00_B 1 word 01_B 2 words 10_B 4 words 11_B Do not use this combination

(table continues...)

(continued)

Field	Bits	Type	Description
RXFA	9:8	rw	**RX FIFO Alignment** 00_B Byte aligned (character alignment) 01_B Half word aligned (character alignment of two characters) 10_B Word aligned (character alignment of four characters) 11_B Do not use this combination
TXFA	13:12	rw	**TX FIFO Alignment** 00_B Byte aligned (character alignment) 01_B Half word aligned (character alignment of two characters) 10_B Word aligned (character alignment of four characters) 11_B Do not use this combination
RXFC	16	rw	**RX FIFO Flow Control** 0_B RX FIFO not as flow controller 1_B RX FIFO as flow controller
TXFC	17	rw	**TX FIFO Flow Control** 0_B TX FIFO not as flow controller 1_B TX FIFO as flow controller
CRBC	18	rw	**Clear Request Behavior Configuration** Used to configure the clear request behavior for the FIFO data request. Can only be used for single request and must be set to “0” when burst accesses are used in the system (eg. when TX/RXBS > 0) 0_B Data request is cleared by Software. 1_B Data request is cleared automatically when Write/Read access to FIFO occurs.
0	3:2, 7:6, 11:10, 15:14, 31:19	r	**Reserved** Read as 0; should be written with 0.

31.4.1.12 Maximum received packet size control register

This register is used to limit the received packet size. The register value may be changed in any state of the FIFO.

MRPSCTRL Offset address: $0002C_H$

Maximum received packet size control register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		MRPS													
r		rwh													

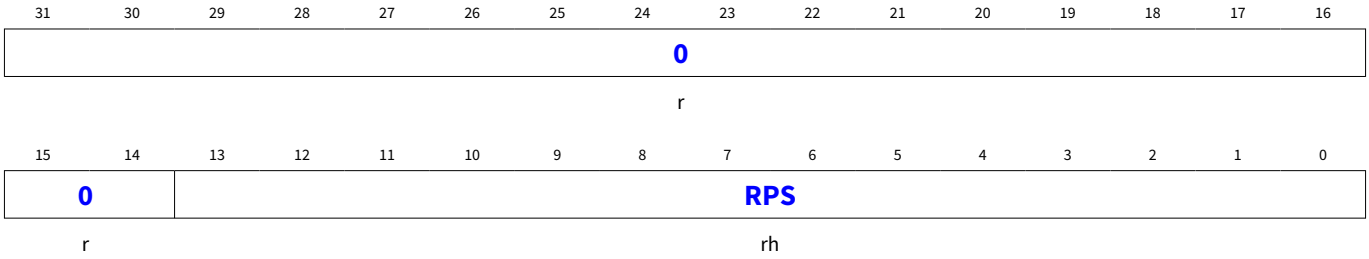
Field	Bits	Type	Description
MRPS	13:0	rwh	**Maximum Received Packet Size** Length in characters of packet to be received; write value range: 0 (unlimited size) to 16383 Reading returns the written value as long as the previous packet has not been read completely from the FIFO. After that, MRPS is loaded to an internal register, reading returns 0 and a new value can be written.
0	31:14	r	**Reserved** Read as 0; should be written with 0.

31.4.1.13 Received packet size status register

This register indicates the size of the received data packet to the software. The software should read this register after the last request of a packet.

RPSSTAT Offset address: 00030_H

Received packet size status register Kernel Reset value: $0000\ 0000_H$



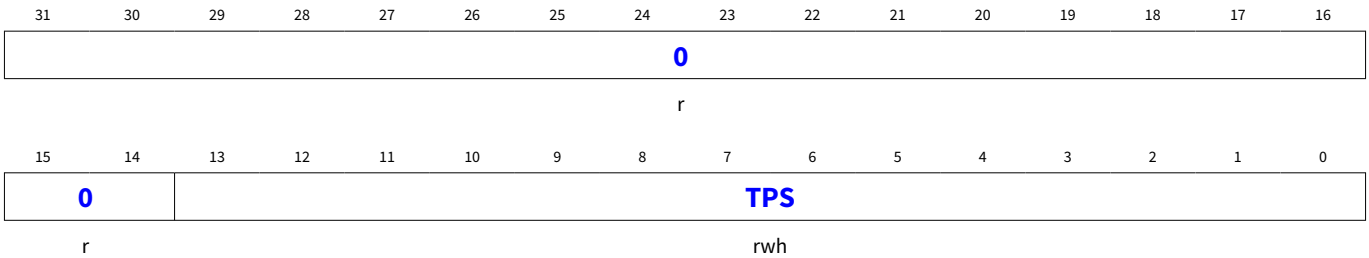
Field	Bits	Type	Description
RPS	13:0	rh	**Received Packet Size** Length in characters of the received packet (0 to 16383)
0	31:14	r	**Reserved** Read as 0.

31.4.1.14 Transmit packet size control register

This register is used to indicate the peripheral the size of the packet to be transmitted. Writing the packet size to this register if the FIFO controller is configured for flow controller mode initiates the data requests (BREQ, SREQ, ...).Writing to this register in configuration state has no impact.

TPSCTRL Offset address: 00034_H

Transmit packet size control register Kernel Reset value: $0000\ 0000_H$



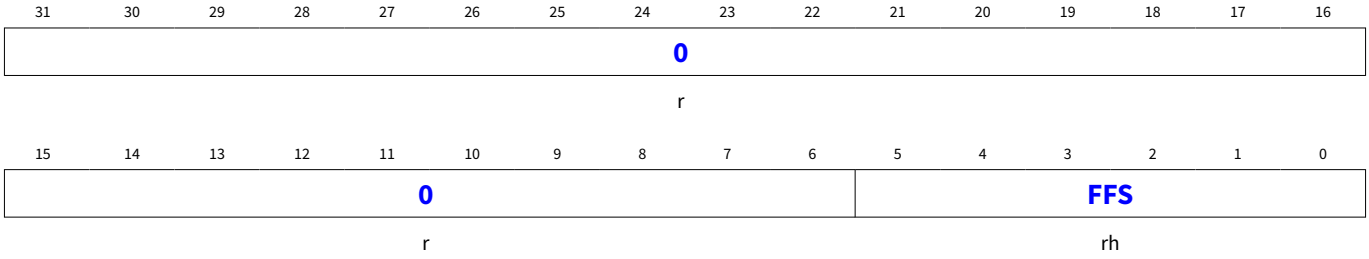
Field	Bits	Type	Description
TPS	13:0	rwh	**Transmit Packet Size** Length in characters of the transmit packet, write value range: 1 to 16383 Reading returns the written value as long as it is not loaded to an internal counter. After that, reading returns 0 and a new value can be written.
0	31:14	r	**Reserved** Read as 0; should be written with 0.

31.4.1.15 Filled FIFO stages status register

This register is used to indicate the number of filled FIFO stages.

FFSSTAT Offset address: 00038_H

Filled FIFO stages status register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
FFS	5:0	rh	**Filled FIFO Stages** Number of filled FIFO stages (0 to 8)
0	31:6	r	**Reserved** Read as 0.

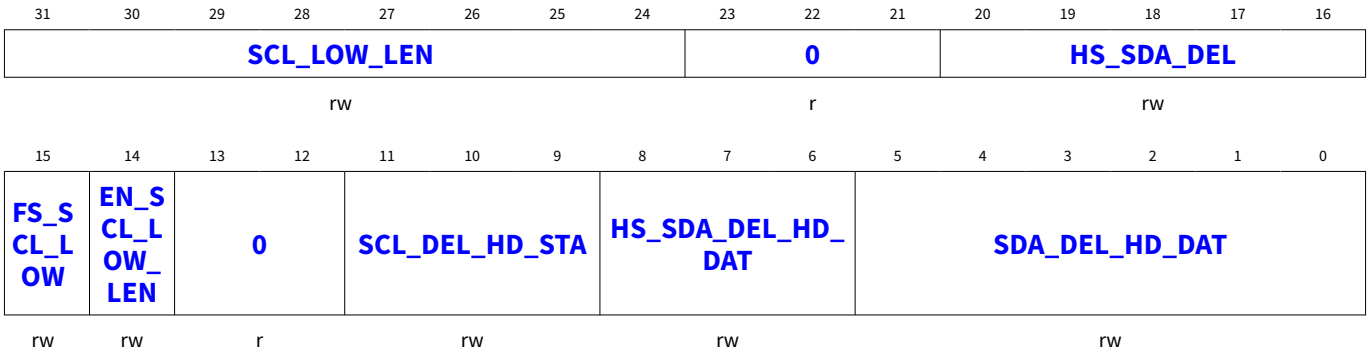
31.4.1.16 Timing configuration register

This configuration register adjusts some timings of the I2C-bus signals SCL and SCA. The delays are given in kernel_clk cycles (denoted as stages below).

The delayed stages may have +/- 1 stage deviation.

TIMCFG Offset address: 00040_H

Timing configuration register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SDA_DEL_HD_DAT	5:0	rw	**SDA Delay Stages for Data Hold Time in Standard and Fast modes** SDA delay stages for data hold time in standard and fast modes. ***Note:*** *SDA delay from SCL falling edge but will also affect SDA Setup time relative to next SCL rising edge* 00_H 3 stages delay … $3F_H$ 66 stages delay
HS_SDA_DEL_HD_DAT	8:6	rw	**SDA Delay Stages for Data Hold Time in High-speed Mode** SDA delay stages for data hold time in HS mode. ***Note:*** *SDA delay from SCL falling edge but will also affect SDA Setup time relative to next SCL rising edge* 000_B 3 stages delay … 111_B 10 stages delay
SCL_DEL_HD_STA	11:9	rw	**SCL Delay Stages for Hold Time Start (Restart) Bit** 000_B 2 stages delay … 111_B 9 stages delay
EN_SCL_LOW_LEN	14	rw	**Enable Direct Configuration of SCL Low Period Length in Fast Mode** 0_B SCL low period is a fixed part of the whole period, as defined by FS_SCL_LOW 1_B SCL low period is determined by the setting of SCL_LOW_LEN
FS_SCL_LOW	15	rw	**Set Fast Mode SCL Low Period Timing** The internal duration of the SCL low time with respect to the period length as defined by the baudrate setting, can be enlarged for the Fast Speed Mode, in order to meet the asymmetric duty cycle requirements from the standard. The detailed formulas are given in the functional specification. 0_B Standard mode SCL low period timing. For INC = 1 it is 5/8 of period. 1_B Fast mode SCL low period timing. For INC = 1 it is 6/8 of period.

(table continues...)

(continued)

Field	Bits	Type	Description
HS_SDA_DEL	20:16	rw	**SDA Delay Stages for Start/Stop bit in High-speed Mode** 00_H 3 stages delay … 07_H 10 stages delay
SCL_LOW_LEN	31:24	rw	**SCL Low Length in Fast Mode** If enabled by EN_SCL_LOW_LEN setting, this field determines the extension of the SCL low time. In case of INC = 1, the low time is extended by the number of kernel_clk cycles. In general, there is a more complex formula, as given in the functional specification. The total period time is not changed, i.e., the SCL high period is reduced accordingly. Setting SCL low time to period length or higher is not supported and would lead to unpredictable results.
0	13:12, 23:21	r	**Reserved** Read as 0; should be written with 0.

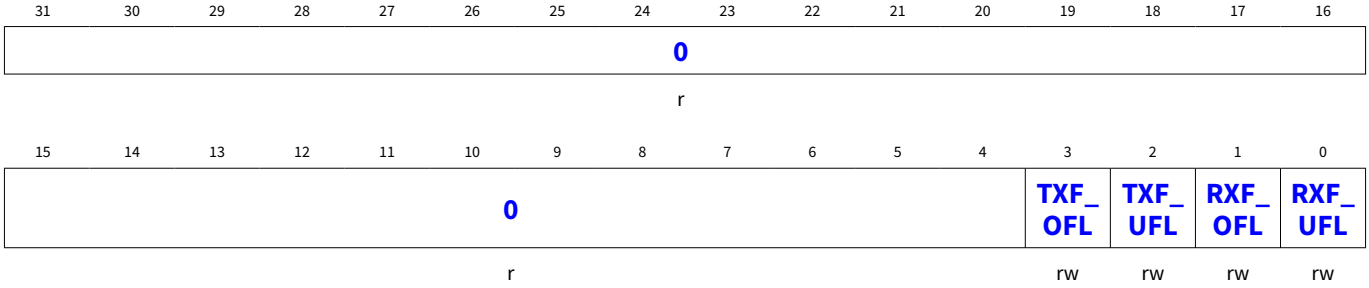
31.4.1.17 Error interrupt request source mask register

A write of 1 to a particular bit of this register enables the corresponding error interrupt request source; a write of 0 disables it. A read to this register returns the current mask bits. After reset all sources are enabled.

The interrupts are explained in detail in description of register ERRIRQSS.

ERRIRQSM Offset address: 00060_H

Error interrupt request source mask register Kernel Reset value: $0000\ 000F_H$



Field	Bits	Type	Description
RXF_UFL	0	rw	**RX FIFO Underflow** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
RXF_OFL	1	rw	**RX FIFO Overflow** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
TXF_UFL	2	rw	**TX FIFO Underflow** 0_B Interrupt request source disabled 1_B Interrupt request source enabled

(table continues...)

(continued)

Field	Bits	Type	Description
TXF_OFL	3	rw	**TX FIFO Overflow** 0_B Interrupt request source disabled 1_B Interrupt request source enabled
0	31:4	r	**Reserved** Read as 0; should be written with 0.

31.4.1.18 Error interrupt request source status register

This read-only register returns the current raw status value (without reflecting the mask) of the error interrupt request sources. A write to this register has no effect. The error status bits are set by hardware and can be cleared by software (via register ERRIRQSC).

ERRIRQSS Offset address: 00064_H

Error interrupt request source status register Kernel Reset value: $0000\ 0000_H$

0	31:6	r	**Reserved** Read as 0; should be written with 0.

31.4.1.28 Transmission data register

The software has to write the characters to be transmitted into this register.

An address range of (8000_H to 8003_H) is reserved for the FIFO.

A read access to TXD register is not possible, it will return 0 in all cases. Reading has no effect on the FIFO.

When using byte or half word access from the bus, the TX FIFO pointer will only be increased, if one of the following conditions is fulfilled:

- The most significant byte or half word of the FIFO stage is written
- The packet end is reached

TXD Offset address: 08000_H

Transmission data register Kernel Reset value: $0000\ 0000_H$

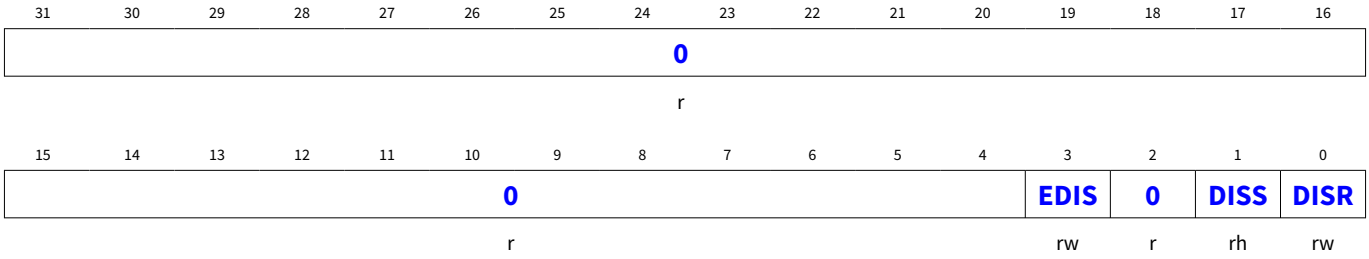
31.4.1.30 Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 10000_H

Clock Control Register Application Reset value: $0000\ 0003_H$

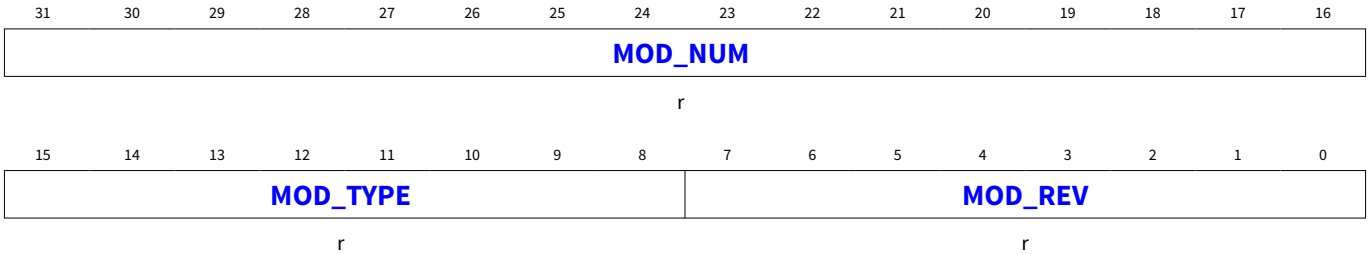


Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

31.4.1.31 Module Identification Register

ID Offset address: 10008_H

Module Identification Register Application Reset value: $00C2\ C000_H$



Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number.

31.4.1.32 Reset Control Register A

RST_CTRLA Offset address: $1000C_H$

Reset Control Register A Application Reset value: $0000\ 0000_H$

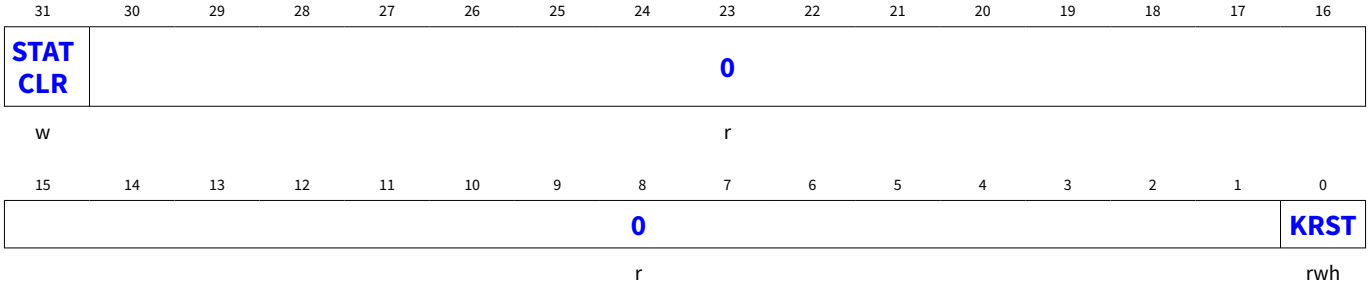
31.4.1.33 Reset Control Register B

RST_CTRLB Offset address: 10010_H

Reset Control Register B Application Reset value: $0000\ 0000_H$



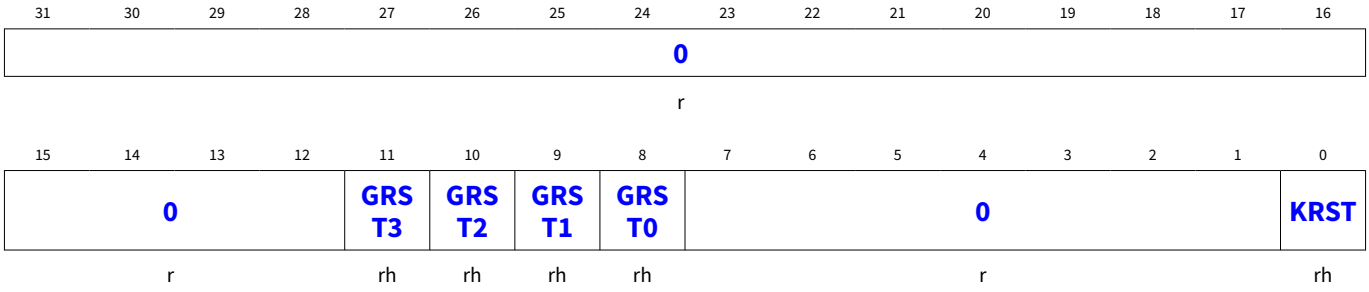
Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
STATCLR	31	w	**Kernel Reset Status Clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits STAT.GRSTx and bit STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

31.4.1.34 Reset Status Register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: 10014_H

Reset Status Register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rh	**Kernel reset status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.

(table continues...)

(continued)

Field	Bits	Type	Description
GRSTx (x=0-3)	x+8	rh	**Status for global module reset group x** 0_B Reset was not triggered by global reset group x 1_B Reset was triggered by global reset group x
0	7:1, 31:12	r	**Reserved** Read as 0.

31.4.1.35 PROT Register Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 10020_H

PROT Register Endinit Application Reset value: $0000\ 0000_H$

STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.

(table continues...)

(continued)

Field	Bits	Type	Description
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1265 Access mode restrictions of PROTE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

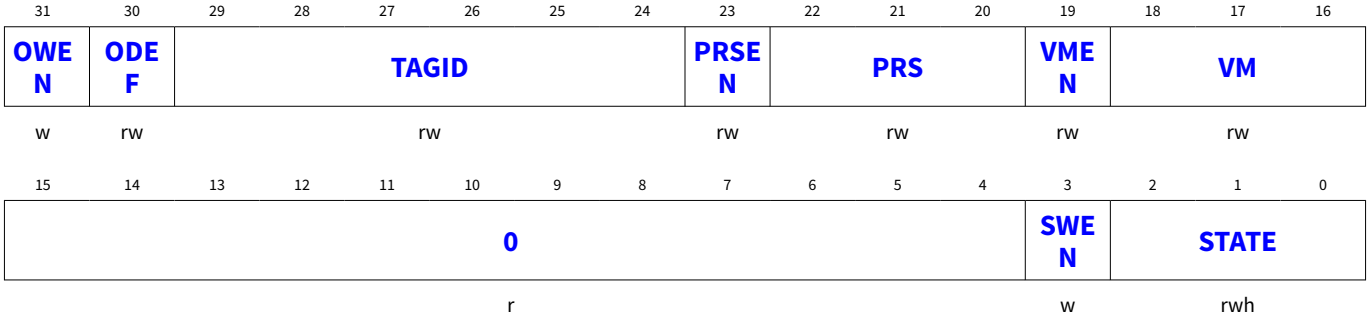
31.4.1.36 PROT Register Safe Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 10024_H

PROT Register Safe Endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1266 Access mode restrictions of PROTSE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

31.4.1.37 Write access enable register A

This register defines which master agent function TAG identifier (TAG-ID) encodings are enabled or disabled for write accesses to the access protected region.

ACCEN_WRA Offset address: 10040_H

Write access enable register A Application Reset value: $1000\ 0003_H$

Field	Bits	Type	Description
RDq (q=00-07)	q	rw	**Read access enable for VM ID q** This bit enables read access to the access protected region for transactions with the VM ID q. 0_B Disabled for read access 1_B Enabled for read access

(table continues...)

(continued)

Field	Bits	Type	Description
WRq (q=00-07)	q+16	rw	**Write access enable for VM ID q** This bit enables write access to the access protected region for transactions with the VM ID q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

31.4.1.42 PRS access enable register

This register defines which protection register set encodings are enabled or disabled for accesses to the access protected region. There is one RDx and WRx bit for each PRSx.

ACCEN_PRS Offset address: 10054_H

PRS access enable register Application Reset value: $00FF\ 00FF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0								RD07	RD06	RD05	RD04	RD03	RD02	RD01	RD00
r								rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
RDq (q=00-07)	q	rw	**Read access enable for PRS q** This bit enables read access to the access protected region for transactions with the PRS q. 0_B Disabled for read access 1_B Enabled for read access
WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

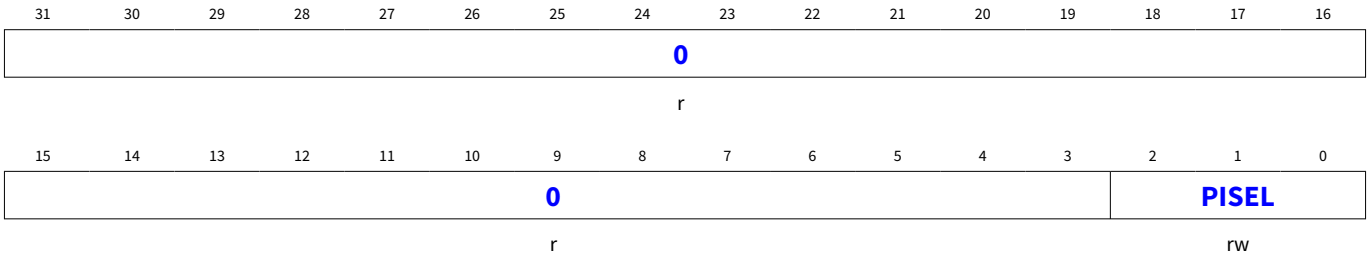
31.4.1.43 General purpose control register

This register implements the PISEL functionality. The SDA and SCL input multiplexors are controlled in parallel with each PISEL setting. Since 3 bits are implemented for PISEL, up to 8 sets of SDA and SCL pins can be defined.

The register is disabled if the module is disabled via CLC.

GPCTL Offset address: 10060_H

General purpose control register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PISEL	2:0	rw	**Port Input Select** Used to select the input pins providing the serial data and clock input signals, in the range of 0 to 7. ***Note**: In TC4Dx, not all PISEL options are available. See Data Sheet.* 000_B SDAxA and SCLxA are selected. 001_B SDAxB and SCLxB are selected. 010_B SDAxC and SCLxC are selected. 011_B SDAxD and SCLxD are selected. 100_B SDAxE and SCLxE are selected. 101_B SDAxF and SCLxF are selected. 110_B SDAxG and SCLxG are selected. 111_B SDAxH and SCLxH are selected.
0	31:3	r	**Reserved** Reads 0. Should be written with 0.

31.5 Debug information

This section is not applicable for the module being described.

31.6 References

31.8 TC4Dx I2C information

31.8.1 TC4Dx I2C configuration

Table 1267 Device specific parameters

Parameter	Value
Number of instances	3

31.8.2 TC4Dx I2C features

There are no deviations from the generic specification.

31.8.3 TC4Dx I2C functional description

In TC4Dx device, the I2C module is connected to ComPB bus interface.

31.8.4 TC4Dx I2C registers

There are no deviations from the generic specification.

31.8.4.1 Register address space - I2C

Table 1268 Registers address space - I2C

Module	Base address	End address	Note
I2C0	$F44C0000_H$	$F44DFFFF_H$	FPI slave interface
I2C1	$F44E0000_H$	$F44FFFFF_H$	FPI slave interface
I2C2	$F4500000_H$	$F451FFFF_H$	FPI slave interface

31.8.4.2 Register overview - access mode glossary

Table 1269 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register I2C0_PROTE or I2C1_PROTE or I2C2_PROTE .
SE	Access protection using PROT register I2C0_PROTSE or I2C1_PROTSE or I2C2_PROTSE .
APU-P	Protection group consisting of registers I2C0_ACCEN_WRA , I2C0_ACCEN_WRB , I2C0_ACCEN_RDA , I2C0_ACCEN_RDB , I2C0_ACCEN_VM , I2C0_ACCEN_PRS or I2C1_ACCEN_WRA , I2C1_ACCEN_WRB , I2C1_ACCEN_RDA , I2C1_ACCEN_RDB , I2C1_ACCEN_VM , I2C1_ACCEN_PRS or I2C2_ACCEN_WRA , I2C2_ACCEN_WRB , I2C2_ACCEN_RDA , I2C2_ACCEN_RDB , I2C2_ACCEN_VM , I2C2_ACCEN_PRS .
P	Access protection using *APU-P* registers.
U	No access restrictions.
BE	Always returns a Bus Error.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.
PROT	Access restrictions as defined in the PROT register access rules.

31.8.6 TC4Dx I2C revision history

Initial release of the chapter.

32 CLOCK

The clocking system is responsible for providing all clocks that are necessary for microcontroller operation. This is valid for all functional, test, and debug modes. It also provides clocks for external applications that can be selected from internal sources.

The clocking system is functionally divided into two major clock domains:

- System clock domain for clocks covering central processing units, interconnect and data transfers structures, non-volatile memories, timers, debug, trace, and the core functions of the communication interfaces
- Peripheral clock domain for the protocol related parts of the communication interfaces and analog digital converters

Each domain has a master clock which is used to derive the related sub-clocks by programmable division and clock gating. System clocks are synchronous to each other, and peripheral clocks are asynchronous to each other and to the system clocks. Selected clocks can be routed to external outputs for debug, test, and further processing.

32.1 Feature list

- Physical SoC interface for externally provided clocks (crystal oscillator (*XTAL OSC*) or HSSL system clock (*SYSCLK*))
- Internally generated back-up clock provided by an embedded voltage regulator (*EVR*) oscillator for independent operation in the absence of a crystal clock
- Internally generated linear ramp clock to support power-up and power-down, reset, and emergency operation with low supply voltage drops and low current peaks
- Up-scaling of externally supplied clocks up to a maximum frequency of *f*PLL0 as specified in the datasheet, phase locked loops (System *PLL*)
- Up-scaling of externally supplied clocks up to a maximum frequency of *f*PLL1, *f*PLL2 and *f*PLL3 as specified in the datasheet, phase locked loops (Peripheral *PLL*)
- System clock domain with frequency modulation to reduce electromagnetic interference (EMI)
- Peripheral clock domain with low jitter and low noise to comply with jitter and the signal-to-noise ratio requirements of selected communication protocols and analog to digital converters (*ADC*)
- Peripheral clock domain with frequency modulation for optional use to reduce EMI
- Low skew distribution of all system clocks to enable global synchronous operation within the microcontroller unit (*MCU*)
- Independent generation and distribution of all system and peripheral clocks
- Software programming interface for clock configuration and status observation
- Clock monitoring to support ASIL D safety protection and security
- Provision of selected internal system and peripheral clocks to physical outputs of the MCU
- Reset support functions (clock gating and frequency adaptation)

32.2 Functional overview

The clock system is built up as a chain composed from different building blocks which allow different function parts for the complete chain.

The building blocks as shown in the following figure are:

- Basic clock generation with internal and external oscillators (Clock Source)
- Clock speed up-scaling with phase locked loops (*PLL*)
- Clock distribution with clock control units (*CCU*)
- Individual clock configuration within other functional blocks

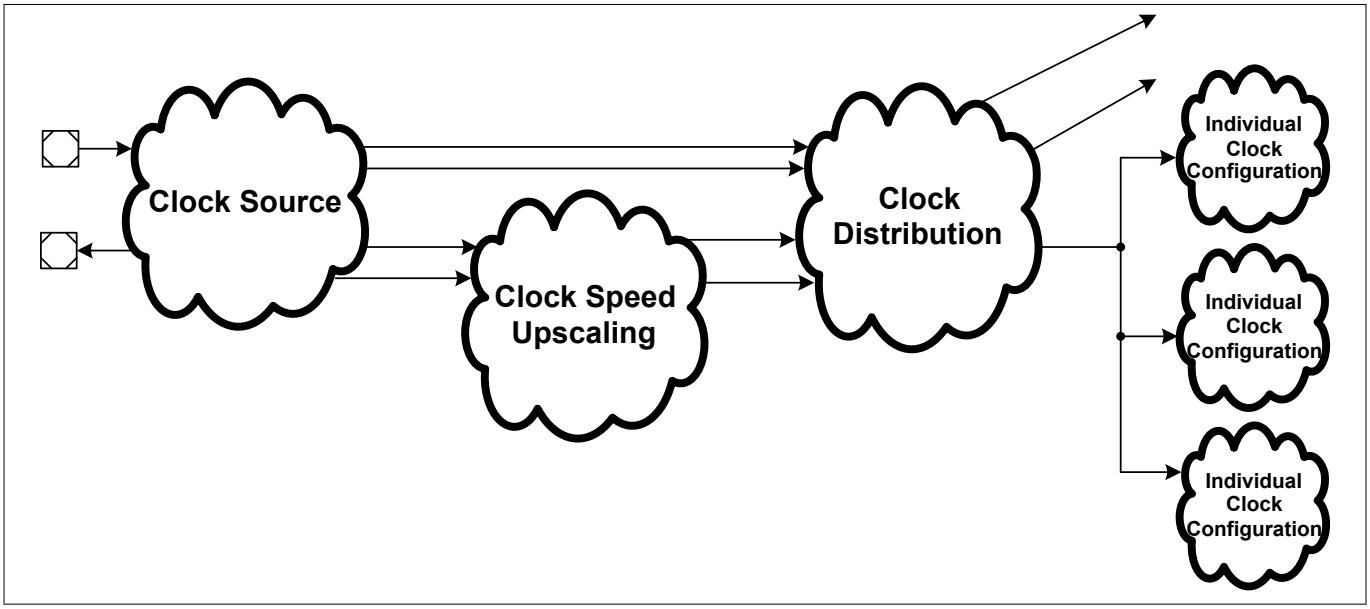

Figure 737 Clock tree

A device specific overview can be found in the device specific section.

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

Related information

TC4Dx SMU alarm mapping tables on page 7233

32.3 Functional description

The clock functional block provides very flexible clock generation for the device. During user program execution, the frequencies can be programmed for an optimal ratio between performance and power consumption.

The clocking system provides two major clocking domains:

- System and compute domain containing:
  - Central processing units (*CPU*) and direct memory access units (*DMA*) with its associated memories
  - System infrastructure such as the interconnects, clocking, reset and power control, interrupt system
  - Timers
  - Core function of communication interface controllers (Ethernet, SENT, PSI5 and PSI5-S)
  - Debug and trace system
- Application and Peripheral domain containing
  - Analog to digital converters (*ADC*)
  - Jitter-sensitive protocol parts of the communication interfaces (for example, ERAY, HSCT, QSPI, MSC, ASCLIN, MCAN, I2C, xSPI, and SDMMC)

This separation allows an independent configuration of the desired Baud rates and conversion rates, independent of the power-optimized configuration of the system. In addition, the clocks generated for the system functions are synchronous to each. The clocks generated for the peripheral functions are asynchronous to each other and to the system clocks.

The clocking system architecture can be divided into several sub-functional units for both domains:

- Clock source
  - External input clocks (SYSCLK and XTAL1)
  - Crystal oscillator (XTAL OSC with XTAL1 and XTAL2)
- Backup clock
  - EVR oscillator
  - Ramp oscillator
- Generation
  - System domain PLL (*SYSPLL*)
  - Peripheral domain PLL (*PERPLL*)
- Distribution
  - Configurable and fixed dividers for both domains(*DIV*)
  - Clock multiplexers and clock gates for both domains (*CG*)
  - External clock provision (from both domains to device outputs)
- Hardware-software interface (*HSI*)
  - Flexible Peripheral Interconnection (*FPI*)
  - Configuration and status registers
- Safety and security
  - Safety monitors for both domains(*Safe Mon*)
  - Security monitors (*Sec Mon*)
  - Register Access control and protection (*Acc Ctrl*)

The following diagram shows the top level view of the clocking system including its functional units.

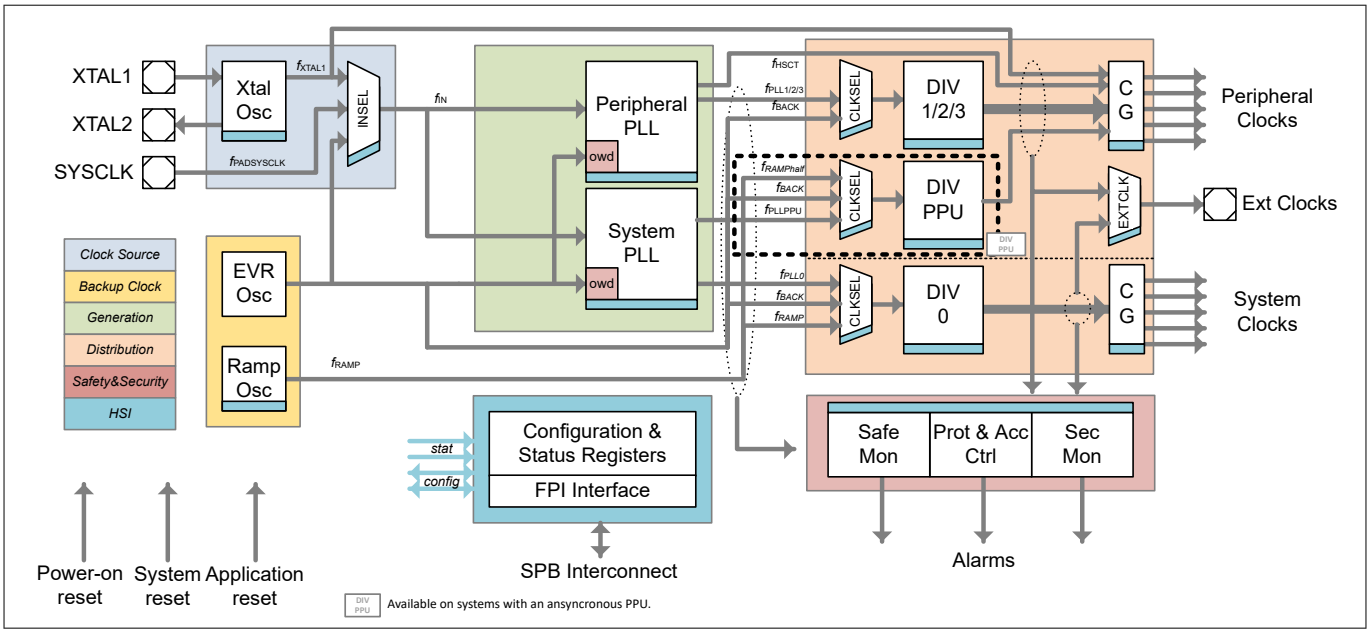

Figure 738 CLOCK block diagram

The figure above shows the clocking system architecture. In devices, where PPU is available, the PPU either runs synchronous or runs slower and asynchronous to the rest of the system. Please refer to the device specific configuration chapter for device specific features and information.

32.3.1 Software interface

In AURIX™ 3rd Generation devices the clocking system has a dedicated flexible peripheral interconnect (*FPI*) slave interface which is connected to the system peripheral bus (*SPB*) interconnect. The FPI slave provides software access to the configuration and status registers of the clocking system.

32.3.2 Clock sources

There are several clock sources available which primary source the system and peripheral clock domains.

There are five clock sources that can be selected to be the input for the downstream connected clock generation (PLL) functions:

1. Internal crystal oscillator driven through the XTAL1 and XTAL2 pads
2. External clock driven through XTAL1 pad
3. HSSL system clock driven through the SYSCLK pad
4. Internal backup clock (for non-safety applications only)
5. fOSC_F is a spike filtered clock only to be used in 20 MHz case to sustain system ESD event, but worse jitter

Software can select between these five sources as described in the following figure and tables:

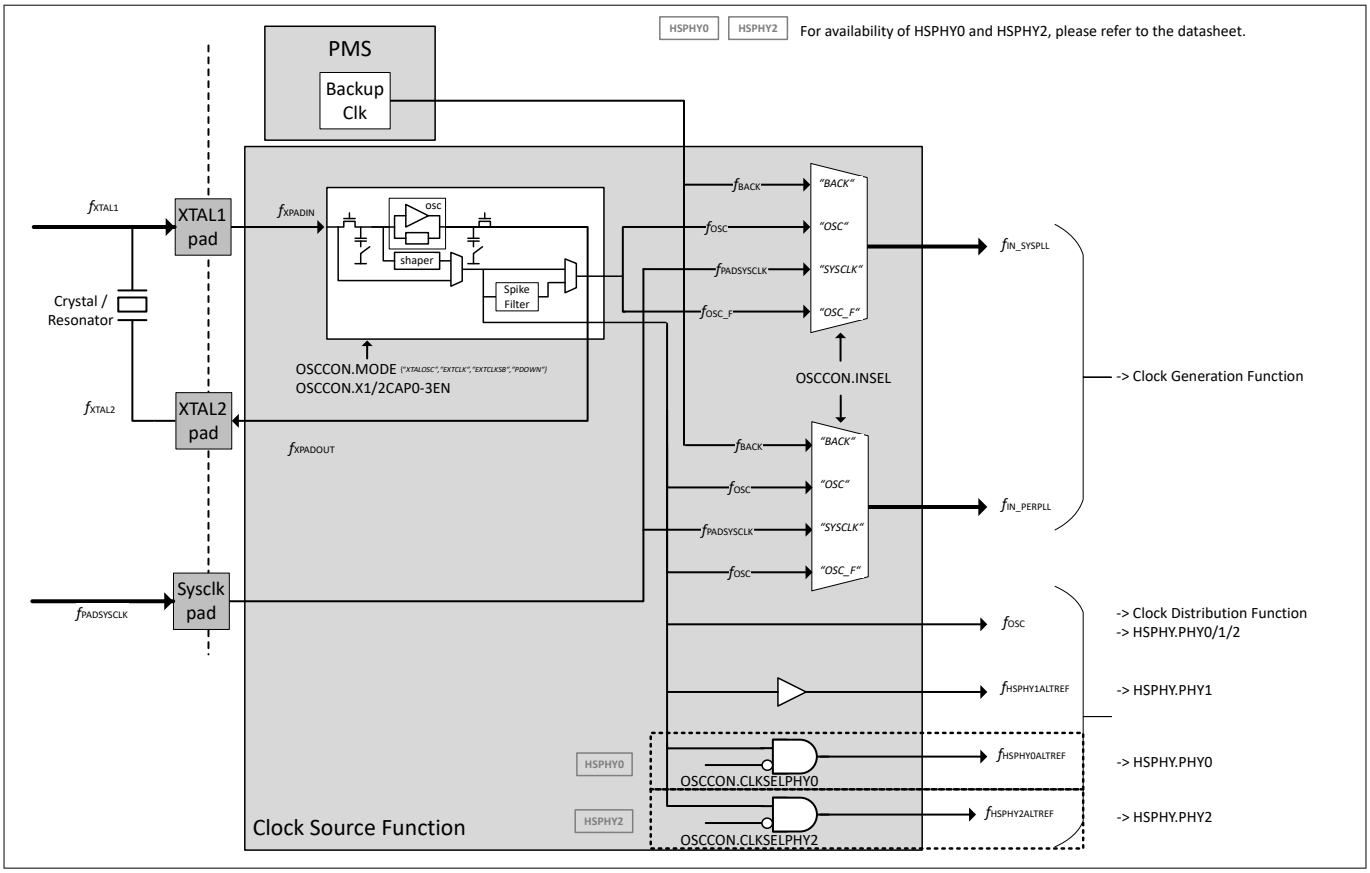

Figure 739 Clock sources

Table 1274 Clock source routing

Clock source	OSCCON.MODE	OSCCON.INSEL	f_{OSC}	f_{IN_SYSPLL}	f_{IN_PERPLL}
Crystal/ resonator	*XTALOSC*	*OSC or OSC_F*	• OSC powered up • Shaper enabled • Shaper not bypassed • Output active	f_{OSC} or f_{OSC_F}	f_{OSC}
External clock	*EXTCLK*	*OSC or OSC_F*	• OSC powered down • Shaper enabled • Shaper not bypassed • Output active	f_{OSC} or f_{OSC_F}	f_{OSC}

(table continues...)

Table 1274 (continued) Clock source routing

Clock source	OSCCON.MODE	OSCCON.INSEL	f_{OSC}	f_{IN_SYSPLL}	f_{IN_PERPLL}
External clock	*EXTCLKSB* [1]	*OSC or OSC_F*	• OSC powered down • Shaper disabled • Shaper bypassed • Output active	f_{OSC} or f_{OSC_F}	f_{OSC}
HSSL system clock	*PDOWN*	*SYSCLK*	• OSC powered down • Shaper disabled • Shaper not bypassed • Output inactive (0)	$f_{PADSYSCLK}$	$f_{PADSYSCLK}$
Backup clock	*PDOWN*	*BACK*	• OSC powered down • Shaper disabled • Shaper not bypassed • Output inactive (0)	f_{BACK}	f_{BACK}

1) This mode should be used only for debug purpose. For normal operation use only modes with shaper enabled.

In addition, software can select the reference clocks for the high-speed PHYs[32] as follows:

Table 1275 HSPHY0 clock reference routing

Clock reference	OSCCON.CLKSELPHY0	$f_{HSPHY0ALTREF}$ (HSPHY.PHY0)
External PCIE refclk	*PCIEREF*[1]	*GND*
Crystal oscillator clock	*OSC*	f_{OSC}

1) In addition, the user has to set the HSPHY PHY0_CTRL1.PRS bits accordingly. For details please refer to the HSPHY UM register section.

Table 1276 HSPHY1 clock reference routing

Clock reference	$f_{HSPHY1ALTREF}$ (HSPHY.PHY1)
Crystal oscillator clock	f_{OSC}

32 For availability of HSPHY0, HSPHY1 and HSPHY2 please refer to the datasheet

Table 1277 HSPHY2 clock reference routing

Clock reference	OSCCON.CLKSELPHY2	$f_{HSPHY0ALTREF}$ (HSPHY.PHY2)
External PCIE refclk	*PCIEREF*[1)]	*GND*
Crystal oscillator clock	*OSC*	f_{OSC}

1) In addition, the user has to set the HSPHY PHY2_CTRL1.PRS bits accordingly. For details please refer to the HSPHY UM register section.

32.3.2.1 Crystal oscillator

The crystal oscillator circuit is used to provide a reference clock for the clock generation function, that means the up-scaling PLLs.

The circuit is designed to work with both an external crystal or ceramic resonator, or an external stable clock source. The main oscillator stage consists of an inverting amplifier with XTAL1 as the input, and XTAL2 as the output with an integrated feedback resistor. A shaper stage is used to convert a sinusoidal oscillation at the pads into a digital clock signal f_{OSC} that can be used as reference for the PLLs and the high speed physical layers (*PHY*). The shaper can be optionally bypassed. A switchable load capacitor array is connected to both pins, XTAL1 and XTAL2, to enable a low bill of material option with integrated on-chip load capacitors. A control register applies the settings for capacitor selection, shaper function and oscillator control like gain selection.

As shown in the figure below, the oscillator circuit consists of the following components:

- Input and output pads, XTAL1 and XTAL2
- Main oscillator stage, a three-stage pierce oscillator
- Adjustable load capacitor arrays, C_1 and C_2
- Shaper circuit and bypass multiplexer
- Control register
- External component, crystal or ceramic resonator

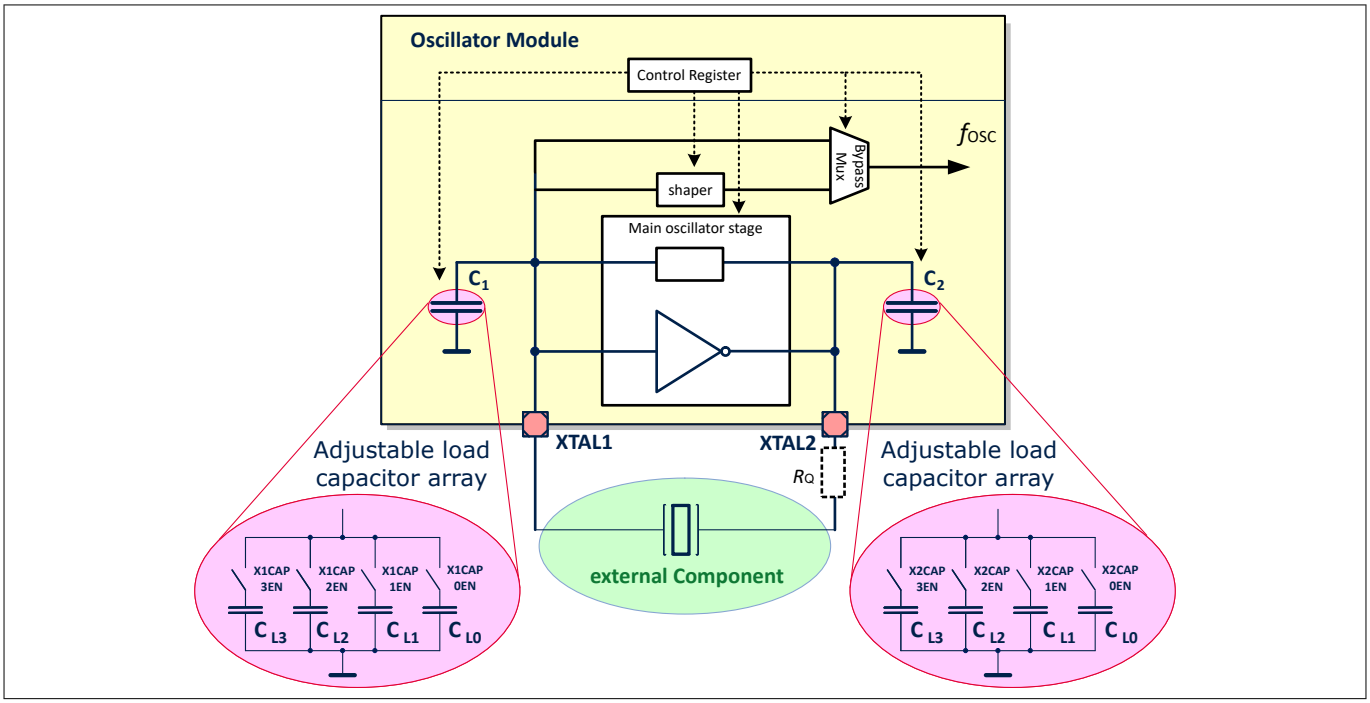

Figure 740 Oscillator block diagram

The crystal oscillator supports four basic operating modes as follows:

1. Crystal mode: Generates an output clock by maintaining oscillation of an external crystal or ceramic resonator
2. External clock mode with shaper: Generates an output clock by forwarding and shaping an external clock
3. External clock mode without shaper: Generates an output clock by forwarding an external clock; this mode is only used for debug purpose, not for field applications, performance is not guaranteed, for field applications use a mode with shaper enabled
4. Power down mode: Oscillator powered down and output is inactive (no signal)

The crystal oscillator can be accessed by software through the following register:

- Crystal oscillator control register (OSCCON): oscillator control parameters, power enable, operating mode, and shaper control

External crystal or ceramic resonator mode

An external oscillator load circuitry can be used, connected to both pins, XTAL1 and XTAL2. Two external load capacitors C_1 and C_2 are needed or the internal loads can be used and configured. In addition, depending on the crystal or ceramic resonator type, a series resistor R_2 is needed to limit the current. A test resistor R_Q may be temporarily inserted to measure the oscillation allowance (negative resistance) of the oscillator circuitry. R_Q values are typically specified by the crystal or ceramic resonator vendor. The C_1 and C_2 values shown in the datasheet can be used as starting points for the negative resistance evaluation and for non-production systems. The crystal oscillator is supplied by the noise reduced $V_{DDEXTOSC}$ and $V_{SSEXTOSC}$ power domains.

The exact values and related operating range are dependent on the crystal or ceramic resonator frequency, and have to be determined and optimized together with the crystal or ceramic resonator vendor using the negative resistance method. Oscillation measurement with the final target system is strongly recommended to verify the input amplitude at XTAL1 and to determine the actual oscillation allowance (margin negative resistance) for the oscillator-crystal or ceramic resonator system. The oscillator can also be used in combination with a ceramic resonator. The final circuitry must also be verified by the resonator vendor. When using an external crystal or ceramic resonator, its frequency must be within the allowed range as specified in the datasheet.

The following figure shows the recommended external circuits for both operating options: External crystal or ceramic resonator mode with and without external components.

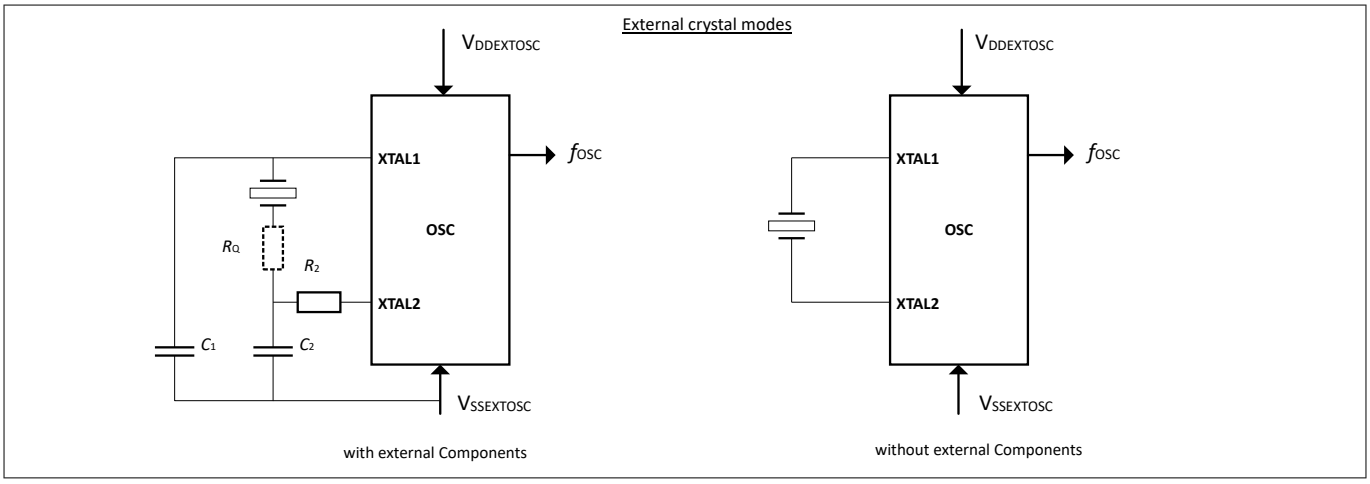

Figure 741 External circuit for crystal or ceramic resonator operation

External input clock mode

When using an external clock signal it must be connected to XTAL1, however, XTAL2 must be left open (unconnected).

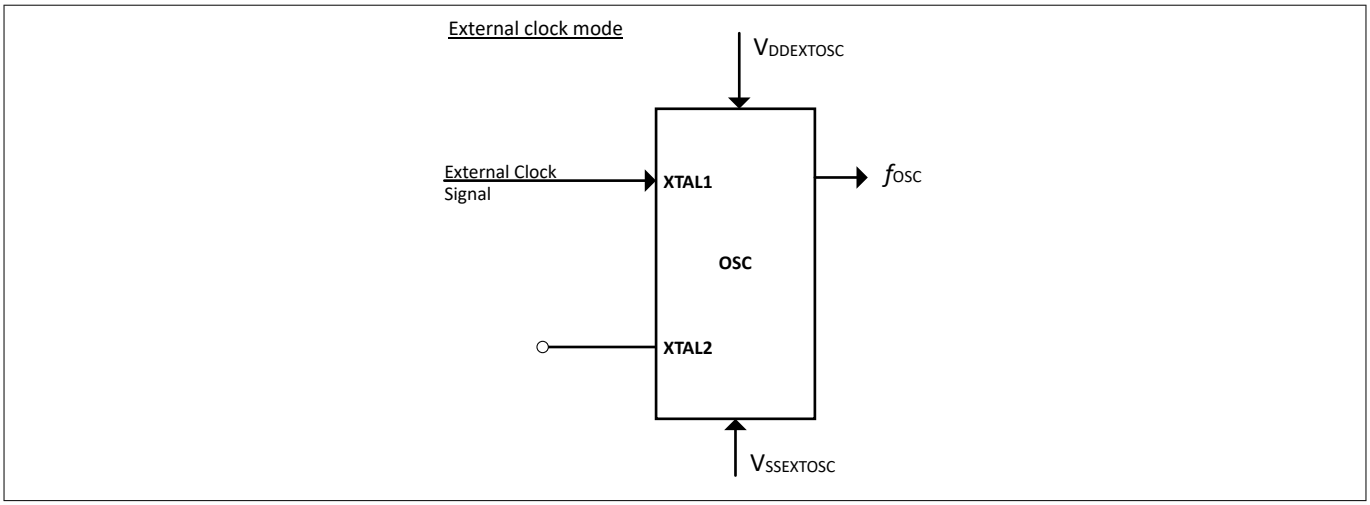

Figure 742 Direct clock input

When supplying the clock signal directly, that means not using an external crystal or ceramic resonator and bypassing the oscillator, the input frequency needs to be in a suitable range for the digitally controlled oscillator (*DCO*) of the PLLs (the value is specified in the datasheet). When using the external input clock mode, the shaper bypass mode is not recommended.

Configuration

A configuration of the oscillator is always required before an external crystal or ceramic resonator can be used as clock source. After a power-on (cold, warm) or system reset the oscillator is disabled and needs to be configured as described in this section. During an application reset, the oscillator is not affected and operates as previously configured, no re-configuration is required for this case.

The oscillator can be configured through the register OSCCON:

It must be enabled by setting bit-field OSCCON.MODE = 000_B. If the integrated capacitors need to be used by the user, they can be enabled through the bit-fields OSCCON.X1CAP0-3EN and OSCCON.X2CAP0-3EN.

***Note**: After powering up the crystal oscillator by setting bit-field OSCCON.MODE = 000_B, it takes up to 3 ms until the oscillator produces a reliable and stable output clock. The user shall implement a waiting period accordingly before any other resources depending on the crystal oscillator need to be used. For further details, refer to the crystal oscillator entries in the datasheet.*

EMC robust clock source fOSC_F

In normal application, the oscillator shaper has a bandwidth of approximately 100 MHz to ensure its jitter performance. In some application, the ECU does not have a metal case and the system ESD pulse can go through the shaper, introducing PLL loss of lock. In this case, the OSC_F can be used instead. An additional low pass filter with a bandwidth of around 50 MHz is sufficient to filter out the system ESD pulse by trading against the jitter performance. When the crystal has a frequency greater than 20 MHz, the OSC_F cannot be used.

Oscillator watchdog

In combination with the PLLs, an input signal monitoring function is implemented. This feature is defined to detect severe malfunctions of an external crystal or ceramic resonator. The system can detect a "loss of clock" at the input or a "too high, too low" input frequency (operation on a higher or lower harmonic).

Each *PLL* (SYSPLL and PERPLL) provides a dedicated oscillator watchdog function that monitors the incoming reference clock frequency f_{IN}.

Both monitors are configured and observed through the following registers:

- OSCMON1: monitor configuration
- OSCSTAT: monitor status

The expected input frequency for both monitors is defined by the bit-field OSCMON1.OSCVAL:

$$f_{IN_EXP} = OSCMON1.OSCVAL - 1 + 16\,Mhz \quad (52)$$

- Bit-fields OSCMON1.SMONEN: enable or disable monitor in SYSPLL
- Bit-fields OSCMON1.PMONEN: enable or disable monitor in PERPLL
- Bit-fields OSCSTAT.SOWDS: reports if input frequency for the SYSPLL is too high, too low or in range
- Bit-fields OSCSTAT.POWDS: reports if input frequency for the PERPLL is too high, too low or in range

Each time before (re)configuring the monitoring function, the watchdog circuit and the related SMU alarms have to be disabled. This avoids unintended alarms in the safety and security alarm management unit (*SMU*). Now the value of the expected input frequency can be set in bit-field OSCMON1.OSCVAL. In the following, the oscillator watchdogs have to be (re)enabled. This initializes the watchdog circuits, presets the status flags OSCSTAT.SOWDS = OSCSTAT.POWDS *InValid*, and re-starts the monitoring with the new configuration. The watchdogs need a full monitoring period of 10 µs + 2 µs evaluation time to flag a valid status. When the status flags are finally changed into *InRange* by the circuit, the input frequency is within the expected range and the SMU alarms can be enabled again.

***Note**: The oscillator watch dog cannot check if the input frequency is in full legal range for PLL operation. It is primarily intended to check if a crystal is oscillating on a harmonic and if an input frequency is available at all. The user has to ensure that the applied input frequency is basically in the allowed range for PLL input. Please check the datasheet accordingly.*

32.3.3 Back-up clock

In AURIX™ 3rd Generation there are two back-up clocks available. Depending on the operating state (power-up, drive, power-down, power-safe, safe-state, and so on) and the user-application, they can be used as alternate clock sources instead of the PLL output clocks.

32.3.3.1 EVR oscillator

An embedded voltage regulator oscillator (*EVR oscillator*) clock with a trimming functionality is available as an alternate primary clock source.

The EVR oscillator provides a stable and reliable 100 MHz clock that can be used for the system if its trimmed accuracy[33] is sufficient for the current operating mode of the application (for example, during power up and boot when the PLLs are not yet activated or in case of a PLL fail operation). It provides less accuracy than an external crystal or ceramic resonator. In addition, it is used as diverse clock for various safety mechanisms.

The back-up clock is always enabled, that means it cannot be disabled by the user, or otherwise controlled in a way that could prevent its general operation.

No other control bits are available except the ones for selecting the backup-clock as source for the clock distribution of the system and peripheral clocks (controlled by bit-field CCUCON.CLKSELS = 01_B) and as optional (non-safety) input reference for the SYSPLL and PERPLL (controlled by bit-field OSCCON.INSEL = 00_B).

32.3.3.2 Ramp oscillator

A second on-chip oscillator is introduced to provide a linear frequency ramp clock to minimize current jumps in the system clock tree during power up and power-down and resets and when a clock emergency occurs.

The ramp oscillator has a register interface as follows:

- Ramp oscillator control register 0 (RAMPCON0): control parameters for the ramp oscillator
- Ramp oscillator status register (RAMPSTAT): actual status of the ramp oscillator

33 The accuracy after trimming is listed in the datasheet

The ramp oscillator's output clock f_{RAMP} represents another alternate clock source during power-up and down, clock emergency switching, or resets, and can be selected as clock source by setting the bit-field CCUCON.CLKSELS accordingly. The ramp process is software controllable by programming an upper target frequency and a ramp command in RAMPCON0. The lower frequency limit equals the frequency of the EVR oscillator which is 100 MHz. When software issues a ramp command, the ramp oscillator executes a linear frequency sweep based on the register defined key parameters. Once the target frequency has been reached, the ramp stops. Ramp status information can be continuously read by software through RAMPSTAT. For further details, refer to the register description.

In order to perform a clock ramp, the oscillator needs to be powered up first by setting the bit-field RAMPCON0.PWR = 1_B. The oscillator is ready to accept a ramp command when the bit-field RAMPSTAT.ACTIVE = 1_B.

RAMPCON0 needs to be programmed with the ramp parameters and a valid command in order to execute a sequence as follows:

- Bit-field RAMPCON0.UFL - defines the upper target frequency in 1 MHz steps for ramp-up, for ramp-down the target is always 100 MHz and cannot be changed. To avoid current over- and undershoots the upper target frequency should be always 100 MHz below the PLL output target frequency
- The step size is fixed to 30 MHz, valid for both directions.
- Bit-field RAMPCON0.CMD - defines the command to be executed which is either *RampUp* or *RampDown*

  Writing the command works as a trigger, that means it is write only, starts the sequence and clears automatically. By writing a valid command, the control parameters are validated towards the ramp oscillator. Changing them without applying a valid command has no immediate effect on the ramp operation

In the RAMPSTAT it is possible to observe the actual status of the ramp oscillator:

- Bit-field RAMPSTAT.ACTIVE - indicates if the ramp oscillator is powered up and ready to accept and execute a command
- Bit-field RAMPSTAT.STAT - reports the actual state of the oscillator's ramp operation which can be *Idle*, *RampUp*, *RampDown*
- Bit-field RAMPSTAT.FSTAT - reports a generic frequency status which reflects if the oscillator resides at the lower or upper target frequency or somewhere in between
- Bit-field RAMPSTAT.FLLLOCK - indicates if the ramp oscillator is locked on the target frequency, which is either 100 MHz on the lower end or at RAMPCON0.UFL on the upper end

The following figures demonstrate a ramp up and down sequence. The values in the figure graphs like frequency, step size and waiting time correspond with the register values listed.

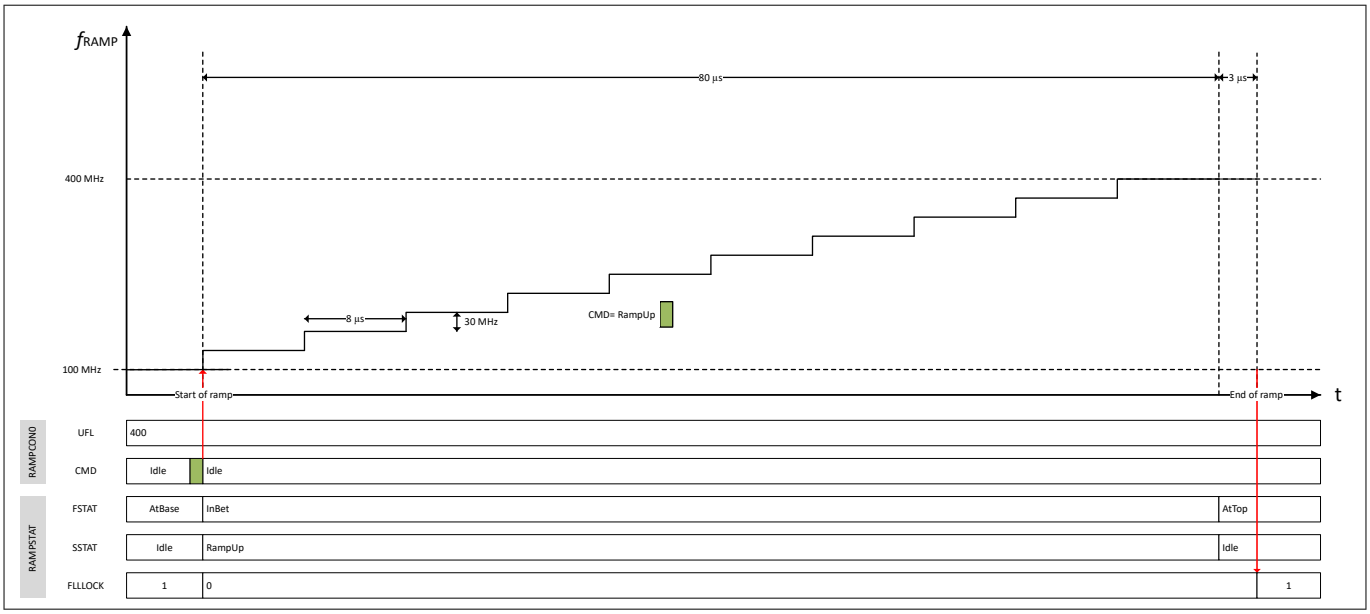

Figure 743 Ramp up sequence

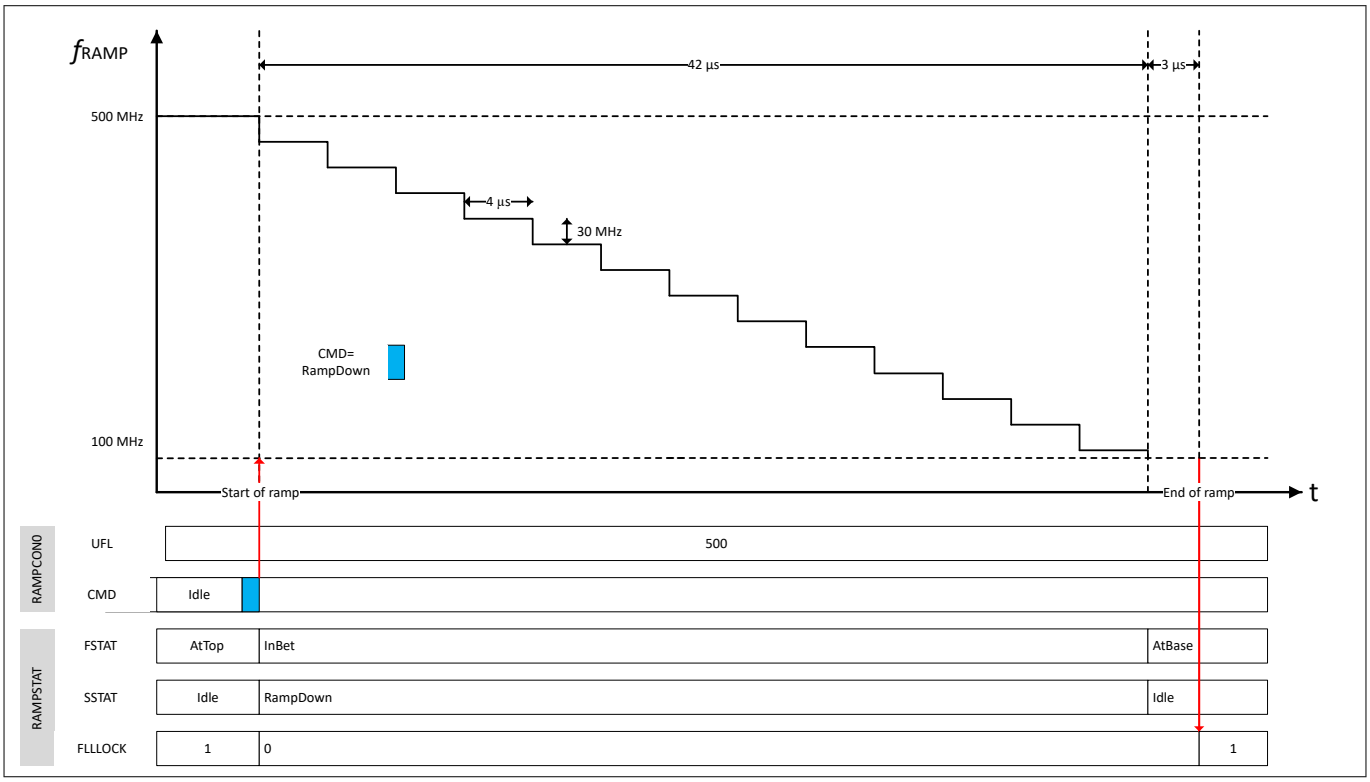

Figure 744 Ramp down sequence

It is not possible to ramp down to a frequency other than the 100 MHz base frequency. To change, for example, from 500 MHz to 300 MHz, the application software has to ramp down to 100 MHz first, reprogram the upper target frequency from 500 MHz to 300 MHz and ramp up again.

In addition to software control, there is hardware control over the ramp oscillator. This is needed to execute frequency ramps for application and system reset and clock emergency switching support. During reset operation or PLL loss of lock, it is desirable to gradually reduce system clock frequency to minimize current over- or undershoots.

A detailed description on how to setup and control the ramp oscillator is given in the Power Pattern chapter.

Attention**:* ***The ramp oscillator is used to support application reset and emergency switching, it shall not be ramped down after the system has been set to its target frequency and is running on the SYSPLL. The ramp oscillator needs to reside at its upper frequency limit in order to establish a smooth clock switch over from PLL to ramp oscillator if either an application reset sequence is started or an emergency switch has to be executed. That means: do not ramp down or switch off the ramp oscillator while running on the SYSPLL. The ramp oscillator has a maximum upper frequency level which is 100 MHz below the PLL frequency. At the same time the upper frequency level of the ramp oscillator should be at least 130 MHz. This implies a minimum PLL frequency of 230 MHz for which the ramp oscillator can be used. Below that frequency level the ramp oscillator must be powered down and must not be used.

***Note**:* *The ramp oscillator shall not be used as a permanent system clock source outside of a ramp-up or a ramp-down scenario..*

32.3.4 Clock generation

Typical CPU operating speeds are often ten times (or more) faster than the speed of the crystal used as the clock source. Therefore an up-scaling of the externally provided clock source clock is required.

Two phase locked loops (*PLL*) are provided for the up-scaling.

32.3.4.1 SYSPLL

The SYSPLL can convert a low-frequency external clock signal to a high-speed internal clock for maximum performance. It supports a wide range of input and output frequencies by varying the different divider factors.

The SYSPLL also has fail-safe logic that detects degenerate external clock behavior, such as abnormal frequency deviations or a total loss of the external clock. It reports if it loses its lock on the reference clock to support a switch over of the system clocks from PLL clock to internal clock sources (for example, the EVR or ramp clock).

32.3.4.1.1 Features

- Digital controlled oscillator (*DCO*)
- Digital phase detector and loop filter
- DCO lock detection
- Input divider P
- Feedback divider N
- P and N divider establish DCO frequency f_{DCO} as specified in the datasheet
- Two independent outputs for system clocks and separate PPU clock[34)]
- Output integer divider K2 for system clocks
- Output integer divider K3 for PPU clock[34)]
- Glitch-less programming of output dividers K2 and K3
- P, N, K2 dividers combined establish SYSPLL output frequency (f_{PLL0})
- P, N, K3 dividers and K3 pre-divider combined establish PPU-PLL output frequency (f_{PLLPPU})[34)]

34 Only present in devices with an asynchronous PPU. Please refer to the device specific chapters for availability

32 CLOCK

- Oscillator watchdog, crystal harmonic and signal presence detection of input frequencies
- Random frequency modulation

32.3.4.1.2 Functional description

The SYSPLL consists of the following building blocks:

- Control and status register block to provide a programming interface for the control settings and the status observation
- Input divider to scale down the input frequency f_{IN} by a factor P which is configurable through the register section
- PLL-core that consists of:
  - Digital controlled oscillator and a phase locked loop. The loop locks to the input reference frequency f_{REF} while multiplying it with the factor N which is configurable through the register section
  - Lock detection circuit that observes and reports the locking status to the register section
  - Random frequency modulator that can optionally modify the DCO frequency to produce a spread spectrum effect. The relative modulation amplitude (MA %) is configurable through the register section
- Output stage for system clocks composed of an integer divider that scales down the DCO frequency by a factor K2, configurable through the register section
- Output stage for PPU clock composed of a pre-divider for fractional divisions (1.0, 1.1, 1.2, 1.4, 1.6, 1.7, 2.0) and an integer divider that scales down the DCO frequency by a factor K3, configurable through the register section[35)]
- Oscillator watchdog based on the backup clock f_{BACK} to supervise the input frequency f_{IN}, configurable through the register section

The following figure shows the general structure of the SYSPLL. In devices with a synchronous PPU there is no separate PPU clock output because the PPU runs synchronous to the rest of the system and its clock is generated from the PLL0 output. In devices with an asynchronous PPU, the PPU clock is generated by the second SYSPLL output.

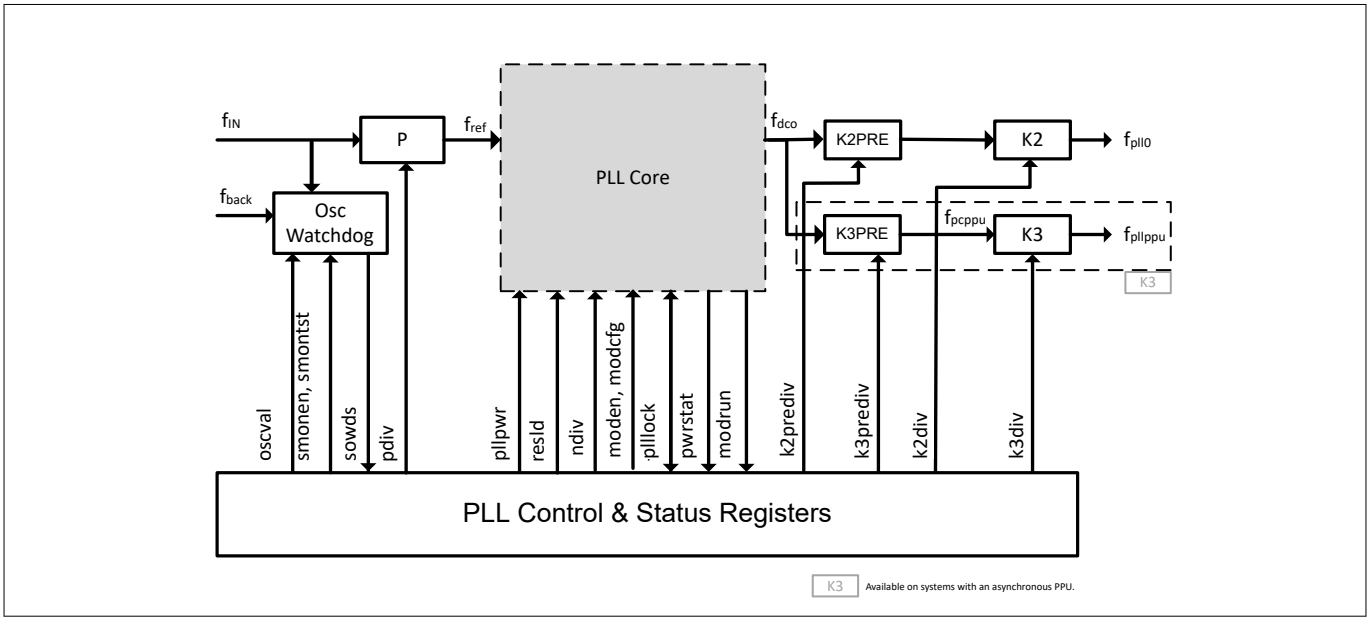

Figure 745 System PLL block diagram

SYSPLL register interface

All control and status values of the SYSPLL are stored in and accessed through:

- SYSPLL configuration register 0 (SYSPLLCON0): P and N divider, power enable, modulation enable, reset lock detection

35 Only present in devices with an asynchronous PPU. Please refer to the device specific chapters for availability

- SYSPLL configuration register 1 (SYSPLLCON1): K2, K3[35] dividers and K3[35] pre-divider
- SYSPLL configuration register 2 (SYSPLLCON2): Modulation control
- SYSPLL status register (SYSPLLSTAT): Power status, lock status, modulation status
- Modulation trim 0 configuration register (SMODCON0): Modulation trimming control

SYSPLL power control

The SYSPLL is disabled after cold and warm power-on reset and needs to be powered up separately by setting bit-field SYSPLLCON0.PLLPWR = 1_B. The PLL power-up status is eventually flagged through bit-field SYSPLLSTAT.PWRSTAT = 1_B.

The PLL can be set into power down mode when it is not needed. The power down mode is entered by setting bit-field SYSPLLCON0.PLLPWR = 0_B and flagged through bit-field SYSPLLSTAT.PWRSTAT = 0_B. While the SYSPLL is in power down mode, no output frequency is generated.

***Note**: Switching to SYSPLL power down mode shall only be performed when the system clock tree is sourced by the backup clock or ramp clock (controlled through bit-field CCUCON.CLKSELS).*

Input frequency watchdog

PLL operation requires a stable input clock frequency of f_{IN}. Therefore it is recommended to check and monitor if an input frequency f_{IN} is available by checking bit-field OSCSTAT.SOWDS == 00_B before enabling and using the PLL.

In case the PLL is driven by the crystal oscillator, an additional wait time after powering up of the crystal oscillator has to be applied. This is due to the fact that the crystal oscillator takes up to 3 ms to generate a reliable output clock after it has been powered up. For detailed timing information of the crystal oscillator, please refer to the datasheet.

Basic SYSPLL operation

The DCO and output frequencies[36] of the SYSPLL are determined by the values of the three dividers and the input reference frequency f_{IN}:

- SYSPLLCON0.PDIV
- SYSPLLCON0.NDIV
- SYSPLLCON1.K2DIV
- SYSPLLCON1.K3DIV and SYSPLLCON1.K3PREDIV[35]

The PLL core input reference frequency f_{REF} is generated by dividing the input frequency f_{IN} by a factor P. The PLL core multiplies the input reference by a factor N to produce the DCO frequency f_{DCO}:

$$f_{\mathrm{REF}} = f_{\mathrm{IN}} \div P,\ f_{\mathrm{DCO}} = f_{\mathrm{REF}} \times N \tag{53}$$

The recommendation is to use as a maximum the f_{DCO} as specified in the datasheet and P to 1, which means SYSPLLCONx.PDIV = 0.

In the system clock output stage, the DCO frequency is divided down by a factor K2.

The output frequency f_{PLL0} is given by:

$$\begin{aligned} f_{\mathrm{PLL0}} &= f_{\mathrm{DCO}} \div (K2 \times 1.0) \rightarrow K2\mathrm{PRE} = 0;\ \text{this value must be used for normal operation} \\ f_{\mathrm{PLL0}} &= f_{\mathrm{DCO}} \div (K2 \times 2.0) \rightarrow K2\mathrm{PRE} = 1 \\ f_{\mathrm{PLL0}} &= f_{\mathrm{DCO}} \div (K2 \times 1.2) \rightarrow K2\mathrm{PRE} = 2 \\ f_{\mathrm{PLL0}} &= f_{\mathrm{DCO}} \div (K2 \times 1.6) \rightarrow K2\mathrm{PRE} = 3 \end{aligned} \tag{54}$$

35 Only present in devices with an asynchronous PPU. Please refer to the device specific chapters for availability

36 Please refer to the datasheet for valid SYSPLL frequencies to determine the appropriate N, P and K2 settings.

SYSPLL lock detection

The SYSPLL has a lock detection feature, that supervises the DCO part of the SYSPLL to differentiate between stable and unstable DCO circuit behavior. The lock detector marks the PLL as locked if the two input frequencies of the lock detector f_{REF} and f_{DIV} (=f_{DCO}÷N) have a phase difference smaller than ½ reference cycle for more than 224 reference cycles.

However, the unlock condition is true immediately if the phase error is bigger than the above given limit. Smaller phase errors can be handled by the PLL without getting unstable and are not marked as "loss of lock".

The SYSPLL may become unlocked, due to a break of the crystal or ceramic resonator or the external clock line. In such a case, an alarm is signaled to the SMU and the PLL switches to an open loop mode and keeps on free running at the last locked frequency.

A modification of the two dividers P and N has a direct influence to the DCO frequency and could lead to a loss of the lock status. However, a modification of the K2 divider has no impact on the lock status, but still changes the SYSPLL output frequency f_{PLL0} directly.

The lock status can be observed in bit-field SYSPLLSTAT.PLLLOCK and the lock detection can be reset by setting bit-field SYSPLLCON0.RESLD = 1_B. Applying the reset will close the loop and eventually enable it to lock again.

Attention**:* ***Once unlocked, the PLL will not make an attempt to lock again until issuing a lock detection reset or a reprogramming of the P or N dividers.

Frequency modulation

The SYSPLL output frequency f_{PLL0} can additionally be modified by a low-frequency modulation to reduce EMI. A random sequence is added to the DCO control word resulting in a randomly modulated f_{DCO}. The rate of the modulation is defined by f_{REF}.

To configure the modulation follow these steps in the given order:

Turn on or off modulation for SYSPLL

```
CLOCK_SYSPLLCON0.MODEN = 0                    // Deactivate Frequency Modulation
CLOCK_SYSPLLCON2.MODCFG = (0x7400 | MG)       // Program Modulation Gain (MG)
if (MG)
     CLOCK_SMODCON0 = 0x80000000              // CAL_EN = 1
     Wait(100ns)                              // Wait to ensure toggling
     CLOCK_SMODCON0 = 0x00000000              // CAL_EN = 0
     CLOCK_SYSPLLCON0.MODEN = 1               // Enable Modulation
     Wait until CLOCK_SYSPLLSTAT.MODRUN == 1  // Wait until modulation is running
end
```

***Note**:* *To turn off modulation, simply set MG=0 in the above sequence*

***Notes**:*
To change the modulation gain:

1. *Turn off modulation*
2. *Turn on modulation with different gain*

The modulation is enabled using bit-field SYSPLLCON0.MODEN. The modulation itself alters the DCO frequency randomly within the range of the configured relative modulation amplitude (MA%). The modulation is controlled through bit-field SYSPLLCON2.MODFCG as follows:

- MODCFG[9:0] = modulation gain

$$\text{modulation gain} = \frac{64}{3.6\text{MHz}} \times f_{\text{DCO}} \times \text{MA}$$
$$\text{Example: MA} = 2\,\% \text{ at} f_{\text{DCO}} = 800\,\text{MHz} \Rightarrow \text{modulation gain } = 0x11C \quad (55)$$

The modulation is performed in a way that the resulting accumulated jitter added by the modulation stays below J_{TOT} (when MA equals to 1.25%).

Configuration sequence for the K-dividers for configuration and re-configuration of PLLs

Special care should be taken during configuration and re-configuration of PLLs with respect to programming the K-dividers to avoid wrong K-divider or dead clock at one of the PLL output paths which can be recovered only through a system reset.

Follow the below configuration sequence for the K-dividers for the configuration or re-configuration of any PLL:

PLL configuration phase

1. PLL off
2. Check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs
3. Configure K-dividers in xPLLCON1 register
    a. Set KxPREDIV = div by 2 (xPLLCON1.KxPREDIV = div by 2)
    b. Set KxDIV = 0x01 (xPLLCON1.KxDIV = 0x01)
    c. Set other PLL parameters as described in the user manual
4. PLL on (power PLL)
5. Check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs
6. Check if PLL is powered: xPLLSTAT.PWRSTAT == 1 with a timeout of at least 100 µs
7. Wait for 1ms to avoid jitter
8. Check for PLL lock: xPLLSTAT.PLLLOCK == 1 with a timeout of at least 100 µs
9. Configure KxPREDIV (if necessary)
    a. Set KxPREDIV to final value
10. Wait for 10 µs and check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs
11. Configure KxDIV
    a. Set KxDIV to final value
    b. Check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs

Changing the KxDIV value during run time (KxPREDIV is not allowed to change during run time)

1. Check for PLL lock: xPLLSTAT.PLLLOCK == 1 with a timeout of at least 100 µs
2. Check for CCU lock: xLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs
3. Configure K-dividers in xPLLCON1 register
    a. KxDIV = 0x01 (xPLLCON1.KxDIV = 0x01)
4. Wait for 10 µs and check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs
5. Configure KxDIV
    a. Set KxDIV to final value
    b. Check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs

32.3.4.2 PERPLL

The PERPLL can convert a low-frequency external clock signal to a high-speed internal clock for maximum performance. In AURIX™ 3rd Generation, the PERPLL shall be configured to f_{DCO} = 800 MHz.

The PERPLL also has fail-safe logic that detects degenerate external clock behavior such as abnormal frequency deviations or a total loss of the external clock. It can execute emergency actions if it loses its lock on the external clock.

32.3.4.2.1 Features

- Digital controlled oscillator (*DCO*)
- Digital phase detector and loop filter
- DCO lock detection
- Three separate outputs, f_{PLL1}, f_{PLL2}, f_{PLL3}
- Additional, direct DCO output to deliver 800 MHz HSCT clock to HSCT PHY
- Input divider P
- Feedback divider N
- P and N divider establish DCO frequency, f_{DCO} = 800 MHz as recommended
- Output divider per output, K2, K3, K4
- Glitch-less programming of output dividers K2, K3, K4
- K2, K3, K4 pre-divider for fractional divisions by 1.0, 1.1, 1.2, 1.4, 1.6, 1.7, and 2.0
- P, N, K2, K3, K4 dividers and K2, K3, K4 pre-divider combined establish PLL output frequencies
- Oscillator watchdog, crystal harmonic and signal presence detection of input frequencies
- Optional random frequency modulation to reduce EMI for GPS use-case

32.3.4.2.2 Functional description

The PERPLL basically consist of the following building blocks:

- Control and status register block to provide a programming interface for the control settings and the status observation
- Input divider to scale down the input frequency f_{IN} by a factor P which is configurable through the register section
- PLL-core that consists of:
  - Digital controlled oscillator and a phase locked loop. The loop locks to the input reference frequency f_{REF} while multiplying it with the factor N which is configurable through the register section
  - Lock detection circuit that observes and reports the locking status to the register section
  - Random frequency modulator that can optionally modify the DCO frequency to produce a spread spectrum effect. The relative modulation amplitude (MA %) is configurable through the register section
- Three output stages composed of pre-dividers for fractional divisions (1.0, 1.2, 1.6 and 2.0) and integer dividers that scale down the DCO frequency by a factor K2,K3, K4 configurable through the register section
- Oscillator watchdog based on the backup clock f_{BACK} to supervise the input frequency f_{IN}, configurable through the register section

The following figure shows the PERPLL block structure.

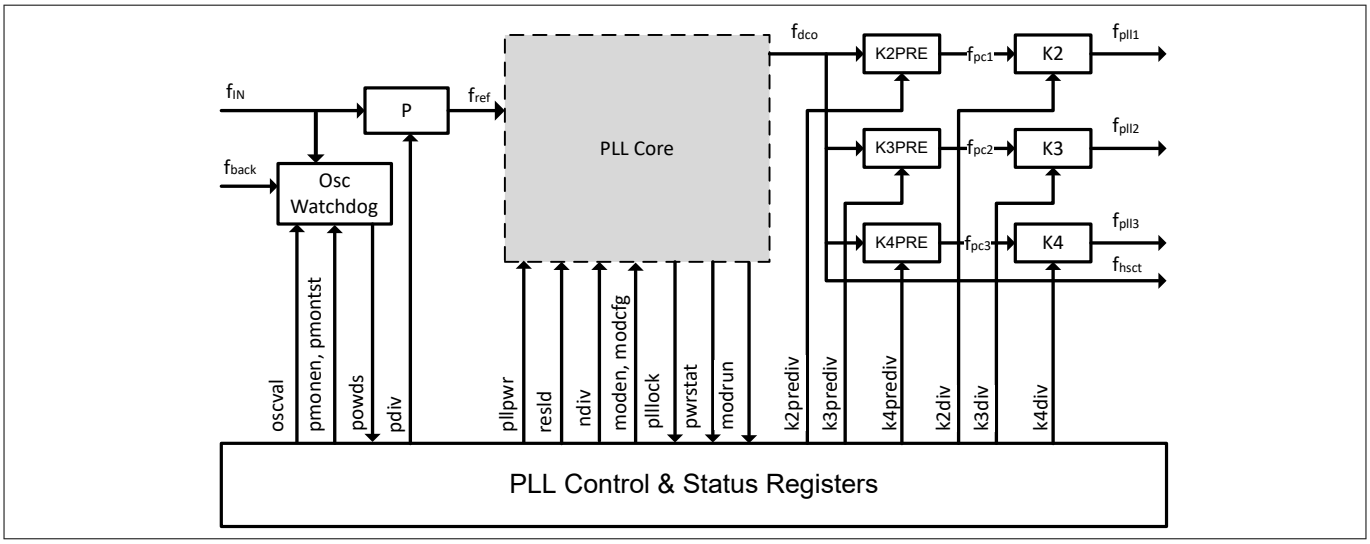

Figure 746 PERPLL block diagram

PERPLL register interface

All control and status values of the SYSPLL are stored in and accessed through:

- PERPLL configuration register 0 (PERPLLCON0): P and N divider, power enable, reset lock detection
- PERPLL configuration register 1 (PERPLLCON1): K2, K3, K4 dividers and K2, K3, K4 pre-dividers
- PERPLL configuration register 2 (PERPLLCON2): Modulation control
- PERPLL status register (PERPLLSTAT): power status, lock status
- Modulation trim 0 configuration register (PMODCON0): Modulation trimming control

PERPLL power control

The PERPLL is disabled after power-on reset and needs to be powered up separately by setting bit-field PERPLLCON0.PLLPWR = 1_B. The PLL power-up status is eventually flagged through bit-field PERPLLSTAT.PWRSTAT = 1_B.

The PLL can be set into power down mode when it is not needed. The power down mode is entered by setting bit-field PERPLLCON0.PLLPWR = 0_B and flagged through bit-field PERPLLSTAT.PWRSTAT = 0_B. While the PERPLL is in power down mode, no output frequency is generated.

***Note**: Switching to PERPLL power down mode shall only be performed when the peripheral clock tree is sourced by the backup clock (controlled through bit-field CCUCON.CLKSELP).*

Input frequency watchdog

PLL operation requires a stable input clock frequency of f_{IN}. Therefore it is recommended to check and monitor if an input frequency f_{IN} is available by checking bit-field OSCSTAT.POWDS == 00_B before enabling and using the PLL.

In case the PLL is driven by the crystal oscillator, an additional wait time after powering up of the crystal oscillator has to be applied. This is due to the fact that the crystal oscillator takes up to 3 ms to generate a reliable output clock after it has been powered up. For detailed timing information of the crystal oscillator, please check the datasheet.

Basic PERPLL operation

The DCO frequency and the three output frequencies[37] of the PERPLL are determined by the values of the dividers and the input reference frequency f_{IN}:

- PERPLLCON0.PDIV
- PERPLLCON0.NDIV
- PERPLLCON1.K2DIV, PERPLLCON1.K3DIV and PERPLLCON1.K4DIV and PERPLLCON1.K2PREDIV, PERPLLCON1.K3PREDIV and PERPLLCON1.K4PREDIV

The PLL core input reference frequency f_{REF} is generated by dividing the input frequency f_{IN} by a factor P. The PLL core multiplies the input reference by a factor N to produce the DCO frequency f_{DCO}:

$$f_{\mathrm{REF}} = f_{\mathrm{IN}} \div P,\ f_{\mathrm{DCO}} = f_{\mathrm{REF}} \times N \tag{56}$$

The recommendation is to use f_{DCO} at 800 MHz and P to 1, that is, means PERPLLCONx.PDIV = 0.

In the output stage, the DCO frequency is divided down by a factor Kx (with x = 2,3,4) combined with KxPREDIV. KxPREDIV is an additional divider circuit that is capable of generating selected non-integer division ratios of factor 1.0, 1.1, 1.2, 1.4, 1.6, 1.7, and 2.0.

The output frequencies $f_{PLL1\text{-}3}$ is given by:

37 Refer to the datasheet for valid PERPLL frequencies to determine appropriate N, P and K2,3,4 and pre-divider settings.

$$
\begin{aligned}
f_{PLL1} &= f_{DCO} \div (K2 \times 1.0) \rightarrow K2PRE = 0 \\
f_{PLL1} &= f_{DCO} \div (K2 \times 2.0) \rightarrow K2PRE = 1 \\
f_{PLL1} &= f_{DCO} \div (K2 \times 1.2) \rightarrow K2PRE = 2 \\
f_{PLL1} &= f_{DCO} \div (K2 \times 1.6) \rightarrow K2PRE = 3
\end{aligned}
$$

$$
\begin{aligned}
f_{PLL2} &= f_{DCO} \div (K3 \times 1.0) \rightarrow K3PRE = 0 \\
f_{PLL2} &= f_{DCO} \div (K3 \times 1.1) \rightarrow K3PRE = 1 \\
f_{PLL2} &= f_{DCO} \div (K3 \times 1.2) \rightarrow K3PRE = 2 \\
f_{PLL2} &= f_{DCO} \div (K3 \times 1.4) \rightarrow K3PRE = 4 \\
f_{PLL2} &= f_{DCO} \div (K3 \times 1.6) \rightarrow K3PRE = 6 \\
f_{PLL2} &= f_{DCO} \div (K3 \times 1.7) \rightarrow K3PRE = 7 \\
f_{PLL2} &= f_{DCO} \div (K3 \times 2.0) \rightarrow K3PRE = 10
\end{aligned}
\tag{57}
$$

$$
\begin{aligned}
f_{PLL3} &= f_{DCO} \div (K4 \times 1.0) \rightarrow K4PRE = 0 \\
f_{PLL3} &= f_{DCO} \div (K4 \times 2.0) \rightarrow K4PRE = 1 \\
f_{PLL3} &= f_{DCO} \div (K4 \times 1.2) \rightarrow K4PRE = 2 \\
f_{PLL3} &= f_{DCO} \div (K4 \times 1.6) \rightarrow K4PRE = 3
\end{aligned}
$$

In addition the PERPLL provides a special clock output f_{HSCT}

$$f_{HSCT} = f_{DCO} \tag{58}$$

PERPLL lock detection

The PERPLL has a lock detection feature, that supervises the DCO part of the PERPLL to differentiate between stable and unstable DCO circuit behavior. The lock detector marks the PLL as locked if its two input frequencies of the lock detector f_{REF} and f_{DIV} (=f_{DCO}÷N) have a phase difference smaller than ½ reference cycle for more than 224 reference cycles.

However, the unlock condition is reported immediately if the phase error is bigger than the above given limit. Smaller phase errors can be handled by the PLL without getting unstable and are not marked as "loss of lock".

The PERPLL may become unlocked, due to a break of the crystal or ceramic resonator or the external clock line. In such a case, an SMU alarm event is generated and the PLL switches to an open loop mode and keeps on free running at the last locked frequency.

The peripheral operation frequencies are controlled by the values of the five dividers: P, N, and K2, K3 and K4. A modification of the two dividers P and N has a direct influence to the DCO frequency and could lead to a loss of the lock status. However, a modification of the K2, K3 and K4 dividers has no impact on the lock status, but still changes the PERPLL output frequencies f_{PLL1}, f_{PLL2} and f_{PLL3} directly.

The lock status can be observed in bit-field PERPLLSTAT.PLLLOCK and the lock detection can be reset by setting bit-field PERPLLCON0.RESLD = 1_B. Applying the reset will close the loop and eventually enable it to lock again.

Attention**: **Once unlocked, the PLL will not make an attempt to lock again until issuing a lock detection reset or a reprogramming of the P or N dividers.

Frequency modulation

The PERPLL output frequencies $f_{PLL1/2/3}$ can additionally be modified by a low-frequency modulation to reduce EMI. A random sequence is added to the DCO control word resulting in a randomly modulated f_{DCO}. The rate of the modulation is defined by f_{REF}.

To configure the modulation follow these steps in the given order:

Turn on or off modulation for PERPLL

```
Wait until CLOCK_CCUSTAT.LCK == 0              // Wait for any ongoing transfer with a timeout
of 100 µs
CLOCK_PERPLLCON0.MODEN = 0                     // Deactivate Frequency Modulation
Wait until CLOCK_CCUSTAT.LCK == 0              // Wait for any ongoing transfer with a timeout
of 100 µs
CLOCK_PERPLLCON2.MODCFG = (0x7400 | MG)        // Program Modulation Gain (MG)
if (MG)
     Wait until CLOCK_CCUSTAT.LCK == 0         // Wait for any ongoing transfer with a timeout
of 100 µs
     CLOCK_PMODCON0 = 0x80000000               // CAL_EN = 1
     Wait(100ns)                               // Wait to ensure toggling
     Wait until CLOCK_CCUSTAT.LCK == 0         // Wait for any ongoing transfer with a timeout
of 100 µs
     CLOCK_PMODCON0 = 0x00000000               // CAL_EN = 0
     Wait until CLOCK_CCUSTAT.LCK == 0         // Wait for any ongoing transfer with a timeout
of 100 µs
     CLOCK_PERPLLCON0.MODEN = 1                // Enable Modulation
     Wait until CLOCK_PERPLLSTAT.MODRUN == 1   // Wait until modulation is running with a
timeout of 100 µs
end
```

***Note**: To turn off modulation, simply set MG=0 in the above sequence*

***Notes**:*
To change the modulation gain:

1. *Turn off modulation*
2. *Turn on modulation with different gain*

The modulation is enabled using bit-field PERPLLCON0.MODEN. The modulation itself alters the DCO frequency randomly within the range of the configured relative modulation amplitude (MA%). The modulation is controlled through bit-field PERPLLCON2.MODFCG as follows:

- MODCFG[9:0] = modulation gain

$$\text{modulation gain} = \frac{64}{3.6\text{MHz}} \times f_{\text{DCO}} \times \text{MA}$$
$$\text{Example: MA} = 2\,\% \text{ at} f_{\text{DCO}} = 800\,\text{MHz} \Rightarrow \text{modulation gain} = 0x11C \quad (59)$$

Configuration sequence for the K-dividers for configuration and re-configuration of PLLs

Special care should be taken during configuration and re-configuration of PLLs with respect to programming the K-dividers to avoid wrong K-divider or dead clock at one of the PLL output paths which can be recovered only through a system reset.

Follow the below configuration sequence for the K-dividers for the configuration or re-configuration of any PLL:

PLL configuration phase

1. PLL off
2. Check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs
3. Configure K-dividers in xPLLCON1 register
    a. Set KxPREDIV = div by 2 (xPLLCON1.KxPREDIV = div by 2)
    b. Check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs
    c. Set KxDIV = 0x01 (xPLLCON1.KxDIV = 0x01)
    d. Check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs
    e. Set other PLL parameters as described in the user manual
    f. Check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs
4. PLL on (power PLL)
5. Check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs
6. Check if PLL is powered: xPLLSTAT.PWRSTAT == 1 with a timeout of at least 100 µs
7. Wait for 1ms to avoid jitter
8. Check for PLL lock: xPLLSTAT.PLLLOCK == 1 with a timeout of at least 100 µs
9. Configure KxPREDIV (if necessary)
    a. Set KxPREDIV to final value
10. Wait for 10 µs and check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs
11. Configure KxDIV
    a. Set KxDIV to final value
    b. Check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs

Changing the KxDIV value during run time (KxPREDIV is not allowed to change during run time)

1. Check for PLL lock: xPLLSTAT.PLLLOCK == 1 with a timeout of at least 100 µs
2. Check for CCU lock: xLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs
3. Configure K-dividers in xPLLCON1 register
    a. KxDIV = 0x01 (xPLLCON1.KxDIV = 0x01)
4. Wait for 10 µs and check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs
5. Configure KxDIV
    a. Set KxDIV to final value
    b. Check for CCU lock: CLOCK_CCUSTAT.B.LCK == 0 with a timeout of at least 100 µs

32.3.5 Distribution

Using the first two parts of the clock system ("clock source" and "clock generation"), all root clocks the system relies on, are defined. These root clocks need to be individually adapted in frequency (divided) and distributed to all functional blocks of the MCU.

For clock distribution, the system is split into several sub-clock domains where the clock speed could be configured individually. There are also limitations for each sub-clock domain derived out of the internal interfaces. Each sub-clock domain defines a logical unit from a clocking perspective point of view.

The clock distribution is done through the clock control unit (*CCU*). The CCU receives the clocks that are created by the two PLLs (f_{PLL0},f_{PLLPPU}[38] and f_{PLL1}, f_{PLL2}, f_{PLL3}), the back-up clock f_{Back}, the ramp clocks f_{Ramp}, $f_{RAMPHALF}$[38], and the crystal oscillator output f_{XTAL}. These clocks are either forwarded directly or divided in order to supply the sub-clock domains.

32.3.5.1 Clock control unit

The clock control unit (*CCU*) finally derives all system and peripheral clocks needed by the functional blocks of the MCU based on the root clocks coming from the PLLs, EVR, ramp and crystal oscillators.

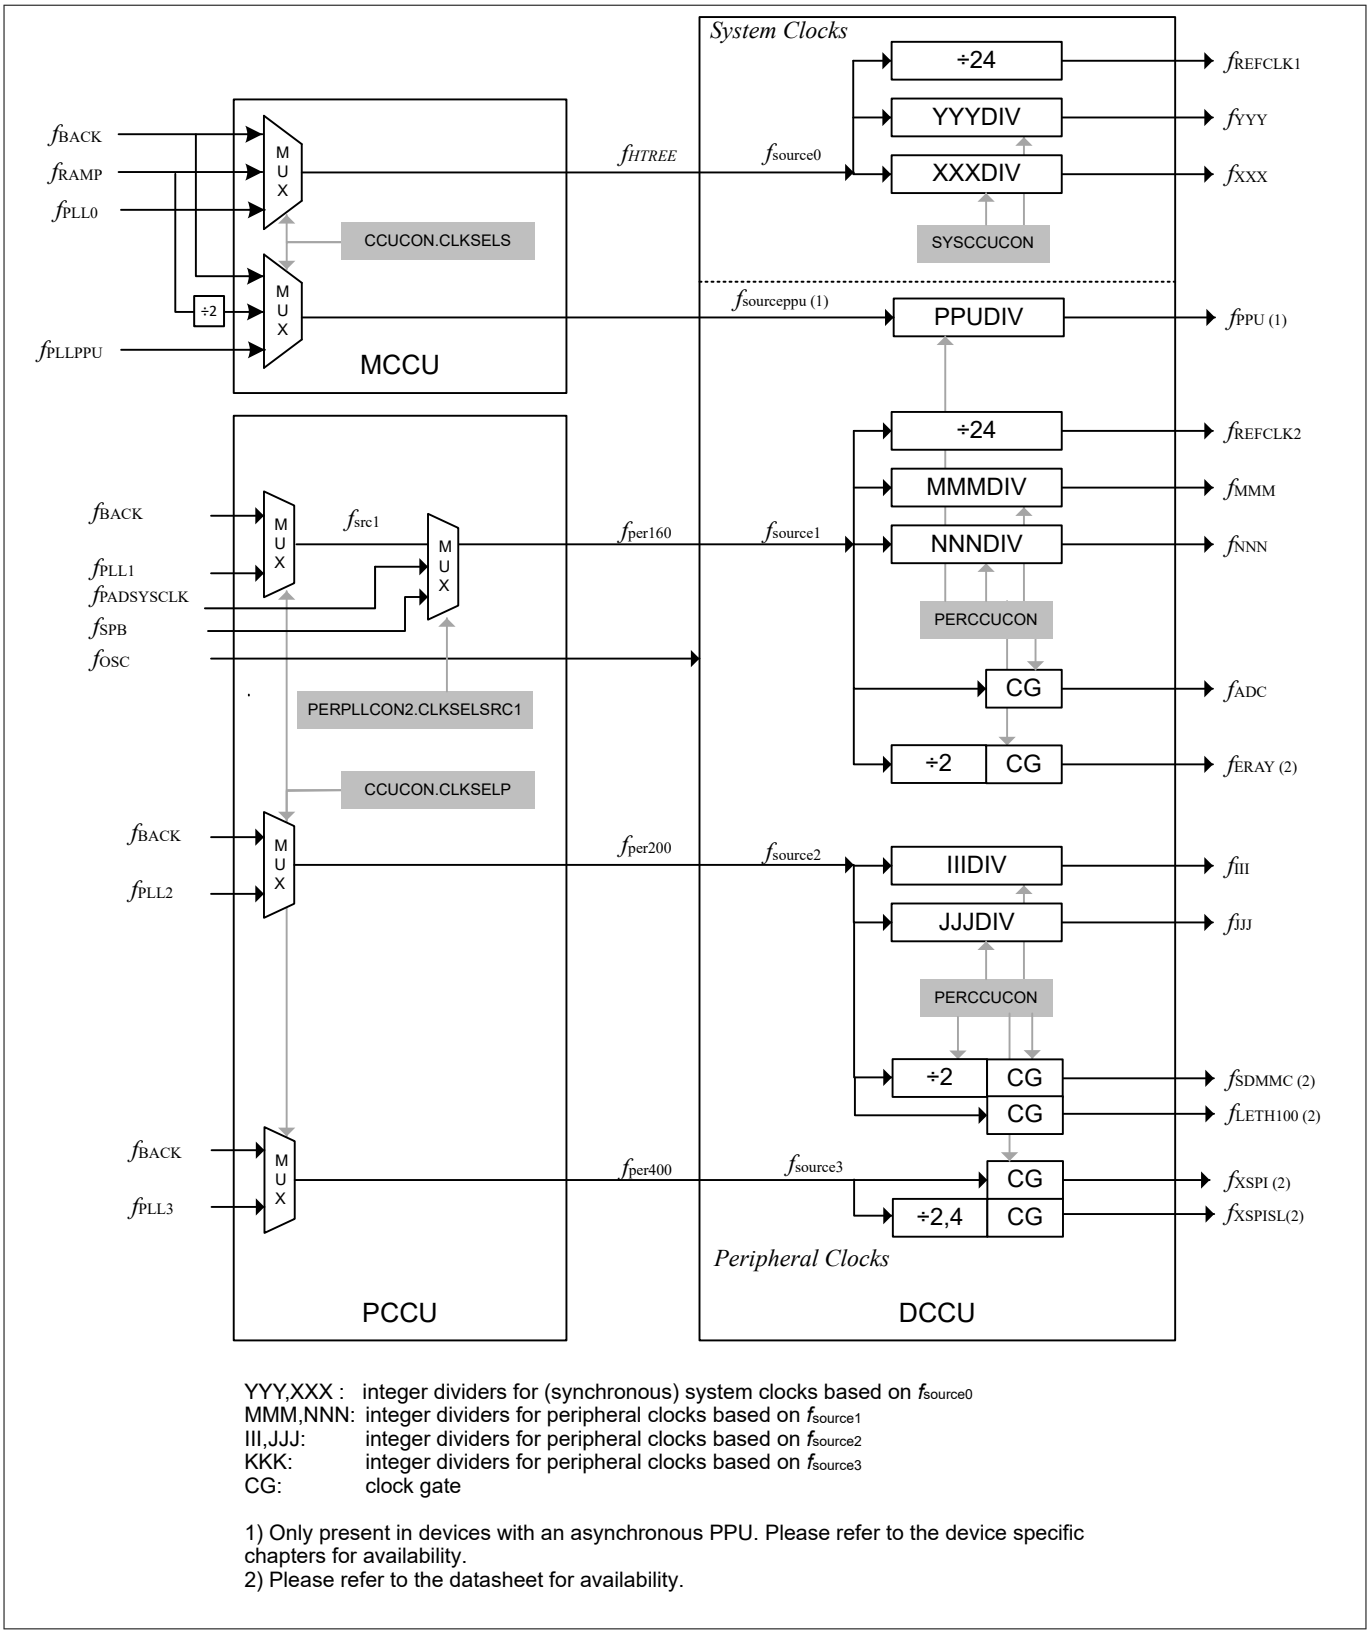
The CCU is logically composed of three units as shown in the following figure:

1. Master CCU (*MCCU*): Generates the root system clock $f_{source0}$ and the root PPU clock $f_{sourceppu}$[39] by selecting either the EVR oscillator f_{BACK}, the ramp oscillator f_{RAMP}, $f_{RAMPHALF}$[39] or the SYSPLL f_{PLL0} as root clock for the system clock tree $f_{HTREE}$and for the PPU clock generation[39]
2. Peripheral CCU (*PCCU*): Generates the root peripheral clocks $f_{source1\text{-}3}$ by selecting either the EVR oscillator f_{BACK} or the PERPLL $f_{PLL1\text{-}3}$ as root clocks
3. Distribution CCU (*DCCU*): Generates all system and peripheral clocks by using (dividing, switching and gating) the output clocks of the MCCU and PCCU. For selected peripheral clocks, the crystal clock f_{XTAL} is used as option

The following figure shows the general structure of the clock control unit.

In devices with a synchronous PPU, there is no separate PPU clock output because the PPU runs synchronous to the rest of the system resources and its clock is generated from the PLL0 output. In devices with an asynchronous PPU, the PPU clock is generated by the second SYSPLL output and is handled like another asynchronous peripheral clock.

38 Only present in devices with an asynchronous PPU. Please refer to the device specific chapters for availability
39 Only present in devices with an asynchronous PPU. Please refer to the device specific chapters for availability



YYY,XXX : integer dividers for (synchronous) system clocks based on $f_{source0}$
MMM,NNN: integer dividers for peripheral clocks based on $f_{source1}$
III,JJJ: integer dividers for peripheral clocks based on $f_{source2}$
KKK: integer dividers for peripheral clocks based on $f_{source3}$
CG: clock gate

2) Please refer to the datasheet for availability.

Figure 747 Clock control unit overview

CCU registers

CCU general:

- Global clock control register (CCUCON): source clock selection control
- Global clock status register (CCUSTAT): clock source selection status

System clocks:

- System CCU clock control register 0 (SYSCCUCON0): Divider and enable setting for system clocks
- System CCU clock control register 1 (SYSCCUCON1): Divider and enable settings for system clocks

Peripheral clocks:

- Peripheral CCU clock control register 0 (PERCCUCON0): Divider and enable settings for peripheral clocks
- Peripheral CCU clock control register 1 (PERCCUCON1): Divider and enable settings for peripheral clocks

Source clock selection and switching

The source clocks for the system, PPU[39] and peripheral clock distribution ($f_{source0}$, $f_{sourceppu}$[39], $f_{source1-3}$) can be selected from the PLL output clocks (f_{PLL0}, f_{PLLPPU}[39], $f_{PLL1/2/3}$), the EVR oscillator clock (f_{BACK}) and the ramp oscillator clock (f_{RAMP}, $f_{RAMPHALF}$[39]). This is done through the CCUCON.

The selection of the input clock is done inside the MCCU with bit-field CCUCON.CLKSELS for the system clocks and inside the PCCU with bit-field CCUCON.CLKSELP for the peripheral clocks. Software selects the source by writing the related value and hardware switches the associated clock multiplexers accordingly.

The actual selection status can be read by software from the CCUSTAT. The bit-fields CCUSTAT.CLKSELS and CCUSTAT.CLKSELP report the currently selected clock sources.

The separation of control and status bit-fields is done to reflect the situation where hardware overrules the actual software setting. This may be the case during clock emergency switching or a frequency ramp triggered by an application reset. The following table lists the settings:

Table 1278 Clock source selection control and status

	CCUCON.CLKSELS	CCUCON.CLKSELP
System clocks sourced by PLL0	00_B	--
System clocks sourced by EVR clock	01_B (default)	--
System clocks sourced by ramp clock	10_B	--
PPU clock [39]sourced by PLLPPU	00_B	--
PPU clock[39] sourced by EVR clock	01_B (default)	--
PPU clock[39] sourced by ramp clock divided	10_B	--
Peripheral clocks sourced by PLL1-3	--	0_B
Peripheral clocks sourced by EVR clock	--	1_B (default)

As shown in the above table, the clock source selection setting for system and peripheral clocks are independent from each other. This is also valid for hardware initiated overruling during emergency switching and application reset execution..

***Note**: The CLKSELS and CLKSELP values in the CCUSTAT register reflect the actual used setting of the clock multiplexers inside the MCCU and PCCU. Under normal operation scenarios this equals the setting in the control register. However, in case of clock emergency switching, status and control values will differ.*

32.3.5.1.1 Module clocks

The clocking system offers many options and a high amount of flexibility. For different functional blocks, options are provided to influence the application execution or performance through the clock control.

Module clock overview

Here we give a detailed overview of the different clocks used for the functional blocks of the MCU:

Table 1279 Central processing units, bus interconnects and timers

Name	Description	Domain
f_{SRI}	Defines the operating performance of the system resource interconnect fabric (*SRI*), and therefore the data exchange rate between all connected master- and slave-agents. The CPUs and DMAs also run on f_{SRI}	System
f_{SPB} [1)]	Defines the operating performance of the system peripheral bus (*SPB*) interconnect, and therefore the data exchange rate between all connected master- and slave-agent	System
f_{CPB} [2)]	Defines the operating performance of the converter peripheral bus (*CPB*) interconnect, and therefore the data exchange rate between all connected master- and slave-agents	System
f_{STM}	Defines the basic frequency for the system timers (*STM*) independent of the rest of the system	System
f_{RCB} [2)]	Defines the operating performance of the radar configuration bus (*RCB*) interconnect, and therefore the data exchange rate between all connected master- and slave-agents	System
f_{GTM} [2)]	Defines the basic frequency for the generic timer (*GTM*) module independent of the rest of the system	System
f_{eGTM} [2)]	Defines the basic frequency for the enhanced generic time (*eGTM*) module independent of the rest of the system	System
$f_{eGTMhalf}$ [2)]	Defines the divided by half frequency for the enhanced generic time (*eGTM*) module. This frequency is always half of f_{eGTM}	System

1) On some devices the COMPB also uses this clock. Please refer to the device specific chapters for further details.
2) Please refer to the datasheet for availability

Table 1280 Parallel processing unit

Name	Description	Domain
f_{PPU} [2)]	Defines the operating frequency of the parallel processing unit	System

Table 1281 Ethernet modules

Name	Description	Domain
f_{GETH} [2)]	Defines the operating frequency of the Gigabit Ethernet subsystem	System
f_{LETH}	Defines the operating frequency of the Light Ethernet mac modules	System

Table 1282 CAN modules

Name	Description	Domain
f_{MCANH} [2)]	Defines the host frequency of the MCAN subsystem	System
f_{CANXLH}	Defines the host frequency of the CANXL subsystem	System

Table 1283 Flash (DMU) controls

Name	Description	Domain
f_{FSI2}	Defines the execution speed of the flash standard interface (*FSI*) for program flash reading operations	System
f_{FSI}	Defines the execution speed for all other FSI operations	System

Table 1284 Cyber security module

Name	Description	Domain
f_{SRICS}	The components of the cyber security real-time module (CSRM) run either on f_{SRICS} or f_{SPB}. f_{SRICS} is configured to be equal to f_{SRI} when the control bit-field SYSCCUCON0.SRICSDIV = 0. If the bit-field is set to 1, f_{SRICS} is half the frequency of f_{SRI}	System

Table 1285 Trace system

Name	Description	Domain
f_{TPB}	Because tracing should be non-intrusive to the application system, a separate clock f_{TPB} for dedicated trace resources is available. Note that f_{TPB} needs to be at least two times higher than f_{SPB}	System
$f_{REFCLK1}$	Defines a fixed timebase for the trace system. This allows the trace system (MCDS) to generate timestamps independent of the selected SRI and SPB clock speeds	System
$f_{REFCLK2}$	Defines a fixed timebase for the trace system. This allows the MCDS to generate timestamps independent of the selected SRI and SPB clock speeds	Peripheral

Table 1286 Miscellaneous clocks

name	Description	Domain
f_{MT0} [2)]	This is the macrotick 0 signal from the flexray (*ERAY*) module which can be routed to the external clock output	System

Table 1287 Peripheral clocks of communication modules

name	Description	Domain
f_{MCAN} [2)]	Defines the basic frequency for the external communication protocol of the MCAN modules independent of the rest of the system	Peripheral
f_{CANXL}	Defines the basic frequency for the external communication protocol of the CANXL modules independent of the rest of the system	Peripheral
f_{MSC} [2)]	Defines the basic frequency for the micro second channel (*MSC*) modules independent of the rest of the system	Peripheral
f_{QSPI}	Defines the basic frequency for the queued synchronous peripheral interface (*QSPI*) modules independent of the rest of the system	Peripheral
$f_{ASCLINF}$	Defines the basic frequencies for the fast asynchronous/synchronous interface (*ASCLINF*) module independent of the rest of the system	Peripheral
$f_{ASCLINS}$	Defines the basic frequencies for the slow asynchronous/synchronous interface (*ASCLINS*) module independent of the rest of the system	Peripheral
f_{I2C}	Defines the basic frequency for the inter-integrated circuit (*I2C*) modules independent of the rest of the system	Peripheral
f_{ERAY} [2)]	Defines the basic frequency for the flexray (*ERAY*) modules independent of the rest of the system	Peripheral

(table continues...)

Table 1287 (continued) Peripheral clocks of communication modules

name	Description	Domain
f_{HSCT} [2]	Defines the basic frequency for the high speed communication tunnel (*HSCT*) module independent of the rest of the system	Peripheral
f_{xSPI} [2]	Defines the basic frequency for the *xSPI* Interface independent of the rest of the system	Peripheral
f_{xSPISL} [1]	Defines the slow basic frequency for the *xSPI* Interface independent of the rest of the system	Peripheral
f_{SDMMC} [2]	Defines the basic frequency for the secure digital multimedia card (*SDMMC*) module independent of the rest of the system	Peripheral
$f_{LETH100}$	Defines the reference clock frequency for the *LETH* modules independent of the rest of the system	Peripheral

1) Please refer to the device specific chapters for availability

Table 1288 Converters

name	Description	Domain
f_{ADC}	Defines the basic frequency for the analog digital converters (*ADC*) independent of the rest of the system	Peripheral

Module clock sources and dividers

The following table lists for all generated clocks what clock source is available and what divider is used to scale the frequency. A divider value of 0 switches off the clocks. In the below listed tables all clock dividers and clock selectors can be programmed through the following registers:

- CCUCON for clock source settings
- SYSCCUCON0 and SYSCCUCON1 for system clock dividers
- PERCCUCON0 and PERCCUCON1 and for peripheral clock dividers and selectors

Table 1289 CCU system clock options

5) Set by SW at anytime, CLKSELSRC1 = 3
6) Set by HW due to system reset or clock emergency switch, set by SW at anytime, CLKSELP = 1_B
7) The 5-phase 320 MHz HSCT clock is generated within the HSCT Phy. The DCO frequency of the PERPLL must be set to 800 MHz to achieve 320 MBaud data rate.
8) Set by SW through respective divider or clock selection setting

9) Set by HW due to system reset

32.3.5.1.2 Clock divider limitations

For the clock dividers which control the different sub-clock domains or modules, the allowed values are limited and the following ratios have to be observed. The ratios are defined in the following way:

clock A = f_{XXX}; clock B = f_{YYY} the allowed ratio is 1 : n where n has a defined range of values.

Clock A is always faster or equal to clock B in this definition with f_{XXX} [MHz] = n × f_{YYY} [MHz].

For synchronous clocks, n must be an integer value.

In addition, the divider values are limited by the resulting minimum or maximum frequencies. These frequencies are defined in the datasheet.

Table 1293 Divider ratio restrictions

Clock A	Clock B	Allowed values	Recommended value for 400 MHz use-case[1]	Recommended value for 500 MHz use-case[2]
f_{SRI}	f_{SPB}[3]	n ≥ 1[4]	n = 4	n = 5
f_{SRI}	f_{CPB}[6]	n ≥ 1	n = 4	n = 5
f_{SRI}	f_{TPB}	n = 1, 2[5]	n = 2	n = 2
f_{TPB}	f_{GTM}[6]	n ≥ 1	n = 1	NA
f_{TPB}	$f_{eGTMhalf}$[6]	n ≥ 1[7]	n = 1	n = 1
f_{TPB}	f_{SPB}[3]	n ≥ 2	n = 2	n = 2.5[11]
f_{SRI}	f_{STM}	n ≥ 1	n = 1	n = 1
f_{SRIcs}	f_{STM}	n ≥ 1	n = 1	n = 1
f_{SRI}	f_{FSI}	n = 1, 2, 3,4,5[8] [9]	n = 4	n = 5
f_{SRI}	f_{FSI2}	n = 1	n = 1	n = 1
f_{FSI2}	f_{FSI}	n = 1, 2, 3,4, 5 [10]	n = 4	n = 5
f_{FSI}	f_{SPB}[3]	n ≥ 1	n = 2	n = 2
f_{GTM}[6]	f_{SPB}[3]	n ≥ 1	n = 2	NA
f_{MCANH}[6]	f_{MCAN}[6]	n ≥ 1.0[11]	n = 1.25[12] [11]	n = 1.56/1.25 [13] [11]
f_{CANXLH}	f_{CANXL}	n ≥ 1.0[11]	n = 1.25[14] [11]	n = 1.56/1.25 [15] [11]
f_{SRI}	f_{RCB}[6]	n = 2	n = 2	NA
f_{SRICS}	f_{FSI}	n = 1, 2, 3,4,5[16] [17]	n = 4	n = 5

1) The recommended defaults apply for a system source clock frequency of $f_{source0}$ = 400 MHz only.
2) The recommended defaults apply for a system source clock frequency of $f_{source0}$ = 500 MHz only.
3) On some devices the COMPB also uses this clock. Please refer to the device specific chapters for further details.
4) Not all values of n are available for all derivatives. Please refer to the device specific chapters for restrictions on the values of n
5) n=1 shall only be applied if $f_{SRI} \leq f_{TPBmax}$
6) Please refer to the datasheet for availability
7) To avoid timing violations at this interface, the EGTMDIV must not be set to an odd value, but only to 1 or an even value.
8) Note that f_{SRI}/f_{FSI}=1 is not supported by all devices. Please refer to the device specific chapters for further restrictions.
9) Do not apply values that would lower f_{FSI} below its reset value which is 100 MHz. This is needed to guarantee a graceful shutdown operation.
10) Note that f_{FSI2}/f_{FSI}=1 is not supported by all devices. Please refer to the device specific chapters for further restrictions.
11) n is not an integer as the related clocks are asynchronous to each other

12) f_{MCANH} must always be greater than f_{MCAN}, with f_{MCAN} = 160/80 MHz, f_{MCANH} = 200/100 MHz
13) f_{MCANH} must always be greater than f_{MCAN}, with f_{MCAN} = 160/80 MHz, f_{MCANH} = 250/100 MHz
14) f_{CANXLH} must always be greater than f_{CANXL}, with f_{CANXL} = 160/80 MHz, f_{CANXLH} = 200/100 MHz
15) f_{CANXLH} must always be greater than f_{CANXL}, with f_{CANXL} = 160/80 MHz, f_{CANXLH} = 250/100 MHz
16) Note that f_{SRICS}/f_{FSI}=1 is not supported by all devices. Please refer to the device specific chapters for further restrictions.
17) Do not apply values that would lower f_{FSI} below its reset value which is 100 MHz. This is needed to guarantee a graceful shutdown operation.

Attention**: **The recommended values do not necessarily reflect the default configuration after a reset event. Instead they should give a hint about how to configure the system for the optimal performance. In addition, it may happen that applying an allowed ratio on two selected clocks violates the ratio of others. Due to the complexity, this cannot be shown here in all combinations. The User has to take care not to violate clock ratios depending on the enabled clocks and the use-case.

32.3.5.1.3 Start-up and shut-down

For power up, power down, system and application resets or clock emergencies the clocking system needs to be started up or shut down. This is done by firmware, application software, or by hardware support.

Start-up

- After boot phase controlled by application software: Following power-on reset or system reset
- At the end of boot phase controlled by firmware: Following application reset

Shut-down

- For power down execution by application software
- By hardware during system reset, application reset or clock emergency

Software controlled

Start up controlled by application software

For start up, the ramp oscillator is used to increase the system clock frequency in small steps to avoid large current jumps. Following the boot phase, clock system start-up is under control of the application software. The application software knows the device's setup with respect to the availability of an external clock source (type and frequency) and the needed target frequencies for the SYSPLL and PERPLL. For peripheral clock start-up, the ramp oscillator is not used. The fan-out load of the related clock trees and the target frequencies are lower. Therefore, the current jump is lower and no clock ramp is needed. Here the legacy mode of K-divider stepping can be applied.

Basic Steps for start-up:

- T0:
  - Power up and configure crystal oscillator
  - Power up and configure ramp oscillator (target frequency)
  - Power up and configure SYSPLL with P, N to target DCO frequency, K divider to target frequency
  - Power up and configure PERPLL with P, N to target DCO frequency, set K-dividers to the desired frequencies
- T1: Switch system clock selection to ramp oscillator
- T2: Trigger ramp up
- T3: Wait for end of ramp execution and stable target frequency by observing the RAMPSTAT.FLLLOCK bit
- T4: Switch system clock selection to SYSPLL once the SYSPLL is locked, switch peripheral clock selection to PERPLL once PERPLL is locked
- T5: Step down PERPLL K-dividers towards target frequencies

If the maximum system frequency of the device is 400 MHz and the PPU configured frequency is 400 MHz, the PPU is operated with f_{SRI} which is synchronous to the rest of the system, that means the PPU clock is sourced

from $f_{source0}$. Please be aware that the target f_{RAMP} frequency should be 100 MHz below the configured f_{PLL0} frequency.

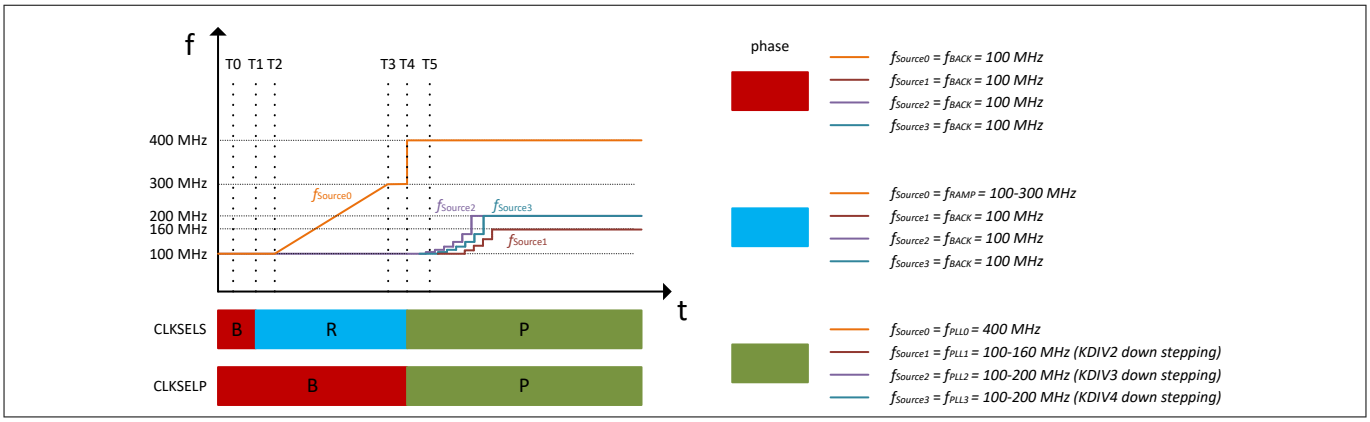

Figure 748 Start up 400 MHz use case

***Note**: Ramp up case : During ramp up it is needed that application software performs a "frequency throttling" in order to avoid generating VDD under voltage that can trigger cold reset.*

Shut down controlled by application software

For shut down, the ramp oscillator is also used to decrease the system clock frequency in small steps to avoid large current jumps. For peripheral clock shut down, the legacy mode of K-divider stepping can be applied. The clock system shut down is under control of the application software.

Basic Steps for shut down:

- T0: Configure the PERPLL K-dividers to achieve 100 MHz frequency
- T1: Switch system clock selection to ramp oscillator once the ramp oscillator reached UFL, switch peripheral clock selection to backup clock
- T2: Trigger ramp down
- T3: Wait for end of ramp execution and stable target frequency
- T4: Switch system clock selection to backup clock
- T5:
  - Power down SYSPLL with P, N to target DCO frequency, K divider to target frequencies
  - Power down PERPLL with P, N to target DCO frequency, K dividers to target frequencies
  - Power down ramp oscillator (ramp slope, target frequency)
  - Power down crystal oscillator

If the maximum system frequency of the device is 400 MHz which is inline with the maximum frequency of the PPU, the PPU is operated with f_{SRI} which is synchronous to the rest of the system, that means the PPU clock is sourced from $f_{source0}$.

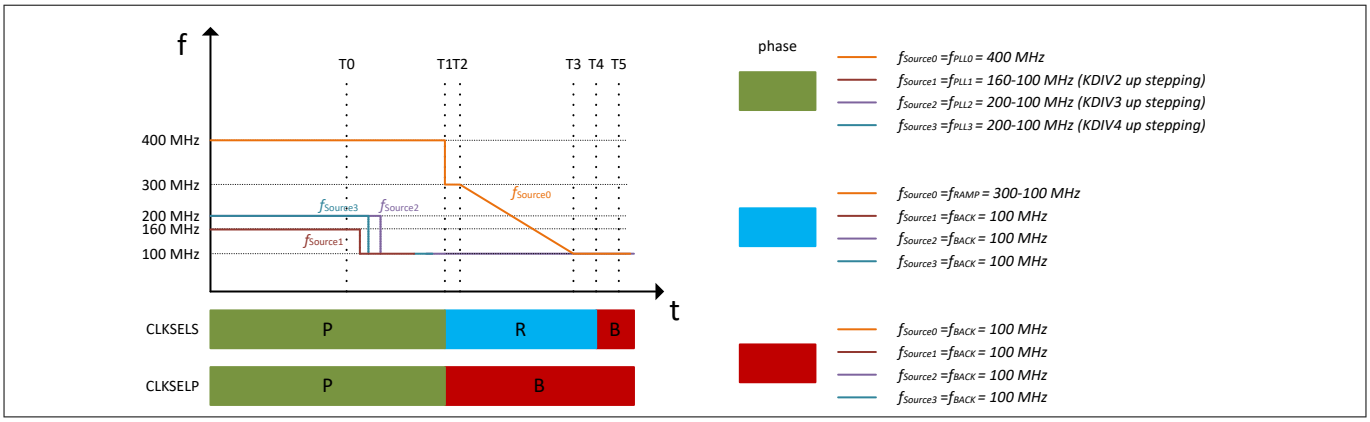

Figure 749 Shut down 400 MHz use case

***Note**: Ramp down case: During ramp down "frequency throttling" of PERPLL is not required. According to load jump assessment, it will not generate a higher VDD voltage that would introduce a long-term reliability issue.*

Hardware-software controlled

During application- or system-reset, system clocks are reduced in frequency before the clock is halted to finally execute the reset. A loss of lock of the *SYSPLL* requires a switch over to a reliable independent clock source. This is also done through continuous frequency reduction using the ramp oscillator.

Application and system reset

For the application and system resets, the device automatically executes a shutdown sequence initiated by the System Modes and Reset (SMR) controller. The processing units, memories and ports are getting triggered to shut down their current operation.

Finally, the clocking system gets triggered to ramp down the system clock frequencies and to halt the clocks while the related hardware reset signals are getting activated to execute the reset. The ramp oscillator is used to gracefully change the frequency of the system root clock f_{HTREE} in small steps. This is done to avoid current load undershoots or overshoot due to an abrupt change in load of active clocked components during reset execution. As resets might occur at any time, hardware takes control of the ramp down process to allow a quick execution of the ramp.

During re-boot following an application reset, firmware re-installs the system clock settings as originally configured by the application. That means, ramp up of root clock frequency as stored by the application in register bit-field CCUCON.CLKSELS. In application and system reset, the PERPLL throttling is not needed.

***Attention**: As $f_{source0}$ is the root source for system clocks, all system clocks are reduced and increased too, while the hardware initiated ramp-down and -up process is executed. Actual settings of related clock dividers are not changed by hardware during that time.*

The following figure shows the sequence which is executed by hardware and firmware in cooperation. The hardware override of the clock selection can be seen in the difference of the CCUCON.CLKSELS and CCUSTAT.CLKSELS. When firmware sets the CCUCON.CLKSELS during re-boot, the override gets cleared.

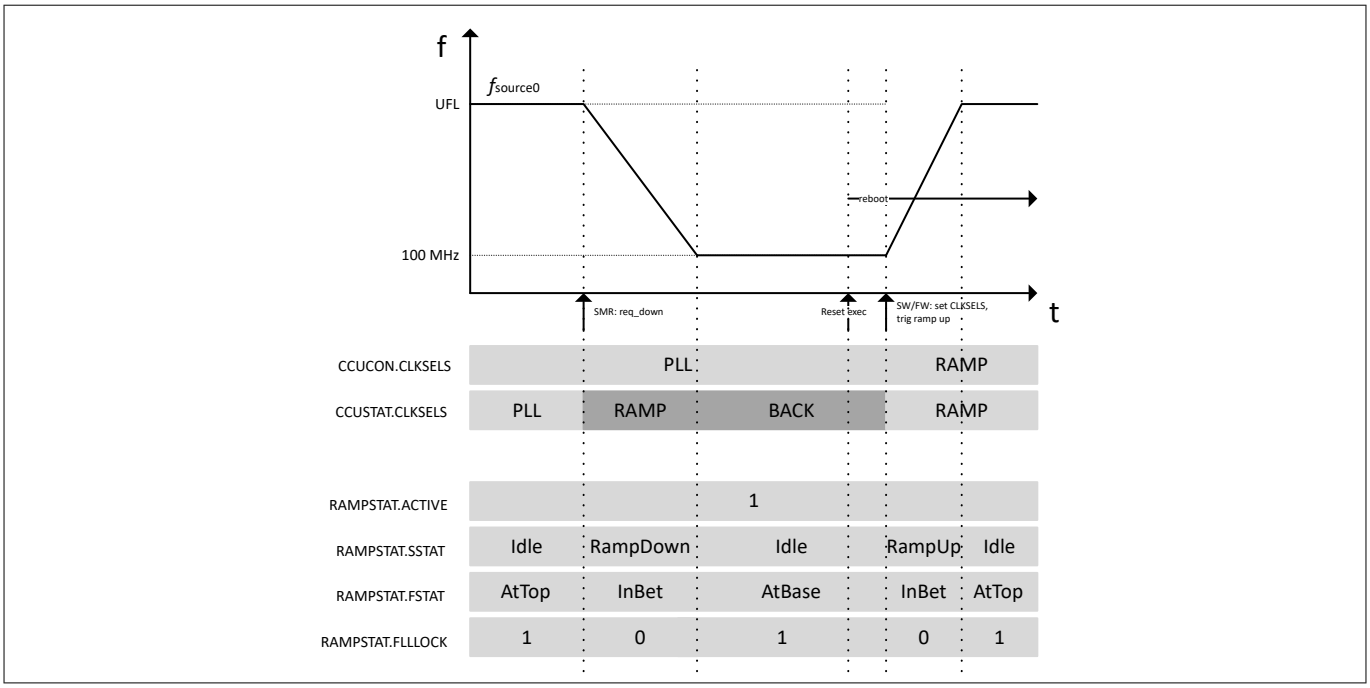

Figure 750 Ramp hardware-software interface during application or system reset

Emergency switch

During normal operation, all module clocks are generated using the PLLs. If there is a failure in PLL operation and they lose their lock, the clocking system automatically switches to an internal, alternate clock source to maintain operation with reduced performance.

In case of a SYSPLL error, the MCCU intermediately switches to the ramp clock f_{RAMP} and finally to f_{BACK} as alternate clock source. After switching over to f_{RAMP}, a ramp down sequence is executed by hardware to reduce current jumps before finally switching over to f_{BACK}.

In case of a PERPLL error, the PCCU directly switches to f_{BACK} as alternate clock source.

Both PLLs operate independent from each other, that means in case of an loss of lock event, only the affected clock domain (System or Peripheral) is switched to its alternate clock source.

A clock emergency switch is triggered by the occurrence of at least one of the following conditions:

- Loss of lock event of the SYSPLL while selected as clock source (CCUCON.CLKSELS = PLL)
- Loss of lock event of the PERPLL while selected as clock source for (CCUCON.CLKSELP = PLL)

A clock emergency switch stays active until CLKSELx is re-written by software.

On detection of clock emergency switch, an alarm is signaled to the SMU.

***Note**: After a clock emergency, the bit-fields CLKSELx have to be re-written. After the root cause for the clock error disappears, the application can reconfigure the clock system, including CLKSELx.*

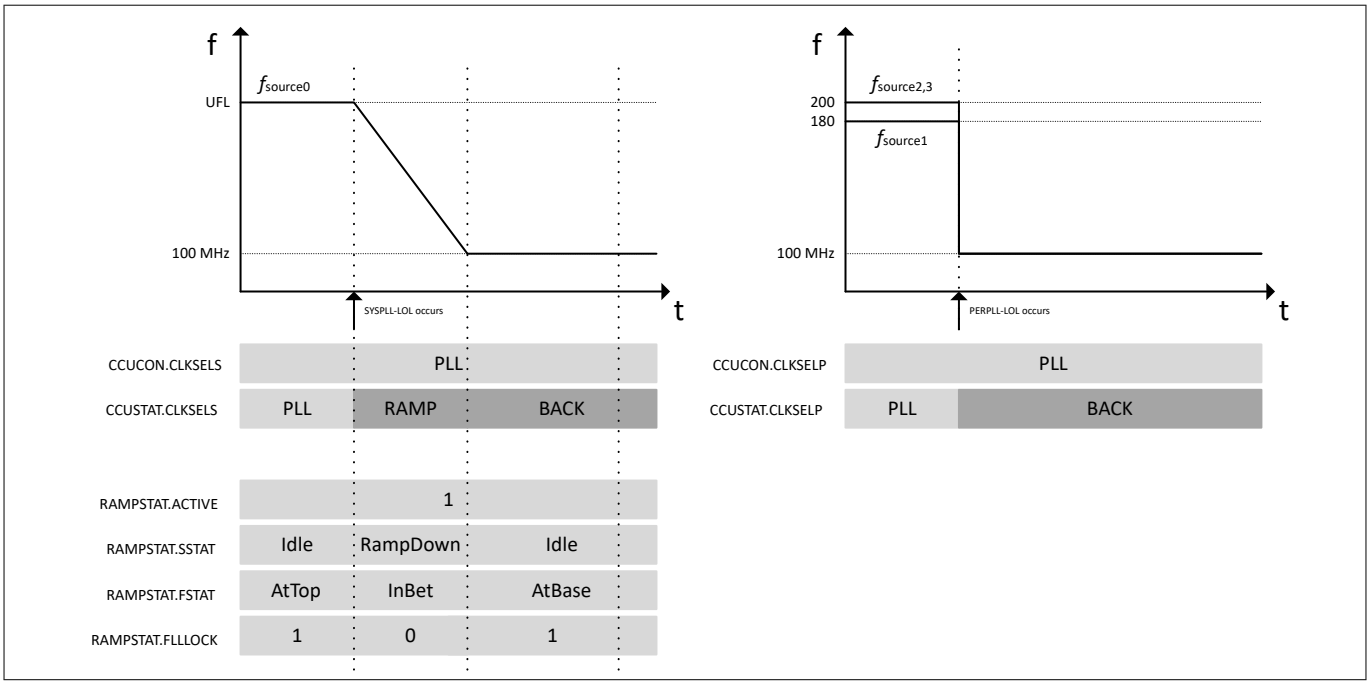

Figure 751 Ramp hardware-software interface during clock emergency switch

32.3.5.2 External clock output

Two external clock outputs are provided through pins EXTCLK0 and EXTCLK1. These external clocks can be enabled or disabled using the external clock control register (EXTCON):

- EXTCON.EN0: enables pin EXTCLK0
- EXTCON.EN1: enables pin EXTCLK1
- EXTCON.SEL0: selects internal clock to be presented at EXTCLK0
- EXTCON.SEL1: selects internal clock to be presented at EXTCLK1
- EXTCON.NSEL1: selects if the clock on EXTCLK1 is inverted or not

***Note**: Changing the content of bit-field EXTCON.SEL0 and EXTCON.SEL1 can lead to glitches in the clock signal at pins EXTCLK0 and EXTCLK1*

There are two kinds of additional clock dividers that can be used to generate auxiliary clocks presented on the external outputs. This is to generate a wide range of frequencies for external use.

1. Fractional divider based on f_{SPB}
2. Integer divider based on f_{SPB}

In addition, EXTCLK1 output can be inverted to support differential output signal generation on GPIOs.

32.3.5.2.1 Fractional divider

The fractional divider function enables application software to generate an external clock derived from the f_{SPB} by using a programmable divider.

Overview

The fractional divider is controlled through the Fractional divider control register (EXTFDCON).

The circuit divides the input clock f_{SPB} either by the factor 1÷n or by a fraction of n÷1024 for any value of n from 0 to 1023. This clock is additionally divided by a factor of two to guarantee a 50% duty cycle and outputs the clock f_{FRAC}.

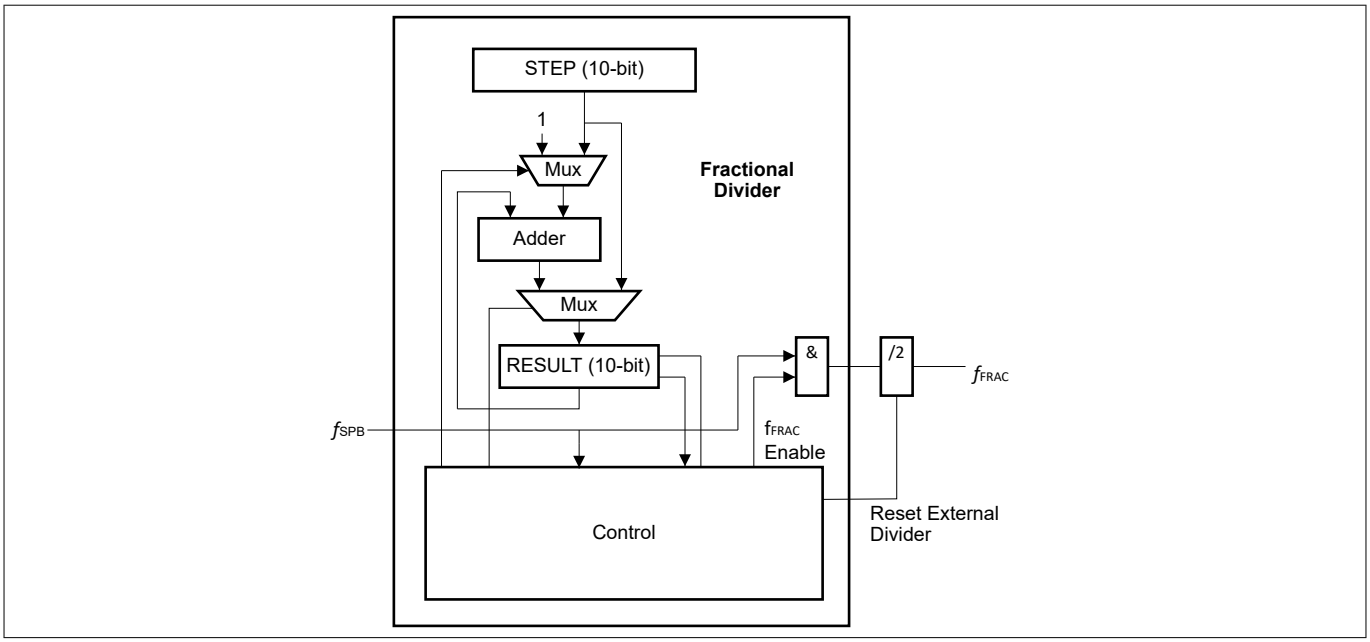

Figure 752 Fractional divider block diagram

The adder logic of the fractional divider can be configured for two operating modes:

- Normal mode: Reload counter (RESULT = RESULT + 1), generating an output clock pulse on counter overflow
- Fractional divider mode: Adder that adds a STEP value to the RESULT value and generates an output clock pulse on counter overflow

Normal divider mode

In normal divider mode (EXTFDCON.DM = 01_B), the fractional divider behaves as a reload counter (addition of +1) that generates an output clock pulse on the transition from $3FF_H$ to 000_H. EXTFDCON.STEP determines the reload value. For details, please refer to the register section).

The output frequencies in Normal Divider Mode are defined according to the following formulas:

$$f_{FRAC} = \frac{f_{SPB} \times \frac{1}{n}}{2}, \text{with } n = 1024 - \text{STEP} \quad (60)$$

In order to get $f_{FRAC} = f_{SPB} \div 2$, STEP must be programmed with $3FF_H$.

Fractional divider mode

When the fractional divider mode is selected (EXTFDCON.DM = 10_B), the output is derived from the input clock f_{SPB} by division of a fraction of n÷1024, for any value of n from 0 to 1023, followed by the division of two. In general, the fractional divider mode makes it possible to program the average output clock frequency with a higher accuracy than in normal divider mode.

In fractional divider mode, a pulse is generated depending on the result of the addition RESULT + STEP. If the addition leads to an overflow over $3FF_H$, a pulse is generated for the divider by two.

***Note**: This clock should only be used to observe the clock frequency/shape but not jitter.*

The output frequencies in fractional divider mode are defined according to the following formula:

$$f_{FRAC} = \frac{f_{SPB} \times \frac{STEP}{1024}}{2} \quad (61)$$

32.3.5.2.2 Output multiplexing

The clock output EXTCLK0 and EXTCLK1 can be configured for either a programmable frequency output f_{FRAC} (fractional divider) or f_{DIV1} (integer divider) or one of the internal system and peripheral frequencies f_{XXX}.

Clocks f_{FRAC} and f_{DIV1}, using $f_{OUT} = \frac{f_{SPB}}{DIV1 + 1}$, are generated through a counter, so the output frequency can be selected in small steps.

The EXTCON provides control over the output generation (frequency and activation).

The following figure summarizes which internal clocks can be multiplexed to the external clock pins. The detailed list of $f_{XXX\text{-}YYY}$ and $f_{III\text{-}JJJ}$ can be taken from register bit-fields EXTCONSEL0 and EXTCON.SEL1.

32.4 Registers

32.4.1 Overview

All clocking system related registers may be accessed by any CPU in the system. However, it is strongly suggested that only one CPU is used to control the clocks to avoid consistency issues. After reset, only CPU0 and the Cerberus are enabled for write access through the APU control registers.

The clocking system contains several registers that cannot be directly written but through a posting mechanism, that means there is a "master" register inside the MCCU and "mirror" registers in DCCU or PCCU. In order to maintain data coherency during a programming sequence, it is necessary to wait with any following register access while a posted write transaction is ongoing and the write finally takes effect on the final destination.

The bit-field CCUSTAT.LCK has been introduced to reflect the status of posted write transactions. It indicates if a writable clock system registers can be updated with a new value or if the register is still locked (due to an ongoing previous write access) and a write action from the bus side has no effect. It shall be monitored to pause the sequence of register accesses until it is cleared by hardware. The worst case delay of CCUSTAT.LCK being set is 70 µs.

***Note**: There will be no bus error reported if there is a write access to a clocking system registers while the lock bit set.*

The lock bit is blocking writes to the following registers:

- OSCCON
- RAMPCON0
- SYSPLLCON0, SYSPLLCON1, SYSPLLCON2
- PERPLLCON0, PERPLLCON1, PERPLLCON2
- PMODCON0
- CCUCON
- SYSCCUCON0, SYSCCUCON1
- PERCCUCON0, PERCCUCON1

The lock bit is set under any of the below listed conditions. It is cleared when the posted write transaction is complete:

- Write to SYSPLLCON1
- Write to PERPLLCON0, PERPLLCON1, PERPLLCON2
- Write to PMODCON0
- Write 1_B to bit-field SYSCCUCON0.UP, SYSCCUCON1.UP
- Write to PERCCUCON0, PERCCUCON1

32.4.2 Register overview - access mode glossary

Table 1294 Register overview - access mode glossary

Keyword	Description
CSE	Access protection using PROT register PROTCSE.
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
APU-PCS	Protection group consisting of registers ACCENCS_WRA, ACCENCS_WRB, ACCENCS_RDA, ACCENCS_RDB, ACCENCS_VM, ACCENCS_PRS.
PCS	Access protection using *APU-PCS* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
STP	Access only during start-up, before start-up protection is set (SMM_STCON.ST_PROT=1).

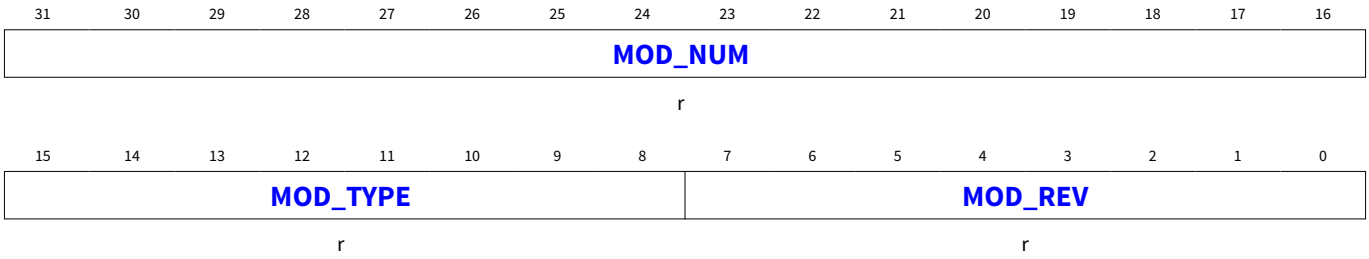
32.4.4 Module Identification register

ID Offset address: 0008_H

Module Identification register PowerOn Reset value: $00EE\ C013_H$



Field	Bits	Type	Description
MOD_REV	7:0	r	**Module revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module number** Indicates the module identification number ($00EE_H$ = CLOCK).

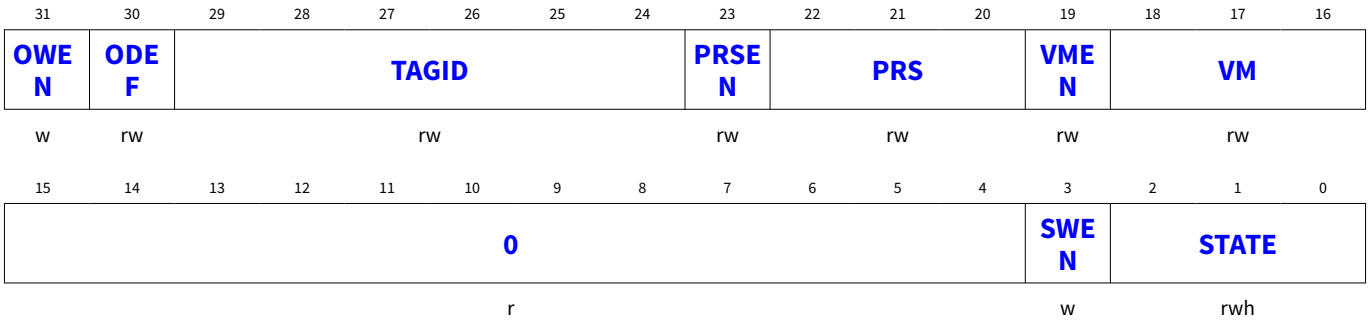
32.4.5 PROT Register Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 0020_H

PROT Register Endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; must be written with 0.

Table 1296 Access mode restrictions of PROTE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

32.4.6 PROT register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 0024_H

PROT register safe endinit Application Reset value: $0000\ 0000_H$

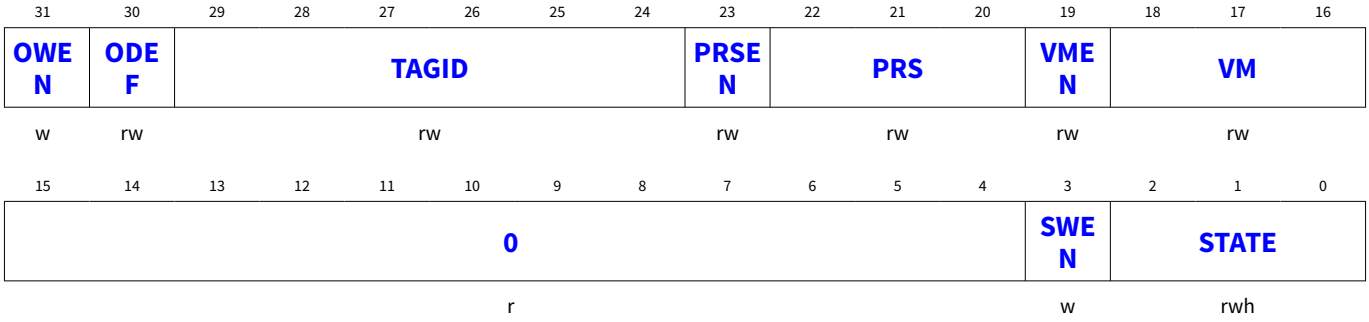
32.4.7 PROT Register Cyber-Secure APU Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTCSE register controls lock / unlock of the local Cyber Secure APU Endinit (CSAE) protected control registers.

PROTCSE Offset address: 0028_H

PROT Register Cyber-Secure APU Endinit Reset values see: Table 1299



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.

(table continues...)

(continued)

Field	Bits	Type	Description
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; must be written with 0.

Table 1298 Access mode restrictions of PROTCSE sorted by descending priority

Mode name	Access mode		Description

32.4.21 Ramp oscillator control register 0

This register configures the sequencer within the ramp oscillator.

RAMPCON0 Offset address: 0200_H

Ramp oscillator control register 0 System Reset value: $0000\ 0190_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0												PWR	CMD		
r												rw	rwh		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						UFL									
r						rw									

Field	Bits	Type	Description
UFL	9:0	rw	**Upper frequency limit** Upper frequency limit in 1 MHz units. Acceptable values are integer multiples of 100 MHz up to a maximum of *f*PLL0-100 MHz as per the datasheet. This recommendation is due to the ramp oscillator inaccuracy. ***Note**: A new value only takes effect with the start of the next ramping sequence, that means it does not change a running sequence.* ***Note**: It is mandatory by the application software to enter this value during clocking system setup. This is necessary as the value is used by firmware during the re-boot process after an application reset.* ***Note**: Ensure a waiting time of 20 f_{SPB} clock cycles before the next write access to RAMPCON0.* ***Note**: The minimum upper frequency is UFLmin = 130 [MHz]. Frequencies below this limit should not be used.* *The UFL_min is calculated with the formula : 100 [MHz]+ StepSize_min* *StepSize_min = 30 MHz*
CMD	18:16	rwh	**Ramp sequencer command** These bits will direct a ramp sequence according to its control parameters (*UFL*). Writing to this field directly triggers execution of a ramp sequence. The cmd automatically clears to *IDLE* after 20 f_{SPB} clock cycles. ***Note**: The control parameters are activated together with a command trigger, that means changing them without issuing a command has no direct effect on the actual output frequency of the oscillator or the ramp sequence. The new parameters get active with the next command.* *A command trigger only gets executed when the ramp oscillator is not busy as indicated by RAMPSTAT.SSTAT = Idle. Otherwise it is ignored.* ***Note**: Ensure a waiting time of 20 f_{SPB} clock cycles before the next write access to RAMPCON0.* 000_B **Idle**: Idle, do nothing, actual frequency is kept constant. 001_B **RampUp**: Ramp-up until the upper frequency limit has been reached. 010_B **RampDown**: Ramp-down until the base frequency has been reached. **others,** Reserved, do not use.

(table continues...)

(continued)

Field	Bits	Type	Description
PWR	19	rw	**Power** This bit is used to power-up and power-down the Ramp Oscillator. ***Note:*** *Ensure a waiting time of 20 f_{SPB} clock cycles before the next write access to RAMPCON0.* 0_B power down 1_B power up
0	15:10, 31:20	r	**Reserved** Read as 0; must be written with 0.

0															
r															

Field	Bits	Type	Description
FSTAT	17:16	rh	**Frequency status** These bits reflect the ramp frequency status of the ramp oscillator. They automatically change during a ramp-up and ramp-down sequence. 00_B **InBet**: The ramp oscillator's output frequency is between the base frequency and the upper frequency limit. 01_B **AtBase**: The ramp oscillator's output frequency equals the base frequency which is 100 MHz. 10_B **AtTop**: The ramp oscillator's output frequency equals the upper frequency limit. **others,** Reserved, undefined state
SSTAT	21:20	rh	**Sequencer status** Status bits to reflect the current state of the ramp sequencer. 00_B **Idle**: The ramp oscillator's control sequencer is idle, that means not executing a ramp. The output frequency f_{RAMP} is constant either at the base frequency or at the top frequency as reported in FSTAT. 01_B **RampUp**: Frequency increasing 10_B **RampDown**: Frequency decreasing **others,** Reserved, undefined state
ACTIVE	23	rh	**Power status** This bit is used to reflect the actual operational status of the ramp oscillator. 0_B Powered down 1_B Powered up
FLLLOCK	24	rh	**FLL lock status** Reflects if the ramp oscillator has locked to its configured target frequency. ***Note**: This field is only valid if SSTAT = Idle; a change from 1 to 0 is considered as "Loss of Lock". A change from 1 to 0 during ramp operation is intended and not considered as "Loss of Lock".* 0_B The ramp oscillator is not locked to its target frequency and shall not be used for system operation. 1_B The ramp oscillator is locked to its target frequency and can be used for system operation.
RSVD25	25	rh	**Reserved** Read as 0.
RSVD26	26	rh	**Reserved** Read as 0.
RSVD27	27	rh	**Reserved** Read as 0.

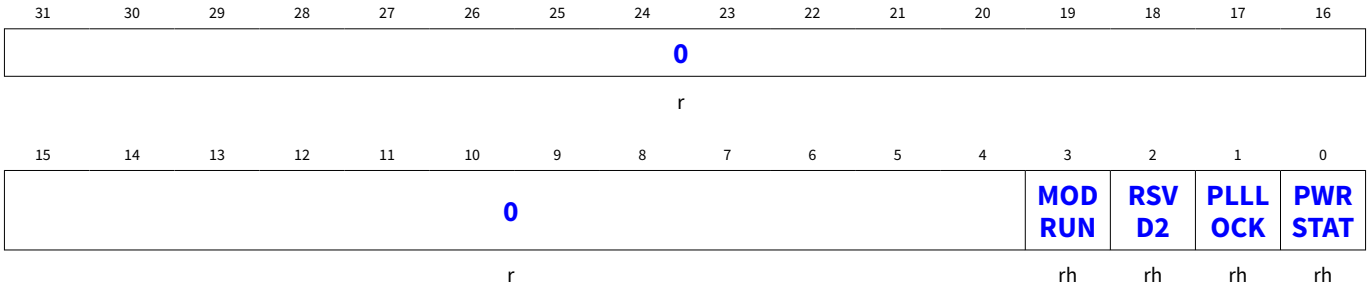
32.4.31 Peripheral-PLL status register

These registers reflects the settings of the Peripheral-PLL.

PERPLLSTAT Offset address: $038C_H$

Peripheral-PLL status register System Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PWRSTAT	0	rh	**Peripheral-PLL power mode status** 0_B Peripheral-PLL is powered down 1_B Peripheral-PLL is powered up
PLLLOCK	1	rh	**Peripheral-PLL lock status** ***Note:*** *In case of a loss of lock, the f_{DCO} is kept on the previous constant frequency.* 0_B The frequency of the Peripheral-PLL is not stable and does not enable system operation 1_B The frequency of the Peripheral-PLL is stable and enables system operation
RSVD2	2	rh	**Reserved** Read as 0.
MODRUN	3	rh	**Peripheral-PLL Modulation run** This bit indicates if the frequency modulation of the Peripheral-PLL is activated or not. 0_B Frequency modulation is not active 1_B Frequency modulation is active
0	31:4	r	**Reserved** Read as 0; must be written with 0.

32.4.32 Peripheral-PLL modulation trim configuration register 0

This register defines the software interface for (optional) modulation amplitude trimming. The complete feature is gated by bit PERPLLCON0.MODEN. If this bit is cleared, this feature is disabled.

Writing to this register sets the CCUSTAT.LCK bit and automatically triggers an update transfer of the register value to the Peripheral-PLL.

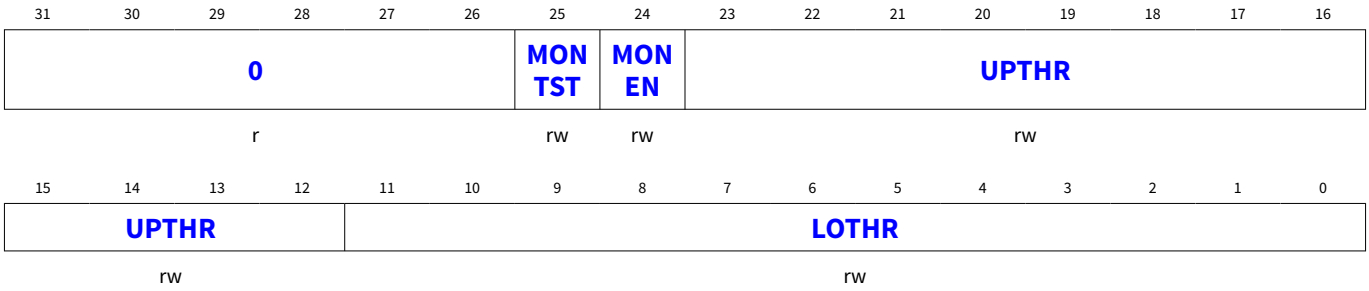
32.4.42 EVR oscillator monitor register

OSCMON0 Offset address: 0504_H

EVR oscillator monitor register System Reset value: $0000\ 0000_H$

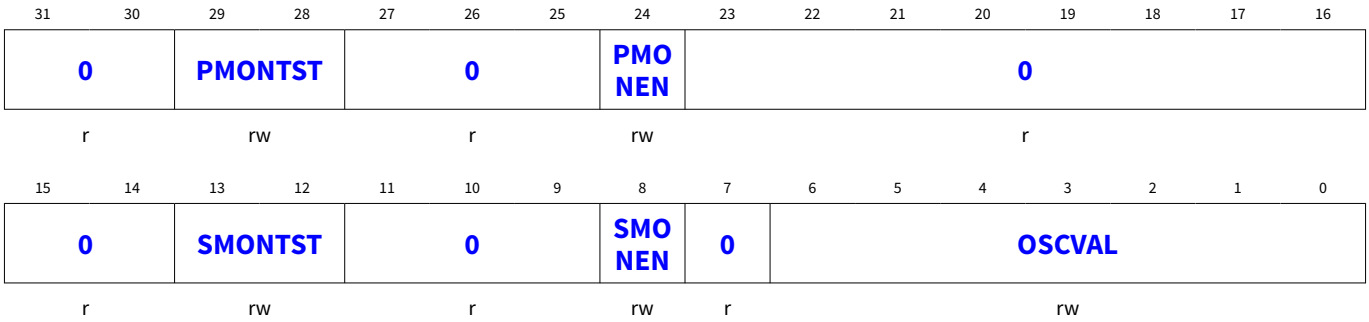


Field	Bits	Type	Description
LOTHR	11:0	rw	**Monitor lower threshold** lower threshold = 512÷f_{PLL0} x 0.9 x 100 MHz ***Note:*** *For proper operation and to avoid false alarms, the monitor needs to be disabled through MONEN=0 before programming the threshold values.*
UPTHR	23:12	rw	**Monitor upper threshold** upper threshold = 512÷f_{PLL0} x 1.1 x 100 MHz ***Note:*** *For proper operation and to avoid false alarms, the monitor needs to be disabled through MONEN=0 before programming the threshold values.*
MONEN	24	rw	**Monitor enable** 0_B Monitoring is disabled 1_B Monitoring is enabled
MONTST	25	rw	**Monitor test** Set this bit to 1 to test alarm generation. The test enable bit is a direct trigger for the alarm. 0_B Normal operation 1_B Test alarm will be generated
0	31:26	r	**Reserved** Read as 0; must be written with 0.

32.4.43 Crystal oscillator monitor register

OSCMON1 Offset address: 0508_H

Crystal oscillator monitor register System Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
OSCVAL	6:0	rw	**Reference input frequency value for crystal oscillator monitors** This bit-field defines the oscillator frequency reference value for the System- and Peripheral-PLL crystal oscillator monitors. Valid range is from 16 to 50 MHz, that means 1 to 35. f_{IN_REF} = (OSCVAL + 15) MHz ***Note**: For any other value set outside the valid range of f_{IN_REF}, the status of flags SOWDS and POWDS is undefined.*
SMONEN	8	rw	**System-PLL crystal oscillator monitor enable** This bit enables the System-PLL's crystal oscillator monitor. 0_B Monitoring is disabled and kept in reset. 1_B Monitoring is enabled.
SMONTST	13:12	rw	**System-PLL crystal oscillator monitor test** This bit is used to test the System-PLL's crystal oscillator monitoring logic and the related alarm forwarding. ***Note**: SMONEN must be set prior to triggering SMONTST.* 00_B **TestOff**: Normal operation 01_B **TestLV**: Overrides, that means minimizes the internal monitoring value to trigger the LV alarm. 10_B **TestHV**: Overrides, that means maximizes the internal monitoring value to trigger the HV alarm. **others,** Reserved, do not use.
PMONEN	24	rw	**Peripheral-PLL crystal oscillator monitor enable** This bit enables the Peripheral-PLL's crystal oscillator monitor. 0_B Monitoring is disabled and kept in reset. 1_B Monitoring is enabled.

(table continues...)

(continued)

Field	Bits	Type	Description
PMONTST	29:28	rw	**Peripheral-PLL crystal oscillator monitor test** This bit is used to test the Peripheral-PLL's crystal oscillator monitoring logic and the related alarm forwarding. ***Note:*** *PMONEN must be set prior to triggering PMONTST.* 00_B **TestOff**: Normal operation 01_B **TestLV**: Overrides, that means minimizes the internal monitoring value to trigger the LV alarm. 10_B **TestHV**: Overrides, that means maximizes the internal monitoring value to trigger the HV alarm. **others,** Reserved, do not use.
0	7, 11:9, 23:14, 27:25, 31:30	r	**Reserved** Read as 0; must be written with 0.

32.4.44 Crystal oscillator status register

OSCSTAT Offset address: $050C_H$

Crystal oscillator status register System Reset value: $0003\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r											rh	r		rh	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														SOWDS	
r														rh	

Field	Bits	Type	Description
SOWDS	1:0	rh	**Oscillator watchdog status for System-PLL** Thes bits indicate if the frequency input f_{IN} is in valid range to be usable for the DCO part of the System-PLL. This is checked by the crystal oscillator monitor (watchdog) of the System-PLL using the backup clock f_{BACK}. By using the reference frequency (f_{IN_REF}), the crystal oscillator's watchdog lower and upper limits calculate as follows: $f_{LV} = (f_{IN_REF} \times 0.75 - 0.31)$ MHz $f_{HV} = (f_{IN_REF} \times 1.46 + 0.29)$ MHz ***Note**: The OSCMON1.OSCVAL value must be set within its legal range (1 to 64) and the monitor must be enabled through OSCMON1.SMONEN = 1. After enabling, it takes a full measurement period plus evaluation (10 µs + 2 µs) until the output reflects a vaild result.* 00_B **InRange**: The OSC frequency is usable. Frequency f_{OSC} is in range: $f_{LV} < f_{OSC} < f_{HV}$ 01_B **TooLow**: The OSC frequency is not usable. Frequency f_{OSC} is too low: $f_{OSC} < f_{LV}$ 10_B **TooHigh**: The OSC frequency is not usable. Frequency f_{OSC} is too high: $f_{OSC} > f_{HV}$ 11_B **InValid**: System-PLL OWD Monitor Result not valid (yet). This is the default value after reset or when the monitor is disabled.
POWDS	17:16	rh	**Oscillator watchdog status for Peripheral-PLL** These bits indicate if the frequency input f_{IN} is in valid range to be usable for the DCO part of the Peripheral-PLL. This is checked by the crystal oscillator monitor (watchdog) of the Peripheral-PLL using the backup clock f_{BACK}. By using the reference frequency (f_{IN_REF}), the crystal oscillator's watchdog lower and upper limits calculate as follows: $f_{LV} = (f_{IN_REF} \times 0.75 - 0.31)$ MHz $f_{HV} = (f_{IN_REF} \times 1.46 + 0.29)$ MHz ***Note**: The OSCMON1.OSCVAL value must be set within its legal range (1 to 64) and the monitor must be enabled through OSCMON1.PMONEN = 1. After enabling, it takes a full measurement period plus evaluation (10 µs + 2 µs) until the output reflects a vaild result.* 00_B **InRange**: The OSC frequency is usable. Frequency f_{OSC} is in range: $f_{LV} < f_{OSC} < f_{HV}$ 01_B **TooLow**: The OSC frequency is not usable. Frequency f_{OSC} is too low: $f_{OSC} < f_{LV}$ 10_B **TooHigh**: The OSC frequency is not usable. Frequency f_{OSC} is too high: $f_{OSC} > f_{HV}$ 11_B **InValid**: Peripheral-PLL OWD Monitor Result not valid (yet). This is the default value after reset or when the monitor is disabled.

32.5 Debug information

This section is not applicable for the module being described.

32.6 References

This section is not applicable for the module being described.

32.7 CLOCK revision history

Reference	Description of change(s)
Date range: 2024-10-16 to 2025-02-28	
Crystal oscillator control register	• OSCCON.SUPM is reserved and must not be used. This reference is now removed from the register description.
Crystal oscillator	• Supply mode is reserved and must not be used. This reference is now removed from the chapter.
Features	• K2 pre-divider for SYSPLL is reserved and must not be used. This reference is now removed from the feature list.
Clock divider limitations	• Removed /2 and the footnote.
Functional description	• Added K2PRE to figure System PLL block diagram • Changed the equation and added remark for K2PRE=0. • Changed remark for K2PRE=0.
Module clocks	• FIS2DIV=0 mode option is reserved and must not be used. The reference is now removed from the CCU system clock options table.
Clock divider limitations	• Added line for relation between fSRICS and fFSI
Module clocks	• Added footnote that configuring CPBDIV=0 can lead to a bus error.
Feature list	• Refer to Datasheet in Feature list with respect to Peripheral PLL output frequencies
Clock divider limitations	• Added footnote to the Divider ratio restrictions table with respect to derivative specific deviations for f_{SRI}/f_{FSI}.
Clock divider limitations	• Added footnote to the Divider ratio restrictions table with respect to derivative specific deviations for f_{FSI2}/f_{FSI}.
Module clock sources and dividers	• Corrected CCU system clock options table with respect to fBACK entry for FSI2DIV and added footnote to check for device specific deviations.
Date range: 2024-05-15 to 2024-10-15	
Software controlled	• Typo fixed in RAMPSTAT link
Feature list	• Added "up to" to the sentence about Peripheral PLL
Clock sources	• Added a footnote to EXTCLKSB
MONSTAT	• Describe MONSTAT register KDIV1, KDIV2, KDIV3 bitfields • Changed description of SDIV and PDIV
(Whole functional block)	• Change phrase CLOCKING to CLOCK
Clock control unit	• Added feGTMhalf in module clock overview and divider ratio limitations
Module clocks	• Corrected the note for fTPB

32 CLOCK

Reference	Description of change(s)
OSCCON	• OSCCON Reset value was moved to the derivative specific section and added a note to that effect • OSCCON MODE descriptions aligned to descriptions in Crystal Oscillator chapter
PERPLLCON1, SYSPLLCON1	• Note corrected from SYSPLLCON1 and PERPLLCON1 KxPREDIV
CCUCON	• CCUCON Reset value was moved to the derivative specific section and added a note to that effect

32.8 TC4Dx CLOCK information

32.8.1 TC4Dx CLOCK configuration

There are no deviations from the generic specification.

32.8.2 TC4Dx CLOCK features

- Maximum clock frequency of system clocks is 500 MHz
- PPU integration with asynchronous clocking with respect to system clocks
  - PPUDIV bit-field located in PERCCUCON0
- Second System-PLL output used to provide dedicated PPU source clock f_{PLLPPU}
- Maximum PPU clock frequency is 454 MHz
  - f_{PLLPPU} configured through bit-fields SYSPLLCON1.K3DIV and K3PREDIV
- Clock provided to PPU during ramp process (start-up/shut-down and clock emergency) is $f_{RAMP} \div 2$
- COMPB interconnect is present and uses f_{SPB}
- Seven Distribution CCU (DCCU) instances: 0, 1, 2, 3, 4, 5, and 6

32.8.3 TC4Dx CLOCK functional description

SYSPLL

Features

In addition, TC4Dx also includes:

- K3 pre-divider (phase combiner) for fractional divisions by 1.0, 1.1, 1.2, 1.4, 1.6, 1.7, 2.0 for PPU-PLL pre-divider frequencies (f_{PCPPU})

Functional description

In addition, the SYSPLL also consists of the following building blocks:

- Output stage for PPU clock composed of a pre-divider for fractional divisions (1.0, 1.1, 1.2, 1.4, 1.6, 1.7, 2.0) and an integer divider that scales down the DCO frequency by a factor K3, configurable through the register section

SYSPLL register interface

In addition, all control and status values of the SYSPLL are stored in and accessed through:

- SYSPLL configuration register 1 (SYSPLLCON1): K2, K3 dividers and K3 pre-divider

Basic SYSPLL operation

In addition, the following dividers are available in TC4Dx:

- SYSPLLCON1.K3DIV and SYSPLLCON1.K3PREDIV

In the PPU clock output stage, the DCO frequency is divided down by a factor K3 combined with K3PRE. K3PRE is an additional divider circuit that is capable of generating selected non-integer division ratios of factor 1.0, 1.1, 1.2, 1.4, 1.6, 1.7 and 2.0.

