Field	Bits	Type	Description
CLK_SRC	15:12	rwh	**CMU clock source for SOMP mode** ***Note**: The register CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC can be synchronously updated with the value of CLSi_ATOM_CHx_CTRL_SR.CLK_SRC_SR together with the update of register CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM1.CM1.* ***Note**: After (channel) reset the channel operation will run with CLS[j]_CLK. This fact is not reflected by reset value of CLSi_ATOM_CHx_CTRL.CLK_SRC bit field (which is set to 0000_B after channel reset). Only directly writing CLSi_ATOM_CHx_CTRL.CLK_SRC does not change the **CMU** clock source selection. The value read from CLSi_ATOM_CHx_CTRL.CLK_SRC bit field after channel reset does not reflect the current clock source selection status.* ***Note**: After (channel) reset the channel operation will run with CLS[j]_CLK. In order to change the clock source resolution, it is necessary to perform a synchronous update (via CLSi_ATOM_CHx_CTRL_SR.CLK_SRC_SR) before enabling the channel. This can be done by performing the following configuration sequence before enabling the channel:* CLSi_ATOM_CHx_CTRL_SR.CLK_SRC_SR=<selected **CCM** clock source> CLSi_ATOM_CHx_SR0=0_H CLSi_ATOM_CHx_CM0=0_H CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk ***(k=x)*** = 10_H *With this configuration sequence, CLSi_ATOM_CHx_CTRL.CLK_SRC will be immediately updated with the clock source value stored in the shadow register. Afterwards once the channel is enabled, the channel will operate on the selected clock source. Since then, the value read from the register CLSi_ATOM_CHx_CTRL.CLK_SRC reflects the actual selected clock source of operation.* ***Note**: After the register has been updated once from its shadow register after reset state, it is possible to change the clock source also by directly writing CLSi_ATOM_CHx_CTRL.CLK_SRC. That means if the running channel is disabled but not reset afterwards, it is possible to directly configure CLSi_ATOM_CHx_CTRL.CLK_SRC with a new clock source selection.* ***Note**: The clock of the channel is stopped, if "1100_B" value is configured. Restarting a channel by writing a value for a valid clock selection again is possible.*

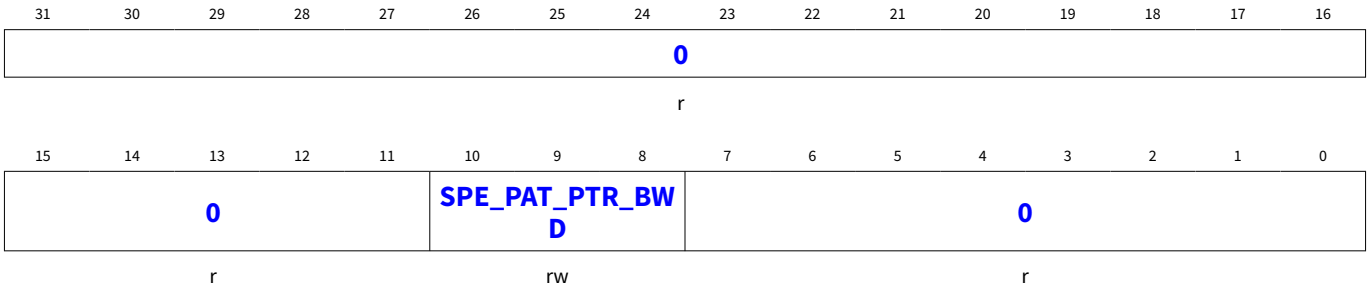
SPE[i] control status register 2 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SPE_PAT_PTR_BWD	10:8	rw	**Pattern selector for TOM output signals in case of CLSi_SPE_CMD.SPE_CTRL_CMD = 01_B (e.g. backward direction).** • Index into the CLSi_SPE_OUT_PATp register table in case of CLSi_SPE_CMD.SPE_CTRL_CMD = 01_B which may be used for backward direction. • Each register CLSi_SPE_OUT_PATp is fixed assigned to one bit field CLSi_SPE_PAT.IPt_PAT of register CLSi_SPE_PAT. Thus, the pointer CLSi_SPE_CTRL_STAT2.SPE_PAT_PTR_BWD represents an index to the selected CLSi_SPE_OUT_PATp register as well as the detected input pattern CLSi_SPE_PAT.IPt_PAT. • The index pointer CLSi_SPE_CTRL_STAT2.SPE_PAT_PTR_BWD is used if CLSi_SPE_CMD.SPE_CTRL_CMD = 01_B. • The index pointer CLSi_SPE_CTRL_STAT.SPE_PAT_PTR is used if CLSi_SPE_CMD.SPE_CTRL_CMD = 00_B (by default). • 000_B = CLSi_SPE_OUT_PATp**(p=0)** selected
0	7:0, 31:11	r	**Reserved** Read as 0; must be written with 0.

44.5.159 SPE[i] command register (i=0-2)

CLSi_SPE_CMD (i=0-2) Offset address: $004C4C_H+i*20000_H$

SPE[i] command register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
SPE_CTRL_CMD	1:0	rw	**SPE control command** ***Note**: On switch between 00_B and 01_B the direction flag CLSi_SPE_CTRL_STAT.ADIR will be independently set according to the input pattern CLSi_SPE_CTRL_STAT.NIP and CLSi_SPE_CTRL_STAT.AIP.* 00_B Use pi: CLSi_SPE_CTRL_STAT.SPE_PAT_PTR as an index pointer to select CLSi_SPE_OUT_PATp 01_B Use pi: CLSi_SPE_CTRL_STAT2.SPE_PAT_PTR_BWD as an index pointer to select CLSi_SPE_OUT_PATp 10_B Select CLSi_SPE_OUT_PATp (p=6) 11_B Select CLSi_SPE_OUT_PATp (p=7)
SPE_UPD_TRIG	16	rwh	**SPE updater trigger** ***Note**: This bit is automatically reset to 0.* 0_B Do nothing 1_B Trigger update of CLSi_SPE_OUT_CTRL.SPE_OUT_CTRLo with register selected by CLSi_SPE_CMD.SPE_CTRL_CMD multiplexer
0	15:2, 31:17	r	**Reserved** Read as 0; must be written with 0.

44.5.160 Clock control register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 060000_H

Clock control register Application Reset value: $0000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock

(table continues...)

(continued)

Field	Bits	Type	Description
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved, must not be used.** Read as 0; must be written with 0.

44.5.161 OCDS control and status register

OCS

OCDS control and status register

Offset address: 060004_H

Debug Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		SUSSTA	SUS_P	SUS				0							
r		rh	w	rw				r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															
r															

Field	Bits	Type	Description
SUS	27:24	rw	**OCDS suspend control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS). Not listed combinations are reserved. 0_H Will not suspend 1_H Reserved, must not be used. 2_H Reserved, must not be used. 3_H Soft suspend mode For soft-suspend, the GTM_HALT input of the GTM-IP is used. Thus, all outputs remain at their current state when soft-suspend is activated. Reads as well as writes on GTM-IP are possible.
SUS_P	28	w	**SUS write protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend state** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:0, 31:30	r	**Reserved, must not be used.** Read as 0; shall be written with 0.

Table 2360 Access types of OCS in order of evaluation

Condition	Type		Description

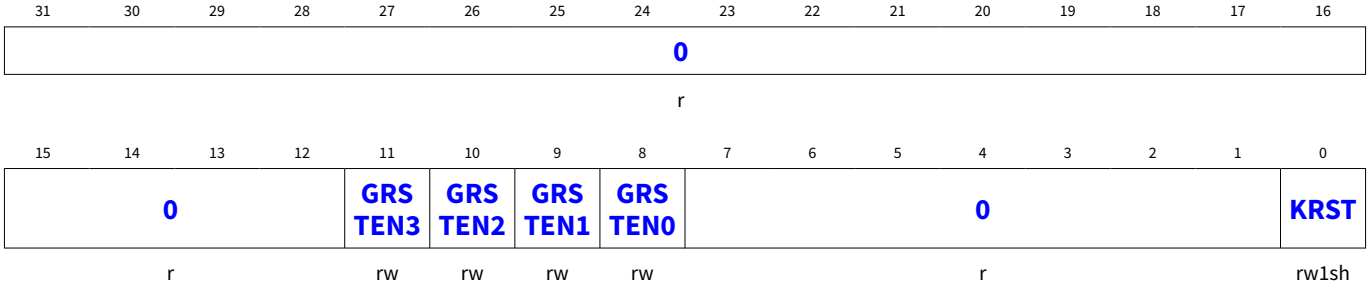
otherwise	r	SUS	

44.5.162 Reset control register A

RST_CTRLA Offset address: 060010_H

Reset control register A Application Reset value: $0000\ 0000_H$

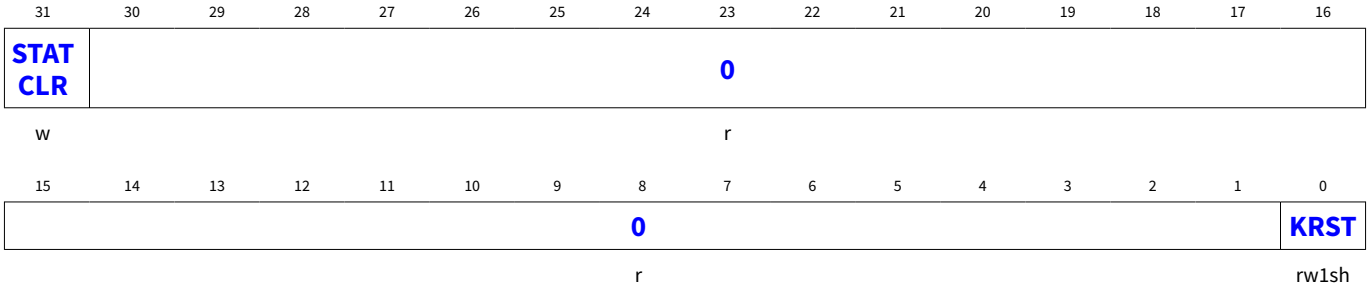


Field	Bits	Type	Description
KRST	0	rw1sh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for Global Module Reset Group x** 0_B Global module reset group x does not have any effect 1_B Global module reset group x results in a kernel reset
0	7:1, 31:12	r	**Reserved, must not be used.** Read as 0; must be written with 0.

44.5.163 Reset control register B

RST_CTRLB Offset address: 060014_H

Reset control register B Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rw1sh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
STATCLR	31	w	**Kernel Reset Status Clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits STAT.GRSTx and bit STAT.KRST .
0	30:1	r	**Reserved, must not be used.** Read as 0; must be written with 0.

44.5.164 Reset status register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: 060018_H

Reset status register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				GRST3	GRST2	GRST1	GRST0	0							KRST
r				rh	rh	rh	rh	r							rh

Field	Bits	Type	Description
KRST	0	rh	**Kernel Reset Status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.
GRSTx (x=0-3)	x+8	rh	**Status for Global Module Reset Group x** 0_B Reset was not triggered by Global Reset Group x 1_B Reset was triggered by Global Reset Group x
0	7:1, 31:12	r	**Reserved, must not be used.** Read as 0.

44.5.165 PROT register Safe Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: $06001C_H$

PROT register Safe Endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

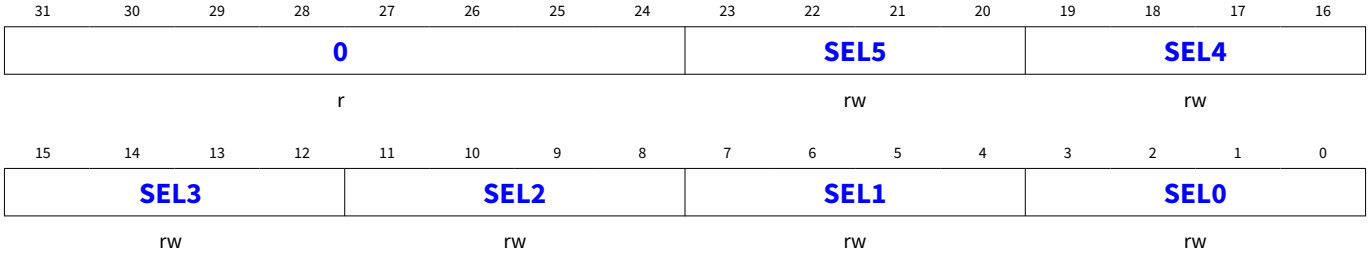
44.5.218 eGTM to PSI5 output trigger selection register

The bit fields in this register define which TOM/ATOM channel output is used as PSI5 trigger x.

PSI5_OUT Offset address: 061400_H

eGTM to PSI5 output trigger selection register Kernel Reset value: $0000\ 0000_H$



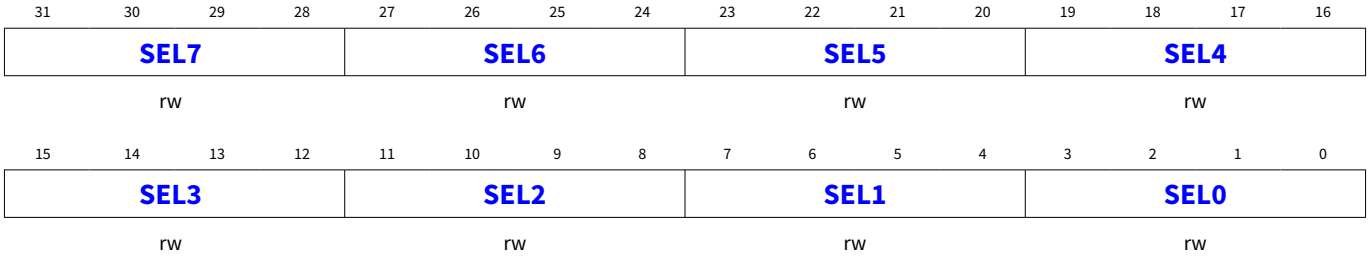
Field	Bits	Type	Description
SELx (x=0-5)	4*x+3:4*x	rw	**eGTM to PSI5 trigger x output selection**
0	31:24	r	**Reserved, must not be used.** Read as 0, shall be written with 0.

44.5.219 eGTM to PSI5-Sn output trigger selection register (n=0-1)

The bit fields in this register define which TOM/ATOM channel output is used as PSI5-Sn trigger x.

PSI5Sn_OUT (n=0-1) Offset address: 061410_H+n*4

eGTM to PSI5-Sn output trigger selection register Kernel Reset value: $0000\ 0000_H$



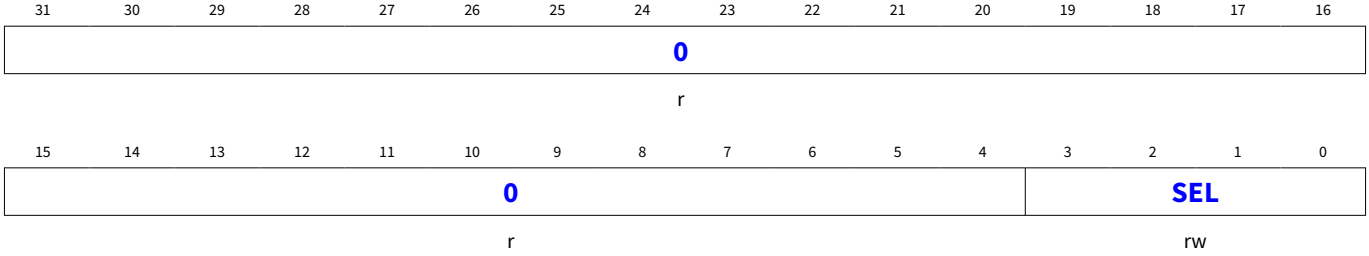
Field	Bits	Type	Description
SELx (x=0-7)	4*x+3:4*x	rw	**eGTM to PSI5-Sn trigger x output selection**

44.5.220 eGTM to LCDCDC output trigger selection register

The bit field in this register defines which TOM/ATOM channel output is used as LCDCDC trigger.

LCDCDC_OUT Offset address: 061420_H

eGTM to LCDCDC output trigger selection register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SEL	3:0	rw	**eGTM to LCDCDC trigger output selection**
0	31:4	r	**Reserved, must not be used.** Read as 0, shall be written with 0.

44.5.221 eGTM to CANn output selection register x. n*4+ x<24 , if interface exists. (x=0-3;n=0-5)

The bit field in this register defines which TOM/ATOM channel output is used as CANn node trigger x.

CANn_OUTx (n=0-5;x=0-3)

Offset address: 061480_H+n*10_H+x*4

eGTM to CANn output selection register x. n*4+ x<24 , if interface exists.

Kernel Reset value: $0000\ 0000_H$

44.6 Debug information

This section is not applicable for the module being described.

44.7 References

The module is based on GTM4.1, a delivery from Bosch AE.

44.8 eGTM revision history

Reference	Description of change(s)
Date range: 2024-08-17 to 2025-03-27	
Enhanced Generic Timer Module (eGTM)	• Import new Bosch AE specification • Fixed typos, rephrased sentences, updated register descriptions.

44.9 TC4Dx eGTM information

44.9.1 TC4Dx eGTM configuration

eGTM represents the 3 cluster module.

Table 2363 eGTM specific parameters

Parameter	Value
Number of eGTM instances	1 eGTM
TIM sub-block	3 x 8 channels (TIM0-TIM2)
TOM sub-block	3 x 16 channels (TOM0-TOM2)
High resolution on TOM	not existing
ATOM sub-block	3 x 8 channels (ATOM0-ATOM2)
High resolution block connected to analogue block	not existing
DTM/CDTM sub-blocks	12 @TOMs (TOM0-TOM2) 6 @ATOMs (ATOM0-ATOM2)
MCS sub-block	not existing
ARU sub-block	not existing
MAP sub-block	not existing
SPE sub-block	3 (SPE0-SPE2)
PSM sub-block	not existing
DPLL sub-block	not existing. SUB_INCn signals are DPLL signals
TBU sub-block	3 channels (TS0-TS2) TBU channel 3 is only usable with DPLL, therefore the 4th TBU channel exists only in devices with DPLL.
BRC sub-block	not existing
MON sub-block	1
CMP sub-block	1
eGTM Clusters	3 (CCM0-CCM2)
TIO sub-block	No TIO is present in any Infineon device of the TC4x family

Table 2364 eGTM connections in SoC

Connecting to module	Superset Connections with registers for control	eGTM connections with modules connected
ASCLIN	28	28
CAN	24	24
ADC-TMADC	7	4
ADC-FCC	10	0

Table 2364 (continued) eGTM connections in SoC

Connecting to module	Superset Connections with registers for control	eGTM connections with modules connected
ADC-DSADC	10	0
ADC-CDSP	12	2
ADC-EXMOD	8	0
ERAY (FlexRay)	2	2
GPT12	4	0
SENT	2	2
PSI5	4	2
PSI5S	2	1
LETH/GETH	4/2	4/2
TOUT	294	294
MSC	3	1
QSPI	8	8

44.9.2 TC4Dx eGTM feature list

The device specific registers can be found in the subsection eGTM registers. The family subsection includes all register structures for the device.

The configuration table of the eGTM itself can be found in eGTM configuration.

The cluster frequency is limited to 250 MHz.

44.9.3 TC4Dx eGTM functional description

The functional description is listed in the family part. Please be aware, that no HRPWM analogue block exists, therefore the corresponding feature does not work, even though the eGTM-IP itself is capable of the feature.

44.9.3.1 TOUTSEL and TIMnINSEL(B) Reference Tables

The following table includes the registers available to support mapping between the module and the ports. Dependent on the mapping inside the datasheet, those may see a connection to a port pin or not. In any case the connection mentioned in the datasheet is correct.

Table 2365 TOUTSEL registers in relation to their select bit fields

Registername	SEL5	SEL4	SEL3	SEL2	SEL1	SEL0
TOUTSEL0	TOUT5	TOUT4	TOUT3	TOUT2	TOUT1	TOUT0

44.9.4 TC4Dx eGTM registers

44.9.4.1 Register address space - EGTM

Table 2367 Registers address space - EGTM

Module	Base address	End address	Note
EGTM	$F9080000_H$	$F90E2FFF_H$	LLI slave interface

44.9.4.2 Register overview - access mode glossary

Table 2368 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register EGTM_CTRL_PROTE .
SE	Access protection using PROT register EGTM_PROTSE .

(table continues...)

Table 2368 (continued) Register overview - access mode glossary

Keyword	Description
APU-P	Protection group consisting of registers EGTM_CTRL_ACCEN_WRA , EGTM_CTRL_ACCEN_WRB , EGTM_CTRL_ACCEN_RDA , EGTM_CTRL_ACCEN_RDB , EGTM_CTRL_ACCEN_VM , EGTM_CTRL_ACCEN_PRS .
P	Access protection using *APU-P* registers.
APU-PCLi (i=0-2)	Protection group consisting of registers EGTM_CLi_ACCEN_WRA , EGTM_CLi_ACCEN_WRB , EGTM_CLi_ACCEN_RDA , EGTM_CLi_ACCEN_RDB , EGTM_CLi_ACCEN_VM , EGTM_CLi_ACCEN_PRS .
PCLi	Access protection using *APU-PCLi* registers.
APU-PGTM	Protection group consisting of registers EGTM_CTRLGTM_ACCEN_WRA , EGTM_CTRLGTM_ACCEN_WRB , EGTM_CTRLGTM_ACCEN_RDA , EGTM_CTRLGTM_ACCEN_RDB , EGTM_CTRLGTM_ACCEN_VM , EGTM_CTRLGTM_ACCEN_PRS .
PGTM	Access protection using *APU-PGTM* registers.
APU-PSAFE	Protection group consisting of registers EGTM_SAFEGTM_ACCEN_WRA , EGTM_SAFEGTM_ACCEN_WRB , EGTM_SAFEGTM_ACCEN_RDA , EGTM_SAFEGTM_ACCEN_RDB , EGTM_SAFEGTM_ACCEN_VM , EGTM_SAFEGTM_ACCEN_PRS .
PSAFE	Access protection using *APU-PSAFE* registers.
APU-PWRAP	Protection group consisting of registers EGTM_WRAP_ACCEN_WRA , EGTM_WRAP_ACCEN_WRB , EGTM_WRAP_ACCEN_RDA , EGTM_WRAP_ACCEN_RDB , EGTM_WRAP_ACCEN_VM , EGTM_WRAP_ACCEN_PRS .
PWRAP	Access protection using *APU-PWRAP* registers.
32	Access only when using 32-bit width.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.

44.9.5 TC4Dx eGTM connectivity

The table below lists interfaces to and from this functional block to other blocks in the device.

Table 2370 List of eGTM interface signals

Interface signals	I/O	Description
CLOCK_EGTM_feGTM	In	eGTM clock input
LLI_EGTM_AXI32S	In	Bridge to eGTM
CAN0_EGTM_SRC_CANINT[15:12]	In	TIMx_INy_z: CANn_INT_O[15:12]; n=0..5; CANn interrupt outputs

(table continues...)

Table 2370 (continued) List of eGTM interface signals

Interface signals	I/O	Description
CAN1_EGTM_SRC_CANINT[15:12]	In	TIMx_INy_z: CANn_INT_O[15:12]; n=0..5; CANn interrupt outputs
CAN2_EGTM_SRC_CANINT[15:12]	In	TIMx_INy_z: CANn_INT_O[15:12]; n=0..5; CANn interrupt outputs
CAN3_EGTM_SRC_CANINT[15:12]	In	TIMx_INy_z: CANn_INT_O[15:12]; n=0..5; CANn interrupt outputs
CAN4_EGTM_SRC_CANINT[15:12]	In	TIMx_INy_z: CANn_INT_O[15:12]; n=0..5; CANn interrupt outputs
SCU_EGTM_ERU_TIMnINSEL	In	PDOUT[7:0]; SCU pattern detection outputs: TIMx_INy_z
PMS_EGTM_RTCOUT	In	PMS RTC Multiplexer Input. RTCOUT, output of the RTC
ERAY0_EGTM_MACROTICK	In	MT0; Macrotick-clock from CC (synchronous to FPI clock)
ERAY1_EGTM_MACROTICK	In	MT0; Macrotick-clock from CC (synchronous to FPI clock)
GETH0_EGTM_SRC_GETHPPS[3:0]	In	GETHPP[3:0]; Gigabit,Ethernet PPS interrupt
LETH0_EGTM_Pi_PPS[i=0:3]	In	LETHPP[3:0]; Lite Ethernet PPS interrupt
PMS_EGTM_WUTOUT	In	TIMx_INy_z: WUTUFLOW; Underflow output to support WUT calibration
PMS_EGTM_DCDCSYNCO	In	TIMx_INy_z: DCDC_SYNC; Sync signal from PMS for DCDC control
ADC_EGTM_SRC_TMADCxSR[5:0]x=[7:0]	In	TMADC SR information
PORTS_EGTM_RX_2_TIM	In	Port input signals
ADC_EGTM_CLUSTERx_BFLY[3:0]x=[2:0]	In	ETBFnOUTx; n=0..NTIM-1; x=0..5; Output from ADC multiplexer
PORTS_EGTM_RX_2_DTM	In	Port input signals
EGTM_PSI5_TRIG[5:0]	Out	eGTM timer output trigger for PSI5
EGTM_PSI5S0_TRIG[7:0]	Out	eGTM timer output trigger for PSI5_Sn
EGTM_ADC_TRIG[11:0]	Out	eGTM timer output trigger for ADC[59:48] called [11:0] on EGTM side.
EGTM_ASCLIN0_TRIG	Out	eGTM timer output trigger for ASCLINn
EGTM_ASCLIN1_TRIG	Out	eGTM timer output trigger for ASCLINn
EGTM_ASCLIN2_TRIG	Out	eGTM timer output trigger for ASCLINn
EGTM_ASCLIN3_TRIG	Out	eGTM timer output trigger for ASCLINn
EGTM_ASCLIN4_TRIG	Out	eGTM timer output trigger for ASCLINn
EGTM_ASCLIN5_TRIG	Out	eGTM timer output trigger for ASCLINn
EGTM_ASCLIN6_TRIG	Out	eGTM timer output trigger for ASCLINn
EGTM_ASCLIN7_TRIG	Out	eGTM timer output trigger for ASCLINn
EGTM_ASCLIN8_TRIG	Out	eGTM timer output trigger for ASCLINn

(table continues...)

Table 2370 (continued) List of eGTM interface signals

Interface signals	I/O	Description
EGTM_ASCLIN9_TRIG	Out	eGTM timer output trigger for ASCLINn
EGTM_ASCLIN10_TRIG	Out	eGTM timer output trigger for ASCLINn
EGTM_ASCLIN11_TRIG	Out	eGTM timer output trigger for ASCLINn

45 Analog-to-Digital Converter (ADC)

The Analog-to-Digital Converter (ADC) is used to convert the analog input digital data and post- process the conversion result to extract different signal characteristics.

Depending on the device, ADC functions can include:

- Time-Multiplexed Analog-to-Digital Converter
- Fast Compare Comparator (FCC)
- Delta-Sigma Analog-to-Digital Converter (DSADC), including on-chip modulator and external modulator support
- Converter Digital Signal Processing (CDSP)

45.1 Feature list

- Analog supply support for 3.3 V and 5 V
- High number of analog inputs depending on variant and package. This can be extended with support for external analog multiplexers (EMUX)
- ASIL-D analog acquisition supported with redundant ADC channels
- Global alarms directly connected to Safety Management Unit (SMU) and Interrupt Router (IR)
- Support for individual and combined service requests
- TMADC with 12 bit resolution and direct result data interface to GTM
- Boundary flag connected from ADC to GTM and to eGTM
- Digital comparator with hysteresis support
- Synchronous sampling on all channels connected to TMADC
- DSADC with SNR up to 86 dB
- External modulator demodulation support with optional Manchester Decoding and clock recovery
- Programmable CDSP cores to implement and configure various functions

45.2 Functional overview

The ADC is built of several functions which are used for analog acquisition of external analog signals, the demodulation of an external PDM bit-stream, and post processing of the results. The super-set of functionality is documented here. Please refer to the device specific section for specific implementation details. At least one TMADC instance exists in all function subsets. Optional features are:

- Delta-Sigma ADC (DSADC)
- External modulator support (EXMOD)
- Fast Compare Comparator (FCC)
- Converter Digital Signal Processor (CDSP)
- ADC interface to GTM and eGTM (depending on the presence of GTM or eGTM)

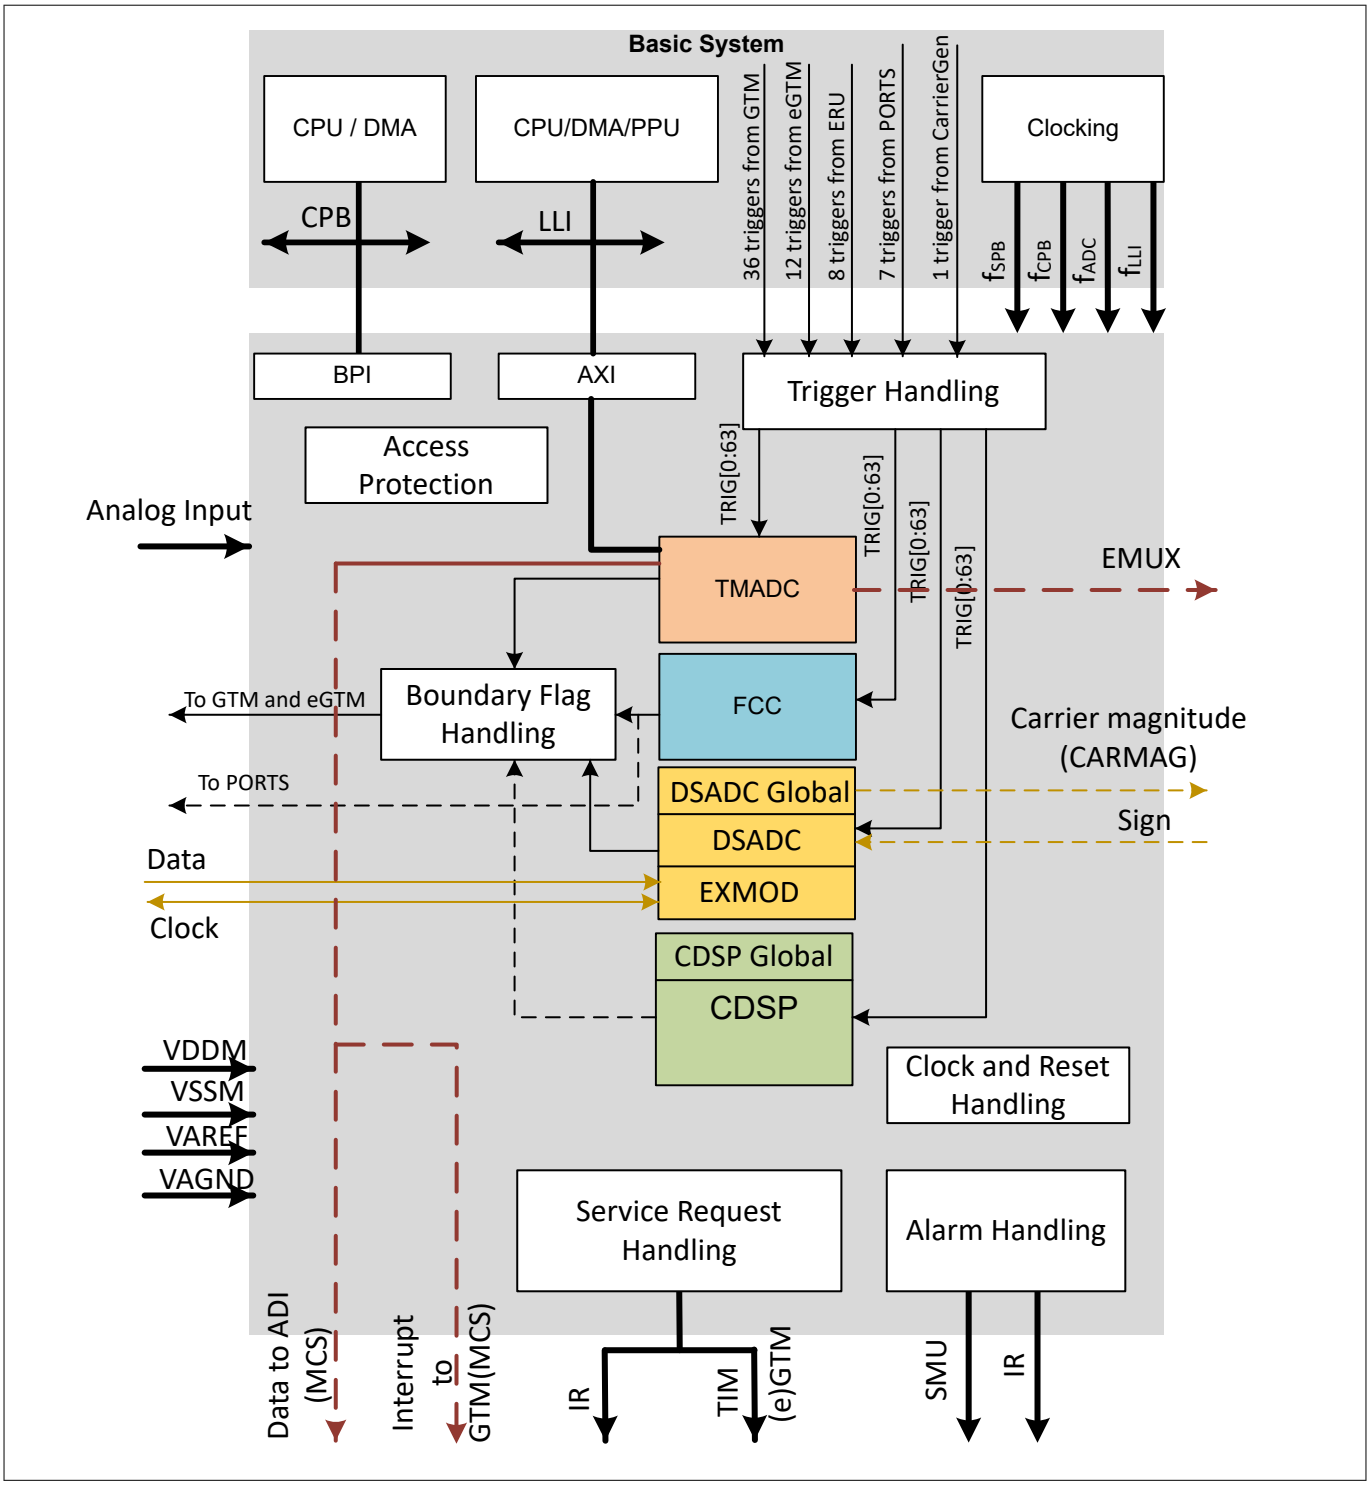

Figure 1183 ADC system interconnect

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

The block diagram gives an overview of how the ADC and its sub-functions are connected to the rest of the system. Please note that:

- ADC has two bus slaves:
  - BPI slave connected to either CPB, COMPB or SPB.
    - All the ADC registers and memories are accessible through this interface

***Note**: Please check the device specific feature section which bus is connected.*

- AXI slave connected to LLI
  - Only the TMADC result, monitoring result, and timestamp registers can be read over this interface

  ***Note**: The Wait-for-read functionality is not supported over the AXI slave interface for TMADC*

  ***Note**: The LLI connection is not available in all device variants, please check the device specific feature section.*

- Boundary flags from different ADC sub-functions are handled centrally and are connected to GTM and eGTM. In addition, FCC boundary flags are also connected to ports
- TMADC receives on its monitoring sampler, low-precision band gap output voltage for conversion
- TMADC results RES14 and RES15 are accessible by every MCS(GTM) over the ADI interface. The availability of a new result on this interface could be signaled by sending an interrupt directly from ADC to MCS(GTM)
- TMADC supports the control of an external analog MUX with up to 8 analog inputs
- To support external modulator demodulation (EXMOD), it can receive the data as well as clock from an external modulator. As an option, EXMOD can also provide its clock to the external modulator
- The PWM signal for carrier generation is supported by DSADC and can receive the sign information from ports for carrier cancellation
- There are 8 alarms which are connected to SMU. The same alarms can be sent as service requests to IR

  ***Note**: The number of alarms vary from device to device*

- Each sub-function can directly send service requests to IR:
  - TMADC has 6 service requests per instance and 4 global service requests
  - FCC has 2 service requests per instance
  - DSADC has 4 service requests per instance
  - EXMOD has 4 service requests per instance
  - CDSP has 3 service requests per instance
- ADC has up to 64 input trigger lines, which are distributed to all the sub-functions. The sources of input triggers are:
  - Up to 36 triggers from GTM
  - Up to 12 triggers from eGTM
  - Up to 8 triggers from SCU(ERU)
  - Up to 7 triggers from ports
  - One trigger from carrier generator (DSADC)

  ***Note**: The number of triggers depends on the device configuration and the package variant used. The maximum number of all triggers is 64*

45.3 Functional description

This section focuses on the central function within ADC, also referred as ADC top. Sub-functions inside ADC top, such as TMADC, are explained in subsequent sections.

The following functions are covered in this section:

- Register access protection, resource and reset allocation
- Global service request and alarm generation
- ADC interface to timer (GTM and eGTM)
- Initializing the ADC

45.3.1 Access protection, resource and reset allocation

This section explains how the access to different registers and memories of ADC is granted. A similar approach is followed for the reset of registers. The whole ADC is divided into resources to allow individual and independent configuration.

A resource within ADC is defined as a single instance of a sub-function. Each resource is assigned a unique resource ID.

The following table lists the resource ID assignment for specific ADC resources.

Table 2371 Resource ID for different resources within ADC

Resource ID	Resource	Resource allocation register	Registers included
00	ADC global registers (central function in ADC)	RESALLOC_GLOB	GL*, GT*, ETBF*, PDDCFG, SUPLLEV, TMSMOD, OCSTM
01 - 08	TMADC [0:7]	RESALLOC_TMADC	TMADC[0:7]*
09 - 16	FCC [0:7]	RESALLOC_FCCA	FCC[0:7]*
17 - 18	FCC [8:9]	RESALLOC_FCCB	FCC[8:9]*
19	DSADC and EXMOD global registers	RESALLOC_GLOB	DSADC_GLOB*
20 - 27	DSADC [0:7]	RESALLOC_DSADCA	DSADC[0:7]*
28 - 29	DSADC [8:9]	RESALLOC_DSADCB	DSADC[8:9]*
30 - 37	EXMOD [0:7]	RESALLOC_EXMOD	DSADC_EX[0:7]*
38	CDSP global registers	RESALLOC_GLOB	CDSP_GLOB*
39 - 56	CDSP [0:7]	RESALLOC_CDSPA	CDSP_DSP[0:7]*
	CDSP [8:15]	RESALLOC_CDSPB	CDSP_DSP[8:15]*
	CDSP [16:17]	RESALLOC_CDSPC	CDSP_DSP[16:17]*

The number of resources is product specific, but the resource ID is fixed for all products of the family. Example: EXMOD0 will have resource ID = 34 in all variants of the product family.

Access protection and reset

Read and write accesses to the ADC top registers and memories are controlled through the following registers:

- ACCENy_WRA
- ACCENy_WRB
- ACCENy_RDA

- ACCENy_RDB
- ACCENy_VM
- ACCENy_PRS

Access protection details can be found in the System interconnect chapter in the User Manual. To configure these registers, the protection has to be in an unlocked state, which is configurable through PROTSE and PROTEx.

There are 16 sets of ACCEN registers. Access is granted when PROTSE is configured in the unlocked state.

There are 16 reset control register sets available. Reset of an individual set is configured by the registers:

- RSTi_CTRLA
- RSTi_CTRLB

The status can be read through RSTi_STAT.

If RSTi_CTRL_A and RSTi_CTRL_B are set, all resources assigned to APUi are reset.

When the resource ID =0 (ADC global registers) is reset, it affects the functionality of other resources through global run control registers. Reset has to be asserted in a bottom-up manner. Before a global resource is reset, all dependent resources have to be reset to avoid unpredictable behavior.

***Note**: In the case that any enabled TMADC instance is assigned to the same APU as resource ADC GLOBAL, all enabled TMADC instances have to be assigned to the same APU so that the bottom-up manner kernel reset concept is not violated.*

Resource allocation to Access Protection Unit (APU)

You have the possibility to configure the assignment of different resources to different ACCEN and reset sets by configuring the resource allocation registers.

Each register is divided into up to 8 segments of 4 bits each. Each 4 bit segment is allocated to a fixed resource (resource name is written in the bit-field). The figure below shows the layout of resource allocation register 0.

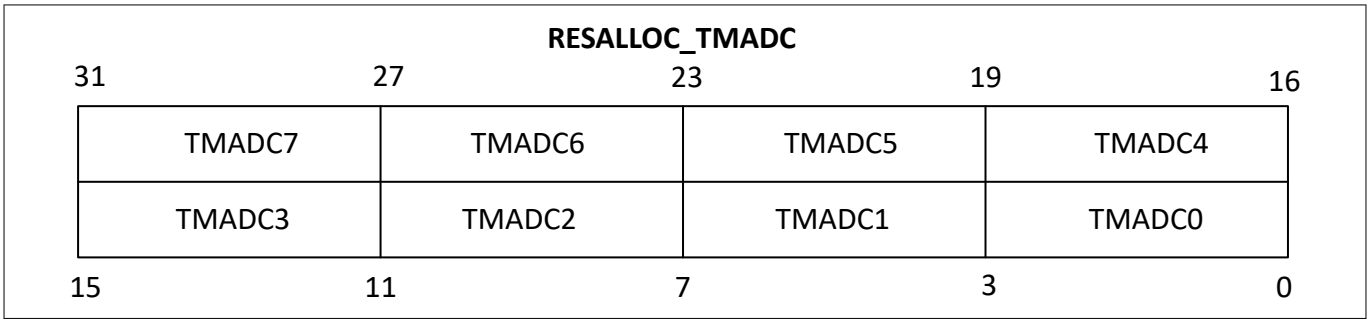

Figure 1184 Resource allocation register layout example

Use the 4-bit segment to assign a resource to an APU. For example if bits [3:0] (TMADC0) are written with 0010_B, then TMADC0 is access protected by configuration in ACCEN2, and reset by configuration in RST2. Multiple resources could be assigned to the same APU or a different one.

***Note**: There is no independent configuration for reset assignment to a resource. The same configuration as ACCEN assignment to a resource is also taken for reset sets.*

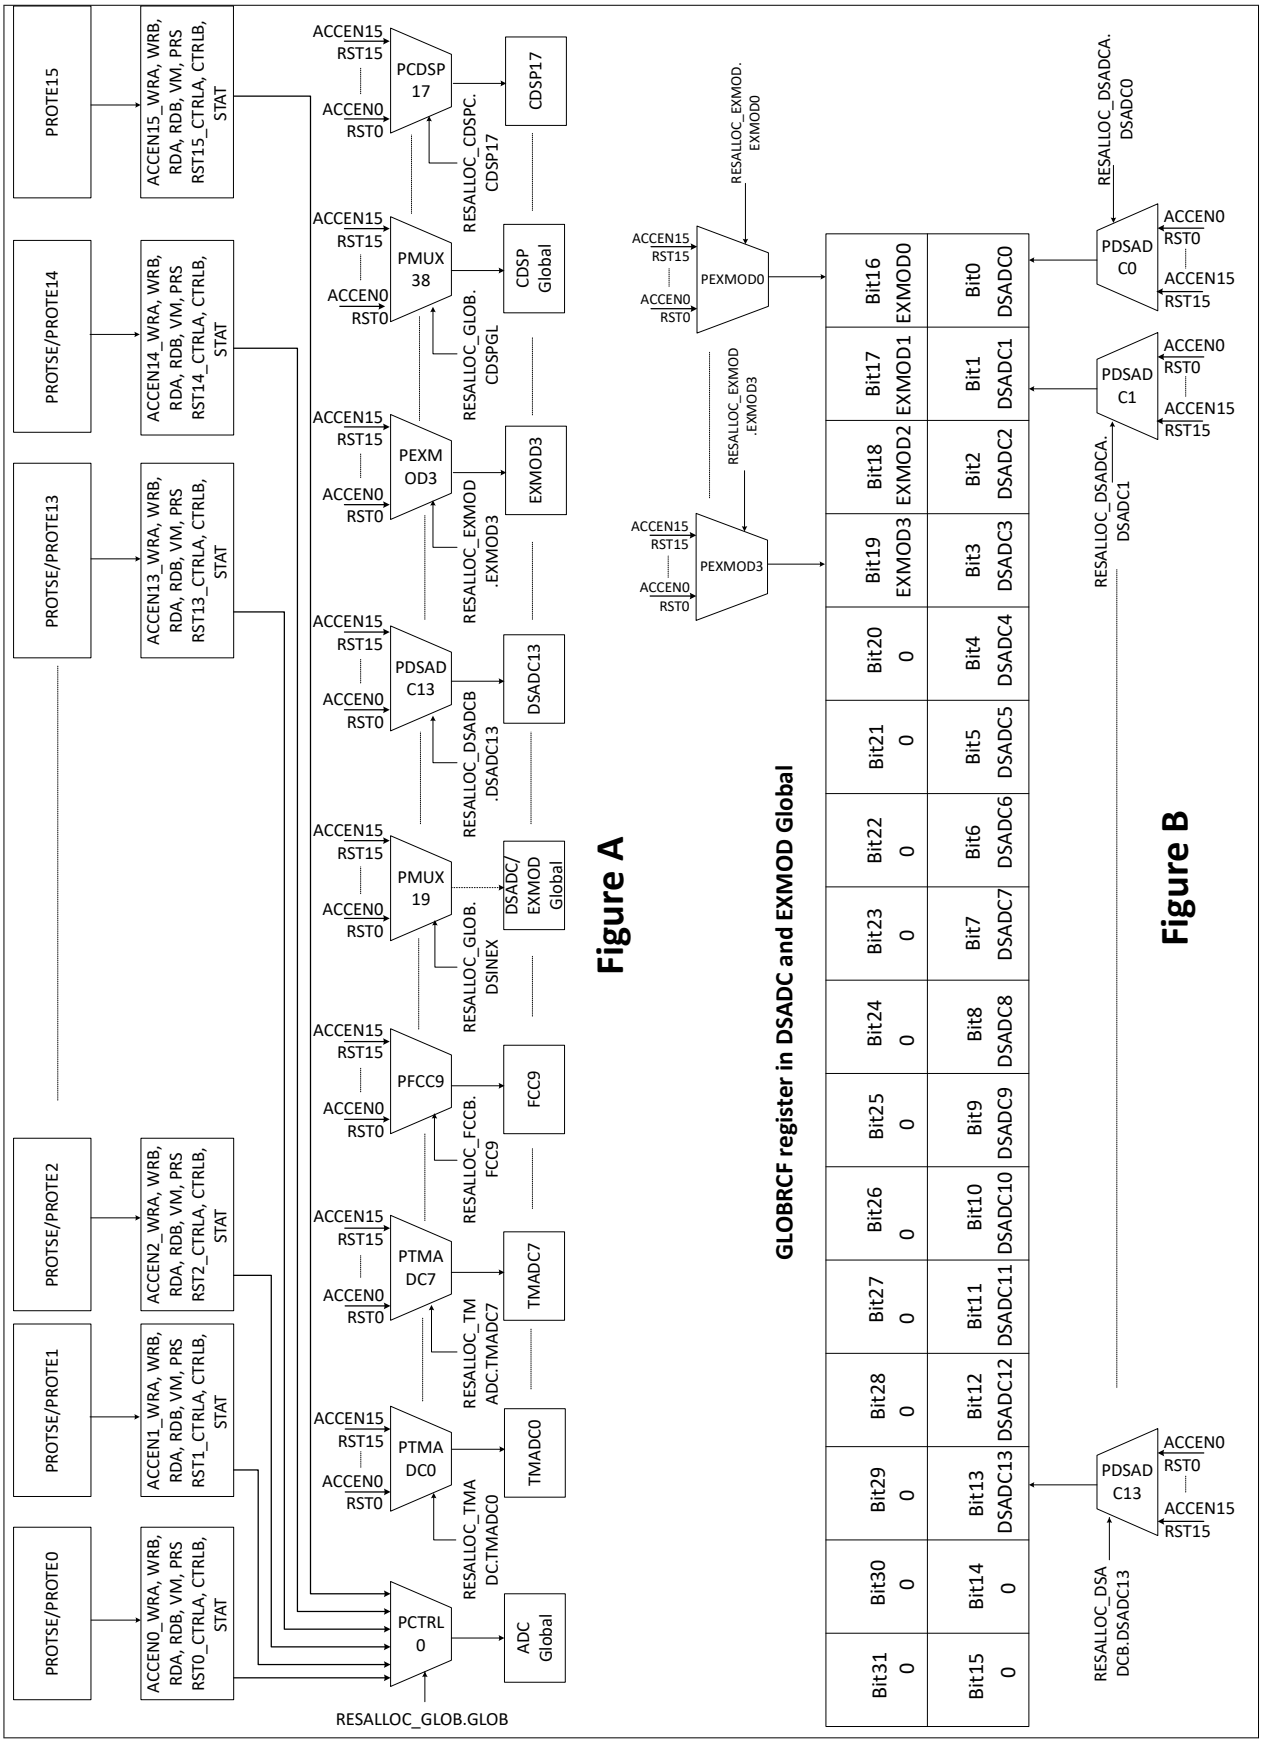

Figure 1185 Resource allocation concept

The Resource allocation concept figure shows the concept and structure of access protection and reset for different resources inside ADC. When an unauthorized master tries to access the registers and memories of a resource, it will result in a bus error.

***Note**: In the registers overview of the of the ADC registers chapter, it shows which ACCEN is used to control access to specific registers.*

In ADC there are three global resources:

- ADC global registers, where central registers of the ADC are defined
- DSADC and EXMOD global registers, where global registers of DSADC and EXMOD are defined
- CDSP global registers, where global registers of CDSP are defined

The global resources have a fixed resourced ID of 0, 19, and 38. ACCEN and reset allocation is controlled through programming registers RESALLOC_GLOB.

These global resources contain bit fields which impact the functionality of related resources. To provide more control of access protection and reset of the global resources, bit-field specific ACCEN and reset is introduced for some registers (Figure B).

Although the registers are physically in one of these global resources, ACCEN and reset of the register bits are controlled by the resource ID's named in the table below.

Table 2372 Bit-fields with individual access protection

Bit-field	Resource ID
CLKEN_TMADC.TMADCEN	8:1
CLKEN_FCC.FCCEN[9:0]	18:9
CLKEN_DSINEX.DSINEN	33:20
CLKEN_DSINEX.DSENEX	37:34
CLKEN_DSINEX.DSADCEN	19
CLKEN_CDSP.CDSPGL	38
CLKEN_CDSP.CDSPEN	56:39
CDSP_BNDCF.BNDF	56:39

CDSP_OCSCDSPB.SUS	56:48
CDSP_OCSCDSPB.SUSSTA	56:48

(table continues...)

Table 2372 (continued) Bit-fields with individual access protection

Bit-field	Resource ID
DSADC_GLOBRCF.CHRUN	33:20
DSADC_GLOBRCF.CHRUNE	37:34
DSADC_GLOBRCM.CHRUNM	33:20
DSADC_BOUNDF.BNDEVEX	37:34
DSADC_BOUNDF.BNDEXIN	33:20
DSADC_BOUNDFCL.BNDEXCL	37:34
DSADC_BOUNDFCL.BNDINCL	33:20
DSADC_RESMF.REMEVEX	37:34
DSADC_RESMF.REMEVIN	33:20
DSADC_RESAF.REAEVEX	37:34
DSADC_RESAF.REAEVIN	33:20
DSADC_RESMFCL.REMEXCL	37:34
DSADC_RESMFCL.REMINCL	33:20
DSADC_RESAFCL.REAEXCL	37:34
DSADC_RESAFCL.REAINCL	33:20

***Note**: When an unauthorized master writes, reads, or resets the register bit-fields, only bit-fields where access is granted can be read or written or reset. Other bit-fields will read as 0 and will be returned with no-error. Write and reset will not affect the bit-fields. No bus error will be issued.*

45.3.2 Initializing the ADC

This section explains the steps to be followed before enabling any of the ADC sub-functions.

- Enable the ADC clock by writing into register bit-filed CLC.DISR =0. Once enabled, all the ADC global registers are accessible
- Allocate the ADC resources to their ACCEN and reset sets
- Enable the clocks of resources by writing to registers:
  - CLKEN_TMADC
  - CLKEN_FCC
  - CLKEN_DSINEX
  - CLKEN_CDSP

  ***Note**: Enable the clock of DSADC global, EXMOD global, or CDSP global, if any respective DSADC, EXMOD, or CDSP instance is used in any application*

- Wait 10 SPB/CPB/COMPB clock cycles. Enabling of module clocks after setting the corresponding bit in an ADC_CLKEN_* register can take up to 10 peripheral bus clock cycles
- Select the supply level for ADC depending on the VDDM used in the application by configuring the bit-fields:
  - SUPLLEV.TMADCSUP
  - SUPLLEV.FCCSUP
  - DSADC_GLOBCFG.DSADCSUP

***Note**: Since all ADCs are connected to the same VDDM, the supply setting for all ADC sub-functions is the same*

The configuration registers within different resources can now be configured.

45.3.3 Global service request and alarm generation

This section explains the configuration and generation of global service requests and alarms.

Global service request

Use the global service request generator to reduce the number of service requests of the TMADC instances. SR6 of each TMADCx is connected to the global service request generator.

- Use GLSRCFGi.EVEN to enable the use of the global service request of a TMADCx
- Set GLSRCFGi.EVOP to generate a global service request when all TMADCx.SR6 are set
- Clear GLSRCFGi.EVOP to generate a global service request for each TMADCx.SR6

For example, by writing 00001101_B in the bit field EVEN, SR6 from TMADC0, TMADC2, and TMADC3 are enabled for combining. If EVOP =1, a global service request is generated when all the SR6's from the respective TMADCs have arrived.

***Note**: SR6 coming from TMADCx is latched, before doing a logical operation. A global service request is active for 1 f_{SPB} clock period. The latches are reset after 1 f_{SPB} clock period or when GLSRCFG.EVEN or GLSRCFG.EVOP are reconfigured.*

Write to GLSRSET to trigger the global service requests for debug purposes.

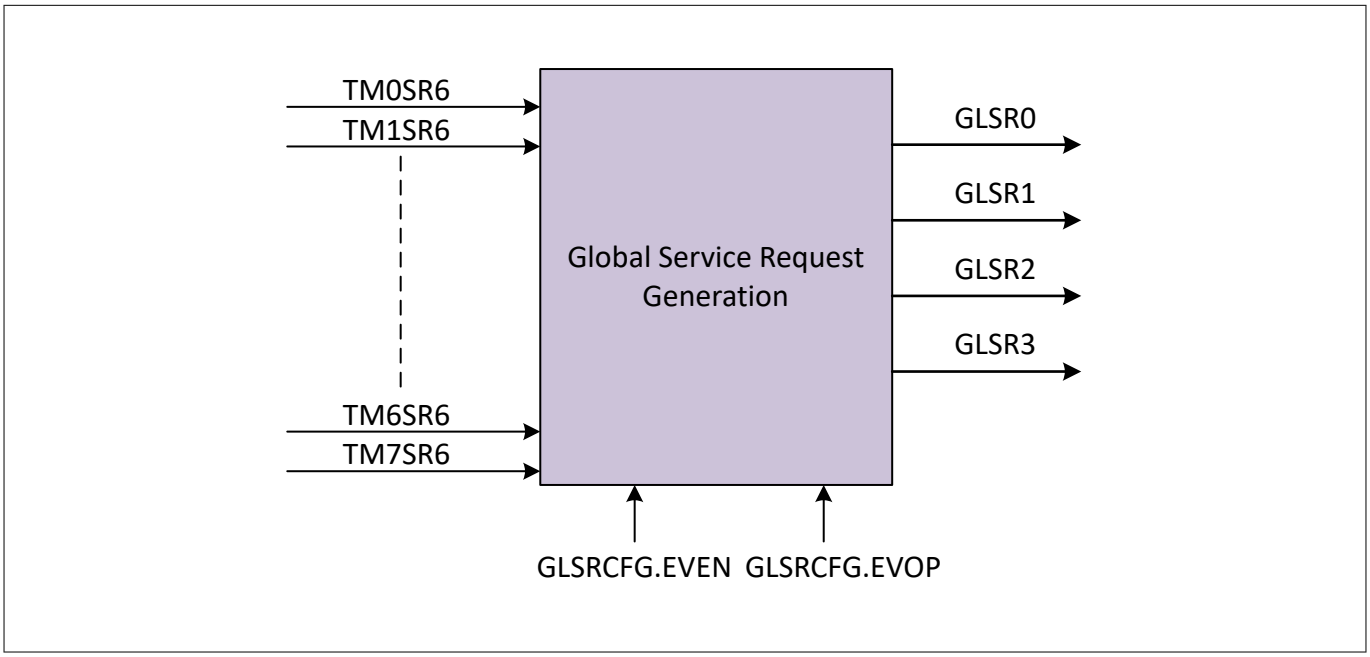

Figure 1186 Global service request generation

Global alarms

Unlike global service requests, global alarms can be used to combine 2 boundary flags of any ADC sub-module.

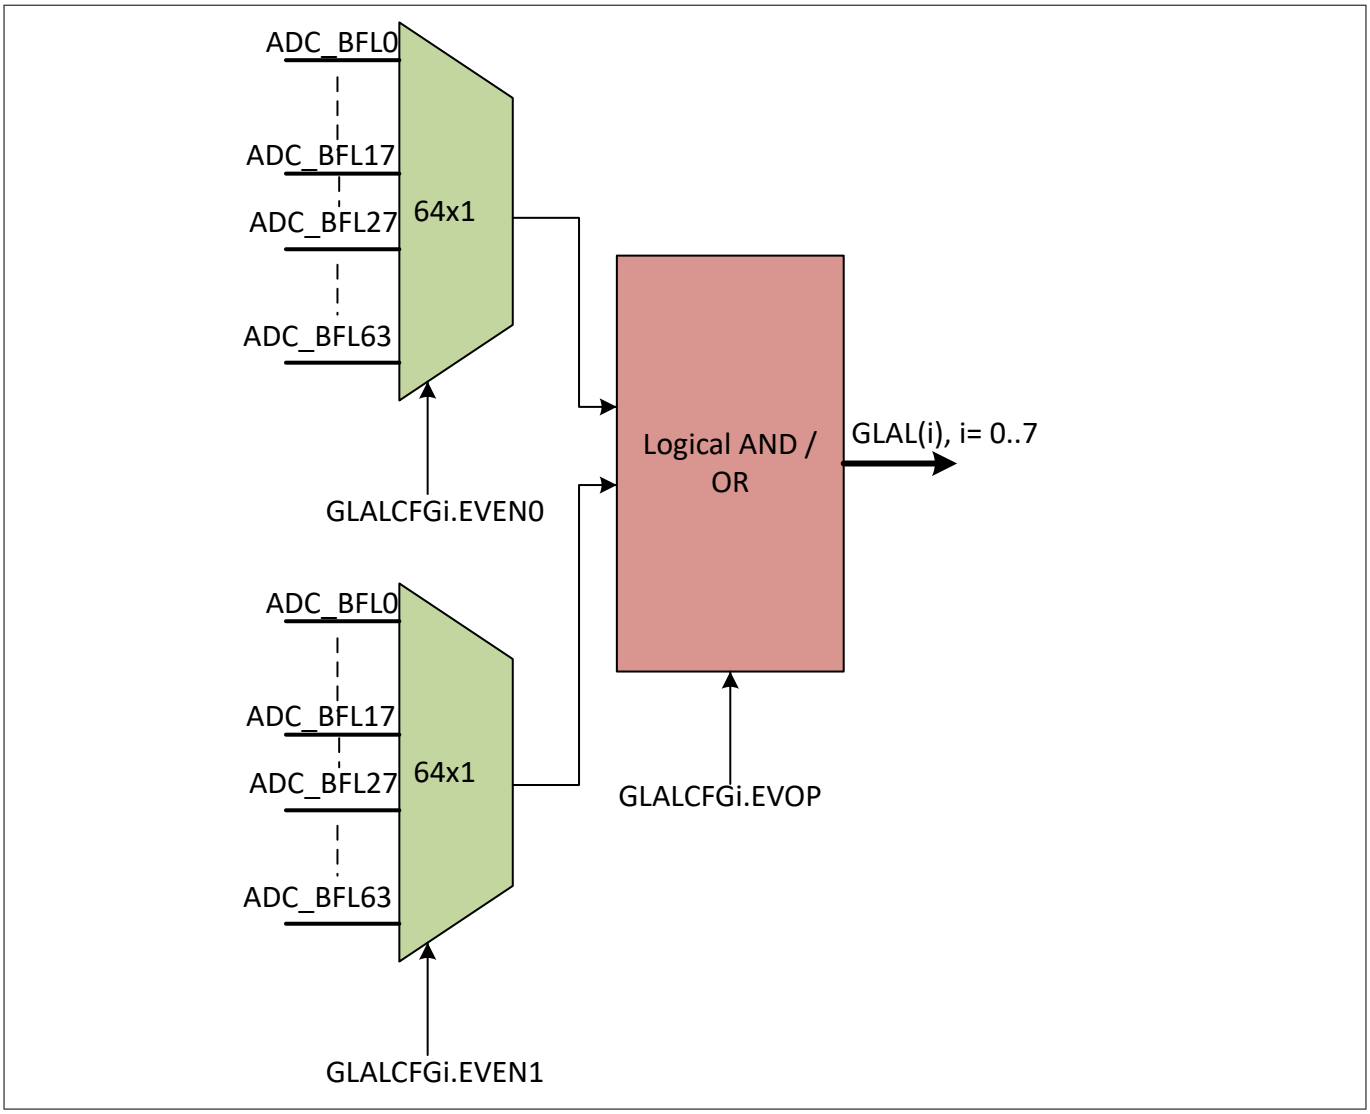

Figure 1187 Global alarm generation

The sources of the boundary flags are from TMADC, DSADC, and EXMOD channels, FCC and CDSP. Please refer to table below for the boundary flag mapping from different instances to ADC top:

Table 2373 Boundary flag mapping

Boundary flag from module	Boundary flag at ADC
TMADCx_BFLy ; x =[7:0], y =[1:0]	ADC_BFLz ; z=[15:0]
FCCx_BFL ; x =[9:0]	ADC_BFLz ; z=[25:16]
DSADCx_BFL ; x =[9:0]	ADC_BFLz ; z=[35:26]
EXMODx_BFL ; x=[7:0]	ADC_BFLz ; z=[43:36]
CDSPx_BFL ; x=[17:0]	ADC_BFLz ; z=[61:44]
Reserved	ADC_BFL62 and ADC_BFL63

Specific device variants offer 2 additional boundary flag comparators per CDSP. Selection for global alarms is shown in the picture below.

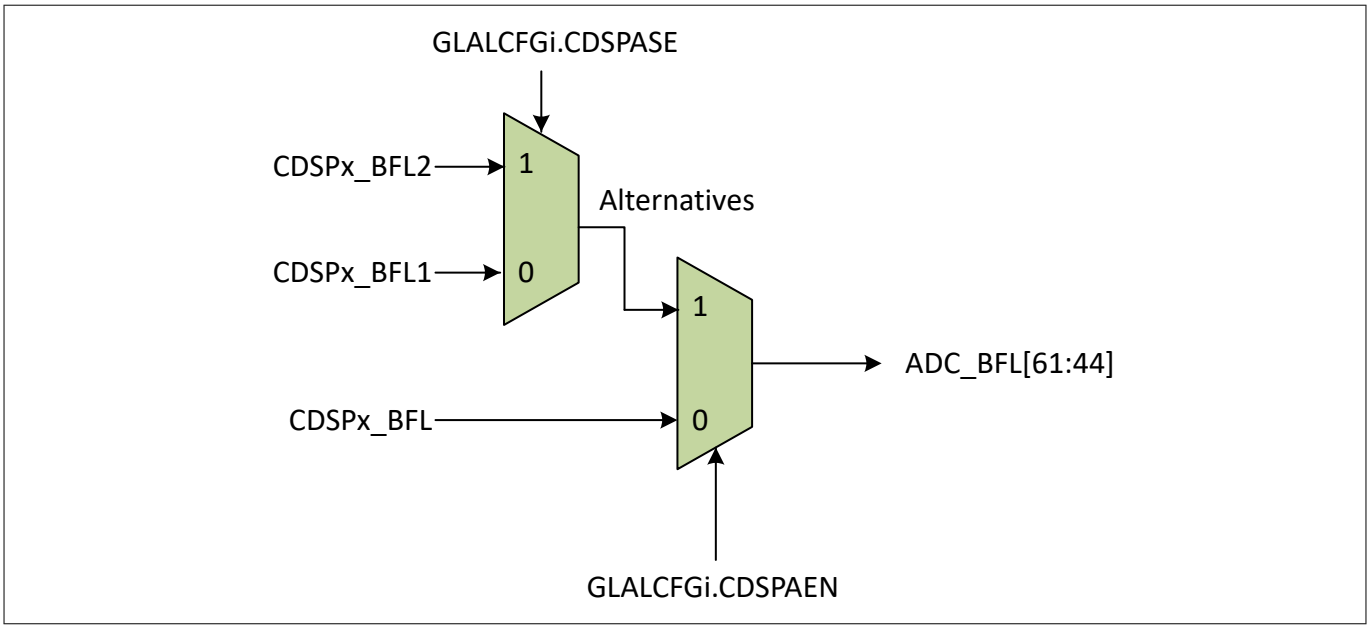

Figure 1188 Optional selection of additional CDSP boundary flags

GLALCFGi.CDSPAEN= 1_B maps in the additional CDSP boundary flags. GLALCFGi.CDSPASE does select between the 2 additional boundary flag sources. The device specific appendix will name, if the additional boundary flag comparators are available.

We configure alarms using GLALCFGi. Two boundary flags can be selected by configuring bit-fields EVEN0 and EVEN1. You can decide to generate an alarm under conditions configured through bit-field EVOP.

***Note**: There are up to 8 alarms which can be configured by the user. Alarms go as pulses into the system. Pulse width is at least 1 fSPB clock period. The same alarms are connected to IR as well as to SMU.*

You can initiate a test of the alarm connection by setting the corresponding bit of bit-field ALSET in the GLALSET register.

45.3.4 Hardware triggers to ADC

There are 5 sources for hardware triggers inside the microcontroller to trigger different functions inside ADC top. These sources are GTM, eGTM, PORTS, SCU(ERU), and the Carrier Generator (DSADC)

Table 2374 Hardware triggers to ADC

Trigger number	Source	Source trigger connection	In case no GTM/eGTM available
TRIG[3:0]	GTM Cluster 0	GTM_ADC_TRIG[3:0]	GPT12_ADC_TRIG[3:0] (GPT12[2:5], T6OUT signal connected)
TRIG[7:4]	GTM Cluster 1	GTM_ADC_TRIG[7:4]	
TRIG[11:8]	GTM Cluster 2	GTM_ADC_TRIG[11:8]	
TRIG[15:12]	GTM Cluster 3	GTM_ADC_TRIG[15:12]	
TRIG[19:16]	GTM Cluster 4	GTM_ADC_TRIG[19:16]	

(table continues...)

Table 2374 (continued) Hardware triggers to ADC

Trigger number	Source	Source trigger connection	In case no GTM/eGTM available
TRIG[23:20]	GTM Cluster 5	GTM_ADC_TRIG[23:20]	
TRIG[25:24]	GTM Cluster 6	GTM_ADC_TRIG[25:24]	
TRIG[27:26]	GTM Cluster 7	GTM_ADC_TRIG[29:28]	
TRIG[29:28]	GTM Cluster 8	GTM_ADC_TRIG[33:32]	
TRIG[31:30]	GTM Cluster 9	GTM_ADC_TRIG[37:36]	
TRIG[33:32]	GTM Cluster 10	GTM_ADC_TRIG[41:40]	
TRIG[35:34]	GTM Cluster 11	GTM_ADC_TRIG[45:44]	
TRIG[39:36]	eGTM Cluster 0	eGTM_ADC_TRIG[51:48]	
TRIG[43:40]	eGTM Cluster 1	eGTM_ADC_TRIG[55:52]	
TRIG[47:44]	eGTM Cluster 2	eGTM_ADC_TRIG[59:56]	
TRIG[55:48]	SCU (ERU)	SCU_ADC_TRIG[7:0]	
TRIG[62:56]	PORTS	PORTS_ADC_TRIG[6:0]	
TRIG[63]	Carrier Generator (DSADC), see section "Trigger Generation" in chapter "Carrier Signal Generation"	Internal Signal from DSADC	

The defined hardware triggers are routed to TMADC, FCC, DSADC, EXMOD, and CDSP channels. The same trigger can be mapped to control multiple functions of the ADCs. For example the end of sampling on all or a part of the analog inputs on TMADCs synchronously.

***Note**: Please refer to the GTM and eGTM documentation to select TOM and ATOM channel(s) of a cluster which will generate the corresponding trigger(s).*

***Note**: Please refer to the SCU(ERU) documentation for the configuration of ERU triggers to ADC.*

***Note**: Depending on the device configuration, some triggers might not be available. Please refer to device specific documentation for the available registers, connectivity, and the mapped PORTS pins for triggering.*

45.3.5 ADC interface to GTM and eGTM

This section explains the interface between ADC top and Timers (GTM and eGTM). There is no interface from ADC to GPT12.

There are 5 interfaces existing between ADC and the timers GTM and eGTM:

- Triggers coming from GTM and eGTM to ADC
- Boundary Flags from different ADC modules to GTM and eGTM
- Data from TMADC to the GTM (ADI Interface)
- Service Requests from ADC to GTM (MCS)
- Service Requests from ADC to GTM and eGTM (TIM)

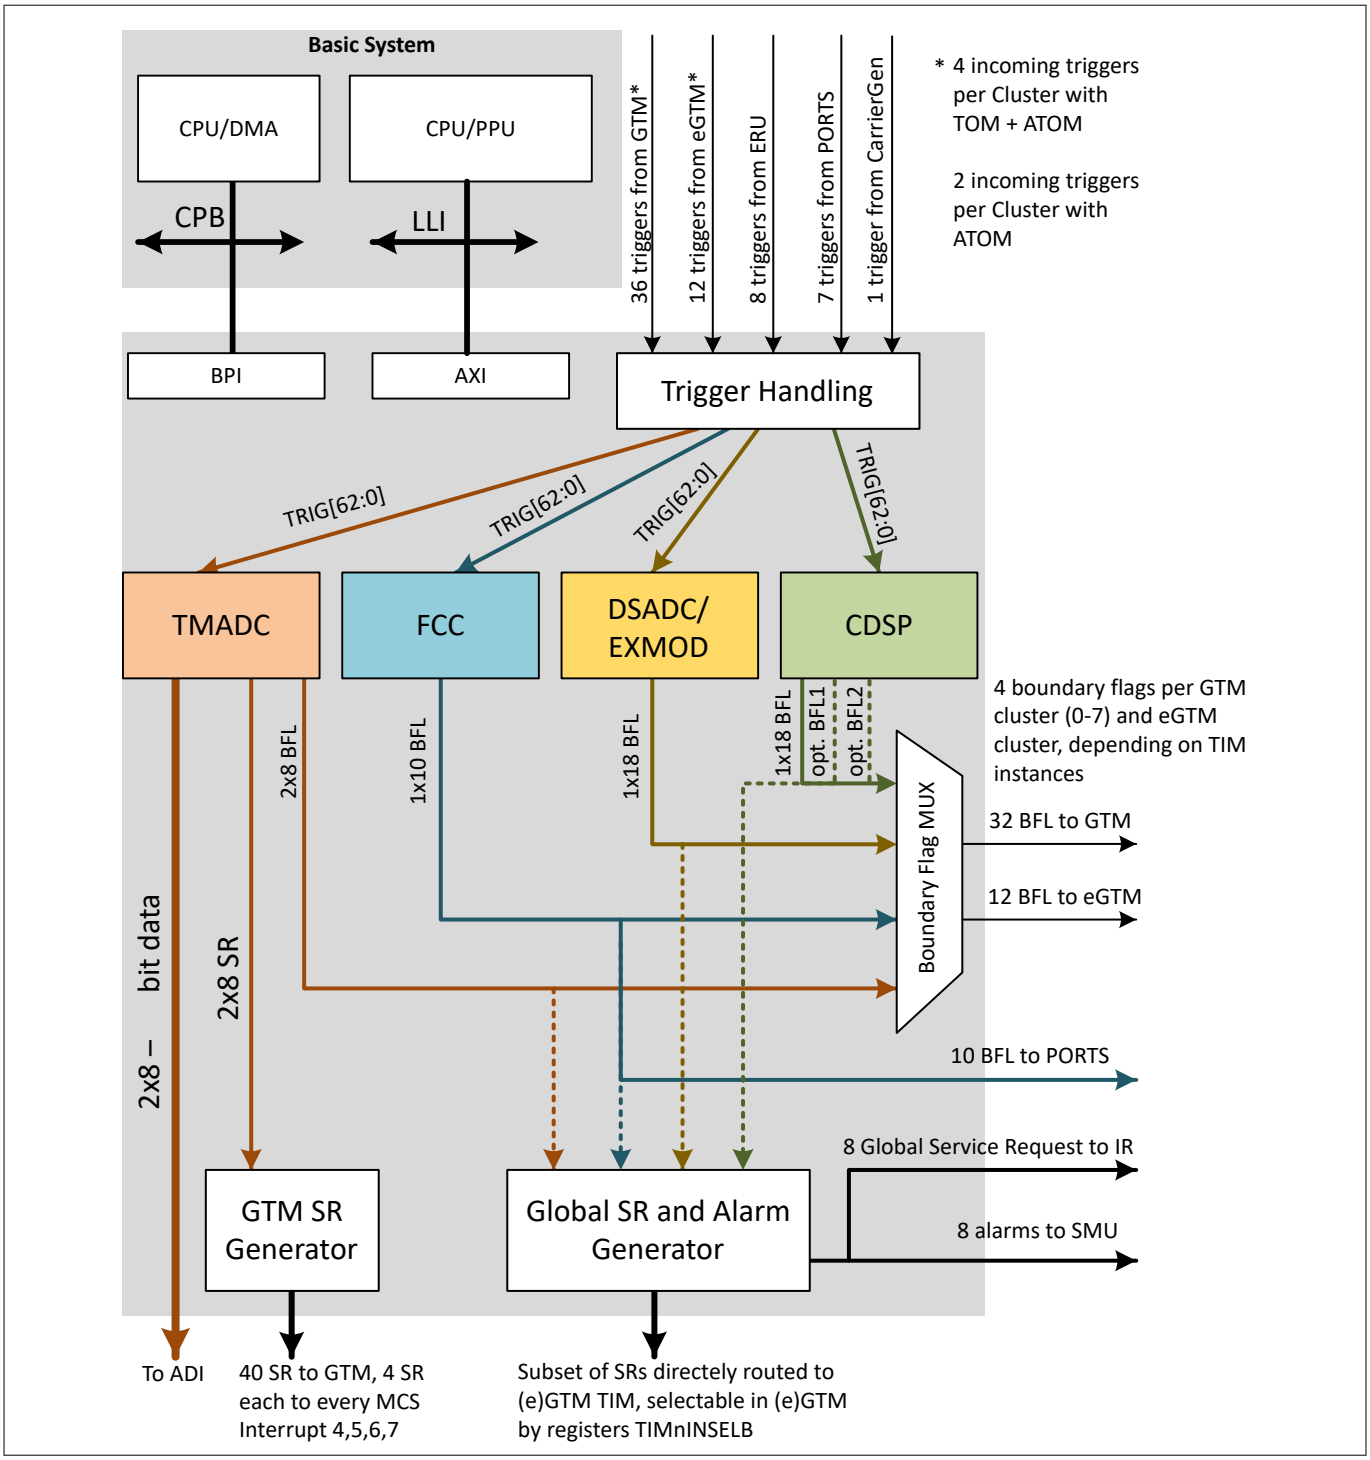

Figure 1189 ADC interface to timer (GTM and eGTM)

The figure shows the interface between ADC, GTM, and eGTM.
Every GTM and eGTM cluster with ATOM and TOM can output 4 dedicated triggers to ADC.
Every GTM and eGTM cluster with ATOM but not TOM, can output 2 triggers to ADC.
7 triggers come from PORTS directly to ADC.

***Note**: Please refer to the variant specific data-sheet for the appropriate PORT information*

Eight triggers come from SCU (ERU) to ADC, and you can use a glitch filter inside ERU to filter glitches on the trigger coming from PORTS before ERU sends a trigger to ADC. There is also one trigger signal from the carrier generator within DSADC to all of the ADC module.

45.3.5.1 Boundary flag interface to timer

This section explains the Boundary Flag interface between ADC top and Timer (GTM and eGTM).

Because of the real-time performance and deterministic functionality that several applications require, boundary flags generated inside ADC top must be directly accessible by the timer resources, GTM and eGTM respectively.

Up to 64 flags exist within ADC top. ADC top provides a configurable interface, which allows individual selection of boundary flags for each cluster of timers. The number of available boundary flags depends on the specific device variant.

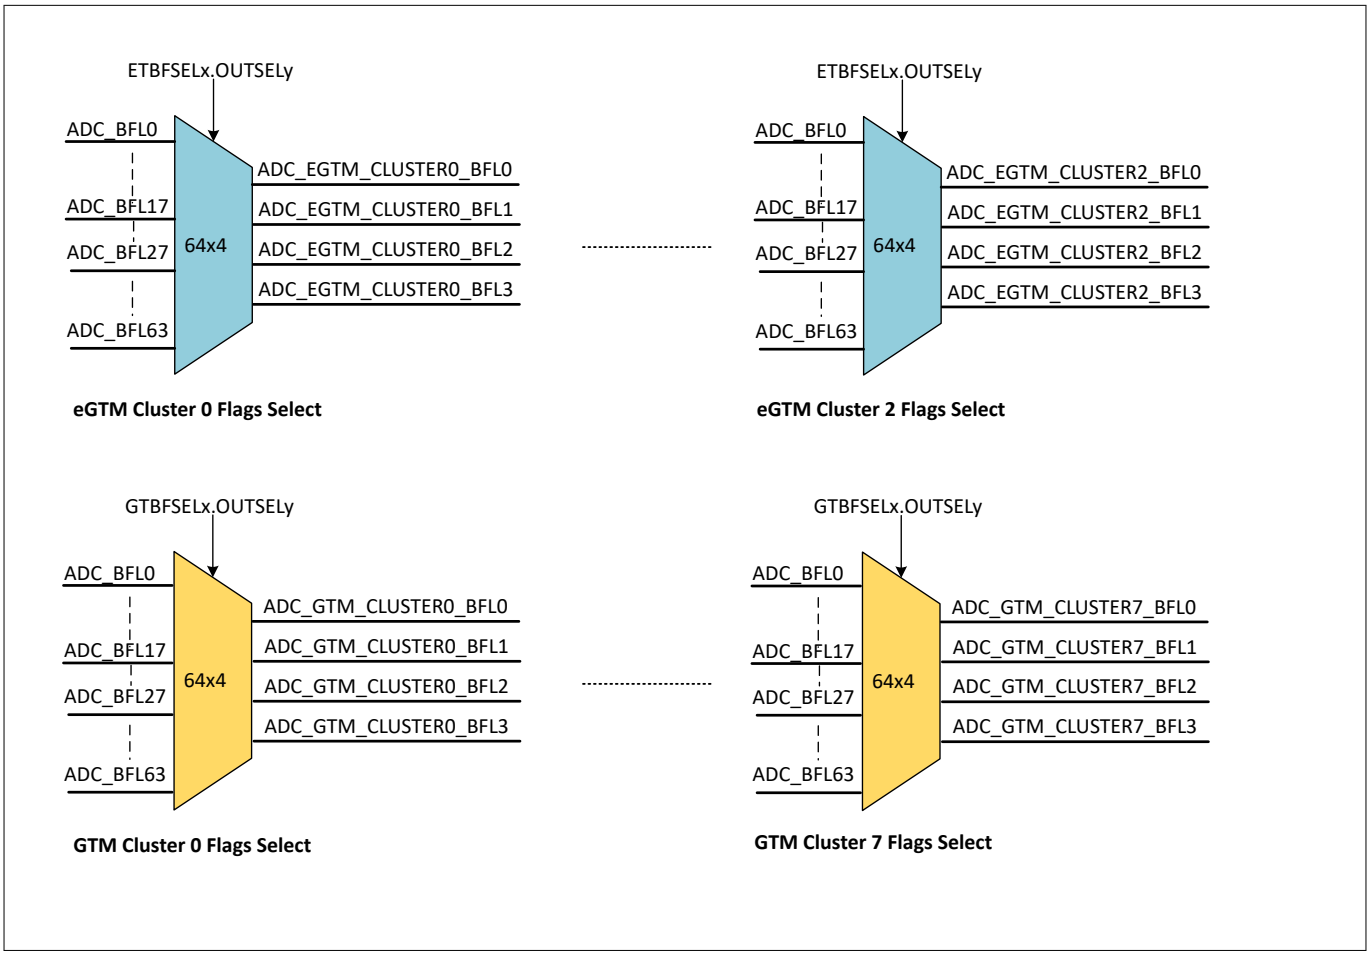

Figure 1190 Boundary flag selection for GTM and eGTM clusters

4 boundary flags can be connected to each cluster of eGTM and up to 8 clusters of GTM. Only the clusters with TIM are supported. The selection of the boundary flags for eGTM clusters is configured through the register ETBFxSEL.OUTnSEL and for GTM clusters through the register GTBFxSEL.OUTnSEL.

OUT0SEL, OUT1SEL, OUT2SEL, and OUT3SEL can be used to assign up to 4 BFL outputs to a single eGTM or GTM cluster.

***Note**: Within GTM and eGTM clusters, boundary flags are connected to TIM and DTM channels. Please refer to the GTM and eGTM chapters for more details.*

The mapping of the boundary flags of the specific ADC instances to ADC_BFL[63:0] available at ADC top can be found in chapter 'Global service request and alarm generation'.

Like described in Global service request and alarm generation, some device variants offer 2 additional boundary flag comparators per CDSP. The overrides for the boundary flags connected to GTM and eGTM are individual per eGTM and GTM cluster.

If bits ETBFxSEL.CDSPAEN[3:0] or GTBFxSEL.CDSPAEN[3:0] are set, the corresponding alternative CDSP boundary flags are mapped to eGTM or GTM.

ETBFxSEL.CDSPASE[3:0] and GTBFxSEL.CDSPASE[3:0] do select, what alternative comparator is used. If bits are set to 1_B the flags from CDSP_DSPa_BNDCFG2 are used. If set to 0_B the flags from CDSP_DSPa_BNDCFG1 are used.

The device specific appendix will name, if the additional boundary flag comparators are available.

45.3.5.2 Service request from ADC to GTM

This section explains the Service Request (SR) connections from ADC to GTM and eGTM. The Micro Channel Sequencer (MCS) inside GTM can service requests from TMADC stand-alone. Timer Input Modules (TIMs) inside GTM and eGTM can receive ADC interrupts as event signals.

Service requests from ADC to MCS

Result register 14 and result register 15 of each TMADC are mapped to the ADI interface of the MCS.

***Note**: Each channel result can be configured to go to RES14 and RES15.*

A pulse to the ADI is generated to signal new results in RES14 and RES15. Please refer to chapter "ADC Data Interface (ADI)" for more details.

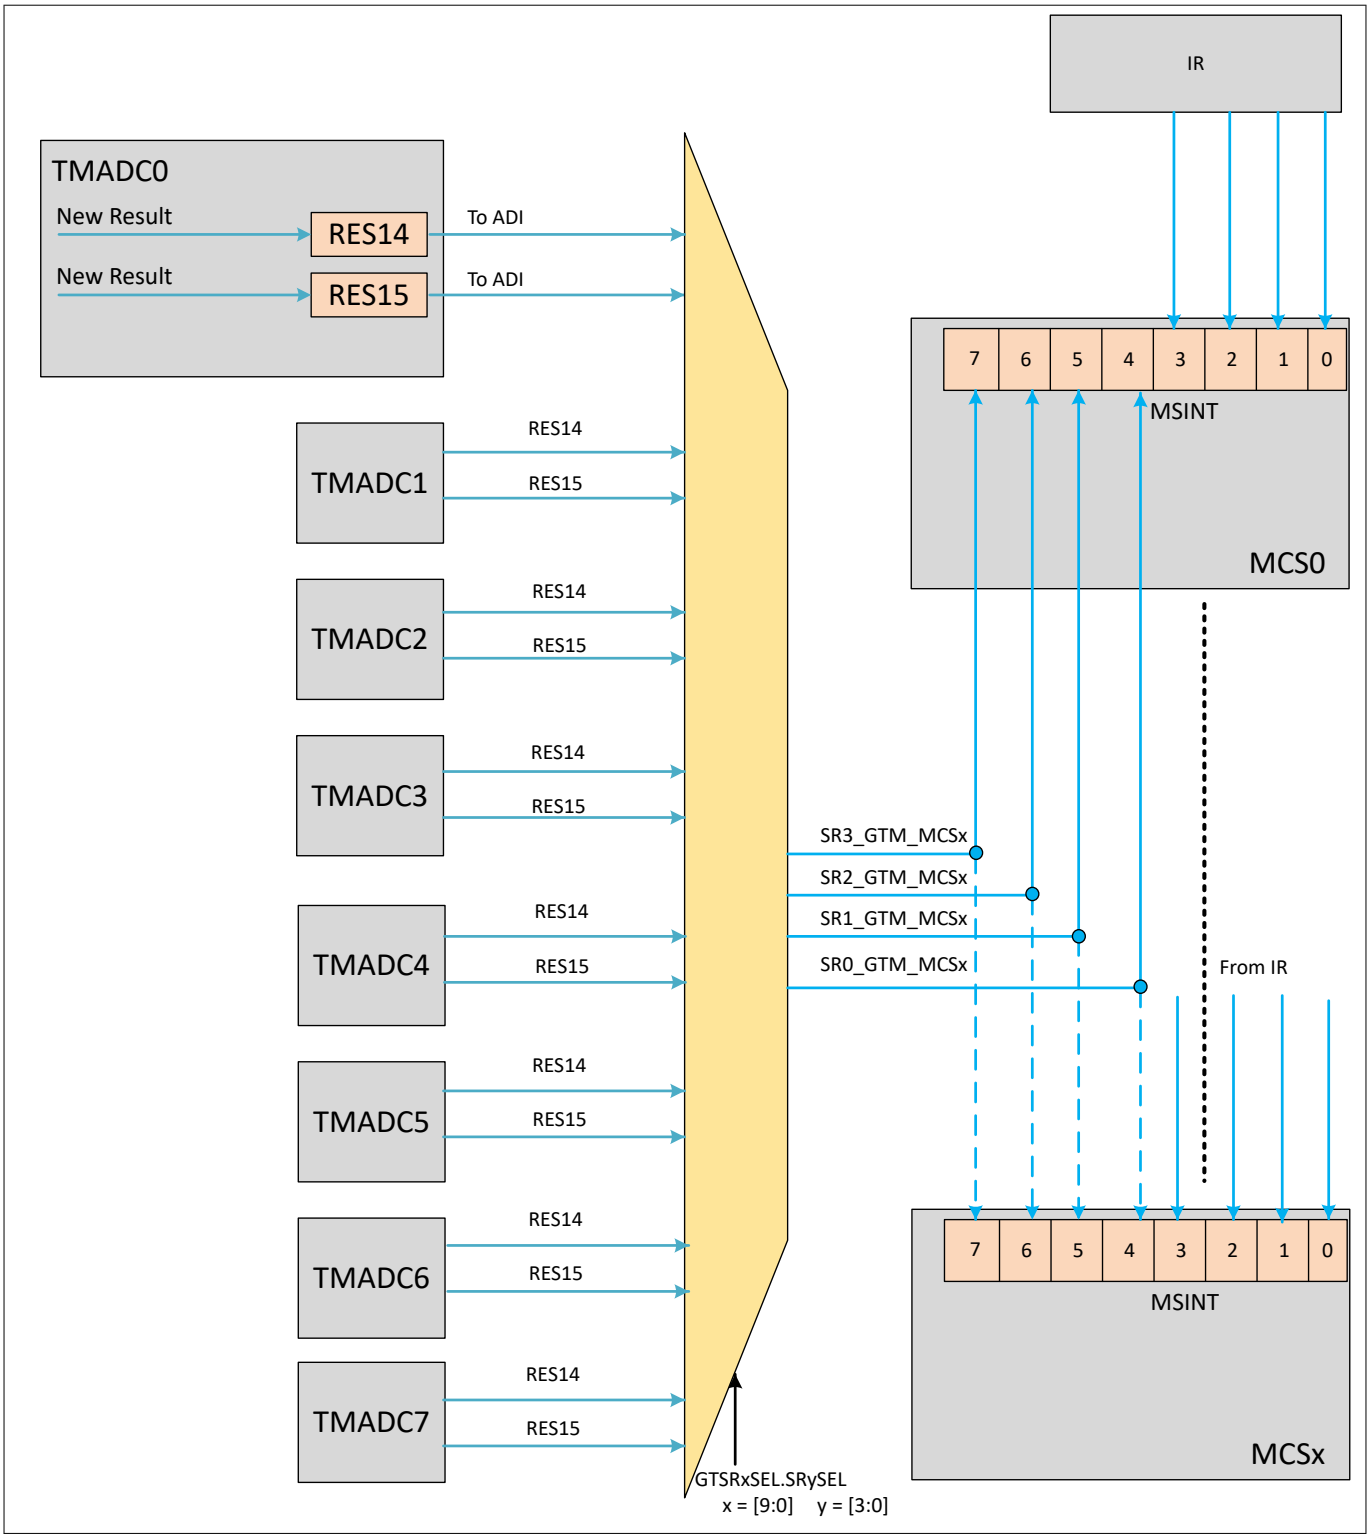

Figure 1191 Service request interface from ADC to GTM (MCS)

This figure shows the basic concept of service requests going from ADC to GTM. Service requests indicating new results in RES14 and RES15 can get routed to GTM (MCS).

Each MCS inside GTM has 8 shared interrupts, connected to MSINT register inside MCS.

- Interrupt lines 0-3 are connected to IR
- Interrupt lines 4-7 of each MCS are connected to ADC, so ADC can directly send an interrupt

For each MCS you can select 4 interrupts from up to 16 TMADC interrupts. Selection is configured through the register GTSRxSEL.SRySEL. Service request to MCS are first enabled through bit-field SRyEN.

It is possible to send the same service request to all MCS. By sending the same service request to all MCS, they all get the information about the data available on ADI and can fetch the data.

***Note**: Data is only available on the ADI interface. Additional information related to valid input has been removed from ADI. Data is qualified by SR. Please refer to the GTM chapter for more details.*

Service requests from ADC to TIM

The Timer input modules of GTM and eGTM can select a subset of ADC interrupts as trigger event. Selection is done in register TIMnINSELB. Details can be found in the timer description.

Related information

ADC data interface (ADI) on page 8350

45.4 Time-multiplexed analog-to-digital converter (TMADC)

TMADC is based on a Successive Approximation Register (SAR) concept and provides 12-bit analog to digital conversion of up-to 16 external analog input channels using 2 SAR cores supporting a maximum output sample-rate of 4 MSPS.

45.4.1 Feature list

- Analog supply voltage 5.0 V or 3.3 V
- Input voltage range from analog reference ground (VAGND) up to analog reference supply voltage (VAREF)
  - In case V_{IN} exceeds VAREF, the conversion result will be 0xFFF
  - In case V_{IN} is lower than VAGND, the conversion result will be 0x000
- Each TMADC module supports up to 16 external analog input channels mapped to 2 SAR cores
- Programmable sampling time on each input channel with 12.5 ns resolution
- Maximum output data rate up to 4 MSPS
- Flexible trigger source selection
  - Conversions triggered by software, timer events, or external events
  - Up to two hardware trigger request sources for each channel out of 64 available sources
  - Synchronous sampling support on multiple input channels with a single trigger source
- One shot or continuous conversion modes supported on single or multiple input channels
- Powerful result handling
  - Independent channel-specific result registers
  - Burst read access support for time-stamp and result registers
- Configurable checking against programmable limits
  - Support boundary value update on hardware trigger
  - Limit check on conversion results for up to two independent input channels
- Service request generation based on result events and error events
- External analog multiplexer control support
- Reference voltage monitoring support
- Built-in diagnostic features
  - Broken wire diagnostics
  - Converter self-diagnostics to verify the correct operation of the SAR cores
  - Monitoring of selected internal voltages (supplies, references)

45.4.2 Functional overview

Each external analog input channel of a TMADC has its dedicated sample and hold (SH) circuitry, therefore allowing independent SH operation on each channel. Each channel can be mapped to one of the two available SAR cores for conversion through the channel core mapping connection matrix.

The channels are triggered for conversion either by a software write, hardware timer signals, automatic triggering, or by external events. There are 2 internal monitor channels provided for the purpose of supervising other on-chip signals like internal core supply voltages, or supply voltages from other TMADC or DSADC.

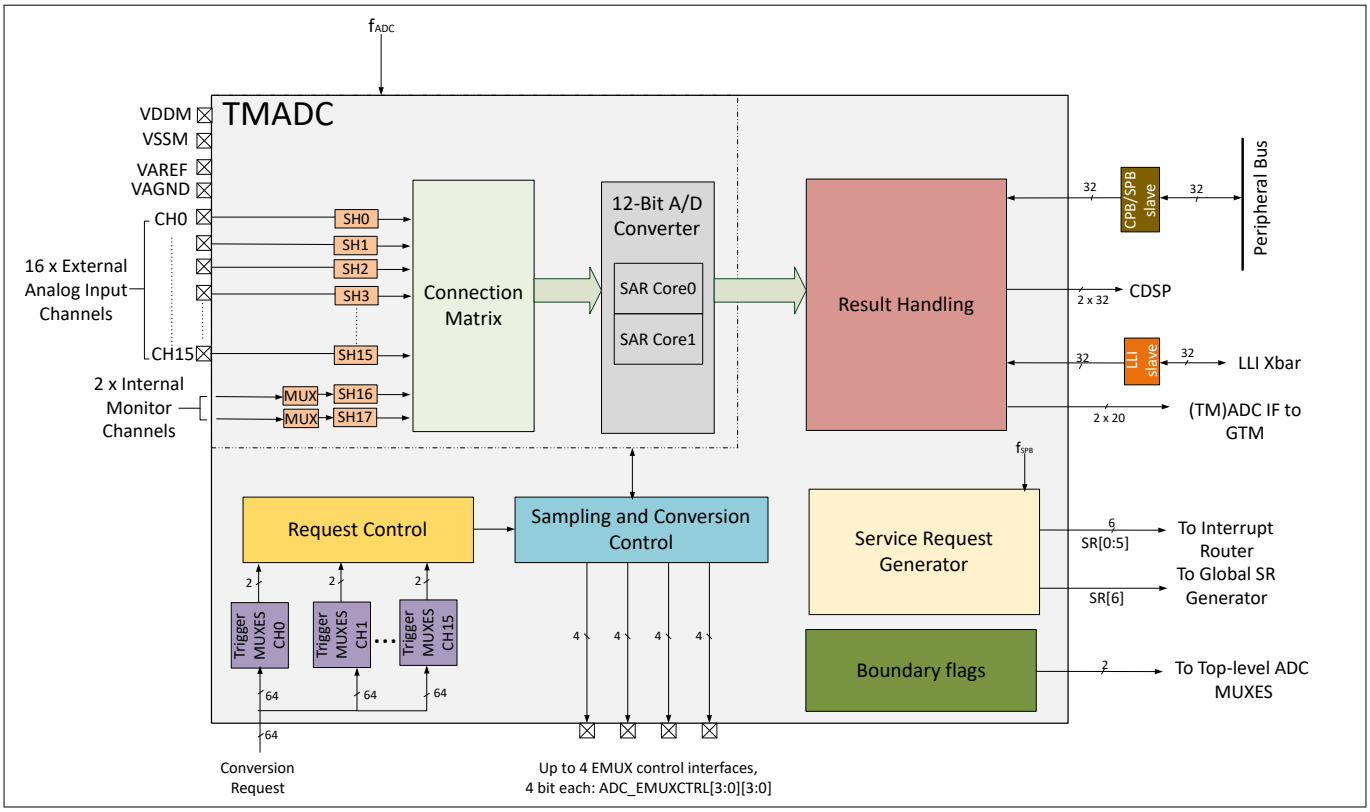

Figure 1192 TMADC block diagram

Request control

An external input channel is configurable to receive a conversion request from different request sources; 2 hardware trigger sources and a software trigger source. The selection of these two hardware trigger sources is made through the trigger multiplexers from an available option of 64 sources (see chapter "Trigger request control"). The request control logic block handles the conversion requests for the channel. A trigger event, if processed, switches the channel to a hold state for conversion. Different trigger mode configurations offer flexibility to the user to initiate a conversion request on a rising edge, falling edge or both rising and falling edges of the hardware trigger. Handling of concurrent trigger requests in the same cycle is also controlled here.

Sampling and conversion control

Channel and core state transitions are handled here (see chapters "Sampling" and "Conversion"). Intrinsic core's round-robin channel arbitration implementation handles simultaneous conversion requests on multiple channels connected to it. For off-chip analog multiplexer control, selection lines are provided for the external multiplexer's channel selection through MCU GPIO pins.

Result handling

This unit handles the configuration of the result registers where the conversion results are stored (see chapter "Conversion result handling"). The conversion result of the external analog channels is stored into one of 16 result registers. Internal monitor channel results are stored in specific monitor channel result registers. The wait-for-read mode configuration for the result registers stalls further subsequent conversion on the respective channel until their corresponding result is read, therefore, avoiding any data loss due to data overwrite.

Boundary conditions checks on the conversion results (if enabled) are configurable. TMADC result data (RES0 and RES1) can be read and further processed by CDSP module for advanced filter operations. A low latency path is available between PPU and TMADC through LLI providing faster result data read access capability. Additionally, each TMADC module provides a 20-bit ADC Data Interface (ADI) for the results (RES14 and RES15) to GTM.

Service request generation

TMADC has 6 service request lines going to the interrupt router and 1 service request line connected to the global service request generator (see chapter "Service request generation"). The generation of these service requests is configurable based on error, result or boundary event(s). These three event types are described below:

- Error event indicates an error condition on a channel that arises on receiving a conversion request trigger during its sampling or hold phases, while conversion is ongoing or while trigger delay counter is running
- Result events indicate the availability of new result data in the result registers
- Boundary events indicate successful configured boundary checks on the channel results

45.4.3 Functional description

The functional description of TMADC is divided into the following sections:

- Module operation states
- Changing module configuration
- Module start-up calibration
- Trigger request control
- Analog input channel configuration
- Conversion result handling
- Service request generation
- Diagnostics
- On-chip signal monitoring and supervision
- External Multiplexer Control

45.4.3.1 TMADC operation states

This section describes the behavior of the module response to enable, disable, run and suspend request.

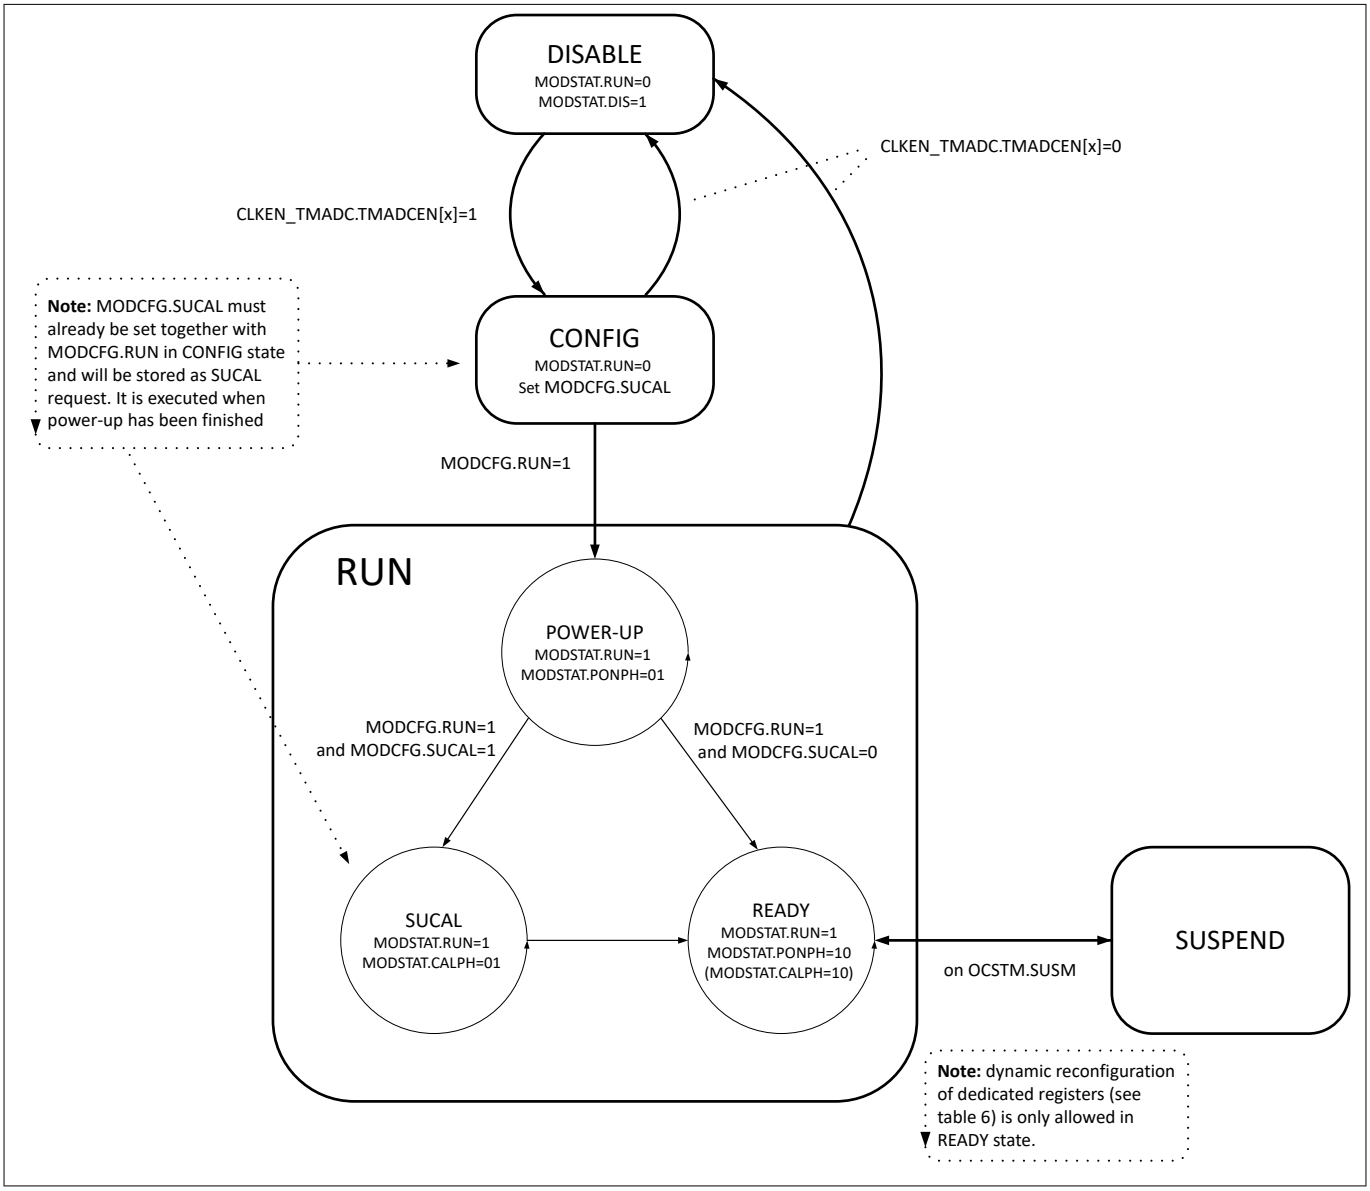

Figure 1193 TMADC module operation states

Disable

TMADC module registers are to be initialized in the CONFIG state upon setting CLKEN_TMADC.TMADCEN[x]=1_B.The TMADC module in CONFIG state is indicated with TMADCx_MODSTAT.RUN=0_B. Before setting the module to RUN state, all required settings for example trigger sources, channel enable, channel configuration registers, result registers, connection matrix setting and operation modes, should be configured in this state.

