
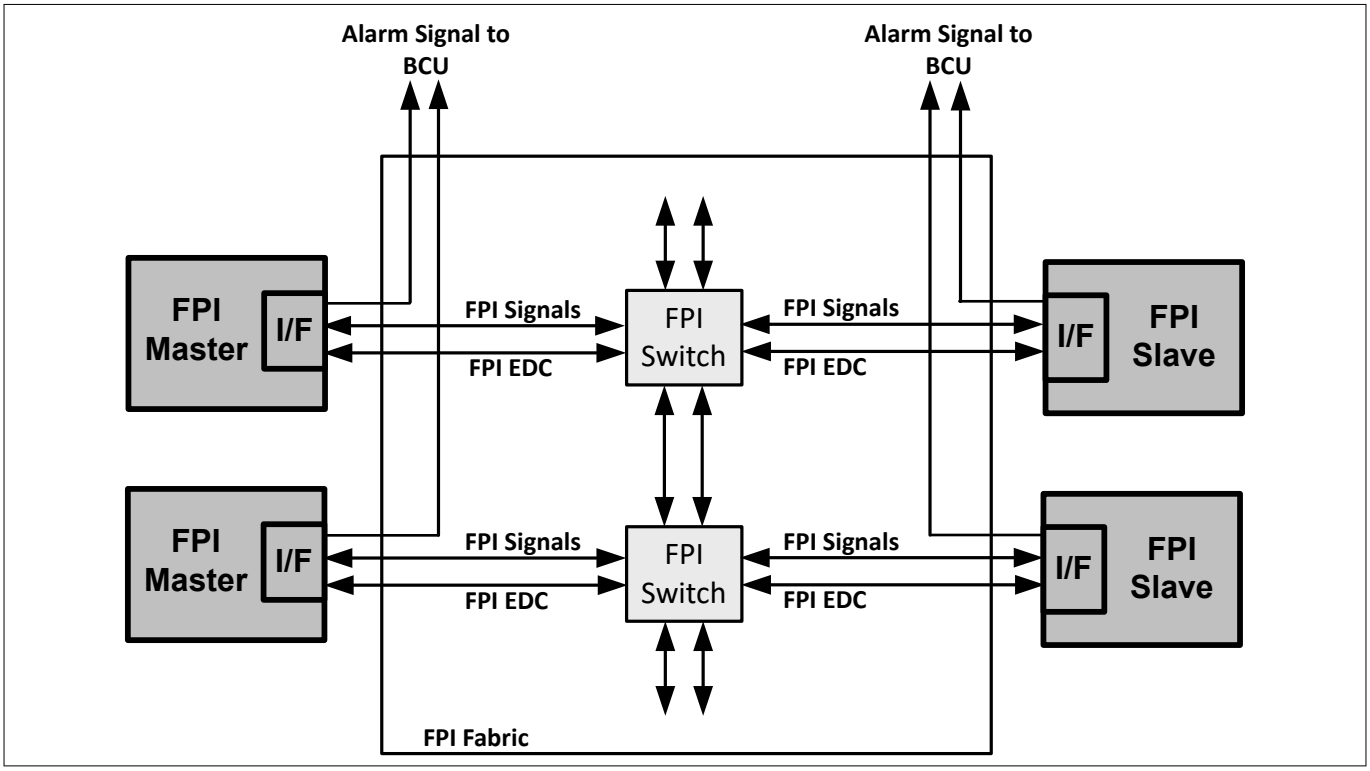

Figure 80 FPI EDC: Master and slave agent EDC alarm signals to the BCU

7.3.12.3 FPI error injection

The FPI EDC implementation allows to test all MEDM and SEDM decoder functions in the master and slave agents and the related alarm signal paths to the SMU by error injection.

At each FPI interconnect errors can be injected in the EDC encoder of one MEDM and one SEDM each. To test an EDC decoder in a slave agent and to trigger an alarm for it, a master agent access to this slave agent is initiated where an error is injected into the corresponding Master EDC Encoder (MEDM). Vice versa for the test of a master agent EDC decoder.

The error injection is controlled through the FPI Error Generation (FEGEN) in the BCU.

- Slave EDC encoder error injection (FEGEN.SEDM): The slave agent SEDM through which the error can be injected is the slave agent of the local BCU functional block. This can then be used to check all master agent error decoders (MEDM) at the local FPI. For example the SBCU with its FGEN register can be used to check the MEDM of all master agents connected to the SPB
- Master EDC encoder error injection (FEGEN.MEDM): The master agent MEDM through which the error can be injected is the one defined in the register bit-field PRIOH[3:0] (index 8) of the respective BCU. This can then be used to check all slave error decoders (SEDM) at the local FPI
- VMEN.EN allows to inject EDC errors into the output-enable signals for address-phase, data-phase and data informations signaled from the BCU slave agent and from the master agent assigned to PRIOH[3:0] to the FPI. Also here: the errors are affecting only the EDC information of these signals, not the output-signals directly therefore the normal communication is not affected but the related EDC error is detected and the corresponding ALSTAT bit in the BCU is set
- VMEN.BCU allows for injection errors in the EDC information of the FPI grant signal from the BCU to the master agent assigned to PRIOH[3:0] (master index 8) and in the EDC information of the FPI timeout (TOUT) signaled by the BCU

MEDM decoder test

To test a master agents MEDM decoder and the alarm signal path to the SMU the following sequence can be used:

- Enable the error injection related to the encoder where an error has to be injected in BCU SEDM through the FEGEN.SEDM register , for example to test a master agents read data EDC decoder
- The FPI master related to the MEDM where the decoder alarm signal path has to be tested, must access the BCU with an appropriate transaction. For example on SPB: DMA0 reads a SBCU control register in order to get an DMA related FPI EDC alarm from the SBCU
- Disable the error injection by clearing the error injection by setting FEGEN.SEDM to 000_H

SEDM decoder test

To test a slave agents SEDM decoder and the alarm signal path to the SMU the following sequence can be used:

- Enable the error injection related to the master agent that is mapped on the BCU register bit-field PRIOH[3:0] (index 8). This is the master agent where an FPI EDC error can to be injected through the register FEGEN.MEDM register. For example to test a slave agents FPI address phase EDC decoder
- The master agent that is mapped to PRIOH[3:0] has to access now the FPI slave agent related to the SEDM where the decoder alarm signal path has to be tested. For example on SPB: CPU0 data access to FCE to get an alarm from the FCE related alarm signal on the SPB
- Disable the error injection by setting FEGEN.SEDM to 000_H

7.3.12.4 Mapping of EDC ALARM signals to BCU ALSTAT and ALCLR registers

Each BCU provides a set of EDC Alarm Status registers (ALSTATx) and Alarm Clear Registers (ALCLRx):

- For each master agent and each slave on the local FPI there is one fix bit in the ALSTATx register that is set by hardware when an EDC error was detected for this master or slave agent
- For each master agent and each slave on the local FPI there is one fix bit in the ALCLRx register that can be used by software to clear the corresponding bit in the ALSTATx register
- The ALCTRL register provides additional status and clear functions to detect if there was more than one alarm while the corresponding ALSTATx register bit was already set (important if errors are injected during

run-time) or if multiple alarm events were signaled in the same cycle (then the ALSTATx bits may be corrupted)

The mapping of the FPI EDC alarm signals from the connected FPI master and slave agents and the alarm events from the BCU internal output enable checks to the Alarm Status (ALSTATx; x = 0-4) and Alarm Clear (ALCLRx; x = 0-4) registers is described in the device specific chapter.

The mapping of the module alarm signals to the ALSTATx[y] and ALCLRx[y] in the different devices is compatible. This means that the alarm of module x is always on a fixed register bit. If module x is not present in a derivative then the bit is reserved.

***Note**: The register ALSTATx, ALCLRx and ALCTRL do not influence the signaling of a detected EDC error through ALARM_NCS to SMU_SAFE.*

7.3.13 FPI to FPI interconnect register stage (F2F)

The FPI to FPI bridge implements a uni-directional bridge that forwards FPI transactions from one part of the one FPI interconnect instance to a second part of the same FPI interconnect instance.

The F2F bridge can be used as a register stage in an FPI interconnect to connect one or more distant slave agents to the respective FPI interconnect.

Each F2F bridge shows up with a dedicated alarm signal in the ALSTATx registers of the respective BCU. The respective product users manual describes in which FPI interconnects F2F bridges are used and how they are used there, which master and which slave agents are affected.

***Note**: If a transaction to a slave agent behind the F2F Bridge gets a FPI timeout, the F2F Bridge is blocked until application reset. All further accesses to the slave agents behind the bridge are terminated with FPI Error until the next application reset.*

7.3.14 Characteristic of the FPI interconnect

The following table shows the FPI interconnects as implemented in the different devices.

The table enables the customer to write generic software that can be easily ported between the targeted derivatives and to recognize the differences between the derivatives.

All BCU instances marked with an asterisk ´yes*´ are implemented with QoS control and QoS observation functions. BCUs not marked with asterisk are implemented without QoS functions because they do not need them for functional reasons or from the product point of view. Example: CSBCU does not need the QoS functions because the CSPB is essentially only used by the secure application. TBCU does not need the QoS functions since the TPB is essentially only used by the MCDS.

Table 606 FPI interconnects and interconnect instance names

	SPB	CPB	CSPB	TPB	COMPB	RCB
TC4Zx	yes*	no	yes	yes	yes*	no
TC48x	yes*	no	yes	yes	yes*	no
TC4Dx	yes*	no	yes	yes	yes*	no
TC49xN	yes*	yes*	yes	yes	no	no
TC46x	yes*	yes*	yes	yes	no	no
TC44x	yes*	yes*	yes	yes	no	no

(table continues...)

Table 606 (continued) FPI interconnects and interconnect instance names

	SPB	CPB	CSPB	TPB	COMPB	RCB
TC4Ex	yes*	yes*	yes	yes	no	no
TC4Px	yes*	yes*	yes	yes	no	no
TC42x	yes*	yes*	yes	yes	no	no
TC45x	yes	no	yes	yes	no	yes

Each interconnect instance provides a dedicated BCU:

- SPB → SBCU
- CPB → CBCU
- CSPB → CSBCU
- TPB → TBCU
- COMPB → COMBCU
- RCB → RBCU

7.4 Registers

7.4.1 Register overview - access mode glossary

Table 607 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

7.4.2 Registers overview - BCU (ascending offset address)

Table 608 Registers overview - BCU (ascending offset address)

Field	Bits	Type	Description
MOD_REV	7:0	r	**Module revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module number** Indicates the module identification number.

7.4.5 PROT register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock and unlock of the local Endinit (E) protected control registers.

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism

PROTE Offset address: $00C_H$

Field	Bits	Type	Description
RDq (q=00-07)	q	rw	**Read access enable for PRS q** This bit enables read access to the access protected region for transactions in the PRS q. 0_B Disabled for read access 1_B Enabled for read access

(table continues...)

(continued)

Field	Bits	Type	Description
WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions in the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

7.4.13 Round-robin group control

The Round Share mechanism of a round-robin group only affects arbitration when requests of master agents assigned to the related round-robin group or higher priority master agents arrives so frequently that pending master agent request with lower priority are not granted.

When this occurs a maximum of RRx grants are given to the master agents of the related round-robin group and master agents with a higher priority, and then a single grant is given to the lower priority master agents if there is any request pending.

RRCTRL Offset address: 030_H

Round-robin group control Application Reset value: $0006\ 0006_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r												rw			r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												RR8			0
r												rw			r

Field	Bits	Type	Description
RR8	3:1	rw	**RR Group 8 Priority Round Share** The Register defines the number of consecutive transactions granted to master agents of this round-robin group and master agents with higher priority before a request for a master agent with lower priority is granted. The register defines the number in multiples of 2. The mechanism is inactive if the register is configured with 0. A detailed description of the arbitration mechanisms can be found in the System Interconnect FPI chapter.
RR4	19:17	rw	**RR Group 4 Priority Round Share** The register defines the number of consecutive transactions granted to master agents of this round-robin group and master agents with higher priority before a request for a master agent with lower priority is granted. The register defines the number in multiples of 2. The mechanism is inactive if the register is configured with 0. A detailed description of the arbitration mechanisms can be found in the System Interconnect FPI chapter.

(table continues...)

(continued)

Field	Bits	Type	Description
0	0, 16:4, 31:20	r	**Reserved** Read as 0; should be written with 0.

7.4.14 Master agent priority register high

Priority 4 and priority 8 are implemented as round-robin groups.
Master agents can be mapped to a round-robin group by configuration with priority 4 or priority 8.
A detailed description of the arbitration mechanisms can be found in the System Interconnect FPI chapter.

PRIOH Offset address: 034_H

Master agent priority register high Application Reset value: $0888\ 8888_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
MASTERi (i=0-7)	4*i+3:4*i	rw	**Master i Priority** Master agent i priority for access on the FPI. A lower number has a higher priority in the arbitration round than a higher one.

7.4.16 BCU control register

The BCU control register controls the overall operation of the BCU, including setting the starvation sample period, the timeout period, enabling starvation-protection mode, and error handling.

CON Offset address: $03C_H$

BCU control register Application Reset value: $FFF1\ FFFF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SPC												0			DBG
rw												r			rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TOUT															
rw															

Field	Bits	Type	Description
TOUT	15:0	rw	**BCU timeout value** The bit field determines the number of wait state cycles before the BCU terminates a data phase and the related transaction with a timeout. Default value after reset is $FFFF_H$ (= 65536 local interconnect cycles). ***Note**: TOUT value must be >= 5 and shall be configured with a value that it is not violated during normal operation.*
DBG	16	rw	**BCU Debug Trace Enable** The bit enables and disables the error capture mechanism for the registers BCU_ECON, BCU_EADD, BCU_EDAT. The bit has no affect on the signalling of alarms and interrupts when an error condition is detected. 0_B BCU debug trace disabled 1_B BCU debug trace enabled (default after reset)
SPC	31:20	rw	**Starvation period control** Determines the sample period for the starvation counter. Must be larger than the number of masters. The reset value is FFF_H.
0	19:17	r	**Reserved** Read as 0; should be written with 0.

7.4.17 BCU error control capture register

Application software can clear the register by writing the content.

ECON Offset address: 040_H

BCU error control capture register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OPC				TAG						RDN	WRN	SVM	ACK		ABT

rwh	rwh	rwh					rwh	rwh	rwh			rwh	rwh		

Field	Bits	Type	Description
VM	2:0	rwh	**FPI virtual machine information** This bit indicates the state of the Virtual machine information at an FBI error
VM_VALID	3	rwh	**FPI virtual machine information valid signal** This bit indicates the state of the Virtual Machine valid signal at an FBI error. 0_B Virtual machine information is not valid 1_B Virtual machine information is valid
PRS	6:4	rwh	**FPI Protection Set Information** This bit field indicates the protection set information of the FPI transaction at an FPI error.
PRS_VALID	7	rwh	**FPI protection set information valid signal** This bit indicates the state of the protection set valid signal at an FBI error. 0_B Protection set information is not valid 1_B Protection set information is valid
CS_VALID	8	rwh	**FPI CS valid signal** This bit indicates the state of the CS valid signal at an FBI error. 0_B Wait state(s) have been inserted. Ready signal was active 1_B Ready signal was inactive
ERRCNT	13:9	rwh	**FPI error counter** ERRCNT is incremented with each Error or Timeout event. If it is not reset by reading, it counts the events up to the max. counter value and then stops at this value. ERRCNT is reset to 0 with a read of the ECON register. A write access is not executed in the register if an error is detected in parallel. 1)

(table continues...)

(continued)

Field	Bits	Type	Description
TOUT	14	rwh	**State of FPI timeout signal** This bit indicates the state of the timeout signal at an FBI error. 0_B No timeout occurred 1_B Timeout has occurred
RDY	15	rwh	**State of FPI ready signal** This bit indicates the state of the ready signal at an FBI error. 0_B Wait state(s) have been inserted. Ready signal was active 1_B Ready signal was inactive
ABT	16	rwh	**State of FPI abort signal** This bit indicates the state of the abort signal at an FBI error. 0_B Master has aborted an FPI transfer. Abort signal was active 1_B Abort signal was inactive
ACK	18:17	rwh	**State of FPI acknowledge signals** This bit field indicates the acknowledge code that has been output by the selected slave at an FPI error. 00_B NSC: No special case 01_B Reserved 10_B RTY: Retry 11_B ERR: FPI error
SVM	19	rwh	**State of FPI supervisor mode signal** This bit indicates whether the FPI error occurred in supervisor mode or in user mode. 0_B Transfer was initiated in user mode 1_B Transfer was initiated in supervisor mode
WRN	20	rwh	**State of FPI write signal** This bit indicates whether the FPI error occurred at a write transaction.
RDN	21	rwh	**State of FPI read signal** This bit indicates whether the FPI error occurred at a read transaction.
TAG	27:22	rwh	**FPI master agent function TAG-ID** This bit field indicates the FPI master agent function identifier (TAG-ID).
OPC	31:28	rwh	**FPI operation code signals** The FPI operation codes are defined in .

1) Aborted accesses to a 0 wait state SPB slave may also increment ERRCNT when the slave generates an error acknowledge.

Table 612 FPI read and write error indication

$\overline{RD}$	$\overline{WR}$	FPI Cycle
0	0	FPI error occurred at the read transfer of a read-modify-write transfer.
0	1	FPI error occurred at a read cycle of a single transfer.
1	0	FPI error occurred at a write cycle of a single transfer or at the write cycle of a read-modify-write transfer.
1	1	Does not occur.

7.4.18 BCU error address capture register

Application software can clear the register by writing the content.

EADD Offset address: 044_H

BCU error address capture register Application Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FPIDAT															
rwh															

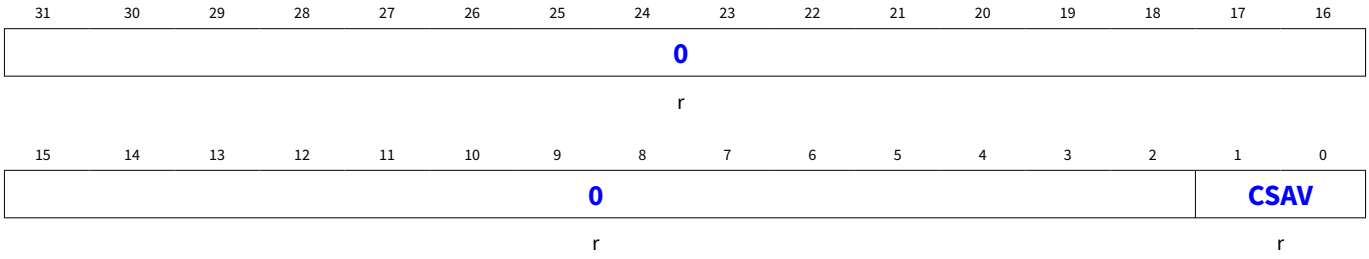
Field	Bits	Type	Description
FPIDAT	31:0	rwh	**Captured FPI Data** This bit field holds the 32-bit FPI data that has been captured in the data phase that was acknowledged with FPI error by the active slave agent. Note that if multiple FPI errors occurred, only the data of the first FPI error is captured.

7.4.20 CSAV status register

Register shows the status of cyber security activity visibility (CSAV) signals.
CS related transactions are identified in the transaction address phase through CS_VALID=1.

CSAVSTAT Offset address: $04C_H$

CSAV status register Debug Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CSAV	1:0	r	**Status of the CSAV signals** This bitfield shows the current CSAV status. CSAV is controlled through the CSCU. The CSAV status controls if and how information of CS related transactions (CSVALID=1) can be traced through OCMTS and captured by the BCU. 00_B No - Tracing of CS transactions and capturing of CS transactions in the BCU is disabled 01_B Limited - Tracing of CS transactions through OCMTS and capturing of CS transactions in the BCU is enabled with limited information. Address, data, VM and PRS information are masked and read with 0. 10_B Reserved - Tracing of CS transactions and capturing of CS transaction information in the BCU is disabled 11_B Full - Tracing of CS transactions through OCMTS and capturing of CS transaction information in the BCU is enabled
0	31:2	r	**Reserved** Read as 0; should be written with 0.

7.4.21 BCU EDC alarm status register x.

The BCU provides one alarm status register bit for each implemented FPI master agent and FPI slave agent. The assignment of the FPI master-slave and master-agent alarm signals is contained in the bit descriptions of the product-specific ALSTAT register description. The source of an alarm signal is described there using <module name>_S for a slave agent interface, <module name>_M for a master agent interface.

ALSTATx (x=0-4) Offset address: 050_H+x*4

BCU EDC alarm status register x. Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

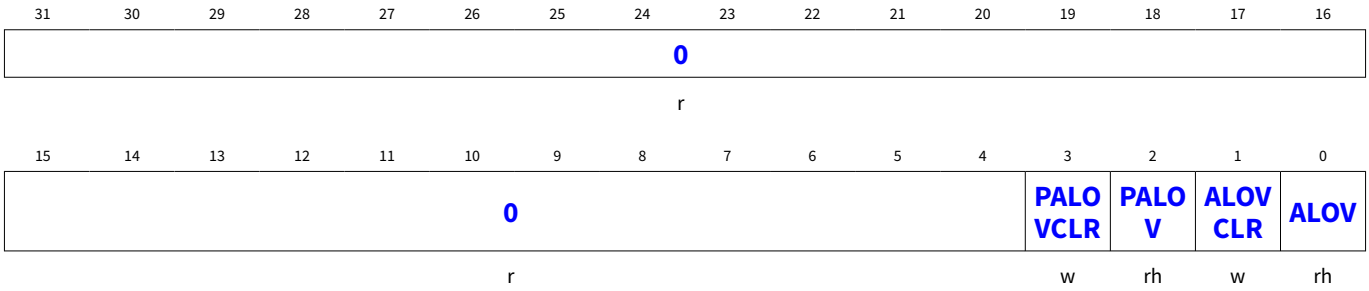
Field	Bits	Type	Description
CLRy (y=00-31)	y	w	**Clear alarm y** The alarm bit shows if an EDC error was detected in an active phase of the related FPI slave and master interface. 0_B No action 1_B Clears related SBC_ALSTATx.[y] (clear = set to ´0´); read always returns 0

7.4.23 BCU EDC alarm control register

ALCTRL Offset address: 090_H

BCU EDC alarm control register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ALOV	0	rh	**Alarm overflow** The ALOV bit is set if multiple FPI EDC alarms for the same FPI slave or the same FPI master were detected while the related ALSTATx[y] bit was still set. ***Note**: Some errors result in a static fault situation, for example address phase, data phase or data enable signal faults. Static faults do not generate multiple alarms and will not set the ALOV bit.* 0_B No alarm overflow for any FPI EDC alarm detected 1_B Alarm overflow detected for at least one of the set ALSTATx[y] bits
ALOVCLR	1	w	**Alarm overflow clear** The ALOVCLR bit is required to clear the ALOV bit. 0_B No action 1_B Clear ALOV (clear = set to 0); bit value is not stored; read always returns 0
PALOV	2	rh	**Parallel alarm overflow** The PALOV bit is set if multiple FPI EDC alarms from different slave agents or master agents are signaled in the same clock cycle. Corresponding ALSTAT Bits are not set. ***Note**: Some errors result in a static fault situation, for example address phase, data phase or data enable signal faults. Static faults do not generate multiple alarms and will not set the ALOV bit.* 0_B No alarm overflow for any FPI EDC alarm detected 1_B Alarm overflow detected for at least one of the set ALSTATx[y] bits
PALOVCLR	3	w	**Parallel alarm overflow clear** The PALOVCLR bit is required to clear the PALOV bit. 0_B No action 1_B Clear ALOV (clear = set to 0); bit value is not stored; read always returns 0
0	31:4	r	**Reserved** Read as 0; should be written with 0.

7.4.24 FPI error generation control register

The FEGEN register controls the injection of errors in the FPI EDC mechanism to test the alarm path from the implemented EDC decoders to the SMU.

Errors can be injected in the FPI EDC related encoders and the mechanism that checks the module output enable signal:

- BCU FPI slave agent EDC encoder (SEDM)
- FPI master agent EDC encoder (MEDM) for the master agent mapped on PRIOH[3:0] (master index 8)
- BCU FPI timeout signal
- BCU FPI grant signals
- All groups of FPI slave and master output enable signals that are checked in the BCU

FEGEN Offset address: 094_H

FPI error generation control register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0						BCU		0					EN

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					MEDM			0					SEDM		
r					rw			r					rw		

Field	Bits	Type	Description
SEDM	2:0	rw	**SEDM (slave encoder)** The errors are injected into the FPI-EDC encoder information of the SEDM which is assigned to the BCU. The injected errors are detected by the master agents MEDM, which access the BCU registers. Other bit combinations are reserved and do not inject errors. 000_B SEDM error injection is disabled 011_B Slave agent data phase (disable inversion of the FPI_ACK[0] signal) 101_B Slave read data (ECC LSB flip) **others,** Reserved, no SEDM errors are injected

(table continues...)

(continued)

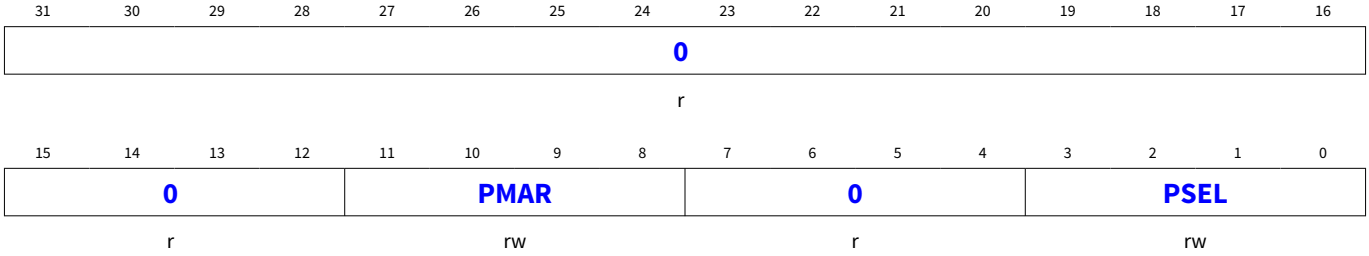
Field	Bits	Type	Description
MEDM	10:8	rw	**MEDM (master encoder) type of error** The errors are injected into the MEDM's FPI-EDC coding associated with the PRIOH[3:0] (master index 8) assigned master agent. The injected errors are detected by the SEDM of the slave agent accessed by the master agent. Other bit combinations are reserved and do not inject errors. 000_B MEDM error injection is disabled 001_B Master agent REQUEST signal (disable REQUEST signal inversion) 010_B Master agent LOCK signal (disable LOCK signal inversion) 011_B Master agent address phase (invert ECC LSB) 101_B Master agent data phase (disable inversion of the FPI_ACK[0] signal, default master agent) 110_B Master agent write data (invert ECC LSB) 111_B Master agent abort signal (disable abort signal inversion)
EN	18:16	rw	**Enable signal type of error** The errors of the enable signals are injected into the BCU without affecting the transactions executed on the FPI. For each group of enable signals, it is checked that no more than one signal is active at any time. For the error injection, the BCU activates the respective enable signals, going into the error checking mechanisms, related to the BCU and the master agent assigned to PRIOH[3:0] (master index 8). Other bit combinations are reserved and do not inject errors. 000_B EN error injection is disabled 011_B Address phase enable (A_EN_N, master agent) 101_B Data phase enable (ABORT_EN_N, master agent) 110_B Data enable (D_EN_N, master and slave agent) 111_B Data phase output enable (ACK_EN_N, master and slave agent) **others,** Reserved, no EN errors are injected
BCU	25:24	rw	**BCU type of error** The errors are injected into the FPI-EDC information. Other bit combinations are reserved and do not inject errors. 00_B BCU timout and grant error injection is disabled 10_B BCU grant: disable inversion of grant signal to the master agent mapped to PRIOH[3:0] (master index 8). Error is detected by the MEDM related to this master agent. 11_B BCU timeout: disable BCU timeout signal inversion inside the BCU in front of the error checking mechanism. The injected error is detected by the BCU. **others,** BCU timout and grant error injection is disabled
0	7:3, 15:11, 23:19, 31:26	r	**Reserved** Read as 0; should be written with 0.

7.4.25 BCU performance event select

This function can be used when only one MCDS counter is available to control which event is routed to the MCDS counter through the BCU.

PSELECT Offset address: 098_H

BCU performance event select Application Reset value: $0000\ 000F_H$



Field	Bits	Type	Description
PSEL	3:0	rw	**TS16_BCU_performance_events[15] selector** Register controls which event from the TS16_BCU_performance_events list is mapped to PSELECT that it can be observed by the MCDS. PSELECT= x : TS16_BCU[x] mapped to PSELECT.
PMAR	11:8	rw	**Parallel master agent requests** The register controls the threshold value from which a pulse is signalled through TS16_BCU_performance_events[8] (Interconnect_contention_cycles). PMAR= 0 : no pulse is generated PMAR = x: pulse is generated on every local FPI cycle where >= x master agent requests for FPI access are active in parallel to the actual transaction.
0	7:4, 31:12	r	**Reserved** Read as 0; should be written with 0.

7.4.26 QoS time interval control register

The QOSICTRL register allows the enabling and disabling of the QoS function and the defining of the QoS time interval for this interconnect.

QOSICTRL Offset address: 100_H

QoS time interval control register Application Reset value: $0000\ FFFF_H$

Field	Bits	Type	Description
QOSINT	15:0	rw	**QoS time interval** The bit field determines the QoS time interval in multiples of 16 local interconnect clock cycles.
QOSEN	31	rw	**QoS enable** 0_B QoS function is disabled for the local interconnect 1_B QoS function is enabled for the local interconnect
0	30:16	r	**Reserved** Read as 0; should be written with 0.

7.4.27 QoS time interval counter status

Indicates the status of the QoS time interval counter.

QOSISTAT Offset address: 104_H

QoS time interval counter status Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0												QOSICNT			
r												rh			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QOSICNT															
rh															

Field	Bits	Type	Description
QOSICNT	19:0	rh	**QoS time interval counter status** The bit field shows the current values of the QoS time interval counter. In QoS mode, the decrementing counter indicates the number of local clock cycles before the current time interval has expired. when the counter is counted down to 0, it is reloaded with QOSINT.
0	31:20	r	**Reserved** Read as 0; should be written with 0.

7.4.28 QoS master agent x control register

The BCU provides one QOSM CTRL register for each master agent connected to the local interconnect.

QOSMx_CTRL (x=0-15) Offset address: 110_H+x*8

QoS master agent x control register Application Reset value: $07FF\ 7FFF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	w	r			rw										

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	MICC														
r	rw														

Field	Bits	Type	Description
MICC	14:0	rw	**Master agent interconnnect cycle count** Bit field defines how many clock cycles the master agent can use the interconnect in the QoS time interval before it is set to request delay mode. The bit field defines the number in multiples of 16 local FPI clock cycles.
MRD	26:16	rw	**Master agent request delay** Bit field determines in request delay mode the number of FPI clock cycles a master request is delayed before it is taken into account in arbitration.
MSBCLR	30	w	**QoS master agent sticky bit clear** Bit can be used to clear the master agent sticky bit (MSB). Bit is always read as 0. 0_B No action 1_B Bit MSB bit is cleared.
MEN	31	rw	**Master agent enable** 0_B QoS function is disabled for this master agent 1_B QoS function is enabled for this master agent
0	15, 29:27	r	**Reserved** Read as 0; should be written with 0.

7.4.29 QoS master agent x status register

The BCU provides one QOSM STAT register for each master agent connected to the local interconnect.

QOSMx_STAT (x=0-15) Offset address: 114_H+x*8

QoS master agent x status register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSTAT	MSB	0											MCNT		
rh	rh	r											rh		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MCNT															
rh															

Field	Bits	Type	Description
MCNT	18:0	rh	**Master agent cycle counter** In QoS mode the current usage of this counter is indicated by the MSTAT bit. Depending on the mode, the counter is loaded with MICC or MRD and then decremented according to the mode. MSTAT=0 This counter shows the remaining clock cycles for the master agent that it can still use in the current QoS time interval before it switches to request delay mode. MSTAT=1 the master agent is in request delay mode until the end of the QoS time interval. With each new request, the counter is loaded with the MRD value and counted down. If the counter value is 0, the master agent request is considered in the arbitration.
MSB	30	rh	**QoS master agent sticky bit** Determines whether the master agent was in request delay mode in one or more of the previous QoS time intervals. Note: The bit is set from 0 to 1 at the end of a QoS time interval if MSTAT=1. In parallel a QoS interrupt is triggered whenever any MSB bit changes from 0 to 1. 0_B Master agent was not in request delay mode 1_B Master agent was in request delay mode
MSTAT	31	rh	**Master agent status** Determines whether the master agent is in request delay mode in the current QoS time interval. Note: the MSTAT bit changes from 0 to 1 when MCNT is counted down from 1 to 0. 0_B Master agent is not in request delay mode 1_B Master agent is in request delay mode
0	29:19	r	**Reserved** Read as 0; should be written with 0.

7.4.30 ARP x TAG-ID assignment register A

ARPx_TAGIDA (x=0-7) Offset address: 190_H+x*1C_H

ARP x TAG-ID assignment register A Application Reset value: $0000\ 0000_H$

THV															
rw															

Field	Bits	Type	Description
THV	15:0	rw	**ARP x threshold value** Bit field defines how many clock cycles the master agent functions assigned to ARPx can use the observed resource in the QoS time interval before it is identified as an ARPx usage violation. The bit field defines the number in multiples of 16 local interconnect clock cycles.
0	31:16	r	**Reserved-0** Read as 0; should be written with 0.

7.4.34 ARP x control register

Register provides control for the ARPx function and indicates the status of ARPx.

ARPx_CTRL (x=0-7) Offset address: $1A0_H+x*1C_H$

ARP x control register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0															EN
r															rw

Field	Bits	Type	Description
EN	0	rw	**ARPx enable** 0_B ARPx function is disabled 1_B ARPx function is enabled

(table continues...)

(continued)

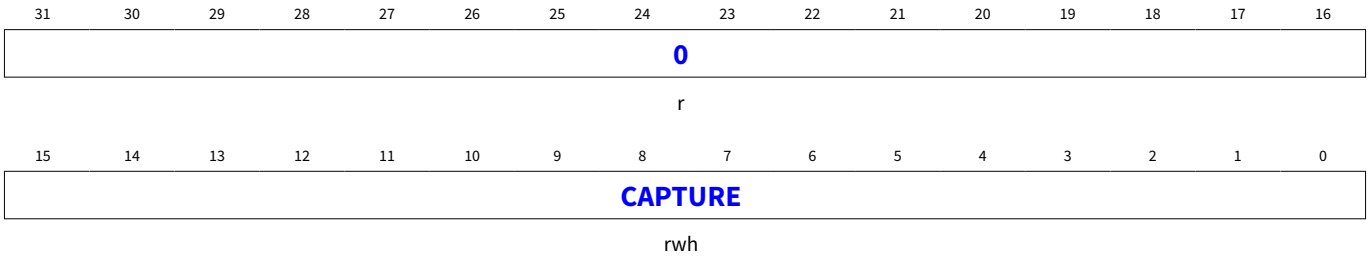
Field	Bits	Type	Description
CLR	30	w	**ARPx status clear** Bit can be used to clear the ARPx status bit (STAT). Bit is always read as 0. 0_B No action 1_B STAT bit is cleared
STAT	31	rh	**ARPx status** The STAT bit is set by the ARPx function at the end of a QoS interval if an ARPx usage violation was identified in the QoS interval. If the STAT bit is not already set at that time, the CAPTURE register is simultaneously updated and its contents are protected against being overwritten by the hardware until the STAT bit is reset by the application software.. 0_B This partition has not had a usage violation 1_B This partition has had a usage violation
0	29:1	r	**Reserved-0** Read as 0; should be written with 0.

7.4.35 ARP x cycle count capture register

Register shows the bandwidth used by the master agent functions mapped to ARPx in a QoS interval.

ARPx_CCC (x=0-7) Offset address: $1A4_H+x*1C_H$

ARP x cycle count capture register Application Reset value: $0000\ 0000_H$



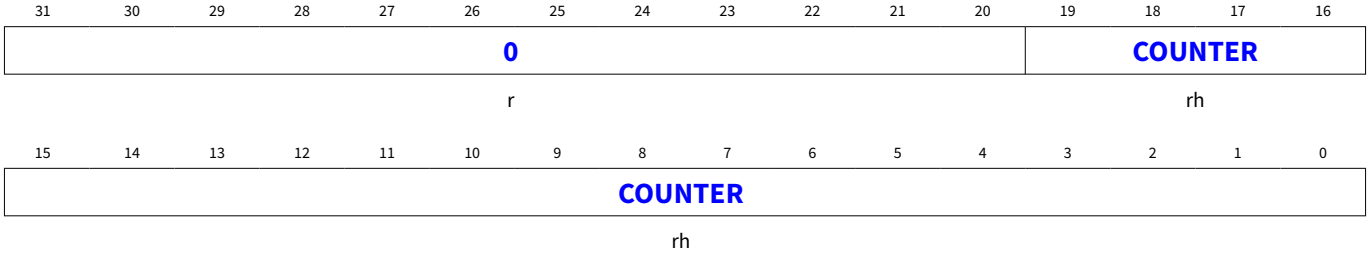
Field	Bits	Type	Description
CAPTURE	15:0	rwh	**ARP x captured cycle count** Bit field indicates how many clock cycles the master agent functions assigned to the ARPx have used the observed resource in a QoS time interval. The register is updated at the end of a QoS time interval if the CTRL.STAT bit is not set. The bit field provides the number in multiples of 16 local interconnect clock cycles.
0	31:16	r	**Reserved-0** Read as 0; should be written with 0.

7.4.36 ARP x current counter value register

Register shows the state of the ARPx counter with which the clocks are counted in which ARPx master agent functions have occupied the interconnect in the current QoS interval.

ARPx_CCV (x=0-7) Offset address: $1A8_H+x*1C_H$

ARP x current counter value register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
COUNTER	19:0	rh	**ARP x cycle count** Bit field shows the current state of the ARPx clock cycle counter and thus how many clock cycles the master agent functions assigned to the ARPx have used the observed resouce in the current QoS time interval so far. Note: The ARPx clock cycle counter counts only when ARPx is enabled.
0	31:20	r	**Reserved-0** Read as 0; should be written with 0.

7.5 Debug information

The BCU contains an interface to the OCMTS through which the activities on the local FPI can be monitored. The observation must be released through the global CSAV signals to activate the interface. In addition, the BCU has an error capture register that captures information about the transaction that ended with a FPI error or FPI timeout. Cyber Security related transactions, which are transactions with CS_VALID=1, are only captured if previously enabled by CSRM. A detailed description of these functions can be found in the respective BCU chapters.

7.8.4.31 BCU EDC alarm status register x. (x=0)

The BCU provides one alarm status register bit for each implemented FPI master agent and FPI slave agent. The assignment of the FPI master-slave and master-agent alarm signals is contained in the bit descriptions of the product-specific ALSTAT register description. The source of an alarm signal is described there using <module name>_S for a slave agent interface, <module name>_M for a master agent interface.

SBCU_ALSTATx (x=0) Offset address: 050_H+x*4

BCU EDC alarm status register x. Application Reset value: 0000 0000_H

Field	Bits	Type	Description
ALy (y=07)	y	rh	**Alarm y** The alarm bit shows if an EDC error was detected in an active phase of the related FPI Slave and Master interface. Register bits without constant definition are reserved in this product. 0 means: no EDC error detected. 1_B **PMS_S**: EDC error was detected by the PMS slave agent that also provides access to the SCR.
ALy (y=08)	y	rh	**Alarm y** The alarm bit shows if an EDC error was detected in an active phase of the related FPI Slave and Master interface. Register bits without constant definition are reserved in this product. 0 means: no EDC error detected. 1_B **SMM_S**: EDC error was detected by the SMM slave agent.
ALy (y=09)	y	rh	**Alarm y** The alarm bit shows if an EDC error was detected in an active phase of the related FPI Slave and Master interface. Register bits without constant definition are reserved in this product. 0 means: no EDC error detected. 1_B **TRI_S**: EDC error was detected by the TRI slave agent.
ALy (y=10)	y	rh	**Alarm y** The alarm bit shows if an EDC error was detected in an active phase of the related FPI Slave and Master interface. Register bits without constant definition are reserved in this product. 0 means: no EDC error detected. 1_B **VTMON_S**: EDC error was detected by the VTMON slave agent.
ALy (y=12)	y	rh	**Alarm y** The alarm bit shows if an EDC error was detected in an active phase of the related FPI Slave and Master interface. Register bits without constant definition are reserved in this product. 0 means: no EDC error detected. 1_B **CLOCK_S**: EDC error was detected by the CLOCK slave agent.
ALy (y=15)	y	rh	**Alarm y** The alarm bit shows if an EDC error was detected in an active phase of the related FPI Slave and Master interface. Register bits without constant definition are reserved in this product. 0 means: no EDC error detected. 1_B **VMT0_S**: EDC error was detected by the VMT0 slave agent.
ALy (y=16)	y	rh	**Alarm y** The alarm bit shows if an EDC error was detected in an active phase of the related FPI Slave and Master interface. Register bits without constant definition are reserved in this product. 0 means: no EDC error detected. 1_B **VMT1_S**: EDC error was detected by the VMT1 slave agent.

7.8.6 TC4Dx FPI revision history

Initial release of the chapter.

8 LLI - NDA only

Information for this functional block is only available under NDA.

9 System Direct Memory Access (SDMA)

The System DMA is a safe and flexible DMA controller capable of mastering data move operations without direct CPU involvement.

The System DMA, more commonly referred to as just the DMA, implements multiple master interfaces to the system interconnect, and contains two move engines to allow two data movement operations to run simultaneously. It also implements multiple DMA channels which undergo priority arbitration to become active in the move engines.

9.1 Feature list

- Safe movement of data
  - The DMA implements a lockstep mechanism using a redundant checker core for safety
  - The DMA implements ECC protection on the DMARAM
- Ability to detect patterns in DMA move data
  - Pattern detection can be configured on 8-bit, 16-bit, and 32-bit data moves
- Virtualization and resource partitions to provide freedom from interference
  - The DMA implements virtualization using the concept of resource partitions (RPs). Each DMA instance implements up to 16 RPs
  - An application in one RP running a set of defined DMA move functions has functional freedom from interference from another application running another set of defined DMA move functions in a different RP
  - Each RP has independent access protection controls which enable individual Master TAG identifiers, virtual machine IDs, and protection register sets (PRS) to have read and write access to the RP and assigned DMA channels
  - Each RP may be assigned to a cyber-secure or non-cyber-secure group and only interrupt requests from the same group may trigger DMA hardware requests
  - Each RP can be configured with a master agent function tag identifier, a virtual machine number (VM), a protection register set (PRS), user or supervisor mode, and secure master identification to be driven onto the system interconnect during a DMA move
- Multiple independent DMA channels which can be individually programmed and scheduled
  - Each DMA channel may be assigned to a resource partition
  - Each DMA channel's transaction control set is stored in the DMARAM
  - The DMA channel source and destination address pointers support 32-bit wide address counters
  - Programmable data width of DMA moves
- Multiple move engines to support parallel servicing of DMA requests
  - Any move engine can service a DMA request from any DMA channel
  - Arbitration rules to pick the highest priority DMA channels with pending DMA requests for service by the move engines
  - SRI-source to SRI-destination data block moves up to 16 Mbyte DMA moves per DMA transaction
  - FPI-source to FPI-destination data block moves up to 8 Mbyte DMA moves per DMA transaction
- Multiple ways to request DMA move operations or chains of DMA move operations
  - DMA software requests
  - DMA hardware requests triggered by hardware interrupts
  - DMA daisy-chain requests to automatically trigger successive channels
  - Linked list and conditional linked list operations - the current DMA transaction can load the next DMA channel transaction control set (TCS) into the DMARAM by overwriting the existing DMA channel TCS. The next DMA transaction can be auto-started
- Generation of interrupts and alarms
  - Channel completion, pattern match and circular buffer wrap interrupts

  - Resource partition, and global error interrupts
  - Safety alarms generated on all safety events such as lockstep mismatches and EDC errors
- DMA timestamp
  - The DMA channel can be configured to write out a timestamp when the DMA transaction is completed. This timestamp can be used by application software to implement temporal monitoring of data transfers
- DMA CRC computation
  - The DMA channel can be configured to compute a CRC on the addresses or data transferred during a DMA transaction using the IEEE 802.3 CRC32 algorithm

9.2 Functional overview

The DMA moves data from source locations to destination locations without the intervention of the CPU or other on chip devices.

A data move is controlled by the transaction control set of an active DMA channel and is executed by a move engine. The transaction control sets are loaded into the DMARAM either directly through software writes through the configuration interface, or indirectly through linked list operations.

A DMA channel is activated by a DMA request, which can be a software request, a hardware request or a daisy chain request. DMA channels can be configured to raise an interrupt on transaction completion or other events. DMA channels are each assigned to a unique resource partition and inherit the access enable rules and master tag identifiers of that resource partition.

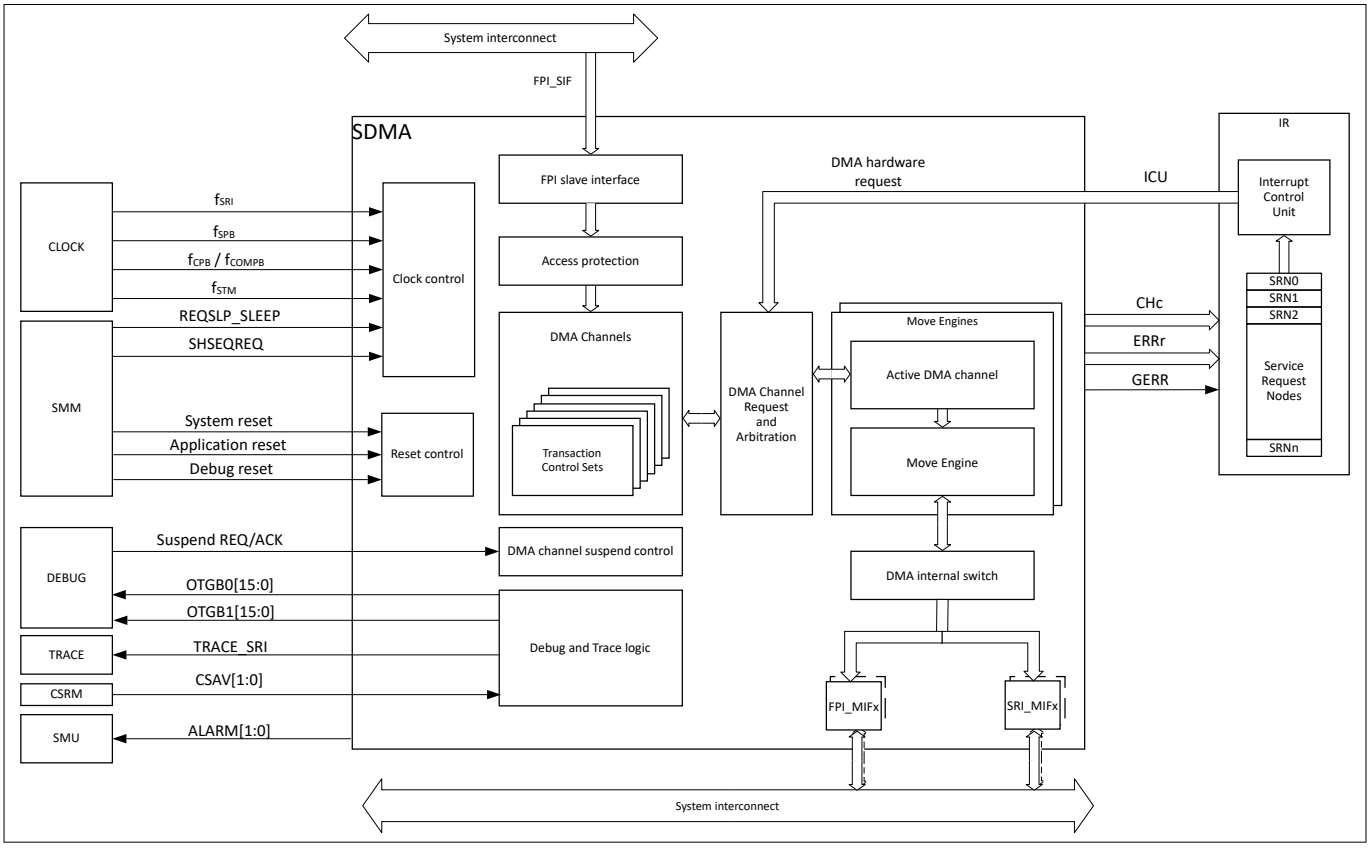

Figure 81 SDMA block diagram

The DMA is configured by software over the FPI_SIF interface and implements access protection to provide functional freedom from interference between different applications using the DMA.

Each DMA channel stores the context of an independent DMA operation in a transaction control set (TCS). Each application can configure and use one or more DMA channels. The DMA channels can be triggered by software requests, through hardware requests coming from the interrupt router (IR), or through other internal triggers. All DMA channels with pending DMA requests are then arbitrated so they can begin processing on one of the available move engines (MEs). DMA moves generated by the MEs result in read and write transactions being sent out through the DMA master agents FPI_MIFx and SRI_MIFx onto the system interconnect.

Each DMA channel can be configured to generate interrupts to the IR for completion and other events on the CHc interface. The DMA resource partitions (RPs) can also generate error interrupts to the IR on the ERRr interface. Errors which cannot be attributed to a single resource partition are reported to the IR through the GERR interface.

The DMA also implements interfaces to various infrastructure components for clocks, resets, sleep and shutdown requests. It implements debug and trace functionality through the interfaces with the DEBUG and TRACE functional blocks. The DMA debug and trace functions for CS resource partitions can be disabled by the CSRM through the CSAV interface.

The DMA also generates alarms for safety relevant events to the SMU.

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

Related information

TC4Dx SMU alarm mapping tables on page 7233

9.3 Functional description

Please refer to the following tables of information to help in your understanding of the SDMA functional description.

DMA glossary

The following tables introduce some DMA acronyms and terms that are used in the rest of the chapter.

Table 624 DMA acronyms

Acronym	Description
ACCLL	Accumulated Linked List
CONLL	Conditional Linked List
CH	Channel
DER	Destination Error
DLLER	Linked List Error
DMA	Direct Memory Access
DMALL	Direct Memory Access Linked List
DMARAM	Direct Memory Access Random Access Memory
EH	Error Handler
ME	Move Engine
PATDET	Pattern Detection
RAMER	RAM Error
RDCRC	Read Data Cyclic Redundancy Check
RP	Resource Partition
RROAT	Reset Request Only After Transaction
CHKLL	Checked Linked List
SDCRC	Source Destination Cyclic Redundancy Check
SER	Source Error
CLLER	Checked Linked List Error
TCS	Transaction Control Set
TRL	Transaction Request Lost
TS	Trigger Set

Table 625 DMA terms

Term	Description
DMA configuration data	The DMA configuration data configures the DMA configuration structure.

(table continues...)

Table 625 (continued) DMA terms

Term	Description
DMA configuration structure	The DMA configuration structure is used to configure CH, RP and ME. The DMA configuration structure is defined by the DMA register address map. ***Note**: The DMA configuration structure does not include the configuration of other functional blocks such as the IR and the SMU which are needed to make the DMA function within the system.* The DMA configuration structure and DMA configuration data defines all DMA move functions.
DMA software request	The CPU initiates a DMA transfer or a DMA transaction in a DMA channel.
DMA hardware request	The Interrupt Router initiates a DMA transfer or a DMA transaction in a DMA channel.
DMA daisy chain request	As soon as the current DMA transaction completes, the DMA channel initiates a DMA transfer or a DMA transaction in the next lower priority DMA channel.
DMA auto start request	As soon as the current DMA transaction completes, a linked list operation loads a new TCS and initiates a DMA transfer or a DMA transaction.
DMA request	DMA software request, DMA hardware request, DMA daisy chain request or DMA auto start request.
DMA read move data	Data read from the source module.
DMA write move data	Data written to the destination module.
DMA channel interrupt triggers	DMA signaling of the successful completion of a DMA move function.
DMA RP error interrupt triggers	DMA signaling of a DMA move function error.
DMA alarms	DMA signaling of a DMA safety error.
DMA address checksum	Cyclic redundancy checksum calculated according to the IEEE 802.3 standard for addresses generated during a DMA transaction.
DMA data checksum	Cyclic redundancy checksum calculated according to the IEEE 802.3 standard for data moved during a DMA transaction.
DMA timestamp	Appendage of timestamp to a DMA transaction.
DMA linked list	A DMA linked list is a series of DMA transactions executed in the same DMA channel.
DMA channel	A DMA channel stores the context of each independent DMA transaction.

Table 626 Structure of data move function

Term	Description
DMA move	A DMA move is an operation that always consists of two parts: **1.** A DMA read move that loads DMA read move data from a source module to the DMA **2.** A DMA write move that stores DMA write move data from the DMA to a destination module
DMA transfer	A DMA transfer is composed of 1, 2, 3, 4, 5, 8, 9 or 16 DMA moves. Once a DMA transfer is started on a DMA Move Engine, it cannot be interrupted unless an error occurs.
DMA transaction	A DMA transaction is composed of at least one DMA transfer.

Table 627 DMA channel states

State	Comments
Idle state	No DMA request is pending in this DMA channel
Reset state	No DMA request is pending in this DMA channel. DMA channel TCS bits cleared
Halt state	The DMA channel is halted by software configuration of the DMA channel registers. A DMA request will not be serviced by a ME
Suspend state	The DMA channel is suspended by the debug logic. A DMA request will not be serviced by a ME
Pending state	A DMA request in this DMA channel is waiting to be serviced by a ME
Active state	The ME is servicing a DMA request in this DMA channel

9.3.1 Configuration interface

The DMA implements a standard FPI slave interface (FPI_SIF) compliant with the FPI bus protocol. The DMA configuration interface supports single and block data transfers.

9.3.2 DMA operating modes

Each DMA channel can be configured to operate in any of the operating modes described in DMA channel operation. Each operating mode is described in the following sections.

Related information

DMA channel operation on page 1251

9.3.2.1 Move operation

The DMA moves data from source locations to destination locations. The source and destination addresses and other characteristics of the transaction like the size are all configured in the transaction control set for the current channel.

The size of a single DMA move within a transaction is defined by the channel data width (CHCFGRc.CHDW). The number of DMA moves in a transaction may be calculated from the following:

- Block mode (CHCFGRc.BLKM) defines the number of DMA moves in a DMA transfer
- Transfer reload (CHCFGRc.TREL) defines the number of DMA transfers in a DMA transaction

After a DMA move, the next source and destination addresses are calculated. Source and destination addresses are calculated independently of each other. The following address calculation parameters may be selected:

- The address offset, which is a multiple of the selected data width
- The offset direction: Addition, subtraction, or none (unchanged address)

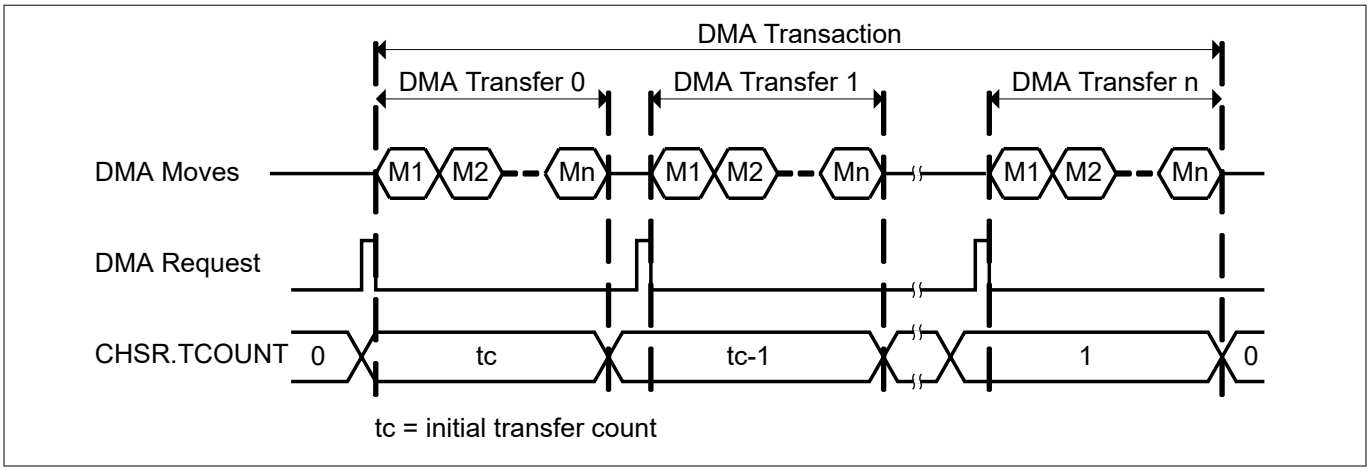

Figure 82 Block mode and transfer count

9.3.2.1.1 Address generation

Address control bits in DMA channel ADICRc determine how the addresses increment or decrement. The data width is defined in DMA channel CHCFGRc.CHDW and is taken into account during the address calculation. The address offset calculation tables below show the offset values that are added to or subtracted from the source address based on the ADICRc.SMF and ADICRc.INCS parameters, or the destination address based on the ADICRc.DMF and ADICRc.INCD parameters after each DMA move.

Attention: ***Software shall ensure that a DMA transaction is not configured such that the source or destination addresses cross from an SRI address space to an FPI address space or vice versa.***

Address calculation examples

The following examples demonstrate address generation for a data width of 16-bit (CHCFGRc.CHDW = 001_B).

Programmable address generation - example 1

16-bit half-words are moved from a source memory with an incrementing source address offset of 10_H to a destination memory with a decrementing destination address offset of 08_H.

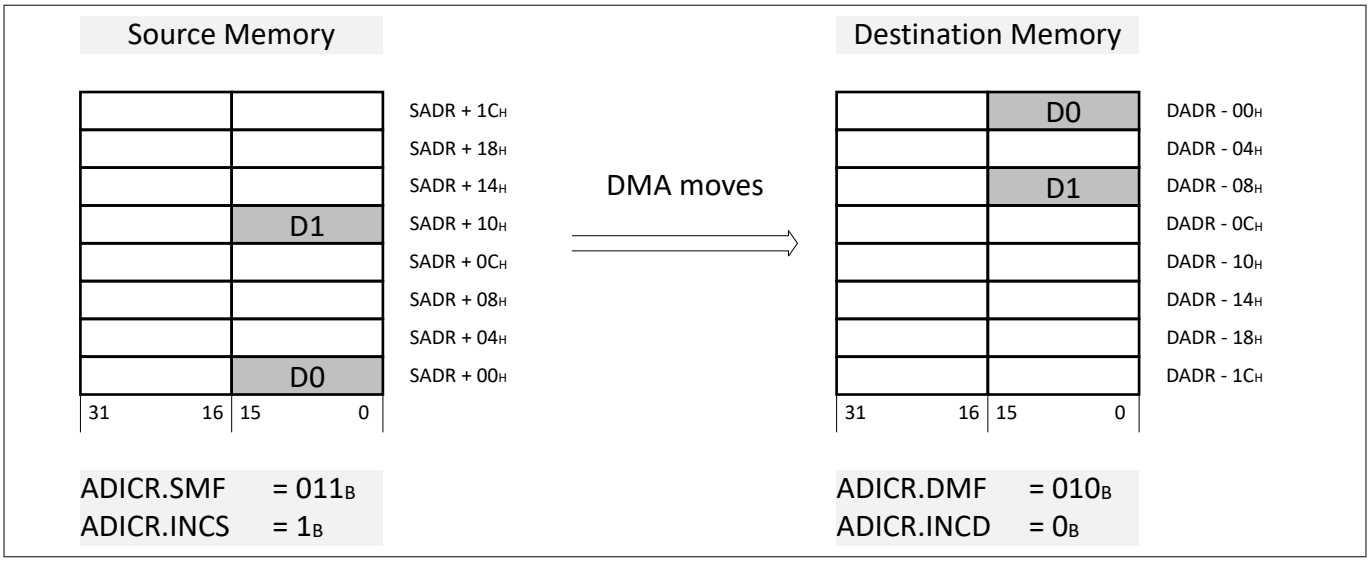

Figure 83 Programmable address generation - example 1

Programmable address generation - example 2

16-bit half-words are moved from a source memory with an incrementing source address offset of 02_H to a destination memory with an incrementing destination address offset of 04_H.

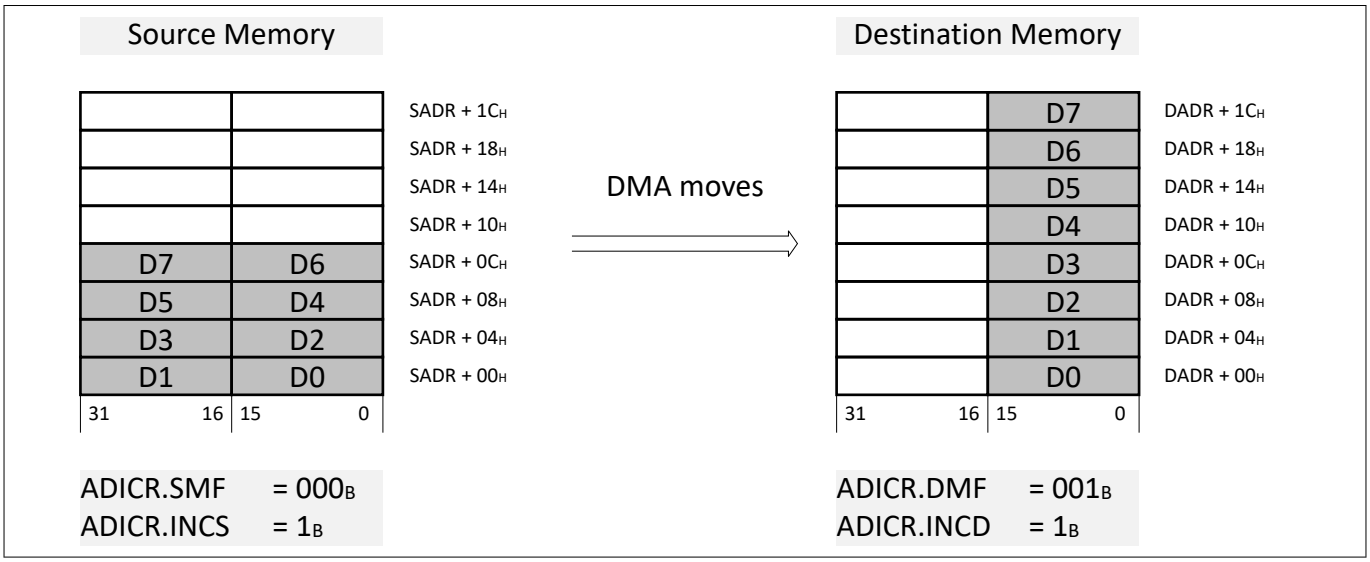

Figure 84 Programmable address generation - example 2

Circular buffer

The source and destination circular buffers are enabled by setting the DMA channel circular buffer enable bits ADICRc.SCBE and ADICRc.DCBE respectively. The source address and destination address may be configured to build a circular buffer separately for source and destination data. Within a circular buffer, the addresses are updated within the circular buffer wrap-around limits. The circular buffer length is determined by bit-fields ADICRc.CBLS for the source buffer and ADICRc.CBLD for the destination buffer. These 4-bit wide bit-fields determine which bits of the 32-bit address remain unchanged during an address update. Possible buffer sizes of the circular buffers can be 2^{CBLS} or 2^{CBLD} bytes (= 1, 2, 4, 8, 16, … up to 32k bytes). Source and destination addresses are incremented or decremented during a DMA move, all upper bits [31:CBLS] of source address and [31:CBLD] of destination address are frozen and remain unchanged, even if a wrap-around from the lower address bits [CBLS-1:0] or [CBLD-1:0] occurred. This address-freezing mechanism always causes the circular

buffers to be aligned to a multiple integer value of its size. If the circular buffer size is less than or equal to the selected address offset then the same circular buffer address will always be accessed.

Address alignment

The DMA can initiate transactions on SRI and FPI interconnects. Software must ensure that the address alignment rules for each type of interconnect are observed when configuring the address generation parameters.

FPI address alignment

The FPI interconnect interface width is 32 bits. Burst transaction are supported up to a burst length of 8, which is a 256 bit move operation. All source addresses and destination addresses shall be aligned to the correct address boundary as follows:

- Single transfers: the source address and destination address boundaries shall align with the channel data width (CHCFGRc.CHDW set to byte, half-word, word)
- Block transfers: the source address and destination address boundaries shall align to a word boundary. The FPI protocol defines a wrap around addressing scheme for block transfers not starting with a block transfer sized start address. The effect on a DMA transaction is demonstrated by different scenarios for BTR2 , BTR4 and BTR8 transactions on an FPI interconnect below

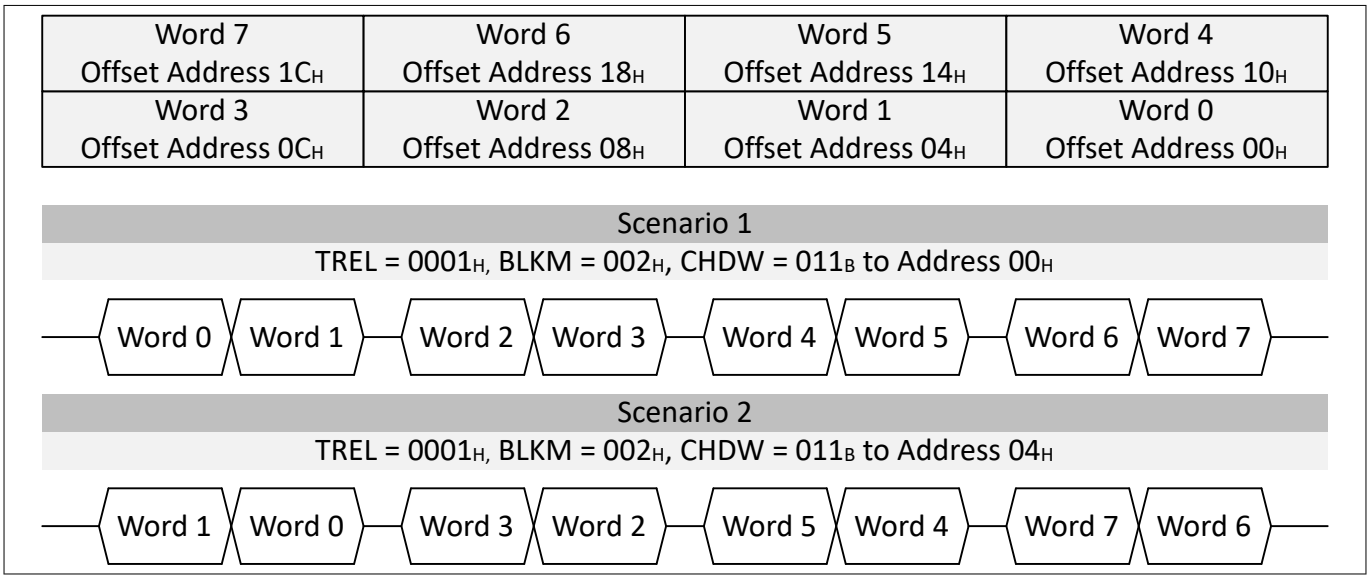

Figure 85 FPI protocol block transfer request - 2 transfers

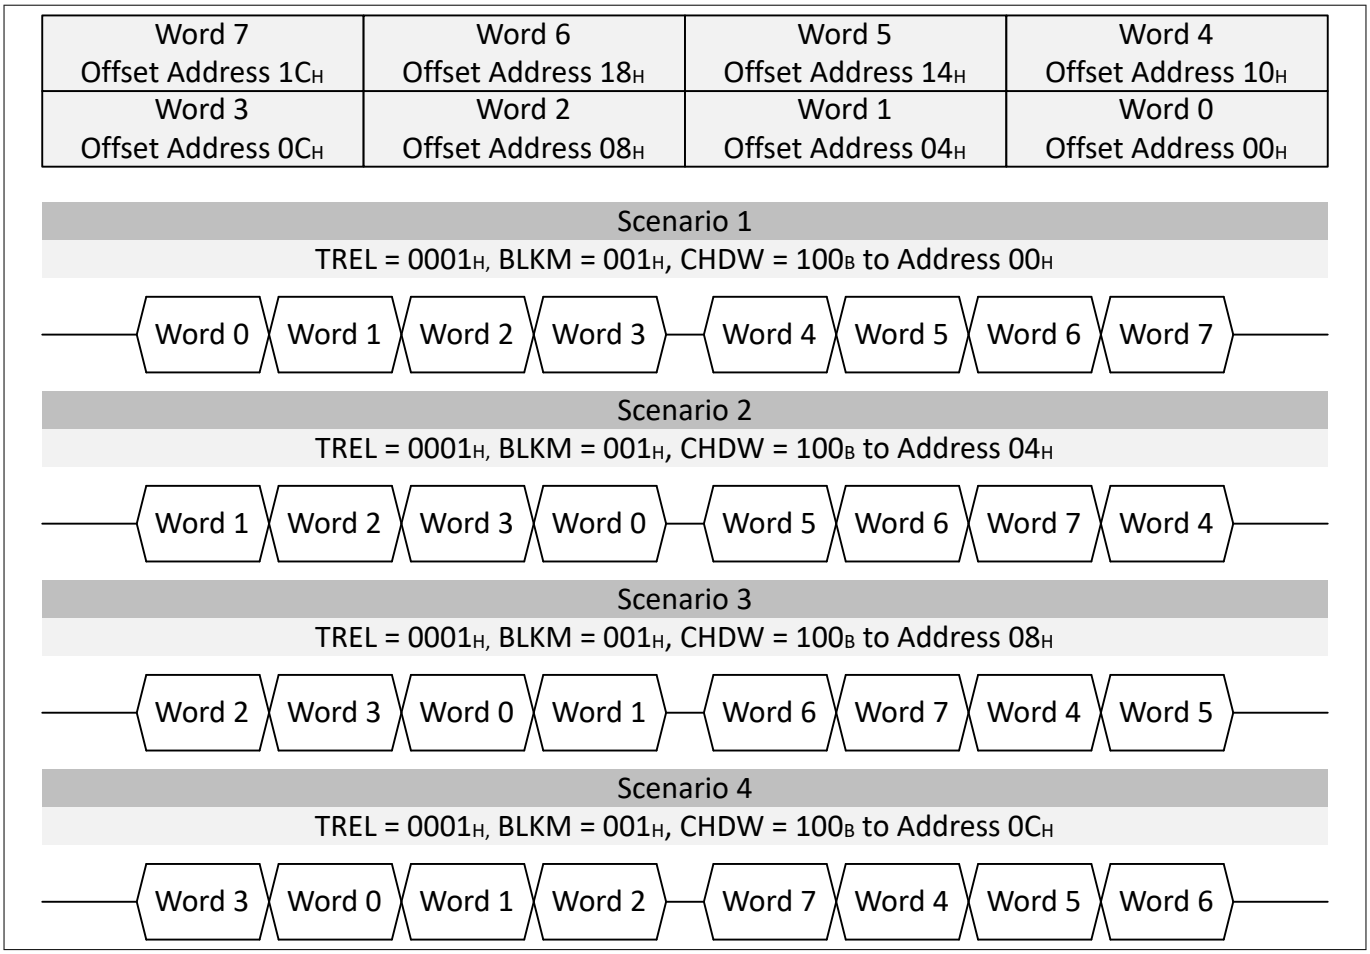

Figure 86 FPI protocol block transfer request - 4 transfers

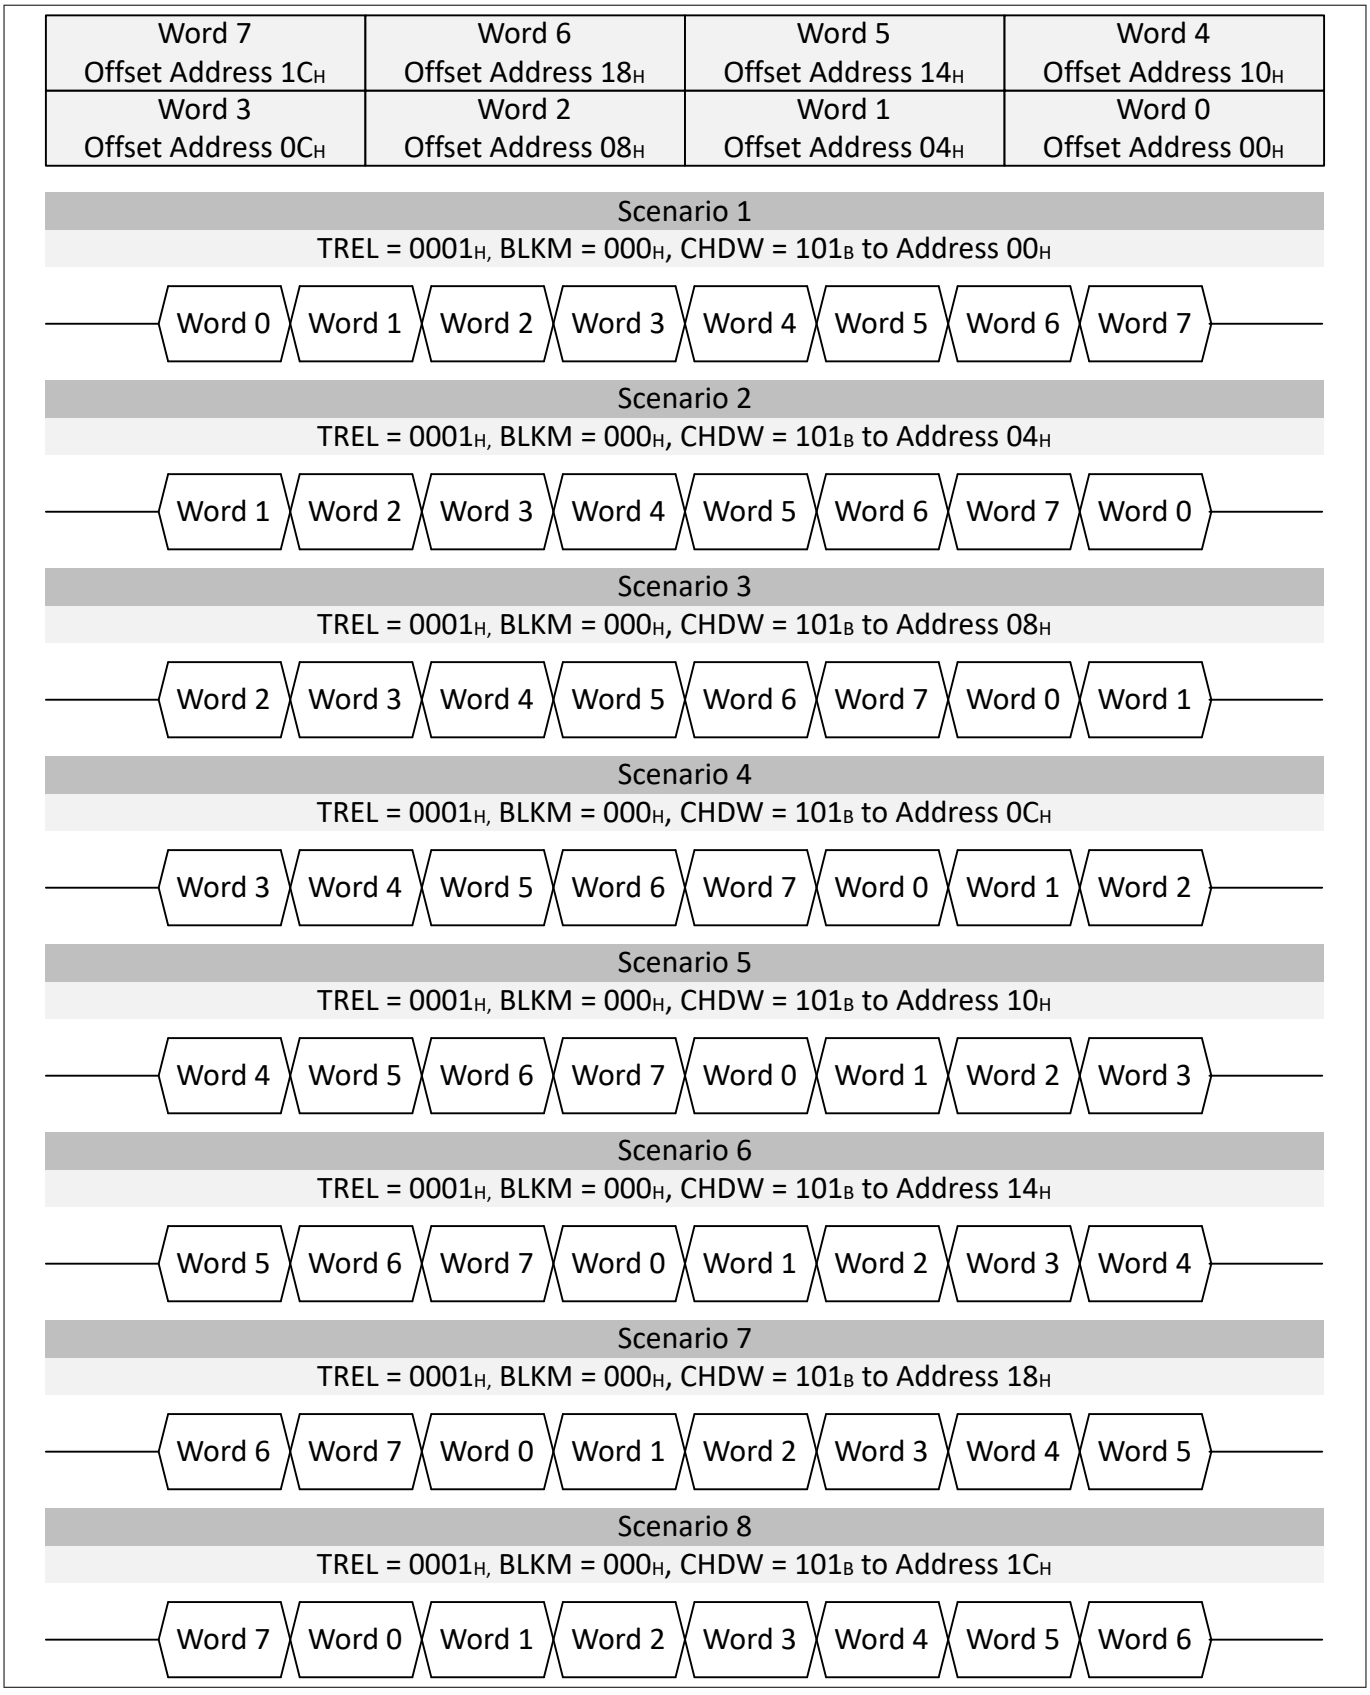

Figure 87 FPI protocol block transfer request - 8 transfers

SRI address alignment

The SRI interconnect interface width is 64 bits. Burst transaction are supported up to a burst length of 8, which is a 512 bit move operation. All source addresses and destination addresses shall be aligned to the correct address boundary as follows:

- Single transfers: The source address and destination address boundaries shall align with the channel data width (CHCFGRc.CHDW set to byte, half-word, word or double-word)
- Block transfers: The source address and destination address boundaries shall align to a double-word boundary. The SRI protocol defines a wrap around addressing scheme for block transfers not starting with a block transfer sized start address. The effect on a DMA transaction is demonstrated by different scenarios for BTR2 , BTR4 and BTR8 transactions on an SRI interconnect below

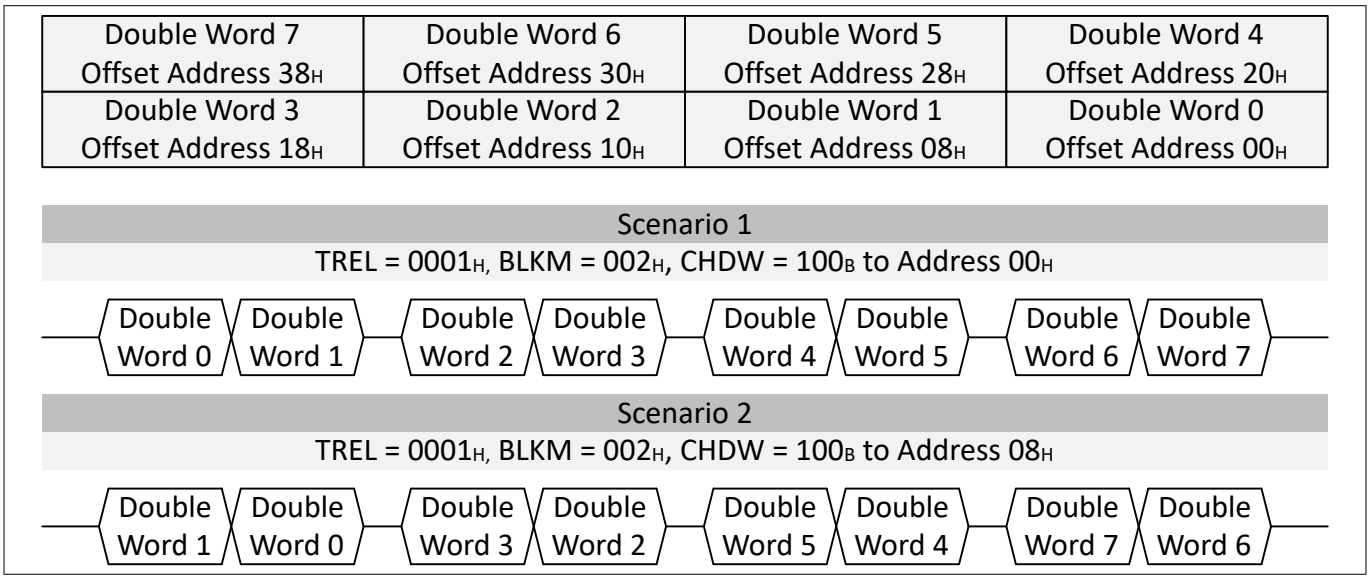

Figure 88 SRI protocol block transfer request - 2 transfers

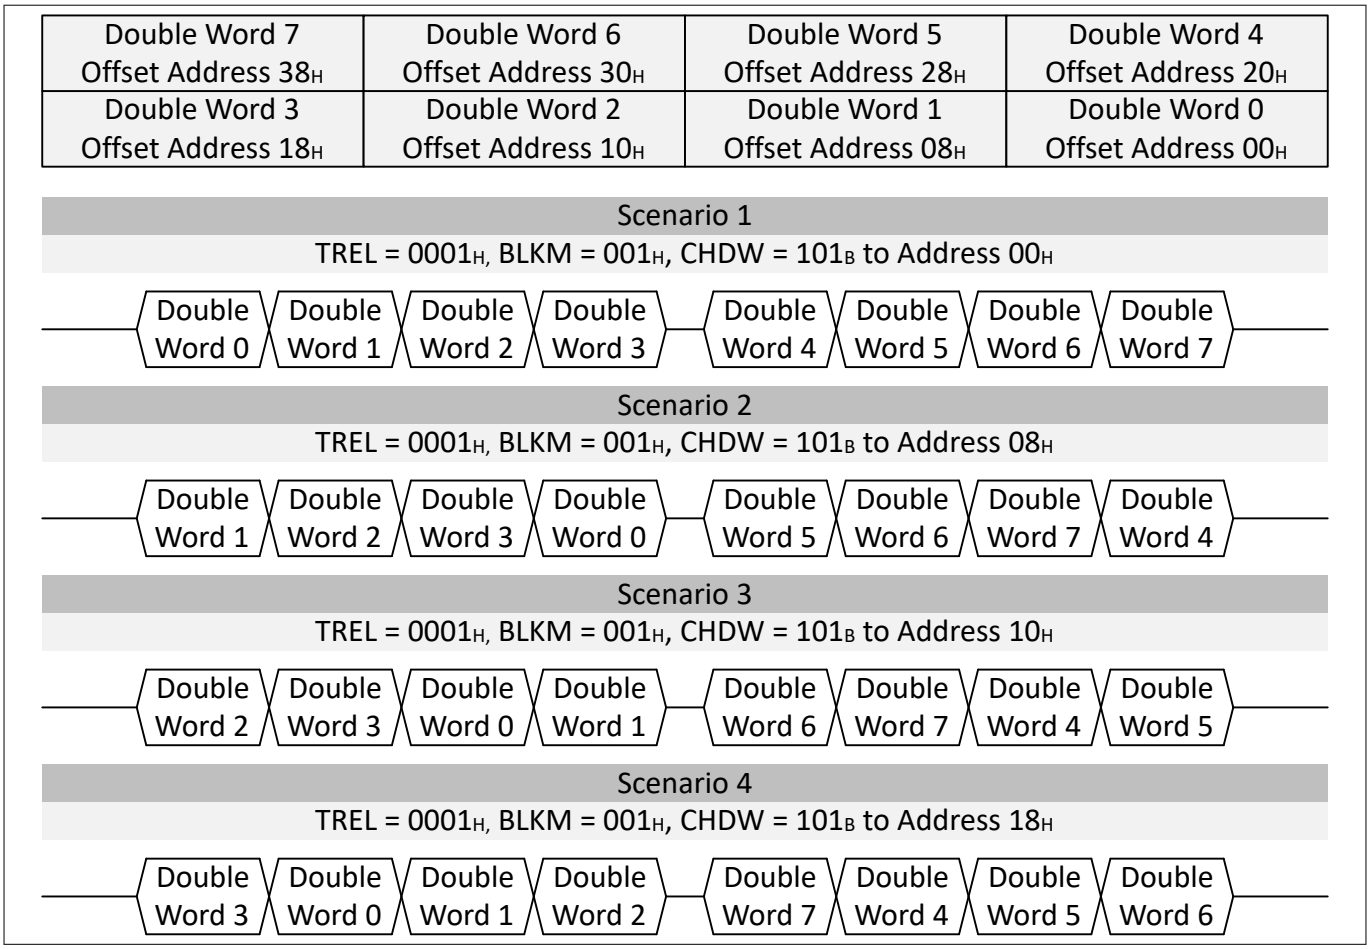

Figure 89 SRI protocol block transfer request - 4 transfers

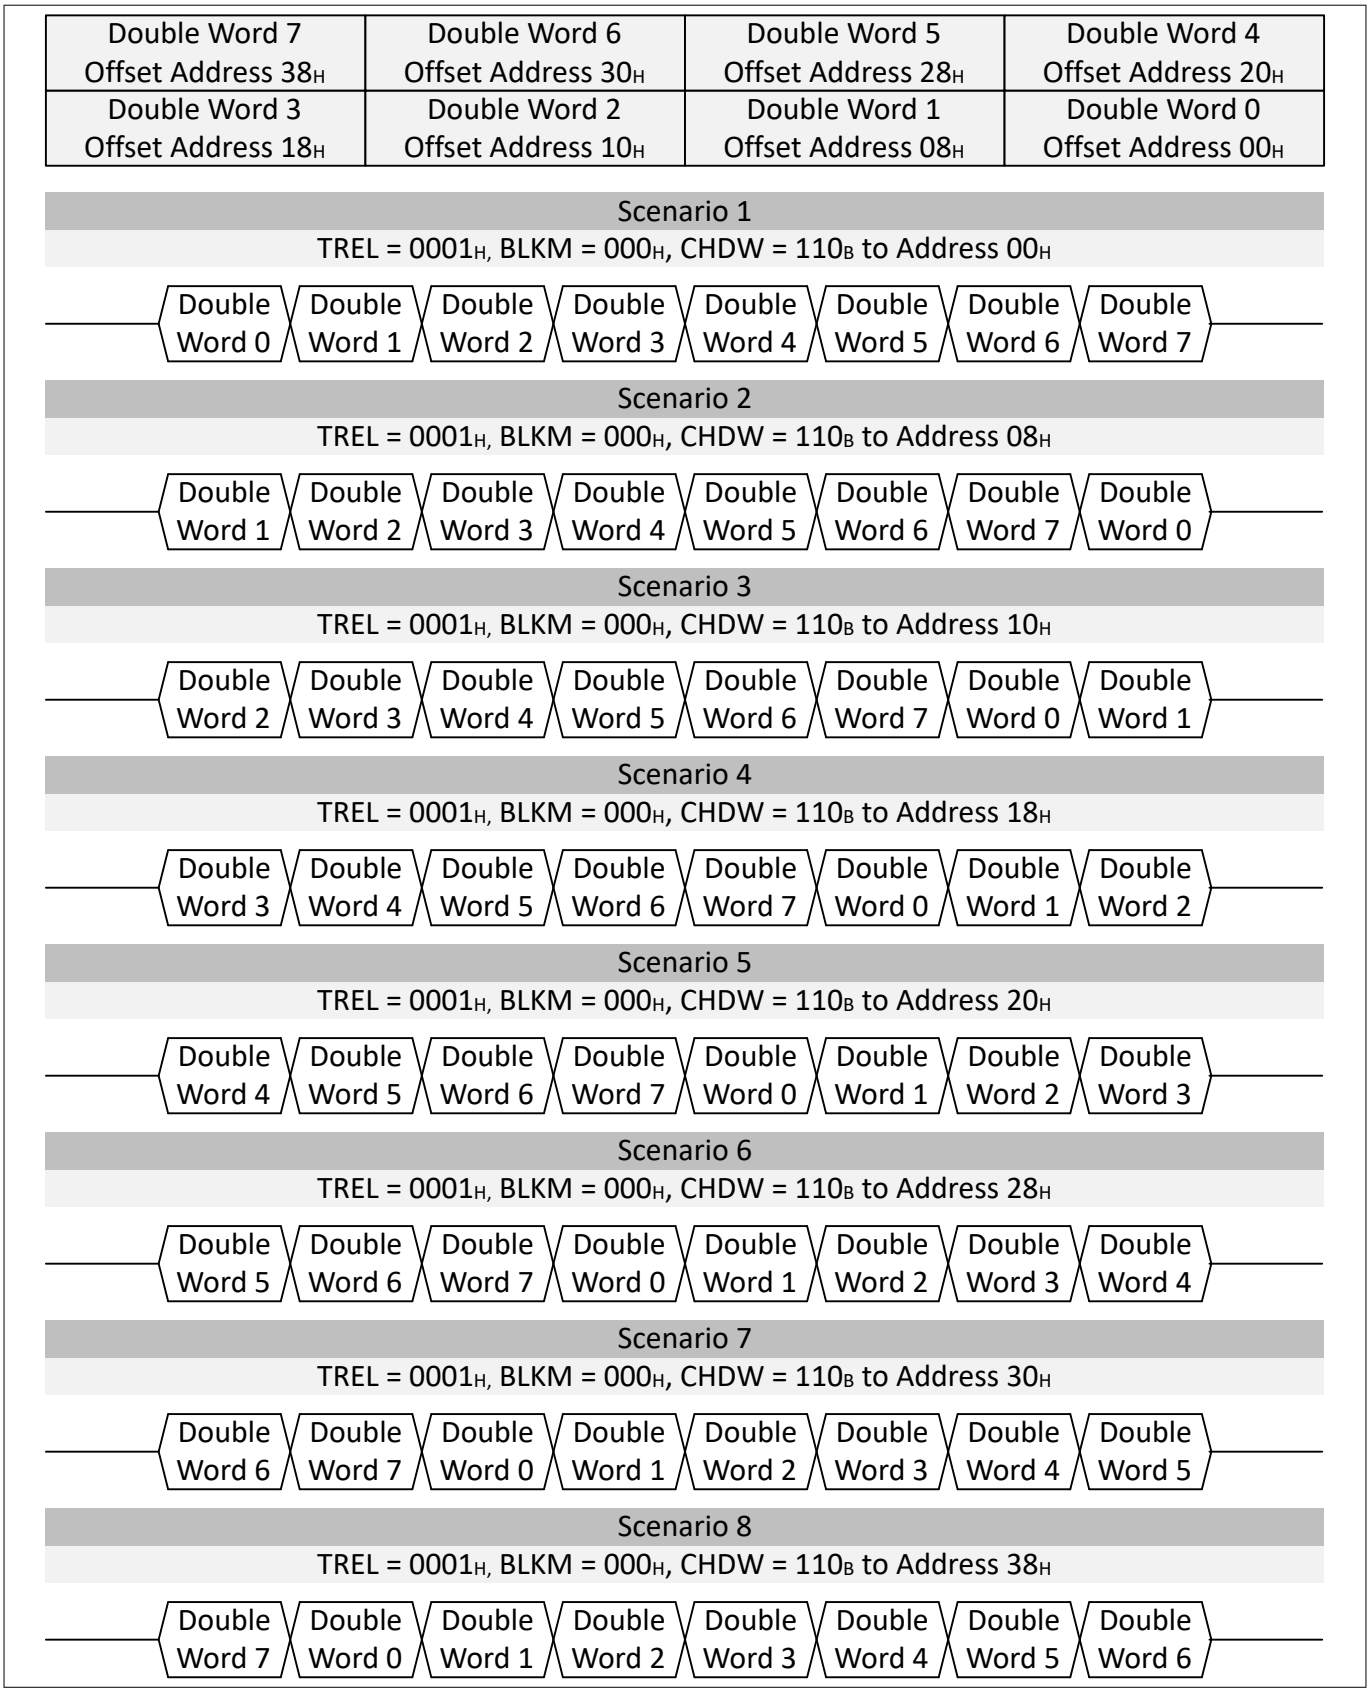

Figure 90 SRI protocol block transfer request - 8 transfers

Address counter

If the source circular buffer is not enabled (ADICRc.SCBE = 0_B) then the source address will increment or decrement across the entire 32-bit address field. If the destination circular buffer is not enabled (ADICRc.DCBE = 0_B) then the destination address will increment or decrement across the entire 32-bit address field. The address offset is determined by the DMA channel CHCFGRc.CHDW. The address will wrap around on the 32-bit address boundary:

- If the address is incrementing, it will wrap from $FFFFFFFF_H$ to 00000000_H
- If the address is decrementing, it will wrap from 00000000_H to $FFFFFFFF_H$

9.3.2.1.2 DMA address checksum

The DMA calculates a SDCRC checksum in accordance with the IEEE 802.3 standard using the source and destination addresses presented to the system interconnect as input data. Software can compare the calculated DMA address checksum (SDCRC) with an expected DMA address checksum stored in memory to validate the address generation during a DMA transaction.

Attention**: **DMA address checksum calculation is considered deprecated functionality in the AURIX™ TC4xx family. This functionality may be removed in a future AURIX™ generation.

To check the DMA channel address generation use the following steps:

- Software shall initialize the DMA address checksum stored in DMARAM to a known initial value
- The DMA channel receives a DMA request
- If the DMA channel is in the active state and no error or retry event is reported, the ME calculates an updated DMA address checksum for each DMA read move and DMA write move
- On completion of the DMA transaction, the DMA shall store the final DMA address checksum in DMARAM
- Software shall compare the calculated DMA address checksum
  - If the calculated and expected DMA address checksum match, the DMA has correctly calculated the source and destination address. If the checksums do not match, software shall report a fault

The DMA address checksum is not available for the following configurations of DMA channel operation:

- DMA double source buffering Software switch only
- DMA double source buffering Software switch and Automatic hardware switch
- DMA double destination buffering Software switch only
- DMA double destination buffering Software switch and Automatic hardware switch
- Conditional Linked List (CONLL)

9.3.2.1.3 DMA data checksum

To support enhanced data integrity checking the DMA calculates a 32-bit read data CRC (RDCRCRc) in accordance with the IEEE 802.3 standard on DMA move data as it passes through the DMA.

Move operation or shadow operation

To calculate a DMA data checksum for DMA move data the DMA channel RDCRCRc must be initialized, for example written with 00000000_H or another desired initial value, in addition to the standard DMA transaction configuration set for the size of DMA move data.

If no error or retry event is reported during DMA move then the ME calculates an updated DMA data checksum value for each DMA move. On completion of the DMA transaction the ME stores the DMA data checksum in the DMA channel RDCRCRc. Software may compare the calculated DMA data checksum with an expected DMA data checksum to verify the integrity of DMA move data.

Swap byte

The DMA data checksum is calculated for all DMA channel data widths and may be configured to swap the byte order (at the following figure). If DMA channel swap byte is selected (CHCFGRc.SWAP = 1_B) then the order of bytes are swapped before DMA data checksum computation. Big-endian input is converted to little-endian and vice versa. If the DMA channel is configured for 8-bit channel data width (CHCFGRc.CHDW = 000_B) then swap byte has no effect.

Swap byte does not change the byte order of data between a DMA read move and a DMA write move.

DMA timestamp

If the DMA channel is configured to append a DMA timestamp then the DMA timestamp is not part of the DMA data checksum calculation.

Double buffering operations

The DMA data checksum is accumulated across all the DMA move data moved into both buffers. Software may re-initialize the DMA data checksum after a Software switch and before the next data sample is received.

DMA linked List (DMALL)

The DMA data checksum is initialized to 00000000_H at the start of each DMA transaction.

Accumulated linked list (ACCLL), checked linked list (CHKLL) and conditional linked list (CONLL)

The DMA data checksum is accumulated across all the DMA transactions in the linked list.

9.3.2.2 Pattern detection

Each DMA resource partition (RP) provides two pattern detection registers that can be used by the DMA channels assigned to the RP. If a DMA channel is configured for pattern detection then after each DMA read move, the DMA move engine (ME) compares move data with a value stored in the Pattern Read Registers (PRR) belonging to the corresponding resource partition. The pattern detection operation depends on the channel data width (CHCFGRc.CHDW). The control field CHCFGRc.PATSEL selects different pattern detection operations for a specific value of CHDW.

The pattern compare logic compares the DMA move data stored in the ME read buffer to the selected PRR register. If the bytes of move data to be compared are spread across different words of move data, the ME may combine the pattern match result of the current DMA move and the pattern match result stored in MEmCHSR.LXO of the previous DMA move.

Configuration

If a DMA channel is configured for pattern detection:

- The channel data width (CHCFGRc.CHDW) shall be configured to 8-bit, 16-bit or 32-bit
- The source address shall not be configured to a cached address (segments 8 and 9). A non-cached address (segments A and B) shall be configured to prevent the ME read buffer from re-aligning the move data

Interrupt service request

If a DMA channel is configured for pattern detection and a pattern match is detected:

- The DMA transaction ends with the current DMA move
- DMA channel TSRc.HTRE is cleared to stop DMA transfers in the current active DMA channel
- DMA channel TSRc.CH will clear when the DMA write move has completed
- The ME writes back the next DMA move values of SADRc and DADRc
  - If the DMA channel is configured for Shadow operation Read only mode, the ME does not perform a shadow address update. The ME writes backs the current value of SHADRc into the DMARAM
- A pattern detection interrupt service request is triggered

Software may read the DMA channel status to identify the location of the pattern match in the data stream

Errors

If a SER is reported during the current DMA read move, the ME does not perform a pattern match

Related information

Shadow operation on page 1230
Read only mode on page 1231

9.3.2.2.1 Application of pattern detection

In a typical application, there is an incoming data stream from one of the communication interfaces which the application has to scan for a fixed pattern which might indicate, for example, the end of the communication. The application can then offload this task to the DMA by configuring a DMA channel in pattern detection mode. If the DMA detects the configured pattern in the data stream, the DMA channel activates the DMA channel pattern match interrupt service request. The application may then read the SADRc register to determine the address at which the pattern match occurred after allowing for the increment or decrement of the source address after the matching DMA move completes.

9.3.2.2.2 Pattern compare logic

The ME COMPare (COMP) logic shown below compares move data against a reference pattern. One COMP block controls either 8 bits or 16 bits of data. The COMP block may be configured to mask each data bit for the pattern compare.

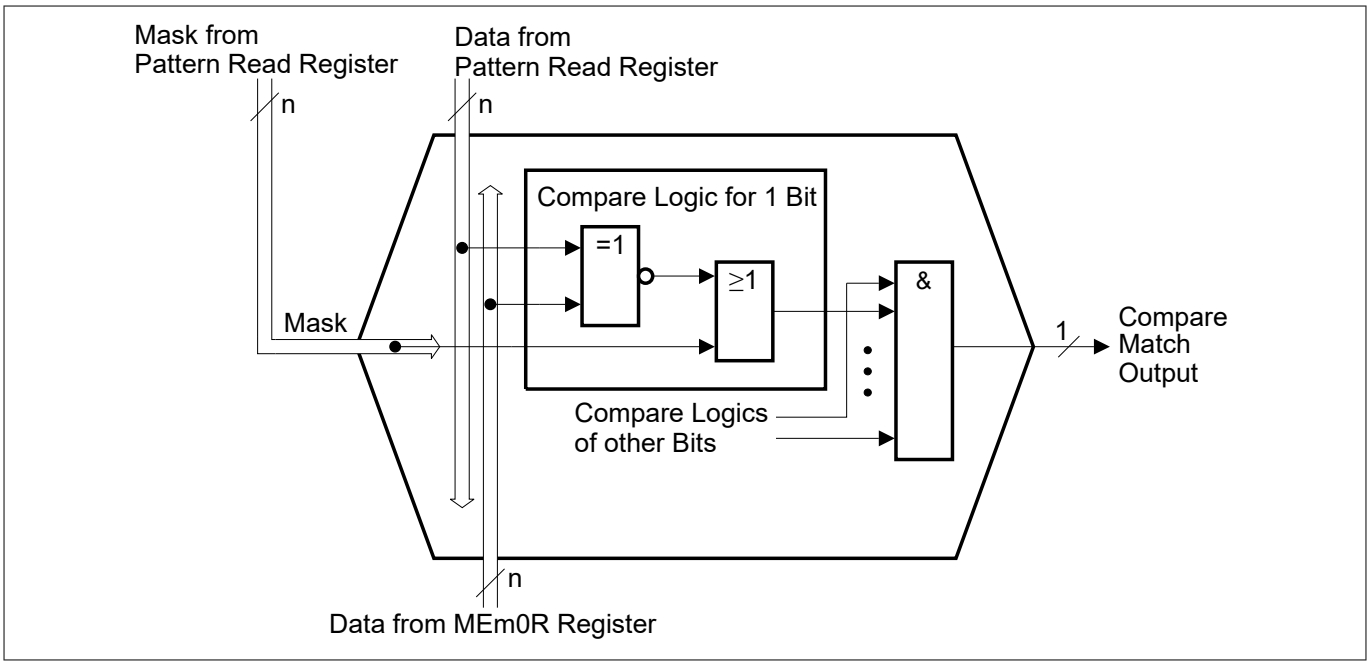

Figure 92 Pattern compare logic (COMP block)

In the COMP logic, one data bit from a ME read register is compared to the corresponding pattern bit stored in the selected PRR. If both bits are equal and a pattern mask bit stored in another PRR bit-field is 0_B then the compare matched condition becomes active. When the pattern mask bit is set to 1_B, the compare matched condition is always active (set) for the related bit. When the compare matched conditions for each bit within the COMP logic are true, the compare match output line of the COMP block becomes active.

9.3.2.2.3 Pattern detection for 8-bit channel data width

If a DMA channel is configured for Pattern detection for 8-bit channel data width, the ME uses the source address to select byte(s) of move data to be compared with patterns stored in PRRAr or PRRBr.

The pattern compare logic allows a byte of DMA move data to be compared with two different patterns. A mask operation of each compared bit is possible.

Example of pattern detection for 8-bit channel data width

The DMA channel is configured for pattern detection for 8-bit channel data width (CHCFGRc.CHDW = 000_B).
If the current DMA read move stores the move data byte in the lowest byte of the ME read buffer:

- The ME uses the source address to select the move data byte stored in the lowest byte of the ME read buffer
- The ME compares move data byte stored in the lowest byte of the ME read buffer to PRRAr

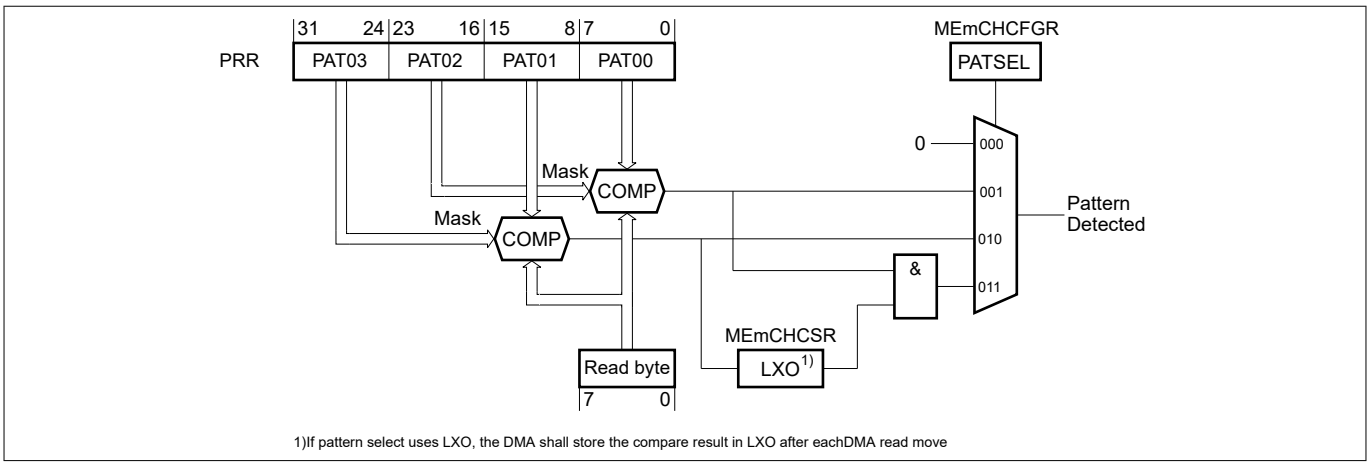

Figure 93 Pattern detection for 8-bit channel data width

The DMA channel may be configured for one of three pattern compare operations.

Table 631 Pattern detection for 8-bit channel data width

PATSEL	Pattern detection operating modes
000_B	Pattern detection disabled
001_B	Pattern compare of the lowest byte of the DMA read move data to PRRAr.PAT00, masked by PRRAr.PAT02
010_B	Pattern compare of the lowest byte of the DMA read move data to PRRAr.PAT01, masked by PRRAr.PAT03
011_B	Pattern compare of the lowest byte of the current DMA read move data to PRRAr.PAT00, masked by PRRAr.PAT02 and Pattern compare of the lowest byte of the previous DMA read move data to PRRAr.PAT01, masked by PRRAr.PAT03
100_B	Pattern detection disabled
101_B	Pattern compare of the lowest byte of the DMA read move data to PRRBr.PAT10, masked by PRRBr.PAT12
110_B	Pattern compare of the lowest byte of the DMA read move data to PRRBr.PAT11, masked by PRRBr.PAT13
111_B	Pattern compare of the lowest byte of the current DMA read move data to PRRBr.PAT10, masked by PRRBr.PAT12 and Pattern compare of the lowest byte of the previous DMA read move data to PRRBr.PAT11, masked by PRRBr.PAT13

Example of two byte pattern detection sequence

If a DMA channel is configured for a two byte pattern detection sequence compared to PRRAr (CHCFGRc.PATSEL[2:0] = 011_B) then after each DMA move the pattern match result of move data compared with PRRAr.PAT01, masked by PRRAr.PAT03 is stored in bit MEmCHSR.LXO.

This DMA channel configuration allows, for example, two-byte sequences to be detected in an 8-bit data stream coming from a serial module unit with 8-bit data width - for example recognition of carriage-return and line-feed characters.

9.3.2.2.4 Pattern detection for 16-bit channel data width

If a DMA channel is configured for Pattern detection for 16-bit channel data width, the ME uses the source address to select bytes of move data to be compared with patterns stored in PRRAr or PRRBr. Three pattern match configurations are possible defined by the DMA channel pattern select (CHCFGRc.PATSEL[1:0]):

- Aligned mode: compare complete half-word of one DMA move only
- Unaligned mode: compare upper and lower byte of two consecutive DMA moves
- Combined mode: combine Aligned mode and Unaligned mode

A mask operation of each compared bit is possible.

Example of pattern detection for 16-bit channel data width

The DMA channel is configured for pattern detection for 16-bit channel data width (CHCFGRc.CHDW = 001_B).

If the current DMA read move stores the move data half word in the lowest half word of the ME read buffer:

- The ME uses the source address to select the move data half word stored in the lowest half word of the ME read buffer
- The ME compares move data half word stored in the lowest half word of the ME read buffer to PRRAr

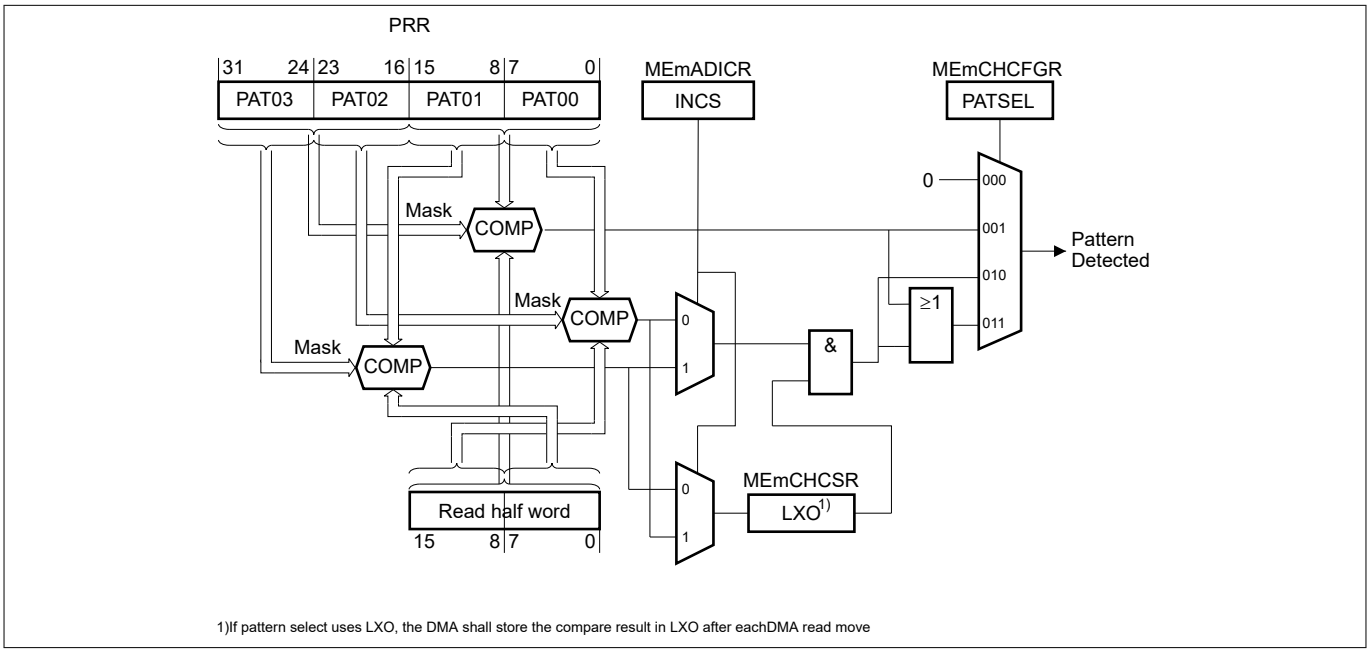

Figure 94 Pattern detection for 16-bit channel data width

The DMA channel may be configured for one of four pattern compare operations.

- Aligned mode
- Unaligned mode 1 (source address decrement)
  - The high byte of the current 16-bit DMA read move data and the low byte of the previous 16-bit DMA read move data are compared
- Unaligned mode 2 (source address increment)
  - The low byte of the current 16-bit DMA read move data and the high byte of the previous 16-bit DMA read move data are compared
- Combined mode
  - If it is not known on which byte boundary (even or odd address) the 16-bit pattern to be detected is located, the DMA channel should be configured for combined mode
  - The combined mode is the most flexible mode that combines the pattern search capability for aligned and unaligned 16-bit data searches

Table 632 Pattern detection for 16-bit channel data width

PATSEL	INCS	Pattern detection operating modes
000_B	–	Pattern detection disabled
001_B	–	Aligned mode Pattern compare of the lowest half word of the DMA read move data to PRRAr.PAT01||PAT00, masked by PRRAr.PAT03||PAT02
010_B	0	Unaligned mode 1 (source address decrement) Pattern compare of the second lowest byte of the current DMA read move data to PRRAr.PAT00, masked by PRRAr.PAT02 and Pattern compare of the lowest byte of the previous DMA read move data to PRRAr.PAT01, masked by PRRAr.PAT03 (LXO)
	1	Unaligned mode 2 (source address increment) Pattern compare of the lowest byte of the current DMA read move data to PRRAr.PAT01, masked by PRRAr.PAT03 and Pattern compare of the second lowest byte of the previous DMA read move data to PRRAr.PAT00, masked by PRRAr.PAT02 (LXO)
011_B	0 or 1	Combined mode Pattern compare for aligned mode (PATSEL = 001_B) or unaligned modes (PATSEL = 010_B)
100_B	–	Pattern detection disabled
101_B	–	Aligned mode Pattern compare of the lowest half word of the DMA read move data to PRRBr.PAT11||PAT10, masked by PRRBr.PAT13||PAT12
110_B	0	Unaligned mode 1 (source address decrement) Pattern compare of the second lowest byte of the current DMA read move data to PRRBr.PAT10, masked by PRRBr.PAT12 and Pattern compare of the lowest byte of the previous DMA read move data to PRRBr.PAT11, masked by PRRBr.PAT13 (LXO)
	1	Unaligned mode 2 (source address increment) Pattern compare of the lowest byte of the current DMA read move data to PRRBr.PAT11, masked by PRRBr.PAT13 and Pattern compare of the second lowest byte of the previous DMA read move data to PRRBr.PAT10, masked by PRRBr.PAT12 (LXO)
111_B	0 or 1	Combined mode Pattern compare for aligned mode (PATSEL = 101_B) or unaligned modes (PATSEL = 110_B)

9.3.2.2.5 Pattern detection for 32-bit channel data width

If a DMA channel is configured for Pattern detection for 32-bit channel data width, the ME compares a move data word with patterns stored in PRRAr or PRRBr. Three pattern compare configurations are possible defined by the DMA channel pattern select (CHCFGRc.PATSEL[1:0]). A mask operation is not possible.

Example of pattern detection for 32-bit channel data width

The DMA channel is configured for pattern detection and 32-bit channel data width (CHCFGRc.CHDW = 010_B).
If the current DMA read move stores the move data word in the lowest word then

- The ME uses the source address to select the move data word stored in the lowest word of the ME read buffer
- The ME compares move data word stored in the lowest word of the ME read buffer to PRRAr

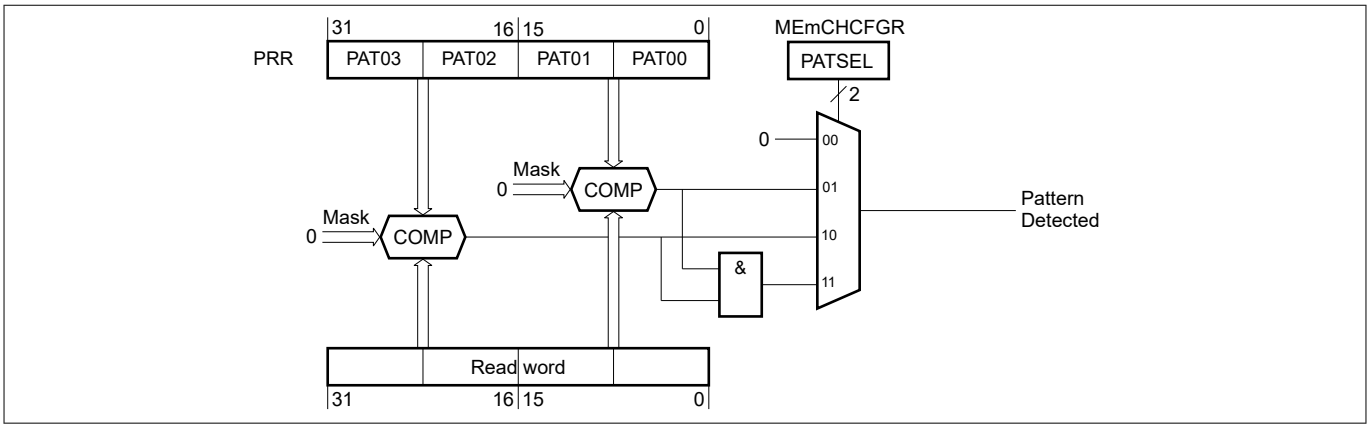

Figure 95 Pattern detection for 32-bit channel data width

The DMA channel may be configured for one of three pattern compare operations.

- Lower half-word only compared to pattern stored in PRRAr or PRRBr
- Upper half-word only compared to pattern stored in PRRAr or PRRBr
- Complete 32-bit word compared to pattern stored in PRRAr or PRRBr

Table 633 Pattern detection for 32-bit channel data width

PATSEL	Pattern detection operating modes
000_B	Pattern detection disabled
001_B	Unmasked pattern compare of lowest half word of the DMA read move data to PRRAr.PAT01||PAT00
010_B	Unmasked pattern compare of second lowest half word of the DMA read move data to PRRAr.PAT03||PAT02
011_B	Unmasked pattern compare of lowest word of the DMA read move data to PRRAr.PAT03||PAT02||PAT01||PAT00
100_B	Pattern detection disabled
101_B	Unmasked pattern compare of lowest half word of the DMA read move data to PRRBr.PAT11||PAT10
110_B	Unmasked pattern compare of second lowest half word of the DMA read move data to PRRBr.PAT13||PAT12
111_B	Unmasked pattern compare of lowest word of the DMA read move data to PRRBr.PAT13||PAT12||PAT11||PAT10

9.3.2.3 Shadow operation

If a DMA channel is configured for shadow operation, the DMA buffers a variable source or destination address.

9.3.2.3.1 Application of shadow operation

In a typical application, an ASCLIN module that receives data (fixed DMA channel source address) has to deliver the data to a memory buffer using a DMA transaction (variable DMA channel destination address). After a certain amount of data has been transferred, a new DMA transaction should be initiated to deliver further ASC data into another memory buffer. While the destination address register is updated during a running DMA transaction with the actual destination address, a shadow mechanism allows programming of a new destination address without disturbing the content of the destination address register. In this case, the new

destination address is written and buffered in the shadow address register. At the start of the next DMA transaction, the destination address register uses the new address without CPU intervention.

The shadow operation enables the application to immediately set up the next transaction after the current one has started, and without having to wait for the current one to complete. This can give the software a larger time window to configure the next transaction and therefore enable better application performance.

9.3.2.3.2 Shadowed address register

The shadow address register SHADRc stores either a new source address, or a new destination address. If both the source address and destination address have to be updated for the next DMA transaction, a running DMA transaction for this DMA channel must be finished. After that, source and destination address registers may be written before the next DMA transaction is started.

Only one address register may be shadowed while a DMA transaction is running, because the shadow register can only be assigned either to the source address or to the destination address. Note that the shadow address transfer mechanism has the same behavior in Single Mode and Continuous Mode.

The function of the shadow address register is defined by the mode of the shadow operation:

- Read only mode: If software writes to the shadow address register, the DMA does not execute the write and store a RP TCS configuration error
- Direct write mode: If software writes to the shadow address register, the DMA stores a new shadow address in the shadow address register

Related information

DMA hardware request on page 1257

TCS configuration error interrupt service request on page 1279

9.3.2.3.3 Read only mode

If software writes a new DMA channel source or destination address value, the DMA stores the new address value as follows:

- Idle state (with DMA channel CHCSRc.TCOUNT=0)
  - If software writes a new DMA channel source address value, the DMA stores the new source address value in the DMA channel SADRc
  - If software writes a new DMA channel destination address value, the DMA stores the new destination address value in the DMA channel DADRc
- Idle state (with DMA channel CHCSRc.TCOUNT!=0) or pending state
  - If software writes a new DMA channel source or destination address value, the DMA stores the new address value in the DMA channel SHADRc
- Active state
  - If software writes a new DMA channel source or destination address value, the DMA stores the new address value in the MEmSHADR

End of DMA transaction

As soon as the DMA completes a DMA transaction, the DMA checks the value of MEmSHADR.

If ME SHADR is not equal to 0000 0000_H, the ME writes back data to the DMARAM as follows:

- Shadow operation read-only mode source address
  - The DMA stores the MEmSHADR value into DMA channel SADRc
  - The DMA stores 0000 0000$_H$ into DMA channel SHADRc
- Shadow operation read-only mode destination address
  - The DMA stores the MEmSHADR value into DMA channel DADRc
  - The DMA stores 0000 0000$_H$ into DMA channel SHADRc

If software has not executed a shadow address update, MEmSHADR is equal to 0000 0000$_H$. The ME writes back data to the DMARAM as follows:

- Shadow operation read only mode source address
  - The DMA stores 0000 0000$_H$ into DMA channel SADRc (see Error conditions)
- Shadow operation read only mode destination address
  - The DMA stores 0000 0000$_H$ into DMA channel DADRc (see Error conditions)

Related information

DMA channel states on page 1262

Error conditions on page 1232

9.3.2.3.4 Direct write mode

If software writes a new DMA channel shadow address value, the DMA stores the new shadow address value as follows:

- Idle state or Pending state:
  - If software writes a new DMA channel shadow address value, the DMA stores the new shadow address value in the DMA channel SHADRc
- Active state:
  - If software writes a new DMA channel shadow address value, the DMA stores the new shadow address value in the MEmSHADR. As soon as the ME writes back data to the DMA RAM, the DMA stores the MEmSHADR value in the DMA channel SHADRc word

Start of DMA transaction

As soon as the DMA services a DMA request, the DMA performs a shadow address transfer as follows:

- Shadow operation direct write mode source address:
  - If DMA channel SHADRc is not 0000 0000$_H$, the DMA stores the DMA channel SHADRc value into MEmSADR
- Shadow operation direct write mode destination address:
  - If DMA channel SHADRc is not 0000 0000$_H$, the DMA stores the DMA channel SHADRc value into MEmDADR

End of shadow operation

If software writes a new DMA channel shadow address value of 0000 0000$_H$ or applies a DMA channel reset, the DMA shall not perform a shadow address update at the start of the next DMA transaction.

9.3.2.3.5 Error conditions

If a DMA channel is configured for Shadow operation and a new DMA request is serviced before software updates the shadow address, the DMA performs a DMA move to address 0000 0000$_H$ resulting in a bus error.

Related information

Shadow operation on page 1230

9.3.2.3.6 Transfer count update

The transfer count of a DMA transaction, stored in the DMA channel bit-field CHCFGRc.TREL, may be programmed if a DMA transaction is running. At the start of a DMA transaction, CHCFGRc.TREL is transferred to the MEmCHSR.TCOUNT. No reload of address or counter will be done if MEmCHSR.TCOUNT is not equal to 0.

The reprogramming of channel specific values except for the selected shadow address register must be avoided while a DMA channel is active as the data transfer may be corrupted.

Transfer count and source address update - example

The contents of the ME transfer count and the ME source address register are updated as shown in the figure below during two DMA transactions with a transfer count and a shadowed source address update.

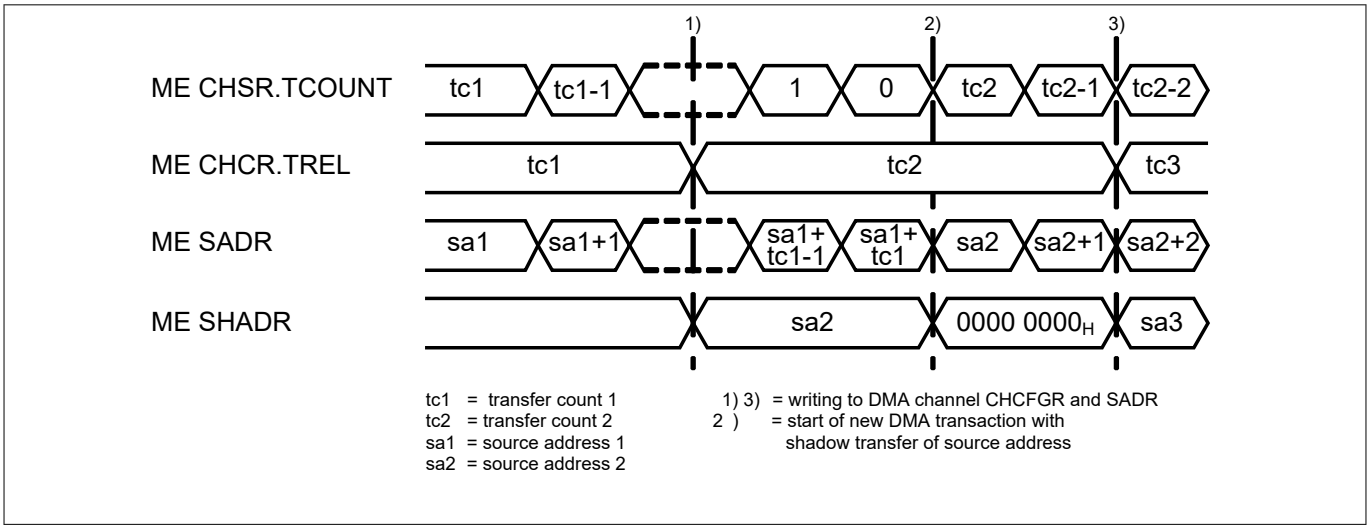

Figure 96 Shadow operation read only mode source address: Transfer count and source address update

At reference point 2) the DMA transaction 1 is finished and DMA transaction 2 is started. At 1) the DMA channel is reprogrammed with two new parameters for the next DMA transaction: Transfer count tc2 and source address sa2. Source address sa2 is buffered in MEmSHADR and transferred to MEmSADR when the new DMA transaction is started at 2). At this time, transfer count tc2 is also transferred to MEmCHSR.TCOUNT. Note that the shadow address register is only reset by hardware to 0000 0000_H as shown in this example, if read-only mode is selected.

In the event that DMA channel CHCFGRc.TREL is written while DMA channel is active:

- A write to DMA channel CHCFGRc.TREL will update the MEmCHCR.TREL value
- On write back DMA channel CHCFGRc.TREL is updated with the latest MEmCHCR.TREL value
- MEmCHSR.TCOUNT is updated to the new DMA channel CHCFGRc.TREL value at the start of the next DMA transaction

9.3.2.4 Double buffering operations

The DMA supports double buffering, which can be used for tasks which are schedule driven rather than being interrupt driven. For example, double destination buffering is as follows:

- DMA read moves transfer a continuous data stream from a module to the DMA
- DMA write moves transfer the read data from the DMA to one of two destination buffers stored in memory

The dormant buffer is frozen and available for cyclic software tasks to consume while the other buffer continues to be filled.

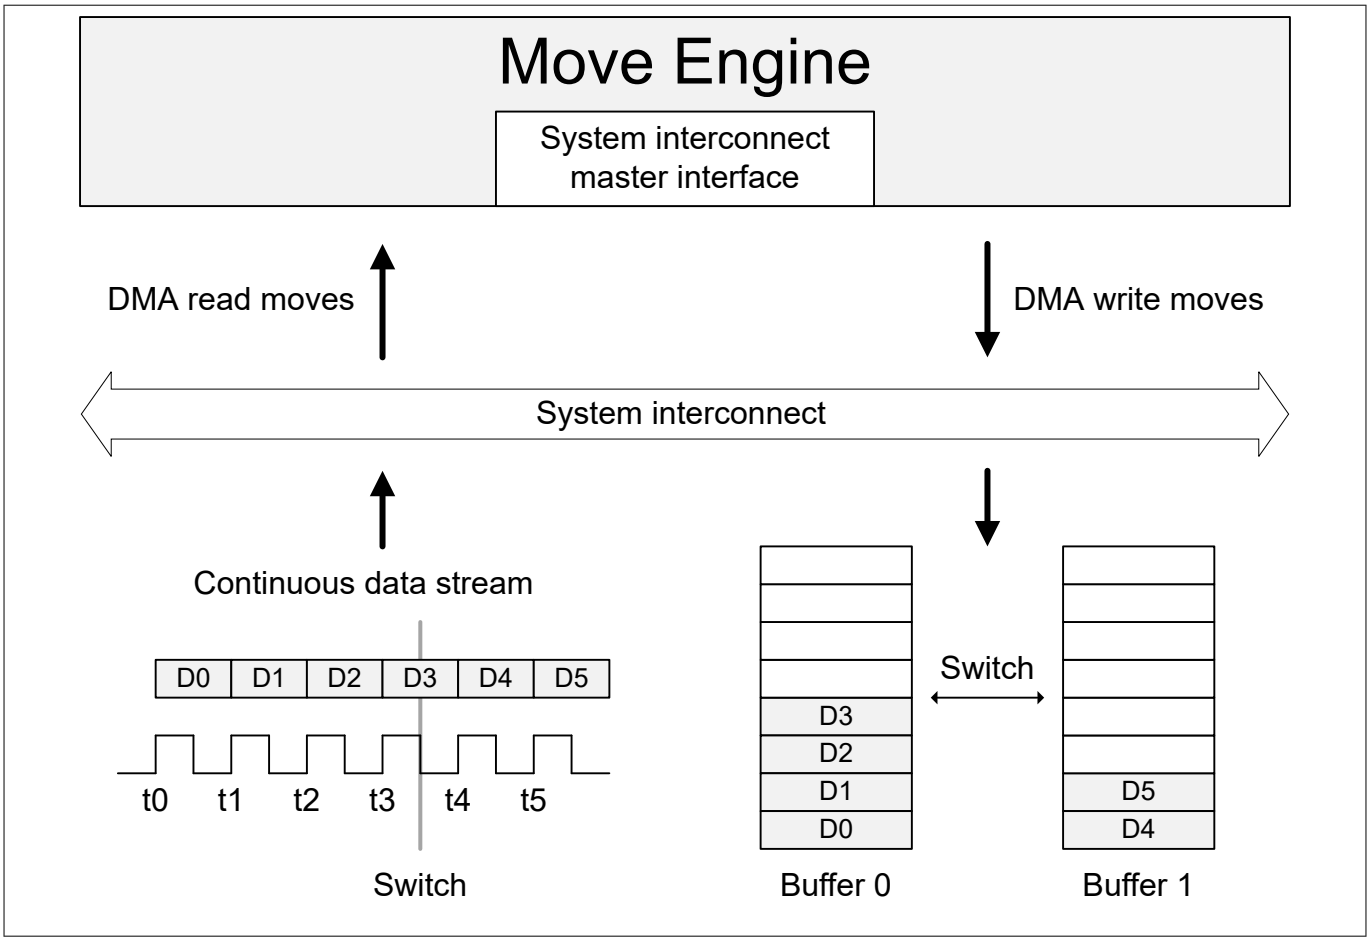

Figure 97 DMA double buffering

If a DMA channel is configured for one of the Double buffering operations and is triggered by DMA hardware request, software should configure the DMA channel for continuous mode (DMA channel CHCFGRc.CHMODE = 1_B).

Related information

DMA hardware request on page 1257

9.3.2.4.1 DMA double source buffering

Data is streamed by the DMA from one of two data buffers (buffer 0 and buffer 1) stored in memory to a continuous output data stream. The double source buffering addresses are:

- The source address SADRc addresses source buffer 0
- The shadow address SHADRc addresses source buffer 1

9.3.2.4.2 DMA double destination buffering

A continuous input data stream is directed by the DMA to one of two data buffers (buffer 0 and buffer 1) stored in memory. The double destination buffering addresses are:

- The destination address DADRc addresses destination buffer 0
- The shadow address SHADRc addresses destination buffer 1

9.3.2.4.3 Size of buffer

The data size of the two source and destination buffers is equal and determined by the following TCS parameters:

- The channel data width (CHCFGRc.CHDW)
- The block mode value (CHCFGRc.BLKM)
- The transfer reload value (CHCFGRc.TREL)

The memory size of the two source and destination buffers is determined by the additional TCS parameters:

- The source circular buffer enable or disable control (ADICRc.SCBE)
- The destination circular buffer enable or disable control (ADICRc.DCBE)
- The source address modification factor (ADICRc.SMF)
- The destination address modification factor (ADICRc.DMF)
- The increment of the source address (ADICRc.INCS)
- The increment of the destination address (ADICRc.INCD)

The size of one buffer is equal to the size of one DMA transaction.

9.3.2.4.4 Buffer switch

The re-direction of the data stream from one buffer to the other buffer is controlled by a software switch and additionally an automatic hardware switch. During a buffer switch:

- No DMA requests are lost by the DMA
- There is no loss, duplication or split of data across the two buffers

Active buffer status

During DMA double buffering the DMA channel CHCSRc.BUFFER bit is used to indicate which buffer is active.

- DMA channel CHCSRc.BUFFER = 0_B: Buffer 0 is read or filled by the DMA
- DMA channel CHCSRc.BUFFER = 1_B: Buffer 1 is read or filled by the DMA

Frozen buffer status

When the DMA switches buffers the DMA channel frozen bit is set (CHCSRc.FROZEN= 1_B). The frozen buffer is then available for a cyclic software task. On completion of the software task the status bit CHCSRc.FROZEN is cleared by software and the buffer address pointer is re-programmed to the start address ready for the next DMA transaction that reads or fills the buffer.

Active buffer empty or full

If the active buffer is emptied (in the case of DMA double source buffering) or filled (in the case of DMA double destination buffering) and no automatic hardware switch occurs before a software buffer switch is received then the DMA channel will stop and no more DMA transfers are made. When the DMA channel stops, the transfer count (CHCSRc.TCOUNT) is equal to 0000_H.

A buffer empty or full event may be signaled by a DMA channel interrupt service request. The DMA channel interrupt control ADICRc.INTCT should be configured to 10_B and the interrupt raise detect value ADICRc.IRDV to 0000_B. When the transfer count equals zero then the DMA channel will raise a DMA channel interrupt service request.

The DMA channel interrupt handler can interrogate the DMA to identify which DMA channel generated the interrupt service request. Software may initialize the DMA channel ready to restart double buffering operations.

Active buffer overflow

If the data rate is faster than the DMA is able to transfer the data to one of the buffers then the DMA reports a double buffer TRL error (DMA channel TSRc.TRL = 1_B and RP ERRSRr.DBTRLER = 1_B). If the DMA channel enable TRL bit is set (TSRc.ETRL = 1_B), the DMA triggers a DMA RP error interrupt service request

Related information

Software switch on page 1236
Automatic hardware switch on page 1236
DMA channel interrupt service request on page 1267
DMA RP error interrupt service request on page 1275

9.3.2.4.5 Software switch

Before a DMA transaction completes and the active buffer is full software shall re-direct the data stream from the active buffer to the other buffer by setting the DMA channel CHCSRc.SWB. If a ME is actively servicing a DMA channel configured for double buffering then the current DMA transfer completes before the buffer switch is made. On completion of the DMA transfer the DMA will:

- Automatically re-load DMA channel CHCSRc.TCOUNT with CHCFGRc.TREL
- Switch the address pointer:
  - Buffer 0 address pointer (source address or destination address)
  - Buffer 1 address pointer (shadow address)

The TCS address control factors remain the same. The next DMA transaction controlling the filling or reading of the new buffer will start when a DMA request is received.

If software re-directs the data stream by setting DMA channel CHCSRc.SWB = 1_B, software shall poll DMA channel CHCSRc.FROZEN AND DMA channel CHCSRc.BUFFER. If software reads DMA channel CHCSRc.FROZEN = 1_B and an active buffer transition, software may start to analyze the frozen buffer.

If a DMA channel is configured for software switch only and the DMA transaction is completed before the DMA receives a software switch, the DMA reports a Double Buffer TRL error (DMA channel TSRc.TRL = 1_B and RP ERRSR.DBTRLER = 1_B). If the DMA channel enable TRL bit is set (TSRc.ETRL = 1_B), the DMA triggers a DMA RP error interrupt service request.

Related information

DMA RP error interrupt service request on page 1275

9.3.2.4.6 Automatic hardware switch

The DMA will automatically switch from the active buffer to the other buffer when the DMA transaction reading or filling the active buffer completes. On switching buffers the DMA channel CHCSRc.FROZEN bit is set to indicate that one buffer is frozen and available for cyclic software tasks. The completion of a DMA transaction may be signaled by a DMA channel interrupt service request. On completion of the DMA transaction when MEmCHSR.TCOUNT equals 0000_H the DMA will:

- Automatically re-load DMA channel CHCSRc.TCOUNT with CHCFGRc.TREL
- Switch the address pointer to select the other buffer:
  - Buffer 0 address pointer (source address or destination address)
  - Buffer 1 address pointer (shadow address)

The DMA channel TCS address control factors remain the same. The next DMA transaction controlling the writing or reading of the new buffer will start when a DMA request is received.

If DMA channel CHCSRc.FROZEN is equal to 1_B, the automatic hardware switch will not occur and the DMA will report a double buffer TRL error (DMA channel TSRc.TRL = 1_B and RP ERRSRr.DBTRLER = 1_B). If the DMA channel enable TRL bit is set (TSRc.ETRL = 1_B), the DMA triggers a DMA RP error interrupt service request.

Related information

DMA channel interrupt service request on page 1267
DMA RP error interrupt service request on page 1275

9.3.2.4.7 Application of double buffering

A typical DMA double buffer application is shown in the following figure:

- DMA channel m is configured for DMA double destination buffering. The DMA channel moves the input data generated by a sensor into the active destination buffer
- A cyclic software task processes the input data stored in the frozen destination buffer and writes the output into the frozen source buffer. The CPU controls both the source and destination buffer switching
- DMA channel n is configured for DMA double source buffering. The DMA channel moves the processed data from the frozen source buffer to the actuator

The system configuration shall balance the input data rate, the duration of cyclic software tasks and the buffer size in order to prevent TRL events. In particular, enabling wait for write completion using the TSRc.WWC bit can delay the completion of the DMA transfers or transactions and this delay should be considered while determining the maximum data rate.

9.3.2.5 Linked list operations

Linked list operations are an extension of DMA channel functionality to support the more flexible use of the DMA.

A linked list operation consists of a series of DMA transactions executed by the same DMA channel. Each DMA transaction has a unique TCS. The source and destination areas do not have to exist in contiguous areas of memory.

If a DMA channel is configured for linked list operation then as soon as the ME completes the current DMA transaction, the ME reads the next TCS from memory and overwrite the current TCS at the DMA channel location in DMARAM. The current DMA transaction uses a 32-byte aligned address pointer to point to the next TCS stored in either internal or external memory. The DMA starts reading the next TCS from word 0 upwards. There is no limit to the number of DMA transactions in a linked list operation. The first DMA transaction in a linked list operation has to be initiated by a DMA hardware request or a DMA software request. Subsequent DMA transactions may be initiated by a DMA auto start request.

Each DMA channel supports the following types of linked list operation:

- DMA Linked List (DMALL)
- Accumulated Linked List (ACCLL)
- Checked Linked List (CHKLL)
- Conditional Linked List (CONLL)

Related information

DMA auto start request on page 1261

Accumulated linked list (ACCLL) on page 1243

DMA linked list (DMALL) on page 1241

Checked linked list (CHKLL) on page 1243

Conditional linked list (CONLL) on page 1246

9.3.2.5.1 Last DMA transaction

A DMA linked list chain of operations may be terminated in one of the following two ways.

- With a non-linked list TCS: If the last TCS is not configured for linked list operation, the last TCS should be configured for a move operation instead by setting ADICRc.SHCT = 0_H. In this case, the DMA channel exits linked list operation. The last TCS will be loaded into the DMA channel, but a DMA auto start request will not initiate the transaction
- With a linked list TCS: If the last TCS is configured for a linked list operation but has the DMA auto start request bit (CHCSRc.SCH) bit clear, the last TCS is loaded into the DMA channel but is not triggered

A DMA channel interrupt service request may be used to signal the completion of the last DMA transaction in a sequence of linked list operations.

Related information

Move operation on page 1211

DMA auto start request on page 1261

DMA channel interrupt service request on page 1267

9.3.2.5.2 Circular linked list operations

A sequence of linked list operations may be configured for circular operation. The same series of DMA transactions is repeated.

9.3.2.5.3 DMA linked list (DMALL)

The DMA channel shadow address register (SHADRc) stores the 32-bit address pointer to the next TCS. As soon as the current DMA transaction completes, the ME reads the next TCS and stores it in DMARAM.

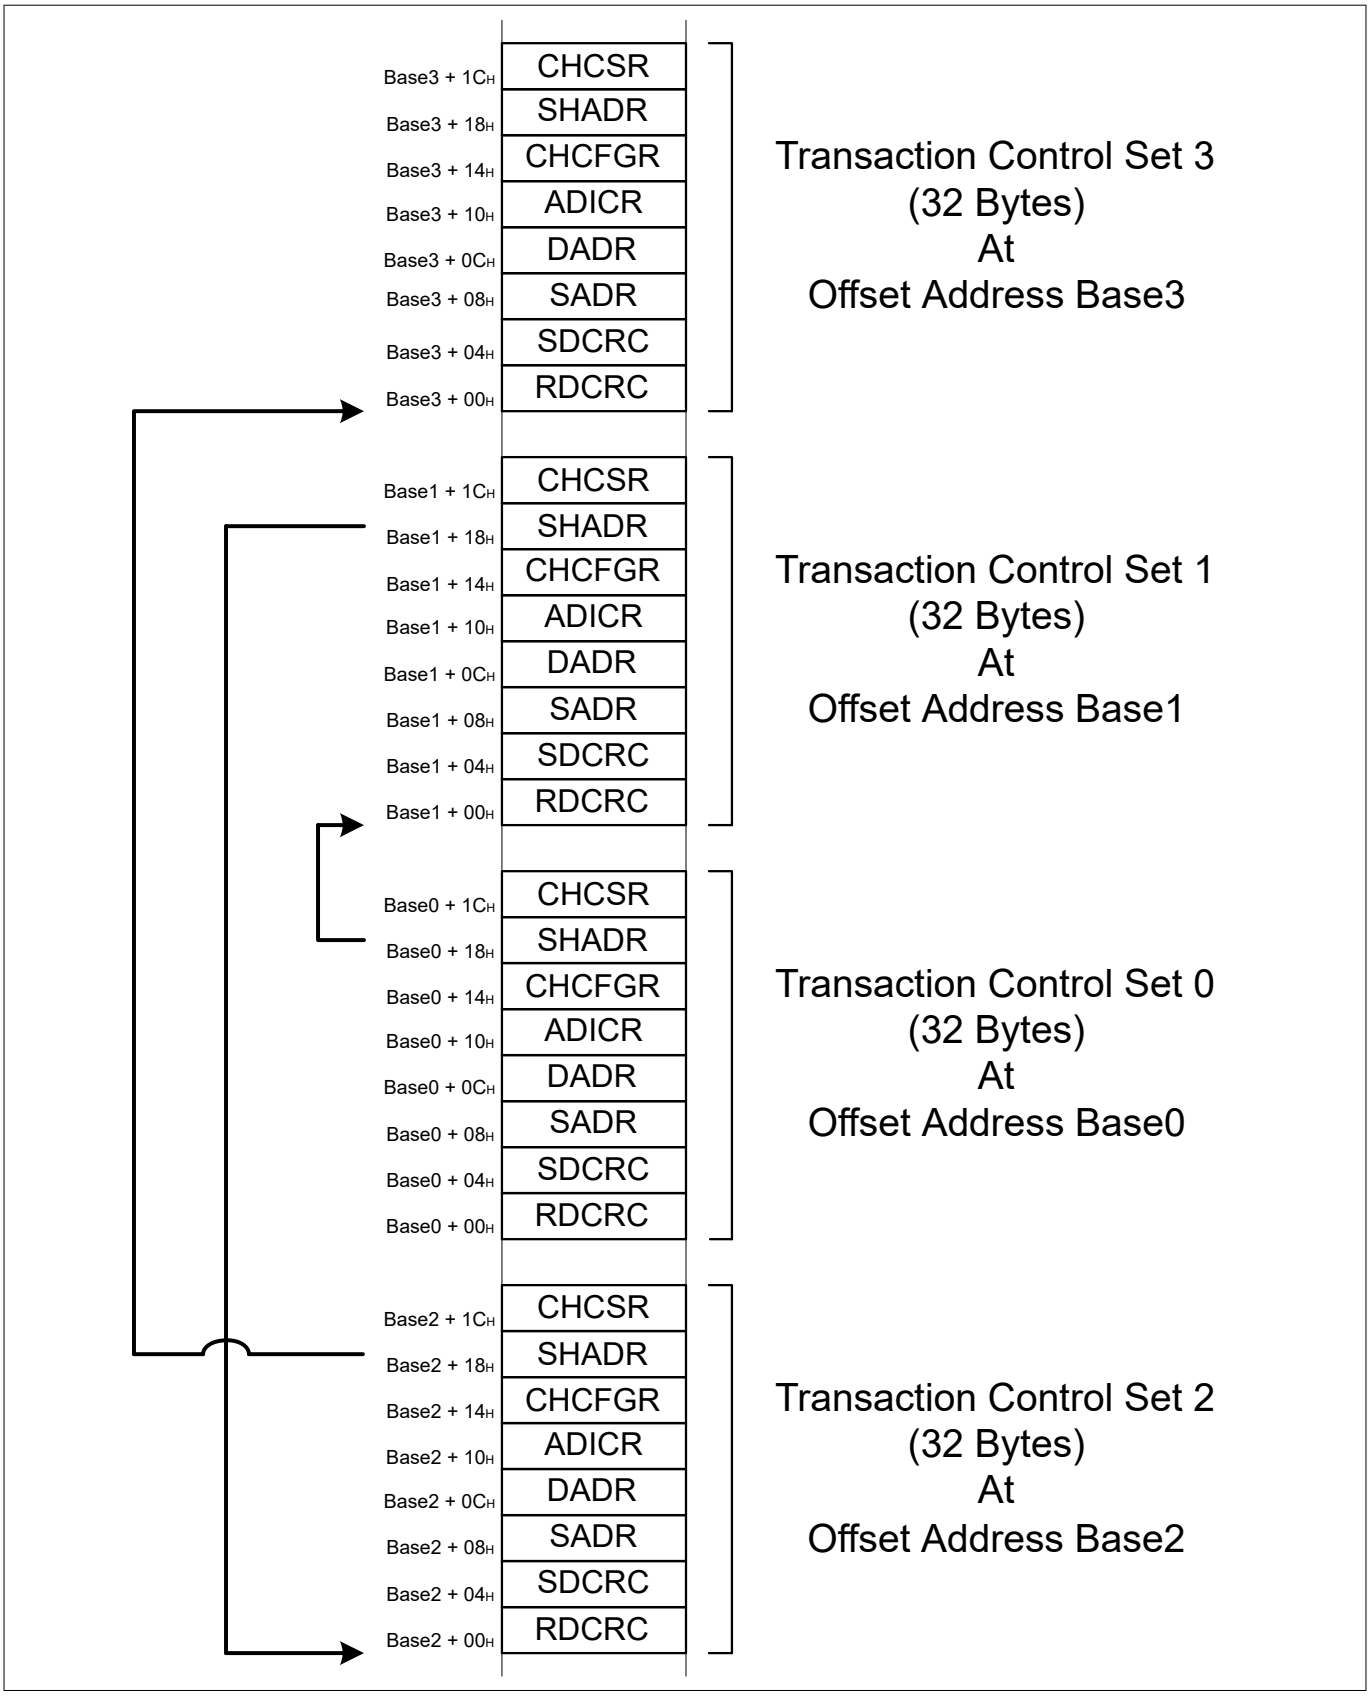

Figure 101 DMA linked list

DMA address checksum and DMA data checksum

Software shall configure the initial value of DMA address checksum and DMA data checksum used during the first DMA transaction. When the ME reads the next TCS, the DMA address checksum and DMA data checksum is initialized to 00000000_H.