The output frequency f_{PLLPPU} is given by:

$$
\begin{aligned}
f_{\mathrm{PLLPPU}} &= f_{\mathrm{DCO}} \div (K3 \times 1.0) \rightarrow K3\mathrm{PRE} = 0 \\
f_{\mathrm{PLLPPU}} &= f_{\mathrm{DCO}} \div (K3 \times 1.1) \rightarrow K3\mathrm{PRE} = 1 \\
f_{\mathrm{PLLPPU}} &= f_{\mathrm{DCO}} \div (K3 \times 1.2) \rightarrow K3\mathrm{PRE} = 2 \\
f_{\mathrm{PLLPPU}} &= f_{\mathrm{DCO}} \div (K3 \times 1.4) \rightarrow K3\mathrm{PRE} = 4 \\
f_{\mathrm{PLLPPU}} &= f_{\mathrm{DCO}} \div (K3 \times 1.6) \rightarrow K3\mathrm{PRE} = 6 \\
f_{\mathrm{PLLPPU}} &= f_{\mathrm{DCO}} \div (K3 \times 1.7) \rightarrow K3\mathrm{PRE} = 7 \\
f_{\mathrm{PLLPPU}} &= f_{\mathrm{DCO}} \div (K3 \times 2.0) \rightarrow K3\mathrm{PRE} = 10
\end{aligned}
\tag{62}
$$

***Note**: If the KDIVs are changed during runtime, CCUMON.KDV0MONEN and CCUMON.KDVPPUMONEN must be disabled before changing the KDIV values and then re-enabled after the change.*

PERPLL

Basic PERPLL operation

***Note**: If the KDIVs are changed during runtime, CCUMON.KDVxMONEN (x=1..3) must be disabled before changing the KDIV values and then re-enabled after the change.*

Distribution

Clock control unit

In TC4Dx, the PPU clock is generated by the second SYSPLL output and is handled like another asynchronous peripheral clock.

Clock divider limitations

Table 1319 Divider ratio restrictions

Clock A	Clock B	Allowed values
f_{SRI}	f_{SPB}	n ≥ 1

Start-up and shut-down

Software controlled

Startup controlled by application software

If the target system frequency of the device is 500 MHz which is higher than the maximum frequency of the PPU, the PPU must run slower and asynchronous to the rest of the system. That means the PPU has a dedicated clock f_{PPU} which is sourced from $f_{sourceppu}$. This is a fixed configuration which cannot be changed for the device. During the ramp phase, the $f_{sourceppu}$ is driven by a divided version of the ramp clock. This is needed because the ramp oscillator has only one target frequency which is set to 500 MHz while the target frequency of the PPU is lower. This avoids overclocking of the PPU. Please be aware that the target f_{RAMP} frequency should be 100 MHz below the configured f_{PLL0} frequency.

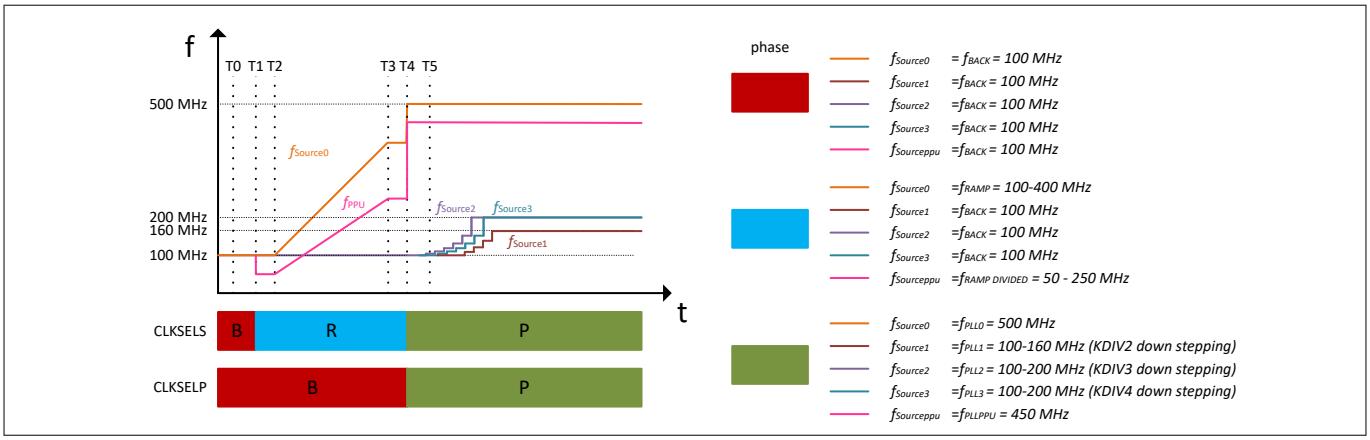

Figure 753 Start up 500 MHz use case

Shutdown controlled by application software

If the maximum system frequency of the device is 500 MHz which is higher than the maximum frequency of the PPU, the PPU must run slower and asynchronous to the rest of the system. That means the PPU has a dedicated clock f_{PPU} which is sourced from $f_{sourceppu}$. This is a fixed configuration which cannot be changed for the device. During the ramp phase, the $f_{sourceppu}$ is driven by a divided version of the ramp clock.

32.8.6 TC4Dx CLOCK revision history

Reference	Description of change(s)
Date range: 2024-10-16 to 2025-02-28	
Crystal oscillator control register	• OSCCON.SUPM is reserved and must not be used. This reference is now removed from the register description.
Date range: 2024-05-15 to 2024-10-15	
Clock control unit	• Added feGTMhalf in module clock overview and divider ratio limitations • Update to connectivity
OSCCON	• OSCCON MODE descriptions aligned to descriptions in Crystal Oscillator chapter
PERPLLCON1, SYSPLLCON1	• Note corrected from SYSPLLCON1 and PERPLLCON1 KxPREDIV
CCUCON	• CCUCON Reset value was moved to the derivative specific section and added a note to that effect
TC4Dx CLOCK features	• Removed sentence about SYSCCUCONx and PERCCUCONx

33 Logic-Test (TRI)

LBIST (Logic Built-In Self Test) is an on-chip hardware mechanism that can be used to detect latent faults in the microcontroller. The LBIST implementation in the AURIX™ TC4xx platform allows the execution of periodic self-tests of the microcontroller logic. It is accessed through registers in the test register interface (TRI) unit.

33.1 Feature list

- Logic-BIST (built-in self-test) provides a full, automatic test of the digital components within the device
- To support Logic-BIST, the chip design is clustered into hierarchical scan domains
- Two LBIST test scenarios are supported:
  1. Key-on LBIST: Targeting only stuck-at faults of on chip functional safety logic within each hierarchical domain
  2. Key-off LBIST: Targeting stuck-at (permanent) faults of all logic within each hierarchical domain
- Key-on LBIST features:
  - Can be executed automatically during the boot sequence of the device (using default firmware configuration) or started manually based on user software trigger
  - Key-On LBIST only involves safety-relevant flip-flops (~8-10% of total flop count) within any hierarchical domain. Other flip-flops are not toggled
  - Target stuck-at coverage: 90%
  - Target execution time: t_{LBIST}
  - Because of the reduced toggle rate, multiple hierarchical scan domains of the chip design can be tested in parallel
- Key-off LBIST features:
  - Can be configured and started for a single or multiple hierarchical domains by user application software.
  - Key-off LBIST involves all flip-flops within a hierarchical domain, therefore in case of a multiple domain configuration the key-off LBIST will test the selected domains sequentially
  - Target stuck-at coverage for full digital hierarchical domain: 90%
  - Target execution time for stuck-at test: 50 ms per hierarchical scan domain
- Number of patterns (that is the number of shift and capture sequences) can be configured. For stored Multi Input Shift Register (MISR) signatures a specific key-on and key-off configuration is provided
- After any LBIST execution, the system will execute a LBIST reset and reboot automatically
- Execution status and MISR results are provided for each hierarchical domain after reboot of the device, to be compared against golden signatures by application software
- LBIST power reduction features:
  - Configurable clock frequency for LBIST controller (affecting scan-chain shift and capture speed)
  - Split-shift:
    - Allows to distribute each scan shift cycle to 2 or 4 clock pulses to reduce the current jump for each shift clock pulse
  - Key-On LBIST to cover the functional safety logic (for example the lockstep compare logic in CPU) exclusively involves safety-relevant flip-flops (8-10%) within any hierarchical domain

33.2 Functional overview

Logic-BIST is an automatic structural self-testing mechanism, which is based on the structural scan test approach. It serves two main purposes:

- Safety measures (“key-on”): 90% stuck-at test coverage on all safety monitoring logic (lock-step comparator, ECC, SMU, …) within 5-6 ms execution time at system start-up
- In-system test (“key-off”): 90% stuck-at test coverage on all digital logic in 50 ms execution time per hierarchical scan domain at system shut-down

Due to complexity the device is divided into several hierarchical scan domains. Domain structure (number, complexity and LBIST runtime per domain) varies from device to device. Start of LBIST in any hierarchical domain brings the entire device automatically to scan mode during which no functional operation is possible. During LBIST execution the IOs reflect a static reset behavior.

The execution of Logic built-in self test in the microcontroller application mode is based on the design for test structures implemented for production testing and therefore reusing scan chains, control, and status mechanisms already available in microcontroller. The scan test operation is enabled through dedicated pseudo-random pattern generator (PRPG) modules, which generate patterns to be applied to the corresponding hierarchical domains. The PRPG generates pseudo-random patterns using a linear feedback shift register (LFSR). These patterns are loaded (this mean serially shifted) into the design scan-chains.

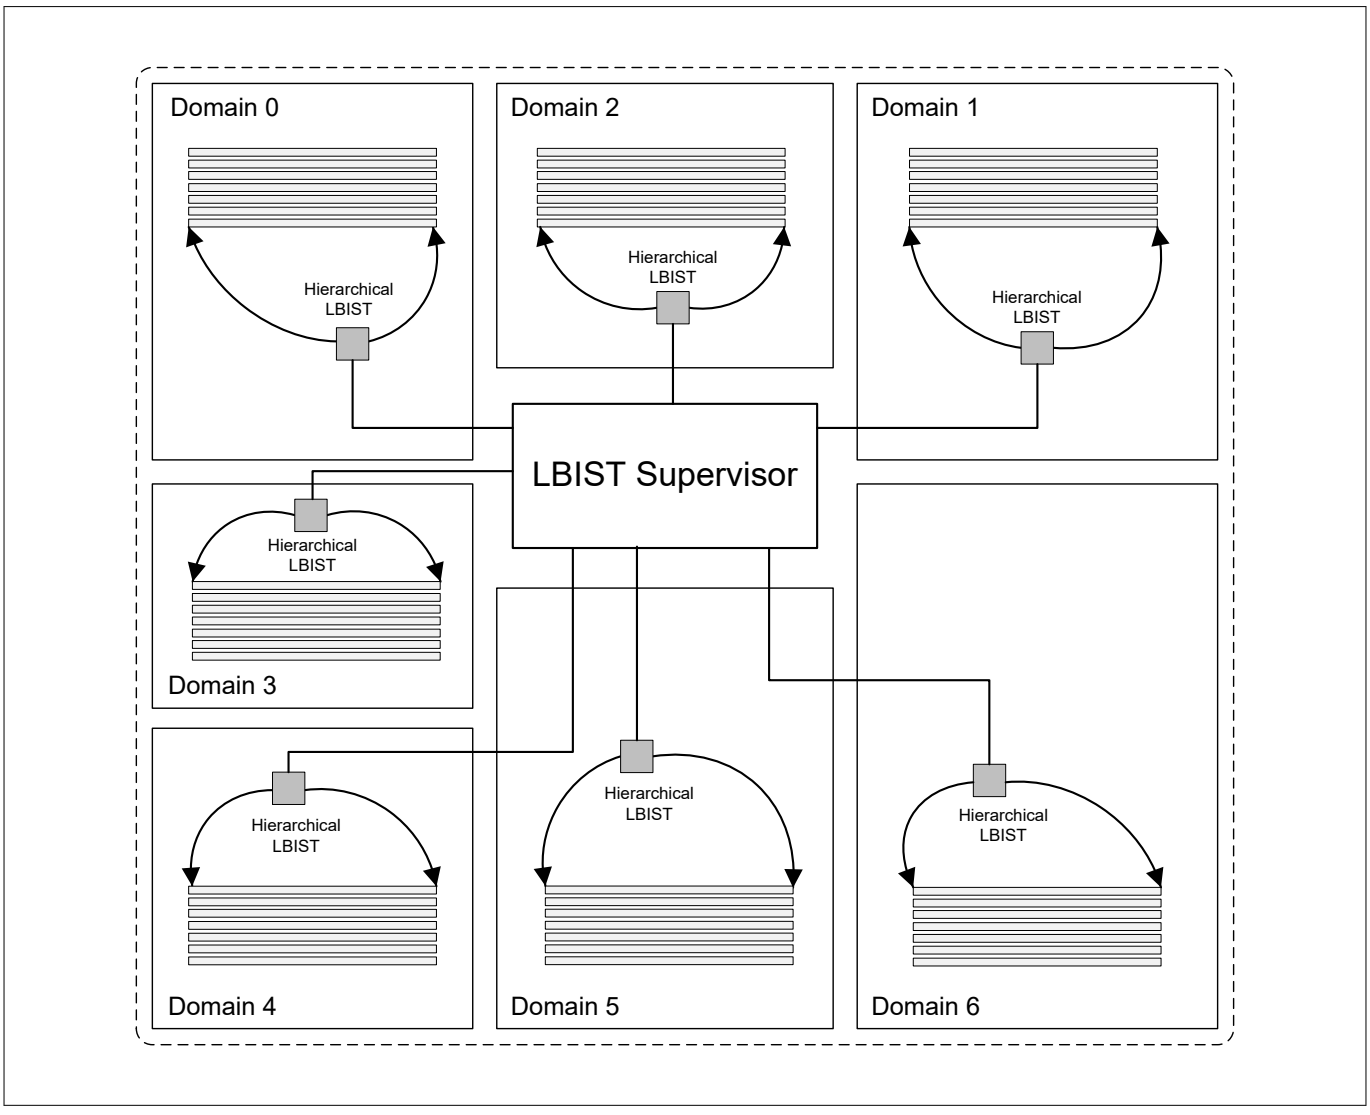

Figure 755 Hierarchical LBIST architecture

It shall be noted, that LBIST is a scan based structural test method which also covers the redundancy logic of the SRAMs within each hierarchical scan domain. Therefore the SRAM contents is not reliable after LBIST execution except for the Stand-by controller (SCR) SRAMs.

In the following sections the general LBIST operation scheme, possible configuration options and application scenarios are explained. In this conjunction also the LBIST integration into a hierarchical scan architecture is shown.

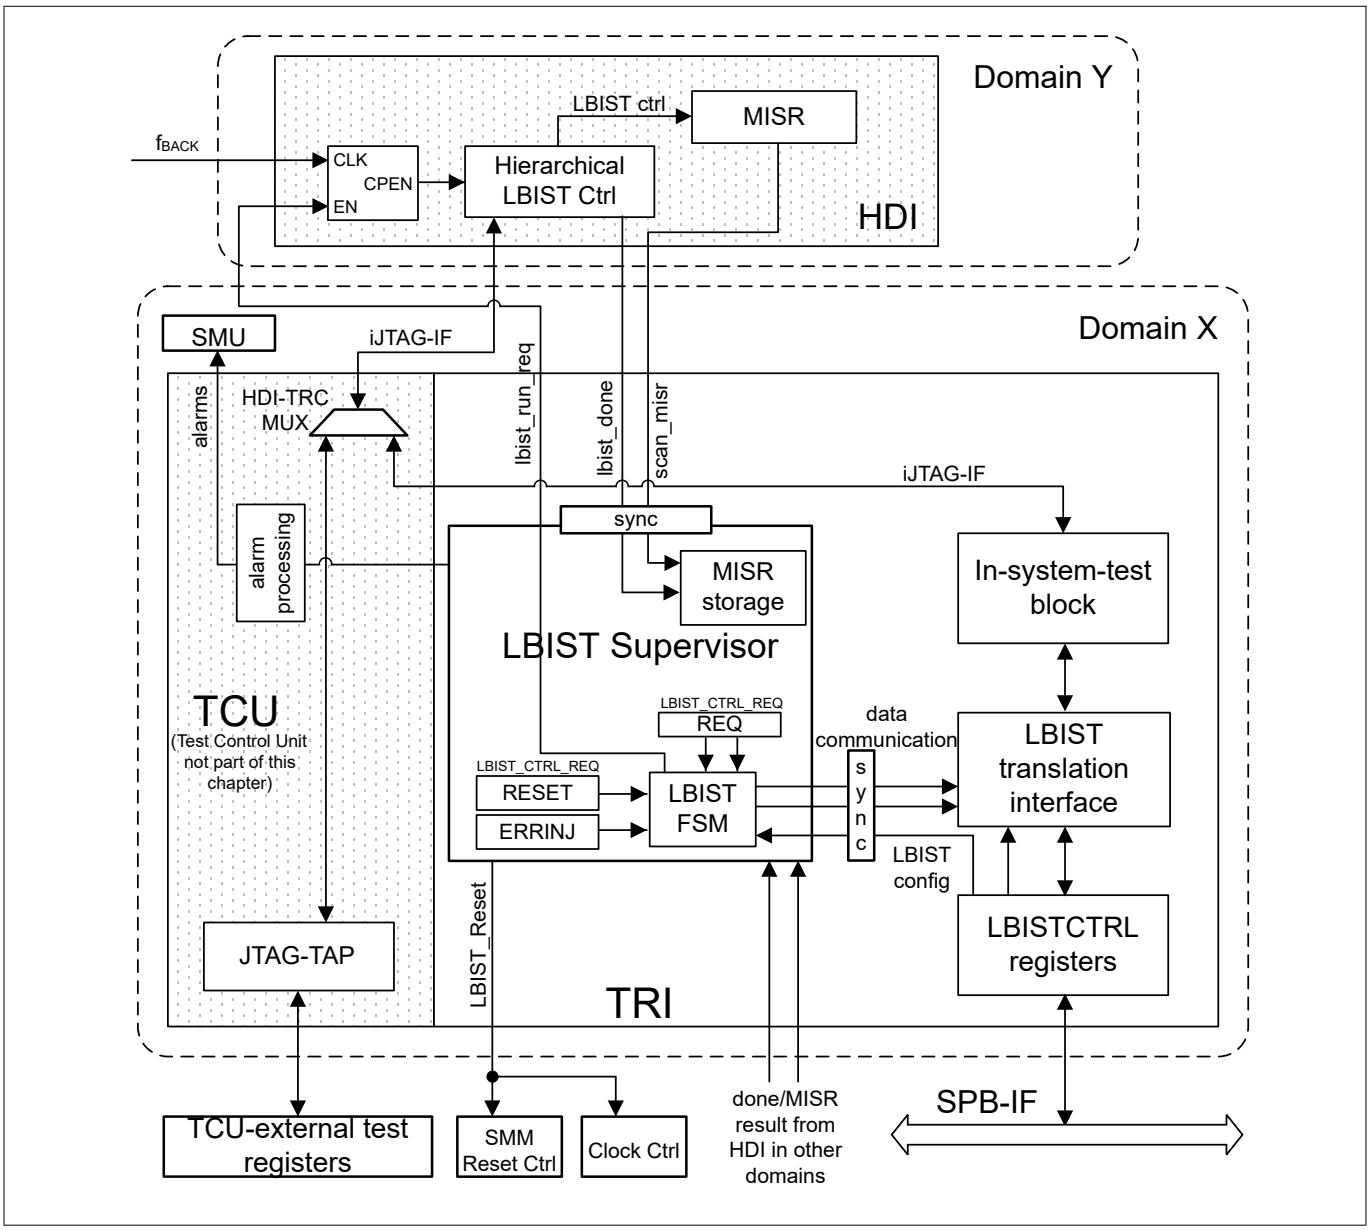

Figure 756 TRI block diagram

LBIST operation is controlled through a central LBIST supervisor logic, which resides in the test register interface (TRI) block. From this central supervisor all LBIST operations are controlled through a single state machine (LBIST FSM). From application side the LBIST operation is accessed by writing and reading specific LBISTCTRL registers through the SPB interface (SPB-IF). In this way a specific LBIST configuration (LBIST config) is handed over to the LBIST supervisor.

Once LBIST operation is started, the LBIST supervisor block configures the hierarchical LBIST controllers (Hierarchical LBIST Ctrl) through an iJTAG interface (iJTAG-IF). These hierarchical LBIST controllers are part of the hierarchical TRI interface (HDI), which is implemented within each domain. The LBIST translation interface and the in-system-test block within TRI will be used to establish a data communication between LBIST supervisor and the hierarchical LBIST controllers.

33 Logic-Test (TRI)

After initialization of the hierarchical LBIST controllers the LBIST supervisor will start each hierarchical LBIST operation individually through a lbist_run_req signal. It will then await the successful termination of the LBIST operation in each domain, which is indicated through individual lbist_done signals. As soon LBIST operation in all domains is finished, the LBIST supervisor block captures the domain individual MISR signature results (scan_misr) and triggers a LBIST reset to the whole system.

After LBIST operation is finished the LBIST FSM has to be set into a safe reset state through a specific RESET bit within the LBISTCTRL registers.

Specific alarm signals are defined to indicate any unwanted LBIST activity within the TRI to SMU. These alarms are processed through the test control unit (TCU) and can be triggered manually for testing purpose through the ERRINJ bit within the LBISTCTRL registers.

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

33.3.2 LBIST operation scheme

The Logic-BIST function is a structural test method for automatic in-system health check of the digital design part. LBIST schemes use on-chip circuitry to generate test stimuli and analyze test responses, without any help from a chip-external test system.

LBIST covers all digital logic of the device with the following exceptions:

- Logic in power management system, linked to the EVR and standby controller
- A part on the test register interface unit (TRI), including the LBIST controller

The LBIST structure applies pseudo-random patterns generated by a PRPG (Pseudo-Random Pattern Generator) to a full-scan circuit in parallel and compacts the test responses into a signature with a MISR (Multiple-Input Signature Register).

In this conjunction it shall be noted, that the microcontroller is partitioned into hierarchical domains, from which each one is scan tested independently through a local LBIST controller. This LBIST controller is implemented as part of a local HDI (Hierarchical TRI Interface) block. A central LBIST supervisor block is implemented in the TRI which is responsible for the organized execution of the whole LBIST procedure. From this supervisor all LBIST operations are controlled through a single state machine ('LBIST FSM').

After LBIST execution has been triggered from system-side (through LBIST_CTRL_CFGA ... LBIST_CTRL_CFGF, LBIST_CTRL_DOM and LBIST_CTRL_REQ registers), the LBIST FSM in TRI automatically initializes the domain-individual LBIST controller blocks (Hierarchical LBIST Ctrl) through a chip internal iJTAG network and also switches the hierarchical domain locally into scan mode. This initialization is done by using the LBIST translation interface and the in-system-test block within TRI to establish a data communication between LBIST supervisor and the hierarchical LBIST controllers. If this domain specific scan mode is active, the design's flip-flops are not operated in their functional mode but are organized in scan-chains to allow a serial shift of these pseudo-random patterns into the digital design. For each domain where this is done, the local (hierarchical) LBIST controller in HDI starts LBIST execution as soon as the LBIST supervisor block activated its local operating clock (by changing the corresponding 'lbist_run_req' signal to 1). Each hierarchical LBIST controller will execute the automatic scan test according to its configuration data, concerning number of scan-loads and execution-speed. A specific shift counter keeps track of the number of shift-cycles to issue for each pattern.

The LBIST controller in each hierarchical domain also uses the shift counter to separate the shift cycles from the capture cycles. Once a random pattern has been completely loaded into the digital logic scan-chains, the LBIST controller generates a single capture cycle. In this case the flip-flops are switched back from serial scan-chain

mode to their normal functional behavior, therefore allowing capture of an actual state of the combinatorial logic (see the following figure).

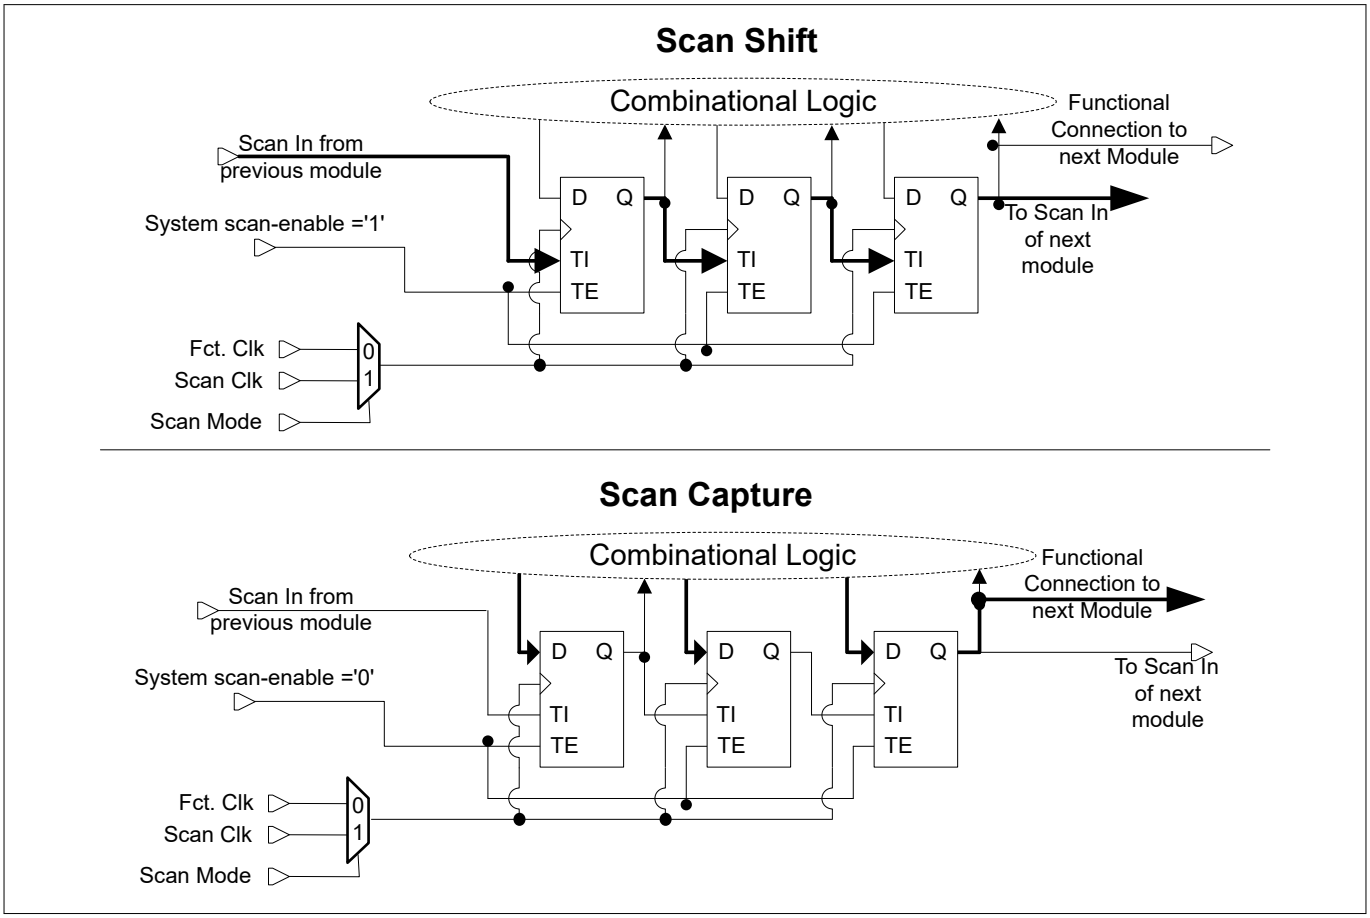

Figure 757 Scan shift and capture process

The pattern for each scan-chain load is generated by the domain-local PRPG as configured through the local LBIST controller. The number of executed scan loads within a domain is selectable by software through the LBIST_CTRL_CFGA.PATTERNS field. This field must be set (together with the other configuration options) before starting LBIST execution. Each domain-local LBIST controller keeps track of how many patterns have been driven through the core and automatically stops the LBIST run when the programmed LBIST_CTRL_CFGA.PATTERNS value has been reached. It will also indicate the successful LBIST termination to the supervisor block its individual 'lbist_done' signal.

During serial scan-chain shift cycles the outputs of the core flip-flop-chains are compressed through a XOR-gate network implemented in specific scan compaction logic and permanently monitored through the MISR block, which generates a unique signature for each hierarchical domain. This signature allows application software to check if the MCU was tested by LBIST with or without errors (see the following figure). The LBIST controller will automatically put the MISR into a static hold condition during the warmup-phase. This means at the start of each LBIST operation 3-4 warmup patterns will be executed during which pseudo-random pattern are shifted through the scan-chains without checking the results. This ensures a proper initialization of the scan-chain values and also increases the run time stability of LBIST. After successful LBIST termination the MISR signature result is also handed over to the central supervisor block in TRI through the domain individual 'scan_misr' vector.

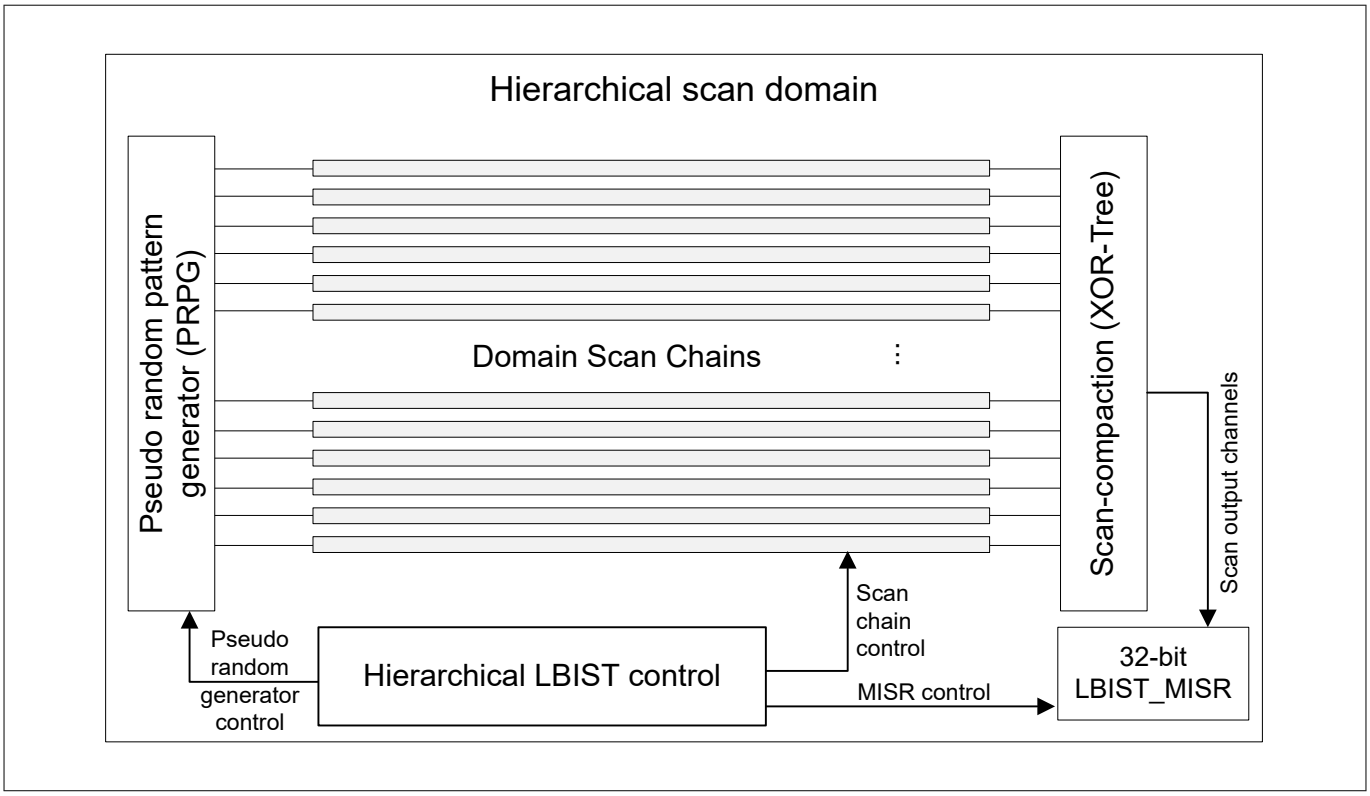

Figure 758 Scan components in LBIST

After LBIST execution is finished for a specific domain the LBIST operation of the next requested domain will be started. After LBIST is finished for all hierarchical domains for which it was requested, the MISR signature results from all these domains can be read out through the LBIST_STAT_RESx_SIG.SIGNATURE fields. Their value is only valid if LBIST_STAT_TEST.DONE='1' and the corresponding LBIST_STAT_TEST.DOMDONE<0-7> bit also indicates a high value, meaning LBIST run terminated successfully. In general the LBIST_STAT_TEST.DOMDONE<0-7> bits indicate for which domains a LBIST procedure has been executed since the last reset. It shall be noted, that for hierarchical scan domains which are not existing on the device the corresponding LBIST_STAT_TEST.DOMDONEx bits will always indicate a stable high value and the corresponding LBIST_STAT_TEST.SIGNATURE result bits show a stable low value.

LBIST execution always terminates with an LBIST reset ('cold_porst_req'), which affects all logical parts except the PMS/EVR system (also in case of a LBIST watchdog timeout counter overflow). From software side this reset will be clearly distinguishable from an external cold PORST (PMS/EVR settings of the startup software are not affected by this LBIST reset). In this way application software can easily verify if the LBIST execution was properly terminated and not interrupted by an external warm or cold PORST. For that purpose the PMS_CLDRSTRIG register in PMS and also the WRMRSTTRIG and WRMRSTTRIGH registers in SMM contain two status bits which reflect the LBIST termination status:

- PMS_CLDRSTRIG.LBPORST: This status bit indicates if LBIST execution was terminated earlier due to an external warm or cold PORST assertion. If the status of this bit-field is 0, the application must still check the PMS_CLDRSTRIG.LBTERM to determine if the LBIST was terminated properly
- PMS_CLDRSTRIG.LBTERM: This bit stores the status if the LBIST execution was terminated by the LBIST supervisor block through a LBIST reset

As mentioned above, a successfully finished LBIST procedure is indicated by the LBIST_STAT_TEST.DONE and the LBIST_STAT_TEST.DOMDONE<1-7> bits. All contents of the LBIST_STAT_TEST and also of the LBIST_STAT_RESx_SIG register fields is automatically restored after any system reset with the captured values from LBIST supervisor block. In case of an external warm or cold power-on resets, these stored values in LBIST supervisor are cleared, which also resets the DOMDONE<1-7> bits and LBIST_STAT_RESx_SIG.SIGNATURE

registers to 0. The same behavior will also be visible if the central LBIST controller is manually reset by setting LBIST_CTRL_REQ.RESET bit to high value.

Attention: Some of the hierarchical domains contain logic, whose power supply can be disabled through the PMS_PD_CON0 and PMS_PD_CON1 registers in PMS. For a proper LBIST execution it must always be ensured that all logic in the targeted domain(s) is actively powered.

Attention: During LBIST operation it is strongly recommended to keep the TESTMODE_N / P20.2 input pin at a static high level. The general purpose input functionality of this pin is not available while a LBIST procedure is underway. In case of an externally triggered warm power-on reset or in case of a power fail the TESTMODE_N / P20.2 input value will determine, if the device is operating in mission mode or in general test mode. So driving it with a different value than static H level during LBIST operation induces a certain risk that the device will erroneously branch into test mode.

33.3.3 LBIST configuration options

The following sections describe the possible LBIST control and configuration options, which can be accessible through the LBIST_CTRL_CFGA ... LBIST_CTRL_CFGF, LBIST_CTRL_DOM and LBIST_CTRL_REQ registers:

- LBIST_CTRL_REQ.REQ, REQRED: If both of these bits are set to high value, the execution of a new LBIST procedure is triggered. All domains which are selected in the LBIST_CTRL_DOM.SEL<0-7> register will be included. Precondition to start a new LBIST run is that the central LBIST controller currently remains in a safe idle state (indicated through LBIST_STAT_TEST.DONE='0'). This state can be reached through an external warm or cold PORST or by setting LBIST_CTRL_REQ.RESET='1'
- LBIST_CTRL_REQ.RESET: This bit resets the central LBIST controller to its safe idle state. After a successful LBIST run, the LBIST alarm signal remains active until this bit has been set to high value. This will also clear the stored MISR results and allow to trigger a new LBIST procedure
- LBIST_CTRL_REQ.FAILCIN: This bit-field has no direct hardware effect on LBIST execution itself, but serves as memory function for the application software. The value written to this field will be stored in the central LBIST controller and mirrored to the LBIST_STAT_TEST.FAILCOUT field after LBIST execution is finished
- LBIST_CTRL_REQ.ERRINJ: If this bit is set to high value, the LBIST and test mode alarm signals will be asserted for testing purpose. This function should only be used to ensure that the alarm signals are still working properly. The bit has no direct influence on the LBIST operation
- LBIST_CTRL_CFGA.PATTERNS: This field defines the LBIST pattern count which will be executed during LBIST procedure for each selected hierarchical domain. The value programmed to the LBIST_CTRL_CFGA.PATTERNS field determines the number of scan-capture phases and not the number of scan-chain load-unload phases: A value of 00001_h will result in two scan-chain loads with one capture in between; a value of 00002_h will result in 3 scan-chain loads with 2 captures and so on). Consequently a value of 00000_h is not valid, because no capture would be executed in this case
- LBIST_CTRL_CFGA.TFREQU: This field allows to determine the iJTAG clock speed. The iJTAG network is used to initialize the hierarchical LBIST controllers after a LBIST procedure has been triggered through LBIST_CTRL_REQ register. Main intention is to operate the iJTAG network with TFREQU=1 → 50 MHz, but slower frequencies like TFREQU=2 → 33 MHz or TFREQU=3 → 25 MHz may also be applied in case of stability problems. Please note that this TFREQU field has only a low influence in the overall LBIST execution time, because it only affects the initialization phase. The operation frequency of the local LBIST controllers inside the hierarchical domains is influenced independently through the LBIST_CTRL_CFGA.FREQU field
- LBIST_CTRL_CFGA.SAFESEL[40]: This bit is directly used to decide if all scannable logic in the selected hierarchical domains will be targeted by LBIST operation (SAFESEL='0') or only that part, which is assigned to primary safety mechanisms (SAFESEL='1'). The SAFESEL bit value will be stored In the central LBIST supervisor block and mirrored to the LBIST_STAT_TEST.SAFEIND field after LBIST execution finished. In this

[40] It shall be noted, that the explicit LBIST test of safety structures is not implemented in all derivatives of the AURIX™ TC4xx platform. The information if a specific "key-on" LBIST scenario is implemented or not, can be found in the device specific Logic-Test (TRI) description.

way the application firmware can recognize which kind of LBIST operation has been triggered. Please note that the safety LBIST option shall only be used for stuck-at tests with a stable 100 MHz clock source

- LBIST_CTRL_CFGA.ENPARA: If LBIST test of safety-mechanism structures is selected (LBIST_CTRL_CFGA.SAFESEL='1'), the value of this bit chooses if LBIST execution of all selected scan domains is triggered in parallel (if ENPARA='1') or one after the other (if ENPARA='0'). The parallel execution is significantly faster but only possible if acceptable from power side. In case of full LBIST test LBIST_CTRL_CFGA.SAFESEL='0' only a sequential execution is possible
- LBIST_CTRL_CFGA.KEYOFF: This bit has no direct influence on the LBIST execution sequence but just serves as indicator for the application software, that the current LBIST procedure was launched under key-off conditions. Consequently it will be stored in the central LBIST supervisor block and is mirrored back to the LBIST_STAT_TEST.KEYIND field after the LBIST execution finished
- LBIST_CTRL_CFGA.SPLITSH: This field influences the on-chip power consumption during LBIST execution. If set to 0x0, all scan-chains are shifted concurrently during LBIST operation, which may cause the power consumption to exceed the one of the maximum power pattern. This might cause stability problems in certain application environments depending on the general supply strategy. If power related stability problems should occur during LBIST execution it is possible to divide the core scan-chains either into two (SPLITSH=0x3) or four (SPLITSH=0x2) partitions, which are then shifted sequentially. Depending on the selected split-shift operation mode, the LBIST execution time will increase by a factor of 2 or 4. This however can be compensated by also increasing the shift operation frequency through FREQU. In fact the average power consumption remains equal if split-shift 2 is selected instead of concurrent shift and the operation frequency is doubled. However the split-shift operation is still of advantage, because it helps to distribute on-chip activity more equally over time
- LBIST_CTRL_CFGA.FREQU: This field will influence the LBIST execution speed (shift-frequency). The local LBIST Controllers are operating on base of a 100 MHz oscillator, whose output frequency can be scaled down by an integer value between 1 to 16 (determined through FREQU hex value + 1). A FREQU value of 1 or higher is recommended for a stable LBIST execution: FREQU=1 → 50 MHz, FREQU=2 → 33 MHz, FREQ=3 → 25 MHz, FREQU=4 → 20 MHz, …, FREQU=15 → 6.25 MHz. Value FREQU=0 [100 MHz] is only to be used in conjunction with LBIST_CTRL_CFGA.SPLITSH=3 or 2 for a stable LBIST execution.
- LBIST_CTRL_CFGB ... LBIST_CTRL_CFGE.LENGTH<0-7>, SLENGTH<0-7>: These register fields determine how many shift-cycles are necessary to load the scan chains of the hierarchical domains. Individual values have to be defined for each of these domains, because their scan implementation differs among the family products. The contents of these registers is automatically initialized when booting the microcontroller and shall not be changed by application software
- LBIST_CTRL_CFGF.LBCGTRAN: The value of this field influences the overall capture clock activity. It allows to weigh between coverage gain and power dissipation during LBIST capture phases. The contents of these registers is automatically initialized when booting the microcontroller and shall not be changed by application software
- LBIST_CTRL_CFGF.TPOBSDIS, TPCTRDIS, OBSSCDIS: These register bits allow to disable the scan control and scan observe points as well as specific scan shift observation FFs, which help to increase the LBIST efficiency. The contents of these registers is automatically initialized when booting the microcontroller and shall not be changed by application software
- LBIST_CTRL_DOM.SEL<0-7>: Through these bits the hierarchical domains are selected, which shall be included into the next LBIST procedure (started by setting LBIST_CTRL_REQ.REQ & REQRED='1')

The following sections describe the LBIST status and result fields which are accessible through the LBIST_STAT_TEST and LBIST_STAT_RESx_SIG registers:

- LBIST_STAT_TEST.DONE: The bit indicates if a LBIST procedure has been executed since the last power-on-reset or after LBIST supervisor block has been restarted through LBIST_CTRL_REQ.RESET
- LBIST_STAT_TEST.SAFEIND, KEYIND, FAILCOUT: The values of these fields reflect the latest settings from LBIST_CTRL_CFGA.SAFESEL, KEYOFF and LBIST_CTRL_REQ.FAILCIN register bits. These are captured in the

central LBIST supervisor block when starting the LBIST procedure to allow an easy identification of the selected LBIST scenario from application side

- LBIST_STAT_TEST.DOMDONEx: These bits indicate if the corresponding hierarchical domain has been included in the previous LBIST run or not For hierarchical scan domains, which are not existing on the device, the corresponding DOMDONEx bits will always indicate a stable high value.
- LBIST_STAT_RESx_SIG.SIGNATURE: After a LBIST procedure has been finished, the MISR signature result from each hierarchical domain is stored in the SIGNATURE field of the corresponding LBIST_STAT_RESx_SIG register. The results are valid as long the LBIST_STAT_TEST.DONE='1' and LBIST_STAT_TEST.DOMDONEx bits are reflecting a high value. For hierarchical scan domains, which are not existing on the device, the corresponding SIGNATURE field will always indicate a stable low value.

Summary for LBIST execution: Before starting a LBIST operation, the requested configuration must be selected through LBIST_CTRL_CFGA ... LBIST_CTRL_CFGF and LBIST_CTRL_DOM registers. As a default these registers will be initialized for a typical "key-on" LBIST operation scenario. In order to trigger a new LBIST procedure the LBIST_CTRL_REQ.LBISTREQ & REQRED bits both must be written with a high value. A new LBIST sequence will only start if the LBIST_STAT_TEST.DONE bit reflects a low value. The high value of LBIST_STAT_TEST.DONE bit is also an indication that the LBIST operation terminated normally and the SIGNATURE values are ready for readout. Once this DONE bit is set to high, its value can be changed back to low by setting the LBIST_CTRL_REQ.RESET bit to high value. This will also reset all SIGNATURE results within the LBIST_STAT_RESx_SIG registers from the previous run.

Example configuration for key on LBIST execution: For an easier understanding of the LBIST configuration possibilities a typical "key-on" setup for LBIST is explained in the following.

- LBIST_CTRL_CFGA.PATTERNS: $0FC0_H$ → It is recommended to select a value in the range of ~4032 scan patterns in order to achieve a test coverage of 90%
- LBIST_CTRL_CFGA.TFREQU: 01_B → Selects a iJTAG frequency of 50 MHz. In case of stability problems during LBIST setup use higher settings like 10_B or 11_B. Do not set this field to 0
- LBIST_CTRL_CFGA.SAFESEL: 1_B → Exclusively test the functional safety logic during "key-on" LBIST for a shorter execution time. This will also indicate to application software that previous LBIST was targeting safety logic after LBIST execution (LBIST_STAT_TEST.SAFEIND = 1_B)
- LBIST_CTRL_CFGA.ENPARA: 1_B → Select parallel LBIST execution for multiple hierarchical domains during "key-on" LBIST for a shorter execution time
- LBIST_CTRL_CFGA.KEYOFF: 0_B → Set this bit to 0_B value to indicate to application software that previous LBIST was executed under "key-on"conditions after LBIST execution (LBIST_STAT_TEST.KEYIND = 0_B)
- LBIST_CTRL_CFGA.SPLITSH: 11_B → Select split-shift with 2 scan partitions to reduce the number of flops, which are toggling concurrently. In case of stability problems during LBIST execution use 10_B (split-shift with 4 scan partitions). This will further reduce the maximum shift power but also increase LBIST execution time
- Behavior of the GPIOs (except shared standby pads) is automatically determined through the PMS_PAD_STAT.ALLTRIST register bit value in PMS. If this bit is set to 0_B value all GPIOs remain in a static weak pull-up behavior during LBIST execution. If it is set it to 1_B value all GPIOs show a static tri-state behavior. The behavior of the standby pads (P32.0-4, P33 and P34.1-5) during LBIST operation depends on the SCR_CON0.PADLBIST register bit value in PMS. The default reset value of this bit determines that those pads are handled identically to all other GPIOs during LBIST. In order to support real time clock functionality it is possible to change the SCR_CON0.PADLBIST bit value before triggering LBIST. This allows to keep the standby pads active while LBIST operation is underway. Specific isolation will ensure that no undefined input data can propagate from the standby pads into any scan testable design areas.
- LBIST_CTRL_CFGA.FREQU: 0_H → Selects a LBIST controller operation frequency of 100 MHz. In case of stability problems during LBIST setup use higher settings like 1_H, 2_H or 3_H. This will reduce the maximum shift power but also increase LBIST execution time
- The values in LBIST_CTRL_CFGB ... LBIST_CTRL_CFGE.LENGTH<0-7>, SLENGTH<0-7> fields are automatically initialized during system boot. Their values shall not be changed from application side

- The values in LBIST_CTRL_CFGF.TPOBSDIS, TPCTRDIS, OBSSCDIS and LBCGTRAN register fields are automatically initialized during system boot. Their values shall not be changed from application side
- LBIST_CTRL_DOM.SEL<0-7> = 1_B → As a default all hierarchical scan domains are selected for LBIST execution. If certain domains shall be excluded from LBIST run the corresponding SEL bit can be set to 0_B value
- LBIST_CTRL_REQ.FAILCIN = 0_H → As a default the fail counter shall be set to 0_H value. In case of MISR result mismatches the LBIST, execution can be repeated with increased FAILCIN values. This value will be stored during LBIST execution and indicated to application software through LBIST_STAT_TEST.FAILCOUT field
- LBIST_CTRL_REQ.REQ, REQ_RED → Write both bits with a 1_B value to start a new LBIST run. This will only work if the LBIST controller is in idle state and the LBIST_STAT_TEST.DONE bit indicates a 0_B value. If this is not the case, reset the LBIST controller first by programming LBIST_CTRL_REQ.RESET = 1_B

33.3.4 LBIST application scenarios

In general the LBIST operation clearly distinguishes between 2 different scenarios:

1. **Safety measure, used during “key-on” phase of the device:** In this case it is necessary to check the on-chip primary safety mechanism structures for a fault free behavior. For that purpose a specific LBIST operation mode is implemented, which only involves the logical structure from safety mechanism logic into the test process. In this way the power consumption of that kind of LBIST test is significantly reduced and it is possible to execute it fast enough to achieve 90% stuck-at test coverage within t_{LBIST}. [41)]
2. **Complete in-system test, used during “key-off” phase of the device:** In contrast to the above mode significantly more time is available for execution of this kind of LBIST test). Consequently it targets the complete logical structure within a selectable hierarchical domain. Therefore the power consumption for the "key-off" LBIST lies significantly above that of the "key-on" scenario. The achievable test coverage depends on the available time budget and so, on the number of scan patterns

From above 2 scenarios the following LBIST operation modes are derived:

1. **Parallel "key-on" safety stuck-at LBIST:** The safety structures of all hierarchical domains are tested for stuck-at faults. Due to the reduced power consumption this is done in a parallel way to minimize execution time. The goal is to achieve a stuck-at coverage of 90% for the safety structures within t_{LBIST}.
2. **Sequential "key-off" stuck-at LBIST with stable frequency:** This kind of LBIST operation always targets the full logic of a selectable hierarchical domain. Due to power limitations it is not possible to test more than one domain at a time. If multiple domains are selected they will be tested sequentially. The goal of this test mode is to achieve a stuck-at coverage of 90% for the complete logic of a hierarchical domain within 50 ms (per domain)

The general interaction of firmware and application software with the LBIST configuration and result registers is illustrated in the following figure. During the MCU boot phase the first ("key-on") LBIST operation mode from the above list is required to be executed. Consequently the LBIST_CTRL_CFGA registers are automatically initialized with this configuration through the firmware. In addition to this the "key-on" LBIST execution can also be triggered automatically through the firmware after an externally triggered cold power-on reset if this is configured in the LBISTEXE.LBEX UCB. In case of a LBIST reset or a warm PORST firmware directly continues with the boot process so all further LBIST activities have to be triggered from application software side.

After an LBIST execution and LBIST reset the application software can read through the LBIST_STAT_TEST.KEYIND flag, if the current boot phase was initiated by a completed “key-off” LBIST operation or not. In case of an active “key-off” flag certain applications might not be able to grant sufficient time to compare the MISR results with any expected values and to react accordingly. In those scenarios the MISR results shall just be saved to the Flash before continuing with the “key-off” sequence. In this way they can

41 It shall be noted, that the explicit LBIST test of safety structures is not implemented in all derivatives of the AURIX™ TC4xx platform. Especially those devices, which are defined as ASIL-B, can achieve the required stuck-at test coverage of 60% within t_{LBIST} by using conventional ("key-off") LBIST execution, which involves all logical structures in the device. The information if a specific "key-on" LBIST scenario is implemented or not, can be found in the device specific Logic-Test (TRI) description.

be checked during the next “key-on” boot sequence together with the results from the safety LBIST (which might have been automatically started from firmware-side). In this conjunction it is recommended to always clear the “key-off” MISR results from Flash after a successful check to make sure, that they are not erroneously reused for the next LBIST execution.

The flowchart of the following figure shows how the different LBIST modes should be handled from firmware and application software side. The red numbers in the figure indicate which flow branches are used for the following LBIST use-cases:

1. Boot without LBIST execution or MISR-check
2. Boot without LBIST execution, followed by a check of the MISR-signature from a previously executed “key-off” LBIST-run (stored in Flash)
3. Automatic execution of safety-LBIST by firmware during “key-on”, followed by a check of the MISR-results by App-software (no MISR-signature stored in Flash from a previous “key-off” LBIST-run)
4. Automatic execution of safety-LBIST by firmware during “key-on”, followed by a check of the MISR-results by App-software (including the MISR-signature results stored in Flash from a previous “key-off” LBIST-run)
5. Manual execution of safety-LBIST by App-software during “key-on” or within application, followed by a check of the safety MISR-results
6. Manual execution of full LBIST by App-software during “key-off” or other LBIST-execution case, followed by a check of the full MISR-results
7. Manual execution of full LBIST by App-software during “key-off” LBIST-execution case, followed by storing the MISR-results in Flash. The check has to be done during next “key-on” sequence

33.3.5 Other Logic Test (TRI) configuration registers

The Logic Test (TRI) IP includes further registers which are not related to the LBIST functionality but are used for diverse debug features.

The following registers belong to this category:

- DXCCTR: This register determines, if the debug over CAN physical layer (DXCPL) and the application test mode (ATM) functions are available or disabled. The register's fields are automatically initialized through the boot firmware according to the installed configuration sector values in the non volatile memory.

33.4 Registers

33.4.1 Register overview - access mode glossary

Table 1336 Register overview - access mode glossary

Keyword	Description
CSE	Access protection using PROT register PROTCSE.
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
SV	Access only when supervisor mode is active on the interconnect.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
STP	Access only during start-up, before start-up protection is set (SMM_STCON.ST_PROT=1).

33.4.2 Registers overview - TRI (ascending offset address)

33.4.3 Clock control register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 000_H

Clock control register Application Reset value: $0000\ 0000_H$

MOD_TYPE								MOD_REV							
r								r							

Field	Bits	Type	Description
MOD_REV	7:0	r	**Module revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module number** Indicates the module identification number (example: $00C5_H$ = SARADC).

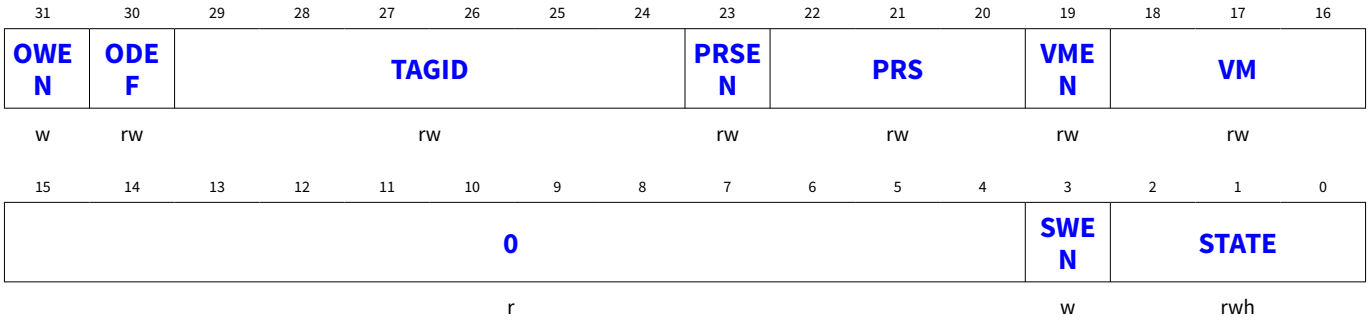
33.4.5 PROT register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 020_H

PROT register endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.

(table continues...)

(continued)

Field	Bits	Type	Description
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1338 Access mode restrictions of PROTE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

33.4.6 PROT register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 024_H

PROT register safe endinit Application Reset value: $0000\ 0000_H$

(table continues...)

(continued)

Field	Bits	Type	Description
WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

33.4.14 Logic BIST request register

LBIST_CTRL_REQ Offset address: 060_H

Logic BIST request register PowerOn Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REQ_RED	ERRINJ	0													
rwh	rwh	r													

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FAILCIN			0											RESET	REQ
rw			r											w	rwh

Field	Bits	Type	Description
REQ	0	rwh	**LBIST request** If written high this bit requests the execution of an automatic scan-test procedure for each hierarchical scan domain which is selected via LBIST_CTRL_DOM.SEL0..7. Due to safety reasons the LBIST_CTRL_REQ.REQ_RED bit as well must be set to high value in order to generate the LBIST request. The request will only be approved if LBIST_STAT_TEST.DONE bit reflects a low value, meaning no LBIST-procedure was triggered since the last power-on-reset or LBIST-controller has been restarted through the LBIST_CTRL_REQ.RESET-bit. This bit will reset automatically after internal synchronisation of the LBIST request. ***Note**: LBIST execution time depends on the number of scan-loads as defined in the LBIST_CTRL_CFGA.PATTERNS field.*
RESET	1	w	**LBIST-reset** If written high this bit synchronously brings back the LBIST-controller to its initial Reset/Idle-state and also clears the stored MISR-signature to allow another execution from CPU-side. As a consequence the LBIST_STAT_TEST.DONE- and LBIST_STAT_RESx_SIG.SIGNATURE-bits will be set to low value. If read this bit always returns a low value.

(table continues...)

(continued)

Field	Bits	Type	Description
FAILCIN	15:13	rw	**Fail counter input** This bit-field has no direct hardware effect on LBIST-execution itself, but shall serve as memory function for the application software. In case of a LBIST failure software can use it to memorize the number of times LBIST was not executed successfully or MISR-results did not match to the expected value. Because any LBIST operation will terminate with an internal reset and reboot-phase during which all application registers settings are lost, application needs to be able to remember the number of LBIST fails afterwards. The value written to of this bit-filed is memorized during a LBIST-procedure and indicated through the LBIST_STAT_TEST.FAILCOUT-field after the internal reset and reboot-phase.
ERRINJ	30	rwh	**LBIST / test-mode alarm error injection** If written high, this bit triggers both the LBIST- and the test-mode-alarm. This is required to allow self-testing of all LBIST-(and test-mode-)related safety mechanisms in the TCU. The bit will be reset automatically once the LBIST and test-mode alarm indicator signals from TCU are asserted. From these indicator signals TRI will also generate corresponding alarm trigger signals for SMU.
REQ_RED	31	rwh	**LBIST request redundancy** This bit represents the safety double of LBIST_CTRL_REQ.REQ. In order to generate a new LBIST request both, REQ_RED and REQ bits must be set to high due to safety reasons. The request will only be approved if LBIST_STAT_TEST.DONE bit reflects a low value. This bit will reset automatically after internal synchronisation of the LBIST request.
0	12:2, 29:16	r	**Reserved** Read as 0; should be written with 0.

Table 1341 Access mode restrictions of LBIST_CTRL_REQ sorted by descending priority

Mode name	Access mode		Description
write 1 to .**REQ_RED**	rwh	REQ	Set REQ_RED during write access
(default)	rh	REQ	

33.4.15 Logic BIST configuration register A

LBIST_CTRL_CFGA Offset address: 064_H

Logic BIST configuration register A Reset values see: Table 1342

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FREQU				0	SPLITSH		KEY OFF	RSV D23	ENP ARA	SAFE SEL	TFREQU		RSV D18	PATTERNS	
rw				r	rw		rw	rw	rw	rw	rw		rw	rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PATTERNS															
rw															

Field	Bits	Type	Description
PATTERNS	17:0	rw	**LBIST pattern number** This field defines the number of scan-patterns (scan-loads), which will be executed during the LBIST-procedure for each hierarchical block selected via LBIST_CTRL_DOM.SEL0..7. Please note that the value programmed to this field determines the number scan-capture phases not the number of scan-chain load-unload phases. This means a value of 0x00001 will result in two scan-chain loads with on capture in-between, a value of 0x00002 will result in 3 scan-chain loads with 2 captures and so on. Consequently a value of 0x00000 is not valid, because no capture would be executed in this case.
RSVD18	18	rw	**Reserved** Must not be changed from its reset value.
TFREQU	20:19	rw	**LBIST transaction frequency selection** Through this bit-field a pre-scaler factor between 2..4 is selectable for LBIST transaction clock (derived from EVR-oscillator). It allows to determine the operation speed of the on-chip iJTAG interface through which the LBIST configuration is transferred from the SPB-registers to the hierarchical scan domain. Value of this bit-field is mirrored inside of LBIST-controller and becomes effective with the start of a new LBIST-procedure (via LBIST_CTRL_REQ.REQ/REQ_RED). Please note that a divider factor of 1 is not supported, so this field must be set to a value between 1-3 to enable LBIST initialization. 00_B iJTAG clock disabled (no LBIST initialization possible). 01_B iJTAG interface runs at 50MHz. 10_B iJTAG interface runs at 33MHz. 11_B iJTAG interface runs at 25MHz.
SAFESEL	21	rw	**Safety LBIST test indicator** The value of this bit determines if LBIST-operation is executed only on the safety-relevant (safety-LBIST) or on the complete digital logic (full-scan) of each hierarchical scan domain which is selected via LBIST_CTRL_DOM.SEL0..7. For boot operations with limited execution time this option allows to exclude all non-safety-relevant parts of the digital logic from the scan-path. This allows a lower power consumption and hence enables faster execution of the LBIST procedure. For application scenarios with relaxed time conditions a complete LBIST test is executed on all parts of the hierarchical domain. 0_B For each hierarchical domain selected via LBIST_CTRL_DOM.SEL0..7 LBIST is performed with full-scan operation. This condition is applicable for key-off or all in-system-test application scenarios where sufficient LBIST execution time is available. 1_B For each hierarchical domain selected via LBIST_CTRL_DOM.SEL0..7 only those scan-chains are operated during LBIST execution which contain safety-relevant logic. This condition typically refers to key-on application scenarios where LBIST execution time is limited.

(table continues...)

(continued)

Field	Bits	Type	Description
ENPARA	22	rw	**Parallel LBIST execution indicator** This bit allows to select if LBIST test is executed for all hierarchical hierarchical scan domains sequentially or if LBIST is operated for all hierarchies in parallel. The second option can safe significant operation time for the total key-on LBIST scenario but may only be used if permissible from power consumption perspective. 0_B LBIST operation is executed sequentially for each hierarchical domain selected via LBIST_CTRL_DOM.SEL0..7. 1_B LBIST operation is executed concurrently for all hierarchical domain at a time which are selected via LBIST_CTRL_DOM.SEL0..7. This setting can only be used if permissable from power consumption perspective.
RSVD23	23	rw	**Reserved** Must not be changed from its reset value.
KEYOFF	24	rw	**Key-off indicator** This bit has no direct hardware effect on LBIST-execution itself, but shall serve as memory function for the application software. In case of a key-off request the application may trigger a final LBIST procedure before shutting down the system. Because this LBIST procedure will terminate with an additional reset and reboot-phase during which all application registers settings are lost, application needs to be able to distinguish the key-on case from the key-off case. The value of this bit is memorized during a LBIST-procedure and indicated through the LBIST_STAT_TEST.KEYIND-bit after the internal reset and reboot-phase. 0_B After the next LBIST-execution the LBIST_STAT_TEST.KEYIND-bit will indicate a low value, meaning the previous LBIST operation was triggered during a key-on sequence or a normal run-time event. 1_B After the next LBIST-execution the LBIST_STAT_TEST.KEYIND-bit will indicate a high value, meaning the previous LBIST operation was triggered on base of a pending key-off request.
SPLITSH	26:25	rw	**LBIST split-shift selection** The value of this bit will allow to run LBIST with partitioned scan-shift operation in order to reduce the power consumption. 00_B Concurrent scan-shift is selected. 01_B Concurrent scan-shift is selected. 10_B Partitioned scan-shift is selected (four scan partitions). 11_B Partitioned scan-shift is selected (two scan partitions).
FREQU	31:28	rw	**LBIST frequency selection** Through this bit-field a pre-scaler factor between 1..16 is selectable for LBIST operation clock (derived from EVR-oscillator). It allows to determine the LBIST scan-shift frequency. Value of these bit-field will be transported to the local LBIST-controllers within each domain and becomes effective with the start of a new LBIST-procedure (via LBIST_CTRL_REQ.REQ/REQ_RED).
0	27	r	**Reserved** Read as 0; should be written with 0.

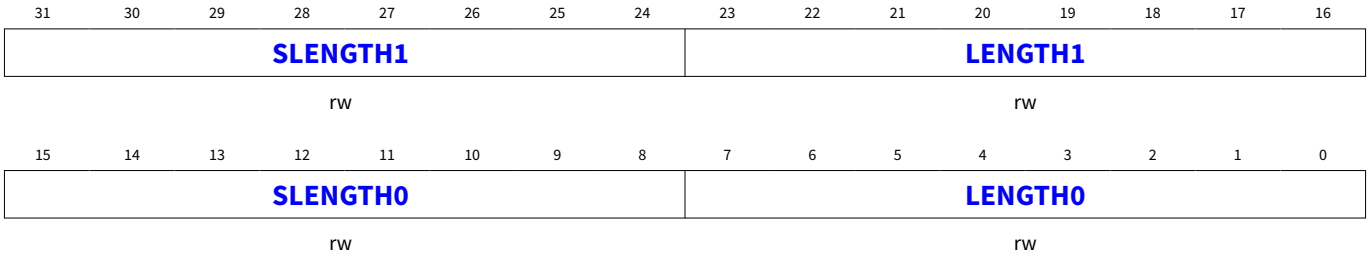
Table 1342 Reset values of LBIST_CTRL_CFGA

Reset type	Reset value	Note
PowerOn Reset	0000 0000_H	
After Boot-FW Value	---- X--- X--- -X-- ---- ---- ---- ----$_B$	The correct CFS value of the LBIST_CTRL_CFGA bit-fields has to be looked up in the device-specific section.

33.4.16 Logic BIST configuration register B

LBIST_CTRL_CFGB Offset address: 068_H

Logic BIST configuration register B Reset values see: Table 1343



Field	Bits	Type	Description
LENGTH0	7:0	rw	**LBIST maximum scan-chain length for scan domain #0** If LBIST_CTRL_CFGA.SAFESEL='0' this field defines the number of shift-cycles for each LBIST scan-load (applied to hierarchical scan domain #0). It will be automatically loaded with the product-specific value, stored in Flash config-sector during startup-software execution.
SLENGTH0	15:8	rw	**LBIST maximum safety scan-chain length for scan domain #0** If LBIST_CTRL_CFGA.SAFESEL='1' this field defines the number of shift-cycles for each LBIST scan-load (applied to hierarchical scan domain #0). It will be automatically loaded with the product-specific value, stored in Flash config-sector during startup-software execution.
LENGTH1	23:16	rw	**LBIST maximum scan-chain length for scan domain #1** If LBIST_CTRL_CFGA.SAFESEL='0' this field defines the number of shift-cycles for each LBIST scan-load (applied to hierarchical scan domain #1). It will be automatically loaded with the product-specific value, stored in Flash config-sector during startup-software execution.
SLENGTH1	31:24	rw	**LBIST maximum safety scan-chain length for scan domain #1** If LBIST_CTRL_CFGA.SAFESEL='1' this field defines the number of shift-cycles for each LBIST scan-load (applied to hierarchical scan domain #1). It will be automatically loaded with the product-specific value, stored in Flash config-sector during startup-software execution.

Table 1343 Reset values of LBIST_CTRL_CFGB

Reset type	Reset value	Note
PowerOn Reset	0000 0000_H	
After Boot-FW Value	---- ----$_H$	The correct CFS value of the LBIST_CTRL_CFGB bit-fields has to be looked up in the device-specific section.

33.4.17 Logic BIST configuration register C

LBIST_CTRL_CFGC Offset address: $06C_H$

Logic BIST configuration register C Reset values see: Table 1344

33.4.20 Logic BIST configuration register F

LBIST_CTRL_CFGF Offset address: 078_H

Logic BIST configuration register F Reset values see: Table 1347

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD12				0							OBSSCDIS	TPCTRDIS	TPOBSDIS	LBCGTRAN	
rw				r							rw	rw	rw	rw	

Field	Bits	Type	Description
LBCGTRAN	1:0	rw	**(LBIST) clock gate transparency control** For LBIST-operation it is possible to force certain groups of power-related clock-gate stages transparent through a specific 'pwrcmp_clkgate_en_o[6:0]' vector during the scan capture phase. This enables a quick coverage gain but also increases the overall power dissipation during LBIST-operation. Therefore this function shall be handled with care. 00_B All off: All 'pwrcmp_clkgate_en_o[6:0]' signals are constrained to low value during capture-phase. 01_B One-hot encoding: Only 1 'pwrcmp_clkgate_en_o[6:0]' signal may be set to high during capture-phase. 10_B Two-hot encoding: Only 2 'pwrcmp_clkgate_en_o[6:0]' signals may be set to high during capture-phase. 11_B Three-hot encoding: Only 3 'pwrcmp_clkgate_en_o[6:0]' signals may be set to high during capture-phase.
TPOBSDIS	2	rw	**Test observe point disabling** Setting this bit to low enables all scan observe test points for test coverage optimization. Setting this bit to high value will prevent the test observe FFs from capturing any scan-data. In this case they will only be clocked during the scan-shift phase.
TPCTRDIS	3	rw	**Test control point disabling** Setting this bit to low enables all scan control test points for test coverage optimization. Setting this bit to high value will prevent the test control FFs from influencing any structural paths within the scan design. In this case they will only be clocked during the scan-shift phase.
OBSSCDIS	4	rw	**Scan shift observation disabling** Setting this bit to low enables the observation scan feature in LBIST-operation under the precondition that LBIST_CTRL_CFGF.TPOBSDIS='0'. Setting this bit to high value will prevent the scan observation FFs from capturing any data during scan shift and capture process. Active scan observe FFs reduce the time to achieve the target stuck-at test-coverage compared to standard LBIST operation, where test observation points are active during capture phase only.
RSVD12	15:12	rw	**Reserved** Must not be changed from its reset value.
0	11:5, 31:16	r	**Reserved** Read as 0; should be written with 0.

Table 1347 Reset values of LBIST_CTRL_CFGF

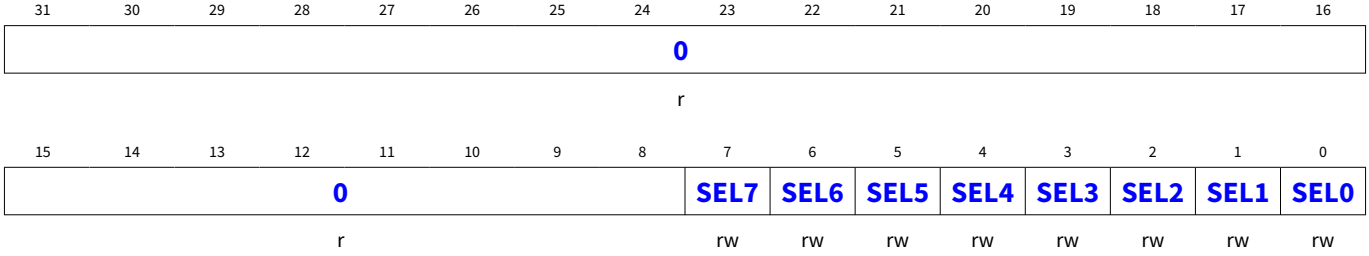
After Boot-FW Value	$0000\ 0000\ 0000\ 0000$ $UUXX\ XXXX\ XXX–\ ----_B$	The correct CFS value of the LBIST_CTRL_CFGF bit-fields has to be looked up in the device-specific section.

33.4.21 Logic BIST domain selection

LBIST_CTRL_DOM Offset address: $07C_H$

Logic BIST domain selection Reset values see: Table 1348



Field	Bits	Type	Description
SEL0	0	rw	**LBIST hierarchical scan domain 0 selection** This bit-field defines for which hierarchical scan domains LBIST operation will be performed. LBIST operations will usually be executed sequential for each selected domain. If permissible from power side it is possible to select the concurrent LBIST execution for all selected hierarchical domains via LBIST_CTRL_CFGA.ENPARA='1'. 0_B No LBIST will be executed for hierarchical scan domain #0 if a new LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit. 1_B LBIST operation will be executed for hierarchical scan domain #0 if LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit.
SEL1	1	rw	**LBIST hierarchical scan domain 1 selection** This bit-field defines for which hierarchical scan domains LBIST operation will be performed. LBIST operations will usually be executed sequential for each selected domain. If permissible from power side it is possible to select the concurrent LBIST execution for all selected hierarchical domains via LBIST_CTRL_CFGA.ENPARA='1'. 0_B No LBIST will be executed for hierarchical scan domain #1 if a new LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit. 1_B LBIST operation will be executed for hierarchical scan domain #1 if LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit.
SEL2	2	rw	**LBIST hierarchical scan domain 2 selection** This bit-field defines for which hierarchical scan domains LBIST operation will be performed. LBIST operations will usually be executed sequential for each selected domain. If permissible from power side it is possible to select the concurrent LBIST execution for all selected hierarchical domains via LBIST_CTRL_CFGA.ENPARA='1'. 0_B No LBIST will be executed for hierarchical scan domain #2 if a new LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit. 1_B LBIST operation will be executed for hierarchical scan domain #2 if LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit.

(table continues...)

(continued)

Field	Bits	Type	Description
SEL3	3	rw	**LBIST hierarchical scan domain 3 selection** This bit-field defines for which hierarchical scan domains LBIST operation will be performed. LBIST operations will usually be executed sequential for each selected domain. If permissible from power side it is possible to select the concurrent LBIST execution for all selected hierarchical domains via LBIST_CTRL_CFGA.ENPARA='1'. 0_B No LBIST will be executed for hierarchical scan domain #3 if a new LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit. 1_B LBIST operation will be executed for hierarchical scan domain #3 if LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit.
SEL4	4	rw	**LBIST hierarchical scan domain 4 selection** This bit-field defines for which hierarchical scan domains LBIST operation will be performed. LBIST operations will usually be executed sequential for each selected domain. If permissible from power side it is possible to select the concurrent LBIST execution for all selected hierarchical domains via LBIST_CTRL_CFGA.ENPARA='1'. 0_B No LBIST will be executed for hierarchical scan domain #4 if a new LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit. 1_B LBIST operation will be executed for hierarchical scan domain #4 if LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit.
SEL5	5	rw	**LBIST hierarchical scan domain 5 selection** This bit-field defines for which hierarchical scan domains LBIST operation will be performed. LBIST operations will usually be executed sequential for each selected domain. If permissible from power side it is possible to select the concurrent LBIST execution for all selected hierarchical domains via LBIST_CTRL_CFGA.ENPARA='1'. 0_B No LBIST will be executed for hierarchical scan domain #5 if a new LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit. 1_B LBIST operation will be executed for hierarchical scan domain #5 if LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit.
SEL6	6	rw	**LBIST hierarchical scan domain 6 selection** This bit-field defines for which hierarchical scan domains LBIST operation will be performed. LBIST operations will usually be executed sequential for each selected domain. If permissible from power side it is possible to select the concurrent LBIST execution for all selected hierarchical domains via LBIST_CTRL_CFGA.ENPARA='1'. 0_B No LBIST will be executed for hierarchical scan domain #6 if a new LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit. 1_B LBIST operation will be executed for hierarchical scan domain #6 if LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit.

(table continues...)

(continued)

Field	Bits	Type	Description
SEL7	7	rw	**LBIST hierarchical scan domain 7 selection** This bit-field defines for which hierarchical scan domains LBIST operation will be performed. LBIST operations will usually be executed sequential for each selected domain. If permissible from power side it is possible to select the concurrent LBIST execution for all selected hierarchical domains via LBIST_CTRL_CFGA.ENPARA='1'. 0_B No LBIST will be executed for hierarchical scan domain #7 if a new LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit. 1_B LBIST operation will be executed for hierarchical scan domain #7 if LBIST procedure is triggered via LBIST_CTRL_REQ.LBISTREQ-bit.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

Table 1348 Reset values of LBIST_CTRL_DOM

Reset type	Reset value	Note
PowerOn Reset	0000 0000$_H$	
After Boot-FW Value	0000 00--$_H$	The correct CFS value of the LBIST_CTRL_DOM bit-fields has to be looked up in the device-specific section.

33.4.22 Logic BIST status register

LBIST_STAT_TEST Offset address: 080$_H$

Logic BIST status register Reset values see: Table 1349

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								DOMDONE7	DOMDONE6	DOMDONE5	DOMDONE4	DOMDONE3	DOMDONE2	DOMDONE1	DOMDONE0
r								rh	rh	rh	rh	rh	rh	rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FAILCOUT			0									KEYIND	RSVD2	SAFEIND	DONE
rh			r									rh	rh	rh	rh

Field	Bits	Type	Description
DONE	0	rh	**LBIST execution indicator** This bit indicates the actual LBIST-controller execution status: 0_B No LBIST executed since last power-on-reset or LBIST-controller has been restarted (via LBIST_CTRL_REQ.RESET function) or LBIST was interrupted by external PORST during runtime (LBIST completion status is indicated via LBIST_STAT_TEST.DOMDONE0..7). Values in LBIST_STAT_RESx_SIG.SIGNATURE-fields are all set to low value. 1_B A LBIST-procedure successfully finished since last power-on-reset for all hierarchical scan domains which are selected via LBIST_CTRL_DOM.SEL0..7. Values in LBIST_STAT_RESx_SIG.SIGNATURE-fields reflect the resulting MISR-signature for each hierarchical scan domain.
SAFEIND	1	rh	**Safety LBIST memory bit** The value of this bit indicates if the previous Logic-BIST operation was executed under safety-LBIST test or a full-scan test conditions (please refer to LBIST_CTRL_CFGA.SAFESEL definition). This bit is only valid in LBIST_STAT_TEST.DONE='1' case. In DONE='0' case it always reflects a low value. 0_B The previous Logic-BIST operation was executed under full-scan test conditions. This means all design parts of the selected hierarchical domains are involved. 1_B The previous Logic-BIST operation was executed under safety-LBIST test conditions. This mean only safety-relevant design parts of the selected hierarchical domains are involved.
RSVD2	2	rh	**Reserved** Internally used function. Read value can be ignored.
KEYIND	3	rh	**Key-off LBIST memory bit** The value of this bit indicates if the previous LBIST-operation was triggered on base of a pending key-off request (please refer to LBIST_CTRL_CFGA.KEYOFF definition). This bit is only valid in LBIST_STAT_TEST.DONE='1' case. In DONE='0' case it always reflects a low value. 0_B The previous LBIST test was triggered during a key-on sequence or a normal run-time event. 1_B The previous LBIST test was triggered on base of a pending key-off request.
FAILCOUT	15:13	rh	**Fail counter output** This bit-field indicates how many times a previously triggered LBIST-operation failed (please refer to the LBIST_CTRL_REQ.FAILCIN-field definition). This field is only valid in LBIST_STAT_TEST.DONE='1' case. In DONE='0' case it always reflects a "000" value.

(table continues...)

(continued)

Field	Bits	Type	Description
DOMDONE0	16	rh	**LBIST hierarchical scan domain 0 execution status indicator** This bit indicates the actual LBIST-controller execution status for each hierarchical scan domain. If the scan domain is not implemented this bit always indicates a high value. 0_B No LBIST executed for hierarchical scan domain #0 since last power-on-reset or LBIST-controller has been restarted. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field are all set to low value. 1_B An LBIST-procedure successfully finished for hierarchical scan domain #0 since last power-on-reset. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field reflect the resulting MISR-signature.
DOMDONE1	17	rh	**LBIST hierarchical scan domain 1 execution status indicator** This bit indicates the actual LBIST-controller execution status for each hierarchical scan domain. If the scan domain is not implemented this bit always indicates a high value. 0_B No LBIST executed for hierarchical scan domain #1 since last power-on-reset or LBIST-controller has been restarted. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field are all set to low value. 1_B An LBIST-procedure successfully finished for hierarchical scan domain #1 since last power-on-reset. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field reflect the resulting MISR-signature.
DOMDONE2	18	rh	**LBIST hierarchical scan domain 2 execution status indicator** This bit indicates the actual LBIST-controller execution status for each hierarchical scan domain. If the scan domain is not implemented this bit always indicates a high value. 0_B No LBIST executed for hierarchical scan domain #2 since last power-on-reset or LBIST-controller has been restarted. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field are all set to low value. 1_B An LBIST-procedure successfully finished for hierarchical scan domain #2 since last power-on-reset. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field reflect the resulting MISR-signature.
DOMDONE3	19	rh	**LBIST hierarchical scan domain 3 execution status indicator** This bit indicates the actual LBIST-controller execution status for each hierarchical scan domain. If the scan domain is not implemented this bit always indicates a high value. 0_B No LBIST executed for hierarchical scan domain #3 since last power-on-reset or LBIST-controller has been restarted. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field are all set to low value. 1_B An LBIST-procedure successfully finished for hierarchical scan domain #3 since last power-on-reset. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field reflect the resulting MISR-signature.

(table continues...)

(continued)

Field	Bits	Type	Description
DOMDONE4	20	rh	**LBIST hierarchical scan domain 4 execution status indicator** This bit indicates the actual LBIST-controller execution status for each hierarchical scan domain. If the scan domain is not implemented this bit always indicates a high value. 0_B No LBIST executed for hierarchical scan domain #4 since last power-on-reset or LBIST-controller has been restarted. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field are all set to low value. 1_B An LBIST-procedure successfully finished for hierarchical scan domain #4 since last power-on-reset. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field reflect the resulting MISR-signature.
DOMDONE5	21	rh	**LBIST hierarchical scan domain 5 execution status indicator** This bit indicates the actual LBIST-controller execution status for each hierarchical scan domain. If the scan domain is not implemented this bit always indicates a high value. 0_B No LBIST executed for hierarchical scan domain #5 since last power-on-reset or LBIST-controller has been restarted. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field are all set to low value. 1_B An LBIST-procedure successfully finished for hierarchical scan domain #5 since last power-on-reset. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field reflect the resulting MISR-signature.
DOMDONE6	22	rh	**LBIST hierarchical scan domain 6 execution status indicator** This bit indicates the actual LBIST-controller execution status for each hierarchical scan domain. If the scan domain is not implemented this bit always indicates a high value. 0_B No LBIST executed for hierarchical scan domain #6 since last power-on-reset or LBIST-controller has been restarted. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field are all set to low value. 1_B An LBIST-procedure successfully finished for hierarchical scan domain #6 since last power-on-reset. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field reflect the resulting MISR-signature.
DOMDONE7	23	rh	**LBIST hierarchical scan domain 7 execution status indicator** This bit indicates the actual LBIST-controller execution status for each hierarchical scan domain. If the scan domain is not implemented this bit always indicates a high value. 0_B No LBIST executed for hierarchical scan domain #7 since last power-on-reset or LBIST-controller has been restarted. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field are all set to low value. 1_B An LBIST-procedure successfully finished for hierarchical scan domain #7 since last power-on-reset. Values in LBIST_STAT_RESx_SIG.SIGNATURE-field reflect the resulting MISR-signature.
0	12:4, 31:24	r	**Reserved** Read as 0; should be written with 0.

Table 1349 Reset values of LBIST_STAT_TEST

Reset type	Reset value	Note
PowerOn Reset	0000 0000_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SIGNATURE															
rh															

Field	Bits	Type	Description
SIGNATURE	31:0	rh	**LBIST domain x signature** This field reflects the MISR signature from the last LBIST execution of hierarchical scan domain #x. It is mirrored from LBIST-controller inside TRI and only valid if LBIST_STAT_TEST.DONE is read with a high value. In case of a restart of the LBIST-controller (via LBIST_CTRL_REQ.RESET function), the signature value will be synchronously reset to all-0. Please check the device specific section for a description on the SIGNATURE value, depending on the LBIST run configuration.

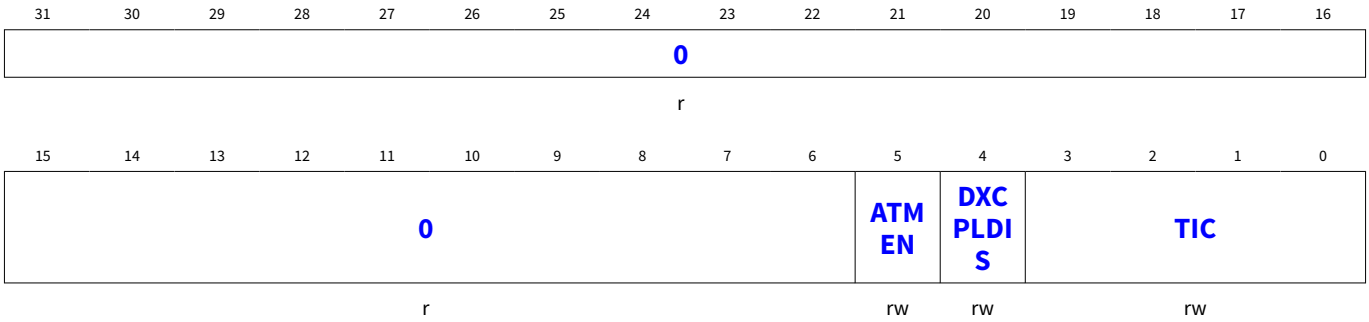
Table 1350 Reset values of LBIST_STAT_RESx_SIG (x=0-7)

Reset type	Reset value	Note
PowerOn Reset	0000 0000_H	
After Boot-FW Value	---- ----$_H$	After reset the SIGNATURE bits in this register will be updated automatically with the stored values in the central LBIST supervisor block.

33.4.24 Debug over CAN enabling control

DXCCTR Offset address: $0F8_H$

Debug over CAN enabling control Reset values see: Table 1351



Field	Bits	Type	Description
TIC	3:0	rw	**Tool interface control** DAP over CAN Physical Layer (DXCPL). 0_H DXCPL will be disabled if not already activated by the tool after power-on-reset. 1_H DXCPL will stay enabled/activated for standard CAN pins. 2_H DXCPL is enabled for alternative CAN pins. **others,** Reserved, do not use.
DXCPLDIS	4	rw	**Debug over CAN disabling control** This bit determines if Debug over CAN (DXCPL) operation mode is enabled or not. 0_B DXCPL operation mode can be enabled. 1_B DXCPL operation mode cannot be enabled (if it has already been entered it will be disabled again).
ATMEN	5	rw	**Application test mode enabling control** This bit determines if after enabling of Debug over CAN (DXCPL) operation mode the Application Test Mode (ATM) can be entered or not. 0_B ATM cannot be enabled after DXCPL entry. 1_B ATM can be enabled after DXCPL entry.
0	31:6	r	**Reserved** Read as 0; should be written with 0.

This section is not applicable for the module being described.

33.6 References

This section is not applicable for the module being described.

33.7 TRI revision history

Initial release of the chapter.

33.8 TC4Dx TRI information

33.8.1 TC4Dx TRI configuration

It shall be noted, that the term '_DFT_', which is used in the TC4Dx TRI connectivity, means a synonym for '_TRI_' and always refers to connections between Logic-Test (TRI) and other functional blocks.

33.8.1.1 LBIST domain assignment for TC4Dx

The following hierarchical scan domains are available in TC4Dx product:

Table 1352 Hierarchical scan domain assignment to LBIST_CTRL_DOM

Domain #	LBIST_CTRL_DOM	Domain Name	Description
0	SEL0	SRI0	Compute domain 1 (CPU0, CPU1, CPU2)
1	SEL1	SRI5	Communication domain (LETH, MCAN, I2C, RGMII)
2	SEL2	SRI4_Conv	Cyber security CPU and Converter
3	SEL3	SRI2	High speed interfaces (XGETH, PCIE)
4	SEL4	SRI3_PPU	PPU
5	SEL5	PMS	Power management
6	SEL6	SRI1	Compute domain 2 (CPU3, CPU4, CPU5, LMU)
7	SEL7	unused	

The default boot configuration of the LBIST control registers will select domains #0-#6. Those domains will be tested if automatic key-on LBIST execution after externally triggered cold power-on reset is selected in the UCB. In order to allow a successful LBIST execution of domain #3 the V_{DDPHYx} supply rails have to be connected to the V_{DD} supply voltage even if the respective HSPHYs are not used.

33.8.1.2 Key-on LBIST scenario for TC4Dx

The following default LBIST key-on configuration is provided automatically after cold power-on reset in TC4Dx A11 product. This will target only the safety logic in the selected hierarchical scan domains:

Table 1353 LBIST_CTRL_CFGA key-on default configuration for TC4Dx A11

Configuration type	Configuration value
Pattern count [PATTERNS]	5000 [1388_H]
iJTAG configuration speed [TFREQ]	25 MHz [11_B]
Safety LBIST test indicator [SAFESEL]	Test safety logic only [1_B]
Parallel Test Execution [ENPARA]	Run LBIST of hierarchical scan domains in parallel [1_B]
Key-off indicator [KEYOFF]	No key-off indication [0_B]
LBIST split-shift selection [SPLITSH]	Split-shift 2 [11_B]
LBIST frequency selection [FREQU]	100 MHz [0_H]

In TC4Dx A21 product the default LBIST key-on configuration has been changed in a way, that significant less patterns are executed with a reduced frequency. In this way the power consumption of key-on LBIST will be

reduced by roughly 50% but the test coverage goal of 90% is still achieved for the safety mechanisms in all hierarchical scan domains.

Table 1354 LBIST_CTRL_CFGA key-on default configuration for TC4Dx A21

Configuration type	Configuration value
Pattern count [PATTERNS]	2100 [834_H]
iJTAG configuration speed [TFREQ]	25 MHz [11_B]
Safety LBIST test indicator [SAFESEL]	Test safety logic only [1_B]
Parallel Test Execution [ENPARA]	Run LBIST of hierarchical scan domains in parallel [1_B]
Key-off indicator [KEYOFF]	No key-off indication [0_B]
LBIST split-shift selection [SPLITSH]	Split-shift 2 [11_B]
LBIST frequency selection [FREQU]	50 MHz [1_H]

The following table gives an overview about the maximal scan chain length for each hierarchical scan domain. LENGTHx register fields represent the scan chain lengths for key-off LBIST, SLENGTHx register fields determine the scan chain lengths for the key-on LBIST scenario. The maximal number of FFs in a domain's scan chain determines the number of clock cycles, which are required to execute one LBIST pattern and therefore is direct proportional to the LBIST execution time.

Table 1355 LBIST_CTRL_CFGB - LBIST_CTRL_CFGE maximal scan chain length

Domain #	Register	Field Name	Max chain length [Default value]
0 [SRI0]	LBIST_CTRL_CFGB	LENGTH0	166 [$A6_H$] (preliminary value)
0 [SRI0]	LBIST_CTRL_CFGB	SLENGTH0	52 [34_H] (preliminary value)
1 [SRI5]	LBIST_CTRL_CFGB	LENGTH1	77 [$4D_H$] (preliminary value)
1 [SRI5]	LBIST_CTRL_CFGB	SLENGTH1	51 [33_H] (preliminary value)
2 [SRI4]	LBIST_CTRL_CFGC	LENGTH2	53 [35_H] (preliminary value)
2 [SRI4]	LBIST_CTRL_CFGC	SLENGTH2	40 [28_H] (preliminary value)
3 [SRI2]	LBIST_CTRL_CFGC	LENGTH3	132 [84_H] (preliminary value)
3 [SRI2]	LBIST_CTRL_CFGC	SLENGTH3	46 [$2E_H$] (preliminary value)
4 [PPU]	LBIST_CTRL_CFGD	LENGTH4	65 [41_H] (preliminary value)
4 [PPU]	LBIST_CTRL_CFGD	SLENGTH4	40 [28_H] (preliminary value)
5 [PMS]	LBIST_CTRL_CFGD	LENGTH5	53 [35_H] (preliminary value)
5 [PMS]	LBIST_CTRL_CFGD	SLENGTH5	40 [28_H] (preliminary value)
6 [SRI1]	LBIST_CTRL_CFGE	LENGTH6	168 [$A8_H$] (preliminary value)
6 [SRI1]	LBIST_CTRL_CFGE	SLENGTH6	50 [32_H] (preliminary value)
7 [unused]	LBIST_CTRL_CFGE	LENGTH7	0 [0_H]
7 [unused]	LBIST_CTRL_CFGE	SLENGTH7	0 [0_H]

Expected MISR Signatures for key-on LBIST scenario in TC4Dx A11 product:

Table 1356 Expected MISR Signatures for key-on LBIST for TC4Dx A11

Domain #	Register	Field Name	MISR expected value
0 [SRI0]	LBIST_STAT_RESx_SIG (x=0)	SIGNATURE	$00AF297B_H$
1 [SRI5]	LBIST_STAT_RESx_SIG (x=1)	SIGNATURE	$00E616E6_H$

Key-on LBIST scenario for TC4Dx, Key-off LBIST scenario for TC4Dx	• Added MISR signature reference values for TC4Dx A21 key-on and key-off LBIST

34 Volatile Memory Test (VMT)

The Volatile Memory Test (VMT) controls and monitors the test, initialization, and data integrity checking functions of the various internal memories in the device.

Each SRAM has digital logic surrounding it, known as SRAM Support Hardware (SSH). The SSH is a hardware block that controls the error detection and correction, Memory Built-In-Self-Test (MBIST) of internal memories. Each SSH block provides a unified interface for controlling its various functions. There are multiple such SSH instances, each of which controls one or more of the different internal memories. The VMT provides register interfaces to configure and control these various memory controllers.

34.1 Feature list

- A unified register interface to control the operation and functionality of each internal SSH instance:
  - Each VMTx provides a unified register interface to control the operation and functionality of each internal SSH instance
  - Each VMTx can be used to control various configurable test types for each of the SRAM blocks in the system
- Data initialization:
  - Each SRAM block in the system can be hardware initialized through the VMT
  - Security sensitive memories can be auto-initialized to avoid unauthorized access
- Memory error correction and detection:
  - Memory error correction and detection for SRAM blocks configurable through the VMT
  - Correctable and uncorrectable error detection
  - Address error detection
- Alarm notification to the SMU for each SRAM or SSH:
  - From each SRAM or SSH, three alarms are sent to the VMT, which are then OR combined for each alarm type and forwarded to the SMU, although separately for security and non-security related SSHs. The alarms are:
    - Correctable error (CE) alarm
    - Uncorrectable error (UCE) alarm
    - Miscellaneous error (ME) alarm
- MBIST done interrupt to signal the completion of all running tests

34.2 Functional overview

Multiple VMT instances (VMTx) are distributed over the chip. Each VMTx handles up to 32 SSHs. The figure shows the system level view of the VMTx, SSH instances, and SRAMs.

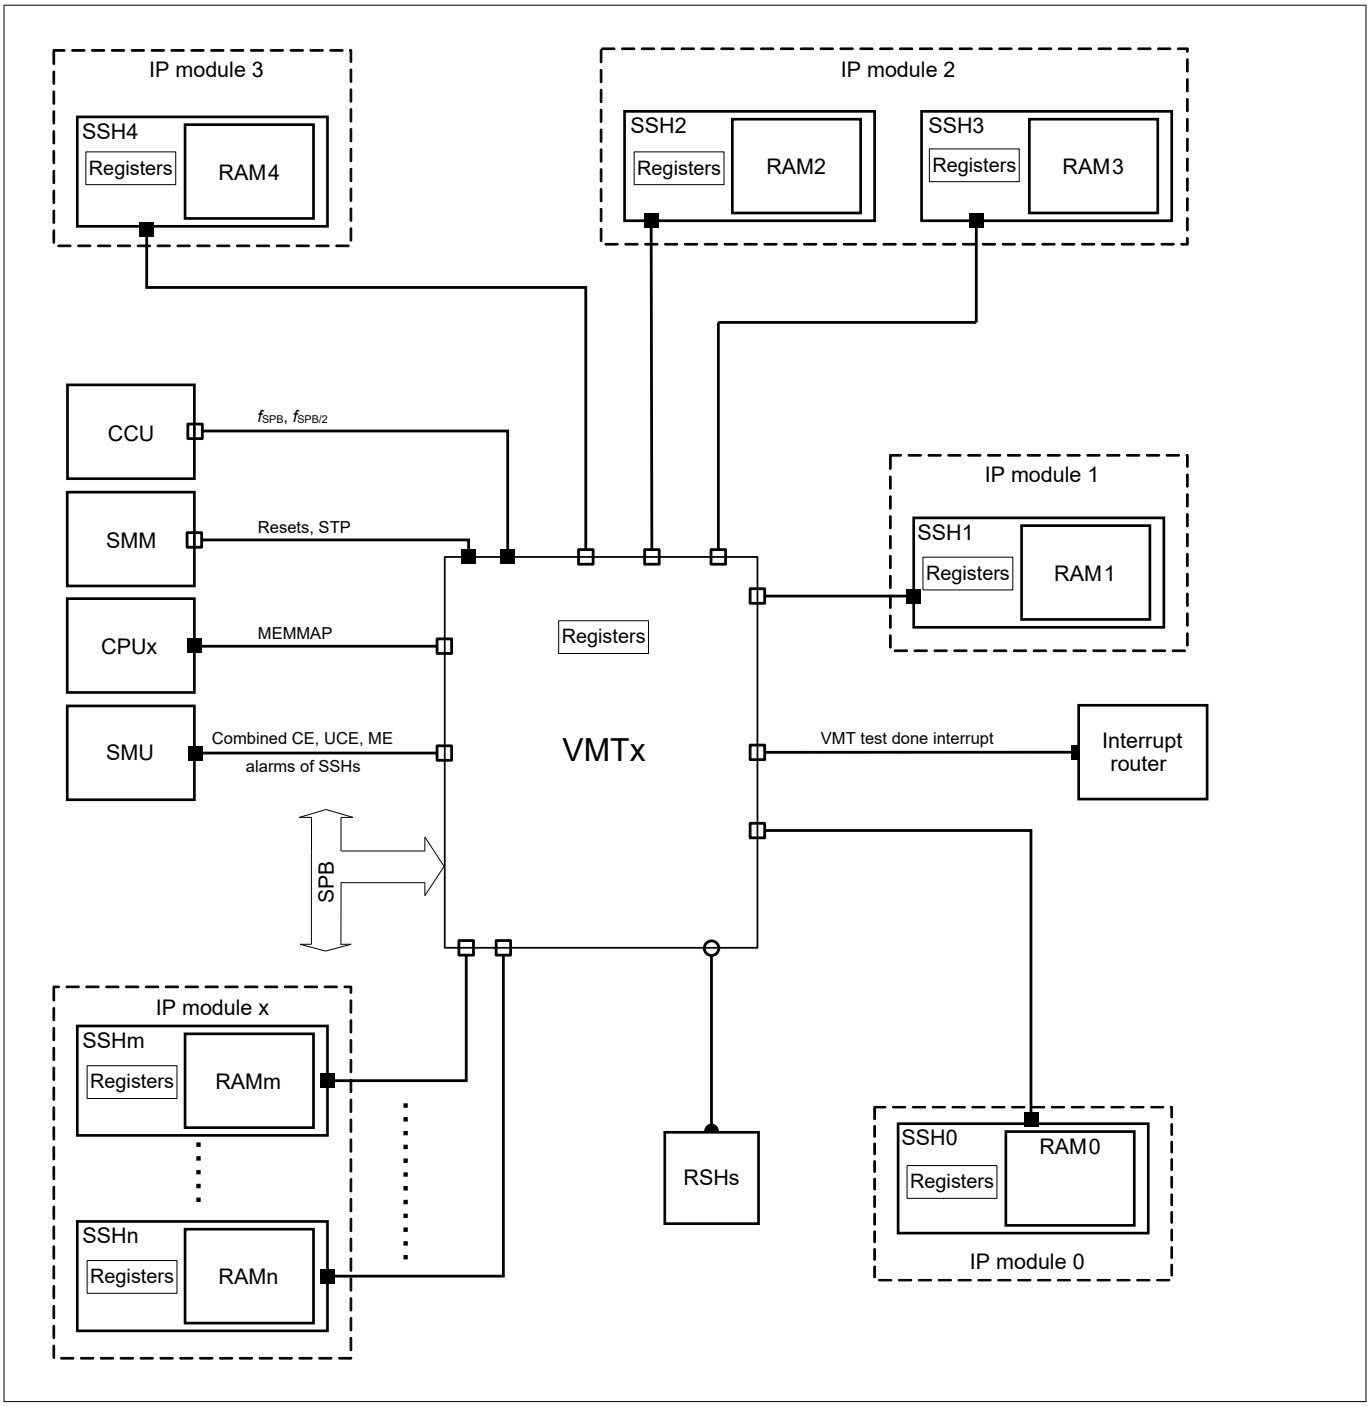

Figure 760 VMT block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

Note that STP connections from SMM as well as ROM support hardware (RSH) connections shown in the figure above are not relevant for the user and will not be explained in greater detail herein.

Different functional blocks such as the CPU, LMU, or CAN for example, may have one or more SRAMs inside them. Every SRAM is embedded in its own SSH module, with its own SSH registers and MBIST logic. Each SSH is separately connected to a VMTx through internal interfaces.

Each VMTx is connected to the SPB and provides access to the registers of the SSHs connected to it.

Each SPB access is internally forwarded and returned, to and from the corresponding SSH by the VMTx.

34 Volatile Memory Test (VMT)

34.3 Functional description

The following chapters provide a functional overview of VMTx, SSH, and SRAM.

34.3.1 SRAM support hardware (SSH)

Any on-chip SRAM in the AURIX™ 3rd Generation is assigned to an SSH (SRAM support hardware) for test purposes. A single SSH instance can cover multiple on-chip SRAMs. Any SSH is assigned to one of the implemented VMT modules. All SSH instances are connected to an internal bus through a unified VMTx-SSH Interface. The SSH provides direct access to the memories, without involving the CPU.

34.3.2 Control and status interfaces

The following section explains the hardware interface to access each individual SSH instance by the CPU through the system peripheral bus (SPB).

34.3.2.1 Interface to the CPU

The registers of an individual SSH can be accessed by the CPU via the VMTx through the peripheral bus.

The registers of individual controllers are located in the SSH block. Logically they all have a VMTx system address and are accessed through SPB accesses from the VMTx. As this goes through the VMTx->SSH interface, the accesses to individual SSH registers will be slower than normal SPB accesses to peripheral registers.

***Note**: Any SSH register writes are ignored during an ongoing test and the values are not written to the register, however a read access will return the correct value. In both cases the access finishes normally on the SPB without bus errors. The MCi_MCONTROL can be written to during a test to clear the start and resume bits.*

34.3.3 Enabling the SRAM support hardware (SSH)

Each SSH has an enable bit associated with it in the MEMTEST(CS). Refer to the register descriptions for the implemented enable bits.

The control registers of each SSH are accessible only when the SSH is enabled (MEMTEST(CS).ENn = 1).

In each SSH instance, the only exceptions to this are:

- MC i Nominal ECC safety register
- MC i Nominal Memory ECC detection register
- MC i Nominal error information register
- MC i Nominal error tracking register
- MC i Nominal alarm sources configuration register
- MC i Nominal SSH safety faults status register

These registers are available at all times to permit easy runtime access to ECC features. That is, above noted registers can be read and written with the only precondition that the VMT clock is enabled in the CLC register and no register access protections are violated.

All other registers in the SSH can only be accessed when the SSH is enabled in the MEMTEST(CS) register, otherwise the VMT returns a bus error on the SPB.

For certain SSHs, enabling or disabling the SSH in the MEMTEST(CS) register may result in whole or part of the memory being automatically initialized, depending on the configuration. This auto-initialization can take hundreds of clock cycles to complete. During this time, no SSH register is accessible, including registers that are

normally accessible without the SSH being enabled. Any register access to the SSH running the auto-initialization will result in a bus error on the SPB.

***Note**: The clock input to the module containing the SRAM has to be enabled upstream in the CCU of the CLOCK functional block, before any SSH registers can be accessed through the VMT. SSH register access is not gated by the local CLC register of that module.*

1. When an SSH is enabled, functional access to the memory is unavailable. When a memory is being tested, the software shall prevent any functional access to that memory. For example, while testing a CPU's local memory, the CPU should be in an idle state, or executing from other memory.
2. Correct execution of an SSH operation, for example an MBIST test, requires that both the VMTx and the module containing the memory-under-test are operational for the duration of the SSH operation. A reset of the module containing the memory-under-test, may result in unexpected behavior when an SSH is enabled. Software has to take care that events such as application reset, module resets, standby entry, clock frequency change, and so forth are not triggered when an SSH is enabled. For example, a module reset may result in the module trying to access the SRAM functionally after the reset, when the SSH is still enabled, therefore functional access is disabled. Such scenarios have to be avoided by software.
3. If communication is ongoing (for example, SSH register read or write) between the VMTx and SSH when a module reset occurs, the communication is aborted and a bus error is triggered on the SPB within a few cycles, without the need to wait for a VMTx-SSH communication timeout. That is, an SPB error during reads and silent ignore (no error) during writes. The SSH also generates a miscellaneous alarm in this case and the corresponding error status is stored in a FAULTSTS register. Only the ongoing read/write may be corrupted, future accesses are not affected
4. In case a non-existing SSH register is accessed in an existing SSH instance, this will result in a miscellaneous alarm and the corresponding error status is stored in FAULTSTS. If a non-existing SSH instance is accessed, it will result in a bus error on the SPB.
5. If a non-existing VMT register is accessed, it will result in a bus error on the SPB.

Related information

Security-sensitive memories and auto-initialization on page 5737

34.3.3.1 Security-sensitive memories and auto-initialization

Certain internal memories are considered security sensitive. Each VMTx supports up to 32 SSHs. A SSH on index "i" is either considered nominal or security sensitive. The configuration registers in the VMTx are separated for security sensitive and nominal SSHs to allow for different protections. However, the general functionality of the registers is the same. To configure or enable security sensitive SSHs, the cyber security (CS) registers in the VMTx have to be used:

Table 1370 VMT registers for nominal and security sensitive SSHs

Nominal SSH MCi	Security sensitive SSH MCCSi
MEMTEST	MEMTESTCS
MEMMAP	MEMMAPCS
MEMSTAT	MEMSTATCS
MEMDONE	MEMDONECS
MEMFDA	MEMFDACS
CEALARM	CEALARMCS

(table continues...)

Table 1370 (continued) VMT registers for nominal and security sensitive SSHs

Nominal SSH MCi	Security sensitive SSH MCCSi
UCEALARM	UCEALARMCS
MEALARM	MEALARMCS

Security sensitive memories support auto-initialization. For certain applications which are security sensitive, reading or modifying the contents of these memories through the SSH modules has to be prevented by the VMTx. For these memories, enabling the corresponding SSH results in the memory being cleared, before the SSH is actually enabled. This operation can take hundreds of clock cycles. The software must wait for the MEMSTAT(CS).AIUn bit to be cleared before the SSH will be enabled.

Refer to subchapter "VMT security information" in the device specific configuration chapter for more information on which memories are considered security related and which memories feature auto-initialization.

In the case of non-security applications, for example safety, it may be important that the modification of the memory contents is allowed through the SSH, for example ECC error injection.

It is possible to enable or disable the auto-initialization and partial-erase features. Refer to the RAMINIT description in Register Overview - UCB0_17 (ascending Offset Address) and the CSSRAM_init description in Register Overview - UCB1_15 (ascending Offset Address), which can be found in the FIRMWARE chapter of the User Manual.

34.3.3.1.1 Security applications

For security applications, the contents of the security sensitive memories can be auto-initialized to erase the existing contents. Automatic initialization of security-sensitive memories is triggered whenever the corresponding MEMTEST(CS).ENn or MEMMAP(CS).ENn is changed, that is, the corresponding SSH is enabled or disabled or if memory map mode is changed.

The MEMSTAT(CS).AIUn bits indicate whether an automatic data initialization of memory n has been triggered and whether the initialization has completed. If an AIUn bit in MEMSTAT(CS) register is set, this means that auto-initialization for that memory is still underway. The SSH is enabled or disabled only after the auto-initialization has completed. The software can wait for the auto-initialization to be completed by polling this bit.

34.3.3.1.2 Nominal applications

If RAMIN=11_B in the RAMINIT or CSSRAM_init registers, then no automatic initialization of RAM content is performed when SSH modules are enabled or disabled with MEMTEST(CS).ENn or MEMMAP(CS).ENn register bits.

This permits the use of the SSH by an application without unwanted corruption of memory content. Use cases for this include error injection, data modification or runtime memory testing.

34.3.3.2 Memory map selection

The memory mapping enable register (MEMMAP(CS)) has configurable control bits to select memory-mapped test mode for CPU cache and tag memory. The cache and tag memories are mapped to the system address space when the corresponding control bit is set. The MBIST tests and other SSH operations work on the SRAM independent of the MEMMAP(CS) register settings.

Refer to subchapter "MEMMAP configuration" in the device specific configuration chapter of this manual for more information.

34.3.4 SRAM support hardware (SSH) operation

The operation and functionality of each internal SSH instance can be controlled from a set of registers. These registers are accessible through the VMTx. An SSH instance has to be enabled first before the memory can be tested.

The main functionalities provided by each SSH instance are explained in the following sections.

Related information

Enabling the SRAM support hardware (SSH) on page 5736

34.3.4.1 Memory testing and initialization

Here we explain how to configure the SSH instances using the VMTx, to perform various tests on the memory and obtain the results, or initialize the memories from the SSH.

***Note**: The following operations can be performed only when the SSH instance under test has been enabled using the corresponding ENn bit in the MEMTEST(CS) register.*

34.3.4.1.1 Starting a memory test sequence

As a first step, before the MCONTROL.START is set, the software should properly configure the configuration registers, CONFIG0 (MC i Nominal configuration register 0) and CONFIG1 (MC i Nominal configuration register 1) registers.

CONFIG0.ACCSTYPE specifies the access type (read or write) to be performed on each single address in the current test sequence, while CONFIG1.ACCSPAT specifies the access pattern. CONFIG0.NUMACCS specifies the total number of accesses to a single address in the current marching element. The SSH supports some complex addressing schemes. The software can enable this using the CONFIG1.AG_MOD bits.

Each memory test sequence is started by writing to the MCONTROL.START bit of the corresponding SSH (MC i Nominal MBIST control register). Once started, the SSH test hardware proceeds to test the SRAM by accessing each memory address one after the other until the last address of the memory test range is reached. When the test is complete, the MSTATUS.DONE (Nominal memory test done status register) is set by the hardware, if the software has cleared the MCONTROL.START bit. Software can poll the MEMDONE(CS) (Nominal or Cyber-secure memory test done status register) in the VMTx to get the status of test completion. This register just reflects the DONE bit in the MSTATUS register of each SSH.

It is possible to select a fixed range of the memory to be tested, instead of the whole memory, using the RANGE.RAEN bit (MC i Nominal range register, single address mode). When RANGE.RAEN is set to ‘1’, the RANGE.ADDR[14:0] bits are interpreted as two separate addresses, providing the upper and lower boundaries of the range to be tested. The lower address boundary is given by (RANGE.ADDR[6:0] & “00000000”b) while the upper boundary is given by (RANGE.ADDR[13:7] & “11111111”b).

Once the test is complete (MSTATUS.DONE=1), the MSTATUS.FAIL bit will be set in case of any failures.

34.3.4.1.2 MBIST done interrupt

On completion of all running tests, a VMTx signals an interrupt to the interrupt router (IR). The IR provides a dedicated interrupt control register SRC_VMTwSR for each VMTx. The reset value of this signal is high. When a test on any SRAM is started, this signal goes low. On completion of all ongoing tests, this signal again goes high, and this rising edge triggers the interrupt.

34.3.4.1.3 Getting detailed memory test results

The MSTATUS.FAIL and MSTATUS.DONE bits, which can be polled from the VMTx itself through the MEMDONE(CS) (Nominal or Cyber-secure memory test done status register) and MEMFDA(CS) (Nominal or Cyber-secure memory test FDA status register), provide a general pass and fail information as well as test completion status.

If MCONTROL.FAILDMP = 1, the test stops after a failure and the fail information is immediately available for dump. MSTATUS.FDA (fail dump available) is set in this case. Any dump information has to be polled from registers RDBFLy and ETRR. RDBFLy contains the fail bit map and ETRR the failed address. Reading MSTATUS and the RDBFLy(n-1) registers with MSTATUS.FDA = 1 will reset MSTATUS.FDA back to 0. A consequent setting of MCONTROL.RESUME will resume the interrupted test sequence.

The fail bitmap is simply (expected data pattern) XOR (actual data pattern).

The RANGE register can be used to run consecutive tests on constantly shifted memory ranges so that in the end the complete memory has been analyzed.

Please note that if a test is stopped due to an intermediate failure, the MSTATUS.DONE is not set. MSTATUS.DONE is set only once the whole test sequence is completed and MCONTROL.START has been cleared by software.

***Note**: In order to finish the test without the fail information, MCONTROL.FAILDMP should be reset by SW in the same write access to the MCONTROL, where MCONTROL.RESUME is set.*

34.3.4.1.4 Error injection during memory tests

It is possible to manually inject errors during memory tests, for example, to test the software.

For a non-destructive MBIST test, an error in the data can be introduced by programming a word with the wrong ECC before the test, using the ECCMAP bits.

During a destructive MBIST test, it is possible to inject data errors with the MCONTROL.INJERR bit. When this bit is set (and RANGE.RAEN = 1), then the RANGE.ADDR field is taken as a pointer to a physical SRAM location to which write accesses during the test are not executed. The following steps show how to use this method:

- Write ones at the memory location where error injection is desired with the procedure explained in the section „Writing to a single memory location“
  - For a single bit error, write a single one while keeping all other bits to zero
  - For two or more bit errors, write two or more ones accordingly
- Configure the destructive MBIST as explained in the corresponding chapter, but for the steps Kx:Test or K3:Extract set the MCONTROL.INJERR to one, set RANGE.RAEN to one and then write in RANGE.ADDR the address of the memory location where the error was previously injected
- Start the MBIST by setting MCONTROL.START to one

The destructive MBIST then runs over the full memory, and writes are not executed on the address corresponding to RANGE.ADDR. This results in a mismatch of the expected data during the test, resulting in a FAIL.

The method explained above is limited to a single address in the memory. For injection of errors at multiple memory locations, like for example multiple single bit errors or a bitline error, the following method can be applied:

- Initialize the memory to all zero by following the procedure explained in the section „Filling a memory with defined contents“
- Write ones at the memory locations where error injection is desired with the procedure explained in the section „Writing to a single memory location“
  - For multiple single bit errors, write a single one while keeping all other bits to zero at each memory location
  - For two or more bit errors, write two or more ones accordingly
  - For a bitline error, write a single one at the same bit position for at least three successive memory locations
- Start the destructive MBIST as explained in the corresponding chapter, but for the steps Kx:Test or K3:Extract use the following sequence instead: {r0,w1,r1,w1}
  - While 3 accesses {r0,w1,r1} would be sufficient, using 4 keeps the runtime of the MBIST neutral compared to the original destructive MBIST procedure

The destructive MBIST then runs over the full memory and during the first read access, any bits previously set to one are identified as failed bits.

With errors injected, all normal diagnostics and notifications can be tested. That is, alarms are triggered, errors are tracked in the ETRR/ERRINFO registers during a non-destructive test. During a destructive MBIST test, the MSTATUS FAIL bit is set, and when MCONTROL FAILDMP = 1, the fail bitmap is captured in the RDBFLy registers, MSTATUS.FDA is set and the failing local address is captured in the ETRR register.

Address errors are triggered during an MBIST by simply setting SFLE bit to 1.

***Note**: Setting SFLE bit to 1 will trigger an address error from each address that is accessed until the SFLE is set back to 0.*

Related information

Writing to a single memory location on page 5743
Destructive MBIST on page 5744
Filling a memory with defined contents on page 5741

34.3.4.1.5 Filling a memory with defined contents

The SSH can be used to fill a memory range or a complete memory with a defined pattern very fast, that is, one write access per cycle with the full memory data width, using the MCONTROL.DINIT bit. For this, ensure that MCONTROL.SRAM_CLR = 0.

Before setting the MCONTROL.DINIT, the software should first fill the RDBFL register with the desired bit pattern (MC i Nominal read data and bit flip register y). It is not mandatory to have a valid ECC in this pattern.

Next, the RANGE register needs to be set with the memory range into which the pattern needs to be filled.

Next, set the MCONTROL.DINIT, and then the MCONTROL.START bit should be set to start initializing the RAM. The software should then clear the MCONTROL.START.

When MSTATUS.DONE bit is set by the hardware, the memory filling operation is complete.

***Note**: It is generally recommended to initialize the whole address range of an SRAM.*

34.3.4.1.6 Initializing SRAMs

Using the MCONTROL.SRAM_CLR bit, it is possible to initialize the complete SRAM.

***Note**: The SRAM_CLR functionality shall not be used with the SSH instances specified with "SRAM clear = no" in the chapter "SSH functionality exceptions". If an SRAM_CLR operation is started on any of these memories, its content is filled with ECC-incorrect values which can then lead to ECC alarms when accessing them. These memories shall be initialized by the application software instead, for example with an initialization routine or a DMA request. For the software initialization, it is recommended to use the TriCore™ CPU instruction ST.D (Store Doubleword) to avoid potential traps and alarms due to ECC errors.*

For this operation, enable the SSH (MEMTEST(CS).ENn = 1), and:

1. Set the MCONTROL.SRAM_CLR
2. Start the initialization using MCONTROL.START
3. Clear the MCONTROL.START
4. Wait for the end of the initialization by polling the MSTATUS.DONE (can also be polled using the MEMDONE(CS) register) bit
5. Clear the MCONTROL.SRAM_CLR and leave the test mode (MEMTEST(CS).ENn = 0)

***Note**: This will trigger an UCE alarm. Therefore, the alarm reaction may need to be disabled before. Software can set ALMSRCS.OPENE before.*

With this initialization, the complete SRAM will be filled with ECC-correct zero value.

Clear the UCERR and OPERR flags set due to this operation. Re-enable ALMSRCS.OPENE if it was disabled before the test.

***Note**: For SRAMs described in chapter "Secure-sensitive memories and auto-initialization" enabling or disabling the SSH using the MEMTEST(CS) register takes time for the initialization to complete. Therefore software must wait for the corresponding MEMSTAT(CS).AIUn bits to be cleared, to ensure that this operation is complete.*

Security-sensitive memories and auto-initialization on page 5737

34.3.4.1.7 Reading a single memory location

The SSH can also be used to read the content of a single word. The RDBFLy register holds the content of a complete memory word and so it is possible to read all memory bits, including ECC bits. The necessary steps are:

***Note**: This will trigger an UCE alarm. Therefore, the alarm reaction may need to be disabled before.*

1. Enter memory test mode by setting MEMTEST(CS).ENn = 1
2. Initialize registers
   a. RANGE.RAEN:= 0 (range disabled = single address) and address to be read in RANGE.ADDR
   b. CONFIG0:= 1001_H (NUMACCS = 1_H, ACCSTYPE = 01_H (read))
   c. CONFIG1:= 0000_H (linear mode, non inverted pattern)
3. MCONTROL:= 0009_H (FAILDMP = 0, direction up, start): Start read operation. MSTATUS.DONE will be cleared now

4. MCONTROL:= 0008_H (clear START)
5. Wait for MSTATUS.DONE to be set again (poll the corresponding bit in the MEMDONE(CS))
6. Read RDBFLy register
7. Leave memory test mode by setting MEMTEST(CS).ENn = 0
8. Clear the UCERR and OPERR flags set due to this operation

34.3.4.1.8 Writing to a single memory location

The SSH can also be used to write the content of RDBFLy register to a single memory location. RDBFLy holds the contents of a complete memory word and so it is possible to write to all memory bits, including ECC bits. The necessary steps are:

***Note**: This will trigger an UCE alarm. Therefore, the alarm reaction may need to be disabled before.*

1. Enter memory test mode by setting MEMTEST(CS).ENn = 1
2. Initialize registers RDBFLy: = write data
   a. RANGE: = RAEN = 0 (range disabled = single address) and address to be written to in RANGE.ADDR
   b. CONFIG0: = 1000_H (NUMACCS = 1_H, ACCSTYPE = 00_H (write))
   c. CONFIG1: = 0000_H (linear mode, non inverted pattern)
3. MCONTROL: = 0009_H (FAILDMP = 0, direction up, start): Start write operation. MSTATUS.DONE will be cleared now
4. MCONTROL : = 0008_H (clear START)
5. Wait for MSTATUS.DONE to be set again (poll the corresponding bit in the MEMDONE(CS))
6. Leave memory test mode by setting MEMTEST(CS).ENn = 0
7. Clear the UCERR and OPERR flags set due to this operation

34.3.5 Resets and clocks in the VMTx, SSH and SRAM

The sections below provide details about the clocks and reset types affecting the VMTx, the SRAMs embedded in each module, and their surrounding SSHs.

34.3.5.1 Clock domains

The VMTx runs on the SPB clock. The interface between the VMTx and SSH runs on a clock which is always at a fixed divider of 1/2 times the SPB clock. The SRAM and the SSH logic registers, such as Finite State Machine (FSM), run at the module clock frequency, that is, the module where the SRAM is embedded in. The SSH register accesses and alarm forwarding still work correctly even if the system is running with a lower clock divider in the LPDIV mode (see SYSCCUCON0 CLOCK register description).

Table 1371 VMT, SSH and SRAMs clock domains

	Clock
VMTx	fSPB, Communication to SSH on fSPB/2 clock
SSH	Communication to VMTx on fSPB/2 clock, other SSH logic on module clock
SRAM	Module clock
Alarms	Propagated to SMU on fSPB/2 clock

34.3.5.2 Reset domains

There are different reset domains to be considered within the VMTx, SSH, and SRAMs.

Table 1372 VMTx, SSH and SRAM reset domains

Module/Register/Function	Reset domain
VMTx and alarm path VMTx<->SMU	Application reset
VMTx: Interface to SSH (including FFs in the interface path)	Application reset
SSH: ECCS, ALMSRCS registers and notification enable bits	Application reset
SSH: Alarm status flags (ECCD.CERR, UCERR, and MERR)	Application reset
SSH: ETRR/ERRINFO, FAULTSTS registers and ECCD.VAL	Warm PORST
SSH: Test related registers (MCONTROL, CONFIG0, CONFIG1, MSTATUS, RDBFLy, and RANGE)	Application reset
SRAM	Cold PORST

34.3.5.2.1 Alarm status after reset

If an alarm occurred, the system may perform a reset.

The alarm status bits in the ECCD register (CERR, UCERR and MERR) are cleared after an application reset.

However, the error status bits in ETRR, ERRINFO and FAULTSTS registers are still available for diagnostic purposes until the next power-on reset. They can only be cleared by software and are reset only with a warm PORST.

The alarm itself is also cleared with an application reset. This prevents a single alarm creating a reset loop.

34.3.6 MBIST algorithms

In order to check the integrity of the SRAM, an MBIST may be run by configuring the SSH.

The test type and parameters are programmed using the SSH registers CONFIG0 and CONFIG1, and certain parameters in the MCONTROL register.

Additional memory test algorithms are supported by the SSH, but are used in production test modes only.

34.3.6.1 Destructive MBIST

A destructive MBIST algorithm is implemented that offers a higher permanent hardware random fault diagnostic coverage than the former non-destructive inversion test (NDIT). The basic principle of operation is that the SSH hardware writes a known pattern into a specific memory location and reads it back. By comparing the read data with the expected value, faults in individual cells and memory logic can be found.

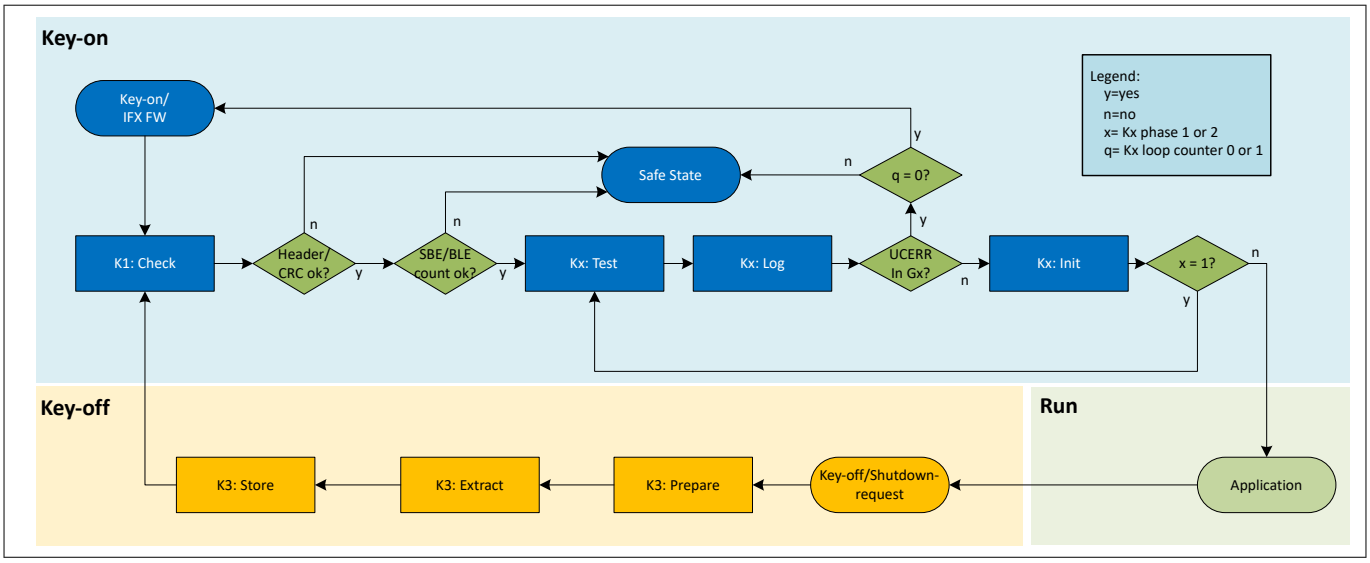

Figure 761 MBIST Cycle

The destructive MBIST is divided in two macro-phases:

- Key-on MBIST (K1 and K2)
- Key-off MBIST(K3)

The separation into macro-phases essentially addresses start-up time and load jump constraints, and is the first choice in case system start-up time is critical. Both key-on and key-off macro phases could be merged into a single consolidated flow if the system start-up time requirements allow it. Such procedure saves complexity induced by the data-transfer from key-on to key-off.

The key-on phase essentially focuses on identification of uncorrectable errors (UCERR); in case of occurrence, a retest cycle shall be initiated. Typically done by reset trigger and re-execution of MBIST, in order to distinguish soft from persistent fault. The existence of UCERR is regarded as serious degradation resulting in unavailability of the functions related to the affected memory.

Both key-on and key-off MBIST phases are executed from the Main-Ctrl-Core (typically CPU0) and need a Working RAM (WR) to temporarily store test relevant data. Since RAM access is blocked while the test is running, the WR needs to be tested separately. For this purpose, the key-on phase MBIST is divided into two sub-phases K1 and K2:

- K1 shall test at least the *Working-RAM of Main-Ctrl-Core* (WR)
- K2 all others (group G2 which consists of subgroups G2_1 and G2_2)

G1, G2_1 and G2_2

To provide better guidance into which memories are targeted by each test phase, the MCU memory instances are divided into three groups: G1, G2_1, and G2_2. The mapping of the memory instances to each memory group can be found under the chapter "SSH instances" in the VMT device specific section of this document.

In order to integrate considerations for cache enabling and secure-boot, K1 naturally combines test of TAG and DMA-RAMs, which are allocated to group G1. G2_2 contains SRAMs integrated to modules providing own ECC-encoding, G2_1 all others which are using Infineon ECC algorithm.

The key-on macro-phases K1 and K2 are both source and recipient of information with respect to key-off macro-phase K3. As mentioned before, the key-on phase focuses on detecting critical errors like UCERR. In case no critical errors are found, K1 and K2 are used to scan for non-critical permanent errors, that is, errors that do not have an impact on safety nor availability of the computing platform.

The result of this scan is a list of the memory instances containing non-critical errors that is provided as input to for K3. This list is provided in a data structure called FAILID which is explained with more details later in this chapter. K3 then takes the FAILID structure and performs a more detailed analysis on each of the memory instances to count and classify the non-critical errors.

This refined scan information is then passed from K3 to K1. Each K1 execution receives and checks the information provided by the previous K3 cycle in order to judge if the accumulated non-critical errors are above the tolerable threshold.

Micro-phases

The targets described above, explain the further split of macro-phases into micro-phases, namely:

- K1 holds a Check-Phase (K1: Check); interlinked with the result stored by K3 (K3: Store)
- K1 and K2 contains Test and Log phases (Kx: Test and Kx: Log)

The K3: Prepare micro-phase shown in the previous MBIST cycle figure reads in the FAILID data structure provided by the key-on phase to select the memory instances that need further analysis. The extraction phase K3: Extract then performs the detailed analysis of non-critical permanent errors that serves essentially two purposes:

- *Logging* of occurring fail patterns, that is, determination of error number and type for G1 and G2
- Identification of early SRAM degradation revealing as fast accumulation, relative to number of reset cycles and operating hours, of correctable hard errors. The thresholds for accumulated errors are specified in the product specific datasheet under the parameters Maximum number of acceptable single-bit errors (M_{SBE}) and Maximum number of bitline-oriented errors (M_{BLE})

In the case that during the next K1 execution the K1: Check phase detects a violation of the M_{SBE} or M_{BLE} thresholds, K1 has to transfer the MCU to a safe state. The maximum acceptable error thresholds are related to decreased robustness due to potential combination of hard errors with soft errors. It is derived from technology-specific base-failure rate and MCU-specific SRAM architecture.

Data storage

The data exchanged between K3: Store and K1: Check shall be stored in a way that its availability is ensured for the next key-on event, for example, by saving the FAILID structure in the EEPROM area at the end of K3: Store. Data to be provided from Kx: Log to K3: Prepare can alternatively be intermediately stored in RAM (MCU stays powered). In the latter case, to avoid interference from other software tasks, it is recommended to restrict the access to the selected RAM region, for example, by using the range-adjustable APU of DLMU.

In order to enable validation of respective data integrity, FAILID contains a header structure containing its Storage Address Location (SAL), a flag indicating its validity (V-flag), as well as CRC. Correct start-up, even in case of fails during programming cycle (for example, non-stable supply), can be assured by a redundancy approach for FAILID: Storage locations for FAILID might be foreseen twice (FAILID_ORIG/_COPY) with the V-flag (one in ORIG and one in COPY) being used to indicate the validity state.

Consequently, during all steps of an update, one of the copies is kept valid. This redundant storage strategy is however not mandatory: it is up to the system integrator to decide if it is worth the effort.

Implementation

Implementations of K1, K2, and K3 employ a destructive test-approach, that is, SRAM data content is overwritten by test pattern and read back/compared with expected value. In this sense, it does not distinguish between logical and ECC-bits, but provides full coverage for hard errors irrespective of bit-usage and SRAM architecture. Therefore, after the destructive testing is completed, the Kx: Init initialization phase is needed to bring the tested RAMs to an ECC-coherent state.

For the memory groups G1 and G2_1 the SSH can be used for the initialization as shown in the subchapter Initializing SRAMs. For memories in the group G2_2, the initialization can only be performed by software-based write operations. For certain functional blocks (for example PPU) this could be done later as part of their module initialization sequence and therefore not necessarily part of Kx: Init.

FAILID reference structure

…	…	…	…	…	…	…
CRC						

Figure 762 FAILID reference structure

The figure is a visual representation in table form of the contents and structure of the FAILID data structure. The fields colored with yellow are the ones provided by the K3: Store phase and saved to non-volatile memory. They consist of:

- Header: containing the SAL and the V-flag, where a V-flag value equal to $57B5327_H$ means valid while any other means invalid
- VMTj and MCi correspond to the indexes of the RAM instance as provided in the SSH instances table in the device specific section of this chapter
- #SBE and #BLE contain respectively the amount of single bit errors and bit-line errors found
- CRC contains the CRC checksum for the entire FAILID structure stored in non-volatile memory (yellow fields), of course excluding the CRC itself

The fields colored with green on the other hand, are used only temporarily by the K3: Extract phase and not saved after key-off. They consist of:

- Error-AddressX with X=0...9: local physical address to the specific RAM instance, not the system address. It is provided by the MBIST engine in the ETRR register whenever an error is found by the destructive test procedure
- FailPositionX[63:0] with X=0...9 contains the position of a failed bit within an address. For example, if the 6th bit of an address is found to be faulty, then this field's value would be 6_H
- FailMarkerX[15:0] with X=0...9 contains the type of error found: 0_H = no error, 1_H = SBE and 2_H = BLE

***Note**: Array of Error-Address, vectors for Failposition and FailMarker shall be initialized to 0_B.*

***Note**: The number of rows per RAM instance in the green portion of the FAILID data structure depends on the M_{SBE} datasheet parameter. See also step 5 of K3: Extract below.*

SSH instances on page 5825

34.3.6.2 MBIST cycle test phases

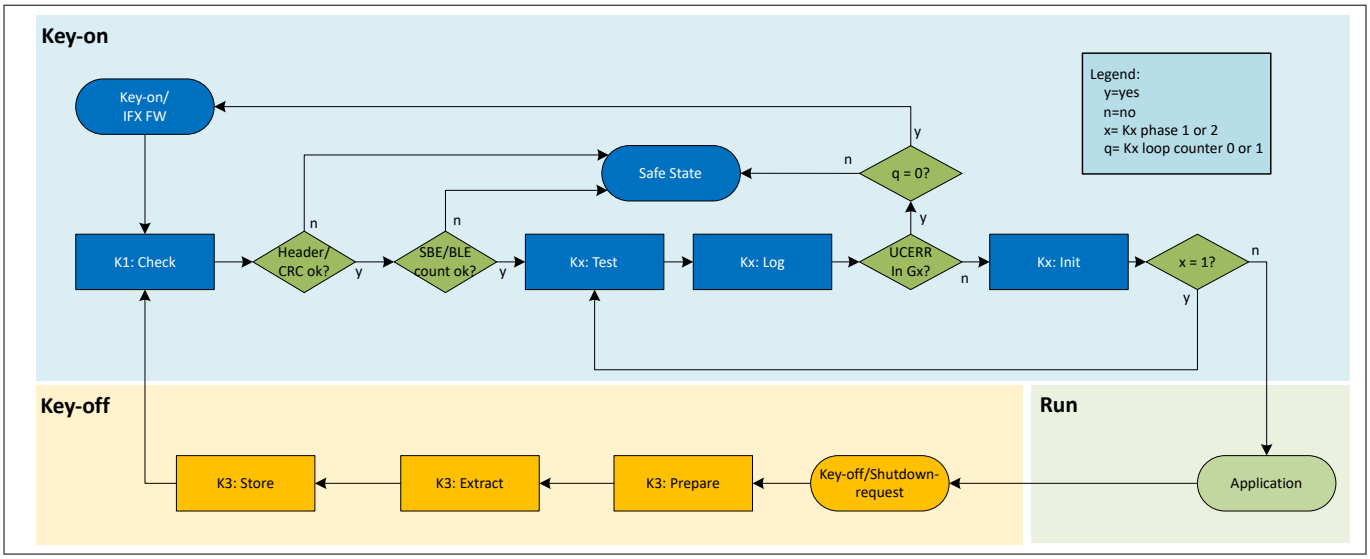

Figure 763 MBIST Cycle

The following sections explain with more detail the different test phases shown in the MBIST Cycle.

K1: Check

The main purpose of the first phase of key-on MBIST is evaluation of result of previous Key-off phase, in order to determine health status of the memory stack. This can be done as follows:

1. Read in the FAILID structure from its storage location in non-volatile memory and check CRC and Header contents:
   a. In case of a SAL or CRC mismatch, or V-flag is not equal to $57B5327F_H$ (that is, no valid information on HE is available), then a transition to safe-state shall be triggered

      ***Note**: Only in case both redundant structures (ORIG and COPY) fail the previous step, it shall be regarded as fail*

      ***Note**: An alternative to direct safe-state transition is immediate re-generation of FAILID within the Key-off cycle. The necessity of such a measure has to be decided in context of ECU architecture and application*

2. Add together the #SBE of each MCi to get the overall number of SBE in the MCU. Do the same for the #BLE entries
3. In case the added overall MCU SBE > M_{SBE} or BLE>M_{BLE} datasheet parameters, trigger transition to safe-state. Otherwise proceed to Kx: Test

***Note**: Steps for preparation of initial FAILID are described as part of K3: Store*

Kx: Test

For K1 the memory group G1 covers the priority group as required for setup of stack/CSA, Cache-enabling, and Secure Boot.

For K2 the memory group G2 covers the remainder of the MCU memories. The z and i indexes of VMTz and MCi respectively shall be taken from the SSH instances table in the device specific section of this chapter.

For all i in Gx:

***Note**: The following steps are performed at the clock frequency f_{BACK} in order to achieve maximum test-parallelism within DS-specified load-jump constraints. Therefore, the single steps below can be applied for all the memories within a memory group Gx at the same time.*

1. Set the corresponding bit-fields of the MEMTEST(CS) [i] = 1_B and check for MEMSTAT(CS) [i] == 0_B

   ***Note**: It is recommended to set testmode for all memories targeted by test in a single write operation to the respective MEMTEST(CS). Rationale: In case Auto-Data-Init/Partial-Erase has been activated (UCB0_17/18, namely, UCB_RTC_USERCFG) such proceeding will limit wait.*

   ***Note**: In order to avoid generation of spurious alarms (including forwarding to and capturing in SMU), it is recommended to disable their generation through ALMSRCS == 7_H. Alarm disabling will result in generation of miscellaneous alarm, which shall be cleared after completion of MBIST sequence*

2. Program March {w1,r1,w0,r0}: CONFIG0 = $400A_H$, CONFIG1 = 0003_H
3. Start Test by MCONTROL = 0001_H
4. Check for MSTATUS.DONE == 0_B, then set MCONTROL = 0000_H

   ***Note**: Former check can be replaced by short wait time (few cycles) before clearing of MCONTROL is performed*

5. Check for test being completed using MSTATUS.DONE == 1_B

   ***Note**: The test completion time is documented under the key-on tMBIST parameter in the datasheet.*

Kx: Log

1. Evaluate result using ECCD:
   - **a.** If UCERR==1_B, check counter q:
     1. q==0_B --> Increment q and trigger additional cycle (typically with reset) to exclude potential effect of Soft-Errors
     2. q==1_B --> Trigger transition to Safe State
   - **b.** If CERR = 1_B, store the VMTz and MCi indexes in the FAILID data structure
   - **c.** Store the FAILID data structure in a memory location for later access by the K3 test phase and assure its non-modification during application run-time (for example, protected RAM-Range)

     ***Note**: The Header, V-flag and CRC of the FAILID data structure are not mandatory at this stage.*

Kx: Init

1. For memory groups G1 and G2_1:
   - **a.** Set MCONTROL = 8001_H (bit-fields SRAM_CLR and START) and check for MSTATUS.DONE == 0_B
   - **b.** Then clear the START bit by setting the setting MCONTROL = 8000_H and check for test being completed with MSTATUS.DONE == 1_B
2. For ALL memories: MEMTEST(CS) [i] = 0_B and check for MEMSTAT(CS) [i] == 0_B

   ***Note**: Only after this step, functional access to memories-under-test is available. Alarm generation shall be re-enabled through ALMSRCS == 27_H*

3. For G2_2: Initialization shall be performed through the TriCore™ CPU instruction ST.D (Store Double-word) to avoid potential traps due to ECC errors. Alternatively, the RAM can be initialized with code or data copied from another location (for example with DMA)

   ***Note**: This step can also be performed at later time-point, for example, before PPU starts execution or before COM-Stack is ramped for GETH*

K3: Prepare

1. Read in the FAILID data structure in order to identify the memories which require further testing. In case the working RAM (WR), that is the RAM that holds the stack, variables, temporary data, and so on, is in the list, then principally two possibilities exist:
   a. Execute K3 on an alternate CPU different from the core which is associated with WR (here the corresponding alternate WR is assumed to be fault-free). This implies that the respective code needs to be executable on different CPUs (position-independent)
   b. Execute K3 on all memories but WR. Then migrate the respective data to different memory within the same CPU (for example, from DSPR to PSPR or DLMU) and test WR

K3: Extract

The purpose of this test phase is to perform a detailed analysis of non-critical single bit errors present in a RAM instance. The previous Kx: Test phase marks RAM instances containing at least one single bit error without any further details.

This detailed analysis allows to:

- Count the number of individual single bit errors
- Detect bitline-oriented errors

This is done by scanning through the whole memory range and collecting the location of each error found. If more than a certain number of error bits are located along the same bitline, then this is considered a bitline-oriented error. Otherwise they can be considered as single isolated errors. In order to detect bitline-oriented errors, details of the RAM architecture are required.

The figure shows an example of how the RAM architecture looks like. Each tower contains multiple bit columns and each bit column contains multiple bitlines. The multiplexer factor is the number of bitlines per bit column, however this does not play a role in this step. This is because there is a 1:1 mapping between each bitline inside the RAM and each individual bit in the MCi_RDBFLy registers, as shown in the figure, regardless of multiplexer factor. So for example, if the number of bitlines per tower (tower width) is equal to 32 and there are a total of 2 towers, 2x32=64 total bits of the MCi_RDBFLy registers are used to capture errors found during the test. Since each MCi_RDBFLy has a width of 16 bits, four of these registers are used in this example.

***Note**: The number of RDBFLys, number of towers per SSH, tower width can be found in the device specific part of the user manual.*

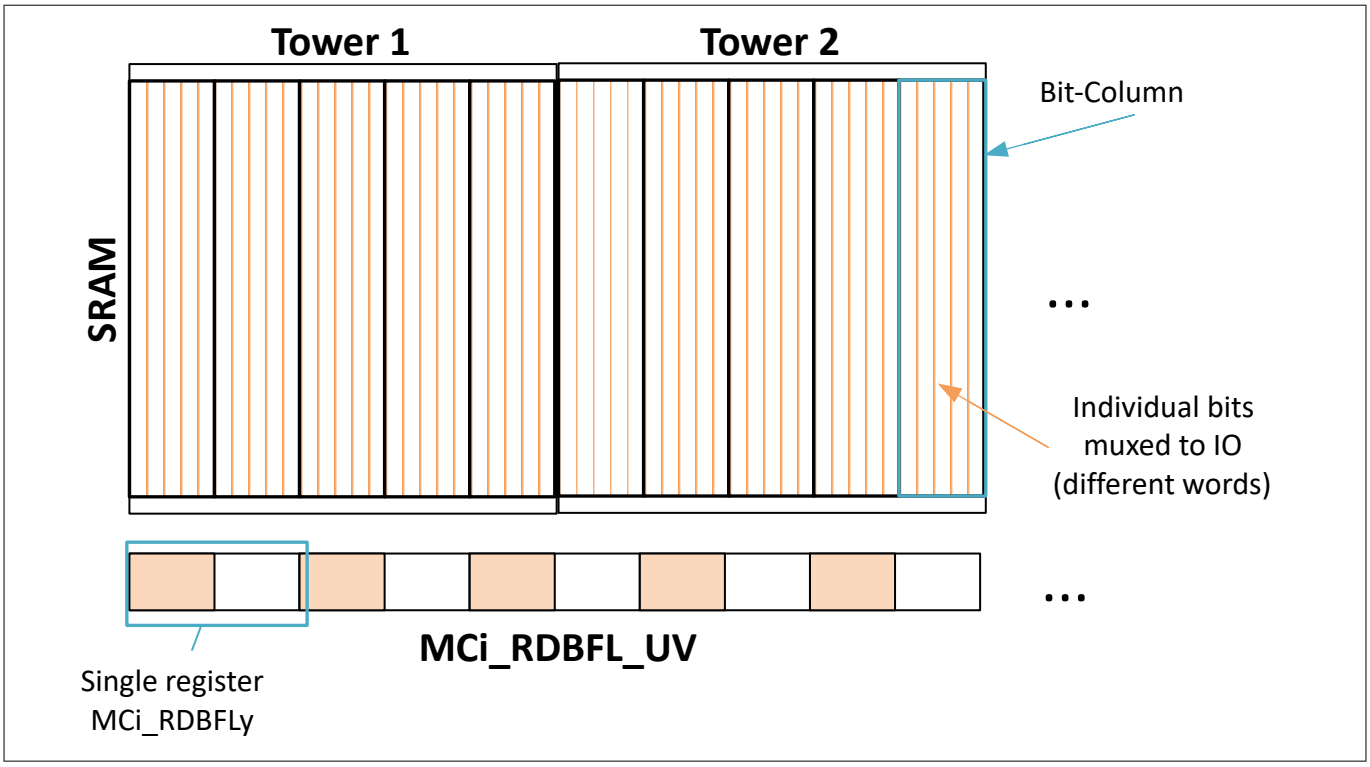

Figure 764 SRAM microarchitecture

Exemplary SRAM microarchitecture: Two macros 'Towers' including associated RDBFLy registers are shown, where RDBFLy_UV is the concatenation done by software of all RDBFLy. Upon execution of reads during MBIST execution, the XOR pattern between individual bits (stored in a tower) and expectation according to used March element are written to the RDBFLy registers. The number of register bits used by the MBIST test is determined by the number of towers and the tower width. The total number of available RDBFLy registers (and bits) could however be greater than that.

***Note**: The following steps shall be executed sequentially for each memory within FAILID. No parallel execution of memories in this step.*

For each memory instance in the FAILID data structure, a fail bitmap and an evaluation of the respective failure type needs to be established. For this purpose, the FAILID table loaded in the previous step is extended with the three green columns shown in the FAILID reference structure, containing the error address, its bitline position and the identified error type (Error-Address, FailPosition, and FailMarker respectively). The extraction is performed considering each RAM instance's microarchitecture and the following associated parameters: Tower Width (tw) and Tower Count (tc).

Steps to be performed are:

1. Set MEMTEST[i] = 1_B and wait for MEMSTAT[i] == 0_B

***Note**: In order to avoid generation of spurious alarms (including forwarding to and capturing in SMU), it is recommended to disable their generation through MCi_ALMSRCS == 7_H. Alarm disabling will result in generation of miscellaneous alarm, which shall be cleared after completion of MBIST sequence*

2. Program March {w1,r1,w0,r0}: CONFIG0 = $400A_H$, CONFIG1 = 0003_H

3. Enable MCONTROL.FAILDMP and start test by MCONTROL = 0201_H

***Note**: The test completion time is documented under the key-off tMBIST parameter in the datasheet.*

4. Check for MSTATUS.DONE == 0_B, then set MCONTROL = 0200_H and initialize the failbit counter FBC to zero
5. While MSTATUS.DONE is not equal to MSTATUS1_B, poll MSTATUS.FDA:
   a. If MSTATUS.FDA==1_B --> Bitmap data available:
      1. Increment failbit count FBC and temporarily store ETRR and *all* RDBFLy (associated with the SSH-under-test) to WR
      2. Concatenate all the RDBFLy (provides an 'unrolled view' RDBFLy_UV)
      3. Then the individual bits of RDBFLy_UV are allocated to the individual towers, through consideration of tower width as index-increment, that is, all bits with index [(t+1)*tw-1:t*tw] are to be evaluated to collect the fail position in tower t, with t=0...tc, found in the SSH instances subchapter of the device specific section of this functional block
      4. Consequently, the position of 1_B in this range is stored 8 bit-encoded to fail position[8(t+1)-1,8t] in FAILID
      5. This provides the SSH-internal error-address, as well as the tower-granular (muxed) failbit-positions. The latter are then marked by '1' (XOR with expected pattern) in the entries of the assembled SSHs fail-table
      6. If FBC ≤ M_{SBE}, then resume the test by setting MCONTROL = 0202_H. Otherwise run the MBIST to the end with FAILDMP disabled by setting MCONTROL = 0002_H
   b. Once MSTATUS.DONE == 1_B --> Evaluate failure-type from information stored to WR in previous step:
      1. Soft CE: No fail information available, that is, the memory has been mapped to FAILID due to a transient event during Kx: Test. Probability is very low to observe such case
      2. Bitline-oriented errors: If three or more entries showing the same bit-position in the same tower, the respective memory instance contains a bitline-oriented error, which shall be counted as such in FAILID (respective entry in FailMarker[2(t+1)-1,2t] is set to *2*)
      3. Hard individual CEs: If less than three entries in the SSHs fail-table (that is, entries with different ETRRs) have the same failbit-position in RDBFLy (allocated to same tower), all entries in the table shall be counted as individual errors (respective entry in FailMarker[2(t+1)-1,2t] is set to 1_B)
   c. Clear MEMTEST(CS) [i] = 0_B and wait for MEMSTAT(CS) [i] == 0_B

***Note**: Alarm generation shall be reenabled through ALMSRCS == 27_H*

K3: Store

This phase essentially focuses on removing temporary data, comparing with results from previous K3 executions stored in non-volatile memory, and finally updating FAILID in non-volatile memory if required; it is to be seen as prerequisite for next execution of K1: Check. Following steps are to be performed:

1. Number of bitline-oriented errors are determined by evaluating number of different Error-Address entries containing 10_B in FailMarker, that is, all entries marked with 10_B are associated with a singular BL-oriented fault
2. Number of SBE are determined by number of Error-Address entries with FailMarker equal to 01_B
3. The counted numbers are finally stored in the first row associated with the SSH under consideration as shown by the yellow color coding in the FAILID reference structure. All other rows are removed from the table
4. Consequently, the SBE and BLE counts are compared against the FAILID version currently stored in non-volatile memory, in order to check whether update of the latter is required (that is, table update shall be only performed upon increase of SBE/BLE). If this is case, the following steps shall be performed:
   a. Invalidate or erase (both resulting in invalid V-flag) FAILID_ORIG, recalculate CRC and store the updated fail information array together with V-flag to targeted SAL (during this step FAILID_COPY is assumed to be valid containing data from previous K3 cycle)
   b. In case update of FAILID_ORIG has been successfully completed, FAILID_COPY can be kept in its current state, considering that K1: Check is evaluating the first valid data structure, starting with

ORIG. COPY shall then be used for next required update (while invalidating V-flag of ORIG after completion of operation on COPY)

***Note**: The device shall be initially programmed with a valid FAILID information containing valid Header and CRC (in case duplication ORIG/COPY is used, pre-programming of one is sufficient).*

34.3.6.3 NDT for DLMU

There are applications that during the startup phase generate non-ASIL data before the execution of MBIST. This data is needed for later stages of the startup procedure and for higher layers of the software stack. For this purpose a mailbox (MB) RAM can be designated as storage location for this data. However, the destructive MBIST cannot be applied on the MB, as it would wipe out the previously stored data.

In case DLMU is used for mailbox purpose and is therefore excluded from destructive MBIST test sequence described above, a non-destructive test (NDT) can be executed on this memory. The latter (*MB*) shall be excluded from memory groups G1 and G2, and tested using the configuration described below. This can be done either as integral part of Kx: Test or also at a later point in time (for example, after Kx: Init, in order to save the mandatory initialization step before running the actual test).

***Note**: In this context, the MB RAM is used for non-ASIL data only. In case that storage of ASIL data in MB RAM is required, then additional measures against data corruption shall be applied, for example, appended CRC checksum.*

The NDT algorithm reads a word from the SRAM (data + ECC bits), inverts it and writes it back. If the ECC does not match the expected value when reading, an error is assumed and notified. The target pattern to be executed here is {r, w*, r*, w, r}, where r stands for read and w for write. An (*) symbol in this notation always indicates that the data during that access is inverted with respect to the original content in the RAM.

Before using the MB RAM, it must be initialized completely either by software or by using the SSH functionalities. This is necessary to ensure that all contents of the RAM are ECC coherent. Refer to the chapter "Initializing SRAMs" for instructions on how to initialize a RAM using the SSH functionality.

After this initialization step, the MB RAM is ready for use. At a later point in time, for example as part of Kx: Test, the actual NDT can be executed.

Testing steps:

1. Set MEMTEST(CS)[i] = 1_B and wait for MEMSTAT(CS)[i] == 0_B

   ***Note**: In order to avoid generation of spurious alarms (including forwarding to and capturing in SMU), it is recommended to disable their generation through ALMSRCS == 7_H. Alarm disabling will result in generation of misc. alarm, which shall be cleared after completion of MBIST sequence.*

2. Set CONFIG0 = 5015_H and CONFIG1= 5018_H
3. Set MCONTROL = 1_H, and check for MSTATUS.DONE == 0_B
4. Then set MCONTROL = 0_H and check for initialization being completed through MSTATUS.DONE == 1_B

Closure step:

1. Evaluate result using ECCD:
   a. If UCERR==1_B: Trigger transition to Safe State
   b. Otherwise proceed with disabling of MB's SSH: MEMTEST(CS)[i] = 0_B and check for MEMSTAT(CS)[i] == 0_B

      ***Note**: Alarm generation shall be reenabled through ALMSRCS == 27_H*

34.3.7 SRAM addressing

When considering SRAM addressing, different levels of addressing need to be considered. At the highest level, all SRAMs which appear on the overall system memory map could be potentially accessed via a portion of the system address space. This is the logical address space to access the SRAM as far as the system is concerned.

However, from the SSH point of view, this system level logical address cannot be seen, since the SSH is tightly coupled to the SRAM, and the system address translation or mapping occurs at a higher level before arriving at the SSH. Therefore, unless otherwise specifically mentioned, any “address” in this chapter does not correspond to any of the system address that is mentioned in the memory map chapter.

Within the SSH, the logical addresses increment linearly from 00_H until a maximum address depending on the size of the SRAM.

During normal system operation, the incoming address is directly input to the SRAM. This address at the input of the SRAM is also stored in ETRR register in case of any error. In order to access the error address location stored in the ETRR during normal functional mode, the same address can be provided to the RANGE.ADDR, with RANGE.RAEN = 0.

***Note**: For actual individual SSH reset values of RANGE, refer to the SSH instances table.*

34.3.8 Safety measures

Always refer to the device specific safety manual to find out which safety mechanisms of this functional block need to be considered for safety relevant applications.

The following chapter aims to provide a generic description of the safety measures.

There are a number of safety features that help to detect random hardware faults in the SRAM cells as well as periphery.

Random hardware faults in the data (data path as well as SRAM cell), address logic within the SRAM, and control logic within the SRAM are detected by safety mechanisms.

Combined safety notifications (alarms) are provided to the SMU separately for security and non-security related SSHs.

This section provides a short summary of these safety mechanisms and safety notifications. Additionally, some of these features may be explained in more detail in other sections.

34.3.8.1 Safety features

The safety features implemented in the SRAMs, SSH instances, and the VMTx are the following:

- Error detection and correction codes, logic and ECC monitoring
- Address error monitor
- SRAM multiplexer factor
- Error tracking registers
- Safety flip-flop implementation for critical register bits

34.3.8.1.1 SRAM error detection and correction (EDC/ECC)

EDC (Error detecting code) or ECC (Error correcting code) is available for the stored data of selected SRAMs. Refer to the subchapter "SSH instances" in the device specific configuration chapter of this manual to find out which SRAMs feature EDC or ECC.

During a WRITE operation, checksum bits (ECC bits) for the input data word are generated using an ECC encoder. These bits are stored in the SRAM along with and additionally to the data word itself.

During a READ operation, an ECC decoder compares the read data word and ECC bits to the expected ECC value. If due to any random hardware failure or soft error for example, the data word stored in the SRAM was corrupted, then there will be a mismatch compared to the expected ECC value. This is notified as an alarm and the corresponding bits in the error flag register are set.

Two different kinds of ECC codes are used in the system for different SRAMs: SECDED codes and DED codes.

- SECDED codes can detect: a double bit error (DBE), as well as correct a single bit error (SBE). That is, the Hamming distance of these codes is four
- DED codes can detect up to a double bit error, but cannot correct any error

The column “ECC Type” in the tables under the subchapter "SSH instances" in the device specific configuration chapter of this manual show which type of ECC code is used for each SRAM.

There are two error notifications sent to the SMU from the ECC decoder through the CE and UCE alarms. For SRAMs with SECDED ECC these are correctable error event (that is, SBE detected and corrected) alarm and uncorrectable error event (that is, DBE detected) alarm. For SRAMs with DED ECC, there is only one error notification and this is notified by the DBE error and UCE alarm.

SBE notification (depending on ECCS.ECE, forwarded as CE alarm or UCE alarm) is enabled by setting ALMSRCS.SBE = 1.

DBE notification (forwarded as UCE alarm) as well as tracking in the ETRR/ERRINFO is enabled by setting ALMSRCS.DBE = 1.

***Note**: The ECCS.CENE, UCENE, and TRE bits act as a further global enable and have to be set for the ECC alarm notifications to be sent to SMU as well as to enable error tracking in the ETRR/ERRINFO. Please refer to the chapter "Safety notifications" for more details.*

The number of ECC words in a SRAM tower is defined by the ECC granularity, described in the SSH instances table in the device specific configuration chapter.

For example: An ECC granularity of two implies that there are two ECC words per physical SRAM block.

In the product family most SSHs with SECDED capability are equipped with a monitor to allow for fault detection within the ECC encoders and decoders. A detected fault is forwarded as UCE alarm (FAULTSTS.OPERR[4] and FAULTSTS.OPERR[5]).

Some SSHs are not equipped with a monitor for ECC encoders and decoders. Refer to the section "SSH functionality exceptions" in the device specific configuration chapter for more information.

SSH instances on page 5825

34.3.8.1.2 Address error monitor

Similar to how the ECC helps to monitor errors in the data, the address error monitoring mechanism helps to detect failures in the address generation logic within the SRAMs.

An error in the address generation within the SRAM can lead to:

- A valid input address selecting no wordline/bitline
- A valid input address selecting multiple wordlines/bitlines
- A valid input address selecting a wrong wordline/bitline
- A valid input address selecting a non-existing (for example out of range) wordline/bitline

All the above SRAM failure modes are detected by the address error monitor.

Whenever an error is detected by the address error monitor, an alarm is sent to the SMU.

The address error detection, tracking and notification is enabled by setting ALMSRCS.ADDRE, and the alarm is forwarded as UCE alarm.

If the address error detection is enabled (ALMSRCS.ADDRE = 1) and an error is detected, then it is tracked in the ETRR and ERRINFO registers (ERRINFO.ADDRERR is set). Please note that the ECCS.UCENE and TRE bits act as a further global enable and have to be set for the address error alarm notifications to be sent to SMU as well as to enable error tracking in the ETRR/ERRINFO.

34.3.8.1.3 SRAM multiplexer factor

In order to reduce the probability of a single random hardware fault (for example, an alpha particle strike or contact fail) causing more than a single-bit error, the bits in each logical data word are interleaved by a certain factor (4, 8, or 16). This means, two consecutive bits in a logical data word are actually physically 4, 8, or 16 bits apart. The multiplexer factor used in each SRAM is mentioned in the SSH instances table.

34.3.8.1.4 Error tracking registers

The error tracking registers store the address (ETRR) and the corresponding type (ERRINFO) of errors in the SRAM.

Error tracking is globally enabled by setting ECCS.TRE. Tracking of individual error types (DBE, ADDRE) can be enabled or disabled with the corresponding bits in the ALMSRCS register.

***Note**: The tracking of single bit errors is not implemented.*

Error tracking

It is possible for the software to track the error type and the address in which it occurred. The ECCS.TRE enables the tracking of the address and type of a detected error.

***Note**: The address corresponds to the local SRAM address. Refer to the chapter "SRAM addressing" for more details.*

***Note**: The tracking capabilities are reduced for some SSHs. Refer to the device specific configuration chapter for more information.*

Whenever address tracking is enabled, the ETRR contains the physical address of the first detected error. The ECCD.VAL is a bit field associated with the ETRR register. When the ETRR register contains a valid error address, the ECCD.VAL bit is also set. The ERRINFO register contains the error type (uncorrectable or address error) at the address in the ETRR register entry.

Software can clear the ECCD.VAL and the ETRR and ERRINFO registers by setting the tracking clear bit, ECCD.TRC. Only the first error after register clear is tracked. Errors happening afterwards do not overwrite the content of the ETRR and ERRINFO registers.

Related information

SRAM addressing on page 5754

34.3.8.1.5 Safety flip-flops

Certain critical registers have to be protected against soft errors changing their values. Some flip-flops are implemented in the VMTx itself while others are part of each SSH instance.

The safety flip-flops (SFF) in the VMTx report errors directly to the SMU. The SFFs in the SSH report errors through the UCE alarm and the status through FAULTSTS.OPERR[2].

Self testing of the SSH SFFs is triggered through the SFFD bit. This bit is cleared when the test is complete. The FAIL status from the test is notified through FAULTSTS.MISCERR[0] - but this does not trigger an ME alarm.

34.3.8.2 Safety notifications

The error notifications from all security and non-security related SRAMs/SSHs in the system can be reported to the Safety Management Unit (SMU). The SMU may be programmed to initiate appropriate action.

As shown in the diagram below, each SSH provides the following alarms to the VMTx:

- Correctable Error (CE) Alarm - Status through ECCD.CERR bit
- Uncorrectable Error (UCE) Alarm - Status through ECCD.UCERR bit
- Miscellaneous Error (ME) Alarm - Status through ECCD.MERR bit

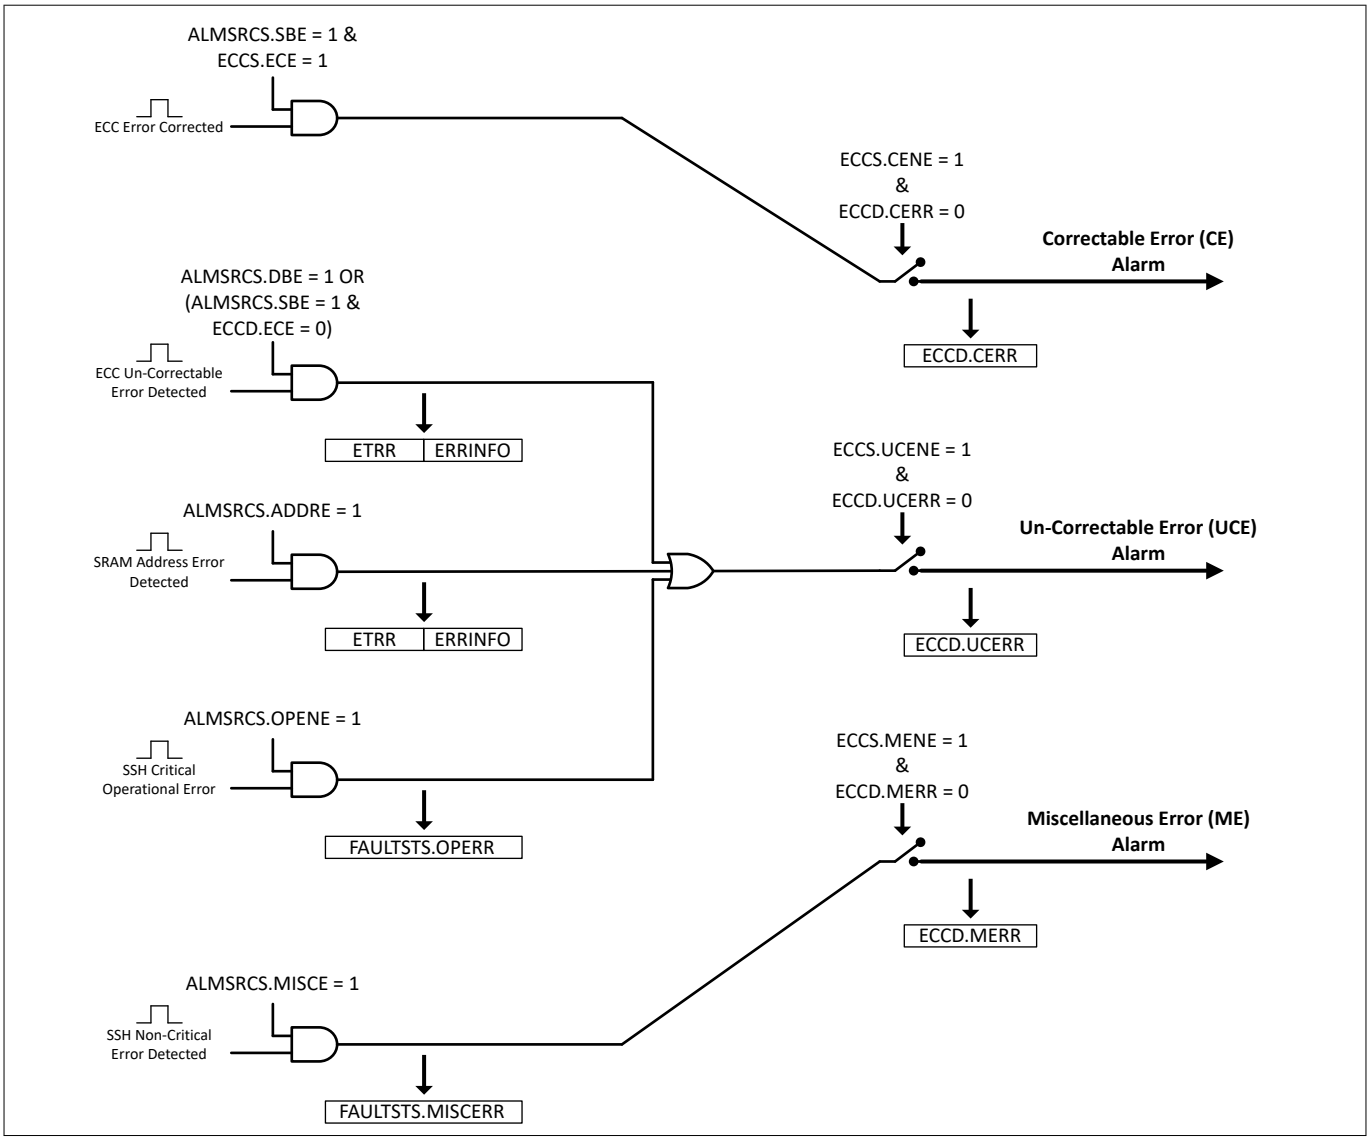

Figure 765 Alarms and error detection enabling (ECCS.TRE assumed to be set)

Alarms of the same type (CE, UCE and ME) originating from all SSH instances are merged together with an OR-gate in the VMTx (separately for security and non-security related SSHs) and then forwarded to the SMU as a single alarm. Software can check CEALARM(CS), UCEALARM(CS) and MEALARM(CS) registers to check which SSH caused the alarm.

When an alarm occurs, the corresponding *ERR bit in the ECCD register is set. No new alarms of the same type are forwarded as long as this bit remains set. Therefore, once an alarm occurs, the software shall clear the corresponding *ERR bit in order to enable forwarding of further alarms of the same type.

Normally, there is a time window of multiple clock cycles from when an alarm event occurs (that is, ECCD.*ERR is set) until the software reacts and clears the flag to enable forwarding of additional alarms. During this time window, additional new errors corresponding to the same alarm type may occur. For any such new event, no new alarm is generated.

Even if the new hardware event occurs exactly at the same cycle as the software clear event takes effect - the ECCD bits are cleared and a new alarm is not generated.

Table 1373 SSH safety notifications summary

Alarm	Errors or events mapped	Enable	Software handling/clearing
CE	- ECC Correction Event Occurred	ECCS.CENE = 1 and ECCS.ECE = 1 and ALMSRCS.SBE = 1	ECCD.CERR has to be cleared to forward further CE alarms
UCE	-ECC Uncorrectable Event Detected -Address Error Detected -Error Critical for SSH Operation Detected (including Critical SFF Errors)	ECCS.UCENE = 1 and (ALMSRCS.DBE = 1 or (ECCS.ECE = 0 and ALMSRCS.SBE = 1) or ALMSRCS.ADDRE = 1 or ALMSRCS.OPENE = 1)	ECCD.UCERR has to be cleared to forward further UCE alarms. The errors and status are always tracked in the ETRR, ERRINFO, and FAULTSTS registers independent of the value of UCERR
ME	- Less Critical SFF Errors (Enable Bits in ECCS, ALMSRCS) - Disabling of alarm notifications - Disabling of safety mechanisms	ECCS.MENE = 1 and ALMSRCS.MISCE = 1	ECCD.MERR has to be cleared to forward further ME alarms

34.3.8.2.1 Alarm handling

There are three alarms from each SSH and different events/errors are mapped to each alarm. Each alarm is enabled by the corresponding enable bit in the ECCS register (that is, ECCS.CENE, UCENE, and MENE).

When an alarm occurs, the corresponding status flag in the ECCD register is set (that is, ECCD.CERR; UCERR, and MERR).

For the events mapped to each alarm type, there are separate enable bits in the ALMSRCS register (all enabled by default).

For DBE error event and address faults (ADDRE) - the status of the error can be obtained from the ETRR and ERRINFO registers (including ECCD.VALID bits).

For safety reasons, some operational faults are detected which affect the normal operation or access to the SRAM (for example, SSH gets accidentally enabled, auto-data-init gets triggered). These are also notified through the UCE alarm, and can be enabled from the ALMSRCS register OPENE bit (Operational Error Notification Enable). Refer to the tables “Mapping of errors to FAULTSTS.OPERR and UCE alarm” and “Mapping of errors to FAULTSTS.MISCERR and ME alarm” in the "Error mapping" chapter of this manual for detailed information on error mapping.

Attention: The VMTx clock has to be enabled via the CLC register of the VMTx to forward any SSH alarm.

Certain faults do not directly impact the usage of the SRAM, but if left latent, could potentially have a serious effect. For example, the ECC or address error notification enable bits or the alarm enable bits get flipped due to a soft error. Such error notifications are enabled by the ALMSRCS.MISCE bit.

Diagnostics

When an alarm is raised by a SSH, the software has to check multiple registers to diagnose the cause of the fault.

ECCD.CERR, UCERR, and MERR bits give the overall status of which alarm occurred.

ETRR and ERRINFO registers store the address and the fault type of a fault in the SRAM (that is, DBE or ADDR error). FAULTSTS register bits store the status of other faults in the SSH itself which are mapped to UCE or ME alarm.

All the error status bits (ETRR, ERRINFO, FAULTSTS, and ECCD.VAL) are preserved until a power-on reset. The alarm status (ECCD.CERR, UCERR, MERR, and SERR) are cleared on an application reset.

Software can clear the bits by writing to them (when specified) or by setting the ECCD.TRC bit as appropriate.

***Note**: The VMTx needs three fSPB/2 clock cycles (6 fSPB cycles) to process SSH alarms.*

Error mapping

Both the UCE and the ME alarms have multiple events mapped to them. These events are separated in the design in such a way that the underlying hardware logic that can potentially cause the fault is covered as much as possible.

The OPERR bit field in the FAULTSTS register stores the status of various errors critical to SSH or SRAM operation.

Table 1374 Mapping of errors to FAULTSTS.OPERR and UCE alarm

Error status bit	Error description during normal application run	Hints for software reaction for recovery
FAULTSTS.OPERR[0]	SSH enabled. Functional access to SRAM is disabled	Perform an application reset
FAULTSTS.OPERR[1]	Auto-data-init or partial erase (caches) was triggered, resulting in overwriting of SRAM data	Perform an application reset
FAULTSTS.OPERR[2]	Safety flip-flop error detected in one of the registers. After a self test triggered by ECCS.SFFD, this error has to be taken into account together with FAULTSTS.MISCERR[0]	Perform a system reset. - Initialize the SRAM and SSH registers - Trigger a safety flip-flop self test via ECCS.SFFD. - Check that the test does not report a fail (FAULTSTS.MISCERR[0]). If the error still persists and cannot be cleared, a warm PORST has to be issued before performing the initialization and safety flip-flop self test
FAULTSTS.OPERR[3]	MBIST FSM got triggered, test multiplexers got enabled in the data path, or some other random hardware failure caused data in the SRAM to be overwritten or corrupted by a part of SSH logic	Perform an application reset
FAULTSTS.OPERR[4]	A mismatch occurred between one of the outputs of the ECC encoder and the ECC monitoring encoder	Perform an application reset
FAULTSTS.OPERR[5]	A mismatch occurred between one of the outputs of the ECC decoder and the ECC monitoring decoder	Perform an application reset

Please note:

- For FSI, a system reset is required
- For SCR RAMs, a cold PORST is required

The MISCERR bit filed in the FAULTSTS register stores the status of various errors which may not be directly critical for SSH or SRAM operation, but if left latent, may result in a critical failure in the future. One example is unintended deactivation of the ECC due to a bit-flip.

Table 1375 Mapping of errors to FAULTSTS.MISCERR and ME alarm

Error status bit	Error description during normal application run	Proposed software reaction for recovery
FAULTSTS.MISCERR[0]	This bit can be set only after the software has triggered a safety flip-flop self test via the ECCS.SFFD bit. If the test detected an error and the test failed, this bit is set. The ME alarm is not triggered in this case	Perform a system reset. - Initialize the SRAM and SSH registers - Trigger a safety flip-flop self test via ECCS.SFFD. - Check that the test does not report a fail (FAULTSTS.MISCERR[0]). If the error still persists and cannot be cleared, a warm PORST has to be issued before performing the initialization and safety flip-flop self test
FAULTSTS.MISCERR[1]	Any of the alarm notifications of UCENE or CENE got disabled (that is, one or more of the bits CENE or UCENE in the ECCS register went from 1 to 0) ***Note:*** *ECCS.MENE is protected by a safety flip-flop.*	Re-initialize SSH registers (ECCS)
FAULTSTS.MISCERR[2]	Any of the safety mechanisms got disabled (that is, ECE, TRE, SBE, DBE, ADDRE, OPENE) was set from 1 to 0 ***Note:*** *ALMSRCS.MISCE is protected by a safety flip-flop.*	Re-initialize SSH registers (ECCD, ALMSRCS)
FAULTSTS.MISCERR[3]	Access to a non-existing register in an existing SSH instance	Provide a valid address (that is, the address of a register that does exist in an SSH instance)
FAULTSTS.MISCERR[4]	An ongoing VMTx-SSH communication was aborted due to a module reset of the IP where the relevant SSH is embedded	

Error injection and alarm triggering

To ensure proper behavior of safety related software, it may be required to inject errors and trigger different safety notifications.

In order to trigger ECC errors (status denoted by ERRINFO.DBERR), the ECCMAP bits may be used. When ECCMAP is not equal to 0, then either data or ECC bits alone can be accessed. Using this feature, single or double bit soft errors may be introduced in the SRAM.

***Note**: When using ECCMAP to inject errors for Non-Destructive MBIST Test (NDT), the errors shall be injected before the NDT. ECCMAP shall set back to zero before starting and during the NDT.*

The address errors (status denoted by ERRINFO.ADDRERR) may be triggered by setting ECCS.SFLE, which can force an error into the address by flipping one address bit.

The CE and UCE alarms may be triggered by injecting an ECC or address error.

In order to trigger an ME alarm for test purposes, any of the safety notifications can be simply disabled. This will trigger an ME alarm.

34.4 Registers

34.4.1 Register overview - access mode glossary

Table 1376 Register overview - access mode glossary

Keyword	Description
CSP	Access protection using PROT register PROTCSP.
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-PCS	Protection group consisting of registers ACCENCS_WRA, ACCENCS_WRB, ACCENCS_RDA, ACCENCS_RDB, ACCENCS_VM, ACCENCS_PRS.
PCS	Access protection using *APU-PCS* registers.
APU-PNOM	Protection group consisting of registers ACCENNOM_WRA, ACCENNOM_WRB, ACCENNOM_RDA, ACCENNOM_RDB, ACCENNOM_VM, ACCENNOM_PRS.
PNOM	Access protection using *APU-PNOM* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
STP	Access only during start-up, before start-up protection is set (SMM_STCON.ST_PROT=1).
32	Access only when using 32-bit width.