The TMADC module can be disabled while in the RUN or CONFIG state by setting CLKEN_TMADC.TMADCEN[x]=0_B. On disabling, the module ignores any further trigger requests, finishes the conversion of any currently active channel(s) in hold or conversion phase on the core(s), stores the result for the converted channel(s) and sets corresponding status flag for the result(s). Subsequently the module is powered-down, all internal module states are cleared, and all module clocks are switched-off.

The module disabled state is indicated with TMADCx_MODSTAT.DIS=1_B.

Run

Once the module registers are configured, the converter is started by setting TMADCx_MODCFG.RUN=1_B. When the module is set to RUN state, the module iss powered-on in time t_{WUDIS} (please refer to the respective data sheet for appropriate values). An active module power-on sequence is indicated with MODSTAT.PONPH=1_B and a running module state is indicated with TMADCx_MODSTAT.RUN=1_B.

When transitioning to DISABLE state from RUN state by setting CLKEN_TMADC.TMADCEN[x]= 0_B, the module ignores any further trigger requests, finishes the conversion of any currently active channel(s) in hold or conversion phase on the core(s), stores the result for the converted channel(s) and the sets corresponding status flag for the result(s). Subsequently, the TMADC analog block is powered-down, all internal module states are cleared, and transition is made to the DISABLE state, which is indicated with the clear of TMADCx_MODSTAT.RUN bit. Note that in the CONFIG state, anytime the channel configuration matrix is modified, you must enable the start-up calibration process on setting the module to RUN state.

Suspend

The module can be suspended in a hard-suspend or soft-suspend manner. On receiving a hard-suspend request OCSTM.SUSM=01_B, the module clock is disabled immediately and the module moves to suspend state. On setting OCSTM.SUSM=11_B, all channels currently in their hold state are converted as per the round-robin arbitration and any incoming conversion trigger request on the channels is ignored. The module is suspended after the result of the last converted channel is stored and the status flag set.

***Note**: The channel(s) in hold state start loosing the captured charge on the sampling capacitor(s) as the channel hold time extends above 16 periods of t_{CONV}. This can happen when the module gets suspended with OCSTM.SUSM=01_B request causing channel(s) being suspended in hold or conversion or hold state, respectively. Therefore, upon suspend removal, the conversion results for those channel(s) shall be considered invalid until the channel(s) have been re-sampled for at-least an accumulated duration of t_{mstc} + 1.6 µs.*

The following table shows the state transitions. Transitions marked as 'User scenario' result from intended use cases.

Table 2375 State transitions

Current State	Next: RUN	Next: CONFIG	Next: DISABLE	Next: SUCAL	NEXT:SUSPEND
RUN	N/A	N/A	User scenario	No user scenario	User scenario
CONFIG	User scenario	N/A	User scenario	User scenario	No user scenario
DISABLE	Unreachable	User scenario	N/A	No user scenario	Unreachable
SUCAL	User scenario	No user scenario	No user scenario	N/A	No user scenario
SUSPEND	User scenario	No user scenario	No user scenario	No user scenario	N/A

45.4.3.2 Changing module configuration

The configuration bit-fields control the operation of the functional blocks of the TMADC. Configure the TMADC while in CONFIG state.

While in READY state the following register bits can be modified:

Table 2376 TMADC dynamic configuration and implication

Dynamic configuration	Implication
Module enable (TMADCx_MODCFG.RUN)	Start or stop module. For start and stop procedure (see chapter Module operation states)

(table continues...)

Table 2376 (continued) TMADC dynamic configuration and implication

Dynamic configuration	Implication
Output supervision signal select (TMADCx_MODCFG.OSSEL)	Multiple TMADC output supervision signals (see device specific chapter) are connected on the same line. The user must ensure at any given time only one signal is active on the line
Software trigger (TMADCx_SWTRCFG.SCHSEL)	This is a channel conversion request from software and it can get triggered at any time
Monitor channel multiplexer setting (TMADCx_MCHy_CFG.SEL)	The monitor channel multiplexer setting selects the internal signal to be sampled and converted. The setting can be reconfigured in READY state
Channel broken-wire diagnostics current source enable/disable (TMADCx_BWDCFG)	BWD can be enabled or disabled on any input channel in READY state
Channel-core self diagnostics settings (TMADCx_BWDCFG)	CSD settings can be changed in READY state
TMADCx_SRi_CFG.EVEN	As described in scenarios below
TMADCx_SRi_CFG.EVSEL	As described in scenarios below
TMADCx_SRi_CFG.EVOP	As described in scenarios below
TMADCx_CHy_CFG.HWTRxM	As described in scenarios below
TMADCx_CHy_CFG.HWTRxMS	As described in scenarios below
TMADCx_CHy_CFG.ATREN	As described in scenarios below
TMADCx_RSLTu_CFG.WFR	As described in scenarios below
TMADCx_CHy_STC.TRD	As described in scenarios below

Following use cases are supported with dynamic reconfiguration:

TMADCx_CHy_CFG.HWTRxM (trigger mode) and TMADCx_CHy_CFG.HWTRxMS (tigger source) channel configuration register bitfields are changed on the fly

- Switch off the HWTRx and delay counter enable (HWTRDLYEN) in configuration register TMADCx_CHy_CFG
- Reconfigure the HWTRx source, change trigger delay (TRD) if necessary
- Re-enable the HWTRx and delay counter enable (i.e. change the HWTRx mode for the channel and set HWTRDLYEN)

  In general the trigger delay counter (TRD) can get changed any time. In case the counter is enabled and running, the new value is taken after the actual delay count expires. If counter is idle, new value is taken immediately.

Change channel configuration between ATREN (TMADCx_CHy_CFG. ATREN) and HWTR mode

- Disable the ATREN (HwTRx are already disabled)
- Configure the HWTRx source
- Configure the HWTRx mode (i.e. enable it)
- Run in HWTRx mode
- Disable HWTRx
- Re-enable the ATREN
- Run in automatic trigger mode

Scenarios for service request configuration register using TMADCx_SRi_CFG.EVEN, EVSEL, EVOP. Reconfiguration of TMADCx_SRi_CFG.EVEN is only supported in AND mode (EVOP=10b)

Change event and its operation mode.

- Disable the EVSEL = 00b (Disable)
- Reconfigure the EVEN, EVOP field
- Re-enable EVSEL = 11b/10b(Boundary/ Result)

For continuous triggered groups, the application SW may want to keep TMADCx_RSLTu_CFG.WFR= true to reduce interrupt load

- Disable trigger sources for the channel
- Update WFR for the result register associated to disabled channel
- Re-enable trigger source for the channel

45.4.3.3 Module start-up calibration

Calibration reduces deviation errors caused by manufacturing process variations. To ensure high accuracy of generated conversion results throughout the operation time, it is required to run the start-up calibration sequence before transition to RUN state. Start-up calibration can only be triggered when t_{WUDIS} has passed.

Exception: if the channel-core mapping settings have not been altered since the previous RUN state, the calibration procedure is not required to be executed. The start-up calibration is initiated by writing 1 to bit SUCAL in register TMADCx_MODCFG.SUCAL.

It is required to run the calibration before entering the RUN state, so that after a duration of t_{WUDIS}+ t_{CAL}, the converter starts its operation with the set configurations.

Initiating calibration from RUN state requires transition to DISABLE and CONFIG state. RUN request with SUCAL bit set in CONFIG state will activate the calibration (SUCAL state)

The respective TMADC modules must be enabled when running a start-up calibration. Conversions are started, only after the calibration has completed (completed calibration sequence is indicated by bit TMADCx_MODSTAT.CALPH = 10_B). The duration of the start-up calibration phase is up to t_{CAL} (see datasheet). A currently active calibration sequence is indicated with TMADCx_MODSTAT.CALPH= 01_B.

45.4.3.4 Trigger request control

This chapter describes the trigger definition with respect to TMADC sampling behavior and handling of hardware and software trigger events.

45.4.3.4.1 Trigger definition

In TMADC a channel's sampling time (t_{st}) has 2 phases, the minimum sampling time (t_{mstc}) and the extended sampling time (t_{ext}), as shown in the next figure.

The extended sampling time is the time duration after the end of minimum sampling time and the end-of-sampling caused by a trigger event. The trigger event switches the channel to hold state for conversion. The minimum value of the hardware trigger PWM period should be configured greater than the sum of the total channel conversion time and the total sampling time. In TMADC, the total channel conversion time is a function of the channel hold time t_{hold} and channel conversion time t_{conv}, where t_{hold} depends on the numbers of channels connected to a SAR core (see chapter "Conversion" for details). A hardware trigger is processed only if it occurs after the minimum defined sampling time window is over. A software trigger can occur during minimum sampling time.

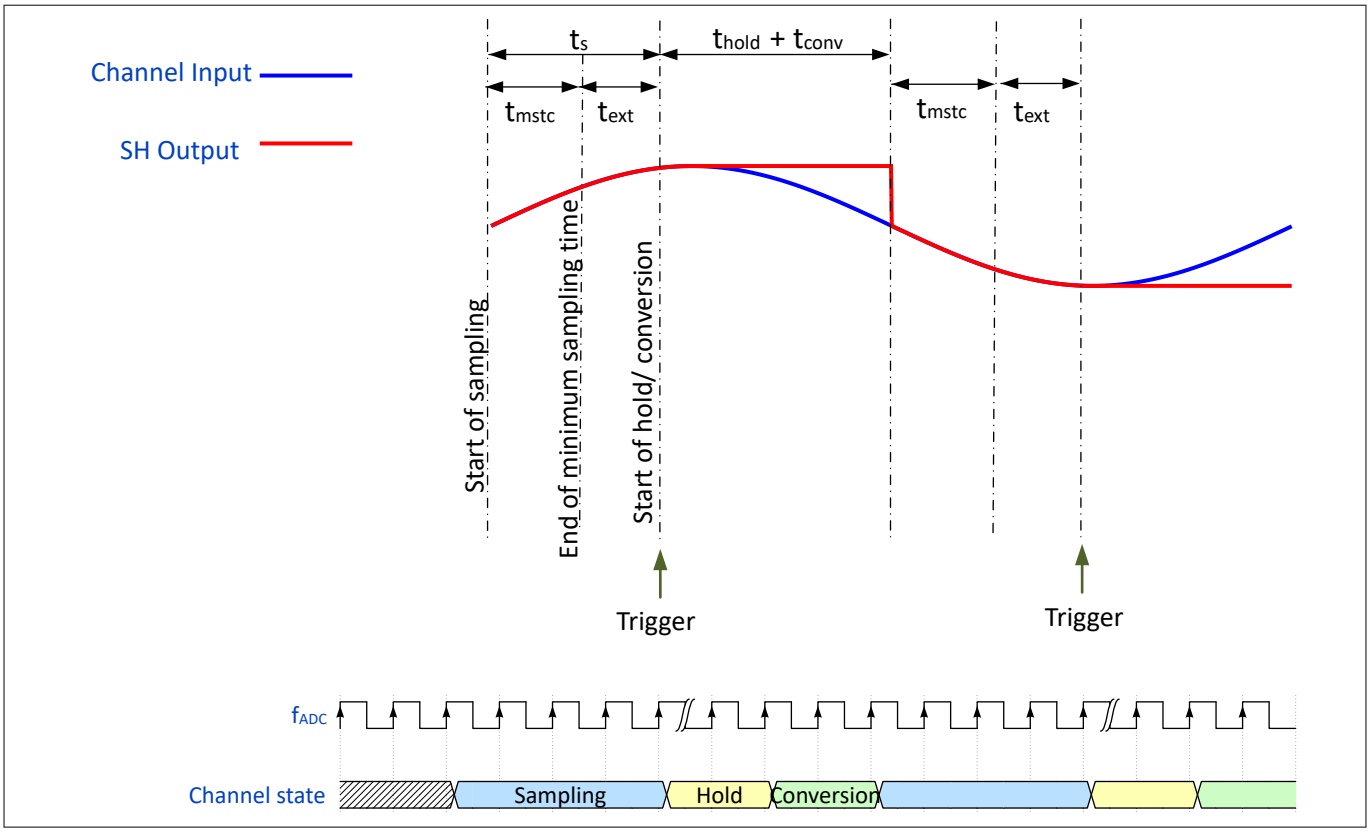

Figure 1194 TMADC trigger concept

Trigger events

The input trigger interface of TMADC is shown in the figure below. The 64 request sources are shared among all TMADC modules .

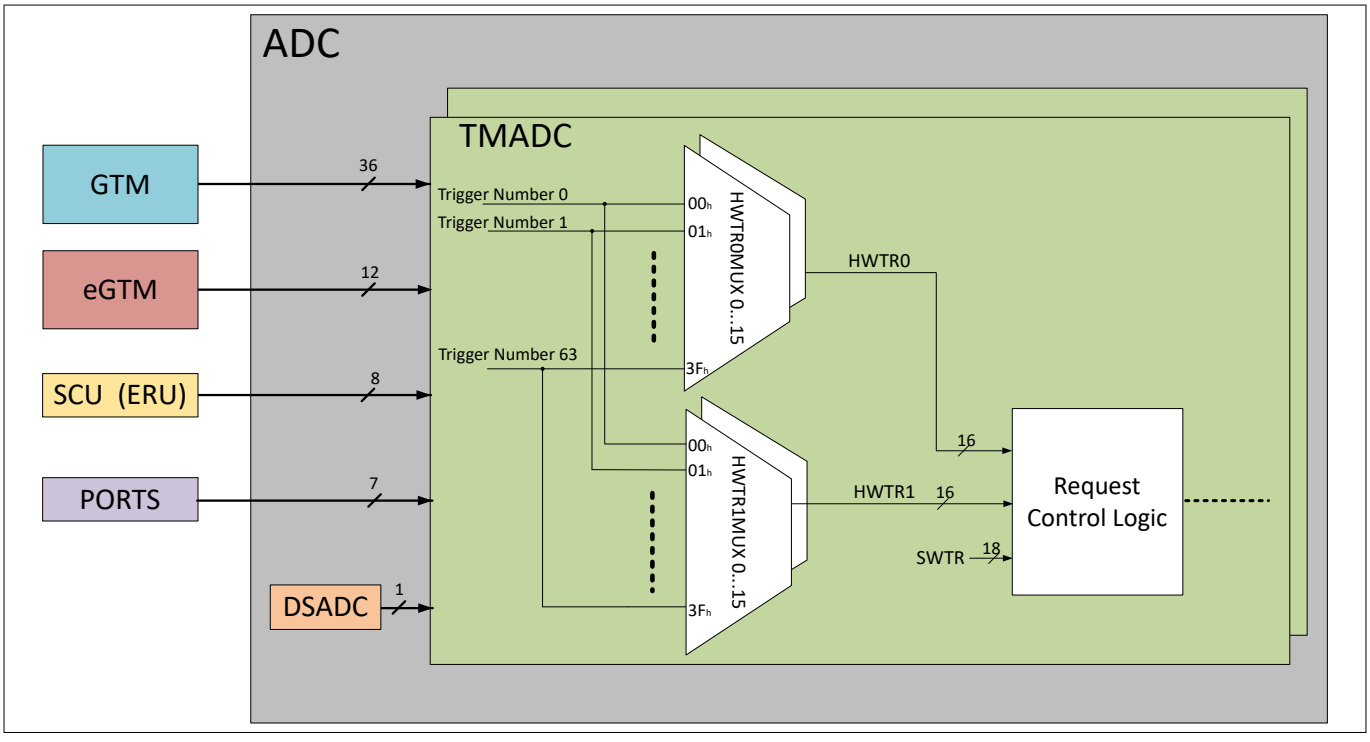

Figure 1195 TMADC trigger interface

There are 2 type of request sources for a channel as described below:

- Hardware triggers request source: For each channel 2 hardware trigger request sources can be selected from 64 available possibilities. These are configured through bit-fields HWTR0MS and HWTR1MS in the register TMADCx_CHy_CFG
- Software trigger request source: Application software can directly trigger a channel or multiple channels of a TMADC for conversion through the setting of bit-field SCHSEL in the register TMADCx_SWTRCFG. A software trigger generates a single conversion request for the channel every time the respective channel bit is set in the register TMADCx_SWTRCFG. For example, by setting TMADCx_SWTRCFG.SCHSEL=3_H software triggered conversion request is generated for channels CH0 and CH1

Related information

Conversion on page 8338

45.4.3.4.2 Trigger handling and arbitration logic

The request control logic for each channel comprises of a trigger edge detector logic, programmable trigger delay counter and a trigger source arbiter for concurrent trigger requests management from multiple request sources.

The figure below shows the hardware and software trigger propagation through request control logic block in a simplified block diagram.

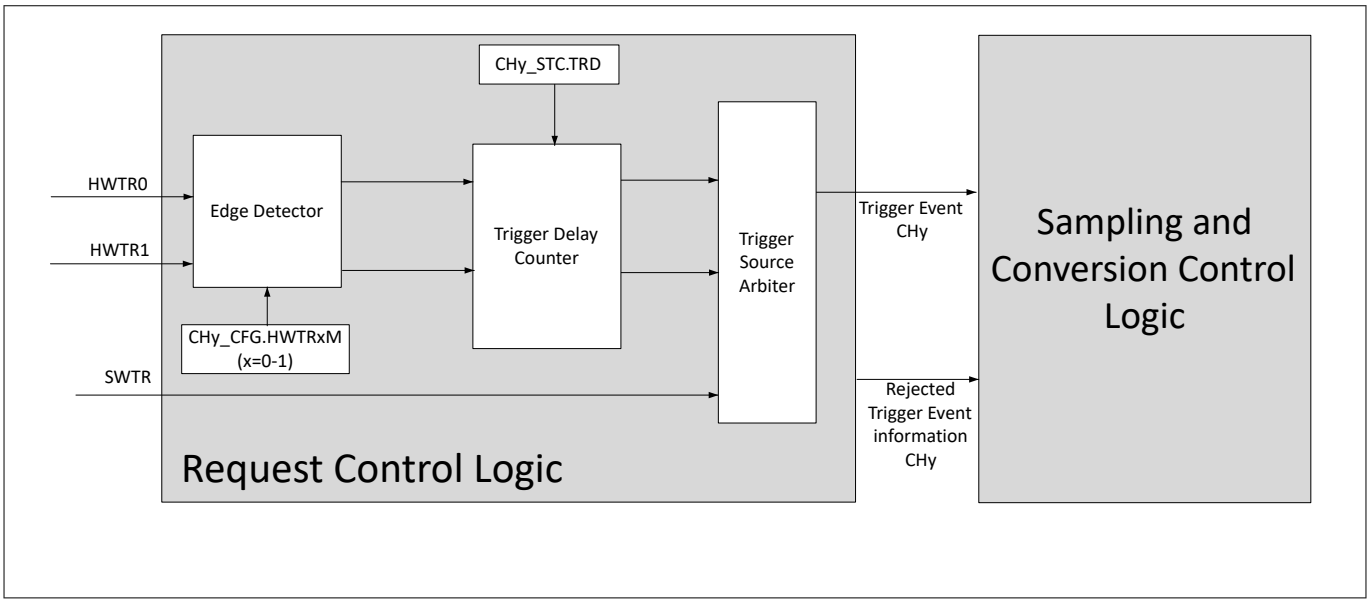

Figure 1196 Request control logic

Edge detection

A hardware trigger can be configured to initiate a channel conversion request on either its rising or falling edge or on both the edges. The edge selection for the hardware trigger used by a channel is done through bit-fields HWTR0M and HWTR1M in the register TMADCx_CHy_CFG for sources HWTR0 and HWTR1 respectively. A hardware trigger can be disabled for the channel by setting TMADCx_CHy_CFG.HWTRiM = 00_B (i=0-1). An example is shown in figure below with different trigger mode configurations of HWTR0 for channel CH0.

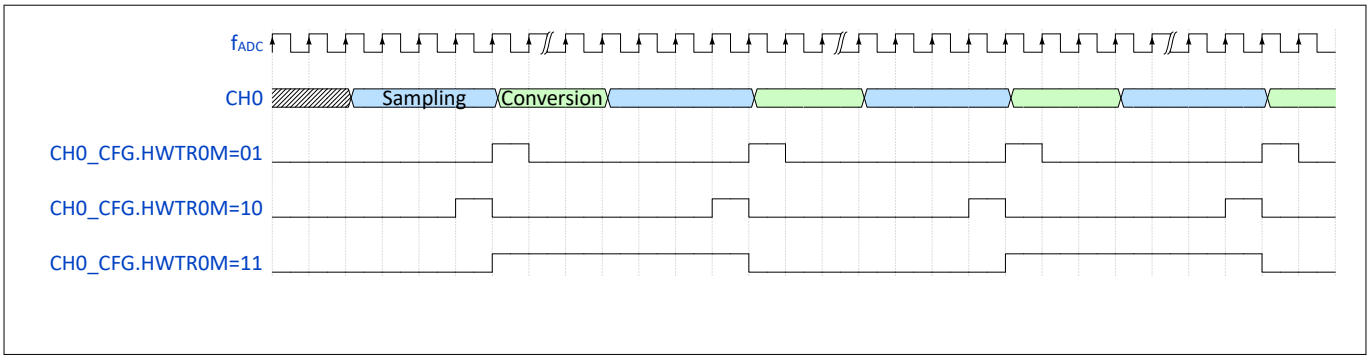

Figure 1197 TMADC trigger configuration

Trigger delay

The trigger delay counter adds a programmable delay to the input hardware trigger. It is configured through the bit-field TRD in the TMADCx_CHy_STC register. It is enabled and disabled with the bit-field HWTRDLYEN in the register TMADCx_CHy_CFG. The delay counter operates with a fixed clock frequency of 80 MHz. The trigger delay counter operates when there is a non-zero value of TRD bit-field set in the TMADCx_CHy_STC register. The counter is common to both of the hardware trigger sources so the trigger which arrives earlier sets the counter in operation and all further trigger events arriving at the counter input are ignored and indicated with error flag bit HWTRE along with the hardware trigger number information in bit-field TRENR in the TMADCx_CHy_STAT register until the counter resets back to the value specified by TMADCx_CHy_STC.TRD. When the hardware triggers HWTR0 and HWTR1 arrive in the same clock cycle at the counter input, then HWTR1 is ignored and error is flagged in the TMADCx_CHy_STAT register. Setting TMADCx_CHy_STC.TRD=00_H disables the counter and the hardware triggers HWTR0 and HWTR1 are propagated to the trigger source arbiter. For cases when the channel conversion is requested on a rising and falling edge of a trigger signal, the user must configure the trigger delay smaller than duty cycle period of the trigger. The table below displays the hardware trigger delay settings and corresponding values.

Table 2377 Hardware trigger delay configuration

Trigger delay configuration CHy_STC.TRD	Absolute trigger delay
00_H	0 ns
01_H	12.5 ns
02_H	25 ns
03_H	37.5 ns
04_H	50 ns
05_H	62.5 ns
06_H	75 ns
07_H	87.5 ns
08_H	100 ns
…	…
$FFFF_H$	819.1875 µs

***Note**: Receiving any new trigger event on either of the selected hardware trigger while the trigger delay counter is running will result in rejection of the new requests. And if the new trigger events arrive in the same cycle then only HWTR0 information will be visible to the user in the TMADCx_CHy_STAT register.*

Trigger source arbiter

The trigger source arbiter handles the incoming trigger requests. The arbiter can receive input trigger requests from 3 sources; 2 hardware trigger (HWTRx) events and a software trigger (SWTR) event as shown in Figure 1196. A software trigger event is asynchronous to the hardware trigger events. The following points describe the trigger request handling:

- Hardware triggers are processed if they occur in the extended sampling time. The extended sampling time starts once the minimum sampling time is over. Triggers are ignored during a running minimum sampling time phase or if a channel is in a hold or conversion state. Ignored hardware triggers set the hardware trigger error (HWTRE) along with the trigger error number (TRENR) in the TMADCx_CHy_STAT register
- A software trigger event is processed if the request occurs either during a running minimum sampling time phase or during extended sampling time phase. Occurrence of a software trigger during minimum sampling time phase results in channel transition to the hold state after the minimum sampling-time counter is expired. A software trigger will be ignored if it occurs in the channel's hold state. An ignored software trigger information is indicated to the user through the Software Trigger Error bit (SWTRE) in the TMADCx_CHy_STAT register

During extended sampling state of a channel, the next trigger event will get processed and others are ignored. Ignored hardware or software triggers are discarded and will not be repeated any more. The table below shows/describes the trigger source arbitration.

Table 2378 Trigger source arbitration

Channel state	Concurrent triggers	Processed trigger	Ignored trigger(s)
Minimum sampling-time phase	SWTR, HWTRx	SWTR	HWTRx
	HWTR0, HWTR1	None	HWTR0, HWTR1
Extended sampling-time phase	SWTR, HWTRx	HWTRx [1)]	SWTR
	HWTR0, HWTR1	HWTR0	HWTR1
Hold or conversion phase	SWTR, HWTRx	None	SWTR, HWTRx
	HWTR0, HWTR1	None	HWTR0, HWTR1

1) Here if both HWTR0 and HWTR1 occur simultaneously, then HWTR0 is processed and HWTR1 is ignored.

***Note**: In cases where both hardware triggers HWTRx are ignored, only the most recently ignored hardware trigger information will be available in the CHy_STAT register and if both triggers are ignored at the same time then only HWTR0 information will be visible to the user.*

Following table describes the detailed trigger and error behavior after a running trigger delay counter gets disabled by Software.

Table 2379 Trigger arbitration after Software disable of trigger delay counter

Scenario	Trigger behavior
Channel in minimum sampling/hold/conversion time window (in example: minimum sampling time not reached)	If delay counter triggered by HWTR1 expires at the same clock cycle as trigger pulse coming from HWTR0 then both hardware triggers are ignored and the ch_stat of the respective channel will be updated with the error information of HWTR1.
Channel in extended sampling time window	If delay counter triggered by HWTR1 expires at the same clock cycle as trigger pulse coming from HWTR0 then HWTR1 will be used for triggering a conversion. HWTR0 pulse will not be processed and no error flag will be set in the ch_stat register.

(table continues...)

Table 2379 (continued) Trigger arbitration after Software disable of trigger delay counter

Scenario	Trigger behavior
	If delay counter triggered by HWTR0 expires at the same clock cycle as trigger pulse coming from HWTR1 then HWTR0 will be used for triggering a conversion. HWTR1 pulse will not be processed and no error flag will be set in the ch_stat register.

The figure below shows the timing windows during channel sampling where the triggers are accepted or ignored. No triggers are accepted in channel's hold or conversion phase.

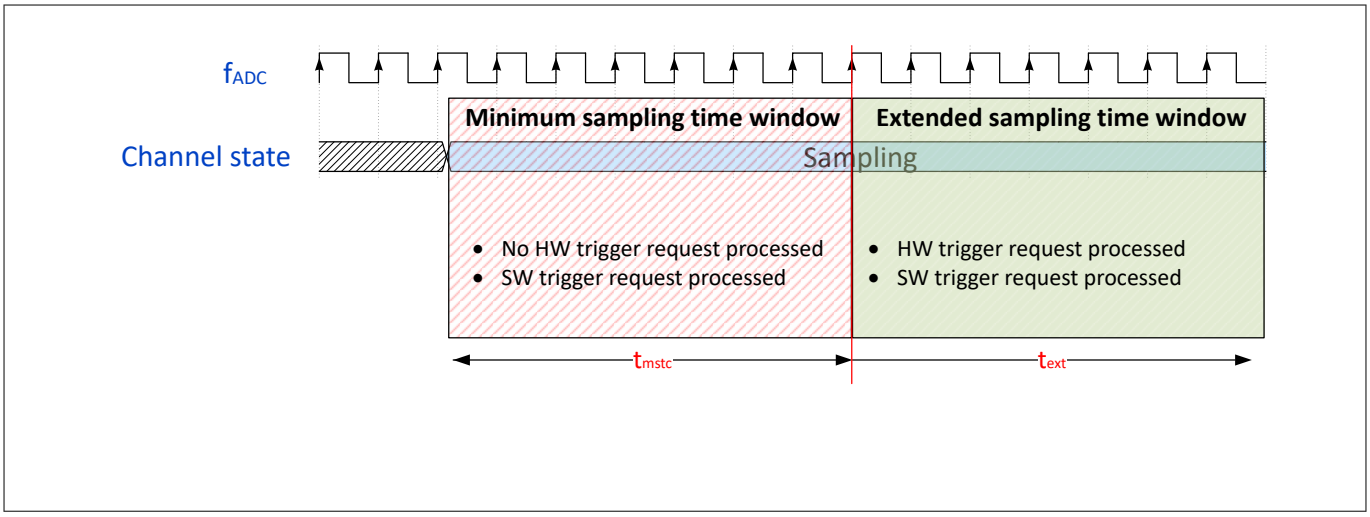

Figure 1198 TMADC trigger handling

45.4.3.5 Analog input channel configuration

This chapter describes the sampling and conversion configurations for the input channel.

45.4.3.5.1 Sampling

Channel sampling configuration

The sample and hold (SH) unit tracks the analog input signal on the channel during the sampling time. A channel is enabled by setting TMADCx_CHy_CFG.EN=1_B. The minimum sampling time (ST) is configurable by the user through bit-field ST in the TMADCx_CHy_STC register. Please check product-specific datasheet for minimum sampling time values with respect to different types of conversion.

The SH has to get enabled in CONFIG state. Transition to RUN state initiates the input sampling by loading the sampling counter with ST value. The counter operates with a clock frequency of $f_{ADC}/2$. The configurable minimum sampling time values for a channel are given in the table below. There are 2 SAR cores (Core-0 and Core-1) available for performing channel conversions. The mapping of the channel to the core is done through bit-field CHCSEL in the TMADCx_CMATCFG register.

***Note**: For low or medium range supply voltage, the sampling time shall be configured with resolution of 25 ns with minimum allowable setting of TMADCx_CHy_STC.ST = 07_H. Please check product-specific datasheet for minimum sampling time values with respect to supply voltage.*

Table 2380 Sample time coding

Sampling time configuration TMADCx_CHy_STC.ST	Minimum sampling time t_{mstc}
00_H (Reserved)	12.5 ns
01_H (Reserved)	25 ns
02_H (Reserved)	37.5 ns
03_H	50 ns
04_H	62.5 ns
05_H	75 ns
06_H	87.5 ns
07_H	100 ns
...	...
…	...
$FFFF_H$	819.2 µs

45.4.3.5.2 Conversion

TMADC supports conversion of a single channel or a group of channels in one-shot (trigger based) or continuous (auto-scan) manner. The type of TMADC channel conversions supported with some example cases are further described in this chapter.

- Single channel one-shot conversion
  - Each conversion of a channel is initiated either on a hardware trigger (HWTRx) or a software trigger. An interrupt can be configured for indicating the availability of every new channel conversion result
- Channel group one-shot conversion
  - A channel group consists of multiple TMADC channels. Each conversion of a channel group can be initiated either on the common hardware trigger or through a software trigger register. An interrupt can be configured for indicating availability of new channel group results, that is when all the results of the group are available
- Single channel continuous conversion
  - A channel can be configured in continuous conversion operation. In this mode, no external request sources are needed for initiating a channel conversion. User can stall any further channel conversion by enabling wait-for-read functionality to avoid overwriting previous data
- Channel group continuous conversion
  - Continuous conversion can be configured to a group of channels. An interrupt can be configured for indicating availability of new channel group results that is when all the results are available in the result registers pertaining to each channel in the group

A channel is added to the connected core's arbitration queue for conversion on a trigger event for one-shot conversion, or after the minimum sampling time is completed, for continuous conversion. Each core handles the conversion requests on multiple channels in parallel by following an intrinsic round-robin arbitration over the connected channels on that particular core. The round-robin algorithm implies the selection of the next higher indexed channel number in queue from the previous converted channel number. The arbitration is done at the end of the ongoing conversion cycle. There is no priority assignment to a channel in the queue. With N channels connected to a core, in the worst case a channel's conversion time can take is up to $N \times t_{conv}$.

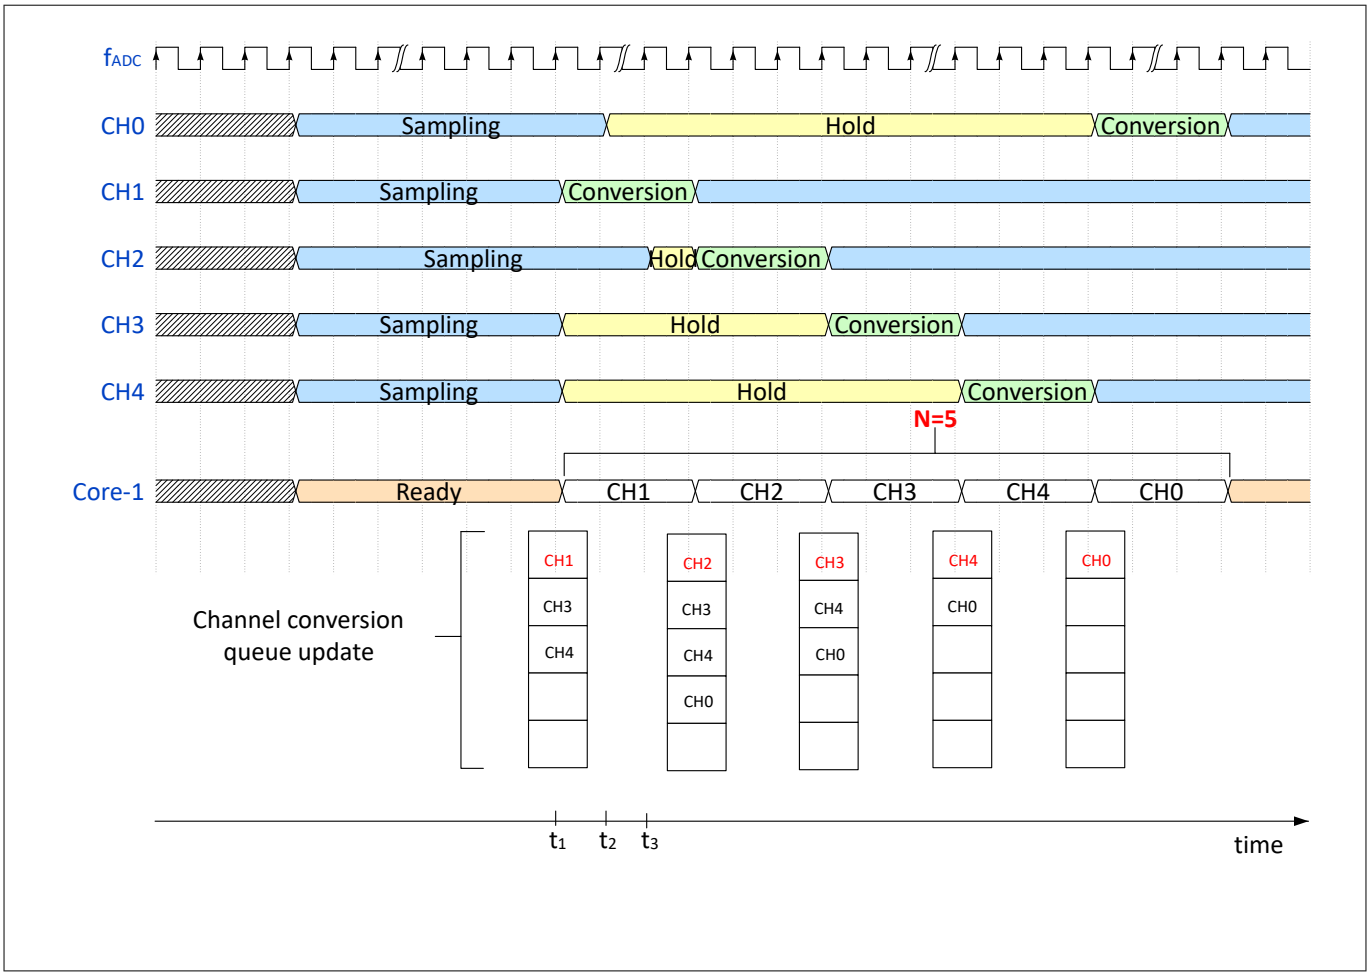

Figure 1199 Channel conversion arbitration example 1

In the figure above 5 channels, CH0 through to CH4, are connected to Core-1. Core-1 is in a ready state waiting to start a channel conversion when available. At time t = t_1, channels CH1, CH3 and CH4 are available for conversion. The queue is updated and Core-1 proceeds with the conversion of CH1 (lowest channel index holds priority) followed by the next higher index channel CH3 and then CH4. Before the end of CH1 conversion, CH0 and CH2 are available at t = t_2 and t = t_3, respectively. The next higher index after CH1 is CH2. CH2 becomes the top of the queue whereas CH0 holds the least priority and is placed at the bottom. From there, channels in the queue get converted as per the sequence.

In the example of the figure above the conversion of the 4 channels delays the conversion of CH0 (by approximately $4 \times t_{conv}$) from the time it finished sampling.

***Note**: With assignment of multiple inputs to a single SAR core, the hold time for pending samples TMADC t_{HOLD} can get violated. Channels need to be distributed across Core-0 and Core-1 in a way the TMADC t_{HOLD} constraint is satisfied.*

Another example is shown in the figure below considering the same channels and core. Here after CH2 is converted, the core goes to ready state since no further channel is ready for conversion since CH1, CH3 and CH4 are still sampling. When CH1, CH3 and CH4 are available for conversion, CH3 gets selected on the basis of being the next higher indexed channel from the last converted channel (CH2), followed by CH4 and then CH1.

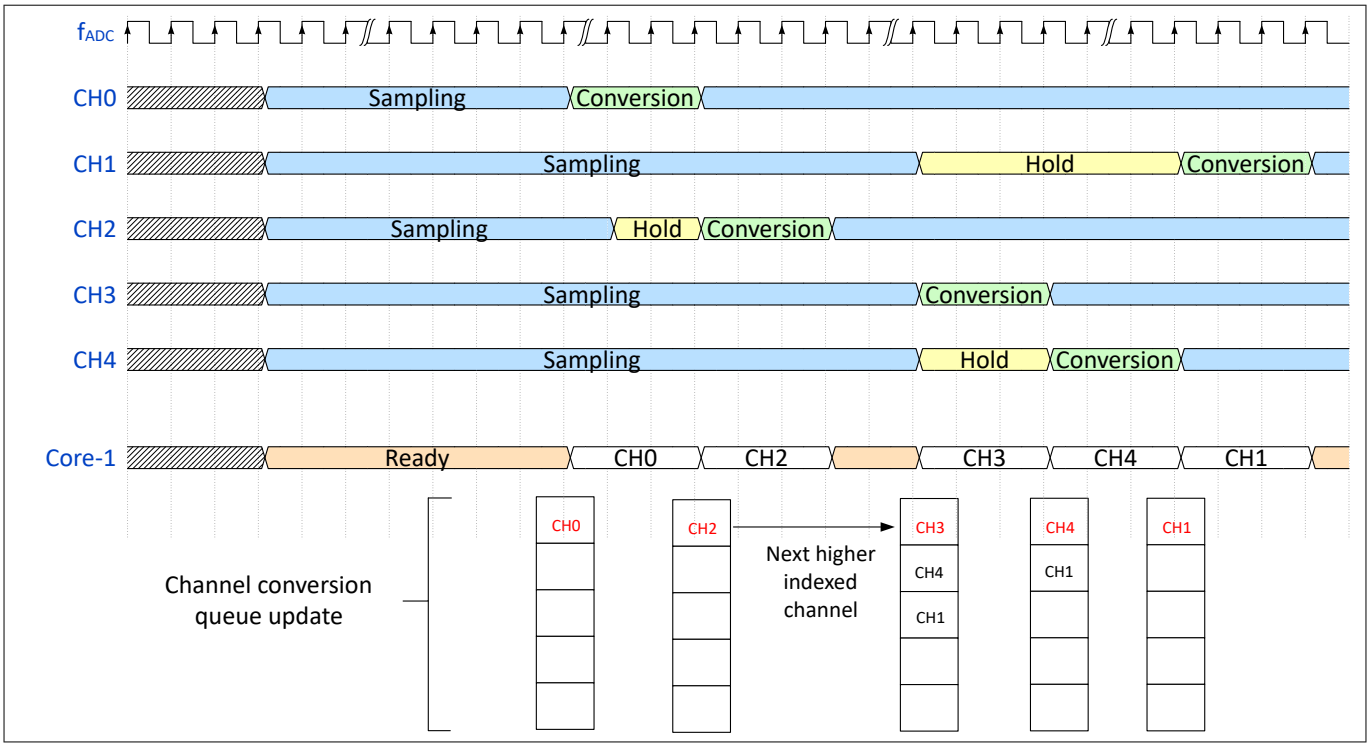

Figure 1200 Channel conversion arbitration example 2

Single channel one-shot conversion

One-shot conversion means that a channel conversion takes place on a hardware trigger (HWTR0 or HWTR1) or software trigger.

Each time the conversion takes place the result is stored in the channel-specific result registers TMADCx_AW0_RESv.

The figure below illustrates the one-shot channel conversion example for channel CH1 connected to Core-0 and channel is configured to initiate conversion on request from either of the request sources HWTR0 and HWTR1. The user should configure the hardware trigger offset time and trigger period with respect to the channel's minimum sampling time and hold time (if multiple channels connected on the core) so that the triggers are processed each time on arrival. The trigger offset duration should take into account the module power-up time, start-up calibration time and the channel's minimum sampling time as shown in the figure below. Here because HWTR1 is occurring after HWTR0, the $t_{offset1}$ needs to take into account the additional delay caused due to the conversion triggered by HWTR0. Therefore, for the illustrated case:

$$t_{\text{offset0}} \geq t_{\text{mstc}}(\text{CHi}) + t_{\text{WUDIS}} + t_{\text{CAL}}$$

$$t_{\text{offset1}} \geq 2 \times t_{\text{mstc}}(\text{CHi}) + M \times t_{\text{conv}} + t_{\text{WUDIS}} + t_{\text{CAL}}$$

In this instance the value of i is 1, and the value of M (total number of channels connected to a core) is 1 because it is considered that no other channels are connected to the same core. The table below shows the minimum hardware trigger period requirement with respect to single channel conversions on a core using single or both hardware request sources.

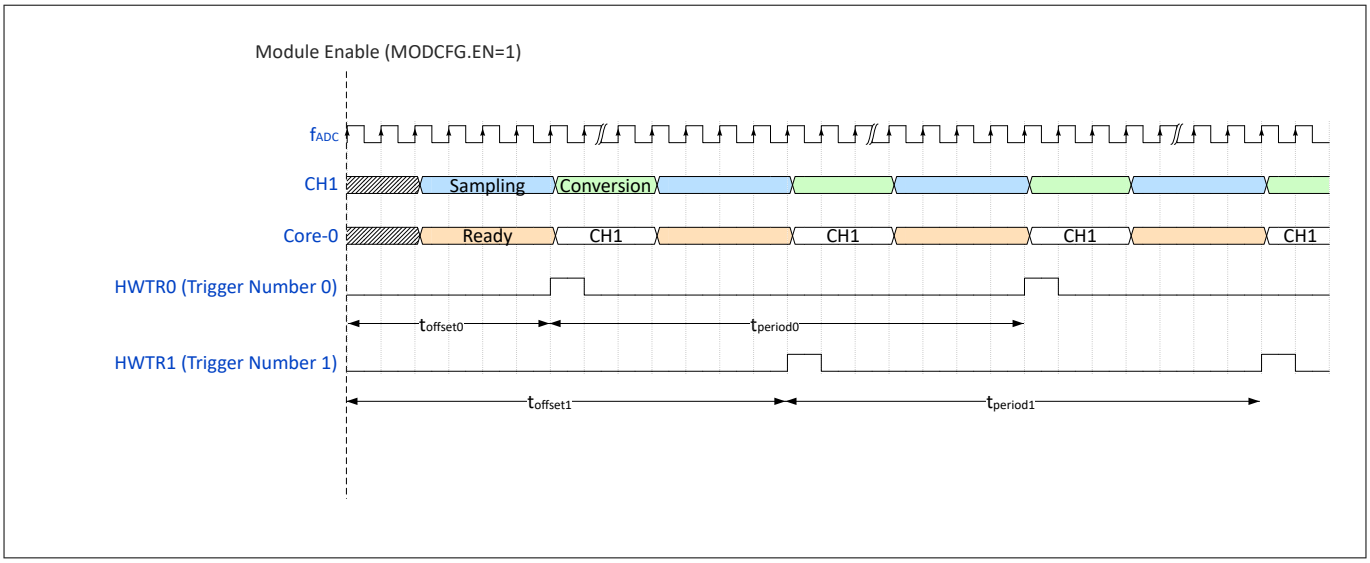

Figure 1201 Single channel one-shot conversion

Table 2382 Minimum hardware trigger period (t_{period}) requirement for a single TMADC channel (CHi) conversion

Channels connected to the core	When only one hardware request source is used	When both hardware request sources are used
1 (only CHi connected to the core)	$t_{period} \geq t_{mstc}(CHi) + t_{conv}$	$t_{period0}\ (or\ \ t_{period1}) \geq 2 \times (t_{mstc}(CHi) + t_{conv})$
M channels (where m>1 number of channels connected to the core)	$t_{period} \geq t_{mstc}(CHi) + M \times t_{conv}$	$t_{period0}\ (or\ \ t_{period1}) \geq 2 \times (t_{mstc}(CHi) + M \times t_{conv})$

Channel group one-shot conversion

A synchronous end of sampling on a channel group can be obtained by configuring the channel group on the same trigger source.

The trigger period must be configured sufficiently long enough to account for:

- The maximum sampling time value of the channel among the channel group
- The conversion time for the channel group connected to the group
- The conversion time of other channels connected to the same core

The figure below shows an example of multiple channel group one-shot conversions where the channel group consisting of 5 channels, CH1 through to CH5, is connected to Core-0 and share the same trigger that is trigger number 4 (TMADCx_CHy_CFG.HWTRxMS=04_H). The trigger event ends the sampling phase of all channels in the group and core starts the conversion. The user can enable and configure the service request on event when all the conversion results of the group are available in the result registers TMADCx_AW0_RESv.

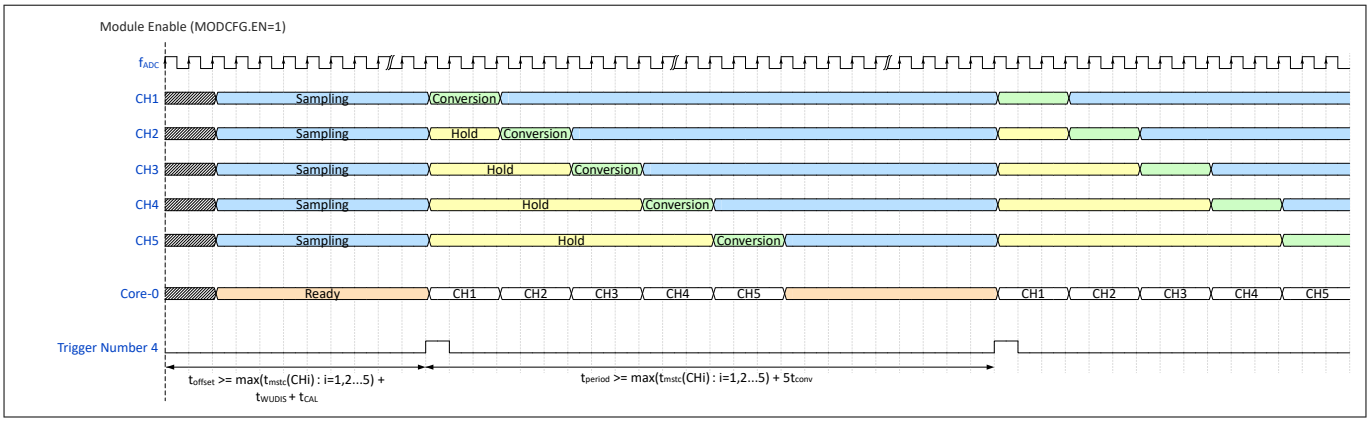

Figure 1202 Multiple channel group one-shot conversion

Table 2383 Minimum hardware trigger period (t_{period}) requirement for TMADC channel group conversion

Channel(s) connected on the core	When only one hardware request source is used	When both hardware request sources are used
One channel group of N channels	$t_{period} \geq \max(t_{mstc}(CHi)) + N \times t_{conv}$ Here CHi represents a channel of the channel group	$t_{period0}$ (or $t_{period1}$) $\geq 2 \times (\max(t_{mstc}(CHi)) + N \times t_{conv})$ Here CHi represents a channel of the channel group
One channel group of N channels + M additional channels	$t_{period} \geq \max(t_{mstc}(CHi)) + (N+M) \times t_{conv}$ Here CHi represents a channel of the channel group	$t_{period0}$ (or $t_{period1}$) $\geq 2 \times (\max(t_{mstc}(CHi)) + (N+M) \times t_{conv})$ Here CHi represents a channel of the channel group

Single channel continuous conversion

A channel is set for continuous conversion mode by setting TMADCx_CHy_CFG.ATREN=1_B. In this mode, the channel switches directly to the hold or conversion state once the configured minimum sampling time has elapsed.

Result data can be overwritten by newer conversion results if not read frequently enough. Use the sampling time to adjust the frequency of conversion results. Use wait-for-read (WFR) to avoid overwriting conversion results before reading it. Set TMADCx_RSLTu_CFG.WFR to 1 to start a conversion once the result register has been read. The sampling time of the channel is extended until the result register is read.

The figure below shows an example of continuous conversion on channel CH0 connected to Core-0, without and with using wait-for-read mode. Here the result register RES0 is configured to store the conversion result of CH0.

***Note**: Using wait-for-read mode for hardware or software trigger based channel conversion causes masking of all triggers on a channel until its result data is read by the software.*

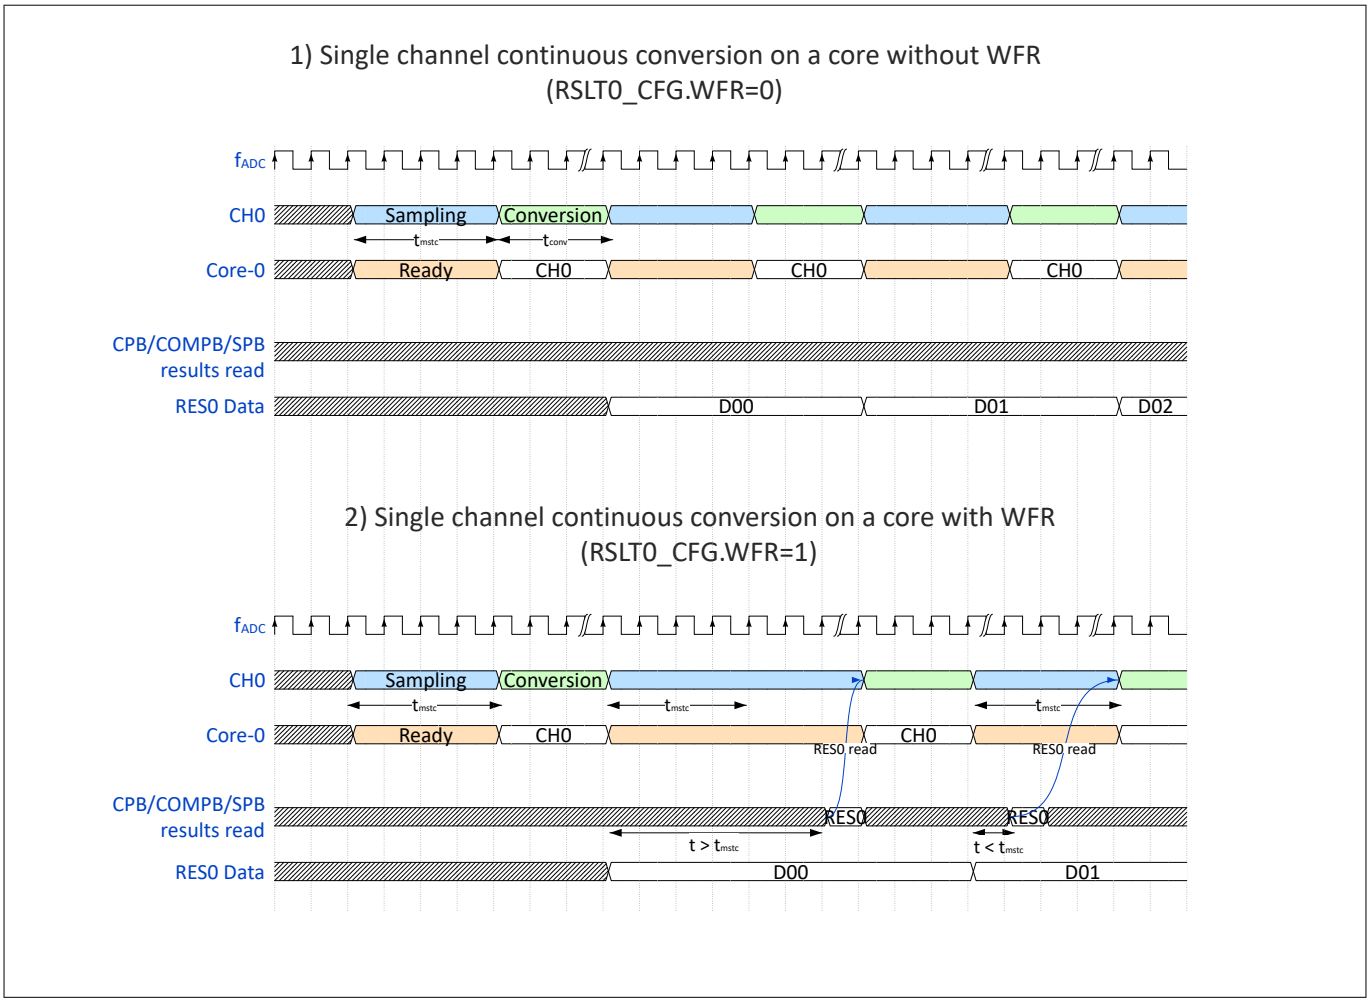

Figure 1203 Single channel continuous conversion

Channel group continuous conversion

A group of channels can be operated in continuous conversion by setting TMADCx_CHy_CFG.ATREN=1_B in the respective channel configuration register.

A service request can be configured for any new result data within a channel group or it can be configured for a single event when new result data is available for all channels in the group (see the Service request generation chapter).

The figure below shows an example of a channel group in continuous conversion mode. Here, the channel group consists of channels CH1, CH2, CH3 and CH4 connected to Core-0 and the channel conversion results are stored in result registers RES1, RES2, RES3 and RES4, respectively. The result registers are configured with wait-for-read mode enabled. A result read ends the corresponding channel's sampling phase (in this case it is shown with a burst read request of 4 result registers).

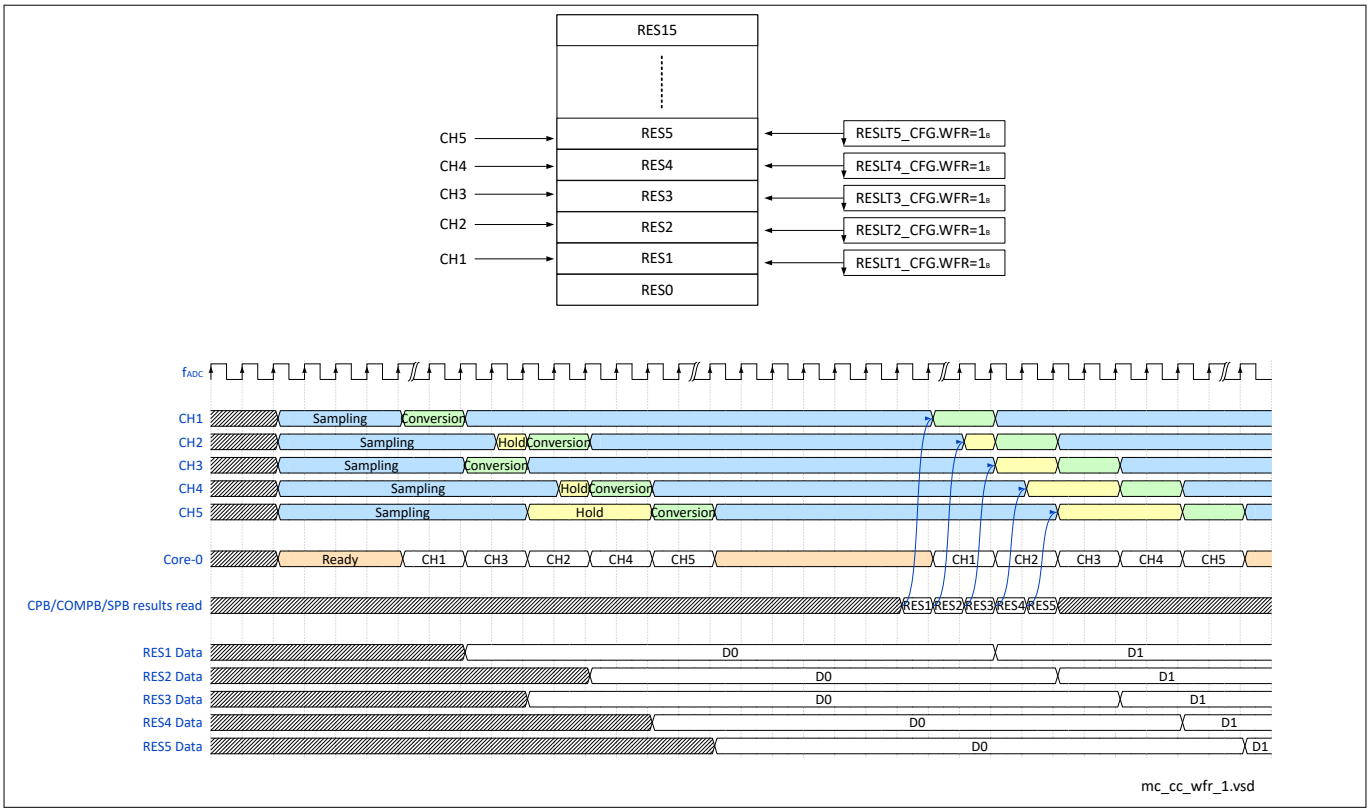

Figure 1204 Multiple channel group continuous conversion

TMADC result read through LLI on page 8352

45.4.3.6.1 Storage of conversion results

The channel conversion result is stored in the result register selected by TMADCx_CHy_CFG.RSEL. The result is stored in the bit-field RESULT in result register TMADCx_AW0_RESv

Additional status information such as channel conversion request by a hardware or a software trigger, hardware trigger number that initiated the channel conversion request, hardware trigger edge used for the conversion request initiation, TMADC channel number and broken wire or converter diagnostics data indication is available in the upper 2 bytes of the result register TMADCx_AW0_RESv.

Registers MRES0 and MRES1 are used to store the monitor channel results.

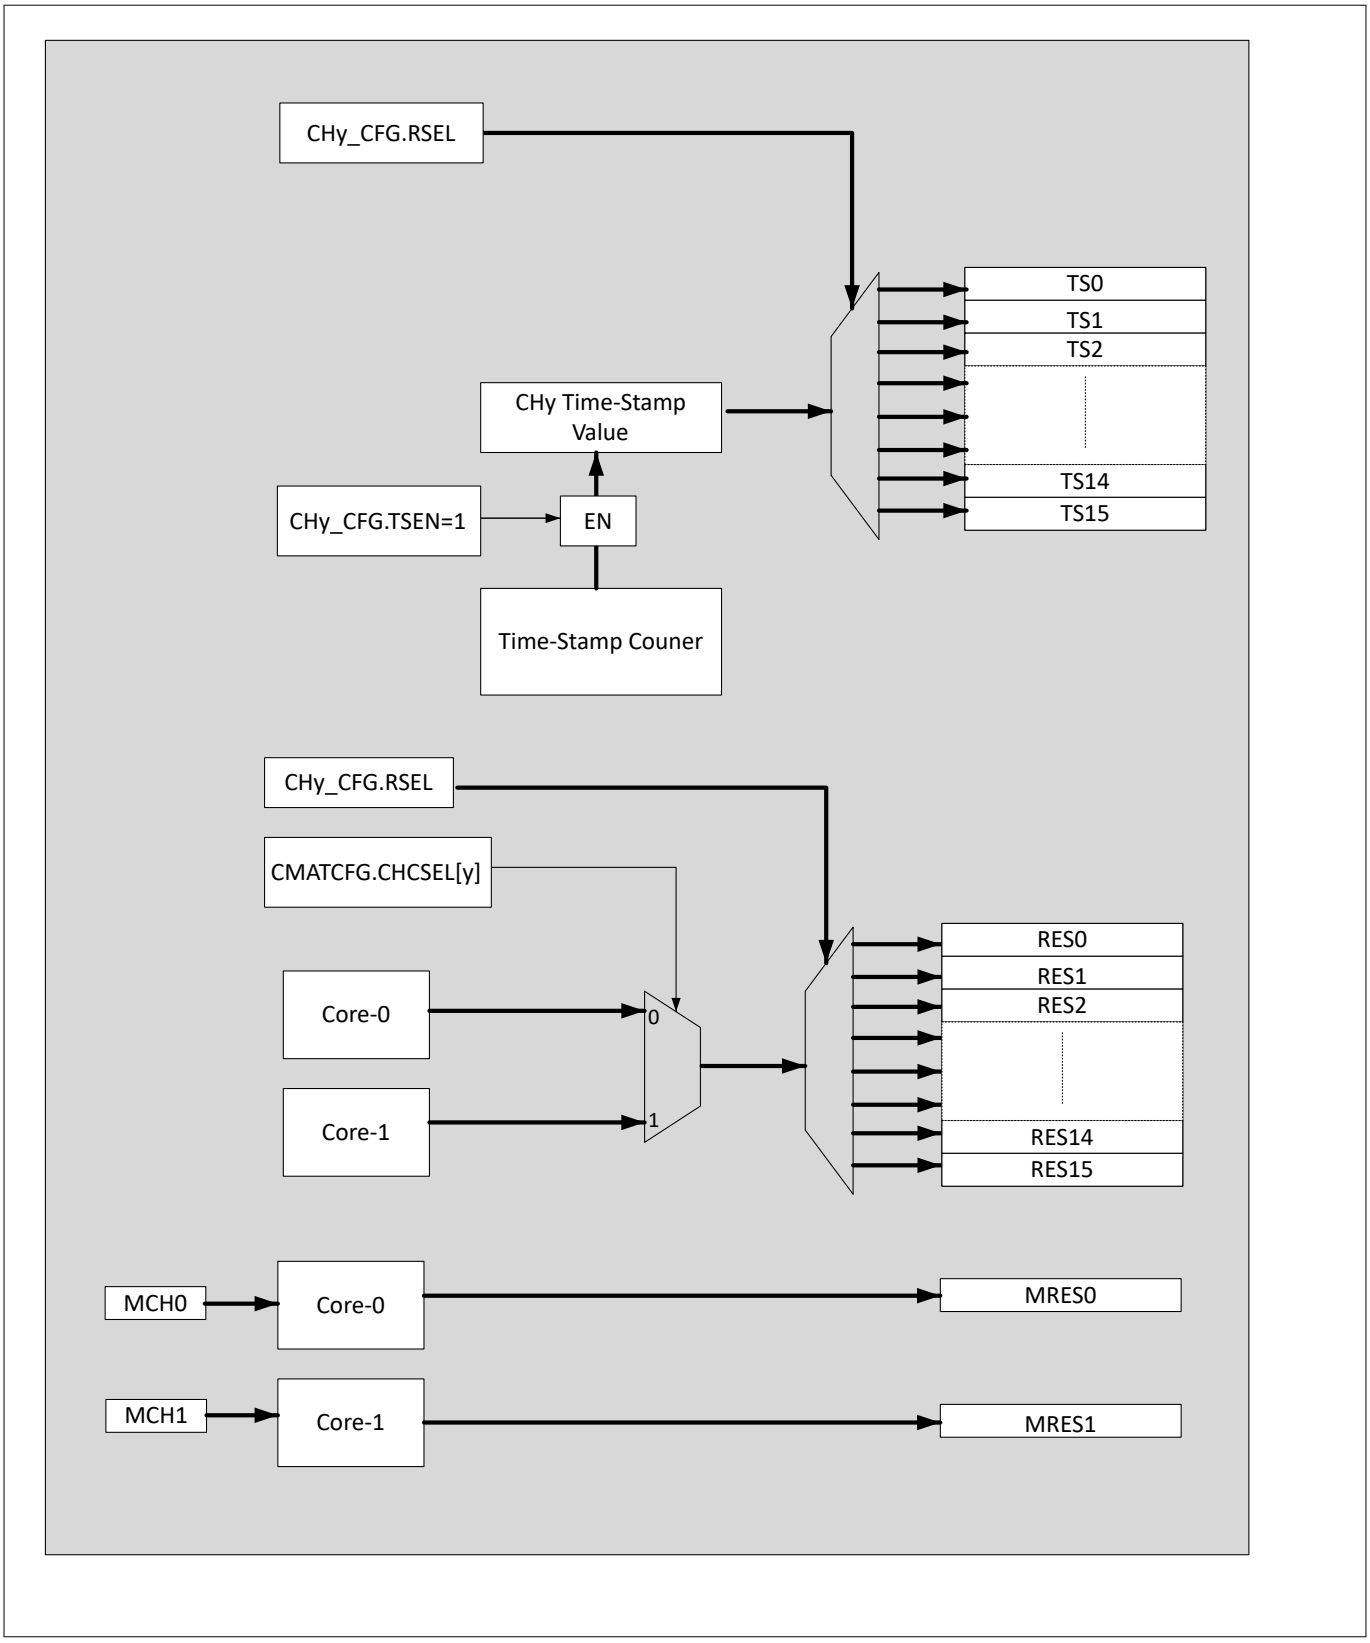

Figure 1205 TMADC time-stamp value and conversion result storage

***Note**: You must not select the same result register for more than one channel. It must be ensured by the user that the conversion result is stored in its channel-specific result register to avoid data collision. The only exception is the predictive maintenance application described in TMADC result read from CDSP chapter.*

Time-stamp support

Each TMADC kernel has a 16-bit time-stamp counter for generating time-stamp values for TMADC channels. This counter operates with a fixed 200 ns resolution and resets after every 13.1 ms. The counter is started by setting TMADCx_MODCFG.TSCRUN=1. The time-stamp value is the time-instant when a channel ends its sampling phase. This feature can be enabled for a channel by setting TMADCx_CHy_CFG.TSEN=1. The value is stored in the corresponding time-stamp register TMADCx_AW0_TSv selected via bit field TMADCx_CHy_CFG.RSEL for the channel.

The time-stamp value is stored at the same time in the time-stamp register as the corresponding result register data for the channel. If time-stamp feature is enabled for multiple channels, then user must ensure that independent time-stamp registers are selected for storing the time-stamp value for the channel. The time-stamp feature allows user to validate the channel's result for older or new data. In case a new timestamp is not equal to the old timestamp a new result has been generated.

CPB, COMPB orSPB address windows for reading result and time-stamp registers

Time-stamp and result registers read through peripheral bus (CPB, COMPB or SPB depending on variant) can take place from four available address windows, AW0, AW1, AW2 and AW3, as also shown in the following figure. The alignment of these registers in the address windows allows different type of burst read capability depending on the application use case.

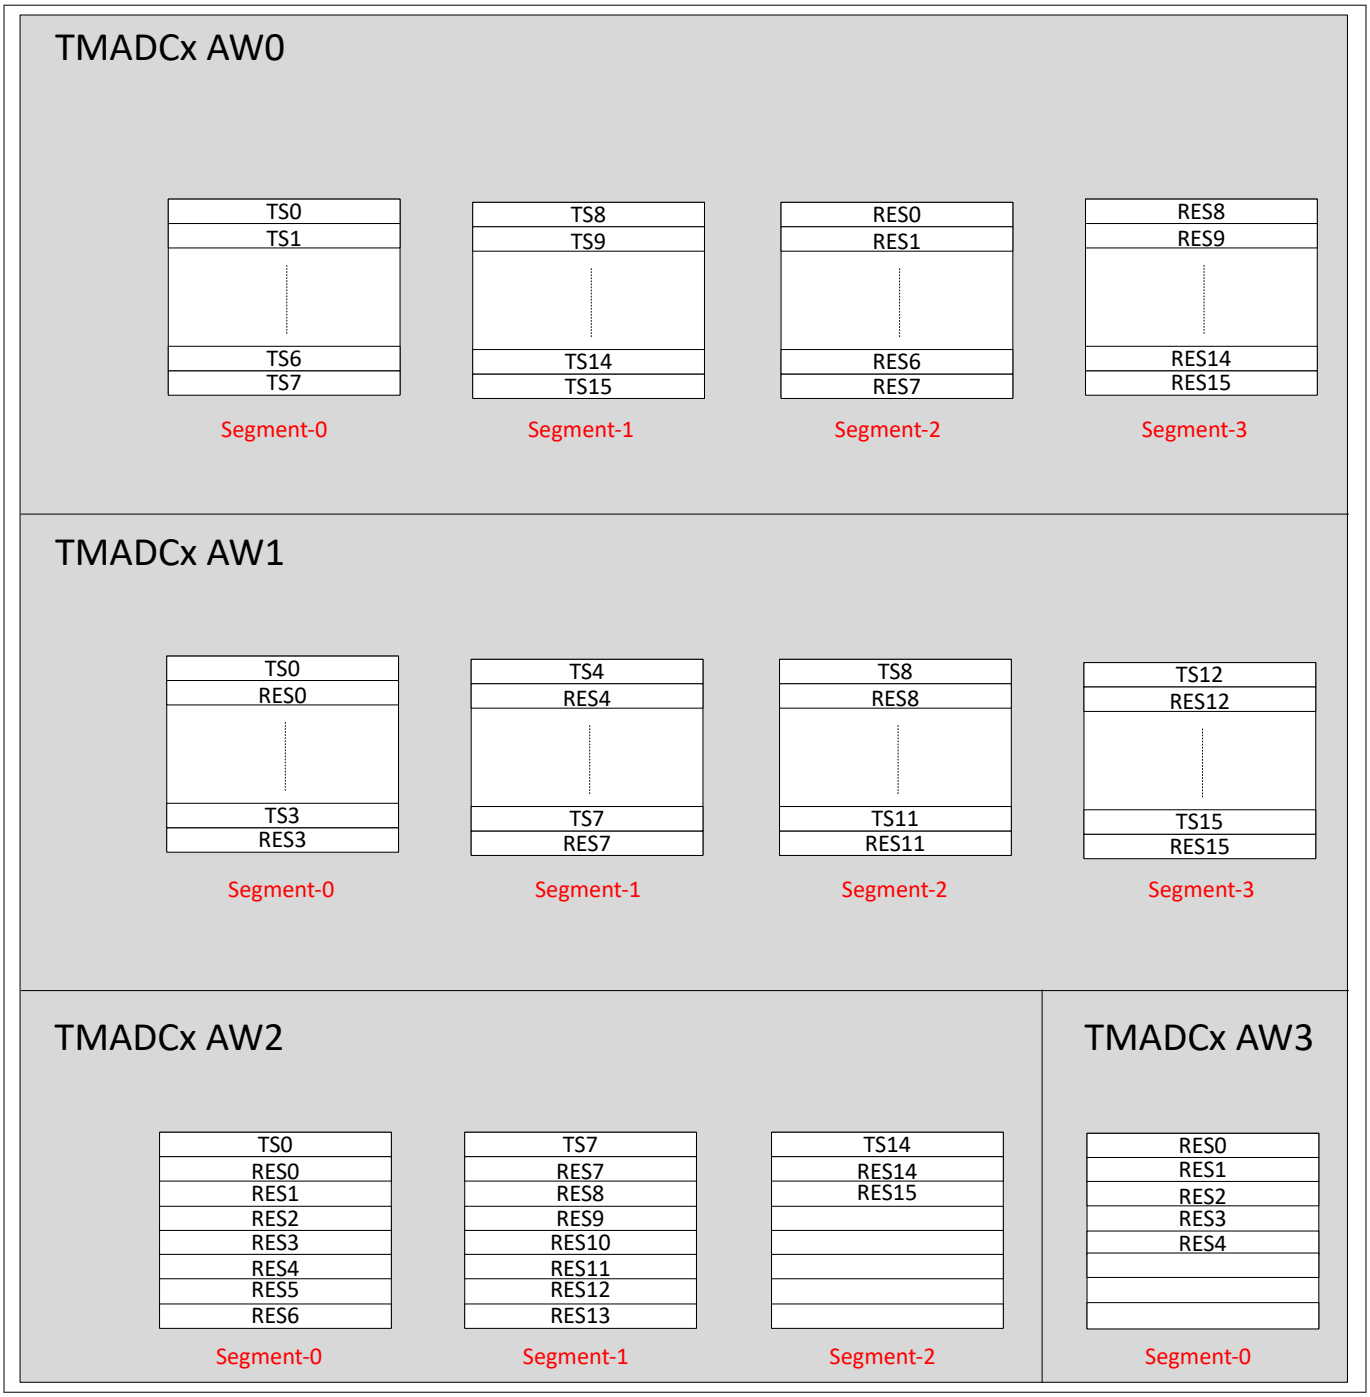

Figure 1206 Address window concept for result and time-stamp register read through peripheral bus (CPB,COMPB or SPB bus depending on variant)

A burst read from address window-0 (AW0) provides a read on the segment of time-stamp (TS0-TS7 or TS8-TS15) and result registers (RES0-RES7 or RES8-RES15) depending on size of the burst.

In address window-1 (AW1), the time-stamp registers and result registers are aligned in space-interleaved manner allowing a burst read of form TSx, RESx, TSy, RESy... so on, on each of the 4 address segments. Reading registers from address windows 2 and 3 (AW2, AW3) is useful in applications where multiple channels are grouped together on a single trigger event so that a single burst read on a segment fetches both the time-stamp value and channel group results (for example TS0, RES0, RES1, and so on). It is noted however only 3 time-stamp registers are available for read (TS0, TS7 and TS14) in AW2. AW3 allows to combine RES0-RES4 with TS7 and TS14. The register address space information on the address windows for each TMADC can be found in the register description chapter.

45.4.3.6.2 Boundary conditions

Limit checking on the channel conversion result can be performed in TMADC itself to offload CPU tasks by issuing service requests only when results are within or outside the configured limit. The type of boundary check for a result is configured with TMADCx_RSLTu_CFG.BNDSEL value.

The boundary values can be defined through bit-fields UB for upper boundary and LB for lower boundary in the boundary register TMADCx_BNDn_SEL.

The selection of the boundary register to be used for the conversion result's limit check is done with TMADCx_RSLTu_CFG.BNDSELR.

The selection of the boundary region that is if the result is within or outside the configured boundaries is done through TMADCx_RSLTu_CFG.BNDMODE bit.

A boundary event flag is raised for the result when it fulfills the boundary check conditions.

A result is considered within the boundary under following conditions:

- Only the upper limit is used (TMADCx_RSLTu_CFG.BNDSEL=01_B) and the result is less than or equal to the boundary, otherwise result is outside the band
- Only the lower limit is used (TMADCx_RSLTu_CFG.BNDSEL=10_B) and the result is greater than or equal to the boundary, otherwise result is outside the band
- Both upper and lower limit are used (TMADCx_RSLTu_CFG.BNDSEL=11_B) and the result is greater than or equal to the lower boundary and less than or equal to the upper boundary, otherwise result is outside the band

The service request configuration on boundary events is described in detail (see chapter "Service request generation") and boundary status of results can also be read through boundary event flag register TMADCx_BNDF.

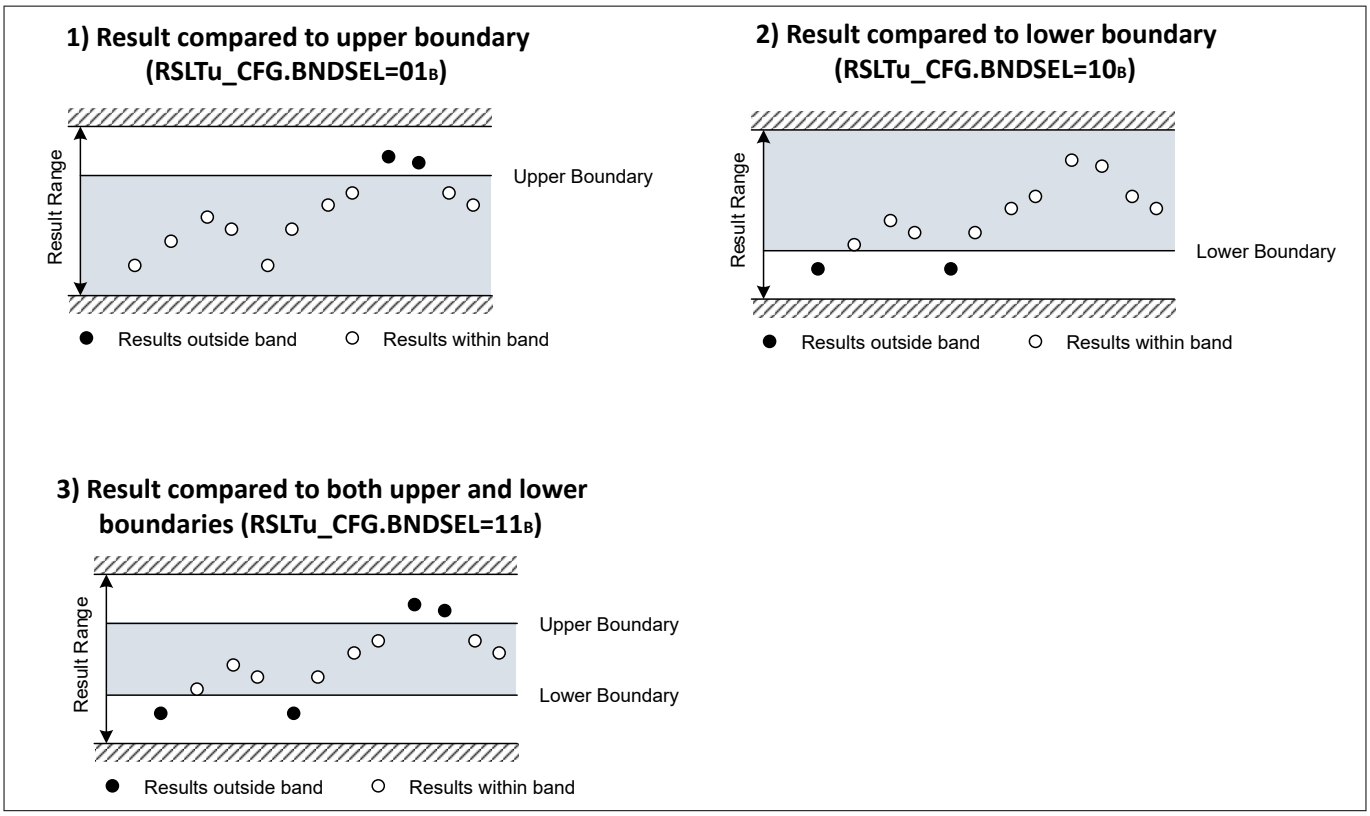

Figure 1207 Conversion result boundary conditions

Boundary values update condition

TMADC supports modification of boundary values in the TMADCx_BNDn_SEL registers during running application. There are 2 operation modes, active mode and shadow mode which define when updated boundary values become effective. The boundary update state of boundaries defined in registers BND0_SEL and BND1_SEL are controlled by the respective bit-fields BNDUPD0 and BNDUPD1 in the register TMADCx_MODCFG. Setting BNDUPDn = 0 enables the immediate update of the boundary value Setting BNDUPDn = 1 enables the update of the boundary value at the next hardware trigger event. The current boundary values can be read in TMADCx_BNDn_STAT register. The trigger configuration is done in the TMADCx_BNDn_TRGCFG register.

***Note**: After module configuration and enabling TMADC module (MODCFG.RUN=1), the configured boundary values will get initialized immediately. Afterwards update of boundary values is done immediately or with hardware trigger (shadow update) depending on TMADCx_MODCFG.BNDnUPD.*

Boundary flags

In the boundary mode, two boundary flags (BFL0 and BFL1) are provided.TMADCx_BFLn_CFG.RESEL defines the setected conversion result register corresponding with the boundary flag BFLn. The boundary flag value can be read through bit field BFL in the TMADCx_BFLn_STAT register.

Hysteresis mode

Hysteresis mode allows capturing different events (higher than upper boundary and lower than lower boundary) by timer modules using the same boundary flag signal. Configuring TMADCx_RSLTu_CFG.BNDSEL=11_B and setting TMADCx_RSLTu_CFG.HYSTM=1_B, enables the hysteresis mode where the upper and lower boundary values specified in the corresponding TMADCx_BNDn_SEL register form a hysteresis band for the selected channel result. In the hysteresis mode, the boundary value depends on the previous boundary flag output and the BNDMODE (BFL polarity) selected as shown below.

When BNDMODE=1:

- If previous BFL= 0, channel result is compared with SEL.UB
  - Next BFL = 1 if result > SEL.UB
  - Otherwise BFL = 0
- If previous BFL= 1, channel result is compared with SEL.LB
  - Next BFL = 0 if result < SEL.LB
  - Otherwise BFL = 1

When BNDMODE=0:

- If previous BFL = 0, channel result is compared with SEL.LB
  - Next BFL= 1 if result < SEL.LB
  - Otherwise BFL= 0
- If previous BFL = 1, channel result is compared with SEL.UB
  - Next BFL= 0 if result > SEL.UB
  - Otherwise BFL= 1

After module power-on the BFL value remains 0 until a comparison decision is available.

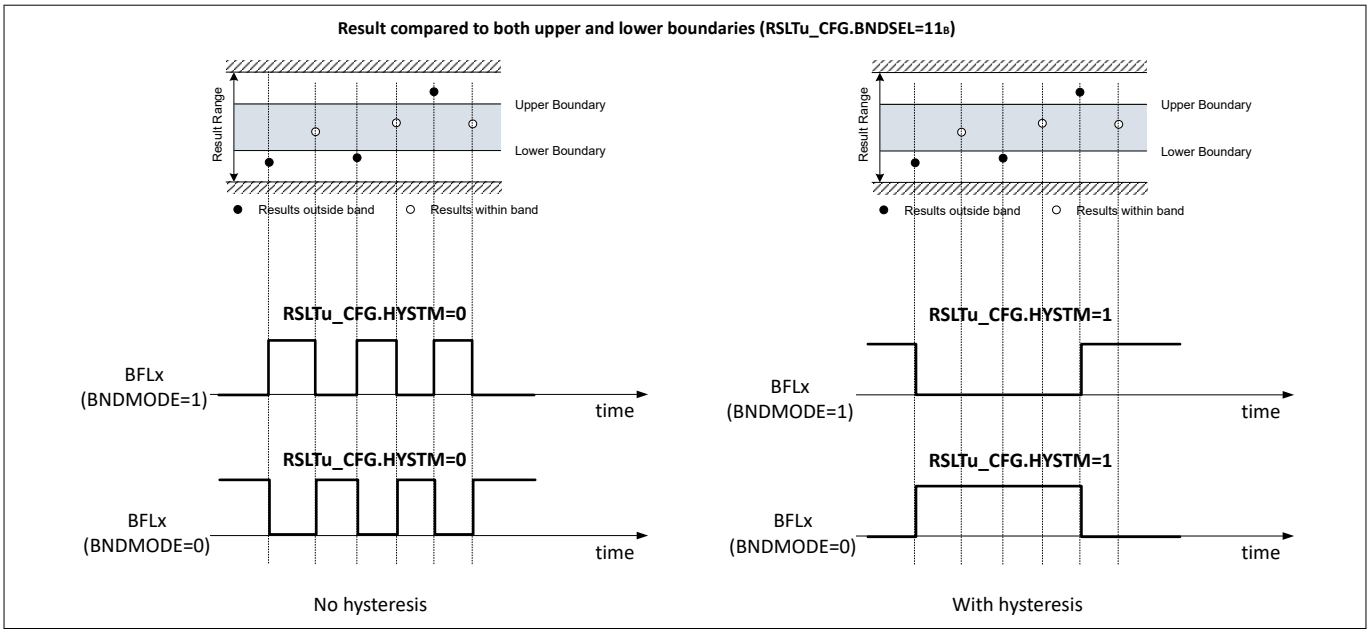

Figure 1208 Boundary conditions with and without hysteresis

45.4.3.6.3 ADC data interface (ADI)

The digital conversion results in result registers RES14 and RES15 from each TMADC instance are directly available at the TMADC/ADC top module boundary through the ADC data interface (ADI). Each time RES14 and RES15 are updated, the ADI updates the data vector.

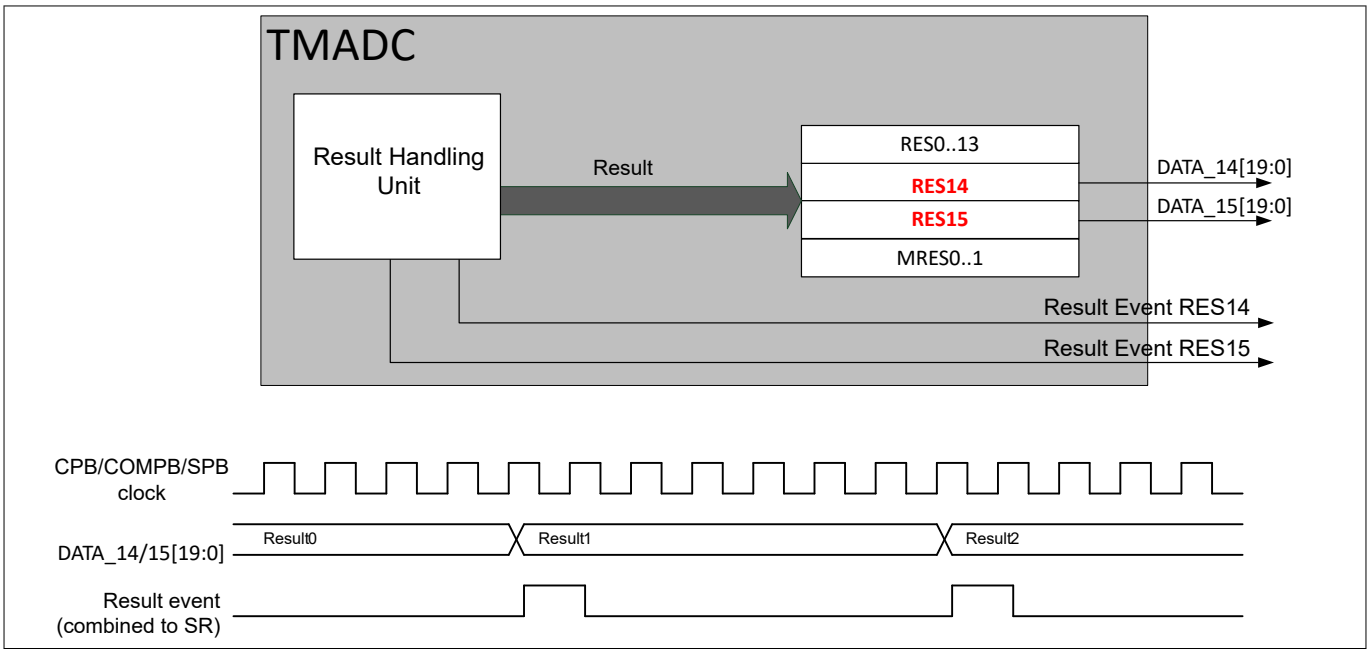

Figure 1209 ADI interface between TMADC and GTM

Qualification of the data can be done with service requests based on the respective result events. Service requests need to get routed to MCS (GTM component). MCS can process the data. The following data elements are available through the ADI:

Table 2384 ADI data assignment

Bit position	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Data content	CHNR				RESULT															

45.4.3.6.4 TMADC result read from CDSP

For post-processing of TMADC conversion results each TMADC module has 6 result registers allocated, RES0 to RES5, which can be read from any CDSP module. CDSP result data read from these registers does not consider the wait-for-read feature.

Wait-for-read if enabled will keep masking all the trigger requests until result is read from the result registers through CPB/COMPB/SPB slave, depending on variant.

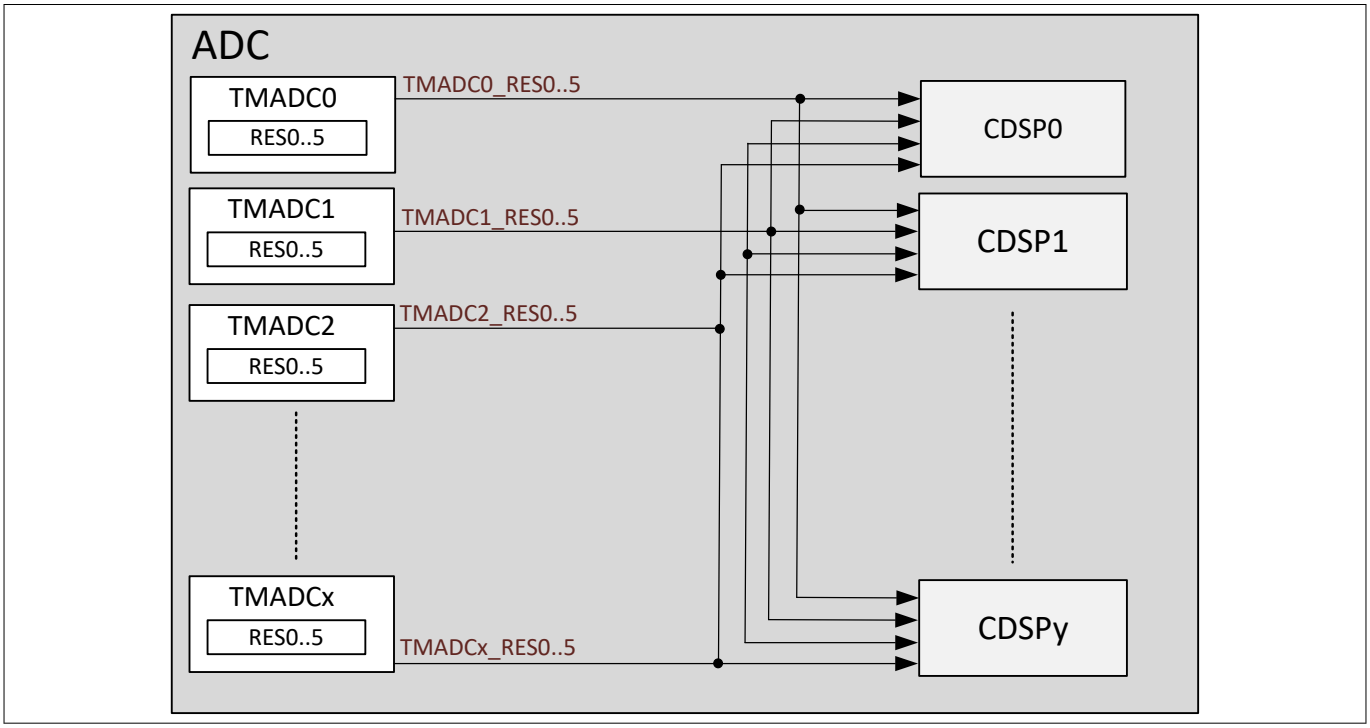

Figure 1210 TMADC result read from CDSP through AHB interface

Only the lower 16 bits of the result registers can be used as data for post-processing by the CDSP softare.

TMADC multiple channel results read from single CDSP

For predictive maintenance application, one CDSP core is used to post-process up to 16 channel results, but only RES0..5 are connected to CDSP inputs. In order to maintain the correct order of channel results which are read from CDSP, the following constraints shall be considered during the "CONFIG" state. No dynamic reconfiguration, no AUTOSAR™ support:

- Map all the used channels within the TMADC module for this application to the same CORE and same results register TMADCx_CHy_CFG.RESL=[0:5]. The CDSP shall select the same result register as input
- When other channels within the same module are used, they shall be mapped to another CORE and each of them shall be mapped to different unused result registers
- Use the same hardware trigger defined by either HWTR0MS or HWTR1MS for all channels. Only one hardware trigger is allowed
- No wait for read (TMADCx_RSLTu_CFG.WFR=0)
- Auto-trigger disabled (TMADCx_CHy_CFG.ARTEN=0), EMUX disabled (TMADCx_CHy_CFG.EMUXEN=0)

- The conversion delay between 2 successive channels shall be at least 50_H with 5 V supply mode or at least $A0_H$ with 3.3 V supply mode in trigger delay register in TMADCx_CHy_STC.TRD. The conversion delay between 2 successive channels equals TMADCx_CHy_STC.TRD*12.5 ns
- The minimum trigger period shall be 17*(TMADCx_CHy_STC.TRD*12.5 ns)
- Set minimal sampling time TMADCx_CHy_STC.ST= 28_H (500 ns) for all channels

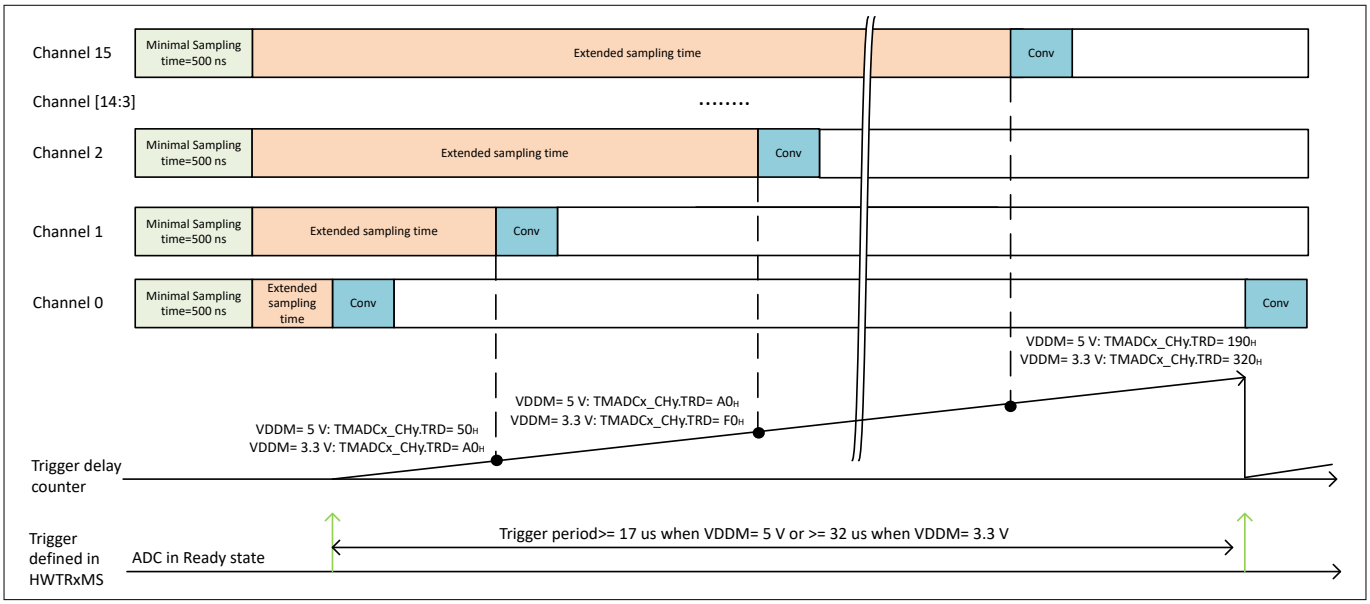

Figure 1211 TMADC multi-channel results read from single CDSP, round-robin controlled by trigger delay

***Note**: For other application, you must not select the same result register for more than one channel to avoid data collision.*

***Note**: The trigger shall satisfy the minimal sampling time definition. If the first trigger for the first channel comes during its minimum sampling time, then the trigger is ignored and no conversion will be started on this channel.*

45.4.3.6.5 TMADC result read through LLI

The time-stamp TMADCx_TSAXIv, TMADCx_RESAXIv input channel result registers and TMADCx_MRESAXIv monitor channel result registers can also be read over the low latency interconnect (LLI) interface. The wait-for-read feature is not valid for a result read through LLI.

45.4.3.7 Service request generation

Each TMADC instance can generate a total of 7 service requests (SR0...6) for issuing interrupts. Of those 7 service request, 6 (SR0...5) have direct connection to the Interrupt Router. Service request SR6 goes to the ADC global service request generator.

These service requests can be generated by three event types:

- Result event
  - Indicates a new result in the result register to trigger a read action. Result events are indicated with the result event flag setting in the TMADCx_RESF register. Software can clear the result event flag in the RESF register by writing to the corresponding result event flag clear bit in the TMADCx_RESFCLR register. For debug purposes application software can set the result event flag in the RESF register by writing to the corresponding flag set bit in the TMADCx_RESFSET register

- Boundary event
  - Indicates the boundary check comparison result for a conversion result. Boundary events are indicated with the boundary event flag setting in the TMADCx_BNDF register. Software can clear the boundary events by writing to boundary event flag clear bit in the TMADCx_BNDFCLR register
- Error event
  - Indicates channel error events that is an event of any missed channel trigger for each channel. Channel error events are indicated by the error event flag of the channel in the TMADCx_ERRF register. Software can clear the error event by writing to the corresponding error event flag clear bit in the TMADCx_ERRFCLR register. Clearing the error event flag also clears the TMADCx_CHy_STAT register of this channel

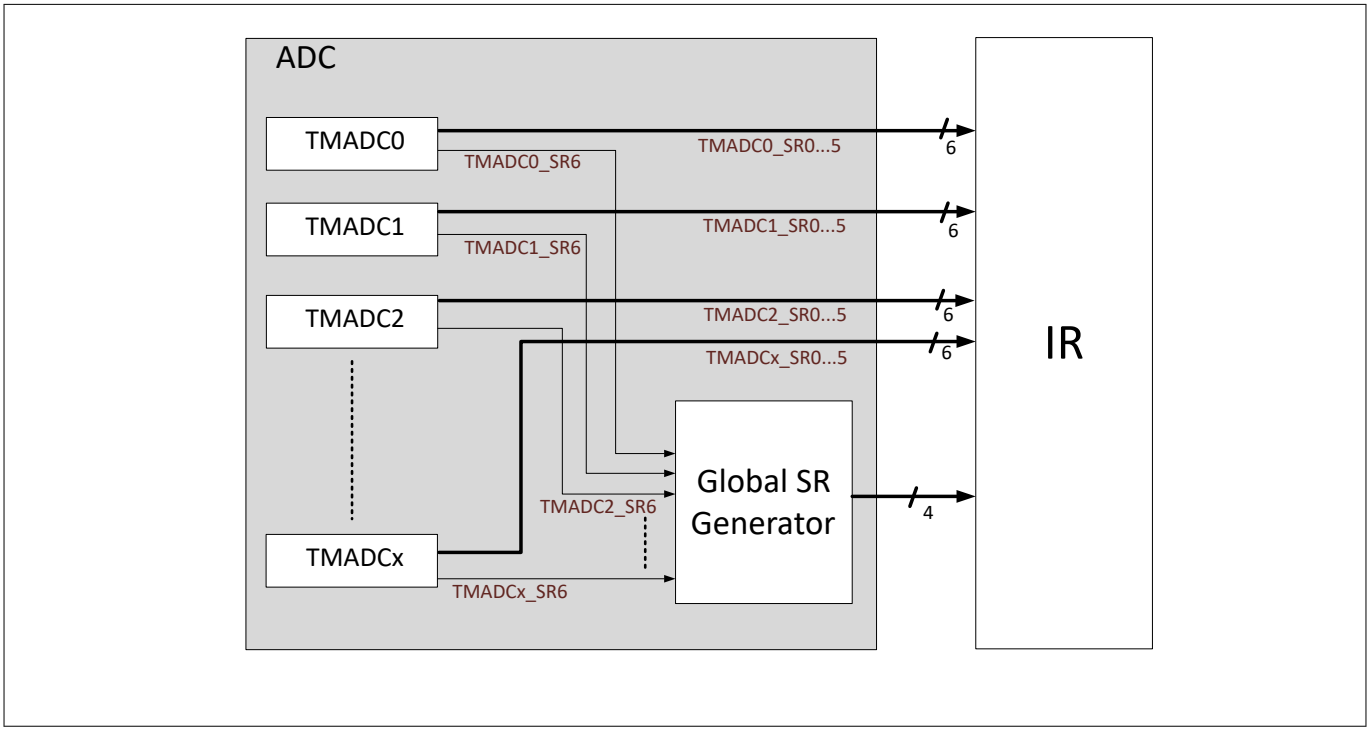

Figure 1212 TMADC service request generation overview

Each service request can be configured in the corresponding service request configuration register TMADCx_SRi_CFG. The meaning of the event enable bit-field TMADCx_SRi_CFG.EVEN depends on the setting of the event selection bit-field TMADCx_SRi_CFG.EVSEL as illustrated in the next table.

Table 2385 Service request event enable bit-field definition

SRi_CFG.EVSEL	SRi_CFG.EVEN
00_B (SRi disabled)	-
01_B (Channel error event)	Each bit corresponds to a channel
10_B (Result event)	Each bit corresponds to a result register
11_B (Boundary event)	Each bit corresponds to a result register

As shown in the next figure, you can group multiple events together by setting TMADCx_SRi_CFG.EVOP=10_B so that the service request is generated when all the user-configured events are available (AND logical operation on the enabled events).