Related information

DMA address checksum on page 1222
DMA data checksum on page 1223

9.3.2.5.4 Accumulated linked list (ACCLL)

ACCLL is a variant of DMALL and has an identical footprint in memory (size and structure). The SDCRC and RDCRC checksums are accumulated across DMA transactions.

DMA address checksum and DMA data checksum

The DMA address checksum and DMA data checksum are not overwritten when the next TCS is loaded into the DMA channel. As long as the DMA channel is configured for ACCLL, the DMA address checksum and DMA data checksum are calculated across all DMA transactions.

Related information

DMA address checksum on page 1222
DMA data checksum on page 1223

9.3.2.5.5 Checked linked list (CHKLL)

CHKLL provides protection against software errors. If the address pointer in a sequence of linked list operations is incorrectly written then the address pointer may point to any random area of memory and load the next TCS from the wrong location and execute it. As long as a DMA channel is configured for CHKLL, the ME checks that the calculated DMA address checksum matches an expected DMA address checksum stored in the next TCS.

Attention**: **Checked Linked List support is considered deprecated functionality in the AURIX™ TC4xx family. This functionality may be removed in a future AURIX™ generation.

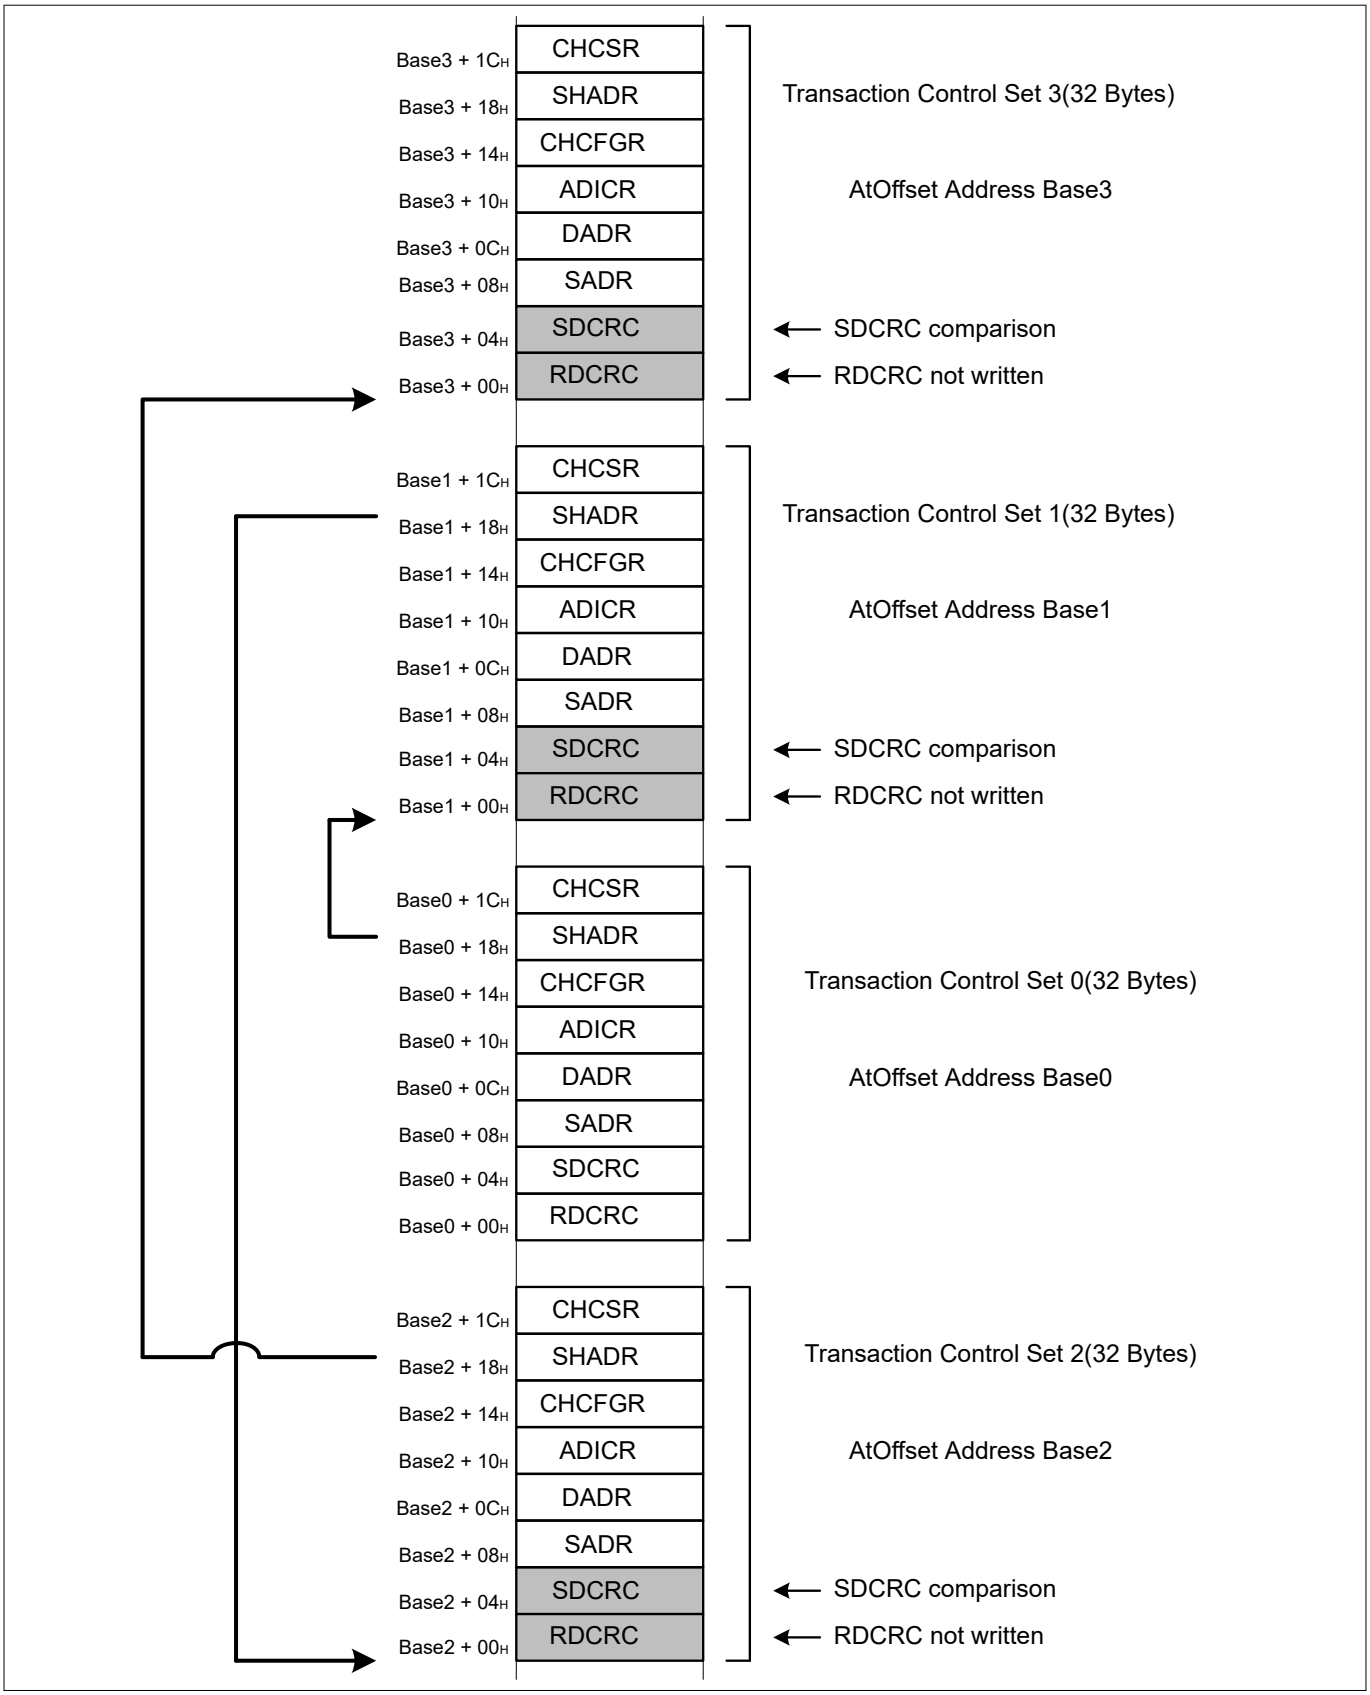

Figure 102 Checked linked list

DMA address checksum

The user is required to load the SDCRC word with an expected DMA address checksum value. As soon as the ME has read the next TCS from memory, the ME compares the DMA address checksum calculated by the current DMA transaction against the expected DMA address checksum stored in the next TCS. If the checksums match then the DMA proceeds with the execution of the next TCS. If the checksums do not match then the ME records a CHKLL DMA address checksum error and triggers a DMA RP error interrupt service request. The DMA stops the execution of the linked list operation. Assuming all the DMA address checksum values match during the sequence of linked list operations then the DMA address checksum is calculated across all DMA transactions.

DMA data checksum

The DMA data checksum is not overwritten when the new TCS is loaded into the DMA channel. The DMA data checksum is calculated across all DMA transactions.

Related information

DMA address checksum on page 1222
DMA RP error interrupt service request on page 1275
DMA data checksum on page 1223

9.3.2.5.6 Conditional linked list (CONLL)

A special use of a linked list is CONLL. Selection of the address pointer to the next TCS is determined by a conditional state. CONLL uses the shadow address (SHADRc) and the source and destination address CRC registers (SDCRCRc) as address pointers.

A CONLL operation is limited to 8-bit DMA moves (CHCFGRc.CHDW = 000_B). The source address shall not be configured to a cached address (segments 8 and 9). A non-cached address (segments A and B) shall be configured to prevent the ME read buffer re-aligning the move data.

CONLL pattern detection

The DMA channel in the figure below is configured for CONLL. In this example, the TCS is configured to select PRRAr for a pattern compare.

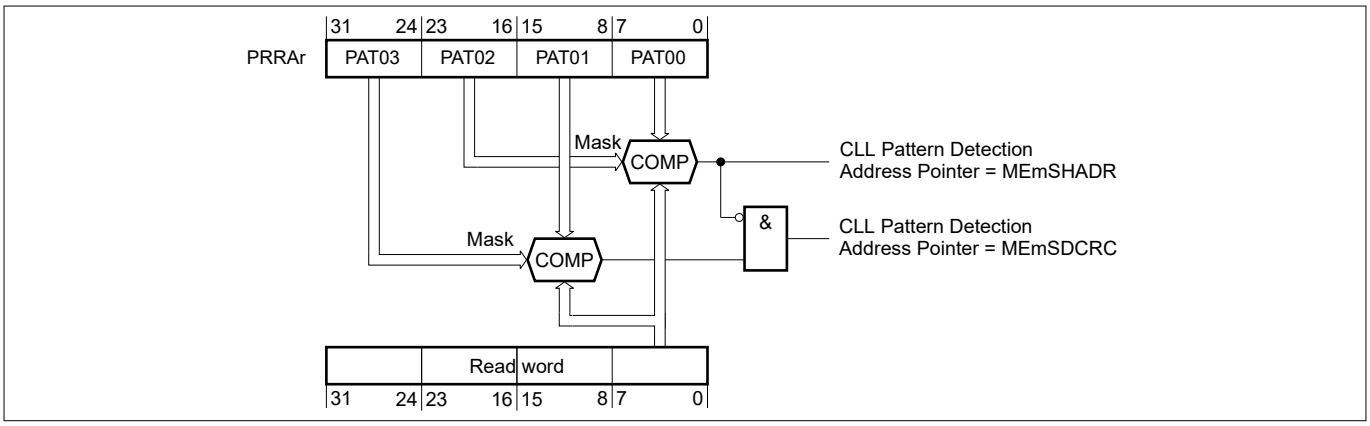

Figure 103 Conditional linked list and pattern compare logic

During each DMA move the pattern detection logic determines the selection of the address pointer:

- If PAT00 masked by PAT02 matches the lowest byte of the DMA read move data then as soon as the DMA move completes the ME loads the DMA channel with the next TCS read from an address stored in SHADRc
- If PAT01 masked by PAT03 matches the lowest byte of the DMA read move data then as soon as the DMA move completes the ME loads the DMA channel with the next TCS read from an address stored in SDCRCRc
- If both PAT00 masked by PAT02 and PAT01 masked by PAT03 match the lowest byte of the DMA read move data then as soon as the DMA move completes, the ME loads the DMA channel with the next TCS read from an address stored in SHADRc
- If there is no pattern match then the ME continues with the DMA transaction

If a pattern match is detected:

- The DMA transaction ends with the current DMA move
- The DMA channel TSRc.CH will be cleared when the DMA write move has completed

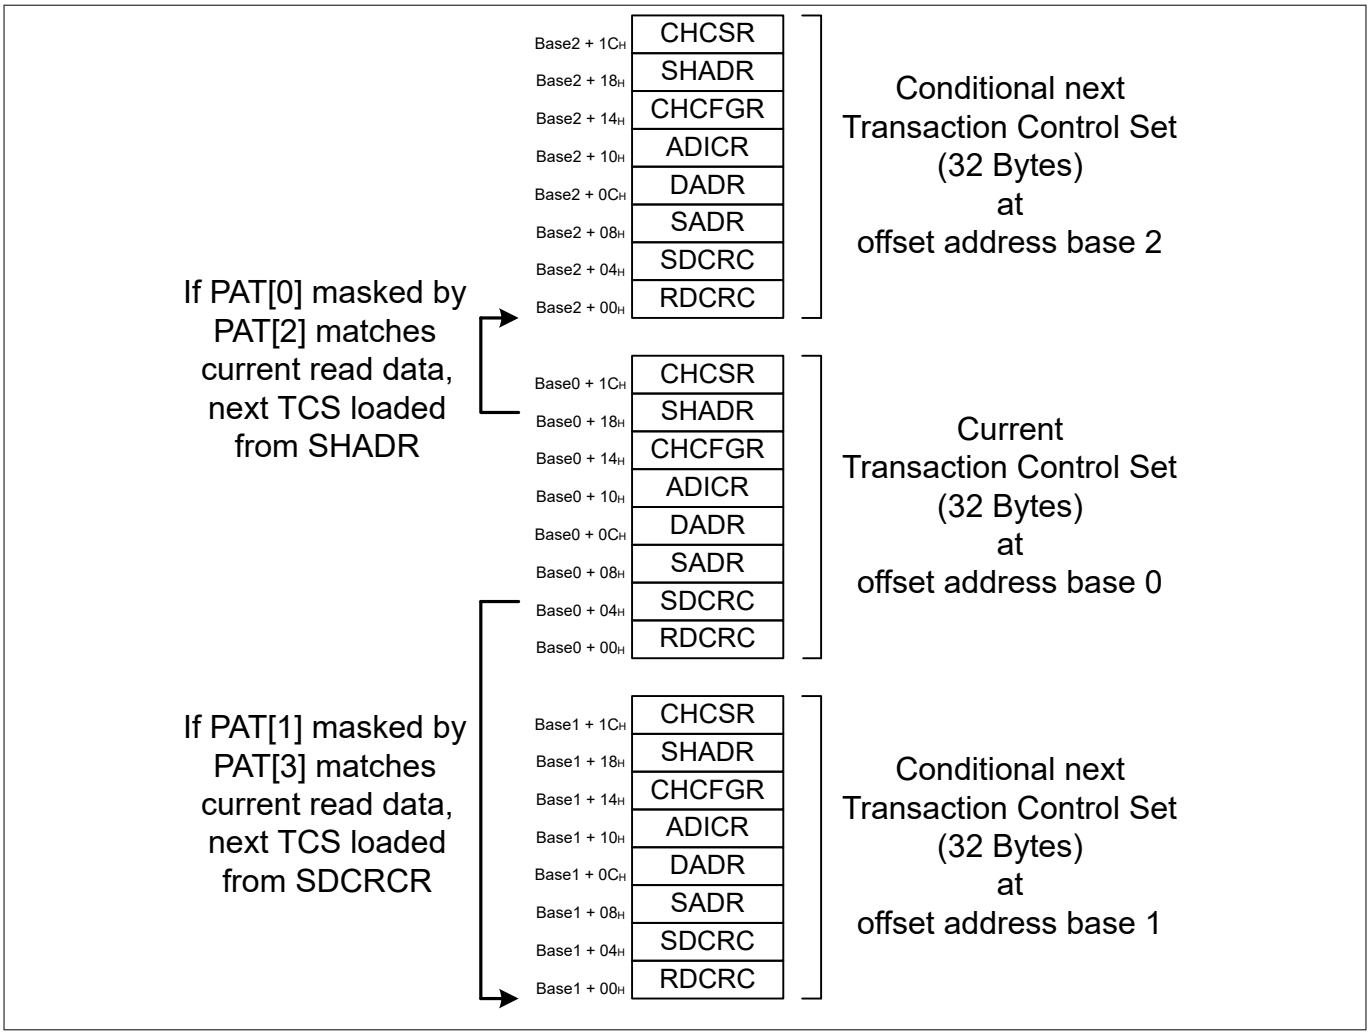

Figure 104 Conditional linked list operation

Completion of current DMA transaction

If the current DMA transaction completes when MEmCHSR.TCOUNT = 0_D and there is no pattern match then the CONLL will load the DMA channel with the next TCS read from an address stored in SHADRc.

Multiple pattern detection conditions

The user may intentionally program PAT00 masked by PAT02 shall not match with the lowest byte of the DMA read move data and transition across a series of DMA transactions in the CONLL. For each DMA transaction the user may program a series of different PAT01 masked by PAT03 values and test if each value matches with the current lowest byte of the DMA read move data. If PAT01 masked by PAT03 matches the current lowest byte of the DMA read move data, then as soon as the DMA move is completed, the ME loads the DMA channel with the next TCS read from an address stored in SDCRCRc.

Related information

ME read buffer on page 1280

9.3.2.6 DMA timestamp

As soon as the last DMA transfer of a DMA transaction has completed, a 32-bit DMA timestamp may be appended to record the occurrence of a DMA operation.

The DMA timestamp is the time at which the event was recorded by the DMA and not the real time. The DMA transaction completes after the DMA timestamp is written.

9.3.2.6.1 Generation of DMA timestamp

The DMA timestamp is generated from a 32-bit binary upwards synchronous counter clocked by the global system timer clock (f_{STM}). The counter is reset by system reset and counts as long as the f_{STM} clock is running and has not been suspended through the OCDS suspend input and the DMA TIMEOCS register. The current 32-bit timestamp value may be read or updated through the DMA TIME register.

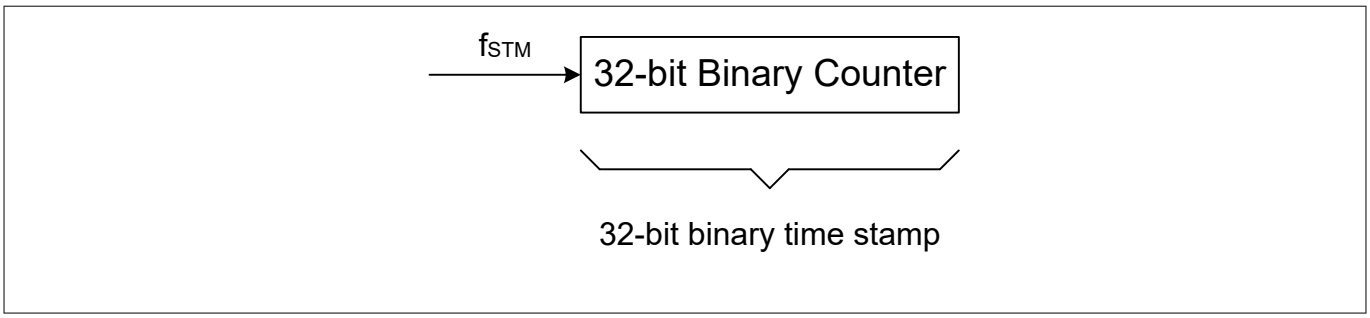

Figure 105 Generation of DMA timestamp

9.3.2.6.2 Appendage of DMA timestamp to non-destination circular buffer

The appendage of a DMA timestamp to the destination data is controlled by the DMA channel ADICRc.STAMP bit.

If a DMA channel is configured for the appendage of a DMA timestamp and not destination circular buffer operation (ADICRc.DCBE = 0_B), the ME writes a DMA timestamp at a destination address defined by:

- If ADICRc.INCD = 1_B, the address of the DMA timestamp is the next higher word aligned destination address
- If ADICRc.INCD = 0_B, the address of the DMA timestamp is the next lower word aligned destination address

Appendage of DMA timestamp - example 1

16-bit half-words are moved from a source memory with an incrementing source address offset of 10_H to a destination memory with an incrementing destination address offset of 08_H.

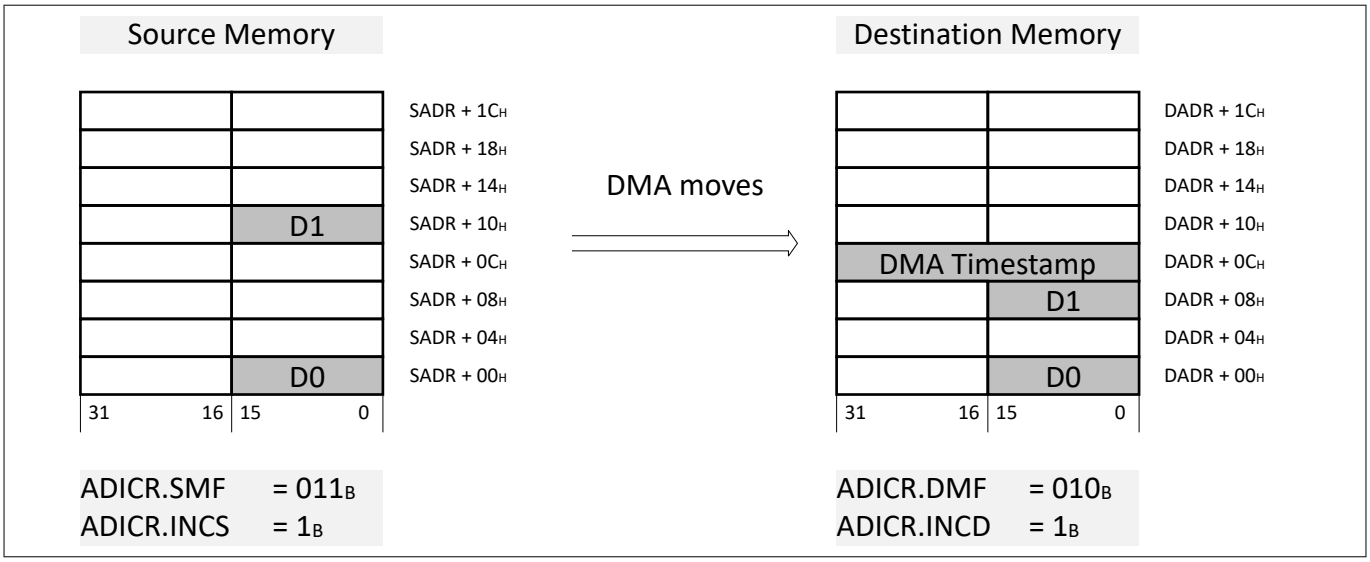

Figure 106 Incrementing destination address: DMA timestamp appended above DMA write move data

Appendage of DMA timestamp - example 2

16-bit half-words are moved from a source memory with an incrementing source address offset of 02_H to a destination memory with a decrementing destination address offset of 04_H.

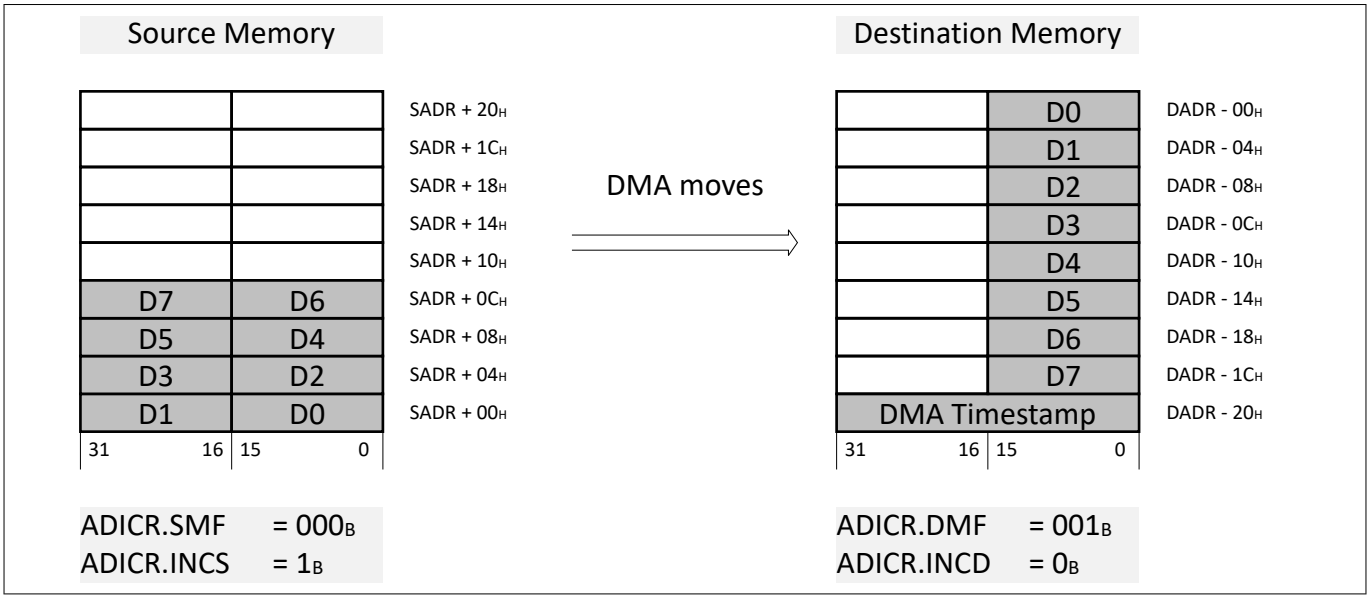

Figure 107 Decrementing destination address: DMA timestamp appended below DMA write move data

Destination address generation

The destination address of the next DMA write move of the next DMA transaction is calculated using:

- The destination address of the last DMA write move of the current DMA transaction
- The destination address offset defined by ADICRc.INCD, ADICRc.DMF and CHCFGRc.CHDW

The ME checks the destination address of the next DMA write move.

If the currently calculated destination address of the next DMA write move results in DMA write move data overwriting the DMA timestamp of the current DMA transaction, the ME calculates a new destination address:

- If DMA channel ADICRc.INCD = 1_B, the ME selects the greater value of the following:
  - Add (2_D x destination address offset) to the destination address of last DMA write move
  - Add 8_D to the destination address of last DMA write move of the current DMA transaction
- If DMA channel ADICRc.INCD = 0_B, the ME selects the lesser value of the following:
  - Subtract (2_D x destination address offset) from the destination address of last DMA write move
  - Subtract 8_D from the destination address of last DMA write move of the current DMA transaction

The ME writes back the DMA channel TCS including the updated destination address to the DMARAM.

9.3.2.6.3 Appendage of DMA timestamp to destination circular buffer

If a DMA channel is configured for the appendage of a DMA timestamp and destination circular buffer operation (ADICRc.DCBE = 1_B), the ME writes a DMA timestamp at a destination address defined by:

- If ADICRc.INCD = 1_B AND ADICRc.CBLD = 1 or 0, the address of the DMA timestamp = (DADRc[31:2] + 1) << 2
- If ADICRc.INCD = 1_B AND ADICRc.CBLD > 1, the address of the DMA timestamp = (DADRc[31:CBLD] + 1) << CBLD
- If ADICRc.INCD = 0_B AND ADICRc.CBLD = 1 or 0, the address of the DMA timestamp = (DADRc[31:2] << 2) - 4
- If ADICRc.INCD = 0_B AND ADICRc.CBLD > 1, the address of the DMA timestamp = (DADRc[31:CBLD]) << CBLD) - 4

The ME writes back to the DMARAM an incremented and wrapped destination address.

9.3.2.6.4 Application of DMA timestamp

The appendage of a DMA timestamp may be used by software to perform a temporal analysis of DMA transaction completion times. Software may for example analyze relative DMA timestamp values to determine the correct sequencing of DMA transactions.

9.3.3 DMA channels

Each DMA channel stores the context of an independent DMA operation.

9.3.3.1 Transaction control set

Each DMA channel provides eight 32-bit control registers, together called the DMA channel transaction control set (TCS) that define the DMA channel operation. Software may configure the DMA channel TCS to define the move function of each DMA channel.

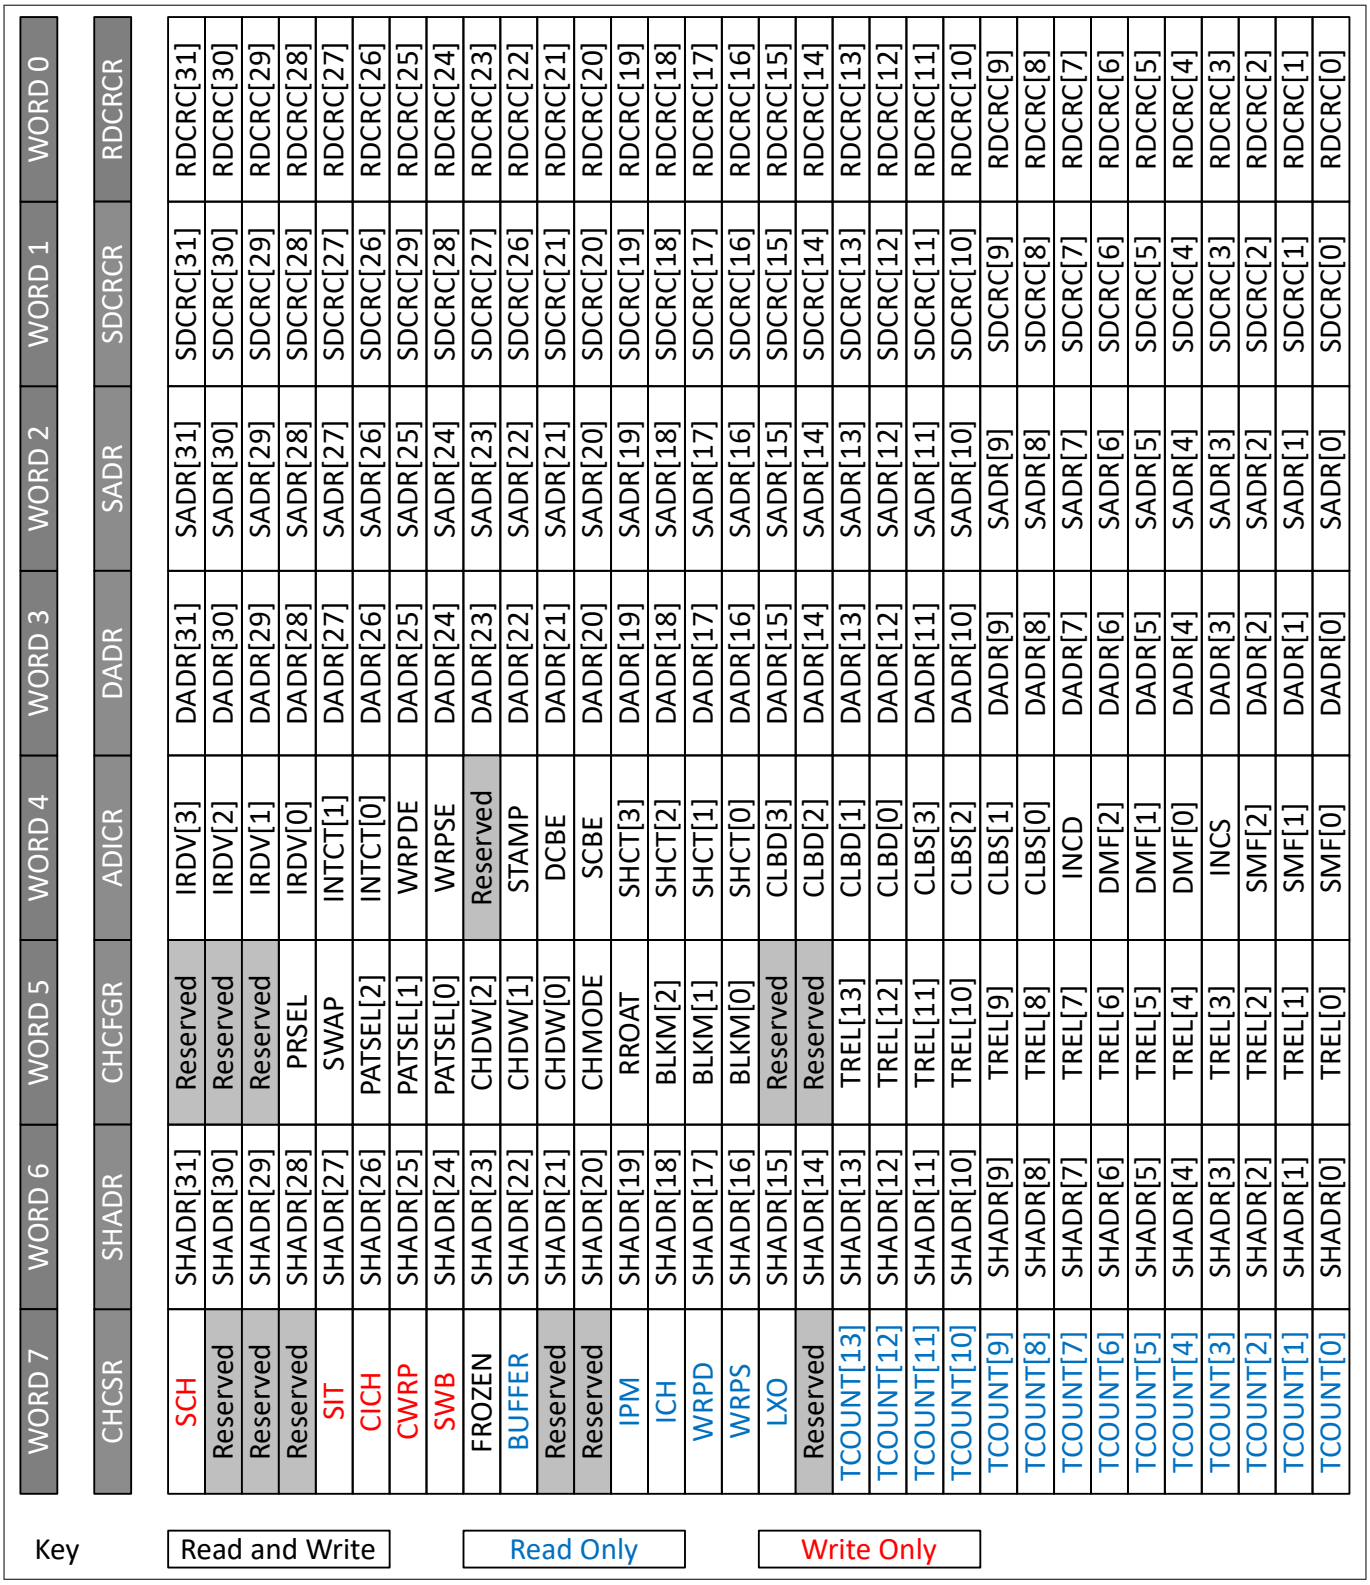

Figure 108 DMA channel TCS organization

9.3.3.1.1 DMA channel operation

The following table lists the supported types of DMA channel operation and system interconnect access sizes that can be configured in the DMA channel TCS.

9.3.3.1.2 TCS initialization

On the assertion of an application reset, the DMA initializes the TCS configuration data of all channels to all zeros to prevent the triggering of DMARAM data integrity errors in the application.

9.3.3.2 DMA channel request control

DMA channel request control logic as shown in the following figure is implemented for each DMA channel.

The DMA channel operation is individually programmable. The following types of DMA requests are possible:

- DMA software request initiated by a CPU
- DMA hardware request initiated by the Interrupt Router (IR) Interrupt Control Unit (ICU)
- DMA daisy chain request initiated by the next higher priority DMA channel
- DMA auto start request initiated by the loading of the next TCS during a DMA Linked List (DMALL), Accumulated Linked List (ACCLL), Checked Linked List (CHKLL), or Conditional Linked List (CONLL) operation

The DMA channel status flag TSRc.CH indicates if a DMA request is pending. TSRc.CH may be cleared at the start of a DMA transfer or at the end of a DMA transaction depending on the value of CHCFGRc.RROAT. It follows that a DMA request may trigger a single DMA transfer or one complete DMA transaction.

9.3.3.2.1 Reset request only after transaction (RROAT)

The clearing of the DMA channel TSRc.CH bit is controlled as follows:

- CHCFGRc.RROAT = 0_B
  - DMA channel TSRc.CH is cleared at the start of each DMA transfer
  - One DMA request starts one single DMA transfer
- CHCFGRc.RROAT = 1_B
  - DMA channel TSRc.CH is cleared at the end of each DMA transaction
  - One DMA request starts one complete DMA transaction

9.3.3.2.2 DMA software request

One DMA software request may start one complete DMA transaction or one single DMA transfer.

Software may configure the DMA channel to be triggered only by software by disabling DMA hardware requests. Software must set TSRc.DCH to 1_B to disable a DMA hardware request (TSRc.HTRE = 0_B).

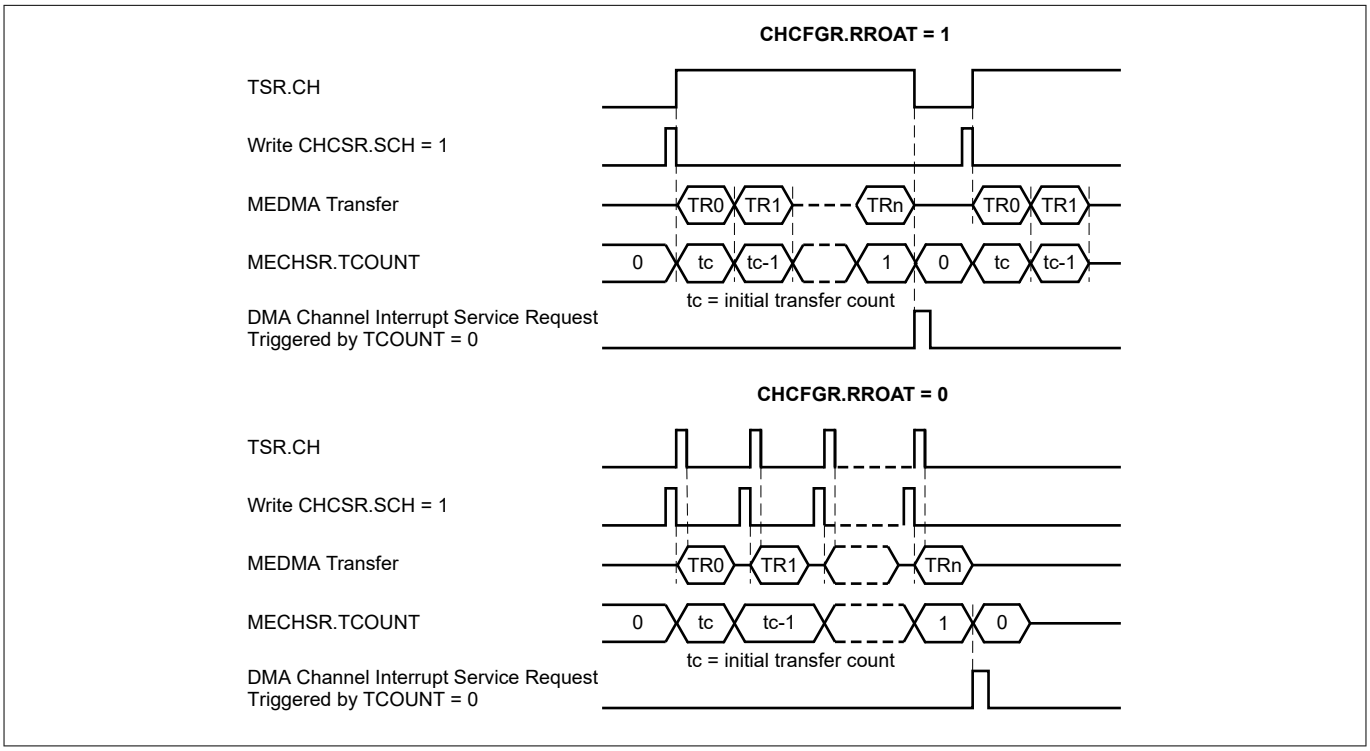

Figure 110 Software control

The following DMA channel configuration is required to initiate one complete DMA transaction under software control:

- DMA channel CHCFGRc.RROAT = 1_B

A DMA software request is initiated by setting the DMA channel CHCSRc.SCH to 1_B with the result that TSRc.CH is set to 1_B. At the start of the DMA transaction, the value of the DMA channel reload value CHCFGRc.TREL is loaded into MEmCHSR.TCOUNT and DMA transfers are executed. After each DMA transfer, MEmCHSR.TCOUNT is decremented and the next source and destination addresses are calculated. When TCOUNT decrements to 0_D, the DMA channel status flag TSRc.CH is reset. Setting the DMA channel CHCSRc.SCH = 1_B again starts a new DMA transaction of the DMA channel with the stored TCS parameters.

The following DMA channel configuration is required to initiate each single DMA transfer under software control:

- DMA channel CHCFGRc.RROAT = 0_B

A DMA software request must be initiated for each DMA transfer by setting the DMA channel CHCSRc.SCH to 1_B.

Related information

DMA hardware request on page 1257
DMA software request on page 1256

9.3.3.2.3 DMA hardware request

Interrupt Requests are prioritized by the Interrupt Router and processed by one of the Service Providers (CPU, DMA or other modules). The DMA interfaces to an interrupt control unit (ICU) instantiated in the interrupt router (IR). Interrupts processed by the DMA ICU interface are treated as DMA hardware requests.

DMA channels are associated with the Service Request Priority Number (SRPN) bit-field programmed in the IR service request control (SRC) register. For example:

- DMA channel 000 equates to SRPN = 0_D programmed in IR
- DMA channel 001 equates to SRPN = 1_D programmed in IR
- DMA channel 002 equates to SPRN = 2_D programmed in IR
- DMA channel 003 equates to SRPN = 3_D programmed in IR
- DMA channel 004 equates to SPRN = 4_D programmed in IR

The DMA will acknowledge all service requests from the IR. If the value programmed in the SRC.SRPN is for an invalid DMA channel then the DMA will take no action. The user must program valid SRC.SRPN values for the DMA.

The interrupt request from the IR contains a CS bit which indicates whether the corresponding interrupt has been configured as part of the cyber-security (CS) or non-cyber-security (non-CS) groups in the IR. The DMA takes no action for a DMA hardware service request where the CS bit from the IR does not match the MODEr.CS bit from the resource partition the triggered DMA channel belongs to.

A DMA hardware request is enabled or disabled by the DMA channel TSRc.HTRE bit. The HTRE functionality is as follows:

- Software may set (TSRc.ECH = 1_B) or clear (TSRc.DCH = 1_B) DMA channel TSRc.HTRE
- Cleared as a result of the ME reporting an error for the DMA channel
- Single mode: At the start of the last DMA transfer of a DMA transaction

Table 635 Conditions to set or reset DMA channel TSRc.HTRE

DMA channel TSRc.ECH	DMA channel TSRc.DCH	Start of last DMA transfer of a DMA transaction[1)]	Modification of DMA channel TSRc.HTRE
0	0	0	Unchanged
1	0	0	Set
X	1	X	Reset
X	X	1	Reset

1) In single mode only. In continuous mode, the end of a DMA transaction has no impact.

DMA channel mode

The DMA channel mode bit CHCFGRc.CHMODE controls the DMA channel mode as follows:

- Single mode (DMA channel CHCFGRc.CHMODE = 0_B)
  - DMA hardware request is disabled by hardware at the start of the last DMA transfer of a DMA transaction
- Continuous mode (DMA channel CHCFGRc.CHMODE = 1_B)
  - DMA hardware request is not disabled by hardware on completion of a DMA transaction

Single mode

The following DMA channel configuration is required to initiate one complete DMA transaction under hardware control in single mode:

- DMA channel CHCFGRc.CHMODE = 0_B
- DMA channel CHCFGRc.RROAT = 1_B
- DMA channel CHCFGRc.PRSEL = 0_B
- DMA channel TSRc.ECH = 1_B

Setting DMA channel TSRc.ECH to 1_B enables a DMA hardware request (TSRc.HTRE = 1_B) for the DMA channel. When the ICU generates a DMA hardware request, TSRc.CH is set high. If the DMA channel wins channel arbitration then the DMA channel transitions to the active state. The value of CHCFGRc.TREL is loaded into the MEmCHSR.TCOUNT and the DMA transaction is started by executing the first DMA transfer. After each DMA transfer, MEmCHSR.TCOUNT is decremented and the next source and destination addresses are calculated. At the start of the last DMA transfer of a DMA transaction, further DMA hardware requests are disabled and TSRc.HTRE is reset. In order to start a new hardware-controlled DMA transaction, a DMA hardware request must be enabled again by software writing TSRc.ECH = 1_B to set TSRc.HTRE.

The following DMA channel configuration is required to initiate each single DMA transfer under hardware control in single mode:

- DMA channel CHCFGRc.CHMODE = 0_B
- DMA channel CHCFGRc.RROAT = 0_B
- DMA channel CHCFGRc.PRSEL = 0_B
- DMA channel TSRc.ECH = 1_B

In this DMA channel configuration, TSRc.CH is cleared at the start of each DMA transfer and a new DMA hardware request must be generated to start the next DMA transfer.

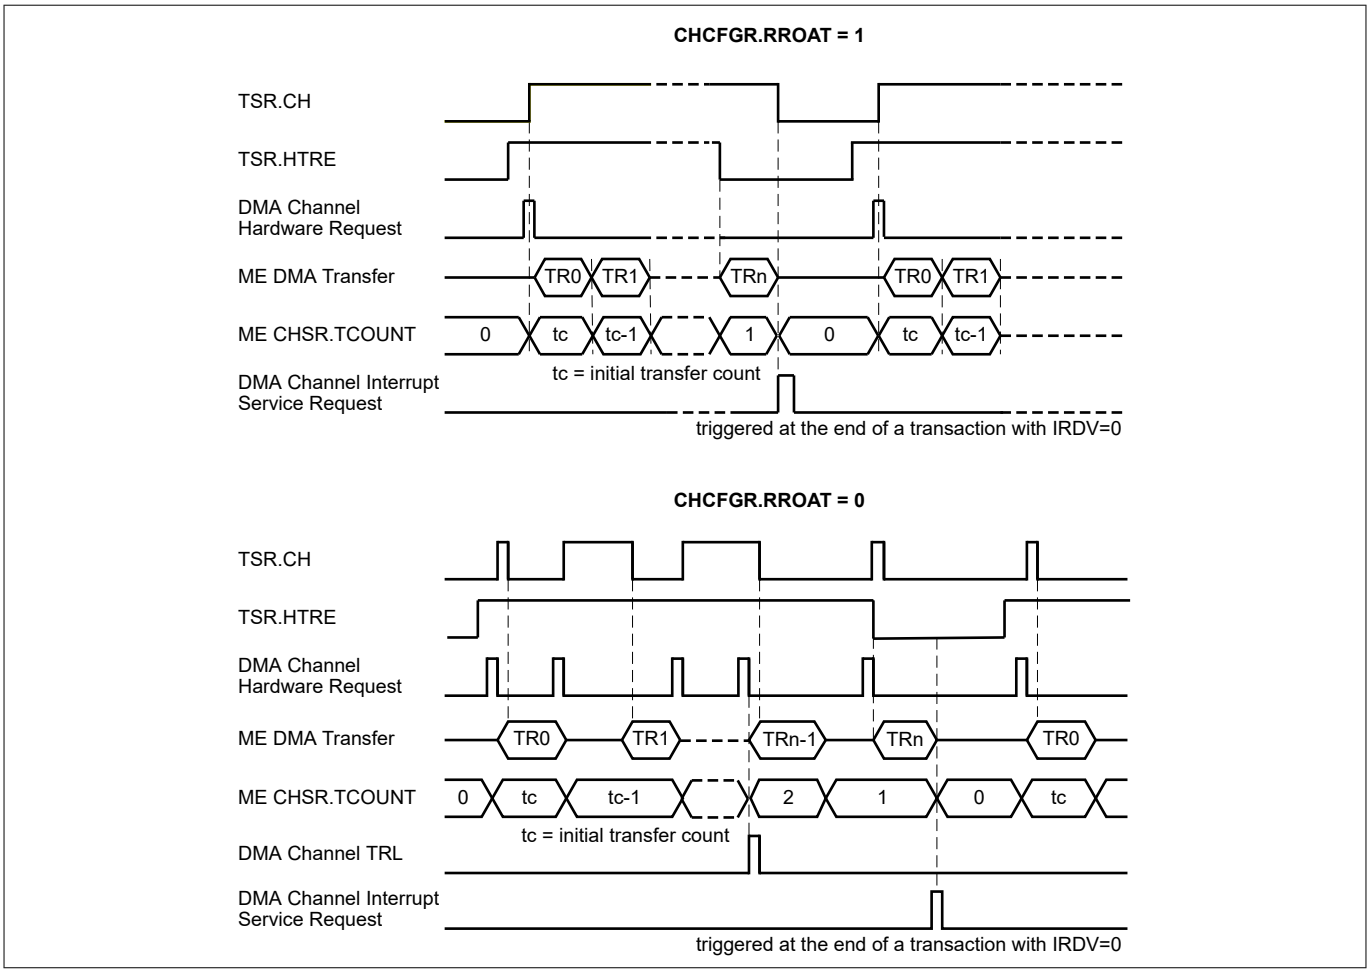

Figure 111 Hardware control in single mode

Continuous mode

If the DMA channel is configured for continuous mode (CHCFGRc.CHMODE = 1_B), then TSRc.HTRE is not reset at the start of the last DMA transfer in a DMA transaction. On completion of the current DMA transaction (MEmCHSR.TCOUNT = 0_D) each new DMA hardware request will start a new DMA transaction with the stored DMA channel TCS.

Related information

DMA hardware request on page 1257

9.3.3.2.4 Combined DMA software request and DMA hardware request

A DMA channel may be operated under combined software and hardware control. The example in the figure below demonstrates combined control:

- The first DMA transfer is triggered by a DMA software request setting the DMA channel CHCSRc.SCH = 1_B
- A DMA hardware request is still disabled (DMA channel TSRc.HTRE = 0_B)
- Software enables a DMA hardware request by setting the DMA channel TSRc.ECH = 1_B
- Each subsequent DMA transfer is triggered by a DMA hardware request from the ICU

In the example, the DMA channel operates in single mode (DMA channel CHCFGRc.CHMODE = 0_B). In single mode, the DMA channel TSRc.HTRE is reset by hardware at the start of the last DMA transfer in the DMA transaction.

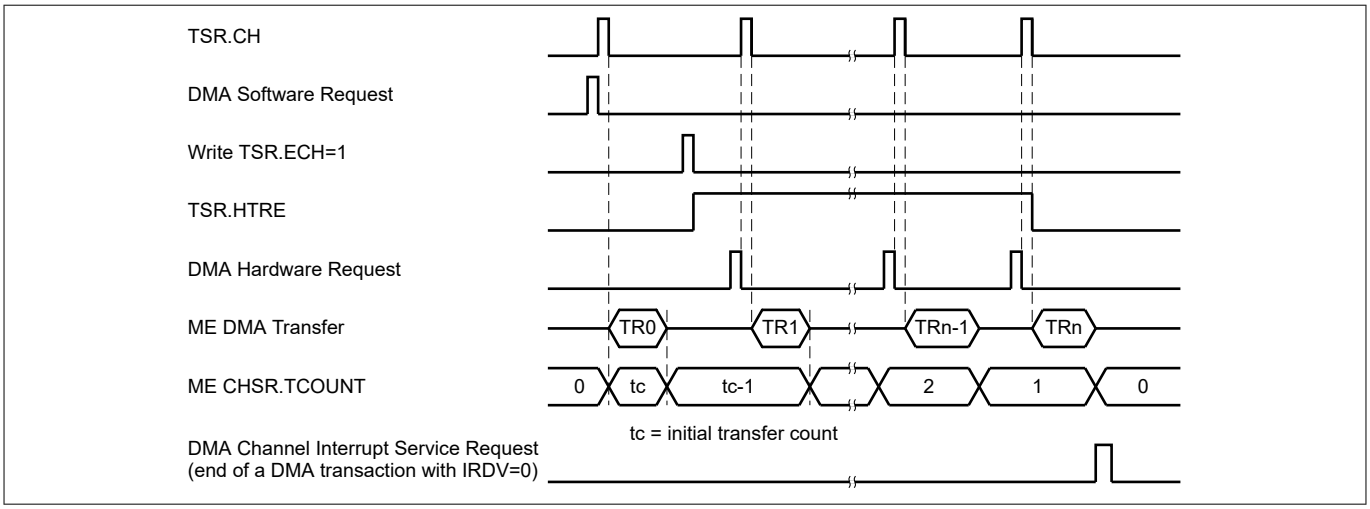

Figure 112 Transaction start by software, continuation by hardware

Transaction request lost (TRL)

When a DMA channel is configured to be triggered by parallel hardware and software requests, if a DMA software request and a DMA hardware request collide in the same clock cycle then a CBTRLER event is flagged.

Related information

DMA hardware request on page 1257
DMA software request on page 1256
DMA channel TRL error interrupt service request on page 1276

9.3.3.2.5 DMA daisy chain request

DMA channels are configured for DMA daisy chain request by setting DMA channel CHCFGRc.PRSEL.

Attention*: *DMA daisy chain requests are considered deprecated functionality in the AURIX™ TC4xx family. This functionality may be removed in a future AURIX™ generation.

When a higher priority DMA channel completes a DMA transaction it will initiate a DMA transaction in the next lower priority DMA channel by setting the channel request pending bit (TSRc.CH). DMA daisy chain request is limited to a higher priority DMA channel initiating a DMA request in the next lower priority DMA channel. The DMA daisy chain request from a higher priority channel will not trigger the next lower priority channel if the lower priority channel is assigned to a different resource partition or no resource partition and will instead set TSRc.TRL in the higher priority channel as well as set ERRSRr.DCTRLER in the RP that the higher priority channel belongs to. If TSR.ETRL is 1_B in the higher priority channel, an RP error interrupt will also be signaled.

Enabling the daisy chain disables the DMA channel interrupt service request trigger in the higher priority DMA channel. In a typical DMA daisy chain application only the lowest priority DMA channel in the daisy chain is required to generate a DMA channel interrupt service request. When the sequence of DMA transactions from the highest to lowest priority DMA channel has completed then the lowest priority DMA channel in the daisy chain can be configured to generate a DMA channel interrupt service request to signal the end of the DMA operation. DMA channel 0 will never trigger a DMA daisy chain request and the PRSEL setting will be ignored.

If DMA channels are configured in a daisy chain, a DMA transfer or DMA transaction in the highest priority DMA channel is initiated by a DMA software request or a DMA hardware request. DMA transactions in the lower priority DMA channels are triggered by a DMA daisy chain request in order to improve DMA latency.

***Note**: Software should ensure that a DMA channel configured to trigger the next lower priority DMA channel through a daisy chain request does not receive a new DMA request before the previous execution of the daisy chain is complete. If such a DMA request is generated, it is possible that the lower priority DMA channels in the daisy chain do not complete their pending DMA requests.*

DMA hardware request on page 1257
DMA software request on page 1256
TC4Dx DMA daisy chain request on page 1335

9.3.3.2.6 DMA auto start request

If a DMA auto start request is selected in the next TCS (CHCSRc.SCH = 1_B) during a linked list operation and the next TCS is configured for linked list operation, the request pending bit TSRc.CH for the DMA channel is set. The DMA then performs a new DMA request arbitration sequence to determine the highest priority DMA request. A DMA auto start request bypasses the Interrupt Router so reducing the cumulative latency over a number of DMA transactions.

Related information

DMA request arbitration on page 1261

9.3.3.3 DMA request arbitration

The DMA arbiter continuously monitors all DMA channels for a pending DMA request when the DMA channel is not in the halt state (TSRc.HLTACK = 1_B) or the suspend state (SUSACRc.SUSAC = 1_B).

The highest number DMA channel with a pending DMA request wins the DMA channel arbitration. The DMA channel which wins the DMA channel arbitration is loaded onto the highest numbered ME which is not busy servicing other DMA channels. If both MEs are busy, the DMA channel which has won the DMA channel arbitration waits for one of the MEs to complete an ongoing DMA transfer. If the DMA channel which has won the DMA channel arbitration has a higher priority than the DMA channel being serviced on the ME, the ME stops servicing the lower priority DMA channel at the end of the ongoing DMA transfer and after any required interrupts have been signaled. The ME then reads the new DMA channel TCS from the DMARAM, loads the TCS into the ME active channel register set and executes a DMA transfer.

To prevent a lower ASIL task from interfering (for example delayed DMA transaction) with a higher ASIL task, the system configuration should assign the higher ASIL tasks to higher number DMA channels.

Arbitration sequence

- Rule 1: If there is a higher priority DMA channel with a pending DMA request, then:
  - Rule 1.1: An ME which is idle or running the lowest priority DMA channel completes any ongoing DMA transfer and then writes back the active DMA channel updated TCS to the DMARAM
  - Rule 1.2: The ME reads the higher priority DMA channel TCS from the DMARAM to the ME
  - Rule 1.3: The ME executes a DMA transfer
  - Rule 1.4: On completion of the DMA transfer, the DMA performs an arbitration sequence
- Rule 2: If there is not a higher priority DMA channel pending DMA request and for the ME active DMA channel CHCFGRc.RROAT = 0_B, then:
  - Rule 2.1: The updated TCS is written back from the ME to the DMARAM
  - Rule 2.2: During each clock cycle the DMA performs an arbitration sequence

  - Rule 2.3: If a DMA Request is received then the ME executes a DMA transfer
  - Rule 2.4: On completion of the DMA transfer, the DMA performs an arbitration sequence
- Rule 3: If there is not a higher priority DMA channel pending DMA request and for the ME active DMA channel CHCFGRc.RROAT = 1_B, then:
  - Rule 3.1: The ME executes a DMA transfer
  - Rule 3.2: On completion of the DMA transfer, the DMA performs an arbitration sequence
- Rule 4: On completion of a DMA transfer, if the ME sets the active DMA channel MEmCHSR.ICH, MEmCHSR.WRPS or MEmCHSR.WRPD bits, the updated TCS is written back from the ME to the DMARAM
- Rule 5: On completion of the last DMA transfer, the DMA channel request bit is cleared (TSRc.CH = 0_B)
- Rule 6: The arbitration sequence continues until all DMA channels with pending DMA requests are serviced by an ME

Write completion signaling on page 1269

9.3.3.4 DMA channel states

The table below describes the possible DMA channel states.

Table 636 DMA channel states

State	Status	Comments
Idle state	DMA channel TSRc.CH = 0_B	No DMA request is pending in this DMA channel
Reset state	DMA channel TSRc.CH = 0_B	No DMA request is pending in this DMA channel. DMA channel TCS bits cleared
Halt state	DMA channel TSRc.HLTACK = 1_B	The DMA channel is halted by software configuration of the DMA channel registers. A DMA request will not be serviced by a ME
Suspend state	DMA channel SUSACRc.SUSAC = 1_B	The DMA channel is suspended by the debug logic. A DMA request will not be serviced by a ME
Pending state	DMA channel TSRc.CH = 1_B	A DMA request in this DMA channel is waiting to be serviced by a ME
Active state		The ME is servicing a DMA request in this DMA channel

Related information

DMA channel reset on page 1262
DMA channel halt and resume on page 1263
DMA channel suspend on page 1330

9.3.3.4.1 DMA channel reset

Software shall reset an individual DMA channel by setting the DMA channel reset bit (TSRc.RST = 1_B). When a DMA channel reset is applied to a DMA channel, the transition to the reset state (TSRc.RST = 0_B) is as follows:

- Idle state, halt state, suspend state and pending state: The DMA channel transitions to the reset state
- Active state: On completion of the current DMA transfer, the ME writes back the updated DMA channel TCS to the DMARAM. The DMA channel then transitions to the reset state

Reset state

On completion of a DMA channel reset the DMA channel enters the reset state defined as:

- The following DMA channel bits are reset:
  - DMA transaction state register: TSRc.HLTREQ, TSRc.HLTACK, TSRc.HTRE, TSRc.CH and TSRc.TRL
  - DMA channel TCS: CHCFGRc.PRSEL, CHCSRc.ICH, CHCSRc.IPM, CHCSRc.WRPD, CHCSRc.WRPS, CHCSRc.FROZEN, CHCSRc.BUFFER, CHCSRc.LXO and CHCSRc.TCOUNT
- If a circular buffer ADICRc.SCBE is enabled for the DMA channel, the source address register will be set to the wrap boundary else the source address register is cleared
- If a circular buffer ADICRc.DCBE is enabled for the DMA channel, the destination address register will be set to the wrap boundary else the destination address register is cleared
- DMA channel shadow address register (SHADRc) is cleared

Resetting a DMA channel

A user program must execute the following steps to reset a DMA channel:

1. If a DMA hardware request is enabled, disable hardware requests (TSRc.DCH = 1_B)
2. Software requests a DMA channel reset (TSRc.RST = 1_B)
3. Software shall monitor the DMA channel reset and the DMA channel SADRc, DADRc and SHADRc registers
4. As soon as the DMA has cleared the DMA channel reset (TSRc.RST = 0_B) and the DMA has reset the DMA channel SADRc, DADRc and SHADRc registers, the DMA channel reset has completed

During a DMA channel reset operation, a DMA software request must not be initiated by setting CHCSRc.SCH = 1_B.

Restarting a DMA channel

A user program must execute the following steps to restart a DMA channel after a DMA channel reset:

1. Configure the DMA channel TCS including:
   a. DMA double buffering: Program address pointers to the base address
2. The DMA channel is restarted as follows:
   a. DMA software request: Software initiates a DMA request (DMA channel CHCSRc.SCH = 1_B)
   b. DMA hardware request: Software enables a DMA request (DMA channel TSRc.ECH = 1_B)

Related information

DMA channel states on page 1262
DMA hardware request on page 1257
DMA software request on page 1256

9.3.3.4.2 DMA channel halt and resume

A DMA channel may be halted during a DMA transaction and the state frozen to allow a background RAM test to be run over a destination memory in order to detect stuck bits and distinguish between static errors and transient errors. On completion of the RAM test the DMA channel may be re-started and the DMA transaction completed.

The DMA channel halt logic shown below utilizes a set and clear mechanism to request the DMA channel transitions to and from the HALT state on completion of the current DMA transfer. Only writing a logic ‘1’ to set or clear a halt request to a DMA channel has an effect. The status of other DMA channels is ignored.

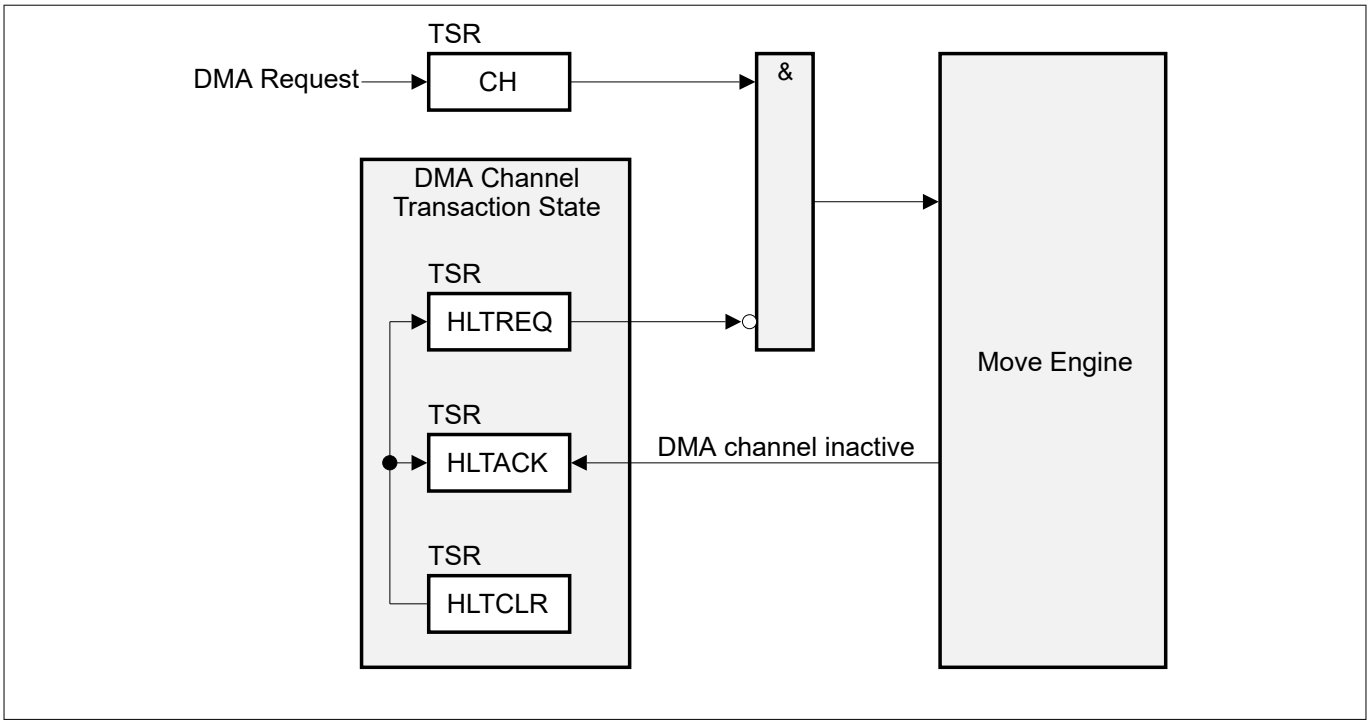

Figure 113 DMA channel halt logic

Halt state

A DMA channel is defined to be in the halt state when DMA channel TSRc.HLTACK = 1_B.

Entering DMA channel halt

A DMA channel is halted by software writing the DMA channel halt request bit (TSRc.HLTREQ = 1_B). The DMA channel enters the halt state as follows:

- Idle state, reset state and pending state: As soon as the DMA channel receives the halt request, the DMA channel transitions to the halt state
- Active state: On completion of the current DMA transfer, the DMA channel transitions to the halt state

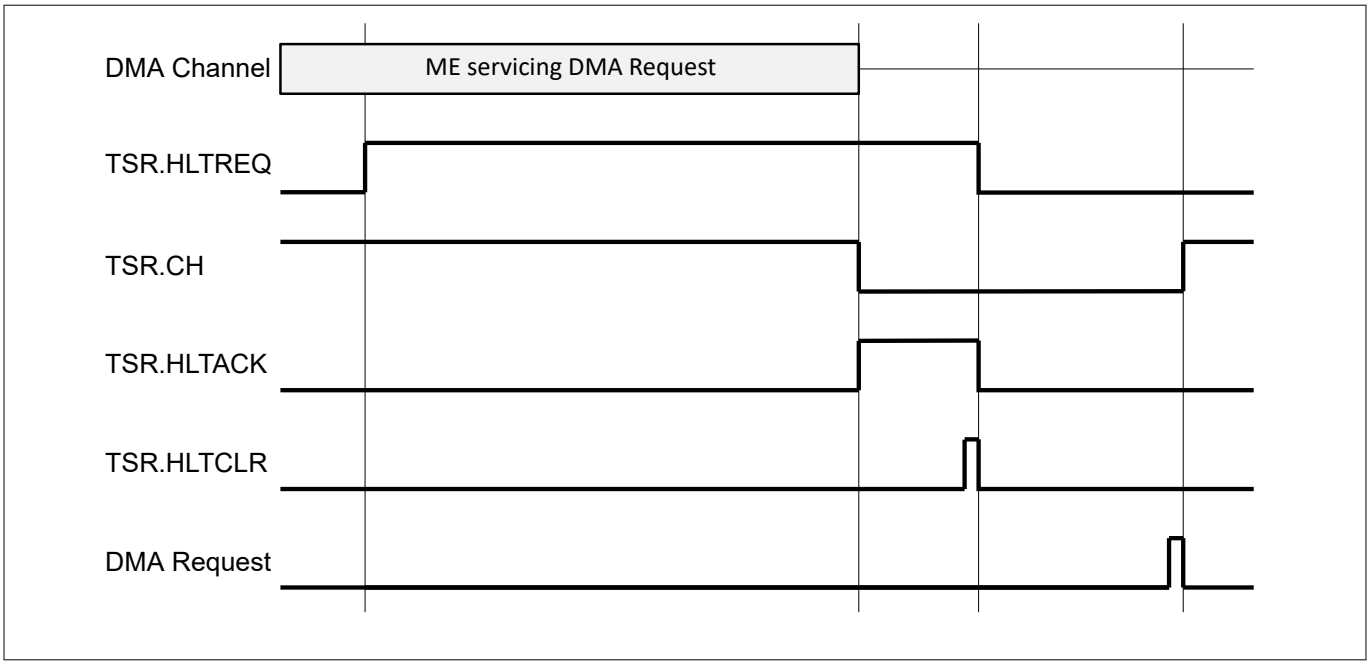

Figure 114 DMA channel halt operation

Exiting DMA channel halt

A DMA channel is released from the halt state by software writing the DMA channel halt clear bit (TSRc.HLTCLR = 1_B). The DMA operation is resumed. If the halt request is cleared before it is acknowledged then there is no effect on DMA operation.

DMA channel hardware request during DMA channel halt

If a DMA channel is in the halt state and Hardware Transaction Request is enabled (TSRc.HTRE = 1_B) then the DMA channel will respond to a DMA hardware request as follows:

- No DMA request pending (TSRc.CH = 0_B): The DMA channel sets the access pending bit (TSRc.CH = 1_B). The DMA hardware request is serviced when DMA channel exits the halt state
- DMA request pending (TSRc.CH = 1_B): The DMA channel records a TRL event. If the DMA channel TRL enable bit is set (TSRc.ETRL = 1_B), the DMA triggers a DMA RP error interrupt service request

9.3.3.6 DMA channel reconfiguration

If a DMA channel is to be configured, software shall apply a DMA channel reset to initialize the DMA channel. After the DMA channel has entered reset state, software shall configure the DMA channel for a DMA operation.

Related information

DMA channel reset on page 1262

9.3.3.7 DMA channel interrupt service request

Each DMA channel generates an interrupt service request (CHc) to report the following DMA channel events:

- DMA channel transfer interrupt service request (ICH)
- DMA channel pattern match interrupt service request (IPM)
- DMA channel wrap buffer interrupt service request (WRPS and WRPD)

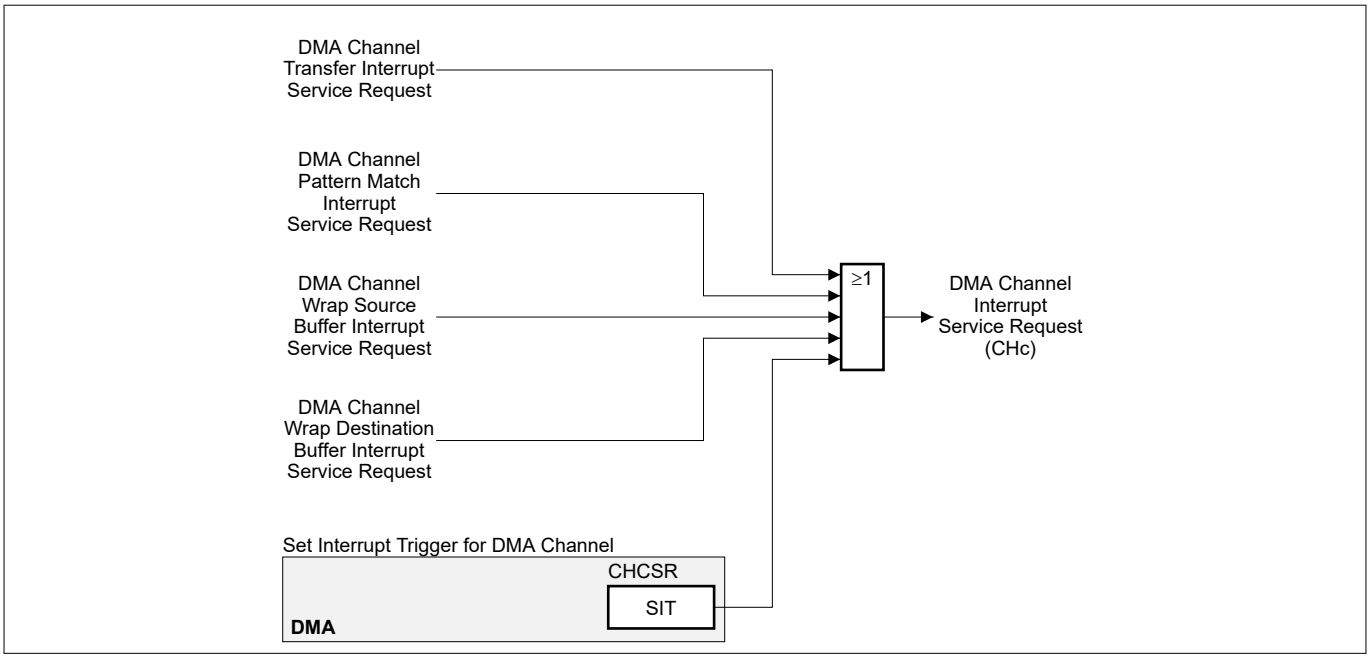

Figure 115 DMA channel interrupt service request

Related information

DMA channel transfer interrupt service request on page 1268
DMA channel pattern match interrupt service request on page 1270
DMA channel wrap buffer interrupt service request on page 1270

9.3.3.7.1 DMA channel transfer interrupt service request

If a DMA channel is in the active state then a DMA channel transfer interrupt service request may be activated on completion of a DMA transfer, or when MEmCHSR.TCOUNT matches with the value of bit-field ADICRc.IRDV after it has been decremented after a DMA transfer. An interrupt service request from a DMA channel is indicated when status flag CHCSRc.ICH is set. The status flag is reset by software setting DMA channel CHCSRc.CICH = 1_B (or TSRc.RST = 1_B). The DMA channel interrupt service request is enabled when DMA channel ADICRc.INTCT[1] is set.

Bit ADICRc.INTCT[0] selects one of two types of interrupt source. For the compare operation, bit-field ADICRc.IRDV (4-bit) is zero-extended to 14-bit and then compared with the 14-bit TCOUNT value. This means that a TCOUNT match interrupt may be generated after one of the last 16 DMA transfers of a DMA transaction. Note that with IRDV = 0000_B, the match interrupt is generated at the end of a DMA transaction (after the last DMA transfer).

The DMA channel transfer interrupt service request may also be activated or deactivated during a linked list load operation. The DMA CHCSRc.ICH bit is set if the ICH bit in the new TCS is set when the CICH bit in the new TCS is clear. The DMA CHCSRc.ICH bit is cleared if the ICH bit in the new TCS is clear (irrespective of the CICH bit in the new TCS). If both the ICH and CICH bits in the new TCS are set, the TCS load does not affect the DMA CHCSRc.ICH bit and the current value is retained as-is. If the linked list load operation causes the DMA CHCSRc.ICH bit to be set, the DMA Channel transfer interrupt service request is activated depending on the value of CHCFGRc.PRSEL and ADICRc.INTCT[1] from the new TCS.

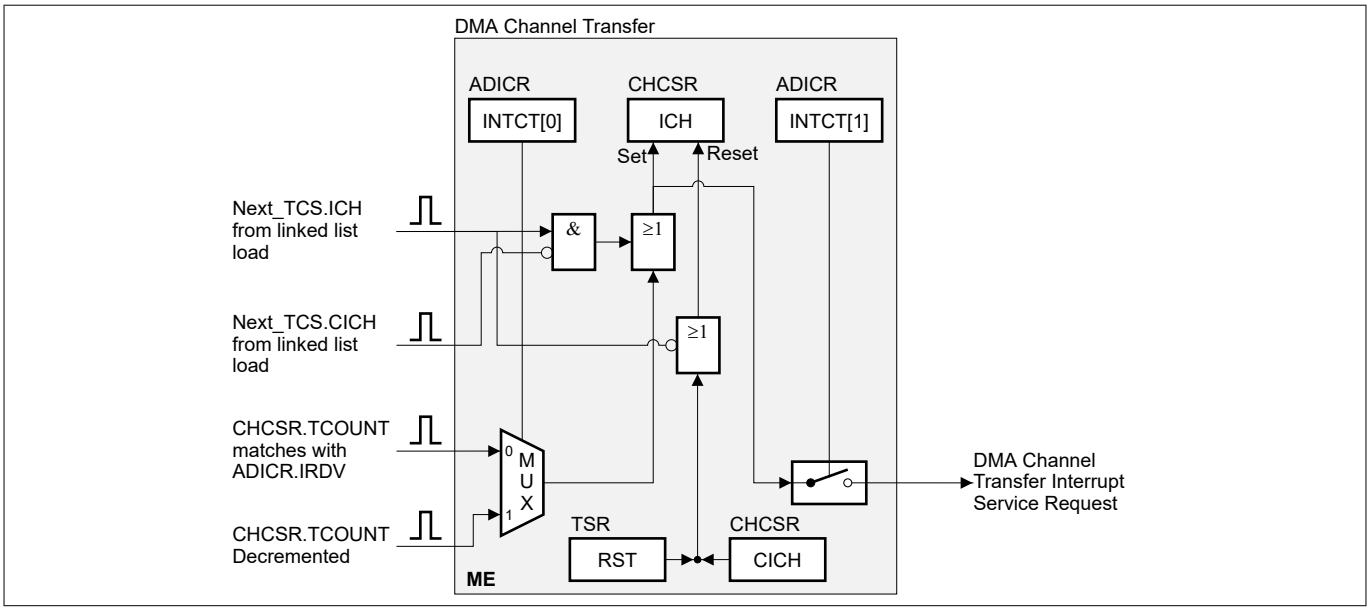

Figure 116 DMA channel transfer interrupt service request

Related information

DMA channel states on page 1262
Write completion signaling on page 1269
TC4Dx DMA channel transfer interrupt service request on page 1335

Write completion signaling

When the application software is operating in a model where the destination location has to be accessed immediately after the DMA channel transfer interrupt service request is received and there is no higher level coordination between producer and consumer, it may be necessary to ensure that the DMA write moves have reached their final destination before the DMA channel transfer interrupt service request is activated.

When TSRc.WWC is set to 0_B, the DMA channel activates the DMA channel transfer interrupt service request as soon as it has issued the write data for the last DMA write move of the DMA transfer or transaction as configured by ADICRc.INTCT. When TSRc.WWC is set to 1_B, the DMA channel waits for write completion signaling from the system interconnect to ensure that all previous writes from the DMA channel have reached their final destination before updating the CHCSRc.ICH bit and if enabled in ADICRc.INTCT, activating the DMA channel transfer interrupt service request.

***Note**: Software shall only change the value of the TSRc.WWC bit when the DMA channel is in the idle, reset, halted or suspend states.*

The system interconnect offers write completion signaling independently for each system interconnect master tag identifier. A master agent on the system interconnect shall not issue further writes onto the system interconnect using the same master tag identifier while it is waiting for the write completion signal for that master tag identifier. When TSRc.WWC is set to 1_B and while a DMA channel is waiting for the write completion signaling from the system interconnect, a different DMA channel that wins DMA request arbitration may begin execution in the DMA move engine. However, the new DMA channel cannot start a DMA write move if it uses the same master tag identifier as another DMA channel (regardless of its priority) which is waiting for a write completion signal.

***Note**: Because the granularity of write completion signaling is for a given master tag identifier, there is the possibility of temporal interference between different DMA channels using the same master tag identifier if even one of them uses the write completion signaling feature. Software should therefore restrict the usage of DMA channels with TSRc.WWC set to 1_B and instead prefer the usage of higher level coordination between the producer and consumer where possible.*

Related information

DMA channel transfer interrupt service request on page 1268
DMA request arbitration on page 1261

9.3.3.7.2 DMA channel pattern match interrupt service request

The DMA channel pattern detection interrupt service request is enabled when CHCFGRc.PATSEL[1:0] is not equal to 00_B. The pattern detection interrupt is indicated when status flag CHCSRc.IPM is set. The status flag CHCSRc.IPM is reset by software setting bit DMA channel CHCSRc.CICH = 1_B (or TSRc.RST = 1_B).

The DMA CHCSRc.IPM bit is cleared by a linked list load operation since a pattern match operation cannot be combined with a linked list operation.

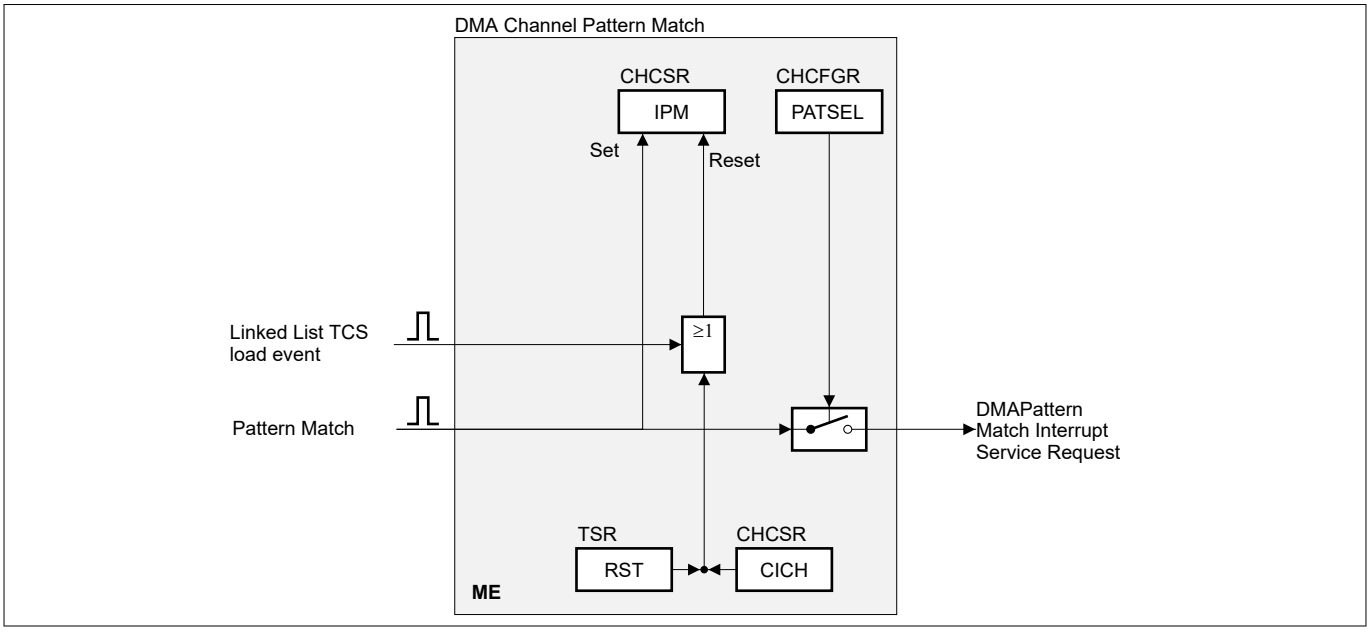

Figure 117 DMA channel pattern match interrupt service request

9.3.3.7.3 DMA channel wrap buffer interrupt service request

Each DMA channel reports a source buffer wraparound or a destination buffer wraparound as follows:

- A wrap source buffer wraparound is indicated by status flag CHCSRc.WRPS
- A wrap destination buffer wraparound is indicated by the status flag CHCSRc.WRPD

Software may reset both buffer wraparound status flags by setting CHCSRc.CWRP = 1_B (or TSRc.RST = 1_B).

A DMA channel wrap buffer interrupt service request is enabled as follows:

- A DMA channel wrap source buffer interrupt service request is enabled when bit ADICRc.WRPSE is set
- A DMA channel wrap destination buffer interrupt service request is enabled when bit ADICRc.WRPDE is set

The DMA channel wrap source or destination interrupt service request may also be activated or deactivated during a linked list load operation.

- The DMA CHCSRc.WRPS and CHCSRc.WRPD bits are set if the WRPS or WRPD bits respectively in the new TCS are set when the CWRP bit in the new TCS is clear
- The DMA CHCSRc.WRPS and CHCSRc.WRPD bits are cleared if the WRPS or WRPD bits respectively in the new TCS are clear (irrespective of the CWRP bit in the new TCS)
- If both the WRPS and CWRP bits in the new TCS are set, the TCS load does not affect the DMA CHCSRc.WRPS bit and the current value is retained as-is
- If both the WRPD and CWRP bits in the new TCS are set, the TCS load does not affect the DMA CHCSRc.WRPD bit and the current value is retained as-is
- If the linked list load operation causes the DMA CHCSRc.WRPS bit to be set, a DMA channel wrap source buffer interrupt service request is generated depending on the values of ADICRc.WRPSE from the new TCS
- If the linked list load operation causes the DMA CHCSRc.WRPD bit to be set, a DMA channel wrap source buffer interrupt service request is generated depending on the values of ADICRc.WRPDE from the new TCS

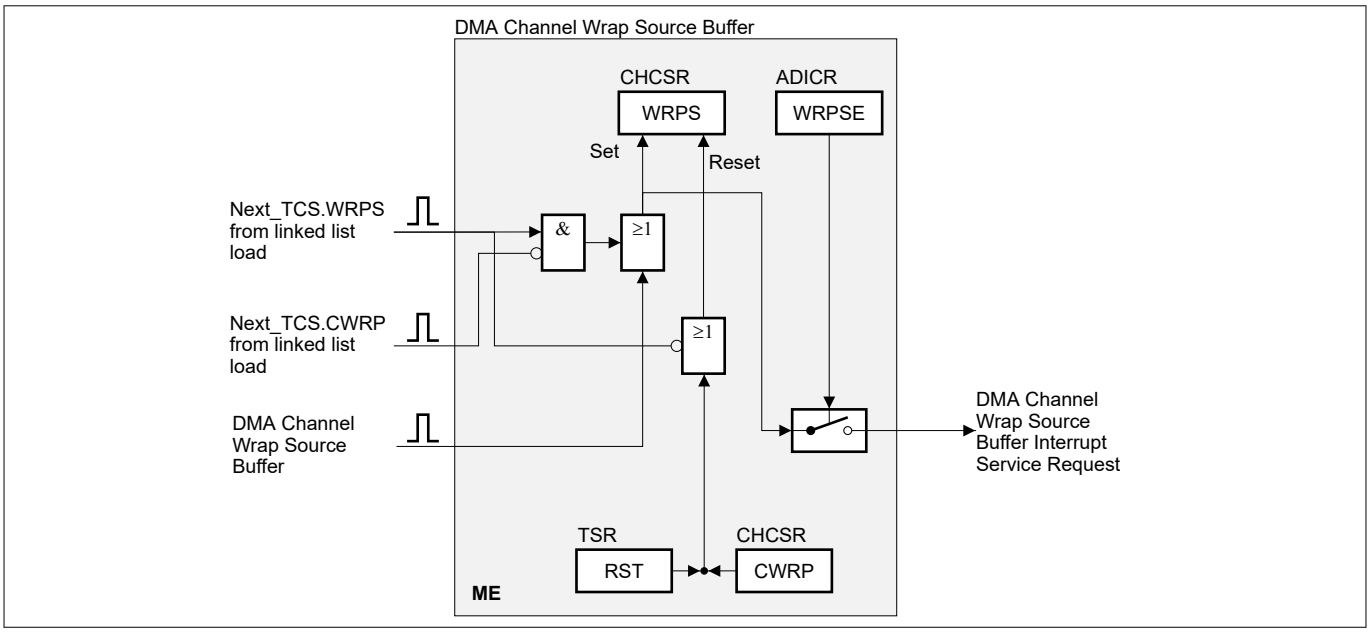

Figure 118 DMA channel wrap source buffer interrupt service request

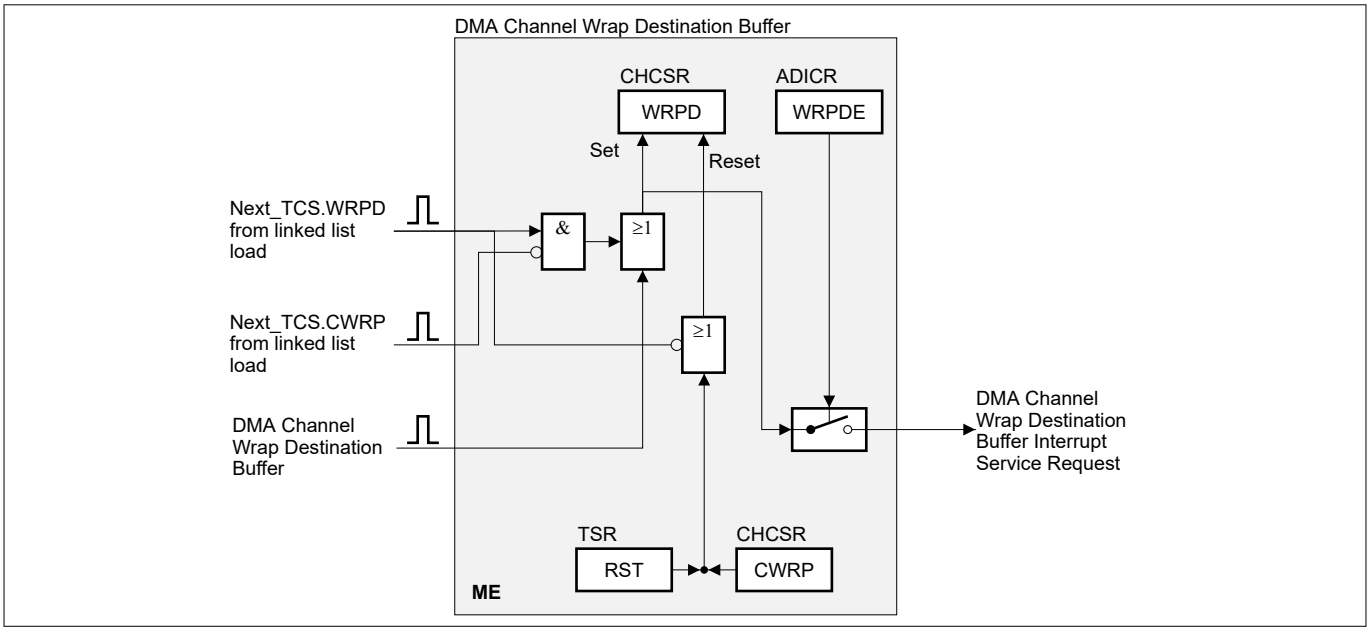

Figure 119 DMA channel wrap destination buffer interrupt service request

9.3.4 Resource partitions

Resource partitions (RPs) are used to group sets of DMA channels together.

Each resource partition may be assigned to a software application or a set of software applications using the PROTRPr and ACCENRPr registers. Each DMA channel may then be assigned to a resource partition using the HRRc register.

Once assigned and configured, the RP access protection mechanisms can be used to isolate the set of DMA channels assigned to that RP from other software applications using other RPs. The DMA channels assigned to an RP also share certain common configuration parameters like those in the MODEr register, including RP TAG-ID assignment.

9.3.4.1 Access protection

Each RP has its own RP PROT mechanism (PROTRPr) and RP APU (ACCENRPr). The RP PROT mechanism provides write protection to the RP APU registers, the channel assignment registers (HRRc) and the channel suspend control registers (SUSENRc). The RP APU in turn provides read and write protection to all the RP specific registers as well as all other channel specific registers for channels that are assigned to that RP.

Software shall use an appropriate synchronization mechanism such as a read-back or synchronization instruction after updating the contents of the PROTRPr or ACCENRPr registers in order to ensure that subsequent accesses to the protected registers use the updated access protection configuration.

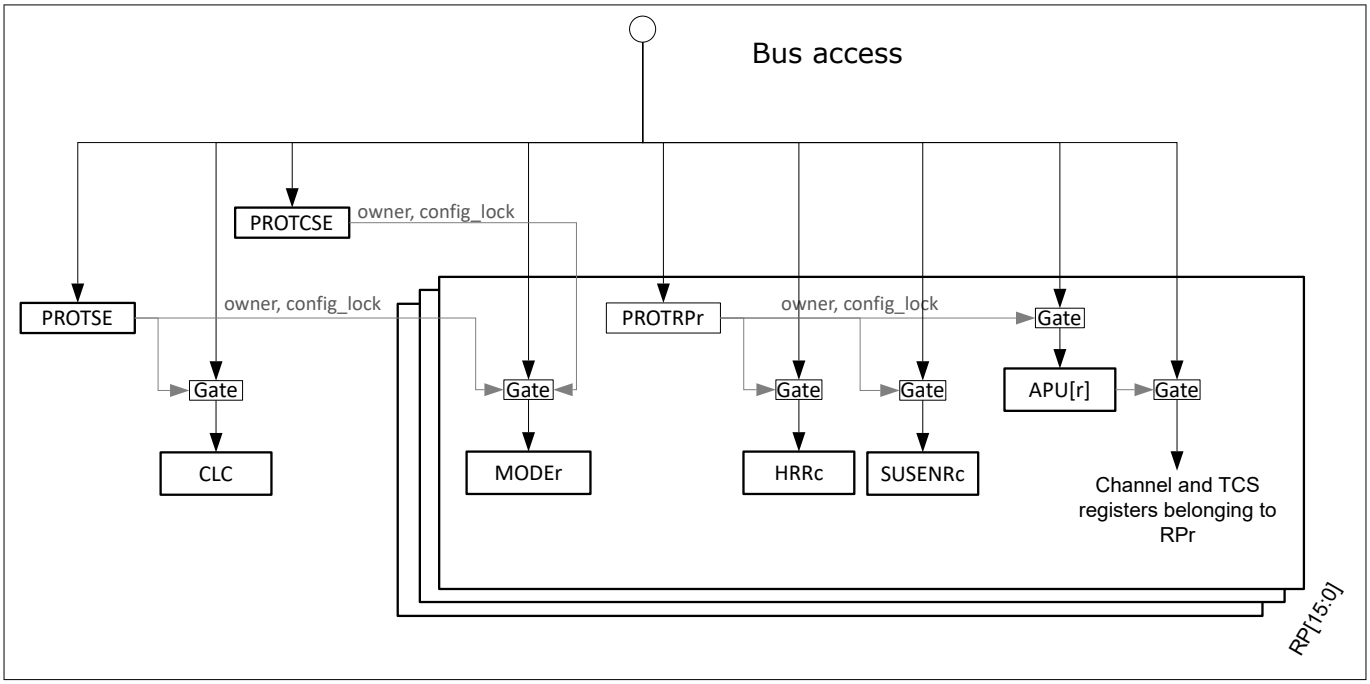

Figure 120 DMA access protection

The system configuration should define the access protection of each RP to prevent a lower ASIL application from issuing a DMA software request, DMA channel reset or DMA channel halt to a DMA channel assigned to a higher ASIL application.

9.3.4.2 Resource partition configuration

Each RP is configured with a master agent function identifier consisting of a TAG ID from the group of DMA TAG IDs and optionally with VM and PRS information. The DMA channels assigned to an RP use this master agent function identifier for all DMA read or write requests on the system interconnect.

Each DMA instance in a device is provided up to eight unique TAG-IDs as listed in the system interconnect chapter. Each RP in each DMA instance can be configured with one of these eight TAG-IDs by configuring the MODEr.TAGOFF bit-field. Each RP can also be configured with VM and PRS information using the MODEr.VMEN, MODEr.VM, MODEr.PRSEN and MODEr.PRS bit-fields.

The MODEr.MODE bit selects if a DMA move system interconnect access is made in supervisor mode or user mode.

The MODEr.CS bit selects if the RP is marked as a CS or a non-CS RP. It restricts hardware requests to DMA channels in the RP to be triggered from the correct CS or non-CS applications. The CS bit is also used on every DMA read or write request to set the cs_valid bit on FPI interconnects and sri_sm bit on SRI interconnects to indicate whether the move has been triggered by a CS or non-CS application.

The system configuration should define the access protection and privilege level (supervisor or user mode) of source modules and destination modules and to isolate DMA moves between RPs.

Access protection of RP MODEr registers

The RP MODEr registers define the tags that DMA channels in each RP present on the interconnect and therefore may have to be configured in a safe and secure manner. The PROTCSE owner can configure the resource partitions assigned to cybersecurity tasks, and the PROTSE owner can configure the resource partitions assigned to non-cybersecurity tasks. These two owners can independently assign and configure the MODE register for their respective resource partitions.

Each RP can be in one of three states:

1. Unassigned: When MODEr.VALID = 0_B, the RP is unassigned. Either the PROTSE or the PROTCSE owner can claim and configure the resource partition
2. Marked as a non-CS RP: When MODEr.VALID = 1_B and MODEr.CS = 0_B, the RP is marked as a non-CS RP. Only the enabled PROTSE owner can reconfigure the fields in the RP MODEr register
3. Marked as a CS RP: When MODEr.VALID = 1_B and MODEr.CS = 1_B, the RP is marked as a CS RP. Only the enabled PROTCSE owner can reconfigure the fields in the RP MODEr register

The table below shows the master agent functions which are permitted to write to the RP MODEr registers for different combinations of the current RP state and the new write data. Writes to the RP MODEr registers are only executed when the respective PROT state machine is in an unlocked state, and any writes which are not executed terminate with a bus error.

Table 639 Allowed master agents for write to RP MODEr register

PROTCSE.CSEN	Current MODEr.VALID	Current MODEr.CS	Wdata.VALID	Wdata.CS	Wdata.TAGOFF == PROTCSE.CSTAGOFF?	Allowed master agents for write

1	0	X	0	0	0	PROTSE owner[1)]
1	0	X	0	0	1	None
1	0	X	0	1	0	None
1	0	X	0	1	1	PROTCSE owner[2)]
1	0	X	1	0	0	PROTSE owner[1)]

(table continues...)

Table 639 (continued) Allowed master agents for write to RP MODEr register

PROTCSE.CSEN	Current MODEr.VALID	Current MODEr.CS	Wdata.VALID	Wdata.CS	Wdata.TAGOFF == PROTCSE.CSTAGOFF?	Allowed master agents for write
1	0	X	1	0	1	None
1	0	X	1	1	0	None
1	0	X	1	1	1	PROTCSE owner[2)]
1	1	0	0	0	0	PROTSE owner[1)]
1	1	0	0	0	1	None
1	1	0	0	1	X	None
1	1	0	1	0	0	PROTSE owner[1)]
1	1	0	1	0	1	None
1	1	0	1	1	X	None
1	1	1	0	X	X	PROTCSE owner[2)]
1	1	1	1	0	X	None
1	1	1	1	1	0	None
1	1	1	1	1	1	PROTCSE owner[2)]

1) When PROTSE.ODEF=0, any master (including the PROTCSE owner if one is defined) can behave as the PROTSE owner.
2) When PROTCSE.ODEF=0, any master (including the PROTSE owner if one is defined) can behave as the PROTCSE owner.

9.3.4.3 DMA channel assignment

After an application reset, DMA channels are not assigned to any resource partition and cannot be triggered. During DMA configuration, each used DMA channel can be assigned to a valid resource partition.

DMA channels are assigned to a resource partition using the HRRc register. The assignment of channels to resource partitions has to be achieved in a safe and secure manner. There are therefore a few restrictions on the assignment of channels to resource partitions.

The table below shows the master agent functions which are permitted to write to the HRRc registers for different combinations of the current HRRc state and the new write data. Writes to the HRRc registers are only executed when the respective PROT state machine is in an unlocked state, and any writes which are not executed terminate with a bus error.

Software shall use an appropriate synchronization mechanism such as a read-back or synchronization instruction after updating the contents of the HRRc registers in order to ensure that subsequent accesses to the respective DMA channel TSRc and DMA channel 'c' TCS registers use the updated access protection configuration.

Table 640 Allowed master agents for writes to HRRc register

Channel 'c' state active or pending?	TSRc.HTRE	Current HRRc.HRPV	Current HRRc.HRP	Wdata.HRPV	Wdata.HRP	Allowed master agents for write to HRRc
1	X	X	X	X	X	None
0	1	X	X	X	X	None
0	0	0	X	0	X	Any PROTRPr owner[1)]
0	0	0	X	1	'r'	PROTRPr owner[1) 2)]
0	0	1	'a'	1	'r'	• None, if 'r' is not equal to 'a' • PROTRPr owner[1)], if 'r' is equal to 'a'
0	0	1	'r'	0	X	PROTRPr owner[1)]

1) When PROTRPr.ODEF=0, any master agent can behave as the PROTRPr owner
2) The write is not executed if 'r' does not correspond to an implemented RP in the current DMA instance

The table below shows the master agents which are permitted to access the DMA channel TSRc and DMA channel 'c' TCS registers for different combinations of the current HRRc state. Any accesses which are not executed terminate with a bus error.

Table 641 Allowed master agents for accesses to DMA TSRc and DMA channel 'c' TCS registers

HRRc.HRPV	HRRc.HRP	Allowed master agents for accesses to DMA TSRc and DMA channel 'c' TCS registers
0	X	None
1	'r'	Master agents enabled for access in ACCENRPr* registers

9.3.4.4 DMA RP error interrupt service request

Each RP generates one error interrupt service request (ERRr) to cover all error events for DMA channels assigned to that RP including servicing of DMA requests by the ME. Each application software task using a DMA RP should include an error handler to resolve RP and DMA error conditions.

- DMA channel TRL error interrupt service request that can be attributed to an RP (CBTRLER, CDTRLER, DCTRLER, DBTRLER, IRTRLER)
- RP DMARAM integrity error interrupt service request
- RP SER and DER error interrupt service request
- RP linked list operation TCS load error interrupt service request

- RP CHKLL DMA address checksum error interrupt service request
- RP TCS configuration error interrupt service request

If a DMA RP error interrupt service request is triggered then the software RP application error handler shall read the contents of the error status registers to identify the origin of the error.

In the case of multiple errors occurring at the same time, the error bits are set according to the error conditions (that is more than one error flag may be set).If a previous RP error status flag is still set when a new error occurs that requires an update of the RP error status bits, the RP error status overflow bit ERRSRr.OVFLER is set. Software may clear the RP error status overflow bit by writing a 1_B to the CLREr.COVFLER bit-field.

For all error conditions, the DMA performs the following actions:

- The RP records the number of the DMA channel in the RP last error channel bit-field ERRSRr.LEC
- If the DMA channel is enabled for DMA channel hardware request then DMA channel TSRc.HTRE is cleared

Related information

DMA channel TRL error interrupt service request on page 1276

9.3.4.4.1 DMA channel TRL error interrupt service request

DMA channel TRL events that can be attributed to a certain resource partition occur for the following conditions.

- Channel Busy TRL Error (CBTRLER): If a DMA request is detected and the DMA channel TSRc.CH is already set or multiple DMA requests occur simultaneously on a DMA channel
- Channel Disabled TRL Error (CDTRLER): If a DMA hardware request is detected and the DMA channel is disabled for hardware requests
- Daisy Chain TRL Error (DCTRLER): If a DMA daisy chain request from the current channel attempts to trigger the next lower priority channel assigned to a different resource partition or no resource partition (the TRL event is processed on the current channel)
- Double Buffer TRL Error (DBTRLER): If a DMA channel is configured for a double buffering operation and one of the following conditions occur:
  - The DMA channel is configured for software switch only AND the DMA transaction is completed before the DMA receives a software switch
  - The DMA channel is configured for automatic hardware switch AND the DMA transaction is completed when CHCSRc.FROZEN is still 1_B
- Invalid Resource partition TRL Error (IRTRLER): If a DMA request is detected and the resource partition that the DMA channel is assigned to is marked invalid (MODEr.VALID is set to 0_B)

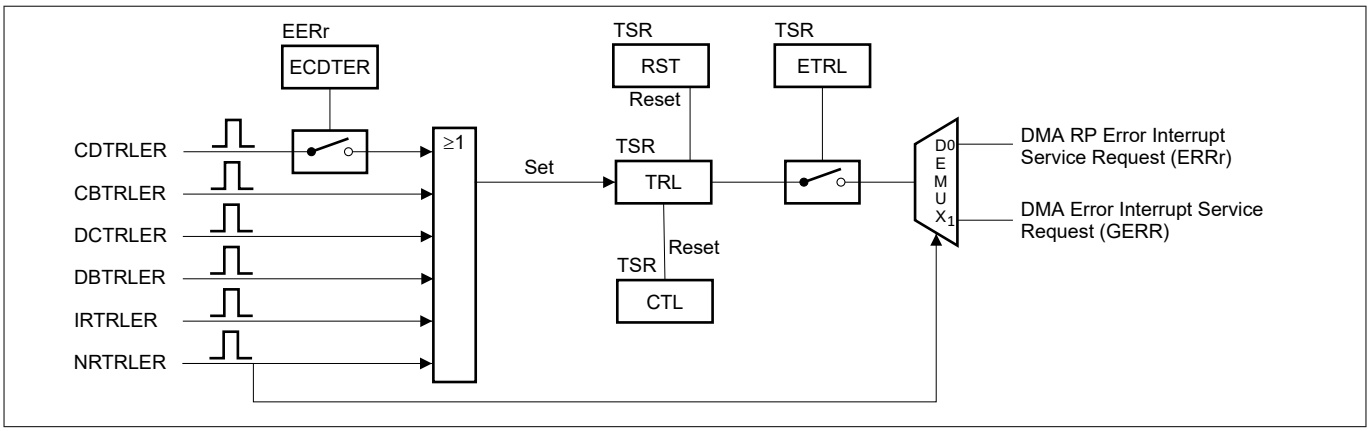

Figure 121 DMA channel transaction request lost interrupt service request

For error conditions CBTRLER, DCTRLER, DBTRLER and IRTRLER, the DMA sets the DMA channel TRL bit (TSRc.TRL = 1_B) and if the DMA channel enable TRL bit is set (TSRc.ETRL = 1_B), the DMA triggers a DMA RP error interrupt service request.

Error condition CDTRLER is enabled or disabled by the RP CDTRLER enable bit (EERr.ECDTER). If CDTRLER is enabled and the error condition CDTRLER occurs, the DMA sets the DMA channel TRL bit (TSRc.TRL = 1_B) and if the DMA channel enable TRL bit (TSRc.ETRL) is set, the DMA triggers a DMA RP error interrupt service request.

An error handler shall interrogate the DMA channels to identify the source of the error. Software may clear TSRc.TRL by setting the DMA channel TSRc.CTL or TSRc.RST.

DMA RP error interrupt service request on page 1275
No resource partition TRL error interrupt service request on page 1282

9.3.4.4.2 DMARAM integrity error interrupt service request

When a DMA channel wins arbitration, a ME accesses the DMARAM to read the TCS. If an ECC error is detected, the RP sets the error flag ERRSRr.RAMER. The DMA transaction does not take place.

- A RAMER is indicated by the RP error status flag ERRSRr.RAMER
- The DMA triggers a DMA RP error interrupt service request
- If software sets CLREr.CRAMER, the DMA clears error status flag ERRSRr.RAMER

Related information

DMA RP error interrupt service request on page 1275
TC4Dx DMARAM integrity error interrupt service request on page 1336

9.3.4.4.3 Source and destination error interrupt service request

SER and DER include access protection errors and unsupported types of bus transaction.

The RP detects the following error conditions:

- An SER indicates a bus error occurred during a DMA read move from a source address
  - An SER is indicated by the RP error status flag ERRSRr.SER
  - If EERr.ESER is set, the DMA triggers a DMA RP error interrupt service request
  - If software sets CLREr.CSER, the DMA clears error status flag ERRSRr.SER
- A DER indicates a bus error that occurred during a DMA write move to a destination address
  - A DER is indicated by the RP error status flag ERRSRr.DER
  - If EERr.EDER is set, the DMA triggers a DMA RP error interrupt service request
  - If software sets CLREr.CDER, the DMA clears error status flag ERRSRr.DER

If a SER or DER is reported then the ME completes the DMA transaction. If a SER is reported during a DMA read move then the DMA write move is not executed, but the destination address is updated.

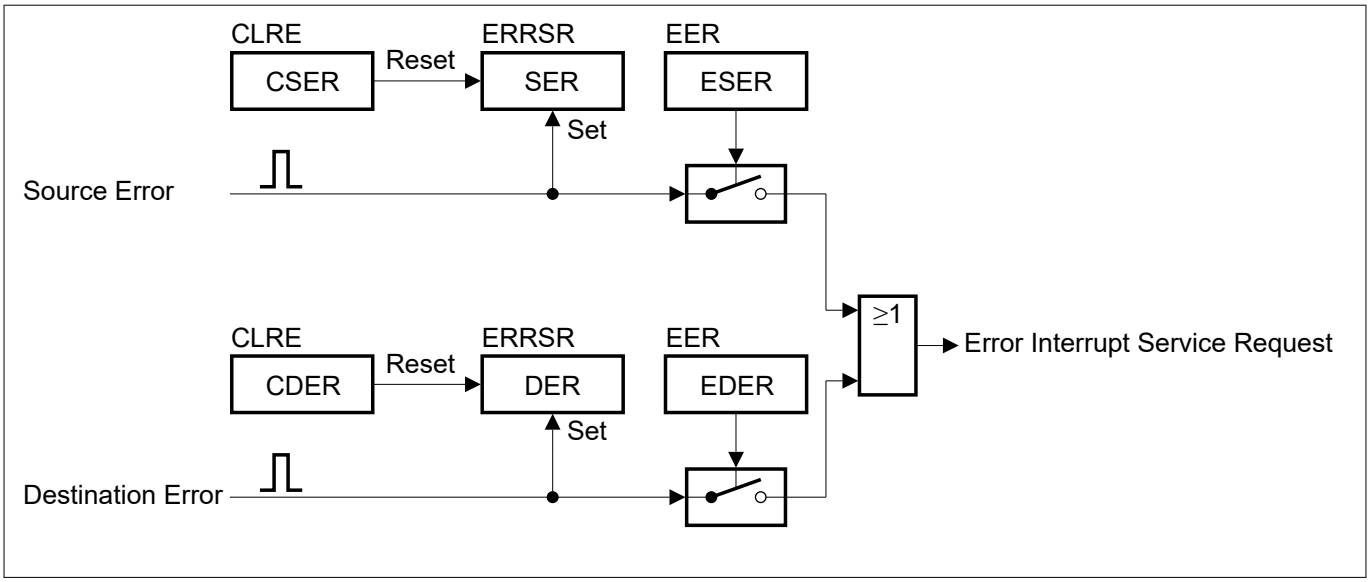

Figure 122 Source and destination error interrupt service request

Related information

DMA RP error interrupt service request on page 1275

9.3.4.4.4 Linked list operation TCS error interrupt service request

During DMALL, ACCL, CHKLL and CONLL operations if an error is reported during the loading of the next TCS from the system interconnect, the RP sets the error flag ERRSRr.DLLER. The linked list operation is aborted and the DMA channel transaction request state bit TSRc.CH bit cleared.

- A DLLER is indicated by the RP error status flag ERRSRr.DLLER
- If EERr.ELER is set, the DMA triggers a DMA RP error interrupt service request
- If software sets CLREr.CDLLER, the DMA clears error status flag ERRSRr.DLLER

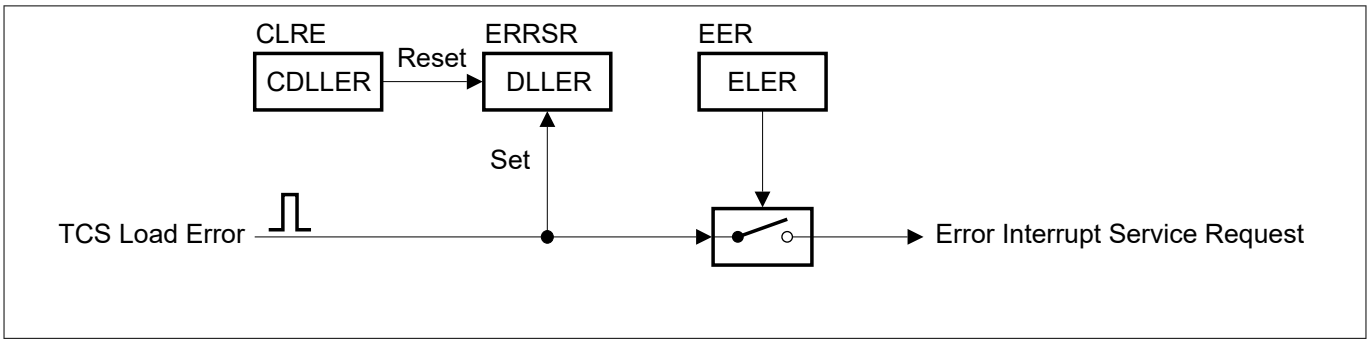

Figure 123 Linked list operation TCS error interrupt service request

Related information

DMA RP error interrupt service request on page 1275

9.3.4.4.5 CHKLL DMA address checksum error interrupt service request

The ME compares the DMA address checksum calculated by the current DMA transaction against the expected DMA address checksum stored in the next TCS. If the checksums do not match then the RP sets the error flag ERRSRr.CLLER.

- A CLLER is indicated by the RP error status flag ERRSRr.CLLER

- The DMA triggers a DMA RP error interrupt service request
- If software sets CLREr.CCLLER, the DMA clears error status flag ERRSRr.CLLER

Related information

DMA address checksum on page 1222
DMA RP error interrupt service request on page 1275

9.3.4.4.6 TCS configuration error interrupt service request

During DMA channel TCS configuration, some configuration errors are detected:

- If software writes to the shadow address register when shadow operation read only mode is configured, the DMA stores a RP TCS configuration error

On detection of such an error, the RP sets the error flag ERRSRr.TCSCER. The write is aborted.

- An TCSCER is indicated by the RP error status flag ERRSRr.TCSCER
- The DMA triggers a DMA RP error interrupt service request
- If software sets CLREr.CTCSCER, the DMA clears error status flag ERRSRr.TCSCER

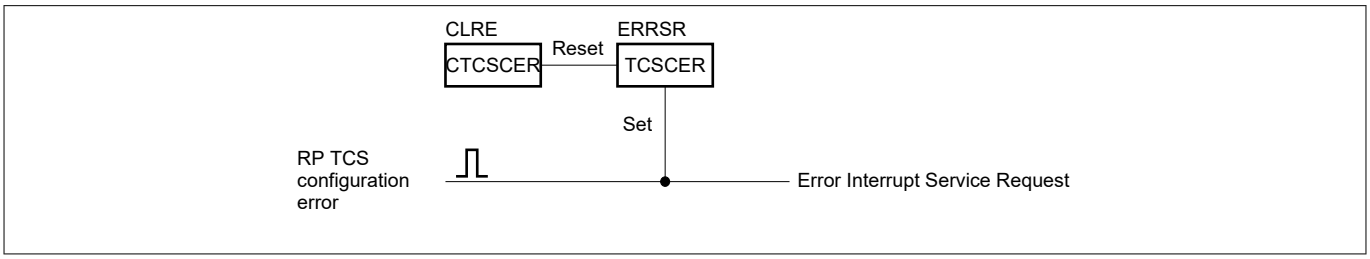

Figure 124 TCS configuration error interrupt service request

Related information

DMA RP error interrupt service request on page 1275

9.3.5 DMA move engine

The DMA move engine services the move operations as defined by the TCS of the active channel.

Any ME may service a DMA request from any DMA channel. As soon as a DMA channel wins arbitration, the DMA selects one of the available MEs to execute the pending DMA request. When the selected ME is idle, the TCS is copied from the DMARAM into the channel registers of the ME and the DMA request is serviced. The ME requests the required system interconnect master interfaces and reads or writes data according to the TCS parameters of the active DMA channel. The ME is able to wait if the source or destination target is not available.

The processing of a DMA transfer (composed of several DMA moves) by the ME cannot be interrupted and is always completed, except for the case where pattern detection is enabled and a pattern match is detected. A DMA channel interrupt, reset, halt request or debug suspend only becomes active when the current DMA transfer is complete and the TCS has written back to the DMARAM. Error conditions are reported. On completion of a DMA transaction or when a DMA channel loses channel arbitration the ME writes the TCS back to the DMARAM.

Related information

DMA request arbitration on page 1261

9.3.5.1 ME read buffer

The ME stores the DMA read move data in eight 32-bit read buffer locations. If a DMA channel is configured for 8-bit, 16-bit, 32-bit, 64-bit or 128-bit channel data width and a DMA read move is to a cached address[13], the ME translates the read access on the system interconnect into an SRI BTR4 access to a 32-byte aligned address. The ME uses the DMA read move data in the ME read buffer together with the 32-byte aligned address as follows:

- Hit, if the 32-byte aligned address of the next DMA read move matches the 32-byte aligned address stored in the ME read buffer then the DMA read move data is read from the ME read buffer. No read access to the system interconnect occurs
- Miss, if the 32-byte aligned address of the next DMA read move does not match the 32-byte aligned address stored in the ME read buffer then the ME invalidates the contents of the ME buffer. The ME executes the DMA read move by performing a read access to the system interconnect

The ME invalidates the ME read buffer at the start of a DMA transfer.

9.3.5.1.1 DMA address checksum

If a DMA read move is to a cached address, then the ME calculates the DMA address checksum using the 32-byte aligned address source address.

Related information

DMA address checksum on page 1222

9.3.6 DMA internal switch

The DMA internal switch arbitrates between each system interconnect request from the move engines. Address routing across the whole memory map directs a request to a system interconnect master interface.

The DMA internal switch also implements buffering capabilities for move actions on the system interconnect (at least one DMA move per master interface is buffered).

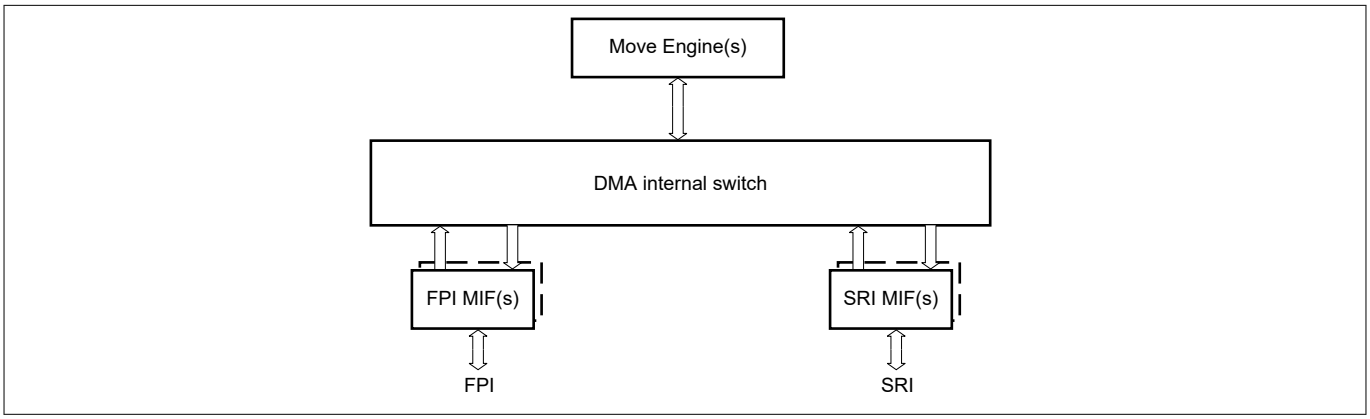

Figure 125 DMA internal switch

9.3.6.1 DMA master agents

The DMA instances master agents to the SRI and FPI system interconnect instances.

The DMA FPI master agents support

- Single data read and write transactions (8-bit, 16-bit, 32-bit)
- Block transfer read and write transactions (64-bit, 128-bit, 256-bit)

13 Segments 8 and 9 (see system address map for details).

- Accesses in supervisor mode according to the setting in the MODEr.MODE bit-field
- Generation of interleaved FPI transactions from different access requesters (MEs)
- De-assertion of request after retry in order to prevent bus blocking
- Out of order transactions from different sources in order to avoid side effects (blocking) between the different access requesters (MEs)

The DMA SRI master agents support

- Single data read and write transactions (8-bit, 16-bit, 32-bit, 64-bit)
- Block transfer read and write transactions (128-bit, 256-bit, 512-bit)[14)]
- Accesses in supervisor mode according to the setting in the MODEr.MODE bit-field
- Generation of interleaved SRI transactions from different access requesters (MEs)
- Data pacing to transmit data on the interface only on cycles when the slave indicates that it is ready to accept the data

Read modify write (RMW) Support

The DMA does not support RMW accesses to the system interconnect.

9.3.6.2 DMA internal switch arbitration

If requests from both move engines conflict, the DMA internal switch priorities listed in the table below determine arbitration.

Table 642 DMA internal switch priorities

Priority	Agent requests	Comment
Highest	ME write	For concurrent write requests, the highest DMA channel wins.
Lowest	ME read	For concurrent read requests, the highest DMA channel wins.

The DMA internal switch supports pipelining. High and low priority ME0 and ME1 requests may be pipelined.

9.3.7 DMA error interrupt service request

The DMA generates one error interrupt service request (GERR) to cover all error events that cannot be attributed to a single RP.

- DMA channel TRL error interrupt service request that cannot be attributed to a single RP (NRTRLER)

If a DMA error interrupt service request is triggered then the software application error handler shall read the contents of the error status registers to identify the origin of the error.

For all such error conditions, the DMA performs the following actions:

- The DMA sets the corresponding error status bit in the ERRSR register
- The DMA records the number of the DMA channel in the DMA last error channel bit-field ERRSR.LEC
- If the DMA channel is enabled for DMA channel hardware request then DMA channel TSRc.HTRE is cleared
- If software sets a bit in the CLRE register, the corresponding status bit in the ERRSR register is cleared

If a previous DMA error status flag is still set when a new error occurs that requires an update of the DMA error status bits, the DMA error status overflow bit ERRSR.OVFLER is set. Software may clear the DMA error status overflow bit by writing a 1_B to the CLRE.COVFLER bit-field.

14 512-bit block transfer DMA move supported for DMA read move from SRI source to DMA write move to SRI destination.

Related information

No resource partition TRL error interrupt service request on page 1282

9.3.7.1 No resource partition TRL error interrupt service request

A DMA channel No resource partition TRL event occurs for the following conditions.

- No Resource partition TRL Error (NRTRLER): If a DMA hardware request or a DMA auto-start request is detected and the DMA channel has not been assigned to a resource partition (HRRc.HRPV is set to 0_B)

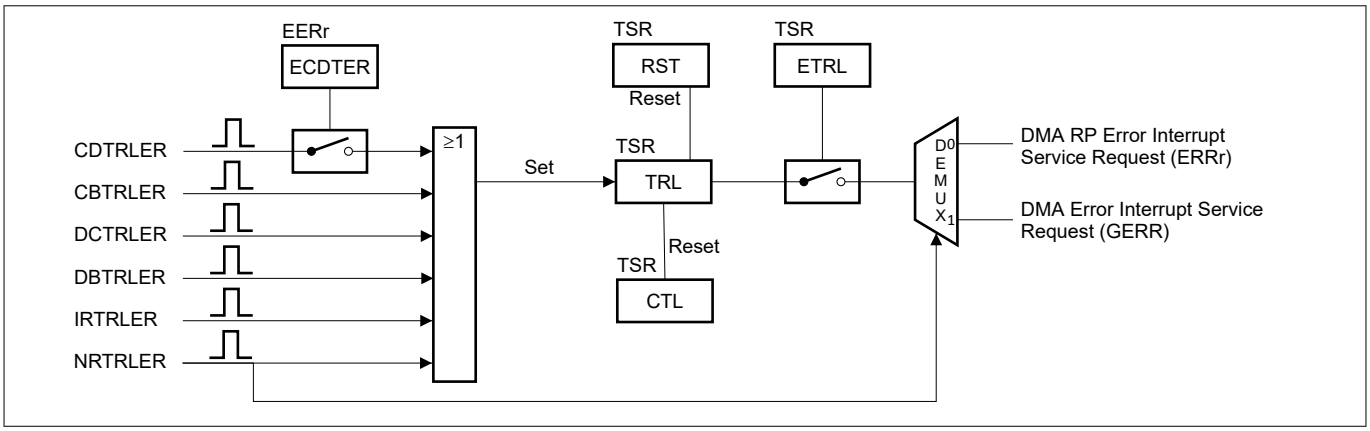

Figure 126 DMA channel transaction request lost interrupt service request

For error condition NRTRLER, the DMA sets the DMA channel TRL bit (TSRc.TRL = 1_B) and if the DMA channel enable TRL bit is set (TSRc.ETRL = 1_B), the DMA triggers a DMA error interrupt service request.

An error handler shall interrogate the DMA channels to identify the source of the error. Software may clear TSRc.TRL by setting the DMA channel TSRc.CTL or TSRc.RST.

Related information

DMA channel TRL error interrupt service request on page 1276

9.3.8 Power modes

The DMA disable status bit (CLC.DISS) reports the state of the DMA module clock.

After the assertion of an application reset, the DMA module clock is disabled (CLC.DISS = 1_B).

9.3.8.1 Sleep mode

The DMA enters sleep mode as follows:

- If the sleep mode enable control bit is enabled (CLC.EDIS = 0_B) and the system sleep request control (REQSLP_SLEEP) is activated, the DMA enters sleep mode when the ME(s) have completed any ongoing DMA transfers and any DMA channel interrupts, DMA RP error interrupts or DMA error interrupts have been sent to the Interrupt Router
- If the sleep mode enable control bit is enabled (CLC.EDIS = 0_B) and the system shutdown request control (SHSEQREQx) is activated, the DMA enters sleep mode when the ME(s) have completed any pending DMA transfers and any DMA channel, DMA RP error or DMA error interrupts have been sent to the Interrupt Router
- If software writes a DMA disable request (CLC.DISR = 1_B), the DMA enters sleep mode when the ME(s) have completed any pending DMA transfers and any DMA channel, DMA RP error or DMA error interrupts have been sent to the Interrupt Router

***Note**: Software should ensure that CLC.EDIS is set to 0_B as described above if the DMA should react to the system shutdown request.*

If DMA sleep mode is requested as in any of the conditions above:

- DMA SFRs
  - Software accesses to the CLC, OTSS, ID, TIMEOCS, PROTSE, PROTCSE, PROTRPr and ACCENRPr SFRs are executed
  - Software accesses to the other DMA registers result in a bus error
- DMARAM
  - Software accesses the to the DMARAM results in a bus error

If the DMA is in sleep mode:

- The DMA disables the DMA module clock to minimize DMA power consumption
- DMA SFRs
  - Software accesses to the CLC, OTSS, ID, TIMEOCS, PROTSE, PROTCSE, PROTRPr and ACCENRPr SFRs are executed
  - Software accesses to the other DMA registers result in a bus error
- DMARAM
  - Software accesses the to the DMARAM results in a bus error

If the system sleep request control and the system shutdown request control are deactivated and software clears the DMA disable request (CLC.DISR = 1_B):

- The DMA enables the DMA module clock
- The DMA resumes the servicing of DMA requests

9.4 Registers

9.4.1 Register overview - access mode glossary

Table 643 Register overview - access mode glossary

Keyword	Description
CSE	Access protection using PROT register PROTCSE.
RPr (r=0-15)	Access protection using PROT register PROTRPr.
SE	Access protection using PROT register PROTSE.
APU-Pr (r=0-15)	Protection group consisting of registers ACCENRPrWRA, ACCENRPrWRB, ACCENRPrRDA, ACCENRPrRDB, ACCENRPrVM, ACCENRPrPRS.
Pr	Access protection using *APU-Pr* registers.
U	No access restrictions.
BE	Always returns a Bus Error.
PROT	Access restrictions as defined in the PROT register access rules.
32	Access only when using 32-bit width.
OEN	Access only when OCDS is enabled.
M	Indicates a module specific access condition. Refer to the register description for details of the specific access condition.

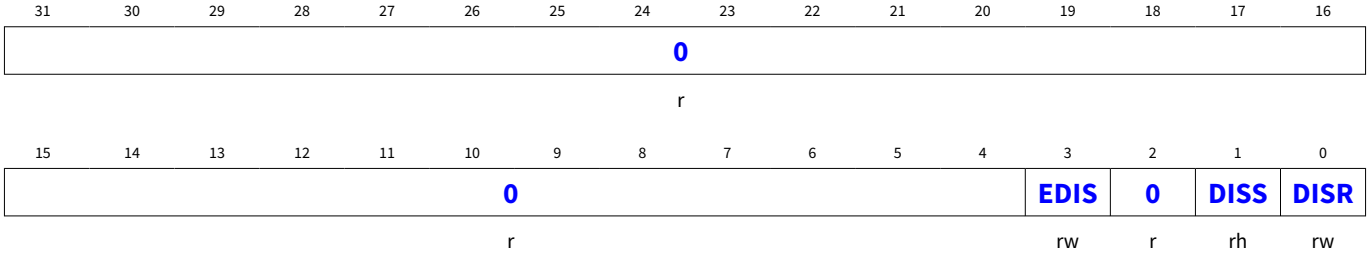
9.4.3 Clock control register

The clock control register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep request control signal (REQSLP_SLEEP).

CLC Offset address: 0000_H

Clock control register Application Reset value: $0000\ 0001_H$



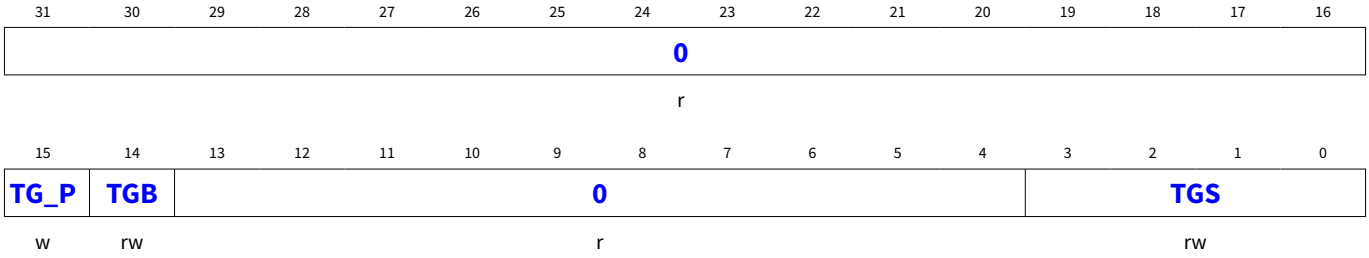
Field	Bits	Type	Description
DISR	0	rw	**Module disable request bit** Used for enable and disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module disable status bit** When CLC.DISS=1_B, registers CLC, OTSS, ID, TIMEOCS, PROTSE, PROTCSE, PROTRPr and ACCENRPr are still accessible. Accesses to other DMA registers are not executed and will result in a bus error. 0_B Module clock is enabled 1_B Module is not clocked
EDIS	3	rw	**Sleep mode enable control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep request control signal (REQSLP_SLEEP)
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

9.4.4 OCDS trigger set select

The OTSS register controls the selection of the OCDS Trigger Bus (OTGB).

OTSS Offset address: 0004_H

OCDS trigger set select Debug Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TGS	3:0	rw	**Trigger set for OTGB0 or OTGB1** 0_H No trigger set output 1_H Trigger set 1 2_H Trigger set 2 3_H Reserved … 7_H Reserved 8_H Trigger set 8 9_H Trigger set 9 A_H Trigger set 10 B_H Trigger set 11 C_H Trigger set 12 D_H Trigger set 13 E_H Trigger set 14 F_H Trigger set 15
TGB	14	rw	**OTGB0 or OTGB1 bus select** 0_B Trigger set is output on OTGB0 1_B Trigger set is output on OTGB1
TG_P	15	w	**TGS, TGB write protection** TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
0	13:4, 31:16	r	**Reserved** Read as 0; should be written with 0.

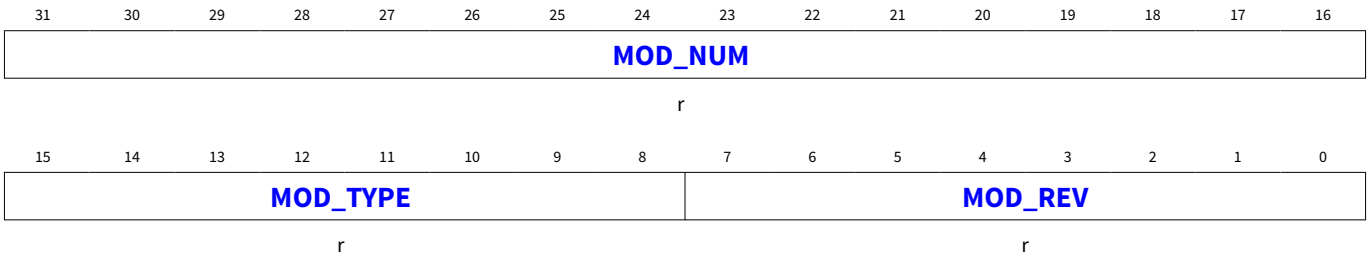
Table 645 Access mode restrictions of OTSS sorted by descending priority

Mode name	Access mode		Description
write 1 to .**TG_P**	rw	TGB, TGS	Set TG_P during write access
(default)	r	TGB, TGS	

9.4.5 Module identification register

ID Offset address: 0008_H

Module identification register PowerOn Reset value: $0087\ C005_H$



Field	Bits	Type	Description
MOD_REV	7:0	r	**Module revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module number** Indicates the module identification number (0087_H = DMA).

9.4.6 PROT register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock and unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 0024_H

PROT register safe endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

9.4.7 PROT register cyber-security endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

This register defines the cyber-security master that coordinates with the PROTSE owner to configure the DMA resource partitions.

PROTCSE Offset address: 0028_H

PROT register cyber-security endinit Application Reset value: $4C00\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r				rw	rw			r				w	rwh		

Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
CSTAGOFF	10:8	rw	**CS asset tag offset** When CSEN is set, defines the tag offset that is reserved for the CyberSecurity master. As long as CSEN remains set, the hardware ensures that resource partitions configured as a non-CS asset cannot re-use the CS asset tag offset.
CSEN	11	rw	**Enable for CSTAGOFF reservation** 0_B CSTAGOFF is ignored. All tag offsets may be used in any resource partition. 1_B Tag offset in CSTAGOFF is reserved for use in RPs which are CS assets.

(table continues...)

(continued)

Field	Bits	Type	Description
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition

rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COUNT															
rwh															

Field	Bits	Type	Description
COUNT	31:0	rwh	**Timestamp count** The count value used during the appendage of DMA timestamps.

9.4.9 DMA error status register

The error status register indicates if the DMA controller could not service a DMA request that cannot be attributed to a single RP. The channel number of the channel that last triggered an error is recorded in ERRSR.LEC.

ERRSR Offset address: 0084_H

DMA error status register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0													**OVFL ER**	**0**	**NRT RLER**
r													rh	r	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0									**LEC**						
r									rh						

Field	Bits	Type	Description
LEC	6:0	rh	**DMA last error channel** This bit field indicates the DMA channel number of the last DMA channel generating an error reported in the ERRSR register.
NRTRLER	16	rh	**No resource partition TRL error** This bit is set when a DMA request is detected and the DMA channel has not been assigned to a resource partition (HRRc.HRPV is set to 0_B). 0_B No error occurred. 1_B A TRL error has occurred.
OVFLER	18	rh	**DMA error status overflow** This bit is set whenever the DMA error status overflows - that is, when any previously reported DMA error status remains set in the ERRSR register and a new DMA error is reported. 0_B No error overflow occurred. 1_B An error overflow occurred.
0	15:7, 17, 31:19	r	**Reserved** Read as 0; should be written with 0.

9.4.10 DMA clear error register

The clear error register contains bits to clear the corresponding DMA error flags.

CLRE Offset address: 0088_H

DMA clear error register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0															
r															

Field	Bits	Type	Description
CNRTRLER	16	w	**Clear no resource partition TRL error** 0_B No action 1_B Clear DMA no resource partition TRL error flag ERRSR.NRTRLER.
COVFLER	18	w	**Clear DMA error status overflow** 0_B No action 1_B Clear DMA error status overflow flag ERRSR.OVFLER.
0	15:0, 17, 31:19	r	**Reserved** Read as 0; should be written with 0.

9.4.11 DMA time OCDS control and status register

The DMA time OCDS control and status register (TIMEOCS) controls the DMA timestamp behavior in suspend mode. When OCDS is disabled the TIMEOCS suspend control is ineffective.

TIMEOCS Offset address: $008C_H$

DMA time OCDS control and status register Debug Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r		rh	w	rw				r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															
r															

Field	Bits	Type	Description
SUS	27:24	rw	**OCDS suspend control** Controls the sensitivity of the DMA timestamp counter to the OCDS suspend signal 0_H Will not suspend 1_H Reserved, do not use this combination 2_H 32-bit DMA timestamp counter will be stopped **others,** Reserved, do not use this combination
SUS_P	28	w	**SUS write protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend state** 0_B DMA timestamp counter is not (yet) suspended 1_B DMA timestamp counter is suspended
0	23:0, 31:30	r	**Reserved** Read as 0; should be written with 0.

Table 648 Access mode restrictions of TIMEOCS sorted by descending priority

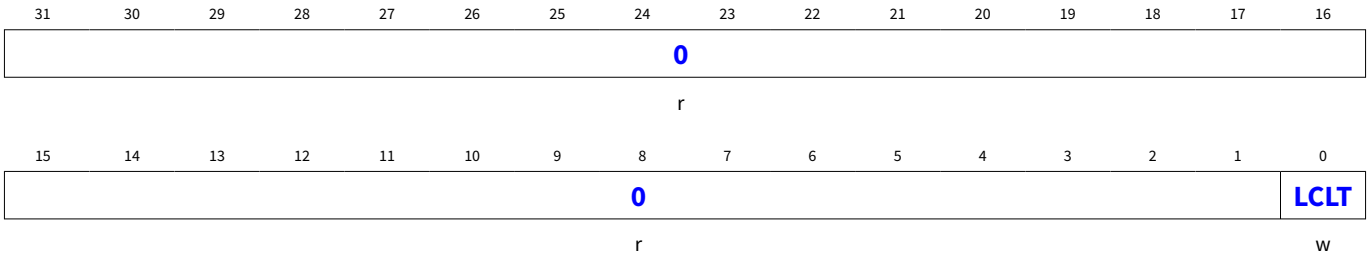
Mode name	Access mode		Description
write 1 to .**SUS_P**	rw	SUS	
(default)	r	SUS	

9.4.12 DMA LCL test register

Provides the capability for software to inject a fault condition into the comparators of each lockstep comparator logic block. The implementation should generate a single cycle fault each time the bit is written with '1'.

LCLTEST Offset address: 0090_H

DMA LCL test register Application Reset value: $0000\ 0000_H$



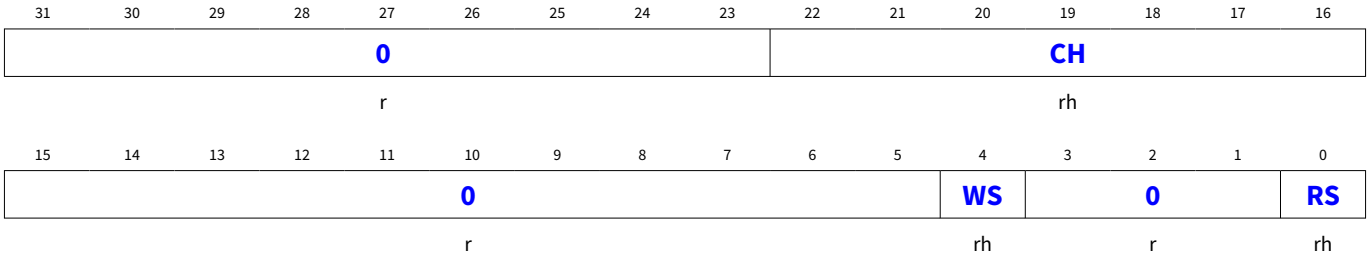
Field	Bits	Type	Description
LCLT	0	w	**LCL lockstep test** Fault injection for LCL. Reads as zero. 0_B No action 1_B Inject single fault in the LCL
0	31:1	r	**Reserved** Read as 0; should be written with 0.

9.4.13 ME m status register

The ME status register holds status information about the DMA transaction handled by the ME.

MEmSR (m=0-1) Offset address: $0410_H+m*200_H$

ME m status register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RS	0	rh	**ME read status** 0_B ME is not performing a DMA read move. 1_B ME is performing a DMA read move.
WS	4	rh	**ME write status** 0_B ME is not performing a DMA write move. 1_B ME is performing a DMA write move.
CH	22:16	rh	**ME active channel** Indicates the number of the DMA channel currently processed by the ME.
0	3:1, 15:5, 31:23	r	**Reserved** Read as 0; should be written with 0.