34.4.2 Registers overview - VMT (ascending offset address)

Table 1377 Registers overview - VMT (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write

34.4.3 Clock control register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 00000_H

Clock control register Reset values see: Table 1378

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** When CLC.DISS=1_B, registers CLC, ID, PROTE, PROTSE, PROTCSP, ACCENNOM and ACCENCS are still accessible. Accesses to other VMT registers are not executed and will result in a bus error. 0_B Module clock is enabled 1_B Module clock is disabled
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved, write 0**

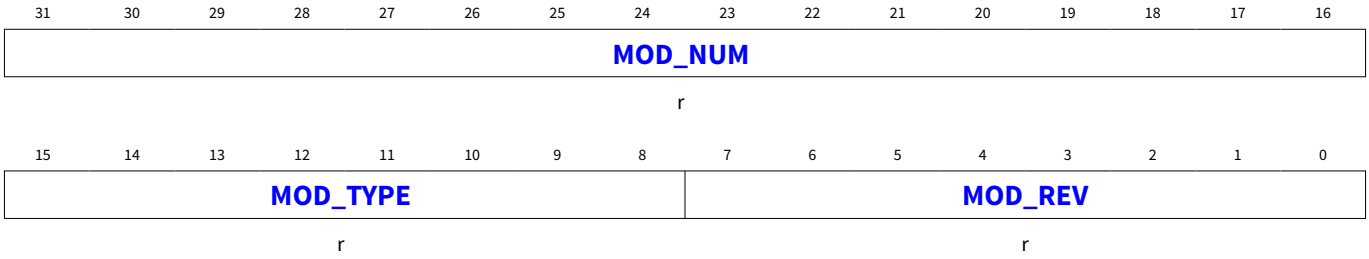
Table 1378 Reset values of CLC

Reset type	Reset value	Note
Application Reset	0000 0003$_H$	
After Boot-FW Value	0000 0000$_H$	Value installed by Boot Firmware.

34.4.4 Module identification register

ID Offset address: 00008$_H$

Module identification register PowerOn Reset value: 00C5 C013$_H$



Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to C0$_H$.
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number.

34.4.5 PROT register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 00020_H

PROT register endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0												SWEN	STATE		
r												w	rwh		

Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection Set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.

(table continues...)

(continued)

Field	Bits	Type	Description
PRSEN	23	rw	**Protection Set definition Enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; must be written as 0.

Table 1379 Access mode restrictions of PROTE sorted by descending priority

Mode name	Access mode		Description
PROT_OWNER and write 1 to .**SWEN**	rwh	STATE	PROT owner can modify the PROT state (for allowed and valid transitions)
PROT_OWNER and write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	PROT owner can modify the existing PROT owner
SECURE_MASTER and write 1 to .**SWEN**	rwh	STATE	Secure master can modify the PROT state (for allowed and valid transitions)
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

34.4.6 PROT register safe endinit

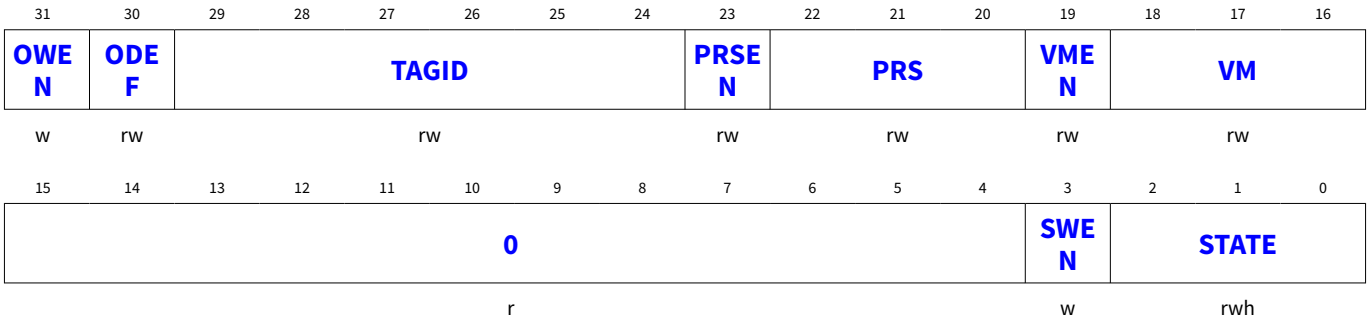
The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 00024_H

PROT register safe endinit Application Reset value: $0000\ 0000_H$

34 Volatile Memory Test (VMT)



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection Set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection Set definition Enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; must be written as 0.

Table 1380 Access mode restrictions of PROTSE sorted by descending priority

Mode name	Access mode		Description
PROT_OWNER and write 1 to .**SWEN**	rwh	STATE	PROT owner can modify the PROT state (for allowed and valid transitions)
PROT_OWNER and write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	PROT owner can modify the existing PROT owner

0	31:8	r	**Reserved** Read as 0; must be written as 0.

34.4.12 ACCENNOM VM access enable register

This register defines which virtual machine encodings are enabled or disabled for accesses to the access protected region. There is one RDx and WRx bit for each VMx.

ACCENNOM_VM Offset address: 00050_H

ACCENNOM VM access enable register Application Reset value: $00FF\ 00FF_H$

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
AIUn (n=0-31)	n	rh	**Autoinitialization of Cache Partition Underway n** This bit indicates whether an automatic data initialization has been triggered by a change of state of MEMTEST.ENn or MEMMAP.ENn and whether the initialization has completed. 0_B SSHn is not running an autoinitialization. 1_B SSHn is running an autoinitialization.

34.4.23 Nominal memory test done status register

Each bit in the memory test done status register MEMDONE reflects the status of the MSTATUS.DONE bit in the corresponding SSH.

It notifies when a test is finished. It is 0 while a test is running and set to 1 again by hardware once the test is finished. This only happens if MCi_MCONTROL.START is reset by software first.

MEMDONE Offset address: $0008C_H$

Nominal memory test done status register Application Reset value: $FFFF\ FFFF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
DONEn (n=0-31)	n	rh	**Memory Test Done Status n** This bit indicates whether an SRAM test is underway. 0_B Test is running. 1_B Test is finished.

34.4.24 Nominal memory test FDA status register

Each bit in the memory fail dump available status register MEMFDA reflects the status of the MSTATUS.FDA bit in the corresponding SSH.

MEMFDA Offset address: 00090_H

Nominal memory test FDA status register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
FDAn (n=0-31)	n	rh	**Memory Test FDA Status** This bit indicates whether Fail Bit Map data are available for read out. The value of this bit is only reliable if the corresponding MEMDONE bit is set to '1'. 0_B SSHn fail dump data not available. 1_B SSHn fail dump data available.

34.4.25 Nominal SSH CE alarm register

Each bit in the SSH CE alarm status register CEALARM reflects the status of the CE alarm signal of the corresponding SSH.

CEALARM Offset address: $000A4_H$

Nominal SSH CE alarm register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
CEALMn (n=0-31)	n	rh	**SSH CE Alarm Occurred** This bit indicates whether a CE alarm has been triggered by the corresponding SSH. 0_B SSHn ECCD.CERR = 0. 1_B SSHn ECCD.CERR = 1.

34.4.26 Nominal SSH UCE alarm register

Each bit in the SSH UCE alarm status register UCEALARM reflects the status of the UCE alarm signal of the corresponding SSH.

UCEALARM Offset address: 000A8$_H$

Nominal SSH UCE alarm register Application Reset value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UCEALM31	UCEALM30	UCEALM29	UCEALM28	UCEALM27	UCEALM26	UCEALM25	UCEALM24	UCEALM23	UCEALM22	UCEALM21	UCEALM20	UCEALM19	UCEALM18	UCEALM17	UCEALM16

rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
UCEALMn (n=0-31)	n	rh	**SSH UCE Alarm Occurred** This bit indicates whether an UCE alarm has been triggered by the corresponding SSH. 0_B SSHn ECCD.UCERR = 0. 1_B SSHn ECCD.UCERR = 1.

34.4.27 Nominal SSH ME alarm register

Each bit in the SSH ME alarm status register MEALARM reflects the status of the ME alarm signal of the corresponding SSH.

MEALARM Offset address: 000AC$_H$

Nominal SSH ME alarm register Application Reset value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
AIUn (n=0-31)	n	rh	**Autoinitialization of Cache Partition Underway n** This bit indicates whether an automatic data initialization has been triggered by a change of state of MEMTESTCS.ENn or MEMMAPCS.ENn and whether the initialization has completed. 0_B SSHn is not running an autoinitialization. 1_B SSHn is running an autoinitialization.

34.4.31 Cyber-secure memory test done status register

Each bit in the memory test done status register MEMDONECS reflects the status of the MSTATUS.DONE bit in the corresponding SSH.

It notifies when a test is finished. It is 0 while a test is running and set to 1 again by hardware once the test is finished. This only happens if MCCSi_MCONTROL.START is reset by software first.

MEMDONECS Offset address: $000C0_H$

Cyber-secure memory test done status register Application Reset value: $FFFF\ FFFF_H$

Field	Bits	Type	Description
MEALMn (n=0-31)	n	rh	**SSH ME Alarm Occurred** This bit indicates whether an ME alarm has been triggered by the corresponding SSH. 0_B SSHn ECCD.MERR = 0. 1_B SSHn ECCD.MERR = 1.

34.4.36 MC i Nominal configuration register 0

The bits in the MCONTROL and CONFIG0/1 registers can be used to control and program any march and hammer sequences. All bits concerning these test are concentrated here. All bits do not change during a test run. Setting MCONTROL.START will start the tests defined here. MSTATUS.DONE is reset at the beginning of a test and set after completion once MCONTROL.START is cleared by software. If no legal operation was defined in CONFIG1.AG_MOD nothing will be done but the handshake of MCONTROL.START and MSTATUS.DONE is carried out.

The reset values of the CONFIG0/1 and MCONTROL registers will perform a {↑(w0,r0)} operation (direction up, write 0 to all cells and check for 0) which initializes the whole memory with 0 and checks the contents if MCONTROL.START is set. This is the start sequence of many tests.

MCi_CONFIG0 (i=0-31) Offset address: 01000$_H$+i*200$_H$

MC i Nominal configuration register 0 Application Reset value: 0000 2002$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NUMACCS				0				ACCSTYPE							
rw				r				rw							

Field	Bits	Type	Description
ACCSTYPE	7:0	rw	**Access type** This field specifies the type of access which is being performed to each single address in the current marching element. ACCSTYPE[n] specifies the n-th access of the marching element. 0_B write access 1_B read access
NUMACCS	15:12	rw	**Number of accesses per address** This field specifies the total number of accesses which are being performed to each single address in the current marching element. Allowed values: 0-8 (Due to size limitation of CONFIG0.ACCSTYPE and CONFIG1.ACCSPAT fields). If NUMACCS=0 no access will be performed. If NUMACCS > 8, 8 accesses will be performed.
0	11:8, 31:16	r	**Reserved** Read as 0; must be written as 0.

34.4.37 MC i Nominal configuration register 1

MCi_CONFIG1 (i=0-31) Offset address: $01004_H+i*200_H$

MC i Nominal configuration register 1 Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
AG_MOD				SELFASTB				ACCSPAT							
rw				rw				rw							

Field	Bits	Type	Description
ACCSPAT	7:0	rw	**Access Pattern** When AG_MOD selects any test other than the non-destructive test, this field specifies directly the bit pattern (i.e. '0' or '1') which is being used for an access to each single address in the current marching element. ACCSPAT[n] specifies the n-th access of the marching element. These patterns are toggled according to MCONTROL.BITTOG and MCONTROL.ROWTOG. When AG_MOD selects the non-destructive test: Program 0 when the previous read access was with normal data; and 1 when the previous read was with inverted data. Note: When considering the previous read access, consider that the last access is a previous access to the first, as a 'wrap around'. Refer to section on non-destructive test for more details on how to program these bits.
SELFASTB	11:8	rw	**Select Fast Bit** Reserved Read as 0; must be written as 0.
AG_MOD	15:12	rw	**Address Generator Mode** These bits enable the special hardware for performing the more complex addressing schemes. In case RANGE.RAEN (range enable) is set to 0 (single access) linear address mode has to be selected and NUMACCS set to 1. 1_H-4_H, 8_H, and A_H are reserved. 0_H run the test with linear address generation 5_H run the non-destructive test. The march elements, direction and backgrounds are defined by other settings in CONFIG0/1 and MCONTROL. For this test, the SRAM has to be pre-initialized with valid content (i.e. with ECC correct data). Unlike a normal MBIST march test, this test uses the ECC itself to find errors in the data. The result of the test is not reflected via MSTATUS.FAIL - instead, the detected ECC errors are tracked in the ETRR and ERRINFO registers, and additionally ECCD:*ERR bits if the alarm notifications are enabled. **others,** only the handshake of START and DONE is carried out.
0	31:16	r	**Reserved** Read as 0; must be written as 0.

34.4.38 MC i Nominal MBIST control register

The bits in the MCONTROL and CONFIG0/1 registers can be used to control and program any march and hammer sequences. All bits concerning these test are concentrated here. All bits do not change during a test run. Setting MCONTROL.START will start the tests defined here. MSTATUS.DONE is reset at the beginning of a test and set after completion once MCONTROL.START is cleared by software. If no legal operation was defined in CONFIG1.AG_MOD nothing will be done but the handshake of MCONTROL.START and MSTATUS.DONE is carried out.

The reset values of the CONFIG0/1 and MCONTROL registers will perform a {↑(w0,r0)} operation (direction up, write 0 to all cells and check for 0) which initializes the whole memory with 0 and checks the contents if MCONTROL.START is set. This is the start sequence of many tests.

MCi_MCONTROL (i=0-31) Offset address: $0100C_H+i*200_H$

MC i Nominal MBIST control register Application Reset value: $0000\ 0008_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SRAM_CLR	0	RSVD12		INJERR	0	FAILDMP	RSVD8	BITTOG	ROWTOG	RCADR	DINIT	DIR	ESTF	RESUME	START
rw	r	rw		rw	r	rw	rw	rw	rw	rw	rw	rw	rw	rwh	rw

Field	Bits	Type	Description
START	0	rw	**START** If this bit is written to 1 by software the memory test will start. If it is reset by software, and the test has finished, MSTATUS.DONE will be set to 1. If MCONTROL.FAILDMP is set, a fail will stop the current execution. MCONTROL.RESUME will continue a suspended test. MCONTROL.START and MCONTROL.FAILDMP must be set with the same write access by the software. 0_B No test started, finished or waiting for test end 1_B Start memory test
RESUME	1	rwh	**Resume failed test** This bit allows a failing test that got suspended to be resumed after the dump of the fail bit map. A restart is possible only if MSTATUS.FDA was reset by hardware. It will be reset by hardware once the test is resumed. 0_B Do not resume 1_B Resume suspended MBIST run
ESTF	2	rw	**Enable Sticky Fail Bit** This bit enables the sticky fail bit MSTATUS.SFAIL. If set any fails will be collected in MSTATUS.SFAIL. Resetting this bit to 0 will also reset MSTATUS.SFAIL. 0_B Do not collect fail events 1_B Collect fail events

(table continues...)

(continued)

Field	Bits	Type	Description
DIR	3	rw	**Direction Select** This field specifies the direction of a memory test operation. 0_B DOWN: Address direction is highest to lowest. 1_B UP: Address direction is lowest to highest.
DINIT	4	rw	**Data Initialization Enable** This bit enables a write of the RDBFL data to all locations defined by the range register. RDBFL can contain data that will produce an ECC error. Execution is started with MCONTROL.START. For this predefined action any information contained in CONFIG0/1 registers and the bits MCONTROL.BITTOG, MCONTROL.ROWTAG and MCONTROL.DIR are ignored. 0_B Disabled 1_B Enabled
RCADR	5	rw	**Fast Row / Fast Column Addressing Scheme Select** This bit selects between fast row and fast column addressing. 'Fast Row' moves along the word-lines first and then in bit-line direction, 'Fast Column' along the bit-lines first. 0_B Fast row 1_B Fast column
ROWTOG	6	rw	**Row toggling** This field specifies whether to toggle the used bit pattern (non inverted/ inverted) with each physical memory row. This is required when writing a checkerboard pattern or a row stripe pattern. 0_B Do not toggle 1_B Do toggle with each row
BITTOG	7	rw	**Bit toggling** This field specifies whether to toggle the used bit pattern (non inverted/ inverted) with each physical memory column. This is required when writing a checkerboard pattern or a column stripe pattern. 0_B Do not toggle 1_B Do toggle with each column
RSVD8	8	rw	**Reserved** Read as 0; must be written as 0.

(table continues...)

(continued)

Field	Bits	Type	Description
FAILDMP	9	rw	**Fail bit map dump** This field enables a dump of the failing address and a fail bit map after a fault has been detected. The memory test is suspended afterwards and resumed by MCONTROL.RESUME. MSTATUS.FDA shows that a fail dump is available. In order to resume the test without the fail information, MCONTROL.FAILDMP should be reset by SW in the same write access to the MCONTROL, where MCONTROL.RESUME is set. In case a fail dump is available, RDBFL will contain the fail bit map and ETRR the failing address. MCONTROL.START and MCONTROL.FAILDMP must be set with the same write access by the software. 0_B Do not dump 1_B Dump each fault
INJERR	11	rw	**Inject Error** Enables error-injection during march tests. This is supported only for linear march tests if RANGE.RAEN = 1. This bit should be set before a march test is started and before the address where an error should be injected is written into the RANGE register with RAEN = 1. 0_B Do not mask any writes during march tests. RANGE.ADDR and RANGE.RAEN used normally. 1_B Use RANGE.ADDR as a pointer to a physical SRAM address to which write accesses during a march test will not be executed. This bit helps in error injection during a march test over the whole SRAM. This bit has an effect only when RANGE.RAEN is also set. With MCONTROL.INJERR and RANGE.RAEN = '1', the test is by default run over the entire SRAM.
RSVD12	13:12	rw	**Reserved** Read as 0; must be written as 0.
SRAM_CLR	15	rw	**Clear the SRAM** This bit initializes the complete SRAM with ECC correct 'All-0' data. Execution is started with MCONTROL.START. For this predefined action any information contained in CONFIG0/1, RANGE and the bits MCONTROL.BITTOG, MCONTROL.ROWTOG and MCONTROL.DIR are ignored. This bit shall not be set together with other initialization or test configurations. After the SRAM clearing is complete, the software has to reset this bit back to '0' before disabling the SSH. 0_B Do not clear the entire SRAM. 1_B Clear the entire SRAM. The SRAM is fully filled with zeroes and is also ECC correct.
0	10, 14, 31:16	r	**Reserved** Read as 0; must be written as 0.

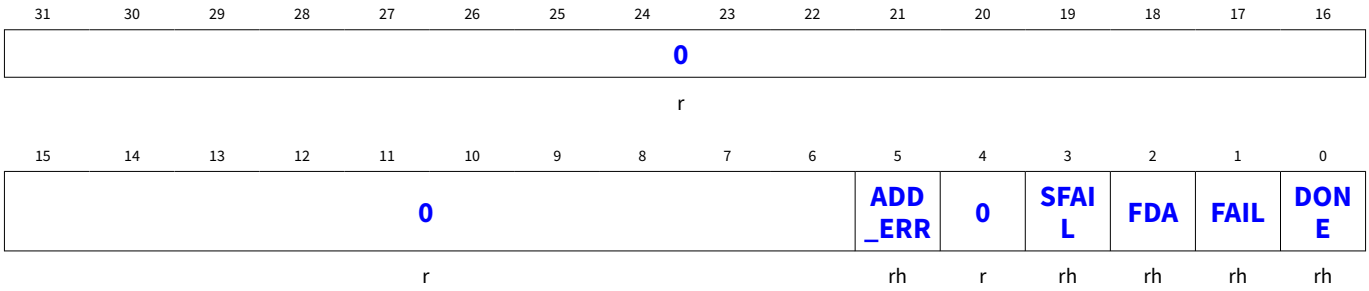
34.4.39 MC i Nominal status register

The bits in the status register show the status of the currently running and last test respectively.

MCi_MSTATUS (i=0-31) Offset address: $01010_H+i*200_H$

MC i Nominal status register Application Reset value: $0000\ 0001_H$

34 Volatile Memory Test (VMT)



Field	Bits	Type	Description
DONE	0	rh	**DONE** This bit is reset at the start of a test and set when a test is completed and MCONTROL.START was reset by software. It is not set when a test is interrupted for fail dump. 0_B Test is underway or a test has finished but MCONTROL.START was not reset by software 1_B Test has finished and MCONTROL.START was reset by software
FAIL	1	rh	**FAIL** This bit will be reset when a test is being started. It will be set to '1' by hardware under the following conditions: a) when performing a test: FAIL is set if the memory has at least one fault. Here fault includes any error in the data, as well as an address error, when enabled via ALMSRCS.ADDRE. In this case, an application reset has to be issued to clear the FAIL bit. b) when performing a test with MCONTROL.FAILDMP = '1': FAIL is set if the memory has at least one fault. The test is stopped and the fail bit map should be read from the RDBFL register 0_B No error occurred 1_B Detailed description see above
FDA	2	rh	**Fail Dump Available** This bit shows that a fail has occurred if MCONTROL.FAILDMP is set. The test is suspended and fail dump information is available. The fail bit map is in RDBFL and the associated address is in ETRR. As long as no fail has occurred RDBFL contains the last read information and ETRR has no valid data . This bit will be set by hardware. It will be reset when MSTATUS was read with MSTATUS.FDA = 1 and the dump information was read from ETRR and RDBFL. Only the last read from the last word of RDBFL is checked by the hardware and taken as an indication for a complete read. A suspended test will be resumed by MCONTROL.RESUME if FDA was reset. This forms some sort of handshake to insure that a suspended test can only be resumed (by a broadcasted) MCONTROL.RESUME if the last fail information was actually collected. 0_B No fail dump data available. A suspended MBIST run can be resumed. 1_B Fail dump data is available and waiting for read.

(table continues...)

(continued)

Field	Bits	Type	Description
SFAIL	3	rh	**Sticky Fail Bit** This bit is set to 1 together with MSTATUS.FAIL provided MCONTROL.ESTF is set. In contrast to MSTATUS.FAIL it will not be reset when a new test is started. Therefore it will collect fail information over more than one MBIST run. It will be reset when MCONTROL.ESTF is reset, or MBIST mode is switched off. 0_B No fail collected. 1_B A fail occured during one of the test runs since MCONTROL.ESTF was set to 1.
ADD_ERR	5	rh	**Address Error Detected During March Test** This bit will be reset when a test is being started. It will be set to '1' by hardware if the memory has an address error and the address error detection is enabled via ALMSRCS.ADDRE. 0_B No address error occurred 1_B Detailed description see above
0	4, 31:6	r	**Reserved** Read as 0; must be written as 0.

34.4.40 MC i Nominal range register, single address mode

The RANGE register can only be written if no test is underway and can be used to run a test only on a dedicated part of the RAM.

The range can be set in 256 word increments.

The RANGE register can be used to write to one specific address or read from it. In this case the range is disabled with RANGE.RAEN = '0' and the remaining part of the register is used as the address field.

The RANGE register can also be used to inject errors during a March test. This functionality can be enabled with MCONTROL.INJERR = '1'. MCONTROL.INJERR has to be set to '1' before the address (with RANGE.RAEN = '0') where an error should be injected is written into the RANGE register.

MCi_RANGE (i=0-31) Offset address: $01014_H+i*200_H$

MC i Nominal range register, single address mode Application Reset value: $0000\ XXXX_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RAEN	ADDR														
rw	rw														

Field	Bits	Type	Description
ADDR	14:0	rw	**Address** When RAEN = 0, this field specifies the address of a single memory location. Reads and writes to this location are possible. When RAEN=1, this field is interpreted as 2 different fields. ADDR[13:7] is interpreted as upper range limit. ADDR[6:0] is interpreted as lower range limit. For smaller SRAMs which require fewer address bits, the MSB bits are reserved. Writes to these bits are ignored, and reads return ‘0’.
RAEN	15	rw	**Range Enable** When RAEN = 0, a single word can be addressed for read or write. Config registers have to be set as follows: CONFIG0.NUMACCS:= '0001' (single access) CONFIG1.AG_MOD := '0000' (linear) MCONTROL.DIR :=1 (up) For read just the value in this location will be delivered. No check against expected values is done; i.e. MSTATUS.FAIL will not be set. When RAEN = 1, ADDR[13:7] is interpreted as upper range limit. ADDR[6:0] is interpreted as lower range limit. 0_B Disabled; single address mode is used 1_B Enabled; upper and lower range limit is used
0	31:16	r	**Reserved** Read as 0; must be written as 0.

Setting Address Ranges

If the RAEN field is set to ‘1’ then range mode is enabled. In this case, the ADDR field of the RANGE register is interpreted as two separate fields:

ADDR[13:7] is interpreted as the upper range limit.

This field specifies the upper logical block address limit in 256 word increments. Upper end of the address range is the concatenation of UPLIMIT and 0b11111111.

ADDR[6:0] is interpreted as the lower range limit

This field specifies the lower logical block address limit in 256 word increments. Lower end of the address range is the concatenation of LOLIMIT and 0b00000000.

Note that the default reset value of the ADDR field will be set to the maximum range of the physical memory. The default behaviour is therefore that an initialization or test will operate over the whole memory.

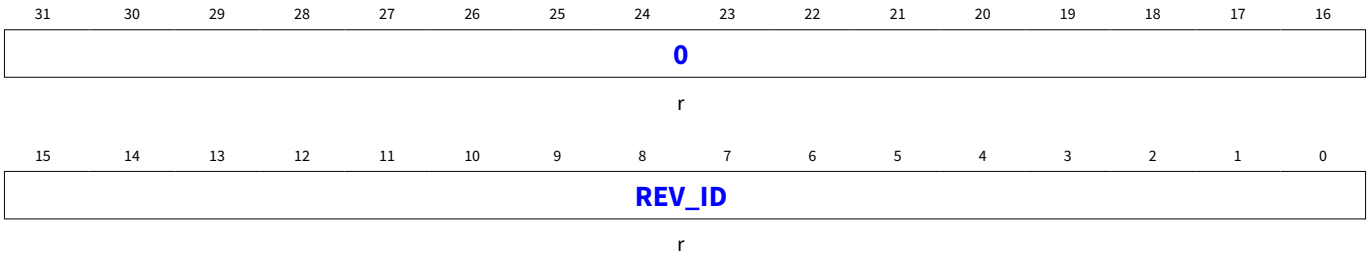
Also note that for smaller memories which require less than 15 bits of addressing, the relevant MSB bits of the address field are reserved.

34.4.41 MC i Nominal revision ID register

The revision ID register contains a hard-coded read only constant which describes the current version of the SSH IP.

MCi_REVID (i=0-31) Offset address: $0101C_H+i*200_H$

MC i Nominal revision ID register Application Reset value: $0000\ 0710_H$



Field	Bits	Type	Description
REV_ID	15:0	r	**Revision Identifier** This field defines the currently implemented release, version and functionality of the used SSH controller to track the SSH version for easier handling at the tester.
0	31:16	r	**Reserved** Read as 0; must be written as 0.

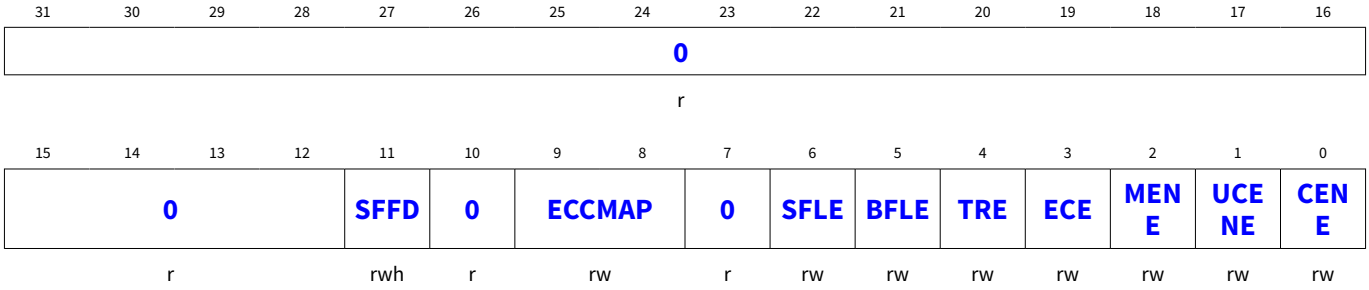
34.4.42 MC i Nominal ECC safety register

This register controls the various error detection and notification modes. This register can be accessed even if the corresponding SSH is not enabled using the MEMTEST.ENn bit.

The hardware features that implement fault tolerance mechanisms for the SRAMs (e.g. single bit correction) shall be enabled per default after any reset. This is ensured by the reset value of the ECC safety register where ECCS.ECE = 1 after a reset.

MCi_ECCS (i=0-31) Offset address: $01020_H+i*200_H$

MC i Nominal ECC safety register Application Reset value: $0000\ 001F_H$



Field	Bits	Type	Description
CENE	0	rw	**ECC Correction Event Alarm Notification Enable** This bit enables the forwarding of the CE alarm from the SSH to the SMU. 0_B Do not forward CE alarm to SMU. 1_B Forward the CE alarm to SMU.
UCENE	1	rw	**Uncorrectable Alarm Notification Enable** This bit enables the forwarding of the UCE alarm from the SSH to the SMU. Refer to the section on safety for more details. 0_B Do not forward the UCE alarm to the SMU. 1_B Forward the UCE alarm to the SMU

(table continues...)

(continued)

Field	Bits	Type	Description
MENE	2	rw	**Miscellaneous Alarm Notification Enable: MENE** This bit enables the forwarding of the ME alarm from the SSH to the SMU. Refer to the section on safety for more details. 0_B Do not forward the ME alarm to the SMU. 1_B Forward the ME alarm to the SMU.
ECE	3	rw	**Error Correction Enable** This enables the single bit error correction by the ECC. If this bit is 1, single bit errors are flagged via the CE alarm. If this bit is 0, single bit errors are flagged via the UCE alarm. 0_B Do not correct correctable errors. 1_B Correct correctable errors
TRE	4	rw	**Tracking Enable** Uncorrectable and address errors will be tracked, if the associated notification enable bit is set. This bit is enabled by default. 0_B Do not track address of detected error. 1_B Track address of detected error.
BFLE	5	rw	**Bit Flip Enable** 0_B Normal operation. 1_B Test mode only. Flips data and check bits according to RDBFL.
SFLE	6	rw	**Signature Bit Flip Enables** If this bit is set and address error detection is enabled (ALMSRCS.ADDRE = 1) then an address error is notified and tracked in the ETRR and ERRINFO registers. In addition an alarm is generated if enabled. 0_B Do not force address error injection. 1_B Forces address error injection by flipping bit 0 of the address to the address error detection logic, but not to the SRAM. This results in an address error.
ECCMAP	9:8	rw	**ECC Bit Mapping Mode** ECCMAP sets three different test modes to allow access to data or ECC bits separately and independently. 00_B Normal operation 01_B Test mode. Only data bits mapped. All ECC functionality disabled. 10_B Test mode. ECC check bits mapped to lower data bit positions. Other bits read as zero. All ECC functionality disabled. Data bits are not affected by write operations. 11_B Test mode. Do not use this setting.
SFFD	11	rwh	**Safety Flip-Flop Diagnostics** Safety flip-flop diagnostics bit. Setting this bit triggers a safety flip-flop self test. The result of the test (i.e. any error status in the safety FFs) - can be obtained from FAULTSTS.OPERR or FAULTSTS.MISCERR fields. 0_B Do not trigger a SFF self test. 1_B Trigger a SFF self test. Bit is cleared automatically by the hardware when the test is complete.

(table continues...)

(continued)

Field	Bits	Type	Description
0	7, 10, 31:12	r	**Reserved** Read as 0; must be written as 0.

34.4.43 MC i Nominal Memory ECC detection register

The ECC detection register contains information on the detected errors. The error bitfields of this register (SERR, CERR, UCERR, MERR) will be reset for easier software handling under the following conditions.

- The SSH is in MBIST mode (MEMTEST.ENn = 1) and no test is running (MEMDONE.DONEn = 0) and MCONTROL is written with both MCONTROL.START = 1 and MCONTROL.FAILDMP =1
- When the test is running with MCONTROL.FAILDMP = 1

The error bits will not be set as long as a test is running with MCONTROL.FAILDMP = 1.

MCi_ECCD (i=0-31) Offset address: $01024_H+i*200_H$

MC i Nominal Memory ECC detection register Reset values see: Table 1382

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0										VAL	TRC	MERR	UCERR	CERR	SERR
r										rh	w	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
SERR	0	rwh	**Error Detected** Write of ’0’ clears the sticky status. Write of ’1’ has no effect. In the case of a write of ‘0’ simultaneously with an error detection, the setting of the bit by hardware will take priority. This bit is reset with an application reset. Read as: 0_B No error detected. 1_B An error was detected and alarm forwarded: CERR, UCERR or MERR.
CERR	1	rwh	**Correctable Error Alarm Occurred** Write of ’0’ clears the bit, and enables further alarms to be forwarded to SMU. Write of ’1’ has no effect. Read as: 0_B No CE alarm event occurred. 1_B CE alarm event occurred.

(table continues...)

(continued)

Field	Bits	Type	Description
UCERR	2	rwh	**Uncorrectable Error Alarm Occurred** Write of ’0’ clears the bit, and enables further alarms to be forwarded to SMU. When the bit is set, software can perform additional diagnostics from the information in the ETRR/ERRINFO registers. Refer to the safety section for more details. Write of '1' has no effect. This bit is cleared on an application reset. Read as: 0_B No UCE alarm event occurred. 1_B UCE alarm event occurred.
MERR	3	rwh	**Miscellaneous Error Alarm Occurred** Write of ’0’ clears the bit, and enables further alarms to be forwarded to SMU. When the bit is set, software can perform additional diagnostics from the information in the FAULTSTS register. Refer to the safety section for more details. Write of '1' has no effect. This bit is reset with an application reset. Read as: 0_B No ME alarm event occurred. 1_B ME alarm event occurred.
TRC	4	w	**Tracking Clear** Writing this bit with '1' clears the VAL bit and the contents of the ETRR and ERRINFO registers. This bit will always read 0. 0_B No effect. 1_B Clears the ETRR and ERRINFO registers as well as the ECCD.VAL bit.
VAL	5	rh	**Valid Bits** The tracking register (ETRR) has a valid bit associated. Reset by ECCD.TRC. One error tracking register is available and one valid bit. This bit is preserved until a PORST.
0	31:6	r	**Reserved** Read as 0; must be written as 0.

Application Reset	XXXX XXXX XXXX XXXX XXXX XXXX XXX0 0000$_B$	Application Reset

34.4.44 MC i Nominal error tracking register

This register contains the address of a detected error. One register is implemented per SSH instance. ETRR contains the first detected error. Uncorrectable and address errors are stored here in the same manner.

The error type (double-bit error (DBERR) or address error (ADDRERR)) for the tracked address is stored in the ERRINFO register. Only uncorrectable errors (double-bit errors or address errors) are tracked.

Only one error can be tracked at one time. If more than one error occurs at the same time in different memory blocks (SRAM towers) then the error that occurred in the lowest memory index will be tracked. The lowest memory index in which an error occurs will be stored in ERRINFO.MBI. In case multiple errors occur in two different halves of the same memory block (ECC granularity = 2), the errors in two different halves will be combined to a single error and the address of the corresponding memory block (SRAM tower) will be stored in the ETRR register.

The UCERR and the SERR bits in the ECCD register are also set accordingly if enabled.

The address tracked is physical, i.e. the address is directly equivalent to the SRAM address input signals.

The associated valid bit is contained in the register ECCD.VAL. ECCD.TRC clears the valid bit and the contents of ETRR and ERRINFO will also be cleared.

MCi_ETRR (i=0-31) Offset address: $01028_H+i*200_H$

Field	Bits	Type	Description
ADDR	14:0	rh	**Address of Error** Address of the first error detected since last clear operation. If some MSBs are not required for addressing smaller memories, they are reserved and read as ‘0’.
0	31:15	r	**Reserved** Read as 0; must be written as 0.

34.4.45 MC i Nominal read data and bit flip register y

This register is used for several purposes whenever a register with the size of the memory width is needed.

Normally when test mode is enabled this register contains the data which is directly read back from the RAM during the last read access.

During test mode, it contains the bit flip information. If ECCS.BFLE is set, this information is used to flip bits written to the SRAM.

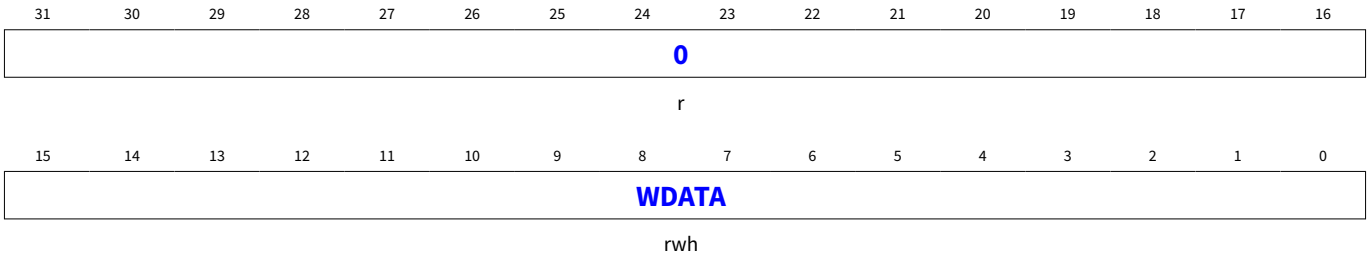
After a failed test it contains the fail bit map if MCONTROL.FAILDMP is set. The corresponding failure address is contained in the error tracking register.

When MCONTROL.DINIT is set, the content of RDBFL is written to all locations within range.

Writes to this register are not permitted while a test is underway.

MCi_RDBFLy (i=0-31;y=0-79) Offset address: $01080_H+i*200_H+y*4$

MC i Nominal read data and bit flip register y Application Reset value: $0000\ 0000_H$



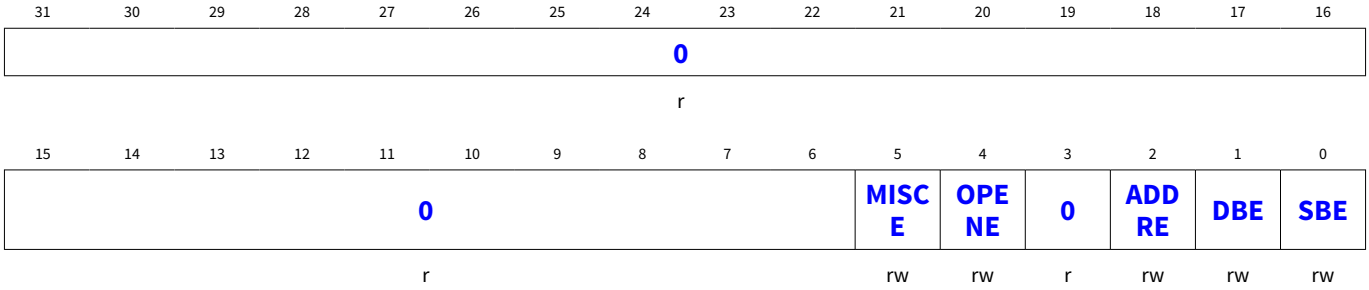
Field	Bits	Type	Description
WDATA	15:0	rwh	**Word Data** This field contains the data of the last memory read operation.
0	31:16	r	**Reserved** Read as 0; must be written as 0.

34.4.46 MC i Nominal alarm sources configuration register

This register controls the internal sources of the 3 SSH alarms (CE, UCE and ME). Individual sources can be enabled and disabled, and additionally provides individual status bits for the error/event sources.

MCi_ALMSRCS (i=0-31) Offset address: $011D0_H+i*200_H$

MC i Nominal alarm sources configuration register Reset values see: Table 1383



Field	Bits	Type	Description
SBE	0	rw	**Single Bit Error Notification** This bit enables ECC Single Bit Detection/Correction event to generate a CE or UCE alarm. If ECCS.ECE bit is '1', then SBE errors generate a CE alarm. Otherwise an UCE alarm is generated. Please note that SBEs are not tracked. 0_B SBEs are not notified via an alarm. 1_B SBEs are notified via an alarm (CE if ECCS.ECE = 1, UCE if ECCS.ECE = 0).
DBE	1	rw	**Double Bit Error Notification Enable** This bit enables ECC Double Bit Errors in the SRAM to be tracked and to generate an UCE alarm. The error status can be read from the ERRINFO register (ERRINFO.DBERR). 0_B DBEs are neither tracked in the ETRR, nor notified via an alarm. 1_B DBEs are tracked in the ETRR and ERRINFO, and notified via a UCE alarm.

(table continues...)

(continued)

Field	Bits	Type	Description
ADDRE	2	rw	**Address Error Notification Enable** This bit enables the detection and tracking of address faults in the SRAM and to generate an UCE alarm. The error status can be read from the ERRINFO register (ERRINFO.ADDRERR). 0_B Address faults in the SRAM are neither tracked in the ETRR, nor notified via an alarm. 1_B Address faults in the SRAM are tracked in the ETRR and ERRINFO, and notified via a UCE alarm.
OPENE	4	rw	**SSH Operational Error Notification Enable** This bit enables the forwarding of many errors which are critical to the operation of the SRAM or SSH. These errors generate an UCE alarm. The error status can be read from FAULTSTS.OPERR bits. This bit is enabled by default. 0_B Do not enable the detection and UCE alarm generation for SSH/SRAM operation critical errors. 1_B Enable the detection and UCE alarm generation for SSH/SRAM operation critical errors.
MISCE	5	rw	**SSH Miscellaneous Errors Notification Enable** This bit enables the forwarding of errors which may be critical to the operation of the SRAM or SSH. These errors generate an ME alarm. The error status can be read from FAULSTS.MISCERR. This bit is enabled by default. 0_B Do not enable the detection and ME alarm generation for miscellaneous SSH/SRAM errors. 1_B Enable the detection and ME alarm generation for miscellaneous SSH/SRAM errors.
0	3, 31:6	r	**Reserved** Read as 0; must be written as 0.

Reset type	Reset value	Note
After Boot-FW Value	$0000\ 0037_H$	Value installed by Boot Firmware.

34.4.47 MC i Nominal SSH safety faults status register

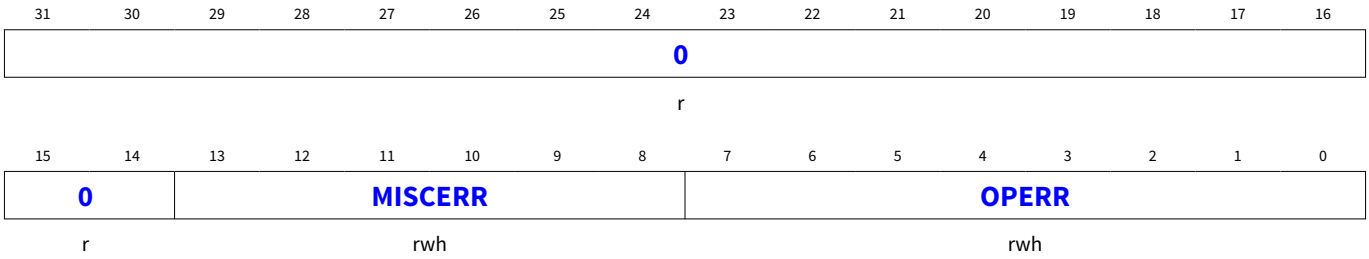
This register shows the status of the errors detected in the SRAM, which are notified by the UCE and ME alarms.

After power-up and before initialization by the SSW the safety flip-flops in the SSH can indicate a fault due to uninitialized internal registers. As a consequence MCi_FAULTSTS.OPERR[2] could be set and result in an alarm. LBIST does initialize the internal registers and clears the error. Alarms resulting from MCi_FAULTSTS.OPERR[2] should be ignored during start-up and cleared right after execution of the SSW in case LBIST was not run.

MCi_FAULTSTS (i=0-31) Offset address: $011D4_H+i*200_H$

MC i Nominal SSH safety faults status register PowerOn Reset value: $0000\ 0000_H$

34 Volatile Memory Test (VMT)



Field	Bits	Type	Description
OPERR	7:0	rwh	**SSH Critical Operation Error Status** Each bit reflects the status of a separate error source as described below. Bit field is enabled by ALMSRCS.OPENE. If multiple errors happened, multiple bits are set at the same time. To clear, write '0'. Write of '1' has no effect. Even if any bit is set, further errors are still forwarded. Unspecified bits are reserved for future use and shall always return 0. 01_H SSH has been enabled. Functional access to SRAM is disabled. 02_H Auto-data-init or partial-erase has been triggered. Part or whole of the SRAM may be overwritten. 04_H An error has been detected by safety flip-flops in one of the registers in the SSH. This bit is also always set at the end of a safety flip-flop self test (triggered by setting ECCS.SFFD) since the error paths are tested - but a real fail in the test is only indicated if FAULTSTS.MISCERR[0] is also set. 08_H Unexpected triggering of MBIST FSM, or test access to SRAM, or test features (e.g. multiplexer) in the data path, leading to potential data corruption. 10_H A mismatch occurred between one of the outputs of the ECC encoder and the ECC monitoring encoder. 20_H A mismatch occurred between one of the outputs of the ECC decoder and the ECC monitoring decoder.
MISCERR	13:8	rwh	**SSH Miscellaneous Error Status** Each bit reflects the status of a separate error source as described below. Bit field is enabled by ALMSRCS.MISCE. If multiple errors happened, multiple bits are set at the same time. To clear, write '0'. Write of '1' has no effect. Even if any bit is set, further errors are still forwarded. Unspecified bits are reserved for future use and shall always return 0. 01_H Failure detected during safety flip-flop self test (triggered by setting ECCS.SFFD). The ME alarm is not triggered by this fail. Hence the software shall read the status of this bit to check if the safety flip-flop self test failed. 02_H Alarm notification disabling detected. Any of the alarms may not be forwarded in the future. 04_H Safety mechanism disabling detected. Some of the SRAM or SSH related errors may not be detected in the future. 08_H Attempted access to a non-existing register in an existing SSH instance. 10_H An ongoing VMTx-SSH communication was aborted due to a module reset of the IP where the relevant SSH is embedded.

(table continues...)

(continued)

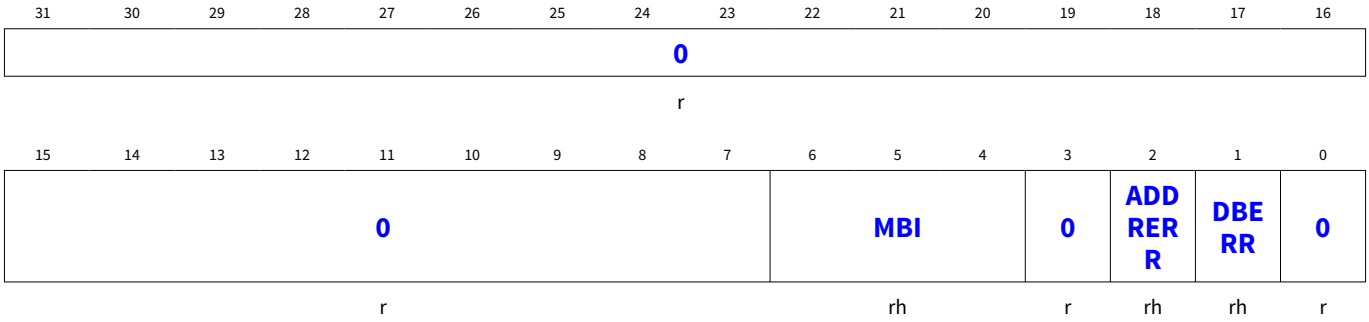
Field	Bits	Type	Description
0	31:14	r	**Reserved** Read as 0; must be written as 0.

34.4.48 MC i Nominal error information register

The register contains the type of error at the memory location corresponding to the ETRR address entry. The ERRINFO register is valid only when the ETRR entry is valid (ECCD.VAL = 1) and is cleared by ECCD.TRC.

MCi_ERRINFO (i=0-31) Offset address: $011D8_H+i*200_H$

MC i Nominal error information register PowerOn Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DBERR	1	rh	**Double Bit Error Detected** This bit will be set to '1' by hardware if the memory has a double bit (or uncorrectable) error and the double bit error notification is enabled via ALMSRCS.DBE. The bit is cleared by ECCD.TRC. 0_B No double bit error detected at the memory address in the corresponding ETRR register. 1_B Double bit error detected at the memory address in the corresponding ETRR register.
ADDRERR	2	rh	**Address Fault Detected** This bit will be set to '1' by hardware if the memory has an address error and the address error notification is enabled via ALMSRCS.ADDRE. The bit is cleared by ECCD.TRC 0_B No address error detected at the memory address in the corresponding ETRR register. 1_B Address error detected at the memory address in the corresponding ETRR register.
MBI	6:4	rh	**Memory Block Index of Error** If more than one memory is implemented in parallel, these three bits contain the index of the erroneous memory block. The tracked address belongs to this memory. Otherwise these bits always are set to 0.
0	0, 3, 31:7	r	**Reserved** Read as 0; must be written as 0.

34.4.49 MCCS i Cyber-secure configuration register 0

The bits in the MCONTROL and CONFIG0/1 registers can be used to control and program any march and hammer sequences. All bits concerning these test are concentrated here. All bits do not change during a test run. Setting MCONTROL.START will start the tests defined here. MSTATUS.DONE is reset at the beginning of a test and set after completion once MCONTROL.START is cleared by software. If no legal operation was defined in CONFIG1.AG_MOD nothing will be done but the handshake of MCONTROL.START and MSTATUS.DONE is carried out.

The reset values of the CONFIG0/1 and MCONTROL registers will perform a {↑(w0,r0)} operation (direction up, write 0 to all cells and check for 0) which initializes the whole memory with 0 and checks the contents if MCONTROL.START is set. This is the start sequence of many tests.

MCCSi_CONFIG0 (i=0-31) Offset address: $11000_H+i*200_H$

MCCS i Cyber-secure configuration register 0 Application Reset value: $0000\ 2002_H$

NUMACCS				0				ACCSTYPE							
rw				r				rw							

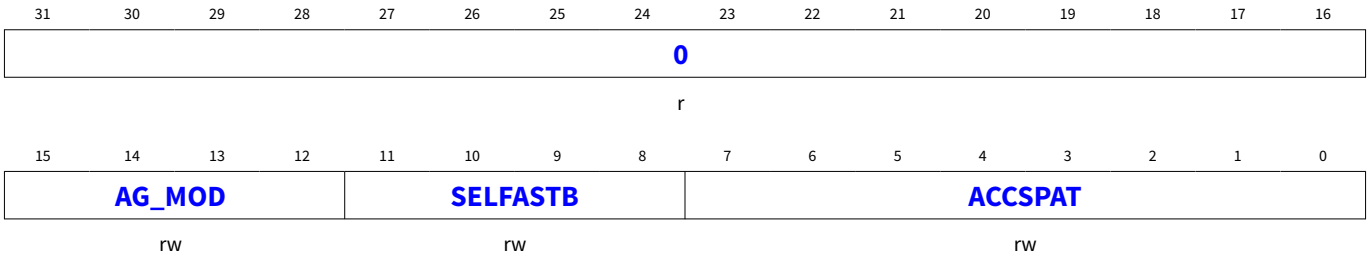
Field	Bits	Type	Description
ACCSTYPE	7:0	rw	**Access type** This field specifies the type of access which is being performed to each single address in the current marching element. ACCSTYPE[n] specifies the n-th access of the marching element. 0_B write access 1_B read access
NUMACCS	15:12	rw	**Number of accesses per address** This field specifies the total number of accesses which are being performed to each single address in the current marching element. Allowed values: 0-8 (Due to size limitation of CONFIG0.ACCSTYPE and CONFIG1.ACCSPAT fields). If NUMACCS=0 no access will be performed. If NUMACCS > 8, 8 accesses will be performed.
0	11:8, 31:16	r	**Reserved** Read as 0; must be written as 0.

34.4.50 MCCS i Cyber-secure configuration register 1

MCCSi_CONFIG1 (i=0-31) Offset address: $11004_H+i*200_H$

MCCS i Cyber-secure configuration register 1 Application Reset value: $0000\ 0000_H$

34 Volatile Memory Test (VMT)



Field	Bits	Type	Description
ACCSPAT	7:0	rw	**Access Pattern** When AG_MOD selects any test other than the non-destructive test, this field specifies directly the bit pattern (i.e. '0' or '1') which is being used for an access to each single address in the current marching element. ACCSPAT[n] specifies the n-th access of the marching element. These patterns are toggled according to MCONTROL.BITTOG and MCONTROL.ROWTOG. When AG_MOD selects the non-destructive test: Program 0 when the previous read access was with normal data; and 1 when the previous read was with inverted data. Note: When considering the previous read access, consider that the last access is a previous access to the first, as a 'wrap around'. Refer to section on non-destructive test for more details on how to program these bits.
SELFASTB	11:8	rw	**Select Fast Bit** Reserved Read as 0; must be written as 0.
AG_MOD	15:12	rw	**Address Generator Mode** These bits enable the special hardware for performing more complex addressing schemes. In case RANGE.RAEN (range enable) is set to 0 (single access) linear address mode has to be selected and NUMACCS set to 1. 1_H-4_H, 8_H, and A_H are reserved. 0_H run the test with linear address generation 5_H run the non-destructive test. The march elements, direction and backgrounds are defined by other settings in CONFIG0/1 and MCONTROL. For this test, the SRAM has to be pre-initialized with valid content (i.e. with ECC correct data). Unlike a normal MBIST march test, this test uses the ECC itself to find errors in the data. The result of the test is not reflected via MSTATUS.FAIL - instead, the detected ECC errors are tracked in the ETRR and ERRINFO registers, and additionally ECCD:*ERR bits if the alarm notifications are enabled. **others,** only the handshake of START and DONE is carried out.
0	31:16	r	**Reserved** Read as 0; must be written as 0.

34.4.51 MCCS i Cyber-secure MBIST control register

The bits in the MCONTROL and CONFIG0/1 registers can be used to control and program any march and hammer sequences. All bits concerning these test are concentrated here. All bits do not change during a test run. Setting MCONTROL.START will start the tests defined here. MSTATUS.DONE is reset at the beginning of a test and set after completion once MCONTROL.START is cleared by software. If no legal operation was defined in CONFIG1.AG_MOD nothing will be done but the handshake of MCONTROL.START and MSTATUS.DONE is carried out.

The reset values of the CONFIG0/1 and MCONTROL registers will perform a {↑(w0,r0)} operation (direction up, write 0 to all cells and check for 0) which initializes the whole memory with 0 and checks the contents if MCONTROL.START is set. This is the start sequence of many tests.

Field	Bits	Type	Description
START	0	rw	**START** If this bit is written to 1 by software the memory test will start. If it is reset by software, and the test has finished, MSTATUS.DONE will be set to 1. If MCONTROL.FAILDMP is set, a fail will stop the current execution. MCONTROL.RESUME will continue a suspended test. MCONTROL.START and MCONTROL.FAILDMP must be set with the same write access by the software. 0_B No test started, finished or waiting for test end 1_B Start memory test
RESUME	1	rwh	**Resume failed test** This bit allows a failed test that got suspended to be resumed after the dump of the fail bit map. A restart is possible only if MSTATUS.FDA was reset by hardware. It will be reset by hardware once the test is resumed. 0_B Do not resume 1_B Resume suspended MBIST run
ESTF	2	rw	**Enable Sticky Fail Bit** This bit enables the sticky fail bit MSTATUS.SFAIL. If set any fails will be collected in MSTATUS.SFAIL. Resetting this bit to 0 will also reset MSTATUS.SFAIL. 0_B Do not collect fail events 1_B Collect fail events

(table continues...)

(continued)

Field	Bits	Type	Description
DIR	3	rw	**Direction Select** This field specifies the direction of a memory test operation. 0_B DOWN: Address direction is highest to lowest. 1_B UP: Address direction is lowest to highest.
DINIT	4	rw	**Data Initialization Enable** This bit enables a write of the RDBFL data to all locations defined by the range register. RDBFL can contain data that will produce an ECC error. Execution is started with MCONTROL.START. For this predefined action any information contained in CONFIG0/1 registers and the bits MCONTROL.BITTOG, MCONTROL.ROWTOG and MCONTROL.DINIT are ignored. 0_B Disabled 1_B Enabled
RCADR	5	rw	**Fast Row / Fast Column Addressing Scheme Select** This bit selects between fast row and fast column addressing. 'Fast Row' moves along the word-lines first and then in bit-line direction, 'Fast Column' along the bit-lines first. 0_B Fast row 1_B Fast column
ROWTOG	6	rw	**Row toggling** This field specifies whether to toggle the used bit pattern (non inverted/ inverted) with each physical memory row. This is required when writing a checkerboard pattern or a row stripe pattern. 0_B Do not toggle 1_B Do toggle with each row
BITTOG	7	rw	**Bit toggling** This field specifies whether to toggle the used bit pattern (non inverted/ inverted) with each physical memory column. This is required when writing a checkerboard pattern or a column stripe pattern. 0_B Do not toggle 1_B Do toggle with each column
RSVD8	8	rw	**Reserved** Read as 0; must be written as 0.

(table continues...)

(continued)

Field	Bits	Type	Description
FAILDMP	9	rw	**Fail bit map dump** This field enables a dump of the failing address and a fail bit map after a fault has been detected. The memory test is suspended afterwards and resumed by MCONTROL.RESUME. MSTATUS.FDA shows that a fail dump is available. In order to resume the test without the fail information, MCONTROL.FAILDMP should be reset by SW in the same write access to the MCONTROL, where MCONTROL.RESUME is set. In case a fail dump is available, RDBFL will contain the fail bit map and ETRR the failing address. MCONTROL.START and MCONTROL.FAILDMP must be set with the same write access by the software. 0_B Do not dump 1_B Dump each fault
INJERR	11	rw	**Inject Error** Enables error-injection during march tests. This is supported only for linear march tests if RANGE.RAEN = 1. This bit should be set before a march test is started and before the address where an error should be injected is written into the RANGE register with RAEN = 1. 0_B Do not mask any writes during march tests. RANGE.ADDR and RANGE.RAEN used normally. 1_B Use RANGE.ADDR as a pointer to a physical SRAM address to which write accesses during a march test will not be executed. This bit helps in error injection during a march test over the whole SRAM. This bit has an effect only when RANGE.RAEN is also set. With MCONTROL.INJERR and RANGE.RAEN = '1', the test is by default run over the entire SRAM.
RSVD12	13:12	rw	**Reserved** Read as 0; must be written as 0.
SRAM_CLR	15	rw	**Clear the SRAM** This bit initializes the complete SRAM with ECC correct 'All-0' data. Execution is started with MCONTROL.START. For this predefined action any information contained in CONFIG0/1, RANGE registers and the bits MCONTROL.BITTOG, MCONTROL.ROWTOG and MCONTROL.DIR are ignored. This bit shall not be set together with other initialization or test configurations. After the SRAM clearing is complete, the software has to reset this bit back to '0' before disabling the SSH. 0_B Do not clear the entire SRAM. 1_B Clear the entire SRAM. The SRAM is fully filled with zeroes and is also ECC correct.
0	10, 14, 31:16	r	**Reserved** Read as 0; must be written as 0.

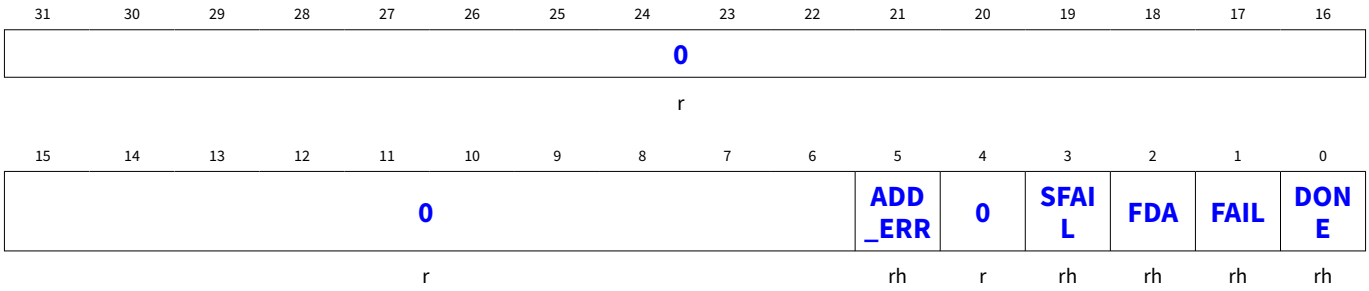
34.4.52 MCCS i Cyber-secure status register

The bits in the status register show the status of the currently running and last test respectively.

MCCSi_MSTATUS (i=0-31) Offset address: $11010_H+i*200_H$

MCCS i Cyber-secure status register Application Reset value: $0000\ 0001_H$

34 Volatile Memory Test (VMT)



Field	Bits	Type	Description
DONE	0	rh	**DONE** This bit is reset at the start of a test and set when a test is completed and MCONTROL.START was reset by software. It is not set when a test is interrupted for fail dump. 0_B Test is underway or a test has finished but MCONTROL.START was not reset by software 1_B Test has finished and MCONTROL.START was reset by software
FAIL	1	rh	**FAIL** This bit will be reset when a test is being started. It will be set to '1' by hardware under the following conditions: a) when performing a test: FAIL is set, if the memory has at least one fault. Here fault includes any error in the data, as well as an address error, when enabled via ALMSRCS.ADDRE. In this case, an application reset has to be issued to clear the FAIL bit. b) when performing a test with MCONTROL.FAILDMP = '1': FAIL is set, if the memory has at least one fault. The test is stopped and the fail bit map should be read from the RDBFL register 0_B No error occurred 1_B Detailed description see above
FDA	2	rh	**Fail Dump Available** This bit shows that a fail has occurred if MCONTROL.FAILDMP is set. The test is suspended and fail dump information is available. The fail bit map is in RDBFL and the associated address is in ETRR. As long as no fail has occurred RDBFL contains the last read information and ETRR has no valid data . This bit will be set by hardware. It will be reset when MSTATUS was read with MSTATUS.FDA = 1 and the dump information was read from ETRR and RDBFL. Only the last read from the last word of RDBFL is checked by the hardware and taken as an indication for a complete read. A suspended test will be resumed by MCONTROL.RESUME if FDA was reset. This forms some sort of handshake to insure that a suspended test can only be resumed (by a broadcasted) MCONTROL.RESUME if the last fail information was actually collected. 0_B No fail dump data available. A suspended MBIST run can be resumed. 1_B Fail dump data is available and waiting for read.

(table continues...)

(continued)

Field	Bits	Type	Description
SFAIL	3	rh	**Sticky Fail Bit** This bit is set to 1 together with MSTATUS.FAIL provided MCONTROL.ESTF is set. In contrast to MSTATUS.FAIL it will not be reset when a new test is started. Therefore it will collect fail information over more than one MBIST run. It will be reset when MCONTROL.ESTF is reset, or MBIST mode is switched off. 0_B No fail collected. 1_B A fail occurred during one of the test runs since MCONTROL.ESTF was set to 1.
ADD_ERR	5	rh	**Address Error Detected During March Test** This bit will be reset when a test is being started. It will be set to '1' by hardware if the memory has an address error and the address error detection is enabled via ALMSRCS.ADDRE. 0_B No address error occurred 1_B Detailed description see above
0	4, 31:6	r	**Reserved** Read as 0; must be written as 0.

34.4.53 MCCS i Cyber-secure range register, single address mode

The RANGE register can only be written if no test is underway and can be used to run a test only on a dedicated part of the RAM.

The range can be set in 256 word increments.

The RANGE register can be used to write to one specific address or read from it. In this case the range is disabled with RANGE.RAEN = '0' and the remaining part of the register is used as the address field.

The RANGE register can also be used to inject errors during a March test. This functionality can be enabled with MCONTROL.INJERR = '1'. MCONTROL.INJERR has to be set to '1' before the address (with RANGE.RAEN = '0') where an error should be injected is written into the RANGE register.

MCCSi_RANGE (i=0-31) Offset address: $11014_H+i*200_H$

MCCS i Cyber-secure range register, single address mode Application Reset value: $0000\ XXXX_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RAEN	ADDR														
rw	rw														

Field	Bits	Type	Description
ADDR	14:0	rw	**Address** When RAEN = 0, this field specifies the address of a single memory location. Reads and writes to this location are possible. When RAEN=1, this field is interpreted as 2 different fields. ADDR[13:7] is interpreted as upper range limit. ADDR[6:0] is interpreted as lower range limit. For smaller SRAMs which require fewer address bits, the MSB bits are reserved. Writes to these bits are ignored, and reads return ‘0’.
RAEN	15	rw	**Range Enable** When RAEN = 0, a single word can be addressed for read or write. Config registers have to be set as follows: CONFIG0.NUMACCS:= '0001' (single access) CONFIG1.AG_MOD := '0000' (linear) MCONTROL.DIR :=1 (up) For read just the value in this location will be delivered. No check against expected values is done; i.e. MSTATUS.FAIL will not be set. When RAEN = 1, ADDR[13:7] is interpreted as upper range limit. ADDR[6:0] is interpreted as lower range limit. 0_B Disabled; single address mode is used 1_B Enabled; upper and lower range limit is used
0	31:16	r	**Reserved** Read as 0; must be written as 0.

Setting Address Ranges

If the RAEN field is set to ‘1’ then range mode is enabled. In this case, the ADDR field of the RANGE register is interpreted as two separate fields:

ADDR[13:7] is interpreted as the upper range limit.

This field specifies the upper logical block address limit in 256 word increments. Upper end of the address range is the concatenation of UPLIMIT and 0b11111111.

ADDR[6:0] is interpreted as the lower range limit

This field specifies the lower logical block address limit in 256 word increments. Lower end of the address range is the concatenation of LOLIMIT and 0b00000000.

Note that the default reset value of the ADDR field will be set to the maximum range of the physical memory. The default behaviour is therefore that an initialization or test will operate over the whole memory.

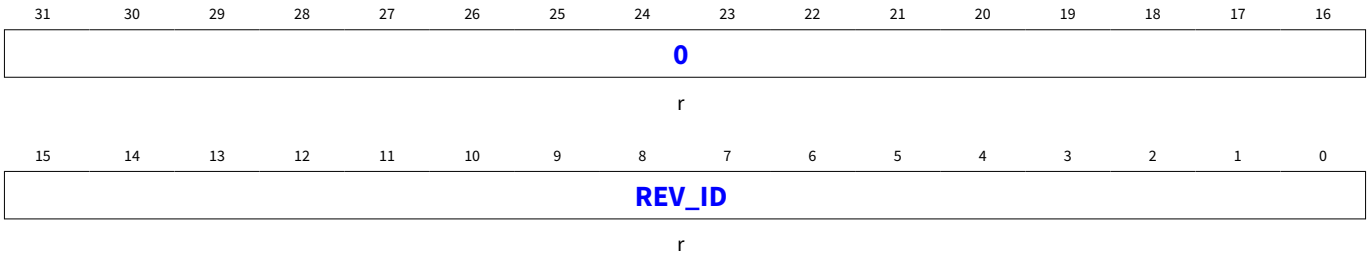
Also note that for smaller memories which require less than 15 bits of addressing, the relevant MSB bits of the address field are reserved.

34.4.54 MCCS i Cyber-secure revision ID register

The revision ID register contains a hard-coded read only constant which describes the current version of the SSH IP.

MCCSi_REVID (i=0-31) Offset address: $1101C_H+i*200_H$

MCCS i Cyber-secure revision ID register Application Reset value: $0000\ 0710_H$



Field	Bits	Type	Description
REV_ID	15:0	r	**Revision Identifier** This field defines the currently implemented release, version and functionality of the used SSH controller to track the SSH version for easier handling at the tester.
0	31:16	r	**Reserved** Read as 0; must be written as 0.

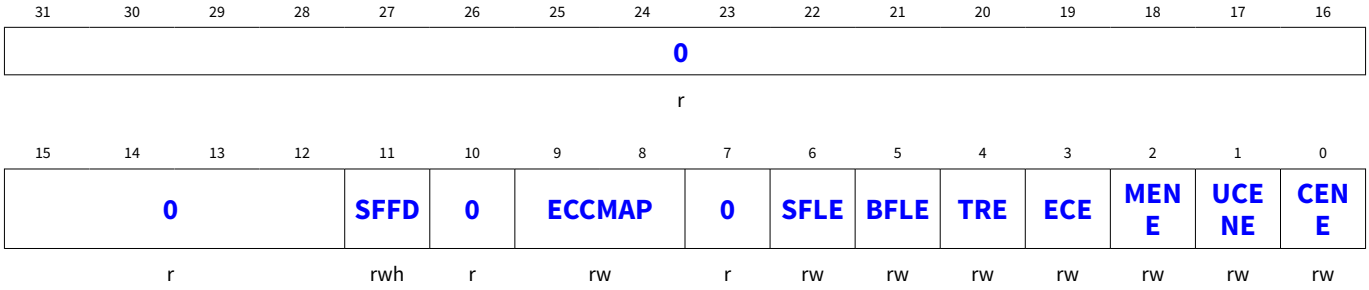
34.4.55 MCCS i Cyber-secure ECC safety register

This register controls the various error detection and notification modes. This register can be accessed even if the corresponding SSH is not enabled using the MEMTESTCS.ENn bit.

The hardware features that implement fault tolerance mechanisms for the SRAMs (e.g. single bit correction) shall be enabled per default after any reset. This is ensured by the reset value of the ECC safety register where ECCS.ECE = 1 after a reset.

MCCSi_ECCS (i=0-31) Offset address: $11020_H+i*200_H$

MCCS i Cyber-secure ECC safety register Application Reset value: $0000\ 001F_H$



Field	Bits	Type	Description
CENE	0	rw	**ECC Correction Event Alarm Notification Enable** This bit enables the forwarding of the CE alarm from the SSH to the SMU. 0_B Do not forward CE alarm to SMU. 1_B Forward the CE alarm to SMU.
UCENE	1	rw	**Uncorrectable Alarm Notification Enable** This bit enables the forwarding of the UCE alarm from the SSH to the SMU. Refer to the section on safety for more details. 0_B Do not forward the UCE alarm to the SMU. 1_B Forward the UCE alarm to the SMU

(table continues...)

(continued)

Field	Bits	Type	Description
MENE	2	rw	**Miscellaneous Alarm Notification Enable** This bit enables the forwarding of the ME alarm from the SSH to the SMU. Refer to the section on safety for more details. 0_B Do not forward the ME alarm to the SMU. 1_B Forward the ME alarm to the SMU.
ECE	3	rw	**Error Correction Enable** This enables the single bit error correction by the ECC. If this bit is 1, single bit errors are flagged via the CE alarm. If this bit is 0, single bit errors are flagged via the UCE alarm. 0_B Do not correct correctable errors. 1_B Correct correctable errors
TRE	4	rw	**Tracking Enable** Uncorrectable and address errors will be tracked, if the associated notification enable bit is set. This bit is enabled by default. 0_B Do not track address of detected error. 1_B Track address of detected error.
BFLE	5	rw	**Bit Flip Enable** 0_B Normal operation. 1_B Test mode only. Flips data and check bits according to RDBFL.
SFLE	6	rw	**Signature Bit Flip Enable** If this bit is set and address error detection is enabled (ALMSRCS.ADDRE = 1) then an address error is notified and tracked in the ETRR and ERRINFO registers. In addition an alarm is generated if enabled. 0_B Do not force address error injection. 1_B Forces address error injection by flipping bit 0 of the address to the address error detection logic, but not to the SRAM. This results in an address error.
ECCMAP	9:8	rw	**ECC Bit Mapping Mode** ECCMAP sets three different test modes to allow access to data or ECC bits separately and independently. 00_B Normal operation 01_B Test mode. Only data bits mapped. All ECC functionality disabled. 10_B Test mode. ECC check bits mapped to lower data bit positions. Other bits read as zero. All ECC functionality disabled. Data bits are not affected by write operations. 11_B Test mode. Do not use this setting.
SFFD	11	rwh	**Safety Flip-Flop Diagnostics** Safety flip-flop diagnostics bit. Setting this bit triggers a safety flip-flop self test. The result of the test (i.e. any error status in the SFFs) - can be obtained from the FAULTSTS.OPERR or FAULTSTS.MISCERR fields. 0_B Do not trigger a SFF self test. 1_B Trigger a SFF self test. Bit is cleared automatically by the hardware when the test is complete.

(table continues...)

(continued)

Field	Bits	Type	Description
0	7, 10, 31:12	r	**Reserved** Read as 0; must be written as 0.

34.4.56 MCCS i Cyber-secure memory ECC detection register

The ECC detection register contains information on the detected errors. The error bitfields of this register (SERR, CERR, UCERR, MERR) shall be reset for easier software handling under the following conditions.

- The SSH is in MBIST mode (MEMTESTCS.ENn = 1) and no test is running (MEMDONECS.DONEn = 0) and MCONTROL is written with both MCONTROL.START = 1 & MCONTROL.FAILDMP = 1.
- When the test is running with MCONTROL.FAILDMP = 1

The error bits will not be set as long as a test is running with MCONTROL.FAILDMP = 1.

MCCSi_ECCD (i=0-31) Offset address: $11024_H+i*200_H$

MCCS i Cyber-secure memory ECC detection register Reset values see: Table 1384

0										VAL	TRC	MERR	UCERR	CERR	SERR
r										rh	w	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
SERR	0	rwh	**Error Detected** Write of ’0’ clears the sticky status. Write of ’1’ has no effect. In the case of a write of ‘0’ simultaneously with an error detection, the setting of the bit by hardware will take priority. This bit is reset with an application reset. Read as: 0_B No error detected. 1_B An error was detected and alarm forwarded: CERR, UCERR or MERR.
CERR	1	rwh	**Correctable Error Alarm Occurred** Write of ’0’ clears the bit, and enables further alarms to be forwarded to SMU. Write of ’1’ has no effect. Read as: 0_B No CE alarm event occurred. 1_B CE alarm event occurred.

(table continues...)

(continued)

Field	Bits	Type	Description
UCERR	2	rwh	**Uncorrectable Error Alarm Occurred** Write of ’0’ clears the bit, and enables further alarms to be forwarded to SMU. When the bit is set, software can perform additional diagnostics from the information in the ETRR/ERRINFO registers. Refer to the safety section for more details. Write of '1' has no effect. This bit is cleared on an application reset. Read as: 0_B No UCE alarm event occurred. 1_B UCE alarm event occurred
MERR	3	rwh	**Miscellaneous Error Alarm Occurred** Write of ’0’ clears the bit, and enables further alarms to be forwarded to SMU. When the bit is set, software can perform additional diagnostics from the information in the FAULTSTS register. Refer to the safety section for more details. Write of '1' has no effect. This bit is reset with an application reset. Read as: 0_B No ME alarm event occurred. 1_B ME alarm event occurred.
TRC	4	w	**Tracking Clear** Writing this bit with '1' clears the VAL bit and the ETRR and ERRINFO registers. This bit will always read 0. 0_B No effect. 1_B Clear the ETRR and ERRINFO registers as well as the ECCD.VAL bit.
VAL	5	rh	**Valid Bits** The tracking register (ETRR) has a valid bit associated. Reset by ECCD.TRC. One error tracking register is available and one valid bit. This bit is preserved until a PORST.
0	31:6	r	**Reserved** Read as 0; must be written as 0.

34.4.57 MCCS i Cyber-secure error tracking register

This register contains the address of a detected error. One register is implemented per SSH instance. ETRR contains address of the first detected error. Errors happening afterwards do not overwrite the content of the ETRR register. Uncorrectable and address errors are stored here in the same manner.

The error type (double-bit error (DBERR) or address error (ADDRERR)) for the tracked address is stored in the ERRINFO register. Only uncorrectable errors (double-bit errors or address errors) are tracked.

Only one error can be tracked at one time. If more than one error occurs at the same time in different memory blocks (SRAM towers) then the error that occurred in the lowest memory index will be tracked. The lowest memory index in which an error occurs will be stored in ERRINFO.MBI. In case multiple errors occur in two different halves of the same memory block (ECC granularity = 2), the errors in two different halves will be combined to a single error and the address of the corresponding memory block (SRAM tower) will be stored in the ETRR register.

The UCERR and the SERR bits in the ECCD register are also set accordingly if enabled.

The address tracked is physical, i.e. the address is directly equivalent to the SRAM address input signals.

The associated valid bit is contained in the register ECCD.VAL. ECCD.TRC clears the valid bit and the contents of ETRR and ERRINFO will also be cleared.

Field	Bits	Type	Description
ADDR	14:0	rh	**Address of Error** Address of the first error detected since last clear operation. If some MSBs are not required for addressing smaller memories, they are reserved and read as ‘0’.
0	31:15	r	**Reserved** Read as 0; must be written as 0.

34.4.58 MCCS i Cyber-secure read data and bit flip register y

This register is used for several purposes whenever a register with the size of the memory width is needed.

Normally when test mode is enabled this register contains the data which is directly read back from the RAM during the last read access.

During test mode, it contains the bit flip information. If ECCS.BFLE is set, this information is used to flip bits written to the SRAM.

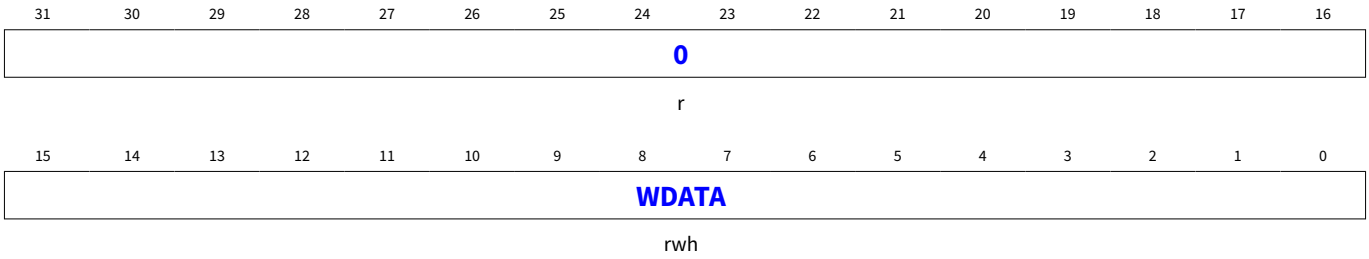
After a failed test it contains the fail bit map if MCONTROL.FAILDMP is set. The corresponding failure address is contained in the error tracking register.

When MCONTROL.DINIT is set, the content of RDBFL is written to all locations within range.

Writes to this register are not permitted while a test is underway.

MCCSi_RDBFLy (i=0-31;y=0-79) Offset address: $11080_H+i*200_H+y*4$

MCCS i Cyber-secure read data and bit flip register y Application Reset value: $0000\ 0000_H$



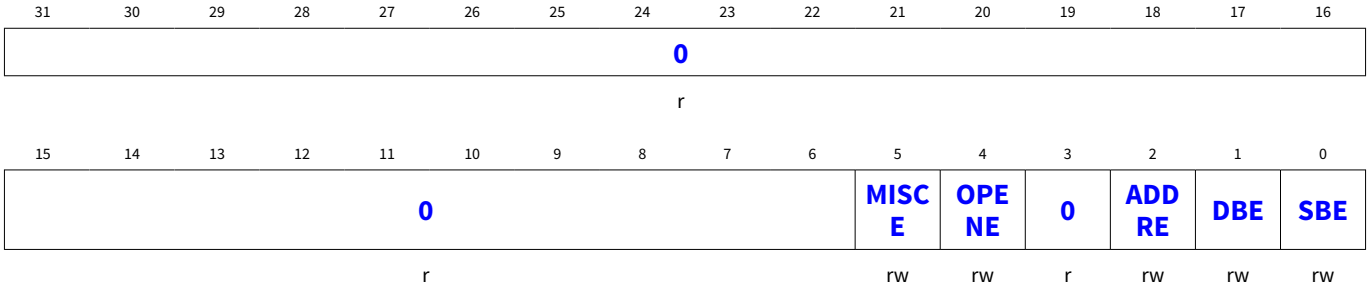
Field	Bits	Type	Description
WDATA	15:0	rwh	**Word Data** This field contains the data of the last memory read operation.
0	31:16	r	**Reserved** Read as 0; must be written as 0.

34.4.59 MCCS i Cyber-secure alarm sources configuration register

This register controls the internal sources of the 3 SSH alarms (CE, UCE and ME). Individual sources can be enabled and disabled.

MCCSi_ALMSRCS (i=0-31) Offset address: $111D0_H+i*200_H$

MCCS i Cyber-secure alarm sources configuration register Reset values see: Table 1385



Field	Bits	Type	Description
SBE	0	rw	**Single Bit Error Notification** This bit enables ECC Single Bit Detection/Correction event to generate an CE or UCE alarm. If ECCS.ECE bit is '1', then SBEs generate an CE alarm. Otherwise an UCE alarm is generated. Please note that SBEs are not tracked. 0_B SBE errors are not notified via an alarm. 1_B SBE errors are notified via an alarm (CE if ECCS.ECE = 1, UCE if ECCS.ECE = 0).

(table continues...)

(continued)

Field	Bits	Type	Description
DBE	1	rw	**Double Bit Error Notification Enable** This bit enables ECC Double Bit Errors in the SRAM to be tracked and to generate an UCE alarm. The error status can be read from the ERRINFO register (ERRINFO.DBERR). 0_B DBE errors are neither tracked in the ETRR, nor notified via an alarm. 1_B DBE errors are tracked in the ETRR & ERRINFO, and notified via a UCE alarm.
ADDRE	2	rw	**Address Error Notification Enable** This bit enables the detection and tracking of address faults in the SRAM and to generate an UCE alarm. The error status can be read from the ERRINFO register (ERRINFO.ADDRERR). 0_B Address faults in the SRAM are neither tracked in the ETRR, nor notified via an alarm. 1_B Address faults in the SRAM are tracked in the ETRR & ERRINFO, and notified via a UCE alarm.
OPENE	4	rw	**SSH Operational Error Notification Enable** This bit enables the forwarding of many errors which are critical to the operation of the SRAM or SSH. These errors generate an UCE alarm. The error status can be read from FAULTSTS.OPERR bits. This bit is enabled by default. 0_B Do not enable the detection and UCE alarm generation for SSH/SRAM operation critical errors. 1_B Enable the detection and UCE alarm generation for SSH/SRAM operation critical errors.
MISCE	5	rw	**SSH Miscellaneous Errors Notification Enable** This bit enables the forwarding of errors which may be critical to the operation of the SRAM or SSH. These errors generate an ME alarm. The error status can be read from FAULSTS.MISCERR. This bit is enabled by default. 0_B Do not enable the detection and ME alarm generation for miscellaneous SSH/SRAM errors. 1_B Enable the detection and miscellaneous alarm generation for misc. SSH/SRAM errors.
0	3, 31:6	r	**Reserved** Read as 0; must be written as 0.

34.4.60 MCCS i Cyber-secure SSH safety faults status register

This register shows the status of the errors detected in the SRAM, which are notified by the UCE and ME alarms.

After power-up and before initialization by the SSW the safety flip-flops in the SSH can indicate a fault due to uninitialized internal registers. As a consequence MCCSi_FAULTSTS.OPERR[2] could be set and result in an alarm. LBIST does initialize the internal registers and clears the error. Alarms resulting from MCCSi_FAULTSTS.OPERR[2] should be ignored during start-up and cleared right after execution of the SSW in case LBIST was not run.

MCCSi_FAULTSTS (i=0-31) Offset address: $111D4_H+i*200_H$

MCCS i Cyber-secure SSH safety faults status register PowerOn Reset value: $0000\ 0000_H$

0		MISCERR						OPERR							
r		rwh						rwh							

Field	Bits	Type	Description
OPERR	7:0	rwh	**SSH Critical Operation Error Occurred** Each bit reflects the status of a separate error source as described below. Bit field is enabled by ALMSRCS.OPENE. If multiple errors happened, multiple bits are set at the same time. To clear, write '0'. Write of '1' has no effect. Even if any bit is set, further errors are still forwarded. Unspecified bits are reserved for future use and shall always return 0. 01_H SSH has been enabled. Functional access to SRAM is disabled. 02_H Auto-data-init or partial-erase has been triggered. Part or whole of the SRAM may be overwritten. 04_H An error has been detected by safety flip-flops in one of the registers in the SSH. This bit is also always set at the end of a safety flip-flop self test (triggered by setting ECCS.SFFD) since the error paths are tested - but a real fail in the test is only indicated if FAULTSTS.MISCERR[0] is also set. 08_H Unexpected triggering of MBIST FSM, or test access to SRAM, or test features (e.g. multiplexer) in the data path, leading to potential data corruption. 10_H A mismatch occurred between one of the outputs of the ECC encoder and the ECC monitoring encoder. 20_H A mismatch occurred between one of the outputs of the ECC decoder and the ECC monitoring decoder.

(table continues...)

(continued)

Field	Bits	Type	Description
MISCERR	13:8	rwh	**SSH Miscellaneous Error Status** Each bit reflects the status of a separate error source as described below. Bit field is enabled by ALMSRCS.MISCE. If multiple errors happened, multiple bits are set at the same time. To clear, write '0'. Write of '1' has no effect. Even if any bit is set, further errors are still forwarded. Unspecified bits are reserved for future use and shall always return 0. 01_H Failure detected during safety flip-flop self test (triggered by setting ECCS.SFFD). The ME alarm is not triggered by this fail. Hence the software shall read the status of this bit to check if the safety flip-flop self test failed. 02_H Alarm notification disabling detected. Any of the alarms may not be forwarded in the future. 04_H Safety mechanism disabling detected. Some of the SRAM or SSH related errors may not be detected in the future. 08_H Attempted access to a non-existing register in an existing SSH instance. 10_H An ongoing VMTx-SSH communication was aborted due to a module reset of the IP where the relevant SSH is embedded.
0	31:14	r	**Reserved** Read as 0; must be written as 0.

34.4.61 MCCS i Cyber-secure error information register

The register contains the type of error at the memory location corresponding to the ETRR address entry. The ERRINFO register is valid only when the ETRR entry is valid (ECCD.VAL = 1) and is cleared by ECCD.TRC.

MCCSi_ERRINFO (i=0-31) Offset address: $111D8_H+i*200_H$

34.8 TC4Dx VMT information

34.8.1 TC4Dx VMT configuration

34.8.1.1 VMT module mapping

Multiple VMTs (VMTx) are distributed over the chip. Each VMTx handles up to 32 SSHs (SRAM Support Hardware). The following table gives an overview of which modules are covered by which VMT instance.

Table 1386 VMT module mapping

VMTx (x=)	Modules
0	CPU0-2, CSS, DMA0, MCDS4P, LMU0-1, LMU4-6
1	LMU2-3, LMU7-9, DMA1, MCDS2P, ERAY0-1, PSI5, CPU3-5
2	FSI0-1, HSPHY, PCIE0, GETH, PCIE1
3	PPU
4	CSRM, PKC, CDSP
5	CANXL, DRE, CAN0-4, SDMMC, LETH
6	SCR

34.8.1.2 SSH instances

The SRAMs have different configurations. The following table shows the instance-specific configurations of the SSH in each VMTx instance. Each SSH bit-index position "i" can be directly derived from "MC(CS)i" column in the SSH instances table for the following registers:

- MEMTEST(CS)
- MEMSTAT(CS)
- MEMDONE(CS)
- MEMFDA(CS)
- CEALARM(CS)
- UCEALARM(CS)
- MEALARM(CS)

Table 1387 SSH instances

VMTx (x=)	MC(CS)i (i=)	SRAM Name	Group	ECC Type	ECC Granularity	MUX Factor	# of Towers	Tower width	# of RDBFLs	Reset-Val MC(CS)i_RANGE	Note
0	0	CPU0_DMEM	G1	SECDED	2	16	4	44	11	$9F80_H$	SRAM_CLR

***Note**: Always refer to the device specific safety manual to find out which functional block SRAMs need to be considered for destructive MBIST*

34.8.1.3 SSH functionality exceptions

Depending on the SSH configuration, some functionalities may be or not available. The followingfunction s might be affected:

- SRAM Clear (MCONTROL.SRAM_CLR)
- Non-Destructive Test (NDT)
- Restricted error tracking:
  - No alarm and error indication in case of single (SBERR) errors from SSH
  - Tracking of double (DBERR) errors is not supported

***Note**: In AURIX™ 3rd Generation the default memory test algorithm is the destructive MBIST. The Non-Destructive MBIST is still available but with limited diagnostic capabilities and only for some memories of the MCU.*

The table "SSH instance exceptions" gives an overview about the functionality exceptions.

***Note**: For all SSHs listed in the table "SSH instance exceptions" there is no ECC monitoring available.*

***Note**: The SRAM_CLR functionality shall not be used with the SSH instances specified with “SRAM clear = no”. If an SRAM_CLR operation is started on any of these memories, its content is filled with ECC-incorrect values which can then lead to ECC alarms when accessing them. These memories shall be initialized by the application software instead, for example with an initialization routine or a DMA request. For the software initialization, it is recommended to use the TriCore™ CPU instruction ST.D (Store Doubleword) to avoid potential traps and alarms due to ECC errors.*

Table 1389 (continued) MEMMAP configuration

VMTx (x=)	Bits	Field	Type	Description
0	8	CPU1_PTMAP	rh	**CPU1 PTAG Mapping** Read only. Mirrors the state of CPU1_PCMAP. CPU P-cache memories can only be mapped simultaneously. 0_B Normal cache function 1_B Memory-mapped
0	9	Reserved	r	**Reserved** Read as 0; must be written as 0.
0	10	CPU2_DCMAP	rwh	**CPU2 DCache Mapping** 0_B Normal cache function 1_B Memory-mapped
0	11	CPU2_DTMAP	rh	**CPU2 DTAG Mapping** Read only. Mirrors the state of CPU2_DCMAP. CPU D-cache memories can only be mapped simultaneously. 0_B Normal cache function 1_B Memory-mapped
0	12	CPU2_PCMAP	rwh	**CPU2 PCACHE Mapping** 0_B Normal cache function 1_B Memory-mapped
0	13	CPU2_PTMAP	rh	**CPU2 PTAG Mapping** Read only. Mirrors the state of CPU2_PCMAP. CPU P-cache memories can only be mapped simultaneously. 0_B Normal cache function 1_B Memory-mapped
0	31:14	Reserved	r	**Reserved** Read as 0; must be written as 0.
1	15	CPU3_DCMAP	rwh	**CPU3 DCache Mapping** 0_B Normal cache function 1_B Memory-mapped
1	16	CPU3_DTMAP	rh	**CPU3 DTAG Mapping** Read only. Mirrors the state of CPU3_DCMAP. CPU D-cache memories can only be mapped simultaneously. 0_B Normal cache function 1_B Memory-mapped
1	17	CPU3_PCMAP	rwh	**CPU3 PCACHE Mapping** 0_B Normal cache function 1_B Memory-mapped

(table continues...)

Table 1389 (continued) MEMMAP configuration

VMTx (x=)	Bits	Field	Type	Description
1	18	CPU3_PTMAP	rh	**CPU3 PTAG Mapping** Read only. Mirrors the state of CPU3_PCMAP. CPU P-cache memories can only be mapped simultaneously. 0_B Normal cache function 1_B Memory-mapped
1	19	Reserved	r	**Reserved** Read as 0; must be written as 0.
1	20	CPU4_DCMAP	rwh	**CPU4 DCache Mapping** 0_B Normal cache function 1_B Memory-mapped
1	21	CPU4_DTMAP	rh	**CPU4 DTAG Mapping** Read only. Mirrors the state of CPU4_DCMAP. CPU D-cache memories can only be mapped simultaneously. 0_B Normal cache function 1_B Memory-mapped
1	22	CPU4_PCMAP	rwh	**CPU4 PCACHE Mapping** 0_B Normal cache function 1_B Memory-mapped
1	23	CPU4_PTMAP	rh	**CPU4 PTAG Mapping** Read only. Mirrors the state of CPU4_PCMAP. CPU P-cache memories can only be mapped simultaneously. 0_B Normal cache function 1_B Memory-mapped
1	24	Reserved	r	**Reserved** Read as 0; must be written as 0.
1	25	CPU5_DCMAP	rwh	**CPU5 DCache Mapping** 0_B Normal cache function 1_B Memory-mapped
1	26	CPU5_DTMAP	rh	**CPU5 DTAG Mapping** Read only. Mirrors the state of CPU5_DCMAP. CPU D-cache memories can only be mapped simultaneously. 0_B Normal cache function 1_B Memory-mapped
1	27	CPU5_PCMAP	rwh	**CPU5 PCACHE Mapping** 0_B Normal cache function 1_B Memory-mapped

(table continues...)

Table 1389 (continued) MEMMAP configuration

VMTx (x=)	Bits	Field	Type	Description
1	28	CPU5_PTMAP	rh	**CPU5 PTAG Mapping** Read only. Mirrors the state of CPU5_PCMAP. CPU P-cache memories can only be mapped simultaneously. 0_B Normal cache function 1_B Memory-mapped
1	14:0, 31:29	Reserved	r	**Reserved** Read as 0; must be written as 0.
2	31:0	Reserved	r	**Reserved** Read as 0; must be written as 0.
3	31:0	Reserved	r	**Reserved** Read as 0; must be written as 0.
4	31:0	Reserved	r	**Reserved** Read as 0; must be written as 0.
5	31:0	Reserved	r	**Reserved** Read as 0; must be written as 0.
6	31:0	Reserved	r	**Reserved** Read as 0; must be written as 0.

Table 1390 MEMMAPCS configuration

VMTx (x=)	Bits	Field	Type	Description
0	31:0	Reserved	r	**Reserved** Read as 0; must be written as 0.
1	31:0	Reserved	r	**Reserved** Read as 0; must be written as 0.
2	31:0	Reserved	r	**Reserved** Read as 0; must be written as 0.
3	31:0	Reserved	r	**Reserved** Read as 0; must be written as 0.
4	0	CSRM_DCMAP	rwh	**CSRM DCache Mapping** 0_B Normal cache function 1_B Memory-mapped

(table continues...)

Table 1390 (continued) MEMMAPCS configuration

4	1	CSRM_DTMAP	rh	**CSRM DTAG Mapping** Read only. Mirrors the state of CSRM_DCMAP. CPU D-cache memories can only be mapped simultaneously. 0_B Normal cache function 1_B Memory-mapped
4	2	CSRM_PCMAP	rwh	**CSRM PCACHE Mapping** 0_B Normal cache function 1_B Memory-mapped
4	3	CSRM_PTMAP	rh	**CSRM PTAG Mapping** Read only. Mirrors the state of CSRM_PCMAP. CPU P-cache memories can only be mapped simultaneously. 0_B Normal cache function 1_B Memory-mapped
4	31:4	Reserved	r	**Reserved** Read as 0; must be written as 0.
5	31:0	Reserved	r	**Reserved** Read as 0; must be written as 0.
6	31:0	Reserved	r	**Reserved** Read as 0; must be written as 0.

34.8.1.5 VMT security information

The following memories are considered security related and feature auto-initialization:

- CSS_KEYATTR
- CSS_KEYSTORE
- CSS_FIFOx (x = 0 or 1)
- CSS_CONTEXT
- PKC
- FSIx (x = 1)
- CSRM_DMEM
- CSRM_PMEM
- CSRM_DTAG
- CSRM_PTAG

The following memories are considered non-security related but are also featuring auto-initialization:

- CPUx_DMEM(x = 0 - 5) - Only the cache part of the memory is considered security related.
- CPUx_DTAG(x = 0 - 5)
- CPUx_PMEM(x = 0 - 5) - Only the cache part of the memory is considered security related.
- CPUx_PTAG(x = 0 - 5)
- FSIx (x = 0)

34.8.2 TC4Dx VMT features

There are no deviations from the generic specification.

34.8.3 TC4Dx VMT functional description

There are no deviations from the generic specification.

34.8.4 TC4Dx VMT registers

34.8.4.1 Register address space - VMT

Table 1391 Registers address space - VMT

Module	Base address	End address	Note
VMT0	$F0400000_H$	$F041FFFF_H$	FPI slave interface
VMT1	$F0420000_H$	$F043FFFF_H$	FPI slave interface
VMT2	$F0440000_H$	$F045FFFF_H$	FPI slave interface
VMT3	$F0460000_H$	$F047FFFF_H$	FPI slave interface
VMT4	$F0480000_H$	$F049FFFF_H$	FPI slave interface
VMT5	$F04A0000_H$	$F04BFFFF_H$	FPI slave interface
VMT6	$F04C0000_H$	$F04DFFFF_H$	FPI slave interface

34.8.4.2 Register overview - access mode glossary

Table 1392 Register overview - access mode glossary

Keyword	Description
CSP	Access protection using PROT register VMT0_PROTCSP or VMT1_PROTCSP or VMT2_PROTCSP or VMT3_PROTCSP or VMT4_PROTCSP or VMT5_PROTCSP or VMT6_PROTCSP .
E	Access protection using PROT register VMT0_PROTE or VMT1_PROTE or VMT2_PROTE or VMT3_PROTE or VMT4_PROTE or VMT5_PROTE or VMT6_PROTE .
SE	Access protection using PROT register VMT0_PROTSE or VMT1_PROTSE or VMT2_PROTSE or VMT3_PROTSE or VMT4_PROTSE or VMT5_PROTSE or VMT6_PROTSE .
APU-PCS	Protection group consisting of registers VMT0_ACCENCS_WRA , VMT0_ACCENCS_WRB , VMT0_ACCENCS_RDA , VMT0_ACCENCS_RDB , VMT0_ACCENCS_VM , VMT0_ACCENCS_PRS or VMT1_ACCENCS_WRA , VMT1_ACCENCS_WRB , VMT1_ACCENCS_RDA , VMT1_ACCENCS_RDB , VMT1_ACCENCS_VM , VMT1_ACCENCS_PRS or VMT2_ACCENCS_WRA , VMT2_ACCENCS_WRB , VMT2_ACCENCS_RDA , VMT2_ACCENCS_RDB , VMT2_ACCENCS_VM , VMT2_ACCENCS_PRS or VMT3_ACCENCS_WRA , VMT3_ACCENCS_WRB , VMT3_ACCENCS_RDA , VMT3_ACCENCS_RDB , VMT3_ACCENCS_VM , VMT3_ACCENCS_PRS or VMT4_ACCENCS_WRA , VMT4_ACCENCS_WRB , VMT4_ACCENCS_RDA , VMT4_ACCENCS_RDB , VMT4_ACCENCS_VM , VMT4_ACCENCS_PRS or VMT5_ACCENCS_WRA , VMT5_ACCENCS_WRB , VMT5_ACCENCS_RDA , VMT5_ACCENCS_RDB , VMT5_ACCENCS_VM , VMT5_ACCENCS_PRS or VMT6_ACCENCS_WRA , VMT6_ACCENCS_WRB , VMT6_ACCENCS_RDA , VMT6_ACCENCS_RDB , VMT6_ACCENCS_VM , VMT6_ACCENCS_PRS .
PCS	Access protection using *APU-PCS* registers.

(table continues...)

Table 1392 (continued) Register overview - access mode glossary

Keyword	Description
APU-PNOM	Protection group consisting of registers VMT0_ACCENNOM_WRA , VMT0_ACCENNOM_WRB , VMT0_ACCENNOM_RDA , VMT0_ACCENNOM_RDB , VMT0_ACCENNOM_VM , VMT0_ACCENNOM_PRS or VMT1_ACCENNOM_WRA , VMT1_ACCENNOM_WRB , VMT1_ACCENNOM_RDA , VMT1_ACCENNOM_RDB , VMT1_ACCENNOM_VM , VMT1_ACCENNOM_PRS or VMT2_ACCENNOM_WRA , VMT2_ACCENNOM_WRB , VMT2_ACCENNOM_RDA , VMT2_ACCENNOM_RDB , VMT2_ACCENNOM_VM , VMT2_ACCENNOM_PRS or VMT3_ACCENNOM_WRA , VMT3_ACCENNOM_WRB , VMT3_ACCENNOM_RDA , VMT3_ACCENNOM_RDB , VMT3_ACCENNOM_VM , VMT3_ACCENNOM_PRS or VMT4_ACCENNOM_WRA , VMT4_ACCENNOM_WRB , VMT4_ACCENNOM_RDA , VMT4_ACCENNOM_RDB , VMT4_ACCENNOM_VM , VMT4_ACCENNOM_PRS or VMT5_ACCENNOM_WRA , VMT5_ACCENNOM_WRB , VMT5_ACCENNOM_RDA , VMT5_ACCENNOM_RDB , VMT5_ACCENNOM_VM , VMT5_ACCENNOM_PRS or VMT6_ACCENNOM_WRA , VMT6_ACCENNOM_WRB , VMT6_ACCENNOM_RDA , VMT6_ACCENNOM_RDB , VMT6_ACCENNOM_VM , VMT6_ACCENNOM_PRS .
PNOM	Access protection using *APU-PNOM* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
STP	Access only during start-up, before start-up protection is set (SMM_STCON.ST_PROT=1).
32	Access only when using 32-bit width.

35 System Control Unit (SCU)

The System Control Unit (SCU) provides a collection of functions that are common for all CPUs like trap/NMI handling, global overlay control and software-over-the-air (SOTA) swap control, and various system functions that includes ERU cross-triggering, basic chip-information.

35.1 Feature list

- Trap or NMI (non-maskable interrupt) generation (TR)
- External request handling (ERU)
- CPU Global overlay control (OVC)
- SOTA control register (SOTACTRL)
- Chip information register (CHIPINFO)

35.2 Functional overview

SCU provides common CPU and system functions that include trap handling, global overlay control, SOTA swap control, ERU triggering and chip information. The main components of the SCU are illustrated in the following figure.

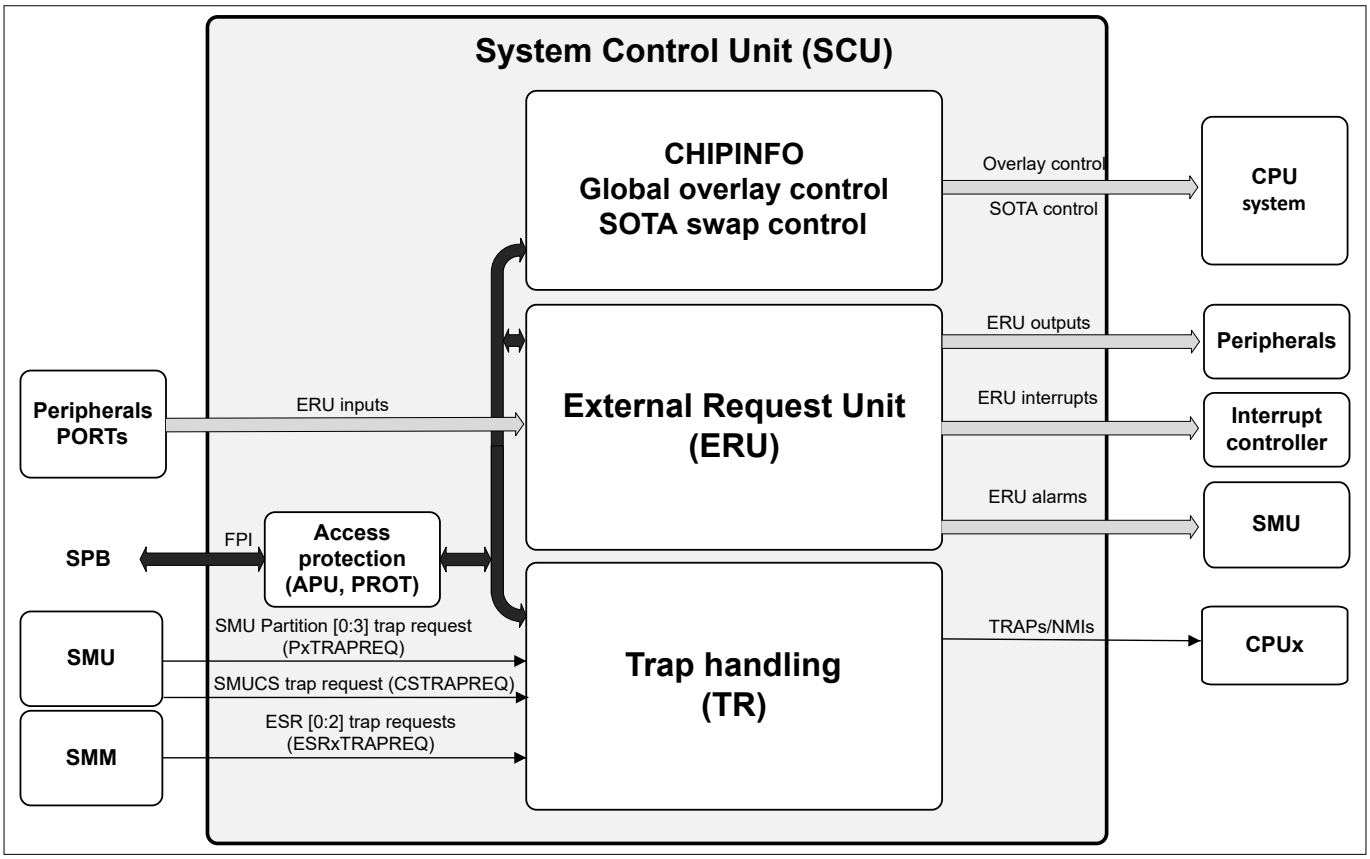

Figure 766 SCU block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

Trap/NMI handling for both non-secure and secure CPUs is done inside TR block. ERU block provides cross triggering functionality, connecting several ports and peripherals as sources to interrupt controller, SMU, ADC, timers and other peripherals as destinations. Beside TR and ERU functions, SCU also includes several control registers for common CPU and system functionality: memory overlay, SOTA swap control and basic chip information.

35.3 Functional description

Details on the SCU functionality are covered in following sub-sections.

35.3.1 Trap generation (TR)

The Trap generation function enables the application software to map different trap events from SMU, ESR-pins and SW to the NMI inputs of implemented CPUs. In addition, it provides special functions to separate the security and four non-security applications.

To set a trap-request flag in a STAT (status) register (TRAPS_CPU_STAT or TRAPS_CS_STAT), there shall be either a trap source event or intentional trap-set by software by writing to the corresponding bit-field in a SET register (TRAPS_CPU_SETCLRGRPg_SET or TRAPS_CS_SETCLR_SET). Each trap-request flag in a STAT register can be cleared by software by writing to the corresponding bit-field in a CLR register (TRAPS_CPU_SETCLRGRPg_CLR or TRAPS_CS_SETCLR_CLR).

Register bits in a DIS register (TRAPS_CPU_DISy, y=0-5, and TRAPS_CS_DIS) determine, for each CPU separately, which traps are forwarded as NMI to the respective CPU. If a trap source is disabled for a certain CPU, setting of a STAT flag will not trigger a trap-routine in that CPU.

***Note**: In case a certain CPU is not available in the device (smaller devices can have less than 6 CPU cores), its respective DIS register will still be there, but its function will be ignored.*

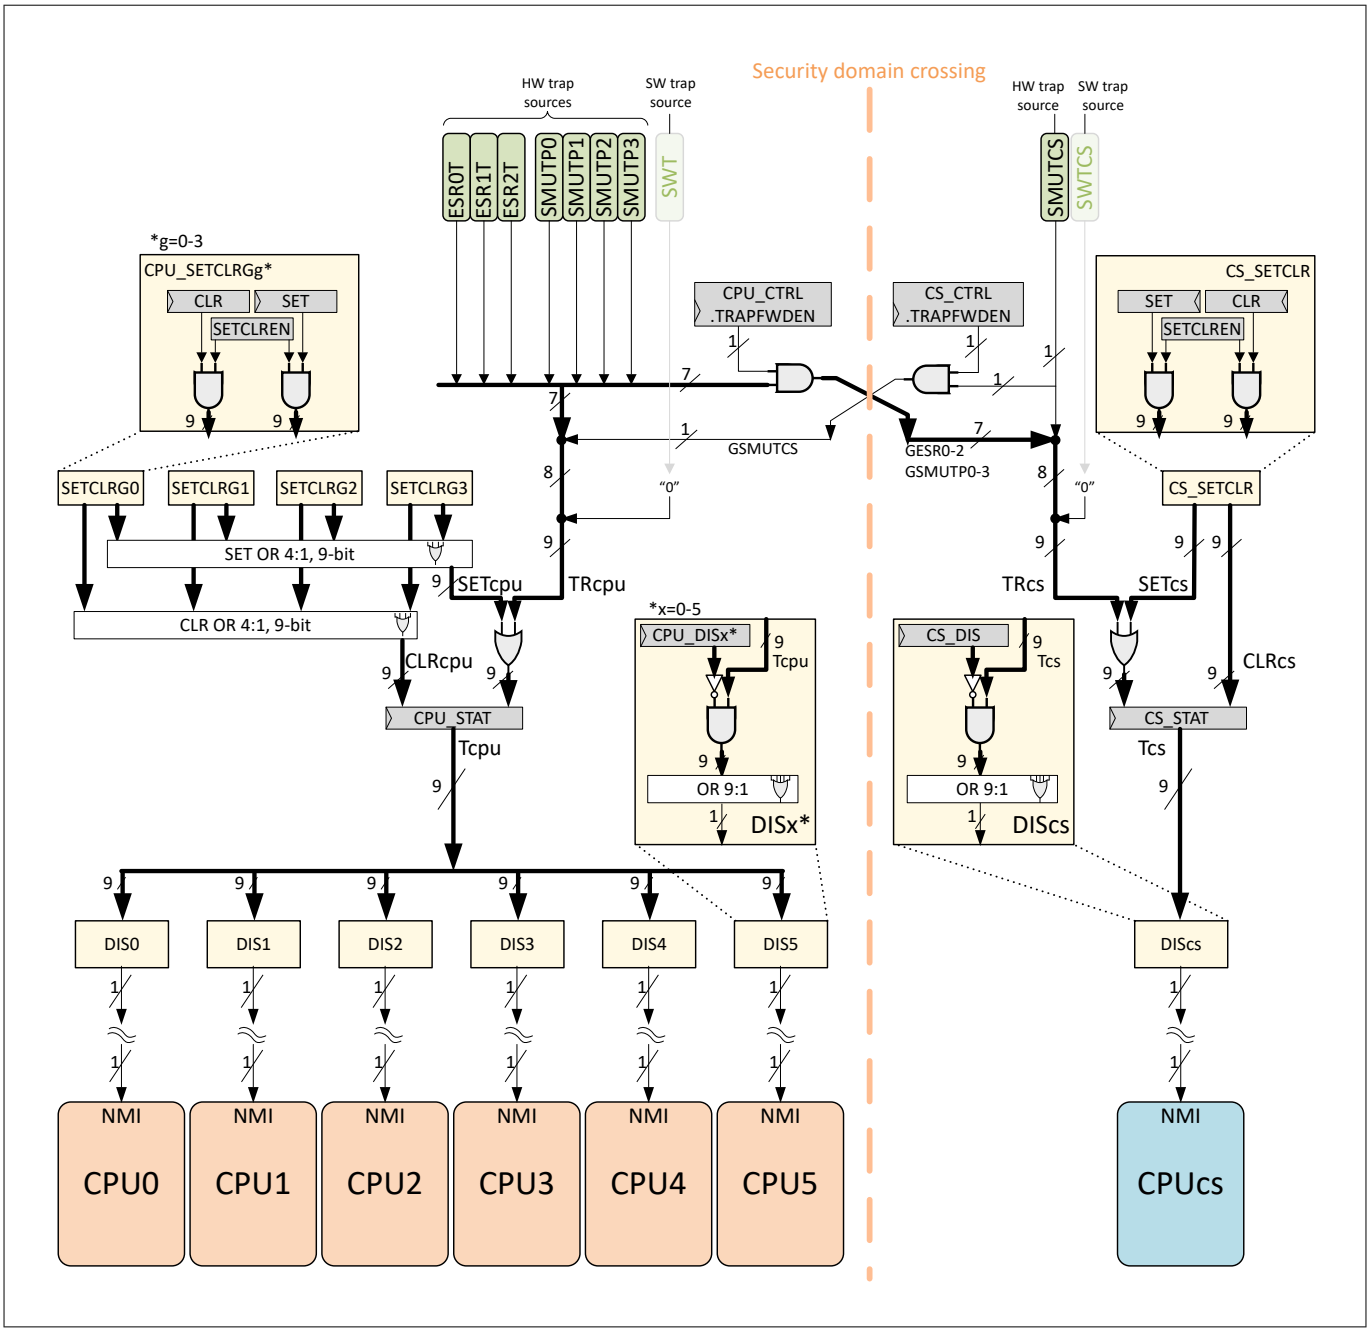

Figure 767 Trap generation

Trap sources

There are 8 hardware trap sources (also mentioned in figure as HW trap sources) and 1 dedicated SW trap source:

- SMU - 5 sources resulting in 5 STAT flags:
  - 4 from each SMU_SAFE partition - SMUTP0-3
  - 1 from SMU_CS partition - SMUTCS
- ESR - 3 sources resulting in 3 STAT flags:
  - ESR0T, ESR1T and ESR2T
- Software - 1 dedicated STAT flag:
  - SWT for non-security and SWTCS for security application

Trap-request from the SMU_CS partition is assigned to the security application.

Four SMU_SAFE sources and three ESR sources are assigned to the non-security application.

Both security and non-security applications can trigger a software trap by setting a dedicated SWTCS or SWT flag in the corresponding STAT register.

Trap control overview

- CPU traps may be triggered by hardware and software trap sources
- CPU trap-request events are captured in a status register (STAT)
  - There are separate status registers for:
    - The secured domain (TRAPS_CS_STAT)
    - The non-secured domain (TRAPS_CPU_STAT)
- It is possible to set or clear captured CPU trap-request flags by software, using SET and CLR registers
  - To achieve freedom from interference in between the secure application and the four non-secure application, control over SET and CLR functionality of each trap request source is configurable to up-to 4 non-secured partitions and 1 secured partition:
    - TRAPS_CPU: SETCLRGRPg_SET, SETCLRGRPg_CLR, SETCLRGRPg_SETCLREN registers
    - TRAPS_CS: SETCLR_SET, SETCLR_CLR, SETCLR_SETCLREN registers
- It is possible to disable or enable traps for each CPU individually using TRAPS_CPU_DISy and TRAPS_CS_DIS registers
  - The logical "OR"-combined resulting trap is routed to each CPU (CPU0-5, CPUcs) as an NMI input

Before enabling a trap source through the DIS register it is recommended to clear the trap request flag in the STAT register by writing to the respective CLR register. It is recommended to clear the trap-request flag in the STAT register by writing to the respective CLR register before a trap source is enabled in the DIS register. The trap-request flag could be set before the trap source is enabled, and simply enabling the trap source could result in an unintended CPU trap.

It is also recommended to clear the trap-request flag at the end of a trap handling routine.

35.3.1.1 Trap handling

Storing, setting and clearing traps

- For each trap source, there is a dedicated status bit in the STAT register, indicating if a trap request was received. A total of 9 bits are available in TRAPS_*_STAT registers (respectively TRAPS_CPU_STAT, TRAPS_CS_STAT)
- The SCU provides for each of the 5 partitions/groups, one security and four non-security groups, a dedicated access protection and dedicated SET, CLR, and SETCLREN registers.
  - SET and CLR registers are read and write protected by the corresponding group APU (ACCENGRPg (PGg) for non-security, ACCENCS (PCS) for security application)
  - SETCLREN registers are protected for write by PROTE and PROTCSE, and by the APU registers ACCENNOM (PNOM) and ACCENCS (PCS) for read

Enabling traps to be seen on NMI input of CPUs

- For each CPU (CPU0-5, CPUcs), there is a disable register (TRAPS_CPU_DISy, TRAPS_CS_DIS) to selectively mask trap requests.
- TRAPS_CPU_DIS0-5 registers for CPU0-5 are protected by PROTE for write and by general APU ACCENNOM (PNOM) for read
- TRAPS_CS_DIS register for CPUcs is protected by PROTCSE for write and by CS-APU ACCENCS (PCS) for read

Security considerations

Two trap domains are defined:

- A secured trap domain, containing the CPUcs and the related SMU_CS trap request (SMUTCS). This domain is controlled through TRAPS_CS_* registers
- A non-secured trap domain, containing the four non-secure partitions to control the seven non-secure trap requests to CPU0-5 (ESRyT, SMUTPx, y = 0-2, x = 0-3). This domain is controlled through TRAPS_CPU_* registers

For isolation between the two domains, a trap-request-forwarding gate is defined through the TRAPS_*_CTRL.TRAPFWDEN configuration bit (TRAPS_CPU_CTRL, TRAPS_CS_CTRL), allowing each domain to decide whether traps from that domain will be visible on the other domain. The default behavior is:

- After application reset, traps from the secured domain are not visible in the non-secured domain. Security software can decide to enable visibility
- After application reset, traps from the non-secure domain are not visible in the secured domain. Application software can decide to enable visibility

In addition to the gate, there is a dedicated DIS register (TRAPS_CPU_DIS0-5, TRAPS_CS_DIS) per CPU to enable or disable individual trap sources on a per CPU granularity.

Reset behavior

After application reset only CPU0 and CPUcs are in RUN mode. The default TRAPS behavior is:

- Both CPU_CTRL.TRAPFWDEN and CS_CTRL.TRAPFWDEN bits are disabled
- Access protections:
  - ACCENGRPg_{WR/RD}{A/B}: D and DS TAG IDs of CPU0 along with Cerberus are enabled for write access. All the master agent functions are enabled for read access.
  - ACCENNOM_{WR/RD}{A/B}: D and DS TAG IDs of CPU0 along with Cerberus are enabled for write access. All the master agent functions are enabled for read access.
  - ACCENCS_{WR/RD}{A/B}: Only D TAG ID of CPUcs is enabled for read and write, all other master agent functions are disabled for read and write
- SETCLR registers:
  - CPU_SETCLRGRPg: These registers enable SET and CLR of all 9 trap sources for the corresponding group
  - CS_SETCLR: The register enables SET and CLR of only SMUTCS and SWTCS trap sources
- Default values for DIS registers are:
  - CPU_DIS0: SMUTP0, SWT are enabled; other trap sources are disabled
  - CPU_DIS1-5: All trap sources are disabled
  - CS_DIS: SMUTCS and SWTCS are enabled; other trap sources are disabled

35.3.2 External request unit (ERU)

The external request unit (ERU) is a versatile event and pattern detection unit. Its major task is the generation of interrupt trigger events, alarms and other trigger signals based on selectable trigger events (for example to generate external interrupt requests if an edge occurs at an input pin). The detected events can also be used by other target modules to trigger or to gate module-specific actions.

The available trigger sources and defined target modules are defined in sections “ERU Input Pin Connections” and “ERU Output Pin Connections” respectively.

35.3.2.1 Feature list

- Supports generation of interrupt trigger events based on selectable trigger events at different inputs
- 8 independent input channels for input selection and conditioning of trigger or gating functions
- Event distribution with a Connecting Matrix which defines the events of the Input Channel x that lead to a reaction of an Output Channel y
- 8 independent Output Channels for combination of events, definition of their effects and distribution to the system (for example interrupt generation, timer triggering ...)

35.3.2.2 Introduction

The ERU can be split in three main functional parts:

- Input Channels x
- Connecting Matrix
- Output Channels y

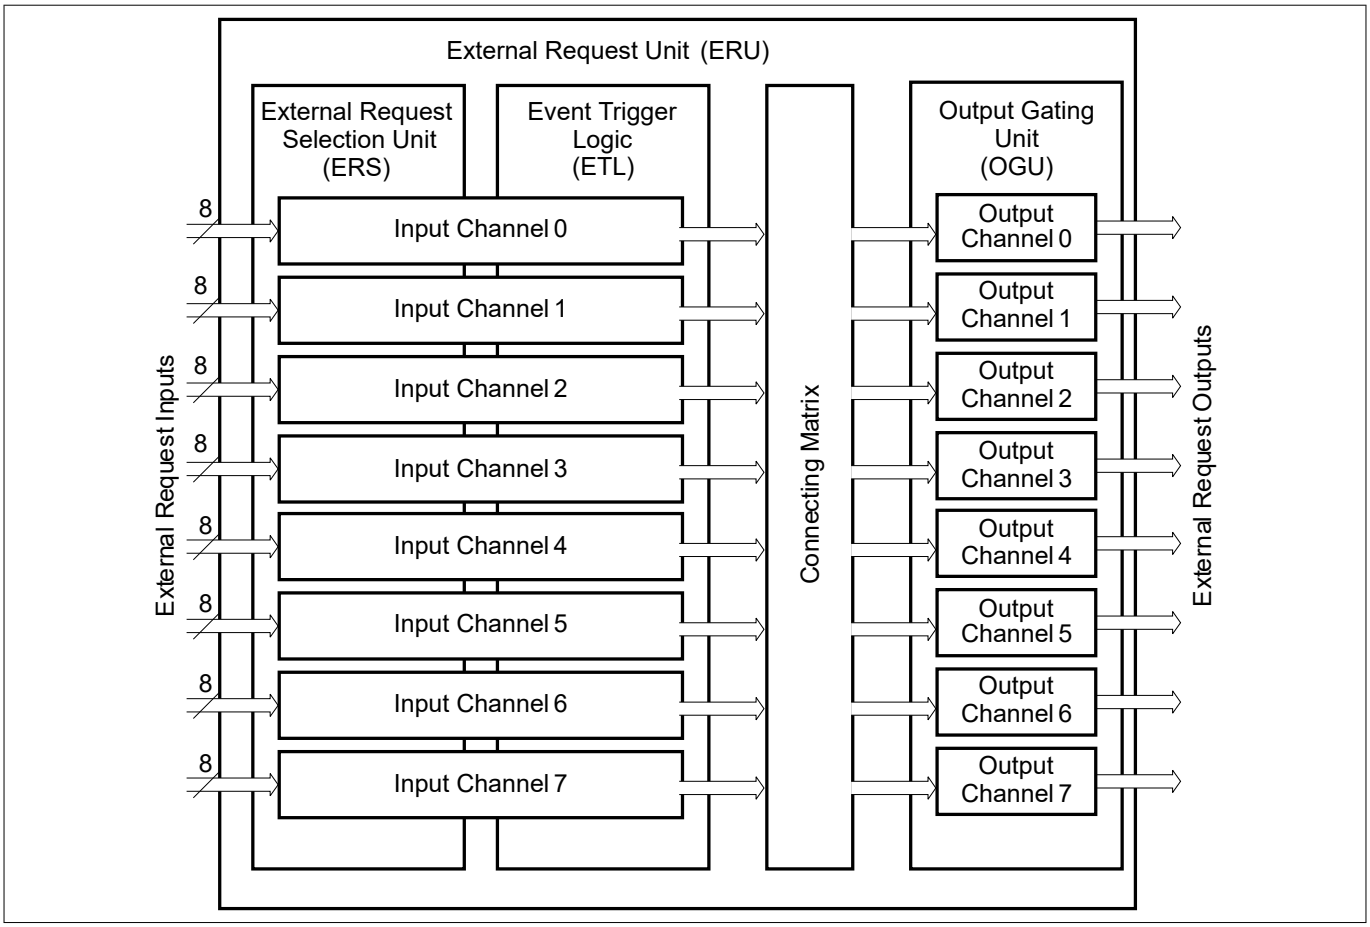

Figure 768 External request unit overview

These tasks are handled by the following building blocks:

- An External Request Select unit (ERSx) per input channel allows the selection of one input out of the 8 possible available inputs
- An Event Trigger Logic (ETLx) per input channel allows the definition of the transition (edge selection or by software) that leads to a trigger event and can also store this status. Here, the input levels of the selected signals are translated into events (event detected = event flag becomes set, independent of the polarity of the original input signals)
- The Connecting Matrix distributes the events and status flags generated by the input channels to the output channels
- An Output Gating Unit (OGUy) per output channel that combines the available trigger events and status information from the input channels. An event at one input channel can be forwarded to several output channels, or also events of several input channels can be combined to a reaction of one output channel (pattern detection). Different types of reactions are possible, for example interrupt generation (based on signals ERU_IOUTy)

35.3.2.3 REQx digital port input glitch filter (FILT)

Signal noise can lead to glitches on input pins from PORTS. These glitches due to signal noise may be suppressed by digital glitch filters similar to Filter and Prescaler Cells (FPC) in Delayed Debounce Filter Mode with up and down (no reset).

The filter calculates the integral of the signal. If the integral reaches a programmable saturation point, the input change is passed on to the ERS.

The REQx glitch filters are only available on the REQx inputs coming directly from PORTS. They are enabled and configured using register ERU_EIFILT. The input filter sample frequency is f_{FILT},where $f_{FILT} = f_{SPB}$/ ERU_EIFILT.FILTDIV.

On each new input filter sample, if the state of the input sample differs from the current state of the filter output, then an internal counter is incremented by one. When the state of the input sample matches the current state of the filter output and the counter is not zero, the counter is decremented by one. When the counter matches the compare threshold value stored in ERU_EIFILT.DEPTH, the state of the filter output is toggled and the counter is reset to zero, as shown in the next figure.

The filter clock divider and threshold can both be independently programmed to a value between 1 and 15, giving a range of possible glitch characteristics from 10 ns to more than 2 µs, assuming f_{FILT} of 100 MHz. Typically a threshold (depth) of 3 to 5 T_{filt} is sufficient. If DEPTH or FILTDIV is 0 (default value) all filters are inactive.

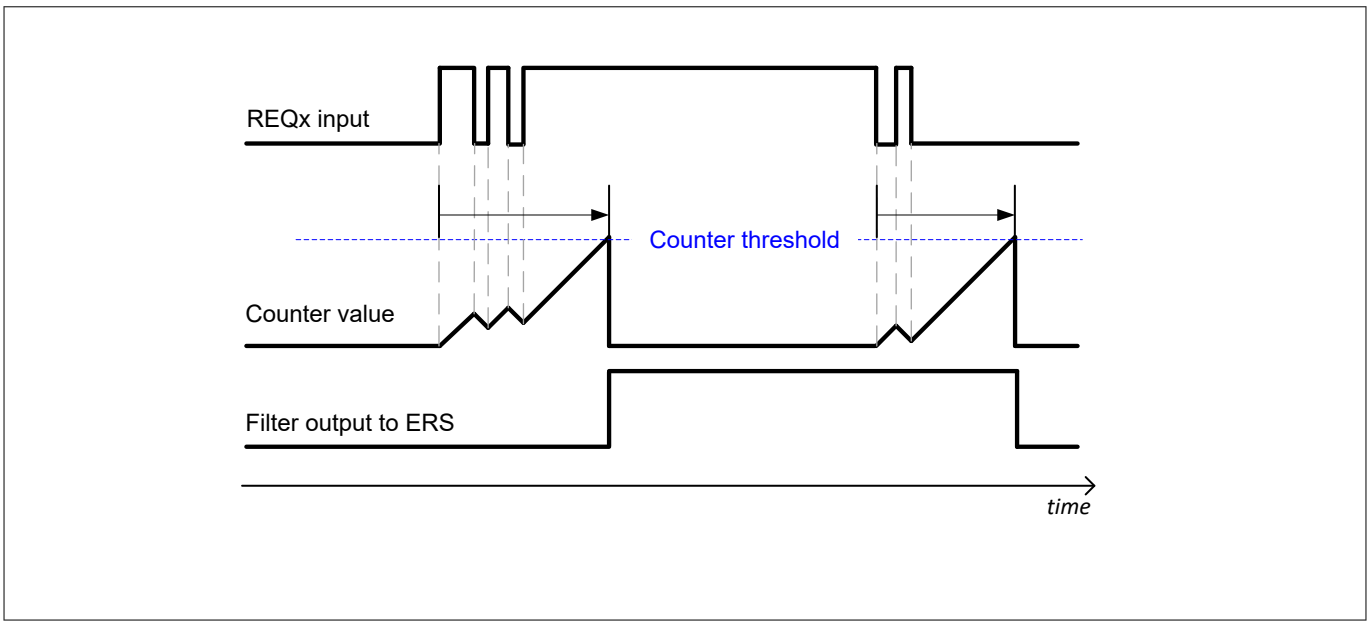

Figure 769 REQx digital filter

35.3.2.4 External request selector unit (ERS)

Each ERS selects one of eight inputs as the one input signal of the respective input channel. Figure below shows the structure of this block.

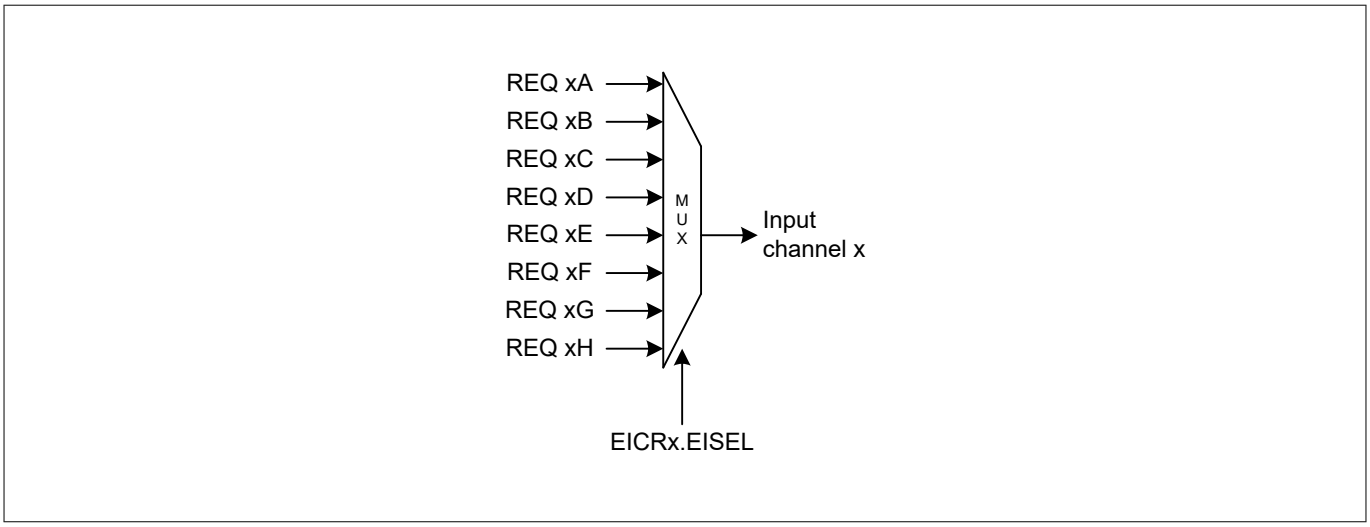

Figure 770 External request select unit overview

The ERS unit for channel x is controlled through bit-field ERU_EICRx.EISEL. Since ERU inputs can in general come from signals in different clock domains it is necessary to synchronize the signals to the local clock. In order to save power additional control is available through ERU_EICRx.EIEN to explicitly enable or disable clock of input synchronization logic.

***Note**: The External Request Unit (ERU) may react on changes of control registers even if there is no level change or edge at its inputs. For example in case the level at the input of the input synchronization logic is different from the registered value, switching on the synchronization function with the ERU_EICRx.EIEN bits will then be perceived by the ERU as an edge and will therefore result in the configured ERU reaction.*

35.3.2.5 Event trigger logic (ETL)

For each Input Channel x, an Event trigger logic ETLx derives a trigger event and a status from the input channel x delivered by the associated ERSx unit. Each ETLx is based on an edge detection block, where the detection of a rising or a falling edge can be individually enabled. Both edges lead to a trigger event if both enable bits are set (for example to handle a toggling input). Each ETLx unit has an associated ERU_EICRx register, that controls it (the register also holds control bits for the associated ERSx unit pair).

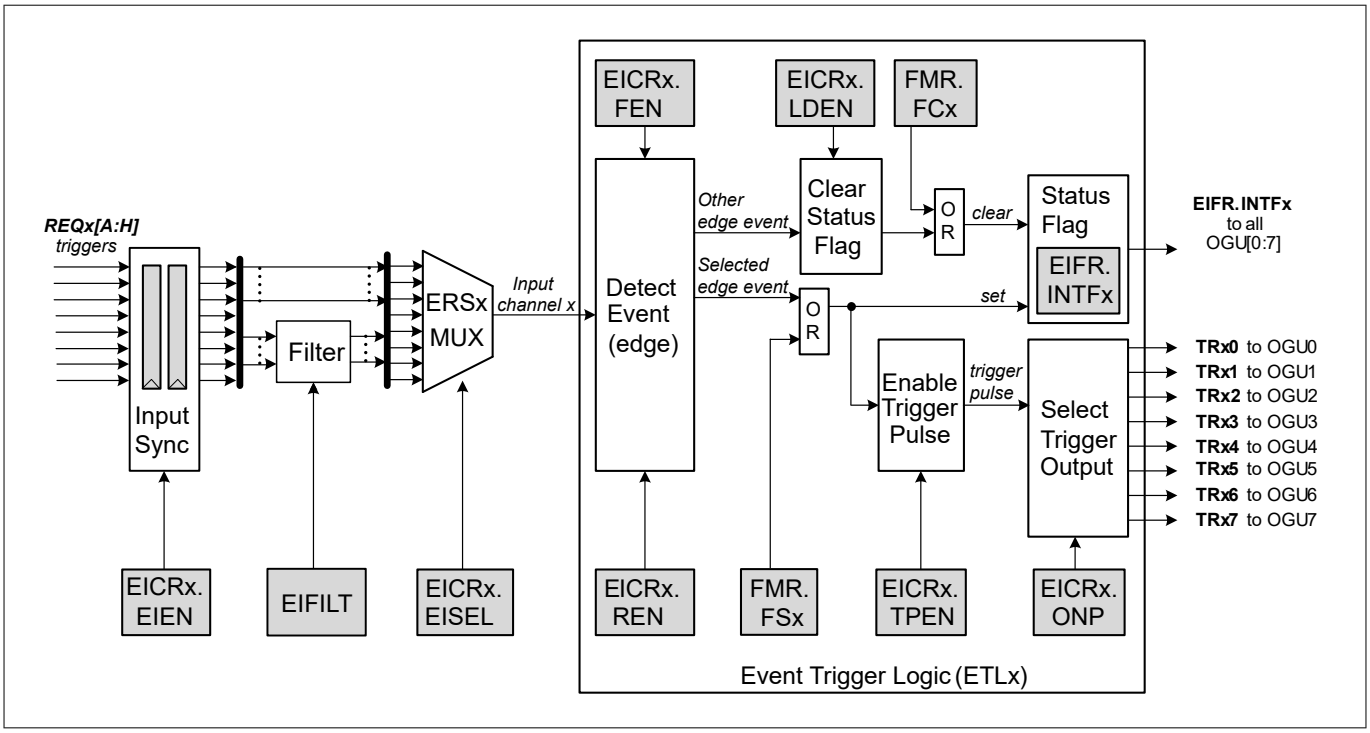

Figure 771 Event trigger logic overview

When the selected edge event is detected, the status flag ERU_EIFR.INTFx becomes set. The status flag is cleared automatically if the “opposite” event is detected, if so is enabled through bit ERU_EICRx.LDEN=1. For example, if only the falling edge detection is enabled to set the status flag, it is cleared when the rising edge is detected. In this mode, it can be used for pattern detection where the actual status of the input is important (enabling both edge detections is not useful in this mode). The output of the status flag is connected to all following Output Gating Units (OGUy) in parallel (see figure in related information) to provide pattern detection capability of all OGUy units based on different or the same status flags.

In addition to the modification of the status flag, a trigger pulse output TRxy of ETLx can be enabled (by bit ERU_EICRx.TPEN) and selected to trigger actions in one of the OGUy units. The target OGUy for the trigger is selected by bit-field ERU_EICRx.ONP. The trigger becomes active when the selected edge event is detected, independently from the status flag ERU_EIFR.INTFx.

Related information

Connecting matrix on page 5883

35.3.2.6 Connecting matrix

The Connecting matrix distributes the trigger signals (TRxy) and status signals (ERU_EIFR.INTFx) from the different ETLx units between the OGUy units. Figure below provides a complete overview of the connections between the ETLx and the OGUy units.

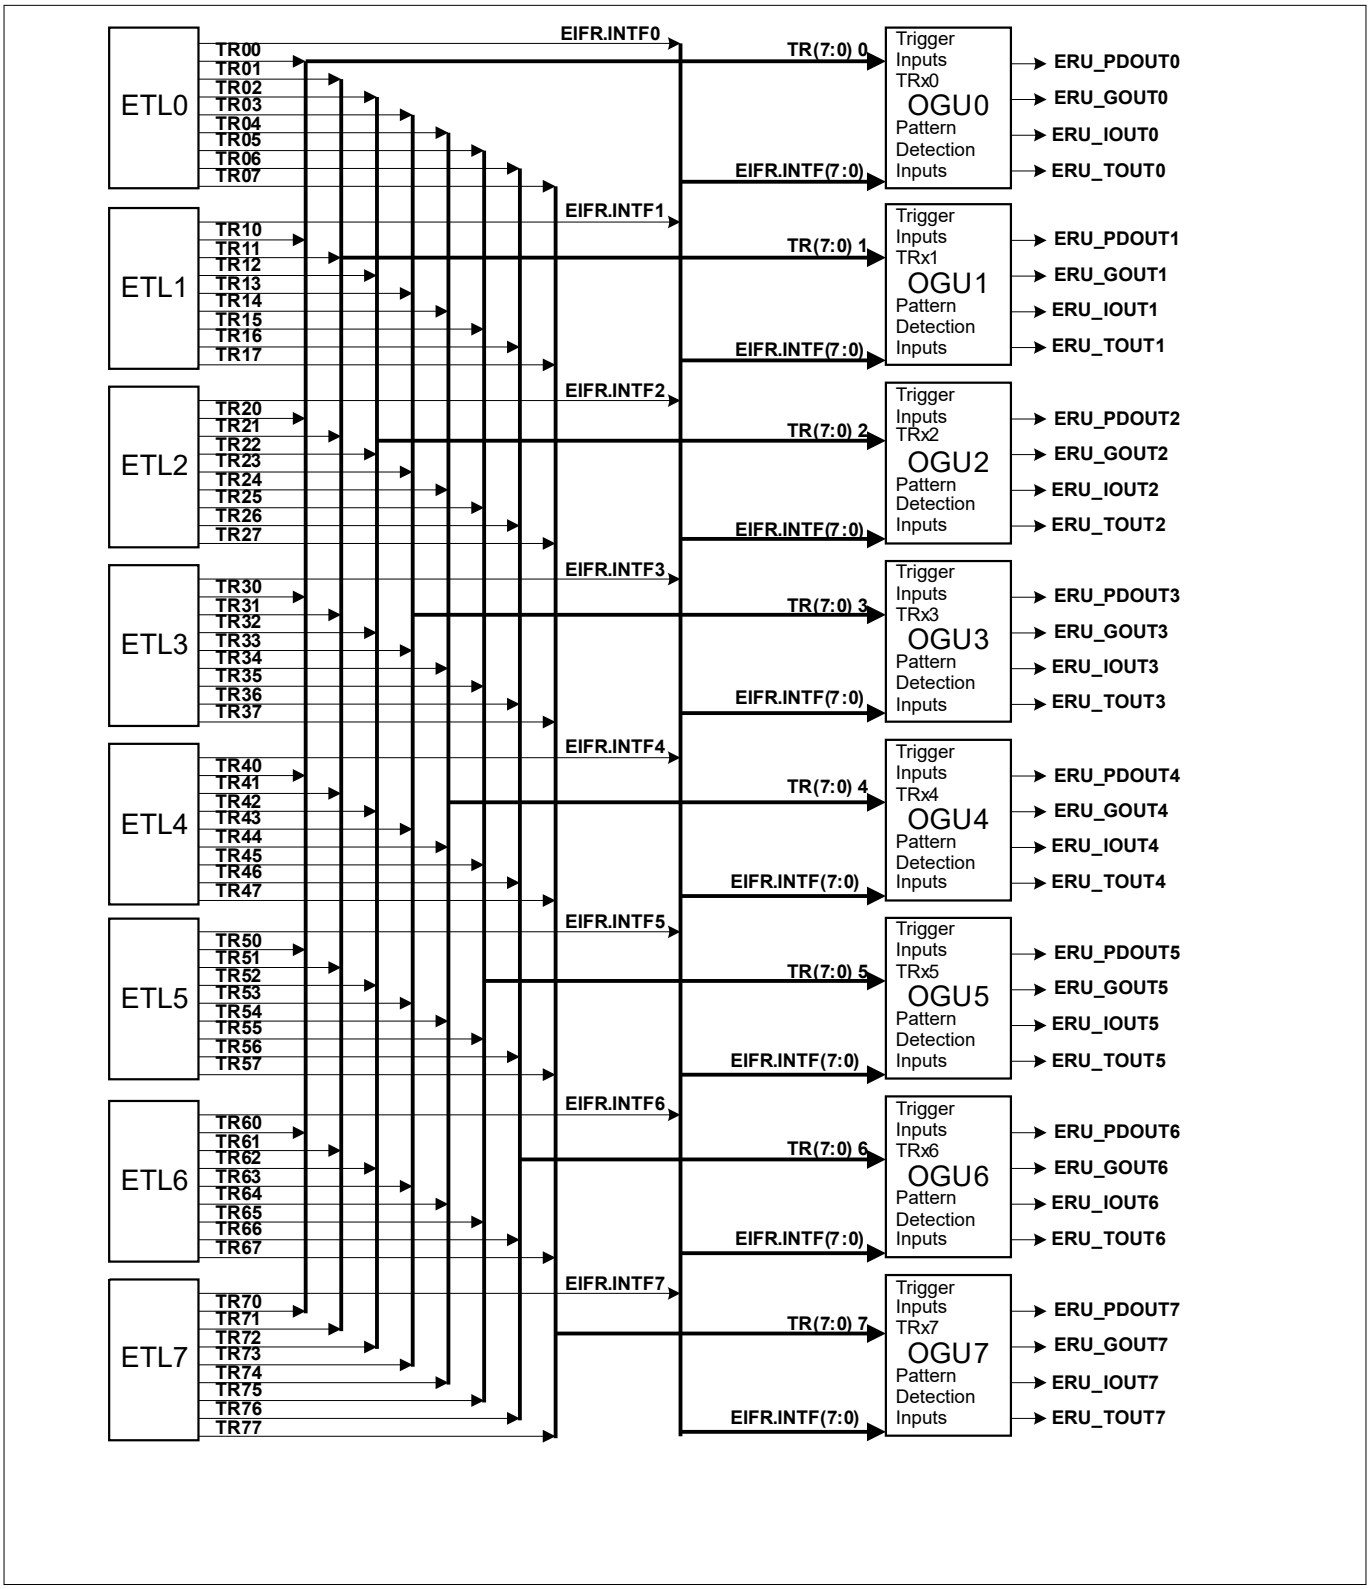

Figure 772 Connecting matrix between ETLx and OGUy

35.3.2.7 Output gating unit (OGU)

Each OGUy unit combines the available trigger events and status flags from the Input Channels and distributes the results to the system. Next figure illustrates the logic blocks within an OGUy unit. All functions of an OGUy unit are controlled by the associated ERU_IGCRy registers, one for each output channel. The function of an OGUy unit can be split into two parts:

- Trigger combination: All trigger signals TRxy from the Input Channels that are enabled and directed to OGUy and a pattern change event (if enabled) are logically OR-combined
- Pattern detection: The status flags ERU_EIFR.INTFx of the Input Channels can be enabled to take part in the pattern detection. A pattern match is detected while all enabled status flags are set, and stored in ERU_PDRR register

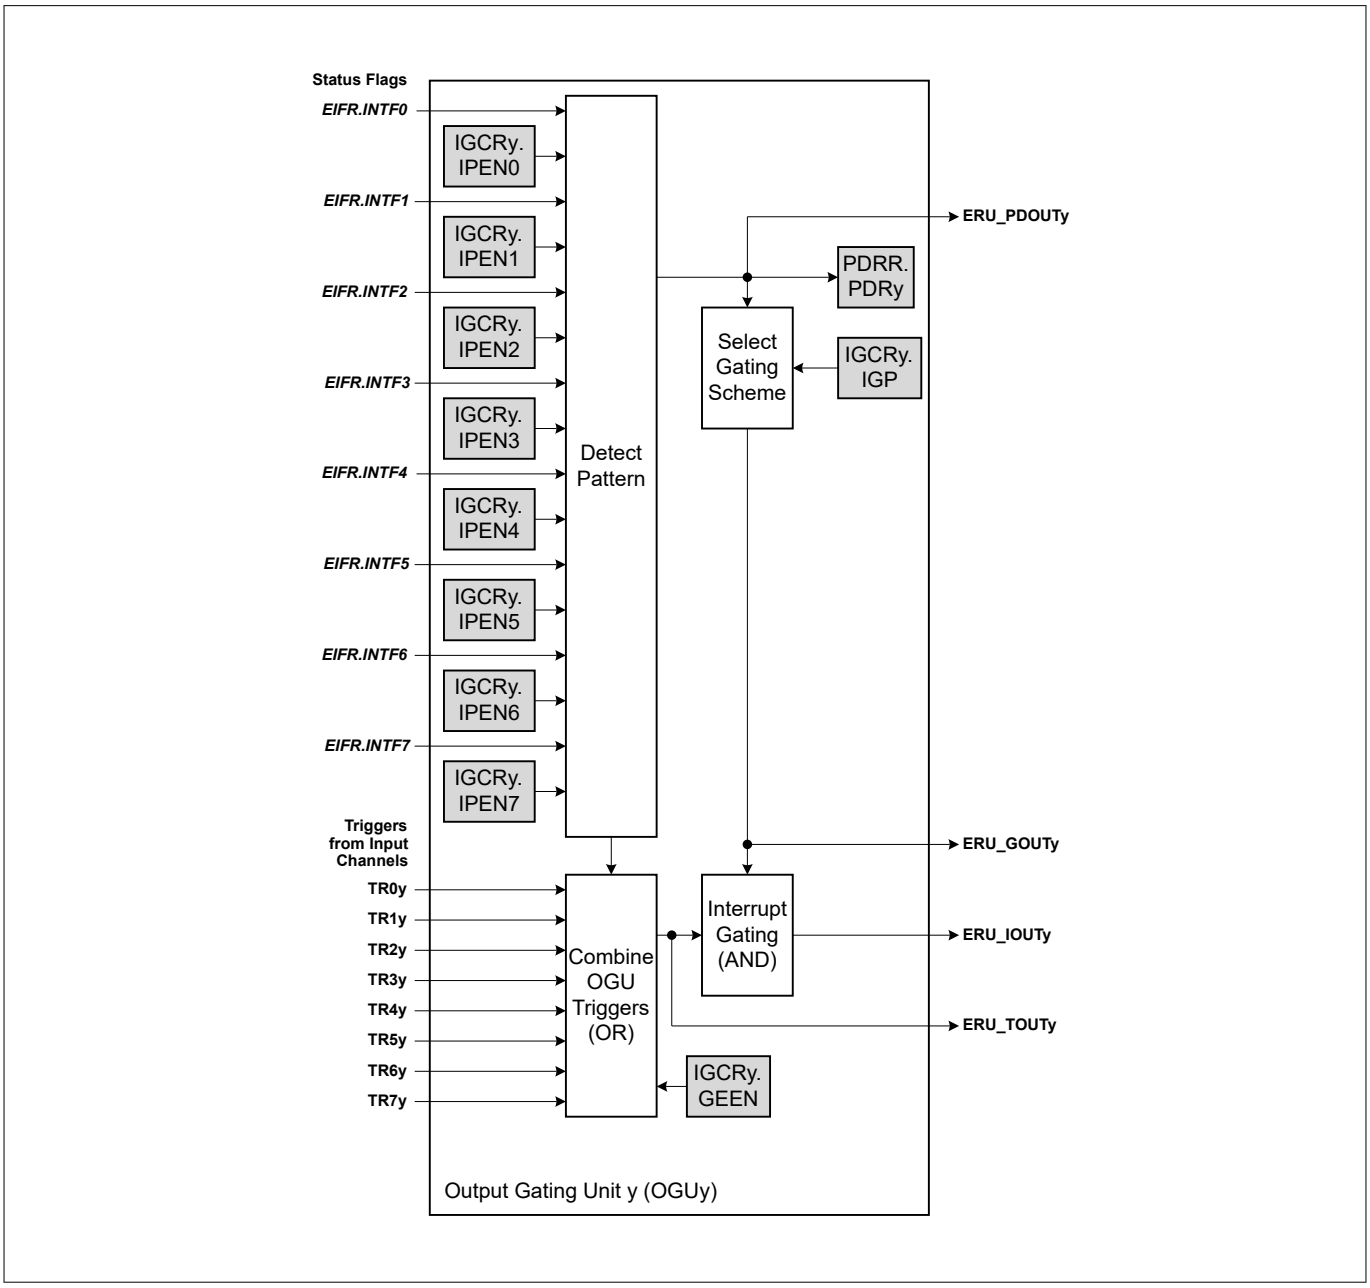

Figure 773 Output gating unit for output channel y

Each OGUy units generates 4 output signals that are distributed to the system.

- ERU_PDOUTy to directly output the pattern match information for gating purposes in defined target modules (pattern match ERU_PDRR.PDRy = '1')
- ERU_GOUTy to output the pattern match or pattern miss information (inverted pattern match), or a permanent 0 or 1 under software control for gating purposes in other modules
- ERU_TOUTy as combination of a peripheral trigger, a pattern detection result change event, or the ETLx trigger outputs TRxy to trigger actions in other modules
- ERU_IOUTy as gated trigger output (ERU_GOUTy logical AND-combined with ERU_TOUTy) to trigger interrupts (for example the interrupt generation can be gated to allow interrupt activation only during a certain time window)

35.3.2.7.1 Trigger combination

The “Combine OGU Triggers” block logically OR-combines different trigger inputs to form a common trigger ERU_TOUTy. Possible trigger inputs are:

- In each ETLx unit of the Input Channels, the trigger output TRxy can be enabled and the trigger event can be directed to one of the OGUy units
- In case that at least one pattern detection input is enabled (ERU_IGCRy.IPENx) and a change of the pattern detection result from pattern match to pattern miss (or vice-versa) is detected, a trigger event is generated to indicate a pattern detection result event (if enabled by ERU_IGCRy.GEEN)

The Trigger combination offers the possibility to program different trigger criteria for several input signals (independently for each Input Channel) or peripheral signals, and to combine their effects to a single output, for example to generate an interrupt or to start an ADC conversion. This combination capability allows the generation of an interrupt per OGUy that can be triggered by several inputs (multitude of request sources leads to one reaction).

35.3.2.7.2 Pattern detection

The “Detect Pattern” block allows the combination of the status flags of all ETLx units. Each status flag can be individually included or excluded from the pattern detection for each OGUy, through control bits ERU_IGCRy.IPENx. The pattern detection block outputs the following pattern detection results:

- Pattern match (ERU_PDRR.PDRy = '1' and ERU_PDOUTy = '1'): A pattern match is indicated while all status flags that are included in the pattern detection are '1'
- Pattern miss (ERU_PDRR.PDRy = '0' and ERU_PDOUTy = '0'): A pattern miss is indicated while at least one of the status flags that are included in the pattern detection is '0'

In addition, the pattern detection can deliver a trigger event if the pattern detection result changes from match to miss or vice-versa (if enabled by ERU_IGCRy.GEEN='1'). The pattern result change event is logically OR-combined with the other enabled trigger events to support interrupt generation or to trigger other module functions (for example in an ADC). The event is indicated when the pattern detection result changes and ERU_PDRR.PDRy becomes updated.

The interrupt generation in the OGUy is based on the trigger ERU_TOUTy that can be gated (masked) with the pattern detection result ERU_PDOUTy. This allows an automatic and reproducible generation of interrupts during a certain time window, where the request event is elaborated by the trigger combination block and the time window information (gating) is given by the pattern detection. For example, interrupts can be issued on a regular time base while a combination of input signals occurs (pattern detection based on ETLx status bits).

In total eight interrupts are generated by the ERU. The mapping of interrupt requests to OGUy blocks is shown in the ERU connection diagram.

A programmable gating scheme introduces flexibility to adapt to application requirements and allows the generation of interrupt requests ERU_IOUTy under different conditions:

- Pattern match (ERU_IGCRy.IGP = 10_B): An interrupt request is issued when a trigger event occurs while the pattern detection shows a pattern match

- Pattern miss (ERU_IGCRy.IGP = 11_B): An interrupt request is issued when the trigger event occurs while the pattern detection shows a pattern miss
- Independent of pattern detection (ERU_IGCRy.IGP = 01_B): In this mode, each occurring trigger event leads to an interrupt request. The pattern detection output can be used independently from the trigger combination for gating purposes of other peripherals (independent use of ERU_TOUTy and ERU_PDOUTy with interrupt requests on trigger events)
- No interrupts (ERU_IGCRy.IGP = 00_B, default setting). In this mode, an occurring trigger event does not lead to an interrupt request. The pattern detection output can be used independently from the trigger combination for gating purposes of other peripherals (independent use of ERU_TOUTy and ERU_PDOUTy without interrupt requests on trigger events)

35.3.2.7.3 Triggering SMU alarms

It is possible to trigger alarms to the SMU through the functional outputs of the ERU.

This is normally used to trigger an alarm from an external component, for example the component fail signal is connected to the ERU inputs and when it fails the ERU detects a transition on this input, it will trigger an alarm to the SMU.

The ERU outputs that are connected to the SMU are the ERU_IOUTy signals - ERU_IOUT0 throughout ERU_IOUT7.

Please address the SMU chapter to know which alarm lines are being used for each signal.

To enable the triggers on the ERU, one shall do the following steps:

1. Identify which ERU input signal shall be used as an alarm signal

2. Configure the specific ETLx unit by:
- Configure the ERU_EICRx.EISEL bit-field to select the input
- Configure the ERU_EICRx.REN and ERU_EICRx.FEN bit-fields to select if the input signal is active on a rising edge or falling edge
- If the trigger signal from the ETLx shall be used instead of the status flag, as source for the alarm, then configure the ERU_EICRx.ONP bit-field

3. Configure the specific OGUy that shall be used to trigger the SMU alarm - this is linked to which output shall be used, for example. ERU_IOUT4, then the OGU4 shall be configured:
- Configure the ERU_IGCRy.IPEN0 to IPEN7 if one or more status flags are used to generate or gate the trigger signal
- Configure ERU_IGCRy.GEEN bit-field to use the pattern detection path to trigger/generate the alarm/IOUT
- Configure the ERU_IGCRy.IGP bit-field to select the gating scheme for the output alarm/IOUT

One shall address the SMU chapter, to understand if additional configuration is needed to enable a specific alarm line.

35.3.2.8 ERU input pin connections

***Note**: All signal connections listed in the table below are subject to availability: if respective Module or Port Pin is not available in a given product and package then the connection is not available either.*

35.3.3 Global overlay controls

Overlay functionality is described in detail in the CPU Overlay sub-chapter named "Data Access Overlay (OVC)".

Two registers globally control the overlay operation for all CPUs:

- Overlay Enable Register OVCENABLE disables or enables data access overlay individually for each CPU
  - Global Overlay Disable (GOD) signal is one-time programmable bit used to globally disable overlay function until the next application reset
- Overlay Control Register OVCCON can be used to perform the following actions on a selected set of CPUs:
  - Concurrently enable/disable selected overlay blocks
  - Invalidate data cache

All overlay control registers are reset to their default values with the Application Reset.

***Note**: In case a certain CPU is not available in the device (smaller devices can have less than 6 CPU cores), its respective overlay control bits will still be there, but their function will be ignored.*

Related information

Data access overlay (OVC) on page 159

35.3.4 Miscellaneous system control

This section collects functions that serve various system control purposes.

35.3.4.1 Chip information register (CHIPINFO)

The CHIPINFO register can be used to determine basic information about the device, such as:

- Department within Infineon Technologies AG (for example Automotive), through the DEPT bit-field
- The JEDEC normalized manufacturer code, through the MANUF bit-field
- Revision number of the TC4x device, through the CHREV bit-field
- Product family, through CHTEC bit-field

35.3.4.2 SOTA address region control

The software-over-the-air (SOTA) control register SOTACTRL provides the firmware with the capability to install the currently used address region for supporting the SOTA feature.

The currently used address region is selected through the SOTACTRL.SOTASEL register bit-field. More details on the SOTACTRL register are provided in the SCU registers and CPU sections.

35.4 Registers

35.4.1 Register overview - access mode glossary

Table 1403 Register overview - access mode glossary

Keyword	Description
CSAE	Access protection using PROT register PROTCSAE.
CSE	Access protection using PROT register PROTCSE.
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-PCS	Protection group consisting of registers ACCENCS_WRA, ACCENCS_WRB, ACCENCS_RDA, ACCENCS_RDB, ACCENCS_VM, ACCENCS_PRS.
PCS	Access protection using *APU-PCS* registers.
APU-PGg (g=0-3)	Protection group consisting of registers ACCENGRPg_WRA, ACCENGRPg_WRB, ACCENGRPg_RDA, ACCENGRPg_RDB, ACCENGRPg_VM, ACCENGRPg_PRS.
PGg	Access protection using *APU-PGg* registers.
APU-PNOM	Protection group consisting of registers ACCENNOM_WRA, ACCENNOM_WRB, ACCENNOM_RDA, ACCENNOM_RDB, ACCENNOM_VM, ACCENNOM_PRS.
PNOM	Access protection using *APU-PNOM* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
STP	Access only during start-up, before start-up protection is set (SMM_STCON.ST_PROT=1).

MOD_NUM															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOD_TYPE								MOD_REV							
r								r							

Field	Bits	Type	Description
MOD_REV	7:0	r	**Module revision number** This bit field indicates the revision number of the SCU module (01_H). Bits [5:0] define the SCU module IP revision number. Bits [7:6] define the family. This allows a continuous numbering of the revision AND a distinction of the different SCU generations. The revision number starts with 000001 and is incremented when a SCU change is detectable by customer software. MOD_REV for other variants will be defined by Design Team.
MOD_TYPE	15:8	r	**Module type** The bit field is set to $C0_H$, which defines the module as a 32-bit module.
MOD_NUM	31:16	r	**Module number value** This bit field defines the module identification number.The identification number for the SCU is $00C4_H$.

35.4.4 PROT register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 018_H

PROT register endinit Application Reset value: $0000\ 0000_H$

VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection Set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection Set definition Enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1407 Access mode restrictions of PROTCSE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

35.4.7 PROT register cyber-secure APU endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTCSAE register controls lock / unlock of the local Cyber Secure APU Endinit (CSAE) protected control registers.

PROTCSAE Offset address: 024_H

PROT register cyber-secure APU endinit Application Reset value: $4C00\ 0000_H$

0	3, 31:10	r	**Reserved** Read as 0; should be written with 0.

35.4.30 Trap status register for traps related to CPU0-5

These bits are individually set if a corresponding trap request event is triggered.

Each bit can also be set by setting corresponding bit in TRAPS_CPU_SETCLRGRPg_SET register. Action of setting is protected by respective group APU and masking register SETCLREN.

Each bit can be cleared by setting corresponding bit in TRAPS_CPU_SETCLRGRPg_CLR register. Action of clearing is protected by respective group APU and masking register SETCLREN.

Observed reset value after boot will be 0 for all trap sources, except for ESR0 where it depends upon ARI mode because of ESR pin transition.

TRAPS_CPU_STAT Offset address: $11C_H$

FILRQ7A	21	rw	**Filter enable for REQ7A** 0_B REQ is unfiltered 1_B REQ glitch filter is enabled
FILRQ7B	22	rw	**Filter enable for REQ7B** 0_B REQ is unfiltered 1_B REQ glitch filter is enabled
FILRQ7G	23	rw	**Filter enable for REQ7G** 0_B REQ is unfiltered 1_B REQ glitch filter is enabled
FILTDIV	27:24	rw	**Digital glitch filter clock predivider** This field controls a predivider to generate the digital filter sample clock $T_{filt} = T_{spb}$ * FILTDIV A value of zero in this register disables all glitch filtering.

(table continues...)

(continued)

Field	Bits	Type	Description
DEPTH	31:28	rw	**Digital glitch filter depth** DEPTH determines the number of port input samples considered in the calculation of the floating average digital filter output for all enabled FILRQ filters. A value of zero in this register disables all glitch filtering.

35.4.39 External input channel register x

Each external input channel register ERU_EICRx contains bits to configure the external request selection (ERS) and the event trigger logic (ETL).

ERU_EICRx (x=0-7) Offset address: 154_H+x*4

External input channel register x Application Reset value: $0000\ 0000_H$

0	ONP			TPEN	LDEN	REN	FEN	0	EISEL			0		EIEN_P	EIEN
r	rw			rw	rw	rw	rw	r	rw			r		w	rw

Field	Bits	Type	Description
EIEN	0	rw	**External input enable for channel x** Used to enable clock for synchonization logic of external inputs related to this channel. 0_B Synchronization logic clock is disabled 1_B Synchronization logic clock is enabled
EIEN_P	1	w	**Write protection for EIEN** This bit enables ERU_EICRx.EIEN write during ERU_EICRx.EICRx write. Return 0 if read. 0_B EIEN remains unchanged. 1_B EIEN can be changed with write access to register ERU_EICR0
EISEL	6:4	rw	**External input selection** This bit field determines which input line is selected for input channel. 000_B Input A is selected. 001_B Input B is selected. 010_B Input C is selected. 011_B Input D is selected. 100_B Input E is selected. 101_B Input F is selected. 110_B Input G is selected. 111_B Input H is selected.

(table continues...)

(continued)

Field	Bits	Type	Description
FEN	8	rw	**Falling Edge Enable** This bit determines if the falling edge of input channel is used to set bit INTF. 0_B The falling edge is not used 1_B The detection of a falling edge of input channel generates a trigger event. INTF becomes set.
REN	9	rw	**Rising edge enable** This bit determines if the rising edge of input channel is used to set bit INTF. 0_B The rising edge is not used 1_B The detection of a rising edge of input channel generates a trigger event. INTF becomes set.
LDEN	10	rw	**Level detection enable** This bit determines if bit ERU_EIFR.INTF is cleared automatically if an edge of the input channel is detected, which has not been selected (rising edge with REN=0 or falling edge with FEN=0). 0_B Bit INTF will not be cleared 1_B Bit INTF will be cleared
TPEN	11	rw	**Trigger pulse enable** This bit enables the generation of a trigger pulse event when a selected edge is detected. 0_B The trigger event is disabled 1_B The trigger event is enabled
ONP	14:12	rw	**Output node pointer** This bit field determines the destination (output channel) for related trigger pulse event (if enabled by TPEN). 000_B An event from input ETLx triggers output OGU0 (signal TRx0). 001_B An event from input ETLx triggers output OGU1 (signal TRx1) 010_B An event from input ETLx triggers output OGU2 (signal TRx2) 011_B An event from input ETLx triggers output OGU3 (signal TRx3) 100_B An event from input ETLx triggers output OGU4 (signal TRx4) 101_B An event from input ETLx triggers output OGU5 (signal TRx5) 110_B An event from input ETLx triggers output OGU6 (signal TRx6) 111_B An event from input ETLx triggers output OGU7 (signal TRx7)
0	3:2, 7, 31:15	r	**Reserved** Read as 0; should be written with 0.

Table 1410 Access mode restrictions of ERU_EICRx (x=0-7) sorted by descending priority

Mode name	Access mode		Description
write 1 to .**EIEN_P**	rw	EIEN	
(default)	r	EIEN	

35.4.40 External input flag register

The external input flag register ERU_EIFR contains all status flags for the external input channels. The bits in this register can be cleared by software by setting ERU_FMR.FCx, and set by setting ERU_FMR.FSx.

ERU_EIFR Offset address: 174_H

External input flag register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0								INTF7	INTF6	INTF5	INTF4	INTF3	INTF2	INTF1	INTF0
r								rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
INTFx (x=0-7)	x	rh	**External event flag of channel x** This bit monitors the status flag of the event trigger condition for the input channel x. This bit is automatically cleared when the selected condition (see ERU_EICRx.REN, ERU_EICRx.FEN) is no longer met (if ERU_EICRx.LDEN='1') or remains set until it is cleared by software (if ERU_EICRx.LDEN='0').
0	31:8	r	**Reserved** Read as 0; should be written with 0.

35.4.41 Flag modification register

If a set event and a clear event for bit ERU_EIFR.INTFx occur at the same time, the set event is taken into account.

ERU_FMR Offset address: 178_H

Flag modification register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0								FS7	FS6	FS5	FS4	FS3	FS2	FS1	FS0
r								w	w	w	w	w	w	w	w

Field	Bits	Type	Description
FSx (x=0-7)	x	w	**Set flag ERU_EIFR.INTFx for channel x** Setting this bit will set the corresponding bit ERU_INTFx in register ERU_EIFR. Reading this bit always delivers a 0. If both FSx and FCx are written with '1' in the same access then set takes precedence. 0_B The bit x in register ERU_EIFR is not modified 1_B The bit x in register ERU_EIFR is set
FCx (x=0-7)	x+16	w	**Clear flag ERU_INTFx for channel x** Setting this bit will clear the corresponding bit ERU_EIFR.INTFx in register ERU_EIFR. Reading this bit always delivers a 0. If both FSx and FCx are written with '1' in the same access then set takes precedence. 0_B The bit x in register ERU_EIFR is not modified 1_B The bit x in register ERU_EIFR is cleared
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

35.4.42 Interrupt gating control register y

Each interrupt gating control registers ERU_IGCRy contains bits to enable the pattern detection and to control the gating for one output channel.

ERU_IGCRy (y=0-7) Offset address: $17C_H+y*4$

Interrupt gating control register y Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IGP		GEEN	0					IPEN7	IPEN6	IPEN5	IPEN4	IPEN3	IPEN2	IPEN1	IPEN0
rw		rw	r					rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
IPENx (x=0-7)	x	rw	**Flag pattern enable for input channel x** Bit IPENx determines if the flag INTFx of channel x takes part in the pattern detection for the gating of the requests for the output signals GOUTy and IOUTy. 0_B The bit INTFx does not take part in the pattern detection 1_B The bit INTFx is taken into consideration for the pattern detection

(table continues...)

(continued)

Field	Bits	Type	Description
GEEN	13	rw	**Generate event enable** Bit GEEN enables the generation of a trigger event for output channel y when the result of the pattern detection changes. If enabled, a trigger (e.g. for an interrupt) is generated during the first clock cycle when a pattern is detected or when pattern is no longer detected. 0_B The trigger generation at a change of the pattern detection result is disabled. 1_B The trigger generation at a change of the pattern detection result is enabled.
IGP	15:14	rw	**Interrupt gating pattern** In each register ERU_IGCRy, bit-field IGP determines how the pattern detection influences the output lines GOUTy and IOUTy. 00_B IOUTy is inactive.The pattern is not considered. 01_B IOUTy is activated in response to a trigger event. The pattern is not considered. 10_B The detected pattern is considered. IOUTy is activated if a trigger event occurs while the pattern is present. 11_B The detected pattern is considered. IOUTy is activated if a trigger event occurs while the pattern is not present.
0	12:8, 31:16	r	**Reserved** Read as 0; should be written with 0.

35.4.43 Pattern detection result register

The Pattern detection result register monitors the combinatorial output status of the pattern detection units.

ERU_PDRR Offset address: $19C_H$

Pattern detection result register Application Reset value: $0000\ 00FF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0										CSEL5	CSEL4	CSEL3	CSEL2	CSEL1	CSEL0
r										w	w	w	w	w	w

Field	Bits	Type	Description
CSEL0	0	w	**CPU select 0** Return 0 if read. 0_B CPU0 not affected. 1_B Action selected by OVSTRT, OVSTP, DCINVAL bits, set by the same register write access, is applied to CPU0.
CSEL1	1	w	**CPU select 1** Return 0 if read. 0_B CPU1 not affected. 1_B Action selected by OVSTRT, OVSTP, DCINVAL bits, set by the same register write access, is applied to CPU1.
CSEL2	2	w	**CPU select 2** Return 0 if read. 0_B CPU2 not affected. 1_B Action selected by OVSTRT, OVSTP, DCINVAL bits, set by the same register write access, is applied to CPU2.
CSEL3	3	w	**CPU select 3** Return 0 if read. 0_B CPU3 not affected. 1_B Action selected by OVSTRT, OVSTP, DCINVAL bits, set by the same register write access, is applied to CPU3.
CSEL4	4	w	**CPU select 4** Return 0 if read. 0_B CPU4 not affected. 1_B Action selected by OVSTRT, OVSTP, DCINVAL bits, set by the same register write access, is applied to CPU4.

(table continues...)

(continued)

Field	Bits	Type	Description
CSEL5	5	w	**CPU select 5** Return 0 if read. 0_B CPU5 not affected. 1_B Action selected by OVSTRT, OVSTP, DCINVAL bits, set by the same register write access, is applied to CPU5.
OVSTRT	16	w	**Overlay start** No action is taken if OVSTP is also set. Return 0 if read. 0_B No action 1_B For each CPU selected with CSEL, all the blocks selected with OVCx_OSEL will be activated. In the selected CPUs all the blocks deselected with OVCx_OSEL will be deactivated.
OVSTP	17	w	**Overlay stop** No action is taken if OVSTRT is also set. Return 0 if read. 0_B No action 1_B For CPUs selected with CSEL, all the overlay blocks are deactivated. OVCx_RABRy.OVEN bits are cleared.
DCINVAL	18	w	**Data cache invalidate** Data cache is affected only in the CPUs selected with CSEL. Return 0 if read. 0_B No action 1_B Data Cache Lines in DMI are invalidated [1)]
OVCONF	24	rw	**Overlay configured** Overlay configured status bit This bit may be used as handshake bit between a debug device (via JTAG interface and Cerberus) and CPU(s). 0_B Overlay is not configured or it has been already started 1_B Overlay block control registers are configured and ready for overlay start
OVCONF_P	25	w	**Write protection for OVCONF** This bit enables OVCONF write during OVCCON write. Return 0 if read. 0_B OVCONF remains unchanged. 1_B OVCONF can be changed with write access to register OVCCON.
0	15:6, 23:19, 31:26	r	**Reserved** Read as 0; should be written with 0.

1) Dirty (modified) cache lines are not affected by this operation. If data cache contains modified data, it is not invalidated, and has to be written-back and invalidated by the user. Therefore, it is highly recommended to either: access overlaid data in read-only mode, or use only non-cached access.

TC4Dx SCU connectivity	• Removed ERU output connections to LETH (LETH AUX feature not available in TC4Dx)

36 Power Management System (PMS)

The Power Management System (PMS) provides supply voltage selection, internal supply voltage generation, supply voltage monitoring, power domain and isolation control, and power management functions for the microcontroller. It also supports other microcontroller infrastructure functions through reset triggers, standby mode transitions, and real-time clock services.

36.1 Feature list

Power Management System

- Integrated on-chip voltage regulators enabling a 5 V ± 10% or 3.3 V ± 10% single source power supply concept. External supply on all rails also supported
- Core buck regulator (EVRC) to generate V_{DD} core supply from $V_{DDEXTDC}$ input supply up to 7 V (depending upon product variant) to enable MOSFET supply from external pre-regulator. Synchronization support with external DCDC regulators
- Static voltage scaling support between 0.95 V – 1.025 V ± 10%, depending on product variant, in steps of 2.83 mV (using the embedded voltage regulator EVRC), depending on product variant and device type
- Primary under-voltage monitoring of supply rails including V_{DD}, V_{DDEXT},$V_{DDEXTHS}$, ($V_{DDEXTDC}$-V_{SSDCHS}), $V_{DDEXTDC}$, V_{DDDCLS}, $V_{DDEVRSB}$, V_{DD3PMS}, $V_{DDP3NVM}$, V_{DDM}, $V_{DDPHPHYx}$, $V_{DDPHRIFx}$, V_{DDHSIF}, V_{DDPAD}, V_{DDCPUx}, V_{DDPPU}, V_{DDLMUx}, V_{DDPHYx}, and V_{DDRIFx}, depending on product variant (not all supply rails are available on each product variant), irrespective of whether externally supplied or internally generated, to put the microcontroller into cold reset state
- Secondary independent over and under-voltage monitoring on $V_{DDEVRSB}$, V_{DD3PMS}, V_{DDEXT},$V_{DDEXTHS}$, $V_{DDP3NVM}$, V_{DDM}, V_{DDFLEX}, V_{DD}, V_{DDPMS0}, V_{DDPMS1}, V_{DDPMS2}, $V_{DDSBRAM}$, V_{DDPAD}, $V_{DDPHPHYx}$, $V_{DDPHRIFx}$, V_{DDHSIF}, V_{DDPHYx}, V_{DDRIFx}, V_{DDCPUx}, V_{DDPPU}, V_{DDLMUx}, and $V_{DDEXTDC}$ supplies, depending on product variant (not all supply rails are available on each product variant). In case of violation of the thresholds, alarms are reported to the SMU (safety and security alarm management unit) and CSRM (cyber security real-time module)
- Support of multiple standby power domains PMS0, PMS1, and PMS2 supplied by separate standby supply pin ($V_{DDEVRSB}$) and internal standby core regulators to meet low quiescent standby current targets. Wake-up possible from RTC, WUT, pin events, and V_{DDEXT} supply ramp events
- 256 kB standby RAM support split across CPU0 dLMU and CPU1 dLMU and 32 kB SCR XRAM supplied in standby mode, depending on product variant
- Real Time Clock and timer support with external 32 kHz crystal with temperature trimming, depending on product variant
- Enhanced standby controller subsystem running up to maximum frequency of 100 MHz and with 32 kB XRAM, depending on product variant

Power distribution

- Support of multiple core power domains for CPU, PPU, and LMU functional blocks (depending on product variant) to reduce overall power consumption for use cases where the modules are not required
- Separate ADC power domain supplied by V_{DDM}/V_{SSM} supply rails to ensure minimum noise interference from the digital core and pad domains. Separate V_{DDM}/V_{AREF} reference supply for ADC modules
- Mixed IO support
  - Flexport (V_{DDFLEX}) has separate dedicated supply pins and may be supplied with either 5 V or 3.3 V
  - ADC channels supported in dedicated analog and shared digital port (P00/P33) domains
- XTAL/Oscillator/PLL supply with separate supply and ground pins for minimal noise interference
- Separate port domain for standby controller and standby functions supplied by $V_{DDEVRSB}$ supply rail
- Separate port power domains for high speed communication interfaces
  - SGMIIx and PCIe modules supplied by dedicated $V_{DDPHPHYx}$ and V_{DDPHYx} supply rails
  - NOR Flash interface or ethernet RGMII supplied by dedicated V_{DDHSIF} supply rail
  - Ethernet RMII/MII supplied by dedicated V_{DDFLEX} supply rail

36.2 Functional overview

The PMS functional block constitutes the power management infrastructure, control of power related sub-functions of all modules, control of multiple power domains and voltage rails, supply generation using internal regulators, supply voltage monitors, and system power transitions.

On-chip voltage regulators are implemented in TC4xx thereby enabling a single source power supply concept. The external nominal system supply from external regulator may be either 5 V or 3.3 V. The embedded core voltage regulator (EVRC) in turn may be used to generate the V_{DD} core supply for the core domain depending on hardware configuration pin settings. It is also possible to supply all supply pin voltages externally. All supply and generated voltages need to be available and within the operational limits to release the reset. The primary voltage monitors check for brownout conditions, setting the device into cold power-on reset state in case any voltage is below the operational limits.

This power management block ensures adequate power delivery to all modules, load transient management, and interfaces to external regulators.