Setting TMADCx_SRi_CFG.EVOP=00_B results in a service request generation for each user-configured event (OR logical operation on the enabled events).

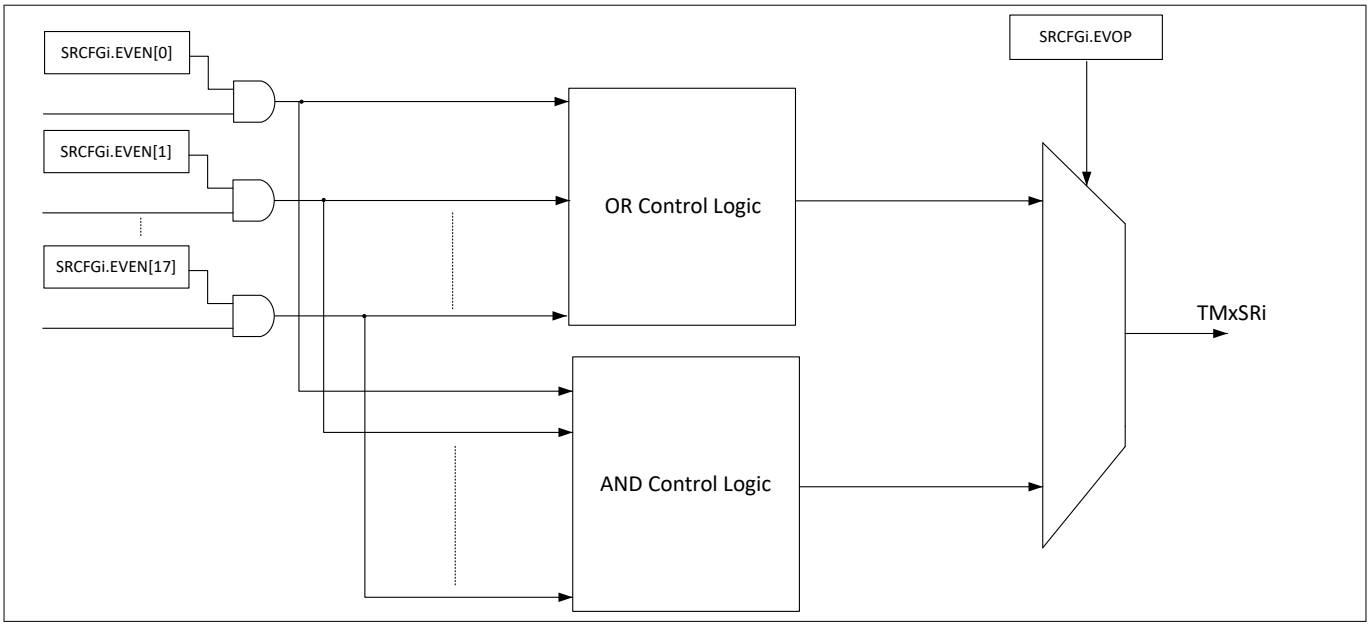

Figure 1213 Service request configuration

Result events

The following figures show examples of service request generation with different settings of the EVOP bit-field for the same configured result events (same EVEN bit-field settings). Conversion results for CH0,CH2, CH4, and CH6 are stored in result registers RES0, RES1, RES2, and RES3, respectively.

In the following figure using setting EVOP=00_B, the service request is generated each time a new result is available in any of the 4 configured result registers. Reading TMADCx_RESF returns the service request flags.

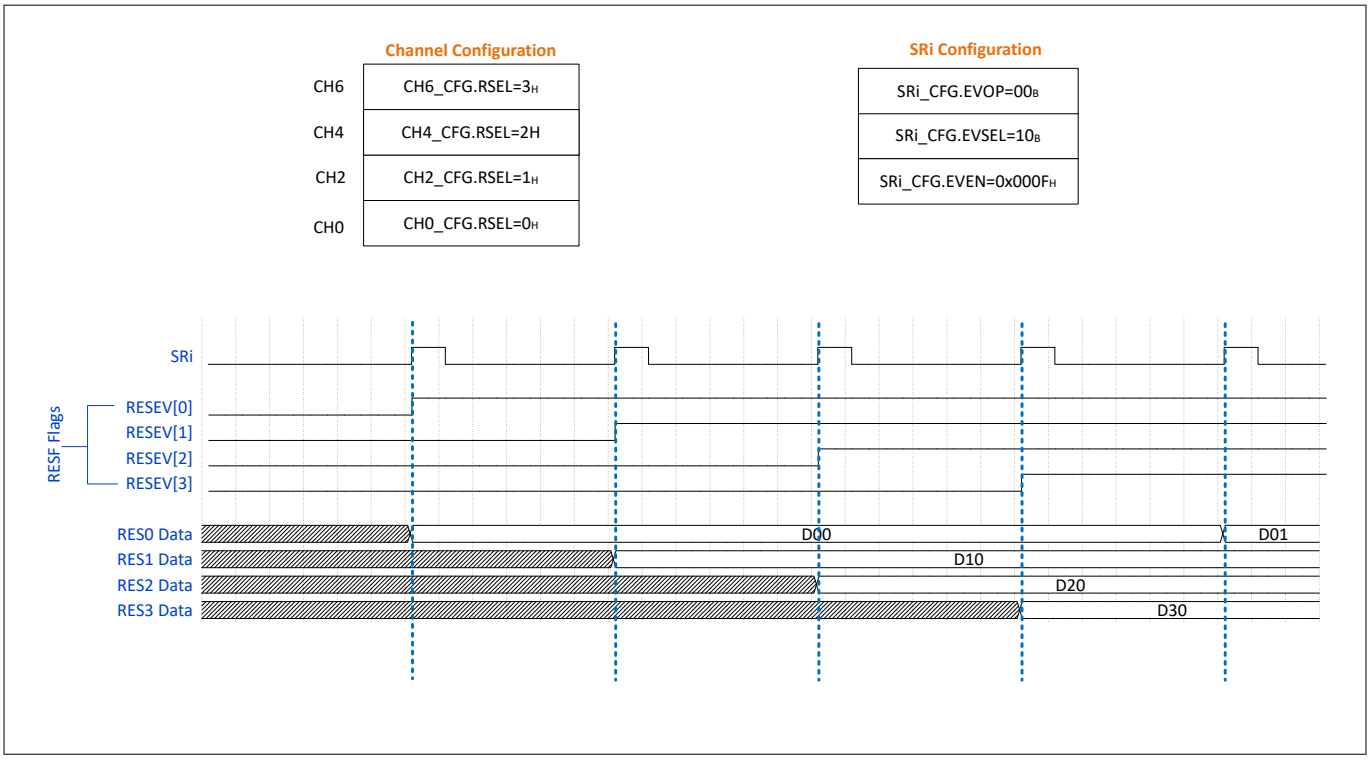

Figure 1214 TMADC service request generation on each valid result event EVOP=00_B

The following figure shows the behaviour if EVOP=10_B. The service request is generated once all 4 result registers hold new data. All RESEV flags in RESF register can be cleared using the RESFCLR register. SR gets generated for an event even when corresponding flag value is already high.

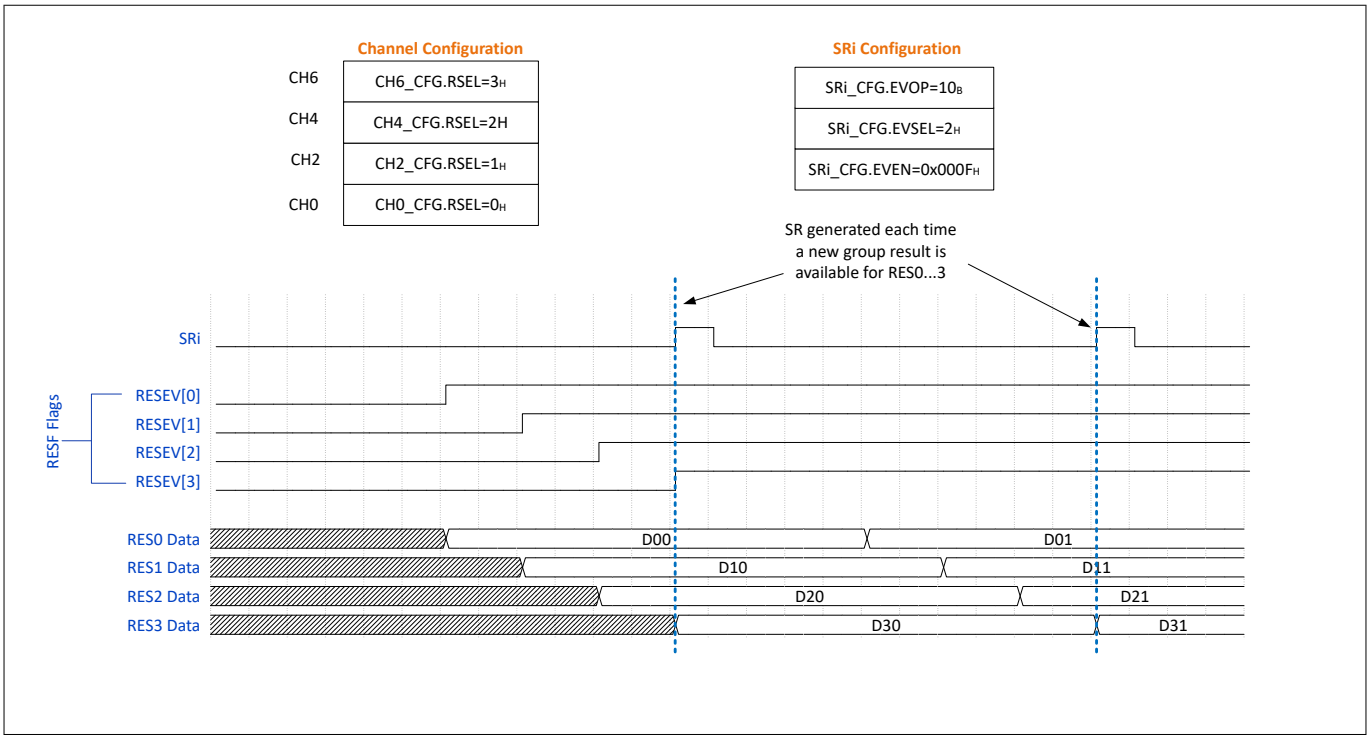

Figure 1215 TMADC service request generation on valid result group event EVOP=10_B

Boundary events

A service request is configured for boundary event(s) by setting TMADCx_SRi_CFG.EVSEL=11_B. You need to enable the individual boundary events for the results required to trigger the service request in the TMADCx_SRi_CFG.EVEN bit-field. Boundary event flags are generated only when the boundary mode for a result is enabled: That is TMADCx_RSLTu_CFG.BNDSEL≠ 00_B.

The following figure shows an example where SR gets generated for RES0, RES2, and RES3. There is no SR set for RES1.

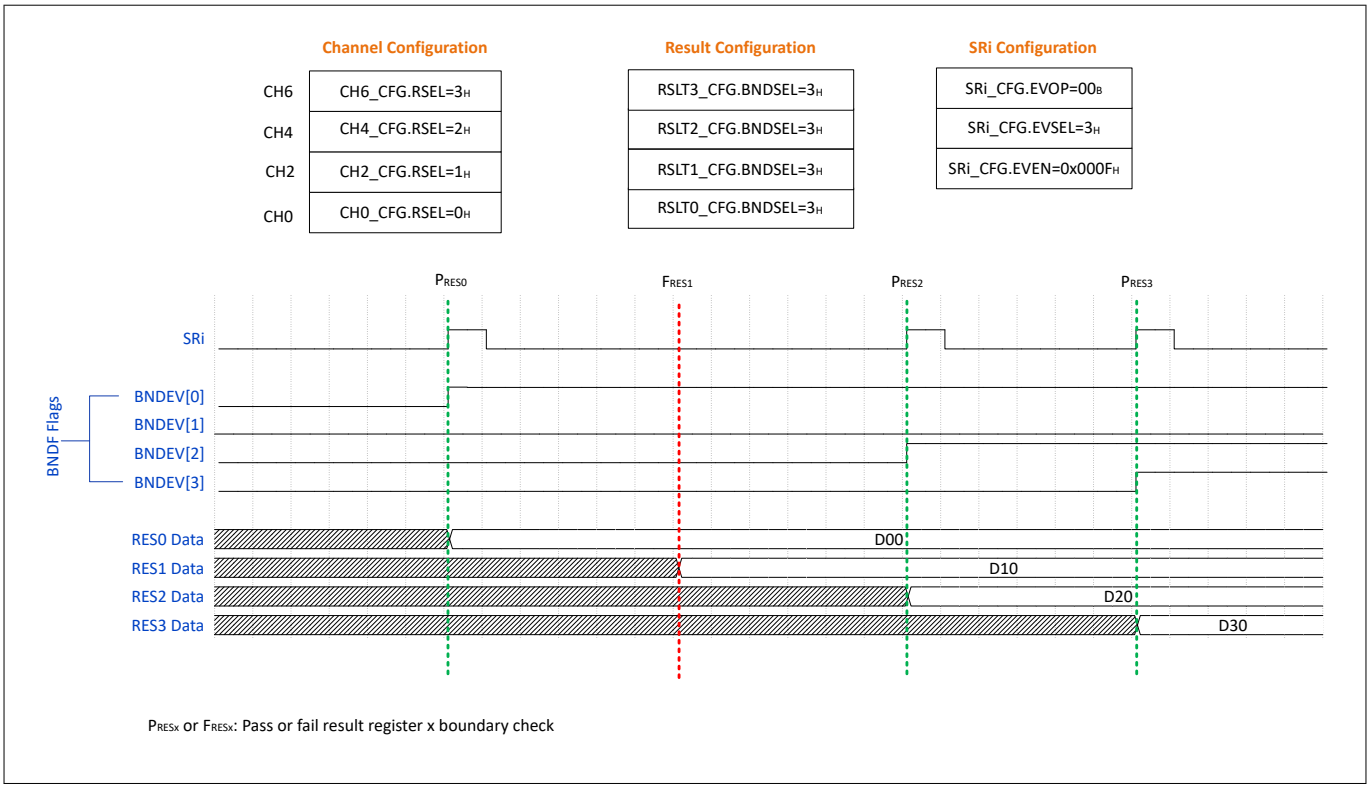

Figure 1216 TMADC service request generation: SR generated for RES0, RES2, and RES3

Another example is shown in the following figure where multiple results with boundary conditions are grouped a SR is raised, if all boundary event flags are set.

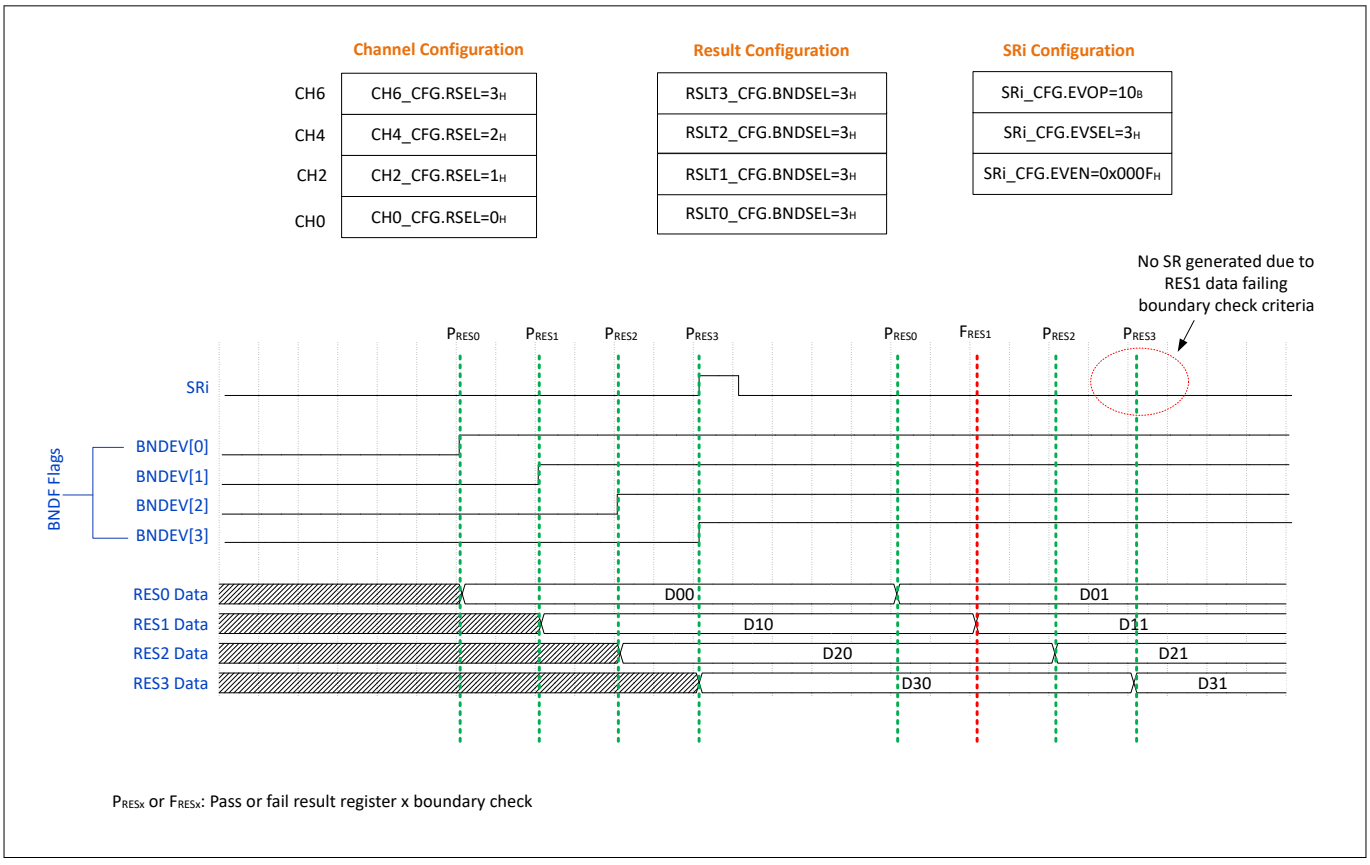

Figure 1217 TMADC service request generation: SR is raised, if all boundary event flags are set

Channel error events

Channel error events are ignored hardware or software conversion requests due to the arrival of triggers when a channel is busy. The ignored trigger event information is stored in the TMADCx_CHy_STAT register. The ignored trigger is discarded permanently and will not be repeated later.

A service request is configured for channel error event(s) by setting TMADCx_SRi_CFG.EVSEL= 01_B.

The individual error events for the channel required to trigger the service request are configured in the TMADCx_SRi_CFG.EVEN bit-field.

The following figure shows an example for the generation of a service request (SR) on an error event on CH0 and CH6. It is noted that the ERREV flag(s) in ERRF register once set after an event remains set and software shall clear the flag(s) by writing to the flag clear bit(s) in the TMADCx_ERRFCLR register. SR gets generated for an event even when the corresponding flag value is already high.

***Note**: Channel error events are configured with TMADCx_SRi_CFG.EVOP=00_B to generate an interrupt when any error event occurs.*

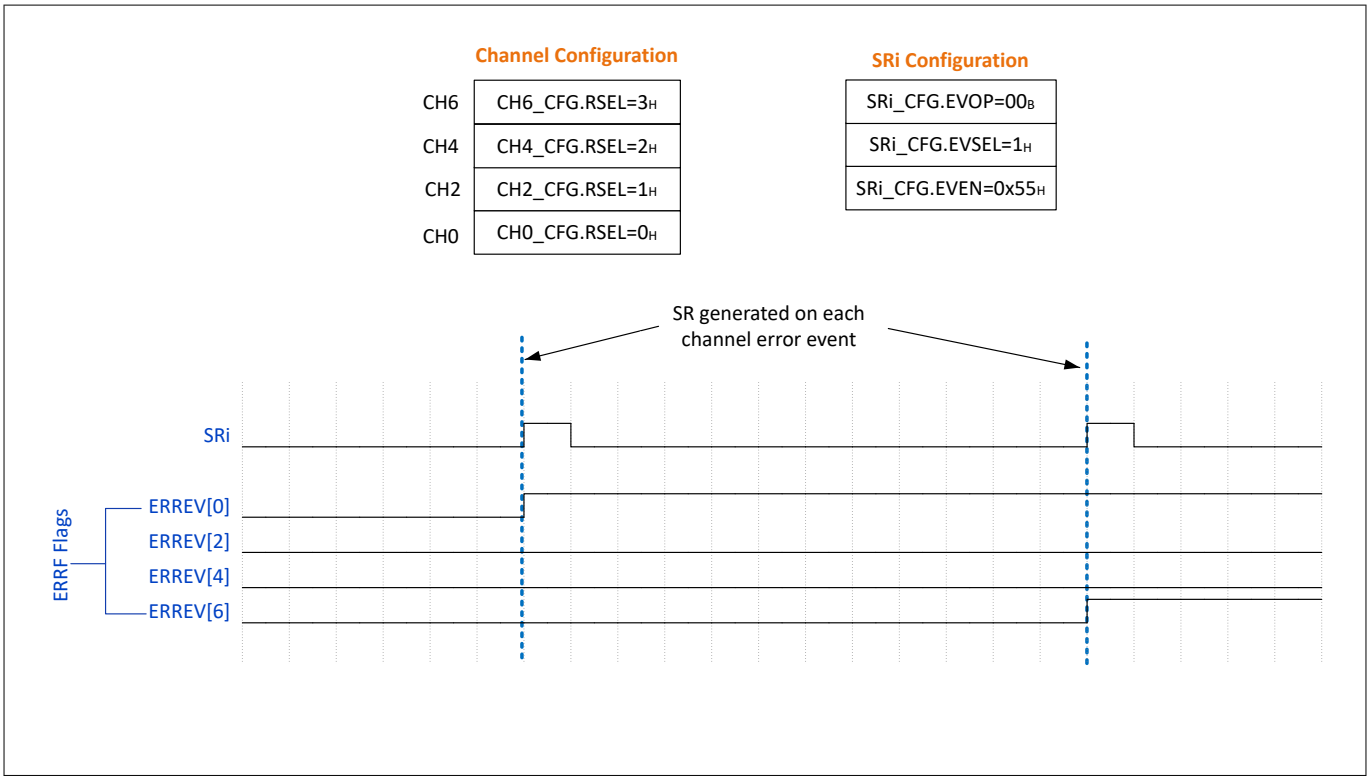

Figure 1218 TMADC service request generation on each channel error event

Wait-for-clear

The wait-for-clear functionality for the service request allows you to stall subsequent service request generation until the software clears the corresponding event flag register bit(s). This feature is enabled by setting TMADCx_SRi_CFG.EVOP=01_B.

The following figure shows an example of the wait-for-clear feature. The service request is generated on the first result event, in this case after RES0 data is available, and only after the software clears the RESEV[0:3] bit-field in the RESF register. The service request is generated again on the next available result event, in this case after RES2 data is available.

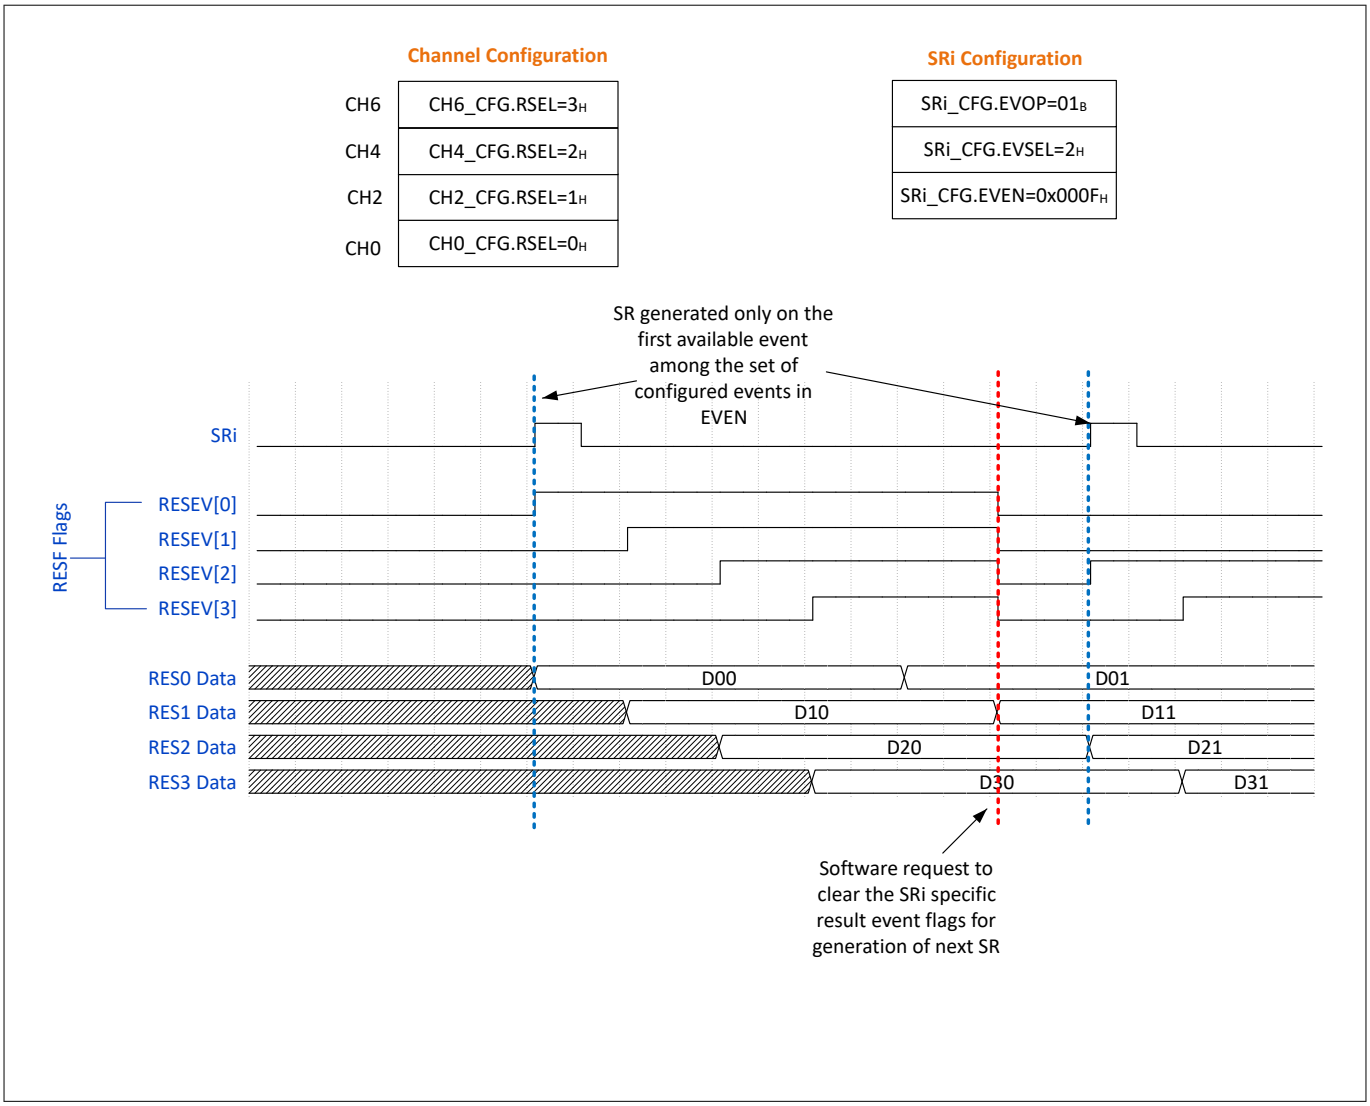

Figure 1219 TMADC service request generation with wait-for-clear feature

Related information

Global service request and alarm generation on page 8317

45.4.3.8 Diagnostics

TMADC diagnostic features are used to check the correct operation of the converter and to verify connection to the external sensor during a running application.

45.4.3.8.1 Channel-core self diagnostics (CSD)

A CSD check can be used to verify the correct functional operation of the converter during a running application. It provides the ability to sample known good values based on of VAREF and (if supported in device variant) VDDM supply.

During CSD a channel samples a known voltage (in example reference voltage). Evaluating the conversion result indicates if the converter is operating correctly. Observations of deviations outside tolerance (refer to the respective datasheet for CSD result variation) are an indication of a potential fault on a channel or core.

The CSD mechanism is configured in the core specific TMADCx_CSDn register. The CSD can be enabled for one TMADC channel (of that specific core) at a time. This is selected through the bit-field CHSEL in the CSDn register. The channel selected here should already be mapped to the core in the CMATCFG register.

The voltage to be sampled on the channel during CSD is selected through bit-field TMADCx_CSDn.SEL. 2 implementations do exist. Please refer to the description of the TMADCx_CSDn register in the device specific appendix to identify it. Variants are shown in the table below.

Table 2386 CSD configuration options

TMADCx_CSDn	Implementation 1	Implementation 2
00_B	(1972/4096)*VAREF	Shall not be used
01_B	(220/4096)*VAREF	Shall not be used
10_B	(1972/4096)*VDDM	Sampler CSD, VAREF, transfer curve shifted by 16 LSBs to match 0x07B4
11_B	(220/4096)*VDDM	Sampler CSD, VAREF, transfer curve shifted by 16 LSBs to match 0x00DC

Implementation 1 allows measurement of VDDM and VAREF fractions. Implementation 2 is based on measurement of VAREF, but the transfer curve of the converting core is modified. Therefore a positive error component can still be detected without saturating to the full-scale output code.

CSD is enabled for the channel with setting TMADCx_CSDn.EN=1 for the corresponding core.

A CSD request on a channel in sampling, hold or conversion phase is stalled until the end of its current conversion. With next sampling start the CSD setting is considered and CSD results are generated with this subsequent conversion onwards. When CSD is disabled the next result will still be with CSD settings and subsequently normal conversion results without CSD settings will be generated.

The CSD enabled channel conversion result is indicated with TMADCx_AW0_RESv.DR=1_B in the corresponding result register. Monitoring channels have dedicated result registers, where the CSD conversion can get read.

An example is shown in the figure below for CSD with respect to a channel CH5..

***Note**: To avoid VAREF loading effects, during CSD only one channel per TMADC should be configured to sample a fraction of VAREF at any given time.*

By default internal monitoring channels MCH0 and MCH1 are connected to Core-0 and Core-1 respectively. Performing CSD on these channels is done by setting CSD0.CHSEL=10_H and MCH0_CFG.SEL=11_B for MCH0 and CSD1.CHSEL=11_H and MCH1_CFG.SEL=11_B for MCH1, respectively.

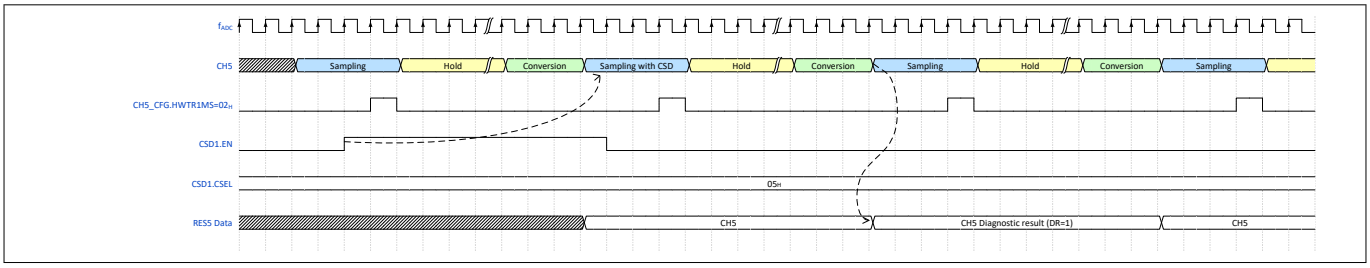

Figure 1220 Example of converter self-diagnostic sequence

45.4.3.8.2 Broken wire detection

Testing the proper connection of the external sensor to the TMADC's analog input pin can be done by enabling the broken-wire detection (BWD) mode on a channel.

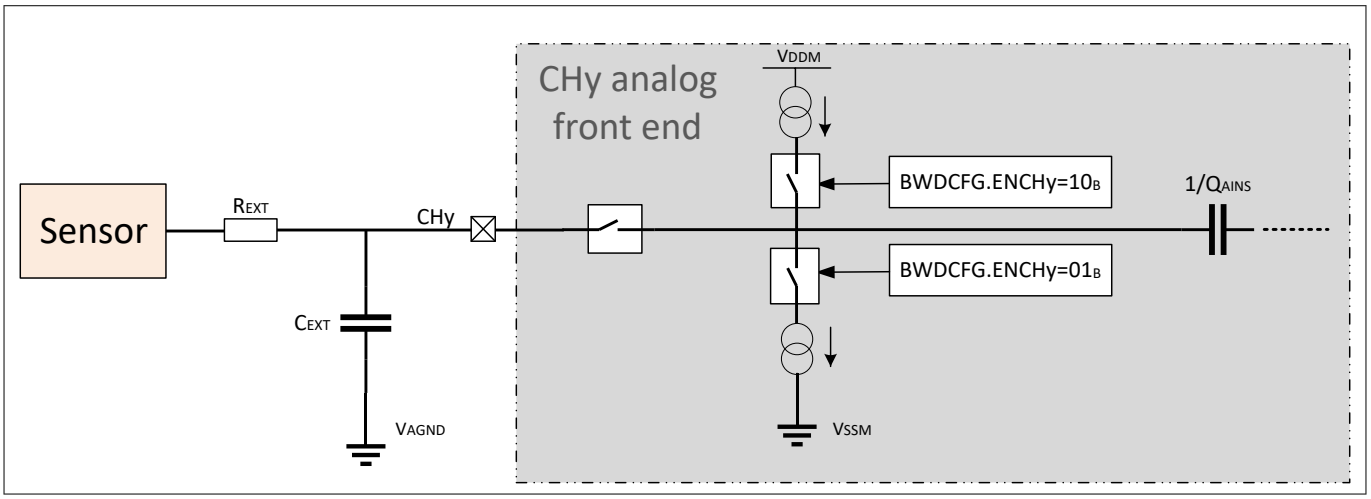

Figure 1221 Broken-wire detection circuit

A BWD mode is enabled with the setting of bit ENCHy for the respective channel's input pull-up or pull-down in the TMADCx_BWDCFG register.

The input pull-down current source can be enabled with the setting ENCHy=01_B.

The input pull-up current source can be enabled with the setting ENCHy=10_B.

The channel input is pulled up or down depending on the configuration, with the enabled current source during the sampling phase. It is disabled during conversion phase. The application software shall verify the expected behavior on the channel input with data reads on the channel conversion result.

Activation of the current sources will happen for the next full sampling phase following the activation. Matching the timing relation shown in the Channel-core self diagnostic (CSD) section.

The expected result is a function of the sensors current, the channels total sampling time and the channel capacitance.The circuit to be considered is dominated by elements outside the MCU.

Please check the device specific datasheet for the specified parameter values and consider:

- $1/Q_{AINS}$ is the sampling capacitor equivalent, datasheet value, likely to be neglected in comparison to C_{EXT}.
- C_{IO} + 2.5pF (representing the package) have to be added to C_{EXT}, but are likely neglectable in comparison to C_{EXT}.
- C_{EXT} is the off-chip external capacitor (external element, selected by user)
- I_{BWCHG} and $I_{BWDISCHG}$ are the broken wire pull-up and pull-down currents, respectively
- I_{OZ} is the pin leakage current (datasheet value, reduces I_{BW} currents)

Related information

Channel-core self diagnostics (CSD) on page 8358

45.4.3.8.3 Pull-down diagnostics (PDD)

Some TMADC modules provide a strong pull-down capability on certain analog input pins to verify the external sensor connection. The strong pull-down quickly discharges a large external buffer capacitor connected on the channel and therefore allows for the faster evaluation of diagnostic results.

PDD is enabled on the channel by setting PDDCFG.ENx=1_B.

Disable ENx and read the subsequent channel conversion result data to identify a broken sensor connection.

***Note**: Analog input pins with pull-down diagnostics device are marked in the device specific chapter.*

45.4.3.9 On-chip signal monitoring and supervision

For the purpose of monitoring on-chip signals during running application, there are dedicated internal monitor channels MCH0 and MCH1 which are mapped to TMADC channels 16 and 17.

The signal selection for conversion by the monitor channels is made by bit SEL in the TMADCx_MCHy_CFG register. The selection signals are given in following tables for the 2 monitor channels. The input connections to TMADCxMCHyIN1 are given in the device specific datasheet.

Channels MCH0 and MCH1 are by default connected to core-0 and core-1. The monitor channels are enabled by setting TMADCx_MCHy_CFG.EN=1_B. The minimum sampling time configuration for the monitor channel signals is 1 µs (TMADCx_MCHy_CFG.ST $04F_H$).

Conversion request on monitor channel(s) can be initiated on software trigger(s) configured in TMADCx_SWTRCFG.SCHSEL (bit 16 or bit 17) and TMADCx_MCHy_CFG.ATREN=1_B for the monitor channel. Software trigger is processed only during the monitor channel's sampling phase. When configured with TMADCx_MCHy_CFG.ATREN=1_B, the monitor channels do not require any external triggers for end of sampling and automatically transitions to hold phase when their configured minimum sampling time is over and get added to the respective core's round-robin arbitration queue.

The conversion results for channels MCH0 and MCH1 are stored in result register (TMADCx_MRESv) MRES0 and MRES1. Enabling wait-for-read (TMADCx_MRSLTu_CFG.WFR=1) on the monitor channel result stalls the subsequent conversion of the monitor channel signal until the corresponding result is read by the software. A change in the monitor channel's signal selection during the channel sampling, hold or conversion phase is considered only after the current conversion is completed. The figure below does show an example update sequence switching the monitoring input.

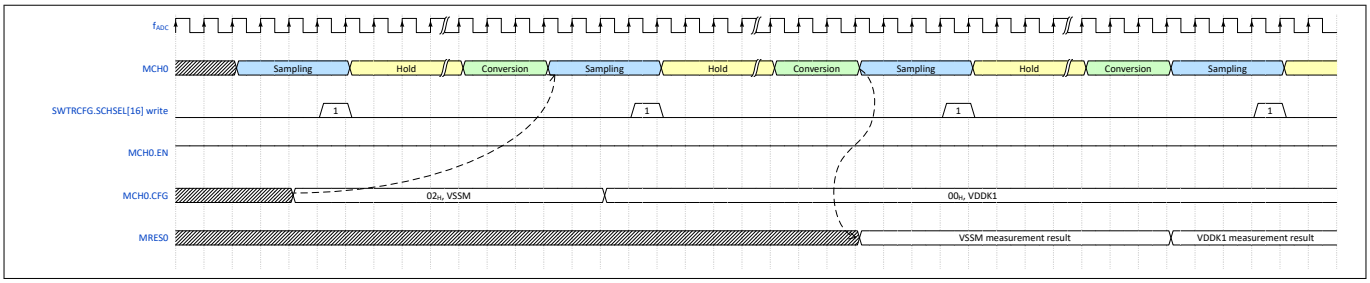

Figure 1222 Monitoring update sequence

Boundary checks can be applied on the monitor channel results by configuring the boundary mode settings in the MRSLTu register.

Each TMADC module has an output supervisor multiplexer to select signals for monitoring by another TMADC. The selection is made through bit-field OSSEL in the TMADCx_MODCFG register.

Please see the device specific chapter to check the TMADC output supervision signal connection mapping to the other TMADC module.

Table 2387 Monitor channel 0 signals

MCH0_CFG.SEL	Signal name	Signal description
0	MCH0IN0	Core-1 supply voltage (VDDK1), TMADC x
1	MCH0IN1	Supply voltages from other modules
2	MCH0IN2	VSSM
3	MCH0IN3	CSD monitor channel 0

Table 2388 Monitor channel 1 signals

MCH1_CFG.SEL	Signal name	Signal description
0	MCH1IN0	Core-0 supply voltage (VDDK0), TMADC x
1	MCH1IN1	Supply voltages from other modules
2	MCH1IN2	VSSM
3	MCH1IN3	CSD monitor channel 1

The accuracy of VAREF can be tested by measuring an internal converter core-specific bandgap signal VDDKx for example VDDK0 or VDDK1. The variation of VDDKx level depends on manufacturing deviation, supply voltage VDDM, and the die temperature. To compensate for this variation, converter core-specific correction values are measured during production at hot and cold temperature points and are stored in the on-chip Flash.

A pair of correction values for each core contains an offset (in [mV]) from a typical TMADC IVR output voltage level (V_{DDK} Controller Characteristics (CC)) measured at -40°C and 127°C. The values are recorded in the 16-bit 2's complement format. To compute the expected VDDK value, the user has to interpolate the correction value for the specific temperature (Die Temperature Sensor (DTS) reading) and reference the interpolated value to the typical IVR output voltage (V_{DDK} CC) value.

The following formula uses the current die temperature (T_j in [°C]) to compute the expected converter core-specific VDDK0 voltage level:

$VDDK0(T) = IVR_typ\ (V_{DDK}\ [mV]) + (dVDDK0(-40°C) + ((dVDDK0(127°C) - dVDDK0(-40°C))/167°C) * (T_j + 40°C))$

***Note**: On top of the computed VDDK range, the user has to also consider the tolerance of DTS and the accuracy of TMADC (TUE and noise). Ripple and noise on the VAREF rail can additionally affect VDDK measurement accuracy. For more reliable VDDK measurements it is recommended to average several consecutive samples.*

The converter core-specific correction values are stored in the User Configuration Block (UCB0) within the on-chip Flash memory. The area assigned to the TMADC begins at the offset 13004_H from UCB0 and provides records of two 32-bit words per TMADC instance. The lower half-word of a record stores the VDDK0 correction value (dVDDK0) and the next half-word stores the VDDK1 correction value (dVDDK1) as shown in Table 2389.

***Note**: Converter core-specific correction records are stored in the 16-bit 2's complement format and can represent both positive and negative values.*

Table 2389 Structure of TMADC correction values (dVDDK)

	Upper 2 bytes	Lower 2 bytes	Upper 2 bytes	Lower 2 bytes
Location TMADC0	$1300A_H$	13008_H	13006_H	13004_H

45.4.3.10 External multiplexer control

For applications requiring more than 16 channels to be converted per TMADC kernel, external analog multiplexer (EMUX) inputs can be connected to TMADC channels. TMADCs can get configured to control one out of four 4-bit EMUX control interfaces (EMUXCTRLx[0:3], x= 0-3).

The input channel driven by an external multiplexer has to be exclusively mapped to one of the TMADCs SAR cores. All other channels need to get mapped to the alternative SAR core.

This allows to use the wait for read feature on the EMUX channel result without interference to other channels. Prerequisite for AUTOSAR support of the EMUX feature.

The TMADC channel on which the EMUX is connected should be set to the configuration TMADCx_CHy_CFG.EMUXEN=1. The TMADC is expecting an external MUX for the selected channels as shown in the example below for channel number 3.

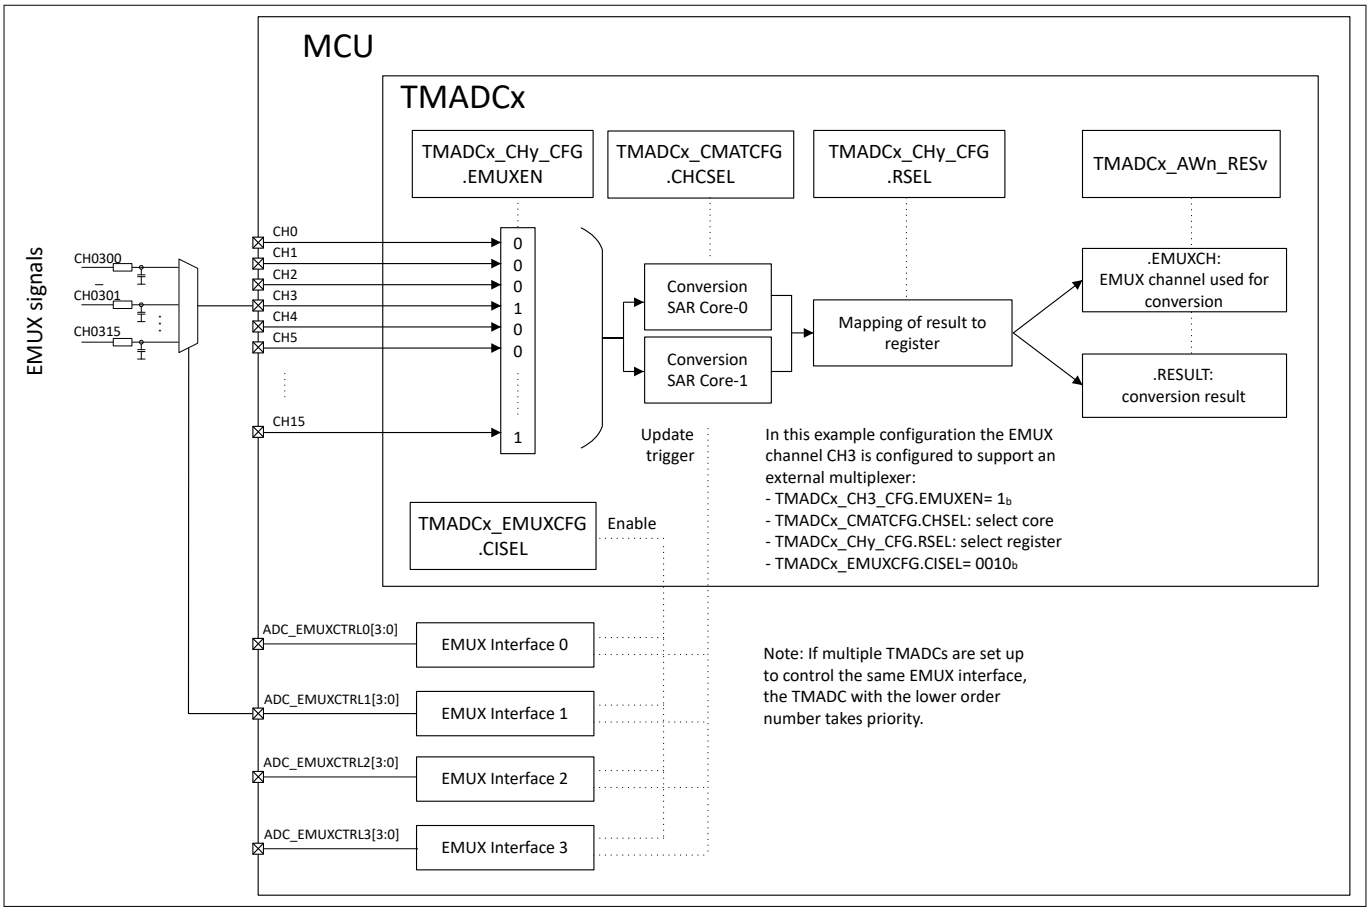

Figure 1223 TMADC EMUX control

It is possible to use up to external 16:1 multiplexers for up to 4 TMADC channels. If multiple TMADCs are set up to control the same EMUX interface, the TMADC with the lower order number takes priority.

Constraints that apply for EMUX channels

- The EMUX input channel needs to get exclusively mapped to a single SAR core (either core 0 or core 1). No other channel is allowed for that SAR core
- Switching the external multiplexers can introduce worst case transitions in the analog input signal. To suppress non-linear effects in the input channel, the minimum sampling time for EMUX channels is 1.6 µs
- Hardware trigger must be used for the EMUX channel, no automatic triggering (TMADCx_CHy_CFG.ARTEN= 0_B)
- No use of monitoring channel on the SAR core selected for EMUX use
- External multiplexer impedance adds to R_{EXT}

All the EMUX input conversion results for a single TMADC channel are stored in the same channel-specific result register configured through bit-field TMADCx_CHy_CFG.RSEL.

EMUX channels must be enabled setting TMADCx_CHy_CFG.EN=1 in CONFIG state.

EMUX operation

The EMUX channels starting from EMUX channel number 0 to the channel number specified in the TMADCx_EMUXCFG.CHCNT bit-field are selected for conversion one-by-one. After the last channel in the sequence is converted, the sequence starts from channel 0 again.

The figure below shows an example of timing waveforms for EMUX connection on CH3 with TMADCx_EMUXCFG.CHCNT = F_H for an arbitrary TMADC.

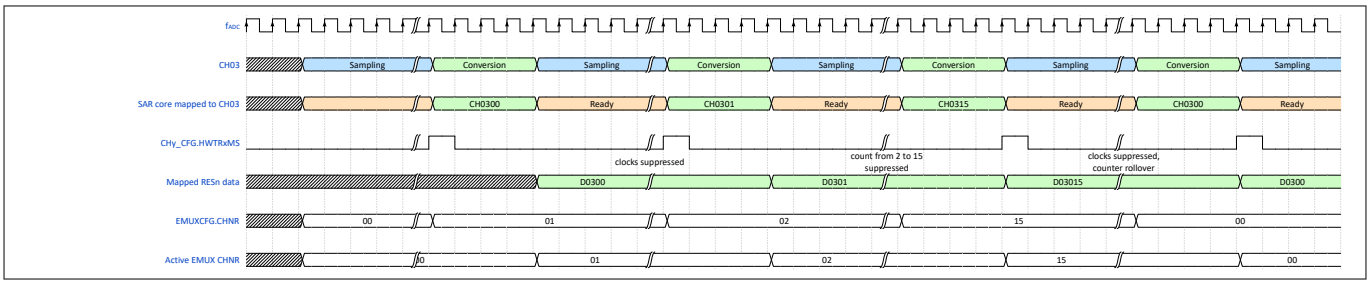

Figure 1224 EMUX automatic channel selection mode

The conversion results are stored with the corresponding EMUX channel select in the 4 most significant bits of the timestamp register (TMADCx_AW0_TSv.EMUXCH).

EMUX control signals

The EMUX control interface signals can be output in standard 4-bit binary or gray-coded format. Gray code avoids intermediate multiplexer switching when selecting a channel. The channel selection coding scheme is configured in the CS bit-field in the TMADCx_EMUXCFG register.

Table 2390 EMUX control signal coding

Channel	**0**	**1**	**2**	**3**	**4**	**5**	**6**	**7**
Binary	0000_B	0001_B	0010_B	0011_B	0100_B	0101_B	0110_B	0111_B
Gray	0000	0001	0011	0010	0110	0111	0101	0100
Channel	**8**	**9**	**10**	**11**	**12**	**13**	**14**	**15**
Binary	1000_B	1001_B	1010_B	1011_B	1100_B	1101_B	1110_B	1111_B
Gray	1100	1101	1111	1110	1010	1011	1001	1000

45.5 Converter digital signal processor (CDSP)

The CDSP is a hardware platform for customized data processing. Depending on the variant, it consists of up to 18 independent processor cores with corresponding control and computation logic. For variant specific details please refer to the device specific User Manual appendix.

The cores utilize a 32-bit architecture with highly efficient three-stage pipeline.

Each core can be programmed and configured individually to process data from Delta Sigma ADC (DSADC), External Modulator support (EXMOD), Time Multiplexed ADC (TMADC), Carrier Pattern Magnitude (CARMAG) or General Purpose (GP) registers (see chapter "Input and Output Data Interface of CDSP").

Filter chains and algorithms provided by Infineon to serve different applications are for example:

- Configurable digital filter chains
- Fourier transformation algorithm for up to 512 points
- Angle tracking observer

Parameters of the Infineon CDSP software remain configurable in order to support existing and enable new applications. Details are described in the AURIX™ TC4xx CDSP Software User Manual.

45.5.1 Feature list

- Individually programmable and independent 32 bit RISC processors
  - 3kB program RAM per processor
  - 3kB data RAM per processor
  - Clock frequency of 160 MHz
- Independent processor input interfaces
  - Internal result registers of DSADC
  - Internal auxiliary result registers of DSADC
  - Internal result registers of EXMOD
  - Carrier magnitude value (CARMAG) of DSADC carrier generator
  - Internal result register 0-5 of TMADC instances
  - 4 general purpose registers
  - Write access for program and data RAM through FPI bus system
- Output interfaces per processor
  - Main result path (RES0) with a FIFO of depth 4
  - 2 auxiliary result registers
  - Read access for data RAM through FPI bus system
- Debug support
  - APB interface
  - Input monitor and status registers
  - Suspend mode
- Time-stamp generation
  - Adjustable resolution
  - Time-stamp information directly accessible from main result register (RES0)
- Automatic limit checking
  - Result comparison with configurable upper and lower boundary value
  - Out of or within range indicator
  - Hysteresis mode

- Hardware triggers with configurable delay
  - Service request gate
  - Boundary update
  - Time-stamp generation
  - Software control
- Event signaling (service request generation)
  - Result generation (in FIFO mode configurable according to FIFO fill level)
  - Time-stamp generation
  - Limit checking conditions (signal within or out of range)
  - Processor status (processor wake-up error, system halted)

45.5.2 Functional overview

CDSP is connected to DSADC, EXMOD, TMADC, CARMAG and General Purpose (GP) registers to process the results coming from various sources.

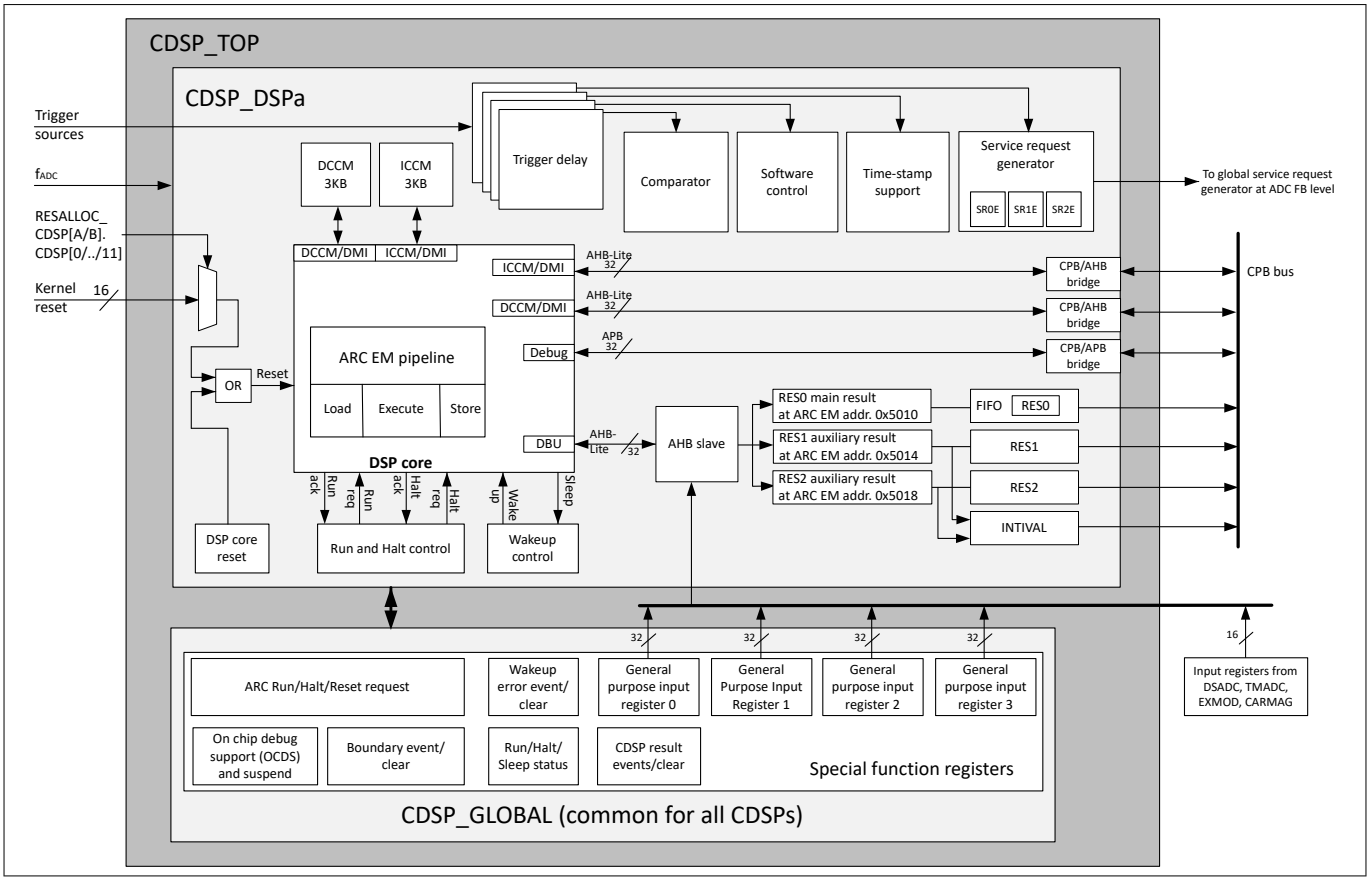

Figure 1225 CDSP architecture

CDSP operates with clock frequency f_{ADC}. The DSP core on CDSP is a three stage pipeline processor core. CDSP has two memories:

- Instruction memory, called ICCM, of 3 KB
- Data memory, called DCCM, of 3 KB

External masters can access these two memories using DSP slave ports:

- ICCM-DMI
- DCCM-DMI

DSP core reads the data from input registers using the Data Bus Unit (DBU) master port and the connected AHB slave. After processing the data, DSP core can write the output data through the DBU master interface into the

result registers of CDSP. Only DBU single word accesses are supported by CDSP AHB slave. Service request generation is combined only with the main result path RES0.

CDSP has different capabilities of handling the output result. The CDSP provides the option to generate time-stamps. You can access the time-stamp information through result registers, if configured. Results on the main result path can optionally be queued in a FIFO. CDSP can generate service requests on events such as the time-stamp information, the boundary flag event, or when the result is available in the result register. A comparator supports limit checking, for example for over-current detection. Two limit values can be defined to restrict the generation of service requests to result values within a configurable range.

45.5.3 Functional description

The CDSP hardware consists of circuitry for data processing and control logic.

The functionality of the building blocks is summarized in the following sections. An example which describes the procedure for starting up the CDSP is described in section CDSP start-up.

45.5.3.1 Central functions

CDSP_GLOBAL implements a set of central control and status registers of which the majority implements instance-specific bits with equal functionality. With this register layout the following basic functions can be triggered in different CDSP instances (CDSP_DSPa) simultaneously:

- Run, halt and reset request generation
- Wake-up, boundary or result event and service request generation
- Clearing of event flags

Corresponding status information is organized either in the same (CDSP_OCSCDSPA/CDSP_OCSCDSPB) or separate registers. Read and write accesses to the bits of these registers are controlled by the APUs which are assigned to CDSP_DSPa.

Exceptions exist for the suspend control bit fields CDSP_OCSCDSPA.SUSM, CDSP_OCSCDSPA.SUS_P, CDSP_OCSCDSPB.SUSM, CDSP_OCSCDSPB.SUS_P and the general purpose registers CDSP_GPx. These bit fields and registers are shared by multiple CDSP instances and are controlled only by the APU which is assigned to CDSP_GLOBAL.

CDSP_OCSCDSPA.SUSM and CDSP_OCSCDSPA.SUSP are shared by the CDSP instances CDSP_DSPa (a= 0-8), CDSP_OCSCDSPB.SUSM and CDSP_OCSCDSPB.SUSP are shared by the CDSP instances CDSP_DSPa (a= 9-17) and the CDSP_GPx registers are shared by all CDSP instances. An overview of the central control and status registers including implemented access protection is given in the table below.

Table 2391 Global control and status registers

Register	Function	Access protection	Details in section
CDSP_GLOBRD	DSP core reset requests	Individual CDSP (Resource ID 39-56)	Clock and reset
CDSP_GLOBRCD	Run requests	Individual CDSP (Resource ID 39-56)	Run and halt
CDSP_GLOBRSD	Run status	Individual CDSP (Resource ID 39-56)	Run and Halt
CDSP_GLOBHCD	Halt requests	Individual CDSP (Resource ID 39-56)	Run and halt
CDSP_GLOBHSTD	Halt status	Individual CDSP (Resource ID 39-56)	Run and halt

(table continues...)

Table 2391 (continued) Global control and status registers

Register	Function	Access protection	Details in section
CDSP_SLPST	Sleep status	Individual CDSP (Resource ID 39-56)	Sleep and wake-up
CDSP_RESEVy	Result event flag	Individual CDSP (Resource ID 39-56)	Result handling
CDSP_RESEVCLRy	Result event flag clearing	Individual CDSP (Resource ID 39-56)	Result handling
CDSP_GPx	General purpose input	CDSP global (Resource ID 38)	Input and output data interface
CDSP_WUERREV	Wake-up error event flags	Individual CDSP (Resource ID 39-56)	Sleep and wake-up
CDSP_WUERRCL	Wake-up error event clearing	Individual CDSP (Resource ID 39-56)	Sleep and wake-up
CDSP_BNDCF, CDSP_BNDCF1, CDSP_BNDCF2	Boundary event flags	Individual CDSP (Resource ID 39-56)	Limit checking
CDSP_BNDCFCL, CDSP_BNDCFCL1, CDSP_BNDCFCL2	Boundary event flag clearing	Individual CDSP (Resource ID 39-56)	Limit checking
CDSP_OCSCDSPA	OCDS control and status	Individual CDSP (Resource ID 39-56)	Debug
CDSP_OCSCDSPB	OCDS control and status	Individual CDSP (Resource ID 39-56)	Debug

***Note**: Central functions which are triggered in two or more CDSP instances simultaneously, will be executed simultaneously. However, corresponding status information can arrive in the status register with a synchronization jitter of 1 SPB clock cycle.*

***Note**: The event status flags of a disabled CDSP(i) are cleared, when CDSP_GLOBRCD.CHRUND(i) is set.*

Writing to registers CDSP_BNDCF, CDSP_RESEV and CDSP_WUERREV is enabled as debug option. It allows to check if the related service requests are generated for CDSP channels.

For further diagnostic and debugging, please use the global OCDS control and status registers CDSP_OCSCDSPA and CDSP_OCSCDSPB per CDSP. More details are available in the ADC Debug chapter.

45.5.3.2 Input and output data interface

Each CDSP can access input data from DSADC, EXMOD, TMADC, general purpose registers (CDSP_GPx) and the carrier magnitude register of DSADC using DSP software. Results are stored in result registers CDSP_DSPa_RESy. In addition DCCM and ICCM are address mapped to the MCU-level. They can be accessed directly through the peripheral bus (CPB, COMPB or SPB depending on variant). DSADC/EXMOD/CARMAG input registers are not available for all variants.

Input data path

45 Analog-to-Digital Converter (ADC)

The figure below shows the structure of the input data path to the DSP core. The data assembler combines the results coming from different sources with the control signals (WU, SWEN, SWINIT). This information is mapped to the internal DSP core address space.

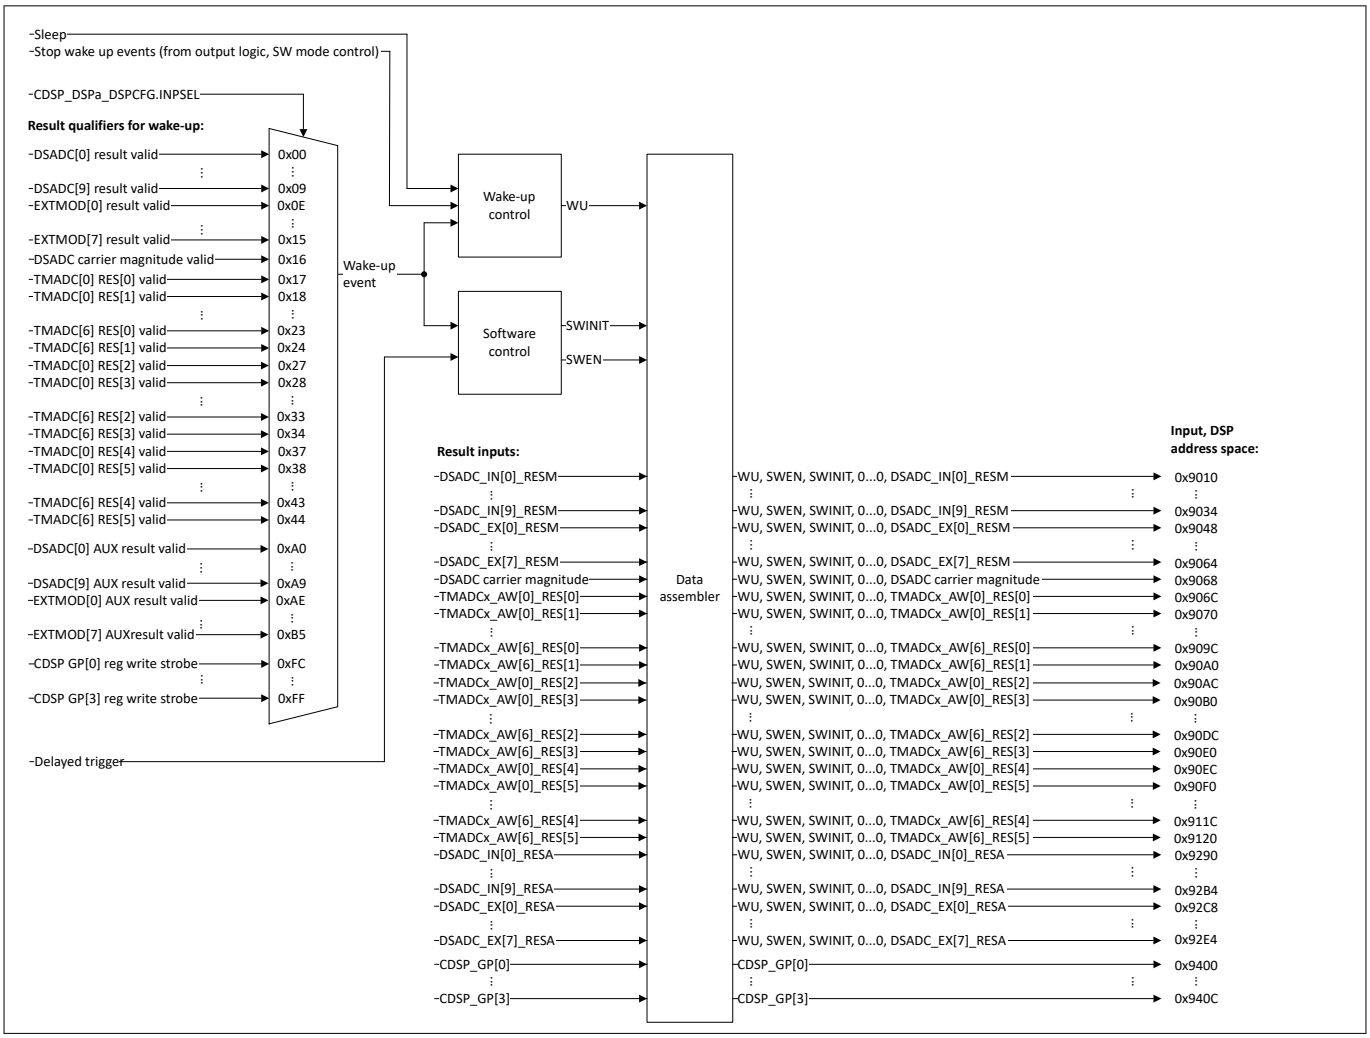

Figure 1226 Input data path

***Note**: The diagram shows the maximum configuration with respect to the data sources. If a data source is unavailable in a certain derivative, the corresponding connections will be tied to 0.*

***Note**: DSP core software access to input registers is to 32 bit.*

The control signals added to the result information are:

- WU, wake-up request generated out of wake-up event from selected input register, automatically cleared after software enable
- SWEN, enable signal for DSP software
- SWINIT, initialization signal for DSP software

The general purpose input data registers CDSP_GPx can be used to process data originating from generic sources.

When the DSP software performs a read operation from an input address, multiplexer operation between CDSP and desired input registers is done by hardware (AHB slave address decoder). In the system address map every CDSP_DSPa instance is mapped to a separate region. The DSP core address maps are equal but separated. DSP software uses the module addresses according to the table below.

Table 2392 Address mapping of input and output registers from DSP perspective

Name	System address (CPB, COMPB, SPB)	DSP core address	Description
ICCM	0xF50C0000 + a*2000$_H$	0x0000-0x0C00	DSP Instruction close coupled memory
DCCM	0xF50C1000 + a*2000$_H$	0x8000- 0x8C00	DSP data close coupled memory (input/output)
DSADCRESx, (x= 0-9)	In Register chapter	(0x9010 + 4*x)$_H$	Main result register of DSADC (input for DSP)
EXMODRESx, (x= 0-7)	In Register chapter	(0x9048 + 4*x)$_H$	Main result register of EXMOD (input for DSP)
DSADC carrier magnitude	In Register chapter	(0x9068)$_H$	Carrier signal magnitude from DSADC (input for DSP)
TMADCx_AW0_RESv, (v= 0-1), (x= 0-6)	In Register chapter	(0x906C + (4*(2*x+v)))$_H$	RES0 and RES1 of TMADC (input for DSP)
TMADCx_AW0_RESv, (v= 2-3), (x= 0-6)	In Register chapter	(0x90AC + (4*(2*x+v)))$_H$	RES2 and RES3 of TMADC (input for DSP)
TMADCx_AW0_RESv, (v= 4-5), (x= 0-6)	In Register chapter	(0x90EC + (4*(2*x+v)))$_H$	RES4 and RES5 of TMADC (input for DSP)
DSADCAUXx, (x= 0-9)	In Register chapter	(0x9290 + 4*x)$_H$	Auxiliary result register of DSADC (input for DSP)
EXMODAUXx, (x= 0-7)	In Register chapter	(0x92C8 + 4*x)$_H$	Auxiliary result register of EXMOD (input for DSP)
CDSP_GPx, x=[0:3]	In Register chapter	(0x9400 + 4*x)$_H$	General purpose register (input for DSP)
CDSP_DSPa_RESy(a=0-17;y=0-2)	In Register chapter	(0x5010 + 4*y)$_H$	Result register of CDSP (output of CDSP)

Following points shall be considered for the input data interface:

- Only the lower 16 bits of all input registers are used as data for post-processing by DSP software
- Upper 16 bits contain control information which is required by DSP software to support specific modes
- When CDSP_GPx registers are used as input for Infineon DSP software, the register layout shall follow the DSADC/TMADC input layout
- If a CDSP_GPx register is selected as wake-up source, it shall just get updated when the CDSP is in sleep mode. Otherwise a wake-up error is issued
- CDSP results are available in result registers RES0, RES1 and RES2. RES0 is a standard 32 bit main result register used for all software functions.

Input monitoring

The CDSP_DSPa_INPUTMON status register monitors the input data and allows to check the status of control signals WU, SWEN and SWINIT.

The input source to monitor in CDSP_DSPa_INPUTMON.MONDATA can be configured by CDSP_DSPa_DSPCFG.HSIMON settings according to following table.

Data selection for input monitoring

Input register	Index	HSIMON
DSADC_INx_RESM	x= 0-9	00_h - 09_h
Reserved		$0A_h$ - $0D_h$
DSADC_EXz_RESM	z= 0-7	$0E_h$ - 15_h
DSADC carrier magnitude		16_h
TMADCx_AW0_RESv	x= 0-6, v= 0-1	17_h - 24_h
Reserved		25_h - 26_h
TMADCx_AW0_RESv	x= 0-6, v= 2-3	27_h - 34_h
Reserved		35_h - 36_h
TMADCx_AW0_RESv	x= 0-6, v= 4-5	37_h - 44_h
Reserved		45_h - $9F_h$
DSADC_INx_RESA	x= 0-9	$A0_h$ - $A9_h$
Reserved		AA_h - AD_h
DSADC_EXz_RESA	z= 0-7	AE_h - $B5_h$
Reserved		$B6_h$ - FB_h
CDSP_GPx	x= 0-3	FC_h - FF_h

***Note**: In case a source is selected, that does not exist in a specific variant 0_h is read all the time.*

The next table shows the content monitored in CDSP_DSPa_INPUTMON.MONDATA depending on the selected type of source.

Table 2393 CDSP_DSPa_INPUTMON.MONDATA interpretation dependent on input source

CDSP_DSPa_INPUTMON	31	30	29	28:16	15:0
CDSP_GPx	General purpose register data [31:16]				General purpose register data [15:0]
DSADC/EXMOD	WU	SWEN	SWINIT	0	16 Bit DSADC/EXMOD result, 2's complement
TMADC	WU	SWEN	SWINIT	0	16 Bit TMADC result, 2's complement
CARMAG	WU	SWEN	SWINIT	0	5 Bit carrier magnitude, sign extended, 2's complement

Output data path

Once the processing of the input data is done on DSP core, the results are stored in result registers. The usage of the result registers depends on the CDSP software. The following scenarios are supported by the CDSP hardware and can be configured in CDSP_DSPa_SWCFG.SWMODE:

- 00_B: Software results are transmitted to the result registers as generated. INTIVAL updates are blocked. The running DSP core is sensitive to wake-up events all the time, if not in halt state. Used for example for filter chains without integrator

- 01_B: Software results are transmitted to the result registers as generated upon write access to RES1. INTIVAL register updates together with RES1 and RES2. The running DSP is sensitive to wake-up events all the time. Used for example for filter chains with integrator
- 10_B: Software results are transmitted to result registers as generated. INTIVAL updates are blocked. The running DSP core is sensitive to wake-up events until write access to RES2. Used for example for FFT

The figure below shows the structure of the output data path.

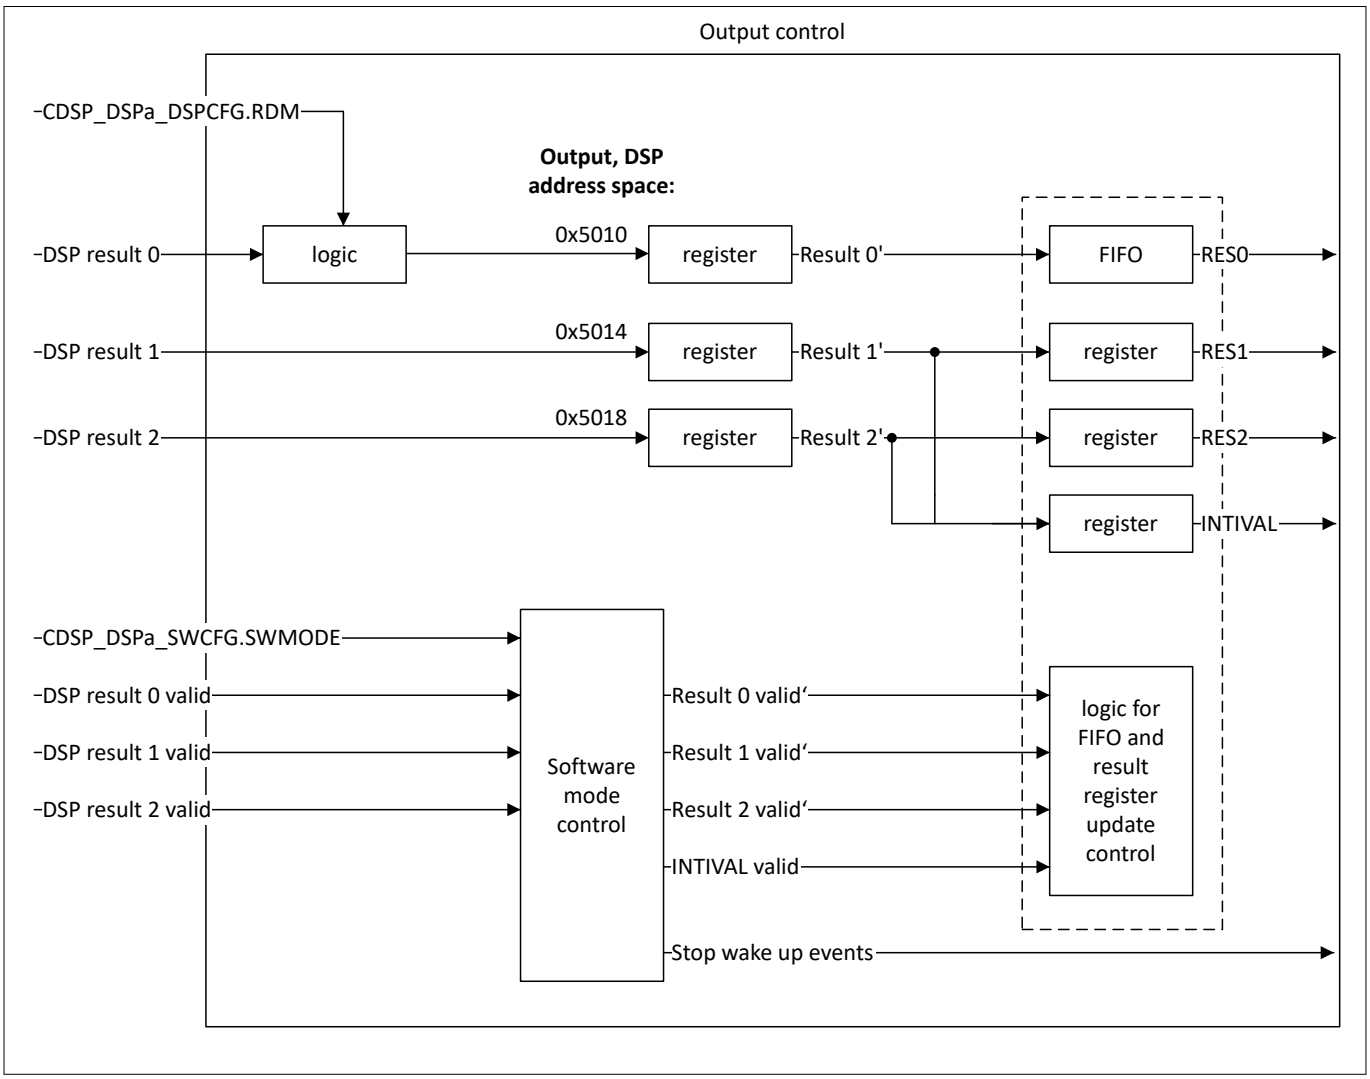

Figure 1227 Output data path

***Note**: DSP core software access to output registers is to 32 bit.*

FIFO mode is only supported through register RES0. Check section "Result Handling" for more details.

45.5.3.3 Clock and reset

The CDSP clock gets enabled by the clock control register CLKEN_CDSP.CDSPEN(a). In case a particular DSP core is used, the global clock (CLKEN_CDSP.CDSPGL) has to be enabled as well. Additional prerequisite is that CLC.DISR was configured to 1_b

The reset for the DSP core reset input Rst_a is dependent on CDSP_GLOBRD.DSPRST and APU controlled Kernel reset. When any of these resets is triggered, the DSP core is reset which sets the DSP core into the halt mode. Below is the block diagram explaining the clock and reset functionality.

The Debug reset resets the registers CDSP_OCSCDSPA and CDSP_OCSCDSPB.

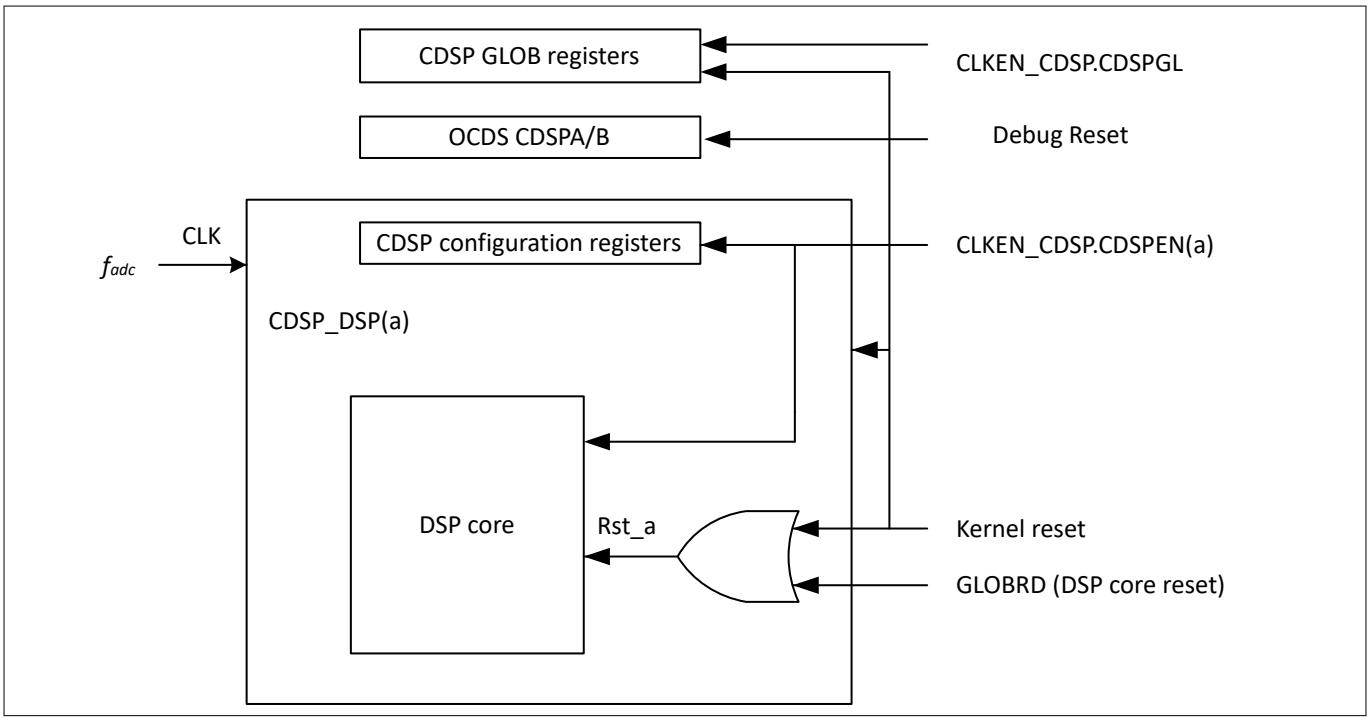

Figure 1228 CDSP clock and reset

45.5.3.4 Run and halt

By default a CDSP instance (a) is disabled after reset. It can be enabled by writing 1_b to CDSP_GLOBRCD.CHRUND(a). This action triggers a run request for the DSP core of CDSP instance (a). When this DSP core is running, the corresponding run status bit CDSP_GLOBRSD(a) will be set to 1_b, the halt status bit CDSP_GLOBHSTD(a) will be set to 0_b and all other control units of the CDSP instance (a) will be re-initialized. In this state the DSP core is ready to process data based on wake-up events as described in section 'Sleep and wake-up'.

Apart from any higher class reset (e.g. module reset or application reset), a running CDSP instance can be disabled by a halt request, a DSP reset, on demand of the CDSP software or by an uncorrectable error on the data path. A halt request for CDSP instance (a) can be issued by writing 1_b to CDSP_GLOBHCD.CHHLTD(a) and a DSP reset by writing 1_b to CDSP_GLOBRD.DSPRST(a). A DSP software call of a halt routine or an uncorrectable error on the data path will be handled automatically by the DSP core.

When the DSP core is halted, the corresponding run status bit CDSP_GLOBRSD.DSPRST(a) will be set to 0_b, the halt status bit CDSP_GLOBHSTD.DSPHST(a) will be set to 1_b. In this state wake-up events will be ignored.

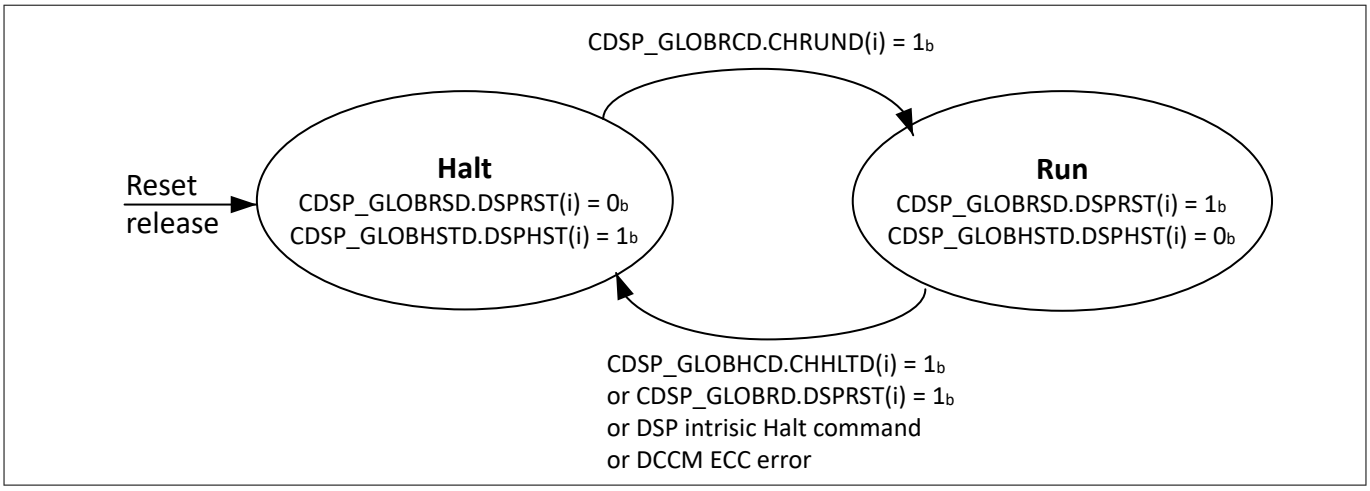

Figure 1229 Run and Halt state diagram

Due to synchronization and implementation delays the processing of run and halt requests can take up to 12 f_{ADC} + 4 peripheral bus (SPB/COMPB/CPB depending on device variant) clock cycles. The new run/halt status will be available at the latest 3 peripheral bus (SPB) clock cycles after that. This is the worst case scenario where either the enabling or the disabling of at least 2 CDSP instances happens successively within two peripheral bus (SPB/COMPB/CPB depending on device variant) clock cycles.

45.5.3.5 Sleep and wake-up

The CDSP supports wake-up and sleep based data processing. Sleep and wake status of DSP core is used to control program execution dependent on input data availability.

To this end a CDSP instance (a) must be enabled first as described in chapter Run and Halt. Afterwards the running DSP core (a) alternates between an active (awake) and an inactive (sleep) phase. During the active phase it executes the DSP software and during the inactive phase it is idle. The active phase is initiated by a hardware wake-up event and the inactive phase is entered when the DSP software executes a sleep instruction. The actual phase of DSP core(a) can be read from CDSP_SLPST.DSPSLP(a).

Wake-up events are generated by each data source whenever it stores new data. A CDSP instance (a) can be configured in CDSP_DSPa_DSPCFG.INPSEL, to listen to the wake-up events of exactly one data source. An overview of the configuration options is given in the table below.

Input register	Index	INPSEL bits
DSADC_INx_RESM	x= 0-9	00_h - 09_h
Reserved		$0A_h$ - $0D_h$
DSADC_EXz_RESM	z= 0-7	$0E_h$ - 15_h
DSADC carrier magnitude		16_h
TMADCx_AW0_RESv	x= 0-6, v= 0-1	17_h - 24_h
Reserved		25_h - 26_h
TMADCx_AW0_RESv	x= 0-6, v= 2-3	27_h - 34_h
Reserved		35_h - 36_h
TMADCx_AW0_RESv	x= 0-6, v= 4-5	37_h - 44_h
Reserved		45_h - $9F_h$
DSADC_INx_RESA	x= 0-9	$A0_h$ - $A9_h$
Reserved		AA_h - AD_h
DSADC_EXz_RESA	z= 0-7	AE_h - $B5_h$

Input register	Index	INPSEL bits
Reserved		$B6_h$ - FB_h
CDSP_GPx	x= 0-3	FC_h - FF_h

***Note**: DSP core can take up to 6 f_{ADC} clock cycles after the execution of sleep instruction to go into sleep state. DSP core can take up to 6 f_{ADC} clock cycles after receiving wake signal to completely wake up.*

Figure below explains sleep and wake up control for CDSP.

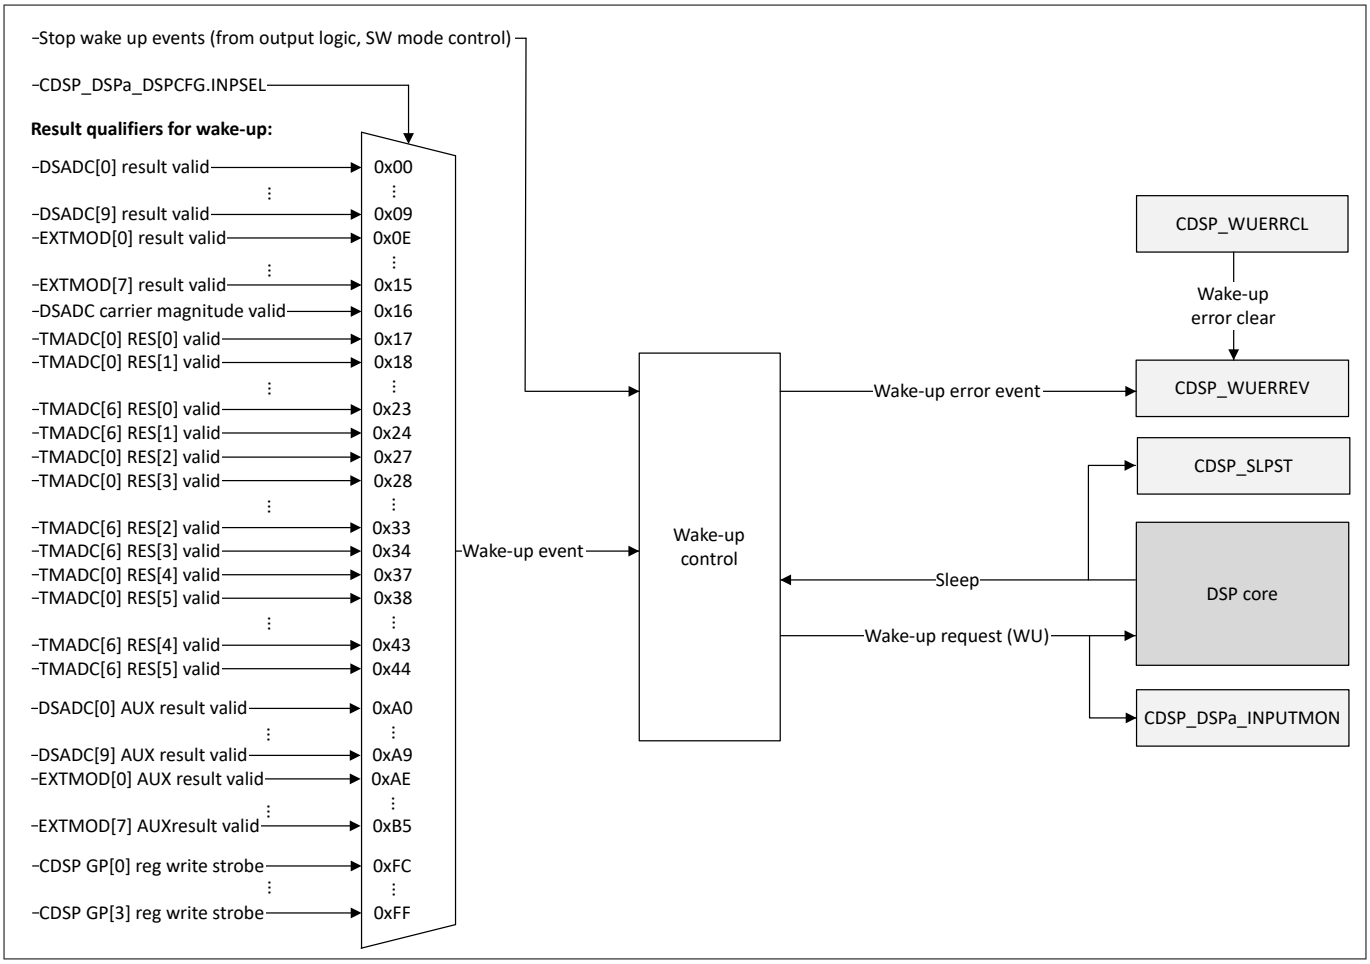

Figure 1230 Sleep and wake-up of CDSP

For proper data processing the overall system must be configured in a way that wake-up events do not arrive at DSP core (a) while it is busy (CDSP_GLOBRSD.DSPRST(a)= 1_b, CDSP_GLOBHSTD.DSPHST(a)= 0_b, CDSP_SLPST.DSPSLP(a)= 0_b). Else CDSP instance (a) will generate wake-up errors which are stored in the event flag register CDSP_WUERREV.WUERREV(a).

A wake-up error indicates that the data processing became unpredictable. The stored wake-up error flag can be cleared by writing 1_b to CDSP_WUERRCL.WUERRCL(a). Enabling a disabled DSP core with writing 1_b to instance specific bit in CDSP_GLOBRCD.CHRUND will also clear a wake-up error. Wake-up errors can cause assertion of service request line SR1 if configured by the settings CDSP_DSPa_SRCFG.SR1E (setting 10_b or 11_b).

A halt event for CDSP instance (a) freezes the current state of DSP core (a) and CDSP instance (a) will block further wake-up events. It is mandatory to reset a DSP core before reactivation.

With a reset a DSP core will be set in a state where it is halted but awake. This setting mainly serves the purpose of polling based data processing which is not supported by the CDSP hardware. But it can be usedfor the execution of a wake-up event independent startup routine when a CDSP instance (a) is started through CDSP_GLOBRCD.CHRUND for the first time after reset. In this way initialization and data processing phase can

be separated better. The duration of the startup routine depends on the CDSP software. At the end of this routine a sleep instruction must be executed.

The relations between run, halt, wake-up and sleep state of an DSP core (a) as well as the possible wake-up error conditions are visualized in figure below. Dashed lines at run requests and halt events highlight exceptional cases for these events. The normal process flow is described by the solid run request and halt event lines.

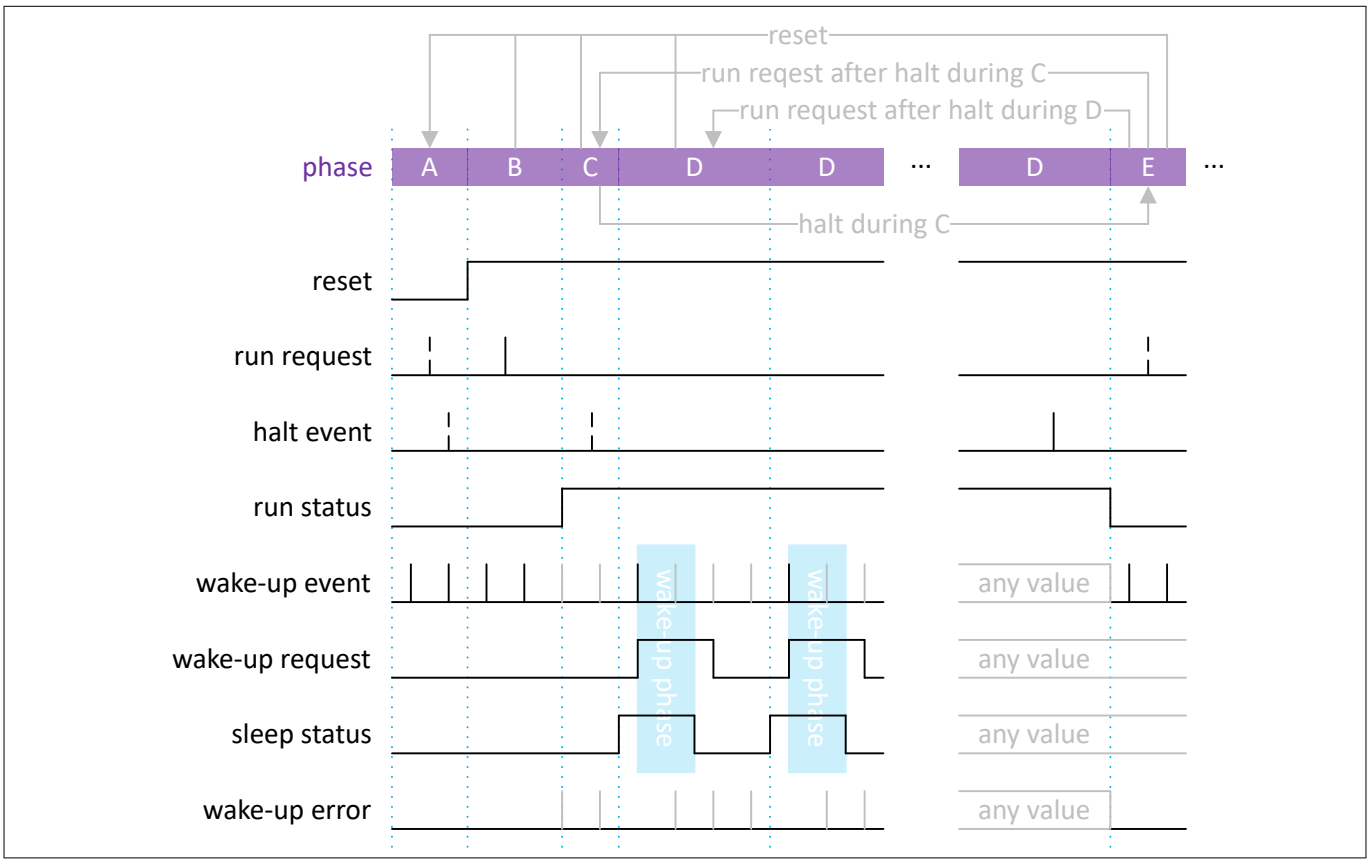

Figure 1231 Sleep and wake-up timing

Following the description of the different phases.

A) Reset

- During an active reset the DSP core will be set in a state where it is halted and awake
- A possible new run request (dashed line at run request) will be queued by the CDSP hardware and executed directly after the reset. An additional halt event (dashed line at halt event) cancels the run request again
- Since the DSP core is halted while the reset is active, wake-up events will be ignored by the CDSP hardware

B) Halt after reset

- After reset the DSP core preserves its state until it receives a run request. The run request will be processed as described in section Run and halt

C) Run with wake-up independent startup

- When the DSP core acknowledges the run request from any of the previous phases, it switches its run status to 1_b and executes a wake-up event independent startup routine (Infineon CDSP software uses this for initialization). At the end of this routine the CDSP software sets the DSP core into sleep state
- Since the DSP core is running during this phase, it is sensitive to wake-up events. For the reason that it is also awake and busy with the execution of the startup routine, all wake-up events of the selected wake-up source will cause wake-up errors (highlighted by grey wake-up events and grey wake-up errors). The wake-up errors can be avoided by selecting a reserved CDSP_DSPa_DSPCFG.INPSEL configuration after reset as long as CDSP_SLPST.DSPSLP(a) is 0_b
- If a halt event occurs during this phase (dashed line at halt event), the DSP core will stop its current activity and switch to phase E

D) Run with data processing

- At the beginning of this phase the DSP core is always running and sleeping and ready for wake-up event based data processing
- The data processing is initiated by the first wake-up event which the DSP core receives during sleep state and it is finished when the CDSP software has executed a sleep instruction
- Any wake-up event while the DSP core is about to wake-up (highlighted as wake-up phase) or busy with the execution of the CDSP software (sleep status is 0_b) will cause a wake-up error because of potential data loss (highlighted by grey wake-up events and grey wake-up errors)
- If a halt event occurs during this phase, the DSP core will stop its current activity and switch to phase E

E) Halt after run

- Whenever a halt event occurs while the DSP core is running, the DSP core freezes its current state and switches to this phase
- The wake-up request state and sleep status depends on the state in which the DSP core was at the halt event
- Wake-up events from the selected wake-up source will be ignored by the CDSP hardware because the DSP core is halted

***Note**: If CDSP_DSPa_SWCFG.SWMODE= 10_b, wake-up events of the selected wake-up source will be blocked during phase C or D as soon as the CDSP software writes to address 0x5018 (CDSP_DSPa_RES2). Infineon CDSP software uses phase D. Details about this functionality and how to release the wake-up event blocking again are described section Software control, Software mode 2*

45.5.3.6 Trigger handling

The CDSP can select between 64 trigger inputs from different hardware sources. They are used for software control, gating of service requests, time-stamp generation and update of compare values for limit checking.

The triggers received are synchronized to the f_{ADC} clock domain before reaching the CDSP. Triggers can be delayed individually in steps of 2 f_{ADC} clock cycles. The complete list can be found in the overarching ADC chapter in the topic 'Hardware triggers to ADC'.

Active edges of the incoming triggers are configured in the trigger mode registers CDSP_DSPa_TSTRCFG.TSTRM, CDSP_DSPa_SWTRCFG.SWTRM and CDSP_DSPa_BNDTRCFG.BNDTRM. The trigger based result event gating is controlled in CDSP_DSPa_SRCFG.SR0E.