9.4.14 ME m channel read data CRC register

The read only DMA active channel read data CRC register will store one polynomial calculation during each DMA read move provided that there is no retry or error condition flagged.

MEmRDCRC (m=0-1) Offset address: $0460_H+m*200_H$

ME m channel read data CRC register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDCRC															
rh															

Field	Bits	Type	Description
RDCRC	31:0	rh	**Read data CRC** Active DMA channel read data CRC32 ethernet polynomial checksum.

9.4.15 ME m channel source and destination address CRC register

The read only DMA active channel source and destination address CRC Register will store one polynomial calculation during each DMA read and each DMA write move provided there is no retry or error condition flagged.

MEmSDCRC (m=0-1) Offset address: $0464_H+m*200_H$

ME m channel source and destination address CRC register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SDCRC															
rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SDCRC															
rh															

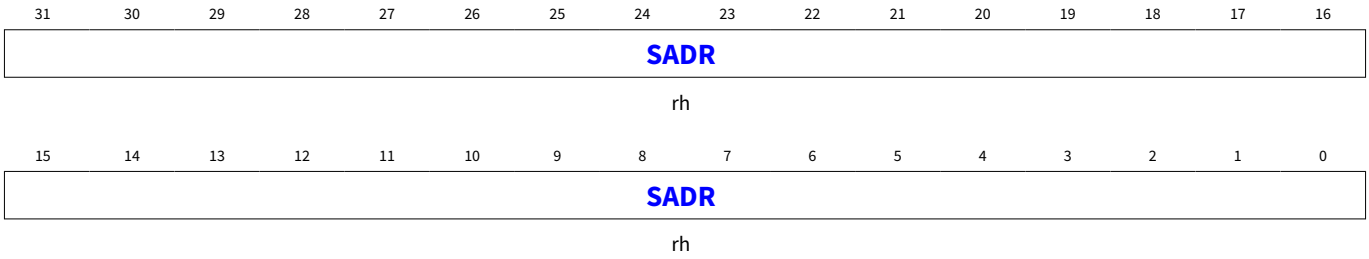
Field	Bits	Type	Description
SDCRC	31:0	rh	**Source and destination address CRC** Active DMA channel source and destination address CRC32 ethernet polynomial checksum.

9.4.16 ME m channel source address register

The read only DMA active channel source address register holds the 32-bit source address. If a DMA channel is active, MEmSADR is updated continuously and shows the actual source address used for DMA read moves.

MEmSADR (m=0-1) Offset address: $0468_H+m*200_H$

ME m channel source address register Application Reset value: $0000\ 0000_H$



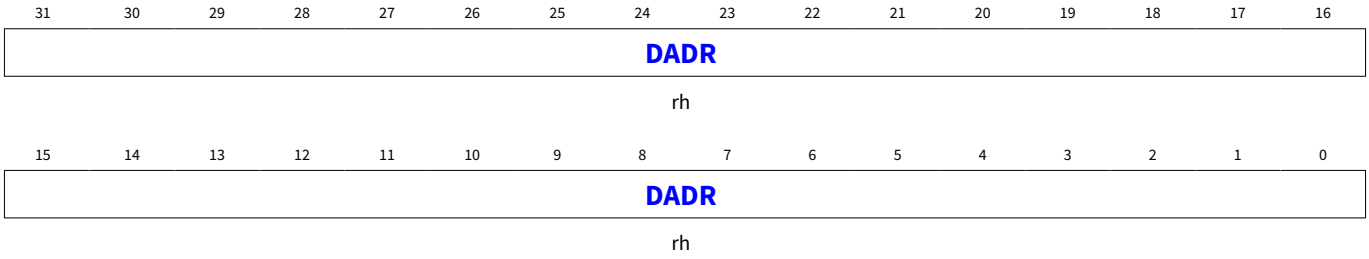
Field	Bits	Type	Description
SADR	31:0	rh	**Source address** Active DMA channel 32-bit source address used for DMA read moves.

9.4.17 ME m channel destination address register

The read only DMA active channel destination address register holds the 32-bit destination address. If a DMA channel is active, MEmDADR is updated continuously and shows the actual destination address used for DMA write moves.

MEmDADR (m=0-1) Offset address: $046C_H+m*200_H$

ME m channel destination address register Application Reset value: $0000\ 0000_H$



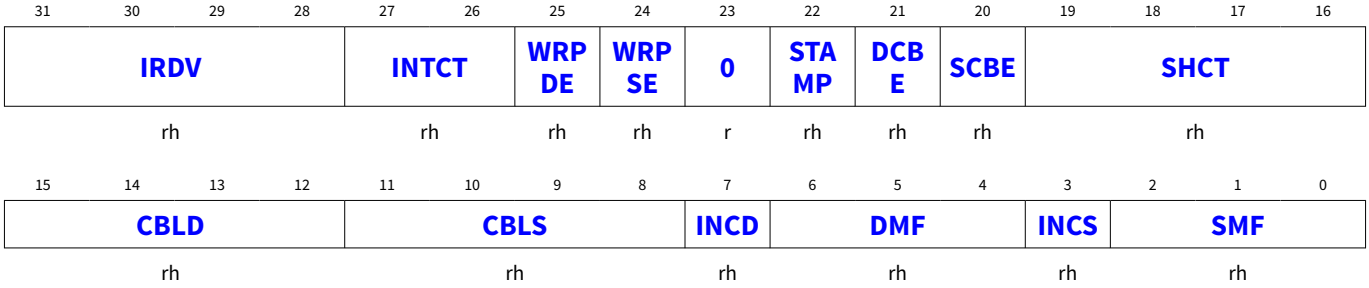
Field	Bits	Type	Description
DADR	31:0	rh	**Destination address** Active DMA channel 32-bit destination address used for DMA write moves.

9.4.18 ME m channel address and interrupt control register

The read only DMA active channel address and interrupt control register shows the address update and interrupt configuration of the active DMA channel.

MEmADICR (m=0-1) Offset address: $0470_H+m*200_H$

ME m channel address and interrupt control register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SMF	2:0	rh	**Source address modification factor** Active DMA channel source address modification factor.
INCS	3	rh	**Increment of source address** Active DMA channel increment of source address control.
DMF	6:4	rh	**Destination address modification factor** Active DMA channel destination address modification factor.
INCD	7	rh	**Increment of destination address** Active DMA channel increment of destination address control.
CBLS	11:8	rh	**Source circular buffer length** Active DMA channel circular source buffer control.
CBLD	15:12	rh	**Destination circular buffer length** Active DMA channel circular destination buffer control.
SHCT	19:16	rh	**Shadow control** Active DMA channel control of shadow address register function.
SCBE	20	rh	**Source circular buffer enable** Active DMA channel circular source buffer enable or disable.
DCBE	21	rh	**Destination circular buffer enable** Active DMA channel circular destination buffer enable or disable.
STAMP	22	rh	**Timestamp** Active DMA channel control to enable the appendage of a timestamp after the end of the last DMA move during a DMA transaction.
WRPSE	24	rh	**Wrap source enable** Active DMA channel source buffer interrupt trigger enable or disable.
WRPDE	25	rh	**Wrap destination enable** Active DMA channel destination buffer interrupt trigger enable or disable.
INTCT	27:26	rh	**Interrupt control** Active DMA channel interrupt service request control.
IRDV	31:28	rh	**Interrupt raise detect value** Active DMA channel control of the threshold limit of of DMA channel CHSR.TCOUNT for triggering a channel interrupt service request.
0	23	r	**Reserved** Read as 0; should be written with 0.

9.4.19 ME m channel control register

The read only DMA active channel channel control register shows the configuration and control bits of the active DMA channel.

MEmCHCR (m=0-1) Offset address: $0474_H+m*200_H$

ME m channel control register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		TREL													
r		rh													

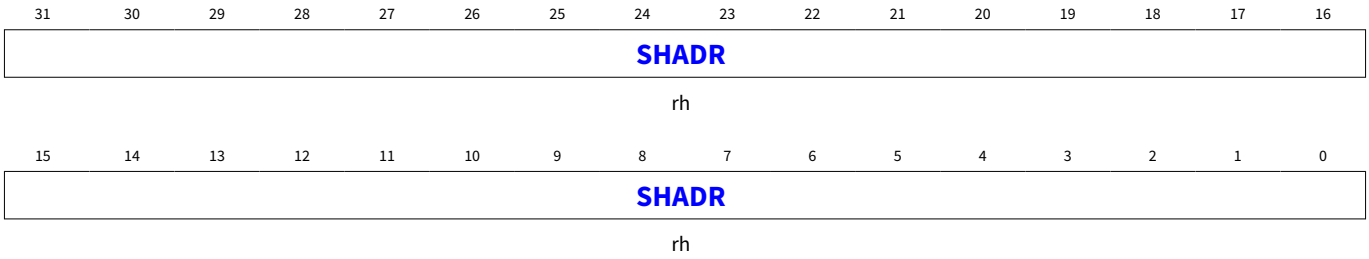
Field	Bits	Type	Description
TREL	13:0	rh	**Transfer reload value** Active DMA channel transfer reload value.
BLKM	18:16	rh	**Block mode** Active DMA channel block mode.
RROAT	19	rh	**Reset request only after transaction** Active DMA channel reset request only after transaction.
CHMODE	20	rh	**Channel operation mode** Active DMA channel channel operation mode.
CHDW	23:21	rh	**Channel data width** Active DMA channel DMA move channel data width.
PATSEL	26:24	rh	**Pattern select** Active DMA channel pattern select control.
SWAP	27	rh	**Swap data CRC byte order** Active DMA channel swap data CRC byte order.
PRSEL	28	rh	**Peripheral request select** Active DMA channel peripheral request select.
0	15:14, 31:29	r	**Reserved** Read as 0; should be written with 0.

9.4.20 ME m channel shadow address register

The read only DMA active channel shadow address register holds the 32-bit shadow address.

MEmSHADR (m=0-1) Offset address: $0478_H+m*200_H$

ME m channel shadow address register Application Reset value: $0000\ 0000_H$



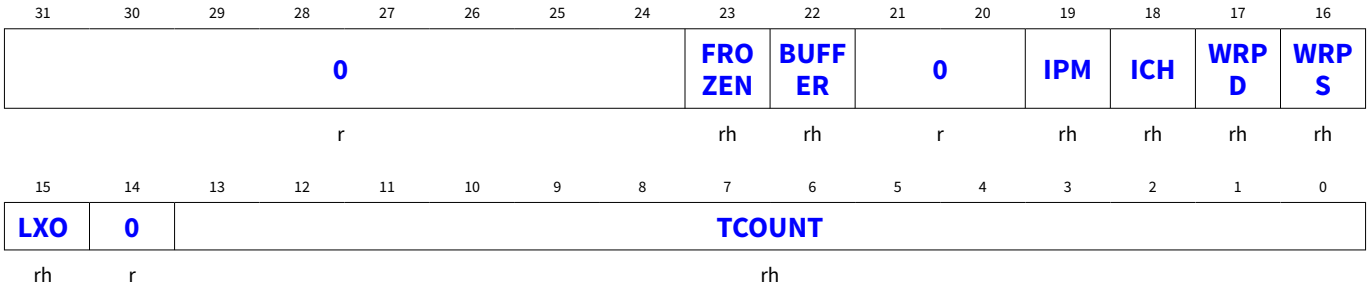
Field	Bits	Type	Description
SHADR	31:0	rh	**Shadowed address** This bit field holds the 32-bit shadow address of the active DMA channel. The function of the shadow address is set by the shadow control settings.

9.4.21 ME m channel status register

The read only DMA active channel channel status register contains the current transfer count, pattern detection compare result and the status of traffic management interrupt triggers.

MEmCHSR (m=0-1) Offset address: $047C_H+m*200_H$

ME m channel status register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TCOUNT	13:0	rh	**Transfer count status** Active DMA channel count of the number of DMA transfers. TCOUNT is loaded with the DMA channel value of CHCFGRc.TREL when TSRc.CH becomes set (and TCOUNT = 0). After each DMA transfer, TCOUNT is decremented by 1.
LXO	15	rh	**Old value of pattern detection** Active DMA channel compare result of a pattern compare operation when 8-bit or 16-bit data width is selected.
WRPS	16	rh	**Wrap source buffer** Active DMA channel wrap source buffer status bit.
WRPD	17	rh	**Wrap destination buffer** Active DMA channel wrap destination buffer status bit.
ICH	18	rh	**Interrupt from channel** Active DMA channel detection of channel interrupt service request.

(table continues...)

(continued)

Field	Bits	Type	Description
IPM	19	rh	**Pattern detection from channel** Active DMA channel detection of pattern match interrupt service request.
BUFFER	22	rh	**DMA double buffering active buffer** Active DMA channel DMA double buffering active buffer status bit. 0_B Buffer 0 read or filled by DMA. 1_B Buffer 1 read or filled by DMA.
FROZEN	23	rh	**DMA double buffering frozen buffer** Active DMA channel DMA double buffering frozen buffer status bit.
0	14, 21:20, 31:24	r	**Reserved** Read as 0; should be written with 0.

9.4.22 RP r write access enable register A

This register defines which master agent function TAG identifier (TAG-ID) encodings are enabled or disabled for write accesses to the access protected region.

ACCENRPrWRA (r=0-15) Offset address: 1000_H+r*80_H

RP r write access enable register A Application Reset value: $1000\ 0003_H$

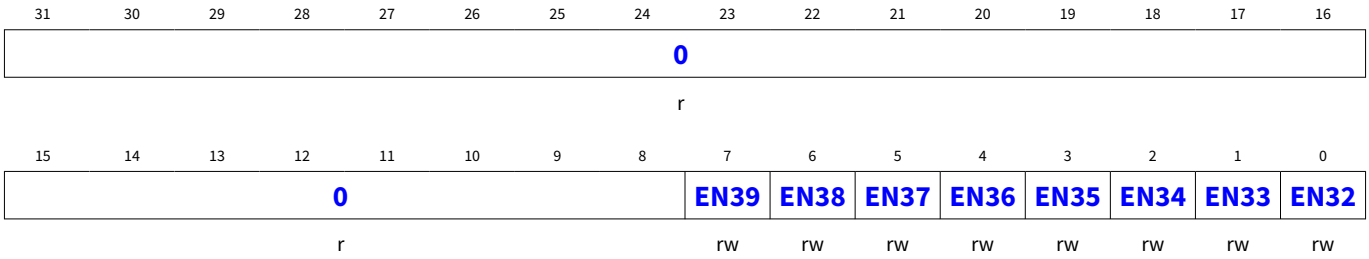
9.4.23 RP r write access enable register B

This register defines which master agent function TAG identifier (TAG-ID) encodings are enabled or disabled for write accesses to the access protected region.

ACCENRPrWRB (r=0-15) Offset address: 1004_H+r*80_H

RP r write access enable register B Application Reset value: $0000\ 0000_H$



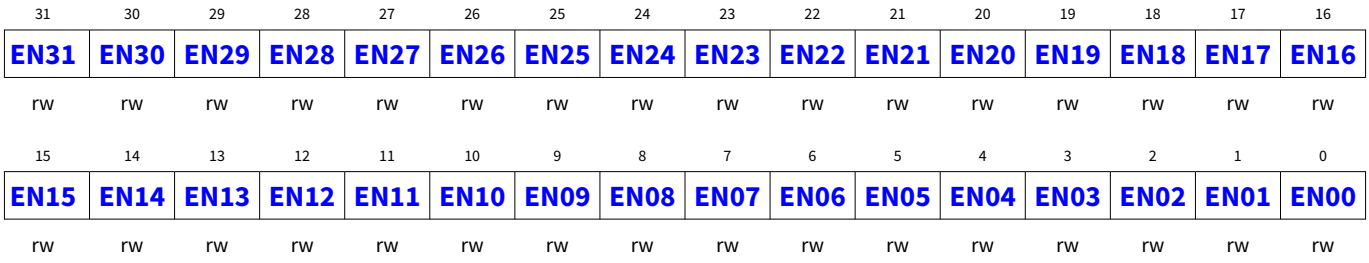
Field	Bits	Type	Description
ENq (q=32-39)	q-32	rw	**Write access enable for TAG-ID q** This bit enables write access to the access protected region for transactions with the TAG-ID q. 0_B Disabled for write access 1_B Enabled for write access
0	31:8	r	**Reserved** Read as 0; should be written with 0.

9.4.24 RP r read access enable register A

This register defines which master agent function TAG identifier (TAG-ID) encodings are enabled or disabled for read accesses to the access protected region.

ACCENRPrRDA (r=0-15) Offset address: 1008_H+r*80_H

RP r read access enable register A Application Reset value: FFFF $FFFF_H$



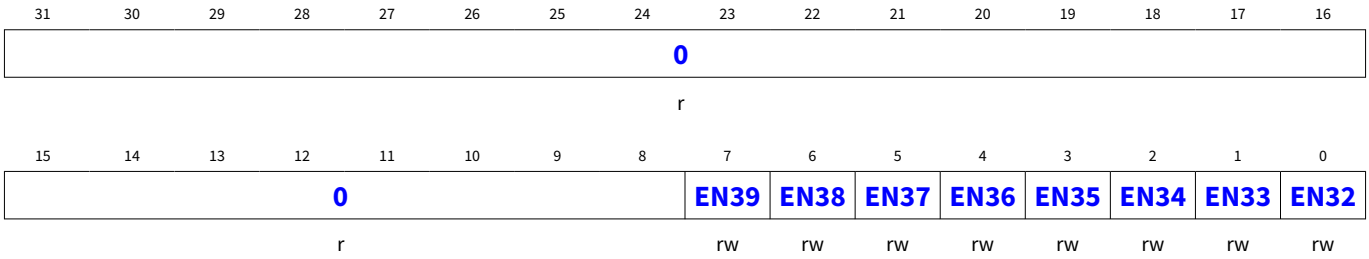
Field	Bits	Type	Description
ENq (q=00-31)	q	rw	**Read access enable for TAG-ID q** This bit enables read access to the access protected region for transactions with the TAG-ID q. 0_B Disabled for read access 1_B Enabled for read access

9.4.25 RP r read access enable register B

This register defines which master agent function TAG identifier (TAG-ID) encodings are enabled or disabled for read accesses to the access protected region.

ACCENRPrRDB (r=0-15) Offset address: $100C_H+r*80_H$

RP r read access enable register B Application Reset value: 0000 $00FF_H$



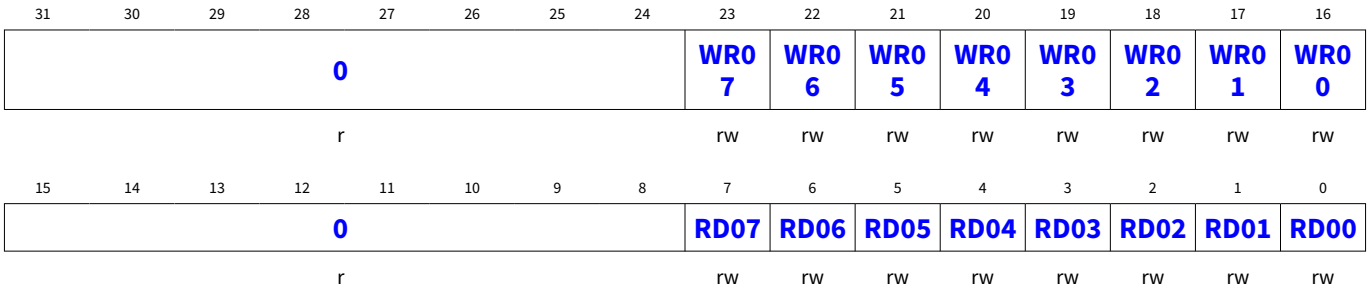
Field	Bits	Type	Description
ENq (q=32-39)	q-32	rw	**Read access enable for TAG-ID q** This bit enables read access to the access protected region for transactions with the TAG-ID q. 0_B Disabled for read access 1_B Enabled for read access
0	31:8	r	**Reserved** Read as 0; should be written with 0.

9.4.26 RP r VM access enable register

This register defines which virtual machine encodings are enabled or disabled for accesses to the access protected region. There is one RDx and WRx bit for each VMx.

ACCENRPrVM (r=0-15) Offset address: 1010_H+r*80_H

RP r VM access enable register Application Reset value: $00FF\ 00FF_H$



Field	Bits	Type	Description
RDq (q=00-07)	q	rw	**Read access enable for VM ID q** This bit enables read access to the access protected region for transactions with the VM ID q. 0_B Disabled for read access 1_B Enabled for read access
WRq (q=00-07)	q+16	rw	**Write access enable for VM ID q** This bit enables write access to the access protected region for transactions with the VM ID q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

9.4.27 RP r PRS access enable register

This register defines which protection register set encodings are enabled or disabled for accesses to the access protected region. There is one RDx and WRx bit for each PRSx.

ACCENRPrPRS (r=0-15) Offset address: 1014_H+r*80_H

RP r PRS access enable register Application Reset value: $00FF\ 00FF_H$

WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

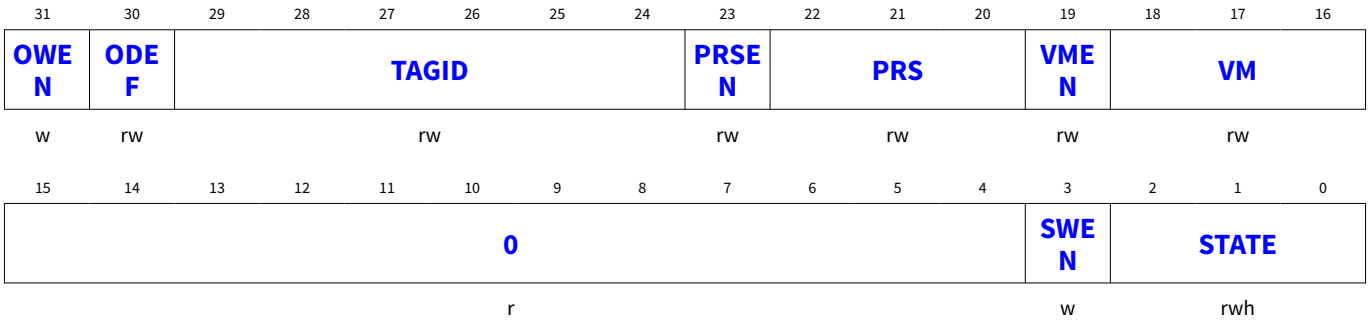
9.4.28 PROT register RP r

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

This register provides assignment and write protection to the RP registers as well as the channel registers for channels assigned to the RP. The RP PROT owner can assign or deassign channels to that RP, set up the APU for the channels in the RP etc.

PROTRPr (r=0-15) Offset address: 1020_H+r*80_H

PROT register RP r Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 649 Access mode restrictions of PROTRPr (r=0-15) sorted by descending priority

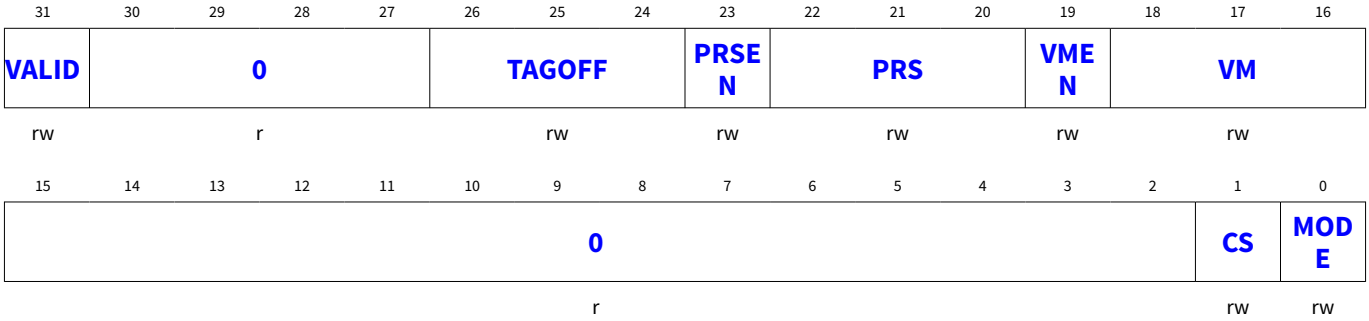
Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

9.4.29 RP r mode register

The mode register defines the attributes used by the DMA system interconnect master interfaces when a channel in the RP accesses the system interconnect. See section "Resource partition configuration" for details of the module specific access protection rules for this register.

MODEr (r=0-15) Offset address: 1030_H+r*80_H

RP r mode register Application Reset value: $0000\ 0001_H$



Field	Bits	Type	Description
MODE	0	rw	**Resource partition supervisor mode** 0_B System interconnect master interface accesses system interconnect in user mode. 1_B System interconnect master interface accesses system interconnect in supervisor mode.

(table continues...)

(continued)

Field	Bits	Type	Description
CS	1	rw	**Cyber-security assignment** 0_B Resource partition is marked as a non-CS RP. 1_B Resource partition is marked as a CS RP.
VM	18:16	rw	**Virtual machine information**
VMEN	19	rw	**Virtual machine enable** 0_B **Disable**: VM disabled 1_B **Enable**: VM enabled
PRS	22:20	rw	**Protection set information**
PRSEN	23	rw	**Protection set enable** 0_B **Disable**: PRS disabled 1_B **Enable**: PRS enabled
TAGOFF	26:24	rw	**Tag offset** Selection of TAG-ID to be used by DMA channels assigned to this RP when accessing the system interconnect
VALID	31	rw	**Resource partition valid** 0_B Resource partition is disabled. 1_B Resource partition is enabled.
0	15:2, 30:27	r	**Reserved** Read as 0; should be written with 0.

9.4.30 RP r pattern read register 0

The pattern read register 0 stores the pattern data (mask and compare bits) to be processed by the pattern compare logic.

PRRAr (r=0-15) Offset address: 1038_H+r*80_H

RP r pattern read register 0 Application Reset value: $0000\ 0000_H$

r															

Field	Bits	Type	Description
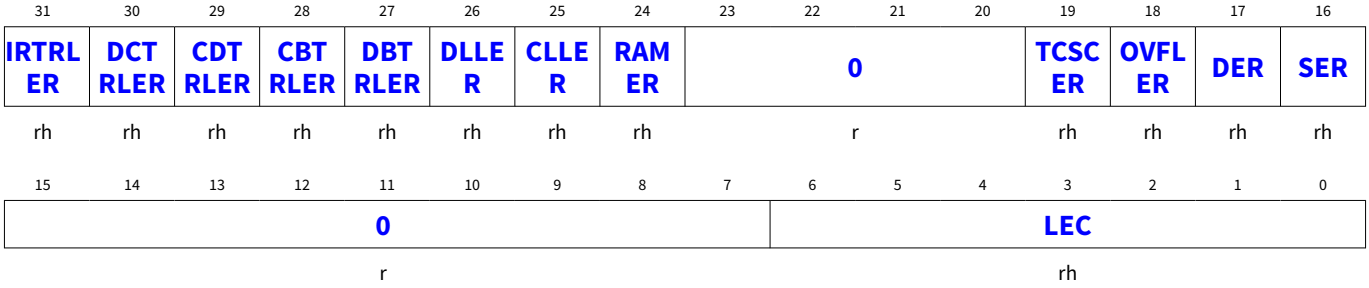
ESER	16	rw	**Enable RP source error** This bit enables the generation of a RP source error interrupt. 0_B RP source error interrupt is disabled. 1_B RP source error interrupt is enabled.
EDER	17	rw	**Enable RP destination error** This bit enables the generation of a RP destination error interrupt. 0_B RP destination error interrupt is disabled. 1_B RP destination error interrupt is enabled.
ELER	26	rw	**Enable RP DMA linked list error** This bit enables the generation of a RP DMA linked list error interrupt. 0_B RP DMA linked list error interrupt is disabled. 1_B RP DMA linked list error interrupt is enabled.
ECDTER	29	rw	**Enable RP channel disabled TRL error** This bit enables the generation of a RP channel disabled TRL error. 0_B RP channel disabled TRL error is disabled. 1_B RP channel disabled TRL error is enabled.
0	15:0, 25:18, 28:27, 31:30	r	**Reserved** Read as 0; should be written with 0.

9.4.34 RP r error status register

The error status register indicates if the DMA controller could not service a DMA request in a particular RP. The channel number of the channel that last triggered an error is recorded in ERRSRr.LEC.

ERRSRr (r=0-15) Offset address: 1048_H+r*80_H

RP r error status register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
LEC	6:0	rh	**RP last error channel** This bit field indicates the DMA channel number of the last DMA channel in the RP generating an error reported in the ERRSRr register.
SER	16	rh	**RP source error** This bit is set whenever an RP error occurs during a source (read) move of a DMA transfer, or a request cannot be serviced due to the access protection. 0_B No RP source error has occurred. 1_B RP source error has occurred.
DER	17	rh	**RP destination error** This bit is set whenever an RP error occurs during a destination (write) move of a DMA transfer, or a request cannot be serviced due to the access protection. 0_B No RP destination error has occurred. 1_B RP destination error has occurred.
OVFLER	18	rh	**RP error status overflow** This bit is set whenever the RP error status overflows - that is, when any previously reported RP error status remains set in the ERRSRr register and a new RP error is reported. 0_B No error overflow occurred. 1_B An error overflow occurred.
TCSCER	19	rh	**RP TCS configuration error** This bit is set when a TCS configuration error is detected as follows: • The SHADRc register is written to when the channel is in DMA shadow operation read only mode. 0_B No RP TCS configuration error has occurred. 1_B RP TCS configuration error has occurred.
RAMER	24	rh	**RP RAM error** This bit is set whenever an RP error occurs during the loading of a TCS from the DMARAM to the ME channel registers. 0_B No error occurred. 1_B An error occurred during the load of a TCS.

(table continues...)

(continued)

Field	Bits	Type	Description
CLLER	25	rh	**RP checked linked list error** This bit is set when an RP error occurs during the comparison of a SDCRC checksum as part of a checked linked list operation. 0_B No error occurred. 1_B An error occurred during the SDCRC checksum comparison.
DLLER	26	rh	**RP DMA linked list error** This bit is set when an RP error occurs during a DMALL, ACCLL, CHKLL or CONLL operation when a new TCS is loaded from memory to overwrite the current TCS stored in the DMARAM. 0_B No error occurred. 1_B An error occurred during the loading of a new TCS.
DBTRLER	27	rh	**Double buffer TRL error** This bit is set when a DMA channel is configured for a double buffering operation and one of the following conditions occur. • The DMA channel is configured for software switch only AND the DMA transaction is completed before the DMA receives a software switch. • The DMA channel is configured for automatic hardware switch AND the DMA transaction is completed when CHCSRc.FROZEN is still . 0_B No error occurred. 1_B A TRL error has occurred.
CBTRLER	28	rh	**Channel busy TRL error** This bit is set when a DMA request is detected and the DMA channel TSRc.CH is set. 0_B No error occurred. 1_B A TRL error has occurred.
CDTRLER	29	rh	**Channel disabled TRL error** This bit is set when a DMA hardware request is detected and the DMA channel is disabled for hardware requests. 0_B No error occurred. 1_B A TRL error has occurred.
DCTRLER	30	rh	**Daisy chain TRL error** This bit is set when a DMA daisy chain request from the current channel attempts to trigger the next lower priority channel assigned to a different resource partition (the TRL event is processed on the current channel). 0_B No error occurred. 1_B A TRL error has occurred.
IRTRLER	31	rh	**Invalid resource partition TRL error** This bit is set when a DMA request is detected and the resource partition that the DMA channel is assigned to is not configured (MODEr.VALID is set to 0_B). 0_B No error occurred. 1_B A TRL error has occurred.

(table continues...)

(continued)

Field	Bits	Type	Description
0	15:7, 23:20	r	**Reserved** Read as 0; should be written with 0.

9.4.35 RP r clear error register

The clear error register contains bits to clear the corresponding RP error flags.

CLREr (r=0-15) Offset address: $104C_H+r*80_H$

RP r clear error register Application Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0											HRPV	HRP			
r											rw	rw			

Field	Bits	Type	Description
HRP	3:0	rw	**DMA channel resource partition assignment** 0_H Resource Partition 0 (RP0). 1_H Resource Partition 1 (RP1). 2_H Resource Partition 2 (RP2). 3_H Resource Partition 3 (RP3). 4_H Resource Partition 4 (RP4). 5_H Resource Partition 5 (RP5). 6_H Resource Partition 6 (RP6). 7_H Resource Partition 7 (RP7). 8_H Resource Partition 8 (RP8). 9_H Resource Partition 9 (RP9). A_H Resource Partition 10 (RP10). B_H Resource Partition 11 (RP11). C_H Resource Partition 12 (RP12). D_H Resource Partition 13 (RP13). E_H Resource Partition 14 (RP14). F_H Resource Partition 15 (RP15).
HRPV	4	rw	**DMA channel resource partition assignment valid** 0_B Channel is unassigned. Channel registers other than HRRc cannot be accessed. 1_B Channel is assigned to the resource partition specified in HRP. Channel registers are protected by the resource partition APU.
0	31:5	r	**Reserved** Read as 0; should be written with 0.

9.4.37 DMA channel c suspend enable register

The suspend enable register enables or disables soft suspend state capability. This register is write-protected by the PROTRP register in the RP to which the current channel is assigned.

SUSENRc (c=000-127) Offset address: $1A00_H$+c*4

DMA channel c suspend enable register Debug Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															SUSEN
r															rw

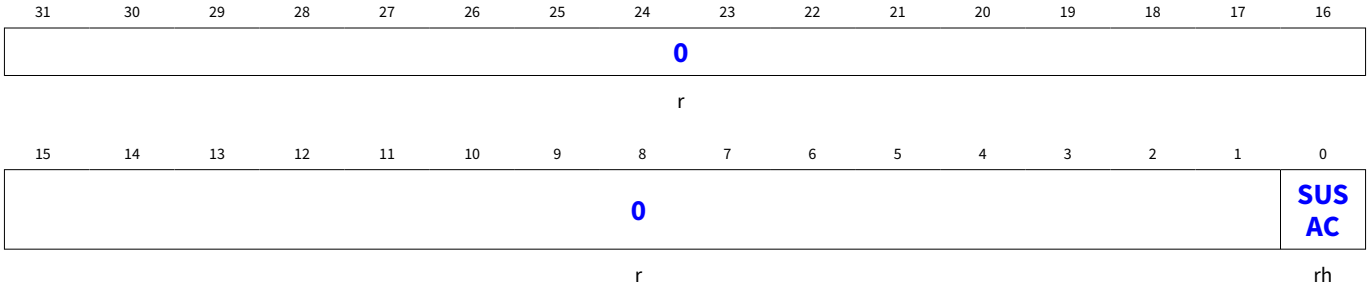
Field	Bits	Type	Description
SUSEN	0	rw	**Channel suspend enable for DMA channel** 0_B DMA channel is disabled for DMA channel suspend. The DMA channel does not react on an active suspend request signal (Suspend REQ). 1_B DMA channel is enabled for DMA channel suspend. If the suspend request signal (Suspend REQ) becomes active, a DMA transaction of the DMA channel is stopped after the current DMA transfer has completed.
0	31:1	r	**Reserved** Read as 0; should be written with 0.

9.4.38 DMA channel c suspend acknowledge register

The suspend acknowledge register indicates the DMA channel soft suspend status.

SUSACRc (c=000-127) Offset address: $1C00_H$+c*4

DMA channel c suspend acknowledge register Debug Reset value: $0000\ 0000_H$



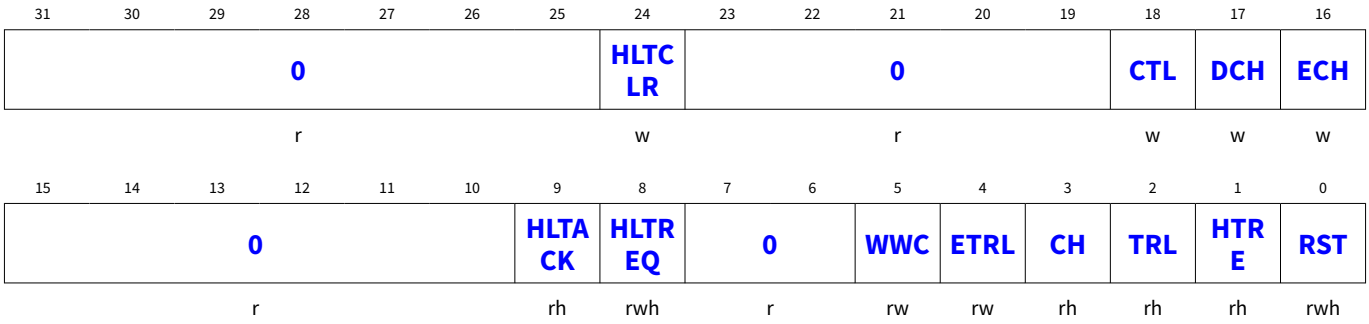
Field	Bits	Type	Description
SUSAC	0	rh	**DMA channel suspend state or frozen state active for DMA channel** Indicates when a DMA channel is in channel suspend state. 0_B DMA channel is not in channel suspend state, frozen state or internal actions are not completed after the channel suspend state or frozen state was requested. 1_B DMA channel is in channel suspend state or frozen state.
0	31:1	r	**Reserved** Read as 0; should be written with 0.

9.4.39 DMA channel c transaction state register

This register is protected by the APU in the RP to which the current channel is assigned.

TSRc (c=000-127) Offset address: $1E00_H$+c*4

DMA channel c transaction state register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RST	0	rwh	**DMA channel reset** The DMA channel reset bit is set by software (DMA channel TSRc.RST=1_B) and cleared by hardware when the DMA channel has been reset. 0_B After the application of a DMA channel reset, the DMA channel is in the DMA channel reset state. Software write to 0 has no effect. 1_B A DMA channel reset is pending.
HTRE	1	rh	**DMA channel hardware request enable** 0_B DMA hardware request is disabled for DMA channel. 1_B DMA hardware request is enabled for DMA channel.
TRL	2	rh	**DMA channel transaction request lost** This bit is set by hardware in response to a TRL event. This bit is reset by software clearing TRL (writing DMA channel TSRc.CTL = 1_B) or resetting the DMA channel (writing DMA channel TSRc.RST = 1_B). 0_B No TRL event has been detected for DMA channel. 1_B TRL event has been detected for DMA channel.
CH	3	rh	**DMA channel transaction request state** Indicates if a DMA request is pending. 0_B No DMA request is pending for DMA channel. 1_B DMA request is pending for DMA channel.
ETRL	4	rw	**Enable DMA channel transaction request lost interrupt** DMA channel control bit to enable the generation of an error interrupt service request when DMA channel TSRc.TRL is set. 0_B Interrupt generation for DMA channel TRL event is disabled. 1_B Interrupt generation for DMA channel TRL event is enabled.
WWC	5	rw	**Wait for write completion** DMA channel control bit to enable waiting for write completion signaling from the system interconnect before the generation of a DMA channel interrupt service request. 0_B **DISABLE**: DMA channel does not wait for write completion signaling 1_B **ENABLE**: DMA channel waits for write completion signaling

(table continues...)

(continued)

Field	Bits	Type	Description
HLTREQ	8	rwh	**DMA channel halt request** A DMA channel may be halted by software writing the DMA channel halt request bit (TSRc.HLTREQ = 1_B). Software can check when the halt request has completed by polling on the TSRc.HLTACK bit. 0_B No action. 1_B Halt request.
HLTACK	9	rh	**DMA channel halt acknowledge** 0_B DMA channel is not halted. 1_B DMA channel is halted.
ECH	16	w	**Enable DMA channel hardware transaction request** Setting DMA channel TSRc.ECH to 1_B enables DMA hardware requests (TSRc.HTRE = 1_B) for the DMA channel. Reading this bit returns a 0.
DCH	17	w	**Disable DMA channel hardware transaction request** Setting DMA channel TSRc.DCH to 1_B disables DMA hardware requests (TSRc.HTRE = 0_B) for the DMA channel. Reading this bit returns a 0.
CTL	18	w	**Clear DMA channel transaction request lost** Software clear of the DMA channel TRL status flag. Reading this bit returns a 0. 0_B No action. 1_B Clear DMA channel TRL flag (TSRc.TRL).
HLTCLR	24	w	**Clear DMA channel halt request and acknowledge** A DMA channel is released from the halt state by software writing the DMA channel halt clear bit (TSRc.HLTCLR = 1_B). The DMA operation is resumed. If the halt request is cleared before it is acknowledged then there is no effect on DMA operation. 0_B No action. 1_B Clear DMA channel halt request (TSRc.HLTREQ) and halt acknowledge (TSRc.HLTACK).
0	7:6, 15:10, 23:19, 31:25	r	**Reserved** Read as 0; should be written with 0.

9.4.40 DMA channel c read data CRC register

This register is protected by the APU in the RP to which the current channel is assigned.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		TREL													
r		rwh													

Field	Bits	Type	Description
TREL	13:0	rwh	**Transfer reload value** DMA channel TCS transfer reload value to control the number of DMA transfers in a DMA transaction. The 14-bit transfer count value is loaded into ME CHSR.TCOUNT at the start of a DMA transaction (when TSRc.CH becomes set and CHSR.TCOUNT = 0). A write to CHCFGRc.TREL during a running DMA transaction has no influence on the running DMA transaction. If CHCFGRc.TREL = 0 or if CHCFGRc.TREL = 1 then ME CHSR.TCOUNT will be loaded with 1 when a new DMA transaction is started (at least one DMA transfer must be executed per DMA transaction).
BLKM	18:16	rwh	**Block mode** Defines the number of DMA moves executed during one DMA transfer. 000_B One DMA transfer has 1 DMA move 001_B One DMA transfer has 2 DMA moves 010_B One DMA transfer has 4 DMA moves 011_B One DMA transfer has 8 DMA moves 100_B One DMA transfer has 16 DMA moves 101_B One DMA transfer has 3 DMA moves 110_B One DMA transfer has 5 DMA moves 111_B One DMA transfer has 9 DMA moves
RROAT	19	rwh	**Reset request only after transaction** DMA channel control bit to determine if the DMA request state flag (DMA channel TSRc.CH) is reset after each DMA transfer. 0_B DMA channel TSRc.CH is reset after the start of each DMA transfer. A DMA request is required for each DMA transfer. 1_B DMA channel TSRc.CH is reset when CHSR.TCOUNT = 0 and after the completion of the last DMA transfer (i.e. on completion of the DMA transaction). One DMA request starts a complete DMA transaction.
CHMODE	20	rwh	**Channel operation mode** DMA channel TCS control to determine TSRc.HTRE reset condition. 0_B **Single_Mode**: At the start of the last DMA trasfter of a DMA transaction, DMA channel is disabled for further hardware requests (TSRc.HTRE is reset by hardware). TSRc.HTRE must be set again by software for starting a new transaction. 1_B **Continuous_Mode**: TSRc.HTRE is not reset at the start of the last DMA transfer of a DMA transaction.

(table continues...)

(continued)

Field	Bits	Type	Description
CHDW	23:21	rwh	**Channel data width** DMA channel TCS data width for DMA read moves and DMA write moves. 000_B 8-bit data width for moves selected Single Data Transfer Byte (SDTB) 001_B 16-bit data width for moves selected Single Data Transfer Half-Word (SDTH) 010_B 32-bit data width for moves selected Single Data Transfer Word (SDTW) 011_B 64-bit data width transaction selected SRI: Single Data Transfer Double Word (SDTD) FPI: Block Transfer Request - 2 transfers (BTR2) 100_B 128-bit data width transaction selected SRI: Block Transfer Request - 2 transfers (BTR2) FPI: Block Transfer Request - 4 transfers (BTR4) 101_B 256-bit data width transaction selected SRI: Block Transfer Request - 4 transfers (BTR4) FPI: Block Transfer Request - 8 transfers (BTR8) 110_B 512-bit data width transaction selected SRI: Block Transfer Request - 8 transfers (BTR8) FPI: Not supported. 111_B Reserved.
PATSEL	26:24	rwh	**Pattern select** DMA channel TCS bit field to select the pattern detection operation (see functional description). If PATSEL[1:0] is not equal to 00_B then a pattern detection operation defined by the channel data width (CHDW) will be performed. PATSEL[2] selects the pattern read register. If a pattern match is detected then a DMA channel interrupt shall be triggered.
SWAP	27	rwh	**Swap data CRC byte order** DMA channel TCS swap data CRC byte order. 0_B Byte order is not swapped 1_B Byte order is swapped.
PRSEL	28	rwh	**Peripheral request select** DMA channel TCS control bit field to select the source of a DMA request. 0_B DMA hardware request selected. 1_B DMA daisy chain request selected.
0	15:14, 31:29	r	**Reserved** Read as 0; should be written with 0.

9.4.46 DMA channel c shadow address register

Field	Bits	Type	Description
TCOUNT	13:0	rh	**Transfer count** DMA channel status transfer count updated after DMARAM write back.
LXO	15	rh	**Old value of pattern detection match status** DMA channel status bit to store the result of a previous pattern detection operation when 8-bit or 16-bit data width is selected. 0_B The corresponding pattern compare operation did not find a pattern match during the previous DMA read move. 1_B The corresponding pattern compare operation found a pattern match during the previous DMA read move.

(table continues...)

(continued)

Field	Bits	Type	Description
WRPS	16	rh	**Wrap source buffer** Status bit indicates that a DMA channel has reached a wrap source buffer boundary. Bit is reset by software writing DMA channel CHCSRc.CWRP = 1_B or DMA channel reset TSRc.RST = 1_B. 0_B No wrap source buffer occurred. 1_B Wrap source buffer occurred.
WRPD	17	rh	**Wrap destination buffer** Status bit indicates that a DMA channel has reached a wrap destination buffer boundary. Bit is reset by software writing DMA channel CHCSRc.CWRP = 1_B or DMA channel reset TSRc.RST = 1_B. 0_B No wrap destination buffer occurred. 1_B Wrap destination buffer occurred.
ICH	18	rh	**Interrupt from channel** Status bit indicates when a channel interrupt has been raised (see also ADICRc.INTCT, ADICRc.IRDV). Bit is reset by software writing DMA channel CHCSRc.CICH = 1_B or by a DMA channel reset TSRc.RST = 1_B. 0_B An interrupt from channel has not been detected. 1_B An interrupt from channel has been detected.
IPM	19	rh	**Pattern detection from channel** Status bit indicates that a pattern match has been detected for the DMA channel when pattern detection is enabled. This bit is reset by software writing DMA channel CHCSRc.CICH = 1_B or DMA channel reset TSRc.RST = 1_B. 0_B A pattern match has not been detected. 1_B A pattern match has been detected.
BUFFER	22	rh	**DMA double buffering active buffer** During a DMA double buffering operation, the status bit indicates which buffer is read or filled. 0_B Buffer 0 read or filled by DMA. 1_B Buffer 1 read or filled by DMA.
FROZEN	23	rwh	**DMA double buffering frozen buffer** If a DMA channel is configured for double buffering operation, the FROZEN bit indicates that one of the buffers is frozen and available for processing by a cyclic software task. ***Note**: FROZEN bit shall only be set by the hardware and shall only be cleared by software.* 0_B Buffer is not frozen. 1_B Buffer is frozen.

(table continues...)

(continued)

Field	Bits	Type	Description
SWB	24	w	**DMA double buffering switch buffer** When DMA double buffering is configured, the control bit is used to re-direct data from one buffer to the other buffer. ***Note**: If a DMALL, ACCLL, CHKLL or CONLL operation is configured then SWB shall be 0_B.* 0_B No action. 1_B Switch from buffer.
CWRP	25	w	**Clear wrap buffer interrupt** Software clear of the DMA channel source and destination wrap buffer flags stored at CHCSRc.WRPS and CHCSRc.WRPD. If the DMA channel is active in an ME then clear ME bit-fields CHSR.WRPS and CHSR.WRPD. Reading this bit returns a 0. 0_B No action. 1_B Clear DMA channel bits CSR.WRPS and CSR.WRPD.
CICH	26	w	**Clear interrupt for DMA channel** Software clear of the DMA channel flags stored at CHCSRc.ICH and CHCSRc.IPM. If the DMA channel is active in a ME then clear ME bit fields CHSR.ICH and CHSR.IPM. Reading this bit returns a 0. 0_B No action. 1_B Clear DMA channel bits CSR.ICH and CSR.IPM.
SIT	27	w	**Set interrupt trigger for DMA channel** Reading this bit returns a 0. ***Note**: If a DMALL, ACCLL, CHKLL or CONLL operation is configured then SIT must be 0_B.* 0_B No action. 1_B DMA channel interrupt trigger will be activated.
SCH	31	w	**Set transaction request** Triggers a DMA software request when written with a 1_B. All other TCS registers (RDCRCRc, SDCRCRc, SADRc, DADRc, ADICRc, CHCFGRc, SHADRc) should be written with the required channel configuration before the DMA software request is triggered. Reading this bit returns a 0. 0_B No action. 1_B DMA software request initiated for DMA channel. When SCH is set, DMA channel TSRc.CH is set to indicate a DMA request is pending.
0	14, 21:20, 30:28	r	**Reserved** Read as 0; should be written with 0.

9.5 Debug information

This section describes the following topics:

- DMA channel suspend
- Software activation of DMA channel interrupt service requests
- Software activation of DMA RP error interrupt service requests
- OCDS trigger bus (OTGB) interface
- MCDS trace interface

9.5.1 DMA channel suspend

Two DMA channel registers control and report the channel suspend operation:

- The suspend enable register (SUSENRc) enables and disables DMA channel soft suspend state capability
- The suspend acknowledge register (SUSACRc) indicates the DMA channel soft suspend status

The On Chip Debug System (OCDS) is able to generate a DMA suspend request (Suspend REQ). When the suspend request becomes active, the DMA channel enters the suspend state where the DMA channel state is frozen to ensure that it can be analyzed by reading the DMA channel register contents. If a DMA channel is active then the current DMA transfer is completed before the DMA channel enters the suspend state. The DMA signals the suspend state status back to the OCDS through a suspend acknowledge (Suspend ACK) signal.

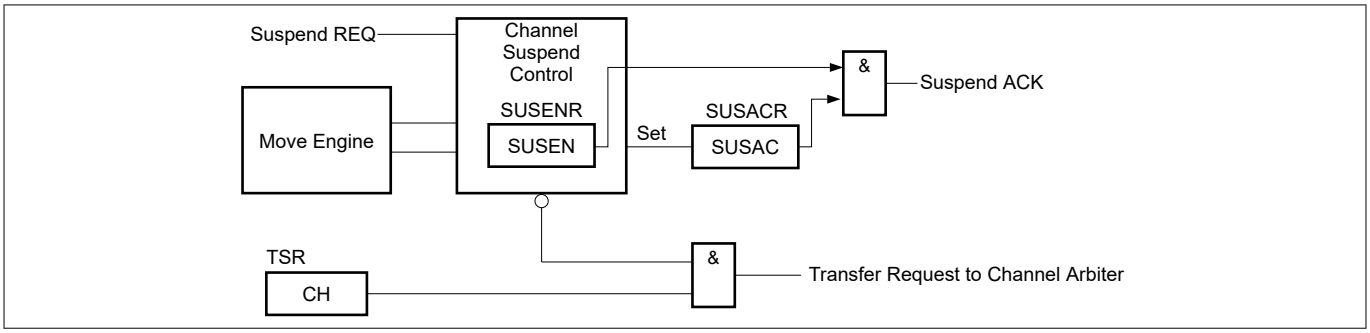

Figure 127 DMA channel suspend

Entering DMA channel suspend state

A DMA channel is enabled for suspend state when the DMA channel suspend enable bit in the Suspend State Enable Register SUSENRc.SUSEN is set. When Suspend REQ becomes active, for DMA channels enabled for DMA channel suspend, the operation is as follows:

- Idle state, reset state, halt state and pending state: The DMA channel suspend active status flag SUSACRc.SUSAC is set and the DMA channel enters the suspend state
- Active state: The DMA channel suspend active status flag SUSACRc.SUSAC is set when the current DMA transfer is complete, the updated TCS is written back to the DMARAM, and the DMA channel enters the suspend state

The DMA suspend acknowledge flag becomes active when all DMA channels that are enabled for DMA channel suspend have set their DMA channel suspend active status flag SUSACRc.SUSAC. In the suspend state, the DMA channel contents may be modified. These modifications are taken into account for further DMA transfers or DMA transactions of the related DMA channel after the suspend state has been left.

DMA channels that are disabled for suspend state (SUSENRc.SUSEN = 0) continue to execute the DMA channel operation.

Exiting DMA channel suspend state

The DMA channel suspend state is left and the DMA channel operation is resumed if either the Suspend REQ signal becomes inactive, or if the enable bit SUSENRc.SUSEN is reset by software.

9.5.2 Software activation of DMA channel interrupt service requests

Each DMA channel interrupt service request may be activated for testing purposes by programming the DMA channel CHCSRc.SIT = 1_B.

9.5.3 Software activation of DMA RP error interrupt service requests

Each DMA RP error interrupt service request may be activated for testing purposes by programming the RP ERRINTr.SIT = 1_B.

9.5.4 OCDS trigger bus (OTGB) interface

A Trigger Set (TS) is a collection of signals which supports a specific debug use case. The OCDS Trigger Set Select (OTSS) register controls which TS is applied to one of two DMA OTGB interfaces: OTGB0 or OTGB1. A TS is routed by the OCDS Trigger Multiplexer (OTGM) to the OCDS Trigger Switch (OTGS).

DMA trigger sets

The DMA trigger sets are selected and routed to the 16-bit OTGB0 or OTGB1 interface by programming the OTSS register. Only one TS shall be output at a time either on OTGB0 or on OTGB1. The OTGB0 and OTGB1 have no dependency on the OCDS enabled state.

***Note**: The OTGB interfaces may operate at a lower clock frequency than the signals being traced in the various DMA trigger sets. Certain higher frequency transitions on the traced signals may therefore not be visible on the OTGB interface.*

DMA TS are unique to each DMA configuration and dependent on the number of DMA channels and ME.

Table 650 DMA trigger sets

Index	Description	Details
0	No trigger set selected	
1	Channels (TS16_PF) Active channels	Table 651
2	Channels (TS16_ERR) Error channel number and flags	Table 652
8	Transaction request state (TS16_C15) Transaction request state channel [15:0]	
9	Transaction request state (TS16_C31) Transaction request state channel [31:16]	
10	Transaction request state (TS16_C47) Transaction request state channel [47:32]	
11	Transaction request state (TS16_C63) Transaction request state channel [63:48]	
12	Transaction request state (TS16_C79) Transaction request state channel [79:64]	
13	Transaction request state (TS16_C95) Transaction request state channel [95:80]	

(table continues...)

Table 650 (continued) DMA trigger sets

Index	Description	Details
14	Transaction request state (TS16_C111) Transaction request state channel [111:96]	
15	Transaction request state (TS16_C127) Transaction request state channel [127:112]	
Other	Reserved. No trigger set selected	

The information in the TS is suppressed depending on the value of the CSAV input signal. See chapter CSRM for details of the CSAV signal.

- When CSAV is "Full", no TS information is suppressed
- When CSAV is "Limited", no TS information is suppressed
- When CSAV is "No" and for channels belonging to a resource partition assigned as a CS asset, all information about the channel or ME executing the channel is suppressed from the TS

Performance trigger set

The performance TS (TS16_PF) continuously monitors ME activity. While a ME is servicing a DMA request, the ME activity status bit TS16_PF.MEm is set and the TS16_PF.CHm field is set to the number of the DMA channel. When the ME is idle the activity status bit TS16_PF.MEm goes low. The TS16_PF.CHm bit field retains the value of the last active DMA channel.

Table 651 TS16_PF trigger set channels

Bits	Name	Description
[6:0]	CH0	Number of DMA channel active in ME0
7	ME0	ME0 active 0_B ME0 is idle 1_B ME0 is active
[14:8]	CH1	Number of DMA channel active in ME1
15	ME1	ME1 active 0_B ME1 is idle 1_B ME1 is active

Error trigger set

The error TS (TS16_ERR) triggers an event for DMA source errors and DMA destination errors.

If an ME detects an SER or DER, the DMA sets TS16_ERR as follows:

- If MEm detects an SER, the DMA sets TS16_ERR.MEmSE for one trigger cycle
- If MEm detects a DER, the DMA sets TS16_ERR.MEmDE for one trigger cycle
- The DMA sets TS16_ERR.LEC to the last error channel for one trigger cycle. If both MEs generate an SER or a DER in the same clock cycle, the DMA shall set TS16_ERR.LEC to the ME0 last error channel

Table 652 TS16_ERR trigger set channels

Bits	Name	Description
[6:0]	LEC	Last error channel number
[11:7]		Reserved
12	ME0SE	ME0 source error

(table continues...)

Table 652 (continued) TS16_ERR trigger set channels

Bits	Name	Description
13	ME0DE	ME0 destination error
14	ME1SE	ME1 source error
15	ME1DE	ME1 destination error

Request trigger sets

The request trigger sets (TS16_C15, etc.) continuously monitor the state of the DMA channel TSRc.CH bits.

9.5.5 MCDS trace interface

The DMA implements trace ports for SRI master interface 0 and SRI master interface 1 (for instances which have SRI master interface 1) which send trace information to the MCDS.

The trace ports send transaction information to the trace data multiplexer (DMUX), which selects what information is then traced by the MCDS. The following information is sent to the DMUX:

- Address
- Data (either read or write data depending on the type of transaction)
- Read transaction ID
- Error
- Opcode
- Read
- Write
- Ready
- Write data valid
- Write transaction ID
- Supervisor mode
- Virtual machine number
- Protection register set number
- Virtual machine valid
- Protection register set valid
- Special master
- Sideband signals

Sideband signals are used in the DMA to identify the channel number and move engine used for the transactions seen by the FPI BCUs and the SRI XBARs as follows.

Table 653 DMA side band signal definition

Bits	Trace
[6:0]	DMA Channel
[7]	Move Engine 0_B ME0 1_B ME1

The information in the trace ports is suppressed depending on the value of the CSAV input signal. See chapter CSRM for details of the CSAV signal and its encoding.

- When CSAV is "Full", no trace port information is suppressed

- When CSAV is "Limited" and for channels belonging to a resource partition assigned as a CS asset, address and data information in the trace port are suppressed and set to 0
- When CSAV is "No" and for channels belonging to a resource partition assigned as a CS asset, all trace port information is suppressed

9.6 References

This section is not applicable for the module being described.

9.7 SDMA revision history

Initial release of the chapter.

9.8 TC4Dx SDMA information

9.8.1 TC4Dx SDMA configuration

The following table describes the TC4Dx SDMA configuration.

Table 654 TC4Dx SDMA configuration

Feature	DMA0	DMA1
Number of DMA channels	128	64
Number of DMA resource partitions	16	8
Number of DMA move engines	2	2
Number of FPI MIFs	2	2
Number of SRI MIFs	3	3

9.8.2 TC4Dx SDMA features

- Two SDMA instances - SDMA0 and SDMA1
  - Similar connectivity on both SDMA instances for maximum flexibility
- SDMA0 features 128 DMA channels and 16 DMA resource partitions
- SDMA1 features 64 DMA channels and 8 DMA resource partitions

9.8.3 TC4Dx SDMA functional description

9.8.3.1 TC4Dx DMA daisy chain request

When a DMA daisy chain request from a higher priority channel attempts to trigger the next lower priority channel and the lower priority channel is assigned to a different resource partition or no resource partition, the DMA should take the following actions:

- The lower priority DMA channel is not triggered
- The TSRc.TRL status bit is set
- The ERRSRr.DCTRLER status bit is set
- If TSRc.ETRL is 1_B in the higher priority channel, an RP error interrupt is signaled

On the AURIX™ TC4Dx device, the ERRSRr.DCTRLER status bit is not always set depending on which of the two MEs the higher priority DMA channel executes on. As a result, software should not rely on the ERRSRr.DCTRLER status bit and should instead infer the cause of the TRL error from the configuration of the DMA channel.

Related information

DMA daisy chain request on page 1260

9.8.3.2 TC4Dx DMA channel transfer interrupt service request

On the AURIX™ TC4Dx device, a DMA channel transfer interrupt service request may not be signaled from the DMA to the IR when all of the following conditions are true:

- The DMA channel is enabled to wait for write completion signaling (TSRc.WWC = 1_B)

- The DMA channel is configured to signal a DMA channel transfer interrupt service request at the end of every DMA transfer (ADICRc.INTCT = 11_B)
- The DMA channel receives an error from the interconnect for a DMA read move
- There are other DMA write requests pending on the interconnect with the same SRI master agent function identifier, even if these are from other DMA resource partitions

On an AURIX™ TC4Dx device, the DMA will merge the DMA channel transfer interrupt service request for the recently errored transfer with the DMA channel transfer interrupt service request for the next transfer and signal a single interrupt. The read error received by the DMA channel will cause the DMA to report a DMA RP error interrupt if configured to do so.

Related information

DMA channel transfer interrupt service request on page 1268

9.8.3.3 TC4Dx DMARAM integrity error interrupt service request

When a double-bit ECC error is detected during a DMA move engine access to the DMARAM to read the TCS on a AURIX™ TC4Dx device, the DMA transaction is not aborted under the following circumstances.

- The SPB clock frequency is configured to be the same as the SRI clock frequency AND
- The ECC error is preceded shortly by one of the following
  - A system sleep request
  - A DMA channel halt request
  - A DMA channel reset request
  - A suspend request from the debug system

The DMARAM ECC error is still reported to the SMU as an alarm, and software should select an appropriate safe reaction to this event.

9.8.6 TC4Dx SDMA revision history

Initial release of the chapter.

10 Local Memory Unit (LMU)

The local memory unit is a resource attached to the System Resource Interconnect (SRI) that provides SRAM for general purpose use. A product may contain multiple instances of the LMU, and each instance has its own set of configuration registers.

Data stored in the SRAM is protected by error-correcting codes (ECC). Master access to areas of each LMU can be permitted or denied by configuring up to 16 address ranges using an Access Protection Unit (APU) in the LMU. The ranges can be sized in 64-byte increments and the master agent functions can be granted access for read and write independently. A master agent function is identified by its number (ID), Protection Register Set (PRS) and Virtual Machine (VM) identifier.

***Note**: Please refer to the system address map for the availability of LMU instances in a specific product.*

10.1 Feature list

- Each LMU instance has 512 KByte of SRAM
- Provides byte, half-word, word, and double-word accesses, as well as double-word burst transactions of length 2,4, or 8 to SRAM
- Provides word and double-word access to most configuration registers
- Each LMU has sixteen Access Protection Units (APUs) for memory access protection

10.2 Functional overview

The LMU SRAM can be used for code execution, data storage or overlay memory. The address range of the memory for each LMU instance is defined in the system memory map. The memory supports being aliased to more than one address range, for example, cached and non-cached segments. A block diagram of the LMU is shown below.

Access to the SRAM is protected by 16 Access Protection Units (APUs), each of which can be configured to limit access by masters to a configurable memory range. By default (after reset), read access is allowed by any master to the whole memory and write access is to certain masters, details of which can be found inthe reset value of RGNx_ACCEN_WRA. The safety configuration and monitoring registers are protected by PROTSE.

The memory implements memory integrity checking for error detection and correction. This means that the memory must be initialized before reading with the integrity checking enabled to avoid generating spurious data corruption errors. Initializing with the memory integrity logic disabled allows the LMU SRAM to support initialization using word (32-bit) or smaller writes. Initialization using 64-bit writes is always possible.

If memory integrity checking is enabled, a read access which fails the integrity check will cause an error condition to be flagged to the initiating bus master. This behavior can be changed by setting the MEMCON.ERRDIS bit to 1_B. If ERRDIS is set, the access will terminate without an integrity error being reported to the SRI. The ERRDIS bit-field of the MEMCON register is protected by the MEMCON.ERRDISWE bit. If the data written to the register has the MEMCON.ERRDISWE bit set to 0_B, no change will be made to ERRDIS regardless of the data written to the field.

An alarm will be triggered whenever there is an ECC error, regardless of the value of MEMCON.ERRDIS.

The SRAM can be written as a 64-bit memory without using internal Read-Modify-Write (iRMW) operations. Any write access of less than 64 bits of data results in an iRMW operation to correctly write the data and update the ECC data. This happens transparently to the rest of the system unless an uncorrected ECC error is detected during the read phase of the iRMW. Any such ECC error will be flagged with an alarm in the same way as a data ECC error occurring during a normal read. In addition, the MEMCON.RMWERR flag will be set. The write operation will not take place as this would write potentially incorrect data to the memory.

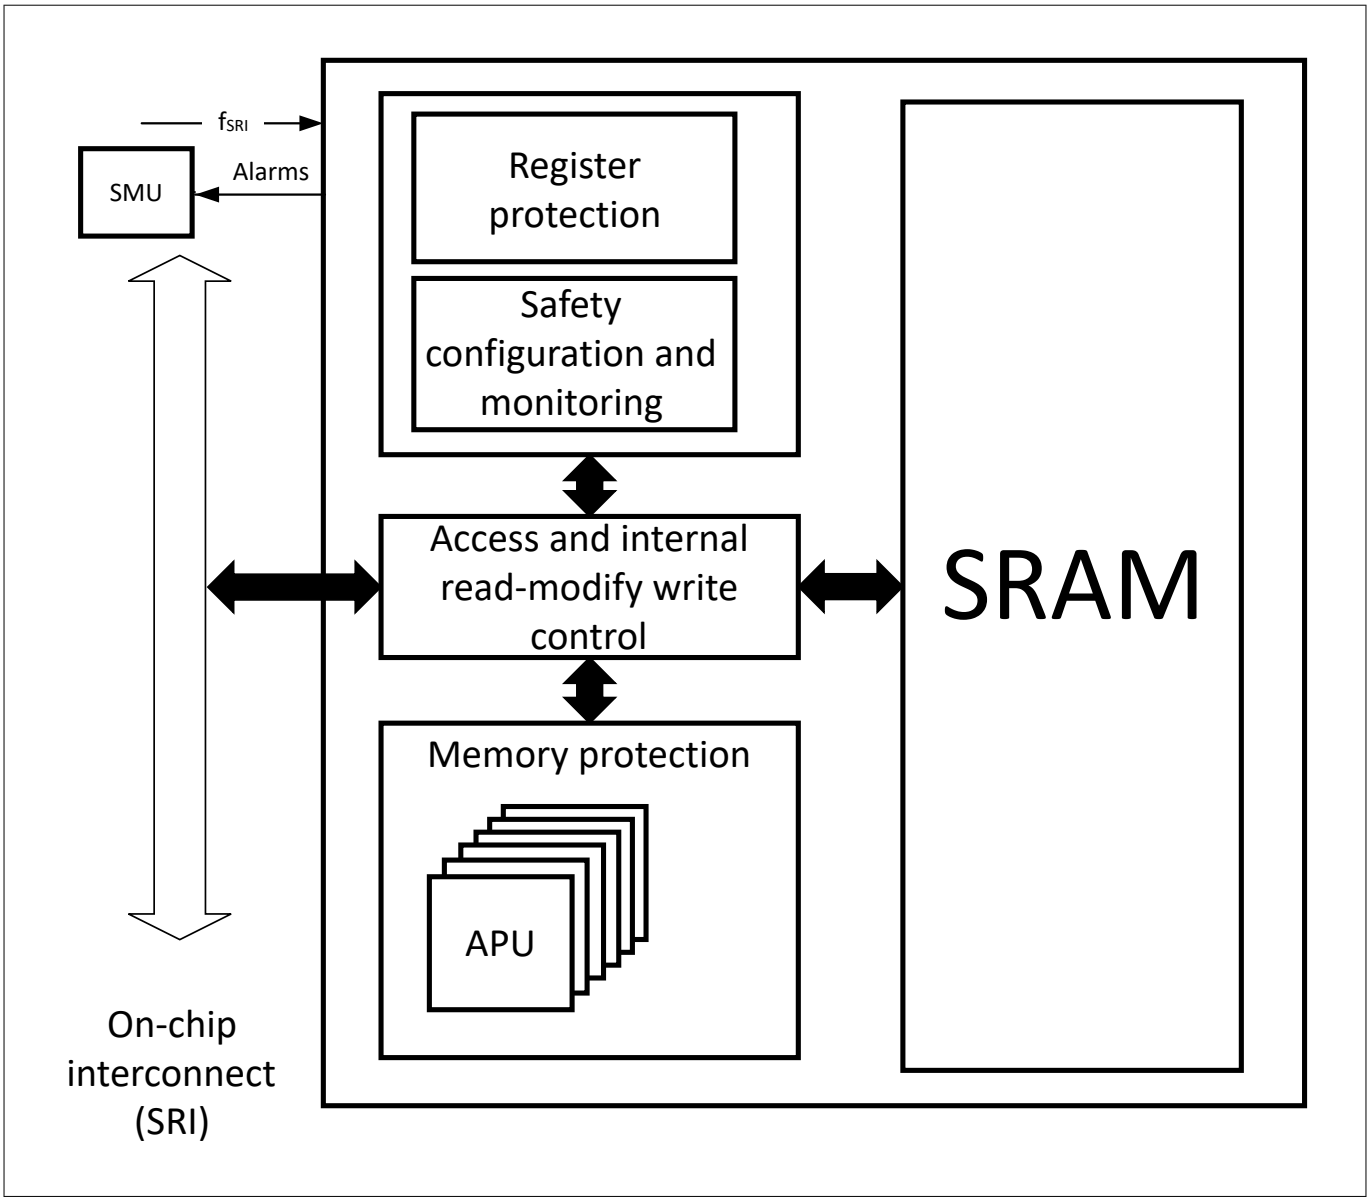

Figure 128 LMU block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

10.3 Functional description

The following sections describe the functions of the LMU.

10.3.1 Memory protection

The LMU allows for the definition of 16, 64-byte aligned, protected regions of SRAM memory defined by an array of access protection unit (APU) instances. This protection applies only to accesses to SRAM included in the LMU, not to registers.

The configuration of the protection regions is held in the set of registers named with the prefix RGNx_, where x is the number of the APU instance. After reset, the protection region range registers will be set to include the whole of the LMU SRAM address space, and read access by all masters will be enabled but write access is to CPU0 and Cerberus. If overlapping regions are defined, then an access only needs to be permittedby one of the overlapping regions for it to succeed.

An APU can only be configured by writing to the equivalent shadow register in the set named with the prefix ACCENCFG_. The shadow register set is protected by a mechanism controlled by the PROTRGN register. The SEL field in this register selects which region is to be configured and write access to the shadow registers is only given when the PROTRGN.STATE field is in an unlocked state. For full details of how the protection mechanism operates, see the access protection section of the manual.

If the access protection is violated by a read access, the LMU will trigger an APU alarm and cause an SRI error on the data phase. If the access protection is violated by a write access, the LMU will trigger an APU alarm and inhibit the write to the SRAM.

In the case of an SRI RMW access, the APU checks for both the read and the write part of the access are done in the address phase of the read part. If either the read or write part would violate the access protection then the LMU will trigger an APU alarm and cause an SRI error on the read data phase.

Related information

PROT mechanism on page 64

Access protection unit (APU) on page 76

10.3.2 Register protection

The registers that control and monitor safety mechanisms are protected by the PROTSE register. Write access to these registers is only given when the PROTSE.STATE field is in an unlocked state.

Any access to an address in the configuration register space of the LMU that is not to a defined register will cause an SRI error which will trigger an alarm in the SRI. Any access to an SFR that does not comply with the access mode for that SFR will cause an SRI error, which will trigger an alarm in the SRI. Any access to the PROTSE or PROTRGN registers that violates the PROT register access rules will trigger an APU alarm.

10.3.3 Clock control

The LMU contains power saving logic that only clocks the SRAM and other functions when an access is being performed.

10.4 Registers

The registers in the LMU are accessible using 32-bit-and 64-bit SRI read and write transactions, except where documented as 32-bit only in the register overview table.

10.4.1 Register overview - access mode glossary

Table 660 Register overview - access mode glossary

Keyword	Description
RGN	Access protection using PROT register PROTRGN.
SE	Access protection using PROT register PROTSE.
32	Access only when using 32-bit width.
BE	Always returns a Bus Error.
PROT	Access restrictions as defined in the PROT register access rules.
U	No access restrictions.

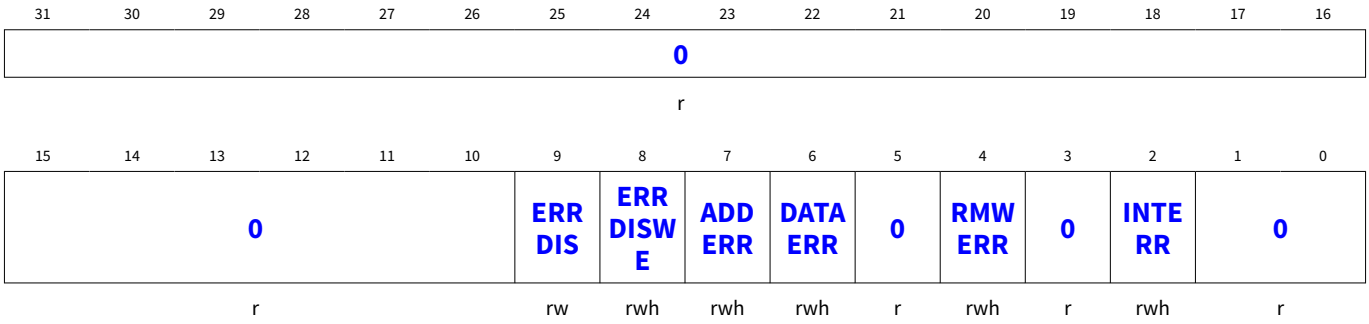
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

10.4.5 Memory control register

This register allows software to monitor both the memory integrity error checking and the error signalling to the SMU.

MEMCON Offset address: 00060_H

Memory control register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
INTERR	2	rwh	**Internal ECC error** Flag set by hardware when the LMU detects an ECC error on the internal data path registers while accessing the SRAM. This bit is cleared by writing 0_B but cannot be set by software. 0_B No error has occurred. 1_B An error has been observed during a RAM access.
RMWERR	4	rwh	**Internal read modify write error** Flag set by hardware when an uncorrected ECC error is reported by the SRAM on the read phase of an internal RMW operation. This bit is cleared by writing 0_B but cannot be set by software. 0_B No error has occurred. 1_B An error has been observed during an internal RMW operation.
DATAERR	6	rwh	**SRI write data phase ECC error** Flag set by hardware when the SRI interface detects an ECC error in the data phase of an incoming write transaction. This bit is cleared by writing 0_B but cannot be set by software. 0_B No error has occurred. 1_B An ECC error has been observed on an SRI transaction addressed to the LMU.
ADDERR	7	rwh	**SRI address phase ECC error** Flag set by hardware when the SRI interface detects an ECC error in the address phase of an incoming transaction. This bit is cleared by writing 0_B but cannot be set by software. 0_B No error has occurred. 1_B An ECC address error has been observed on an SRI transaction addressed to the LMU.
ERRDISWE	8	rwh	**ERRDIS write enable** Will always return 0_B when read. 0_B Bit Protected: ERRDIS bit remains unchanged after MEMCON write. 1_B ERRDIS bit will be updated by the current write to MEMCON.

(table continues...)

(continued)

Field	Bits	Type	Description
ERRDIS	9	rw	**ECC error disable** When set to 1_B, SRI error reporting of ECC errors in data read from the SRAM will be disabled, and an ECC error on the read phase of an internal RMW will not cause the write phase to be aborted. The value of this bit does not affect the generation of alarms. 0_B Normal behavior. SRI read errors will occur for read transactions with SRAM ECC errors. Default after reset. 1_B Test or initialisation mode. SRI read errors will not be generated on SRAM ECC errors.
0	1:0, 3, 5, 31:10	r	**Reserved** Read as 0; should be written with 0.

Table 663 Access mode restrictions of MEMCON sorted by descending priority

Mode name	Access mode		Description
write 1 to .**ERRDISWE**	rw	ERRDIS	ERDISS will only be written if ERRDISWE is written with a 1 at the same time
(default)	r	ERRDIS	Field can always be read

10.4.6 Safety control register

This register provides control of the user-configurable safety mechanisms of the LMU.

SCTRL Offset address: 00064_H

Safety control register Application Reset value: $0000\ 0400_H$

0				CMPTST		0									GED
r				rw		r									w

Field	Bits	Type	Description
GED	0	w	**Generate error in EDC for data protection** The data paths between the SRAM and the LMU SRI interface are protected by error detection code (EDC) logic. This bit is used to inject an error into the EDC code on the next write access so that the EDC check and SMU alarm (internal data transfer EDC error) can be tested. The next write will not be inhibited as a result of this error injection. Reading this bit always returns 0_B. Writing works as follows: 0_B No effect 1_B Inject an error into the LMU data path EDC on the next write access to the LMU.

(table continues...)

(continued)

Field	Bits	Type	Description
CMPTST	11:10	rw	**Comparator test** Setting this bit-field to ON will inject an error in to the comparators checking the duplicated logic area. This will allow the correct operation of the control redundancy mismatch alarm to be verified. An error will continue to be injected until this field is set to OFF or the module is reset. Writing either of the invalid values (00_b or 11_b) to this redundantly encoded control field will trigger the control redundancy self-test mismatch alarm allowing it to be tested. 00_B **RES0**: Invalid 01_B **OFF**: No error injected 10_B **ON**: Error injected 11_B **RES3**: Invalid
0	9:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

10.4.7 Protection for memory regions

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The SEL bit-field is an index into the APU array selecting the APU to be configured.

PROTRGN Offset address: 00070_H

Protection for memory regions Application Reset value: $0000\ 0000_H$

10.4.22 Configure region lower address register

The shadow region access enable registers allow atomic update of one region configuration under the control of the PROTRGN state machine. The value of the PROTRGN.SEL register bit-field determines which APU is configured.

This register sets the lower bound of the access protected region. Addresses greater than or equal to the lower bound are considered part of the access protected region.

ACCENCFG_RGNLA Offset address: 00318_H

Configure region lower address register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDRH		0	ADDR												
rw		r	rw												

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR										0					
rw										r					

Field	Bits	Type	Description
ADDR	28:6	rw	**Defines bits 28:6 of the lower bound of the access protected region**
ADDRH	31:30	rw	**Defines bits 31:30 of the lower bound of the access protected region**
0	5:0, 29	r	**Reserved** Read as 0; should be written with 0.

10.4.23 Configure region upper address register

The shadow region access enable registers allow atomic update of one region configuration under the control of the PROTRGN state machine. The value of the PROTRGN.SEL register bit-field determines which APU is configured.

This register sets the upper bound of the access protected region. Addresses stricly less than the upper bound are considered part of the access protected region.

ACCENCFG_RGNUA Offset address: $0031C_H$

Configure region upper address register Application Reset value: $DFFF\ FFC0_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDRH		0	ADDR												
rw		r	rw												

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR										0					
rw										r					

Field	Bits	Type	Description
ADDR	28:6	rw	**Defines bits 28:6 of the upper bound of the access protected region**
ADDRH	31:30	rw	**Defines bits 31:30 of the upper bound of the access protected region**
0	5:0, 29	r	**Reserved** Read as 0; should be written with 0.

10.5 Debug information

This section is not applicable for the module being described.

10.6 References

This section is not applicable for the module being described.

10.7 LMU revision history

Initial release of the chapter.

10.8 TC4Dx LMU information

10.8.1 TC4Dx LMU configuration

The TC4Dx device has ten instances of the LMU named LMU0 to LMU9. Six of these, LMU4 to LMU9, are capable of being powered off.

10.8.2 TC4Dx LMU features

Six instances of the LMU (LMU4 to LMU9) are capable of being powered off to save power if they are not required for the application. None, three or six instances can be powered off after reset if they are not intended to be used. The power is controlled and monitored in two groups of instances powered by the domains named as follows:

- LMU4, LMU5 and LMU6: V_{DDLMU0}
- LMU7, LMU8, and LMU9: V_{DDLMU1}

***Note**: although these two groups of LMU instances can be powered off, they are only powered on after a power-on reset.*

10.8.3 TC4Dx LMU functional description

Instances LMU4 to LMU9 of the LMU have the ability to power down their SRAM according to the controls in the power management system (PMS). When an LMU instance is powered down it will respond to any access to its SRI interface with an SRI error which will trigger an alarm from the SRI.

10.8.4 TC4Dx LMU registers

10.8.4.1 Memory overview tables of LMU

Table 665 Memory overview - LMU (ascending address)

Short name	Long name	Address
LMU0_LMU	LMU0 memory (80000_H Byte)	90400000_H
LMU1_LMU	LMU1 memory (80000_H Byte)	90480000_H
LMU2_LMU	LMU2 memory (80000_H Byte)	90500000_H
LMU3_LMU	LMU3 memory (80000_H Byte)	90580000_H

LMU9	$FB090000_H$	$FB09FFFF_H$	LMU9 SFR address range

10.8.4.3 Register overview - access mode glossary

Table 667 Register overview - access mode glossary

Keyword	Description
RGN	Access protection using PROT register LMU0_PROTRGN or LMU1_PROTRGN or LMU2_PROTRGN or LMU3_PROTRGN or LMU4_PROTRGN or LMU5_PROTRGN or LMU6_PROTRGN or LMU7_PROTRGN or LMU8_PROTRGN or LMU9_PROTRGN .
SE	Access protection using PROT register LMU0_PROTSE or LMU1_PROTSE or LMU2_PROTSE or LMU3_PROTSE or LMU4_PROTSE or LMU5_PROTSE or LMU6_PROTSE or LMU7_PROTSE or LMU8_PROTSE or LMU9_PROTSE .
32	Access only when using 32-bit width.
BE	Always returns a Bus Error.
PROT	Access restrictions as defined in the PROT register access rules.
U	No access restrictions.

10.8.6 TC4Dx LMU revision history

Initial release of the chapter.

11 CSRM - NDA only

Information for this functional block is only available under NDA.

12 CSS - NDA only

Information for this functional block is only available under NDA.

13 PPU - NDA only

Information for this functional block is only available under NDA.

14 Gigabit Ethernet (GETH)

The Gigabit Ethernet (GETH) is a functional block that implements Ethernet functions. GETH is connected to SRI with a master interface and with a slave interface with a set of special function registers (SFRs).

14.1 Feature list

- Ethernet port capable of supporting 10M, 100M, 1G, 2.5G, 5G speed in full-duplex mode
- Ethernet port capable of supporting half-duplex mode in 10M and 100M speed
- Host port with single master interface (64-bit wide data bus) for data transfer
- Multichannel DMA Engine on the host interface to transfer data with minimal software intervention
- Single 32-bit Slave interface for configuration by the application
- Ethernet port supports the hardware requirements of IEEE 802.1 AVB and TSN specifications as listed below:
  - IEEE 802.1Qav – Forwarding and Queueing enhancements for Time Sensitive Streams
  - IEEE 802.1AS 2020 – Timing and Synchronization for Time Sensitive Applications
  - IEEE 802.1Qbu – Frame Preemption
  - IEEE 802.1Qbv – Enhancements for Scheduled Traffic
- Classification of traffic between the host port and the ingress/egress port
- Flexible/programmable packet header inspection for filtering, monitoring schemes and enable firewall protection and intrusion detection service
- Bridge function (in products with Ethernet Bridge only):
  - The bridge connects two Ethernet ports and one common host interface
  - It allows to statically establish the data paths between these three blocks. This is called forwarding of Ethernet Frames
- Automotive Safety Features:

  The automotive safety features improve the reliability and reduce the time taken to detect faults. GETH supports the following features for automotive safety:
  - Error correction code (ECC) protection for memories
  - FSM parity and timeout protection
  - Application/CSR interface timeout protection

14.2 Functional overview

This module provides a communication capability according to the Ethernet IEEE 802.1 standard.

The following figure shows the basic architecture.

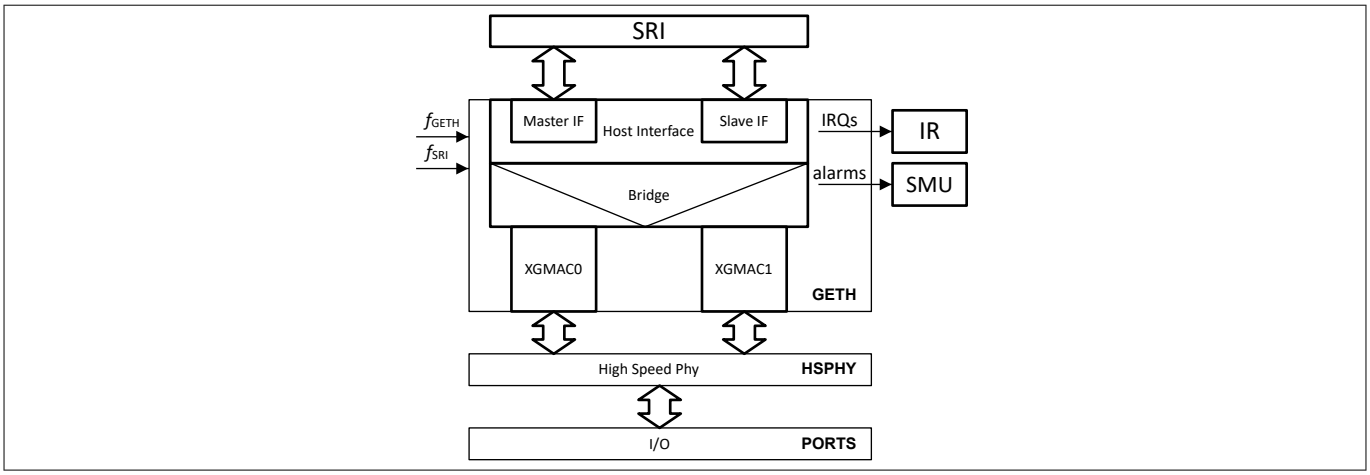

Figure 129 GETH block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

The module consists of the following blocks:

- Host Interface
  - Master interface for transfer of Ethernet-frame-data to and from host
  - Slave interface for configuration
- Bridge (exists in products with Ethernet Bridge only)
  - Connects two XGMACs and the host
  - Forwards Ethernet frames
    - From the host to a XGMAC
    - From the two XGMACs to the host
    - From one XGMAC to the other XGMAC
- XGMAC core
  - Contains the blocks for protocol handling
  - Contains Ethernet frame filters and forwarding rules
  - Contains buffers for Ethernet frames

Note that GETH has no own connection (with the exception of PPS outputs) to I/O but they are routed to the High Speed Phy (HSPHY) which controls the connections with the actual I/O in the PORTS. PPS outputs are connected directly to PORTS output. Please refer to High Speed Physical Layer (HSPHY) chapter for correct setup.

HSPHY provides connection to physical pads for the following interfaces.

- SGMII
- UXSGMII
- RGMII
- RMII
- MII
- MDIO

***Note**: Kindly refer to HSPHY device specific chapter for availability of an interface in the corresponding device.*

14.3 Functional description

The functional description is divided in two parts:

- XGMAC (10 gigabit media access controller)
- Bridge (exists in products with Ethernet Bridge only)

Related information

XGMAC on page 1396
Bridge on page 1594

14.3.1 Detailed architecture

This section describes the architecture of GETH in detail. This information is needed only if performance needs to be optimized.

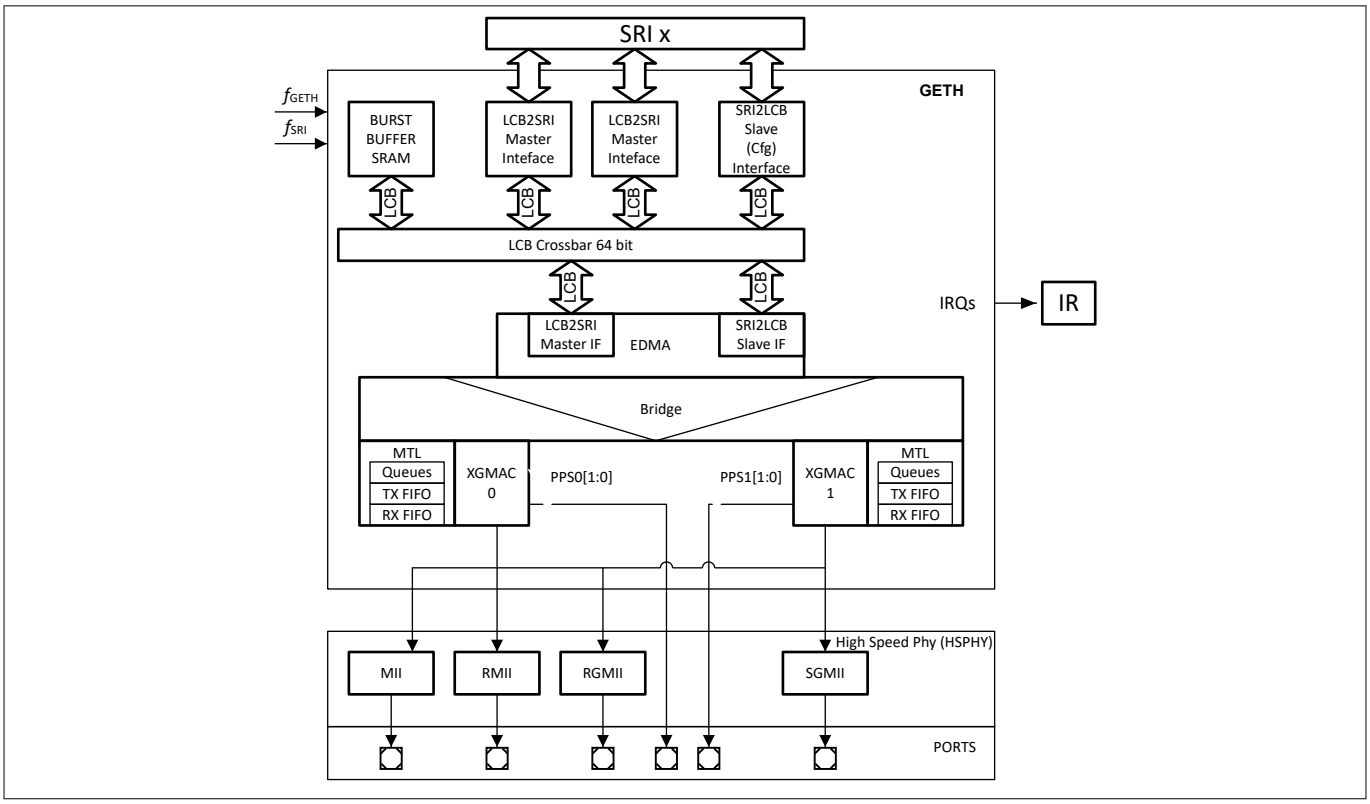

Figure 130 GETH detailed block diagram

The module consists of the following blocks:

- Local Cross Bar (LCB)
  - 64 bit wide
  - Two master interfaces to SRI
  - One slave interface to SRI

  - One SRAM with 64 KBytes (for products with Ethernet Bridge only)
  - One EDMA with
    - One master interface for transfer of Ethernet-frame-data to and from SRI through the local cross bar
    - One slave interface for configuration
- DMA
  - Eight communication channels
  - Communicates through two data structures:
    - Control and Status registers (CSR)
    - Descriptor lists and data buffers
  - Packet transfer is optimized by the following tasks in parallel:
    - Multiple Descriptor Fetch
    - Data Transfer
    - Descriptor Write-back
- Bridge (for products with Ethernet Bridge only) provides:
  - Forwarding of frames from each MAC to the other
  - Transfer of RX frames from each MAC to DMA
  - Transfer of TX frames from the DMA to each MAC
- MAC transaction layer provides
  - Data transmit storage (TX FIFO)
  - Data receive storage (RX FIFO)
  - Data queues for prioritized traffic
- MAC core
  - Containing the blocks for protocol handling

GETH has two LCB2SRI connections. This can be used by applications where sustained data throughput to and from the SRI system is very critical. One LCB2SRI can be used to perform only read transfers and the other to perform only write transfers. This can be achieved by locating the data buffers for TX frames in the address space that is addressed by the first master and the data buffers for RX frames in the address space that is addressed by the second master. This way the whole buffer depth of an LCB2SRI can be fully used by frame data of one direction. Ideally the descriptors shall be located in the local buffer RAM. This will avoid blocking situations on the LCB2SRI caused by single word transfers. Such transfers are performed by the EDAM for example to write back the status of the descriptor or to clear the OWN bit of the descriptor.

***Note**:* *The local buffer RAM provides performance gain. It does not support full channel-separation ("virtualization support"). The APUs are located in the slave interface from SRI to GETH. They protect the address space of the GETH against outside accesses. For example, they protect against accesses from a CPU to a MAC or the local buffer RAM. These APUs cannot protect accesses from MAC DMAs to addresses inside GETH like the local buffer RAM. Still, it is possible to setup eight segments with individual ACCEN protection that will protect each segment of the local buffer RAM against accesses from outside GETH. In addition, MAC DMAs cannot address MAC registers. Such a DMA receives an error response and stop before the access takes place.*

14.3.2 Access protection

The address space of GETH is divided into 11 areas that can be protected with individual APUs.

The APUs are located in the slave interface from SRI to GETH. They protect the address space of the GETH from outside accesses, for example from a CPU or the system DMA. Accesses from MAC DMAs to addresses inside GETH can not be protected by these APUs.

The following APUs are available:

- ACCENGLOBAL allows protection of the Bridge specific CSRs (in products with Ethernet Bridge only) and the bus peripheral interface (BPI) registers (CLC, RST_CTRLA, RST_CTRLB, RST_STAT, MACEN and ID)
- ACCENMAC[1:0] allows per MAC protection of the CSRs except the DMA channel specific ones
- ACCENCH[7:0] allows protection of the CSRs per channel consisting of DMA_CHx, MTL_TCQx and memory region of the local buffer RAM in terms of 8 kByte segments. The first 8Kbyte of RAM segment protected by ACCENCH0 and correspondingly the last 8 kByte protected by ACCENCH7

***Note**: All registers shall be declared as "volatile". Note that volatile bits are not marked as"rh", "wh" or "rwh" in the bit access restriction field but as "r", "w" and "rw" respectively. The bit description field defines the actual behavior verbally*

14.3.3 Master TAG ID

The module has 8 DMA Channels that share one master interface connecting them to the SRI bus. In order to distinguish the 8 DMAs from each other in the system, the master tag ID will dynamically be changed depending on the currently active DMA. The following table details which ID is presented for each DMA. Accesses to descriptors are tagged according to the DMA channel requesting the access.

Table 679 Master TAG IDs for Gigabit Ethernet

DMA	Master TAG ID
DMA0	$0x30_H$
DMA1	$0x31_H$
DMA2	$0x32_H$
DMA3	$0x33_H$
DMA4	$0x34_H$
DMA5	$0x35_H$
DMA6	$0x36_H$
DMA7	$0x37_H$

14.3.4 SRI slave and master interface error notification

The following tables describe the Error detection methods and corresponding notification method for SRI slave and master interface of GETH.

Table 680 SRI slave interface error notification method

Description of error	Notification method
SRI Address phase ECC errors	SRI transaction error and SRI XBAR Bus Error Event Alarm
AXI write error	SRI Write Data phase alarm

Table 681 SRI master interface error notification method

Description of error	Notification method
SRI read data ECC errors	SRC_GETHSE alarm

14.3.5 System related considerations

The following chapters gives recommendation on system related topics.

14.3.5.1 System start-up

Before using the bridge (exists in products with Ethernet Bridge only) with one or both of the MACs the application has to execute the following steps:

- High-Speed Physical Layer (HSPHY) needs to be configured first
- Switch on f_{GETH} by configuring in the SCU bit-field SYSCCUCON1.GETHDIV
- Clear GETH_ CLC.DISR and
- Set GETH_MACEN.MAC0 or MAC1 or both depending on the MAC to use

If the application wants to use the IP in RGMII mode, the application has to execute the following steps:

- Prior to the application reset, the application must switch on f_{GETH} by configuring in the SCU SYSCCUCON1.GETHDIV
- Attach an external 125 MHz clock to input GREFCLK
- Activate the application reset
- Wait for 10 µs

***Note**: CLC.DISR is used to pause the GETH, whilst MACEN.MAC0 and MACEN.MAC1 are used to completely turn off the MAC cores.*

- *CLC.DISR = 1: GETH disables the application clock (on SRI side) and the asynchronous Tx clocks (on PHY side).*

  CLC.DISR does not disable the asynchronous Rx clock, because it is needed in order to wake-up the rest of the GETH in the event that wake-up frames are received. In this event, the small receive portion of the MAC, which is still active and clocked with the Rx clock will generate an interrupt and the software can turn on the rest of the GETH (CLC.DISR = 0).

  There is only one CLC.DISR for the two MAC cores. Writing it to 1 disables for both MAC cores the application clock as well as the Tx asynchronous clocks
- *MACEN.MAC0 and MACEN.MAC1: Used to enable or disable the MAC cores individually. If any of this register fields are zero, the corresponding MAC core is disabled and its asynchronous Rx clock is turned off. The corresponding MAC core is turned off completely and cannot be awaken even in the case of wake-up frames*

14.3.5.2 Reset

This chapter explains how to bring the IP to reset state.

There are two sources of reset provided by the module for it's operation:

- Kernel reset: The complete functional block GETH supports a general reset, the so called kernel reset by setting KRST_CTRLA.KRST and RST_CTRLB.KRST. This resets all registers in the wrapper and the kernel
- Software Reset: The XGMAC kernel IP inside GETH supports an own software reset by setting DMA_Mode.SWR. When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC

Any reset operation is completed only after all resets in all active clock domains are de-asserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for reset completion.

If one of these resets (SW reset or kernel reset) is applied this reset will propagate to SSH (SRAM support hardware) controlling the FIFO RAMs of GETH. The RAM content will be no longer reliable. The kernel logic will have lost all information about its content.

Note that in both cases both MACs (Port0_MAC... and Port1_MAC...) will be reset. It is not possible to individually reset only one MAC port or execute a partial reset for MTL and MAC port (without the DMA).

The recommended way to achieve an equivalent result is to gracefully stop all the DMA channels allocated/mapped to a MAC port, their connected TxQ/RxQ and MAC port through programming and bring them to the default/reset state.

For TX side, follow this programming sequence:

1. Stop the associated TxDMA connected/mapped to a MAC port
2. Check the status of the TxDMA. If all the TxDMA went to STOP state, it means that it has gracefully completed the ongoing packet transfers
3. Check the status of the MTL TxQ of that port. If they are empty, it means that all pending packets are transmitted
4. Disable the MTL TxQs and MAC TX

This moves the required MAC port (MAC + MTL + DMA) to idle/initial state (equivalent to reset).

For RX side, adopt a similar strategy but in reverse way:

1. Stop the MAC receiver of the port
2. Check the status (fill-level) of all the MTL RxQ of that port. If it is empty, all the packets of that port have been transferred to the host
3. Stop all the RxDMAs associated with that port

This moves the required MAC port (MAC + MTL + DMA) to idle/initial state (equivalent to reset).

14.3.5.3 Buffer and descriptor alignment

The GETH is implemented as a 32-bit peripheral. Nevertheless it is connected to 64-bit wide bus (SRI). To make full use of the possible performance of SRI and its bridges, the data buffers and the descriptors need to be aligned to 64-bit addresses.

The start address and length of descriptors (containing pointers to data buffers) and data buffers (with the actual frame data) must be aligned to the burst size for performance optimization. This is needed by the AXI2SRI bridges to forward the burst. Others alignments will result in single (word) transfers.

14.3.5.4 DMA burst lengths limitations by the system

Other than specified in the XGMAC IP only the following burst lengths are supported by the system memories: SINGLE, INCR2, INCR4, INCR8, INCR16. As consequence, in DMA_SysBus_Mode only the following burst length modes are allowed: BLEN4, BLEN8 and BLEN16. Do not choose UBL, BLEN32 through BLEN128, they can not be processed by the system and an alarm (SRC_GETHSE) is generated.

Note that the INCR16 is translated into two BTR8 on SRI.

Note that the AXI standard defines that a burst must not cross a 4 KB address boundary. You can set this limit in DMA_SysBus_Mode.ONEKBBE.

In addition, the system does not support outstanding transactions nor bursts reordering or data interleaving.

14.4 XGMAC

This chapter gives the overview of the configuration, features and detailed specifications of the XGMAC.

Software configuration is done by the application by writing to registers.

- Up to eight Tx queues or DMA channels
- Up to eight Rx queues in Receive FIFO
- Audio Video (AV) Bridging
- Up to eight Rx DMA channels
- 32-bit addressing support
- Up to 32 kBytes of receive memory in Transaction layer
- Up to 32 kBytes of transmit memory in Transaction layer
- 64-bit application interface data bus width (Master IF)
- VLAN Tag based perfect and hash filtering in Rx
- SA and VLAN insertion in Tx
- Up to 32 MAC address registers for filtering
- RMON counters (MMC) with individual register selection
- Power Management Module (PMT) with magic packet and remote wake-up frame processing options
- Checksum Offload Engine (TCP/IP layer) for the Transmit and Receive paths
- IEEE 1588 time-stamping and PTP support
- Energy Efficient Ethernet
- Station Management Agent (SMA) MDIO module
- Transmit Packet Status
  - Maximum number of packets in Transmit FIFO = 2
- Transmit Time stamping FIFO depth = 4
- Time-Based Scheduling (TBS) enabled on all DMA channels
- RGMII PHY interface support
- RMII PHY interface support
- Number of synchronizer stages in CDC path = 2

***Note**: Products with a bridge use two identical instances of this XGMAC. This is why the description is done only one time here. The two XGMACs in a subsystem with a bridge are referenced as Port0 and Port1 in the register chapter.*

14.4.1 Feature list

The features of XGMAC are described in the chapters below.

14.4.1.1 XGMAC-CORE

The XGMAC (XGMAC controller) includes the following features:

- Full-duplex operation at 5 Gbps/2.5 Gbps (XGMII), 2.5 Gbps/1 Gbps (GMII), 100 Mbps/10 Mbps(MII)
- Full-duplex RGMII support (1 Gbps/100 Mbps/10 Mbps)
- Full-duplex RMII support (100 Mbps/10 Mbps)
- Half-duplex operation in 10 Mbps/100 Mbps modes. Supports:
  - CSMA/CD protocol
  - Flow control using back pressure support
- Communication with an external 5 gigabit/2.5 gigabit PHY provided by an XGMII interface that fully complies with Clause 46 of the IEEE 802.3-2008 standard
- Link fault detection in the XGMII receiver and automatic fault signaling in the XGMII Transmit interface
- Communication with an external 1 Gbps/100 Mbps/10 Mbps PHY provided by a GMII/MII interface that fully complies with Clause 35/72 of the IEEE 802.3-2008 standard. Existing XGMII I/O can be used for GMII/MII operation, or a separate GMII/MII I/O can be configured
- 2.5 Gbps operation using an 8-bit GMII interface operating at 312.5 MHz
- 1 Gbps/100 Mbps/10 Mbpps operation using 4-bit RGMII interface working at 125/25/2.5 MHz
- Clause 78 (Energy Efficient Ethernet (EEE) feature) of the IEEE 802.3az, standard support
- Separate transmission, reception, and slave (control and status register) interfaces to the application
- 64-bit data transfer interface on the system side
- Preamble, SFD, and other control character insertion (in transmit path) and deletion (in receive path)
- Programmable minimum Inter-Packet Gap (IPG) from 64 bit times to 224 bit times
- Padding in transmit side for short (less-than-64 byte long) frames received from the application. Pad stripping on the receive side for short frames
- Programmable source address inclusion or replacement for Transmit frames
- Programmable frame length, supporting standard or jumbo (extendable to 16 KB) Ethernet frames if the communication rate is equal to or below 100 Mbit/s
  - Support for jumbo frames up to 9 KB expandable up to 16 KB
  - Truncation support for oversized frame reception and transmission at fixed thresholds of 2,048, 10,240, or 16,383 bytes. Alternatively, the truncation thresholds can be programmed in steps of 1 KB from 2 KB onwards
- Supports IEEE 802.3 flow-control
  - Forwarding of received PAUSE control frames to the application
  - Automatic transmission of zero-quanta PAUSE frames on flow-control input deassertion
  - Support for unicast PAUSE frame reception
  - Transmission of PAUSE frames triggered by software controlled register bit or based on queue fill level
- Support for VLAN-tagged frame processing in compliance with the IEEE 802.1Q standard
  - Support for VLAN-tagged frame detection, stripping, and filtering
  - Support for VLAN tag inclusion, replacement, or deletion in transmit frames
  - Support for up to two Stacked-VLAN tagged packets
- Support for the following flexible address filtering modes for received frames:
  - Up to 32 destination address (DA) perfect match address filters with masks for each byte
  - Up to 32 source address (SA) perfect match filters with masks for each byte
  - Posibility to pass all multicast-addressed frames
  - Promiscuous mode to pass all frames without any filtering for network monitoring
  - Up to eight VLAN-based perfect matched and hash filtering

  - Up to eight Layer 3 and Layer 4-based (TCP or UDP over IPv4 or IPv6) match filters
  - Pass all incoming packets with a status report as determined by the filter
- Forward all control frames other than PAUSE control frames
- Filter unicast control frames that fail the DA address perfect match filter
- Network statistics with RMON or MIB Counters (RFC2819/RFC2665)
- Features to support Ethernet packet timestamping as described in IEEE 1588-2008 (64-bit timestamps given in the Tx or Rx status of each packet)
  - Possibility to store up to 16 timestamps with packet identifier in the CSR
  - One-step timestamping in Tx direction with the host providing a 64-bit timestamp along with TX packet. XGMAC-CORE parses PTP (over Ethernet) packets and insert or correct timestamp in appropriate header field
  - Parses received frames for PTP packets and takes timestamps as per configured node
  - Provides registers for asymmetric time correction
  - Supports internal System time generation and update
  - Support for dynamic selection of reference time source through control bit in CSR
  - Flexibility to control the Pulse-Per-Second (PPS) output signal (ptp_pps_o)
  - Support for capturing timestamp based on external trigger and providing it in CSR
- Loopback capability at XGMII/GMII (transmit data to receive path)
- Detection of LAN wake-up frames and AMD Magic Packet frames during the power-down mode. Wake-on LAN support up to four filters
- MDIO Master interface for multiple PHY devices and their configuration and management
- Interrupt generation mechanism for MDIO
- IPv4 header checksum offload on reception
- TCP, UDP, or ICMP checksum offload (IPv4 and IPv6) for received packets

14.4.1.2 DMA

The DMA block exchanges the data between the MTL block and the host memory. The host can use a set of registers (DMA CSR) to control the DMA operations. The DMA block supports the following features:

- 64-bit data transfers
- Multi-channel Transmit and Receive engines (eight Transmit and eight Receive channels)
- Separate DMA channel in the Transmit path for each queue in MTL. Single or multiple DMA channels for any number of queues in MTL Receive path
- Descriptor structure to support the following:
  - Byte-aligned addressing for data buffer
  - Dual-buffer descriptor ring and support for 32-bit addressing in descriptor structure. Expandable descriptor with context descriptor for additional control and status information
  - Descriptor architecture to allow large blocks of data transfer with minimum CPU intervention (each descriptor can transfer up to 8 KB of data)
  - IEEE 1588 timestamps
  - One-step PTP time correction in Tx, that is, input 64-bit timestamp provided in descriptor
  - Possibility to provide 64-bit timestamp for received packets
  - Possibility to provide up to two VLAN tags in descriptor for insertion or replacement in Tx and stripped VLAN tags in Rx
  - Possibility to split the packet header (Layer 3 and Layer 4) and Layer 4 payload in different buffers

- Individual programmable burst size for Tx DMA and Rx DMA engines for optimal host bus utilization
- Routing of received packets to the DMA channels based on the Ethernet DA or VLAN Priority in multi-channel DMA configurations
- Register programmable RX buffer sizes for each DMA channel
- Additional per-DMA channel interrupt for normal packet transfers
- Per-packet Transmit and Receive Interrupt control in descriptors
- Supports pre-fetching and caching up to 16 descriptors for each DMA channel
- Descriptor fetches, Data transfers and Descriptor writes are de-linked and performed independently so as to reduce gaps between data transfers of each DMA
- TxDMA engines have capability to issue up to 2 outstanding requests for packet/burst transfer
- DMA descriptor writes can be “posted”, so that next descriptor can be processed immediately for next packet
- Descriptor memory cache
- Time-sensitive conditional packet transmission by comparing the Slot Time information provided in the descriptor (useful for AV applications)

14.4.1.3 AXI interface

This section discusses the AXI Interface features.

AXI master interface

The AXI master interface is compatible to interface with AXI-4 slave ports. It supports the following features:

- 32-bit address width, little-endian
- 64-bit data
- OKAY, SLVERR, and DECERR responses from AXI slaves
- Software-selected type of AXI burst
- AXI 4 KB boundary burst splitting and option to limit burst splitting boundary to 1 KB boundary
- Outstanding read and write transactions with register programmable control. Two outstanding requests per channel in configuration of eight TxDMA and eight RxDMA channels
- One of the outstanding requests is reserved for high priority Descriptor operation
- Posted writes during multiple data transfers from the AXI master interface to maximize the bus utilization
- AXI-ID based on DMA channel number. Each TX and RX DMA has its own ID for data transfer

The AXI master interface does not generate the following:

- Atomic, exclusive, locked, and protected accesses
- EXOKAY access

AXI slave interface

The AXI Slave interface supports the following features:

- 32-bit for CSR access
- 32-bit address width
- Little-endian
- No narrow burst and FIXED or INCR burst

The AXI slave interface does not support the Exclusive, Atomic, Locked, Cache, and Protected accesses.

14.4.1.4 Audio video support

XGMAC supports the following Audio Video (AV) features:

- Separate channels or queues for AV data transfer
- Up to eight queues on the Receive paths for AV traffic and 3 queues on the Transmit path for AV traffic
- IEEE 802.1-Qav specified credit-based shaper (CBS) algorithm for Transmit channels
- Single Tx FIFO and Rx FIFO (MTL) for all selected queues

14.4.1.5 Time Sensitive Networking Features

XGMAC supports the following Time Sensitive Networking (TSN) features:

- IEEE 802.1Qbv-2015, Enhancements to Scheduling Traffic
- IEEE 802.1Qbu/802.3br, Frame preemption and Interspersing Express Traffic
- IEEE 802.1Qci-2017, Stream-Gate Filtering and Policing
- Time Based Scheduling

14.4.1.6 Automotive safety features

The automotive safety features are targeted to improve the reliability and reduce the time taken to detect faults in the controller:

XGMAC supports the following features for automotive safety:

- Error correction code (ECC) protection for memories
- FSM parity and timeout protection
- Application/CSR interface timeout protection
- On chip data path parity and AXI ECC are not connected in this device

14.4.1.7 Monitoring, testing, and debugging support

- Support for internal loopback on the XGMII/GMII for debugging
- DMA states (Tx and Rx) as status bits
- Current Tx or Rx Buffer pointer as status registers
- Current Tx or Rx Descriptor pointer as status registers
- Tx or Rx memory accessible through Slave port for debug
- Provides debug status register that gives the status of FSMs in the Transmit and Receive data paths and FIFO fill-levels
- Provides complete network ethernet statistics) with RMON-MIB counters (RFCs 2819 and 2665)

14.4.2 Functional overview

This chapter provides an overview of the XGMAC and describes its components and features.

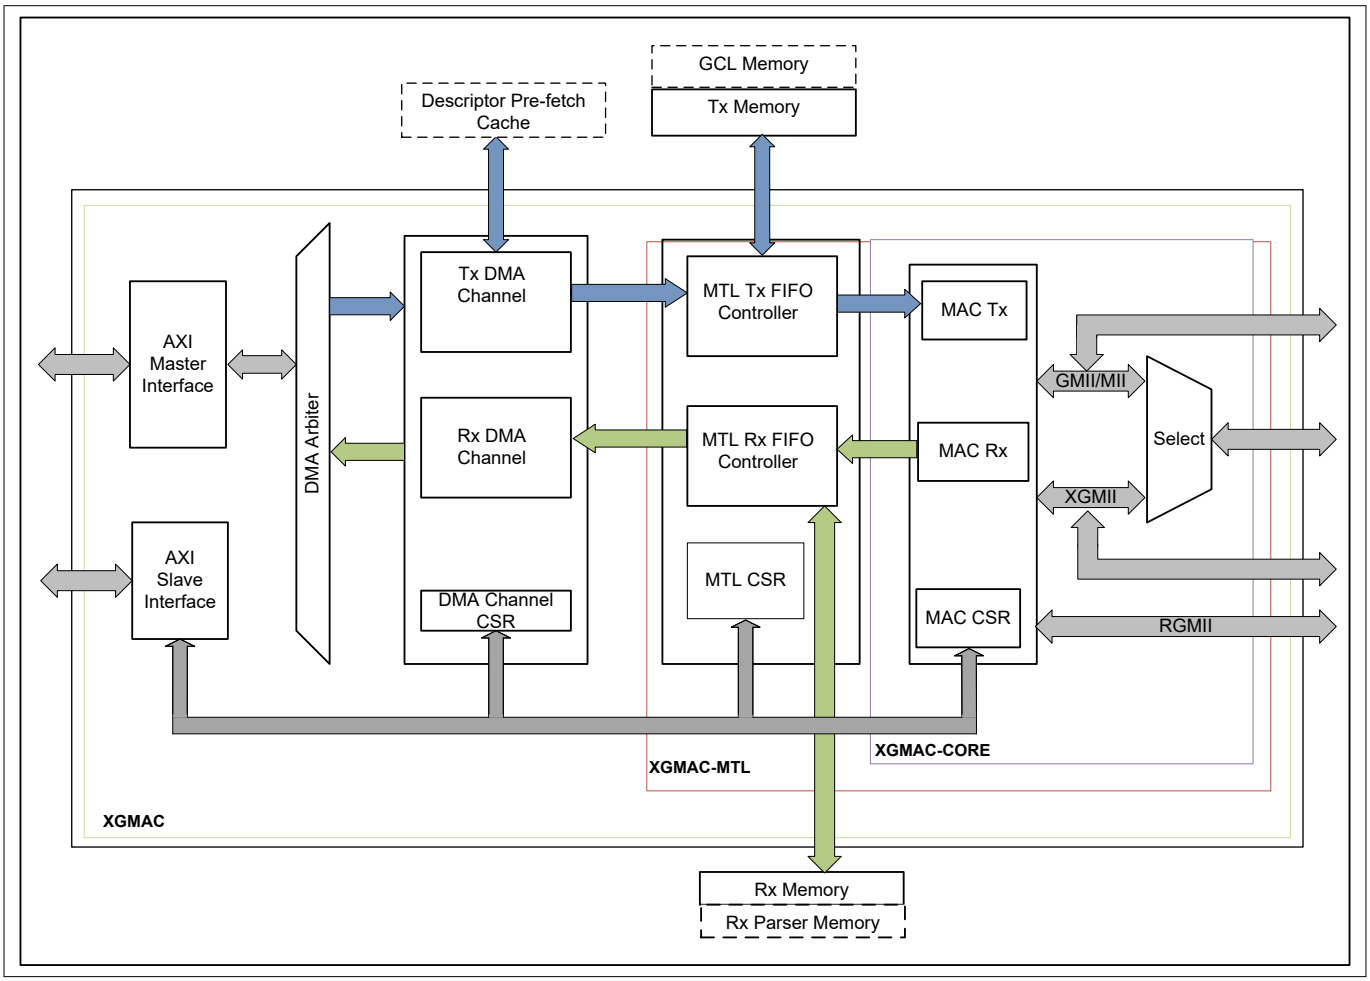

Figure 131 XGMAC block diagram

The XGMAC enables a host to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2008 standard.

Interfaces

The XGMAC has the following interfaces.

AXI interface

The AXI interface transfers the data to and from the system memory as a master interface. The host CPU uses the AXI slave interface to access the Control and Status registers (CSRs).

14.4.2.1 Standard Compliance

In addition to the default interfaces defined in the IEEE 802.3 specifications, the XGMAC supports several industry standard interfaces to the PHY. The XGMAC is compliant with the following standards:

- IEEE 802.1AS 2020 and 802.1-Qav-2009 for Audio Video (AV) traffic
- IEEE 802.3-2015 for Ethernet MAC, Gigabit Media Independent Interface (GMII), 10G Media Independent Interface (XGMII).
- IEEE 1588-2008 for precision networked clock synchronization
- IEEE 802.3az-2010 for Energy Efficient Ethernet (EEE)

- AMBA 3.0 and APB3 slave ports
- AMBA4 AXI and ACE protocol specification, February 2013, ARM Ltd for AXI4 and APB4 interface
- NBASE-T Alliance 2.5 and 5 Gigabit Ethernet (USXGMII)
- Reduced Gigabit Media Independent Interface (RGMII), Version 2.6, Broadcom Corp., Hewlett-Packard Co., Marvell Technology Group, Ltd.
- RMII specification version 1.2 from RMII consortium

14.4.2.2 Buffers and memories

This gives an overview of the buffers and memories used by one XGMAC.

Transmit and receive FIFOs

The Transmit FIFO (Tx FIFO) buffers the data transferred from the application to the XGMAC. Similarly, the Receive FIFO (Rx FIFO) stores the Ethernet frames received from the line until they can be transferred to the application. These are asynchronous FIFOs because they also transfer the data between the application clock and the MAC line clocks. Tx memory and Rx memory are of 64-bit data width.

The size of the Tx FIFO is 32 kBytes

The size of the Rx FIFO is 32 kBytes

Descriptor cache

The memory is used to store the pre-fetched descriptors of all the DMAs active in the controller. Each DMA (Tx or Rx) has allocated space for caching 16 descriptors (256 bytes).

Enhancements to scheduled traffic (EST)

This memory is used for the Gate Control List (The list in the controller memory that holds the gate controls and the associated time intervals) in the 802.1Qbv EST function. The memory depth is 256 lines.

14.4.3 Functional description

The following sub-section give the details on the functions of XGMAC.

14.4.3.1 Introduction

The Figure 131 provides a block diagram of the XGMAC subsystem of 2 ports with a bridge.

The main building layers of the XGMAC are:

- XGMAC-CORE:

  Using CSR, software can configure the XGMAC-CORE to operate at 5/2.5G(XGMII), 1/2.5G (GMII), 100M/10M (MII and RMII) or 1G/100M/10M (RGMII) speeds. The XGMAC-CORE contains the MAC Transmitter and Receiver functions specified in the IEEE 802.3-2008/RMII/RGMII standard. It interfaces to the line side with the XGMII/GMII/MII/RGMII/RMII and with a native interface to the system side. These system side interfaces, called the MAC Transmit Interface (MTI) and the MAC Receive Interface (MRI) are synchronous, respectively, to the XGMII/GMII/MII/RGMII/RMII Transmit and XGMII/GMII/MII/RGMII/RMII Receive clocks. In addition to these interfaces, the application can access the Control and Status Registers (CSR) through a MAC Control Interface (MCI) or APB3
- XGMAC-MTL:

  This layer introduces a FIFO buffer into the transmit and receive paths. It interfaces to the system with native interfaces called the Application Transmit Interface (ATI) and the Application Receive Interface (ARI). These interfaces are synchronous to the system clock
- XGMAC-AXI

  The AXI interface transfers the data to and from the system memory through AXI4-compatible master interface. The host CPU uses the AXI slave interface to access the Control and Status registers (CSRs) of the XGMAC subsystem

14.4.3.2 DMA Controller

The DMA has independent Transmit (Tx) and Receive (Rx) engines, and a CSR space. The Tx engine transfers data from the system memory to the device port (MTL), whereas the Rx engine transfers data from the device port to the system memory. The controller uses descriptors to efficiently move data from source to destination with minimal application CPU intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The controller can be programmed to interrupt the application CPU for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

The DMA and the application communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA transfers the data packets received by the MAC to the Rx Buffer in system memory and Tx data packets from the Tx Buffer in the system memory. The descriptors that reside in the system memory contains the pointers to these buffers.

The DMA supports up to 8 Tx and 8 Rx Descriptor lists (or DMA channels). The base address of each list is written to the respective Tx Descriptor List Address register and Rx Descriptor List Address register. The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. The offset is controlled by the programming of the DSL field of DMA_Ch(#i)_Control register. The number of descriptors in the list is programmed in the respective Tx (or Rx) Descriptor Ring Length register. After the DMA processes the last descriptor in the list, it jumps back to the descriptor in the List Address register to create a descriptor ring.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. Buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when EOP is detected.

The XGMAC supports the ring structure for the DMA descriptor. For details about descriptor structure and how the DMA accesses the descriptors, see chapter "Descriptors".

The XGMAC-AXI always uses DMA controller for descriptor fetch, descriptor write-back and data transfer. In DMA, the efficiency of packet transfer is optimized by the following tasks in parallel:

- Multiple Descriptor Fetch
- Data Transfer
- Descriptor write-back.

All these DMA phases work independently in a pipelined fashion such that the descriptor fetch of a new packet can be performed along with data transfer of the previous packet and the descriptor write-back of the last to previous packet. In this way, packet transfers throughput is improved with minimal gaps between them.

***Note**: In case of Rx DMAs, the Data transfer Phase and Descriptor write-back phase cannot be made totally independent, since the order of the data transfer and descriptor write-back has to be strictly followed for maintaining synchronization between the software processing of descriptors and the packet transfers. This ensures that the software processes the closed descriptors only after the corresponding packet buffer is transferred and written into system memory.*

When DSPW bit in the DMA_Mode register is set, the descriptor writes are made as posted writes. XGMAC does not wait for the Write response from the AXI slave to take further actions. This makes the interrupt generation based on the IOC bit in the Descriptor unreliable. Therefore, when DSPW is set, the IOC bit in the Rx Descriptor should not be set.

Related information

Descriptors on page 1559

14.4.3.2.1 Application Bus Burst Access

When configured through Bit 0 of the DMA_SysBus_Mode register, the DMA attempts to execute the fixed-length burst transfers on the AXI master interface. The PBL field of Transmit Control and Receive Control registers of respective DMA channel indicates and limits the maximum burst length. The Rx and Tx descriptors are always accessed in the maximum possible (limited by PBL or 16 * 8/64) burst length for 16 bytes to be read. For more details please refer to DMA_SysBus_Mode register.

The Tx DMA initiates a data transfer only when sufficient space is available in the MTL Tx Queue to accommodate the minimum of the following:

- Bytes corresponding to the configured burst (PBL * 64/8)
- Remaining bytes in Tx Buffer without EOP
- Number of bytes till EOP

The DMA indicates the start address and the number of transfers required to the AXI master interface. When the AXI Interface is configured for fixed-length burst, it transfers the data using the best combination of INCR4, INCR8, or INCR16 or higher if enabled and SINGLE transactions. Note that the SRI system supports fixed-length burst only and only up to BTR16. You must not configure the DMA for using any undefined burst length (INCRx) transactions.

The Rx DMA initiates a data transfer in the following conditions:

- Sufficient data is available in MTL Rx Queue to accommodate the configured burst
- EOP (when it is less than the configured burst length) is detected in the Rx Queue (possible only in store and forward mode)

The DMA indicates the start address and the number of transfers required to the AXI master interface. If EOP is reached before the fixed-burst ends on the AXI interface, dummy transfers are performed in-order to complete the fixed-burst. Otherwise (Bit 0 of DMA_SysBus_Mode register is reset), the DMA transfers the data using INCRx transactions.

When the AXI interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer initiated by the AXI is less than or equal to the size of the configured PBL. Therefore, all subsequent beats start at an address that is aligned to the configured PBL.

***Note**: The DMA can align the address for up to 256 beats because the AXI interface does support up to BLEN 256. But if a system memory is addressed only SINGLE, BLEN4, BLEN8 and BLEN16 are allowed as the SRI bridge is limited to BTR16.*

14.4.3.2.2 Application Data Buffer Alignment

The Tx and Rx data buffers do not have any restrictions on start address alignment. The start address for buffers can be aligned to an unaligned address. However, the DMA always initiates write transfers with address aligned to the bus width and dummy data (old data) in the invalid byte lanes. This typically happens during the transfer of the beginning or end of an Ethernet packet. The software driver should discard the dummy bytes based on the start address of the buffer and size of the packet.

Table 682 Application Data Buffer Alignment Examples

Examples	
Buffer Read	If the Tx buffer address is 32'h00000FF2 (for 128-bit data bus), and 32 bytes need to be transferred, the DMA reads three full words from address 32'h00000FF0, but when transferring data to the MTL Tx queue, the additional bytes (the first two bytes) are dropped or ignored. Similarly, the last 14 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL Tx queue, unless it is the end of packet.
Buffer Write	If the Rx buffer address is 32'h0000FF2 (for 64-bit data bus) and 16 bytes of a received packet need to be transferred, the DMA writes 3 full words from address 32'h00000FF0. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first Rx buffer of the packet. The DMA ignores the offset address and performs full word writes for the middle and the last Rx buffer of the packet.

14.4.3.2.3 Buffer Size Calculations

The DMA does not provide Buffer size in the Rx descriptors. The DMA updates only the status fields (RDES) of the descriptors. The driver has to perform the size calculations.

The Tx DMA transfers the exact number of bytes (indicated by buffer size field of TDES2) towards the MAC. If a descriptor is marked as first (FD bit of TDES3 is set), the DMA marks the first transfer from the buffer as SOP. If a descriptor is marked as last (LD bit of TDES3), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The Rx DMA transfers data to a buffer until the buffer is full or the end of packet is received from the MTL. When the FD bit of a descriptor is set, the amount of valid data in a buffer is accurately indicated by its buffer size field minus the data buffer pointer offset. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by the buffer size in Bits [14:1] of

Receive Control Register). To compute the amount of valid data in this final buffer, the driver must read the packet length (PL bits of RDES3[13:0]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The Rx DMA always transfers the start of next packet with a new descriptor.

***Note**: Even when the start address of a Rx buffer is not aligned to the data width of system bus, the system should allocate a Rx buffer of a size aligned to the system bus width. For example, if the system allocates a Rx buffer of 1,024 bytes (1 KB) starting from address 0x1000, the software can program the buffer start address in the Rx descriptor to 0x1002.*

The Rx DMA writes the packet to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual packet is written from location 0x1002. Therefore, the actual useful space in this buffer is 1,022 bytes, even though the buffer size is programmed as 1,024 bytes, because of the start address offset.

14.4.3.2.4 Error response to DMA

For any data transfer initiated by a DMA channel, if the slave replies with an error response, the DMA stops all operations and updates the error bits and the Fatal Bus Error bit in the Status Register of corresponding DMA channel. The application can either perform a reset to XGMAC or re-initialize the DMA descriptor list and start again. The rest of the DMA channels are not affected by such errors.

14.4.3.2.5 DMA Descriptor Fetch Operation

Each DMA (TX or RX) has allocated space for caching 16 descriptors (256 bytes).

Therefore, the DMA attempts to fetch multiple descriptors in a burst. The maximum burst length during descriptor fetches for a DMA Channel, is dependent on

- Programmed Burst Length in DMA_CH(#i)_Tx_Control register (TxPBL)
- Space available in the Descriptor Cache for that DMA Channel
- Number of descriptors created by the Host (Offset of the Tail Pointer with respect to the last fetched descriptor)
- The Address Alignment requirement with respect to current descriptor address in case bit[12] AAL of DMA_SysBus_Mode is set to 1

The XGMAC-AXI selects minimum of these, to calculate the burst length for descriptor fetches and fill-up the cache. After the current descriptor burst fetch is completed, the TxDMA/RxDMA engines do not initiate further descriptor fetches until the space available in the descriptor cache falls below the threshold size programmed in the respective DMA_Tx_EDMA_Control or DMA_Rx_EDMA_Control register.

The DMA engine also checks the OWN bit (xDES3[31]) of the descriptor to confirm whether the descriptor contents are valid and can be processed by the DMA. In case any of the descriptor has its OWN bit = 0, then, that descriptor and the rest of the descriptors in that burst are dropped and not written into the cache. The DMA tries to fetch the descriptors again in a burst of length decided as per the conditions, from that point onwards.

The descriptors in the cache are read and given to the Data Transfer engine. Once the Data Transfer engine accepts the descriptor, the next descriptor is read from the cache and thus free up the cache space.The Buffer Unavailable (TBU/RBU) interrupt is generated when all the descriptors created by the host (as indicated by the Tail Pointer) are fetched. It is asserted even if some descriptors are still available in the cache for processing. This advance interrupt provides the opportunity for the software to create more descriptors in advance before the cache gets emptied out completely.

The xBU interrupt is also generated when the DMA engine finds that the OWN bit = 0 for two successive fetches of the same descriptor. It then goes into SUSPEND mode and waits for the software to wake it up by updating/ writing into the Tail Pointer register.

***Note**: A descriptor ring must provide a minimum of four descriptors or more to the XGMAC.*

14.4.3.2.6 DMA Tx Data Transfer Operation

The data transfer operation by TxDMA is as follows:

1. The Descriptor fetch engine reads a valid descriptor (OWN=1) either from the system memory or the descriptor pre-fetch cache and gives it to the Data transfer engine.
2. It processes the descriptor control bits, buffer sizes and calculates the size of data transfer to be requested as per the settings of the registers (TxPBL). It checks if space is available in the corresponding TxQ before it issues the request for data transfer.
3. Once the request is accepted by the AXI master (for scheduling on the bus), this engine calculates the next data transfer size and issues another request. The second request can be for one of the following:
   a. Next burst of data transfer from the same buffer in case the first request is only for part of the buffer
   b. Burst of data transfer from Buffer 2 in case the first request completed the transfer of Buffer 1
   c. Burst of data transfer from Buffer 1 of next descriptor in case the first request completed Buffer 2 (or Buffer 2 was empty)
   d. Start of new packet transfer from Buffer of next descriptor in case the first request completes a packet transfer.
4. At any given time, up to two requests can be outstanding for data transfer completion.
5. A request is considered to be completed once the requested data is fetched and written to the corresponding TxQ in MTL. After this, the engine can issue the next request as given in step 3.
6. After the valid buffers of a descriptor is fetched, the descriptor is freed-up and pushed to the Descriptor write-back engine for closure and the next descriptor from the pre-fetched cache is accepted for processing (Step 2).

All these operations are implemented in a pipe-lined fashion so as to avoid any bottlenecks and overheads due to descriptor reads or writes. Moreover, the engine can request for two packet transfers in sequence (for packets of size smaller than the programmed PBL) without completing the fetch of the first one. This allows the hiding of the system latencies of a read command behind the data transfer of the previous command and thus improve the throughput.

14.4.3.2.7 DMA Rx Data Transfer Operation

The data transfer operation by the RxDMA is different from that of the TxDMA and is as follows:

1. The Descriptor fetch engine reads a valid descriptor (OWN=1) either from the system memory or the descriptor pre-fetch cache and gives it to the Data transfer engine.
2. The data transfer engine indicates its readiness to transfer data to the MTL RxQ read Controller along with the supported burst-size length as calculated from the buffer sizes and as per the register settings (RxPBL).
3. When the RxQ Read controller selects an RxQ (in case of multiple RxQ configuration) and triggers the RxDMA to start the data transfer.
4. The RxDMA engine issues the request which is then accepted and driven by the AXI master. This requested data is then transferred to the buffer in system memory through the AXI write channel.
5. Once the requested data transfer is internally completed (driven on the AXI bus), the data transfer engine jumps back to Step 2 in case the packet transfer is not over (no EOP transferred) in step 4.

6. If both the RxBuffers, pointed in the descriptor are full, it pushes the descriptor to the “Descriptor write-back engine” along with the intermediate status and then accept the next descriptor from the pre-fetch cache and go to Step 2.
7. If the EOP is transferred during the last burst transfer, the engine pushes the descriptor to be closed along with the final packet status read from the RxQ after the EOP and then jump to step 2.

The descriptor pre-fetch and the descriptor closure activities are implemented in a pipe-lined fashion so as to avoid any bottlenecks and overheads due to descriptor reads. However, in step 2, the engine does not initiate another data transfer request unless the previous descriptor write transfer is indicated to be complete as explained in the next section.

***Note**: Instead of DMA_CHj_Rx_Data_Xfer_Ring_Offset register indicating the ring offset of the descriptor currently processed by the receive DMA and is transferring the packet data to the buffers specified in the descriptor, it indicates the ring offset of the descriptor for which the packet data transfer is completed by the receive DMA. Hence software must interpret the value read from the DMA_CHj_Rx_Data_Xfer_Ring_Offset status register as one less (except when the value read is 0 in which case the software will not be able to distinguish whether the current ring offset is 0 or 1), unless the receive DMA is suspended due to the unavailability of the descriptors or is in the stopped state (the RDFS, RDTS, and RDWS fields of the DMA_CHj_Debug status register indicate the STOP or SUSPEND state).*

14.4.3.2.8 DMA Descriptor Write-Back Operation

The DMA descriptor write-back operation is triggered when the descriptor is passed on to it by the Data Transfer Engine after the corresponding buffer contents are transferred. This engine closes the descriptor with OWN bit = 0 to indicate to the software that the descriptor is freed-up.

For TxDMA, the Descriptor write-back operation clears TDES3 while the other TDES0-TDES2 are not modified. This write-back request is issued independently of the Buffer data transfer requests (pointed by the next descriptor) by the TxDMA engine.

For RxDMA, the Descriptor is closed with the status fields also updated in RDES0-RDES3 fields. To ensure that the buffer transfer to system memory is complete before the descriptor is closed, these transfer operations are performed in sequence with the same AXI-ID. In other words, the RxDMA engine starts performing the next descriptor's buffer transfer only after the current descriptor is written back and closed. This sequencing is done to ensure that the software does not process the descriptor and read the buffer contents before the buffer data transfers are completed by the hardware.

The transfer complete Interrupts TI (bit[0]) in case of TxDMA and RI (bit[6]) in the case of RxDMA is generated when the descriptor corresponding to the last segment of the packet data is closed and also has the Interrupt On Completion bit set. Note that the interrupt is generated only after the AXI response to the descriptor write transfer is received from the AXI slave.

If the interrupt generation is not enabled for that packet, the descriptor write operation is deemed to be completed once the descriptor write request is accepted by the AXI slave (without waiting for the response from the slave). This reduces the latency of descriptor write completion and improves the throughput.

14.4.3.2.9 DMA Error Handling

Tx DMA Bus Error Handling Flow

If AXI Bus Error is detected by XGMAC while fetching the Tx Descriptors from system memory, it stops fetching descriptors and ignores all the descriptors it would have fetched as a part of burst. However, it processes all the normal pre-fetched descriptors (if any) in the descriptor Cache memory. While processing the descriptor where

the Bus Error is detected, the packet transfer is terminated forcibly along with a control to tag, which enables MAC transmitter to automatically insert CRC error for that packet. The XGMAC completes pending outstanding read requests on the AXI of that Tx Channel. Also, it makes an attempt to close the descriptor with the Error Status (bit[27] of TDES3) and then automatically STOPs the corresponding Tx DMA Channel.

If AXI Bus Error is detected by the XGMAC while transferring Tx packet data from system memory, it stops fetching descriptors, stops packet data reads and ignores all the descriptors it would have fetched as a part of burst. The packet transfer is also terminated forcibly along with a control to tag which enables MAC transmitter to automatically insert CRC error for that packet. It completes pending outstanding read requests on the AXI of that Tx Channel. Also, XGMAC makes an attempt to close the descriptor with the Error Status (bit[27] of TDES3) and then automatically STOPs the corresponding Tx DMA Channel.

If AXI Bus Error is detected by the XGMAC while writing back the Descriptor to the System memory, it stops fetching descriptors, stops packet data reads and ignores all the descriptors it would have fetched as a part of burst. The packet transfer is also terminated forcibly along with a control to tag which enables MAC transmitter to automatically insert CRC error for that packet. It completes pending outstanding read requests on the AXI of that Tx Channel. Then it STOPs the corresponding Tx DMA Channel. In this case the Error Status (bit[27] of TDES3) write may not be successful as Bus Error is detected while writing back the descriptor itself.

When a Tx DMA channel is stopped by the XGMAC due to Bus Error, the software driver is expected to follow the steps as described in Bus Error Handling.

Rx DMA Bus Error Handling Flow

If AXI Bus Error is detected by the XGMAC while fetching the Rx Descriptors from system memory, it stops fetching descriptors and ignores all the descriptors it would have fetched as a part of burst. However, it processes all the normal pre-fetched descriptors (if any) in the descriptor cache memory. While processing the descriptor where the Bus Error is detected, the packet transfer to system memory is terminated forcibly by flushing the current packet in the Rx Queue. The XGMAC completes any pending outstanding read/write requests on the AXI of the Rx channel. Also, XGMAC attempts to close the descriptor with the Error Status (bit[15] =1 and bit[19:16] = 4’h1000 of RDES3) and then automatically STOPs the corresponding Rx DMA channel.

If AXI Bus Error is detected by the XGMAC while transferring Rx packet data to the system memory, XGMAC stops fetching descriptors, stops packet data writes and also ignores all the descriptors it would have fetched as a part of burst. The packet transfer to system memory is terminated forcibly by flushing the current packet in the Rx Queue. The XGMAC completes any pending outstanding read/write requests on the AXI of that Rx Channel. Also, it makes an attempt to close the descriptor with the Error Status (bit[15] =1 and bit[19:16] = 4’h1000 of RDES3) and then automatically STOPs the corresponding Rx DMA Channel.

If AXI Bus Error is detected by the XGMAC while writing back the Descriptor to the system memory, XGMAC stops fetching descriptors, stops packet data writes and ignores all the descriptors it would have fetched as a part of burst. The packet transfer to system memory is terminated forcibly by flushing the current packet in the Rx Queue. The XGMAC completes pending outstanding read/write requests on the AXI of that Rx Channel. Then it STOPs the corresponding Rx DMA Channel. In this case the Error Status (bit[15] =1 and bit[19:16] = 4’h1000 RDES3) write may not be successful as Bus Error is detected while writing back the descriptor itself.

When a Rx DMA channel is stopped by the XGMAC due to Bus Error, the software driver is expected to follow the steps as described in Bus Error Handling The software driver can optionally program the bit[31] (RPF) of DMA_CHx_Rx_Control Register to prevent any Head of the Line (HOL) blocking of the other DMA Channels which are not stopped. When this bit is set and corresponding DMA is stopped (either by software or XGMAC) the Rx packets routed to that Rx channel is automatically flushed in the Rx Queues. When the DMA is started by the software driver later, the new packets that would have received in the XGMAC after the DMA is started are routed to the Rx DMA Channel. For more information see, Receive Path.

***Notes**:*

1. *When RPF=1, dynamic mapping causes flushing of packets from unintended queues to the stopped Rx DMA*
2. *When RPF=0, when one of the Rx DMA channels is stopped, it causes unintended stopping of Rx DMA channels*

14.4.3.2.10 DMA related Interrupts

An interrupt can be generated as a result of various events in the XGMAC. These events are captured in status registers and interrupt enables are provided for each source of interrupt such that the interrupt signal (sbd_intr_o) is asserted for an event only when the corresponding interrupt enable is set.

The interrupt status and corresponding enable registers are organized in an hierarchical manner so that it is easier for software to traverse and identify the source of interrupt event quickly. When sbd_intr_o is asserted, the DMA_Interrupt_Status register is first level that indicates the major blocks for the interrupt event source. This register is read-only, and it contains bits corresponding to each DMA channel (TX & RX pair), the MTL, and the MAC. The software application must then read one (or more) of the following registers corresponding to the bits that are set:

- DMA_CH(#i)_Status register
- MTL_Interrupt_Status register
- MAC_Interrupt_Status register

The sbd_intr_o interrupt is a level signal and gets de-asserted only when all the enabled interrupt events are cleared in their respective status registers and correspondingly all the bits in the DMA_Interrupt_Status register are cleared.

The DMA_CH(#i)_Status register captures all the interrupt events of that TxDMA and RxDMA channel pair. The DMA_CH(#i)_Interrupt_Enable register contains the corresponding enable bits for each of the interrupt event. There are two groups of interrupts in the DMA channel namely: Normal and Abnormal interrupts. They are indicated by Bits[15:14] of DMA_CH(#i)_Status register respectively. The normal group is for events that happen during the normal transfer of packets (TI, RI, TBU) while the abnormal interrupt events are for error events. Interrupt events are cleared by writing 1'b1 to the corresponding bit position. When all the enabled interrupt events are cleared (including the NIS and AIS), the interrupt source from the DMA Channel is cleared and the corresponding bit in DMA_Interrupt_Status register is also cleared.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated. For example, Receive Interrupt Bit[6] of DMA_CH(#i)_Status register indicates that one or more packets were transferred to the application buffer. The driver must scan all descriptors, from the last recorded position to the first one, owned by the DMA to determine how many packets are received.

An interrupt is generated only once for multiple events. The driver must scan the DMA_Interrupt_Status register for the cause of the interrupt and clear the source in the respective Status register. The sbd_intr_o is cleared only when all the bits of DMA_Interrupt_Status register are cleared.

Periodic scheduling of transmit and receive interrupt

It is not preferable to generate interrupts for every packet transferred by DMA (RI and TI) for system throughput performance reasons. The XGMAC gives the flexibility to schedule the interrupt at regular intervals using two methods:

1. Set Interrupt on Completion bit in Transmit descriptor (TDES2[31]) once for every "required" number of packets to be transmitted
2. Similarly, set the IOC (RDES3[30] in Table 758 bit only at some specific intervals of Receive descriptors. This way, whenever a received packet transfer to system memory is complete and any of the descriptors used for that packet transfer has the IOC bit set, only then the RI event is generated

In addition, an interrupt timer (DMA_CH(#i)_Rx_Interrupt_Watchdog_Timer) is given for flexible control and periodic scheduling of Receive Interrupt as described:

1. Rx Interrupt Watchdog Timer based on number of application clock cycles: When the RWT field of DMA_CH(#i)_Rx_Interrupt_Watchdog_Timer is programmed with a non-zero value, interrupt timer gets activated as soon as the Rx DMA completes a transfer of a received packet to system memory without asserting the Receive Interrupt because the corresponding interrupt of completion IOC bit (RDES3[30]) is not set. When this timer runs out as per the programmed value, RI bit is set and the interrupt is asserted if the corresponding RIE is enabled in DMA_CH(#i)_Interrupt_Enable register. The 2-bit RWTU field in the same register selects the granularity of RWT (8-bit) field. The granularity can be programmed to 256, 512, 1024, or 2048 clock cycles, giving a maximum range of 522240 ($= 255 \times 2048$) application clock cycles
2. Rx Interrupt Watchdog Timer based on number of transferred bytes: When RBCT field is programmed with a non-zero value, the interrupt timer accumulates the packet size in bytes (extracted from the received packet status), beginning with the packet for which the RxDMA does not assert the Receive Interrupt because the corresponding interrupt of completion IOC bit (RDES3[30]) is not set. When the accumulated bytes equals or exceeds the programmed value, RI bit is set and the interrupt is asserted if the corresponding RIE is enabled in DMA_CH(#i)_Interrupt_Enable register. The active range of the RBCT field in DMA_CH(#i)_Rx_Interrupt_Watchdog_Timer register is 1 to 1023. The granularity is 1 KB, which gives a maximum threshold of 1023 KB for the interrupt timer

Both the interrupt timers are stopped and cleared, if the RI is set for a packet transfer whose descriptor's IOC was set or due to expiry of any one of the interrupt timer. The timer is reactivated automatically after the next packet transfer is complete for which the RI event is not generated.

***Note**: When DSPW bit in the DMA_Mode register is set,the generation of the Rx interrupt based on IOC in the Rx Descriptoris not reliable. Therefore, if the DSPW bit set, IOC bit shouldnot be enabled in the Rx Descriptor.*

Per channel transfer complete interrupt

The Transmit Transfer complete interrupt (TI) and Receive Transfer complete interrupt (RI) are reflected in DMA_CH(#i)_Status register. The TI bit is set whenever the Tx DMA channel closes a descriptor in which the IOC (Interrupt On Completion - TDES2[30]) bit is set. Similarly, the RI bit is set whenever the Rx DMA channel closes the descriptor with LD bit set and in any of the descriptors used for transferring that packet, IOC (Interrupt Enable on completion - RDES3[30]) bit is set.