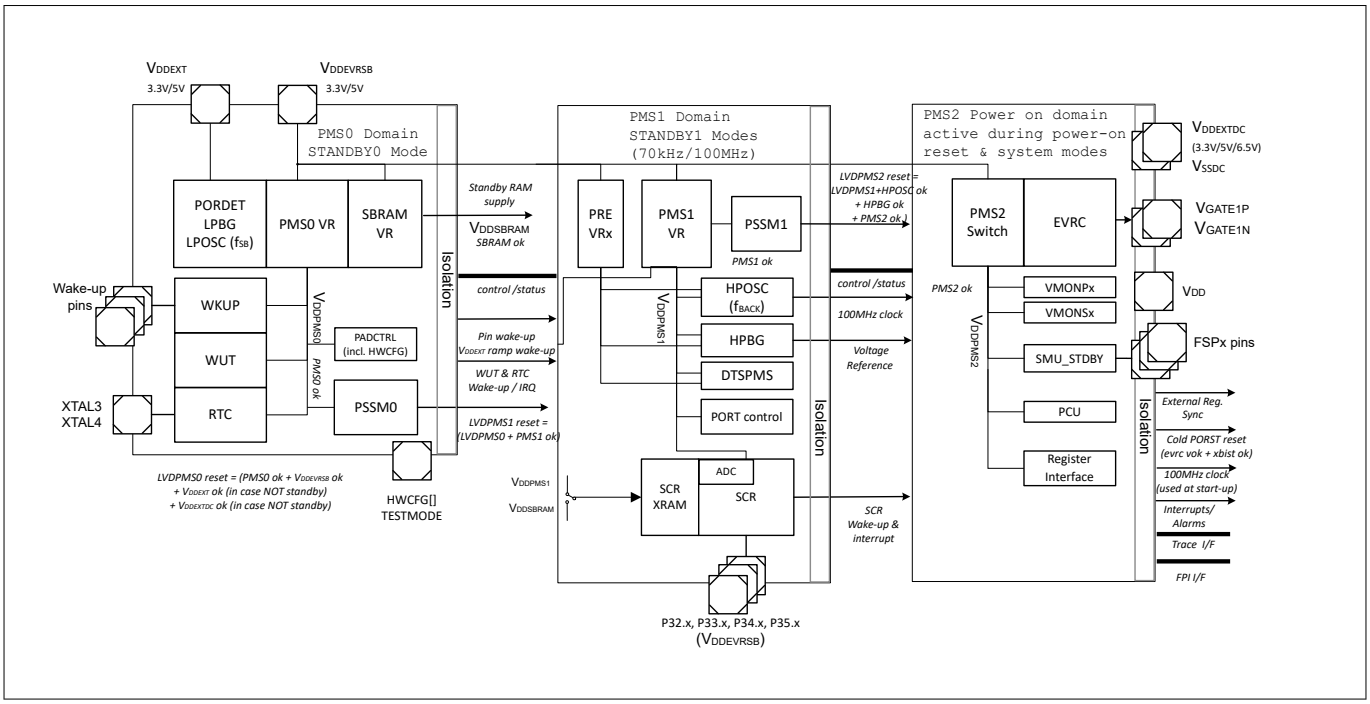

Figure 774 PMS block diagram (not all features are available for all variants)

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

TC4Dx SMU alarm mapping tables on page 7233

36.3 Functional description

This part describes the functionality of the PMS. Details on the various functions are provided in the enclosed sections.

36.3.1 Power supply rails and distribution

The following supply rails are implemented on TC4xx:

The following table provides an overview of the external supply rails. Refer to the functional description for the specific product variant for detailed information.

Table 1418 External supply rails

Voltage rail	Description
$V_{DDEVRSB}$	Standby domain supply. Separate dedicated standby supply for: • Standby pad domain (P32/33/34/35) • Standby power domains (PMS0, PMS1, PMS2) • Standby controller (SCR) 3.3 V or 5 V depending on application requirements
V_{DD3PMS}	Dedicated PMS supply for Power Management components. Generated by internal EVR3PMS voltage regulator (not available in all derivatives). 2.7V
$V_{DDEXTHS}$	I/O port supply. Separate dedicated supply for high speed communication modules. 3.3 V or 5 V depending on application requirements $V_{DDEXTHS_SENSE}$ sense supply is an unloaded $V_{DDEXTHS}$ pin to sense internal $V_{DDEXTHS}$ voltage to account for voltage drops.
V_{DDEXT}	I/O port supply. Main IO pad supply for ports and pins. 3.3 V or 5 V depending on application requirements V_{DDEXT_SENSE} sense supply is an unloaded V_{DDEXT} pin to sense internal V_{DDEXT} voltage to account for voltage drops.
$V_{DDEXTOSC}$	I/O supply for XTAL pads. Supply for PLLs, Clock generation and VTMON logic. 3.3 V or 5 V depending on application requirements
$V_{DDP3NVMx}$	Supply voltage for non-volatile memory 3.3 V
V_{DDM}	Separate dedicated ADC VDDM supply for ADC and DSADC modules. 3.3 V or 5 V depending on application requirements
V_{DDFLEX}	Flexport supply. Separate dedicated supply for high speed communication modules. 3.3 V or 5 V depending on application requirements

(table continues...)

Table 1418 (continued) External supply rails

Voltage rail	Description
$V_{DDEXTDC}$	This is the supply of the EVRC and of the external MOSFETs. EVRC and external MOSFETs must be supplied with the same voltage. Dedicated supply for the EVRC, MOSFET gate drivers, and for the external MOSFETs. 3.3 V to 6.5 V depending on application requirements
$V_{DDPHPHY0}$	High-speed PHY 0 supply. Separate dedicated IO and module supply for high-speed PHY 0 module 1.8 V
$V_{DDPHPHY1}$	High-speed PHY 1 supply. Separate dedicated IO and module supply for high-speed PHY 1 module 1.8 V
$V_{DDPHPHY2}$	High-speed PHY 2 supply. Separate dedicated IO and module supply for high-speed PHY 2 module 1.8 V
$V_{DDP3RIFx}$	Radar interface 0 supply (only on certain product variants). To be connected to V_{DDEXT}. Input supply for the embedded D-PHY LDO. 3.3 V
$V_{DDPHRIFx}$	Radar interface 0 supply (only on certain product variants). Separate dedicated IO and module supply for CSI2 D-PHY module. This is connected to the output of the embedded D-PHY LDO. If using the embedded D-PHY LDO, then this supply pin should be connected to an external capacitor. Only if not using the embedded D-PHY LDO, a separate 1.8 V supply can be connected to this pin. During start-up, including LBIST, the embedded D-PHY LDO is disabled. It can be enabled after the start-up, by the application software. Therefore, the application must ensure that the D-PHY pins are not externally driven with a voltage level above or equal to 0.7 V, as long as the $V_{DDPHRIF0}$ is not powered. 1.8 V
V_{DDHSIF}	RGMII or NOR Flash I/F supply. Separate dedicated IO and module supply for the xSPI interface and RGMII module. 3.3 V for RGMII usage 1.8 V or 3.3 V for xSPI usage, depending on application requirements

(table continues...)

Table 1418 (continued) External supply rails

Voltage rail	Description
V_{DD}	Core supply of the device. The supply is split internally in domain supplies V_{DDCPUx}, V_{DDPPU}, and V_{DDLMU}. Depending on product variant, either: • or 1.0 V on slow and typical (POR) samples, respectively 0.95 V on fast samples • or 1.025 V on slow and typical (POR) samples, respectively 0.975 V on fast samples The same voltage split applies to all supply rails with typical value of 1.0 V/ 0.95 V, or 1.025 V/ 0.975 V V_{DD_SENSE} sense supply is an unloaded VDD pin to sense internal VDD voltage to account for voltage drops.
V_{DDPHY0}	Ethernet SGMII0 core and IO supply, or debugging interface core and IO supply (depending on product variant).
V_{DDPHY1}	Ethernet SGMII1 or PCIe core and IO supply. Separate dedicated core supply for SGMII1 or PCIe module
V_{DDPHY2}	Debugging interface core and IO supply (only on certain product variants). Separate dedicated core supply for SGBT debugging module
V_{DDRIFx}	Radar interface core and IO supply (only on certain product variants). Separate dedicated core supply for CSI2 D-PHY module
V_{DDSB}	Dedicated LMU supply

The following table provides an overview of the internal supply rails. Depending upon the product variants all supply rails may not be available. Refer to the functional description for the specific product variant for detailed information.

Table 1419 Internal power domains

Voltage rail	Description
V_{SSDCHS}	EVRC MOSFET driver supply. Internal elevated ground supply for VGATE1P P channel driver. • 0 V if $V_{DDEXTDC}$ = 3.3 V/5 V • 1.5 V if $V_{DDEXTDC}$ = 6.5 V 0 V - 1.5 V
V_{DDDCLS}	EVRC MOSFET driver supply. Internal supply for VGATE1N N channel driver. • 3.3 V if $V_{DDEXTDC}$ = 3.3 V • 5 V if $V_{DDEXTDC}$ = 5 V/6.5 V 3.3 V - 5 V
V_{DDLMU0}	Switchable LMU power domain. Internal supply rail for the LMU.

(table continues...)

Table 1419 (continued) Internal power domains

Voltage rail	Description
V_{DDLMU1}	Switchable LMU power domain. Internal supply rail for the LMU.
V_{DDPAD}	V_{DD} pads supply voltage.
V_{DDPPU}	Switchable PPU power supply. Internal supply rail after power domain switches.
V_{DDPMS0}	Internal core supply for PMS0 domain. 0.95 V
V_{DDPMS1}	Internal core supply for PMS1 domain. 0.95 V/1.0 V
V_{DDPMS2}	Internal core supply for PMS2 domain. 0.95 V/1.0 V
$V_{DDSBRAM}$	Internal core supply for Standby RAMs. 0.95 V

The following table shows the state of the supply rails during the different system modes. The mentioned system modes are defined in the standby mode management (SMM) chapter. The names STANDBY0 ($V_{DDEVRSB}$) and STANDBY1 ($V_{DDEVRSB}$) denote the STANDBY0 mode respectively STANDBY1 mode where only $V_{DDEVRSB}$ is supplied. The names STANDBY0 ($V_{DDEVRSB}$ + V_{DDEXT}) and STANDBY1 ($V_{DDEVRSB}$ + V_{DDEXT}) denote the STANDBY0 mode respectively STANDBY1 mode where both $V_{DDEVRSB}$ and V_{DDEXT} are supplied.

Table 1420 Supply rail states during different system modes

V_{DDPMS0}	ON	ON	ON	ON	ON	ON	ON	ON
V_{DDPMS1}	ON	ON	ON	ON	OFF	OFF	ON	ON
V_{DDPMS2}	ON	ON	ON	ON	OFF	OFF	OFF	OFF
$V_{DDSBRAM}$	ON	ON	ON	ON	ON	ON	ON	ON

1) See cranking voltage ranges in the datasheet.
2) Depending on external regulator capabilities: ON if supply during standby is supported, OFF otherwise.
3) Depending on external regulator capabilities: OFF if switch-off independently from V_{DDEXT} during standby is supported, ON otherwise.
4) If $V_{DDEXTDC}$ remains supplied in standby mode, the additional current I_{DCSTBY} is drawn, as specified in the datasheet.
5) ON if $V_{DDEXTDC}$>5 V (depending on HWCFG[2:1] setting), OFF otherwise
6) ON if at least one high-speed PHY is used, OFF otherwise. If no PHY is used, it is recommended to tie to GND via resistor
7) Wake-up from standby possible through wake-up capable pins (see section on standby exit and wake-up sources).
8) The embedded LDO must be enabled after start-up and after LBIST by application SW, or, alternatively, a 1.8 V external supply can be used. While the $V_{DDPHRIFx}$ supply is not powered, all D-PHY pins must not be driven with a voltage level above or equal to 0.7 V.
9) Required by key-on LBIST to supply V_{DDPHYx} even if the respective high-speed PHY is not used.

If not all high-speed PHYs (like Ethernet SGMII, PCIe, or debug interface) which are available on a certain MCU product variant are used, then following constraints must be considered:

- If at least one high-speed PHY is used, then all $V_{DDPHPHYx}$ supply rails must be connected to 1.8 V
- All V_{DDPHYx} supply rails must be connected to the V_{DD} supply voltage, independently if the respective high-speed PHY is used or not, in order to enable testing of all safety logic in the SRI clusters

In the following table, all supply rails shall have been ramped up to their minimum voltage operational limits as documented in the datasheet before the external regulator releases the warm PORST of the MCU via the external PORST pin. It is not allowed to leave any supply rail unsupplied after the warm PORST reset release by the external regulator. If a supply rail is not supplied after the warm PORST release, the primary voltage monitors will keep the MCU in cold PORST state until all monitored supply rails are above their minimum operational limits ($V_{RSTxx}/V_{xxPRIUV}$). Also if a supply rail has a failure during operation, the primary voltage monitors will trigger a cold PORST and will keep the MCU in cold PORST as long as the supply rail is below the respective cold PORST threshold ($V_{RSTxx}/V_{xxPRIUV}$). In addition, at start-up, the PBIST1 and PBIST2 voltage tests are done, for over-voltage and under-voltage conditions, as described in the respective PBIST1/2 section, and if PBIST1 or PBIST2 fails, the MCU does not release the cold PORST. In the following table, multiple sub-columns mean several voltage levels are allowed, depending on the application requirements.

Table 1421 Allowed combinations of nominal supply voltages for the external voltage rails

Supply rails	V_{DDEXT} = 5 V nominal voltage level[2]		V_{DDEXT} = $V_{DDEVRSB}$ = 3.3 V nominal voltage level	
$V_{DDEVRSB}$	5 V	3.3 V	3.3 V	
$V_{DDEXTHS}$	5 V	3.3 V	3.3 V	
V_{DDEXT}	5 V		3.3 V	
$V_{DDP3NVM}$	N/A[1]		3.3 V	
$V_{DDP3RIF0}$	N/A[1]		3.3 V	
V_{DDM}	5 V only, no 3.3 V allowed		5 V[2]	3.3 V
V_{DDFLEX}	5 V	3.3 V	3.3 V	
$V_{DDEXTDC}$	3.3-5 V/5.5-6.5 V[3]		3.3-5 V/5.5-6.5 V[3]	
$V_{DDPHPHY0}$	1.8 V[6]		1.8 V[6]	
$V_{DDPHPHY1}$	1.8 V[6]		1.8 V[6]	
$V_{DDPHPHY2}$	1.8 V[6]		1.8 V[6]	
$V_{DDPHRIF0}$	N/A[1]		1.8 V[4]	
V_{DDHSIF}	1.8 V/3.3 V[5]		1.8 V/3.3 V[5]	
V_{DD}	1.025 V/0.975 V[6] (external supply or generated by EVRC)		1.025 V/0.975 V[6] (external supply or generated by EVRC)	
V_{DDPHY0}	1.025 V/0.975 V[6] (external supply or generated by EVRC)		1.025 V/0.975 V[6] (external supply or generated by EVRC)	
V_{DDPHY1}	1.025 V/0.975 V[6] (external supply or generated by EVRC)		1.025 V/0.975 V[6] (external supply or generated by EVRC)	
V_{DDPHY2}	1.025 V/0.975 V[6] (external supply or generated by EVRC)		1.025 V/0.975 V[6] (external supply or generated by EVRC)	
V_{DDRIF0}	N/A[1]		1.025 V/0.975 V (external supply or generated by EVRC)	
V_{DDSB}	1.025 V/0.975 V[6] (external supply or generated by EVRC)		1.025 V/0.975 V[6] (external supply or generated by EVRC)	

1) Supply rail not available on product variants with 5 V supply.
2) Except in certain product variants, where the voltage is limited to 3.3 V
3) Depending on the available external pre-regulator voltage. $V_{DDEXTDC}$ is limited to the datasheet parameter $V_{DDEXTDC}$ for maximum allowed voltage
4) Can be supplied from on-chip regulator.
5) V_{DDHSIF} voltage options:
   - 3.3 V for RGMII usage
   - 1.8 V or 3.3 V for xSPI usage, depending on application requirements
6) Voltage level dependent on product variant and sample type

36.3.2 PMS infrastructure and domains

The PMS is comprised of 3 power domain partitions PMS0, PMS1, and PMS2, to support low power STANDBY0 and STANDBY1 modes.

The PMS0 domain constitutes the smallest standby domain with minimum functionality required to recognize wake-up from pins, supply and wake-up timer modules. The PMS0 domain contains the V_{DDEXT} and $V_{DDEVRSB}$ start-up detectors which release the LVD reset, the 70 kHz standby clock, the RTC with 32 kHz external crystal clock[42)] and regulators to keep standby RAM supplied[42)].

The PMS1 domain constitutes the next scalable standby domain including the 8-bit standby controller subsystem, the high precision band-gap for SCR ADC conversions and high precision 100 MHz clock which serves as SCR clock, back-up clock and start-up clock for the system. The external hardware configuration pins (*HWCFG[1-6]*) are latched in PMS to distinguish various boot modes .

The PMS2 domain includes the regulators and monitors. The EVRC synchronous step-down regulator controls the external complementary MOSFETs through VGATEx pins to buffer the energy in a LC filter in order to generate a regulated core supply. The primary under-voltage monitoring of the external and internal supplies are inherently carried out by multiple VMONPx monitors to ensure proper functioning of the system . Additional VMONSx secondary safety over-voltage and under-voltage monitoring against programmable thresholds is provided for all supplied and generated voltages . The standby SMU ensures the activation of the safe error pin path in case of critical safety alarms to inform external regulator or external safety monitors.

36.3.2.1 Independent standby supply domains (PMS0, PMS1, PMS2)

The PMS standby domains include the following components. Refer to the functional description for the specific product variant for an overview figure of the components.

42 Except in certain product variants

Table 1422 PMS domains and included functions

Functional Block	Function/Component	Description
PMS	PMS0, PMS1, and PMS2	Standby power domain partitions. PMS0.VR, PMS1.VR and PMS0.SBRAMVR are the internal regulators to supply these partitions. PMS2 Switch isolates the PMS2 domain from the PMS1 domain
	PMS0.PORDET	Low-voltage supply detectors (for power-on reset release)
	PMS0.PSSM0 PMS1.PSSM1	Power start-up state machines
	PMS0.LPBG	Low-power band-gap voltage reference
	PMS0.LPOSC	70 kHz standby clock source (fSB)
	PMS0.WKUP	Wake-up unit to wake-up on pin events or V_{DDEXT} supply-ramp-up
	PMS0.WUT	Wake-up timer
	PMS0.RTC	Real time clock and 32 kHz XTAL support
	PMS1.HPOSC	100 MHz infrastructure clock (fBACK)
	PMS1.HPBG	Secondary high-precision band-gap voltage reference
	PMS0 VR SBRAM VR PMS1 VR PRE VRx PMS2 Switch	Internal voltage regulators for the PMS internal supply rails, respectively power switch for the V_{DDPMS2} rail
	PMS2.EVRC	Embedded core voltage regulator
	PMS2.VMONPx	Primary voltage monitors and cold PORST reset
	PMS2.VMONSx	Secondary voltage monitors and safety alarms
SCR	SCR modules	8-bit standby controller sub-system integrated in the PMS1 domain
DTS	DTSPMS	Die temperature module integrated in the PMS1 domain
SMU	SMU_STDBY	Standby SMU integrated in the PMS2 domain

The objective of the integrated voltage regulators (PMS0 VR, SBRAM VR, PRE VRx, PMS1 VR) is to supply the basic infrastructure components, the standby domain, and certain safety components with a dedicated low-noise supply independent from the rest of the chip. The V_{DDPMSx} regulators are supplied by the external 5 V or 3.3 V $V_{DDEVRSB}$ supply. They are implemented as low drop-out regulators, generating the V_{DDPMSx} internal voltage, which is buffered internally and is not routed to any external supply pin. Since $V_{DDPMS0-1}$ domains are powered in STANDBY1 mode, they are implemented to have low power consumption to meet the $I_{STANDBY}$ current parameter limits in the data sheet. The V_{DDPMSx} supplies the high precision band-gap, the 100 MHz infrastructure clock source, and the embedded EVRC regulator, as voltage regulators have to be supplied independently from their generated voltages. The V_{DDPMSx} regulators also supply the wake-up timer, the standby controller, and a part of the port domain (Port 32-35). During standby mode, the standby RAMs are supplied by the $V_{DDSBRAM}$ (SBRAM VR) regulator.

TC4Dx independent standby supply domains (PMS0, PMS1, PMS2) on page 6148

36.3.2.2 Reference voltage generation (HPBG)

The objective of the secondary[43] high precision band-gap (HPBG) and reference current circuitry is to provide an accurate voltage reference and reference currents to various modules. The reference is used by EVRC and supply monitors.

The secondary high precision band-gap reference is checked against the primary low-power band-gap reference or V_{DDPMSx} voltage to detect band-gap drifts during the start-up phase. This is part of the power BIST which is carried out only during a supply ramp-up. Furthermore, the HPBG voltage can be measured on an ADC channel configured through GLOBCFG.SVCH and GLOBCFG.SVSIG bit-fields. This provides a diagnostic between the internal band-gap reference and the external ADC V_{AREFx} reference voltage.

A dynamic temperature-dependent trimming of the high-precision band-gap is available and can be enabled in the HPBGTRIM register. This feature is enabled using the HPBGTRIM.TRIMEN bit and it applies a selected trim value, as documented in the HPBGTRIM.TRIMx bit-fields, depending on the temperature measured by the PMS die temperature sensor (DTSPMS). Using this trimming feature requires the DTSPMS to be enabled and started (through the DTS_CON register). During LIN communication, the application software must ensure that the trim value is not changed until the end of the communication schedule, therefore it must set the SCR bit LIN_BCON.TTDIS to 1_B at the beginning of the LIN communication schedule and clear it to 0_B at the end of the communication schedule. The PMS hardware ensures that a temperature-dependent change of the trim value is only allowed when the SCR bit LIN_BCON.TTDIS is equal to 0_B.

The application software must be aware that the HPBGTRIM register is reset whenever entering STANDBY0 mode (to the value indicated by the LVDPMS1 reset type). Therefore, if an application switches from STANDBY0 mode directly to STANDBY1 mode (for instance, if the application enters STANDBY0, then wakes up to STANDBY1) and if the application requires the dynamic trimming feature for increased HPBG accuracy in STANDBY1 mode, it needs to store the content of this register into the SCR standby XRAM before going into STBANDBY0. After waking up from STANDBY0 directly into STANDBY1, the SCR software can read the stored values from SCR XRAM and perform the following steps in order to emulate the hardware behavior of the temperature-dependent trimming:

- Select the temperature-dependent TRIMx value depending on the DTS_STAT.RESULT temperature reading
- Add the TRIMx value (considering sign interpretation) to the content of the SCR SCU_PMSHPBG_BGTRIM register

36.3.2.3 70 kHz standby clock (f_{SB}) and 100 MHz infrastructure clock (f_{BACKT})

The 70 kHz clock source is used during standby mode. Its accuracy is specified by the f_{SB} parameter in the datasheet. This clock source is trimmed after start-up.

The 100 MHz clock source is a precise on-chip clock used by the PMS infrastructure including on-chip voltage regulators, state machines, and the Standby Controller (SCR). After start-up, the 100 MHz clock source has a lower accuracy (see f_{BACKUT} parameter in the datasheet) and the clock source is later trimmed by the start-up software (see f_{BACKT} parameter in the data sheet).

A fine trimming is option is available in the register field HPOSCCON1.OSCFTRIM. The fine trim value is reset on a cold PORST reset, to be able to revert to the default setting in case of erroneous trimming. The frequency trim steps are non-linear and dependent on process, temperature, and voltage.

43 There are two band-gaps implemented in the PMS, a primary low-power band-gap, and a secondary high-precision band-gap.

A dynamic temperature-dependent trimming of the 100 MHz clock is available and can be enabled in the HPOSCTRIM register. This feature is enabled using the HPOSCTRIM.TRIMEN bit and it applies a selected trim value, as documented in the HPOSCTRIM.TRIMx bit-fields, depending on the temperature measured by the PMS die temperature sensor (DTSPMS). Using this trimming feature requires the DTSPMS to be enabled and started (through the DTS_CON register). During LIN communication, the application software must ensure that the trim value is not changed until the end of the communication schedule, therefore it must set the SCR bit LIN_BCON.TTDIS to 1_B at the beginning of the LIN communication schedule and clear it to 0_B at the end of the communication schedule. The PMS hardware ensures that a temperature-dependent change of the trim value is only allowed when the SCR bit LIN_BCON.TTDIS is equal to 0_B.

The application software must be aware that HPOSCTRIM and HPOSCCON1 registers are reset whenever entering STANDBY0 mode (to the value indicated by the LVDPMS1 reset type). Therefore, if an application switches from STANDBY0 mode directly to STANDBY1 mode (for instance, if the application enters STANDBY0, then wakes up to STANDBY1) and if the application requires the dynamic trimming feature for increased accuracy in STANDBY1 mode (for instance for LIN communication), it needs to store the content of these registers into the SCR standby XRAM before going into STBANDBY0. After waking up from STANDBY0 directly into STANDBY1, the SCR software can read the stored values from SCR XRAM and perform the following steps in order to emulate the hardware behavior of the temperature-dependent trimming:

- Select the temperature-dependent TRIMx value depending on the DTS_STAT.RESULT temperature reading
- Read the previously stored HPOSCCON1.OSCFTRIM value
- Add the OSCFTRIM and the TRIMx values (considering sign interpretation) and write the result into the SCR registers SCU_PMSHPOSC_FTRIM7_0 and SCU_PMSHPOSC_FTRIM8_8

36.3.3 Supply start-up and POR release

This section provides details on the PMS functionality related to the supply selection, ramp-up and ramp-down behavior, and power-on reset (POR).

36.3.3.1 Supply mode selection

Refer to the functional description for the specific product variant for an image showing the hardware configuration (HWCFG) pins.

The choice of the supply scheme at start-up is based on the latched status of *HWCFG[2:1]* pins before cold PORST release and is indicated by the PAD_STAT.HWCFGx status flags. Following supply modes are available depending on product variant and are further enumerated in the following table:

- Single source 5 V supply level ($V_{DDEXTDC} = V_{DDEXT}$ = 5 V, or V_{DDEXT} = 5 V and 3.3 V ≤ $V_{DDEXTDC}$ ≤ 5 V) with EVRC in SMPS mode using external switches. This 5 V supply mode is not available on certain product variants
- Single source 3.3 V supply level ($V_{DDEXTDC} = V_{DDEXT}$ = 3.3 V, or V_{DDEXT} = 3.3 V and 3.3 V ≤ $V_{DDEXTDC}$ ≤ 5 V) with EVRC in SMPS mode using external switches. On certain product variantsonly $V_{DDEXTDC}$ = 3.3 V is supported
- High-voltage supply level (5.5 V[44] ≤ $V_{DDEXTDC}$ *(Typ)* ≤ 6.5 V, not available on certain product variants) with EVRC in SMPS mode using external switches:
  - V_{DDEXT} = 5 V
  - V_{DDEXT} = 3.3 V
- V_{DD} supply provided externally and EVRC is in disabled state:
  - $V_{DDEXTDC} = V_{DDEXT}$ = 5 V and V_{DD} supplied externally. Not available on certain product variants
  - $V_{DDEXTDC} = V_{DDEXT}$ = 3.3 V and V_{DD} supplied externally

[44] Minimum static voltage value for the high-voltage mode. Dynamic undershoots down to 5 V are supported in this mode.

The above-mentioned supply voltage conditions refer to the nominal values of the supply voltages (static conditions). In addition, a dynamic operational range for each supply voltage, as defined in the supply operating conditions in the data sheet, is supported.

EVRC is enabled or disabled at start-up through the *HWCFG[2:1]* configuration pins. In case EVRC is enabled, *VGATE1P* and *VGATE1N* pins must be connected to the gate of an external P-channel MOSFET and N-channel MOSFET respectively. In case EVRC is disabled, it is recommended to tie $V_{DDEXTDC}$ to V_{DDEXT}.

On certain product variants , *HWCFG[2]* is used to configure the high-end (HE) or low-end (LE) configuration of the EVRC, if enabled, with respect to the available switching frequencies:

- *HWCFG[2]*=0 selects the EVRC HE configuration, with supported f_{DCDC} frequencies of either 0.8 MHz or 0.45 MHz
- *HWCFG[2]*=1 selects the EVRC LE configuration, with supported f_{DCDC} frequencies of either 1.82 MHz or 0.8 MHz

The allowed combinations of nominal external supply voltages among different supply rails are documented in chapter Power supply rails and distribution . All externally provided supplies must be available and be stable before warm PORST reset release by the external regulator(s) (the external regulator releases a warm PORST of the MCU via the external PORST pin). If an externally provided supply rail is not available after the warm PORST release, the primary voltage monitors will keep the MCU in cold PORST state until all monitored supply rails are above their minimum operational limits (V_{RSTxx}/$V_{xxPRIUV}$). In addition, at start-up, the PBIST1 and PBIST2 voltage tests are done, for over-voltage and under-voltage conditions, as described in the respective PBIST1/2 section, and if PBIST1 or PBIST2 fails, the MCU does not release the cold PORST.

HWCFG[2:1] are latched during supply ramp-up and the EVRC regulator, if enabled, is consequently started. The latched values are stored in the PAD_STAT.HWCFGx register bits. The latched values are retained through a cold PORST and are only reset if LVD (Low Voltage Detector) reset (LVDANA reset) is asserted. HWCFG signals are filtered through a spike/glitch filter and are monitored for a constant level over a 28 µs - 115 µs nominal debouncing period before the value is considered as valid so as to ensure reliable operation in noisy environment. The current state of EVRC is reflected in the EVRC_STAT0.EVRC flag. For small package variants, some of the *HWCFG* configuration pins may be absent and the EVRC is activated by default at start-up.

HWCFG[6] pin state is propagated to pads in the V_{DDEXT} and $V_{DDEVRSB}$ domain during early V_{DDEXT} supply ramp-up ($V_{DDEXT} \geq V_{DDPPA}$, data sheet parameter) to decide and set the default reset state of port pins as early as possible. During the initial ramp-up phase of V_{DDEXT} and $V_{DDEVRSB}$ supply voltage from 0 V up to V_{DDPPA} limit, the voltage levels of pins are undefined till the transistor threshold voltages are reached. After V_{DDPPA} limit, the pins behave as inputs with pull-up if *HWCFG[6]* = 1 or are in tristate if *HWCFG[6]* = 0. During the later stage of ramp-up, after $V_{DDEXT} \geq V_{LVDRSTEXT}$ (data sheet parameter) and after LVDANA reset release, the *HWCFG[6]* inverted value is latched and stored in the PAD_STAT.ALLTRIST and PAD_STAT.SBTRIST register bits.

HWCFG[1,2,3,6] pins have weak internal pull-up active at start-up, irrespective of *HWCFG[6]* pin level, to ensure that the device boots with a defined configuration if *HWCFG[1,2,3,6]* pins are left unconnected. *HWCFG[1,2,3,6]* pins are only latched by the PMS on every initial supply ramp-up and are not re-latched during warm reset events (warm PORST, system or application resets) or upon exit from standby mode (all standby modes). All *HWCFG* pins are additionally latched by the SMM functional block in the STSTAT register (start-up status register) on every warm reset release, see the documentation of the SMM functional block.

- *HWCFG[6]* and *HWCFG[1,2]* are recognized as high when the respective pin is open or pulled up to V_{DDEXT} supply with pull device on the external system, according to the R_{HWCFG} value indicated in the data sheet
- *HWCFG[6]* and *HWCFG[1,2]* are recognized as low when the respective pin is pulled down to *GND* with pull device on the external system, according to the R_{HWCFG} value indicated in the data sheet

Table 1423 Pad state depending on $V_{DDEVRSB}$ and V_{DDEXT} supply

$V_{DDEVRSB}$ level	V_{DDEXT} level	$V_{DDEVRSB}$ pads state	V_{DDEXT} pads state
$V_{DDEVRSB} > V_{LVDRSTSB}$	$V_{DDEXT} < V_{DDPPA}$	Undefined (pull-up not guaranteed)	Undefined
$V_{DDEVRSB} > V_{LVDRSTSB}$	$V_{DDPPA} \le V_{DDEXT} < V_{LVDRSTEXT}$	As defined by *HWCFG[6]*	As defined by *HWCFG[6]*

(table continues...)

[44] Minimum static voltage value for the high-voltage mode. Dynamic undershoots down to 5 V are supported in this mode.

Table 1424 (continued) Supply mode and topology selection

Power mode	*HWCFG[2:1]*	*VGATE1P*/*VGATE1N*	Supply pin voltage level/source	Selected supply scheme
	Not supported on variants where only HWCFG[2:1] is used for the EVRC enable/ disable & switching frequency selection.		Not supported.	
b2.)	11_B on variants where HWCFG[2:1] is used for V_{DDEXT} & $V_{DDEXTDC}$ range selection.	*VGATE1P*/*VGATE1N* connected to gate of P-/N-ch. MOSFET	5.5 V[44] ≤ $V_{DDEXTDC}$ ≤ 6.5 V V_{DDEXT} & $V_{DDEVRSB}$ = 3.3 V V_{DD} supplied by EVRC.	High-voltage $V_{DDEXTDC}$ mode. 3.3 V external supply. EVRC in SMPS mode. Standby mode supported (with higher standby current, see I_{DCSTBY} datasheet parameter).
	Not supported on variants where only HWCFG[2:1] is used for the EVRC enable/ disable & switching frequency selection.		Not supported.	

If *HWCFG[2,1]* pins are left unconnected, it is ensured that EVRC is active, owing to the internal weak pull-up active by default after start-up/cold PORST. Only the nominal voltage values of the respective rails are indicated in the table. The tolerances of the supply voltages are documented in the datasheet.

For *HWCFG[2:1]*=00_B, all three supply rails $V_{DDEXTDC}$, V_{DDEXT}, and $V_{DDEVRSB}$ must be on the same level, that is $V_{DDEXTDC}$ = V_{DDEXT} = $V_{DDEVRSB}$ = either 5 V or 3.3 V (on certain product variants only 3.3 V is supported). Also when *HWCFG[2:1]*= 01_B, or 10_B, or 11_B, V_{DDEXT} and $V_{DDEVRSB}$ must be on the same level, that is V_{DDEXT} = $V_{DDEVRSB}$ = either 5 V or 3.3 V (on certain product variants only 3.3 V is supported).

36.3.3.1.1 Using HWCFG pins as GPIOs

If *HWCFG[5:1]* are not exclusively used as configuration pins and are left unconnected or used as GPIOs after startup then certain conditions are to be carefully considered

44 Minimum static voltage value for the high-voltage mode. Dynamic undershoots down to 5 V are supported in this mode.

If a deterministic behavior for the pins during reset execution is wanted the *HWCFG[6]* pin needs to be tied to 1_B to ensure pull-up behavior for all GPIO pins, including HWCFG pins, during and after reset execution.

If *HWCFG[5:1]* pins are used as output pins then the following conditions are to be considered

- If *HWCFG[6]* is tied to 1_B or left open then *HWCFG[6:1]* will be configured as weak pull-up. This weak pull-up condition of any particular pin can be overridden by connecting appropriate voltage levels from outside
- If *HWCFG[6]* is tied to 0_B then *HWCFG[5:1]* are in tristate. During the reset execution *HWCFG[5:1]* pins are needed to be driven to appropriate voltage

If *HWCFG[5:1]* are used as input pins then the following condition is to be considered

- If *HWCFG[5:1]* are used as inputs then during the during the boot up phase it to ensured those pins are connected to expected stable voltage levels

If *HWCFG[5:1]* are unconnected then depending on which *HWCFG* pin is unconnected different behaviors are expected

- If *HWCFG[6]* is unconnected then before the cold PORST release it would be sampled as 1_B. As a result of it the internal pull-up of all the GPIOs including *HWCFG* pins will be enabled unless the Pad configuration register.ALLTRIST bit field is set to 1_B. If Pad configuration register.ALLTRIST bit field is set to 1_B during runtime then after application reset no deterministic behavior can be ensured for the unconnected *HWCFG* pins. It is recommended to avoid this situation
- if HWCFG[2:1] are unconnected then for proper operation of EVRC, it has to be ensured that $V_{DDEXTDC}$ is within the range specified by the datasheet parameter $V_{INEXTDC}$ for HWCFG[2:1]=11_B
- If *HWCFG[5:3]* pins are unconnected then
  - If *HWCFG[6]* is sampled as 1_B and Pad configuration register.ALLTRIST bit-field is set to 0_B during runtime then the *HWCFG[3]* pin would be pulled up which will ensure start from BMHD
  - If If *HWCFG[6]* is tied to 0_B and Pad configuration register.ALLTRIST bit-field is set to 1_B during runtime then *HWCFG[5:3]* pins are in tristate. After the application reset no deterministic behavior for *HWCFG[5:3]* pins can be expected which can lead to unwanted boot behavior. In this scenario at least *HWCFG[3]* pin must be connected to 1_B to ensure the start from BMHD BMI
  - If If *HWCFG[6]* is tied to 0_B and Pad configuration register.ALLTRIST bit-field is set to 1_B during runtime then *HWCFG[5:3]* pins are in tristate. After the application reset no deterministic behavior for *HWCFG[5:3]* pins can be expected which can lead to unwanted boot behavior. In addition if *HWCFG[3]* is connected to 0_B then *HWCFG[5:4]* must be defined to valid input (0_B or 1_B)
  - If UCB1_15_BML.BML bit-field is activated then the HWCFG[5:3] states are ignored

36.3.3.2 Supply ramp-up and ramp-down behavior

This section presents the behavior of the supply rails during ramp-up, ramp-down, and dynamic operational phases.

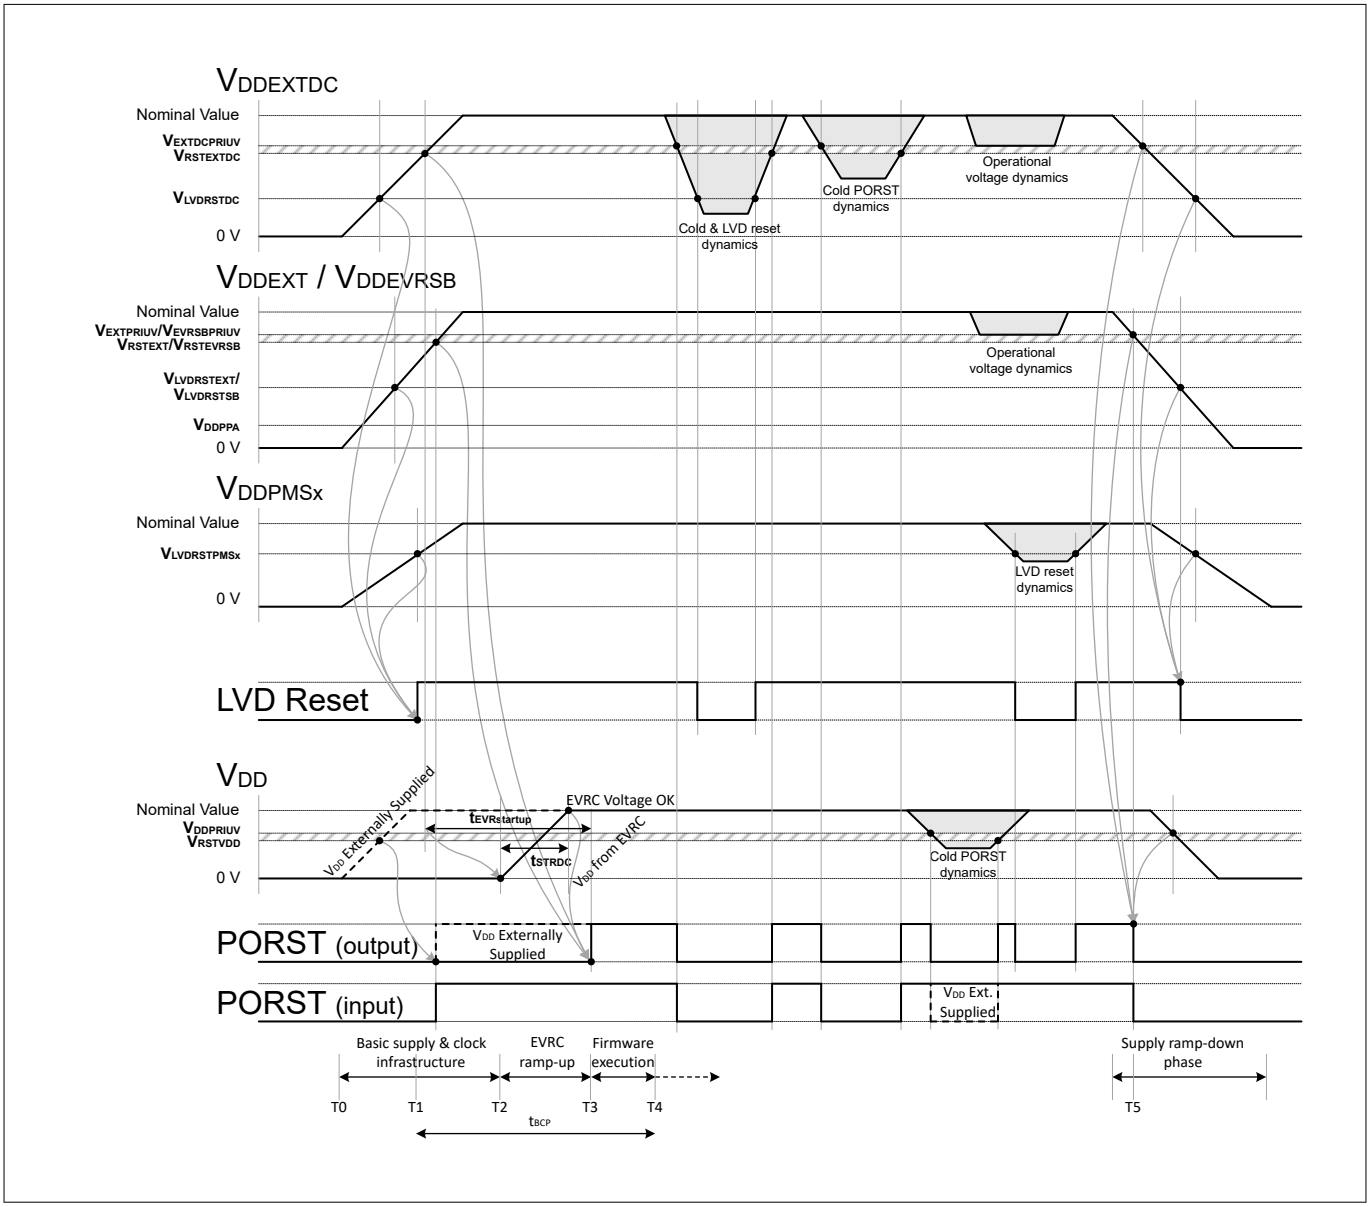

Figure 777 Supply ramp-up and ramp-down behavior

- The start-up slew rates for the supply rails shall comply to the respective data sheet parameters dV_{XX}/dt. The slope is defined as the maximum tangential slope between 0% to 100% voltage level. The actual waveform may not represent the specification
- In case of an external regulator for the V_{DD} supply rail, it is ensured that the load jumps to the external regulator (from the V_{DD} rail) are limited during the start-up phase to the dI_{DDDYN_STRT} data sheet parameter
- PORST is active or asserted when either PORST (input) or PORST (output) is active or asserted
- PORST (input) active means that the reset is held active by external agents by pulling the PORST pin low. It is recommended to keep the PORST (input) asserted until the external supply is above the respective primary reset threshold (V_{RSTxx} parameter in the datasheet)
- PORST (output) active means that the microcontroller asserts the reset internally and drives the PORST pin low, propagating the reset to external devices. The PORST (output) is asserted by the MCU when at least one supply domain violates its primary under-voltage reset threshold. The PORST (output) is de-asserted

by the microcontroller when all relevant supplies (with VMONP_VxxRST.RESETOFF = 0) are above their primary reset thresholds and the basic supply and clock infrastructure is available

The power sequence as shown in the figure above is enumerated as follows:

- T0 is the begin of the supply ramp-up from the external regulator
- T1 is the point in time when LVD reset is released. The LVD resets are released when $V_{DDEXTDC}$, V_{DDEXT}, $V_{DDEVRSB}$, and V_{DDPMSx} are above their LVD reset levels (denoted as $V_{LVDRSTxx}$)
- T0 up to T2 refers to the period in time when basic supply and clock infrastructure components are made available as the external supply ramps up. The band-gap and internal clock sources are started. The supply mode is evaluated based on the *HWCFG* pins. These events are initiated after LVD reset release at T1
- T2 refers to the point in time where a soft start of the EVRC is initiated. PORST (input) does not have any effect on the EVRC output and the regulator continues to generate the respective voltage though PORST is asserted and the device is in reset state. The generated voltage follows a soft ramp-up over the t_{STRDC} time (data sheet parameter) to avoid overshoots
- T3 refers to the point in time when all supplies are above their primary reset thresholds, denoted as V_{RSTxx}. There are two parameters denoting the primary reset threshold, respectively V_{RSTxx} (which is the untrimmed threshold) and $V_{xxPRIUV}$ (which is the trimmed threshold). Their values are located closely to each other and are indicated therefore as a thin hashed region in the figure above. During the supply ramp-up phase, the untrimmed threshold V_{RSTxx} is used for the first PORST release. After the firmware execution phase, the trimmed threshold $V_{xxPRIUV}$ is used for the PORST assertions. Subsequent reset releases occur at the untrimmed threshold V_{RSTxx}, since the primary voltage monitors reset thresholds VMONP_VxxRST.RESETTRIM are being reset to the V_{RSTxx} values also after a cold PORST (see the "Cold PORST" reset values of the VMONP_VxxRST registers)
- The supply start-up phase is completed when the regulator outputs are stable and operational and all voltages have ramped up. Consequently cold PORST reset is released when all voltages on the primary monitors are above their minimum operational limits (V_{RSTxx}/$V_{xxPRIUV}$)
- T4 refers to the point in time when the firmware execution is completed and the user code execution starts, with CPU0 running at the f_{BACKT} clock frequency. The time between T1 and T4 is documented as t_{BCP} (cold power on reset boot time, datasheet parameter)
- T5 refers to the point in time during the supply ramp-down phase when at least one of the supplies (either externally provided or internally generated) drops below its respective primary under-voltage reset threshold $V_{xxPRIUV}$

36.3.3.3 LVD reset

This section introduces the power-on reset detectors for minimum voltage detection (PMS0.PORDET, also called LVD detectors) and the low voltage detection (LVD) reset concepts.

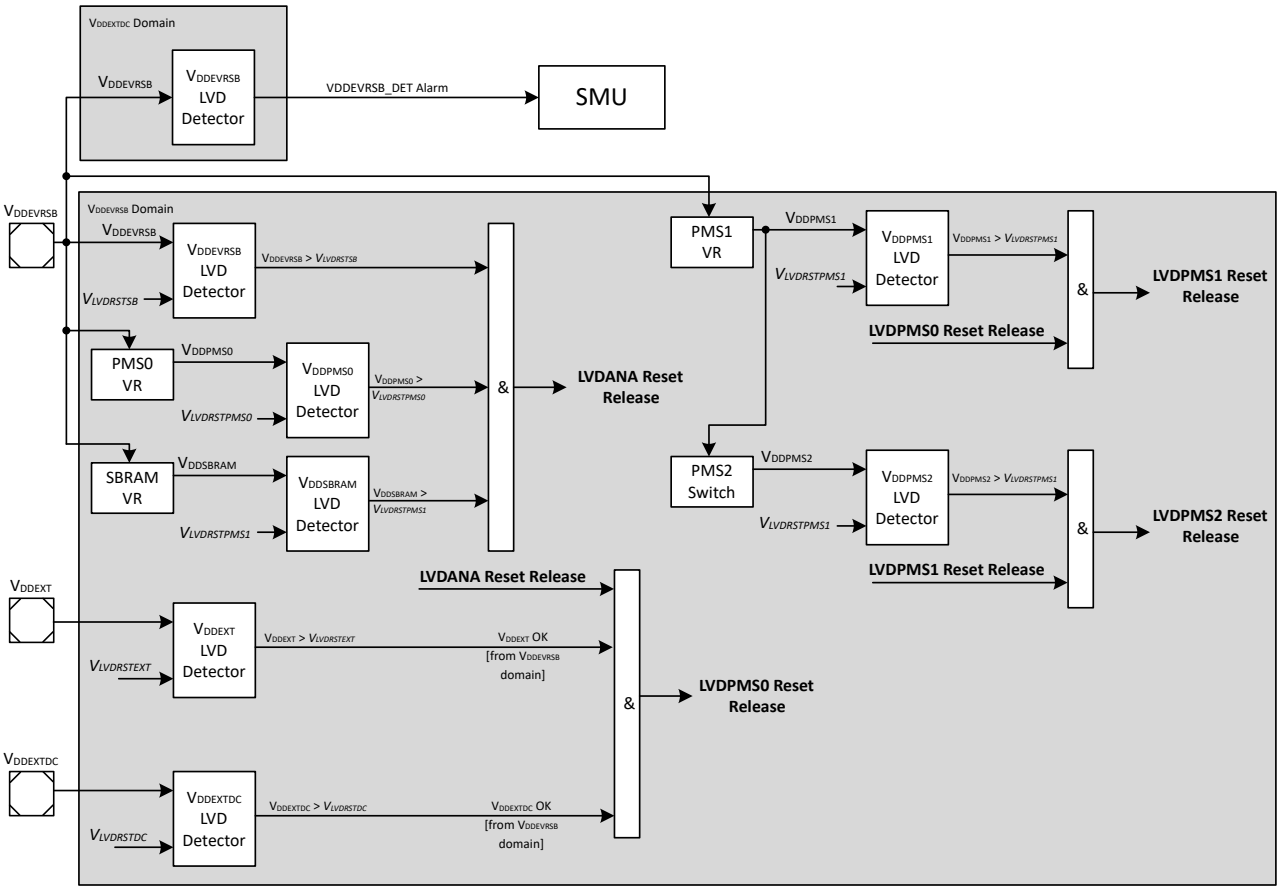
The power-on reset detectors constitute a minimum voltage detection logic, which ensures that a minimum voltage level is available on the V_{DDEXT}, $V_{DDEVRSB}$, $V_{DDEXTDC}$ external supplies, and on the internally generated V_{DDPMSx} supplies. The V_{DDEXT} supply is monitored and compared to the minimum level defined by the $V_{LVDRSTEXT}$ parameter, to ensure that adequate voltage is available to latch the *HWCFG* pins. $V_{DDEVRSB}$ is monitored for a minimum voltage level of $V_{LVDRSTSB}$. Likewise, the internal V_{DDPMSx} supplies are monitored for minimum $V_{LVDRSTPMSx}$ voltage level by detectors with built-in reference (low-power band-gap).

Power-on detectors are available for the $V_{DDEVRSB}$, V_{DDEXT}, $V_{DDEXTDC}$, V_{DDPMS0}, V_{DDPMS1}, V_{DDPMS2}, and $V_{DDSBRAM}$ (if available on the respective product variant), to ensure a proper minimum power detection, robust start-up, and standby operation. Under-voltage of the respective supplies will lead to the assertion of the LVD (Low Voltage Detector) reset. Assertion of LVD reset is reflected in the CLDRSTSTAT register (4 LVDx status bits for the 4 different LVD reset types) and can be evaluated by the software at the next start-up.

There are four types of LVD reset, as shown in the following figure: LVDANA, LVDPMS0, LVDPMS1, and LVDPMS2. The reset levels are hierarchical in nature (LVDANA < LVDPMS0 < LVDPMS1 < LVDPMS2). If a lower-level reset is asserted, also the higher-level resets are asserted as well. The following figure shows the LVD reset release.

Figure 778 LVD reset types

36 Power Management System (PMS)



LVDANA reset is released when $V_{DDEVRSB}$, V_{DDPMS0}, and $V_{DDSBRAM}$ are above their respective minimum voltage levels ($V_{LVDRSTSB}$, $V_{LVDRSTPMS0}$, and $V_{LVDRSTPMS1}$ respectively). This reset affects several analog modules within the PMS. The LVDPMS0 reset affects the PMS0 domain and is released after the LVDANA reset, when, in addition, V_{DDEXT}, and $V_{DDEXTDC}$ are above their minimum voltage levels ($V_{LVDRSTEXT}$ and $V_{LVDRSTDC}$ respectively). The LVDPMS1 reset affects the PMS1 domain and is released after the LVDPMS0 reset, when, in addition, V_{DDPMS1} is above its minimum voltage level defined by the $V_{LVDPMS1}$ parameter. The LVDPMS2 reset affects the PMS2 domain and is released after the LVDPMS1 reset, when, in addition, V_{DDPMS2} is above its minimum voltage level defined by the same parameter $V_{LVDPMS1}$.

After the release of the LVDPMS1 reset, the 100 MHz clock and high precision band-gap are consequently started. The *HWCFG* pins are evaluated (after the release of LVDPMS0 reset) to establish the supply mode which needs to be activated. Further, after LVDPMS2 reset release, if the EVRC is enabled by the *HWCFG* pins, it is started in a soft ramp-up to ensure a V_{DD} voltage ramp-up with minimal overshoots.

For all PMS0 registers (which are reset by the LVDANA or by the LVDPMS0 reset), indicated by an "LVDANA Reset" or an "LVDPMS0 Reset" type in the reset table of the respective register, it is recommended to:

- Wait before reading from the register until REGACCSTAT.FIFOEMPTY = 1
- Wait before writing to the register until REGACCSTAT.FIFOFULL = 0

These checks are recommended since the full status of the FIFO in the register access interface could be reached after writing 32 times to LVDANA or LVDPMS0 registers within 14 µs. In order to check for the status of the FIFOEMPTY and FIFOFULL bits, there are corresponding interrupts which can be enabled in the INT_CON2 register.

36.3.3.4 PORST pin

The PORST pin is the main reset input pin and triggers a warm power on reset of the device. It shall be connected to the external regulator or supply monitor. If this pin is left open then the default behavior is that the device remains in a reset state.

The PORST pin supports following functions:

- Warm PORST reset input function: It is expected that external monitor or regulator asserts PORST pin if operating conditions are violated, namely supply voltages. It is also expected that the external monitor asserts PORST pin if microcontroller is stuck and not responding or the external watchdog was not serviced by the microcontroller.
- If PORST pin is externally asserted, a warm PORST reset is triggered. It is ensured that all warm resets are sequenced internally and RAM contents are not affected. Reset is executed only after RAM write operations are completed and processing units have reached IDLE state.
- If the PORST pin is kept asserted externally after a system start-up and supply voltages are within operating range, then the warm PORST reset state will be kept extended until PORST pin is de-asserted.
- The PORST pin is driven low by PMS on a cold PORST reset trigger by activating a strong pull-down capable of sinking I_{PORST} current as documented in the datasheet. The strong pull-down is deactivated after system is back to RUN0 mode. During initial Boot strong pull-down is only released on reaching RUN0 (Operation) mode. During Standby state and during transition from Standby state to RUN0 (Operation) mode, strong pull-down is not activated.
- The PORST pin has an integrated weak pull-down function to ensure that device stays in reset state if pin connection or PCB routing to the PORST pin is broken. The weak pull-down is active in all system states except Standby mode. In Standby mode, the weak pull-down is deactivated to reduce standby current. The weak pull-down is activated by default during Supply Start-up phase and during Standby-exit.
- Multiple masters can trigger PORST if connected together in an open-drain circuit with an external pull-up. Depending on push-pull or open drain implementation of reset output by external regulator, care should be taken in the dimensioning of the pull-up and series resistances on PORST connection.
- The PORST pin has a basic analog spike filter to filter out noise as documented in the datasheet. It supports TTL input level for 5 V operation and degraded TTL levels for 3.3 V operations as documented in the datasheet.
- In addition to the inherent analog spike filter, PORST pin supports a digital filter that can be additionally activated via PMS.PAD_CON.PORSTDFEN register bitfield to filter higher noise at input.

36.3.3.5 External service request interface (ESRx)

The external service request ESRx pin functions are described in this section.

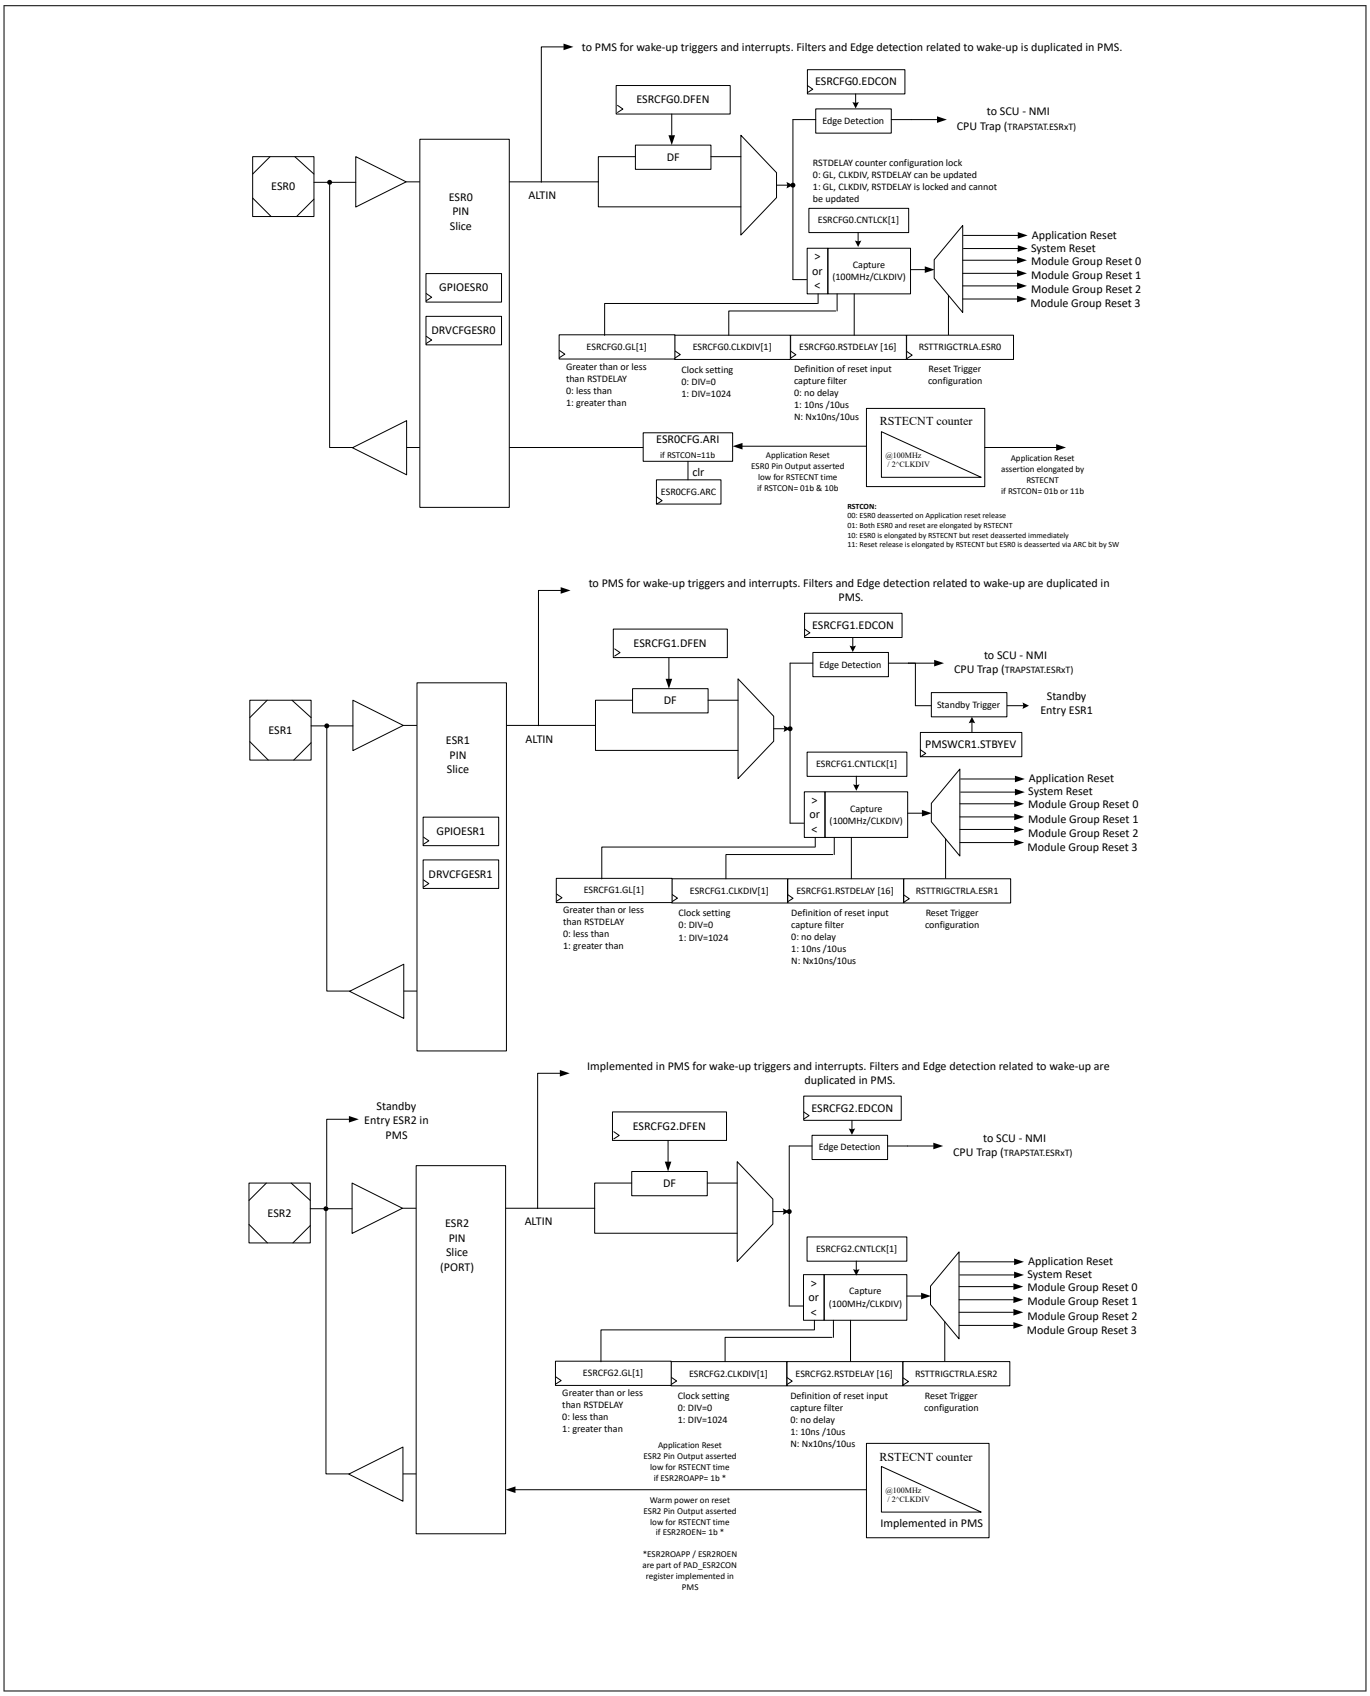


Figure 779 ESR pins connectivity and behavior

36.3.3.6 Primary voltage monitors VMONPx and cold PORST

Primary under-voltage monitoring is carried out for the following supply rails, to ensure proper functioning of the system: V_{DD}, V_{DDEXT}, ($V_{DDEXTDC}$-V_{SSDCHS}), $V_{DDEXTDC}$, V_{DDDCLS}, $V_{DDEVRSB}$, $V_{DDP3NVM}$, V_{DDM}, $V_{DDPHPHYx}$, $V_{DDPHRIFx}$, V_{DDHSIF}, V_{DDPAD}, V_{DDCPUx}, V_{DDPPU}, V_{DDLMUx}, V_{DDSB}, V_{DDPHYx}, and V_{DDRIFx}, depending on product variant (not all supply rails are available on each product variant).

The primary supply monitors are monitoring the ramp-up of external supply voltages and keep the MCU in cold PORST state as long as the supply has not reached the operational region. Likewise, they allow detecting ramp-down or brown-out conditions of the external supplies, such that the device can be brought into a cold PORST state when the voltage has dropped below the lowest operational threshold. Nevertheless, it is recommended to monitor externally all supplies generated external to the MCU and assert the PORST reset pin in case of violation of the lowest operational limits.

The thresholds for the primary monitors are determined by the lowest possible voltages for the correct functioning of the system. The thresholds and their respective tolerance are documented in the datasheet as $V_{xxPRIUV}$ parameters. In case of violation of these thresholds, cold PORST is activated and the PORST pin is pulled low (strong current sink), thus setting the device into reset state. Following the reset release and firmware boot, it can be inferred from the CLDRSTSTAT, CLDRSTRIG, and CLDRSTRIGL registers as to whether the violation of these thresholds led to the previous reset. CLDRSTSTAT shows the asserted reset types which occurred after the last CLDRSTSTATCLR.CLEAR. CLDRSTRIG shows the asserted reset triggers which occurred after the last CLDRSTSTATCLR.CLEAR. The CLDRSTRIGL register shows only the last reset trigger event. After evaluating the reset during start-up, the flags can be cleared through the CLDRSTSTATCLR.CLEAR bit.

The primary under-voltage cold PORST thresholds are trimmed through the VMONP_VxxRST registers. The under-voltage cold PORST triggering is activated or deactivated through the VMONP_VxxRST.RESETOFF bits, individually for each supply rail. There are following exceptions:

- For the ($V_{DDEXTDC}$-V_{SSDCHS}) and V_{DDDCLS} internal supply rails (if available on the respective product variant), the cold PORST triggering is available only in the high-voltage $V_{DDEXTDC}$ mode, when *HWCFG[2:1]* = 11_B. In all other modes, the VMONP_VSSDCHSRST.RESETOFF and VMONP_VDDDCLSRST.RESETOFF bits are ignored and under-voltage cold PORST is not triggered for these rails
- For the $V_{DDEXTDC}$ rail:
  - If EVRC is enabled (when *HWCFG[2:1]* = 01_B, or 10_B, or 11_B or on certain product variants only *HWCFG[1]*=1_B),
    - upon the $V_{DDEXTDC}$ rail under-voltage occurrence, a power state corresponding to an EVRC failure, which then switches off the EVRC. Therefore, the $V_{DDEXTDC}$ primary monitor does not just trigger a cold PORST upon under-voltage, but a deeper power state where the EVRC regulator is switched off and then restarted after the $V_{DDEXTDC}$ voltage recovers
    - Since, the VMONP_VDDEXTDCRST.RESETOFF setting is reset to 0 at each cold PORST, it can occur that this deeper power state is triggered during cold PORST whenever $V_{DDEXTDC}$ falls below the primary monitor under-voltage threshold
  - If EVRC is disabled, the VMONP_VDDEXTDCRST.RESETOFF bit is ignored and no under-voltage reaction is triggered for the $V_{DDEXTDC}$ rail

- For the $V_{DDEVRSB}$ rail:
  - If EVRC is enabled,
    - the primary voltage monitor triggers, upon an under-voltage occurrence, a power state corresponding to an EVRC failure, which then switches off the EVRC (if VMONP_VDDEVRSBRST.RESETOFF = 0)
    - Since the VMONP_VDDEVRSBRST.RESETOFF setting is reset to 0 at each cold PORST, it can occur that this deeper power state is triggered during cold PORST whenever $V_{DDEVRSB}$ falls below the primary monitor under-voltage threshold
  - If EVRC is disabled, the primary voltage monitor triggers, upon an under-voltage occurrence, a cold PORST (if VMONP_VDDEVRSBRST.RESETOFF = 0)
- For all switchable power domain voltage rails (if switchable power domains are available on the respective product variant), the boot firmware always disables the under-voltage cold PORST triggering, at every boot-up, by setting the VMONP_VxxRST.RESETOFF bits to 1. If the application does not switch off these switchable power domains, then in order to enable the under-voltage cold PORST triggering for these power domains, the application software must configure the respective VMONP_VxxRST.RESETOFF bits back to 0

The cold PORST is asserted when the supply voltage drops below the VMONP_VxxRST.RESETTRIM+VMONP_VxxRST.RESETPTRIM value. During cold PORST reset release, to avoid consecutive PORST toggling during slow supply ramp-ups, a voltage hysteresis is supported as configured through the VMONP_VxxRST.RESETHYS bit-field. The cold PORST is de-asserted or released when the supply rises above the RESETTRIM+RESETPTRIM+RESETHYS value. The PORST pin is driven low for a minimum time of t_{EVRPOR} (data sheet parameter) upon recognition of cold PORST, irrespective whether the voltages have been immediately restored, such that there is an adequate time to recognize the PORST event externally.

The VMONP_VxxRST.RESETPTRIM and VMONP_VxxRST.RESETHYS bit-fields are initialized after LVD reset (LVDPMS2), after cold PORST, and by the boot firmware and shall not be re-configured by the application software. Note that after each supply ramp-up and cold PORST primary voltage monitor thresholds for the voltage rails V_{DD}, V_{DDPAD}, V_{DDCPUx}, V_{DDPPU}, V_{DDLMUx}, V_{DDSB}, V_{DDPHYx}, V_{DDRIFx} (not all supply rails are available on each product variant) are configured for the lower voltage level. Therefore after start-up the application software must readjust these thresholds to correct voltage levels for each device type. The correct V_{DD} voltage level for the respective device can be read from the VID_CON0.VDDNOM bits and the targeted thresholds for the different device types are defined in the datasheet table for primary voltage monitoring characteristics.

Refer to the functional description for the specific product variant for an image showing an overview of the primary voltage monitors.

The supplies monitored by primary voltage monitors are measured by primary monitor ADCs and the measured values are updated in the VMONP_VxxSTAT registers, after conversion completion. As indicated in the overview figures for the primary voltage monitors of the respective product variants, some supply rails are measured by tracking ADCs, with filter parameters configured in the VMONP_TRKTRIM0 register. The other supply rails are measured by SAR ADCs, with similar characteristics as the ADCs used for the secondary voltage monitors.

In case of primary monitor cold PORST threshold violation, the status bit CLDRSTSTAT.CLDPORST is set to indicate the event. In addition, the bits corresponding to the respective supply voltage violations are set in the CLDRSTRIG register (CLDRSTRIG.Vxx bits). These bits may be evaluated during consequent start-up after a cold PORST, to recognize which of the monitored supply rails experienced the power failure. If several bits are set in the CLDRSTRIG register, the last reset trigger event can be observed in the CLDRSTRIGL register. After reading the status from these registers, the application software should clear the flags through the CLDRSTSTATCLR.CLEAR bit.

Besides the primary under-voltage cold PORST thresholds, configured in the VMONP_VxxRST registers, a separate set of under-voltage and over-voltage thresholds are configured in the VMONP_VxxCON registers, by programming the UVVAL and OVVAL bit-fields. These under-voltage and over-voltage thresholds are used to configure the operational range of each monitored supply rail.

The violation of the primary under-voltage and over-voltage thresholds (that is of the operational limits), is communicated to the CSRM security module and to the SMU, if the respective under-voltage and over-voltage alarms are enabled, through the UVENABLE, respectively OVENABLE bits in the VMONP_VxxCON registers. The violations of the under-voltage and over-voltage thresholds are indicated in the VMONP_VxxSTAT status flags.

For security reasons, the primary monitor ADC measurements are used to detect voltage fluctuations on the supply rails and to provide alarms also to the CSRM, besides the SMU. The CSRM module may lock access to PMS registers, so that supply generation cannot be influenced by other masters. This measure ensures that malicious software does not manipulate the supplies to gain access to the system.

Note that the VMONP_VSSDCHSCON/VMONP_VSSDCHSRST/VMONP_VSSDCHSSTAT registers refer to the monitor of the ($V_{DDEXTDC}$-V_{SSDCHS}) voltage difference (if V_{SSDCHS} is available on the respective product variant).

The following figure shows the signal flows through a primary voltage monitor and indicates the related register bit-fields for the configuration and status of the primary monitors.

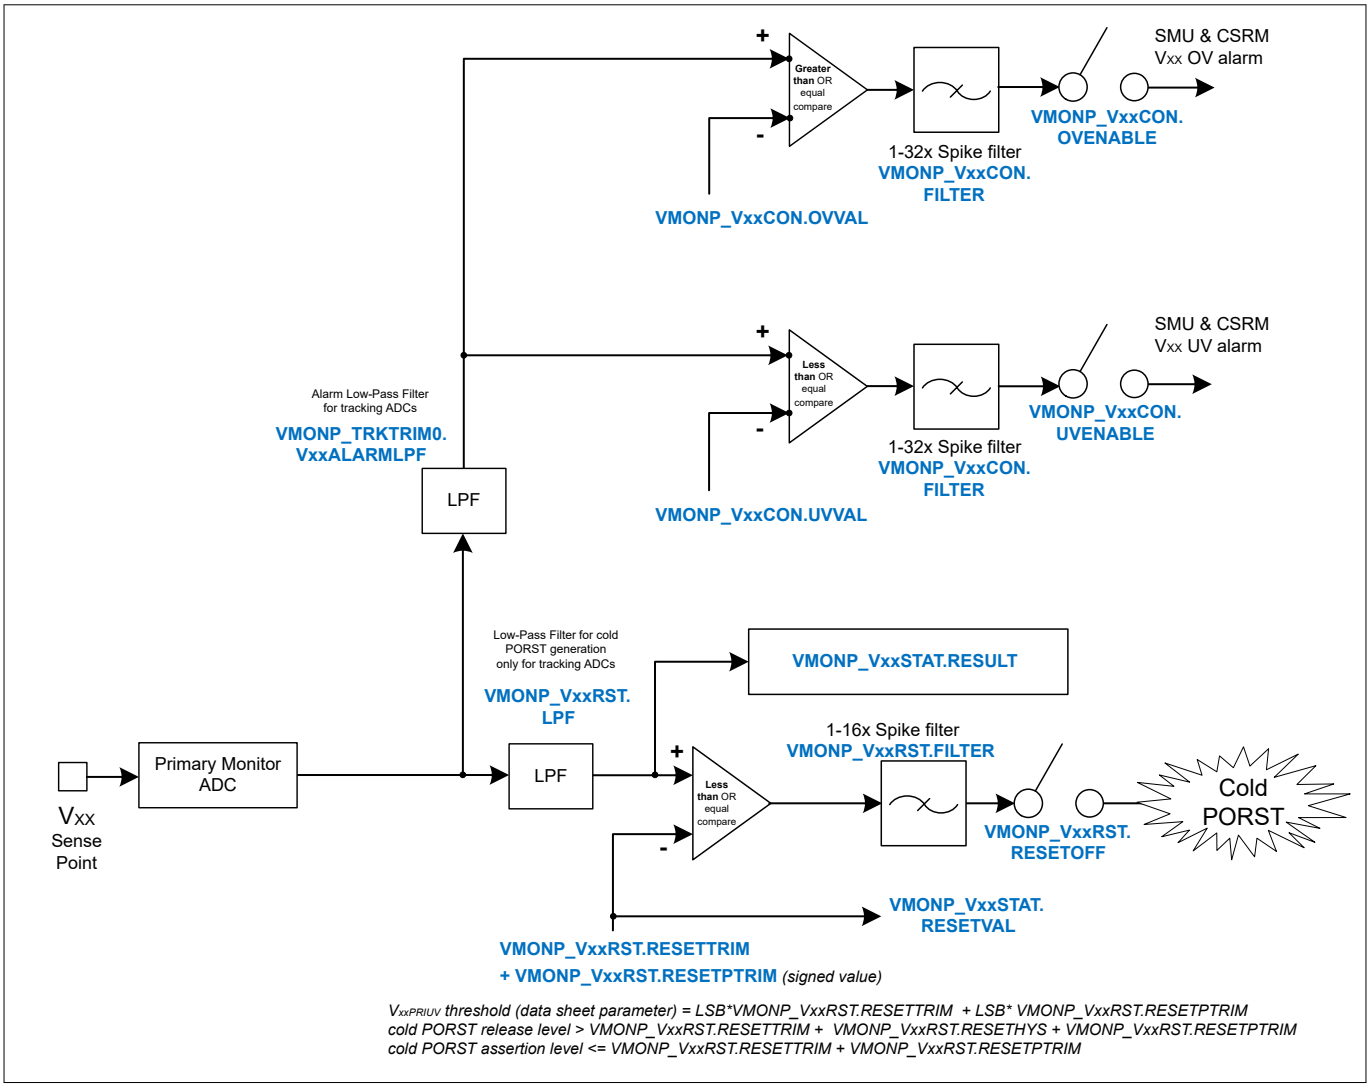

Figure 780 Primary voltage monitors configuration and outputs

Only the supply rails monitored on tracking ADCs (that is on VMONP0-3, see the overview figure) have an implemented low-pass filter (LPF) on the cold PORST trigger path, configured in the VMONP_VxxRST.LPF bit-field. The other supply rails on the SAR ADC (that is on VMONP4, see the overview figure), do not have this filter implemented and, for these supply rails, writing into the VMONP_VxxRST.LPF bit-field has no effect.

The last value measured by the primary monitoring ADCs is updated, for each supply rail, in the VMONP_VxxSTAT.RESULT bit-field, when the respective channel is converted. Conversions occur on a primary ADC channel if any of the following conditions is true:

- The supply rail is monitored by a tracking ADC - the tracking ADC channels are always converted
- If VMONP_VxxCON.UVENABLE or VMONP_VxxCON.OVENABLE is not 0 for the respective rail
- If VMONP_VxxRST.RESETOFF is not 1 for the respective rail
- For the V_{DD}, or V_{DDEXT} or $V_{DDEXTDC}$ rail if peak voltage detection is enabled (PEAK_Vxx.ENABLE = 1)
- For the V_{DD}, or V_{DDEXT} or $V_{DDEXTDC}$ rail if drift monitoring is enabled (DRMON_Vxx.ENABLE = 1)
- If VMONP_VxxCON.UVENABLE and VMONP_VxxCON.OVENABLE have just been set to zero but the conversion already started
- If VMONP_VxxCON.RESETOFF has just been set to 1 but the conversion already started

The VMONP_VxxSTAT.RESULT value is stored without spike filtering.

The under-voltage threshold for triggering the cold PORST is configured in the VMONP_VxxRST.RESETTRIM and VMONP_VxxRST.RESETPTRIM bit-fields, as shown in the previous figure . A spike filter is applied on the cold PORST trigger output, configured in VMONP_VxxRST.FILTER. The cold PORST triggering by the primary monitors can be enabled or disabled through the VMONP_VxxRST .RESETOFF bit. If the software enables the under-voltage reset for a voltage rail, by setting the corresponding VMONP_VxxRST.RESETOFF bit to zero (including bit protection), then the rail voltage will be evaluated and the under-voltage reset is then only asserted if the measured voltage is below the configured threshold and if the under-voltage evaluation passes all configured filters (VMONP_VxxRST.LPF and VMONP_VxxRST.FILTER).

Only the supply rails monitored on tracking ADCs (that is on VMONP0-3, see the overview figure) have an implemented low-pass filter (LPF) on alarm triggering path, configured in the VMONP_TRKTRIM0.VxxALARMLPF bit-fields, for the respective voltage rail (as shown in the 'Primary voltage monitors configuration and outputs' figure, above).

The over-voltage and under-voltage alarm thresholds are configured in the VMONP_VxxCON.OVVAL and VMONP_VxxCON.UVVAL, respectively. Another spike filter is applied on the alarm trigger outputs, configured in VMONP_VxxCON.FILTER. The over-voltage and under-voltage alarms triggering by the primary monitors can be enabled or disabled through the VMONP_VxxCON.OVENABLE, respectively VMONP_VxxCON.UVENABLE bits.

The measurement latency of the monitoring ADCs is determined as follows:

- For core tracking ADCs, the measurement latency is defined by the $t_{TRKCORE}$ data sheet parameter. The time duration for triggering cold PORST or alarms of a supply rail on a core tracking ADC is equal to $t_{TRKCORE}$ multiplied by FILTER + 1 (which is the spike filter setting, either VMONP_VxxRST.FILTER, for cold PORST triggering, or VMONP_VxxCON.FILTER, for alarm triggering) and multiplied by the number of input channels used on the respective tracking ADC. VMONP0 is, for instance, a core tracking ADC, where only one input channel is used
- For high-voltage tracking ADCs, the measurement latency is defined by the t_{TRKHV} data sheet parameter. The time duration for triggering cold PORST or alarms of a supply rail on a high-voltage tracking ADC is equal to t_{TRKHV} multiplied by FILTER + 1 (which is the spike filter setting, either VMONP_VxxRST.FILTER, for cold PORST triggering, or VMONP_VxxCON.FILTER, for alarm triggering) and multiplied by the number of input channels used on the respective tracking ADC. VMONP1, VMONP2, and VMONP3 are examples of high-voltage tracking ADCs. VMONP1 uses only one input channel, whereas VMONP2 and VMONP3 use two input channels
- For core-level channels of a SAR ADC, the measurement latency is defined by the $t_{SARCORE}$ data sheet parameter. The time duration for triggering cold PORST or alarms of a supply rail on a core SAR ADC input is equal to $t_{SARCORE}$ multiplied by FILTER + 1 (which is the spike filter setting, either VMONP_VxxRST.FILTER, for cold PORST triggering, or VMONP_VxxCON.FILTER, for alarm triggering) and multiplied by the number of input channels used on the respective SAR ADC. VMONP4 is a SAR ADC, which uses several core-level and high-voltage input channels
- For high-voltage channels of a SAR ADC, the measurement latency is defined by the t_{SARHV} data sheet parameter. The time duration for triggering cold PORST or alarms of a supply rail on a high-voltage SAR ADC input is equal to t_{SARHV} multiplied by FILTER + 1 (which is the spike filter setting, either

VMONP_VxxRST.FILTER, for cold PORST triggering, or VMONP_VxxCON.FILTER, for alarm triggering) and multiplied by the number of input channels used on the respective SAR ADC

The LSB values for VMONP_VxxRST.RESETTRIM, VMONP_VxxRST.RESETHYS, VMONP_VxxCON.UVVAL, and VMONP_VxxCON.OVVAL values, as well as the measurement latencies are provided in the following tables:

Table 1425 Primary voltage monitors parameters

Voltage rail	VMONP LSB datasheet parameter	Primary under-voltage reset threshold after trimming - datasheet parameter	Effect of primary under-voltage reset threshold violation[1)]
V_{DD}	$V_{TRKCORELSB}$	$V_{DDPRIUV}$	Cold PORST
V_{DDEXT}	$V_{TRKHVLSB}$	$V_{EXTPRIUV}$	Cold PORST
($V_{DDEXTDC}$-V_{SSDCHS})	$V_{TRKHVLSB}$	$V_{DCHSPRIUV}$	Cold PORST only if *HWCFG[2:1]* = 11_B
$V_{DDEXTDC}$	$V_{TRKHVLSB}$	$V_{EXTDCPRIUV}$	Only when EVRC is enabled, a power state transition corresponding to an EVRC failure is triggered. The primary monitor triggers not only a cold PORST, but a deeper power state where the EVRC regulator is disabled, until the supply raises above the reset release threshold.
V_{DDDCLS}	$V_{TRKHVLSB}$	$V_{DCLSPRIUV}$	Cold PORST only if *HWCFG[2:1]* = 11_B
$V_{DDEVRSB}$	$V_{SARHVLSB}$	$V_{EVRSBPRIUV}$	Cold PORST
$V_{DDP3NVM}$	$V_{SARHVLSB}$	$V_{DDP3NVMPRIUV}$	Cold PORST
V_{DDM}	$V_{SARHVLSB}$	$V_{DDMPRIUV}$	Cold PORST
$V_{DDPHPHYx}$	$V_{SARHVLSB}$	$V_{PHPHYPRIUV}$	Cold PORST
$V_{DDPHRIFx}$	$V_{SARHVLSB}$	$V_{PHRIFPRIUV}$	Cold PORST
V_{DDHSIF}	$V_{SARHVLSB}$	$V_{HSIFPRIUV}$	Cold PORST

36.3.3.6.1 Enabling non-mandatory supply rails

Depending on product variant, there are several supply rails which are not mandatory to be powered at start-up. These supply rails are indicated by the default value of VMONP_VxxRST.RESETOFF = 1_B. This indicates that cold PORST can be released at start-up without powering the respective supply rail. It also means that primary voltage monitoring is not enabled for this rail, but must be enabled by the application SW if this supply rail is required by the application.

If the application requires to use a supply rail with VMONP_VxxRST.RESETOFF = 1_B, then the rail must be powered and the application SW must perform the following steps to enable monitoring and usage of this supply domain:

1. Set VMONP_VxxCON.OVENABLE, to enable primary monitoring ADC conversion on the respective supply rail
2. Poll VMONP_VxxSTAT.RESULT bit-field and compare against VMONP_VxxSTAT.RESETVAL
3. After VMONP_VxxSTAT.RESULT > VMONP_VxxSTAT.RESETVAL, SW should set VMONP_VxxRST.RESETOFF = 0_B (consider setting also the protection bit VMONP_VxxRST.RESETOFF_P in the same write operation)
4. Depending on the monitoring requirements of the application, configure VMONP_VxxCON.OVVAL, VMONP_VxxCON.OVENABLE, VMONP_VxxCON.UVVAL, and VMONP_VxxCON.UVENABLE as needed. As

mentioned in the primary voltage monitors section, the thresholds and alarm functions configured in the VMONP_VxxCON registers

36.3.3.7 Switching off power domains

This section describes the function and usage of switchable power domains, on the product variants which support this feature (see internal supply rails and their availability on each product variant). This section does not apply to product variants which do not support switchable power domains.

The following figure shows the relevant voltage, reset, and load current flows for switching off and on the power domain switches for the CPUx, PPU, LMU, and other switchable power domains. All power domains are active by default and are intended to be switched off after a cold start-up to reduce power consumption. Power domain activation and deactivation is intended to be static in nature and shall be done explicitly at start-up. It is not allowed to dynamically activate / deactivate the power domains during full operational modes.

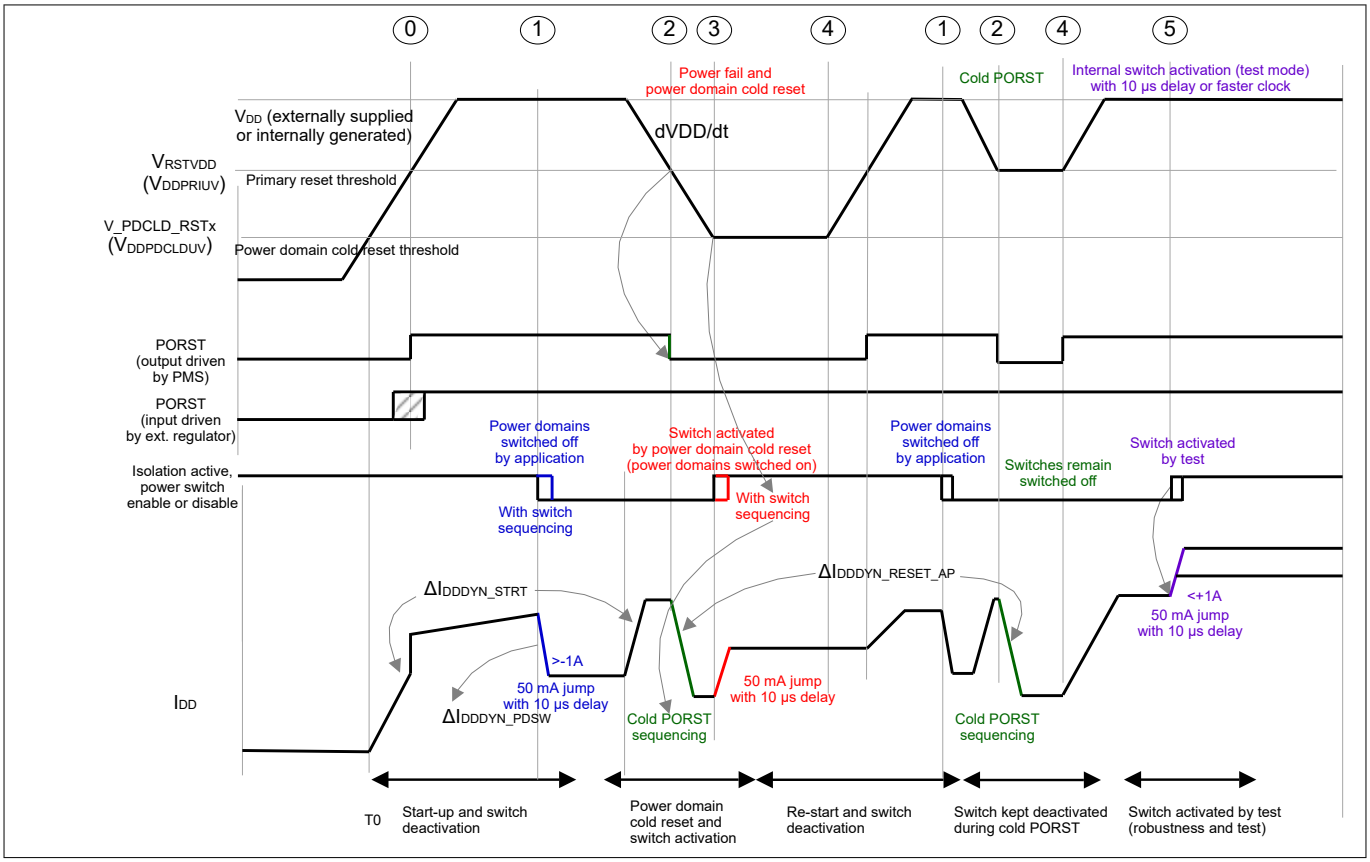

Figure 781 Power domains switch-off

At time point 0, V_{DD} has ramped up and has exceeded the primary reset threshold V_{RSTVDD}. At time point 1, the application switches off the unneeded power domains and the load current drops. At time point 2, a power fail occurs and the V_{DD} voltage crosses the primary under-voltage threshold $V_{DDPRIUV}$. If the voltage continues to drop, it can further cross the power domain cold reset threshold $V_{DDPDCLDUV}$, as shown at time point 3. Later, when the V_{DD} voltage recovers and ramps back up again, it crosses the $V_{DDPDCLDUV}$ threshold, respectively $V_{DDPRIUV}$ (or V_{RSTVDD}) at time points 4 in the previous figure. A test mode activation of the power switches is shown at time point 5.

The PORST is released when all supply voltages, including V_{DD}, have reached their respective primary monitor under-voltage thresholds. After PORST release, the application may switch off the power domains for the CPUx, PPU, or LMUx, by following the next sequence:

- Disable the primary monitor under-voltage reset, primary monitor alarms, and secondary monitor alarms for the domains to be switched off. This step is required before enabling the power domain switch-off by

the application. Otherwise, under-voltage reset or under-voltage alarms could be triggered when the domain is switched off

- Configure the individual clock dividers for the power switches of each power domain as needed in the PD_CON0.CLKCPU, PD_CON0.CLKPPU, or PD_CON0.CLKLMU bit-fields, respectively (depending on power domain availability on the respective product variant)
- Enable the power-down of the respective domains through the *PDEN bits in the PD_CON0 register (setting the respective protection bit(s) is required in the same write operation)
- After the powering down of the respective domains is enabled, the application software can trigger the power-down request for the respective domains through the *OFFREQ bits in the PD_CON1 register (also requiring setting the respective protection bit(s)). This request will switch off the power switches for the selected power domains

The status of the power domain switches can be read by the application from the PD_STAT0 .xxSWSTAT bit-fields (a value of 1 means the power domain is switched off, whereas a value of 0 means the power domain is switched on). Furthermore, from the PD_STAT0.xxREQ bit-fields it can be inferred which power domain switch off was requested after the last cold PORST.

If a power failure occurs and the V_{DD} voltage drops below the primary under-voltage monitor threshold, indicated by the $V_{DDPRIUV}$ parameter, a cold power on reset is triggered by the PMS and the MCU is in reset. If, in addition, the V_{DD} voltage continues to drop further and crosses the power domain cold reset threshold, indicated by the $V_{DDPDCLDUV}$ parameter, the power switches are also reset (re-activated) and the power domains are switched back on. After such a power domain cold reset occurs, the application software has to re-enable the power switches again after the power-up sequence, after the reset release, using the same procedure and registers as described above. When the V_{DD} voltage reaches the $V_{DDPDCLDUV}$ threshold, an immediate (that is asynchronous) cold PORST is triggered by the PMS to the SMM.

If only the cold PORST occurs, without V_{DD} crossing the $V_{DDPDCLDUV}$ threshold, the power switches remain switched off as configured by the application. If the V_{DD} voltage only crosses the $V_{DDPRIUV}$ threshold, but does not cross the lower $V_{DDPDCLDUV}$ threshold, the PMS triggers a sequenced cold PORST trigger to the SMM.

The $V_{DDPDCLDUV}$ threshold parameter is described in the datasheet and is trimmed by firmware using the VMONP_VDDCLDRST.VDDPDCLDUV register bit-field. This reset threshold can be disabled using the VMONP_VDDCLDRST.VDDPDCLDOFF (and respective bit protection) bit. The VMONP_VDDCLDRST.VDDPDCLDUV and VMONP_VDDCLDRST.VDDPDCLDOFF bit-fields shall not be re-configured by the application software. The following figure shows the two reset paths available in the V_{DD} primary monitor, for cold PORST and for power domain (PD) cold reset.

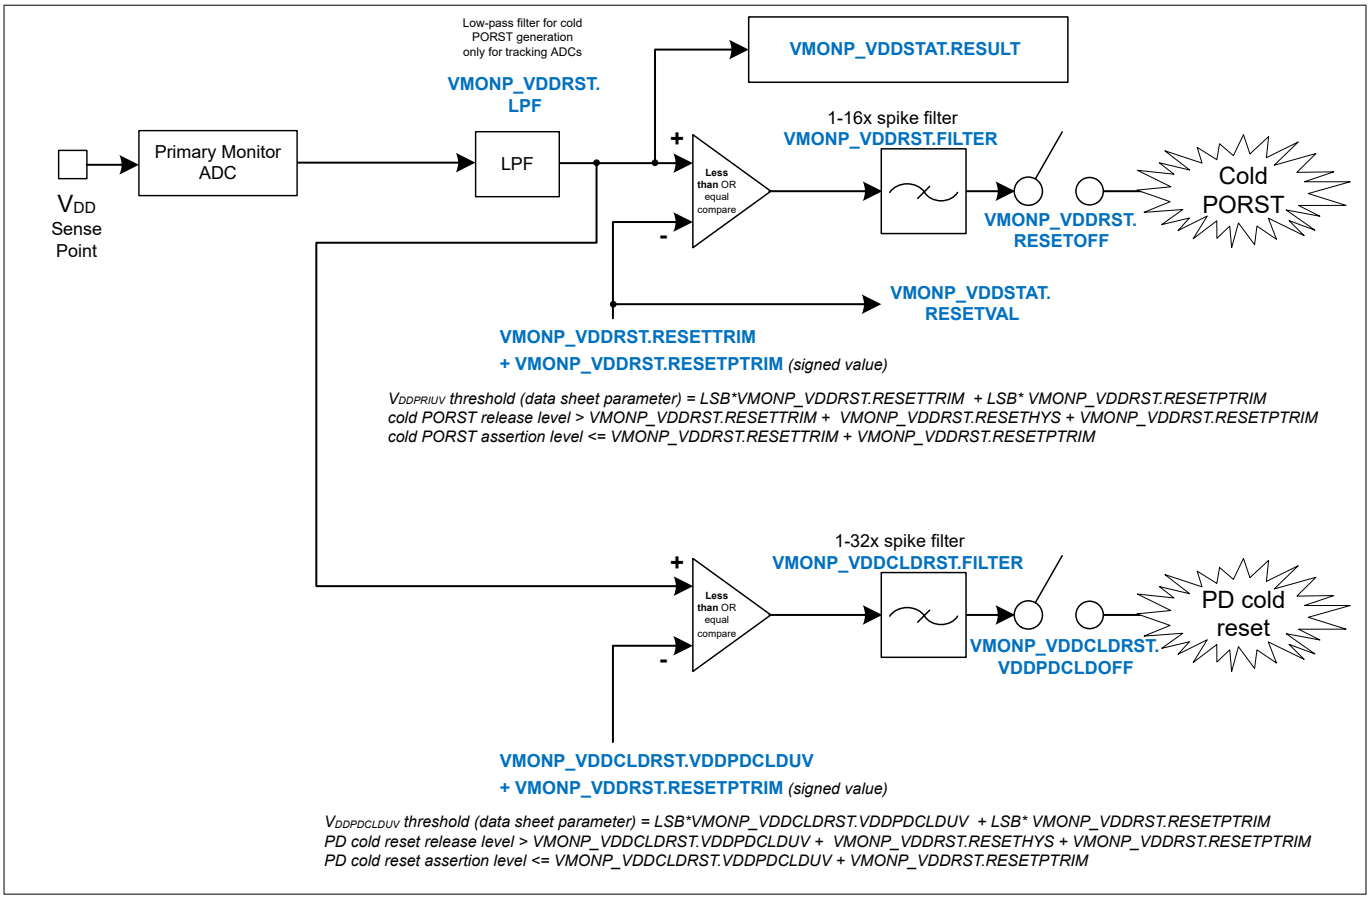

Figure 782 Overview of the reset paths in the V_{DD} primary voltage monitor

36.3.4 Supply generation

This section describes the supply generation function of the PMS, which includes the embedded DCDC regulator (EVRC).

36.3.4.1 Step-down regulator (EVRC)

This section describes the EVRC step-down regulator, generating the V_{DD} supply.

The step-down regulator provides a higher efficiency of power conversion compared to a linear voltage regulator. However it requires additional external components and injects more switching noise into the system. The integrated EVRC regulator modulates an external charge device to buffer the energy in a LC filter in order to generate a regulated digital (core) supply.

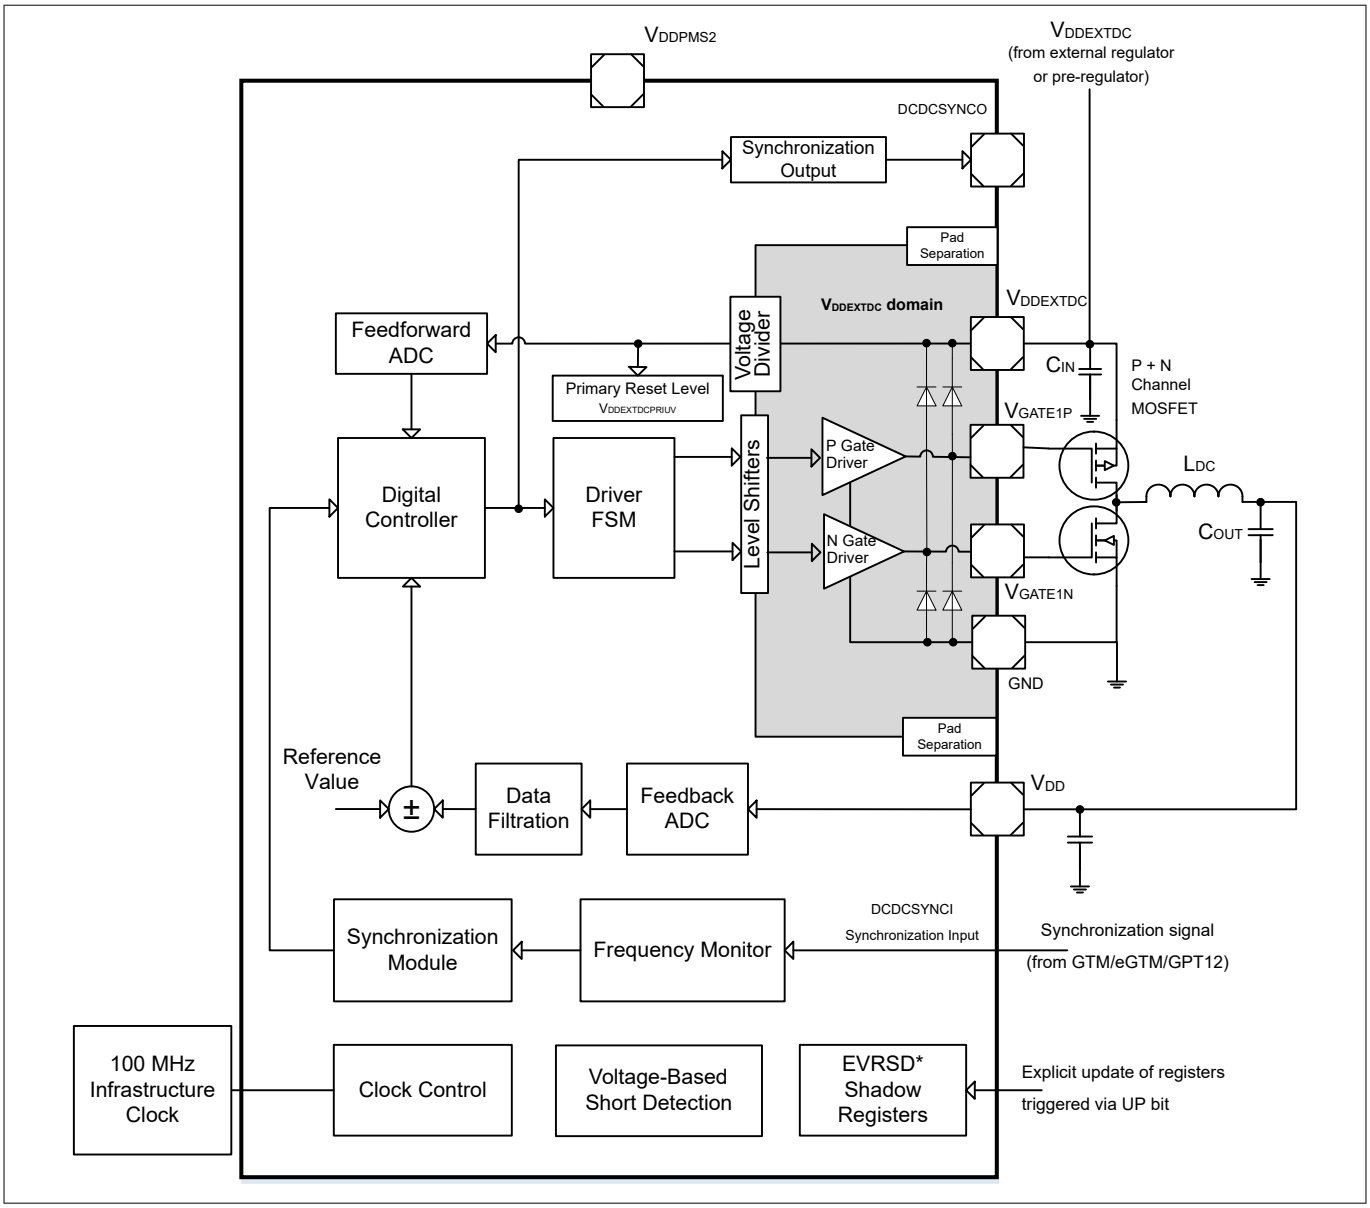

Figure 783 EVRC step-down regulator

The following table gives a brief description of the main components of the EVRC.

Table 1427 EVRC components

Component	Description
Digital Controller	Block implementing the digital regulation loop of the DCDC converter
Driver FSM	FSM adjusting the duty cycle for the gate drivers
P and N Gate Drivers	Internal gate drivers for driving the external power MOSFETs
VGATE1P, *VGATE1N*	Pins connected to the gate of external P-channel and N-channel MOSFETs
Level Shifters	Level shifters converting the drive signals from the V_{DDPMS2} domain to the $V_{DDEXTDC}$ domain

(table continues...)

Table 1427 (continued) EVRC components

Component	Description
Feed-forward ADC (FFADC)	ADC providing the feed-forward information to the digital controller, measuring the $V_{DDEXTDC}$ supply in order to facilitate a parameter switch in case the voltage crosses a threshold
Feedback ADC (FBADC)	Tracking ADC providing the feed-back information to the digital controller, measuring the output V_{DD} voltage. The measured voltage is reported in the EVRC_STAT1.FBADCV bit-field.
Data Filtration	Digital filter applied to the measured output voltage before providing it to the digital controller. Configured through the EVRC_COEFF0.FBADCLPF bit-field
Voltage Divider	Voltage divider for the $V_{DDEXTDC}$ feed-forward voltage for adapting to the valid voltage range of the FFADC. It is part of the FFADC input channels
Primary reset level $V_{DDEXTDCPRIUV}$	This is just an indication of the location of the sense point for the $V_{DDEXTDC}$ primary voltage monitor, which compares the $V_{DDEXTDC}$ with the primary under-voltage reset level $V_{DDEXTDCPRIUV}$
Synchronization Output	Scaled switching output derived from the EVRC switching signal, to synchronize an external regulator to the internal EVRC regulator
Pad Separation	Isolation between the $V_{DDEXTDC}$ pad domain and lower voltage pads
Reference Value	Reference voltage from the secondary high-precision band-gap (HPBG)
DCDCSYNCI Synchronization Input	Synchronization input from the eGTM, or GTM, or GPT12 module to synchronize frequency and phase of the internal EVRC regulator to an external DCDC regulator. The input from GPT12 is only available on certain product variants
Frequency Monitor	Monitoring function to detect when the input synchronization frequency is within the valid range
Synchronization Module	Module performing the frequency and phase synchronization to the input from an external regulator
100 MHz Infrastructure Clock	The PMS infrastructure on-chip clock, also used by the EVRC regulator
Clock Control	Clock control functions
Voltage-Based Short Detection	Detection of EVRC short to supply/ground, based on programmable voltage thresholds (configurable through the EVRC_CON2.SHHTHR, EVRC_CON2.SHLTHR, EVRC_CON2.SHHTIM, and EVRC_CON2.SHLTIM bit-fields)
EVRSD* Shadow Registers	Internal regulator registers that retain their values during standby mode. They are updated from the PMS register settings whenever software triggers a shadow register update through the EVRC_CON0.UP bit. After setting the UP bit, the application SW must wait for the UP bit to be de-asserted, before further writing into EVRC registers which have shadow registers. Otherwise the write accesses would be lost

The EVRC and external MOSFETs must be supplied with the same $V_{DDEXTDC}$ voltage.

36.3.4.1.1 Supply voltages

Following supply voltages are applied to the EVRC module:

- V_{DDPMS2}, which is one of the PMS internal supplies, derived from the V_{DDPMS1}supply (using an internal switch), is applied to most of the EVRC regulator components
- $V_{DDEXTDC}$ is the supply from the external pre-regulator and is applied to the complementary MOSFET switches and to the *VDDEXTDC* pin supplying the internal $V_{DDEXTDC}$ domain of the EVRC regulator (mainly including the gate drivers)
- Only on applicable product variants: V_{SSDCHS} is an internal supply within the $V_{DDEXTDC}$ domain, internally generated for the high-side driver
- Only on applicable product variants: V_{DDDCLS} is an internal supply within the $V_{DDEXTDC}$ domain, internally generated for the low-side driver

36.3.4.1.2 Switching frequency

The EVRC step-down converter switches the complementary P-channel and N-channel MOSFETs at a defined switching frequency using pulse width modulation (PWM) and it operates in continuous conduction mode (the inductor current does not fall to zero during the commutation cycle).

The nominal switching frequency is configured through EVRC_CON1.SDFREQ register bits, with a resolution of 100 MHz clock cycles (base clock frequency, that is a switching period resolution of 10 ns). The frequency is derived from the EVRC_CON1.SDFREQ setting as follows:

f_{DCDC} = 100 MHz/EVRC_CON1.SDFREQ

Depending on product variant, up to three nominal frequency settings are supported: 0.45 MHz, 0.8 MHz, and 1.82 MHz. The reset configuration of EVRC_CON1.SDFREQ generates f_{DCDC} = 0.8 MHz. To configure the different switching frequencies, use the following settings:

Table 1428 Parameter configuration for different switching frequencies

Condition	Setting	Comments
f_{DCDC} = 0.45 MHz	Set EVRC_CON1.SDFREQ to DE_H ***Note**: 100 MHz/SDFREQ=0.45 MHz*	Not supported on all product variants. For details on the supported switching frequencies see the data sheet of each product
f_{DCDC} = 0.8 MHz	Set EVRC_CON1.SDFREQ to $7D_H$ ***Note**: 100 MHz/SDFREQ=0.8 MHz*	
f_{DCDC} = 1.82 MHz	Set EVRC_CON1.SDFREQ to 37_H ***Note**: 100 MHz/SDFREQ=1.82 MHz*	Not supported on all product variants. For details on the supported switching frequencies see the data sheet of each product

36.3.4.1.3 Duty cycle

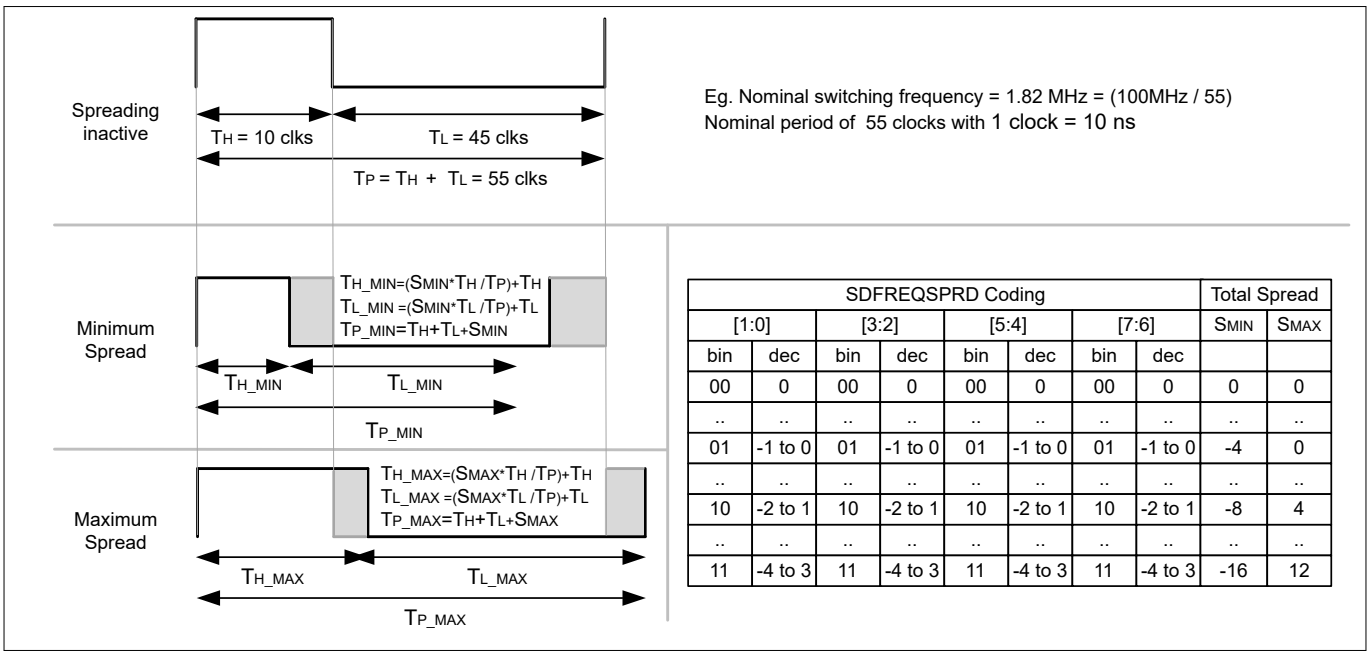
The duty cycle of the switching signal controlling the external power MOSFETs is determined by the input and output voltage values and controlled by the digital controller, which reacts to the deviation of the input and output voltage against a reference voltage. The output voltage value (configured in the EVRC_CON0.SDVOUTSEL register bit-field) is approximately equal to the input voltage multiplied by the duty cycle factor, neglecting the parasitic components and losses. This relationship determines the duty cycle value. The target of the digital controller is to compute the duty cycle and the skip pulse information considering the output voltage measured by the feedback ADC. The duty cycle is limited between a maximum and minimum value (configured through the EVRC_COEFF4.MINTON and MINTOFF bit-fields) in order to ensure proper

commutation in the power switches. The duty cycle is realized by a digital pulse width modulator which controls the respective gate drivers.

The duty cycle of the previous period is indicated in the EVRC_STAT1.DUTYCYCLE status bits. It has a resolution of the base clock frequency of 100 MHz internal clock. In case the controller output is above a certain threshold (configured through the EVRC_CON4.SKPLSTHR) at the start of a switching period and based on internal controller states, a pulse skipping mechanism is employed and the p-channel MOSFET will remain for a whole switching period in the OFF state.

36.3.4.1.4 Frequency spreading

In order to comply with EMI/EMC requirements, frequency spreading is supported. When activated, the switching period is varied randomly between a minimum and a maximum spread around the nominal value as depicted in the following figure.



SDFREQSPRD Coding								Total Spread	
[1:0]		[3:2]		[5:4]		[7:6]		SMIN	SMAX
bin	dec	bin	dec	bin	dec	bin	dec		
00	0	00	0	00	0	00	0	0	0
..	..	..	..	..	..	..	..	..	..
01	-1 to 0	01	-1 to 0	01	-1 to 0	01	-1 to 0	-4	0
..	..	..	..	..	..	..	..	..	..
10	-2 to 1	10	-2 to 1	10	-2 to 1	10	-2 to 1	-8	4
..	..	..	..	..	..	..	..	..	..
11	-4 to 3	11	-4 to 3	11	-4 to 3	11	-4 to 3	-16	12

Figure 784 EVRC regulator switching frequency spreading (without input synchronization)

Only the switching frequency is changed, while it is ensured that duty cycle changes are compensated over consecutive periods, in order to keep the voltage ripple induced by frequency spreading to a minimum.

Frequency spreading is activated and configured by setting the value of the bit-field EVRC_CON1.SDFREQSPRD. The reference setting for enabling frequency spreading is EVRC_CON1.SDFREQSPRD=02_H. An example is presented below.

Assume the switching frequency has been configured to 1.82 MHz (that is EVRC_CON1.SDFREQ=36_H, the switching period is 55 clocks). The nominal duty cycle for a $V_{DDEXTDC}$ supply of 5 V would be:

$D = 0.9\ V/5\ V = 0.18$

This duty cycle value leads to $T_H = 0.18*55 = 10$ clocks (on-time), respectively $T_L = 45$ clocks (off-time). The frequency spreading is configured in EVRC_CON1.SDFREQSPRD, as shown in the figure above. For each of the bit-pairs EVRC_CON1.SDFREQSPRD[1:0], [3:2], [5:4], and [7:6], the spreading factors S_{MIN} and S_{MAX} (both initially zero) are adjusted as follows:

- 00_B: Contributes with 0 to both S_{MIN} and S_{MAX}
- 01_B: Contributes with -1 to S_{MIN} and with 0 to S_{MAX}
- 10_B: Contributes with -2 to S_{MIN} and with +1 to S_{MAX}
- 11_B: Contributes with -4 to S_{MIN} and with +3 to S_{MAX}

Here are a few examples:

- EVRC_CON1.SDFREQSPRD = 0x02$_H$, then, S_{MIN} = -2 and S_{MAX} = 1
- EVRC_CON1.SDFREQSPRD = 0x15$_H$, then, S_{MIN} = -3 (that is $3 \times (-1)$) and S_{MAX} = 0
- EVRC_CON1.SDFREQSPRD = 0x1A$_H$, then, S_{MIN} = -5 (that is $2 \times (-2) + (-1)$) and S_{MAX} = 2 (that is $2 \times (+1) + 0$)
- EVRC_CON1.SDFREQSPRD = 0x7F$_H$, then, S_{MIN} = -13 (that is$3 \times (-4) + (-1)$) and S_{MAX} = 9 (that is $3 \times (+3) + 0$)
- and so on.

For the first example with S_{MIN}=-2 and S_{MAX} = 1, the minimum and maximum high/low state durations, respectively gate signal periods, are calculated as follows:

$T_{H_MIN} = (S_{MIN} * T_H / T_P) + T_H$ = 9.636 clks

$T_{L_MIN} = (S_{MIN} * T_L / T_P) + T_L$ = 43.364 clks

$T_{P_MIN} = T_{H_MIN} + T_{L_MIN}$ = 53 clks

$T_{H_MAX} = (S_{MAX} * T_H / T_P) + T_H$ = 10.182 clks

$T_{L_MAX} = (S_{MAX} * T_L / T_P) + T_L$ = 45.818 clks

$T_{P_MAX} = T_{H_MAX} + T_{L_MAX}$ = 56 clks

In the above example, the frequency would spread between:

f_{MIN} = 100 MHz/T_{P_MAX} = 1.79 MHz

f_{MAX} = 100 MHz/T_{P_MIN} = 1.89 MHz

The frequency spreading unit randomizes the switching frequency of the EVRC within the [f_{MIN}, f_{MAX}] range, programmable as described above. The principle is to randomly discard one clock cycle at 100 MHz from time to time. If this happens, the switching period becomes 1 clock cycle longer compared to the nominal value. The clocks to be removed are selected using a pseudo-random number generator. The clock cycles are skipped from the regular clock train in a random fashion to get uncorrelated noise to the DC/DC control algorithm (and output voltage) and to get an uncorrelated frequency jitter.

If there is a need for concurrently activating both input synchronization and frequency spreading, it is then recommended to program only bit-fields EVRC_CON1.SDFREQSPRD[1:0] and EVRC_CON1.SDFREQSPRD[3:2], leaving SDFREQSPRD[5:4] = 00$_B$ and SDFREQSPRD[7:6] = 00$_B$. In this case, when both features are enabled, the resulting spreading limits S_{MIN} and S_{MAX} are calculated differently, as shown in the following figure.

SDFREQSPRD Coding								Total Spread	
[1:0]		[3:2]		[5:4]		[7:6]		SMIN	SMAX
bin	dec	bin	dec	bin	dec	bin	dec

Figure 785 Frequency spreading limits when input synchronization is also enabled

36.3.4.1.5 Output voltage setting and voltage scaling

The EVRC output voltage level is configured in the EVRC_CON0.SDVOUTSEL bit-field and is preconfigured by the reset value to the nominal V_{DD} value (see the typical value of the V_{DDDCUT} parameter in the datasheet) of the respective product variant. The voltage is calculated as:

V_{DD} = *LSB* * EVRC_CON0.SDVOUTSEL

where LSB = dV_{FBADC} datasheet parameter.

This register bit-field requires a parameter update via EVRC_CON0.UP and reaching of the new target value is indicated via EVRC_STAT0.SDVOK bit.

To change the EVRC output voltage level, primary reset thresholds, and secondary over- and under-voltage thresholds, all settings shall be carried out in a sequential manner as shown below:

- Disable the core supply secondary under-voltage alarm through the VMONS_VDDCON register: VMONS_VDDCON.UVMOD=00_B. Over-voltage monitoring is left active at the limit as configured in VMONS_VDDCON.OVVAL register bits
- VMONS_VDDCON.OVVAL = $V_{DDMON}/V_{SARCORELSB}$ (over-voltage threshold value derived from the datasheet V_{DDMON} example values)
- The EVRC set-point value may be changed in maximum steps of 2.5% of the nominal V_{DD} value, to limit the current dynamics. The default EVRC set-point value is changed in EVRC_CON0.SDVOUTSEL register if the internal EVRC regulator is used: EVRC_CON0.SDVOUTSEL = [(V_{DD} set-point)/LSB], according to the nominal value of the V_{DD} parameter in the datasheet (supply operating conditions section, for the respective voltage ID, VID). If the V_{DD} core supply is provided externally, then the external regulator needs to be configured to the new voltage value. The actual trimmed set-point value of the internal EVRC can be read from the status register EVRC_STAT0.SETPOINT respectively
- The V_{DD} voltage value is measured and is indicated in the EVRC_STAT1.FBADCV register bits. This may allow a plausibility check whether the voltage change happened by comparing the value before and after the change. The voltage change would take less than 20 µs in case of internal regulators to be visible at the V_{DD} rail. In case of the internal EVRC regulator, the reaching of the new set-point is indicated through EVRC_STAT0.SDVOK bit

- The primary reset threshold limit is trimmed through VMONP_VDDRST.RESETTRIM register bits. The reset threshold must be adapted for the V_{DD} voltage change, and is derived from the $V_{DDPRIUV}$ datasheet parameter, corresponding to the selected V_{DD} set-point in the $V_{DDPRIUV}$ parameter conditions. The actual reset trim value used can be read out from the VMONP_VDDSTAT.RESETVAL status register bits
- VMONP_VDDRST.RESETTRIM = $V_{DDPRIUV}/V_{TRKCORELSB}$ (derived from the datasheet $V_{DDPRIUV}$ value)
- If not enough margin is available for the application, secondary under-voltage monitoring of core voltage may be completely disabled. Otherwise the default limit of VMONS_VDDCON.UVVAL bits may be adapted corresponding to the selected V_{DD} set-point, as documented in the V_{DDMON} parameter conditions
- VMONS_VDDCON.UVVAL = $V_{DDMON}/V_{SARCORELSB}$ (under-voltage threshold value derived from the datasheet V_{DDMON} example values)

The following figure shows the available configuration settings and status bit-field for the V_{DD} feedback ADC of the EVRC:

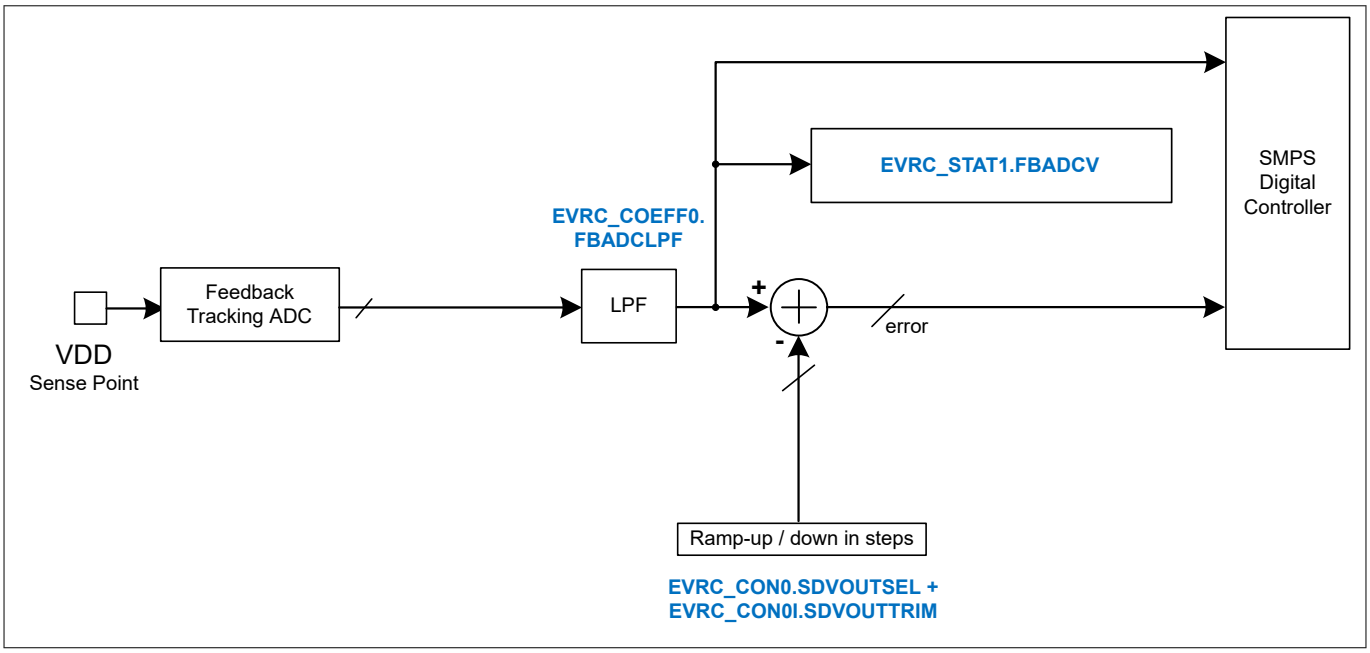

Figure 786 V_{DD} feedback ADC settings

The LPF configuration is done in the EVRC_COEFF0.FBADCLPF bit-field and the last conversion result of the feedback ADC, after the LPF, can be read in the EVRC_STAT1.FBADCV bit-field.

36.3.4.1.6 Driver strength adaptation

Programmable slope control of the external MOSFETs is implemented by controlling the driver strength and slew rate and shall be adapted to the external components. This has an impact on the efficiency, as dynamic switching losses increase with decreasing the switching slope.

The driver strength for the N and P driver current is adjusted in the EVRC_COEFF2 and EVRC_COEFF3 register bit-fields. 16 settings are available, increasing from minimum to full driver strength.

Further, trimming options for the commutation parameters are available:

- For 5 V and high-voltage mode supply, if supported by the respective product variant, in the EVRC_COEFF3 register
- For 3.3 V supply, in the EVRC_COEFF2 register

These settings shall be adapted to the switching transistors.

Recommended settings

36.3.4.1.7 Load jump and dynamic response

Maximum load jumps on the V_{DD} domain are limited by the range of the nominal voltage for the maximum overshoots/undershoots (see the V_{DDDC} and V_{DD} parameters in the datasheet). The load transients on the V_{DD} rail are described by the dI_{DDDYN_x} parameters in the datasheet. Restricting the maximum load jumps to the limits of the dI_{DDDYN_RIPPLE} parameter leads to better EMI/EMC performance on the system level, which can be achieved by a user application through the gradual MCU frequency/load control.

The reaction of the EVRC on a load jump can be decomposed into three phases:

1. In the first phase, the capacitor is linearly discharged and the regulator has not yet detected the load jump. The ESR voltage peak occurs in this phase, approximated by I_{load_jump} * *ESR*. By increasing the switching frequency, the ESR overshoot can be reduced, as well as the inductor current ripple
2. In the second phase, the regulator has recognized an increase in output voltage and tries to reduce the duty cycle rapidly. In this phase, the inductor current is decreasing linearly and the capacitor voltage is increasing in a parabolic fashion. The ESR voltage peak gradually disappears in the second phase
3. In the third phase, the regulator regulates back to the new load current. The output voltage which reached a maximum at the end of the second phase starts to gradually ramp down to the nominal output voltage. The overshoot is generally limited as documented by the EVRC parameters in the datasheet

36.3.4.1.8 Regulator efficiency

The regulator efficiency varies for different components and frequency cases at different temperatures, supply voltages, and load current. Typical values for different switching frequencies are specified in the datasheet (n_{DC} parameter). The efficiency is optimized for nominal load currents. As the load current reduces or increases beyond this range, the efficiency drops.

The reduction of switching frequency improves the efficiency with the cost of higher ripple, inductor size, and regulator transient response.

36.3.4.1.9 Start-up mode

The EVRC regulator is started during the ramp-up of the $V_{DDEXTDC}$ supply, after the $V_{DDEXTDC}$ voltage has reached the $V_{RSTEXTDC}$ level (datasheet parameter). During the start-up phase, a different control strategy is used, in order to avoid a current overload in the coil, an overshoot of the output V_{DD} voltage, and to charge the output capacitor in shortest time.

During this phase, the EVRC uses the parameter set which has been loaded in the shadow registers after reset (or, if no parameters were loaded, it starts with the reset configuration). The EVRC start-up flow is depicted in the following figure.

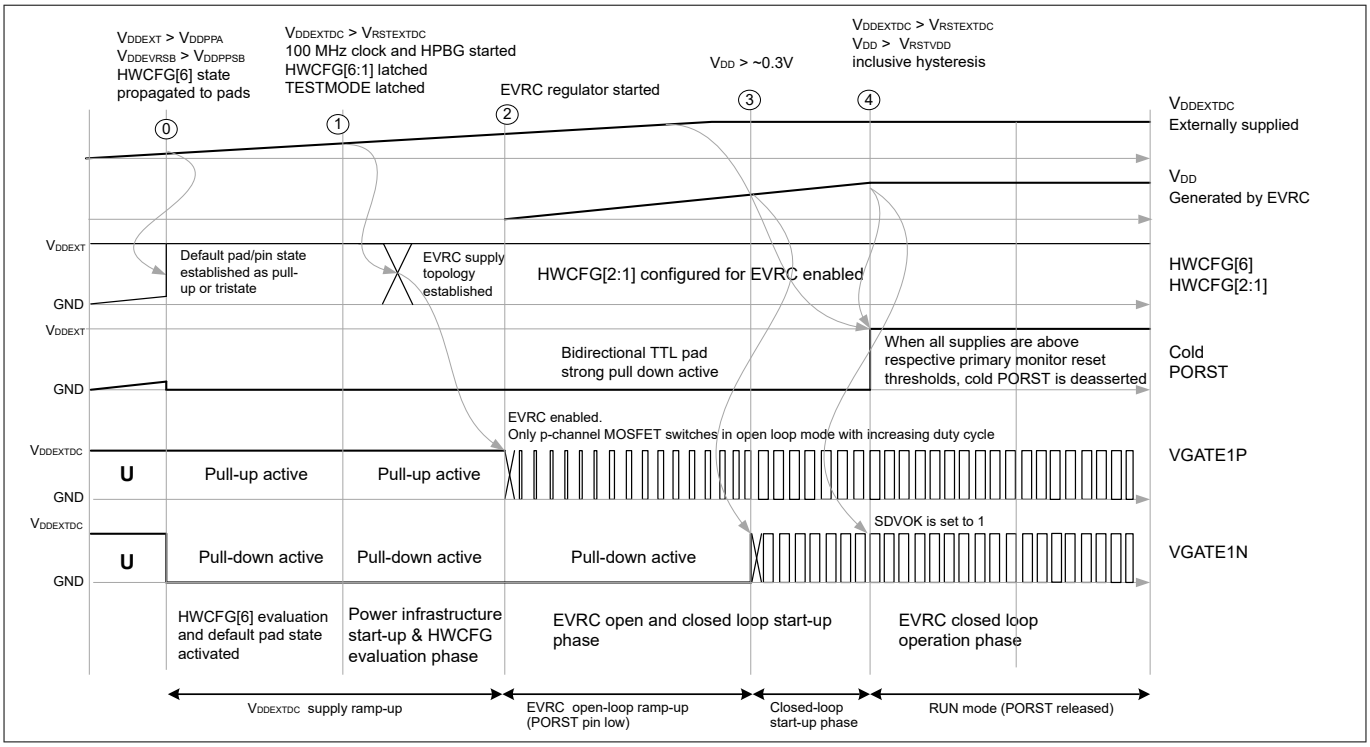

Figure 787 EVRC start-up flow

The start-up procedure occurs as follows:

1. To enable the EVRC regulator, the *HWCFG[1:2]* pins shall be asserted (for example through external or internal pull devices). Its state is latched during $V_{DDEXTDC}$ ramp-up, indicated at time point 1 in the figure above. The latched *HWCFG* pin state can be checked through PADSTAT.HWCFGx status bits and the enable state of EVRC can be checked through the EVRC_STAT0.EVRC flag
2. During the $V_{DDEXTDC}$ ramp-up, the *VGATE1P* signal is in pull-up (PU) state, such that the P-channel MOSFET is completely switched off and the *VGATE1N* pin is in pull-down (PD) state
3. Once the $V_{DDEXTDC}$ voltage reaches the $V_{RSTEXTDC}$ level (data sheet parameter), EVRC is ramping up and starts operating in open-loop mode, as indicated at time point 2 in the figure above. In this mode, only the P-channel MOSFET (*VGATE1P*) is switched on/off, with a gradually increasing duty cycle, starting at a small preset value (programmable through EVRC_COEFF4.MINTON). Soft ramp-up avoids undesired dynamics and too large coil currents, while switching only the P-channel MOSFET facilitates a fast ramp-up to the target voltage without discharges of the capacitor during switching periods. The default switching frequency during open-loop operation is of approximately 0.45 MHz
4. During open-loop operation, the *VGATE1N* signal remains low and keeps the N-channel MOSFET switched off. Only the bulk diode of the NMOS conducts. This prevents negative inductor current in case of a cold MCU reset with pre-charged output buffer capacitor
5. The open-loop operation ends as soon as the output voltage V_{DD}, measured by the feed-back ADC, has crossed a threshold value (characteristic to the EVRC regulator design), as indicated at time point 3 in the figure above . At this point, the controller settings are adapted and the normal closed loop operation begins. The switching frequency is changed to the configured value (in EVRC_CON1.SDFREQ) and the *VGATE1N* pin starts driving the N-channel MOSFET. Both N-channel and P-channel MOSFETs switch with appropriate duty cycle
6. After a voltage transient (typically an overshoot), EVRC is ready and the OK status of the regulator output voltage is asserted in the EVRC_STAT0.SDVOK bit, as indicated at time point 4 in the figure above . Once

the output voltage is stable and all supplies are above the reset threshold, the cold PORST is released. After reset release, EVRC runs in the normal operation Run Mode

7. EVRC_STAT0.SDVOK remains set during Run Mode and is reset only if the V_{DD} set-point was changed or upon a V_{DD} droop request during Run Mode

36.3.4.1.10 Accuracy trimming

After start-up, the firmware (FW) updates the regulator parameters (trimming of the regulator components) to achieve a more accurate EVRC output voltage and improved performance (dynamic regulation). The figure below illustrates the accuracy improvement after trimming.

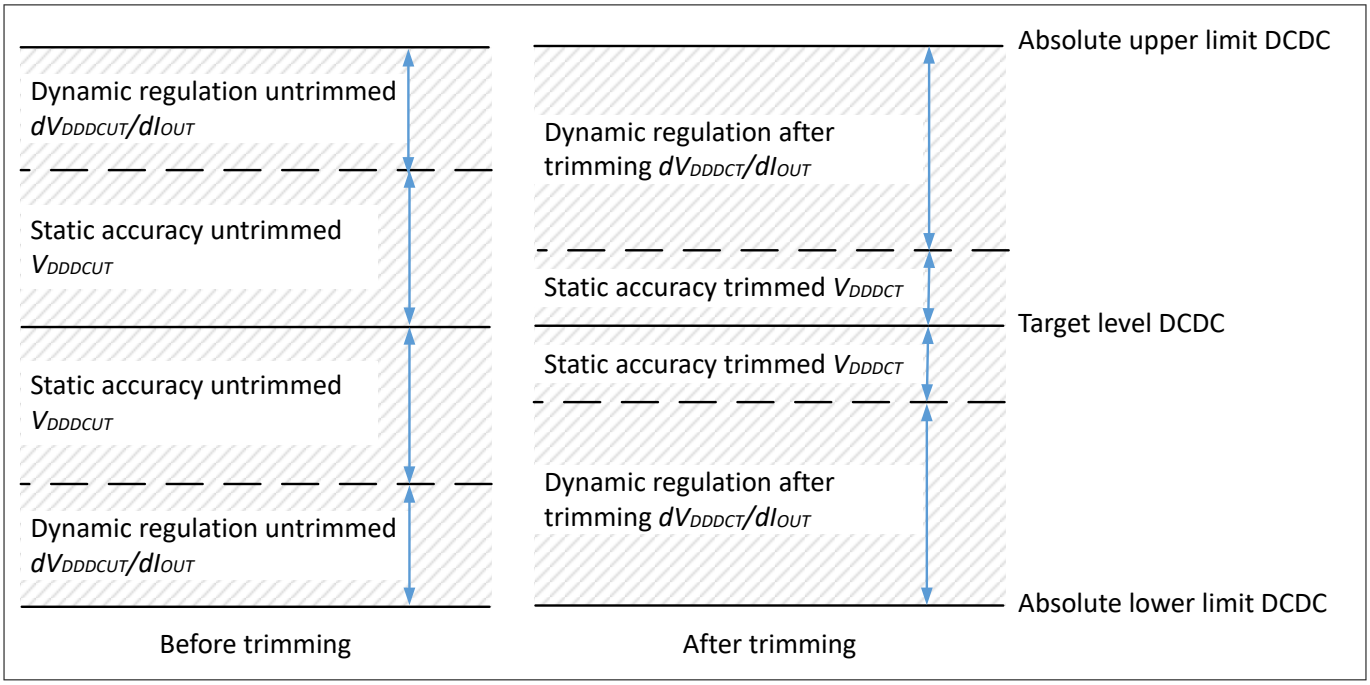

Figure 788 EVRC output voltage accuracy before and after firmware trimming

The overall accuracy can be split into following components:

- Static accuracy: V_{DDDCUT} before trimming, V_{DDDCT} after trimming
- Dynamic response bandwidth of the converter to load jumps: dV_{DDDCUT}/dI_{OUT} before trimming, respectively dV_{DDDCT}/dI_{OUT} after trimming

During the Start-Up phase and firmware execution, the regulator components are in untrimmed state. The static accuracy is V_{DDDCUT}, therefore the allowed dynamic regulation margin is limited to dV_{DDDCUT}/dI_{OUT}. During this phase, the system runs at limited frequency, which is 100 MHz for CPUs/SRI bus and 50 MHz for peripherals, and the total start-up current is approximately 1/3rd of the normal operation current.

Once the firmware trims the analog components, the static accuracy of the regulator improves down to V_{DDDCT}, which allows for larger dynamic margin consequently, as indicated by the dV_{DDDCT}/dI_{OUT} parameter. The regulator can then handle larger load jumps and the application can increase the system frequency.

The register settings of the regulator shall be adapted after start-up (with respect to component trimming) as described in the recommended settings section . Frequency spreading is activated after trimming has been carried out. The register settings for the regulator shall be updated before ramping up the main system clock or activating additional CPU subsystems.

Related information

Recommended settings

36.3.4.1.11 Supply ramp-down

During supply ramp-down phase or standby mode entry, the EVRC ensures a graceful shutdown devoid of output voltage overshoots and coil overload. The gate drivers are always actively keeping off the external MOSFETs during the EVRC shutdown mode.

36.3.4.1.12 Input synchronization

For applications which require DCDC synchronization across the system (potentially for improved EMC), the EVRC regulator features a synchronization input (DCDCSYNCI). This input can be connected to the eGTM, or GTM, or GPT12 module (depending on availability of these modules on the respective product variant) to synchronize the frequency and phase of the PWM signal to an external DCDC regulator (which may for example run at lower switching frequencies than the internal regulator). For this feature, the eGTM, GTM, and GPT12 modules provide two phase synchronized PWM signals:

- A PWM output, routed to the internal EVRC regulator
- A bi-directional (input/output) signal, to be connected to an external DCDC regulator through a port pin, as shown in the figure below

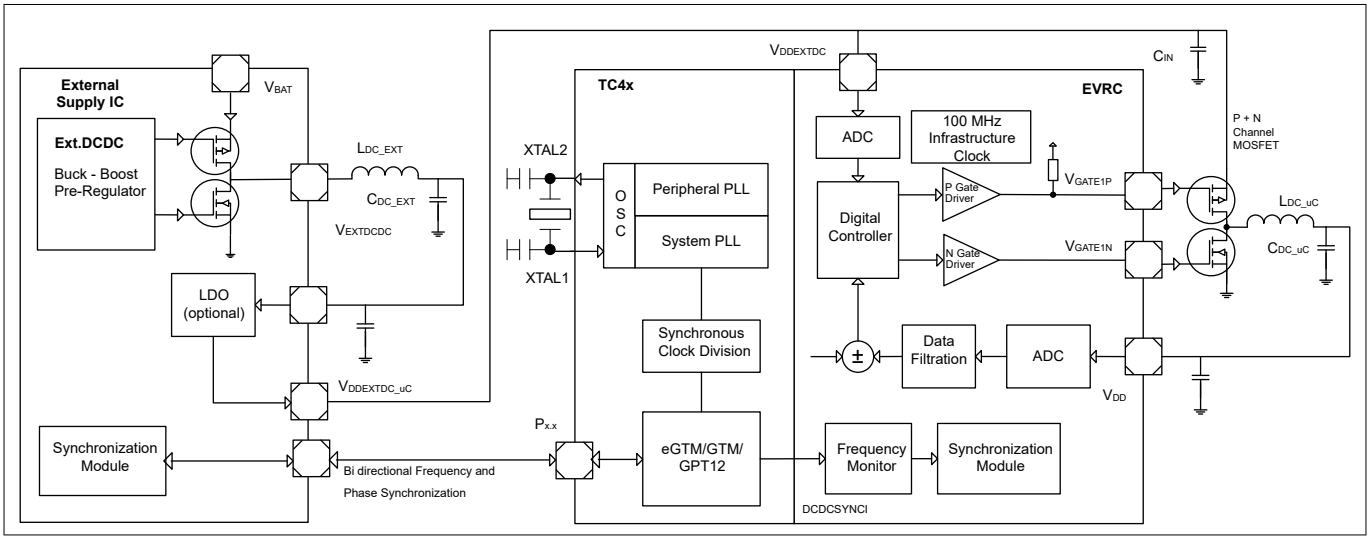

Figure 789 EVRC synchronization input

Important aspects of the synchronization feature are enumerated below:

- The nominal frequencies of the synchronization input are, depending on product variant, 1.82 MHz, 0.8 MHz, or 0.45 MHz, as specified in the datasheet ($f_{DCDCSYNC}$). A bi-directional signal to/from the external regulator is provided by the eGTM, or GTM, or GPT12 module
- Frequency monitoring is carried out in the region between the minimum and maximum values of the $f_{DCDCSYNC}$ parameter, as specified in the datasheet
- Loss of synchronization lock event is triggered if the switching frequency range is violated. The loss of synchronization lock event is indicated through status bit (EVRC_STAT0.SYNCLCK) and interrupt (see INT_CON2.DCDCSYNCLCK bit)
- Lock hysteresis is provided for the synchronization lock signal to avoid limit cycling behavior, as defined in the EVRC_CON1.SYNCHYST bit-field
- The ARU-connected Timer Output Module (ATOM) channels ATOM [0-8]_1 and the Timer Output Module (TOM) channels TOM [0-5]_1 of either the GTM or the eGTM functional block, or the T6OUT output from the GPT12 module (depending on availability of these modules on the respective product variant) can be connected internally to the EVRC synchronization input

Requirements for the synchronization function

In order to use the input synchronization function, the following requirements must be met:

- Synchronization to an external signal is only supported in normal PWM operation mode (run mode). The feature is not supported during start-up mode
- The frequency of the input synchronization signal shall be within the supported monitoring range, as defined in the datasheet (see $f_{DCDCSYNC}$ parameter)
- Component tolerances shall support the frequency monitoring range and the dynamics introduced in case of synchronization loss
- The maximum tolerable deviation from the nominal EVRC switching frequency (configured in EVRC_CON1.SDFREQ) shall be within a configurable maximum deviation, which is configured in EVRC_CON1.SYMCMAXDEV
- The duty cycle of the input signal is not monitored, but must be wide enough to allow proper sampling of the rising edges (minimum 2 cycles of the 100 MHz clock, that is 20 ns)

The synchronization signal may be subjected to delays and jitter when it crosses over from the system PLL domain to the back-up clock domain, which would have an impact on the static accuracy of the EVRC regulator.

Frequency step changes are limited to ±100 kHz from the eGTM, or GTM, or GPT12 module and the dynamic frequency change in case of loss of synchronization is limited to ±200 kHz.

Enabling or disabling synchronization

The synchronization function can be enabled or disabled by configuring the EVRC_CON3.SYNCIN register bit.

Synchronization lock status

The locked or unlocked status of the synchronization function is indicated by the EVRC_STAT0.SYNCLCK status bit.

Hysteresis for synchronization locking and unlocking

A hysteresis is applied for the locking and unlocking, such that toggling lock behavior is avoided around the frequency monitoring limits. The hysteresis width is configured in the EVRC_CON1.SYNCHYST register bit-field. The recommended setting for the EVRC_CON1.SYNCHYST register bit-field for the different f_{DCDC} is presented in the following table,

Table 1429 Recommended SYNCHYST settings for different switching frequencies

Condition	Recommended setting
f_{DCDC} = 0.45 MHz	Set EVRC_CON1.SYNCHYST to 001001_B
f_{DCDC} = 0.8 MHz	Set EVRC_CON1.SYNCHYST to 000101_B
f_{DCDC} = 1.82 MHz	Set EVRC_CON1.SYNCHYST to 000010_B

The EVRC locks to the synchronization signal if its period is within the following range:

- Sync. signal period < EVRC_CON1.SDFREQ + EVRC_CON1.SYNCMAXDEV - EVRC_CON1.SYNCHYST
- Sync. signal period > EVRC_CON1.SDFREQ - EVRC_CON1.SYNCMAXDEV + EVRC_CON1.SYNCHYST

Synchronization is unlocked when the synchronization signal leaves the hysteresis range, that is:

- Sync. signal period > EVRC_CON1.SDFREQ + EVRC_CON1.SYNCMAXDEV
- Sync. signal period < EVRC_CON1.SDFREQ - EVRC_CON1.SYNCMAXDEV

where EVRC_CON1.SDFREQ is the period of the EVRC switching frequency f_{DCDC} , EVRC_CON1.SYNCMAXDEV is the maximum deviation, expressed in 100 MHz cycles, and EVRC_CON1.SYNCHYST is the locking hysteresis, also expressed in 100 MHz cycles.

The maximum deviation EVRC_CON1.SYNCMAXDEV must be chosen to be greater than the value of EVRC_CON1.SYNCHYST and unequal to zero (otherwise the EVRC will lock to the synchronization input only if

its period matches the period programmed in EVRC_CON1.SDFREQ). Also the maximum frequency monitoring range (as defined in the datasheet) has to be considered.

Loss of synchronization

In case the synchronization input signal violates the programmed limits, the EVRC unlocks and continues switching with the programmed nominal switching period (as defined in EVRC_CON1.SDFREQ). The dynamics introduced by the synchronization loss are limited to ±200 kHz and must be supported by component tolerances, as previously mentioned (see requirements for the synchronization function). The loss of synchronization lock event is indicated by an interrupt which can be enabled through the INT_CON2.DCDCSYNCLCK register bit.

Frequency spreading

Frequency spreading is available and can be used when the synchronization input is enabled. When enabled, the synchronized rising edge of the PWM signal is delayed by a random number of cycles, as specified in the section related to frequency spreading.

However, frequency spreading may be deactivated (in the EVRC_CON1.SDFREQSPRD register bit-field), since synchronization inherently provides additional jitter on the switching signals, which may be adequate for the EMI/EMC performance. It is therefore recommended to deactivate frequency spreading when using input synchronization, since the combination of frequency spreading and synchronization jitter may increase the V_{DD} voltage ripple.

Synchronization lock procedure

During the synchronization lock phase, an application is expected to perform the following steps:

- Check the EVRC nominal switching frequency in the EVRC_CON1.SDFREQ register bits. The configured nominal frequency must be either 1.82 MHz, or 0.8 MHz, or 0.45 MHz (depending on the frequencies supported by the respective product variant, and according to the application requirements)
- Configure EVRC_CON1.SYNCMAXDEV and SYNCHYST fields. These values are responsible for the frequency deviation from the nominal frequency and the hysteresis window for locking and unlocking respectively. Violation of the SYNCMAXDEV limits leads to a loss of synchronization lock
- Select a synchronization input in EVRC_CON3.SYNCMUXSEL. The eGTM, or GTM, or GPT12 module shall be configured accordingly for the input signal. The output signal to the EVRC and to the external DCDC regulator is either:
  - GTM LCDCDCOUT signal, selected through the LCDCDCOUTSEL register in the GTM module
  - eGTM LCDCDCOUT signal, selected through the LCDCDCOUTSEL register in the eGTM module
  - GPT12 T6OUT signal

  The signal to the external DCDC regulator can be provided with a phase shift, if necessary
- When no load/line transients are ongoing, EVRC_CON3.SYNCIN shall be set to initiate the synchronization lock procedure
- A successful synchronization lock is reflected in the EVRC_STAT0.SYNCLCK status bit. The procedure takes less than 4 switching periods

Synchronization unlock procedure

Before entering standby mode, the synchronization unlock procedure shall be performed:

- The EVRC_CON3.SYNCIN bit shall be reset to initiate the synchronization unlock procedure
- As a result, the EVRC_STAT0.SYNCLCK bit is set into unlocked state. The Synchronization unlock interrupt is generated if enabled (in INT_CON2.DCDCSYNCLCK). The synchronization unlock procedure takes less than 4 switching periods. The synchronization logic is consequently disabled
- The synchronization input signal from the GTM, or eGTM, or GPT12 module is consequently deselected through configuration of the EVRC_CON3.SYNCMUXSEL bit-field by software. The phase shifted signal to the external DCDC regulator from GTM, or eGTM, or GPT12 is also deactivated

Synchronization unlock event

If the period of the incoming synchronization signal is longer than the nominal period + maximum deviation or shorter than nominal period - maximum deviation (see the above section on locking/unlocking hysteresis), a synchronization unlock event is triggered:

- The EVRC_STAT0.SYNCLCK status bit switches to unlocked state. The synchronization unlock interrupt is generated if enabled (in INT_CON2.DCDCSYNCLCK)
- EVRC switches back to the internal 100 MHz clock source at the default switching frequency with an arbitrary phase. The dynamic voltage transient may be higher during loss of synchronization with consequent load jump and might violate voltage accuracy limits during this frequency switch
- A re-lock is initiated automatically according to the hysteresis, that is only if the incoming signal period is less than:
  - Nominal period + maximum deviation - sync hysteresis

  and higher than:
  - Nominal period - maximum deviation + sync hysteresis

  (see the above section on locking/unlocking hysteresis for the respective settings)

36.3.4.1.13 Short detection

The EVRC features a voltage-based detection mechanism for short to supply (short to high voltage) and short to ground (short to low voltage) failures.

The short-to-high voltage detection can be enabled by application software through the EVRC_CON2.SHHEN bit. The detection threshold is determined using the EVRC_CON2.SHHTHR bit-field, which can be adjusted by application software:

Short-to-high detection voltage threshold = (EVRC_CON0.SDVOUTSEL + EVRC_CON2.SHHTHR) * $V_{TRKCORELSB}$

The short-to-high detection is triggered when the EVRC output voltage exceeds the configured threshold for a time longer or equal to the detection time configured in the EVRC_CON2.SHHTIM bit-field. The EVRC_CON2.SHHTIM bit-field can be adjusted by the application software and is configured in milliseconds.

The short-to-low voltage detection can be enabled by application software through the EVRC_CON2.SHLEN bit. The detection threshold is determined using the EVRC_CON2.SHLTHR bit-field, which can be adjusted by application software:

Short-to-low detection voltage threshold = (EVRC_CON0.SDVOUTSEL - EVRC_CON2.SHLTHR) * $V_{TRKCORELSB}$

The short-to-low detection is triggered when the EVRC output voltage drops below the configured threshold for a time longer or equal to the detection time configured in the EVRC_CON2.SHLTIM bit-field. The EVRC_CON2.SHLTIM bit-field can be adjusted by the application software and is configured in milliseconds.

If the short detection is enabled (using EVRC_CON2.SHHEN or EVRC_CON2.SHLEN), an alarm is triggered to the SMU in case of a short detection.

If desired by the application, in addition to the short detection alarm, a switch-off of the EVRC can be triggered after a short detection. The switch-off of the EVRC can be enabled by application software through the EVRC_CON2.SHOFFEN bit. If this bit is enabled, the EVRC will be switched off with a delay of approximately 3 ms after a short detection.

36.3.4.1.14 Recommended settings

This section presents a few examples of settings for different load capabilities, switching frequencies, and external voltages.

Application-dependent settings

For different application profiles, the following parameters are configured:

Table 1430 Parameter configuration for different application profiles

Condition	Parameters
MOSFETs BUK4D38-20P and BUK4D16-20, $I_{DD} \le I_{DDDCMAX}$ HE case, f_{DCDC} = 0.8 MHz	• EVRC_CON2 = 0x33C29F0 • EVRC_CON3 = 0x1200 • EVRC_CON4 = 0x60 • EVRC_COEFF2 = 0x02F7EFFD • EVRC_COEFF3 = 0x24F8CFAF • EVRC_COEFF4 =0x00664664 • EVRC_COEFF5 = 0x0000FFFF • Set EVRC_CON0.UP = 1 • Wait for 30 µs • Check that EVRC_CON0.UP is de-asserted, then continue • EVRC_CON1 = 0x098A007D • EVRC_COEFF0 = 0x8483C014 • EVRC_COEFF1 = 0x09C01EB8 • Set EVRC_CON0.UP = 1 • Wait for 20 µs • Check that EVRC_CON0.UP is de-asserted, then continue • EVRC_CON1 = 0x098A007D • EVRC_CON4=0x000000B1 • EVRC_COEFF0 = 0x84942003 • EVRC_COEFF1 = 0x0A3000C6 • Set EVRC_CON0.UP = 1 • Wait for 30 µs • Check that EVRC_CON0.UP is de-asserted, then continue

(table continues...)

(table continues...)

Table 1430 (continued) Parameter configuration for different application profiles

Condition	Parameters
MOSFETs SQA407CEJW and SQA446CEJW, $I_{DD} \leq I_{DDDCMAX}$ HE case, f_{DCDC} = 0.45 MHz	• EVRC_CON2 = 0x33C29F0 • EVRC_CON3 = 0x1200 • EVRC_CON4 = 0x60 • EVRC_COEFF2 = 0x02F75FA9 • EVRC_COEFF3 = 0x04F88F6A • EVRC_COEFF4 =0x00664664 • EVRC_COEFF5 = 0x00148F8C • Set EVRC_CON0.UP = 1 • Wait for 30 µs • Check that EVRC_CON0.UP is de-asserted, then continue • EVRC_CON1 = 0x0D9200DE • EVRC_COEFF0 = 0x64BCA324 • EVRC_COEFF1 = 0x0A232299 • Set EVRC_CON0.UP = 1 • Wait for 20 µs • Check that EVRC_CON0.UP is de-asserted, then continue • EVRC_CON1 = 0x0D9200DE • EVRC_CON4 = 0x000000C1 • EVRC_COEFF0 = 0x64BCA324 • EVRC_COEFF1 = 0x0A232299 • Set EVRC_CON0.UP = 1 • Wait for 30 µs • Check that EVRC_CON0.UP is de-asserted, then continue

External voltage settings

There is no specific EVRC parameter setting for $V_{DDEXTDC}$ = 3.3 V vs. $V_{DDEXTDC}$ = 5 V, this configuration is set at start-up through the *HWCFG* pins.

36.3.4.2 External regulator interface and voltage scaling

This section describes the interface between PMS and an external regulator or power management IC and provides details on the voltage scaling procedure.

External regulator interface

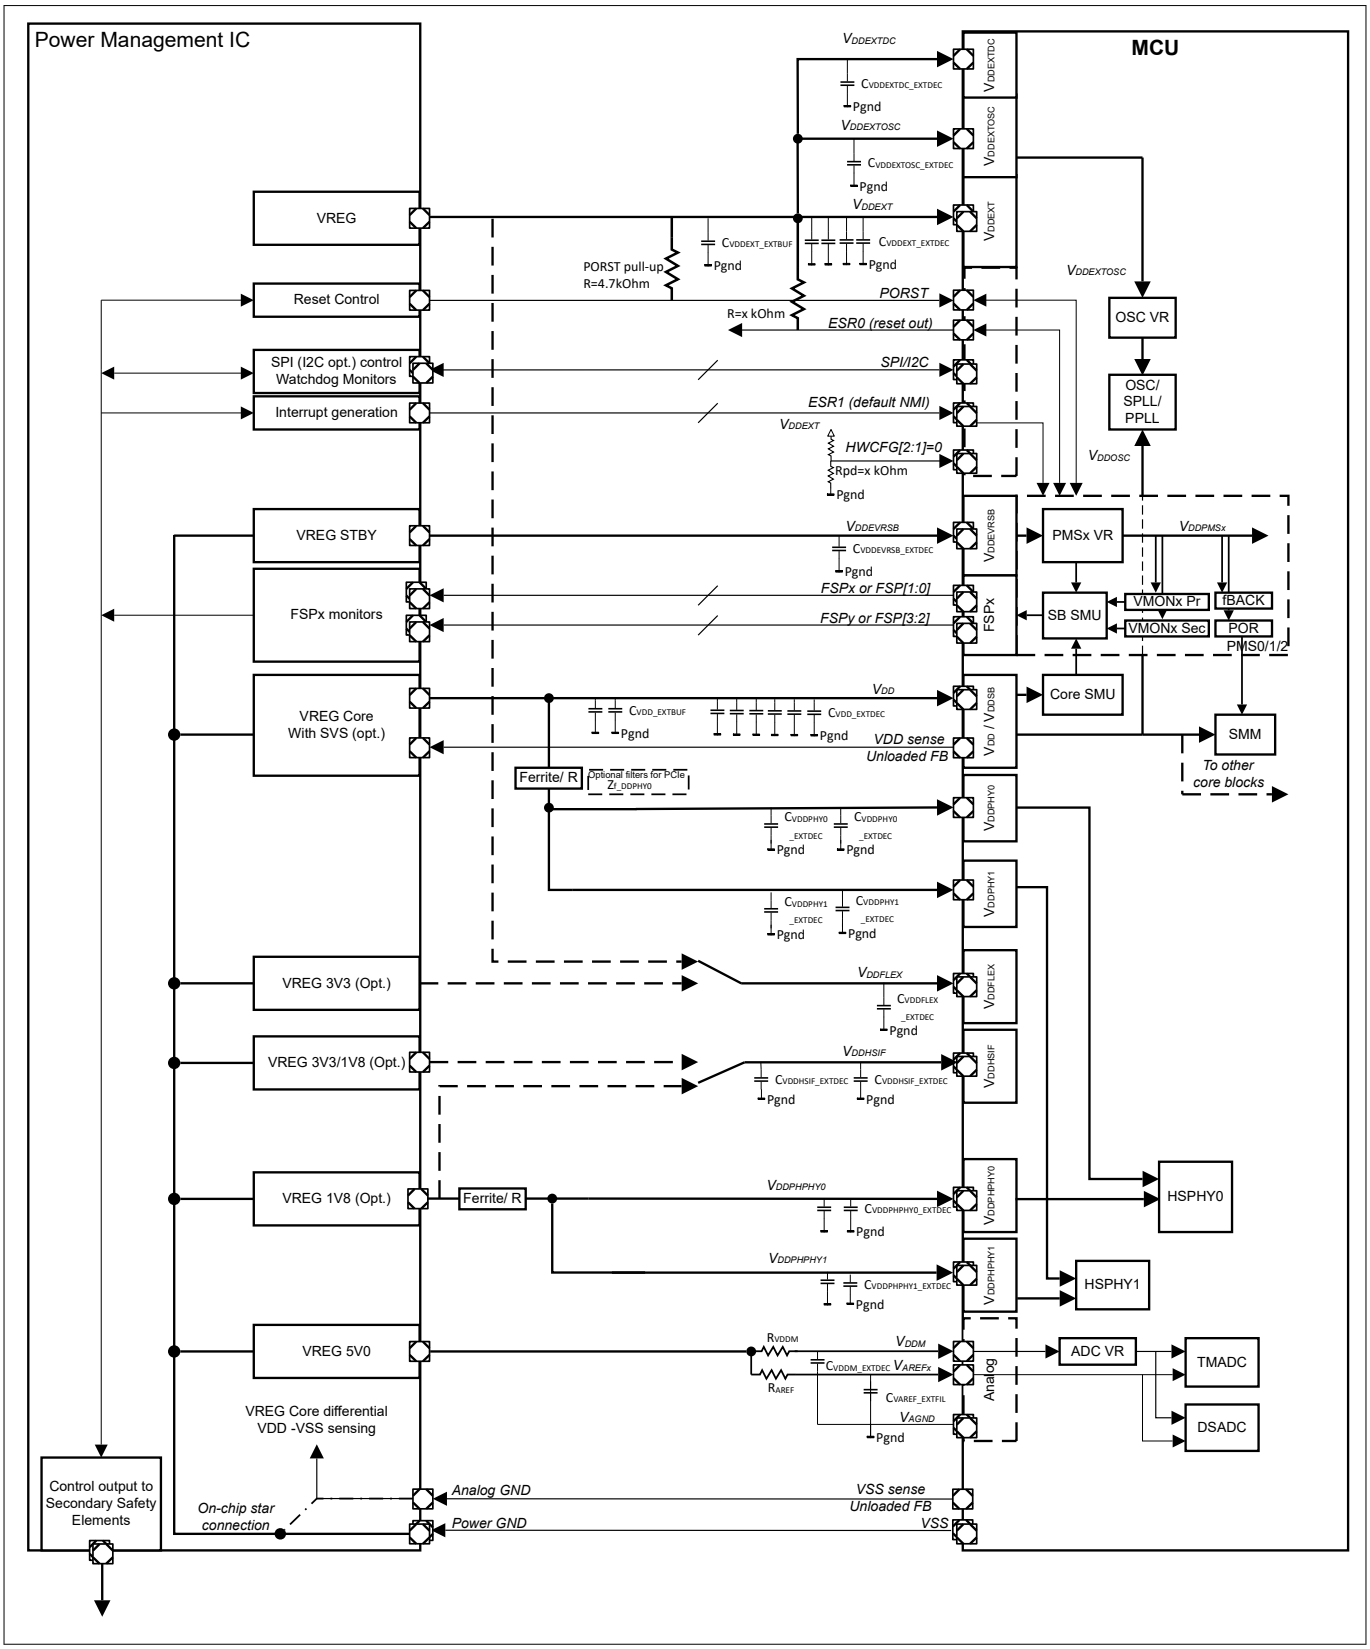

Figure 790 External regulator interface and capacitors. All features may not be available in all variants.

The previous figure illustrates an abstract of the connectivity scheme between the MCU and the external regulator (or power management IC), including the supply rails and control interfaces. While some of them are optional, the majority of the interfaces are mandatory for MCU operation.

Mandatory supply rails:

- V_{DDEXT}
- $V_{DDEXTDC}$ supply for the EVRC regulator. $V_{DDEXTDC}$ shall be supplied with the same voltage as V_{DDEXT} if the V_{DD} voltage is supplied externally
- $V_{DDEVRSB}$ supply for the PMS subsystem and $V_{DDEVRSB}$-buffered pads. Powered from an individual regulator, to provide availability of the PMS0/PMS1/PMS2 domains during the cold reset of the other power domains. It usually provides support for the low-power standby function. Optionally it may be powered from the same regulator as the V_{DDEXT} supply rail
- V_{DDFLEX} (if available on the respective product variant), may be supplied from an individual regulator, or connected to the same regulator as the V_{DDEXT} supply rail
- V_{DD}/V_{DDSB} supply for the core domain (if available on the respective product variant). Optionally, the responsible regulator supports static voltage scaling to leverage the production characteristics of an individual chip for power consumption improvement. The unloaded V_{DD} and unloaded *GND* pins may be used by the V_{DD} regulator for direct feedback connection, to compensate for the static voltage drop of the PCB and device package parasitics
- V_{DDHSIF} (if available on the respective product variant), may be supplied from an individual regulator, or connected to the same regulator as the V_{DDEXT}, V_{DDFLEX}, or $V_{DDPHPHYx}$ supply rail
- V_{DDM}/V_{AREFx} for the analog domain. V_{AREFx} is used as the reference supply inputs for the TMADC and DSADC

Optional supply rails:

- $V_{DDPHPHYx}$/V_{DDPHYx} are related to the SGMII and PCIe PHY interfaces (if available on the respective product variant). Optional external filter elements may be used for each interface instance (x = 0, 1, 2)

Mandatory control links:

- *PORST* bi-directional open-drain control interface. Input: Warm reset request from external reset element. Output: Cold reset signal generated internally by the primary voltage monitors (VMONP). It must be pulled up to the same supply as V_{DDEXT}
- *HWCFG[2:1]* input, deciding the EVRC usage and its configuration

Optional control links:

- *ESR0*: Reset elongation output. Used by default as the reset control from the MCU to other external ICs. Optionally used as NMI/trap generation input
- *ESR1/2*: Trap inputs. Optionally used as reset elongation outputs or system/application reset request inputs
- *ESR0/1/2*: May be alternatively configured for the module group reset (MGRx) request input
- *ESR0/1/2*: May be alternatively configured as GPIOs
- *ESR2*: May be alternatively configured as standby wake-up trigger
- FSPx: Fault signal protocol outputs. Used as an interface controlled from the standby SMU to signal an internal alarm occurrence to the external supervisory elements. Depending on the chosen FSP protocol, the *FSP0/1/2/3* outputs may be used individually or in groups with various alarm mapping. It is decided at the system level what kinds of reactions (for example cold or warm reset) each of the FSPx mapped alarms are expected to trigger
- SPI/I2C: Standard interface to the external PMIC, used for control functions as well as for safety service functions such as external watchdogs

Static voltage scaling

Static voltage scaling is the procedure of adapting the core voltage to the required nominal level based on the characteristics of the particular MCU device sample. TC4xx devices are designed to support static voltage scaling, leveraging production information of each device sample in order to achieve a better power to performance ratio.

On the TC4xx product variants supporting this feature, the voltage scaling procedure differs depending on whether the V_{DD} voltage is supplied by an external core voltage regulator or by the embedded EVRC and is illustrated in the following.

Static V_{DD} voltage scaling with external core voltage generation

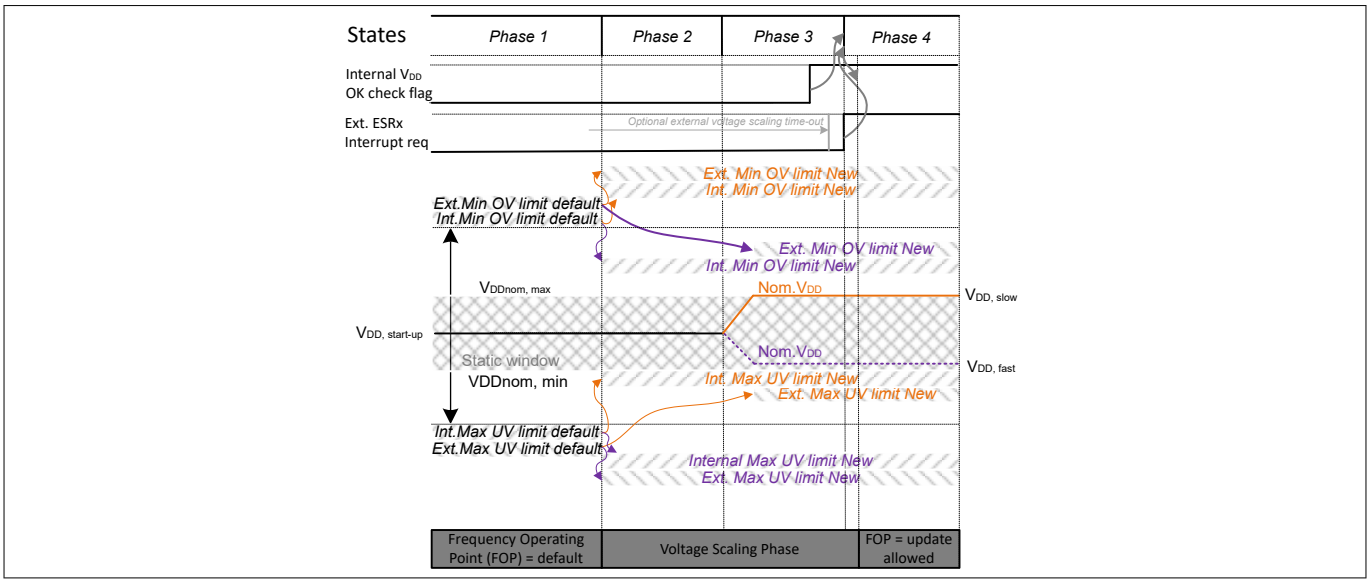

Figure 791 Static V_{DD} voltage scaling with external core voltage generation

Phase 1 (internal monitoring threshold adaptation and voltage scaling trigger):

- Read-out of the stored device type and corresponding nominal voltage level (voltage ID) in the VID_CON0 register
- Disable the V_{DD} primary under-voltage reset in the VMONP_VDDRST register, primary OV/UV alarms in the VMONP_VDDCON register, and the secondary OV/UV alarms in the VMONS_VDDCON register. Optionally only the OV or UV alarms can be disabled individually, depending on the direction of the required V_{DD} voltage change
- Adapt the under-voltage reset (in the VMONP_VDDRST.RESETTRIM bit-field), as well as the OV/UV alarm thresholds to the new voltage set-point
- Send the command to the external core voltage regulator for the new V_{DD} voltage set-point. It is expected that the interface to the external regulator is already initialized

Phase 2 (external monitoring threshold adaptation):

- Depending on the system safety integrity requirements, the external voltage monitoring limits (of the external V_{DD} regulator) may need to be adapted to the new voltage set-point. The exact procedure depends on the respective implementation of this feature in the external power management IC. The example flow illustrated in the previous figure shows the change of the OV and UV limits done in an order that depends on the direction of the required voltage change. For instance, a new set-point greater than the default V_{DD} voltage results in an OV threshold change before the V_{DD} voltage change, while the UV threshold can be changed after raising the V_{DD} voltage

Phase 3 (voltage scaling active phase):

- The external V_{DD} regulator reaches the new desired voltage set-point
- If under-voltage reset and voltage monitor alarms are not disabled, it is recommended to minimize the load dynamics during the phases 2 and 3 by reducing the MCU utilization to a minimum acceptable by the application in order to prevent under-voltage resets and OV/UV alarms until the voltage reaches the target nominal value

Phase 4 (voltage scaling completed and re-enabling of alarms):

- The software can read the new V_{DD} voltage value from the status bits of the primary or secondary voltage monitors. The software can also optionally wait for an interrupt from the external core voltage regulator as soon as the voltage scaling active phase is completed

- If no confirmation of the voltage scaling status is received within a user defined timeout, the software may repeat the flow or trigger an error handler. If a successful voltage scaling status is achieved, the software may now re-enable the under-voltage reset and the voltage monitor alarms
- After successful completion of the above steps, the operation can continue with the new frequency operation point

Static V_{DD} voltage scaling with EVRC

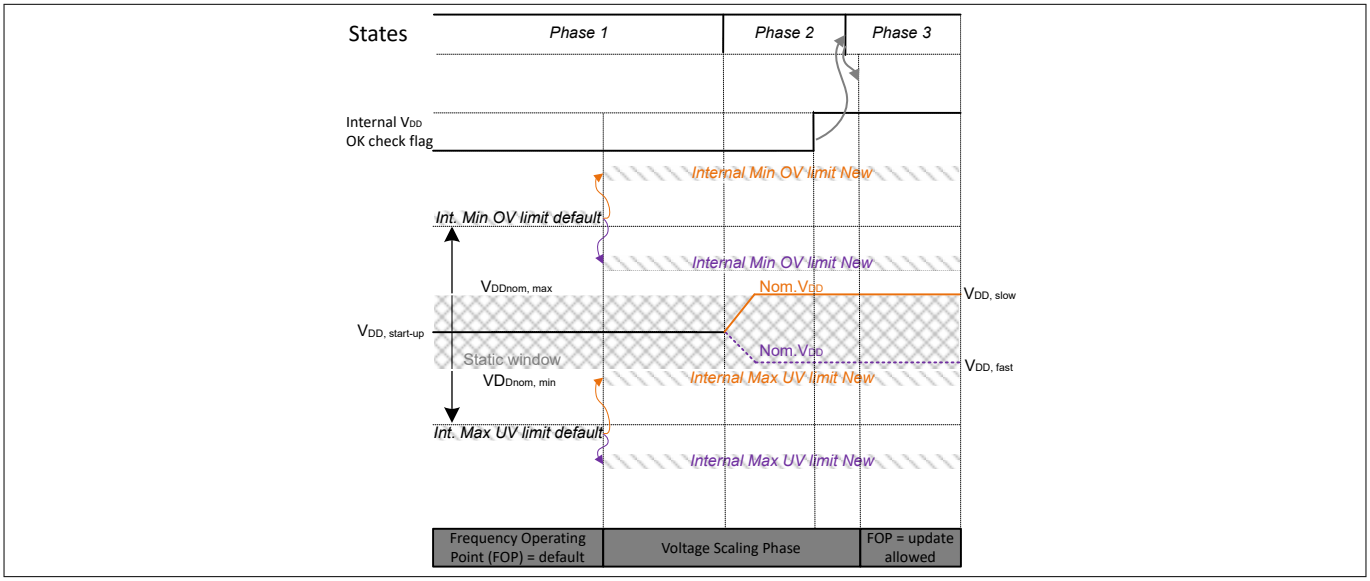

Figure 792 Static V_{DD} voltage scaling with EVRC

Phase 1 (internal monitoring threshold adaptation and voltage scaling trigger):

- Read-out of the stored device type and corresponding nominal voltage level (voltage ID) in the VID_CON0 register
- Disable the V_{DD} primary under-voltage reset in the VMONP_VDDRST register, primary OV/UV alarms in the VMONP_VDDCON register, and the secondary OV/UV alarms through the VMONS_VDDCON register. Optionally only the OV or UV alarms can be disabled individually, depending on the direction of the required V_{DD} voltage change
- Adapt the under-voltage reset (in the VMONP_VDDRST.RESETTRIM bit-field), as well as the OV/UV alarm thresholds to the new voltage set-point

Phase 2 (voltage scaling active phase):

- The voltage scaling active phase is started as soon as the software changes the default EVRC set-point through the EVRC_CON0.SDVOUTSEL bit-field
- If under-voltage reset and voltage monitor alarms are not disabled, it is recommended to minimize the load dynamics during the phases 2 and 3 by reducing the MCU utilization to a minimum acceptable by the application, in order to prevent OV/UV alarms until the voltage reaches the target nominal value

Phase 3 (voltage scaling completed and re-enabling of alarms)

- The software can poll the EVRC_STAT0.SDVOK bit which indicates when the new regulator set-point has been reached
- If no confirmation of the voltage scaling status is received within a user defined timeout, the software may repeat the flow or trigger an error handler. If a successful voltage scaling status is achieved, the software may now re-enable the under-voltage reset and the voltage monitor alarms
- After successful completion of the above steps, the operation can continue with the new frequency operation point

Primary voltage monitors VMONPx and cold PORST on page 5971

36.3.5.1 Secondary over- and under-voltage monitors (VMONSx)

Secondary over-voltage and under-voltage monitoring against programmable thresholds is provided for the following supply rails: $V_{DDEVRSB}$, V_{DDEXT}, $V_{DDP3NVM}$, V_{DDM}, V_{DDFLEX}, V_{DD}, V_{DDPMS0}, V_{DDPMS1}, V_{DDPMS2}, $V_{DDSBRAM}$, V_{DDPAD}, $V_{DDPHPHYx}$, $V_{DDPHRIFx}$, V_{DDHSIF}, V_{DDPHYx}, V_{DDRIFx}, V_{DDCPUx}, V_{DDPPU}, V_{DDLMUx}, and $V_{DDEXTDC}$, depending on product variant (not all supply rails are available on each product variant). The secondary monitors are based on a secondary band-gap reference independent from the primary band-gap reference used by the embedded PMS voltage regulators. In case of a threshold violation, an SMU alarm event is generated (as configured by the SW) and an interrupt is triggered (if enabled by the SW). The tolerance of the threshold for each monitored supply rail is documented in the data sheet as V_{XXMON} parameter.