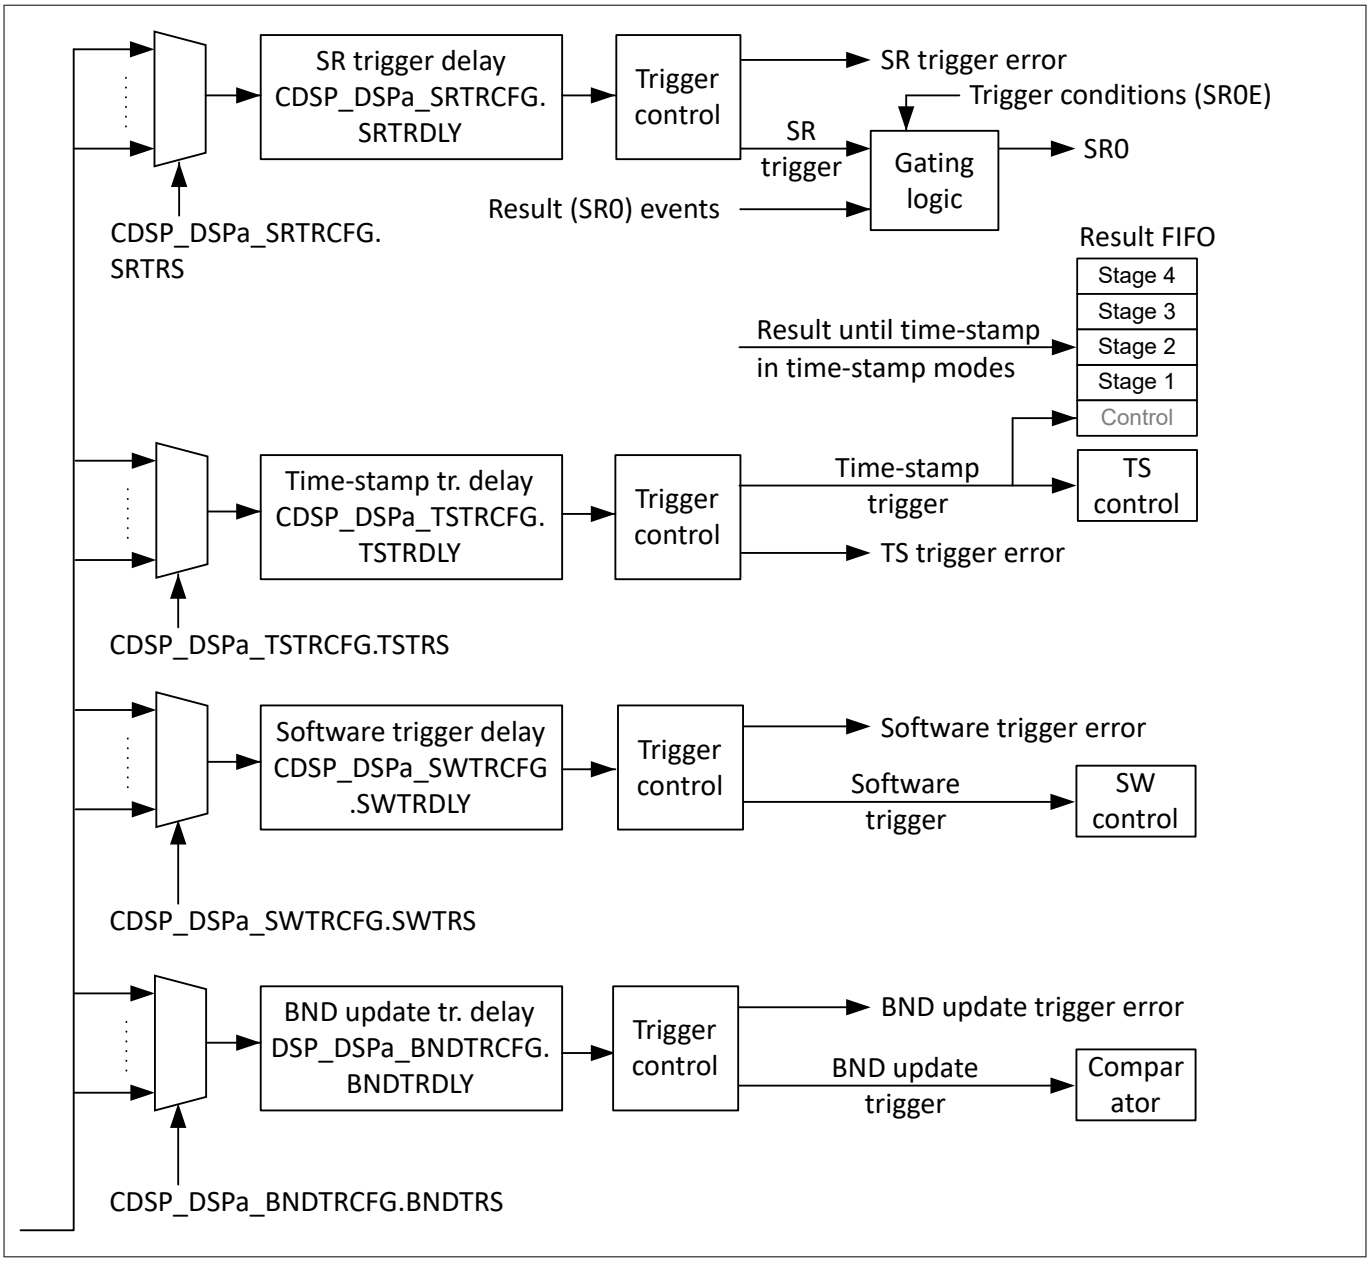

Figure 1232 Overview of trigger functionality

Trigger sources for the service request trigger are selected by CDSP_DSPa_SRTRCFG.SRTRS. The service request trigger is gating the SR0 result service request of the CDSP_DSPa. Trigger delay can get programmed in CDSP_DSPa_SRTRCFG.STRDLY. For the service request trigger there are individual trigger delay counters for positive and negative edge. The delay value is common for both edges. In case of a trigger error both trigger delay counters are reset.

The gating of the result service request can be enabled or disabled permanently. It can also be controlled by a high-active or low-active trigger (CDSP_DSPa_SRCFG.SR0E). If the Result FIFO is not in time-stamp mode, it will collect data only if service requests are enabled.

The time-stamp trigger source is selected with CDSP_DSPa_TSTRCFG.TSTRS. Trigger delay can get programmed in CDSP_DSPa_TSTRCFG.TSTRDLY. For the time-stamp trigger there are individual trigger delay counters for positive and negative edge. The delay value is common for both edges. The time-stamp trigger controls the time-stamp generation. If the FIFO is in time-stamp mode it will also control the FIFO operation.

The boundary update trigger source is selected with CDSP_DSPa_BNDTRCFG.BNDTRS. Trigger delay can get programmed in CDSP_DSPa_BNDTRCFG.TSTRDLY. For the boundary update trigger there are individual trigger

delay counters for positive and negative edge. The delay value is common for both edges. The boundary update trigger controls the update of the compare values for limit checking.

The software trigger source is set with CDSP_DSPa_SWTRCFG.SWTRS. The trigger sources are hardware based and have to be assumed asynchronous to DSP Core software execution. The software trigger is translated into software control signals SWEN and SWINIT evaluated by DSP software. The hardware timed trigger has to be translated into the software context. A fixed relation between software triggers and wake-up and sleep state of the DSPs is not expected. The CDSP hardware does this alignment automatically. Trigger delay can get programmed in CDSP_DSPa_SWTRCFG.SWTRDLY.

Trigger errors occur when

- The configured delay value is greater than the time between two equal edges of the selected trigger. In order to avoid this error condition the setup must always satisfy the relation: delay value ≤ time between two equal edges of the selected trigger.
- A new delay configuration becomes effective and changes the order of delayed edges for the actual trigger event.

45.5.3.7 Time-stamp support

Some applications need to determine the result value at certain points of time in between two regular output values. The interpolation algorithm determines the position of the required point of time. This interpolation is supported by providing a time-stamp that marks the delay since the last scheduled output value. Depending on the input/output decimation this known fraction of an output cycle enables the interpolation.

The time-stamp information is generated by the time-stamp counter. This 16-bit counter is clocked with the prescaled f_{ADC} and configurable by CDSP_DSPa_DSPCFG.TSCLK. The current value can be read from register CDSP_DSPa_TSCNT. The clock divider ratio CDSP_DSPa_DSPCFG.TSCLK shall not be changed at run-time.

Time-stamp generation is gated by Time-stamp counter run control (CDSP_DSPa_DSPCFG.TSCRUN)

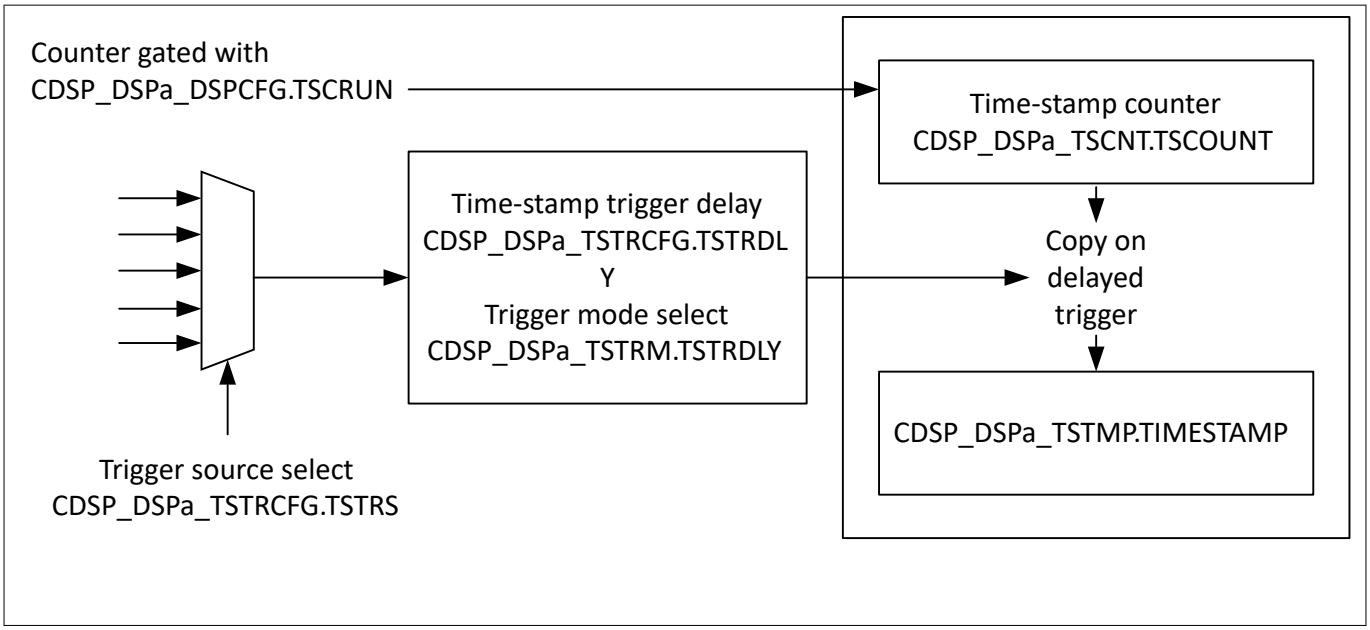

Figure 1233 Time-stamp generation

The time-stamp information is captured into the time-stamp register CDSP_DSPa_TSTMP upon a trigger event. For this purpose, the trigger signal is used, which is selected by bit-field TSTRS in register CDSP_DSPa_TSTRCFG . Bit-field CDSP_DSPa_TSTRCFG.TSTRM selects the edge(s) that capture(s) time-stamp information. With the bit field CDSP_DSPa_TSTRCFG.TSTRDELY the effective trigger edge can be optionally delayed.

In case CDSP_DSPa_SRCFG.SR1E is set to 1_h or 3_h a time-stamp trigger selected by bit-field CDSP_DSPa_SRTRCFG.SRTRS generates a service request.

The valid flag TSVAL is set when time-stamp information is stored and is cleared when the time-stamp is read from register CDSP_DSPa_TSTMP.TIMESTAMP. In addition the time-stamp counter is reset:

- If a disabled DSP core gets enabled by setting CDSP_GLOBRCD.CHRUND
- If CDSP_DSPa_DSPCFG.TSCRUN changes from 0_b to 1_b
- If the DSP core writes a new result to RES0

The time-stamp data is also available through the standard result register. More details can be found in chapter 'Result handling'.

Related information

Storage of processed data from DSP core on page 8380

45.5.3.8 Automatic reinitialization triggered by DSADC calibration

A DSP core can get reinitialized automatically when a DSADC channel starts calibration. This ensures that the start conditions for the next measurement are defined and parameters like the filter settling time remain predictable.

The filter chain of a DSADC is reset automatically by the DSADC calibration algorithm. A DSP core can select the calibration start of a specific DSADC to trigger a DSP reset. This is controlled in the bit field CDSP_DSPa_DSPCFG.INITSRC. The feature is switched off by default.

The DSP core reset triggered by DSADC calibration start does not affect the circuitry for storing run or halt requests. The last run or halt request will be executed. CDSP run status before the DSADC calibration start event is re-established. Result registers keep old measurement results until the next measurement starts.

The time-stamp control unit and the software management is reset in order to provide correct data and control signals when a new measurement starts following the DSADC calibration.

45.5.3.9 Result handling

The results from CDSP can be stored in result registers which can be retrieved by the CPU or by the DMA. One of these result registers (RES0) is combined with service request generation and can be connected additionally to a FIFO. It is also possible to leave results in the RAM so that the application software reads them directly from there.

Result handling comprises of the following functions:

- Storing CDSP output data
- Result service request generation and read sequencing

45.5.3.9.1 Storage of processed data from DSP core

The CDSP results can be stored in a FIFO-structure which is accessible through the result register CDSP_DSPa_RESy (y= 0). To this end CDSP_DSPa_DSPCFG.DRM must be configured with FIFO mode (DRM= 00_b or 10_b) and the CDSP software must write the result to address $0x5010_h$.

This enables the following features:

- Buffering reduces the result interrupt frequency depending on CDSP_DSPa_DSPCFG.SRLVL
- Two result values can be read by one single read access
- Two subsequent read accesses enable an efficient transfer of up to 4 result values
- The previous result value is still available to calculate interpolation values for time-stamp operation

- Time-stamp information can be accessed through the result register independent of FIFO mode
- One DMA channel can transfer all relevant data

***Note**:* *FIFO is supported by Result register CDSP_DSPa_RESy (y= 0), the other two result registers CDSP_DSPa_RESy (y= 1,2) can be used to retrieve results in case of special software functions, where multiple results are generated to reflect additional information. For example: filter chains with integrator. If CDSP generates only one output, then the content of CDSP_DSPa_RESy (y= 1,2) will not be changed.*

Result handling without FIFO

Depending on the single word read mode CDSP_DSPa_DSPCFG.DRM= 01_B the result values are stored in CDSP_DSPa_RESy (y= 0) directly. The result register returns the last result value if CDSP_DSPa_DSPCFG.TSM = 0_b. The high word can optionally be overwritten with the time-stamp, if TSM= 1_b. Result service requests are generated according to the CDSP_DSPa_SRCFG.SR0E configuration.

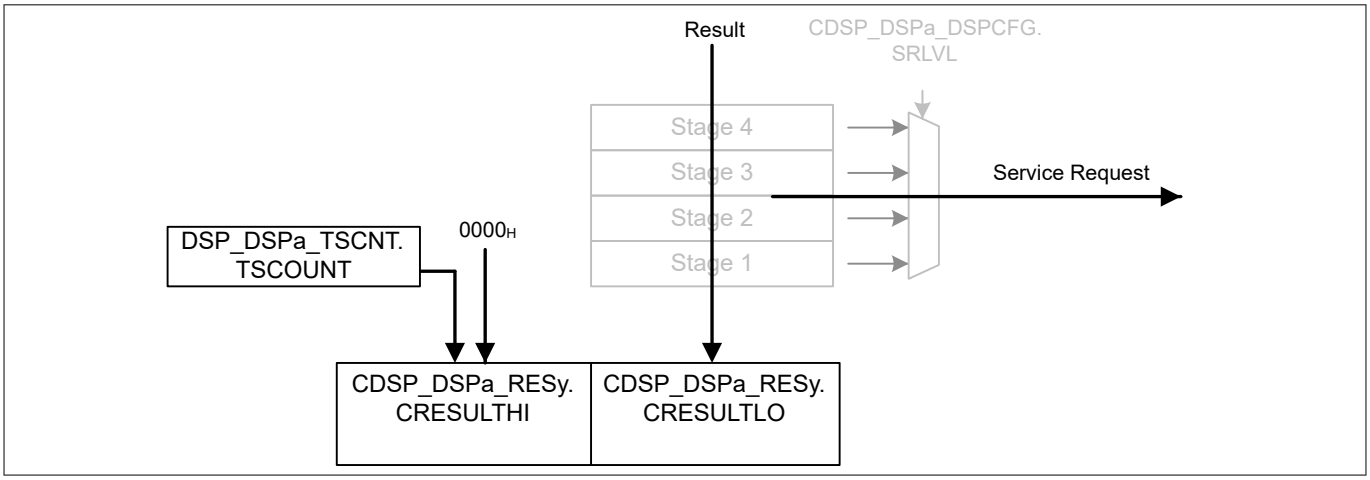

Figure 1234 Direct result storage

FIFO modes

In FIFO mode (CDSP_DSPa_DSPCFG.DRM= 00_B or CDSP_DSPa_DSPCFG.DRM= 10_B) the main filter chain results and optionally time-stamp information (CDSP_DSPa_DSPCFG.TSM= 1_b) will be stored in a FIFO. The FIFO content can be accessed via the result register CDSP_DSPa_RESy (y= 0). If the FIFO is full, additional results will be discarded and DSPST.WRERR status bit is asserted. The user should read results only based on service requests and before the next result is stored, especially after initialization.

The FIFO will be initialized (emptied) when the user:

- Enables- the DSP core by setting CDSP_GLOBRCD.CHRUND
- Flushes the FIFO by setting CDSP_DSPa_DSPCFG.FIFL
- Activates the service request generation (in modes without time-stamp)
- At the disabling edge of the time-stamp trigger (in time-stamp modes)

The FIFO can be configured in four different ways:

1. Single data read mode without time-stamp

In this mode the FIFO is queuing results in incoming order. Results will be stored in this mode only if service requests are enabled. The user has read access to the FIFO stage 1. Stage 1 is assigned to CDSP_DSPa_RESy.CRESULTLO (y= 0) and the higher 16 bits are sign extended.

Necessary setup:

- CDSP_DSPa_DSPCFG.DRM= 00_b
- CDSP_DSPa_DSPCFG.TSM= 0_b

- CDSP_DSPa_DSPCFG.SRLVL=any
- CDSP_DSPa_SRCFG.SR0E={01_b} + trigger or {10_b} + trigger or {11_b}

Figure below illustrates the data flow.

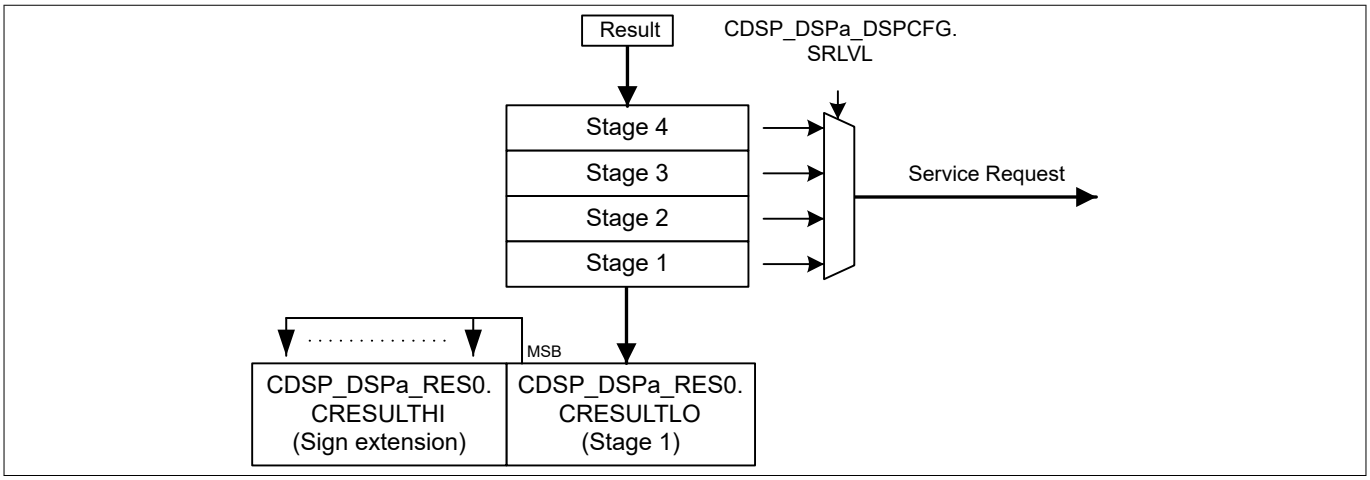

Figure 1235 Single data read mode without time-stamp

2. Single data read mode with time-stamp

In this mode the user will read the following sequence of values from the FIFO when the time-stamp was generated by the selected trigger edge (make sure that CDSP_DSPa_DSPCFG.TSCRUN=1_b in order to enable the time-stamp counter and CDSP_DSPa_TSTRCFG.TSTRM= {01_B} + trigger or {10_B} + trigger for time-stamp trigger control):

1. Time-stamp (this time-stamp will also be stored in CDSP_DSPa_TSTMP.TIMESTAMP)
2. Result before time-stamp or result at time-stamp when the time-stamp is generated at the same point in time when a new result is generated
3. 1^{st} result after time-stamp
4. 2^{nd} result after time-stamp
5. ….. n^{th} result after time-stamp

The purpose of this fixed order is that the user can differentiate between results and time-stamp because the time-stamp does not have a unique identifier. The FIFO switches between two sub-modes according to (CDSP_DSPa_TSTRCFG.TSTRM):

1. Waiting for time-stamp
   - Entered after initialization
   - Service requests will not be generated
   - User has no read access to the FIFO (read accesses will result in a read error indicated by CDSP_DSPa_DSPST.RDERR)
2. Storing results (similar to single data read mode without time-stamp)
   - Entered after time-stamp trigger
   - Result service requests on SR0 will be generated if configured by CDSP_DSPa_SRCFG.SR0E, time-stamp service requests will be generated on SR1, if configured by CDSP_DSPa_SRCFG.SR1E.
   - User has read access

After the initialization the user should wait for a service request (generated after configured time-stamp trigger edge) before reading CDSP_DSPa_RESy (y= 0).

Furthermore, it should be considered that the FIFO reacts only on the edges of the trigger signal. If for example the time-stamp trigger is high before and after setting CDSP_GLOBRCD.CHRUND= 1_b and a time-stamp shall be generated upon the rising edge of the time-stamp trigger (CDSP_DSPa_TSTRCFG.TSTRM= 10_B), then the FIFO will stay in sub-mode 'waiting for time-stamp' until the rising edge of the time-stamp trigger is generated. The FIFO will be initialized before, because the time-stamp trigger must be inactive before activating it again and therefore, a disabling time-stamp trigger edge will be generated.

Necessary setup:

- CDSP_DSPa_DSPCFG.DRM= 00_b
- CDSP_DSPa_DSPCFG.TSM= 1_b
- CDSP_DSPa_DSPCFG.TSCRUN= 1_b
- CDSP_DSPa_TSTRCFG.TSTRM= $\{01_b\}$ + trigger or $\{10_b\}$ + trigger
- CDSP_DSPa_DSPCFG.SRLVL=$\{01_b\}$ or $\{10_b\}$ or $\{11_b\}$
- CDSP_DSPa_SRCFG.SR0E=$\{01_b\}$ + trigger or $\{10_b\}$ + trigger or $\{11_b\}$

Figure below illustrates the data flow.

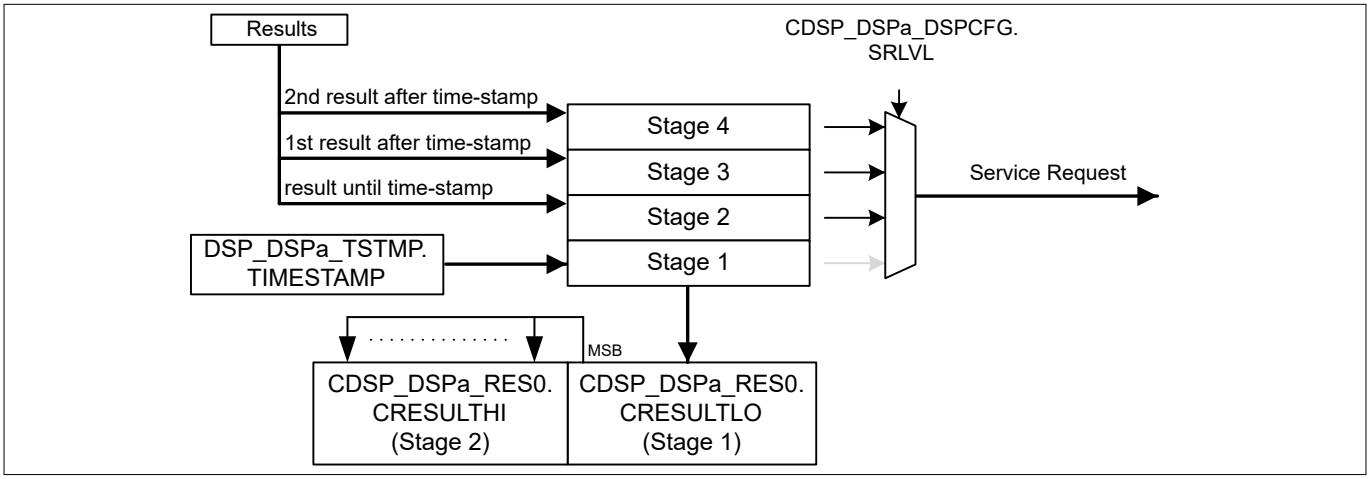

Figure 1236 Single data read mode with time-stamp

3. Double data read mode without time-stamp

In this mode the FIFO is queuing results in the order of arrival. Results will be stored in this mode only if service requests are enabled. The user has parallel read access to the FIFO stages 1 and 2. Stage 1 is assigned to CDSP_DSPa_RESy.CRESULTLO (y= 0) and stage 2 is assigned to CDSP_DSPa_RESy.CRESULTHI (y= 0)

Necessary setup:

- CDSP_DSPa_DSPCFG.DRM= 10_b
- CDSP_DSPa_DSPCFG.TSM= 0_b
- CDSP_DSPa_DSPCFG.SRLVL=$\{01_b\}$ or $\{11_b\}$
- CDSP_DSPa_SRCFG.SR0E=$\{01_b\}$ + trigger or $\{10_b\}$ + trigger or $\{11_b\}$

Figure below illustrates the data flow.

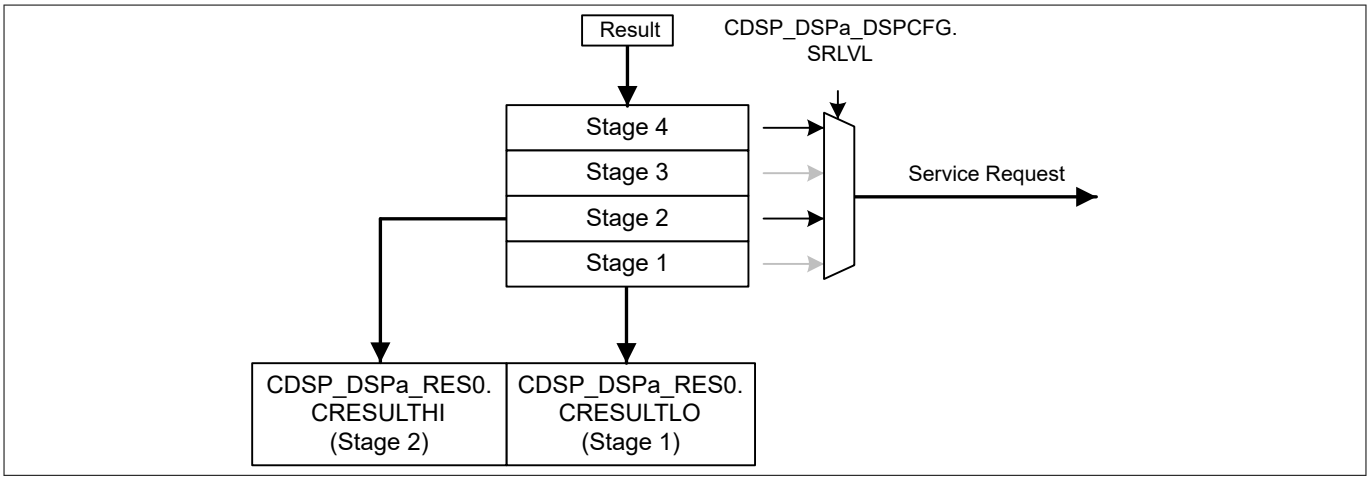

Figure 1237 Double data read mode without time-stamp

4. Double data read mode with time-stamp

In this mode the user reads the following sequence of values from the FIFO when the time-stamp was generated by the selected trigger edge:

1. Time-stamp (this time-stamp will also be stored in CDSP_DSPa_TSTMP.TIMESTAMP)
2. Result before time-stamp or result at time-stamp when the time-stamp is generated at the same point in time when a new result is generated
3. 1st result after time-stamp
4. 2nd result after time-stamp
5. …..nthresult after time-stamp

The purpose of this fixed order is that the user can differentiate between results and time-stamp because the time-stamp does not have a unique identifier. The FIFO switches between two sub-modes according to CDSP_DSPa_TSTRCFG.TSTRM:

1. Waiting for time-stamp
   - Entered after initialization
   - Service requests will not be generated
   - User has no read access to the FIFO (read accesses will result in a read error indicated by CDSP_DSPa_DSPST.RDERR)
2. Storing results (similar to double data read mode without time-stamp)
   - Entered after time-stamp trigger
   - Service requests will be generated if configured
   - User has read access

After the initialization the user should wait for a service request (generated after configured time-stamp trigger edge) before reading CDSP_DSPa_RESy (y=0).

Furthermore, it should be considered that the FIFO reacts only on the edges of the trigger signal. If for example the time-stamp trigger is high before and after setting CDSP_GLOBRCD.CHRUND= 1_b and a time-stamp shall be generated upon the rising edge of the time-stamp trigger (CDSP_DSPa_TSTRCFG.TSTRM= 10_B), then the FIFO will stay in sub-mode 'waiting for time-stamp' until the rising edge of the time-stamp trigger is generated. The FIFO will be initialized before, because the time-stamp trigger must be inactive before activating it again and therefore, a disabling time-stamp trigger edge will be generated.

Necessary setup:

- CDSP_DSPa_DSPCFG.DRM= 10_b
- CDSP_DSPa_DSPCFG.TSM= 1_b
- CDSP_DSPa_DSPCFG.TSCRUN= 1_b
- CDSP_DSPa_TSTRCFG.TSTRM= {01_b} + trigger or {10_b} + trigger
- CDSP_DSPa_DSPCFG.SRLVL={01_b} or {11_b}
- CDSP_DSPa_SRCFG.SR0E={01_b} + trigger or {10_b} + trigger or {11_b}

Figure below illustrates the data flow.

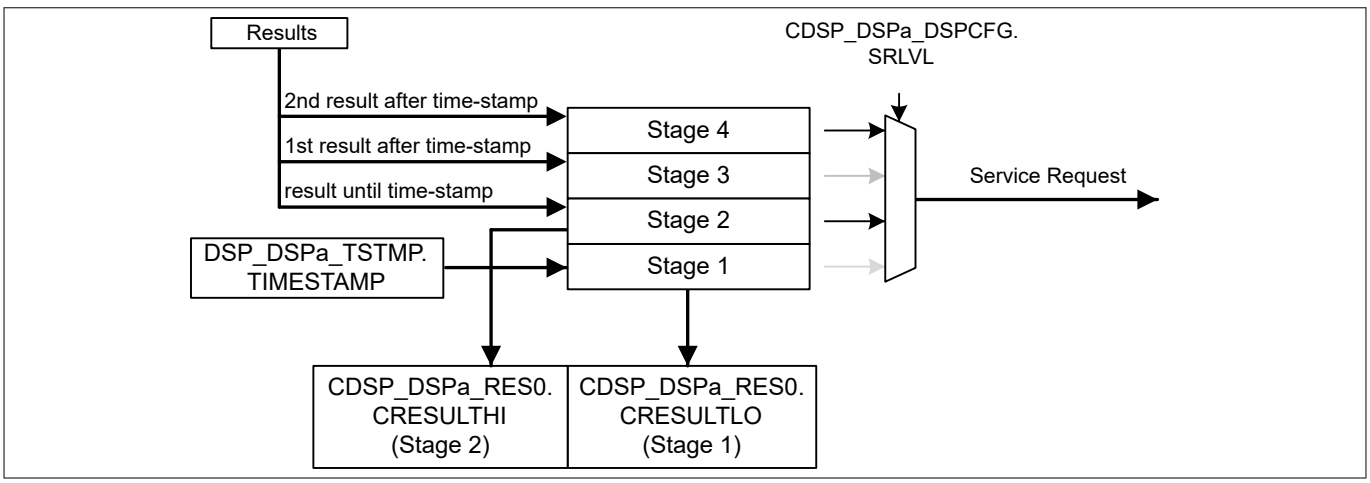

Figure 1238 Double data read mode with time-stamp

45.5.3.9.2 RES0 service request generation and read sequencing

The result values in CDSP_DSPa_RES0 (including time-stamp values, if enabled) are retrieved in a defined sequence. Result events are generated for each of these results. Result service requests are generated on SR0 depending on the configured read mode and the FIFO fill level. Each data transfer from CDSP_DSPa_RES0 (result data values or time-stamp information) is initiated by a service request. This service request is issued when a defined number of values configured in CDSP_DSPa_DSPCFG.SRLVL is available.

45.5.3.10 Limit checking

A comparator provides automatic limit checking by comparing each result with two configurable threshold values. This feature can be used to supervise the input signal and detect abnormal input values. The comparator can generate a dedicated service request.

For specific variants 2 additional equivalent comparator resources are available. Presence is noted in the device specific appendix. Register description placed at the end of this chapter.

The two threshold values are defined by the boundary select register CDSP_DSPa_BOUNDSEL and determine for example the expected result value band. The comparator could get configured to signal unexpected deviation.

The digital comparator can be used in following modes, configurable through CDSP_DSPa_BNDCFG.

- Boundary Mode: This mode is enabled by setting bit CDSP_DSPa_BNDCFG.BNDMODE= 1_b. The user can configure the generation of the boundary flags. Please refer to the figure below.

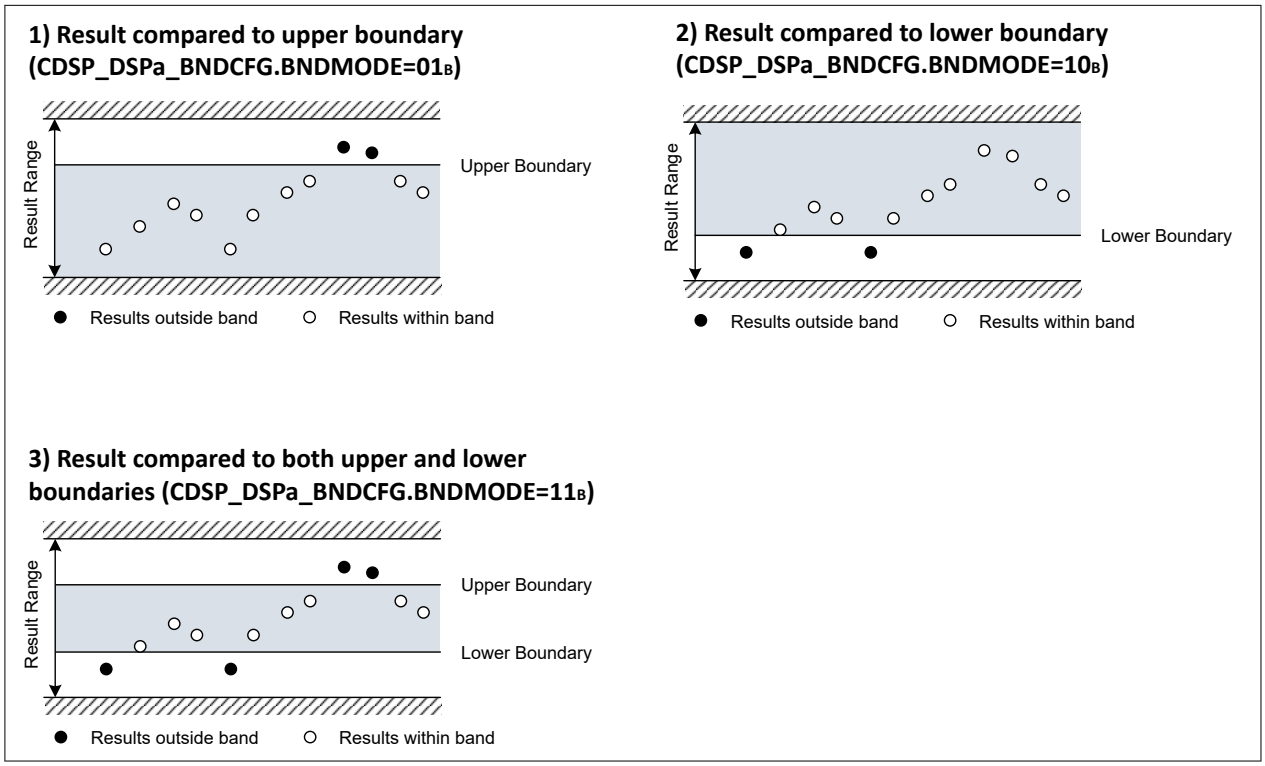

Figure 1239 Boundary mode in limit checking

- When CDSP_DSPa_BNDCFG.BNDMODE = 01_B, boundary flag is set when result exceeds upper limit

- When CDSP_DSPa_BNDCFG.BNDMODE = 10_B, boundary flag is set when result is lower than lower limit
- When CDSP_DSPa_BNDCFG,BNDMODE = 11_B, boundary flag is set if the result is either greater than the upper threshold or if the result falls short of the lower threshold.

- Hysteresis Mode: This mode is enabled by setting bit CDSP_DSPa_BNDCFG.HYSTEN =1. In this mode, the result value is compared to the upper and to the lower boundary. Boundary flag indicates when then result exceeds the upper boundary. It is cleared if the result falls short of the lower boundary

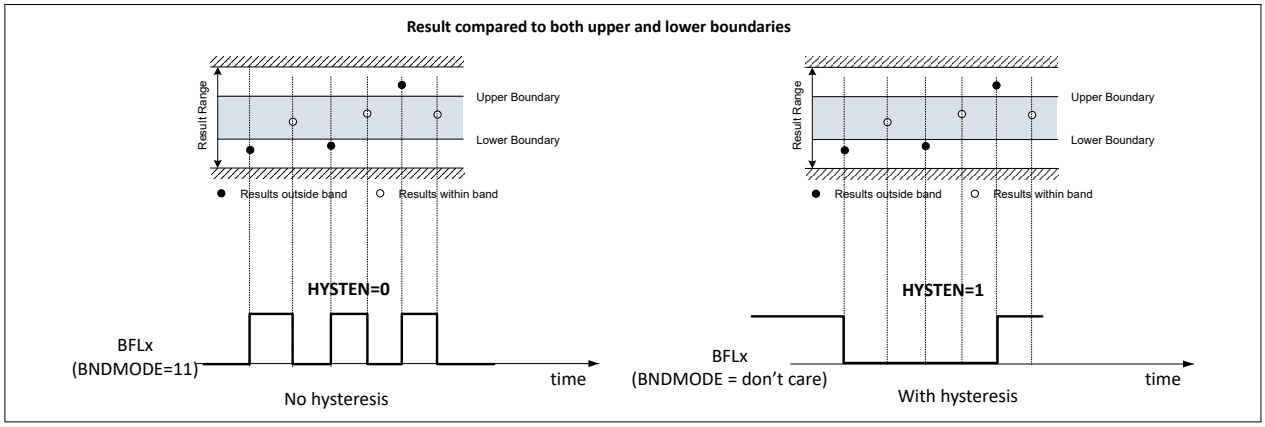

Figure 1240 Hysteresis mode in limit checking

A result value is considered between the defined boundaries when both of the following conditions are true:

- The value is less than or equal to the selected upper boundary
- The value is greater than or equal to the selected lower boundary

The limit checker can generate two types of output:

- Service requests configurable through CDSP_DSPa_SRCFG.SR2E and CDSP_DSPa_BNDCFG.SR2CFG
- Boundary flags configured by bits HYSTEN and BNDMODE of CDSP_DSPa_BNDTRCFG

The boundary values in the CDSP_DSPa_BOUNDSEL registers can be updated during runtime. The boundary update can be controlled by a selected hardware trigger. Trigger source is selectable through CDSP_DSPa_BNDTRCFG.BNDTRS and trigger mode by CDSP_DSPa_BNDTRCFG.BNDTRM. To apply a delay on the selected trigger, a delay value can be configured in CDSP_DSPa_BNDTRCFG.BNDTRDLY. Corresponding delay counters run on a fixed $f_{ADC}/2$ clock. Reading CDSP_DSPa_BOUNDST returns the active threshold for the in-band check.

Boundary events can be to result values that are inside or outside a user-defined band. This featuresupports automatic range monitoring and minimizes the CPU load by issuing service requests only under certain conditions.

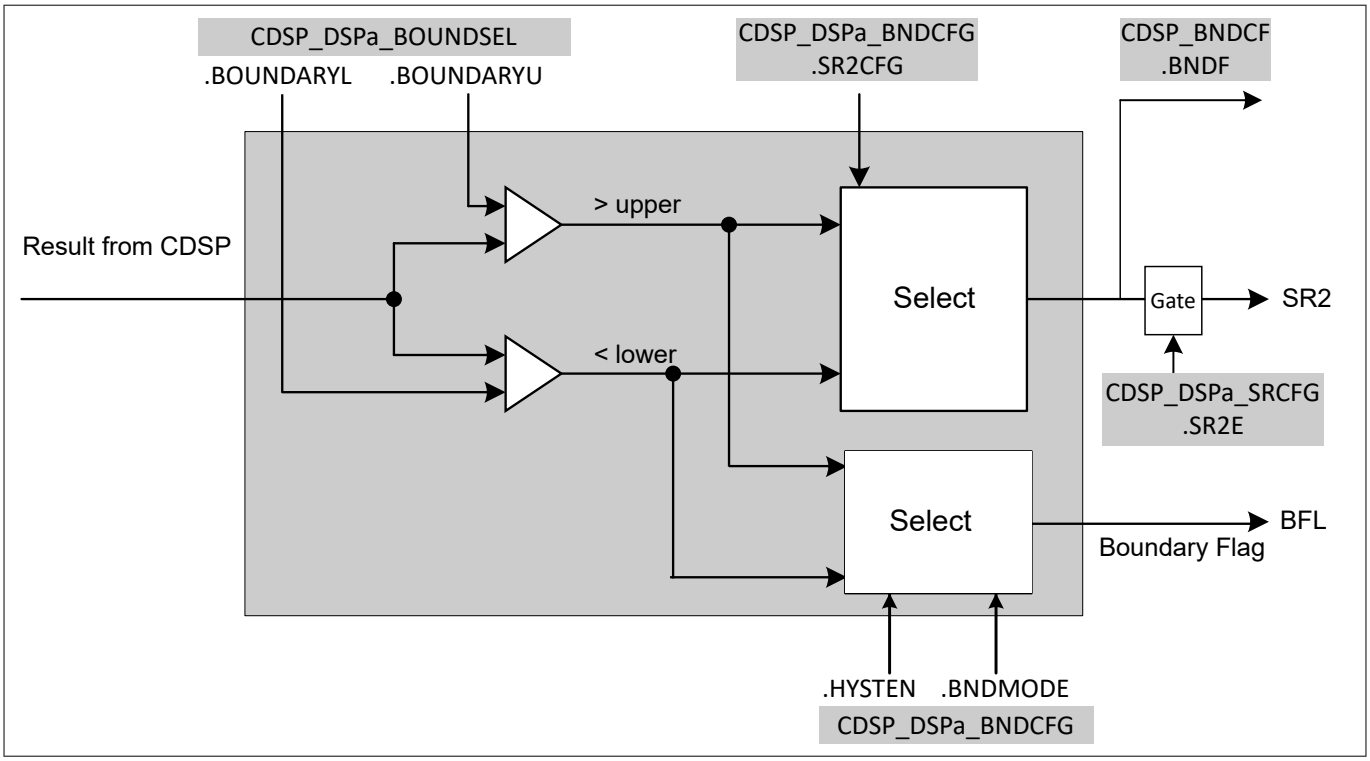

Figure 1241 Comparator structure

Only CDSP_DSPa_RESy (y= 0) lower 16 bits are used for comparison. The internal comparison is signed. In case of CDSP_DSPa_DSPCFG.RDM= 1_b (unsigned), the limits have to reflect this. 32768_d has to be subtracted from desired positive integer limit values.

In case the device variant holds 2 additional comparator resources, they can get configured and used like described above. The table below shows the equivalent register mapping for the additional comparators.

Table 2394

Family default	Additional comparator #1	Additional comparator #2
CDSP_BNDCF	CDSP_BNDCF1	CDSP_BNDCF2
CDSP_BNDCFCL	CDSP_BNDCFCL1	CDSP boundary flag event clear 2
CDSP_DSPa_BNDCFG	CDSP_DSPa_BNDCFG1	CDSP_DSPa_BNDCFG2
CDSP_DSPa_BNDTRCFG	CDSP_DSPa_BNDTRCFG1	CDSP_DSPa_BNDTRCFG2
CDSP_DSPa_BOUNDST	CDSP_DSPa_BOUNDST1	CDSP_DSPa_BOUNDST2

Service request 2 enable bits for the additional channels are CDSP_DSPa_SRCFG.SR2E1/SR2E2.

45.5.3.11 Service request generation

The CDSP can activate service request output signals to issue interrupts, to trigger DMA channels or to trigger other on-chip modules.

CDSP internal events can be assigned to service request outputs. Service requests can be generated by several types of events:

- Result events: Indicate the availability of new results. Result events are generated at the software output data rate (indicated by CDSP_RESEVy.RESEV, y= 0-2). Register RESEV0 captures the events of RES0 in all CDSPs, RESEV1 captures the events of RES1 in all CDSPs and RESEV2 captures the events of RES2 in

all CDSPs. Result service requests can be generated only for RES0 events. The corresponding control is provided by CDSP_DSPa_SRCFG.SR0E. The output rate of result service requests depends additionally on the selected FIFO fill level (see CDSP_DSPa_DSPCFG.SRLVL)

***Note**: Reading a result register (CDSP_DSPa_RESy) automatically clears the respective result event in CDSP_RESEVy.*

- Special events: Time-stamp trigger event, wake up error event or DSP core system halt event. Service requests for these events can be configured through CDSP_DSPa_SRCFG.SR1E.
- Boundary events: Indicate that a conversion result value is within or outside a programmable value range (event flags are saved in CDSP_BNDCF.BNDF). A service request is only activated if the specified conversion result range is met or exceeded. Can be configured through CDSP_DSPa_SRCFG.SR2E and CDSP_DSPa_BNDCFG.SR2CFG.

Each event is signaled by a dedicated flag. If a service request is enabled for an event, the service request is generated for each event, independent of the status of the corresponding event flag. This ensures efficient DMA handling of CDSP events (the event can generate a service request without the need to clear the indication flag).

Event flags are cleared by setting the corresponding event clear bit. The result events can be cleared manually with CDSP_RESEVCLRy.RESEVCLR. Boundary and wake-up error events can get cleared by setting the corresponding bits in DSADC_BOUNDFCL.BNDFCLR and CDSP_WUERRCL.WUERRCL. In addition event registers are cleared with assertion of a run request in CDSP_GLOBRCD.CHRUND(a).

45.5.3.12 CDSP start-up (Initialization)

Initialization steps:

1. Copy instruction code from Flash memory into the instruction memory of CDSP (ICCM)
2. Copy software configuration from the Flash memory to the dedicated area in the data memory of CDSP (DCCM)
3. Configure the CDSP_DSPa setup registers
4. Program CDSP_GLOBRCD to start program execution

45.6 Delta-Sigma Analog-to-Digital Converter (DSADC)

DSADC converts differential or single-ended analog inputs into 16-bit digital words. It is used for the continuous monitoring of signals. An external modulator can also be connected to EXMOD input channels and then the incoming bit-stream is demodulated by the EXMOD hardware.

Attention**: **DSADC is not present in this device, and so is not further described in this documentation.

45.7 Fast compare comparator (FCC)

***Attention**: FCC is not present in this device, and so is not further described in this documentation.*

45.8.4 Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 00000_H

Clock Control Register Application Reset value: $0000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

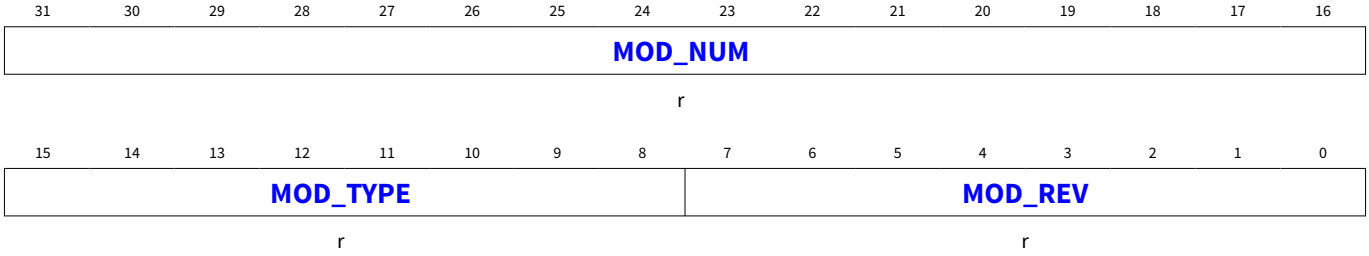
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable and disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

45.8.5 Module Identification Register

ID Offset address: 00008_H

Module Identification Register PowerOn Reset value: $0108\ C002_H$



Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number

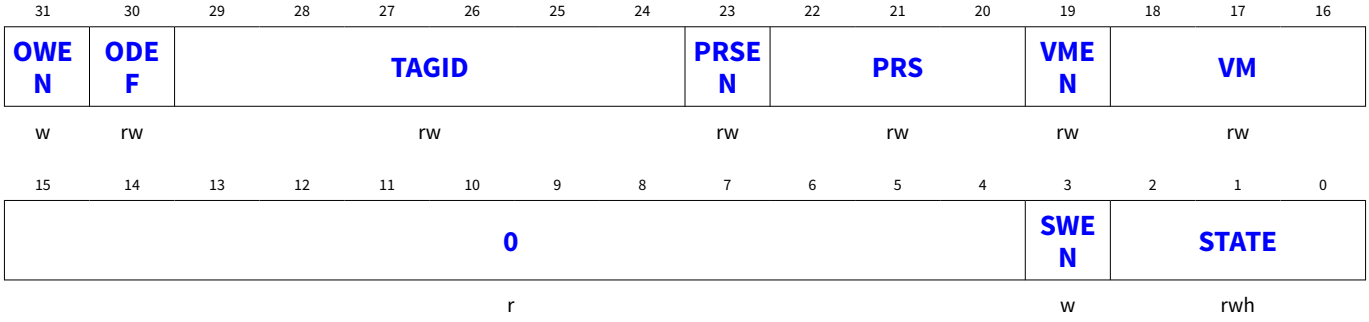
45.8.6 PROT Register Safe Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock and unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: $0000C_H$

PROT Register Safe Endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection Set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection Set definition Enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 2398 Access mode restrictions of PROTSE sorted by descending priority

Mode name	Access mode		Description

r				rh	rh	rh	rh	r							rh

Field	Bits	Type	Description
KRST	0	rh	**Kernel Reset Status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.
GRSTx (x=0-3)	x+8	rh	**Status for Global Module Reset Group x** 0_B Reset was not triggered by Global Reset Group x 1_B Reset was triggered by Global Reset Group x
0	7:1, 31:12	r	**Reserved** Read as 0.

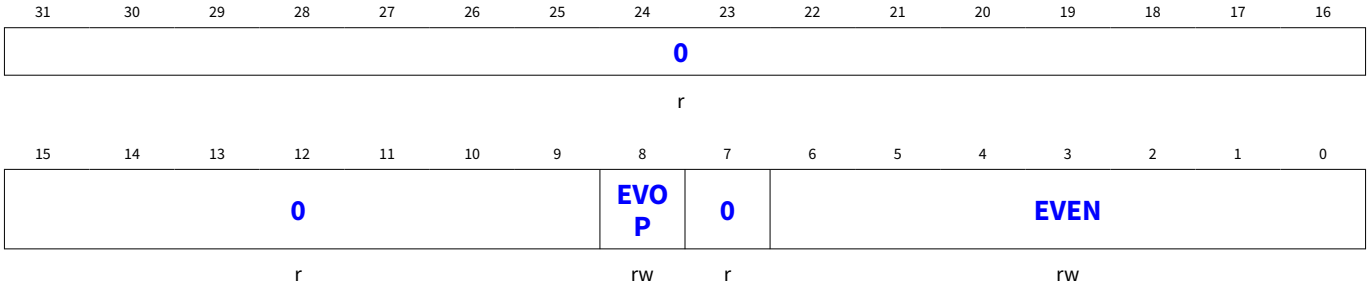
45.8.26 ADC global service request i configuration register

Global service requests are used for generating result events to IR when a set of analog channles have finished converting and results of these channels are available. The set of analog channels in this case are distributed across different TMADC instances. Global service requests are limited to TMADC channels.

Only the service request configured with SRCFG6 register in TMADCx is a valid input to the global service request.

GLSRCFGi (i=0-3) Offset address: 00800_H+i*4

ADC global service request i configuration register Kernel Reset value: $0000\ 0000_H$



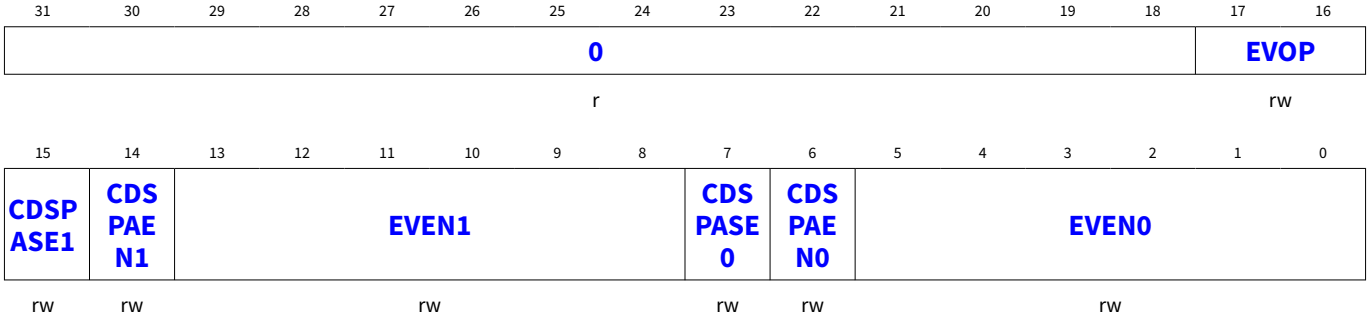
Field	Bits	Type	Description
EVEN	6:0	rw	**Event Enable** Each bit in this bitfield, if set, enables the event on SR6 for the corressponding TMADCx to be an input to the corressponding global service request 0_B Event disabled 1_B Event enabled
EVOP	8	rw	**Event Operation** This bit defines what logical operation shall be executed and under which situation global service request is generated 0_B OR logic operation 1_B AND logic operation
0	7, 31:9	r	**Reserved** Read as 0; should be written with 0

45.8.27 ADC global alarm i configuration register

Global alarms are used for generating alarms to SMU and also same alarms go as interrupts to IR. They can be generated combining 2 bounday flags from any converter.

GLALCFGi (i=0-7) Offset address: 00810_H+i*4

ADC global alarm i configuration register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EVEN0	5:0	rw	**Event Enable** 1st input to alarm generation. Select one of the 64 boundary flags. BFL0 - BFL15 are from TMADC. 2 BFLs for each TMADC BFL16-BFL25 are from FC. 1 BFL from each FC BFL26 - BFL35 are from DSINT. 1 BFL from each DSINT BFL36-BFL43 are from DSEXT. 1 BFL from each DSEXT BFL44-BFL61 are from CDSPs. 1 BFL from each CDSP BFL62 and BFL63 are reserved and not connected
CDSPAEN0	6	rw	**Alternative CDSP boundary flags mapped to EVEN0** Setting this bit maps the alternative BFL source configured by CDSP_DSPa_BNDCFG1 or CDSP_DSPa_BNDCFG2 to BFL44-BFL61 (selected by EVEN0).
CDSPASE0	7	rw	**Select of the alternative CDSP BFL source for EVEN0** 0_B Alternative BFL source configured by CDSP_DSPa_BNDCFG1 selected 1_B Alternative BFL source configured by CDSP_DSPa_BNDCFG2 selected
EVEN1	13:8	rw	**Event Enable** 2nd input to alarm generation. Select one of the 64 boundary flags. BFL0 - BFL15 are from TMADC. 2 BFLs for each TMADC BFL16-BFL25 are from FC. 1 BFL from each FC BFL26 - BFL35 are from DSINT. 1 BFL from each DSINT BFL36-BFL43 are from DSEXT. 1 BFL from each DSEXT BFL44-BFL61 are from CDSPs. 1 BFL from each CDSP BFL62 and BFL63 are reserved and not connected
CDSPAEN1	14	rw	**Alternative CDSP boundary flags mapped to EVEN1** Setting this bit maps the alternative BFL source configured by CDSP_DSPa_BNDCFG1 or CDSP_DSPa_BNDCFG2 to BFL44-BFL61 (selected by EVEN1).
CDSPASE1	15	rw	**Select of the alternative CDSP BFL source for EVEN1** 0_B Alternative BFL source configured by CDSP_DSPa_BNDCFG1 selected 1_B Alternative BFL source configured by CDSP_DSPa_BNDCFG2 selected

(table continues...)

(continued)

Field	Bits	Type	Description
EVOP	17:16	rw	**Event Operation** This bit defines what logical operation shall be executed and under which situation global service request is generated 00_B Alarm disabled 01_B OR logical operation The input to the OR gate are the input selected by EVENT0 and EVENT1. As soon as first high input comes then the alarm is generated. Every time there is a high input on EVENT0 or EVENT1 an alarm is generated 10_B AND logical operation The input to the AND gate are the input selected by EVENT0 and EVENT1. If EVENT0 and EVENT1 are coming at different time, the events remain latched until the alarm is generated 11_B Reserved
0	31:18	r	**Reserved** Read as 0; should be written with 0

45.8.28 ADC global alarm set register

By writing into this register, SW can generate corresponding alarms

GLALSET Offset address: 00830_H

ADC global alarm set register Kernel Reset value: $0000\ 0000_H$

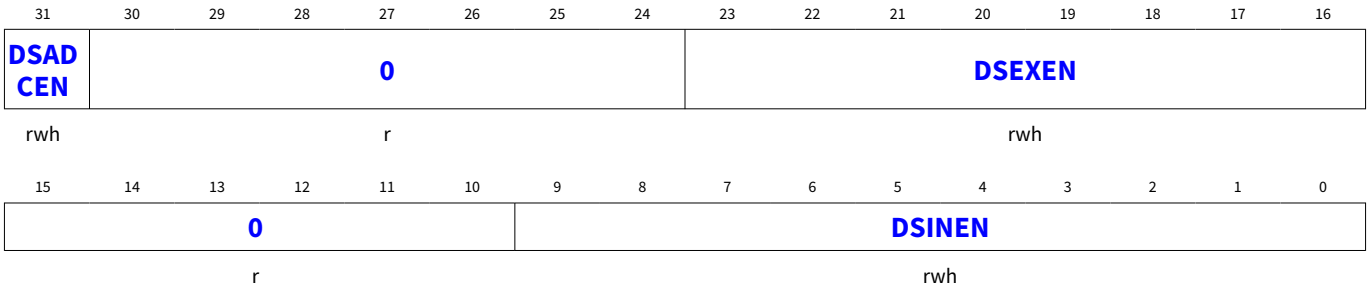
CLKEN_DSINEX Offset address: 00898_H

Clock enable for DSADC and EXMOD Kernel Reset value: $0000\ 0000_H$



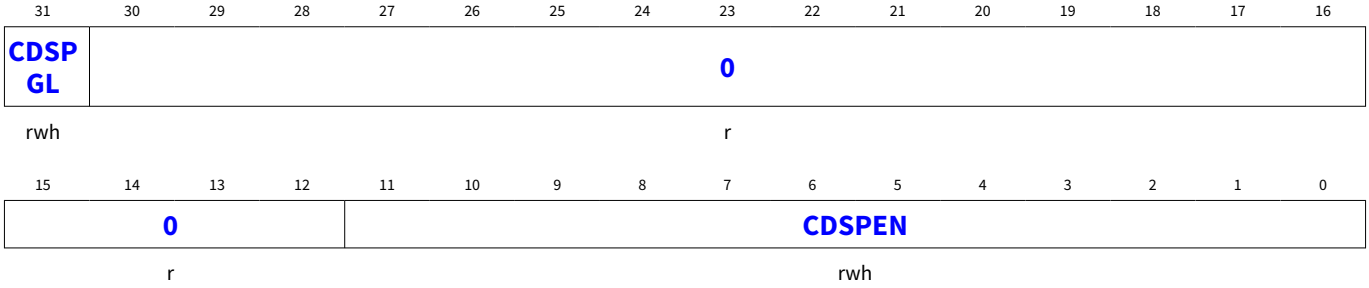
Field	Bits	Type	Description
DSINEN	9:0	rwh	**DSADC Clock Enable** Each bit controls the clock for the corresponding DSADC channel. E.g: bit0 for DSADC0.
DSEXEN	23:16	rwh	**EXMOD Clock Enable** Each bit controls the clock for the corresponding EXMOD channel. E.g: LSB for EXMOD0.
DSADCEN	31	rwh	**Enables the global part of DSADC and EXMOD** If the user intends to use DSADC or EXMOD channel, then this bit must be set to 1.
0	15:10, 30:24	r	**Reserved** Read as 0; should be written with 0

45.8.37 Clock enable for CDSP

- No action
- Clock enable for CDSP instance

CLKEN_CDSP Offset address: $0089C_H$

Clock enable for CDSP Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CDSPEN	11:0	rwh	**Clock enable for corressponding CDSP** When set to '1' clock is enabled for the corresponding CDSP
CDSPGL	31	rwh	**Enables the global part of CDSP** If the user intends to use any CDSP, then this bit shall be set to 1
0	30:12	r	**Reserved** Read as 0; should be written with 0

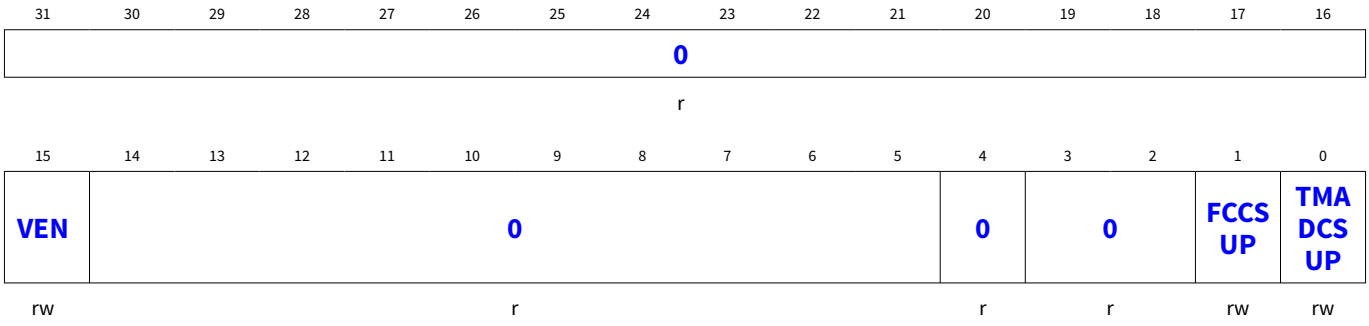
45.8.38 Supply level selection for ADC

SUPLLEV

Supply level selection for ADC

Offset address: $008A0_H$

Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TMADCSUP	0	rw	**TMADC supply level** With this bit-field operating frequency of TMADC has to be set in relation to VDDM range 0_B 80 MHz (4.5 V <= VDDM < = 5.5 V) 1_B 40 MHz (VDDM < 4.5 V)
FCCSUP	1	rw	**FCC supply level** With this bit-field operating frequency of FCC has to be set in relation to VDDM range 0_B 80 MHz (3.7 V <= VDDM < = 5.5 V) 1_B 40 MHz (VDDM < 3.7 V)

(table continues...)

(continued)

Field	Bits	Type	Description
VEN	15	rw	**High ohmic reference voltage enable** With this bit a reference voltage (VDDMDIV) of 3/4VDDM is enabled to the input analog MUX of monitoring sampler 1 of TMADC 0. This voltage can be used to calculate on-chip clock jitter.
0	3:2, 4, 14:5, 31:16	r	**Reserved** Read as 0; should be written with 0

45.8.39 TMADC supervision module register

TMSMOD Offset address: $008A4_H$

TMADC supervision module register Kernel Reset value: $0000\ 0000_H$

0													SEL		
r													rw		

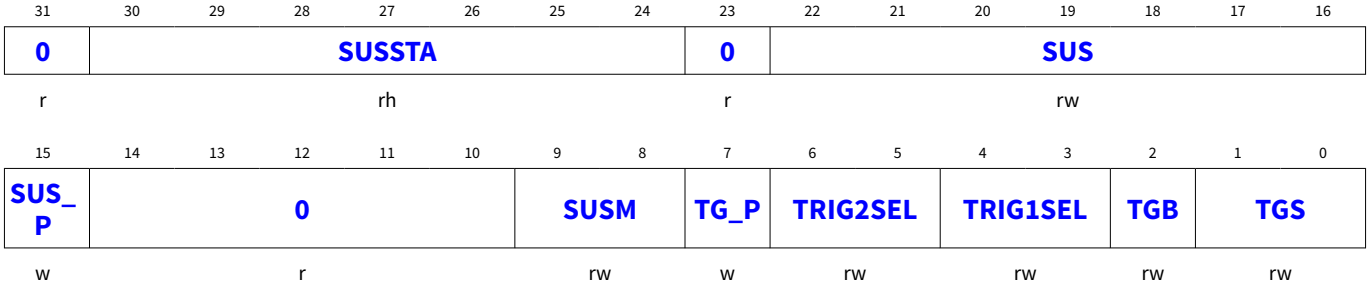
Field	Bits	Type	Description
SEL	2:0	rw	**Select** This bitfield selects the TMADC module that drives the output supervision signal that is configured in bitfield OSSEL. 0_H TMADC0 1_H TMADC1 ... 7_H TMADC7
0	31:3	r	**Reserved** Read as 0; should be written with 0

45.8.40 OCDS control and status register for TMADC

This OCDS control and status register controls the debug and trace behavior by selecting suspend modes and OTGB trigger sets. When OCDS is disabled the suspend control is ineffective. This register only controls all instances of TMADC

OCSTM Offset address: $008A8_H$

OCDS control and status register for TMADC Debug Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TGS	1:0	rw	**Trigger set for OTGB0 and OTGB1** 00_B No trigger set output 01_B Trigger set 1 Start of conversion trigger signal of TMADC input channels. For selecting the right TMADC, refer to TRIG1SEL 10_B Trigger set 2 Start of conversion trigger signal of TMADC input channels. For selecting the right TMADC, refer to TRIG2SEL 11_B Reserved
TGB	2	rw	**OTGB0 and OTGB1 bus select** 0_B Trigger set is output on OTGB0 1_B Trigger set is output on OTGB1
TRIG1SEL	4:3	rw	**Trigger set 1 select** These bits select which TMADC instance trigger signals are put on trigger set 1 00_B TMADC1 01_B TMADC3 10_B TMADC5 11_B TMADC7
TRIG2SEL	6:5	rw	**Trigger set 2 select** These bits select which TMADC instance trigger signals are put on trigger set 2 00_B TMADC0 01_B TMADC2 10_B TMADC4 11_B TMADC6
TG_P	7	w	**TGS, TGB write protection** TGS,TGB TRIG1SEL and TRIG2SEL are only written when TG_P is 1, otherwise unchanged. Read as 0.

(table continues...)

(continued)

Field	Bits	Type	Description
SUSM	9:8	rw	**OCDS suspend control mode - SUS** These bits select the suspend mode for the module 00_B Will not suspend 01_B Hard suspend Clocks will be disabled immediately 10_B Reserved, not to be used Reserved, will not suspend 11_B Soft suspend mode All the channels in hold state for the TMADC will be converted and then module will go into suspend
SUS_P	15	w	**SUS write protection** SUS and SUSM are only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUS	22:16	rw	**OCDS suspend control** Suspends the corresponding TMADC. 0 - Module not suspended, 1 - Module Suspended. Each bit controls a TMADC, with LSB for TMADC0 and MSB for the maximum number of TMADC in device.
SUSSTA	30:24	rh	**Suspend state** Suspend State of TMADC. 0 - Module not suspended. 1 - Module Suspended. Each bit gives status of a TMADC, with LSB for TMADC0 and MSB for the maximum number of TMADC in device.
0	14:10, 23, 31	r	**Reserved** Read as 0; should be written with 0.

Table 2400 Access mode restrictions of OCSTM sorted by descending priority

Mode name	Access mode		Description
write 1 to .**TG_P**	rw	TGB, TGS, TRIG1SEL, TRIG2SEL	Set TG_P during write access
write 1 to .**SUS_P**	rw	SUS, SUSM	Set SUS_P during write access
(default)	r	SUS, SUSM, TGB, TGS, TRIG1SEL, TRIG2SEL	

45.8.41 TMADCx module configuration register

TMADCx_MODCFG (x=0-6) Offset address: $20000_H+x*800_H$

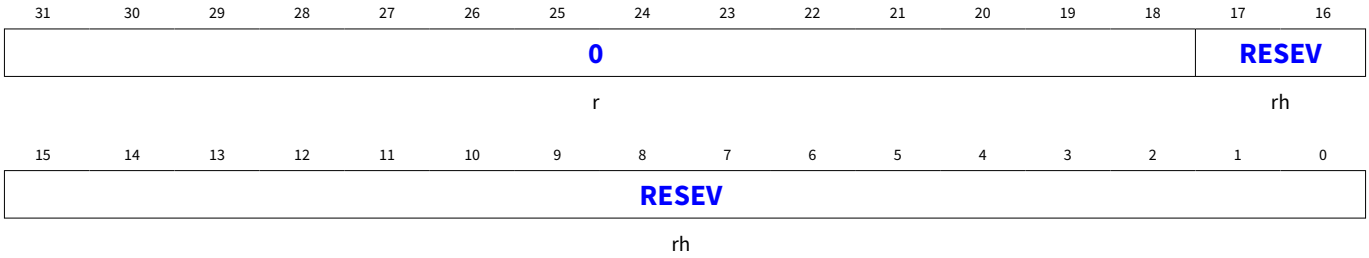
TMADCx_RESF (x=0-6) Offset address: $20194_H+x*800_H$

TMADCx result event flag register Kernel Reset value: $0000\ 0000_H$

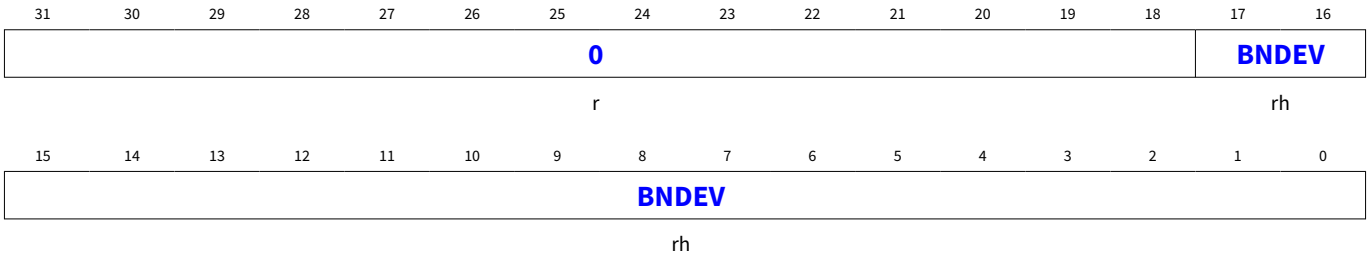


Field	Bits	Type	Description
RESEV	17:0	rh	**Result event** Each bit in this bitfield corresponds to a result event for the result register. 0_B No result event 1_B New data available in the result register
0	31:18	r	**Reserved** Read as 0; should be written with 0

45.8.58 TMADCx boundary event flag register

TMADCx_BNDF (x=0-6) Offset address: $20198_H+x*800_H$

TMADCx boundary event flag register Kernel Reset value: $0000\ 0000_H$

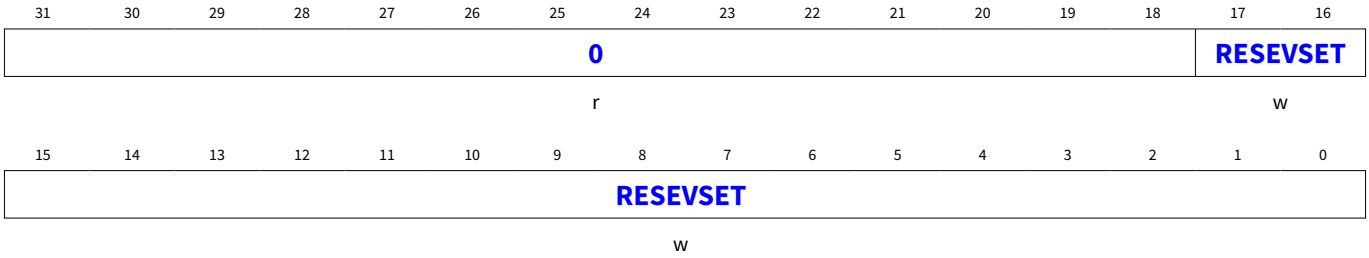


Field	Bits	Type	Description
BNDEV	17:0	rh	**Boundary event** Each bit in this bitfield corresponds to a boundary event for the respective result register. 0_B Boundary check failure 1_B Boundary check successful
0	31:18	r	**Reserved** Read as 0; should be written with 0

45.8.59 TMADCx result event flag set register

TMADCx_RESFSET (x=0-6) Offset address: $201A0_H+x*800_H$

TMADCx result event flag set register Kernel Reset value: $0000\ 0000_H$

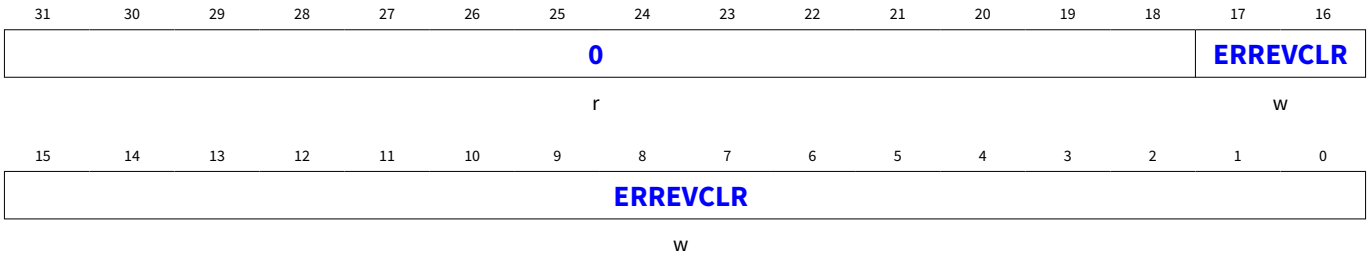


Field	Bits	Type	Description
RESEVSET	17:0	w	**Result event set** By writing to the respective result event flag set bit, the corresonding event flag in the RESF register is set. 0_B No action 1_B Set the corresponding RESEVx flag in RESF register
0	31:18	r	**Reserved** Read as 0; should be written with 0

45.8.60 TMADCx error event flag clear register

TMADCx_ERRFCLR (x=0-6) Offset address: $201A4_H+x*800_H$

TMADCx error event flag clear register Kernel Reset value: $0000\ 0000_H$

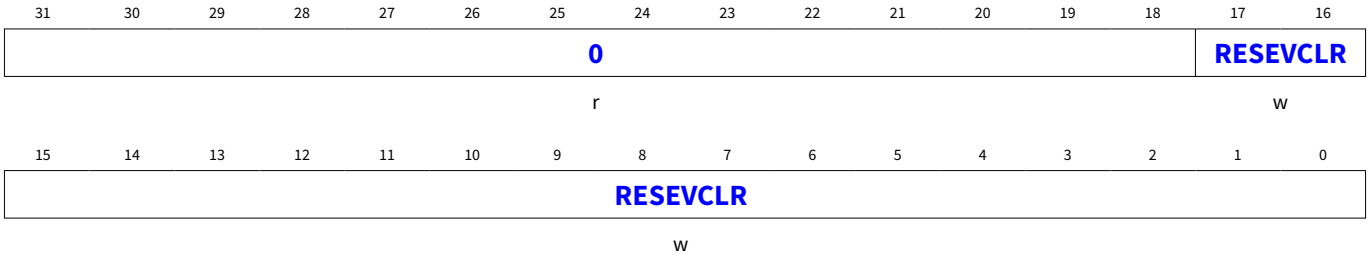


Field	Bits	Type	Description
ERREVCLR	17:0	w	**Error event clear** Each bit in this bitfield, if set, clears the error event and the error status bits of the respective channel. 0_B No action 1_B Clear the corresponding error event flag in TMx_ERRF
0	31:18	r	**Reserved** Read as 0; should be written with 0

45.8.61 TMADCx result event flag clear register

TMADCx_RESFCLR (x=0-6) Offset address: $201A8_H+x*800_H$

TMADCx result event flag clear register Kernel Reset value: $0000\ 0000_H$

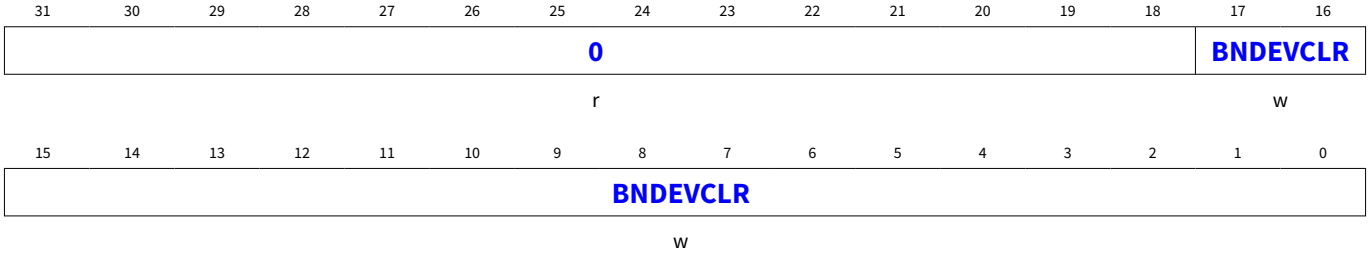


Field	Bits	Type	Description
RESEVCLR	17:0	w	**Result event clear** Each bit in this bitfield, if set, clears the result event for the respective result register. 0_B No action 1_B Clear the corresponding RESEVx flag in the RESF register
0	31:18	r	**Reserved** Read as 0; should be written with 0

45.8.62 TMADCx boundary event flag clear register

TMADCx_BNDFCLR (x=0-6) Offset address: $201AC_H+x*800_H$

TMADCx boundary event flag clear register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
BNDEVCLR	17:0	w	**Boundary event clear** Each bit in this bitfield, if set, clears the boundary event for the respective result register. 0_B No action 1_B Clear the corresponding boundary event flag in TMx_BNDF
0	31:18	r	**Reserved** Read as 0; should be written with 0

45.8.63 TMADCx service request configuration register i

TMADCx_SRi_CFG (i=0-6;x=0-6) Offset address: $201B0_H+x*800_H+i*4$

TMADCx service request configuration register i Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
EVEN	17:0	rw	**Event enable** Each bit in this bitfield, if set enables the event on the channel or result register depending on the value of the bit EVSEL for service request generation. If EVSEL=01_B,each bit here corresponds to the respective channel. If EVSEL=10_B or EVSEL=11_B, then each bit in the bitfield corresponds to the result register. 0_B Event disabled 1_B Event enabled
EVSEL	19:18	rw	**Event selection** This bit defines the selection of the events set in the bitfield EVEN. 00_B Disable service request 01_B Error event 10_B Result event 11_B Boundary event

(table continues...)

(continued)

Field	Bits	Type	Description
EVOP	21:20	rw	**Event operation** This bit if set, defines that condition of generation for service request. 00_B OR logic operation without wait-for-clear This setting corresponds to the generation of service request on the occurence of each event configured in the bitfield EVEN. 01_B OR logic operation with wait-for-clear A service request is generated only on the first available event and on the first available event after the corresponding flag register bits for the event(s) specified in EVEN bitfield are cleared by SW. 10_B AND logic operation This setting corresponds to the generation of service request only on the occurence of all events configured in the bitfield EVEN. 11_B Reserved for future use (treated same as AND logical operation if configured)
0	31:22	r	**Reserved** Read as 0; should be written with 0

45.8.64 TMADCx monitor channel v result register

TMADCx_MRESv (v=0-1;x=0-6) Offset address: $201CC_H+x*800_H+v*4$

TMADCx monitor channel v result register Kernel Reset value: $0000\ 0000_H$

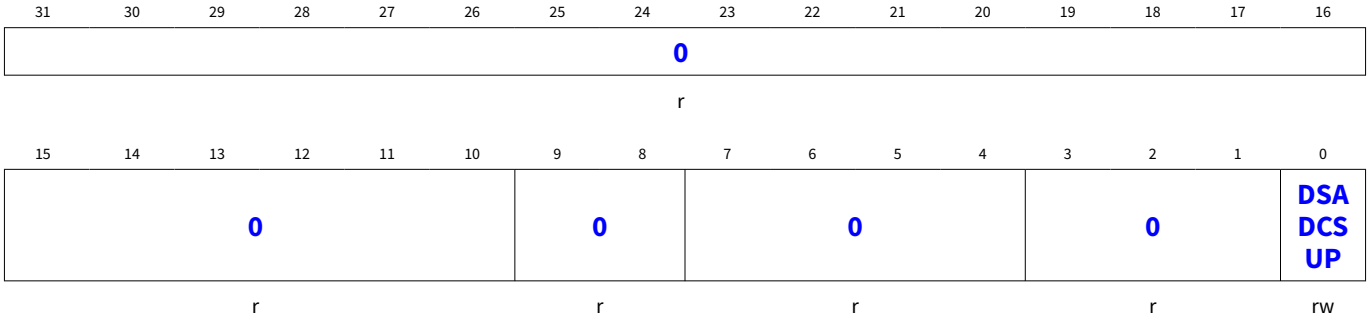
45.8.81 DSADC global configuration register

Global configuration register control the selection of the supervision voltage to be converted in TMADC. User shall make sure that selection of the signal is done prior to triggering the conversion (sampling time shall be taken into consideration).

DSADC_GLOBCFG Offset address: $5F800_H$

DSADC global configuration register Kernel Reset value: $0000\ 0000_H$



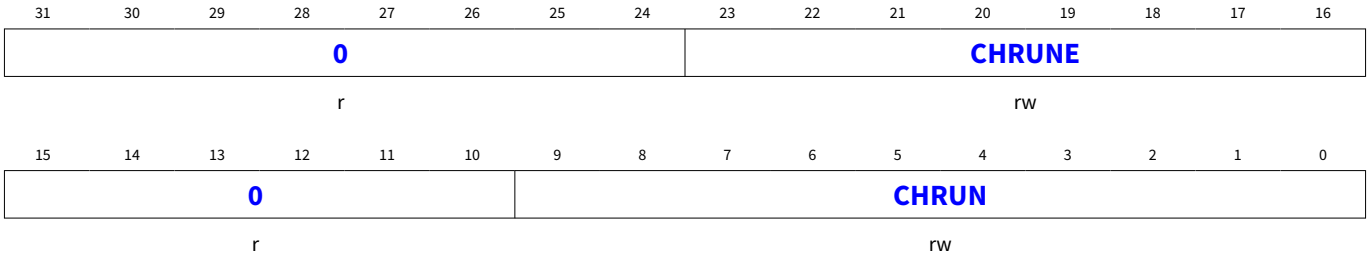
Field	Bits	Type	Description
DSADCSUP	0	rw	**DSADC supply level** With this bit-filed internal operating point of DSADC is defined by hardware based on VDDM voltage range 0_B 3.7 V <= VDDM < = 5.5 V 1_B VDDM < 3.7 V
0	3:1, 7:4, 9:8, 31:10	r	**Reserved** Read as 0; should be written with 0

45.8.82 DSADC global run control register for filter chain

Register control the run control of demodulator chain of DSADC and EXMOD channels

DSADC_GLOBRCF Offset address: $5F804_H$

DSADC global run control register for filter chain Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CHRUN	9:0	rw	**Channel run for DSADC channels** Each bit controls a DSADC, with LSB for DSADC0 and MSB for the maximum number of DSADC in the device.
CHRUNE	23:16	rw	**Channel run for EXMOD channels** Each bit controls an EXMOD, with LSB for EXMOD0 and MSB for the maximum number of EXMOD in the device.
0	15:10, 31:24	r	**Reserved** Read as 0; should be written with 0

45.8.83 DSADC global run control register for analog modulator

Register control the run control of analog modulator for DSADC channels

DSADC_GLOBRCM Offset address: $5F808_H$

DSADC global run control register for analog modulator Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r						rwh									

Field	Bits	Type	Description
REMEVIN	9:0	rwh	**Result event for main result register RESM of DSADC channels** Each bit corresponds to a DSADC, with LSB for DSADC0 and MSB for the maximum number of DSADC in the device.
REMEVEX	23:16	rwh	**Result event for main result register RESM of EXMOD channels** Each bit corresponds to an EXMOD, with LSB for EXMOD0 and MSB for the maximum number of EXMOD in the device.

(table continues...)

(continued)

Field	Bits	Type	Description
0	15:10, 31:24	r	**Reserved** Read as 0; should be written with 0

45.8.87 DSADC event flag register on auxiliary result register

The register capture the result events on auxiliary result register for the DSADC and EXMOD channels.

DSADC_RESAF Offset address: $5F818_H$

DSADC event flag register on auxiliary result register Kernel Reset value: $0000\ 0000_H$

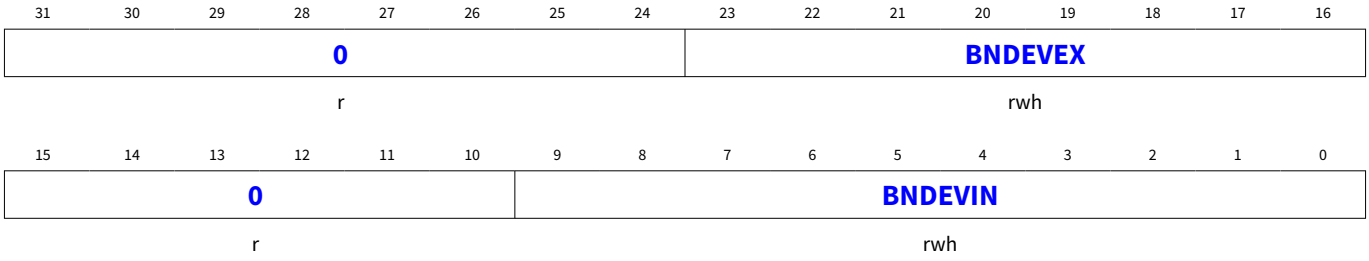
Field	Bits	Type	Description
REAEVIN	9:0	rwh	**Result event for auxiliary result register RESA of DSADC channels** Each bit corresponds to a DSADC, with LSB for DSADC0 and MSB for the maximum number of DSADC in the device.
REAEVEX	23:16	rwh	**Result event for auxiliary result register RESA of EXMOD channels** Each bit corresponds to an EXMOD, with LSB for EXMOD0 and MSB for the maximum number of EXMOD in the device.
0	15:10, 31:24	r	**Reserved** Read as 0; should be written with 0

45.8.88 DSADC boundary flag event register

Register capture the Boundary flag events for DSADC and EXMOD channels

DSADC_BOUNDF Offset address: $5F81C_H$

DSADC boundary flag event register Kernel Reset value: $0000\ 0000_H$



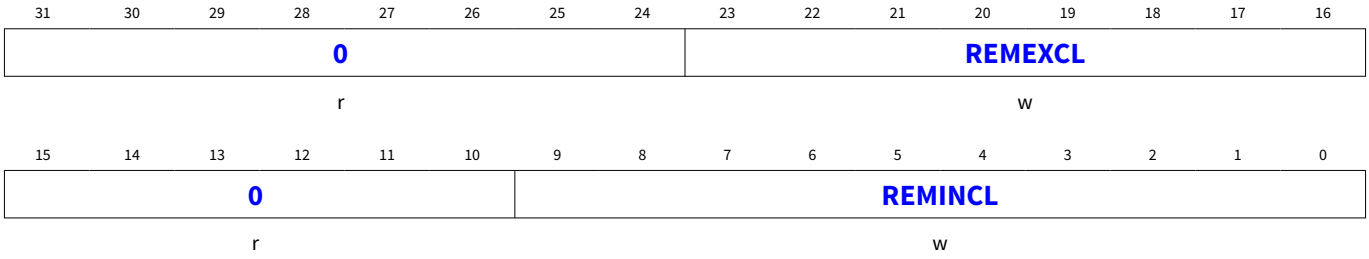
Field	Bits	Type	Description
BNDEVIN	9:0	rwh	**Boundary event for DSADC channels** Each bit corresponds to a DSADC, with LSB for DSADC0 and MSB for the maximum number of DSADC in the device.
BNDEVEX	23:16	rwh	**Boundary event for EXMOD channels** Each bit corresponds to an EXMOD, with LSB for EXMOD0 and MSB for the maximum number of EXMOD in the device.
0	15:10, 31:24	r	**Reserved** Read as 0; should be written with 0

45.8.89 DSADC result event (main) flag clear register

Clear the result event flags bits in RESMF register

DSADC_RESMFCL Offset address: $5F820_H$

DSADC result event [main) flag clear register Kernel Reset value: $0000\ 0000_H$



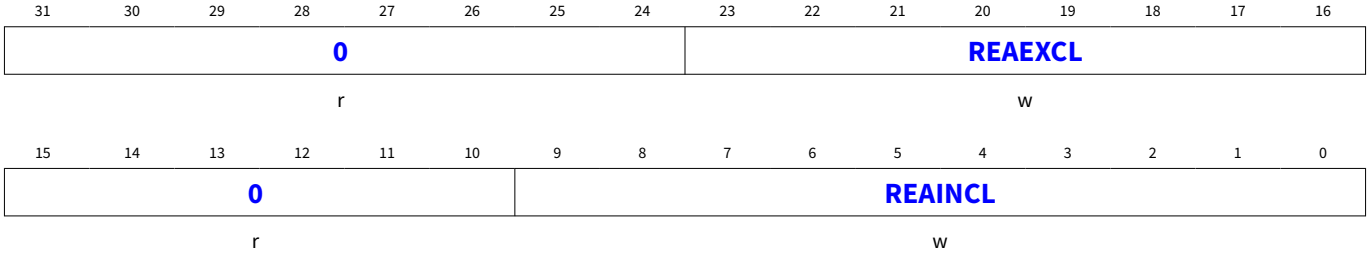
Field	Bits	Type	Description
REMINCL	9:0	w	**Result event clear for DSADC channels** Each bit corresponds to a DSADC, with LSB for DSADC0 and MSB for the maximum number of DSADC in the device.
REMEXCL	23:16	w	**Result event clear for EXMOD channels** Each bit corresponds to an EXMOD, with LSB for EXMOD0 and MSB for the maximum number of EXMOD in the device.
0	15:10, 31:24	r	**Reserved** Read as 0; should be written with 0

45.8.90 DSADC result event (auxiliary) flag clear register

Clear the result event flags bits in RESAF register

DSADC_RESAFCL Offset address: $5F824_H$

DSADC result event [auxiliary) flag clear register Kernel Reset value: $0000\ 0000_H$



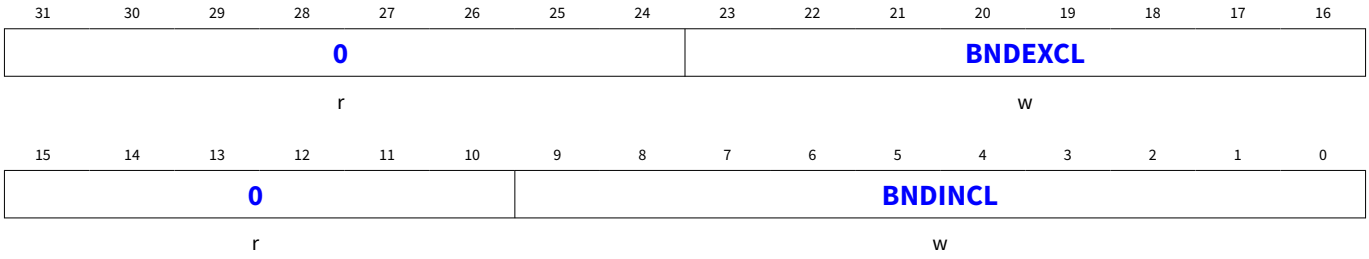
Field	Bits	Type	Description
REAINCL	9:0	w	**Auxiliary result event clear for DSADC channels** Each bit corresponds to a DSADC, with LSB for DSADC0 and MSB for the maximum number of DSADC in the device.
REAEXCL	23:16	w	**Auxiliary result event clear for EXMOD channels** Each bit corresponds to an EXMOD, with LSB for EXMOD0 and MSB for the maximum number of EXMOD in the device.
0	15:10, 31:24	r	**Reserved** Read as 0; should be written with 0

45.8.91 DSADC boundary event flag clear register

Clear the boundary event flags bits in BOUNDF register

DSADC_BOUNDFCL Offset address: $5F828_H$

DSADC boundary event flag clear register Kernel Reset value: $0000\ 0000_H$



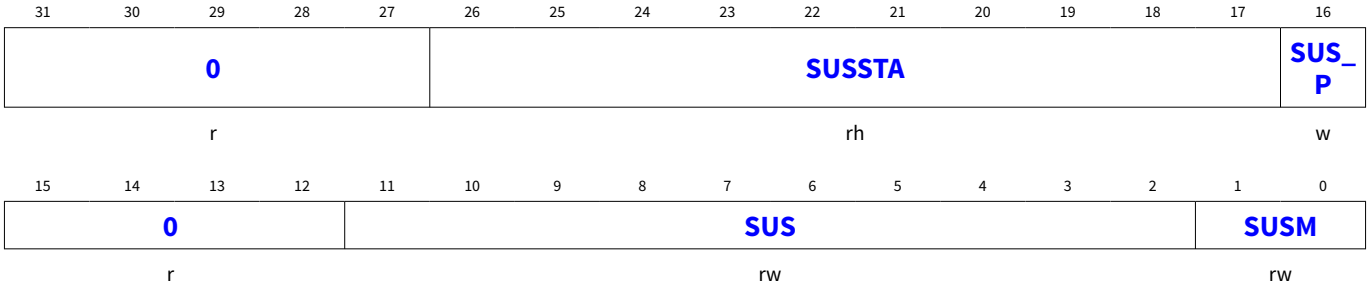
Field	Bits	Type	Description
BNDINCL	9:0	w	**Boundary event clear for DSADC channels** Each bit corresponds to a DSADC, with LSB for DSADC0 and MSB for the maximum number of DSADC in the device.
BNDEXCL	23:16	w	**Boundary event clear for EXMOD channels** Each bit corresponds to an EXMOD, with LSB for EXMOD0 and MSB for the maximum number of EXMOD in the device.
0	15:10, 31:24	r	**Reserved** Read as 0; should be written with 0

45.8.92 OCDS control and status register for DSADC

This OCDS control and status register controls the debug and trace behavior by selecting suspend modes. When OCDS is disabled the suspend control is ineffective. This register only controls all instances of DSADC. No trigger sets are supported for DSADC

DSADC_OCSDSADC Offset address: $5F82C_H$

OCDS control and status register for DSADC Debug Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SUSM	1:0	rw	**OCDS suspend control mode - SUS** Selects the suspend mode for the module 00_B Will not suspend 01_B Hard suspend Clocks will be disabled immediately 10_B Soft suspend mode Clock will be disabled after generating the output from the auxiliary filter chain. 11_B Soft suspend mode Clock will be disabled after generating the output from the main filter chain.
SUS	11:2	rw	**OCDS suspend control** Suspends the corresponding DSADC. 0 - Module not suspended, 1 - Module suspended. Each bit controls a DSADC, with LSB for DSADC0 and MSB for the maximum number of DSADC in the device.
SUS_P	16	w	**SUS write protection** SUS and SUSM are only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	26:17	rh	**Suspend state** Suspend state of DSADC. 0 - Module not suspended. 1 - Module suspended. Each bit gives the status of a DSADC, with LSB for DSADC0 and MSB for the maximum number of DSADC in the device.
0	15:12, 31:27	r	**Reserved** Read as 0; should be written with 0.

Table 2403 Access mode restrictions of DSADC_OCSDSADC sorted by descending priority

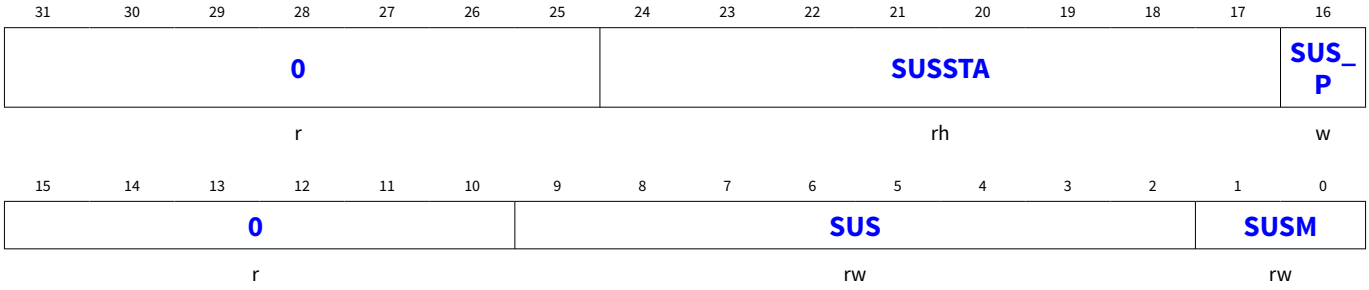
Mode name	Access mode		Description
write 1 to .**SUS_P**	rw	SUS, SUSM	Set SUS_P during write access
(default)	r	SUS, SUSM	

45.8.93 OCDS control and status register for EXMOD

This OCDS control and status register controls the debug and trace behavior by selecting suspend modes. When OCDS is disabled the suspend control is ineffective. This register only controls all instances of EXMOD. No trigger sets are supported for EXMOD

DSADC_OCSEXMOD Offset address: $5F830_H$

OCDS control and status register for EXMOD Debug Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SUSM	1:0	rw	**OCDS suspend control mode for EXMOD - SUS** Selects the suspend mode for the Module 00_B Will not suspend 01_B Hard suspend Clocks will be disabled immediately 10_B Soft suspend mode Clock will be disabled after generating the output from the Auxiliary filter chain. 11_B Soft suspend mode Clock will be disabled after generating the output from the main filter chain.
SUS	9:2	rw	**OCDS suspend control for EXMOD** Suspends the corresponding EXMOD. 0 - Module not suspended, 1 - Module suspended. Each bit controls a EXMOD, with LSB for EXMOD0 and MSB for the maximum number of EXMOD in the device.
SUS_P	16	w	**SUS write protection** SUS and SUSM are only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	24:17	rh	**Suspend state for EXMOD** Suspend state of EXMOD. 0 - Module not suspended. 1 - Module suspended. Each bit gives the status of an EXMOD, with LSB for EXMOD0 and MSB for the maximum number of EXMOD in the device.
0	15:10, 31:25	r	**Reserved** Read as 0; should be written with 0.

Table 2404 Access mode restrictions of DSADC_OCSEXMOD sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SUS_P**	rw	SUS, SUSM	Set SUS_P during write access
(default)	r	SUS, SUSM	

45.8.94 DSADCx channel configuration register

The DSADC channel configuration register selects the mode of operation of DSADC channel

- Change of modulator clock or time stamp clock division is not allowed during the run-time.
- Change in offset compensation filter during the run-time will result in invalid output and is not recommended.

DSADC_INx_CHCFG (x=0-9) Offset address: $60000_H+x*400_H$

DSADCx channel configuration register Kernel Reset value: $0000\ 0A00_H$

rw		rw		rw		rw	r		rw	rw		rw		rw	

Field	Bits	Type	Description
INCFGP	1:0	rw	**Configuration of positive input line** Defines the internal connection of the positive input. 00_B Input pin 01_B Reference voltage V_{AREF} 10_B VDDM/2 11_B Reference ground V_{AGND}
INCFGN	3:2	rw	**Configuration of negative input line** Defines the internal connection of the negative input. 00_B Input pin 01_B Reference voltage V_{AREF} 10_B VDDM/2 11_B Reference ground V_{AGND}
INSEL	5:4	rw	**Input pin selection** Defines the initial or permanent setting for the input multiplexer (bitfield INMUX) depending on the selected operating mode (bitfield IMXTRM). 00_B Input pin position A 01_B Input pin position B 10_B Input pin position C 11_B Input pin position D
INMAC	6	rw	**Input multiplexer action control** Defines the mechanism by which the input multiplexer is controlled. 0_B Preset mode (load INMUX upon a trigger) 1_B Single-step mode (decrement INMUX upon a trigger, wrap around to <INSEL>)

(table continues...)

(continued)

Field	Bits	Type	Description
DITHEN	9	rw	**Dithering enable** 0_B Dithering disabled 1_B Dithering enabled
DITRIM	11:10	rw	**Dithering function trim value** Controls the dithering levels for each modulator separately. For 3.3V operation, dithering levels (mV) are lower by a factor 1/3 00_B Dithering level 0 (20 mV) 01_B Dithering level 1 (40 mV) 10_B Dithering level 2 (80 mV), also default level 11_B Dithering level 3 (160 mV)
DIVM	13:12	rw	**Modulator clock frequency** Defines the frequency of the modulator clock (on-chip), derived from the peripheral clock: $f_{MOD} = f_{ADC} / 2^{(DIVM+2)}$ 00_B $f_{MOD} = f_{ADC} / 4 = 40$ MHz ($f_{ADC} = 160$ MHz) 01_B $f_{MOD} = f_{ADC} / 8 = 20$ MHz ($f_{ADC} = 160$ MHz) 10_B $f_{MOD} = f_{ADC} / 16 = 10$ MHz ($f_{ADC} = 160$ MHz) 11_B Reserved
DRM	15:14	rw	**Data read mode** Selects the data that is returned when register RESMx is read. 00_B Single: issue one 16-bit value per read access (sign on high bits) 01_B Single: issue one 16-bit value per read access (timestamp or zero on high bits) 10_B Double: issue two 16-bit values per read access 11_B Reserved
TSM	16	rw	**Time-stamp mode** 0_B No timestamp, only issue result values 1_B Insert timestamp upon the timestamp trigger
TSCLK	18:17	rw	**Timestamp counter clock selection** 00_B $f_{TSTMP} = f_{MOD}$ 01_B $f_{TSTMP} = f_{MOD} / 2$ 10_B $f_{TSTMP} = f_{MOD} / 4$ 11_B $f_{TSTMP} = f_{MOD} / 8$
TSCRUN	19	rw	**Timestamp counter run control** 0_B Timestamp counter is off 1_B Timestamp counter is counting at the rate selected by bitfield TSCLK
SRLVL	21:20	rw	**Service request FIFO Level** 00_B Generate service request when FIFO fill level reaches 1 value 01_B Generate service request when FIFO fill level reaches 2 values 10_B Generate service request when FIFO fill level reaches 3 values 11_B Generate service request when FIFO fill level reaches 4 values

(table continues...)