The common sbd_intr_o output signal is asserted for the Transfer complete interrupts only when the corresponding interrupts are enabled in DMA_CH(#i)_Interrupt_Enable register.

The XGMAC also supports the following per Channel Transfer Complete interrupt signals.

- sbd_perch_tx_intr_o[] (Transmit Per Channel Interrupts)
- sbd_perch_rx_intr_o[] (Receive Per Channel Interrupts)

The behavior of the RI/TI/ sbd_perch_tx_intr_o[]/sbd_perch_rx_intr_o[] changes depending on the settings of INTM field bit[13:12] in DMA_Mode Register.

14.4.3.3 MAC transaction layer (MTL)

The MAC Transaction Layer provides FIFO memory to buffer and regulate the frames between the application system memory and the XGMAC IP. The native interface enables data transfer between the host and the MAC transaction layer through a simple handshake protocol.

The MTL block also provides a reliable synchronization mechanism for data transfer between the application and XGMAC clock domains. The MTL has an asynchronous FIFO on the transmit and receive paths, which are 68 bits wide in this 64-bit system. It contains 64 bits of data and 4 control bits.

The MTL block communicates with the application through the Application Transmit Interface (ATI), Application Receive Interface (ARI), and XGMAC Control Interface (MCI).

14.4.3.3.1 Transmit Path

The application SW pushes the Ethernet packets into the corresponding queue via TX DMA channels. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or complete packet is in the queue (store-and-forward mode).

14.4.3.3.2 Receive Path

The Rx module receives the packets given by the MAC and pushes them into the Rx Queue. The status (fill level, through PBL and watermark) of the queue is indicated to the DMA when it crosses the configured Receive threshold (Bits[1:0] of MTL_RxQ(#i)_Operation_Mode register), in threshold mode or when a complete packet is received in store and forward mode. The DMA can use the fill level of the queue to initiate pre-configured burst transfers towards the AXI interface.

14.4.3.4 The MAC layer

The MAC layer complies fully with the IEEE 802.3-2008/industry standard, implementing the XGMII/GMII/MII/ RGMII/RMII full duplex interface for communication with the physical coding sub-layer. The MAC layer communicates with the application side through the MAC Transmit Interface (MTI), MAC Receive Interface (MRI) and the MAC Control Interface (MCI).

PHY interface selection

The XGMAC-CORE supports the following PHY interfaces. You can select from the following supported modes, by programing the MAC_Tx_Configuration register as shown in Table 683.

Table 683 PHY interfaces supported by XGMAC

Speed	Interface	Data width	Interface clock frequency	Programming MAC_Tx_Configuration.SS
5 Gbps	XGMII	32-bit	156.25 MHz	3'b101
2.5 Gbps	XGMII	32-bit	78.125 MHz	3'b110
1 Gbps	GMII	8-bit	125 MHz	3'b011
2.5 Gbps	GMII	8-bit	312.5 MHz	3'b010
100 Mbps	MII	4-bit	25 MHz	3'b100
10 Mbps	MII	4-bit	2.5 MHz	3'b111

- RGMII interface is selected by configuring RGMII mode in the module HSPHY before a software reset of the MAC or a kernel reset of GETH. Write HSPHY register CTRL0_PHY.EPR = 3'b001. After that, a software reset of the MAC or a kernel reset of GETH needs to be applied. RGMII speed modes (2.5 G/1 G/100 M/10 M) is based on SS[2:0] values of 3’b010, 3'b011, 3'b100, and 3'b111 respectively
- RMII interface is selected by configuring RMII mode in the module HSPHY before a software reset of the MAC or a kernel reset of GETH. Write HSPHY register CTRL0_PHY.EPR = 3'b010. After that, a software reset of the MAC or a kernel reset of GETH needs to be applied. RMII speed modes (100 M/10 M) is based on ss[2:0] values 3’b100 and 3’b111

14.4.3.4.1 Transmission

Transmission is initiated when the MTL or application pushes data towards XGMAC with the SOP signal asserted. When the SOP signal is detected, XGMAC accepts the data and begins transmitting to the XGMII/ GMII/MII/RGMII/RMII. The time required to transmit the frame data to the XGMII/GMII/MII/RGMII/RMII after the application initiates transmission is variable, depending on such delay factors as inter-frame gap (IFG) delay, pause transmission requests from the XGMAC receiver, and the time required to transmit preamble and SFD and

any back-off delays for half-duplex mode. As long as XGMAC can accommodate the data from the application in the internal buffer, XGMAC accepts data received from the MTL.

After the end-of-frame is transferred to the XGMAC-CORE, the application can wait until the controller completes normal transmission, or start transferring the next frame to the XGMAC, then receive the transmission status.

In the half-duplex mode, if a normal collision occurs during transmission, the MAC sends the Transmit Status to MTL, with the retry bit set to 1. The MAC sends retry request, until one of the following condition is true:

- Packet is successfully transmitted
- Maximum number of retry requests are completed

When maximum number of retry requests are completed, the MAC aborts the packet transmission with Excessive Collision Transmit Status. The MAC accepts and drops all further data until the next SOP is received. The MTL block should retransmit the same packet from SOP, when it observes a Retry request (in the Status) from the MAC. If any one of the following occurs, the MAC aborts the packet transmission:

- No carrier (half-duplex mode)
- Loss of carrier (half-duplex mode)
- Excessive deferral (half-duplex mode)
- Late collisions (half-duplex mode)
- Jabber

The MAC accepts and drops all further data until the next SOP is received.

If the MTL cannot provide the data continuously during the transmission, XGMAC issues an underflow status. During the normal transfer of a frame from MTL, if the XGMAC receives an SOF without receiving an EOF for the previous frame, the SOF is ignored and the new frame is considered a continuation of the previous frame.

Transmit bus interface module (TBU)

This section describes the transmit bus interface module (TBU).

The TBU adds a VLAN tag and/or SA bytes, replaces the VLAN tag, or deletes VLAN tag from the input frame data. The XGMAC provides for VLAN tag inclusion/deletion or replacement and source address inclusion or replacement. Both the VLAN tagging and untagging feature, and the source address inclusion or replacement feature can be controlled through CSR.

VLAN Tag Modification

VLAN tag inclusion

The TBU module adds the VLAN tag to the transmitted packet. It uses the VLT bits of the VLAN Tag Inclusion/Replacement (MAC_VLAN_Incl) register to add the VLAN tag value. The VLAN tag can be included on a per-frame basis. MAC_VLAN_Incl register also provides options for inclusion, deletion, or replacement of VLAN tag. The application can program MAC_VLAN_Incl register to include the VLAN tag for all the transmit frames.

VLAN tag replacement

The TBU module replaces the transmitted packet's existing VLAN tag with the contents of MAC_VLAN_Incl register. The VLAN tag can be replaced on a per-frame basis.

VLAN tag deletion

The TBU module also deletes the VLAN tag for each transmitted frame. MAC_VLAN_Incl register also provides options for VLAN tag inclusion/deletion or replacement. The application can program MAC_VLAN_Incl register to remove the VLAN tag for all transmit frames.

Source Address Modification

SA inclusion

The TBU module adds the source address to the packet transferred from the application, using the contents of MAC_Address0_High and MAC_Address0_Low registers to add the SA to the SA field. If the frame transferred to XGMAC has FCS, it is replaced with an accurate FCS value. The source address inclusion request can be triggered on a per-frame basis by the source address inclusion/replacement control bits in the MAC_Tx_Configuration register.

SA replacement

The TBU module replaces the source address of the transmitted packet with the contents of MAC_Address0_High and MAC_Address0_Low registers to the SA field. The source address replacement request is serviced in the same way as an SA inclusion.

Transmit frame controller module (TFC)

This section describes the transmit frame controller module (TFC).

The Transmit Frame Controller (TFC) consists of a two-stage register, which holds the data and byte enables received from the TBU module. This register regulates data flow to TPE by providing a buffer between the application and the TPE. The TFC also requires this buffer for adding CRC and pad bytes to the frame data input the TBU module sends to the TPE (Transmit Protocol Engine).

The TBU module performs the following types of CRC and Pad insertion related operations:

CRC and pad insertion

The MAC appends a cyclic redundancy check (CRC) to the end of the transmitted packet of length greater than or equal to 60 bytes. When the number of bytes received from the application is less than 60 (DA + SA + LT + Data < 60), the MAC automatically appends zeros to make the packet length exactly 60 bytes and 4 bytes of CRC.

CRC insertion (disable pad insertion)

The MAC appends cyclic redundancy check (CRC) to the end of the transmitted packet, but does not append padding. The application should ensure that the padding bytes are present in the packet being transferred, that is, that the packet being transferred is of length greater than or equal to 60 bytes.

Disable CRC insertion

The MAC does not append a cyclic redundancy check (CRC) to the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred.

CRC replacement

The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred.

The application must select the correct type of CRC and Pad insertion operation based on the transmit packet modifications expected/enabled in the MAC.

The TFC handles the XGMAC transmit pause operation because of reception of PAUSE frames. The TFC gives higher priority to transmit a PAUSE frame request from FTX block than the request received from TBU block.

Transmit protocol engine module (TPE)

This section describes the transmit protocol engine module (TPE).

The Transmit Protocol Engine module (TPE) consists of a transmit state machine that controls Ethernet frame transmission. In XGMII and GMII/MII mode, the transmit state machine of this module contains the following features to conform to IEEE 802.3/802.3z specifications.

- Generates preamble and SFD
- Generates jam pattern after normal collision, in the half-duplex mode
- Supports jabber timeout
- Supports flow control for the half-duplex mode (backpressure)
- Generates transmit packet status
- Contains timestamp snapshot logic for IEEE 1588 support

When the TPC module requests the TPE module for a new packet transmission, the Transmit State Machine sends out the preamble and SFD, followed by the data received. The preamble is defined as 7 bytes of 8’b10101010 pattern and the SFD is defined as 1 byte of 8b’10101011 pattern. The collision window is defined as 1 slot time (512-bit times for 10/100 Mbps Ethernet). The jam pattern generation is applicable only to half-duplex mode, not to full duplex mode. In full-duplex mode, the Transmit State Machine ignores the collision signal from the PHY.

In MII mode, if a collision occurs any time from the beginning of the packet to the end of the CRC field, the Transmit State Machine sends a 32-bit jam pattern of 32’h55555555 on MII to inform all other stations that a collision has occurred. If the collision is seen during the preamble transmission phase, the Transmit State Machine completes the transmission of preamble and SFD, and then sends the jam pattern. If the collision occurs after the collision window and before the end of the FCS field the Transmit State Machine sends a 32-bit jam pattern and sets the late collision bit in the transmit packet status.

The TPE module maintains a jabber timer to stop the transmission of Ethernet packets if the TFC module transfers more than 2,048 (default) bytes. The timeout is changed to 10,240 bytes when the Jumbo packet is enabled. The Transmit State Machine uses the deferral mechanism for flow control (backpressure) in the half-duplex mode. When the application requests to stop receiving packets, the Transmit State Machine sends a JAM pattern of (8'h55) 32 bytes when it senses a reception of a packet, provided the Transmit flow control is enabled. This results in a collision and the remote station backs off. The application requests the flow control by setting the FCB bit of the Flow Control Register of the corresponding MTL queue. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure continues to be active for a long time (and more than 16 consecutive collision events occur), the remote stations abort their transmissions because of excessive collisions.

If IEEE 1588 timestamp is enabled for the Transmit packet, this block takes a snapshot of the system time when the SFD is put onto the Transmit GMII or MII bus. The system time source is either an external input or generated internally based on the configuration selected.

XGMII mode

The TPE module’s transmit state machine performs the following functions to conform to Clause 46 of IEEE 802.3-2008:

- Generates Start Control Character (SCC), preamble, and SFD
- Generates transmit frame status

- Blocks frame data from the TFC when the STX blocks transmission due to an IFG delay
- Based on the link fault status from the FSM in the XGMAC receiver, aborts frame transmission and transmits the remote fault messages/idles during the IFG

When a new frame transmission from the TFC is requested, the transmit state machine sends the SCC, preamble, and SFD, followed by the received data. The SCC is defined as 1 byte of the 8'b11011111 pattern, the preamble is defined as 7 bytes of the 8'b10101010 pattern, and the SFD is defined as 1 byte of the 8b'10101011 pattern. The Transmit Control signal (TXC[3:0]) is generated synchronously with the TXD[31:0] from this block. This includes the control character during frame transmission and fault messaging.

GMII/MII mode

The TPE module's transmit state machine performs the following functions to conform to Clause 35 of IEEE 802.3-2008:

- Generates preamble and SFD
- Generates transmit frame status
- Blocks frame data from the TFC when the STX blocks transmission due to IFG delay
- Converts the 32-bit data from the TFC to 8-bit or 4-bit data (depending on GMII or MII mode) that can be sent on the GMII data bus (TXD[7:0])

When a new frame transmission from the TFC is requested, the transmit state machine sends the preamble and SFD, followed by the received data. The preamble is defined as 7 bytes of the 8'b10101010 pattern and the SFD is defined as 1 byte of the 8b'10101011 pattern. The TPE state machine transmits a single byte every clock over TXD[7:0]. The transmit control signals TX_EN and TX_ER are generated synchronously with the TXD[7:0] from this block. If an underflow occurs (no valid data available for transmission even though end-of-frame data is not received), the state machine ends the frame transmission on GMII by asserting the TXER signal on the last byte.

Transmit scheduler module (STX)

This section describes the transmit scheduler module (STX).

The Transmit scheduler module (STX) schedules frame transmission on the GMII or MII interface. It provides an enable signal to the TPE module after satisfying the IPG and back-off delays. The STX module performs the following functions:

- Maintains the inter-packet-gap (IPG) between two transmitted packets:

  When operating in XGMII mode, this module maintains an average inter-frame gap (as controlled by the DDIC bit of MAC_Tx_configuration register) between two transmitted frames using the Deficit Idle Counter (DIC) algorithm. When operating in GMII mode, this module ensures that there is a minimum inter-frame gap between two transmit frames (controlled by the IFG bits of MAC_Tx_Configuration register)

  In the half-duplex mode, when IPG is configured for 96-bit times, the STX module follows the rule of deference specified in the IEEE802.3,Section 4.2.3.2.1. The module resets its IPG counter if a carrier is detected during the first two thirds (64-bit times for all IPG values) of the IPG interval. If the carrier is detected during the final third of the IPG interval, the STX module continues the IPG count and enables the transmitter after the IPG interval
- Implements the Truncated Binary Exponential Back-off algorithm:

  The STX module implements the Truncated Binary Exponential Back-off algorithm when it operates in the half-duplex mode
- In XGMII mode, this module can reduce the data transmission rate to SONET/SDH rates, using a rate adaptation algorithm that stretches the IFG. The rate adaptation can be enabled through MAC_Tx_Configuration register
- This module also ensures that the transmitter defers transmission (of data frames) when a PAUSE frame with non-zero pause quanta is received

After satisfying IFG requirements, the STX enables the TPE to transmit the frame.

In XGMII mode, the STX module maintains an idle period according to the DIC Algorithm and performs IFG stretching for rate adaptation if the SONET/SDH rate match bit in MAC_Tx_Configuration register is enabled. If frames from the TFC arrive at the TPE module sooner than the calculated IFG time, the TPE waits for the enable signal from the STX before starting the transmission on the XGMII. The STX starts its IFG counter after the EOF, followed by the IDLE, is transmitted on the line. At the end of the IFG count (when the count is zero) the module issues an enable signal to the TPE.

In GMII mode, the STX module maintains an idle period of the configured inter-frame gap (IFG bits of MAC_Tx_Configuration register) between any two transmitted frames. If frames from the TFC arrive at the TPE module sooner than the configured IFG time, the TPE module waits for the Enable signal from the STX module before starting transmission on the GMII. The STX module starts its IFG counter as soon as the carrier signal of the GMII goes inactive. At the end of the programmed IFG value, the module issues an Enable signal to the TPE.

Link fault signaling

The link fault detection and signaling feature of XGMAC is fully compliant to the Link Fault Signaling FSM described in Section 46.3.4.3 of IEEE 802.3. XGMAC receiver performs link fault detection and indicates the link status to XGMAC transmitter. When the XGMAC receiver detects a local fault during frame reception, XGMAC aborts the frame transmission with an error control character and instead sends Remote Fault messages continuously on the XGMII lanes.

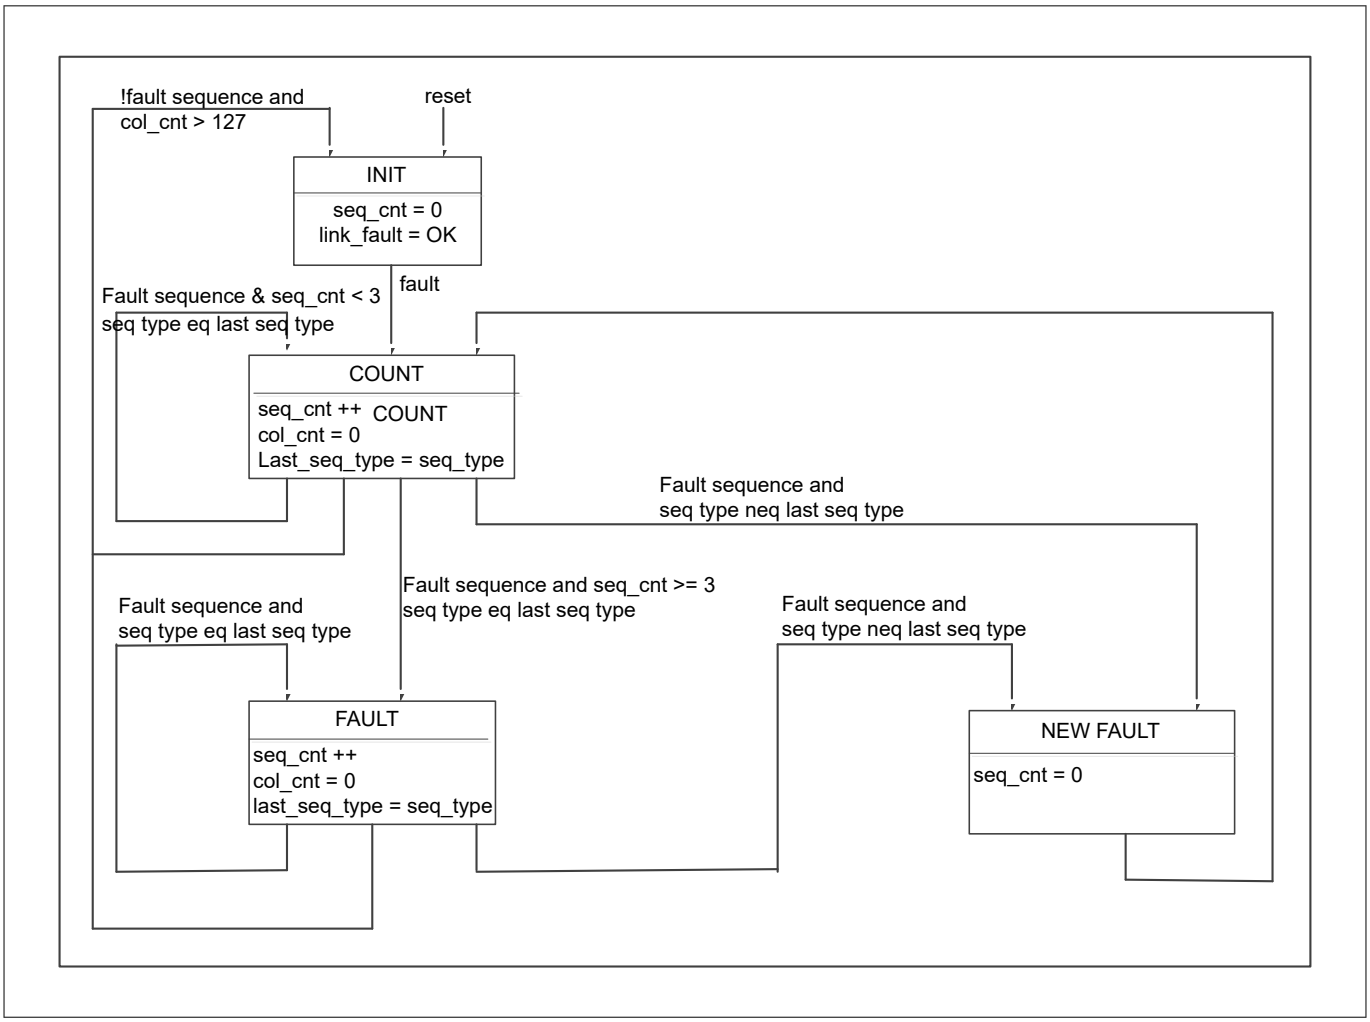

Figure 132 Link fault signaling

When it detects Remote Fault messages on the receive side, XGMAC starts sending Idle control characters continuously on the transmit XGMII lines. If a remote fault is detected during a normal frame transmission, the frame is aborted by sending an Error control character. No data is accepted from the application until the link status is OK.

***Note**:* *Detection of local or remote fault events are validated with the reception of 4 fault_sequences containing the same fault value, with each pair of fault sequences separated by less than 128 columns and no intervening fault_sequences of a different fault value as described in IEEE 802.3 Section 4, Chapter 46.3.4.3.*

XGMAC only supports sequence order set (0x9c) for the remote and local fault detection on the XGMII. If XGMII receives signal order set (0x5c), it is ignored. Section 4 of IEEE 802.3-2008 specification mentions this as RESERVED for INCITS T11 Fiber Channel use

Transmit CRC generator module (CTX)

This section describes the transmit CRC generator module (CTX).

The Transmit CRC Generator module interfaces with the TFC module to calculate CRC for insertion into the Ethernet frame's FCS field. The figure below explains how CRC is transmitted.

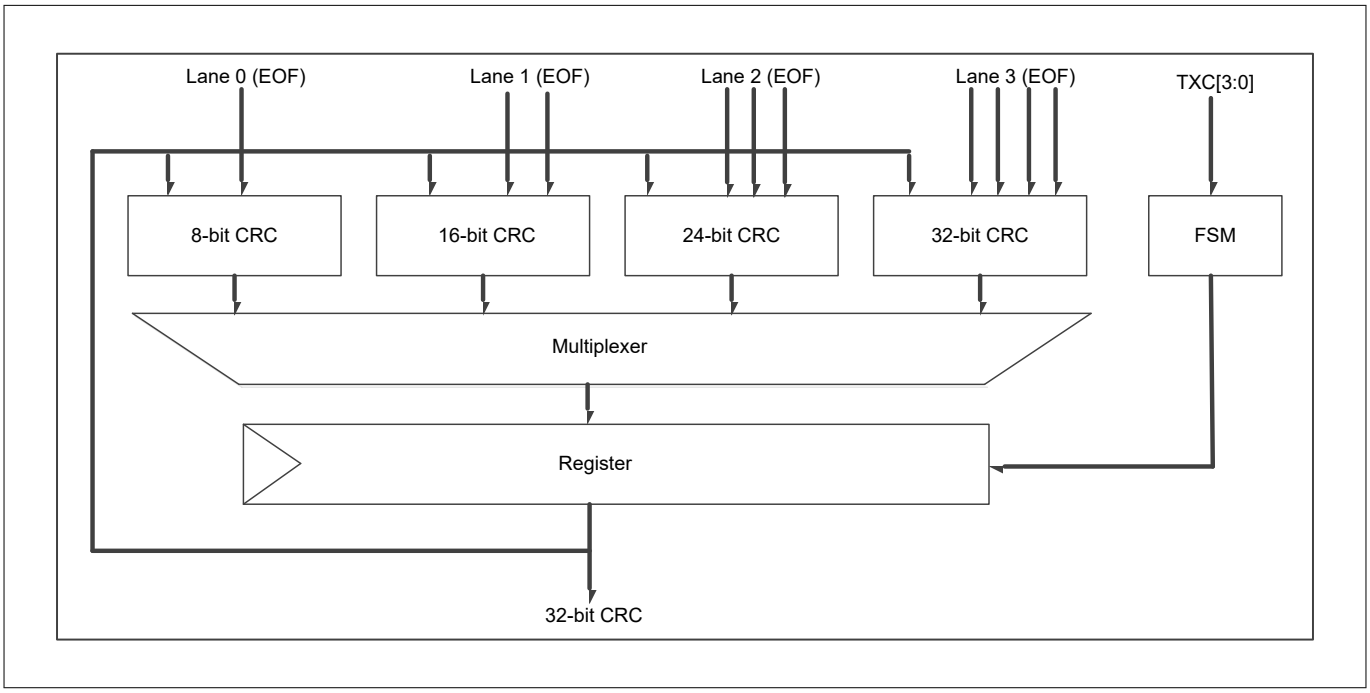

Figure 133 CRC calculation and transmission

The CTX calculates the 32-bit CRC for the Ethernet frame's FCS field. The encoding is defined by the following generating polynomial.

G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1

This module gets the Ethernet frame as 32-bit words from the TFC module which includes (DA + SA + LT + Data + PAD) qualified with a Data Valid signal. The TFC module issues the Start command to reset the CRC before starting the CRC calculation for the new frame.

TXC[3:0] (Transmit Control)indicates whether data or control characters are being driven Transmit Data TXD lanes. If any of these bits are de-asserted, data is driven to the corresponding Transmit data lane. If a bit remains asserted, control characters are driven to the corresponding Transmit data lane

Transmit flow control module (FTX)

This section describes the transmit flow control module (FTX).

The Transmit Flow Control module (FTX) generates PAUSE frames and drives them to the TFC module. The TFC receives PAUSE frames from the FTX, appends the calculated CRC, and sends the frames to the TPE.

The application initiates PAUSE frame generation by requesting the FTX module to send a PAUSE frame in one of the following ways:

- Setting the Flow Control Busy (FCB) bit in the Flow Control register
- Asserting the mti_flowctrl_i signal in response to an MTL Receive FIFO Full condition or due to the assertion of the sbd_flowctrl_i sideband signal in the XGMAC Subsystem

If the application requests flow control by setting the FCB bit of Flow Control register, the FTX generates and transmits a PAUSE frame to the TFC. The generated frame contains the Pause Time value programmed in MAC_Q(#i)_Tx_Flow_Ctrl register. To extend or end the pause prior to the time specified in the previously transmitted PAUSE frame, the application must request another PAUSE frame transmission after programming the appropriate value in the Pause Time register.

If the request for PAUSE goes inactive prior to the sampling time, the FTX transmits a PAUSE frame with 0 pause time to indicate the other end (a switch, for example) that the Receive buffer is ready to receive new data frames. Zero-quanta PAUSE frame generation is controlled using the Flow Control register's DZQP bit (bit[7] of Flow Control register).

14.4.3.4.2 Reception

When MAC detects an SFD on the XGMII/GMII, a receive operation is initiated. The controller strips the preamble and SFD before processing the frame.

The frame is dropped in the following scenarios:

- The Start control character occurs in any lane other than Lane 0
- The SFD and preamble are less than 8
- The SFD is not received on Lane 3 after the start control character

***Note**:*

- *TPRE field of the `MAC_Extended_Configuration` register is not supported for preemptive packets*
- *In configurations with Frame Preemption (FPE), for packet reception in XGMII mode, the minimum gap between the last valid byte of previous and first valid byte after SFD of current packet is 4 cycles of the receiver clock (IPG columns + Preamble columns)*

However, when operating in the 2.5G speed in XGMII mode, if the TPRE field of `MAC_Extended_Configuration` register is set, packets with SCC and 5 or 6 preamble bytes are accepted.

When operating in GMII mode, the MAC receiver can receive a frame with a variable preamble and does not drop the frame if preamble bytes are missing.

The header fields are checked for filtering and the FCS field is used to verify the frame's CRC. The received frame is stored in a shallow buffer until the address filtering is performed. XGMAC drops the frame if it fails the address filter.

Packet filtering on page 1432

Receive protocol engine module (RPE)

The RPE consists of the Receive state machines (one for XGMII and another for GMII), which strip the preamble and SFD. At any time only one FSM is enabled, depending on the configuration programmed by software through CSR (the SS field of MAC_TX_Configuration register).

XGMII mode

This section describes the XGMII mode.

In XGMII mode, the RPE's XGMII receive state machine seeks the Start control character on Lane 0, then seeks the SFD field in the XGMII lanes. Until the SFD field is detected, the state machine drops receive preambles. Once the SFD is detected on Lane 3, the state machine begins sending the Ethernet frame's data to the RFC, beginning with the first byte after the SFD (that is, the destination address). The RPE FSM stops sending data to the RFC when any control character other than the Error control character is received in any lane.

The RPE module detects the local and remote fault messages received on the XGMII lines, implements the Link fault signaling protocol, and sends requests to the XGMAC transmitter to send Remote Fault or Idle messages. It also detects invalid control characters (except the Terminate control character) received on any lane during frame reception and ensures that the frame checksum error status is set. The figure in the "Link fault signaling" section shows how the XGMAC monitors the Link Fault message from the PHY or remote device(s) to determine the link fault status. The link fault status from the RPE determines whether the MAC transmitter transmits a Normal Frame message or a Fault message.

Related information

Link fault signaling on page 1418

GMII/MII mode

This section describes the GMII/MII mode.

In GMII mode, when the RX_DV signal of the GMII/XGMII becomes active, the receive state machine of the RPE seeks the SFD field from the receive modifier logic. Until the SFD field is detected, the state machine drops receive preambles. When the SFD is detected, the state machine sends the Ethernet frame data to the RFC module, beginning with the first byte following the SFD (destination address).

Auto pad/CRC stripping

The RPE module's receive state machine decodes the Length/Type field of the Ethernet frame being received. If the Length/Type field is less than 64 bytes and the MAC is programmed with the Auto Pad Stripping or CRC Stripping options, the state machine sends the frame's data up to the count specified in the Length/Type field, then drops bytes (including the FCS field). If the received Length/Type field is greater than or equal to 64 bytes, the state machine performs no pad stripping, but does strip the FCS. The state machine sends the RFC the appropriate byte enables, along with the last word transferred after receiving the Terminate control character. The state machine enters the status phase, where it sends the received frame status. If the Length/Type field is greater than 600 (hexadecimal), the RPE module sends all received Ethernet frame data to the RFC module, irrespective of the value on the programmed auto-pad or CRC stripping option.

Watchdog timer

The XGMAC has an internal watchdog timer, which is programmed to truncate the receive frame. This timer is enabled by default; therefore, frames bigger than 2,048 bytes (10,240 bytes if Jumbo Frame is enabled) are cut off after 2,048 bytes (10,240 bytes) are received at the RPE. This feature can be disabled by programming the watchdog timer disable in the MAC_Rx_Configuration register. However, even if the watchdog timer is disabled, larger-than-16383 bytes frames are cut off and a watchdog time-out status is given. There is a programmable watchdog timer option provided, where cut-off limit can be specified in steps of 1 KB from 2 KB to 16383 bytes.

Loopback support

The XGMAC supports the loopback of transmitted frames onto its receiver in XGMII mode. By default, the XGMAC loopback function is disabled, but this feature can be enabled by programming the Loopback bit in the MAC_Rx_Configuration register.

Enable the loopback only in the full-duplex mode. In the half-duplex mode, the carrier sense signal (csr) or collision (col) signal inputs are sampled which might result in packet drop.

The transmit and receive clocks are asynchronous, so a free-running, asynchronous FIFO is used to loop transmit data back onto the receive path.

In GMII mode, the same FIFO is used for loopback (5 deep, 36 bits wide). The write and read pointers are re-initialized to have an offset of 2 at the start of each frame read from the FIFO. This helps avoid over- or underflow during the transfer of a frame, and ensures that the over- or underflow occurs only during the IFG between the frames.

A FIFO depth of 5 is sufficient to prevent data corruption for frame sizes up to 9,022 bytes with a difference of 200 ppm between the GMII transmit and receive clock frequencies. Hence, larger frames should not be looped back in GMII mode, as they may become corrupted in this loopback FIFO.

***Note**: The XGMAC uses the XGMII receive clock in the receive path during loopback operation.*

Frame status generation

At the end of every received frame, the RPE module generates a received frame status and sends it to the RFC module. Control, missed frame, and filter fail statuses are added to the receive status in the RFC module.

Receive CRC module (CRX)

This section describes the receive CRC module (CRX).

The Receive CRC (CRX) interfaces to the RPE to check for CRC errors in the frame being received. The upper 4 bits of VLAN tag CRC are also used for VLAN-based hash filtering of VLAN frames.

This module calculates the 32-bit CRC for the received frame, which includes the Destination Address field through the FCS field. The following polynomial is used to calculate the CRC.

G (x) = x32 + x26 + x23 + x22 + x16 + x12 + x11 + x10 + x8 + x7 + x5 + x4 + x2 + x + 1

The module takes its data from the RPE (that is, DA + SA + LT + Data + PAD + FCS). The RPE also sends a control signal that indicates the validity of the data. The CRC calculation architecture is same as that of the Transmit CRC described in the "Transmit CRC generator module (CTX)" section. Irrespective of whether Auto Pad or CRC stripping is invoked, the CRX module receives the entire frame to compute the CRC check for a received frame.

Related information

Transmit CRC generator module (CTX) on page 1419

Receive frame controller module (RFC)

This section describes the receive frame controller module (RFC).

The Receive Frame Controller (RFC) receives Ethernet frame data and status from the RPE. The RFC consists of a five-deep FIFO, to delay the data until the filter status is received from the Address Filter block. XGMAC supports the following address filtering options:

- Perfect match destination address filtering for all frames
- Perfect source address filtering for all frames
- VLAN tag hash-based frame filtering for VLAN frames
- VLAN-based perfect filtering of VLAN frames
- Filtering of PAUSE control frames based on the pass control frame setting in the MAC_Packet_Filter register

If the RA bit of the MAC_Packet_Filter register is set, the RFC does not wait for the address filter result and transfers all received frames to the RBU. At the end of data transfer, the RFC sends the received frame status, which includes the Frame Filter bits (SA Filter Fail, DA Filter Fail, VLAN Filter Fail) and the status from the RFC module. These bits are generated based on the AFM filter-fail signals. The RFC does not drop frames in this mode.

If the RA bit is reset, the RFC module waits up to five clocks for the packet filtering result from the AFM module. If it detects a filter-fail from AFM or a runt packet is received (of size <16 bytes), the RFC drops the frame and does not transfer it to the application.

If the filter response from the AFM is delayed more than 5 clocks, the RFC proceeds with frame transfer to the RBU. It still accepts the delayed response from AFM on a DA or SA filter failure and VLAN filter failure, but does not drop the rest of the frame. The Rx status word indicates the filter-fail status. If there is no response from the AFM until the end-of-frame is transmitted, the Rx status word is updated as Filter Fail.

Receive flow control module (FRX)

This section describes the receive flow control module (FRX).

The Receive Flow Controller (FRX) detects the receiving PAUSE frame and passes the pause time received with the frame to the XGMAC transmitter. PAUSE frame detection can be enabled or disabled with the Receive Flow Control Enable (RFE) bit of the MAC_Rx_Flow_Ctrl.

Once receive flow control is enabled, the FRX begins monitoring the received frame destination address for any match with the control frame's multicast address (48'h0180C2000001). If the FRX detects a match, it indicates to the RFC module that the destination address of the received frame matches the reserved control frame destination address. The RFC then determines whether to transfer the received control frame to the application, based on the Pass Control Frames (PCF) bit setting of the MAC_Packet_Filter register.

The FRX also decodes the Type, Opcode, and Pause Timer fields of the control frame being received. At the end of a received frame, the FRX gets the received frame status from the RPE. If the byte count of the status indicates 64 bytes and there is no CRC error, the FRX requests the MAC transmitter to pause data frame transmission for the duration of the decoded pause time value, multiplied by the slot time (64 byte times). Meanwhile, if another PAUSE frame is detected with a zero pause time value, the FRX transfers the pause time value to the transmitter, which exits the pause state immediately. If the received control frame matches neither the Type field (16'h8808), the opcode (16'h00001), nor the byte length (64 bytes), or if there is a CRC error, the FRX does not generate a pause request to the transmitter.

For a PAUSE frame with a unicast destination address, filtering in the FRX module depends on whether the DA matched the contents of MAC Address0 register and the Unicast Detect bit of the MAC_Rx_Flow_Ctrl register is set (detecting a PAUSE frame even with a unicast destination address). The PCF field (MAC_Packet_Filter register) controls the filtering for control frames in addition to the Address filter.

The RFC can also detect the MAC control frames that have opcode fields other than the PAUSE frame Opcode field, which can be called control frames. The status is updated as a Control frame received.

Receive bus interface unit module (RBU)

The RBU interfaces with the application through the MAC receive interface (MRI).

Address filtering module (AFM)

This section describes the address filtering module (AFM).

The Address Filtering module (AFM) checks the destination and/or source address on all received frames and reports the address filtering status to the RFC. It also performs perfect VLAN and VLAN-based hashing for VLAN frames.

Address filtering is based on different parameters programmed by the application. These parameters are input to the AFM as control signals, and the AFM reports the address filtering status based on the combination of these inputs. The AFM does not itself filter the receive frames; rather, it reports the address filtering status (whether or not to drop the frame) to the RFC. The AFM also reports whether the receiving frame is a multicast or broadcast frame. The detailed operation of the packet filter in various is described in chapter "Packet Filtering".

14.4.3.5 Interrupt hierarchy

Interrupts can be generated as a result of various events in the XGMAC. These events are captured in status registers and interrupt enables are provided for each source of interrupt such that the interrupt signal (sbd_intr_o) is asserted for an event only when the corresponding interrupt enable is set.

The MTL_Interrupt_Status register identifies the top level modules that can cause the interrupt to be asserted.

- Bits[7:0] identify eight Queues (Tx or Rx). They are read-only bits and the application should read the corresponding MTL_Q(#i)_Interrupt_Status register to identify the exact cause and set the corresponding bits to 1’b1 to clear the interrupt event. The assertion of sbd_intr_o due to these events is enabled by the corresponding enable bits in MTL_Q(#i)_Interrupt_Enable register
- Bit[16] is made high in case the event is present in the MAC. The application should in turn read the MAC_Interrupt_Status register to identify the cause

Bit[17] is related to indirect access completion events to the TxFIFO and RxFIFO memory in Debug Mode. For more details, see chapter "Memory Access in Debug Mode".

The SRC_GETHNCE (sbd_sfty_ue_intr_o) interrupt is generated when unrecoverable errors are detected and these errors cannot be masked. Appropriate status is indicated in the following registers:

- DMA_AM/DMA_AS_Sfty_ECC_Intr_Sts
- DMA_AM/DMA_AS_Sfty_DPP_Intr_Sts
- DMA/MTL_Safety_Interrupt_Status
- DMA/MAC_DPP_FSM_Interrupt_Status

The SRC_GETHCE (sbd_sfty_ce_intr_o) interrupt is generated when correctable errors are detected. XGMAC sets the respective interrupt enable bits (in the DMA_AM/DMA_AS_Sfty_Intr_En and DMA/MTL_ECC_Interrupt_enable register). To find the root cause of the error, read the DMA_AM/DMA_AS_Sfty_ECC_Intr_Sts, DMA/MTL_Safety_Interrupt_Status and DMA/MTL_ECC_Interrupt_Status registers.

The MAC_Interrupt_Status register bits[1:0] identify the modules that can cause an interrupt from XGMAC. Each event can be prevented from asserting an interrupt on sbd_intr_o by programming the MAC_Interrupt_Enable register.

Some of the interrupt events are enabled (such as, MMC and MDIO) and controlled by the respective Interrupt Enable register inside the module (MMC, MDIO, and so on). The figure below shows the interrupt hierarchy.

In summary, the XGMAC can assert an interrupt on the following events:

- Any change in XGMII link fault status (XGMAC receiver)

- Any event in the SMA (MDIO) function
  - Hot-plugging or removal of PHY port0 to port3 (SMA)
  - Alive status change in any of the MMD devices of PHY port0 to port3 (SMA)
  - Link status change in any of the MMD devices of PHY port0 to port3 (SMA)
  - Completion of a continuous write command (SMA)
  - Completion of a single read/write command (SMA)
- Any RMON counter reaching a value equal to the threshold value programmed in the MMC Control register (MMC Rx/Tx)
- MAC receiving an expected magic packet or remote wake-up packet in the power-down mode
- MAC receiver or transmitter enters or exits the Low-Power IDLE mode when Energy Efficient feature is enabled
- Any event on the timestamp functions
- Any packet error event in the MAC Transmitter or Receiver

***Note**: By default, the MAC interrupt status bits are cleared when the register that contains the source of the interrupt is read. If RCWE bit of the MAC_CSR_SW_Ctrl register is programmed to 1, the MAC interrupt status bits are cleared when the bit that contains the source of the interrupt is explicitly written to 1.*

***Note**: If multiple interrupt events are generated simultaneously and they are grouped to a single interrupt trigger, then only one interrupt trigger event is generated.*

14.4.3.6 Source Address or VLAN Insertion, Replacement or Deletion

You can enable the Source Address (SA) and VLAN insertion by selecting the Enable SA and VLAN Insertion on Tx option.

The XGMAC supports the following functions for Transmit packets.

Related information

Source Address Insertion or Replacement on page 1429
VLAN Insertion, Replacement, or Deletion on page 1429
Queue/Channel based VLAN Insertion on Tx on page 1430

14.4.3.6.1 Source Address Insertion or Replacement

The application can use the SA insertion or replacement feature to instruct the MAC to do the following for Tx packets:

- Insert the content of the MAC Address Registers in the SA field
- Replace the content of the SA field with the content of the MAC Address registers

When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address registers in the SA field. Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC. The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address registers.

You can enable the SA insertion or replacement feature for all Transmit packets or selective packets:

- Enabling SA insertion or replacement for all packets

  To enable this feature for all packets, program the SARC field of the MAC_Tx_Configuration register.
- Enabling SA insertion or replacement for selective packets
  - Program the SA Insertion Control field (Bits[25:23] of TDES3) in the first Transmit descriptor of the packet. When Bit 25 of TDES3 is set, the SA Insertion Control field indicates insertion or replacement by MAC_Address1 registers. When Bit 25 of TDES3 is reset, it indicates insertion or replacement by MAC_Address0 registers.

If MAC_Address1 registers are not enabled, the MAC_Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA Insertion Control field.

14.4.3.6.2 VLAN Insertion, Replacement, or Deletion

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields
- Insert or replace the VLAN Type and VLAN Tag fields

  Insertion or replacement is done based on the setting of VLTI bit in the MAC_VLAN_Incl register as described in Table 684 .

Table 684 VLAN Insertion or Replacement Based on VLTI Bit

Condition	Description
VLTI bit is set	The MAC inserts or replaces the following: - VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of the MAC_VLAN_Incl register) - VLAN Tag field with Content of the VT field of Transmit context descriptor of the packet
VLTI bit is reset	The MAC inserts or replaces the following: - VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of the MAC_VLAN_Incl register) - VLAN Tag field with the VLT field of the MAC_VLAN_Incl register

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88a8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.

You can enable the VLAN insertion, replacement, or deletion feature for all Tx packets or selective packets:

- To enable this feature for all packets, program the VLC field of the MAC_VLAN_Incl register.
- To enable this feature for selective packets,
  - Program the VTIR field of TDES2 Normal Descriptor

14.4.3.6.3 Queue/Channel based VLAN Insertion on Tx

XGMAC supports channel/queue based VLAN tag insertion on all transmitted packets. Queue/Channel specific VLAN tag registers are accessed using indirect addressing through the MAC_VLAN_Incl register. VLAN type and tag value can be independently programmed for each queue/channel.

14.4.3.7 Double VLAN Processing

The XGMAC supports the double VLAN tagging feature in which the MAC can process up to two VLAN tags (inner and outer). When you enable this feature, the XGMAC supports the following:

- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status

Enable this feature by selecting the Enable Double VLAN Processing option.

14.4.3.7.1 Transmit Path

Table 685 describes the features supported by the MAC on the Transmit side.

Table 685 Double VLAN Processing Features in Tx Path

Feature	Description
Support for C-VLAN and S-VLAN Tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of MAC_VLAN_Incl and registers. The XGMAC supports processing of any sequence of outer and inner VLAN tags. Note: The XGMAC does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following: • The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. • The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. • The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN. • The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN.
VLAN Tag deletion	You can enable the VLAN tag deletion for outer or inner tag through VLC field in the MAC_VLAN_Incl and register, respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the tag.
VLAN Tag Insertion or Replacement	You can enable the VLAN tag insertion or replacement for outer or inner tag through VLC field in the MAC_VLAN_Incl and register, respectively. When VLAN tag insertion or replacement is enabled, the VLTI bit in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register is used to determine whether the VLAN tag should be taken from the register.

14.4.3.7.2 Receive Path

Table 686 describes the features supported by the MAC on the Receive side and the corresponding bits in the MAC_VLAN_Tag register.

Table 686 Double VLAN Processing in Rx Path

Feature	Description
Outer or inner VLAN tag-based filtering	The MAC can filter packets based on the outer or inner VLAN tag through the ERIVLT bit.
C-VLAN or S-VLAN tag-based filtering	The MAC can filter packets based on the C-VLAN or S-VLAN type based on the ERSVLM bit.
Outer and Inner VLAN Tag stripping	The MAC can strip the outer and inner VLAN Tags from received frame based on the EVLS and EIVLS bits.
16-bit outer and inner VLAN Tag and Type in Rx status	The MAC can provide the 16-bit outer and inner VLAN Tag and Type in the Rx status based on the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN Tag type	The MAC can disable or skip checking of outer VLAN Tag type to match C-VLAN or S-VLAN based on the DOVLTC bit.

14.4.3.8 Packet filtering

The XGMAC supports the following types of filtering for Rx packets:

- Source Address or Destination Address Filtering:

  The Address Filtering Module (AFM) checks the source address and destination address fields of each incoming packet
- Extended VLAN Filtering:

  The XGMAC supports multiple VLAN tag-based and VLAN hash filtering
- Layer 3 and layer 4 match filtering:

  Layer 3 filtering refers to source address and destination address filtering. Layer 4 filtering refers to source port and destination port filtering

The figure below shows the filtering sequence for Rx packets.

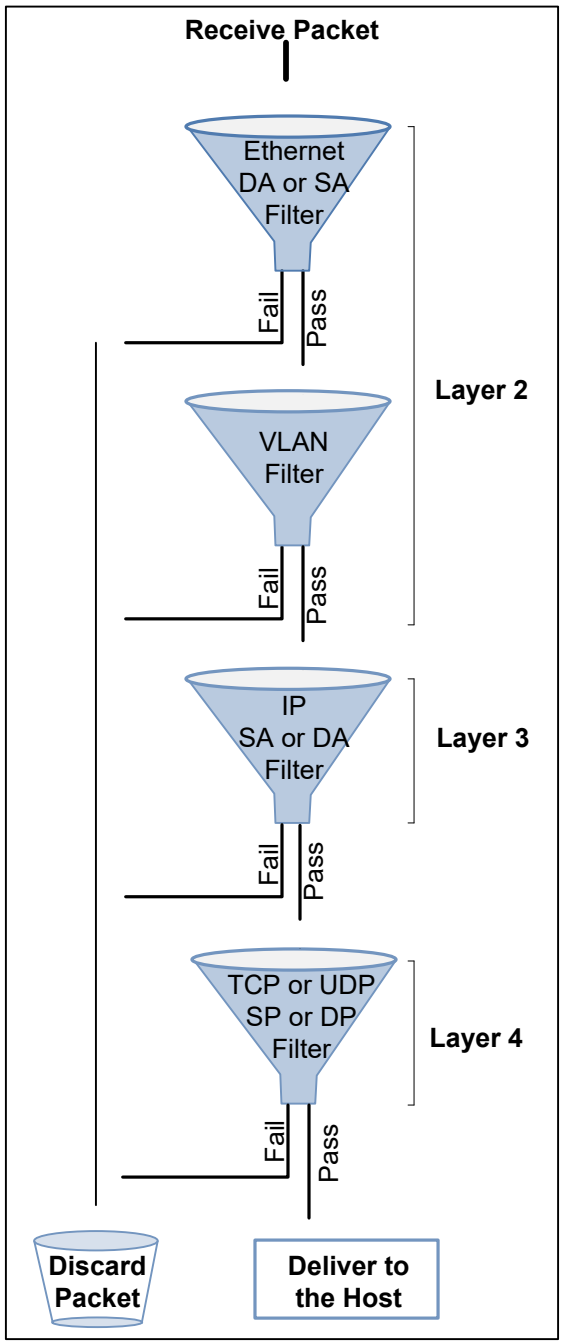

Figure 137 Packet filtering sequence

14.4.3.8.1 Source address or destination address filtering

The Address Filtering Module of the MAC checks the source address (SA) and destination address (DA) fields of each incoming packet.

Unicast destination address filtering

The MAC supports up to 32 MAC addresses for unicast perfect filtering. The MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. The default MacAddr0 is always enabled.

The MacAddr1 to MacAddr31 addresses are selected with an individual enable bit. For MacAddr1 to MacAddr31 addresses, you can mask each byte during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This enables group address filtering for the DA.

Multicast destination address filtering

To program the MAC to pass all multicast packets, set the PM bit in the MAC_Packet_Filter register. If the PM bit is reset, the multicast address is compared with the programmed MAC Destination Address registers (1-31). Group address filtering is also supported.

In Perfect filtering mode, the multicast address is compared with the programmed MAC Destination Address registers (1-31). Group address filtering is also supported.

Broadcast address filtering

The MAC does not filter any broadcast packets by default. To program the MAC to reject all broadcast packets, set the DBF bit in the MAC_Packet_Filter register.

Unicast source address filtering

The MAC can perform perfect filtering based on the source address field of received packets. By default, the MAC compares the SA field with the values programmed in the SA registers. You can configure the MAC Address registers [1-31] to use SA instead of DA for comparison by setting Bit 30 of the corresponding register.

The MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in the MAC_Packet_Filter register. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word. When the SAF bit is set, the SA filter and DA filter result is ANDed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order. In this case, the DMA channel is selected based on the corresponding DA filter configuration.

Inverse filtering

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of the MAC_Packet_Filter register. The DAIF bit is applicable for both unicast and multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

The following tables summarize the DA and SA filtering based on the type of packets received.

***Note**: When the RA bit of the MAC_Packet_Filter register is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.*

Table 687 Destination address filtering

Packet type	PR	DAIF	PM	DBF	DA filter operation
Broadcast	1	X	X	X	Pass
	0	X	X	0	Pass
	0	X	X	1	Fail
Unicast	1	X	X	X	Pass all packets
	0	0	X	X	Pass on Perfect/Group filter match
	0	1	X	X	Fail on Perfect/Group filter match
Multicast	1	X	X	X	Pass all packets
	X	X	1	X	Pass all packets

(table continues...)

Table 687 (continued) Destination address filtering

Packet type	PR	DAIF	PM	DBF	DA filter operation
	0	0	0	X	Pass on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	1	0	X	Fail on Perfect/Group filter match and drop Pause packets if PCF = 0x

Table 688 Source address filtering

Packet type	PR	SAIF	SAF	SA filter operation
Unicast	1	X	X	Pass all packets
	0	0	0	Pass status on Perfect or Group filter match but do not drop packets that fail
	0	1	0	Fail status on Perfect or Group filter match but do not drop packet
	0	0	1	Pass on Perfect or Group filter match and drop packets that fail
	0	1	1	Fail on Perfect or Group filter match and drop packets that fail

14.4.3.8.2 Extended VLAN filtering

Perfect filtering is done for the VLAN Tag Filters. For each VLAN Tag Filter, the VLAN Tag ID is compared. The combined result of all the enabled VLAN Tag Filters determines the overall VLAN Tag Filter result. The filter result is passed to the application as part of the status bits.

When the VLAN Tag Filter gives a pass result, the frame is considered to have passed the VLAN Tag Filters. If the frame fails all the filters, the frame is considered to have failed the VLAN filter.

In addition to Perfect Filtering, Hash Filtering can also be enabled. In Hash Filtering, the overall VLAN Filter result is determined by the Hash Filter result and the perfect filter result. The overall filter result determines if the frame is dropped or forwarded to the application based on the programming on the VTFE and RA bits of the MAC Filter Register.

Comparison modes of extended receive VLAN filtering

For each VLAN Tag filter, the application has the following comparison modes:

- Program the MAC to compare an outer VLAN Tag or an inner VLAN Tag with the programmed VID
- Choose the width of the VID field, 12 or 16 bits, for the comparison
- Enable or disable type check for each filter. When type check is enabled, the application can choose if the VID comparison should be only for the SVLAN or CVLAN types frames. For example, when a filter is enabled for 16 bit comparison, type is SVLAN, and outer VLAN tag, any single or double VLAN tagged frames with outer SVLAN tags are compared with this filter, and result is obtained

Filtering

When Extended RX VLAN Filtering & Routing feature is enabled, the application can enable both Perfect and Hash Filtering. The overall VLAN Filter Result is based on the perfect filter result and the Hash Filter result (if enabled). The filter result is passed to the application as part of the status bits.

Perfect Filtering is done based on the MAC_VLAN_Tag_Filter registers. For each VLAN Tag Filter, the MAC compares the relevant VLAN Tag ID and gives a result. If any one of the VLAN Tag Filters gives a match then the frame is considered to have passed the VLAN Tag Filters. If the frame mismatches all the filters, then the frame is considered to have failed the VLAN filter. This behavior is applicable only when the Inverse Filtering is not enabled in MAC_VLAN_Tag_Ctrl Register.

If inverse Filtering is enabled and the frame has mis-matched all the relevant filters then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters then it is considered as a fail. If none

of the enabled filters can perform a comparison or if none of the filters are enabled, then the frame is bypassed to the application.

The overall filter result and the programming on the VTFE and RA bits of the MAC Filter Register determine if the frame is dropped or forwarded to the application. If RA is set, it does not matter if the filter result is a pass or fail. The frame is always forwarded. If RA is 0 and VTFE is set, then only if the VLAN Tag Filter result is a pass does the MAC forward the frame. If RA is 0 and VTFE is also 0, then the frame is forwarded always irrespective of the filter result. If the frame is forwarded to the application, then the relevant filter result is indicated through the Status bits.

Filter status

Currently the MAC indicates the VLAN Filter Status through one bit in the status - VF in RDES2. When Extended RX VLAN Filtering & Routing is enabled, two status bits are used to indicate the comparison result of VLAN tags. The Outer VLAN Tag Filter Pass and Inner VLAN Tag Filter Pass bits are defined in the following positions in various configurations. The status indicated through these bits is highly dependent on the programming:

In RDES2:

- Bit 15 - Outer VLAN Tag Filter Status
- Bit 13 - Inner VLAN Tag Filter Status

In ARI status: MAC Filter Status

- Bit 15 - Outer VLAN Tag Filter Status
- Bit 13 - Inner VLAN Tag Filter Status

MRI Status:

- Bit 47 - Outer VLAN Tag Filter Status
- Bit 45 - Inner VLAN Tag Filter Status

Outer VLAN Tag Filter Status (OTS)

- In Perfect filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Outer VLAN Tag has matched one of the VLAN Tag Filters
- If this bit is reset, it indicates that the frame's Outer VLAN Tag has either failed the relevant Outer VLAN Tag Filters or bypassed them
- If none of the filters are enabled for Outer VLAN Tag Comparison, this bit is reset
- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, it has failed at least one of or bypassed all the Filters programmed for Outer VLAN Tag Comparison
- This bit is valid for both Single and Double VLAN Tagged frames

Inner VLAN Tag Filter Status (ITS)

- In Perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Inner VLAN Tag has matched one of the VLAN Tag Filters
- If this bit is reset, it indicates that the frame's Inner VLAN Tag has either failed the relevant Inner VLAN Tag Filters or bypassed them
- If none of the filters are enabled for Inner VLAN Tag Comparison, this bit is reset
- If Inverse Filtering is enabled and this bit is set, the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, it has failed at least one of or bypassed all the Filters programmed for Inner VLAN Tag Comparison
- This bit is valid for only Double VLAN Tagged frames when Double VLAN Processing is enabled

The application must look at the status bits and the programming to determine if the Frame has passed or failed the VLAN Filter.

The following two tables show the possible Filter combinations and the corresponding filter results. These tables explain the scenarios when Double VLAN Processing and Hash VLAN filter are enabled in the design.

Legend for the Table:

- VTIM – VLAN Tag Inverse Match Enable – bit 17 in VLAN_Tag_Ctrl Register
- HFO – Hash Filter enabled for Outer VLAN Tag Comparison – bit 25 and bit 27 in VLAN_Tag_Ctrl Register

- HFI – Hash Filter enabled for Inner VLAN Tag Comparison – bit 25 and bit 27 in VLAN_Tag_Ctrl Register
- PFO – Perfect Filter comparison enabled for Outer VLAN Tag - Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Outer VLAN Tag comparison (bit 20 is set to 0)
- PFI – Perfect Filter comparison enabled for Inner VLAN Tag - Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Inner VLAN Tag comparison (bit 20 is set to 1)
- OTS – Outer VLAN Tag Filter Status
- ITS – Inner VLAN Tag Filter Status

The table below shows the possible values of status bits (OTS and ITS) when at least one Perfect filter is enabled.

Table 689 OTS and ITS bit values with at least 1 perfect filter enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

The table below shows the possible values of status bits (OTS and ITS) when none of the perfect filters are enabled and only the VLAN Hash Filter is enabled.

Table 690 OTS and ITS bit values with only VLAN hash filter enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0
0	1	0	1/0	0
0	0	1	0	1/0
1	0	0	0	0
1	1	0	1/0	0
1	0	1	0	1/0

With no perfect filters enabled, any VLAN packet is considered to have bypassed the perfect filter. If Hash Filter is enabled for one of the Tags, then the respective Status bit depends on the Filter's result. The Status bits are set to 0 if VLAN Hash Filter is also not enabled.

If the value of ITS/OTS is shown as 1/0; then it indicates that the final result is dependent on the enabled relevant filter's result.

Example 1: The second row of Table 689 indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes atleast one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame doesn't pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: Last Row of Table 689 indicates that Inverse Filtering is enabled, Hash Filter and atleast one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tag mismatches with both the Hash Filter and all the enabled Perfect filters, then the frame has the ITS bit set to 1; else it is set to 0. OTS is set to 0 as no comparison is performed.

Limitations:

The status bits in the descriptor for Extended RX VLAN Filtering & Routing Feature have some restrictions based on other features enabled in the MAC. Certain configurations, the entire VLAN Filter result is provided as VF instead of two separate bits – OTS & ITS. The following points describe the scenarios where a single VLAN Filter status is provided.

- The bits OTS and ITS both are valid
- The IVT and OVT fields of the RDES3 hold the VLAN Tag values if programmed accordingly

When the Status bit 15 of RDES2 is defined as VF instead of OTS; the behavior is as follows:

- When Inverse Filtering is not enabled:
  - The Status Bit is set if any of the VLAN Tag Filter passes
  - If the frame’s VLAN tags do not match any of the relevant VLAN Filters, the VF bit is set to 0. In this case, if VTFE bit of the Packet Filter register is set, the frame is not forwarded to the application
  - If both the VLAN tags bypass the relevant filters, the VF bit is set to 0. In this case, if VTFE bit of the Packet Filter register is set, the frame is forwarded to the application
- When Inverse Filtering is enabled
  - VF bit is set only when both the Tags (if applicable) have mismatched the relevant enabled filters
  - If one of the tags has mismatched the relevant filters and the other tag has bypassed it, the VF bit is set to 1
  - If either of the tags matches any of the relevant filters, the VF bit is set to 0
  - If both the tags have bypassed the relevant filters, the frame is forwarded to the application with the status bit VF set to 0

The VLAN Tag stripping is still dependent on the individual tags match or mismatch. For example, if the MAC has “Strip on Tag Match” enabled for the Outer VLAN Tag; even though the Over All Filter Result as indicated by the Bit VF is a fail (set to 0); this tag is stripped.

Stripping

Each of the VLAN Tags has individual control over stripping. The programming options of Always strip, never strip, strip on pass and strip on fail are available. Inner or Outer VLAN Tag Stripping is based on the individual tags’ pass or fail results. If a tag is bypassed by all the relevant filters then stripping is not applicable for it.

- If strip on Pass is enabled for the outer VLAN Tag, the stripping occurs only if the Outer VLAN tag has passed the relevant Filters. The Outer VLAN Tag Filter Result bit is set
- If strip on Fail is enabled for the outer VLAN Tag, stripping occurs only if the Outer VLAN Tag has failed relevant filters. The Outer VLAN Tag Filter Result Bit is reset
- If the Outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), the tag is not stripped, though the Status Bit is still 0

- As multiple filters are enabled, it is possible that the received VLAN frame could have matched any one or more of the filters. The VLAN Tag's value is not always deterministic from the filter status bits
- So if the application strips the VLAN Tag based on the filter result, it might lose the VID. So the suggested use is: if Stripping is enabled for any of the tags, then the tag can be put in the status. For this, the application must enable the respective "VLAN Tag in Status" bit – 24 or 31 in the MAC VLAN Tag Control Register

14.4.3.8.3 Layer 3 and layer 4 match filtering

The XGMAC supports Layer 3 and Layer 4 based packet filtering. The Layer 3 filtering refers to the IP Source or Destination Address filtering in the IPv4 or IPv6 packets whereas Layer 4 filtering refers to the Source or Destination Port number filtering in TCP or UDP.

For Layer 3 or Layer 4 filtering operation, you must set the IPC bit of the MAC_Rx_Configuration register to enable the Rx Checksum Offload Engine.

When Layer 3 and Layer 4 filtering is enabled, the packets are filtered in the following way:

- Matched Packets: The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC forwards the matched field status only if the IPC bit of the MAC_Rx_Configuration register is set and one of the following conditions is true:
  - All enabled Layer 3 and Layer 4 fields match
  - At least one of the enabled field matches and other fields are bypassed or disabled

  When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides the status of the lowest filter where Filter 0 is the lowest filter and Filter 7 is the highest filter. For example, if Filter 0 and Filter 1 match, the MAC gives the status corresponding to filter 0.

***Note**: The source or destination address and VLAN tag filters (if enabled) have precedence over Layer 3 and Layer 4 filter. This means that a packet which fails the source or destination address or VLAN tag filter is dropped irrespective of the Layer 3 and Layer 4 filter results.*

- Unmatched Packets: The MAC drops the packets that do not match any of the enabled fields. The user can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets.

  Aborted or partial packets are dropped in the MTL Rx FIFO. If the Rx FIFO operates in the threshold (cut-through) mode and the threshold is programmed to a small value, such that packet transfer to application starts before the failed Layer 3 and Layer 4 filter results are available, the application may receive a partial packet with appropriate abort status
- Non-TCP or UDP IP packets: By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. The user can optionally program the MAC to drop all non-TCP or UDP over IP packets

Layer 3 and layer 4 filters register set

The MAC implements a set of indirect registers for Layer 3 and Layer 4 based packet filtering. The indirect register set contains a control register namely, MAC_L3_L4_Control0, to control the packet filtering. In addition, there are five address registers to program the Layer 3 and Layer 4 fields to be matched, such as:

- MAC_Layer4_Address0
- MAC_Layer3_Addr0_Reg0
- MAC_Layer3_Addr1_Reg0
- MAC_Layer3_Addr2_Reg0
- MAC_Layer3_Addr3_Reg0

XGMAC has eight such independent set of registers.

Layer 3 filtering

The XGMAC supports perfect matching or inverse matching for IP Source Address and Destination Address. In addition, you can match the complete IP address or mask the lower bits matching, that is, compare all bits of the address except the specified lower mask bits.

For IPv6 packets filtering, you can the 4 MAC_Layer3_Addr[0:3]_Reg(#i) to contain the 128-bit IP Source Address or IP Destination Address. The IP Source Address or Destination Address should be programmed in the order defined in the IPv6 specification, that is, the first byte of the IP Source Address or Destination Address in the received packet is in the higher byte of the register and the subsequent registers follow the same order.

For IPv4 packet filtering, you can use the MAC_Layer3_Addr0_Reg#(i) and MAC_Layer3_Addr1_Reg#(i) registers to contain the 32-bit IP Source Address and IP Destination Address, respectively. The remaining two registers are reserved. The IP Source Address or Destination Address should be programmed in the order defined in the IPv4 specification, that is, the first byte of IP Source Address and Destination Address in the received packet in the higher byte of the respective register.

Layer 4 filtering

The XGMAC supports perfect matching or inverse matching for TCP or UDP Source and Destination Port numbers. However, you can program only one type (TCP or UDP) at a time. The MAC_Layer4_Address(#i) register contains the 16-bit Source and Destination Port numbers of TCP or UDP, that is, the lower 16 bits for Source Port number and higher 16 bits for Destination Port number.

The TCP or UDP Source and Destination Port numbers should be programmed in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP Source and Destination Port number in the received packet is in the higher byte of the register.

14.4.3.9 Flexible Receive Parser

14.4.3.9.1 Overview of Flexible Receive Parser

The XGMAC controller has in-built programmable parser to parse the Ethernet packet based on a software controlled/programmable rule-set. This helps to support filtering and packet steering decision (DMA channel selection) of the received packet, based on any header field of existing protocols or custom/future protocols.

The parser uses a software programmed lookup table that contains instructions and filtering and routing decisions to be taken by the controller on the received packets.

- The maximum length of the packet data that the parser can operate on, is 256B.
- Support for up to 256 instructions, each processing 32-bit frame data with a mask
  - Match and Inverse Match support per instruction
  - Packet data compared with programmed data and mask bits
- Frame filtering based on any of the packet fields
  - Drop/accept packet or bypass packet filtering.
- Determine the DMA channel for packet parsing
- Support for out-of-order packet parsing
  - Decision tree can be out of order; decision tree need not be based on the same order as the packet data arrival.

- Flexible receive parser always operates in receive clock domain
- Flexible receive parser supports stream gate filtering, a subset of IEEE 802.1 Qci specification; stream filter classification and stream gate instance. Stream gate filtering is supported only in
  - Full duplex mode
  - 100 Mbps or higher link speed

14.4.3.9.2 Description of Flexible Receive Parser

This section describes the block diagram and the details of the flexible receive parser.

Flexible Receive Parser Instruction Table (IT) Format

Before enabling the Flexible Receive Parser, the software must build the 128-bit wide instruction table for the parser. Each instruction is programmed as an entry in the instruction memory.

The following figure shows the graphical representation of the instruction table.

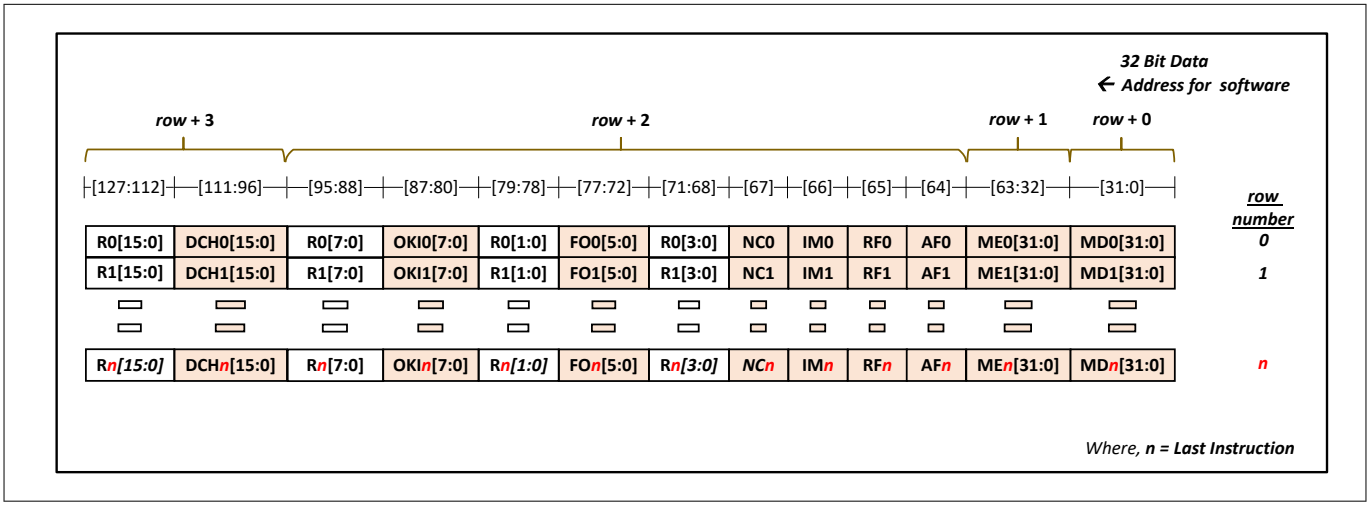

Figure 138 Flexible Receive Parser Instruction Table

The format of each entry in the instruction table is shown below.

Table 691 Flexible Receive Parser Instruction Entry Format

Field	Field Name	Description
31:0	MD	Match Data The 4-byte data. This data is used for comparing with incoming packet data starts at the frame offset as defined in [77:72] of the entry. The comparison is done only on those bits whose corresponding mask bits are set to 1 (ME bits of [63:32]).
63:32	ME	Match Enable When the ME bit is set to 1, the corresponding packet data bit is used for comparing. Otherwise, corresponding data bit is ignored.
64	AF	Accept Frame
65	RF	Reject Frame
66	IM	Inverse Match

(table continues...)

Table 691 (continued) Flexible Receive Parser Instruction Entry Format

Field	Field Name	Description
67	NIC	Next Instruction Control match = MD & ME Bits == (Packet data [frame offset* 8*4]) & ME bits If IM = 0; ENTRY_MATCH = match If IM = 1; ENTRY_MATCH = !match • When ENTRY_MATCH == 1 - if AF == 1 and RF == 0, (PASS result) Accept and route the frame to DMA channel given by the DCH field (Bits[111:96]) of this entry - else if AF == 0 and RF = 1, reject or drop the frame - else if AF == 1 and RF = 1, (Routing BYPASS result) Accept the frame, but ignore DCH but route the frame to DMA Channel number given by MAC - else if AF == 0 and RF == 0, (intermediate result) - If NIC == 1 Continue to next sequential entry in the Instruction Table - else NIC = 0 Jump to next entry given by OKI field (Bits[87:80]) in this entry • When ENTRY_MATCH == 0 (intermediate result) - if NIC == 1 Jump to next entry given by OKI field (Bits[87:80]) in this entry - else NIC == 0 Continue to next sequential entry in the instruction table
71:68	Reserved	Reserved, shall be written as 0 and read as 0.
77:72	FO	Frame Offset [77:72] indicates the frame offset in terms of 4 bytes Frame offset in the packet data to be compared for match, in terms of 4 bytes. • 0 (value): 0 (frame offset in bytes) • 1: 4 • 2: 8 • ... • 63: 252
79:78	Reserved	

(table continues...)

Table 691 (continued) Flexible Receive Parser Instruction Entry Format

Field	Field Name	Description
87:80	OKI/PCV, PCN / GIV,GID	OK Index (OKI) This field gives the next entry in the instruction table, to be processed, OKI field is valid only when, • ENTRY_MATCH = 0 and NIC = 1 • ENTRY_MATCH = 1 and NIC = 0, AF = 0, RF = 0. • OKI is 8 bits wide When you enable the Policing Counter feature, interpret this field as follows: • Bit [80]: PCV (Policing Counter Valid) • Bits [84:81]: PCN (Policing Counter Number) • Bits [87: 85]: Reserved When you do not enable Policing Counter feature, but enable Stream-Gate filtering feature, and when AF = 1 and NIC = 0, interpret this field as follows: • Bit [80]: GIV • Bits [84:81]: GID • Bits [87: 85]: Reserved
88	GIV	Gate-ID Valid When this field is 1, ENTRY_MATCH = 1, and AF = 1, indicates that the packet is further checked against the Stream Gate Filter, given by GID. **Note:** Only when both Stream-Gate Filtering and Policing Counter features are enabled, interpret this field as GIV. Otherwise, this field is reserved.
91:89	GID	Gate-ID This field represents the Stream-Gate filter number to be applied on the packet, when GIV = 1. **Note:** Only when both Stream-Gate Filtering and Policing Counter features are enabled, interpret this field as GID. Otherwise, this field is reserved.
95:92	Reserved	Shall be written and read as 0.
111:96	DCH	DMA Channel Number Indicates the DMA Channel Number when ENTRY_MATCH==1 and AF == 1. The encoding is as follows: • bit[0]: DMA channel number 0 • bit[1]: DMA channel number 1 • bit[2]: DMA channel number 2 • ... • bit[7]: DMA channel number 7 bits[15:8]: Reserved, shall be written as 0. ***Note**: The DMA Channel number is encoded bitwise. XGMAC IP supports multicast/broadcast across DMA channels.*

(table continues...)

Table 691 (continued) Flexible Receive Parser Instruction Entry Format

Field	Field Name	Description
127:112	Reserved	These bits are not implemented. This field is only for software to view.

***Note**:*
- *Instruction Table Width: 128 bits*
- *Instruction Table Depth: 256*
- *Byte Ordering: The first byte received on the line is compared with MD[7:0] of the instruction table.*
- *Entry and instruction are used synonymously.*
- *All the reserved bits are read as zeros.*

***Note**: Error Correction Code (ECC) is used only for security purpose. During programming, ECC is calculated for the whole instruction data (except MSB, reserved bits) as well its address. After programming, XGMAC recomputes the ECC and compares with existing ECC bits. If it finds a mismatch, it generates safety interrupt.*

The parser begins parsing from the 0^{th} entry, for each received packet. The subsequent parsing entry location (next entry or OKI) depends on the parser result of the current entry. The figure below shows the flexible receive parser flow.

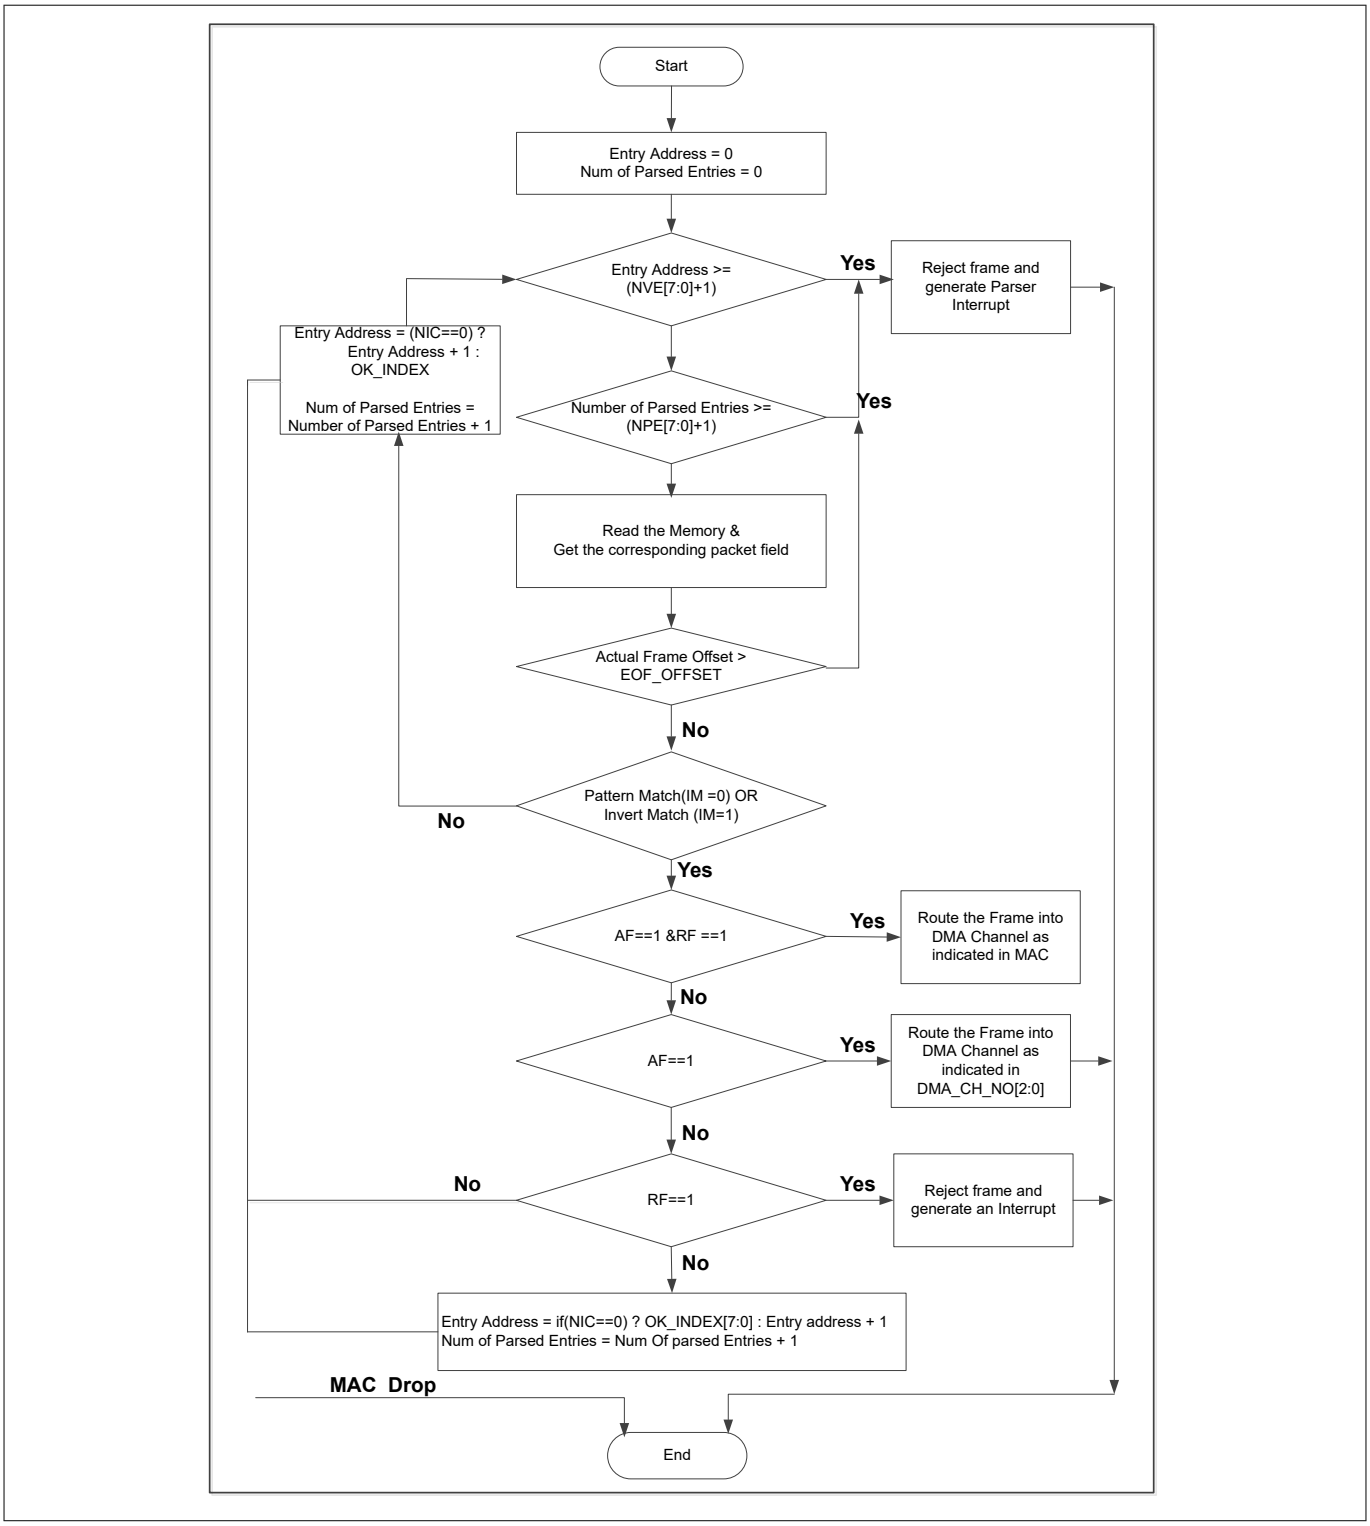

Figure 139 Flexible Receive Parser Flow Chart

Software Access to the Instruction Table

The software can write/read the flexible receive parser instruction table using the following register sets through indirect addressing:

- MTL_RXP_Indirect_Acc_Control_Status
- MTL_RXP_Indirect_Acc_data

***Note**: The indirect registers are shared by multiple indirect accessible blocks. Set the ACCSEL field of the MTL_RXP_Indirect_Acc_Control_Status register to access the Instruction Table.*

It is recommended not to update valid entries in the instruction table when frame reception and frame parsing is in progress. This can cause unintended results.

For more details, see the section "Registers".

***Note**: To program multiple parsing scheme, program them across instruction table and select either of it to run it first by programming the following at instruction 0:*

- *Set all bits to 0 except OKI[]. Set OKI to the first instruction location of the parsing scheme which you want to run first*

It is possible to reprogram the unused instructions when parsing is in progress, to build a new instruction list (or sequence).

Related information

Registers on page 802

Number of Valid Entries in Instruction Table (NVE)

This is the number of valid entries in the Instruction Table starting from the 0th instruction. The default value is set to number of supported instructions minus 1. Software can override the default value by writing into the NVE field of the MTL_RXP_Control_Status register (Number of Valid Entries). Possible values can be from 0 to number of supported instructions minus 1; 0 implies 1st instruction, 1 implies 2nd instruction, and so on.

While parsing, if the instruction address is greater than NVE, an error is flagged in the NVEOVIS field of MTL_RXP_Interrupt_Control_Status register. Also, XGMAC generates an interrupt status, MTLPIS field of the MTL_Interrupt_Status register.

***Note**: NVE Overflow error status is reported as consolidated error status in the receive descriptor (write-back format). For more details, see the "Receive normal descriptor (write-back format)" section.*

Related information

Receive Normal Descriptor (Write-Back Format) on page 1572

Number of Parsable Entries (NPE)

Indicates the number of entries/instructions that can be parsed on an incoming packet. The default value is set to number of supported instructions minus 1. Software can override the default value by writing into MTL_RXP_Control_Status registers field (Number of Parsable Entries). Possible values can be from 0 to number of supported instructions minus 1; 0 implies 1st parsable instruction and so on.

During parsing, if the number of parsed entries is more than NPE+1, an error is flagged in the NPIOVIS field of MTL_RXP_Interrupt_Control_Status register. Also, XGMAC generates an interrupt status in the MTLPIS field of MT_ Interrupt_Status register.

***Note**: NVE indicates the number of valid entries starting from 0th entry of the instruction table built by the software,whereas NPE indicates the worst case number of parsable entries considering the various possible paths that can be taken.*

NVE Overflow error status is reported as consolidated error status in the receive descriptor (write-back format). For more details, see the "Receive normal descriptor (write-back format)" section.

Related information

Receive Normal Descriptor (Write-Back Format) on page 1572

Frame Offset

Indicates the frame offset, in terms of 4 bytes; used to compare respective receive frame offset data with the instruction's match data.

In an instruction, an error is flagged in the MTL_RXP_Interrupt_Control_Status register, FOOVIS (Frame Offset Overflow Interrupt Status) when Frame Offset is more than packet's EOF size or supported number of parsable bytes.

Also, XGMAC generates an interrupt status in the MTLPIS field of MTL_Interrupt_Status register.

***Note**:*

- *If the frame ends after the (frame_offset *4) bytes but before ((frame_offset *4)+3) bytes, the Receive parser declares Frame Offset Error if comparison is enabled (using MASK bits) for the non-received bytes; from (frame_offset *4) to ((frame_offset *4)+3).*
- *Frame Offset Overflow error status is reported as a consolidated error status in the receive descriptor (write-back format). For more details, see the "Receive normal descriptor (write-back format)" section*

Related information

Receive Normal Descriptor (Write-Back Format) on page 1572

VLAN Strip Handling

The MAC supports stripping the outer as well as inner VLAN tags. When MAC is programmed to strip the VLAN tags, the Flexible Receive parser considers the stripped VLAN tags as part of the incoming packet.

PAD Strip/CRC Strip Handling

The pad strip and CRC strip are controlled by the software and applicable to all the received packets. When these features are enabled, software must build the flexible receive parser instructions accordingly.

***Note**:* *It is recommended to enable PAD and CRC stripping.*

Runt Packet Handling

The flexible receive parser is designed for minimum packet size to be of 64B. If the runt packet is received without an additional IPG (at least 64B minus Runt packet size), the ongoing parsing of preceding packet could be impacted.

Out of Order Processing

The flexible receive parser flow can be out of order within the bytes of a received frame. The decision tree need not be based on the order in which packet arrives. This implies that the next entry and next frame offset (FO[]) can be less than the current instruction number and current Frame Offset.

For example, you can look for matching/mismatching IP header and then look for Ethernet header to decide on filtering/channel selection. Also, it can skip from higher address entry to lower address entry in the table.

Ethernet line speed dependency

The flexible receive parser is implemented in the receive (Rx) clock domain.

Example: For 1G Line Speed and 125 MHz receive (Rx) clock, assuming worst case example of back-to-back 64 bytes frame reception.

The processor has 672 ns (including 64B of next frame, 12B of IPG, 8B of Preamble time of next to next frame) to process the current frame.

Number of parser cycles available at 125 MHz: 672 ns/8 ns = 84 cycles.

The flexible receive parser stops the current parsing when it detects SOF of the next packet. To account for the implementation latency, actual parsing cycles are: 84 - 3 = 81.

So, with one Parallel Instruction Processor Engine, the parser can process up to 81 instructions.

Four Parallel Instruction Processor Engines (PIPEs) are implemented, in the worst-case example, theoretically the parser can parse a total of 83 * 4 = 324 instructions. Practically this means, the full parser instruction table with 256 entries can be used in this case.

When the link speed changes, it is assumed that software does not program the number of parsable entries/ instructions beyond the intended limit as per the calculations above. If programmed incorrectly, parser does not parse the packet further and flags a parsing error and is treated as NPE[] overflow.

There are no constraints on the number of JUMPs in the Instruction Table. The architecture does not have additional latency to execute the JUMPs.

Frame Accept

In case of an Entry Match (considering the Inverse match) and Frame Accept bit is set and RF is not set, the frame is accepted and routed to the corresponding instruction's DMA channel number.

Frame Reject

In case of an Entry Match (considering the Inverse match) and Frame Accept bit is not set and Frame Reject bit is set, the frame is dropped.

An interrupt is generated when the frame is dropped due to AF = 0 and RF = 1;
MTL_RXP_Interrupt_Control_Status register bit PDRFIE is set.

XGMAC also generates an interrupt status, MTLPIS bit of the MTL_Interrupt_Status register.

Flexible Receive Parser Bypass Routing

In case of an Entry Match (considering the Inverse match) and AF and RF bits are set, accept the frame, but bypass the DMA channel routing selected by the flexible receive parser. In such cases DMA channel number provided by MAC/MTL, based on one of the filtering and routing mechanisms is selected.

DMA Channel Selection

The MAC/MTL also determines the DMA Channel number based on incoming packet fields.

When the parser is enabled (FRPE bit is set to 1 in MTL_Operation_Mode register) the parser overrides the DMA selection criteria of the MAC.

When the parser is disabled (FRPE is set to 0 in MTL_Operation_Mode register) the MAC/MTL determines the DMA channel number.

Frames that pass the FRP filtering, are routed based on the Instruction Table. All the other frames that meet any of the following criteria, are treated as residual frames.

- Parsing errors such as NVE, NPE, FOO, and so on

- Incomplete parsing
- Any other frames that could not be dropped despite the drop result from FRP. For more details, see the "Receive packet drop indication" section

Residual frames are routed to

- Channel 0, for express traffic
- Channel number configured in the FPE_RCH field of MTL_RXP_Control_Status register, for preemption traffic

***Note**: DMA channel number in the instruction has one-hot encoding. So, the frame is routed to the channel whose respective bit is set.*

Related information

Receive Packet Drop Indication on page 1451

Receive Queue Selection

The receive queue is determined by the existing MAC functionality, irrespective of the enabling/disabling of the flexible receive parser. This is because the flexible receive parser is mainly designed for selecting the DMA channel and Rx queuing is decided by the MAC to enable the proper functioning of the Pause feature.

***Note**: When there are multiple queues with multiple DMA Channels enabled, a specific DMA channel might receive packets out-of-order. This is because, queue selection is based on MAC criteria (VLAN Priority and other criteria) and Rx DMA channel selection is based on flexible receive parser. If in-order packet reception is necessary, you must program Single Queue configuration.*

MAC (L2) Packet Filtering/Drop/Error Handling

The MAC does the packet filtering based on the received packet fields. MAC filtering/L2 filtering can also be enabled with flexible receive parser. But MAC filtering has higher priority over flexible receiver parser.

Flexible receiver parser 's result has impact on RA (Receive All) and L2 Filtering (such as SA, DA, and VLAN).

Table 692 RXP Impact on RA and L2 Filtering

RA (Receive All)	L2 Filter Pass (MAC)	Impact on Flexible Receive Parser (FRP) Result
No	No (L2 Drop)	Bypass FRP result.
No	Yes (L2 Accept)	FRP result is used.
Yes	No (L2 Drop)	Bypass FRP result.
Yes	Yes (L2 Accept)	If FRP Result is Accept Use FRP Result. If the result from flexible receive parser is Reject, bypass the FRP result and route the frame to residual channel based on the traffic. For more details, see the "DMA channel selection" section.

***Note**: When you enable flexible receive parser, it is recommended to use only L2 filtering and routing (DA, SA, and VLAN).*

Related information

DMA Channel Selection on page 1448

Multicast and Broadcast Support

XGMAC supports multicast and broadcast only when DDS (DA duplication select) is enabled and the packet is routed to the highest queue number.

When flexible receive parser is enabled, the packet routing is decided by the DMA Channel Numbers (DCH[]) in the instruction table. In other words, such multicast packets are transferred to all the DMA channels for which the DCH bits are set.

***Note**: When a frame does not fulfill the requirement for broadcast/multicast, Flexible Receive Parser routes the frame to the lowest selected DMA Channel Number in the instruction table.*

Statistical Counters

When Flexible Receive Parser is enabled, following counters are implemented in the indirect IFR register block:

1. MTL_RXP_Drop_Cnt

   Incremented when flexible receive parser drops a packet due to AF = 0 and RF = 1
2. DMA_RXP_Error_Cnt

   Incremented when a RXP encounters error. The error scenarios are:

   - Current Instruction Number > NVE[]
   - Number Parsed Instructions > NPE[] + 1
   - Current Instruction's Frame offset > EOF frame offset or last parsable frame offset
   - Parsing is not complete even after receiving the next to next packet SOF
3. MTL_RXP_Bypass_cnt

   This is incremented when Rx Parser bypasses a packet due to AF = 1 and RF = 1
4. DMA_CH(#i)_RXP_Accept_cnt (i=0-7)

   This is per DMA Channel register. It is incremented when a Rx Parser accept a packet due to AF = 1 and RF = 0.

   For more details, see the "Software access to indirect FRP register (IFR) block" section

Related information

Software Access to Indirect FRP Register (IFR) Block on page 1450

Software Access to Indirect FRP Register (IFR) Block

The software can write/read the flexible receive parser's Indirect Registers using the following register sets through indirect addressing:

- MTL_RXP_Indirect_Acc_Control_Status
- MTL_RXP_Indirect_Acc_data

***Note**: All indirect Registers of flexible receive parser are 32-bit wide.*

The indirect registers are shared by multiple indirect accessible blocks. Set the ACCSEL field of the MTL_RXP_Indirect_Acc_Control_Status register to access the indirect Register block of flexible receive parser.

For more details, see the section "Registers".

Related information

Registers on page 802

Receive Cut-Through Functionality

In the cut-through mode, the Rx controller attempts to transfer the received packets to DMA just after the cut-through threshold amount of packet data is received.

However due to flexible receive parser's result, worst case arrival time can be more than the programmed cut-through threshold. So, the Rx controller delays the packet transfer to DMA accordingly. So, the cut-through functionality is re-defined as, the Rx controller attempts to transfer the packet to DMA after at least RTC number of bytes are received and flexible receive parser results are available.

Receive Packet Drop Indication

In most cases, the packet drops internally in the Rx Queue. However, back-to-back packets can arrive for the same queue and first packet's flexible receive parser result is not available when the second packet arrives. In such cases, the packet cannot be flushed internally and forwarded to DMA or the Application Interface and status is indicated accordingly.

For more details, see the FPS[2:0] bits of RDES2 and RDES3 described in the "Receive normal descriptor (write-back format)" section.

Related information

Receive Normal Descriptor (Write-Back Format) on page 1572

Uncorrectable ECC Error Handling

When the flexible receive parser detects an uncorrectable ECC error while checking the instruction table, software gets the interrupt for unrecoverable error. In such a case, software should re-program the instruction table.

In such a case, FRPE bit is reset and parsing is suspended for all subsequent packets.

14.4.3.9.3 Enabling and disabling the flexible receive parser

To enable the Flexible Receive Parser, set FRPE bit to 1, in the MTL_Operation_Mode register.

It is not required to disable the L2 filtering when flexible receive parser is enabled, though L2 filtering result has an effect on flexible receiver parser result.

After setting FRPE bit to 1, optionally, software can wait until RXPI field of MTL_RXP_Control_Status register becomes 1 (active).

For details about these options, see the "MAC (L2) packet filtering/drop/error handling" section.

14.4.3.10 IEEE 1588 Timestamps

The IEEE 1588 defines a Precision Time Protocol (PTP) which enables precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The PTP applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The XGMAC supports the IEEE 1588-2002 (version 1) and IEEE 1588-2008 (version 2). The IEEE 1588-2002 supports PTP transported over UDP/IP. The IEEE 1588-2008 supports PTP transported over Ethernet. The XGMAC provides programmable support for both standards. It supports the following features:

- Supports both timestamp formats
- Provides an option to take snapshot of all packets or only PTP type packets
- Provides an option to take snapshot of only event messages
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent
- Provides an option to select the node to be a master or slave for ordinary and boundary clock
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Provides an option to measure sub-second time in digital or binary format

14.4.3.10.1 Delay Request-Response Mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information. Figure 140 shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

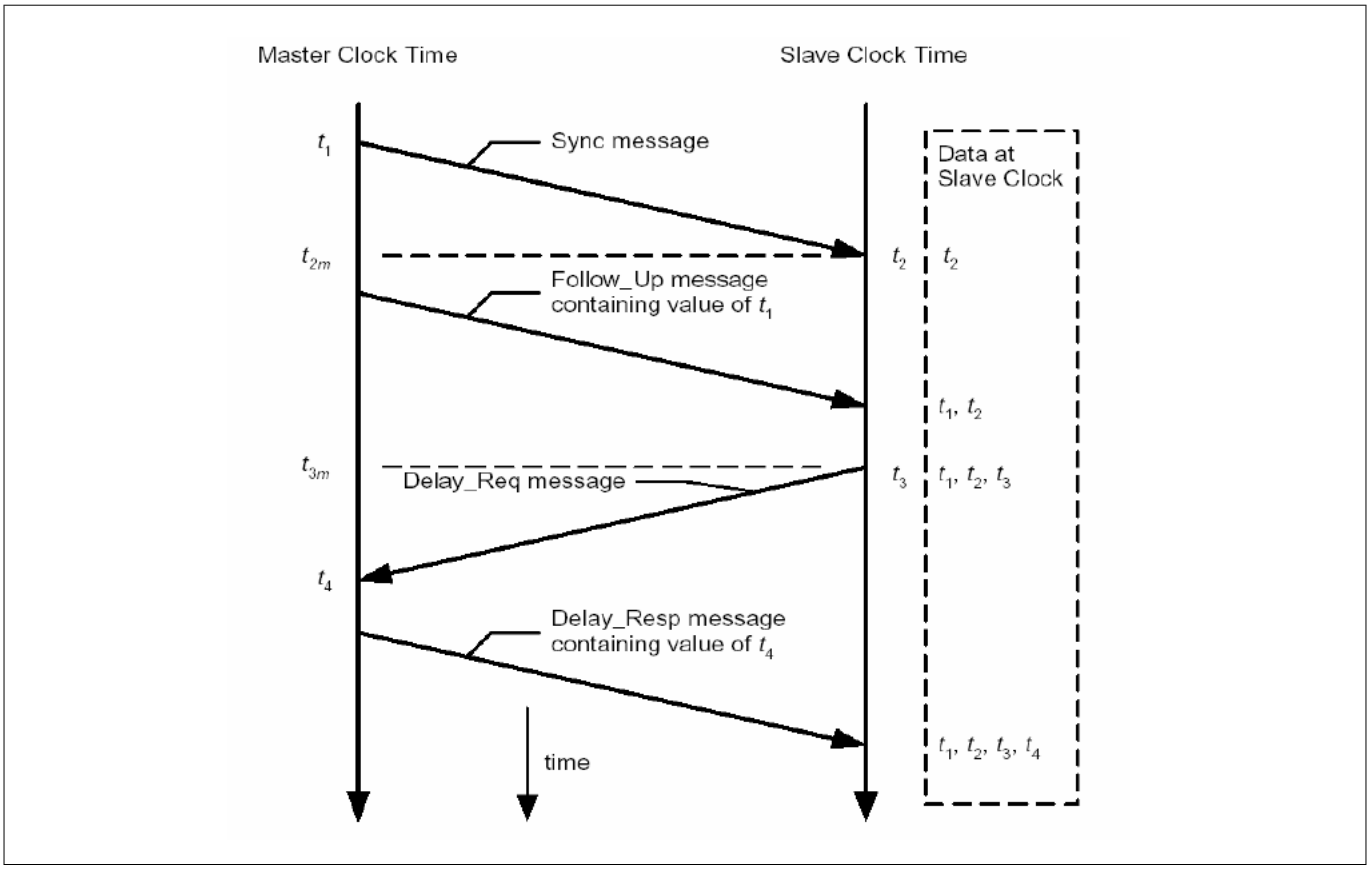

Figure 140 Networked Time Synchronization

As shown in Figure 140, the PTP uses the following process:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at t1. This time must be captured for Ethernet ports at GMII or XGMII.
2. The slave receives the Sync message and also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and notes the exact time, t3, at which this packet leaves the GMII or XGMII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the timing reference of the master.

Most of the PTP implementation is done in the software that is above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the GMII or XGMII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

14.4.3.10.2 Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 supports peer-to-peer PTP (Pdelay) message in addition to the SYNC, Delay Request, Follow-up, and Delay Response messages. Figure 141 shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

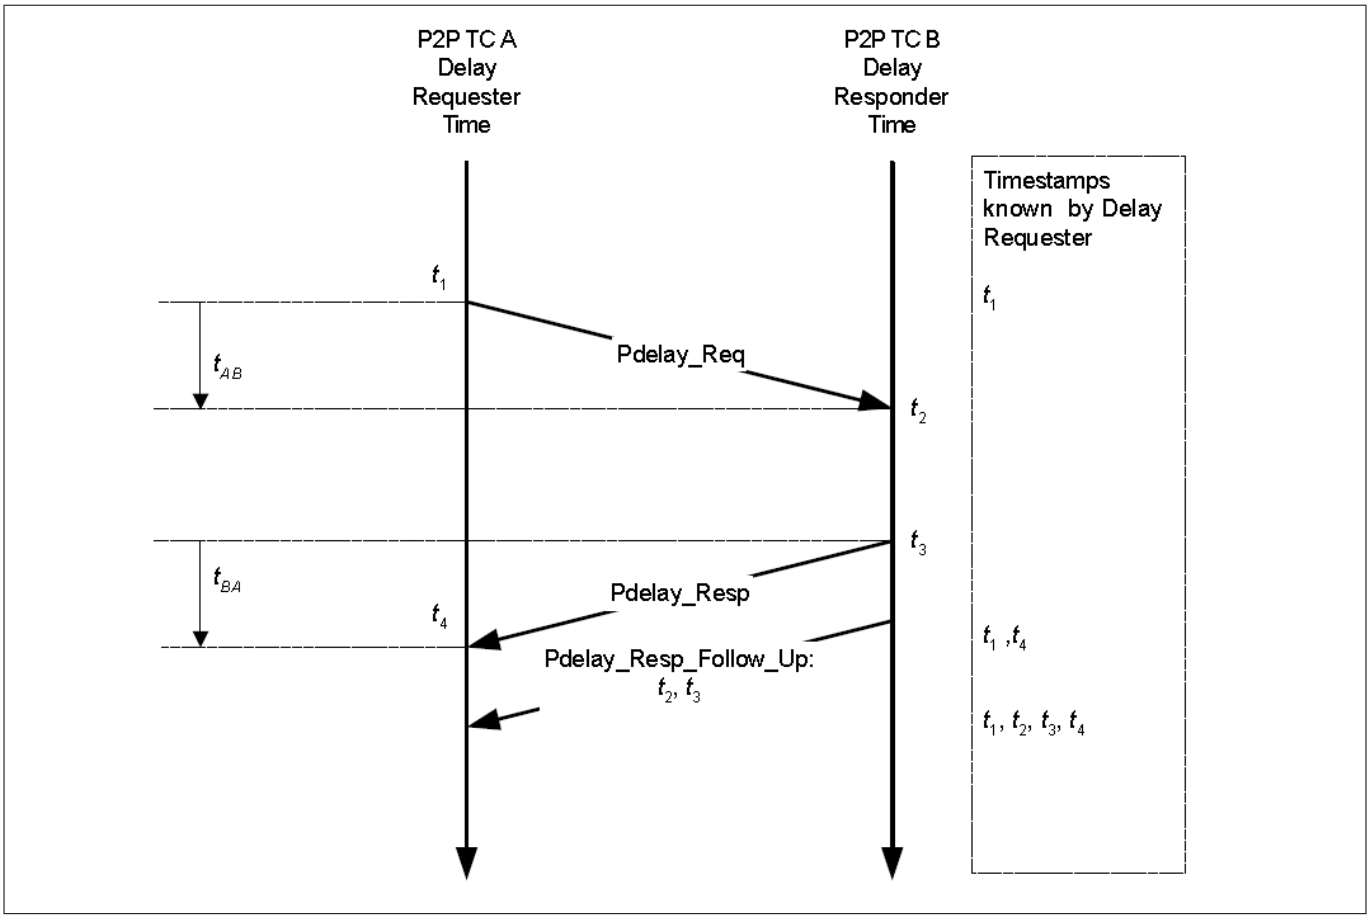

Figure 141 Propagation Delay Calculation in Clocks Supporting Peer-to-Peer Path Correction

As shown in Figure 141, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message.

   To minimize errors because of any frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:

   - Difference between the timestamps t2 and t3 in the Pdelay_Resp message
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
   - Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively
4. Port 1 generates a timestamp (t4) on receiving the Pdelay_Resp message.
5. Port 1 uses all four timestamps to compute the mean link delay.

14.4.3.10.3 Clock Types

The XGMAC supports the following clock types defined in the IEEE 1588-2008:

- Ordinary Clock
- Boundary Clock
- End-to-End Transparent Clock
- Peer-to-Peer Transparent Clock

Ordinary Clock

The ordinary clock in a domain supports a single copy of the protocol. The ordinary clock has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or an actuator. In telecoms applications, the ordinary clock can be associated with a timing demarcation device.

The ordinary clock can be a grandmaster or a slave clock. It supports the following features:

- Sends and receives PTP messages. The timestamp snapshot can be controlled as described in Portj_MAC_Timestamp_Control in the section "Registers".
- Maintains the data sets such as timestamp values

Table 693 shows the messages for which you can take the timestamp snapshot on the receive side for master and slave nodes.

Table 693 Ordinary Clock: PTP Messages for Snapshot

Master	Slave
Delay_Req	SYNC

For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the TSVER2ENA bit and selecting the snapshot mode in Port j MAC Timestamp Control.

Boundary Clock

The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy, and signaling terminate in the protocol engine of the boundary clock and such messages are not forwarded. The PTP message type status given by the MAC helps you to identify the type of message and take appropriate action.

The boundary clock is similar to the ordinary clock except for the following features:

- The clock data sets are common to all ports of the boundary clock
- The local clock is common to all ports of the boundary clock

End-to-End Transparent Clock

The end-to-end transparent clock supports the end-to-end delay measurement mechanism between the slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the Ingress port to the Egress port.

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet, inside the end-to-end transparent clock, is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both Ingress and Egress ports only for the messages mentioned in Table 694. You can take the snapshot by setting the SNAPTYPSEL bits to 10 in the Portj_MAC_Timestamp_Control register as shown in Table 702.

Table 694 End to End Transparent Clock: PTP Messages for Snapshot

PTP Messages
SYNC
Delay_Req

Peer-to-Peer Transparent Clock

The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer. The residence time of the Pdelay_Req and the associated Pdelay_Resp packets is added and inserted into the correction field of the associated Pdely_Resp_Followup packet. Therefore, support for taking snapshot for the event messages related to Pdelay is added as shown in Table 695.

Table 695 Peer-to-Peer Transparent Clock: PTP Messages for Snapshot

PTP Messages
SYNC
Pdelay_Req
Pdelay_Resp

You can take the snapshot by setting the SNAPTYPESEL bit to 11 in the Portj_MAC_Timestamp_Control register.

Related information

Registers on page 802

14.4.3.10.4 Reference timing source

To get a snapshot of the time, the MAC requires a reference time in 64-bit format as defined in the IEEE 1588-2002 (80-bit format as defined in the IEEE 1588-2008). The XGMAC provides the following method for using the reference timing source in a node:

- Internal Reference Time (80-bit)

  It takes only the reference clock input and uses it to internally generate the reference time (also called the system time) and capture timestamps. The timestamp has the following fields:

  - UInteger48 secondsField:

    The seconds field is the integer portion of the timestamp in units of seconds. It is 48-bits wide. For example, 2.000000001 seconds are represented as secondsField = 0x0000_0000_0002
  - UInteger32 nanosecondsField:

    The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds. For example, 2.000000001 seconds are represented as nanosecondsField = 0x0000_0001

    The nanoseconds field supports the following two modes:

    - Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds
    - Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is ~0.466 ns per bit

      You can set these modes through TSCTRLSSR bit in the Port j MAC Timestamp Control register
- External Reference Time (80-bit):

  If this is selected by setting MAC_Timestamp_Control.ESTI, the reference clock output from the other XGMAC (only available in products with two XGMACs) is used as the reference time (also called the system time)to capture timestamps. This allows to have the identical time on both XGMACs

The timestamp maintained in the MAC is 64-bit wide. The upper 16-bits of the seconds field can be read from the Port j MAC System Time Higher Word Seconds register.

The XGMAC supports the following reference timing source features:

- Fixed pulse-per-second output
- Flexible pulse-per-second output

Related information

Fixed pulse-per-second output on page 1457
Flexible pulse-per-second output on page 1457

Fixed pulse-per-second output

The XGMAC supports the pulse-per-second (PPS) output that is given to indicate 1 second interval (default). You can change the frequency of the PPS output by setting the PPSCTRL0 field in the Port j MAC PPS Control register.

Flexible pulse-per-second output

The XGMAC also provides the flexibility to program the start or stop time, width, and interval of the pulse generated on the ptp_pps_o output. You can configure up to two separate PPS outputs.

The XGMAC provides the following features with the flexible PPS output option:

- Supports programming the start or stop time in terms of system time
- Supports programming the start point of the single pulse and start and stop points of the pulse train in terms of 64-bit system time. The Target Time registers are used to program the start and stop time
- Supports programming the stop time in advance, that is you can program the stop time before the actual start time has elapsed
- Supports programming the width between the rising edge and corresponding falling edge of PPS signal output in terms of number of units of sub-second increment value programmed in the Port j MAC Sub Second Increment register. You can program the width of pulse from 1 to 2^{32}-1 units of sub-second increment value
- Supports programming the interval between the rising edges of PPS signal, in terms of number of units of sub-second increment value. You can program the interval between pulses from 1 to 2^{32}-1 units of sub-second increment value
- Provides the option to cancel the programmed PPS start or stop request
- Indicates error if the start or stop time being programmed has already elapsed

***Note**: The PTP Reference clock mentioned in the following sections is the clock at which the system time gets updated. It is defined in the "Clocks" section. When the TSCFUPDT bit of the Port j MAC Timestamp Control register is set to 0, this clock is similar to the clk_ptp_ref_i clock. In the Fine Correction mode, this is the clock tick at which the system time gets updated using incr_sub_sec_reg as described in the "System time register module" section.*

Related information

System Time Register Module on page 1458
Clocks on page 1592

PPS start or stop time

You can initially program the start time in the Target Time registers, Port j MAC PPS0 Target Time Seconds and Port j MAC PPS0 Target Time Nanoseconds. Similarly also for the second Flexible PPS output.

If required, you can again program the start or stop time but you can do it only after the earlier programmed value is synchronized to the PTP clock domain. Bit 31 of MAC_PPS(#i)_Target_Time_Nanoseconds register indicates that the synchronization is complete. This enables you to program the start or stop time in advance even before the earlier stop or start time has elapsed.

To ensure proper PPS signal output, you should program advanced system time for the start or stop time. If the application programs a start or stop time that has already elapsed, the MAC sets an error status bit indicating

the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

PPS width and interval

The PPS width and interval are programmed in terms of granularity of system time, that is, number of the units of sub-second increment value. For example, to have a PPS pulse width of 40 ns and interval of 100 ns with PTP reference clock of 50 MHz, you should program the width and interval to values 2 and 5, respectively. You can achieve smaller granularity by using a faster PTP reference clock.

Before giving the command to trigger a pulse or pulse train on the PPS output, you should program or update the interval and width of the PPS signal output.

14.4.3.10.5 System Time Register Module

The system time generator module maintains the 64-bit time and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets being transmitted or received at the GMII interface.

The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, the system time counter is written with the value in the Timestamp Update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, the frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register, as shown in Figure 142. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. The accumulator acts as a high-precision frequency multiplier or divider.

This algorithm is shown in Figure 142.

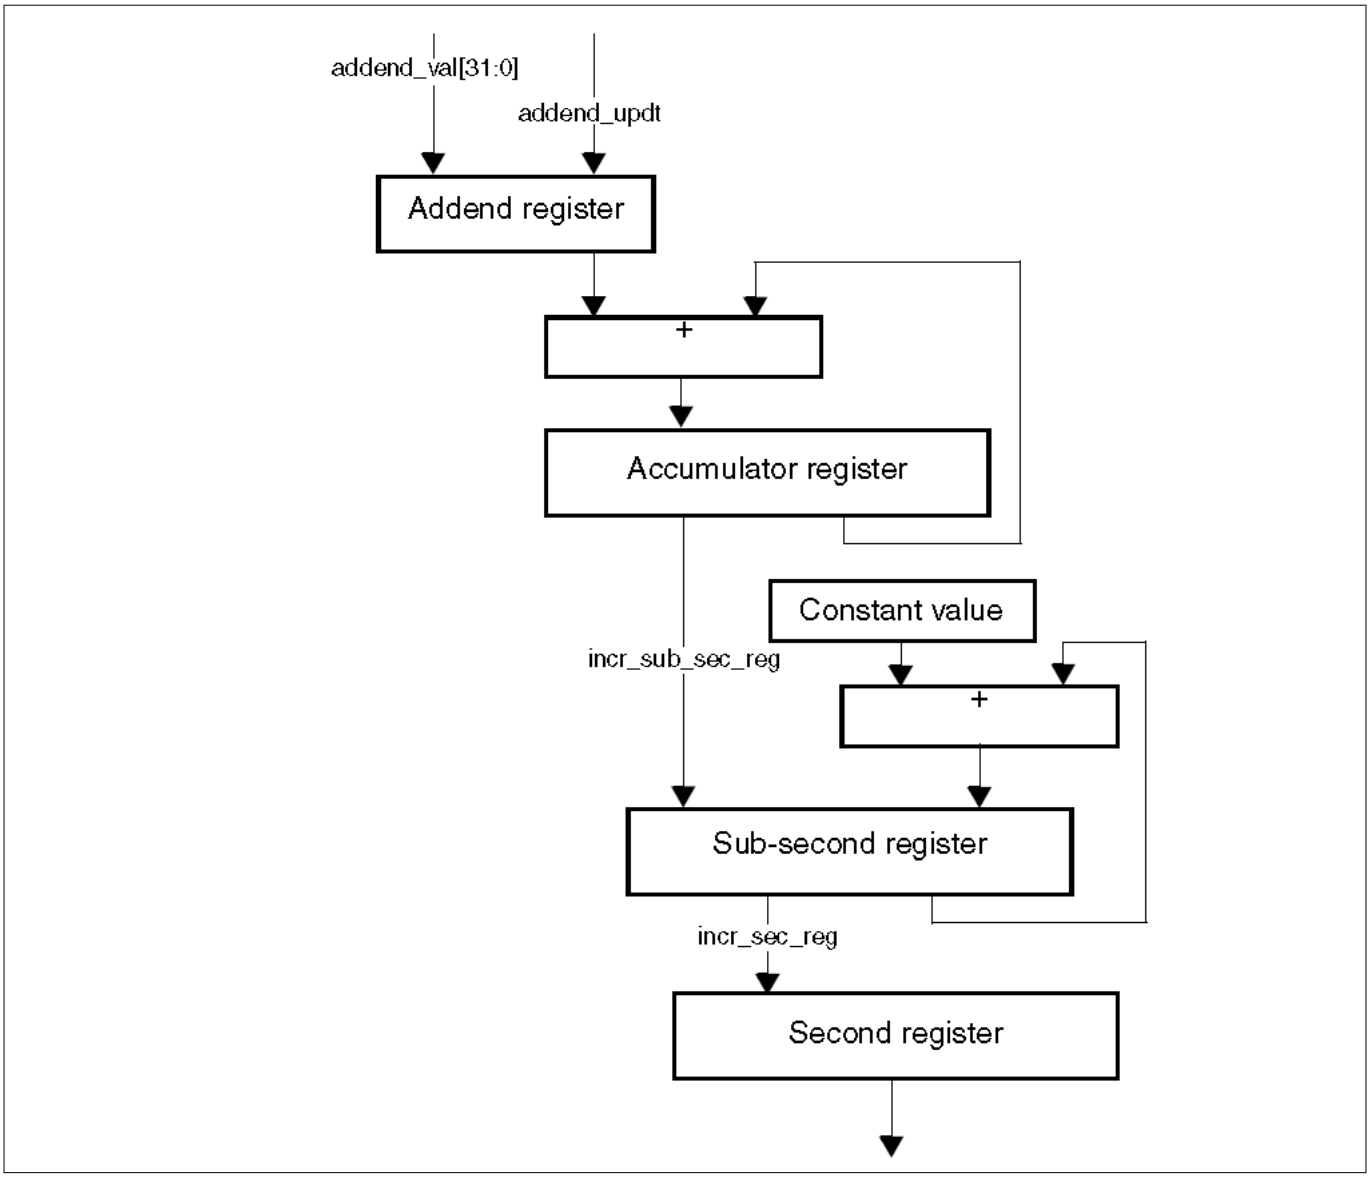

Figure 142 System Time Update Using Fine Method

The System Time Update logic requires a 50 MHz clock frequency to achieve 20 ns accuracy. The frequency division (FreqDivisionRatio) is the ratio of the reference clock frequency to the required clock frequency. For example, if the reference clock (clk_ptp_ref_i) is 250 MHz, this ratio is calculated as 250 MHz / 50 MHz = 5. Therefore, the default addend value to be set in the register is 2^{32} / 5, 0x33333333.

If the reference clock drifts lower, for example, to 248 MHz, the ratio is 248 / 50, or 4.96 and the value to set in the addend register is 2^{32} / 4.96, or 0x339CE739. If the clock drifts higher, for example, to 252 MHz, the addend register must be set to 0x32CB2CB2. When the clock drift is nil, the default addend value of 0x33333333 (2^{32} / 5) must be programmed.

In Figure 142, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20 ns steps). When External Time Update is enabled, the optional System Time module is not available. Two different methods are used to update the System Time register depending on the configuration.

The software must calculate the drift in frequency based on the Sync messages and accordingly update the Addend register.

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

$FreqCompensationValue_0 = 2^{32}$ / FreqDivisionRatio

If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm given in this section must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and synchronize again with the master, using the new value.

The algorithm is as follows:

- At time $MasterSyncTime_n$ the master sends the slave clock a Sync message. The slave receives this message when its local clock is $SlaveClockTime_n$ and computes$MasterClockTime_n$ as
  $MasterClockTime_n = MasterSyncTime_n + MasterToSlaveDelay_n$
- The master clock count for current Sync cycle, $MasterClockCount_n$ is
  $MasterClockCount_n = MasterClockTime_n - MasterClockTime_{n-1}$ (assuming that MasterToSlaveDelay is the same for Sync cycles n and n – 1)
- The slave clock count for current Sync cycle, $SlaveClockCount_n$ is
  $SlaveClockCount_n = SlaveClockTime_n - SlaveClockTime_{n-1}$
- The difference between master and slave clock counts for current Sync cycle, $ClockDiffCount_n$ is
  $ClockDiffCount_n = MasterClockTime_n - SlaveClockTime_n$
- The frequency-scaling factor for slave clock, $FreqScaleFactor_n$ is
  $FreqScaleFactor_n = (MasterClockCount_n + ClockDiffCount_n)/ SlaveClockCount_n$
- The frequency compensation value for Addend register, $FreqCompensationValue_n$ is
  $FreqCompensationValue_n = FreqScaleFactor_n * FreqCompensationValue_{n-1}$

In theory, this algorithm achieves lock in one Sync cycle. However, it might take several cycles, because of changing network propagation delays and operating conditions. This algorithm is self-correcting. If the slave clock is initially set to an incorrect value from the master, the algorithm corrects it at the cost of more Sync cycles.

14.4.3.10.6 Transmit Path Functions

The section text below enclosed in a comment is the 3rd party read-only source text. To make it editable, it has been cut and pasted below the comment. The text remains as a reference, should it change in the future.

The MAC captures a timestamp when the Start Frame Delimiter (SFD) of a packet is sent on the GMII or XGMII interface. The packets, for which you want to capture timestamps, can be controlled on per-packet basis. Each Transmit packet can be marked to indicate whether a timestamp should be captured for it.

The MAC does not process the transmitted packets to identify the PTP packets. You must specify the packets for which you want to capture timestamps. You can do this as follows: The MAC captures a timestamp when the Start Packet Delimiter (SFD) of a packet is sent on the GMII or XGMII interface. The packets, for which you want to capture timestamps, can be controlled on per-packet basis. Each Transmit packet can be marked to indicate whether a timestamp should be captured for

You can specify the packets by using the control bits in the Transmit descriptor. The 64-bit timestamp information is written to the Port j MAC Tx Timestamp Status Seconds and Port j MAC Tx Timestamp Status Nanoseconds register. The MAC generates "Tx Timestamp Captured" interrupt when 64-bit timestamp information is written to these registers.

Tx Timestamp Status FIFO with Packet Identifier

The MAC provides option to store 16 captured timestamps with associated packet identifier provided by the application. These can be accessed through Port j MAC Tx Timestamp Status PktID, MAC_TxTimestamp_Status_Seconds and Port j MAC Tx Timestamp Status Nanoseconds registers. The packet identifier helps the application to correlate the timestamp with the packet.

Table 696 Details of the Operating Modes

TTSE	OSTC	OSTPA	ATI Control Word 1 (TTSL & TTSH)	Timestamp Captured & Given in TS StatusFIFO	Comments
0	0	X	Not Valid	No	Default non-PTP packet
0	1	0	Not Valid	No	1-step PTP packet to insert Origin TS only (for example, SYNC, DelayResp. PdelayResp)
0	1	1	Ingress TS	No	1-step PTP packet to insert Origin TS and/or update Correction
1	0	0	Not Valid	Yes (PID = 0)	PTP 2-step without PID (for example, any PTP Event Message)
1	1	0	Not Valid	Yes (PID = 0)	1-step PTP packet to insert Origin TS (Example: SYNC, DelayResp. PdelayResp)
1	0	1	Packet ID	Yes with PID	PTP 2-step with PID (Example: Any PTP Event Message)
1	1	1	Ingress TS	Yes (PID = 0)	1-step PTP packet to insert Origin TS, update Correction & also give Origin TS it to software (DelayReq, PDelayReq)

14.4.3.10.7 Receive Path Functions

The MAC can be programmed to capture the timestamp of all packets received on the GMII or XGMII interface or to process packets to identify the valid PTP messages. You can control the snapshot of the time to be sent to the application by using the following options of the MAC_Timestamp_Control register.

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet or UDP-IP-Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

  This feature controls the type of messages for which snapshots are taken.

***Note**: The XGMAC also supports the PTP messages over VLAN packets.*

The timestamp is provided as follows:

- The DMA returns the timestamp to the software inside the context Receive Descriptor. The timestamp message status is written in RDES3 and the snapshot of the timestamp is written in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

  ***Note**: The timestamp on RX packet is captured and provided in Rx Status only for valid Ethernet packets without any of the following errors:*

  - *Giant packet error*
  - *Length error*
  - *CRC error*
  - *Invalid code error*
  - *Watchdog timeout error*

14.4.3.10.8 Timestamp Correction

According to the IEEE 1588 standard, a timestamp must be captured when the message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network. Because the reference timing source (the PTP clock clk_ptp_ref_i) is different from the MAC Tx/Rx clock, correction needs to be performed to the captured timestamp for latency due to synchronization. Also, correction due to the latency between the internal snapshot point (XGMII/GMII) and the recommended capture point (the boundary between the node and the network) needs to be performed.

Ingress Correction

In the receive side, the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (Ingress Correction Value) programmed in the Port j MAC Timestamp Ingress Corr Nanosecond. The value that needs to be programmed in the ingress correction register is calculated as described as follows.

The timestamp correction due to synchronization is compensated by adding INGRESS_SYNC_CORR to the synchronized timestamp value, which is as follows: `INGRESS_SYNC_CORR = (1*PTP_CLK_PER + 4*RX_CLK_PER)`

The latency correction between the message timestamp point and the XGMII receive interface is done by subtracting the latency value (INGRESS_LATENCY) with the captured timestamp.

Thus Ingress correction is as follows:

`Ingress Correction = INGRESS_SYNC_CORR - INGRESS_LATENCY - (3*RX_CLK_PER)`

(3*RC_CLK_PER) is due to the internal latency between the XGMII receive interface and the internal timestamp snapshot point. Ingress correction is performed by programming the TSIC field in the Port j MAC Timestamp Ingress Corr Nanosecond register. The ingress correction can be positive/negative and has an unit of nanoseconds. A negative value is represented in complement form as described as follows.

When the TSCTRLSSR bit in the Port j MAC Timestamp Control register is set, this has an accuracy of 1 ns. If the correction is positive, it is represented by setting bit 31 to 0 and bits 30:0 containing <ingress_correction_value> represented in binary. The value should not exceed 0x 3B9A_C9FF (1 second or 10^9 nanoseconds). If the correction is negative, it is represented by setting bit 31 to 1 and bits 30:0 containing 10^9 – <ingress_correction_value> represented in binary.

For example, if the required correction value is -5 ns, then the programmed value should be 0xBB9A_C9FB.

When the TSCTRLSSR bit in the Port j MAC Timestamp Control register is reset, this has an accuracy of ~0.466 ns. If the correction is positive, it is represented by setting bit 31 to 0 and bits 30:0 containing <ingress_correction_value> represented in binary. The maximum value is 0x7FFF_FFFF. If the correction is negative, it is represented by setting bit 31 to 1 and bits 30:0 containing 2^{31} – <ingress_correction_value> represented in binary.

Egress Correction

In the transmit side, the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (Egress Correction Value) programmed in the Port j MAC Timestamp Egress Asym Corr register. The value that needs to be programmed in the egress correction register is calculated as described as follows.

The timestamp correction due to synchronization is compensated by adding EGRESS_SYNC_CORR to the synchronized timestamp value, which is as follows:

`EGRESS_SYNC_CORR = (1*PTP_CLK_PER + 4*TX_CLK_PER)`

The latency correction between the recommended capture point and the internal timestamp snapshot point is done by adding the latency value (EGRESS_LATENCY) with the captured timestamp.

Thus, Egress correction is as follows:

`Egress Correction = EGRESS_SYNC_CORR + EGRESS_LATENCY`

Egress correction is performed by programming the TSEC field in the Port j MAC Timestamp Egress Corr Nanosecond register. The egress correction is always positive and has an unit of nanoseconds.

When TSCTRLSSR bit in Port j MAC Timestamp Control register is set, this has an accuracy of 1 ns.

The value should not exceed 0x 3B9A_C9FF. When TSCTRLSSR bit in Port j MAC Timestamp Control register is reset, this has an accuracy of ~0.466 ns. The maximum value is 0x7FFF_FFFF.

Sub-Nanosecond Accuracy

When Enable IEEE 1588 Sub-Nanoseconds Timestamp Support is selected, then ingress and egress correction can have sub-nanoseconds accuracy. The sub-nanosecond part of the ingress and egress correction is programmed in the TSICSNS and TSECSNS field of the Port j MAC Timestamp Ingress Corr Subnanosecond and Port j MAC Timestamp Egress Corr Subnanosecond registers, respectively.

In this case, the correction has a unit of nanosecond, multiplied by 2^8. The least significant 8 bits of the value must be programmed in the sub-nanoseconds register.

For example, if the required egress correction is 3.6 ns and the TSCTRLSSR bit is set, the TSEC should be 0x3 and the TSECSNS should be 0x99 (3.6 * 256). Similarly, if the required ingress correction is -3.6 ns and the TSCTRLSSR bit is set, the TSIC should be 0xBB9A_C9FC and the TSICSNS should be 0x66 ((10^9 – 3.6) * 256).

Maximum PTP Clock Frequency

The resolution or granularity of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance.

Minimum PTP Clock Frequency

The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes and the time taken for synchronizing the time to the GMII or MII clock domain. This relationship is given in the following equation:

```
3 * PTP clock period + 4 * GMII/MII clock period <= Minimum gap between two SFDs
```

The GMII or MII clock frequency is fixed by IEEE specification. Therefore, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC as shown in Table 697.

***Note**:*

- *Use a clock that has constant frequency, preferably a divided application clock*
- *When IEEE 1588 timestamp feature is enabled with internal timestamp, use a PTP clock frequency which is greater than 5 MHz. This is because the 8-bit Port j MAC Sub Second Increment register limits the minimum PTP frequency that can be used to ~4 MHz*

Table 697 Minimum PTP Clock Frequency Example

Mode	Minimum Gap Between Two SFDs	Minimum PTP Frequency with External Timestamp Input	Minimum PTP Frequency with Internal Timestamp
10 Mbps full duplex	168 MII clocks (128 clocks for a 64-byte packet + 24 clocks of min IFG + 16 clocks of preamble)	~45 KHz	5 MHz
100 Mbps full duplex	168 MII clocks (128 clocks for a 64-byte packet + 24 clocks of min IFG + 16 clocks of preamble)	~0.5 MHz	5 MHz

(table continues...)

Table 697 (continued) Minimum PTP Clock Frequency Example

Mode	Minimum Gap Between Two SFDs	Minimum PTP Frequency with External Timestamp Input	Minimum PTP Frequency with Internal Timestamp
1G Mbps full duplex	84 GMII clocks (64 clocks for a 64-byte packet + 12 clocks of min IFG + 8 clocks of preamble)	~4.7 MHz	5 MHz
2.5G Full duplex (GMII)	84 GMII clocks (64 clocks for a 64-byte packet + 12 clocks of min IFG + 8 clocks of preamble)	12 MHz	12 MHz
2.5G Full duplex (XGMII)	21 XGMII clocks (64 clocks for a 64-byte packet + 12 clocks of min IFG + 8 clocks of preamble)	14 MHz	14 MHz
5G full duplex	21 XGMII clocks (16 clocks for a 64-byte packet + 3 clocks of min IFG + 2 clocks of preamble)	28 MHz	28 MHz

14.4.3.10.9 PTP Processing and Control

Table 698 shows the common message header for the PTP messages. This format is taken from the IEEE 1588-2008.

Table 698 Message Format Defined in IEEE 1588-2008

Bits								Octets	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField (*)								1	32
logMessageInterval								1	33

(*) – controlField is used in version 1. In version 2, messageType field is used for detecting different message types.

There are some fields in the Ethernet payload that you can use to detect the PTP packet type and control the snapshot to be taken. These fields are different for the following PTP packets:

- PTP Packets Over IPv4
- PTP Frames Over IPv6
- PTP Packets Over Ethernet

PTP Packets Over IPv4

Table 699 shows the fields that are matched to control snapshot for the PTP packets sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format defined in Table 699.

Table 699 IPv4-UDP PTP Packet Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Packet Type	12, 13	0x0800	IPv4 datagram
IP version and Header Length	14	0x45	IP version is IPv4
Layer 4 Protocol	23	0x11	UDP
IP Multicast Address (IEEE 1588 version 1)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (or 0x82 or 0x83 or 0x84)	Multicast IPv4 addresses allowed: • 224.0.1.129 • 224.0.1.130 • 224.0.1.131 • 224.0.1.132
IP Multicast Address (IEEE 1588 version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex) 0xE0, 0x00, 0x00, 0x6B (Hex)	• PTP Primary multicast address: 224.0.1.129 • PTP Pdelay multicast address: 224.0.0.107
UDP Destination Port	36, 37	0x013F, 0x0140	• 0x013F: PTP event message[1)] • 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	74	0x00, 0x01, 0x02, 0x03, 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management

(table continues...)

Table 699 (continued) IPv4-UDP PTP Packet Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
PTP Message Type Field (IEEE 1588 version 2)	42 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP Version	43 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

1) PTP event messages are SYNC, Delay_Req (IEEE 1588 version 1 and 2) or Pdelay_Req, Pdelay_Resp (IEEE 1588 version 2 only)

PTP Frames Over IPv6

Table 700 provides information about the fields that are matched to control the snapshots for the PTP packets sent over UDP over IPv6 for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format defined in Table 698.

Table 700 IPv6-UDP PTP Packet Fields Required for Control and Status

Field Matched	Octet Position	Matched Value	Description
MAC Packet Type	12, 13	0x86DD	IP datagram
IP Version	14 (Bits [7:4])	0x6	IP version is IPv6
Layer 4 Protocol	20[1)] (*)	0x11	UDP
PTP Multicast Address	38 – 53	FF0x:0:0:0:0:0:0:181 (Hex) FF02:0:0:0:0:0:0:6B (Hex)	• PTP Primary multicast address: FF0x:0:0:0:0:0:0:0:181 (Hex) • PTP Pdelay multicast address: FF02:0:0:0:0:0:0:0:6B (Hex)
UDP Destination Port	56, 57[a]	0x013F, 0x140	• 0x013F: PTP event message • 0x0140: PTP general messages
PTP Control Field (IEEE 1588 version 1)	94[a]	0x00, 0x01, 0x02, 0x03, or 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management (version1)

(table continues...)

Field Matched	Octet Position	Matched Value	Description
PTP Message Type Field (IEEE 1588 version 2)	62[a] (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP Version	63 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

1) The Extension Header is not defined for PTP packets.

PTP Packets Over Ethernet

Table 701 provides information about the fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format defined in Table 698.

Table 701 Ethernet PTP Packet Fields Required for Control And Status

Field Matched	Octet Position	Matched Value	Description
MAC Destination Multicast Address[1)]	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses[2)]: • 01-1B-19-00-00-00 • 01-80-C2-00-00-0E[3)]
MAC Packet Type	12, 13	0x88F7	PTP Ethernet packet
PTP Control Field (IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, or 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management

(table continues...)

Table 701 (continued) Ethernet PTP Packet Fields Required for Control And Status

Field Matched	Octet Position	Matched Value	Description
PTP Message Type Field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP Version	15 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

1) The unicast address match of destination addresses (DA), programmed in MAC address 0 to 31, is used if the TSENMACADDR bit of the MAC_Timestamp_Control register is set.

2) IEEE 1588-2008, Annex F

3) The MAC does not consider the PTP version 1 messages with Peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

14.4.3.11 One-Step Timestamp

The XGMAC supports the one-step timestamp feature. When this feature is enabled, the MAC identifies the offset in the packet and inserts the timestamp received from the application or the timestamp taken for the packet being transmitted at that offset.

You can enable the one-step timestamp feature by selecting the Enable One-Step Timestamp Feature option. You can enable the one-step timestamp feature for a packet as follows:

- Set the OSTC bit in the transmit context descriptor

For updating the correction field in certain PTP packets, the ingress timestamp is to be given in the TSSL and TSSH fields. The timestamp is 80-bit and it also contains the content of higher 16 bits of Higher Timestamp Word Register.

***Note**: One-step timestamps require the sub-second time is programmed to operate in digital format (TSCTRLSSR bit in Port j MAC Timestamp Control register).*

MAC Transmit PTP Mode

Depending upon the type of message and its mode, the MAC updates the following fields of Transmit PTP packets:

- correctionField in the PTP header of messages
- originTimestamp in SYNC, Delay_Req, and Pdelay_Req messages

***Note**: For residence/turnaround time correction, it is assumed that the differences between egress and ingress timestamp may be a few seconds, therefore, the XGMAC-CORE supports a difference up to eight seconds. Do not use this feature if your implementations requires a residence/turnaround time greater than eight seconds.*

The table below shows how the PTP mode is selected for a message based on the settings of SNAPTYPSEL, TSMSTRENA, and TSEVNTENA bits of the Port j MAC Timestamp Control register. The MAC updates the corresponding fields (originTimestamp, correction field) in the transmit PTP packets received from the application.

Table 702 MAC Transmit PTP Mode

Programming			Mode	Per Packet Control[1]			Messages Processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE[2]	OSTC[3]	TTS[4]	
2'b00	X	0	End-to-end transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
							Delay_Req (correction field for residence time and Egress Asym Cor)
2'b00	0	1	Ordinary or Boundary Slave	1	1	X	Delay_Req (originTimestamp field) Delay_Req (correction field for Egress Asym cor)
2'b00	1	1	Ordinary or Boundary Master	0	1	X	Sync (originTimestamp field) Sync (correction field for sub-nanosecond cor)
2’b01	X	0	End-to-End Transparent with support for peer delay mechanism	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
						Ingress TS	Pdelay_Req (correction field for residence time and Egress Asym Cor)
						Ingress TS	Pdelay_Resp (correction field for residence time and Ingress Asym Cor)
2’b01	0	1	Ordinary or Boundary Slave with support for peer delay mechanism or Peer to Peer Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor) (applicable only for Peer to Peer transparent clock operation)
				1	1	X	Delay_Req (originTimestamp field) Delay_Req (correction field for Egress Asym cor)
				1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)
2’b01	1	1	Ordinary or Boundary Master with support for	0	1	X	Sync (originTimestamp field) Sync (correction field for sub-nanosecond cor)

(table continues...)

Table 702 (continued) MAC Transmit PTP Mode

Programming			Mode	Per Packet Control[1]			Messages Processed on Tx
SNAPTYPSEL	TSMSTRENA	TSEVNTENA		TTSE[2]	OSTC[3]	TTS[4]	
			peer delay mechanism	1	1	X	Pdelay_Req (originTimestamp field) Pdelay_Req (correction field for Egress Asym Cor)
				0	1	Ingress TS for Pdelay_Req	Pdelay_Resp (correction field for turnaround time and Ingress Asym Cor)
2'b10	X	X	End-to-End Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)
						Ingress TS	Delay_Req (correction field for residence time and Egress Asym Cor)
2'b11	X	X	Peer-to-Peer Transparent	0	1	Ingress TS	Sync (correction field for residence time and Ingress Asym cor)

1) The per packet control values provided here are the recommended settings used by devices in typical PTP operation, for the programmed mode.
2) TTSE represents TTSE bit of transmit descriptor. The TTSE function is independent of the OST (One Step Timestamp) function and the programmed operation mode for OST. The MAC captures and returns the timestamp when the TTSE bit is set.
3) OSTC represents OSTC bit of transmit descriptor. When OSTC is set to 0, OST operation is not performed; that is PTP packet is not modified.
4) TTTS represents the timestamp value provided in the TTSH, TTSL fields of transmit descriptor.

***Notes**:*

1. *Residence time/turnaround time is calculated as the difference between the captured timestamp (egress timestamp) and the ingress timestamp*
2. *When sub-nanosecond feature is enabled, residence time calculation includes sub-nanosecond accuracy*
3. *Clocks supporting peer delay mechanism does not use delay request/response, but it is included in OST for flexibility*

Enable One-Step Time Stamping for PTP Over UDP

One step timestamp for PTP over UDP/IP is a configurable feature available in configurations with Enable IEEE 1588 Timestamp Support option selected. When this feature is selected, XGMAC supports the one step timestamp operation for PTP messages sent over UDP/IPv4 and UDP/IPv6. Because origin timestamp and/or correction field (based on the PTP message type and the programmed PTP mode) in the PTP message are updated as part of the one step timestamp operation, it also requires update to the checksum field of the UDP header encapsulating the PTP message payload.

In XGMAC, checksum is updated for a packet, in the MTL before the packet is sent to the MAC where the PTP message is updated for one step timestamp operation. PTP requires the timestamp to be captured while the packet (SFD of the packet) is on the line and one step timestamp requires the origin timestamp and/or correction field to be updated in the PTP header while the packet is being transmitted on the line. Because the PTP message is present in the UDP payload, it is not possible to update the checksum field in the UDP header for modifications made to the PTP message, because it is already transmitted by then. Instead, the following options are supported that are in line with specification mentioned in Annex D & E of IEEE 1588-2008:

- When PTP message is sent over UDP/IPv4, the UDP checksum may be set to 0. The application must set the UDP checksum to 0 and set CIC to 0 or 1 while providing the packet to the MAC and the MAC does not update checksum for changes in origin timestamp or correction field
- When PTP message is sent over UDP/IPv6, a transmitting node extends the UDP payload of all PTP messages by 2 octets beyond the end of the PTP message. The contents of the UDP checksum field or the final 2 octets of the UDP payload might be modified to ensure that the UDP checksum remains intact after modification of PTP fields. The application must add the two additional bytes at the end of the PTP message while providing the packet to the MAC and the MAC updates these two bytes to keep the checksum correct

A programmable option (CSC field in Port j MAC Timestamp Control register) supports UDP with non-zero checksum for IPv4. When set, the two bytes at the end of the PTP message are updated to keep the UDP checksum correct, similar to PTP over UDP/IPv6. So, the application must add two pad bytes at the end of the PTP message sent to the XGMAC and XGMAC updates these two bytes to keep the checksum correct.

Updating the pad bytes to keep the checksum correct requires the old value of correction field and/or origin timestamp in the packet. To get better latency and area, the application can set the origin timestamp field to zero, for PTP message in particular modes in which XGMAC overwrites the origin timestamp. For example, XGMAC operating in Ordinary/Boundary master mode overwrites the origin timestamp field of the sync message, when OSTC is set. Because the sync message is originated by the port operating in Ordinary/ Boundary master mode, it is possible for the application generating the message to set the origin timestamp field to zero.

The transmit checksum engine is automatically enabled when this feature is selected. XGMAC uses the transmit checksum engine to identify the start of the PTP message in the UDP/IP packet. The checksum engine has the capability to detect some kind of errors in the header (L3) and payload (L4). Also checksum is not computed for some type of packets, which is indicated by "No" in the table "Transmit Checksum Offload Engine Functions for Different Packet Types". For one step operation the packet is free of those errors and have "Yes/Not applicable" for the corresponding packet type in the same table. If an error is reported by the checksum engine or there is a "No" in the table, for PTP messages sent over UDP/IP, no update is performed on the PTP message.

For more details about the errors detected by transmit checksum offload engine, see the section "Transmit Checksum Offload Engine" (see link in Related information).

Note:
- *XGMAC assumes an IP packet with OSTC set as a PTP packet. Therefore it is the responsibility of the application to set the OSTC bit only for IP packets which contains PTP messages*
- *For PTP over UPD/IPv6 and PTP over UDP/IPv4 with CSC set, the XGMAC does not verify the presence of the two pad bytes, instead it overwrites the last two bytes of the UDP payload*
- *When Enable One step timestamp for PTP over UDP/IP feature is selected, Enable Transmit TCP/IP Checksum Offload feature is automatically enabled and this is enabled only for Queue 0 in multiple transmit queue configurations. If the application requires OST support for PTP messages sent over UDP/IP for packets sent from queues other than 0, transmit checksum engine must be manually enabled for those transmit queues. If checksum engine is not enabled, no updates are done for PTP messages sent over UDP/IP even though OSTC is set*
- *When Enable One step timestamp for PTP over UDP/IP feature is selected and OSTC is set, the Transmit Checksum Offload Engine processes the UDP/IP packet for identifying the PTP Message Header start offset irrespective of value in CIC field. The CIC field needs to be appropriately set based on whether Transmit Checksum Offload Engine is expected to perform checksum insertion for that packet*
- *One step timestamp operation is not supported for tunneled packets*

When Enable One step timestamp for PTP over UDP/IP feature is selected and OSTC is set, the Transmit Checksum Offload Engine processes the UDP/IP packet for identifying the PTP Message Header start offset irrespective of value in CIC field. The CIC field needs to be appropriately set based on whether Transmit Checksum Offload Engine is expected to perform checksum insertion for that packet.

1. TTSE represents
- TTSE bit of transmit descriptor

2. OSTC represents
   - OSTC bit of transmit descriptor
3. TTS represents the timestamp value provided in the
   - TTSH and TTSL fields of transmit descriptor
4. The per packet control values specified are the recommended settings used by devices in a typical PTP operation, for the programmed mode
5. The TTSE function is independent of the OST function and the programmed operation mode for OST. The MAC captures and returns the timestamp when the TTSE bit is set
6. Residence time/turnaround time is calculated as the difference between the captured timestamp (egress timestamp) and the ingress timestamp
7. When sub-nanosecond feature is enabled, residence time calculation includes sub-nanosecond accuracy
8. Clocks supporting peer delay mechanism does not use delay request/response, but it is included in OST for flexibility

14.4.3.12 Memory Access in Debug Mode

The XGMAC supports the debug access to the FIFO memory. When you enable this feature in Register MTL_Debug_Control, you must assign the entire selected Tx memory to Tx Queue 0 and Rx memory to Rx Queue 0. In addition, the offload features such as Checksum Offload Engine and IEEE timestamp should not be enabled with this feature.

When this feature is enabled, the MAC insert the pad (if required) and computed CRC in the Transmit packet. The FIFOs operate in the store-and-forward mode.

***Note**:*

- *The debug access mode is not designed for dynamic switching from normal operation mode to debug access mode. The software/application must ensure that the Transmit and Receive paths are idle (All the debug status registers in CSR space are read as all-zeros). The software/ application should wait for idle state or use mechanism such as Transmit Queue flush or soft reset to reach the idle state faster, prior to switching to debug access mode.*
- *While switching from debug access mode to the normal mode of operation, DMA should be reconfigured.*
- *In both the memory debug access modes, that is, Debug Mode Access and Slave Mode Access for applicable memories, the respective whole memory is accessed as a single memory; there is no per queue or hardware or software owned lists based logical partitioning. For example, the whole of Transmit Queue memory must be allocated to Transmit Queue 0 by programming TQS field of MTL_TxQ0_Operation_Mode register. Similarly, the whole of Receive Queue memory must be allocated to Receive Queue 0 by programming RQS field of MTL_RxQ0_Operation_Mode register. Size for other memories such as EST memory and Receive Parser Memory cannot be programmed by user. In debug access mode, the MAC internally switches to accessing the respective entire memory as a single memory.*

14.4.3.12.1 Slave Mode Access

You can use this mode to send or receive a packet using the Register interface. The host controller can push a complete packet into the Tx FIFO and then schedule it for transmission. Similarly, it can read the packet received and stored in the Rx FIFO through the registers.

The following section describes the sequence of programming to transmit or receive a packet in this mode.

Transmitting Packets through a Slave Interface

To write a packet to the Tx memory through the slave interface, complete the steps given in Table 703.