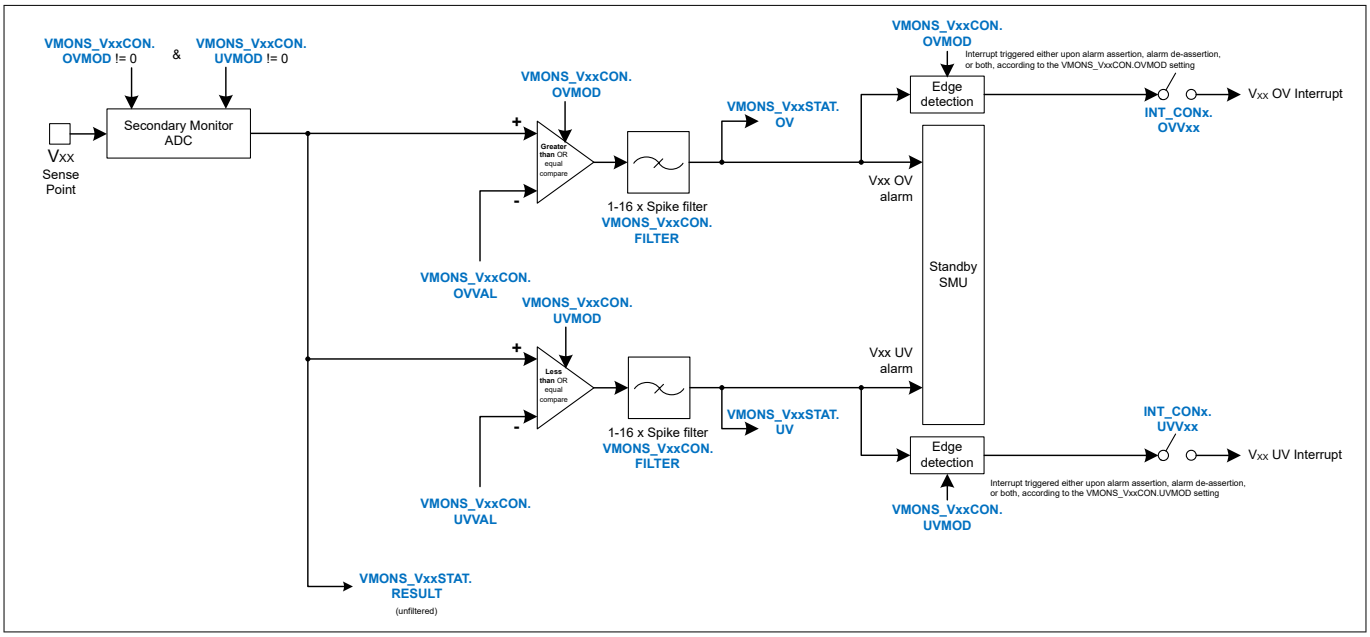

Figure 793 Secondary voltage monitors configuration and outputs

Refer to the functional description for the specific product variant for an image showing an overview of the secondary voltage monitors.

The appropriate thresholds for voltage monitoring can be programmed in the VMONS_VxxCON registers. The over-voltage and under-voltage threshold settings in the OVVAL and UVVAL bit-fields can be calculated by linear interpolation from the multiple voltage levels and corresponding thresholds provided in the V_{XXMON} parameters in the data sheet. The secondary monitor violation is notified through an alarm, for over-voltage if OVMOD ≠ 00_B, respectively for under-voltage if UVMOD ≠ 00_B, independent of the threshold crossing direction. In addition to the SMU alarm, an interrupt is triggered if the corresponding INT_CONx.OVVxx respectively INT_CONx.UVVxx bit is enabled, either upon alarm assertion, alarm de-assertion, or both, as programmed in the UVMOD and OVMOD bit-fields (00_B = interrupt disabled, 01_B = interrupt triggered upon alarm assertion, 10_B = interrupt triggered when the alarm is de-asserted, and 11_B = interrupt triggered either when the alarm is asserted or de-asserted). In case of a violation, the respective status flags (OV or UV) are set in the corresponding VMONS_VxxSTAT registers. These status bits may be evaluated to differentiate which supply rail has triggered the alarm event to the SMU. The VMONS_VxxSTAT UV and OV flags reflect the instantaneous status

of the under-voltage or over-voltage event. They are not latched within the PMS registers, instead they are latched in the standby SMU registers.

In case both OV and UV thresholds are configured to the same value (or within a distance lower than the accuracy of the voltage monitors), then both OV and UV alarms could be triggered at the same time.

A configurable spike filtering function is applied on the consecutive ADC results, and can be individually configured in the VMONS_VxxCON.FILTER bit-fields. A sequence of at least VMONS_VxxCON.FILTER+1 consecutive threshold violations is then required to trigger the OV/UV event. This filter is applied for generating the SMU alarms and for setting the OV/UV status bits in the VMONS-VxxSTAT registers.

The supply rails connected to the same secondary monitor (VMONS0 or VMONS1) are converted one after another in a continuous scan mode. Please refer to the figure, 'Overview of the secondary voltage monitors' in the device specific section of the PMS chapter to see which supply rails are connected to which secondary monitor. The monitoring latency of each supply rail depends on the spike filter setting, the supply rail conversion latency and the number of supply channels being converted by each secondary monitor as given below,

- The latency for $V_{DDEXTDC}$ rail is t_{TRKHV}*(FILTER+1), where t_{TRKHV} is datasheet parameter and FILTER refers to the spike filter setting
- For the voltage rails connected to VMONS0 or VMONS1 the latency is given by the following formula:

  T_{VMONSx}=(FILTER+1)*((A*t_{SARHV})+(B*$t_{SARCORE}$))

  In the formula above t_{SARHV} and $t_{SARCORE}$ are datasheet parameters and FILTER refers to the spike filter setting and x is the index of the VMONSx. A is the number of voltage rails monitored by VMONSx that have an individual conversion latency t_{SARHV} and B is the number of voltage rails monitored by VMONSx that have an individual conversion latency of $t_{SARCORE}$. Please refer to the table “Secondary voltage monitor parameters” below to find out which conversion latency applies for each voltage rail. Please note that A and B values depend on the number of channels being actually monitored by a specific VMONSx as monitoring of a supply rail can be selectively activated or deactivated by the user

***Note**: VMONS1 is not available for all derivatives.*

As shown in the figure below, the $V_{DDEXTDC}$ voltage is monitored using a tracking ADC (called VMONP3), while all other voltages are monitored by SAR ADCs. Therefore, there is a difference in the configuration of the secondary monitor for $V_{DDEXTDC}$ vs. all other monitored voltages, as the tracking ADCs have a low-pass filter in the alarm triggering path. The alarm low-pass filter for the $V_{DDEXTDC}$ secondary monitor tracking ADC is configured in the VMONP_TRKTRIM0.VDDEXTDCVMONSLPF bit-field.

The VMONS_LVLSEL register bit-fields shall not be modified by the application software (as they are not related to the secondary monitoring thresholds, but are instead used by other modules of the MCU, to differentiate between the different possible voltage levels used by applications on the respective supply rails). The VMONS_LVLSEL.NVMMINSEL bit-field indicates the threshold for stable NVM operation, while the VMONS_LVLSTAT.NVMMIN status bit indicates the VMONS evaluation of V_{DDEXT} voltage against this threshold, using an internal spike filter of 2 samples.

The last value measured by the secondary monitoring ADCs is updated, for each supply rail, in the VMONS_VxxSTAT.RESULT bit-field, when the respective channel is converted. Conversions occur on a secondary ADC channel if any of the following conditions is true:

- The supply rail is on a tracking ADC (that is $V_{DDEXTDC}$) - the tracking ADC channels are always converted
- For the V_{DDEXT} and V_{DDM} rails the channels are always converted
- If UVMOD or OVMOD is not 0
- For the V_{DDPMS0} or V_{DDPMS2} rail if drift monitoring is enabled (DRMON_Vxx.ENABLE = 1)
- If UVMOD and OVMOD have just been set to zero but the conversion already started

The VMONS_VxxSTAT.RESULT value is stored without spike filtering and shows the current value measured by the ADC.

The VMONS_VxxSTAT.ACTIVITY bit-field stores an activity counter, which serves as a safety check that the respective secondary monitor is currently running. This counter cumulatively counts the end of conversion signals per secondary monitor VMONSx, in a background scan over all channels of a VMONSx monitor and respective filter configurations of each channel. The total number of conversions is ConvTot = Σ[ChX * (VxxCON.FILTER+1)]. The counter is reset to zero on a ConvTot overflow.

To configure the VMONS_VxxCON.UVVAL and VMONS_VxxCON.OVVAL values, the LSB value for each voltage rail is provided in the following table:

Table 1431 Secondary voltage monitors parameters

Voltage rail	VMONS LSB datasheet parameter	Secondary voltage monitor accuracy after trimming - datasheet parameter	Effects of secondary voltage monitoring thresholds violation[1)]
$V_{DDEVRSB}$	$V_{SARHVLSB}$	$V_{DDEVRSBMON}$	UV, OV alarm
V_{DDEXT}	$V_{SARHVLSB}$	$V_{DDEXTMON}$	UV, OV alarm
$V_{DDP3NVM}$	$V_{SARHVLSB}$	$V_{DDP3NVMMON}$	UV, OV alarm
V_{DDM}	$V_{SARHVLSB}$	V_{DDMMON}	UV, OV alarm
V_{DDFLEX}	$V_{SARHVLSB}$	$V_{DDFLEXMON}$	UV, OV alarm
V_{DD}	$V_{SARCORELSB}$	V_{DDMON}	UV, OV alarm
V_{DDPMS0}	$V_{SARCORELSB}$	$V_{DDPMS0MON}$	UV, OV alarm
$V_{DDPMS1,2}$	$V_{SARCORELSB}$	$V_{DDPMS2MON}$	UV, OV alarm
$V_{DDSBRAM}$	$V_{SARCORELSB}$	$V_{DDPMS0MON}$	UV, OV alarm
V_{DDPAD}	$V_{SARCORELSB}$	$V_{DDPADMON}$	UV, OV alarm
$V_{DDPHPHYx}$	$V_{SARHVLSB}$	$V_{DDPHPHYxMON}$	UV, OV alarm
$V_{DDPHRIFx}$	$V_{SARHVLSB}$	$V_{DDPHRIFxMON}$	UV, OV alarm
V_{DDHSIF}	$V_{SARHVLSB}$	$V_{DDHSIFMON}$	UV, OV alarm
V_{DDPHYx}	$V_{SARCORELSB}$	$V_{DDPHYxMON}$	UV, OV alarm
V_{DDRIFx}	$V_{SARCORELSB}$	$V_{DDRIFxMON}$	UV, OV alarm
V_{DDCPUx}	$V_{SARCORELSB}$	$V_{DDCPUxMON}$	UV, OV alarm
V_{DDPPU}	$V_{SARCORELSB}$	$V_{DDPPUMON}$	UV, OV alarm
V_{DDLMUx}	$V_{SARCORELSB}$	$V_{DDLMUMON}$	UV, OV alarm
$V_{DDEXTDC}$	$V_{TRKHVLSB}$	$V_{DDEXTDCMON}$	UV, OV alarm

1) Only if the corresponding VMONS_VxxCON.UVMOD, respectively VMONS_VxxCON.OVMOD, are not zero.

In case of over-voltage supply alarms, it may be ensured that the supply to the device is switched off to avoid damage. The Error Pin Fail Safe Protocol (*FSP*x), triggered by the standby SMU (if enabled in the standby SMU CMDSTDBY register bit-fields), ensures that the over-voltage condition is communicated to the external safety supply even when the MCU is in warm reset state.

After start-up, it may happen that supply over- or under-voltage alarms may already have been triggered depending on residual start-up voltages or supply dynamics. Likewise during VMONS_VxxCON reconfigurations, spurious alarms may be raised depending on filter state and changed configuration. Therefore, before activating SMU alarm generation or triggering latent fault supply alarm tests, the secondary monitors and filters need to be completely reset. It needs to be ensured that SMU alarms and associated interrupts are foremost deactivated in VMONS_VxxCON and INT_CONx registers. Alarms and interrupts are then consequently

re-configured to the intended voltage level and filter settings in VMONS_VxxCON. The spike filters for over-voltage and under-voltage alarms are automatically reset whenever writing into the VMONS_VxxCON.OVVAL, respectively into VMONS_VxxCON.UVVAL bit-fields, therefore there is no need to explicitly de-activate and re-activate the filters. A delay time of 4 µs has to be awaited by the application SW before alarm activation after configuration is changed in VMONS_VxxCON registers.

In case of application and system resets, PMS alarms occurring during the respective reset shutdown and release will be reflected in SMU_stdby AGX alarm status registers and consequently SMU_stdby FSP reaction may be triggered, if configured in the SMU_stdby AGFSP.FEx registers. On the contrary, PMS alarms occurring during warm reset phase will not be latched in SMU_core AGX alarm status registers, as these registers are in reset state. Furthermore, alarms which have occurred during the reset phase would not be consequently forwarded to the SMU_core on reset release.

36.3.5.2 Peak voltage detection

The peak voltage detection feature performs a continuous recording of the absolute maximum voltage on the V_{DD}, V_{DDEXT}, and $V_{DDEXTDC}$ supply rails across a driving cycle. SW can read the recorded value and reset the corresponding register to restart the measurement. This can be used for reliability and lifetime profile checks.

The measurement is performed by the primary voltage monitoring (tracking) ADC of the respective rail. Therefore, only voltage peaks with transients within the maximum slope specified in the data sheet for the primary voltage monitors are captured.

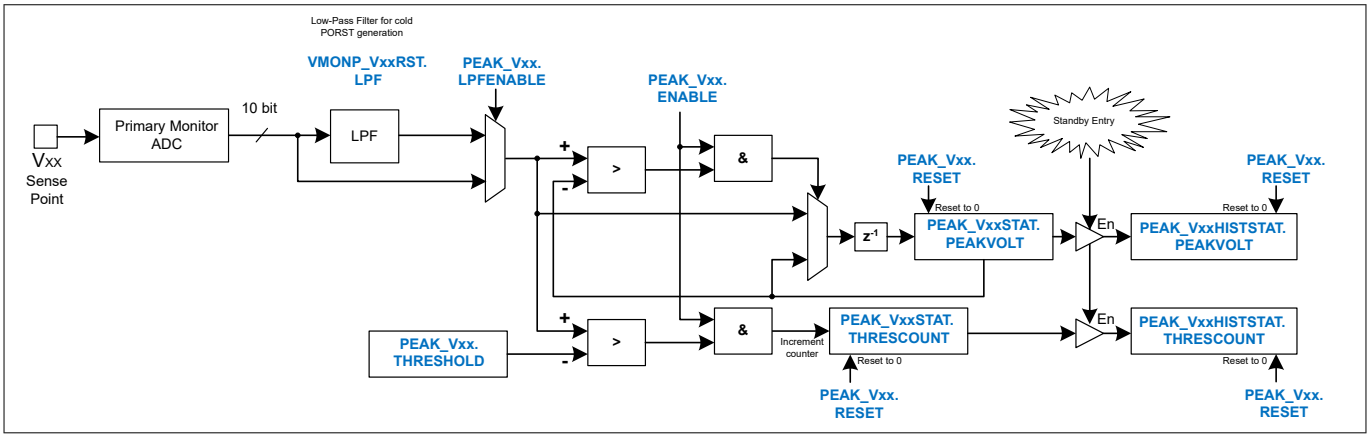

Figure 794 Overview of the peak voltage detection feature

The feature can be enabled by setting the PEAK_Vxx.ENABLE bit, for the respective supply rail (as mentioned before, the feature is supported for the V_{DD}, V_{DDEXT}, and $V_{DDEXTDC}$ supply rails). A low-pass filter can be enabled by setting the PEAK_Vxx.LPFENABLE bit. When this bit is set, the same LPF filter as used by the primary voltage monitors for cold PORST generation (which is configured in the VMONP_VxxRST.LPF bit-field) is applied also to the peak voltage detection.

The maximum absolute voltage value detected by the ADC is updated in the PEAK_VxxSTAT.PEAKVOLT bit-field, whenever a new maximum value has been measured. In addition, a configurable threshold can be defined by the application SW in the PEAK_Vxx.THRESHOLD bit-field. All measured voltage samples larger than this threshold are then counted in the PEAK_VxxSTAT.THRESCOUNT bit-field.

In order to retain the measurement through a standby transition, a set of history status registers are defined in the PMS1 domain, named PEAK_VxxHISTSTAT (their content is kept in STANDBY1 mode, but not in STANDBY0 mode). These registers copy the content of the PEAK_VxxSTAT registers upon a standby entry and are available for reading by SW after the wake-up.

SW can restart the measurement at any time by setting the PEAK_Vxx.RESET bit, which resets the PEAK_VxxSTAT and PEAK_VxxHISTSTAT registers to their respective reset values.

If the peak voltage detection is disabled after running a measurement, by setting PEAK_Vxx.ENABLE=0, the corresponding PEAK_VxxSTAT registers are not updated anymore with new measurements, that is the PEAKVOLT and THRESCOUNT bit-fields keep their current values until the next LVD reset or standby transition (as PEAK_VxxSTAT registers are being reset in standby mode or at an LVDPMS2 reset).

The PEAK_VxxHISTSTAT registers are updated with the content of the respective PEAK_VxxSTAT registers at every standby entry, independent of the PEAK_VxxENABLE setting. The PEAK_VxxHISTSTAT registers are being reset in STANDBY0 mode or at an LVDPMS1 reset.

36.3.5.3 Drift monitoring

The drift monitoring feature targets the detection of a slow drift of the voltage levels caused by for example reliability, aging, or other effects with slow impact over the lifetime of an MCU device. It includes monitoring of the V_{DD}, V_{DDEXT}, $V_{DDEXTDC}$, V_{DDM}, V_{DDPMS0}, and V_{DDPMS2} supply rails.

The measurement is carried out by the primary monitoring (tracking) ADCs for V_{DD}, V_{DDEXT}, and $V_{DDEXTDC}$, respectively by the secondary monitoring (SAR) ADC for V_{DDM}, V_{DDPMS0}, and V_{DDPMS2}.

The evaluation of a potential drift of the voltage level must be done by the application SW. The MCU HW provides only the filtered value of the voltage level for the measured supply rails, accumulated across a driving cycle (that is since the last reset or standby event) using a filter function as described in the following.

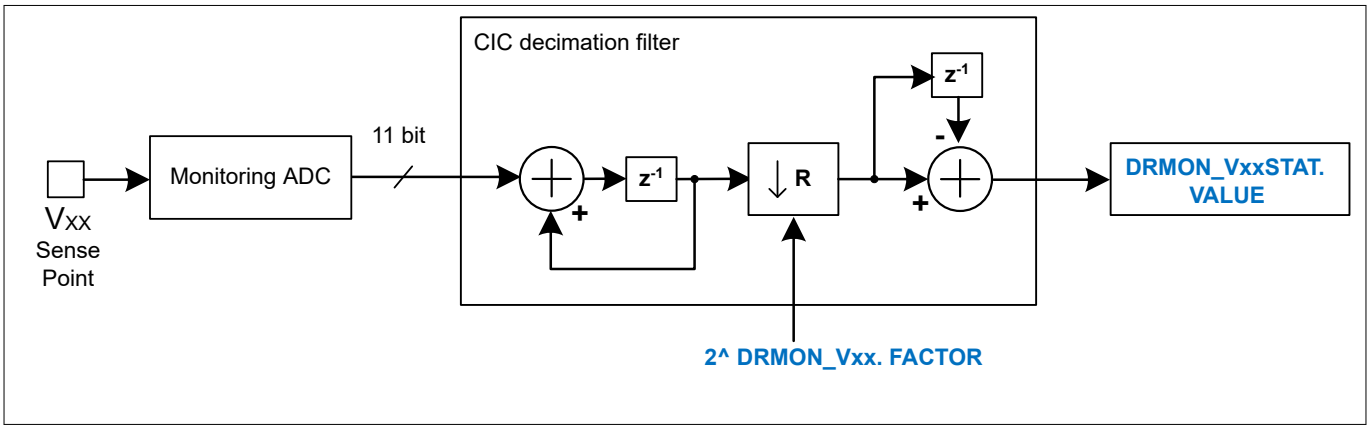

Figure 795 Overview of the hardware feature for drift monitoring

The feature can be enabled by setting the DRMON_Vxx.ENABLE bit, for the respective supply rail.

A single-stage cascaded-integrator-comb (CIC) filter is implemented, as shown in the previous figure. The CIC filter factor R can be configured in the DRMON_Vxx.FACTOR bit-field (R = 2^FACTOR). Following the CIC filter, a median filter is appended, which outputs the filtered value stored in the DRMON_VxxSTAT.VALUE bit-field.

The application SW can read at any time the filtered value of a monitored rail in the respective DRMON_VxxSTAT register, it can decide if it deviates from the nominal value by an unacceptable amount, and can then take appropriate actions.

A re-configuration of the DRMON_Vxx.FACTOR bit-field during a running measurement invalidates and resets the VALUE result in the corresponding DRMON_VxxSTAT register. If the ENABLE bit is kept asserted, the measurement restarts with the new FACTOR setting. To just restart the measurement without changing the FACTOR setting, the SW can re-write the same FACTOR setting in the DRMON_Vxx register. A write access into the DRMON_Vxx.FACTOR bit-field triggers a restart of the measurement cycle.

When the measurement is disabled, by clearing the DRMON_Vxx.ENABLE bit, the corresponding DRMON_VxxSTAT.VALUE bit-field keeps its result until a new measurement is started or until the next reset or standby.

During MONBIST, the drift monitoring results in the DRMON_VxxSTAT.VALUE bit-fields are not being updated.

36.3.5.4 Power built-in self-test (PBIST1/2)

A power built-in self-test (PBIST) at start-up allows the testing of supply levels (for over-voltage and under-voltage conditions), power functions, and voltage monitors before cold PORST reset release. This test is distributed into two phases, one executed before EVRC start-up (PBIST1) and the second one executed afterwards.

The first phase of the test, PBIST1, targets the checks for EVRC operation. In this phase, the V_{DDEXT} and $V_{DDEVRSB}$ voltage rails are tested for over-voltage conditions, and the $V_{DDEXTDC}$, V_{DDPMS0}, V_{DDPMS1}, and V_{DDPMS2} voltage rails are tested for over-voltage and under-voltage conditions. Based on the configuration of the *HWCFG[2:1]* pins, EVRC is started only after the PBIST1 phase is successfully completed.

The PBIST2 phase occurs after EVRC is started (if activated) and after it reaches the Voltage OK state (indicated by the EVRC_STAT0.SDVOK bit). Also, this test is only executed after all voltage rails reach the reset release threshold (including reset hysteresis). The voltage rails tested during PBIST2 and the voltage monitoring ADCs used in the tests are indicated in the following table.

The following table provides an overview of the voltage rails and over-voltage/under-voltage tests executed during PBIST1 and PBIST2, if the respective voltage rails are available on the considered product variant:

Table 1432 PBIST overview

Voltage rail	ADC used	PBIST1		PBIST2	
		Over-voltage test	Under-voltage test	Over-voltage test	Under-voltage test
V_{DDEXT}	VMONP	Yes	Yes	Yes	Yes
$V_{DDEVRSB}$	VMONP	Yes	Yes	Yes	Yes
$V_{DDP3NVM}$	VMONP	Yes	Yes	Yes	Yes
$V_{DDEXTDC}$	VMONP	Yes	Yes	Yes	Yes
V_{DDDCLS}	VMONP	No	No	Yes[1)]	Yes[1)]
$V_{DDEXTDC}$-V_{SSDCHS}	VMONP	No	No	Yes[1)]	Yes[1)]
V_{DD}	VMONP	No	No	Yes	Yes
V_{DDM}	VMONP	No	No	Yes	No
V_{DDPMS0}	VMONS	Yes	Yes	Yes	Yes
V_{DDPMS1}	VMONS	Yes	Yes	Yes	Yes
V_{DDPMS2}	VMONS	Yes	Yes	Yes	Yes

1) Voltage rail tested in PBIST only if *HWCFG[2:1]*=11_B

For all voltage rails documented in the table above, used for PBIST1/2 testing, the reset values of the VMONP_VxxSTAT.OV and VMONP_VxxSTAT.UV status flags (if VMONP ADC is used for PBIST testing), respectively of the the VMONS_VxxSTAT.OV, and VMONS_VxxSTAT.UV status flags (if VMONS ADC is used for PBIST testing) are set to "false positive" before running the PBIST. After the PBIST runs, the flags are cleared if the voltages are within the limits configured in VMONP_VxxCON.OVVAL/UVVAL, respectively VMONS_VxxCON.OVVAL/UVVAL. If PBIST1 or PBIST2 fails, the MCU does not release the cold PORST.

36.3.5.5 Standby SMU integration and monitor BIST (MONBIST)

MONBIST is a built-in self test for the functionality of secondary voltage monitors and for the alarm generation path and can be triggered by user software after reset release. This secondary monitor BIST ensures a high

latent fault coverage for the secondary monitors and for the associated alarm and error pin fault logic, which is routed to the standby SMU.

The MONBIST can be triggered during start-up by setting the MONBISTCTRL.TSTEN register bit in the Standby SMU module. During the ongoing MONBIST, the test of the PMS safety flip-flops (SFF) shall not be triggered. MONBIST tests only the monitors and alarms for which the OVMOD/UVMOD bit-fields have been enabled by the application software prior to triggering the test. MONBIST test can take up to 30 µs execution time. The procedure is as follows:

- User SW configuration steps before MONBIST execution:
  - The user software shall enable the standby SMU through the CMDSTDBY.SMUEN register bit (of the Standby SMU module), to enable MONBIST functionality
  - The (standby SMU) MONBISTCTRL.TSTCLR bit shall be set foremost to clear all the flags and reset the test logic. This clears the MONBISTCTRL.TSTEN bit, as well as the TSTRUN, TSTDONE, TSTOK, SMUERRx, and PMSERR bits in the (standby SMU) MONBISTSTAT register
  - The STANDBY_CON0.VDDEXTSBEN and STANDBY_CON1.VDDSBEN bits shall be set to "disabled", to avoid triggering a standby entry when the MONBIST test simulates the occurrence of an under-voltage condition on the V_{DDEXT} and V_{DD} supply rails
  - The user software must clear all spike filters of the secondary voltage monitors before running MONBIST, by setting all VMONS_VxxCON.FILTER = 0
  - VMONS_VxxCON.OVMOD is set to 01_B and VMONS_VxxCON.UVMOD is set to 10_B to activate under-voltage and over-voltage alarms
  - The corresponding over-voltage and under-voltage interrupts are disabled by clearing the INT_CONx.OVVxx and INT_CONx.UVVxx register bit-fields
  - FSP reactions on alarms are disabled by setting AGSTDBYi_FSPj.FEx to 0 (in the standby SMU)
  - (Standby SMU) CMDSTDBY.FSP0EN, FSP1EN, FSP2EN, and FSP3EN configuration bits are cleared to avoid spurious error pin activation during MONBIST
  - (Standby SMU) CMDSTDBY.ASCE is set to 1 to ensure that all pending alarms are cleared in AGx registers
  - Consequently the MONBIST is enabled through the (standby SMU) MONBISTCTRL.TSTEN register bit
- MONBIST execution in HW:
  - The (standby SMU) MONBISTSTAT.TSTRUN register bit is then set by hardware, to indicate an ongoing test by MONBIST logic
  - Once the test is completed, the hardware sets the MONBISTSTAT.TSTDONE bit and clears the MONBISTSTAT.TSTRUN bit
  - The MONBISTSTAT.TSTOK bit indicates if the test was successfully completed
  - The MONBISTSTAT.SMUERRx (where x = 0,1,2,3) and MONBISTSTAT.PMSERR bits indicate that errors were detected during the MONBIST
- User SW configuration steps after MONBIST execution:
  - The (standby SMU)AGTSTDBY0_STS .FSPxERR (where x = 0,1,2,3) bits shall be cleared by software after MONBIST before enabling FSP reaction. If alarms happened during MONBIST, status registers may be updated and shall be cleared before Standby SMU initialization. MONBISTCTRL.TSTEN bit is cleared at the end of MONBIST
  - After MONBIST execution, the user software must restore the configuration of the spike filters of the secondary voltage monitors (VMONS_VxxCON.FILTER) either to the reset configuration or as required by the application

During MONBIST execution, the drift monitoring results (if enabled) are not being updated.

36.3.6 Interrupts

Interrupts from PMS are triggered only during RUN mode. During STANDBY mode, there are no interrupt triggers but some interrupt events are recognized as wake-up events depending on configuration. Following events may be configured to lead to interrupts routed to the interrupt router (IR) in normal run and sleep system modes. If enabled by the related interrupt enable bit in the registers INT_CONx, an interrupt pulse is generated on one of the service request outputs (SRC_PMS0, SRC_PMS1, SRC_PMS2, SRC_PMS3, SRC_PMS4, SRC_PMS5, SRC_PMS6, or SRC_PMS7). Interrupts are forwarded from PMS to the IR module within 4 f_{SPB} clock cycles (see datasheet parameter) after the occurrence of the event.

Refer to the functional description for the specific product variant for an image showing the interrupt sources and events.

TC4Dx interrupts on page 6152

36.3.7 Standby mode management

The PMS is partitioned into 3 power domains PMS0, PMS1 and PMS2 to ensure scalable standby modes with lowest standby currents.

Standby domains

The PMS0 power domain is the smallest standby domain with bare minimum functionality required to keep standby RAMs supplied and recognize wake-up from pins, supply ramp-up, and timer modules. In STANDBY0 mode only PMS0 power domain is supplied and the remaining part of the microcontroller is completely switched off. The PMS0 domain contains the V_{DDEXT} wake-up detector, Pin Wake-up unit, the Real Time Clock (RTC), the Wake-Up Timer (WUT) and standby RAM regulator to keep dLMU standby RAMs supplied.

The PMS1 domain offers the next scalable standby domain including the 8-bit standby controller (SCR) with the capability of running on the 100 MHz back-up clock or the 70 kHz internal standby clock. In STANDBY1 mode, both PMS0 and PMS1 power domains are supplied and the remaining part of the microcontroller is completely switched off. Both PMS0 and PMS1 standby power domains are supplied from the $V_{DDEVRSB}$ supply rail which also supplies a part of Port domain (P3x.y). V_{DDEXT} supply may continue to be kept supplied in case wake up from pins supplied by V_{DDEXT} rail is required.

The PMS1 domain supports configurable activation or deactivation of 100 MHz back-up clock and switching to 70 kHz standby clock for the 8-bit standby controller to reduce standby currents. Furthermore, if SCR ADCOMP analog channel conversions are not required, the high precision band-gap and ADC may also be completely powered off to reduce standby currents. The activation and deactivation of the clock, band-gap and ADC modules are managed by SCR software. During transition from STANDBY1 to STANDBY0 mode, the SCR XRAM is switched from V_{DDPMS1} supply to $V_{DDSBRAM}$ supply, in case data retention is enabled (through the STANDBY_CON0.SCRRAMSEL bit-field).

36 Power Management System (PMS)

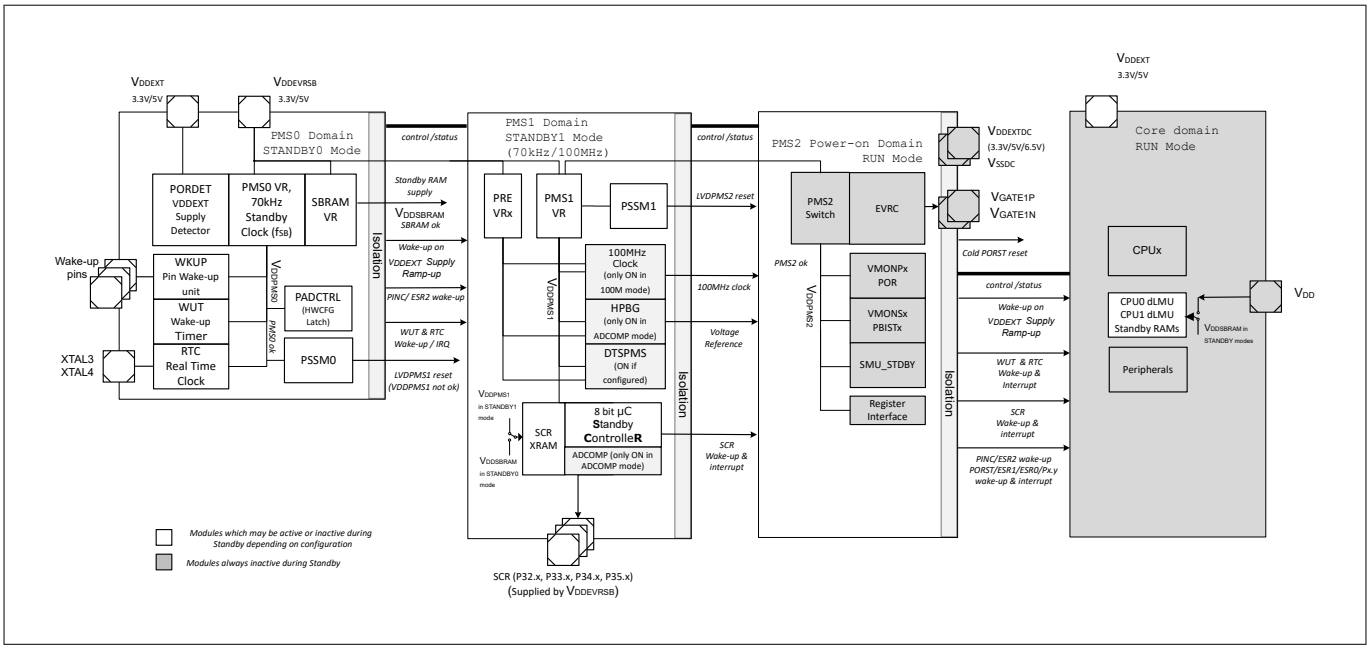

Figure 796 Standby domains

The $V_{DDEVRSB}$ and V_{DDEXT} supply rails may be supplied by a single external supply source or have separate supply sources depending on the application. The $I_{DDEVRSB}$ datasheet parameter is however considering only the current consumption from the $V_{DDEVRSB}$ pins. If single supply source is used (same external regulator for V_{DDEXT} and $V_{DDEVRSB}$), the external regulator would support low quiescent power modes to allow low standby currents at system level. It is also allowed that V_{DDM} and V_{DDFLEX} supply rails are also supplied from the same V_{DDEXT} supply source but at the cost of higher standby currents. As shown in the following figure, only PMS0 and PMS1 domains are kept supplied during standby modes.

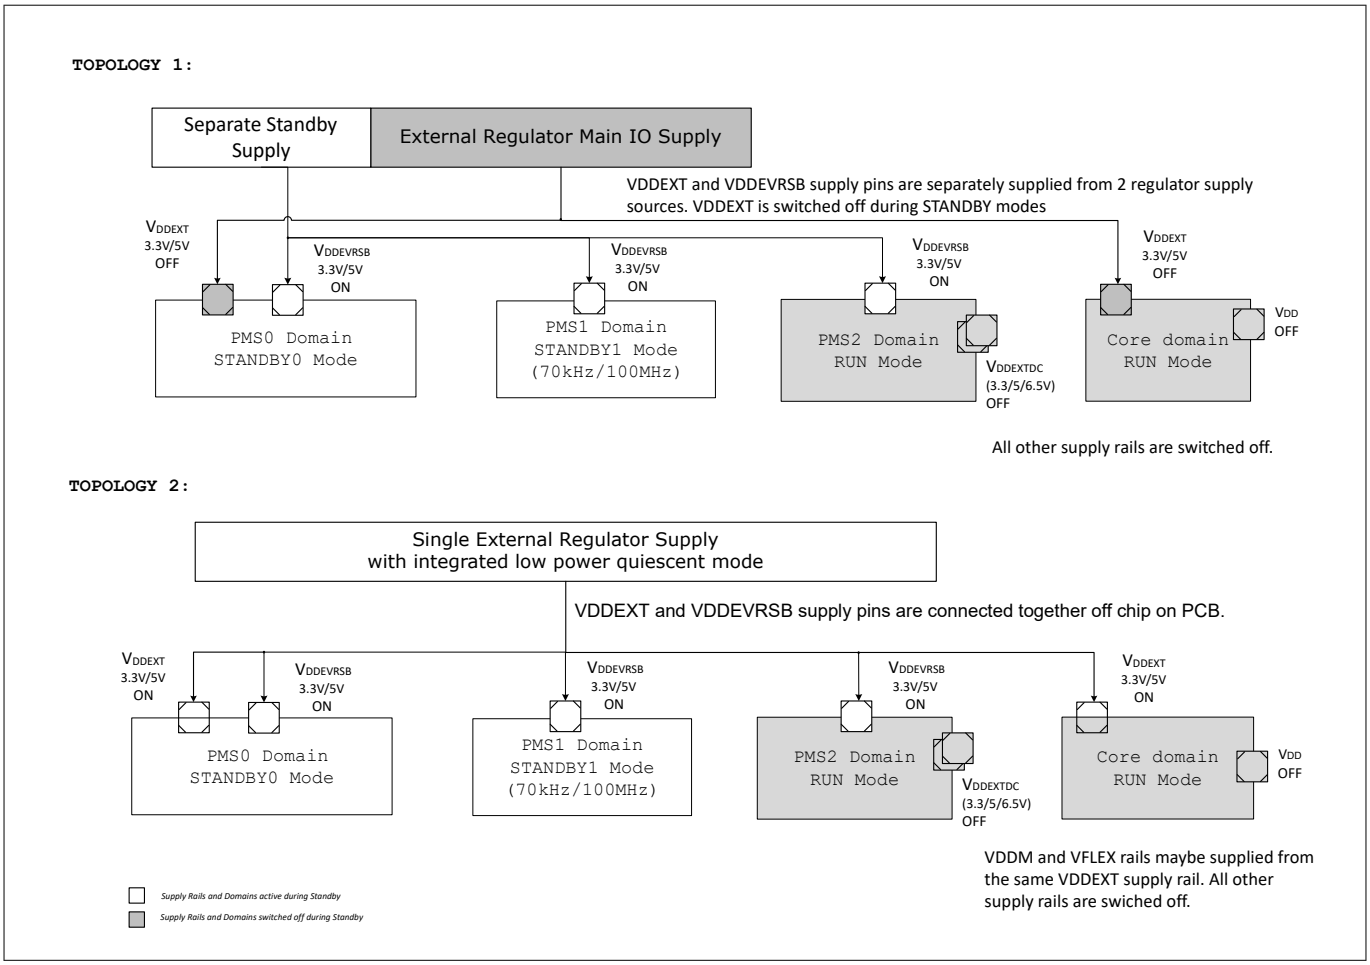

Figure 797 Standby domains and supply topologies

36.3.7.1 Standby modes

Standby modes

Following STANDBY Modes are supported:

- STANDBY0 Mode:

  Only PMS0 domain is supplied. This refers to the Standby state with lowest power consumption running at 70 kHz clock. RTC, WUT, Standby RAM retention, SCR RAM retention and Pin wake-up modules may be active during this state
- STANDBY1 Modes:

  ***Note**: Both PMS0 and PMS1 domains are supplied.*

  1. STANDBY1_70k State: In this state PMS0 and PMS1 domains are both active and running at 70 kHz clock. Standby Controller (SCR) is active during this mode running at 70 kHz clock. Standby Port domain (P32/P33/P34/P35) is additionally active in this state
  2. STANDBY1_100M State: In this state PMS0 and PMS1 domains are both active and PMS1 is running at 100 MHz clock. Standby Controller (SCR) is active during this mode running at up to 100 MHz clock. Standby Port domain (P32/P33/P34/P35) is active in this state. The high precision band-gap and SCR ADCOMP modules are switched off during this state
  3. STANDBY1_ADCOMP State: In this state PMS0 and PMS1 domains are both active and PMS1 is running up to 100 MHz clock. Standby Controller (SCR) is active during this mode running at up to 100 MHz clock. Standby Port domain (P32/P33/P34/P35) is active in this state. In addition the high

precision band-gap and SCR ADCOMP module are active during this state and ADC conversions can be additionally carried out

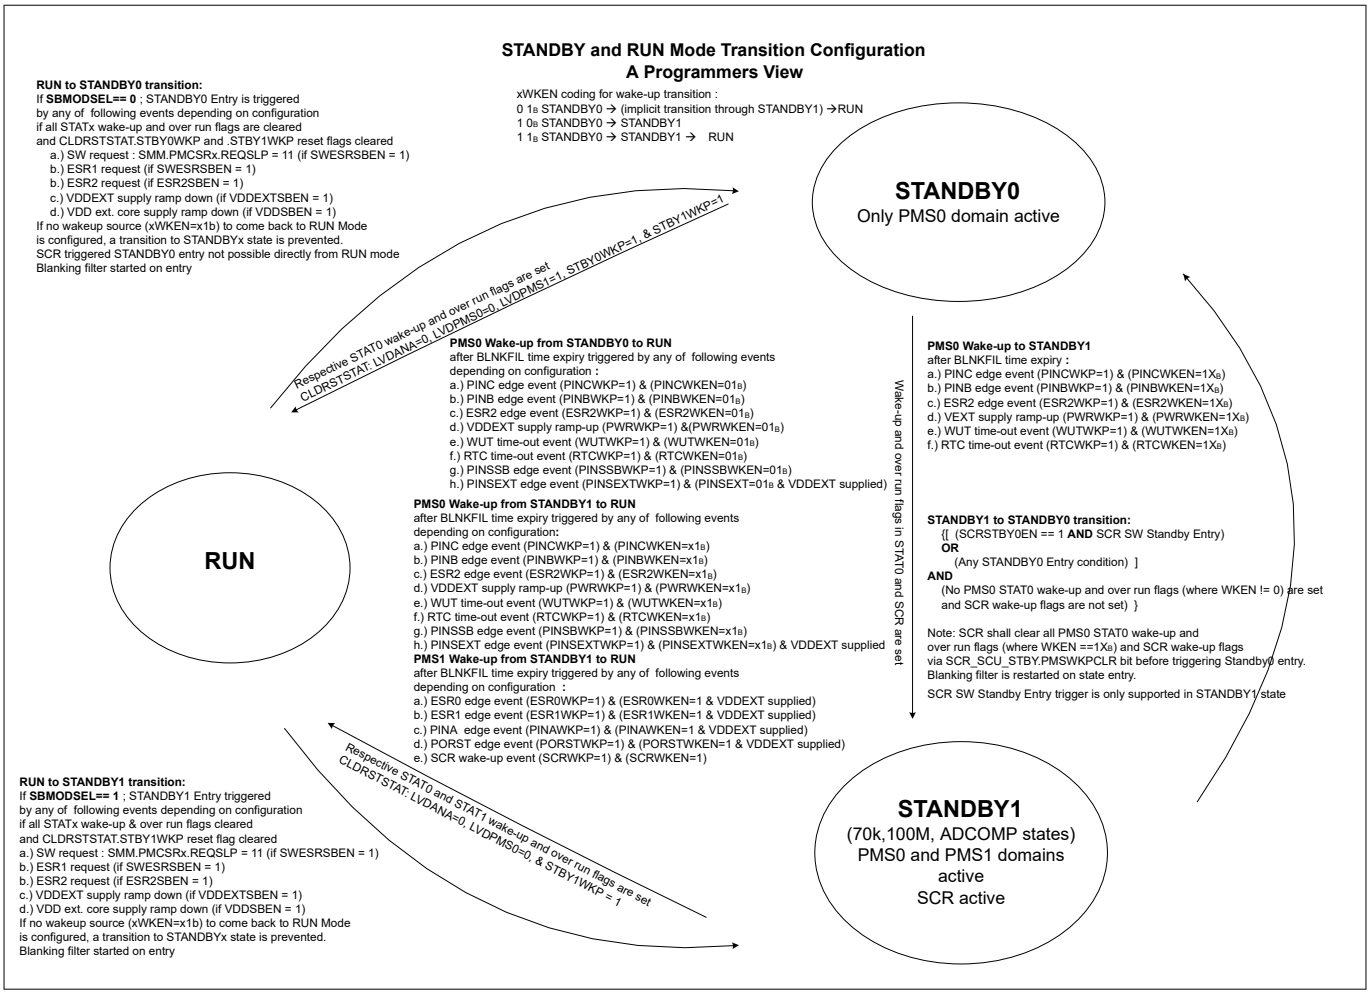

Figure 798 Standby mode configuration and transitions

STANDBY Mode transitions and conditions for transitions are depicted in the figure above.

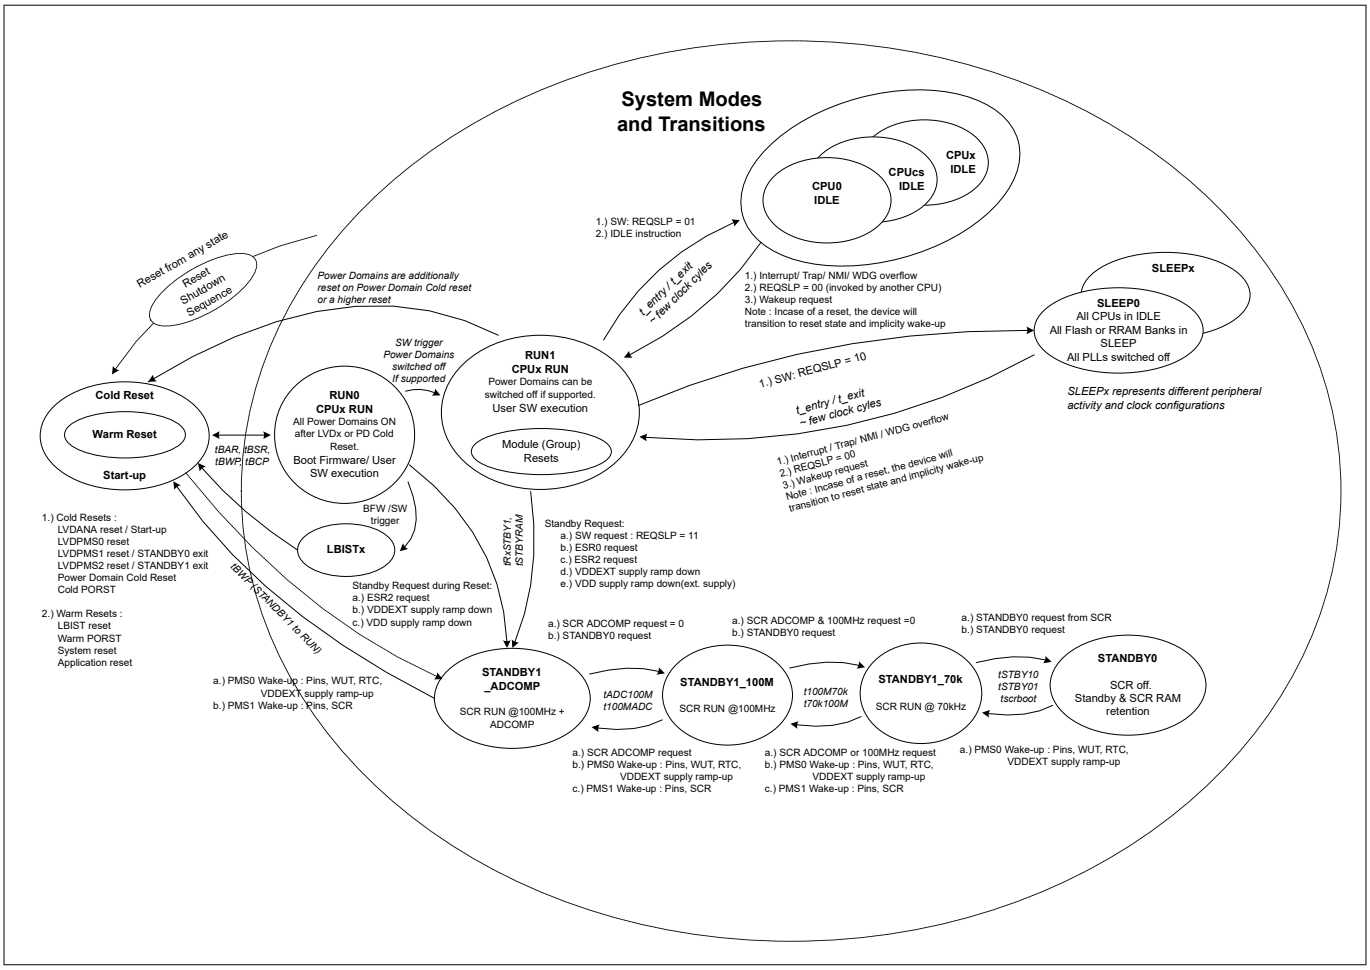

Figure 799 System states and transitions

The above figure depicts the STANDBY mode transitions in context of the System modes. STANDBY modes are entered from RUN1 state on a STANDBY request. Transition within STANDBY states take place sequentially from STANDBY1_ADCOMP to STANDBY1_100M to STANDBY1_70k to finally STANDBY0 state depending on transition conditions.

Table 1433 Standby entry and WUT and RTC wake-up use cases

Mode transition	Wake-up event WUT	Wake-up event RTC
STANDBY0 ← → RUN	WUT in Auto Stop or Auto reload mode. WAKEUP_CON0.WUTWKEN = 1 STANDBY0 entry triggered by V_{DDEXT} or V_{DD} supply ramp-down or software request, or *ESR1* pin rising / falling edge event or *ESR2* falling edge event. On wake-up, *ESR2* pin can be asserted to ramp V_{DDEXT} or V_{DD} external supply if not available. Wake-up flag cleared by CPU via WKPCLR0 register before renewed standby entry.	RTC running on 70 kHz Standby clock or 32 kHz external crystal. WAKEUP_CON0.RTCWKEN = 1 STANDBY0 entry triggered by V_{DDEXT} or V_{DD} supply ramp-down or software request, or *ESR1* pin rising / falling edge event or *ESR2* falling edge event. On wake-up, *ESR2* pin can be asserted to ramp V_{DDEXT} or V_{DD} external supply if not available. Wake-up flag cleared by CPU via WKPCLR0 register before renewed standby entry.

(table continues...)

Table 1433 (continued) Standby entry and WUT and RTC wake-up use cases

Mode transition	Wake-up event WUT	Wake-up event RTC
STANDBY0 ← → STANDBY1	WUT in Auto Stop or Auto reload mode. WAKEUP_CON0.WUTWKEN = 2 STANDBY0 entry triggered by SCR. Wake-up flag cleared by SCR via WKPCLR register before renewed standby entry.	RTC Calibration maybe done depending on temperature measurement in SCR. WAKEUP_CON0.RTCWKEN = 2 STANDBY0 entry triggered by SCR. Wake-up flag cleared by SCR via WKPCLR register before renewed standby entry.
STANDBY1 ← → RUN	WUT in Auto Stop or Auto reload mode. Only transition between RUN and STANDBY1 mode allowed. WAKEUP_CON0.WUTWKEN = 1 STANDBY1 entry triggered by V_{DDEXT} or V_{DD} supply ramp-down or software request, or *ESR1* pin rising / falling edge event or *ESR2* falling edge event. On wake-up, *ESR2* pin can be asserted to ramp V_{DDEXT} or V_{DD} external supply if not available. Wake-up flag cleared by CPU via WKPCLR0 register before renewed standby entry.	Only transition between RUN and STANDBY1 mode allowed. WAKEUP_CON0.RTCWKEN = 1 STANDBY1 entry triggered by V_{DDEXT} or V_{DD} supply ramp-down or software request, or *ESR1* pin rising / falling edge event or *ESR2* falling edge event. On wake-up, *ESR2* pin can be asserted to ramp V_{DDEXT} or V_{DD} external supply if not available. Wake-up flag cleared by CPU via WKPCLR0 register before renewed standby entry.
Sequential wake-up from STANDBY0 ← → STANDBY1 ← → RUN	WUT in Auto reload mode. WAKEUP_CON0.WUTWKEN = 3 STANDBY0 entry triggered by V_{DDEXT} or V_{DD} supply ramp-down or software request, or *ESR1* pin rising / falling edge event or *ESR2* falling edge event. On wake-up, *ESR2* pin can be asserted to ramp V_{DDEXT} or V_{DD} external supply if not available on a STANDBY1 to RUN transition. Wake-up flag cleared by CPU via WKPCLR0 register before renewed standby entry. No need for interim wake-up clear in STANDBY1 mode. Wake-up flag triggers the first wake-up to STANDBY1 and over-run flag triggers the second wake-up to RUN.	WAKEUP_CON0.RTCWKEN = 3 STANDBY0 entry triggered by V_{DDEXT} or V_{DD} supply ramp-down or software request, or *ESR1* pin rising / falling edge event or *ESR2* falling edge event. On wake-up, *ESR2* pin can be asserted to ramp V_{DDEXT} or V_{DD} external supply if not available on a STANDBY1 to RUN transition. Wake-up flag cleared by CPU via WKPCLR0 register before renewed standby entry. No need for interim wake-up clear in STANDBY1 mode. Wake-up flag triggers the first wake-up to STANDBY1 and over-run flag triggers the second wake-up to RUN.

Table 1434 Standby entry and SCR and supply wake-up use cases

Mode transition	Wake-up event V_{DDEXT} supply ramp-up	Wake-up event SCR
STANDBY0 ← → RUN	STANDBY0 entry event - V_{DDEXT} or V_{DD} supply ramp-down. WAKEUP_CON0.PWRWKEN = 1 Wake-up flag cleared by CPU via WKPCLR0 register before renewed standby entry.	Not supported
STANDBY0 ← → STANDBY1	STANDBY0 entry event - V_{DDEXT} or V_{DD} supply ramp-down. WAKEUP_CON0.PWRWKEN = 2 Wake-up flag cleared by SCR via WKPCLR register before renewed standby entry.	Not supported
STANDBY1 ← → RUN	Only transition between RUN and STANDBY1 mode allowed. STANDBY1 entry event - V_{DDEXT} or V_{DD} supply ramp-down. WAKEUP_CON0.PWRWKEN = 1 Wake-up flag cleared by CPU via WKPCLR0 register before renewed standby entry.	SCR is active. Only transition between RUN and STANDBY1 mode allowed. WAKEUP_CON0.SCRWKEN = 1 STANDBY1 entry triggered by V_{DDEXT} or V_{DD} supply ramp-down or software request, or *ESR1* pin rising / falling edge event or *ESR2* falling edge event. On wake-up, *ESR2* pin can be asserted to ramp V_{DDEXT} or V_{DD} external Supply if not available. Wake-up flag cleared by CPU via WKPCLR0 register before renewed standby entry.
Sequential wake-up from STANDBY0 ← → STANDBY1 ← → RUN	Not supported	Not supported

Table 1435 Standby entry and pin wake-up use cases

Mode transition	Wake-up event *PINC*/*ESR2*/*PINB*	Wake-up event *PINSSB*/*PINSEXT*	Wake-up event *PINA*/*ESR0*/*ESR1*/*PORST*
STANDBY0 ← → RUN	WAKEUP_CON0. PINC/PINB/ ESR2WKEN = 1. EDCON and DFEN configures the pin edge and filter. STANDBY0 entry triggered by V_{DDEXT} or V_{DD} supply ramp-down or software request, or *ESR1* pin rising / falling edge event or *ESR2* falling edge event. On a pin edge event , wake-up is triggered. On wake-up, *ESR2* pin can be asserted to ramp V_{DDEXT} or V_{DD} external supply if not available. Wake-up flag cleared by CPU via WKPCLR0 register before renewed standby entry.	WAKEUP_CON0. PINSSBWKEN/ PINSEXTWKEN = 1. Wake-up pin configuration in PORT registers. STANDBY0 entry triggered by V_{DDEXT} or V_{DD} supply ramp-down or software request, or *ESR1* pin rising / falling edge event or *ESR2* falling edge event. On a pin edge event , wake-up is triggered. On wake-up, *ESR2* pin can be asserted to ramp V_{DDEXT} or V_{DD} external supply if not available. Wake-up source can be read out from PORT registers as to which pin caused the wake-up. Wake-up flag cleared by CPU via WKPCLR0 register before renewed standby entry.	Not supported
STANDBY0 ← → STANDBY1	WAKEUP_CON0. PINC/ PINB / ESR2WKEN = 2. EDCON and DFEN configures the pin edge and filter. STANDBY0 entry triggered by SCR. Wake-up flag cleared by SCR via WKPCLR register before renewed Standby entry.	Not supported	Not supported

On wake-up, *ESR2* pin can be asserted to ramp V_{DDEXT} or V_{DD} external supply if not available. Wake-up flag cleared by CPU via WKPCLR0 register before renewed standby entry.	Only transition between RUN and STANDBY1 mode allowed. WAKEUP_CON0. PINSSBWKEN/ PINSEXTWKEN= 1. Wake-up pin configuration in PORT registers. STANDBY1 entry triggered by V_{DDEXT} or V_{DD} supply ramp-down or software request, or *ESR1* pin rising / falling edge event or *ESR2* falling edge event. On wake-up, *ESR2* pin can be asserted to ramp V_{DDEXT} or V_{DD} external Supply if not available. Wake-up source can be read out from PORT registers as to which pin caused the wake-up. Wake-up flag cleared by CPU via WKPCLR0 register before renewed Standby entry.	Only transition between RUN and STANDBY1 mode allowed. WAKEUP_CON0. PINA/ESR0/ ESR1/ PORSTWKEN = 1. EDCON and DFEN configures the pin edge and filter except for PORST pin. STANDBY1 entry triggered by V_{DDEXT} or V_{DD} supply ramp-down or software request, or *ESR1* pin rising / falling edge event or *ESR2* falling edge event. On wake-up, *ESR2* pin can be asserted to ramp V_{DDEXT} or V_{DD} external supply if not available. Wake-up flag cleared by CPU via WKPCLR0 register before renewed standby entry.
Sequential wake-up from STANDBY0 ← → STANDBY1 ← → RUN	WAKEUP_CON0. PINC/ PINB/ ESR2WKEN = 3 STANDBY0 entry triggered by V_{DDEXT} or V_{DD} supply ramp-down or software request, or *ESR1* pin rising / falling edge event or *ESR2* falling edge event. On wake-up, *ESR2* pin can be asserted to ramp V_{DDEXT} or V_{DD} external supply if not available on a STANDBY1 to RUN transition. Wake-up flag cleared by CPU via WKPCLR0 register before renewed standby entry. No need for interim wake-up clear in STANDBY1 mode. Wake-up flag triggers the first wake-up to STANDBY1 and over-run flag triggers the second wake-up to RUN.	Not supported	Not supported

There is a power saving option available for STANDBY1_100M mode, for intermediate performance use cases, in which the standby controller (SCR) runs with maximum 20 MHz frequency. This option can be configured by the

SCR, in the SCR register SCU_PMS1IVRCON. The feature allows the configuration of the embedded V_{DDPMS1} voltage regulator into a medium power mode, with 2 current sinks disabled (that is, SCU_PMS1IVRCON.SINKCTRLEN = 1_B and SCU_PMS1IVRCON.SINKCTRL = 01_B), resulting into a reduction of the $V_{DDEVRSB}$ current consumption in STANDBY1 mode, for use cases in which the load jumps in the PMS1 domain are reduced. Refer to the SCR chapter for more details. The default configuration is with all current sinks enabled (SINKCTRLEN = 0_B, full SCR performance allowed). In case SINKCTRLEN = 1_B, the state transition times $t_{100MADC}$, $t_{ADC100M}$, and $t_{100M70k}$ (datasheet parameters) are increased.

36.3.7.2 Standby entry

Standby mode entry section documents the trigger events to enter standby state and the sequence to be followed from the system side for a mode transition.

36.3.7.2.1 Standby entry trigger events

STANDBY Entry is triggered by any of the following events to enter STANDBY0 or STANDBY1 mode from RUN mode depending on SBMODSEL bit.

1. Standby entry on V_{DDEXT} supply ramp-down is triggered by the V_{DDEXT} secondary under-voltage event. As an additional robustness measure to retain Standby RAM content during fast supply ramp-down, Standby entry is triggered latest when the primary under-voltage event happens. In this case, cold PORST is not triggered, instead the device enters Standby mode when VDDEXTSBEN enable bit is set
2. Standby entry on V_{DD} supply ramp-down is triggered by the V_{DD} secondary under-voltage event. As an additional robustness measure to retain Standby RAM content during fast supply ramp-down, Standby entry is triggered latest when the primary under-voltage event happens. In this case, cold PORST is not triggered, instead the device enters Standby mode when VDDSBEN enable bit is set. Standby entry on VDD ramp-down is always possible, independent of whether VDDEXT and VDDEVRSB is supplied by separate or common supply rail
3. Standby entry on Software request (write to register bit-field PMCSRx.REQSLP = 11B). The software request is handled in SMM module and need to be additionally configured in SMM.PMSWCR1.STBYEV = 0 and STANDBY_CON1.SWESRSBEN = 1 register bit-fields. Standby mode through software may be entered based on a singular decision from a master CPU based on the configuration in the CPUSEL register. It may also be entered as an unanimous decision of all the CPUs when ALL of the PMCSRx registers in the system request it and CPUSEL = 111B
4. Standby entry on *ESR1* pin rising or falling edge event. The selection of rising and falling edge and the filter is configured in SMM ESRCFG1.EDCON and DFEN register bit-fields. The ESR 1 request is handled in SMM module and need to be additionally configured through SMM.PMSWCR1.STBYEV = 1 STANDBY_CON1.SWESRSBEN = 1 register bit-fields
5. Standby entry on *ESR2* pin falling edge event, if configured in STANDBY_CON0.ESR2SBEN = 1 register bit-field. A digital filter can be selected in the STANDBY_CON0.ESR2DFEN register bit-field

SCR can trigger STANDBY1 to STANDBY0 entry on a SCR software request if SCRSTBY0EN bit is set.

To ensure the standby entry triggered by the secondary under-voltage event, for a supply ramp-down slope of maximum 10 V/ms, it is recommended to configure the VMONS under-voltage threshold higher than the $V_{xxPRIUV}$ level by at least 2% of the nominal voltage level on the respective rail.

36.3.7.2.2 Configuration for standby entry sequence on V_{DDEXT} ramp-down and wake-up on V_{DDEXT} ramp-up

It is recommended to ramp-down modules before entering Standby mode to avoid large load jumps during Standby entry. The required steps are detailed here.

1. Disabling Processing Units and Peripherals sequentially:
   - All peripherals and interrupts associated with CPUs except master CPU are switched off and all pending interrupt flags shall be cleared. This is to avoid wake-up of the CPUs once they are put into IDLE state
   - All CPUs except the master CPU are sequentially put into IDLE state. PPU is also set into IDLE state if available
   - All watchdogs may be disabled or reconfigured for slower modes
   - Peripheral module clocks are switched off in the respective CLC.DISR registers
   - Standby SMU module shall be disabled before going into Standby mode. The SMM PMSWCR1.IRADIS bit set to disable Idle Request Acknowledge sequence activation for fast Standby Mode entry
2. Ramping Down System Clock:
   - System Clock is ramped down using the Ramp Oscillator/FLL and switched to internal 100 MHz clock source
   - System PLL and Peripheral PLL are switched off
   - Clock dividers are programmed to lower values
   - Master CPU frequency reduction in steps or using the ramp oscillator compliant to load jump constraints
3. Switching from Flash to RAM Execution:
   - Master CPU code execution switched from Flash to Program RAM
   - Flash modules may be deactivated
4. Standby RAM Configuration:
   - Standby RAM blocks which need to be kept supplied during STANDBY modes are selected through STANDBY_CON0.SBRAMSEL and STANDBY_CON0.SCRRAMSEL bits. D-Cache write back to be executed before Standby entry
5. Pad State during Standby:
   - Configure pad state through PAD_CON.ALLTRIST bit for V_{DDEXT} supplied pins and PAD_CON.SBTRIST bit for $V_{DDEVRSB}$ supplied pins. All pads may be set into tristate or have pull-up device active
   - Configure PAD_CON.ESR0PD bit to set *ESR0* behavior as reset output active or tristate during Standby
   - In case of *HWCFG [2:1,6]* pins it is recommended to tie them to external pull devices
6. SCR Configuration during Standby:
   - SCR may be kept running before entering the Standby state. In standby mode the shared ports supplied by $V_{DDEVRSB}$ are configured to be in tristate or pulled up or left to the control of SCR . Note that if the port control is granted to SCR by setting PCRSEL.PCSRx bit to 1_B but the port is disabled by SCR by setting SCR_Pn_PDISC.PDISm bit to 1_B then the behavior of the port depends upon the PAD_CON.SBTRIST bit
   - The enabling of wake-up from SCR through WAKEUP_CON1.SCRWKEN shall be programmed if wake-up source is SCR
   - Take care that SCR is not reset on a standby entry by clearing SCR_CON0.PORSTREQ bit-field. Select the 70 kHz Standby clock source (fSB) through SCR_CON0.SCRCLKSEL bit if required
7. Clearing Wake-up flags:
   - All xWKP/xOVRUN flags activated by the respective xWKEN bits shall be cleared before a renewed Standby entry request, otherwise the System will remain in RUN state and not enter STANDBY state

8. Selection of either entry to STANDBY0 or STANDBY1 state when entering Standby from RUN mode through STANDBY_CON1.SBMODSEL bit
   - Transitions from STANDBY1 to STANDBY0 state can be enabled by configuring the STANDBY_CON0.SCRSTBY0EN register bit. It shall be ensured that the primary under-voltage reset monitors are active before Standby entry is triggered and shall not be disabled
9. Configure Blanking filter:
   - Blanking filter blocks immediate wake-up of the device for a configurable duration during and immediately after standby entry trigger
   - A minimum blanking filter shall be configured to suppress wake-up during transition to standby through WAKEUP_CON0.BLNKFIL bits. The wake-up events happening during the blanking filter active phase would be lost
   - The wake-up event is recognized and triggered only in the STANDBY state after blanking filter expiry and not during transition states. If the same event trigger (for example ESR2) is used for standby entry and for wake-up, then it has to be ensured that the blanking filter is activated
10. Wake-up Trigger Configurations:
   - Enable wake-up on V_{DDEXT} supply ramp-up using the WAKEUP_CON0.PWRWKEN bit
   - Ensure that both PWRWKEN and STANDBY_CON0.VDDEXTSBEN register bits are both set before entering Standby mode
11. Standby Entry configuration on V_{DDEXT} supply ramp-down:
   - Configure Standby entry event in VDDEXTSBEN and VDDSBEN register bits respectively. In case standby entry is triggered by V_{DDEXT} supply ramp-down, the threshold is configured in VMONS_VDDEXTCON.UVVAL and transition condition in VMONS_VDDEXTCON.UVMOD register bit-fields respectively
   - In case of nominal V_{DDEXT} supply voltage of 5 V, it is recommended to configure the UVVAL register bit-field at 4 V for standby entry to have adequate distance to primary reset levels as well as operational region limits
   - In case of nominal V_{DDEXT} supply voltage of 3.3 V, it is recommended to configure the UVVAL register bit-field at 3.1 V for standby entry above primary reset levels. Nevertheless since there is only a minimal margin to reset levels in this case, Standby entry is additionally triggered by the crossing of primary under-voltage limits if the VDDEXTSBEN register bit is set to ensure Standby entry in case of fast V_{DDEXT} slopes
   - In states where VMONP or VMONS monitors are not available, the standby entry is triggered by LVD detector on V_{DDEXT} supply ramp-down
   - During V_{DDEXT} supply ramp-down, depending on external regulator and V_{DD} buffer capacitors, it may happen that consequently V_{DD} ramps down faster before the V_{DDEXT} standby entry threshold is reached. In this case once V_{DD} supply drops below primary under-voltage threshold, cold PORST state is entered and maintained until the V_{DDEXT} supply ramps down to the standby entry threshold. Additionally in case of external V_{DD} supply, to avoid a power fail event before going into standby mode, standby entry may also be triggered on a threshold additionally based on V_{DD} supply level by setting STANDBY_CON1.VDDSBEN bit to 1_B . If V_{DD} is generated using the EVRC DCDC regulator, standby entry using V_{DD} ramp-down is not supported
   - If Standby entry is triggered by V_{DD} supply ramp-down, the threshold is configured in VMONS_VDDCON.UVVAL and the transition condition in the VMONS_VDDCON.UVMOD register respectively
   - Standby entry filter based on multiple secondary monitor events can be configured in the VMONS_VxxCON.FILTER register bit-field. The VDDEXTSBEN register bit shall be set to ensure that

when V_{DDEXT} supply is removed during Standby state, no LVD reset is generated consequently exiting from Standby mode

- When entering standby with external MOSFET complementary switch in case of EVRC regulator, it should be taken care that when V_{DDEXT} supply is ramped down that also the supply to the MOSFETs is ramped down along with the V_{DDEXT} supply. Otherwise it may happen that the $V_{DDEXTDC}$ supply is still held high through the diode path through the *VGATE1P/VGATE1N* pins to the $V_{DDEXTDC}$ supply rail. If $V_{DDEXTDC}$ and V_{DDEXT} are connected together, this would lead to immediate wake-up after blanking time has expired as $V_{DDEXTDC}$ supply is above the wake-up voltage threshold between 2,6 - 2,97 V. Adequate blanking filter time shall be configured before entering standby to ensure that $V_{DDEXTDC}$ has ramped down completely within this time to avoid immediate wake-up

12. External Standby trigger and Standby transition:

- The external regulator is communicated to switch off V_{DDEXT} supply. A controlled ramp-down of V_{DDEXT} slope during Standby entry is recommended from the external regulator. For example - 0.5 V/ms to 1.5 V/ms
- Ensure that the V_{DDEXT} supply is ramped below the V_{DDEXT} LVD reset level after standby entry before the blanking filter time has expired. This is to avoid an immediate wake-up triggered by the residual V_{DDEXT} voltage if it is above V_{DDEXT} LVD reset level after blanking time has expired
- Ensure that the V_{DD} supply rail is consequently switched off after V_{DDEXT} ramp-down to reduce standby current within the blanking filter time
- Once a Standby entry event is recognized, the primary under-voltage reset generation is disabled and Standby RAM supply is switched from V_{DD} to $V_{DDSBRAM}$ within a few clock cycles. On entry into Standby mode, the blanking filter is activated. The external standby regulator continues to supply the Standby domain through $V_{DDEVRSB}$ supply pin. The blanking filter is always activated on Standby entry

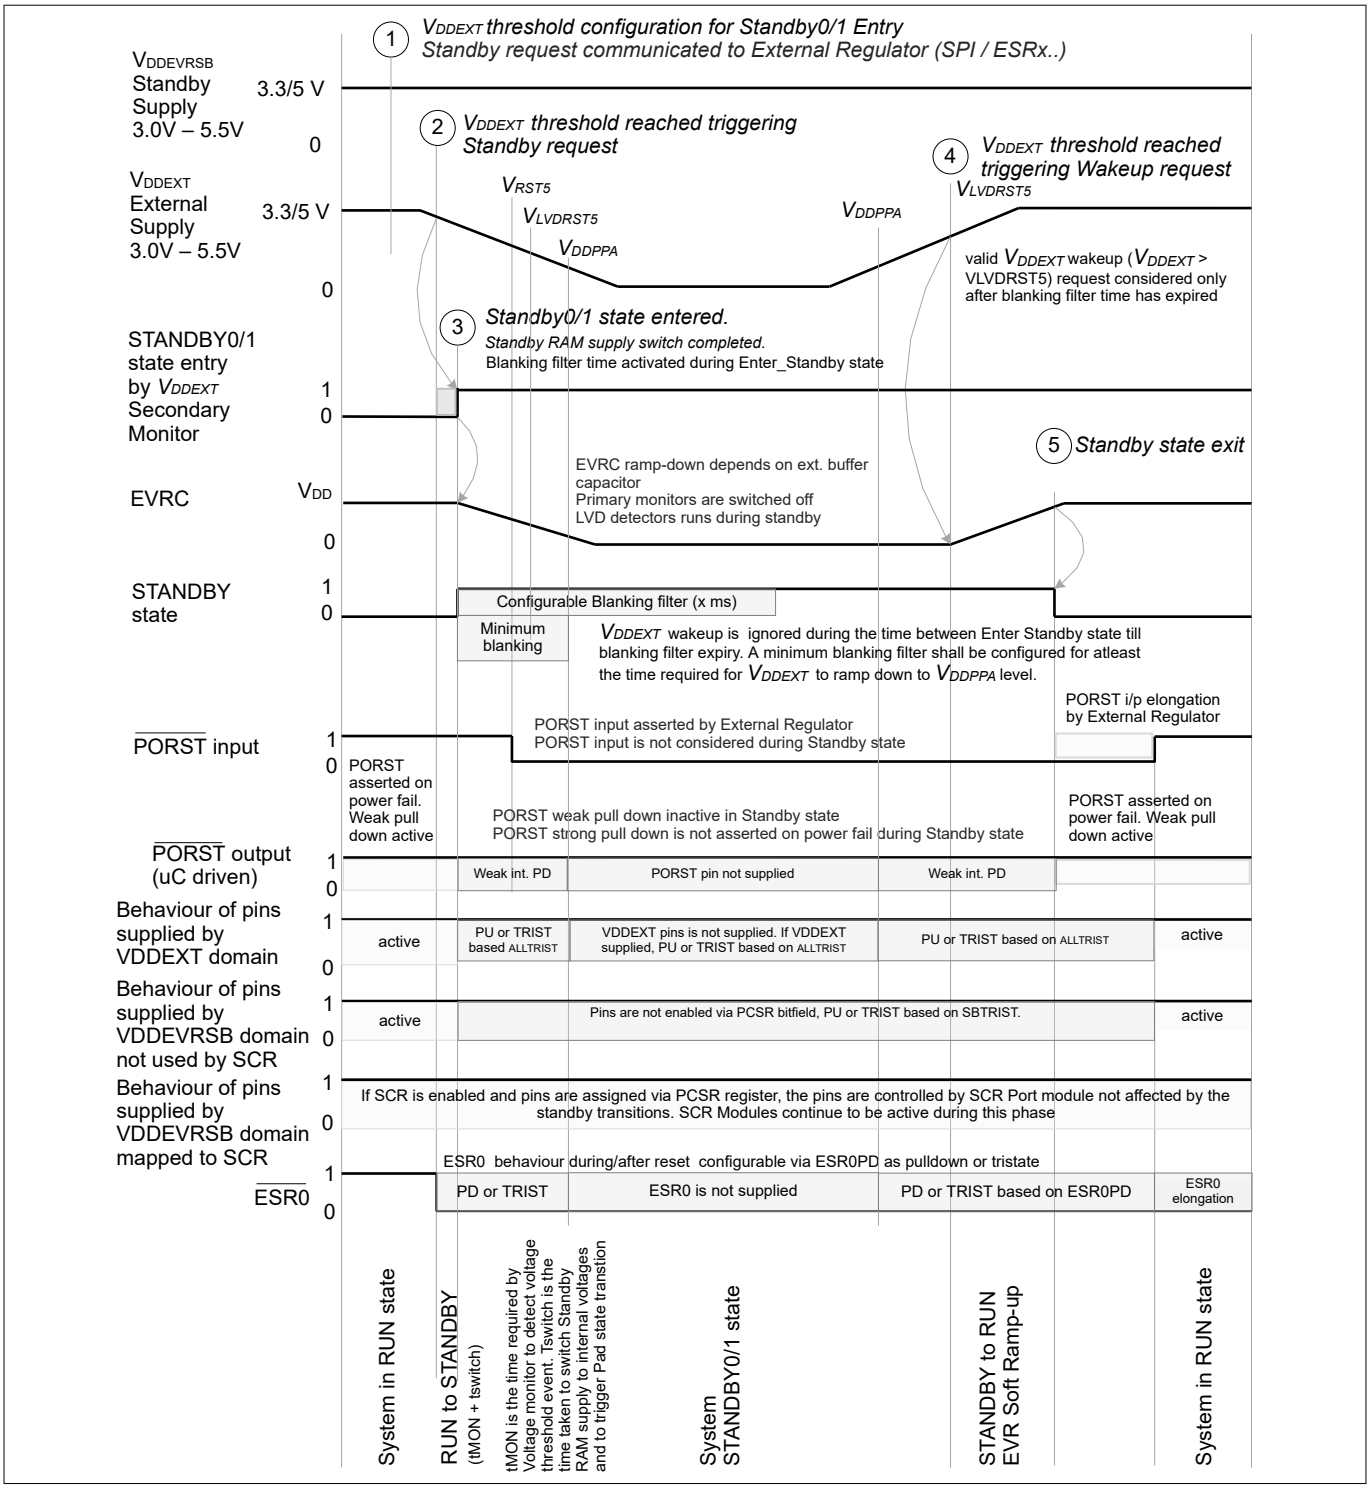

Figure 800 Standby entry on V_{DDEXT} ramp-down and wake-up on V_{DDEXT} ramp-up

36.3.7.2.3 Configuration for standby entry sequence upon SW or ESRx trigger

1. Disabling Processing Units and Peripherals sequentially:

- All peripherals and interrupts associated with CPUs except master CPU are switched off and all pending interrupt flags shall be cleared. This is to avoid wake-up of the CPUs once they are put into IDLE state

- All CPUs except the master CPU are sequentially put into IDLE state. PPU is also set into IDLE state if available
- All watchdogs may be disabled or reconfigured for slower modes
- Peripheral module clocks are switched off in the respective CLC.DISR registers
- Standby SMU module shall be disabled before going into Standby mode. The SMM PMSWCR1.IRADIS bit set to disable Idle Request Acknowledge sequence activation for fast Standby Mode entry

2. Ramping Down System Clock:

- System Clock is ramped down using the Ramp Oscillator/FLL and switched to internal 100 MHz clock source
- System PLL and Peripheral PLL are switched off
- Clock dividers are programmed to lower values
- Master CPU frequency reduction in steps or using the ramp oscillator compliant to load jump constraints

3. Switching from Flash to RAM Execution:

- Master CPU code execution switched from Flash to Program RAM
- Flash modules may be deactivated

4. Standby RAM Configuration:

- Standby RAM blocks which need to be kept supplied during STANDBY modes are selected through STANDBY_CON0.SBRAMSEL and STANDBY_CON0.SCRRAMSEL bits. D-Cache write back to be executed before Standby entry

5. Pad State during Standby:

- Configure pad state through PAD_CON.ALLTRIST bit for V_{DDEXT} supplied pins and PAD_CON.SBTRIST bit for $V_{DDEVRSB}$ supplied pins. All pads may be set into tristate or have pull-up device active
- Configure PAD_CON.ESR0PD bit to set *ESR0* behavior as reset output active or tristate during Standby
- In case of *HWCFG [2:1,6]* pins it is recommended to tie them to external pull devices

6. SCR Configuration during Standby:

- SCR may be kept running before entering the Standby state. In standby mode the shared ports supplied by $V_{DDEVRSB}$ are configured to be in tristate or pulled up or left to the control of SCR . Note that if the port control is granted to SCR by setting PCRSEL.PCSRx bit to 1_B but the port is disabled by SCR by setting SCR_Pn_PDISC.PDISm bit to 1_B then the behavior of the port depends upon the PAD_CON.SBTRIST bit
- The enabling of wake-up from SCR through WAKEUP_CON1.SCRWKEN shall be programmed if wake-up source is SCR
- Take care that SCR is not reset on a standby entry by clearing SCR_CON0.PORSTREQ bit-field. Select the 70 kHz Standby clock source (fSB) through SCR_CON0.SCRCLKSEL bit if required

7. Clearing Wake-up flags:

- All xWKP/xOVRUN flags activated by the respective xWKEN bits shall be cleared before a renewed Standby entry request, otherwise the System will remain in RUN state and not enter STANDBY state

8. Selection of either entry to STANDBY0 or STANDBY1 state when entering Standby from RUN mode through STANDBY_CON1.SBMODSEL bit

- Transitions from STANDBY1 to STANDBY0 state can be enabled by configuring the STANDBY_CON0.SCRSTBY0EN register bit. It shall be ensured that the primary under-voltage reset monitors are active before Standby entry is triggered and shall not be disabled

9. Configure Blanking filter:

- Blanking filter blocks immediate wake-up of the device for a configurable duration during and immediately after standby entry trigger

- A minimum blanking filter shall be configured to suppress wake-up during transition to standby through WAKEUP_CON0.BLNKFIL bits. The wake-up events happening during the blanking filter active phase would be lost
- The wake-up event is recognized and triggered only in the STANDBY state after blanking filter expiry and not during transition states. If the same event trigger (for example ESR2) is used for standby entry and for wake-up, then it has to be ensured that the blanking filter is activated

10. One of the following Wake-up Trigger Configurations may be chosen:

- Wake-up Timer may also be kept running before entering the Standby state. The wake-up from WUT may be activated through WAKEUP_CON0.WUTWKEN bit
- Real Time Clock may also be kept running before entering the Standby state. The wake-up from RTC may be activated through WAKEUP_CON0.RTCWKEN bit
- Wake-up configuration and filter activation for *ESR2*, *PINC*, *PORST*, *PINA*, *PINB*, *ESR0*, and *ESR1* is configured through xWKEN, EDCON, and DFEN bits

11. Standby Entry configuration:

- Configure Standby Entry event in SMM.PMSWCR1.STBYEV register bits. Standby request is issued through software or ESRx event

12. Pending Interrupt handling before Standby request:

- If a write to PMCSRx.REQSLP register bit-field occurs while the interrupt router has a pending interrupt for CPU, the device may not enter Standby mode. To ensure the transition to Standby mode, all interrupts that are not intended to cause Run Mode to be re-entered or retained, should either have the SRE bit cleared in the respective SRN or be guaranteed to have the SRR bit clear
- So long as the SRE bit and SRR bit are not both set, there will not be a pending interrupt to inhibit standby mode transition. If the SRR bits are cleared, after the last SRN is modified, there also needs to be a synchronization step for the interrupt router outputs to reflect the update before the PMCSRx.REQSLP bit-field is written
- To ensure a deterministic end of CPU execution after the Standby mode request, the write to PMCSRx.REQSLP should be followed by a DSYNC and a WAIT instruction

13. Standby trigger and Standby transition:

- Once a Standby entry event is recognized, the primary under-voltage reset generation is disabled and the Standby RAM supply is switched from V_{DD} to $V_{DDSBRAM}$ within a few clock cycles. On entry into Standby mode, the blanking filter is activated. The blanking filter is always activated on entry to the Standby state

36.3.7.3 Interaction of warm reset and standby mode transitions

This section addresses following use cases:

- A standby request by V_{DDEXT} ramp-down is issued during warm reset
- A warm reset is triggered when a standby mode transition is ongoing

The PMS has separate state machines, which operate independently from the rest of the MCU. The PMS states are not affected by warm resets (including system reset and application reset). The table "Effect of Reset on Device Functions" from the SMM chapter shows how the MCU modules are affected by different reset types.

Therefore, standby mode entry is achieved even in the warm reset state of the MCU system modes.

36.3.7.4 Wake-up from standby

Wake-up from standby modes is triggered by supply ramp-up events, rising or falling edge events on multiple pins, and compare match events from timers and real time clock units.

Exiting standby mode - wake-up events

Wake-up events are categorized as shown in the following figures as to whether the device is in STANDBY0 or STANDBY1 state and whether V_{DDEXT} is kept supplied during Standby state in addition to $V_{DDEVRSB}$ supply. If V_{DDEXT} is not supplied, the wake-up is delayed until V_{DDEXT} has ramped up. The wake-up event in case of standby mode occurs after the blanking filter time has expired upon any of the following triggers:

1. On a V_{DDEXT} Supply ramp-up after the blanking filter time has expired. The Standby controller unit or *ESR2* pin maybe used to re-trigger V_{DDEXT} IO supply ramp-up to the external regulator
   - SCR may be active and wake-up can indirectly be triggered through SCR by communicating to external regulator to request the ramp-up of V_{DDEXT} voltage
   - Likewise wake-up can indirectly be triggered through *ESR2* pin by communicating to external regulator to request the ramp-up of V_{DDEXT} voltage configured through PAD_CON.ESR2WKPRUNPD register bit-field

   After V_{DDEXT} wake-up is recognized, it is expected that the V_{DDEXT} supply is stable afterwards. The detection time of the V_{DDEXT} ramp-up supply detector itself on reaching $V_{LVDRSTEXT}$ level is within 10 µs. Nevertheless the complete time for start-up from Standby mode is quite the same as that for normal start-up and is documented t_{BP} parameter in datasheet. In case of immediate V_{DDEXT} power fail consequent to V_{DDEXT} wake-up, LVD reset or cold PORST may be triggered. It is expected that the V_{DDEXT} supply has ramped down within the configured blanking filter time. Blanking filter shall be configured for at least the time required for V_{DDEXT} to ramp down to $V_{LVDRSTEXT}$ level + 1 ms. V_{DDEXT} wake-up is ignored during the time between Enter Standby state till blanking filter expiry. Wake-up triggered on a V_{DDEXT} Supply ramp-up is indicated in WAKEUP_STAT0.PWRWKP register bit and shall be cleared by WAKEUP_CLR0.PWRWKPCLR clear register bit
2. Wake-up from SCR as indicated in WAKEUP_STAT1.SCRWKP status register is in turn caused by the following events:
   - Edge transitions at the shared ports
   - RTC interrupt
   - SCR watchdog overflow
   - Selected interrupts from communication modules
   - ADCOMP analog channel compare event

   The WAKEUP_STAT1.SCRWKP flag is set on wake-up. The WAKEUP_STAT1.SCROVRUN flag is set to indicate overrun behavior in case of multiple unserviced wake-ups. The SCR wake-up is ignored during the time between the enter standby transition until the blanking filter time expiry
3. Wake-up from Wake-up Timer (WUT)
4. Wake-up from Real Time Clock (RTC)
5. Wake-up from Pins: External events may be mapped to ESRx/PINx pins in turn acting as wake-up signals for the system. In Run Mode, *ESR1* pin may be used as NMI interface from external devices and *ESR0* for reset output propagation. *ESR2* pin may be used to indicate wake-up events to external devices. In Standby Mode, an edge event on any of the ESRx pins may be configured to trigger wake-up of the main core domain through WAKEUP_CONx.ESRxWKEN bit and is reflected in WAKEUP_STATx.ESRxWKP status flag. It can be configured to trigger a wake-up on rising, falling, or both edges via WAKEUP_CONx.ESRxEDCON bit. The minimum pulse width of the external wake-up input signal without the digital filter activated shall be at least 3 clock cycles (of the 70 kHz standby clock). Glitches on ESRx input are filtered out by activating the filter through WAKEUP_CONx.ESRxDFEN bit. The reset behavior of the *ESR*x pins is documented in the External Service Requests section in the SMM chapter. Additional pins (*PINA*, *PINB*, and *PINC*) may likewise be configured to trigger wake-up through xEDCON, xDFEN, and

xWKEN bits. On wake-up, WAKEUP_STATx.PINxWKP event flags provide information as to the wake-up source. Application SW must take care after wake-up to clear the event flags through WAKEUP_CLRx.xWKPCLR flags, otherwise standby re-entry is not possible. In case new wake-up events are captured while WAKEUP_STATx.xWKP flags are still set, then WAKEUP_STATx.xOVRRUN flags are set to indicate an overrun state owing to consecutive unserviced wake-up events. xWKP / xOVRUN flags are only set during Standby mode after Blanking Filter expiry when the respective wake-up event happens. The wake-up feature from PORST, ESR0, ESR1, PINA and PINSEXT pins is supported only if VDDEXT is kept supplied in standby modes, otherwise wake-up trigger shall be disabled in xWKEN bit-fields

- Wake-up through *PINC* (P33.12) edge rising or falling edge event
- Wake-up through *ESR2* (P33.11) edge rising or falling edge event
- Wake-up through *PINSSB* low level detection. Refer PORT chapter for more information. The blanking filter shall be enabled for standby entry time to ensure wake-up is triggered
- Wake-up through *PINSEXT* low level detection if V_{DDEXT} is supplied. Refer PORT chapter for more information. If V_{DDEXT} is not supplied during standby mode, the PINSEXTWKEN shall be set to 0 to avoid spurious wake-up. The blanking filter shall be enabled for standby entry time to ensure wake-up is triggered
- Wake-up through *PINB* (P33.13) edge rising or falling edge event
- Wake-up through *PINA* (P14.1) if V_{DDEXT} is supplied. If V_{DDEXT} is not supplied during standby mode, the PINAWKEN shall be set to 0 to avoid spurious wake-up
- Wake-up through *ESR1* if V_{DDEXT} is supplied. If V_{DDEXT} is not supplied during standby mode, the ESR1WKEN shall be set to 0 to avoid spurious wake-up
- Wake-up through *ESR0* if V_{DDEXT} is supplied. If V_{DDEXT} is not supplied during standby mode, the ESR0WKEN shall be set to 0 to avoid spurious wake-up
- Wake-up through *PORST* if V_{DDEXT} is supplied. If V_{DDEXT} is not supplied during standby mode, the PORSTWKEN shall be set to 0 to avoid spurious wake-up

The wake-up from STANDBY0 state is indicated in the CLDRSTSTAT.STBY0WKP and CLDRSTSTAT.STBY1WKP status bits and wake-up from STANDBY1 state is indicated in the CLDRSTSTAT.STBY1WKP status bit respectively. The EVRC regulator is ramped up on wake-up based on the earlier latched configuration in HWCFGx register bits. On wake-up, all pads are either in tristate or are connected to pull-ups as indicated in PAD_STAT.ALLTRIST and PAD_STAT.SBTRIST register bits. *ESR0* behavior is indicated in PAD_CON.ESR0PD register bit. If standby RAM was supplied during the standby state, it is indicated in the STANDBY_CON0.SBRAMSEL register bits. CLDRSTSTATLVDANA bit indicates if the RAM supply was reliable during standby. If CLDRSTSTAT.LVDANA or CLDRSTSTAT.LVDPMS0 is set to 1, this indicates that any of the required supplies for the respective standby mode was not reliable. CLDRSTSTAT.LVDPMS1 bit indicates if the PMS1 domain was in reset.

In case of a transition from STANDBY0 to RUN mode, it is expected that both CLDRSTSTAT.STBY0WKP and CLDRSTSTAT.STBY1WKP bits are set. If any of the CLDRSTSTAT.LVDANA or CLDRSTSTAT.LVDPMS0 is set, then a voltage issue was detected during standby.

In case of a transition from STANDBY1 to RUN mode, it is expected that the CLDRSTSTAT.STBY1WKP bit is set. If any of the CLDRSTSTAT.LVDANA, CLDRSTSTAT.LVDPMS0, or CLDRSTSTAT.LVDPMS1 bits are set, then a voltage issue was detected during standby.

The reset relevant flags shall be cleared through the CLDRSTSTATCLR.CLEAR register bit. The wake-up and over-run status flags are set in WAKEUP_STATx registers and shall be cleared in the WAKEUP_CLRx registers. The wake-up time is nearly the same as the normal boot time as EVRC needs to be started and firmware needs to be consequently executed. The PORST pin output driving function by the PMS is resumed only after all supplies have ramped up.

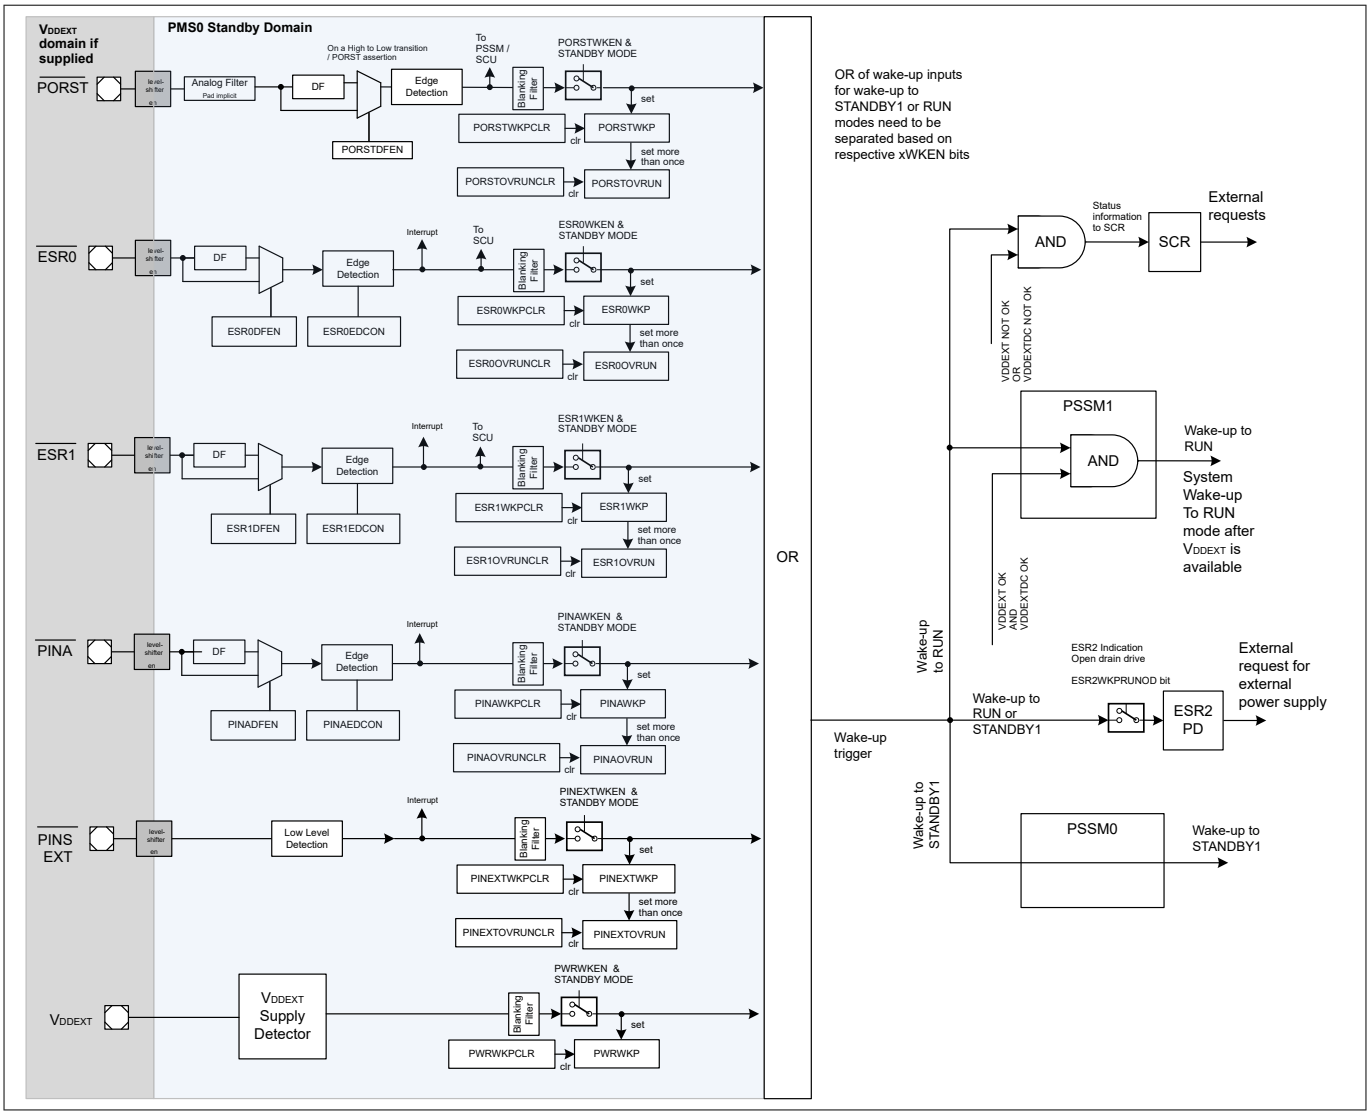

Figure 801 Wake-up sources when V_{DDEXT} is available

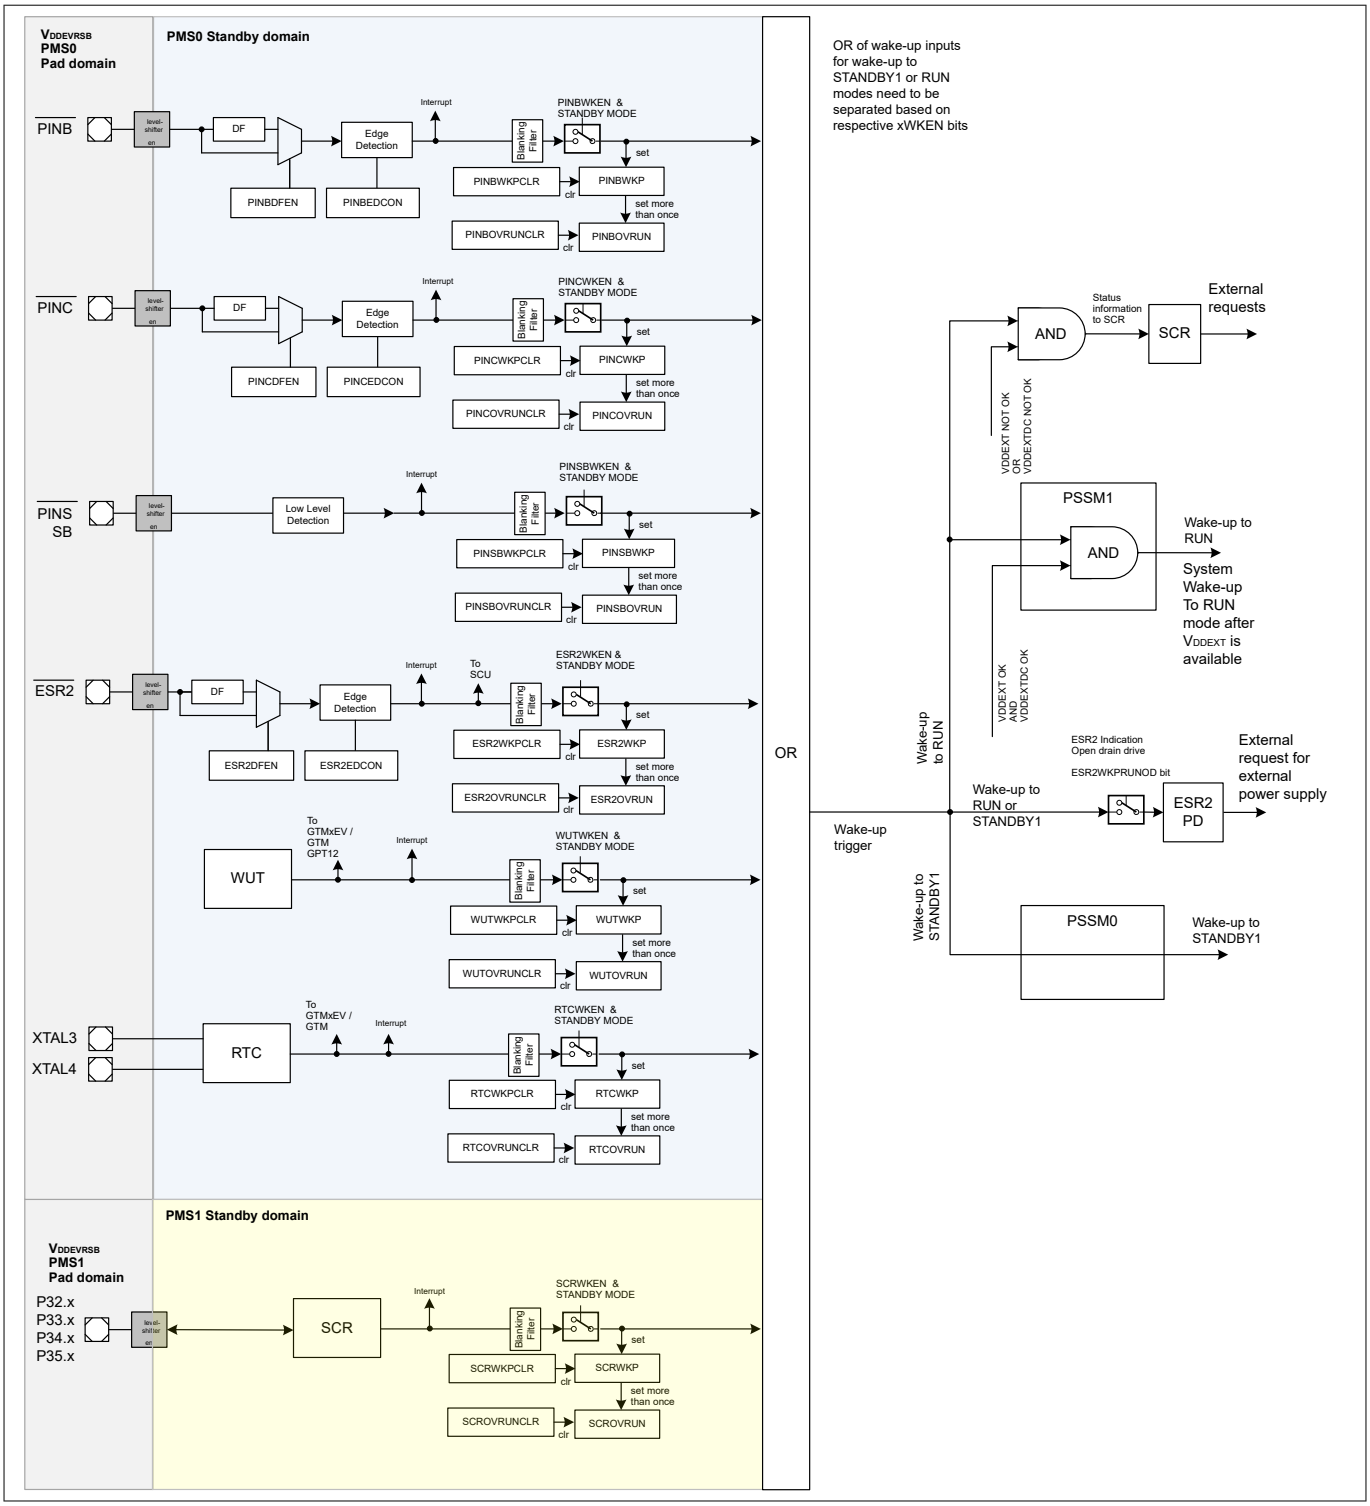

Figure 802 Wake-up sources when $V_{DDEVRSB}$ is available

Exiting standby mode - power fail or reset event

A power fail event of the Standby supply ($V_{DDEVRSB}$ pin) during Standby mode may inevitably result in the loss of Standby RAM contents. Consequently, LVDANA reset event is issued and the Standby domain is set into reset. An under-voltage violation of the $V_{DDSBRAM}$ pre-regulator is indicated in the CLDRSTSTAT.LVDANA flag, which can be used as an indication of a standby supply fail, respectively if the standby RAM content is, as a consequence, not reliable anymore. Cold reset flags CLDRSTSTAT.LVDPMS2, .CLDPORST, and .PDCLDRST flags would always be set after the wake-up from all standby modes, as these domains are devoid of power during STANDBY to

eliminate leakage current. It is recommended to keep a copy of the critical data also in Dflash in order to mitigate the effects if unwanted power fail events cannot be avoided.

In case of V_{DDEXT} supply wake-up, *PORST* pin, *ESR0/1* pins and *PINA* input are not evaluated during Standby mode as it is supplied by V_{DDEXT} domain which is switched off during the STANDBY mode. In case V_{DDEXT} domain is supplied during STANDBY mode, the Standby domain is woken up on PORST assertion depending on PORSTWKEN bit. The SCR may also set into reset simultaneously depending on PORSTREQ bit. The device boots up ramping up the regulators followed by firmware execution similar to a normal device start-up. On PORST wake-up, PORSTWKP event flag is set providing information as to the wake-up source. It should be taken care after wake-up to clear the event flags via PORSTWKPCLR register. In case new PORST wake-up events are captured while PORSTWKP flags are still set, then PORSTOVRRUN flags are set to indicate an overrun state owing to consecutive un-serviced wake-up events. The overrun flag is cleared via PORSTOVRUNCLR bit.

The Standby RAM contents are kept intact after a wake-up caused by PORST assertion. In case of V_{DD} supply under-voltage condition during wake-up phase, It is ensured that the Standby RAM is kept supplied by $V_{DDSBRAM}$ until V_{DD} is back in operational range to avoid Standby RAM data loss or corruption during transition. Reset is propagated to external devices via the *ESR0* pin on exit from Standby mode depending on ESR0PD configuration. Firmware may elongate *ESR0* reset output depending on *ESR0* configuration (which is done in the SMM, see the SMM ESR0CNTCTRL register).

Additional PORST digital filter activated via PORSTDF bit provides additional spike filtering of at least $t_{PORSTDF}$ duration to provide enhanced immunity against spurious spikes. This is in addition to the inherent analog PORST filter delay of the *PORST* pad / pin as documented in the data sheet. After cold PORST the additional PORST digital filter delay is by default inactive. If V_{DDEXT} is supplied, PORST (high to low) during Standby state after blanking filter expiry triggers wake-up.

Table 1436 *PORST* pin assertion behavior on PMS and SCR subsystem during system modes

Reaction to *PORST* pin assertion	RUN mode SLEEP mode	STANDBY1 mode
No reaction	No effect on PMS domain. No reaction on SCR if PORSTREQ = 0 but an SCR_NMI is triggered via the RST bit.	No effect on PMS domain if PORSTWKEN = 0. No reaction on SCR if PORSTREQ = 0
Wake-up	No effect on PMS or SCR domain as the system is already awake	PMS Standby to RUN transition takes place on PORST assertion when V_{DDEXT} is supplied if PORSTWKEN=1
Reset	No reset of PMS domain SCR is reset if PORSTREQ = 1	No reset of PMS domain SCR is reset if PORSTREQ = 1

36.3.7.5 Standby RAM retention

The standby RAM feature is device specific and therefore not applicable to all product variants, please refer to the device feature set in the data sheet (low power features). Therefore, also the STANDBY_CON0 register, which is used to configure this feature, is described in the device-specific section.

The RAMs remain supplied during Standby mode if configured in STANDBY_CON0.SBRAMSEL bits. On wake-up, the status which Standby RAMs remain supplied is reflected in STANDBY_CON0.SBRAMSEL bits. Additional RAM integrity checks may be carried out after wake-up.

The Standby RAM cell array is supplied by a separate supply pin ($V_{DDEVRSB}$) during Standby state via the internal $V_{DDSBRAM}$ regulator. It shall be ensured that the external standby supply source continues to supply $V_{DDEVRSB}$ supply pin during Standby state in operational region. Standby supply status is also monitored and indicated via CLDRSTSTAT.LVDANA status bit which indicates $V_{DDSBRAM}$ supply under-voltage LVD reset. It is to be taken care by the Start-up software after wake-up that Standby RAMs are not initialized if SBRAMSEL bits are set and LVDANA reset had not taken place. Furthermore, if STANDBY_CON0.SBRAMSEL bits are set to enable Standby RAM function and there was a V_{DD} primary under-voltage event, it is ensured that the Standby RAM supply is switched immediately to $V_{DDSBRAM}$ supply rail. This ensures that RAM contents are not corrupted also during main V_{DD} core supply loss.

The SCR RAM constitutes ECC protected 32 kB of XRAM. The SCR XRAM remains supplied during STANDBY0 mode if configured in STANDBY_CON0.SCRRAMSEL bits by $V_{DDSBRAM}$ regulator. On wake-up, the status which Standby RAMs remain supplied is reflected in STANDBY_CON0.SCRRAMSEL bits. During STANDBY1 mode and RUN modes, the SCR XRAM is supplied by V_{DDPMS1} regulator.

36.3.7.6 Wake-up timer (WUT)

The Wake-up Timer is a basic low power counter which may be used to wake-up the system periodically from STANDBY mode. The timer may also be used during RUN, IDLE or SLEEP modes. The following list enumerates the salient features:

- 24-bit counter running on 70 kHz clock source with programmable reload value
- 24-bit counter status register providing the current count value
- Timer resolution of 70 kHz or (70 kHz/2^10) configured through a clock divider:
  - 14.3 µs resolution: 14.3 µs - 240 s range ± tolerance after trimming as stated in datasheet
  - 14.3 ms resolution: 14.3 ms - 2.7 days range ± tolerance after trimming as stated in datasheet
- 3 operating modes:
  - Auto Reload mode - WUT is started and stopped through Software. Automatic reload on counter underflow triggers a system wake-up. WUT runs continuously through STANDBY and run mode transitions
  - STANDBY0 Auto Stop mode - Counter starts counting down from reload value on STANDBY0 entry. Counter stops on underflow and triggers a system wake-up
  - STANDBY1 Auto Stop mode - Counter starts counting down from reload value on STANDBY1 entry. Counter stops on underflow and triggers a system wake-up
- Events on WUT counter underflow:
  - Interrupt request on SRC_PMS2 (WUT) interrupt node on counter underflow during RUN modes
  - Wake-up trigger on counter underflow during STANDBY modes
  - Capture trigger on counter underflow to eGTM (TIM0_7.11) and GTM (TIM0_7.11) for trimming purpose
- Over-run indication of consecutive unserviced wake-up triggers

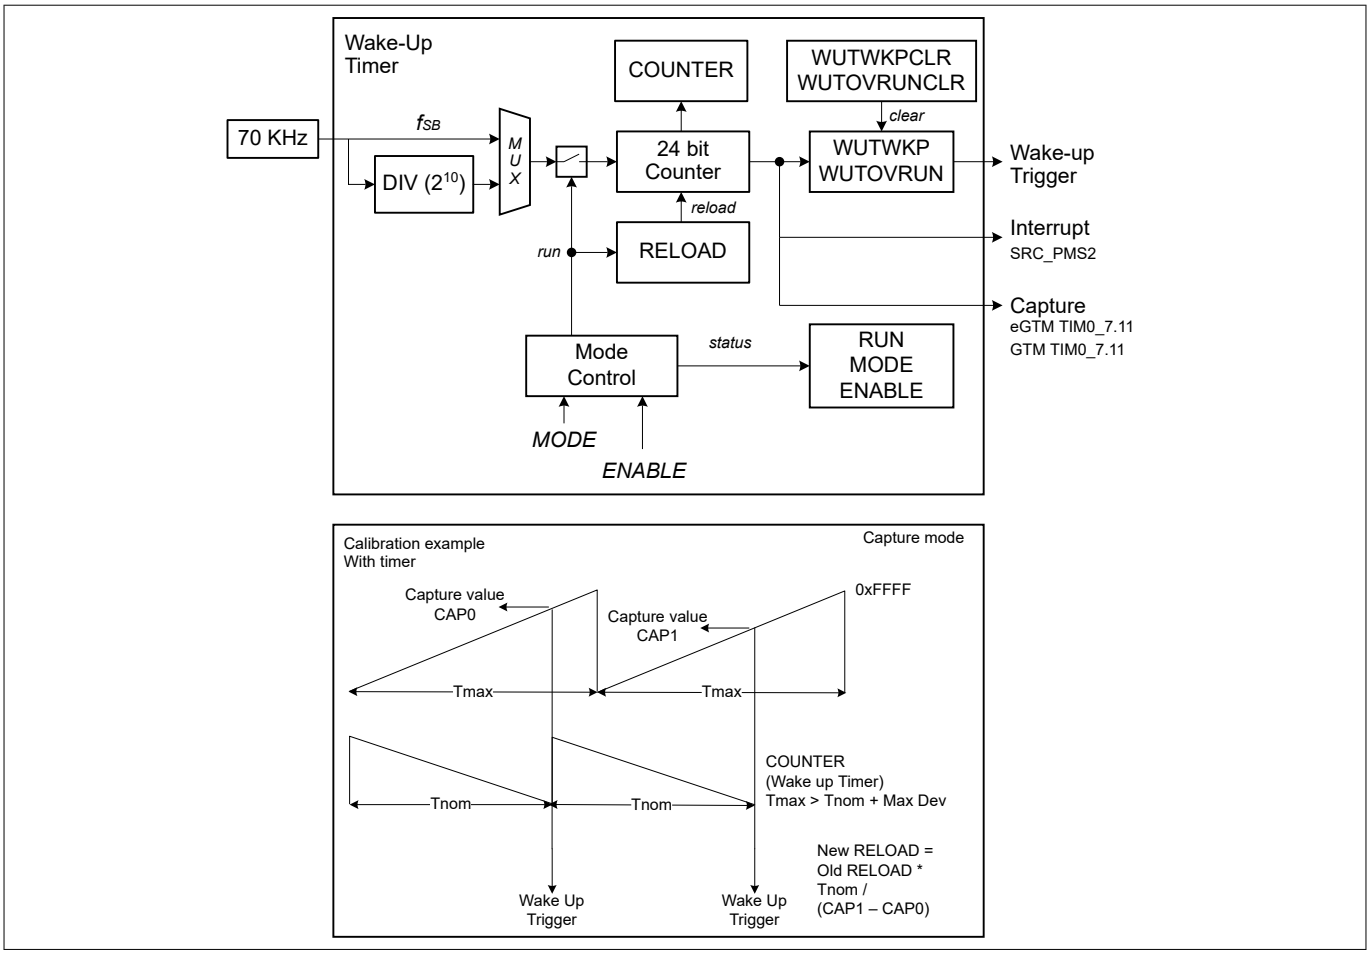

Figure 803 Wake-up timer (WUT)

Table 1437 Wake-up timer operation and modes

WUT_CON.ENABLE	WUT_CON.MODE	Mode description
0_B	X_B	WUT is disabled and counter is stopped. WUT_CON.RELOAD, MODE and DIV value shall be updated only when WUT is not enabled. WUT_STAT.COUNTER and .RUN read 0. In addition,WAKEUP_STAT0.WUTWKP and .WUTOVRUN flags are not updated and retain earlier value irrespective of WUTWKEN setting and should be cleared explicitly by the user.

(table continues...)

Table 1437 (continued) Wake-up timer operation and modes

WUT_CON.ENABLE	WUT_CON.MODE	Mode description
1_B	00_B	Software Auto Reload mode : WUT starts running when WUT_CON.ENABLE = 1 and .MODE = 0 is set. WAKEUP_CON0.WUTWKEN = 1 must be set to activate system wake-up from STANDBY state. WUT_STAT.RUN bit is set indicating that WUT timer is currently running. WUT_STAT.COUNTER bit-field indicates the actual counter value. On counter underflow, WUT is automatically reloaded with the WUT_CON.RELOAD value. During STANDBY, WUT underflow triggers system wake-up if WAKEUP_CON0.WUTWKEN is set and WAKEUP_STAT0.WUTWKP flag is set. During Run, Idle or Sleep modes, WUT underflow triggers an interrupt request and WAKEUP_STAT0.WUTWKP flag is set. WUT_CON.RELOAD and DIV value shall not be updated in this state. On wake-up, the WAKEUP_STAT0.WUTWKP flag shall be cleared by WAKEUP_CLR0.WUTWKPCLR bit. In case of un-serviced consecutive counter underflow events, WAKEUP_STAT0.WUTOVRUN flag is set to indicate an over-run wake-up event. Interrupt over-run event can be detected via SRC.IOV bit during RUN mode.
1_B	01_B	STANDBY0 PMS0 Auto Stop mode: The mode is selected by setting WUT_CON.ENABLE = 1, .MODE = 1. WAKEUP_CON0.WUTWKEN = 1 is set to activate system wake-up from STANDBY state. WUT starts running only when STANDBY0 mode is entered. On counter underflow, WUT stops running and the wake-up of system is triggered and WAKEUP_STAT0.WUTWKP flag is set. WUT starts running again on the next STANDBY0 mode entry. The intention is to have the timer running only during the STANDBY0 state. WUT_STAT.COUNTER reloads WUT_CON.RELOAD value on a wake-up. WUT_STAT.RUN reads 0 after a wake-up. WUT_CON.RELOAD and DIV value shall not be updated in this state. On wake-up, the WAKEUP_STAT0.WUTWKP flag shall be cleared by WAKEUP_CLR0.WUTWKPCLR bit in RUN mode. In case of wake-up to STANDBY1 state, the WUTWKP flag is cleared by SCR.WKPCLR clear flag event. In case system was woken up by other wake-up triggers while WUT was still running, an interrupt request is generated on WUT underflow.

(table continues...)

Table 1437 (continued) Wake-up timer operation and modes

WUT_CON.ENABLE	WUT_CON.MODE	Mode description
1_B	10_B	STANDBY1 PMS1 Auto Stop mode: The mode is selected by setting WUT_CON.ENABLE = 1, .MODE = 2. WAKEUP_CON0.WUTWKEN = 1 is set to activate system wake-up from STANDBY state. WUT starts running only when STANDBY1 mode is entered. On counter underflow, WUT stops running and the wake-up of system to RUN mode is triggered and WAKEUP_STAT0.WUTWKP flag is set. WUT starts running again on the next STANDBY1 mode entry. The intention is to have the timer running only during the STANDBY1 state. WUT does not run in either STANDBY0 state. In case of STANDBY0 entry, WUT freezes at the last count value and starts counting again from that value on STANDBY1 mode re-entry. WUT_STAT.COUNTER reloads WUT_CON.RELOAD value on a wake-up. WUT_STAT.RUN reads 0 after a wake-up. WUT_CON.RELOAD and DIV value shall not be updated in this state. On wake-up, the WAKEUP_STAT0.WUTWKP flag shall be cleared by WAKEUP_CLR0.WUTWKPCLR bit. In case system was woken up by other wake-up triggers while WUT was still running, an interrupt request is generated on WUT underflow.
1_B	11_B	Reserved

Table 1438 WUTWKEN configuration and mode transitions

WUTWKEN	Intended system mode transition	Intended WUT modes to be used
0 1 B	STANDBY0 from/to RUN	Software Auto reload mode STANDBY0 Auto Stop mode
1 0 B	STANDBY0 from/to STANDBY1	Software Auto reload mode STANDBY0 Auto Stop mode - Clear WUTWKP flag via SCR.WKPCLR bit in SCR in STANDBY1 mode to be able to go back to STANDBY0 mode.
1 1 B	STANDBY1 from/to RUN	Software Auto reload mode STANDBY1 Auto Stop mode - Only transition between RUN and STANDBY1 mode is allowed in this mode.
1 1 B	STANDBY0 from/to STANDBY1 from/to RUN	Software Auto reload mode - In STANDBY0 mode, on first wake-up, transition happens to STANDBY1. Consecutive Wake-up event may trigger a transition to RUN mode. Both WUTWKP and WUTOVRUN flags would be set in this case.

In case of timer underflow, an interrupt is issued on the interrupt node SRC_PMSx (WUT). Wake-up Timer reload value maybe trimmed during Run mode by comparing the time stamp on a WUT underflow captured by a GTM-TIM or eGTM based on a more precise clock as shown in the figure above. This allows to compensate on short term the 70 kHz (fSB) clock source variations owing to technology, voltage and temperature.

36.3.7.7 RTC - real time clock

The PMS integrates a real time clock (RTC) running at 32.768 kHz, with temperature trimming and parametric characteristics as specified in the datasheet.

The RTC in the PMS provides a free running 64-bit global system timer, which keeps running through all resets except the LVDPMS0 reset. All 64 bits of the counter can be read synchronously.

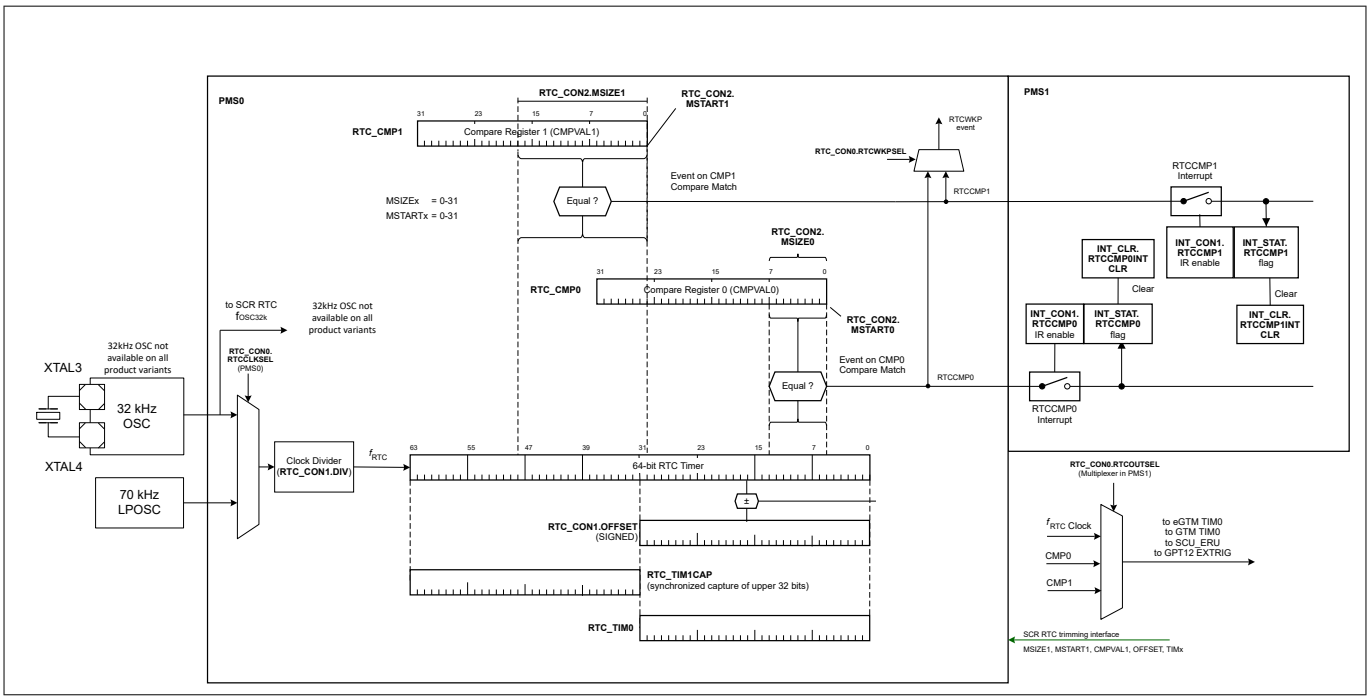

Figure 804 General block diagram of the RTC module

The clock source of the RTC can be selected between a 32 kHz oscillator (also used by the RTC of the SCR subsystem) and the 70 kHz low-power oscillator of the PMS, using the RTC_CON0.RTCCLKSEL configuration bit. On certain product variants, the 32kHz oscillator is not available. The clock of the RTC can be enabled or disabled using the RTC_CON0.RTCEN bit. The counter period can be configured by adjusting the clock divider with the RTC_CON1.DIV bit-field (16-bit). The division factor is DIV+1, that is if the RTC input frequency is 32.768 kHz, use for example RTC_CON1.DIV=$7FFF_H$ (division by 32768) to generate a 1 second time base.

Due to the 64-bit width of the RTC timer, it is not possible to read its entire content with one instruction. It needs to be load with two load instructions. Since the timer would continue to count between the two load operations, there is a chance that the two values read are not consistent (due to a possible overflow from the low part of the timer to the high part between the two read operations). To enable a synchronous and consistent reading of the RTC content, a capture register RTC_TIM1CAP is implemented. It latches the content of the high part of the RTC each time when the register RTC_TIM0 is read. Thus, RTC_TIM1CAP holds the upper value of the timer at exactly the same time when the lower part is read. The second read operation would then read the content of the RTC_TIM1CAP to get the complete timer value.

The content of the 64-bit RTC timer can be compared against the content of two compare values stored in the RTC_CMP0 and RTC_CMP1 registers. Service interrupts can be generated on a compare match of the RTC timer with the RTC_CMP0 or RTC_CMP1 registers and can be enabled via the INT_CON2.RTCCMP0 respectively INT_CON2.RTCCMP1 bits. A configurable number of bits can be selected from the RTC_CMP0 and RTC_CMP1 registers for the compare operation, by programming the RTC_CON2.MSIZE0 respectively MSIZE1 bit-fields. As shown in the previous figure, only a sub-set of the RTC_CMP0 and RTC_CMP1 registers, as defined in the MSIZE0 and MSIZE1, will then be selected for the compare match.

Two parameters are programmable for the compare operation:

1. RTC_CON2.MSIZE0/MSIZE1: The number of bits which are selected from the registers RTC_CMP0/ RTC_CMP1 for the compare operation, can be programmed from 0 to 31
2. RTC_CON2.MSTART0/MSTART1: The first bit location in the 64-bit timer that is taken for the compare operation can be programmed from 0 to 31. Note that by setting MSTART0/1 to 31 and MSIZE0/1 to 31, the bits 31 to 62 from RTC_CMP0/1 will be used for the compare operation (bit 63 of the RTC timer is not included in the compare operation).

These programming capabilities enable a very flexible compare functionality. It is possible to detect bit transitions of a single bit n (n = 0 to 31) within the 64-bit RTC by setting MSIZE = 0 and MSTART = n

The example illustrated in the previous figure shows a compare operation in which following parameters are programmed:

- MSIZE1 = $10001_B = 17_D$; MSTART1 = $11111_B = 31_D$
- MSIZE0 = $00111_B = 7_D$; MSTART0 = $00110_B = 6_D$

Upon a compare match event on the RTC_CMP0 or RTC_CMP1, an interrupt is triggered if enabled in INT_CON2.RTCCMP0 or INT_CON2.RTCCMP1.

Upon a compare match event on the RTC_CMP0 or RTC_CMP1, a wake-up request is triggered (RTCWKP) in the PMS0 standby domain, issuing a wake-up to STANDBY1 or to RUN mode depending on the configuration of WAKEUP_CON0.RTCWKEN bit. The wake-up request is selectable between RTC_CMP0 and RTC_CMP1 via RTC_CON0.RTCWKPSEL configuration bit.

A trimming of the RTC clock can be done by the application software, using the RTC_CON1.OFFSET bit-field, in order to correct the crystal frequency accuracy as needed by the application. The application configures the RTC_CMP1 compare register and MSIZE1, MSTART1 parameters, to trigger a compare match event whenever the application needs to check and apply the trimming. Then the application programs the required offset in RTC_CON1.OFFSET (signed value). The offset correction is then only applied at the next RTC_CMP0 compare match (as configured using RTC_CMP0, MSTART0, and MSIZE0).

The CMP0 match shall be used to generate RTC timer interrupt and CMP1 match interrupt to trim the crystal based on temperature. It is recommended that CMP1 match is less frequent than CMP0 match and therefore CMP1 compare match period shall have a higher value than CMP0 compare match period. Likewise it is expected that CMP0 compare match period shall have a higher value than OFFSET. As OFFSET representing the periodic crystal trim value with temperature deviations is expected to have a much smaller value than RTC timer tick period triggered on CMP0 interrupt. If OFFSET has larger values, the effects of negative OFFSET application need to be considered as shown in the figure below. The RTC configuration of MSIZE1, MSTART1 and CMPVAL1 can also be configured by the SCR for RTC trimming in STANDBY1 mode. f_{RTC} and RTC timer values are also provided as inputs to SCR.

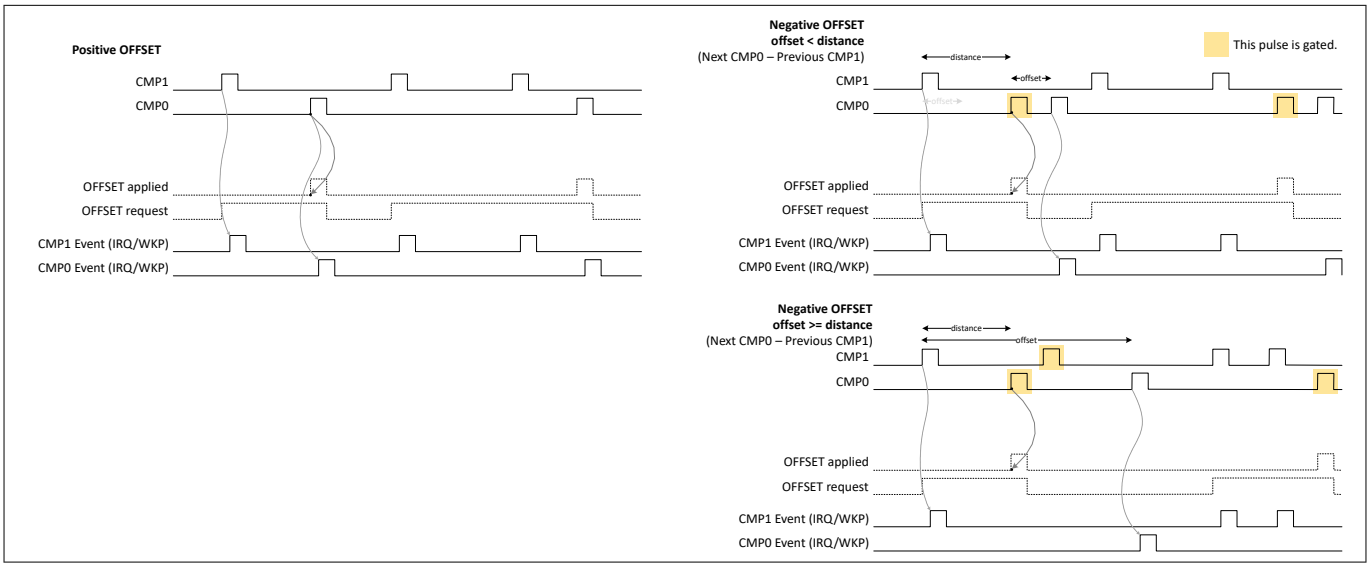

Figure 805 OFFSET application on running RTC timer

Behavior on a positive OFFSET correction:

- OFFSET is triggered on a CMP1 match but the offset addition to the actual timer value is done at the consequent CMP0 match

Behavior on a negative OFFSET correction:

- OFFSET is triggered on a CMP1[x] match but the offset subtraction to the actual timer value is done at the consequent CMP0[y] match
- CMP0[y] event is suppressed and interrupt/wake-up is triggered on next CMP0[y+1] match. This is because once negative OFFSET is applied, CMP0 match would be again triggered spuriously after the OFFSET time interval is expired
- If a CMP1[x+1] match comes before the latter CMP0[y+1] match, it is also suppressed and no OFFSET correction takes place at that CMP1[x+1] match

The output of the RTC timer can be selected using the RTC_CON0.RTCOUTSEL bit-field between the following three signals:

- The clock of the RTC, f_{RTC}
- The CMP0 compare output
- The CMP1 compare output

This output is then routed to eGTM, GTM, SCU_ERU, and GPT12 modules.

When using the 32 kHz oscillator as input for the RTC (not available on certain product variants), this oscillator can be further configured using the bit-fields from register RTC_CON0. The oscillator is enabled through RTC_CON0.RTCOSCEN. After enabling the oscillator, a wait time of maximum 5 seconds must be considered, for the oscillator to start up, before switching the RTC clock source to 32 kHz using RTC_CON0.RTCCLKSEL. An oscillator amplitude regulation can be enabled by setting the bit RTC_CON0.REGEN. As a result, the oscillation amplitude at the *XTPADIN* pin is approximately 0.5 V, independent of the gain settings and on board elements. The gain of the oscillator circuit can be configured via the RTC_CON0.GAINSEL setting, with a default setting of 01_B, that is a gain setting of 4x.

36.3.8 Die temperature sensor (DTSPMS)

The die temperature sensor in the PMS (DTSPMS) indicates the local junction temperature in the PMS subsystem. It is one of the multiple die temperature sensor (DTS) instances of TC4xx, which are distributed across the die and described in more detail in the VTMON functional block chapter.

The DTS periodically generates a measurement result that can be converted into the current die temperature at the location of the sensor. In the event of thermal limit violations, alarms can be generated to support thermal performance throttling operations. Each DTS operates within the T_{SR} temperature range specified in the data sheet, with an accuracy of T_{NL}+T_{CALACC} (see data sheet parameter values). The temperature sensing resolution is 0.22 K/code, with a maximum conversion time of not more than the value of the t_M parameter documented in the data sheet. Gain and offsets errors are compensated by trimming executed by start-up software, and systematic non-linearity is linearized through digital post-processing.

The analog circuitry for the DTS is enabled by setting the DTS_CON.EN register bit. When the DTS_CON.START register bit is set, temperature measurements will be carried out continuously during RUN/SLEEP modes, with the latest measurement result being updated in the DTS_STAT.RESULT bit-field. Both the DTS_CON.EN and DTS_CON.START bits can be set concurrently, though the first conversion will take slightly longer for the analog circuitry to be properly initialized. The DTS_STAT.DTSREADY register bit is set when the analog circuitry has finished the first conversion and only then the alarms are forwarded to the SMU.

The DTSPMS and corresponding registers are not affected by a warm PORST, system or application reset; consequently the temperature result in the DTS_STAT register, from an earlier conversion, is available for immediate use after any warm reset. All other DTS instances in VTMON (except DTSPMS) are reset upon an application reset.

The DTS result DTS_STAT.RESULT can be converted to temperature by the following transfer function:

T[°C] = DTS_STAT.RESULT / g_{nom}-273.15, where g_{nom} = 4.781 Codes/K

A peak temperature detector records the highest temperature measurement result in DTS_STAT.PEAK since the last reset operation. This can be reset by writing a '1' into the DTS_CON.PEAKDETRST register field.

Upper and lower thermal warnings with adjustable threshold, hysteresis, and filters are supported and are intended for thermal throttling and control functions. In addition, a thermal-shutdown warning is included, to trigger a reset (if configured in the SMU as an alarm reaction) during thermal runaway scenarios. All warnings can be triggered only when the DTS_CON.WRNEN bit is set. The DTS_CON.WRNEN bit is disabled per default, such that alarms are disabled after start-up.

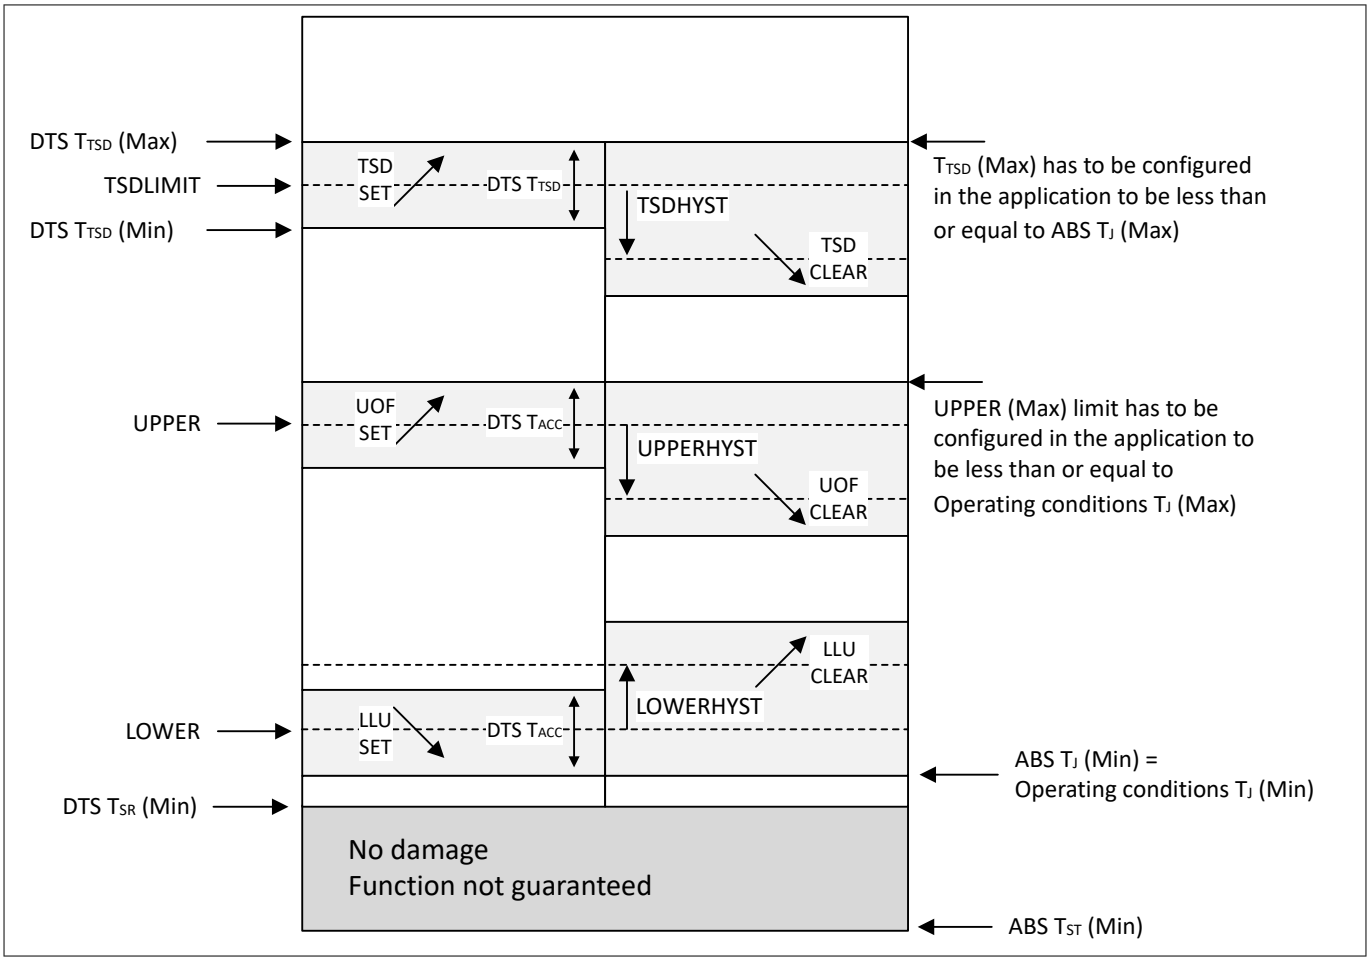

Figure 806 DTS alarm generation

The functionality of all warnings is summarized in the following. Die temperature thermal shutdown, upper, and lower limits are configured in the DTS_LIM2.TSDLIMIT, DTS_LIM1.UPPER, and DTS_LIM1.LOWER register bits respectively. Upon violation of these limits, DTS_STAT.TSD, DTS_STAT.UOF, and DTS_STAT.LLU status bits are set and alarms are forwarded to the SMU and CSRM. After start-up, the DTS limits have to be re-configured appropriately, depending on the application, before alarm reactions from SMU or CSRM are activated. Only when a new DTS conversion result is available, the DTS comparators are consequently triggered to check the actual DTS_STAT.RESULT against the thermal shutdown, upper, and lower limits.

The set criteria for all warnings also allows the implementation of a filter, whereby a warning will be triggered only when the configured limit is crossed for a number of consecutive temperature measurements (that is limit violations). The DTS_STAT.TSD warning is triggered when DTS_STAT.RESULT exceeds DTS_LIM2.TSDLIMIT for DTS_LIM2.TSDFILT + 1 consecutive conversions. The DTS_STAT.UOF warning is triggered when DTS_STAT.RESULT exceeds DTS_LIM1.UPPER for DTS_CON.UPPERFILT + 1 consecutive conversions. The DTS_STAT.LLU warning is triggered when DTS_STAT.RESULT is below DTS_LIM1.LOWER for DTS_CON.LOWERFILT + 1 consecutive conversions.

The clear criteria for DTS_STAT.TSD warning is satisfied when DTS_STAT.RESULT is below DTS_LIM2.TSDLIMIT - DTS_LIM2.TSDHYST. The clear criteria for DTS_STAT.UOF warning is satisfied when DTS_STAT.RESULT is below DTS_LIM1.UPPER - DTS_LIM1.UPPERHYST. Similarly, the clear criteria for DTS_STAT.LLU warning is satisfied when DTS_STAT.RESULT exceeds DTS_LIM1.LOWER + DTS_LIM1.LOWERHYST.

36.3.9 Standby controller extension RAM (XRAM)

The SCR XRAM is also protected by PMS access protection mechanisms.

The following tables show the memory overview and the according access protection mechanisms employed.

Table 1439 SCR XRAM memory overview

Short name	Long name	Address	Access mode	
			Read	Write
PMS_XRAM	Standby controller extension RAM (8000_H byte)	$F0240000_H$	P	SV, E, P

Table 1440 Access mode glossary

Keyword	Description
P	Access protection using APU-P registers.
E	Access protection using PROT register PMS_PROTE.
SV	Access only when supervisor mode is active on the interconnect.

36.4.1 Register overview - access mode glossary

Table 1441 Register overview - access mode glossary

Keyword	Description
CSE	Access protection using PROT register PROTCSE.
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
APU-Pcs	Protection group consisting of registers ACCENCS_WRA, ACCENCS_WRB, ACCENCS_RDA, ACCENCS_RDB, ACCENCS_VM, ACCENCS_PRS.
Pcs	Access protection using *APU-Pcs* registers.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
BE	Always returns a Bus Error.
STP	Access only during start-up, before start-up protection is set (SMM_STCON.ST_PROT=1).
M	Indicates a module specific access condition. Refer to the register description for details of the specific access condition.

36.4.2 Registers overview - PMS (ascending offset address)

Table 1442 Registers overview - PMS (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
PROTE	PROT register endinit	9000_H	U	SV, PROT	Application Reset	6044
PROTSE	PROT register safe endinit	9004_H	U	SV, PROT	Application Reset	6046
ID	Module identification register	9008_H	P	BE	Application Reset	6048
ACCEN_WRA	Write access enable register A	$900C_H$	U	SE, SV	Application Reset	6048
ACCEN_WRB	Write access enable register B	9010_H	U	SE, SV	Application Reset	6049
ACCEN_RDA	Read access enable register A	9014_H	U	SE, SV	Application Reset	6049
ACCEN_RDB	Read access enable register B	9018_H	U	SE, SV	Application Reset	6050

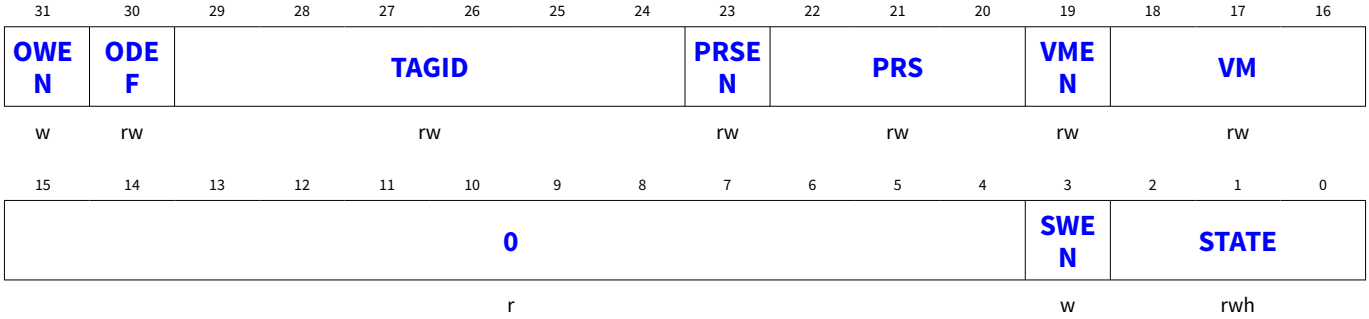
36.4.3 PROT register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock and unlock of the local endinit (E) protected control registers.

PROTE Offset address: 9000_H

PROT register endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM portion of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS portion of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID portion of the PROT owner. This field is ignored if ODEF=0_B.

(table continues...)

(continued)

Field	Bits	Type	Description
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1443 Access mode restrictions of PROTE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

36.4.4 PROT register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock and unlock of the local safe endinit (SE) protected control registers.

PROTSE Offset address: 9004_H

PROT register safe endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0												**SWEN**	**STATE**		
r												w	rwh		

Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM portion of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS portion of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID portion of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1444 Access mode restrictions of PROTSE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

36.4.5 Module identification register

ID Offset address: 9008_H

Module identification register Application Reset value: $00E8\ C001_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MOD_NUM															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOD_TYPE								MOD_REV							
r								r							

Field	Bits	Type	Description
MOD_REV	7:0	r	**Module revision** Indicates the revision number of the implementation. …
MOD_TYPE	15:8	r	**Module type** This bit field is fixed coded as $C0_H$. It defines a 32-bit module.
MOD_NUM	31:16	r	**Module number** This bit field defines the module identification number. The identification number for the PMS is $00E8_H$.

36.4.6 Write access enable register A

This register provides controls to enable or disable write accesses for transactions with TAG IDs corresponding to the numbered bits.

ACCEN_WRA Offset address: $900C_H$

Write access enable register A Application Reset value: $1000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r								rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
RDq (q=00-07)	q	rw	**Read access enable for PRS q** This bit enables read access to the access protected region for transactions in the PRS q. 0_B Disabled for read access 1_B Enabled for read access
WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions in the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

36.4.12 Register access status register

REGACCSTAT Offset address: 9024_H

Register access status register LVDPMS2 Reset value: $0000\ 0002_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														FIFOEMPTY	FIFOFULL
r														rh	rh

Field	Bits	Type	Description
FIFOFULL	0	rh	**RAI FIFO full status** Full status of the FIFO in the register access interface (RAI). This status could be reached after writing 32 times to PMS0 registers within 14 µs. PMS0 registers are indicated by an "LVDPMS0 Reset" or an "LVDANA Reset" type in the reset table of the respective register. 0_B RAI FIFO not full. 1_B RAI FIFO is full.
FIFOEMPTY	1	rh	**RAI FIFO empty status** Empty status of the FIFO in the register access interface (RAI). This status gets set when all previous write accesses to PMS0 registers have been executed. PMS0 registers are indicated by an "LVDPMS0 Reset" type in the reset table of the respective register. It is recommended to check the FIFOEMPTY status before writing into PMS0 registers. 0_B RAI FIFO not empty. 1_B RAI FIFO is empty.

(table continues...)

(continued)

Field	Bits	Type	Description
0	31:2	r	**Reserved** Read as 0.

36.4.13 PROT register cyber security endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTCSE register controls lock and unlock of the local cyber security endinit (CSE) protected control registers.

PROTCSE Offset address: 9028_H

PROT register cyber security endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

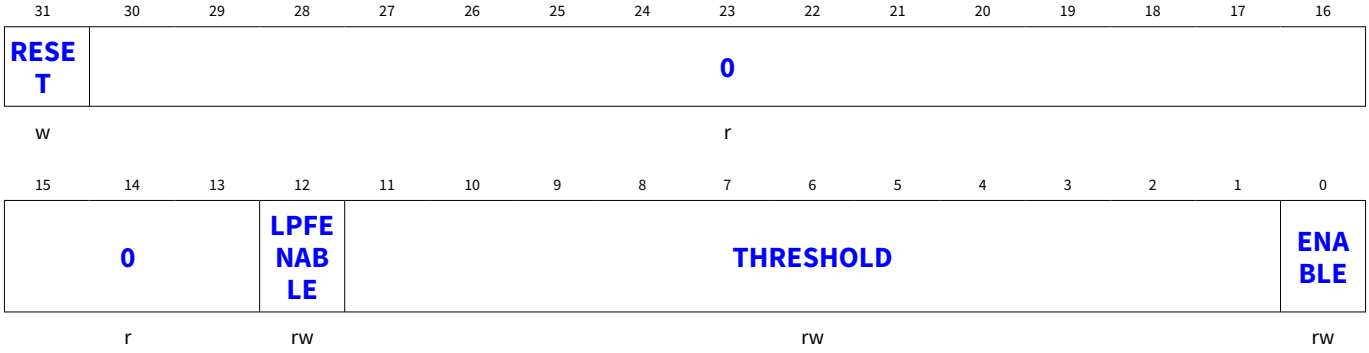
0			LPFENABLE	THRESHOLD											ENABLE
r			rw	rw											rw

Field	Bits	Type	Description
ENABLE	0	rw	**Enable/disable peak voltage detection for respective supply**
THRESHOLD	11:1	rw	**Threshold value configured by sw for peak voltage detection** Application software can configure a threshold value for detecting peak voltages higher than this threshold. Expressed as number of LSBs of the voltage monitoring ADC for the respective supply voltage.
LPFENABLE	12	rw	**Enable/disable the low-pass filtering of the recorded peak values** This bit allows to either apply the same low-pass filter as applied for the primary voltage monitor alarms to the recorded peak voltage value, or use the unfiltered ADC results instead.
RESET	31	w	**SW reset bit for peak voltage detection** Application software can restart the peak voltage detection cycle by setting this bit to 1, which resets the PEAK_VxxSTAT und PEAK_VxxHISTSTAT registers to their reset value for the respective Vxx voltage rail.
0	30:13	r	**Reserved** Read as 0; should be written with 0.

36.4.22 VDDEXT peak voltage detection configuration register

PEAK_VDDEXT Offset address: 9208_H

VDDEXT peak voltage detection configuration register LVDPMS2 Reset value: $0000\ 1001_H$



Field	Bits	Type	Description
ENABLE	0	rw	**Enable/disable peak voltage detection for respective supply**
THRESHOLD	11:1	rw	**Threshold value configured by sw for peak voltage detection** Application software can configure a threshold value for detecting peak voltages higher than this threshold. Expressed as number of LSBs of the voltage monitoring ADC for the respective supply voltage.
LPFENABLE	12	rw	**Enable/disable the low-pass filtering of the recorded peak values** This bit allows to either apply the same low-pass filter as applied for the primary voltage monitor alarms to the recorded peak voltage value, or use the unfiltered ADC results instead.
RESET	31	w	**SW reset bit for peak voltage detection** Application software can restart the peak voltage detection cycle by setting this bit to 1, which resets the PEAK_VxxSTAT und PEAK_VxxHISTSTAT registers to their reset value for the respective Vxx voltage rail.
0	30:13	r	**Reserved** Read as 0; should be written with 0.

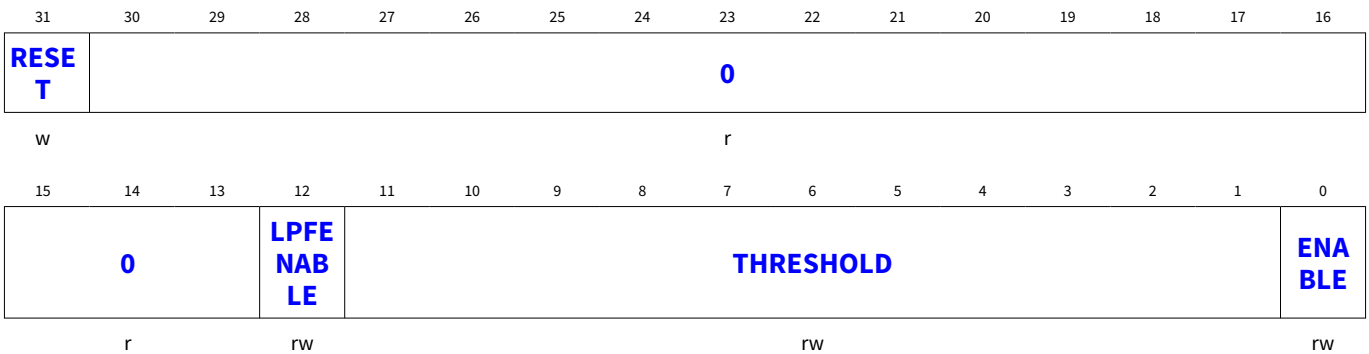
36.4.23 VDDEXTDC peak voltage detection configuration register

PEAK_VDDEXTDC

VDDEXTDC peak voltage detection configuration register

Offset address: $920C_H$

LVDPMS2 Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ENABLE	0	rw	**Enable/disable peak voltage detection for respective supply**
THRESHOLD	11:1	rw	**Threshold value configured by sw for peak voltage detection** Application software can configure a threshold value for detecting peak voltages higher than this threshold. Expressed as number of LSBs of the voltage monitoring ADC for the respective supply voltage.
LPFENABLE	12	rw	**Enable/disable the low-pass filtering of the recorded peak values** This bit allows to either apply the same low-pass filter as applied for the primary voltage monitor alarms to the recorded peak voltage value, or use the unfiltered ADC results instead.
RESET	31	w	**SW reset bit for peak voltage detection** Application software can restart the peak voltage detection cycle by setting this bit to 1, which resets the PEAK_VxxSTAT und PEAK_VxxHISTSTAT registers to their reset value for the respective Vxx voltage rail.
0	30:13	r	**Reserved** Read as 0; should be written with 0.

36.4.24 VDD peak voltage detection status register

PEAK_VDDSTAT Offset address: 9210_H

VDD peak voltage detection status register LVDPMS2 Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
THRESCOUNT					PEAKVOLT										
rh					rh										

Field	Bits	Type	Description
PEAKVOLT	10:0	rh	**Peak voltage detected value** This bit-field indicates the peak value detected for the respective supply voltage. Expressed as number of LSBs of the voltage monitoring ADC for the respective supply voltage.
THRESCOUNT	31:11	rh	**Detected sample count above configured threshold value** This bit-field indicates the number of voltage samples which were detected, after filtering, above the configured threshold value (PEAK_Vxx.THRESHOLD). During the reset phase if the peak detection is enabled for a supply rail and the the peak detection threslod is not configured (default 0x0) then THRESCOUNT must be ignored. The application software must configure the proper peak detection threshold and then reset the PEAK_VxxSTAT register.

36.4.25 VDDEXT peak voltage detection status register

PEAK_VDDEXTSTAT Offset address: 9214_H

VDDEXT peak voltage detection status register LVDPMS2 Reset value: $0000\ 0000_H$

rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
THRESCOUNT					PEAKVOLT										
rh					rh										

Field	Bits	Type	Description
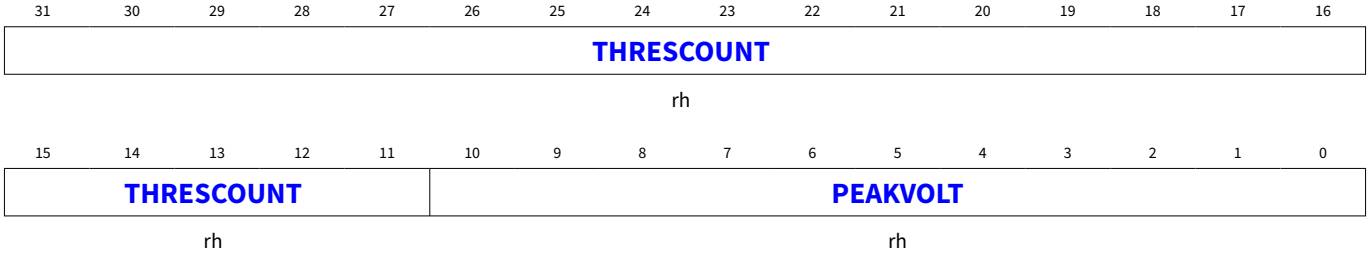
PEAKVOLT	10:0	rh	**Peak voltage detected value** This bit-field indicates the peak value detected for the respective supply voltage. Expressed as number of LSBs of the secondary monitor ADC for the respective supply voltage. Peak Voltage = [LSB * (VxxPVDVAL-1)] ; LSB = tbd mV
THRESCOUNT	31:11	rh	**Detected sample count above configured threshold value** This bit-field indicates the number of voltage samples which were detected, after filtering, above the configured threshold value (PVDVxxTHR).

36.4.28 VDDEXT peak voltage detection history status register

PEAK_VDDEXTHISTSTAT Offset address: 9220_H

VDDEXT peak voltage detection history status register LVDPMS1 Reset value: $0000\ 0000_H$

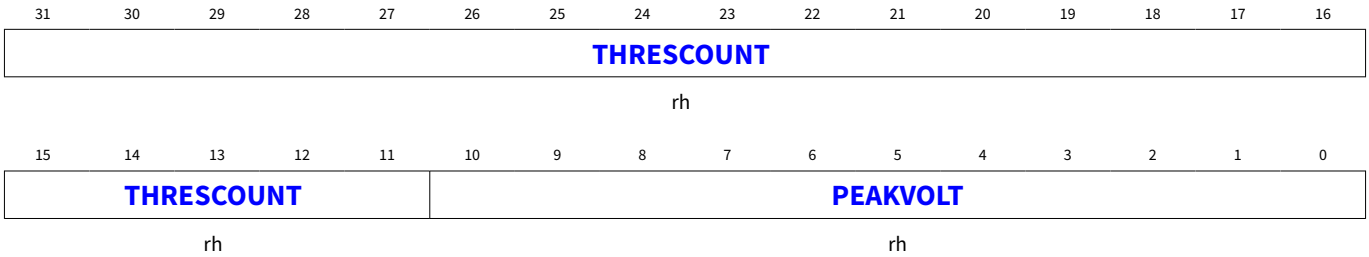


Field	Bits	Type	Description
PEAKVOLT	10:0	rh	**Peak voltage detected value** This bit-field indicates the peak value detected for the respective supply voltage. Expressed as number of LSBs of the secondary monitor ADC for the respective supply voltage. Peak Voltage = [LSB * (VxxPVDVAL-1)] ; LSB = tbd mV
THRESCOUNT	31:11	rh	**Detected sample count above configured threshold value** This bit-field indicates the number of voltage samples which were detected, after filtering, above the configured threshold value (PVDVxxTHR).

36.4.29 VDDEXTDC peak voltage detection history status register

PEAK_VDDEXTDCHISTSTAT Offset address: 9224_H

VDDEXTDC peak voltage detection history status register LVDPMS1 Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PEAKVOLT	10:0	rh	**Peak voltage detected value** This bit-field indicates the peak value detected for the respective supply voltage. Expressed as number of LSBs of the secondary monitor ADC for the respective supply voltage. Peak Voltage = [LSB * (VxxPVDVAL-1)] ; LSB = tbd mV
THRESCOUNT	31:11	rh	**Detected sample count above configured threshold value** This bit-field indicates the number of voltage samples which were detected, after filtering, above the configured threshold value (PVDVxxTHR).

36.4.30 VDD drift monitoring configuration register

DRMON_VDD Offset address: 9228_H

VDD drift monitoring configuration register LVDPMS2 Reset value: $0000\ 0000_H$

0	31:11	r	**Reserved** Read as 0.

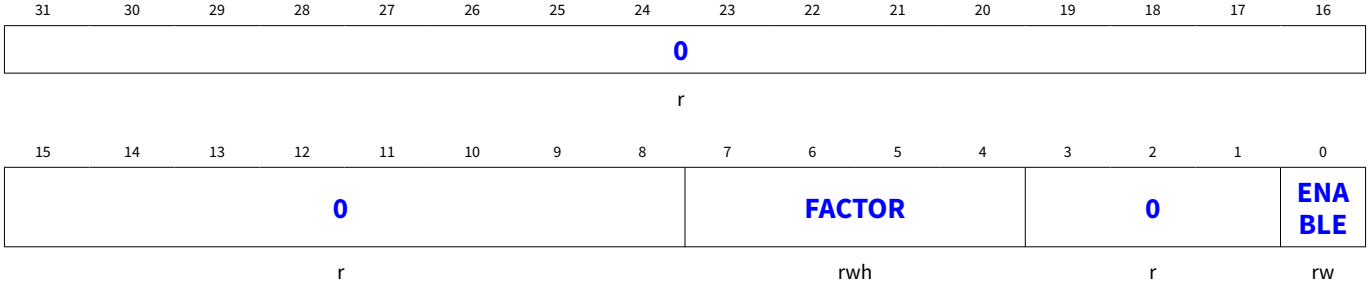
36.4.40 VDDPMS2 drift monitoring configuration register

DRMON_VDDPMS2 Offset address: 9250_H

VDDPMS2 drift monitoring configuration register LVDPMS2 Reset value: $0000\ 0000_H$

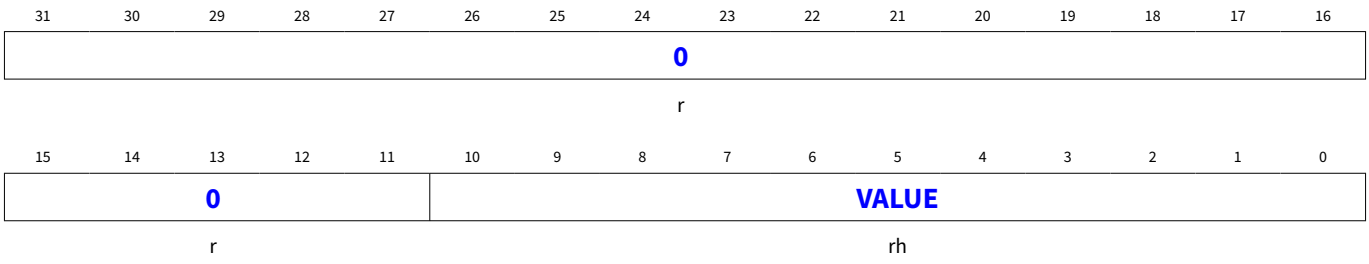


Field	Bits	Type	Description
ENABLE	0	rw	**Enable/disable drift monitoring**
FACTOR	7:4	rwh	**Exponent of the downsampling factor R** Downsampling factor R = 2^FACTOR.
0	3:1, 31:8	r	**Reserved** Read as 0; should be written with 0.

36.4.41 VDDPMS2 drift monitor status register

DRMON_VDDPMS2STAT Offset address: 9254_H

VDDPMS2 drift monitor status register LVDPMS2 Reset value: $0000\ 0000_H$

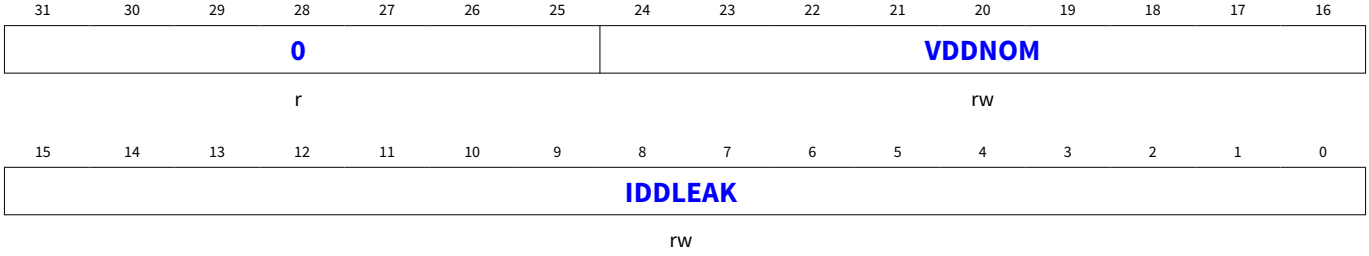


Field	Bits	Type	Description
VALUE	10:0	rh	**Accumulated filtered value** This bit-field indicates the supply voltage filtered value accumulated for drift monitoring. Expressed as number of LSBs of the voltage monitoring ADC for the respective rail.
0	31:11	r	**Reserved** Read as 0.

36.4.42 Voltage ID (VID) configuration register 0

VID_CON0 Offset address: 9258_H

Voltage ID [VID] configuration register 0 Reset values see: Table 1447



Field	Bits	Type	Description
IDDLEAK	15:0	rw	**Leakage current at 127°C** Total leakage current $I_{DD} + I_{DDPHYx}$ for this device, measured at T_j=127°C, at the lower nominal V_{DD} voltage level as documented in the data sheet operating conditions. LSB= 1mA
VDDNOM	24:16	rw	**Nominal VDD voltage level** V_{DD} nominal voltage level = VDDNOM * LSB LSB = $V_{TRKCORELSB}$ data sheet parameter Only two values are allowed, either the V_{DD} value for Slow and POR samples,or the V_{DD} value for fast samples, according to the typical value documented in the data sheet. For fast devices, the lower typical V_{DD} voltage level as documented in the data sheet operating conditions is used (0x159). For slow and typical devices, the higher typical V_{DD} voltage level as documented in the data sheet operating conditions is used (0x16A).
0	31:25	r	**Reserved** Read as 0; should be written with 0.

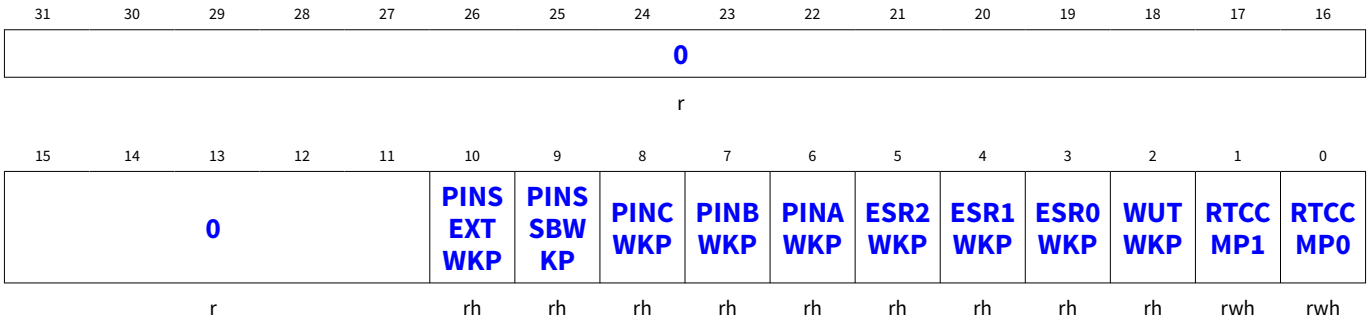
36.4.44 Interrupt status register

INT_STAT Offset address: 9278_H

Interrupt status register Reset values see: Table 1449



Field	Bits	Type	Description
RTCCMP0	0	rwh	**RTC CMP0 interrupt flag** In case interrupt was triggered by RTC event during RUN mode, this flag is set. The bit shall be cleared explicitly via INT_CLR.RTCCMP0INTCLR bit after interrupt is serviced. Application SW can also set this bit by writing 1 to it. 0_B No interrupt event detected from RTC. 1_B An interrupt event from RTC detected.
RTCCMP1	1	rwh	**RTC CMP1 interrupt flag** In case interrupt was triggered by RTC event during RUN mode, this flag is set. The bit shall be cleared explicitly via INT_CLR.RTCCMP1INTCLR bit after interrupt is serviced. Application SW can also set this bit by writing 1 to it. 0_B No interrupt event detected from RTC. 1_B An interrupt event from RTC detected.
WUTWKP	2	rh	**WUTWKP interrupt flag** In case interrupt was triggered by Wake-Up Timer (WUT) event during RUN mode, this flag is set. The bit shall be cleared explicitly via INT_CLR.WUTINTCLR bit after interrupt is serviced. 0_B No interrupt event detected from WUT. 1_B An interrupt event from WUT detected.
ESR0WKP	3	rh	**ESR0WKP interrupt flag** In case interrupt was triggered by ESR0 pin event during RUN mode, this flag is set. The bit shall be cleared explicitly via INT_CLR.ESR0INTCLR bit after interrupt is serviced. 0_B No interrupt event detected on ESR0 input. 1_B An interrupt event as defined by WAKEUP_CON1. ESR0EDCON detected on ESR0 input.
ESR1WKP	4	rh	**ESR1WKP interrupt flag** In case interrupt was triggered by ESR1 pin event during RUN mode, this flag is set. The bit shall be cleared explicitly via INT_CLR.ESR1INTCLR bit after interrupt is serviced. 0_B No interrupt event detected on ESR1 input. 1_B An interrupt event as defined by WAKEUP_CON1. ESR1EDCON detected on ESR1 input.

(table continues...)

(continued)

Field	Bits	Type	Description
ESR2WKP	5	rh	**ESR2WKP interrupt flag** In case interrupt was triggered by ESR2 pin event during RUN mode, this flag is set. The bit shall be cleared explicitly via INT_CLR.ESR2INTCLR bit after interrupt is serviced. 0_B No interrupt event detected on ESR2 input. 1_B An interrupt event as defined by WAKEUP_CON0.ESR2EDCON detected on ESR2 input.
PINAWKP	6	rh	**PINAWKP interrupt flag** In case interrupt was triggered by PINA pin event during RUN mode, this flag is set. The bit shall be cleared explicitly via INT_CLR.PINAINTCLR bit after interrupt is serviced. 0_B No interrupt event detected on Pin A input. 1_B An interrupt event as defined by WAKEUP_CON1. PINAEDCON detected on Pin A input.
PINBWKP	7	rh	**PINBWKP interrupt flag** In case interrupt was triggered by PINB pin event during RUN mode, this flag is set. The bit shall be cleared explicitly via INT_CLR.PINBINTCLR bit after interrupt is serviced. 0_B No interrupt event detected on the Pin B input. 1_B An interrupt event as defined by WAKEUP_CON0. PINBEDCON detected on Pin B input.
PINCWKP	8	rh	**PINCWKP interrupt flag** In case interrupt was triggered by PINC pin event during RUN mode, this flag is set. The bit shall be cleared explicitly via INT_CLR.PINCINTCLR bit after interrupt is serviced. 0_B No interrupt event detected on the Pin C input. 1_B An interrupt event as defined by WAKEUP_CON0. PINCEDCON detected on Pin C input.
PINSSBWKP	9	rh	**PINSSBWKP interrupt flag** 0_B No interrupt event detected on the $V_{DDEVRSB}$ pins input. 1_B An interrupt event as detected on $V_{DDEVRSB}$ pins input.
PINSEXTWKP	10	rh	**PINSEXTWKP interrupt flag** 0_B No interrupt event detected on the V_{DDEXT} pins input. 1_B An interrupt event as detected on V_{DDEXT} pins input.
0	31:11	r	**Reserved** Read as 0.

0								PORSTDFEN		ESR2WKPRUNPD	ESR0PD	SBTRIST_P	SBTRIST	ALLTRIST_P	ALLTRIST
r								rw		rw	rw	w	rwh	w	rwh

Field	Bits	Type	Description
ALLTRIST	0	rwh	**Tristate enable for all pads** This bit decides whether pads behave as inputs with weak pull-up or tristate on reset assertion/de-assertion or Standby- Wake-up transition. After supply ramp-up or LVD reset, ALLTRIST = ! HWCFG[6]. 0_B No request to switch the input pad state of all the pads to tristate from pull-up (default reset state) 1_B Pad domain in tristate.

(table continues...)

(continued)

Field	Bits	Type	Description
ALLTRIST_P	1	w	**Bit protection for ALLTRIST** Writing 1 into this bit enables that ALLTRIST bit can be changed in the same write operation. 0_B TRISTREQ keeps the previous state and cannot be changed. 1_B TRISTREQ bit can be changed with a write operation.
SBTRIST	2	rwh	**Tristate enable for standby pads** This bit decides whether Standby pads behave as inputs with weak pull-up or tristate on reset assertion/de-assertion or Standby- Wake-up transition. After supply ramp-up or LVD reset, SBTRIST = ! HWCFG[6]. 0_B No request to switch the input pad state of all the pads to tristate from pull-up (default reset state) 1_B Pad domain in tristate.
SBTRIST_P	3	w	**Bit protection for SBTRIST** Writing 1 into this bit enables that SBTRIST bit can be changed in the same write operation. 0_B TRISTREQ keeps the previous state and cannot be changed. 1_B TRISTREQ bit can be changed with a write operation.
ESR0PD	4	rw	**ESR0 pull-down enable** This bit configures ESR0 pin behavior either as reset output (pull-down) or tristate/pull-up during Standby mode if VDDEXT is supplied. 0_B ESR0 configured as tristate or pull-up (depending on ALLTRIST setting) during Standby state 1_B ESR0 in pull-down state during Standby state.
ESR2WKPRUNPD	5	rw	**ESR2 is pulled down in case of STBY to RUN transition** 0_B No pull low. 1_B Pulled low during STBY to RUN transition. The deassertion of active pull down is delayed by maximum of 1 clock cycle of 70KHz clock once the STBY to RUN transition is completed

(table continues...)

(continued)

Field	Bits	Type	Description
PORSTDFEN	7:6	rw	**PORST digital filter enable** This bit field enables additional PORST digital filter ($t_{PORSTDF}$ parameter) to provide enhanced immunity against spurious spikes. 00_B PORST recognition delay = Analog PORST pad filter delay (see t_{SF2} data sheet parameter). 01_B PORST recognition delay = Analog PORST pad filter delay (see t_{SF2} data sheet parameter) + digital filter delay. If the system is in RUN or STANDBY1 mode at 100MHz, then the digital filter delay is ~800ns (20 clock cycles of 25MHz). Otherwise (system runs at 70kHz), the digital filter delay is ~28.6us (2 clock cycles of 70kHz). Exception: When PORST is used for waking up from standby, the digital filter delay is always ~28.6us (2 clock cycles of 70kHz). 10_B PORST recognition delay = Analog PORST pad filter delay (see t_{SF2} data sheet parameter) + digital filter delay. If the system is in RUN or STANDBY1 mode at 100MHz, then the digital filter delay is ~8.1us (203 clock cycles of 25MHz). Otherwise (system runs at 70kHz), the digital filter delay is ~28.6us (2 clock cycles of 70kHz). Exception: When PORST is used for waking up from standby, the digital filter delay is always ~28.6us (2 clock cycles of 70kHz). 11_B Reserved

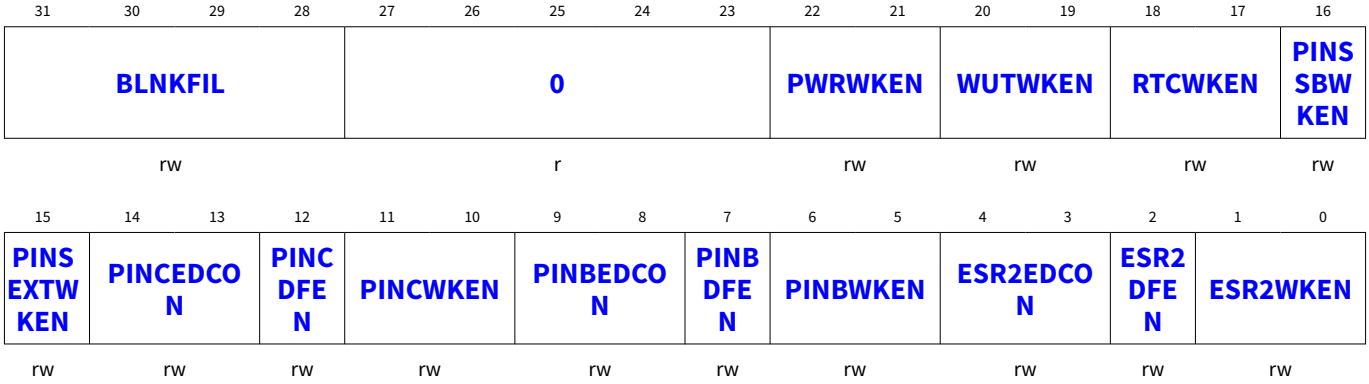
36.4.51 Wake-up configuration register 0

Before accessing, check the REGACCSTAT.FIFOEMPTY and REGACCSTAT.FIFOFULL status as described in the user manual (LVD reset section).

WAKEUP_CON0 Offset address: $92AC_H$

Wake-up configuration register 0 Reset values see: Table 1456



Field	Bits	Type	Description
ESR2WKEN	1:0	rw	**ESR2 wake-up enable from standby** These bits configure wake-up via ESR2 pin from STANDBY mode. 00_B Wake-up via ESR2 pin is disabled. 01_B Wake-up via ESR2 pin from any standby mode directly to RUN mode is enabled. 10_B Wake-up via ESR2 pin from STANDBY0 to STANDBY1 mode is enabled. 11_B Sequential wake-up via ESR2 pin from STANDBY0: Wake-up from STANDBY0 to STANDBY1, setting the WAKEUP_STAT0.ESR2WKP flag. Subsequent wake-up from STANDBY1 to RUN mode, setting the WAKEUP_STAT0.ESR2OVRUN flag.
ESR2DFEN	2	rw	**ESR2 digital filter enable** This bit activates digital spike filter. If the digital filter (majority filter of 3 consecutive values, running on the 70 kHz standby clock) is enabled, then pulses less than 5 µs are suppressed and pulses longer than 50 µs will always result in a trigger. 0_B The filter is bypassed 1_B The filter is used
ESR2EDCON	4:3	rw	**ESR2 edge detection control** This bit field defines the edge of a ESR2 wake-up trigger 00_B No trigger is generated 01_B A trigger is generated upon a rising edge 10_B A trigger is generated upon a falling edge 11_B A trigger is generated upon a rising OR falling edge

(table continues...)