(continued)

Field	Bits	Type	Description
FIFL	22	w	**FIFO flush** 0_B No action 1_B Remove all entries from result FIFO
RDM	23	rw	**Result display mode** 0_B Signed mode Result values range from -2^{15} to $+2^{15}-1$ 1_B Unsigned mode Result values range from 0 to $+2^{16}-1$ (shifted by 2^{15})
AMXCOPY	24	rw	**Analog MUX setting copy enable** Allows copying of bitfield AMX into bitfield TIMESTAMP (in register TSTMPx). 0_B Do not copy, timestamp uses all 16 bits 1_B Copy AMX to bits TIMESTAMP[15:14], timestamp uses lower 14 bits
OCEN	27:25	rw	**Offset compensation filter enable** 000_B Offset compensation filter disabled, register OFFCOMP not changed 001_B Enable offset compensation filter, set cutoff frequency to rate 1 … 111_B Enable offset compensation filter, set cutoff frequency to rate 7
OFFPROT	28	rw	**Offset protection** Controls the influence of the calibration sequence on register OFFCOMP. 0_B Unprotected, calibration sequence updates bitfield OFFSET 1_B Protected, bitfield OFFSET is locked and not modified by calibration
CALIB	29	w	**Calibration trigger** 0_B No action 1_B Start the calibration algorithm now
AUTOCAL	30	rw	**Automatic calibration control** 0_B Calibration algorithm started by software (set bit CALIB) 1_B Automatically start the calibration algorithm When the selected service request gate closes
0	8:7, 31	r	**Reserved** Read as 0; should be written with 0

45.8.95 DSADCx channel status register

The DSADC channel status register gives the following information:

- Input MUX setting value
- CIC decimation count value
- CIC (auxiliary) decimation count value
- Trigger error flag status
- Calibration status

DSADC_INx_CHST (x=0-9) Offset address: $60004_H+x*400_H$

DSADCx channel status register Kernel Reset value: $0000\ 0000_H$

CFMDCNT										INMUX		0	FILL		
rh										rh		r	rh		

Field	Bits	Type	Description
FILL	2:0	rh	**FIFO fill level** Not listed combinations are reserved. 000_B Result FIFO is empty 001_B Result FIFO contains 1 valid value 010_B Result FIFO contains 2 valid values 011_B Result FIFO contains 3 valid values 100_B Result FIFO contains 4 valid values
INMUX	5:4	rh	**Input multiplexer setting** Indicates the current setting of the input multiplexer connecting the input pins to the buffer inputs. The product-specific appendix details the available channels and their inputs. 00_B Input pin position A 01_B Input pin position B 10_B Input pin position C 11_B Input pin position D
CFMDCNT	15:6	rh	**CIC filter decimation counter** The decimation counter counts the filter cycles until an output is generated, i.e. the oversampling rate. CFMDCNT counts down from the respective start value.
CFADCNT	22:16	rh	**CIC filter (auxiliary) decimation counter** The decimation counter counts the filter cycles until an output is generated, i.e. the oversampling rate.

(table continues...)

(continued)

Field	Bits	Type	Description
RDERR	23	rh	**Read error flag** 0_B No problem encountered 1_B A read access occurred while the FIFO was empty A read error is also indicated when a read access occurs during the FIFO's synchronization stall phase (4 SPB clock cycles after a read access). Clear this sticky flag by writing 1 to bit RDEC.
WRERR	24	rh	**Write error flag** 0_B No problem encountered 1_B A write access occurred while the FIFO was full Clear this sticky flag by writing 1 to bit WREC.
INTTRER	25	rh	**Integrator trigger error flag** This bit tells the status of the integrator trigger error flag. If the integrator trigger could not be executed the bit will be set to 1
TSTRER	26	rh	**Timestamp trigger error flag** This bit tells the status of the timestamp trigger error flag. If the timestamp trigger could not be executed the bit will be set to 1
IMXTRER	27	rh	**Input MUX trigger error flag** This bit tells the status of the analog input mux trigger error flag. If the input mux trigger could not be executed the bit will be set to 1
SRTRER	28	rh	**Service request trigger error flag** This bit tells the status of the service request trigger error flag. If the service request trigger could not be executed the bit will be set to 1
BNDTRER	29	rh	**Boundary update trigger error flag** This bit tells the status of the boundary update trigger error flag. If the boundary update trigger could not be executed the bit will be set to 1
CAL	31:30	rh	**Calibration status flag** ***Note**:* *Bitfield CAL is set to 01_B in the next clock cycle after setting bit CALIB or after detecting the selected trigger (if auto-calibration is activated).* 00_B Uncalibrated, initial state after reset 01_B The calibration algorithm is currently running 10_B Calibrated, normal operation is possible 11_B Calibration terminated incorrectly
0	3	r	**Reserved** Read as 0; should be written with 0

45.8.96 DSADCx common mode voltage register

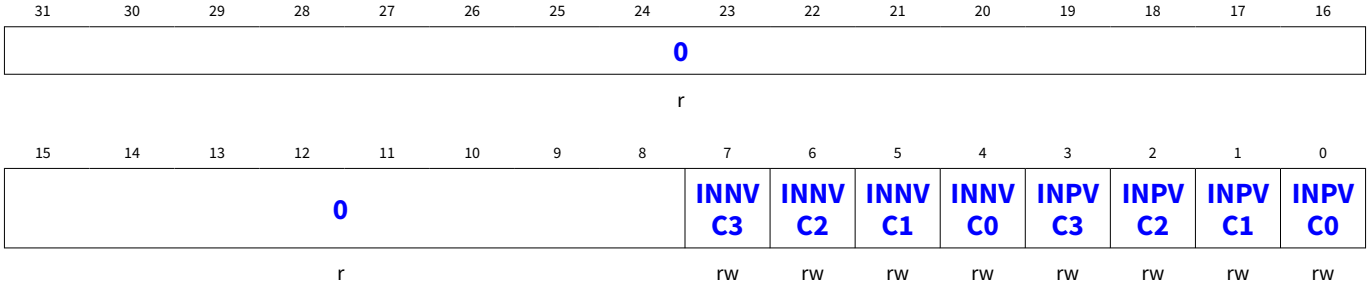
The common mode voltage registers enable the voltage generators and select which input pins are connected to the common mode hold voltage.

Only those bits are valid that correspond to an existing input pin (see datasheet for pinning).

Changes to this register during run time may result in invalid outputs. User shall avoid this.

DSADC_INx_VCM (x=0-9) Offset address: $60008_H+x*400_H$

DSADCx common mode voltage register Kernel Reset value: $0000\ 0000_H$



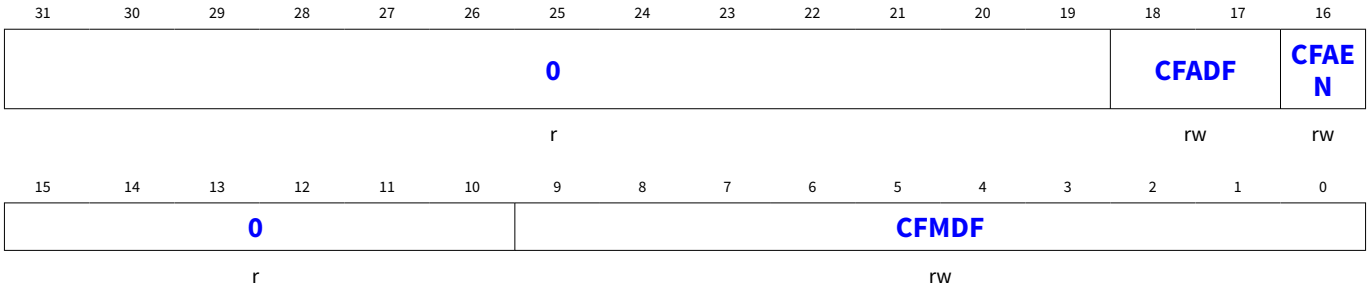
Field	Bits	Type	Description
INPVCy (y=0-3)	y	rw	**Voltage control of positive inputs y of CHx** Defines the connection of the respective positive input y to the common mode voltage. y indicates the input of the analog multiplexers (if available). 0_B No connection to common mode voltage 1_B This pin is connected to the common mode voltage
INNVCy (y=0-3)	y+4	rw	**Voltage control of negative inputs y of CHx** Defines the connection of the respective negative input y to the common mode voltage. y indicates the input of the analog multiplexers (if available). 0_B No connection to common mode voltage 1_B This pin is connected to the common mode voltage
0	31:8	r	**Reserved** Read as 0; should be written with 0

45.8.97 DSADCx CIC configuration register

Change of the decimation factor for CIC or AUX CIC during run time shall be avoided.

DSADC_INx_CICCFG (x=0-9) Offset address: $6000C_H+x*400_H$

DSADCx CIC configuration register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CFMDF	9:0	rw	**CIC filter decimation factor** Defines the oversampling rate of the CIC filter: OSR = CFMDF + 1. Valid values are 003_H to $3FF_H$ (OSR = 4 to 1024).

(table continues...)

(continued)

Field	Bits	Type	Description
CFAEN	16	rw	**CIC filter (auxiliary) enable** 0_B Off: auxiliary filter is not active 1_B Auxiliary filter is active and generates results and alarm events
CFADF	18:17	rw	**CIC filter (auxiliary) decimation factor** 00_B OSR = 16 01_B OSR = 32 10_B OSR = 64 11_B OSR = 128
0	15:10, 31:19	r	**Reserved** Read as 0; should be written with 0

45.8.98 DSADCx integrator configuration register

Configures the hardware integrator and the mode of operation of the integrator.
Integrator configuration change shall be avoided when INTEN = 1, if changed, may result in invalid outputs.

DSADC_INx_INTCFG (x=0-9) Offset address: $60010_H+x*400_H$

DSADCx integrator configuration register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
ISC	2:0	rw	**Integrator shift control** Controls the data shifter after the integrator that selects the portion of the integrator data for the result register. 111_B is reserved. ***Note**: ISC selects the respective bits in an internal register. The lowest selected bit is used for rounding and is then removed.* 000_B Select bits 4 … 20 (integration of 2 values) 001_B Select bits 5 … 21 (integration of 3 to 4 values) … 110_B Select bits 10 … 26 (integration of 65 to 128 values)

(table continues...)

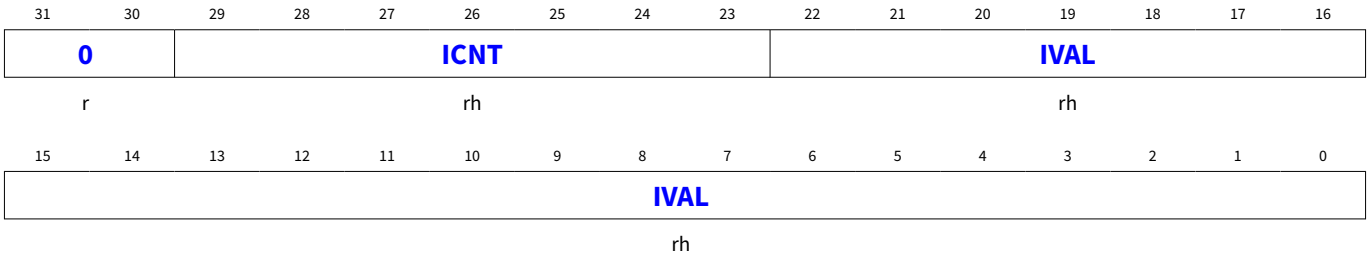
(continued)

Field	Bits	Type	Description
IWS	5:4	rw	**Integration window size** 00_B Internal control: stop integrator after REPVAL+1 integration cycles 01_B External control: stop integrator upon the inverse trigger event 10_B Software control Stop integrator when INTEN = 0 or INTTRM = 00 (when changing INTTRDLY during runtime the integration window restarts with the next selected HW trigger edge) 11_B Reserved
FRC	7:6	rw	**Filter chain restart control** 00_B Restart the main filter chain when an integration window starts, auxiliary filter chain is not restarted 01_B Restart the main and auxilary filter chain when an integration window starts 10_B No influence on main and auxiliary filter chain when an integration window starts, except for the integrator itself 11_B No influence on main filter chain when an integration window starts, except for the integrator itself and auxiliary filter chain
REPVAL	11:8	rw	**Number of integration cycles** Defines the number of integration cycles to be counted by REPCNT if activated (IWS = 0). The number of cycles is REPVAL+1.
RUM	15	rw	**Result update mode** Configures the result update behaviour 0_B Results generated independent of integration window 1_B Results generated only during integration window
NVALDIS	22:16	rw	**Number of values discarded** Start the integration cycle after NVALDIS values
NVALINT	30:24	rw	**Number of values to be accumulated** Stop the integration cycle after NVALINT+1 values ***Note**: Use intervals of 2 minimum, so no data is lost due to the data shifter.*
INTEN	31	rw	**Integrator Enable** Controls if the integrator is enabled or disabled
0	3, 14:12, 23	r	**Reserved** Read as 0; should be written with 0

45.8.99 DSADCx intermediate integration value register

DSADC_INx_INTIVAL (x=0-9) Offset address: $60014_H+x*400_H$

DSADCx intermediate integration value register Kernel Reset value: $0000\ 0000_H$

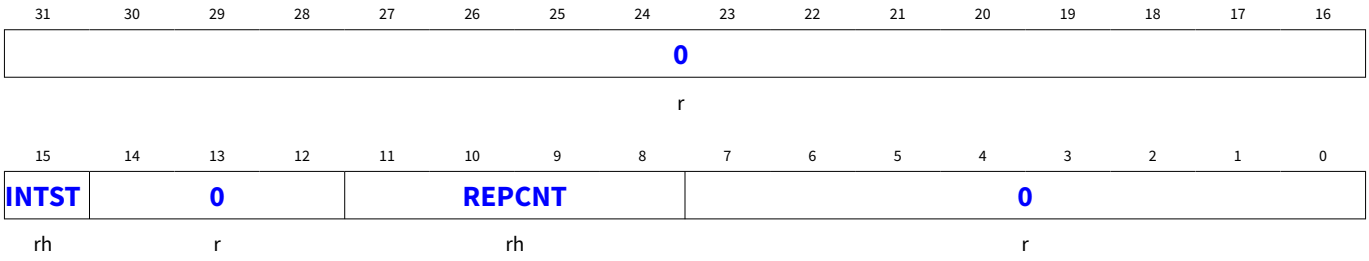


Field	Bits	Type	Description
IVAL	22:0	rh	**Integrator intermediate value** These bits output the intermediate accumulated value.
ICNT	29:23	rh	**Integrator intermediate count** The bits output the intermediate number of accumulated values or the number of discarded samples during integrator discard phase.
0	31:30	r	**Reserved** Read as 0; should be written with 0

45.8.100 DSADCx integrator status register

DSADC_INx_INTST (x=0-9) Offset address: $60018_H+x*400_H$

DSADCx integrator status register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
REPCNT	11:8	rh	**Integration cycle counter** Counts the number of integration cycles if activated (IWS = 0). This number is selected via bitfield REPVAL.
INTST	15	rh	**Integration enable status- INTST** Indicates the activity of the integrator. 0_B Integration stopped INTST is cleared at the end of the integration window, i.e. after REPVAL cycles or upon the inverse trigger event transition of the external trigger signal. 1_B Integration enabled INTST is set when the channel is started while permanent integration is selected (ITRMODE = 11_B) or upon the defined trigger event.

(table continues...)

(continued)

Field	Bits	Type	Description
0	7:0, 14:12, 31:16	r	**Reserved** Read as 0; should be written with 0

45.8.101 DSADCx gain calibration register

DSADC_INx_GAINCAL (x=0-9) Offset address: $6001C_H+x*400_H$

DSADCx gain calibration register Kernel Reset value: $61A8\ 1000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	rw														

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CALFACTOR														
r	rwh														

Field	Bits	Type	Description
CALFACTOR	12:0	rwh	**Multiplication factor for gain calibration** The resulting factor is (<CALFACTOR> / 4 096) ***Note**: The initial value of 4 096 (1000_H) corresponds to a factor of 1.000.*
CALTARGET	30:16	rw	**Target value for calibrated fullscale** Defines the target value for the calibration algorithm. ***Note**: The initial value of 25 000 ($61A8_H$) corresponds to 0.2 mV per LSB.*
0	15:13, 31	r	**Reserved** Read as 0; should be written with 0

45.8.102 DSADCx gain control register

DSADC_INx_GAINCTR (x=0-9) Offset address: $60020_H+x*400_H$

DSADCx gain control register Kernel Reset value: $0000\ 1000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r							rw	r			rw				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CALGFAC														
r	rw														

Field	Bits	Type	Description
CALGFAC	12:0	rw	**Multiplication factor for gain correction during calibration** The resulting factor is (<CALGFAC> / 4 096)
CALCICS	20:16	rw	**Position of the CIC filter output shifter during calibration** Selects the valid outputs bits from the CIC filter, depending on the chosen decimation factor (see data shifter formula), $1D_H$ … $1F_H$ are reserved. 00_H Use bits 0 ... 16 … $1C_H$ Use bits 28 ... 44
CICDEC	24	rw	**Decimation rate of the CIC filter during calibration** 0_B CIC decimation of 128 during calibration 1_B CIC decimation of 256 during calibration
0	15:13, 23:21, 31:25	r	**Reserved** Read as 0; should be written with 0

45.8.103 DSADCx gain correction register

DSADC_INx_GAINCORR (x=0-9) Offset address: $60024_H+x*400_H$

DSADCx gain correction register Kernel Reset value: $0000\ 1000_H$

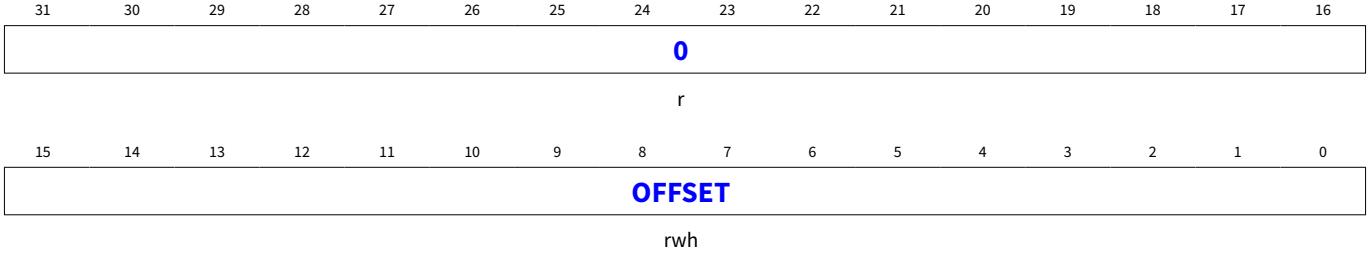
0			GAINFACTOR												
r			rw												

Field	Bits	Type	Description
GAINFACTOR	12:0	rw	**Multiplication factor for gain correction** The resulting factor is (<GAINFACTOR> / 4 096)
CICSHIFT	20:16	rw	**Position of the CIC filter output shifter** Selects the valid outputs bits from the CIC filter $1D_H$ … $1F_H$ are reserved. 00_H Use bits 0 ... 16 … $1C_H$ Use bits 28 ... 44
0	15:13, 31:21	r	**Reserved** Read as 0; should be written with 0

45.8.104 DSADCx offset compensation register

DSADC_INx_OFFCOMP (x=0-9) Offset address: $60028_H+x*400_H$

DSADCx offset compensation register Kernel Reset value: $0000\ 0000_H$

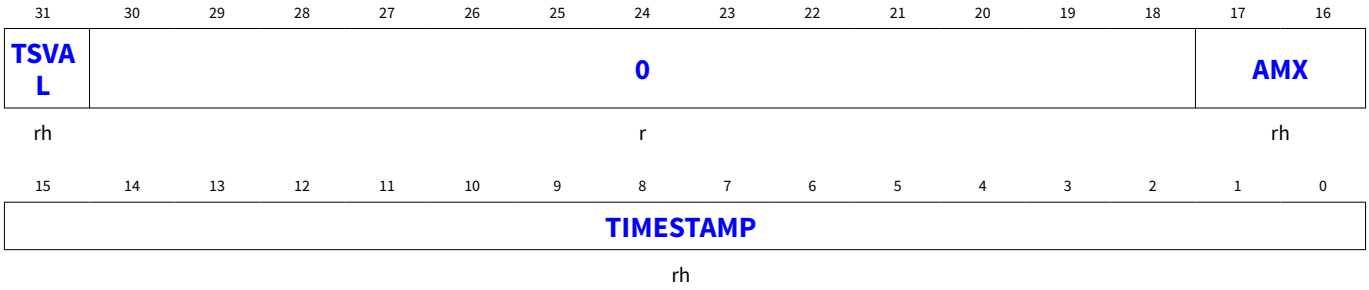


Field	Bits	Type	Description
OFFSET	15:0	rwh	**Offset value** Half of this signed value is subtracted from each result produced by the filter chain. ***Note**: Bit 0 represents 1/2 LSB. This increases the precision in case of accumulated result values, e.g. in the integrator.*
0	31:16	r	**Reserved** Read as 0; should be written with 0

45.8.105 DSADCx timestamp register

DSADC_INx_TSTMP (x=0-9) Offset address: $6002C_H+x*400_H$

DSADCx timestamp register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TIMESTAMP	15:0	rh	**The most recent captured timestamp value** This value is copied from the timestamp counter TSCOUNT ***Note**: If bit AMXCOPY in register TSCNT is 1, bits TIMESTAMP[15:14] are replaced with a copy of bitfield AMX.*
AMX	17:16	rh	**Analog multiplexer setting** This value is copied from bitfield INMUX in register CHCFGx

(table continues...)

(continued)

Field	Bits	Type	Description
TSVAL	31	rh	**Timestamp valid** Indicates valid timestamp information. 0_B No timestamp trigger occurred since last read access 1_B Timestamp information has been stored after a timestamp trigger
0	30:18	r	**Reserved** Read as 0; should be written with 0

45.8.106 DSADCx timestamp counter

DSADC_INx_TSCNT (x=0-9) Offset address: $60030_H+x*400_H$

DSADCx timestamp counter Kernel Reset value: $0000\ 0000_H$

TSCOUNT															
rh															

Field	Bits	Type	Description
TSCOUNT	15:0	rh	**Timestamp counter value** TSCOUNT is clocked with the modulator clock and is cleared when a new result value has been generated.
0	31:16	r	**Reserved** Read as 0; should be written with 0

45.8.107 DSADCx result register main

DSADC_INx_RESM (x=0-9) Offset address: $60034_H+x*400_H$

DSADCx result register main Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RESULTHI															
rh															

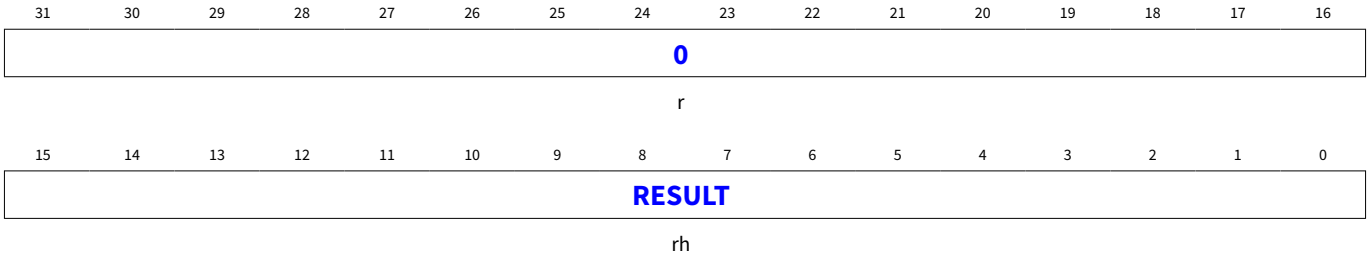
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESULTLO															
rh															

Field	Bits	Type	Description
RESULTLO	15:0	rh	**Result value lower part** Returns the next value from the result FIFO
RESULTHI	31:16	rh	**Result value higher part** Returns an additional value

45.8.108 DSADCx result register auxiliary

DSADC_INx_RESA (x=0-9) Offset address: $60038_H+x*400_H$

DSADCx result register auxiliary Kernel Reset value: $0000\ 0000_H$

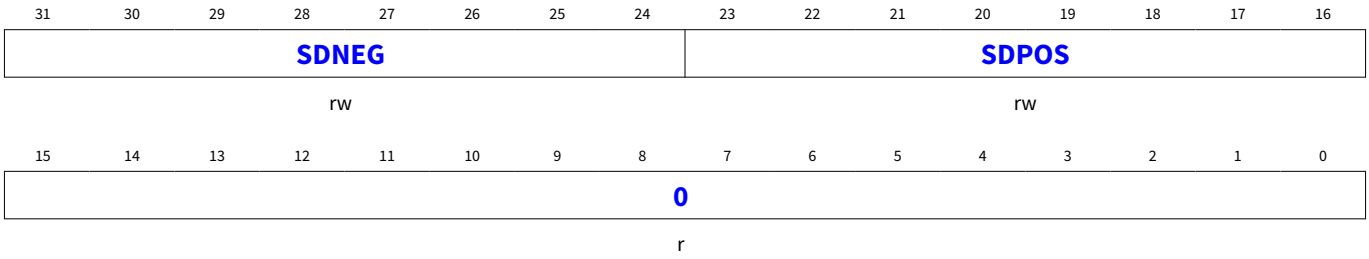


Field	Bits	Type	Description
RESULT	15:0	rh	**Most recent result of auxiliary filter**
0	31:16	r	**Reserved** Read as 0; should be written with 0

45.8.109 DSADCx carrier generator synchronization register

DSADC_INx_CGSYNC (x=0-9) Offset address: $6003C_H+x*400_H$

DSADCx carrier generator synchronization register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SDPOS	23:16	rw	**Sign delay value for positive halfwave** Defines the content of SDCOUNT to generate a negative delayed sign signal (SGND).
SDNEG	31:24	rw	**Sign delay value for negative halfwave** Defines the content of SDCOUNT to generate a positive delayed sign signal (SGND).

(table continues...)

(continued)

Field	Bits	Type	Description
0	15:0	r	**Reserved** Read as 0; should be written with 0

45.8.110 DSADCx rectification configuration register

DSADC_INx_RECTCFG (x=0-9) Offset address: $60040_H+x*400_H$

DSADCx rectification configuration register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				SSCH				0		SSRC		0		SDUM	RFEN
r				rw				r		rw		r		rw	rw

Field	Bits	Type	Description
RFEN	0	rw	**Rectification enable** General control of the rectifier circuit. ***Note:*** *Rectification is only active while the integrator is active.* 0_B No rectification, data not altered 1_B Data are rectified according to SGND
SDUM	1	rw	**Sign delay update mode** Controls behaviour of sign delay value updates for the carrier synchronization. 0_B Sign delay values become effective immediately 1_B Sign delay values become effective after sign update
SSRC	5:4	rw	**Sign source** Selects the sign signal that is to be delayed. 00_B On-chip carrier generator 01_B Sign of result of channel selected by bitfield SSCH 10_B External sign signal A 11_B External sign signal B
SSCH	11:8	rw	**Sign source channel** Selects the channel providing the sign signal if SSRC = 01_B. Other products of the family may have less channels and, consequently, less valid SSCH codes. Not listed combinations are reserved. 0_H Sign result from channel 0 … 9_H Sign result from channel 9

(table continues...)

(continued)

Field	Bits	Type	Description
0	3:2, 7:6, 31:12	r	**Reserved** Read as 0; should be written with 0

45.8.111 DSADCx boundary select register

DSADC_INx_BOUNDSEL (x=0-9) Offset address: $60044_H+x*400_H$

DSADCx boundary select register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BOUNDARYU															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOUNDARYL															
rw															

Field	Bits	Type	Description
BOUNDARYL	15:0	rw	**Lower boundary value for limit checking** This (two's complement) value is compared to the upper 16 bits of the CIC filter results.
BOUNDARYU	31:16	rw	**Upper boundary value for limit checking** This (two's complement) value is compared to the upper 16 bits of the CIC filter results.

45.8.112 DSADCx integrator trigger configuration register

Configure the trigger source for doing trigger based integration.

DSADC_INx_INTTRCFG (x=0-9) Offset address: $60048_H+x*400_H$

DSADCx integrator trigger configuration register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
INTTRS	5:0	rw	**Trigger source select for integrator** Refer "Hardware triggers to ADC" about the trigger source definition. [1)]

(table continues...)

(continued)

Field	Bits	Type	Description
INTTRM	9:8	rw	**Trigger mode select** 00_B No trigger edge selected, integrator bypassed 01_B Rising trigger edge selected 10_B Falling trigger edge selected 11_B No trigger, integrator active all the time
INTTRDLY	31:16	rw	**Trigger delay** Controls how much the selected trigger(s) shall be delayed before being executed The period of the configured edge(s) shall be greater than the configured delay value, else an error event will occur
0	7:6, 15:10	r	**Reserved** Read as 0; should be written with 0

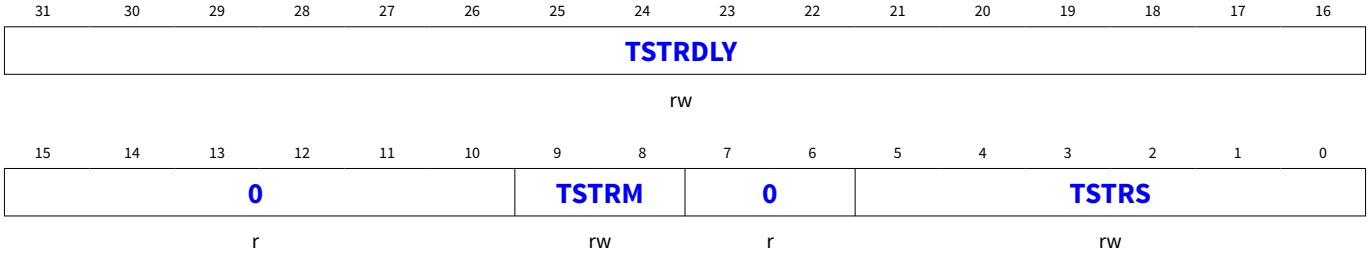
1) To avoid unintended triggers, select the trigger source first before enabling the corresponding function.

45.8.113 DSADCx timestamp trigger configuration register

Configure the trigger source for generating timestamp with hardware trigger.

DSADC_INx_TSTRCFG (x=0-9) Offset address: $6004C_H+x*400_H$

DSADCx timestamp trigger configuration register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TSTRS	5:0	rw	**Trigger source select** Selects an input for the trigger signal used for timestamp. *1)*
TSTRM	9:8	rw	**Trigger mode select** 00_B No trigger edge selected 01_B Rising trigger edge selected 10_B Falling trigger edge selected 11_B Both trigger edges selected
TSTRDLY	31:16	rw	**Trigger delay** Controls how much the selected trigger shall be delayed before being executed The period of the configured edge(s) shall be greater than the configured delay value, else an error event will occur
0	7:6, 15:10	r	**Reserved** Read as 0; should be written with 0

1) To avoid unintended triggers, select the trigger source first before enabling the corresponding function.

45.8.114 DSADCx input mux trigger configuration register

Configure the trigger source for changing the input of the analog input MUX.

DSADC_INx_IMXTRCFG (x=0-9) Offset address: $60050_H+x*400_H$

DSADCx input mux trigger configuration register Kernel Reset value: $0000\ 0000_H$

r						rw		r		rw					

Field	Bits	Type	Description
IMXTRS	5:0	rw	**Trigger source select for switching analog input MUX** Refer "Hardware triggers to ADC" about the trigger source definition 1)
IMXTRM	9:8	rw	**Trigger mode select** 00_B Software control, value configured in INSEL is taken 01_B Rising trigger edge selected 10_B Falling trigger edge selected 11_B Both trigger edges selected
IMXTRDLY	31:16	rw	**Trigger delay** Controls how much the selected trigger shall be delayed before being executed The period of the configured edge(s) shall be greater than the configured delay value, else an error event will occur
0	7:6, 15:10	r	**Reserved** Read as 0; should be written with 0

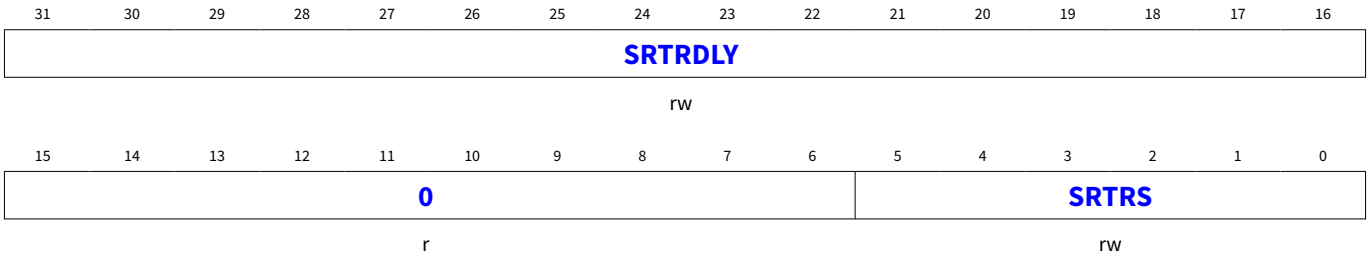
1) To avoid unintended triggers, select the trigger source first before enabling the corresponding function.

45.8.115 DSADCx service request trigger configuration register

Configures the trigger source and trigger delay for the service request trigger. Please also refer to DSADC_INx_SRCFG.SR0E register for configuring the proper mode of trigger.

DSADC_INx_SRTRCFG (x=0-9) Offset address: $60054_H+x*400_H$

DSADCx service request trigger configuration register Kernel Reset value: $0000\ 0000_H$



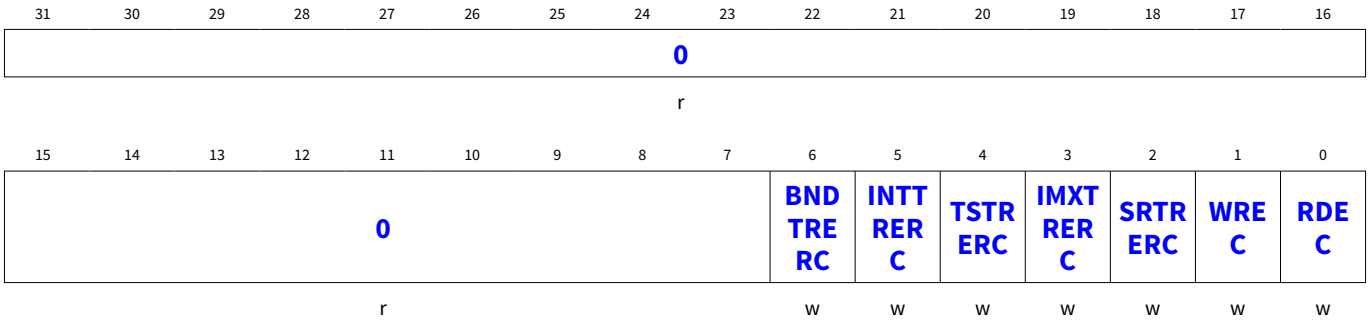
Field	Bits	Type	Description
SRTRS	5:0	rw	**Trigger source select for service request** Refer "Hardware triggers to ADC" about the trigger source definition. 1)
SRTRDLY	31:16	rw	**Trigger delay** Controls how much the selected trigger shall be delayed before being executed The period of the configured edge(s) shall be greater than the configured delay value, else an error event will occur
0	15:6	r	**Reserved** Read as 0; should be written with 0

1) To avoid unintended triggers, select the trigger source first before enabling the corresponding function.

45.8.116 DSADCx channel error clear register

DSADC_INx_CHERRCL (x=0-9) Offset address: $60058_H+x*400_H$

DSADCx channel error clear register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RDEC	0	w	**Read error flag clear** 0_B No action 1_B Clear flag RDERR
WREC	1	w	**Write error flag clear** 0_B No action 1_B Clear flag WRERR

(table continues...)

(continued)

Field	Bits	Type	Description
SRTRERC	2	w	**Service request trigger error clear** 0_B No action 1_B Clear flag SRTRER
IMXTRERC	3	w	**Analog input mux trigger error clear** 0_B No action 1_B Clear flag IMXTRER
TSTRERC	4	w	**Time stamp trigger error clear** 0_B No action 1_B Clear flag TSTRER
INTTRERC	5	w	**Integrator trigger error clear** 0_B No action 1_B Clear flag INTTRER
BNDTRERC	6	w	**Boundary request trigger error clear** 0_B No action 1_B Clear flag BNDTRER
0	31:7	r	**Reserved** Read as 0; should be written with 0

45.8.117 DSADCx service request configuration register

Configure and enable the service requests generated by DSADC channel towards IR.

DSADC_INx_SRCFG (x=0-9) Offset address: $6005C_H+x*400_H$

DSADCx service request configuration register Kernel Reset value: $0000\ 0000_H$

rh	rh	r													rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SDCAP								SDCOUNT							
rh								rh							

Field	Bits	Type	Description
SDCOUNT	7:0	rh	**Sign delay counter** Counts the result values from the filter chain to delay the carrier sign signal
SDCAP	15:8	rh	**Sign delay capture value** Indicates the result values counted between the begin of the positive halfwave of the carrier signal and the first received positive value.
SDCVAL	16	rh	**Valid flag** Indicates a new value in bitfield SDCAP. 0_B No new result available 1_B Bitfield SDCAP has been updated with a new captured value and has not yet been read
SGNCS	30	rh	**Selected carrier sign signal** 0_B Positive values 1_B Negative values
SGND	31	rh	**Sign signal delayed** 0_B Positive values 1_B Negative values
0	29:17	r	**Reserved** Read as 0; should be written with 0

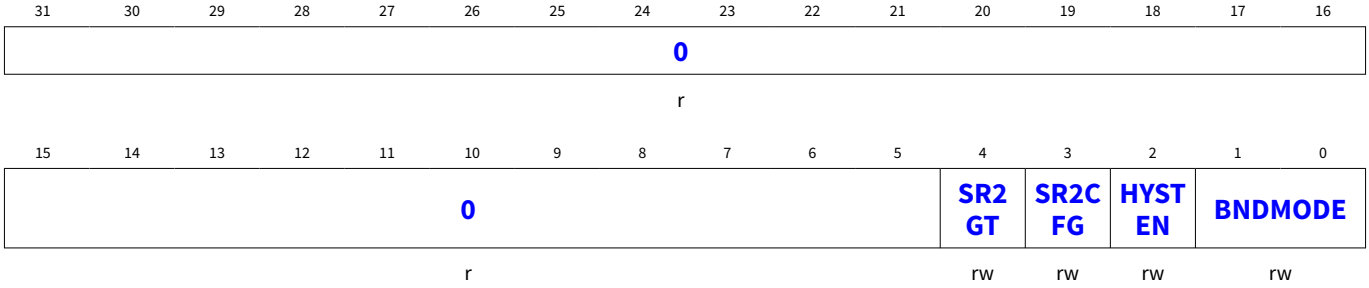
45.8.120 DSADCx boundary mode configuration register

DSADC_INx_BNDCFG (x=0-9)

DSADCx boundary mode configuration register

Offset address: $60068_H+x*400_H$

Kernel Reset value: $0000\ 0000_H$



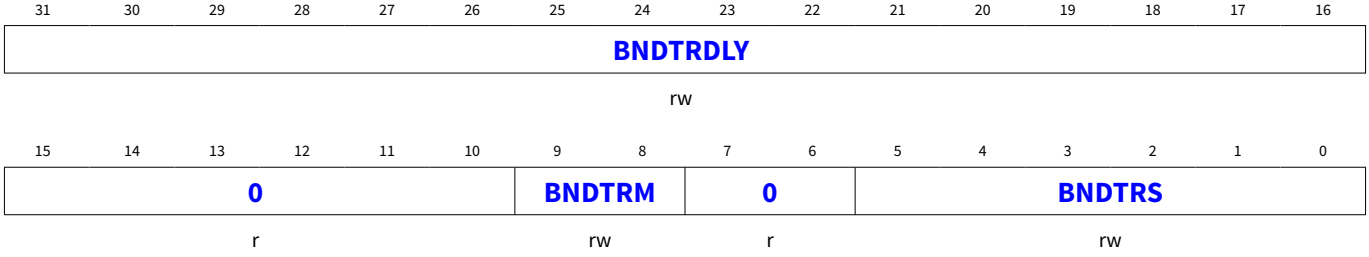
Field	Bits	Type	Description
BNDMODE	1:0	rw	**Boundary flag mode - BNDMOD** Configure the condition under which boundary flag is generated 00_B Disabled 01_B Boudary flag is high when result exceeds upper limit 10_B Boudary flag is high when result is lower than lower limit 11_B Boudary flag is high when result is out of the band
HYSTEN	2	rw	**Hysteresis enable** Enables the Hysteresis Mode. In this mode BNDMODE configuration is ignored
SR2CFG	3	rw	**Conditions under which SR2 is generated** 0_B If the result is inside boundary band 1_B If the result is outisde the boudary band
SR2GT	4	rw	**Service request gate for SR2** 0_B Service request 2 gate disabled 1_B Service request 2 is only generated when the integrator is enabled and after the discard of values defined by NVALDIS
0	31:5	r	**Reserved** Read as 0; should be written with 0

45.8.121 DSADCx boundary request trigger configuration register

Configure the trigger source for updating the boundary value for limit checking.

DSADC_INx_BNDTRCFG (x=0-9) Offset address: $6006C_H+x*400_H$

DSADCx boundary request trigger configuration register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
BNDTRS	5:0	rw	**Trigger source select for updating the boundary value.** Refer "Hardware triggers to ADC" about the trigger source definition. 1)
BNDTRM	9:8	rw	**Trigger mode select** 00_B No trigger selected, boundary update immediately 01_B Boundary update on the rising edge of the trigger 10_B Boundary update on the falling edge of the trigger 11_B Boundary update at both rising and falling edges of the trigger
BNDTRDLY	31:16	rw	**Trigger delay** Controls how much the selected trigger shall be delayed before being executed The period of the configured edge(s) shall be greater than the configured delay value, else an error event will occur
0	7:6, 15:10	r	**Reserved** Read as 0; should be written with 0

1) To avoid unintended triggers, select the trigger source first before enabling the corresponding function.

45.8.122 DSADCx boundary status register

Boundary status register gives the current used boundary values for limit checking

DSADC_INx_BOUNDST (x=0-9) Offset address: $60070_H+x*400_H$

DSADCx boundary status register Kernel Reset value: $0000\ 0000_H$

CFMDF	9:0	rw	**CIC filter decimation factor** Defines the oversampling rate of the CIC filter: OSR = CFMDF + 1. Valid values are 003_H to $2FF_H$ (OSR = 4 to 1024).
CFAEN	16	rw	**CIC filter (auxiliary) enable** 0_B Off: auxiliary filter is not active 1_B Auxiliary filter is active and generates results and alarm events
CFADF	18:17	rw	**CIC filter (auxiliary) decimation factor** 00_B OSR = 16 01_B OSR = 32 10_B OSR = 64 11_B OSR = 128

(table continues...)

(continued)

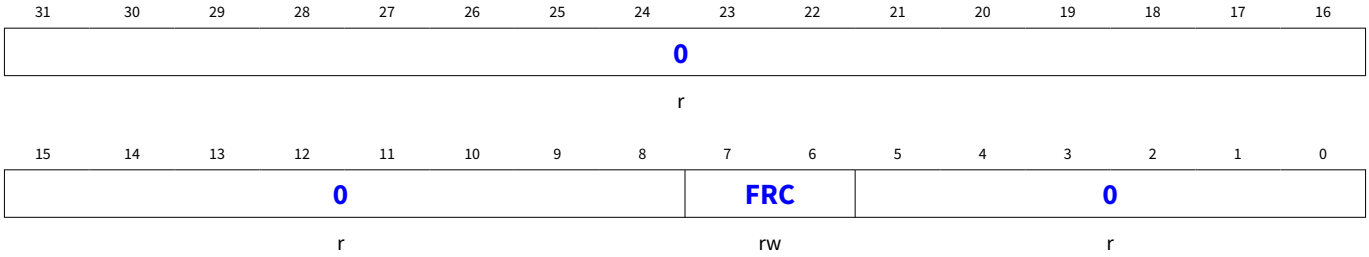
Field	Bits	Type	Description
0	15:10, 31:19	r	**Reserved** Read as 0; should be written with 0

45.8.126 EXMODz integrator configuration register

Configures the hardware integrator and the mode of operation of the integrator.
Integrator configuration change shall be avoided when INTEN = 1, if changed, may result in invalid outputs.

DSADC_EXz_INTCFG (z=0-7) Offset address: $6380C_H+z*400_H$

EXMODz integrator configuration register Kernel Reset value: $0000\ 0000_H$

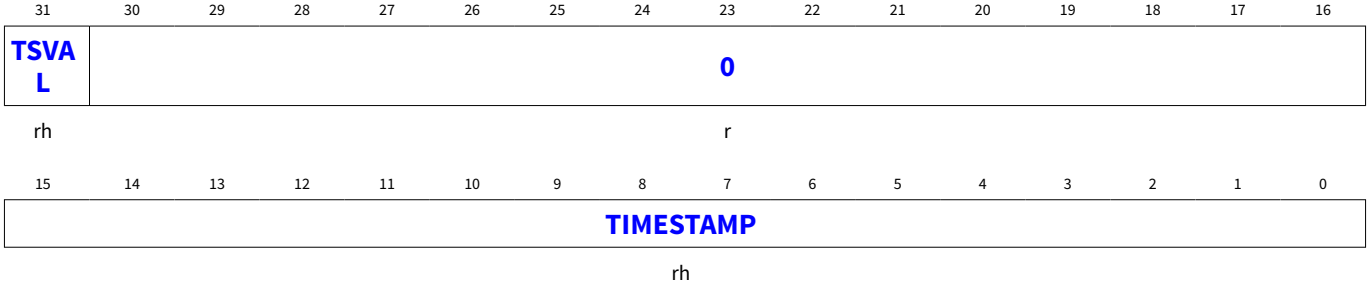


Field	Bits	Type	Description
FRC	7:6	rw	**Filter chain restart control** 00_B Restart the main filter chain when an integration window starts, auxiliary filter chain is not restarted 01_B Restart the main and auxilary filter chain when an integration window starts 10_B No influence on main and auxiliary filter chain when an integration window starts, except for the integrator itself 11_B No influence on main filter chain when an integration window starts, except for the integrator itself and auxiliary filter chain
0	5:0, 31:8	r	**Reserved** Read as 0; should be written with 0

45.8.127 EXMODz timestamp register

DSADC_EXz_TSTMP (z=0-7) Offset address: $63810_H+z*400_H$

EXMODz timestamp register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TIMESTAMP	15:0	rh	**The most recent captured timestamp value** This value is copied from the timestamp counter TSCOUNT
TSVAL	31	rh	**Timestamp valid** Indicates valid timestamp information. 0_B No timestamp trigger occurred since last read access 1_B Timestamp information has been stored after a timestamp trigger
0	30:16	r	**Reserved** Read as 0; should be written with 0

45.8.128 EXMODz timestamp counter

DSADC_EXz_TSCNT (z=0-7) Offset address: $63814_H+z*400_H$

EXMODz timestamp counter Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
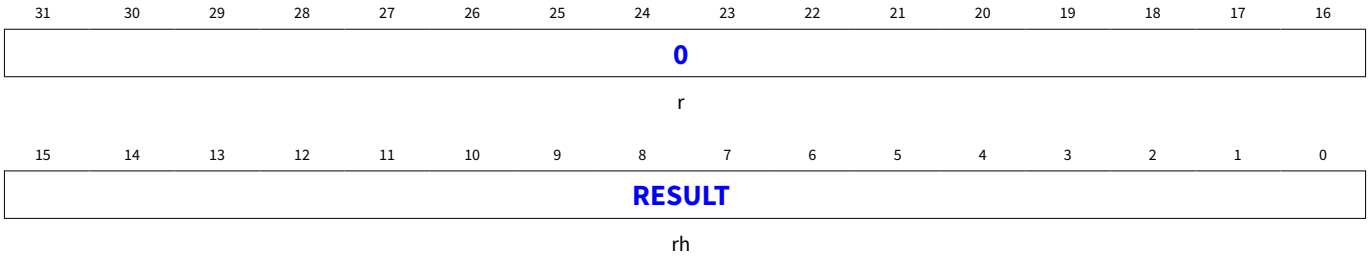
RESULTLO	15:0	rh	**Result value lower part** Returns the next value from the result FIFO
RESULTHI	31:16	rh	**Result value higher part** Returns an additional value

45.8.130 EXMODz result register auxiliary

DSADC_EXz_RESA (z=0-7) Offset address: $6381C_H+z*400_H$

EXMODz result register auxiliary Kernel Reset value: $0000\ 0000_H$

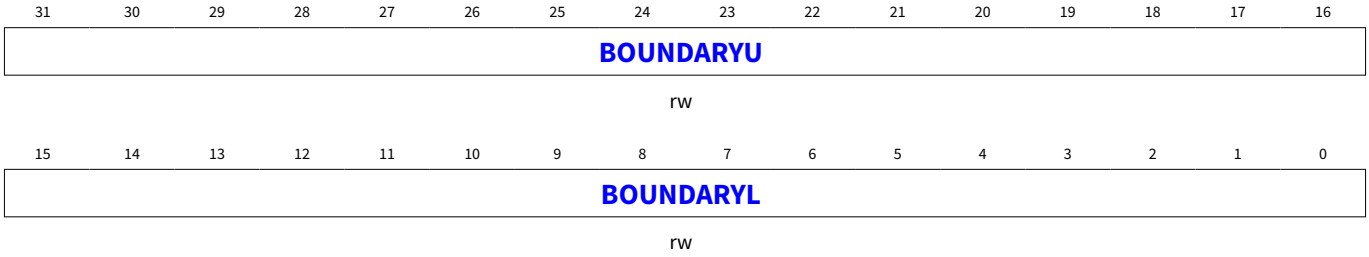


Field	Bits	Type	Description
RESULT	15:0	rh	**Most recent result of auxiliary filter**
0	31:16	r	**Reserved** Read as 0; should be written with 0

45.8.131 EXMODz boundary select register

DSADC_EXz_BOUNDSEL (z=0-7) Offset address: $63820_H+z*400_H$

EXMODz boundary select register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
BOUNDARYL	15:0	rw	**Lower boundary value for limit checking** This (two's complement) value is compared to the upper bits of the CIC filter results.
BOUNDARYU	31:16	rw	**Upper boundary value for limit checking** This (two's complement) value is compared to the upper bits of the CIC filter results.

45.8.132 EXMODz integrator trigger configuration register

Configure the trigger source for doing trigger based integration.

DSADC_EXz_INTTRCFG (z=0-7) Offset address: $63824_H+z*400_H$

EXMODz integrator trigger configuration register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
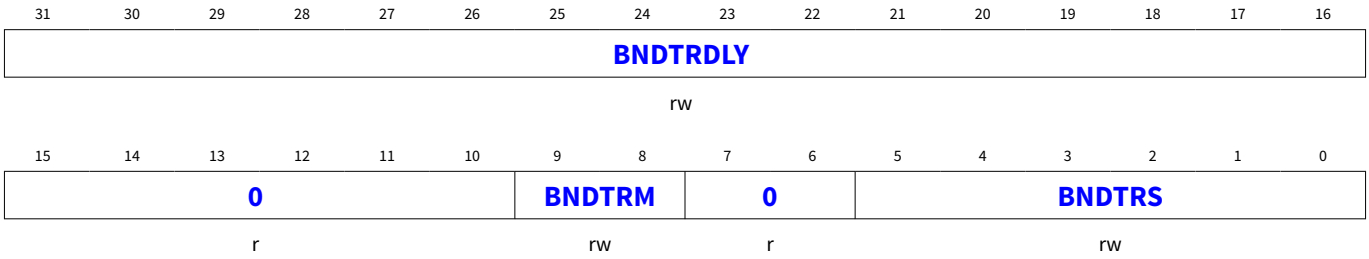
BNDMODE	1:0	rw	**Boundary flag mode - BNDMOD** Defines the conditions in which boundary flag shall be raised 00_B Disabled 01_B Boudary flag is high when result exceeds upper limit 10_B Boudary flag is high when result is lower than lower limit 11_B Boudary flag is high when result is out of the band
HYSTEN	2	rw	**Hysteresis enable** Enables the hysteresis mode. In this mode BNDMODE configuration is ignored
SR2CFG	3	rw	**Conditions under which SR2 is generated** 0_B If the result is inside boundary band 1_B If the result is outisde the boudary band
0	31:4	r	**Reserved** Read as 0; should be written with 0

45.8.139 EXMODz boundary request trigger configuration register

Configures the trigger source and trigger delay for the update of the boundary values in a channel.

DSADC_EXz_BNDTRCFG (z=0-7) Offset address: $63840_H+z*400_H$

EXMODz boundary request trigger configuration register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
BNDTRS	5:0	rw	**Trigger source select for updating boundary values** Refer "Hardware triggers to ADC" about the trigger source definition. [1]
BNDTRM	9:8	rw	**Trigger mode select** 00_B No trigger selected, boundary update immediately 01_B Boundary update on the rising edge of the trigger 10_B Boundary update on the falling edge of the trigger 11_B Boundary update at both rising and falling edges
BNDTRDLY	31:16	rw	**Trigger delay** Controls how much the selected trigger shall be delayed before being executed The period of the configured edge(s) shall be longer than the configured delay value, else an error event will occur
0	7:6, 15:10	r	**Reserved** Read as 0; should be written with 0

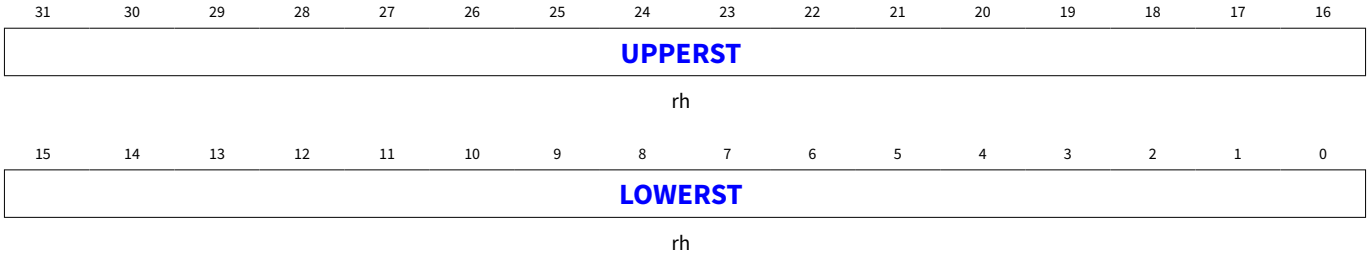
1) To avoid unintended triggers, select the trigger source first before enabling the corresponding function.

45.8.140 EXMODz boundary status register

Boundary status register gives the current used boundary values for limit checking

DSADC_EXz_BOUNDST (z=0-7) Offset address: $63844_H+z*400_H$

EXMODz boundary status register Kernel Reset value: $0000\ 0000_H$

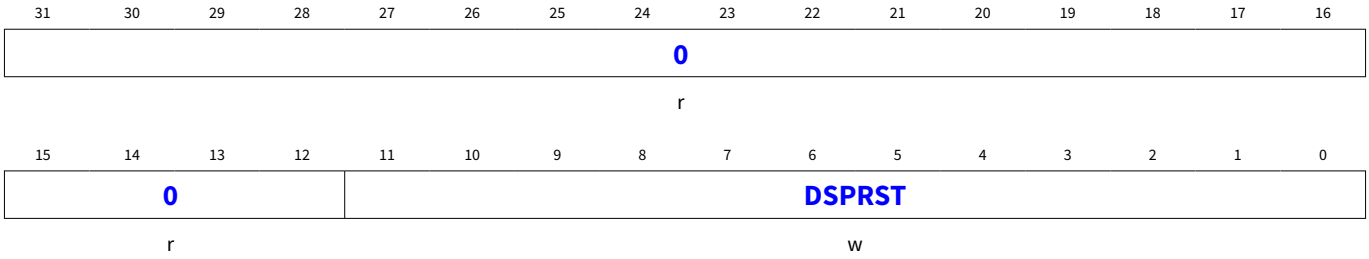


Field	Bits	Type	Description
LOWERST	15:0	rh	**Lower boundary value currently used for limit checking** The current used lower boundary value
UPPERST	31:16	rh	**Upper boundary value currently used for limit checking** The current used upper boundary value

45.8.141 CDSP global reset control

CDSP_GLOBRD Offset address: $BF804_H$

CDSP global reset control Kernel Reset value: $0000\ 0000_H$

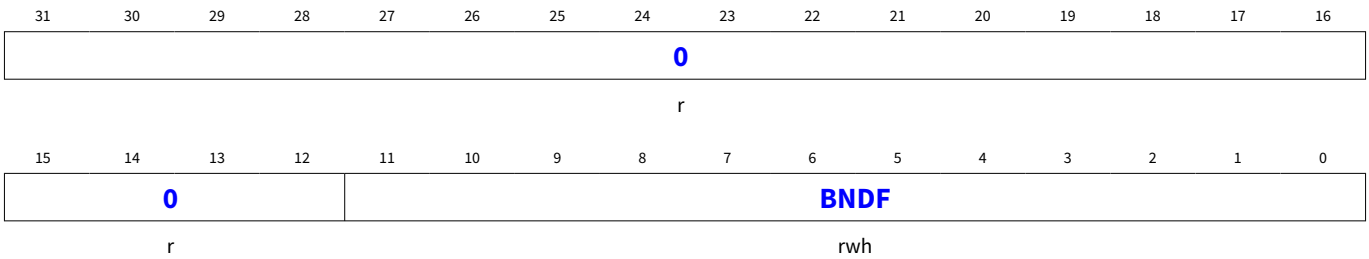


Field	Bits	Type	Description
DSPRST	11:0	w	**DSP reset** Each bit resets the corresponding CDSP instance. For example bit 0 of this register resets CDSP0.
0	31:12	r	**Reserved** Read as 0; should be written with 0

45.8.142 CDSP boudary flag event register

CDSP_BNDCF Offset address: $BF808_H$

CDSP boudary flag event register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
BNDF	11:0	rwh	**Boundary event for CDSP channel** Status of the boundary flag event of the corresponding CDSP instance. For example bit 0 of this register indicates the status of boundary flag event of CDSP0

(table continues...)

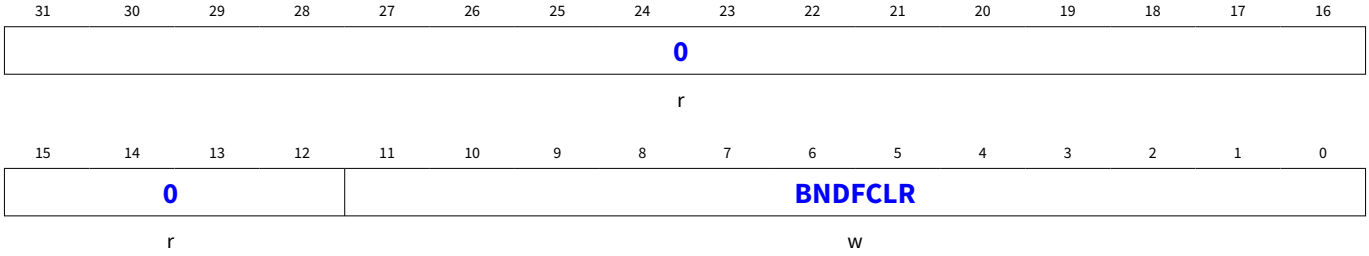
(continued)

Field	Bits	Type	Description
0	31:12	r	**Reserved** Read as 0; should be written with 0

45.8.143 CDSP boundary flag event clear

CDSP_BNDCFCL Offset address: $BF80C_H$

CDSP boundary flag event clear Kernel Reset value: $0000\ 0000_H$

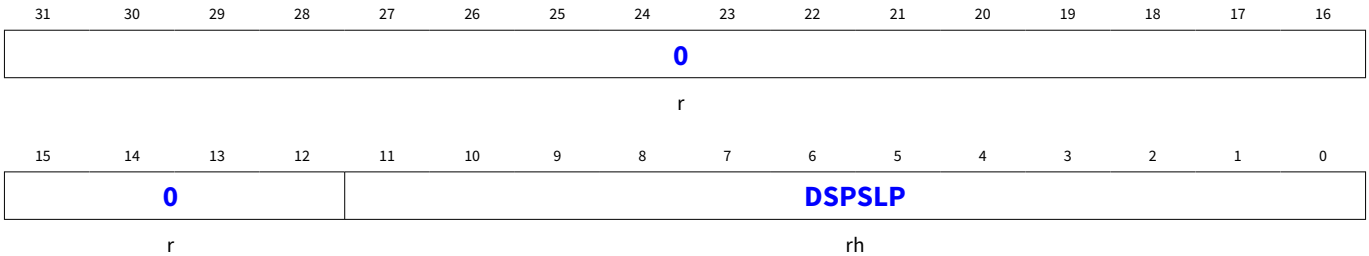


Field	Bits	Type	Description
BNDFCLR	11:0	w	**Boundary event clear for CDSP channels** Setting bits clears the bouandy event of the corresponding CDSP instance. For example bit 0 of this register clears the boundary event of the CDSP0.
0	31:12	r	**Reserved** Read as 0; should be written with 0

45.8.144 CDSP sleep status register

CDSP_SLPST Offset address: $BF810_H$

CDSP sleep status register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DSPSLP	11:0	rh	**CDSP sleep status** Sleep status of the DSP core of the corresponding CDSP instance. For example bit 0 of this register indicates the sleep status of the DSP core of the CDSP0.
0	31:12	r	**Reserved** Read as 0; should be written with 0

45.8.145 CDSP event flag register y

CDSP_RESEVy (y=0-2) Offset address: $BF814_H$+y*4

CDSP event flag register y Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
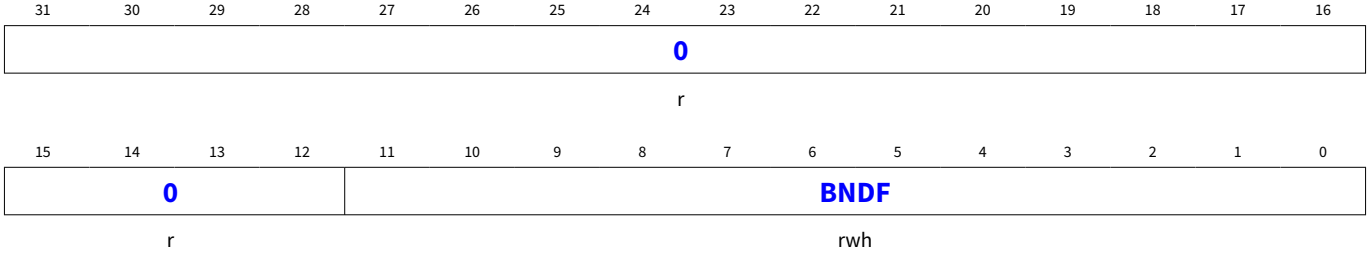
0				RESEVCLR											
r				w											

Field	Bits	Type	Description
RESEVCLR	11:0	w	**Result event clear for result register y of CDSP** Each bit clears the result event of the corresponding CDSP instance. For example setting bit 0 of this register clears the result event of the CDSP0.
0	31:12	r	**Reserved** Read as 0; should be written with 0

45.8.147 CDSP boudary flag event register 1

CDSP_BNDCF1 Offset address: BF82C$_H$

CDSP boudary flag event register 1 Kernel Reset value: 0000 0000$_H$

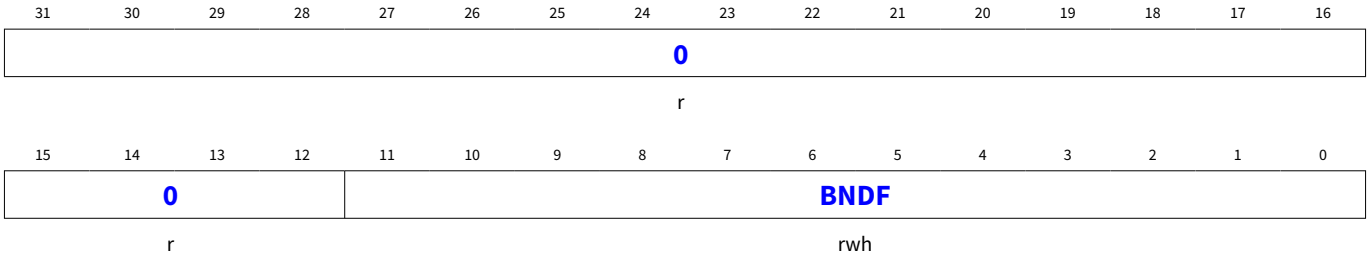


Field	Bits	Type	Description
BNDF	11:0	rwh	**Boundary event for CDSP channel** Status of the boundary flag event of the corresponding CDSP instance. For example bit 0 of this register indicates the status of boundary flag event of CDSP0
0	31:12	r	**Reserved** Read as 0; should be written with 0

45.8.148 CDSP boudary flag event register 2

CDSP_BNDCF2 Offset address: BF830$_H$

CDSP boudary flag event register 2 Kernel Reset value: 0000 0000$_H$

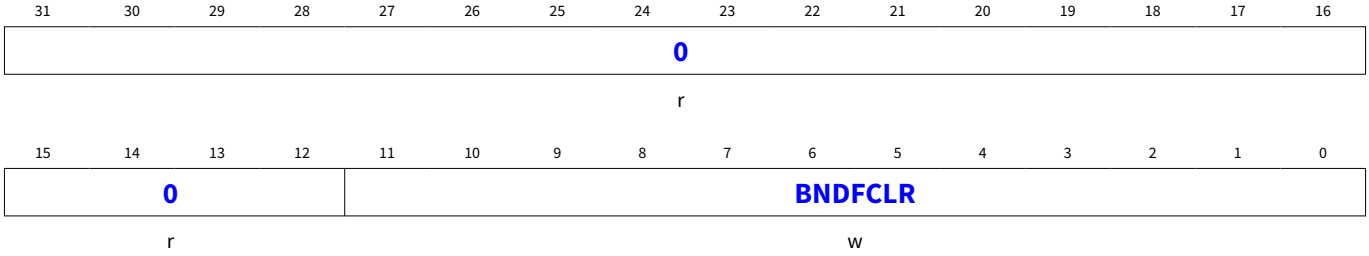


Field	Bits	Type	Description
BNDF	11:0	rwh	**Boundary event for CDSP channel** Status of the boundary flag event of the corresponding CDSP instance. For example bit 0 of this register indicates the status of boundary flag event of CDSP0
0	31:12	r	**Reserved** Read as 0; should be written with 0

45.8.149 CDSP boundary flag event clear 1

CDSP_BNDCFCL1 Offset address: BF834$_H$

CDSP boundary flag event clear 1 Kernel Reset value: 0000 0000$_H$

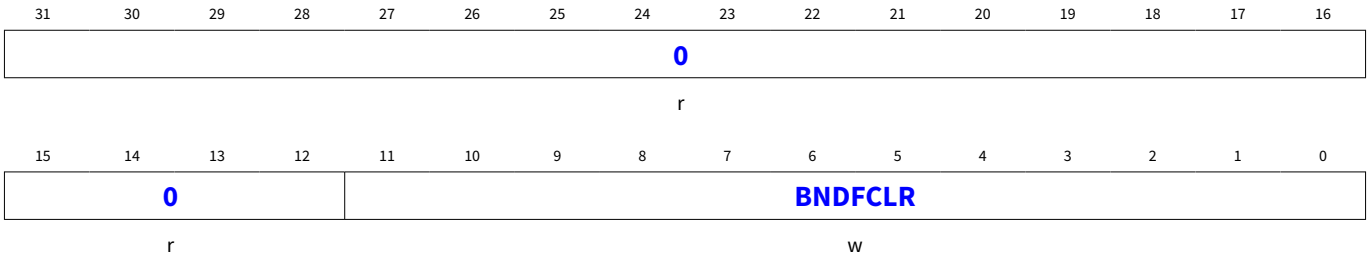


Field	Bits	Type	Description
BNDFCLR	11:0	w	**Boundary event clear for CDSP channels** Setting bits clears the bouandy event of the corresponding CDSP instance. For example bit 0 of this register clears the boundary event of the CDSP0.
0	31:12	r	**Reserved** Read as 0; should be written with 0

45.8.150 CDSP boundary flag event clear 2

CDSP_BNDCFCL2 Offset address: $BF838_H$

CDSP boundary flag event clear 2 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
BNDFCLR	11:0	w	**Boundary event clear for CDSP channels** Setting bits clears the bouandy event of the corresponding CDSP instance. For example bit 0 of this register clears the boundary event of the CDSP0.
0	31:12	r	**Reserved** Read as 0; should be written with 0

45.8.151 CDSP input from general purpose register x

Input data for CDSP apart from ADCs

Note: Infineon software requires register layout of this register according to DSADC_INx_RESM.

CDSP_GPx (x=0-3) Offset address: $BF8C0_H+x*4$

CDSP input from general purpose register x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r						rh									w

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					SUS									SUSM	
r					rw									rw	

Field	Bits	Type	Description
SUSM	1:0	rw	**OCDS suspend control mode** Selects the suspend mode for the module. *Note: For reaching soft suspend condition the selected input data source must send enough inputs to the CDSP for a result event to be generated.* 00_B Will not suspend 01_B Hard suspend Clocks will be disabled immediately 10_B Soft suspend mode Clock will be disabled after processing the current sample. 11_B Soft suspend mode Clock will be disabled after generating the next result event, visible in the corresponding bit of CDSP_RESEV0.
SUS	10:2	rw	**OCDS suspend control** Suspends the corresponding CDSP. 0 - Module not suspended, 1 - Module Suspended. Each bit control a CDSP, with LSB for CDSP0 and MSB for the CDSP8. *Note: Please check how many CDSP are there in device*
SUS_P	16	w	**SUS write protection** SUS and SUSM are only written when SUS_P is 1, otherwise unchanged. Read as 0.

(table continues...)

(continued)

Field	Bits	Type	Description
SUSSTA	25:17	rh	**Suspend state** Suspend state of CDSP. 0 - Module not suspended. 1 - Module suspended. Each bit controls a CDSP, with LSB for CDSP0 and MSB for the CDSP8. *Note: Please check how many CDSP are there in device*
0	15:11, 31:26	r	**Reserved** Read as 0; should be written with 0.

Table 2405 Access mode restrictions of CDSP_OCSCDSPA sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SUS_P**	rw	SUS, SUSM	Set SUS_P during write access
(default)	r	SUS, SUSM	

45.8.159 OCDS control and status register 1 for CDSP9-17

CDSP_OCSCDSPB Offset address: $BF8EC_H$

OCDS control and status register 1 for CDSP9-17 Debug Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
SUSM	1:0	rw	**OCDS suspend control mode** Selects the suspend mode for the module. *Note: For reaching soft suspend condition the selected input data source must send enough inputs to the CDSP for a result event to be generated.* 00_B Will not suspend 01_B Hard suspend Clocks will be disabled immediately 10_B Soft suspend mode Clock will be disabled after processing the current sample. 11_B Soft suspend mode Clock will be disabled after generating the next result event, visible in the corresponding bit of CDSP_RESEV0.
SUS	4:2	rw	**OCDS suspend control** Suspends the corresponding CDSP. 0 - Module not suspended, 1 - Module suspended. Each bit control a CDSP, with LSB for CDSP9 and MSB for the CDSP17. *Note: Please check how many CDSP are there in device*

(table continues...)

(continued)

Field	Bits	Type	Description
SUS_P	16	w	**SUS write protection** SUS and SUSM are only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	19:17	rh	**Suspend state** Suspend state of CDSP. 0 - Module not suspended. 1 - Module suspended. Each bit control a CDSP, with LSB for CDSP9 and MSB for the CDSP17. *Note: Please check how many CDSP are there in device*
0	15:5, 31:20	r	**Reserved** Read as 0; should be written with 0.

Table 2406 Access mode restrictions of CDSP_OCSCDSPB sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SUS_P**	rw	SUS, SUSM	Set SUS_P during write access
(default)	r	SUS, SUSM	

45.8.160 CDSPd debug status register

The DB_STATUS register provides information on all DEBUG operations. Writing to this register initiates the debug operation defined in DB_CMD. This register is volatile.

CDSP_DBd_STATUS (d=0-11) Offset address: $BFC00_H+d*20_H$

CDSPd debug status register Kernel Reset value: $0000\ 0024_H$

0										RA	RU	0	RD	FL	ST
r										rh	rh	r	rh	rh	rh

Field	Bits	Type	Description
ST	0	rh	**The stalled (ST) flag indicates that the debug interface is busy** 0_B Debug interface is not busy 1_B Debug interface is busy
FL	1	rh	**When true, the failure (FL) flag indicates that the debug operation has failed** 0_B Debug operation has not failed 1_B Debug operation has failed

(table continues...)

(continued)

Field	Bits	Type	Description
RD	2	rh	**Ready flag** The ready (RD) flag indicates whether the debug interface is available to accept another transaction command 0_B Debug interface is not available to accept another transaction command 1_B Debug interface is available to accept another transaction command
RU	4	rh	**The run (RU) flag is set to one when the ARC HS processor is running** 0_B Processor is not running 1_B Processor is running
RA	5	rh	**Reset applied** The Reset Applied (RA) flag is used by the debug host to determine that a target reset has occurred 0_B Target reset has not occurred 1_B Target reset has occurred
0	3, 31:6	r	**Reserved** Reserved. read-as-zero; ignored on write

45.8.161 CDSPd debug command register

The DB_CMD register defines the debug command (read and write to auxiliary register, core and memory).

CDSP_DBd_CMD (d=0-11) Offset address: $BFC04_H+d*20_H$

CDSPd debug command register Kernel Reset value: $0000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												COMMAND			
r												rw			

Field	Bits	Type	Description
COMMAND	3:0	rw	**Defines the debug command (read/write to aux/core/mem)** All non-enumerated values are reserved. 0_H Write to memory location 1_H Write to core register 2_H Write to auxiliary register 3_H Initiate a core and system reset 4_H Read memory location 5_H Read core register 6_H Read auxiliary register **others,** Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
0	31:4	r	**Reserved** Reserved. read-as-zero; ignored on write

45.8.162 CDSPd debug address register

The DB_ADDR register specifies auxiliary register, core and memory address location. This register is volatile.

CDSP_DBd_ADDR (d=0-11) Offset address: $BFC08_H+d*20_H$

CDSPd debug address register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
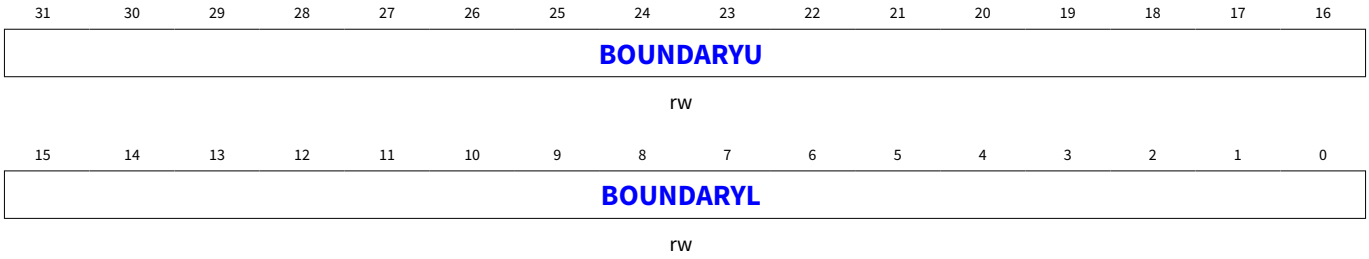
LOWERST	15:0	rh	**Lower boundary value for limit checking** The current used lower boundary value
UPPERST	31:16	rh	**Upper boundary value for limit checking** The current used upper boundary value

45.8.169 CDSPa boundary select register

CDSP_DSPa_BOUNDSEL (a=0-11) Offset address: $C1C10_H+a*2000_H$

CDSPa boundary select register Kernel Reset value: $0000\ 0000_H$



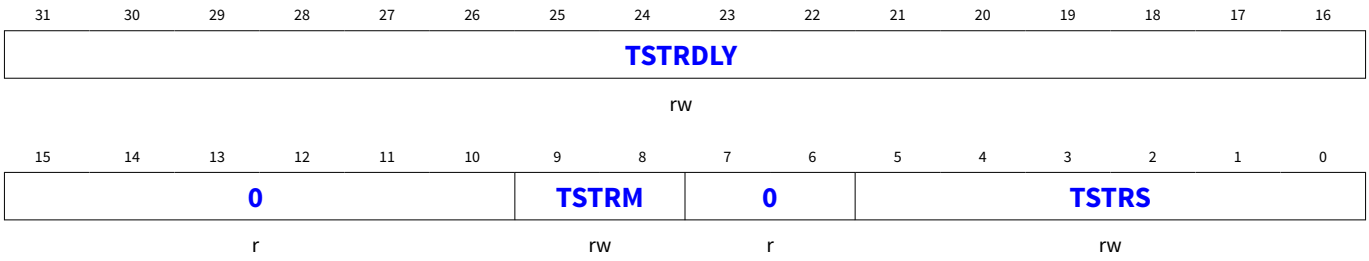
Field	Bits	Type	Description
BOUNDARYL	15:0	rw	**Lower boundary value for limit checking** Lower boundary value (two's complement) compared with lower 16 bits of CDSP result (CDSP_DSPa_RESy.CRESULTLO).
BOUNDARYU	31:16	rw	**Upper boundary value for limit checking** Upper boundary value (two's complement) compared with lower 16 bits of CDSP result (CDSP_DSPa_RESy.CRESULTLO).

45.8.170 CDSPa time stamp trigger configuration register

Configures the trigger source and trigger delay for the timestamp.

CDSP_DSPa_TSTRCFG (a=0-11) Offset address: $C1C14_H+a*2000_H$

CDSPa time stamp trigger configuration register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TSTRS	5:0	rw	**Trigger source select for timestamp** Refer "Hardware triggers to ADC" about the trigger source definition. [1)]

(table continues...)

(continued)

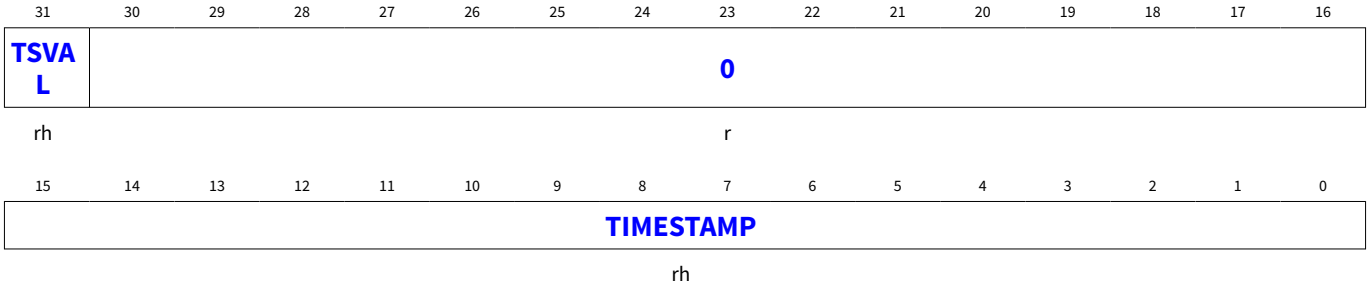
Field	Bits	Type	Description
TSTRM	9:8	rw	**Trigger mode select** 00_B No trigger edge selected 01_B Rising trigger edge selected 10_B Falling trigger edge selected 11_B Both trigger edges selected
TSTRDLY	31:16	rw	**Trigger delay** Controls how much the selected trigger shall be delayed before being executed The period of the configured edge(s) shall be longer than the configured delay value, else a trigger error event will occur
0	7:6, 15:10	r	**Reserved** Read as 0; should be written with 0

1) To avoid unintended triggers, select the trigger source first before enabling the corresponding function.

45.8.171 CDSPa time-stamp register

CDSP_DSPa_TSTMP (a=0-11) Offset address: $C1C18_H+a*2000_H$

CDSPa time-stamp register Kernel Reset value: $0000\ 0000_H$

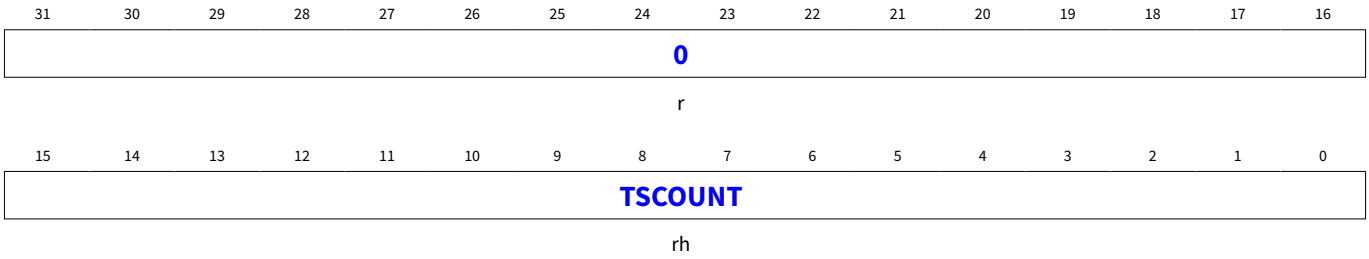


Field	Bits	Type	Description
TIMESTAMP	15:0	rh	**The most recent captured timestamp value** This value is copied from the timestamp counter TSCOUNT.
TSVAL	31	rh	**Timestamp valid** Indicates valid timestamp information. 0_B No timestamp trigger occurred since last read access 1_B Timestamp information has been stored after a timestamp trigger
0	30:16	r	**Reserved** Read as 0; should be written with 0

45.8.172 CDSPa time-stamp counter

CDSP_DSPa_TSCNT (a=0-11) Offset address: $C1C1C_H+a*2000_H$

CDSPa time-stamp counter Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TSCOUNT	15:0	rh	**Timestamp counter value** TSCOUNT is counting on CDSP clocks and is cleared when a new result value has been generated.
0	31:16	r	**Reserved** Read as 0; should be written with 0

45.8.173 CDSPa service request trigger configuration register

Configures the trigger source and trigger delay for the service request trigger. Please also refer to CDSP_DSPa_SRCFG.SR0E register for configuring the proper mode of trigger.

CDSP_DSPa_SRTRCFG (a=0-11) Offset address: $C1C20_H+a*2000_H$

CDSPa service request trigger configuration register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
SRTRS	5:0	rw	**Trigger source select for service request** Refer "Hardware triggers to ADC" about the trigger source definition. [1)]
SRTRDLY	31:16	rw	**Trigger delay** Controls how much the selected trigger shall be delayed before being executed The period of the configured edge(s) shall be longer than the configured delay value, else an error event will occur
0	15:6	r	**Reserved** Read as 0; should be written with 0

1) To avoid unintended triggers, select the trigger source first before enabling the corresponding function.

45.8.174 CDSPa service request configuration register

CDSP_DSPa_SRCFG (a=0-11) Offset address: $C1C24_H+a*2000_H$

CDSPa service request configuration register Kernel Reset value: $0000\ 0000_H$

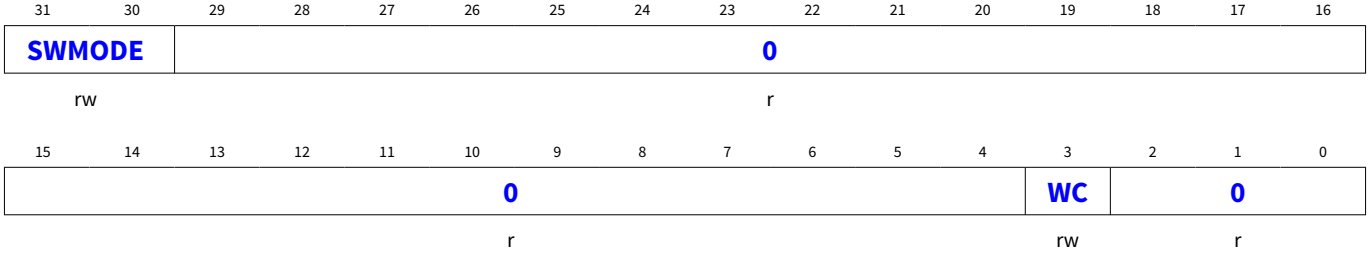
45.8.175 CDSPa software configuration register

CDSP_DSPa_SWCFG (a=0-11) Offset address: $C1C28_H+a*2000_H$

CDSPa software configuration register Kernel Reset value: $0000\ 0000_H$

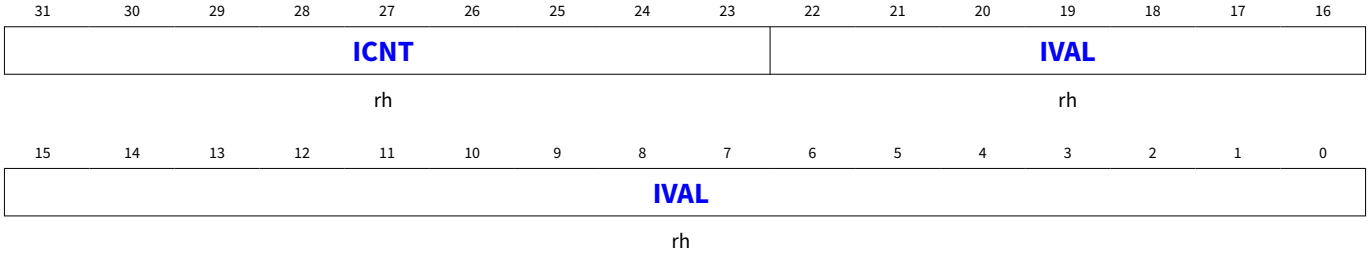


Field	Bits	Type	Description
WC	3	rw	**Window control** 0_B Internal control : trigger controlled software function will be stopped automatically according to the configuration *NOTE: the inverse activation trigger edge will be ignored* 1_B External control : trigger controlled software function will be stopped by the inverse activation trigger edge *NOTE: the FFT will stop automatically according to the configuration, if there was no inverse activation trigger edge during the FFT calculation*
SWMODE	31:30	rw	**Software mode** 00_B Software results transmitted to the result registers as generated, INTIVAL updates blocked, the running DSP is sensitive to wake-up events all the time *NOTE: to be used for filter chains without integrator* 01_B Software results transmitted to the result registers as generated upon write access to RES1, INTIVAL updates together with RES1 and RES2, the running DSP is sensitive to wake-up events all the time *NOTE: to be used for filter chains with integrator* 10_B Software results transmitted to result registers as generated, INTIVAL updates blocked, the running DSP is sensitive to wake-up events until write access to RES2 *NOTE: to be used for FFT, wake-up event sensitivity will be re-established with software function reactivation or when changing SWMODE* 11_B Reserved
0	2:0, 29:4	r	**Reserved** Read as 0; should be written with 0

45.8.176 CDSPa intermediate integration value

CDSP_DSPa_INTIVAL (a=0-11) Offset address: $C1C2C_H+a*2000_H$

CDSPa intermediate integration value Kernel Reset value: $0000\ 0000_H$

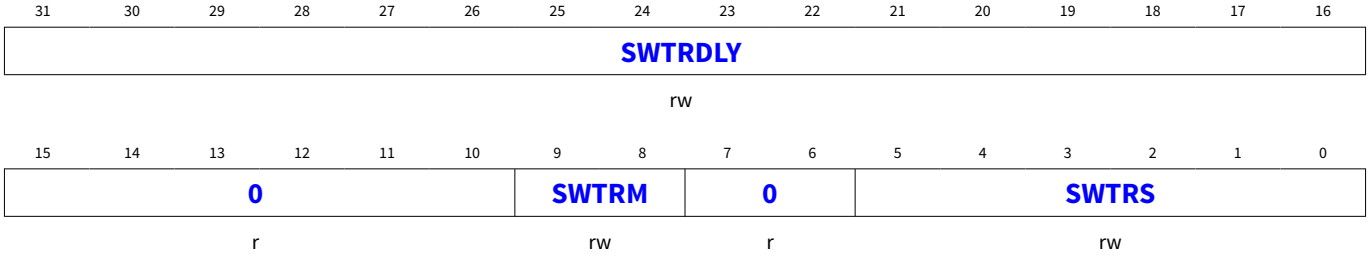


Field	Bits	Type	Description
IVAL	22:0	rh	**Integrator intermediate value**
ICNT	31:23	rh	**Integrator intermediate count**

45.8.177 CDSPa software trigger configuration register

CDSP_DSPa_SWTRCFG (a=0-11) Offset address: $C1C30_H+a*2000_H$

CDSPa software trigger configuration register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SWTRS	5:0	rw	**Software trigger source for the configured software function** Refer "Hardware triggers to ADC" about the trigger source definition.
SWTRM	9:8	rw	**Trigger mode select** 00_B No trigger edge selected, trigger controlled software function deactivated 01_B Rising trigger edge selected to (re)activate the trigger controlled software function 10_B Falling trigger edge selected to (re)activate the trigger controlled software function 11_B No trigger edge selected, trigger controlled software function activated *NOTE: IF SWTRM=11, the FFT will stop automatically according to the configuration (at the end of the FFT calculation) if it was not stopped before by setting SWTRM=00. The FFT can be restarted e.g. by setting SWTRM=00 and then SWTRM=11.*
SWTRDLY	31:16	rw	**Trigger delay** Controls how much the selected trigger shall be delayed before being executed. NOTE: The time between two equal trigger edges must be greater or equal the configured delay value, else an error event will be generated.

(table continues...)

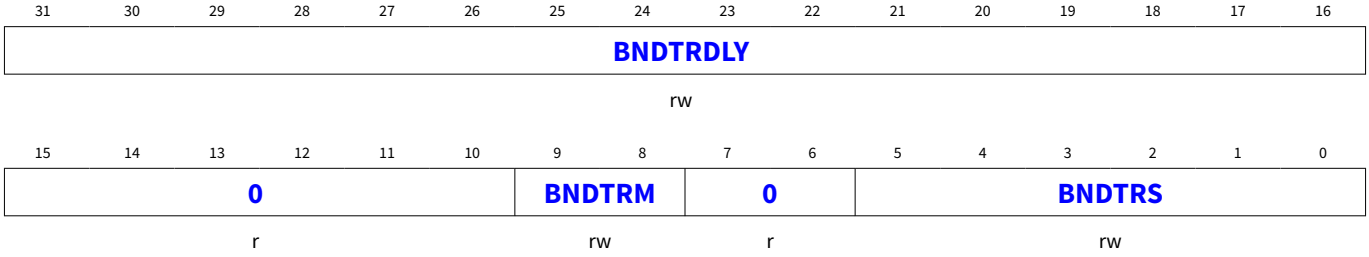
CRESULTLO	15:0	rh	**CDSP result value lower part** Returns the next value from the result FIFO
CRESULTHI	31:16	rh	**CDSP result value higher part** Returns an additional value

45.8.182 CDSPa boundary trigger configuration register 1

Configures the trigger source, trigger mode and trigger delay for the update of the boundary values in CDSP.

CDSP_DSPa_BNDTRCFG1 (a=0-11) Offset address: $C1C4C_H+a*2000_H$

CDSPa boundary trigger configuration register 1 Kernel Reset value: $0000\ 0000_H$



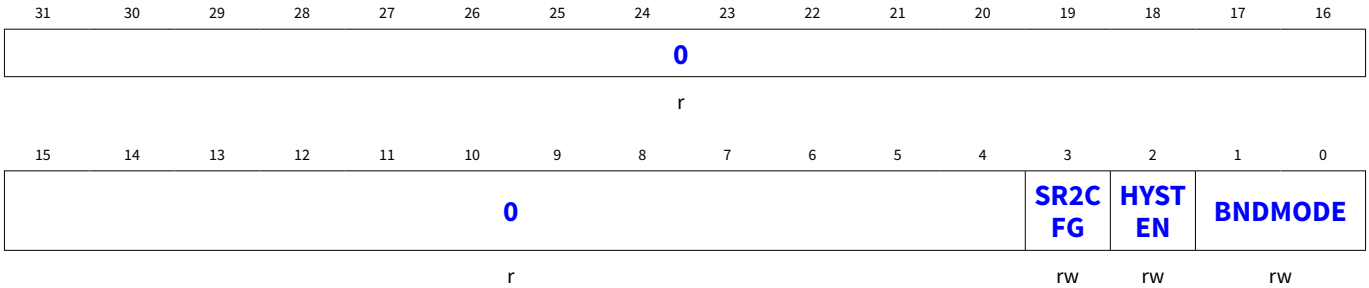
Field	Bits	Type	Description
BNDTRS	5:0	rw	**Trigger selection select for boundary value update** Refer "Hardware triggers to ADC" about the trigger source definition. 1)
BNDTRM	9:8	rw	**Trigger mode select** 00_B No trigger selected, Boundary update immediately 01_B Boundary update on the rising edge of the trigger 10_B Boundary update on the falling edge of the trigger 11_B Boundary update at both rising and falling edges
BNDTRDLY	31:16	rw	**Trigger delay** Controls how much the selected trigger shall be delayed before being executed The period of the configured edge(s) shall be longer than the configured delay value, else a trigger error event will occur
0	7:6, 15:10	r	**Reserved** Read as 0; should be written with 0

1) To avoid unintended triggers, select the trigger source first before enabling the corresponding function.

45.8.183 CDSPa boundary mode configuration register 1

CDSP_DSPa_BNDCFG1 (a=0-11) Offset address: $C1C50_H+a*2000_H$

CDSPa boundary mode configuration register 1 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
BNDMODE	1:0	rw	**Boundary flag mode** Defines the conditions in which boundary flag shall be raised 00_B Disabled 01_B Boudary flag is high when result exceeds upper limit 10_B Boudary flag is high when result is lower than lower limit 11_B Boudary flag is high when result is out of the band
HYSTEN	2	rw	**Hysteresis enable** Enables the hysteresis mode. In this mode BNDMODE configuration is ignored
SR2CFG	3	rw	**Conditions under which SR2 is generated** 0_B If the result is inside boundary band 1_B If the result is outisde the boudary band
0	31:4	r	**Reserved** Read as 0; should be written with 0

45.8.184 CDSPa boundary status register 1

Boundary status register gives the current used boundary values for limit checking.

CDSP_DSPa_BOUNDST1 (a=0-11) Offset address: $C1C54_H+a*2000_H$

CDSPa boundary status register 1 Kernel Reset value: $0000\ 0000_H$

RESULTHI	31:16	rh	**Result value higher part** Returns an additional value

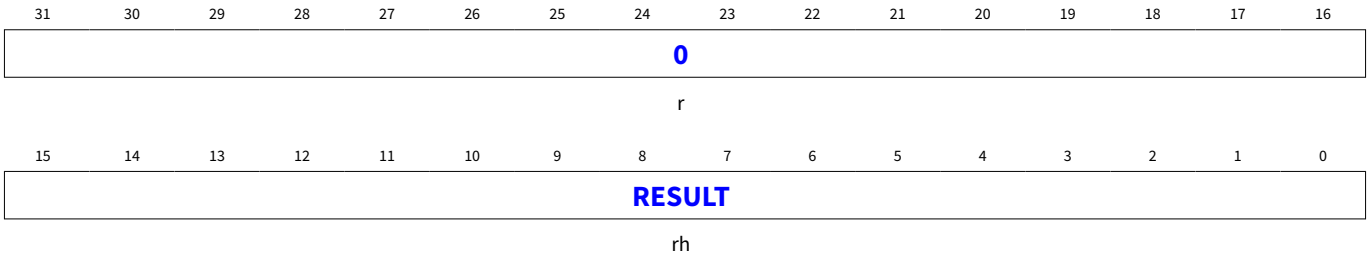
45.8.196 EXMODz result register auxiliary

DSADCRES_EXz_RESA (z=0-7) Offset address: $28004_H+z*400_H$

EXMODz result register auxiliary Kernel Reset value: $0000\ 0000_H$

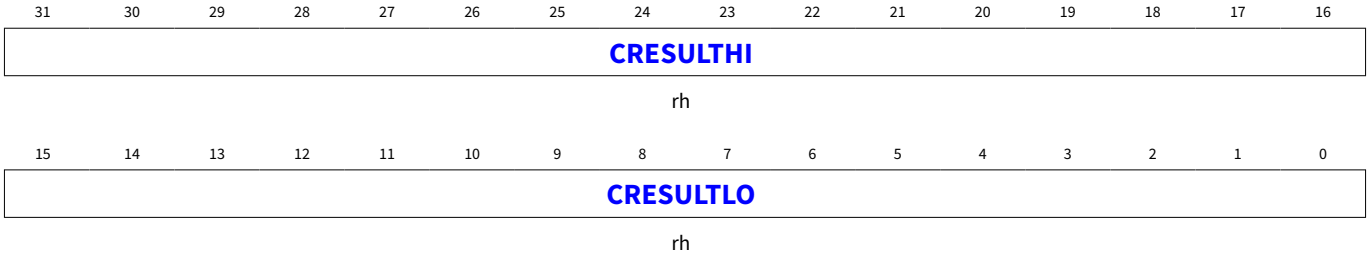


Field	Bits	Type	Description
RESULT	15:0	rh	**Most recent result of auxiliary filter**
0	31:16	r	**Reserved** Read as 0; should be written with 0

45.8.197 CDSPa result register y

CDSPRESa_RESy (a=0-11;y=0-2) Offset address: $2B000_H+a*2000_H+y*4$

CDSPa result register y Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CRESULTLO	15:0	rh	**CDSP result value lower part** Returns the next value from the result FIFO
CRESULTHI	31:16	rh	**CDSP result value higher part** Returns an additional value

45.9 Debug information

TMADC, DSADC, EXMOD and CDSP provide individual registers for on-chip debug support. They control suspend modes and provide debug status information..

***Note**: When a module is suspended, user shall avoid kernel reset, it may result in wrong suspend status information.*

TMADC debug information

TMADC debug can be configured by the register OCSTM. Two trigger sets provide trigger information for start of conversion per TMADC instance. Select trigger sets through bit-field TGS. The selected trigger set can be output to OTGB0 or OTGB1. It is configured with bit-filed TGB. Source (TMADC instance) for the trigger set can be configured by bit-fields TRIG1SEL and TRIG2SEL (Figure below).

***Note**: Start of Conversion (SoC) is a trigger with pulse-width of 1 fSPB.*

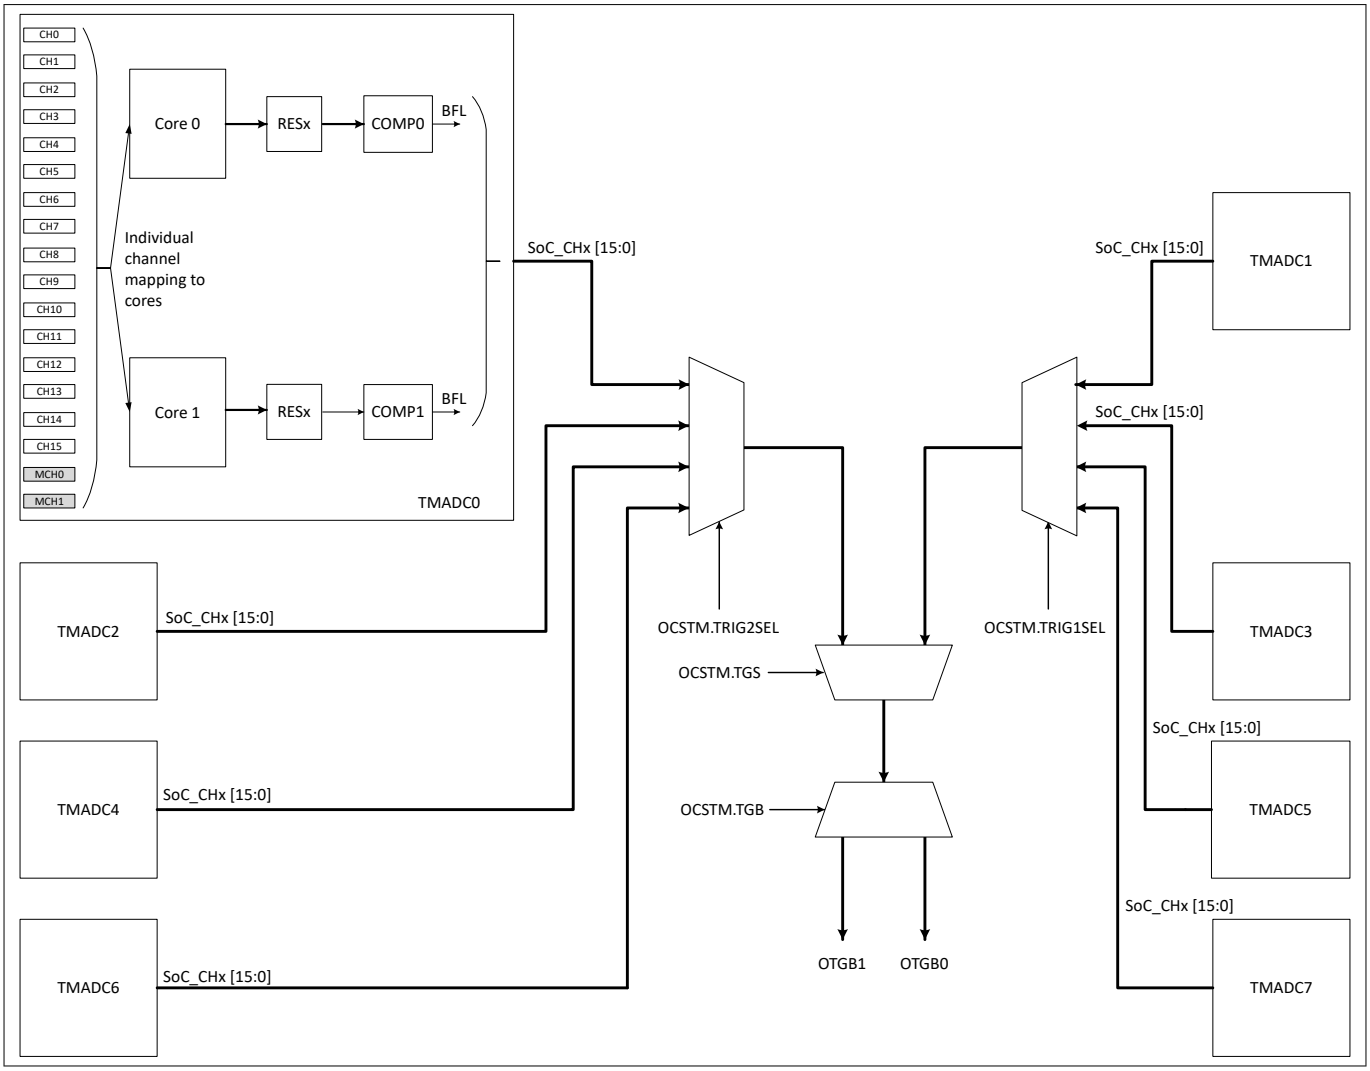


Figure 1242 Trigger source select from TMADC to OTGB

TMADC supports hard and soft suspend modes. They are selectable through bit-field SUSM. In hard suspend mode; SUSM = 01_B, module clock is immediately stopped. This may result in states not expected as static.

***Note**: Hard suspend mode shall be avoided, soft suspend modes are more useful for TMADC.*

In the soft suspend mode; SUSM = 11_B, TMADC will suspend after finishing all conversions which are in hold-state and waiting for conversion on Core 0 & Core 1. If the digital comparator is configured, the generated result is compared to threshold and a boundary flag is generated before module is suspended. User can decide to suspend multiple TMADC modules. The TMADC modules can be suspended by writing into bit-filed SUS. The status of the corresponding TMADC module is reflected in bit-field SUSTA.