Table 703 Steps to Write a Packet to Tx Memory Through a Slave Interface

Register Name	Step Number and Description
MTL_Debug_Control	1. Select the FIFO for slave access by using the DBGMOD, FDBGEN, and FIFOSEL fields.
MTL_FIFO_Debug_Data	2. Write the control word in the FDBGDATA field.
MTL_Debug_Control	3. Complete the following: a. Write the Control Word encoding to the PKTSTATE field. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit. Note: The Control Word must contain the valid packet size.
MTL_Debug_Status	4. Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_FIFO_Debug_Data	5. Write the SOP data in the FDBGDATA field.
MTL_Debug_Control	6. Complete the following steps: a. Write the SOP encoding in the PKTSTATE field. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit.
MTL_Debug_Status	7. Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_FIFO_Debug_Data	8. Write subsequent data words in the FDBGDATA field.
MTL_Debug_Control	9. Complete the following steps: a. Write the packet data encoding in the PKTSTATE field. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit.
MTL_Debug_Status	10. Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
MTL_Debug_Control and MTL_Debug_Status	11. Repeat, Step 8, Step 9, and Step 10 and till the last word of the packet data.
MTL_FIFO_Debug_Data	12. Write the last data word in the FDBGDATA field.
MTL_Debug_Control	13. Complete the following steps: a. Write the EOP encoding in the PKTSTATE field. b. Set the FIFOSEL field to Tx FIFO. c. Set the FIFOWREN bit. d. Set the number of valid bytes in the BYTEEN field.
MTL_Debug_Status	14. Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required). The packet is transmitted after the EOP is written.

Receiving Packets through a Slave Interface

To read a packet from the Rx memory through a slave interface, complete the steps given in Table 704.

Table 704 Steps to Read a Packet from Rx Memory Through a Slave Interface

Register Name	Step Number and Description
MTL_Debug_Control	1. Select the FIFO for slave access by programming the PKTIE, DBGMOD, and FDBGEN fields.
MTL_Debug_Status	2. Wait for the PKTI interrupt.
MTL_Debug_Control	3. Complete the following: a. Set the FIFOSEL field to Rx FIFO. b. Set the FIFORDEN bit.
MTL_Debug_Status	4. Read the FIFOBUSY bit and wait till this bit is low.
MTL_Debug_Control	5. Read the PKTSTATE and BYTEEN fields.
MTL_FIFO_Debug_Data	6. Read the data in the FDBGDATA field.
MTL_Debug_Status	7. Read the LOCR field (if required).
MTL_Debug_Status, MTL_Debug_Control, MTL_FIFO_Debug_Data	8. Repeat Step 3 through Step 7 till the complete packet, along with the Rx status, is received.

14.4.3.12.2 Debug Mode Access

You can use this mode to test the FIFO memories by performing writes operations in a location and read back the same. You can switch the mode when the complete word is read or written in one location. The following sections describe how to write to or read from FIFO memory in debug mode.

Writing to FIFO Memory in Debug Mode

To write to FIFO memory in the debug mode, complete the steps given in Table 705.

Table 705 Steps to Write to FIFO memory in Debug Mode

Register Name	Step Number and Description
Port j MTL Debug Control	1. Select the FIFO for debug access by using the DBGMOD and FDBGEN fields. Set RSTALL to clear all the pointers to the start location (0x0). If you want to clear the pointers of a specific memory, select using FIFOSEL and set RSTSEL.
Port j MTL FIFO Debug Data	2. Write the data in the FDBGDATA field.
Port j MTL Debug Control	3. Complete the following: a. Set the FIFOSEL field to Tx FIFO, Rx FIFO. b. Set the FIFOWREN bit.
Port j MTL Debug Status	4. Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required).
Port j MTL Debug Control Port j MTL Debug Status	5. Repeat Step 2, Step 3, and Step 4 twice to write one complete data word in 64-bit mode. Repeat these steps four times in 128-bit mode. The LOCR field is incremented to the next location when a complete data word is written. You can repeat the Step 2 to Step 5 for writing in to the subsequent locations.

Reading from FIFO Memory in Debug Mode

To read from FIFO memory in the debug mode, complete the steps given in Table 706.

Table 706 Steps to Read from FIFO Memory in Debug Mode

Register Name	Step Number and Description
Port j MTL Debug Control	**1.** Select the FIFO for debug access by using the DBGMOD and FDBGEN fields. Set RSTALL to clear all the pointers to the start location (0x0). If you want to clear the pointers of a specific memory, select using FIFOSEL and set RSTSEL **2.** Complete the following: a. Set the FIFOSEL field to Tx FIFO, Rx FIFO b. Set the FIFORDEN bit
Port j MTL Debug Status	3. Read the FIFOBUSY bit and wait till this bit is low. When this bit is low, read the LOCR field (if required)
Port j MTL FIFO Debug Data	4. Read the data in the FDBGDATA field
Port j MTL Debug Status	5. Read the LOCR field (if required)
Port j MTL Debug Control, Port j MTL Debug Status, Port j MTL FIFO Debug Data	6. Repeat Step 2 and Step 5 twice to read one complete data word in 64-bit mode. Repeat these steps four times in 128-bit mode. The LOCR field is incremented to the next location when a complete data word is read. You can repeat the Step 2 to Step 5 for reading from the subsequent locations

14.4.3.13 Flow Control

This section describes the flow control for Transmit and Receive paths.

14.4.3.13.1 Transmit flow control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode, to control the flow of packets from the remote end.

The Transmit Flow Control is enabled, when the TFE bit is set in the MAC_Q(#i)_Tx_Flow_Ctrl register. Only PAUSE packets are transmitted.

Flow control trigger

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode, and back pressure in half-duplex mode, to control the flow of packets from the remote end. The application can request the MAC to send a Pause packet by using the following method:

- Software Trigger: In this method, the application sets the FCB bit in the corresponding `MAC_Q(#i)_Tx_Flow_Ctrl` register

The flow control is triggered based on the following:

- Rx Queue Threshold: The flow control operation of the MAC is enabled when the EHFC bit of corresponding MTL_RxQ(#i)_Operation_Mode register is set. The flow control signal to the MAC is asserted when the fill level of the Rx queue crosses the threshold configured in RFA field of MTL_RxQ(#i)_Flow_Control register. This flow control signal is de-asserted when the fill-level of the queue falls below the threshold configured in the RFD field

  The hardware flow control generated based on the Rx Queue threshold crossing condition is applicable only when the Rx queue size is 4,096 bytes or more

***Note**: The RFS sets the threshold at which the flowcontrol is triggered and the MAC schedules to send a PAUSE frame to be sent by the local transmitter. The remote transmitter can continue to send packets until it receives the PAUSE packet. So the RXQ needs space to take in this data even after the flow-control is triggered,to avoid overflow and loss of packets. The max-space required that is calculated theoretically can be 2 max-sized packets, assuming that the read from the RXFIFO does not occur during this time. Theoretically, this makes RFA=4 or more, which implies that RxQ must have at the least 4 KB size. Practically, the system works with RFA=2 (Full – 2 KB, with very little probability of overflow).If you have FIFO size of less than 4 KB, with RFA=2, the flow control is triggered with just 1000 B in the RxQ which is even less than maxpacket size. The RFA field of MTL_RxQ(#i)_Flow_Control register is used for activating the Flow Control. These bits control the threshold(fill-level of Rx queue) at which the flow control is activated. For example, if your RXQ size is 2 KB and you set the RFA to 1 KB; as soon as you receive 1 KB, the Flow Control is activated. If you send a packet of 1500 bytes (which is allowed as per spec), this triggers,flow-control even before you receive a complete packet, which reduces the throughput considerably. If your RXQ size is 4 KB, you can set the RFA to 2 KB, so that you are able to receive the whole packet*

Flow control in half-duplex mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is active for a long time (more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

Table 708 describes the flow control in the Tx path for Queue0 based on the setting of the following bits:

- EHFC bit of the MTL_RxQ0_Operation_Mode register
- TFE and FCB bits of the MAC_Q0_Tx_Flow_Ctrl register
- HD (Half-Duplex mode) bit of MAC_Extended_Configuration register

Flow control is similar for all queues.

Flow control in full duplex mode

The XGMAC uses one of the following packet types for flow control:

- IEEE 802.3x Pause packets

MAC can send only PAUSE packet as per the programming of the MAC_Q0_Tx_Flow_Ctrl register.

Pause Packet Structure

Table 707 describes the fields of a Pause packet.

Table 707 Pause packet fields

Octets	Field	Pause packet
0 - 5	DA	Special Multicast address = 0180-c200-0001
6 - 11	SA	MAC_Adddress0 register
12 - 13	Type	Control type = 0x8808
14 - 15	Opcode	0x0001
16 - 17	PT/PEV	PT field of MAC_Q0_Tx_Flow_Ctrl register
	...	Reserved
60 - 63	FCS	CRC

Pause packet control

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

Table 708 describes the flow control based on the setting of the following bits:

- EHFC bit of the MTL_RxQ0_Operation_Mode register
- TFE bit of the MAC_Q0_Tx_Flow_Ctrl register

Flow control is similar for all queues.

Table 708 Flow control in Tx path

EHFC	TFE	HD	Description
x	0	x	The MAC transmitter does not perform the flowcontrol or back-pressure operation
0	1	1	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set
1	1	1	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set. In addition, the MAC Tx performs back-pressure when Rx Queue level crosses the threshold set by RFA field of MTL_RxQ#_Flow_Controlregister
0	1	0	The MAC transmitter sends the Pause packet when Bit 0 of the MAC_Q0_Tx_Flow_Ctrl register is set
1	1	0	The MAC transmitter sends the Pause packet when Bit 0 of the MAC_Q0_Tx_Flow_Ctrl register is set

14.4.3.13.2 Receive flow control

In the receive path, the flow control is functional only in full-duplex mode. If pause packet is received in half-duplex mode, the packet is considered as a normal control packet.

Table 709 describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of the `MAC_Rx_Flow_Ctrl` register

Table 709 Flow control in Rx path

RFE	Description
0	The MAC receiver does not detect the received Pause packets
1	The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter

The following list describes the Rx flow control:

1. The MAC checks the destination address of the received Pause packet for either of the following:

- Multicast destination address: The DA matches the unique multicast address specified for the control packet (48'h0180C2000001)
- Unicast destination address: The DA matches the content of the MAC Address Register 0 and the UP bit of the `MAC_Rx_Flow_Ctrl` register is set.

  If the UP bit is set and the MAC processes Pause packets with unicast destination address in addition to the unique multicast address

2. The MAC decodes the following fields of the received packet:
   - Type field: This field is checked for 16'h8808
   - Opcode field: This field is checked for 16'h0001 (Pause packet)
   - Pause Time field: The Pause time (for Pause packet) is captured to determine the time for which transmitter needs to be blocked
3. If the byte count of the status indicates 64 bytes and there is no CRC error, the MAC transmitter does the following:
   - For 802.3x Pause packets, the MAC pauses the transmission of any data packet for the duration of the decoded Pause Time value multiplied by the slot time (64 byte times)
4. The MAC transfers the received control packet to the application based on the setting of the PCF field in the MAC_Packet_Filter register
5. If subsequent Pause packets are received before the earlier Pause Time expires, the MAC updates the Pause Timer with new value

14.4.3.14 Power management

The XGMAC supports the IEEE 1801 standard, also known as the Unified Power Format (UPF), for power management. In XGMAC, the power management functionality is implemented through Power Management block which supports the reception and detection of magic packets and remote wake-up (or wake-on-LAN) frames.

The power management functionality of XGMAC has the following features:

- Supports Power management block for coming out of the power-down mode
- Supports Destination Address (DA) filtering with perfect unicast MAC 0 address match for magic packets and remote wake-up frames
- Supports VLAN-tagged magic packets and remote wake-up frames
- Provides interrupts to allow software to switch off major blocks or during the power-down mode

14.4.3.14.1 Power management block

The Power Management (PMT) block is available in the receive path of XGMAC. The PMT block does not perform the clock gate function, but generates interrupts for remote wake-up frames and magic packets received by the MAC.

You can select any one or both power management frames (remote wake-up and magic packet). When you enable the power-down mode by switching off the application clock in register CLC, the MAC drops all received frames and does not forward these frames to the application. If software does not switch off the application clock during power down mode in register CLC, the magic packet is not dropped. The MAC comes out of the power-down mode only when a magic packet or a remote wake-up frame is received and the corresponding detection is enabled. After coming out of power-down mode, the software needs to switch on the application clock in register CLC. To generate power management events, the application can program the bits of the MAC_PMT_Control_Status.

Remote wake-up frame detection

When the MAC is in sleep mode and the remote wake-up bit is enabled in the MAC_PMT_Control_Status (0x00C0), the normal operation is resumed after a remote wake-up frame is received. The application writes all eight wake-up filter registers (two registers for each of the 4 wake-up filters), by performing a sequential Write to address (0x00C4). The application enables remote wake-up by writing 1 to bit 2 (RWKPKTEN) of the MAC_PMT_Control_Status.

The PMT block supports the following four programmable filters that enable you to define different receive frame patterns:

- The Filter Offset determines the offset from which the frame is examined
- The Filter Byte Mask determines the bytes of the frame that must be examined
- The Filter Command controls the filter operation
- The Filter CRC-16 contains the CRC_16 value calculated from the pattern

The MAC identifies a frame as remote wake-up frame if the following conditions are true:

- The destination address (DA) matches the value in MAC Address 0 for unicast packets, or the incoming packet is a multicast packet (including broadcast)
- The Filter CRC-16 matches the CRC of the incoming pattern. The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16

The remote wake-up frame is checked only for length error, FCS error, and XGMII error to ensure that it is not a runt frame. The remote wake-up frame detection is updated in the PMT Control and Status register for every remote wake-up frame received. A PMT interrupt to the application triggers a read operation to the PMT Control and Status register to determine reception of a remote wake-up frame.

VLAN frame support

The PMT block also supports the VLAN frames. The VLAN frame and a remote wake-up frame have the same wake-up pattern but at a different offset (4 bytes difference). In a VLAN frame, a four byte VLAN header is inserted between the Source Address and Frame Type field.

The VLAN header includes the following:

- Type ID assigned to bytes 12:13
- VLAN identifier, VID, assigned to bytes 14:15

The PMT block logic reads the VLAN type in the type ID field of offset 12 in bytes 12:13. If the VLAN type is detected, the PMT block increments the offset (by 4 bytes) to value 16. The hardware logic in the PMT block handles the VLAN packet identification and offset increment functionality.

Magic packet detection

The magic packet is based on a method that uses Advanced Micro Device's Magic Packet technology to power up the sleeping device on the network.

The MAC receives a specific packet of information, called a magic packet, addressed to the node on the network. The MAC checks the following types of packets to determine whether these packets meet the wake-up requirements:

- Unicast: The packets that are addressed to the MAC. For unicast packets, the Destination Address (DA) matches the value in MAC Address 0
- Multicast: The packets with multicast address (including broadcast)

The packets that pass the address filtering (unicast or multicast) are checked to determine whether they meet the remote magic packet data format of 6 bytes of all ones followed by a MAC address (Unicast MAC Address that matches the value in MAC Address0) appearing 16 times.

The application enables the magic packet detection by writing 1 to bit 1 (MGKPKTEN) of the MAC_PMT_Control_Status register. The PMT block constantly monitors each frame addressed to the node for a specific magic packet pattern. Each frame received is checked for a 48'hFF_FF_FF_FF_FF_FF pattern following the destination and source address fields, and the Length or Type fields. The PMT block then checks the frame for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the PMT block again scans the 48'hFF_FF_FF_FF_FF_FF pattern in the incoming frame. The 16 repetitions can be anywhere in the frame, but must be preceded by the synchronization stream (48'hFF_FF_FF_FF_FF_FF). The device can also accept a multicast frame, as long as the 16 duplications of the MAC address are detected. If the number of repetitions of 8'hFF are more than 6, the PMT block checks for 16 repetitions of the MAC address without any breaks or interruptions, after the last 6 repetitions of 8'hFF.

If the MAC address of a node is 48'h00_11_22_33_44_55, then the PMT block scans the address for the following data sequence:

Destination Address Source Address Length/Type…….. FF FF FF FF FF FF

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55

…CRC

The magic packet is checked only for length error, FCS error, and XGMII error to ensure that it is not a runt frame.

The magic packet detection is updated in the MAC_PMT_Control_Status for the received magic packet. A PMT interrupt to the application triggers a read to the MAC_PMT_Control_Status to determine whether a magic packet frame has been received.

14.4.3.14.2 PMT Registers

You can access the following PMT registers in similar manner as you access the XGMAC CSR registers. For mapping information, see MAC Registers Map in the section "Registers".

- MAC_PMT_Control_Status
- MAC_RWK_Packet_Filter

***Note**: The features defined in the bits PWRDWN and RWKPFE are not functional because power gating is not implemented. When power gating is not enabled, these features are non-functional.*

Registers on page 802

14.4.3.15 Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) is an optional operational mode that enables the IEEE 802.3 Media Access Control (MAC) sub-layer along with a family of Physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps, 1000 Mbps, and 10 Gbps.

The LPI mode allows power saving by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on the both sides of the link can disable some functionality and save power during low link-utilization period. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY.

The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported and then select the best set of parameters common to both devices.

14.4.3.15.1 LPI transmit path functions

In the transmit path, the software must set the LPITXEN bit of the Port j MAC LPI Control Status register to indicate to the MAC to stop the transmission and initiate the LPI protocol. The MAC completes the transmission in progress and generates its transmission status. The MAC starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been UP continuously for a period specified in the LPI LS TIMER field of Port j MAC LPI Timers Control register. The PHY Link Status bit of the LPI Control and Status Register indicates the link status of the PHY.

To make the PHY enter the LPI state, the MAC performs the tasks described in the following table.

Table 710 Transmit path functions for the GMII and XGMII interfaces

GMII/MII interface	XGMII interface
1. De-asserts TX_EN **2.** Asserts TX_ER **3.** Sets TXD[7:0] to 0x01 in GMII and TXD[3:0] in MII **4.** Updates the LPI entry status in the Port j MAC LPI Control Status register and generates the sbd_intr_o interrupt if the LPIIE bit of the Port j MAC Interrupt Enable register is set to 1	**1.** Drives XGMII_TXC[3:0] to 4'b1111 **2.** Drives XGMII_TXD[31:0] to 32'h06060606 **3.** Updates the LPI entry status in the Port j MAC LPI Control Status register and generates the sbd_intr_o interrupt if the LPIIE bit of the Port j MAC Interrupt Enable register is set to 1

***Note**: The MAC maintains the same state for the specified signals while it remains in the LPI state.*

To bring the PHY out of the LPI state, that is, when the software resets the LPITXEN bit, the MAC performs the following tasks:

1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern
2. Starts the LPI TW TIMER

   The MAC cannot start the normal frame transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the TWT field (bits [15:0]) of `Port j MAC LPI Timers Control` register
3. Updates the LPI exit status of the `Port j MAC LPI Control Status` register and generates the `sbd_intr_o` interrupt if the LPIIE bit of the `Port j MAC Interrupt Enable` register is set to 1

The following figure shows the behavior of the TX_EN, TX_ER, and TXD[7:0] signals during the LPI mode transitions.

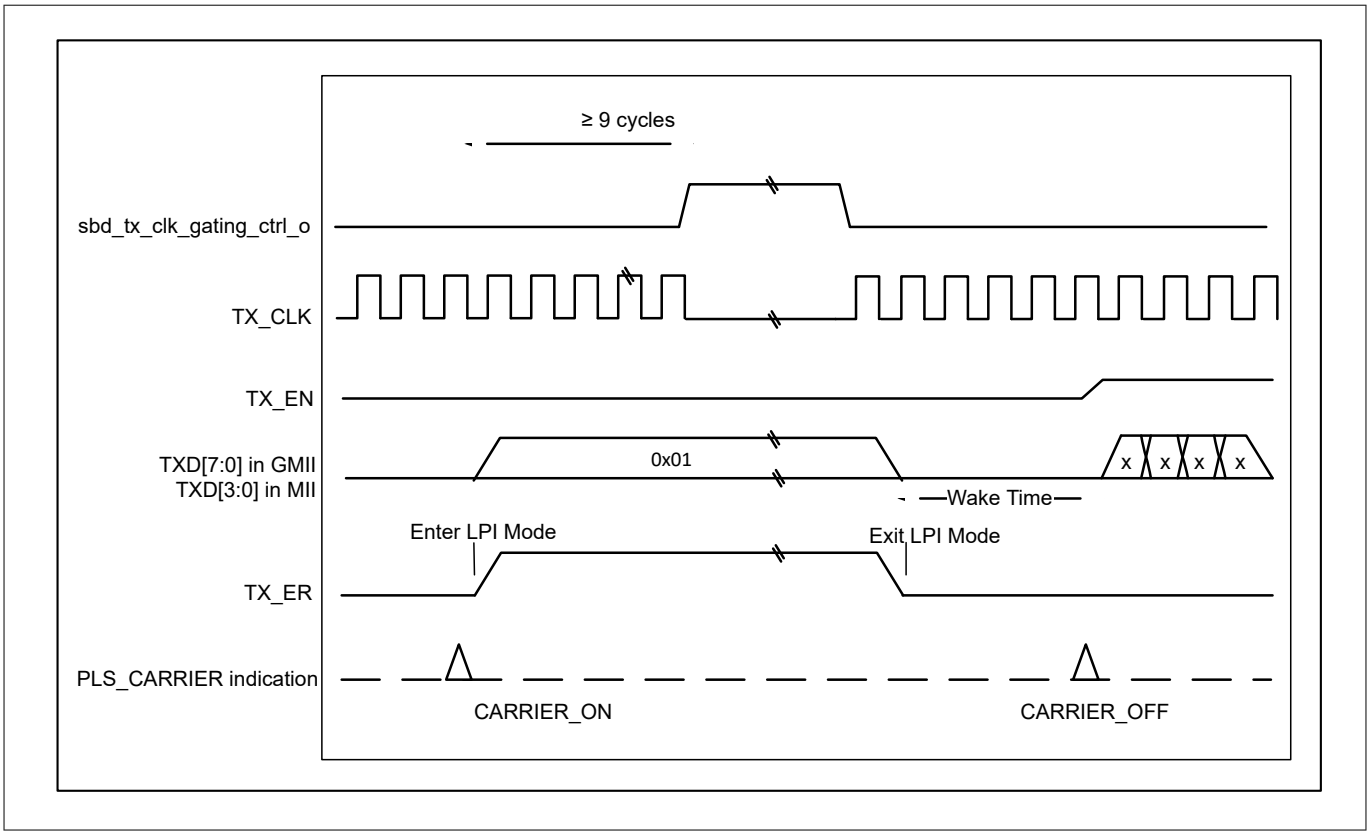

Figure 143 LPI transitions for GMII/MII (transmit)

The following figure shows the behavior of the XGMII_TXD[31:0] and XGMII_TXC[3:0] signals during the LPI mode transitions.

***Note**: When the MAC drives the LPI pattern, it does not internally generate the PLS_CARRIER indication (required by the Energy Efficient Ethernet standard) to defer normal transmission. The internal logic of the MAC ensures that it does not transmit normal frame when it is driving the LPI pattern and also during the subsequent LPI TW time.*

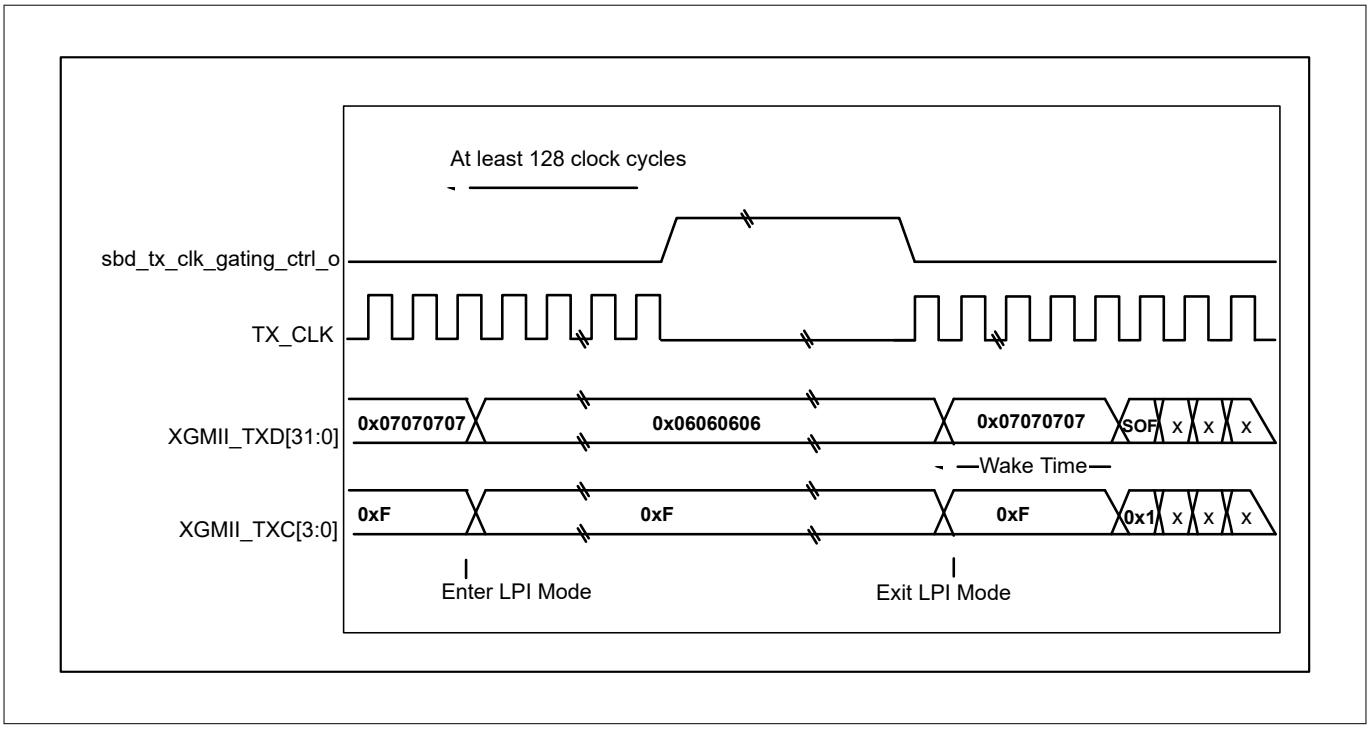

Figure 144 LPI transitions for XGMII (transmit)

Automated entry/exit of LPI mode in transmit path

The MAC transmitter can be programmed to enter and exit LPI IDLE mode automatically based on whether it is IDLE for a specific period of time or has a packet to transfer. These modes are enabled and controlled by Port j MAC LPI Control Status register.

When LPITXA (Bit[19]) and LPITXEN (Bit[16]) of Port j MAC LPI Control Status register are set, the MAC transmitter enters LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter exits the LPI IDLE state and clear the LPITXEN bit as soon as any of functions in the TX path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition, when Bit[20] (LPIATE) is also set, the MAC transmitter enters LPI IDLE state only if the Transmit path remains in idle state (no activity) for the time period indicated by the value in Port j MAC LPI Auto Entry Timer. In this mode also, the MAC transmitter exits the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPITXEN bit is not cleared but remains active so that re-entry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.

When both LPIATE and LPITXA bits are clear, the entry and exit of LPI IDLE state is directly controlled by the software by programming the LPITXEN bit.

14.4.3.15.2 LPI receive path functions

When the PHY receives the signals from the link partner to enter the LPI state, the PHY and MAC perform the tasks mentioned in the following table.

Table 711 Receive path functions for the GMII and XGMII interfaces

GMII/MII interface	XGMII interface
1. The PHY asserts RX_ER 2. The PHY sets RXD[7:0] to 0x01 in GMII and RXD[3:0] in MII 3. The PHY de-asserts RX_DV 4. The MAC updates the RLPIEN bit of the MAC_LPI_Control_Status register and generates the sbd_intr_o interrupt if the LPIIE bit of the MAC_Interrupt_Enable register is set to 1	1. The PHY drives XGMII_RXC[3:0] to 4'b1111 2. The PHY drives XGMII_RXD[31:0] to 32'h06060606 3. The MAC updates the RLPIEN bit of the MAC_LPI_Control_Status register and generates the sbd_intr_o interrupt if the LPIIE bit of the MAC_Interrupt_Enable register is set to 1
Note: The PHY maintains the specified signals while it remains in the LPI state	

When the PHY receives the signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER
2. The PHY sets the RXD[7:0] in GMII/RXD[3:0] in MII to 8'h00 for GMII or XGMII_RXD[31:0] to 32'h07070707 for XGMII
3. The PHY returns to a normal interframe state
4. The MAC updates the RLPIEX bit of the MAC_LPI_Control_Status register and generates the sbd_intr_o interrupt if the LPIIE bit of the MAC_Interrupt_Enable register is set to 1. The MAC also generates the sbd_intr_o interrupt on the additional sideband signal synchronized to Rx clock (lpi_intr_o)

The following table shows the behavior of the RX_ER, RX_DV, and RXD[7:0] signals during the LPI transitions.

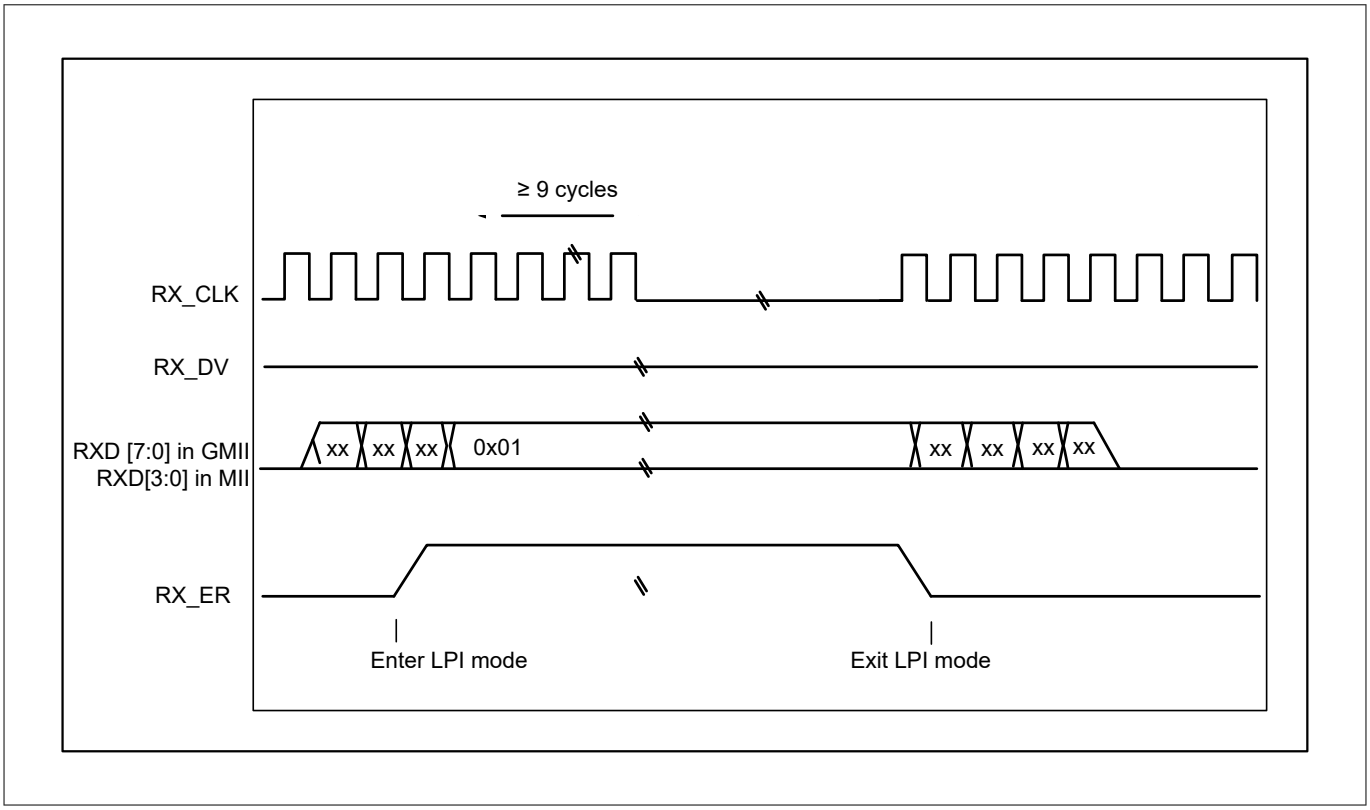

Figure 145 LPI transitions for GMII/MII (receive)

The following table shows the behavior of XGMII_RXD[31:0] and XGMII_RXC[3:0] signals during the LPI mode transitions.

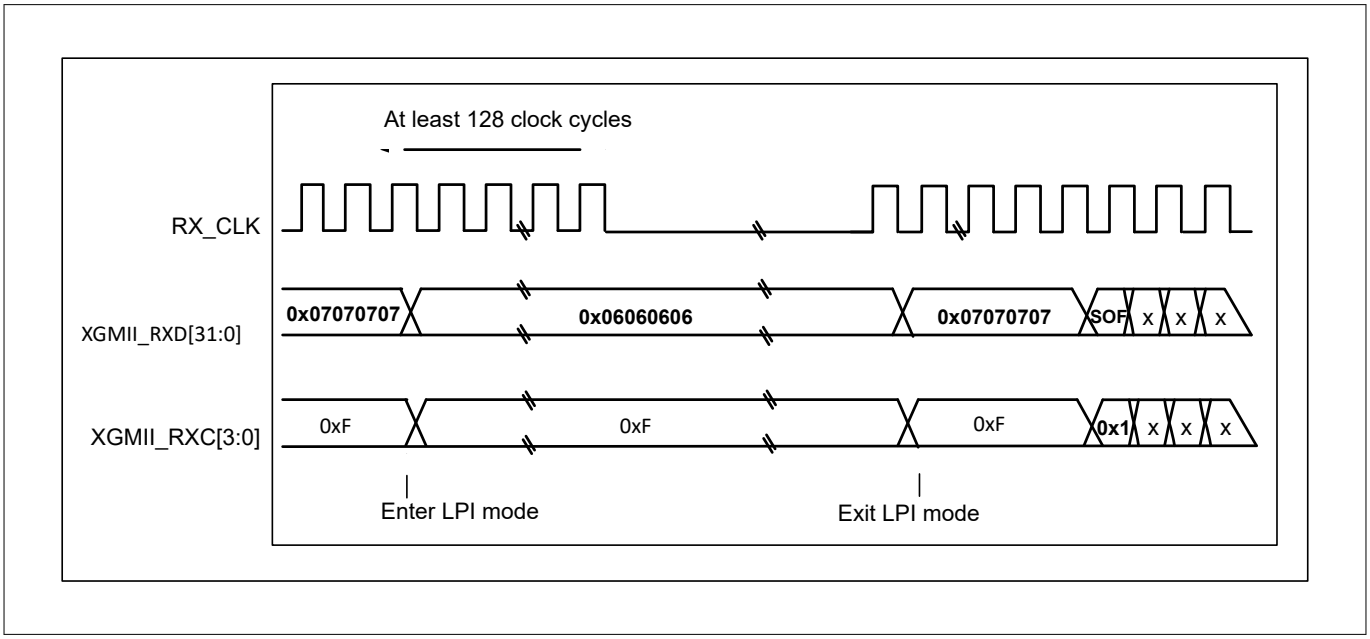

Figure 146 LPI transitions for XGMII (receive)

***Note**:*

- *If the RX_CLK_stoppable bit (in PHY register written through MDIO) is asserted when the PHY is indicating LPI to the MAC, the PHY may halt the RX_CLK at any time more than 128 clock cycles (for XGMII) and 9 clock cycles (for GMII) after the start of the LPI state as shown in figure "LPI Transitions for GMII/MII (Receive)" above*
- *If the MAC is in RX LPI mode and the RX clock is stopped by PHY, the application should not write to CSR registers that are synchronized to RX clock domain*

14.4.3.15.3 LPI Timers

The transmitter maintains the following timers that are loaded with the respective values from MAC_LPI_Timers_Control and MAC_LPI_Auto_Entry_Timer registers:

- LPI LS TIMER

  The LPI LS TIMER counts, in milliseconds, the time expired since the link status is UP. This timer is cleared every time the link goes down and is incremented when the link is UP.

  The XGMAC-CORE does not drive the LPI pattern unless the terminal count, programmed by the software, is reached. This ensures a minimum time during which no LPI pattern is driven after a link is established with the remote station. This period is defined as 1 second in the IEEE standard 802.3-az, version 2.0. The LPI LS TIMER is 10-bit wide. Therefore, the software can program up to 1023 milliseconds.
- LPI TW TIMER

  The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of Transmit LPI. The MAC can resume the normal transmit operation after the Transmit TW time. The software programs the Transmit TW time based on auto-negotiation.

  The MAC supports the LPI TW TIMER in units of microsecond. The LPI TW TIMER is 16-bit wide. Therefore, the software can program up to 65535 µs.
- LPI AUTO ENTRY TIMER

This timer counts in steps of eight microseconds, the time for which the MAC transmit path has to remain in idle state (no activity), before the MAC Transmitter enters the LPI IDLE state and starts transmitting the LPI pattern. This timer is enabled when LPIATE field of the `MAC_LPI_Control_Status` register is set.

14.4.3.16 Checksum Offload Engine

Communication protocols such as TCP/UDP implement checksum fields, which are useful to determine the integrity of the data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP/UDP over IP datagrams, the XGMAC Subsystem has an optional Checksum Offload Engine to support checksum calculation and insertion in the transmit path, and error detection in the receive path.

14.4.3.16.1 Transmit checksum offload engine

The checksum offload engine supports two types of checksum calculation and insertion.

- IP header checksum engine
- TCP/UDP/ICMP checksum engine

The checksum engine can be controlled for each packet by the CIC bits:

- TDES3 Bits[17:16]

***Note**:*

- *The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled in a packet, the corresponding TxQ automatically operates in the store-and-forward mode even if the XGMAC is configured for Threshold (cut-through) mode*
- *You must make sure that the TxQ is deep enough to store a complete packet before that packet is transferred to the MAC transmitter. The reason being that when space is not available to accept the programmed burst length of data, then the MTL TxQ starts reading out the packet to avoid dead-lock. Therefore, you must enable the check-sum insertion only in the packets that are less than the following number of bytes in size:*

  TXQ SIZE in bytes – $((PBL + 5) \times 8)$,where TxQ SIZE is given by the TQS field in MTL_TxQ(#i)_Operation_Mode register.

  This calculation is also applicable for the normal and jumbo packets. The PBL is the TxPBL field in DMA_CH(#i)_Control_Register

***Note**: See IETF specifications RFC 791, RFC 793, RFC768, RFC 792, RFC 2460, and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6,and ICMPv6 packet header specifications, respectively.*

IP header checksum engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The IP Header Checksum engine considers the packet having an error for the following conditions:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4

- The IPv4 Header Length field indicates a value less than 0x5 (20 bytes)
- The total packet length is less than the value given in the IPv4 Header Length field

- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received

If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload. The IP Header Error and Payload Checksum Error is provided in the MAC_Rx_Tx_Status register; an interrupt is generated when enabled.

The Payload Checksum engine declares an error when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received or when the Packet size (as indicated by IP header) is such that it can not accommodate minimum header size of TCP, UDP or ICMP header. When this engine detects these type of errors, it does not modify the TCP, UDP, or ICMP header.

When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects this, it still inserts the calculated checksum into the corresponding TCP, UDP, or ICMP header field.

TCP/UDP/ICMP checksum engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the checksum field of the input packet. This engine includes the checksum field in the checksum calculation, and then replaces the checksum field with the final calculated checksum
- The engine ignores the checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value

***Note**:* *For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16'h0000, an incorrect checksum may be inserted into the packet.*

The Payload Checksum engine declares an error when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received or when the Packet size (as indicated by IP header) is such that it can not accommodate minimum header size of TCP, UDP or ICMP header. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Table 712 describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as “No” in the table.

***Note**:* *Checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Transmit Checksum Offload Engine should not be enabled because it may result in incorrect checksum insertion or unexpected behavior.*

If the total packet size from the ATI interface or DMA engine exceeds the limit of 14'h3FFF, the checksum is not inserted for that packet.

Table 712 Transmit checksum offload engine functions for different packet types

Packet type	Hardware IP header checksum insertion	Hardware TCP/UDP checksum insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Not applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Authentication • Any other next header field in main or extension headers	• Not applicable • Not applicable • Not applicable • Not applicable • Not applicable • Not applicable • Not applicable • Not applicable	• Yes • No • Yes • No • No • Yes • No • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

14.4.3.16.2 Receive checksum offload engine

You can enable the Receive Checksum Offload Engine (Rx COE) by setting the IPC bit of the MAC_Rx_Configuration register. When this option is selected, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the Enable Double VLAN Processing option is selected and the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 header), when DIS_TCP_EF bit is set in the MTL_RxQ(#i)_Operation_Mode register.

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Table 713 describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as “No” in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

***Note**: The MAC does not append any payload checksum bytes to the received Ethernet packets.*

Table 713 Receive checksum offload engine functions for different packet types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
Authentication	Not applicable	Yes
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Any other next header field in main or extension headers	• Not applicable • Not applicable • Not applicable • Not applicable • Not applicable • Not applicable • Not applicable	• Yes • No • Yes • Yes • No • Yes • No

(table continues...)

Table 713 (continued) Receive checksum offload engine functions for different packet types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

14.4.3.17 Management counters

The MMC maintains a set of registers for statistics on the received and transmitted frames. These include a control register for controlling the behavior of the MMC counters, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Receive and Transmit Interrupt registers. The application can access these registers through the MAC Control Interface (MCI). The counter can be 32-bit or 64-bit wide. Non-32 bit accesses are allowed only when the address is word-aligned.

The organization of these registers is shown in the section "Registers". MMC registers are accessed using transactions in the same way that CSR addresses are accessed. This section describes the statistics counters and lists the address for each. Counters, which are 64-bits wide, are divided into two 32-bit registers for access through the MCI.

The receive MMC counters are updated only for frames passed by the Destination Address Filter (AFM) block. Statistics of frames that are dropped by the AFM are not updated unless they are runt frames of less than 6 bytes (that is, DA bytes that are not fully received).

Related information

Registers on page 802

14.4.3.17.1 Address assignments

The MMC register naming convention is as follows:

- “tx” as a prefix or suffix indicates a transmit counter
- “rx” as a prefix or suffix indicates a receive counter
- “_g” as a suffix indicates a register that counts good frames only
- “_gb” as a suffix indicates a register that counts all frames, whether they are good or bad
- “_lo” as a suffix indicates the lower 32 bits of a 64-bit counter
- “_hi” as a suffix indicates the upper 32 bits of a 64-bit counter

The following explanations pertain to terminology used in Table 714:

- Transmitted frames are considered good frames when none of the following errors is observed:
  - Frame Underflow error
  - Local/remote fault detected

  - Jabber time-out
  - No carrier or loss of carrier
  - Late collision
  - Excessive Deferral
  - Excessive Collision
- Received frames are considered good when none of the following errors is observed:
  - CRC error
  - Length error
  - Runt frames (with or without CRC errors)
  - Out-of-range frames
  - Watchdog time-out
- The maximum transmit frame size depends on the frame type, as follows:
  - Untagged frame maxsize = 1,518
  - VLAN Frame maxsize = 1,522
  - Jumbo Frame maxsize = 9,018
  - JumboVLAN Frame maxsize = 9,022
- The maximum receive frame size depends on the frame type and control bits (JE, S2KP, GPSLCE and EDVLP) as follows:

Table 714 Maximum frame size dependency

JE	S2KP	GPSLCE	EDVLP	Untagged framemaxsize in bytes	Single VLAN framemaxsize in bytes	Double VLAN framemaxsize in bytes
1	X	X	1	9018	9022	9026
0	1	X	X	2000	2000	2000
0	0	1	1	GPSL	GPSL+4	GPSL+8
0	0	0	1	1518	1522	1526
1	X	X	0	9018	9022	9022
0	0	1	0	GPSL	GPSL+4	GPSL+4
0	0	0	0	1518	1522	1522

***Note**: Preambles of frames are not counted in the octet counters.*

14.4.3.18 Station Management Agent

The Station Management Agent (SMA) allows the application to access any PHY register through a two-wire Station Management Interface (SMI). To increase the number of MDIO Managed Devices (MMD) per port, the existing MDIO interface (IEEE 802.3, Clause 22) has been extended to support more device registers while still retaining logical compatibility with earlier MDIO interfaces. This extended MDIO interface is specified in IEEE 802.3, Clause 45.

An extension to the existing MDIO management frame structure defines indirect addressing to extend the address space, allowing more registers within each MMD to be addressed. The MDIO address space is orthogonal to the earlier MII management address space; that is, the start-of-frame delimiter is different from the one used for MII management frame structure.

The new management frame structure is as follows:

Table 715 Management Frame Fields

Frame	PRE	ST	OP	PORTAD	DEVAD	TA	REGAD	IDLE
Address	1…1	00	00	PPPPP	EEEEE	10	4'hAAAA	Z
Write	1…1	00	01	PPPPP	EEEEE	10	4'hDDDD	Z
Read	1…1	00	11	PPPPP	EEEEE	Z0	4'hDDDD	Z
Post-Read Increment Address	1…1	00	10	PPPPP	EEEEE	Z0	4'hDDDD	Z

Using this extended MDIO interface, the application can address one of the 32 PHYs, any one of 32 devices within the PHY, and one of the many registers within the given device and send control data or receive status information. Only one register in one PHY can be addressed at a time. For more details on frame protocol see Clause 45 of IEEE 802.ae.

The application sends control data to the PHY (MIM write cycle) and receives status information from the PHY (MIM read cycle) through the SMA.

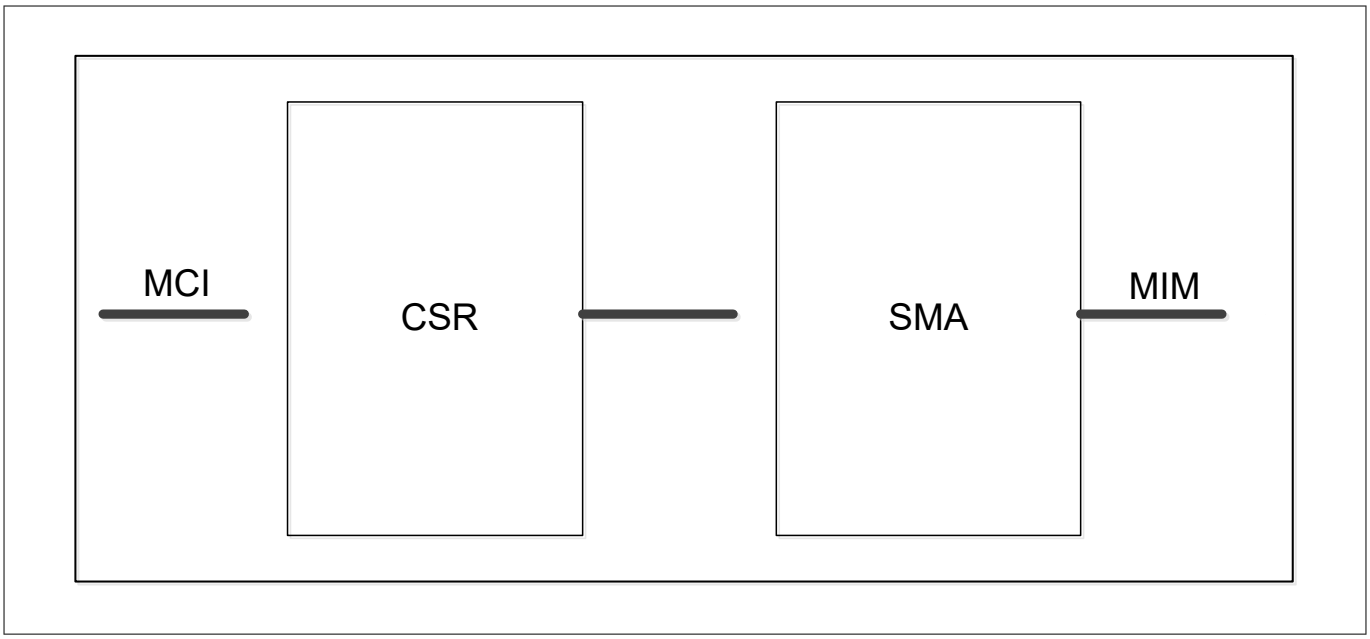

Figure 147 SMA Interface Block

14.4.3.18.1 Functional description

Note that HSPHY provides connection to physical pads of MDIO.

For MIM accesses, the maximum operating frequency of the MDC is 2.5 MHz, as specified in IEEE 802.3. In the XGMAC, the MDC clock is derived from the application clock, clk_csr_i, using a divider-counter. The divide factor depends on the clock range setting (CR field and CRS field) in the MDIO Single Command Control/Data register.

You can select the clock divide factor as recommended in Table 716 to meet IEEE specifications. However, if your system supports higher clock frequencies on the MIM interface, you can select a different divider.

Table 716 MDC clock generation with CRS = 0

CRS field of MDIO single command control/data	CR[2:0] field of MDIO single command control/ data	clk_csr_i frequency (MHz)	Generated MDC clock frequency
0	3’b000	100-150	clk_csr_i/62
0	3’b001	150-250	clk_csr_i/102
0	3’b010	250-300	clk_csr_i/122
0	3’b011	300-450	clk_csr_i/142
0	3’b100	350-400	clk_csr_i/162
0	3’b101	400-500	clk_csr_i/202
0	3’b110 - 3’b111	Reserved	Reserved

If you require higher MDC clock frequency, set the CRS field of the MDIO Single Command Control/Data register. Table 717 show the MDC clock generation based on CR field when CRS is set to 1.

Table 717 MDC clock generation with CRS = 1

CRS field of MDIO single command control/data	CR[2:0] field of MDIO single command control/ data	clk_csr_i frequency (MHz)	Generated MDC clock frequency
1	3’b000	-	clk_csr_i/4
1	3’b001	-	clk_csr_i/6
1	3’b010	-	clk_csr_i/8
1	3’b011	-	clk_csr_i/10
1	3’b100	-	clk_csr_i/12

Table 718 shows the MDIO frame structure:

Table 718 MDIO clause 45 frame structure

Frame	Description
IDLE	The MDIO line is three-state; there is no clock on MDC
PREAMBLE	32 bits of continuous ones
START	Start of frame is 2’00
OPCODE	• 2’b00: Address • 2’b01: Write • 2’b10: Post-read increment address • 2’b11: Read
PHY ADDR	5-bit address select for one of 32 PHYs

(table continues...)

Table 718 (continued) MDIO clause 45 frame structure

Frame	Description
DEV ADDR	5-bit address select for one of 32 devices
TA	Turnaround • 2'bZ0: Read and post-read increment address • 2'b10: Write and address MDIO accesses Where Z is the tri-state level
DATA/ADDRESS	16-bit value: For an address cycle (OPCODE = 2'b00), this frame contains the address of the register to be accessed on the next cycle. For the data cycle of a write frame, this field contains the data to be written to the register. For read or post-read increment address frames, this field contains the contents of the register read from the PHY. • In address and data write cycles, the XGMAC drives the MDIO line during the transfer of these 16 bits • In read and post-read increment address cycles, the PHY drives the MDIO line during the transfer of these 16 bits

The frame structure for Clause 22 frames is also supported and shown in Table 719. The control register (MDIO Clause 22 Port) indicates which ports are Clause 22 and which are Clause 45. The Clause 22 frame format is shown in Table 719. For Clause 22 frames, only the lower five bits of the RA field (MDIO Single Command Address Register) are used as the frame's REG ADDR field.

Table 719 MDIO clause 22 frame structure

Frame	Description
IDLE	The MDIO line is three-state; there is no clock on MDC
PREAMBLE	32 bits of continuous ones
START	Start-of-frame is 2'01
OPCODE	• 2'b01 for Write • 2'b10 for Read
PHY ADDR	5-bit address select for one of 32 PHYs
REG ADDR	5-bit register address to select the register within each MMD
TA	Turnaround • 2'bZ0: Read • 2'b10: Write Where Z is the tri-state level
DATA	Any 16-bit value • In a write operation, the XGMAC drives MDIO • In a read operation, the PHY drives MDIO

In addition to normal single-read and single-write operations, the SMA also supports continuous write, continuous scan, and post-read increment address. These operations are described the following sections.

***Note**: The SMA module supports accesses to four PHY ports (addresses 0–3) only in the Continuous Scan and Continuous Write modes of operation (See Continuous write operation and Continuous scan operation).*

MDIO Preamble Suppression

XGMAC supports 32-bit preamble generation on all Read or Write operation. Some PHYs support reduction in the preamble content which can operate with only 1-bit preamble. When PSE (Preamble Suppression Enable, bit[30] of MDIO Single Command Control/Data Register) is set, preamble suppression mode is enabled and XGMAC drives only 1-bit preamble for all MDIO operations.

Single read/write operations

The software can perform a read or write operation to a specific register of any device of any port by programming SMA MDIO Single Command Address register and MDIO Single Command Control/Data register. If the PHY port is specified (in MDIO clause 22 port) as conforming to IEEE 802.3, Clause 45, the SMA automatically initiates the transfer, as the clause specifies. Otherwise, the SMA initiates a read/write transfer in the frame format specified in Clause 22. The SMA assumes all ports conform to Clause 45 by default.

The Single Read/Write command usually has the highest priority among the three possible operations in the SMA (single read/write, continuous write and continuous scan) followed by the continuous write operation. On receiving a single read/write command, the SMA suspends continuous write/scan operation at the end of the current write/read cycle (access to a register is over) and initiates this command.

The sequence for initiating this operation (programming guidelines) is as follows:

1. Program the MDIO Single Command Address register with the appropriate PHY port number, device ID and register address
2. Program the MDIO Single Command Control/Data register to initiate the required operation. If you are not performing 32-bit accesses to the CSR, make sure you write the Busy bit after writing the other bits, because setting the Busy bit triggers the command
3. The SMA automatically performs the address cycle (if not disabled by SADDR bit in MDIO Single Command Control/Data register) followed by the read/write/post-increment read data transfer cycle. The Busy bit remains high during this period
4. Wait for the Busy bit to clear (for polling) or for the Single Command Completion interrupt to be set
5. On receiving the interrupt (or when Busy bit is cleared), the given single-command operation is completed and the data bits in MDIO Single Command Control/Data register have valid data read from the required PHY Device register
6. The SMA is ready for another single command.

Continuous write operation

This command helps reduce the software's load when it must perform write operations to the same register in multiple devices or to multiple PHY ports. The software can give a single command and the SMA initiates writes to the target registers sequentially.

Continuous write operation is available for ports 0 to 31, and this command only accesses the devices enabled in the corresponding MDIO Port Device In-Use register. Thus, these registers must be configured properly for correct and fast completion of this command.

The programming sequence is as follows:

1. Program the MDIO Continuous Write Data register with the required data value
2. Configure the required operation in the MDIO Continuous Write Address register by programming the CPRT and CADDR bits
   - If CPRT is low, CADDR is taken as the common device address in all ports to which register write operations are performed
   - If CPRT is set high, CADDR is taken as the port number whose devices are all accessed in the register write operation. CADDR must have values of 0–3 in this mode: other PHY port numbers are invalid

3. Configure the register address in the CREGADDR bits and set the Continuous Write Busy bit. This step and Step 2 can be done in a single 32-bit write access to the register
4. The SMA schedules the continuous write operation to all the ports or devices. It performs the two-transfer cycle if the PHY port is configured as a Clause 45 port or a single cycle if it is a Clause 22 port
5. Wait until the Continuous Write Busy bit is cleared (for polling) or the Continuous Write Completion interrupt is set
6. When the SMA asserts the interrupt (or the Busy bit is cleared), the given command is complete and the SMA is ready for another continuous write command to a different port, device, or register

Continuous scan operation

This command helps reduce the load on the software for checking the status of the devices on each port. It also helps in automatic connectivity detection (hot-plug-in) of PHY devices (on a XENPAK module). This command usually has the lowest priority and can be enabled to always run in the background. This command performs read accesses to two specific registers (MDIO Single Command Address register and MDIO Port Connect/ Disconnect Status register) of each device on all ports to check their link and device statuses and to update the corresponding status registers in the SMA (MDIO Port Nx4P0 Link and MDIO Port Nx4P0 Alive status registers).

Continuous scan operation only applies to ports and this command only accesses the devices enabled in the corresponding MDIO Port Device In Use register. These registers must be configured properly for correct and fast completion of a scan cycle.

The programming sequence is as follows:

1. Configure the MDIO Port Nx4P0 Device In Use registers to enable the devices present in the PHY port. If a particular port does not have any PHY connected to it (that is, its current status is disconnected), enable only one of the devices (for example, PMDPMA) to check for connectivity
2. Enable the continuous scan to the required ports by setting the bits in the MDIO Continuous Scan Port Enable register. The SMA scans the ports in sequence
3. Enable the required interrupts in the MDIO Interrupt Enable register (bits 11:0)
4. The SMA scans all the ports and updates the corresponding status registers
5. The MDIO Port Connect-Disconnect Status register is updated as soon as the read access to any device register to that port is completed. The corresponding interrupt is asserted if any bit's value changes
6. The MDIO Port Nx4P0 Link and MDIO Port Nx4P0 Alive status registers are updated at the end of each scan cycle and if any bits in the corresponding ports change, the corresponding interrupt is asserted
7. A new sequence is started automatically from Port 0
8. The scan continues as long as any MDIO Continuous Scan Port Enable register bit is set

14.4.3.19 Flexible header feature

This chapter describes the support for additional bytes in the frame header. This is for non standard, proprietary frame formats only.

Some applications require proprietary information to be transported in the Ethernet packet in the form of a custom header (referred to as Flexible Header (FH) in this document).

When the FH feature is enabled in the controller, it is expected that all the packets passing through the MAC (both Rx, and Tx) will have the custom header.

The Flexible Header position can be any of the following within the Ethernet packet:

- Byte 0: Between preamble/SFD and DA field of Ethernet packet
- Byte 12: After MAC SA field in the Ethernet packet
- Byte 14 to 29: Any position in this range (inclusive)

This is programmed in FHL field of MAC_Flex_Hdr_Cfg register.

Flexible Header length can be programmed to any value from 1 to 8 bytes as per the FHL bits in MAC_Flex_Hdr_Cfg register.

The Flexible Header feature has programmable control bits (FHTX and FHRX in MAC_Flex_Hdr_Cfg register) to enable support in TX and RX path separately.

When enabled, proprietary Ethernet packets in which extra “custom” header bytes are present in Ethernet packets will be sent/received in the respective TX or RX path.

When disabled, normal Ethernet packets as specified in IEEE 802.3 standard will be transferred on the line. An additional programmable control bit is available to include FH support in MAC/Link-layer auto-generated packets like PAUSE packets, Preemption Verify/Response packets.

The content for this FH is taken from programmable registers (MAC_Flex_Hdr_High/Low).

All the existing offload features of the XGMAC IP like VLAN tagging, Packet filtering and queueing based on L2/L3/L4 headers, etc. will be supported when the FH is present. RMON/MMC counters, Giant Packet, Watchdog timeout, min/max packet size checks will ignore the presence of Flexible Header bytes.

14.4.3.19.1 Transmit path

When Flexible Header (FH) for Tx path is enabled, software must insert the header in the first 8 bytes of the Packet Buffer irrespective of programmed FH length and position, as shown in the below figure. Packet’s first buffer size) programming should account for extra 8 bytes. The packet length should accurately account for the actual length of the FH (corresponding to FHL field of MAC_Flex_Hdr_Cfg register). TxCOE offload will work as-is without being impacted by the presence of FH.

For the Link Layer auto-generated packets such as Pause frames, static custom header will be inserted in the packet only if EFLL bit is set. The VLAN/SA Insertion/Replacement/Deletion features are supported as-is independent of the presence of Flexible Header.

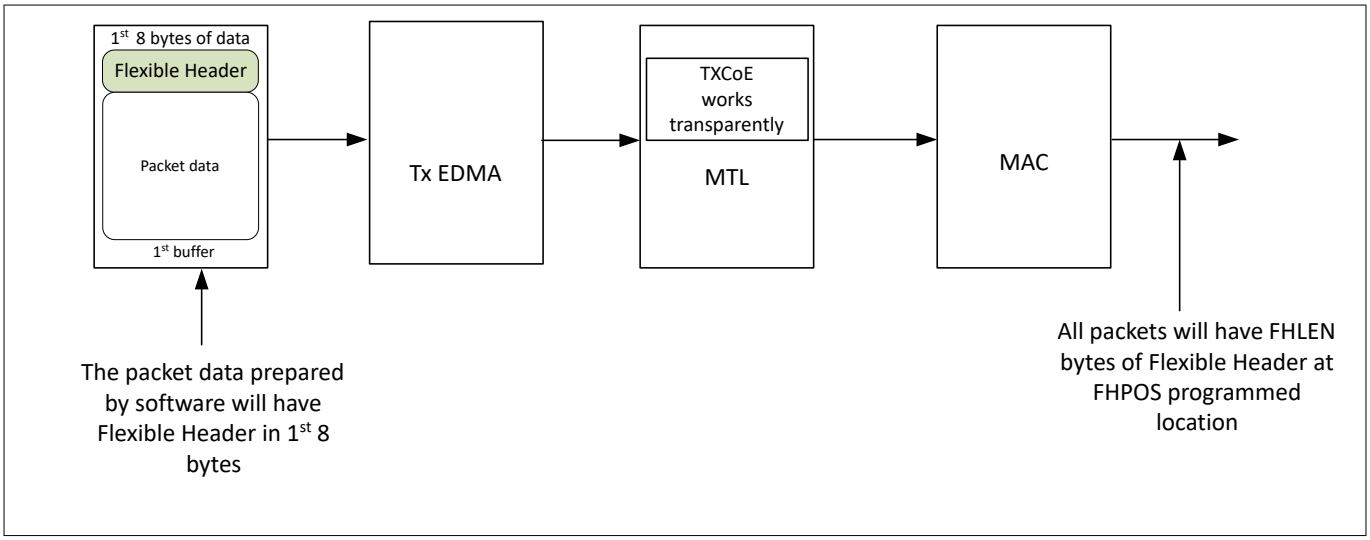

Figure 148 1 Tx path with flexible header high level block diagram

***Note**: First eight bytes of data will contain FH independent of the Buff1 addresses alignment.*

For example: If FH length is five bytes and Buff1 start address is 0x2, even then FH will occupy first eight addresses of the buffer and the actual packet data will start from address 0x2 + 0x8 = 0xA. (This format is applicable for FH in both Tx and Rx paths)

When FH is configured and FHTX bit is set to 1, the Transmit Descriptor **read format fields**’ interpretation will change as follows

TDES2[9:0]	reserved
TDES2[13:0]	Buf1 Length should include the 8 bytes of FH location
TDES2[29:16]	If B1L=0, then Buf2 Length should include the 8 bytes of FH location

TDES3[14:0]	Packet Length

***Note**: FH will be part of CRC computation and will not be part of L3/L4 checksum calculation/Tx MMC counters, and will be placed at the predetermined location in the packets transmitted on the line.*

14.4.3.19.2 Receive path

When FH for Rx path is enabled, ingress packets (including the ones consumed in the MAC for offloads) must have FH in the programmed location and length. Link layer auto-generated packets such as Pause packets are expected to have FH only when EFLL bit is set.

When FH is enabled, the MAC Receiver will always strip the Flexible Header present at the programmed start position (only exception being EFLL related packets). The stripped Flexible Header is sent to the Software as first 8 bytes of data (irrespective of FH length) before start of packet in first buffer of the packet, as shown in the figure below. The actual packet data will start from the given Buffer Address pointer plus 8 bytes, and the packet length, header length and 1st buffer size (if applicable) of the packet status includes the additional 8 bytes consumed by FH (independent of the programmed flexible header length).

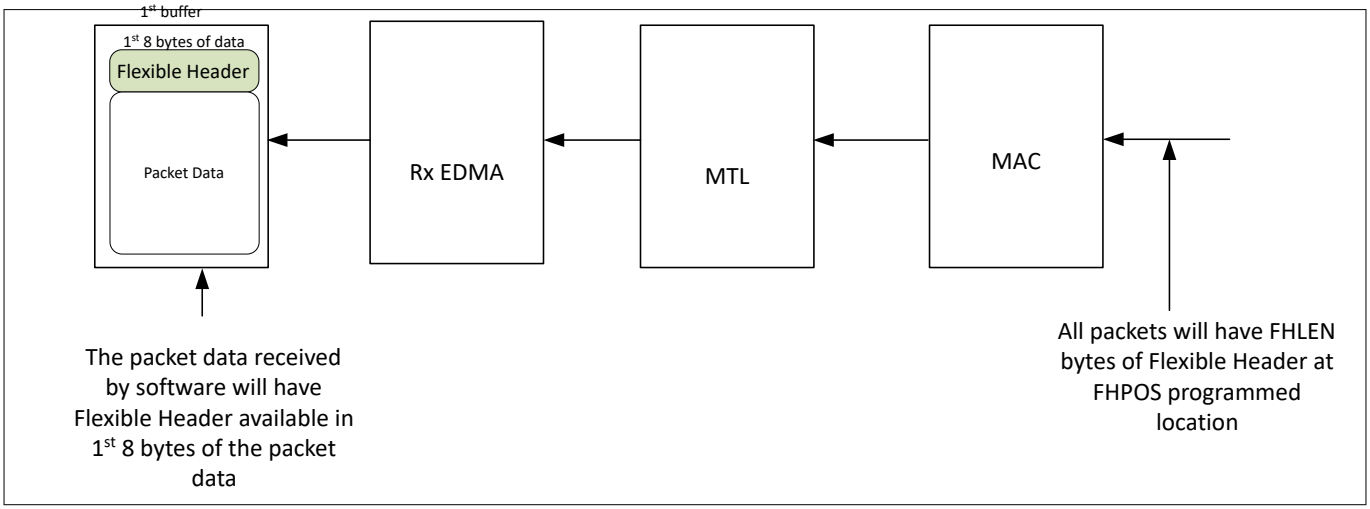

Figure 149 Rx path with flexible header high level block diagram

Filtering, Queueing, channel routing, RxParser and RxCoE functions, when enabled, work as intended with the FH feature enabled. In other words, these functions process the normal packets after the FH is stripped and therefore are not impacted when FH is enabled.

***Note**:*
- *The FH is stripped and discarded for all the packets that are not sent to the application (that is consumed in the MAC or dropped)*
- *In this mode, the FH bytes are blindly stripped (except for PAUSE). Far-end must not send any packets without the FH that are processed by any of the filtering functions. In case, such packets (without FH) are present in this mode, filtering must not be enabled*
- *When FHRX bit is set, packet length; PL field of (RDES3[13:0]) in Descriptor Write-back format will be reported as follows*

Table 720 Packet length status with FH enabled

Packet length with added 8 bytes of flexible header	PL [13:0]
16384	*1*

(table continues...)

Table 720 (continued) Packet length status with FH enabled

16385	*2*
16386	*3*
16387	*4*
16388	*5*
16388	*6*
16390	*7*
16391	*8*

When FH is configured and FHRX bit is set to 1, the Receive Descriptor write back fields will be written as follows to account for the eight additional FH bytes:

RDES2[9:0]	Header Length + 8
RDES3[13:0]	Packet Length + 8

14.4.3.19.3 Format of the FH to be written/read by the software

Flexible header will be written by software (SW) in the memory for the Transmit packets and will be made available to SW in RX path as described below. For example, if the Flexible Header is 4 bytes, and if 0x0a0b0c0d is to be programmed into a transmit packet then in the memory, the 8 Byte FH should be written as 0x000000000a0b0c0d.

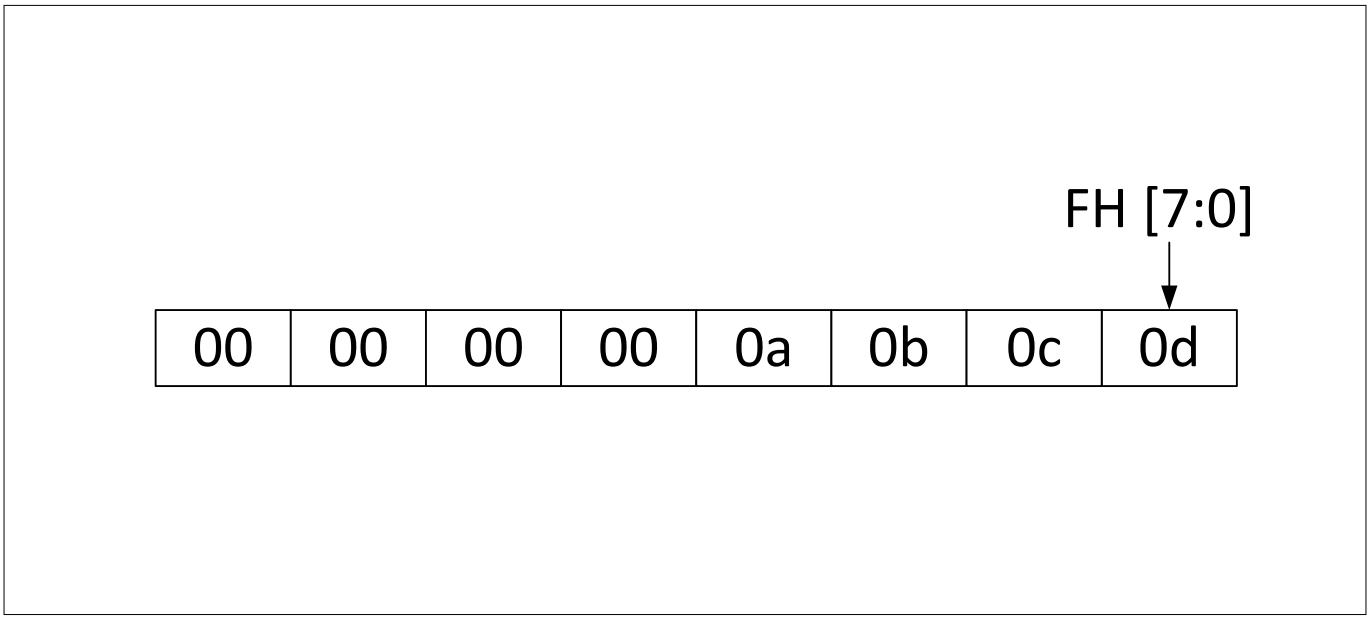

Figure 150 Tx packet FH to be written/Rx packet FH to be read by software

This FH will be written in SW as explained below

0a	0b	0c	0d	Addr offset=0x4			
DA3	DA2	DA1	DA0	4 Dummy FH bytes			
SA5	SA4	SA3	SA2	SA1	SA0	DA5	DA4
P	K	T	*	D	A	T	A

On the line side, if the FH position is Byte 12 (after DA-SA), while transmitting/receiving a packet on the line FH is embedded as shown below:

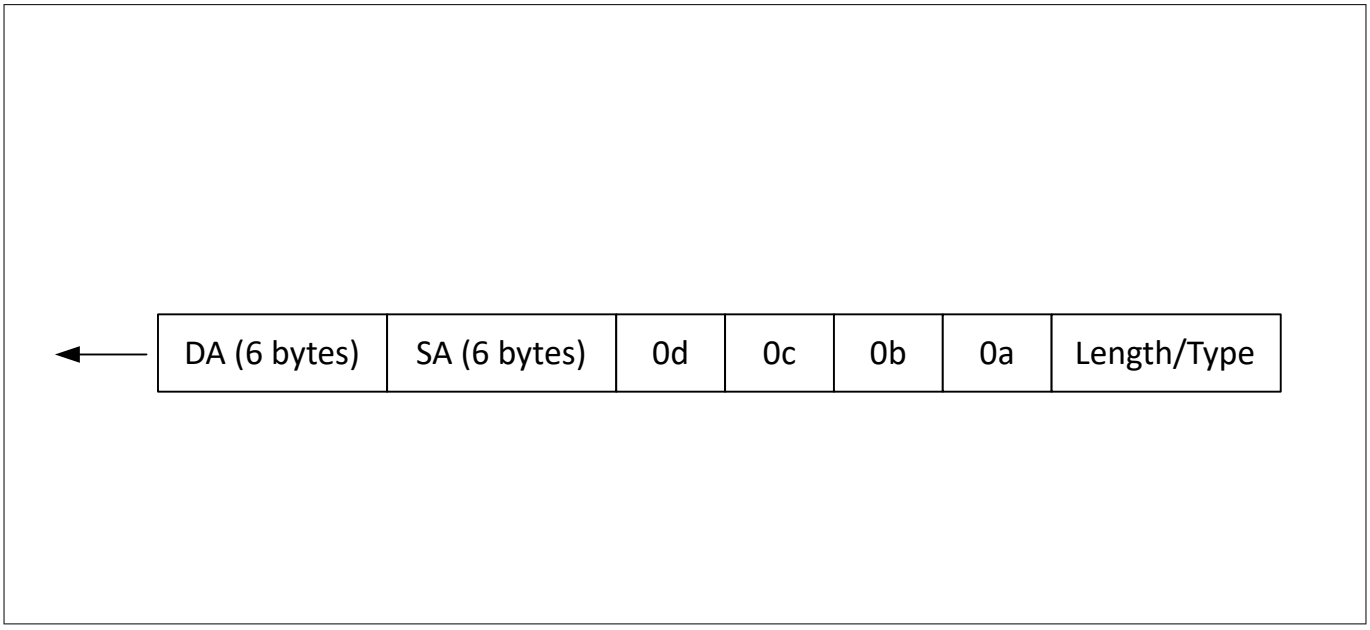

Figure 151 Packet transmitted/received on the line with FH inserted on GMII

FH [7:0] bytes will be the first flexible header bytes to go on the line/to be stored in the buffer address on Rx and Tx paths respectively, followed by subsequent higher bytes.

In case of MAC-generated / Link layer generated packets, the Static Flexible Header can be programmed in the MAC_Flex_Hdr_Low and MAC_Flex_Hdr_High registers respectively as follows,

FH of length 7 bytes and value 0x06050403020100 will be programmed as follows

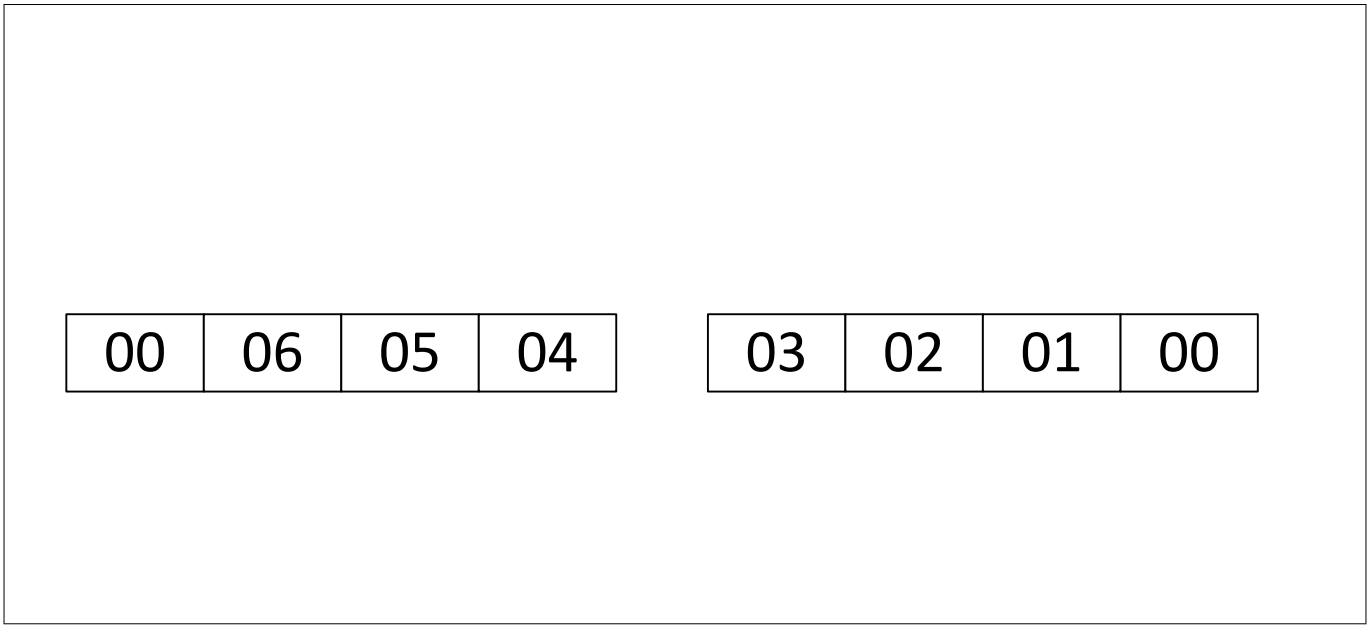

Figure 152 MAC_Flex_Hdr_High and MAC_Flex_Hdr_Low register programming

Here MAC_Flex_Hdr_Low [7:0] will be the first FH byte to go on the line followed by [15:8], [23:16] and [31:24] respectively.

If FH length is more than 4 bytes, then MAC_Flex_Hdr_High will follow MAC_Flex_Hdr_Low in similar way.

In this example, MAC_Flex_Hdr_Low register and only bytes 0x060504 from MAC_Flex_Hdr_High register will be sent on the line as MAC_Flex_Hdr_High[31:24] is not a part of the FH.

14.4.3.19.4 Restrictions

1. For Length packets, length value of Ethernet header (LT field) will not include FH length when FH is enabled
2. When FHRX is enabled and when EFLL=0, Unicast Pause frames will not be supported as the ingress PAUSE packet is identified (for the decision to strip FH or not) by the special multicast DA address only
3. In Rx path, when MAC_Packet_Filter[7:6], PCF field is set to 2'b10 or 2'b11, PAUSE packets can be forwarded to application. In this case, if EFLL bit is not set, then the first 8 bytes of such Pause packets transferred to the memory by RxDMA will contain dummy/invalid bytes(all-zero), even though FH was not stripped in such packets
4. Pause packets with special multicast DA (01:80:C2:00:00:01) is supported when FH is enabled (FHRX and EFLL is set) except for the following cases
   a. In Tx path, if the DMA fetches a Pause packet with special multicast DA, FH (written by the software) will be inserted at programmed position, even if EFLL bit is not set
   b. In Rx path, when EFLL bit is cleared to 0, and FH position is programmed at 0th byte location, FH will be stripped only if the first 6 bytes (FH and subsequent DA bytes) do not make up special multicast DA (01:80:C2:00:00:01) applicable for Pause frames

      For example: FH length = 3 bytes, FH position = 0th byte and EFLL=0

      1. If FH = 0x0180C2 and DA = 0x000102030405

         The 3 FH bytes and the 3 DA bytes, {0180c2,000102} != {0180C2000001}. So FH will be stripped from the received packet
      2. If FH = 0x0180C2 and DA = 0x000001020304

         The 3 FH bytes and the 3 DA bytes, {0180C2,000001} == {0180C2000001}. So FH will not be stripped from the received packet as 3 FH bytes and 3 DA bytes made up special multicast DA identified for Pause packets

In other words, if Flexible Header bytes and subsequent DA bytes are equal to Pause special multicast DA, then the packet will be recognized as a Pause packet when EFLL bit is set to 0 and hence the FH will not be stripped from such packets.

14.4.3.20 Multiple channels and queues support

This chapter describes how the XGMAC controller supports multiple queues and channels.

The topics are as follows:

14.4.3.20.1 Block diagram

The XGMAC supports up to 8 queues and channels on Tx and Rx paths. The figure below shows the architecture of XGMAC with multiple queues and channels.

***Note**: In multiple channel/queue configurations, for :*

- *Half-duplex operations, enable only the Q0/CH0 on Tx*
- *Full-duplex operations, for single queue or channel, enable any queue/channel*

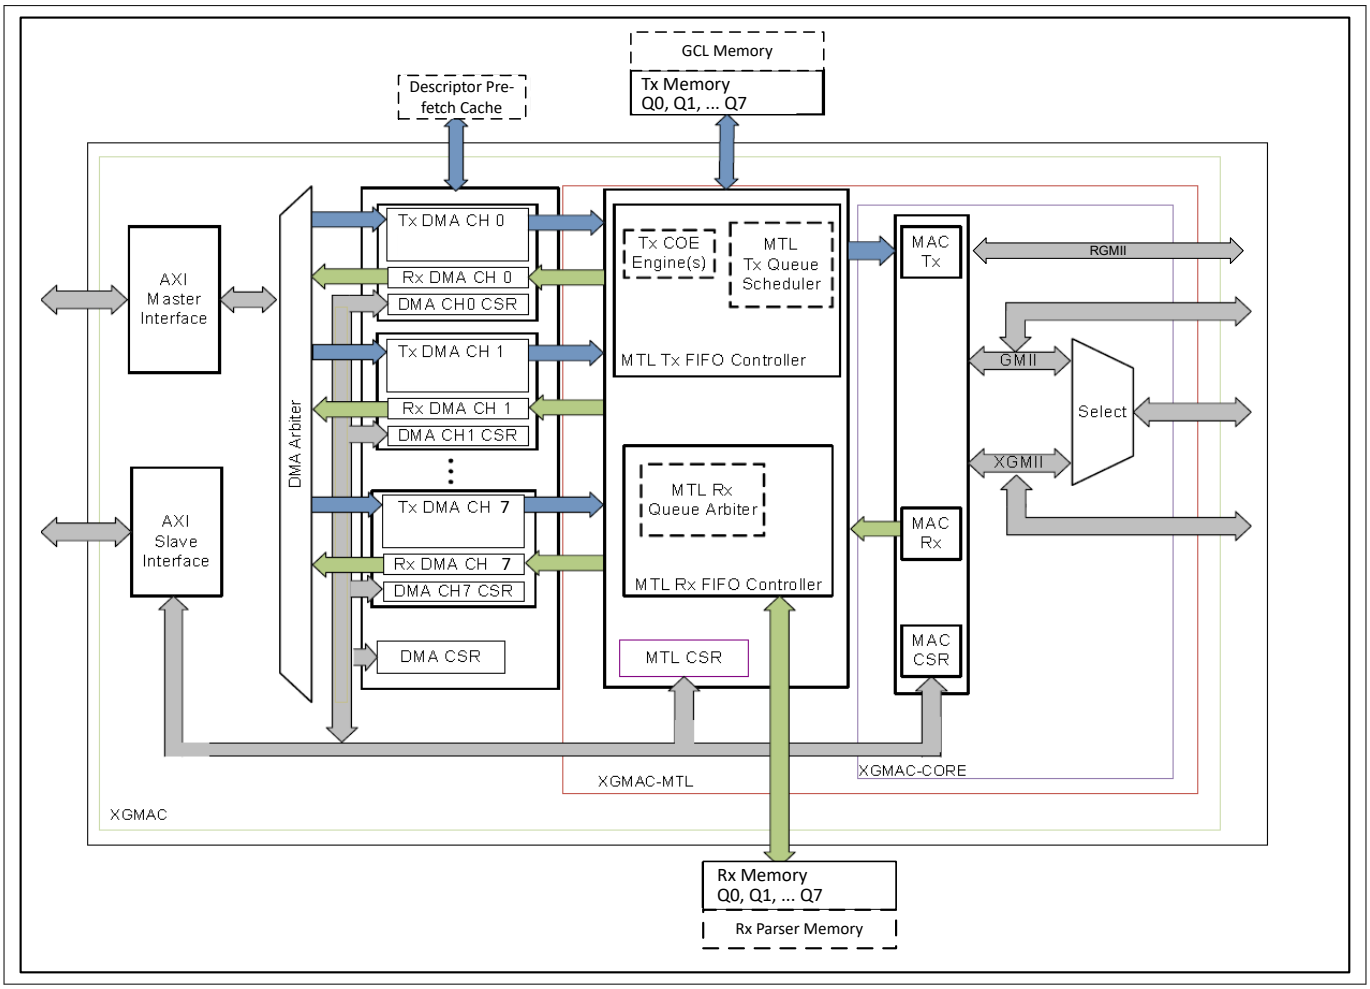

Figure 153 XGMAC with multiple channels and queues

14.4.3.20.2 DMA

This section describes how multiple channels are supported in the Transmit and Receive paths.

Transmit path

The XGMAC supports eight Tx channels. The fixed priority scheme is used in the Transmit path to arbitrate between the multiple Tx DMA channels to access the common AXI bus. In this scheme, the channel with highest

priority always wins the arbitration when it requests the bus. Table 721 provides information about the priority levels of Tx DMA channels.

Table 721 Fixed priority scheme for Tx DMA channels

Priority level	Channel
0 (low)	Channel 0
1	Channel 1
2	Channel 2
3	Channel 3
...	...
7 (high)	Channel 7

The Fixed Priority scheme does not necessarily cause “starving” of lower priority channels for the AXI bus. The AXI4 protocol capabilities and the Tx DMA characteristics are as follows:

- Read command requests from a Tx DMA for a burst of data transfers is driven on a separate AXI channel and gets executed in one clock cycle. The actual data transfer starts on a separate AXI channel only after the request is accepted and takes multiple clock cycles to complete with relatively large read access latencies
- AXI master is free to drive out subsequent requests even before the previous data transfers are completed
- The Tx DMA requests for another data transfer only after the data transfer for its previous request is completed and transferred to the MTL TxQ and space is available in TxQ to take in the next request
- The XGMAC can be programmed to control the maximum number of outstanding requests, Requested Burst sizes by DMA, and the burst sizes of each data transfer on AXI

Considering these, XGMAC can be programmed such that the requests of all the Tx DMA are placed and executed on the AXI bus before the data transfer of the first Tx DMA is completed and it raises the next request to the arbiter.

Receive path

The XGMAC supports up to eight Rx channels. In the Rx direction, the MTL Rx Controller selects the Rx DMA for which it is transferring or reading the data from the Rx FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that is has to transfer. The scheduler checks whether sufficient data (of requested burst length) is available to be transferred to these DMAs and then selects the Rx DMA that gets serviced using the programmed priorities.

Priority Scheme for Tx DMA and Rx DMA

The DMA arbiter performs the fixed priority arbitration between the Tx and Rx paths of DMA channels for accessing descriptors and data buffers. Descriptor accesses of a Tx or Rx channel is given higher priority when requests from both are active together.

WRR Arbitration Support for AXI Data-Reads on Tx DMA

The Weighted Round Robin arbitration is supported for Transmit DMA channel read access to AXI Read Data Channel. The weights corresponding to each Transmit DMA Channel is programmed in the indirect registers using the DMA CH Ind Ctrl and DMA CH Ind Data registers. The default weights in the indirect register correspond to Round Robin arbitration.

14.4.3.20.3 Multiple queues support in the MAC

You can enable or disable a Tx Queue by programming the TXQEN field MTL_TxQ(#i)_Operation_Mode register of corresponding queue.

The queuing is based on the CBS or SP algorithms.

You can enable or disable a Rx Queue by programming the RXQ#EN field of corresponding queue in the MAC_RxQ_Ctrl0 register. The following list explains how Rx queues are enabled based on the selected features:

1. Received tagged packets can be routed to any of the Rx Queues from Q0 to Q7
2. Each queue has a corresponding field (PSRQ fields in the MAC_RxQ_Ctrl2/3 registers) by which you can indicate the packets of specific VLAN priority values that should be routed/pushed into that queue
3. It should be ensured that each priority value can be routed to a specific queue within the set of enabled queues. That means bits corresponding to the same priority value should not be set in multiple PSRQx fields within the enabled queues, but the user can route multiple priorities into the same queue
4. Other types of packets such as untagged packets, multicast packets, PTP and AV control packets, are routed to specific Rx queues as programmed in the MAC_RxQ_Ctrl1 register.
5. A pause frame is generated when the flow control is triggered in any of the Rx Queues
6. AV is enabled for all selected Rx queues. The queuing is done based on the VLAN Tag priority for AV packets. The VLAN Tag priority should match the PSRQ field of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly matched MAC address register. The AV control packets (tagged or untagged) are routed based on the AVCPQ field of the MAC_RxQ_Ctrl1 register. The PTP over Ethernet packets are routed based on the AVPTPQ field of MAC_RxQ_Ctrl1 register

14.4.3.20.4 Multiple queue support in the MAC transaction layer (MTL)

The XGMAC supports eight queues in the Tx direction and eight queues in the Rx direction. The number of active Tx queues and Rx queues can be configured independently by software. You can control a Tx queue through MTL_TxQ(#i)_Operation_Mode register. You can control an Rx queue through MTL_RxQ(#i)_Operation_Mode register.

Queue memory

All MTL Tx queues share one Tx memory and all Rx queues share one Rx memory with programmable individual queue sizes in blocks of 256 bytes. The application can program the Tx queue size in the TQS field of MTL_TxQ(#i)_Operation_Mode register and the Rx queue size in the RQS field of the MTL_RxQ(#i)_Operation_Mode register.

The XGMAC supports the total Tx memory size of 32 KB and total Rx memory size of 32 KB.

Traffic classes and transmit queues

The XGMAC controller supports independent configuration of transmit queues and traffic classes (TC), where you can select up to eight traffic classes and up to eight transmit queues. You can program the bandwidth required for each traffic class by programming the MTL_TCn_Quantum_Weight register corresponding to a traffic class.

A queue must be mapped to a traffic class by programming the Q2TCMAP field in the MTL_Txn_Operation_Mode register for a particular queue.

The scheduling between traffic classes is determined by the scheduling algorithm implemented in the transmit scheduler.

***Note**: All Queues within a traffic class are selected in a round robin fashion (when packets are available) when the traffic class is selected by the scheduler for packet transmission. This is true for any of the scheduling algorithms.*

The following scheduling algorithms are supported:

- Weighted Round Robin
- Strict Priority

Weighted Round Robin

In Weighted Round Robin (WRR) algorithm, each traffic class is assigned a weight based on the percentage of configured bandwidth. All traffic classes are serviced in the round-robin order according to the programmed weights. Large packets get more bandwidth in this algorithm.

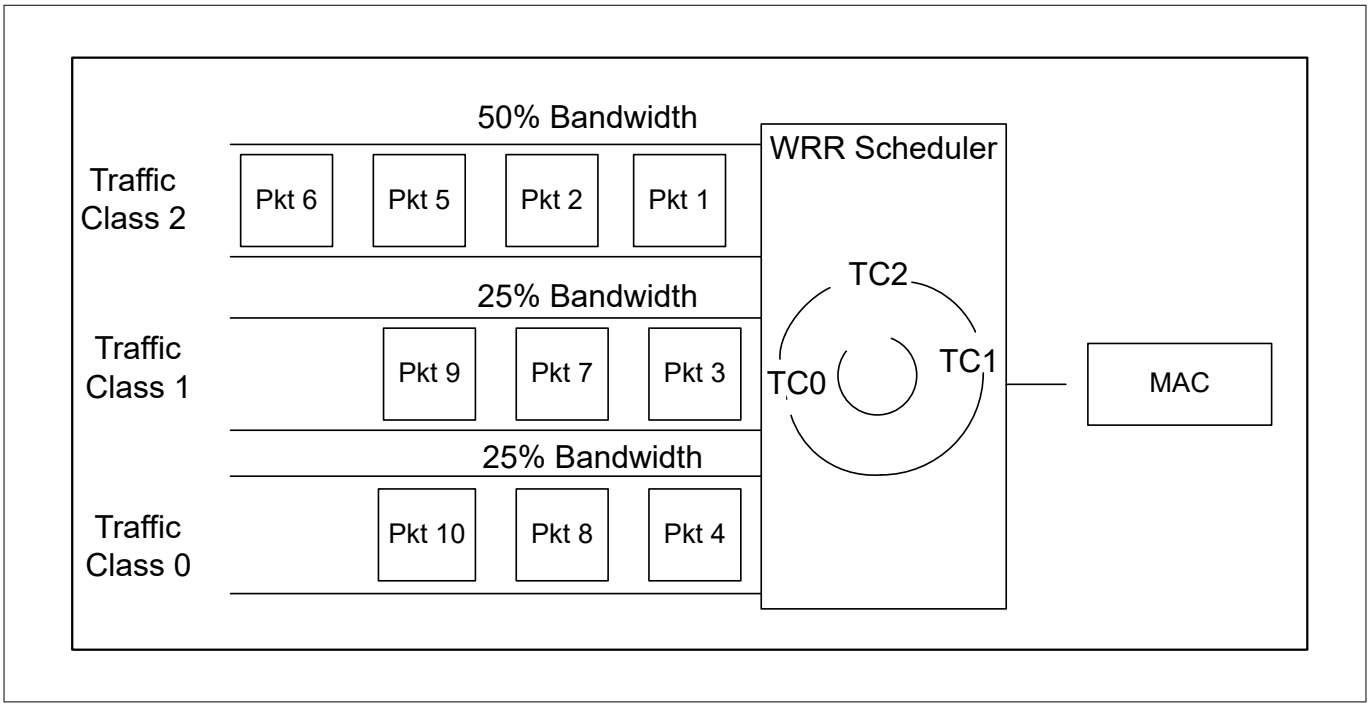

Figure 154 Weighted Round Robin Example

In Figure 154, Traffic Class 2, Traffic Class1 and Traffic Class 0 are configured for 50%, 25%, and 25% bandwidth respectively. The corresponding weights are 2, 1, and 1. Before the WRR scheduler is started, Traffic Class 2 has four packets; Traffic Class 1 has three packets; and Traffic Class 0 has three packets. The packets are transmitted in the following order:

Table 722 Packet transmission order

Packet sequence	Traffic class number
Packet 1	Traffic Class 2
Packet 2	Traffic Class 2
Packet 3	Traffic Class 1
Packet 4	Traffic Class 0
Packet 5	Traffic Class 2
Packet 6	Traffic Class 2
Packet 7	Traffic Class 1

(table continues...)

Table 722 (continued) Packet transmission order

Packet sequence	Traffic class number
Packet 8	Traffic Class 0
Packet 9	Traffic Class 1
Packet 10	Traffic Class 0

Strict priority

In the strict priority algorithm, Traffic Class 0 has the lowest priority and the priority increases with the Traffic Class number. For example, in a four-TC configuration, TC3 has the highest priority, followed by TC2, TC1, and finally TC0.

The highest priority Traffic Class is serviced first. If there is no packet in the highest priority Traffic Class, then the next priority Traffic Class is serviced.

Audio Video Bridging

Overview of Audio Video Feature

XGMAC supports the AV data transfer in all speed modes. The AV feature enables transmission of time-sensitive traffic over bridged local area networks (LANs). The following standards define various aspects of the AV feature implementation:

- IEEE 802.1Qav-2009: Allows the bridges to provide time-sensitive and loss-sensitive real-time audio video data transmission (AV traffic). It specifies the priority regeneration and controlled bandwidth queue draining algorithms that are used in bridges and AV traffic sources
- IEEE 802.1Qat-2009: Allows the network resources to be reserved for specific traffic streams traversing a bridged local area network
- IEEE 802.1AS-2020: Specifies the protocol and procedures used to ensure that the synchronization requirements are met for time-sensitive applications such as audio and video across bridged and virtual-bridged LANs consisting of LAN media where the transmission delays are fixed and symmetrical. For example, IEEE 802.3 full-duplex links include the maintenance of synchronized time during normal operation followed by addition, removal, or failure of network components and network reconfiguration

Transmit Path Functions

The Transmit path of Queue 0 supports the strict priority algorithm, and it is used for best-effort traffic. For a queue, the strict priority algorithm determines that a packet is available for transmission if the queue contains one or more packets. When the threshold mode for MTL Tx FIFO is enabled, the strict priority algorithm determines that a packet is available for transmission if the queue contains a partial packet of size equal to the programmed threshold limit.

The Transmit paths of additional queues support traffic management by using the credit-based shaper algorithm. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if the following conditions are true:

- The queue contains one or more packets.
- The credit for the queue is positive as per the algorithm.

By default Credit Based Shaper (CBS) is disabled for all queues. CBS support for the queues must be enabled from higher Queue index to lower Queue index, that is enable CBS from Queue 7 before Queue 6 and so on.

Each Transmit DMA has a separate descriptor chain for fetching the transmit data. The Transmit channel that gets the access to the system bus depends on the DMA arbiter.

The Transmit path has a shared FIFO (MTL layer) for each queue, as shown in Figure 131. The data fetched by the DMA is put in the respective part of the FIFO. The MTL Tx Queue Scheduler controls which part of the FIFO data is transmitted by the MAC. If the credit-based shaper algorithm is enabled for a queue, the corresponding queue is selected for transmission if the following conditions are true:

- If the packet is available in the channel and has a positive or zero credit.
- If the higher priority queue has no packet waiting in the FIFO.

If the credit-based shaper algorithm is disabled for all queues, the packet to be transmitted from a queue is selected based on the priority scheme described in Figure 154.

Receive Path Functions

XGMAC having 8 RxQs allows user to demultiplex the received data to send the packets into separate receive channels.

To differentiate between the AV and non-AV traffic, the MAC provides a status that indicates if it is an AV packet and its corresponding VLAN Priority tag value. This status is updated in the Extended Status field of the Receive descriptor. All received packets with the EtherType field of 0x22F0 are detected as AV packets. The AV packets can be of the following two types:

- AV data packets: The AV data packets are always tagged. The tagged AV data packets are received based on the programmed priority value. To specify the queue to which an AV packet with a given priority must be sent, program respective priority bit in PSRQ(#i) field of MAC_RxQ_Ctrl2 or MAC_RxQ_Ctrl3 register corresponding to the queue.
- AV control packets: The AV control packets can be either tagged or untagged. The untagged AV control packets are received on Queue 0 by default. To receive these packets on any other queue, you can program Bits[2:0] of the MAC_RxQ_Ctrl1 register. Similar to the AV data packets, the tagged AV control packets are received based on the programmed priority value.

In addition to the AV packets, you can receive the untagged PTP packets on any queue. By default, the PTP packets (tagged or untagged) are received on Queue 0. To receive these packets on any other queue, you need to program Bits[6:4] of the MAC_RxQ_Ctrl1 register.

Credit-Based Shaper Algorithm

The MTL Queue Scheduler uses the credit-based shaper algorithm to arbitrate the AV traffic in all AV enabled Traffic Classes and the legacy Ethernet traffic in Traffic Class 0. You can program the additional queues to use the credit-based shaper algorithm.

The following sections provide information about configuration of credit-based shaper algorithm.

Credit Value

The credit value is accumulated every transmit clock cycle. The credit to be added or subtracted per cycle can be fractional based on the required idleSlope and sendSlope values. The credit for a TC builds up only when the packet is available but it cannot be transmitted because the MAC is sending a packet from another TC. The XGMAC supports a mode (CC field of ETS control register) in which the credit can build up in advance for a TC which has no outstanding packets. This enables sending a burst of high priority traffic in a TC as soon as the data is available. When the CC field is reset, the accumulated credit parameter in the credit-based shaper algorithm is set to zero if there is positive credit, and there is no packet to transmit in a TC. The credit does not accumulate when there is no packet waiting in a queue and other queues are transmitting. When set, the accumulated credit parameter in the credit-based shaper algorithm is not reset to zero if there is positive credit and no packet to transmit in a queue. The credit accumulates even when there is no packet waiting in a queue and other queues are transmitting.

idleSlopeCredit and sendSlopeCredit Values

The software must program the idleSlopeCredit and sendSlopeCredit values. The programmed values should be the credit accumulated or drained per clock cycle scaled by 1024, such as, 320 x 1024 = 327680 and 480 x 1024 = 491520. In addition, the software must program the hiCredit and loCredit values, scaled by 1024, to adjust for scaling of the idleSlopeCredit and sendSlopeCredit values.

Programming example for idleSlope, sendSlope, hiCredit, and loCredit

The idleSlope, sendSlope, hiCredit and loCredit is computed as below:

idleSlope = BW * portTransmitRate

sendSlope = idleSlope – portTransmitRate

hiCredit = maxInterferenceSize * BW * 8bits

loCredit = maxFrameSize * (sendSlope/portTransmitRate) * 8bits

The portTransmitRate = 4, 8 and 32 for 10/100Mbps, 1 / 2.5Gbps and 5Gbps modes respectively.

maxInterferenceSize is:

-For highest priority queue, it is maximum frame size supported by the MAC

-For lower priority queue, it is the sum of maximum frame sizes supported by higher priority queues and maximum frame size supported by the MAC

It can be calculated using (total number of queues on which traffic is sent - the particular queue number) * maxFrameSize

For example: if traffic is sent on 8 queues, the maxInterference for respective queue will be:

maxInterferenceSize for Q7 = (8 - 7) * maxFrameSize

maxInterferenceSize for Q6 = (8 - 6) * maxFrameSize

maxInterferenceSize for Q5 = (8 - 5) * maxFrameSize

The above formulae's can be used for determining the values to be programmed in the per queue AV related MTL registers.

For example: In 1 Gbps mode, if TC7 (highest priority) is allocated BW=60%, TC6 (lower priority) is allocated BW=25% and Q0 is best effort queue. The maximum frame size supported by MAC in each of the queues is 1500 bytes.

TC7 Programming

idleSlope: (60/100) * 8 = 4.8 (i.e., program (4.8 * 1024) = 0x1333 in the idleSlope register)

sendSlope: 4.8 – 8 = -3.2 ((3.2 * 1024) = 0xCCD (value programmed in the sendSlope register)

hiCredit: 1500 * (60/100) * 8 = 7200 (i.e., program (7200 * 1024) = 0x708000 in the hiCredit register)

loCredit: 1500 * (-3.2/8) * 8 = -4800 ((4800 * 1024) = 0x4B0000, program twos complement which is 0x1FB50000)

TC6 Programming

idleSlope: (25/100) * 8 = 2 (i.e., program (2 * 1024) = 0x800 in the idleSlope register)

sendSlope: 2 – 8 = -6 ((6 * 1024) = 0x1800 (program this value in the sendSlope register)

hiCredit: 1500 * 2 * (25/100) * 8 = 6000 (i.e., program (6000 * 1024) = 0x5DC000 in the hiCredit register)

loCredit: 1500 (-6/8) * 8 = -9000 ((-9000 * 1024) = 0x8CA000, program twos complement which is 0x1F736000)

The 2's complement value should be programmed for loCredit field because it is always a negative value.

Bandwidth Status

The hardware maintains the status of the actual bandwidth consumed by each higher priority queue in the CBS status registers. This enables the software to estimate the average bandwidth consumed by numerically higher traffic classes as compared to the reserved bandwidth.

The CBS status register gives the average number of bits transmitted during the previous programmed slot interval (1, 2, 4, 8, or 16 slots of 125 µs) in a queue. The status register is updated even if the credit-based shaper algorithm is not enabled for a queue. The number of slots over which the average bits transmitted per slot are computed is programmed in Bits[6:4] of the Porti_MTL_TCQ[i]_TC[i]_ETS_Control register of the respective traffic class. For example, if you have programmed two slots, the average bits are computed over slot numbers 0–1, 2–3, 4–5, and so on.

The value programmed in the idleSlopeCredit register of a queue is proportional to the bandwidth reserved for the queue. The software can allocate any bandwidth that is not used by the higher priority queue to the reserved bandwidth of the lower priority queue.

A lower priority queue, which is using the credit-based shaper algorithm, cannot use the unused reserved bandwidth of any higher priority queue that is using the credit-based shaper algorithm. However, a lower priority queue, which is using the strict-priority algorithm, can use the unused reserved bandwidth of any higher priority queue that uses the credit-based shaper algorithm. For example, Queue 1 and Queue 2 use the credit-based shaper algorithm (with reserved bandwidth of 50% and 25%, respectively) and Queue 0 uses the strict-priority algorithm. If Queue 1 uses only 40% of reserved bandwidth, the remaining 10% is used by Queue 0. Queue 2 cannot exceed the reserved bandwidth of 25%.

14.4.3.20.5 TX Side Arbitration Between DMA and MTL

As the number of Tx DMA channels is always equal to the number of Tx Queues in the MTL, they are always mapped directly. For instance, each Tx DMA pushes data into its respective Tx Queue assigned to it.

14.4.3.20.6 Rx Side Arbitration between MTL and DMA

After completing the current packet processing, the DMA Channel controller fetches the next descriptor. Once the descriptor fetching is complete, it evaluates the amount of data to be transferred to the Rx Buffer based on the programmed PBL and Rx Buffer Length, and accordingly requests the MTL to transfer the data.

After servicing the current request, the MTL Rx arbiter selects a Rx Queue based on the arbitration scheme (RAA field of the MTL_Operation_Mode register) and the weights programmed in the MTL_RxQn_Control Register. Arbitration is done among Queues that have the packet to be transferred to a DMA, which are ready to transfer data. For example, if the DMA is in the process of fetching or closing a descriptor, it is not in the “ready” state. It is ready to transfer data only after it reads in a valid descriptor with non-empty buffer locations. Once the Rx Queue is selected, a complete frame/PBL (programmable burst length) amount of data (based on the RXQ_FRM_ARBIT field of the MTL_RxQn_Control register) is read out from that Queue and routed to the Rx DMA Channel based on the Rx Channel selection criteria defined in the "Rx queue to DMA mapping" section.

Related information

Rx queue to DMA mapping on page 1509

14.4.3.20.7 Rx queue to DMA mapping

The packets in the Rx Queue can be routed to any one of the multiple DMA channels by programming the following registers:

- MTL_RxQ_DMA_Map0 Register (for queues 0, 1, 2 and 3)
- MTL_RxQ_DMA_Map1 Register (for queues 4, 5, 6 and 7)

Two types of Rx Queue to DMA mapping is possible through programming.

Static Mapping

In this mode, all the packets of a Rx Queue are routed to a specific DMA channel. For example, all the packets from Rx Queue 0 can be routed to a DMA channel by programming Q0MDMACH (bit[2:0]) and Q0DDMACH (bit[7] = 0) of the Port j MTL RxQ DMA Map0 register.

Similarly, packets from other Rx Queues can be routed to any DMA channel by programming register fields corresponding to each Queue.

Dynamic (per packet) mapping

In this mode, the destination DMA channel of a packet being read from a Rx Queue is not constant but decided independently for each packet. For example, if the Q1DDMACH bit of the MTL_RxQ_DMA_Map0 register is set, the static mapping is disabled for Rx Queue 1 and the value in Q1MDMACH is ignored. The destination DMA channel is decided by the controller receiver for each packet, depending on the following, in the decreasing order of priority.

1. L3-L4 filter Based DMA Selection

   The TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the MAC_L3_L4_Controlx register. If the match is successful, the DMA channel number programmed in the DMCHN field of the MAC_L3_L4_Controlx register is selected as the destination DMA channel number provided DMCHEN bit of the same register is set.

If none of the L3-L4 Registers give a comparison match, the next category, makes the DMA channel selection

2. Extended VLAN Based DMA Selection

   The MAC uses the VLAN Tags of the received frame to determine the destination DMA Channel number. For more details, see the "VLAN based DMA mapping" section.

   If none of the VLAN filters result in a comparison match, the next category Ethernet DA-Based DMA Selection, makes the DMA Channel selection.

   Routing is applicable only if the entire VLAN Filter has passed. Routing is only based on Perfect Filter Result. Each perfect filter has a DMA Channel Enable and a DMA Channel Number field which can be programmed. Only if the DMA Channel Enable bit is set, routing is applicable for that filter.

   The frame is routed to the DMA Channel of the smallest Matching Filter, if enabled. If the DMA Channel number of the filter is not enabled, the frame gets routed to Channel 0. For example, if the VLAN tag of frame matches filters 7, 3, and 1, the MAC checks if the DMA Channel Number of Filter 1 is enabled through programming. If yes, the frame is routed to the programmed value; otherwise it is routed to the DA filter based DMA channel or to channel 0. When the inverse filter is enabled; it is routed to the DMA channel number of the least mismatched filter, if enabled.

   If VLAN Hash Filter is also enabled, it is used to determine the Filter result only. For non-tunneled packets, routing depends on the enabled Perfect Filters. If none of the perfect filters are enabled or if all of them are bypassed, the VLAN Filter based routing does not take place. If all the perfect filters give a fail result and the Hash Filter has passed, the VLAN Filter result is a pass but routing is based on DA Based Addressing or to Channel 0. Similar behavior is seen when inverse Filtering is enabled as well.

   The overall VLAN Filter is produced and it decides if the frame can be dropped or forwarded. If the frame gets a fail result from the VLAN Filter, then it is dropped if VTFE = 1 & RA = 0.

   RDES0 cannot be used to give the outer/& inner VLAN Tags of the outer header. If stripping is enabled, the matching tag value is lost as it cannot be passed through the status. The application needs to be cautious before enabling stripping.

3. Ethernet DA-Based DMA Selection

   The DA address of the received packet is compared against the programmed DA values in MAC Address Registers. If the address matches any of the programmed values, the corresponding DCS field determines the destination DMA channel number

   If none of the previous operations are able to make a successful match/decision, then the packet is routed to DMA Channel 0 by default. A summary of the filtering result and the DMA channel selection in this mode is given in Table 723

Table 723 L3L4 filter results

L2/VLAN filter match	MAC_Packet _Filter[IPFE]	L3/L4 filter match	Action on packet	DMCHEN	DMA channel assigned
1	0	Fail	Forward	X	MACAddr-DCS[1)]
1	X	Fail	Drop	X	MACAddr-DCS
1	X	Pass	Forward	1	L3L4-DMCHN[2)]
1	X	Pass	Forward	0	MACAddr-DCS
1	X	Bypass	Forward	X	MACAddr-DCS
1	X	Bypass	Drop	X	MACAddr-DCS
1	1	Fail	Drop	X	MACAddr-DCS
0	X	Pass	Drop	1	L3L4-DMCHN
0	X	X	Drop	X	0

1) MACAddr-DCS: Field of the MAC_Addressx_High register that gave a DA match
2) L3L4-DMCHN: Field (DMCHN) of the MAC_L3_L4_Controlx register that gave a match

L2/VLAN Filter match means the combined result of the Ethernet DA, SA, VLAN perfect & hash match filters. When all of the enabled filters give a match, then this is taken as “1”, otherwise “0”

L3-L4 Filter match has following three values:

- Fail: All enabled L3L4 filter failed
- Pass: Any of enabled L3L4 filter gave a match
- Bypass: No L3L4 filter enabled for received packet type

Action on Packet: DMA channel number is indicated even if packet is “Drop” because of packet may reach the application because of MAC_packet_Filter[RA] = 1

DMCHEN: Field of the MAC_L3_L4_Controlx register that gave a match

***Note**: You can also assign multiple queues to one DMA channel. In this case the order of the packets that gets to the DMA channel from different Queues are affected and does not follow the Scheduling scheme programmed in the RAA field of the Port j MTL Operation Mode register. For more details, see the "Tx side arbitration between DMA and MTL" section.*

Broadcast/Multicast Packet Duplication

Broadcast/Multicast Packet Duplication supports sending and receiving Broadcast/Multicast packets to multiple DMA channels.

In a virtual system that supports multiple guest OS's (for instance, each OS owning a DMA), where each DMA acts as an independent Ethernet Node, there can be requirement to route the received multicast/broadcast packets to all/multiple DMA channels. This is implemented by reading the packet from the same queue multiple times and route the same packet to the specified multiple DMA channels.

To support multiple DMA channels through software control, program the Duplication Selection of the DA (DDS field of MAC_Extended_Configuration register).

When DDS is 0_B, the DCS value holds the binary number of the destination channel (unique destination with no duplication).

When DDS is set to 1, the XDCS field in the MAC_DChSel_IndReg(#i) Register is taken as the destination Rx DMA for the packet matching the associated DA/SA filter register. The XDCS field is specified as one-hot format where each bit when set, represents the RxDMA channel to which the packet should be transferred. In other words, when multiple bits are set, the packet is duplicated and distributed to all the corresponding RxDMA channels.

Programmable Unicast Packet Duplication

Program the UDC field, bit[31] of the MAC_RxQ_Ctrl4 register to enable the unicast packet duplication.

The unicast packet duplication occurs only when the following conditions are met:

- Highest receive queue is selected and enabled in the configuration
- DA, SA, and VLAN filters pass
- More than 1 bit is set in the DMA channel number that is specified in the XDCS field of the MAC_DchSel_IndReg(#i) register that matches the unicast designation address of the received packet

The XGMAC controller performs packet duplication by default when the received packets have multicast or broadcast destination address.

The following table shows various scenarios when duplication occurs and when it does not.

Table 724 Unicast packet duplication scenarios

UDC	Unicast packet received	DDS = 1 & multiple bits of XDCS field of MAC_DChSel_IndReg(#i) matching the Packet DA, are set to 1	Packet mapped to highest RxQ	Duplication	Behavior
X	Yes	No (either of the condition is false)	No	No	If DDS =0, then packet routed to RxDMA indicated by DCS field of MAC DA register else as per lowest bit set in XDCS field
0	Yes	Yes	X (Do not care)	No	Packet is only routed to DMA corresponding to lowest numbered bit set to 1
1	Yes	Yes	Yes	Yes	Packet routed to multiple RxDMA as programmed

Packet flush for Duplicated packets

When RPF bit of DMA_CH(#i)Rx_Control remains set and the DMA is re-started by the software driver the packets residing in the Rx Queues that were received when the DMA is stopped, still gets flushed out when the packet is not enabled for duplication to multiple Rx DMA.

When packet is enabled for duplication to multiple Rx DMA, the packet will not be flushed by Rx DMA in active state irrespective of RPF bit of DMA_CH(#i)Rx_Control register.

14.4.3.20.8 Selection of tag priorities assigned to Tx and Rx queues

In the Receive direction, the VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ# field in the corresponding MAC_RxQ_Ctrl2/3 registers. The bit corresponding to the VLAN Tag priority can be set in the PSRQ field for assigning that priority to the corresponding Rx Queue. For example, to assign VLAN Tag priority of 3 to Rx Queue 0, set bit [3] in the PSRQ0 field of the MAC_RxQ_Ctrl2 register. More than one Rx Queue cannot be assigned the same VLAN Tag priority. However, more than one VLAN Tag priorities can be assigned to the same Rx Queue. A maximum of eight priority queues are supported as there are only eight priorities available (3-bit field in the VLAN Tag). A programmable PRQSO field of the MAC_RxQ_Ctrl5 register provides the flexibility to select the start offset of the priority queue.

***Note**:*

- *When PRQSO is programmed to a non-zero value, the highest valid PSRQ(#i) field is only up to the one corresponding to highest Receive Queue selected in the configuration. Otherwise, the received packets corresponding to programmed VLAN Tag priorities in the unmapped PSRQ(#i) field are routed to Receive Queue 0. For example, when eight Receive Queues are selected in the configuration and PRQSO is programmed to 4, the highest PSRQ(#i) that can be programmed is PSRQ3*
- *The following requirements of PRQSO = 0 apply even when it is programmed to a non-zero value:*
  - *The Express packets priority queue and Preempt packets special queues must not be mapped to the same Receive Queue*
  - *The Preempt packets priority queue and Express packets special queues must not be mapped to the same Receive Queue*

The received VLAN Tagged Rx packet is routed to the Rx Queue that has the VLAN Tag priority match.

14.4.3.20.9 Distribution of Rx Packets from MAC to Rx Queues

The XGMAC controller provides multiple Rx queues to support classification and distribution of ingress packets. The MAC receiver pushes the ingress packets to the Rx queues based on packet type (tagged, untagged, multicast, PTP, AVB and so on), tag priorities, MAC packet filter results, preemptable or express packet, and so on. The distribution is controlled by the settings of the MAC_RxQ_Ctrl* and MAC_Packet_Filter register fields.

Based on the packet filter settings, the MAC receiver decides to either drop or forward the Ingress packet. However, the results of Layer 3 and Layer 4 filtering are not considered for the distribution of ingress packets into the Rx queues. Only the results of DA/SA/VLAN filters mentioned in Source address or destination address filtering and Extended VLAN Filtering are applicable.

Filtering of the broadcast packets is exclusively controlled by the DBF field, bit[5] of the MAC_Packet_Filter register. The filtering of multicast packets is controlled by the PM field, bit[4] of the MAC_Packet_Filter register, in addition to the DA/SA match.

By default, packets that fail any of the DA/SA filters, are dropped by the MAC Receiver. However, packets that fail the DA/SA/VLAN filter can still be forwarded to the application when the RA field of the MAC_Packet_Filter register is 1. Even when RA field is 0, VLAN filter fail packets can be forwarded if the VTFE field of the MAC_Packet_Filter register is 0.

The ingress packets go through the following operations in the decreasing order of priority.

1. RA = 0: Ingress packets are dropped if any one of the following condition is true
   - DA/SA filter fail
   - VLAN filter fail and VTFE field of the MAC_Packet_Filter register is 1
2. RA = 1: Ingress packets that fail the DA/SA filter are also forwarded to the Rx queue as mentioned in Table 725

Table 725 Routing DA/SA Failed Packets to Rx Queue

Packet Type	TSN Type	Destination Rx Queue Determined By
Broadcast/Multicast	Express	if MFFQE = 1, MFFQ; else if VFFQE = 1, VFFQ; (only for tagged packets) else RxQ0
Unicast	Express	if UFFQE = 1, UFFQ; else if VFFQE = 1, VFFQ; (only for tagged packets) else RxQ0
All	Preemptable	RQ field

3. RA = 1 and VTFE = 0: Ingress tagged packets that pass the DA/SA filter but fail the VLAN filter, are forwarded to the Rx queue as mentioned in Table 726.

Table 726 Routing DA/SA Pass But VLAN Filter Fail Packets to Rx Queue

TSN Packet Type	Destination Rx Queue Determined By
Express	if VFFQE = 1, VFFQ; else RxQ0
Preemptable	RQ field

4. Ingress packets that pass the DA/SA/VLAN filters are forwarded to the Rx queue

		Yes	PSRQ

***Note**:*

- *If the RxQ pointed by the various fields in Table 725 through Table 728 is not enabled in the RxQ_Ctrl0 register as per the packet type, the packet is written to*
  - *RxQ0 for Express packets*
  - *Port j MAC RxQ Ctrl1.RQ for Preemptable packets*

  If RxQ0/RQ is not enabled, the packet is dropped
- *If the AV8021ASMEN field of the MAC_Timestamp_Control register is 1, MAC receiver checks only for untagged PTP packet. Tagged packet with PTP payload are considered as Remaining (Unicast/Broadcast/Multicast) tagged packets in Table 725 through Table 728*

14.4.3.20.10 Rx side routing from MAC to queues

The MAC routes the Rx packets to the Rx Queues based on the following packet types specified in that order:

1. Unicast/Multicast destination address packets that fail the destination address filter
2. Multicast/Broadcast destination address packets that pass the destination address filter
3. VLAN Tag Priority field in VLAN Tagged AV data packets
4. AV Control packets
5. VLAN Tagged IEEE 1588 PTP over Ethernet packets
6. Untagged IEEE1588 PTP over Ethernet packets
7. VLAN Tag Priority field in VLAN Tagged packets
8. Untagged packets

The outer C-VLAN Tagged AV data Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding `Port j MAC RxQ Ctrl2` and `Port j MAC RxQ Ctrl3` registers and the corresponding Rx Queue is enabled for AV through RXQ#EN field in `Port j MAC RxQ Ctrl0` register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in `Port j MAC VLAN Tag Ctrl` register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in `Port j MAC VLAN Tag Ctrl` register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The AV Control Rx packets can be routed based on the Rx Queue number specified in the AVCPQ field in `Port j MAC RxQ Ctrl1` register and corresponding Rx Queue is enabled for AV through RXQ#EN field in `Port j MAC RxQ Ctrl0` register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in `Port j MAC VLAN Tag Ctrl` register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in `Port j MAC VLAN Tag Ctrl` register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The VLAN Tagged Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding `Port j MAC RxQ Ctrl2` and `Port j MAC RxQ Ctrl3` registers and the corresponding Rx Queue is enabled through RXQ#EN field in `Port j MAC RxQ Ctrl0` register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the Rx Queue number specified in the PTPQ field in `Port j MAC RxQ Ctrl1` register and the corresponding Rx Queue is enabled through RXQ#EN field in `Port j MAC RxQ Ctrl0` register.

The VLAN tagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding Port j MAC RxQ Ctrl2 and Port j MAC RxQ Ctrl3 registers or the Rx Queue number specified in the PTPQ field in Port j MAC RxQ Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in Port j MAC RxQ Ctrl0 register. This is determined by programming in TPQC field of Port j MAC RxQ Ctrl1 register. This type of Rx packet routing is available when IEEE 1588 Timestamp feature support and Multiple Rx Queues are selected in the configuration. The VLAN Tagged IEEE 1588 PTP over Ethernet Rx packets are detected only when 802.1AS mode is disabled (AV8021ASMEN bit in Port j MAC Timestamp Control register is set to 0), otherwise this type of Rx packets are routed as generic VLAN Tagged Rx packets.

The multicast/broadcast destination address Rx packets that pass the destination address filter can be routed based on the Rx Queue number specified in the MCBCQ field of Port j MAC RxQ Ctrl1 register when enabled through MCBCQEN bit of Port j MAC RxQ Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in Port j MAC RxQ Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration. XGMAC supports a programmable option to de-prioritize the MCBC queue priority over the packet type based queue routing (PTP/AV) for Multicast and Broadcast packets. MCBC queue priority can be changed by setting OMCBCQ field [bit 20] of the Port j MAC RxQ Ctrl1 register.

The untagged Rx packets can be routed based on the Rx Queue number specified in the UPQ field of Port j MAC RxQ Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in Port j MAC RxQ Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The unicast destination address Rx packets that fail the destination address filter can be routed based on the Rx Queue number specified in the UFFQ field of MAC_RxQ_Routing_Ctrl register when enabled through UFFQE bit of MAC_RxQ_Routing_Ctrl register, RA bit of Port j MAC Packet Filter register is set to 1 and the corresponding Rx Queue is enabled through RXQ#EN field in Port j MAC RxQ Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The multicast destination address Rx packets that fail the destination address filter can be routed based on the Rx Queue number specified in the MFFQ field of MAC_RxQ_Routing_Ctrl register when enabled through MFFQE bit of MAC_RxQ_Routing_Ctrl register, RA bit of Port j MAC Packet Filter register is set to 1 and the corresponding Rx Queue is enabled through RXQ#EN field in Port j MAC RxQ Ctrl0 register. This type of Rx packet routing is available when multiple Rx Queues are selected in the configuration.

***Note**: Queue routing behavior for the received runt packet cannot be predicted*

If the Rx packet cannot be classified in any of the defined packet type for routing, it is routed through Rx Queue 0.

For more details, see the section "Registers".

14.4.3.20.11 Receive Queue Selection Based on Filter Fail

This feature enables the selection of RxQ when the unicast/multicast filter fails and VLAN filter also fails.

The multicast destination address Rx packets that fail the destination or source address filter are routed based on the Rx queue number specified in the MFFQ field of Port j MAC RxQ Ctrl4 register. When enabled through MFFQE bit of Port j MAC RxQ Ctrl4 register, RA bit of Port j MAC Packet Filter register is set to 1 and the corresponding Rx queue is enabled through RXQ#EN field in the Port j MAC RxQ Ctrl0 register. This type of Rx packet routing is available when multiple Rx queues are selected in the configuration.

The unicast destination address Rx packets that fail the destination or source address filter can be routed based on the Rx queue number specified in the UFFQ field of Port j MAC RxQ Ctrl4 register. When enabled through

UFFQE bit of Port j MAC RxQ Ctrl4 register, RA bit of Port j MAC Packet Filter register is set to 1 and the corresponding Rx queue is enabled through RXQ#EN field in Port j MAC RxQ Ctrl0 register. This type of Rx packet routing is available when Multiple Rx queues are selected in the configuration.

14.4.3.20.12 VLAN based DMA Mapping

This section discusses the Extended RX VLAN Filtering function with regards to the DMA Channel mapping. Routing is applicable only if the entire VLAN Filter has passed. Routing is only based on Perfect Filter Result. Each perfect filter has a DMA Channel Enable and a DMA Channel Number field which can be programmed. Only if the DMA Channel Enable bit is set, routing is applicable for that filter.

The frame is routed to the smallest Matching Filter's DMA Channel provided the DMA Channel is enabled. If that filter's DMA Channel number is not enabled, the frame gets routed to Channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1. Then the MAC checks if Filter 1's DMA Channel Number is enabled through programming. If yes, the frame gets routed to the programmed value; otherwise it gets routed to 0. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided the DMA Channel is enabled.

If Hash Filter is also enabled, it is used to determine the Filter result only. Routing still depends on the Perfect Filters enabled. If none of the perfect filters are enabled or if all of them are bypassed, then the VLAN Filter based routing does not take place. If all the perfect filters give a fail result and the Hash Filter has passed, then the VLAN Filter result is a pass but routing is based on DA Based Addressing or to Channel 0. Similar behavior is seen when inverse Filtering is enabled as well. This behavior is for non-tunnel frames.

The overall VLAN Filter is produced and it decides if the frame can be dropped or forwarded. If the frame gets a fail result from the VLAN Filter, then it is dropped if VTFE = 1 & RA = 0.

If stripping is enabled, the matching tag value is lost as it cannot be passed through the status. The application needs to be cautious before enabling stripping.

14.4.3.21 Time-Sensitive Networking

Time sensitive network (TSN) is a set of standards developed by the IEEE 802.1 work group. The standards define mechanisms for the time-sensitive transmission of data over Ethernet.

14.4.3.21.1 Policing Counters

Overview of Policing Counters

Policing counters feature counts the filter events and gathers the diagnostic information of the received packets. This feature can monitor events associated with filters such as DA/SA, VLAN, L3_L4, flexible receive parser, and stream-gate filtering. This feature maintains a set of registers to gather the filter events information that include, register for controlling the behavior of the 32-bit policing counters and policing counter status registers for providing status of the filter events. When a counter value crosses the programmed threshold, all the subsequent packets which asserts the filter events associated to the counter are dropped as a corrective measure. Interrupts are generated based on the programmed threshold and the selected time window.

Description of policing counters

This feature supports sixteen 32-bit policing counters to track the filter event. The policing counters can track the following filter events, only for perfect filtering:

- DA/SA filter pass
- DA/SA filter fail
- VLAN filter pass
- VLAN filter fail
- L3_L4 filter pass
- L3_L4 filter fail
- Flexible receive parser, accept frame
- Flexible receive parser, reject frame
- stream-gate filter pass

***Note**: Do not associate policing counter with inverse filtering of DA, VLAN, and L3_L4, as this can cause unpredictable behavior.*

You can program the filter events to be associated with any of these policing counters. A policing counter can be associated with more than one filter event. Each policing counter has a programmable time window and threshold.

A time window is provided as a sideband input, using the `sbd_pc_tim_wdw_i` input signal. The connections (with PPS outputs) on system level is described in chapter "Connectivity".

The rising edge of the signal represents the start of the time window, and the falling edge represents the end of the time window. You can program the counters to select any one of the four sideband time windows. You can program the policing counter to increment

- Irrespective of the selected time window (free running mode)
- Within the selected time window (time-window mode)

The programmable threshold is controlled by the `MAC_PCCtrl_IndReg` register. When the count reaches the programmed threshold, an interrupt is generated. You can program the register to restart the counters at the end of each time window.

Event Generators

The policing counter captures the filter events in the status registers, to indicate that an event is generated. Each filter event has an enable and a counter selection programming as described in the "Policing counter selection and filter status" section. When multiple filter events are associated with the same counter, the events are merged and updated in the corresponding counter.

Setting/resetting of the IPFE, VTFE, and SAF fields of the `MAC_Packet_Filter` register has no impact on the policing counter.

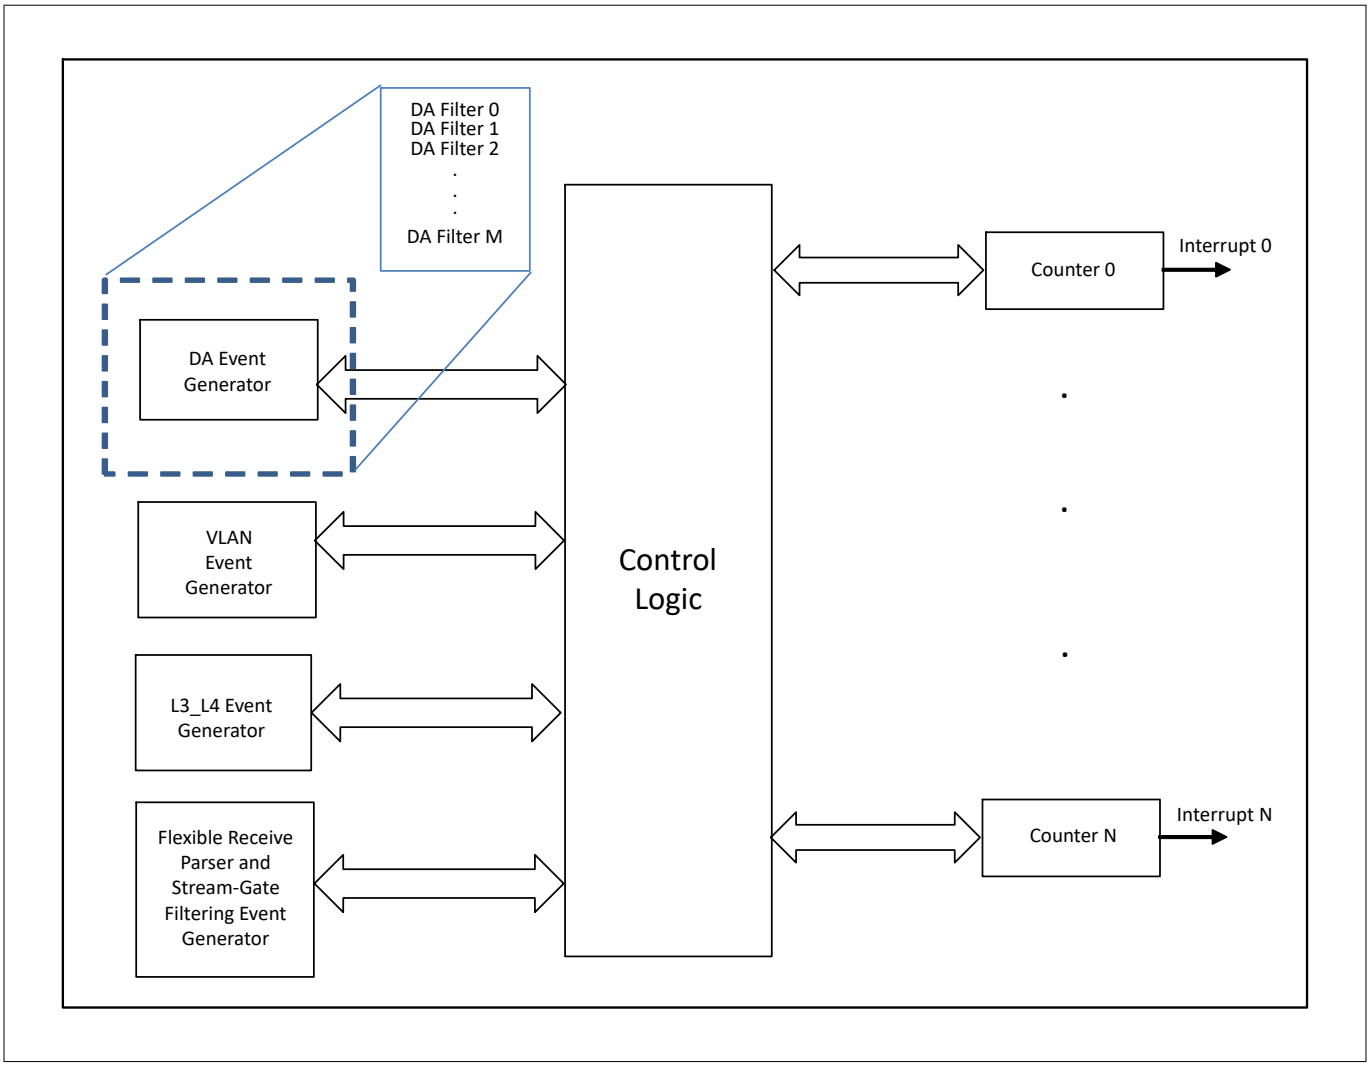

Figure 155 Policing Counter Flow Diagram

Related information

Policing Counter Selection and Filter Status on page 1520

Policing Counter Interrupts

Policing counters support 2 types of interrupts:

- Time window based interrupt

  When you enable time window based interrupt, the interrupt is triggered at the end of a time window. Each policing counter has a time window based interrupt status bit, which is either write-1 to clear or clear-on-read based on the value programmed in the RCWE field of the `Port j MAC CSR SW Ctrl` register
- Threshold based interrupt

  When the counter reaches the threshold that you programmed, an interrupt is asserted. Each policing counter has a threshold-based interrupt status bit, which is either write-1 to clear or clear-on-read based on the value programmed in the RCWE field of the `Port j MAC CSR SW Ctrl` register

The combined status of the policing counter interrupts is indicated in the PCIS field of the `Port j MAC Interrupt Status` register.

Policing Counter Selection and Filter Status

Table 729 shows the registers to be programmed to enable policing counters for various filters and where the filter event status is indicated. The filter event status is set when at the least one corresponding filter event is triggered. Based on the value of the RCWE field of the MAC_CSR_SW_Ctrl register, the status bits of the various policing counter status registers can be cleared either by writing 1 or by clear-on-read.

Table 729 Policing Counter Selection and Filter Status Indication

Filter Type	Register for Enabling/Selection of Policing Counter	Indicating the Filter Event Status in the Policing Counter Status Register
SA/DA pass	MAC_DPCSel_IndReg	MAC_PCStatus_DA_IndReg
VLAN pass	MAC_VPCSel_IndReg	MAC_PCStatus_VLAN_IndReg
L3_L4 pass	MAC_LPCSel_IndReg	MAC_PCStatus_L3L4_IndReg
Flexible Receive Parser and Stream-gate filtering	See the description of the bit position 91:80 in the "Flexible receive parser instruction table (IT) format" section.	Receive Parser, Receive Status
Filter fail	MAC_FPCSel_IndReg0	FFAIL field of the MAC_PCStatus_Filter_Event_IndReg

Related information

Flexible Receive Parser Instruction Table (IT) Format on page 1441

Policing the Bandwidth

The policing counters mapped to various filter pass events also provide bandwidth estimates of number of packets and the associated traffic type that are forwarded to the application. When a filter pass event's policing counter value exceeds the programmed threshold value, and the FFAT field of the MAC_PCCtrl_IndReg is set, the packets are treated as filter fail, and processed accordingly, until the associated counter is cleared. Therefore, the bandwidth policing is in terms of number of packets and not in terms of packet sizes.

When a packet is considered filter fail, based on the FFAT field of the MAC_PCCtrl_IndReg,

- A filter fail event is not asserted. This is because, there is no actual filter failure, but only a threshold exceed.
- Policing counters associated with the filter pass events are incremented and the status for the corresponding filter is also updated.
- If the filter corresponding to a filter pass event is not enabled to drop the packets using IPFE/VTFE and SAF fields of the MAC_Packet_Filter register, the packets are not dropped. Instead, the packets are forwarded to the application with a fail status.
- Multicast pass-all packets are forwarded to the application.

14.4.3.21.2 Stream-Gate Filtering

The flexible receive parser supports a subset of IEEE 802.1 Qci specification, stream-gate filtering. The stream-gate filtering support is based on stream-gate instance and stream filter instance. Policing or metering functions of the flow meter instance should be implemented by the application, as shown in the figure below.

- **Stream Filter**

  Identifies the Stream ID and maps to one of the eight Gate IDs; Only eight Gate IDs are supported
- **Stream Gate Instance**

  All Gate IDs share the same GCL

Based on the configuration, the flexible receive parser can parse the first 256 bytes of a frame. When you enable stream-gate filtering in the configuration, in addition to filtering and DMA channel routing, the parser performs stream-gate filtering. The result of the stream-gate filtering is based on the Gate ID of the received frames and the GCL programming. For details of the Gate ID and Gate ID valid fields, see the section "Flexible Receive Parser Instruction Table (IT) Format".

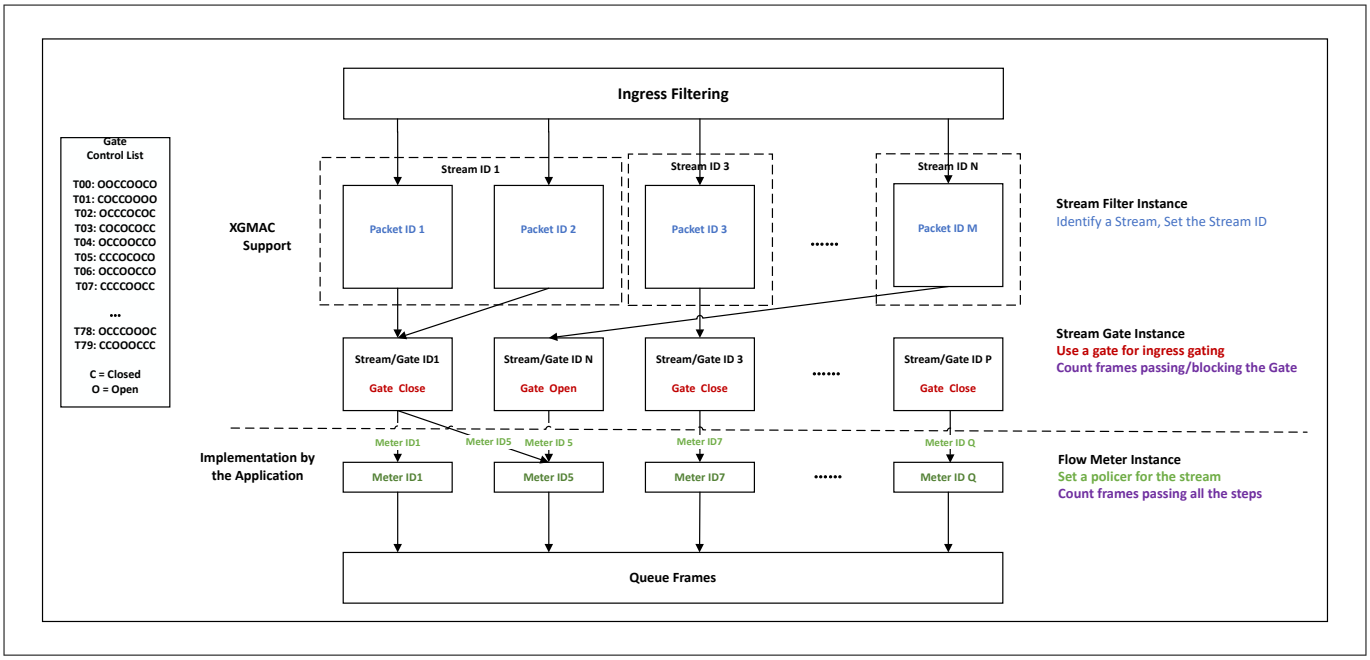

Figure 156 Block Diagram of Stream-Gate Filtering

When the Flexible receive parser result is available, the parser uses the Gate ID (GID field) of the Instruction Table and the Gate Open/Close status of the stream-gate filtering, to determine if the result is pass or fail. When the stream-gate filtering fails, the failed traffic is routed in one of the following ways:

- DMA channel, channel 0 for express traffic
- Channel number configured in the FPE_RCH field of Port j MTL RXP Control Status register, for preemption traffic

The details of the fail/drop are indicated by FPS[2:0] bits of RDES2 and RDES3 as shown in the table "Flexible Receive Parser Receive Status" in the section "Receive Normal Descriptor (Writ-Back Format).

When the stream-gate filtering passes, the frames are processed by the flexible receive parser.

If the receive management counter is enabled in the configuration, the stream-gate filtering tracks the pass/fail packets in the MMC_Stream_Gate_Passed_Packets and MMC_Stream_Gate_Failed packets counters respectively.

Stream-Gate Filtering with EST

To support stream-gate filtering with EST, flexible receive parser implements one external GCL memory that can be used by both EST and stream-gate filtering. A memory arbiter is used to avoid EST and stream-gate filtering accessing the same GCL memory simultaneously, as shown in Figure 157.

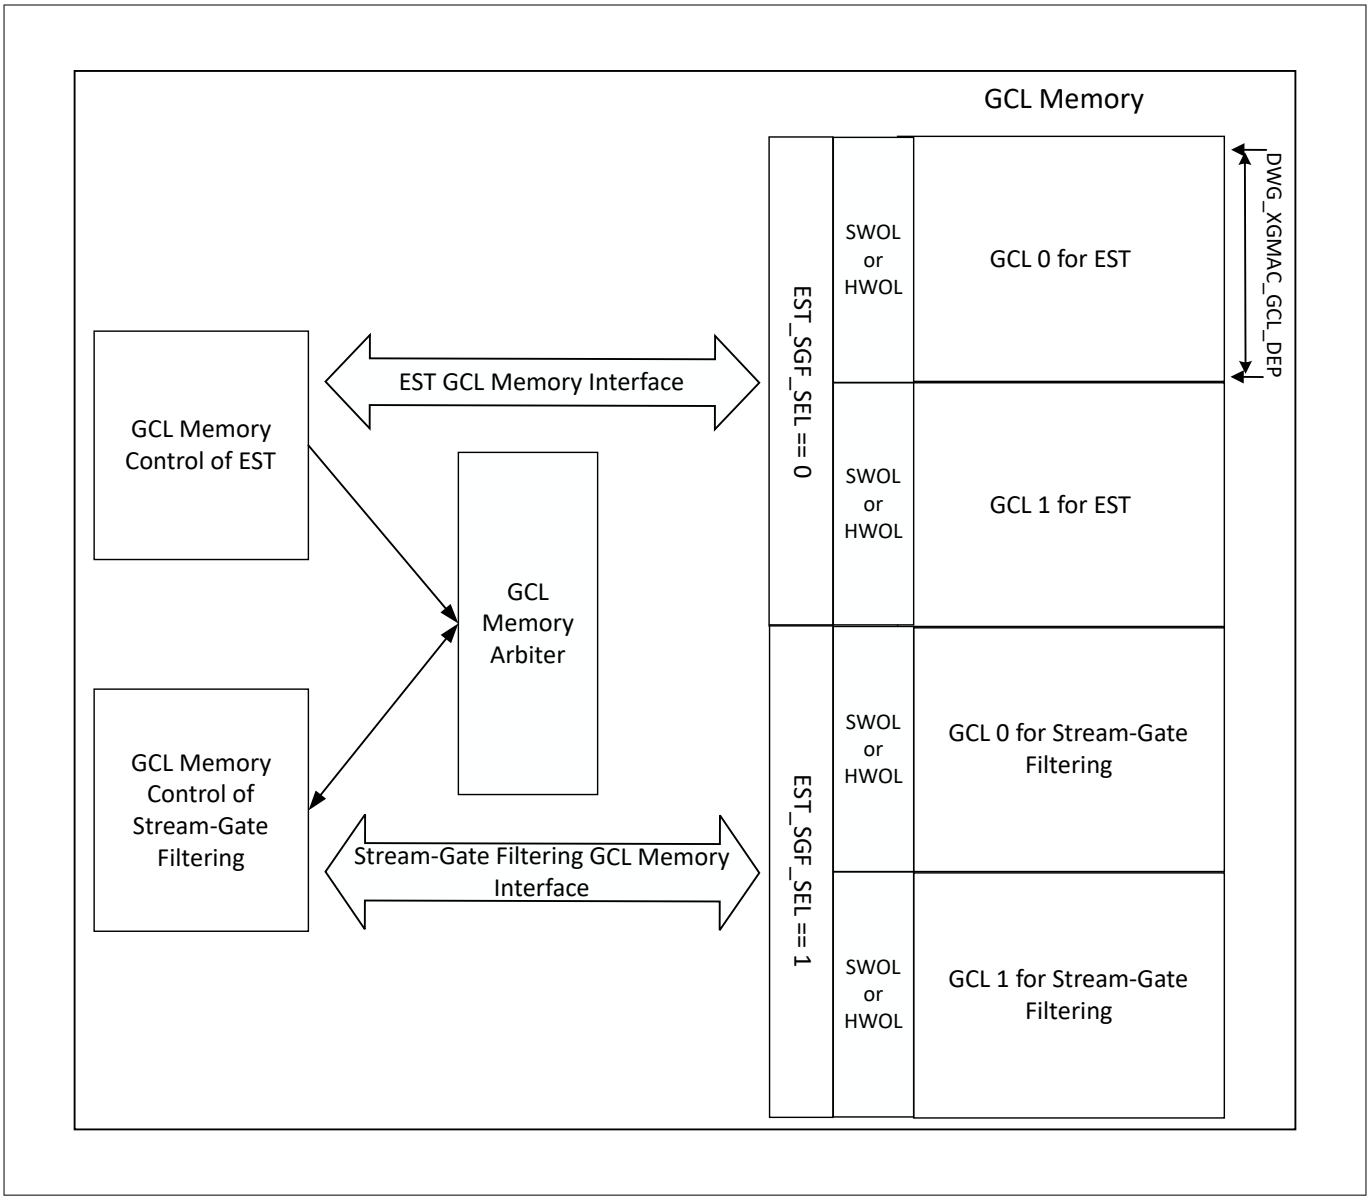

Figure 157 Memory Implementation for Stream-Gate Filtering with EST

Stream-Gate Filtering with Frame Preemption

When you enable stream-gate filtering for preemption frames, the filtering is performed on the preemption frames. For fragmented frames, stream-gate filtering is performed only on the first fragment. Continuation fragments are not considered for stream-gate filtering.