(continued)

Field	Bits	Type	Description
PINBWKEN	6:5	rw	**Pin B wake-up enable from standby** These bits configure wake-up via PINB pin from STANDBY mode. 00_B System wake-up via Pin B is disabled. 01_B Wake-up via Pin B from any standby mode directly to RUN mode is enabled. 10_B Wake-up via Pin B from STANDBY0 to STANDBY1 mode is enabled. 11_B Sequential wake-up via Pin B from STANDBY0: Wake-up from STANDBY0 to STANDBY1, setting the WAKEUP_STAT0.PINBWKP flag. Subsequent wake-up from STANDBY1 to RUN mode, setting the WAKEUP_STAT0.PINBOVRUN flag.
PINBDFEN	7	rw	**PINB digital filter enable** This bit activates digital spike filter. If the digital filter (majority filter of 3 consecutive values, running on the 70 kHz standby clock) is enabled, then pulses less than 5 µs are suppressed and pulses longer than 50 µs will always result in a trigger. 0_B The filter is bypassed 1_B The filter is used
PINBEDCON	9:8	rw	**PINB edge detection control** This bit field defines the edge of a Pin B wake-up trigger 00_B No trigger is generated 01_B A trigger is generated upon a rising edge 10_B A trigger is generated upon a falling edge 11_B A trigger is generated upon a rising OR falling edge
PINCWKEN	11:10	rw	**Pin C wake-up enable from standby** These bits configure wake-up via PINC pin from STANDBY mode. 00_B Wake-up via Pin C is disabled. 01_B Wake-up via Pin C from any standby mode directly to RUN mode is enabled. 10_B Wake-up via Pin C from STANDBY0 to STANDBY1 mode is enabled. 11_B Sequential wake-up via Pin C from STANDBY0: Wake-up from STANDBY0 to STANDBY1, setting the WAKEUP_STAT0.PINCWKP flag. Subsequent wake-up from STANDBY1 to RUN mode, setting the WAKEUP_STAT0.PINCOVRUN flag.
PINCDFEN	12	rw	**PINC digital filter enable** This bit activates digital spike filter. If the digital filter (majority filter of 3 consecutive values, running on the 70 kHz standby clock) is enabled, then pulses less than 5 µs are suppressed and pulses longer than 50 µs will always result in a trigger. 0_B The filter is bypassed 1_B The filter is used

(table continues...)

(continued)

Field	Bits	Type	Description
PINCEDCON	14:13	rw	**PINC edge detection control** This bit field defines the edge of a Pin C wake-up trigger 00_B No trigger is generated 01_B A trigger is generated upon a rising edge 10_B A trigger is generated upon a falling edge 11_B A trigger is generated upon a rising OR falling edge
PINSEXTWKEN	15	rw	**VDDEXT pins wake-up enable from standby** These bits configure wake-up via VDDEXT pins from STANDBY mode. 0_B Wake-up via VDDEXT pins is disabled. 1_B Wake-up via VDDEXT pins from any standby mode directly to RUN mode is enabled.
PINSSBWKEN	16	rw	**VDDEVRSB pins wake-up enable from standby** These bits configure wake-up via VDDEVRSB pins from STANDBY mode. 0_B Wake-up via VDDEVRSB pins is disabled. 1_B Wake-up via VDDEVRSB pins from any standby mode directly to RUN mode is enabled.
RTCWKEN	18:17	rw	**RTC wake-up enable from standby** These bits configure wake-up via RTC from STANDBY mode. 00_B Wake-up via RTC is disabled. 01_B Wake-up via RTC from any standby mode directly to RUN mode is enabled. 10_B Wake-up via RTC from STANDBY0 to STANDBY1 mode is enabled. 11_B Sequential wake-up via RTC from STANDBY0: Wake-up from STANDBY0 to STANDBY1, setting the WAKEUP_STAT0.RTCWKP flag. Subsequent wake-up from STANDBY1 to RUN mode, setting the WAKEUP_STAT0.RTCOVRUN flag.
WUTWKEN	20:19	rw	**WUT wake-up enable from standby** These bits configure wake-up via WUT from STANDBY mode. 00_B Wake-up via WUT is disabled. 01_B Wake-up via WUT from any standby mode directly to RUN mode is enabled. 10_B Wake-up via WUT from STANDBY0 to STANDBY1 mode is enabled. 11_B Sequential wake-up via WUT from STANDBY0: Wake-up from STANDBY0 to STANDBY1, setting the WAKEUP_STAT0.WUTWKP flag. Subsequent wake-up from STANDBY1 to RUN mode, setting the WAKEUP_STAT0.WUTOVRUN flag.

(table continues...)

(continued)

Field	Bits	Type	Description
PWRWKEN	22:21	rw	**Standby wake-up enable on VDDEXT supply ramp-up** This bit field enables wake-up on VDDEXT supply ramp-up after blanking filter time has expired. This is supported only in case Standby domain is supplied separately via VDDEVRSB supply pin and VDDEXT rail is switched off during Standby. 00_B Wake-up on VDDEXT supply ramp-up is disabled. Blanking filter configuration has no effect. 01_B Wake-up on VDDEXT supply ramp-up from any standby mode directly to RUN mode, after blanking filter time expiry, is enabled. 10_B Wake-up on VDDEXT supply ramp-up from STANDBY0 to STANDBY1 mode, after blanking time expiry, is enabled. 11_B Reserved
BLNKFIL	31:28	rw	**Blanking filter delay for wake-up** This bitfield enables a nominal blanking filter delay time immediately after Standby entry only after which a valid wake-up event is recognized and reacted upon. The actual delay may vary +- 30% to this nominal value. ***Note**: All other bit combinations are reserved. Incase WUT is used as a wake-up source, the blanking filter should be configured for a period greater than 0 µs.* 0_H 0 µs 1_H ~156 µs 2_H 1,25 ms 3_H 2,5 ms 4_H 5 ms 5_H 10 ms 6_H 20 ms 7_H 40 ms 8_H 80 ms 9_H 160 ms A_H 320 ms B_H 640 ms C_H 1280 ms D_H 2560 ms
0	27:23	r	**Reserved** Read as 0; should be written with 0.

Field	Bits	Type	Description
ESR2WKP	0	rh	**ESR2 wake-up flag** In case wake-up was triggered by ESR2 pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR0.ESR2WKPCLR bit before next STANDBY entry. 0_B No wake-up event detected on ESR2 input during STANDBY. 1_B An event as defined by WAKEUP_CON0.ESR2EDCON detected on ESR2 input.
PINBWKP	1	rh	**Pin B wake-up flag** In case wake-up was triggered by PINB pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR0.PINBWKPCLR bit before next STANDBY entry. 0_B No wake-up event occurred on the Pin B input during STANDBY. 1_B An event as defined by WAKEUP_CON0. PINBEDCON detected on Pin B input.
PINCWKP	2	rh	**Pin C wake-up flag** In case wake-up was triggered by PINC pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR0.PINCWKPCLR bit before next STANDBY entry. 0_B No wake-up event occurred on the Pin C input during STANDBY. 1_B An event as defined by WAKEUP_CON0. PINCEDCON detected on Pin C input.
PINSEXTWKP	3	rh	**VDDEXT pins wake-up flag** In case wake-up was triggered by VDDEXT pins during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR0.PINSEXTWKPCLR bit before next STANDBY entry. 0_B No wake-up event occurred on the VDDEXT pins input during STANDBY. 1_B An event detected on VDDEXT pins input.

(table continues...)

(continued)

Field	Bits	Type	Description
PINSSBWKP	4	rh	**VDDEVRSB pins wake-up flag** In case wake-up was triggered by VDDEVRSB pins during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR0.PINSSBWKPCLR bit before next STANDBY entry. 0_B No wake-up event occurred on the VDDEXT pins input during STANDBY. 1_B An event detected on VDDEVRSB pins input.
RTCWKP	5	rh	**RTC wake-up flag** In case wake-up was triggered by RTC during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR0.RTCWKPCLR bit before next STANDBY entry. 0_B No wake-up event detected due to RTC underflow. 1_B A wake-up event from STANDBY was detected due to RTC underflow.
WUTWKP	6	rh	**WUT wake-up flag** In case wake-up was triggered by Wake-up timer during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR0.WUTWKPCLR bit before next STANDBY entry. 0_B No wake-up event detected due to WUT underflow. 1_B A wake-up event from STANDBY was detected due to WUT underflow.
PWRWKP	7	rh	**Wake-up event on VDDEXT supply ramp-up** In case wake-up was triggered by VDDEXT ramp-up pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR0.PWRWKPCLR bit before next STANDBY entry. 0_B No VDDEXT supply wake-up event detected. 1_B VDDEXT monitor threshold exceeded on VDDEXT supply ramp-up leading to system wake-up from STANDBY.
ESR2OVRUN	16	rh	**ESR2 overrun status flag** This flag indicates that a consecutive ESR2 wake-up event occurred while ESR2WKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR0.ESR2OVRUNCLR bit before next STANDBY entry. 0_B No overrun condition detected on ESR1 input. 1_B An overrun condition detected on ESR1 input.
PINBOVRUN	17	rh	**Pin B overrun status flag** This flag indicates that a consecutive PINB wake-up event occurred while PINBWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR0.PINBOVRUNCLR bit before next STANDBY entry. 0_B No overrun condition detected on Pin B input. 1_B An overrun condition detected on Pin B input.

(table continues...)

(continued)

Field	Bits	Type	Description
PINCOVRUN	18	rh	**Pin C overrun status flag** This flag indicates that a consecutive PINC wake-up event occurred while PINCWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR0.PINCOVRUNCLR bit before next STANDBY entry. 0_B No overrun condition detected on Pin C input. 1_B An overrun condition detected on Pin C input.
RTCOVRUN	19	rh	**RTC overrun status flag** This flag indicates that a consecutive RTC wake-up event occurred while RTCWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR0.RTCOVRUNCLR bit before next STANDBY entry. 0_B No overrun condition detected of RTC events. 1_B An overrun condition detected of RTC events.
WUTOVRUN	20	rh	**WUT overrun status flag** This flag indicates that a consecutive WUT wake-up event occurred while WUTWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR0.WUTOVRUNCLR bit before next STANDBY entry. WUT_CON.RELOAD need to be greater than 10 during Standby mode to be able to latch consecutive WUT underflow events and update the WUTOVRUN register bitfield. 0_B No overrun condition detected of WUT events. 1_B An overrun condition detected of WUT events.
0	15:8, 31:21	r	**Reserved** Read as 0.

0											POR STW KP	SCR WKP	PINA WKP	ESR1 WKP	ESR0 WKP
r											rh	rh	rh	rh	rh

Field	Bits	Type	Description
ESR0WKP	0	rh	**ESR0 wake-up flag** In case wake-up was triggered by ESR0 pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR1.ESR0WKPCLR bit before next STANDBY entry. 0_B No wake-up event detected on ESR0 input during STANDBY. 1_B An event as defined by WAKEUP_CON1. ESR0EDCON detected on ESR0 input.
ESR1WKP	1	rh	**ESR1 wake-up flag** In case wake-up was triggered by ESR1 pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR1.ESR1WKPCLR bit before next STANDBY entry. 0_B No wake-up event detected on ESR1 input during STANDBY. 1_B An event as defined by WAKEUP_CON1.ESR1EDCON detected on ESR1 input.
PINAWKP	2	rh	**Pin wake-up flag** In case wake-up was triggered by PINA pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR1.PINAWKPCLR bit before next STANDBY entry. 0_B No wake-up event detected on Pin A input during STANDBY. 1_B An event as defined by WAKEUP_CON1. PINAEDCON detected on Pin A input.
SCRWKP	3	rh	**SCR wake-up flag** In case wake-up is triggered by SCR to the main controller during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR1.SCRWKPCLR bit before next STANDBY entry. 0_B No SCR wake-up event detected. 1_B A SCR wake-up event occurred.
PORSTWKP	4	rh	**PORST wake-up flag** In case wake-up was triggered by PORST pin during STANDBY, this flag is set. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR1.PORSTWKPCLR bit before next STANDBY entry. 0_B No wake-up event detected on PORST input during STANDBY if enabled via WAKEUP_CON1.PORSTWKEN bit. 1_B A wake-up event detected on PORST input if enabled via WAKEUP_CON1.PORSTWKEN bit.
ESR0OVRUN	16	rh	**ESR0 overrun status flag** This flag indicates that a consecutive ESR0 wake-up event occurred while ESR0WKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR1.ESR0OVRUNCLR bit before next STANDBY entry. 0_B No overrun condition detected on ESR0 input. 1_B An overrun condition detected on ESR0 input.

(table continues...)

(continued)

Field	Bits	Type	Description
ESR1OVRUN	17	rh	**ESR1 overrun status flag** This flag indicates that a consecutive ESR1 wake-up event occurred while ESR1WKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR1.ESR1OVRUNCLR bit before next STANDBY entry. 0_B No overrun condition detected on ESR1 input. 1_B An overrun condition detected on ESR1 input.
PINAOVRUN	18	rh	**Pin A overrun status flag** This flag indicates that a consecutive PINA wake-up event occurred while PINAWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR1.PINAOVRUNCLR bit before next STANDBY entry. 0_B No overrun condition detected on Pin A input. 1_B An overrun condition detected on Pin A input.
SCROVRUN	19	rh	**SCR overrun status flag** This flag indicates that a consecutive SCR wake-up event occurred while SCRWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR1.SCROVRUNCLR bit before next STANDBY entry. 0_B No overrun condition detected of SCR wake-up event. 1_B An overrun condition detected of SCR wake-up event.
PORSTOVRUN	20	rh	**PORST overrun status flag** This flag indicates that a consecutive PORST wake-up event occurred while PORSTWKP flag was already set during STANDBY. The bit shall be cleared explicitly after wakeup via WAKEUP_CLR1.PORSTOVRUNCLR bit before next STANDBY entry. 0_B No overrun condition detected on PORST input if enabled via WAKEUP_CON1.PORSTWKEN bit. 1_B An overrun condition detected on PORST input if enabled via WAKEUP_CON1.PORSTWKEN bit.

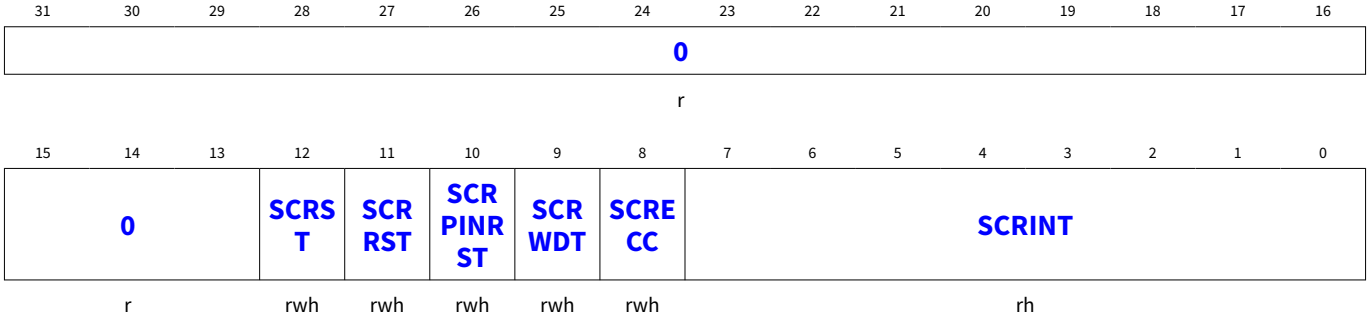
36.4.62 SCR status register

Write access protected by module-specific ("M") protection, as follows:

- When SCR_CON0.SCREN=0, write access to SCR_STAT register is blocked.
- In order to write into the SCR_STAT register, proceed as follows:
- If SCR_CON0.SCREN=0, then enable the SCR by writing SCR_CON0.SCREN=1
- Poll REGACCSTAT.FIFOEMPTY until FIFOEMPTY=1
- Then write into SCR_STAT as needed.

SCR_STAT Offset address: $92DC_H$

SCR status register LVDPMS1 Reset value: $0000\ 1000_H$



Field	Bits	Type	Description
SCRINT	7:0	rh	**Data exchange from standby controller to PMS main domain** This bit field allows fast data exchange from SCR to PMS/CPUx. The data maybe read by CPUx consequent to an interrupt from the SCR to decode the interrupt. Incase SCR is enabled, at the end of the SCR Firmware routine, a value of 80H is set in SCRINT register to indicate that SCR has finished executing the startup code.
SCRECC	8	rwh	**SCR RAM ECC error / reset flag** ***Note**: The flag is set by SCR and cleared by explicit write to the register bit. The flag is not cleared by SCR. If reset trigger by SCR RAM ECC error is enabled in SCR, this flag is set.* 0_B No ECC error / reset reported by SCR. 1_B ECC error / reset was detected in SCR RAM.
SCRWDT	9	rwh	**SCR watchdog timer error / reset flag** ***Note**: The flag is set by SCR and cleared by explicit write to the register bit. The flag is not cleared by SCR. If reset trigger by SCR WDT error is enabled in SCR, this flag is set.* 0_B No WDT error / reset reported by SCR. 1_B WDT timer error / reset reported by SCR.
SCRPINRST	10	rwh	**SCR pin reset flag** ***Note**: The flag is set by SCR and cleared by explicit write to the register bit. The flag is not cleared by SCR. When the SCR is being reset triggered by SCR pin, this flag is set.* 0_B No reset occurred in SCR. 1_B A reset has occurred in SCR.
SCRRST	11	rwh	**SCR software reset flag** ***Note**: The flag is set by SCR and cleared by explicit write to the register bit. The flag is not cleared by SCR. When the SCR is being reset triggered by SCR software, this flag is set.* 0_B No reset occurred in SCR. 1_B A reset has occurred in SCR.

(table continues...)

(continued)

Field	Bits	Type	Description
SCRST	12	rwh	**Standby controller reset indication flag** This bit is set after a power-on reset as SCR is in reset state. This bit is consequently set when a reset is issued via SCR_CON1.SCRSTREQ bit. This status flag is set on every SCR reset caused by any SCR reset source. This flag cannot be cleared while the SCR reset is active. The SCR reset is active for four PCLK cycles (SCR clock PCLK). 0_B No reset of Standby controller took place. 1_B Reset of Standby controller took place.
0	31:13	r	**Reserved** Read as 0.

36.4.63 EVRC status register 1

The EVRC status registers EVRC_STATx are updated during start-up and operation with the actual EVRC status and therefore the read value may differ from the reset value.

EVRC_STAT1 Offset address: $92E4_H$

Field	Bits	Type	Description
SYNCHYST	22:17	rw	**Lock and unlock hysteresis window** This bitfield defines the hysteresis window for synchronization locking and unlocking. The limit is applied to the period counter running at 100 MHz. Upper unlock condition= SDFREQ + SYNCMAXDEV Upper lock condition= SDFREQ + SYNCMAXDEV - SYNCHYST Lower unlock condition = SDFREQ - SYNCMAXDEV Lower lock condition = SDFREQ - SYNCMAXDEV + SYNCHYST SYNCHYST = round [df_{HYST} * (SDFREQ ± SYNCMAXDEV)^2 / [100MHz ± df_{HYST} * (SDFREQ ± SYNCMAXDEV)]] First hysteresis band: df_{HYST} = 100 MHz / (SDFREQ + SYNCMAXDEV - SYNCHYST) - 100MHz / (SDFREQ + SYNCMAXDEV) Second hysteresis band: df_{HYST} = 100 MHz / (SDFREQ - SYNCMAXDEV) - 100MHz / (SDFREQ - SYNCMAXDEV + SYNCHYST)
SYNCMAXDEV	29:23	rw	**Maximum deviation of the synchronization input frequency** This bitfield defines the maximum allowed frequency deviation of the synchronization input signal frequency from the programmed nominal DCDC switching frequency (EVRC_CON1.SDFREQ). Violation of limit leads to loss of synchronization.The frequency window is defined as follows df_{MAXDEV} = 100 MHz *(2*SYNCMAXDEV) / (SDFREQ^2-SYNCMAXDEV^2) SYNCMAXDEV = round [sqrt((100 MHz / df_{MAXDEV})^2 + SDFREQ^2) - (100 MHz / df_{MAXDEV})]
0	31:30	r	**Reserved** Read as 0; should be written with 0.

SHLEN	1	rw	**Short-to-low detection enable** 0_B Short-to-low detection disabled 1_B Short-to-low detection enabled
SHOFFEN	2	rw	**Enable bit for EVRC switch-off upon short detection** This bit enables the switch-off of the EVRC regulator after a delay of ~3ms after an EVRC short-circuit condition has been detected (either to high-voltage or to low-voltage). 0_B EVRC is not switched off after a short detection. 1_B EVRC is switched off after a short detection.

(table continues...)

(continued)

Field	Bits	Type	Description
SHHTHR	11:4	rw	**Short-to-high detection threshold** This bit-field sets the threshold for the short to high voltage detection. The threshold value is (EVRC_CON0.SDVOUTSEL + EVRC_CON2.SHHTHR) * $V_{TRKCORELSB}$ (see data sheet parameter).
SHLTHR	19:12	rw	**Short-to-low detection threshold** This bit-field sets the threshold for the short to low voltage detection. The threshold value is: (EVRC_CON0.SDVOUTSEL - EVRC_CON2.SHLTHR) * $V_{TRKCORELSB}$ (see data sheet parameter).
SHHTIM	23:20	rw	**Timeout for short-to-high detection** This bit-field sets the time duration, in milliseconds, until a short-to-high detection is triggered. The short-to-high condition must persist for at least the configured time, in order to trigger a short detection. LSB = 1 ms
SHLTIM	27:24	rw	**Timeout for short-to-low detection** This bit-field sets the time duration, in milliseconds, until a short-to-low detection is triggered. The short-to-low condition must persist for at least the configured time, in order to trigger a short detection. LSB = 1 ms
0	3, 31:28	r	**Reserved** Read as 0; should be written with 0.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		VOLTOKLPF		VOLTOKTHR				0	SYNCDIVFAC			SYNCMUXSEL		SYNCOUT	SYNCIN
r		rw		rw				r	rw			rw		rw	rw

Field	Bits	Type	Description
SYNCIN	0	rw	**EVRC input synchronization enable** This bit enables the EVRC input synchronization to the external DCDCSYNCI input signal. When set to 1, the DCDC will start to lock to the external synchronization input signal. This EVRC Synchronization status is indicated in EVRC_STAT0.SYNCLCK status bits. 0_B Synchronization of EVRC switching gate outputs to external input signal is disabled. 1_B Synchronization of EVRC switching gate outputs to external input signal is enabled.
SYNCOUT	1	rw	**EVRC DCDCSYNCO output synchronization enable** This bitfield enables the synchronization output DCDCSYNCO of the EVRC, to synchronize an external SMPS regulator to the internal EVRC regulator. 0_B DC-DC Synchronisation signal not available. 1_B DC-DC Synchronisation signal available.
SYNCMUXSEL	3:2	rw	**Synchronisation input multiplexer** This bitfield selects synchronisation input either from GTM or eGTM inputs to be forwarded to EVRC SMPS regulator. 00_B Synchronization input open or unconnected. 01_B eGTM 10_B GTM 11_B Reserved
SYNCDIVFAC	6:4	rw	**Switching frequency division factor for external synchronization** This bit field defines the divider factor for the SMPS switching output to generate the DCDCSYNCO output to synchronize an external regulator to the internal EVRC regulator. The signal is routed to the pin if enabled through EVRC_CON3.SYNCOUT bit. If the divider factor is changed while the output synchronization is enabled (EVRC_CON3.SYNCOUT=1), then the first period of the synchronization output signal (after the change) can be shorter than what both, the old and the new divider factor value, indicate. In cases where this behavior is not acceptable, the divider factor must not be changed when the output synchronization is enabled. All other combinations are reserved. 000_B $f_{DCDCSYNCO} = f_{DCDC}$. The actual duty cycle is routed. 001_B $f_{DCDCSYNCO} = f_{DCDC}/2$. Duty cycle is constant at 50%. 010_B $f_{DCDCSYNCO} = f_{DCDC}/4$. Duty cycle is constant at 50%. 011_B $f_{DCDCSYNCO} = f_{DCDC}/8$. Duty cycle is constant at 50%. 100_B $f_{DCDCSYNCO} = f_{DCDC}/16$. Duty cycle is constant at 50%. 101_B $f_{DCDCSYNCO} = f_{DCDC}/32$. Duty cycle is constant at 50%. **others,** Reserved
VOLTOKTHR	11:8	rw	**Threshold level for the voltage OK logic** This bitfield controls the threshold for the dection in the Voltage OK logic. It is expressed in ADC LSBs, nominally 2.83mV.

(table continues...)

(continued)

Field	Bits	Type	Description
VOLTOKLPF	13:12	rw	**Filter coefficient for the voltage OK logic** This bitfield controls the time constant of the Voltage OK filter. Larger values correspond to lower time constant of the filter.
0	7, 31:14	r	**Reserved** Read as 0; should be written with 0.

INTGOFFS				ZEROBIN				SKPLSTHR				0		RMPFFEN	SKPLSEN
rw				rw				rw				r		rw	rw

Field	Bits	Type	Description
SKPLSEN	0	rw	**Enable skip pulse feature** Enables the possibility to skip pulses in the PWM signal, in case of detection of large overshoots on the feedback voltage. The detection threshold can be set in the SKPLSTHR bitfield. When enabled, the switching frequency is allowed to momentarily change (i.e. decrease) during transients. 0_B 0: Skip pulse disabled 0_B 1: Skip pulse enabled
RMPFFEN	1	rw	**Enable feed-forward correction of artificial ramp slope** When enabled, the slope of the artificial ramp depends on the feed-forward voltage ($V_{DDEXTDC}$). 0_B 0: disabled. The slope of the artificial ramp is constant. 0_B 1: enabled. The slope of the artificial ramp is adapted based on the VDDEXTDC monitored value.

(table continues...)

(continued)

Field	Bits	Type	Description
SKPLSTHR	7:4	rw	**Skip pulse threshold** Digital representation of the threshold level needed to trigger a skip pulse. A larger value leads to larger threshold, decreasing the likelihood of a skip pulse.
ZEROBIN	11:8	rw	**Zero-bin setting** This bit-field adds an offset to the zero-bin, used in the integrator.
INTGOFFS	15:12	rw	**Initial offset of the integrator** Preloaded value that is used to initialize the integrator before the transition to PWM. It can be used to minimize the transients occurring at the transition from open-loop to closed-loop operation.
0	3:2, 31:16	r	**Reserved** Read as 0; should be written with 0.

Field	Bits	Type	Description
DRV5VNOVLRISE	31:28	rw	**Non-overlapping time (rising edge) between n-cmd and p-cmd** Non-overlapping time (expressed in clock cycles) added at the rising edge of the switching node between the turn-off of the external NMOS and the turn-on of the external PMOS in order to avoid shoot-through currents. Non-overlapping time (expressed in clock cycles) = (bits[3:1] + 1) + bit[0] * 0.5 Minimum value: 1 clock cycle

DRVFFHYS				DRVFFTHRES				DRVNCLAMPDEL				DRVPCLAMPDEL			
rw				rw				rw				rw			

Field	Bits	Type	Description
DRVPCLAMPDEL	3:0	rw	**Delay for clamping external PMOS** Delay, expressed in clock cycles, from the start of the switching phase after which clamping is applied, i.e. the strength DRVxxxPSTR is used.
DRVNCLAMPDEL	7:4	rw	**Delay for clamping external NMOS** Delay, expressed in clock cycles, from the start of the switching phase after which clamping is applied, i.e. the strength DRVxxxNSTR is used.
DRVFFTHRES	11:8	rw	**Driver feed-forward threshold** Threshold used to switch between 3V3 and 5V driver configuration based on feedforward voltage ($V_{DDEXTDC}$). The corresponding voltage can be calculated as: 2.83mV * (1166 + 32 * DRVFFTHRES) which results in a range from 3.3V to 4.65V.
DRVFFHYS	15:12	rw	**Driver feed-forward hysteresis** Hysteresis band applied when switching from 5V to 3V3 configuration. The corresponding voltage can be calculated as 2.83mV * 16 * DRVFFHYS.
MINTON	19:16	rw	**Minimum on time during PWM operation** This bit-field configures the minimum on-time within one switching period during closed loop operation. Expressed as number of 100MHz clock periods. The minimum on-time will be ignored if skip pulse is enabled and the skip pulse conditions are verified. MINTON = max(floor(EVRC_COEFF2.DRV3V3NOVLRISE[3:1] or EVRC_COEFF3.DRV5VNOVLRISE[3:1], depending on application voltage level), EVRC_COEFF5.DRVNBOOSTOFFDEL) + 1

(table continues...)

(continued)

Field	Bits	Type	Description
MINTOFF	23:20	rw	**Minimum off time during PWM operation** This bit-field configures the minimum off-time within one switching period during closed loop operation. Expressed as number of 100MHz clock periods. MINTOFF = max(floor(EVRC_COEFF2.DRV3V3NOVLFALL[3:1] or EVRC_COEFF3.DRV5VNOVLFALL[3:1], depending on application voltage level), EVRC_COEFF5.DRVPBOOSTOFFDEL) + 1

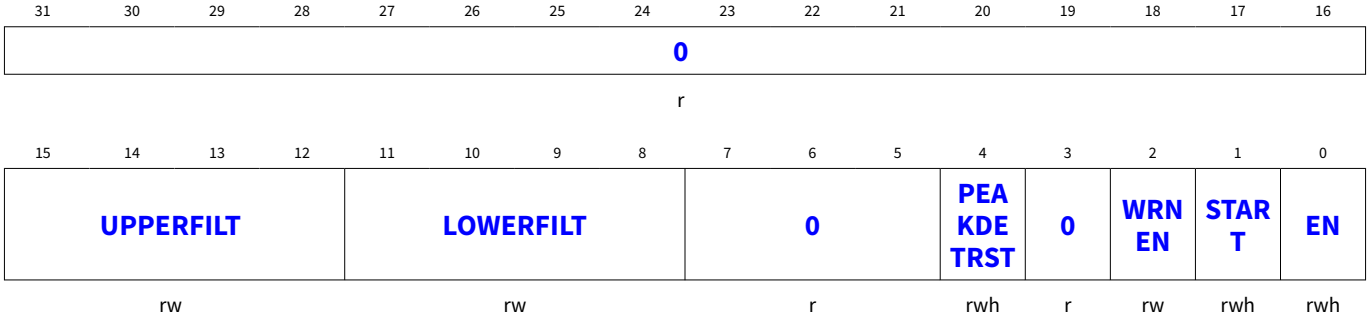
36.4.80 Die temperature sensor control register

DTS_CON Offset address: 9334_H

Die temperature sensor control register Reset values see: Table 1489



Field	Bits	Type	Description
EN	0	rwh	**DTS enable** This field is used to enable the DTS analog circuitry. 0_B DTS is disabled 1_B DTS is enabled
START	1	rwh	**ADC conversion control** This field is used to start DTS conversions. 0_B DTS conversion is stopped or stopping 1_B DTS conversion is started
WRNEN	2	rw	**Warning enable** This field is used as a global enable for all warnings/alarms. 0_B All warnings are disabled 1_B All warnings are enabled
PEAKDETRST	4	rwh	**DTS peak temperature detector reset** This field, when written with '1', resets the peak temperature detector. The bit is cleared to 0 after the peak temperature detector has been reset. 0_B Peak temperature detector is not reset 1_B Peak temperature detector is reset
LOWERFILT	11:8	rw	**Temperature-sensing mode warning filter** This field configures the filter length for generation of LLU warning/ alarm. Warning/alarm is triggered after RESULT goes under LOWER by (LOWERFILT + 1) consecutive conversions.
UPPERFILT	15:12	rw	**Temperature-sensing mode warning filter** This field configures the filter length for generation of UOF warning/ alarm. Warning/alarm is triggered after RESULT exceeds UPPER by (UPPERFILT + 1) consecutive conversions.
0	3, 7:5, 31:16	r	**Reserved** Read as 0; should be written with 0.

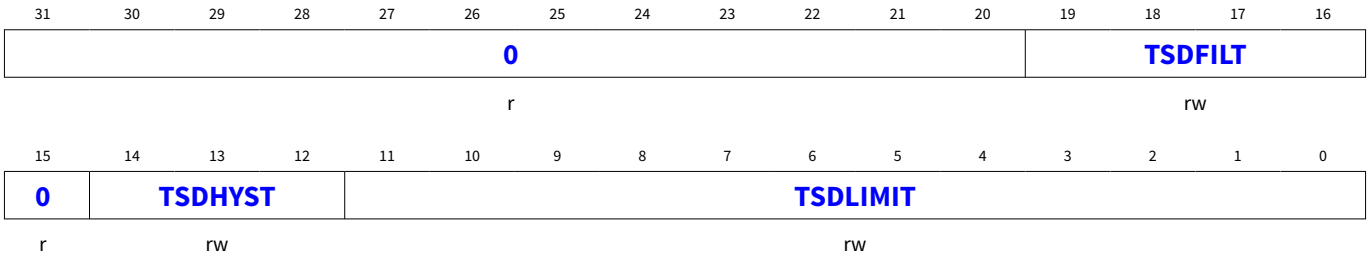
0	LOWERHYST			LOWER											
r	rw			rw											

Field	Bits	Type	Description
LOWER	11:0	rw	**DTS lower warning threshold** This field configures the falling threshold for LLU warning/alarm. (Default at -37°C)
LOWERHYST	14:12	rw	**Temperature-sensing mode warning hysteresis** This field configures the hysteresis for rising threshold of LLU warning/alarm, defined by (LOWER + LOWERHYST).
UPPER	27:16	rw	**DTS upper warning threshold** This field configures the rising threshold for UOF warning/alarm. (Default at 155°C)
UPPERHYST	30:28	rw	**Temperature-sensing mode warning hysteresis** This field configures the hysteresis for falling threshold of UOF warning/alarm, defined by (UPPER - UPPERHYST).
0	15, 31	r	**Reserved** Read as 0; should be written with 0.

36.4.82 Die temperature sensor limit register 2

DTS_LIM2 Offset address: 933C$_H$

Die temperature sensor limit register 2 LVDPMS1 Reset value: 0000 0850$_H$



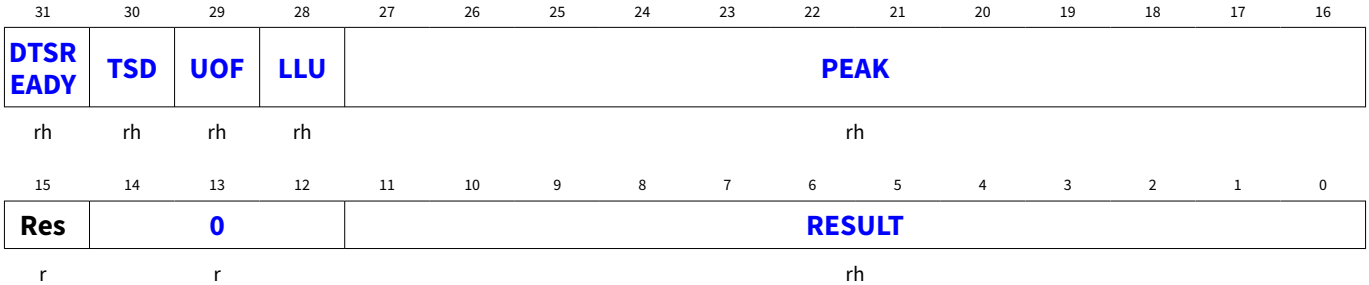
Field	Bits	Type	Description
TSDLIMIT	11:0	rw	**Temperature shut down warning threshold** This field configures the rising threshold for Temperature Shut down warning/alarm. (Default at 172°C)
TSDHYST	14:12	rw	**Temperature-sensing mode warning hysteresis** This field configures the hysteresis for falling threshold of TSD, defined by (TSDLIMIT - TSDHYST).
TSDFILT	19:16	rw	**Temperature-sensing mode warning filter** This field configures the filter length for generation of TSD warning/ alarm. Warning is triggered after RESULT exceeds TSDLIMIT by (TSDFILT + 1) consecutive conversions.
0	15, 31:20	r	**Reserved** Read as 0; should be written with 0.

36.4.83 Die temperature sensor status register

The DTS status register value is updated regularly by a polling state machine which periodically polls the local DTS status registers and transfers the data every 200us interval. The status register is updated ~5us after the conversion is completed at the local DTS instance.

DTS_STAT Offset address: 9340_H

Die temperature sensor status register LVDPMS1 Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RESULT	11:0	rh	**DTS result** This field contains the last temperature measurement result. This can be converted to temperature (in Kelvins) by dividing the readout by 4.781.

(table continues...)

(continued)

Field	Bits	Type	Description
PEAK	27:16	rh	**DTS peak temperature result** This field contains the peak temperature readout. This can be converted to temperature (Kelvins) by dividing by 4.781.
LLU	28	rh	**Low temperature warning** This field indicates if an under-temperature warning is active. 0_B Warning not active Last DTS result > DTSxLIM1.LOWER. 1_B Warning triggered Last DTS result ≤ DTSxLIM1.LOWER.
UOF	29	rh	**High temperature warning** This field indicates if an over-temperature warning is active. 0_B Warning not active Last DTS result < DTSxLIM1.UPPER. 1_B Warning triggered Last DTS result ≥ DTSxLIM1.UPPER.
TSD	30	rh	**Thermal shutdown warning** This field indicates if a thermal shutdown warning is active. 0_B Warning not active Last DTS result < DTSxLIM2.TSDLIMIT. 1_B Warning triggered Last DTS result ≥ DTSxLIM2.TSDLIMIT.
DTSREADY	31	rh	**Ready indicator** This bit is cleared when DTS is disabled, and will be set only after we have the first DTS conversion result. Any alarm generation is gated with this bit, to avoid interrupts/alarms from triggering before the first conversion is complete. 0_B DTS is disabled, or still starting up 1_B DTS has completed startup
0	14:12	r	**Reserved** Read as 0.

36.5 Debug information

This section describes the debug features available for the PMS functional block.

36.5.1 OCDS Trigger Bus (OTGB) Interface

This section describes the PMS signals and internal status information available on the debugging interface.

The PMS OTGB interface provides debugging information including:

- Primary voltage monitors ADC measurement values for all VMONP channels
- Secondary voltage monitors ADC measurement values for V_{DDPMS0} and V_{DDPMS2}
- Die temperature sensor (DTSPMS) measurement values
- Peak voltage detection measurement values
- Wake-up timer counter values
- RTC counter values
- EVRC voltages and status information

The next figure shows an overview of the interface, register bit-fields for selecting the debug output, and the available debug triggers:

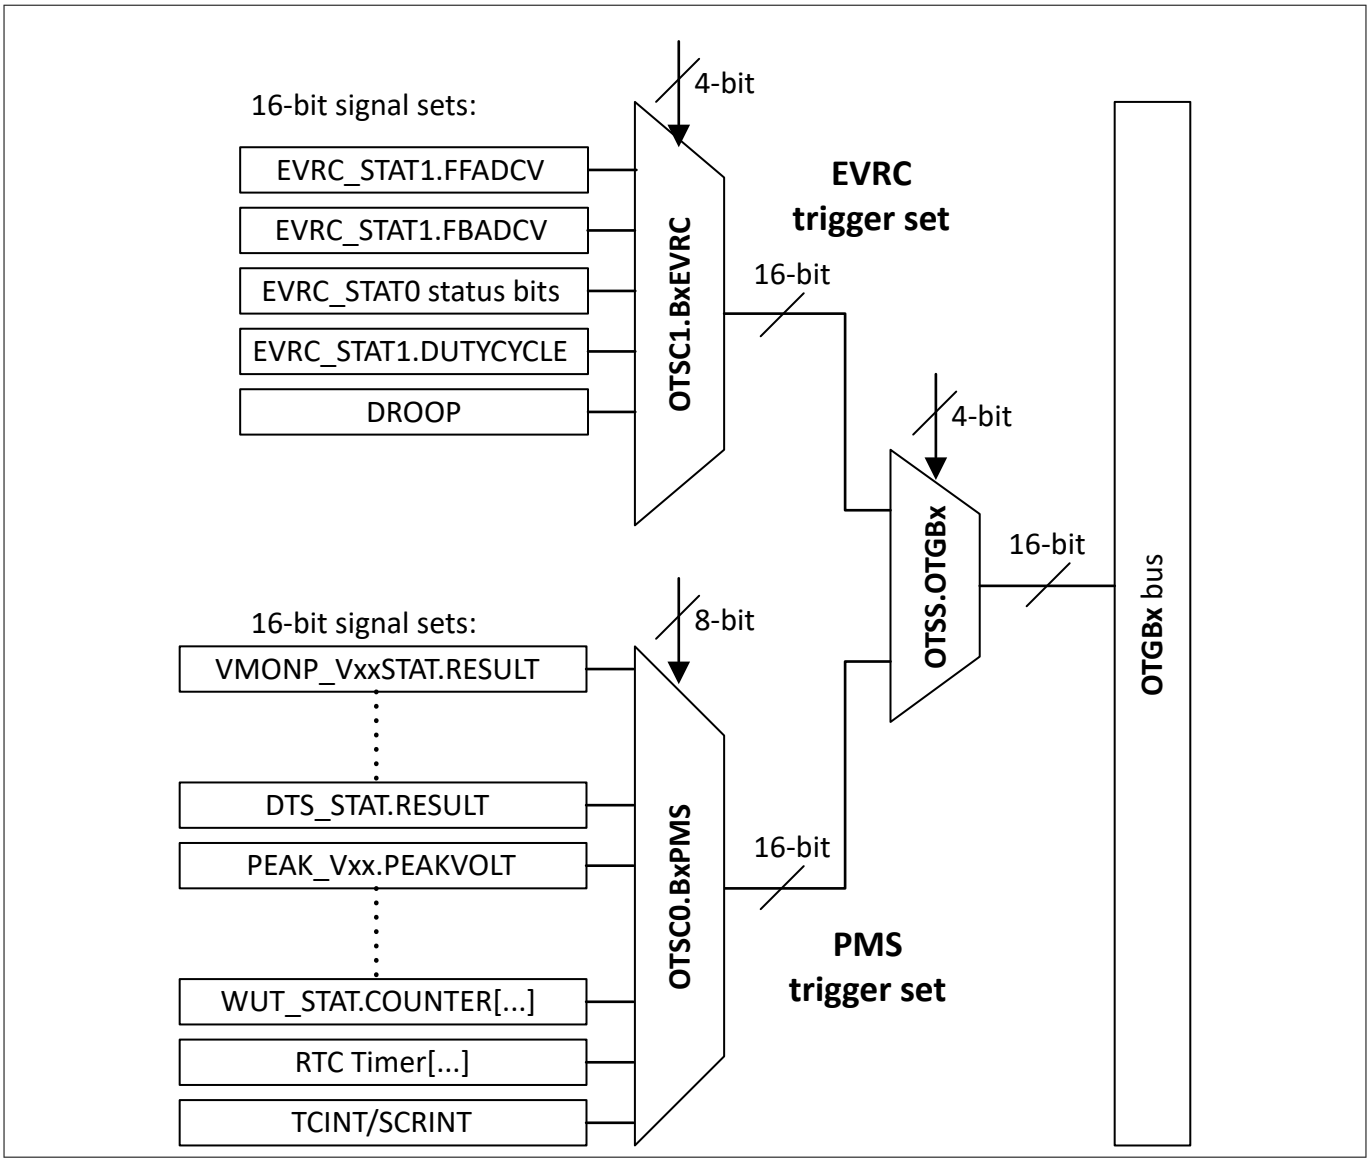

Figure 807 Overview of the PMS OTGB interface

The PMS OTGB interface module has two 16-bit trigger sets: the PMS and the EVRC trigger set. Each trigger set can be selected with the OTSS.OTGBx register bit-fields, for mapping to either OTGB0 or OTGB1 buses.

Table 1495 PMS trigger set

OTSC0.BxPMS selection	Bits	Description
VMONP_VDDSTAT.RESULT	[10:0]	Primary voltage monitor measurement result
VMONP_VDDEXTSTAT.RESULT	[10:0]	Primary voltage monitor measurement result
VMONP_VSSDCHSSTAT.RESULT	[10:0]	Primary voltage monitor measurement result
VMONP_VDDEXTDCSTAT.RESULT	[10:0]	Primary voltage monitor measurement result
VMONP_VDDDCLSSTAT.RESULT	[10:0]	Primary voltage monitor measurement result
VMONP_VDDEVRSBSTAT.RESULT	[10:0]	Primary voltage monitor measurement result
VMONP_VDDMSTAT.RESULT	[10:0]	Primary voltage monitor measurement result

(table continues...)

Table 1495 (continued) PMS trigger set

OTSC0.BxPMS selection	Bits	Description
VMONP_VDDPHPHY0STAT.RESULT	[10:0]	Primary voltage monitor measurement result
VMONP_VDDPHPHY1STAT.RESULT	[10:0]	Primary voltage monitor measurement result

VMONP_VDDPPUSTAT.RESULT	[10:0]	Primary voltage monitor measurement result
VMONP_VDDPHY0STAT.RESULT	[10:0]	Primary voltage monitor measurement result
VMONP_VDDPHY1STAT.RESULT	[10:0]	Primary voltage monitor measurement result
VMONP_VDDRIF0STAT.RESULT	[10:0]	Primary voltage monitor measurement result
VMONP_VDDPHY2STAT.RESULT	[10:0]	Primary voltage monitor measurement result
VMPONS_VDDPMS0STAT.RESULT	[10:0]	Secondary voltage monitor measurement result
VMPONS_VDDPMS2STAT.RESULT	[10:0]	Secondary voltage monitor measurement result
DTS_STAT.RESULT	[11:0]	PMS temperature sensor measurement result
PEAK_VDD.PEAKVOLT	[10:0]	Peak voltage detection measurement result
PEAK_VDDEXT.PEAKVOLT	[10:0]	Peak voltage detection measurement result
PEAK_VDDEXTDC.PEAKVOLT	[10:0]	Peak voltage detection measurement result
WUT_STAT.COUNTER[11:0]	[11:0]	Lower half of WUT counter value
WUT_STAT.COUNTER[23:12]	[11:0]	Upper half of WUT counter value
RTC Timer[15:0]	[15:0]	Part of the RTC timer value
RTC Timer[31:16]	[15:0]	Part of the RTC timer value
RTC Timer[47:32]	[15:0]	Part of the RTC timer value
RTC Timer[63:48]	[15:0]	Part of the RTC timer value
TCINT/SCRINT	[7:0] SCRINT [15:8] TCINT	PMS and SCR output and input bus interface

Table 1496 EVRC trigger set

OTSC1.BxEVRC selection	Bits	Description
EVRC_STAT1.FFADCV	[11:0]	EVRC input voltage value (feed-forward ADC measurement result)
EVRC_STAT1.FBADCV	[10:0]	EVRC output voltage value (feedback ADC measurement result, including offset compensation)
EVRC_STAT0 Status Bits	[0] EVRCSYNCIN	EVRC synchronization input signal
	[1] EVRC_STAT0.SYNCLCK	EVRC input synchronization locked status
	[2] EVRC_STAT0.EVRCSHLV	Short to ground flag
	[3] EVRC_STAT0.EVRCSHHV	Short to supply flag
	[12:4] EVRC_STAT0.SETPOINT	EVRC target output voltage
	[13] EVRC_STAT0.SDVOK	EVRC voltage OK status
EVRC_STAT1.DUTYCYCLE	[8:0]	PWM duty cycle provided to the external MOSFET switches
DROOP	[3:0] DROOPSTEP	Droop compensation amplitude
	[4] DROOPDIR	Droop compensation direction (0=down, 1=up)

36.6 References

This section is not applicable for the module being described.

36.7 PMS revision history

Reference	Description of change(s)
Date range: 2025-03-28 to 2024-02-03	
Recommended settings	• Changed value of EVRC_COEFF3.DRV5VNSTRON bit-field
Standby controller extension RAM (XRAM)	• Added section with information on SCR XRAM access protection

36.8 TC4Dx PMS information

36.8.1 TC4Dx PMS configuration

There are no deviations from the generic specification.

36.8.2 TC4Dx PMS features

There are no deviations from the generic specification.

36.8.3 TC4Dx PMS functional description

This part provides additional information about the functionality of the PMS for the TC4Dx product variant.

36.8.3.1 TC4Dx power supply rails and distribution

This section describes the power supply rails implemented on the TC4Dx. Refer to the generic functional description for typical values.

The following external supply rails are available:

- $V_{DDEVRSB}$
- V_{DDEXT}
- V_{DDM}
- $V_{DDEXTDC}$
- V_{DD}
- $V_{DDPHPHY0}$
- $V_{DDPHPHY1}$
- $V_{DDPHPHY2}$
- V_{DDPHY0}
- V_{DDPHY1}
- V_{DDPHY2}
- V_{DDHSIF}

The following internal supply rails are available:

- V_{DDPMS0}
- V_{DDPMS1}
- V_{DDPMS2}
- V_{DDDCLS}
- V_{SSDCHS}
- V_{DDLMU0}
- V_{DDLMU1}
- V_{DDPPU}
- V_{DDPAD}

Supply rail mapping for V_{DDCPUA} is not applicable for TC4Dx.

The following figure provides an overview of the supply rails listed above and in the generic PMS functional description.

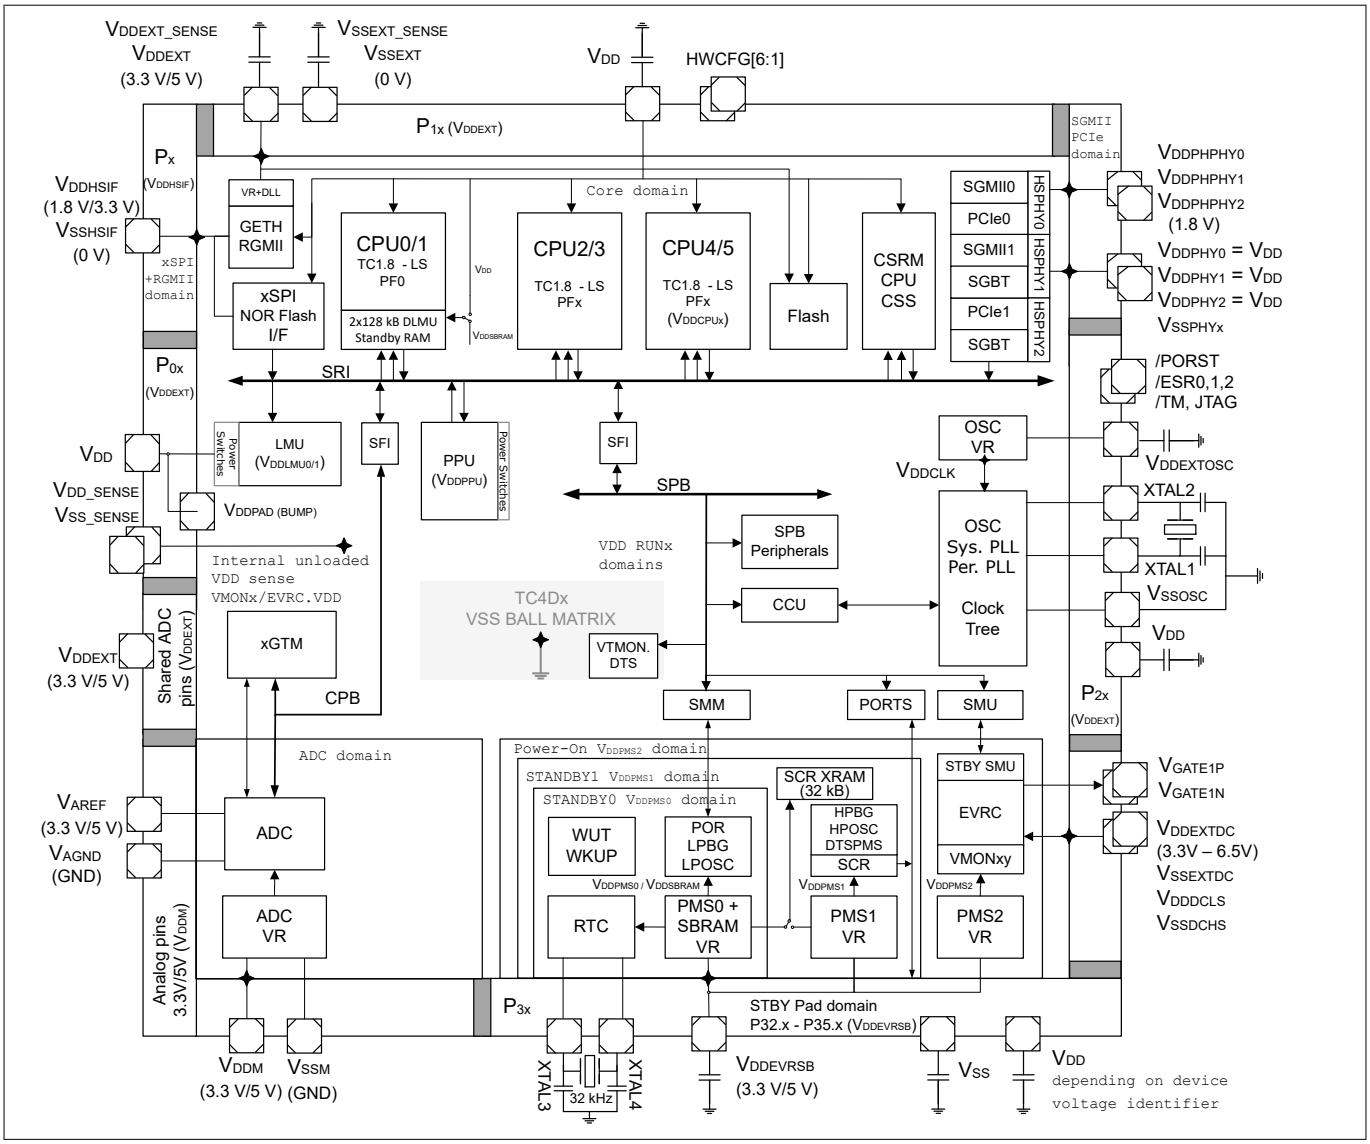

Figure 808 TC4Dx supply rails overview

Related information

Power supply rails and distribution on page 5948

36.8.3.2 TC4Dx independent standby supply domains (PMS0, PMS1, PMS2)

This section describes the standby supply domains for the power management system.

The PMS standby domains include the components shown in the figure below. Refer to the generic functional description for a list of the domains and included functions.

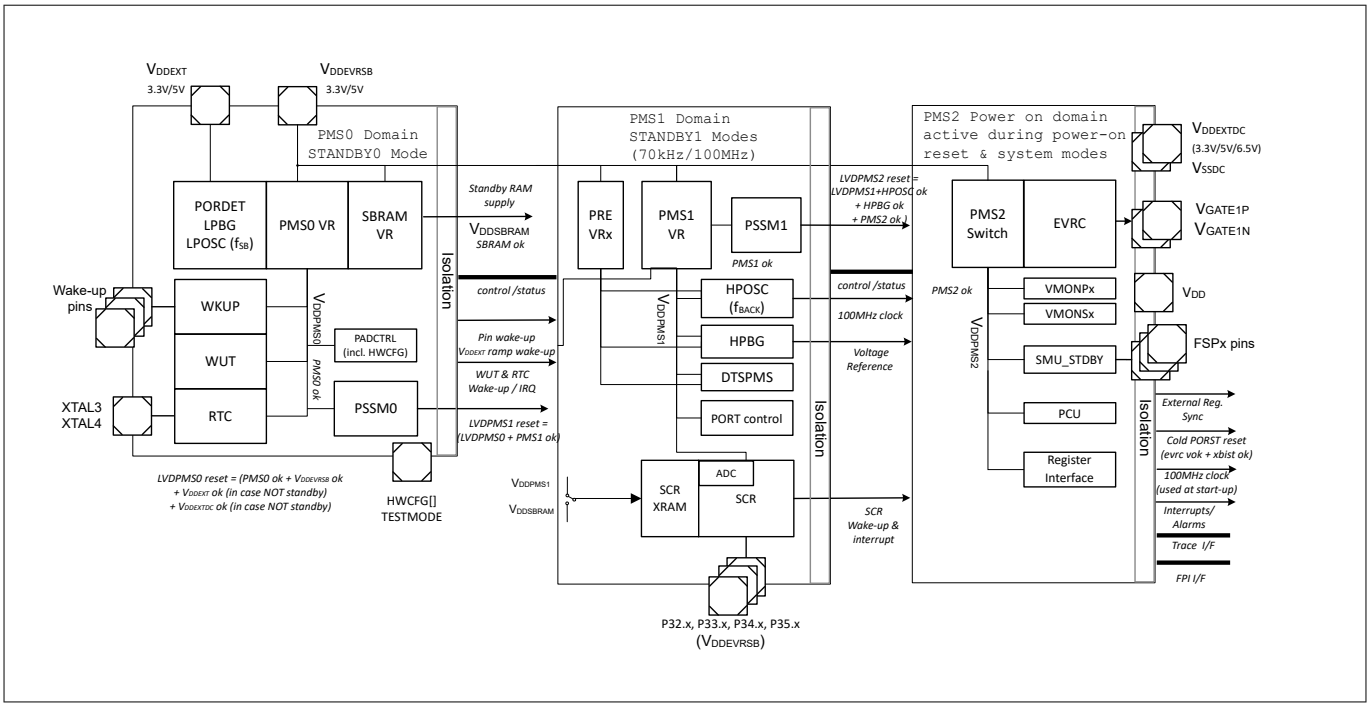

Figure 809 Standby supply domains of the power management system

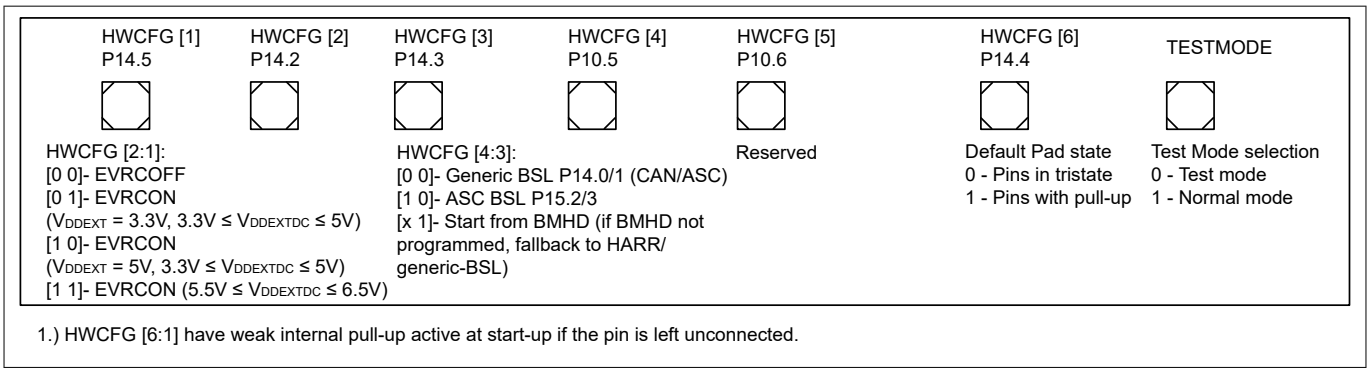
Related information

Independent standby supply domains (PMS0, PMS1, PMS2) on page 5956

36.8.3.3 TC4Dx supply mode selection

This section provides additional details related to the supply selection for the TC4Dx product variant.



1.) HWCFG [6:1] have weak internal pull-up active at start-up if the pin is left unconnected.

Figure 810 Hardware configuration (HWCFG) pins for TC4Dx product variant

Related information

Supply mode selection on page 5959

36.8.3.4 TC4Dx primary voltage monitors

This section provides additional details related to the primary voltage monitors VMONPx and cold PORST for the TC4Dx product variant.

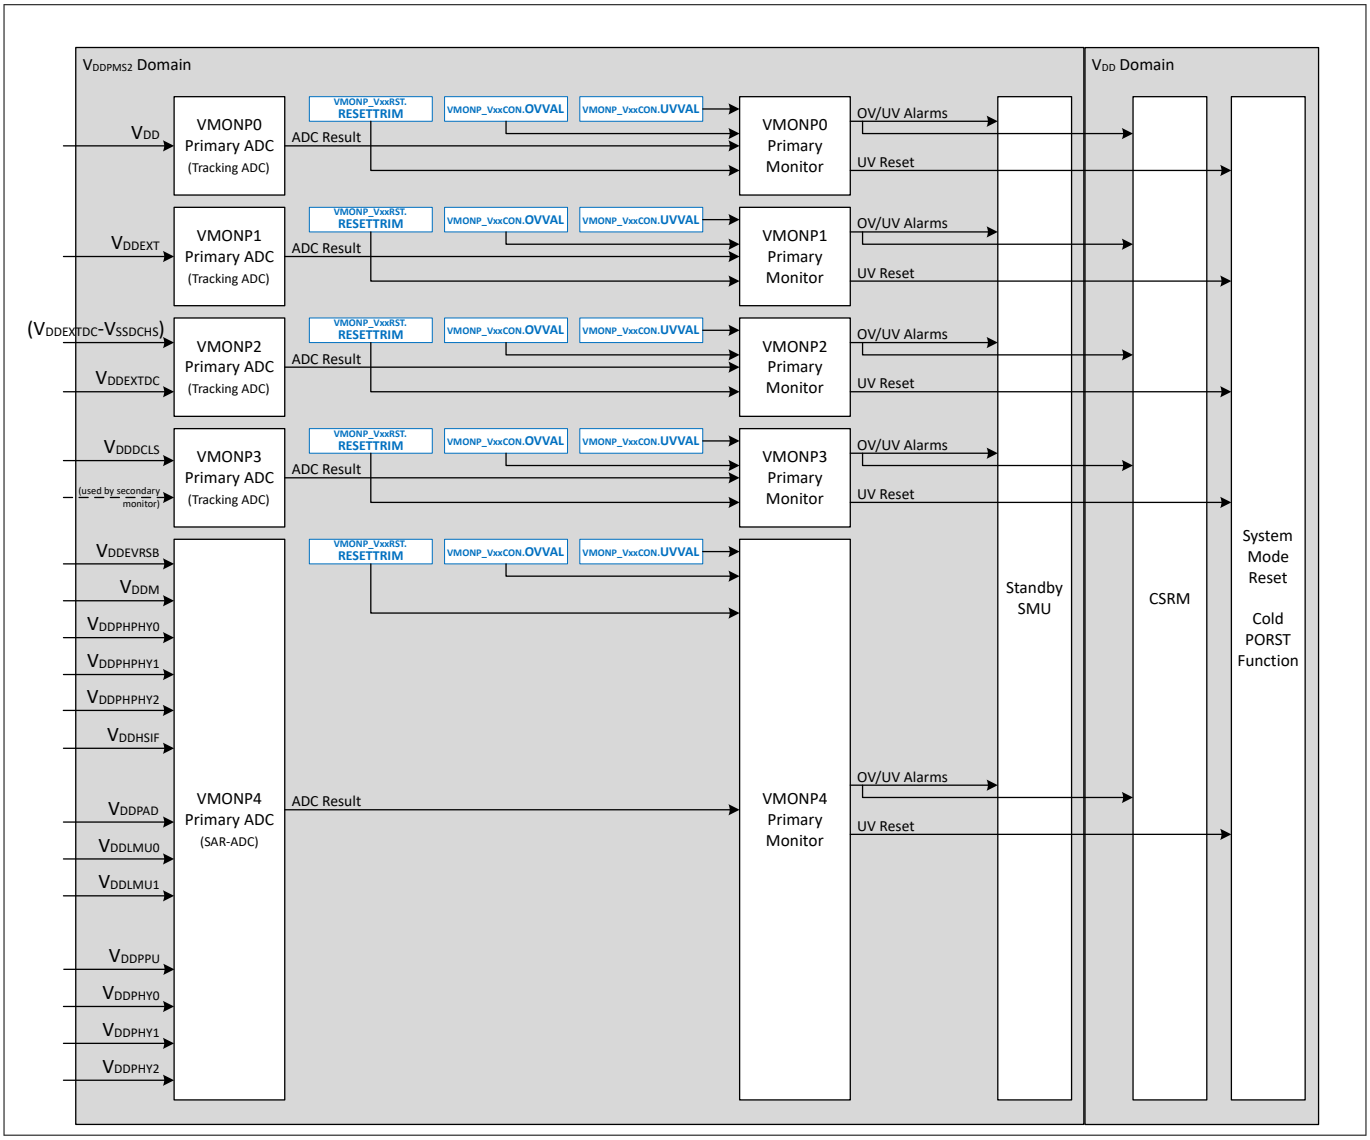


Figure 811 Overview of the primary voltage monitors for the TC4Dx product variant

Related information

Primary voltage monitors VMONPx and cold PORST on page 5971
Peak voltage detection on page 6006
Drift monitoring on page 6007

36.8.3.5 TC4Dx secondary over- and under-voltage monitors

This section provides additional details related to the secondary over- and under-voltage monitors (VMONSx) for the TC4Dx product variant.

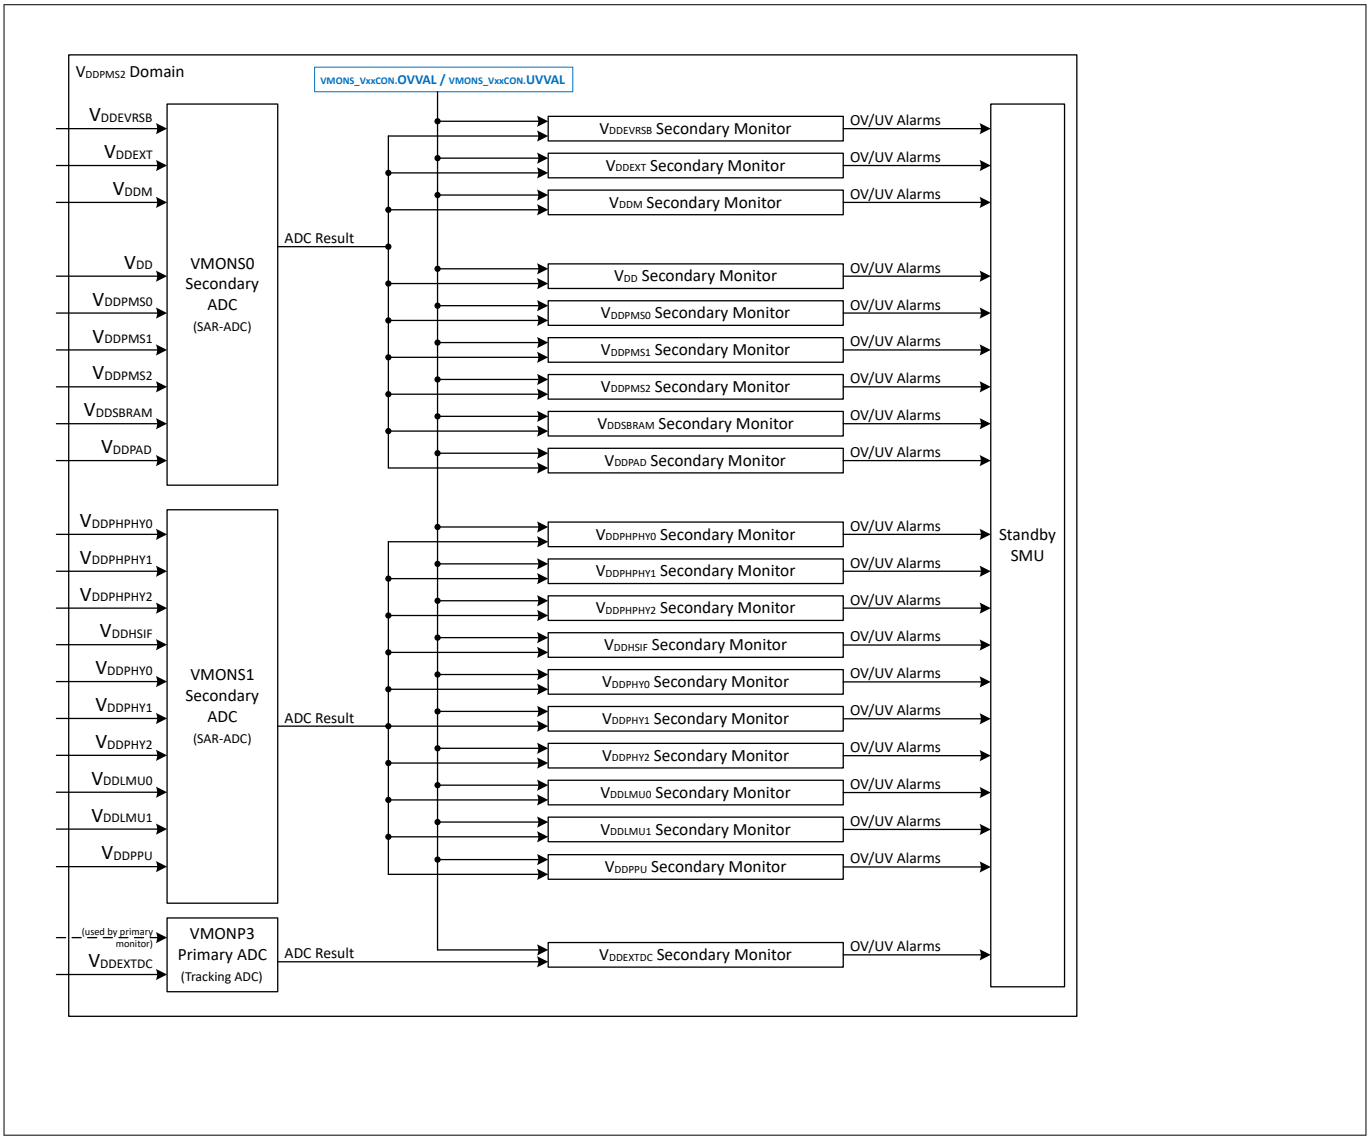

Figure 812 Overview of the secondary voltage monitors for the TC4Dx product variant

Related information

Secondary over- and under-voltage monitors (VMONSx) on page 6003

36.8.3.6 TC4Dx interrupts

This section provides additional details related to the interrupt sources and events for the TC4Dx product variant.

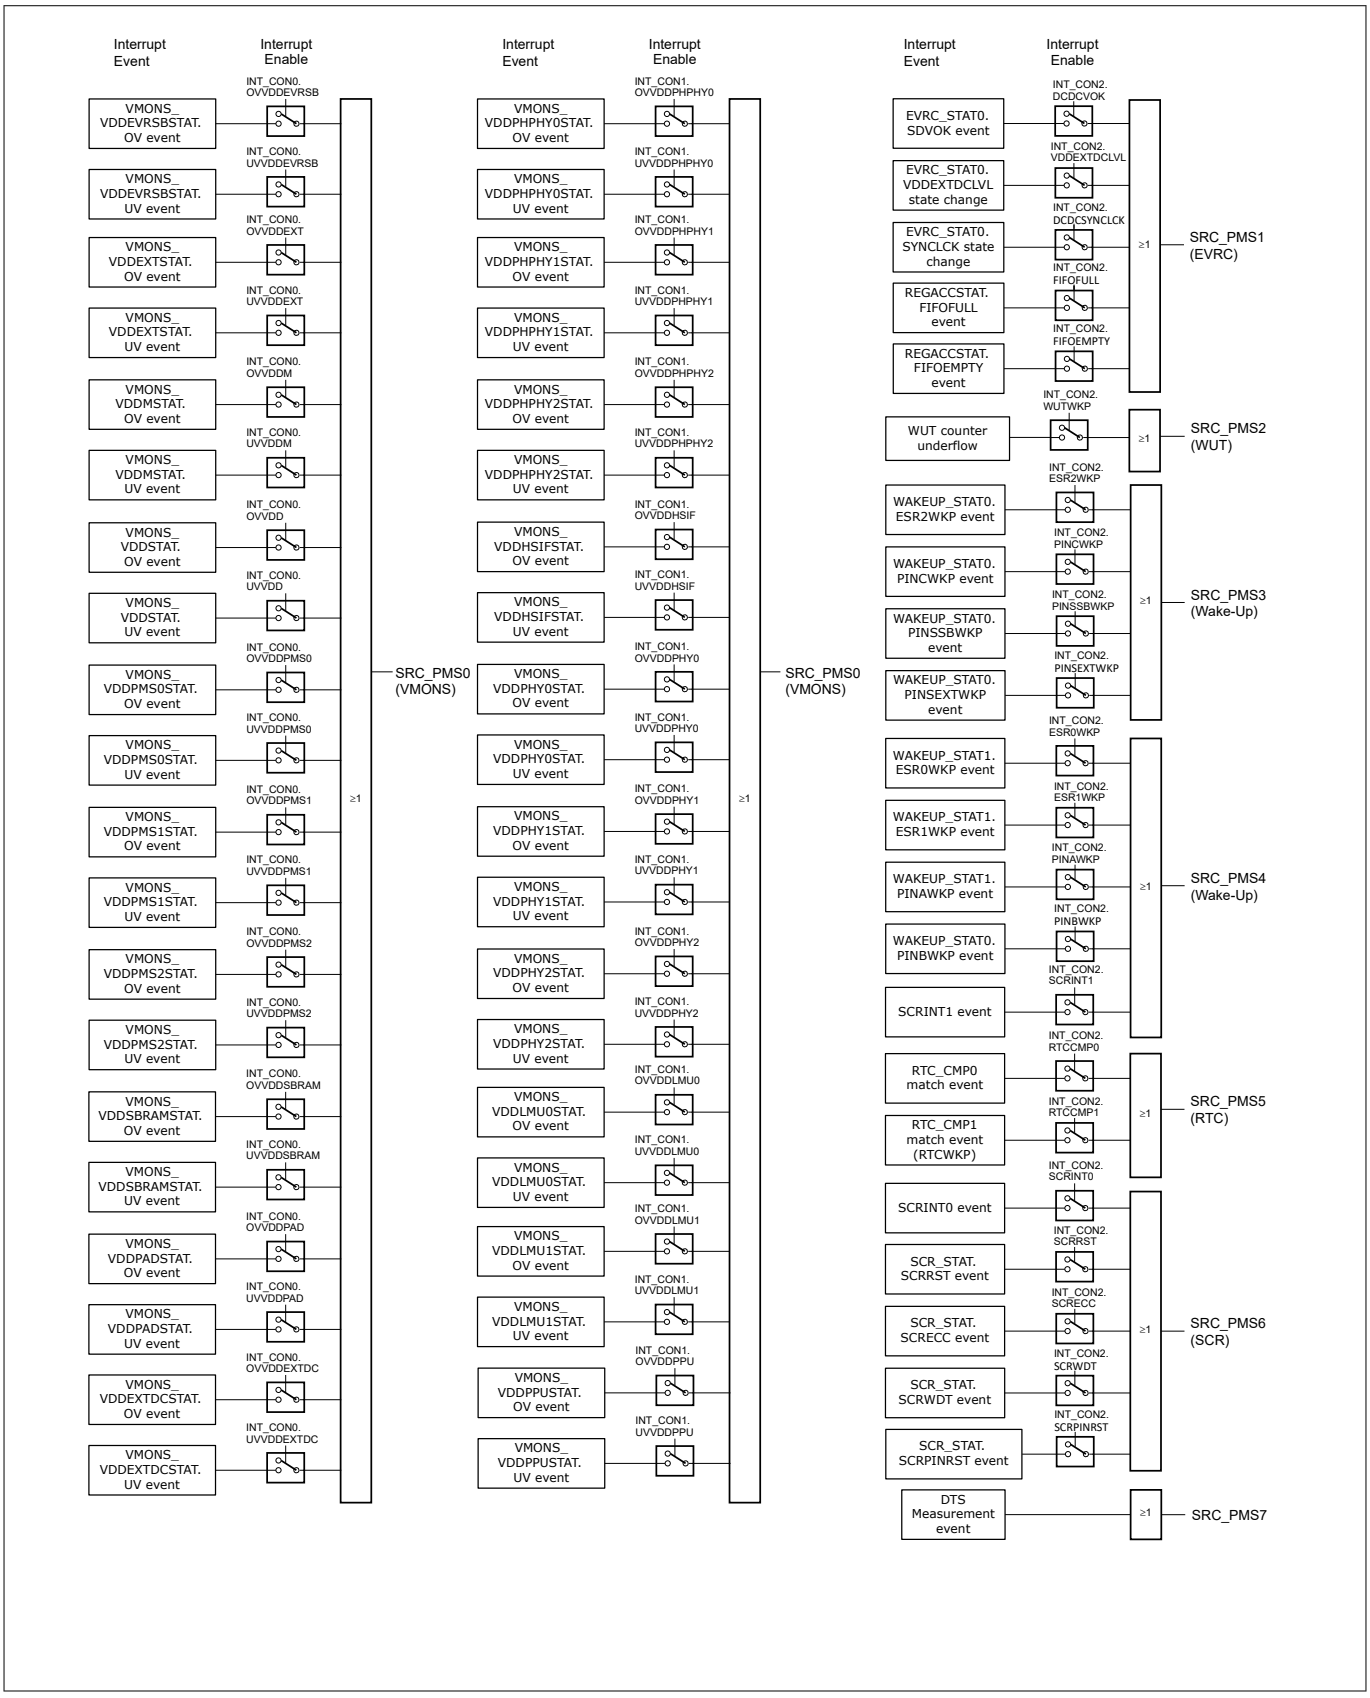

Figure 813 Interrupt sources and events for the TC4Dx product variant

Related information

Interrupts on page 6010

36.8.4 TC4Dx PMS registers

There are no deviations from the generic specification.

36.8.4.1 Memory overview tables of PMS

Table 1497 Memory overview - PMS (ascending address)

Short name	Long name	Address
PMS_XRAM	Standby controller extension RAM (8000_H Byte)	$F0240000_H$

36.8.4.2 Register address space - PMS

Table 1498 Registers address space - PMS

Module	Base address	End address	Note
PMS	$F0240000_H$	$F0249FFF_H$	FPI slave interface

36.8.4.3 Register overview - access mode glossary

Table 1499 Register overview - access mode glossary

Keyword	Description
CSE	Access protection using PROT register PMS_PROTCSE .
E	Access protection using PROT register PMS_PROTE .
SE	Access protection using PROT register PMS_PROTSE .
APU-P	Protection group consisting of registers PMS_ACCEN_WRA , PMS_ACCEN_WRB , PMS_ACCEN_RDA , PMS_ACCEN_RDB , PMS_ACCEN_VM , PMS_ACCEN_PRS .
P	Access protection using *APU-P* registers.
APU-Pcs	Protection group consisting of registers PMS_ACCENCS_WRA , PMS_ACCENCS_WRB , PMS_ACCENCS_RDA , PMS_ACCENCS_RDB , PMS_ACCENCS_VM , PMS_ACCENCS_PRS .
Pcs	Access protection using *APU-Pcs* registers.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
BE	Always returns a Bus Error.
STP	Access only during start-up, before start-up protection is set (SMM_STCON.ST_PROT=1).
M	Indicates a module specific access condition. Refer to the register description for details of the specific access condition.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FILTER				UVENABLE	UVVAL										
rw				rw	rw										

Field	Bits	Type	Description
UVVAL	10:0	rw	**Primary monitor alarm under-voltage threshold** This field defines the under-voltage monitoring threshold level. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
UVENABLE	11	rw	**Primary monitor under-voltage alarm enable** 0_B No alarm trigger signal is generated. 1_B An alarm trigger signal is generated and forwarded depending on the configured threshold value.
FILTER	16:12	rw	**Primary monitor alarm spike filter** 00_H Each conversion result is compared with threshold to generate alarm $1F_H$ A spike filter of consecutive 32 ADC results are used to generate alarm.
OVVAL	27:17	rw	**Primary monitor alarm over-voltage threshold** This field defines the over-voltage monitoring threshold level. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
OVENABLE	28	rw	**Primary monitor over-voltage alarm enable** 0_B No alarm trigger signal is generated. 1_B An alarm trigger signal is generated and forwarded depending on the configured threshold value.
0	31:29	r	**Reserved**

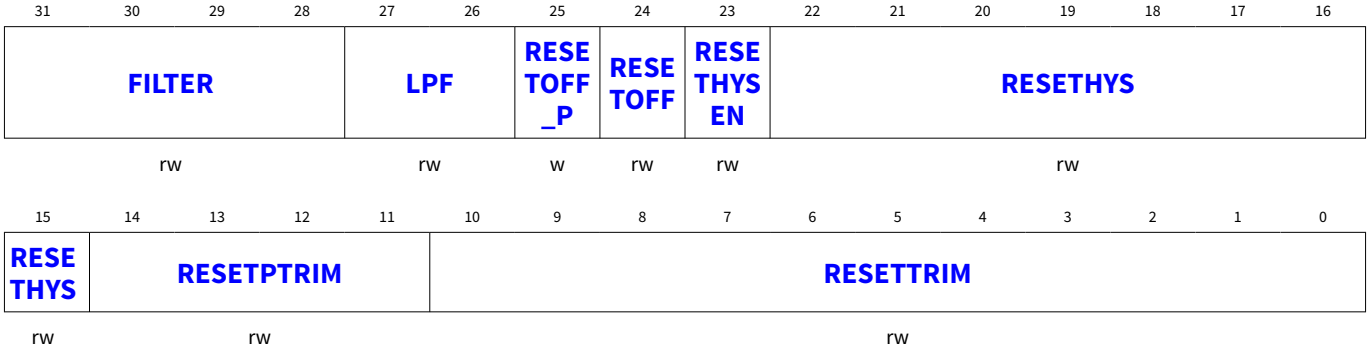
36.8.4.6 VDD primary voltage monitor reset configuration register

PMS_VMONP_VDDRST

VDD primary voltage monitor reset configuration register

Offset address: 9048_H

Reset values see: Table 1503



Field	Bits	Type	Description
RESETTRIM	10:0	rw	**Supply reset trim value** This bit field selects the hard reset generation level of the respective supply rail. This bitfield is trimmed by Firmware. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
RESETPTRIM	14:11	rw	**Signed reset trim value** This bit field allows fine trimming of the reset threshold. Binary signed two's complement representation.
RESETHYS	22:15	rw	**Supply reset hysteresis trim value** This bit field selects the reset hysteresis offset level of the primary voltage monitor. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
RESETHYSEN	23	rw	**Reset release hysteresis enable** 0_B Hysteresis for reset release is not active. 1_B Hysteresis for reset release is active.
RESETOFF	24	rw	**Reset enable** This bit can only be changed if bit RESETOFF_P is set in parallel. RESETOFF is intended to be used only for internal test purposes and the primary reset generation is not to be disabled in customer application. 0_B A reset trigger signal is generated and forwarded to the SCU by the primary monitor depending on the selected reset trim value. 1_B No reset trigger signal is generated and forwarded to the SCU by the primary monitor.
RESETOFF_P	25	w	**RESETOFF bit protection** Writing 1 into this bit enables that bit RESETOFF can be changed in this write operation. This bit is read as zero.

(table continues...)

(continued)

Field	Bits	Type	Description
LPF	27:26	rw	**Primary monitor reset LPF coefficient** This bitfield configures the coefficient of the low pass filter of the primary monitor tracking ADC counter value. The low pass filter is used for cold PORST generation and VMONP_VxxSTAT.RESULT value. y [k] = { y [k-1] * (1-a) } + { x [k] * a} ; y [k] is filter output; x [k] is ADC output a = {1 / (2 ^ LPF)}.If LPF = 0, the filter output is the same as ADC output.
FILTER	31:28	rw	**Primary monitor reset spike filter** 0_H Each conversion result is compared with threshold to generate alarm F_H A spike filter of consecutive 16 ADC results are used to generate reset.

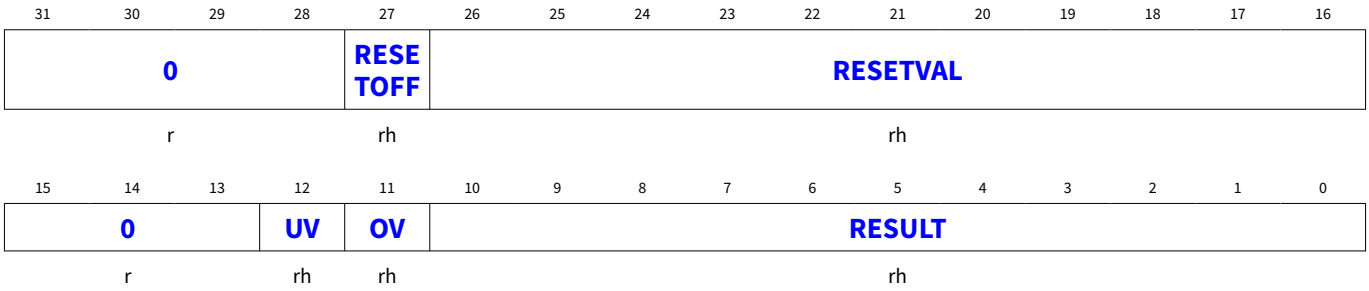
36.8.4.8 VDD primary voltage monitor status register

PMS_VMONP_VDDSTAT Offset address: 9050_H

VDD primary voltage monitor status register Reset values see: Table 1506



Field	Bits	Type	Description
RESULT	10:0	rh	**Primary monitor ADC conversion result** This bit field contains the last conversion result of the ADC measurement of the primary voltage monitor. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
OV	11	rh	**Primary monitor over-voltage event flag** This bit is set if the primary voltage monitor recognizes an over-voltage event. An alarm is raised to the CSRM and SMU. 0_B No over-voltage condition happened. 1_B Over-voltage event indication as configured in the respective VMONP_VxxCON register.
UV	12	rh	**Primary monitor under-voltage event flag** This bit is set if the primary voltage monitor recognizes an under-voltage event. An alarm is raised to the CSRM and SMU. 0_B No under-voltage condition happened. 1_B Under-voltage event indication as configured in the respective VMONP_VxxCON register.
RESETVAL	26:16	rh	**Supply reset value status** This bit field indicates the actual cold PORST reset trim setpoint used by the primary voltage monitors.
RESETOFF	27	rh	**Reset enable status** 0_B A cold PORST is triggered in case of primary under-voltage event 1_B No cold PORST is generated in case of a primary under-voltage event.
0	15:13, 31:28	r	**Reserved**

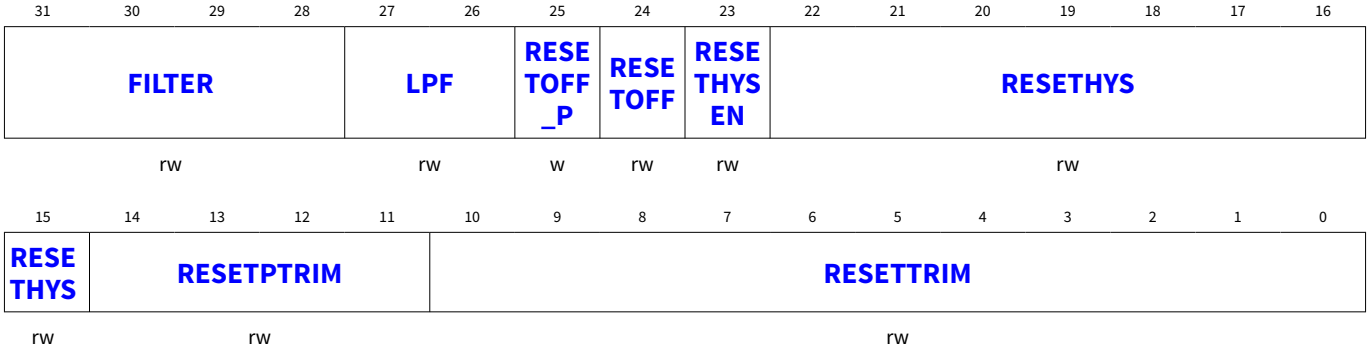
36.8.4.10 VDDEXT primary voltage monitor reset configuration register

PMS_VMONP_VDDEXTRST

VDDEXT primary voltage monitor reset configuration register

Offset address: 9058_H

Reset values see: Table 1509



Field	Bits	Type	Description
RESETTRIM	10:0	rw	**Supply reset trim value** This bit field selects the hard reset generation level of the respective supply rail. This bitfield is trimmed by Firmware. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
RESETPTRIM	14:11	rw	**Signed reset trim value** This bit field allows fine trimming of the reset threshold. Binary signed two's complement representation.
RESETHYS	22:15	rw	**Supply reset hysteresis trim value** This bit field selects the reset hysteresis offset level of the primary voltage monitor. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
RESETHYSEN	23	rw	**Reset release hysteresis enable** 0_B Hysteresis for reset release is not active. 1_B Hysteresis for reset release is active.
RESETOFF	24	rw	**Reset enable** This bit can only be changed if bit RESETOFF_P is set in parallel. RESETOFF is intended to be used only for internal test purposes and the primary reset generation is not to be disabled in customer application. 0_B A reset trigger signal is generated and forwarded to the SCU by the primary monitor depending on the selected reset trim value. 1_B No reset trigger signal is generated and forwarded to the SCU by the primary monitor.
RESETOFF_P	25	w	**RESETOFF bit protection** Writing 1 into this bit enables that bit RESETOFF can be changed in this write operation. This bit is read as zero.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESETHYS	RESETPTRIM				RESETTRIM										
rw	rw				rw										

Field	Bits	Type	Description
RESETTRIM	10:0	rw	**Supply reset trim value** This bit field selects the hard reset generation level of the respective supply rail. This bitfield is trimmed by Firmware. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
RESETPTRIM	14:11	rw	**Signed reset trim value** This bit field allows fine trimming of the reset threshold. Binary signed two's complement representation.
RESETHYS	22:15	rw	**Supply reset hysteresis trim value** This bit field selects the reset hysteresis offset level of the primary voltage monitor. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
RESETHYSEN	23	rw	**Reset release hysteresis enable** 0_B Hysteresis for reset release is not active. 1_B Hysteresis for reset release is active.
RESETOFF	24	rw	**Reset enable** This bit can only be changed if bit RESETOFF_P is set in parallel. RESETOFF is intended to be used only for internal test purposes and the primary reset generation is not to be disabled in customer application. 0_B A reset trigger signal is generated and forwarded to the SCU by the primary monitor depending on the selected reset trim value. 1_B No reset trigger signal is generated and forwarded to the SCU by the primary monitor.
RESETOFF_P	25	w	**RESETOFF bit protection** Writing 1 into this bit enables that bit RESETOFF can be changed in this write operation. This bit is read as zero.
LPF	27:26	rw	**Primary monitor reset LPF coefficient** This bitfield configures the coefficient of the low pass filter of the primary monitor tracking ADC counter value. The low pass filter is used for cold PORST generation and VMONP_VxxSTAT.RESULT value. y [k] = { y [k-1] * (1-a) } + { x [k] * a} ; y [k] is filter output; x [k] is ADC output a = {1 / (2 ^ LPF)}.If LPF = 0, the filter output is the same as ADC output.
FILTER	31:28	rw	**Primary monitor reset spike filter** 0_H Each conversion result is compared with threshold to generate alarm F_H A spike filter of consecutive 16 ADC results are used to generate reset.

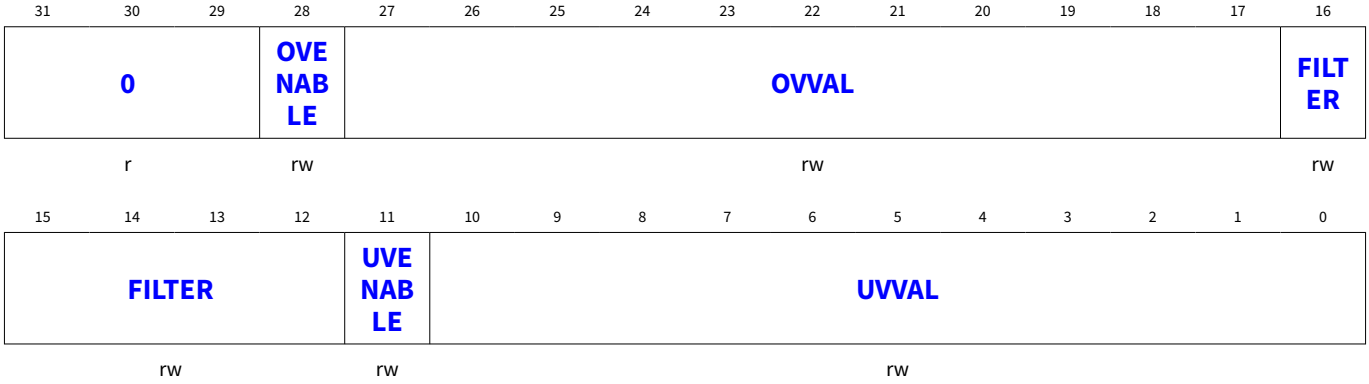
PMS_VMONP_VDDLMU1CON Offset address: 90F0$_H$

VDDLMU1 primary voltage monitor configuration register Reset values see: Table 1555



Field	Bits	Type	Description
UVVAL	10:0	rw	**Primary monitor alarm under-voltage threshold** This field defines the under-voltage monitoring threshold level. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
UVENABLE	11	rw	**Primary monitor under-voltage alarm enable** 0_B No alarm trigger signal is generated. 1_B An alarm trigger signal is generated and forwarded depending on the configured threshold value.
FILTER	16:12	rw	**Primary monitor alarm spike filter** 00_H Each conversion result is compared with threshold to generate alarm $1F_H$ A spike filter of consecutive 32 ADC results are used to generate alarm.
OVVAL	27:17	rw	**Primary monitor alarm over-voltage threshold** This field defines the over-voltage monitoring threshold level. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
OVENABLE	28	rw	**Primary monitor over-voltage alarm enable** 0_B No alarm trigger signal is generated. 1_B An alarm trigger signal is generated and forwarded depending on the configured threshold value.
0	31:29	r	**Reserved**

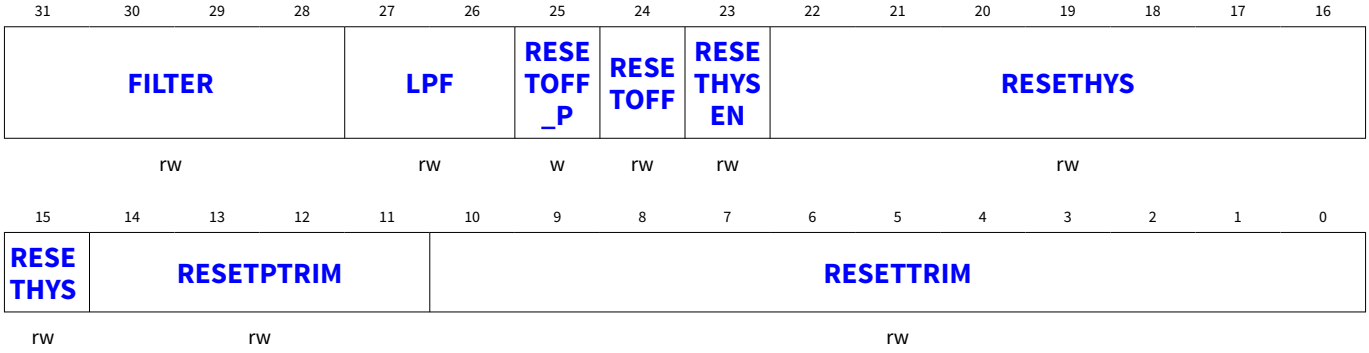
PMS_VMONP_VDDLMU1RST Offset address: 90F4$_H$

VDDLMU1 primary voltage monitor reset configuration register Reset values see: Table 1557



Field	Bits	Type	Description
RESETTRIM	10:0	rw	**Supply reset trim value** This bit field selects the hard reset generation level of the respective supply rail. This bitfield is trimmed by Firmware. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
RESETPTRIM	14:11	rw	**Signed reset trim value** This bit field allows fine trimming of the reset threshold. Binary signed two's complement representation.
RESETHYS	22:15	rw	**Supply reset hysteresis trim value** This bit field selects the reset hysteresis offset level of the primary voltage monitor. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
RESETHYSEN	23	rw	**Reset release hysteresis enable** 0_B Hysteresis for reset release is not active. 1_B Hysteresis for reset release is active.
RESETOFF	24	rw	**Reset enable** This bit can only be changed if bit RESETOFF_P is set in parallel. RESETOFF is intended to be used only for internal test purposes and the primary reset generation is not to be disabled in customer application. 0_B A reset trigger signal is generated and forwarded to the SCU by the primary monitor depending on the selected reset trim value. 1_B No reset trigger signal is generated and forwarded to the SCU by the primary monitor.
RESETOFF_P	25	w	**RESETOFF bit protection** Writing 1 into this bit enables that bit RESETOFF can be changed in this write operation. This bit is read as zero.
LPF	27:26	rw	**Primary monitor reset LPF coefficient** This bitfield configures the coefficient of the low pass filter of the primary monitor tracking ADC counter value. The low pass filter is used for cold PORST generation and VMONP_VxxSTAT.RESULT value. y [k] = { y [k-1] * (1-a) } + { x [k] * a} ; y [k] is filter output; x [k] is ADC output a = {1 / (2 ^ LPF)}.If LPF = 0, the filter output is the same as ADC output.

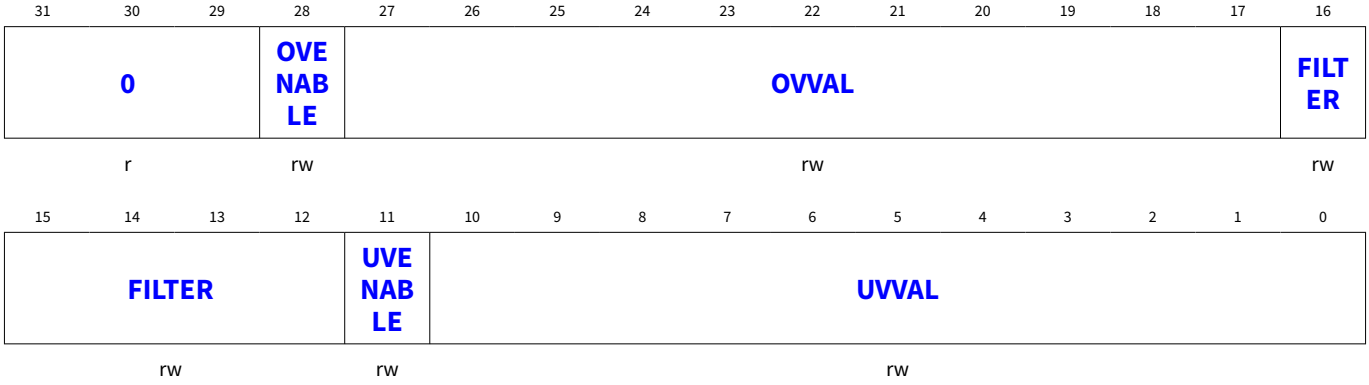
PMS_VMONP_VDDPHY2CON

VDDPHY2 primary voltage monitor configuration register

Offset address: $912C_H$

Reset values see: Table 1571



Field	Bits	Type	Description
UVVAL	10:0	rw	**Primary monitor alarm under-voltage threshold** This field defines the under-voltage monitoring threshold level. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
UVENABLE	11	rw	**Primary monitor under-voltage alarm enable** 0_B No alarm trigger signal is generated. 1_B An alarm trigger signal is generated and forwarded depending on the configured threshold value.
FILTER	16:12	rw	**Primary monitor alarm spike filter** 00_H Each conversion result is compared with threshold to generate alarm $1F_H$ A spike filter of consecutive 32 ADC results are used to generate alarm.
OVVAL	27:17	rw	**Primary monitor alarm over-voltage threshold** This field defines the over-voltage monitoring threshold level. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
OVENABLE	28	rw	**Primary monitor over-voltage alarm enable** 0_B No alarm trigger signal is generated. 1_B An alarm trigger signal is generated and forwarded depending on the configured threshold value.
0	31:29	r	**Reserved**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESETHYS	RESETPTRIM								RESETTRIM						
rw	rw								rw						

Field	Bits	Type	Description
RESETTRIM	10:0	rw	**Supply reset trim value** This bit field selects the hard reset generation level of the respective supply rail. This bitfield is trimmed by Firmware. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
RESETPTRIM	14:11	rw	**Signed reset trim value** This bit field allows fine trimming of the reset threshold. Binary signed two's complement representation.
RESETHYS	22:15	rw	**Supply reset hysteresis trim value** This bit field selects the reset hysteresis offset level of the primary voltage monitor. The LSB is documented for each supply rail in the user manual (primary voltage monitors section).
RESETHYSEN	23	rw	**Reset release hysteresis enable** 0_B Hysteresis for reset release is not active. 1_B Hysteresis for reset release is active.
RESETOFF	24	rw	**Reset enable** This bit can only be changed if bit RESETOFF_P is set in parallel. RESETOFF is intended to be used only for internal test purposes and the primary reset generation is not to be disabled in customer application. 0_B A reset trigger signal is generated and forwarded to the SCU by the primary monitor depending on the selected reset trim value. 1_B No reset trigger signal is generated and forwarded to the SCU by the primary monitor.
RESETOFF_P	25	w	**RESETOFF bit protection** Writing 1 into this bit enables that bit RESETOFF can be changed in this write operation. This bit is read as zero.

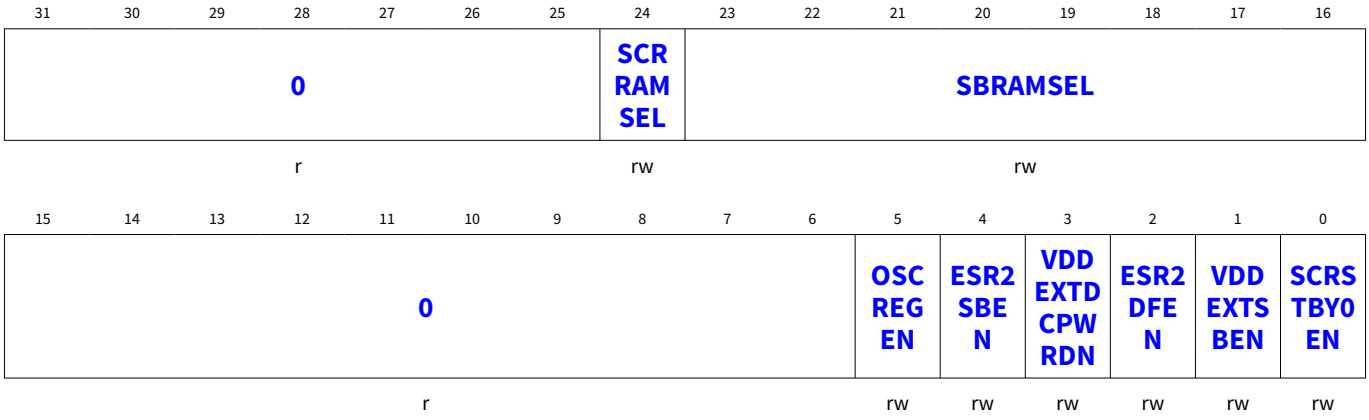
36.8.4.110 Standby configuration register 0

Before accessing, check the REGACCSTAT.FIFOEMPTY and REGACCSTAT.FIFOFULL status as described in the user manual (LVD reset section).

PMS_STANDBY_CON0 Offset address: $92C4_H$

Standby configuration register 0 Reset values see: Table 1627



Field	Bits	Type	Description
SCRSTBY0EN	0	rw	**Enable that SCR can trigger a transition from STBY1 to STBY0** 0_B Transition from STBY1 to STBY0 is disabled. 1_B Transition from STBY1 to STBY0 is enabled.

(table continues...)

(continued)

Field	Bits	Type	Description
VDDEXTSBEN	1	rw	**Standby entry on VDDEXT Supply ramp-down** This bit field enables Standby Entry on VDDEXT supply ramp-down. This is supported only in case Standby domain is supplied separately via VDDEVRSB supply pin and VDDEXT rail is switched off during Standby. The voltage threshold for entry is configured in VMONS_VDDEXTCON register. 0_B Standby Entry on VDDEXT supply ramp-down is disabled. 1_B Standby Entry triggered on a VDDEXT Supply undervoltage event (VDDEXTUV). Blanking filter active on Standby mode entry.
ESR2DFEN	2	rw	**ESR2 digital filter enable** This bit activates a digital filter for the standby entry trigger. If the digital filter (majority filter of 3 consecutive values, running on the 70 kHz standby clock) is enabled, then single pulses of less than 10 µs within a 60 µs window are suppressed and pulses longer than 50 µs will always result in a trigger. 0_B The filter is bypassed 1_B The filter is used
VDDEXTDCPWRDN	3	rw	**Enable powering down of VDDEXTDC during standby modes** This bit field enables the power-down of the $V_{DDEXTDC}$ external supply during standby modes. 0_B VDDEXTDC must be powered on during standby modes. 1_B VDDEXTDC can be powered off during standby modes.
ESR2SBEN	4	rw	**Standby entry on ESR2 trigger** 0_B Standby Entry on ESR2 trigger is disabled. 1_B Standby entry entry on ESR2 trigger is enabled.
OSCREGEN	5	rw	**Enable bit for the HPOSC pre-regulator during STANDBY0 and STANDBY1_70k** 0_B HPOSC pre-regulator disabled in STANDBY0 and STANDBY1_70k modes 1_B HPOSC pre-regulator enabled in STANDBY0 and STANDBY1_70k modes

(table continues...)

0							SUPPLYCFG		SDF REQ CFG	SDV OK	VDD EXTD CLVL	EVRC SHH V	EVRC SHLV	SYNC LCK	EVRC
r							rh		rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
EVRC	0	rh	**EVRC status** This bit is set if the internal EVRC regulator is currently active and no error occurred. 0_B EVRC is inactive. 1_B EVRC is active.
SYNCLCK	1	rh	**EVRC synchronization input locked status** This bitfield indicates the current synchronization status of the EVRC regulator to the external DCDCSYNCI input signal. When the EVRC switching frequency and edge is locked to the synchronization input, the SYNCLCK bit is set to HIGH indicating the locked state. When the synchronization is lost owing to frequency deviations beyond SYNCMAXDEV or the feature is disabled via SYNCIN, the SYNCLCK bit is set to LOW. 0_B EVRC regulator runs on internal configured switching frequency and is not currently synchronized to external DCDCSYNCI input signal. 1_B EVRC regulator switching frequency and VGATE output edge is currently synchronized to external DCDCSYNCI input signal.
EVRCSHLV	2	rh	**Short to ground** This bit is set if a short condition to ground has been detected. The measured EVRC output is below the operational supply range and the upper controller limits are reached.The feature is supported only during closed loop operation. 0_B No short to ground detected on VDD rail. 1_B Short to ground detected on VDD rail.
EVRCSHHV	3	rh	**Short to supply** This bit is set if a short condition to supply has been detected. The measured EVRC output exceeds the allowed supply range and the lower controller limits are reached. The feature is supported only during closed loop operation. 0_B No short to supply detected on VDD rail. 1_B Short to supply detected on VDD rail.
VDDEXTDCLVL	4	rh	**VDDEXTDC external supply level status** This bit indicates that the VDDEXTDC voltage has dropped below the threshold configured in EVRC_COEFF8.DRVFFTHRES ~4 V to indicate EVRC driver configuration switch to differentiate between 5V or 3.3V external supply. A hysteresis as configured in EVRC_COEFF8.DRVFFHYS is implemented on this detector. 0_B VDDEXTDC external supply is below the threshold, i.e. the 3.3V driver configuration is selected and used. 1_B VDDEXTDC external supply is above the threshold, i.e. the 5V driver configuration is selected and used.

(table continues...)

(continued)

Field	Bits	Type	Description
SDVOK	5	rh	**EVRC regulator voltage OK status** This bit is set by the EVRC voltage OK detector to indicate that the new regulator output value has been reached. This bit is reset whenever EVRC_CON0.SDVOUTSEL is changed (to adjust the V_{DD} voltage) and is set when the new output setpoint is reached. This bit is also reset in case droop compensation is requested before a load jump event. A time-out period of 20 µs shall be waited when polling the SDVOK bit. 0_B EVRC regulator setpoint voltage has not been reached. 1_B EVRC regulator setpoint voltage is reached and VDD voltage is ok.
SDFREQCFG	6	rh	**EVRC switching frequency configuration** This bit indicates the status of an EVRC configuration setting. 0_B Low-frequency configuration 1_B High-frequency configuration
SUPPLYCFG	8:7	rh	**EVRC supply configuration** This bit-field indicates the status of an EVRC configuration setting. 00_B EVRC disabled 01_B VDDEXTDC 3.3V supply mode 10_B VDDEXTDC 5.5V supply mode 11_B VDDEXTDC high-voltage supply mode
SETPOINT	24:16	rh	**EVRC target output voltage** The SETPOINT is the target output voltage of the EVRC including SDVOUTSEL, and droop compensation. Target voltage value = SETPOINT * LSB LSB = 2.83 mV
0	15:9, 31:25	r	**Reserved** Read as 0.

36.8.4.112 EVRC configuration register 0

PMS_EVRC_CON0 Offset address: $92EC_H$

EVRC configuration register 0 Reset values see: Table 1629

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UP								**0**							
rwh								r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0							**SDVOUTSEL**								
r							rw								

Field	Bits	Type	Description
SDVOUTSEL	8:0	rw	**EVRC regulator output voltage target value** The V_{DD} output level of the EVRC. SDVOUTSEL = (V_{DD} / LSB); V_{DD} = LSB * SDVOUTSEL; LSB = 1.2V/424 (~=2.83 mV). This register bitfield requires a parameter update via EVRC_CON0.UP for transfer to EVRC SMPS shadow register. The reaching of the new target value is indicated by the EVRC_STAT0.SDVOK bit.
UP	31	rwh	**Update request for SMPS register values** This bitfield triggers the update of the current register values from PMS-FPI EVRC registers to the local SMPS module registers. It shall be ensured that all EVRC_CONx and EVRC_COEFFx registers have correct and coherent values across the various registers before the update request is issued. In case of singular register update, the other register values should match and be consistent. The parameter update via UP bit is not allowed in start-up mode. After setting the UP bit, the SW must wait for the UP bit to get de-asserted before performing further write accesses into EVRC registers which have shadow registers, otherwise the write accesses performed while the UP bit is asserted would be lost. 0_B No action is undertaken. 1_B A new complete EVRC parameter set is transferred to the SMPS module. All EVRC_CONx and EVRC_COEFFx register contents are transferred.
0	30:9	r	**Reserved** Read as 0; should be written with 0.

36.8.5 TC4Dx PMS connectivity

The table below lists interfaces to and from this functional block to other blocks in the device.

Table 1634 List of PMS interface signals

Interface signals	I/O	Description
EGTM_PMS_DCDCSYNCI	In	EVRC synchronization input.
PMS_PORTS_DCDCSYNCO	Out	EVRC synchronization output.
PMS_EGTM_DCDCSYNCO	Out	EVRC synchronization output.
PMS_EGTM_RTCOUT	Out	RTC output.
PMS_EGTM_WUTOUT	Out	WUT output.
PMS_SMM_ColdPORST	Out	Reset type triggered by PMS upon under-voltage conditions.
PMS_SMM_WarmPORST	Out	Warm PORST request from PORST pin.
PMS_SMM_RSTSTATy.z	Out	Reset status registers to indicate reset types and triggers.
SMM_PMS_VDROOP	In	Voltage droop request to PMS EVRC.
SMM_PMS_REQSLP_STANDBY	In	Standby request.
PMS_CLOCK_fBACK	Out	70KHz backup clock
PMS_DFT_fBACK	Out	70KHz backup clock
PMS_SCR_fBACK	Out	70KHz backup clock

Date range: 2024-08-17 to 2024-11-07	
TC4Dx supply mode selection	• Image replaced for TC4Dx

37 System Mode Management (SMM)

The System Mode Management (SMM) and Reset Unit coordinate the system mode transitions including supply ramp-up, reset, start-up, operation, and ramp-down or standby states. The functional blocks PMS, PORTS, SMM, LBIST, SMU, processing units , CLOCKING and SSW interact to realize the various system states by triggering and propagating the transition events.

37.1 Feature list

Supported system modes

- RESET State: The device supports the following hierarchical reset states - Low Voltage Detector reset, Cold Power-On reset, Power Domain cold reset , Logical BIST reset, warm Power-On reset, System reset and Application reset
- RUN0 Mode: The device is in operation after the de-assertion of all resets and Boot Firmware is executed. CPU0 and CPUcs are active in this phase. All switchable power domains in VDD core domain are active
- RUN1 Mode: The device is in operation and user start-up software is executed. The switchable power domains which are not required are powered off
- IDLE Modes: The IDLE Mode is available for every processing unit such as CPUs where the respective cores are put into idle state
- SLEEP Modes: All CPUs are in Idle mode and only a few selected peripherals are active to realize wake-up functions. The SRI and SPB frequency can be reduced to reduce power consumption
- STANDBYx Modes: Only PMS0 and/or PMS1 standby domains are active. All other modules and VDD Core domain is switched off

Supported reset types

- Low Voltage Detector triggered resets: These resets are triggered by PMS in case of power fails of the standby supply domains or indicated after an initial supply ramp-up
- Power Domain Cold reset: This reset is triggered by PMS in the case of a VDD core voltage supply fail beyond which the power domain infrastructure and switch components need to be initialized
- Cold Power-On reset: This reset is triggered by PMS in the case of a power fail of critical IO and core supply rails below the operating minimum voltage limits . All modules are in reset state except parts of PMS module
- LBIST reset: This reset represents the device state when LBIST is active or being performed. After LBIST is completed or aborted, internal cold PORST is triggered. All modules are in reset state except PMS module
- Warm Power-on reset: This reset is triggered when the external power-on reset pin (PORST) is asserted low. This reset is triggered predominantly by external regulators in case the microcontroller does not service external watchdogs within a defined time period. All modules are in reset state except PMS, SCR if configured, Standby RAMs, and SMM and RRAM[45]. RAMs of processing units maintain data content during and after reset
- System reset: This reset is triggered by software, safety and security alarms, and watchdogs through the SMU unit, ESRx reset pins, system timers, test and debug modules. All modules are reset except PMS, SCR, SMM, RRAM[45], Standby RAMs, and parts of SMU and debug system, based on configuration. RAMs of processing units maintain data content during and after reset
- Application reset: This reset is triggered by software, safety and security alarms, and watchdogs through the SMU unit, ESRx reset pins, system timers and test and debug modules. All modules are reset except PMS, SCR, SMM, Standby RAMs, Clock, Flash[45],RRAM[45], parts of SMU, SCU and the debug system based on configuration. RAMs of processing units maintain data content during and after reset. This reset ensures a fast overall microcontroller reset with minimal reset time

45 Not available on all devices of the AURIX™ TC4xx family

- Module Group Resets: A predefined group of modules provide partitioning between multiple applications. These resets are triggered for such groups of modules which are bundled together to be reset together. The module reset behavior is the same as that after individual module resets
- Module reset: The respective module is reset. Module reset is not available for CPU0, CPUcs, Flash[45], RRAM[45], PMS, IR, SCU, SMM, and CCU. This reset is also used to specifically re-initialize the respective modules

External interfaces and features

- Bi-directional PORST pin: During cold resets, the PORST pin is asserted low internally therefore driving a reset output. The PORST pin is consequently de-asserted with additional voltage hysteresis once the supply is back in the operating region
- The external request pins (ESR0, ESR1 and ESR2) support reset input trigger requests
- The external request pins (ESR0 and ESR2) support reset output propagation with configurable delay to external driver and memory devices. This is to support open-drain star connected reset architectures and cascaded sequential reset architectures
- The external request pins (ESR0, ESR1 and ESR2) support trap requests, NMI inputs, and wake-up requests, depending on configuration and system modes
- Shut-down reset sequencing of modules after a reset request over a time period to ensure regulator friendly load transients

Start-up

- Coordination together with PMS of reset release and boot
- The startup configuration (HWCFG Pins) is latched into status register in PMS

Load jump management

- Adaption of core voltage set points voltage levels for load jump handling
- Shutdown sequencing for negative load jumps in case of reset events

37.2 Functional overview

The System Mode Management (SMM) functional block describes the device system modes and transitions between them. SMM co-ordinates supply ramp-up, reset, start-up, operation, and ramp-down or standby states.

The LVD resets, Power Domain Cold Reset, Cold PORST Reset, LBIST Reset, warm PORST Reset, System Reset, and Application Reset are hierarchical in nature with the higher reset triggering the lower reset class. The Module Group Resets and module resets are exceptions to this general rule.

The PMS.PORDET detectors release the low voltage detector resets once adequate supply voltage levels are reached for isolation release, ensuring the start of the basic infrastructure and power supplies.

Once the supply system, internal clock and reference voltages are up and running, the primary voltage monitors PMS.VMONPx release the cold PORST ensuring that all internal and external supply voltages are above their minimum operational level. The LBIST would manifest externally as a device being in reset state but the device having high power consumption and load transients. The PORST pin is externally asserted or de-asserted by the external power supply to reset the microcontroller. The release of PORST activates CPU0 and CPUcs into RUN mode and starts the start-up software, and consequently the user application.

System and application resets are triggered by software and hardware sources to debounce errors and failures of parts of the microcontroller. The choice of reset depends on the time available for reset, the reset trigger, and the application needs. The SMM collects the triggers from various reset sources and issues warm reset (warm PORST, system, or application resets). All resets are propagated to external devices using ESRx, FSPx, and PORST pins.

45 Not available on all devices of the AURIX™ TC4xx family

37.3 Functional description

The SMM functional block constitutes following sub-blocks:

- Start-up
  - The start-up block latches hardware and software configuration on a reset release, coordinates along with PMS the reset release to the modules and manages boot modes together with Boot Firmware
- System Mode control
  - The System Modes manages the triggering of Idle, Sleep, and Standby Modes to various modules in the device
- Load Jump Management
  - The Load Jump Management block adapts core voltage set point voltage levels of EVRC before load jump events are triggered to have adequate voltage headroom. The shut-down sequencing scheme manages negative load jumps on reset events and mode transitions
- External Interface
  - The External Interface block manages the IO interface of ESR and PORST reset pins
- Reset Generation
  - The Reset block evaluates reset triggers and generates the required reset types

37.3.1 Start-up

The start-up phase of the device is shown below with regards to supply ramp-up, reset release, and mode transitions.

Start-up on a supply ramp-up

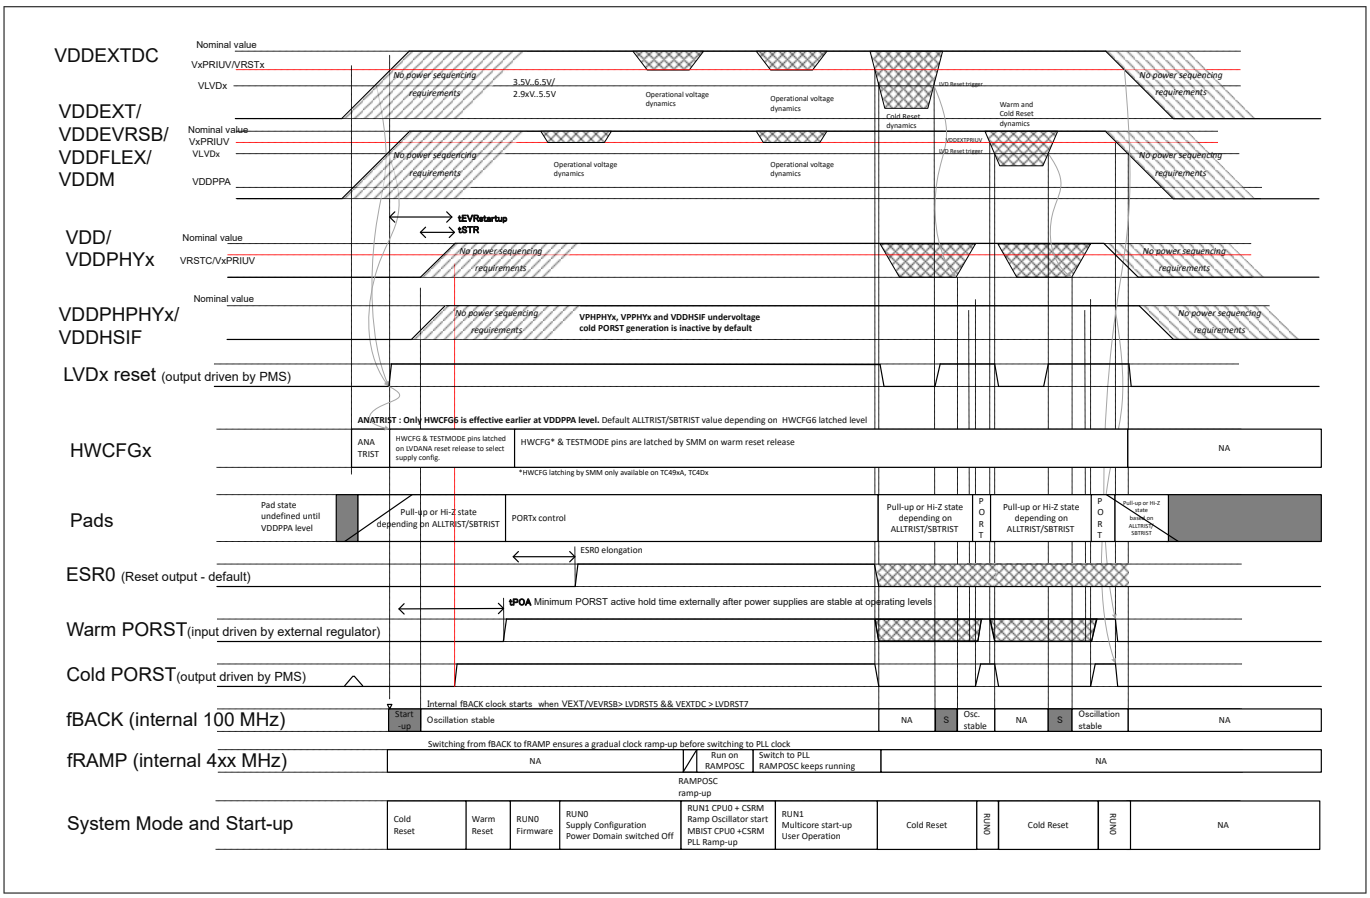

Figure 815 Cold start-up

All voltage supplies are generated externally except for the VDD supply. VDD supply may be generated externally or internally. All externally generated supplies may ramp-up and ramp-down independently with regards to start, rise and fall time(s).

If VDD (and VDDPHYx) is generated internally by the EVRC regulator, then tEVRstartup timings define EVRC start-up delay from the moment when all LVD resets are de-asserted. The EVRC start-up delay includes start-up of PMS infrastructure components including the start-up of fBACK internal 100 MHz back-up clock. The EVRC ramp-up timing is defined by the parameter tSTR.

A number of LVD detectors monitor external supply voltages VDDEVRSB, VDDEXT, and VDDEXTDC, and internal supply voltages (not present on this diagram) VDDPMS0, VDDSBRAM, VDDPMS1, and VDDPMS2. LVD reset is de-asserted when respective supplies are above the LVD limits. Refer to PMS chapter for more details.

HWCFG pads are latched directly by PMS when LVDANA reset is de-asserted and VDDEXT is supplied. Supply mode is selected based on the HWCFG[1, 2] and TESTMODE pins.

The states of general purpose pads depend on the state of the VDDEXT during ramp-up. Once the VDDPPA level is reached, the pull devices are activated. Therefore the default pad state before LVDANA reset release depends directly on the level of the HWCFG[6] pad after the moment when VDDEXT/VDDEVRSB = VDDPPA.

After LVDANA reset, the ALLTRIST/SBTRIST signal state of the PAD_CON register from PMS takes over the control of the default reset state of the pads based on the HWCFG[6] pin state latched at the moment when LVDANA reset is released. The ALLTRIST/SBTRIST signal differentiates the reset state of pads in the PORT unit in VDDEXT and standby domain respectively.

***Note**: For details about LVDANA reset refer to the PMS chapter*

Cold PORST (output) active means that the microcontroller asserts the reset internally and drives the PORST pin low thereby propagating the reset to external devices. The Cold PORST (output) is asserted by the microcontroller when at least one of the supply voltages is below the respective primary under voltage VxPRIUV or VRSTx thresholds. The Cold PORST (output) is de-asserted by the microcontroller when all supplies are above their respective primary reset thresholds, and PMS infrastructure including internal PMS supplies and fBACK clock are ready.

Cold PORST (output) generation is inactive for VDDPHYx, VDDPHPHYx, and VDDHSIFx after LVDPMS2 reset is de-asserted. Respective monitors can be activated by run-time configuration.

All operational voltage dynamics within operational limits (above cold reset limits) do not trigger the Cold PORST (output) generation.

Warm PORST (input) active means that the reset is held active by external agents by pulling the PORST pin low. It is recommended to keep Warm PORST (input) asserted until all the external supplies are above their primary reset thresholds for the time duration defined as the tPOA parameter. During warm reset release, a positive load jump on IDD rail is expected, as documented in the datasheet.

RUN0 phase starts on warm PORST de-assertion. The firmware and start-up software programs are executed on CPU0 and CPUcs. The power supply is initialized and any user configuration is applied at this step. User program enables the ramp-up oscillator RMPOSC, which allows for gradually ramping-up of the operating frequency of the modules (including CPUx) in order to limit the load current profile. At the same time, PLL ramp-up is enabled and once completed the internal clocks can be switched to the PLL clock output.

Start-up after warm PORST

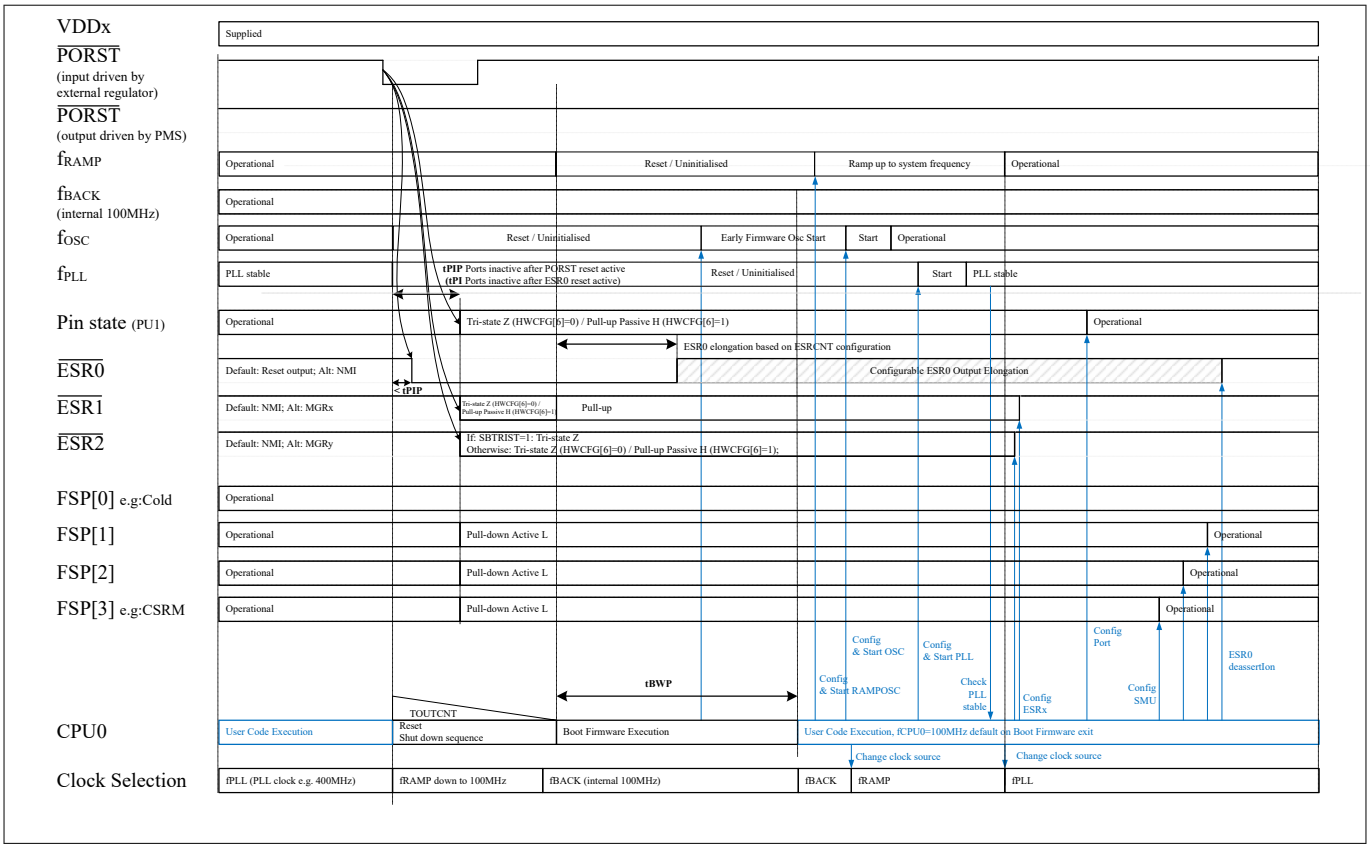

Figure 816 Start-up on warm power-on reset

The figure above illustrates the start-up of the microcontroller modules during and after warm PORST.

The warm PORST is driven low by the external agent, while internal PORST reset output remains released, power supplies remain stable within operational limits, and the primary voltage monitoring subsystem does not trigger Cold PORST.

37 System Mode Management (SMM)

The Power Management Subsystem (PMS) is operational through the reset assertion phase including internal clock fBACK.

Once PORST is asserted, shut down reset sequencing is activated which is completed within the time defined by TOUTCNT. After TOUTCNT expires, the reset is triggered.

The reset time of the PU1 or PU2 pins (whose default state is active) is defined by the time delay tPIP in the datasheet. The tPIP time also includes the delay for ESR0 and FSPx outputs if configured to be driven low. Default state of the common PU1 pads is defined by HWCFG[6] latched in the ALLTRIST/SBTRIST bit in register PAD_CON in PMS after initial cold start.

On PORST reset release after reset shut down sequence is completed, CPU0 and CPUcs start execution of the boot firmware for tBWP time duration. At boot firmware completion, CPU0 PC is set to the start-up address of the user program based on configuration and Oscillator and PLL configurations shall be reinitialized.

37.3.1.1 Start-up configuration

Hardware configuration (HWCFG) pins latch and start-up

The HWCFG pins are latched on LVDANA reset release into the PMS.PADSTAT register by PMS to determine the start-up hardware configuration and whether the internal EVRC regulator needs to be started.

***Note**: For supply start-up, cold PORST reset release and HWCFG latch on LVDANA reset release, please refer to the PMS chapter.*

Based on the STSTAT latched value, selection of Test Mode and Debug interface is decided.

Test mode and debug interface selection

On Power-On Reset release, the decision has to be made as to whether the device should operate in Test Mode or in RUN (User) Mode. The Test Mode is only for Infineon internal device testing and is not intended for an application. It is recommended to tie the $\overline{\text{TESTMODE}}$ pin permanently to an external pull-up in the application. The entry into Test Mode is made based on the latched value of the $\overline{\text{TESTMODE}}$ pin. The result is visible in the STSTAT.MODE bits. If device accidentally enters Test Mode after PORST, GPIO would be in reset state and pull devices would be activated as configured.

If the RUN(User) Mode was selected the next decision is which debug interface type shall be active for debugging until the next warm power-on reset. This decision is made based on the latched value of the pin $\overline{\text{TRST}}$ on $\overline{\text{PORST}}$ release.

Table 1635 Normal mode/test mode input selection

Pins	Description
$\overline{\text{TESTMODE}}$	Latched $\overline{\text{TESTMODE}}$ Pin on warm power-on reset release ($\overline{\text{PORST}}$ pin deassertion) The information if test mode is entered is visible in STSTAT.MODE1 and STSTAT.MODE2 bitfields. 0 A Test Mode can be selected 1 RUN (User) Mode is selected
$\overline{\text{TRST}}$	Latched $\overline{\text{TRST}}$ Pin on warm power-on reset release ($\overline{\text{PORST}}$ pin deassertion) The information about the latched value is visible in STSTAT.TRSTL bitfield. 0 The JTAG interface is active 1 The DAP interface is active

37.3.1.2 Software reset trigger

A software reset trigger can be initiated through SWRSTCON.SWRSTREQ bit-field. An application, system or Module Group Reset is triggered depending on the configuration in the RSTTRIGCTRLA.SW bit-field.

37.3.2 System modes

Different system modes ensure that the device operates with minimum required power for the corresponding device state. A progressive reduction in power consumption is achieved by invoking IDLE, SLEEP or STANDBY modes. The IDLE modes are specific to processing units where as SLEEP and STANDBY modes influence the complete system.

On start-up, the device first enters RUN0 mode with CPU0 and CPUcs running and all core power domains active. To reduce power consumption, the user may switch off power domains if present triggering a transition to RUN1 mode. Depending on configuration, the power domains shall again be switched off after every power domain cold reset type to transition to RUN1 mode. The clock is ramped-up thereafter and remaining CPUs and Peripherals are activated. The available power domains are documented in PMS chapter.

Processing units can be individually set into IDLE mode depending on application needs to be woken by interrupts, watchdog or other wake-up sources. In addition an arbitrary selection of peripherals and processing units can be clock gated using SLEEP modes depending on application needs to be woken up by interrupts, watchdog and other wake-up sources. The STANDBY modes are triggered to reach the lowest power states. Standby RAM is kept supplied and only SCR, RTC or WUT are kept active during STANDBY modes.

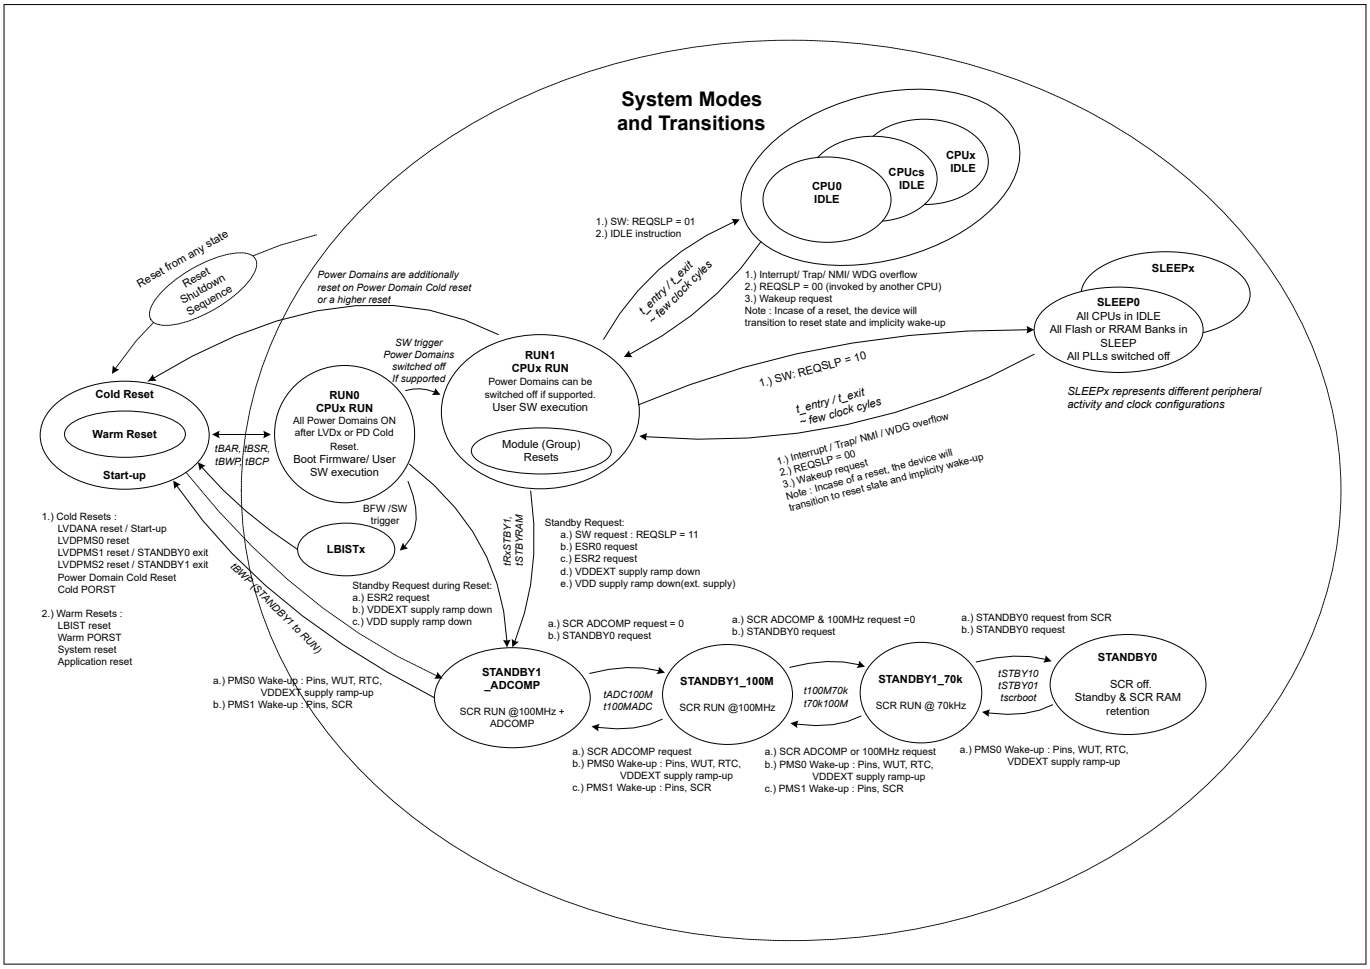

Figure 817 System states and transitions

As shown in the figure, there are two power modes available for each CPU:

- CPU Run Mode
- CPU Idle Mode

Table 1636 CPU modes

Mode	Description
Run mode	The CPU clock is active and code is being executed by CPU.
Idle mode	CPU may enter IDLE Mode in the following cases: • When a software Idle request is issued by setting register bits PMCSRn.REQSLP = 01_B because CPU has no active tasks to perform. • When a software Idle request (PMCSRx.REQSLP = 01_B) is issued by another CPU • WAIT instruction executed by CPU The CPU code execution is halted and CPU clock is disabled in Idle state. The peripherals continue to remain active. CPU RAM memories are accessible to other bus masters and peripherals. CPU may exit Idle Mode in the following cases: • When an interrupt occurs to a CPU returning the CPU to Run Mode • When a trap occurs like an NMI trap event • When the CPU watchdog or safety watchdog timer overflow events trigger an SMU alarm in turn leading to a CPU interrupt • When a MSB bit wrap of the CPU Watchdog counter takes place • When an application reset, system reset or any higher reset occurs • When a software run request (PMCSRx.REQSLP = 00_B is issued by another CPU

As shown in figure, there are three mode categories available for the system:

- Run Mode
- Sleep Mode
- Standby Mode

Furthermore, flexible reduction of power consumption is possible through the following measures:

- Reducing individual CPU power consumption by means of CPU clock scaling
- Disabling the module clock by setting bit DISR in respective module CLC register if the module need not be active at the current point of time
- Reducing the system frequency (e.g. fSPB; fSRI) without changing individual peripheral clocks
- Reducing individual peripheral clock frequency without changing system clock frequency. Main peripherals are provided with independent clocks separately from system SRI and SPB clocks

Table 1637 System modes

Mode	Description
Run mode	At least one CPU is not in Idle mode and Sleep or Standby mode has not been requested.

(table continues...)

Table 1637 (continued) System modes

Mode	Description
Sleep mode	System may enter Sleep Mode in the following cases: • When a software Sleep request is issued by setting PMCSRn.REQSLP = 10_B by the master CPU CPU code execution is halted and CPU Idle state is entered. Peripherals are set into sleep state if so configured in the respective CLCx.EDIS bit. Ports retain their earlier programmed state. System may exit Sleep Mode in the following cases: • When an interrupt or trap occurs on the CPU • When an NMI trap event takes place • When CPU watchdog or safety watchdog timer overflow events trigger an SMU alarm leading in turn to a CPU interrupt • When a MSB bit wrap of master CPU watchdog counter takes place • When an application reset, system reset or any higher reset occurs
Standby mode	System may enter Standby Mode STANDBY0 or STANDBY1 in the following cases if configured to do so: • Standby entry on a software standby request issued by setting PMCSRn.REQSLP= 11_B by the master CPU • Standby entry on an ESR1 (NMI) or ESR2 (implemented in PMS) assertion event • Standby entry on a primary or secondary under-voltage event during VDD supply ramp-down • Standby entry on a primary or secondary under-voltage event during VDDEXT supply ramp-down (Only VDDEVRSB supplied during STANDBY mode) The Standby domain constituting the Standby RAM, the 8 bit standby controller, standby ports including pin wake-up logic remain actively supplied. The power to the rest of the chip is completely switched off. VDD supply rail is switched off. SCR, WUT, RTC and Standby RAM supply maybe active or inactive during Standby mode (Refer PMS module chapter for details). System may exit Standby Mode in the following cases: • When a wake-up edge is detected on selected pins/ESRx • When a wake-up request is issued by the 8-bit Standby Controller (SCR) • When a wake-up request is issued by Wake-up timer or RTC • When PORST pin is asserted • When VDDEXT supply ramps up (Only VDDEVRSB supplied during STANDBY mode)

37.3.2.1 IDLE mode

In case there are no active tasks to perform, a CPU may be requested to enter Idle mode during run time by writing to the respective PMCSRx register and setting the bit-field REQSLP = 01_B.

Entering Idle mode

The following events can invoke a CPUx Idle request:

- CPUx setting itself in Idle by writing its own PMCSRx register: Idle mode may also be simultaneously triggered for additional CPUs based on PMSWCR1.CPUIDLSEL configuration
- Another CPU[y] setting CPUx into Idle: The Idle request is issued immediately on setting PMCSRx.REQSLP = 01_B

The CPU watchdog may be disabled or slowed down by reprogramming the timers before triggering Idle request through Software. On an Idle request, the CPU finishes its current operations and sends an acknowledge signal back to the SMM module. It then enters an inactive state in which the CPU clocks and the respective RAM memory units are clocked off.

State during Idle mode

During Idle Mode, memory accesses to the CPU memories from other bus masters cause these units to wake-up automatically to handle these transactions. When memory transactions are complete, the CPU memories return to Idle state again. Once Idle mode is entered, the state is reflected in the PMCSRx.PMST status bits.

Exiting Idle mode

In Idle mode, the CPU will return to Run mode in response to the following wake-up events:

- An interrupt request from a source mapped to the CPU.
- An NMI trap request is received to wake-up the corresponding CPUs
- A MSB bit wrap of the corresponding CPU Watchdog counter occurs. A wake-up signal is provided by the respective watchdog toward CPU on a timer-value transition $7FFF_H$ to 8000_H. Further details are documented in Watchdog Timer Unit chapter
- Setting the register bits PMCSRx.REQSLP = 00_B to set the CPUx into Run mode by another processing unit
- Exit owing to a reset event: The system enters reset state on an Application reset or any higher reset.

If it is woken by a watchdog timer overflow event routed through the SMU to the CPU, or by an NMI or an interrupt, the CPU will immediately vector to the appropriate interrupt or trap handler.

CPU module reset will not result in exit from Idle mode if it was already in Idle state. An explicit wake-up event has to happen before the CPU is in the Run state again.

Table 1638 CPU[x] Idle mode entry sequence, behavior and status indication

Condition	CPU sets only itself into Idle CPU[x] writes PMCSR[x].REQSLP = 01_B	Another CPU setting a CPU into Idle CPU[y] writes PMCSR[x].REQSLP = 01_B	CPU sets all CPUs into Idle CPU[y] writes PMCSR[y].REQSLP = 01_B
CPU entry event to idle mode	A CPU[x] should be able to set itself into Idle. CPUIDLSEL = 0	A CPU[y] or (other CPUs should be able to set CPU[x] into Idle if they have the access rights. CPUIDLSEL = 0	CPUIDLSEL = y+1 is already set by a CPU having access rights.

(table continues...)

Table 1638 (continued) CPU[x] Idle mode entry sequence, behavior and status indication

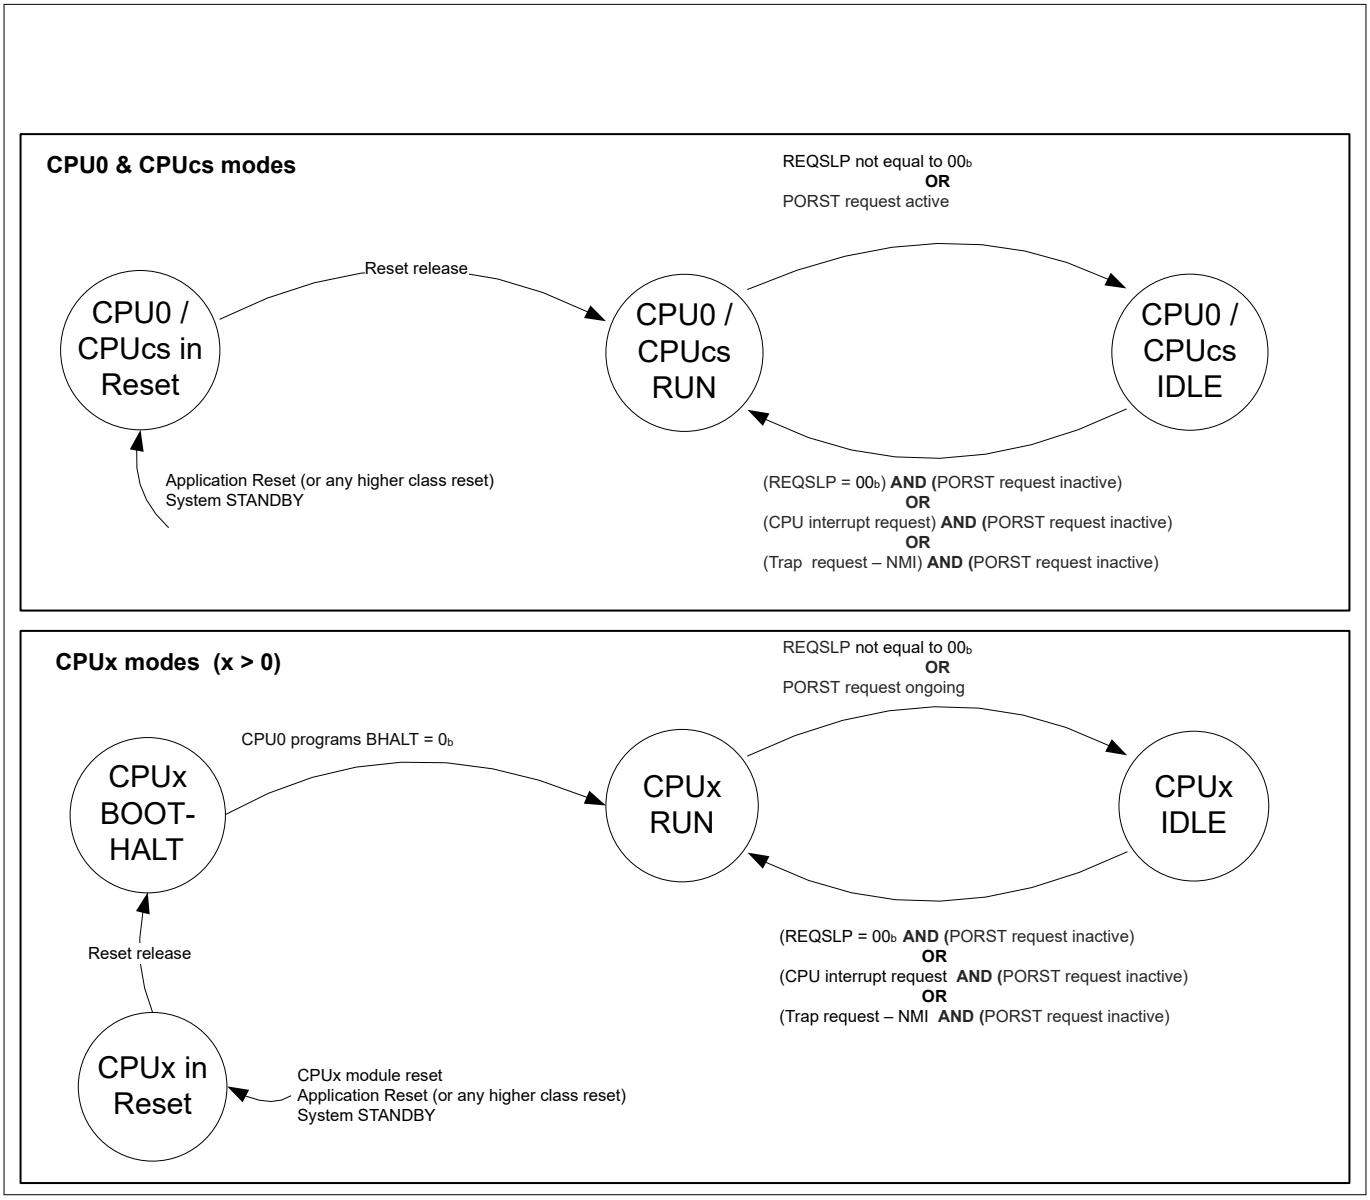

Figure 818 Idle modes and transitions

37.3.2.2 SLEEP mode

Entering SLEEP mode

System may be requested to enter Sleep mode via software by writing to the CPU's PMCSRx register and setting the bit field PMCSRx.REQSLP = 10_B.

An example sequence for Sleep mode is enumerated below:

- The Sleep mode entry shall be enabled in respective module configuration registers. The respective module CLCx.EDIS register bit shall be cleared for all peripherals intended to be inactive in Sleep mode
- The respective CPU watchdogs may be disabled or re-configured for slower modes
- Master CPU code execution maybe switched from Flash[46] or RRAM[46] to RAM if required. Individual Flash or RRAM banks may be explicitly set into (bank) sleep state as documented in NVM or NVMR and DMU sections
- The analog modules TMADC and DSADC[46] maybe switched off in Sleep state. The high speed communication modules and HSPHYx modules[46] maybe switched off in sequence if not required to be active in Sleep state
- It should be ensured to select the individual clocks from Clock Control Unit for peripherals which need to remain active during Sleep mode. Certain communication and timer peripherals have clocks independent from the system frequencies, namely SRI and SPB clocks, to allow the possibility to bypass the system PLL. In such cases, the System PLL is switched into bypass mode and consequently the DCO would be switched off. Peripheral clock will continue to run clocking the modules active during sleep mode. The system clock frequencies, namely SRI and SPB clocks, maybe then reduced to the minimum possible values through the low power divider and Kx divider to reduce the current consumption. In some cases the respective peripherals may be clocked directly from external crystal / resonator depending on application
- The interrupt control unit provides the infrastructure for wake-up from sleep state and therefore need to be kept active with a minimum SPB bus frequency. The respective module wake-up interrupts are routed to CPU to wake-up on an interrupt event
- Sleep Mode may be entered as a unanimous decision of all the CPUs when all of the PMCSRx registers in the system request it AND PMSWCR1.CPUSEL = 111_B. Sleep Mode may also be entered based on a singular decision of a master CPU based on the configuration of the CPUSEL register. The master CPU watchdog may also be disabled or slowed down before issuing a Sleep request

State during SLEEP mode

Sleep Mode is disabled for a module if the respective module CLCx.EDIS bit is set. The sleep request is ignored in this case and the corresponding unit continues operation as configured. If CLCx.EDIS is cleared, the clock of the module is gated. The current consumption during Sleep mode is documented in datasheet.

***Note**: The module list in the table below is representing the whole AURIX™ TC4xx family. If respective module or module function is not available in a given product then the information is not relevant*

Table 1639 Module activity and configuration during sleep mode

Module active during sleep mode	Module and clock state during sleep mode
PPU	PPU continues to run during Sleep mode. If required, it shall be ensured that PPU is set into Idle before Sleep mode is triggered
CPUcs	CPUcs is put into Idle state. CPUcs wakes-up on respective interrupt.
CPU	All CPUs are put into Idle state. CPU watchdogs maybe active with slower configuration. CPUs wake-up on respective interrupt

(table continues...)

[46] Not available on all devices of the AURIX™ TC4xx family

Table 1639 (continued) Module activity and configuration during sleep mode

Module active during sleep mode	Module and clock state during sleep mode
Flash	Flash banks may be selectively set into bank sleep state. ***Note**: For details about "deep sleep" refer to the NVM section of the user manual*
Ports	All Ports retain their earlier programmed state.
CAN ASCLIN QSPI I2C	Peripheral PLL maybe kept active providing the minimal required module clock for function (for example - f_{MOD} = 5 MHz - 40 MHz). Module may alternatively run on f_{OSC} allowing also complete switch off of the Peripheral PLL. System PLL may be switched into low power mode if supported. $f_{SRI}$and f_{SPB} clocks can be reduced (for example - ~1-2 MHz) via LPDIV and / or Kx dividers. System PLL may also be switched off and switched to Back-up clock depending on application. Module FIFO and DMA allows autonomous handling of messages without involvement of CPU. External communication may selectively remain active.. QSPI may need to service external watchdog if required by application. A timer module maybe used to trigger DMA or fill the FIFO allowing autonomous handling of messages without involvement of CPU. Input messages are monitored and wake-up interrupt is triggered. Wake-up on CAN wake-up message identifier via CAN interrupt or Wake-up on LIN wake-up frame via ASCLIN interrupt or Wake-up in case of fault diagnosis of external device via a QSPI interrupt
HSPHYx	HSPHY modules are inactive.
GTM STM eGTM	Peripheral PLL is disabled. System PLL is active and provides the module clock (for example -f_{MOD} ~ 1-2 MHz). $f_{SRI}$and f_{SPB} clocks are reduced to (for example - ~1-2 MHz) via LPDIV and / or Kx dividers. It is recommended to switch off the GTM/eGTM module completely and use smaller timer modules like RTC, STM or WUT during Sleep state to reduce power consumption. Wake-up on timer overflow or capture event via GTM/eGTM interrupt or Wake-up on timer overflow via STM interrupt
xADC	All ADC units are switched off. Peripheral PLL is disabled. System PLL is active and provides the module clock (for example - f MOD ~f SPB ~ 1-2 MHz). SCR.ADCOMP units is used to handle ADC conversions and wake-up interrupt is issued by the SCR
Pin Wake-up ESR1 ESR2	Infrastructure modules SMM, CLOCK and Interrupt Router is kept active. Peripheral PLL may be disabled. $f_{SRI}$and f_{SPB} clocks reduced to (for example - ~1-2 MHz) via LPDIV / Kx dividers. System PLL may also be switched off and switched to Back-up clock depending on application. Wake-up on Edge / Level detection on pin routed to ERUx, ESR1, ESR2 or PORT module via interrupts or polling Port registers on an active timer interrupt
PMS WUT RTC	PMS and SCR is kept active Peripheral PLL is disabled and System PLL is bypassed. $f_{SRI}$and f_{SPB}clocks reduced to (for example - ~1-2 MHz) via LPDIV / Kx dividers. System PLL may also be switched off as module clock is derived from Back-up clock Wake-up on timer overflow via WUT interrupt. Wake-up on RTC Compare 0 or Compare 1 interrupt

(table continues...)

Table 1639 (continued) Module activity and configuration during sleep mode

Module active during sleep mode	Module and clock state during sleep mode
RRAM	RRAM banks may be selectively set into sleep state.

Exiting SLEEP mode

The system will exit Sleep mode on any wake-up event that causes any master CPU to exit Idle Mode depending on CPUSEL configuration. Only the master CPU associated with the interrupt wake-up event would be set into Run mode (REQSLP = RUN, PMST = RUN). Other CPUs will remain in Idle (REQSLP = SLEEP, PMST = IDLE)[47]. An NMI trap event will wake-up the respective CPU as configured in TRAPS_CPU_DISx and TRAPS_CS_DIS registers. A MSB bit wrap of the corresponding master CPU Watchdog counter would also wake-up the master CPU. The response of the CPU to being woken up from Sleep Mode is also the same as for Idle Mode. Peripheral units that have entered Sleep Mode will switch back to their selected Run Mode operation. Wake-up latency from Sleep mode depends mainly on the extent of clock ramp-up required after wake-up keeping the load jump constraints. If PLL is switched off, the wake-up latency would include the time to ramp and lock the PLL. The sequence after wake-up is dependent on the entry sequence and mainly constitutes ramping back the clock system, activating analog and Flash or RRAM modules[46], switching from RAM to Flash or RRAM execution and activating additional CPUs. The time taken between interrupt trigger availability until CPU has woken up and is executing next instruction is less than 3 SPB + 20 SRI clock cycles.

Table 1640 System sleep mode entry sequence, behavior and status indication

Condition	Master CPU[x] writes PMCSR[x].REQSLP = 10_B	All CPUs write respective PMCSR[y].REQSLP = 10_B
System entry event to sleep mode	A master CPUx (any CPU except CPUcs) should be able to trigger SLEEP mode if CPUSEL = x+1_B is already set by a CPU having access rights. PPU Idle request is not triggered.	CPUSEL = 111_B is already set by a CPU having access rights before. PMCSR[y].REQSLP= 10_B System enters SLEEP mode if all CPUs have requested for SLEEP entry. PPU Idle request is not triggered.

37.3.2.3 Low frequency applications

If an application has the need for a reduced power consumption but does not want to go into a SLEEP mode the restrictions mentioned in this section need to be considered.

Certain applications may require reduced system frequencies, namely f_{SRI} , f_{SPB} and f_{CPB}[48)]. to a minimum allowed value according to the datasheet. If therefore the system frequency f_{pll0} is being configured below 100 MHz there are specific constraints applicable as described in this section.

***Note**: Radar devices of the AURIX™ TC4xx shall not run applications on system frequencies below 100 MHz*

Requirements for low frequency mode

For low frequency application the following conditions shall be met.

- The System PLL shall be configured using the N and P divider to the required target output frequency which shall not be divided further down for example for f_{SRI}
- The system frequency clock dividers shall not be configured to reduce the System PLL output f_{pll0} further down. This means a division by 1 shall be applied
- The Peripheral PLL shall be configured to nominal output values f_{pll1}=160 Mhz, f_{pll2}=200 Mhz, f_{pll3}=200 Mhz

Module restrictions for system frequencies below 100 MHz

A reduced frequency can have limiting effects on different IPs as well as on the clock ratios between different clock domains.

If the system frequency is being reduced below 100 MHz the SystemPLL shall be configured to the required output frequency f_{pll0} while all dividers for the system clocks are set to 1 to ensure a 1:1 ratio between all system frequencies. The respective dividers are SPBDIV, CPBDIV[48)], TPBDIV, SRIDIV, FSIDIV, FSI2DIV, STMDIV, , GETHDIV; RCBDIV, GTMDIV[48)]; eGTMDIV[48)], MCANHDIV, LETHDIV, CANXLHDIV.

If a clock is not needed in this case it shall be switched off.

For 400 MHz devices, if the CSRM subsystem is used, the minimum allowed system frequency f_{pll0} is 50 MHz to ensure the minimum frequency of CPU-CS is valid.

48 Not available on all devices of the AURIX™ TC4xx

37 System Mode Management (SMM)

The Peripheral clock tree (including peripheral PLL and Peripheral clock dividers) shall stay on nominal settings with the exception of f_{MCAN} and f_{CANXL} due to the dependency on the host frequency.

***Note**: The restrictions given by the CLOCKING chapter are still applicable as well as the related information given in the datasheet*

***Note**: The module list in the table below is representing the whole AURIX™ TC4xx family. If respective module or module function is not available in a given product then the information is not relevant*

Table 1641 Module restrictions for system frequencies below 100 MHz

Module	Restriction
HSSL	HSCT shall not be used for cases of f_{SRI} below 100 MHz
xSPI	The XiP Write feature[1)] shall only be used if sclk_out is lower or equal to f_{SRI}. To achieve this the xSPI internal clock dividers shall be used
CANXL	CANXL IP shall only be used with a minimum host frequency of f_{CANXLH} 80 MHz in case it is used for CANXL protocol
MSC	FAST mode shall not be used for system frequencies below 100 MHz Please refer to the baud rate configuration table of the MSC chapter for more details on baud rates for low frequencies
PSI5-S	PSI5-S shall not be used for cases of f_{SRI} below 100 MHz
NVM	The bank sleep feature shall not be used for f_{SRI} below 100 MHz
NVMR	For effects on writing operations for f_{FSI} below 100 MHz please refer to the datasheet of the respective derivative Reading operations can have a reduced performance up to 80%
HS communication including HSPHY LETH GETH PCIe xSPI	High speed communication which involves HSPHY shall not be used for cases of f_{SRI} and f_{SPB} below 100 MHz
DRE	DRE shall not be used for system frequencies f_{SRI} and f_{SPB} below 100 MHz

1) feature is not available on all derivatives of the AURIX™ TC4xx

37.3.3 External interface

This chapter describes the behavior of main external interface pins supporting reset function, interrupt/NMI function and error feedback function.

PORST bidirectional reset pin function

The PORST pin is the main reset input pin of the device and supports following functions:

- If PORST pin is externally asserted, a warm PORST reset type is triggered
- The PORST pin is driven low by PMS on supply fail detected by primary supply monitors leading to cold PORST reset state

ESR0 pin function

The ESR0 pin provides external indication of internal resets and can be used as a reset input or output pin. Following functions are supported by ESR0 pin:

- The pin provides reset indication of a PORST, System or Application Reset. The pin is driven low by default on an internal application reset. It is used to reset the external device immediately when microcontroller is set into reset state. The ESR0 pin de-assertion can be delayed to microcontroller reset release by configuring an elongation counter
- The pin can trigger a Trap request
- The pin can trigger an Application or System or Module Group Reset
- The pin can trigger a wake-up event from Standby Mode in PMS if VDDEXT is supplied during Standby Mode
- The pin can be used as a GPIO pin

***Note**: If configured as GPIO the ESR0 will keep its previously configured state until the reset assertion of the System Reset at the end of the shutdown sequence. In this case the ESR0 will start the reset indication as configured in ESR0CNTCTRL with System Reset assertion.*

ESR1 pin function

The ESR1 interface pin is configured as an Trap/Interrupt trigger by default. This is connected to external regulator or safety monitor to trigger communication with device to service an external alarm event. Following functions are supported by ESR1 pin:

- The pin is configured to trigger a trap request by default after reset. The trap/NMI request is used together with SPI communication with the external regulator/monitor to complete the communication transaction
- The pin can trigger a wake-up event from standby mode in PMS if VDDEXT is supplied during Standby Mode
- The pin can trigger an Application or System or Module Group Reset
- The pin can be used as a GPIO pin
- The pin can be used as trigger for standby entry

***Note**: In debug mode the standby entry by ESR1 can be blocked by CPUs being in debug halt mode. If in that case an unconditional standby entry is needed the PMSWCR1.IRADIS shall be used*

ESR2 pin function

The ESR2 interface pin is implemented in the standby domain to ensure reset, wake-up and trap functionality also in the lowest power-down modes. Following functions are supported by ESR2 pin:

- The pin can trigger a trap request
- The pin can trigger an Application or System or Module Group Reset
- The pin can trigger a wake-up event from Standby modes in PMS. ESR2 can be used to trigger ramp-up of external supply on a wake-up event
- External reset indication to external driver and memory devices implemented in PMS

- The pin can be used as a GPIO pin
- The pin can be used as trigger for standby entry

***Note**: GPIO registers implemented in PORTS module, instance P33*

Error pins - FSP0, FSP1, FSP2 and FSP3

Error pins are asserted low or stop toggling when there is a critical alarm which needs to be debounced externally through a warm PORST event or supply cycling of the microcontroller. Multiple FSP pins are provided to differentiate the external reaction of the monitors. FSP0 is in general configured to trigger warm PORST reaction. The other FSP pins may be configured to trigger a supply re-ramp and a cold PORST event if the alarm is supply related.

37.3.3.1 PORST pin

The PORST pin is the main reset input pin and triggers a warm power on reset of the device. It shall be connected to the external regulator or supply monitor. If this pin is left open then the default behavior is that the device remains in a reset state.

The PORST pin supports following functions:

- Warm PORST reset input function: It is expected that external monitor or regulator asserts PORST pin if operating conditions are violated, namely supply voltages. It is also expected that the external monitor asserts PORST pin if microcontroller is stuck and not responding or the external watchdog was not serviced by the microcontroller.
- If PORST pin is externally asserted, a warm PORST reset is triggered. It is ensured that all warm resets are sequenced internally and RAM contents are not affected. Reset is executed only after RAM write operations are completed and processing units have reached IDLE state.
- If the PORST pin is kept asserted externally after a system start-up and supply voltages are within operating range, then the warm PORST reset state will be kept extended until PORST pin is de-asserted.
- The PORST pin is driven low by PMS on a cold PORST reset trigger by activating a strong pull-down capable of sinking I_{PORST} current as documented in the datasheet. The strong pull-down is deactivated after system is back to RUN0 mode. During initial Boot strong pull-down is only released on reaching RUN0 (Operation) mode. During Standby state and during transition from Standby state to RUN0 (Operation) mode, strong pull-down is not activated.
- The PORST pin has an integrated weak pull-down function to ensure that device stays in reset state if pin connection or PCB routing to the PORST pin is broken. The weak pull-down is active in all system states except Standby mode. In Standby mode, the weak pull-down is deactivated to reduce standby current. The weak pull-down is activated by default during Supply Start-up phase and during Standby-exit.
- Multiple masters can trigger PORST if connected together in an open-drain circuit with an external pull-up. Depending on push-pull or open drain implementation of reset output by external regulator, care should be taken in the dimensioning of the pull-up and series resistances on PORST connection.
- The PORST pin has a basic analog spike filter to filter out noise as documented in the datasheet. It supports TTL input level for 5 V operation and degraded TTL levels for 3.3 V operations as documented in the datasheet.
- In addition to the inherent analog spike filter, PORST pin supports a digital filter that can be additionally activated via PMS.PAD_CON.PORSTDFEN register bitfield to filter higher noise at input.

37.3.3.2 External service request interface (ESRx)

The external service request ESRx pin functions are described in this section.

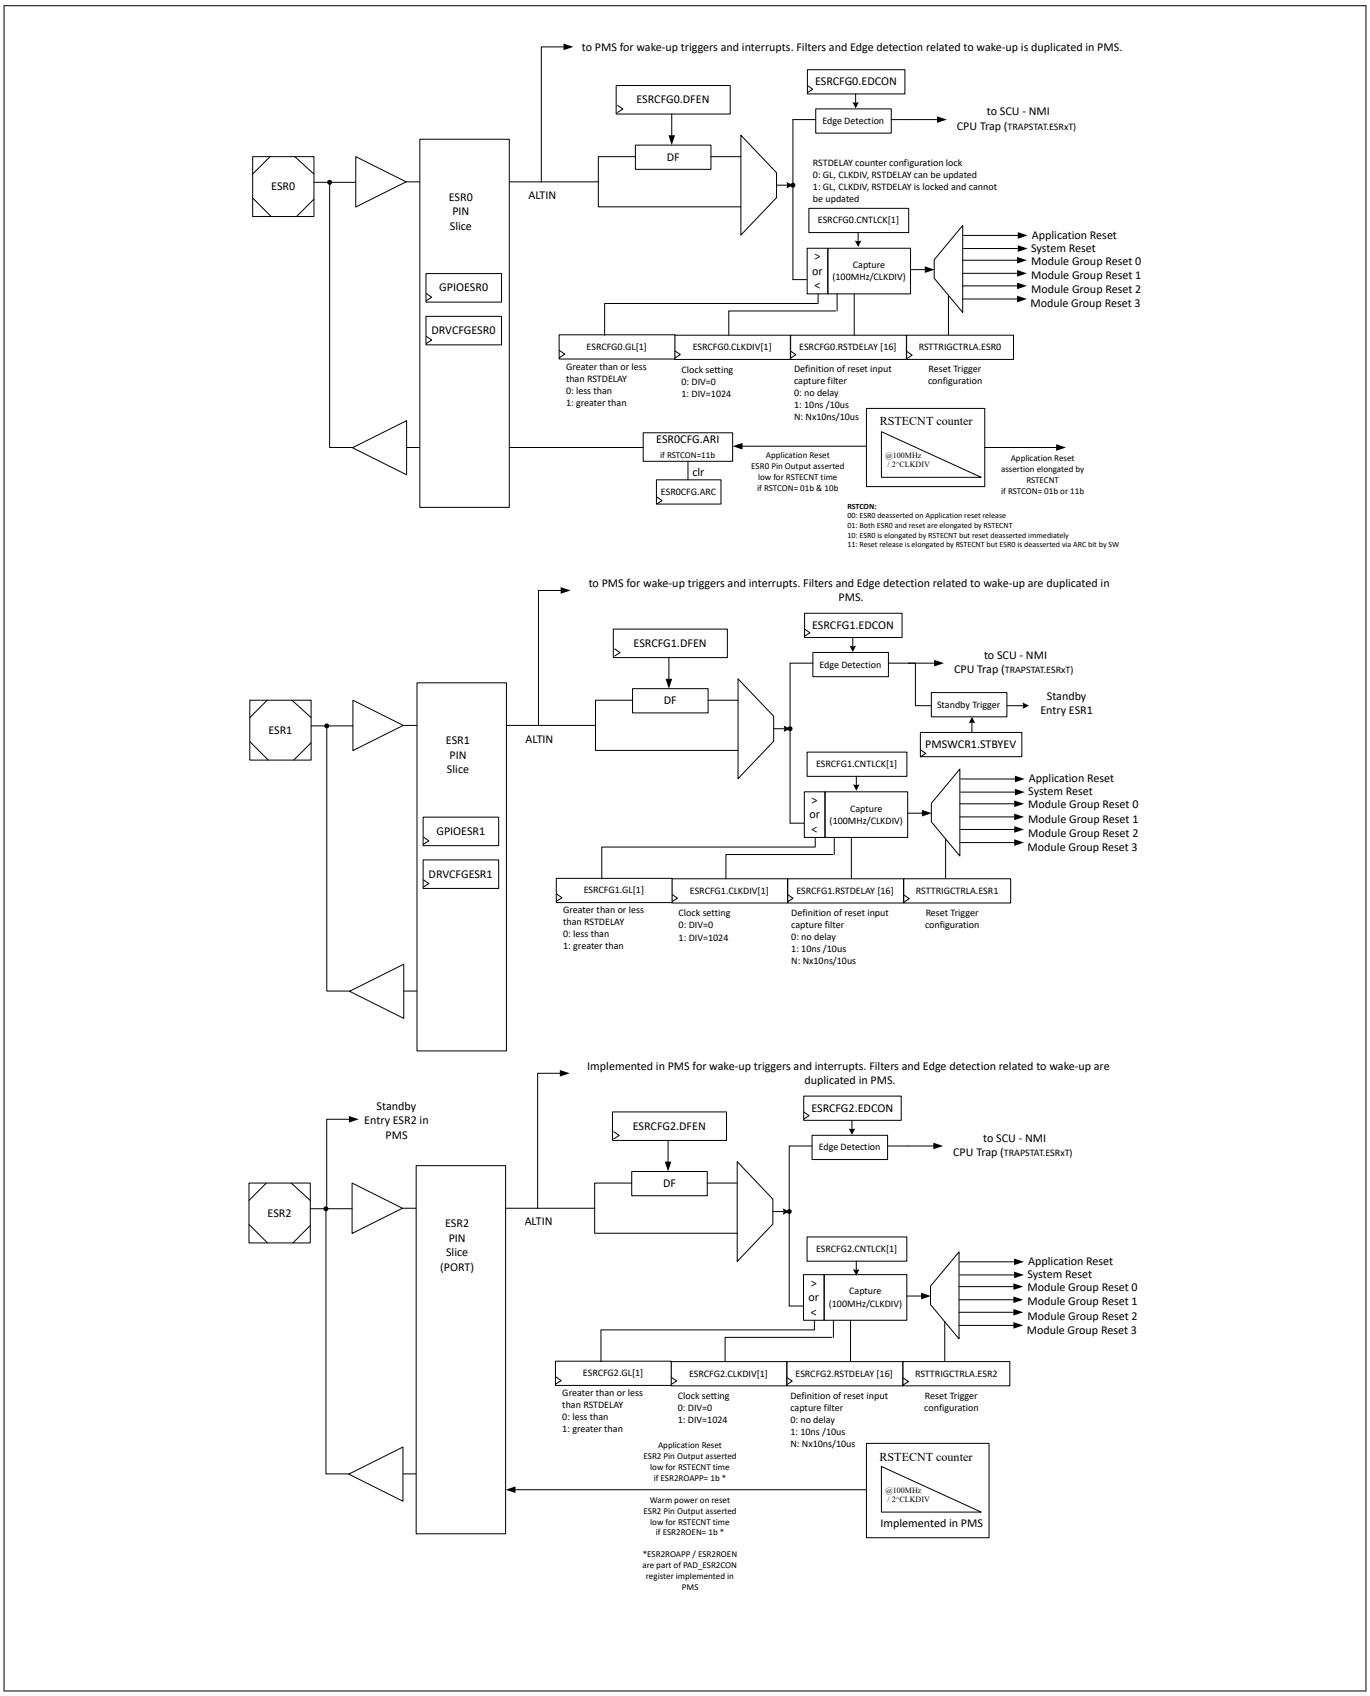

Figure 819 ESR pins connectivity and behavior

37.3.3.2.1 ESRx pin reset input

An $\overline{ESR0}$/$\overline{ESR1}$/$\overline{ESR2}$ pin reset request trigger can lead to a System Reset or an Application Reset or any Module Group Reset. The type of the reset to be triggered on an external ESRx pin low assertion is configured through RSTTRIGCTRLA.ESRx.

By default after a power-on reset, ESR0 is configured to trigger an application reset as shown in the following figure. An external device may extend an existing reset condition by holding the ESR0 pin active if RSTCON=00b or RSTCON=01b.