Bit-fields TG_P and SUS_P protect against unintended trigger set selection and unintended module suspension.

***Note**: The first conversion result coming out of soft suspend mode will be inaccurate.*

DSADC and EXMOD debug information

DSADC and EXMOD channels can be debugged by configuring the register DSADC_OCSDSADC and DSADC_OCSEXMOD respectively.

***Note**: No trigger set on OTGB is supported by DSADC and EXMOD.*

DSADC and EXMOD support hard and soft suspend modes. In the hard suspend mode; SUSM = 01_B, module clock is immediately stopped. This may result in some unexpected static states.

***Note**: Hard suspend mode shall be avoided, soft suspend modes are more useful for DSADC and EXMOD.*

In the Soft suspend mode SUSM = 10_B DSADC and EXMOD module will suspend immediately after generating an auxiliary filter chain output. In the Soft suspend mode SUSM = 11_B the DSADC and EXMOD channels will suspend after generating a final result from the main filter chain. If the digital comparator is configured, the generated result is compared to thresholds and a boundary flag is generated before module is suspended. User can decide to suspend multiple DSADC and EXMOD channels by writing into bit-filed SUS. The status of the suspended channel i is reflected in bit-field SUSTA at bit i.

Bit-field SUS_P, protects against unintended module suspension.

CDSP debug information

CDSPs can be debugged by configuring the register CDSP_OCSCDSPA and CDSP_OCSCDSPB . CDSP_OCSCDSPB does exist for devices with more than 9 CDSP core instances.

***Note**: No trigger set on OTGB is supported by CDSP.*

CDSP supports hard and soft suspend modes. In the hard suspend mode; SUSM = 01_B module clock is immediately stopped.

***Note**: Switching to hard suspend mode may corrupt ongoing program execution after suspend mode is left and it may corrupt ongoing data memory accesses. Hard suspend mode shall be avoided, soft suspend modes are more useful for CDSP.*

In the Soft suspend mode; SUSM = 10_B CDSP will suspend operation immediately after processing the current input sample. In case a CDSP is in Halt state (indicated by CDSP_GLOBRSD.DSPRSTi= 0), it will suspend immediately.

In the Soft suspend mode; SUSM = 11_B, the CDSP will suspend after generating final result in result register RES0. In both the soft suspend modes, if the digital comparator is configured, the generated result is compared to thresholds and a boundary flag is generated before module is suspended. User can decide to suspend multiple CDSPs by writing into bit-filed SUS. The status of the corresponding suspended channel is reflected in bit-field SUSTA.

***Note**: DCCM, ICCM and DSP debug registers can not get read in suspend mode.*

Bit-field SUS_P, protects against unintended module suspension.

DSP debug access

The CDSP includes feature extensions and an embedded DSP core. Direct debug of the DSP is controlled with dedicated registers shown in the table below.

Table 2407 DSP debug registers

Register	Use
CDSP_DBd_STATUS	Provides status of all DEBUG operations. Writing to this register initiates the debug operation defined in CDSP_DBd_CMD
CDSP_DBd_CMD	Defines the debug command (read/write to aux/core/mem)
CDSP_DBd_AD	Specifies auxiliary/core/memory address location
CDSP_DBd_DATA	Specifies the data to be written for debug write operations and holds the returned data for debug read operations
CDSP_DBd_RESET	Writing triggers a reset of DSP internal debug registers. Deviation from DSP specification.

For details about debug commands please refer to the Synopsys document 'DesignWare ARC EM Databook'.

45.9.1 ARC DSP core debug features

ARM Peripheral Bus (APB) port access allows to debug the core. The debug APB port is used to interface external host (or debugger) to the resources available to the ARC EM core, including internal registers and the entire memory space.

The Debug interface is made available for systems that require access to the internals of the core. The interface is composed of memory mapped setup registers that can be written to initiate read and write operations to internal core/auxiliary registers and memory locations, as well as control operations such as instruction-stepping.

Configuration options of ARC core debug and status informations are provided by CDSP_DB_ADDR, CDSP_DB_CMD, CDSP_DB_DATA, CDSP_DB_RESET and CDSP_DB_STATUS.

Writing to the register CDSP_DB_RESET only triggers the reset of the DSP internal debug registers CDSP_DBd_ADDR and CDSP_DBd_DATA. This is a deviation from the DSP specification where CDSP system reset functionality is named and the CDSP_DBd_CMD register is reset in addition. Complete CDSP logic can get reset using Kernel reset.

CDSP_DB_STATUS.RA can be cleared by clearing the RA bit of DSP internal auxiliary register DEBUG, address 0x05.

45.9.1.1 Debug Access to ARC Core over APB

To access registers and memory within an ARC core you first need to set up the access with the DB_ADDR and DB_STATUS registers The remainder of this section lists example sequences for reads and writes.

45.9.1.1.1 Example Sequence to Read From ARC IDENTITY Register

- Read DB_STATUS (0xFFFF_0000), check bit 2 set and bit 0 clear.
- Write address to DB_ADDR (0xFFFF_0008) with 0x4.
- Write command to DB_CMD (0xFFFF_0004) with 0x6 (read from auxiliary register).
- Write DB_STATUS (0xFFFF_0000) with any value to trigger the access.
- Read DB_STATUS until bit 2 set, bit 0 clear to indicate the access has completed.
- Read data from DB_DATA (0xFFFF_000C) - should be 0x054 for ARC HS processor (single core, ARCNUM = 0) or 0x44 for ARC EM processor (single core, ARCNUM = 0).

45.9.1.1.2 Example Sequence to Write to the ARC Memory

- Read DB_STATUS (0xFFFF_0000), check bit 2 set and bit 0 clear (can be omitted if not the first access for a sequence).
- Write memory address to DB_ADDR (0xFFFF_0008).
- Write data value to DB_DATA (0xFFFF_000C).
- Write DB_CMD with 0x00 (write to memory location).
- Write DB_STATUS (0xFFFF_0000), with any value to initiate the access.
- Read DB_STATUS (0xFFFF_0000), until bit 2 set, bit 0 cleared to indicate the access completed, failure is indicated if bit 1 is set.

45.9.1.1.3 Example Sequence to Write Then Read an ARC Core Register

Write:

- Read DB_STATUS (0xFFFF_0000), check bit 2 set and bit 0 clear.
- Write address to DB_ADDR (0xFFFF_0008) with 0x0.
- Write test data to DB_DATA (0xFFFF_000C) - for example, 0xcafef00d.
- Write command to DB_CMD (0xFFFF_0004) with 0x1 (write to core register).
- Write DB_STATUS (0xFFFF_0000), with any value to trigger the access.
- Read DB_STATUS (0xFFFF_0000), until bit 2 set, bit 0 clear to indicate the access has completed.

Read Back:

- Write address to DB_ADDR (0xFFFF_0008) with 0x0.
- Write command to DB_CMD (0xFFFF_0004) with 0x5 (read from core register).
- Write DB_STATUS (0xFFFF_0000), with any value to trigger the access.
- Read DB_STATUS (0xFFFF_0000),until bit 2 set, bit 0 clear to indicate the access has completed.
- Read data from DB_DATA (0xFFFF_000C), compare with written value.

45.9.1.2 Interface Signals

***Note**: The interface supports synchronous clock ratios between the core clock and the APB debug-port clock using a clock-enable input to indicate cycles with a rising edge in both domains.*

Table 2408 APB Interface Signals

Name	Width	Direction	Comment
pclkdbg_en	1	Input	APB clock enable (tie to 1'b1 for 1:1 clocking)
presetdbgn	1	Input	Active low reset
paddrdbg	30 [31:2]	Input	32-bit addressing only
pseldbg	1	Input	Selects the external debug interface
penabledbg	1	Input	Indicates second, and subsequent, cycle of a transfer
pwritedbg	1	Input	Indicates access is a write transfer Distinguishes between a read, LOW, and a write, HIGH
pwdatadbg	32	Input	Writer data bus

(table continues...)

Table 2408 (continued) APB Interface Signals

Name	Width	Direction	Comment
preadydbg	1	Output	Extends a APB transfer by the inserting wait states.
prdatadbg	32	Output	Read data bus.
pslverrdbg	1	Output	Slave-generated error response.
dbg_prot_sel	1	Input	Assert high to select the APB port. Assert low to select the BVCI debug port.

Table 2409 CoreSight Authentication Interface Signals

Name	Width	Direction	Comments
dbgen	1	Input	Authentication interface (tie high if not in use)
niden	1	Input	Authentication interface (tie high if not in use)

For full details on the CoreSight Authentication Interface, see the ARM CoreSight Architecture Specification.

45.10 References

For more information about the CDSP programming, user can refer to:

- ARC V2 programmers reference for ARC EM 5 processor

45.11 ADC revision history

Reference	Description of change(s)
Date range: 2025-03-14 to 2025-04-11	
Global service request and alarm generation, Boundary flag interface to timer, Central functions (CDSP), Limit checking (CDSP)	• Additional limit check resource options per CDSP
Time-stamp support (CDSP)	• Typo fixed: figure title "Time-stamp generation" moved to the right position
Date range: 2024-11-22 to 2025-03-13	
Trigger handling and arbitration (TMADC)	• Extended exception to cover implementation
Channel-core self diagnostics (TMADC)	• Added CSD implementation option for RRAM devices
External multiplexer control (TMADC)	• Clarification on minimum sampling time for EMUX channels
Functional overview (DSADC)	• Corrected EXMOD channels from [8:1] to [7:0] • Replaced VREFX with VDDM/2
Gain adjustment (DSADC)	• Gain adjustment calculation corrections
Group delay and setting time (DSADC)	• Correction of group delay and settling time calculation
Ramp mode (FCC)	• Set minimum glitch filter depth in FCC ramp mode #5 to 4
Date range: 2024-08-17 to 2024-11-21	
On-chip signal monitoring and supervision	• Revised description of V_{DDK} measurement
Module start-up calibration, Single channel one-shot conversion	• Corrected references to data-sheet parameter t_{CAL}
Figure 1183, ADC interface to GTM and eGTM, Service request from ADC to GTM	• Additional interrupt routing to TIM (eGTM, GTM)

45.12 TC4Dx ADC information

45.12.1 TC4Dx ADC configuration

Table 2410 ADC configuration for TC4D

Functional block	Number of instances
TMADC	4 (8 cores)
DSADC	0
CDSP	2
FCC	0
EXMOD	0

The following table shows the pull-down diagnostic (PDD) resistor connections in TC4Dx:

Table 2411 Pull-down diagnostic

Control bit	Analog input
PDDCFG.EN0	AN7
PDDCFG.EN1	AN11
PDDCFG.EN2	AN19
PDDCFG.EN3	AN27
PDDCFG.EN4	AN35
PDDCFG.EN5	AN43

***Note**: Not all the analog inputs are available in all packages. Please refer to data-sheet for pinning information.*

Related information

On-chip signal monitoring and supervision on page 8361

45.12.2 TC4Dx ADC features

The functional description is listed in the family part. Please be aware, that no DSADC, EXMOD or FCC blocks exist in this specific device.

45.12.3 TC4Dx ADC functional description

The ADC cluster is connected to the COMPB bus. It does not connect to the Low Latency Interface (LLI).

Due to the absence of DSADC and GTM, the corresponding hardware trigger sources are not available. Similarly, the input of CDSP cannot be connected to the not available DSADC, EXMOD or CARMAG result registers. Further more, the ADI connection between TMADC and GTM does not exist.

CDSP limit checking

TC4Dx does include a single comparator for limit checking per CDSP (family default).

TMADC output supervision signal

Each TMADC module has an output supervision multiplexer to select the output supervision signal (OSS) to be monitored by another TMADC. The signal to be monitored is selected with TMADCx_MODCFG.OSSEL.

Only one TMADC output signal can be selected for output supervision signal generation at any given time and the module selection is made through bit SEL in the TMSMOD register.

The supervision signals are connected to the monitor channels MCH0 of TMADC1 and MCH1 of TMADC2 as shown in the following figure:

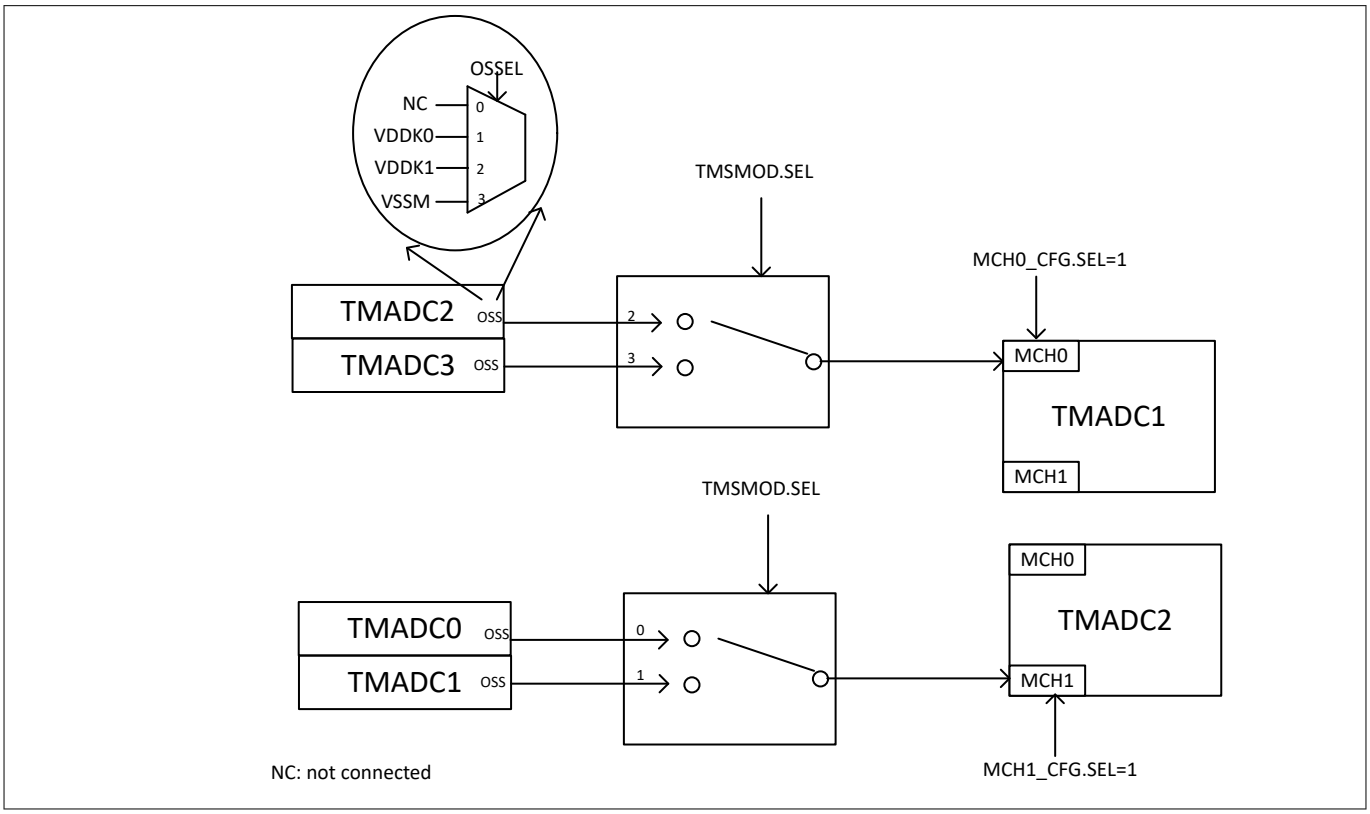

Figure 1243 TC4Dx supervision signal

45.12.4.8 ADC global service request i configuration register

Global service requests are used for generating result events to IR when a set of analog channles have finished converting and results of these channels are available. The set of analog channels in this case are distributed across different TMADC instances. Global service requests are limited to TMADC channels.

Only the service request configured with SRCFG6 register in TMADCx is a valid input to the global service request.

ADC_GLSRCFGi (i=0-3) Offset address: 00800_H+i*4

ADC global service request i configuration register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0							EVOP	0				EVEN			
r							rw	r				rw			

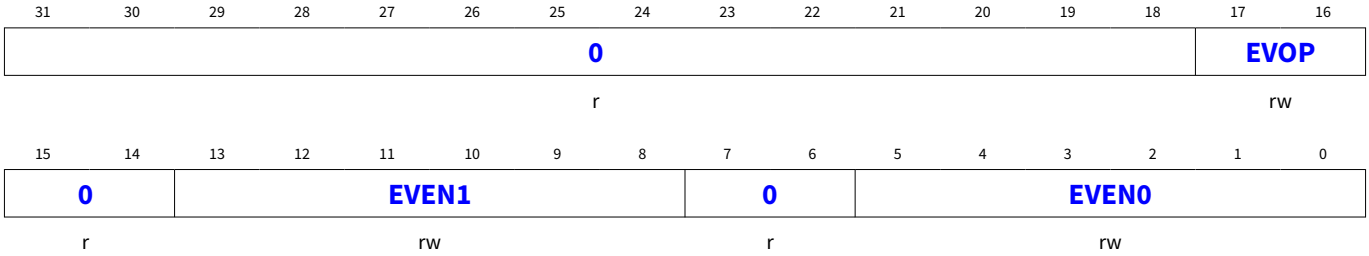
Field	Bits	Type	Description
EVEN	3:0	rw	**Event Enable** Each bit in this bitfield, if set, enables the event on SR6 for the corressponding TMADCx to be an input to the corressponding global service request 0_B Event disabled 1_B Event enabled
EVOP	8	rw	**Event Operation** This bit defines what logical operation shall be executed and under which situation global service request is generated 0_B OR logic operation 1_B AND logic operation
0	7:4, 31:9	r	**Reserved** Read as 0; should be written with 0

45.12.4.9 ADC global alarm i configuration register

Global alarms are used for generating alarms to SMU and also same alarms go as interrupts to IR. They can be generated combining 2 bounday flags from any converter.

ADC_GLALCFGi (i=0-7) Offset address: 00810_H+i*4

ADC global alarm i configuration register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EVEN0	5:0	rw	**Event Enable** 1st input to alarm generation. Select one of the 64 boundary flags. BFL0 - BFL15 are from TMADC. 2 BFLs for each TMADC BFL16-BFL25 are from FC. 1 BFL from each FC BFL26 - BFL35 are from DSINT. 1 BFL from each DSINT BFL36-BFL43 are from DSEXT. 1 BFL from each DSEXT BFL44-BFL61 are from CDSPs. 1 BFL from each CDSP BFL62 and BFL63 are reserved and not connected

(table continues...)

(continued)

Field	Bits	Type	Description
EVEN1	13:8	rw	**Event Enable** 2nd input to alarm generation. Select one of the 64 boundary flags. BFL0 - BFL15 are from TMADC. 2 BFLs for each TMADC BFL16-BFL25 are from FC. 1 BFL from each FC BFL26 - BFL35 are from DSINT. 1 BFL from each DSINT BFL36-BFL43 are from DSEXT. 1 BFL from each DSEXT BFL44-BFL61 are from CDSPs. 1 BFL from each CDSP BFL62 and BFL63 are reserved and not connected
EVOP	17:16	rw	**Event Operation** This bit defines what logical operation shall be executed and under which situation global service request is generated 00_B Alarm disabled 01_B OR logical operation The input to the OR gate are the input selected by EVENT0 and EVENT1. As soon as first high input comes then the alarm is generated. Every time there is a high input on EVENT0 or EVENT1 an alarm is generated 10_B AND logical operation The input to the AND gate are the input selected by EVENT0 and EVENT1. If EVENT0 and EVENT1 are coming at different time, the events remain latched until the alarm is generated 11_B Reserved
0	7:6, 15:14, 31:18	r	**Reserved** Read as 0; should be written with 0

45.12.4.10 ADC to eGTM boundary flag select register, cluster x

ADC_ETBFxSEL (x=0-2) Offset address: 00838_H+x*4

ADC to eGTM boundary flag select register, cluster x Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

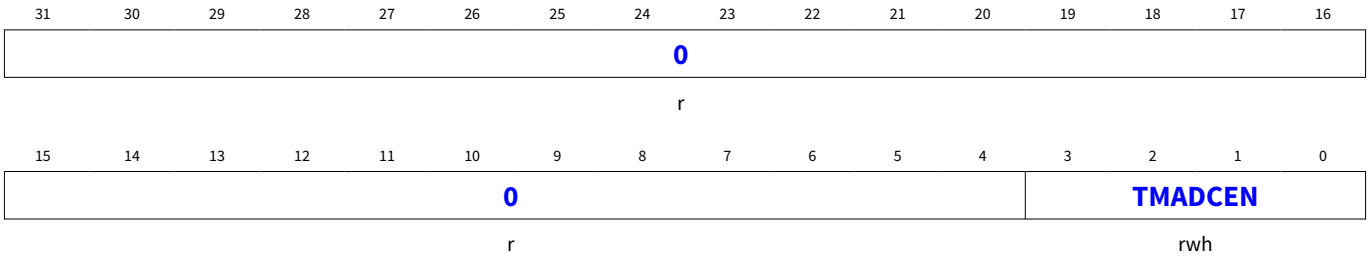
OUTySEL (y=2-3)	6*y+9:6*y+4	rw	**Boundary flag y output select** 00_H Boundary flag 0 selected 01_H Boundary flag 1 selected 02_H Boundary flag 2 selected … $3F_H$ Boundary flag 63 selected
0	15:12, 31:28	r	**Reserved** Read as 0; should be written with 0

45.12.4.11 Clock enable for TMADC

ADC_CLKEN_TMADC Offset address: 00890_H

Clock enable for TMADC Kernel Reset value: $0000\ 0000_H$



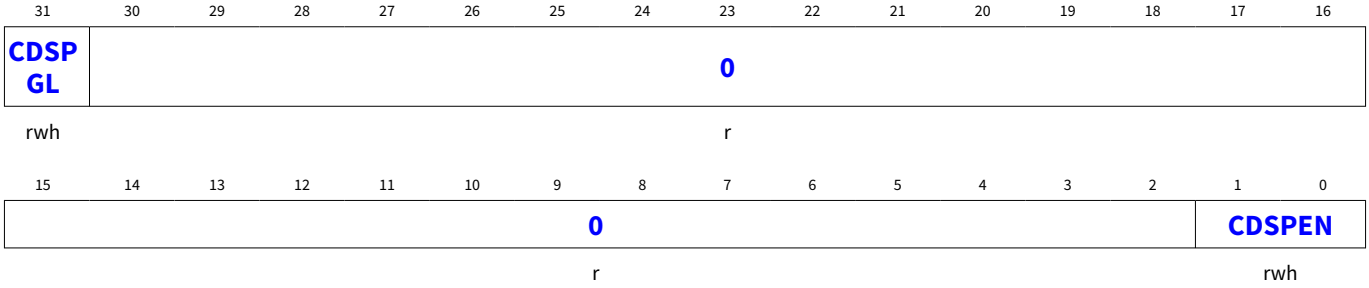
Field	Bits	Type	Description
TMADCEN	3:0	rwh	**Clock enable for TMADC** Each bit controls the clock for the corresponding TMADC channel. E.g: bit0 for TMADC0. 0 - No action 1 - Clock enable for TMADC instance
0	31:4	r	**Reserved** Read as 0; should be written with 0

45.12.4.12 Clock enable for CDSP

- No action
- Clock enable for CDSP instance

ADC_CLKEN_CDSP Offset address: $0089C_H$

Clock enable for CDSP Kernel Reset value: $0000\ 0000_H$



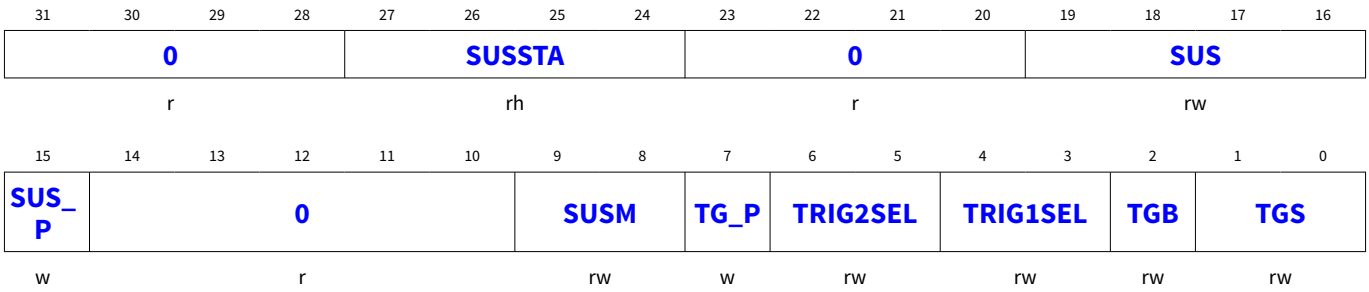
Field	Bits	Type	Description
CDSPEN	1:0	rwh	**Clock enable for corressponding CDSP** When set to '1' clock is enabled for the corresponding CDSP
CDSPGL	31	rwh	**Enables the global part of CDSP** If the user intends to use any CDSP, then this bit shall be set to 1
0	30:2	r	**Reserved** Read as 0; should be written with 0

45.12.4.13 OCDS control and status register for TMADC

This OCDS control and status register controls the debug and trace behavior by selecting suspend modes and OTGB trigger sets. When OCDS is disabled the suspend control is ineffective. This register only controls all instances of TMADC

ADC_OCSTM Offset address: $008A8_H$

OCDS control and status register for TMADC Debug Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TGS	1:0	rw	**Trigger set for OTGB0 and OTGB1** 00_B No trigger set output 01_B Trigger set 1 Start of conversion trigger signal of TMADC input channels. For selecting the right TMADC, refer to TRIG1SEL 10_B Trigger set 2 Start of conversion trigger signal of TMADC input channels. For selecting the right TMADC, refer to TRIG2SEL 11_B Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
TGB	2	rw	**OTGB0 and OTGB1 bus select** 0_B Trigger set is output on OTGB0 1_B Trigger set is output on OTGB1
TRIG1SEL	4:3	rw	**Trigger set 1 select** These bits select which TMADC instance trigger signals are put on trigger set 1 00_B TMADC1 01_B TMADC3 10_B TMADC5 11_B TMADC7
TRIG2SEL	6:5	rw	**Trigger set 2 select** These bits select which TMADC instance trigger signals are put on trigger set 2 00_B TMADC0 01_B TMADC2 10_B TMADC4 11_B TMADC6
TG_P	7	w	**TGS, TGB write protection** TGS,TGB TRIG1SEL and TRIG2SEL are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUSM	9:8	rw	**OCDS suspend control mode - SUS** These bits select the suspend mode for the module 00_B Will not suspend 01_B Hard suspend Clocks will be disabled immediately 10_B Reserved, not to be used Reserved, will not suspend 11_B Soft suspend mode All the channels in hold state for the TMADC will be converted and then module will go into suspend
SUS_P	15	w	**SUS write protection** SUS and SUSM are only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUS	19:16	rw	**OCDS suspend control** Suspends the corresponding TMADC. 0 - Module not suspended, 1 - Module Suspended. Each bit controls a TMADC, with LSB for TMADC0 and MSB for the maximum number of TMADC in device.
SUSSTA	27:24	rh	**Suspend state** Suspend State of TMADC. 0 - Module not suspended. 1 - Module Suspended. Each bit gives status of a TMADC, with LSB for TMADC0 and MSB for the maximum number of TMADC in device.
0	14:10, 23:20, 31:28	r	**Reserved** Read as 0; should be written with 0.

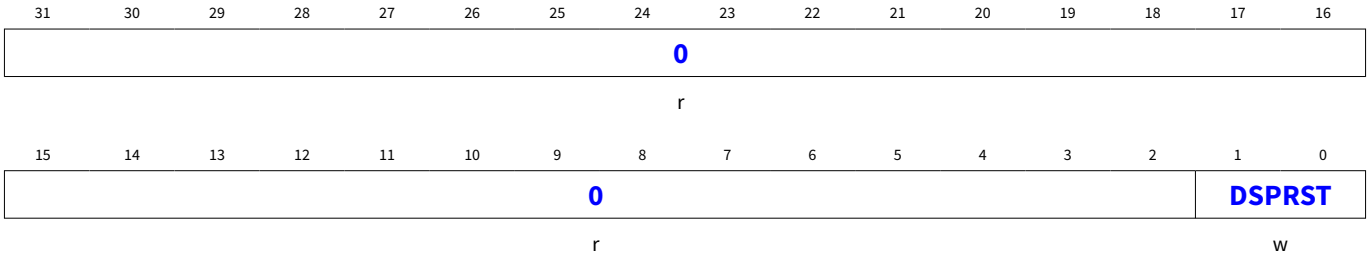
Table 2417 Access mode restrictions of ADC_OCSTM sorted by descending priority

Mode name	Access mode		Description
write 1 to .**TG_P**	rw	TGB, TGS, TRIG1SEL, TRIG2SEL	Set TG_P during write access
write 1 to .**SUS_P**	rw	SUS, SUSM	Set SUS_P during write access
(default)	r	SUS, SUSM, TGB, TGS, TRIG1SEL, TRIG2SEL	

45.12.4.14 CDSP global reset control

ADC_CDSP_GLOBRD Offset address: $BF804_H$

CDSP global reset control Kernel Reset value: $0000\ 0000_H$

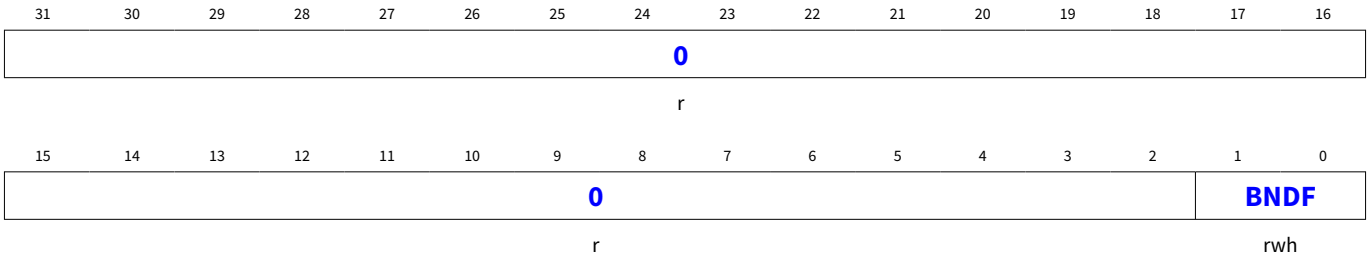


Field	Bits	Type	Description
DSPRST	1:0	w	**DSP reset** Each bit resets the corresponding CDSP instance. For example bit 0 of this register resets CDSP0.
0	31:2	r	**Reserved** Read as 0; should be written with 0

45.12.4.15 CDSP boudary flag event register

ADC_CDSP_BNDCF Offset address: $BF808_H$

CDSP boudary flag event register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
BNDF	1:0	rwh	**Boundary event for CDSP channel** Status of the boundary flag event of the corresponding CDSP instance. For example bit 0 of this register indicates the status of boundary flag event of CDSP0

(table continues...)

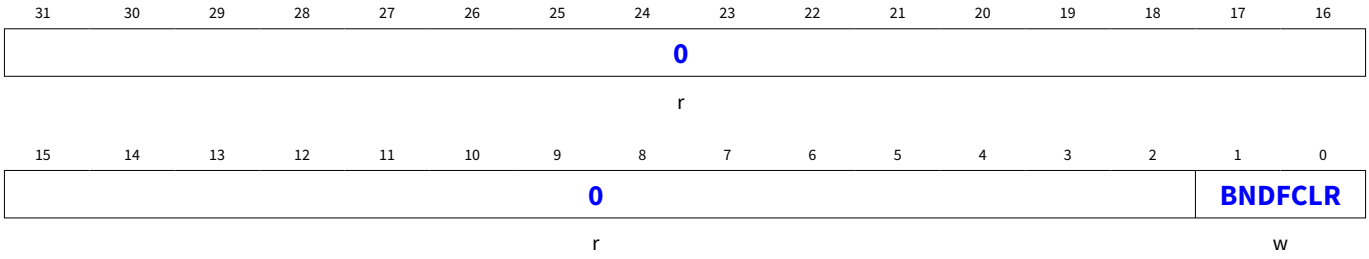
(continued)

Field	Bits	Type	Description
0	31:2	r	**Reserved** Read as 0; should be written with 0

45.12.4.16 CDSP boundary flag event clear

ADC_CDSP_BNDCFCL Offset address: $BF80C_H$

CDSP boundary flag event clear Kernel Reset value: $0000\ 0000_H$

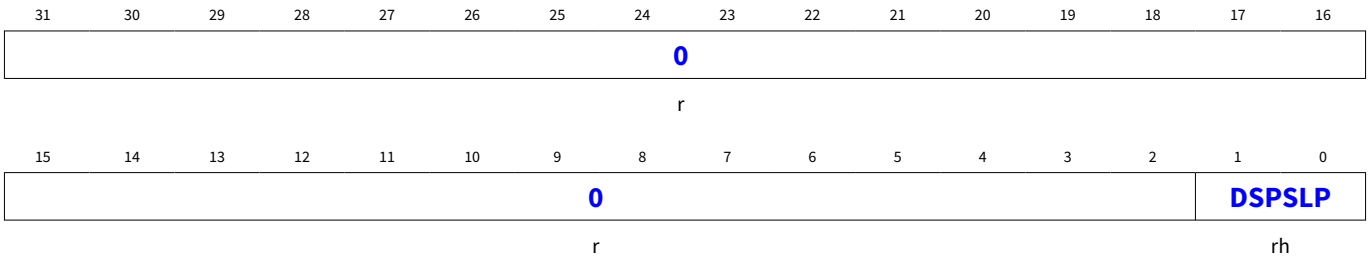


Field	Bits	Type	Description
BNDFCLR	1:0	w	**Boundary event clear for CDSP channels** Setting bits clears the bouandy event of the corresponding CDSP instance. For example bit 0 of this register clears the boundary event of the CDSP0.
0	31:2	r	**Reserved** Read as 0; should be written with 0

45.12.4.17 CDSP sleep status register

ADC_CDSP_SLPST Offset address: $BF810_H$

CDSP sleep status register Kernel Reset value: $0000\ 0000_H$

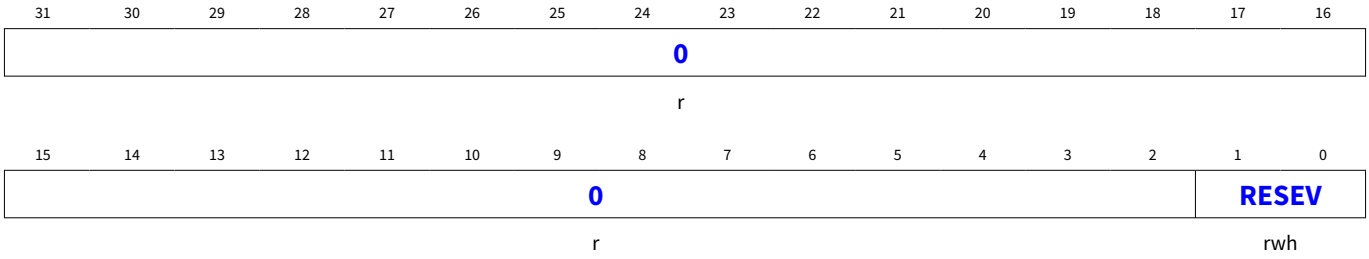


Field	Bits	Type	Description
DSPSLP	1:0	rh	**CDSP sleep status** Sleep status of the DSP core of the corresponding CDSP instance. For example bit 0 of this register indicates the sleep status of the DSP core of the CDSP0.
0	31:2	r	**Reserved** Read as 0; should be written with 0

45.12.4.18 CDSP event flag register y

ADC_CDSP_RESEVy (y=0-2) Offset address: $BF814_H+y*4$

CDSP event flag register y Kernel Reset value: $0000\ 0000_H$

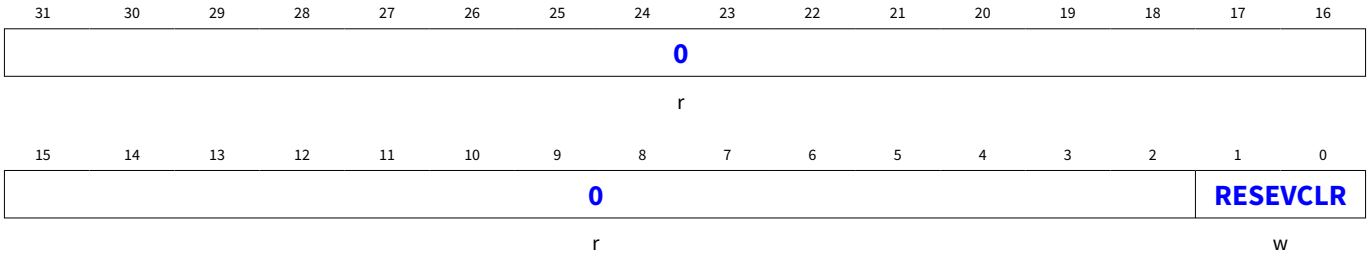


Field	Bits	Type	Description
RESEV	1:0	rwh	**Result event for result register y of CDSP** Status of the result event of the corresponding CDSP instance. For example bit 0 of this register indicates an result event of CDSP0. Reading a result register (CDSP_DSPa_RESy) automatically clears the respective result event in CDSP_RESEVy.
0	31:2	r	**Reserved** Read as 0; should be written with 0

45.12.4.19 CDSP result event flag clear y

ADC_CDSP_RESEVCLRy (y=0-2) Offset address: $BF820_H+y*4$

CDSP result event flag clear y Kernel Reset value: $0000\ 0000_H$

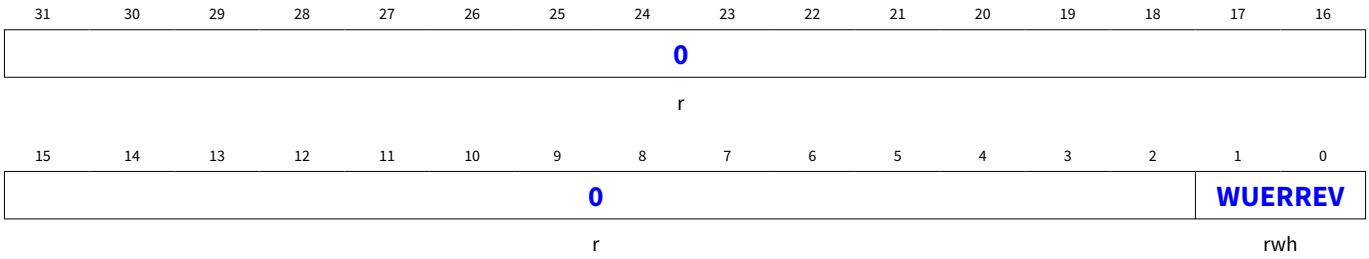


Field	Bits	Type	Description
RESEVCLR	1:0	w	**Result event clear for result register y of CDSP** Each bit clears the result event of the corresponding CDSP instance. For example setting bit 0 of this register clears the result event of the CDSP0.
0	31:2	r	**Reserved** Read as 0; should be written with 0

45.12.4.20 CDSP wake up error flag register

ADC_CDSP_WUERREV Offset address: $BF8D0_H$

CDSP wake up error flag register Kernel Reset value: $0000\ 0000_H$

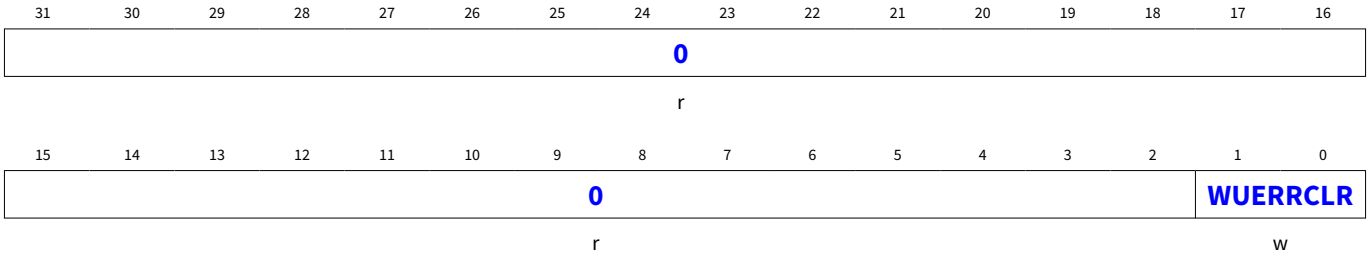


Field	Bits	Type	Description
WUERREV	1:0	rwh	**Wake up error event** Status of the wake up error event of the corresponding CDSP instance. For example bit 0 of this register indicates the status of the wake up error event of CDSP0.
0	31:2	r	**Reserved** Read as 0; should be written with 0

45.12.4.21 CDSP wake up error event clear register

ADC_CDSP_WUERRCL Offset address: $BF8D4_H$

CDSP wake up error event clear register Kernel Reset value: $0000\ 0000_H$

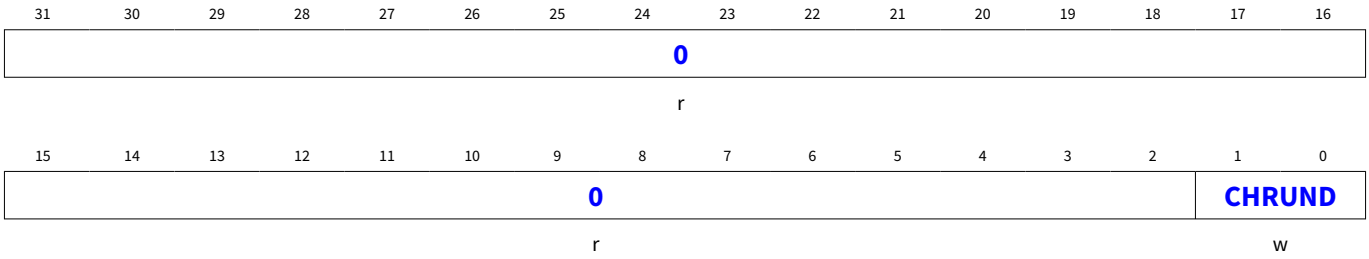


Field	Bits	Type	Description
WUERRCLR	1:0	w	**Wake up error event clear** Each bit clears the wake up error event of the DSP core of the corresponding CDSP instance. For example bit 0 of this register clears the wake up error event of the DSP core of the CDSP0.
0	31:2	r	**Reserved** Read as 0; should be written with 0

45.12.4.22 CDSP global run control register

ADC_CDSP_GLOBRCD Offset address: $BF8D8_H$

CDSP global run control register Kernel Reset value: $0000\ 0000_H$

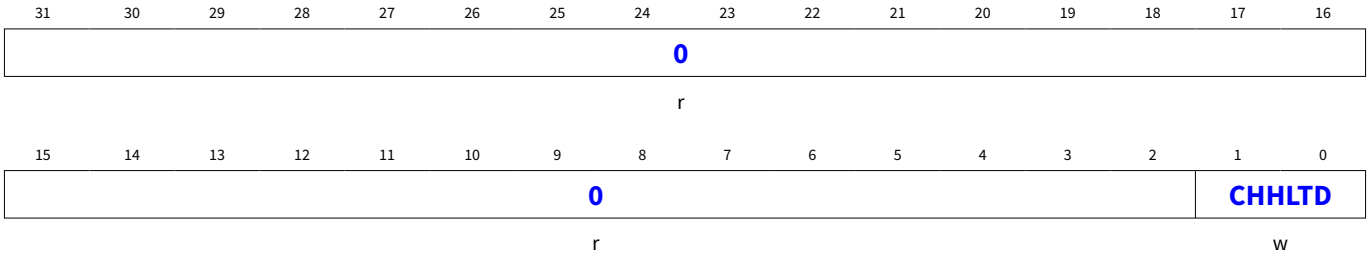


Field	Bits	Type	Description
CHRUND	1:0	w	**Channel run for CDSP** Each bit of this register runs the DSP core of corresponding CDSP and logic around it. By writing '1' the CDSP switches into Run state, i.e program execution starts.
0	31:2	r	**Reserved** Read as 0; should be written with 0

45.12.4.23 CDSP global halt control register

ADC_CDSP_GLOBHCD Offset address: $BF8DC_H$

CDSP global halt control register Kernel Reset value: $0000\ 0000_H$

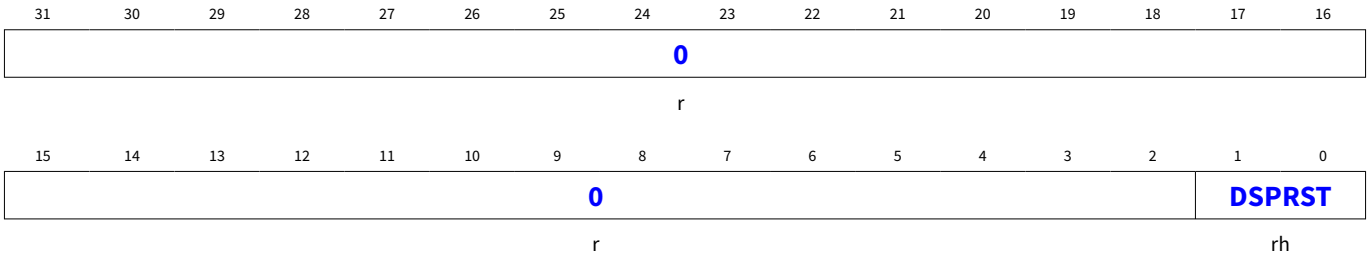


Field	Bits	Type	Description
CHHLTD	1:0	w	**Channel halt for DSP** Each bit of this register halts the DSP core in corresponding CDSP. Read the halt status register to check if DSP has been halted. This register is used, if DSP is halted from outside. For example bit 0 of this register controls the halt of CDSP0.
0	31:2	r	**Reserved** Read as 0; should be written with 0

45.12.4.24 CDSP global run status register

ADC_CDSP_GLOBRSD Offset address: $BF8E0_H$

CDSP global run status register Kernel Reset value: $0000\ 0000_H$

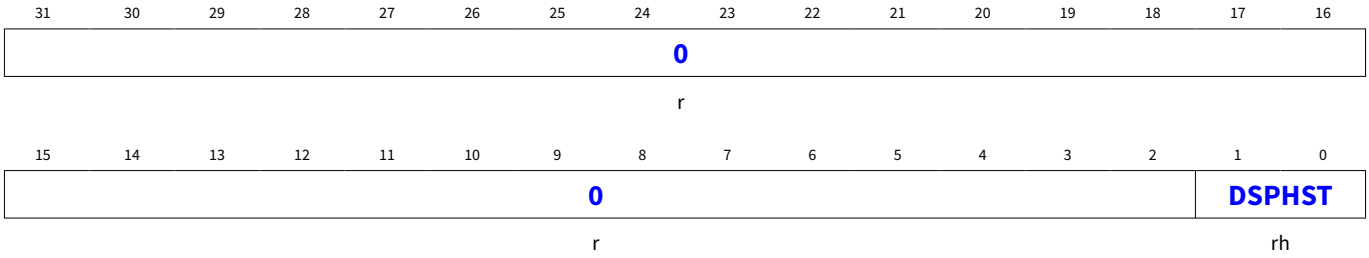


Field	Bits	Type	Description
DSPRST	1:0	rh	**DSP run status** Run status of the DSP core of corresponding CDSP and logic around it. For example bit 0 of this register indicates the Run status of CDSP0. Bit is kept high, until the core goes into Halt status.
0	31:2	r	**Reserved** Read as 0; should be written with 0

45.12.4.25 CDSP global halt status register

ADC_CDSP_GLOBHSTD Offset address: $BF8E4_H$

CDSP global halt status register Kernel Reset value: $0003\ FFFF_H$

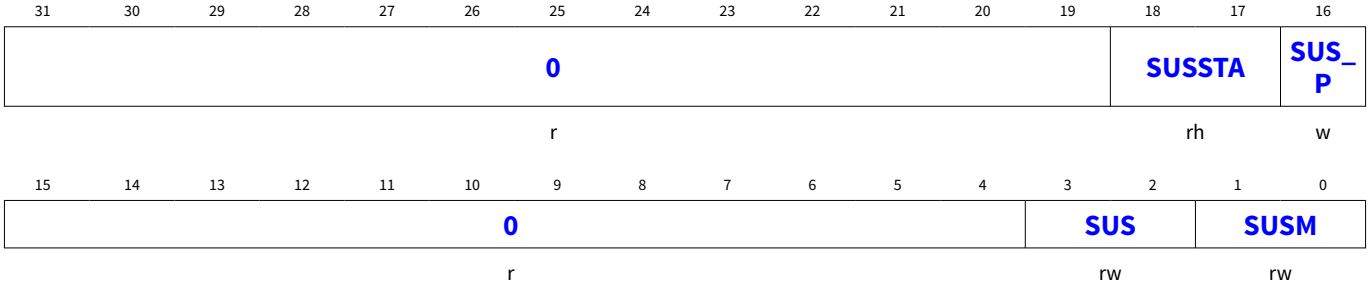


Field	Bits	Type	Description
DSPHST	1:0	rh	**DSP halt status** Halt status of the DSP core of corresponding CDSP and logic around it. For example bit 0 of this register indicates the Halt status of CDSP0. Bit is kept high, until the core goes into Run status.
0	31:2	r	**Reserved** Read as 0; should be written with 0

45.12.4.26 OCDS control and status register 0 for CDSP0-8

ADC_CDSP_OCSCDSPA Offset address: $BF8E8_H$

OCDS control and status register 0 for CDSP0-8 Debug Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SUSM	1:0	rw	**OCDS suspend control mode** Selects the suspend mode for the module. *Note: For reaching soft suspend condition the selected input data source must send enough inputs to the CDSP for a result event to be generated.* 00_B Will not suspend 01_B Hard suspend Clocks will be disabled immediately 10_B Soft suspend mode Clock will be disabled after processing the current sample. 11_B Soft suspend mode Clock will be disabled after generating the next result event, visible in the corresponding bit of CDSP_RESEV0.
SUS	3:2	rw	**OCDS suspend control** Suspends the corresponding CDSP. 0 - Module not suspended, 1 - Module Suspended. Each bit control a CDSP, with LSB for CDSP0 and MSB for the CDSP8. *Note: Please check how many CDSP are there in device*
SUS_P	16	w	**SUS write protection** SUS and SUSM are only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	18:17	rh	**Suspend state** Suspend state of CDSP. 0 - Module not suspended. 1 - Module suspended. Each bit controls a CDSP, with LSB for CDSP0 and MSB for the CDSP8. *Note: Please check how many CDSP are there in device*
0	15:4, 31:19	r	**Reserved** Read as 0; should be written with 0.

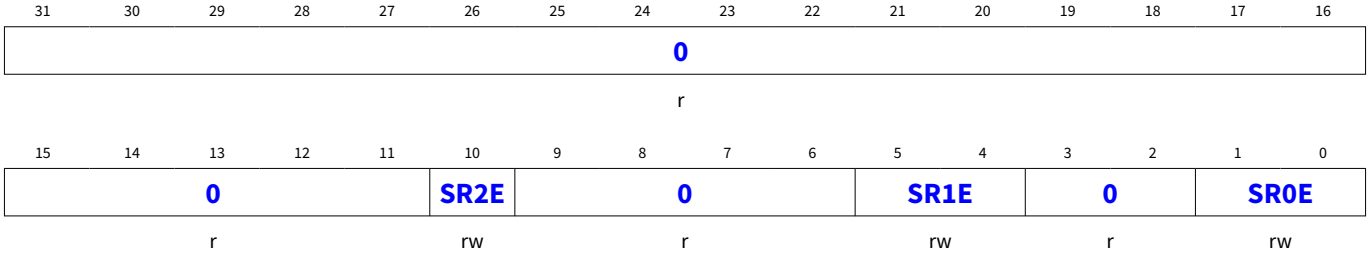
Table 2418 Access mode restrictions of ADC_CDSP_OCSCDSPA sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SUS_P**	rw	SUS, SUSM	Set SUS_P during write access
(default)	r	SUS, SUSM	

45.12.4.27 CDSPa service request configuration register

ADC_CDSP_DSPa_SRCFG (a=0-1) Offset address: $C1C24_H+a*2000_H$

CDSPa service request configuration register Kernel Reset value: $0000\ 0000_H$

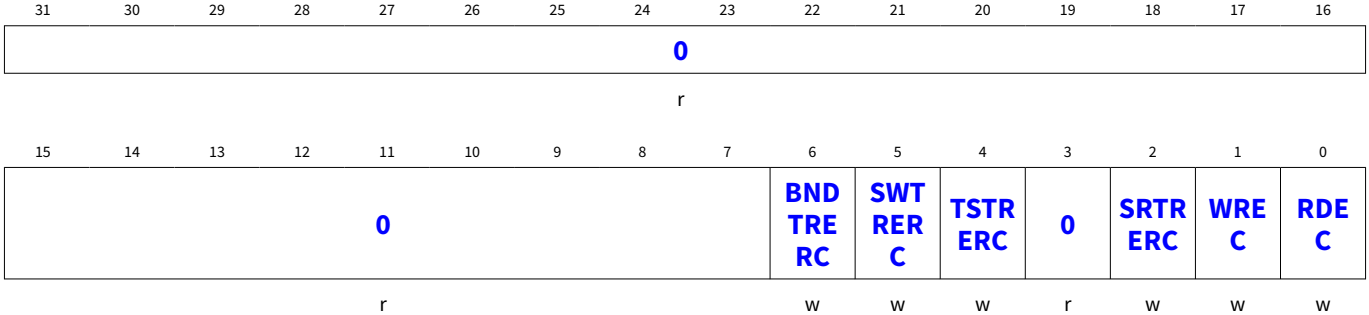


Field	Bits	Type	Description
SR0E	1:0	rw	**Conditions under which SR0 shall be generated** 00_B Never 01_B Generate Service Request only while gate is high 10_B Generate Service Request only while gate is low 11_B Always
SR1E	5:4	rw	**Service request 1 enable** Enable or disable for the service request 1, SR1 is generated at every time stamp generation if enabled 00_B SR1 disabled 01_B SR1 is generated everytime a new timstamp is generated 10_B SR1 is generated when a wakeup error occurs or ARC core is in halt state 11_B SR1 is generated on timestamp generation, wakeup error event or system halt
SR2E	10	rw	**Service request 2 enable** Enable or disable for service request 2, SR2 is generated based on the configured boundary check through SR02CFG in CDSP_DSPa_BNDCFG register
0	3:2, 9:6, 31:11	r	**Reserved** Read as 0; should be written with 0

45.12.4.28 CDSPa channel error clear register

ADC_CDSP_DSPa_CHERRCL (a=0-1) Offset address: $C1C34_H+a*2000_H$

CDSPa channel error clear register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RDEC	0	w	**Read error flag clear** 0_B No action 1_B Clear flag RDERR
WREC	1	w	**Write error flag clear** 0_B No action 1_B Clear flag WRERR
SRTRERC	2	w	**Service request trigger error clear**
TSTRERC	4	w	**Time-stamp trigger error clear**
SWTRERC	5	w	**Software trigger error clear** 0_B No action 1_B Clear flag SWTRER
BNDTRERC	6	w	**Boundary request trigger error clear**
0	3, 31:7	r	**Reserved** Read as 0; should be written with 0

45.12.4.29 CDSPa status register

ADC_CDSP_DSPa_DSPST (a=0-1) Offset address: $C1C38_H+a*2000_H$

CDSPa status register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														FILL	
r														rh	

Field	Bits	Type	Description
FILL	2:0	rh	**FIFO fill level** Not listed combinations are reserved. 000_B Result FIFO is empty 001_B Result FIFO contains 1 valid value 010_B Result FIFO contains 2 valid values 011_B Result FIFO contains 3 valid values 100_B Result FIFO contains 4 valid values

(table continues...)

(continued)

Field	Bits	Type	Description
RDERR	23	rh	**Read error flag** 0_B No problem encountered 1_B A read access occurred while the FIFO was empty A read error is also indicated when a read access occurs during the FIFO's synchronization stall phase (4 fADC after a read access). Clear this sticky flag by writing 1 to bit RDEC.
WRERR	24	rh	**Write error flag** 0_B No problem encountered 1_B A write access occurred while the FIFO was full Clear this sticky flag by writing 1 to bit WREC.
SWTRER	25	rh	**Software trigger error flag** This bit tells the status of the software trigger error flag. If the software trigger could not be executed the bit will be set to 1
TSTRER	26	rh	**Timestamp trigger error flag** This bit tells the status of the timestamp trigger error flag. If the timestamp trigger could not be executed the bit will be set to 1
SRTRER	28	rh	**Service request trigger error flag** This bit tells the status of the service request trigger error flag. If the service request trigger could not be executed the bit will be set to 1
BNDTRER	29	rh	**Boundary update trigger error flag** This bit tells the status of the boundary update trigger error flag. If the boundary update trigger could not be executed the bit will be set to 1
0	22:3, 27, 31:30	r	**Reserved** Read as 0; should be written with 0

45.12.5 TC4Dx ADC connectivity

The table below lists interfaces to and from this functional block to other blocks in the device.

Table 2419 List of ADC interface signals

Interface signals	I/O	Description
LLI_ADC_AXI32S	In	LLI Slave
CLOCK_ADC_fADC	In	ADC Clock
ADC_EGTM_CLUSTERx_BFLY[3:0]x=[2:0]	Out	Each eGTM Cluster with TIM gets 4 flags to be used in TIM and DTM
ADC_PORTS_BFL[9:0]	Out	Connecting FCC BFL to PORTS
ADC_PORTS_EMUXCTRL[5:0]	Out	TMADC EMUX0 & EMUX 1 CTRL signals
EGTM_ADC_TRIG[11:0]	In	Each GTM cluster with TOM & ATOM generated 4 trigger and cluster with ATOM only 2 trigger signals
SCU_ADC_ERU[7:0]	In	8 trigger signals coming from ERU

(table continues...)

Table 2419 (continued) List of ADC interface signals

Interface signals	I/O	Description
PORTS_ADC_TRIG[62:56]	In	8 trigger signals coming from PORTS
PORTS_ADC_DATA[7:0]	In	Data input from PORTS to EXMOD
PORTS_ADC_CLK[7:0]	In	Clock input from PORTS to EXMOD
ADC_PORTS_CLK[3:0]	Out	Clock outputs from EXMOD to PORTS
ADC_PORTS_PWM[1:0]	Out	Carrier Generator Output
PORTS_ADC_SIGN[1:0]	In	Sign input Carrier Signal
ADC_IR_SRC_ADCSR[3:0]	Out	Global Service request from ADC to IR
ADC_IR_SRC_ADCSR[11:4]	Out	Alarms also routed as SR
ADC_IR_SRC_TMADCxSR[5:0]x=[6:0]	Out	TMADC Service request to IR
ADC_EGTM_SRC_TMADCxSR[5:0]x=[6:0]	Out	TMADC Service request to eGTM
ADC_IR_SRC_FCCxSR[1:0]x=[9:0]	Out	FCC Service reuqest to IR
ADC_IR_SRC_DSADCxSR[3:0]x=[9:0]	Out	DSADC Service request to IR
ADC_IR_SRC_EXMODxSR[3:0]x=[7:0]	Out	External Modulator Service request to IR
ADC_IR_SRC_CDSPxSR[2:0]x=[11:0]	Out	CDSP Service request to IR
ADC_SMU_ALARM[7:0]	Out	ADC Alarms to SMU
ADC_EGTM_SR[39:0]	Out	EGTM control does collect ADC SRs

TC4Dx ADC connectivity	• PORTS_ADC_TRIG[62:56]: corrected the description from 8 to 7 trigger signals

46 Debug and Trace

The Debug and Trace functions support the developer in analyzing issues on both a software and system level.

The main Debug and Trace system features are:

- Tool access to debug resources and all other address mapped registers and memories
- Routing of triggers for synchronized start or stop of CPUs and peripherals, and to and from trigger pins
- Parallel multi-core tracing to on-chip buffers or off-chip to dedicated (SGBT, DAP) or functionally shared interfaces (GETH)

***Note**: The on-chip multi-tool system (OCMTS) is composed of Debug and Trace modules. If both modules are involved in a specific topic, then they are also referred to as simply as 'OCMTS'.*

46.1 Feature list

The OCMTS sub-system consists of intrusive Debug and non-intrusive Trace functionality. They offer the following capabilities:

Debug

- Tool access through two Device Access Ports (DAP, DAPE) or JTAG
- Enable tool access to debug and functional resources
- Safe and secure debug function handling
- Run control of embedded processor cores and suspend control of peripherals
- Internal and external trigger action and reaction
- Debug event routing internally and to the debug host
- Stress and fault injection
- Control the debug modes regarding power saving, clock and reset control

Trace

- Supports applications such as trace based measurement or software development (debugging and performance analysis)
- Six operating modes provided: three on-chip memory and three streaming trace options
- Three kinds of trace interfaces available: Device Access Port (DAP), Ethernet (with software support), Serial GigaBit Trace (SGBT)
- Selectable program and data trace sources: all CPU(s) in parallel, PPU, GTM, DMA(s), OLDA, SPB, OTGB (signals of complex peripherals like EVR state or interrupt requests)
- Common programming model for single Multi-Core Debug Solution (MCDS) and dual MCDS configurations
- Common Multi-Trace Stream Container (MTSC) format to simplify trace message decoder development
- Program trace (instructions, program flow, functions only) support for virtualized TriCores™
- Very efficient support for software based data trace filtering
- Pre and post-event trace buffering (“digital oscilloscope”)
- Sophisticated trace qualification or filtering, and optimized trace message compression
- Central time stamp to correlate traces from different trace sources
- Robust recovery from trace buffer memory overflow
- Trace functionality can be enabled independently from debug functionality
- SGBT interface is compliant to the Aurora protocol and can be configured to operate at baud rates of 6.25, 5 or 2.5 Gbps (including 8B/10B encoding) with an available trace bandwidth of 4.816 Gbps at 6.25 Gbps

  Example for bandwidth calculations: 4.816 Gbps = 6.25 Gbps x 8B/10B encoding x (CC efficiency := 9992/10000) x (SGBT frame efficiency := 4096/4116) x (MTSC efficiency := 31/32)

46 Debug and Trace

- Smooth migration path from AURIX™ 2nd Generation for tool vendors and users
- Highly compatible architecture within the AURIX™ TC4xx family from low-end to high-end

46.2 Functional overview

The two main OCMTS functions, Debug and Trace, are implemented as separate entities in the device. They may be used independently or in cooperative mode.

The data flow and connectivity between the two functions and the rest of the device is shown in the following figure:

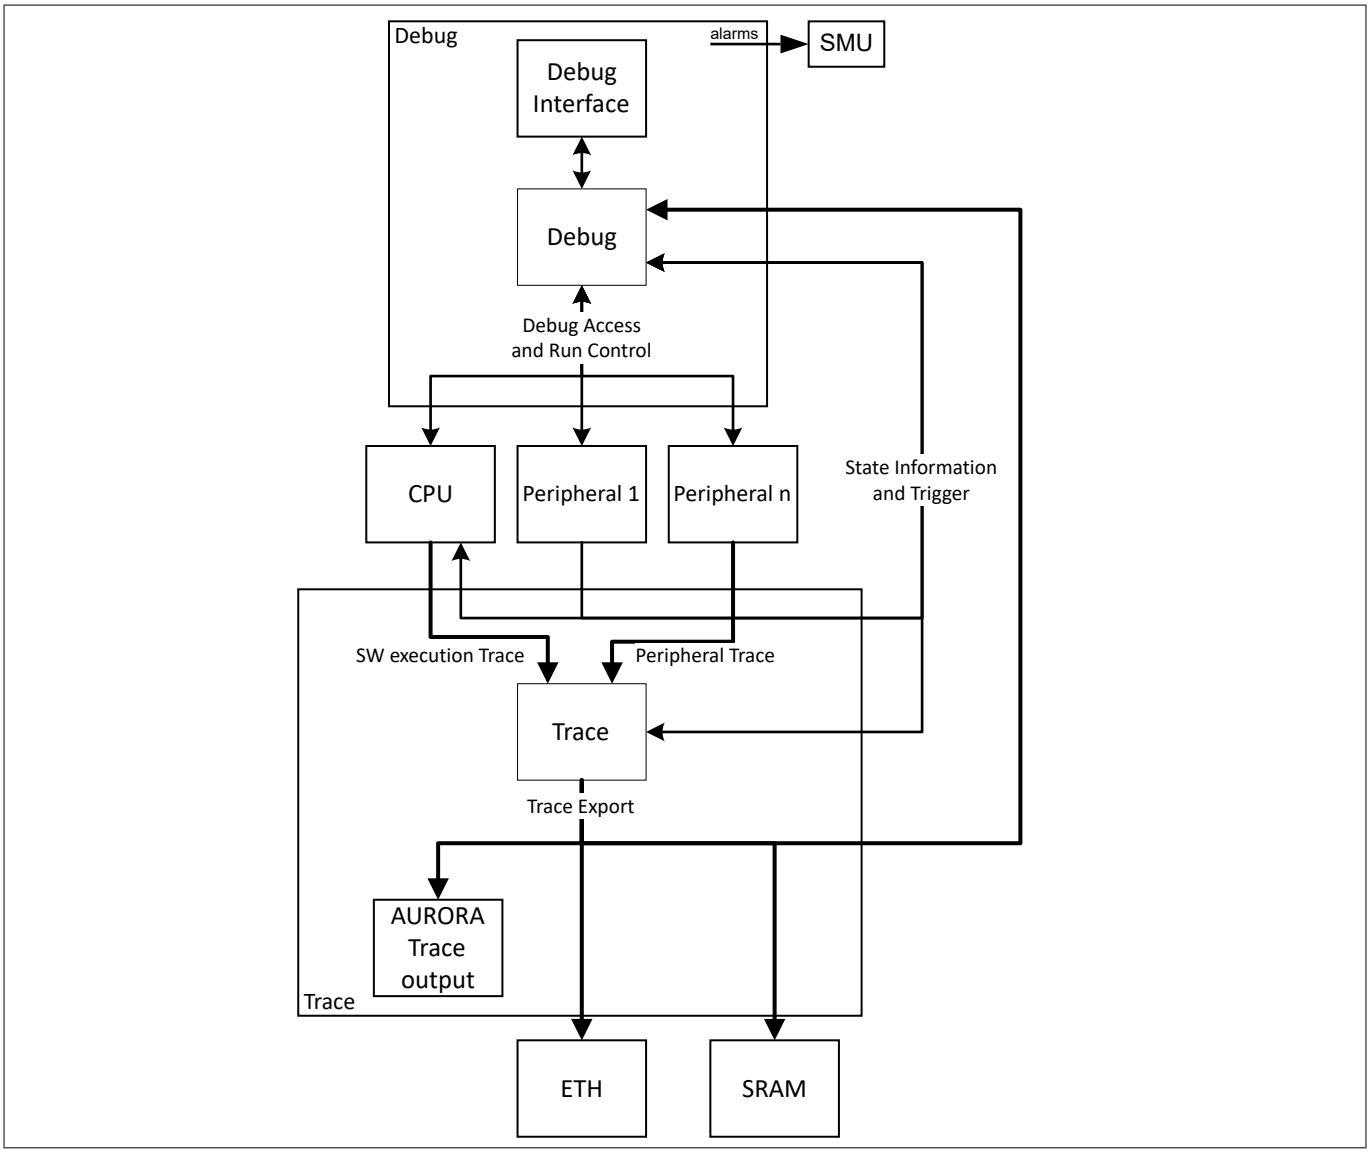

Figure 1244 Debug and Trace block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

The Debug block includes interfaces which are used to interact with the devices external tooling. The tool driven communication reaches the central Debug block by using an IOClient mechanism. The Debug block includes the necessary functionality to interact with the system over in-band bus accesses. Additional dedicated connections allow intrusive control of the program execution in processing cores, influence peripherals based on debug needs, and capture signal states over the triggering system.

The Trace block captures system execution flows in processing cores, peripherals, and the system interconnect. Dedicated connections to these blocks transport the data. The captured data items are processed, converted to a common trace format, and exported to dedicated trace ports or shared capabilities such as SRAM or network connections.

46.3 Functional description

The following figure shows the modular split of the Debug and Trace sub-functions.

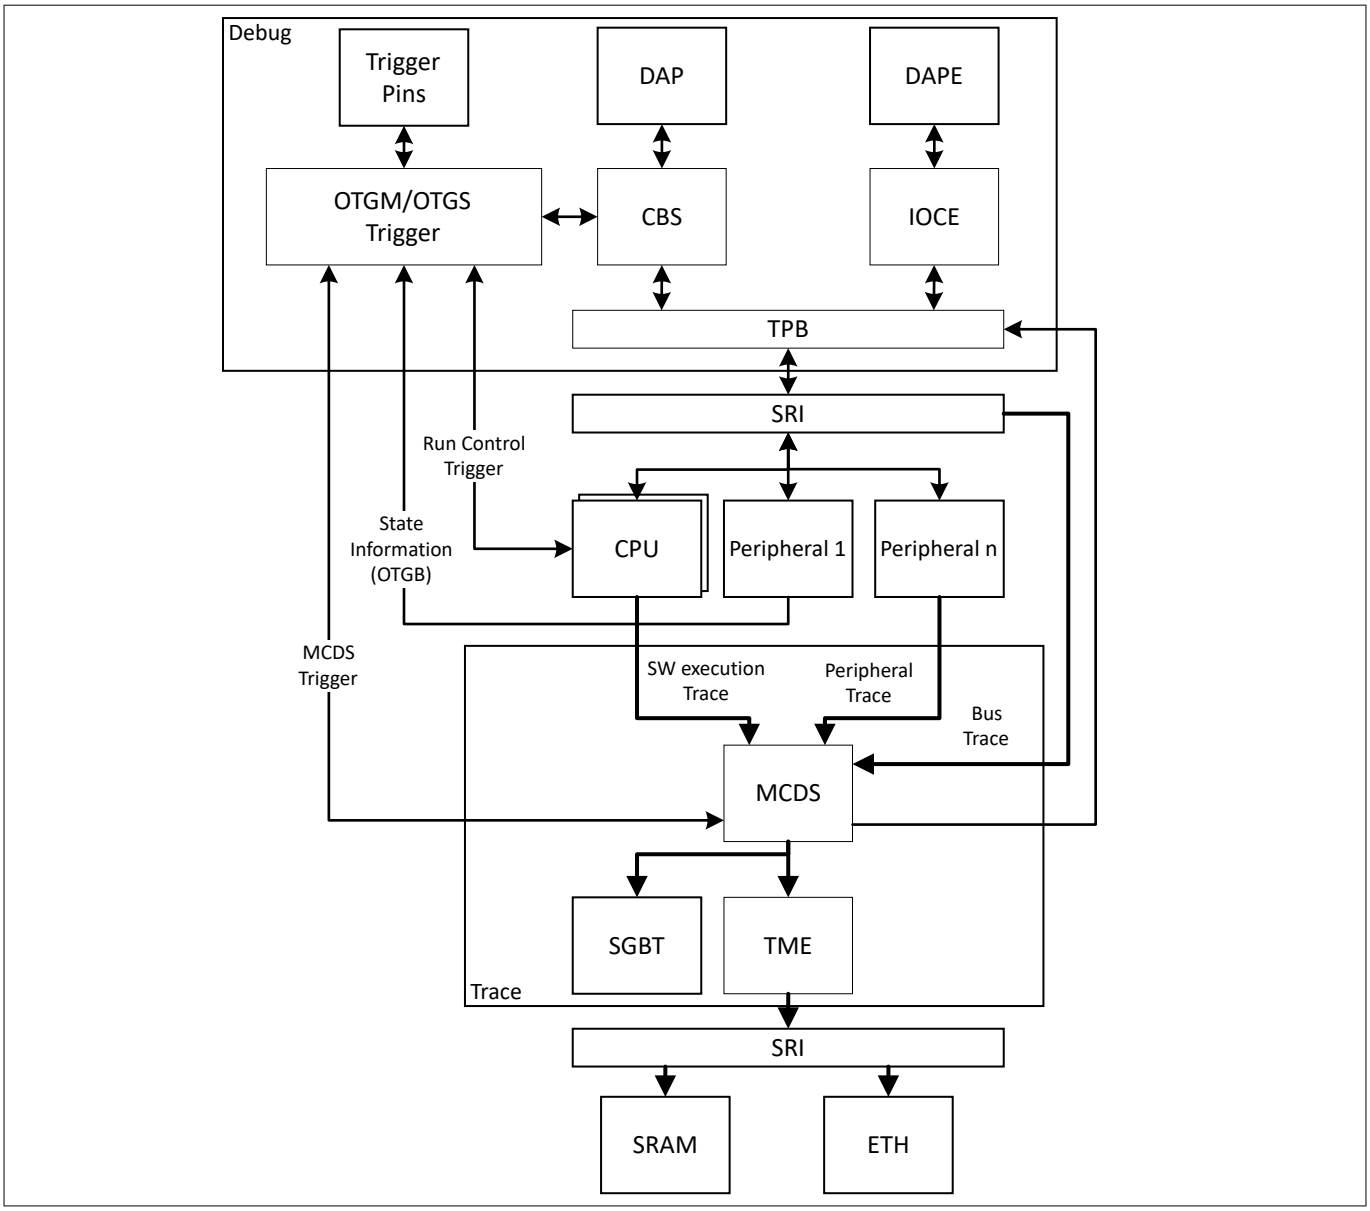

Figure 1245 Module connectivity in the Debug and Trace system

Debug function mapping

Debug functions are mapped on to the following modules:

Debug Interfaces

- Debug access port (DAP/DAPE):
  - 2 to 4 wire debug tool connection.

- Both DAP interfaces may be used in parallel by 2 mostly independent tool connections.
- ***Note**:* *IEEE1149.1 based JTAG access is also supported. However the preferred, more robust, and higher performance method, is to use DAP based connectivity.*

- Trigger Pins:
  - Up to 8 Trigger in and output pins.

Debug system access and control

- Cerberus (CBS) :
  - The main Debug enable, control, and system access block.
  - Directly accessed by the DAP interface.
  - Injector for fault and stress test (IFS).
- IOCE secondary system access:
  - Used by the DAPE interface.

Trigger functions

- OCDS trigger switch (OTGS):
  - Run control and trigger distribution.
- OCDS trigger multiplexer (OTGM):
  - Peripheral trigger collection and forwarding.

Trace function mapping

Trace functions are mapped on to the following modules:

Multi-core debug solution (MCDS):

- Trace data collection from trace sources.
- Filter based on user definable parameters.
- Convert to multi-trace stream container (MTSC) trace format.
- Storage towards user defined DAP, TME, or SGBT path.

Trace move engine (TME):

- Trace data export to system address space:
  - Store towards SRAM.
  - Export on shared device functions such as GETH.

Serial gigabit trace (SGBT)

- AURORA based differential Trace export to pins.

46.3.1 Debug access

Access to the device Debug system can be implemented over several methods, but usually DAP will be used.

Configuration and data retrieval using DAP

A debug tool may use any of the DAP modules to access the system and, assuming access is granted from a security perspective, may configure any of the OCMTS functions over the TPB bus.

***Note**:* *The number of debug access functions differs between DAP and DAPE. DAP may be the first choice for debug centric tooling while the DAPE function space may fit better for pure trace or calibration tools.*

The same path may be used to access the bridge towards the system wide Shared Resource Interconnect (SRI). This link allows a debug tool to configure the CPU, or peripheral local debug and trace features.

Software supported debug

By adding debug monitor software on a CPU, and by using the TPB register access to CBS, most of the debug functions can be made available over GETH for example.

46.3.2 Trace export

Captured and processed Trace data may be exported over several paths: Using DAP, forwarded to GETH, or using SGBT

Using DAP

Data remains stored in MCDS or is forwarded by TME to on-chip SRAM. The tool uses DAP to read the data.

This method does not require any connection other than the tool link. Limitations are the DAP transfer speed and the available storage space in MCDS or SRAM.

Forwarded to GETH

Captured trace data is stored on the device SRAM by TME, and forwarded to GETH.

This path uses the SRAM on the device as a buffer and exports the data with minimal software overhead over an ethernet connection. The CPU needs to handle the interrupt from the Trace sub-system and set up the DMA transfer towards the GETH module.

Using SGBT

Data is directly exported to pins using the SGBT module.

This path offers the highest performance and it is non-intrusive. The limitations of using this method are that a dedicated tool connection with specialized tooling is required, and HSPHY must not be used by other high speed IO.

46.3.3 Tool interface options

The AURIX™ TC4xx offers several options for connecting a tool. The one you choose depends on the target application, but it must be considered very early in the application design so that you do not accidentally block required interface pins or impact startup requirements.

46.3.3.1 Tool interface overview and enabling

This section focuses on dedicated tool interfaces which support controlled, flexible, read and write access. This does not include shared interfaces like Ethernet or the SGBT trace interface.

The options for connecting tools which need read and write access are:

- JTAG
- DAP (Device access port)
- DXCPL (DAP over CAN physical layer)
- DXCM (DAP over CAN messages)
- DAPE (second DAP)

JTAG is available for standard JTAG boundary scan; otherwise, it is always a second choice compared to DAP because of performance, pin count, error detection, and robustness.

The other interface options are optimized for different use cases and provide maximum compatibility due to their design based on DAP.

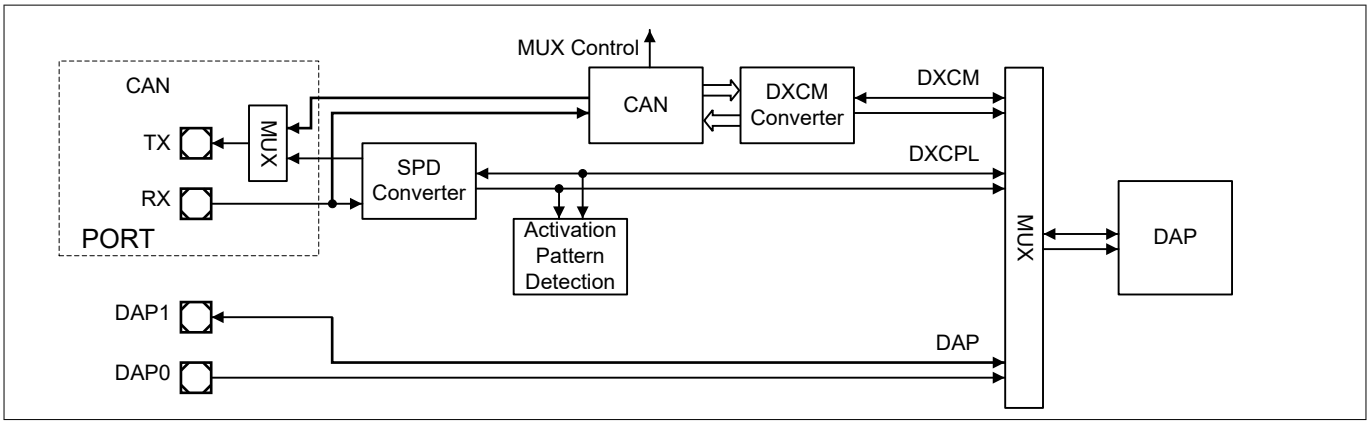

Figure 1246 DAP, DXCPL and DXCM block diagram

The CAN bus signals are usually available at the ECU connector, so this physical connection allows for the connection of all kinds of tools without opening the ECU housing.

The main use case of DXCPL is the analysis of field returns. The DXCPL standard pins are the CAN bootstrap loader pins . Another DXCPL use case is a tool interface for deeply embedded transmission applications. For this use case DXCPL is also available on other pins.

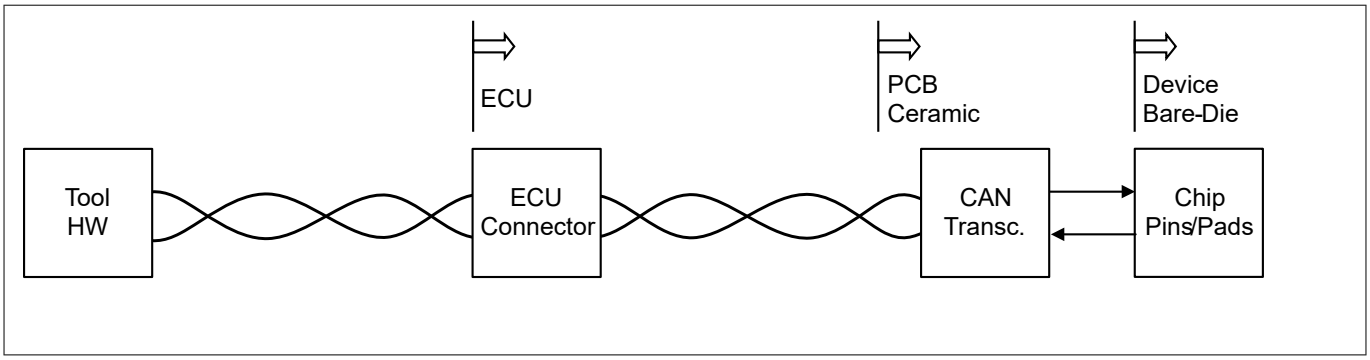

Figure 1247 DXCPL use case transmission ECU

DXCM transmits DAP telegrams and responses as the payload of regular CAN messages. This allows tool access while the system is using CAN. DXCPL is faster and more robust, but CAN cannot be used in parallel.

46.3.3.1.1 Comparison of DAP, DXCPL, and DXCM

The main difference between DXCM and DXCPL is that DXCM shares the CAN bandwidth with the regular CAN bus traffic. The following table shows a comparison between DAP, DXCPL, and DXCM.

Table 2420 Comparison of DAP, DXCPL, and DXCM

Property	DAP	DXCPL	DXCM
Performance	15(30) MB/s	200-800 KB/s	20-40 KB/s
Interface	2(3) DAP pins	CAN pins (for example of ECU connector)	
User resources	None (port function of DAP2 pin)	CAN pins	CAN bandwidth Two CAN IDs Two CAN MOs
Halt after PORST	Yes	Yes for default DXCPL pins.	No
Device test	Structural device test possible if security enabled.		No
Boundary scan	Yes		No
Security	Same security level and operation for all interfaces.		
Robustness against device failures	Reference	Only EVR oscillator as clock source needed.	Flash and clock system have to be functional.
Robustness against operation failures	Setup of physical connection and interface mode selection required (proper board, cable and tool configuration).		Additional matching CAN configuration.

46.3.3.1.2 Enabling of JTAG, DAP, DXCPL, or DXCM

The interface selection has several steps for addressing the different use cases in a robust and flexible way. The following table lists the main decision points for the tool interface enabling. More details about the conditions and transitions are available in the sections about the different interfaces.

Table 2421 Decision points for tool interface enabling

Point	Decision	Interface	Condition	Disabled Tool Interfaces
(1)[1]	JTAG	JTAG	$\overline{\text{TRST}}$ low at $\overline{\text{PORST}}$ release.	DAP, DXCPL, DXCM DAPE on JTAG pins
(2)[2]	Select one of: DAP, DAPE, DXCPL, DXCM.	DAP	Enabled by default, but needs DAPISC telegram to be activated.	DXCPL, DXCM (DAP turn-off to JTAG possible)
		DXCPL	DXCPL activation pattern detected on CAN RX.	JTAG, DAP, DXCM
		DXCM	DXCM is enabled with bit CAN0_MCR.DXCM.	JTAG, DAP
		DAPE	Enabled by default, but needs DAPISC telegram to be activated.	JTAG
(3)[3]	DAP or DAPE pin conflicts	DAP DAPE	DAP has priority when both tools claim the same pin with their private DAPISC.MODE .	JTAG DAPE when DAP claims DAP3 pin DAPE wide mode when DAP claims DAP2

1) Decision point (1) occurs within the startup firmware after release.
2) For decision point (2), the slightly simplified rule is that the first claims the interface.
3) Decision point (3) is only relevant when the DAPE interface is used. See the link to 'DAP, JTAG and trigger pins'.

Related information

For decision point (2), see 'DAP, JTAG, and trigger pins' on page 8586

46.3.3.1.3 Comparison of DAP and DAPE

While sharing the same bus connectivity, there are still differences in the functionality between tool connections over DAP and DAPE. The following table shows what functionality is shared and what is different between DAP and DAPE.

Table 2422 DAP and DAPE comparison

Function	DAP	DAPE
Full Chip Access (RW-mode)	X	X
Halt After Reset	X	X
Chip State readback using IOINFO	X	X
Reset request over OJCONF	X	-
Device unlocking	X	-
Communication mode with Interrupt generation	X	-
JTAG infrastructure access	X	-
Triggered Transfers	X	-

***Notes**:*

1. *X = Function available*

2. *In RW-mode DAPE has the option to access CBS functions through the register interface*

46.3.3.2 DAP, JTAG, and trigger pins

Tool connection through dedicated pins provides the highest robustness and performance. 'Dedicated' means that the pins must not be used for the application if there is any possibility that a tool might be attached at some point. As the attachment of tools can come very late in the design cycle, during calibration for example, this constraint usually results in a total loss of any other functionality overlaid on these pins.

Table 2423 DAP, JTAG, Trigger and GPIO pin configurations

In this table the supported interface configurations are listed with their pin usage. The configuration is controlled with the OIFM and DAPISC registers. All pins listed always use TTL voltage input levels when used for JTAG or DAP. The pins P21.6 and P21.7 have standard port input behavior when configured as GPIO.

Package pin	Two-pin	Three-pin	Four-pin	Trigger	Five-pin		GPIO
DAP0/TCK				-		TCK	-
DAP1/TMS				-		TMS	-
TDO	-	DAP2	DAP2	TGI3/TGO3	DAP2	TDO	P21.7
TDI	-	-	DAP3	TGI2/TGO2	DAP3	TDI	P21.6
$\overline{\text{TRST}}$	Needs to be high at $\overline{\text{PORST}}$ release for enabling DAP.				DAP4	$\overline{\text{TRST}}$	-

Table 2424 DAP/JTAG interface pins' on-chip pull device setting

This table lists the on-chip pull device characteristics. It is possible to operate the DAP and the DAPE interfaces in parallel using the same "JTAG" pins. This table shows the options which are controlled with the OIFM register and the two DAPISC registers of DAP and DAPE.

Package Pin	PORST			normal mode/ GPIO
DAP0/TCK	Please refer to respective device datasheet.	down	down	please refer to datasheet
DAP1/TMS		down	down	please refer to datasheet
TDO		up/down*	tristate	up/down configurable
TDI		up/down*	down	up/down configurable
$\overline{\text{TRST}}$		up	up	please refer to datasheet

***Note**: The value of the marked entries(*) depend on the selected DAP mode- default is 2- pin mode using DAP0, DAP1 only.*

***Note**: When switching from two-pin to a wider mode, a pull-up resistor on TDO might disturb the generation of the start bit in the first response of the configuration message. The debug tool may detect this disturbance when it checks the success of the first message after the mode switch. The pull-up resistor did not corrupt the communication in the given setup if this message was properly acknowledged and executed by the device. The communication may have been disturbed in case the message does not result in a reaction of the device. This is avoidable by using a pull-down resistor on TDO.*

***Note**: OIFM.DAPMODE default selection of the five pin mode must be changed to a narrower pin mode to allow usage of TDI as Trigger pin.*

Table 2425 DAP/DAPE interface configurations on "JTAG" pins

Package pin	Two-pin	Three-pin	Three-pin E	Two-pin E
DAP0/TCK			-	-
DAP1/TMS			-	-
TDO	-	DAP2	DAPE2	
TDI	-	-	DAPE1	DAPE1
$\overline{\text{TRST}}$	-	-	DAPE0	DAPE0

***Note**: DAPE tool hardware needs to sense the $\overline{\text{PORST}}$ pin for ensuring $\overline{\text{TRST}}$ high when $\overline{\text{PORST}}$ becomes inactive. DAPE tool hardware shall keep DAPE0/$\overline{\text{TRST}}$ low when not used for clock pulses.*

The $\overline{\text{PORST}}$ sensing is required for unsolicited resets, such as a chip-internal EVR under-voltage reset pulling $\overline{\text{PORST}}$ low. If JTAG were enabled due to $\overline{\text{TRST}}$ low at $\overline{\text{PORST}}$ release, this state could only be left with another Power-on Reset. Uncontrolled effects due to an unintentionally enabled JTAG interface will not occur when the DAPE tool hardware operates DAPE0/$\overline{\text{TRST}}$ as requested in the note above, effectively keeping the JTAG state machine in reset state.

The trigger in or out signals controlled by the OTGS Trigger Switch can be mapped to different pins controlled by the TIPR and TOPR registers. The possible locations shown in the next table are standardized for the whole device family. The availability of the higher port number trigger pins depends on device and package type. Please refer to the connectivity table in the device specific chapter.

Table 2426 TGI and TGO trigger pins

Package pin	Trigger input	TIPR	Trigger output	TOPR
P20.0	$\overline{\text{TGI0}}$	PIN0	$\overline{\text{TGO0}}$	PIN0
P20.1	$\overline{\text{TGI1}}$	PIN1	$\overline{\text{TGO1}}$	PIN1

It can be seen that there are potential conflicts, but as a general rule the interface signals defined in the pin configurations table and the interface table take precedence; the TGO trigger out connection will only be enabled if a pin is not needed.

The TGI trigger input functionality, configured in the Trigger Switch register TIPR is independent of any other usage of the pin.

46.3.3.3 DAP over CAN physical layer (DXCPL)

The CAN bus physical layer is a bi-directional connection with differential encoding on a single pair of wires. An external CAN transceiver translates between the logical level of the TXD or RXD device pins and the electrically robust signaling of the CAN bus. This direction separated signaling with TXD or RXD can be used to transmit SPD (see related information) encoded DAP messages (shown in the block diagram below).

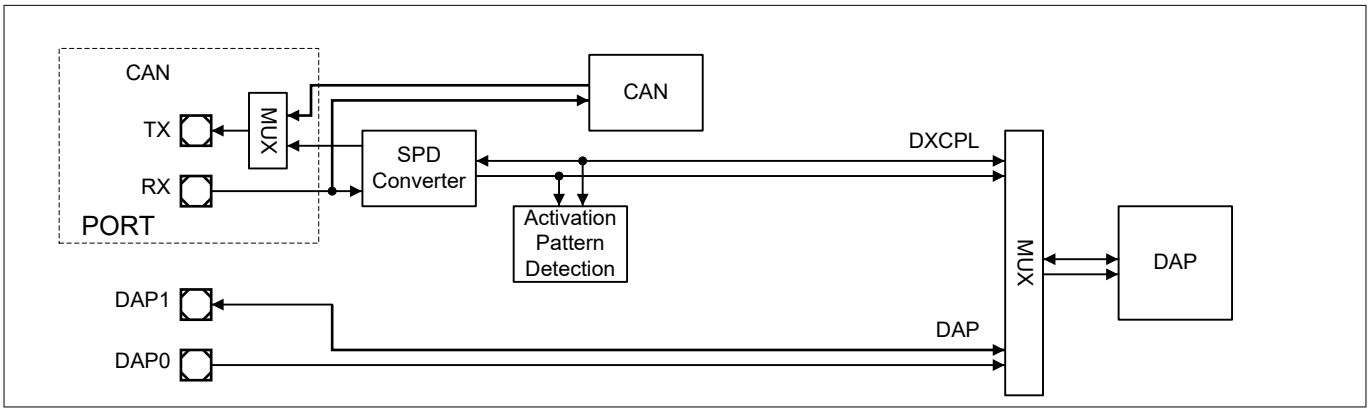

Figure 1248 DXCPL block diagram

The CAN bus signals are usually available at the ECU connector, so this physical connection allows you to connect all kinds of tools without opening the ECU housing.

DXCPL applications

- General debug when no other debug interface is available or accessible. After activation the OCDS infrastructure is accessible without restrictions. Test modes however are locked for safety and security reasons
- An electrically robust two wire measurement and calibration tool connection for deeply embedded applications such as transmission ECUs within the gear box

The other option for tool communication through CAN is DAP over CAN messages (DXCM).

Tool interface overview and enabling on page 8583
SPD protocol overview on page 8593
DXCPL SPD parameters on page 8591

46.3.3.3.1 Enabling and pins

DXCPL is by default enabled after , which means that it listens on the default RX pin for the activation sequence. Only after the activation sequence is sensed, including the DAPISC telegram, will the RX and TX pins be taken over exclusively for DXCPL.

***Notes**:*

1. *If DXCPL is just enabled but not yet activated, it has no impact on any device behavior. It just listens. Only when the DXCPL activation pattern and the DAPISC telegram (50 significant bits) are received, will the RX and TX pins be taken over. With the default settings (TRI_DXCCTR.TIC), this needs to happen in the time window between Power On Reset release and Flash start-up (~ 1 ms)*
2. *A prerequisite for DXCPL communication is an enabled CAN transceiver. This means that for the default TRI_DXCCTR.TIC) the DXCPL activation time window is already over when the user software enables the CAN transceiver. Only the other settings will allow DXCPL communication*
3. *Please refer also to the 'Exceptions for Emergency Stop' in the PORT configuration of the CAN pins used*

It is recommended to ensure that the CAN transceiver is enabled immediately after ; otherwise, it will not be possible to debug a range of situations using DXCPL. The robustness of DXCPL is then just on a similar level to DXCM including that no Halt after is possible.

Table 2427 DXCPL enabling and pins controlled by TRI_DXCCTR.TIC

TIC	Pins	Description
0_H	Default pins:	DXCPL will be disabled if not already activated by the tool after power-on reset.
1_H		DXCPL will stay enabled/activated for standard CAN pins.
2_H	Alternative pins: P33.12 (CAN00_RXDD) P33.13 (CAN00_TXD)	DXCPL is enabled for alternative CAN pins.

Related information

Comparison of DAP, DXCPL, and DXCM on page 8584
Halt after reset request (HARR) on page 8592
DXCPL activation sequence on page 8590

DXCPL activation sequence

DXCPL is only available when DAP is not used after Power-On Reset. The activation pattern is defined as 640 consecutive ‘0’-values in SPD format followed by a DAPISC telegram. The consecutive ‘0’-values mean permanent signal changes every 0.55 µs or less on the CAN bus.

***Note**: Depending on the situation (for example, an untrimmed EVR oscillator), the devices internal SPD decision point will be biased. In such a case a tool can try with a 20% shorter or longer edge distance. As soon as the device responds to the DAPISC telegram, the device internal biasing of the decision point can be determined and the tool can adapt accordingly for robust communication.*

The activation pattern will never occur inside any legal CAN traffic:

- The CAN protocol consists of specific frames (data-frames, remote-frames, and error-frames) with a maximum length of up to 128 bits, where the last seven "End-of-Frame" bits are transmitted as ‘1’. At least three more ’1’ bits must follow before the next frame can start
- Normal CAN data exchange is made with 512 kbit/s, or at fastest 1 Mbit/s. So a signal change will occur not faster than every 1-2 µs
- For CAN FD the data payload of maximum 64 bytes is too small to have an unintended activation by a data pattern

Some further safeguarding:

- SPD will assume a ‘1’-value whenever the time between two signal changes is longer than 0.55µs, which is the case at the latest at the end of every CAN FD frame
- Whenever SPD recognizes a ’1’ before 640 ‘0’-values have been seen, the whole activation sequence must be restarted
- The DXCPL activation is in two steps. The first is the SPD activation pattern, and the second a valid DAPISC telegram. Only after the second step, will the CAN module be disconnected from the RX/TX pins

For the special case that the tool is plugged on to a “live” bus, the following points must be considered:

- Because the transmission of SPD-conforming ‘0’-values represents a violation of the CAN-protocol, any active CAN-node will react by actively sending an error-frame
- This is repeated by the same or another node, until the internal error counter(s) overflow(s)
- Sooner or later all nodes will reach this state and be disabled automatically
- These error-frames may disturb the SPD activation sequence when a ’1’ results from any bus conflict. This may require that more than 640 ‘0’ values must be transmitted until SPD is activated

The DXCPL/SPD active operating condition is also indicated to any user software by SMM register bit STSTAT.SPDEN. This allows you to ignore errors reported by the disconnected CAN module.

DXCPL de-activation

Switching the activated interface pins back to regular CAN mode is only possible through Power-on Reset.

Disabling DXCPL

DXCPL can be disabled with TRI_DXCCTR.DXCPLDIS (even if already active).

Disabling Application Test Mode

After enabling DXCPL TRI_DXCCTR.ATMEN is used to determine whether Application Test Mode (ATM) can be entered or not.

46.3.3.3.2 DXCPL SPD parameters

DXCPL will normally be used with a CAN transceiver. It is however possible to connect any other kind of physical layer. The only restriction from the SPD encoding is the requirement for having similar transmission delays for positive and negative signal edges.

Due to the properties of the CAN physical layer, DXCPL uses inverted signal levels compared to standard SPD, as shown in the next figure. CAN's recessive level (high) corresponds to SPD's inactive level (low).

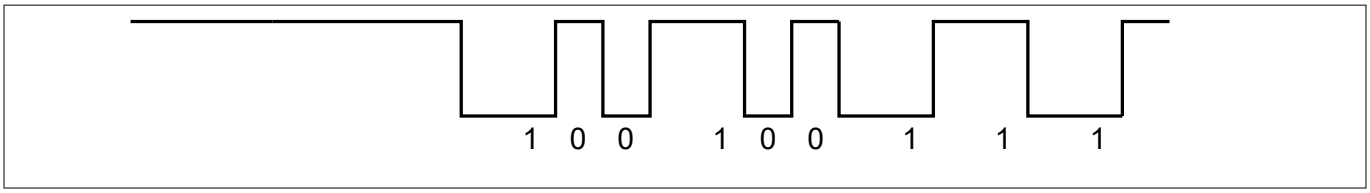

Figure 1249 DXCPL with SPD edge distance encoding

Table 2428 DXCPL SPD parameters

Parameter	Description
Bandwidth	Similar to regular DAP with 1.6 MHz clock with standard settings. It can be increased (DAPISC.CONF) by a factor of 2, 3, or even 4 depending on device type and system design, for example edge delay asymmetry of CAN transceiver.
Clock Source	EVR oscillator (100 MHz nominal)
Transmit Edge distance '0'	0.4 µs (nominal)
Transmit Edge distance '1'	1.1 µs (nominal)
Decision point on receive side	0.75 µs (nominal)
SPD_AUX bit	DAP TGIP trigger information

Attention**: **These DXCPL SPD parameters apply for the whole AURIX™ family.

Achievable bandwidth with a CAN transceiver

The bandwidth is limited by the posedge or negedge asymmetry and the jitter of the transceiver. For CAN transceivers a variation of up to 100 ns has to be taken into account.

The SPD detection fails when, due to this CAN transceiver variation, a short '0' edge distance is prolonged or a long '1' edge distance is shortened so that the receiver detects the wrong value. It also fails when a short

distance is shortened to less than one sample and a long distance to more than the timeout value of the receiver. This effect needs to be taken into account for the SPD parametrization for both tool and device.

On-chip SPD parameters

For minimized quantization loss, an over-sample rate of 5 or more is required. The following parameters are used by the on-chip SPD module:

- Over-sample rate (time step) is 5.
- Transmitter outputs a short edge distance (‘0’) with 4 time steps.
- Transmitter outputs a long edge distance (‘1’) with 11 time steps.
- Receiver recognizes an edge distance of 1 to 7 time steps as ‘0’.
- Receiver recognizes an edge distance of 8 to 14 time steps as ‘1’.

If the same SPD parameters are also used on the tool side, a bandwidth of 600 KB/s can be achieved. This requires good CAN (FD) transceivers at both ends which ensure a 90 ns or less edge distance variation for the whole signal path.

46.3.3.3.3 Halt after reset request (HARR)

For the default DXCPL pins it is possible to have a reliable halt after a . Two options are described here which depend on whether or not the PORST pin can be controlled by the tool. A third option, although not for a , is using a Halt after reset request (HARR), as for DXCM.

***Note**: The target system may have an external watchdog which will create a reset when it is not served by the device software. This effect can be mitigated when the tool takes over this role.*

HARR with controlling the PORST pin

It is possible to have a reliable halt after reset request (HARR) with DXCPL.

The tool needs to execute these steps after releasing the pin:

- Wait for approximately 100 µs for on-board and device internal release
- Apply the DXCPL activation sequence including DAPISC DAP initialization telegram (which takes approximately 300 µs)
- Execute the DAP HARR sequence (see AURIX™ TC4xx debug and trace reference manual)

HARR without controlling the PORST pin

Similar to regular DAP Halt after PORST with DAP, it is possible to have a reliable HARR even in the case that the tool does not control the PORST pin. The tool periodically sends the DXCPL activation sequence, including the DAPISC DAP initialization telegram. When the device responds to the telegram, the tool proceeds with the usual DAP HARR sequence.

For “small” devices with a short HARR time window, the DXCPL activation sequence can be optionally shortened to 170 µs by using half the regular SPD ‘0’ bit width (0.2 µs) for the 640 ‘0’ bits. The DAPISC DAP initialization telegram needs to be sent with a regular bit width.

46.3.3.4 SPD protocol overview

The SPD protocol encodes the DAP bits with the distances between the SPD signal edges. A DAP1 value of ’0’ is encoded with a short distance, while a value of ’1' has a distance that is twice as long. Standard encodings provide data bandwidth and latency performance similar to regular DAP connections clocked at 1.0 MHz to 1.6 MHz.

An SPD receiver implementation which is maximum robust against clock frequency deviations will have the decision point between ’0’ and ’1’ centered, with ’0’ being 2/3 of the decision point and ’1’ being 4/3.

This encoding is used for both directions and all data. Initially the SPD signal level will be low and the SPD module will wait for the first telegram from the tool, which will always start with a positive SPD ’1’ signal pulse with the encoded DAP start bit. The transmission of the rest of the telegram will be independent of the edge direction. If the SPD signal level is high after the last bit of the telegram, the tool has to add a ’0’ bit with a negative edge.

DAP has a clean request response protocol, where the tool is always the requester and the device executes and sends a response. So the DAP module will change the direction after it has received a DAP telegram to send a response. This response is the DAP reply telegram with two additions:

- After the start bit one bit is inserted. This SPD_AUX bit can be the value of the port output bit when SPD is overlaid to a GPIO pin, a trigger indicator like DAP TGIP, or a constant ’0’. Note that this extra bit is not included in the CRC of the DAP reply telegram.
- If the SPD output value is 1 after the last telegram bit, the SPD module will also automatically append an SPD’0’ bit to bring the SPD value back to '0'.