14.4.3.21.3 Enhancements to Scheduled Traffic (EST)

The IEEE 802.1Qbv-2015 defines the schedule for each of the queues on every egress port which makes the implementation aware of traffic arrival schedule. This information can be used to block the lower priority traffic from transmission in this time window/slot. This ensures that scheduled traffic is forwarded from sender to receiver through all the network nodes with a deterministic delay.

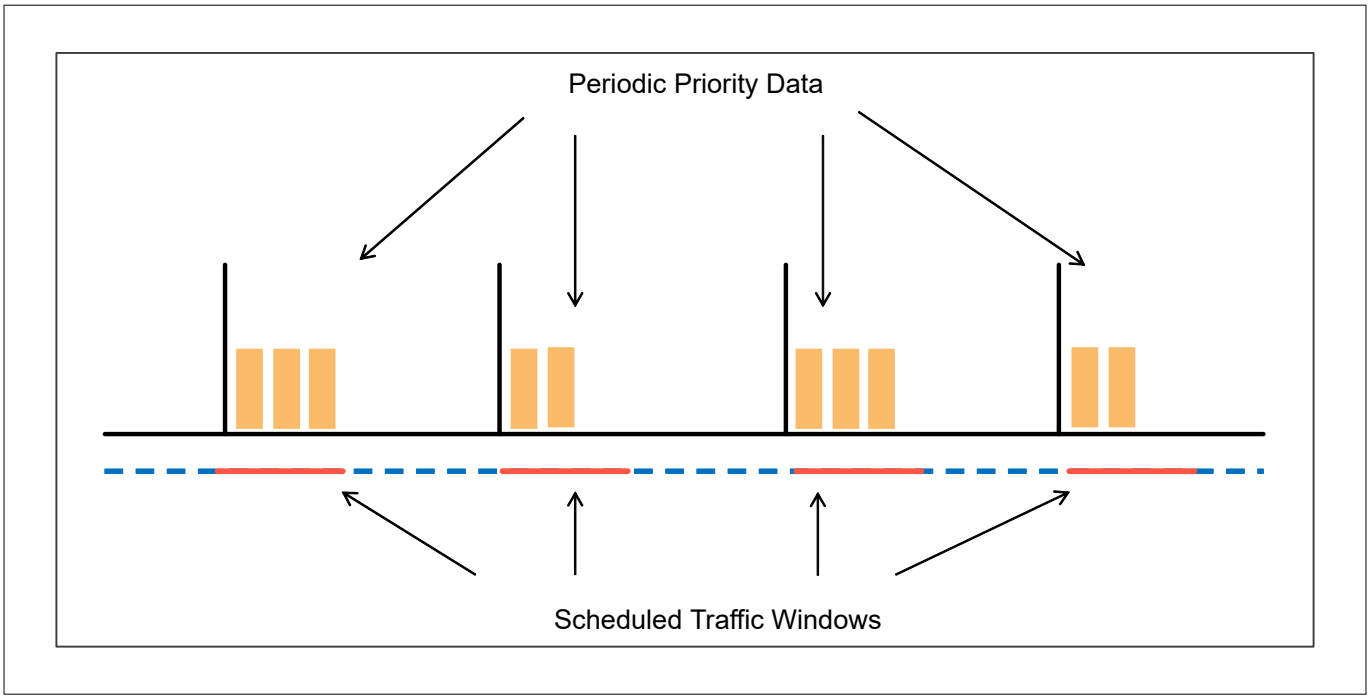

Figure 158 Time Aware Shaper Implementation for Traffic Scheduling

One of the important requirements to achieve a low latency is to ensure there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations while starting a transmission.

As shown in Figure 159, if an interfering frame begins transmission just before the start of a reserved time period, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

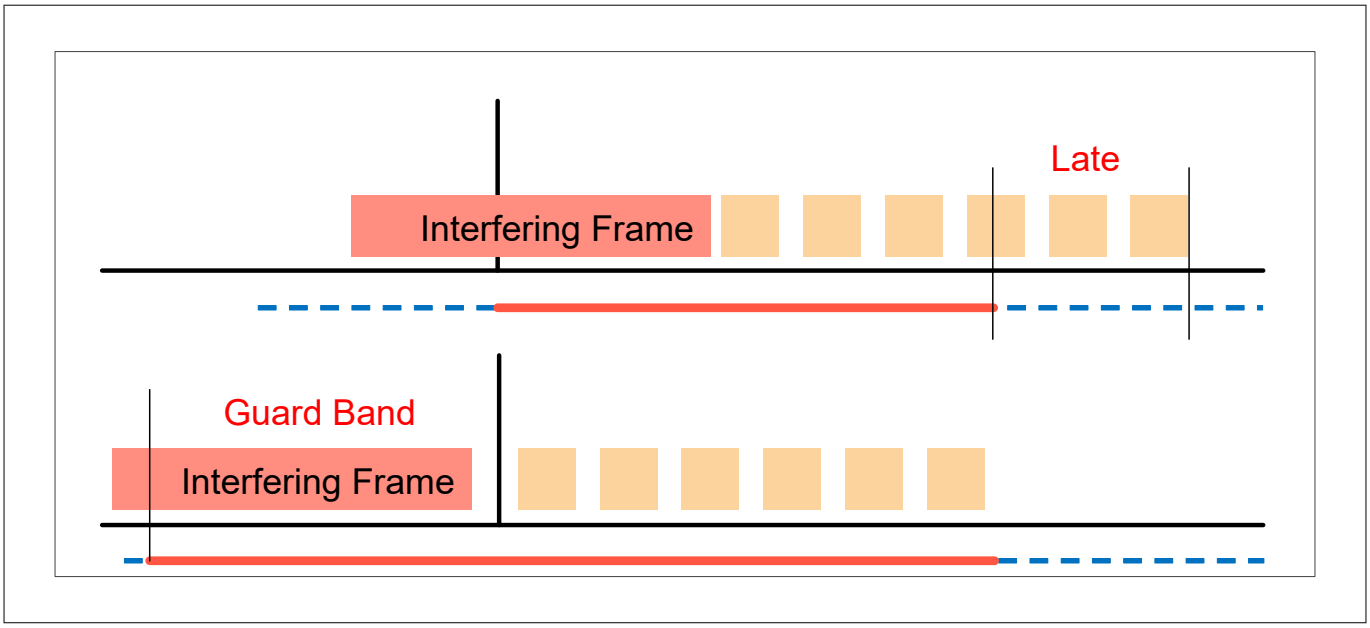

Figure 159 Implementing a Guard Band to Avoid Delays Due to Interfering Frames

A larger guard band equates to a less efficient use of network bandwidth. However, with the implementation of IEEE802.1Qbu (frame preemption), this issue is addressed. Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

Frequently Used Terms in EST

The following are some of the frequently used terms in the EST support and their definitions.

- Gate Control List

  The list in the hardware memory that holds the gate controls and the associated time intervals
- Gate Controls

  For a given schedule (row in gate control list) there is a Gate Open (O) and Gate Close (C) state associated with each Transmit Channel (TC). The set of O or C values, whose width is same as configured TCs is called the Gate Controls. For example, CCOCOOCO means TC7=C, TC6=C, TC5=O and so on
- Time Interval

  Time interval (in nanoseconds) is a 24-bit configurable field in the Gate Control list that indicates the time for which the associated gate controls are valid
- Base Time Register

  Each Gate Control List is associated with a 64-bit Base Time Register that holds the start time (in PTP format) for the list

Updates to the Transmit Scheduling to Support EST

To support EST, following updates are required to the transmit scheduling:

- Implementation of Gate Control List (GCL)
- Enforcing gate controls in the scheduler
- Accounting for Gate Open (O) duty cycle in the computation of idleSlope (CBS)

Implementation of Gate Control List (GCL)

Figure 160 shows block diagram from the IEEE 802.1Qbv spec that illustrates how the gate control list governs the gate close (C) and open (O) events based on the schedule provided for each event.

GCL has the following two parts:

- Time Interval

  Defines the time in nanoseconds for which the gate controls are valid and should be applied before reading the next gate controls from the list. Configurable width of 24-bits to represent a maximum of 16 ms schedule interval. Supports left shift of the time interval up to 7 bits (Portj_MTL_EST_Control.TILS) to be able to apply a multiplication factor from 1 to 128 ns (in steps of 2^n). The maximum value (post shifting) of this field is 999,999,999 ns

  ***Note**: The minimum time interval for CGL entry should be equal to the time required to transmit fragment_size + IPG/EIPG + preamble overheads*

- Gate Control

  Defines the Open (O) represented by logic 1 or Close (C) represented by logic 0 state for the gate of each TC

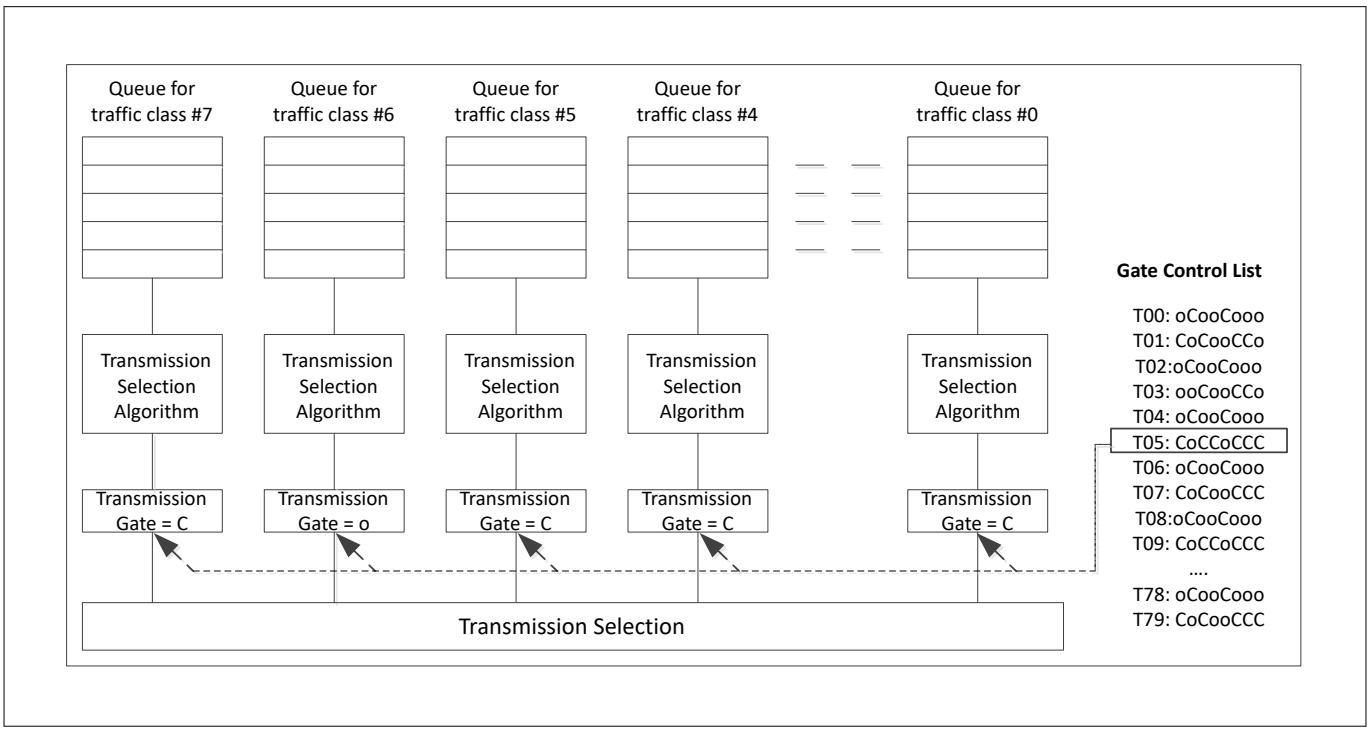

Figure 160 Block Diagram from IEEE 802.1 Qbv Specification - GCL Governing Gate Close and Open Events

The implementation of GCL consists of the following two Gate Control Lists:

- HWOL - Hardware Owned List which is a list for hardware access
- SWOL - Software Owned List which is a list for software access

The access to these lists is mutually exclusive. The ownership to the list is set by hardware in the SWOL field of Port j MTL EST Status register. The following table provides the implementation details of GCL.

Table 730 External Memory Used for Holding the Two Gate-Control Lists

Gate Control (up to 8 bits)	Time Interval (ns) 24 bits	
OOCCCCCC	T0	HWOL or SWOL
OOOOCCCC	T1	
CCCCOOCC	T2	
CCCCCCOO	T3	
…	…	
…	…	
OCOCOCOO		
OOOOCCCC	T last	
OOOOCCCC	T0	SWOL or HWOL
OOOOCCCC	T1	
OOCCCCCC	T2	
OOOOCCCC	T3	
…	…	
…	…	
OCOCCCCC		
OOCCCCCC	T last	

Registers Related to Gate Control List

Following are the set of 4 registers (one for each GCL) related to GCL. These registers are implemented through Indirect Addressing using the GCL_Control and GCL_Data registers.

1. 64-bit Base Time Register (BTR)
2. 40-bit Cycle Time (CTR)
3. m-bit Time Extension (TER)
4. n-bit [Gate Control] List Length (LLR) (n depends of the configured GCL depth)

Base Time Register (BTR)

Base Time Registers is a 64-bit register that holds the start time to execute the GCL. The format of the BTR is same as the PTP format (upper 32-bits holds time in seconds and lower 32 bits hold time in nano seconds). Once the execution of a given list begins, the implementation can update the value in BTR to indicate the next list execution begin time.

Cycle Time Register (CTR)

Cycle Time Register is a 40-bit register that holds the time at which the execution of the GCL should be repeated. The Cycle Time Register consists of an 8-bit value in seconds, and a 32-bit value in nano seconds (similar to the PTP time format with truncated seconds register).

For a given Gate Control List the start time is "Base Time" + N * "Cycle Time" where N is an integer value representing the iteration number starting with 0 for first iteration. If the Gate Control List execution takes longer than the Cycle time, then the list is truncated at the Cycle Time and the subsequent loop begins at Cycle Time.

Time Extension Register (TER)

Time Extension Register (TER) is a m-bit (where m = Configured Time Interval width + 7) register that holds the amount of time (in nano seconds) the current Gate Control List can be extended before switching to the new Gate Control List. This avoids smaller fragments of the current list being executed before switching to a new list.

List Length Register (LLR)

List Length Register (LLR) is an n-bit register (when n is 7, 8, 9, 10, or 11 for a GCL configured depth of 64, 128, 256, 512, or 1024 respectively) that holds the integer value of the length of the GCL (that is the number of valid rows in each GCL). The processing of the GCL stops after the number of rows read equals to the LLR value.

Transmission Gating Implementation

A Bridge or an end station can be enhanced to allow transmission from each TC that is yet to be scheduled relative to a known timescale. To achieve this, a transmission gate is associated with each TC; the state of the transmission gate determines if the queued frames can be selected for transmission.

For a TC, the transmission gate can be in one of the following two states:

1. OPEN

Queued frames are selected for transmission, in accordance with the definition of the transmission selection algorithm associated with the TC.

2. CLOSED

Queued frames are not selected for transmission.

A frame on a traffic class queue is not available for transmission if the transmission gate is in the closed state or if there is insufficient time available to transmit the entirety of that frame before the next gate-close event associated with that queue.

The implementation has visibility to the current schedule of gate controls and the immediate next schedule of the gate controls. So the maximum Gate Open period does not exceed the sum of the two Time Intervals. This is because, a frame is selected for transmission only if the gate is currently Open and the duration of gate open interval is greater than the time taken to transfer the entire frame.

The implementation must know the frame size before the transmission, so that the transmission overruns can be avoided and only the frames that can complete are scheduled at all times.

The implementation adequately compensates for the implementation delays in the data transfer from the buffer to the line by offsetting the current time with all the relevant delays (provided by the CTOV field of MTL_EST_Control register). This ensures that the schedule provided is always accurately implemented at the line.

***Note**:*

- *A 20 Byte overhead is added to the packet size to account for the IFG and Preamble overheads on the line. Therefore for a 128 Byte frame to be transmitted, the Gate Open window should at least be able to accommodate148 Bytes.*
- *In 100 Mbps mode of operation, the rounding down error is about 0.4%. For example, the Gate open duration must be at least 1024 Bytes for transmitting 1000 Byte Frames at a speed of 100 Mbps (20 Bytes for line overheads, and 4 Bytes for rounding down error)*

Idle Slope Computation Updates

When EST is enabled, credit is accumulated only when the gate is open; therefore, the effective data rate of the idleSlope must be increased to reflect the duty cycle for the transmission gate associated with the queue.

The idleSlope is computed based on the GateOpenTime and OperCycleTime values. Program the idleSlope registers (implemented one per CBS enabled TC) based on the following equation. The existing MTL register has sufficient bit width to accommodate the new values for idleSlope.

```
idleSlope = (operIdleSlope(N) * OperCycle/GateOpenTime)
```

Operational Details of GCL

Set the switch to software List, the SSWL field of the MTL_EST_Control Register, so that hardware can access the programmed gate control list. The first set of gate controls are applied when the current time is equal to the value in the Base Time Register (BTR) and is held until the programmed "Time Interval" value.

To avoid transmission overruns, one additional gate control event is always read ahead from the list. This enables the GCL to determine the next gate close events (if any) for the TCs that are open.

The scheduling based on the Gate Open state and Time Interval of only the current and subsequent schedule. An internal accumulator is used to add the time intervals when gate controls are applied. BTR + Accumulator holds the time at which the next set of gate controls are to be applied.

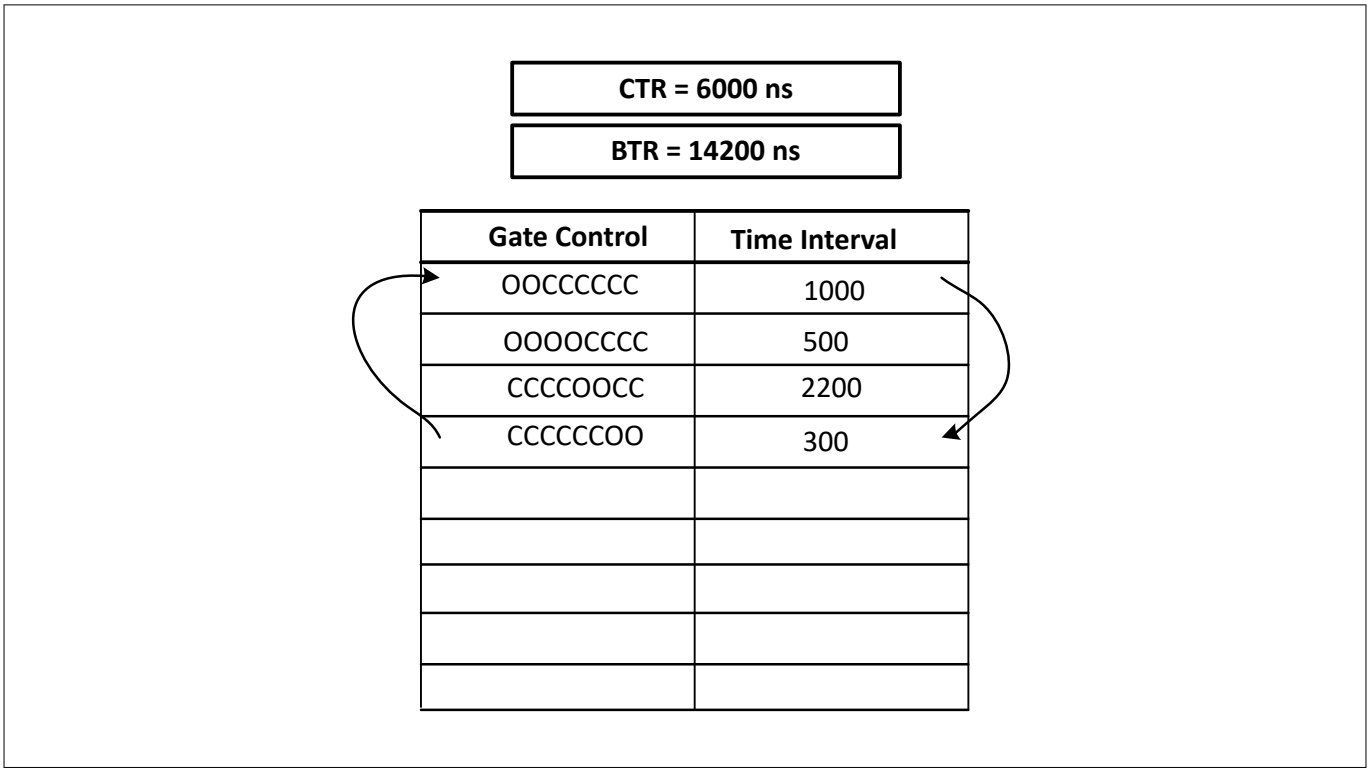

Figure 161 GCL and Associated Registers - BaseTime and CycleTime

The GCL is read progressively from the first row adhering to the schedule. The read operations continue until the List Length (from LLR Register) is reached and the execution of the list restarts at BTR + CTR time. At this point the BTR is incremented by value in CTR to mark the beginning of a new cycle. In the absence of any gate controls, all the gates are deemed to be in Open state, during the execution of the list.

In cases where the execution time of the list is greater than the CycleTime, the list is truncated and the next iteration starts when the current time equals BTR + CTR.

Table 731 GCL and Associated Registers - BTR and CTR

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17900	CCCCCCOO	4000	14200
18200	OOOOOOOO	0	20200
20200	OOCCCCCC	1000	20200
21200	OOOOCCCC	1500	20200

In the example in Table 731, the execution starts at 14200 and the first set of Gate Controls "OOCCCCCC" are applied immediately. As the time interval is 1000ns the next set of gate controls are applied at 14200 (BTR) + 1000 (Accumulator) = 15200 ns as shown in Figure 162. As there are no gate controls available after the execution of the last gate control and before the next iteration of the loop, the gates are deemed to be in open state during that time period as depicted at time 18200 in Table 731.

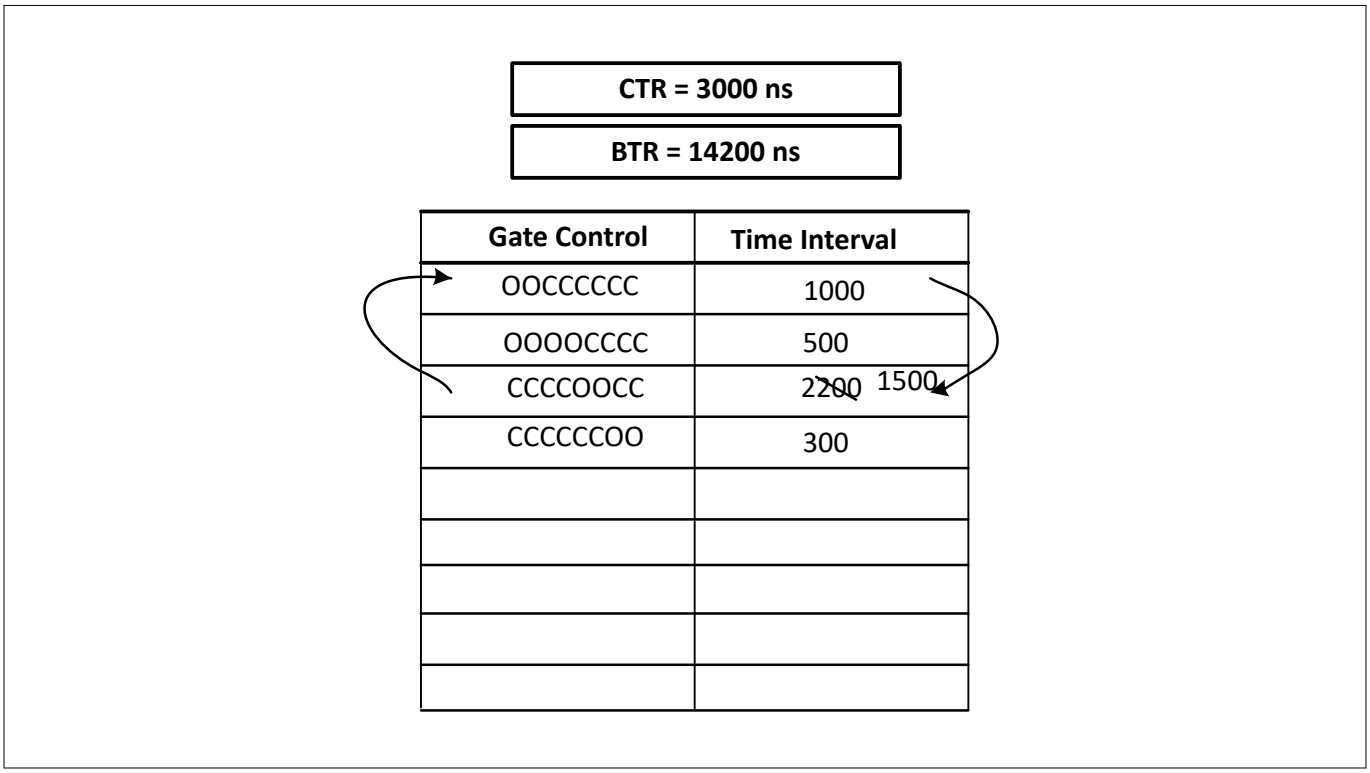

Figure 162 GCL and Associated Registers - BaseTime and CycleTime List Execution Time > CycleTime

As the list execution takes longer than the allocated CycleTime, the list is truncated and the list is started from the BTR+CTR as shown in Table 732.

Table 732 GCL and Associated Registers - BTR and CTR, Execution Time > Cycle Time

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCCCCC	1000	14200

(table continues...)

Table 732 (continued) GCL and Associated Registers - BTR and CTR, Execution Time > Cycle Time

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17200	OOCCCCCC	1000	17200
18200	OOOOCCCC	1500	17200
18700	CCCCOOCC	3700	17200

While applying the third set of gate controls, the BTR + CycleTime (17200) < BTR + Accumulator (17900), so the list is truncated and execution switches to a new iteration at 17200.

***Note**: When the CTR value is less than the GCL loop execution time, and the difference between the CTR and the sum of the BTR and Time Intervals of completely executed GCL rows is less than 8 PTP clock periods, then the first row of the first iteration of the next GCL is skipped. In order to avoid that, software must program the CTR, BTR, and Time Intervals of the GCL rows such that the difference between the CTR and the sum of the BTR and time intervals of fully executed GCL rows must be greater than 8 PTP clock period. If the above cannot be guaranteed by software, then the CTR must be equal to the sum of the BTR and Time Intervals of the fully executed GCL rows.*

Installing a New GCL

When a new software programmed GCL is available and must be executed at the new BTR value, the switch to the new GCL can happen in one of the following ways.

- New Base Time aligned with current schedule
- New Base Time unaligned with current schedule

New Base Time Aligned with Current Schedule

If the choice of cycle time for the new gating cycle is unchanged from the cycle time for the current gating cycle, and if the BTR chosen for the new gating cycle (new BTR) is an integer multiple of the current cycle time (+ current BTR), then the new gating cycle exactly lines up with the old gating cycle, that is, the cycle start times for the new gating cycle is same as they would have been for the old configuration. This could be considered to be the ideal case and allows the new gating cycle to be installed and executed with no timing issues. The implementation completes the execution of an iteration of the current list and switches to the new list at the beginning of the BaseTime listed in the new list.

If (New BaseTime > = Current Time) then,

1. ConfigChangeTime = New BaseTime

Else If (New BaseTime < Current Time)

1. Set the BTRError

2. ConfigChangeTime = (New BaseTime + N* New CycleTime)

where N is the smallest integer for which the relation ConfigChangeTime >= CurrentTime and (N =< 512) is TRUE

When N > 512, the hardware cannot auto recover and the loop count value in BTRL bit-field is set to 11111111 requiring the software to reprogram the New Base Time

Figure 163 illustrates the installation of the new GCL along with the timelines

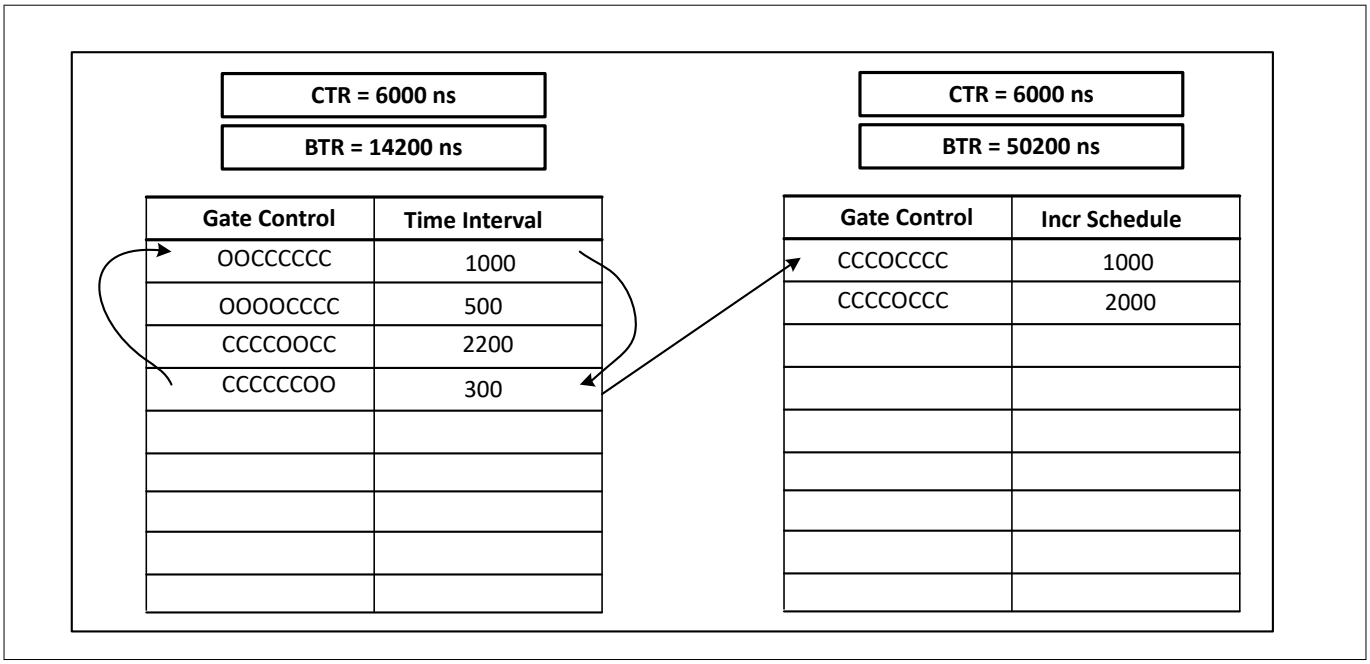

Figure 163 Switching to a New Configuration that is Aligned with the Existing Configuration

From the example in Figure 163, after the sixth iteration of the first GCL, the BTR values of the old and new GCL are equal. At that point the new GCL is processed as a natural extension to the existing GCL.

Table 733 GCL and Associated Registers - BTR and CTR

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
44200	OOCCCCCC	1000	44200
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200
47900	CCCCCCOO	4000	44200
48200	OOOOOOOO	0	50200
50200	CCCOCCCC	1000	50200
51200	CCCCOCCC	3000	50200
53200	OOOOOOOO	0	56200

New Base Time Unaligned with Current Schedule

If new CycleTime differs from current CycleTime or New BaseTime is in the future and is not an integer multiple of current CycleTime, then the old and new cycles do not line up; when new BaseTime is reached (when the new configuration is installed and starts to execute), the last old cycle is normally truncated to start the first new cycle. This could be undesirable if it results in a very short last old cycle; arguably it would be better to simply extend the penultimate old cycle by that small amount, rather than starting a very short cycle. The Cycle Time Extension Register (related to the current config list) allows this extension of the last old cycle to be done in a defined way; if the last complete old cycle ends normally in less than current Cycle Time Extension (TER) ns before the new base time, then the last complete cycle before new BaseTime is reached is extended so that it ends at new BaseTime.

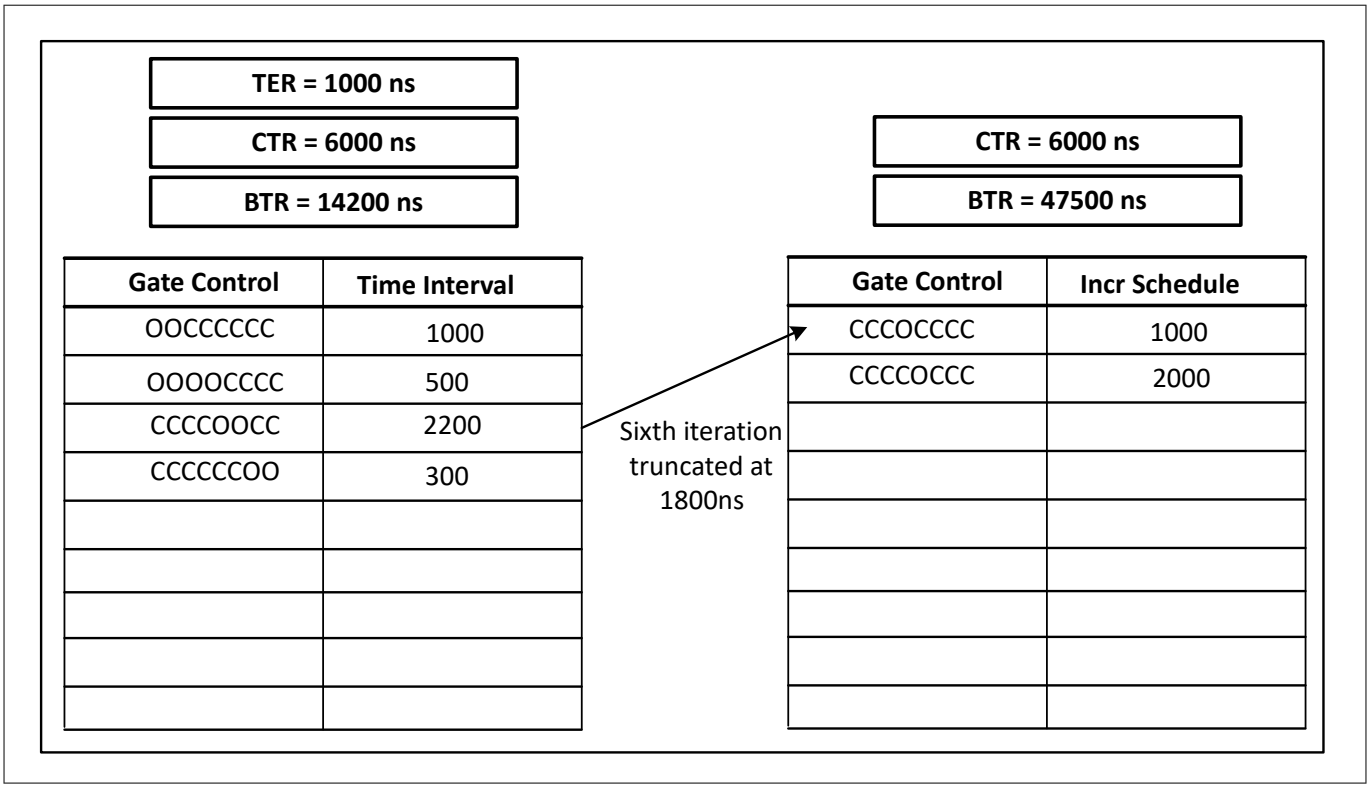

Figure 164 Switching to New List Truncating the Current List

At the end of the fifth iteration the Current time + Cycle time extension (TER) < New BTR so the sixth iteration of current configuration is started. During the sixth iteration of the current list when the new BTR value is smaller than the next schedule in the current list, it switches to the new list.

Table 734 Extending to New List By Truncating the Current List

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
44200	OOCCCCCC	1000	44200
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200
47500	CCCOCCCC	4000	44200
48500	CCCCOCCC	0	50200
50500	OOOOOOOO	1000	50200

In Figure 165, the current configuration list is extended instead of starting a new iteration as the extension time of 800 ns is less than the allowed cycle extension time (TER) of 1000 ns.

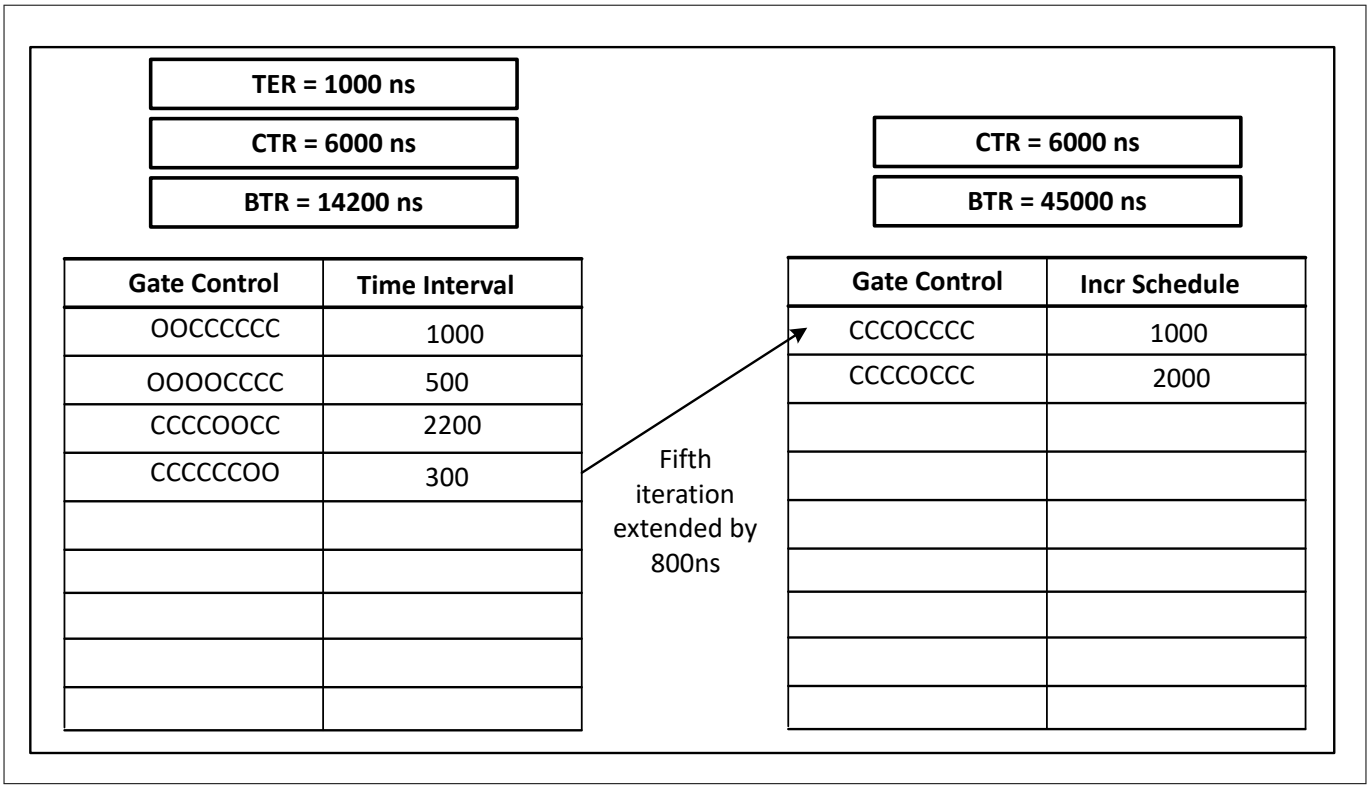

Figure 165 Switching to New List By Extending the Current List

Table 735 Switching to New List By Extending the Current List

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
38200	OOCCCCCC	1000	38200
39200	OOOOCCCC	1500	38200
39700	CCCCOOCC	3700	38200
41900	CCCCCCOO	4000	38200

Impact of Transmit Scheduling Algorithms on EST

When EST is used in isolation, the Gate Control List manages the final open/close state of the Transmit Class along with the checks carried out by the Transmission Selection Algorithm in MTL. As the Gate Controls operate on a predefined repetitive schedule, it is recommended to use Strict Priority or Credit Based Shaper (CBS) scheduling algorithms.

Weighted Round Robin (WRR) implements masking of the transmit channels based on the current winning transmit channel. The algorithm is applied only among the group of transmit channels that open simultaneously. To ensure transmit channels whose gates are "Open" get priority, these algorithms are modified to treat "gate open" transmit channels and "gate closed" transmit channels as separate groups giving priority to gate open transmit channels.

For example, consider four transmit channels (TC3, TC2, TC1, TC0) with weights 4:3:2:1; TC3 & TC2 are in an Open state in one slot, while TC1 & TC0 are in an Open state in another slot. In this case, the scheduler works as follows:

1. In the first slot, the TC3 & TC2 are serviced in the ratio of 4:3 for the duration the slot is open
2. In the second slot, the transmit channels TC1 & TC0 are serviced in the ratio of 2:1
3. Fresh arbitration is started every time a slot is opened

In other words, the traffic does not get distributed in the intended ratio of 4:3:2:1; but as two groups with different ratios and only for the duration of the slot when the gates are open continuously.

When multiple queues map to one TC, XGMAC has a first-stage scheduler (Round Robin) for the queue to TC selection. When EST is enabled, XGMAC uses an enhanced Round Robin. Based on the open window size of EST, the scheduler masks the round robin for queues whose frames do not fit in the window size. This ensures that the scheduler picks the correct queue in the Round Robin, considering the frame sizes too.

Error Reported in EST

Following are the errors reported in EST

- BTR Programming Error

  This error indicates that the value of the New BTR is less than the current time. XGMAC attempts to recover from this error by recursively adding the New Cycle Time to the New BTR such that

  For more details, see the BTRL field of the MTL_EST_Status register in the *"Register Description"* chapter.
- Constant Gate Control Error

  This error occurs when the list length (LLR) is 1 and the programmed Time Interval (TI) value after the optional Left Shifting is more than or equal to the Cycle Time (CTR).

  This implies that the Gates are either always Closed or always Open based on the Gate Control values. As this is not supported, it is reported as an error.

Interrupts in EST for Stream-Gate Filtering

Program the MTL_SGF_Interrupt_Enable register appropriately, to enable interrupts. The field position in this register to enable the interrupts correspond to the field positions in the MTL_SGF_Status register. When interrupt generation is enabled, the following events trigger the generation of an interrupt.

14.4.3.21.4 Frame Preemption (FPE)

Overview of the Frame Preemption

The IEEE 802.1Qbv-2015 defines the schedule for each of the queues on every egress port which makes the implementation aware of traffic arrival schedule. This information can be used to block the lower priority traffic from transmission in this time window/slot. This ensures that scheduled traffic is forwarded from sender to receiver through all the network nodes with a deterministic delay.

One of the important requirements to achieve a low latency is to ensure there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations while starting a transmission.

If an interfering frame begins transmission just before the start of a reserved time period, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

A larger guard band equates to a less efficient use of network bandwidth. However, with the implementation of IEEE802.1Qbu (frame preemption), this issue is addressed. Frame preemption breaks the interfering frame into

smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

Description of the Frame Preemption

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (preemptable) frame; the preemptable frame transmission is resumed and completed after the express frame transmission is complete. To support frame preemption, the following two abstractions of the MAC are used:

- A preemptable MAC, called pMAC, which carries the preemptable traffic
- An express MAC, called eMAC, which carries the express traffic

In the implementation, only parts of the MAC that holds the state during preemption is replicated and represented as pMAC and eMAC. The MAC uses the following two ways to puts on hold, the transmission of the preemptable traffic, in the presence of express traffic:

- The MTL scheduler interrupts the preemptable traffic that is currently being transmitted

  When the preemption capability is active, the MAC interrupts the transmission and reception of preemptable frames. A preempted fragment can be followed by zero or more express frames, before the continuation fragments. The preemptable frame can be fragmented any number of times, however, the minimum final and non-final fragment length criterion must be met.

  However, interleaving of more than 1 preemptable packet is not permitted. This implies that if a preemptable packet is fragmented by an express packet, another preemptable packet cannot be transferred until all the remaining fragments of the first preempted packet are transferred.
- The MTL scheduler prevents starting the transmission of preemptable traffic

  When the preemption capability is inactive, the pMAC entity is disabled and only express traffic is transmitted or received.

Enabling the Frame Preemption

Enable the frame preemption feature by setting EFPE field of the MAC_FPE_CTRL_STS register.

GCL Modification to Support FPE

In the EST-only configuration, the GCL entry has up to 24 bits of Time Interval and up to eight high order bits representing the Gate Open/Close state requirements as shown in Figure 166.

Gate Control (up to 8 bits)	Time Interval(ns) 16, 20 , or 24 bits
OOCCCCCC	T0
OOOOCCCC	T1
CCCCOOCC	T2
CCCCCCOO	T3
|	|
|	|
OCOCOCOO	T126
OOOOCCCC	T127

Figure 166 Gate Control List When FPE is Disabled

EST only supports SetGate operation, which implies that the gates are set to either open or close at a given time interval.

However, when both Frame Preemption (FPE) and EST are enabled, the GCL also supports Set-and-Hold-MAC and Set-and-Release-MAC operations, in addition to the SetGate operation.

To enable the support of hold and release operations, the format of the GCL is slightly changed while configuring and enabling the FPE. The first Queue (Q0) is always programmed to carry preemption traffic and therefore it is always Open. The bit corresponding to Q0 is renamed as Release/Hold MAC control.

The TX Queues whose packets are preemptable are indicated by setting the PEC field of the MTL_FPE_CTRL_STS register. The GCL bit of the corresponding Queue is ignored and considered as always "Open". So, even if the software writes a "0" ("C"), it is ignored for such queues.

Gate Control (up to 7 bits)	Release/Hold Indication	Time Interval(ns) 16, 20, or 24 bits
CCCOOOO	0	T0
CCCCOOO	0	T1
OCCCOOO	1	T2
COCCOOO	1	T3
CCOCOOO	1	T4
CCCOOOO	0	T5
CCCCOOO	0	T6

Figure 167 Gate Control List When FPE is Enabled

When the Release/Hold bit transitions from a 0_B to 1_B, a Set-and-Hold-MAC operation is performed. This marks the end of the preemptable traffic. This is achieved by sending a Hold request to MTL "ha" ns in advance (where

ha is the time interval mentioned in the Hold Advance (HADV) field of the MTL_FPE_Advance register).When the Release/Hold bit transitions from a 1_B to 0_B a Set-and-Release-MAC operation is performed. This marks the resuming of the preemptable traffic. This is achieved by sending a Release request to MTL "ra" ns in advance (where ra is the time interval mentioned in the Release Advance (RADV) field of the MTL_FPE_Advance register).The preemptable traffic is blocked for the time duration the Release/Hold bit is set to a 1_B in the Gate Control List.

***Note**: The value of HADV should be equal to the time required to transmit minimum_fragment_size + IPG/EIPG + Preamble, in nanoseconds.*

Impact of Preemption on CBS

In CBS, the definition of "Transmit" is as follows:

- TRUE for the duration of frame transmission from the queue;
- FALSE when frame transmission from the queue is complete.

When CBS algorithm is used along with frame preemption, the value of "Transmit" is TRUE only while the frame is being transmitted by the MAC. If the frame transmission is delayed or interrupted (for instance, a preemptable frame transmission is interrupted to allow the transmission of an express frame from a different queue, or the start of express frame is delayed because a preemptable frame is being transmitted) the value of "Transmit" is FALSE until transmission of the frame commences or is resumed.

Also, the value of "Transmit" is FALSE during the transmission of any overhead that is a consequence of frame preemption. For example, additional frame overhead (mCRC, Fragment Count) that is added to the preemptable frame.

At any given time, if there are no frames in the queue, and the value of Transmit is FALSE, and credit is positive value, the credit value is set to zero if here is no preemptable frame from the queue for which transmission is in progress but has been interrupted.

mPacket Format

When the preemption capability is active, MAC sends mPackets to the PHY. An mPacket can be one of the following:

1. A express packet
2. A preemptable packet
3. An initial fragment of a preemptable packet
4. A continuation fragment of a preemptable packet

Figure 168 shows the format of the mPacket. It contains an express packet, a complete preemptable packet or the initial fragment of a preemptable packet. Figure 168(b) shows the format of an mPacket containing a continuation fragment of a packet.

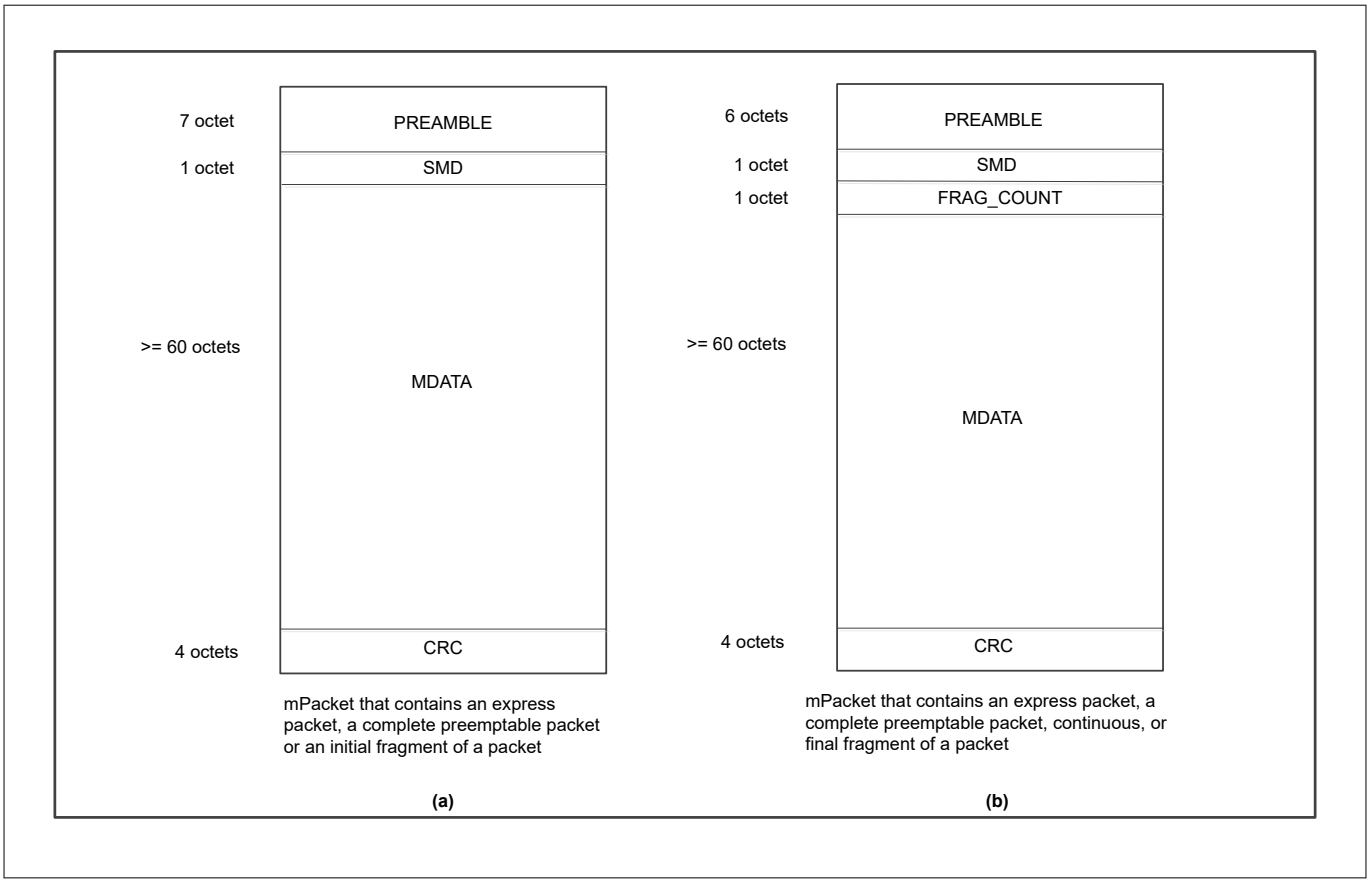

Figure 168 mPacket Formats

Preamble

The preamble in the mPacket shown in Figure 168 (a) contains seven octets. The preamble in the mPacket shown in Figure 168 (b) contains six octets. Each octet contains the value of 0x55 (transmitted in order from left to right 10101010).

Start mPacket Delimiter (SMD)

The value of the SMD indicates whether the mPacket contains an express packet, the start of a preemptable packet (initial fragment or complete packet), or any of continuation fragments of a preemptable packet. Table 736 shows the valid SMD values.

Table 736 Possible SMD Values of mPacket

mPacket Type	Notation	Frame Count	Value
verify packet	SMD-V	-	0x07
respond packet	SMD-R	-	0x19
express packet	SMD-E	-	0xD5
preemptable packet start	SMD-S0	0	0xE6
	SMD-S1	1	0x4C
	SMD-S2	2	0x7F
	SMD-S3	3	0xB3
continuation fragment	SMD-C0	0	0x61

(table continues...)

Table 736 (continued) Possible SMD Values of mPacket

mPacket Type	Notation	Frame Count	Value
	SMD-C1	1	0x52
	SMD-C2	2	0x9E
	SMD-C3	3	0x2A

frag_count

A frag_count is a modulo-4 counter that increments for each continuation fragment of the preemptable packet. The frag_count protects against mPacket reassembly errors by enabling detection of the loss of up to 3 packet fragments.

The frag_count field is present only in mPackets with SMD-C notation (continuation fragment). The frag_count is zero in the first continuation fragment of each preemptable packet.

Table 737 Possible frag_count Values

frag_count	Value
0	0xE6
1	0x4C
2	0x7F
3	0xB3

mData

The contents of the packet from the MAC, starting with the first byte after the SFD to the last byte before the FCS are sent in the mData fields of one or more mPackets for that frame. The minimum size of the mData field is 60 bytes.

CRC

The CRC field contains a cyclic redundancy check (CRC) and has an indication of the final mPacket of a frame. In the final mPacket of a frame, the CRC field contains the last 4 octets of the MAC frame (the FCS field).

For other mPackets, the CRC field contains an mCRC value. The mCRC is calculated on the octets of the packet from the first octet of the frame (the octet following the SFD of preemption frames) to the last octet of the packet transmitted in that mPacket by performing an XOR of the calculated 32 bit CRC value of the fragment and a value of 0x0000FFFF.

Summary of Packet Formats

- Express Packet
  7 bytes of PREAMBLE, SMD-E, Data, and CRC
- Complete Preemptable Packet
  7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, CRC
- Initial Fragment (non-final) of Preemptable Packet
  7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, mCRC
- Continuation fragments (non-final) of Preemptable packet
  6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, mCRC
- Final fragment of Preemptable packet
  6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, CRC

***Note**: When Frame Preemption is enabled, the MAC receiver communicates the exceptions related to received preempted fragments (incorrect fragment sequencing, missed fragment, and so on) to MTL layer by reporting it as CRC error. Software should not set the DCRCC (Disable CRC Checking for Received Packets) bit of MAC_Ext_Configuration register to 1; otherwise the MTL layer might forward the unintended preempted fragments to the application.*

Transmit Preemption

MTL Tx Preemption

To support preemption MAC should have more than 1 TX queue with at least 1 Queue designated as Express Queue. (and 1 queue designated as preemption queue). When FPE is enabled (setting EFPE=1 in MAC_FPE_CTRL_STS register), the MTL preempts a preemptable frame, when a “hold” request is asserted (EST/Qbv configured and enabled) express frames are available for transmission, that is, frame is present in MTL FIFO and is qualified for arbitration, after ensuring that the minimum mPacket mData field size is met. Therefore, preemption occurs only if at least 60 bytes of the preemptable frame have been transmitted and at least 64 bytes (including the frame CRC) remain to be transmitted.

The earliest starting position of preemption is controlled by the AFSZ field of the MTL_ FPE_CTRL_STS Register. Preemption does not occur until at least 64 * (1+ AFSZ) - 4 bytes of the preemptable frame have been sent.

When preemption occurs, all the preemptable queues are blocked and only the express queues are allowed to arbitrate (if more than one express queue has traffic) and transmit.

Continuation fragment of the preempted frame is the first frame to be transmitted after “release” request is asserted (EST/Qbv configured and enabled) and all the express traffic transmission completes.

***Note**: All the PTP packets should be transmitted as express packets.*

MTL communicates the following frame-type information to the MAC using a 2-bit preemption control signal on the MTI interface qualified by SoF and EoF.

- Express Frame
- Preemption Frame (Full or Fragment)
- Continuation Fragment (non-Final or Final)

Table 740 Preemption Control Values on MTI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

If the mti_sof_o and mti_eof_o are sent in the same cycle on the MTI interface, the mti_preemp_ctrl (Preemption Control Value) for EoF is taken as "00", End of Frame.

MTL should wait for the previous fragment status to be received before resuming the continuation fragments of a preempted frame. Fragment status is described in detail in the Tx Fragment Status section

MAC Tx Preemption

MAC supports preemption by implementing the functionality needed to generate the mPackets as described in the section "mPacket Format".

Based on the Preemption Control value received on the MTI interface (qualified with SoF and EoF), MAC determines the frame type (shown in the table "Possible SMD values of mPacket") and generates mPackets accordingly.

When the preemption capability is active, MAC replaces the SFD of a preemption packet with an SMD-S value. A 2-bit rolling frame count is encoded in the SMD-S value.

The SMD-E value is the same as the SFD value so the SFD of an express packet does not need to be replaced.

Related information

mPacket Format on page 1537

Tx Fragment Status

MAC sends Tx fragment status to indicate successful transmission of fragmented mPackets. To indicate a fragment status, bit-31 of the mti_txstatus_o field is set and all other values in the status field is set to '0'.

In case of a transmission error (underflow, jabber, and so on) the frame status is sent (and not a fragment status) with an error indication along with all other relevant status fields. The bit-31 of mti_txstatus_o is set to '0' to indicate a Frame Status. In case of receiving an error status for a transmitted fragment, the MTL drops the remaining fragments and does not send any more continuation fragments.

Receive Preemption

MAC Receive Preemption

When FPE is enabled, the MAC Receiver pases the incoming packets and differentiates between Express packets and preemptable packets. An SMD containing an SMD-E indicates express packet, and SMD containing an SMD-S indicates the first mPacket of a preemptable packet.

If an mPacket containing an SMD-S is received when MAC has not completed receiving the previous preempted packet, MAC sets a CRC Error status for the previously received partial packet.

When an SMD-S is detected, MAC records the frame count indicated by the SMD and then begins sending data on the MRI interface.

The MAC checks the last four bytes of the mPacket . If the last four bytes of the mPacket do not match CRC, that indicates the end of the packet with or without a CRC error as per the CRC check result. If the last four octets of the mPacket match, that indicates that the packet was preempted.

An SMD containing an SMD-C indicates an mPacket that continues the data for a preempted packet. Upon receiving an SMD value of SMD-C, MAC checks the following:

1. A preempted packet is in progress
2. The frame count indicated by the SMD matches the frame count of the packet in progress
3. The frag_count value indicates the next fragment count.

If any of these checks fail, the mPacket is discarded and MAC sets a CRC Error status for the partially received packet.

If all the checks pass, the next fragment count is incremented modulo 4.

When a packet is preempted, the MAC saves the state of the partially received packet (filter check status, timestamp, length fields and so on) and processes the received Express packets until the continuation fragment is received.

The MAC Receiver sends a "dummy status" (all zeros in mri_rxstatus_o) for all the mPacket fragments successfully received and sends the Rx status with the final fragment. If an error is detected during any of the fragments the Rx status is sent and the fragment is marked as final fragment. All subsequent continuation fragments received for this packet are dropped in the MAC.

The MAC communicates the following frame type information to the MTL using a 2-bit preemption control signal on the MRI interface qualified by mri_sof_o and mri_eof_o.

1. Express Frame
2. Preemption Frame (Full or Fragment)
3. Continuation Fragment (non-Final or Final)

Table 741 Preemption Control Values on MRI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

If the mri_sof_o and mri_eof_o are sent in the same cycle on the MRI interface, the mri_preemp_ctrl (Preemption Control Value) for EoF is taken as '0' indicating End of Frame.

***Note**: Minimum Preemptive fragment size supported on Rx is 48 bytes*

Data Alignment

When a received frame cannot be fragmented on any byte boundary, MAC retains the unaligned bytes of data in the previous fragment and resends them with the next fragment as shown in Figure 169.

MTL can choose to ignore the partial data (based on Byte Enable value) that comes with End of Fragment and instead use the "data width aligned" data received in the first beat of the next continuation fragment.

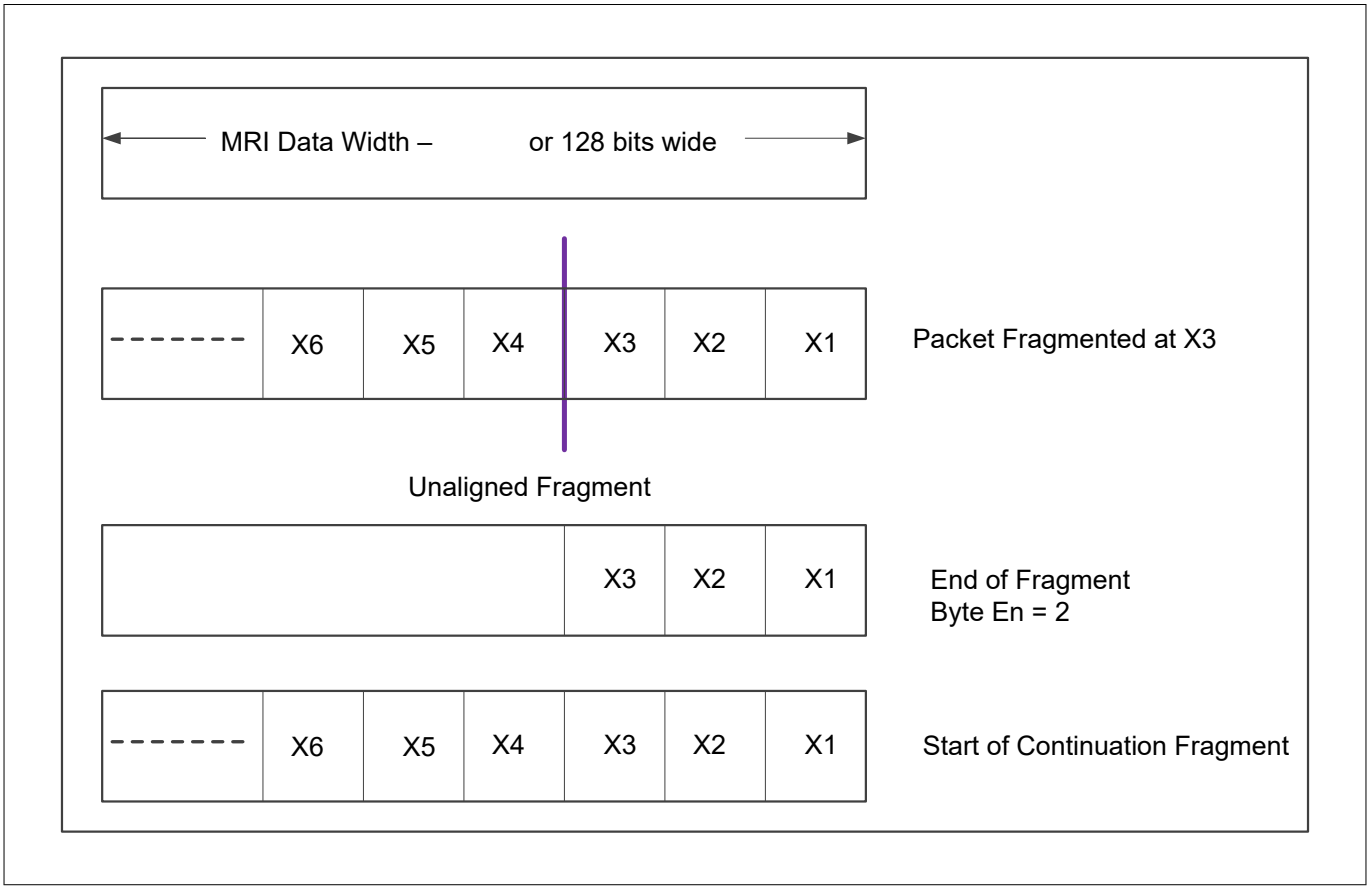

Figure 169 Data Alignment Feature of MAC

MTL Receive Preemption

The MTL RX must have at least 2 Receive Queues to support FPE function as the preemptable packets and the express packets must be routed to separate RX Queues. The destination RX Queue of a received packet is controlled by MAC_RxQ_Ctrl(#i) registers. These must be carefully programmed such that Preemptable traffic and express traffic are not routed to the same RX queue. As the Queue mapping for tagged packets is based on VLAN user-priority field, this means that priority of preemptable and express packets are exclusive to each other. In other words, packets of a certain priority (traffic class) are either express or preemptable but cannot be both.

If MCBCQEN of MAC_RxQ_Ctrl1 register is set, preemptive Multicast/Broadcast packets are routed to PMCBCQ as programmed in MAC_RxQ_Ctrl4. Therefore, ensure that PMCBCQ is not same as any of the queues programmed for express queues.

Preemption traffic routing is carried out as shown in Table 742.

Table 742 Preemption Control Values on MRI Interface for Various Frame Types

Preemption Packet Type	Queue Routing
Multicast and Broadcast Preemptive Frames passing the SA/DA and VLAN filters with MCBCQEN field of MAC_RxQ_Ctrl1 register is set	PMCBCQ[1)]
AV Tagged Packets passing the SA/DA and VLAN filters	PSRQ[2)]
Generic Tagged Packets passing the SA/DA and VLAN filters	PSRQ[3)]
Tagged Packets failing the SA/DA and VLAN filters without setting the Receive All (RA) or setting VTFE	Dropped
All other packets	RQ

1) Only if the queue is enabled for AV feature
2) Only if the queue is enabled for generic VLAN feature
3) Only if the queue is enabled for AV feature

In addition to the PSRQ (Priority Selected in Rx Queue) based Queue routing and PMCBCQ (preemptive multicast/broadcast queue), a programmable “Residue Queue” (RQ) is provided to route all other preemptive packets received (Untagged, SA/ DA or VLAN Filter Fails forwarded due to RA (receive all) being set or VTFE being reset). In case of filter fail, Queue 0 is used as the default queue. So Q0 should not be used by the preemptive traffic routing. Therefore, RQ cannot be programmed as 0.

MTL Receive Arbitration

On the ARI Interface, data is fetched from the MTL Rx FIFO based on the arbitration selected in the MTL_Operation_Mode register. Frame based arbitration can be used only when all the MTL Preemption Queues are operating in Store and Forward mode. Otherwise there is loss of bandwidth on the ARI interface because all the fragments of a preemptable packet are not available. Therefore, express packets received between the fragments are blocked until all the fragments are received and transferred; this defeats the purpose of express traffic.

When operating in either Threshold (cut through) or Store and forward modes of operation, PBL based arbitration is recommended over Frame based arbitration. In case of PBL based arbitration, the watermark check is always performed and the arbitration/transfer of data in terms of chunks of “PBL” size of data which is almost similar to the concepts of “fragments”. Therefore the express queue packets get blocked for less time as well as the ARI interface transfers the data without loss of efficiency.

Received preemption frames support in offload engines

When Frame Preemption is enabled, all PMT, PTP and PAUSE packets must be received as express/normal packets. These offload engine logic and functions do not recognize preemption frames.

Verify and Respond mPackets

When FPE function is present, the MAC can receive and detect the Verify and Respond mPackets, even when FPE is not enabled by software. When MAC detects valid Verify/Respond mPackets, it notifies the software by setting the RVER and RRSP fields of MAC_FPE_CTRL_STS register respectively. Optionally an interrupt can be generated. As such packets have empty (all-zero) data payload, they are dropped inside the MAC and not forwarded to the MRI.

Software can set the SVER and SRSP fields of MAC_FPE_CTRL_STS register to request MAC to transmit Verify and Respond mPackets respectively. Upon successful transmission of these frames, MAC clears the SVER/SRSP bits and sets the TVER & TRSP fields of MAC_FPE_CTRL_STS register. Optionally an interrupt can be generated when these events occur.

When Frame Preemption is enabled,

- For the preemption frames received with CRC error indication, ignore the following status fields
  - Packet length
  - Dribble error indication
  - Runt frame indication
- The preemption frames received with CRC error and with sizes ranging from 64 to 67 bytes are treated as runt packets. So, the corresponding MMC Rx Frame Counter for Runt Frames is incremented
- Do not disable CRC checking on receive. This is required because, internally, FPE error fragments are identified using CRC checks. For more details, see the DCRCC field in the MAC_Ext_Configuration Register in the section "Registers"
- Forward Undersized Good Packets (FUP) field of MTL_RxQ_Operation_Mode register should not be set. A new programmable mode bit (ARV) to autogenerate a Respond packet up on receiving a Verify packet is added

Frame Preemption and MMC Counter and Interrupt Registers

The following MMC counters and associated Interrupt registers are instantiated/present in the MAC when Frame Preemption feature and any one of the existing MMC counters are selected during RTL configuration.

Table 743 MMC Counters and Associated Interrupt Registers

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame Assembly Error Counter	A 32-bit counter that provides the number of MAC frames with reassembly errors on the Receiver, due to mismatch in the Fragment Count value.	MMC_Rx_Packet_Assembly_Err_Cntr
Frame SMD Error Counter	A 32-bit counter that provides the number of received MAC frames rejected due to arriving with an SMD-C when there was no preceding preempted frame	MMC_Rx_Packet_SMD_Err_Cntr

(table continues...)

Table 743 (continued) MMC Counters and Associated Interrupt Registers

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame Assembly OK Counter	A 32-bit counter that provides the number of MAC frames that were successfully reassembled	MMC_Rx_Packet_Assembly_Ok_Cntr
MAC Rx Fragment Counter	A 32-bit counter that provides the number of additional mPackets received due to preemption	MMC_Rx_FPE_Fragment_Cntr
MAC Tx Fragment Counter	A 32-bit counter that provides the number of additional mPackets transmitted due to preemption	MMC_Tx_FPE_Fragment_Cntr
Hold Request Counter	A 32-bit counter that maintains the count of number of times a hold request is given to MAC	MMC_Tx_Hold_Req_Cntr

Additional Registers Associated With MMC Interrupts

Following are the additional registers associated with MMC interrupts for the MMC error counters:

- MMC_FPE_Tx_Interrupt
- MMC_FPE_Tx_Interrupt_Mask
- MMC_Rx_Interrupt
- MMC_FPE_Rx_Interrupt_Mask

14.4.3.21.5 Time-Based Scheduling

Time-based scheduling feature is suitable for traffic whose periodicity and rate are predictable. This is an optional feature. To improve the quality-of-service of such traffic,

- The transmit DMA fetches the packet from the host memory for transmission at designated time. This helps the software to setup the Transmit descriptors in advance even before packet is ready/available. It reduces the overhead on the software and avoids constant monitoring of the time and preparing descriptors just in time when the packet is targeted to be transmitted.
- The MAC transmits the packet only at the designated/pre-determined time even if the packets are fetched in advance. This helps in maintaining a constant transmission rate that can be consumed by the receiver station; therefore avoiding congestion and excessive buffering in the network.

Description of Time-Based Scheduling

The time-based scheduling feature supports fetching and launching an Ethernet packet at (or after) a pre-determined time. The time-based scheduling is supported only in the following modes/configurations:

- Full duplex mode
- Link speed is 100 Mbps or higher
- Time-stamping is enabled.

***Note**:*

- *Do not enable time-based scheduling (or enhanced descriptors) for the channel for which transmit timestamp or one-step timestamping control correction feature is enabled.*
- *When fetch time is enabled, overrides the audio-video slot function.*
- *In EST enabled configurations, the ESTM mode bit setting impacts the time-based scheduling feature only when the DUT processes the GCL list.*
- *When an unaligned new GCL list (with a different CTR) is installed, ensure that there is no traffic during the installation of the new list. Traffic during the switching of the lists might result in unpredictable behavior regarding Fetch, Launch, and Launch expiry as the CTR and BTR values are updated while the frame is being processed.*

Definitions Used

Following are the definitions specific to the time-based scheduling feature:

- Launch Time

  The time beyond which MTL can schedule the packet for transmission
- Fetch Time

  The time beyond which the Tx DMA can schedule a packet-fetch from the host memory
- Expiry Time

  The time beyond which the packet is dropped by MTL

Launch Time

The launch time is specified in the Transmit Enhanced Descriptor in the DMA configurations. For more details, see the section "Enhanced Descriptor for Time-Based Scheduling".

The launch time can also be specified as a Control Word for each packet in the MTL configurations.

When the launch time is specified in the DMA configuration, it is valid only for the specific frame that is scheduled for transmission. The launch time is reset after the transmission of one frame.

Following are the two formats of the launch time.

- Normal/Absolute Format
- EST/Offset Format

Normal/Absolute Format

In this format, the Launch time is an absolute time value at which the packet is launched for transmission. The launch time is interpreted in the Normal/Absolute format if the ESTM bit of the MTL_TBS_CTRL register is set to 0.

The launch time is a 32-bit value, where most-significant 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns. The launch time is compared against the IEEE 1588 based System/PTP Time (bits[39:8]) and rolls over after 256 seconds.

The maximum value of the lower 32-bits of System Time is 999,999,999 decimal (0x3B9AC9FF) and it wraps to 0 when reaching this value (representing a full second). Therefore, the maximum value of the lower 24 bits of the Launch Time (after multiplying by 256) must be 0x3B9AC9.

As the maximum value of Launch time is 256 seconds,

- Launch Time is greater than current System Time when its value is between System Time[39:8] and System Time[39:8] + 128 sec
- Launch Time is less than current System Time when its value is between "System Time[39:8] + 128sec" and "System Time[39:8] + 256 sec", because this is a modulo 256 computation

EST/Offset Format

In this format, the Launch time is a offset value relative to the time indicated by the Base Time Register (BTR) of the GCL list provided in the GCL Slot Number (GSN). The value in the BTR is always updated to the start time of the current loop of the GCL.

For each packet, the GSN value and the Launch Time value are specified in the Transmit Context Descriptor in the DMA configurations, or as Control Word in the MTL configurations.

The launch time offset is a 32-bit value; the upper 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns, which is added to the BTR value corresponding to GCL Slot Number. The value of the Launch Time Offset must be smaller than the value of the Cycle Time (specified in the CTR register that is implemented when EST is enabled).

If the CTR is greater than or equal to 1s, the maximum value of the lower-24 bits of Launch Time offset should be 999,999,999 decimal (0x3B9AC9FF).

In this format, the launch time is a 64-bit value, which is interpreted as,

Launch Time = Launch GSN BTR[63:0] + (Launch Time Offset[31:0] << 8), which is compared with the System Time [63:0].

GSN BTR is the Base Time value at which the Launch GSN loop started execution.

GCL Slot Number (GSN)

A modulo 16 count of the GCL loop count is implemented and known as GSN. The count is incremented for every new GCL loop; installation of new GCL list does not impact the count. The current GCL slot number can be obtained by reading the CGSN field of the MTL_EST_Status register.

The maximum value of GSN is 15. Therefore GSN values between Current GSN (CGSN field of MTL_EST_Status register) and CGSN+8 represent current or future slots; all other GSN values are interpreted as elapsed slots or past slots. So, for the correct interpretation of time, GSN value must be between CGSN and CGSN+8, for correct interpretation of time.

Launch Expiry Time

Normal/Absolute Mode

In the normal mode, when the LEOV (Launch Expiry Offset Valid bit of MTL_TBS_CTRL register) is set, the Launch Expiry Offset (LEOS field of MTL_TBS_CTRL register) determines the maximum amount of time a frame is eligible for launch, starting from the time the frame becomes eligible for launch.

The Launch Expiry Offset is a 24-bit value defined in 256ns units, with a maximum possible value of 999,999,999 ns (0x3B9AC9FF).

Launch Expiry Time = (Launch Time[39:8] + LEOS[32:8]) * 256ns

The packet with a specific Launch time is considered eligible for transmission when the Launch time is less than the System Time and (if LEOV is set) the System Time is less than the Launch Expiry time.

When the System time is greater than the Launch Expiry time, the frame is categorized as expired and is dropped from the MTL FIFO.

***Notes**:*

1. *For correct interpretation and meaningful operation, the Fetch, Launch, and Launch Expiry time should never be set to a value larger than Current System Time + 128 seconds; such a value is interpreted as time that has already elapsed*
2. *In full duplex mode, the frames dropped from the MTL FIFO have Error Summary (Bit 15) and TBS Drop (bit 3) of Transmit Status set*

EST/Offset Mode

In the EST mode of operation, when the LEOV field of the MTL_TBS_CTRL register is set, the launch expiry GSN offset (LEGOS field of the MTL_TBS_CTRL register) and Launch Expiry Offset (LEOS field of MTL_TBS_CTRL register) determine the maximum amount of time a frame remains eligible for launch, starting from the time the frame becomes eligible for launch.

Launch Expiry Offset = (LEGOS: LEOS)

LEGOS holds the GSN offset (multiples of CTR time) and LEOS holds maximum value of CTR (sub CTR values) in ns.

Launch Expiry offset is a 24-bit value defined in the units of 256 ns, with a maximum possible value of the smaller of 999,999,999ns or CTR-1 ns.

The Launch Expiry GSN is computed as follows:

Launch Expiry GSN = (Launch GSN + LEGOS + CCMA)

Where,

CCMA is the CTR Carry due to Modulo addition. This value is 1 if ((Launch Time Offset + LEOS) << 8) is equal to or greater than CTR. When CCMA = 1,

Launch Expiry Offset = (Launch Time Offset+ LEOS) - CTR

When CCMA = 0,

Launch Expiry Offset = (Launch Time Offset + LEOS).

Launch Expiry Time = Launch Expiry GSN BTR[63:0] + Launch Expiry Time Offset.

When LEOV is not set, Launch Expiry Time is not checked.

When LEOV is set, and

- the system time is greater than the Launch Expiry time, the frame is dropped from MTL FIFO. The frame is considered as expired
- the launch time is smaller than the System Time and Launch Expiry Time is greater than system time, the frame is considered eligible for launch

***Notes**:*

1. *Max value of LEGOS is 7. This implies that when LEOV is set, the frame has a maximum life time of <8 GCL loop iterations after it becomes eligible for Launch*

2. *The slot number of the First GCL List executed each time after EST is enabled, is zero*

3. *All computation in TBS EST mode is done with a granularity of 256 ns*

Fetch Time

The Fetch Time can also be indicated for each packet by the software. This is done by setting FTOV field of DMA_TBS_CTRLn (where n = 0, 1, 2, 3) register.

If the FTOV filed is not set, the Fetch Time Offset is not valid and the DMA fetches packets without any time constraints.

The fetch time accounts for all possible delays in the DMA fetch operation and ensures that the frame is present in the MTL FIFO before the launch time.

***Note**:* *The application must program the respective channel's TFSEL bit of DMA_CH(#i)_TX_Control register to select the specific DMA_TBS_CTRLn register to use.*

Normal/Absolute Mode

In the Normal mode fetch time derived/calculated by reducing the time specified in the Fetch Time Offset (FTOS) field of DMA_TBS_CTRL register from the given Launch time.

Normal mode of operation, the Fetch Launch Time is computed as:

Fetch Time[39:8] = (Launch Time[39:8] - FTOS[31:8])

The Fetch time is 32-bits and is compared against System Time[39:8] to determine the Eligible for fetching the frame:

- The Fetch time is defined as "greater" than System Time if the Fetch Time is in the range of "System Time[39:8]" and "System Time[39:8] + 128 seconds". The frame is considered as not-eligible for fetch
- The Fetch time is defined as "smaller" than the System Time if the Fetch time is in the range of "System Time[39:8] + 128 sec" and "System Time[39:8] + 256 seconds". The frame is considered as eligible for fetch

This is a modulo 256 computation.

EST/Offset Mode

In the EST/Offset mode, the Fetch GSN Offset (FGOS field of MTL_TBS_CTRL register) provides the Slot Number offset to be deducted from the Launch GSN. In this case the FTOS value should be the smaller of 999,999,999ns or CTR-1 ns.

If (Launch Time Offset >= FTOS):

Fetch Time Offset = ((Launch Time Offset - FTOS) * 256ns)

CBFS(CTR Borrow for Fetch Subtraction) = 0

If (Launch Time Offset < FTOS)

Fetch Time Offset = CTR + ((Launch Time Offset - FTOS) * 256ns)

CBFS (CTR Borrow for Fetch Subtraction) = 1

The Fetch GSN is computed as follows:

Fetch GSN = Launch GSN - FGOS - CBFS

Fetch Time = Fetch GSN BTR[63:0] + Fetch Time Offset

The frame is marked eligible for DMA fetch when the fetch time is smaller than the System Time.

Note:
- *Maximum value of FGOS is 7. This implies that when FTOV is set, the frame can be fetched at a maximum of < 8 GCL loop iterations before it becomes eligible for Launch*
- *An interrupt is generated when a frame is dropped due to Launch time expiry. For more details, see the section "Registers"*

DMA Operations Sequence

Enhanced Descriptor should be used for Time-Based Scheduling. For more details, see the section "Enhanced Descriptor for Time-Based Scheduling.

Following is the sequence of operation when FTOV = 1.

1. Fetch the first Transmit Enhanced Normal Descriptor. (Check the FD in the Normal Descriptor)
2. If LTV is set and Fetch is enabled, compute the Fetch Time based on the Launch Time. Wait for the System Time to be greater than Fetch Time
3. Read the Frame (Data) from the host memory and transfer to MTL FIFO
4. Close the Enhanced Normal Descriptor
5. Fetch the next Normal Descriptor (if the previous Descriptor was not the Last)
6. Repeat steps 4 to 6, until the last descriptor of the frame (LD is set)

After the Last Descriptor of a frame, program the next Transmit Enhanced Normal Descriptor with a new Launch Time and with LTV bit set. Otherwise, the subsequent frames are processed without any time restrictions.

Control Word (MTL Configurations)

Time-based scheduling ensures that a packet is allowed to arbitrate for transmission only if the System Time is greater than the Launch Time.

In MTL configuration,

- Launch Time and GSN, use the same field that is used to hold the 64-bit timestamp value for OSTC (One Step Timestamping Correction). If the LTV (Bit 31, TBSDW0) bit is set and OSTC and OSTPA bits are not set (bit 19 and 15 of first control word), the Time Stamp field is interpreted as Launch Time
- The last two Control D-words is considered to the Time Stamp for OSTC, when bit-19 of Control-Word0 (OSTC) is set

When the MTL TXFIFO Read Controller reads the first control word, both bit 19 and bit 15 are reset, it fetches the next control word. When the next control word's bit 31 (TBSDW0) is set, the frame has a valid Launch Time (as per the description of TBSDW0 and TBSDW1). If bit-31 is set, it reads the subsequent control words to get the Launch Time. F.

Impact on Transmission Selection Algorithm

Time-Based Scheduler does not directly influence the Transmission Selection Algorithm but has an indirect influence as it determines if a queue is eligible to participate in the scheduling.

If a frame of a specific queue has a valid Launch Time, the Time Based Scheduler ensures that the frame participates in Transmit Scheduling (TRC Scheduler) only after the Launch time has elapsed.

The gating done by Time-Base scheduler is only for the Scheduling (picking frame for Transmission). It might not alter any other characteristics and behavior of the frame. For example, the Frame waiting for the Launch time to lapse continues to gain credits in CBS. The CBS credits are not lost, as the frame is marked as available but not ready. Strict Priority or CBS are recommended Transmit Scheduling algorithms for the TBS implementation because, scheduling for TBS enabled queues are more predictable.

14.4.3.22.1 Description of ECC protection for memories

The Error Correction Code (ECC) block can correct single-bit error and detect double-bit error.

At the write interface, ECC check bits are generated by computing ECC on the contents of the data bus and respective address is appended with the data that is written to the memory.

At the read interface, ECC check bits are recomputed on the content of the read data and the respective address is compared with the received check bits in the memory.

The figure below shows the block diagram of ECC protection for memories

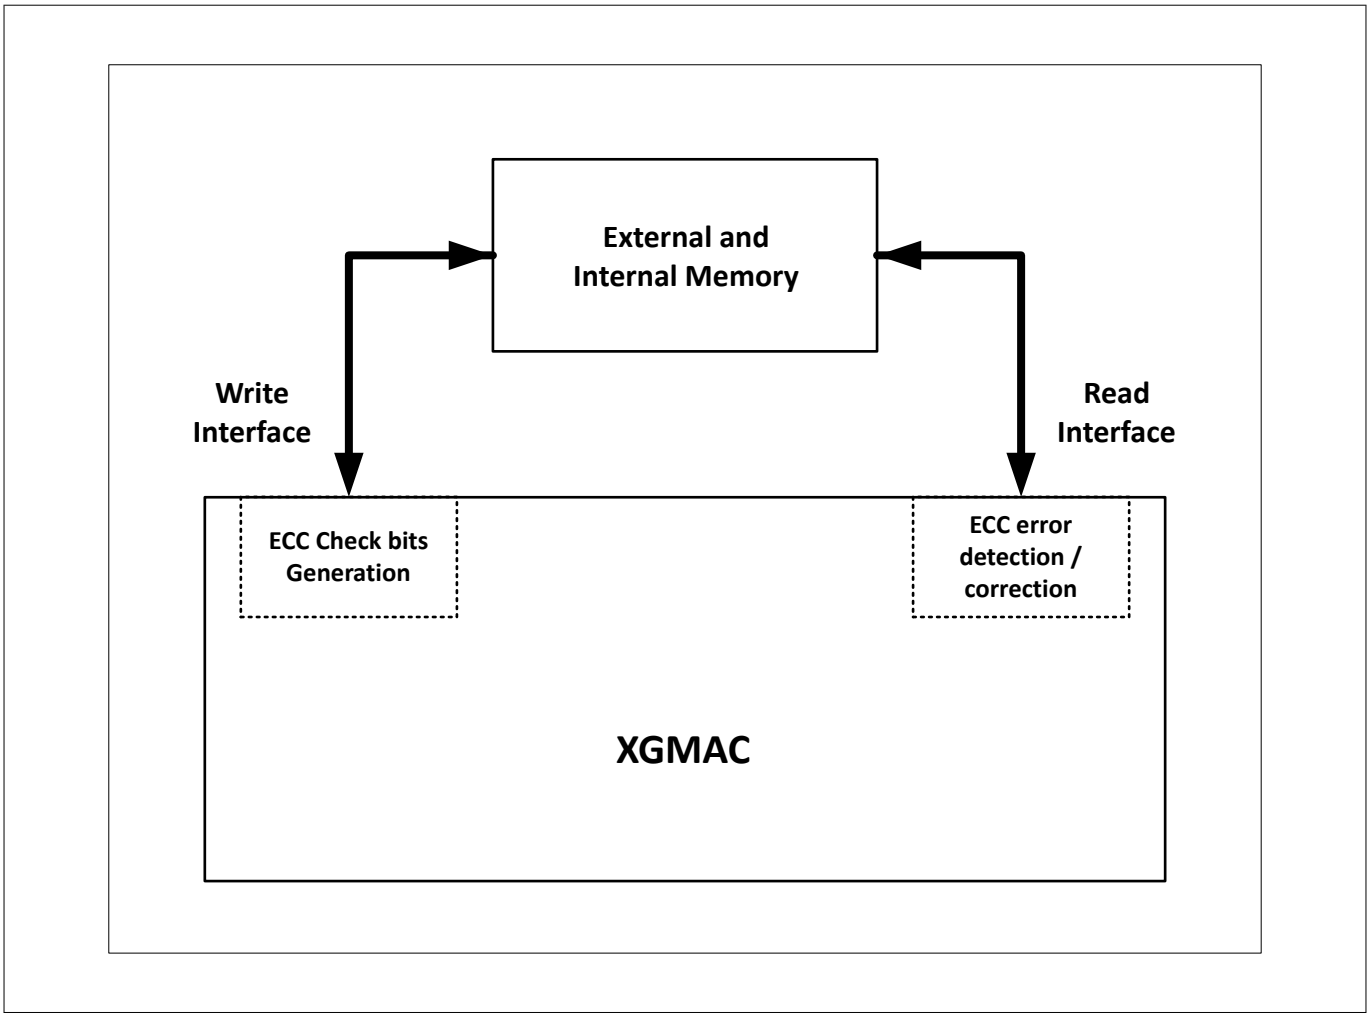

Figure 170 Block diagram of ECC protection for memories

The number of ECC check bits generated for each data block depends on the size of the data bus and address bus.

ECC generator is added to all the memory interfaces in XGMAC. These are:

- Two-port RAM/single-port RAM memories used for the TX Queues and RX Queues in the MTL
- Single-port RAM memory used for the Gate Control List in the 802.1Qbv EST function
- Register array without ECC used for the Instruction Table of rules for the Flexible RX Parser
- Single-port RAM memory used for the descriptor cache

The table below describes the memory bus widths, ECC code size and the generated check bits size.

Table 744 Memory bus width, ECC code size, and checkbits size

Memory block	Configured data width	Additional control bits	Total data width (without ECC)	Address width (Depends on memory size)	ECC code reference range	Required check bits	Total data width (with ECC)
MTL Tx Memory (2 memories)	64	4	68 bits	12	Total Data width + Address width <= 120bits	8 bits	76 bits
MTL Rx Memory (2 memories)	64	4	68 bits	12	Total Data width + Address width <= 120bits	8 bits	76 bits
EST / GCL Memory	32	0	32 bits	8	Total Data width + Address width <= 26 bits Total Data width + Address width <= 57 bits	7 bits	39 bits
Descriptor cache memory	64	0	64 bits	9	Data width + Address width <= 120 bits	8 bits	72 bits

Handling uncorrectable errors

Recovery from an uncorrectable error is based on the memory block and the operating mode of XGMAC.

- MTL Tx memory:

  If an uncorrectable error is detected, the packet is terminated with a forcible EOF. A CRC error (`mti_ecc_err`) is introduced by MAC for the transmitted packet, and the remaining packets in the FIFO are flushed and flush status (bit 13) is indicated to the application.

  When an uncorrectable error is detected, the application should reset XGMAC IP to ensure proper functionality.

  ***Note**: The MTL FIFO flush is issued for XGMAC to recover with limited support.*

  XGMAC generates an interrupt to indicate to the application that a correctable, uncorrectable or address mismatch error has occurred and the status is indicated in `MTL_ECC_Interrupt_Status` register
- MTL Rx memory:

  When an uncorrectable error is detected, reset XGMAC IP to ensure proper functionality.

XGMAC generates an interrupt to indicate to the application that correctable, uncorrectable or address mismatch errors are detected and the status is indicated in MTL_ECC_Interrupt_Status register

***Note**: Issue soft reset*

- MTL EST memory:

  When an uncorrectable error is detected in the MTL EST memory, XGMAC follows these sequence of actions for recovery:

  1. XGMAC disables the EST feature by resetting the EEST bit of MTL_EST_Control register. It sets all the gates to open state, generates an interrupt, and sets the status in the MTL_ECC_Interrupt_status register. This allows the software to reprogram the correct value in the EST memory
  2. The location of the uncorrected error in the EST memory is available in the EUEAS/ECEAS field of the MTL_ECC_Err_Addr_Status register

  XGMAC generates an interrupt to indicate to the application if any correctable, uncorrectable and address mismatch errors are detected and the appropriate status is indicated in MTL_ECC_Interrupt_Status register.

  Software must reprogram and restart EST after an uncorrectable error is reported in the EST memory. Issuing a reset is not mandatory in this case, but other factors might cause a need to reset
- Internal Register Based Instruction Table of MTL Rx Parser Memory:

  When an uncorrectable error is detected in the Instruction Table (IT) of MTL Rx Parser, the parser halts the parsing of all subsequent packets by disabling the parser. After the software completes the necessary steps against the detected ECC error, it can re-enable the FRPE field of the MTL_Operation_Mode register, to continue parsing.

  XGMAC generates an interrupt to indicate to the application that correctable, uncorrectable, or address mismatch errors are detected and the status is indicated in the MTL_ECC_Interrupt_Status register

  ***Note**: Same error could be detected and reported by the periodic flexible receive parser memory checks performed by XGMAC. To avoid recursive reporting of injected ECC UE error, perform a valid write to the corrupted memory location*

Diagnostic Support for the Error Management

Following statistics are provided for monitoring the error behavior on each of the memory blocks.

- Error status provided to management
  - A separate status for correctable, uncorrectable, and address mismatch is specified in the MTL_ECC_Interrupt_Status register
  - Memory locations at which correctable and uncorrectable errors are detected is specified in the MTL_ECC_Err_Addr_Status register. In addition, a control bit (MEEAO field of MTL_ECC_Control register) decides, whether the first errored memory address is reported or the latest errored memory address is reported
  - MTL_ECC_Err_Cntr_Status register has separate counters to count the number of correctable and uncorrectable errors
- Interrupts provided to management
  - Separate interrupts are generated for correctable and unrecoverable errors
  - The sbd_sfty_ue_intr_o interrupt is generated when unrecoverable errors are detected and these errors cannot be masked

- The sbd_sfty_ce_intr_o interrupt is generated when correctable errors are detected. XGMAC sets the respective interrupt enable bits (in the DMA/MTL_ECC_Interrupt_enable register)
- To find the root cause of the error, read the DMA/MTL_Safety_Interrupt_Status and DMA/MTL_ECC_Interrupt_Status registers
- To clear the interrupt, write 1 in the respective interrupt status bit in DMA/MTL_ECC_Interrupt_Status registers

For more details, see the section "Registers".

***Note**:*
- *The status/counters/interrupts are generated per memory*
- *MTL Tx and Rx memory is logically divided into multiple queues. But, ECC diagnostics (status/counter/interrupts) are common to all queues*

Registers on page 802

ECC Error Injection Capabilities

XGMAC supports error injection capabilities for each memory as a static configuration. You can program the position where the errors are injected in the data word/address/ECC bits. This depends on the EIM/BLEI field of the MTL_DPP_ECC_EIC and 3 control bits of the MTL_Debug_Control/MTL_EST_CGL_Control registers. For each memory, four control bits and eight error locations bits are provided to inject errors:

- One bit to enable error injection (EIEE/ESTEIEE field of the MTL_Debug_Control/MTL_EST_GCL_Control register).
- One bit to enable address error injection (EIAEE/ESTEIAEE bit in MTL_Debug_Control/MTL_EST_GCL_Control)
- One bit to enable data or ECC error injection (EIM field of the MTL_DPP_ECC_EIC register).
- Eight bits to indicate the bit location of error injection (BLEI field of MTL_DPP_ECC_EIC register).
- One bit to indicate the type of error to be injected (EIEC/ESTEIEC field of MTL_Debug_Control/MTL_EST_GCL_Control register).

  Position of the error bit should be programmed ahead of error injection.
- One bit to indicate the type of error to be injected
  - 0: 1 bit error
  - 1: 2 bit error

ECC address error injection supports only 1-bit error injection. DUT does not detect multiple bit address error. However, in the ECC 2-bit error injection mode,

- 1-bit error is always inserted at the 0^{th} bit.
- Other 1-bit error is inserted at the location indicated by the BLEI field of MTL_DPP_ECC_EIC register. If BLEI is configured to 0, XGMAC inserts only 1-bit error, at the 0^{th} bit.

While using ECC error injection in the debug mode,

- There should be no traffic in XGMAC
- When multiple CSR writes are required for writing single data word into the memory, the application should ensure that all the CSR writes corresponding to one memory write maintains the same value for the error injection control word.

The control bit descriptions for

- MTL Tx/Rx descriptor cache memories are specified in the MTL_Debug_Control register. MTL_DPP_ECC_EIC register should be programmed before MTL/DMA_DPP_Control register.

- MTL EST memory are specified in the `MTL_EST_GCL_Control` register
- Rx parser are specified in the `MTL_RXP_Indirect_Acc_Control_Status` register

14.4.3.22.2 Finite State Machine (FSM) parity and timeout protection

Overview

The FSM protection feature supports FSM parity and time out protection.

FSM State Parity Protection

XGMAC implements one-hot encoding scheme for holding the state register. Odd parity is implemented on all the FSM state register bits. Parity is monitored for every clock, after the reset is de-asserted. When a bit flips due to transient errors or permanent faults, the erroneous FSM is set to its default state and an unrecoverable error is indicated.

When the FSM state parity protection is enabled, by setting PRTYEN field of MAC_FSM_Control Register, the FSM state error is indicated by setting the FSMPES field of the MAC_DPP_FSM_Interrupt_Status register. Also, the Safety Interrupt (sbd_sfty_ue_intr_o) is asserted when an FSM Error is detected.

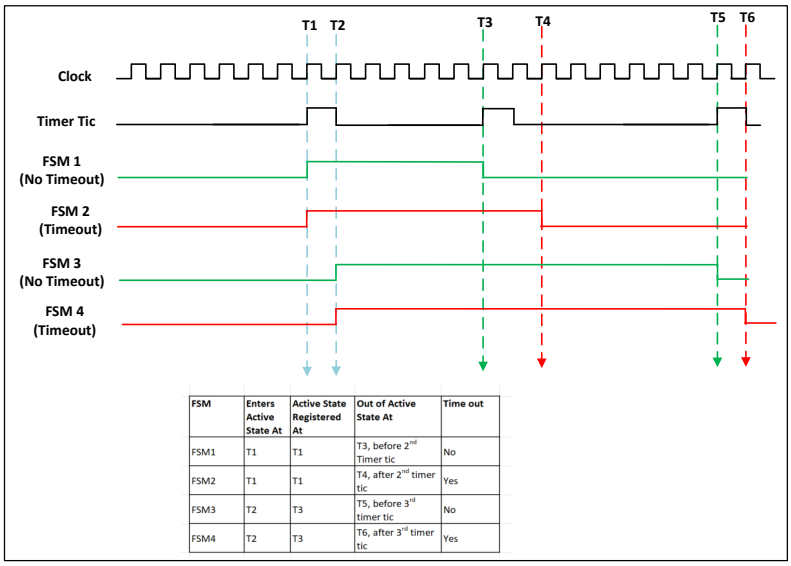
Error Injection mode is also supported for FSM parity error check. Program the Error Injection enable for the respective clock domain denoted by [23:16] bits of MAC_FSM_Control Register.

***Note**: The FSM Parity error is classified as non-recoverable error and software intervention (IP reset) is required to recover from the error state.*

FSM Timeout Protection

The FSM Timeout feature provides a mechanism to ensure that all FSMs in XGMAC can complete a transaction and return to a known completion state (IDLE or any other state that indicates completion of a transaction/ transfer) within the programmed timeout value.

Program the TMR field of MAC_FSM_ACT_Timer register with a value that indicates the number of CSR cycles required to generate a 1 microsecond tic. This microsecond tic is internally used to generate the programmed timeout duration. Two timeout tics (normal mode timeout and large mode timeouts) are generated to provide flexibility to choose one per clock domain, by using the bits [31:24] of MAC_FSM_Control Register. Supported values for Timeout duration are 1us, 1.024ms, 16.384ms, 65.5536ms, 262.144ms, 1048.576ms (~1sec), 4194.304ms (~4s), 8.388s, 16.777s, and 33.554s which is based on the programmable bits NTMRMD, LTMRMD fields of MAC_FSM_ACT_Timer register. Interface timeouts are based on the normal mode tic generation; only the FSM timeouts depend on either normal or large tick selection.



FSM	Enters Active State At	Active State Registered At	Out of Active State At	Time out
FSM1	T1	T1	T3, before 2nd Timer tic	No
FSM2	T1	T1	T4, after 2nd timer tic	Yes
FSM3	T2	T3	T5, before 3rd timer tic	No
FSM4	T2	T3	T6, after 3rd timer tic	Yes

Figure 171 FSM Timeout Timing Diagram

In Figure 171, the timer ticks are generated based on the programmable timeout value. The timer ticks are synchronized and made available in all the clock domains that have the FSMs.

At every timer tick, all the FSMs are monitored for active state (non-IDLE state, which indicates the FSM is actively processing transactions or hand-shakes) and an FSM active flag bit is set. The active flag bit is implemented for every FSM that is monitored for timeout. When the FSM reaches an IDLE or transaction completion state, the active flag bit of that FSM is reset. At the subsequent timer tick, all the FSMs' active flag bits are monitored and any flag that is set indicates a timeout for that FSM. This process of setting the flag and checking at subsequent timer tick is repeated at every tick.

Timeout Error Injection per clock domain is enabled by programming [15:8] fields of MAC_FSM_Control register. When Timeout error injection enable is set for a clock domain, the FSMs in that clock domain automatically timeout and generate an interrupt even without traffic. As error injection is a debug mode, TMR value need not indicate 1us, but can be programmed to a smaller value at which debug mode ticks are needed. FSM Timeout and Parity Error Injection modes can be used for testing at key-on/key-off.

The FSM timeout status is specified in the [15:8] field of MAC_DPP_FSM_Interrupt_Status register as per the respective clock domains. One FSM timeout status bit is made available per clock domain. The safety interrupt (sbd_sfty_ue_intr_o) is asserted when the timeout error is set for any of the clock domains. XGMAC does not attempt to recover from a FSM timeout condition and relies on the application to take the corrective action (resetting XGMAC).

***Note**:*

- *Based on the time at which the FSM enters the active state relative to the timer ticks the timeout period could be any value between the programmed timeout and 2x programmed timeout.*
- *FSM related to PPS (when configured) will not be protected by timeouts as the delays involved in this FSM state transitions can be huge.*

Recovering from FSM Parity/Timeout Errors

If a FSM parity/timeout error is reported, it is recommended to soft-reset the IP. This is because, data path FSM parity/timeout errors are non-recoverable and the functionality of the IP is not guaranteed after a safety non-recoverable interrupt is reported.

14.4.3.22.3 Application/CSR interface timeout protection

This chapter contains the description of the timeout protection.

Overview

This feature provides timeout protection to the application/CSR Interface.

Description

All the interfaces which has the handshake mechanism in XGMAC are monitored for potential hangs due to the external agent (Master/Slave/Interconnect/Application client) not responding to the requests/transfers initiated by XGMAC. After the request is initiated the response arrival interval is monitored. If the response does not arrive within a programmed time (TMR field of `MAC_FSM_ACT_Timer`) the timeout is triggered, using similar trigger generation as explained in the Section FSM protection.

The hardware does not attempt to recover from Application/CSR Interface hangs and relies on software to take appropriate corrective action.

The Application Interface timeout status is provided in the [23:16] field of `MAC_DPP_FSM_Interrupt_Status` register. The Safety interrupt (`sbd_sfty_ue_intr_o`) is asserted when application timeout status is set.

ATI and ARI interface

The timeout is triggered under the following scenarios:

- XGMAC requests for the Transmit packet status transfer and the DMA does not respond within the programmed time
- XGMAC requests for a data/status of receive packet and the DMA does not respond within the programmed time

The Timeout status for the ATI and ARI interface is set in the ATITES and ARITES fields of `MAC_DPP_FSM_Interrupt_Status` register.

AXI Master Interface

The timeout is triggered under the following scenarios:

- The XGMAC initiates Write or Read ADDRESS transfer (by asserting AWVALID or ARVALID) and corresponding ready (AWREADY or ARREADY) is not asserted within the programmed time.
- The XGMAC initiates Write DATA transfer (by asserting WVALID) and corresponding ready (WREADY) is not asserted within a programmed time.

The Timeout status for the AXI master interface is set in the MSTTES field of `MAC_DPP_FSM_Interrupt_Status` register.

AXI Slave Interface

The timeout is triggered under the following scenarios:

- The XGMAC responds to a Read request (by asserting RVALID) and external Master does not accept the response data, by asserting (RREADY) within a programmed time.
- The XGMAC responds to a Write request (by asserting BVALID) and external Master does not accept the response by asserting (BREADY) within a programmed time.

This feature is available in AXI-SLAVE configuration

The Timeout status for the AXI slave interface is set in "SLVTES" field of `MAC_DPP_FSM_Interrupt_Status` register.

***Note**:*
- *Protection is not needed for other Slave interfaces (MCI/APB/AHB) because potential hangs can be only when XGMAC does not respond to the requests. In such cases the XGMAC internal protection logic (FSM timeout) detects such defects.*
- *Based on the time at which the transfer is initiated relative to the timer ticks, the timeout period could be any value between the programmed timeout and 2x times the programmed timeout.*
- *When an unrecoverable safety interrupt is issued and the read of the Interrupt status register returns all zeros, it implies that the CSR read is not functional. As soft reset of XGMAC is not possible without the CSR access, and therefore, a hard reset of XGMAC is recommended.*

14.4.3.23 Descriptors

14.4.3.23.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The XGMAC supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for exchanging packet data and packet control or status information applicable between the application and the XGMAC controller.
- Context Descriptor: Context descriptors are used to provide additional control information applicable to the packets to be transmitted or additional status information for received packets.
  - Tx side: The application prepares the context descriptors and puts the context descriptors in the linked list before the normal descriptor. The XGMAC-AXI interface processes the controls given in the context descriptor for the packet(s) following the context descriptor.
  - Rx side: The application does not create context descriptors. It creates a linked-list of normal descriptors. When the Rx DMA has additional status information for a received packet, it closes the next descriptor with this additional status and marks it as “context descriptor”.

Each normal descriptor contains two address pointers to two buffers.

***Note**:* *A single packet can use any number of descriptors upto the ring length.*
The reserved fields in the descriptor must be set to 0, otherwise the behavior is unpredictable.

14.4.3.23.2 Descriptor Structure

The XGMAC supports the ring structure for DMA descriptor as shown in Figure 172.

***Note**:* *A descriptor ring must provide a minimum of four descriptors or more to the XGMAC.*

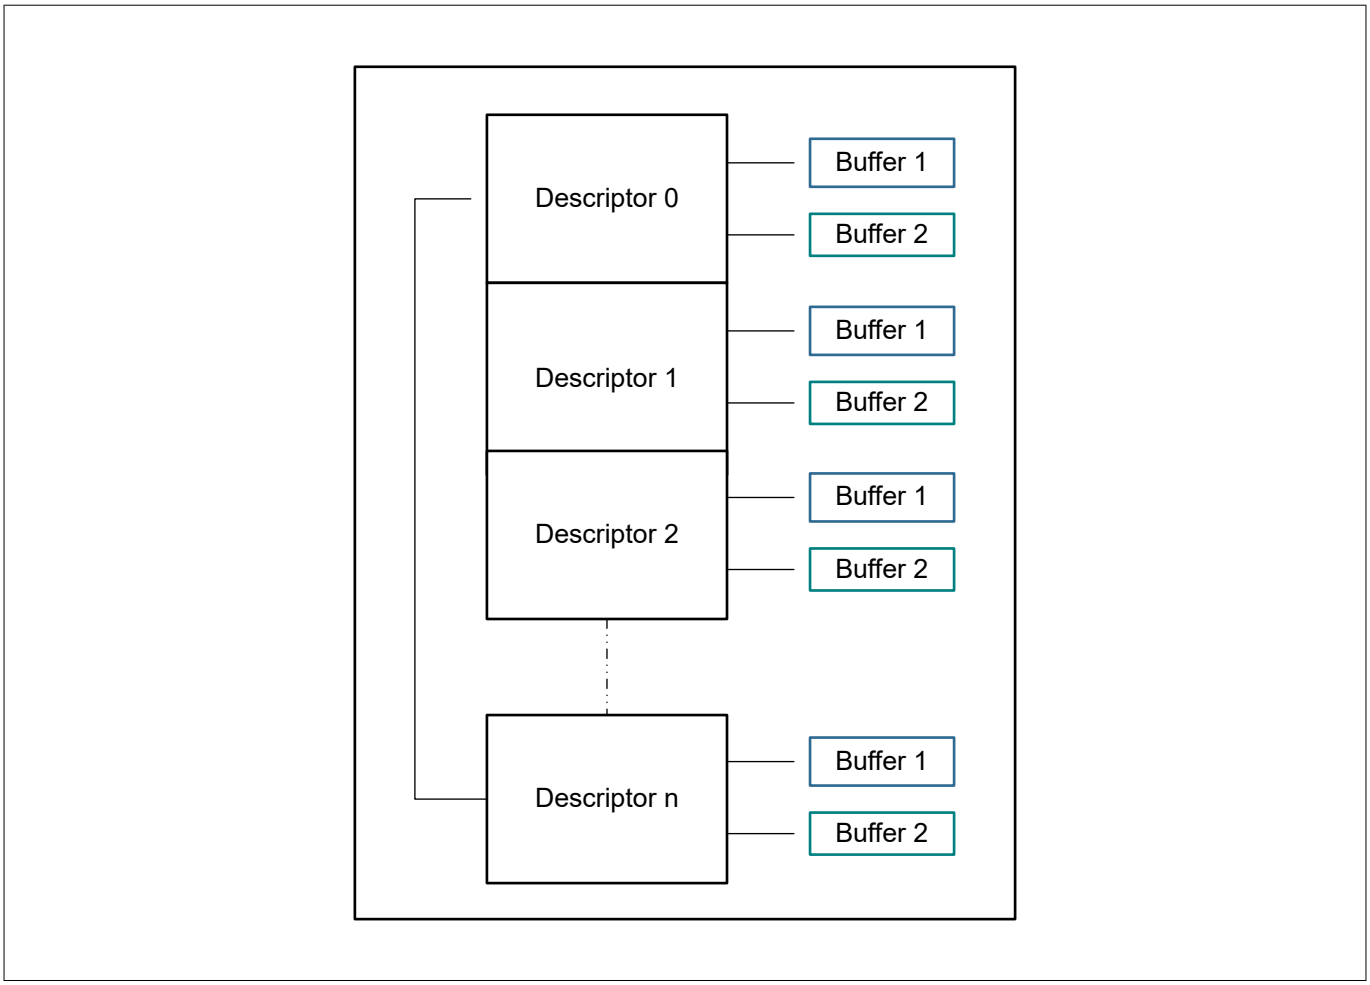


Figure 172 Descriptor Ring Structure

In the ring structure, descriptors are separated by number of 64-bit (DWord) programmed in the DSL field of the DMA_CH(#i)_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH(#i)_Tx_Control2)
- Receive Descriptor Ring Length Register (DMA_CH(#i)_Rx_Control2))

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (i). The descriptors up to one location less than the one indicated by the descriptor tail pointer (i – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

```
Current Descriptor Pointer == Descriptor Tail Pointer
```

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and increase the offset so that the following condition is true:

```
Current Descriptor < Pointer Descriptor Tail Pointer
```

The DMA automatically wraps around the base address when the last descriptor in the ring is processed, as shown in Figure 173.

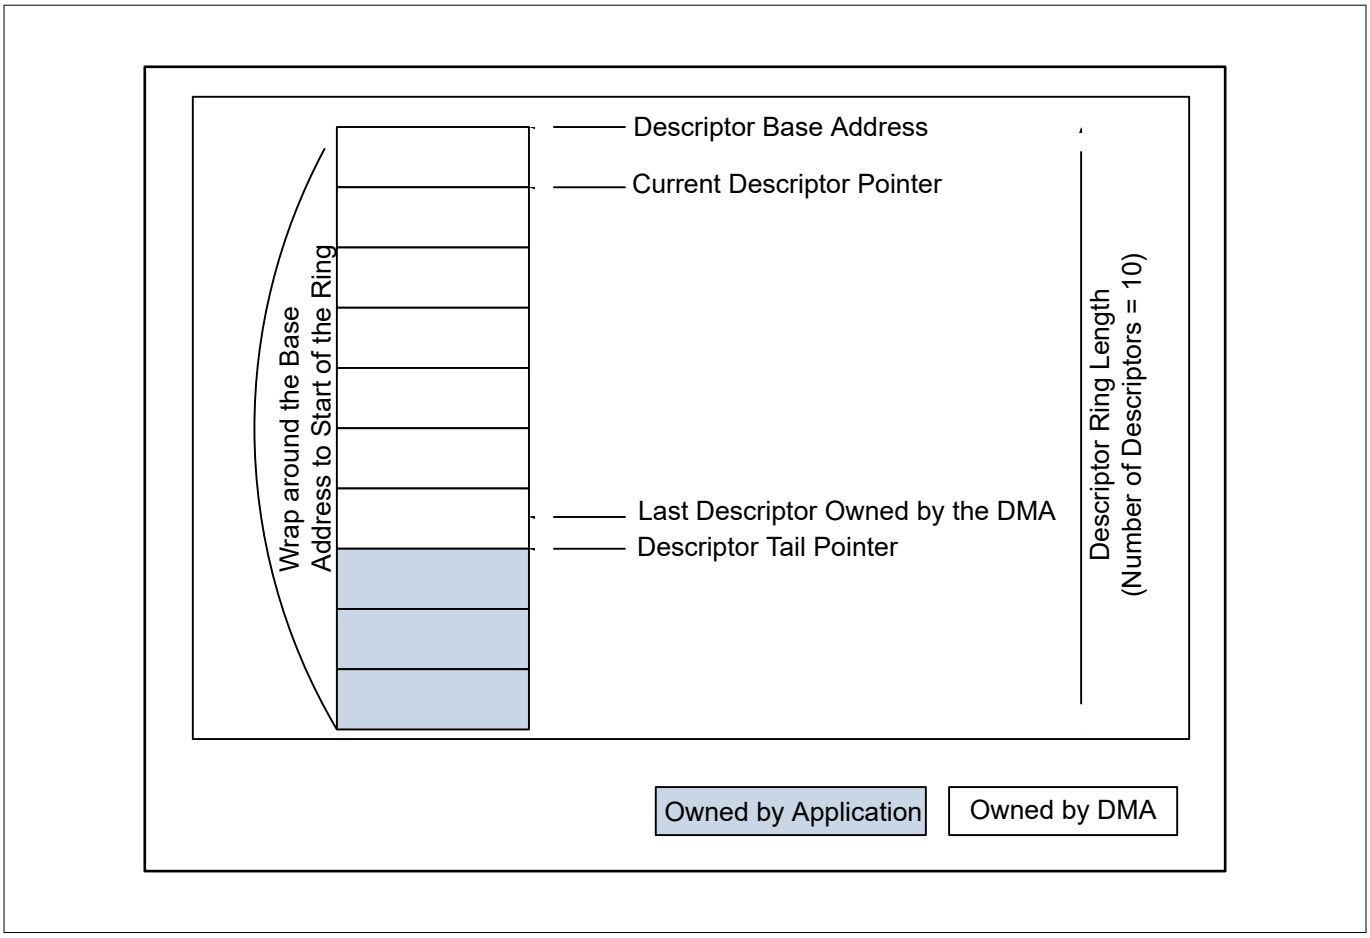

Figure 173 DMA Descriptor Ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only two descriptors in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance change the tail pointer back to Descriptor Base Address.

***Note**: The descriptor list address (DMA_CHi_TxDesc_List_LAddress and DMA_CHi_RxDesc_List_LAddress) and descriptor ring lengths (DMA_CHi_Tx_Control2.TDRL and DMA_CHi_Rx_Control2.RDRL) should be programmed such that the descriptor address does not cross a 4 GB address boundary.*

14.4.3.23.3 Transmit Descriptor

The DMA in XGMAC requires at least one descriptor for a transmit packet. In addition to two buffer length fields, and two address pointers, the transmit descriptor has control fields which can be used to control the packet processing on per-transmit packet basis. The Transmit Normal descriptor has the following two formats: Read format and Write-Back format

Transmit Normal Descriptor (Read Format)

Figure 174 shows the Read Format for a Transmit normal descriptor. This is the format in which the software can prepare the descriptor contents and hand it over to the DMA Engines of the XGMAC.

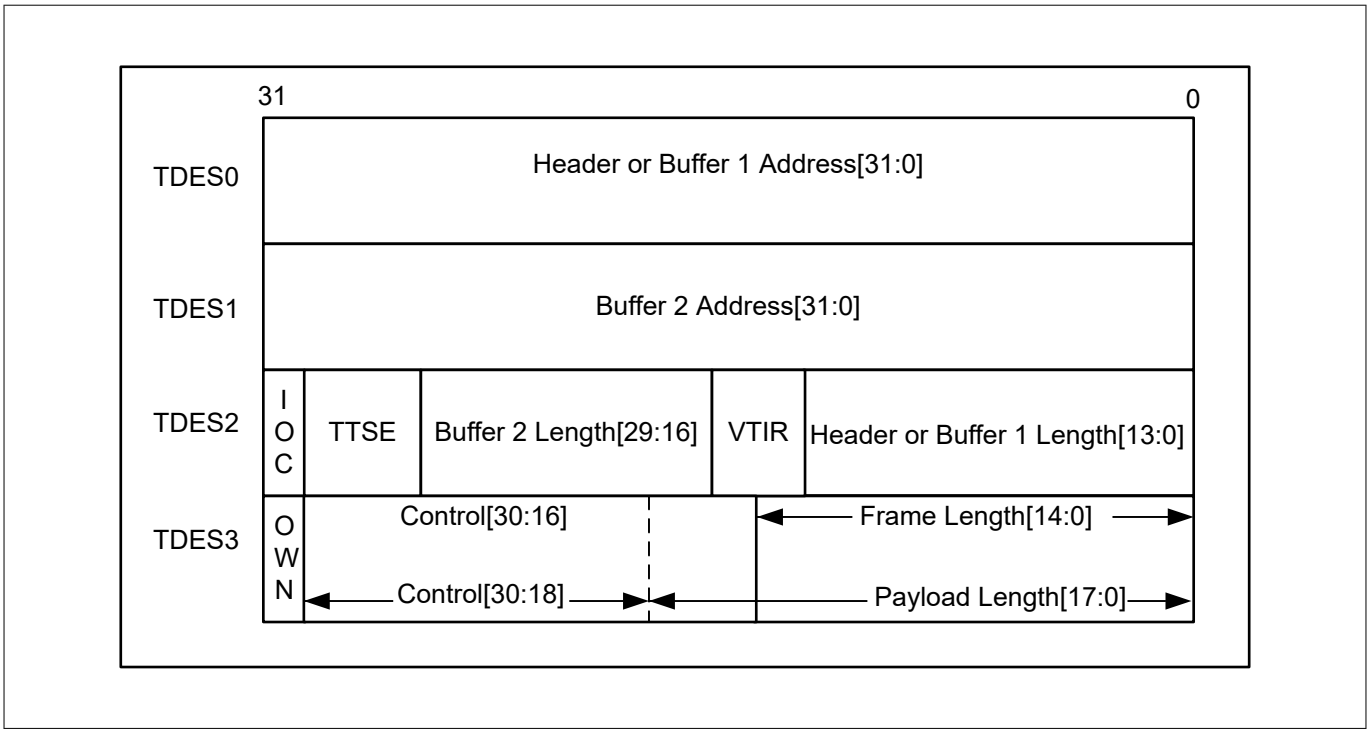

Figure 174 Transmit Descriptor Read Format

TDES0 Normal Descriptor (Read Format)

Table 745 TDES0 Normal Descriptor (Read Format) (Continued)

Bit	Name	Description
31:0	BUF1AP	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1.

TDES1 Normal Descriptor (Read Format)

Table 746 TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 Address Pointer These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used (as shown in Figure 172). There is no limitation for the buffer address alignment.

TDES2 Normal Descriptor (Read Format)

31	30	29:16	15:14	13:0

Bits	Name	Description
31	IOC	Interrupt on Completion This bit sets the TI bit in the DMA_CH(#i)_Status register after the present packet has been transmitted.

(table continues...)

Table 747 (continued) TDES2 Normal Descriptor (Read Format)

Bits	Name	Description
30	TTSE	Transmit Timestamp Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor.
29:16	B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
15:14	VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: • 2'b00: Do not add a VLAN tag. • 2'b01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. • 2'b10: Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. • 2'b11: Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets.
13:0	B1L	Buffer 1 Length

OWN	CTXT	FD	LD	CPC	SAIC	SLOTNUM	Rsvd	CIC	Rsvd	FL

Table 748 TDES3 Normal Descriptor (Read Format)

Bits	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffers.
30	CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
29	FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field must have a non-zero value, else behavior is undefined.

(table continues...)

Table 748 (continued) TDES3 Normal Descriptor (Read Format)

Bits	Name	Description
27:26	CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of Bits[27:26]: • 2'b00: CRC and Pad Insertion The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically adds padding and CRC to a frame shorter than 60 bytes. • 2'b01: CRC Insertion (Disable Pad Insertion) The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. • 2'b10: Disable CRC Insertion The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. • 2'b11: CRC Replacement The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer.
25:23	SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. If the Source Address field is modified in a packet, the MAC automatically recalculates and replaces the CRC bytes. Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[24:23]: • 2'b00: Do not include the source address • 2'b01: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. • 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses. • 2'b11: Reserved These bits are valid when the First Segment control bit (TDES3 [29]) is set.
22:19	SLOTNUM	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH(#i)_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels.
18	Rsvd	Reserved

(table continues...)

Table 748 (continued) TDES3 Normal Descriptor (Read Format)

Bits	Name	Description
17:16	CIC	Checksum Insertion Control or TCP Payload Length These bits control the checksum calculation and insertion. The following list describes the bit encoding: • 2'b00: Checksum Insertion Disabled. • 2'b01: Only IP header checksum calculation and insertion are enabled • 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware • 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware When Timestamping is enabled without One Step Timestamping Feature and OSTC bit is set in the context Descriptor, the content of this field is not effective and Checksum is updated as though CIC field is set to 2'b11.
15	Rsvd	Reserved
14:0	FL	Packet Length This field is equal to the length of the packet to be transmitted in bytes. This field is equal to the total length of the packet to be transmitted: `Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length`

Transmit Normal Descriptor (Write-Band Format)

The XGMAC processes the descriptor, acts on it and then writes back the status content. This operation indicates to the software that the descriptor is free and no longer required by the hardware. The XGMAC writes only the bits[31:24] of TDES3 during this operation and all the other fields of the descriptor in the host memory are not modified.

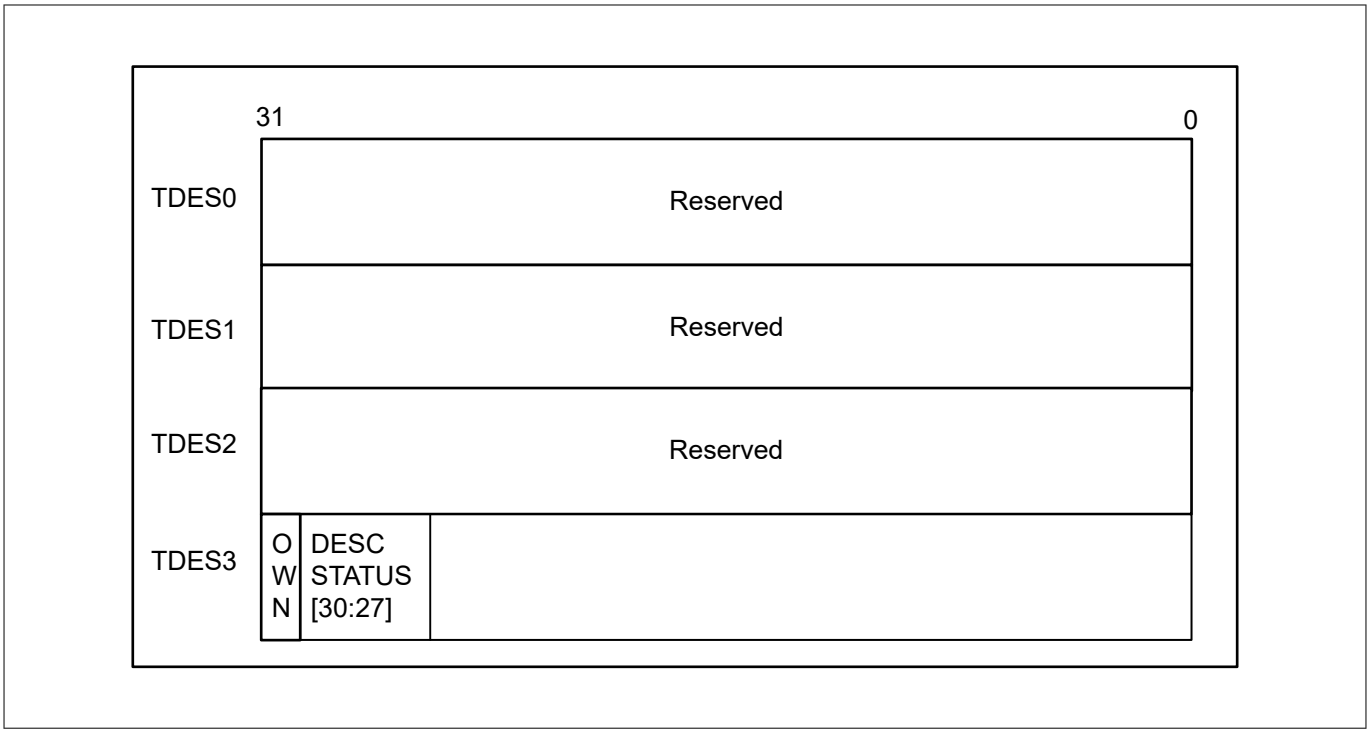

Figure 175 Transmit Descriptor Write-Back Format

TDES3 Normal Descriptor (Write-Back Format)

31	30	29	28	27	26:0
OWN	CTXT	FD	LD	DERR	Rsvd

Table 749 TDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the XGMAC DMA owns the descriptor. The DMA clears this bit when it writes back the descriptor. The DMA closes the descriptor when either of the following conditions are true: • The DMA completes the transfer of data indicated by the buffers from the host memory to the corresponding Tx Queue • The B1L and B2L values are zero, indicating empty buffers
30	CTXT	Context Type This bit is set to 'b0 for Normal descriptor.
29	FD	First Descriptor This bit indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor This bit is set 'b1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet.
27	DERR	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the descriptor. The descriptor errors can be: • AXI Bus Error: This bit is asserted when AXI Bus Error response is received while processing the descriptor. This can be either when the descriptor itself is fetched or when the packet data indicated by its buffer pointers are fetched. • Descriptor Definition Error: 1 This bit is asserted if CTXT and FD or LD bits are set to 1 (CTXT & (FD | LD)). • All 1s
26:0	Rsvd	Reserved

Transmit Context Descriptor

The Transmit Context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature, and SA insertion bit for SA insertion. Write back is done on a context descriptor only to reset the OWN bit and to set the CDE bit if necessary.

***Note**: The VLAN Tag IDs provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA.*

When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The Inner VLAN Tag Control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

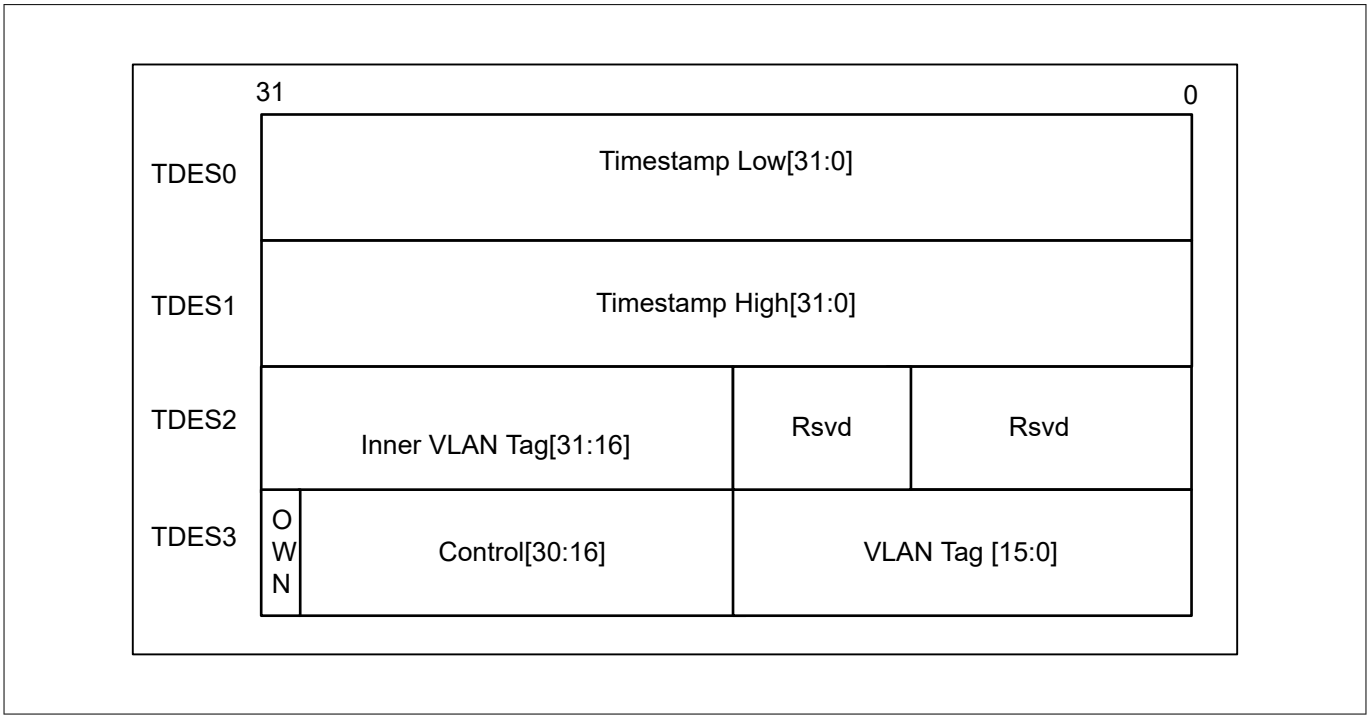

Figure 176 Transmit Context Descriptor Format

TDES0 Context Descriptor

Table 750 TDES0 Context Descriptor

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low or Packet ID For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set. When the OSTC bit is reset and PIDV is set, the lower 10-bits [9:0] indicate the packet ID which is used for 2-step time stamping.

TDES1 Context Descriptor

Table 751 TDES1 Context Descriptor

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High or Packet ID For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

TDES2 Context Descriptor

Table 752 TDES2 Context Descriptor

Bit	Name	Description
31:16	IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is set and the TCMSSV and OSTC bits of TDES3 context descriptor are reset, TDES2[31:16] contains the inner VLAN Tag to be inserted in the subsequent Transmit packets.

30	CTXT	Context Type This bit is set to 1’b1 for Context descriptor.
29:28	Rsvd	Reserved
27	OSTC	One-Step Timestamp Correction Enable When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
26	TCMSSV	One-Step Timestamp Correction When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid. When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.

(table continues...)

Table 753 (continued) TDES3 Context Descriptor (Read format)

Bit	Name	Description
25	PIDV	Packet ID valid When this bit is set and OSTC bit is reset, the bits [9:0] of TDES0 Context Descriptor indicates the Packet ID for 2-step Time stamping.
24	Rsvd	Reserved
23:20	Rsvd	Reserved
19:18	IVTIR	Inner VLAN Tag Insert or Replace When this bit is set, these bits request the MAC to perform Inner VLAN tagging or untagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: • 2'b00: Do not add the inner VLAN tag. • 2'b01: Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames. • 2'b10: Insert an inner VLAN tag with the tag value programmed in the register or context descriptor. • 2'b11: Replace the inner VLAN tag in packets with the tag value programmed in the register or context descriptor. This option should be used only with the VLAN frames. These bits are valid when the Enable SA and VLAN Insertion on Tx and Enable Double VLAN Processing options are selected.
17	IVLTV	Inner VLAN Tag Valid When this bit is set, it indicates that the IVT field of TDES2 is valid.
16	VLTV	VLAN Tag Valid When this bit is set, it indicates that the VT field of TDES3 is valid.
15:0	VT	VLAN Tag This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the MAC_VLAN_Incl register is set.

TDES3 Context Descriptor (Write-Back Format)

Table 754 TDES3 Context Descriptor (Write-back format

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the XGMAC DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it accepts the context descriptor contents.
30	CTXT	Context Type This bit is set to 1’b1 for Context descriptor.
29	CDE	Context Descriptor Error When this bit is set, it indicates that the context descriptor was provided in the incorrect sequence and the DMA ignored it. The DMA sets this bit during write-back while closing the context descriptor. When the context descriptor is read by DMA, this bit is reserved and must be having a value 1‘b0.
28:0	Rsvd	Reserved

14.4.3.23.4 Receive Descriptor

The DMA in the XGMAC attempts to read a descriptor only if the Tail Pointer is different from the Base Pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

There are two receive descriptor type: Normal and Context descriptors. All RX descriptors are prepared by the software and given to the DMA as Normal Descriptors with the content. as shown in figure "Receive Normal Descriptor (Read Format)". The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA closes the descriptor with the corresponding packet status. The format of this status is given in the section "Receive Normal Descriptor (Write-Back Format)".

For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the RX DMA writes the extended status to the next descriptor (without processing or using the Buffers Pointers embedded in that descriptor). The format and content of this descriptor write back is described in the section "Receive Context Descriptor".

Receive Normal Descriptor (Read Format)

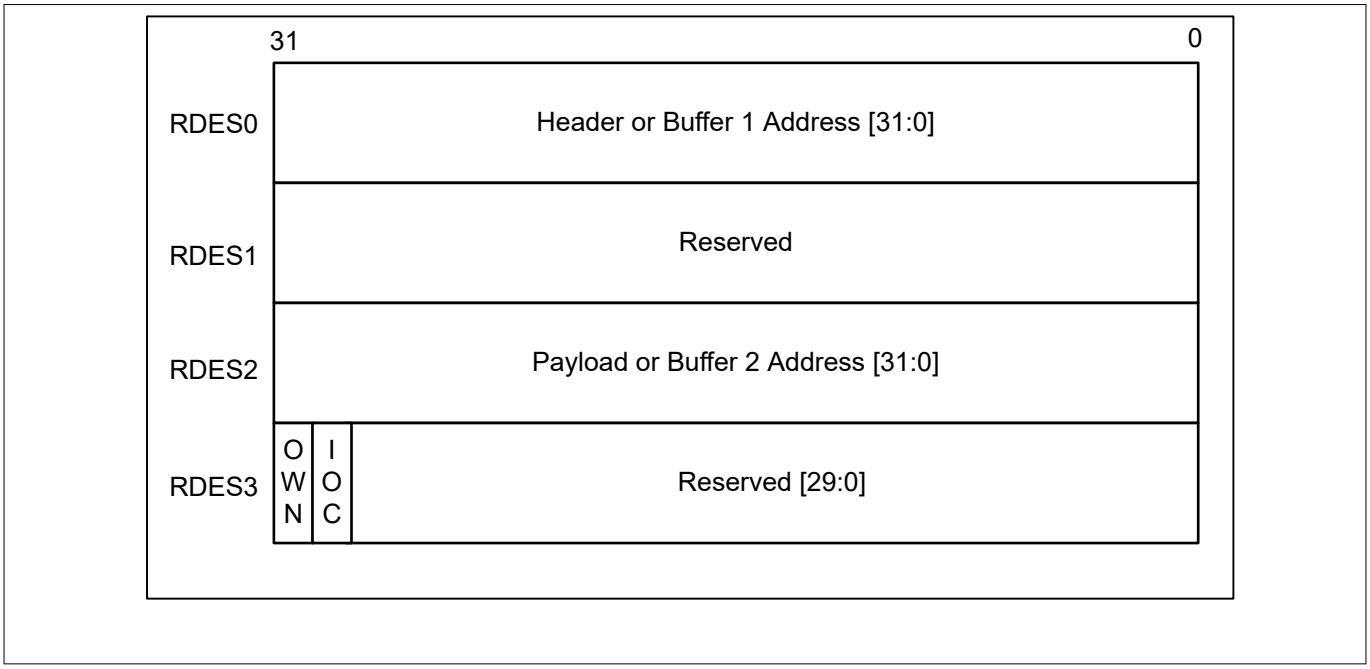

Figure 177 Receive Normal Descriptor (Read Format)

***Note**: In the Receive Descriptor (Read Format), if the Buffer Address field is all 0s, XGMAC does not transfer data to that buffer and skips to the next buffer or next descriptor.*

RDES0 Normal Descriptor (Read Format)

Table 755 RDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Header or Buffer 1 Address Pointer When the SPH bit of DMA_CHi_Control register of a channel is reset, these bits indicate the physical address of Buffer 1. When the SPH bit is set, these bits indicate the physical address of Header Buffer where the Rx DMA writes the L2/L3/L4 header bytes of the received packet. The software can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[3:0] (or RDES0[2:0] in case of 64-bit configuration) as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.

RDES1 Normal Descriptor (Read Format)

Table 756 RDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Reserved

RDES2 Normal Descriptor (Read Format)

Table 757 RDES2 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 Address Pointer These bits indicate the physical address of Buffer 2. When the SPH bit of the DMA_CH(#i)_Control register is set, the buffer address pointer must be bus width-aligned, that is, RDES2[3:0 or 2:0] = 0 corresponding to 128 or 64 bus width. LSBs are ignored internally. When the SPH bit of the DMA_CH(#i)_Control register is reset, the BUF2AP can be of any byte-aligned value. However, the RxDMA uses the LS Bits of the pointer address only while transferring the start bytes of a packet. If the BUF2AP is giving the address of a buffer in which the middle or last part of a packet is stored, the DMA ignores BUF2AP[3:0 or 2:0] (corresponding to 128- or 64-bit databus) and writes to the complete location.

RDES3 Normal Descriptor (Read Format)

Bit	Name	Description
25	Rsvd	Reserved
24	ETM	Ether Type Match/No Coagulation Packet When L34T=000, this bit is set to 1 (ETM Status) when the “Type” field of the received packet matches the value programmed in the MAC_Rx_Eth_Type_Match register. When L34T has any value other than 000, this bit is 0.
23:20	L34T	Layer3/Layer4 packet Type These bits indicate the type of payload encapsulated in the IP datagram and processed by the Receive Checksum Offload Engine (RxCOE). For a tunneled packet, the Layer3/Layer4 packet type refers to the L3/L4 type of the inner packet. • 0000: Not an IP packet • 0001: IPv4 packet with TCP Payload as Layer4 • 0010: IPv4 packet with UDP Payload as Layer4 • 0011: IPv4 packet with ICMP Payload as Layer4 • 0100: IPv4 packet with IGMP Payload is Layer4 • 0101 to 0110: Reserved • 0111: IPv4 with unknown (unsupported) payload • 1000: Reserved • 1001: IPv6 packet with TCP Payload as Layer4 • 1010: IPv6 packet with UDP Payload as Layer4 • 1011: IPv6 packet with ICMP Payload as Layer4 • 1100 to 1110: Reserved • 1111: IPv6 with unknown (unsupported) payload

Table 763 (continued) RDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
19:16	ET/LT	Error Type or L2 Type When the 15th bit of this descriptor (ES) is set to 1, this field indicates the Error Type. When the 15th bit of this descriptor (ES) is set to 0, this field indicates the L2 Packet Type. Following is the encoding: When ES = 1 (Error Type Encoding) • 0000: Reserved • 0001: Watchdog Timeout Error It indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout • 0010: Invalid Code Error or GMII Error In XGMII mode, it indicates that the frame was terminated due to the reception of an invalid code character. In GMII mode, it indicates that the RX_ER and RX_DV signals were asserted for the frame, indicating a receive error signaled to the GMII. • 0011: CRC Error It indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. • 0100: Giant Packet Error It indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set). Note: Giant packet indicates only the packet length. It does not cause any packet truncation. • 0101: IP Header Error It indicates that the 16-bit IPv4 Header checksum calculated by the XGMAC controller does not match the received Checksum bytes or that the IP datagram version is not consistent with the Ethernet Type value. This error is possible only when you select the Enable Receive TCP/IP Checksum Check feature • 0110: Payload (L4) Checksum Error It indicates that the 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the XGMAC controller does not match the received TCP, UDP, or ICMP checksum field. • 0111: Overflow Error It indicates that the received packet is damaged because of buffer overflow in Rx FIFO. Note: This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO. • 1000: Bus Error It indicates that AXI Bus Error response is received while fetching this descriptor or when packet is being transferred to its buffers. Continued on next page

(table continues...)

Table 763 (continued) RDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
19:16	Cont'd	• 1001: Length Error It indicates that the Length value of the current frame is inconsistent with the total number of bytes received in the current frame. This is applicable when Frame Length value is less than 1500. This error is reported when the following type of frames are received: - Frames in which the value of the Length field is less than 46 bytes and the length of the received frame is less than the following: Length field + 18 bytes - Frames in which the value of the Length field is equal to or greater than 46 bytes and the length of the received frame is not equal to the following: Length field + 18 bytes • 1010: Good runt packet. Packet less than 64 bytes but with good CRC • 1011: Reserved • 1100: Dribble Error Indicates that, in the 10/100Mbps speed mode, the packet has ended without a byte boundary • 1101 -1111: Reserved for non-tunneled packets In the case of Tunneled packet, the Error Status is extended to differentiate between the errors in outer Header or Inner Header. In the status types, the following values are applicable for the Outer Header fields: • 0101: Outer IP Header Error • 0110: Outer Header's Payload (L4) Checksum Error Additionally, the following Error Status types are applicable • 1001: Inner Packet's IP Header Error • 1010: Inner Packet's Payload (L4) Checksum Error • 1011: Reserved • 1101-1111: Reserved When ES = 0 (L2 Packet Type Encoding) • 4'b0000: The packet is a length packet • 4'b0001: The packet is a MAC Control packet • 4'b0010: Reserved • 4'b0011: The packet is of ARP Request Packet Type • 4'b0100: The packet is of OAM packet type.(Note: Inner header of a tunneled packet is not parsed for OAM Control type) • 4'b0101: The untagged packet has a Type field which matched the value in the MAC_Rx_Eth_Type_Match register • 4'b0110: Untagged AV Control Packet • 4'b0111: The packet is a other Type Packet • 4'b1000: The packet is type packet with Single SVLAN tag • 4'b1001: The packet is type packet with Single CVLAN tag • 4'b1010: The packet is type packet with Double VLAN tag with outer VLAN is CVLAN and inner is also CVLAN Continued on next page

(table continues...)

Table 763 (continued) RDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
19:16	Cont'd	• 4'b1011: The packet is type packet with Double VLAN tag with outer VLAN is SVLAN and inner is SVLAN • 4'b1100: The packet is type packet with Double VLAN tag with outer VLAN is SVLAN and inner is CVLAN • 4'b1101: The packet is type packet with Double VLAN tag with outer VLAN is CVLAN and inner is SVLAN • 4'b1110 – 4'b1111: Reserved For a tunneled packet, the L2 packet type encoding refers to the L2 type of the Inner packet.
15	ES	Error Summary This bit indicates that the received packet has an error. The type of error is indicated by bits [19:16]. This field is valid only when the LD bit of RDES3 is set.
14	FPS0	Flexible Receive Parser Status bit
13:0	PL	Packet Length These bits indicate the byte length of the received packet that was transferred to system memory. This does not include the VLAN/Pad/CRC bytes if VLAN/Pad/CRC stripping is enabled. This field is valid when the LD (bit[28]) field of RDES3 is set there is no overflow error indication in ET/LT(bits[19:16]).

Receive context descriptor

The Receive context descriptor provides information about the extended status of the last received packet. The Bit 30 of RDES3 indicates the context type descriptor.