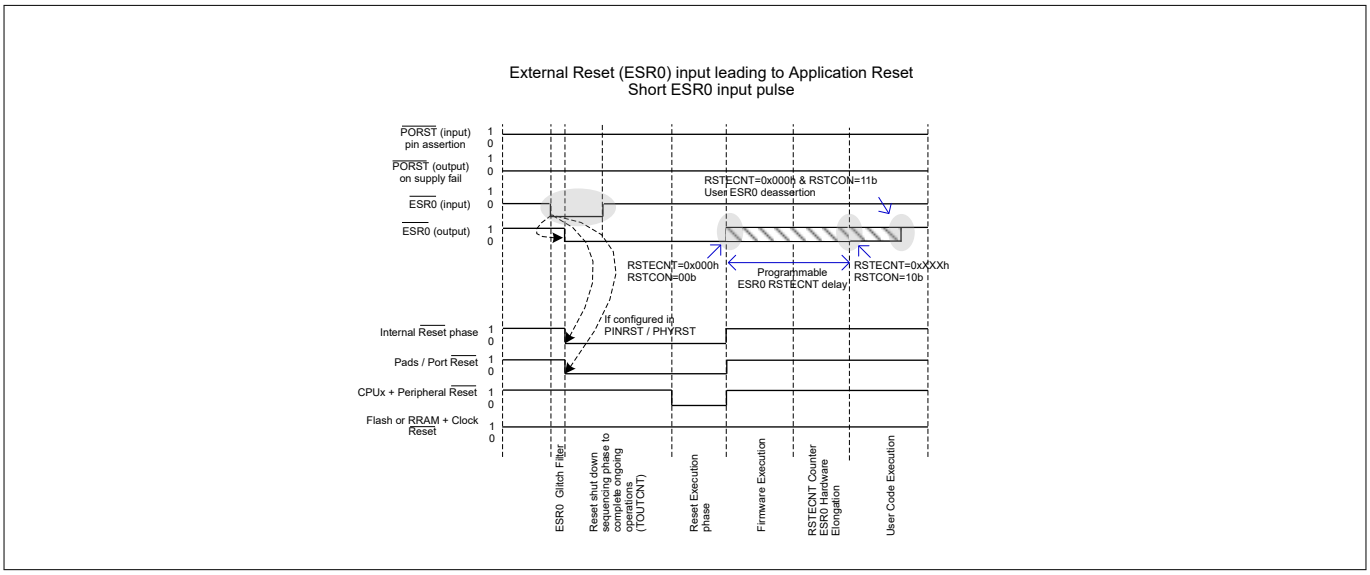

Figure 820 ESR0 reset input behavior with short input pulse

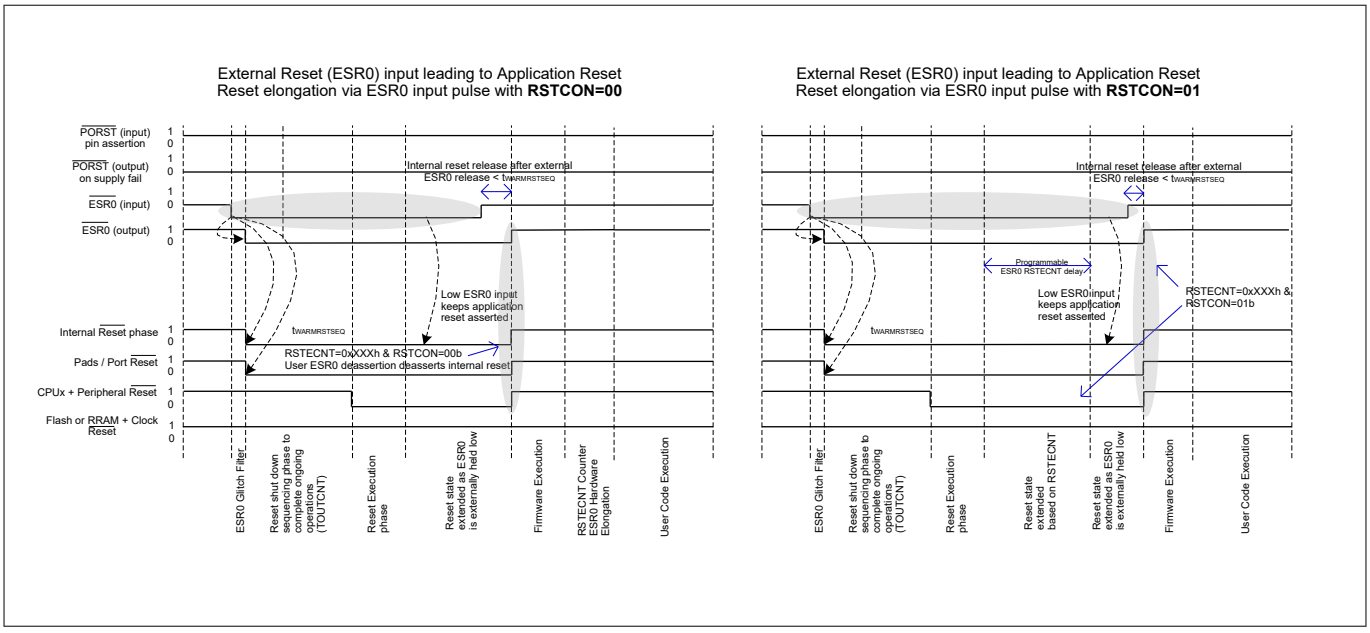

Figure 821 ESR0 reset input with long input pulse

The input signals $\overline{ESR0}$/$\overline{ESR1}$/$\overline{ESR2}$ can be filtered. The filter is enabled by register bit ESRCFGx.DFEN . If the filter is enabled, then pulses less than 10 ns cannot pass the filter and pulses longer than 100 ns will always result in forwarding the trigger to the capture block for fSPB ≥ 20 MHz in RUN mode.

The ESRCFG register defines the reset input capture delay behavior. The reset input low pulse duration is captured and compared to be greater than or less than RSTDELAY value and clocked as configured in CLKDIV bit-field. The CNTLCK bit-field allows update of the parameters and need to be explicitly locked for the updating

the parameters. The intention of this configurability is to use the same ESR pin to generate simultaneously NMI or Trap request and Reset by differentiating the time durations of the respective events.

By default after reset, ESRx pads have pull-ups but during LBIST,the ESRx pin is changed to a weak pull-down.

The GPIO pin functionality of $\overline{\text{ESR0}}$ and $\overline{\text{ESR1}}$ pins is configured through registers GPIOESRx and DRVCFGESRx. The GPIO pin functionality of $\overline{\text{ESR2}}$ is configured through the PORT module registers of instance P33. The pad control can be configured independently for each pin as described in the PORT chapter. The configuration comprises:

- Selection of driver type (open-drain or push-pull)
- Enabling of the output driver (input and output capability)
- Enabling of internal pull-up or pull-down resistance

***Note**: If ESR2 is used as reset input it shall not be used for any other functionality (e.g. reset output indication) in parallel to avoid a permanent reset state of the device*

37.3.3.2.2 ESRx pin reset output

The external pins $\overline{\text{ESR0}}$/$\overline{\text{ESR2}}$ can provide a reset output indication (strong pull-down) for Application Resets.

Some applications require a reset out signal with a configurable reset elongation, as longer initialization time may be required for certain devices. For example memory devices like external RAM, Flash, and EEPROM devices may require that reset be held longer and released with a delay after the main microcontroller reset has been released.

Register ESR0CFG.ARI determines the output of the ESR0 pin when configured as functional reset output. ARI is set automatically when an application reset trigger is detected and cleared after RSTECNT time expiry or by Application software. Note that an Application Reset also occurs on a System Reset or Power-On Reset.

While the ARI bit is set, the configured ESR0 pin drive active low. A subsequent write to ESR0CFG.ARC clears the ARI bit, which de-asserts the ESR0 output in case the pin needs to be cleared by user software depending on ESR0CNTCTRL.RSTCON configuration.

The minimum duration of the ESR0 pulse on cold power-on reset is indicated by datasheet parameter t_{EVRPOR} and the additional elongation is defined through the reset value of ESR0CNTCTRL.RSTECNT and CLKDIV registers.

The application output selection and the default pull behavior is configured in DRVCFGESR0.MODE bit-field. After a system reset, the ESR0 pin is configured as open drain reset output driving application reset with weak pull-up active. When the same ESR pin is configured as a PORT output, its state can instead be controlled directly by application software so that the application has the possibility to reset external devices.

On warm PORST assertion, the ESR0 output elongation behavior depends on the count value written earlier to the ESR0CNTCTRL.RSTECNT and CLKDIV registers, which controls ESR0 elongation duration depending on the ESR0CNTCTRL.RSTCON configuration. An external device may extend an existing reset condition by holding the ESR pin active if ESR0 is simultaneously configured as reset input depending on ESR0CNTCTRL.RSTCON configuration.

When ESR0 pin output is being asserted, ESR0 reset input function is inactive or masked irrespective of configuration.

The ESR0CNTCTRL.RSTECNT reset counter can be used for the following purposes:

- Controlling the length of the internal reset release
- Configuring the reset length in a way that the reset outputs through the ESRx pins match with the reset input requirements of external blocks connected with the reset outputs

The reset counter RSTECNT is a 12-bit counter counting down from the reload value defined by ESR0CNTCTRL.RSTECNT based on the divided 100 MHz back-up clock / 2^CLKDIV. The counter is started by the control block after a reset request trigger condition becomes active and as soon as the system has been

brought into a stable state (or TOUTCNT has expired). If a reset request trigger is asserted continuously longer than the complete count-down process then the reset will not be de-asserted until the reset request trigger is removed. In this case the counter is not restarted. The control block simply holds the reset asserted until the reset request trigger has been de-asserted depending on ESR0CNTCTRL.RSTCON configuration.

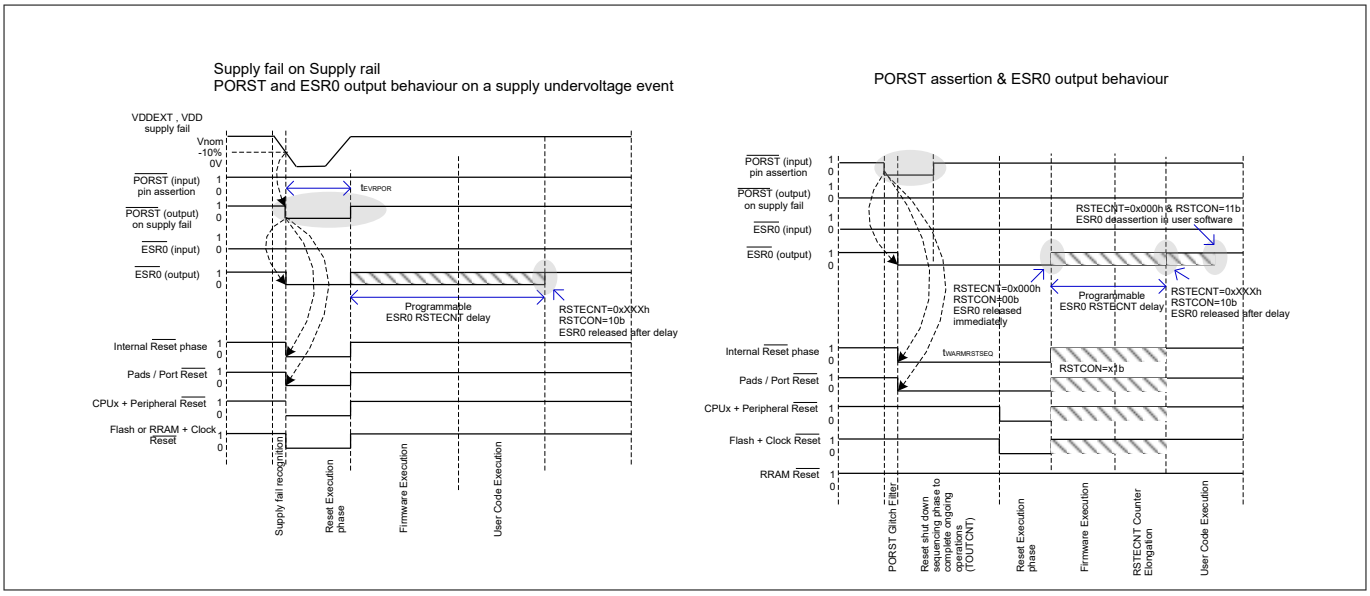

Figure 822 ESR0 reset output behavior

If ESR0 reset input and output function is configured simultaneously, it has to be ensured that the device does not go into a permanent reset state. This is realized by releasing the reset when ESR0 input is externally deasserted after ESR0 output buffer was disabled. This is only supported in specific RSTCON configurations as documented below. This acts as a time hysteresis as the pin will be kept low owing to external capacitance on the ESR0 pin for some more time after it is internally released.

Table 1642 ESR0 reset output behavior

Configuration	Reset release elongation	ESR0 pin output elongation	Simultaneous ESR0 reset input elongation	Update during start-up by Boot Firmware
RSTCON = 00	Immediate reset release	Immediate ESR0 deassertion	After reset sequencing and assertion, ESR0 output is disabled and later when ESR0 input goes high, reset is released	Firmware update of ESR0CNTCTRL effective only on next reset cycle.
RSTCON = 01	Elongation by RSTECNT time	Elongation by RSTECNT time	After reset sequencing and assertion and RSTECNT has expired, ESR0 output is disabled and later when ESR0 input goes high, reset is released	Firmware update of ESR0CNTCTRL effective only on next reset cycle.

(table continues...)

Table 1642 (continued) ESR0 reset output behavior

Configuration	Reset release elongation	ESR0 pin output elongation	Simultaneous ESR0 reset input elongation	Update during start-up by Boot Firmware
RSTCON = 10	Immediate reset release	Elongation by RSTECNT time	Simultaneous reset input feature is not supported	Firmware update of ESR0CNTCTRL effective on the current reset cycle.
RSTCON = 11	Elongation by RSTECNT time	ESR0 pin deasserted by user by writing to ARC bit	Simultaneous reset input feature is not supported	Firmware update of ESR0CNTCTRL effective only on next reset cycle.

The ESR2 pin can also provide a reset output indication for warm power-on reset (warm PORST) or for application reset as configured in PMS.PAD_ESR2CON.

***Note**: ESR2 reset output indication configuration in PMS.PAD_ESR2CON is reset on LVDPMS2 reset. For details about LVDPMS2 reset refer to PMS chapter*

By default the ESR2 pin configured as GPIO and not as reset output indication.

If needed an additional elongation for the warm power- on reset output indication is defined through the value of PMS.PAD_ESR2CON.RESTECNT and PMS.PAD_ESR2CON.CLKDIV as well as PMS.PAD_ESR2CON.ESR2ROEN register. For application reset the elongation is dependent on PMS.PAD_ESR2CON.ESR2ROAPP as well as PMS.PAD_ESR2CON.RESTECNT and PMS.PAD_ESR2CON.CLKDIV.

ESR1 and ESR2 behavior during reset execution

ESR1

The ESR1 pin will indicate a weak pull-up or tristate depending on HWCFG6/PMS.PAD_CON.ALLTRIST as defined as PU1 in the datasheet for the case of cold power-on resets and warm power-on resets. After successful execution of the reset shutdown sequence, the ESR1 behavior will be pull-up with system reset assertion.

In case of a system reset execution the ESR1 will always have internal pull-up active. During the execution of the reset shutdown sequence the ESR1 will keep its previously configured behavior.

The behavior for warm power-on reset and system reset execution can be seen in the figure below.

***Note**: If the duration of the application reset is elongated by configuration of the ESR0CNTCTRL the ESR1 will already behave in pull-up behavior at the beginning of the elongation, so the Internal reset elongation is without effect on the ESR1 behavior*

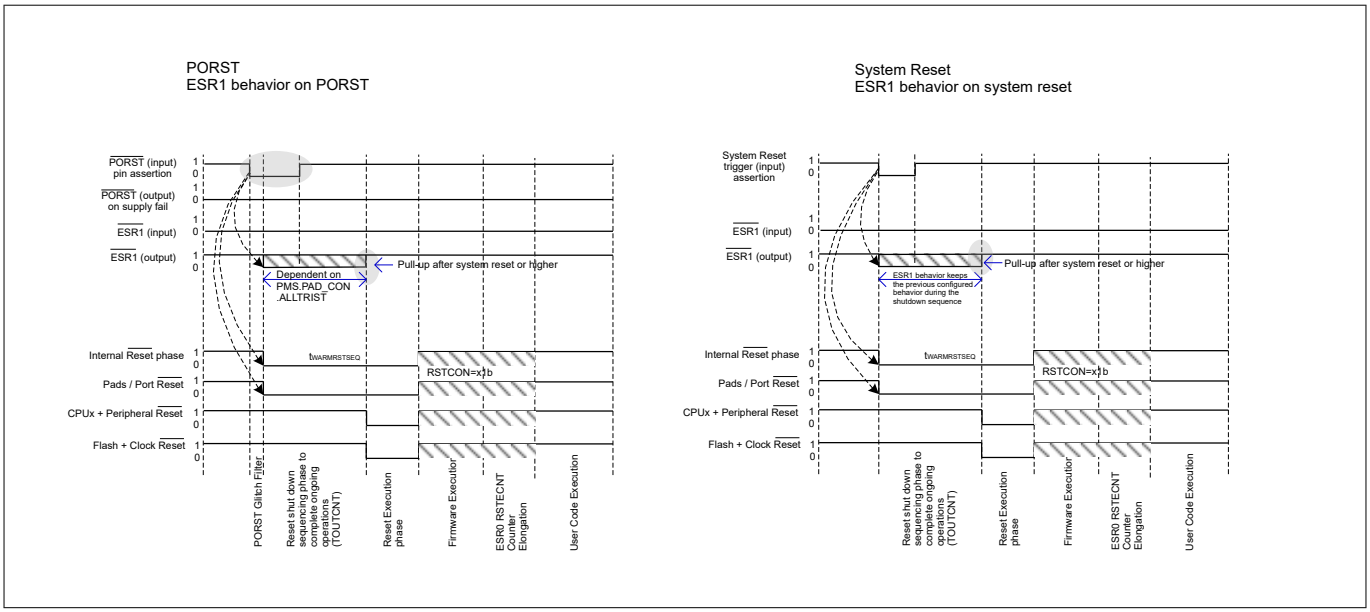

Figure 823 ESR1 behavior for warm power-on reset and system reset

ESR2

The ESR2 can be configured as reset output indication.

If configured as warm PORST output indication via PMS.PAD_ESR2CON.ROEN there are two cases to be considered

- cold power-on reset execution:

  In case of a cold power on reset the ESR2 will be asserted at the same time as the PORST Pad. The de-assertion is also on the same timing as the PORST Pad but can be elongated through PAD_ESR2CON.RSTECNT and PAD_ESR2CON.CLKDIV

  ***Note**: For cases of cold resets (except LVD) the PORST pad will be driven low for at least 80us by PMS*

- warm power-on reset execution:

  In case of a warm PORST triggered by assertion of the PORST Pad the ESR2 will be pulled low as long as the PORST Pad is asserted. The timing can be elongated though PAD_ESR2CON.RSTECNT and PAD_ESR2CON.CLKDIV

If configured as application reset output indication via PMS.PAD_ESR2CON.ROAPP=1 the ESR2 will be pulled low for the duration of the application reset phase. The shutdown sequence prior reset assertion does not have any effect on the ESR2 in that case.

***Note**: The duration of the application reset phase can be elongated by ESR0CNTCTRL configuration. Please refer to "ESRx pin reset output" section for details*

The scenario for warm power-on reset and application reset with respective configuration can be seen in the figure below.

***Note**: In case of activating the output indication for application reset and power-on reset simultaneously a superposition of the waveforms below can be observed.*

37 System Mode Management (SMM)

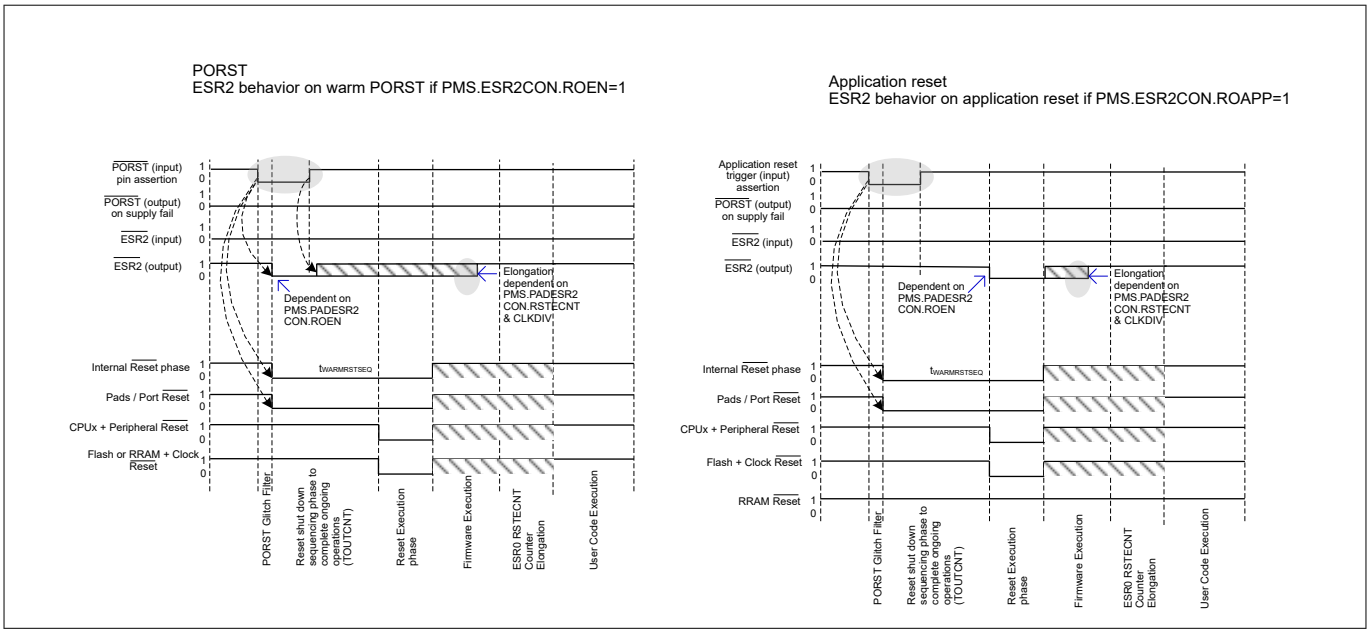

Figure 824 ESR2 behavior for warm PORST and application reset if configured as reset output

37.3.4 Reset

The AURIX™ TC4xx supports flexible reset concept to support open drain star reset architectures or cascaded reset architectures as shown in the figure. PORST and ESRx pins can be connected and configured flexibly to Power Management ICs, drivers, memory and communication devices depending on application needs. PORST supports bi-directional reset input and reset output function. ESR0/2 can be used as reset input or output. Error path can be configured in flexible manner to trigger immediate device reset or forwarded to PMIC. Hierarchical complete resets of the chip and partial selective resets of modules are supported in the reset architecture.

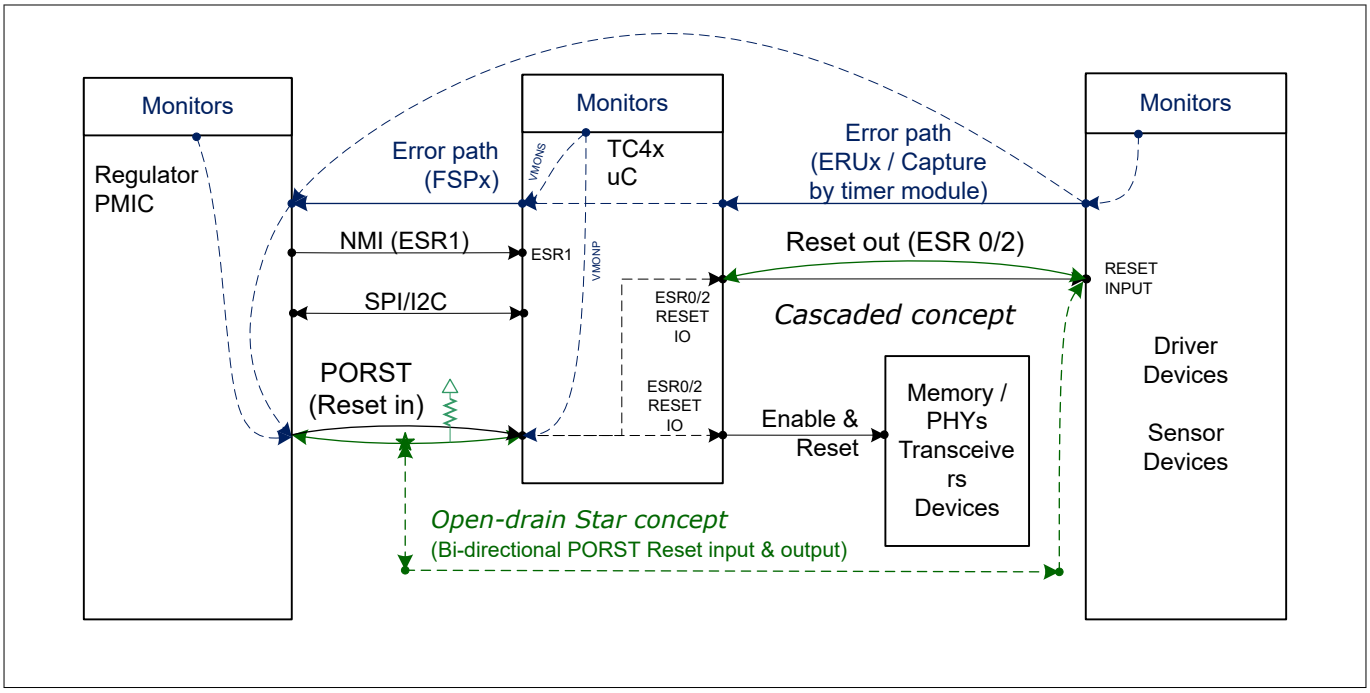

Figure 825 Reset connectivity

37.3.4.1 Overview

This section describes the conditions under which the AURIX™ TC4xx will be reset and the various reset types, triggers and effects.

37.3.4.1.1 Reset Types

The following list describes the different reset types and associated triggers.

Cold resets

- Low Voltage Detector reset (LVDPMS0, LVDPMS1 and LVDPMS2):This reset is triggered in case of power fail of standby supply domains and is the reset state after initial supply ramp-up. All modules are in reset state and all RAM memory content including Standby RAM memory need to be initialized. Refer to PMS chapter for more information
- Power Domain Cold Reset: This reset is triggered in case of power fail of the core supply rail beyond the lowest limits required by the power domain infrastructure. Refer PMS chapter for more information
- Cold Power-on reset (cold PORST): This reset is triggered in case of power fail of critical IO and core supply rails. All modules are in reset state except PMS0/1 and Standby RAMs. The PMS2 domain is partially reset. The individual PMS primary supply monitors are combined by a logical OR to trigger cold PORST which activates the strong pull-down of the PORST pad until supply under-voltage is active

Warm resets

- LBIST Reset: This reset portrays the device state when LBIST is running and after LBIST was successfully completed or aborted by an external power-on reset pin (PORST) assertion. The pins are held in reset state as configured by HWCFG6 pin
- Warm Power-on Reset (warm PORST): This reset sets the complete system into a defined reset state. This reset is triggered in case that the external power-on reset pin (PORST) is asserted low. This reset is triggered for example by external regulator when microcontroller fails to service external watchdogs or safety interfaces within a defined time period. All modules are in reset state except PMS, SMM, RRAM[49] and Standby RAMs. All RAMs are also required to maintain data content during and after the reset. A Power-on Reset also generates a Debug and Trace Reset and a System Reset and therefore also an Application Reset
- System Reset: This reset sets all modules in reset state except PMSx, SMM, RRAM[49] and Standby RAMs. A System Reset also generates an Application Reset. The system reset is triggered by software, safety alarms and watchdogs through the SMU unit, ESRx reset pins, system timers, TCU and debug modules
- Application Reset: This reset leads to an initialization into a defined state of the complete application system including peripherals and the processing units excluding the Clock system. All modules are reset except PMS, SMM, Clock, Flash[49], RRAM[49] and RAM contents are kept intact except for Cache/Tag memories. This reset is triggered by software, safety alarms and watchdogs through the SMU unit, ESRx reset pins, system timers, test and debug modules. This reset ensures a fast overall microcontroller reset with minimal reset time
  - Debug Reset: The debug system is also reset together with the application reset if OCDS is disabled. There is no explicit Debug Reset request possible but together with application reset
  - Trace Reset: This trace system is also reset with the application reset if trace is disabled
- Module Resets: Module resets result in individual modules being initialized into a defined state without any impact on the rest of the system. Module reset is not available for CPU0 and CSRM, Flash[49], RRAM[49] , PMS, IR, SCU, SMM, SMU and CLOCK. This reset is used to re-initialize the modules. The BPI part of the module is not reset in case of a module reset and only the module kernel part
- Module Group Resets: This reset leads to an initialization into a defined state for a configurable group of modules without any impact on the rest of the system

Warm PORST, system and application resets are triggered after the system is operational and the supplies are above the minimum operating conditions. On such a warm reset request, reset of pins will take place immediately, but the internal modules will only be reset after the system has been brought into a state where memory contents and debug trace data will not be corrupted and the load jumps have been sequentially ramped down. With regards to processing units, data integrity is only guaranteed for non-aligned write accesses from CPUs, PPU[49] and DMA. In the very unlikely event of a system hardware failure resulting in a timeout and reset but the memory transfer was not completed before the timeout, midway between two non-aligned bus transfers of a single bus transaction, possible corruption of memory may be unavoidable.

Cold Power-on Reset is triggered for the first time during a system power-up or in response to a temporary power failure of any of the main supply rails. During the power-up the PMS primary under-voltage monitors will trigger a complete reset of the system, placing the system into a known state. The PORST pin is de-asserted only when supplies are above the minimum operating conditions. The pins and modules are placed immediately into their reset state when the trigger is asserted. If the PORST pin is kept asserted after a system power-up or power fail event then the warm PORST will be extended after cold PORST release until the pin is de-asserted.

[49] Not available on all devices of the AURIX™ TC4xx family

37.3.4.1.2 Reset Trigger Sources

The reset trigger sources and the reset types which are generated are shown in the following table.

Table 1643 Reset Trigger Sources and generated Reset Type

Reset Request Trigger	Low Voltage Detector Resets	Cold Power on Reset	LBIST Reset	Warm Power on Reset	System Reset	Application Reset	Module Group Reset
VDDPMSx supply undervoltage below LVD level	Activated PMS LVD trigger	Activated by higher Reset	Not Activated	Activated by higher Reset	Activated by higher Reset	Activated by higher Reset	Not Activated

Table 1644 (continued) Effect of Reset on Device Functions

Module/Function	Low Voltage Detector Resets	Cold Power-on Reset	LBIST	Warm Power-on Reset	System Reset	Application Reset
Standby Port Pins (supplied by VEVRSB)	X	Reset depending on SCR config.	Reset depending on SCR config.	Reset depending on SCR config.	Reset depending on SCR config.	Reset depending on SCR config.
On-chip Static RAMs[1]						
dLMU (Standby RAMs)	reliable if no LVDANA reset [2]	Not affected by reset, reliable				
PSPRs, DSPRs, PPU CSM dLMU (non Standby) LMU RAM CSS RAM (keys & IVs)	Uninitialized. RAM content lost if VDD supply fails.			Not affected, reliable. Boot Firmware uses initial regions of PSPR (2kB RAM) and DSPR (8kB RAM) of CPU0 and CPUcs for the execution of start-up code and these parts are affected. Please refer Boot Firmware section for more details.		
PTAG, DTAG, CPU Cache, PPU Cache	Uninitialized. RAM content lost if VDD supply fails.			Cache invalidated. Initialization required after reset.		
Other RAMs- PKC RAM, CSS RAM (excluding keys & IVs), GTM RAM, CAN RAM, FlexRay RAM, PSI5 RAM, PSI5-S RAM, Ethernet RAM, HSPHY RAM	Uninitialized. RAM content lost if VDD supply fails.			Not reliable. After reset, the peripheral RAMs are filled/initialized with new data.		

1) Reliable here means that also the redundancy is not affected by the reset.
2) For Details about LVDANA please refer to the PMS chapter

The pins are reset depending on the PINRST configuration at the beginning when reset is triggered by default or after shut down sequencing. Likewise the HSPHY interface[50] is reset depending on the PHYRST configuration at the beginning when reset is triggered by default or after shut down sequencing.

50 Not available on all devices of the AURIX™ TC4xx family

37.3.4.1.4 Reset indication and flags

After a chip level reset release, the Reset Status registers provide information on the trigger(s) and the type(s) of the last reset(s).

All the reset types which happened since the last reset clear event through RSTSTATCLR.CLRC bit are cumulatively indicated in reset status register RSTSTAT. All warm reset triggers which happened since the last reset clear event through RSTSTATCLR.CLRC bit are accumulated and indicated in register WRMRSTTRIG. Likewise, all the cold reset triggers which happened since the last cold reset flag clear event through PMS.CLDRSTSTATCLR.CLEAR are indicated in PMS.CLDRSTRIG register. Detailed cold reset types and standby states are indicated in PMS.CLDRSTSTAT register bit field.

The highest reset type which happened since the last reset flag clear event is indicated in RSTSTATH register bits. A reset cycle denotes at least one reset trigger followed by the shut down sequence culminating in final reset. The corresponding reset trigger to trigger the highest warm reset type is indicated after any reset in WRMRSTTRIGH register reset bits. The RSTSTATH and WRMRSTTRIGH register can be cleared through CLRC bit by user software.

The RSTSTATCLR.CLRC bit allows clearing RSTSTATH, RSTSTAT, WRMRSTTRIG and WRMRSTTRIGH registers after the user software has completed reset evaluation. The PMS.CLDRSTSTATCLR.CLEAR clears PMS.CLDRSTSTAT and PMS.CLDRSTTRIG registers.

In case of a reset trigger from SMU as indicated in WRMRSTRIG and WRMRSTRIGH register flags, further information as to which alarm in SMU triggered the reset is indicated in SMURSTSTATA and SMURSTSTATB register bit fields. SMURSTSTATA indicates the corresponding alarms which triggered a reset for SMU SAFE0 unit. SMURSTSTATB indicates the corresponding alarms which triggered a reset for SMU SAFE1 unit. SMURSTSTATB indicates the corresponding alarms which triggered a reset for SMU SEC unit.

In case of consecutive watchdog timeout and permanent reset condition due to consecutive SMU resets which is recovered by external PORST pin assertion, DWR bit indicates that a a double watchdog permanent reset happened.

After a reset event the status bits in SHSEQCTRLD register can be used to determine whether the content of memory is still valid or whether corruption of data may have occurred.

Module level resets (Module Reset & Module Reset Group Reset) have no effect on the Reset Status registers and BPI part of the module.

***Note**: Even though application reset is not affecting the CLOCKING it can happen that after application reset the system PLL is not selected as clock source for the system clocks in case of a nested application reset scenario. Therefore the startup software shall check after application reset release that the CCUCON.CLKSELS bit field in the CLOCKING FB is selecting the expected system clock source*

37.3.4.2 Reset

The Reset Controller captures reset trigger requests and generates and distributes the different resets to all the modules .

A reset is generated if an enabled reset request trigger is asserted. Most reset triggers can be configured to initiate different types of reset depending on configuration.

37.3.4.2.1 Reset generation

The figure below shows the reset generation for the complete device

The Reset Generation detects the different reset requests, schedules a shutdown of the system, and then generates the appropriate internal reset pulse(s).

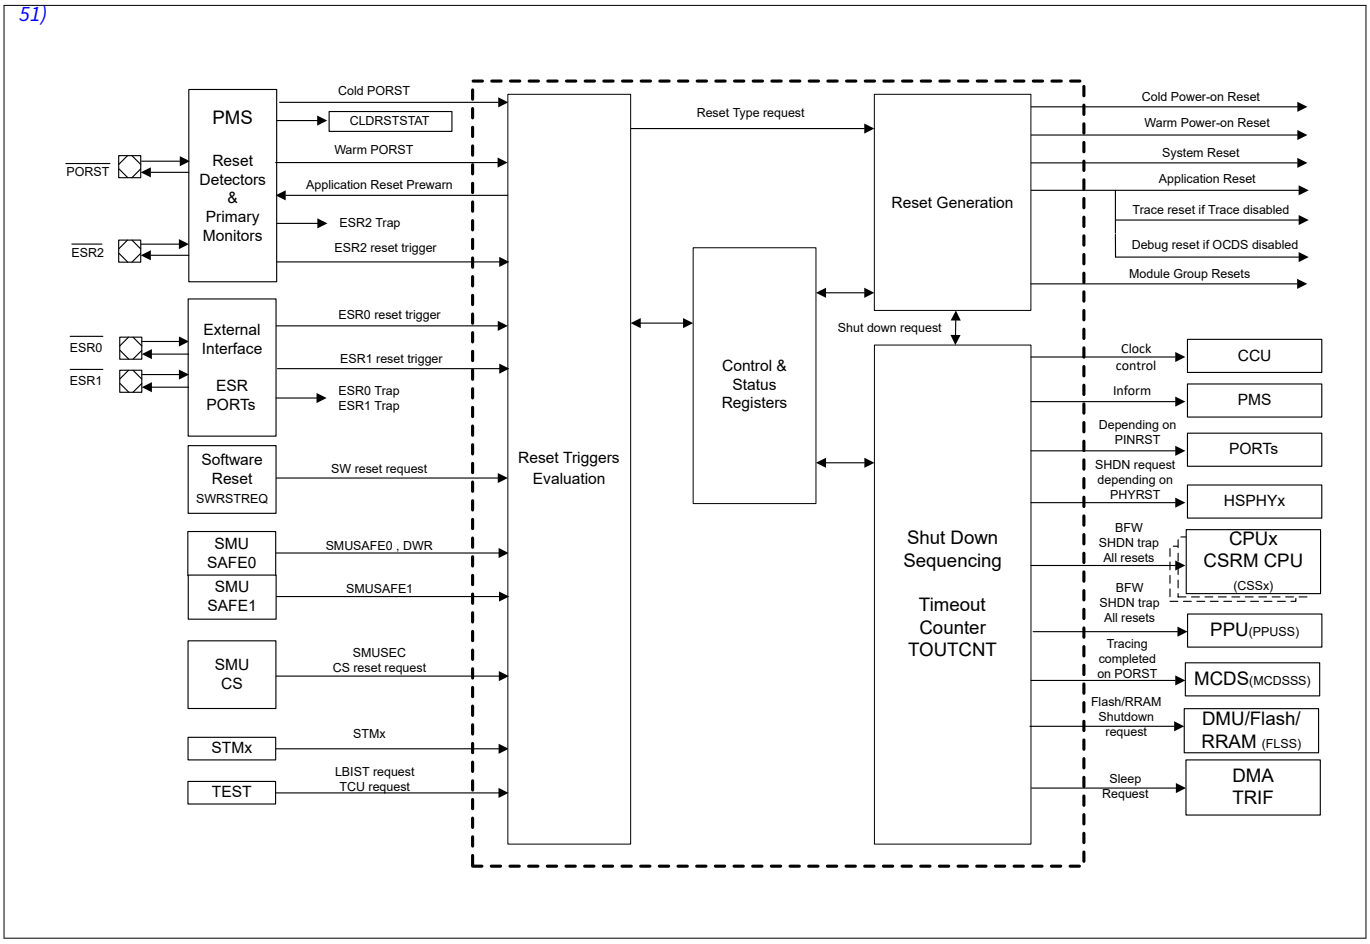

Figure 826 Reset overview

In case of safety-related faults during reset execution the SMM_RESET_ALARM or SMM_REG_ALARM is send to the SMU.

For details about the safety mechanisms please refer to the safety manual.

51 Flash, RRAM, PPU and HSPHYx are not available on all devices of the AURIX™ TC4xx family

37.3.4.2.2 Reset trigger request, assertion and de-assertion

Warm reset sequence

1. A Reset trigger requests a particular Reset Type, namely application reset, system reset or warm PORST
2. Shut-down sequencing is started for a time duration documented by datasheet parameter *t*WARMRSTSEQ. During this time, the modules are sequentially ramped down. An internal reset TOUTCNT counter counts down until the time duration has elapsed as indicated in SHSEQCTRLA register

   ***Note**: The DMA and RDMA[52] are excluded from the shutdown sequencing if their CLC.EDIS bit is disabled*

3. Pins or HSPHY modules[52] are set immediately into reset either when the reset request is taken or at a later time.
4. During the ramp-down phase, it might happen that further reset trigger requests are issued when counter is running, namely application reset, system reset or warm PORST. The additional reset requests are evaluated and highest reset type is executed among the reset requests. The shut-down sequencing is not restarted because of new reset requests as the ramp down phase of modules is already ongoing
5. After the shut-down sequence is completed or the reset counter has expired, the highest chosen reset type and the lower hierarchical resets are issued to all modules. The propagation of the reset to all modules takes less than 20 SPB clock cycles. Then the internal resets are de-asserted and boot firmware starts. The prerequisite for reset release is that no reset request trigger that is configured to generate the same reset is currently asserted and the reset counter has expired

   ***Note**: Elongated reset release only possible for PORST and ESR0*

6. If a reset trigger continues to be asserted externally even after reset issue (PORST or ESR0 reset pin input elongation, DWR), the internal reset type requested by the respective reset trigger is kept asserted until the reset trigger is externally de-asserted
7. ESR0 reset output and/or reset release are elongated for a configured time duration depending on configuration in ESRxCNTCTRL register

Cold reset sequence

1. A supply fail trigger requests a particular cold Reset Type namely, cold PORST, Power domain cold reset or LVD reset
2. Pins or HSPHY[52] modules are set immediately into reset and isolated
3. The cold PORST is immediately issued to all modules. The prerequisite for reset release is that the supply fail violation does not exist anymore
4. If the supply under voltage violation continues to exist, then the cold reset type is kept asserted until the supply has recovered and is in operational range
5. PORST and ESR0 pins are driven low during the cold PORST phase

37.3.4.2.3 Reset triggers and configurability

There are two types of reset triggers for the reset control logic:

- Triggers that lead to a specific reset
- Triggers that lead to a configurable reset

Specific reset triggers

Assertion of Debug tool (Cerberus) reset, TCU reset triggers and Supply fail leads to predefined resets and the triggers can not be enabled/disabled. All specific reset triggers are listed in the table below.

52 Not available on all devices of the AURIX™ TC4xx family

Table 1645 Specific reset triggers

Reset trigger	Reset type request
Cerberus 0 (CB0)	System reset
Cerberus 3 (CB3)	Application reset
VDDx	Cold power-on reset

Configurable reset triggers

Assertion of these triggers leads to a configurable reset type. These triggers can be enabled/disabled. The result of the reset triggers is defined by the corresponding bit-field in registers RSTTRIGCTRLA and RSTTRIGCTRLB.

SMU reset triggers

The SMU can request different resets in response to an alarm. The two Safety SMU partitions can request 2 different reset types each and the Security SMU partition has one available reset request. For detailed information about the possible configurations see Register description RSTTRIGCTRLA.

To indicate which Alarm was responsible for the triggered Reset the SMURSTSTATx provides information about Alarm Group and Alarm ID.

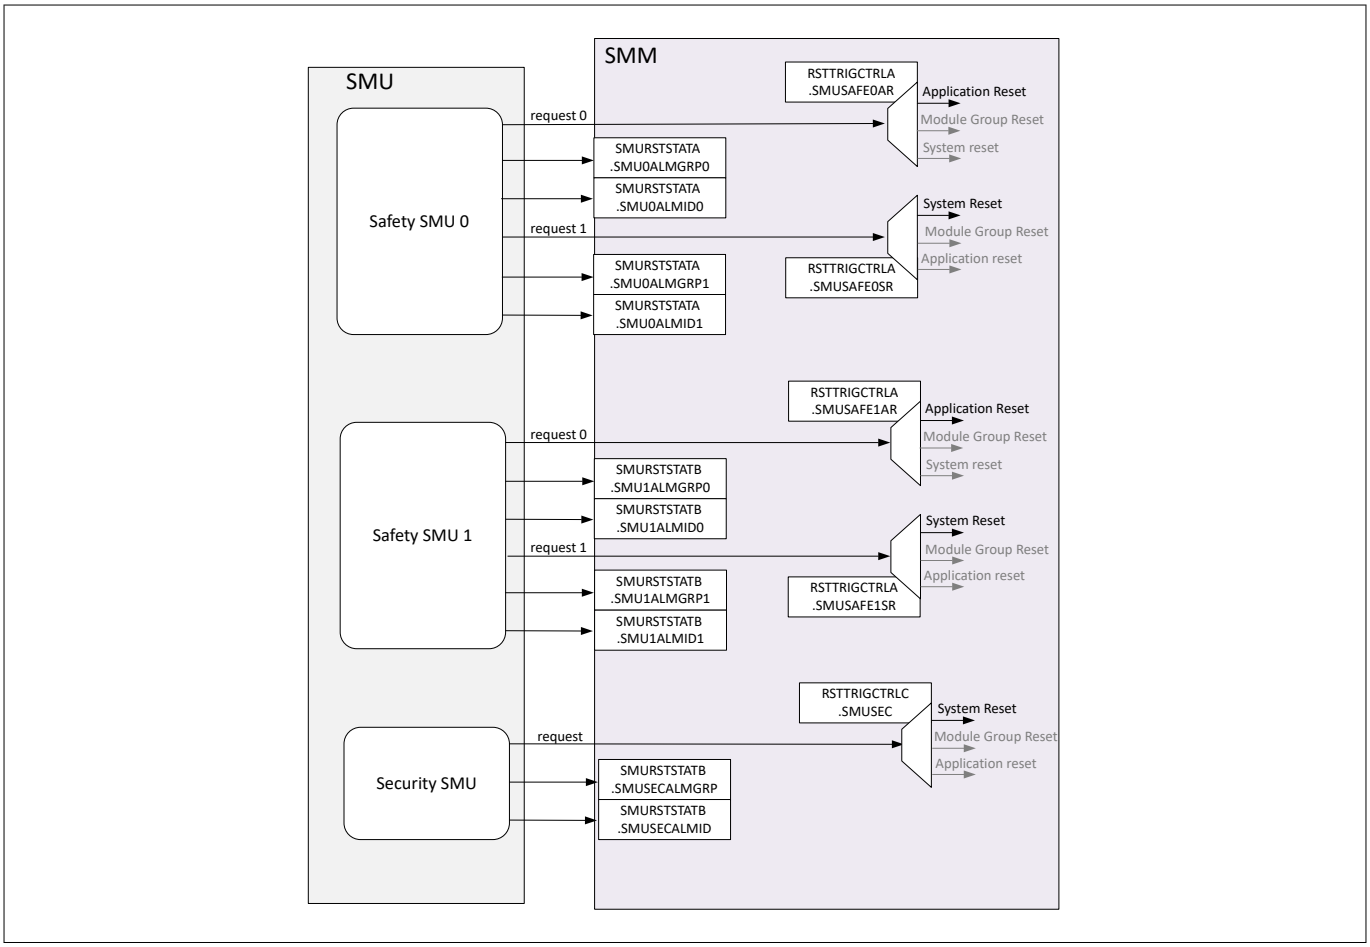

Figure 827 SMU reset request and status indication

Prevention of double SMU resets leading to permanent reset condition

The SMU can request a reset in response to an alarm. The type (Application or System Reset or Module Group Reset) is selected through register RSTTRIGCTRLA.SMUSAFEx or RSTTRIGCTRLC.SMUSEC. After boot firmware

initialization, the default behavior of the SMU WDT is that a Watchdog timeout alarm would result in an NMI followed by an application reset. If an SMU induced application reset occurs twice, a severe system malfunction is assumed and the AURIX™ TC4xx is held in permanent application reset until a Power-On Reset occurs. This prevents the device from being periodically reset if the application fails to service the watchdog correctly and the watchdog repeatedly times out.

An internal flag is set when the first SMU reset is requested. If a second reset is also requested by the SMU when the internal flag is already set, the double SMU reset event has occurred and a permanent reset request is automatically generated. This internal flag is only reset by a System Reset or when bit RSTSTATCLR.CLRSMUIRF is set, which is SMM_PROT_E.ENDINIT protected. A correct service of the WDT does not automatically clear this flag.

If this behavior is undesirable, then the RSTSTATCLR.CLRSMUIRF bit should be written by the application during initialization (before the watchdog times out), to clear the flag and prevent any subsequent occurrence of a permanent reset. The DWR reset flag is set in case of permanent reset event and will be indicated in WRMRSTTRIGx register after the system recovers from permanent Application Reset state after an external PORST assertion event.

Debug and trace resets

Debug reset behavior

It is required by the debugger that if the OCDS system is disabled (OSTATE.OEN=0), a Debug Reset is also asserted every time an Application Reset is asserted.

Trace reset behavior

It is required by the debugger that if the Tracing is disabled (OSTATE.TRACE_EN=0), a Trace Reset is triggered on an Application Reset.

JTAG interface reset behavior

During RUN mode, JTAG interface is reset with TRST pin assertion.

37.3.4.3 Module kernel reset

Many modules can be reset individually. The module or kernel reset has no effect outside the module itself. A module reset can only be triggered by writing '1' into both of the module reset registers RST_CTRLA.KRST and register RST_CTRLB.KRST. The module reset allows fast initialization of module registers to their reset values. It shall be noted that only the module kernel is reset on a module reset and the BPI interface is not reset. After the module reset is executed, the respective module RST_STAT indicates whether the module reset is done.

The table below shows the modules which support Module reset capability. Infrastructure modules are exempt from module resets as resetting them affects more than one module.

***Note**: The module list in the tables below is representing the whole AURIX™ TC4xx family. If respective module or module function is not available in a given product then the information is not relevant*

Table 1646 Functional block supporting module resets

Module	Module reset capability
CANx	Module reset implemented in CAN
DRE	Moduel reset implemented in DRE
ASCLINx	Module reset implemented in ASCLIN
GTM	Module reset implemented in GTM
ERAYx	Module reset implemented in ERAY
QSPIx	Module reset implemented in QSPI
HSSL	Module reset implemented in HSSL
GETH	Module reset implemented in GETH ***Note**: includes MII, RGMII and SGMII*
HSPHY	Module reset implemented in HSPHY
MSCx	Module reset implemented in MSC
SENTx	Module reset implemented in SENT
TMADC, DSADC, CDSPX	Module reset implemented independently for TMADC, DSADC and CDSPx in ADC
SCR	Module reset implemented in SCR ***Note**: SCU_RSTCON.SWRSTREQ to be used*
GPT12	Module reset implemented in GPT12
PSI5	Module reset implemented in PSI5
PSI5-S	Module reset implemented in PSI5-S
DMAx	Per channel reset implemented in DMA ***Note**: TSRc.RST to be used*
I2Cx	Module reset implemented in I2C

CANXL Module kernel reset on page 6440

37.3.4.3.1 CPU module resets

A CPU Module reset has the same effect on an individual CPU as an Application Reset, but without a full reinitialization of other system elements outside the CPU:

- CPU0 and CPUcs - Module reset functionality shall not be used
- Other CPUs - Wait in HALT mode after module reset

The BPI register reset state can be used to determine whether the last CPUx reset had happened.

See CPU and Start-Up Chapters for more details.

***Note**: The individual CPU Module reset includes the respective STM*

37.3.4.3.2 PPU module resets

A PPU[53] Module reset has the same effect as an Application Reset, but without a full reinitialization of other system elements outside the PPU

PPU - Wait in HALT mode after Module Reset.

The BPI register reset state can be used to determine whether the last PPU reset had happened.

See PPU and Start-Up Chapters for more details.

53 Not available on all devices of the AURIX™ TC4xx family

37.3.4.4 Module Group Resets

Modules providing Module reset can be part of four possible Module reset groups. The configuration as to whether a module is part of a Reset Module Group is done in the respective module. When a respective trigger for one of these groups is broadcast by SMM, all modules in the group perform simultaneously a Module Reset.

***Note**: No Module Group Reset available for CPUs*

The triggers for Module Group Resets can be configured in RSTTRIGCTRLA and RSTTRIGCTRLB and may be triggered by the following warm reset triggers:

- ESR0, ESR1 and ESR2 pin triggers
- SMU SAFE0, SAFE1 & SMUSEC alarm triggers
- Software request for Module Group Reset
- STMx compare match triggers

Module Group Resets have no effect outside the configured module groups, since the behavior is similar to that of triggering individual module resets chained all together. Module Group Resets (through register bits in some modules) have no effect on infrastructure and BPI of that module. Modules which do not support module resets also do not support Module Group Reset.

The module participation in Module Group Reset is configured through respective module RST_CTRLA.GRSTENx (x=0-3) bit field. The module register RST_STAT.GRSTx (x=0-3) can be used to determine what kind of reset was ordered to be executed on the module. This bit-field can be cleared through RST_CTRLB.STATCLR.

If a module is assigned to multiple Module Group Resets, the respective flags would be cumulatively set to indicate that the module reset was requested from respective multiple Module Group Reset sources.

The SMM does not contain information about what was the trigger of the Module Group Reset in any status register.

***Note**: To avoid a cold power on reset on assertion of a Module Group Reset it is recommended to consider voltage droops when configuring a module group since all configured modules will reset at the same time without reset shut down sequencing.*

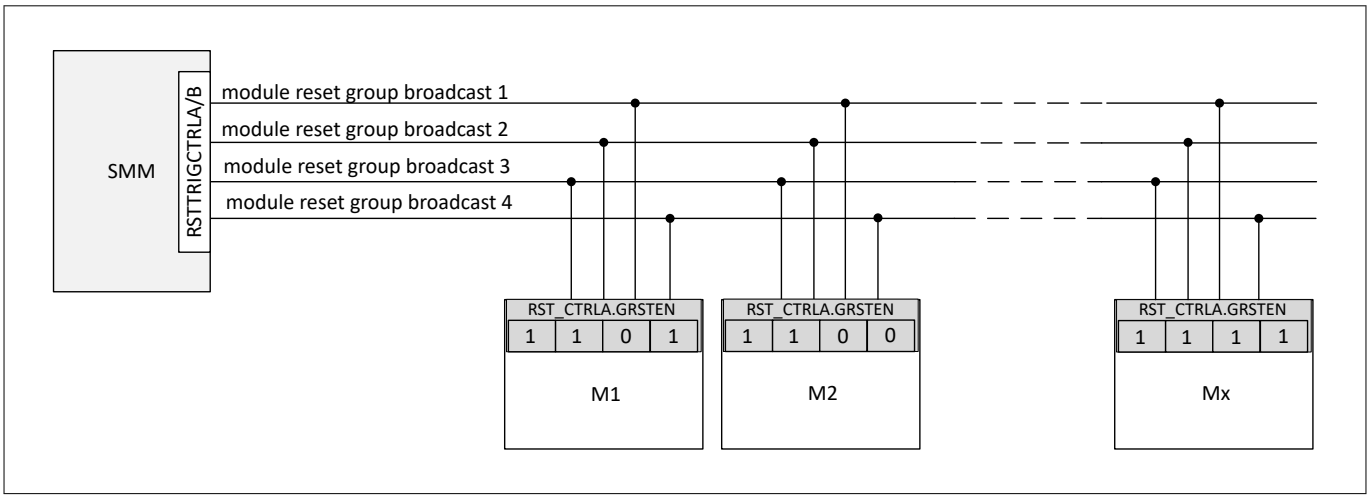

Figure 828 Module reset group overview

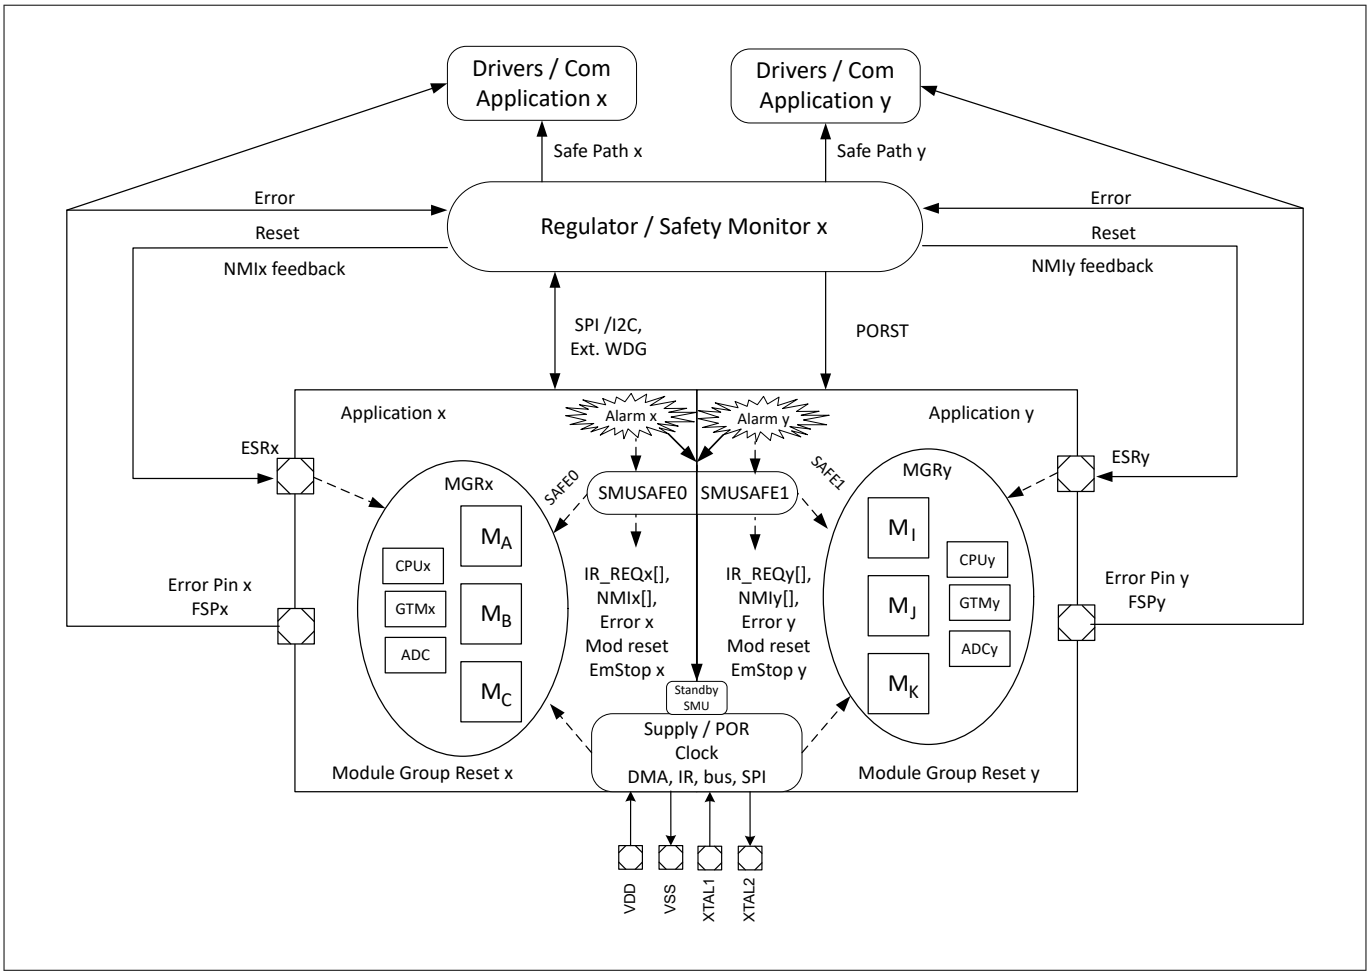

Figure 829 An example of application partitioning

Simultaneous Module Group Reset and NMI trigger by ESR pins

The figure illustrates an example case for MGRx assertion and the behavior of microcontroller modules. MGRx can be triggered by external or internal agent depending on configuration by the user program. In the described case, the ESRx pulse acts as an external MGRx request trigger. Same effects may be triggered by internal agents through MGR reset request to SMM if configured.

Flexibly mapped safety alarms in the SMU_SAFEx instances usually act as initial source of Module Group Reset to the SMM which is triggered directly through internal request from SMU_SAFEx or SMU_SAFEx output FSP[0-3] to external agents.

ESR[1-2], FSP[0-3], MGR[0-3] implement an isolated reset and restart of selected modules for flexible and fast recovery of only those parts of the application where fault is detected. If the fault does not interfere with the rest of application, the MGR can be triggered only on the affected application components, while other parts usually mapped to another group are able to maintain their dedicated application function. Application integrator decides which safety alarms trigger and what class of the reset request is to be configured. This configuration is usually applied by application Start-up initialization routine. Configurations are applied at module level in RST_CTRLA.GRSTEN registers to decide the connections to the respective Module Group Reset broadcasts line(-s).

ESR[1-2] input settings shall be initialized to define signal properties to generate the reaction to the SMM. Both configurations of edge and pulse detection are supported. It is possible to map pulse driven requests to SMM/ MGRx reset triggers. Pulses are captured by the ESR input capture timer and compared with ESRCFG1.RSTDELAY value through a greater than or less than compare filter to assert chosen request type.

At the same time, edge driven requests may still trigger NMI requests based on ESRCFG1.EDCON setting. For instance, the same ESR[1-2] input lines can be used for interrupt generation from the same external agent.

The figure below provides an example case where edge driven MGRx requests are configured on ESR2 input and pulse driven requests are configured on ESR1 input. ESR2 input accept pulses captured by ESRx timer for MGRx requests which are longer than pre-configured time window. Pulse driven requests do not hold modules in reset for the pulse duration time, but rather keep it for the same period as any pulse generated and broadcasted by SMM. Affected group of modules go into reset and restart once the respective module kernel reset is released. In this example FSP[1] trigger is mapped on ESR2 input and FSP[2] is mapped on ESR1 input on a system level. FSP[0-3] can be mapped to different reaction class such as Warm PORST or Cold Reset generation. This is typically done for severe faults that affects all application groups together, and thus require a higher class of recovery measure.

The blocks which are not affected by MGRx reset function include PORST, fBACK/fRAMP, fOSC, PLL, PU1/PU2 Pins and ESR0 function.

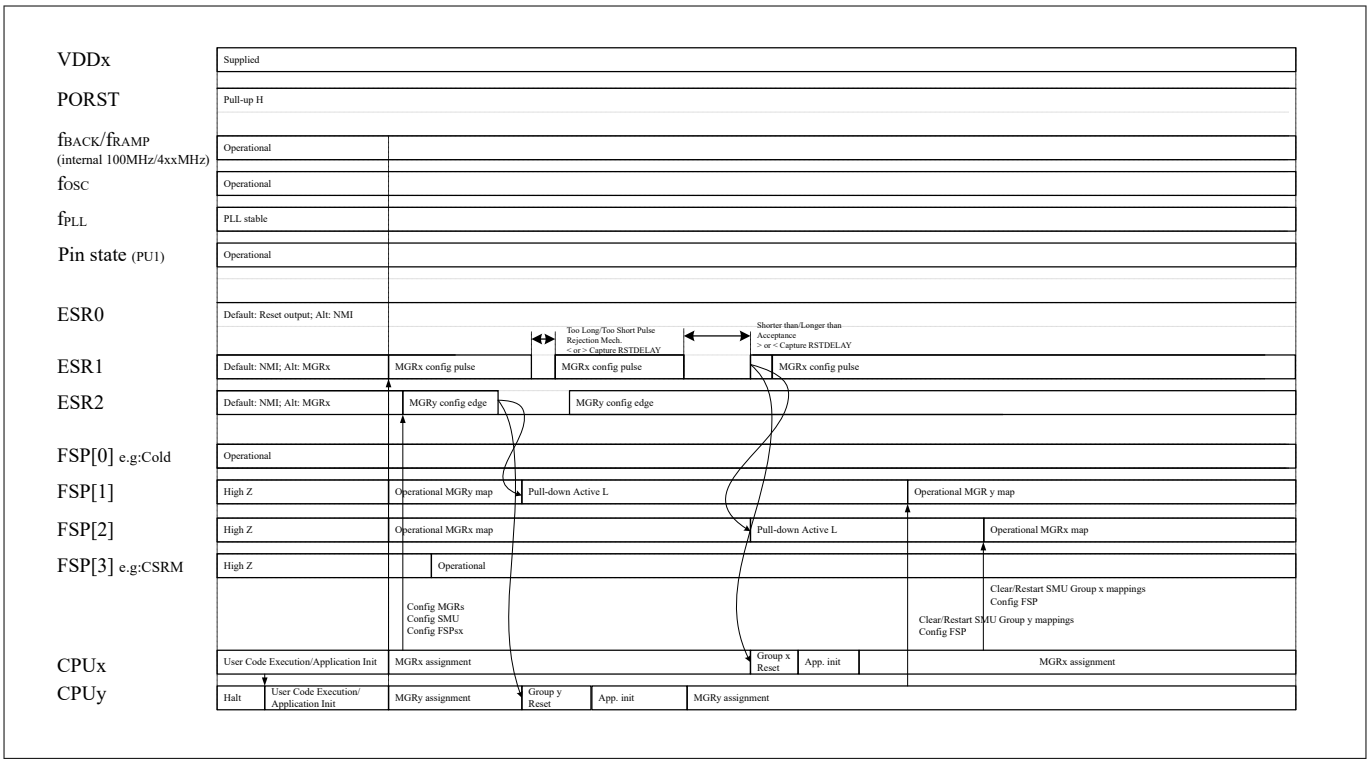

Figure 830 MGRx example using ESRx pins

37.3.5 Load jump management

Load jumps lead to voltage overshoots / undershoots which need to be limited within the regulator dynamic specification and operational bounds of the supply rail. The initial phase after the load jump is buffered immediately by external buffer and decoupling capacitors which consequently leads to a linear discharge of the capacitor. Consequently the regulator feedback loop recognizes the deviation in voltage and reacts to the jump by regulating the power supply unit. The dimensioning of the capacitor depends on the load jump amplitude, equivalent series resistance of the capacitor, the permissible voltage deviation and bandwidth of the regulator. The capacitor size in turn has a tangible impact on cost and PCB space. Minimum required capacitors and indicative load jump transients are documented in datasheet. Minimizing peak-to-peak voltage deviation in the face of large dynamic changes in load current need to be actively managed to avoid brown out reset events and large capacitors.

Load jumps may be triggered by software or user driven actions or asynchronous hardware events. During software triggered non reset events, it is recommended to limit the load jumps as documented in datasheet. For example, during clock ramp-up phase it is recommended to limit the clock switching steps so as not to violate this limit.

Asynchronous events and resulting load jump - resets and NMI

On typical load jump events triggered asynchronously, like Non Maskable Interrupts and reset events, measures are built in to ensure that voltage overshoots are kept within bounds by in-built load sequencing mechanisms.

In case of an NMI event, during RUN mode or waking up from SLEEP mode, the device would activate a large number of hitherto dormant circuits and wake-up the CPUs simultaneously resulting in a large change in load current. To avoid a large load jump on an NMI event, it needs to be ensured that only one CPU is triggered by the NMI or woken out of SLEEP mode and that other CPUs are still in IDLE mode. The other CPUs are consequently started one after another with adequate delay in between during start-up phase. The active CPU woken up on an NMI request is configurable in SCU.

In case of an warm Power-On Reset request, the port pins are set into reset state after t_{PIP} as specidifed in the datasheet. In case of a System or Application Reset request the timing of the reset state assertion for the port pins is configurable in RSTTRIGCTRLA.PINRST. After that the modules are ramped down in a grouped sequence over TOUTCNT period documented in datasheet. This serves to limit the maximum load jump to less than half of the total dynamic IDD current. It needs to be ensured that the supply voltages are above the minimum operational voltage limits during the reset phase after warm reset request not to trigger an additional cold power-fail reset. Larger overshoots are tolerable during and after reset phase for a certain accumulated time but must be limited to operational and absolute maximum voltage ratings as documented in the datasheet.

Load jump events caused by asynchronous failure events like PLL loss of lock or external oscillator watchdog event may lead to overshoots which cannot be sequenced owing to the inherent nature of failure.

37.3.5.1 Load jump sequencing unit A

Handling simultaneous load jump requests triggered by software

Software triggered load jump events include ramping up / down of various system clock frequencies, activating / deactivating processing units, power mode transitions, CPU idle requests, memory tests and so forth.

In case of software triggered events, it is possible to prepare by lowering or raising the voltage set point before the load jump is issued. A negative voltage droop may be done before a negative load jump and a positive voltage droop before a positive load jump respectively. Thus negative load jumps leading to voltage overshoots is compensated partly by the negative voltage droop and likewise positive load jumps leading to voltage undershoots is compensated partly by the positive voltage droop as shown in figure. The voltage droop is configured through PMTRCSR0.SDSTEP register bits. The voltage droop in positive or negative direction is issued via PMTRCSR3.VDROOPREQ register bits. In case a current Vdroop request is not active or the Voltage Droop Timer is not currently running indicated via PMTRCSR3.VDTRUN or the Load Jump Timer is not currently running indicated via PMTRCSR2.LJTRUN, a new Vdroop request is taken. Once a new voltage droop request is

issued, SDVOK is reset and device need to wait for a certain time till the regulator has settled on the new value which is realized using a Voltage Droop Timer. Once the regulator has settled on the new value, SDVOK status bit is set again indicating the end of the Voltage Droop transition and PMTRCSR3.VDTRUN and PMTRCSR3.VDTCNT is reset by hardware. If SDVOK status bit is set by EVRC before compare match of VDT has occurred, VDTOV overflow bit is not set and overrun interrupt is not generated. The Voltage Droop Timer compare value is configured in PMTRCSR1.VDTCV register bits and the current value is indicated in PMTRCSR3.VDTCNT register bits. In case of a compare match, the overflow PMTRCSR3.VDTOV bit is set if enabled via PMTRCSR0.VDTOVEN register bits. In this case, overflow bit has to be explicitly cleared via PMTRCSR3.VDTOVCLR before a new request can be taken to support a sequential polling based approach. Furthermore, interrupt maybe activated on an overflow if PMTRCSR0.VDTOVIEN is enabled.

Simultaneous software triggered load jump events can be likewise avoided by checking whether a Load Jump is ongoing or the Load Jump Timer is currently running. The Load Jump Request is issued by triggering a compare and swap operation on PMTRCSR2 register. A CPU will access data from PMTRCSR2 register and will compare the current value with an expected value. The expected value is that there is no load jump currently ongoing and VDTRUN bit state is 0. If there is a match, the CPU will make the swap by setting PMTRCSR2.LDJMPREQ variable and starting the timer. The idea is to prevent multiple CPUs from doing load jumps simultaneously by treating Load Jump as a critical section and ensuring that only a single CPU can check and issue a load jump request atomically. Once a load jump request is taken, a timer is started and other CPUs have to wait till the regulator output has been restored to the setpoint value and ensures adequate regulator reaction time. The other CPUs are not blocked during the waiting period instead they can continue with some other operations or try to make the request again at a later point of time.

Thus negative load jumps and positive load jumps are followed by a blanking period using a Load Jump Timer as shown in figure below. The Load Jump Timer is configured through PMTRCSR0 register. The load jump request is issued via PMTRCSR2.LDJMPREQ register bits. If a current Load Jump request is not active or the Load Jump Timer is not currently running indicated via PMTRCSR2.LJTRUN or the Voltage Droop Timer is not currently running indicated via PMTRCSR3.VDTRUN, a new Load Jump request is taken. Once a new Load Jump request is issued, the device needs to wait for a certain time till the regulator has reacted to the jump which is realized using a Load Jump Timer. The Load Jump Timer compare value is configured in PMTRCSR1.LJTCV register bits and the current value is indicated in PMTRCSR2.LJTCNT register bits. In case of a compare match, the overflow PMTRCSR2.LJTOV bit is set if enabled via PMTRCSR0.LJTOVEN register bits. In this case, overflow bit has to be explicitly cleared via PMTRCSR2.LJTOVCLR before a new request can be taken to support a sequential polling based approach. Furthermore, an interrupt maybe activated on an overflow if PMTRCSR0.LJTOVIEN is enabled. Overflow bit is routed to an OS interrupt to schedule the next current jump. Overflow bit maybe masked or used in the compare and swap operation if PMTRCSR0.LJTOVEN is set to ensure that explicit clear of the time out has happened before issuing a new request. PMTRCSR2.LJTOVCLR also clears PMTRCSR3.VDROOPREQ and PMTRCSR2.LDJMPREQ request.

***Note**: The droop can only be reversed to nominal when load jump timer is enabled as well as the droop timer. Only then the droop is reversed when LJTOVCLR bit is set*

37 System Mode Management (SMM)

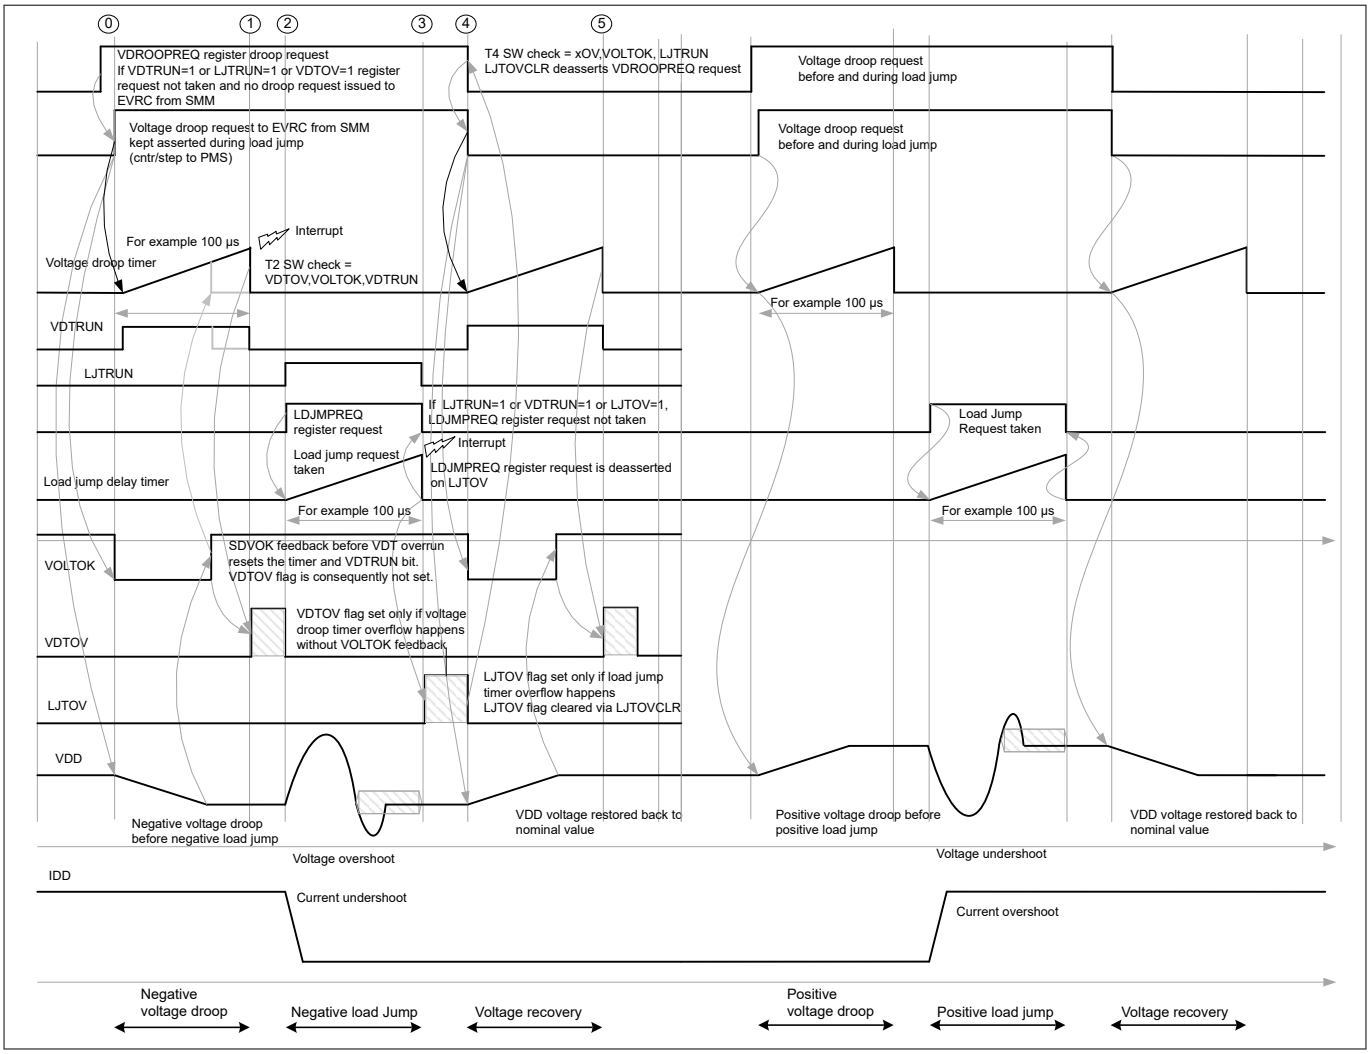

Figure 831 Load jump sequencing unit A

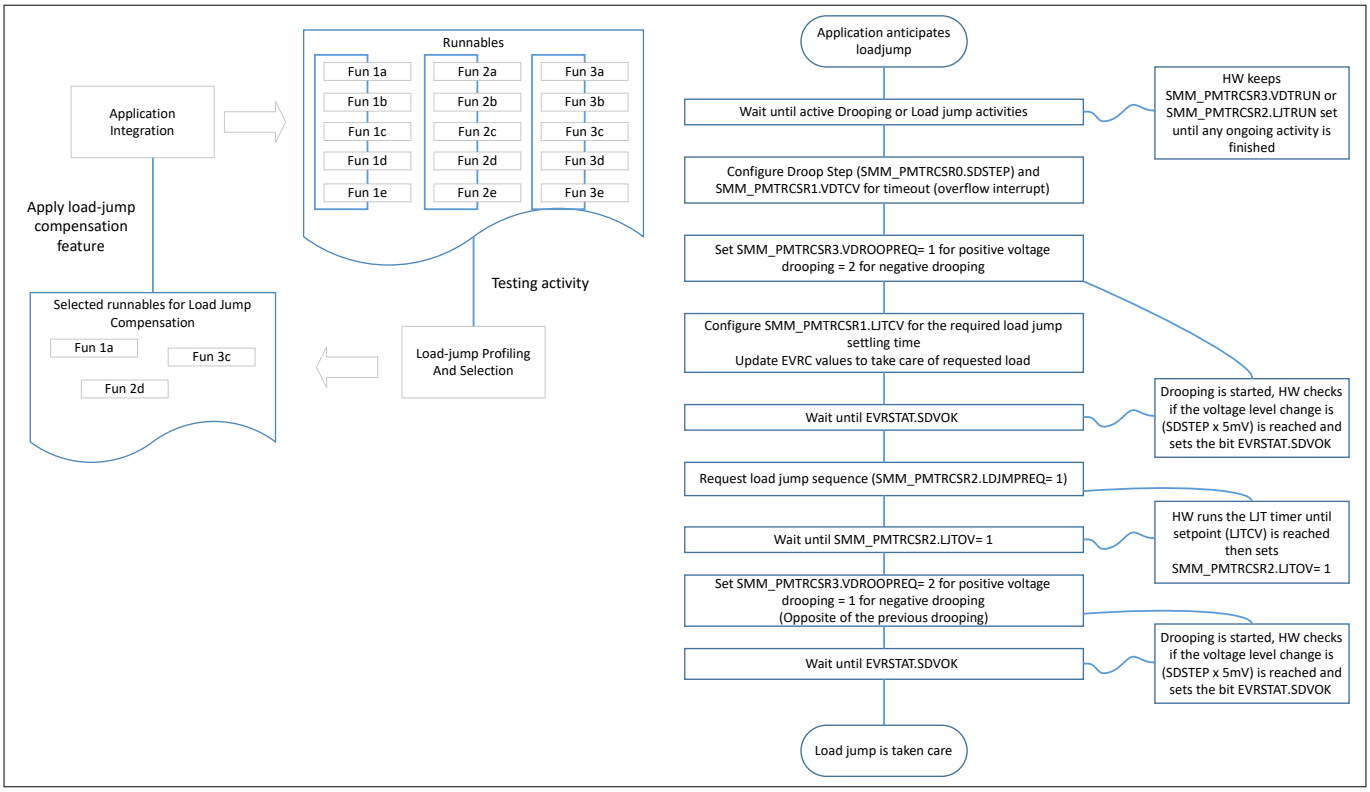

Figure 832 Load jump handling sequence

Interrupts

Following events may be configured to lead to interrupts routed to the interrupt router. If enabled by the related interrupt enable bits, an interrupt pulse is generated on one of the service request outputs (SRC_SMM0 and SRC_SMM1). Interrupts are forwarded from SMM to the IR module within 4 f_{SPB} clock cycles after the occurrence of the event.

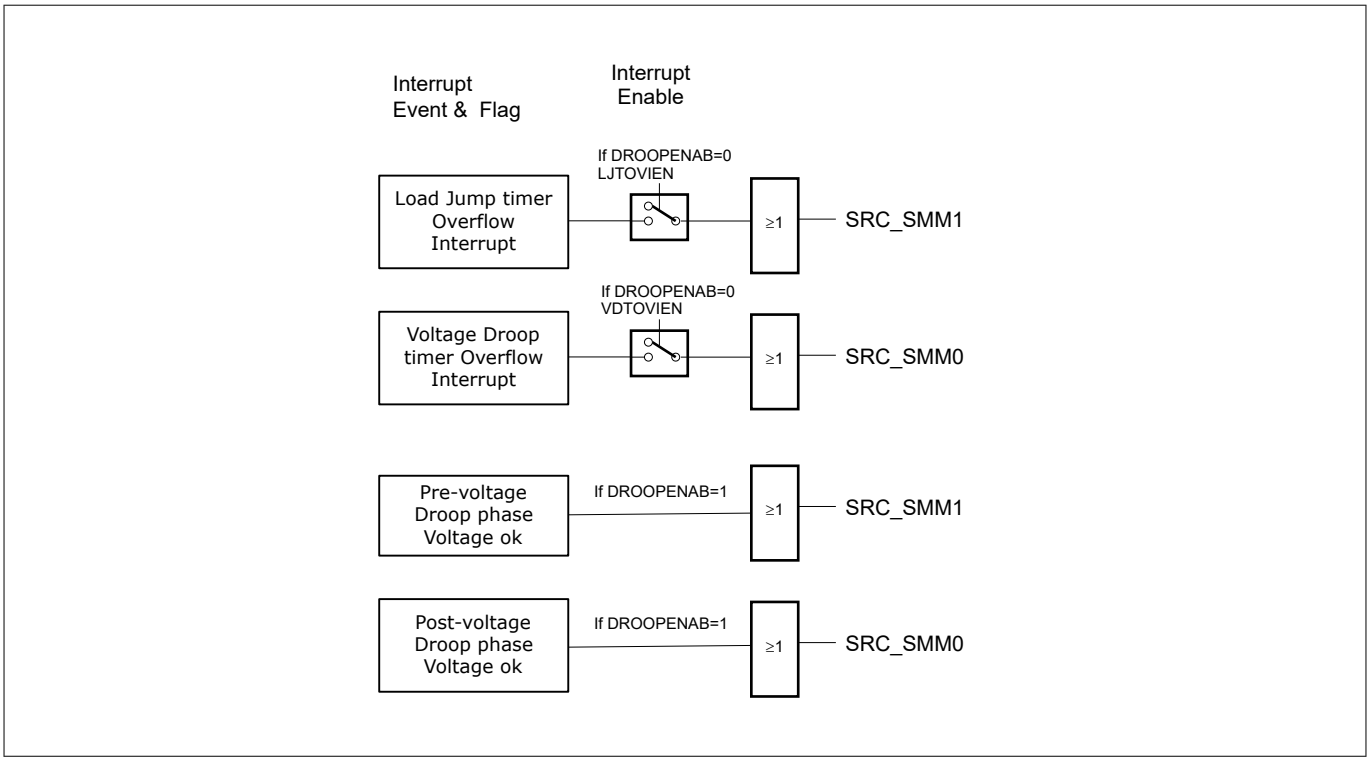

Figure 833 Interrupt sources and events

37.3.5.2 Load jump sequencing unit B

For a more hardware driven approach load jump sequencing unit B is provided.

The sequence of triggering voltage droop before load jump is as follows:

- T0: When droop request is triggered (REQ = 1), a voltage droop request is sent to PMS.EVRC module. The direction of voltage droop and amount of voltage step to be taken is also conveyed to EVRC. The BUSY flag is set immediately to indicate that no further droop requests can be taken until the ongoing activity is completed. V_NOM = 0 is set
- T1: The VDD voltage droop has started
- T2: After the new voltage set point is reached, PMS.EVRC confirms that voltage is ok. Then V_SP = 1 is set and an interrupt is triggered. DWELL counter is started to provide adequate time for software to trigger load jump. DWELL counter is running on the back-up clock
- T3: Tsw after T2 indicates the time when software triggers the load jump and set the LJT bit to confirm that load jump has happened
- T4: When dwell time has expired, the droop request is de-asserted to PMS.EVRC. V_SP = 0 is set on an acknowledge from PMS that droop request is de-asserted
- T5 = PMS.EVRC confirms that voltage is ok and V_NOM = 1 and BUSY = 0 is set and interrupt is triggered
- ERR is set if PMS.EVRC does not acknowledge to the droop request or software does not set LJT Load jump feedback bit before dwell time expiry

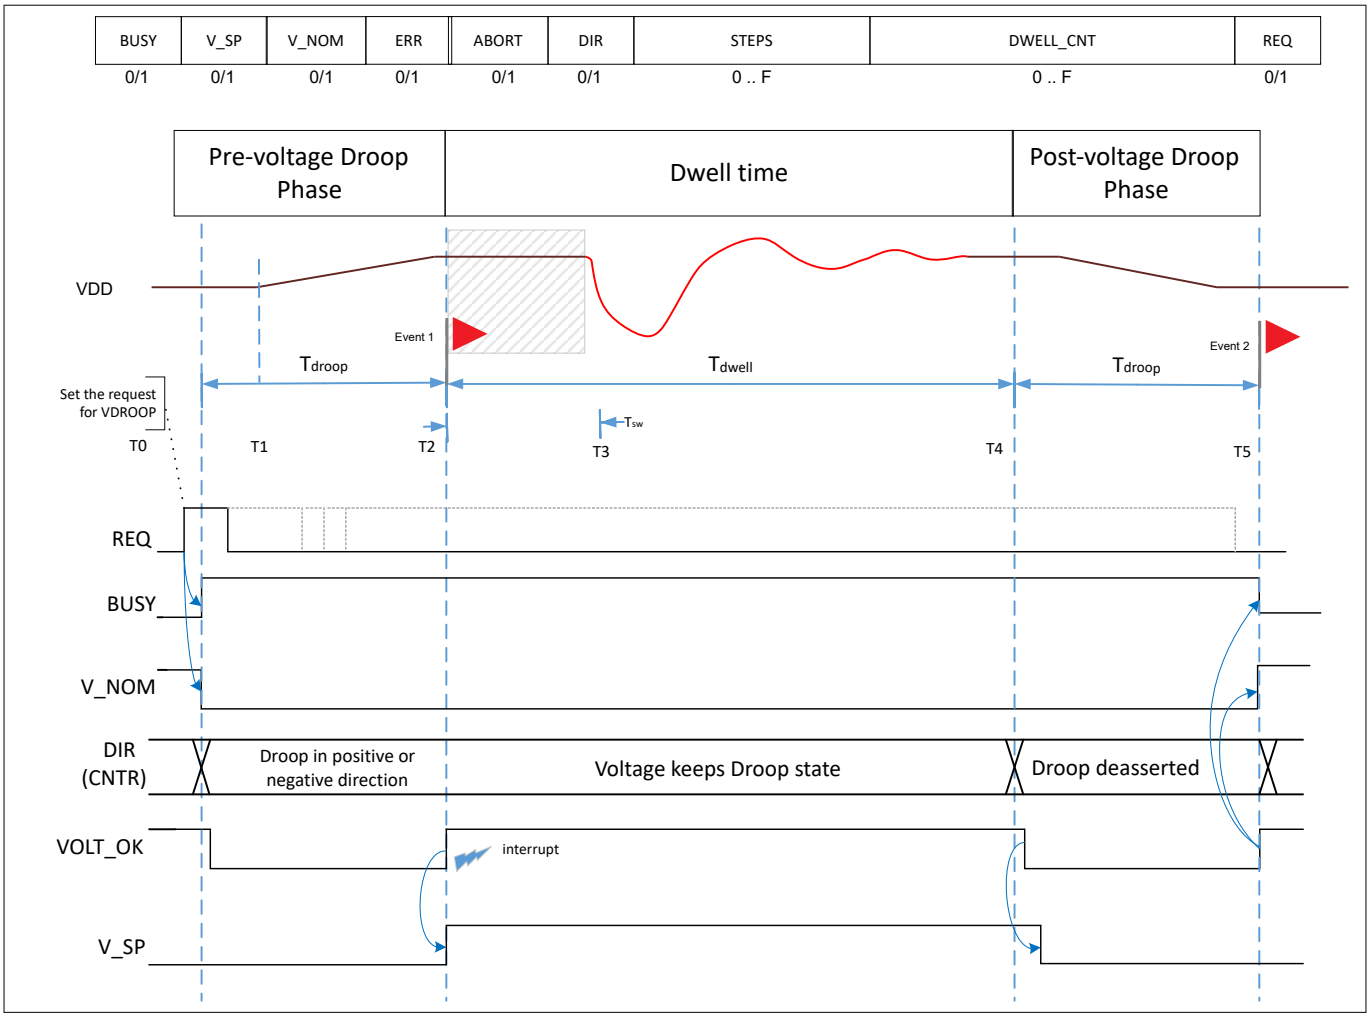

Figure 834 Load jump compensation with voltage droop

Software sequence and interface:

SMM module supports following software interface for voltage droop in register DRPCTRL:

REQ: Request Set to 1 to trigger new voltage droop compensation activity. It is a write only bit. The trigger is ignored if BUSY or ERR is set.

STEPS: Target number of steps to raise or lower voltage level. Control the target number of steps to bring VDD to either to higher or lower side of the nominal voltage level. Voltage is raised in 5 mV steps from nominal voltage level to target number of steps.

DIR: Direction of voltage change.

DWELL_CNT: Dwell count. This control field configures number of timer counts to keep the voltage level at compensation level.

LJT: Once load jump is triggered during Dwell time, the flag is set by user software to indicate that load jump was taken. If not, ERR will be set.

BUSY: Busy status of droop compensation activity. The bit is 1 during the time whole droop compensation activity is going-on.

V_SP: Voltage set point. Current voltage level is at voltage set point.

V_NOM: Voltage at nominal level. Current voltage level is at nominal supply voltage level.

ABORT: Abort control. If set, the voltage level at voltage compensation activity shall be aborted and supply voltage shall be brought back to the nominal voltage level (indicated by V_NOM).

ERR: Error indicator. Set if there is an error that has occurred during the voltage compensation activity.

ERRCLR: Error indicator clear. Clears ERR and LJT flag so that next REQ request can be taken.

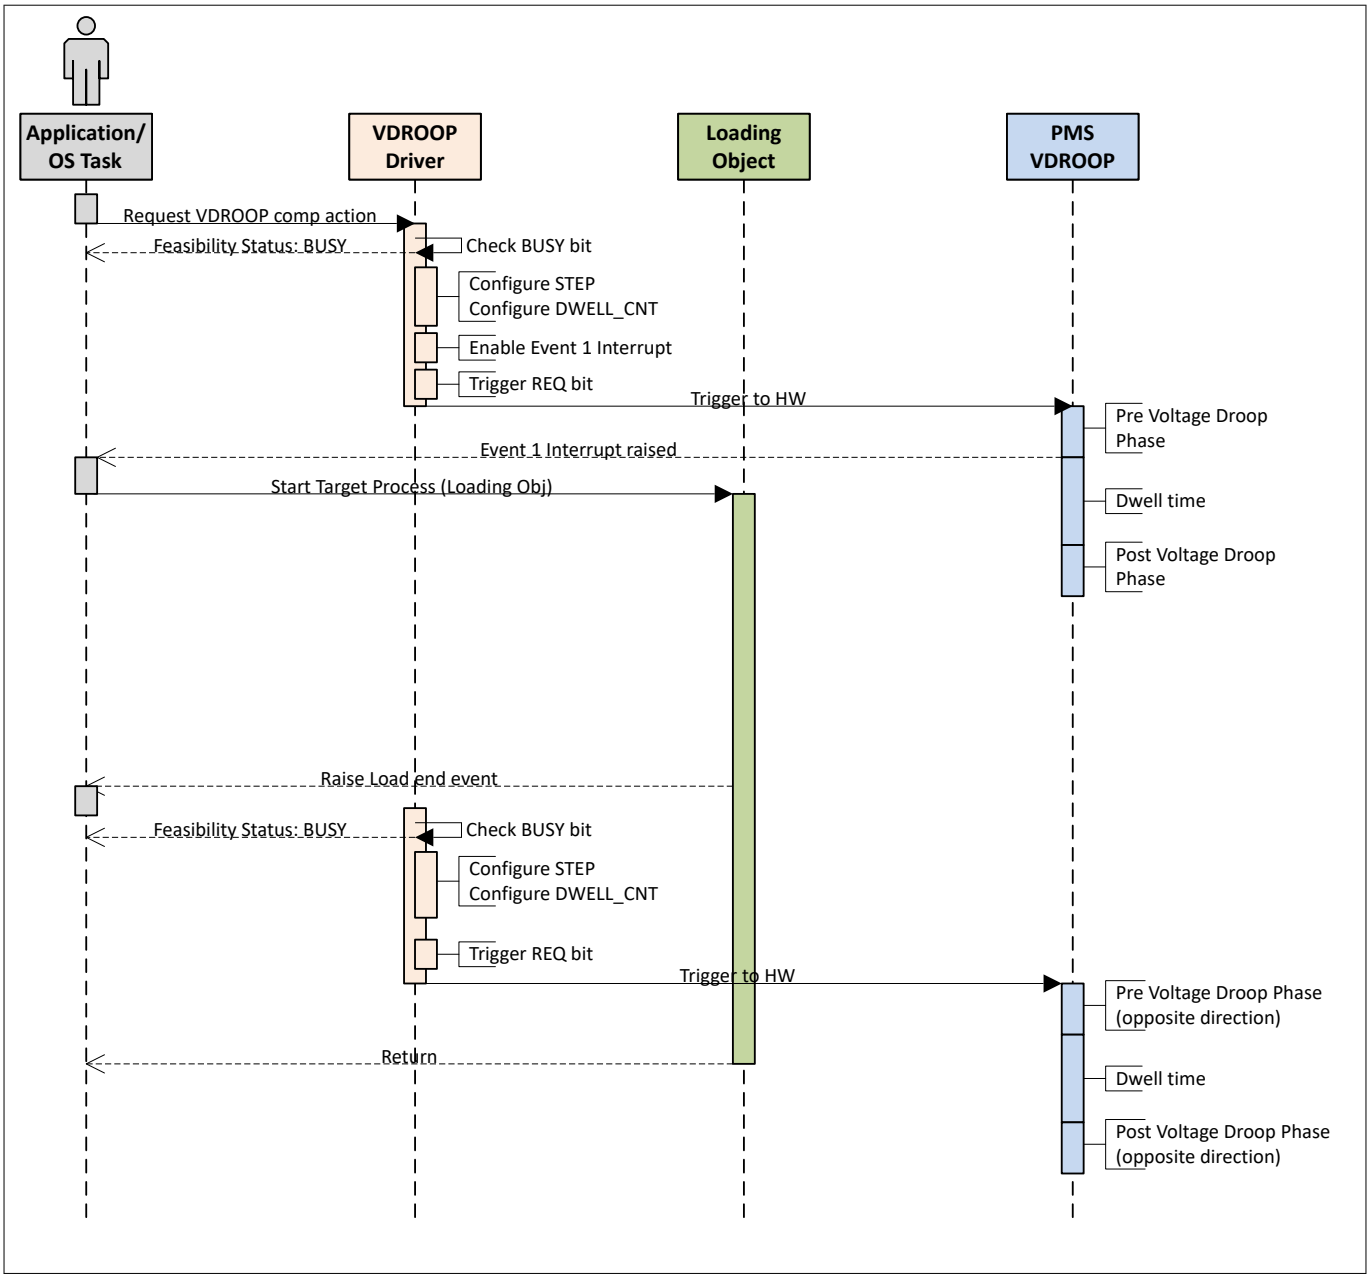

Figure 835 Load jump sequence unit B - software sequence

37.3.5.3 Shutdown sequencing on mode and reset transitions

Shut down sequencing ensures that modules are ramped down in a sequence before the internal reset(s) are issued so that RAM integrity is ensured on a warm reset and load currents are ramped down in a regulator friendly manner.

On detection of an Application Reset, System Reset or Power-On Reset trigger, the shut down sequence is started.

When the reset happens, status of all CPUs, PPU[54], Flash[54], RRAM[54] and other masters are latched in SHSEQCTRLD.

The CSSx bits indicate whether each CPU successfully flushed its write buffers and reached an idle state before the previous reset. The safe state status for PPU[54] is indicated respectively in the PPUSS. These bits can therefore be used to determine whether RAM content integrity can be trusted after the previous reset cycle.

54 not available on all devices of the AURIX™ TC4xx family

37.4 Registers

37.4.1 Register overview - access mode glossary

Table 1648 Register overview - access mode glossary

Keyword	Description
CE	Access protection using PROT register PROTCE.
CSE	Access protection using PROT register PROTCSE.
E	Access protection using PROT register PROTE.
ECPUn (n=0-5)	Access protection using PROT register PROTCPUn.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
APU-PCS	Protection group consisting of registers ACCENCS_WRA, ACCENCS_WRB, ACCENCS_RDA, ACCENCS_RDB, ACCENCS_VM, ACCENCS_PRS.
PCS	Access protection using *APU-PCS* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
STP	Access only during start-up, before start-up protection is set (SMM_STCON.ST_PROT=1).

Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number

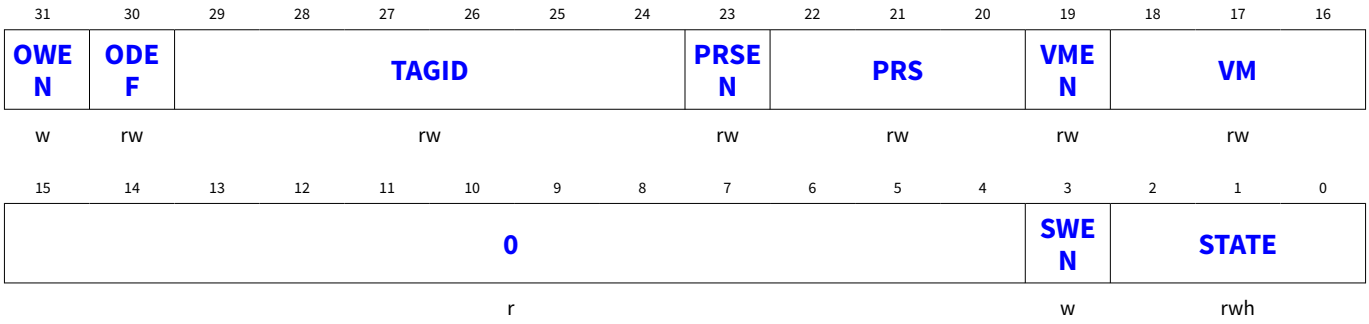
37.4.4 PROT Register Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: $000C_H$

PROT Register Endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection Set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection Set definition Enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1650 Access mode restrictions of PROTE sorted by descending priority

Mode name	Access mode		Description
PROT_OWNER and write 1 to .**SWEN**	rwh	STATE	PROT owner can modify the PROT state (for allowed and valid transitions)
PROT_OWNER and write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	PROT owner can modify the existing PROT owner
SECURE_MASTER and write 1 to .**SWEN**	rwh	STATE	Secure master can modify the PROT state (for allowed and valid transitions)
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

37.4.5 PROT Register Safe Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 0010_H

PROT Register Safe Endinit Application Reset value: $0000\ 0000_H$

0			IRADIS	0	CPUIDLSEL			PROCMODEEN	0						
r			rw	r	rw			rw	r						

Field	Bits	Type	Description
PROCMODEEN	7	rw	**Global IDLE Mode Enable for Processing Units** Global Enable which enables entry to System Modes for all processing units and PMCSRx.REQSLP function. REQSLP request is taken only when this bit is set to 1. 0_B Processing Unit IDLE, SLEEP and STANDBY mode requests via REQSLP register bitfield is disabled 1_B Processing Unit IDLE, SLEEP and STANDBY mode requests via REQSLP register bitfield is enabled

(table continues...)

(continued)

Field	Bits	Type	Description
CPUIDLSEL	10:8	rw	**CPU selection for Idle mode** This bit field allows a CPUx to issue Idle request to other CPUs in addition to itself. A request for Idle via PMCSRx.REQSLP=01 by CPUx will also trigger Idle requests to all other CPUs. ***Note**: All other CPUIDLSEL bit combinations are reserved. CPUcs cannot be selected as master CPU.* *PPU is not available on all devices of the AURIX TC4x family.* *If a CPU is not available in the device the respective bitfield combination is shall not be written.* 000_B Entry to the respective Idle mode is decided by each individual CPU. 001_B CPU0 Idle request will send all CPUs including CPUcs and PPU in Idle. 010_B CPU1 Idle request will send all CPUs including CPUcs and PPU in Idle. 011_B CPU2 Idle request will send all CPUs including CPUcs and PPU in Idle. 100_B CPU3 Idle request will send all CPUs including CPUcs and PPU in Idle. 101_B CPU4 Idle request will send all CPUs including CPUcs and PPU in Idle. 110_B CPU5 Idle request will send all CPUs including CPUcs and PPU in Idle.
IRADIS	12	rw	**Idle-Request-Acknowledge Sequence Disable** This bit enables Idle Request to CPUs and CPUcs on Standby entry. PPU is not set into Idle in this case. Acknowledge is not awaited if bit is set. IRADIS bit has no effect in case of Standby entry triggered via PWRWKEN register bit. This bit shall be set before Standby entry to disable Idle request acknowledge sequence so that Standby request is not blocked by a pending Idle acknowledge feedback. ***Note**: PPU is not available on all devices of the AURIX TC4x family.* 0_B Idle-Request-Acknowledge Sequence issued on Standby entry. 1_B Idle-Request-Acknowledge Sequence skipped on Standby entry.

(table continues...)

(continued)

Field	Bits	Type	Description
CPUSEL	26:24	rw	**CPU selection for Sleep and Standby mode** ***Note**: All other CPUSEL bit combinations are reserved. CPUcs cannot be master CPU.* *If a CPU is not available in the device the respective bitfield combination is shall not be written.* 000_B CPU0 is taken as default master and can trigger power down modes. 001_B Only CPU0 can trigger power down modes. 010_B Only CPU1 can trigger power down modes. 011_B Only CPU2 can trigger power down modes. 100_B Only CPU3 can trigger power down modes. 101_B Only CPU4 can trigger power down modes. 110_B Only CPU5 can trigger power down modes. 111_B Entry to power down modes is unanimously decided by all the CPUs. CPUcs is not included in decision.
STBYEVEN	27	w	**STBYEV Bit protection** 0_B Bit STBYEV is not updated. 1_B Bit STBYEV can be updated.
STBYEV	30:28	rw	**Standby Entry Event Configuration** ***Note**: All other bit combinations are reserved.* 000_B Standby Entry triggered by setting PMCSRx.REQSLP register bit (Default). 100_B Standby Entry triggered on ESR1 / NMI assertion.
0	6:0, 11, 23:13, 31	r	**Reserved** Read as 0; should be written with 0.

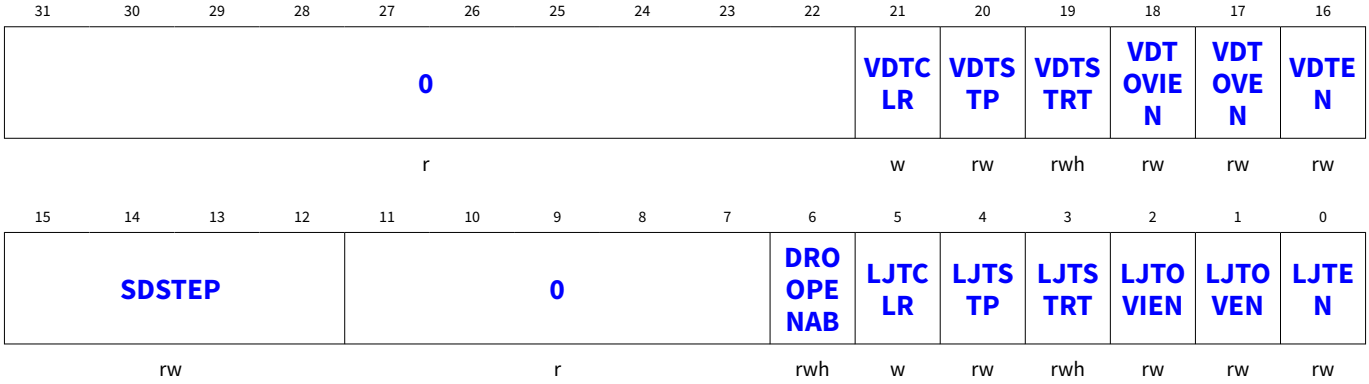
37.4.24 Power Management Transition Control and Status Register 0

PMTRCSR0 Offset address: 0098_H

Power Management Transition Control and Status Register 0 Cold PowerOn Reset value: $0000\ 0040_H$



Field	Bits	Type	Description
LJTEN	0	rw	**Load Jump Timer Enable** This bit field enables the usage of load jump timer. 0_B Load Jump Timer inactive 1_B Load Jump Timer active
LJTOVEN	1	rw	**Load Jump Timer Overflow Enable** This bit field enables the update of LJTOV status bit on timer overflow or time out. 0_B LJTOV bit is not updated on a Load Jump Timer overflow. 1_B LJTOV bit is updated on a Load Jump Timer overflow.
LJTOVIEN	2	rw	**Load Jump Timer Overflow Interrupt Enable** This bit field enables the activation of interrupt on timer overflow or time out. 0_B LJTOV interrupt is inactive. 1_B LJTOV interrupt is activated on a Load Jump Timer overflow.
LJTSTRT	3	rwh	**Load Jump Timer Start** This bit field starts Load jump timer. This is intended for test purposes. The LJTSTRT remains set on a write and is cleared when LJTOV bit is set if LJTOVEN bit is enabled. 0_B Load Jump Timer status not changed. 1_B Load Jump Timer started.
LJTSTP	4	rw	**Load Jump Timer Stop** This bit field stops Load jump timer. This is intended for test purposes. The LJTSTP remains set on a write and is to be explicitly cleared by software. The LJTSTP stops the counter at the current value and timer re-starts from that value when LJTSTP is cleared and LJTSTRT is set. 0_B Load Jump Timer status not changed. 1_B Load Jump Timer stopped.
LJTCLR	5	w	**Load Jump Timer Clear** This bit field clear Load jump timer count. This is intended for test purposes. This bit resets LJT and clears LJTRUN if LJTEN bit is set. 0_B Load Jump Count status not changed. 1_B Load Jump Timer Count cleared.

(table continues...)

(continued)

Field	Bits	Type	Description
DROOPENAB	6	rwh	**Selection between Load Jump Sequencing Units A or B** 0_B Load Jump Sequencing Unit A is active 1_B Load Jump Sequencing Unit B is active
SDSTEP	15:12	rw	**Droop Voltage Step(vdroop_step_i)** This bit field defines the voltage offset for droop compensation on a load jump to the EVRC setpoint value. The request is made via VDROOPREQ (sx_pms_evrc_droop_r_cntr_o) on an anticipated load jump with a voltage offset equal to the SDSTEP x LSB mV. The droop step is a positive offset if VDROOPREQ = 01b and is a negative offset if VDROOPREQ = 10b and no offset is applied if VDROOPREQ = 00b. Maximum Droop = 15 * VTRKCORELSB datasheet parameter ***Note**: Actual VDD voltage during droop time must be within the allowed voltage limits over lifetime as documented in datasheet section "Absolut maximum ratings"*
VDTEN	16	rw	**Voltage Droop Timer Enable** This bit field enables the usage of Voltage Droop timer. 0_B Voltage Droop Timer inactive 1_B Voltage Droop Timer active
VDTOVEN	17	rw	**Voltage Droop Timer Overflow Enable** This bit field enables the update of VDTOV status bit on timer overflow or time out. 0_B VDTOV bit is not updated on a Voltage Droop Timer overflow. 1_B VDTOV bit is updated on a Voltage Droop Timer overflow.
VDTOVIEN	18	rw	**Voltage Droop Timer Overflow Interrupt Enable** This bit field enables the activation of interrupt on timer overflow or time out. 0_B VDTOV interrupt is inactive. 1_B VDTOV interrupt is activated on a Voltage Droop Timer overflow.
VDTSTRT	19	rwh	**Voltage Droop Timer Start** This bit field starts Voltage Droop timer. This is intended for test purposes. The VDTSTRT remains set on a write and is cleared when VDTOV bit is set if VDTOVEN bit is enabled. 0_B Voltage Droop Timer status not changed. 1_B Voltage Droop Timer started.
VDTSTP	20	rw	**Voltage Droop Timer Stop** This bit field stops Voltage Droop timer. SCU cancels the droop request via signal sx_pms_evrc_droop_r_cntr_o = 00. This is intended for test purposes. The VDTSTP remains set on a write and is to be explicitly cleared by software. The VDTSTP stops the counter at the current value and timer re-starts from that value when VDTSTP is cleared and VDTSTRT is set. 0_B Voltage Droop Timer status not changed. 1_B Voltage Droop Timer stopped.

(table continues...)

(continued)

Field	Bits	Type	Description
VDTCLR	21	w	**Voltage Droop Timer Clear** This bit field clears Voltage Droop timer count. This is intended for test purposes. This bit resets VDT and clears VDTRUN if VDTEN bit is set. 0_B Voltage Droop Count status not changed. 1_B Voltage Droop Timer Count cleared.
0	11:7, 31:22	r	**Reserved** Read as 0; should be written with 0.

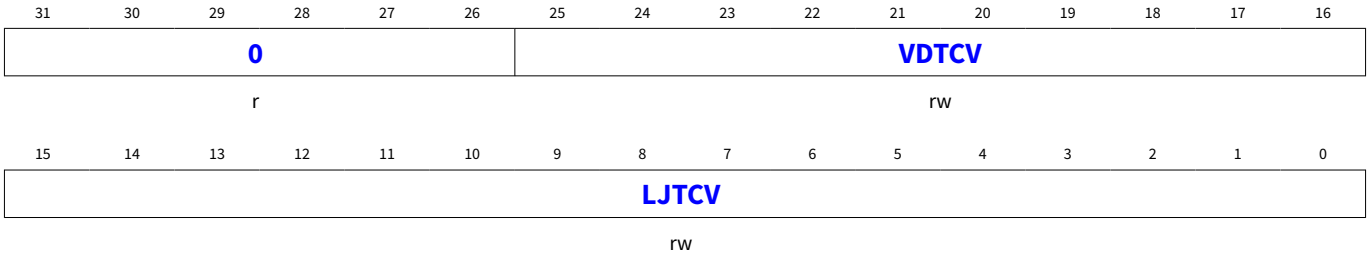
37.4.25 Power Management Transition Control and Status Register 1

PMTRCSR1

Offset address: $009C_H$

Power Management Transition Control and Status Register 1

Cold PowerOn Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
LJTCV	15:0	rw	**Load Jump Timer Compare Setpoint Value** This bit field defines the compare setpoint value of Load Jump timer. The compare event would lead to LJTOV bit being set and LJT interrupt being raised. The LJTRUN status bit, LDJMPREQ bit and LJTCNT value is reset to 0 on a compare event. X µs is the compare value. LSB = 1 µs. Total range = 65.5 ms.
VDTCV	25:16	rw	**Voltage Droop Timer Compare Setpoint Value** This bit field defines the compare setpoint value of Voltage Droop timer. The compare event would lead to VDTOV bit being set and VDT interrupt being raised. The VDTRUN status bit, VDROOPREQ bit and VDTCNT value is reset to 0 on a compare event. X µs is the compare value. LSB = 1 µs. Total range = 1023 µs.
0	31:26	r	**Reserved** Read as 0; should be written with 0.

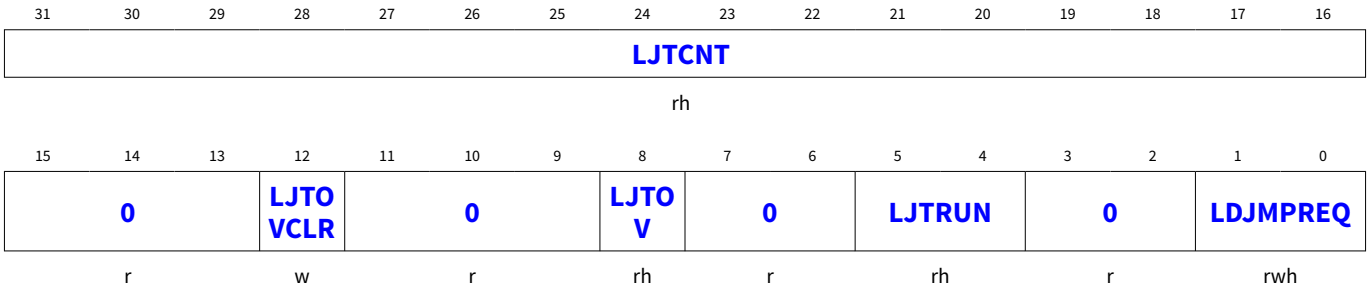
37.4.26 Power Management Transition Control and Status Register 2

PMTRCSR2

Offset address: $00A0_H$

Power Management Transition Control and Status Register 2

Cold PowerOn Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
LDJMPREQ	1:0	rwh	**Load Jump Request** This bit requests a Load Jump consequently leading to Load Jump Timer start and LJTRUN bit being set if LJTEN=1. The request is not taken if LJTRUN bit is already in set state and LJT is currently running. The request is not taken if VDTRUN bit is already in set state and VDT is currently running. The request is also not taken if (LJTOV bit is set AND LJTOVEN bit is enabled). The request is also not taken if (VDTOV bit is set AND VDTOVEN bit is enabled). The LDJMPREQ bit is cleared on a compare overflow. ***Note:*** *All other bit combinations are reserved.* 00_B Load Jump Timer inactive 01_B Load Jump Request made and taken. Load Jump Timer activated.
LJTRUN	5:4	rh	**Load Jump Timer Run Status** This status bit indicates that the Load Jump timer is currently running and a Load Jump is currently taking place. The LJTRUN bit is cleared on a compare overflow. ***Note:*** *All other bit combinations are reserved.* 00_B Load Jump and Load Jump Timer inactive 01_B A SW triggered Load Jump active and Load Jump Timer active
LJTOV	8	rh	**Load Jump Timer Overflow Status** This status bit indicates that the Load Jump timer compare match has happened. If LJTOVEN bit is enabled, then LJTOV can only be cleared explicitly via bit. If LJTOVEN bit is disabled, LJTOV is cleared on a taken Load Jump Request. LJTOV being set will lead to an interrupt if LJTOVIEN is enabled. 0_B Load Jump Timer compare overflow has not happened. 1_B Load Jump Timer compare overflow has happened.
LJTOVCLR	12	w	**Load Jump Timer Overflow Status Clear** This bit clears LJTOV status bit and sets VDROOPREQ and LDJMPREQ to 0 if LJTOVEN bit is enabled. This bit always reads as 0. 0_B This clear bit has no effect on Load Jump Timer overflow flag. 1_B Load Jump Timer overflow flag is cleared.

(table continues...)

(continued)

Field	Bits	Type	Description
LJTCNT	31:16	rh	**Load Jump Timer Value** This bit field reflects the current Load Jump timer value. LJTCNT value is cleared on timer overflow and on a taken Load Jump Request X µs is the compare value. LSB = 1 µs. Total range = 65.5 ms.
0	3:2, 7:6, 11:9, 15:13	r	**Reserved** Read as 0; should be written with 0.

37.4.27 Power Management Transition Control and Status Register 3

PMTRCSR3 Offset address: $00A4_H$

Power Management Transition Control and Status Register 3 Cold PowerOn Reset value: $0000\ 0000_H$

r			w	r			rh	r		rh		r		rwh	

Field	Bits	Type	Description
VDROOPREQ	1:0	rwh	**Voltage Droop Request** This bit requests a Voltage Droop consequently leading to Voltage Droop Timer start and VDTRUN bit being set . The request is not taken if VDTRUN bit is already in set state and VDT is currently running. The request is also not taken if (VDTOV bit is set AND VDTOVEN bit is enabled). The droop step is a positive offset if sx_pms_evrc_droop_r_cntr_o = 01 and is a negative offset if sx_pms_evrc_droop_r_cntr_o = 10 and no offset is applied if sx_pms_evrc_droop_r_cntr_o = 00 and is applied immediately. 00_B Voltage Droop and Voltage Droop Timer inactive 01_B A Positive Voltage Droop Request made and taken. Voltage Droop Timer activated. 10_B A Negative Voltage Droop Request made and taken. Voltage Droop Timer activated. 11_B Voltage Droop and Voltage Droop Timer inactive

(table continues...)

(continued)

Field	Bits	Type	Description
VDTRUN	5:4	rh	**Voltage Droop Timer Run Status** This status bit indicates that the Voltage Droop timer is currently running and a Voltage Droop is currently taking place. The VDTRUN bit is cleared on a compare overflow. ***Note**: All other bit combinations are reserved.* 00_B Voltage Droop and Voltage Droop Timer inactive 01_B A SW triggered Voltage Droop active and Voltage Droop Timer active
VDTOV	8	rh	**Voltage Droop Timer Overflow Status** This status bit indicates that the Voltage Droop timer compare match has happened. If VDTOVEN bit is enabled, then VDTOV can only be cleared by explicitly via bit. if VDTOVEN bit is disabled, VDTOV is cleared on a taken Voltage Droop Request. VDTOV being set will lead to an interrupt if VDTOVIEN is enabled. If SDVOK is set by EVRC before VDT compare match, VDTOV bit is not set. 0_B Voltage Droop Timer compare overflow has not happened. 1_B Voltage Droop Timer compare overflow has happened.
VDTOVCLR	12	w	**Voltage Droop Timer Overflow Status Clear** This bit clears VDTOV status bit if VDTOVEN bit is enabled. If VDTOVEN bit is disabled, this bit has no effect. This bit always reads as 0. 0_B This clear bit has no effect on Voltage Droop Timer overflow flag. 1_B Voltage Droop Timer overflow flag is cleared.
VDTCNT	25:16	rh	**Voltage Droop Timer Value** This bit field reflects the current Voltage Droop timer value. VDTCNT value is cleared on timer overflow and on a taken Voltage Droop Request. X µs is the compare value. LSB = 1 µs. Total range = 65.5 ms.
0	3:2, 7:6, 11:9, 15:13, 31:26	r	**Reserved** Read as 0; should be written with 0.

37.4.28 Power Management Status Register 0

Bitfields regarding CPUs or PPUs which are not available on derviatives of the TC4x family are read as 0

PMSTAT0 Offset address: $00AC_H$

Power Management Status Register 0 Reset values see: Table 1656

0															LJT
r															rwh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ERRCLR	BUSY	V_SP	V_NOM	ERR	ABORT	DIR	STEPS				DWELL_CNT				REQ
w	rh	rh	rh	rh	rw	rw	rw				rw				w

Field	Bits	Type	Description
REQ	0	w	**Set to trigger new voltage droop compensation activity.** When REQ Droop request is set to 1, droop request, direction and voltage step information are transferred to EVRC. The request is ignored if BUSY or ERR bit is currently set. Read as 0. 0_B No droop control request 1_B Droop control request
DWELL_CNT	4:1	rw	**Dwell timer count delay keeping voltage before droop deassertion** The DWELL counter starts running once V_SP is set from 0 to 1. The Dwell counter provides a delay with a LSB granularity of ~ 5us. When DWELL time has expired, the droop request is deasserted to EVRC
STEPS	8:5	rw	**Target number of steps to raise or lower voltage level** Control the target number of steps to bring VDD to either to higher or lower side of the nominal voltage level. Voltage is raised in 5mV steps from nominal voltage level to target number of steps. ***Note**: Actual VDD voltage during droop time must be within the allowed voltage limits over lifetime as documented in datasheet section "Absolut maximum ratings"*
DIR	9	rw	**Definiton of the direction of the voltage (rising/reducing)** 0_B Voltage set point is higher than nominal 1_B Voltage set point is lower than nominal
ABORT	10	rw	**Abort control** 0_B Do not abort 1_B Voltage level at voltage compensation activity shall be aborted and supply voltage shall be brought back to the nominal voltage level (indicated by V_NOM).
ERR	11	rh	**Error indicator** 0_B No Error has occurred during the voltage compensation activity 1_B An Error has occurred during the voltage compensation activity

(table continues...)

(continued)

Field	Bits	Type	Description
V_NOM	12	rh	**Voltage at nominal level** On a new droop request to EVRC (REQ=1) , V_NOM is set to 0 on an acknowledge from EVRC that voltage droop has started. On the deassertion of the droop request after DWELL counter expiry, the V_NOM is set back to 1 when EVRC nominal voltage is restored. When V_NOM is set from 0 to 1, interrupt is triggered. During Voltage drooping phase and Load jump execution phase V_NOM = 0 0_B Current voltage is not at nominal supply voltage level. 1_B Current voltage is at nominal supply voltage level.
V_SP	13	rh	**Voltage Set Point** After the voltage droop phase is completed by EVRC, V_SP = 1 is set to indicate that new voltage set point has reached and load jump can be triggered. When V_SP=1 is set, interrupt is triggered. After expiry of DWELL counter, the droop request is deasserted and V_SP = 0 is set. 0_B Current voltage is not at voltage set point. 1_B Current voltage is at voltage set point.
BUSY	14	rh	**Busy status of droop compensation activity** When REQ request is taken, BUSY flag is set to indicate that no further request can be taken. The BUSY flag is deasserted when nominal voltage is reached again (V_NOM=1) 0_B No droop compensation activity currently running. 1_B Droop compensation activity is on-going.
ERRCLR	15	w	**Clear ERR** Write to ERRCLR bit clears ERR flag and LJT bit so that next Droop REQ can be given. Read as 0.
LJT	16	rwh	**Load Jump Taken flag set by SW during DWELL time** When load jump is triggered by user software, the flag shall be set before DWELL counter has expired. The flag is reset on ERRCLR or REQ write
0	31:17	r	**Reserved** Read as 0; should be written with 0.

37.4.30 Start-Up Status Register

STSTAT Offset address: $00B4_H$

Start-Up Status Register Reset values see: Table 1657

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

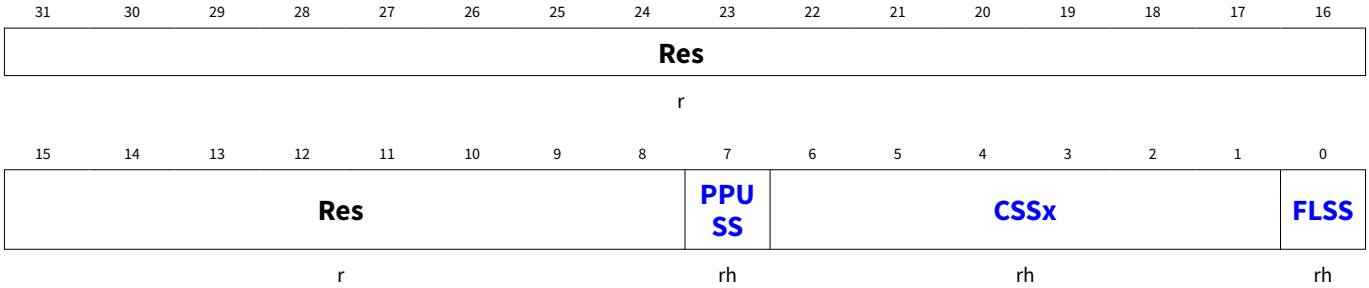
37.4.36 Shut Down Sequence Control Register D

This register indicates whether CPU, FLASH, PPU and all Bridges have been successfully put into shut down state before reset was issued to ensure that no ongoing RAM write operation was aborted by reset event.The state flags are cleared on a new reset request or on a CLRC register clear event

SHSEQCTRLD Offset address: $00F4_H$

Shut Down Sequence Control Register D Cold PowerOn Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
FLSS	0	rh	**Flash Shutdown State Reached and Acknowledge received** The state of Flash acknowledge after the last warm reset. The bitfield represents the state of the FSI before the last warm reset If this bit is zero after a System Reset (or higher) then it is possible that Flash reliability could have been affected by the reset. ***Note**: Flash is not available on all devices of the AURIX TC4x family. For RRAM devices this bitfield is always 1.* 0_B FSI flash shutdown state not reached before last reset 1_B FSI flash shutdown state reached before last reset
CSSx	6:1	rh	**CPUx Shutdown State Reached and Acknowledge received** The state of CPUx acknowledge after the last warm reset. If any bit is zero after an Application Reset (or higher) then it is possible that the SRAM content could have been corrupted by the reset. For products with fewer CPUs, only the LSBs are active and unused upper bits will always read '1'. 00_H CPU x shutdown state not achieved prior to last reset 01_H CPU x in shutdown state at last reset
PPUSS	7	rh	**PPU Shutdown State Reached and Acknowledge received** The state of PPU acknowledge after the last warm reset. If any bit is zero after an Application Reset (or higher) then it is possible that the SRAM content could have been corrupted by the reset. ***Note**: PPU is not available on all devices of the AURIX TC4x family. In these cases this bitfield is read as 1.* 0_B PPU shutdown state not reached before last reset 1_B PPU shutdown state reached before last reset

37.4.37 Reset Trigger Status Register for Warm Reset Events

After a reset has been executed, the WRMRSTTRIG provide information on all the triggers accumulated for the last reset types after the last CLRC event. Multiple resets triggers may have taken place which is captured in this register.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
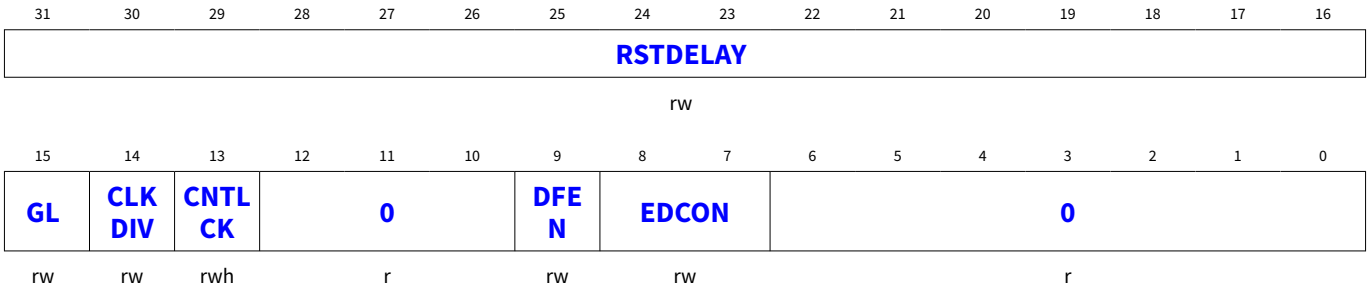
0														ARC	ARI
r														w	rh

Field	Bits	Type	Description
ARI	0	rh	**Application ESR0 Reset Output Indicator** This bit is set when an Application Reset request trigger occurs and cleared by writing to ARC. When the ARI bit is set and an ESR pin is configured as a reset output, the corresponding ESR input will not re-trigger a reset. This prevents feedback of the reset indication causing a new reset request. ***Note**: Observed reset value after boot will depend upon ARI mode.* 0_B No application reset trigger detected (since last clear) 1_B Application reset trigger detected (since last clear)
ARC	1	w	**Application ESR0 Reset Output Indicator Clear** Read as 0 0_B No effect 1_B Clear Application Reset Indicator (ARI)
0	31:2	r	**Reserved** Read as 0; should be written with 0.

37.4.50 ESRx Input Configuration Register

ESRCFGx (x=0-2) Offset address: 0134_H+x*4

ESRx Input Configuration Register PowerOn Reset value: $0000\ A300_H$



Field	Bits	Type	Description
EDCON	8:7	rw	**Edge Detection Control** This bit field defines the edges that lead to an ESRx trigger of the synchronous path. 00_B No trigger is generated 01_B A trigger is generated upon a rising edge 10_B A trigger is generated upon a falling edge 11_B A trigger is generated upon a rising OR falling edge
DFEN	9	rw	**ESR Digital Filter Enable** This bit activates digital spike filter (majority filter of 3 consecutive values) during normal RUN mode. 0_B The filter is bypassed 1_B The filter is used
CNTLCK	13	rwh	**Counter configuration Lock** CNTLCK provides lock mechanism for RSTDELAY, GL and CLKDIV bitfields. CNTLCK is read and if it is 0, RSTDELAY, GL and CLKDIV bitfields are updated after which CNTLCK is set to 1 by software. The hardware updates all the values synchronously and sets CNTLCK back to 0. CNTLCK reset value is 1 to take ESR default configuration at reset but a later read by user would be 0 as hardware set the bit back. Following is the SW sequence to update these bitfields: - Wait until CNTLCK is 0 (required to check about any previous update is on-going) - Configure the RSTDELAY, GL and CLKDIV bitfields and set CNTLCK to 1 This would trigger the HW to process the new configured bitfield values, upon the completion of HW process the CNTLCK is automatically rest to 0 by HW. 0_B The bitfields GL, CLKDIV, RSTDELAY can be updated 1_B The bitfields GL, CLKDIV, RSTDELAY is locked by user software and hardware update is going on
CLKDIV	14	rw	**Backup Clock Divider - 1024** 0_B Counter is clocked by fBACK 1_B Counter is clocked by fBACK/1024
GL	15	rw	**Greater than or Less than Counter Event Selection** 0_B The event is triggered when the captured pulse is less than the RSTDELAY count value 1_B The event is triggered when the captured pulse is greater than the RSTDELAY count value

(table continues...)

(continued)

Field	Bits	Type	Description
RSTDELAY	31:16	rw	**Reset input pulse width compare value**
0	6:0, 12:10	r	**Reserved** Read as 0; should be written with 0.

37.4.51 ESR0 Reset Counter Control Register

This register controls the ESR0 strong pull down reset elongation time after Application reset release. This register controls the reset length setting for Application reset.

ESR0CNTCTRL Offset address: 0140_H

ESR0 Reset Counter Control Register Reset values see: Table 1663

37.7 SMM revision history

Reference	Description of change(s)
Date range: 2024-08-17 to 2025-01-29	
Start-up configuration	• Removed information about HWCFG latching in SMM status register STSTAT throughout the whole SMM chapter
External service request interface (ESRx)	• Changed the wakeup connectivity of the ESRx pads and the standby entry connectivity for ESR2
Module kernel reset	• Added AUDIO IP to the overview table
Low frequency applications	• Added a new section about low frequency applications
System Mode Management (SMM)	Changed "CPU, PPU" to "processing units"

37.8 TC4Dx SMM information

37.8.1 TC4Dx SMM configuration

There are no deviations from the generic specification.

37.8.2 TC4Dx SMM features

There are no deviations from the generic specification.

37.8.3 TC4Dx SMM functional description

37.8.3.1 HWCFG latching on start-up

On a warm reset release, HWCFG port pin inputs are latched on the rising edge of an application reset and stored in register STSTAT.

It is recommended that the boot configuration is selected using the internal BMI configuration and not from pins owing to security concerns. Boot from HWCFG [3,4,5] is to be for test purposes and end of lineprogram ming functions and is not intended for productive usage. The STSTAT status register indication hasdepende nce on Port reset behavior and Software reset configurations. Comparison of latched HWCFG valuereflected in STSTAT register against the latched HWCFG value in PMS.PADSTAT register can be under all conditions ensured only if hardware configuration pins are pulled externally via resistors.

37.8.3.2 CANXL Module kernel reset

Table 1664 TC4Dx considerations for module resets

Module	Module reset capability
CANXL	Module reset implemented in CANXL ***Note**: TC4Dx CANXL Module reset requires special handling as the application software must ensure that X CAN node's Message Handler and Protocol Controller are stopped, before Kernel reset request via KRST or via Module Group Reset trigger (when enabled through MODULE_RST_CTRLA.GRSTEN bit-field)*

37.8.4.4 Start-Up Status Register

SMM_STSTAT Offset address: $00B4_H$

Start-Up Status Register Reset values see: Table 1668

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res				0		MODE2	RAMINT	Res	0	Res	SPDEN	TRSTL	Res		
r				r		rh	rh	r	r	r	rh	rh	r		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MODE1	Res							HWCFG							
rh	r							rh							

Field	Bits	Type	Description
HWCFG	7:0	rh	**Hardware Configuration Setting** This bit field contains the HWCFG latched value used by the boot firmware. STSTAT register latches HWCFG pin values with a delay of multiple clock cycles after reset release on every application reset. HWCFG[7:0] = [Res, P14.4, P10.6, P10.5, P14.3, P14.2, P14.5, Res] ***Note**: The observed reset value after boot depends upon the state of the HWCFG pins*
MODE1	15	rh	**MODE** This bit indicates if the Test Mode is entered or not. Testmode is entered if both MODE1=0 AND MODE2=0 together. 0_B A Test Mode can be selected 1_B Normal Mode is selected
TRSTL	19	rh	**TRSTL Status** This bit simply displays the value of TRSTL.
SPDEN	20	rh	**Single Pin DAP Mode Enable** 0_B Single Pin DAP Mode is disabled 1_B Single Pin DAP Mode is enabled
RAMINT	24	rh	**RAM Content Security Integrity** In normal operation this bit can be set or cleared by the application (via SYSCON.RAMINTM). If a test boot mode is entered, the bit is automatically cleared (and cannot be set again in test mode) because the content may have been altered ***Note**: This bit is reset only by a cold power-on reset.* 0_B RAM Security Integrity cannot be guaranteed 1_B RAM Security Integrity maintained
MODE2	25	rh	**MODE** This bit indicates if the Test Mode is entered or not. Testmode is entered if both MODE1=0 AND MODE2=0. 0_B A Test Mode can be selected 1_B Normal Mode is selected
0	22, 27:26	r	**Reserved** Read as 0.

Table 1668 Reset values of SMM_STSTAT

Reset type	Reset value	Note
After Boot-FW Value	---- 0010 -X-0 --00 1000 0000 ---- ----$_B$	Bit-fields with unknown values depend on fuse or reset value.

HWCFG latching on start-up	• Added the description about HWCFG latching in STSTAT

38 Voltage and Temperature Monitors (VTMON)

The VTMON module interfaces to distributed temperature monitors at different locations across the microcontroller.

38.1 Feature list

Die temperature sensor (DTS)

- Continuous Measurement of the actual silicon temperature by distributed integrated sensors reflecting the actual junction temperature and variation across the die
- Integrated Die Temperature Sensor (DTS) with an overall accuracy of measurement within ±3°C after trimming
- Multiple DTS instances placed at proximity of hot spots to cover spatial temperature variance (dT/ds inclusive hot spots), temporal temperature variations (dT/dt) within measurement interval, and application use-case variations
- The DTS shall generate SMU alarms when the upper or lower configurable temperature limits representing the operating temperature range of the application are violated
- Thermal shut down alarm which can trigger a reset through the SMU (Safety Management Unit) to detect cases of thermal runaway beyond the maximum allowed junction temperature
- Redundant temperature sensing units in different RUN and STANDBY power domains to ensure minimization of common cause faults

38.2 Functional overview

The VTMON provides access to the temperature measurement functions.

The building blocks are:

- Die Temperature Sensors (DTS)
- UBS-Serial bridge to all DTS instances

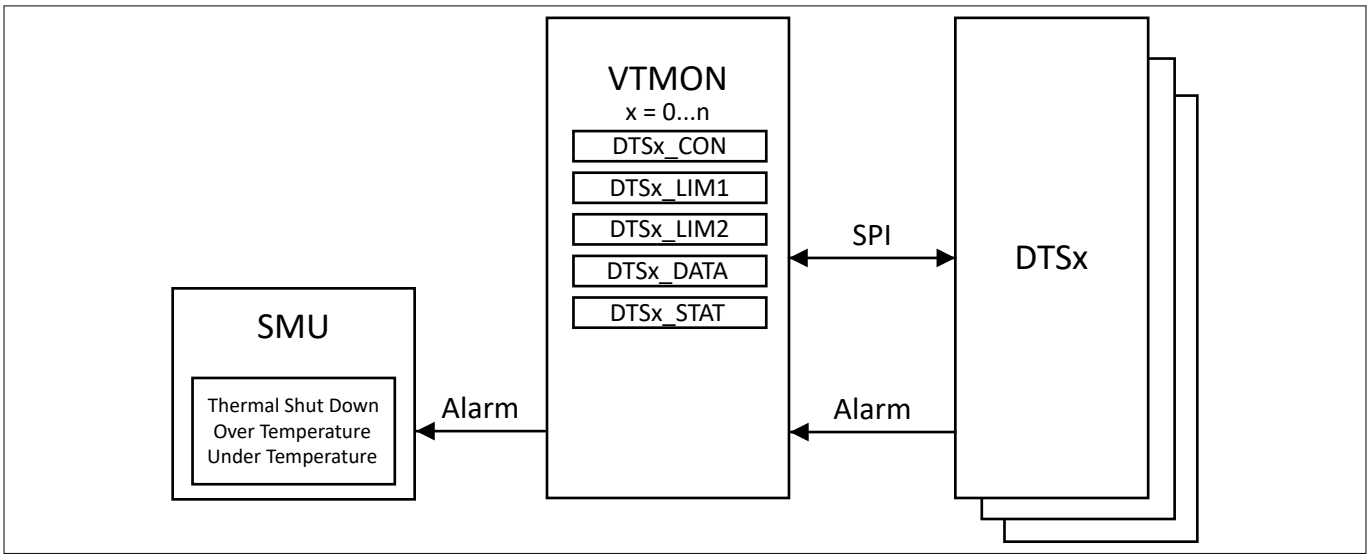

Figure 836 VTMON block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

Related information

TC4Dx SMU alarm mapping tables on page 7233

38.3 Functional description

The VTMON connects to various DTS instances located at different module locations across the die.

Distributed DTS instances

The DTS sensors are instanced predominantly at hot spot areas like processing units. There is also one DTS instance in the Power Management System (PMS) to support temperature measurement during standby modes. The spatial separation of the sensors and instantiation in different power and reset domains allow redundancy from the safety point of view.

Table 1670 DTS instances and domains

DTS instances	Supply domain	Clock	Reset	SMU alarms
DTSPMS	VDDEVRSB	DTS clock: $\left(\frac{fBACK}{50}\right)$ MHz Interface clock: $\left(\frac{fBACK}{5}\right)$ MHz	LVDPMS1 reset	High, Low, Thermal shutdown
DTS0 (SRI0)	VDDEXTOSC		Application reset	High, Low, Thermal shutdown
DTS1 (SRI1)				High, Low, Thermal shutdown
DTS2 (SRI2)				High, Low, Thermal shutdown
DTS3				High, Low, Thermal shutdown
DTS4				High, Low, Thermal shutdown

38.3.1 VTMON serial interface

The VTMON interface is a serial interface connecting to various DTS located at different module locations across the die.

VTMON interface

The VTMON interface serves as a bridge that provides SPB/FPI access to the DTS sensor instances. To mitigate high routing overheads, all communication between the VTMON and the distributed sensor instances are serialized, with the VTMON serving as the serial master to convey read/write operations from the SPB / FPI to the distributed sensor instances. The serial interfaces are clocked by divided back-up clock for DTS instances ($\frac{100\ MHz}{5}$) The DTS module itself runs at a lower clock of $\left(\frac{fBACK}{5}\right)$ MHz .

All configuration registers come with a set of shadow registers located in the distributed sensor instances. The LCK bit in the configuration registers is used to indicate an ongoing serial transfer to the shadow register in the distributed sensor instance. It shall be ensured that the configuration register should not be written when the respective LCK bit is set. Data transfer from shadow configuration registers in the distributed sensor instances to the VTMON configuration registers can be triggered by setting the REQ bitfield. The VALID flag indicates the completion of the data transfer.

38.3.2 DTS measurement function

The Die Temperature Sensor (DTS) indicates directly the current junction temperature.

Each DTS instance periodically generates a measurement result that can be converted into the current die temperature in the region it is located. In the event of thermal limit violations, alarms can be generated to support thermal performance throttling operations. Each DTS operates within the temperature range of TSR, with an accuracy of (TNL+TCALACC), with corresponding parameters as documented in the datasheet. The

temperature sensing resolution is 0.22 °C/code. The maximum conversion time is the t_M parameter documented in the datasheet. Gain and offsets errors are compensated by trimming executed by start-up software. Systematic non-linearity is linearized through digital post-processing. Differential temperature monitoring between DTS instances correlated to application use case based thermal simulations can minimize the thermal margin required and allow tighter monitoring of thermal boundaries.

The analog circuitry for each DTS is enabled by setting the EN register bit. When the START register bit is set, temperature measurements will be carried out continuously during RUN/SLEEP modes, with the latest measurement result being updated in the RESULT bitfield. Both the EN and START can be set concurrently, though the first conversion will take slightly longer for the analog circuitry to be properly initialized. The DTSREADY register bit is set when the analog circuitry has finished the first conversion and only then the alarms are forwarded.

The DTSPMS registers are not affected by a warm PORST, system or application reset; consequently PMS_DTS_STAT temperature result from earlier conversion is available for immediate use after any warm reset as it is reset only on an LVD reset. All the other DTS instances in VTMON are reset on an application reset.

The DTS result RESULT can be converted to temperature by the following transfer function.

$$T[^oC] = \frac{\text{DTSx_STAT.RESULT}}{\text{gnom}} - 273.15$$ where the *gnom* is 4.781 Codes/K

A peak temperature detector records the highest temperature measurement result in PEAK since the last reset operation. This can be reset by writing a ‘1’ to the PEAKDETRST register field.

Upper and lower thermal warnings with adjustable threshold, hysteresis and filters are included and are targeted for thermal throttling and control functions. In addition, a thermal-shutdown warning is included to trigger a reset during thermal runaway scenarios. All warnings can be triggered only when the WRNEN register is set. WRNEN is configured so that warnings are disabled after start-up.

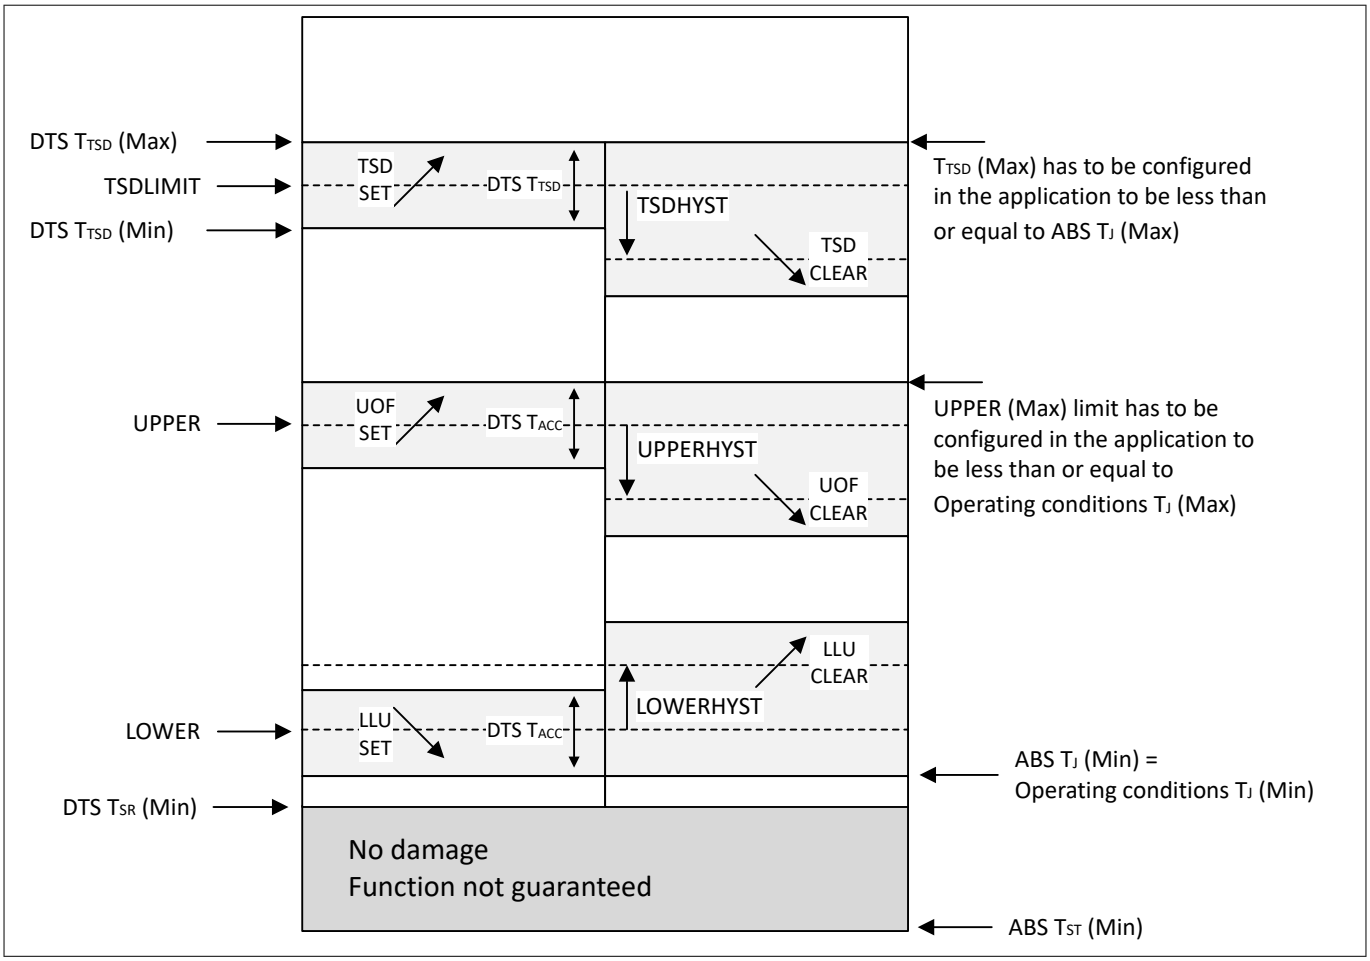

Figure 837 DTS warning generation

The functionality of all warnings are summarized in Table below. Die temperature thermal shutdown, upper and lower limits are configured in TSDLIMIT, UPPER and LOWER register bits respectively. On violation of these limits, TSD, UOF and LLU status bits are set. After start-up, the DTS limits have to be re-configured appropriately depending on the application before alarm reactions from SMU or CSRM are activated. Only when a new DTS conversion result is available, the DTS comparators are consequently triggered to check the actual RESULT against the thermal shutdown, upper and lower limits.

The set criteria for all warnings also allows implementation of a filter whereby the warning will be triggered only when the set limits are satisfied for a number of consecutive temperature measurement violations. The TSD warning is triggered when RESULT exceeds TSDLIMIT for (TSDFILT + 1) consecutive conversions. The UOF warning is triggered when RESULT exceeds UPPER for (UPPERFILT + 1) consecutive conversions. The LLU warning is triggered when RESULT is below LOWER for (LOWERFILT + 1) consecutive conversions.

All warnings are cleared when the corresponding clear criteria are satisfied, which includes an adjustable hysteresis in the clear limits. The clear criteria for TSD warning is satisfied when RESULT is below (TSDLIMIT - TSDHYST). The clear criteria for UOF warning is satisfied when RESULT is below (UPPER - UPPERHYST). Similarly, the clear criteria for LLU warning is satisfied when RESULT exceeds (LOWER + LOWERHYST).

When a warning is triggered, the associated alarm status bits (TSDALRM for thermal shutdown, UOFALRM for over temperature and LLUALRM for under temperature warnings) are set, together with the corresponding alarm being forwarded to the SMU and the CSRM. All alarms status bits are cleared by the user writing a '1' to the CLR bitfield. Unlike warnings, the alarm triggering functions are immediate and not subject to the serial transfer delay.

Table 1671 Alarms, warnings and triggers

Warning type	Warning signal (associated alarm)	Warning and alarm set limits	Warning and alarm set criteria	Warning and alarm clear limits	Warning and alarm clear criteria
Thermal shutdown warning	TSD (TSDALRM)	≥TSDLIMIT	Consecutive (TSDFILT+1) DTS conversions	< TSDLIMIT – TSDHYST	Immediate
Thermal upper warning	UOF (UOFALRM)	≥ UPPER	Consecutive (UPPERFILT+1) DTS conversions	< UPPER – UPPERHYST	Immediate
Thermal lower warning	LLU (LLUALRM)	≤ LOWER	Consecutive (LOWERFILT+1) DTS conversions	> LOWER + LOWERHYST	Immediate

38.4 Registers

38.4.1 Register overview - access mode glossary

Table 1672 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

38.4.2 Registers overview - VTMON (ascending offset address)

Table 1673 Registers overview - VTMON (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write

38.4.3 Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 000_H

Clock Control Register Application Reset value: $0000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked

(table continues...)

(continued)

Field	Bits	Type	Description
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

38.4.4 OCDS Control and Status Register

The OCDS Control and Status register OCS controls the debug behavior by selecting suspend modes. When OCDS is disabled the suspend control is ineffective.

OCS Offset address: 004_H

OCDS Control and Status Register Debug Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		SUSSTA	SUS_P	SUS				0							
r		rh	w	rw				r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												TG_P	TGB	0	
r												w	rw	r	

Field	Bits	Type	Description
TGB	2	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1
TG_P	3	w	**TGS, TGB Write Protection** TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) Not listed combinations lead to soft suspend mode. 0_H Will not suspend 1_H Hard suspend Clocks will be disabled immediately 2_H Soft suspend mode Clock will be disabled after kernel (VTMON) acknowledge.
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.

(table continues...)

(continued)

Field	Bits	Type	Description
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	1:0, 23:4, 31:30	r	**Reserved** Read as 0; should be written with 0.

Table 1674 Access mode restrictions of OCS sorted by descending priority

Mode name	Access mode		Description
write 1 to .**TG_P**	rw	TGB	Set TG_P during write access
write 1 to .**SUS_P**	rw	SUS	Set SUS_P during write access
(default)	r	SUS, TGB	

38.4.5 Module Identification Register

ID Offset address: 008_H

Module Identification Register PowerOn Reset value: $00C5\ C013_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r															

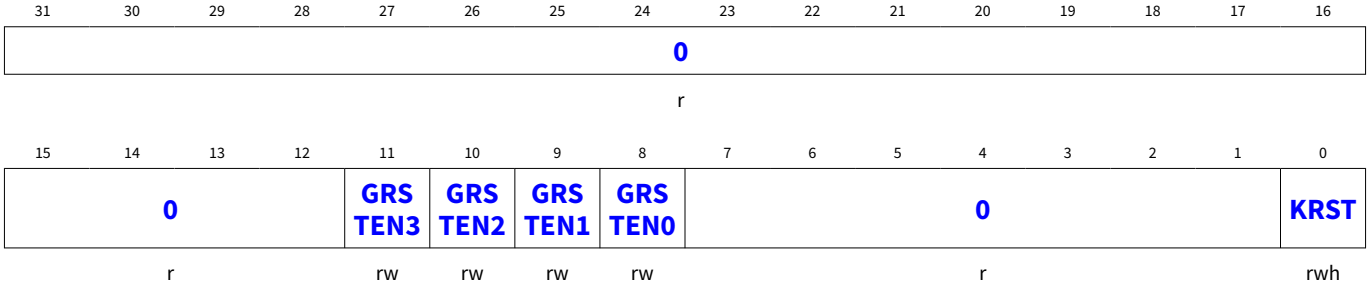
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOD_TYPE								MOD_REV							
r								r							

Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number (example: $00C5_H$ = SARADC).

38.4.6 Reset Control Register A

RST_CTRLA Offset address: $00C_H$

Reset Control Register A Application Reset value: $0000\ 0000_H$

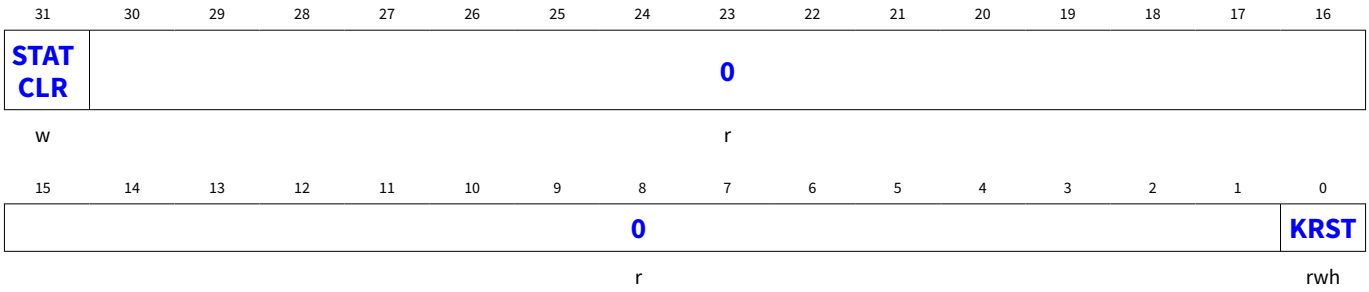


Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. Kernel reset shall not be used for VTMON module as this leads to the loss of trimming values which cannot be installed by the user. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for Global Module Reset Group x** 0_B Global module reset group x does not have any effect 1_B Global module reset group x results in a kernel reset
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

38.4.7 Reset Control Register B

RST_CTRLB Offset address: 010_H

Reset Control Register B Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. Kernel reset shall not be used for VTMON module as this leads to the loss of trimming values which cannot be installed by the user. 0_B No action 1_B A kernel reset was requested
STATCLR	31	w	**Kernel Reset Status Clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits STAT.GRSTx and bit STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

38.4.8 Reset Status Register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: 014_H

Reset Status Register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				GRST3	GRST2	GRST1	GRST0	0							KRST
r				rh	rh	rh	rh	r							rh

Field	Bits	Type	Description
KRST	0	rh	**Kernel Reset Status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.
GRSTx (x=0-3)	x+8	rh	**Status for Global Module Reset Group x** 0_B Reset was not triggered by Global Reset Group x 1_B Reset was triggered by Global Reset Group x
0	7:1, 31:12	r	**Reserved** Read as 0.

38.4.9 PROT Register Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 020_H

PROT Register Endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OWEN	ODEF	TAGID						PRSEN	PRS			VMEN	VM		
w	rw	rw						rw	rw			rw	rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												SWEN	STATE		
r												w	rwh		

Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection Set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.

(table continues...)

(continued)

Field	Bits	Type	Description
PRSEN	23	rw	**Protection Set definition Enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1675 Access mode restrictions of PROTE sorted by descending priority

Mode name	Access mode		Description
PROT_OWNER and write 1 to .**SWEN**	rwh	STATE	PROT owner can modify the PROT state (for allowed and valid transitions)
PROT_OWNER and write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	PROT owner can modify the existing PROT owner
SECURE_MASTER and write 1 to .**SWEN**	rwh	STATE	Secure master can modify the PROT state (for allowed and valid transitions)
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

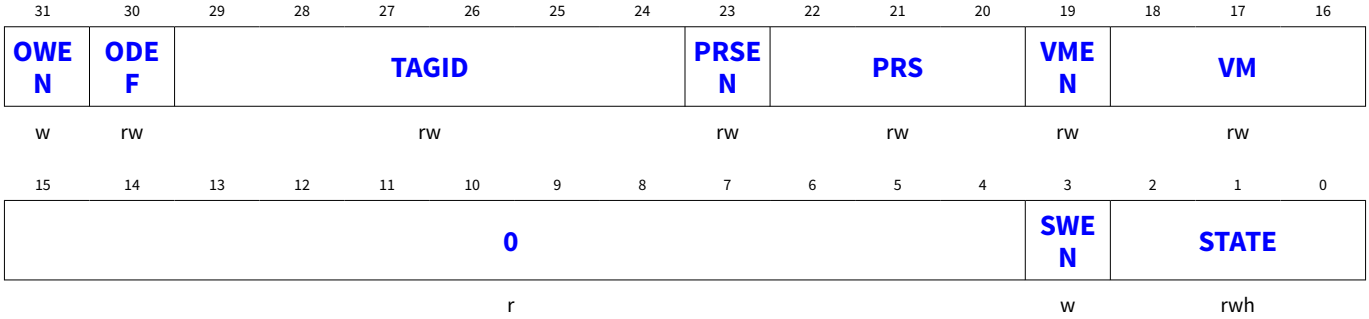
38.4.10 PROT Register Safe Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 024_H

PROT Register Safe Endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection Set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection Set definition Enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1676 Access mode restrictions of PROTSE sorted by descending priority

Mode name	Access mode		Description
PROT_OWNER and write 1 to .**SWEN**	rwh	STATE	PROT owner can modify the PROT state (for allowed and valid transitions)
PROT_OWNER and write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	PROT owner can modify the existing PROT owner
SECURE_MASTER and write 1 to .**SWEN**	rwh	STATE	Secure master can modify the PROT state (for allowed and valid transitions)
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

38.4.11 Write access enable register A

This register defines which master TAG ID encodings are enabled or disabled for write accesses to the access protected region.

ACCEN_WRA Offset address: 040_H

Write access enable register A Application Reset value: $1000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

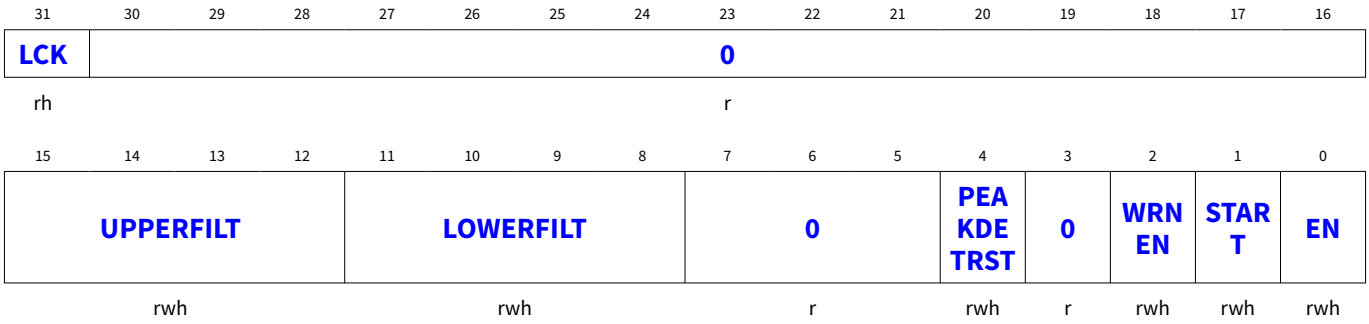
38 Voltage and Temperature Monitors (VTMON)



Field	Bits	Type	Description
EN	0	rwh	**DTS enable** This field is used to enable the DTS analog circuitry. 0_B **DISABLED**: DTS is disabled 1_B **ENABLED**: DTS is enabled
START	1	rwh	**ADC conversion control** This field is used to start DTS conversions. 0_B **STOP**: DTS conversion is stopped or stopping 1_B **START**: DTS conversion is started
WRNEN	2	rwh	**Warning enable** This field is used as a global enable for all warnings/alarms. 0_B **DISABLED**: All warnings are disabled 1_B **ENABLED**: All warnings are enabled
PEAKDETRST	4	rwh	**DTS peak temperature detector reset** This field, when written with '1', resets the peak temperature detector. The bit is reset on LCK bit release after update in local DTS module instance. 0_B **NORESET**: Peak temperature detector is not reset 1_B **RESET**: Peak temperature detector is reset
LOWERFILT	11:8	rwh	**Temperature-sensing mode warning filter** This field configures the filter length for generation of LLU warning/ alarm. Warning/alarm is triggered after RESULT goes under LOWER by (LOWERFILT + 1) consecutive conversions.
UPPERFILT	15:12	rwh	**Temperature-sensing mode warning filter** This field configures the filter length for generation of UOF warning/ alarm. Warning/alarm is triggered after RESULT exceeds UPPER by (UPPERFILT + 1) consecutive conversions.

(table continues...)

(continued)

Field	Bits	Type	Description
LCK	31	rh	**Lock bit** This bit indicates if the register can be updated with a new value or if the register is locked and a write action from the bus side has no effect. Once the shadow register in local module instance is updated, the lock is released and LCK bit is set to 0. 0_B **UNLOCKED**: UNLOCKED The register is unlocked and can be updated. 1_B **LOCKED**: LOCKED The register is locked and cannot be updated.
0	3, 7:5, 30:16	r	**Reserved** Read as 0; should be written with 0.

Table 1677 Access mode restrictions of DTSx_CON (x=0-4) sorted by descending priority

Mode name	Access mode		Description
.LCK == 0	rwh	EN, LOWERFILT, PEAKDETRST, START, UPPERFILT, WRNEN	Write allowed when LCK='0'
(default)	rh	EN, LOWERFILT, PEAKDETRST, START, UPPERFILT, WRNEN	Write gated by LCK bit

39 Stand-by Controller (SCR)

The standby controller is intended to perform basic operations while the rest of the system is in standby, effectively reducing standby-power consumption while still supporting requested standby features. The SCR is based on an 8-bit XC800-core with a limited list of peripherals.

***Note**: SCR is classified as a quality management product, therefore there are no safety mechanisms.*

39.1 Feature list

- XC800 core
  - Based on the standard 8051 8-bit core
  - Two clocks per CPU cycle architecture, for memory access without wait state
  - Two data pointers
  - Maximum 100 MHz frequency
- On-chip memory
  - 4-Kbyte boot ROM for start-up and debug firmware
  - 256-byte internal memory; plus 64-byte Monitor memory
  - 32-Kbyte XRAM for program code and data
  - XRAM accessible by the TriCore™ domain CPUs through the SPB bus and XRAM arbiter
- Real-time clock (RTCSCR) to support periodic wake-up in standby mode
  - Support for crystal oscillator inputs - 32 kHz crystal from XTAL3/4 or external from SCR_P1.2 (P33.10)
  - Access to 64-bit Real-time Clock (RTC) and Die-Temperature Sensor (DTS) located in PMS address space
- Four general purpose I/O ports with up to 32 pins
  - Control of the shared pins in SCR Ports P0, P1, P2, and P3 (overlaid with Ports P32, P33, P34 and P35 of the TriCore™ domain)
- Two 16-bit timers T0 and T1 for general purpose usage (tightly coupled with the XC800 core)
- Two 16-bit timers with capture and compare unit (T2CCU0 and T2CCU1) for digital signal generation
- Watchdog timer (WDTSCR) with programmable window feature for refresh operation and warning prior to overflow
- Full duplex serial interface (UART)
- Synchronous serial channel (SSC)
- Inter-integrated circuit interface (I2CSCR)
- Wake-up CAN module (WCAN) to support Partial Networking (CAN ID filtering)
- ADC compare functionality (ADCOMP) with 16 channels and 11-bit resolution
- Local Interconnect Network (LIN) application support through extended UART features
- Interrupt supported from SCR to the main SoC interrupt system and vice-verse
- On-chip debug support through a single pin DAP interface (SPD)
- Power saving features
  - Idle mode of the SCR core
  - Clock gating control for each peripheral
  - Switch between STANDBY0 and STANDBY1 system modes without wake-up of the TriCore™ domain

***Note**: TriCore™ domain P35 (SCR Ports P2.5 - P2.7 and P3.5 - P3.7) are only available in the packages with extension STD*

39.2 Functional overview

The SCR is an 8-bit microcontroller that can continue to run while the TriCore™ domain is in the STANDBY state. It is based on the 8051 8-bit core which is a widely used industry standard processor. There is an embedded 32 kByte XRAM for program code and data.

Key features include two instances of a 16-bit general purpose timer with a capture/compare unit (T2CCU) for digital signal generation such as pulse generation, pulse width modulation, and pulse width measuring. A 41-bit Real Time Clock (RTCSCR) is included to support periodic wake-up in standby mode, and an On-Chip Debug Support (OCDS) unit for software development and debugging of XC800 based systems. Local Interconnect Network (LIN) applications are supported through extended UART features. SPI functionality is provided through the SSC module. Additionally an Inter-integrated circuit (I2CSCR) module is available. Wake-up CAN capabilities are provided with the WCAN module. An 11-bit SAR ADC is available for analog measurements in standby mode. For low-power applications, various power saving techniques are available. Control of the numerous on-chip peripheral functions is achieved by extending the Special Function Register (SFR) address range with a paging mechanism.

The following figure illustrates the available sub-modules within the SCR of the TC4xx device.

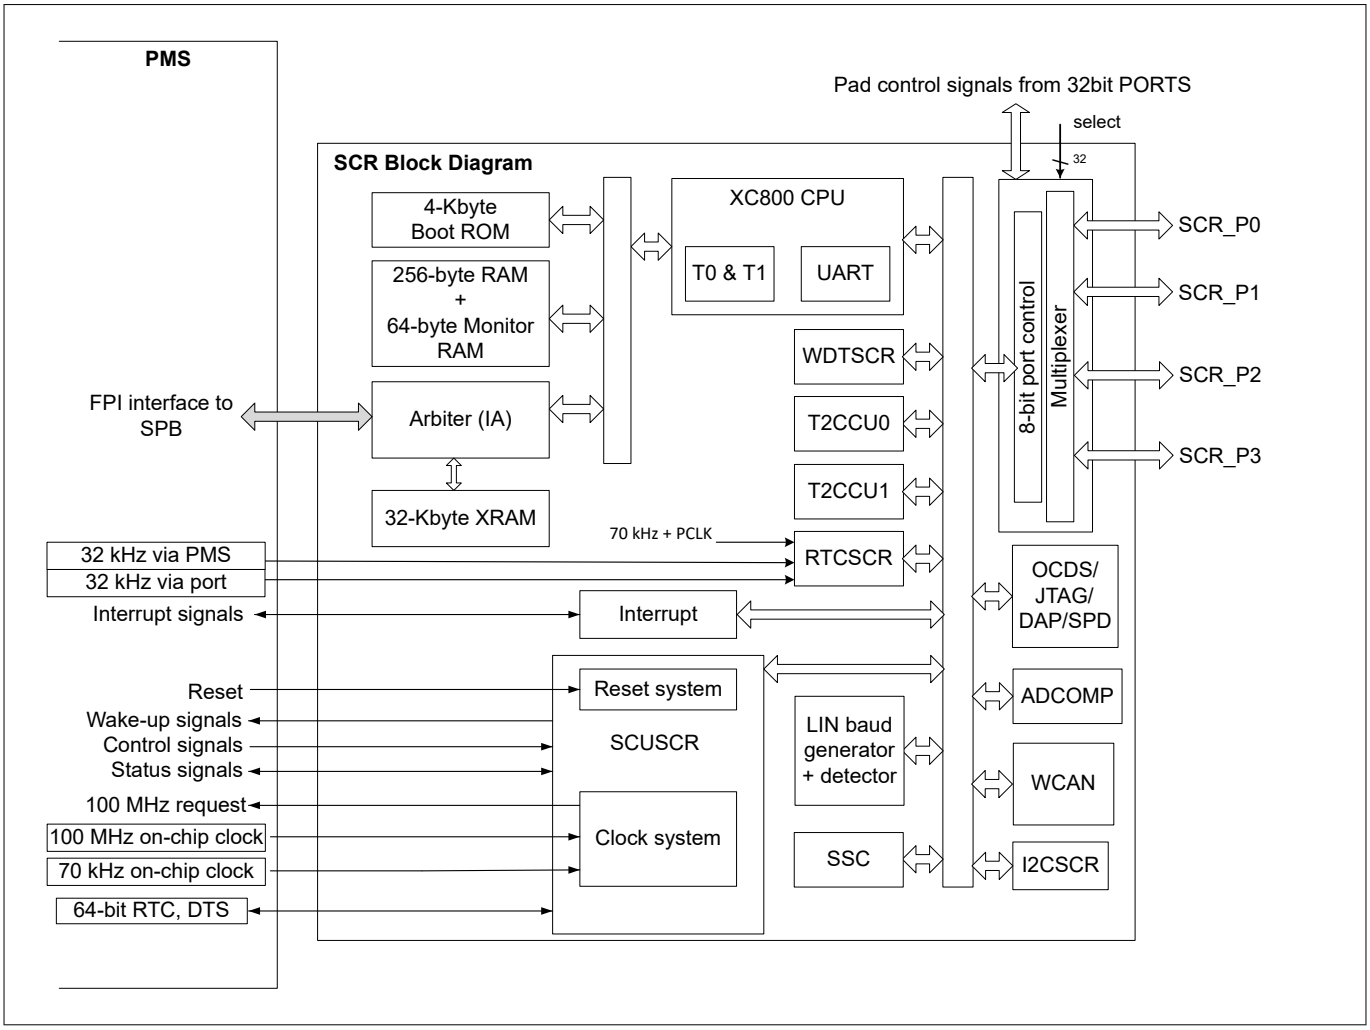

Figure 839 SCR block diagram

39.3 Functional description

The standby controller is a full sub-system consisting of a core, memory, internal bus, and dedicated peripherals.

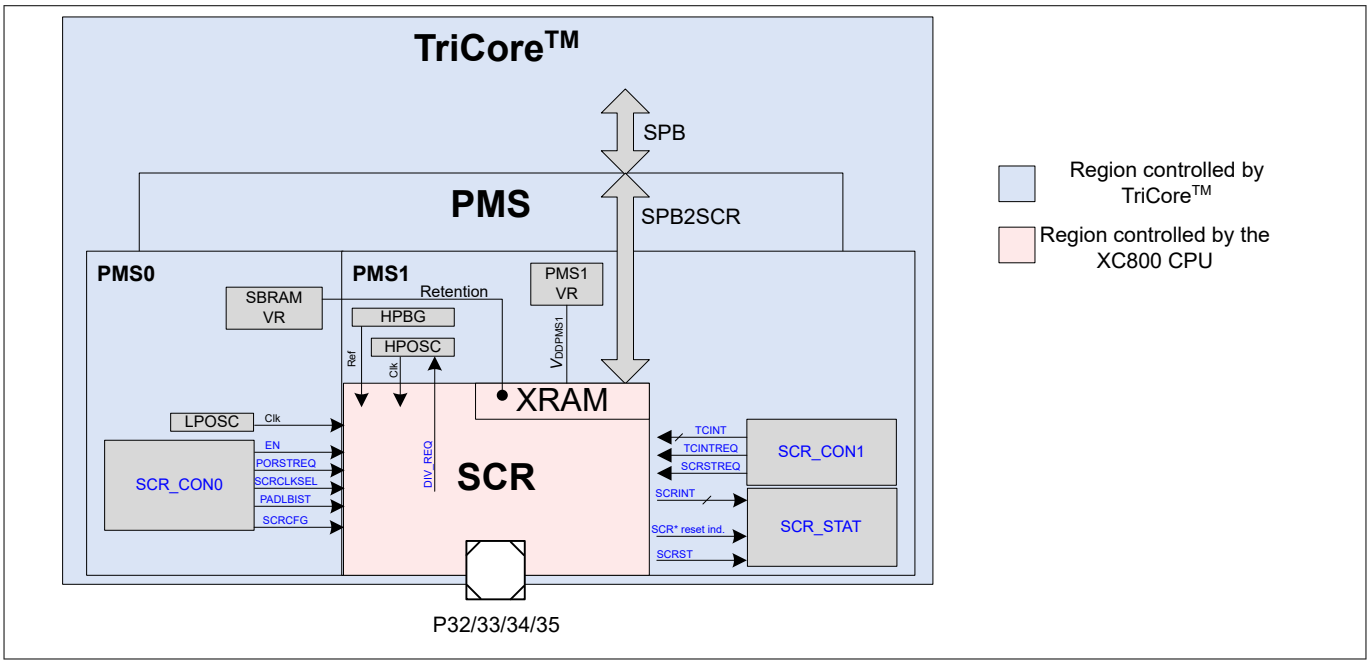

Figure 840 SCR position in the system

39.3.1 XC800 CPU

The SCR registers occupy direct Internal Data Memory space locations in the range 80_H to FF_H.

In the following sections main core and core-peripheral registers are briefly introduced.

***Note**: The SCR includes the XC800 core. Due to the special structure, this consists out of the XC800 CPU, Timer 0 and 1 as well as the UART.*

Related information

Registers on page 802

39.3.1.1 SFRs of the CPU

Stack pointer (SP, $D4_H$)

The SP register contains the stack pointer. The stack pointer is used to store the program counter into internal data memory during LCALL and ACALL instructions and to restore the program counter from memory during RET and RETI instructions. Data may also be saved on or retrieved from the stack using PUSH and POP instructions. Instructions that use the stack automatically pre-increment or post-decrement the stack pointer so that the stack pointer always points to the last byte written to the stack, that is the top of the stack. On reset, the stack pointer is reset to 07_H. This causes the stack to begin at a location = 08_H above register bank zero. The SP can be read or written under software control. The programmer must ensure that the location and size of the stack in internal data memory do not overlap with other application data.

Data pointer (DPTR = DPL-DPH, $D5\text{-}6_H$)

The data pointer (DPTR) consists of a high byte (DPH) and a low byte (DPL). Its intended function is to hold a 16-bit address. It may be manipulated as a 16-bit register or as two independent 8-bit registers. 16-bit addressing is used for:

- External Data Memory accesses (MOVX A,@DPTR and MOVX @DPTR,A)
- Program byte moves (MOVC A,@A+DPTR)
- Indirect program jumps (JMP @A+DPTR)

Two true 16-bit operations are allowed on the data pointer: load immediate (MOVDPTR,#data) and increment (INC DPTR).

Accumulator (ACC, $E0_H$)

This register provides one of the operands for most ALU operations. ACC is the symbol for the accumulator register. The mnemonics for accumulator-specific instructions refer to the accumulator simply as “A”.

B register (B, DA_H)

The B register is used during multiply and divide operations to provide the second operand. For other instructions, it can be treated as another scratch pad register.

Program status word (PSW, $D0_H$)

The PSW register contains program status information – parity, overflow, carry and general purpose flags together with register bank select control bits.

Extended operation (EO, $D7_H$)

The instruction set includes an additional instruction MOVC @(DPTR++),A which writes to program memory implemented as RAM. The instruction copies the contents of the accumulator to the code memory at the location pointed to by the current data pointer, then increments the data pointer.

The instruction uses the opcode $A5_H$, which is the same as the software break instruction TRAP (see also XC800 CPU instruction timing table for related information). Bit TRAP_EN in the Extended Operation (EO) register is used to select the instruction executed by the opcode $A5_H$. When bit TRAP_EN is 0 (default after reset), the $A5_H$ opcode executes the MOVC instruction. When bit TRAP_EN is 1, the $A5_H$ opcode executes the software break instruction TRAP, which switches the CPU to debug mode for breakpoint processing.

Register EO is also used to select the current data pointer through the DPSEL bit-field.

Power control (PCON, $D9_H$)

The PCON register provides:

- Control for entering idle mode
- Baudrate control for UART in mode 2 (for details see UART section)
- Two general purpose flags

In idle mode, the clock to the CPU (CCLK) is halted while all peripherals running on PCLK are still running. A wake-up is initiated by an interrupt.

Interrupt controller, serial port and core timers

Additional registers located inside the XC800 core:

- Interrupt controller (IR) registers
  - Interrupt enable register 0: IEN0
  - Interrupt enable register 1: IEN1
  - Interrupt priority register: IP
  - Interrupt priority 1 register: IP1
  - Interrupt priority high register: IPH
  - Interrupt priority 1 high register: IPH1
- Serial port/Universal Asynchronous Receiver/Transmitter (UART) registers
  - Serial channel control register: UART_SCON
  - Serial data buffer register: UART_SBUF
- Timer 0 and Timer 1 registers
  - Timer 0/1 control register: T01_TCON
  - Timer 0/1 mode register: T01_TMOD
  - Timer 0 low byte register: T01_TL0
  - Timer 1 low byte register: T01_TL1
  - Timer 0 high byte register: T01_TH0
  - Timer 1 high byte register: T01_TH1

These registers and the logic function around them are clocked with the peripheral clock (PCLK).