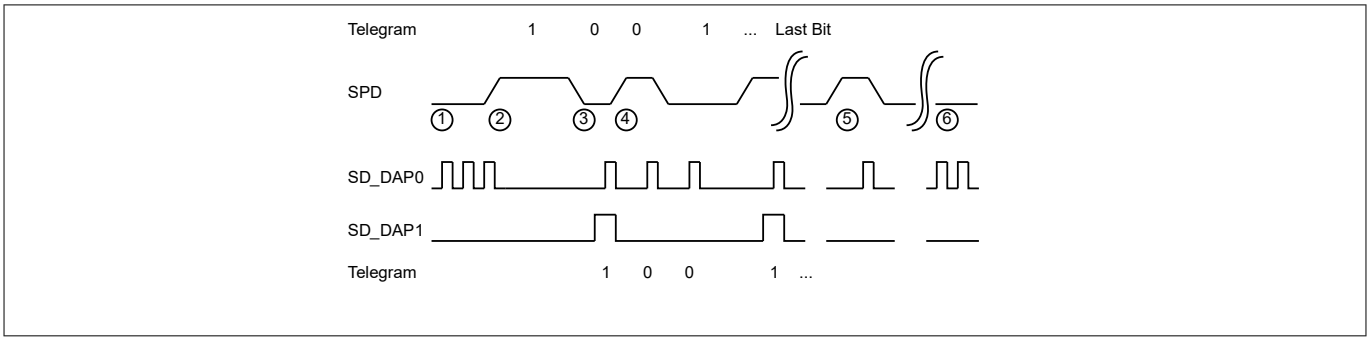

Figure 1250 SPD encoding example

The figure above shows the conversion of an SPD telegram to DAP as an example. SPD shows the input signal to be converted, while the signals SD_* are the signals towards the DAP.

Initially (1) the SPD module is in IDLE state and will clock ’0’ bits into the DAP module.

At point (2) it detects a rising edge which will bring it to RECEIVE state, waiting for the next edge at point (3). The distance between these two points is 1µs which means the first bit is recognized as’1’ (start bit) and output to the DAP module.

At point (4), 0.5 µs later the next bit, in this example with the value’0’, is detected and then output to the DAP module. If the last bit of the DAP telegram results in a rising SPD edge the tool will append a’0’ bit to bring the SPD level back to Low (5).

If the SPD level is Low for a certain amount of time, the SPD module will automatically switch back to IDLE mode (6). The SPD protocol can be used for all DAP telegrams except the poll and turn_off telegrams.

Tool interaction

All SPD/DAP communication is initiated by the tool. So the tool will send an SPD encoded telegram and then just switch the SPD signal direction to input to wait for the response from the device. The device will detect this

state due to the missing SPD edges and will start to create the response. The response will be either an SPD telegram or just an SPD start bit as defined in the DAP protocol.

46.3.3.5 DAP over CAN Messages (DXCM)

AURIX™ TC4xx supports standardized CAN tool access in parallel to regular CAN bus traffic. The main application is debugging, but it can also be used for any other kind of tool, that requires robust device access independent of the user software.

The generic concept is DAP over Serial (DXS) and in this case using CAN messages (DXCM). The effective DAP protocol is two-pin DAP. DAP telegrams and replies are transmitted as regular CAN messages.

The DXCPL/DXCM default pins are CAN01_TXD and CAN01_RXDB.

46.3.3.5.1 DXCM introduction

The basic idea is to have another transmission layer for DAP telegrams and replies. This is accomplished by packaging the DAP payload as CAN message data.

Features

- Tool access in parallel to regular CAN traffic
- Fully compliant to CAN protocol
- Nearly unrestricted support of all DAP features
- Security level and operation the same as for regular DAP
- Performance of 1 MBaud CAN similar to a 300 kHz regular DAP interface

The following figure shows the DXCM integration in AURIX™ TC4xx. The DXCM converter between the CAN module and DAP module serializes the incoming CAN message data and de-serializes the reply from the DAP module.

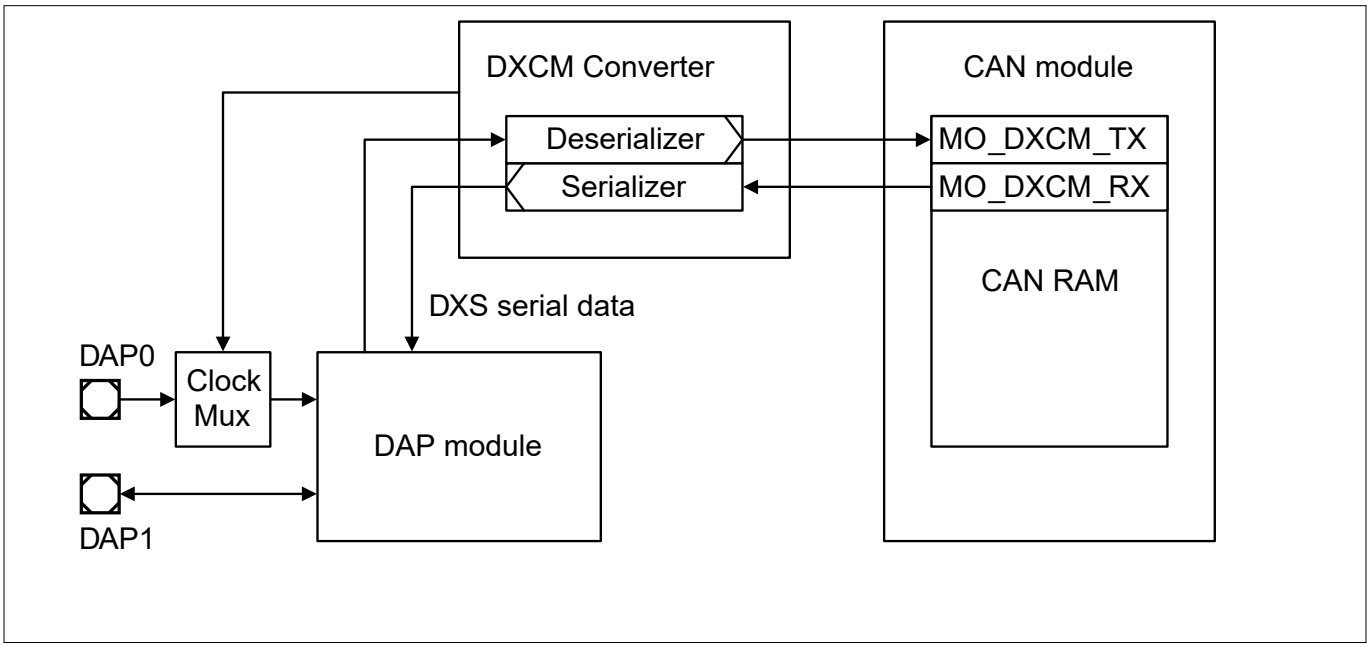

Figure 1251 DXCM block diagram

46.3.3.5.2 DXCM operation overview

There are no special restrictions for configuring the CAN module. The tool is simply another node in the CAN network. The tool must follow in principle the “request and wait for response” scheme. All messages, except for

a DAP turnoff telegram, will lead to a response message. All DAP telegrams can be used except the ones which obviously do not make sense, such as turn off JTAG for example.

There are only a few restrictions for DXCM compared to regular DAP:

- The achievable performance is very limited due to the CAN bit rate
- JTAG boundary scan is not possible since the DXCM pins are part of the scan chain

Related information

Halt after reset request (HARR) on page 8592

DXCM enabling

DXCM is only available when DAP is not used after , so no DAPISC DAP initialization telegram has been received. This means that either DAP, DXCM, or DXCPL can be used at any time. DXCM needs to be initialized in the CAN0 module by user software (MCR.DXCM).

Related information

Controller Area Network interface (CAN) on page 3918

DXCM protocol

DAP telegrams are sent by the tool without a start bit and CRC6 as the data of regular CAN messages. The LSB of the first byte contains the LSB of the DAP CMD field. The CAN message payload has just as many bytes as needed for transmitting the telegram bits. The remaining bits in the last byte must be set to zero.

The device reply is also without a start bit and CRC6. If the Trigger in Protocol (TGIP) is enabled, the DAP1 trigger bit follows immediately after the RDATA field. Reply parcels are sent as individual CAN messages. The trigger bit is appended according to the standard DAP behavior.

If the DAP reply is just a start bit a zero byte CAN message (DLC = 0) is generated.

Pipelining is not supported. The tool operation is a simple request response scheme, just the same as for regular DAP. But for maximum performance the tool can have the next DXCM CAN message fully prepared while it waits for the reply.

Halt after reset request (HARR) with a breakpoint

The initial DXCM tool connection is always a hot attach, and the tool can then request a System or Application Reset using the OJCONF register, which is the same as for regular DAP. It is however not possible to request a HARR on this level, since the CAN module will be reset and the HARR would prevent DXCM initialization by the user software.

The solution is to halt the user software with a breakpoint after the CAN module initialization, since the OCDS resources are not reset by a System or Application Reset.

This breakpoint based HARR approach is not a real restriction since:

- The user software before the CAN module initialization can be debugged through a DXCPL connection if needed. This part of the user software is independent from any CAN bus activity in the system
- The CAN module initialization can be optionally split in two parts: a very early initialization, which just sets up DXCM, and later a full initialization which adds dynamic user settings for example. This allows a very early DXCM connection; for example, before the entry to main()

46.3.3.6 Tool identification

The tool identifier and start-up handshake registers (TIHDAP,TIHDAPE and TIHGP) allow an external tool to identify itself to the device software and optionally set up a handshake procedure to reliably establish a link to the device.

***Note**: The tool identification interface is primarily intended to be used with measurement and calibration tools. Debug tools would not usually make use of this interface.*

46.3.3.7 Recommended tool connectors

Two connection options can be used to gain an easy and reliable connection.

- AP24003 DAP connector: DAP standard connector based on a 0.05 inch double row, 10 pin micro terminal with keying shroud
- AP32536 HSTCU: High speed tool connector based on USB C-type connector

46.3.3.8 Device access server (DAS)

The DAS API provides an abstraction of the physical device interface for tool access. The key paradigm of DAS is to read or write data in one or several address spaces of the target device.

DAS features:

- Standard interface for all types of tools.
- Efficient and robust methods for data transfer.
- Standardized system security support (authorization).
- Several independent tools can share the same physical interface.
- Infineon's DAS miniWiggler supports DAP, SPD, and JTAG.

46.3.4 Debug and Trace interaction

Debug and Trace may be used in a cooperative manner regarding OCMTS configuration and data export.

OCMTS configuration with Debug interface

Because Debug has full system access, it may be used to configure the whole OCMTS space including trace capabilities. This is done by accessing the TPB and SRI based access spaces with the CBS or IOCE Master interface.

***Note**: For Debug support, the device security state must allow Debug IO clients to access the system in read write mode. In addtion, the Debug TAG-ID must be allowed for write accesses in the PROT mechanism of peripherals where a debug tool should be allowed to alter the configuration.*

46.3.5 Emulation Device variant features

Table 2429 Emulation Device (ED)variant features

Features	TC...								
	4Dx	4Zx	48x	44x	49x	46x	4Ex	4xx	45x, 4Px, 42x, 4Sx
	Emulation Device							Productive Device	
Basic Overlay (DSPR, PSPR, DLMU, OLDA	X[1]	X	X	X	X	X	X	X	X
OWN (Overlay with NVM)	X	X	X	X	X	X	X	-[2]	-
LMU (EMEM) for Overlay and trace data	X	X	-	-	X	X	-	-	-
Full MCDS function for 48/32/16 kB TBUF trace	X	X	X	X	X	X	X	X	-
Trace session limitation after reset	No	No	No	No	No	No	No	Yes[3]	-
Trace to any RAM (e.g. LMU, if available)	X	X	X	X	X	X	X	-	-
DAP	X	X	X	X	X	X	X	X	X
DAPE, WM, SWM[4]	X	X	X	X	X	X	X	-	X
SGBT/Aurora trace output	X	X	X	X	X	X	-	-	-
High speed trace via Ethernet (SGMII)	X	X	X	X	X*[5]	X*	-	-	-

1) 'X' in this table, indicates that the feature is supported
2) '-' in this table indicates that the feature is not supported
3) Limited to one trace session after reset. Trace session defines the time between trace start and trace stop. For production devices between one trace session and the following one, a system reset is needed.
4) SWM feature is not available in TC4Dx, TC49x,TC48x
5) 'X*' - Supported in BGA436 package only

The Table above shows the Emulation device specific features and comparison to the Productive devices. All TC4x Productive devices (PD) have basic debug and overlay features. However,TC4x Emulation Device (ED) chips include debug and tracing features relevant for development phase only.

47 Ports

Each Port module 'Port slice' controls a set of assigned General Purpose Input Output (GPIO) port lines which are connected to pads connected to device pins or balls.

47.1 Feature list

Depending on its configuration a port module can have the following features:

- Controls up to 16 port lines
- Multiplexes one out of a maximum of 15 alternate functions to each port line
- Supports direct IO (Input Output) control by a peripheral on a per line granularity
- Enables software to control the output of each port line
  - Each port line has its own set of control registers
  - Output modification registers ease clearing, setting, and toggling of single or multiple port lines without affecting the state of other port lines
  - Enables software to read the input value of each port line
- Supports local access control with up to 8 access groups
  - Each port line inside a port can be mapped freely to an access group
- Supported pad characteristics of the assigned pads such as drive strength, slew rate, pull-up and pull-down, push or pull or open-drain operation, selection of TTL (Transistor-transistor logic) or CMOS (Complementary Metal Oxide Semiconductor) or automotive input levels
- The emergency stop feature allows the SMU (Safety Management Unit) or special port pins to change the driver configuration of configurable port lines
- For pad pairs with LVDS (Low voltage differential signaling) functionality, it controls LVDS characteristics and allows switching between LVDS and CMOS modes
- Also in packages with reduced pin count the port module is used to disable these particular pins which are not available in this packages

Device dependent implementation of ports

***Note**: The implementation of the ports is dependent on the device. Configuration is done partly during start-up by the firmware, for example to disable pins not available in a certain package. Please refer to the device specific documentation for the configuration.*

47.2 Functional overview

Each port line has a number of control and data bits, enabling very flexible usage of the line. Each port pad can be configured for input or output operation.

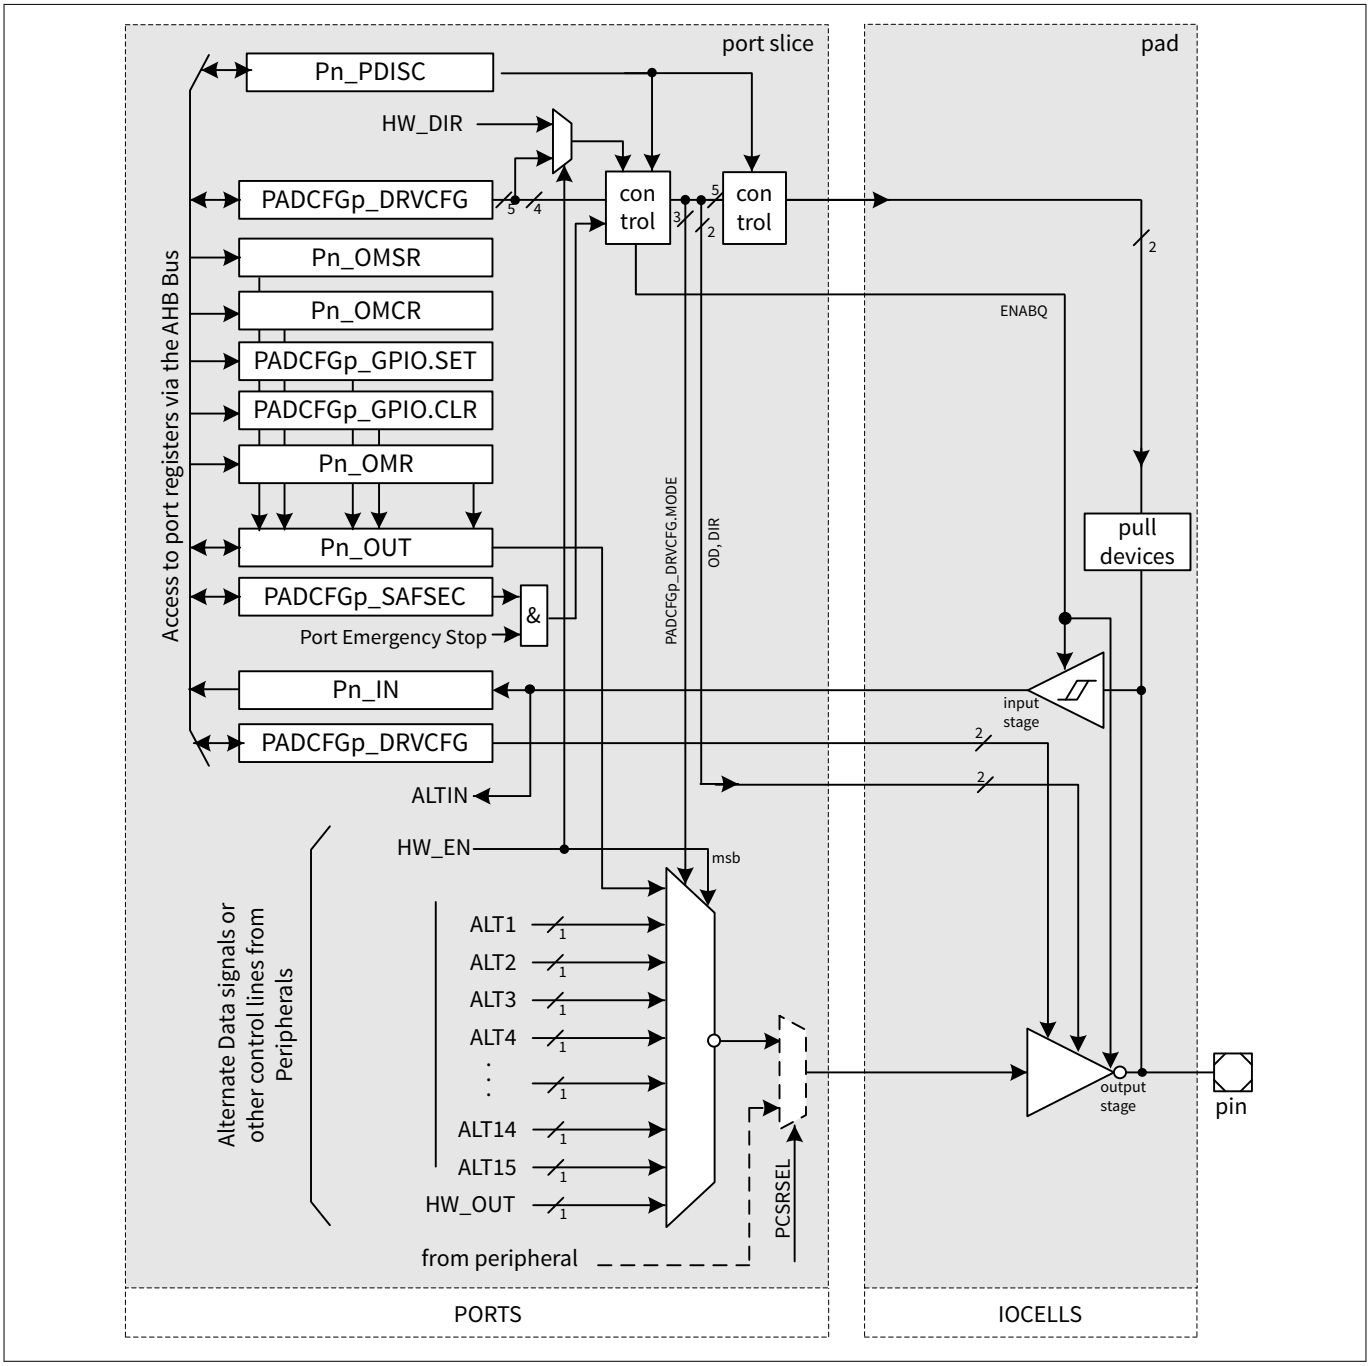

Figure 1252 PORTS block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

The available features depend on the type of pad. For example, input-only pads (e.g. SENT pads) do not offer output control. In this text we describe the capabilities of a general CMOS pad. The section on LVDS Port Operation adds information for switchable LVDS or CMOS pads.

In input mode, which is the default mode after reset, the output driver is switched off (high-impedance). The actual voltage level present at the port pin is translated into a logical 0 or 1 through a Schmitt-Trigger device and can be read with the read-only register IN. Input signals are connected directly to the various inputs of the

peripheral units. The function of the input line from the pin to the input register IN and to the peripheral is independent of whether the port pin operates as input or output. This means that when the port is in output mode, the level of the pin can be read by software through IN or a peripheral can use the pin level as an input.

In output mode, the output driver is activated and drives the value supplied through the multiplexer to the port pin. Switching between input and output mode is accomplished through the PADCFGp_DRVCFG register, which enables or disables the output driver. If a peripheral unit uses a GPIO port line as a bi-directional IO line, register PADCFGp_DRVCFG has to be written in order to configure input and output settings according to system's needs. The PADCFGp_DRVCFG register further controls the driver type of the output driver, and determines whether an internal weak pull-up, pull-down, or without input pull device is alternatively connected to the pin when used as an input.

The output multiplexer in front of the output driver selects the signal source for the GPIO line when used as output. If the pin is used as general-purpose output, the multiplexer is switched by software (PADCFGp_DRVCFG register) to the Output Data Register OUT.

The status of OUT can be changed through separate OMSR or OMCR registers.

The set or clear operations for the bits in OUT can be made by setting the corresponding PADCFGp_GPIO.SET and PADCFGp_GPIO.CLR registers. Alternatively, the set, clear, or toggle function can be achieved through OMR, where all pins within the same port can be set, cleared, or toggled within one write operation. The manipulation of the control bits in these registers can directly influence the state of the port pin. If the on-chip peripheral units use the pin for output signals, the alternate output lines ALT1 to ALT15 can be switched through the multiplexer to the output driver.

The data written into the output register OUT by software can be used as input data to an on-chip peripheral. This enables for example, peripheral tests using software without external circuitry (ALTIN path).

When selected as general-purpose output line, the logic state of each port pin can be changed individually by programming the pin-related bits in the

- Port n Output Modification Set Register: OMSR.PSx (where x_0 through to 15)
- Port n GPIO Control Register for Pin p: PADCFGp_GPIO.SET
- Port n Output Modification Clear Register: OMCR.PCLx (where x=0 through to 15)
- Port n GPIO Control Register for Pin p: PADCFGp_GPIO.CLR
- Port n Output Modification Register: OMR

The bits in OMSR and OMCR make it possible to set and clear the bits in the OUT register.

The bits in OMR allows the bits in OUT to be set, cleared, toggled or remain unchanged.

When the GPIO is selected as general-purpose output line, its actual logic level at the pin can be examined through reading IN and compared against the applied output level, either applied through software through the output register OUT, or through an alternate output function of a peripheral unit. This can be used to detect some electrical failures at the pin caused through external circuitry. In addition, software-supported arbitration schemes can be implemented in this way using the open-drain configuration and an external wired-And circuitry. Collisions on the external communication lines can be detected when a high level (1) is output, but a low level (0) is seen when reading the pin value through the input register IN.

Most of the digital GPIO lines have an emergency stop logic. This logic makes it possible to individually disconnect outputs and put them onto a well defined logic state in an emergency case. In an emergency case, the pin is switched to input function with internal pull-up device connected or tri-state (depending on global configuration). The Emergency Stop Register PADCFGp_SAFSEC determines whether an output is enabled or disabled in an emergency case.

LVDS port operation

The LVDS pads offer LVDS RX or TX functionality for a pair of pins. Additionally, they contain, if not specified differently, a bi-directional CMOS pad for each of the pins. The CMOS functionality is controlled by the set of standard registers. The LVDS functionality is controlled by additional LPCRx.LRXTERM registers.

47.3 Functional description

System connectivity of ports

The connectivity of the Ports is described in the pinning tables, which are available in the datasheet. The following table shows the general structure of a connectivity description of a port pin.

Table 2430 Example port table

Pin number	Symbol	Ctrl.	Buffer type	Function
10	Pxx.y	I	FAST/PU1/VEXT	General -purpose input
	TIMn_m			GTM_TIN
	Pxx.y	O0		General-purpose output
	TOMa_b	O1		GTM_TOUT
	TOMc_d			GTM_TOUT
	IOM_REFv_w			IOM reference input
	ASC_LINz_RTS	O2		ASCLIN0 output
	...	...		...
	ETH0_MDIO	O		Ethernet output

The symbols in the Ctrl. column indicate the multiplexer connectivity:

- I = Input (for GPIO port lines with DRVCFG bit field Selection MODEx = 0XXXB)
- I# = Input (for GPIO port lines which are shared with Standby Controller (SCR))
- AI = Analog input
- O = Output (the assigned function is active when a peripheral takes control of the port line)
- O0 = Output with DRVCFG bit field selection MODEx = 0000_B (Pxx.y)
- O1 = Output with DRVCFG bit field selection MODEx = 0001_B (ALT1)
- O2 = Output with DRVCFG bit field selection MODEx = 0010_B (ALT2)
- O3 = Output with DRVCFG bit field selection MODEx = 0011_B (ALT3)
- O4 = Output with DRVCFG bit field selection MODEx = 0100_B (ALT4)
- O5 = Output with DRVCFG bit field selection MODEx = 0101_B (ALT5)
- O6 = Output with DRVCFG bit field selection MODEx = 0110_B (ALT6)
- O7 = Output with DRVCFG bit field selection MODEx = 0111_B (ALT7)
- …
- O15 = Output with DRVCFG bit field selection MODEx = 1111_B (ALT15)
- O# = Output (for GPIO port lines which are shared with Standby Controller (SCR)) or HW_OUT or direct out (controlled by PCSRSEL bit on port slices not controlled by Standby Controller)

Several functions can be connected to each input. The peripherals' configuration defines if this input is used.

The port module decides which of the 16 output signals O0 to O15 drives the pad.

***Note**: Some Ox rows list more than one function. For example, several TOM outputs. The GTM module has its own sub-multiplexer structure that defines which of the GTM sub-units drives this signal.*

***Note**: In order to achieve a spike free switching of the ouput function selection it is recommended to disable the output driver before the selection, change to the desired output function (ALTx), and then to enable the output driver again.*

Pins without port module

The pinning of some devices shows Px.y pins without assigned Port module “Px”. This is the case for HSPHYx (used for SGBT, PCIe and SGMII functionaltiy) module pins for which the HSPHYx modules themselves contain the necessary control registers.

Control of port line by peripheral (HW_DIR/HW_EN/HW_OUT)

By using the HW_DIR/HW_EN/HW_OUT interface, a peripheral can take over control of the output path of a port line. When the peripheral activates HW_EN its data line connected to HW_OUT is driven to the output driver. With HW_DIR the peripheral can control the output driver activation. The data line connected to HW_OUT is shown in the pinning tables with the ctrl type as “O”.

When a peripheral activates HW_DIR and HW_EN the output driver operates in push/pull mode.

Wakeup control and wakeup status

After a wakeup on a falling edge of a port slice the corresponding wake status (which pin(s) have caused the wakeup) can be read in the corresponding port WKSTS. In order to make the status visible the corresponding bits inside the WKEN have to be set by user software directly after wakeup.

***Note**: During LBIST operation wakeup functionality is disabled but the wakeup status is preserved.*

Ports protection concept

The following figure gives an overview of the port protection concept.

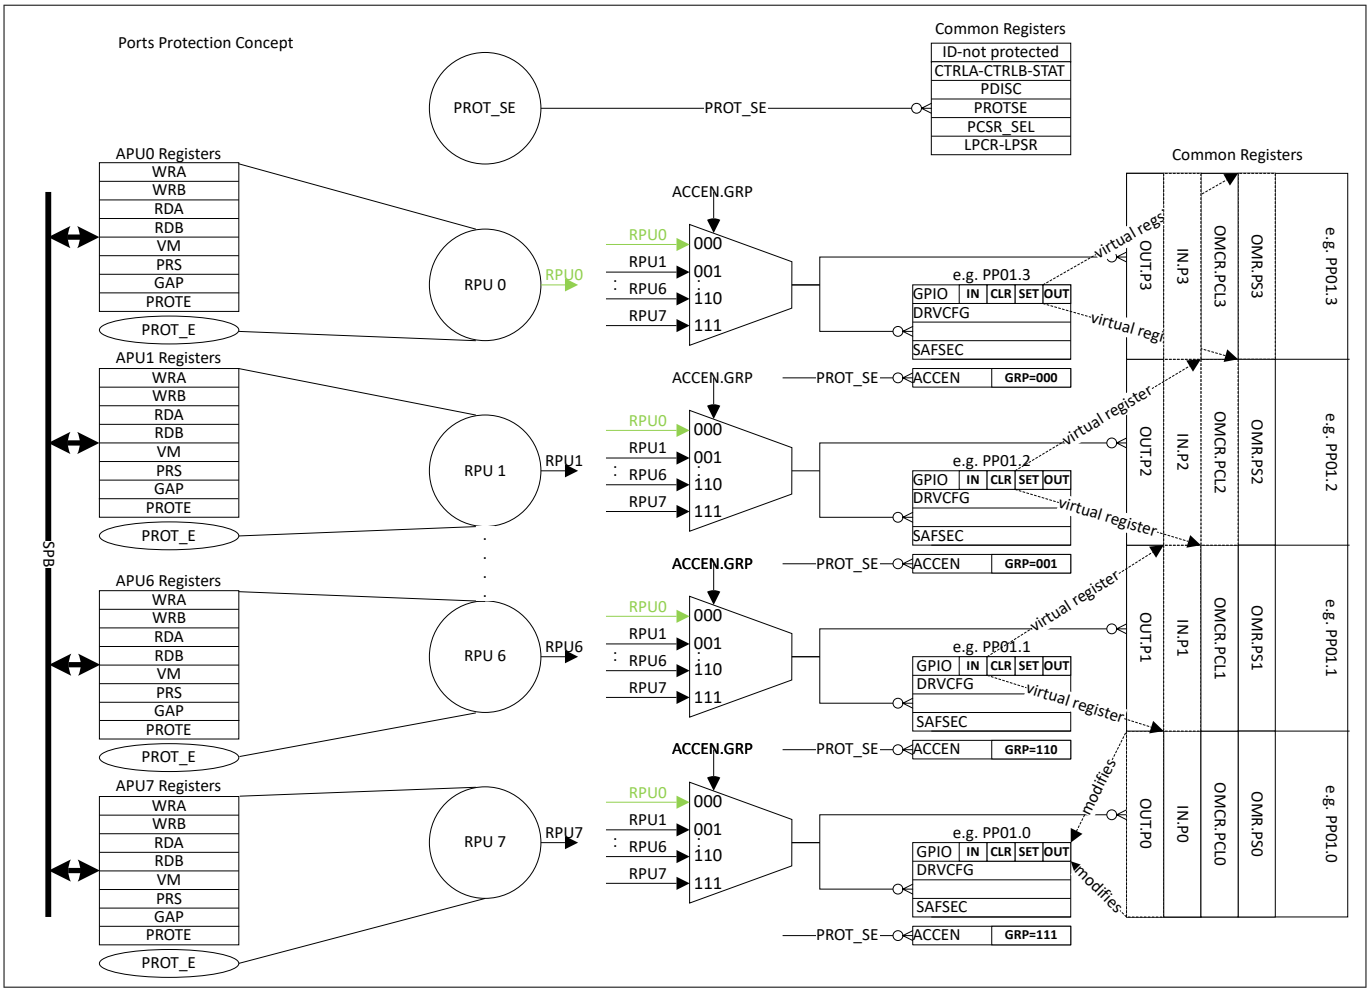

Figure 1253 Protection concept example demonstrated on 8 port slices

Introduction

Once the Power on Reset (PORST) is completed, the SYS_FW will hand over the control to the system start software or Operating system, which runs under Supervisor mode or, in case of a fully booted and virtualized application environment, as Hypervisor with the VM Tag 0. This software will set the remaining configuration, where the set values will depend on the use cases.

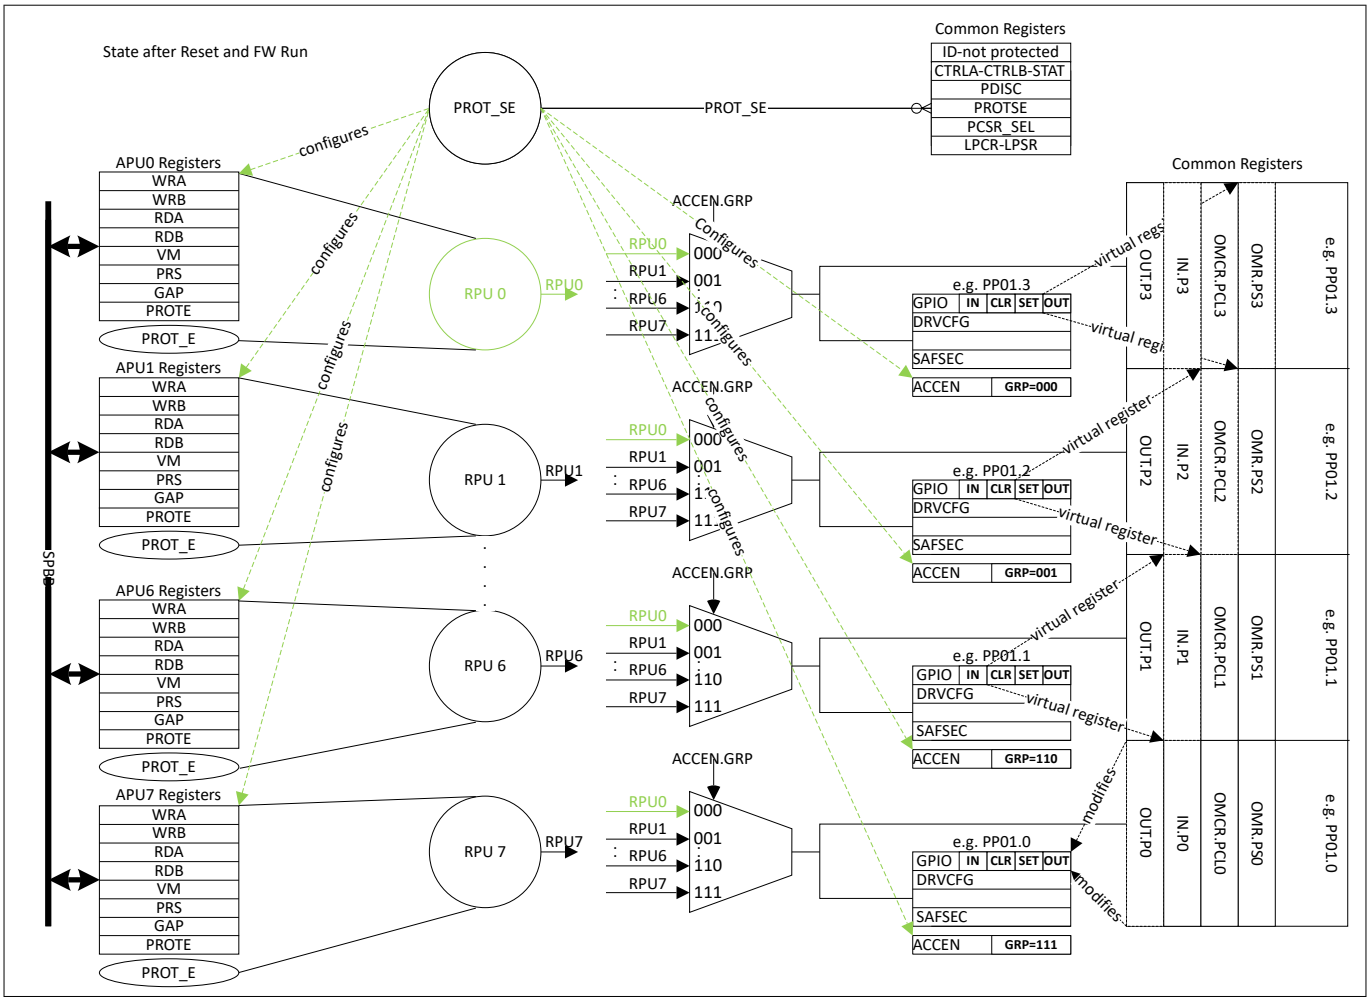

Figure 1254 Protection configuration example by PROT_SE owner

When all PAD configurations like Push Pull, GPIO or the alternative function in use are set, the system software will lock the configuration by setting ENDINIT.

In this mode, the functional driver software will change the GPIO pin levels via the dedicated registers. If such a driver erroneously or in a hostile manner accesses configuration registers, the access will be prohibited and the Safety Management Unit will be informed.

Port slice

Each port consists of maximum 16 port slices which are controlled by their dedicated register sets holding the control of the Pad configuration and GPIO control. Those port slice control registers are:

- PADCFGp_GPIO
- PADCFGp_DRVCFG
- PADCFGp_ACCEN
- PADCFGp_SAFSEC

The access to those port slice registers is offered in a grouped fashion. All slices within a port can be grouped in maximum eight access groups (configurable by the PADCFGp_ACCEN.GRP register).The number of access groups determines the number of APUs (four access groups result in 8 APUs). Each APU includes the configurability for all required ID types by offering a register per ID type.

Access group usage example

The following figure shows an example of an access flow and how the access groups do control the different functions in a port module.

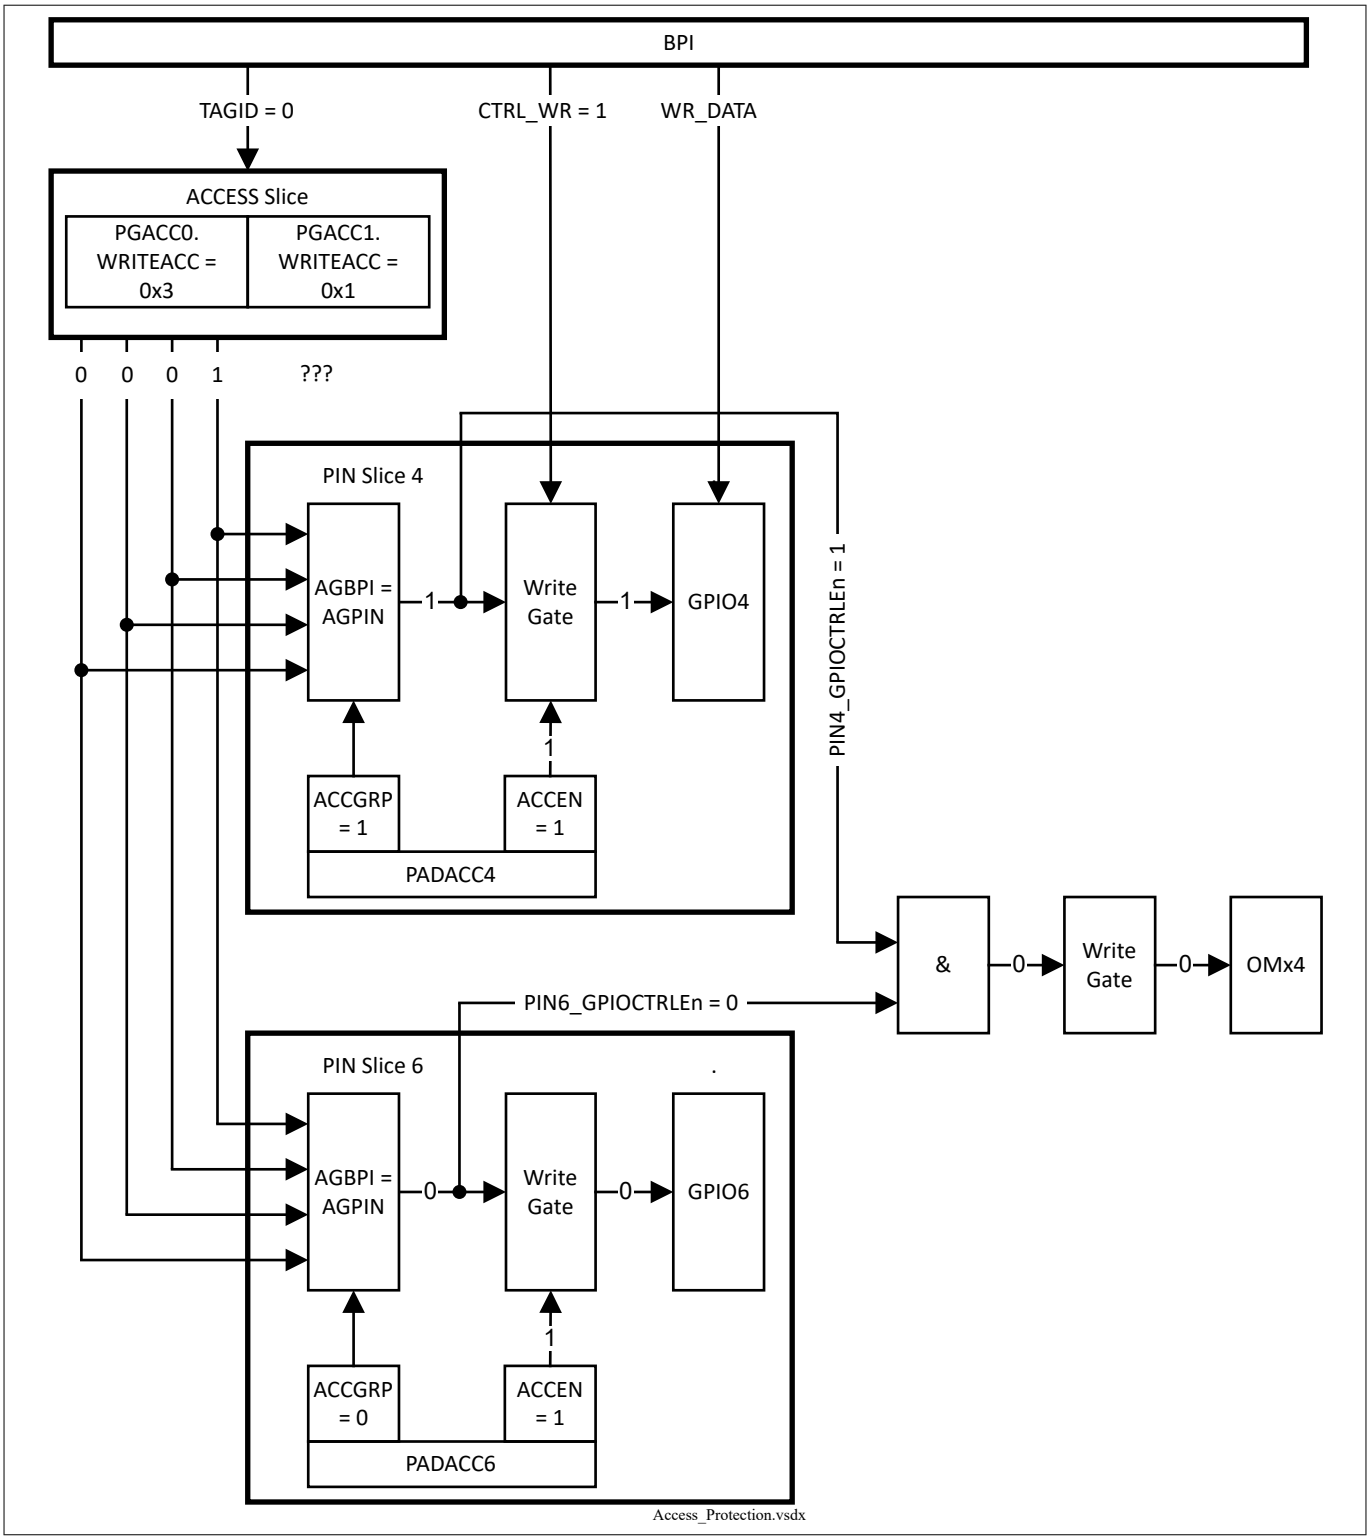

Figure 1255 Access example of two port slices

1. CPU with TAG ID = 0 writes to PORT
2. The ACCESS slice indicates a match in ACCESS group 1
   - Result: TAGID0 is enabled for write accesses on all GPIOs assigned to this group
3. Port slice4 enables write to GPIO4
4. Port slice6 and OMx4 are locked as Pin6 is assigned to non-matching access group 3

Access violation for ID register

The ID register is a read only register where the read access does not generate any access violation.

Access violation for Pn_IN register

The IN and the HWSELSTAT registers are common registers and are read only. In case of a read operation by a master not owning the access rights for a particular bit field this bit field will be read as 0. All other bit fields owned by the reading master will show the real status of the owned pin.

Access violation for Pn_OUT register

The OUT register is a special case within the group of common registers. Either writing a zero or writing a one will affect the status. In this case a modification of a bit field within this register can only be done when the writing master owns this particular bit field it wants to write. All other bit fields not owned by the writing master will not be modified. As the writing master has also tried to modify bits which it does not own, a safety alarm is generated.

In order to be able to perform a simple toggle activity on a pin the dedicated registers PADCFGp_GPIO.SET and PADCFGp_GPIO.CLR have to be set alternately.

Access violation for Pn_OMR, Pn_OMCR and Pn_OMSR register

For registers OMR, OMCR and OMSR only writing a one affects the status. In case group access protection is active, any write of a one to a bit-field not owned by the writing master will not lead to a reaction on pin level and will cause a safety alarm.

Reading those registers will return a zero.

***Note**: The OMR, OMCR and the OMSR registers are virtual registers and therefore do not contain any flip flop.*

Behavior on access failures

The port module reacts differently depending on the cause of access failure:

- An access attempted to a non-existing address triggers a bus error
- In case an access violates the currently valid access group settings, an alarm is raised towards the SMU

47.4 Registers

47.4.1 Register overview - access mode glossary

Table 2431 Register overview - access mode glossary

Keyword	Description
Ey (y=0-7)	Access protection using PROT register ACCGRPy_PROTE.
SE	Access protection using PROT register PROTSE.
APU-PGy (y=0-7)	Protection group consisting of registers ACCGRPy_WRA, ACCGRPy_WRB, ACCGRPy_RDA, ACCGRPy_RDB, ACCGRPy_VM, ACCGRPy_PRS.
PGy	Access protection using *APU-PGy* registers.
PPSz (z=0-15) EPSz (z=0-15)	Access protection using one APU from *APU-PG[y] (y=0-7)*. PROT_E protection using one of *E[y] (y=0-7)*. The protection source to be used is selected by bit-field: z=0-15: PADCFGp_ACCEN.GRP
U	No access restrictions.
BE	Always returns a Bus Error.
PROT	Access restrictions as defined in the PROT register access rules.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.

0	31:16	r	**Reserved** Read as 0; should be written with 0.

47.4.11 Port n Output Register

The port output register determines the value of a GPIO pin when it is selected by Pn_DRVCFGxx as output. Writing a 0 to a Pn_OUT.Px (x = 0-15) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that the bits of Pn_OUT.Px can be individually set or cleared by writing appropriate values into the port output modification set register Pn_OMSR or port output modification clear register Pn_OMCR, respectively. The Pn_OUT.Px bits can also be set, cleared or toggled with register Pn_OMR within the same write operation.

47.4.14 Port n Pin Function Decision Control Register

The pad structure of the GPIO lines offers the possibility to disable/enable port pad, select digital input or analog ADC input functionalities. Note that Class S pads have different characteristics than other digital input pads. For analog inputs, PDISx shall be set to 1 to disable the Schmitt trigger input buffer and digital output driver (if exists). Otherwise the specified accuracy of analog functions on overlaid pins (see TMADC accuracy parameters and their footnotes in datasheet) cannot be applied. For the ADC diagnostic features “PDD” however the corresponding PDISCx needs to be 0 to allow activation of their pull resistors. This feature can be controlled by individual bits in the Pn_PDISC register, independently from input/output and pull-up/pull-down control functionality as programmed in the Pn_DRVCFGx register. One Pn_PDISC register is assigned to each port.

***Note**: After reset, all Px_PDISC registers have the reset value of 0000 0000$_H$. The startup software disables only the pads with digital input/output functionality which are available in that package by writing the corresponding bits of not available pads to one. P40_PDISC and P41_PDISC are configured by the SSW for analog input function (kept disabled). The documented reset value shows the value in the largest package.*

PDISC Offset address: 02C$_H$

47.4.15 PROT Register Safe Endinit (SE)

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

PROTSE controls lock / unlock of the local Safe Endinit (SE) protected control registers.

A detailed description of the PROT mechanism and the underlying state machine can be found in chapter Safe and Secure Lock of control registers (PROT).

Note: as long as MEN=1 TAG-ID, VM, PRS, MEN and M_P can only be changed by the master function M (as defined by TAG-ID, VM, PRS). Write accesses from other master functions do not change these bits / bit fields.

PROTSE Offset address: 030_H

PROT Register Safe Endinit [SE] Application Reset value: $0000\ 0000_H$

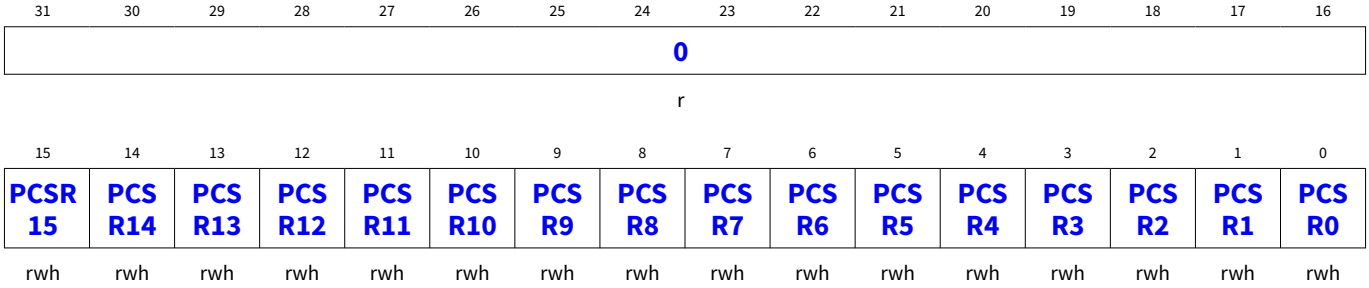
47.4.16 Selection Register for Module x Port n Control

This register enables or disables a module x to have direct port control. Modules making use of this configuration feature are: SCR, xSPI, GETHx, LETHx and HRPWMx

PCSRSEL Offset address: 034_H

Selection Register for Module x Port n Control PowerOn Reset value: $0000\ 0000_H$



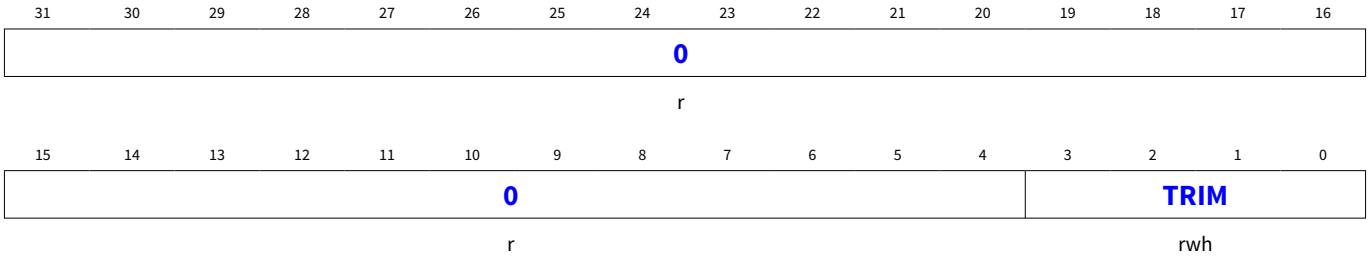
Field	Bits	Type	Description
PCSRx (x=0-15)	x	rwh	**Pad control selection x** This bit indicates whether a module x has control over pad Pn.x. Selection is valid only if the pad is shared with a particular module x and if the module is enabled. 0_B Main system has control over pad 1_B Control over pad is given to a particular module x
0	31:16	r	**Reserved** Read as 0; should be written with 0.

47.4.17 Pad Bandgap Trim Register

The BGTRIM register contains the trimming information of the bandgap located in the padframe.

BGTRIM Offset address: 038_H

Pad Bandgap Trim Register Reset values see: Table 2438



Field	Bits	Type	Description
TRIM	3:0	rwh	**Bandgap Trimming Bit** Trimming value for bandgap reference. 0_H corresponds to a value of 1.199V The trimming value is zero. 1_H corresponds to a value of 1.184V The trimming value is one. 2_H corresponds to a value of 1.168V The trimming value is two. 3_H corresponds to a value of 1.153V The trimming value is three. 4_H corresponds to a value of 1.139V The trimming value is four. 5_H corresponds to a value of 1.125V The trimming value is five. 6_H corresponds to a value of 1.112V The trimming value is six. 7_H corresponds to a value of 1.098V The trimming value is seven. 8_H corresponds to a value of 1.340V, The trimming value is eight. 9_H corresponds to a value of 1.321V The trimming value is nine. A_H corresponds to a value of 1.302V The trimming value is ten. B_H corresponds to a value of 1.283V The trimming value is eleven. C_H corresponds to a value of 1.266V The trimming value is twelve. D_H corresponds to a value of 1.248V The trimming value is thirteen. E_H corresponds to a value of 1.231V The trimming value is fourteen. F_H corresponds to a value of 1.215V The trimming value is fifteen.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Field	Bits	Type	Description
PSx (x=0-15)	x	w	**Set Bit x** Setting this bit will set or toggle the corresponding bit in the port output register Pn_OUT. Read as 0. 0_B No operation 1_B Sets or toggles Pn_OUT.Px.
PCLx (x=0-15)	x+16	w	**Clear Bit x** Setting this bit will clear or toggle the corresponding bit in the port output register Pn_OUT. Read as 0. 0_B No operation 1_B Clears or toggles Pn_OUT.Px.

***Note**: Register Pn_OMR is virtual and does not contain any flip-flop. A read action delivers the value of 0. One 8 or 16-bits write behaves as a 32-bit write padded with zeros.*

- PCL.x/PSx = 0/0 = Bit Pn_OUTPx is not changed.
- PCL.x/PSx = 0/1 = Bit Pn_OUTPx is set.
- PCL.x/PSx = 1/0 = Bit Pn_OUTPx is reset.
- PCL.x/PSx = 1/1 = Bit Pn_OUTPx is toggled.

47.4.19 Port n Output Modification Clear Register

The port output modification clear register contains control bits that make it possible to individually clear the logic state of a single port line by manipulating the output register.

***Note**: Register Pn_OMCR is virtual and does not contain any flip-flop. A read action delivers the value of 0. One 8 or 16-bits write behaves as a 32-bit write padded with zeros.*

Field	Bits	Type	Description
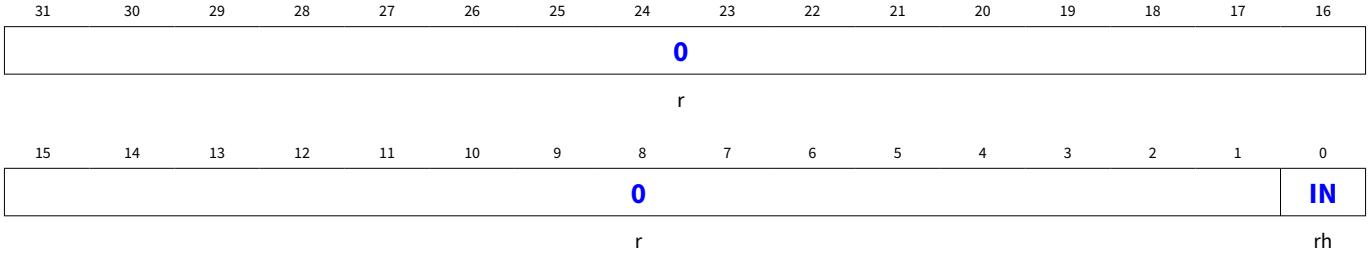
PSx (x=0-15)	x	w	**Set Bit x** Setting this bit will set the corresponding bit in the port output register Pn_OUT. Read as 0. 0_B No operation 1_B Sets Pn_OUT.Px
0	31:16	r	**Reserved** Read as 0; should be written with 0.

47.4.21 Port n LVDS Pad Status Register x

The LVDS Pad Status Register reflects the status of the RX LVDS pads.

LPSRx (x=0-7) Offset address: 048_H+x*8

Port n LVDS Pad Status Register x Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
IN	0	rh	**Input value of LVDS receive pad** 0_B Status of LVDS input is 0. 1_B Status of LVDS input is 1.
0	31:1	r	**Reserved** Read as 0.

47.4.22 Port n LVDS Pad Control Register x

The LVDS Pad Control Register controls the RX or TX functions of the LVDS pads. For usage of RX pad, bit field [7:0] is applicable. If the register is used for TX pad, bit field [15:7] applies.

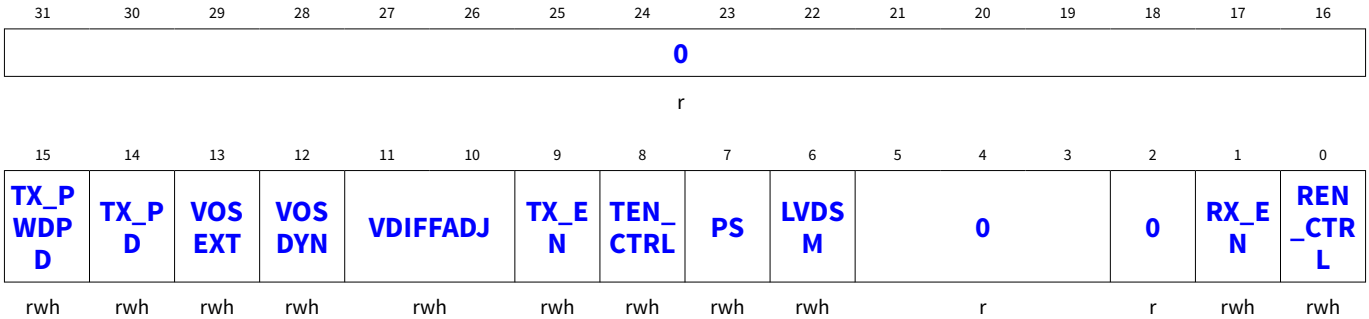
The sleep functionality of the LVDS pads is not controllable by this register. This is exclusively controlled by the HSCT module when this is connected.

The register x controls in general the pad pair 2*x and 2*x+1 of the port n.

Exceptionally when available the pad pair P14.9 and P14.10 is controlled by P14_LPCR5.

LPCRx (x=0-7) Offset address: $04C_H+x*8$

Port n LVDS Pad Control Register x Reset values see: Table 2439



Field	Bits	Type	Description
REN_CTRL	0	rwh	**LVDS RX_EN controller** The LVDS RX_EN control function can be selected from the Port (default) or HSCT module (where this is connected). 0_B Port controlled 1_B HSCT controlled (reserved where no HSCT is connected)
RX_EN	1	rwh	**Enable Receive LVDS** Enable the receive LVDS / disable CMOS path. If this bit is set to 0 – no transfer from the LVDS sender can be received and the receiver LVDS is in low power state. 0_B disable LVDS / enable CMOS mode (reserved for pads without CMOS input stage) 1_B enable LVDS / disable CMOS mode
LVDSM	6	rwh	**LVDS-M Mode** Selects increased frequency mode “LVDS-M” of the receiver. This mode increases the static current of the RX pad. The max data rate is increased to 700 Mbps (350 MHz). 0_B LVDS - Normal Mode 1_B LVDS - Fast Mode
PS	7	rwh	**Pad Supply Selection** Selects between 5V or 3.3V supply on V_{EXT} for the pad-pair. Used in RX and TX pads! 0_B 3.3V supply 1_B 5V supply
TEN_CTRL	8	rwh	**LVDS TX_EN controller** The LVDS TX_EN control function can be selected from the Port (default) or HSCT module (where this is connected). 0_B Port controlled 1_B HSCT controlled (reserved where no HSCT is connected)
TX_EN	9	rwh	**Enable Transmit LVDS** Enable the transmit LVDS / disable CMOS path. If this bit is set to 0 - no transfer on LVDS data path can be initiated and the LVDS driver is disabled (powered down). 0_B disable LVDS / enable CMOS mode 1_B enable LVDS / disable CMOS mode
VDIFFADJ	11:10	rwh	**LVDS Output Amplitude Tuning** With these two configuration bits the LVDS output current/amplitude can be adjusted. The voltage swing depending on VDIFFADJ setting is documented in the Data Sheet, see parameter V_{OD} .
VOSDYN	12	rwh	**Tune Bit of VOS Control Loop Static/Dynamic** Tune bit to change V_{OS} control loop between static and dynamic mode. Don’t change reset value.

(table continues...)

(continued)

Field	Bits	Type	Description
VOSEXT	13	rwh	**Tune Bit of VOS Control Loop Internal/External** Tune bit to change V_{OS} control loop. Don't change reset value.
TX_PD	14	rwh	**LVDS Power Down** Unused in this device. LVDS disabled by TX_EN means power down. 0_B LVDS power on 1_B LVDS power down (default)
TX_PWDPD	15	rwh	**Enable TX Power down pull down.** This function disables or enables the LVDS pull down resistor. The application code must disable TX power down pull down resistor with a power up. With a LVDS Power Down configuration the pull down function must be enabled, if required. 0_B disabled TX Power down pull down resistor. 1_B enabled TX Power down pull down resistor.
0	2, 5:3, 31:16	r	**Reserved** Read as 0; should be written with 0

Field	Bits	Type	Description
RDq (q=00-07)	q	rw	**Read access enable for PRS q** This bit enables read access to the access protected region for transactions with the PRS q. 0_B Disabled for read access 1_B Enabled for read access
WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

47.4.29 PROT Register Endinit

Each group of 4 Registers controls one pin access group OR Pin group y

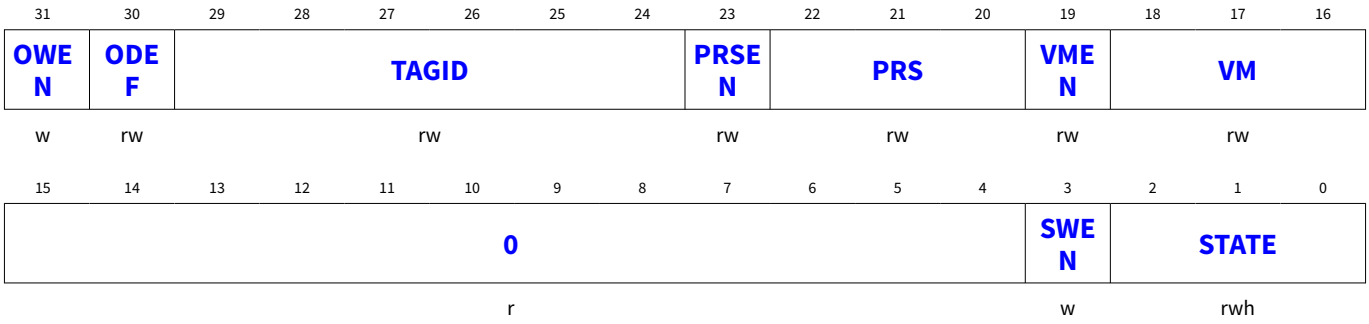
- Pn_ACCGRPy_RDA/B [0..NrOfACCGRPs] - 1 Bit per Master Tag regarding read access
- Pn_ACCGRPy_WRA/B [0..NrOfACCGRPs] - 1 Bit per Master Tag regarding write access
- Pn_ACCGRPy_VM [0..NrOfACCGRPs] - 2 Bits per VMID to controll read and write access
- Pn_ACCGRPy_PRS [0..NrOfACCGRPs] - Access allowance based on PRS ID

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

ACCGRPy_PROTE (y=0-7) Offset address: $0AC_H+y*20_H$

PROT Register Endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection Set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection Set definition Enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

47.4.30 Port n GPIO Control Register for pin p

GPIO level control

If a Pin was configured in DRVCFG to be a general purpose Input or Output this register may be used by Application Software to request a pin level change.

When the Set and Clear Bits are set in the same write cycle to 1, the pin level request will toggle to the inverted value.

PADCFGp_GPIO (p=0-15) Offset address: 300_H+p*10_H

Port n GPIO Control Register for pin p Reset values see: Table 2441

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0							IN	0				CLR	SET	0	OUT
r							rh	r				w	w	r	rh

Field	Bits	Type	Description
OUT	0	rh	**Output value** The port output field reports the requested value of a GPIO pin when it is selected by Pn_DRVVCFGx as output. A 0 in Pn_GPIOx.OUT (x = 0-15) bit equals a low level requested at the corresponding output pin. A high level corresponds to the bit read as 1. Note that the bits Pn_DRVVCFGx.OUT can be individually set or cleared by writing appropriate values into the port output modification set register Pn_OMSR or port output modification clear register Pn_OMCR, respectively. The bits can also be used to set, cleared or toggled with register Pn_OMR within the same write operation. The OUT bit in this register is explicitly set to be read only in order to avoid clashes between this bit and the Set/Clear bits in the same register. 0_B Set the input level of Pn.x to the low state. 1_B Set the level of Pn.x to the high state.
SET	2	w	**Set** Writing a 1 to the SET field will set the Pin to a Voltage level equivalent to the High state
CLR	3	w	**Clear** Writing a 1 to the CLR field will set the Pin to a Voltage level equivalent to the Low state
IN	8	rh	**Read back Pin value** The logic level of a pin can be read via the read-only port input register field Pn_PORTCTRL.IN. Reading the IN field always returns the current logical value at the pin independently from the pin direction or if the pin was set to be driven by GPIO, ALTSEL or HW_SEL. 0_B The input level of Pn.x is 0. 1_B The input level of Pn.x is 1.
0	1, 7:4, 31:9	r	**Reserved** Read as 0; should be written with 0

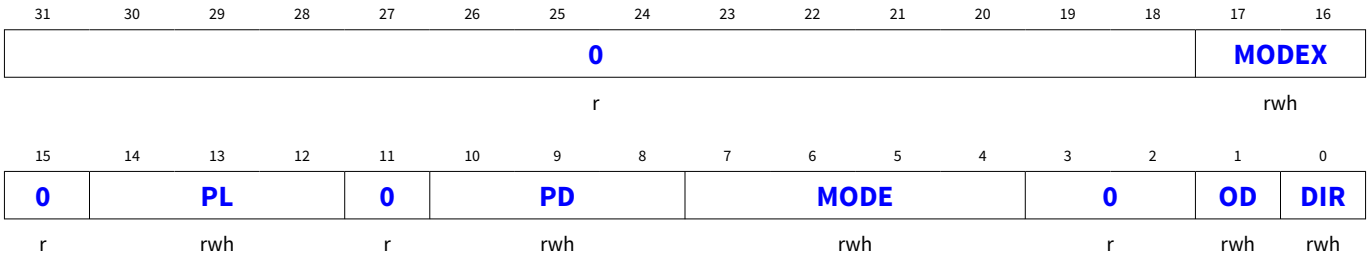
47.4.31 Port n Pad configuration Control Register for padp

Driver Configuration

The Pin Driver Configuration register contains the bit fields needed to set up the required pin configuration such as signal source and driver type selection.

PADCFGp_DRVCFG (p=0-15) Offset address: 304_H+p*10_H

Port n Pad configuration Control Register for padp Reset values see: Table 2442



Field	Bits	Type	Description
DIR	0	rwh	**Pad Signal direction** The DIR field defines the direction of the Port Pad in GPIO mode 0_B **IN**: Pad confligured as Input 1_B **OUT**: Pad confligured as Output
OD	1	rwh	**Output Buffer configuration** The bitfield OD defines the Output driver configuration when the Pin is configured in output mode. The Pad may be configured to Open Drain or Push/Pull driver types. 0_B **PP**: Push Pull 1_B **OD**: Open Drain
MODE	7:4	rwh	**Input configuration or Alternative Output signal selection** If the Pad is configured as Input, the MODE field determinates the Input mode regarding pure tristate mode versus a connected pull device. Note: If the direction is set to input only the lower 2 bits of the Mode field will be evaluated. If the Pad is configured as Output, the MODE field selects the number of the alternative output function driving the value towards the pin number n. Values higher than 0 do select the alternative output function matching to the absolute number of the value (e.g. MODE=1 selects alternative function number 1) When set to 0 the Pin acts as GPIO port. There the Pin state is SW controllable via the register Pn_GPIO 0_H **GPIO_TRI**: Pad configured in Tristate input mode or GPIO output mode 1_H **ALT01_PD**: Pad connected to alternative function 1 or input pull-down device 2_H **ALT02_PU**: Pad connected to alternative function 2 or input pull-up device 3_H **ALT03_TRI**: Pad connected to alternative function 3 or input tristate mode 4_H **4**: Alternative Output function 4 selected … F_H **15**: Alternative Output function 15 selected

Field	Bits	Type	Description
MODEX	17:16	rwh	**Configuration of output driver for HS_Fast pad (1.8V and 3.3V)** The MODEX bits are dedicated configuration bits for Port 16 only. The bit configuration is only valid if the PCSRSEL bit of the corresponding port slice is set to 0. In case Port16 is used for GPIO functionality the MODEX field has to be configured properly according to the applied voltage on the Port16 supply VDDHSIF. **Note:** In case of the usage of xSPI and RGMII function on Port16 the register DLL_CFG (bitfields PEN3VX and PMODE) inside the HSPHY functional block has to be configured properly. 00_B **HSF_DRV_1V8**: HSFast 1.8V xSPI / RGMII driver setting used Pad is configured for 1.8V mode (input buffer and output stage operating with 1.8V supply) . The active driver settings for this mode are the 1.8 V HSFast driver settings (controlled by bitfield PD [2:0]) which are also used for xSPI/RGMII operation.*For Port Slice P16.0 this setting is used to provide a differetial output signal on P16.0 and P16.1.* 01_B **HSF_DRV_1V8**: HS_Fast 1.8V xSPI / RGMII driver setting used Pad is configured for 1.8V mode (input buffer and output stage operating with 1.8V supply) . The active driver settings for this mode are the 1.8 V HSFast driver settings (controlled by bitfield PD [2:0]) which are also used for xSPI/RGMII operation.*For Port Slice P16.0 this setting is used to provide a single ended output signal on P16.0 and P16.1.* 10_B **GPIO_DRV_3V3**: HS_Fast 3.3V GPIO driver setting used Pad is configured for 3.3V mode (input buffer and output stage operating with 3.3V supply). The active driver settings for this mode are the HSFast - GPIO driver settings (controlled by bitfield PD [1:0]). 11_B **HSF_DRV_3V3**: HS_Fast 3.3V xSPI / RGMII driver setting used Pad is configured for 3.3V mode (input buffer and output stage operating with 3.3V supply). The active driver settings for this mode are the 3.3 V HSFast driver settings (controlled by bitfield PD [2:0]) which are also used for xSPI/RGMII operation.
0	3:2, 11, 15, 31:18	r	**Reserved** Read as 0; should be written with 0

r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0										ESR_PD		0		ESR_PPL	ESR_EN
r										rwh		r		rwh	rwh

Field	Bits	Type	Description
ESR_EN	0	rwh	**Emergency Request Action Enable** Most GPIO lines have an emergency stop logic implemented (see Figure “PORTS block diagram” in the Family chapter). Each of these GPIO lines has its own emergency stop enable bit ENx that is located in the emergency stop field ESR of Port Pin n. If the emergency stop signal becomes active, one of two states can be selected. Exceptions for Emergency Stop Implementation The Emergency Stop function is available for all GPIO Ports with the following exceptions: • Not available for P20.2 (General Purpose Input/GPI only, overlayed with Testmode) • Not available for P40_x and P41_x (analog input ANx overlayed with GPI) • Not available for P21.2 (used as SMU_EXT_EMERGENCYSTOP_REQ pin). • Not available for dedicated I/O without General Purpose Output function (e.g ESRx, TMS, TCK) The Emergency Stop function can be overruled on the following GPIO Ports: • P00.x: Emergency Stop can be overruled by the TMADC. Overruling can be disabled via the control register P00_PCSR. • P14.0 and P14.1: Emergency Stop can be overruled in the DXCPL (DAP over CAN physical layer) mode. No Overruling in the DXCM (Debug over can message) mode • P21.6: Emergency Stop can be overruled in JTAG mode if this pin is used as TDI • P21.7: Emergency Stop can be overruled in JTAG or Three Pin DAP mode. • P33.0-7, P33.9-15 and P34.1: Emergency Stop can be overruled by the 8-Bit Standby Controller (SCR), if implemented. Overruling can be disabled via the control register P33_PCSR and P34_PCSR. On pins with LVDS TX pads the Emergency Stop affects only the CMOS driver not the LVDS driver. Thus only when LPCRx.TX_EN selects CMOS mode the output is switched off. When TX_EN selects LVDS mode the output is not switched off. 0_B **DIS**: Emergency stop function disabled. The output line remains connected (alternate function). 1_B **EN**: Emergency stop function enabled. The mapped output function is disconnected and the safe state is entered by switching to input function with internal pull-up connected or tri-state, depending on the configured value of the corresponding Port slice PADCFGp_SAFSEC.ESR_PD register.
ESR_PPL	1	rwh	**Emergency status Push-Pull level** Value driven when pin is put in push-pull setup by ESR_PD 0_B The onput level of Pn.x is 0. 1_B The onput level of Pn.x is 1.

47.5 Debug information

This section is not applicable for the module being described.

47.6 References

This section is not applicable for the module being described.

47.7 PORTS revision history

Reference	Description of change(s)
Date range: 2024-08-17 to 2025-03-13	
Functional overview	• Changed drawing due to AE feedback. Block diagram figure was modified to show PCSRSEL functionality for particular modules like LETH0
Functional description	• Section "Padframe alarm trigger signals" moved to device specific functional description (TC49x-N and TC4Dx only)
Ports	• Typos fixed in several sub chapters
PADCFGp_DRVCFG	Changed bit field description of PD bit field

47.8 TC4Dx PORTS information

47.8.1 TC4Dx PORTS configuration

The following table shows the configuration of all TC4Dx port modules. Also the exceptions are listed:

Table 2446 Port implementation in TC4DxAA-step

Port module	Port slices	Pad supply domain	Available pins per port	Number of Access Groups	Configuration, exceptions
P00	16 slices	VDDEXT	P00.0 - P00.15	8	All port slices are available
P01	16 slices	VDDEXT	P01.0 - P01.15	8	All port slices are available
P02	16 slices	VDDEXT	P02.0 - P02.15	8	All port slices are available
P03	16 slices	VDDEXT	P03.0 - P03.15	8	All port slices are available
P04	10 slices	VDDEXT	P04.0 - P04.9	8	P04.10 - P04.15 not available
P10	15 slices	VDDEXT	P10.0 - P10.15	8	P10.12 not available
P13	16 slices	VDDEXT	P13.0 - P13.15	8	All port slices are available
P14	16 slices	VDDEXT	P14.0 - P14.15	8	All port slices are available
P15	15 slices	VDDEXT	P15.0 - P15.8 and P15.10 - P14.15	8	P15.9 not available
P16	15 slices	VDDHSIF	P16.0 - P16.14	8	P16.15 not available
P20	13 slices	VDDEXT	P20.0 - P20.3 and P20.6 - P20.14	8	P20.4, P20.5 and P20.15 are not available
P21	8 slices	VDDEXT	P21.0 - P21.7	4	P21.8 - P21.15 not available
P22	12 slices	VDDEXT	P22.0 - P22.11	8	P22.12 - P22.15 not available
P23	8 slices	VDDEXT	P23.0 - P23.7	4	P23.8 - P23.15 not available
P25	1 slices	VDDEXT	P25.1	4	P25.0, P25.2 - P25.15 not available;
P30	16 slices	VDDEXT	P30.0 - P30.15	8	All port slices are available
P31	2 slices	VDDEXT	P31.6 - P31.7	4	P31.0 - P31.5 and P31.8 - P31.15 not available

(table continues...)

Table 2446 (continued) Port implementation in TC4DxAA-step

Port module	Port slices	Pad supply domain	Available pins per port	Number of Access Groups	Configuration, exceptions
P32	5 slices	VDDEVRSB	P32.2 - P32.7	4	P32.0 - P32.1, P32.3 and P32.8 - P32.15 not available; Overlaid with SCR functions
P33	16 slices	VDDEVRSB	P33.0 - P33.15	8	Overlaid with SCR functions
P34	5 slices	VDDEVRSB	P34.1 - P34.5	4	P34.0 and P34.6 - P34.15 not available; Overlaid with SCR functions
P35	6 slices	VDDEVRSB	P35.0 - P35.5	4	P35.6 - P35.15 not available; Overlaid with SCR functions
P40	15 slices	VDDM	P40.0 - P40.14	8	P40.15 is not available. Registers dedicated to P40.15 functionality have no effect as the corresponding pad cell is not available; Analog inputs overlaid with SENT functionality

***Note**: Pin names with prefix PHYx_ do not provide any overlaid functionality*

47.8.2 TC4Dx PORTS features

Table 2447 Port implementation in TC4DxAA-step

Port module	Pins	Wake-up capable pins	Exceptions and special features
P00	16 pins	P00.0 - P00.15	Port 00 special features: • All pins of this port support the wake-up feature • GETH0_PX_MDIO (HW_OUT) on P00.0 • P00.1 - P00.12 are used as inputs for TMADC2
P01	16 pins	P01.0 - P01.15	Port 01 special features: • All pins of this port support the wake-up feature • P01.3 - P01.5 are used as inputs for TMADC2
P02	16 pins	P02.0 - P02.15	Port 02 special features: • All pins of this port support the wake-up feature • P02.11 is used as input for TMADC2
P03	16 pins	P03.0 - P03.15	Port 03 special features: • All pins of this port support the wake-up feature • For the usage of LETH0_P2_RMII output function on this port the corresponding PCSRSEL bit slice on P03.0, P03.8 and P03.9 has to be set to one and additionally the proper ALT function related to LETH0_P2_RMII output has to be selected

(table continues...)

Table 2447 (continued) Port implementation in TC4DxAA-step

Port module	Pins	Wake-up capable pins	Exceptions and special features
P04	10 pins	P04.0 - P04.9	Port 04 special features: • All pins of this port support the wake-up feature
P10	15 pins	P10.0 - P10.11 and P10.13 -P10.15	Port 10 special features: • All pins of this port support the wake-up feature • For the usage of LETH0_P2_RMII output function on this port the corresponding PCSRSEL bit slice on P10.10, P10.11 and P10.13 has to be set to one and additionally the proper ALT function related to LETH0_P2_RMII output has to be selected
P13	16 pins	P13.8 - P13.15	Port 13 exceptions and special features: • LVDS pins P13.0 - P13.7 do not support the wake-up feature • All other pins of this port support the wake-up feature • For the usage of LETH0_P3_RMII output function on this port the corresponding PCSRSEL bit slice on P13.8 - P13.10 has to be set to one and additionally the proper ALT function related to LETH0_P3_RMII output has to be selected
P14	16 pins	P14.0 - P14.8 and P14.11 - P14.15	Port 14 exceptions and special features: • LVDS pins P14.9 - P14.10 do not support the wake-up feature • All other pins of this port support the wake-up feature • For the usage of LETH0_P2_RMII output function on this port the corresponding PCSRSEL bit slice P14.7, P14.9 and P14.10 has to be set to one and additionally the proper ALT function related to LETH0_P2_RMII output has to be selected
P15	15 pins	P15.0 - P15.8 and P15.14 - P15.15	Port 15 exceptions and special features: • LVDS pins P15.10 - P15.13 do not support the wake-up feature • All other pins of this port support the wake-up feature
P16	15 pins	-	Port 16 exceptions and special features: • P16 does not support the wake-up feature • For usage of XSPI and GETH0_P0_RGMII output and input function on this port the corresponding PCSRSEL bit slice has to be set to one and ***Note**: Exception is P16.0 where PCSRSEL has to be 0 in order to get XSPI and GETH0_P0_RGMII output and input function (valid for 3 V operation only)*
P20	13 pins	P20.1, P20.12 - P20.14	Port 20 special features: • P20.0, P20.2 - P20.11 do not support the wake-up feature • All other pins of this port support the wake-up feature

(table continues...)

Table 2447 (continued) Port implementation in TC4DxAA-step

Port module	Pins	Wake-up capable pins	Exceptions and special features
P21	8 pins	P21.6 - P21.7	Port 21 exceptions and special features: • LVDS pins P21.0 - P21.5 do not support the wake-up feature • All other pins of this port support the wake-up feature
P22	12 pins	P22.4 - P22.11	Port 22 exceptions and special features: • LVDS pins P22.0 - P22.3 do not support the wake-up feature • All other pins of this port support the wake-up feature
P23	8 pins	P23.0 - P23.7	Port 23 special features: • All pins of this port support the wake-up feature
P25	1 pins	P25.1	Port 25 special features: • All pins of this port support the wake-up feature
P30	16 pins	P30.0 - P30.15	Port 30 special features: • All pins of this port support the wake-up feature • For the usage of LETH0_P1_RMII output function on this port the corresponding PCSRSEL bit slice on P30.9 - P30.11 has to be set to one and additionally the proper ALT function related to LETH0_P1_RMII output has to be selected
P31	2 pins	P31.6 - P31.7	Port 31 special features: • All pins of this port support the wake-up feature
P32	5 pins	P32.4 - P32.7	Port 32 exceptions and special features: • P32.2 and P32.5 do not support the wake-up feature as they are SMU FSP pins • All other pins of this port support the wake-up feature
P33	16 pins	P33.8, P33.11 - P33.15	Port 33 special features: • P33.0 - P33.7, P33.9 and P33.10 do not support the wake-up feature • All other pins of this port support the wake-up feature
P34	5 pins	P34.1 - P34.5	Port 34 special features: • All pins of this port support the wake-up feature
P35	6 pins	P35.0 - P35.5	Port 35 special features: • All pins of this port support the wake-up feature
P40	15 pins	-	Port 40 special features: • All pins have the SENT feature mapped • Port 40 is not affected by the HWCFG[6] configuration option during reset

47.8.3 TC4Dx PORTS functional description

47.8.3.1 Padframe alarm trigger signals

The pads of the device are combined in a padframe which is split over all four sides (Top (where A1 ball is located), Bottom, Left and Right) of the device. All four parts of the padframe have their own reference voltage generation which is required for a proper pad functionality. If one of the reference voltage generators is not working correctly (reference voltage is too low) an alarm trigger to the SMU is issued. The padframe alarm triggers are grouped in the system trigger alarms:

- ALMSF8 [11] indicates an issue in the reference voltage generation of the bottom part of the padframe
- ALMSF8 [12] indicates an issue in the reference voltage generation of the right part of the padframe
- ALMSF8 [13] indicates an issue in the reference voltage generation of the top part of the padframe
- ALMSF8 [14] indicates an issue in the reference voltage generation of the left part of the padframe

In case a padframe alarm is issued it is recommended to check the pad functionality of the device.

47.8.4 TC4Dx PORTS registers

47.8.4.1 Register address space - Pn

Table 2448 Registers address space - Pn

Module	Base address	End address	Note
P00	$F003A000_H$	$F003A3FF_H$	SPB bus slave interface

47.8.4.49 Port 04 Output Register

The port output register determines the value of a GPIO pin when it is selected by Pn_DRVCFGxx as output. Writing a 0 to a Pn_OUT.Px (x = 0-15) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that the bits of Pn_OUT.Px can be individually set or cleared by writing appropriate values into the port output modification set register Pn_OMSR or port output modification clear register Pn_OMCR, respectively. The Pn_OUT.Px bits can also be set, cleared or toggled with register Pn_OMR within the same write operation.

P04_OUT Offset address: 020_H

47.8.4.61 Port 04 HWSEL status Register

The register HWSELSTAT allows reading back the status of the HW selection lines of all the pins.

This allows the SW to determinate if the Pin state is driven by the SW selection or if a HW module like e.g. LETHx or CSRM took over the control over any signal in the port.

Note: An active Emergency stop request is not reflected in this status register

47.8.4.67 Port port_no Pin Function Decision Control Register (port_no=00-03,10,13-33)

The pad structure of the GPIO lines offers the possibility to disable/enable port pad, select digital input or analog ADC input functionalities. Note that Class S pads have different characteristics than other digital input pads. For analog inputs, PDISx shall be set to 1 to disable the Schmitt trigger input buffer and digital output driver (if exists). Otherwise the specified accuracy of analog functions on overlaid pins (see TMADC accuracy parameters and their footnotes in datasheet) cannot be applied. For the ADC diagnostic features “PDD” however the corresponding PDISCx needs to be 0 to allow activation of their pull resistors. This feature can be controlled by individual bits in the Pn_PDISC register, independently from input/output and pull-up/pull-down control functionality as programmed in the Pn_DRVCFGx register. One Pn_PDISC register is assigned to each port.

***Note**: After reset, all Px_PDISC registers have the reset value of 0000 0000$_H$. The startup software disables only the pads with digital input/output functionality which are available in that package by writing the corresponding bits of not available pads to one. P40_PDISC and P41_PDISC are configured by the SSW for analog input function (kept disabled). The documented reset value shows the value in the largest package.*

Field	Bits	Type	Description
0	31:0	r	**Reserved** Read as 0.

47.8.4.102 Port port_no LVDS Pad Control Register x (port_no=13;x=0-3) (port_no=15;x=5-6) (port_no=22;x=0-1) (port_no=21;x=2)

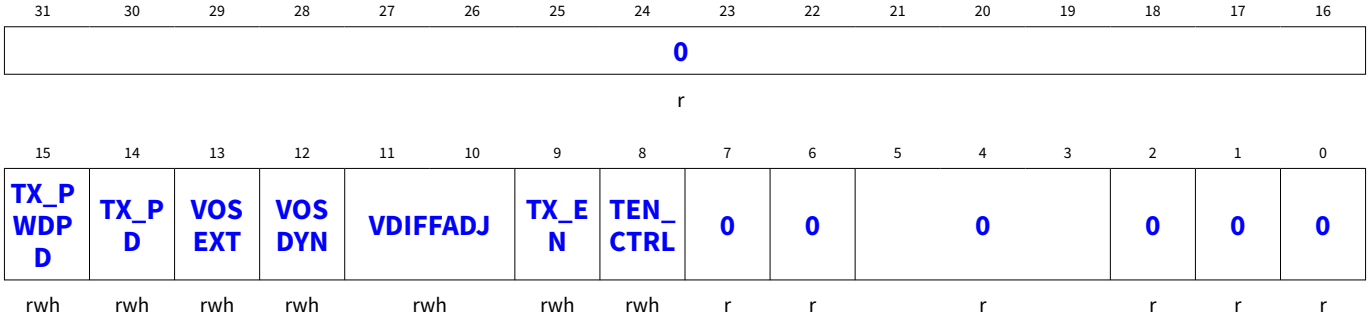
The LVDS Pad Control Register controls the RX or TX functions of the LVDS pads. For usage of RX pad, bit field [7:0] is applicable. If the register is used for TX pad, bit field [15:7] applies.

The sleep functionality of the LVDS pads is not controllable by this register. This is exclusively controlled by the HSCT module when this is connected.

The register x controls in general the pad pair 2*x and 2*x+1 of the port n.

Exceptionally when available the pad pair P14.9 and P14.10 is controlled by P14_LPCR5.

P13_LPCRx (x=0-3)	Offset address:	$04C_H$+x*8
Port 13 LVDS Pad Control Register x	Reset values see:	Table 2501
P22_LPCRx (x=0-1)	Offset address:	$04C_H$+x*8
Port 22 LVDS Pad Control Register x	Reset values see:	Table 2501
P21_LPCRx (x=2)	Offset address:	$04C_H$+x*8
Port 21 LVDS Pad Control Register x	Reset values see:	Table 2502
P15_LPCRx (x=5-6)	Offset address:	$04C_H$+x*8
Port 15 LVDS Pad Control Register x	Reset values see:	Table 2501



Field	Bits	Type	Description
TEN_CTRL	8	rwh	**LVDS TX_EN controller** The LVDS TX_EN control function can be selected from the Port (default) or HSCT module (where this is connected). 0_B Port controlled 1_B Reserved
TX_EN	9	rwh	**Enable Transmit LVDS** Enable the transmit LVDS / disable CMOS path. If this bit is set to 0 - no transfer on LVDS data path can be initiated and the LVDS driver is disabled (powered down). 0_B disable LVDS / enable CMOS mode 1_B enable LVDS / disable CMOS mode
VDIFFADJ	11:10	rwh	**LVDS Output Amplitude Tuning** With these two configuration bits the LVDS output current/amplitude can be adjusted. The voltage swing depending on VDIFFADJ setting is documented in the Data Sheet, see parameter V_{OD} .
VOSDYN	12	rwh	**Tune Bit of VOS Control Loop Static/Dynamic** Tune bit to change V_{OS} control loop between static and dynamic mode. Don’t change reset value.
VOSEXT	13	rwh	**Tune Bit of VOS Control Loop Internal/External** Tune bit to change V_{OS} control loop. Don’t change reset value.
TX_PD	14	rwh	**LVDS Power Down** Unused in this device. LVDS disabled by TX_EN means power down. 0_B LVDS power on 1_B LVDS power down (default)
TX_PWDPD	15	rwh	**Enable TX Power down pull down.** This function disables or enables the LVDS pull down resistor. The application code must disable TX power down pull down resistor with a power up. With a LVDS Power Down configuration the pull down function must be enabled, if required. 0_B disabled TX Power down pull down resistor. 1_B enabled TX Power down pull down resistor.

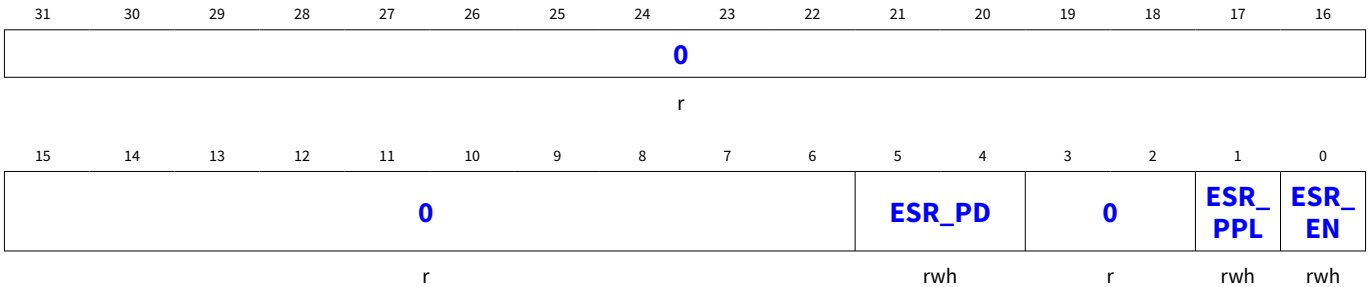
Port 16 Pad Safety and Security Control Register for padp Reset values see: Table 2509



Field	Bits	Type	Description
ESR_EN	0	rwh	**Emergency Request Action Enable** Most GPIO lines have an emergency stop logic implemented (see Figure “PORTS block diagram” in the Family chapter). Each of these GPIO lines has its own emergency stop enable bit ENx that is located in the emergency stop field ESR of Port Pin n. If the emergency stop signal becomes active, one of two states can be selected. Exceptions for Emergency Stop Implementation The Emergency Stop function is available for all GPIO Ports with the following exceptions: • Not available for P20.2 (General Purpose Input/GPI only, overlayed with Testmode) • Not available for P40_x and P41_x (analog input ANx overlayed with GPI) • Not available for P21.2 (used as SMU_EXT_EMERGENCYSTOP_REQ pin). • Not available for dedicated I/O without General Purpose Output function (e.g ESRx, TMS, TCK) The Emergency Stop function can be overruled on the following GPIO Ports: • P00.x: Emergency Stop can be overruled by the TMADC. Overruling can be disabled via the control register P00_PCSR. • P14.0 and P14.1: Emergency Stop can be overruled in the DXCPL (DAP over CAN physical layer) mode. No Overruling in the DXCM (Debug over can message) mode • P21.6: Emergency Stop can be overruled in JTAG mode if this pin is used as TDI • P21.7: Emergency Stop can be overruled in JTAG or Three Pin DAP mode. • P33.0-7, P33.9-15 and P34.1: Emergency Stop can be overruled by the 8-Bit Standby Controller (SCR), if implemented. Overruling can be disabled via the control register P33_PCSR and P34_PCSR. On pins with LVDS TX pads the Emergency Stop affects only the CMOS driver not the LVDS driver. Thus only when LPCRx.TX_EN selects CMOS mode the output is switched off. When TX_EN selects LVDS mode the output is not switched off. 0_B **DIS**: Emergency stop function disabled. The output line remains connected (alternate function). 1_B **EN**: Emergency stop function enabled. The mapped output function is disconnected and the safe state is entered by switching to input function with internal pull-up connected or tri-state, depending on the configured value of the corresponding Port slice PADCFGp_SAFSEC.ESR_PD register.
ESR_PPL	1	rwh	**Emergency status Push-Pull level** Value driven when pin is put in push-pull setup by ESR_PD 0_B The onput level of Pn.x is 0. 1_B The onput level of Pn.x is 1.

Field	Bits	Type	Description
ESR_EN	0	rwh	**Emergency Request Action Enable** Most GPIO lines have an emergency stop logic implemented (see Figure “PORTS block diagram” in the Family chapter). Each of these GPIO lines has its own emergency stop enable bit ENx that is located in the emergency stop field ESR of Port Pin n. If the emergency stop signal becomes active, one of two states can be selected. Exceptions for Emergency Stop Implementation The Emergency Stop function is available for all GPIO Ports with the following exceptions: • Not available for P20.2 (General Purpose Input/GPI only, overlayed with Testmode) • Not available for P40_x and P41_x (analog input ANx overlayed with GPI) • Not available for P21.2 (used as SMU_EXT_EMERGENCYSTOP_REQ pin). • Not available for dedicated I/O without General Purpose Output function (e.g ESRx, TMS, TCK) The Emergency Stop function can be overruled on the following GPIO Ports: • P00.x: Emergency Stop can be overruled by the TMADC. Overruling can be disabled via the control register P00_PCSR. • P14.0 and P14.1: Emergency Stop can be overruled in the DXCPL (DAP over CAN physical layer) mode. No Overruling in the DXCM (Debug over can message) mode • P21.6: Emergency Stop can be overruled in JTAG mode if this pin is used as TDI • P21.7: Emergency Stop can be overruled in JTAG or Three Pin DAP mode. • P33.0-7, P33.9-15 and P34.1: Emergency Stop can be overruled by the 8-Bit Standby Controller (SCR), if implemented. Overruling can be disabled via the control register P33_PCSR and P34_PCSR. On pins with LVDS TX pads the Emergency Stop affects only the CMOS driver not the LVDS driver. Thus only when LPCRx.TX_EN selects CMOS mode the output is switched off. When TX_EN selects LVDS mode the output is not switched off. 0_B **DIS**: Emergency stop function disabled. The output line remains connected (alternate function). 1_B **EN**: Emergency stop function enabled. The mapped output function is disconnected and the safe state is entered by switching to input function with internal pull-up connected or tri-state, depending on the configured value of the corresponding Port slice PADCFGp_SAFSEC.ESR_PD register.
ESR_PPL	1	rwh	**Emergency status Push-Pull level** Value driven when pin is put in push-pull setup by ESR_PD 0_B The onput level of Pn.x is 0. 1_B The onput level of Pn.x is 1.

Date range: 2024-08-17 to 2025-03-13	
Padframe alarm trigger signals	• Section "Padframe alarm trigger signals" moved to device specific functional description (TC49x-N and TC4Dx only)

48 Firmware

Firmware (FW) consists of software components that are stored in read-only memory (ROM). It performs start-up of the device after power-on or reset, and supports additional features such as handling debug access to the device, bootstrap loading of executable code, controlled shut-down after reset request, and power-friendly debug monitor routines for example.

48.1 Feature list

- Real-time cluster (RTC) or system firmware (SYS_FW)
- Cyber-security (CSRM, SECURE) sub-system firmware, abbreviated as CSRM_FW
- User code start address selection and triggering execution
- Standby Controller (SCR) sub-system firmware, abbreviated as SCR_FW

48.2 Functional overview

The figures below summarize the start-up behavior of the device as firmware-controlled after different reset types.

48 Firmware

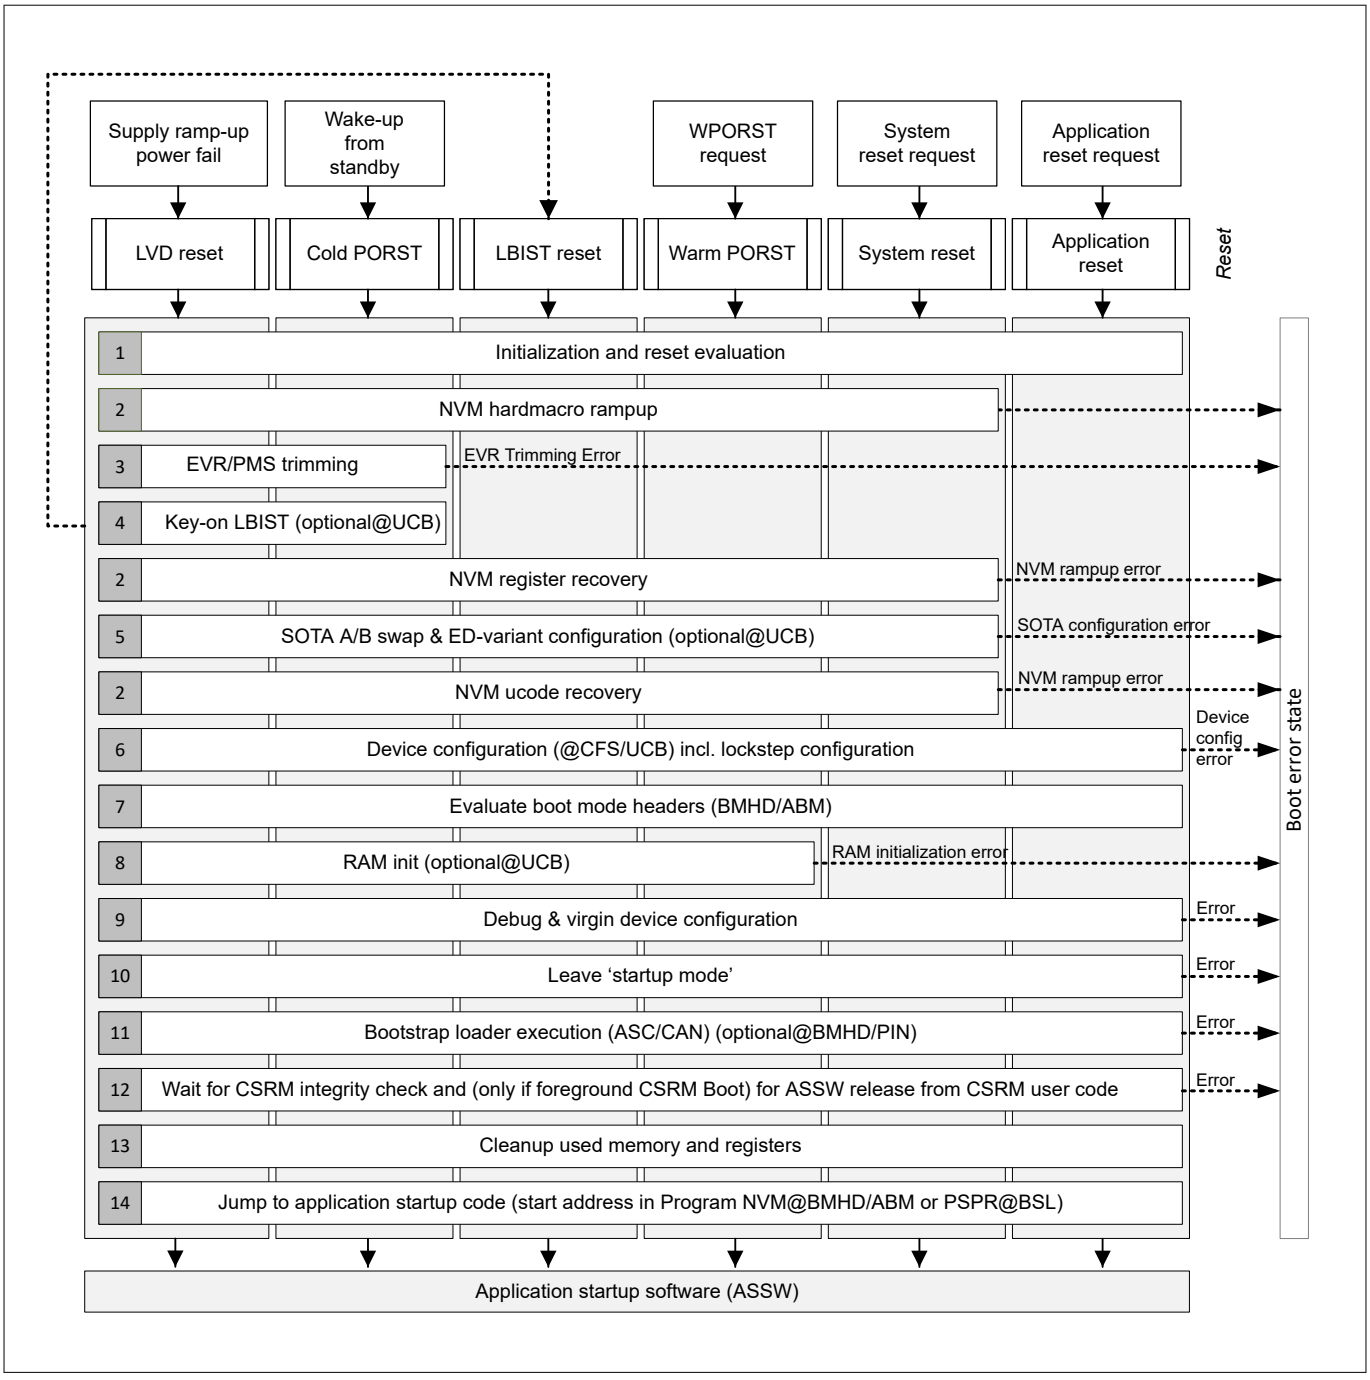

Figure 1256 System firmware flow (HOST cluster)

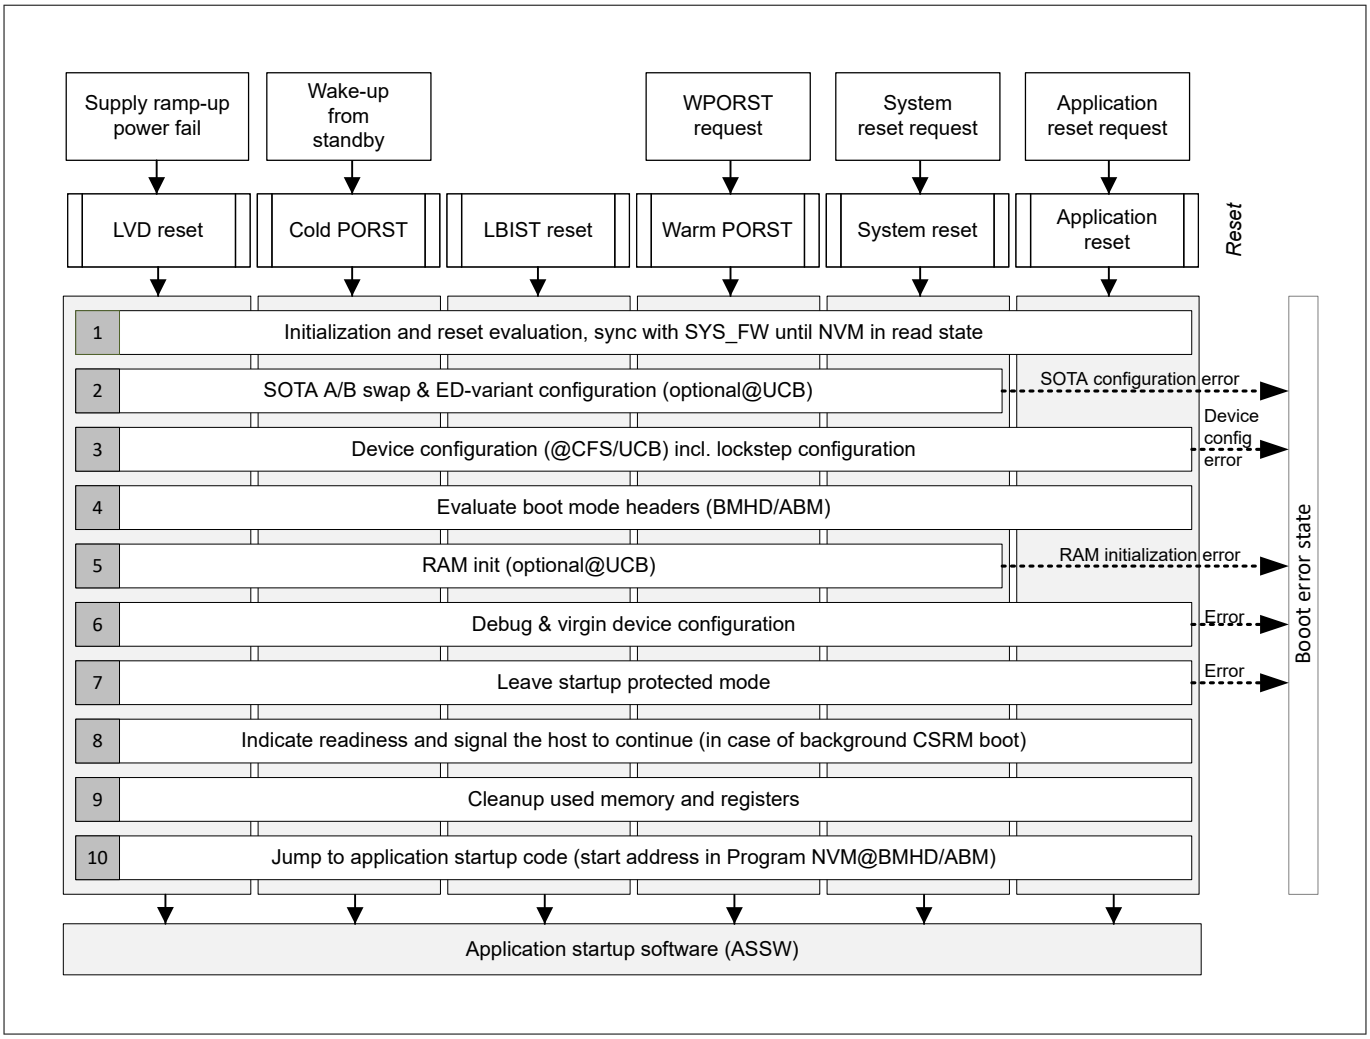

Figure 1257 CSRM firmware flow (SECURE cluster)

Attention*: *Hardware resources used by Firmware

The start-up procedure executed during device boot uses some memories, which means that they can be overwritten during start-up and the content is not preserved through resets, as follows:

- Data scratch-pad RAM (DSPR) of CPU0 and CPUcs - the first 8KBytes, upon any device reset
- Program scratch-pad RAM (PSPR) of CPU0 and CPUcs - the first 2KBytes, upon any device reset

48.3 Functional description

48.3.1 Device dual-core start-up

After every device reset event, Firmware execution starts automatically in parallel on two Central Processing Units (CPU):

- CPU0
  - Also called the Boot Core of the HOST cluster, executing SYS_FW
- Cyber security core (CPUcs)
  - Also called the Boot Core of the SECURE cluster, executing CSRM_FW

It is important to understand that SYS_FW and CSRM_FW work in parallel and are synchronized to ensure for the correct and aligned boot of both the HOST and SECURE clusters.