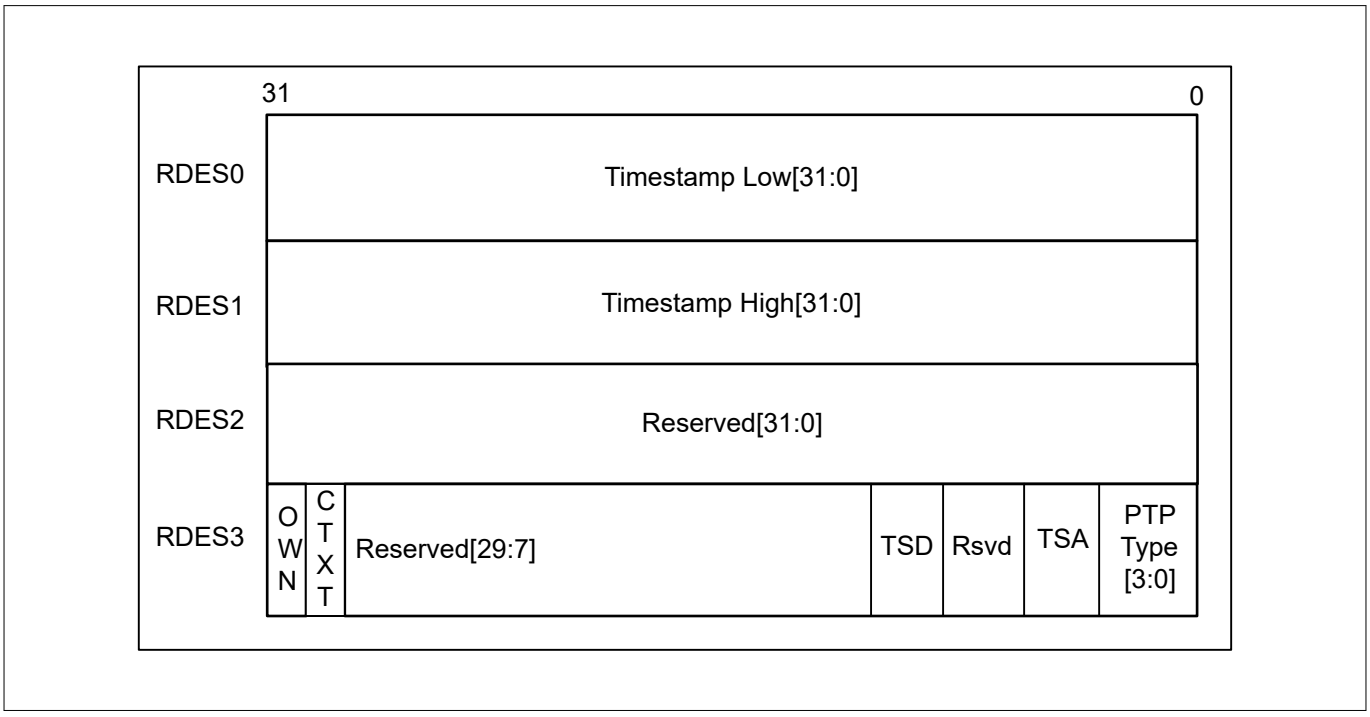

Figure 179 Receive context descriptor

RDES0 context descriptor

Table 764 RDES0 context descriptor

Bit	Name	Description
31:0	RTSL	Receive Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for corresponding Receive packet. When this field and the RTSH field of RDES1 show all-ones value, the timestamp must be considered as corrupt.

RDES1 context descriptor

Table 765 RDES1 Context Descriptor

Bit	Field	Description
31:0	RTSH	Receive Packet Timestamp High The DMA updates this field with most significant 32 bits of the timestamp captured for corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, the timestamp must be considered as corrupt.

RDES2 context descriptor

Table 766 RDES2 context descriptor

Bit	Description
31:0	Reserved

RDES3 context descriptor

31	30	29:7	6	5	4	3:0
OWN	CTXT	Rsvd	TSD	Rsvd	TSA	PMT

Table 767 RDES3 context descriptor

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full
30	CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context descriptor. The DMA writes 1'b1 to this bit for context descriptor.
29:7	Rsvd	Reserved
6	TSD	Timestamp Dropped When set, it indicates that a timestamp was captured for this packet but was dropped due to the lack of space in RxFIFO. The host should consider the RTSL and RTSH as valid only when TSD=0 and TSA=1

(table continues...)

Table 767 (continued) RDES3 context descriptor

Bit	Name	Description
5	Rsvd	Reserved
4	TSA	Timestamp Available When set, this bit indicates that the timestamp value is available in RDES0 and RDES1 of the context descriptor.
3:0	PMT	PTP Message Type: These bits are encoded to give the type of the PTP message received: • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow-up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011-1110: Reserved • 1111: PTP packet with Reserved message type

14.4.3.23.5 Split Header Support

This feature supports splitting the packet header and the payload of received packets in separate buffers (buffer 1 and buffer 2). You can enable the split header feature by selecting the Enable Split Header Structure option and setting the SPH bit in the DMA_CH(#i)_Control register.

HDSMS field of Port j MAC Rx Configuration register indicates maximum header size allowed for splitting the header data in the received packet based on the value programmed. When the ARBS field of the DMA_CHj_Rx_Control2 register is programmed to a non-zero value, ARBS field indicates Receive Buffer size for buffer 1 and the RBSZ field indicates the receive buffer size for buffer 2. The ARBS field can be set to 0, for backward compatibility.

The value in the HDSMS field should be greater than or equal to the buffer 1 size indicated by ARBS field for all the channels.

Table 768 shows how DMA processes a packet based on the packet type.

Table 768 Split Header Support Depending on the Packet Type

Packet Type	SPLM	Description
TCP or UDP Packet	00(L3/L4 Split)	The DMA writes the Ethernet header + IP header + TCP or UDP header into the header buffer.
IP packet (not TCP/ UDP)		The DMA writes the Ethernet header + IP header into the header buffer.
Non-IP packet		The DMA does not split the header and payload

(table continues...)

Table 768 (continued) Split Header Support Depending on the Packet Type

Packet Type	SPLM	Description
Any packet	01 (L2 Split)	The DMA writes the Ethernet headerbased on split offset (SPLOFST) into the header buffer.
IP packet	10(Combination of L2 or L3/L4 Split)	L3/L4 split
Non-IP packet		L2 split
NA	11	Reserved

The IP header includes IPv4 options in case of IPv4 packet and IPv6 extension headers in case of IPv6 frames. The points at which the header is split are shown in Figure 180.

***Note**:*

- *The VLAN tag stripping must be set for the split function. For instance, the DMA separates the header and payload of an untagged packet only. So, when a tagged packet is received, then program XGMAC such that the VLAN tags are deleted/stripped from the received packets*
- *L3/L4 split is applicable for IP packets that are either untagged or VLAN stripped. If VLAN tag is retained in the packet forwarded to the DMA, L3-L4 split is not performed. However, if SPLM field is set to 2, L2 split is performed for VLAN tagged IP packets*
- *For AV packets, to specify an alternative L2 split value, use the SAVE and SAVO fields of the Port j MAC Ext Cfg1 register*
- *L2 Split is not supported for packets with variable preamble*

Table 769 shows the header length availability (HL) in RDES2. This field is valid only when FD = 1 (First Descriptor).

Table 769 Header Length Availability in RDES2

Value of FD	Value of LD	Header Length (HL) Availability in RDES2
0	1	HL not available
1	0	HL is [9:0]
1	1	• IP packets, HL is [9:0] • Non-IP packets, HL is [9:2]

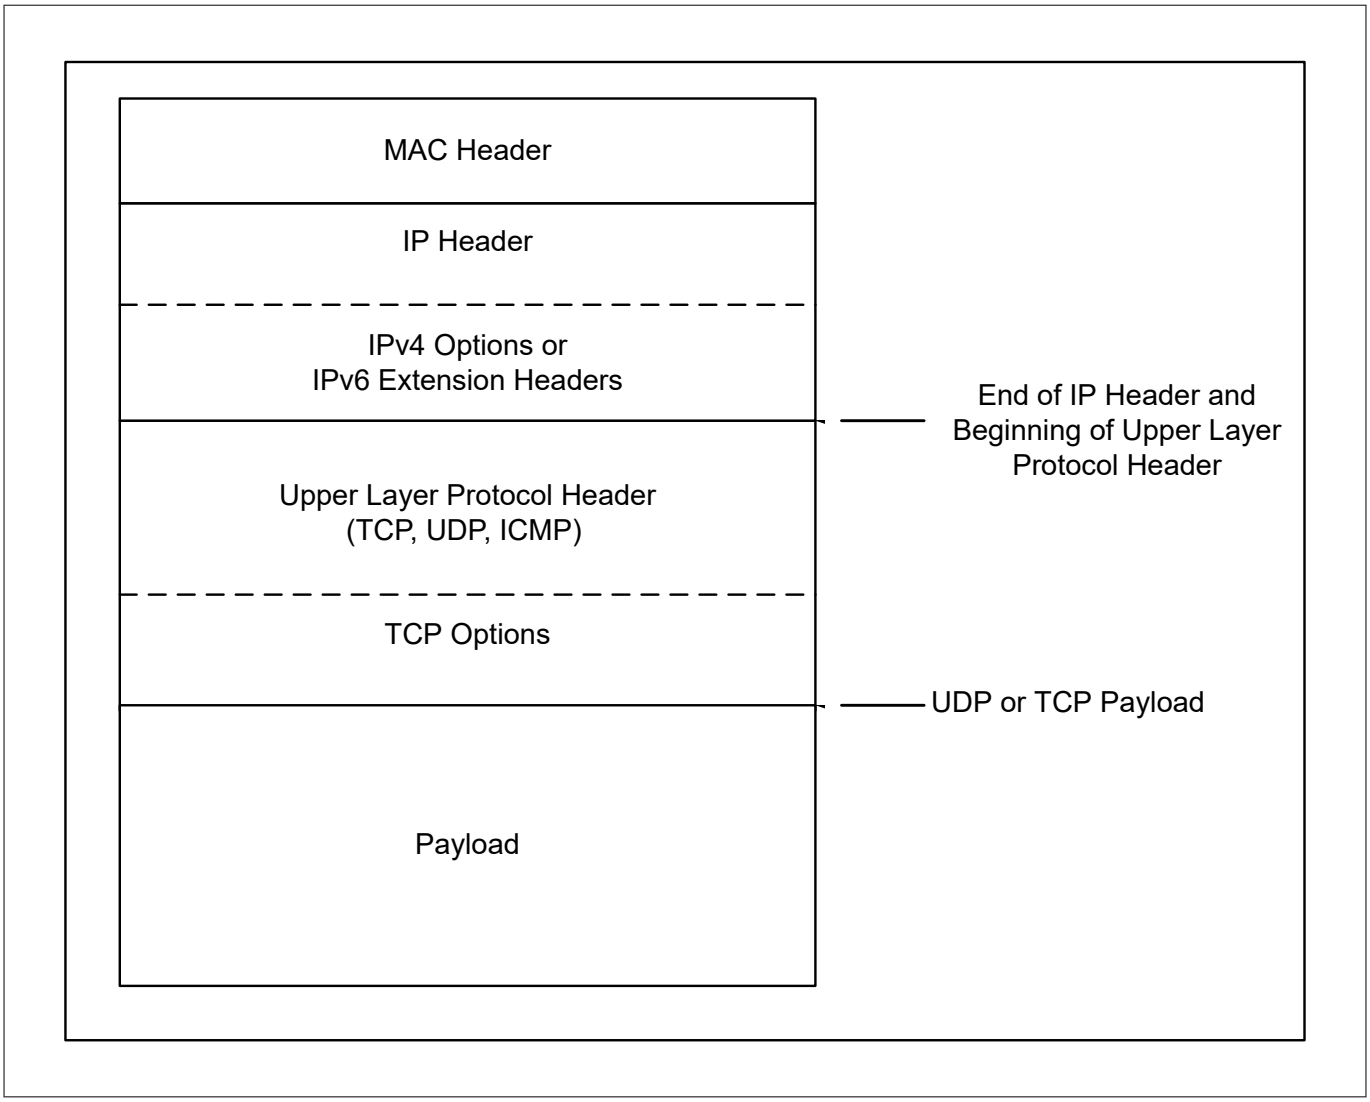

Figure 180 Header Split Points

Descriptor Structure

Figure 181 shows the descriptor structure without the Split Header feature.

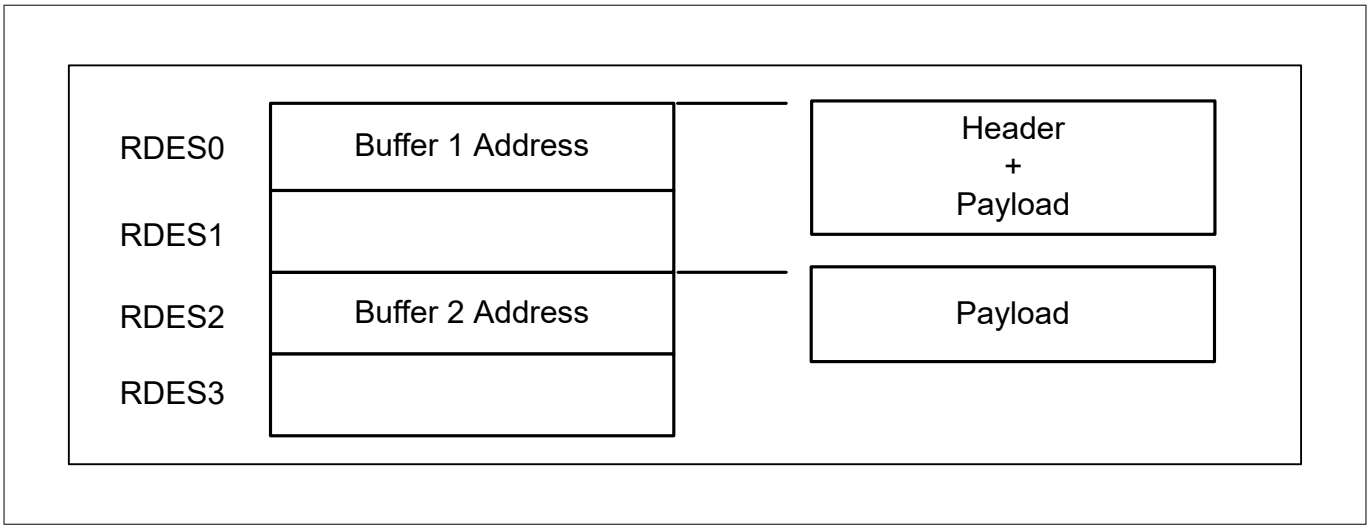

Figure 181 Descriptors without Split Header Feature

Figure 182 shows the descriptor structure with the Split Header feature.

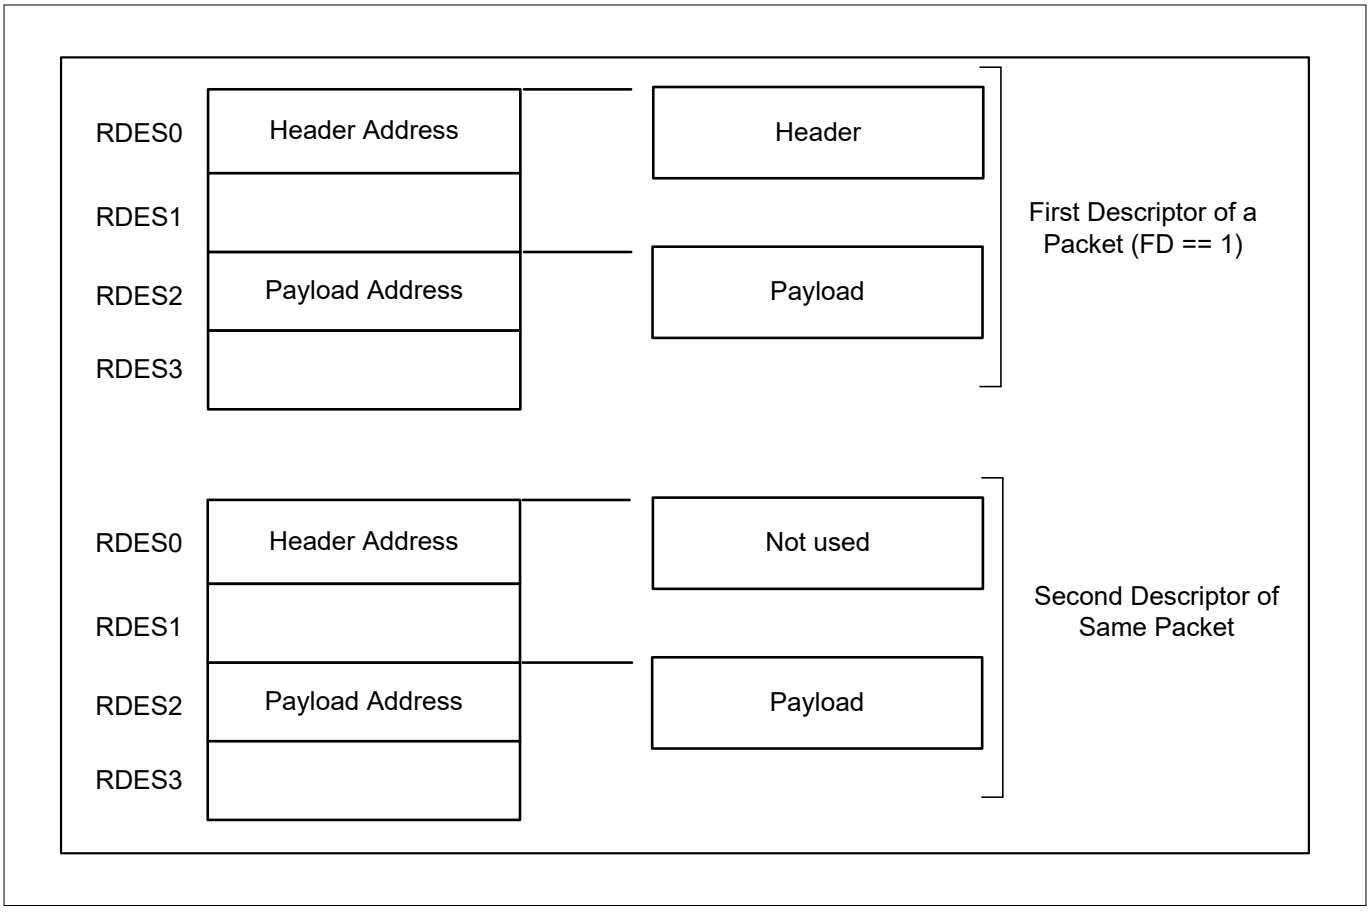

Figure 182 Descriptors with Split Header Feature

The DMA writes the header of the received packet by using the header address to which the RDES0 in the first descriptor is pointing (FD bit of RDES3 is set). The DMA writes the payload of the received packet into the buffer address to which the RDES2 is pointing. For subsequent descriptors (FD is set to 0), the address to which RDES0 (Header address) is pointing is not used. The payload is written only to buffers to which the RDES2 (payload address) is pointing.

The DMA writes the header length in RDES2 of the first receive descriptor (RDES3[29] (FD Bit) is set) for the packet. The packet length is written in RDES3 of the last receive descriptor (RDES3[28] (LD Bit) set). The buffer length for the payload is set by the driver through the RBSZ field in the corresponding DMA Channel Receive Control Register. The DMA fills receive buffers fully in all descriptors except the last receive descriptor. The maximum header length is limited by the value programmed in the HDSMS field of MAC_Rx_Configuration register.

Figure 183 shows the descriptor structure with the Split Header feature for a tunneled packet.

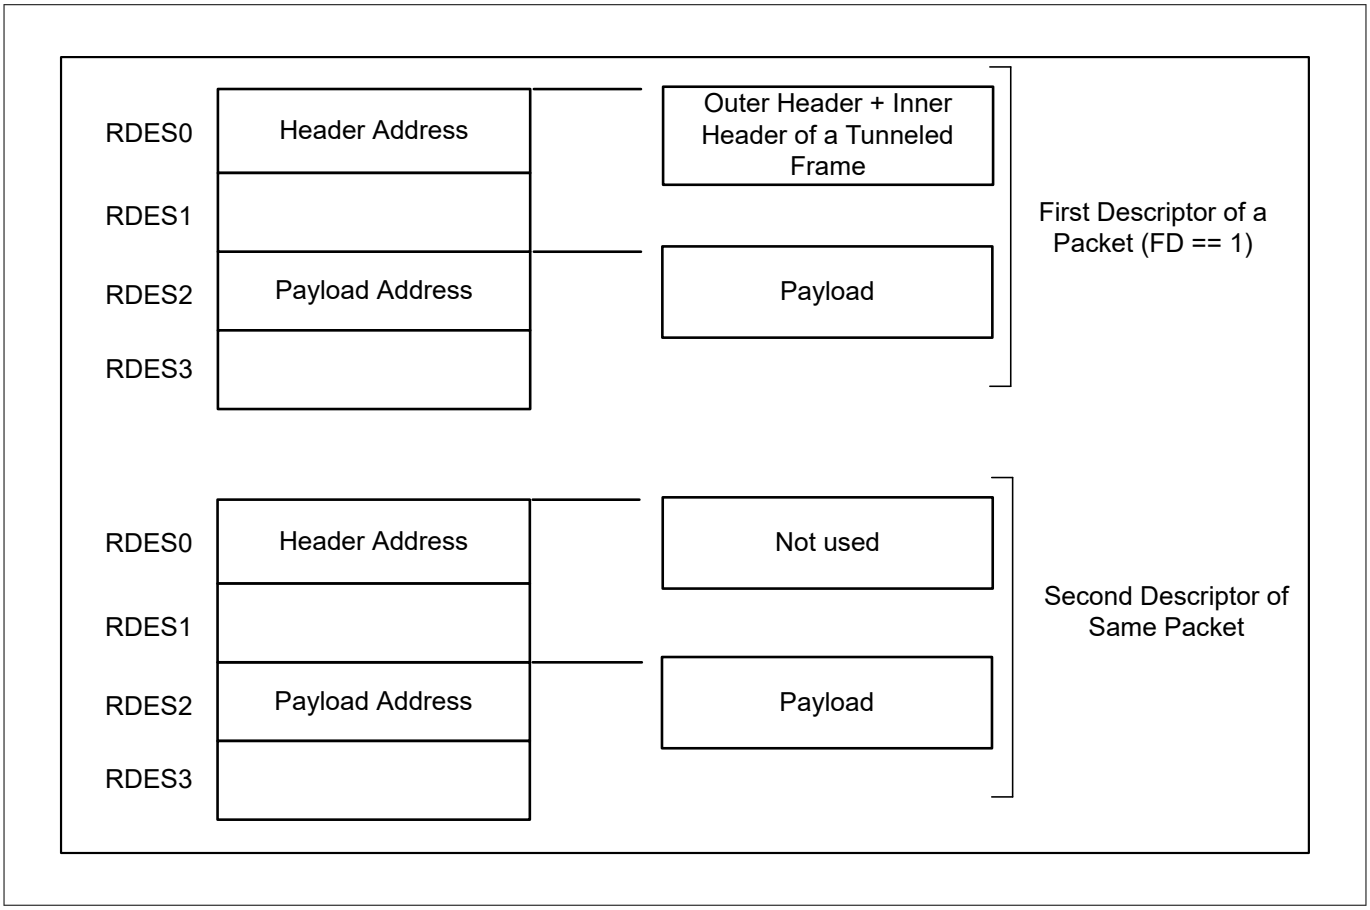

Figure 183 Descriptors with Split Header for Tunneled Packets

The header of Outer Packet and Inner Packet are part of data written in the Header buffer. Only the Payload of the Inner packet is written into the buffers pointed by RDES2.

14.4.3.23.6 Enhanced descriptor for time-based scheduling

The time-based scheduling feature needs Enhanced Descriptors (that are 32 bytes) to be enabled on all the required DMA channels that intend to use the feature by setting the EDSE bit of DMA_CH(#i)_TX_Control register.

The structure of 32-byte Descriptor for the Context and the Normal Descriptor in Read and Write formats are described in the following sections:

Enhanced normal descriptor - read (32-bit mode)

The fields present in the first 16 bytes of the Enhanced Descriptor format of normal descriptor are as follows:

- LTV (Launch Time Valid)
  When FD = 0, this field indicates that the Launch Time (LT) and GSN fields present in the descriptor are valid. Set this field to 1, only if the FD field of the descriptor is 0.

- GSN (GCL Slot Number):
  This field indicates the GCL slot number associated with the packet
- Launch Time (LT):
  The launch time is a 32-bit value, where most-significant 8-bits represent the time in seconds and the rest LT[23:0] represents the launch time in increments of 256 ns. The launch time is compared against the IEEE 1588 based System/PTP Time (bits[39:8]) and rolls over after 256 seconds.

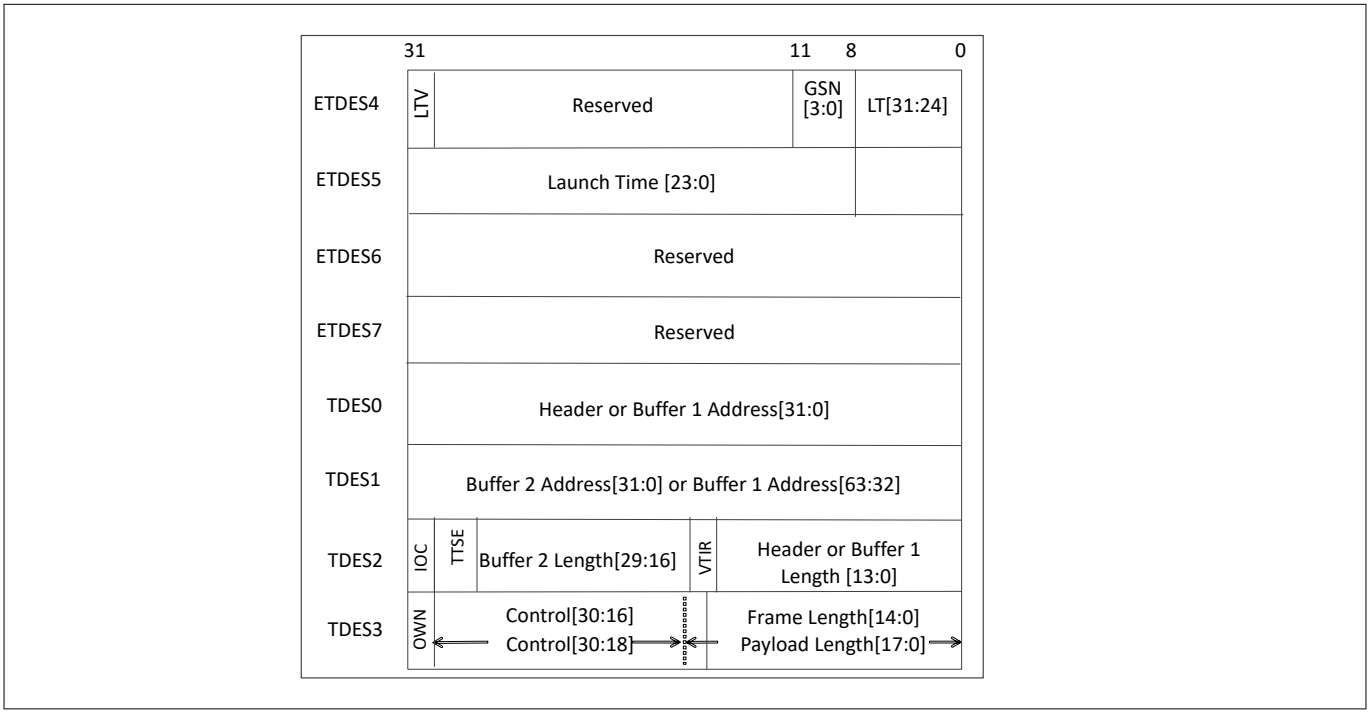

Figure 184 Enhanced normal Descriptor - read (32-bit mode)

Enhanced normal descriptor (write, 32-bit mode)

When the DMA closes the enhanced descriptor, it updates only the TDES0, TDES1, TDES2, and TDES3 fields. So, the values in the TDES4-TDES7 fields are retained in the host memory.

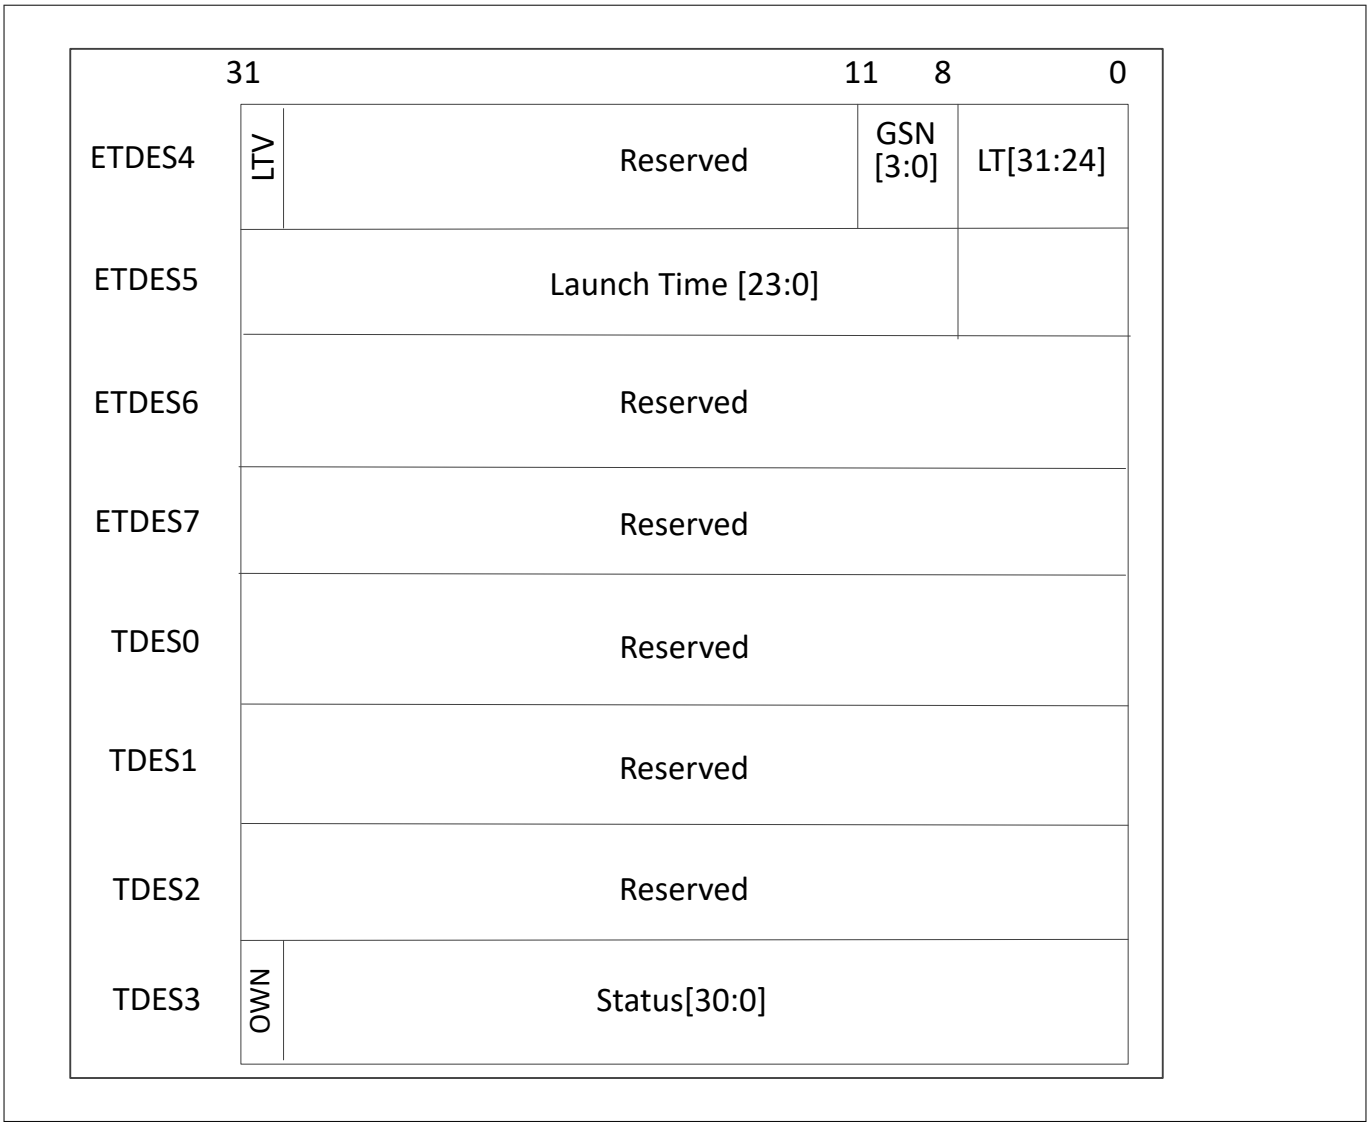

Figure 185 Enhanced normal descriptor (write, 32-bit mode)

Note:

- *All the enhanced descriptor examples assume a 32-bit data width configurations*
- *In both the write back formats, no modifications can be done to the extended 16 bytes. The rest of the 16 bytes (TDESC0 to TDESC3) are written back as per the previous 16 bytes Descriptor format*
- *When enabled, fetch time overrides the AV slot function*
- *When an unaligned new GCL list (with a different CTR) is installed, it is recommended not to have traffic during the installation of the new list. Any traffic during the switching of the lists might have unpredictable behavior regarding Fetch, Launch, and Launch expiry as the CTR and BTR values get updated while the frame is being processed*

Enhanced context descriptor (read, 32-bit mode)

The first 16 bytes of the Enhanced context descriptor (ETDESC4 to ETDESC7) are reserved and must be zeros. The fields present in last bytes of the Descriptor (TDESC0 to TDESC3) are same as the context descriptor (TDESC0 to TDESC3) in 16 byte format.

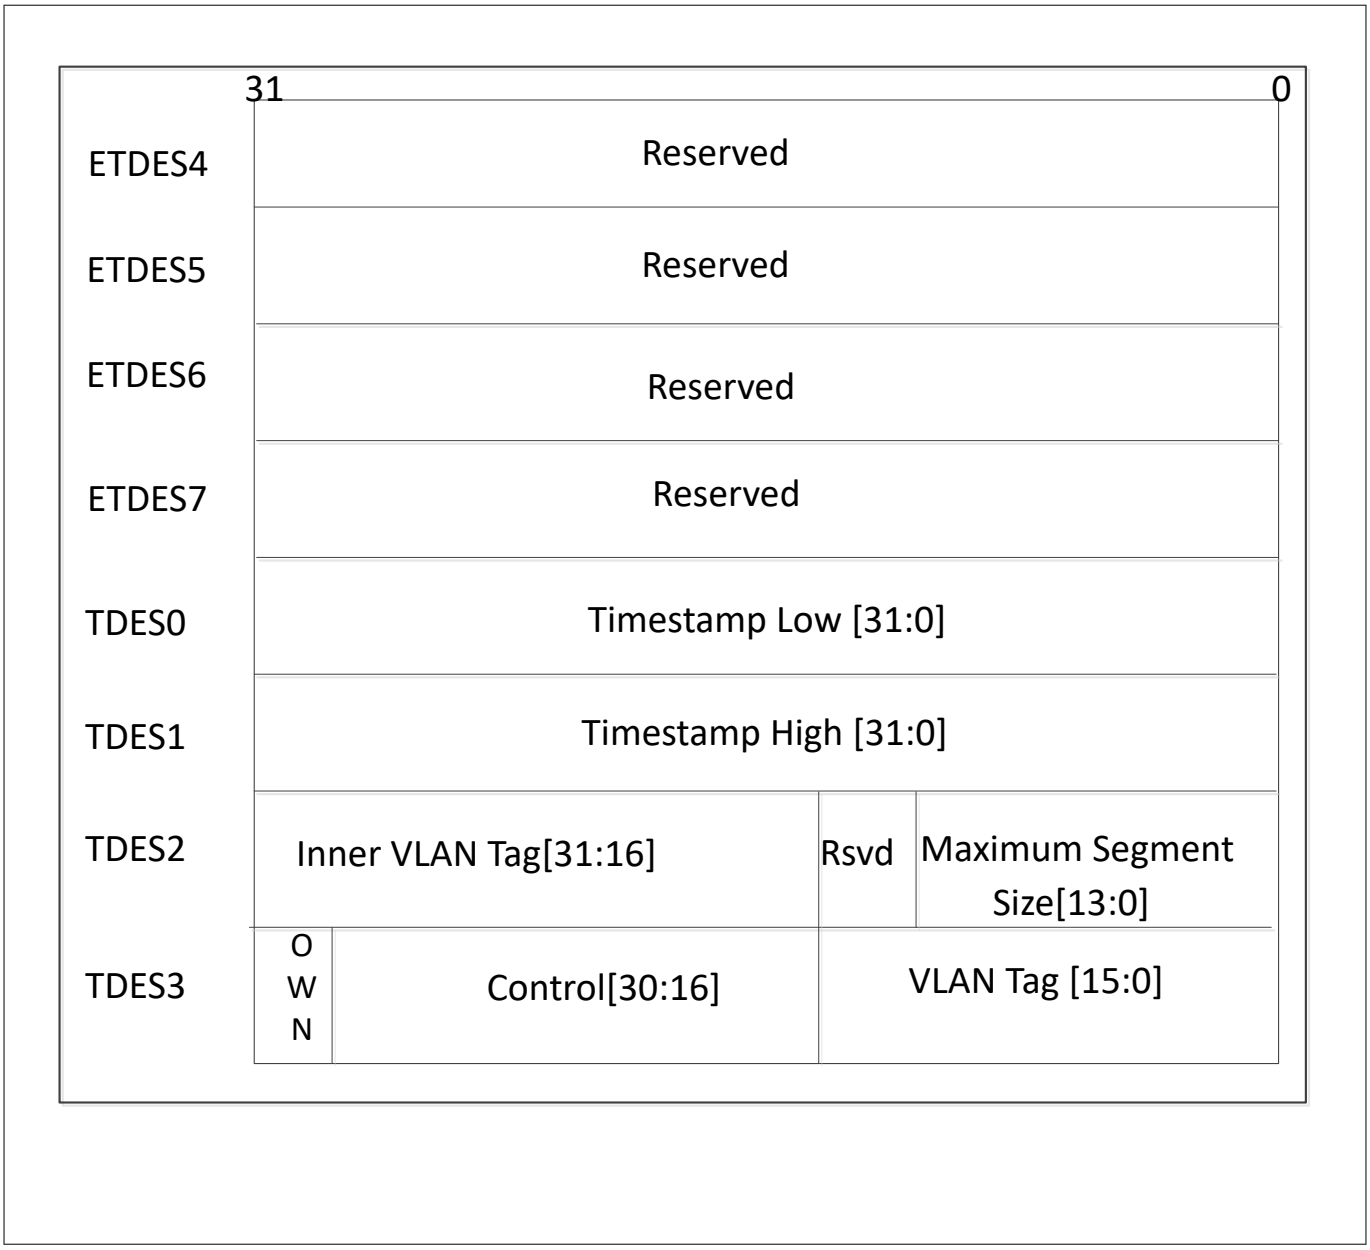

Figure 186 Enhanced context descriptor - read

Enhanced context descriptor (write, 32-bit mode)

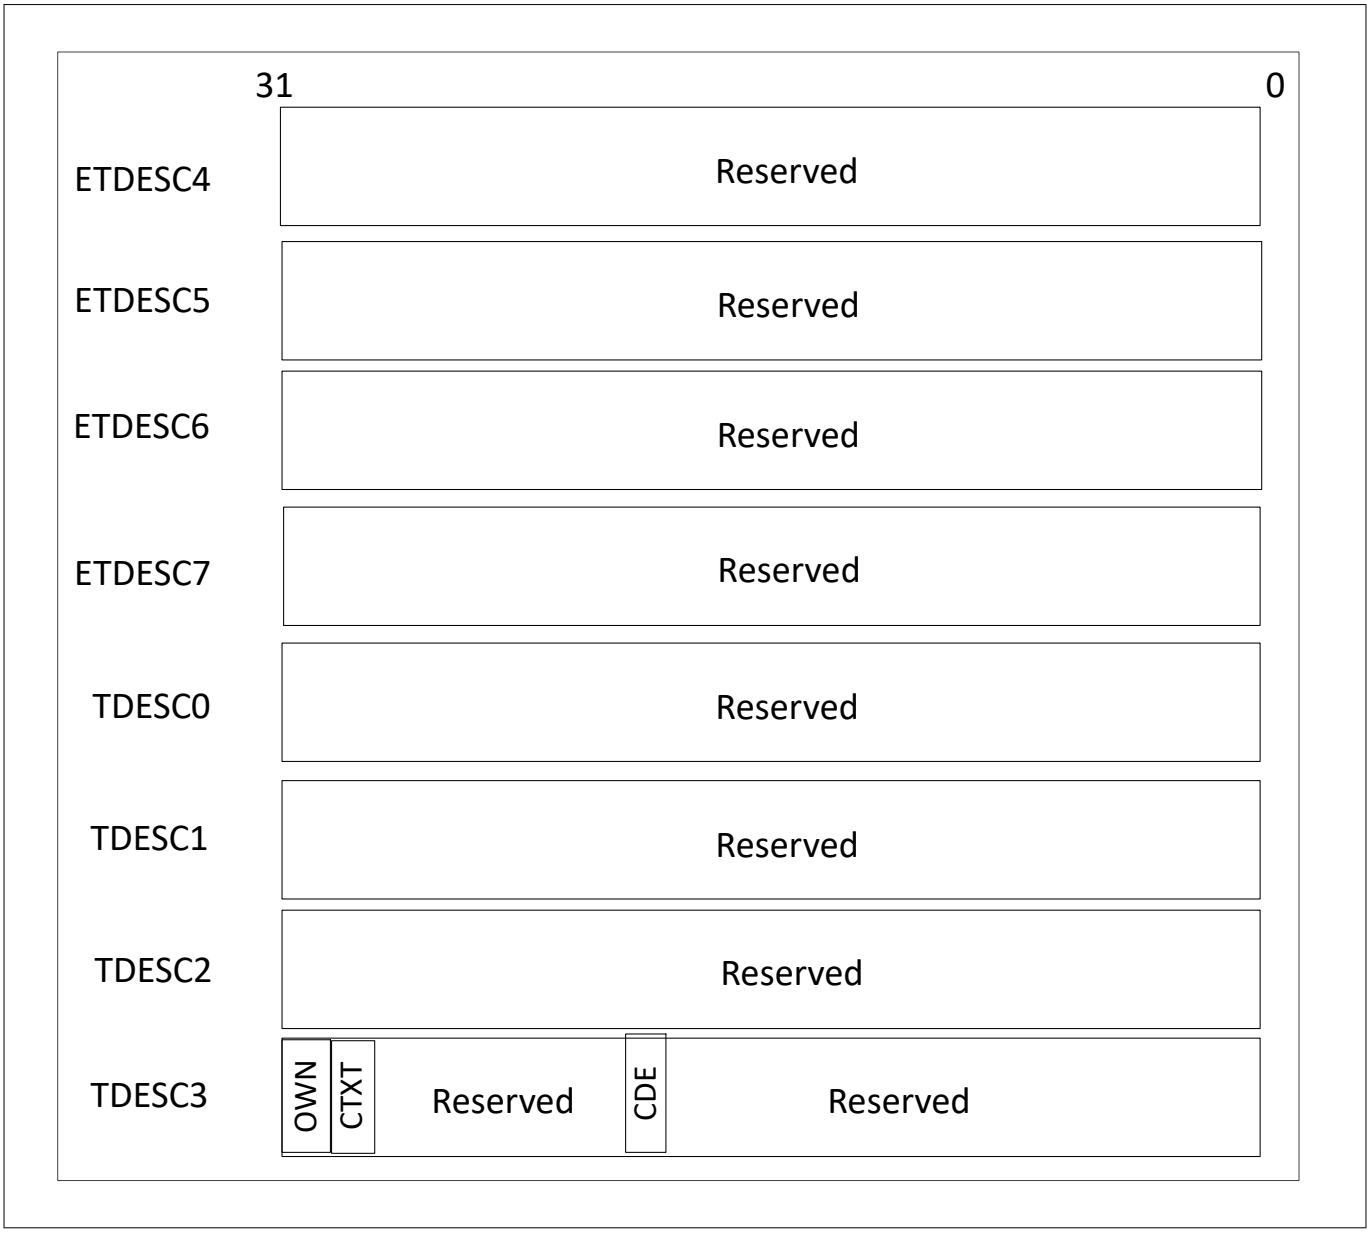

Figure 187 Enhanced context descriptor - write

***Note**: In both the write back formats, no modifications are done to the extended 16 bytes. The rest of the 16 bytes (TDESC0 to TDESC3) are written back as per the previous 16 bytes of the Descriptor format.*

14.4.3.24 IO Interfaces

14.4.3.24.1 Connectivity

Definition of the PHY Interfaces (MII, RMII, RGMII and (UX)SGMII) and the connection of the policing counter inputs from the PTP sub-module.

The module has up to four PHY interfaces. Some products may contain less.

HSPHY controls all of these interfaces. HSPHY needs to be configured before GETH. All connections to external pins are routed from GETH to HSPHY. Refer to High Speed Physical Layer (HSPHY) for correct setup.

Table 770 PHY interfaces

IF	Signal name in standard	GETH signal name	I/O
MII (via HSPHY)	TX_EN	TXEN	O
	TXD[3:0]	TXD[3:0]	O
	TX_ER	TXER	O
	TX_CLK	TXCLK	I
	COL	COL	I
	CRS	CRS	I
	RX_DV	RXDV	I
	RXD[3:0]	RXD[3:0]	I
	RX_ER	RXER	I
	RX_CLK	RXCLK	I
RMII (via HSPHY)	TX_EN	TXEN	O
	TXD[1:0]	TXD[1:0]	O
	CRS_DV	CRSDV	I
	RXD[1:0]	RXD[1:0]	I
	REF_CLK	REFCLK	I
RGMII (via HSPHY)	TD[3:0]	TXD[3:0]	O
	TX_CTL	TCTL	O
	TXC	TXCLK	O
	n. a.	GREFCLK (Reference input)	I
	RD[3:0]	RXD[3:0]	I
	RX_CTL	RCTL	I
	RXC	RXCLK	I
SGMII or UXSGMII (via HSPHY)	TX	SOP (serial out positive signal of the differential pair)	O
	TX	SON (serial out negative signal of the differential pair)	O
	RX	SIP (serial in positive signal of the differential pair)	I
	RX	SIN (serial in negative signal of the differential pair)	I
MDIO (via HSPHY)	MDC	MDC	O
	MDIO	MDIO	I/O
Pulse Per Second signal from Precision Time Protocol (ptp_pps_o[0][0]) MAC0, PPS0 (via PORTS)			O

(table continues...)

Table 770 (continued) PHY interfaces

IF	Signal name in standard	GETH signal name	I/O
Pulse Per Second signal from Precision Time Protocol (ptp_pps_o[0][1]) MAC0, PPS1 (via PORTS)			O
Pulse Per Second signal from Precision Time Protocol (ptp_pps_o[1][0]) MAC1, PPS0 (via PORTS)			O
Pulse Per Second signal from Precision Time Protocol (ptp_pps_o[1][1]) MAC1, PPS1 (via PORTS)			O

Each MAC has 16 policing counters. Each of them can use timer inputs to operate in a time windows mode. The time base for this time windows mode can be selected from the Pulse Per Second signals (PPS). These PPS signals are generated in the precision time protocol sub-module (PTP) described in chapter "IEEE 1588 Time Stamps". Each MAC generates two PPS outputs. So in sum there are four PPS outputs available in the system. Each of them can be selected as time window base for any of the policing counters by programming Register MAC_PCCtrl_IndReg[policing-counter-number].TWSEL (Time window Select) as described below:

Table 771 Connections of the policing counter inputs from the PTP sub-module (PPS to time window select)

PPS output	PORT[1:0].MAC_PCCtrl_IndReg[policing-counter-number].TWSEL
Pulse Per Second signal from Precision Time Protocol (ptp_pps_o[0][0]) MAC0, PPS0	00_B
Pulse Per Second signal from Precision Time Protocol (ptp_pps_o[0][1]) MAC0, PPS1	01_B
Pulse Per Second signal from Precision Time Protocol (ptp_pps_o[1][0]) MAC1, PPS0	10_B
Pulse Per Second signal from Precision Time Protocol (ptp_pps_o[1][1]) MAC1, PPS1	11_B

14.4.3.24.2 Clocks

The module has multiple clock inputs and outputs connecting it to the system.

Table 772 Clock lines of ethernet MAC

Clock line	Connected to	Description
aclk_i, clk_csr_i	f_{GETH}	This is the free-running clock input provided by the clock generation unit CGU. The local AXI, the DMA and the MTL modules also operate with this clock of maximum 250 MHz for full performance. For 2.5 Gbps and 5 Gbps this clock must be 200 MHz or higher.
f_{SRI}	f_{SRI}	AXI2SRI bridges are connected to this free-running clock provided by the clock generation unit (CGU) of maximum 250 MHz for full performance.
clk_tx_i	GETH_TXCLK (port pin)	MII transmit clock Input from PHY (10/100 Mbps) The external PHY or oscillator provides this transmission clock. TXD[3:0] is synchronous to this clock. This is 25 MHz in 100 Mbps mode and 2.5 MHz in 10 Mbps mode. Needs a clock input during SW reset (GETH_DMA_MODE.SWR)

(table continues...)

Table 772 (continued) Clock lines of ethernet MAC

Clock line	Connected to	Description
clk_gref_i	GETH_GREFCLK (port pin)	RGMII transmit clock Reference Input from PHY (1000 Mbps). The external PHY or oscillator provides this clock as reference. TXD[3:0] is not necessarily synchronous to this clock! This is always 125 MHz in 1000/100/10 Mbps/s mode. Needs a clock input during SW reset (GETH_DMA_MODE.SWR)
clk_tx_o	GETH_TXCLK (port pin)	RGMII transmission clock Output to PHY (1000 Mbps) . TXD[3:0] is synchronous (DDR) to this 125 MHz clock to the PHY. If RGMII is downgraded to 100 Mbps it is divided internally to 25 MHz and for 10 Mbps to 2.5 MHz. In each case it is generated from clk_gref_i by respective division. This division is controlled automatically by evaluation of mac_speed_o[1:0] and phy_intf_sel_i[2:0]. TXCLK has the same on chip delay and output pad delay as the TXD signals and TCTL unless clock skew is selected in SKEW.
clk_rx_i	GETH_RXCLK (port pin)	Receive clock from PHY. The external PHY provides this receive clock for RGMII and MII interfaces. This clock is 125 MHz in 1 Gbps mode, 25 MHz in 100 Mbps mode, 2.5 MHz in 10 Mbps mode. Needs a clock input during SW reset (GETH_DMA_MODE.SWR)
clk_rmii_i	GETH_REFCLK (port pin)	50-MHz clock used by the RMII from PHY. In 100 Mbps Mode, it is divided internally to 25 MHz and provided to the internal MII interface. If RMII is downgraded to 10 Mbps it is divided internally to 2.5 MHz. This division is controlled automatically by evaluation of mac_speed_o[1:0] and phy_intf_sel_i[2:0]. Needs a clock input during SW reset (GETH_DMA_MODE.SWR).
clk_ptp_ref_i	f_{GETH}	Reference Clock for the Time Stamp Update Logic of maximum 250 MHz for full performance
sbd_pc_tim_wdw_i[3:0]	ptp_pps_o[1:0][1:0]	The Policing Counters (PC) of the Intrusion Detection System have 4 inputs which are used as Time Window signals (TW). This allows to implement checks in hard ware for a maximum rate of frames. These time window signals are connected to the highly programmable Pulse Per Second (PTP EEE1588) outputs of the MACs. Each MAC has 2 PPS outputs ptp_pps_o[number of MAC] [number of output]. In sum there are 4 PPS signals in a bridge with 2 MACs. These PPS outputs are connected to the Policing Counter system which has 4 time window inputs pc_tw_i[3:0].

Table 773 List of phy interfaces and their clocks

Speed	Interface at MAC	Data line width	Interface at PHY	Interface clock frequency	Clock signal name at PHY
5 Gbps	XGMII	32	UXSGMII	156.25 MHz	No dedicated clock. Clock is always embedded in data.
2.5 Gbps	XGMII	32	SGMII	78.125 MHz	

(table continues...)

Table 773 (continued) List of phy interfaces and their clocks

2.5 Gbps	GMII	8	SGMII	312.5 MHz	
1 Gbps	GMII	8	SGMII	125 MHz	
100 Mbps	MII	4	SGMII	25 MHz	
100 Mbps	MII	4	MII	25 MHz	RXCLK, TXCLK
10 Mbps	MII	4	MII	2.5 MHz	RXCLK, TXCLK
1 Gbps	RGMII	4 (DDR)	RGMII	125 MHz	RXCLK, TXCLK, GREFCLK
100 Mbps	RGMII	4	RGMII	25 MHz	RXCLK, TXCLK, GREFCLK
10 Mbps	RGMII	4	RGMII	2.5 MHz	RXCLK, TXCLK, GREFCLK
100 Mbps	RMII	2	RMII	50 MHz	REFCLK
10 Mbps	RMII	2	RMII	5 MHz	REFCLK

***Note**: Half-duplex is supported in 10/100 MII and RMII modes only. All other modes use full-duplex only.*

***Note**: Clause 37 auto-negotiation is not supported. It is assumed that applications are deterministic and know the speed grade before implementation.*

14.5 Bridge

This chapter gives the overview of features and detailed specifications of the two-port Ethernet Bridge Subsystem.

The Bridge is designed for applications in which an end-station is connected to the Ethernet network using two Ethernet ports. It is capable of terminating traffic from either of the ports to the host through a multichannel DMA interface as well as forwarding traffic between the ports. The latter mainly targets a daisy-chained Ethernet network.

14.5.1 Feature list

This chapter gives the overview of features.

- The bridge connects two XGMACs and one common host interface
- It allows to statically establish the following data paths between these three blocks
- Transmit Ethernet frames on two Ethernet end points (two Ethernet endpoints exist in products with Ethernet Bridge only); the TX data is read from any address and stored in an internal FIFO buffer before transmission
- Receive Ethernet frames from any of the two Ethernet endpoints (two Ethernet endpoints exist in products with Ethernet Bridge only), store them in an internal FIFO and forward them to the other Ethernet endpoint in bridged operation mode or to the application (software side)
- Automotive Safety Features

  The automotive safety features improve the reliability and reduce the time taken to detect faults in the Ethernet Bridge. The Bridge supports the following features for automotive safety:

  - Error correction code (ECC) protection for memories
  - FSM parity and timeout protection
  - Application/CSR interface timeout protection

14.5.2 Functional overview

The block diagram below shows the two-port Ethernet Bridge Subsystem with one host port.

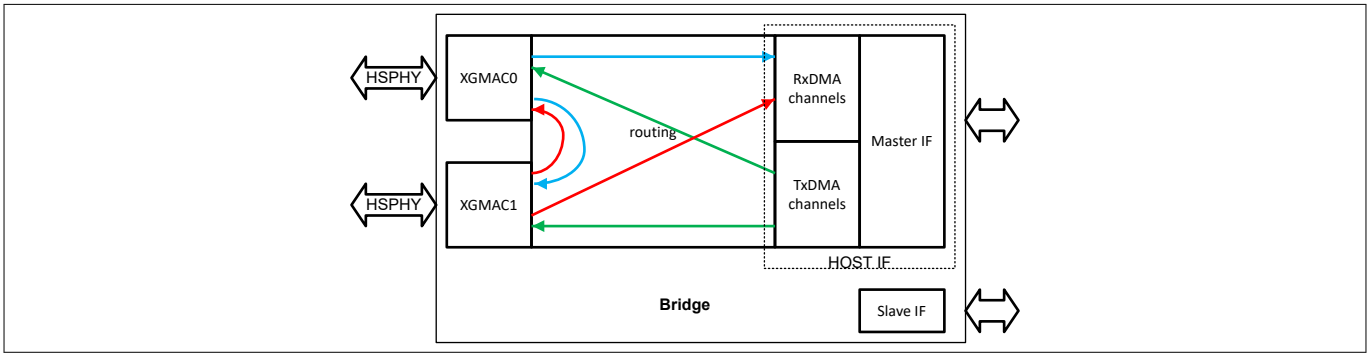

Figure 188 Bridge Overview

Main functionality

The Ethernet Bridge is built with a distributed memory architecture in which ingress/egress buffers are present on each line port. The Ethernet Bridge performs the transfer of packets using a cross-connect concept:

- From ingress to egress port (packet forwarding)
- From ingress to host port
- From host port to egress ports

Main features of the Ethernet Bridge are listed below:

- Each port of the Ethernet Bridge consists of a pair of bidirectional packet transfer interface
- The two Ethernet line ports are on the left side of the Ethernet Bridge as shown in Figure 188. The Ethernet port consist of the MAC and MTL blocks of the XGMAC IP. It has two interfaces to the Ethernet Bridge:
  - ARI-M (master) interface transfers the packets from ingress MAC to the Ethernet Bridge
  - ATI-S (slave) interface accepts the packets from the Ethernet Bridge and transfers to the egress MAC
- The host port is on the right side of the Ethernet Bridge as shown in Figure 188. It connects to the system bus on which the host CPU and host memory reside, through a multi-channel DMA engine. The host port consists of the DMA and master interface blocks of the XGMAC IP. Other than the line ports the host port of the Ethernet Bridge does not have any ingress/egress buffers. The host port will utilize the buffers on the line ports. It has two interfaces to the Ethernet Bridge:
  - ARI-S (slave) interface on the host port accepts the packets from the Ethernet Bridge and transfers to the RX DMA engine which in turn transfers them to the host memory
  - ATI-M (master) interface transfers the packets from the TX DMA engine (host memory) to the Ethernet Bridge

List of sub-blocks

The bridge subsystem is built with XGMAC IP and additional custom blocks

- XGMAC for line and host side ports
- Additional blocks:
  - Arbiter block:
    Prevents contentions at slave side
  - Control status registers
    Allows the application configuration and status read out
  - Clock and reset logic:
    Allows the application to configure the clock and to issue a reset
  - Packet transfer interfaces based on ARI and ATI:
    Allows packet based data transfer inside the bridge
  - Slave Interface:

Provides the application CPU with the ability to access all registers in the various ports of the Bridge through a single slave port

- Ethernet Bridge:
  Provides connection-based classification of traffic between the host port and the ingress/egress ports

14.5.3 Functional description

The following sub-section give more details on the operation modes of the bridge and its configuration. Furthermore the details of forwarding will be described in more detail.

14.5.3.1 Operation mode

The bridge can be configured either in one-port mode or in 2 port mode

In one port mode, only one MAC is active and no bridging available.

In two port mode, two MACs are active and the bridge can either forward frames between ports or send them from ports to the host or from the host to the ports.

One port mode

This is achieved by directly connecting the:

- ARI-M interface of Ethernet line port to ARI-S interface of host (DMA) port
- ATI-S interface of Ethernet line port to ATI-M interface of host (DMA) port

In this mode, the Ethernet line port operates with up to eight TxQ and up to eight RxQs connected to Tx/RxDMA towards the Host port.

You can program the Ethernet Bridge to operate in the one-port MAC mode by programming the Q_CH_MAPPING_EN bit to zero, and select the Ethernet line port through the PORT_SEL field of the Forward_Control register.

Two port mode

The Ethernet Bridge is connecting the two Ethernet ports with the host port.

Within the Ethernet Bridge, there will be three types of simultaneous traffic flows with possible contention in all the three flows at the destination:

- Traffic from the host port (TX DMA) to the egress of the two Ethernet ports. These are shown in Figure 188 as green lines and arrows from ATI-M interface of DMA to ATI-S of Ethernet ports within the Ethernet Bridge
- Traffic from the ingress (RX) interface of each Ethernet port to the host port (RX DMA). These are shown in Figure 188 as blue and red arrows from ARI-M interface of Ethernet ports to ARI-S of the DMA port within the Ethernet Bridge
- Traffic from the ingress port of one Ethernet port to the egress port of the other Ethernet port (forwarding between ports). These are shown in Figure 188 as blue and red arrows from ARI-M interface of Ethernet ingress ports to ATI-S of the Ethernet egress port within the Ethernet Bridge

  In this bridge, the packets from the host port to the Ethernet port (and vice versa), go through the same path as in a 1-port Controller. So, all the features and functions described in the XGMAC Controller hold true with respect to traffic shaping (AVB and TSN), flow control, filtering, and so on

You can program the Ethernet Bridge to operate in the two-port MAC mode by setting the Q_CH_MAPPING_EN bit of the Forward_Control register to 1'b1 and enabling the Ethernet port's TxQ and RxC channel mappings of the two Ethernet ports through the respective Port_i_Control register, TXQ_Map_Port_i register and RXC_Map_Port_i register.

14.5.3.2 Configuration of the bridge

This chapter explains, how queues and DMA channels can be mapped. It gives examples and also reflects the purpose of each configuration.

Naming convention

The following naming convention is used:

- Port: MAC inside bridge

- Host port: interface to the application side containing the DMA
- TxDMA: TxDMA channel in host port
- RxDMA: Rx DMA in host port
- TxQ: Tx Queue in Ethernet line port
- RxQ: Rx Queue in Ethernet line port
  - Inside XGMAC MTL, not used in the bridge for mapping
  - RxQ to DMA channel mapping is done by software configuration of the XGMAC MTL
  - This DMA channel number is used in the bridge as RxC
- RxC: Rx Channel in Ethernet line port
  - Frame filtering or RxQ to DMA mapping results in a DMA number (dynamic mapping)
  - In the bridge, this DMA number is used as RxC number for further bridge mapping
- Bridge mapping
  - Each RxC can be mapped to either a RxDMA of the host port or a TxQ of the other port for forwarding
  - The TxQ can be mapped to either a TxDMA of the host port or an RxC of the other port for forwarding

Configuration

Each MAC (port) has eight TxQs, eight RxCs and eight RxQs. The host port has eight TxDMAs and eight RxDMAs

For full flexibility, use “dynamic mapping” on the Rx path (see XGMAC description). RxDMA number will be based on:

- DA/SA and VLAN register filter engine in the MAC Receiver and/or
- Flexible receive parser engine

This RxDMA number is reused in the bridge configuration and interpreted as RxC number. A mapping table in the Ethernet Bridge allows now to configure two kinds of destination from this RxC: Either to a:

- RxDMA or to a
- TxQ of the other port

On the Tx path, a mapping table can be configured by programming the following registers:

- Port_0_Control Register. The user decides if:
  - TxQi and RxCi are used for forwarding by setting Port_0_Control.FWD_EN
    - TxQi is mapped to an RxC in Port 1, the RxC number is defined in TXQ_Map_Port_0.TXQi
  - Or TxQi and RxCi are each mapped to a TxDMA and RxDMA channel by clearing Port_0_Control.FWD_EN
    - TxQi is mapped to a TxDMA, the TxDMA number is defined in TXQ_Map_Port_0.TXQi
    - RxCi is mapped to an RxDMA, the RxDMA number is defined in RXC_Map_Port_0.RXCi
- Port_1_Control Register. The user decides if:
  - TxQi and RxCi are used for forwarding by setting Port_1_Control.FWD_EN
    - TxQi is mapped to an RxC in Port 0, the RxC number is defined in TXQ_Map_Port_1.TXQi
  - Or TxQi and RxCi are each mapped to a TxDMA and RxDMA channel by clearing Port_1_Control.FWD_EN
    - TxQi is mapped to a TxDMA, the TxDMA number is defined in TXQ_Map_Port_1.TXQi
    - RxCi is mapped to an RxDMA, the RxDMA number is defined in RXC_Map_Port_1.RXCi

***Note**:* *Registers Port_0_Control and Port_1_Control must be programmed after TXQ_Map_Port_0, RXC_Map_Port_0, TXQ_Map_Port_1 and RXC_Map_Port_1!*

TxQ Mapping details

The Ethernet Bridge supports flexible mapping of TxQ:

- TxQ to TxDMA for egress traffic and
- TxQ to RxC for forwarding traffic

The application can configure this through registers.

TxDMA to TxQ static mapping enables virtualization as traffic from TxDMA channel to the TxQ of egress port are isolated from the forwarding traffic between the ports. This way forwarded frames don't need to go to the application interface. AXI bandwidth is efficiently utilized without any backpressure.

RxC Mapping

Similarly, for virtualization purpose, it is recommended to allocate a fixed number of RxDMA channels for the ingress traffic of the two ports. For example RxDMA#0-3 are allocated to Ethernet Port0 RxC#0-3 while RxDMA#4-7 are allocated to Ethernet Port1 RxC#0-3.

For the RxQ to RxDMA mapping, we recommend using dynamic (packet based) mapping to give maximum flexibility. One of the reasons is also that packets from the Ingress MAC are distributed into the RxQs based on "VLAN priority" and not based on destination. Hence packets to be forwarded to other Ethernet port and packets destined for host port can be queued in the same RxQ if they belong to the same traffic class (VLAN tag priority).

***Note**: In single-port mode, the RxQ to RxDMA mapping is not configured in the bridge but it is configured inside the XGMAC, by programming* Port j MTL RxQ DMA Map0 *and* Port j MTL RxQ DMA Map1*.*

The programming of the "destination DMA" numbers in the filter-registers or flexible receive parser should be programmed accordingly, in each of the Ethernet ports, so that host traffic is segregated and goes to its allocated RxDMA channel.

Users can configure in the filters that a specific RxDMA number is assigned to a packet. This number is assigned by the first passing filter. In the bridge configurations, this RxDMA number is reused and interpreted as RxC number. A mapping table in the Ethernet Bridge allows now to configure two kinds of destination from this RxC: Either to a RxDMA or to a TxQ of the other port. This will allow flexibility to do the mapping while retaining common software programming in each Ethernet port.

14.5.3.3 Arbiters in the bridge

Traffic at the destination (egress) ports will have contention between traffic coming from the other ingress ports.

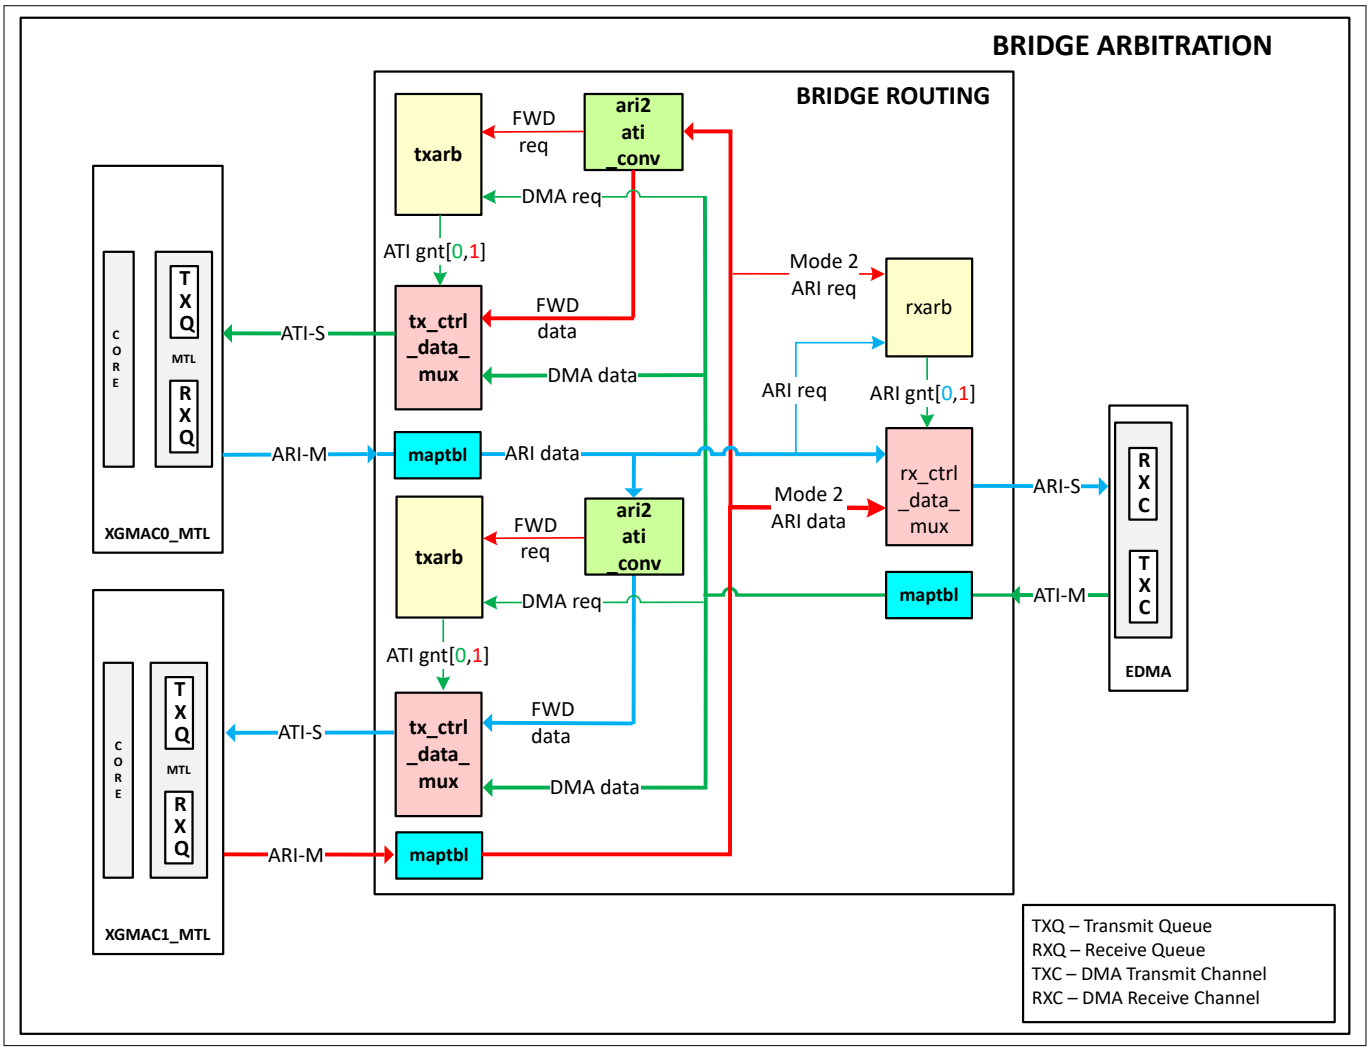

Figure 189 Bridge detailed block diagram

For example

1. ATI-S interface of Ethernet Port 0 can get packets from host port (Tx DMA) and packets forwarded from ARI-M of Ethernet Port 1
2. ATI-S interface of Ethernet Port 1 can get packets from host port (Tx DMA) and packets forwarded from ARI-M of Ethernet Port 0
3. ARI-S interface of host port (Rx DMA) can get packets from ARI-M of Ethernet Port 0 and Port 1

Hence arbiters are required to perform the packet transfers without losing the integrity of the packet.

Arbitration on Ethernet ports: Arbiters for 1. and 2. are simple priority arbiter with traffic from TxDMA (host port) given highest priority (to avoid backpressure on AXI). Arbitration is done every clock so that transactions from host port (AXI) are never blocked. The transactions from the other Ethernet port can be blocked temporarily because the packet is buffered in its RxQ.

Arbitration on host ports: Arbiters for 3. depends on whether RxC are statically allocated between Ethernet Port 1 and 2. If yes, then the arbitration can be Round-Robin between the transactions from the two Ethernet ports. Arbitration cycle is done after every burst transfer initiated from a port is completed.

The specific functionality of the arbiters are as follows:

- In TX path, the bridge is a pass-through with 1-1 connections between the EDMA and corresponding TxQ. The maximum latency that can get added is 1-2 fGETH clock cycles if it gets added to meet any timing requirements. This will not be a factor affecting TBS fetch time
- Port forwarded transfer will have lower priority than host fetched packets. The reason is that port-forwarded packets have ingress buffers while packets fetched from AXI/host does not have buffers and will block the AXI if not serviced immediately. The arbitration on ATI is “clock-cycle” based, that means ATI from EDMA will get priority and ATI from other MAC port will get serviced in free clock cycle windows
- TxQs are statically mapped. That means they are either connected to host/EDMA or connected to port-forwarded traffic from RX of other MAC ports

14.5.3.4 DMA

This section describes how multiple queues are supported in the Transmit and Receive paths in the DMA block. For the architecture of DMA Controller, please refer to chapter XGMAC.

TransmitPath

The bridge supports up to eight Tx channels in the DMA block.

The bridge can be programmed such that the requests of all the TxDMAs are placed and executed on the AXI bus before the data transfer of the first TxDMA is completed and it raises the next request to the arbiter.

Effectively, all the TxDMA channels get equal access to AXI bus and the corresponding TxQs gets filled up at the same rate. The data gets read out from the TxQs as per the Traffic Class scheduler in the MTL. Therefore, at a steady state (assuming that the AXI bandwidth available to fetch data from system memory is always more than the XGMAC operating line rate), the bandwidth for each channel is controlled by the priorities and settings of the Traffic Scheduler.

ReceivePath

The bridge supports up to eight Rx channels in the DMA block.

In the Rx direction, the MTL Rx Controller selects the Rx DMA for which it is transferring or reading the data from the Rx FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it has to transfer. The scheduler checks whether sufficient data (of requested burst length) is available to be transferred to these DMAs and then selects the Rx DMA that gets serviced using the programmed priorities.

Priority scheme for Tx DMA and RxDMA

The DMA arbiter performs the fixed priority arbitration between the Tx and Rx paths of DMA channels for accessing descriptors and data buffers. Descriptor accesses of a Tx or Rx channel is given higher priority when requests from both are active together.

14.6 Registers

14.6.1 Register overview - access mode glossary

Table 774 Register overview - access mode glossary

Keyword	Description
SE	Access protection using PROT register PROTSE.
APU-PCHy (y=0-7)	Protection group consisting of registers ACCENCHy_WRA, ACCENCHy_WRB, ACCENCHy_RDA, ACCENCHy_RDB, ACCENCHy_VM, ACCENCHy_PRS.
PCHy	Access protection using *APU-PCHy* registers.
APU-PG	Protection group consisting of registers ACCENGLOBAL_WRA, ACCENGLOBAL_WRB, ACCENGLOBAL_RDA, ACCENGLOBAL_RDB, ACCENGLOBAL_VM, ACCENGLOBAL_PRS.
PG	Access protection using *APU-PG* registers.
APU-PMy (y=0-1)	Protection group consisting of registers ACCENMACy_WRA, ACCENMACy_WRB, ACCENMACy_RDA, ACCENMACy_RDB, ACCENMACy_VM, ACCENMACy_PRS.
PMy	Access protection using *APU-PMy* registers.
BE	Always returns a Bus Error.
32	Access only when using 32-bit width.
PROT	Access restrictions as defined in the PROT register access rules.

14.6.3 Clock control register

The clock control register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 00000_H

Clock control register Application Reset value: $0000\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

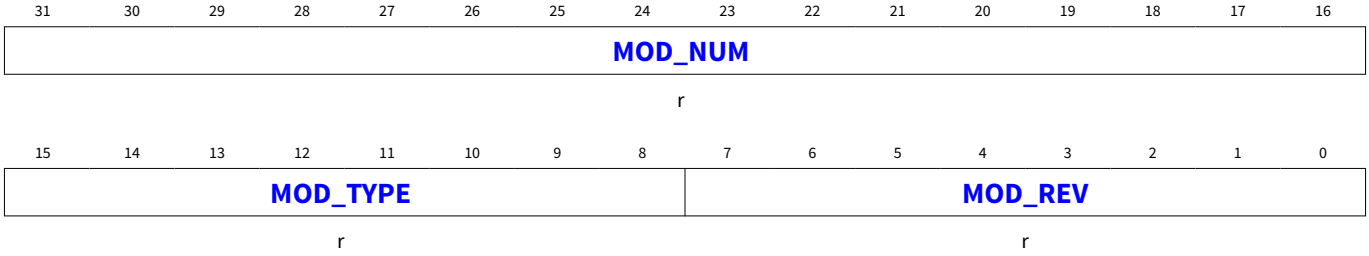
0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module disable request bit** Used for enable and disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module disable status bit** 0_B Module clock is enabled 1_B Module is not clocked
EDIS	3	rw	**Sleep mode enable control** GETH module does not support reaction to sleep mode. 0_B Not applicable 1_B Not applicable
0	2, 31:4	r	**Reserved, write 0, read as 0**

14.6.4 Module identification register

ID Offset address: 00008_H

Module identification register PowerOn Reset value: $00F1\ C001_H$

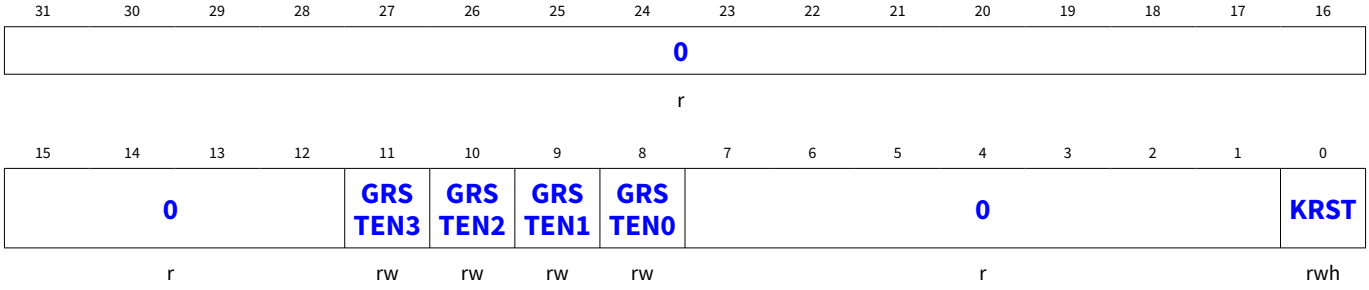


Field	Bits	Type	Description
MOD_REV	7:0	r	**Module revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module number** Indicates the module identification number.

14.6.5 Reset control register A

RST_CTRLA Offset address: $0000C_H$

Reset control register A Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rwh	**Kernel reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for global module reset group x** These bit fields have no functionality, KRST is executed if CTRLA.KRST=1 and CTRLB.KRST=1 independently from GRSTEN bits. 0_B Global module reset group x does not have any effect 1_B Global module reset group x results in a kernel reset
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

14.6.6 Reset Control Register B

RST_CTRLB Offset address: 00010_H

Reset Control Register B Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w								r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															KRST
r															rwh

Field	Bits	Type	Description
KRST	0	rwh	**Kernel reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
STATCLR	31	w	**Kernel reset status clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bit STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

14.6.7 Reset status register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: 00014_H

Reset status register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				GRST3	GRST2	GRST1	GRST0	0							KRST
r				rh	rh	rh	rh	r							rh

Field	Bits	Type	Description
KRST	0	rh	**Kernel reset status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.
GRSTx (x=0-3)	x+8	rh	**Status for global module reset group x** 0_B Reset was not triggered by global reset group x 1_B Reset was triggered by global reset group x
0	7:1, 31:12	r	**Reserved** Read as 0.

14.6.8 Clock control register for MAC

Register used to turn MAC Cores on and off individually.

MACEN Offset address: 00018_H

Clock control register for MAC Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														MAC1	MAC0
r														rw	rw

Field	Bits	Type	Description
MAC0	0	rw	**Used for enabling and disabling MAC0** Used for enabling and disabling MAC0 0_B Off request: Disable MAC0 1_B On Request: Enable MAC0
MAC1	1	rw	**Used for enabling and disabling MAC1** Used for enabling and disabling MAC1 0_B Off request: Disable MAC1 1_B On Request: Enable MAC1
0	31:2	r	**Reserved** Read as 0; should be written with 0.

14.6.9 PROT register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock and unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 00024_H

PROT register safe endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OWEN	ODEF	TAGID						PRSEN	PRS			VMEN	VM

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												SWEN	STATE		
r												w	rwh		

Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.

(table continues...)

(continued)

Field	Bits	Type	Description
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 776 Access mode restrictions of PROTSE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

14.6.10 Write access enable register A

This register defines which master agent function TAG identifier (TAG-ID) encodings are enabled or disabled for write accesses to the access protected region.

ACCENGLOBAL_WRA Offset address: 00040_H

Write access enable register A Application Reset value: $1000\ 0003_H$

14.6.28 Port j MAC Tx Configuration

The MAC Transmit Configuration register establishes the operating mode of the MAC transmitter.

Portj_MAC_Tx_Configuration (j=0-1) Offset address: $10000_H+j*2000_H$

Port j MAC Tx Configuration Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SS			0	0	0	0	0	0	SARC			0	0	0	JD
rw			r	r	r	r	r	r	rw			r	r	r	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		LUD	TC	IFP	IPG			ISR				ISM	0	DDIC	TE
r		rw	rw	rw	rw			rw				rw	r	rw	rw

Field	Bits	Type	Description
TE	0	rw	**Transmitter Enable** When this bit is set, the Tx state machine of the MAC is enabled for transmission on the GMII or XGMII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets.
DDIC	1	rw	**Disable DIC Algorithm** When this bit is set, the Deficit Idle Count (DIC) algorithm is disabled and DWC_xgmac always has a minimum IFG of 12 bytes between transmitted packets. When reset to zero, the DIC is activated and the minimum IFG varies between 9 and 15 bytes.
ISM	3	rw	**IFG Stretch Mode** When this bit is set, DWC_xgmac enforces extended inter-packet spacing (one extra octet of IDLE for every ISR (IFG Stretch Ratio) number of bytes) to support less-than-10-Gbps data rates. When this bit is reset, inter-packet gap extension is not performed.
ISR	7:4	rw	**IFG Stretch Ratio** This value controls the number of bytes in a transmitted packet for which one octet of IDLE is added to the IFG. To operate DWC_xgmac for 10GBASE-W (WIS layer), the value must be 13 (decimal). Note that 0 is not a valid value and must not be written. Before enabling ISM (IFG Stretch Mode) bit, this ISR number must be programmed to a non-zero value.

(table continues...)

(continued)

Field	Bits	Type	Description
IPG	10:8	rw	**Inter-Packet Gap** These bits control the minimum IPG between packets during transmission. When IFP is cleared, the minimum IPG between transmitted packets is reduced in both GMII and XGMII mode. The corresponding IPG values are given as follows. - 3'b000: 96 bit times - 3'b001: 88 bit times - 3'b010: 80 bit times - 3'b011: 72 bit times - 3'b100: 64 bit times - 3'b101: 3'b111: Reserved In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is transmitted because of backpressure activation, the MAC does not consider the minimum IPG. When IFP is set, the minimum IPG is increased in steps of 32 bits as follows. In 10G (XGMII) mode, when IFP is set, it overrides the functions of DDIC and ISM bits. The EIPG bits (in MAC_Extended_Configuration register) along with IPG bits gives a 10-bit value to control the required IPG as follows: - {EIPG,IPG}: Minimum Inter-Packet Gap - 10'h000: 96 bit times - 10'h001: 128 bit times - 10'h002: 160 bit times - 10'h003: 192 bit times - 10'h004: 224 bit times - ... - 10'h3FF: 32832 bit times
IFP	11	rw	**IPG Control** When this bit is set, the minimum IPG is increased in steps of 32 bits from the default 96 bits, depending on the programming of the IPG field. In the XGMII mode, this bit has higher priority than the ISM bit. When this bit is reset, the minimum IFG is decreased in steps of 8 bits from the default 96 bits, depending on the programming of the IPG field.
TC	12	rw	**Transmit Configuration in RGMII** When set, this bit enables the transmission of duplex mode, link speed, and link up or down information to the PHY in the RGMII, port. When this bit is reset, no such information is driven to the PHY. - 1'b0: Disable Transmit Configuration in RGMII - 1'b1: Enable Transmit Configuration in RGMII

(table continues...)

(continued)

Field	Bits	Type	Description
LUD	13	rw	**Link Up or Down** This bit indicates whether the link is up or down during transmission of configuration in the RGMII interface. - 1'b0: Link down - 1'b1: Link up
JD	16	rw	**Jabber Disable** When this bit is set, the DWC_xgmac disables the jabber timer on the transmitter. Transmission of up to 16383-byte packets is supported. When this bit is reset, DWC_xgmac cuts off the transmitter if the application sends more than 2048 bytes of data (10240 bytes if JE (in MAC_Rx_Configuration register is set high) during transmission.
SARC	22:20	rw	**Source Address Insertion or Replacement Control** This field controls the source address insertion or replacement for all transmitted packets. Bit 22 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[21:20]: 2'b0x: The SA insertion-replacement is controlled by SAIC field (Bits[25:23]) of TDES3 Normal Descriptor 2'b10: - If Bit 22 is set to 0, the MAC inserts the content of the MAC Address 0 registers (MAC_Address0_High and MAC_Address0_Low) in the SA field of all transmitted packets. - If Bit 22 is set to 1 the MAC inserts the content of the MAC Address 1 registers (MAC_Address1_High and MAC_Address1_Low) in the SA field of all transmitted packets. 2'b11: - If Bit 22 is set to 0, the MAC replaces the content of the MAC Address 0 registers (MAC_Address0_High and MAC_Address0_Low) in the SA field of all transmitted packets. - If Bit 22 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers (MAC_Address1_High and MAC_Address1_Low) in the SA field of all transmitted packets. Note: - Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.

(table continues...)

(continued)

Field	Bits	Type	Description
SS	31:29	rw	**Speed Selection** Software programs these bits to instruct the MAC to operate in one of the following possible speeds: - 3'b000 Reserved - 3'b001 Reserved - 3'b010 2.5G GMII - 3'b011 1G GMII - 3'b100 100M MII - 3'b101 5G XGMII - 3'b110 2.5G XGMII - 3'b111 10M MII These bits must be programmed only once; after a hardware reset and before the transmitter and receiver are enabled (by bit 0 of this register and bit 0 of the MAC_Rx_Configuration register). Refer to device specific configuration table for the speed modes supported by GETH in corresponding device.
0	2, 15:14, 17, 18, 19, 23, 24, 25, 26, 27, 28	r	**Reserved** Read as 0; should be written with 0.

14.6.29 Port j MAC Rx Configuration

The MAC Receive Configuration register establishes the operating mode of the MAC receiver.

Portj_MAC_Rx_Configuration (j=0-1) Offset address: $10004_H+j*2000_H$

Port j MAC Rx Configuration Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	0	GPSL													
r	r	rw													

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	HDSMS			S2KP	LM	IPC	JE	WD	GPSLCE	USP	SPEN	DCRCC	CST	ACS	RE
r	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
RE	0	rw	**Receiver Enable** When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the GMII or XGMII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the GMII or XGMII interface.
ACS	1	rw	**Automatic Pad or CRC Stripping** When this bit is set, the MAC strips the Pad or FCS field on the incoming packets, only if the value of the length field is less than 1536 bytes. All received packets with length field greater than or equal to 1536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all the incoming packets to the application, without any modification.
CST	2	rw	**CRC stripping for Type packets** When this bit is set, the last four bytes (FCS) of all packets of Ether type (field greater than 1536) are stripped and dropped before forwarding the packet to the application. When this bit is reset,CRC field of Ethernet packet is not stripped.
DCRCC	3	rw	**Disable CRC Checking for Received Packets** When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets.
SPEN	4	rw	**Slow Protocol Detection Enable** When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid sub-types. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets.
USP	5	rw	**Unicast Slow Protocol Packet Detect** When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_Address0_High and MAC_Address0_Low registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2018, Section 5.

(table continues...)

(continued)

Field	Bits	Type	Description
GPSLCE	6	rw	**Giant Packet Size Limit Control Enable** When this bit is set, the MAC considers the value in GPSL field in MAC_Rx_Configuration register to declare a received packet as Giant packet. This field must be programmed to more than 1518 bytes. Otherwise, the MAC considers 1518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9018 bytes (9022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit must be less than the watchdog limit to get the giant packet status.
WD	7	rw	**Watchdog Disable** When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16383 bytes. When this bit is reset, the MAC does not allow more than 2048 bytes (10240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2048 bytes.
JE	8	rw	**Jumbo Packet Enable** When this bit is set, the MAC allows jumbo packets of 9018 bytes (9022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status.
IPC	9	rw	**Checksum Offload** When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled.
LM	10	rw	**Loopback Mode** When this bit is set, the MAC operates in the loopback mode at GMII or XGMII. The (X)GMII Rx clock input is required for the loopback to work properly. This is because the Tx clock is not internally looped back.
S2KP	11	rw	**IEEE 802.3as Support for 2K Packets** When this bit is set, the MAC considers all packets with up to 2000 bytes length as normal packets. When the JE bit is not set, the MAC considers all the received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all the received packets of size more than 1518 bytes (1522 bytes for tagged) as giant packets. Note: When the JE bit is set, setting this bit has no effect on the giant packet status.

(table continues...)

(continued)

Field	Bits	Type	Description
HDSMS	14:12	rw	**Maximum Size for Splitting the Header Data** These bits indicate the maximum header size allowed for splitting the header data in the received packet: - 3'b000: 64 bytes - 3'b001: 128 bytes - 3'b010: 256 bytes - 3'b011: 512 bytes - 3'b100: 1023 bytes - 3'b101-3'b111: Reserved
GPSL	29:16	rw	**Giant Packet Size Limit** If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1518 bytes. Any other programmed value is considered as 1518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. The value in this field is applicable when the GPSLCE bit is set in MAC_Rx_Configuration register.
0	15, 30, 31	r	**Reserved** Read as 0; should be written with 0.

14.6.30 Port j MAC Packet Filter

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

Portj_MAC_Packet_Filter (j=0-1) Offset address: $10008_H+j*2000_H$

Port j MAC Packet Filter Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RA	0								0	DNTU	IPFE	0			VTFE
rw	r								r	rw	rw	r			rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0			DHLFRS		0	SAF	SAIF	PCF		DBF	PM	DAIF	0	0	PR
r			rw		r	rw	rw	rw		rw	rw	rw	r	r	rw

Field	Bits	Type	Description
PR	0	rw	**Promiscuous Mode** When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The MAC clears the SA or DA Filter Fail status bits of the Rx Status Word when PR is set.
DAIF	3	rw	**DA Inverse Filtering** When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed.
PM	4	rw	**Pass All Multicast** When this bit is set, it indicates that all the received packets with a multicast destination address (first bit in the destination address field is 1) are passed. When this bit is reset, filtering of multicast packet is done
DBF	5	rw	**Disable Broadcast Packets** When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all the received broadcast packets.
PCF	7:6	rw	**Pass Control Packets** These bits control the forwarding of all control packets (including unicast and multicast Pause packets). - 00: The MAC filters all control packets from reaching the application. - 01: The MAC forwards all control packets except Pause packets to the application even if they fail the Address filter. - 10: The MAC forwards all control packets to the application even if they fail the Address filter. - 11: The MAC forwards the control packets that pass the Address filter.
SAIF	8	rw	**SA Inverse Filtering** When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the MAC_Address registers, it is marked as failing the SA Address filter. When this bit is reset, if the SA of a packet does not match the values programmed in the MAC_Address registers, it is marked as failing the SA Address filter.

(table continues...)

(continued)

Field	Bits	Type	Description
SAF	9	rw	**Source Address Filter Enable** When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled MAC_Address registers. If the comparison fails, the MAC drops the packet. When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison. Note: According to the IEEE specification, Bit 47 of the SA is reserved. However, in DWC_xgmac, the MAC compares all 48 bits. The software driver must consider this while programming the MAC address registers for SA.
DHLFRS	12:11	rw	**L3/L4 Filter Number in Receive Status** This field selects L3/L4 filter number information to provide in receive descriptor. Values: 0x0: Use backward compatible L3/L4 filter number field (RDES2[31:29]) in receive status. 0x1: Reserved. 0x2: Use combined RDES2[26:19] and RDES2[31:29] fields to provide L3/L4 filter number. 0x3: Reserved.
VTFE	16	rw	**VLAN Tag Filter Enable** When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag.
IPFE	20	rw	**Layer 3 and Layer 4 Filter Enable** When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields.
DNTU	21	rw	**Drop Non-TCP/UDP over IP Packets** When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets.
RA	31	rw	**Receive All** When this bit is set, the MAC Receiver module passes all the received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter.

(table continues...)

Field	Bits	Type	Description
WTO	3:0	rw	**Watchdog Timeout** When the PWE bit is set and the WD bit of the MAC_Rx_Configuration register is reset, this field is used as watchdog timeout limit for a received packet. If the length of a received packet exceeds the value of this field, such a packet is terminated and declared as an error packet. Encoding is as follows: - 4'h0: 2 KB - 4'h1: 3 KB - 4'h2: 4 KB - 4'h3: 5 KB - ... - 4'hC: 14 KB - 4'hD: 15 KB - 4'hE: 16383 Bytes - 4'hF: Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
PWE	8	rw	**Programmable Watchdog Enable** When this bit is set and the WD bit of the MAC_Rx_Configuration register is reset, the WTO field is used as watchdog timeout limit for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in MAC_Rx_Configuration register.
JTO	19:16	rw	**Jabber Timeout** When the PJE bit is set and the JD bit of the MAC_Tx_Configuration register is reset, this field is used as jabber timeout limit for a transmitted packet. If the length of a transmitted packet exceeds the value of this field, such a packet is terminated and declared as an error packet. Encoding is as follows: - 4'h0: 2 KB - 4'h1: 3 KB - 4'h2: 4 KB - 4'h3: 5 KB - ... - 4'hC: 14 KB - 4'hD: 15 KB - 4'hE: 16383 Bytes - 4'hF: Reserved
PJE	24	rw	**Programmable Jabber Enable** When this bit is set and the JD bit of the MAC_Tx_Configuration register is reset, the JTO field is used as jabber timeout limit for a transmitted packet. When this bit is cleared, the jabber timeout limit for a transmitted packet is controlled by setting of JD and JE bits in MAC_Tx_Configuration and MAC_Rx_Configuration registers, respectively.
0	7:4, 15:9, 23:20, 31:25	r	**Reserved** Read as 0; should be written with 0.

14.6.32 Port j MAC VLAN Tag Ctrl

This register holds the control and addressing fields required for indirect accessing of the MAC_VLAN_Tag_Filter registers. And also it holds the control fields for MAC VLAN Hash Filter and perfect filtering.

Portj_MAC_VLAN_Tag_Ctrl (j=0-1) Offset address: $10050_H+j*2000_H$

Port j MAC VLAN Tag Ctrl Kernel Reset value: $0000\ 0000_H$

0		0		0					OFS					CT	OB
r		r		r					rw					rw	rw

Field	Bits	Type	Description
OB	0	rw	**Operation Busy** This bit is set along with a read or write command for initiating the indirect access to per VLAN Tag Filter register. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into the Per VLAN Tag register. During a read operation, the data must be read from the MAC_VLAN_Tag_Data register only after this bit is reset.
CT	1	rw	**Command Type** This bit indicates if the current register access is a read or a write. When set, it indicate a read operation. When reset, it indicates a write operation.
OFS	6:2	rw	**Offset** This field holds the address offset of the MAC VLAN Tag Filter register which the application is trying to access. The width of the field depends on the number of MAC VLAN Tag registers enabled.
ETV	16	rw	**Enable 12-Bit VLAN Tag Comparison for VLAN hash filtering** When this bit is set, a 12-bit VLAN identifier is used for VLAN hash filtering instead of the complete 16-bit VLAN tag. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for VLAN hash filtering.
VTIM	17	rw	**VLAN Tag Inverse Match/Result Enable** When this bit is set, it enables the VLAN Tag inverse matching . A match is marked when Packets have non-matching VLAN tags. When reset, it enables the VLAN Tag perfect matching . A match is marked when packets have matching VLAN tags.
ESVL	18	rw	**Enable S-VLAN** When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets.
ERSVLM	19	rw	**Enable Receive S-VLAN Match for VLAN hash filtering** When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets. The ERIVLT bit determines the VLAN tag position considered for filtering or matching.

(table continues...)

(continued)

Field	Bits	Type	Description
DOVLTC	20	rw	**Disable VLAN Type Check for VLAN hash filtering** When this bit is set, the MAC does not check whether the VLAN Tag specified by the ERIVLT bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the ERIVLT bit only when VLAN Tag type is similar to the one specified by the ERSVLM bit.
EVLS	22:21	rw	**Enable VLAN Tag Stripping on Receive** This field indicates the stripping operation on the outer VLAN Tag in received packet: - 2'b00: Do not strip - 2'b01: Strip if VLAN filter passes - 2'b10: Strip if VLAN filter fails - 2'b11: Always strip
EVLRXS	24	rw	**Enable VLAN Tag in Rx status** When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status.
VTHM	25	rw	**VLAN Tag Hash Table Match Enable** When this bit is set, the most significant four bits of CRC of VLAN Tag are used to index the content of the MAC_VLAN_Hash_Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the packet matched the VLAN hash table. When the ETV bit is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison. When the ETV bit is reset, the CRC of the 16-bit VLAN tag is used for comparison. When this bit is reset, the VLAN Hash Match operation is not performed.
EDVLP	26	rw	**Enable Double VLAN Processing** When this bit is set, the MAC enables processing of up to two VLAN Tags on Tx and Rx (if present). When this bit is reset, the MAC enables processing of up to one VLAN Tag on Tx and Rx (if present).
ERIVLT	27	rw	**Enable Inner VLAN Tag for VLAN hash filtering** When this bit and the EDVLP field are set, the MAC receiver enables hash operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables hash operation on the outer VLAN Tag (if present). The ERSVLM bit determines which VLAN type is enabled for filtering or matching.
EIVLS	29:28	rw	**Enable Inner VLAN Tag Stripping on Receive** This field indicates the stripping operation on inner VLAN Tag in the received packet: - 2'b00: Do not strip - 2'b01: Strip if VLAN filter passes - 2'b10: Strip if VLAN filter fails - 2'b11: Always strip

(table continues...)

(continued)

Field	Bits	Type	Description
EIVLRXS	31	rw	**Enable Inner VLAN Tag in Rx Status** When this bit is set, the MAC provides the inner VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the inner VLAN Tag in Rx status.
0	11:7, 13:12, 15:14, 23, 30	r	**Reserved** Read as 0; should be written with 0.

14.6.33 Port j MAC VLAN Tag Data

This register holds the read/write data for Indirect Access of the Per MAC_VLAN_Tag_Filter registers. During the read access, this field contains valid read data only after the OB bit is reset. During the write access, this field must be valid prior to setting the OB bit in the MAC_VLAN_Tag_Ctrl register.

Portj_MAC_VLAN_Tag_Data (j=0-1) Offset address: $10054_H+j*2000_H$

Port j MAC VLAN Tag Data Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
VID	15:0	rw	**VLAN Tag ID** This field holds the VLAN Tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set.
VEN	16	rw	**VLAN Tag Enable** This bit is used to enable or disable the VLAN Tag. When this bit is set, the MAC compares the VLAN Tag of received packet with the VLAN Tag ID. When this bit is not set, no comparison is performed irrespective of the programming of the other fields.
ETV	17	rw	**Enable 12-Bit VLAN Tag Comparison** When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits[11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. Similarly, when enabled, only 12 bits of the VLAN tag in the received packet are used . When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for comparison
DOVLTC	18	rw	**Disable VLAN Type Check** When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits[11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. Similarly, when enabled, only 12 bits of the VLAN tag in the received packet are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for comparison and VLAN hash filtering.
ERSVLM	19	rw	**Enable Receive S-VLAN Match** When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for CVLAN (Type = 0x8100) packets. The ERIVLT bit determines the VLAN tag position considered for filtering or matching.

(table continues...)

(continued)

Field	Bits	Type	Description
ERIVLT	20	rw	**Enable Inner VLAN Tag** When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). The ERSVLM bit determines which VLAN type is enabled for filtering or matching.
DMACHEN	24	rw	**DMA Channel Number Enable** If this bit is set,it enables the DMA Channel Number value programmed in the field DMACH. If this is reset, then the Routing does not occur based on the VLAN Filter result. The packet is routed based on the DA Based DMA Channel Routing.
DMACHN	27:25	rw	**DMA Channel Number** The DMA Channel number to which the VLAN Tagged Packet is to be routed if it passes this VLAN Tag Filter is programmed in this field. This field is valid only when DMACHEN=1. If the Routing based on the VLAN Tag Filter is not necessary, this field need not be programmed.
0	23:21, 31:28	r	**Reserved** Read as 0; should be written with 0.

14.6.42 Port j MAC VLAN Hash Table

When the ERSVLM bit is set of MAC_VLAN_Tag_Ctrl, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_Tag_Ctrl register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3-2018).
- Perform bit-wise reversal for the value obtained in step 1.
- Take the upper four bits from the value obtained in step 2.

If the VLAN hash Table register is configured to be double-synchronized to the (X)GMII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written.

If double-synchronization is enabled, consecutive writes to this register must be performed after at least four clock cycles in the destination clock domain.

Portj_MAC_VLAN_Hash_Table (j=0-1) Offset address: $10058_H+j*2000_H$

Field	Bits	Type	Description
VLT	15:0	rw	**VLAN Tag for Transmit Packets** This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: - Bits[15:13]: User Priority - Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) - Bits[11:0]: VLAN Identifier (VID) field of VLAN tag
VLC	17:16	rw	**VLAN Tag Control in Transmit Packets** - 2'b00: No VLAN tag deletion, insertion, or replacement - 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. - 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. - 2'b11: VLAN tag replacement The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8). Note: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.
VLP	18	rw	**VLAN Priority Control** When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, bits[17:16] are ignored and the Tx descriptor is used.
CSVL	19	rw	**C-VLAN or S-VLAN** When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.
VLTI	20	rw	**VLAN Tag Input** When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet must be taken from Tx descriptor. When this bit is reset, it indicates that the VLAN tag to be inserted or replaced in Tx packet must be taken from the VLT field of this register.

(table continues...)

(continued)

Field	Bits	Type	Description
CBTI	21	rw	**Channel Based Tag Insertion** When this bit is set, outer VLAN tag is inserted for every packets transmitted by the MAC. The tag value is taken from the queue/channel specific VLAN tag register. This overrides VLTI, VLP, VLC and VLT fields of this register When this bit is set, a write operation to byte 3 of this register initiates the read/write access to the indirect register. When reset, outer VLAN operation is based on the setting of VLTI, VLP, VLC, and VLT fields of this register.
ADDR	26:24	rw	**Address** This field selects one of the queue/channel specific VLAN Inclusion register for read/write access. This does not have any effect when CBTI is reset.
RDWR	30	rw	**Read Write Control** This bit controls the read or write operation for indirectly accessing the queue/channel specific VLAN Inclusion register. When set, indicates write operation and when reset indicates read operation This does not have any effect when CBTI is reset.
BUSY	31	r	**BUSY** This bit indicates the status of the read/write operation of indirect access to the queue/channel specific VLAN inclusion register. When this bit is reset, write to this register is complete in write operation or read data is valid in read operation When this bit is set, No further writes are allowed to this register. This does not have any effect when CBTI is reset.
0	23:22, 29:27	r	**Reserved** Read as 0; should be written with 0.

14.6.54 Port j MAC Q0 Tx Flow Ctrl

The MAC_Q0_Tx_Flow_Ctrl register controls the generation of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit(FCB) set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the IEEE 802.3-2018 specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transmitted by the MAC. The application must make sure that the Busy bit is cleared before writing to the register.

Portj_MAC_Q0_Tx_Flow_Ctrl (j=0-1) Offset address: $10070_H+j*2000_H$

Port j MAC Q0 Tx Flow Ctrl Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0								DZPQ	PLT			0		TFE	FCB
r								rw	rw			r		rw	rw

Field	Bits	Type	Description
FCB	0	rw	**Flow Control Busy or Backpressure Activate** This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. In the full-duplex mode, this bit must be read as 1'b0 before writing to this register.To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You must not write to this register until this bit is cleared. When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. For the backpressure function, this control bit is logically ORed with the H/W transmit pause frame request signal.When the MAC is configured for the full-duplex mode, the BPA is automatically disabled.
TFE	1	rw	**Transmit Flow Control Enable** In the full-duplex mode, when this bit is set, the MAC enables the flow control operation based on the Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets by itself. In the half-duplex mode, when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled.
PLT	6:4	rw	**Pause Low Threshold** This field configures the threshold of the Pause timer at which the input flow control signal from the FIFO layer is checked for automatic retransmission of the Pause packet. The threshold values must be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the transmit pause frame request signal is asserted at 228 (256 - 28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values: - 3'b000: Pause Time minus 4 Slot Times (PT - 4 slot times) - 3'b001: Pause Time minus 28 Slot Times (PT - 28 slot times) - 3'b010: Pause Time minus 36 Slot Times (PT - 36 slot times) - 3'b011: Pause Time minus 144 Slot Times (PT - 144 slot times) - 3'b100: Pause Time minus 256 Slot Times (PT - 256 slot times) - 3'b101 - 3'b111: Reserved The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or XGMII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, or 16384) + 2 Pause Packet Size + IPG in Slot Times.

(continued)

Field	Bits	Type	Description
DZPQ	7	rw	**Disable Zero-Quanta Pause** When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled.
PT	31:16	rw	**Pause Time** This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the (X)GMII clock domain, consecutive writes to this register must be performed only after at least four clock cycles in the destination clock domain.
0	3:2, 15:8	r	**Reserved** Read as 0; should be written with 0.

14.6.55 Port j MAC Rx Flow Ctrl

The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet.

Portj_MAC_Rx_Flow_Ctrl (j=0-1) Offset address: $10090_H+j*2000_H$

Port j MAC Rx Flow Ctrl Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0							0	0						UP	RFE
r							r	r						rw	rw

Field	Bits	Type	Description
RFE	0	rw	**Receive Flow Control Enable** - 1: When MAC operates in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. - 0: When MAC operates in half-duplex mode, the decode function of the Pause packet is disabled.

(table continues...)

(continued)

Field	Bits	Type	Description
UP	1	rw	**Unicast Pause Packet Detect** A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3-2018. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address must be as specified in MAC_Address0_High and MAC_Address0_Low. When this bit is reset, the MAC only detects Pause packets with unique multicast address. Note: The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1Qbb-2011.
0	7:2, 8, 31:9	r	**Reserved** Read as 0; should be written with 0.

14.6.56 Port j MAC RxQ Ctrl4

The Receive Queue Control 4 register controls the routing of

- Packets which fail the Destination or Source Address filter and VLAN Filter. Packets refer to Express packets only when FPE is configured
- Preemptive Multicast/Broadcast packets when MCBCQEN of MAC_RxQ_Ctrl1 is enabled to a separate Rx Queue

Portj_MAC_RxQ_Ctrl4 (j=0-1) Offset address: $10094_H+j*2000_H$

Port j MAC RxQ Ctrl4 Kernel Reset value: $0000\ 0000_H$

0				MFFQ			MFFQE	0				UFFQ			UFFQE
r				rw			rw	r				rw			rw

Field	Bits	Type	Description
UFFQE	0	rw	**Unicast Filter Fail Packets Queuing Enable** When this bit is set, the Unicast packets which fail the Destination or Source address filter are routed to the Rx Queue Number programmed in the UFFQ. When this bit is reset, the Unicast packets which fail the Destination or Source address filter are routed based on other routing options. This bit is valid only when the RA bit of the MAC_Packet_Filter register is set. values: - 0: Unicast Address Filter Fail Packets Queuing is disabled. - 1: Unicast Address Filter Fail Packets Queuing is enabled.

(table continues...)

(continued)

Field	Bits	Type	Description
UFFQ	3:1	rw	**Unicast Address Filter Fail Packets Queue** This field holds the Rx queue number to which Unicast Packets failing the Destination or Source Address filter must be routed. This field is valid only when UFFQE the bit is set.
MFFQE	8	rw	**Multicast Filter Fail Packets Queuing Enable** When this bit is set, the Multicast packets which fail the Destination or Source address filter are routed to the Rx Queue Number programmed in the MFFQ. When this bit is reset, the Multicast packets which fail the Destination or Source address filter are routed based on other routing options. This bit is valid only when the RA bit of the MAC_Packet_Filter register is set. values: - 0: Multicast Address Filter Fail Packets Queuing is disabled. - 1: Multicast Address Filter Fail Packets Queuing is enabled.
MFFQ	11:9	rw	**Multicast Address Filter Fail Packets Queue** This field holds the Rx queue number to which Multicast Packets failing the Destination or Source Address filter must be routed. This field is valid only when MFFQE the bit is set.
VFFQE	16	rw	**VLAN Tag Filter Fail Packets Queuing Enable** When this bit is set, the tagged packets which fail the Destination or Source address filter or fail the VLAN tag filter, are routed to the Rx Queue Number programmed in the VFFQ. When this bit is reset, the tagged packets which fail the Destination or Source address filter or fail the VLAN tag filter are routed based on other routing options. This bit is valid only when the RA bit of the MAC_Packet_Filter register is set. values: - 0: VLAN tag Filter Fail Packets Queuing is disabled. - 1: VLAN tag Filter Fail Packets Queuing is enabled.
VFFQ	19:17	rw	**VLAN Tag Filter Fail Packets Queue** This field holds the Rx queue number to which the tagged packets failing the Destination or Source Address filter (and UFFQE/MFFQE not enabled) or failing the VLAN tag filter must be routed. This field is valid only when the VFFQE bit is set.
PMCBCQ	26:24	rw	**Preemption Multicast/Broadcast Queue** This field holds the Rx queue number to which the preemptive Multicast/Broadcast packets passing the Destination or Source Address filter or the VLAN tag filter must be routed. This field is valid only when the MCBCQEN bit of MAC_RxQ_Ctrl1 register is set.

(table continues...)

(continued)

Field	Bits	Type	Description
UDC	31	rw	**Unicast Packet Duplication Control** When this bit is set along with DDS bit of the MAC_Extended_Configuration register, the MAC routes the received packet with Unicast Destination Address to the highest Receive Queue selected in configuration, provided that more than one bit are set in the DMA Channel number specified in XDCS field of MAC_DChSel_IndReg(#i) register that matched the Unicast Destination Address of the received packet. Note: When the above condition is satisfied for unicast packet but the highest Receive Queue selected in configuration is not enabled or when DA/SA/VLAN filter fails and corresponding filter fail Receive Queue is enabled, it will be routed to Receive Queue determined by other queuing methods. When this bit is reset, the MAC routes the received packet with Unicast Destination Address based other queuing methods, the DMA Channel number selected is binary value from DCS field of MAC_Address(#i)_High register (if DDS bit is reset) or lowest bit set in one-hot value from XDCS field of MAC_DChSel_IndReg(#i) indirect register (if DDS is set) that matched the Unicast Destination Address of the received packet.
0	7:4, 15:12, 23:20, 30:27	r	**Reserved** Read as 0; should be written with 0.

14.6.57 Port j MAC RxQ Ctrl5

The Receive Queue Control 5 register allows selection of start offset of the Receive queue from which received packets are routed based on VLAN Tag Priority field.

Portj_MAC_RxQ_Ctrl5 (j=0-1) Offset address: $10098_H+j*2000_H$

Port j MAC RxQ Ctrl5 Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												PRQSO			
r												rw			

Field	Bits	Type	Description
PRQSO	3:0	rw	**Priority Receive Queue Start Offset** This field holds the Receive queue number from which received packets are routed based on the VLAN Tag Priority field. For example, value of 0 indicates PSRQ0, PSRQ1, .. PSRQ7 fields in MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers are mapped to Receive Queue 0, Receive Queue 1, .. Receive Queue 7 respectively. Similarly, value of 3 indicates PSRQ0, PSRQ1, .. PSRQ7 fields in MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers are mapped to Receive Queue 3, Receive Queue 4, .. Receive Queue 10 respectively. The Receive queue number programmed in this field must not be more than number of Receive queues selected in configuration. Note: When this field is programmed to a value such that Receive queues selected in configuration are lesser than the sum of programmed value and 7, all the PSRQx fields cannot be mapped to the Receive queues. For example, if number of Receive queues selected in configuration is 8 and this field is programmed to 5, only the PSRQ0, PSRQ1 and PSRQ2 can be mapped to Receive Queue 5, Receive Queue 6 and Receive Queue 7 respectively.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

14.6.58 Port j MAC RxQ Ctrl0

The Receive Queue Control 0 register activates the queue management in the MAC Receiver. This register is present only when you select multiple queues in the Receive path.

Portj_MAC_RxQ_Ctrl0 (j=0-1) Offset address: $100A0_H+j*2000_H$

Port j MAC RxQ Ctrl0 Kernel Reset value: $0000\ 0000_H$

MCBCQEN	0			MCBCQ				RQ				UPQ			
rw	r			rw				rw				rw			

Field	Bits	Type	Description
UPQ	3:0	rw	**Untagged Packet Queue** This field specifies the Rx queue on which the received untagged packets are routed. - 4'b0000: Rx Queue 0 - 4'b0001: Rx Queue 1 - ... - 4'b0111: Rx Queue 7 - 4'b1000 - 4'b1111: Reserved
RQ	7:4	rw	**Frame Preemption Residue Queue** This field holds the Rx queue number to which the residual preemption frames must be forwarded. Preemption frames that are tagged and pass the SA/DA/VLAN filtering are routed based on the PSRQ field. All other frames are treated as residual frames and are routed to the queue number mentioned in this field. Queue-0 is used as a default queue for express frames, so this field cannot be programmed to a value 0.
MCBCQ	11:8	rw	**Multicast or Broadcast Queue** This field specifies the Rx queue on which the Multicast or Broadcast packets are routed. - 4'b0000: Rx Queue 0 - 4'b0001: Rx Queue 1 - ... - 4'b0111: Rx Queue 7 - 4'b1000 - 4'b1111: Reserved
MCBCQEN	15	rw	**Multicast or Broadcast Queue Enable** This bit specifies that Multicast or Broadcast packets routing to the Rx Queue is enabled and the Multicast or Broadcast packets must be routed to Rx Queue specified in MCBCQ field.
OMCBCQ	20	rw	**Programmable control for Over-riding MCBCQ Priority** When set to 1, this field enables over-riding the MCBC Queue priority. When set to 0, this field disables over-riding the MCBC Queue priority.
TPQC	22:21	rw	**Tagged PTP over Ethernet Packets Queuing Control** This field controls the routing of the VLAN Tagged PTP over Ethernet packets. The following programmable options are allowed. - 2'b00: VLAN Tagged PTP over Ethernet packets are routed as generic VLAN Tagged packet (based on the PSRQ field for only the non-AV enabled Rx Queues). - 2'b01: VLAN Tagged PTP over Ethernet packets are routed to Rx Queue specified by PTPQ field (That Rx Queue can be enabled for AV or non-AV traffic). - 2'b10: VLAN Tagged PTP over Ethernet packets are routed to only AV enabled Rx Queues based on the PSRQ field. - 2'b11: Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
TACPQE	23	rw	**Tagged AV Control Packets Queuing Enable** When set, the MAC routes the received Tagged AV Control packets to the Rx queue specified by AVCPQ field. If Tagged AV Control packets received are expected to be preempted then do not set the TACPQE bit to enable a separate queue. When reset, the MAC routes the received Tagged AV Control packets based on the tag priority matching the PSRQ fields in MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers.
PTPQ	27:24	rw	**PTP Packets Queue** This field specifies the Rx queue on which the untagged PTP packets sent over the Ethernet payload (not over IPv4 or IPv6) are routed. - 4'b0000: Rx Queue 0 - 4'b0001: Rx Queue 1 - ... - 4'b0111: Rx Queue 7 - 4'b1000 - 4'b1111: Reserved When the AV8021ASMEN bit of MAC_Timestamp_Control register is reset, even though VLAN tagged PTP over Ethernet packets are processed, it is routed based on the VLAN Tag priority.
AVCPQ	31:28	rw	**AV Control Packets Queue** This field specifies the Rx queue on which the received AV Control packets (tagged and untagged) are routed. - 4'b0000: Rx Queue 0 - 4'b0001: Rx Queue 1 - ... - 4'b0111: Rx Queue 7 - 4'b1000 - 4'b1111: Reserved
0	14:12, 19:16	r	**Reserved** Read as 0; should be written with 0.

14.6.60 Port j MAC RxQ Ctrl2

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 3. This register is present when multiple Rx Queues are selected

Portj_MAC_RxQ_Ctrl2 (j=0-1) Offset address: $100A8_H+j*2000_H$

Port j MAC RxQ Ctrl2 Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
PSRQ0	7:0	rw	**Priorities Selected in the Receive Queue 0** This field decides the priorities assigned to Rx Queue 0. All packets with priorities that match the values set in this field are routed to Rx Queue 0. For example, if PSRQ0[5] is set, packets with USP field equal to 5 are routed to Rx Queue 0. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.
PSRQ1	15:8	rw	**Priorities Selected in the Receive Queue 1** This field decides the priorities assigned to Rx Queue 1. All packets with priorities that match the values set in this field are routed to Rx Queue 1. For example, if PSRQ1[4] is set, packets with USP field equal to 4 are routed to Rx Queue 1. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.
PSRQ2	23:16	rw	**Priorities Selected in the Receive Queue 2** This field decides the priorities assigned to Rx Queue 2. All packets with priorities that match the values set in this field are routed to Rx Queue 2. For example, if PSRQ2[1, 0] are set, packets with USP field equal to 1 or 0 are routed to Rx Queue 2. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.
PSRQ3	31:24	rw	**Priorities Selected in the Receive Queue 3** This field decides the priorities assigned to Rx Queue 3. All packets with priorities that match the values set in this field are routed to Rx Queue 3. For example, if PSRQ3[6, 3] are set, packets with USP field equal to 3 or 6 are routed to Rx Queue 3. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.

14.6.61 Port j MAC RxQ Ctrl3

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 4 to 7. This register is present with more than four Rx queues.

Portj_MAC_RxQ_Ctrl3 (j=0-1) Offset address: $100AC_H+j*2000_H$

Port j MAC RxQ Ctrl3 Kernel Reset value: $0000\ 0000_H$

PSRQ5								PSRQ4							
rw								rw							

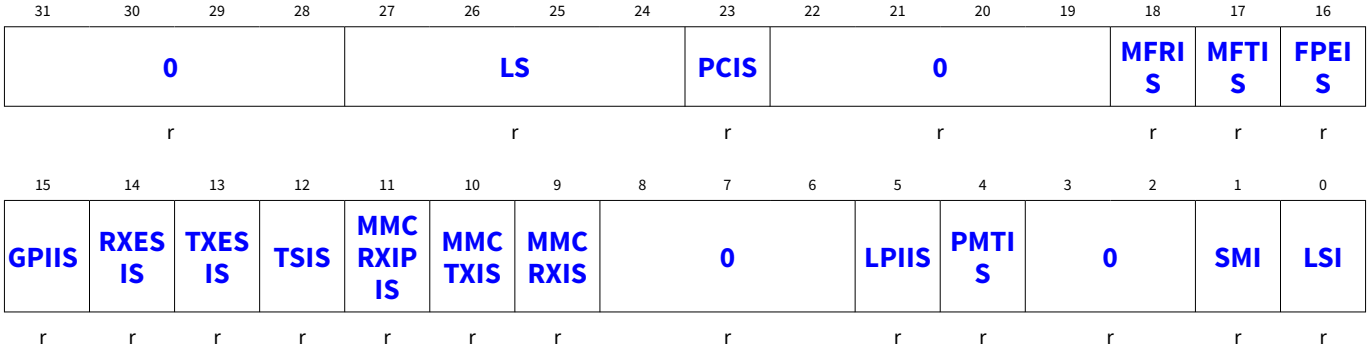
Field	Bits	Type	Description
PSRQ4	7:0	rw	**Priorities Selected in the Receive Queue 4** This field decides the priorities assigned to Rx Queue 4. All packets with priorities that match the values set in this field are routed to Rx Queue 4. For example, if PSRQ4[7:4] is set, packets with USP field equal to 7, 6, 5, or 4 are routed to Rx Queue 4. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.
PSRQ5	15:8	rw	**Priorities Selected in the Receive Queue 5** This field decides the priorities assigned to Rx Queue 5. All packets with priorities that match the values set in this field are routed to Rx Queue 5. For example, if PSRQ5[6] is set, packets with USP field equal to 6 are routed to Rx Queue 5. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.
PSRQ6	23:16	rw	**Priorities Selected in the Receive Queue 6** This field decides the priorities assigned to Rx Queue 6. All packets with priorities that match the values set in this field are routed to Rx Queue 6. For example, if PSRQ6[5] are set, packets with USP field equal to 5 are routed to Rx Queue 6. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.
PSRQ7	31:24	rw	**Priorities Selected in the Receive Queue 7** This field decides the priorities assigned to Rx Queue 7. All packets with priorities that match the values set in this field are routed to Rx Queue 7. For example, if PSRQ7[7, 4] are set, packets with USP field equal to 7 or 4 are routed to Rx Queue 7. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.

14.6.62 Port j MAC Interrupt Status

The Interrupt Status register. The register contains status of the events which generates interrupt when corresponding interrupt is enabled in MAC_Interrupt_Enable register

Portj_MAC_Interrupt_Status (j=0-1) Offset address: $100B0_H+j*2000_H$

Port j MAC Interrupt Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
LSI	0	r	**Link Status change Interrupt** This bit is set when the LS (Link Status) bits change their value. It is cleared when this register is read. This interrupt is generated in RGMII mode when the link status change is detected in the RGMII Rx Interface. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
SMI	1	r	**SMA Interrupt** This bit is set when any of the bits in the MDIO Interrupt Status register is set. This bit is the logical OR of all the bits in that register and is cleared only when all the bits in the MDIO Interrupt register are cleared
PMTIS	4	r	**PMT Interrupt Status** This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in MAC_PMT_Control_Status register). This bit is cleared when Bits[6:5] are cleared because of a Read operation to the MAC_PMT_Control_Status register. Access restriction applies.This bit is cleared when Bits[6:5] of MAC_PMT_Control_Status register is read (or corresponding interrupt source bit of MAC_PMT_Control_Status register is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set).
LPIIS	5	r	**LPI Interrupt Status** This bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. Note: On the transmit side the Exit Interrupt is generate only when the XGMII/GMII interface comes out of the LPI and TW timer expires. Access restriction applies.This bit is cleared when the corresponding interrupt source bit of MAC_LPI_Control_Status register is read (or corresponding interrupt source bit of MAC_LPI_Control_Status register is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set).
MMCRXIS	9	r	**MMC Receive Interrupt Status** This bit is set high when an interrupt is generated in the MMC Receive Interrupt register. This bit is cleared when all bits in this interrupt register are cleared.

(table continues...)

(continued)

Field	Bits	Type	Description
MMCTXIS	10	r	**MMC Transmit Interrupt Status** This bit is set high when an interrupt is generated in the MMC Transmit Interrupt register. This bit is cleared when all bits in this interrupt register are cleared.
MMCRXIPIS	11	r	**MMC Receive Checksum Offload Interrupt Status** This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. 0_B **INACTIVE**: MMC Receive Checksum Offload Interrupt status not active 1_B **ACTIVE**: MMC Receive Checksum Offload Interrupt status active
TSIS	12	r	**Timestamp Interrupt Status** This bit is set when any of the following conditions is true: - The system time value is equal to or exceeds the value specified in the Target Time High and Low registers. - There is an overflow in the Seconds register. - The Target Time Error occurred, that is, programmed target time already elapsed. - When a timestamp of a transmitted PTP packet is available in the MAC_TxTimestamp_Status_Seconds register. Access restriction applies.This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Timestamp_Status register.
TXESIS	13	r	**Transmit Error Status Interrupt** - This bit indicates the error status of transmitted packets. This bit is set when any of the following bits is set in the MAC_Rx_Tx_Status during transmission. - Excessive Collision (EXCOL) - Late Collision (LCOL) - Excessive Deferral (EXDEF) - Loss of Carrier (LCARR) - No Carrier (NCARR) - Jabber Timeout (TJT) Access restriction applies.This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Rx_Tx_Status register.
RXESIS	14	r	**Receive Error Status Interrupt** This bit indicates the error status of received packets. This bit is set when the Watchdog Timeout (WDT) event occurs during reception. Access restriction applies.This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set) in the MAC_Rx_Tx_Status register.

(table continues...)

(continued)

Field	Bits	Type	Description
GPIIS	15	r	**GPI Interrupt Status** This bit is set when an active event (LL or LH) occurs on the GPIS field of the MAC_GPIO_Status register and the corresponding GPIE bit is enabled in the MAC_GPIO_Control register. This bit is cleared on reading lane 0 (GPIS) of the MAC_GPIO_Status register. Access restriction applies.This bit is cleared when this bit is read (or this bit is written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set)
FPEIS	16	r	**Frame Preemption Interrupt Status** This bit indicates an interrupt event during the operation of Frame Preemption (Bits[19:16] of MAC_FPE_CTRL_STS register is set). To reset this bit, the application must clear the event in MAC_FPE_CTRL_STS that has caused the interrupt. 0_B **INACTIVE**: Frame Preemption Interrupt status not active 1_B **ACTIVE**: Frame Preemption Interrupt status active
MFTIS	17	r	**MMC FPE Transmit Interrupt Status** This bit is set high when an interrupt is generated in the MMC FPE Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. 0_B **INACTIVE**: MMC FPE Transmit Interrupt status not active 1_B **ACTIVE**: MMC FPE Transmit Interrupt status active
MFRIS	18	r	**MMC FPE Receive Interrupt Status** This bit is set high when an interrupt is generated in the MMC FPE Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. 0_B **INACTIVE**: MMC FPE Receive Interrupt status not active 1_B **ACTIVE**: MMC FPE Receive Interrupt status active
PCIS	23	r	**Policing Counter Interrupt Status** This bit is set high when an interrupt is generated in the MAC_PCTH_Intr_Status or MAC_PCTW_Intr_Status Register. This bit is cleared when all bits in MAC_PCTH_Intr_Status or MAC_PCTW_Intr_Status register are cleared. 0_B **INACTIVE**: MAC_PCTH_Intr_Status or MAC_PCTW_Intr_Status is not active 1_B **ACTIVE**: MAC_PCTH_Intr_Status or MAC_PCTW_Intr_Status is active

(table continues...)

(continued)

Field	Bits	Type	Description
LS	27:24	r	**Link Status** When current Mode is not RGMII : Bit[25:24] indicate the current link status received on the XGMII receive interface. - 2'b00: Link OK - 2'b01: Reserved - 2'b10: Local link fault - 2'b11: Remote link fault The bits [27:26] are reserved. When current mode is RGMII: Bit[27]: - 0: Link Down - 1: Link Up Bit[26:25]: - 2'b00: 10Mbps - 2'b01: 100Mbps - 2'b10: 1Gbps - 2'b11: Reserved Bit[24]: - 0: Half Duplex - 1: Full Duplex
0	3:2, 8:6, 22:19, 31:28	r	**Reserved** Read as 0; should be written with 0.

14.6.63 Port j MAC Interrupt Enable

The Interrupt Enable register contains the masks for generating the interrupts.

Portj_MAC_Interrupt_Enable (j=0-1) Offset address: $100B4_H+j*2000_H$

Port j MAC Interrupt Enable Kernel Reset value: $0000\ 0001_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		PCE	IHE	0			RWT	0		EXCOL	LCOL	EXDEF	LCARR	NCARR	TJT
r		r	r	r			r	r		r	r	r	r	r	r

Field	Bits	Type	Description
TJT	0	r	**Transmit Jabber Timeout** This bit indicates that the Transmit Jabber Timer expired, which happens when the packet size exceeds 2048 bytes (10240 bytes when the Jumbo packet is enabled) and the JD bit is reset in the MAC_Tx_Configuration register. This bit is set when the packet size exceeds 16383 bytes and the JD bit is set in the MAC_Tx_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
NCARR	1	r	**No Carrier** When the FTS bit is reset in the MTL_Operation_Mode register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: Carrier is present 1_B **ACTIVE**: No carrier
LCARR	2	r	**Loss of Carrier** When the FTS bit is reset in the MTL_Operation_Mode register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the Phy Carrier interface signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: Carrier is present 1_B **ACTIVE**: Loss of carrier
EXDEF	3	r	**Excessive Deferral** When the FTS bit is reset in the MTL_Operation_Mode register and the DC bit is set in the MAC_Extended_Configuration register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (when Jumbo packet is enabled). Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: No Excessive deferral 1_B **ACTIVE**: Excessive deferral
LCOL	4	r	**Late Collision** When the FTS bit is reset in the MTL_Operation_Mode register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode). This bit is not valid if the Underflow error occurs. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: No collision 1_B **ACTIVE**: Late collision is sensed

(table continues...)

(continued)

Field	Bits	Type	Description
EXCOL	5	r	**Excessive Collisions** When the FTS bit is reset in the MTL_Operation_Mode register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after the first collision and the packet transmission is aborted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: No collision 1_B **ACTIVE**: Excessive collision is sensed
RWT	8	r	**Receive Watchdog Timeout** This bit is set when a packet with length greater than 2048 bytes is received (10240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_Rx_Configuration register or when a packet with length greater than 16383 bytes is received and the WD bit is set in the MAC_Rx_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
IHE	12	r	**IP Header Error** This bit indicates that the Checksum Offload engine detected IP header error. This failure can be either because of received Ethernet type is 0x0800 but Version field of IPv4 header is not equal to 0x4, IPv4 Header Length field indicates a value less than 0x5 (20 bytes), total packet length is less than the value given in the IPv4 Header Length field, received Ethernet type is 0x86dd but IPv6 header Version field is not equal to 0x6, packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
PCE	13	r	**Payload Checksum Error** This bit indicates that the Checksum Offload engine detected IP payload error and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit Queue depth is less than the length of the IP packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
0	7:6, 11:9, 31:14	r	**Reserved** Read as 0; should be written with 0.

14.6.65 Port j MAC PMT Control Status

The PMT Control and Status register.

Portj_MAC_PMT_Control_Status (j=0-1) Offset address: $100C0_H+j*2000_H$

Port j MAC PMT Control Status Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RWKFILTRST	0		RWKPTR					0							
rw	r		r					r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0					RWKPFE	GLBLUCAST	0		RWKPRCVD	MGKPRCVD	0		RWKPKTEN	MGKPKTEN	PWRDWN
r					rw	rw	r		r	r	r		rw	rw	rw

Field	Bits	Type	Description
PWRDWN	0	rw	**Power Down** When this bit is set, the MAC receiver drops all the received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high. Note: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit.
MGKPKTEN	1	rw	**Magic Packet Enable** When this bit is set, a power management event is generated when the MAC receives a magic packet.
RWKPKTEN	2	rw	**Remote Wake-Up Packet Enable** When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet.
MGKPRCVD	5	r	**Magic Packet Received** When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.

(table continues...)

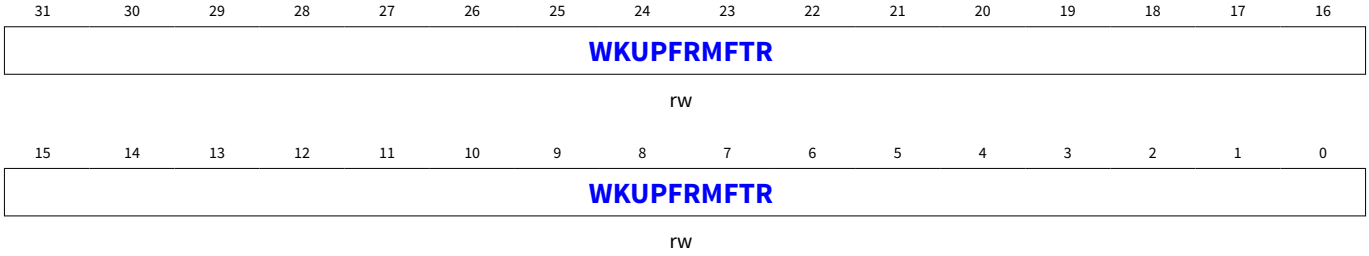
(continued)

Field	Bits	Type	Description
RWKPRCVD	6	r	**Remote Wake-Up Packet Received** When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set).Self-set to 1 on internal event.
GLBLUCAST	9	rw	**Global Unicast** When this bit is set, any unicast packet filtered by the MAC (DA matches MAC_Address0 register) address recognition is detected as a remote wake-up packet.
RWKPFE	10	rw	**Remote Wake-up Packet Forwarding Enable** When this bit is set along with RWKPKTEN, the MAC receiver drops all the received packets until it receives the expected Wake-up packet. All packets after that event including the received wake-up packet are forwarded to application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up packet is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN bit is set low. The setting of this bit has no effect when PWRDWN bit is set high. Note: If Magic Packet Enable and Wake-Up Packet Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up packet, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all packets that are received after the Magic Packet are forwarded to application.
RWKPTR	28:24	r	**Remote Wake-up FIFO Pointer** This field gives the current value of the Remote Wake-up Packet Filter register pointer. When the value of this pointer reaches the maximum for the selected number of filters (which equals 2 times the number of RWK filters -1), the contents of the Remote Wake-up Packet Filter register are transferred to the Rx clock domain when a Write occurs to that register.
RWKFILTRST	31	rw	**Remote Wake-Up Packet Filter Register Pointer Reset** When this bit is set, the remote wake-up packet filter register pointer (RWKPTR) is reset to 0. It is automatically cleared after 1 clock cycle.
0	4:3, 8:7, 23:11, 30:29	r	**Reserved** Read as 0; should be written with 0.

14.6.66 Port j MAC RWK Packet Filter

The Remote Wakeup Filter registers are implemented as 8 indirect access registers (wkuppktfilter_reg#i) and accessed by application through MAC_RWK_Packet_Filter register.. When the Remote Wakeup Filters are to be programmed, the entire set of wkuppktfilter_reg registers must be written. The wkuppktfilter_reg register is programmed by sequentially writing the eight register values in MAC_RWK_Packet_Filter register for wkuppktfilter_reg0, wkuppktfilter_reg1, ..., wkuppktfilter_reg7 respectively. The wkuppktfilter_reg register is read in a similar way. The MAC updates the wkuppktfilter_reg register current pointer value in RWKPTR field of MAC_PMT_Control_Status register. The fields of Remote Wakeup Filter are described as follows: Filter i Byte Mask: The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, .., 3) to determine whether or not a packet is a wake-up packet. - The MSB (31st bit) must be zero. - Bit j[30:0] is the byte mask. - If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored. Filter i Command: The 4-bit filter i command controls the filter i operation. - Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. - Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC-16 value. Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2". - Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. The details are, -- The And_Previous bit setting is applicable within a set of 4 filters. -- Setting of And_Previous bit of filter that is not enabled has no effect, that is setting And_Previous bit of lowest number filter in the set of 4 filters has no effect. For example, setting of And_Previous bit of Filter 0 has no effect. -- If And_Previous bit is set for filter to form AND chained filter, the AND chain breaks at the point any filter is not enabled. For example: If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set) but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 2 is not enabled (bit 0 in Filter 2 command is reset), then since setting of Filter 2 And_Previous bit has no effect only Filter 1 result ORed with Filter 3 result is considered. -- If filters chained by And_Previous bit setting have complementary programming, then a frame might never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 in Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 in Filter 2 command is reset) indicating unicast detection or vice versa, a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address type. - Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled. Filter i Offset: The filter i offset register defines the offset (within the packet) from which the filter i examines the packets. - This 8-bit pattern-offset is the offset for the filter i first byte to be examined. - The minimum allowed offset is 12, which refers to the 13th byte of the packet. - The offset value 0 refers to the first byte of the packet. Filter i CRC-16: The filter i CRC-16 register contains the CRC-16 value calculated from the pattern and the byte mask programmed in the Remote Wakeup filter register. - The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1 - Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following: -- 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1, the corresponding byte is taken into the CRC-16 calculation. -- 8-bit Offset Pointer: Specifies the byte to start the CRC-16 computation. The pointer and the mask are used together to locate the bytes to be used in the CRC-16 calculations.

Portj_MAC_RWK_Packet_Filter (j=0-1)	Offset address:	$100C4_H+j*2000_H$
Port j MAC RWK Packet Filter	Kernel Reset value:	$0000\ 0000_H$



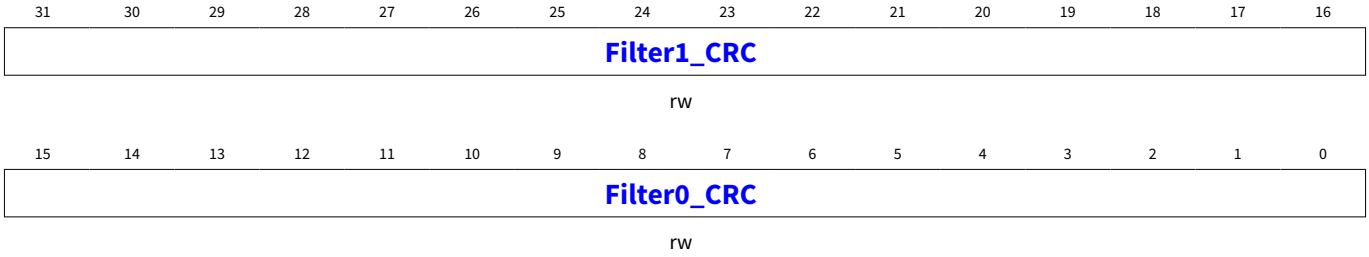
Field	Bits	Type	Description
WKUPFRMFTR	31:0	rw	**Wake-up Packet Filter** This field contains the various controls of RWK Packet filter.

14.6.67 Port j RWK Filter0 1 CRC

Filter i CRC-16. This register contains the CRC-16 to be matched.

Portj_RWK_Filter0_1_CRC (j=0-1) Offset address: $100C4_H+j*2000_H$

Port j RWK Filter0 1 CRC Kernel Reset value: $0000\ 0000_H$



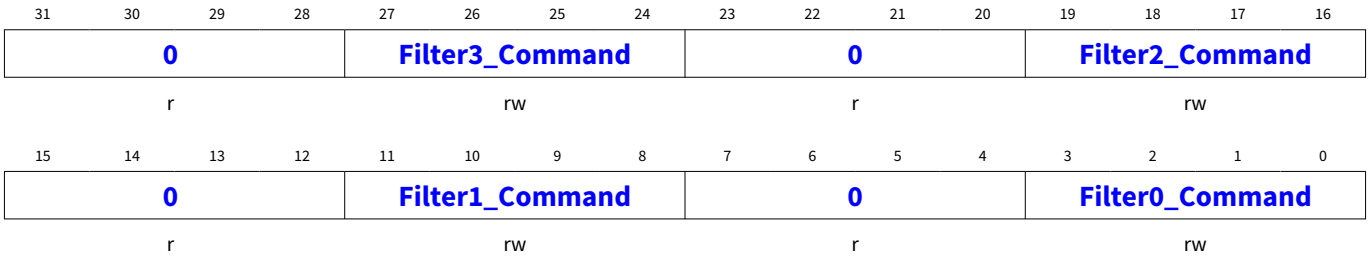
Field	Bits	Type	Description
Filter0_CRC	15:0	rw	**CRC0 This filter CRC-16 contains the CRC_16 value of the pattern** - The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1
Filter1_CRC	31:16	rw	**CRC1 This filter CRC-16 contains the CRC_16 value of the pattern** - The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1

14.6.68 Port j RWK Filter0 3 Command

This register controls the filter operation.

Portj_RWK_Filter0_3_Command (j=0-1) Offset address: $100C4_H+j*2000_H$

Port j RWK Filter0 3 Command Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
Filter0_Command	3:0	rw	**Command 0** The 4-bit filter command controls the filter operation. - Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. - Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value. - Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2". - Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. - Bit 0 is the enable for filter. If Bit 0 is not set, filter is disabled.
Filter1_Command	11:8	rw	**Command1** The 4-bit filter command controls the filter operation. - Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. - Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value. - Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2". - Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. - Bit 0 is the enable for filter. If Bit 0 is not set, filter is disabled.

(table continues...)

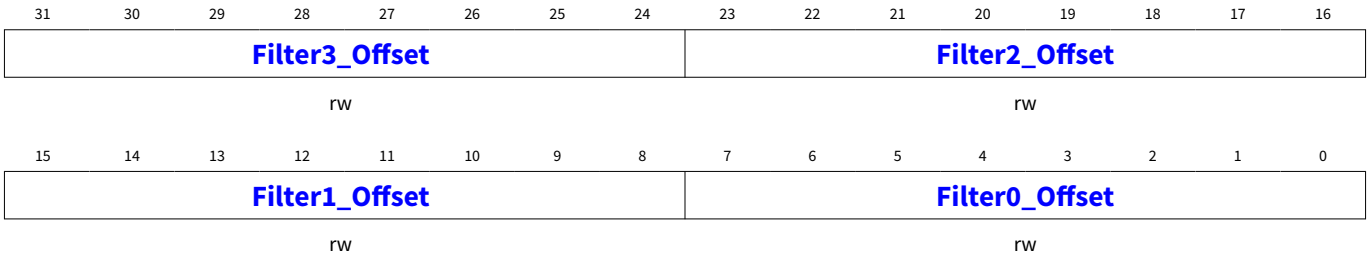
Filter2_Command	19:16	rw	**Command2** The 4-bit filter command controls the filter operation. - Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. - Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value. - Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2". - Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. - Bit 0 is the enable for filter. If Bit 0 is not set, filter is disabled.
Filter3_Command	27:24	rw	**Command3 The 4-bit filter command controls the filter operation** - Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet. - Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC_16 value. - Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2". - Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. - Bit 0 is the enable for filter. If Bit 0 is not set, filter is disabled.
0	7:4, 15:12, 23:20, 31:28	r	**Reserved** Read as 0; should be written with 0.

14.6.69 Port j RWK Filter0 3 Offset

This register defines the offset (within the packet) from which the filter examines the packet.

Portj_RWK_Filter0_3_Offset (j=0-1) Offset address: $100C4_H+j*2000_H$

Port j RWK Filter0 3 Offset Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
Filter0_Offset	7:0	rw	**Offset0** This filter offset defines the offset (within the packet) from which the filter examines the packets. - This 8-bit pattern-offset is the offset for the filter first byte to be examined. - The minimum allowed offset is 12, which refers to the 13th byte of the packet. - The offset value 0 refers to the first byte of the packet.
Filter1_Offset	15:8	rw	**Offset1 This filter offset defines the offset (within the packet) from which the filter examines the packets** - This 8-bit pattern-offset is the offset for the filter first byte to be examined. - The minimum allowed offset is 12, which refers to the 13th byte of the packet. - The offset value 0 refers to the first byte of the packet.
Filter2_Offset	23:16	rw	**Offset2 This filter offset defines the offset (within the packet) from which the filter examines the packets** - This 8-bit pattern-offset is the offset for the filter first byte to be examined. - The minimum allowed offset is 12, which refers to the 13th byte of the packet. - The offset value 0 refers to the first byte of the packet.
Filter3_Offset	31:24	rw	**Offset3 This filter offset defines the offset (within the packet) from which the filter examines the packets** - This 8-bit pattern-offset is the offset for the filter first byte to be examined. - The minimum allowed offset is 12, which refers to the 13th byte of the packet. - The offset value 0 refers to the first byte of the packet.

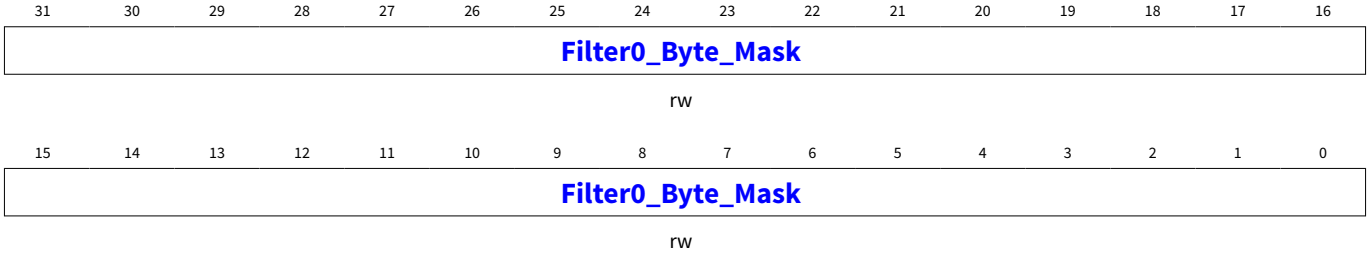
14.6.70 Port j RWK Filter0 Byte Mask

Filter i Byte Mask. The filter i byte mask register defines the bytes of the packet that are examined by filter i to determine whether or not a packet is a wake-up packet. The MSB (31st bit) must be zero. Bit j[30:0] is the byte mask. If Bit j (byte number) of the byte mask is set, the CRC block processes the byte pointed by Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.