More details on these registers and the function associated to them is provided in the respective IR, UART, and T01 sections.

Related information

Instruction timing on page 6483

39.3.1.2 Instruction timing

A CPU cycle comprises two input clock periods, referred to as Phase 1 (P1) and Phase 2 (P2), that correspond to two different CPU states.

A CPU state within an instruction is referenced by the CPU cycle and state number. For example C2P1 means the first clock period within CPU cycle 2.

Memory access takes place during one or both phases of the CPU cycle.

SFR writes occur only at the end of P2.

Instructions are 1, 2, or 3 bytes long and can take 1, 2, or 4 CPU cycles to execute. Registers are generally updated and the next opcode pre-fetched at the end of P2 of the last CPU cycle for the current instruction.

The XC800 CPU supports access to slow memory by using wait cycle(s). Each wait cycle lasts one CPU cycle which is two clock periods. For example, in case of a memory requiring one or two wait state(s), the access time is increased by one CPU cycle for every byte of opcode or operand fetched.

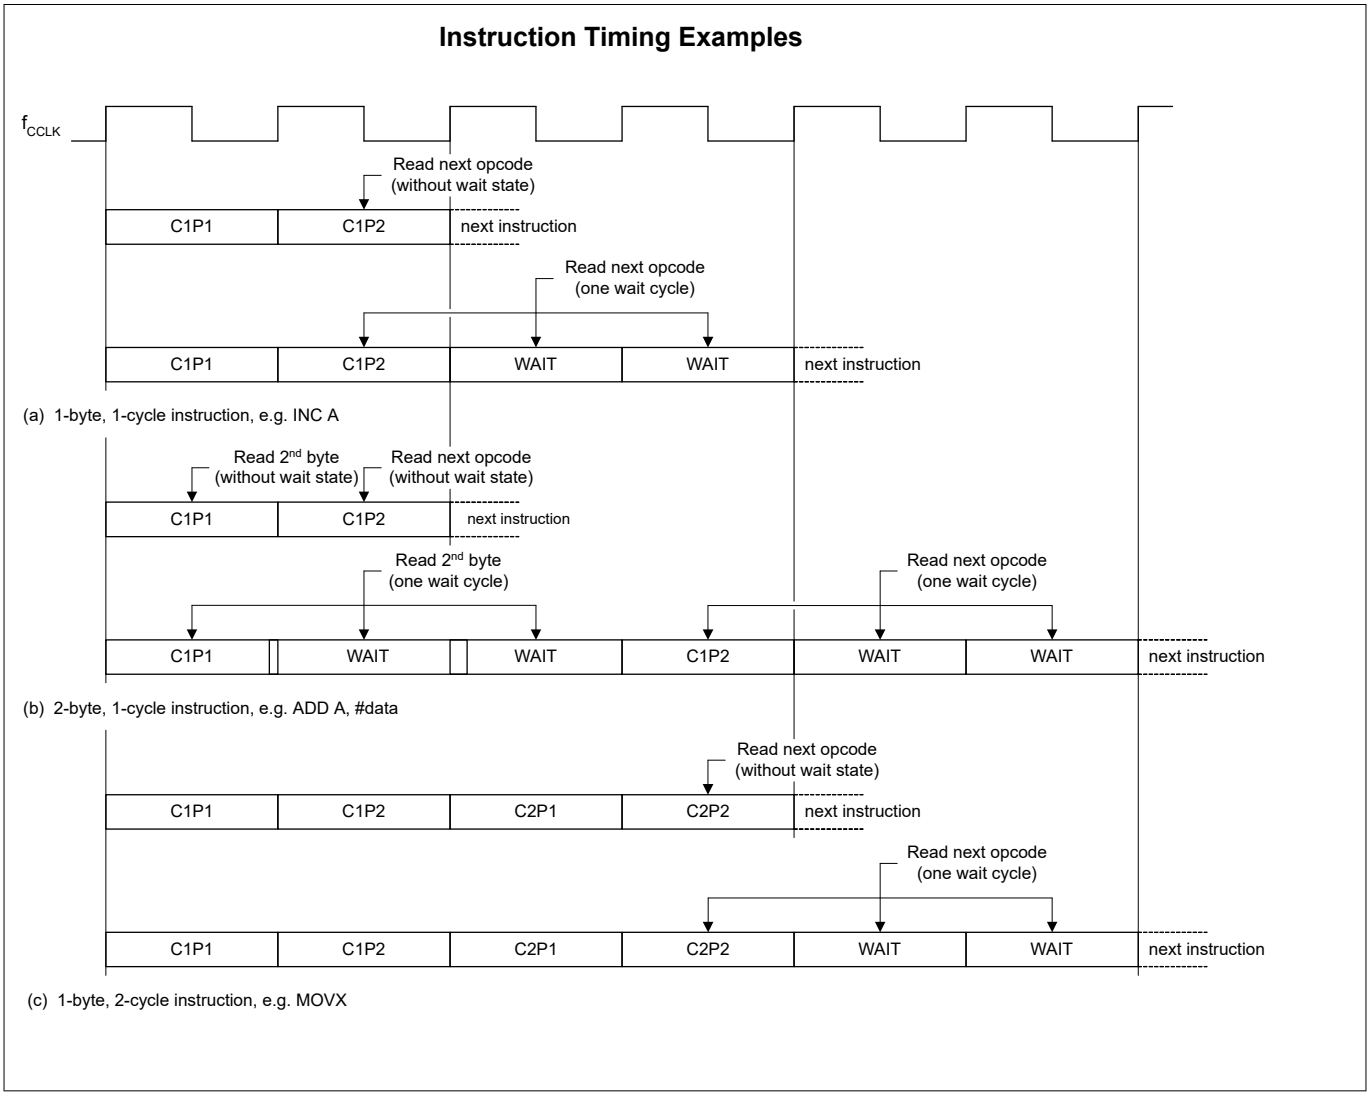

Figure 841 CPU instruction timing

The figure above shows the fetch/execute timing related to the internal states and phases. Execution of an instruction occurs at C1P1. For a 2-byte instruction, the second reading starts at C1P1.

Part (a) of the figure above shows two timing diagrams for a 1-byte, 1-cycle (1 x CPU cycle) instruction. The first diagram shows the instruction being executed within one CPU cycle since the opcode (C1P2) is fetched from a memory without wait state. The second diagram shows the corresponding states of the same instruction being executed over two CPU cycles (instruction time extended), with one wait cycle inserted for opcode fetching from the flash memory.

Part (b) of the figure above shows two timing diagrams for a 2-byte, 1-cycle (1 x CPU cycle) instruction. The first diagram shows the instruction being executed within one CPU cycle since the second byte (C1P1) and the opcode (C1P2) are fetched from a memory without wait state. The second diagram shows the corresponding states of the same instruction being executed over three CPU cycles (instruction time extended), with one wait cycle inserted for each access to the flash memory. In this case, two wait cycles are inserted in total.

Part (c) of the figure above shows two timing diagrams of a 1-byte, 2-cycle (2 x CPU cycle) instruction. The first diagram shows the instruction being executed over two CPU cycles with the opcode (C2P2) fetched from a memory without wait state. The second diagram shows the corresponding states of the same instruction being executed over three CPU cycles (instruction time extended), with one wait cycle inserted for opcode fetching from the slow memory requiring one/two wait state(s).

***Note**: For instructions that are executed over two or more CPU cycles, execution cycle may or may not be extended in case of access to slow memory with one or two wait states. The execution cycle is, nonetheless, guaranteed consistent for each instruction when accessed from slow memory with defined wait state(s).*

The time taken for each instruction includes:

- Decoding/executing the fetched opcode
- Fetching the operand/s (for instructions > 1 byte)
- Fetching the first byte (opcode) of the next instruction (due to CPU pipeline)

***Note**: The XC800 CPU fetches the opcode of the next instruction while executing the current instruction.*

Instructions are 1, 2, or 3 bytes long as indicted in the 'Bytes' column. Each instruction takes 1, 2 or 4 CPU cycles to execute (with no wait cycle). The table below gives two values for the number of CPU cycles required by each instruction. The first value applies to fetching operand/s and opcode from fast memory (for example Boot ROM and XRAM) without wait state. The second value applies to fetching operand/s and opcode (and in some cases accessing data) from slow memory (for example Flash) with wait cycles inserted due to memory requiring one or two wait state(s). One CPU cycle comprises two CCLK clock cycles.

MISCELLANEOUS				
NOP	00	1	1	2
ADDITIONAL INSTRUCTIONS				
MOVC @(DPTR++),A	A5	1	2	2 or 3[2]
TRAP	A5	1	1	–

1) In the case of a fetch from slow memory requiring only 1 wait state, no wait cycle may be required per the instruction fetched (normally for opcodes that do not require fetch in the next cycle).
2) Depending on whether the operation is accessing memory with zero or one/two wait state.
3) For branch instructions, the instruction time may vary depending on jump destination.

39.3.1.3 XRAM addressing modes

External Data Memory (XRAM) is accessed using MOVX instructions only. These use either 8-bit or 16-bit indirect address. The DPTR register is used for 16-bit addressing and either register R0 or R1 is used to form the 8-bit address.

39.3.1.3.1 Access to XRAM using the DPTR (16-bit addressing mode)

The external memory can be accessed by two read/write instructions, which use the 16-bit DPTR for indirect addressing. These instructions are:

- MOVX A, @DPTR (Read)
- MOVX @DPTR, A (Write)

39.3.1.3.2 Access to XRAM using the register R0/R1 (8-bit addressing mode)

The SCR provides also instructions for accesses to XRAM using the 8-bit address (indirect addressing with registers R0 or R1). These instructions are:

- MOVX A, @Ri (Read)
- MOVX @Ri, A (Write)

To access the XRAM properly, a higher order address must be put in SFR XADDRH . This write instruction must precede the MOVX instructions.

39.3.2 Memory organization

The XC800 CPU operates in the following four address spaces:

- 256 byte of internal data memory without ECC protection
- 32 Kbyte of XRAM memory (32-bit memory, accessible to TriCore™ through the System Peripheral Bus in PMS address space):
  - ECC protected
  - XRAM can be read and written as program memory and external data memory
- 128-byte Special Function Register area
- The available memory ECC protection is capable to correct single bit errors and to detect double bit errors (SEC/DED)
- 4 Kbyte of Boot ROM program memory

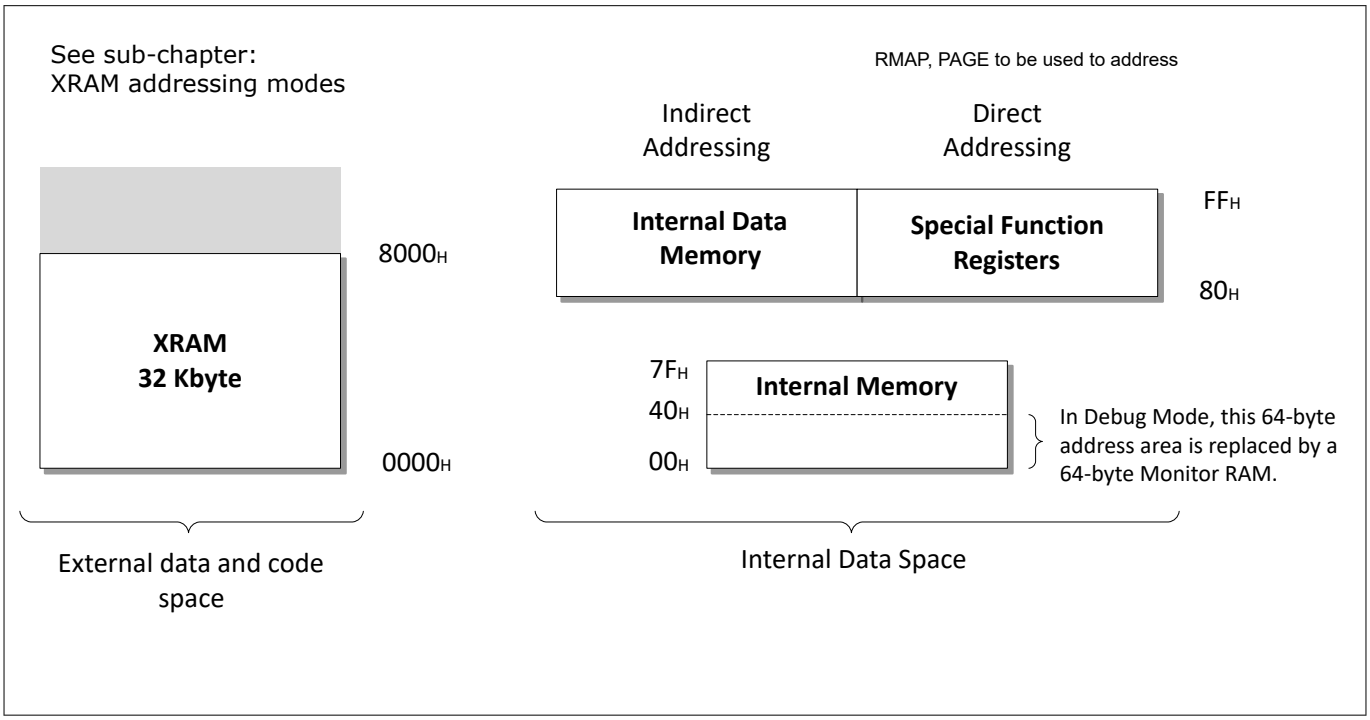

Figure 842 SCR memory map

39.3.2.1 Program memory

However, only access to defined program and data memory regions like XRAM (used for code and data) or Boot ROM is supported. For the memory organization (MemOrg), defined code and data space (XRAM) is occupied by on-chip memories.

Related information

Memory organization on page 6490

39.3.2.2 Data memory

The data space consists of an internal and external data space. Access to internal and external data space are distinguished by different sets of instruction opcodes. In the SCR, the on-chip XRAM is located in external data space and accessed by MOVX instructions.

SCR does not support access to external (off-chip) memory. Internal data space is occupied by Internal Memory and Special Function Registers (SFRs), distinguished by direct or indirect addressing.

39.3.2.2.1 Internal data memory

The internal data memory is divided into two physically separate and distinct blocks: the 256-byte Memory and the 128-byte Special Function Register (SFR) area. While the upper 128 bytes of Memory and the SFR area share the same address locations, they are accessed through different addressing modes.

The lower 128 bytes of Memory can be accessed through either direct or register indirect addressing, while the upper 128 bytes of Memory can be accessed through register indirect addressing only. The SFRs are accessible through direct addressing.

The 16 bytes of Memory that occupy addresses from 20_H to $2F_H$ are bit-addressable. Memory occupying direct addresses from 30_H to $7F_H$ can be used as scratch pad registers or used for the stack.

39.3.2.2.2 External data memory

The 32-Kbyte XRAM is mapped to both the external data memory area and the program memory area. The SCR XRAM can be accessed by both the SCR's XC800 core and the main TriCore™ CPU. The arbiter module determines which CPU has control of the XRAM at any one time. The TriCore™ CPU accesses the XRAM through the peripheral bus. An FPI slave interface is provided to the SCR to interface to the SPB bus. The arbiter module is responsible for arbitrating between the SCR core and the TriCore™ accesses to the XRAM through the SPB.

For memory access protection see PMS Standby controller extension RAM (XRAM) in related information.

SCR core accesses the XRAM using either the 'MOVX' or 'MOVC' instructions. The 'MOVX' instructions for XRAM access use either 8-bit or 16-bit indirect addresses, as shown in the following table.

Table 1684 Instructions for external data memory access

Type of access	16-bit addressing mode	8-bit addressing mode
Read	MOVX A, @DPTR	MOVX A, @Ri
Write	MOVX @DPTR, A	MOVX @Ri, A

While the DPTR register is used for 16-bit addressing, either register R0 or R1 is used to form the 8-bit address. The upper byte of the XRAM address during execution of the 8-bit accesses is defined by the value stored in register XADDRH. Hence, the write instruction for setting the higher order XRAM address in register XADDRH must precede the 'MOVX' instruction.

A write access to a undefined external data memory address has no effect while a read access returns undefined data.

Related information

Standby controller extension RAM (XRAM) on page 6039

39.3.2.3 Special function registers (SFRs)

The Special Function Registers (SFRs) occupy direct internal data memory space in the range 80_H to FF_H. All registers, except the program counter, reside in the SFR area. The SFRs include pointers and registers that provide an interface between the CPU and the on-chip peripherals. As the 128-SFR range is less than the total number of registers required, address extension mechanisms are required to increase the number of addressable SFRs. The address extension mechanisms include:

- Mapping
- Paging

39.3.2.3.1 Address extension by mapping

Address extension is performed at the system level by mapping. The SFR area is extended into two portions: the standard (non-mapped) SFR area and the mapped SFR area. Each portion supports the same address range 80_H

to FF_H, bringing the number of addressable SFRs to 256. The extended address range is not directly controlled by the CPU instruction itself, but is derived in the system control register from ROM bit SYSCON0.RMAP at address DF_H. To access SFRs in the mapped area, bit SYSCON0.RMAP must be set. However, the SFRs in the standard area can be accessed by clearing bit SYSCON0.RMAP. Figure below shows how the SFR area can be selected.

As long as bit SYSCON0.RMAP is set, the mapped SFR area can be accessed. This bit is not cleared automatically by hardware. Therefore, before standard/mapped registers are accessed, bit SYSCON0.RMAP must be cleared/set, respectively, by software.

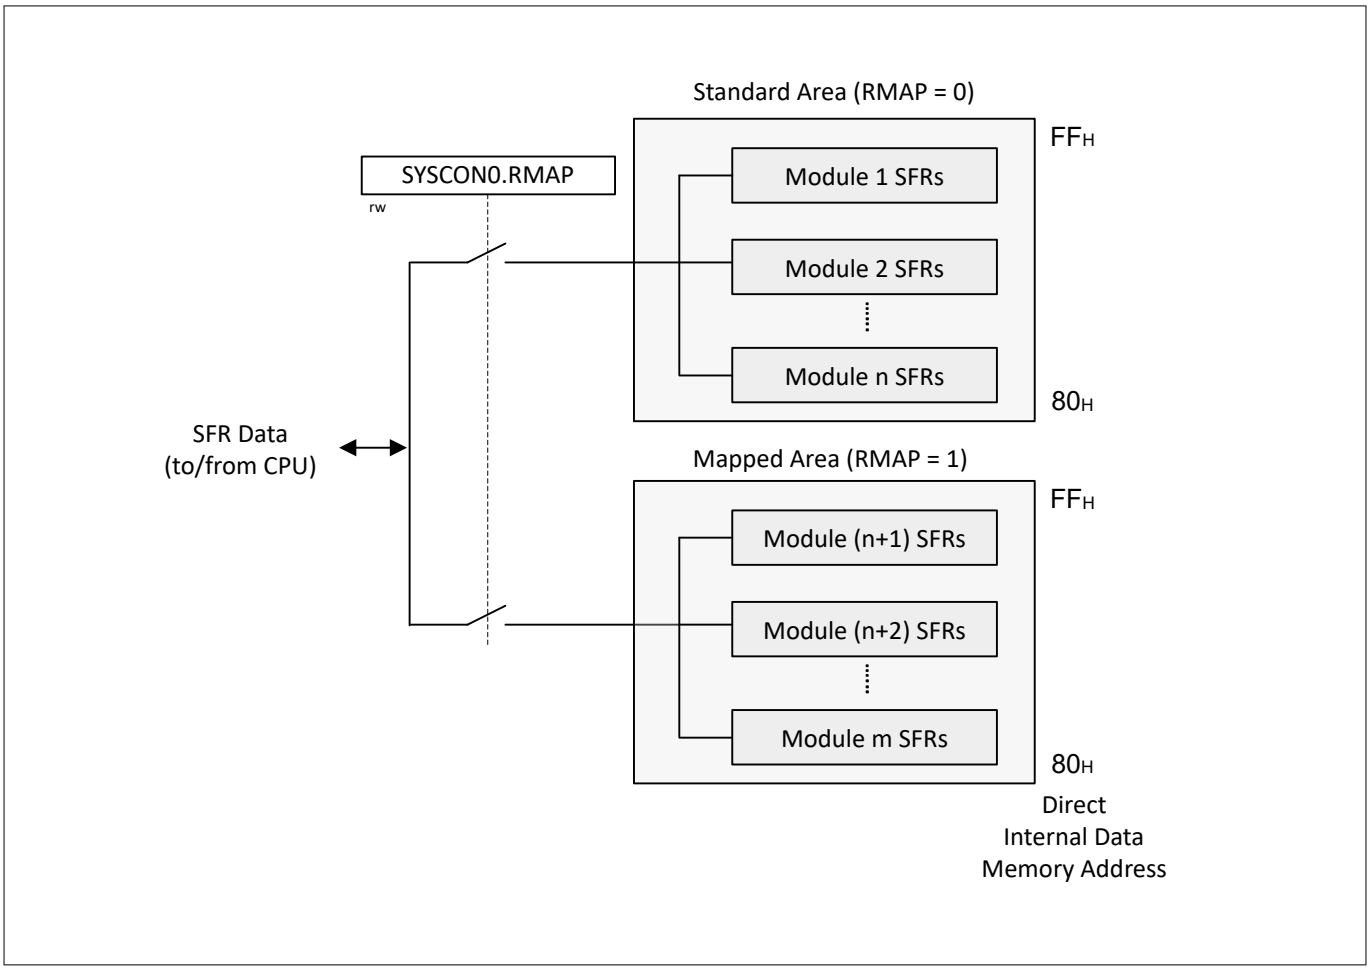

Figure 843 Address extension by mapping

39.3.2.3.2 Address extension by paging

Address extension is further performed at the module level by paging. Certain peripherals have a built-in local address extension mechanism for increasing the number of addressable SFRs. The extended address range is not directly controlled by the CPU instruction itself, but is derived from bit-field PAGE in the module page register MOD_PAGE. Hence, the bit-field PAGE must be programmed before accessing the SFRs of the target module. Each module may contain a different number of pages and a different number of SFRs per page, depending on the specific requirement. Besides setting the correct RMAP bit value to select the SFR area, the user must also ensure that a valid PAGE is selected to target the desired SFRs.

Figure below shows how a page inside the extended address range can be selected.

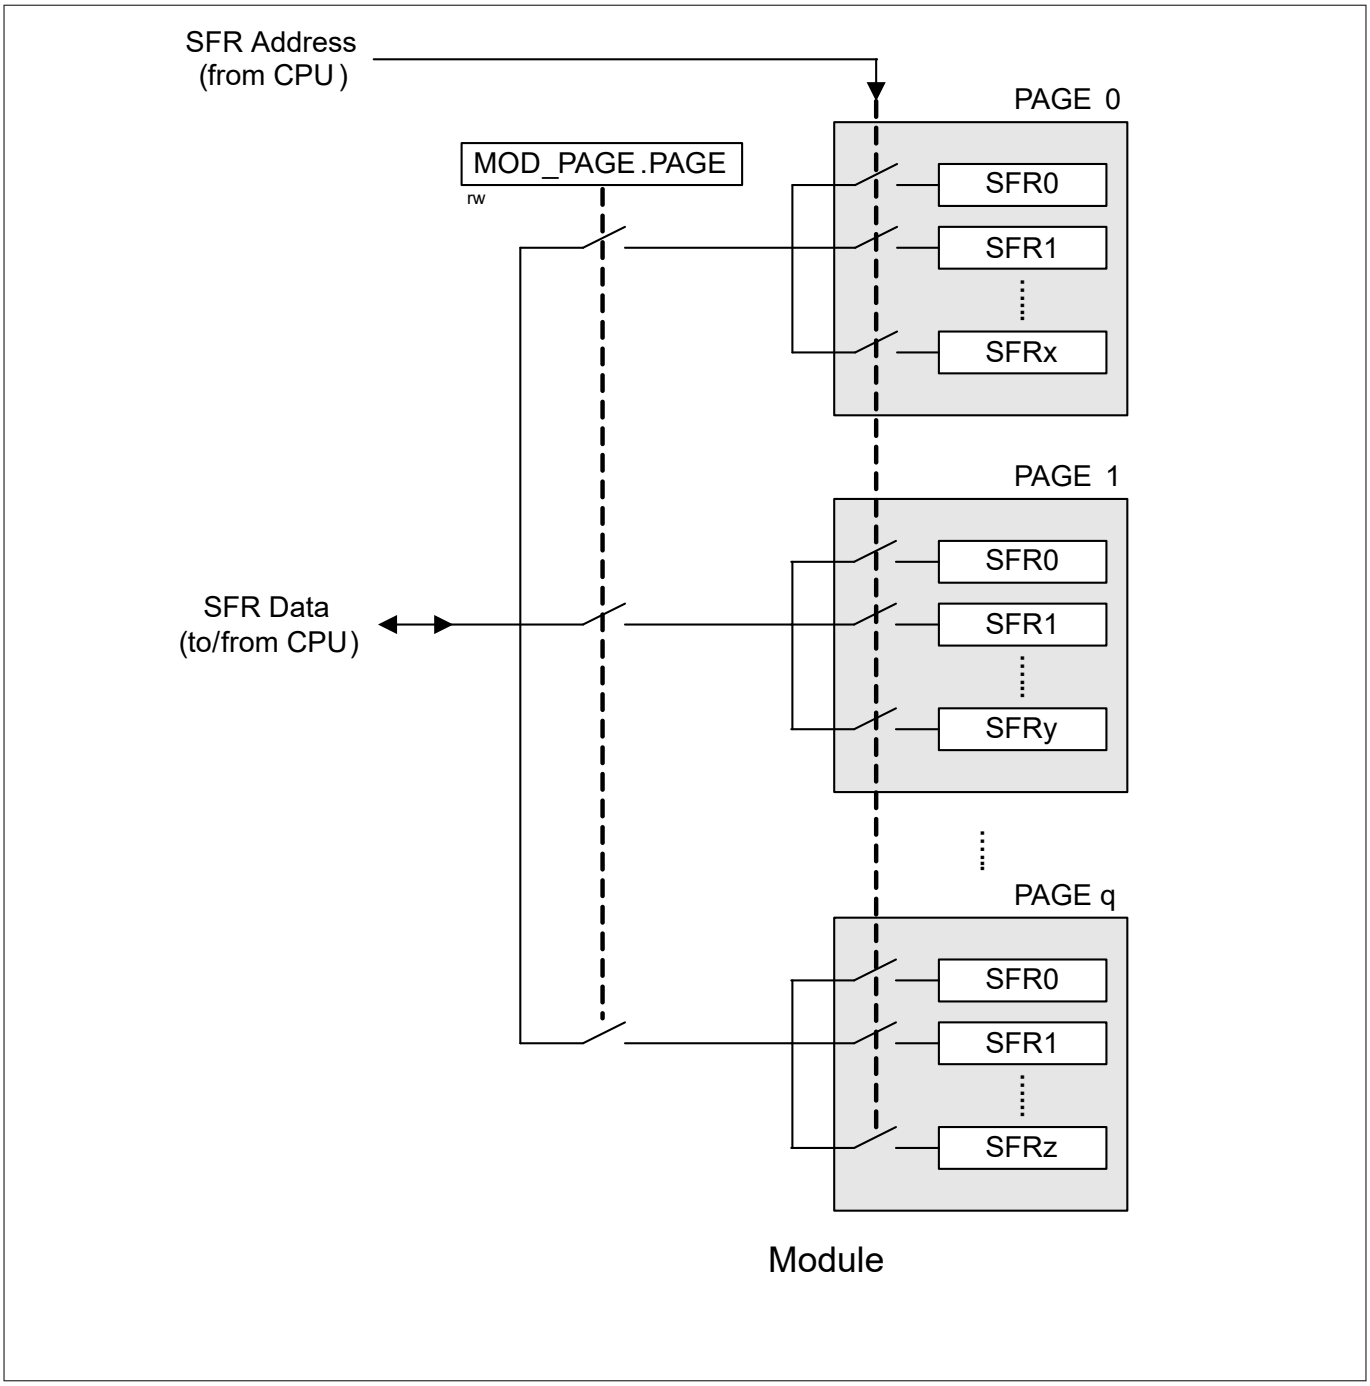

Figure 844 Address extension by paging

In order to access a register located in a page other than the current one, the current page must be exited. This is done by reprogramming the bit-field PAGE in the page register. Only then can the desired access be performed.

If an interrupt routine is initiated between the page register access and the module register access, and the interrupt needs to access a register located in another page, the current page setting can be saved, the new one programmed, and the old page setting restored. This is possible with the storage fields MOD_STx (x=0-3) for the save and restore action of the current page setting. By indicating which storage bit-field should be used in parallel with the new page value, a single write operation can either:

- Save the contents of PAGE in MOD_STx before overwriting with the new value

(this is done at the beginning of the interrupt routine to save the current page setting and program the new page number)

- Overwrite the contents of PAGE with the contents of MOD_STx, ignoring the value written to the bit positions of PAGE

  (this is done at the end of the interrupt routine to restore the previous page setting before the interrupt occurred)

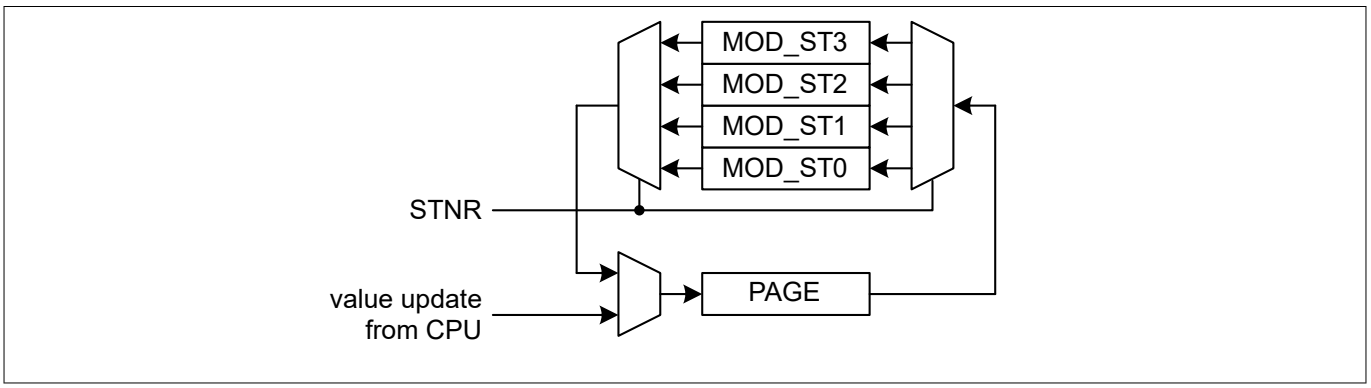

Figure 845 Storage elements for paging

With this mechanism, a certain number of interrupt routines (or other routines) can perform page changes without reading and storing the previously used page information. The use of only write operations makes the system simpler and faster. Consequently, this mechanism significantly improves the performance of short interrupt routines.

Page Register for module MOD

MOD_PAGE Address:

Page Register for module MOD : 00_H

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res								OP		STNR		0	PAGE		
r								w		w		r	rw		

Field	Bits	Type	Description
PAGE	2:0	rw	**Page Bits** When written, the value indicates the new page. When read, the value indicates the currently active page.

(table continues...)

(continued)

Field	Bits	Type	Description
STNR	5:4	w	**Storage Number** This number indicates which storage bit field is the target of the operation defined by bit-field OP. If OP=10_B, the contents of PAGE are saved in MOD_STx before being overwritten with the new value. If OP=11_B, the contents of PAGE are overwritten by the contents of MOD_STx. The value written to the bit positions of PAGE is ignored. 00_B MOD_ST0 is selected. 01_B MOD_ST1 is selected. 10_B MOD_ST2 is selected. 11_B MOD_ST3 is selected.
OP	7:6	w	**Operation** $0X_B$ Manual page mode. The value of STNR is ignored and PAGE is directly written. 10_B New page programming with automatic page saving. The value written to the bit positions of PAGE is stored. In parallel, the previous contents of PAGE are saved in the storage bit-field STx indicated by STNR. 11_B Automatic restore page action. The value written to the bit positions PAGE is ignored and instead, PAGE is overwritten by the contents of the storage bit-field STx indicated by STNR.
0	3	r	**Reserved** Returns 0 if read; shall be written with 0.

39.3.2.3.3 Bit-addressing

SFRs that have addresses in the form of $1XXXX000_B$ (for example,80_H, 88_H, 90_H,..., $F0_H$, $F8_H$) are bit addressable.

39.3.2.3.4 Bit protection scheme

The bit protection scheme prevents direct software writing of selected bits (protected bits) using the PASSWD register. When the bit PASSWD.MODE is 11_B, writing 10011_B to the bit-PASSWD.PASS opens access to writing of all protected bits, and writing 10101_B to the bit-PASSWD.PASS closes access to writing of all protected bits. In both cases, the value of the bit field MODE is not changed even if PASSWD register is written with 98_H or $A8_H$. It can only be changed when bit-field PASS is written with 11000_B, for example, writing $C0_H$ to PASSWD register disables the bit protection scheme.

Note that access is opened for maximum 34 (TC4Dx) / 32 (all other devices) CCLKs if the “close access” password is not written. If “open access” password is written again before the end of 34 (TC4Dx) / 32 (all other devices) CCLK cycles, there will be a recount of 34 (TC4Dx) / 32 (all other devices) CCLK cycles.

Table 1685 List of protected bits

Register	Bit-field(s)
SCUSCR_CLK	DIV_REQ
SCUSCR_RSTCON	SWRSTREQ

WDTSCR_CON	WDTEN
RTCSCR_CNTn (n=0-3)	CNT_VAL bit-fields in all CNT0-3 registers

39.3.2.4 Memory control unit

The Memory Control Unit (MCU Module) is the interface between the CPU and the memories, providing three functions to the MemOrg:

- Active memory map selection
- Allows one physical memory (that is XRAM) to be accessed as both program and data memory at the same time
- Memory protection

39.3.2.4.1 Memory protection unit

The SCR consists of the following memory blocks:

- Boot ROM
- XRAM

The target of the memory protection scheme is to prevent unauthorized read out of critical data from the Boot ROM.

The memory protection scheme is hardware-based and is used to protect the Boot ROM. MOVC read instructions executed out of the “unsafe” program memory address range (for example XRAM) that target the Boot ROM are blocked when protection is enabled.

39.3.2.5 Arbiter

The arbiter serves the following purposes:

- Providing access to the XRAM through the TriCore™ domain System Peripheral Bus (SPB), using an FPI slave interface (over PMS address space)
- Arbitrates the XRAM access between XC800 CPU and TriCore™ CPU (access through the peripheral bus). SCR is given higher priority to access the XRAM

39.3.2.5.1 Arbiter logic

The Arbiter is clocked by either undivided 100 MHz clock (if it is available), or the 70 kHz clock.

The arbiter always grants the SCR higher priority when accessing the XRAM. During a read from the XC800 core, the output from the XRAM is latched until the value is used by the XC800 core. During a write, the data is simply written to the XRAM at the next Arbiter clock edge.

39.3.3 SCR firmware (SCR FW)

The SCR Boot ROM firmware provides the following features:

- Start-up procedure for stable operation of the SCR
- Basic debugging capability through OCDS mode

Start-up procedure initializes the SCR to a known state to ensure stable operation. The start-up procedure consists of all the settings and initialization to be done after SCR reset, before branching to various boot modes. On-Chip Debug Support provides basic debugging capability to the user.

Related information

Debug information on page 6847
Stand-by controller firmware on page 8797

39.3.4 System Control Unit (SCUSCR)

The System Control Unit (SCUSCR) supports all central control tasks in the SCR. The SCUSCR includes the following functions:

- SCR clock system and control
- SCR reset control
- SCR power management
- System wake-up and standby control
- Limited access to RTC, DTS and HPOSC blocks located inside PMS, for checking status and calibration

39.3.4.1 Boot and start-up

SCR boot mode is configured over PMS_SCR_CON0.SCRCFG bit-field. After first power-up, default value of SCR boot mode is 00_H– User mode, but SCR is not enabled (default value of PMS_SCR_CON0.SCREN=0). SCRCFG boot mode is applied when SCR is first enabled (by setting PMS_SCR_CON0.SCREN to 1 for the first time) and it is also applied after every consecutive SCR main reset while SCR remains enabled. A main reset to the SCR can be triggered by a PMS_SCR_CON1.SCRSTREQ bit-field or by PORST if enabled through PMS_SCR_CON0.PORSTREQ. However, in order to request the SCR main reset, SCR needs to be enabled first through PMS_SCR_CON0.SCREN.

In case SCR was enabled and then disabled, an internal clock sequencing is started to reduce the frequency of the system clock. During this sequencing the SCR continues with the code execution. Upon next enable SCR continues from the instruction, it has been stopped. If SCR was disabled during an ongoing SCR reset, the exact state of SCR cannot be guaranteed and SCR must be reset upon next enable.

Table 1686 SCR Boot modes

SCRCFG value	Boot mode	Descriptions
00_H (default)	User mode	After start-up routine, User Code in XRAM at address 0000_H will be executed. If user code is not loaded to XRAM before enabling SCR, the magic-pattern check during start-up routine will fail, SCUSCR_SCRINTEXCHG code 81_H will be sent to the TriCore™ domain, and the SCR will enter an endless loop.
01_H	OCDS modes	Debug mode using the TriCore™ domain - SPD or DAP interface
02_H		Debug mode using SCR DAP0_0 pin and DAP1_0 pins
03_H		Debug mode using SCR DAP0_1 pin and DAP1_1 pins
04_H		Debug mode using SCR SPD_0 pin
05_H		Debug mode using SCR SPD_1 pin
06_H-07_H	Reserved	-

At the end of the start-up routine by SCR firmware (SCR_FW), an interrupt is triggered to the main controller by setting bit IRSCR_NMICON.SCRINTTC0 to 1, and storing a value in SCUSCR_SCRINTEXCHG register:

- 80_H - there were no errors during start-up
- 81_H - in User-mode, magic-pattern is not matching (possibly due to missing user code in XRAM)

***Note**: Changing of boot mode during SCR operation or when SCR is disabled will have no effect. Changed value will only be applied on the next SCR main reset.*

Illustration of a normal boot and operation of SCR is given in the figure below. It shows several example interactions between the TriCore™ domain application software, SCR firmware and SCR application software.

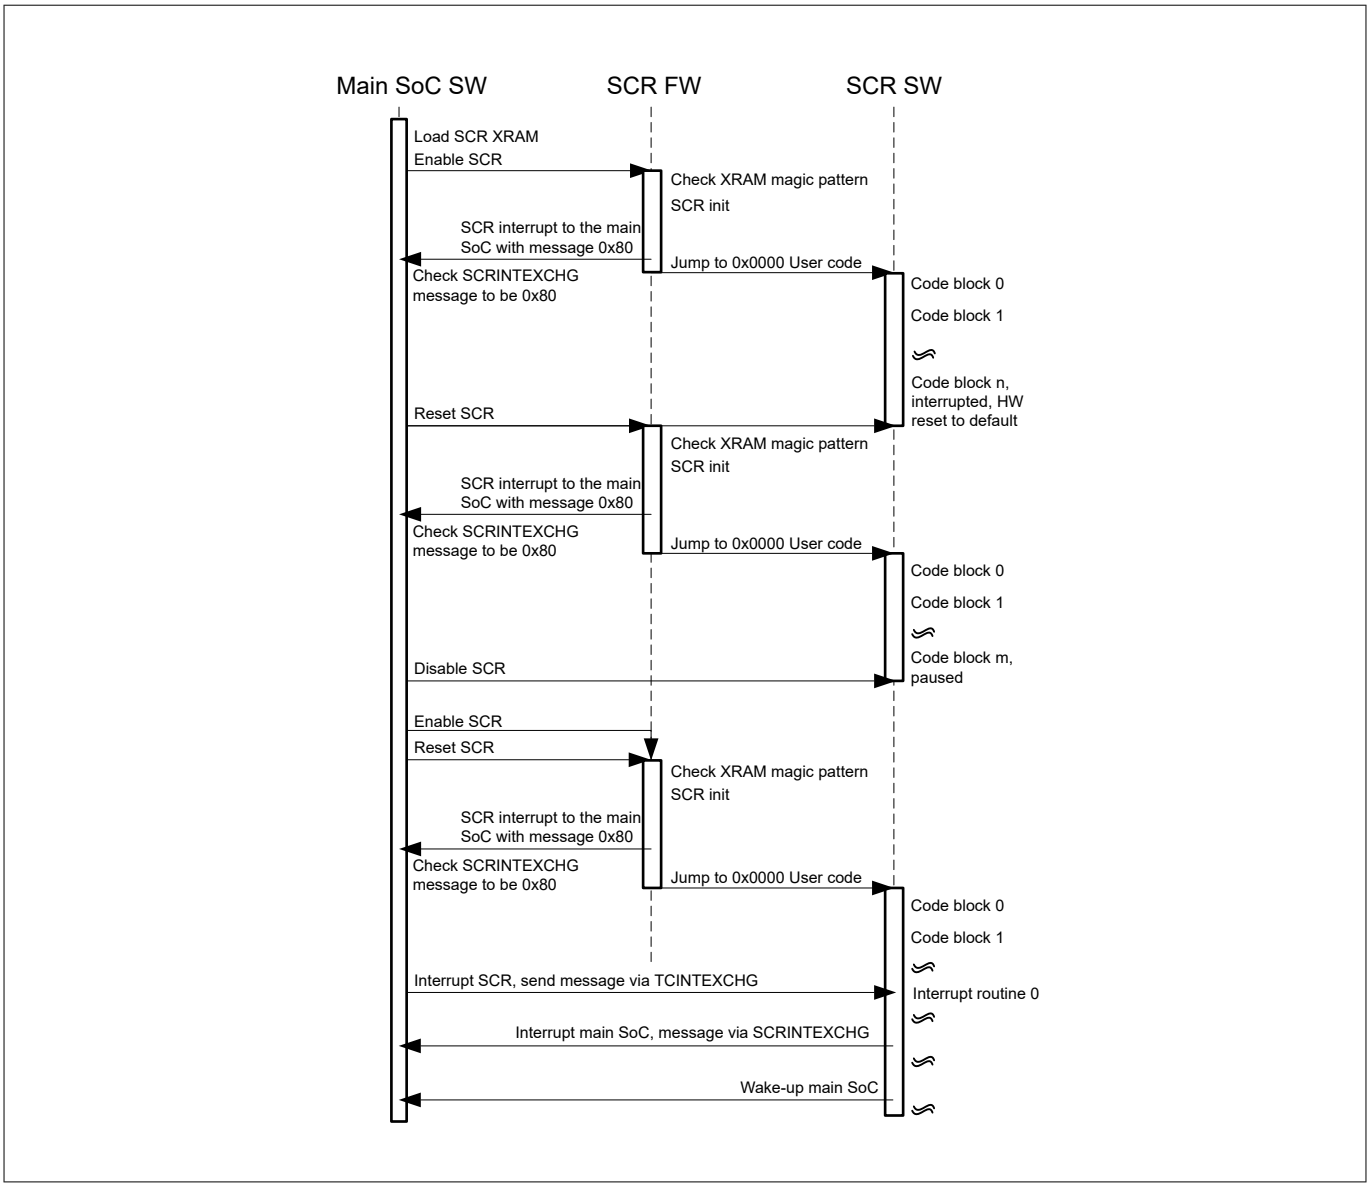

Figure 846 SCR boot and operation time diagram

39.3.4.1.1 Boot ROM operating mode

After a reset, the XC800 CPU will start to execute the Boot ROM code located at the memory address space 0000_H–$07FF_H$. The Boot ROM start-up procedure will first switch the address space for the Boot ROM to $D000_H$–$D7FF_H$. The remaining Boot ROM start-up procedure will be executed from $D60X_H$. The memory organization of the SCR shown in this document is after the Boot ROM address switch where the different operating modes are executed.

User mode

User Mode is the default boot mode after a Low-Voltage Detector (LVD) reset of SCR.

At XRAM addresses $7FF8_H$ through to $7FFF_H$ the "magic" pattern 55_H,AA_H,55_H,AA_H,55_H,AA_H,55_H,AA_H, must be stored. It is used by SCR_FW as check-condition that valid program code is available in the XRAM. Once the SCR starts-up in user mode:

- If the memory content does not match the "magic" pattern user code will not be executed and the SCR will enter an endless loop. Before entering the endless loop, the start-up code will trigger an interrupt to the

TriCore™ domain controller by setting bit IRSCR_NMICON.SCRINTTC0 to 1 with a value of 81_H in SCUSCR_SCRINTEXCHG register

- If there is a match, the same interrupt is triggered to the main controller with a value of 80_H in SCUSCR_SCRINTEXCHG register to indicate the successful start-up. Then SCR firmware ends and user code starts executing from address 0000_H

***Note**: In case of wake-up from STANDBY0 to STANDBY1 mode, the interrupt to the TriCore™ domain will still be issued but main TriCore™ domain controller will not be able to check it until the next RUN mode.*

OCDS mode with SCR DAP/SPD pin

If the OCDS mode with SCR DAP/SPD pin is selected, the debug mode will be entered for debugging the SCR program code. The OCDS hardware is initialized and a jump to program memory address 0000_H is executed. The user code in the XRAM memory is executed and the debugging process may be started.

***Note**: The DAP/SPD pin must be directly accessible by SCR. The control of these pins must be given to SCR before enabling this boot mode. The details on how to give control to the SCR are explained in the PORT8 GPIO section further below.*

OCDS mode with main TriCore™ domain DAP/SPD pin

If the OCDS mode with the TriCore™ domain DAP/SPD pin is selected, the debug mode will be entered for debugging the SCR code using the TriCore™ domain DAP/SPD pins that are also used by the main debug system. The OCDS hardware is initialized and a jump to program memory address 0000_H is executed. The user code in the XRAM memory is executed and the debugging process may be started.

39.3.4.2 Clock system and control

The figure below shows the block diagram of the SCR's clock system.

The two oscillators,

- a 100 MHz oscillator (High-Precision Oscillator, HPOSC)
- and a 70 kHz oscillator (Low-Power Oscillator, LPOSC),

are supplied from inside the PMS.

If SCR is not enabled (PMS_SCR_CON0.SCREN='0') these two clock sources are gated for SCR in both RUN and STANDBY1 mode.

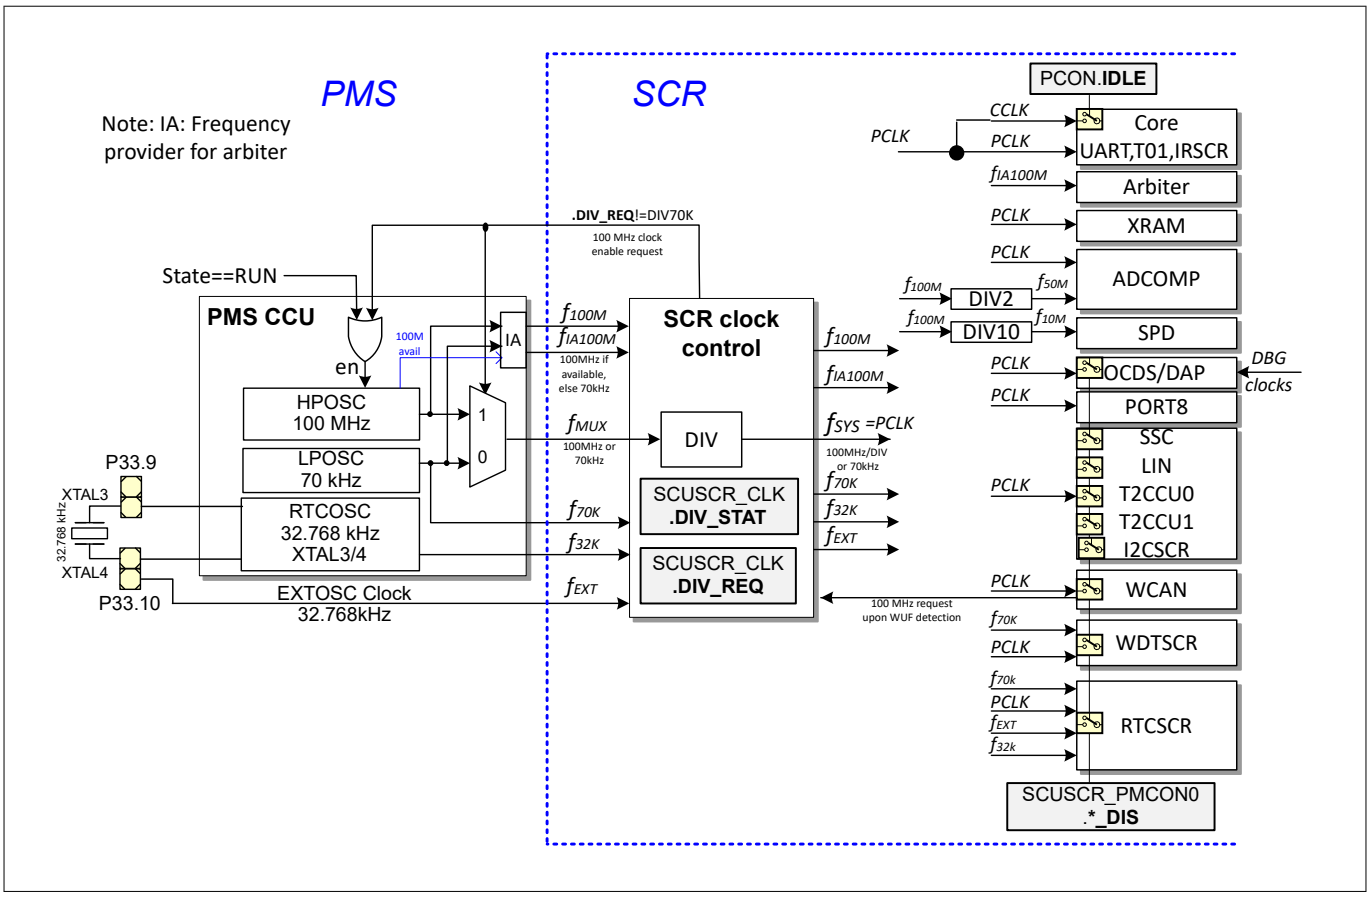

Figure 847 Clock system block diagram

During RUN mode, the 100 MHz clock from HPOSC is always enabled and serves as a backup clock (f_{BACK}) for the TriCore™ domain. During STANDBY0 mode, in order to save power, HPOSC is disabled and only the LPOSC 70 kHz clock is running. In STANDBY1 mode HPOSC is enabled if SCR_SCUSCR_CLK.DIV_REQ!=DIV70kHz. If SCR_SCUSCR_CLK.DIV_REQ==DIV70KHz, HPOSC will be switched off.

When enabled, SCR can select either 70 kHz or some derivative of 100 MHz clock (100 MHz divided by DIV) as its system clock f_{SYS}. This is independent from the TriCore™ status – even when system is in RUN state and 100 MHz oscillator is active, SCR can select 70 kHz as its system clock. However, if in STANDBY1 state HPOSC was not enabled, SCR request to use 100 MHz divided by DIV as a system clock triggers enabling the HPOSC. After an SCR reset default value of f_{SYS} is 20 MHz (DIV=5).

In addition to software request through DIV_REQ, WCAN module can also request 20 MHz clock upon detection of wake-up pattern (WUP).

Beside two internal oscillators (70 kHz and 100 MHz), two other clock sources are supplied to SCR RTCSCR unit:

- 32 kHz crystal oscillator XTAL3/4, forwarded from PMS (P33.9-10), or
- External oscillator coming from pin SCR_P1.2 (P33.10)

The figure above shows the clock source selection and ability of an independent clock gating for each sub-unit inside the SCR.

In active mode, the main module clocks are as follows:

- CPU clock (CCLK)=70 kHz or 100 MHz divided by DIV (default reset value DIV=5 results in 20 MHz clock) = f_{SYS}
- Peripheral clock (PCLK)= f_{SYS}

Most of the peripherals are running on the PCLK clock, for example UART/LIN, T0, T1, T2CCU. There are some exceptions:

- SPD Debug interface can only be supported when the 100 MHz oscillator is available. When it is available, SPD runs on 100 MHz/10 = 10 MHz clock frequency
- ADCOMP also requires that 100 MHz oscillator is available prior to starting measurements. When 100 MHz clock is available, the analog part of ADCOMP runs at 100 MHz/2 = 50 MHz clock frequency. Configuration and status registers of ADCOMP are clocked with PCLK
- Besides running on PCLK, clock watchdog and RTCSCR can select to run at 70 kHz at any time. Additionally, RTCSCR can also run on XTAL3/4 (P33.9-10, forwarded from PMS) or external clock provided from pin SCR_P1.2 (P33.10)
- Arbiter will run on undivided 100 MHz clock if HPOSC is enabled, otherwise it is running on 70 kHz. This is independent from divider DIV setting (for example, if DIV = 5 the arbiter still operates on 100 MHz)
- OCDS/DAP, besides running on PCLK clock, it can also run on the other clocks that are provided with the Debug system (clock from pads, SPD clock or external I/O-Client clock, depending on the mode)

Clock division and sequencing

If 100 MHz clock source is selected for f_{SYS}, the clock will be divided by the programmable factor DIV that is reflected through bit-field SCUSCR_CLK.DIV_STAT.

Transition from 70 kHz clock to higher frequencies is done step-wise to avoid sudden supply current fluctuations. First step is from 70 kHz to 10 MHz (DIV=10) followed by one DIV step at a time (one step every ~15.3 µs), if higher frequencies are requested. Same step-wise approach applies on the way back, or on any change between two frequencies, where at least one of them is higher than 10 MHz.

The following shows an exemplary time schedule, switching from 70 kHz clock to 100 MHz clock:

- Set division request value to divide clock by 1 (SCUSCR_CLK.DIV_REQ = DIV1), which corresponds to the frequency of 100 MHz
- Start of HPOSC is triggered. After around 200 µs, HPOSC is ready to be used
- Intermediate divided value of f_{SYS} is set to 10 MHz and status bit-field becomes SCUSCR_CLK.DIV_STAT = DIV10.
- Frequency is then increased step-wise: 10 MHz → 12.5 MHz → 20 MHz → 25 MHz → 33 MHz → 50 MHz → 100 MHz – total of 6 transitions, taking ~92 µs. Final value of SCUSCR_CLK.DIV_STAT = DIV1 which matches the DIV_REQ requested value

It can take around 300 µs to have SCR system clock reach target frequency. Nevertheless, XC800 CPU can keep executing further instructions without waiting for final clock frequency to settle.

When the SCR is disabled from TriCore™ software via SCR_CON0.SCREN=0 the SCR still remains enabled until the PCLK frequency is reduced to a frequency ≤ 20 MHz. This frequency reduction is done step-wise. For example if the PCLK is running at 100 MHz there will be 5 steps (100 MHz → 50 MHz → 33.3 MHz → 25 MHz → 20 MHz → 12.5 MHz) before the SCR gets disabled. Every step takes typically around 15.3 us. If the PCLK is running at any frequency < 20 MHz the SCR will be disabled immediately.

39.3.4.2.1 Module suspend control

During an active debug session timers in certain modules in the SCR can be suspended based on the settings of their corresponding module suspend bits in register SCUSCR_DBG_MODSUSP. When suspended, only the timer

stops counting as the counter input clock is gated off. The module is still clocked so that module registers are accessible.

39.3.4.3 Reset control

The SCR has three types of resets:

- LVD Reset – power reset caused by an Low-Voltage Detector (LVD) circuit
- Main Reset – SCR reset coming from the main SoC through PMS_SCR_CON1.SCRSTREQ or SCR-PORST pin or Debug reset
- Generated Reset – reset from sources within the SCR

The SCR Watchdog Timer Reset, the RAM double bit ECC Reset, the reset from Pin and the Soft Reset which have the source within the SCR are called Generated Resets. For the generated resets the following applies:

- The Watchdog Timer (WDT) module is capable of resetting the device if it detects a timer overflow (which represents malfunction in the system)
- A double bit ECC event in the SRAM can also trigger a reset
- A low value on the selected pin (after digital glitch filtering) can also trigger a reset
- A Software reset is also possible through write to designated bit-field

39.3.4.3.1 Types of reset

The following reset types affect the SCR:

- **LVD reset**, caused by an under-voltage detection
  - Triggered asynchronously during power failure (under-voltage on PMS1 domain)
  - OCDS/Debug system is reset when the LVD reset occurs
- **Main reset**, reset from the main SoC
  - SCR-PORST triggered by the PORST pin, if enabled using PMS_SCR_CON0.PORSTREQ triggering a main reset. Also OCDS/Debug system is reset by SCR PORST
  - This is a combined reset, consisting of all the Power reset sources and synchronous reset by the main SoC controller CPUx through bit PMS_SCR_CON1.SCRSTREQ
  - Debug reset is also triggering a main reset
  - Main reset also activates the generated reset
  - Resets all registers including the reset indication bits
- **Generated reset**, reset from sources within the SCR
  - Watchdog Timer (WDT) reset
    - Requested by WDT overflow or out of boundary refresh event if it is enabled through SCUSCR_RSTCON.WDTRSTEN
    - Resets all registers except the reset indication bits
    - Reset can also trigger an interrupt to the main SoC (interrupt feature is available independent from the configuration of this reset as a reset source)
  - RAM Double-Bit ECC reset
    - Requested by ECC event if it is enabled through SCUSCR_RSTCON.RAMECCRSTEN
    - Resets all registers except the reset indication bits
    - Reset can also trigger an interrupt to the main SoC (interrupt feature is available independent from the configuration of this reset as a reset source)
  - Reset from one of the reset pins:
    - Requested by low value of selected pin-reset input if it is enabled through SCUSCR_RSTCON.PINRSTEN

- Resets all registers except the reset indication bits
- If the reset is enabled it can also trigger an interrupt to main SoC

- Software triggered reset:
  - Requested by soft reset event through SCUSCR_RSTCON.SWRSTREQ
  - Resets all registers except the reset indication bits
  - Reset can also trigger an interrupt to the main SoC

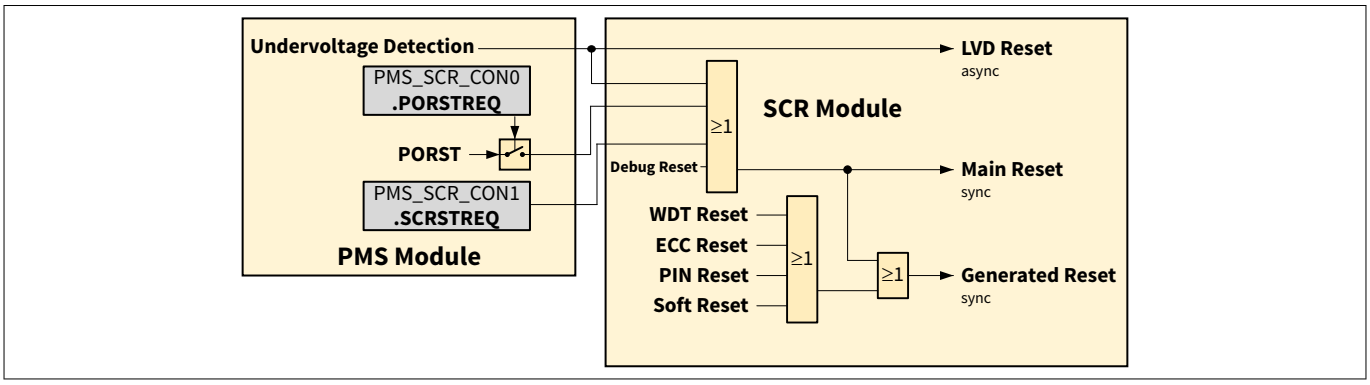

Figure 848 Simplified reset overview

LVD reset (under-voltage reset)

The LVD Reset, resets the complete SCR including the SRAMs and the Debug system.

An LVD Reset will also trigger a Main Reset, which will trigger a Generated Reset.

Main reset (external reset)

The main reset includes PORST and a software triggered reset from the main core (TriCore™) through the PMS_SCR_CON1.SCRSTREQ bit. A main reset will reset the digital logic around SRAMs. Main reset which is caused due to a PORST and will reset the debug system.

A main reset also triggers the generated reset.

If the value of PMS_SCR_CON0.SCRCFG bit-field is changed and, if SCR was already enabled prior to this change, triggering a main reset through the SCRSTREQ will re-initiate SCR from the newly given boot mode.

A debug reset is also triggering a main reset.

Generated reset (SCR reset)

Generated Reset is activated together with Main Reset, or on detection of a Watchdog Timer overflow event, an SRAM ECC error event, a PIN reset, a soft reset or a debug reset.

Same events that lead to generated SCR reset, except the Debug reset, are reported to the TriCore™ domain over PMS status flags which further generate an interrupt to the TriCore™ domain interrupt controller, as shown in following figure:

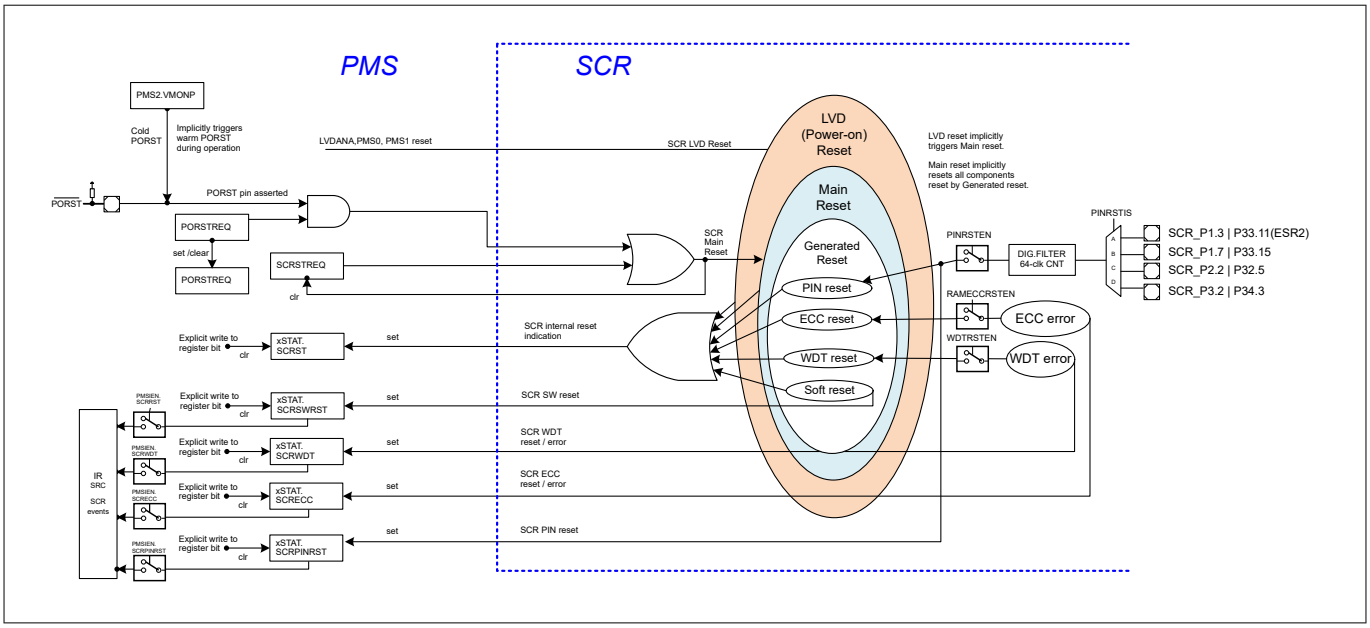

Figure 849 Detailed SCR reset diagram

Generated Reset will not change SCR boot mode, even if it was changed prior to this reset. Only Main Reset will trigger re-latching of PMS by the given SCR boot mode.

***Note**: SCR cannot change its own boot mode, this change has to come from the main CPU.*

Watchdog timer reset

The watchdog timer reset is an internal reset and can be disabled by bit SCUSCR_RSTCON.WDTRSTEN. The Watchdog Timer (WDT) maintains a counter that must be refreshed or cleared periodically. If the WDT is not serviced correctly and in time, it will generate an NMI request to the CPU and then reset the device (WDTSCR_RST) after a predefined time-out period if this reset type is enabled. When the reset is disabled, no reset will be triggered when the overflow event or out of boundary refresh event happens.

Bit SCUSCR_RSTSTAT.WDTRST is used to indicate the watchdog timer reset status.

***Note**: The event status SCUSCR_RSTSTAT.WDTRST can be cleared by Main Reset.*

An event signal will be generated as an output of SCR to indicate that a watchdog timer event happened. This signal is latched by the PMS and the error status can be read through PMS_SCR_STAT.SCRWDT bit.

Double-bit ECC reset

Double-bit ECC error can happen on read access to XRAM..

The double bit ECC reset is an internal reset and can be disabled by bit SCUSCR_RSTCON.RAMECCRSTEN (not advised). The data loaded by TriCore™ is encoded with an Error Correction Code (ECC) before being stored in the XRAM memory. During a read access, data is retrieved from the memory and decoded for dynamic error detection and correction. If a double-bit error is detected, it will generate a reset if this reset type is enabled. When the reset is disabled, no reset will be triggered when the ECC event happens.

Bit SCUSCR_RSTSTAT.RAMECCRST is used to indicate the ECC reset status.

***Note**: The event status SCUSCR_RSTSTAT.RAMECCRST can be cleared by Main Reset.*

An event signal will be generated as an output of SCR to indicate that an ECC event happened. This signal is latched by the main PMS and the error status can be read through PMS_SCR_STAT.SCRECC bit.

Reset from pin

A reset from pin is an internal reset that is caused by low level on selected PINRST pin and can be enabled by bit SCUSCR_RSTCON.PINRSTEN.

Digital glitch filtering is applied with simple 6-bit up-counter (63 clock cycles) that runs on PCLK clock – selected input signal has to be low for at least 63 consecutive PCLK cycles to trigger a reset request. This means If there is a bouncing signal on the input the low value shall be stable for at least 63 cycles to be recorded. This filtering feature is always enabled and cannot be disabled.

If a reset from pin request is detected, it will generate a reset if this reset type is enabled. Before enabling this reset make sure that selected input signal is not already low, as this can unintentionally trigger a reset soon after enabling.

Bit SCUSCR_RSTSTAT.PINRST is used to indicate the pin reset status.

***Note**: The event status SCUSCR_RSTSTAT.PINRST can be cleared by Main Reset.*

Bit-field SCUSCR_MODPISEL1.PINRSTIS is used to select one of the four possible pin reset inputs:

- PINRSTA - SCR_P1.3 (P33.11, ESR2) - this is the default option
- PINRSTB - SCR_P1.7 (P33.15)
- PINRSTC - SCR_P2.2 (P32.5)
- PINRSTD - SCR_P3.2 (P34.3)

An event signal will be generated as an output of SCR to indicate that a pin reset event happened. This signal is latched by the PMS and the reset status can be read through PMS_SCR_STAT.SCRPINRST bit.

Soft reset

Soft reset is an internal reset that is caused by a software set of the soft reset request bit inSCUSCR_RSTCON.SWRSTREQ.register. It can be triggered by application software when necessary.

Bit SCUSCR_RSTSTAT.SWRST indicates the soft reset status.

An event signal will be generated as an output of SCR to indicate that a soft reset event happened. This signal is latched by the PMS and the reset status can be read through PMS_SCR_STAT.SCRRST bit.

***Note**: The event status SCUSCR_RSTSTAT.SWRST can be cleared by Main Reset.*

Debug reset

A debug reset is a generated reset that is caused by debugger reset commands. Status on debug reset is not reported to the TriCore™ domain.

Debug reset is also triggered whenever the LVD reset or PIN reset is triggered. Main reset will trigger the debug reset only if the source of main reset is PORST. software triggered main reset from the TriCore™ will have no effect on the debug system.

39.3.4.3.2 Module reset behavior

Following table gives an overview on how the various modules or functions of the SCR are affected with respect to the reset type. An “X” means that the module/function is reset to its default state.

Table 1687 Effect of reset on modules/functions

Module/function	LVD reset	Main reset	Generated reset (WDT, ECC, PIN, SOFT)
XC800 core	X	X	X
SCUSCR	X	X	All logic is affected except the reset indication bits

(table continues...)

Table 1687 (continued) Effect of reset on modules/functions

Module/function	LVD reset	Main reset	Generated reset (WDT, ECC, PIN, SOFT)
Peripherals	X	X	X
Debug system	X	Affected only by PORST	Affected only by PIN reset
Port control (SCR PORT8 side)	X	X	X
On-chip static RAM	Affected, unreliable	Not affected, reliable	Not affected, reliable
Clock system	X	X	X

SCUSCR_RSTCON register contains enable bits for an ECC, WDT, PIN and soft reset. SCUSCR_RSTSTAT consists of reset indication bit-fields for the same four generated reset sources. SCUSCR_RSTSTAT can be cleared by software or by higher order reset (Main or LVD). Table below shows the value of SCUSCR_RSTSTAT register after these events. An "X" means value is not affected by that reset event.

Table 1688 SCUSCR_RSTSTAT value after reset events

Reset source	Reset value
RAM double-bit ECC reset	$000X_0XX\mathbf{1}_B$
WDT reset	$000X_0X\mathbf{1}X_B$
PIN reset	$000X_0\mathbf{1}XX_B$
Soft reset	$000\mathbf{1}_0XXX_B$
Main reset	$000\mathbf{0}_0\mathbf{000}_B$

39.3.4.4 SCR power management

This section describes the features and functionality provided for power management of the SCR.

Standby mode is one of the power saving modes in the main SoC. System Standby mode can be split in two distinctive modes, STANDBY1 and STANDBY0. During a STANDBY1 mode, SCR is the only CPU subsystem active (TriCore™ CPUs are switched off). During a STANDBY0 mode, even SCR is switched off and just a few peripherals in PMS are active waiting for a wake-up signal.

This section also describes:

- How to exit the Standby Mode
- How to operate the whole chip between two low power modes, STANDBY1 and STANDBY0

These points are described from SCR point of view.

More details on system Standby modes and transitions between different modes is presented in PMS chapter called "Standby Mode Management".

39.3.4.4.1 Overview

The SCR provides software programmable actions to minimize the power consumption.

There are generally two power modes of the SCR subsystem: Active Mode and Idle Mode.

The operation of the system components in each of these two modes can be configured by software. The power modes provide flexible reduction of power consumption through a combination of techniques, including:

- Stopping the CPU clock
- Stopping the clocks of other components individually
- Clock-speed reduction of some peripheral components

In Active mode, the CPU and peripherals are running at system frequency f_{SYS}.

In Idle mode, the SCR core clock (CCLK) is disabled and the Core halts. Peripherals with separate input clock (PCLK) are not disabled.

***Note**: The watchdog timer may generate an warning interrupt (followed by a reset) when an overflow is about to occur and this will disrupt the idle mode. The idle mode is terminated automatically when any enabled interrupt signal is detected.*

39.3.4.4.2 SCR idle mode

Software requests Idle Mode by setting the bit PCON.IDLE to 1.

Based on the IDLE request by the SCR software the CPU finishes its current operation and sends an acknowledge signal (IDLE) to the SCUSCR. Based on the feedback signal the SCU disables the CPU clock (CCLK).

The SCR core returns to the Active Mode when there is an incoming interrupt request to an enabled interrupt node.

An interrupt to the XC800 CPU causes the CCLK to recover. Upon RETI instruction, the CPU will return to execute the next instruction following the instruction which sets the PCON.IDLE bit to 1.

***Note**: The user is advised to disable watchdog timer prior to entering the Idle Mode and use the RTCSCR interrupt as preferred way to schedule wake-up from the Idle Mode.*

39.3.4.4.3 Peripheral clock disable

It is possible to disable the clock for some peripherals separately in order to save power. Each bit of SCUSCR_PMCON0 register controls one peripheral. When the bit is set, the request signal to gate off the clock to

the respective module is asserted. The SCUSCR will then synchronize the gating off of the clock to the peripheral. Upon power on reset (LVD reset) clock inputs of all peripherals as specified in the SCUSCR_PMCON0 register are gated.

39.3.4.4.4 Exit the TriCore™ domain standby mode through SCR

In the system STANDBY1 mode, SCR is operating in either Active Mode or Idle Mode. Therefore, SCR could be one of the wake-up sources for the TriCore™ domain to exit the system Standby mode and transition into a system Run mode. Before issuing the standby request and entering the system Standby mode, the followings steps related to SCR need to be set:

- Configure the wake-up signals related to SCR that trigger the exit from the Standby mode through PMS_WAKEUP_CON1.SCRWKEN bit-field
- Configure the clock selection for SCR in Standby Mode through SCUSCR_STBY.SCRCLKSEL bit

To exit from the Standby Mode, one of the following wake-up sources from SCR could be used:

- RTCSCR compare match interrupt (this is 41-bit RTCSCR located in SCR)
- WCAN Interrupts that include Wake up Frame, Wake up Pattern, System Error and CAN time-out
- Watchdog (WDTSCR) overflow event
- SRAM ECC double bit error event
- Software request through SCUSCR_WKPCON.SWWKPREQ

Besides the specified events such as WDT overflow event, SRAM ECC error, WCAN event or RTCSCR compare match event, other types of events from SSC, T0, T1, T2CCU and UART could be implicitly used to issue a wake-up request through the bit SWWKPREQ in SCUSCR_WKPCON register.

The status bit SCUSCR_STBY.STBYSTAT indicates to SCR software whether the TriCore™ domain is currently in Standby mode or not.

If SCR software and software running on the main cores (TriCore™) desire to exchange information upon wake-up it can be done in two ways:

- Through 8-bit exchange registers: SCUSCR_SCRINTEXCHG and SCUSCR_TCINTEXCHG
- Through XRAM memory that both SCR core and TriCore™ domain cores can access

39.3.4.4.5 Low power operation with STANDBY1 and STANDBY0 modes

In order to achieve low average power, while still supporting functional code to run, system can utilize switching between two low-power standby modes:

- STANDBY1 - low power mode where the main SoC is switched off and SCR subsystem is active
- STANDBY0 - low power mode where the whole system is switched off except few peripherals waiting for a wake-up signal

This represents a special low-power operation where the system is most of the time be in STANDBY0 state, and only waking up to STANDBY1 state for a short time, finishing necessary tasks (for example temperature calibration), and switching back to STANDBY0 state.

To enable this special low-power operation, the main SoC software needs to take several setup steps:

- Enable that STANDBY1 → STANDBY0 transitions can be requested by SCR software
  - This is done through PMS_STANDBY_CON0.SCRSTBY0EN = 1
- Configure which wake-up sources will trigger STANDBY0 → STANDBY1 transitions
  - More details on available wake-up sources is presented in PMS chapter Standby Mode Management

- Configure that chosen wake-up event will trigger a transition into the STANDBY1 mode and not into the RUN mode
  - This is done through SMM_PMCSRx.REQSLP = $1x_B$ and PMS_STANDBY_CON1.SBMODSEL = 1
- Enable XRAM memory retention while the system is in the STANDBY0 mode
  - This is done through PMS_STANDBY_CON0.SCRRAMSEL = 1

This settings have to be done first before transitioning from RUN to STANDBY1 mode.

Following diagram illustrates transitions between RUN, STANDBY1 and STANDBY0 mode from SCR control perspective.

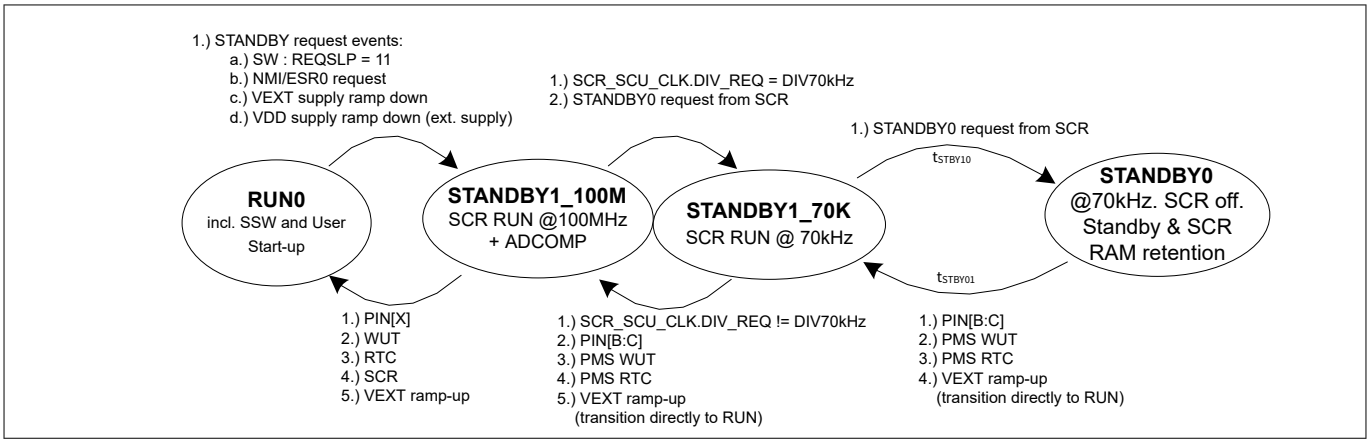

Figure 850 System mode transitions from SCR perspective

***Note**: In most use-cases, optimal power consumption is achieved when alternating between STANDBY1_100M and STANDBY0 states. STANDBY1_70K state has much slower clock and not proportionally lower power consumption comparing to STANDBY1_100M state. Which exact frequency derived from 100 MHz clock (10 MHz, 20 MHz, 50 MHz, 100 MHz or other) gives optimal power depends on exact use-case and is left on user to explore.*

***Note**: STANDBY1_70K mode is useful in case where use-case needs some SCR sources as a system wake-up (for example listening to SCR Port signals), where these sources are not available in STANDBY0 mode. Another useful case for STANDBY1_70K is when wake-ups happen frequently and amount of tasks to finish upon a wake-up is small. In these cases whole operation is alternating between STANDBY1_70K and STANDBY1_70K_IDLE modes, which gives better average power than alternating between STANDBY0 and STANDBY1_100M.*

Enter STANDBY0 mode

STBY0 mode can be entered from the RUN directly or from the STBY1 mode. Transition RUN → STBY0 does not involve SCR subsystem and is explained in PMS chapter "Standby Mode Management".

Transition from STBY1 to STBY0 involves SCR and is described below.

In order to trigger a STBY1 → STBY0 transition following conditions have to be fulfilled:

1. None of the PMS wake-up flags and over-run flags are set

2. There was a STBY1 → STBY0 transition trigger:

a. SCR software has triggered a STBY1 → STBY0 transition (through SCR_SCUSCR_STBY.STBY0REQ = 1, if enabled by PMS_STANDBY_CON0.SCRSTBY0EN = 1), or

b. Hardware condition has triggered a STBY1 → STBY0 transition (for example VDDEXT ramp-down if VDDEXTSBEN = 1)

In other words, if PMS wake-up flags are cleared both SCR software and hardware trigger will cause a transition of the system into STBY0 mode. Clearing of PMS wake-up and over-run flags can be done from SCR side through SCR_SCUSCR_STBY.PMSWKPCLR = 1

***Note**: If some hardware condition for STBY0 entry is already fulfilled (for example VDDEXT is already powered down) then clearing PMS flags from SCR side will directly be followed by transition into STBY0 - no need to explicitly trigger it by the SCR SW. Therefore, the SCR software routine should keep the instruction for clearing of the PMS wakeup-flags at the end of the processing loop.*

If shared ports were granted to the SCR (by setting respective Pn_PCSRSEL and SCREN = 1) while in RUN mode, the ownership will remain on the SCR side when transitioning in STANDBY1 and later in STANDBY0 state. More details on Shared Pads ownership is given in SCR "General Purpose I/O Ports (PORT8)" chapter.

Exit STANDBY0 to STANDBY1 mode

After a wake-up event the system wakes up from STANDBY0 into STANDBY1 if configured through SMM_PMCSRx registers.

After entering the STANDBY1 mode, and SCR boot start-up, SCR software can read the flags STBYSTAT and STBY0WKP in register SCUSCR_STBY to derive if the STANDBY1 entry was from RUN or STANDBY0 state. Based on this information, SCR software can differentiate between the cases:

- STANDBY1 mode was entered from STANDBY0 mode
- STANDBY1 mode was entered from RUN mode

Additionally perform different software routine if necessary.

XRAM keeps its content while in STANDBY0 state. If there is a need to share information between several STANDBY1 sessions which are alternated by STANDBY0 sessions, XRAM memory can be used.

If shared ports were granted to the SCR (by setting respective Pn_PCSRSEL and SCREN='1') while in RUN mode, the ownership will remain on the SCR when transitioning from STANDBY0 to STANDBY1. More details on Shared Pads ownership is given in SCR "General Purpose I/O Ports (PORT8)" chapter.

39.3.5 Interrupt system (IRSCR)

The XC800 Core supports one non-maskable interrupt (NMI) and 14 maskable interrupt requests. In addition to the standard interrupt functions supported by the core, for example, configurable interrupt priority and interrupt masking, the SCR interrupt system provides extended interrupt support capabilities such as the mapping of each interrupt vector to several interrupt sources to increase the number of interrupt sources supported, and additional status registers for detecting and identifying the interrupt source.

39.3.5.1 Interrupt sources

The SCR supports 14 interrupt vectors with four priority levels. These interrupt vectors are assigned to the on-chip peripherals:

- Timer 0, Timer 1, UART, RTCSCR and WCAN are each assigned one dedicated interrupt vector
- T2CCU0 and LIN interrupts have to share an interrupt vector
- SSC, ADC, T2CCU1 and PMS_RTC CMP0 also share one interrupt vector
- External interrupt 0 and 1 are each assigned one dedicated interrupt vector
- External interrupt 2 shares the interrupt vector with PMS_RTC CMP1 and I2CSCR
- remaining 13 external interrupts are shared among 4 interrupt vectors

A non-maskable interrupt (NMI) with the highest priority is shared by the following:

- Watchdog Timer, warning before overflow
- OCDS, on user IMEM event
- RAM ECC error
- External NMI (through rising edge on EXTNMI pin SCR_P1.6/P33.14)
- Main controller: This interrupt is triggered either when software sets PMS_SCR_CON1.TCINTREQ or when SCR_SCUSCR_MRSTST.APPRST or SCR_SCUSCR_MRSTST.SMURST are set
- Wake-up interrupt: This interrupt is triggered when any of the wake-up inputs were triggered, and the VEXT supply did not ramp up even after the blanking time interval. Please see PMS chapter for additional details

Following three figures give a general overview of the interrupt sources and nodes, and their corresponding control and status flags. Figure 'non-maskable Interrupt (NMI) Request Sources' below gives the corresponding overview for the NMI sources.

The details of the peripheral interrupt sources are described in the respective peripheral chapters, while the details of the external interrupt sources can be found in figures in related information.

39.3.5.1.1 Interrupt source and vector of the SCR

Each interrupt event source has an associated interrupt vector address for the interrupt node it belongs to. This vector is accessed to service the corresponding interrupt node request. The interrupt service of each interrupt node can be individually enabled or disabled through an enable bit. The assignment of the SCR interrupt sources to the interrupt vector address and the corresponding interrupt node enable bits are summarized in the following table.

Table 1689 Interrupt vector address

Interrupt node	Vector address	Assignment for SCR	Enable bit	SFR
NMI	0073_H	Watchdog Timer NMI	NMIWDT	NMICON
		RAM Double Bit ECC Error NMI	NMIRAMECC

39.3.5.1.2 Interrupt source and priority

An interrupt that is currently being serviced can only be interrupted by a higher priority interrupt, but not by another interrupt of the same or lower priority. Hence, an interrupt of the highest priority cannot be interrupted by any other interrupt request.

If two or more requests of different priority levels are received simultaneously, the request with the highest priority is serviced first. If requests of the same priority are received simultaneously, an internal polling sequence determines which request is serviced first. Thus, within each priority level, there is a second priority structure determined by the polling sequence as shown in the following table.

Table 1690 Priority structure within interrupt level

Source	Level/interrupt node (XINTR)
Non-Maskable Interrupt (NMI)	NMI (highest)
External Interrupt 0	0
Timer 0	1
External Interrupt 1	2
Timer 1	3
UART	4
T2CCU0	5

39.3.5.2 Interrupt structure

An interrupt event source may be generated from the on-chip peripherals or from external event. The detection of interrupt events is controlled by the respective on-chip peripherals. The interrupt status flags are available for determining which interrupt event has occurred (see the table above: Priority structure within interrupt level), this is especially useful for an interrupt node which is shared by several event sources. Each interrupt node (except NMI) has a global enable/disable bit. In most cases, additional enable bits are provided for enabling/disabling particular interrupt events (provided for NMI events). No interrupt will be requested for any occurred event that has its interrupt enable bit disabled.

The SCR has, in general, two interrupt structures distinguished mainly by the manner in which the pending interrupt request (one per interrupt vector/node going directly to the core) is generated (due to the events) and cleared.

Common among these two interrupt structures is the interrupt masking bit, EA, which is used to globally enable or disable all interrupt requests (except NMI) to the core. Resetting bit EA to 0 only masks the pending interrupt requests from the core, but does not block the capture of incoming interrupt requests.

***Note**: The NMI node is similar to the other interrupt nodes, except for the exclusion of EA bit. Effectively, NMI node is non-maskable.*

***Note**: Please see also table: Location of the interrupt flags*

39.3.5.2.1 Interrupt structure 1

For interrupt structure 1 (see following figure), the interrupt event will set the interrupt status flag which doubles as a pending interrupt request to the core. An active pending interrupt request will interrupt the core only if its corresponding interrupt node is enabled. Once an interrupt node is serviced (interrupt acknowledged), its pending interrupt request (represented by the interrupt status flag) may be automatically cleared by hardware (the core).

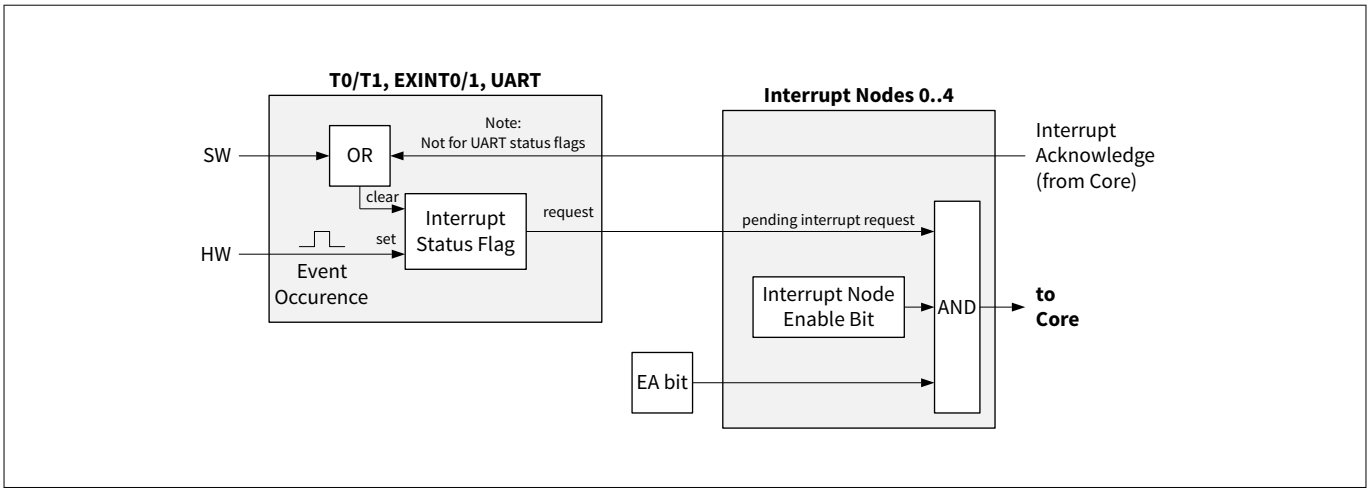

Figure 855 Interrupt structure 1

For the SCR, interrupt sources of Timer 0, Timer 1, external interrupt 0 and external interrupt 1 (each having a dedicated interrupt node) will have their respective interrupt status flags TF0, TF1, IE0 and IE1 in register T01_TCON cleared by the core, once their corresponding pending interrupt request is serviced. In the case that an interrupt node is disabled (for example software polling is used), its interrupt status flag must be cleared by software, since the core will not be interrupted (and therefore the interrupt acknowledge is not generated).

For the UART which has its dedicated interrupt node, interrupt status flags RI and TI in register SCON will NOT be cleared by the core, even when its pending interrupt request is serviced. The UART interrupt status flags (and hence the pending interrupt request) can only be cleared by software.

39.3.5.2.2 Interrupt structure 2

Interrupt structure 2 is implemented for interrupt nodes 5 through 13, relevant for the T2CCU0/1, LIN, external interrupts 2 to 15, WCAN, SSC, PMS RTC, I2CSCR and RTCSCR interrupt sources. For interrupt structure 2, the interrupt status flag does not directly drive the pending interrupt request. Instead, the interrupt nodes have a separate internal pending flag (FF).

An event generated by an associated interrupt source will set the internal pending flag. When the node is enabled, and the CPU is ready to service that interrupt request, the pending flag is automatically cleared by hardware (interrupt acknowledged) on entry into the service routine.

However, the status flag of the associated interrupt source is not automatically cleared; it must be cleared by software (preferably in the service routine).

Most of the interrupt nodes 5 through 13 have more than one associated interrupt source. The request signals of the sources are ORed for the set input of the pending flag. The clear input of the pending flag is either activated by the interrupt acknowledge, or when the status flags of ALL associated interrupt sources are cleared (inactive).

If one wants to clear the internal pending flag in an interrupt node with structure 2, special considerations need to be taken into account, depending on the associated interrupt source(s).

The interrupt sources differ slightly in the configuration of the request and the status lines. This is detailed in the following.

Registers overview on page 6531

Interrupt structure 2 for node 5

The following figure illustrates the configurations for interrupt node 5. Here, two different types of interrupt source configurations (indicated as Type b and Type c) are connected to the same node.

- For the LIN and the CCT0IRQ (of T2CCU0) interrupt sources, the request line as well as the status line are enabled/disabled through the associated interrupt enable bit. This means, when disabling the interrupt source, also the status line to the clear input of the interrupt node's pending flag is deactivated
- For the two interrupt sources T20IRQ and EXF20IRQ of the T2CCU0, only the request line is enabled/disabled through the associated interrupt enable bit. This means, when disabling the interrupt source, the status bit needs to be cleared by software in order to be able to clear the pending flag in the interrupt node

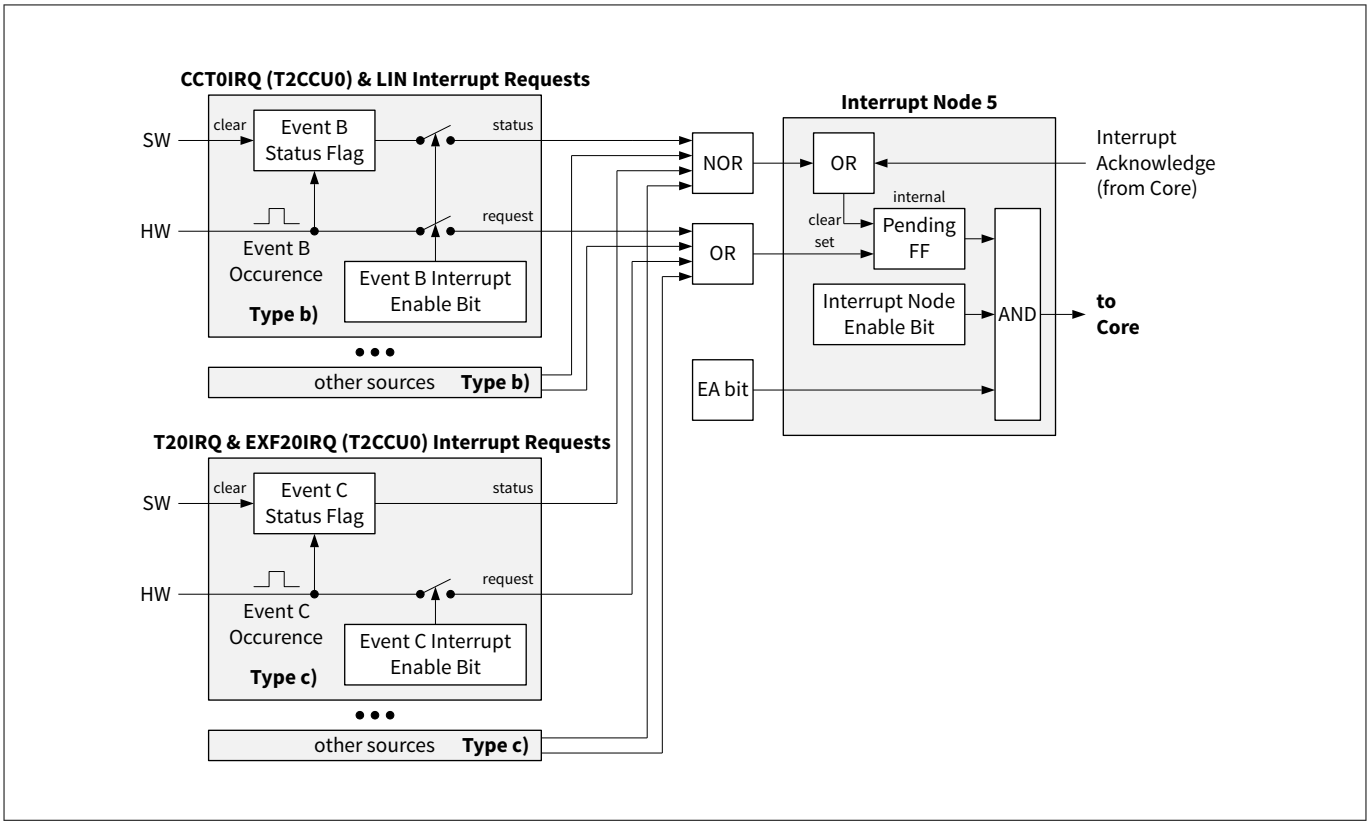

Figure 856 Interrupt structure 2 for node 5

Interrupt structure 2 for node 6

The following figure illustrates the configuration for interrupt node 6, which is connected to the WCAN interrupt sources. Only the request line is enabled/disabled through the associated interrupt enable bit. This means, when disabling the interrupt source, all active status bits of the WCAN module need to be cleared by software in order to be able to clear the pending flag in the interrupt node.

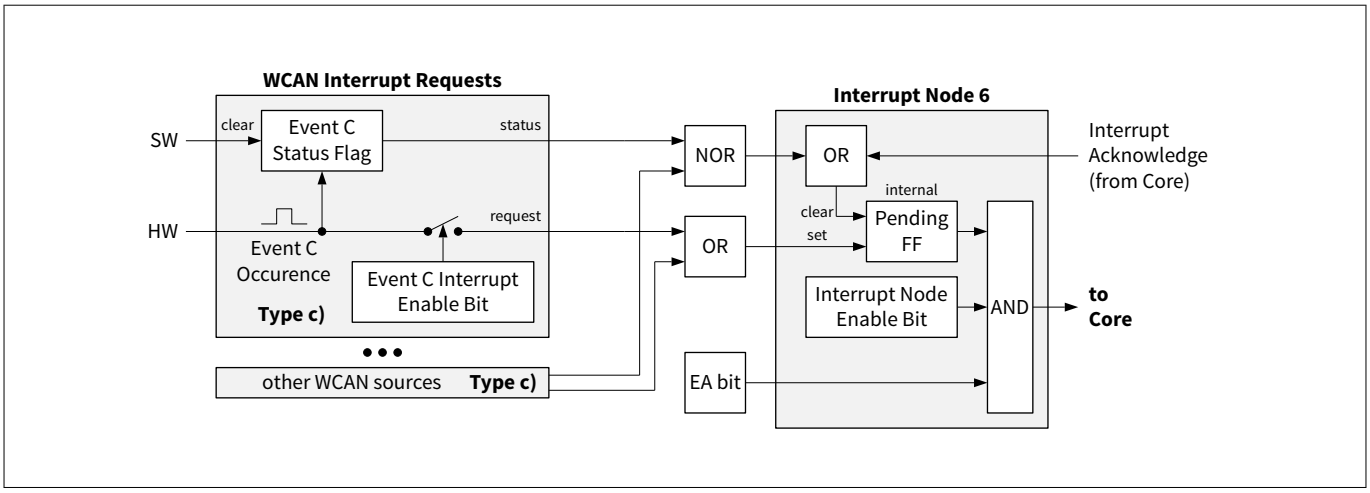

Figure 857 Interrupt structure 2 for node 6

Interrupt structure 2 for node 7

The following figure illustrates the configuration for interrupt node 7, which is connected to the SSC, ADCOMP, T2CCU1 and PMS RTC CMP0 interrupt sources. These interrupt sources are handled by a separate block in the interrupt module, controlled by registers IRSCR_MODIEN, IRSCR_CON1, and IEN1. Three different types of source configurations (indicated as type b, type c and type d) are connected to the same node.

- For the CCT1IRQ (of T2CCU1) interrupt source, the request line as well as the status line are enabled/ disabled through the associated interrupt enable bit. This means, when disabling the interrupt source, also the status line to the clear input of the interrupt node's pending flag is deactivated
- For the two interrupt sources T21IRQ and EXF21IRQ of the T2CCU1, only the request line is enabled/ disabled through the associated interrupt enable bit. This means, when disabling the interrupt source, status bit needs to be cleared by software in order to be able to clear the pending flag in the interrupt node
- Interrupt sources for ADCOMP, SSC and PMS RTC CMP0 are also connected to the interrupt node 7. For these interrupt sources, status flag is only set when the interrupt event is enabled. In order to clear the pending flag in the interrupt node, all the associated status flags for these interrupt sources must be cleared by software

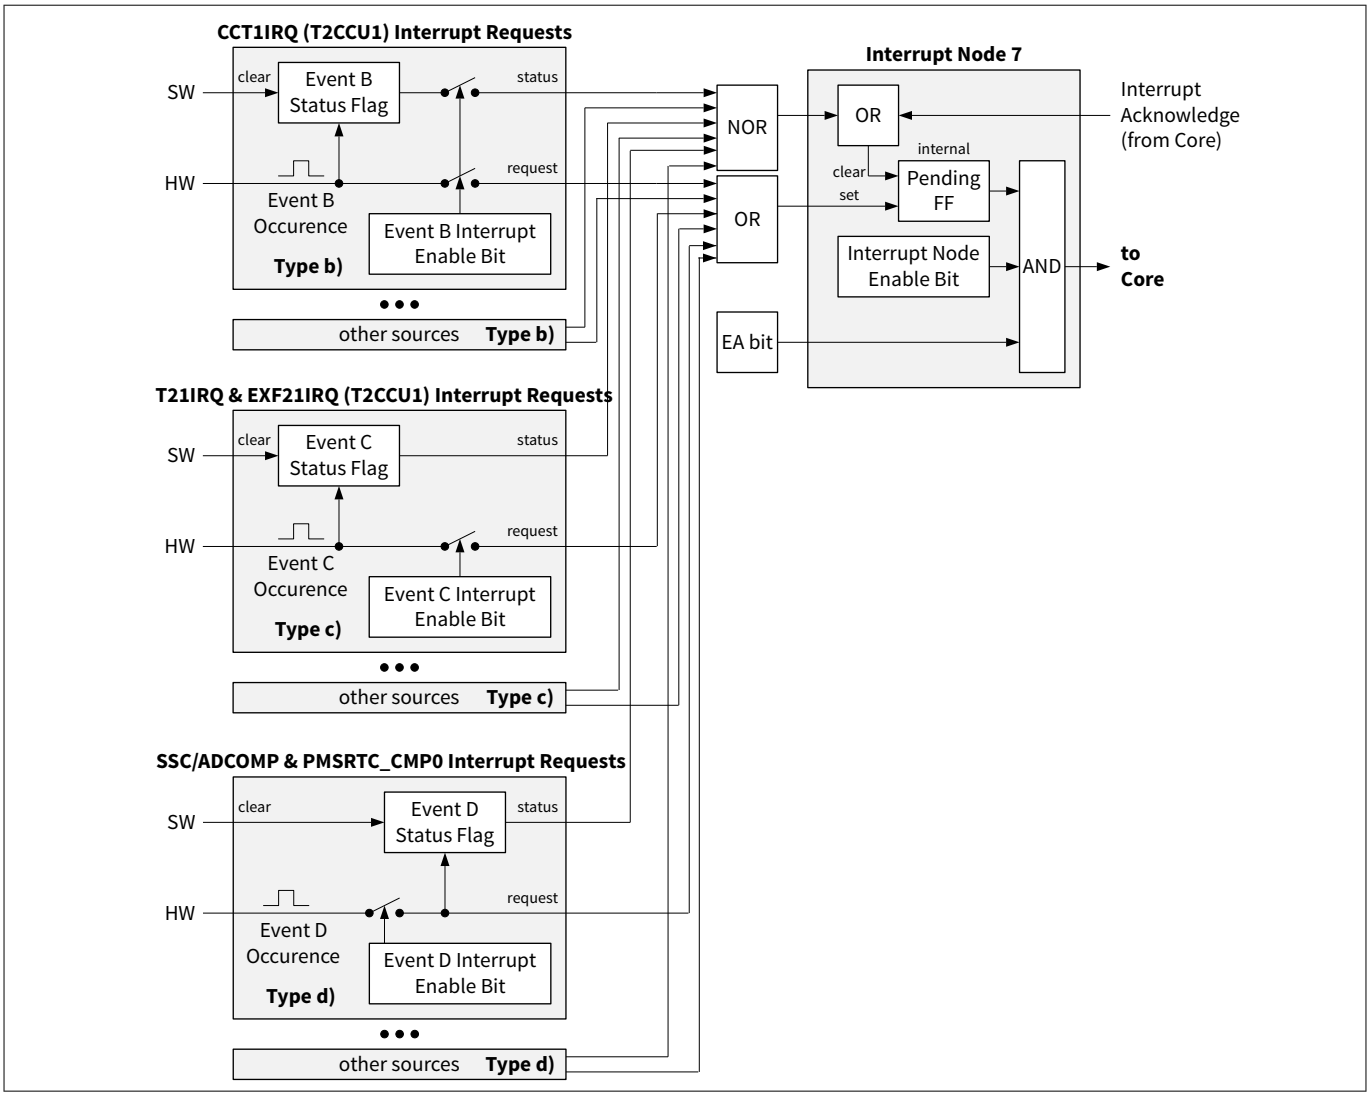

Figure 858 Interrupt structure 2 for node 7

Interrupt structure 2 for node 8

The following figure shows the configurations for interrupt node 8. Three different interrupt source configurations (indicated as Type a, Type b and Type d) are connected to this node.

- The external Interrupt EXINT2 does not have a separate interrupt enable control; instead, an event is disabled by selecting the '0'-input of its edge-detection multiplexer
- For the I2CSCR interrupt source, the request line as well as the status line are enabled/disabled through the associated interrupt enable bit. This means, when disabling the interrupt source, also the status line to the clear input of the interrupt node's pending flag is deactivated
- For interrupt sources PMS_RTC_CMP1, the request line is enabled/disabled through associated interrupt enable bit. Here, the status flag is only set when the interrupt event is enabled

In order to clear the pending flag in the interrupt node, all associated status flags connected to that node must be cleared by software.

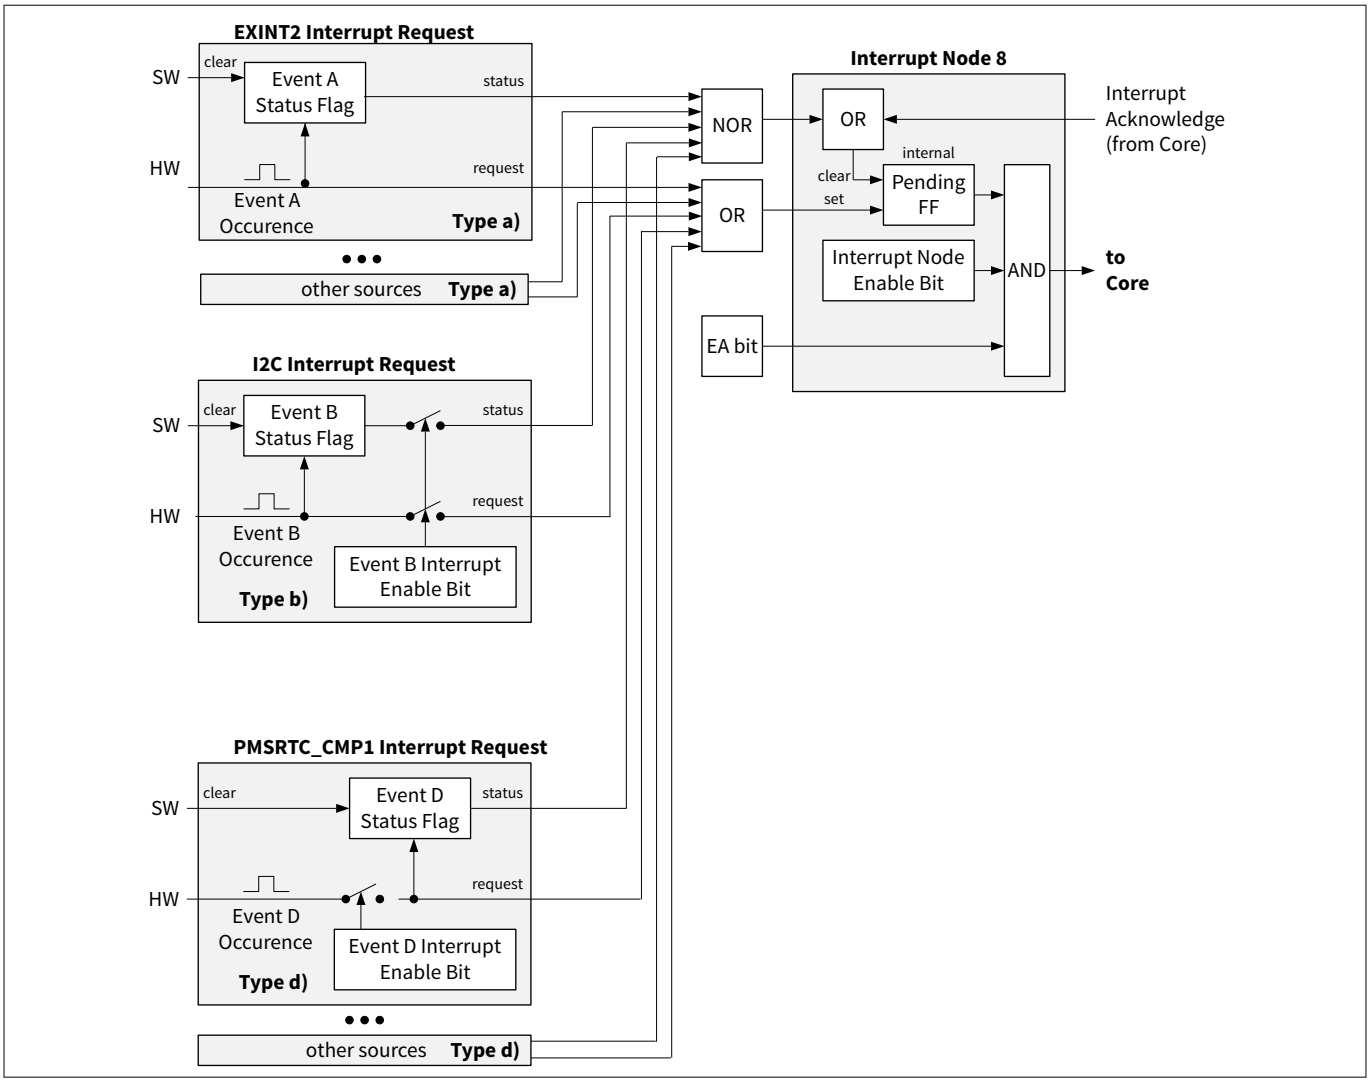

Figure 859 Interrupt structure 2 for node 8

***Note**: I2C here, is the I2CSCR*

Interrupt structure 2 for nodes 9 through 12

The following figure illustrates the configuration (indicated as Type a) for interrupt nodes 9 through 12, which are connected to the external interrupts EXINT3 through EXINT15. All interrupt sources connected to these nodes have the same configuration (Type a). These external interrupts do not have a separate interrupt enable control; instead, an event is disabled by selecting the '0'-input of its edge-detection multiplexer.

In order to clear the pending flag in the interrupt node, all associated status flags connected to that node must be cleared by software.

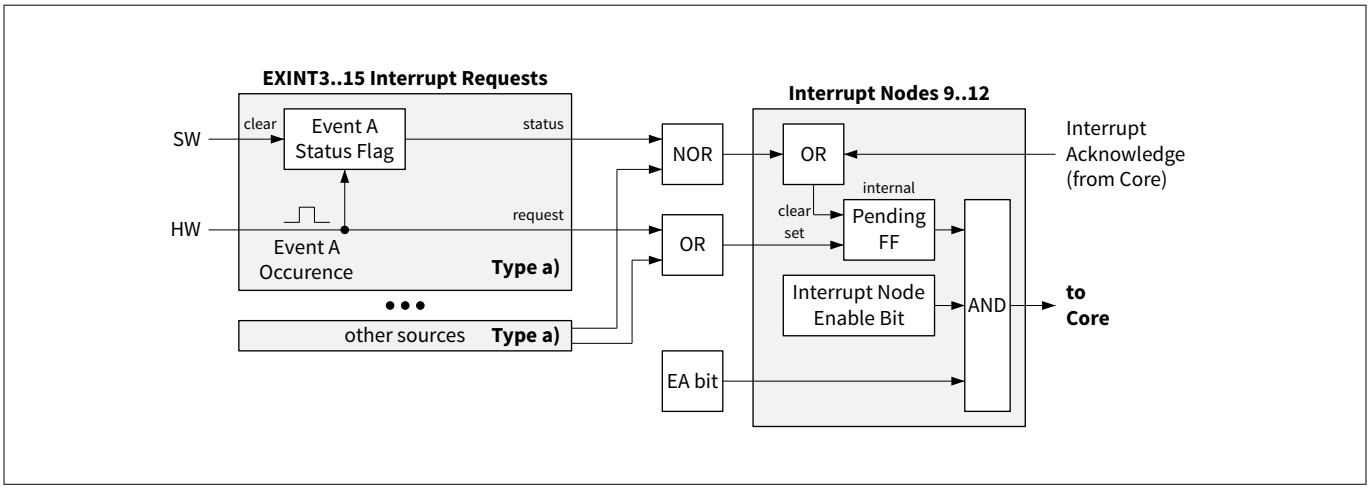

Figure 860 Interrupt structure 2 for nodes 9 through 12

Interrupt structure 2 for node 13

The following figure illustrates the configuration for interrupt node 13, which is solely connected to the RTCSCR interrupt source. Only the request line is enabled/disabled through the associated interrupt enable bit. This means, when disabling the interrupt source, the status bit needs to be cleared by software in order to be able to clear the pending flag in the interrupt node.

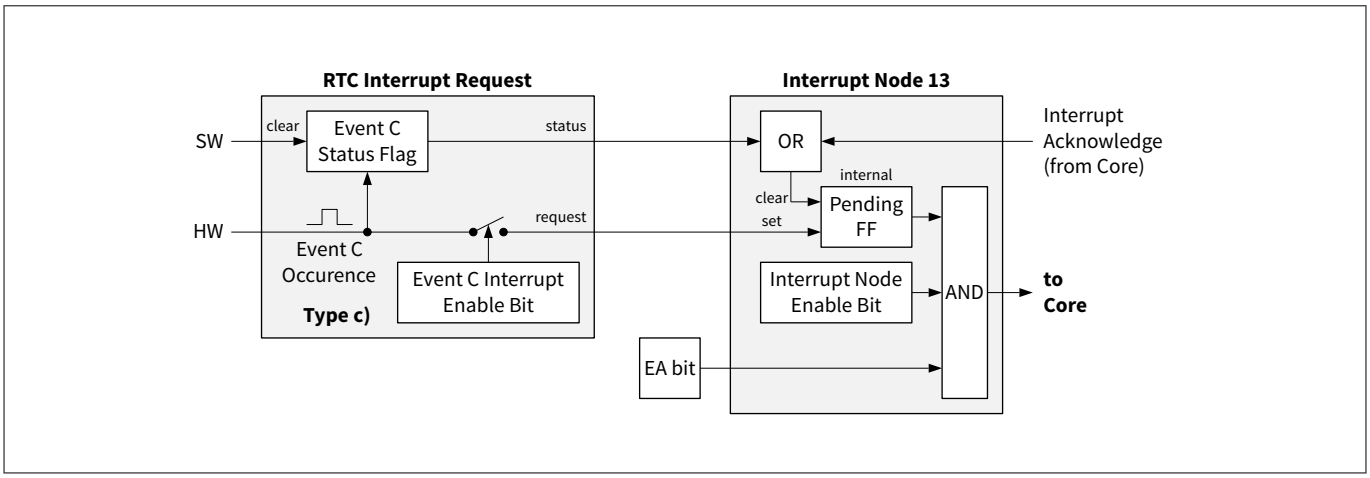

Figure 861 Interrupt structure 2 for node 13

39.3.5.3 Interrupt handling

The interrupt request signals are sampled at phase 2 in each CPU cycle. The sampled requests are then polled during the following CPU cycle. If one interrupt node request was active at phase 2 of the preceding cycle, the polling cycle will find it and the interrupt system will generate a LCALL to the node's service routine, provided this hardware-generated LCALL is not blocked by any of the following conditions:

1. An interrupt of equal or higher priority is already in progress
2. The current (polling) cycle is not in the final cycle of the instruction in progress
3. The instruction in progress is RETI or any write access to registers IEN0/IEN1, IP/IPH or IP1/IPH1

Any of these three conditions will block the generation of the LCALL to the interrupt service routine. Condition 2 ensures that the instruction in progress is completed before vectoring to any service routine. Condition 3 ensures that if the instruction in progress is RETI or any write access to registers IEN0/IEN1 or IP/IPH or IP1/

IPH1, then at least one more instruction will be executed before any interrupt is vectored to; this delay guarantees that changes of the interrupt status can be observed by the CPU.

The polling cycle is repeated with each CPU cycle, and the values polled are the values that were present at phase 2 of the previous CPU cycle. Note that if any interrupt flag is active but its node interrupt request was not responded to for one of the conditions already mentioned, and if the flag is no longer active at a later time when servicing the interrupt node, the corresponding interrupt source will not be serviced. In other words, the fact that the interrupt flag was once active but not serviced is not remembered. Every polling cycle interrogates only the pending interrupt requests.

The processor acknowledges an interrupt request by executing a hardware generated LCALL to the corresponding service routine. In some cases, hardware also clears the flag that generated the interrupt, while in other cases, the flag must be cleared by the user's software. The hardware-generated LCALL pushes the contents of the Program Counter (PC) onto the stack (but it does not save the PSW) and reloads the PC with an address that depends on the interrupt node being vectored to, as shown in the table 'Interrupt Vector Address' in related information.

Program execution returns to the next instruction after calling the interrupt when the RETI instruction is encountered. The RETI instruction informs the processor that the interrupt routine is no longer in progress, then pops the two top bytes from the stack and reloads the PC. Execution of the interrupted program continues from the point where it was stopped. Note that the RETI instruction is important because it informs the processor that the program has left the current interrupt priority level. A simple RET instruction resumes execution to the interrupted program, but it leaves the interrupt control system under the assumption that an interrupt is still in progress. In this case, no interrupt of the same or lower priority level will be acknowledged.

Related information

Interrupt source and vector of the SCR on page 6519

39.3.5.4 Interrupt response time

Due to an interrupt event of (the various sources of) an interrupt node, its corresponding request signal will be sampled active at phase 2 in every CPU cycle. The value is not polled by the circuitry until the next CPU cycle. If the request is active and conditions are right for it to be acknowledged, a hardware subroutine call to the requested service routine will be the next instruction to be executed. The call itself takes two CPU cycles. Therefore, a minimum of three complete CPU cycles will elapse from activation of the interrupt request to the beginning of execution of the first instruction of the service routine as shown in the following figure.

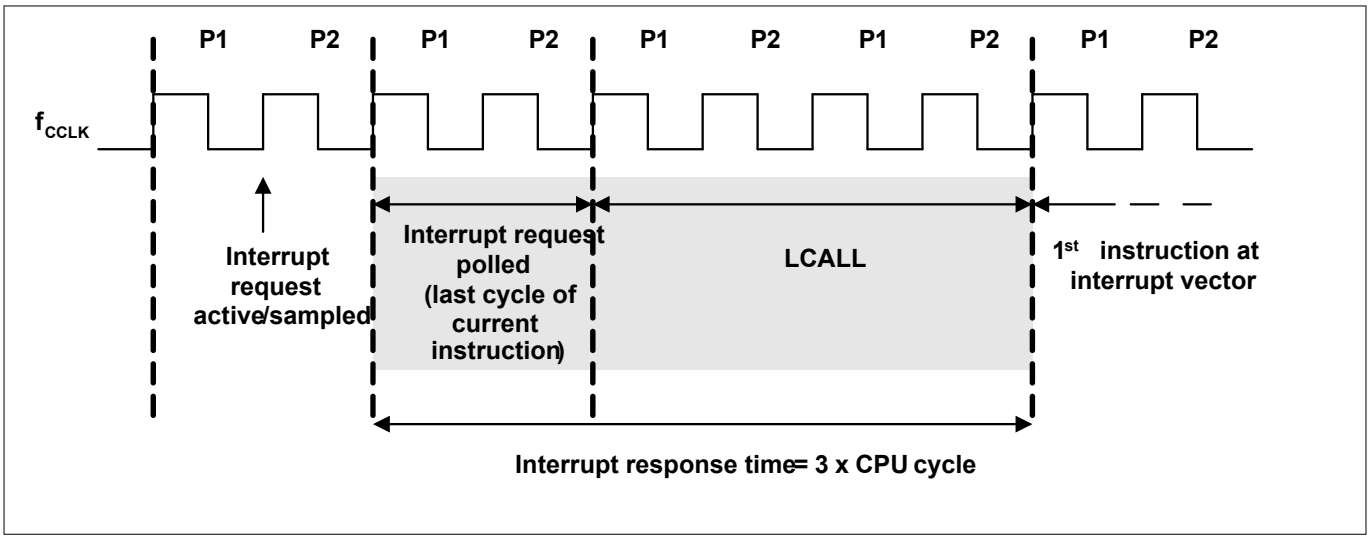

Figure 862 Minimum interrupt response time

A longer response time is obtained if the request is blocked by one of the three previously listed conditions:

1. If an interrupt of equal or higher priority is already in progress, the additional wait time will depend on the nature of the other interrupt's service routine
2. If the instruction in progress is not in its final cycle, the additional wait time cannot be more than three CPU cycles since the longest instructions (MUL and DIV) are only four CPU cycles long. See following figure
3. If the instruction in progress is RETI or a write access to registers IEN0, IEN1 or IP(H), IP1(H), the additional wait time cannot be more than five cycles (a maximum of one more CPU cycle to complete the instruction in progress, plus four CPU cycles to complete the next instruction, if the instruction is MUL or DIV). See figure 'Interrupt Response Time for Condition 3' below

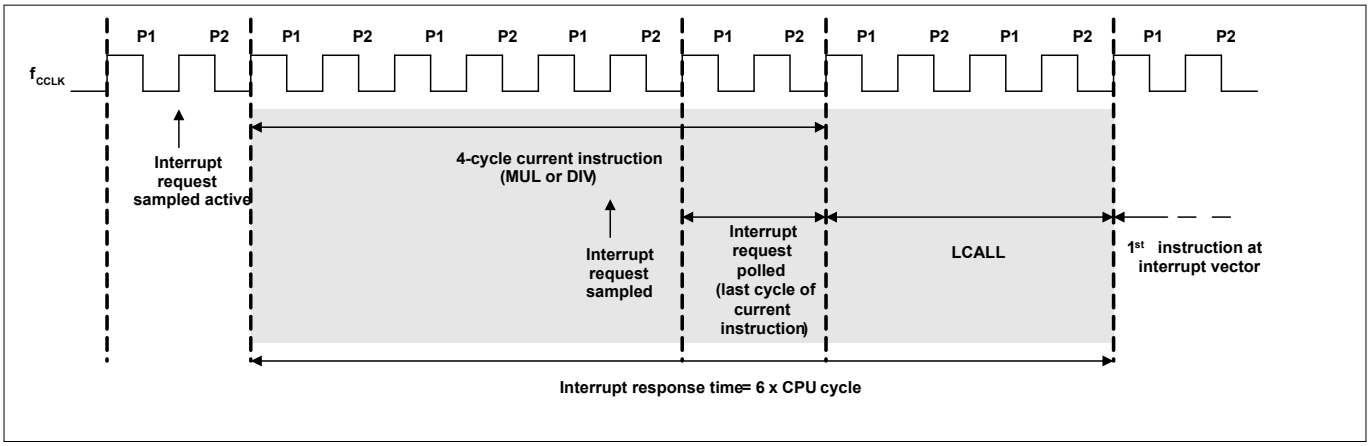

Figure 863 Interrupt response time for condition 2

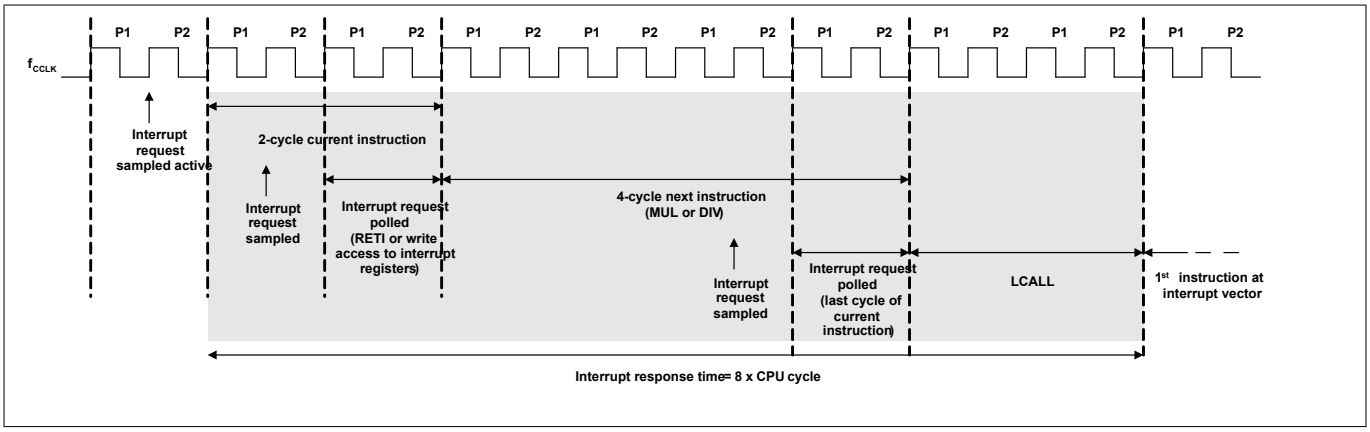

Figure 864 Interrupt response time for condition 3

Thus in a single interrupt system, the response time is always more than three CPU cycles and less than nine CPU cycles (wait states are not considered). When considering wait states, the interrupt response time will be extended depending on the user instructions (also the hardware generated LCALL) being executed during the interrupt response time (shaded region in the figures above).

39.3.5.5 Interrupts from or to TriCore™ CPUx

There is an interrupt signal from TriCore™ CPUx to trigger an SCR NMI event. It is triggered through PMS_SCR_CON1.TCINTREQ bit-field that is located in the PMS register space. The interrupt data exchange register, TCINTEXCHG, is used to indicate the additional message of events that causes this interrupt.

In SCR, there is also an interface to trigger interrupts to CPUx. This is done through bits IRSCR_NMICON.SCRINTTC0 and IRSCR_NMICON.SCRINTTC1 . The additional message of SCR events that causes this interrupt to CPUx can be stored in register SCRINTEXCHG. Interrupt triggered over IRSCR_NMICON.SCRINTTC0 is combined with other SCR-to-PMS interrupt sources (watchdog reset, ECC-error,

PIN-reset, Soft-reset) and routed to TriCore™ domain interrupt router. IRSCR_NMICON.SCRINTTC1 is assigned to a different PMS interrupt line to the main interrupt system. Having two separate interrupt lines to the main interrupt system allows configuring two different reactions – for example, one can be for error handling while other could trigger DMA transfers.

SCR software can send information to the TriCore™ domain through SCRINTEXCHG register. When written it will update the PMS_SCR_STAT.SCRINT bit-field. When read, the registerSCRINTEXCHG includes the data of the register PMS_SCR_CON1.TCINT as it is a virtual register. When IRSCR_NMICON.SCRINTTC0/1 are set, it will be cleared by the hardware with the next clock cycle.

To be able to issue an SCR NMI interrupt, the SCR has to be enabled, as well as respective NMI interrupt. It is set on the edge of the request. When PMS_SCR_CON0.SCREN=0 (SCR is not enabled), write access to PMS_SCR_CON1 register is blocked. (A trap will be generated.) It is not possible to request an interrupt of SCR from TC while SCR is not enabled. In addition to TCINTREQ, SCR NMI can be triggered from the TriCore™ domain, if it gets an SMU reset or an Application reset.

Interrupts triggered by the SCR to the TriCore™ domain have the following limitations:

- Interrupts triggered by the SCR in power down are lost for the TriCore™ domain
- Interrupts during an ongoing reset of the TriCore™ domain are delayed and applied as soon as the TriCore™ domain can service it

39.3.5.6 Registers overview

"Interrupt Special Function" Registers or bits are used for interrupt configuration such as node enable, external interrupt control, interrupt flags and interrupt priority setting.

The table below lists the SFRs and corresponding addresses.

Table 1691 Register map

Interrupt node enable registers

Each interrupt node can be individually enabled or disabled by setting or clearing the corresponding bit in the interrupt enable registers IEN0 and IEN1. Register IEN0 also contains the global interrupt masking bit (EA), which can be cleared to block all pending interrupt requests at once.

The NMI interrupt vector is shared by a number of sources, each of which can be enabled or disabled individually through register IR_NMICON.

After reset, the enable bits in IEN0, IEN1 and IR_NMICON are cleared to 0. This implies that all interrupt nodes are disabled by default.

External interrupt control registers

The 16 external interrupts, EXINT[15:0], are driven into the SCR from the ports. The external interrupt pin assignment for SCR is shown in the table below. Each external interrupt can be positive, negative, or double-edge triggered. Registers IR_EXICON0 through IR_EXICON3 specify the active edge for an external interrupt. Among the external interrupts, external interrupt 0 and external interrupt 1 can be selected to bypass edge detection for direct feed-through to the core. The signal to the core can be further programmed to either low-level or negative transition activated, by bits T01_TCON.IT0 and T01_TCON.IT1. However, for edge detection in IR, T01_TCON.IT0/1 must be set to falling edge triggered. A detected active edge event will generate internally two CCLK cycle low pulse for detection by the core.

If the external interrupt is positive (negative) edge triggered, the external source must hold the request pin low (high)for at least one CCLK cycle, and then hold it high (low) for at least one CCLK cycle to ensure that the transition is recognized (detection is done in the interrupt module outside of the core). If edge detection is bypassed for external interrupt 0 and/or external interrupt 1, the external source must hold the request pin “high” or “low” for at least two CCLK cycles (detection is done inside of the core) In the core there are two configuration possibilities:

T01_TCON.IT[0,1] = 0: low level triggered external interrupt is selected. In this case the request pin must be "low" until the interrupt is detected.

T01_TCON.IT[0,1] = 1: falling edge triggered external interrupt is selected. In this case the external source must hold the requested pin "high" or "low" for at least two CCLK cycles.

External interrupts 2 to 15 share 5 interrupt nodes. Therefore, in addition to the corresponding interrupt node enable, each external interrupt 2 to 15 may be disabled individually; they are disabled by default after reset.

***Note**: Several external interrupts support alternative input signals. When switching inputs, the active edge/ level trigger select and the level on the associated pins should be considered to prevent unintentional interrupt generation.*

The following figures show block diagrams and connection overviews of External Interrupts 0 through 15. EXINT7 has only single input so there are no respective PISEL bits and multiplexer.

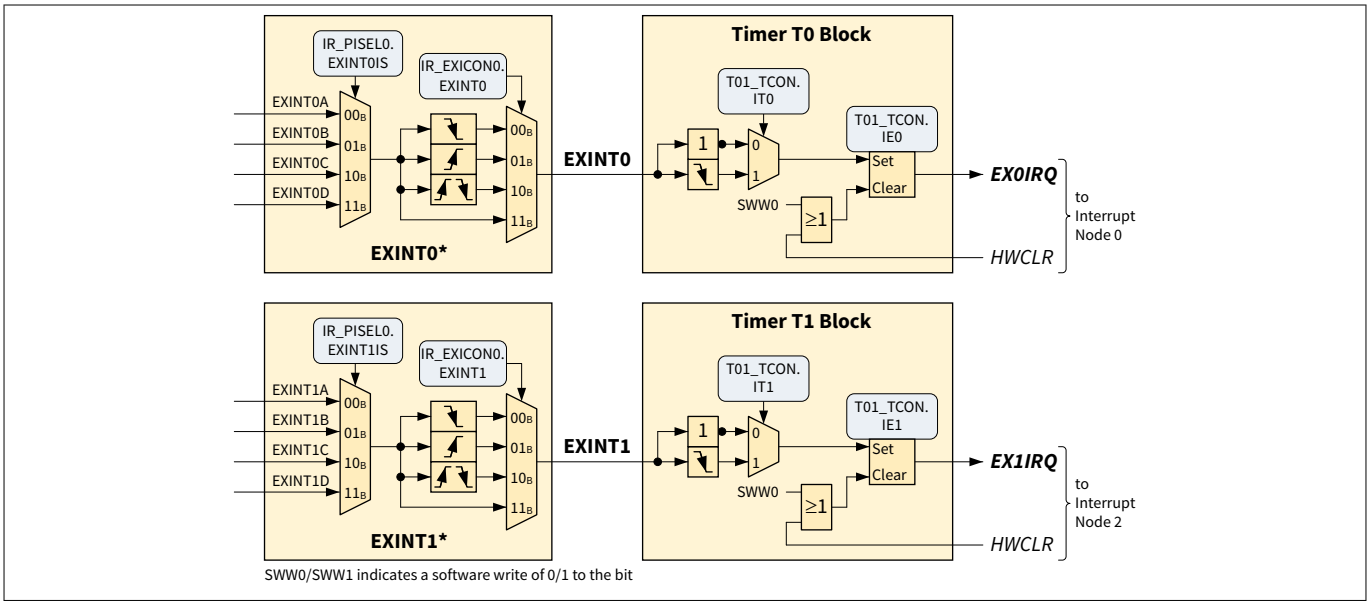

Figure 865 Block diagram and connections of external interrupts EXINT0 and EXINT1

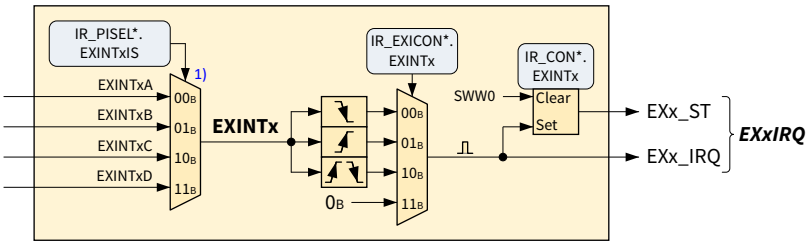

SWW0 indicates a software write of 0 to the bit

Note 1) EXINT7 has only 1 input and no PISEL multiplexer

Figure 866 Generic block diagram of external interrupts EXINT2 through EXINT15. EXINT7 has 1 input and all other have 4 inputs (A-D)

Interrupt flag registers

The interrupt flags for the different interrupt sources are located in several "Special Function Registers". In case of software and hardware access to a flag bit at the same time, hardware will have higher priority.

***Note**: NMISTAT register can only be cleared by software or reset to 0 after a generated SCR_RESET.*

Interrupt priority registers

Each interrupt node can be individually programmed to one of the four priority levels available. Two pairs of Interrupt Priority Registers are available to program the priority level of the each interrupt vector. The first pair of Interrupt Priority Registers are SFRs IP and IPH. The second pair of Interrupt Priority Registers are SFRs IP1 and IPH1.

The corresponding bits in each pair of Interrupt Priority Registers select one of the four priority levels as shown in table below.

Table 1693 Interrupt priority level selection

IPH.x/IPH1.x	IP.x/IP1.x	Priority level
0	0	Level 0 (lowest)
0	1	Level 1
1	0	Level 2
1	1	Level 3 (highest)

***Note**: NMI always has the highest priority (above Level 3); it does not use the priority level given in table above.*

Interrupt event enable control

The five interrupt events of SSC module are of interrupt structure 2. As there is no enable/disable bit(s) for these interrupt events within the module, bits are defined in the IR register IR_MODIEN to provide for this purpose. Also modules like ADCOMP, PMS RTC CMPn are of interrupt structure 2 and their bits are available in the above mentioned register.

Interrupt data exchange register

Two registers are used to exchange interrupt data between main controller and SCR as described in related information.

39.3.6 Watchdog timer (WDTSCR)

39.3.6.1 Overview

The Watchdog timer (WDTSCR) provides a highly reliable and secure way to detect and recover from software or hardware failures. The WDTSCR is reset at a regular interval that is predefined by the user. The CPU must service the WDTSCR within this interval to prevent the WDTSCR from causing generated reset. The routine service of the watchdog confirms that the system is functioning properly. This ensures that an accidental malfunction of the SCR will be aborted in a user-specified time period. The WDTSCR reset is default enabled. It can also be disabled through RSTCON register.

The WDTSCR is by default disabled through SCUSCR_PMCON0.WDT_DIS.

In debug mode, the watchdog is default suspended and stops counting. Its debug suspend bit is default set for example, SCR_SCUSCR_DBG_MODSUSP.WDTSUSP=1. Therefore during debugging, there is no need to refresh the watchdog.

Features

- 16-bit Watchdog timer
- Programmable reload value for upper 8 bits of timer
- Programmable window boundary
- Clock source from either the 70 kHz clock or the 100 MHz/DIV clock
- Selectable input frequency of $f_{WDTCLK}/2$ or $f_{WDTCLK}/128$

39.3.6.2 System information

This section consist of the system information required to use the WDTSCR.

39.3.6.2.1 Reset effects

The Watchdog Timer maintains a counter which must be refreshed or cleared periodically. Otherwise, the counter will overflow and the watchdog reset will be asserted. The assertion of the reset could be disabled by setting bit RSTCON.WDTRSTEN. The occurrence of a WDTSCR reset is indicated by the bit SCUSCR_RSTSTAT.WDTRST.

39.3.6.2.2 Clocking configuration

The WDT runs on either the 70 kHz clock or the 100 MHz/DIV clock. Bit WDTSCR_CON.WDTCLK is used to select the watchdog clock source, f_{WDTCLK}.

39.3.6.2.3 Interrupt events and assignment

The following table shows the non-maskable interrupt node assignment of the WDTSCR interrupt source.

Table 1695 WDTSCR events' non-maskable interrupt node control

Event	Interrupt node enable bit	Interrupt node flag bit	Vector address
WDTSCR Overflow	IRSCR_NMICON.NMIWDT	IRSCR_NMISTAT.FNMIWDT	73_H

39.3.6.2.4 Module suspend control

The timer in the WDTSCR is by default suspended on entering debug mode. The WDTSCR can be allowed to run in debug mode by clearing the bit MODSUSP.WDTSUSP to 0. Refer to the definition of register MODSUSP.

39.3.6.3 Functional description

The Watchdog Timer (WDTSCR) is a 16-bit timer, which is incremented by a count rate of $f_{WDTSCRCLK}/2$ or $f_{WDTSCRCLK}/128$. The f_{WDTCLK} clock input is selectable between the 70 kHz clock or the 100 MHz/DIV (PCLK, f_{SYS}) clock using the WDTCLK bit. This 16-bit timer is realized as two concatenated 8-bit timers. The upper 8 bits of the WDTSCR can be preset to a user-programmable value through a watchdog service access in order to vary the watchdog expire time. The lower 8 bits are reset on each service access. Next figure shows the block diagram of the WDTSCR unit.

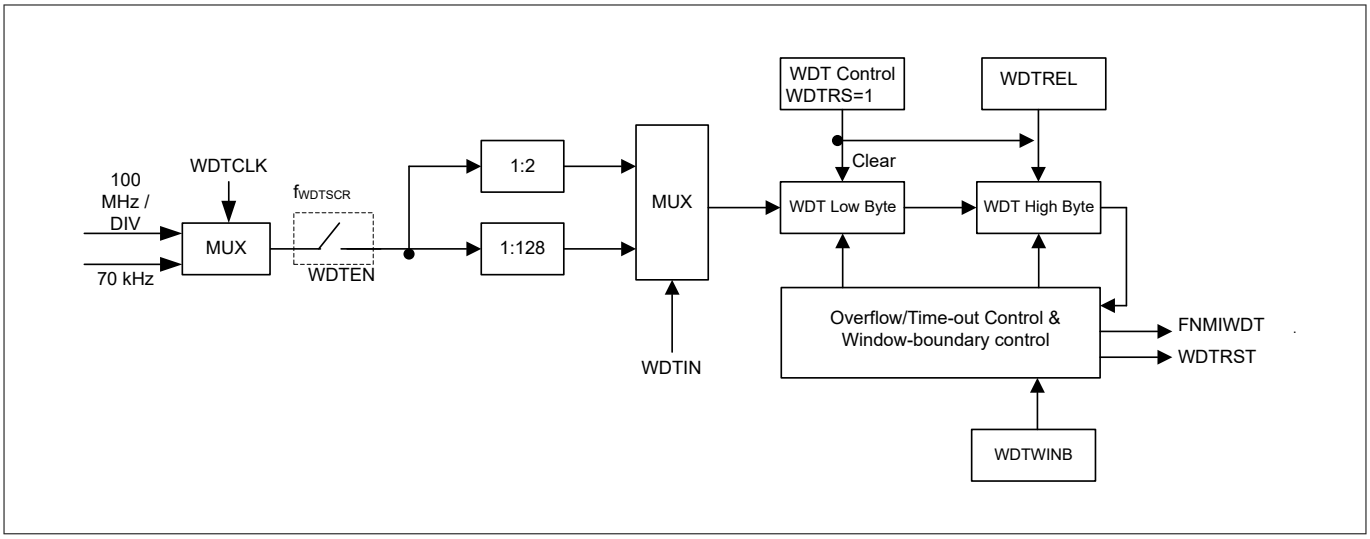

Figure 867 WDTSCR block diagram

***Note**: WDT is WDTSCR*

If the WDTSCR is enabled by setting WDTEN to 1, the timer is set to a user-defined start value (WDTSCR_REL) and begins counting up. It must be serviced before the counter overflows. Servicing is performed through refresh operation (setting bit WDTRS to 1, shown as WDT Control inside the graphic above). This reloads the timer with the start value, and normal operation continues.

If the WDTSCR is not serviced before the timer overflows, a system malfunction is assumed and normal mode is terminated. A WDTSCR NMI request (FNMIWDT) is then asserted and pre-warning is entered. The pre-warning lasts for 20_H count. During the pre-warning period, refreshing of the WDTSCR is possible in order to avoid WDTSCR generated reset. If WDTSCR is not refreshed before expiry of a pre-warning phase, a reset (WDTRST) of the SCR is imminent (if it is enabled by bit SCUSCR_RSTCON.WDTRSTEN). The occurrence of a WDTSCR reset is indicated by the bit SCUSCR_RSTSTAT.WDTRS. If refresh happens at the same time an overflow occurs, WDTSCR will not go into pre-warning period.

***Note**: In the SCR, it is possible to wake-up the main controller from standby mode when the WDTSCR overflow event happened by setting bit SCUSCR_WKPCON.WDTWKSEL to 1.*

The WDTSCR must be serviced periodically so that its count value will not overflow. Servicing the WDTSCR clears the low byte and reloads the high byte with the preset value in bit-field WDTREL. Servicing the WDTSCR also clears the bit WDTRS.

The WDTSCR has a “programmable window boundary”, which disallows any refresh during the WDTSCR’s count-up. A refresh during this window-boundary constitutes an invalid access to the WDTSCR and causes the WDTSCR to activate WDTRST, although no NMI request is generated in this instance. The window boundary is from 0000_H to the value obtained from the concatenation of WDTSCR_WINB and 00_H. This feature can be enabled by WINBEN.

After being serviced, the WDTSCR continues counting up from the value (<WDTREL> * 2^8). The time period for an overflow of the WDTSCR is programmable in two ways:

- The input frequency to the WDTSCR can be selected through bit WDTIN in register WDTSCR_CON to be either $f_{WDTCLK}/2$ or $f_{WDTCLK}/128$
- The reload value WDTREL for the high byte of WDTSCR can be programmed in register WDTSCR_REL

The period P_{WDTSCR} between servicing the watchdog and the next overflow can be determined by the following formula:

$$P_{WDT} = \frac{2^{(1+ <WDTIN> *6)} * \left(2^{16} - WDTREL * 2^{8}\right)}{f_{PCLK}}$$

If the Window-Boundary Refresh feature of the WDTSCR is enabled, the period during which a refresh is allowed is shortened if WDTSCR_WINB is greater than WDTSCR_REL. See also following figure. This period can be calculated by the same formula by replacing WDTSCR_REL WDTSCR_WINB. In order for this feature to be useful, WDTSCR_WINB cannot be smaller than WDTSCR_REL.

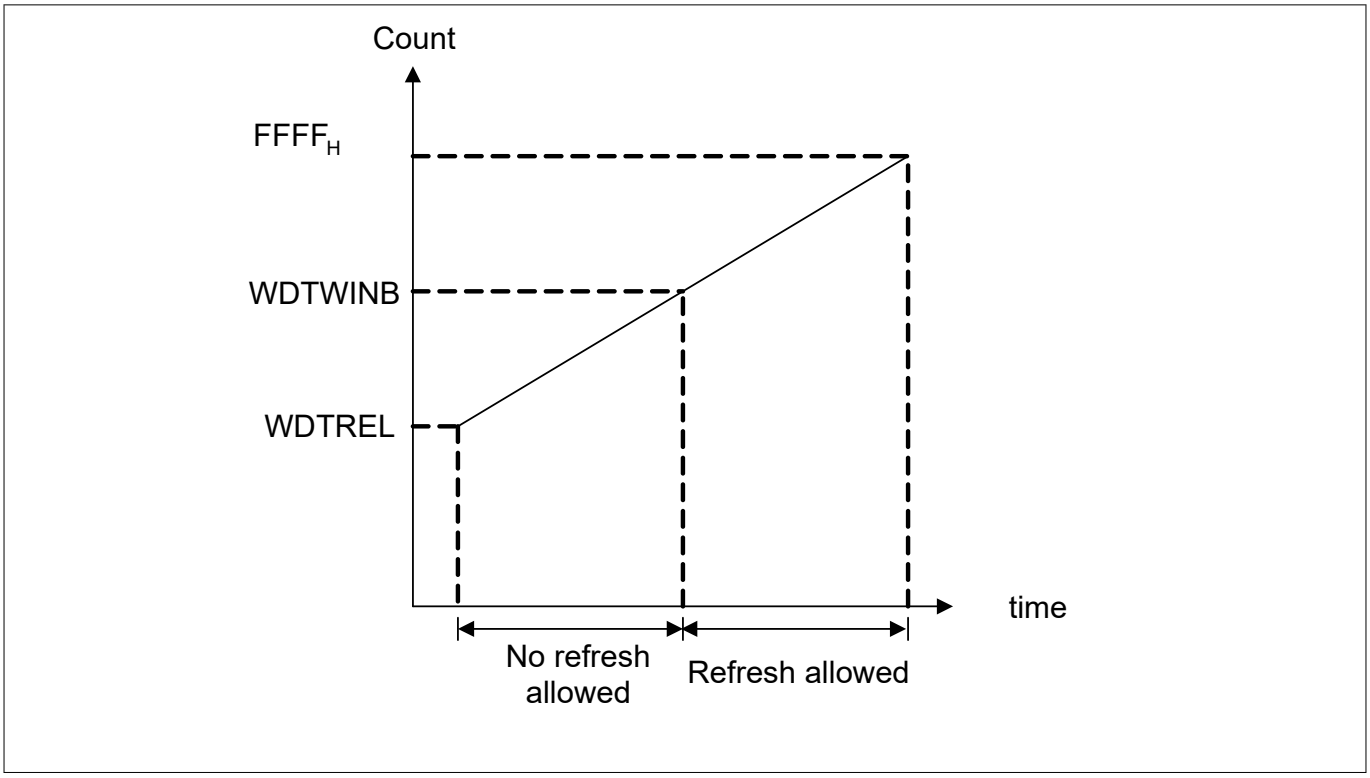

Figure 868 Watchdog timing diagram

Following table lists the possible ranges for the watchdog time which can be achieved using a certain module clock. Some numbers are rounded down to 2 significant digits.

Table 1696 Watchdog time ranges

Reload value in WDTREL	pre-scaler for f_{WDT}					
	2 (WDTIN=0)			128 (WDTIN=1)		
	20 MHz	100 MHz	70 kHz	20 MHz	100 MHz	70 kHz
FF_H	25.6 µs	5.12 µs	7.31 ms	1.63 ms	327.68 µs	486.11 ms
$7F_H$	3.3 ms	660.48 µs	943.54 ms	211.35 ms	42.27 ms	60.38 s
00_H	6.55 ms	1.31 ms	1.87 s	419.43 ms	83.88 ms	119.83 s

***Note**: The user is advised to rewrite WDTSCR_CON each time before the WDT is serviced.*

39 Stand-by Controller (SCR)

The Watchdog Timer Current Count Value is contained in the Watchdog Timer Register WDTSCR_H and WDTSCR_L, which are non-bit-addressable read-only register. The operation of the WDT is controlled by WDT Control Register WDTSCR_CON. This register also selects the input clock pre-scaling factor. The register WDTSCR_REL specifies the reload value for the high byte of the timer. WDTSCR_WINB specifies Watchdog Window-Boundary count value.

39.3.7 General purpose I/O Ports (PORT8)

The SCR has up to 32 general purpose I/O ports with 8-bit peripheral I/O lines that are shared with the 32-bit peripheral I/O lines. It is organized into four parallel ports. Internally within the SCR, these ports are always referred to as SCR_P0-SCR_P3. Same pads are mapped to pins in ports P32, P33, P34 and P35 of the TriCore™ domain. This particular pin assignment of these functions is shown in next table:

Table 1697 Pin assignment for ports in SCR

SCR Ports/pins	TriCore™ domain ports/pins
SCR_P0.0-SCR_P0.7	P33.0-P33.7
SCR_P1.0-SCR_P1.7	P33.8-P33.15
SCR_P2.0-SCR_P2.7	P32.2,P32.4-7,P35.0-2
SCR_P3.0-SCR_P3.7	P34.1-P34.5,P35.3-5

***Note**: Not all pins described in this chapter might be available for a specific device and package.*

During RUN mode, if SCR is enabled, the control of these shared Pads can be switched between SCR and the TriCore™ domain through 32-bit Ports register PCSRSEL in combination with SCREN value. If SCR is enabled, the shared Pads are controlled by the SCR after an Application reset (see default value of PCSRSEL). If SCR is disabled, independent from respective PCSRSEL settings, the 32-bit Ports module has the control over shared Pads.

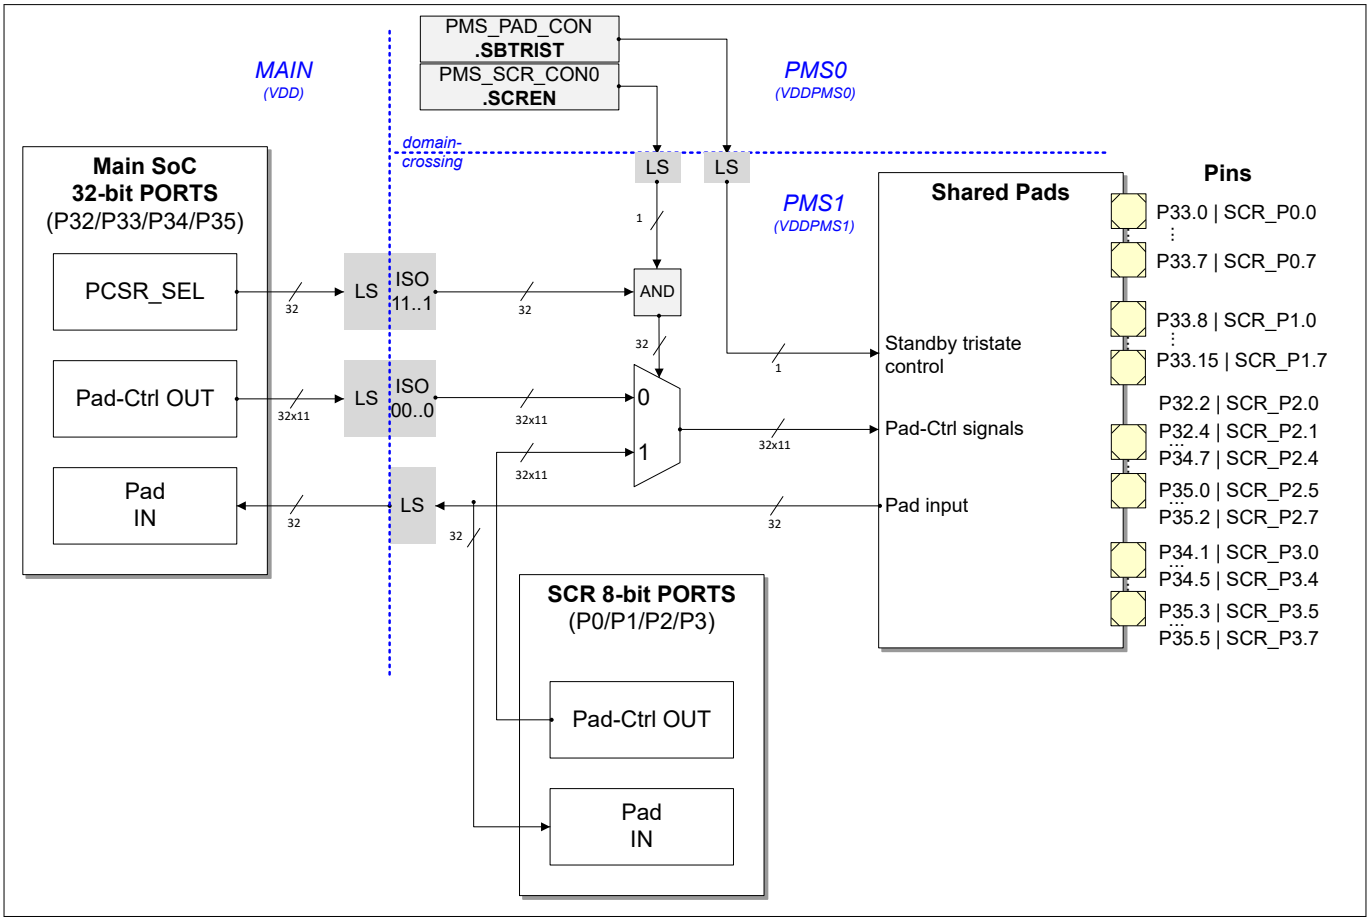

Figure 869 Block diagram for shared pads

After initial TC4xx start-up, the default value of "SCR enable signal" (PMS_SCR_CON0.SCREN) is '0'. Despite the value of PCSRSEL='1' the shared pads are in control of the TriCore™ domain 32-bit Ports module because SCR is not enabled. Dynamics of shared Pads control in different modes is shown in figure below.

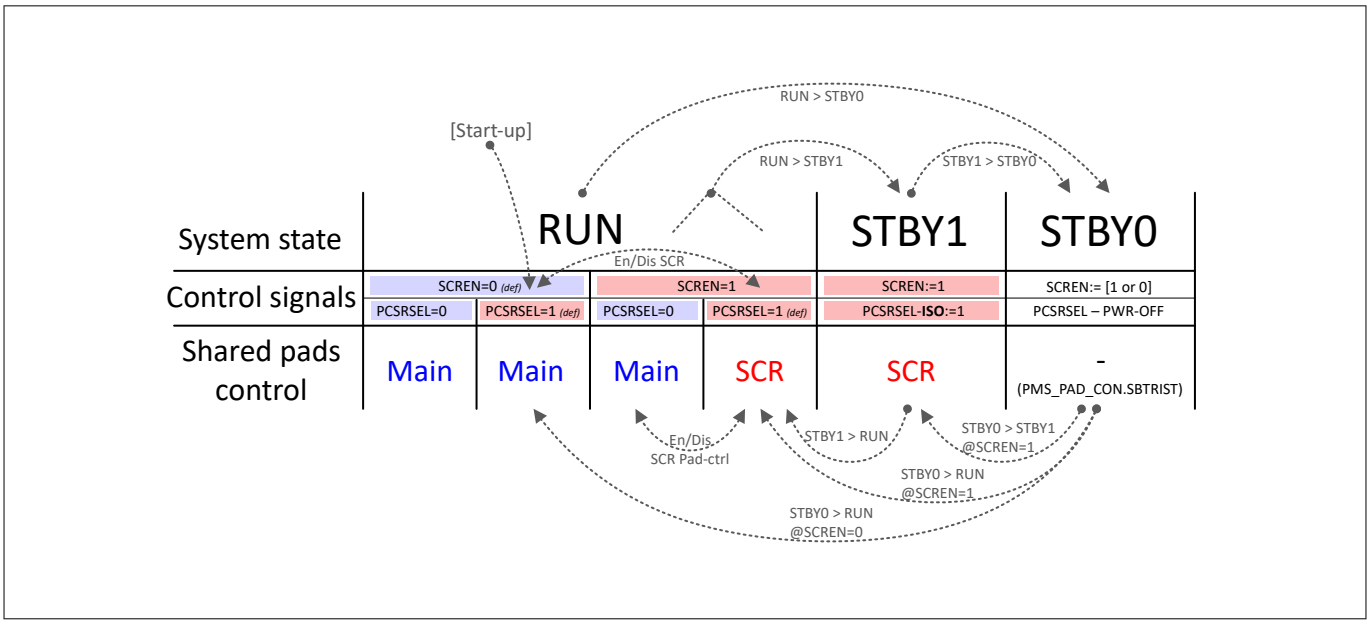

Figure 870 Dynamics of shared pads control

After start-up, and after enabling SCR all shared pads are under SCR control. Like this the system could transition from RUN into STANDBY1 mode and shared pads will remain under SCR control. After wake-up from STANDBY1 to RUN mode, the shared pads will always be controlled by SCR until software on TriCore™ domain takes control by either disabling SCR or by clearing PCSRSEL to 0.

In cases where system transitions from RUN to STANDBY0 mode, since neither 32-bit ports nor 8-bit ports are powered during STANDBY0, shared pads will take value as specified in PMS_PAD_CON.SBTRIST. On return from STANDBY0 to RUN, shared pads will be under SCR control if SCREN=1 or under TriCore™ domain control if SCREN=0. Similarly, transitions between STANDBY1 and STANDBY0 mode transfer the pad control between SCR and tri-state. For these transitions, special care was taken to avoid glitches.

Following timing diagram illustrates how can ownership of shared pads be exchanged between TriCore™ domain, SCR and tri-state. It shows which events lead to change of shared pads control.

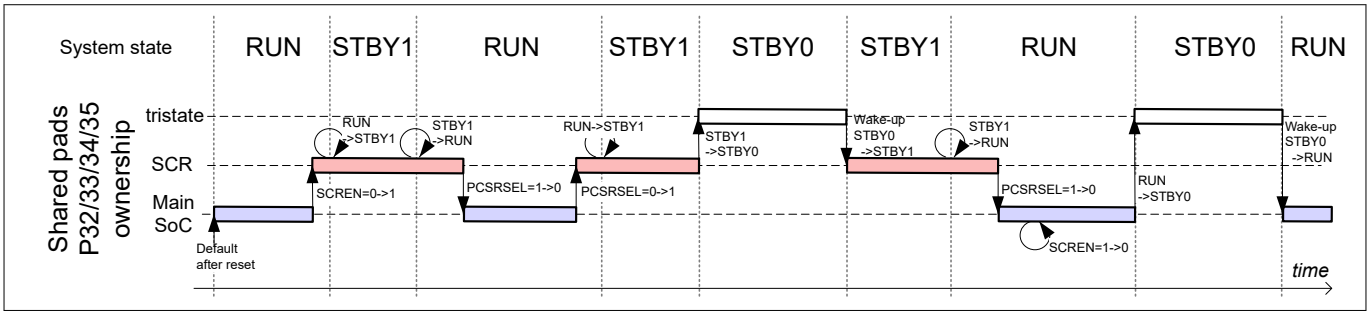

Figure 871 Shared pads control, timing diagram

***Note**: Each change of control between SCR and TriCore™ domain could lead to a sudden change of Pad configuration. Special care must be taken in TriCore™ domain code to avoid undesired transitions which could lead to glitches on shared Pads outputs.*

39.3.7.1 Basic port operation

Following figure illustrates a general block diagram of an SCR GPIO port slice.

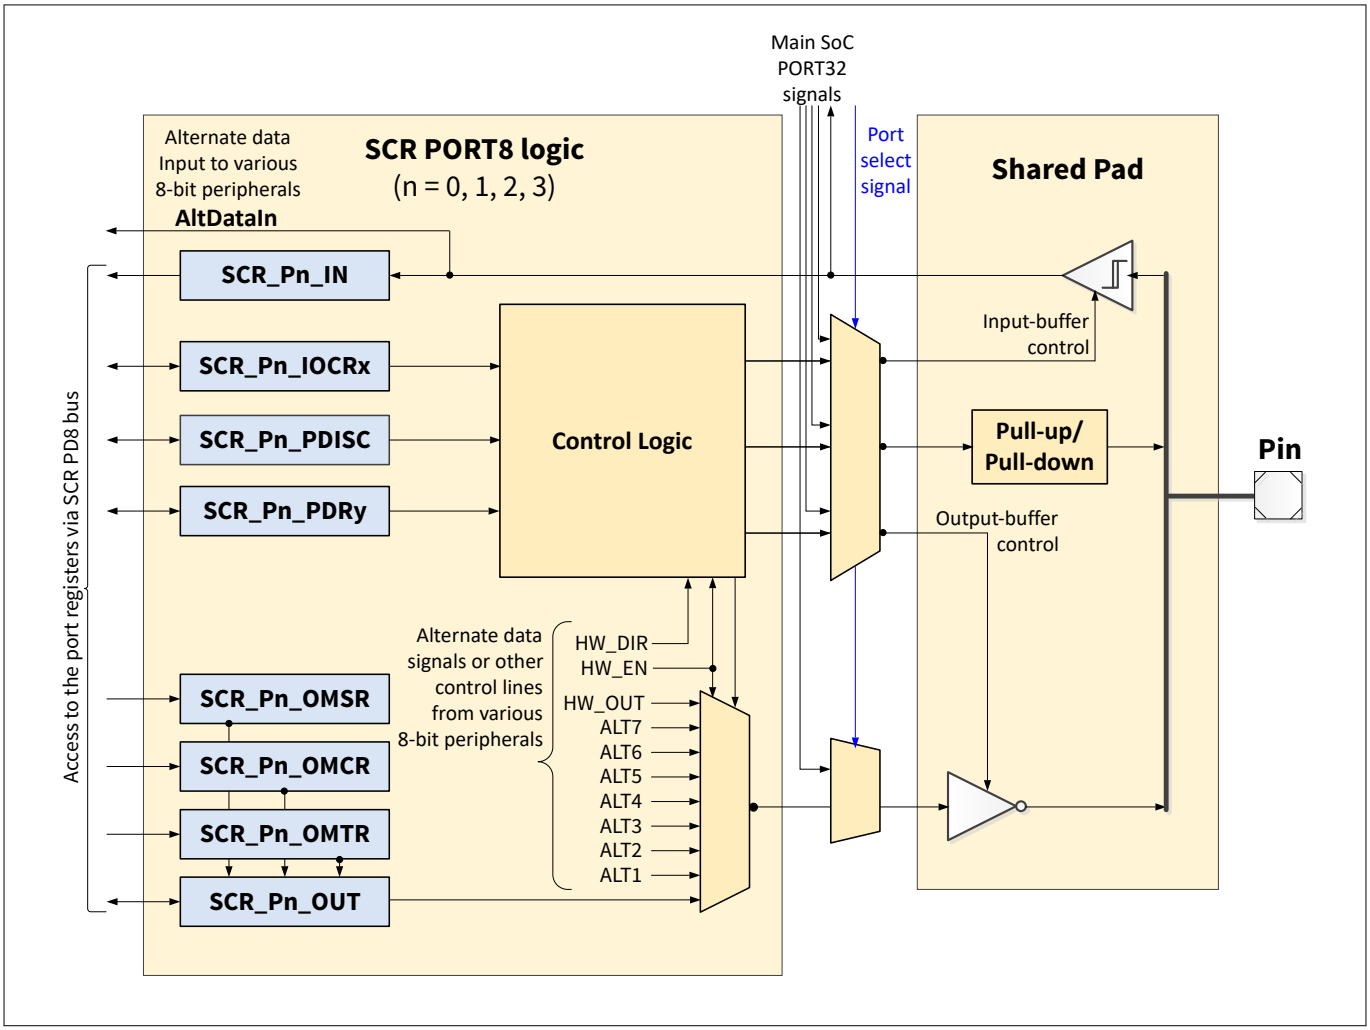

Figure 872 General structure of an SCR Port pin

Each port line has a number of control and data bits, enabling very flexible usage of the line. Each port pin can be configured for input or output operation. In input mode (default after reset), the output driver is switched off (high-impedance). The actual voltage level present at the port pin is translated into a logical 0 or 1 via a Schmitt-Trigger device and can be read via the read-only register SCR_Pn_IN (n=0, 1, 2, 3). Input signals are connected directly to the various inputs of the peripheral units (AltDataIn). The function of the input line from the pin to the input register SCR_Pn_IN and to AltDataIn is independent of whether the port pin operates as input or output.

This means that when the port is in output mode, the level of the pin can be read by software via SCR_Pn_IN or a peripheral can use the pin level as an input.

In output mode, the output driver is activated and drives the value supplied through the multiplexer to the port pin. Switching between input and output mode is selected through the SCR_Pn_IOCR register, which enables or disables the output driver. If a peripheral unit uses a GPIO port line as a bi-directional I/O line, register SCR_Pn_IOCR has to be written for input or output selection. The SCR_Pn_IOCR register further controls the driver type of the output driver, and determines whether an internal weak pull-up, pull-down, or without input pull device is alternatively connected to the pin when used as an input. This offers additional advantages in an application.

The output multiplexer in front of the output driver selects the signal source for the GPIO line when used as output. If the pin is used as general-purpose output, the multiplexer is switched by software (SCR_Pn_IOCR

register) to the Output Data Register SCR_Pn_OUT. Software can set, clear, or toggle the bit in SCR_Pn_OUT through separate SCR_Pn_OMSR, SCR_Pn_OMCR, or SCR_Pn_OMTR registers. The manipulation of the control bits in these registers can directly influence the state of the port pin. If the on-chip peripheral units uses the pin for output signals, the alternate output lines ALT1 to ALT7 can be switched via the multiplexer to the output driver. The data written into the output register SCR_Pn_OUT by software can be used as input data to an on-chip peripheral. This enables, for example, peripheral tests via software without external circuitry.

When selected as general-purpose output line, the logic state of each port pin can be changed individually by programming the pin-related bits in the Output Modification Set Register SCR_Pn_OMSR, Output Modification Clear Register SCR_Pn_OMCR, or the Output Modification Toggle Register SCR_Pn_OMTR.

When selected as general-purpose output line, the actual logic level at the pin can be examined through reading SCR_Pn_IN and compared against the applied output level (either applied through software via the output register SCR_Pn_OUT, or via an alternate output function of a peripheral unit). This can be used to detect some electrical failures at the pin caused through external circuitry. In addition, software-supported arbitration schemes can be implemented in this way using the open-drain configuration and an external wired-And circuitry. Collisions on the external communication lines can be detected when a high level (1) is output, but a low level (0) is seen when reading the pin value via the input register SCR_Pn_IN.

39.3.7.2 Port register overview

The individual control and data bits of each parallel port are implemented in a number of 8-bit registers. Bits with the same meaning and function are assembled together in the same register. The registers configure and use the port as general purpose I/O or alternate function input/output. For some ports, not all registers are implemented. The availability of the registers in the specific ports is described separately. The definition of these registers are similar to the 32-bit format.

The registers are shown below.

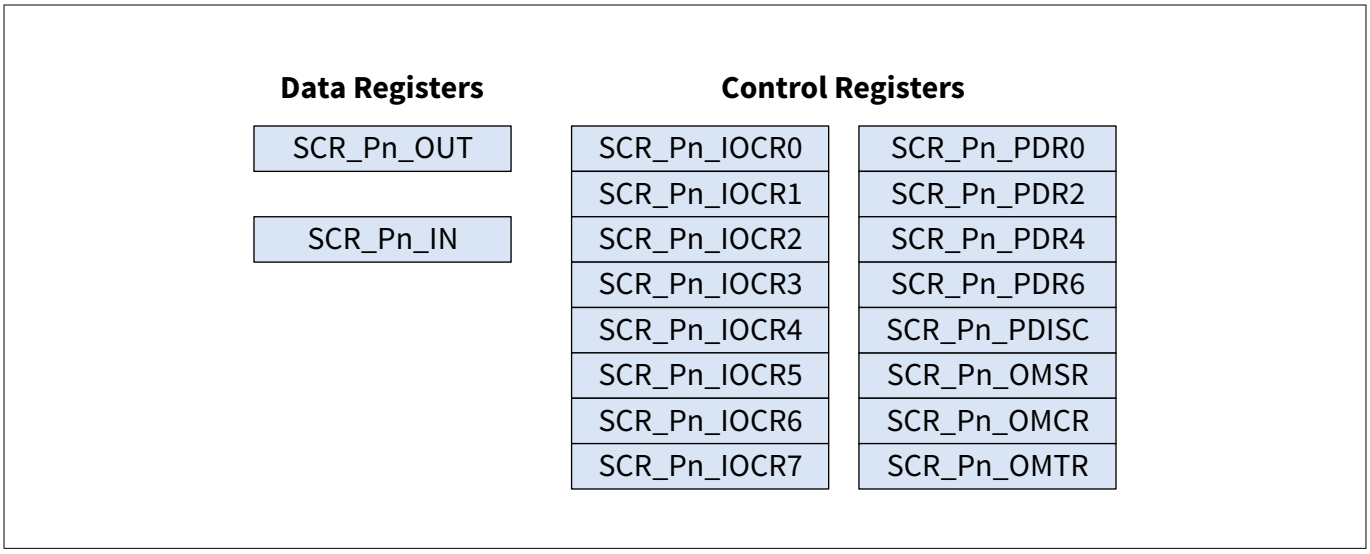

Figure 873 SCR port registers

The Port SFRs are located in the standard memory area (RMAP=0).

39.3.7.2.1 Port input/output control registers

The port input/output control registers select the digital output and input driver functionality and characteristics of a GPIO port pin. Port direction (input or output), pull-up, pull-down, or no pull devices for inputs, and push-pull or open-drain functionality for outputs can be selected by the corresponding bit field PC.

Each 8-bit wide port input/output control register controls one GPIO port line, for example, register SCR_P0_IOCR0 controls the SCR_P0.0 (P33.0) port line, register SCR_P1_IOCR0 controls the SCR_P1.0 port line (P33.8), register SCR_P3_IOCR4 controls the SCR_P3.4 (P34.5) port line.

The pictures below show the register layouts of the port input/output control registers with the PCm bit fields. One PCm bit field controls exactly one port line Pn.m.

***Note**: The post-reset values of 10_H and 00_H for SCR_Pn_IOCRm registers represents input pull-up and no input pull device (tri-state mode) being activated, respectively. The switching of the intended mode of the device is controlled by HWCFG6 and PMS_PAD_CON.SBTRIST. This values are applied after each SCR reset.*

Port control coding

Following table describes the coding of the PCm bit fields that determine the port line functionality.

Table 1698 PCm coding

PCm[4:0]	I/O	Output characteristics	Selected pull-up/pull-down/ selected output function
$0XX00_B$	Input		No input pull device connected, tri-state mode
$0XX01_B$			Input pull-down device connected
$0XX10_B$			Input pull-up device connected
$0XX11_B$			No input pull device connected, tri-state mode
10000_B	Output	Push-pull	General-purpose output

39.3.7.2.2 Pad driver mode register

Overview

The pad structure of the SCR GPIO lines offers the possibility to select the output driver strength and the slew rate. These two parameters are controlled by the PDm bit fields in the pad driver mode registers Pn_PDR0y (y=0, 2, 4, 6), independently from input/output and pull-up/pull-down control functionality as programmed in the Pn_IOCR register. SCR_Pn_PDRy registers are assigned to each port.

The assignment of each port pin to one of these pad classes is shown in the port configuration figures. Further details about pad driver classes that are available in the TC4Dx are summarized in the datasheet.

Depending on the assigned pad class, the 3-bit wide pad driver mode selection bit fields PDm in the pad driver mode registers SCR_Pn_PDRy make it possible to select the port line functionality as shown in the tables below.

Table 1699 Pad driver mode selection - Fast pads

PDm.1	PDm.0	Speed grade	Driver setting
0	0	1	Strong Driver, Sharp Edge (“ss”)

(table continues...)

Table 1699 (continued) Pad driver mode selection - Fast pads

PDm.1	PDm.0	Speed grade	Driver setting
0	1	2	Strong Driver, Medium Edge (“sm”)
1	X	3	Medium Driver (“m”)

Table 1700 Pad driver mode selection- slow pads

PDm.1	PDm.0	Speed grade	Driver setting
X	0	1	Medium Driver, Sharp Edge (“sm”)
X	1	2	Medium Driver (“m”)

***Note**: TC4Dx data-sheet describes the DC characteristics of all pad classes.*

TTL/Automotive input selection

The input function can operate with different VIH and VIL levels depending on the pad supply voltage and the selection done by the PLx bits of the Pn_PDRx registers, as shown in the following table.

PLx.1 additionally also changes the pull-up and pull-down resistors.

Table 1701 Pad level selection

PLx.1	PLx.0	Input levels
0	X	Automotive level “AL”
1	0	TTL level for 5V supply
1	1	TTL level for 3.3V supply

Pad driver mode registers

This is the general description of the PDR registers. Each port contains its own specific PDR registers, described additionally at each port, that can contain between one and eight PDm fields for SCR_Pn_PDRy y (y=0, 2, 4, 6) registers, respectively. Each PDm field controls one pin. For coding of PDm, see 'Pad Driver Mode Selection' tables. Similarly, each PLx bit controls one pin. For coding of PLx, see table above.

39.3.7.2.3 Pin function decision control register

The pad structure of the SCR GPIO lines offers the possibility to disable/enable port pad or select digital input. For the selection of digital input, the parameters defined for Class S pads must be met. This feature can be controlled by individual bits in the SCR_Pn_PDISC register, independently from input/output and pull-up/pull-down control functionality as programmed in the SCR_Pn_IOCR register. One SCR_Pn_PDISC register is assigned to each port.

***Note**: After reset, all SCR_Pn_PDISC registers have the reset value of FF_H.*

39.3.7.2.4 Port output register

The port output register determines the value of a GPIO pin when it is selected by SCR_Pn_IOCRm as output. Writing a 0 to a SCR_Pn_OUT.Pm (m=0-7) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that the bits of SCR_Pn_OUT.Pm can be individually set, cleared, or toggled by writing appropriate values into the port output modification set register SCR_Pn_OMSR, or port output modification clear register SCR_Pn_OMCR, or the port output modification toggle register SCR_Pn_OMTR, respectively.

39.3.7.2.5 Port output modification set register

The port output modification set register contains control bits that make it possible to individually set the logic state of a single port line by manipulating the output register.

39.3.7.2.6 Port output modification clear register

The port output modification clear register contains control bits that make it possible to individually clear the logic state of a single port line by manipulating the output register.

39.3.7.2.7 Port output modification toggle register

The port output modification toggle register contains control bits that make it possible to individually toggle the logic state of a single port line by manipulating the output register.

39.3.7.2.8 Port input register

The logic level of a GPIO pin can be read via the read-only port input register SCR_Pn_IN. Reading the SCR_Pn_IN register always returns the current logical value at the GPIO pin independently whether the pin is selected as input or output.

39.3.7.3 SCR functions in port SCR_P0

This section describes the SCR functions of Port SCR_P0, which is mapped on P33.0-P33.7.

The SCR has functions on Port lines SCR_P0.0 - SCR_P0.7, which can be alternatively used for UART/LIN, WCAN, SSC, T0/T1, T2CCU0/1, ADCOMP, Debug (DAP/SPD) and External Interrupt input and output functions.

Following table summarizes the SCR I/O control selection functions of the 8 Port SCR_P0 lines.

Table 1702 Port P0 functions

Port pin	I/O	Pin functionality	Associated reg./I/O line	Port I/O control selection	
				Reg./bit-field	Value
SCR_P0.0 (P33.0)	I	General-purpose input	SCR_P0_IN.P0	SCR_P0_IOCR0.PC	$0XXXX_B$

39.3.7.4 SCR functions in port SCR_P1

This section describes the SCR functions of Port SCR_P1, which is mapped on P33.8-P33.15.

The SCR has functions on Port lines SCR_P1.0 - SCR_P1.7, which can be alternatively used for I2C, UART, WCAN, SSC, T0/T1, T2CCU0/1, ADCOMP, Pin Reset, single pin 32 kHz clock input, External NMI and External Interrupt input and output functions.

Following table summarizes the SCR I/O control selection functions of the 8 Port SCR_P1 lines.

Table 1703 Port P1 functions

Port pin	I/O	Pin functionality	Associated reg./I/O line	Port I/O control selection	
				Reg./bit-field	Value
SCR_P1.0 (P33.8)	I	General-purpose input	SCR_P1_IN.P0	SCR_P1_IOCR0.PC	$0XXXX_B$
		UART input	UART_RXDF

39.3.7.5 SCR functions in port SCR_P2

This section describes the SCR functions of Port SCR_P2, which is mapped on P32.2, P32.4-P32.7 and P35.0-P35.2.

The SCR has functions on Port lines SCR_P2.0 - SCR_P2.7, which can be alternatively used for I2C, UART, WCAN, SSC, T0/T1, T2CCU0/1, Pin Reset, 32 kHz PMS RTC clock output and External Interrupt input and output functions.

Following table summarizes the SCR I/O control selection functions of the 8 Port SCR_P2 lines.

Table 1704 Port P2 functions

Port pin	I/O	Pin functionality	Associated reg./I/O line	Port I/O control selection	
				Reg./bit-field	Value
SCR_P2.0 (P32.2)	I	General-purpose input	SCR_P2_IN.P0	SCR_P2_IOCR0.PC	$0XXXX_B$
		UART input	UART_RXDH