In addition, it should be noted that:

- CPU0 and CPUcs are only affected by device resets. They are not affected by module or kernel resets
- SCR core is not automatically started by the system. It must be triggered by the user through another core, which may eventually lead to SCR_FW execution
- PPU_FW consists only of functions that support load jump limits during shutdown and software debugging

At the end of the start-up performed by SYS_FW and CSRM_FW, the device is configured and prepared for user software execution according to data stored in the embedded non-volatile memory (NVM) of the device. As the last step from their execution, both the SYS_FW and CSRM_FW perform a jump to the first addresses of respective user software.

48.3.1.1 Variations in the start-up sequence

There are different types of device resets supported in the TC4xx family, all triggering SYS_FW and CSRM_FW execution.

Because the reset types affect different parts of the device, the FW activity after a given reset type also varies. The main variations are distinguished for the following events:

- Power-on, LBIST and system resets
- Application reset

Power-on, LBIST, and system resets

These reset events affect most of the devices functional blocks (FBs), by putting them into their configuration reference state. Most importantly this impacts the clock system and the NVM.

At the end of FW execution after one of these resets:

- Back-up oscillator is used as clock source for the device. The main clock signals have a frequency of 100 MHz or are derived from it keeping the recommended settings. For the clock settings after boot FW phase, refer to “After boot-FW value” information for clock control registers in CLOCKING Chapter of the UM.

  ***Note**: If you have configured the clock system in accordance to the application needs, so that for example PLL is locked and the device is supplied with a higher frequency than 100 MHz, this configuration will be lost after power-on, LBIST, and system resets, and must be re-implemented afterwards.*

- The NVM is ready for execution of all the operations, such as read and program for example

***Note**: If you configure the clock system in accordance to the application needs, so that for example PLL is locked and the device is supplied with a higher frequency than 100 MHz, then the NVM clock dividers must be re-configured to comply with NVM speed limitations.*

After system reset the SYS_FW has a single flow. However there are different flows after power-related and LBIST reset:

- After LVD reset:
  - The SYS_FW performs full device initialization including power system trimming
- After wake-up from stand-by mode:
  - The SYS_FW activity is nearly the same as after LVD reset, except that the SRAMs (volatile memories) being powered during stand-by mode are not initialized, even if selected for initialization after cold power-on according to the user configuration
- After warm power-on and LBIST reset:
  - The SYS_FW flow considers the reset event as “warm power-on”. The power-related components are not touched

Application reset

This type of reset puts fewer functional parts into configuration reference states and the FW activity is the shortest. In particular:

- Clock system configuration is not changed by the application reset or afterward by the firmware
- No memory content is modified, except the memory used by the firmware itself

Please refer to the figures in the 'Start-up sequence' section for the boot flow after different reset types.

48.3.2 Start-up in mission mode (ASIL-D)

The primary purpose of the TC4xx Firmware is to execute safe (ASIL-D) device start-up in so-called 'mission mode'. This is the usual production use of the device as the core part of an automotive ECU (Electronic Control Unit) for example.

The main other non-mission-mode features include development and debug support, which are classified as QM.

***Note**: QM refers to ‘Quality Managed’ – meaning that the development process for such components follows standard and repeatable methodology for development.*

Only after adding some safety mechanisms – e.g. for achieving freedom from interference (FFI) on top of a QM system - given ASIL-level resp. safety compliance can be achieved.

Such features can be invoked within the start-up sequence on user-request, yet they are not meant to be an inherent part of safe mission-mode. QM-feature(s) invocation during the boot is indicated by SYS_FW to the application software (refer to “Exit information after FW execution” Section).

Once development is finalized, deactivation of QM-feature(s) is mandatory in order to support ASIL-claims for boot procedure.

***Note**: CSRM_FW interaction with SYS_FW does not compromise the overall safe start-up of the device in mission mode because of sufficient Freedom From Interference (FFI), which is ensured by the product architecture.*

In case of an error occurring during start-up, such as a lockstep error on CPU0 for example, firmware performs error-handling, resulting in up to 2 additional reboot cycles (refer also to "Firmware exit information" Section).

48 Firmware

The major steps taken by Firmware during safe device start-up are described in the following sections, and the flows are shown in figures at the end of this chapter.

48.3.2.1 Device configuration and trimming of Infineon proprietary features

Configuration and trimming data stored by Infineon during production into NVM is used by Firmware to install essential device settings that ensure correct microcontroller functionality under the specified conditions.

Some data is not installed by Firmware, but can be read by user software. An example of a reason for reading such data is to identify on which exact type of device the user software is running (see CHIPID below).

The settings and data are:

1. Power-management system (PMS) trimming

   The main components covered are the embedded voltage regulators (EVR) and the back-up clock oscillator.

   After this trimming the jitter of the internal oscillator is limited, allowing robust execution of complete start-up. This (fBACK) clock is used as device clock source during the complete start-up procedure after system and power-on resets
2. Variant and package specific configurations

   The following parameters are part of the variant specific configurations:

   - Module and/or pin availability and configuration
   - Timing parameters of SRAMs for optimized performance

     The information from the above groups is installed by Firmware during device start-up in the respective registers.
   - Device identification information on product variant level

   This information can be read by application software from UCB0, where two types of data are available:

   - compact chip-identification within one 32-bit word - CHIPID
   - full product-name known as the SAK number, available for reading by user software in the form of 16-symbol ASCII-coded text - refer to PRODUCT_NAME0 … PRODUCT_NAME3
3. Chip specific configurations:

   - Chip-individual trimming and calibration
   - Security keys
   - Device identification information on chip-unique level

   The device identification information on chip-unique level can be read by the user software from UCID0 … UCID2 and Flash Microcode Version.
4. LBIST configuration and execution

   The LBIST configuration is specific for each AURIX™ derivative, and is optimized for execution time and failure coverage. LBIST configuration is installed into respective control registers by Firmware after cold power-on. LBIST can be triggered during the boot by Firmware if selected by user-programmable settings.

   User selections must be stored in UCB0_17 - refer to Table 2533 - and the detailed description of User selection for LBIST execution.

   If LBIST is triggered by Firmware, the result is available for evaluation by user software after finishing the start-up. The expected LBIST results can be read from LBIST_STAT_RESx_KEYON locations in UCB0, where x represents the target scan domain (x= 0..7).

   The same settings as installed during start-up, if not changed by application, may be used for later user-triggered LBIST execution

   ***Note**: The LBIST configuration settings are always installed after cold power-on, independent of whether LBIST execution during start-up is activated in LBISTEXE.LBEX.*

48.3.2.2 Start-up handling based on user-programmable data

Apart from the Infineon proprietary data stored during production, Firmware also processes and reacts to data stored into NVM by the user.

Attention**:* ***Any incorrectness of the user-programmable data identified during boot will cause the fall-back mechanism to be executed. Note, that following from this for example: even if there is a correct Boot-Mode Header (BMHD) configured but another user configuration is invalid, the device will not execute the start-up according to that BMHD, but according to the fall-back mechanism.
The types of incorrectness which can be identified include (refer to the below definitions):
- wrong system address of this location (SAL) value
- wrong cyclic redundancy check (CRC) value
- undefined/reserved value for some parameter within user-programmable data

Definition of terms used in Register Section:

- System address of this location (SAL)

This 32-bit address is calculated adding the "Offset address" for the location/register shown in its description to the "Base address" of the considered Configuration area module - refer to:

- - Table 2525 for UCB0 module
  - Table 2543 for UCB1 module

The purpose of adding this information is to assure the device start-up against address errors during reading configuration data from NVM. This SAL entry corresponds to the actual address inside the NVM (refer to Configuration area overview table), where from the reading of a configuration data portion starts.

- Length of this table (LEN)

This is the number of 32-bit words, including SAL, LEN itself, all the data in the table and the CRC at its end.

- Check result for this table (CRC)

The validity of configuration data read from NVM is assured by performing a CRC of the data. The data is only used if the check passes.

For the check, IEEE 802.3 standard CRC32 Ethernet polynomial 0x04C11DB7 is used - another representation:
$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$.

48.3.2.2.1 Device handling in delivery state

In delivery state of the device, there are different contents in the various parts of user-programmable data in configuration area/UCB:

- the most of user-programmable data is left in erased state/unprogrammed - meaning all data content is zero and also no valid CRCs are stored, therefore the respective data-blocks are in fact invalid

  If a device is started with such UCB content - no user-code will be started but the firmware will execute so-called "Fall-back mechanism" (refer to the respective Section) allowing the correct user-configuration data to be programmed without erase before that, and then the device started properly
- the following UCBs are programmed during production because if left unprogrammed the device will go into error-state - the information there is security-critical and special coding is used, these are:
  - UCB_CS_DBG_ORIG/COPY (refer to Table 2544)
  - UCB_CS_USERCFG_ORIG/COPY (refer to Table 2553)
  - UCB_RTC_USERCFG_ORIG/COPY (refer to Table 2533)

  If user wants to change the default/programmed state - the respective UCB must be first erased and only afterwards programmed with the target content.

48.3.2.2.2 User-specific device configurations

User configurable options which are handled by Firmware and affect device start-up include:

1. Application reset and/or ESR0 or ESR2 output pin release prolongation.

   This is to allow better start-up synchronization between the microcontroller and other ECU components if or when you forsee such synchronization.

   The values to be installed into ESRxCNTCTRL registers must be stored in UCB0_17 (refer to Table 2533) at SMM_EXTIF_ESR0CNTCTRL and PMS_PAD_ESR2CON locations, according to the register layout described in the SMM and PMS chapters

2. Selectable SRAM initialization and auto-initialization.

   The customer can select - installing respective configuration data in UCB0_17 (refer to Table 2533) - whether the FW execution will impact device SRAMs, in particular:

   - initialize some SRAMs during start-up - for this feature, refer to "SRAM initialization" Section
   - enable or not the auto-initialization of some SRAMs upon enabling of the respective SSH module - refer to "Security-sensitive memories and auto-initialization" in VMT User Manual

3. LBIST execution during start-up

   User selections in regard to this functionality must be stored in UCB0_17 (refer to Table 2533). In delivery state of the device, the LBIST during start-up is deactivated.

   If the user wants to use this feature and activates it in User selection for LBIST execution.LBEX , the following should be considered in regard to customer settings in User selection for LBIST execution.LTC :

   - if LTC = 0..6 – the respective number of sequential unexpected power-drops (1..7) during LBIST execution leading to power-reset and LBIST re-start will at the end put the device into Boot Error state, which is a safe state and can be identified from outside (refer to “Firmware exit information” Section)
   - if LTC = 7 – as long as sequential unexpected power-drops happen during LBIST execution leading to power-reset, LBIST will be continuously restarted; only upon a successful LBIST execution the device will continue and exit the boot phase

4. Re-configuring the Program NVM address map.

   This feature provides the ability to emulate code execution on another device. The advantage of this feature is the easy portability of code, developed and debugged on one device to another one, without the need to relocate software images stored in Program NVM.

   Selections if address re-routing for a device should be activated during start-up must be stored in UCB0_17 (refer to Table 2533) at User selection for ADDRESS ROUTING location.

   The devices from TC4xx family are divided into two groups, and address re-routing is possible only for the devices from a given group. The groups are:

   - Group 1: TC4Dx, TC49xA, TC48x, TC44x, TC42x, TC4Zx
   - Group 2: TC49xN, TC46x, TC4Ex, TC4Px

   Attention**: **The optional configuration described here only affects the access from the CPU side to PFLASH (all CPUs and PFLASH banks) and nothing else. Therefore this feature has to be considered as address re-routing only and not as “full device emulation”.

Additionally to the above, there are user-configuration values which are not handled by Firmware and have no impact on the device start-up - there are two types of such values and respective locations in NVM:

- values, stored by Infineon during production, available for customer usage - these are collected in UCB0_38, refer to Table 2542
- locations, left unprogrammed during production and available for the customer to store there whatever data can be useful for his application - UCB0_15 and UCB0_16, refer to Table 2531, Table 2532

48.3.2.2.3 Boot Mode Lock (BML)

This feature, once installed in UCB, prevents the device from being accessed and user code from being started if invalid boot-mode or other user-programmable information is stored in UCB. See the 'Boot mode evaluation' section. The user selection whether BML is activated must be stored in UCB1 - refer to BML

Attention**:* ***BML is the final switch to set a device into productive state - afterward the Fall-back mechanism is not supported anymore, respectively any configuration-data failure will put the device into errored state. If the failure is permanent - meaning not resolved by consecutive resets - the device can not be booted anymore.

48.3.2.2.4 Software Over-the-Air (SOTA)

SOTA allows 'on-the-fly' update of the software executed on a microcontroller. At any point of time, placeholders for two user-software images are available in NVM. While the microcontroller is executing code from one of these placeholders, the other one can be re-programmed with an alternative code image.

However this is not possible for CPUcs. Aside from having placeholders for two code images, PFLASHcs cannot support reading or executing and programming or verifying simultaneously. This means that while modifying one of the images, no code execution is possible from PFLASHcs.

***Note**:*

- *You must take care that the alternative code is correctly programmed and error-free before selecting it as the active code*
- *The active used or executed code-image is selected from information stored by you into a UCB. The respective UCB and its usage allow for a large number of re-programming cycles during the overall life-time of the device*

The SOTA feature is supported in TC4xx independently for both the HOST and SECURE clusters. This means that the code for execution on either CPUx and/or CPUcs can be fetched from one out of two alternate NVM images for each.

***Note**:* *Because SOTA is supported independently for both HOST and SECURE clusters, if the code images running on the HOST and SECURE clusters must be 'in sync' in regard to the current SOTA or SWAP selections, such synchronization needs to be assured by the user software.*

Your selection if the SOTA feature is in general enabled must be stored:

- For the HOST cluster, in UCB0 at User selection for SWAP activation
- For the SECURE cluster, in UCB1 at User selection for SWAP activation in CS

The selection of the active SWAP configuration is specified in UCB0 for HOST cluster (refer to Register Overview UCB0_19), and UCB1 for the SECURE cluster (refer to Register Overview UCB1_12).

Up to 32 SWAP configurations may be programmed sequentially into any of the UCBs, for HOST and SECURE clusters respectively, without erasing.

After programming and verifying a new SWAP configuration, the previous one must be invalidated by over-programming the SAL and STATUS locations to all-1, which is possible without erasing. The general rules for UCB ORIG and COPY handling (refer to "UCB COPY and ORIG update procedure" Section in NVM Chapter) must be strictly followed for UCB_SWAP and UCB_SWAPcs.

After filling up all the 32 placeholders, the respective UCB should be erased and configuration storage restarted from the beginning of the UCB.

48.3.2.2.5 SRAM initialization

According to the user-programmed information in UCB, Firmware can initialize selected SRAMs both in the HOST and/or SECURE clusters. 'Initialization' here means:

- The data content is set to all-zero
- ECC (error-correction code) values are installed to 'valid'

After initializing the SRAMs can be read, even before being written, and the read will not trigger an ECC error unless there is a real error.

***Note**: Initialization is only done for SRAMs located in power-domains which are supplied during start-up.*

Your selections which SRAMs from the HOST cluster shall be initialized during start-up must be stored in UCB0 - refer to RAMINIT.

Your selections which SRAMs from the SECURE cluster shall be initialized during start-up must be stored in UCB1 - refer to UCB1_15_CSSRAM_init.

48.3.2.3 User code start

The main task of the TC4xx Firmware, targeting both the HOST and SECURE cores, is to prepare and transfer the code execution on CPU0 and CPUcs to user software.

48.3.2.3.1 Boot options

This section summarizes the start-up configurations.

Internal start

In this basic start-up mode, the first user instruction is fetched from the Internal Program NVM of the device.

The user code start address is configurable in the Boot Mode Header data structures, which are programmable in UCB_BMHDx.

Bootstrap loader modes

Different Bootstrap Loader routines are used in these modes to download code or data into the Program Scratchpad RAM of CPU0 (CPU0_PSPR).

The supported Bootloader selections are:

- ASC Bootloader:
  - ASC communication protocol through ASC pins
- Generic Bootloader through CAN pins:
  - The communication protocol is automatically selected by the Firmware between ASC and CAN

After downloading the code, the user code execution is started from the first location in CPU0 Program Scratchpad RAM (PSPR).

Alternate boot modes (ABM)

In these alternate Boot modes, program code is started from a user-defined address, but only if all defined conditions are satisfied. If the conditions are not met, the Firmware can fall back to a Bootstrap Loader mode or Debug Interface connection, to allow download and execution of user code.

All the information needed for the Firmware to handle ABM start-up mode is collected into Alternate Boot Mode Headers (ABMHD).

If this mode is selected and the ABMHD is valid, the user code start address is set to the respective value from the Alternate Boot Mode Header.

48.3.2.3.2 Boot mode evaluation

The Firmware fetches the start address to transfer code execution after device start-up based on user-programmable information structures - called Boot Mode Headers - from the UCBs.

For both the HOST and SECURE clusters, Boot Mode Headers (BMHDx, x=0...3) are evaluated basically with the same sequence:

- The evaluation starts with BMHD0 and goes through up to BMHD3
- For any evaluated BMHDx
  - The confirmation state must be CONFIRMED or UNLOCKED, else the target BMHDx is considered as invalid
  - All the entries must be valid according to the definitions in the next Sections, else the target BMHDx is considered as invalid
  - All the CRC checks must pass, else the target BMHDx is considered as invalid
- Once a valid BMHD is found - it is taken for execution, the rest Boot Mode Headers (if any) remain unchecked
- If no valid BMHD is found - the processing continues as described in "Fall-back mechanism'" section

The Boot Mode Header data-structures allow for selection between:

- Starting the user code directly from a defined NVM address in 'Internal start' mode
- Checking using CRC for validity, a defined NVM address range and start the execution from a defined address if the check is successful, in Alternate Boot mode (ABM)
- For CPU0 (HOST cluster) only:
  - Download code into program scratchpad (volatile memory) of the boot core using a supported communication interface, then start the downloaded code in Bootstrap Loader (BSL) mode

***Note**: All the CRC calculations are made using the TriCore™ instruction CRC32 which implements the IEEE 802.3 standard: CRC-32 polynomial is used and the CRC result is bit-reversed and inverted (where applicable, for ABMHD - refer to "Alternate Boot Mode" Section).*

HOST cluster

***Attention**: For device-specific definitions - refer to "TCxx FIRMWARE information" Section.*

For the HOST cluster, the start-up configuration is stored in one out of four Boot Mode Headers, from UCB_RTC_BMHD0 through to UCB_RTC_BMHD3. Please refer to the detailed structure below, and to:

- Register overview UCB0_09
- Register overview UCB0_10
- Register overview UCB0_11
- Register overview UCB0_12

Table 2513 Boot mode header (UCB_RTC_BMHDx) structure for RTC (HOST cluster)

Field name	Sub-field	Description
SAL	---	System Address of this Location, 32 bit
BMI	---	Boot Mode Index, 16 bit
	reserved bit [0]	Reserved. Must be configured to 1 in UCB_BMHDx

(table continues...)

Table 2513 (continued) Boot mode header (UCB_RTC_BMHDx) structure for RTC (HOST cluster)

Field name	Sub-field	Description
	MODE bits [3:1]	Start-up mode selection: 111_B Internal start from NVM 110_B Alternate Boot Mode (ABM) 100_B Generic Bootstrap Loader Mode (ASC/CAN BSL) 011_B ASC Bootstrap Loader Mode (ASC BSL) else invalid
	reserved bits [15:4]	Reserved. Must be configured to 0 in UCB_BMHDx
BMHDID	---	Boot Mode Header Identifier - 16 bit: $B359_H$ BMHDID OK else BMHDID invalid
STAD	---	Start address, which must always be inside HOST-cluster Program NVM and word-aligned, 32 bit: - if ABM selected - then it is the start address of the Alternate Boot Mode Header - if Internal start selected - then it is the start address of the user code - else - it is not considered for mode selection
CRCBMHD	---	Check result for the Boot Mode Header, 32 bit

SECURE cluster

For the SECURE cluster the start-up configuration is stored in one out of four Boot Mode Headers, from UCB_CS_BMHD0 through to UCB_CS_BMHD3. Please refer to:

- Register overview UCB1_3
- Register overview UCB1_04
- Register overview UCB1_05
- Register overview UCB1_06

Table 2514 Boot mode header (UCB_CS_BMHDx) structure for CSRM (SECURE cluster)

Field name	Sub-field	Description
SAL	---	System Address of this Location, 32 bit
BMI	---	Boot Mode Index. 16 bit
	reserved bit [0]	Reserved, must be configures to 1 in UCB_CS_BMHDx
	MODE bits [3:1]	Start-up mode selection: 111_B Internal start from NVM 110_B Alternate Boot Mode (ABM) else invalid
	reserved bits [15:4]	Reserved. Must be configured to 0 in UCB_BMHDx

(table continues...)

Table 2514 (continued) Boot mode header (UCB_CS_BMHDx) structure for CSRM (SECURE cluster)

Field name	Sub-field	Description
BMHDID	---	Boot Mode Header Identifier, 16 bit: $B359_H$ BMHDID OK else BMHDID invalid
STAD	---	Start address which must always be inside SECURE-cluster NVM and word-aligned, 32 bit: - if ABM selected - then it is the start address of the Alternate Boot Mode Header - if Internal start selected - then it is the start address of the user code - else - not considered for mode selection
CRCBMHD	---	Check result for the Boot Mode Header, 32 bit

Alternate Boot Mode

Alternate Boot Mode handling is controlled by the content of Alternate Boot Mode Headers. The structure of a single Alternate Boot Mode Header is defined below.

Table 2515 Alternate Boot Mode Header (ABMHD) structure

Offset address	Size byte	Field name	Description
00_H	4	STADABM	User Code Start Address in ABM mode
04_H	4	ABMHDID	Alternate Boot Mode Header Identifier: $FA7C\ B359_H$ - ABMHDID OK else - ABMHDID invalid
08_H	4	CHKSTART	Memory Range to be checked - Start Address
$0C_H$	4	CHKEND	Memory Range to be checked - End Address
10_H	4	CRCRANGE	Check Result for the Memory Range
14_H	4	CRCRANGE_N	Inverted Check Result for the Memory Range
18_H	4	CRCABMHD	Check Result for the ABM Header
$1C_H$	4	CRCABMHD_N	Inverted Check Result for the ABM Header

The Alternate Boot Mode Header(s) can be located starting at arbitrary word-aligned locations inside Program NVM. The start address is taken from the STAD field of the Boot Mode Header selecting ABM.

Attention*:** ***Both the NVM address areas for cached and non-cached access are considered as allowed locations by this evaluation procedure. However both CHKSTART and CHKEND must be either in cached or non-cached segment and mixing is not allowed.

***Note*:** *The size of the Memory Range to be checked must not exceed 512 KB otherwise the specified device boot-time will be violated.*

48.3.2.3.3 Boot-Mode Headers handling

All the UCBs intended to contain BMHDs can be programmed without further as long as being in UNLOCKED state.

Once set to CONFIRMED state – the UCB content becomes write-protected and password is needed to deactivate the protection and allow programming. This password should be stored by the customer at the respective locations before setting the UCB to CONFIRMED state, if not – the default password is all-zero.

Besides all the BMHD UCBs do contain locations for holding passwords, it is enough to provide correct password to anyone out of the BMHD UCBs for the respective cluster (HOST/SECURE) to unlock all the BMHD UCBs within that cluster.

The general sequence to be followed (both for HOST and SECURE cluster, short notation clst=RTC, CS below) when a new BMHD must be programmed is:

- check if there is still a not yet programmed UCB_clst_BMHDx to be used for the new BMHD
  - if not – use UCB_clst_BMHD0 for the new BMHD
- check if the target UCB for the new BMHD is in CONFIRMED state
  - if yes – provide correct password to the target or any other BMHD UCB from the respective cluster to de-activate the protection
- program and verify the new BMHD content
- invalidate the previously active BMHD UCB by over-programming the SAL and BMI_BMHDID locations to all-one
- set the target UCB to CONFIRMED state - if desired to make it protected
- once the new BMHD must be taken for device re-start – trigger a system reset

48.3.2.3.4 Fall-back mechanism

This fall-back mechanism is activated if some invalid user-configuration data is found during start-up. The processing in such a case is different for HOST and SECURE clusters, depending primarily on the user-configurable Boot Mode Lock (BML) in UCB1 and which user-configurable data failed the checks.

***Note**: Once Fall-back mechanism is activated - the device start-up is no more safe, and this is indicated by setting STMEM1.QME bit (QM-part entered) - refer to SMM Chapter.*

- In HOST cluster:
  - if BMHD UCB(s) failed AND BML evaluation in UCB1 has been successful
    - if BML is active - device enters Boot Error State, "BMHD invalid" is indicated by SMM_STMEM1.BV=0
    - if BML is not active
      - in case debug access to device is granted and halt-after-reset request is sent through the debug interface - CPU0 shall enter HARR as fall-back state
      - otherwise - SYS_FW starts Generic BSL routine, waiting to start communication for downloading code or data through CAN or ASC interface
  - If other invalid user-programmable data is found in UCBs for HOST cluster
    - device boot continues
    - default configuration settings are taken, as follows:
      - LBIST execution during boot is disabled
      - SWAP is disabled, default address map after reset remains active
      - no SRAM initialization during start-up

- auto data-init enabled
- default ESR settings after reset remain active

- In SECURE cluster:
  - if BMHD UCB(s) failed AND BML evaluation has been successful
    - if BML is active - CPUcs enters Error State meaning no user code is started in SECURE cluster, HOST boot may continue
    - if BML is not active
      - in case debug access to device is granted and CSRM debugging is enabled (in Debug configurations.CSRMDBGDIS) - CPUcs shall enter HARR as fall-back state
      - otherwise - CPUcs enters Error State meaning no user code is started in SECURE cluster, HOST boot may continue
  - if UCB_CS_SWAP evaluation failed
    - device boot continues
    - SWAPcs is disabled, default address map after reset remains active
  - if other invalid user-programmable data is found in UCBs for SECURE cluster
  - - CPUcs enters Error State meaning no user code is started in SECURE cluster
    - HOST boot may continue - this will be the case only if background non-blocking SECURE boot is configured, refer to "Foreground and background CSRM boot" Section.

The CPUcs Error State represents an endless NOP-loop, and this is the fallback behavior for SECURE cluster.

The only error-scenario in SECURE cluster which can be identified from outside is if CPUcs does not enter Error State and:

- no valid BMHD found and BML is not active, AND
- debug access is granted and CSRM debugging is enabled in Debug configurations.CSRMDBGDIS, AND
- CSCU APU has been opened by code executed on CPUcs for accesses from CBS

If the above conditions are met, CSCU_STMEMx registers can be read through debug interface and the following flags checked:

- CSCU_STMEM1.BV = 0 – no valid BMHD found
- CSCU_STMEM1.CON_E = 1 – invalid configuration found in UCB1
- CSCU_STMEM2.BOOT_ADDR = 0 – no valid boot-address for CPUcs

HARR as fall-back state

The handling in this case is basically the same as any Halt-after-reset, with one difference:

- in the generic case, the program counter of the CPU being halted is installed with the address of the first user-software instruction - according to the selected mode and start address as from BMHD information
- when HAR taken as fall-back state, the program counter of the CPU being halted is installed with the first address in the user-area of Program scratch-pad RAM (PSPR) of the respective CPU - 0xC0000800 (the first 2KB of Boot CPU PSPR are used by Firmware).This is the local address, meaning any halted Boot CPU (CPU0, CPUcs) will have PC register pointing to its own PSPR.

48.3.2.3.5 Foreground and background CSRM boot

The start-up of HOST and SECURE clusters is synchronized by interaction between SYS_FW and CSRM_FW.

User Configuration data selects between:

- Foreground CSRM boot
  - With this option CSRM_FW starts the user code execution on the CSRM CPU first. Meanwhile SYS_FW waits for a release trigger handshake from the CSRM user code

    CSRM user code must later release SYS_FW to continue its execution by installing CSCU_CSRM2HT.RL according to the register description (refer to User Manual, CSRM Chapter). Only after such a release trigger from CSRM the user code execution in the Real Time Cluster is started by SYS_FW.

    With this selection, any failure during CSRM boot terminates the start-up and the device enters error-state.
- Background CSRM boot
  - With this option the user code execution in both the HOST (on CPU0) and SECURE (on CPUcs) clusters is started by SYS_FW and CSRM_FW immediately after successful device boot. If further interaction between the clusters is needed, it must be fully handled by the user software.

    There are two options for this CSRM boot type:

    - fatal/blocking - any failure during CSRM boot terminates the start-up and the device enters error-state
    - non-blocking - upon a failure during boot, CSRM_FW enters endless loop, respectively no user-code is started in SECURE cluster. SYS_FW will be completed and user-code started in HOST cluster, if possible - e.g. if Data NVM in SECURE cluster is successfully ramped to allow reading configuration data from there.

      The CSRM boot failure is indicated by setting bit CS_E=1 in STMEM1 register

The selection which CSRM boot mode to use upon any reset type must be stored in UCB1 - refer to CSRM boot - user selection.

IMPORTANT NOTE:

Only combinations between foreground/background CSRM boot mode upon different reset types shall be configured by the user as shown in the below Table.

Table 2516 Allowed CSRM boot mode combinations vs. device reset types

Combination No.	Cold power-on	Warm power-on	System reset	Application reset
1.	Foreground	Foreground	Foreground	Foreground
2.	Foreground	Foreground	Foreground	Background
3.	Foreground	Foreground	Background	Background
4.	Background	Background	Background	Background

48.3.3 Development support

Before a device can be utilized in Mission mode, that is running as part of a real application (ECU), it must first be configured and programmed as required for the given application requirements. The Firmware therefore implements several development support features for this purpose.

***Note**: Once any of the development features are used, device start-up is no longer safe or ASIL-D compliant, because these features are not intended for use in Mission mode. This is indicated by setting STMEM1.QME bit (QM-part entered) - refer to SMM Chapter.*

Related information

Debug information on page 9005

48.3.3.1 Bootstrap loaders

One of the supported ways to start user code after SYS_FW completion is the Bootstrap Loader (BSL) mode.

If selected by user-configuration in UCB, this mode:

- Allows for use of either the CAN or ASC communication interface for downloading code or data into the Program Scratchpad RAM (PSPR) of the HOST boot core (CPU0)

  ***Note**:* *The BSL feature is not supported in SECURE cluster, CPUcs.*

- Start execution of the downloaded code from the first PSPR location after SYS_FW completion

  Attention**:* ***BSL mode is intended for initial programming and/or configuration of the device being initially in delivery state, and not for usage in normal operational mode of the device as part of ECU, and particularly not in case the security functionality is utilized.

Related information

Boot mode evaluation on page 8784

48.3.3.1.1 ASC bootstrap loader

The ASC bootloading routine implements the following steps:

- Configure RxD and TxD pins
- Wait to receive a zero byte (8 data and 1 stop bit)
- Calculate baudrate based on the zero byte duration
- Send acknowledge byte $D5_H$ to the host, indicating the device is ready to accept data transfer
- Enter a loop to receive 128 bytes which are stored as 32 words in CPU0 Program Scratchpad RAM (PSPR), starting from the first address location
- Once 128 bytes are received, user code execution is started from the first CPU0_PSPR address location

  In the intended use-case for initial device programming (refer to the previous Section), the Bootstrap Loader supports the following ASC communication speeds:

  - 28000 Baud
  - 38400 Baud
  - 57600 Baud
  - 115200 Baud
  - 300000 Baud

48.3.3.1.2 CAN bootstrap loader

The CAN bootstrap loader (CAN BSL) transfers program code or data from an external host through a CAN interface into CPU0 Program Scratchpad RAM. It is a primary bootloader, and should not be confused with the secondary bootloader which can be purchased from tool partners.

The main characteristics of the AURIX™ TC4xx CAN Bootstrap Loader are:

- Classical CAN is supported
- The initial identifier is fixed to 555_H
- The number of data frames to be received by BSL is programmable

The communication between the TC4xx and an external host is based on the following three CAN standard frames:

- Initialization frame(s)
  - Sent by the external host to TC4xx
- Acknowledgment frame(s)
  - Sent by the TC4xx to the external host
- Data frame(s)
  - Sent by the external host to TC4xx

Related information

CAN BSL flow on page 8792

Back-up clock used for CANXL

This is the clock system status after device system and power-on reset during CAN BSL execution.

This is the case in the delivery state of the device, when the back-up clock is used as clock-source for the CANXL module during CAN BSL, after performing the following configurations:

• fBACK/5 is selected as clock source for fCANXLI

• fCANXLI is selected as clock source fCANXL

The CANXL module operates with a 20 MHz clock for the asynchronous part as provided by the TC4xx internal back-up clock source.

The supported features are:

- Classical CAN
- Sample point of 60%
- Baudrates:
  - 100 KBit/s
  - 125 KBit/s
  - 250 KBit/s
  - 500 KBit/s

CAN BSL flow

The CAN bootstrap loader flow, shown in the figure below, consists of 3 phases. There is a phase 1 is initialization and knowledge, followed by a phase 2 initialization and knowledge, and then a data loading phase.

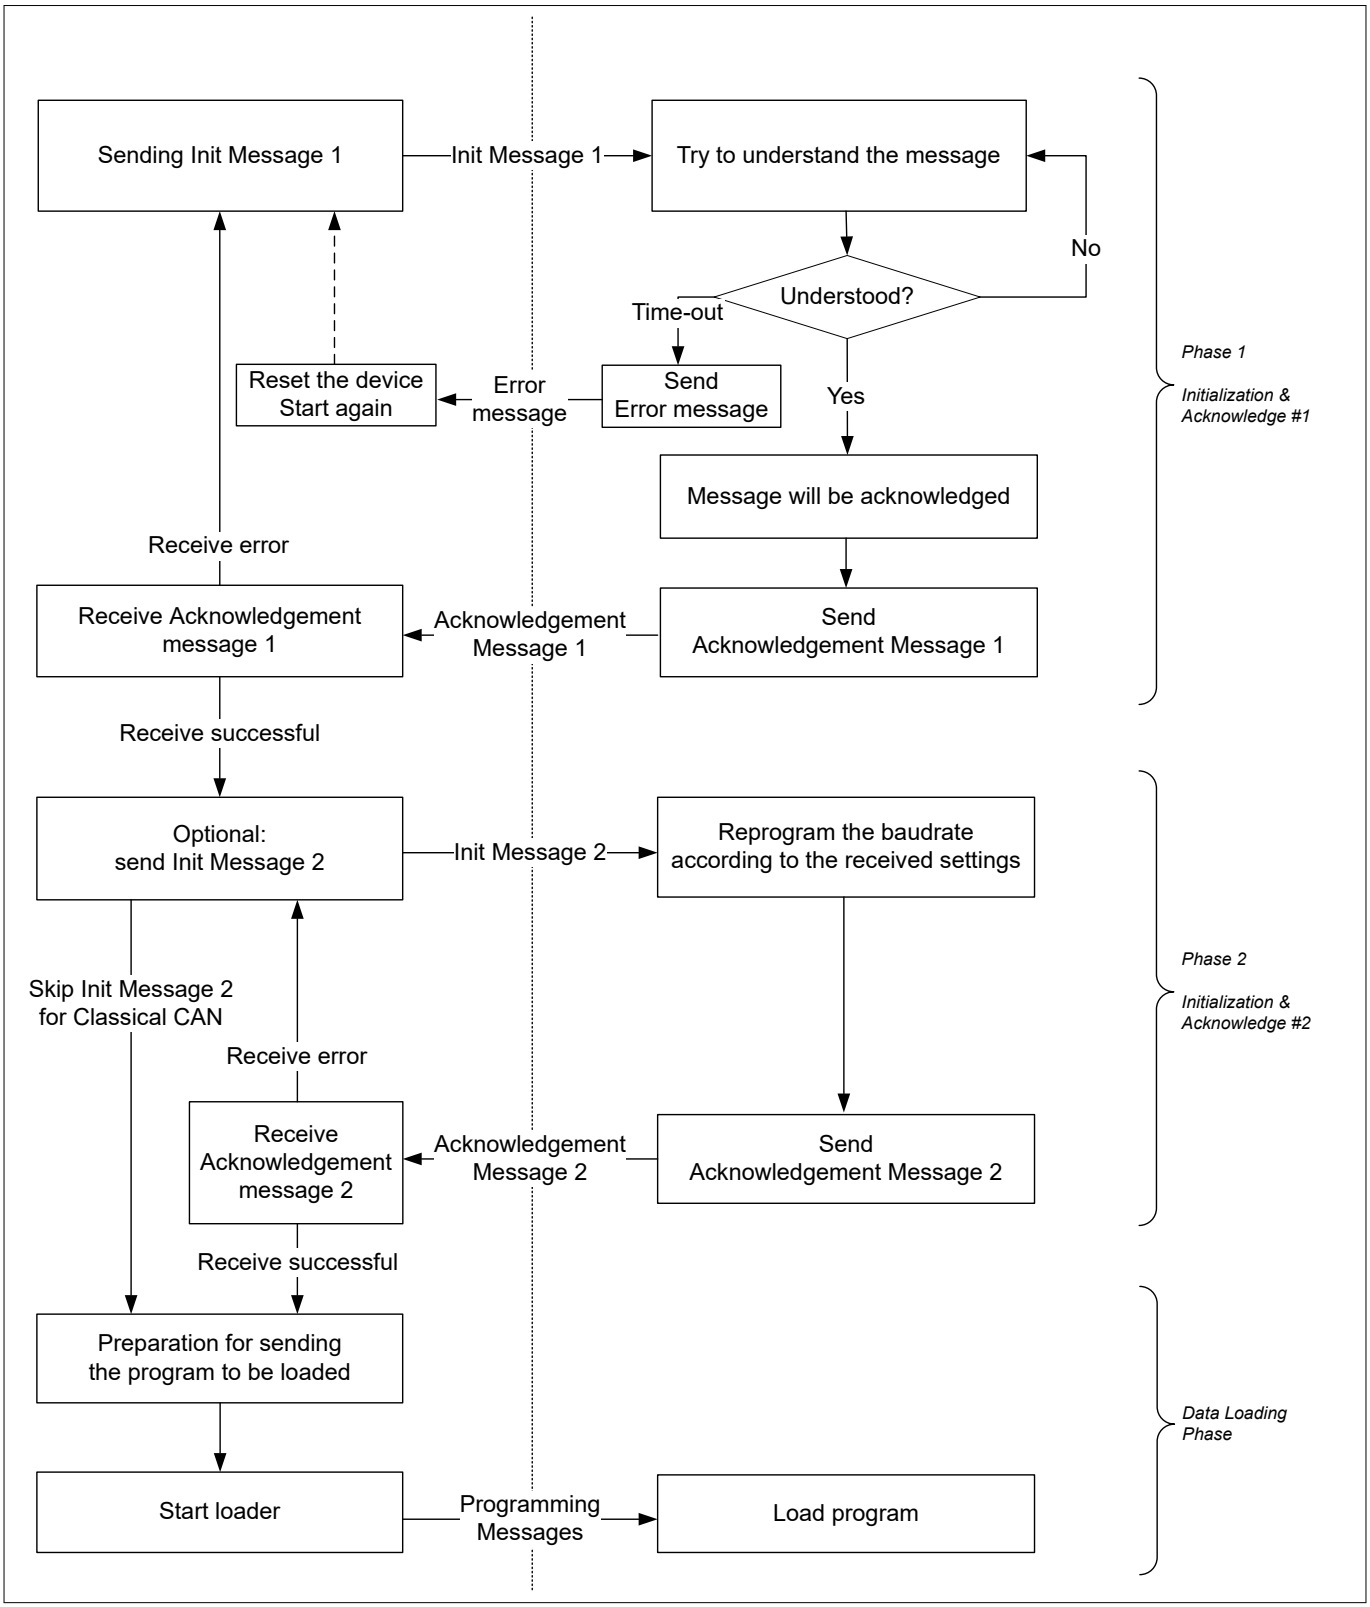

Figure 1258 CAN BSL flow

Key to abbreviations:

- ACKID
  - Acknowledgment Message shall have this 11-bit Identifier (like in register)
- DMSGC (data messages count)
  - Amount of messages which will be sent including the program
- DMSGID (data messages identifier)
  - The data frames will have this 11-bit ID (like in register)
- TSEG1 and TSEG2
  - Baudrate as used (copied from register)
- NBTP
  - Nominal bit timing and pre-scaler register settings (Classical CAN has arbitration segment only)
- DBTP
  - Data bit timing and pre-scaler register settings (Fast Segment)
- DBPM
  - Data Bytes per Message (DLC= [9, 11] is not allowed)

Phase 1 initialization and acknowledge (#1)

During this phase, CAN BSL tries to determine the CAN baud rate at which the external host is communicating and to understand (receive correctly) the initialization message (classical CAN message) sent by the host.

This requires that the external host sends initialization message 1 continuously to the AURIX™ TC4xx in classical CAN format, as shown in the following table:

Table 2517 Initialization message 1

ID	DLC	DB0	DB1	DB2	DB3	DB4	DB5	DB6	DB7
Requested frame format: Classical CAN									
555_H	8	55_H	55_H	ACKID Low	ACKID High	DMSGC Low	DMSGC High	DMSGID Low	DMSGID High

CAN BSL evaluates the incoming messages trying to identify content according to the table above, and according to the result:

- If the message is understood then the CAN BSL:
  - Configures the CANXL module for the selected baudrate settings
  - Acknowledges the next received initialization message 1 Tx ACK bit field as dominant
  - Sends acknowledgment message 1 with the format shown in the acknowledgment table below. This message also informs the host whether the reception was error-free or not
- If initialization messages can not be understood for any supported baudrate settings then:
  - CAN BSL sends error message with the format shown the table below: Error message (No baudrate detected)
  - CAN BSL terminates - the device should be re-started with a reset

Table 2518 Acknowledgment message 1

ID	DLC	DB0	DB1	DB2	DB3	DB4	DB5	DB6	DB7
Frame: Message received error free									
ACKID	8	ACKID Low	ACKID High	DMSGC Low	DMSGC High	DMSGID Low	DMSGID High	TSEG1	TSEG2
Frame: Faulty DLC									
ACKID if not received AA_H	as received	AA_H	AA_H	AA_H	AA_H	AA_H	AA_H	AA_H	AA_H

Table 2519 Error message (No baudrate detected)

Frame	ID	DLC
I do not understand	AAA_H	0

Phase 2 initialization and acknowledge (#2)

Once the acknowledgment message 1 from CAN BSL is successfully received, the host can send initialization message 2 with the format shown in the table below.

This message is optional allowing the host to provide a more precise baudrate for further classical CAN operation. In such a case, a jump in baudrate in any direction for the arbitration segment is not allowed:

Table 2520 Initialization message 2

ID	DLC	DB0	DB1	DB2	DB3	DB4	DB5	DB6	DB7
Frame format requested: Classical CAN									
555_H	4	NBTP. NTSEG2	NBTP. NTSEG1	NBTP. [23..16]	NBTP. [31..24]				

If after sending acknowledgment message 1 that initialization message 2 is received but not programming message (differentiation done on the message ID), the CAN BSL analyzes this message against the format shown in the table below, and then:

- If classical CAN has been requested (DLC=4):
  - Install the (more precise) baudrate settings (NBTP register) as received
  - Send acknowledgment message 2 indicating 'error free' (refer to the table below)
- If the message has been wrongly received (DLC other than 4):
  - Send acknowledgment message 2 indicating 'Faulty DLC' (refer to the table below)

Acknowledgment message 2 sent by CAN BSL and indicating 'Error free', tells the external host that the device is now ready to receive data frames.

Table 2521 Acknowledgment message 2

ID	DLC	DB0	DB1	DB2	DB3	DB4	DB5	DB6	DB7
Frame: Message received error free									
ACKID	4	NBTP. NTSEG2	NBTP. NTSEG1	NBTP. [23..16]	NBTP. [31..24]				

(table continues...)

Table 2521 (continued) Acknowledgment message 2

ID	DLC	DB0	DB1	DB2	DB3	DB4	DB5	DB6	DB7
Frame: Faulty DLC									
ACKID	as received	AA_H	AA_H	AA_H	AA_H	AA_H	AA_H	AA_H	AA_H

Data loading phase

After receiving acknowledgment message 2 from CAN BSL, or if Phase 2 (initialization and acknowledge) has been skipped, the host starts sending programming messages with the format shown in the table below.

CAN BSL receives the data and stores it in CPU0 Program Scratchpad RAM (PSPR) starting from address $C0000000_H$.

Both communication partners evaluate the data message count until the requested number of CAN data frames has been transmitted.

After the reception of the last CAN data frame, CAN BSL terminates and the user code will be started from address $C0000000_H$ in CPU0 PSPR.

Table 2522 Programming message

DLC	DB0	DB1	DB2	DB3	DB4	DB5	DB6	DB7
Frame format requested: Classical CAN								
8	Hex Code Byte	Hex Code Byte	Hex Code Byte	Hex Code Byte	Hex Code Byte	Hex Code Byte	Hex Code Byte	Hex Code Byte

48.3.4 Firmware exit information

After successful completion of the device boot, information is indicated to the application software in System Mode Management (SMM) registers. A summary of that information is provided here - for register layout information, refer to SMM Chapter.

- STMEM1 register indicates the boot status:
  - Which BMHD is valid and taken
  - The start-up mode selected
  - Whether and which SOTA configuration is installed
  - Whether CSRM start was successful
  - Either a QM part of SYS_FW has been executed or not. The device start-up is safe only if no QM part entered
- STMEM2 register contains the address of the first user instruction taken after Firmware
- RSSTATBFW indicates the reset type being processed by Firmware

If Boot Error State is entered during device start-up, the error code can be read-out from COMDATA register through the debug interface.

For the description of COMDATA register in regard to hardware-related attributes (address, access conditions) - refer to the DEBUG chapter in the OCDS documentation.

The bit field description in case the register is used to indicate a boot error is shown in the below table.

Table 2523 COMDATA boot error bit field description

Field	Bits	Description
TYPE	31:30	Error Type: 00b - no error occured 01b - runtime 10b - development 11b - transient
FEATURE_ID	29:24	Feature causing the error: 0x00 - Generic error (e.g. unexpected trap) 0x01 - MCU preparation 0x02 - NVM ramp-up phase A - analog block ramp 0x03 - NVM ramp-up phase B - NVM Bank ramp 0x04 - NVM ramp-up - register recovery phase 0x05 - BMHD evaluation 0x06 - SOTA support handling 0x08 - NVM ramp-up - microcode recovery 0x0F - Debug handling 0x15 - SRAM initialization 0x16 - NVM ramp-up - configure DMU else - contact Infineon representative/FAE for further information
ERROR_ID	7:0	ID of the error - contact Infineon representative/FAE for further information
0	23:8	Reserved

48.3.5 Power-related features

In addition to device configuration, user code start and development support, another Firmware aim is to 'flatten' power-consumption fluctuations during run-time slots that are under Firmware control.

Several Firmware features are available to help reduce these fluctuations, but this section focuses on:

- Limiting load jumps during start-up
- Shutdown request handlers

Related information

Power-friendly debug monitor routines on page 9006

48.3.5.1 Limiting load jumps during start-up

This limiting measure is applied for events other than application reset. Application reset is intended not to change the major device or system settings such as clock configuration, but just to re-start application software execution

After system and power-on resets, firmware takes care for power-consumption increase steps to be within the specified or allowed range. The measures foreseen include:

- Clock increase in steps, if needed, according to the consumption of the modules supposed to be active at any phase
- SRAMs initialization in groups, and not all selected at once. Grouping is adapted to the consumption and work frequency of the target memories

After application reset, the Ramp Oscillator is used to increase the system frequency in small steps.

Related information

Power-friendly debug monitor routines on page 9006

48.3.5.2 Shutdown request handlers

Routines with this purpose are integrated as parts of SYS_FW, CSRM_FW, and PPU_FW, and they are all automatically called, by hardware, after any warm reset request received or processed by the Reset Controller. The Reset Controller is part of the System Mode Management unit (SMM).

The idea behind is the same as the motivation for implementing 'Power-friendly debug monitor routines'. As the user code execution before the reset may have been causing some power-consuming activity, just stopping this activity with a reset will cause a strong drop-down in power consumption, and this may lead to big and undesired fluctuations on the power-supply lines.

These routines are different for CPUs from the HOST cluster (CPU0…n), the SECURE cluster (CPUcs), and the PPU, but the purpose is the same:

- Once entered, any of the routines starts execution of a code loop with “mediate power consumption”
- This loop is executed:
  - For CPUx (x=0…n) and CPUcs, until a dedicated to any CPUx time-out is elapsed, indicating the “shutdown state” is reached for the respective target CPU, then that CPU is put by firmware into IDLE state. This reduces power-consumption for the respective sub-system to a minimum
  - For PPU, until the reset is effectively activated (by SMM)

Additionally, after an application reset request, the Ramp Oscillator is used to decrease the system frequency in small steps.

As result from the above measures, the power-consumption of the device after reset-request activation is consequently reduced without big drops until the reset is effectively triggered. Thus the customer system power supply gets no sudden load-drops - which drops could cause supply voltage to jump outside of the specified range.

Basic debugging capability on page 8798

48.3.6.1 Start-up procedure

This procedure initializes the SCR to a known state after reset to ensure stable operation, before branching to various boot modes.

Which boot mode is taken depends on the SCR configuration (SCRCFG) value provided in the PMS_SCR_CON0 register. The SCRCFG value and corresponding boot mode are detailed in the following table:

Table 2524 SCR boot modes and SCRCFG values

SCRCFG value	SCR boot mode
000_B	User mode. Program execution started from XRAM (default value after reset)
001_B	OCDS mode, SoC debug interface (DAP or SPD, controlled from SoC)
010_B	OCDS mode, SCR DAP interface, DAP0_0 and DAP1_0 pins selected
011_B	OCDS mode, SCR DAP interface, DAP0_1 and DAP1_1 pins selected
100_B	OCDS mode, SCR SPD interface, SPD_0 pin selected
101_B	OCDS mode, SCR SPD interface, SPD_1 pin selected
else	Reserved

Acronyms used in the table:

- DAP
  - Device access port
- SPD
  - Single pin DAP

When the SCR is booted in User mode, the SCR_FW checks whether the content at SCR XRAM addresses $7FF8_H$ through $7FFF_H$ matches the pattern 55_H, AA_H, 55_H, AA_H, 55_H, AA_H, 55_H, AA_H which is used as condition that valid code is available in SCR XRAM:

- if the pattern is found
  - SCR_FW indicates OK with setting SCR_SCRINTEXCHG register to 80_H
  - SCR_FW starts the user software from SCR XRAM address 0_H
- if the pattern not found
  - SCR_FW indicates FAIL with setting SCR_SCRINTEXCHG register to 81_H
  - SCR_FW enters an endless loop until the next SCR reset

This means that before the SCR is released from reset, the SCR user software must be downloaded into SCR XRAM, where:

- The first instruction or jump table must be located at address 0_H
- At addresses $7FF8_H$ through to $7FFF_H$ the pattern 55_H, AA_H, 55_H, AA_H, 55_H, AA_H, 55_H, AA_H must be stored - it is used by SCR_FW as check-condition that valid code is available in SCR XRAM

48.3.6.2 Basic debugging capability

This FW part in combination with the hardware of On-Chip Debug Support (OCDS) system of SCR provides basic debugging capability to the user, when the device is started in OCDS mode (as of the above Table), refer to "Debug Information" Section in SCR Chapter of this Manual for further information.

Access conditions description:

- Y - always accessible
- N - not accessible
- Y but PWD - all content is readable, the PWD is only readable if UCB is UNLOCKED or if the correct password (PWD) was provided to disable protection command
- UNL/PWD - accessible if confirmation state is UNLOCKED or if the correct password (PWD) was provided to disable protection command
- if set UNL - accessible if this "set" is UNLOCKED
- if all set UNL - accessible if all "sets" are UNLOCKED
- EDDM - accessible if confirmation state is UNLOCKED or Destructive Debug Mode is NOT entered

***Note**: In the further descriptions, for the standard locations as:*

- *System address of this location (SAL)*
- *Length of this table*
- *Check result for this table (CRC)*
- *Password*
- *Confirmation Code and (optional) its copy*

only the locations are shown in the Register overview Tables, no detailed description as it is implicitly clear.

Refer to the above Configuration area overview to identify the presence of password for any part.

Reserved - meaning currently not used - locations are not shown, except some ones, which may become used in future - in these cases the potential target registers are shown.

***Note**: In the further detailed register descriptions, the shown (reset) values are in principle not corresponding to the locations' content after device boot – it depends on:*

- *Values stored by Infineon during chip production and by OEM/Tier1 during ECU production (if chip mounted)*
- *Values stored by the customer into user-programmable locations*

For more information – refer to "Start-up handling based on user-programmable data" Section.

48.4.2 User-relevance of the data in Configuration area

The below Table shows how the configuration data areas in DFLASH0 and DFLASH1 are handled in case of error found during boot, and at which phase of chip life-cycle the respective content is programmed.

UCB1_25	UCB_CS_USER_DATA1 - User data CS storage 1 Detailed layout in Table 2555	N.A.	Plant

Handling upon error in content:

- No boot - The device does not boot
- BML - Fallback entered if BML not active
- BML * - Fallback entered if BML not active and all BMHDs failed evaluation
- N.A. - Does not affect the device boot

Programming:

- IFX - During production of the chip
- Plant - During production of the ECU,acc. to customer application requirements **
- Field - On the field, by the customer application **
- N.A. - Not used - left unprogrammed

** The differentiation between “plant” and “field” programming is just a proposal - both are under customer control and can be done wherever appropriate for the target application

rh															

Field	Bits	Type	Description
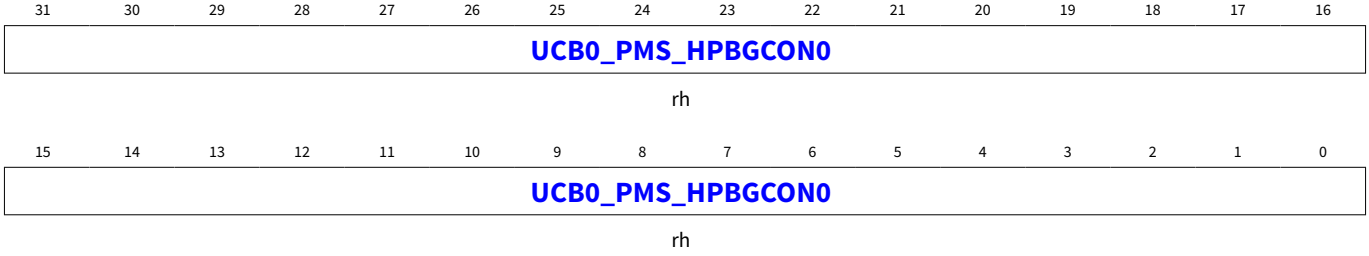
UCB0_PMS_HPOSCCON0	31:0	rh	**PMS_HPOSCCON0 register value**

48.4.3.16.43 HPBGCON0 register value

PMS_HPBGCON0 Offset address: $128A8_H$

HPBGCON0 register value value: $0000\ 0000_H$

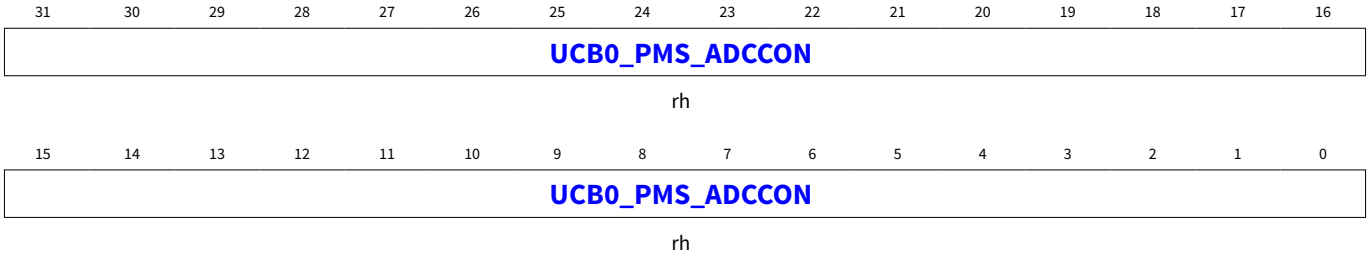


Field	Bits	Type	Description
UCB0_PMS_HPBGCON0	31:0	rh	**PMS_HPBGCON0 register value**

48.4.3.16.44 ADCCON register value

PMS_ADCCON Offset address: $128AC_H$

ADCCON register value value: $0000\ 0000_H$

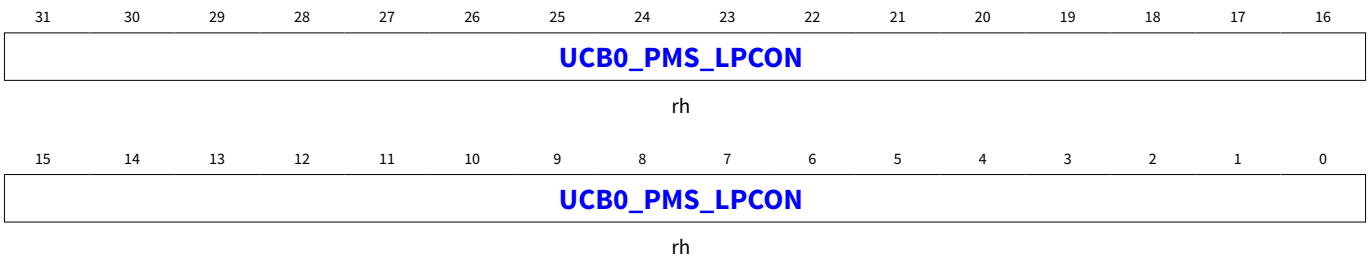


Field	Bits	Type	Description
UCB0_PMS_ADCCON	31:0	rh	**PMS_ADCCON register value**

48.4.3.16.45 LPCON register value

PMS_LPCON Offset address: $128B0_H$

LPCON register value value: $0000\ 0000_H$



Field	Bits	Type	Description
UCB0_PMS_LPCON	31:0	rh	**PMS_LPCON register value**

48.4.3.16.46 EVRC_CON0I register value

PMS_EVRC_CON0I Offset address: $128B4_H$

EVRC_CON0I register value value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
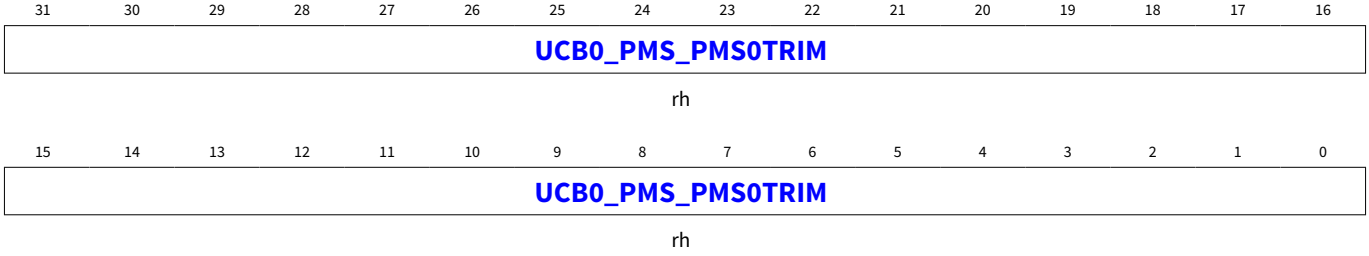
UCB0_PMS_HPBGTRIM	31:0	rh	**PMS_HPBGTRIM register value**

48.4.3.16.69 PMS_PMS0TRIM register value

PMS_PMS0TRIM Offset address: 12910_H

PMS_PMS0TRIM register value value: $0000\ 0000_H$

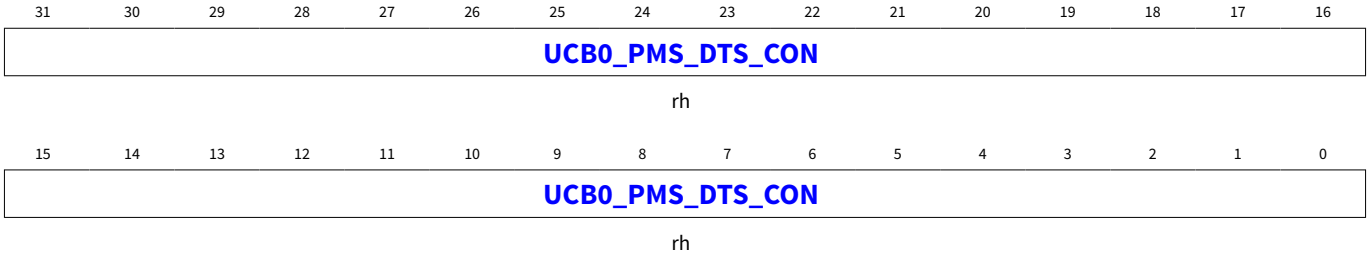


Field	Bits	Type	Description
UCB0_PMS_PMS0TRIM	31:0	rh	**PMS_PMS0TRIM register value**

48.4.3.16.70 PMS_DTS_CON register value

PMS_DTS_CON Offset address: 12914_H

PMS_DTS_CON register value value: $0000\ 0000_H$

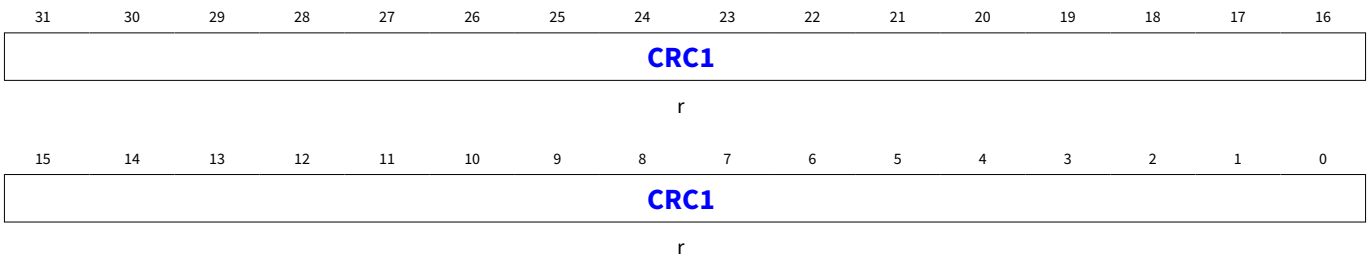


Field	Bits	Type	Description
UCB0_PMS_DTS_CON	31:0	rh	**PMS_DTS_CON register value**

48.4.3.16.71 CRC Checksum for values from RTCCFG1 area

CRC_RTCCFG1 Offset address: 12918_H

CRC Checksum for values from RTCCFG1 area value: $0000\ 0000_H$

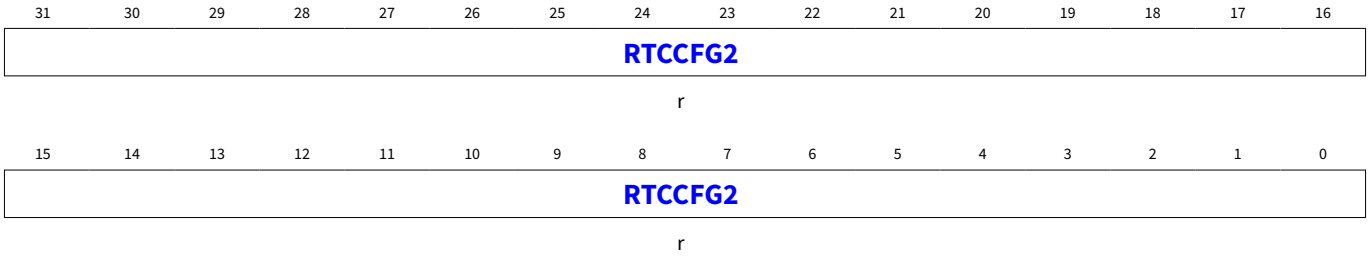


Field	Bits	Type	Description
CRC1	31:0	r	**Check Result** CRC1 check result.

48.4.3.16.72 System Address of this Location

UCB0_RTCCFG2 Offset address: 12960_H

System Address of this Location value: $0000\ 0000_H$

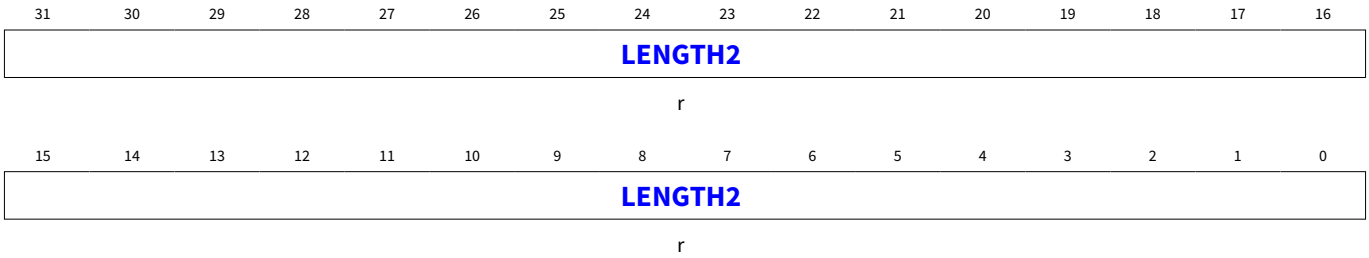


Field	Bits	Type	Description
RTCCFG2	31:0	r	**SAL value for reference 2 in UCB_RTCCFG**

48.4.3.16.73 Length of this table

LENGTH2 Offset address: 12964_H

Length of this table value: $0000\ 000D_H$



Field	Bits	Type	Description
LENGTH2	31:0	r	**Length of this table**

48.4.3.16.74 TRI_LBIST_CTRL_CFGA register value

TRI_LBIST_CTRL_CFGA Offset address: 12968_H

TRI_LBIST_CTRL_CFGA register value value: $0678\ 1388_H$

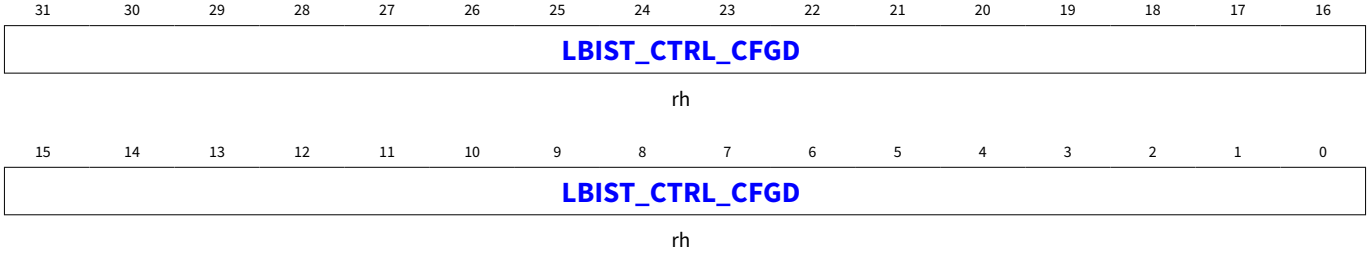
48.4.3.16.77 TRI_LBIST_CTRL_CFGD register value

TRI_LBIST_CTRL_CFGD Offset address: 12974_H

TRI_LBIST_CTRL_CFGD register value value: $2835\ 2841_H$

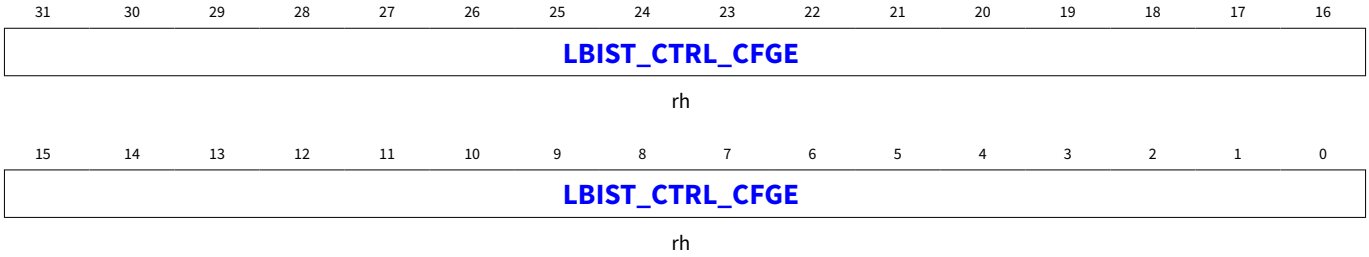


Field	Bits	Type	Description
LBIST_CTRL_CFGD	31:0	rh	**LBIST_CTRL_CFGD register value**

48.4.3.16.78 TRI_LBIST_CTRL_CFGE register value

TRI_LBIST_CTRL_CFGE Offset address: 12978_H

TRI_LBIST_CTRL_CFGE register value value: $0000\ 32A8_H$

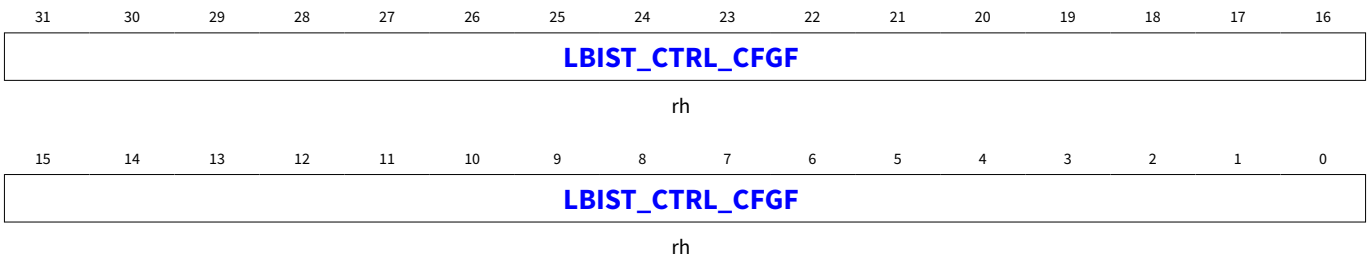


Field	Bits	Type	Description
LBIST_CTRL_CFGE	31:0	rh	**LBIST_CTRL_CFGE register value**

48.4.3.16.79 TRI_LBIST_CTRL_CFGF register value

TRI_LBIST_CTRL_CFGF Offset address: $1297C_H$

TRI_LBIST_CTRL_CFGF register value value: $0000\ 0003_H$

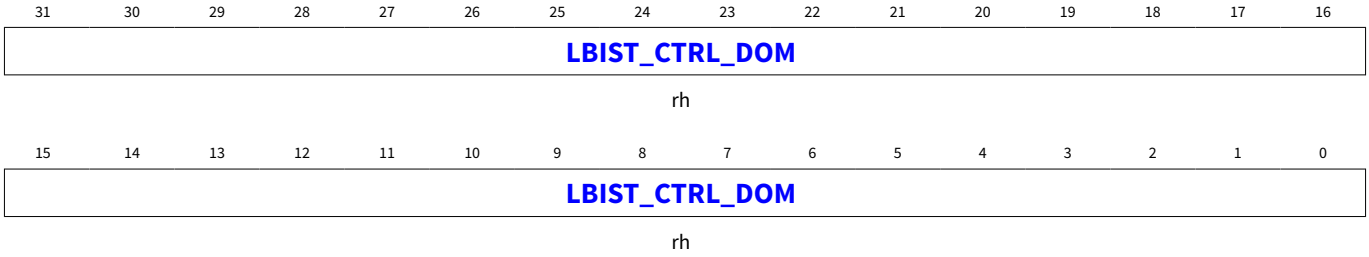


Field	Bits	Type	Description
LBIST_CTRL_CFGF	31:0	rh	**LBIST_CTRL_CFGF register value**

48.4.3.16.80 TRI_LBIST_CTRL_DOM register value

TRI_LBIST_CTRL_DOM Offset address: 12980_H

TRI_LBIST_CTRL_DOM register value value: $0000\ 007F_H$

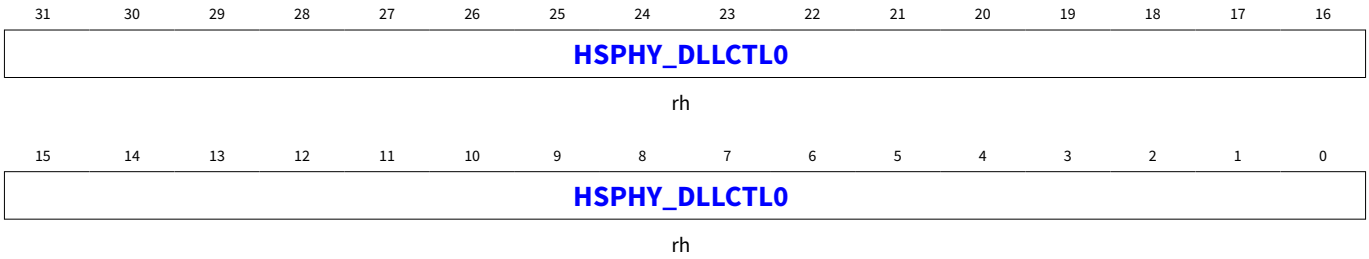


Field	Bits	Type	Description
LBIST_CTRL_DOM	31:0	rh	**LBIST_CTRL_DOM register value**

48.4.3.16.81 HSPHY_DLL_DLLCTL0 register value

HSPHY_DLL_DLLCTL0 Offset address: 12984_H

HSPHY_DLL_DLLCTL0 register value value: $0000\ 0000_H$



Field	Bits	Type	Description
HSPHY_DLLCTL0	31:0	rh	**HSPHY_DLLCTL0 register value**

48.4.3.16.82 HSPHY_DLL_DLLCTL1 register value

HSPHY_DLL_DLLCTL1 Offset address: 12988_H

HSPHY_DLL_DLLCTL1 register value value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HSPHY_DLLCTL1															
rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HSPHY_DLLCTL1															
rh															

Field	Bits	Type	Description
HSPHY_DLLCTL1	31:0	rh	**HSPHY_DLLCTL1 register value**

48.4.3.16.83 HSPHY_PADTRIM register value

HSPHY_PADTRIM Offset address: $1298C_H$

HSPHY_PADTRIM register value value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HSPHY_PADTRIM															
rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HSPHY_PADTRIM															
rh															

Field	Bits	Type	Description
HSPHY_PADTRIM	31:0	rh	**HSPHY_PADTRIM register value**

48.4.3.16.84 CRC Checksum for values from RTCCFG2 area

CRC_RTCCFG2 Offset address: 12990_H

CRC Checksum for values from RTCCFG2 area value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRC2															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC2															
r															

Field	Bits	Type	Description
CRC2	31:0	r	**Check Result** CRC2 check result.

48.4.3.16.85 System Address of this Location

UCB0_RTCCFG3 Offset address: $129F0_H$

System Address of this Location value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RTCCFG3															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RTCCFG3															
r															

Field	Bits	Type	Description
RTCCFG3	31:0	r	**SAL value for reference 3 in UCB_RTCCFG**

48.4.3.16.86 Length of this table

LENGTH3 Offset address: $129F4_H$

Length of this table value: $0000\ 0013_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LENGTH3															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LENGTH3															
r															

Field	Bits	Type	Description
LENGTH3	31:0	r	**Length of this table**

48.4.3.16.87 P13_LPCR0 register value

P13_LPCR0 Offset address: $129F8_H$

P13_LPCR0 register value value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Pm_LPCRn															
r															

Field	Bits	Type	Description
Pm_LPCRn	31:0	r	**Pm_LPCRn register value**

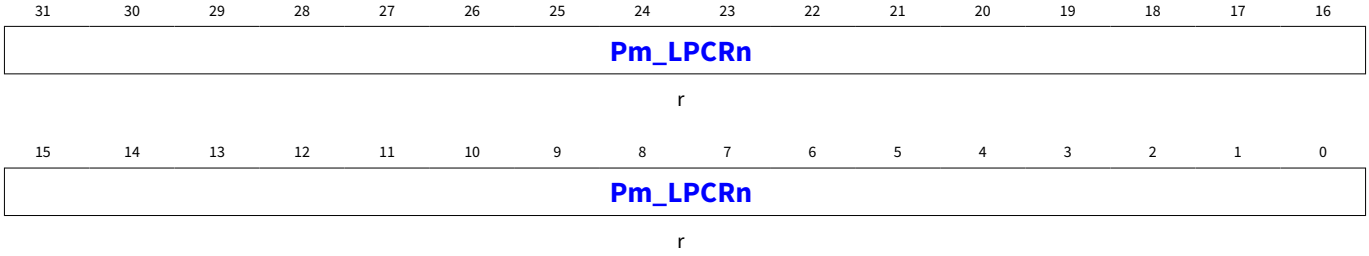
48.4.3.16.96 P21_LPCR2 register value

P21_LPCR2 Offset address: $12A1C_H$

P21_LPCR2 register value value: $0000\ 0000_H$

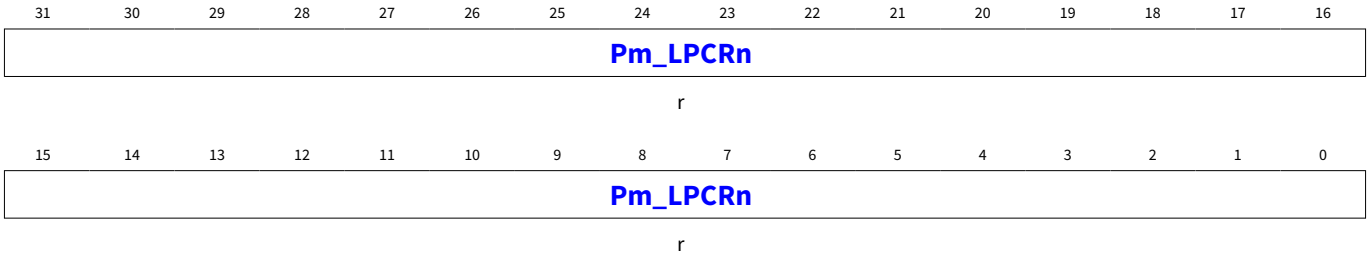


Field	Bits	Type	Description
Pm_LPCRn	31:0	r	**Pm_LPCRn register value**

48.4.3.16.97 P22_LPCR0 register value

P22_LPCR0 Offset address: $12A20_H$

P22_LPCR0 register value value: $0000\ 0000_H$

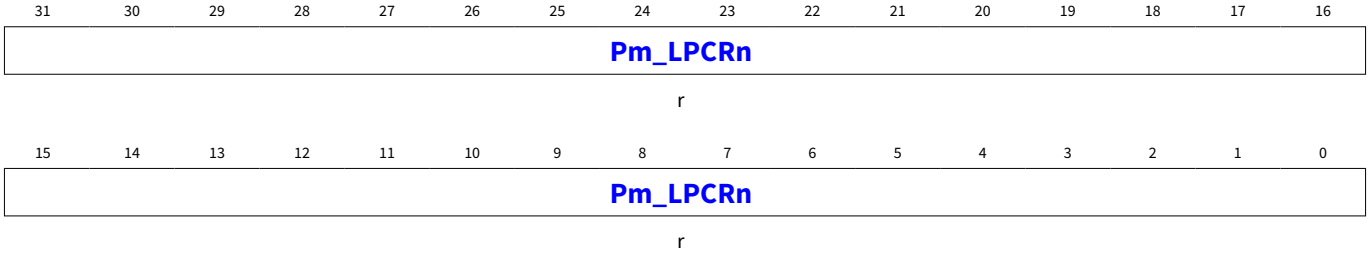


Field	Bits	Type	Description
Pm_LPCRn	31:0	r	**Pm_LPCRn register value**

48.4.3.16.98 P22_LPCR1 register value

P22_LPCR1 Offset address: $12A24_H$

P22_LPCR1 register value value: $0000\ 0000_H$

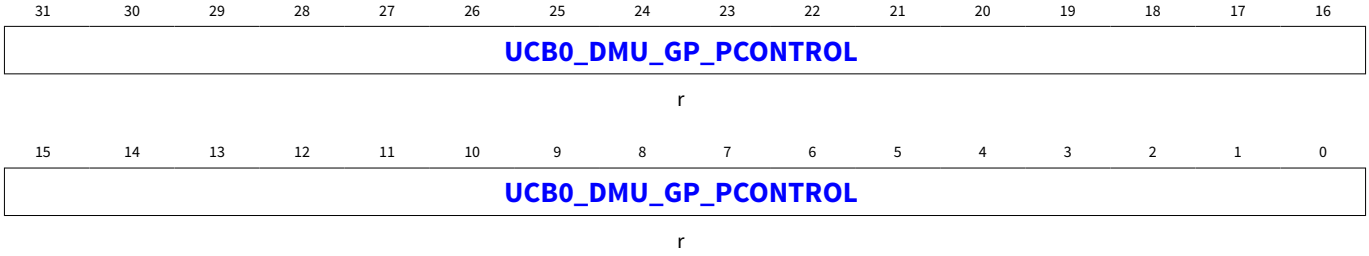


Field	Bits	Type	Description
Pm_LPCRn	31:0	r	**Pm_LPCRn register value**

48.4.3.16.99 DMU_GP_PCONTROL

DMU_GP_PCONTROL Offset address: $12A28_H$

DMU_GP_PCONTROL value: $0000\ 0000_H$

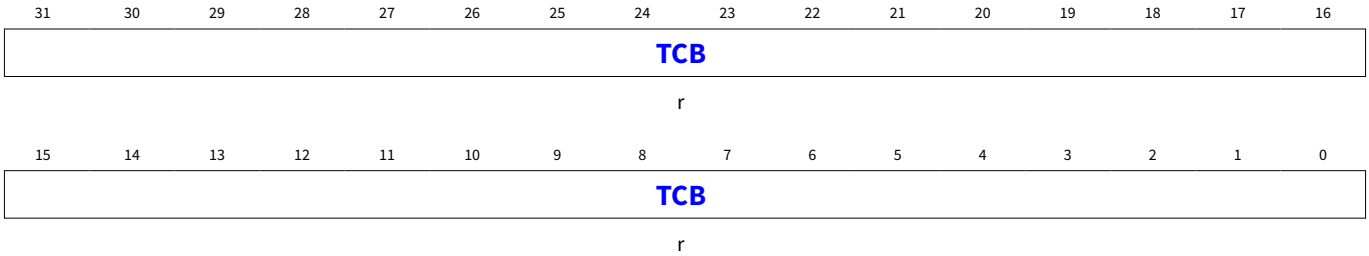


Field	Bits	Type	Description
UCB0_DMU_GP_PCONTROL	31:0	r	**DMU_GP_PCONTROL register value**

48.4.3.16.100 TCB Test constraint Register for Resistor trimming/default

TCB Offset address: $12A2C_H$

TCB Test constraint Register for Resistor trimming/ default value: $0000\ 0000_H$



Field	Bits	Type	Description
TCB	31:0	r	**TCB register value**

48.4.3.16.101 SCU_SPARE0 register value

SCU_SPARE0 Offset address: $12A30_H$

SCU_SPARE0 register value value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
SCU_SPARE1	31:0	r	**SCU_SPARE1 register value**

48.4.3.16.103 CRC Checksum for values from RTCCFG3 area

CRC_RTCCFG3 Offset address: $12A38_H$

CRC Checksum for values from RTCCFG3 area value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRC3															
r															

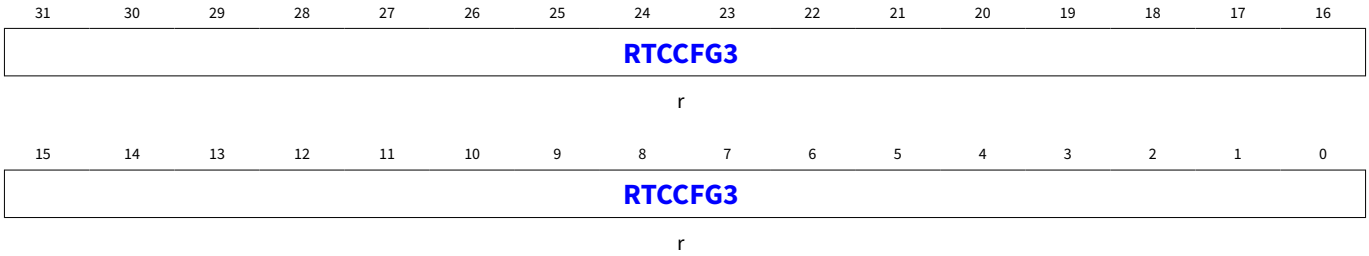
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC3															
r															

Field	Bits	Type	Description
CRC3	31:0	r	**Check Result** CRC3 check result.

48.4.3.16.104 System Address of this Location

UCB0_RTCCFG4 Offset address: $12A40_H$

System Address of this Location value: $0000\ 0000_H$

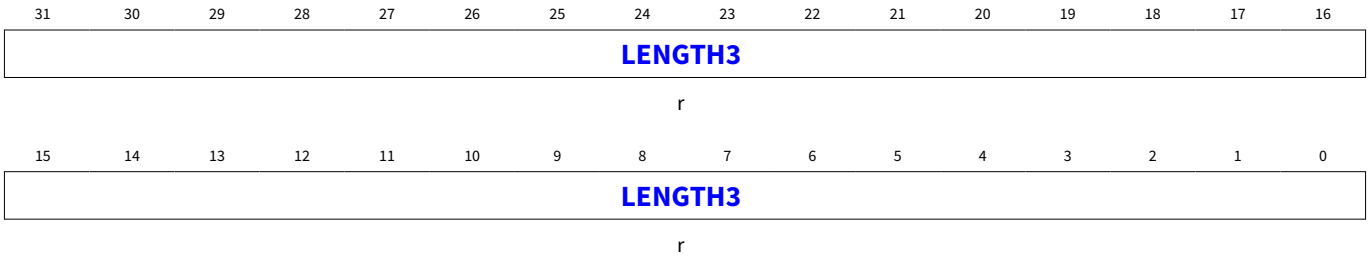


Field	Bits	Type	Description
RTCCFG3	31:0	r	**SAL value for reference 3 in UCB_RTCCFG**

48.4.3.16.105 Length of this table

LENGTH4 Offset address: $12A44_H$

Length of this table value: $0000\ 0009_H$

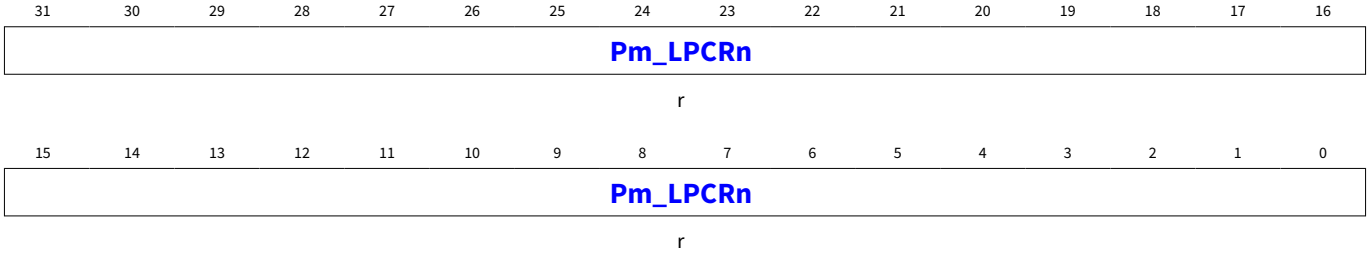


Field	Bits	Type	Description
LENGTH3	31:0	r	**Length of this table**

48.4.3.16.106 P01_BGTRIM register value

P01_BGTRIM Offset address: $12A48_H$

P01_BGTRIM register value value: $0000\ 0000_H$

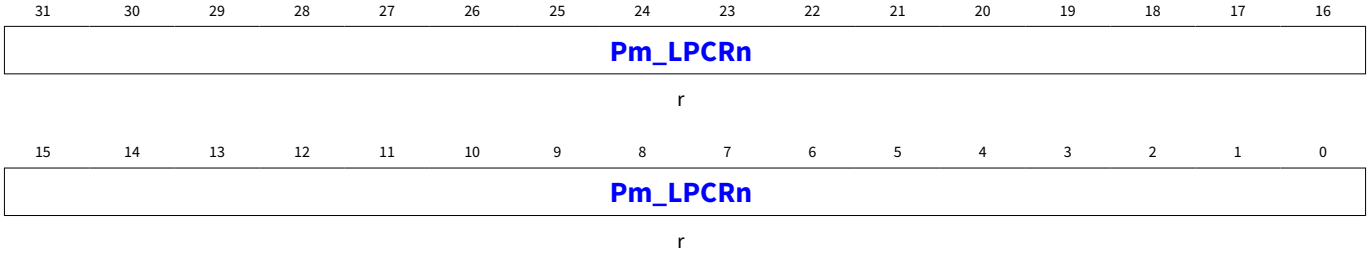


Field	Bits	Type	Description
Pm_LPCRn	31:0	r	**Pm_LPCRn register value**

48.4.3.16.107 P13_BGTRIM register value

P13_BGTRIM Offset address: $12A4C_H$

P13_BGTRIM register value value: $0000\ 0000_H$

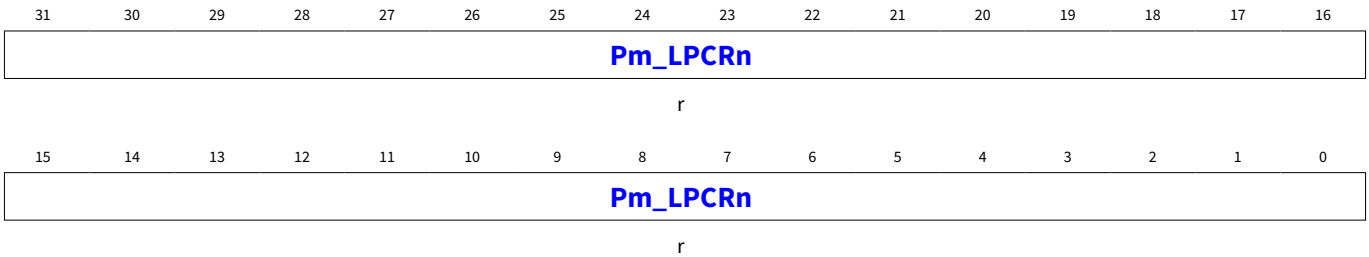


Field	Bits	Type	Description
Pm_LPCRn	31:0	r	**Pm_LPCRn register value**

48.4.3.16.108 P14_BGTRIM register value

P14_BGTRIM Offset address: $12A50_H$

P14_BGTRIM register value value: $0000\ 0000_H$



Field	Bits	Type	Description
Pm_LPCRn	31:0	r	**Pm_LPCRn register value**

48.4.3.16.109 P21_BGTRIM register value

P21_BGTRIM Offset address: $12A54_H$

P21_BGTRIM register value value: $0000\ 0000_H$

48.4.5 Register address space - CFS0

This address area is not user-relevant in eFlash devices.

48.5 Debug information

Firmware performs some debug system handling as described below. Most of the following Sections refer to features provided in HOST and SECURE clusters, the last Section is related to debug functionality supported in Stand-by Controller sub-system.

***Note**: Once debug-access is granted - the device start-up is no more safe, and this is indicated by setting STMEM1.QME bit (QM-part entered) - refer to SMM Chapter.*

48.5.1 Debug access control

TC4xx FW determines during start-up whether to grant access to the device through debug interface – if done, the device is put into “debug mode”.

The decision about allowing the debug is based on the information stored beforehand by the user in UCB, combined with such one provided during start-up by external device connected to the debug interface.

The user can install into UCB1 information related to debug access - refer to

DBGCON.DBGIFXCTRL:

- - if configured to 0b001 - debugging within HOST cluster is enabled, no further conditions/checks
  - if configured to 0b010 - debug will be enabled by firmware during start-up, if correct password is provided by the external device - refer to "Debug password exchange" Section
  - if configured to 0b100 - debug access remains locked after start-up, may be unlocked by user software afterwards
  - otherwise - device enters error-state if Boot Mode Lock (BML - refer to BML) is active, acts as 0b100 if BML inactive

- whether CSRM debugging is enabled – DBGCON.CSRMDBGDIS bitfield (see Debug configurations):

- - if configured to 0b01 - debugging within SECURE cluster is enabled
  - otherwise - debugging within SECURE cluster is disabled
  - ***Note**: If CSRM debugging is disabled acc. to DBGCON.CSRMDBGDIS configuration, it can be still enabled by user software running on SECURE cluster.*

- optional enabling of Debug-Access-Port (DAP) interface over CAN Physical Layer (DXCPL) - must be configured by the user in UCB1 - refer to TIC

To support the debug tools in getting access to any device allowing such access, two features are supported by TC4xx FW as described in the next Sections.

48.5.1.1 Chip-unique identification

Even immediately after reset and before getting “full debug access” i.e. Cerberus read/write mode enabled, the external tool can supply through debug interface a 32-bit word representing “Unique Identification Request” - short notation CMD_UID_REQUEST.

For TC4xx, CMD_UID_REQUEST = 0x76000000.

If the above request is received by device (in CBS_COMDATA register), FW will answer by sending back:

- 32-bit CHIPID – it identifies uniquely the device variant, including package and pin-count, number of cores, accelerator/security/other features, NVM size, maximum frequency and temperature range

  The value sent by FW is taken from UCB0, CHIPID
- 3x32-bit words taken from UCB0, UCID0…UCID2 – these identify uniquely any single device

Based on the above information, the tool can identify exactly the target device – both as type of product and as single piece of silicon. Therefore, the tool can further request full debug access to this device – as described in the next section.

The transmission of the four words must be completed within 1 ms - meaning the external tool must observe the CBS_COMDATA register status continuously and read-out it once new information is provided by Firmware there. If time-out elapsed - Firmware execution continues and the data-exchange with the tool remains not completed.

48.5.1.2 Debug password exchange

To get full debug access to the device i.e. Cerberus read/write mode enabled, the external tool must know the debug-password stored into the device NVM.

As first step in such a case, the external tool must supply through debug interface a 32-bit word representing “Debug Key Exchange Request” - short notation CMD_KEY_EXCHANGE.

For <keyword keyref="family"/>, CMD_KEY_EXCHANGE = 0x76D6E24A.

If the above request is received by device (in CBS_COMDATA register) AND DBGIFXCTRL bitfield in Debug configurations register is configured to 0b010 - debug may be enabled by firmware during start-up, FW will then:

- expect to receive in a similar way (in CBS_COMDATA register) eight more 32-bit words
- handle the received 8 words as 256-bit password, which is compared against the password stored by the customer in UCB1 - refer to Register overview - UCB1_01 (ascending offset address), DEBUG_PW0...DEBUG_PW7, where the first received word is considered as DEBUG_PW0, the last received – as DEBUG_PW7
- If the received password matches the password from UCB1 – debug access is granted, and Cerberus read/write mode – enabled

In case the above sequence is either not initiated or not successfully executed to the end within 1 ms – debug access to the device remains disabled.

48.5.2 Halt-after-reset

An external tool - once connected to the device via debug interface AND debug access is granted - can request that code execution stops just before the first user-software instruction.

This allows the tool to start user-code debugging “right from the beginning” – but to note, debugging during Firmware execution is not possible.

Halt-After-Reset (HAR) is only possible, if Debug interface is enabled, and upon completion of both boot sequences, i.e. for HOST and SECURE Cluster. In case of Foreground CSRM Boot this includes release of HOST by CSRM user application code.

When HAR is taken - the On-Chip Debug System (OCDS) is enabled, so all its features can be used.

For how a halt-after-reset request (HARR) is activated by the tool – refer to “Debug” Chapter of this User Manual.

48.5.3 Power-friendly debug monitor routines

If debug access is enabled, the external tool can set breakpoint(s) over the user code so to observe/debug software execution flow.

Once a breakpoint is hit – the respective CPU goes into break state, meaning the user code execution is interrupted. As the user code execution before the break may have been causing quite for power-consuming activity, “just breaking” such activity will cause a strong drop-down in power consumption, and the later may lead to big fluctuations on the power-supply line(s).

To avoid such fluctuations – which may seriously disturb the device functionality – dedicated routines are integrated as parts of SYS_FW, CSRM_FW and PPU_FW: the “power-friendly debug monitor” routines.

The purpose of these routines is:

- Once entered, any of the routines starts execution of a code loop with “mediate power consumption”
- This loop is executed, until a request from external (tool) is received to exit it and re-start user code execution on the respective CPU

It is still up to debug tool, to install the entry-point of such routine (0xAFFFFF08 for HOST and SECURE CPUs) as vector to be used upon break-point events for the respective debug-supporting resource - meaning, the usage of this routine is not automatically assured after device start-up.

48.6 References

This section is not applicable for the module being described.

48.7 Firmware revision history

Reference	Description of change(s)
Date range: 2024-08-17 to 2025-02-15	
"Boot mode evaluation" Section	HWCFG usage for boot-mode pin-selection de-committed for all devices except TC4Dx
"User-relevance of the data in Configuration area" Section	"Programming where" Column corrected for UCB_RTC_BMHDx entries from "N.A." to "Plant"
Product identification, UCB0_00 in Register Section	"M" introduced as feature ID for customer-specific variant to FEATURE fields in CHIPID and PRODUCT_NAME2 locations

48.8 TC4Dx FIRMWARE information

48.8.1 TC4Dx FIRMWARE configuration

There are no deviations from the generic specification.

48.8.2 TC4Dx FIRMWARE features

There are no deviations from the generic specification.

48.8.3 TC4Dx FIRMWARE functional description

48.8.3.1 Boot mode evaluation for HOST cluster

For RTC in TC4Dx, start-up configuration from pins is possible if Boot Mode Lock is NOT activated - this user-configuration is installed in Boot Mode Lock location of the NVM.

In such a case the mode selection from the HWCFG[4:3] pins is as follows:

Table 2556 Start-up mode selection by pins in HOST cluster

HWCFG pins		Start-up mode
[4]	[3]	
x	1	Start according to BMHD If no correct BMHD found - the Fall-back mechanism is activated
1	0	ACS Bootstrap Loader over P15.2/3
0	0	Generic Bootstrap Loader - CAN/ASC BSL over P14.0/1

***Note**: Mode selection through HWCFG pins has different encoding from BMI.MODE bitfield.*

48.8.4 TC4Dx FIRMWARE registers

There are no deviations from the generic specification.

48.8.5 TC4Dx FIRMWARE connectivity

There are no deviations from the generic specification.

48.8.6 TC4Dx FIRMWARE revision history