You can access these registers indirectly through the MAC_RWK_Packet_Filter register.

Portj_RWK_Filter0_Byte_Mask (j=0-1) Offset address: $100C4_H+j*2000_H$

Port j RWK Filter0 Byte Mask Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
Filter0_Byte_Mask	31:0	rw	**Byte Mask** Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1', the corresponding byte is taken into the CRC16 calculation.

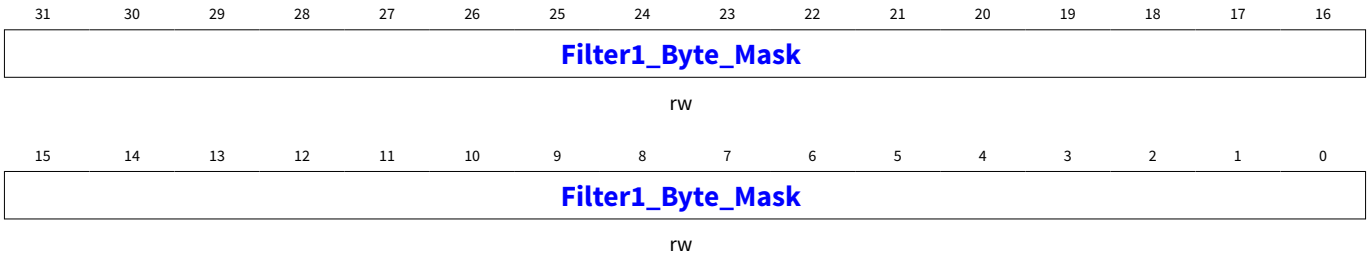
14.6.71 Port j RWK Filter1 Byte Mask

Filter i Byte Mask. The filter i byte mask register defines the bytes of the packet that are examined by filter i to determine whether or not a packet is a wake-up packet. The MSB (31st bit) must be zero. Bit j[30:0] is the byte mask. If Bit j (byte number) of the byte mask is set, the CRC block processes the byte pointed by Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.

You can access these registers indirectly through the MAC_RWK_Packet_Filter register.

Portj_RWK_Filter1_Byte_Mask (j=0-1) Offset address: $100C4_H+j*2000_H$

Port j RWK Filter1 Byte Mask Kernel Reset value: $0000\ 0000_H$



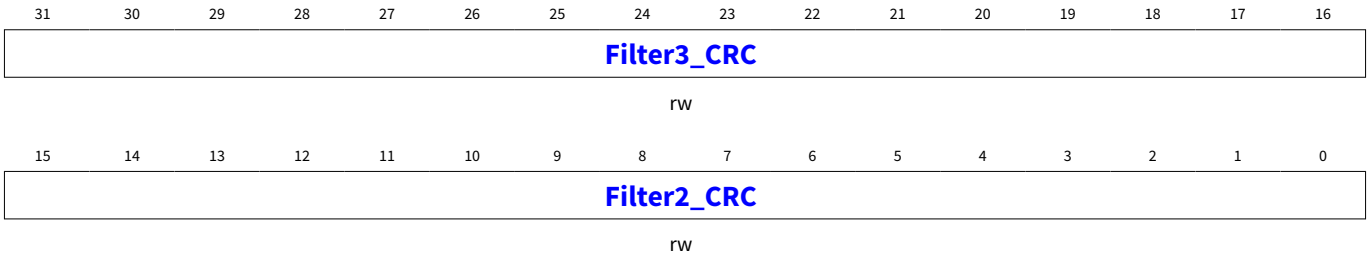
Field	Bits	Type	Description
Filter1_Byte_Mask	31:0	rw	**Byte Mask** Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1', the corresponding byte is taken into the CRC16 calculation.

14.6.72 Port j RWK Filter2 3 CRC

Filter i CRC-16. This register contains the CRC-16 to be matched.

Portj_RWK_Filter2_3_CRC (j=0-1) Offset address: $100C4_H+j*2000_H$

Port j RWK Filter2 3 CRC Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
Filter2_CRC	15:0	rw	**CRC0 This filter CRC-16 contains the CRC_16 value of the pattern** - The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1
Filter3_CRC	31:16	rw	**CRC1 This filter CRC-16 contains the CRC_16 value of the pattern** - The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1

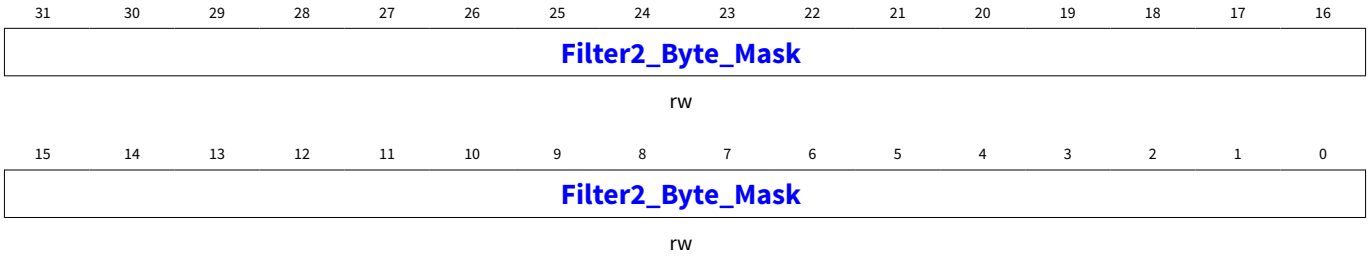
14.6.73 Port j RWK Filter2 Byte Mask

Filter i Byte Mask. The filter i byte mask register defines the bytes of the packet that are examined by filter i to determine whether or not a packet is a wake-up packet. The MSB (31st bit) must be zero. Bit j[30:0] is the byte mask. If Bit j (byte number) of the byte mask is set, the CRC block processes the byte pointed by Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.

You can access these registers indirectly through the MAC_RWK_Packet_Filter register.

Portj_RWK_Filter2_Byte_Mask (j=0-1) Offset address: $100C4_H+j*2000_H$

Port j RWK Filter2 Byte Mask Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
Filter2_Byte_Mask	31:0	rw	**Byte Mask** Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1', the corresponding byte is taken into the CRC16 calculation.

14.6.74 Port j RWK Filter3 Byte Mask

Filter i Byte Mask. The filter i byte mask register defines the bytes of the packet that are examined by filter i to determine whether or not a packet is a wake-up packet. The MSB (31st bit) must be zero. Bit j[30:0] is the byte mask. If Bit j (byte number) of the byte mask is set, the CRC block processes the byte pointed by Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.

You can access these registers indirectly through the MAC_RWK_Packet_Filter register.

Portj_RWK_Filter3_Byte_Mask (j=0-1) Offset address: $100C4_H+j*2000_H$

Port j RWK Filter3 Byte Mask Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
Filter3_Byte_Mask	31:0	rw	**Byte Mask** Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1', the corresponding byte is taken into the CRC16 calculation.

14.6.75 Port j MAC LPI Control Status

The LPI Control and Status register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

Portj_MAC_LPI_Control_Status (j=0-1) Offset address: $100D0_H+j*2000_H$

Port j MAC LPI Control Status Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0										LPITCSE	LPIATE	LPITXA	PLSDIS	PLS	LPITXEN
r										rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				0	0	RLPIST	TLPIST	0				RLPIEX	RLPIEN	TLPIEX	TLPIEN
r				r	r	r	r	r				r	r	r	r

Field	Bits	Type	Description
TLPIEN	0	r	**Transmit LPI Entry** When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPITXEN bit. Access restriction applies.This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set).

(table continues...)

(continued)

Field	Bits	Type	Description
TLPIEX	1	r	**Transmit LPI Exit** When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPITXEN bit and the LPI TW Timer has expired. Access restriction applies.This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set).
RLPIEN	2	r	**Receive LPI Entry** When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. Access restriction applies.This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Note: This bit might not be set if the MAC receives the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.
RLPIEX	3	r	**Receive LPI Exit** When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII or XGMII interface, exited the LPI state, and resumed the normal reception. Access restriction applies.This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Note: This bit might not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.
TLPIST	8	r	**Transmit LPI State** When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the GMII or XGMII interface.
RLPIST	9	r	**Receive LPI State** When this bit is set, it indicates that the MAC is receiving the LPI pattern on the GMII or XGMII interface.
LPITXEN	16	rw	**LPI Transmit Enable** When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission.
PLS	17	rw	**PHY Link Status** This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER. When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down.

(table continues...)

(continued)

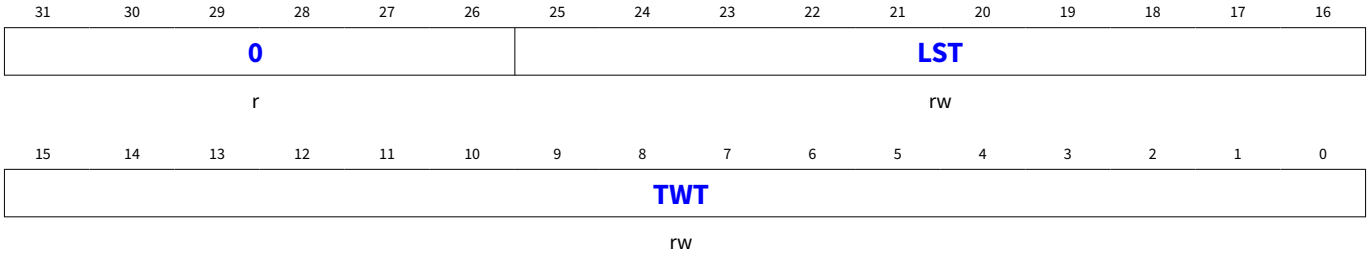
Field	Bits	Type	Description
PLSDIS	18	rw	**PHY Link Status Disable** This bit disables the link status received on the XGMII receive paths, which are used for activating the LPI LS TIMER. When set to 1, the MAC ignores the link status from the XGMII interface and uses the link status from bit 17 (PLS). When set to 0, the MAC uses the link status from the XGMII in the 10G mode. In the GMII or 1G mode, the controller does not use this bit. The controller depends on bit 17 (PLS) for activating the LPI LS TIMER.
LPITXA	19	rw	**LPI Tx Automate** This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. If the LPITXA and LPITXEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the controller) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPITXEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of MTL_TxQ0_Operation_Mode register, when the MAC is in the LPI mode, it exits the LPI mode. When this bit is 0, the LPITXEN bit directly controls the behavior of the MAC when it enters or comes out of the LPI mode.
LPIATE	20	rw	**LPI Auto Timer Enable** This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPIATE, LPITXA, and LPITXEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC Tx data path is IDLE for a period indicated by the MAC_LPI_Auto_Entry_Timer register. After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPITXEN bit. This enables the re-entry into LPI state when it is IDLE again. When LPIATE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPITXEN bit descriptions.
LPITCSE	21	rw	**LPI Tx Clock Stop Enable** When this bit is 0, the output transmit clock gating signal is not asserted. When this bit is 1, the output transmit clock gating signal is asserted during Transmit LPI mode which can be used to Gate the Transmit Clock.
0	7:4, 10, 11, 15:12, 31:22	r	**Reserved** Read as 0; should be written with 0.

14.6.76 Port j MAC LPI Timers Control

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Portj_MAC_LPI_Timers_Control (j=0-1) Offset address: $100D4_H+j*2000_H$

Port j MAC LPI Timers Control Kernel Reset value: $03E8\ 0000_H$



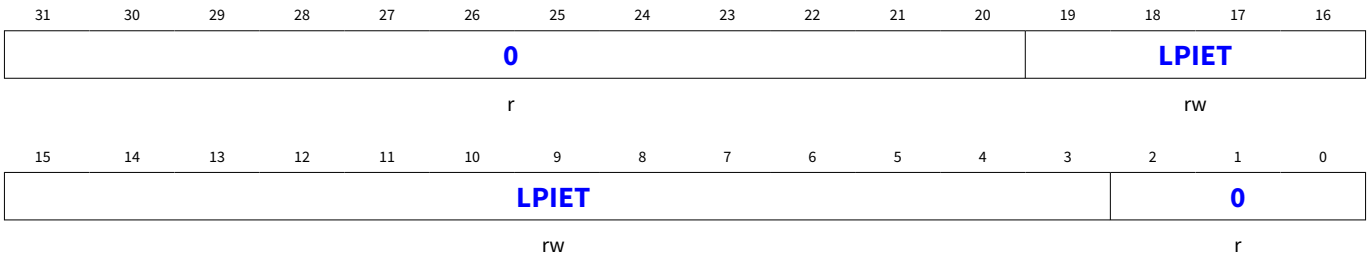
Field	Bits	Type	Description
TWT	15:0	rw	**LPI TW TIMER** This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.
LST	25:16	rw	**LPI LS TIMER** This field specifies the minimum time (in milliseconds) for which the link status from the PHY must be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPITXEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.
0	31:26	r	**Reserved** Read as 0; should be written with 0.

14.6.77 Port j MAC LPI Auto Entry Timer

This register is used to store the LPI Auto Entry Timer Value in Micro-Seconds.

Portj_MAC_LPI_Auto_Entry_Timer (j=0-1) Offset address: $100D8_H+j*2000_H$

Port j MAC LPI Auto Entry Timer Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
LPIET	19:3	rw	**LPI Entry Timer** This field is programmed with a value in micro-seconds. When LPIATE, LPITXA, and LPITXEN bits of the MAC_LPI_Control_Status are set, DWC_xgmac automatically enters Tx LPI mode after transmitter is IDLE for LPIET amount of time. Bits[2:0] are read-only such that the granularity of this timer is 8 micro-seconds.
0	2:0, 31:20	r	**Reserved** Read as 0; should be written with 0.

14.6.78 Port j MAC 1US Tic Counter

This register controls the generation of the Reference time (1micro-second tic) for all the LPI timers. This timer has to be programmed by the software initially.

Portj_MAC_1US_Tic_Counter (j=0-1) Offset address: $100DC_H+j*2000_H$

Port j MAC 1US Tic Counter Kernel Reset value: $0000\ 0063_H$

r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				TIC_1US_CNTR											
r				rw											

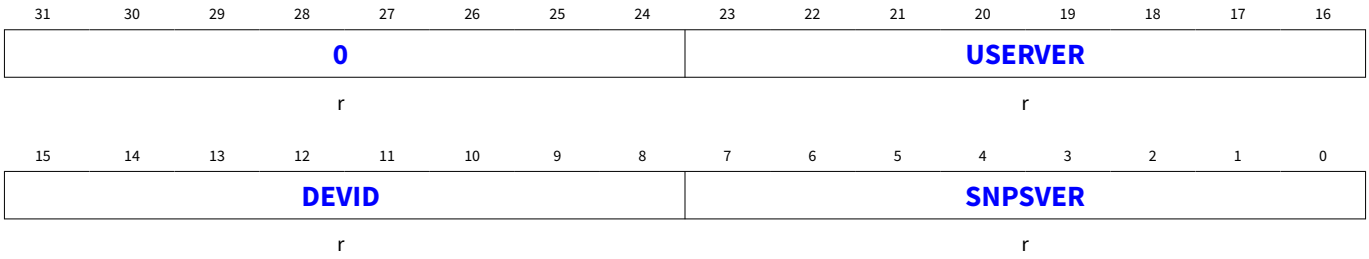
Field	Bits	Type	Description
TIC_1US_CNTR	11:0	rw	**1US TIC Counter** This counter must be programmed with the number of clock cycles of CSR clock that constitutes a period of 1us. (Subtract 1 from the value before programming). For example if the CSR clock frequency is 100MHz, then this field needs to be programmed to value 100 - 1 = 99 (which is 0x63). This is required to generate the 1US events which are used to update some of the EEE related timers and counters.
0	31:12	r	**Reserved** Read as 0; should be written with 0.

14.6.79 Port j MAC Version

The version register identifies the version of DWC_xgmac. This register contains two bytes: one that Synopsys uses to identify the controller release number, and the other is user defined

Portj_MAC_Version (j=0-1) Offset address: $10110_H+j*2000_H$

Port j MAC Version Kernel Reset value: $0010\ 7632_H$



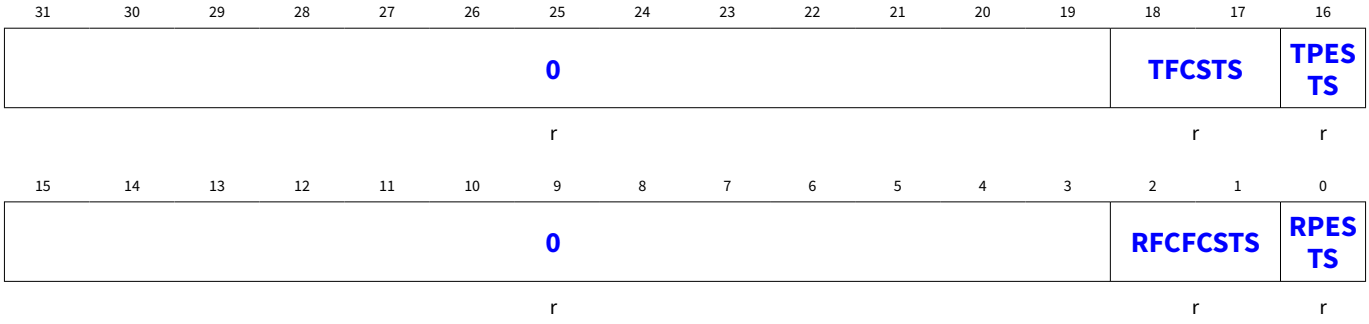
Field	Bits	Type	Description
SNPSVER	7:0	r	**Synopsys-defined Version**
DEVID	15:8	r	**Indicates the Device family**
USERVER	23:16	r	**User-defined Version**
0	31:24	r	**Reserved** Read as 0; should be written with 0.

14.6.80 Port j MAC Debug

The Debug register provides the debug status of various MAC blocks.

Portj_MAC_Debug (j=0-1) Offset address: $10114_H+j*2000_H$

Port j MAC Debug Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RPESTS	0	r	**MAC, GMII, or XGMII Receive Protocol Engine Status** When this bit is set, it indicates that the MAC, GMII, or XGMII receive protocol engine is actively receiving data, and it is not in the Idle state.
RFCFCSTS	2:1	r	**MAC Receive Packet Controller FIFO Status** This field indicates the active state of the small FIFO Read and Write controllers of the MAC Receive Packet Controller module. When bit 2 is set, small FIFO Read controller is active. When bit 1 is set, small FIFO Write controller is active.
TPESTS	16	r	**MAC GMII or XGMII Transmit Protocol Engine Status** When this bit is set, it indicates that the MAC GMII or XGMII transmit protocol engine is actively transmitting data, and it is not in the Idle state.

(table continues...)

(continued)

Field	Bits	Type	Description
TFCSTS	18:17	r	**MAC Transmit Packet Controller Status** This field indicates the state of the MAC Transmit Packet Controller module: - 2'b00: Idle state - 2'b01: Waiting for one of the following: -- Status of the previous packet or -- IPG period to be over - 2'b10: Generating and transmitting a Pause control packet - 2'b11: Transferring input packet for transmission
0	15:3, 31:19	r	**Reserved** Read as 0; should be written with 0.

14.6.81 Port j MAC HW Feature0

This register indicates the presence of the first set of optional features or functions of DWC_xgmac. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Portj_MAC_HW_Feature0 (j=0-1) Offset address: $1011C_H+j*2000_H$

Port j MAC HW Feature0 Kernel Reset value: $8E7D\ 79FF_H$

Field	Bits	Type	Description
PCSEL	1:0	r	**Policing Counters** This value indicates the number of policing counters implemented when PC is enabled 00_B **INACTIVE**: Policing counter feature is not selected 01_B **PCNUM_16**: 16 Policing counters are selected 10_B **PCNUM_32**: 32 Policing counters are selected **others,** Reserved
EASP	4	r	**Extended Automotive Safety Package** This field along with ASP field of MAC_HW_Feature3 register indicates the encoded value for the different Safety features
DSTS	8	r	**Additional Free Running Timestamping Source** This bit is set to 1 after reset when the Additional Free Running Timestamping Source feature is selected.
0	3:2, 7:5, 31:9	r	**Reserved** Read as 0; should be written with 0.

14.6.86 Port j MAC Extended Configuration

The MAC Extended Configuration register establishes the operating mode of the MAC transmitter.

Portj_MAC_Extended_Configuration (j=0-1) Offset address: $10140_H+j*2000_H$

Port j MAC Extended Configuration Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0			0		0		HD	ECRSFD	DO	DCRS	DR	BL		DC	0
r			r		r		rw	rw	rw	rw	rw	rw		rw	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						TPRE	0	DDS	EIPG						
r						rw	r	rw	rw						

Field	Bits	Type	Description
EIPG	6:0	rw	**Extended Inter-Packet Gap** When IFP bit in MAC_Tx_configuration register is set, the minimum IPG is increased in steps of 32 bits, depending on the programming of this field and IPG field in MAC_Tx_Configuration register.EIPG, IPG: Minimum Inter-Packet Gap - 10'h000: 96 bit times - 10'h001: 128 bit times - 10'h002: 160 bit times - 10'h003: 192 bit times - 10'h004: 224 bit times - ... - 10'h3FF: 32832 bit times Note: The extended inter-packet gap (IPG) feature must be enabled only in full-duplex mode. There might be undesirable effects on back-pressure function and frame transmission if it is enabled in half-duplex mode.
DDS	7	rw	**DA Duplication Select** - 1: The received packet with Multicast/Broadcast (and Unicast when UDC bit of MAC_RxQ_Ctrl4 register is set) Destination address is routed to multiple Receive DMA Channels. The Receive DMA Channels is identified by XDCS field of MAC_DChSel_IndReg(#i) register corresponding to the MAC Address register that matches the Multicast/ Broadcast (and Unciast when UDC bit of MAC_RxQ_Ctrl4 register is set) DA. The XDCS field is interpreted to be a one-hot value, each bit corresponding to the Receive DMA Channel. - 0: The received packet is routed to a single Receive DMA Channel. The Receive DMA Channel is identified by the DCS field of MAC_Address_High register corresponding to the MAC Address register that matches the Destination address in the received packet. The DCS field is interpreted as a binary value. Values: - 0x0: DCS field in MAC_Address_High register is interpreted as binary value - 0x1: XDCS field in MAC_DChSel_IndReg register represent the target DMA Channels using a one-hot like encoding.
TPRE	9	rw	**Truncated Preamble Enable** When set, MAC supports processing of packets with 7 bytes preamble on RX side such that SFD is seen on lane2. On reset, packet with truncated preamble are dropped. This field has an impact only if the speed select is set to 3'b110 (XGMII 2.5G mode) TPRE = 1 For express packets, the supported format is - /S/ + Preamble (6/5)+ SFD (lane3/lane2) For preemptive packets, truncated preamble is not supported. Therefore, the supported format is - /S/ + Preamble (6)+ SFD (lane3)

(table continues...)

(continued)

Field	Bits	Type	Description
DC	17	rw	**Deferral Check** When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times, because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision occurs. Because of collision, the transmitter needs to back off and then defer again after back off is complete. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode. 0_B **DISABLE**: Deferral check function is disabled 1_B **ENABLE**: Deferral check function is enabled
BL	19:18	rw	**Back-Off Limit** The back-off limit determines the random integer number (r) of slot time delays (512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. n = retransmission attempt. The random integer r takes the value in the range 0 to 2^k This bit is applicable only in the half-duplex mode. 00_B **MIN_N_10**: k = min(n,10) 01_B **MIN_N_8**: k = min(n,8) 10_B **MIN_N_4**: k = min(n,4) 11_B **MIN_N_1**: k = min(n,1)
DR	20	rw	**Disable Retry** When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode. 0_B **ENABLE**: Enable Retry 1_B **DISABLE**: Disable Retry

(table continues...)

(continued)

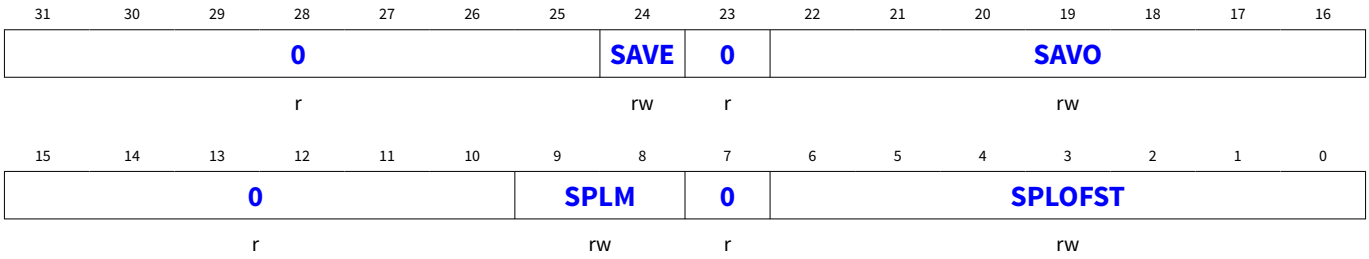
Field	Bits	Type	Description
DCRS	21	rw	**Disable Carrier Sense During Transmission** When this bit is set, the MAC transmitter ignores the MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission. 0_B **ENABLE**: Enable Carrier Sense During Transmission 1_B **DISABLE**: Disable Carrier Sense During Transmission
DO	22	rw	**Disable Receive Own** When this bit is set, the MAC disables the reception of packets when the GMII/MII Transmit Data Enable signal is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. This bit is not applicable in the full-duplex mode. 0_B **ENABLE**: Enable Receive Own 1_B **DISABLE**: Disable Receive Own
ECRSFD	23	rw	**Enable Carrier Sense before Transmission in Full-Duplex mode** When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal. 0_B **DISABLE**: ECRSFD is disabled 1_B **ENABLE**: ECRSFD is enabled
HD	24	rw	**Half-Duplex Mode** When this bit is set, the MAC operates in the half-duplex mode in which it can transmit and receive simultaneously. This bit is RO with default value of 1'b0 in the full-duplex-only configurations. This bit is enabled only for 10/100Mbps. 0_B **FDUPLX**: Full-duplex mode 1_B **HDUPLX**: Half-duplex mode
0	8, 15:10, 16, 27:25, 28, 31:29	r	**Reserved** Read as 0; should be written with 0.

14.6.87 Port j MAC Ext Cfg1

This register contains Split mode control field and offset field for Header-Payload Split feature.

Portj_MAC_Ext_Cfg1 (j=0-1) Offset address: $10144_H+j*2000_H$

Port j MAC Ext Cfg1 Kernel Reset value: $0002\ 0002_H$



Field	Bits	Type	Description
SPLOFST	6:0	rw	**Split Offset** These bits indicate the value of offset from the beginning of Length/ Type field at which header split must take place when the appropriate SPLM is selected. The reset value of this field is 2 bytes indicating a split at L2 header. Value is in terms of bytes.
SPLM	9:8	rw	**Split Mode** These bits control the mode of splitting the incoming Rx packets. They are 00_B **L3L4**: Split at L3/L4 header 01_B **L2OFST**: Split at L2 header with an offset. Always Split at SPLOFST bytes from the beginning of Length/Type field of the Frame 10_B **COMBN**: Combination mode: Split similar to SPLM=00 for IP packets that are untagged or tagged and VLAN stripped and Split similar to SPLM=01 for non-IP packets 11_B **RSVD**: Reserved
SAVO	22:16	rw	**Split AV Offset** When SAVE bit is set to 1, and the received packet is an AV Type packet, these bits indicate the value of the offset from the beginning of Length/ Type field at which header must be split, when appropriate SPLM is selected. The reset value of this field is 2 bytes, indicating a split at L2 header. Value is in terms of bytes.
SAVE	24	rw	**Split AV Enable - When this bit is set to 1, and the received packet is an AV Type packet, the header is split at SAVO bytes from the beginning of Length/Type field of the packet, for L2 Split** - When this bit is set to 0, header is split at SPLOFST bytes from the beginning of Length/Type field of the frame, for L2 Split.
0	7, 15:10, 23, 31:25	r	**Reserved** Read as 0; should be written with 0.

14.6.88 Port j MAC DPP FSM Interrupt Status

This register contains the status of Automotive Safety related Data Path Parity Errors, Interface Timeout Errors, FSM State Parity Errors, and FSM State Timeout Errors.

Portj_MAC_DPP_FSM_Interrupt_Status (j=0-1) Offset address: $10150_H+j*2000_H$

Port j MAC DPP FSM Interrupt Status Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
DPES	1	rw	**Descriptor Cache write data path Parity checker Error Status** When this bit is set, it indicates that a parity error is detected at the Descriptor Cache parity checker (or at PC-desc). Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
MTPES	4	rw	**MTL data path Parity checker Error Status** When this bit is set, it indicates that a parity error is detected at the MTL transmit write controller parity checker (or at PC2). Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: MTL data path Parity checker Error Status not detected 1_B **ACTIVE**: MTL data path Parity checker Error Status detected
MTBUPES	6	rw	**MAC TBU data path Parity checker Error Status** When this bit is set, it indicates that a parity error is detected on the MAC TBU (or at PC4). Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: MAC TBU data path Parity Error Status not detected 1_B **ACTIVE**: MAC TBU data path Parity Error Status detected
MTFCPES	7	rw	**MAC TFC data path Parity checker Error Status** When this bit is set, it indicates that a parity error is detected on the MAC TFC (or at PC5). Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: MAC TFC data path Parity checker Error Status not detected 1_B **ACTIVE**: MAC TFC data path Parity checker Error Status detected

(table continues...)

(continued)

Field	Bits	Type	Description
ARPES	8	rw	**Application Receive interface data path Parity Error Status** When this bit is set, it indicates that a parity error is detected at the parity checker (PC-a) at AXI master interface. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: Application Receive interface data path Parity checker Error Status not detected 1_B **ACTIVE**: Application Receive interface data path Parity checker Error Status detected
MRWCPES	9	rw	**MTL RWC data path Parity checker Error Status** When this bit is set, it indicates that a parity error is detected at the MTL RWC input data parity checker (or at PC6). Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: MTL RWC data path Parity checker Error Status not detected 1_B **ACTIVE**: MTL RWC data path Parity checker Error Status detected
MRRCPES	10	rw	**MTL RRC data path Parity checker Error Status** When this bit is set, it indicates that a parity error is detected at the MTL RRC output data parity checker (or at PC7). Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: MTL RRC data path Parity checker Error Status not detected 1_B **ACTIVE**: MTL RRC data path Parity checker Error Status detected
CWPES	11	rw	**CSR Write data path Parity checker Error Status** When this bit is set, it indicates that parity error is detected at the CSR write data interface This bit is set to 1 when EPSI bit of MTL_DPP_Control register is set and a parity mismatch is detected on the input slave parity ports (or at PC-axi/apb/mci slave checker). Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: CSR Write data path Parity checker Error Status not detected 1_B **ACTIVE**: CSR Write data path Parity checker Error Status detected
ASRPES	12	rw	**AXI Slave Read data path Parity checker Error Status** When this bit is set, it indicates that parity error is detected at the AXI Slave read data interface . Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: AXI Slave Read data path Parity checker Error Status not detected 1_B **ACTIVE**: AXI Slave Read data path Parity checker Error Status detected

Field	Bits	Type	Description
TTES	13	rw	**Tx FSM Timeout Error Status** When this bit is set, it indicates that one of the Tx FSM timeout has occurred. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: Tx FSM timeout has not been detected 1_B **ACTIVE**: Tx FSM timeout has been detected
RTES	14	rw	**Rx FSM Timeout Error Status** When this bit is set, it indicates that one of the Rx FSM timeout has occurred. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: Rx FSM timeout has not been detected 1_B **ACTIVE**: Rx FSM timeout has been detected
ATES	16	rw	**APP FSM Timeout Error Status** When this bit is set, it indicates that one of the APP FSM timeout has occurred. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: APP FSM Timeout Error Status not detected 1_B **ACTIVE**: APP FSM Timeout Error Status detected
PTES	17	rw	**PTP FSM Timeout Error Status** When this bit is set, it indicates that one of the PTP FSM timeout has occurred. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: PTP FSM Timeout Error Status not detected 1_B **ACTIVE**: PTP FSM Timeout Error Status detected
MSTTES	21	rw	**Master Read/Write Timeout Error Status** When this bit is set, it indicates that an Application/CSR timeout has occurred on the master (AXI) interface. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: Master Read/Write Timeout Error Status not detected 1_B **ACTIVE**: Master Read/Write Timeout Error Status detected
SLVTES	22	rw	**Slave Read/Write Timeout Error Status** When this bit is set, it indicates that an Application/CSR timeout has occurred on the AXI slave interface. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: Slave Read/Write Timeout Error Status not detected 1_B **ACTIVE**: Slave Read/Write Timeout Error Status detected

(table continues...)

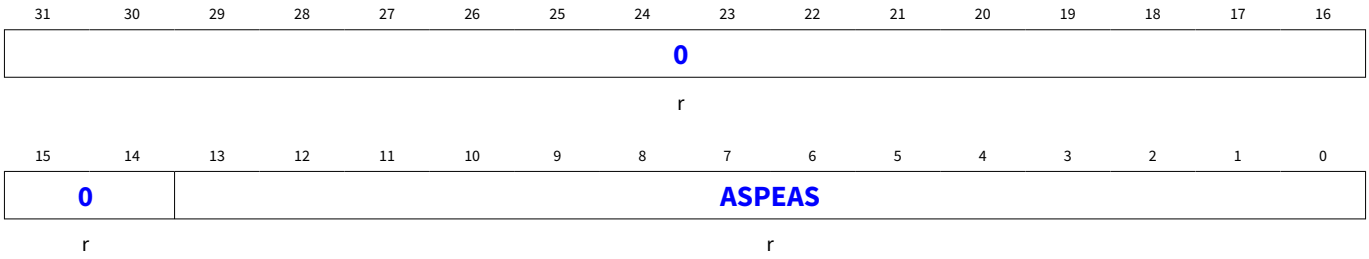
Field	Bits	Type	Description
ATITES	23	rw	**ATI Interface Timeout Error Status** When this bit is set, it indicates that an Application timeout has occurred on ATI Interface. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: Timeout not detected on ATI Interface 1_B **ACTIVE**: Timeout detected on ATI Interface
ARITES	24	rw	**ARI Interface Timeout Error Status** When this bit is set, it indicates that an Application timeout has occurred on ARI Interface. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: Timeout not detected on ARI Interface 1_B **ACTIVE**: Timeout detected on ARI Interface
FSMPES	25	rw	**FSM State Parity Error Status** Indicates that parity error is detected in one of the FSM State registers. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: Slave Read/Write Timeout Error Status not detected 1_B **ACTIVE**: Slave Read/Write Timeout Error Status detected
CPI	31	rw	**Control Register Parity Check Error** When this bit is set, it indicates a parity check error for CSR registers. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
0	0, 2, 3, 5, 15, 18, 19, 20, 30:26	r	**Reserved** Read as 0; should be written with 0.

14.6.89 Port j MAC AXI SLV DPE Addr Status

This register gives the address of the Register Write transaction in which parity error occurred.

Portj_MAC_AXI_SLV_DPE_Addr_Status (j=0-1) Offset address: $10154_H+j*2000_H$

Port j MAC AXI SLV DPE Addr Status Kernel Reset value: $0000\ 0000_H$



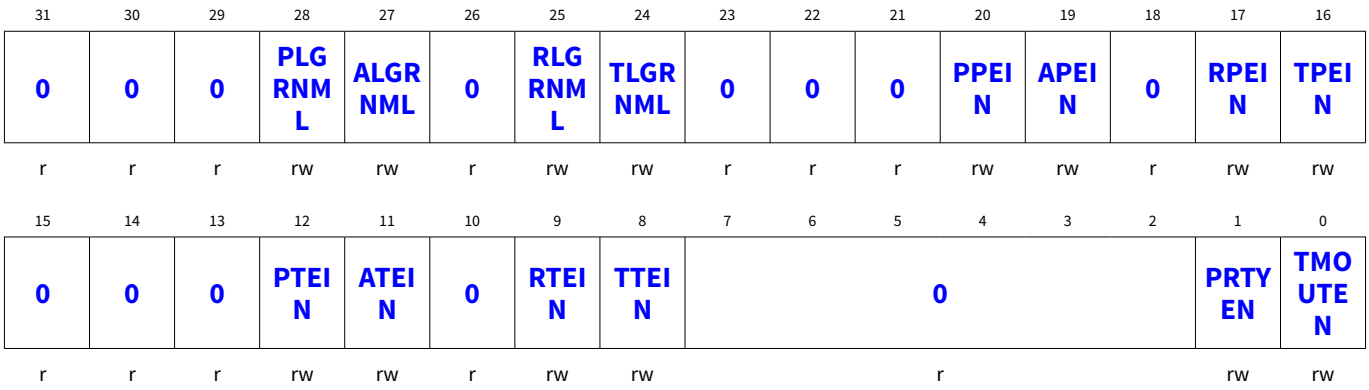
Field	Bits	Type	Description
ASPEAS	13:0	r	**AXI Slave data path Parity Error Address Status** This field holds the CSR address for which parity error is detected on the CSR write data. This field holds the first address for which parity error is detected on the write data which is cleared on read.
0	31:14	r	**Reserved** Read as 0; should be written with 0.

14.6.90 Port j MAC FSM Control

This register is used to control the FSM State parity and timeout error injection in Debug mode.

Portj_MAC_FSM_Control (j=0-1) Offset address: $10158_H+j*2000_H$

Port j MAC FSM Control Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
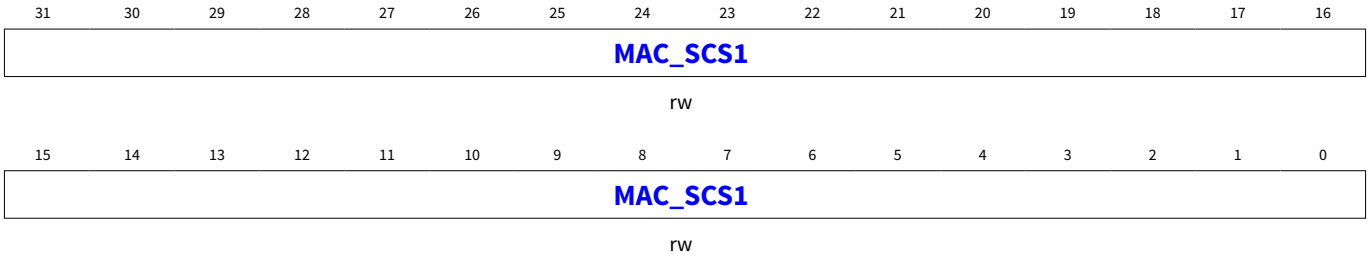
CTMR	30:28	rw	**CSR Parity Or Rx Parser Instruction Table ECC Check Interval Value** This register is used for setting timer value for generating timer tic for CSR parity or Rx Parser Instruction Table ECC check. 000_B **M_1MILLI_SEC**: 1ms 001_B **M_1MICRO_SEC_CSR**: 1us 010_B **M_4MILLI_SEC_CSR**: 4.096ms (~4ms) 011_B **M_16MILLI_SEC_CSR**: 16.384ms (~16ms) 100_B **M_64MILLI_SEC_CSR**: 65.536ms (~64ms) 101_B **M_256MILLI_SEC_CSR**: 262.144ms (~256ms) 110_B **M_1SEC_CSR**: 1.048sec (~1sec) 111_B **ALWAYS_EN**: Always Enabled
0	15:10, 27:24, 31	r	**Reserved** Read as 0; should be written with 0.

14.6.92 Port j SNPS SCS REG1

Synopsys Reserved Register.

Portj_SNPS_SCS_REG1 (j=0-1) Offset address: $10160_H+j*2000_H$

Port j SNPS SCS REG1 Kernel Reset value: $0000\ 0000_H$



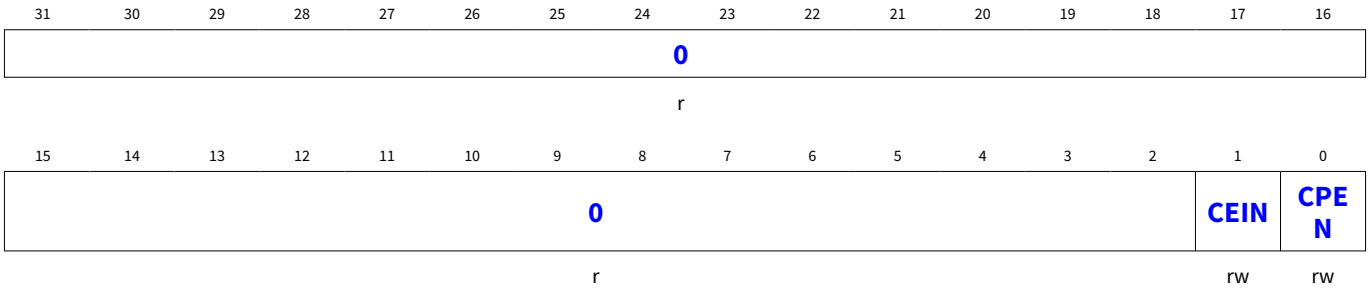
Field	Bits	Type	Description
MAC_SCS1	31:0	rw	**Synopsys Reserved** All the bits must be set to 0. This field is reserved for Synopsys Internal use, and must always be set to 0 unless instructed by Synopsys. Setting any bit to 1 might cause unexpected behavior in the IP.

14.6.93 Port j MAC SCSR Control

This register is used to control safety protected CSR parity generation.

Portj_MAC_SCSR_Control (j=0-1) Offset address: $10164_H+j*2000_H$

Port j MAC SCSR Control Kernel Reset value: $0000\ 0000_H$



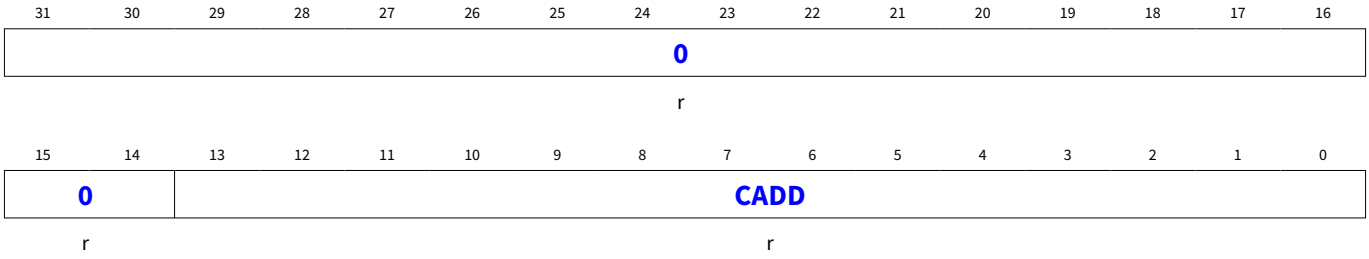
Field	Bits	Type	Description
CPEN	0	rw	**CSR Parity Enable** When this bit is set, CSR parity checking is enabled.
CEIN	1	rw	**CSR Error Injection** When this bit is set, CSR error injection is enabled. Error is injected in the subsequent write operation where at the least one of the byte enable matches with byte enable indicated in CEBE. After error injection, this bit is cleared by the design.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

14.6.94 Port j MAC SCSR Parity Status

This register indicates the offset address of the register where parity_error occurred.

Portj_MAC_SCSR_Parity_Status (j=0-1) Offset address: $10168_H+j*2000_H$

Port j MAC SCSR Parity Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CADD	13:0	r	**CSR Address with error** This field indicates the offset address of last CSR register for which read data parity mismatched with reference parity. For example, when parity mismatch occurred when MAC_Rx_Configuration register is read, this field will contain value of 16'h0004.
0	31:14	r	**Reserved** Read as 0; should be written with 0.

14.6.95 Port j MAC SCSR Parity Err Count

This register indicates error count associated with parity check.

Portj_MAC_SCSR_Parity_Err_Count (j=0-1) Offset address: $1016C_H+j*2000_H$

Port j MAC SCSR Parity Err Count Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r						r									

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						ECCL									
r						r									

Field	Bits	Type	Description
ECCL	9:0	r	**Count of parity errors in current safety loop** This field indicates the Count of parity errors in the current loop of all safety register parity check. Application read related errors are also included in the count. Value saturates at all "1"s and is cleared on read.
ECLL	25:16	r	**Count of parity errors in the previous safety loop** This field indicates the Count of parity errors in previous loop of all safety register parity check. Any application read related errors are also included in the count. Value saturates at all "1"s and is cleared on read.
0	15:10, 31:26	r	**Reserved** Read as 0; should be written with 0.

14.6.96 Port j MAC Flex Hdr Cfg

This register contains flexible header enable, length and start position for Flexible Header Feature.

Portj_MAC_Flex_Hdr_Cfg (j=0-1) Offset address: $10194_H+j*2000_H$

Port j MAC Flex Hdr Cfg Kernel Reset value: $0300\ 0C00_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0					FHL			0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0			FHSP					0					EFLL	FHTX	FHRX
r			rw					r					rw	rw	rw

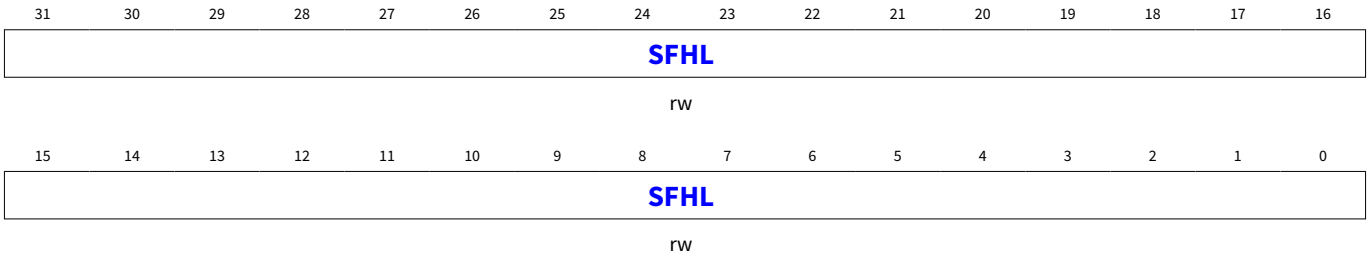
Field	Bits	Type	Description
FHRX	0	rw	**Flexible Header Enable for Rx path** When this is set, all the incoming packets from the Line is expected to have FHL bytes Flexible Header in the Rx path. When set to 0, normal/standard Ethernet packets are expected to be received and transmitted. This bit programming must be not changed when there are packets present in the RX path.
FHTX	1	rw	**Flexible Header Enable for Tx path** When this is set, all the packets from the Software is expected to have FHL bytes Flexible Header in the Tx path. When set to 0, normal/standard Ethernet packets are expected to be received and transmitted. This bit programming must be not changed when there are packets present in the TX path.
EFLL	2	rw	**Insert Flexible Header for Pause frames - When this bit is set along with FHTX, static flexible header of the programmed length is inserted in the MAC-generated pause frames at the programmed position - When this bit is set along with FHRX, in Rx path, pause frame must have FH programmed in the SFH (static flexible header) field** - When this bit is reset, pause frames do not have flexible header inserted in them, in both Tx and Rx paths.
FHSP	12:8	rw	**Flexible Header Start Position** When FHRX/FHTX bit is set, FH is present in Tx/Rx packets at one of the following encoded positions - 5'b00000: Before DA field (Byte 0) - 5'b00001 - 5'b01011: RSVD - 5'b01100: After SA field (Byte 12) - 5'b01101: Reserved - 5'b01110 - 5'11101: Byte 14 to Byte 29
FHL	26:24	rw	**Flexible Header Length** When FHRX/FHTX bit is set, all the packets coming on the line in the Rx path and all the packets transmitted from the application on the Tx path must have Flexible Header of the following size, in bytes: - 3'b000 - 3'b111: 1 Byte to 8 Bytes
0	7:3, 23:13, 31:27	r	**Reserved** Read as 0; should be written with 0.

14.6.97 Port j MAC Flex Hdr Low

This register contains programmable Lower Static Flexible Header for Mac-gen pause/hardware offload engines generated packets (such as PTP) Flexible Header Feature.

Portj_MAC_Flex_Hdr_Low (j=0-1) Offset address: $10198_H+j*2000_H$

Port j MAC Flex Hdr Low Kernel Reset value: $0000\ 0000_H$



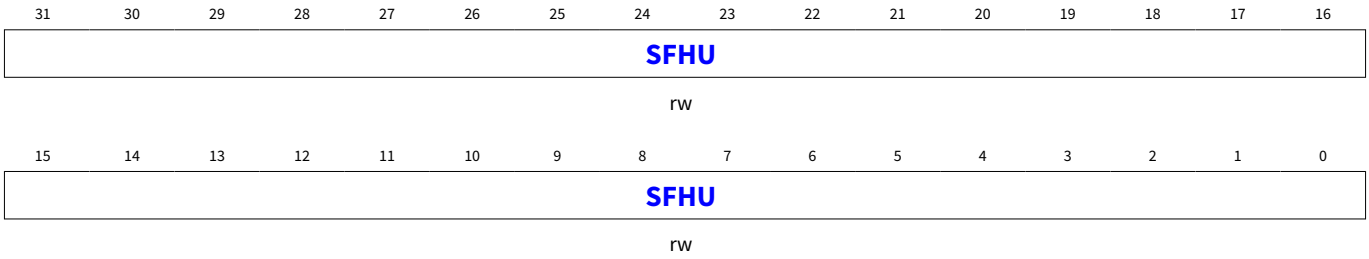
Field	Bits	Type	Description
SFHL	31:0	rw	**Static Flexible Header - Lower** When Flexible header feature is enabled in the Tx path, all the MAC generated Tx packets such as PTP packets and Link Layer packets (such as pause and verify-response if EFLL is set) have FH inserted from this programmable field, at the programmed FH position. This field must be used for FH length of upto 4 bytes

14.6.98 Port j MAC Flex Hdr High

This register contains programmable Upper Static Flexible Header for Mac-gen (pause)/hardware offload engines generated packets(such as PTP) Flexible Header Feature.

Portj_MAC_Flex_Hdr_High (j=0-1) Offset address: $1019C_H+j*2000_H$

Port j MAC Flex Hdr High Kernel Reset value: $0000\ 0000_H$



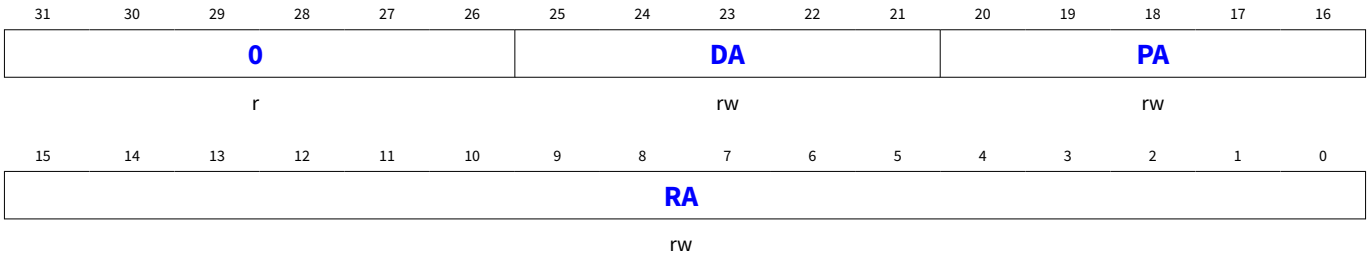
Field	Bits	Type	Description
SFHU	31:0	rw	**Static Flexible Header - Upper** This field is used for programming FH's upper 4 bytes when FH length is from 5 bytes to 8 bytes for Link Layer/ MAC auto-generated packets

14.6.99 Port j MDIO Single Command Address

This register contains the addresses of the ports, devices, and registers accessed by the SMA during single read or write transfers.

Portj_MDIO_Single_Command_Address (j=0-1) Offset address: $10200_H+j*2000_H$

Port j MDIO Single Command Address Kernel Reset value: $0000\ 0000_H$



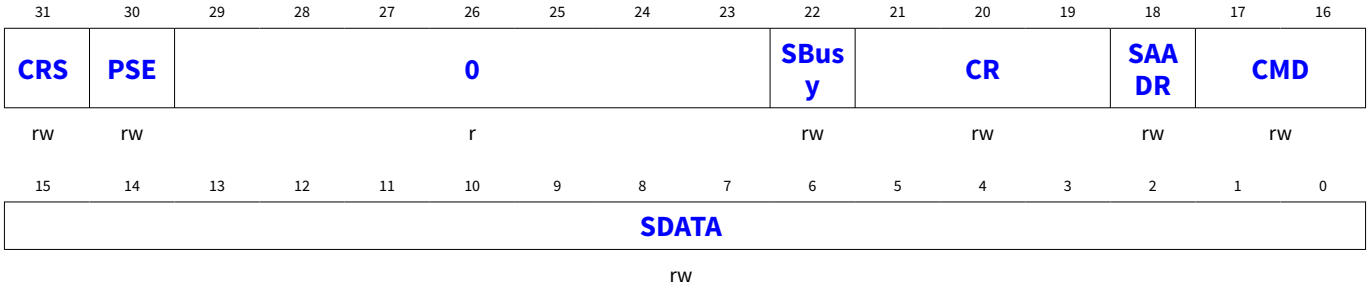
Field	Bits	Type	Description
RA	15:0	rw	**Register Address** Register Address for single read/write. When using Clause 22 frames, only the lower 5 bits of the field are used.
PA	20:16	rw	**Port Address** Port Address used for indirect single read/write access.
DA	25:21	rw	**Device Address** Device Address for indirect addressing of device for single read/write.
0	31:26	r	**Reserved** Read as 0; should be written with 0.

14.6.100 Port j MDIO Single Command Control Data

This register controls single read/write operations, and contains the data bits read on a single-read operation and the data to be written during single-write operations.

Portj_MDIO_Single_Command_Control_Data (j=0-1) Offset address: $10204_H+j*2000_H$

Port j MDIO Single Command Control Data Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SDATA	15:0	rw	**Single Write Data** For single writes, this field contains data to be written. For single reads, this field contains data that has been read.
CMD	17:16	rw	**Control Command** SMA commands are written to these bits. The command codes are: - 2'b11: SINGLE_READ - 2'b01: SINGLE_WRITE - 2'b10: POST INCREMENT READ OPERATION - 2'b00: Reserved (Results are undefined)

(table continues...)

(continued)

Field	Bits	Type	Description
SAADR	18	rw	**Skip Address Frame** The application sets this bit to prevent the SMA from sending address frames before read, write, or post-increment read frames.
CR	21:19	rw	**Application Clock Range** The Application Clock Range selection determines the relationship between the CSR and MDC clocks. Do not change the value of CR bits unless there is no operation (continuous write or scan) in progress on the SMA interface. When CRS bit is set to 0: - 3'b000 -- clk_csr_i: 100-150 MHz -- MDC clock: clk_csr_i/62 - 3'b001 -- clk_csr_i: 150-250 MHz -- MDC clock: clk_csr_i/102 - 3'b010 -- clk_csr_i: 250-300 MHz -- MDC clock: clk_csr_i/122 - 3'b011 -- clk_csr_i: 300-350 MHz -- MDC clock: clk_csr_i/142 - 3'b100 -- clk_csr_i: 350-400 MHz -- MDC clock: clk_csr_i/162 - 3'b101 -- clk_csr_i: 400-500 MHz -- MDC clock: clk_csr_i/202 - 3'b110 -- clk_csr_i: Reserved -- MDC clock: Reserved - 3'b111 -- clk_csr_i: Reserved -- MDC clock: Reserved When CRS bit is set to 1, MDIO clock is derived based on CSR clock as follows: - 3'b000: MDC clock: clk_csr_i/4 - 3'b001: MDC clock: clk_csr_i/6 - 3'b010: MDC clock: clk_csr_i/8 - 3'b011: MDC clock: clk_csr_i/10 - 3'b100: MDC clock: clk_csr_i/12 - 3'b101: MDC clock: clk_csr_i/14 - 3'b110: MDC clock: clk_csr_i/16 - 3'b111: MDC clock: clk_csr_i/18

(table continues...)

(continued)

Field	Bits	Type	Description
SBusy	22	rw	**Busy** When you set this bit, it triggers a single read, single write, or post-increment read operation. DWC_xgmac clears this bit when the triggered operation is completed. During the MDIO transfer cycle, this bit remains high to indicate the cycle in progress. When the Busy bit is high, do not modify any bits in SMA registers 1 or 2. When this bit is set high, bits[15:0] of MDIO_Single_Command_Control_Data must be kept valid for MDIO write access or bits[15:0] of MDIO_Single_Command_Control_Data are invalid (for MDIO read access).
PSE	30	rw	**Preamble Suppression Enable** When this bit is set, the SMA suppresses the 32-bit preamble and transmits MDIO packets with only 1 preamble bit. When this bit is 0, the MDIO packet always has 32 bits of preamble as defined in the IEEE specifications.
CRS	31	rw	**Clock Range Select** When this set overrides the default MDIO clock generation based on CSR clock. When this bit is set MDIO Clock generation using CSR clock such that MDIO frequency is equals to CSR clock divided by 4, 6, 8, 10, 12, 14, 16, 18. Therefore, this mode enables faster clock on MDIO.
0	29:23	r	**Reserved** Read as 0; should be written with 0.

14.6.101 Port j MDIO Continuous Write Address

You can program this register to start continuous write operation.

Portj_MDIO_Continuous_Write_Address (j=0-1) Offset address: $10208_H+j*2000_H$

Port j MDIO Continuous Write Address Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0									CBUSY	CPRT	CADDR				
r									rw	rw	rw				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CREGADDR															
rw															

Field	Bits	Type	Description
CREGADDR	15:0	rw	**Continuous Register Address** Register address to which continuous writes are performed. For Clause 22 ports, only the five least significant bits are valid.

(table continues...)

(continued)

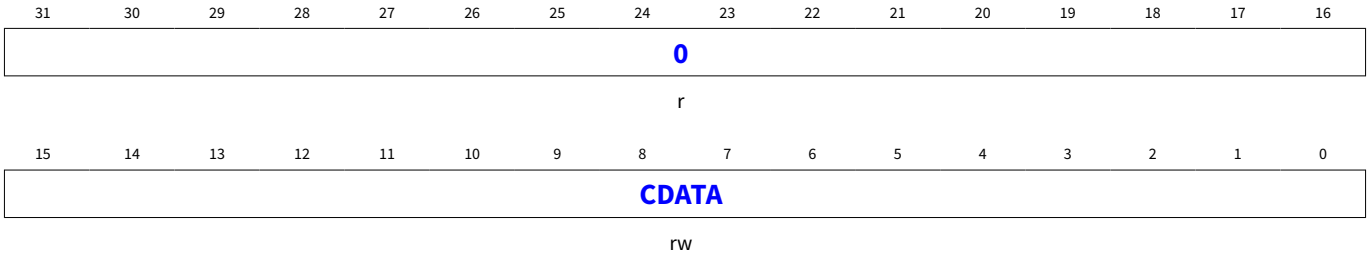
Field	Bits	Type	Description
CADDR	20:16	rw	**Continuous Port or Device Address** Common address to which continuous writes are applied. Used either as a device address or a port address, depending on the CPRT setting. As a port address, the valid range is 0-3 only.
CPRT	21	rw	**Continuous Port or Device Address Select** When this bit is set, the CADDR is used as the port address and continuous writes are performed on all port devices. When this bit is unset, CADDR is used as the device address and continuous writes are performed on all ports.
CBUSY	22	rw	**Continuous Write Busy** When this bit is set, continuous write operation starts. When continuous write operation is complete, this bit is reset. This bit must read as 0 before the next continuous write command is issued.
0	31:23	r	**Reserved** Read as 0; should be written with 0.

14.6.102 Port j MDIO Continuous Write Data

This register contains the data to be written during continuous write operation. Do not change the register's contents until the Continuous Write Busy bit (CBUSY) is cleared.

Portj_MDIO_Continuous_Write_Data (j=0-1) Offset address: $1020C_H+j*2000_H$

Port j MDIO Continuous Write Data Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CDATA	15:0	rw	**Continuous Write Data** Data to be used in the MDIO frame during a continuous write. Do not modify the register's contents unless the Continuous Write Busy bit (CBUSY) is cleared.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.103 Port j MDIO Continuous Scan Port Enable

This register controls the PHY ports and corresponding devices (enabled by the corresponding Device In Use register) to be accessed during the SMA's continuous scan operation. If you change any bit in this register during a continuous scan, it takes effect at the end of the current scan read cycle. In other words, if Bit 2 (Port 2) is enabled while Port 3, 0, or 1 is being scanned, port 2 scanning is scheduled at the end of the Port 1 scan. If any bit is cleared by software, it takes effect at the end of the reading the last register of last enabled device.

Portj_MDIO_Continuous_Scan_Port_Enable (j=0-1) Offset address: $10210_H+j*2000_H$

Port j MDIO Continuous Scan Port Enable Kernel Reset value: $0000\ 0000_H$

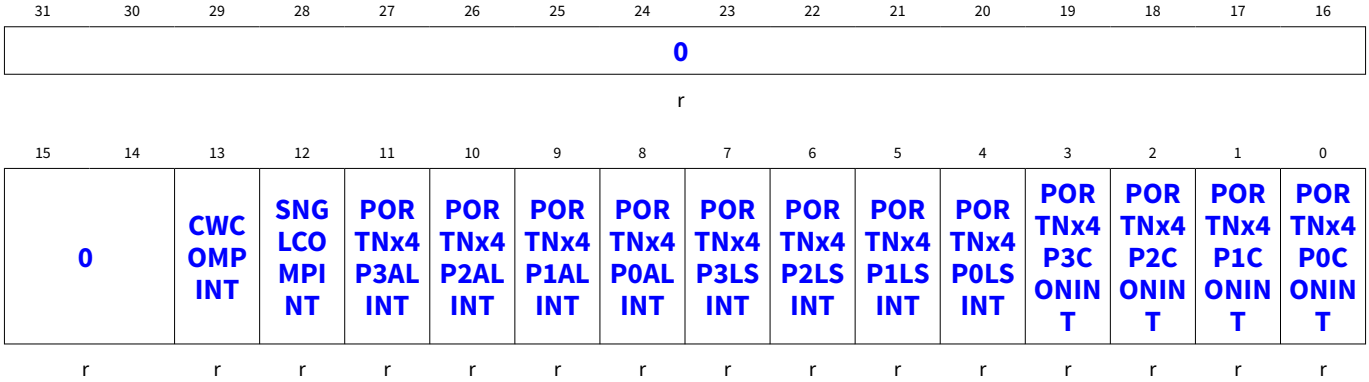
PORT31SCE	31	rw	**Port 31 Continuous Scan Enable** This bit indicates that Port 31 is enabled for continuous scan. Software can disable the port for continuous scan by setting this bit to 0.

14.6.104 Port j MDIO Interrupt Status

This register gives the source of the interrupt raised by the SMA module on the sbd_intr_o output line. The status bits are cleared when the software reads the corresponding bytes.

Portj_MDIO_Interrupt_Status (j=0-1) Offset address: $10214_H+j*2000_H$

Port j MDIO Interrupt Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PORTNx4P0CONINT	0	r	**Connect/Disconnect Event Interrupt (Port Nx4 Plus0)** When set, indicates that Port Nx4 Plus0 caused an interrupt due to a connection or disconnection. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register Access restriction applies. Clears on reading byte-0 (or when byte-0 is written when RCWE bit in MAC_CSR_SW_Ctrl register is set)
PORTNx4P1CONINT	1	r	**Connect/Disconnect Event Interrupt (Port Nx4 Plus1)** When set, indicates that Port Nx4 Plus1 caused an interrupt due to a connection or disconnection. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register Access restriction applies. Clears on reading byte-0 (or when byte-0 is written when RCWE bit in MAC_CSR_SW_Ctrl register is set)
PORTNx4P2CONINT	2	r	**Connect/Disconnect Event Interrupt (Port Nx4 Plus2)** When set, indicates that Port Nx4 Plus2 caused an interrupt due to a connection or disconnection. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register Access restriction applies. Clears on reading byte-0 (or when byte-0 is written when RCWE bit in MAC_CSR_SW_Ctrl register is set)
PORTNx4P3CONINT	3	r	**Connect/Disconnect Event Interrupt (Port Nx4 Plus3)** When set, indicates that Port Nx4 Plus3 caused an interrupt due to a connection or disconnection. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register Access restriction applies. Clears on reading byte-0 (or when byte-0 is written when RCWE bit in MAC_CSR_SW_Ctrl register is set)
PORTNx4P0LSINT	4	r	**Link Status Change Interrupt (Port Nx4 Plus0)** When set, indicates that the link status changed on at least one of the Port Nx4 Plus0 devices. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register Access restriction applies. Clears on reading byte-0 (or when byte-0 is written when RCWE bit in MAC_CSR_SW_Ctrl register is set)

(table continues...)

(continued)

Field	Bits	Type	Description
PORTNx4P1LSINT	5	r	**Link Status Change Interrupt (Port Nx4 Plus1)** When set, indicates that the link status changed on at least one of the Port Nx4 Plus1 devices. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register Access restriction applies. Clears on reading byte-0 (or when byte-0 is written when RCWE bit in MAC_CSR_SW_Ctrl register is set)
PORTNx4P2LSINT	6	r	**Link Status Change Interrupt (Port Nx4 Plus2)** When set, indicates that the link status changed on at least one of the Port Nx4 Plus2 devices. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register Access restriction applies. Clears on reading byte-0 (or when byte-0 is written when RCWE bit in MAC_CSR_SW_Ctrl register is set)
PORTNx4P3LSINT	7	r	**Link Status Change Interrupt (Port Nx4 Plus3)** When set, indicates that the link status changed on at least one of the Port Nx4 Plus3 devices. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register Access restriction applies. Clears on reading byte-0 (or when byte-0 is written when RCWE bit in MAC_CSR_SW_Ctrl register is set)
PORTNx4P0ALINT	8	r	**Device Present Status Change Interrupt (Port Nx4 Plus0)** When set, indicates that an interrupt occurred due to a change in one or more of the Port Nx4 Plus0 device's Alive status. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register Access restriction applies. Clears on reading byte-1 (or when byte-1 is written when RCWE bit in MAC_CSR_SW_Ctrl register is set)
PORTNx4P1ALINT	9	r	**Device Present Status Change Interrupt (Port Nx4 Plus1)** When set, indicates that an interrupt occurred due to a change in one or more of the Port Nx4 Plus1 device's Alive status. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register Access restriction applies. Clears on reading byte-1 (or when byte-1 is written when RCWE bit in MAC_CSR_SW_Ctrl register is set)
PORTNx4P2ALINT	10	r	**Device Present Status Change Interrupt (Port Nx4 Plus2)** When set, indicates that an interrupt occurred due to a change in one or more of the Port Nx4 Plus2 device's Alive status. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register Access restriction applies. Clears on reading byte-1 (or when byte-1 is written when RCWE bit in MAC_CSR_SW_Ctrl register is set)
PORTNx4P3ALINT	11	r	**Device Present Status Change Interrupt (Port Nx4 Plus3)** When set, indicates that an interrupt occurred due to a change in one or more of the Port Nx4 Plus3 device's Alive status. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register Access restriction applies. Clears on reading byte-1 (or when byte-1 is written when RCWE bit in MAC_CSR_SW_Ctrl register is set)

(table continues...)

(continued)

Field	Bits	Type	Description
SNGLCOMPINT	12	r	**Single Command Completion Interrupt** Set when a single command completes. Note: This bit is available only when PRS field of MDIO Port Nx4 Indirect Control register is 0. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
CWCOMPINT	13	r	**Continuous Write Completion Interrupt** Set when a continuous write completes. Note: This bit is valid only when PRS field of MDIO Port Nx4 Indirect Control register is 0. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
0	31:14	r	**Reserved** Read as 0; should be written with 0.

14.6.105 Port j MDIO Interrupt Enable

This register controls the enabling of interrupt sources in the MDIO Interrupt Status register.

Portj_MDIO_Interrupt_Enable (j=0-1) Offset address: $10218_H+j*2000_H$

Port j MDIO Interrupt Enable Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
SNGLCOMPIE	12	rw	**Single Command Completion Interrupt Enable** When set, this bit enables Single Command Completion interrupts. Note: This bit is available only when the PRS field of MDIO Port Nx4 Indirect Control register is 0.
CWCOMPIE	13	rw	**Continuous Write Completion Interrupt Enable** When set, this bit enables the Continuous Write Completion interrupts. Note: This bit is available only when the PRS field of MDIO Port Nx4 Indirect Control register is 0
0	31:14	r	**Reserved** Read as 0; should be written with 0.

14.6.106 Port j MDIO Port Connect Disconnect Status

This register gives the hot plug-in status for Ports 0-31. This register is updated at the end of any read operation to any register of the corresponding PHY port. It is updated during single-read transfers or during continuous scan operations. During continuous scan operation, a PHY port is only accessed when the corresponding MDIO Continuous Scan Port Enable register bit is set.

Portj_MDIO_Port_Connect_Disconnect_Status (j=0-1) Offset address: $1021C_H+j*2000_H$

Port j MDIO Port Connect Disconnect Status Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
PORT17CON	17	r	**Port 17 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 17. It is cleared when a disconnection event is detected.
PORT18CON	18	r	**Port 18 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 18. It is cleared when a disconnection event is detected.
PORT19CON	19	r	**Port 19 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 19. It is cleared when a disconnection event is detected.
PORT20CON	20	r	**Port 20 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 20. It is cleared when a disconnection event is detected.
PORT21CON	21	r	**Port 21 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 21. It is cleared when a disconnection event is detected.
PORT22CON	22	r	**Port 22 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 22. It is cleared when a disconnection event is detected.
PORT23CON	23	r	**Port 23 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 23. It is cleared when a disconnection event is detected.
PORT24CON	24	r	**Port 24 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 24. It is cleared when a disconnection event is detected.
PORT25CON	25	r	**Port 25 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 25. It is cleared when a disconnection event is detected.
PORT26CON	26	r	**Port 26 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 26. It is cleared when a disconnection event is detected.
PORT27CON	27	r	**Port 27 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 27. It is cleared when a disconnection event is detected.
PORT28CON	28	r	**Port 28 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 28. It is cleared when a disconnection event is detected.
PORT29CON	29	r	**Port 29 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 29. It is cleared when a disconnection event is detected.
PORT30CON	30	r	**Port 30 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 30. It is cleared when a disconnection event is detected.

(table continues...)

(continued)

Field	Bits	Type	Description
PORT31CON	31	r	**Port 31 Connect/Disconnect** The hardware sets this bit when a connection event is detected on Port 31. It is cleared when a disconnection event is detected.

14.6.107 Port j MDIO Clause 22 Port

This register configures the SMA to access the PHY ports using either the Clause 22 or Clause 45 packet format. All SMA operations (single or continuous) depend on setting these bits correctly.

Portj_MDIO_Clause_22_Port (j=0-1) Offset address: $10220_H+j*2000_H$

Port j MDIO Clause 22 Port Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
PTR0CL22	0	rw	**Port0CL22 Enable** Indicates that Port 0 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR1CL22	1	rw	**Port1CL22 Enable** Indicates that Port 1 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR2CL22	2	rw	**Port2CL22 Enable** Indicates that Port 2 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR3CL22	3	rw	**Port3CL22 Enable** Indicates that Port 3 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR4CL22	4	rw	**Port4CL22 Enable** Indicates that Port 4 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR5CL22	5	rw	**Port5CL22 Enable** Indicates that Port 5 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.

(table continues...)

(continued)

Field	Bits	Type	Description
PTR6CL22	6	rw	**Port6CL22 Enable** Indicates that Port 6 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR7CL22	7	rw	**Port7CL22 Enable** Indicates that Port 7 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR8CL22	8	rw	**Port8CL22 Enable** Indicates that Port 8 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR9CL22	9	rw	**Port9CL22 Enable** Indicates that Port 9 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR10CL22	10	rw	**Port10CL22 Enable** Indicates that Port 10 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR11CL22	11	rw	**Port11CL22 Enable** Indicates that Port 11 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR12CL22	12	rw	**Port12CL22 Enable** Indicates that Port 12 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR13CL22	13	rw	**Port13CL22 Enable** Indicates that Port 13 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR14CL22	14	rw	**Port14CL22 Enable** Indicates that Port 14 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR15CL22	15	rw	**Port15CL22 Enable** Indicates that Port 15 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR16CL22	16	rw	**Port16CL22 Enable** Indicates that Port 16 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR17CL22	17	rw	**Port17CL22 Enable** Indicates that Port 17 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR18CL22	18	rw	**Port18CL22 Enable** Indicates that Port 18 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR19CL22	19	rw	**Port19CL22 Enable** Indicates that Port 19 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.

(table continues...)

(continued)

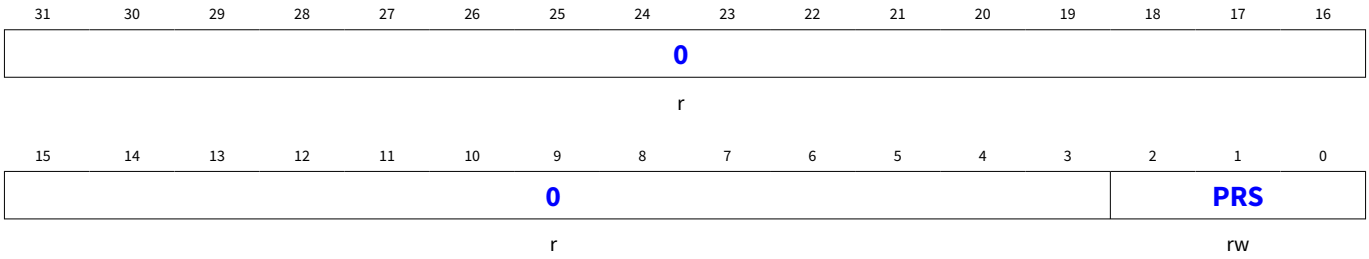
Field	Bits	Type	Description
PTR20CL22	20	rw	**Port20CL22 Enable** Indicates that Port 20 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR21CL22	21	rw	**Port21CL22 Enable** Indicates that Port 21 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR22CL22	22	rw	**Port22CL22 Enable** Indicates that Port 22 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR23CL22	23	rw	**Port23CL22 Enable** Indicates that Port 23 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR24CL22	24	rw	**Port24CL22 Enable** Indicates that Port 24 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR25CL22	25	rw	**Port25CL22 Enable** Indicates that Port 25 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR26CL22	26	rw	**Port26CL22 Enable** Indicates that Port 26 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR27CL22	27	rw	**Port27CL22 Enable** Indicates that Port 27 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR28CL22	28	rw	**Port28CL22 Enable** Indicates that Port 28 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR29CL22	29	rw	**Port29CL22 Enable** Indicates that Port 29 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR30CL22	30	rw	**Port30CL22 Enable** Indicates that Port 30 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.
PTR31CL22	31	rw	**Port31CL22 Enable** Indicates that Port 31 is connected to a PHY that only supports Clause 22. When this bit is reset, the PHY supports Clause 45.

14.6.108 Port j MDIO Port Nx4 Indirect Control

This register contain fields that control the Port range select for accessing register sets.

Portj_MDIO_Port_Nx4_Indirect_Control (j=0-1) Offset address: $10224_H+j*2000_H$

Port j MDIO Port Nx4 Indirect Control Kernel Reset value: $0000\ 0000_H$



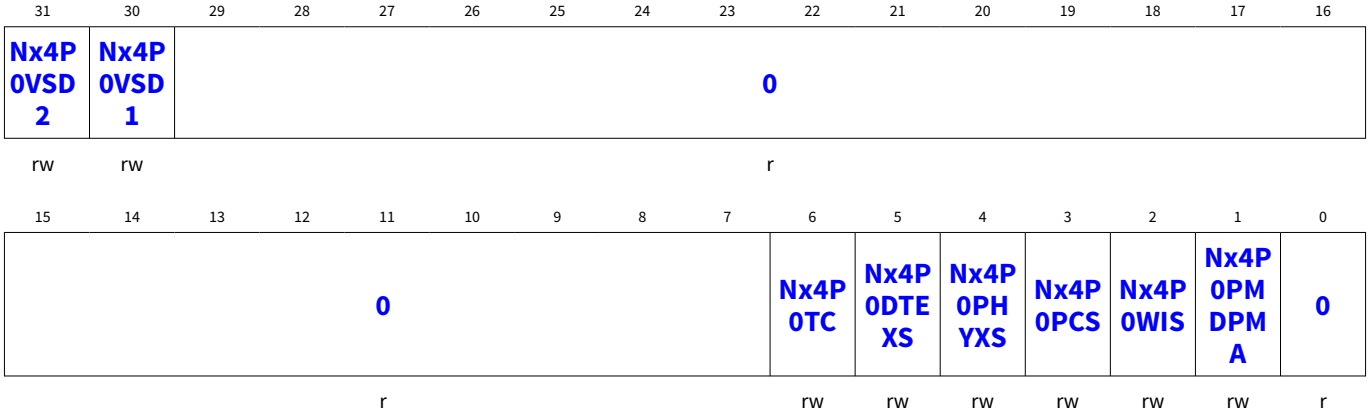
Field	Bits	Type	Description
PRS	2:0	rw	**Port Range Select** This register field controls the Port range select for accessing all the following register sets - MDIO Port Nx4P0/1/2/3 Device In Use register - MDIO Port Nx4P0/1/2/3 Link Status register - MDIO Port Nx4P0/1/2/3 Alive Status register - MDIO Interrupt Status register - MDIO Interrupt Enable register -- 0: Selects the Port address range of 0 to 3 -- 1: Selects the Port Address range of 4 to 7 -- 2: Selects the Port Address range of 8 to 11 -- 3: Selects the Port Address range of 12 to 15 -- 4: Selects the Port Address range of 16 to 19 -- 5: Selects the Port Address range of 20 to 23 -- 6: Selects the Port Address range of 24 to 27 -- 7: Selects the Port Address range of 28 to 31
0	31:3	r	**Reserved** Read as 0; should be written with 0.

14.6.109 Port j MDIO PortNx4P0 Device In Use

This register gives the status of each device on Port Nx4 Plus0 (Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register). Set these bits to indicate that a device is present and that the SMA must access it during continuous scan/write operations. If any bit is cleared, the corresponding device is not scanned when the Continuous Scan command is issued nor is it written when the Continuous Write command is issued. This register setting does not affect single read or write commands.

Portj_MDIO_PortNx4P0_Device_In_Use (j=0-1) Offset address: $10230_H+j*2000_H$

Port j MDIO PortNx4P0 Device In Use Kernel Reset value: $C000\ 007E_H$



Field	Bits	Type	Description
Nx4P0PMDPMA	1	rw	**PMA Device is in Use** When PMD/PMA is present, this bit is set to 1. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register
Nx4P0WIS	2	rw	**WIS Device is in Use** When WIS is present, this bit is set to 1. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register
Nx4P0PCS	3	rw	**PCS Device is in Use** When PCS is present, this bit is set to 1. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register
Nx4P0PHYXS	4	rw	**PHYXS Device is in Use** When PHY XS is present, this bit is set to 1. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register
Nx4P0DTEXS	5	rw	**DTEXS Device is in Use** When DTE XS is present, this bit is set to 1. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register
Nx4P0TC	6	rw	**TC Device is in Use** When TC is present, this bit is set to 1. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register
Nx4P0VSD1	30	rw	**VSD1 Device is in Use** When Vendor-Specific Device 1 is present, this bit is set to 1. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register
Nx4P0VSD2	31	rw	**VSD2 Device is in Use** When Vendor-Specific Device 2 is present, this bit is set to 1. Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register
0	0, 29:7	r	**Reserved** Read as 0; should be written with 0.

14.6.110 Port j MDIO PortNx4P0 Link Status

This register gives the link status of the devices in PHY Port Nx4Plus0 ((Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register) at the end of each continuous scan cycle. Up to eight devices are supported, as specified in IEEE 802.3-2018. You can disable the polling of any device by clearing its corresponding MDIO Port Nx4Plus0 Device In Use register bit.

Note: All the register fields are renamed from P0 to Nx4P0 (Nx4 Plus 0)

Portj_MDIO_PortNx4P0_Link_Status (j=0-1) Offset address: $10234_H+j*2000_H$

14.6.120 Port j MDIO PortNx4P3 Alive Status

This register gives the device status in PHY Port Nx4Plus3 ((Here N is as per the PRS field of MDIO Port Nx4 Indirect Control register) at the end of each continuous scan cycle. Up to eight devices are supported, as specified in IEEE 802.3-2018. You can disable the polling of any device by clearing its corresponding MDIO Port Nx4Plus0 Device In Use register bit.

Note: All the register fields are renamed from P3 to Nx4P3 (Nx4 Plus 3)

Field	Bits	Type	Description
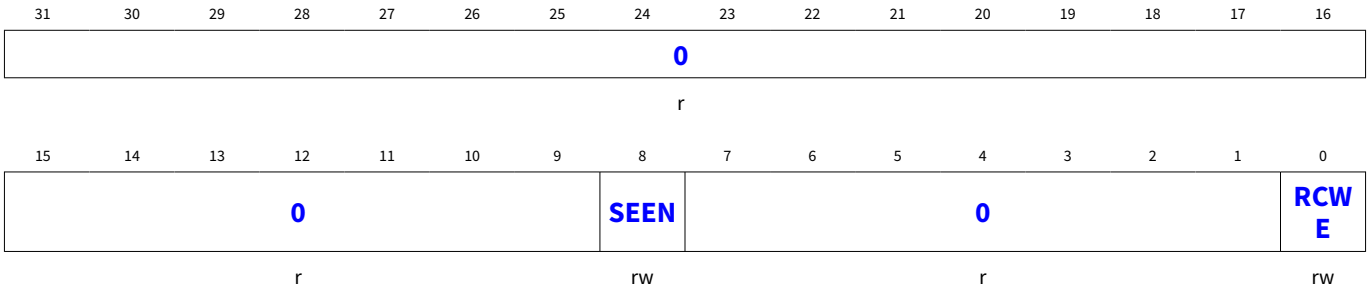
TVER	18	r	**Transmitted Verify Frame** This field is set when a Verify mPacket is transmitted (triggered by setting SVER field). An interrupt can be generated for this event if FPEIE bit of MAC_Interrupt_Enable is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: Not transmitted Verify Frame 1_B **ACTIVE**: transmitted Verify Frame
TRSP	19	r	**Transmitted Respond Frame** This field is set when a Respond mPacket is transmitted (triggered by setting SRSP field). An interrupt can be generated for this event if FPEIE bit of MAC_Interrupt_Enable is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0_B **INACTIVE**: Not transmitted Respond Frame 1_B **ACTIVE**: transmitted Respond Frame
0	15:4, 31:20	r	**Reserved** Read as 0; should be written with 0.

14.6.122 Port j MAC CSR SW Ctrl

This register contains software programmable controls for changing the CSR access response and status bits clearing.

Portj_MAC_CSR_SW_Ctrl (j=0-1) Offset address: $10290_H+j*2000_H$

Port j MAC CSR SW Ctrl Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RCWE	0	rw	**Register Clear on Write 1 Enable** When this bit is set, the access mode of list of register fields provided in Appendix F changes to Clear on Write 1, the application needs to set that respective bit to 1 to clear it. When this bit is reset, the access mode of list of register fields provided in Appendix F remain as Clear on Read. 0_B **DISABLE**: Register Clear on Write 1 Disable 1_B **ENABLE**: Register Clear on Write 1 Enable

(table continues...)

(continued)

Field	Bits	Type	Description
SEEN	8	rw	**Slave Error Response Enable - When this bit is set, the MAC responds with Slave Error for accesses to reserved registers in CSR space** - When this bit is reset, the MAC responds with Okay response to any register accessed from CSR space. 0_B **DISABLE**: Slave Error response Disabled 1_B **ENABLE**: Slave Error response Enabled
0	7:1, 31:9	r	**Reserved** Read as 0; should be written with 0.

14.6.123 Port j MAC Address0 High

The MAC_Address0_High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (X)GMII interface corresponds to the LS byte (Bits [7:0]) of the MAC_Address0_Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (X)GMII as the destination address, then the MAC_Address0 register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the (X)GMII clock domain or Power Management feature is selected, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the MAC_Address0_Low register are written, so MAC_Address0_High register must be written prior to MAC_Address0_Low register. For proper synchronization updates, the consecutive writes to MAC_Address0_Low register must be performed after at least four clock cycles of the slowest clock between the fGETH and (X)GMII clock domains.

Portj_MAC_Address0_High (j=0-1) Offset address: $10300_H+j*2000_H$

Port j MAC Address0 High Kernel Reset value: 8000 FFFF$_H$

The MAC_Address4_High register holds the upper 16 bits of the 4th 6-byte MAC address of the station. The first DA byte that is received on the (X)GMII interface corresponds to the LS byte (Bits [7:0]) of the MAC_Address4_Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (X)GMII as the destination address, then the MAC_Address4 register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the (X)GMII clock domain, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC_Address4_Low register are written, so MAC_Address4_High register must be written prior to MAC_Address4_Low register. For proper synchronization updates, the consecutive writes to MAC_Address4_Low register must be performed after at least four clock cycles of the slowest clock between the source and the destination clock domains.

Portj_MAC_Address4_High (j=0-1) Offset address: $10320_H+j*2000_H$

Field	Bits	Type	Description
ADDRLO	31:0	rw	**MAC Address10 [31:0]** This field contains the lower 32 bits of 10th 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

14.6.145 Port j MAC Address11 High

The MAC_Address11_High register holds the upper 16 bits of the 11th 6-byte MAC address of the station. The first DA byte that is received on the (X)GMII interface corresponds to the LS byte (Bits [7:0]) of the MAC_Address11_Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (X)GMII as the destination address, then the MAC_Address11 register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the (X)GMII clock domain, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC_Address11_Low register are written, so MAC_Address11_High register must be written prior to MAC_Address11_Low register. For proper synchronization updates, the consecutive writes to MAC_Address11_Low register must be performed after at least four clock cycles of the slowest clock between the source and the destination clock domains.

Field	Bits	Type	Description
ADDRLO	31:0	rw	**MAC Address16 [31:0]** This field contains the lower 32 bits of 16th 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

14.6.157 Port j MAC Address17 High

The MAC_Address17_High register holds the upper 16 bits of the 17th 6-byte MAC address of the station. The first DA byte that is received on the (X)GMII interface corresponds to the LS byte (Bits [7:0]) of the MAC_Address17_Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (X)GMII as the destination address, then the MAC_Address17 register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the (X)GMII clock domain, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC_Address17_Low register are written, so MAC_Address17_High register must be written prior to MAC_Address17_Low register. For proper synchronization updates, the consecutive writes to MAC_Address17_Low register must be performed after at least four clock cycles of the slowest clock between the source and the destination clock domains.

Portj_MAC_Address17_High (j=0-1) Offset address: $10388_H+j*2000_H$

Port j MAC Address17 High Kernel Reset value: $0000\ FFFF_H$

Field	Bits	Type	Description
ADDRLO	31:0	rw	**MAC Address22 [31:0]** This field contains the lower 32 bits of 22th 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

14.6.169 Port j MAC Address23 High

The MAC_Address23_High register holds the upper 16 bits of the 23th 6-byte MAC address of the station. The first DA byte that is received on the (X)GMII interface corresponds to the LS byte (Bits [7:0]) of the MAC_Address23_Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (X)GMII as the destination address, then the MAC_Address23 register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the (X)GMII clock domain, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC_Address23_Low register are written, so MAC_Address23_High register must be written prior to MAC_Address23_Low register. For proper synchronization updates, the consecutive writes to MAC_Address23_Low register must be performed after at least four clock cycles of the slowest clock between the source and the destination clock domains.

Portj_MAC_Address23_High (j=0-1) Offset address: $103B8_H+j*2000_H$

Port j MAC Address23 High Kernel Reset value: $0000\ FFFF_H$

ADDRLO	31:0	rw	**MAC Address28 [31:0]** This field contains the lower 32 bits of 28th 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

14.6.181 Port j MAC Address29 High

The MAC_Address29_High register holds the upper 16 bits of the 29th 6-byte MAC address of the station. The first DA byte that is received on the (X)GMII interface corresponds to the LS byte (Bits [7:0]) of the MAC_Address29_Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (X)GMII as the destination address, then the MAC_Address29 register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the (X)GMII clock domain, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC_Address29_Low register are written, so MAC_Address29_High register must be written prior to MAC_Address29_Low register. For proper synchronization updates, the consecutive writes to MAC_Address29_Low register must be performed after at least four clock cycles of the slowest clock between the source and the destination clock domains.

Portj_MAC_Address29_High (j=0-1) Offset address: $103E8_H+j*2000_H$

Port j MAC Address29 High Kernel Reset value: $0000\ FFFF_H$

AOFF								0		AUTO	0			COM	OB
rw								r		rw	r			rw	rw

Field	Bits	Type	Description
OB	0	rw	**Operation Busy** This bit is set along with a read or write command for initiating the indirect access to MAC_(#MSEL)_IndReg(#AOFF) registers. This bit is reset when the read or write command to MAC_(#MSEL)_IndReg(#AOFF) register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into MAC_(#MSEL)_IndReg(#AOFF) register. During a read operation, the data must be read from MAC_Indir_Access_Data register only after this bit is reset. To initiate an indirect access, this bit must be set at last.
COM	1	rw	**Command type** This bit indicates if the current register access is a read or a write. When set, it indicates a read operation. When reset, it indicates a write operation. 0_B **WRITE**: Write operation 1_B **READ**: Read operation
AUTO	5	rw	**Auto increment - When Auto increment is set, AOFF is incremented by 1 and care must be taken by software not to cause a wrap condition** - Byte wise read/write is not supported when auto increment is enabled.

(table continues...)

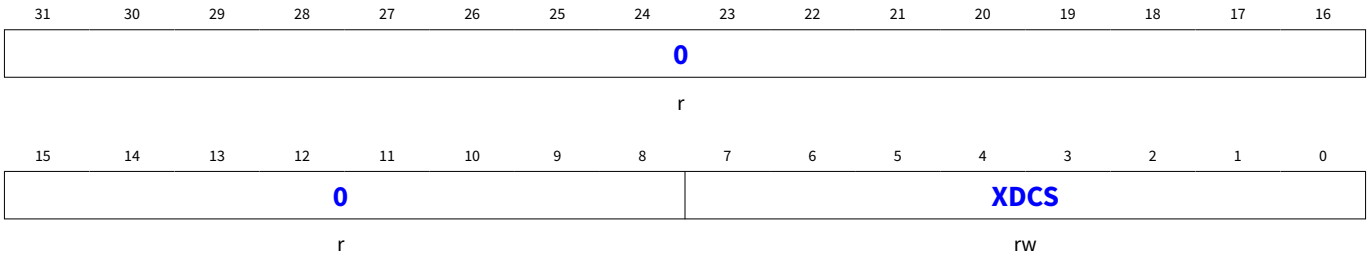
14.6.204 Port j MAC DChSel IndReg22

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg22 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg22 Kernel Reset value: $0000\ 0000_H$



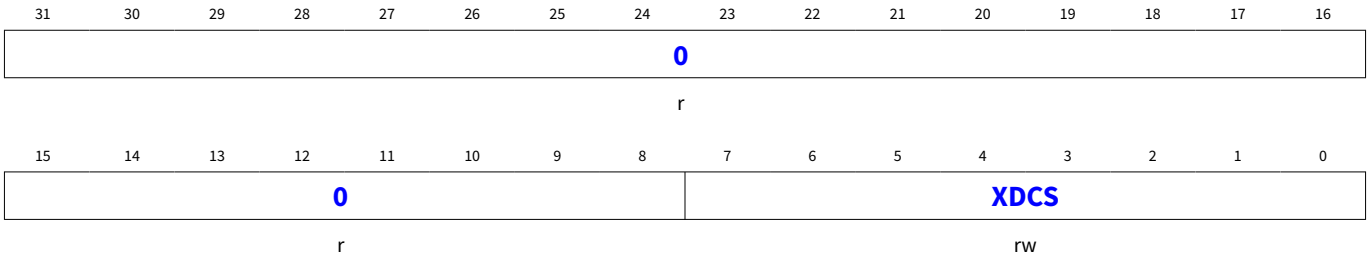
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.205 Port j MAC DChSel IndReg23

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg23 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg23 Kernel Reset value: $0000\ 0000_H$



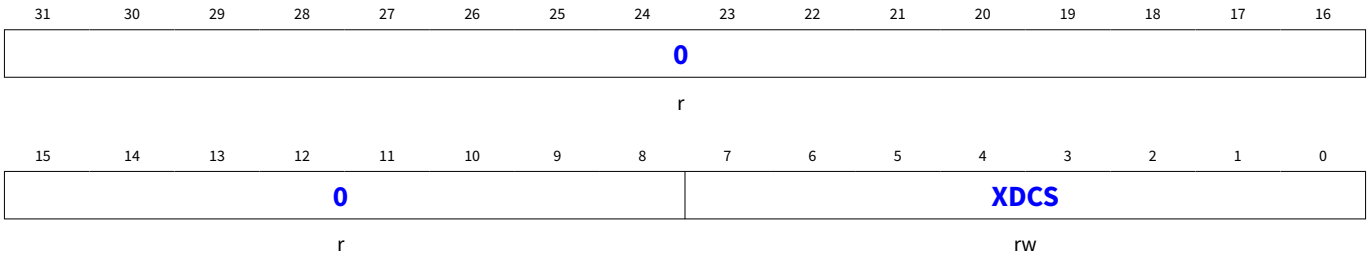
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.206 Port j MAC DChSel IndReg24

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg24 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg24 Kernel Reset value: $0000\ 0000_H$



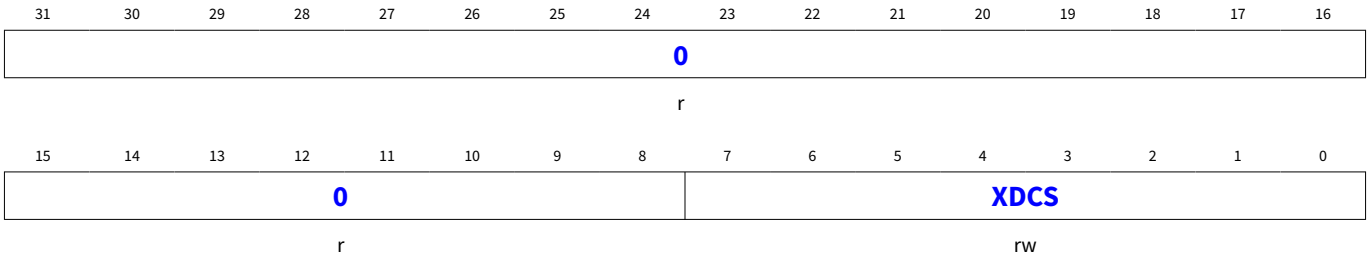
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.207 Port j MAC DChSel IndReg25

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg25 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg25 Kernel Reset value: $0000\ 0000_H$



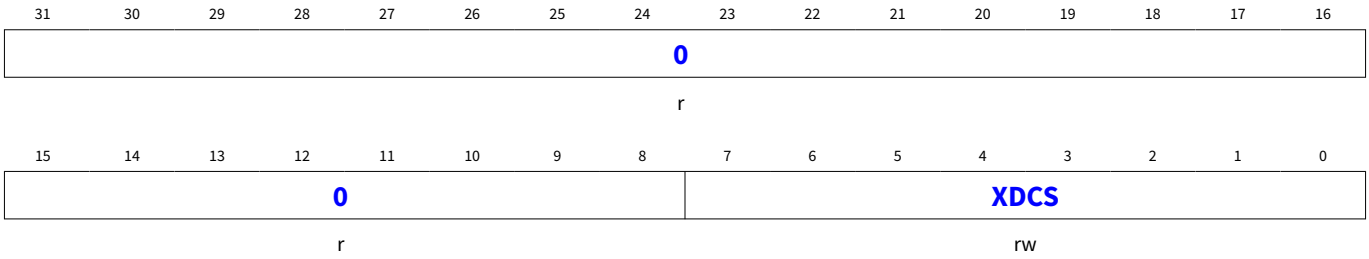
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.208 Port j MAC DChSel IndReg26

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg26 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg26 Kernel Reset value: $0000\ 0000_H$



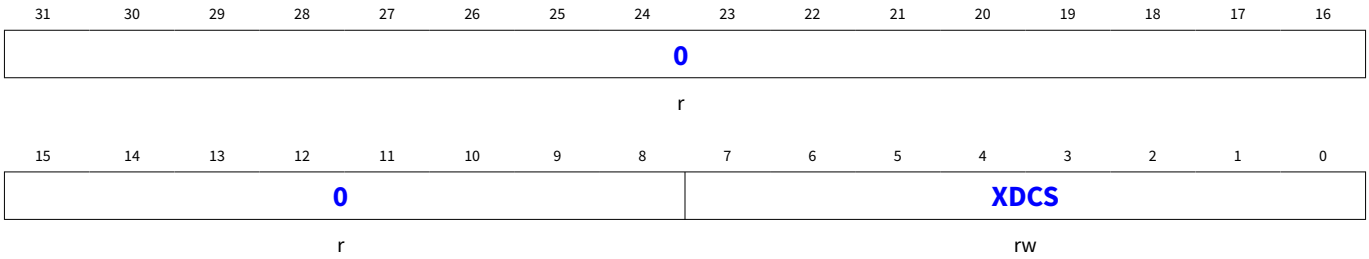
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.209 Port j MAC DChSel IndReg27

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg27 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg27 Kernel Reset value: $0000\ 0000_H$



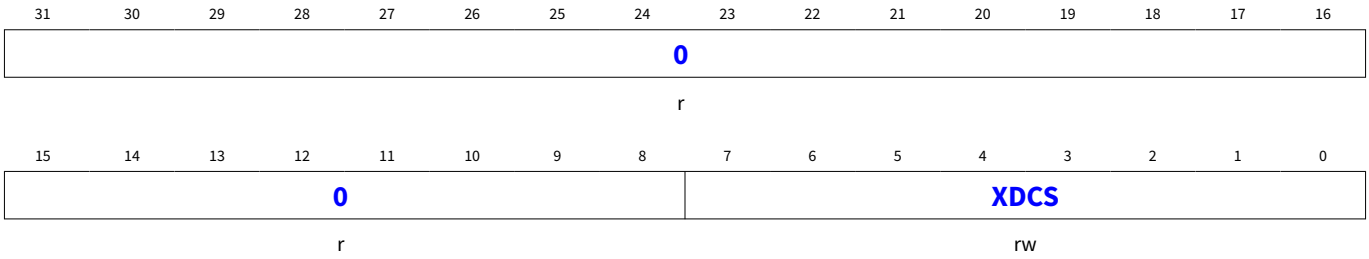
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.210 Port j MAC DChSel IndReg28

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg28 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg28 Kernel Reset value: $0000\ 0000_H$



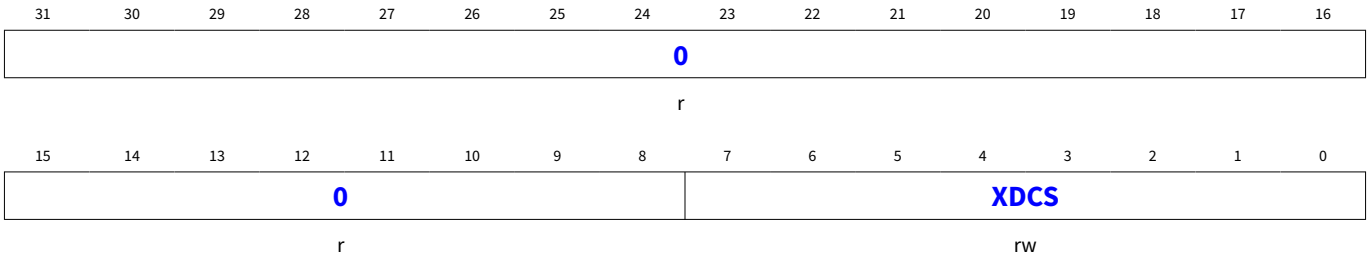
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.211 Port j MAC DChSel IndReg29

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg29 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg29 Kernel Reset value: $0000\ 0000_H$



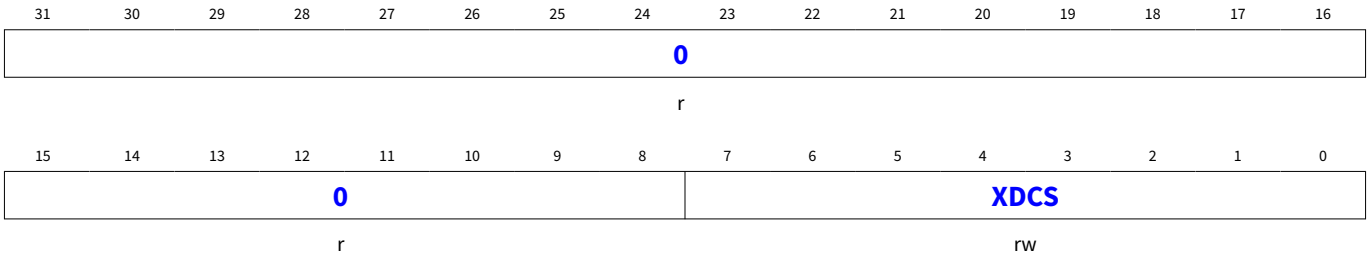
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.212 Port j MAC DChSel IndReg3

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg3 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg3 Kernel Reset value: $0000\ 0000_H$



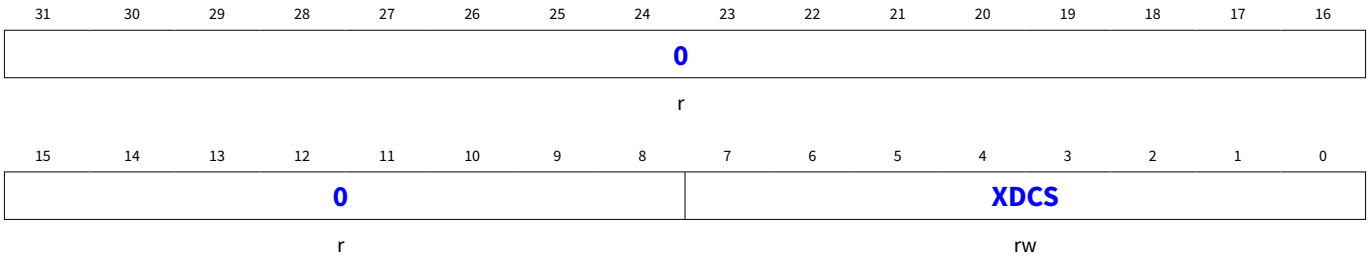
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.213 Port j MAC DChSel IndReg30

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg30 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg30 Kernel Reset value: $0000\ 0000_H$



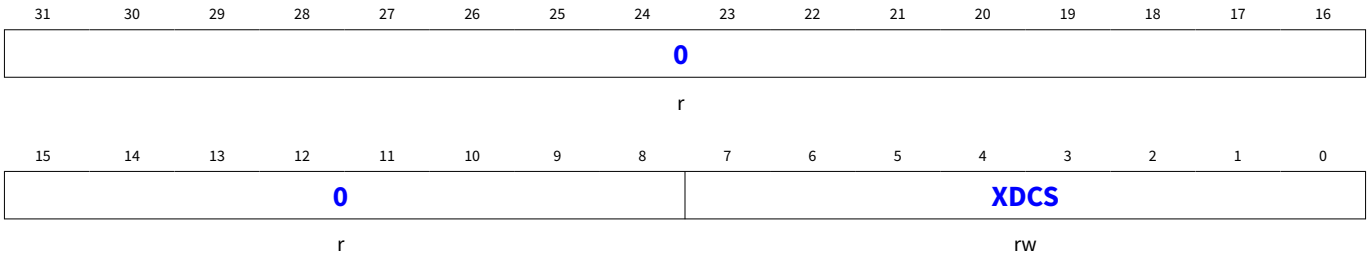
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.214 Port j MAC DChSel IndReg31

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg31 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg31 Kernel Reset value: $0000\ 0000_H$



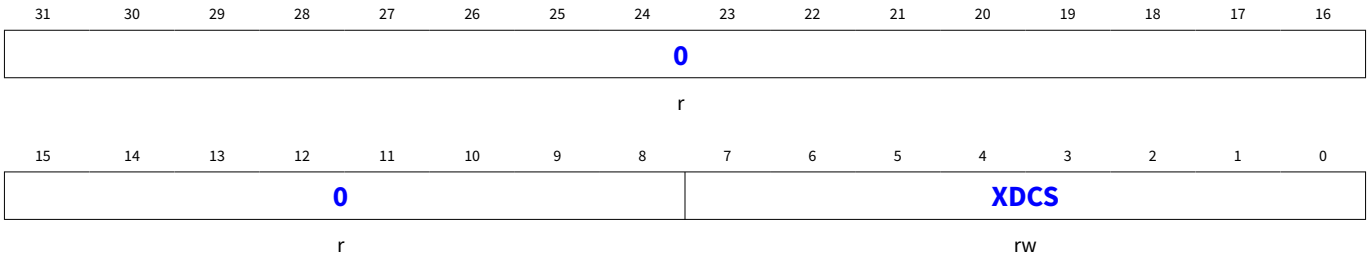
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.215 Port j MAC DChSel IndReg4

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg4 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg4 Kernel Reset value: $0000\ 0000_H$



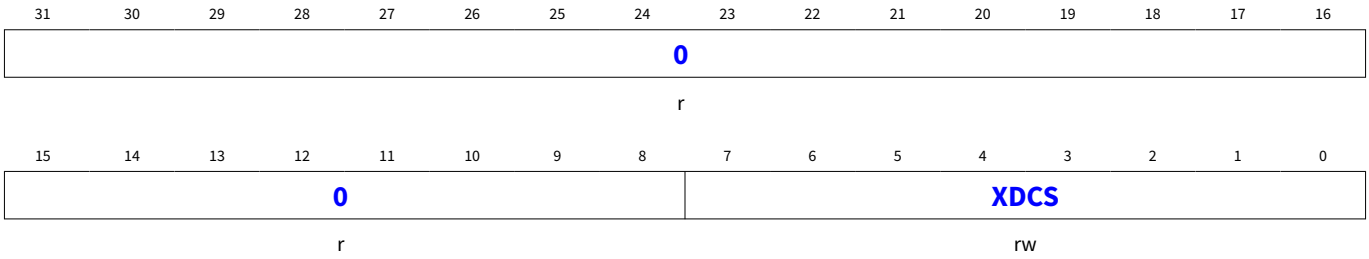
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.216 Port j MAC DChSel IndReg5

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg5 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg5 Kernel Reset value: $0000\ 0000_H$



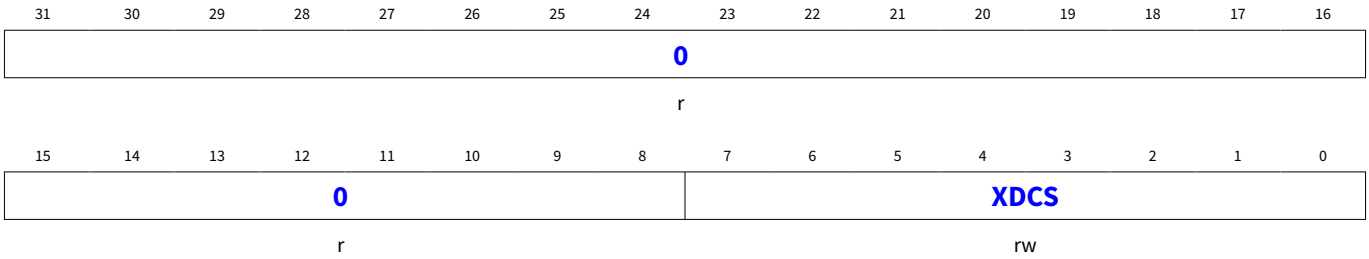
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.217 Port j MAC DChSel IndReg6

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg6 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg6 Kernel Reset value: $0000\ 0000_H$



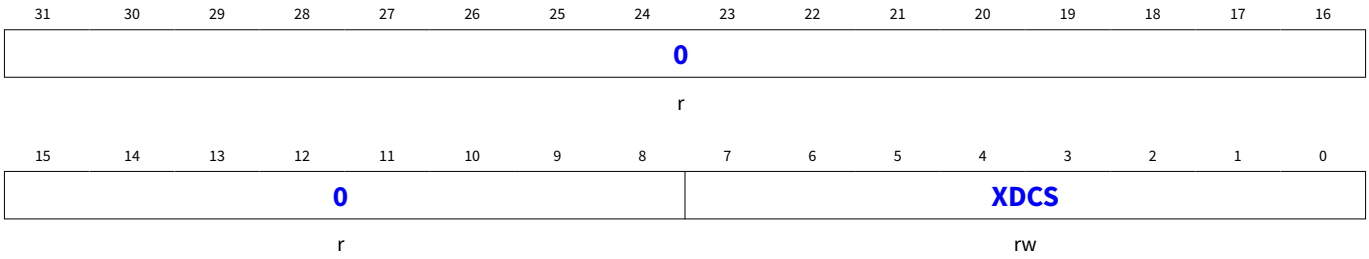
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.218 Port j MAC DChSel IndReg7

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg7 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg7 Kernel Reset value: $0000\ 0000_H$



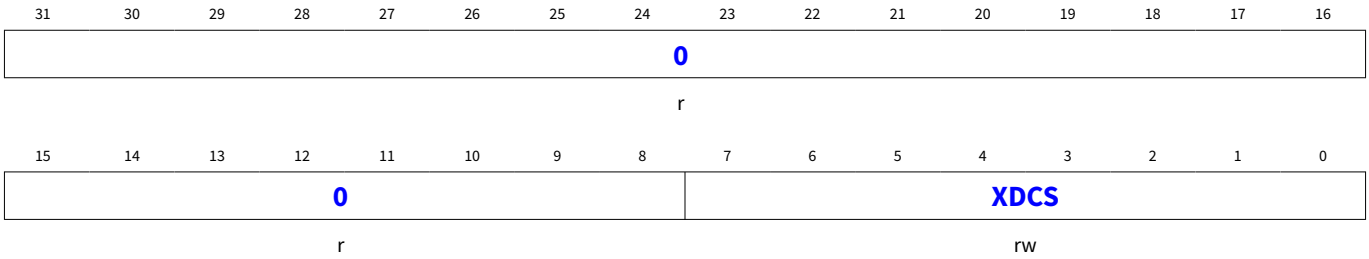
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.219 Port j MAC DChSel IndReg8

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg8 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg8 Kernel Reset value: $0000\ 0000_H$



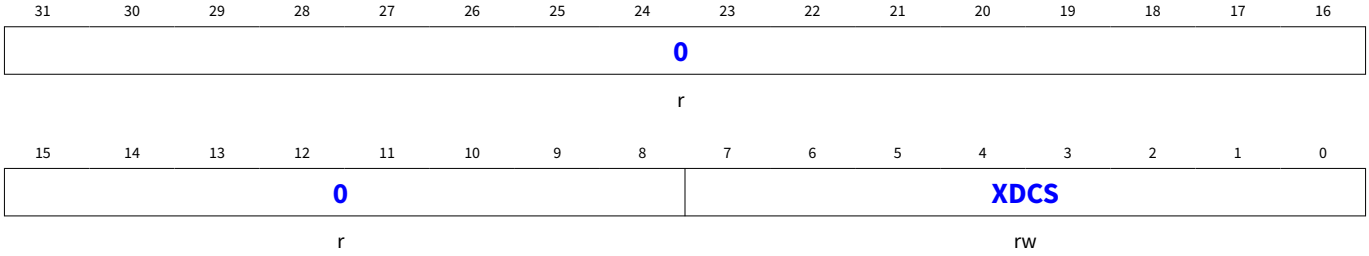
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.220 Port j MAC DChSel IndReg9

This register contains DCS (XDCS) one hot encoded value of receive channel selection for multicast/broadcast.

Portj_MAC_DChSel_IndReg9 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DChSel IndReg9 Kernel Reset value: $0000\ 0000_H$



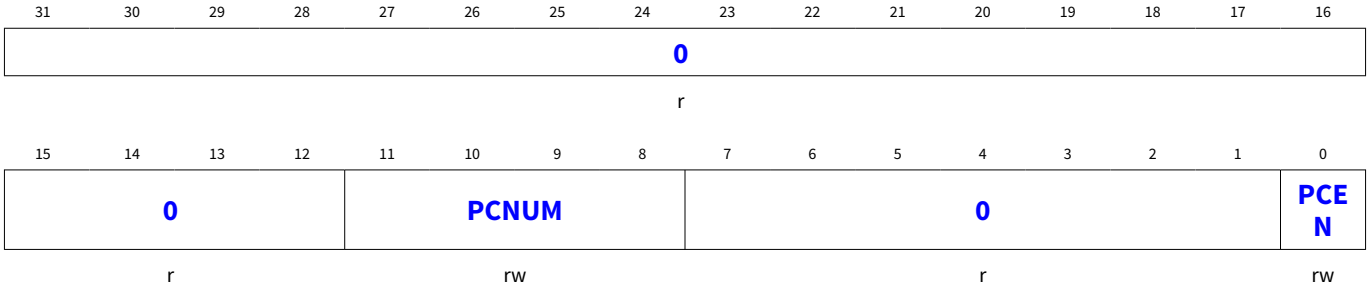
Field	Bits	Type	Description
XDCS	7:0	rw	**DMA Channel Select** This field contains one hot encoded DMA receive channel selection for MAC Address registers to forward the received MC/BC packet.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.221 Port j MAC DPCSel IndReg0

This register contains policing counter number corresponding to each DA or SA filter event.

Portj_MAC_DPCSel_IndReg0 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DPCSel IndReg0 Kernel Reset value: $0000\ 0000_H$



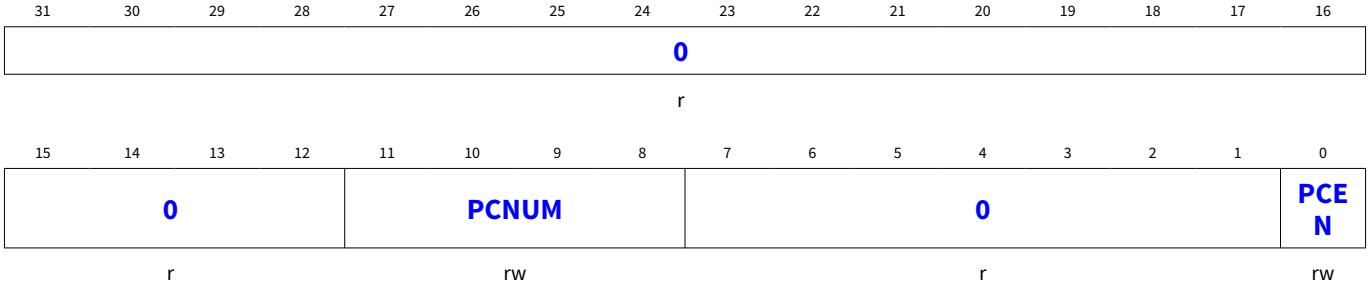
Field	Bits	Type	Description
PCEN	0	rw	**Policing Counter Enable** When set enables the policing counter indicated by the PCNUM field
PCNUM	11:8	rw	**Policing Counter Number** This field specifies the counter number selected for corresponding DA/SA address filter event.
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

14.6.222 Port j MAC DPCSel IndReg1

This register contains policing counter number corresponding to each DA or SA filter event.

Portj_MAC_DPCSel_IndReg1 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DPCSel IndReg1 Kernel Reset value: $0000\ 0000_H$



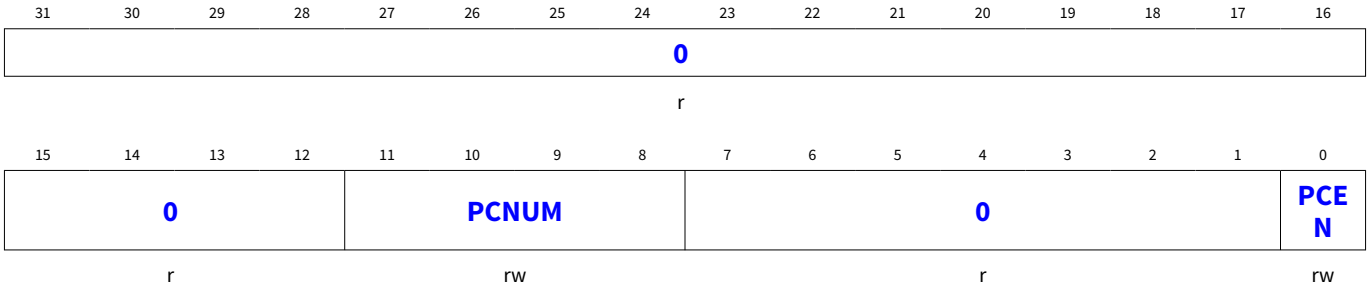
Field	Bits	Type	Description
PCEN	0	rw	**Policing Counter Enable** When set enables the policing counter indicated by the PCNUM field
PCNUM	11:8	rw	**Policing Counter Number** This field specifies the counter number selected for corresponding DA/SA address filter event.
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

14.6.223 Port j MAC DPCSel IndReg10

This register contains policing counter number corresponding to each DA or SA filter event.

Portj_MAC_DPCSel_IndReg10 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DPCSel IndReg10 Kernel Reset value: $0000\ 0000_H$



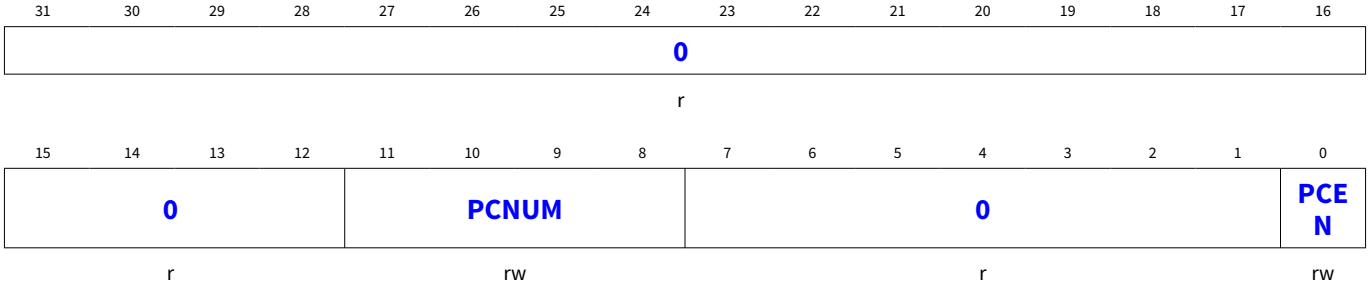
Field	Bits	Type	Description
PCEN	0	rw	**Policing Counter Enable** When set enables the policing counter indicated by the PCNUM field
PCNUM	11:8	rw	**Policing Counter Number** This field specifies the counter number selected for corresponding DA/SA address filter event.
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

14.6.224 Port j MAC DPCSel IndReg11

This register contains policing counter number corresponding to each DA or SA filter event.

Portj_MAC_DPCSel_IndReg11 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DPCSel IndReg11 Kernel Reset value: $0000\ 0000_H$



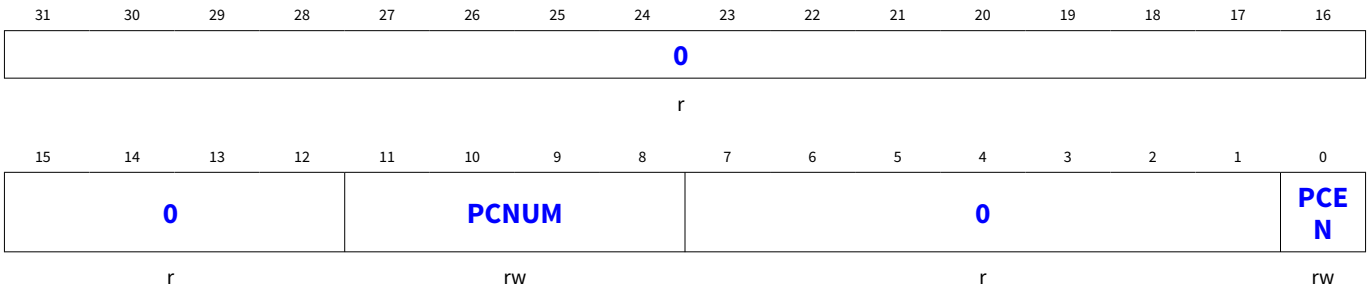
Field	Bits	Type	Description
PCEN	0	rw	**Policing Counter Enable** When set enables the policing counter indicated by the PCNUM field
PCNUM	11:8	rw	**Policing Counter Number** This field specifies the counter number selected for corresponding DA/SA address filter event.
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

14.6.225 Port j MAC DPCSel IndReg12

This register contains policing counter number corresponding to each DA or SA filter event.

Portj_MAC_DPCSel_IndReg12 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DPCSel IndReg12 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PCEN	0	rw	**Policing Counter Enable** When set enables the policing counter indicated by the PCNUM field
PCNUM	11:8	rw	**Policing Counter Number** This field specifies the counter number selected for corresponding DA/SA address filter event.

(table continues...)

(continued)

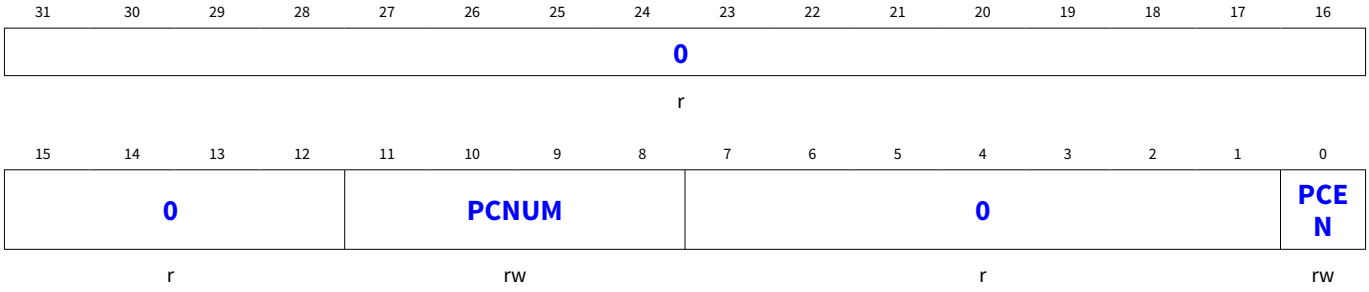
Field	Bits	Type	Description
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

14.6.226 Port j MAC DPCSel IndReg13

This register contains policing counter number corresponding to each DA or SA filter event.

Portj_MAC_DPCSel_IndReg13 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DPCSel IndReg13 Kernel Reset value: $0000\ 0000_H$



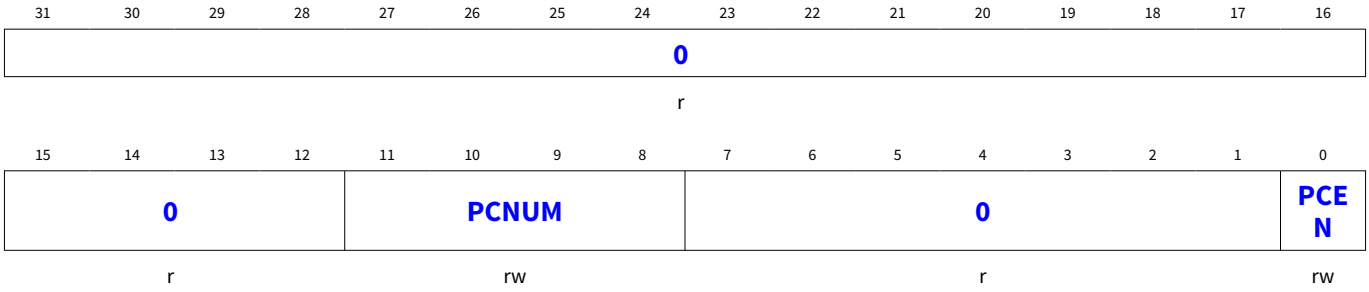
Field	Bits	Type	Description
PCEN	0	rw	**Policing Counter Enable** When set enables the policing counter indicated by the PCNUM field
PCNUM	11:8	rw	**Policing Counter Number** This field specifies the counter number selected for corresponding DA/SA address filter event.
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

14.6.227 Port j MAC DPCSel IndReg14

This register contains policing counter number corresponding to each DA or SA filter event.

Portj_MAC_DPCSel_IndReg14 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DPCSel IndReg14 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PCEN	0	rw	**Policing Counter Enable** When set enables the policing counter indicated by the PCNUM field
PCNUM	11:8	rw	**Policing Counter Number** This field specifies the counter number selected for corresponding DA/SA address filter event.
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

14.6.228 Port j MAC DPCSel IndReg15

This register contains policing counter number corresponding to each DA or SA filter event.

Portj_MAC_DPCSel_IndReg15 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC DPCSel IndReg15 Kernel Reset value: $0000\ 0000_H$

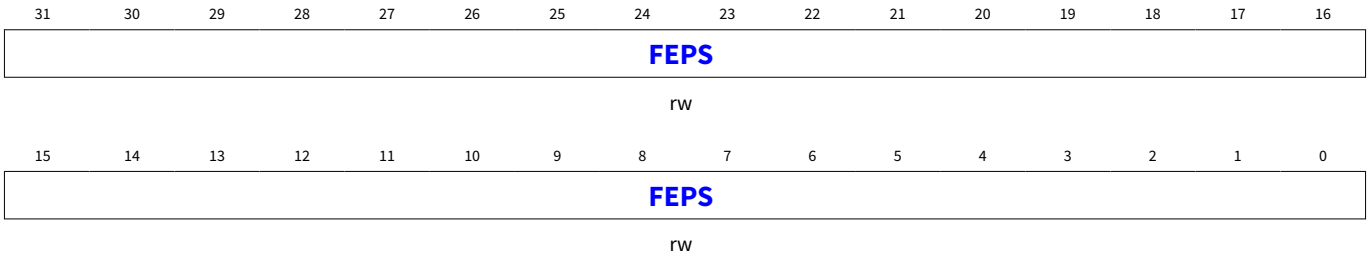
14.6.278 Port j MAC PCStatus DA IndReg

This register contains pass status for DA/SA filter where each bit corresponds to specific DA/SA filter event.

Portj_MAC_PCStatus_DA_IndReg (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC PCStatus DA IndReg Kernel Reset value: $0000\ 0000_H$



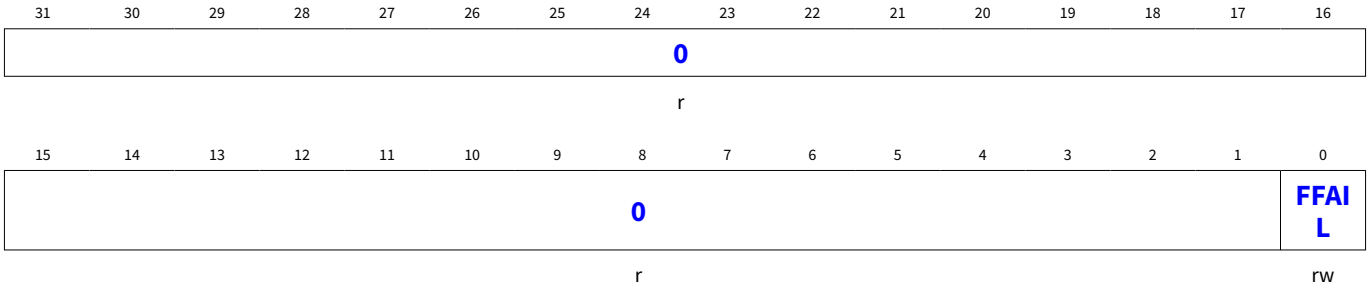
Field	Bits	Type	Description
FEPS	31:0	rw	**Filter Event Pass Status** When set, indicates at least one DA/SA filter event is passed. Each bit represents individual DA/SA filter event. Access restriction applies. This field is cleared when read (or written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set).

14.6.279 Port j MAC PCStatus Filter Event IndReg

This register contains status for the events monitored using policing counters apart from Filter Pass Events which is given below. 1. Filter_Fail

Portj_MAC_PCStatus_Filter_Event_IndReg (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC PCStatus Filter Event IndReg Kernel Reset value: $0000\ 0000_H$



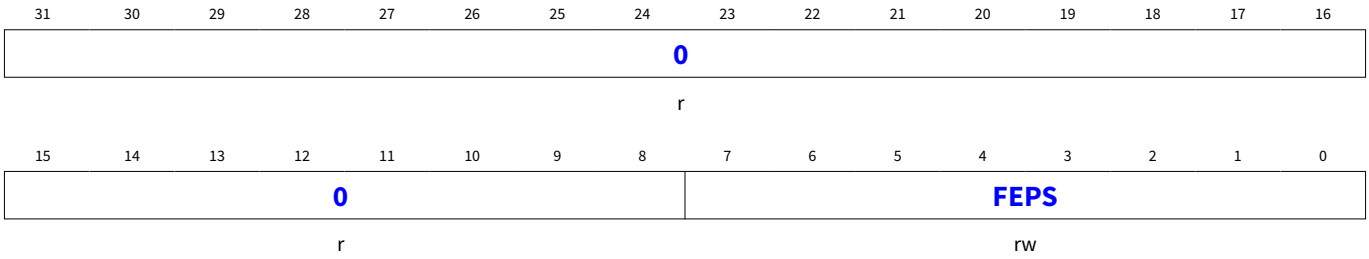
Field	Bits	Type	Description
FFAIL	0	rw	**Filter Fail** This bit is asserted when "Filter fail" event is set/triggered at least once. Access restriction applies. This bit is cleared when read (or written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set).
0	31:1	r	**Reserved** Read as 0; should be written with 0.

14.6.280 Port j MAC PCStatus L3L4 IndReg

This register contains pass status for L3_L4 filter where each bit corresponds to specific L3_L4 address filter event.

Portj_MAC_PCStatus_L3L4_IndReg (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC PCStatus L3L4 IndReg Kernel Reset value: $0000\ 0000_H$



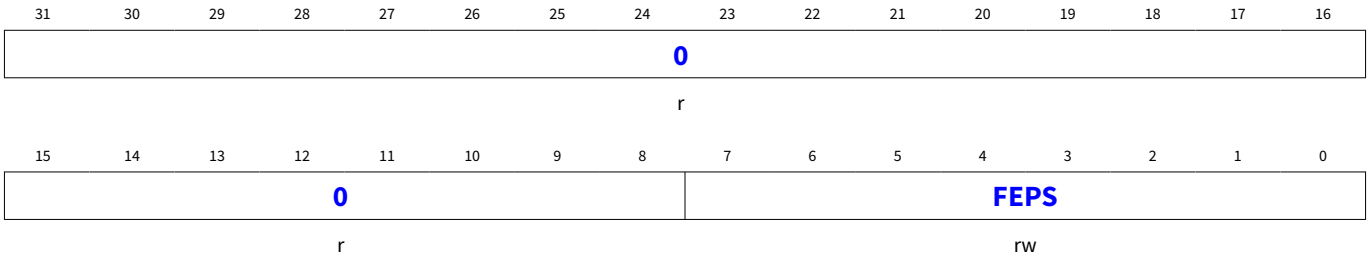
Field	Bits	Type	Description
FEPS	7:0	rw	**Filter Event Pass Status** When set, indicates at least one L3_L4 filter event is passed. Each bit represents individual L3_L4 filter. Access restriction applies. This field is cleared when read (or written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set).
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.281 Port j MAC PCStatus VLAN IndReg

This register contains pass status for VLAN filter where each bit corresponds to specific VLAN filter event.

Portj_MAC_PCStatus_VLAN_IndReg (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC PCStatus VLAN IndReg Kernel Reset value: $0000\ 0000_H$



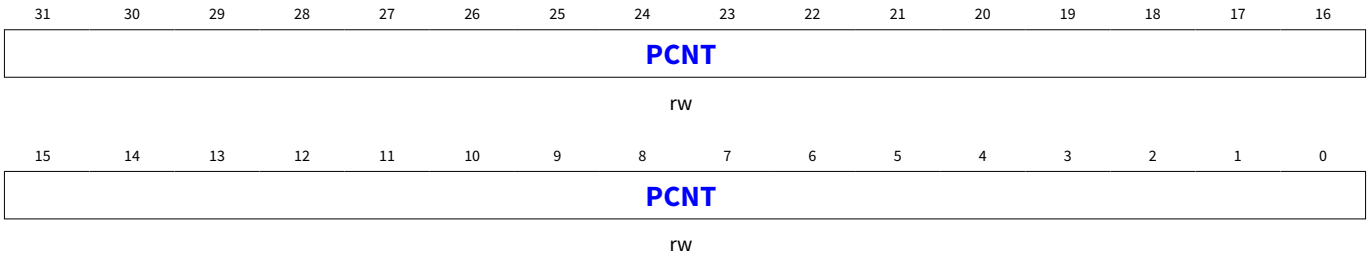
Field	Bits	Type	Description
FEPS	7:0	rw	**Filter Event Pass Status** When set, indicates at-least one VLAN filter event is passed. Each bit represents individual VLAN filters. Access restriction applies. This field is cleared when read (or written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set).
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.282 Port j MAC PCntr IndReg0

This register contains count value of policing counters.

Portj_MAC_PCntr_IndReg0 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC PCntr IndReg0 Kernel Reset value: $0000\ 0000_H$



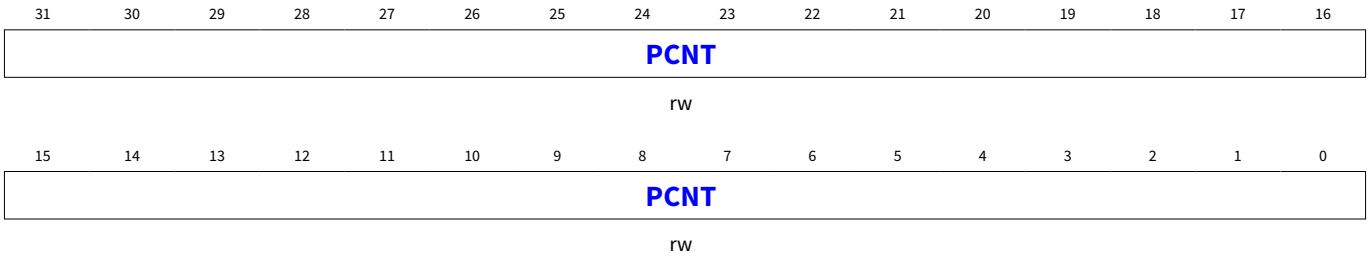
Field	Bits	Type	Description
PCNT	31:0	rw	**Policing Count Value** This field contains count value for policing counters. The counter is incremented within the start and end of the time window. Filter events results in increment of count. - Time window mode: When FRZ is not set, the counter value is cleared when start of the time window is detected. When FRZ is set, the counter is cleared on read. - Free running mode: Counter is cleared on read irrespective of the value of the FRZ bit

14.6.283 Port j MAC PCntr IndReg1

This register contains count value of policing counters.

Portj_MAC_PCntr_IndReg1 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC PCntr IndReg1 Kernel Reset value: $0000\ 0000_H$



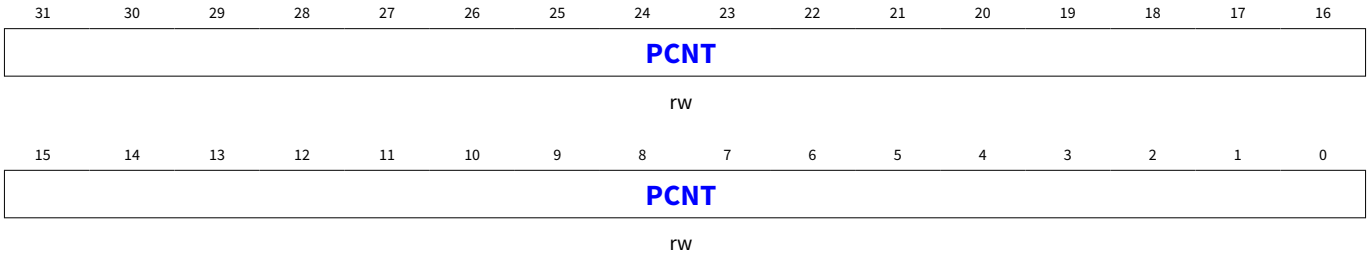
Field	Bits	Type	Description
PCNT	31:0	rw	**Policing Count Value** This field contains count value for policing counters. The counter is incremented within the start and end of the time window. Filter events results in increment of count. - Time window mode: When FRZ is not set, the counter value is cleared when start of the time window is detected. When FRZ is set, the counter is cleared on read. - Free running mode: Counter is cleared on read irrespective of the value of the FRZ bit

14.6.284 Port j MAC PCntr IndReg10

This register contains count value of policing counters.

Portj_MAC_PCntr_IndReg10 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC PCntr IndReg10 Kernel Reset value: $0000\ 0000_H$



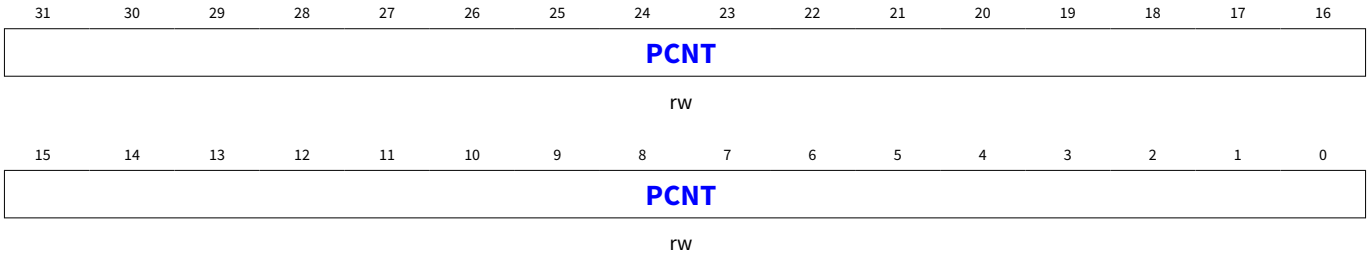
Field	Bits	Type	Description
PCNT	31:0	rw	**Policing Count Value** This field contains count value for policing counters. The counter is incremented within the start and end of the time window. Filter events results in increment of count. - Time window mode: When FRZ is not set, the counter value is cleared when start of the time window is detected. When FRZ is set, the counter is cleared on read. - Free running mode: Counter is cleared on read irrespective of the value of the FRZ bit

14.6.285 Port j MAC PCntr IndReg11

This register contains count value of policing counters.

Portj_MAC_PCntr_IndReg11 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC PCntr IndReg11 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PCNT	31:0	rw	**Policing Count Value** This field contains count value for policing counters. The counter is incremented within the start and end of the time window. Filter events results in increment of count. - Time window mode: When FRZ is not set, the counter value is cleared when start of the time window is detected. When FRZ is set, the counter is cleared on read. - Free running mode: Counter is cleared on read irrespective of the value of the FRZ bit

14.6.286 Port j MAC PCntr IndReg12

This register contains count value of policing counters.

Portj_MAC_PCntr_IndReg12 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC PCntr IndReg12 Kernel Reset value: $0000\ 0000_H$

When FRZ is set, the counter is cleared on read. - Free running mode: Counter is cleared on read irrespective of the value of the FRZ bit

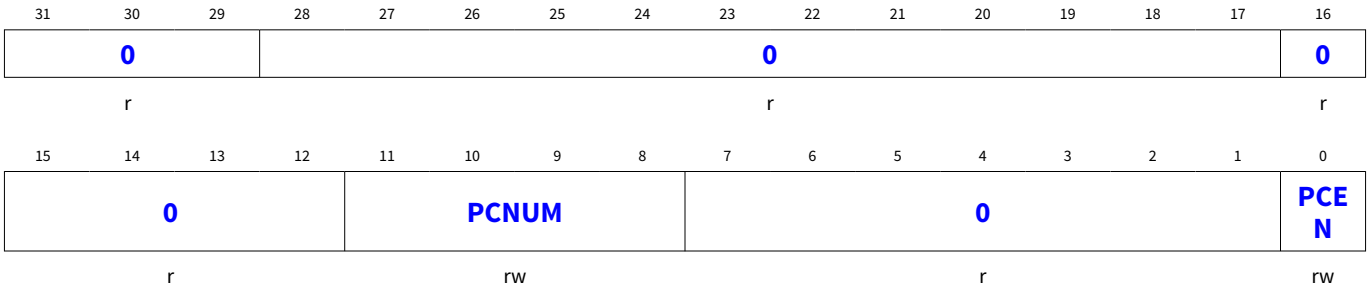
14.6.298 Port j MAC VPCSel IndReg0

This register contains policing counter number corresponding to each VLAN filter event.

Portj_MAC_VPCSel_IndReg0 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC VPCSel IndReg0 Kernel Reset value: $0000\ 0000_H$



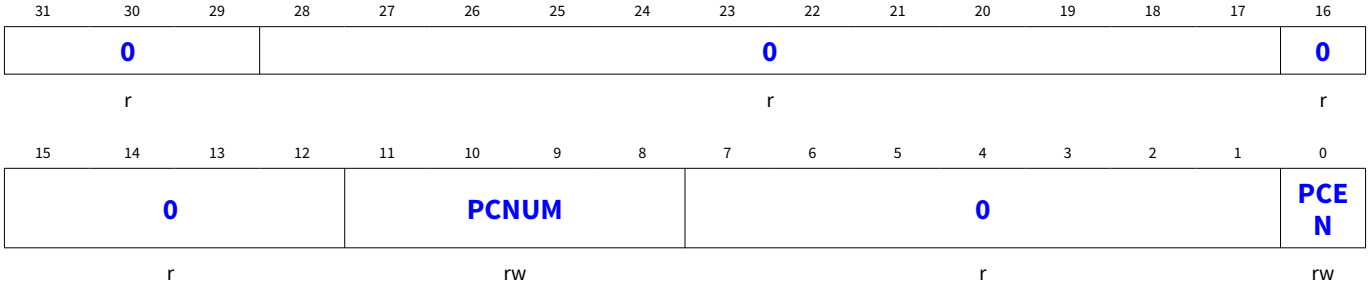
Field	Bits	Type	Description
PCEN	0	rw	**Policing Counter Enable** When set enables the policing counter indicated by the PCNUM field
PCNUM	11:8	rw	**Policing Counter Number** This field specifies the counter number selected for corresponding VLAN filter event.
0	7:1, 15:12, 16, 28:17, 31:29	r	**Reserved** Read as 0; should be written with 0.

14.6.299 Port j MAC VPCSel IndReg1

This register contains policing counter number corresponding to each VLAN filter event.

Portj_MAC_VPCSel_IndReg1 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC VPCSel IndReg1 Kernel Reset value: $0000\ 0000_H$



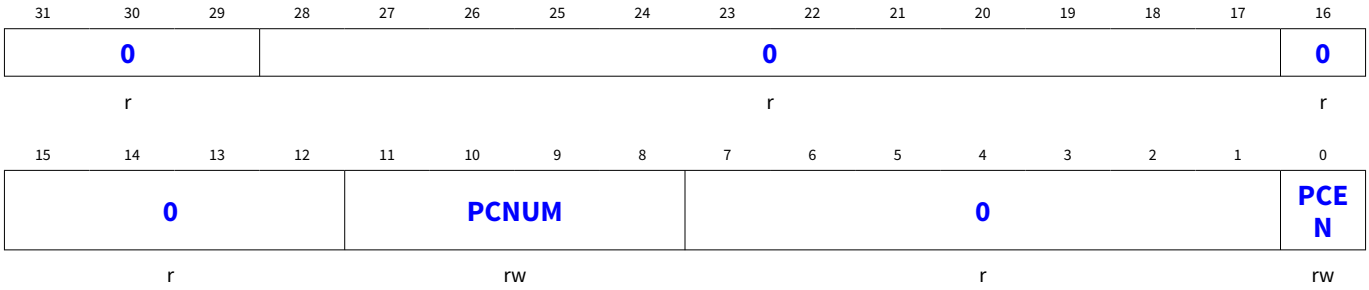
Field	Bits	Type	Description
PCEN	0	rw	**Policing Counter Enable** When set enables the policing counter indicated by the PCNUM field
PCNUM	11:8	rw	**Policing Counter Number** This field specifies the counter number selected for corresponding VLAN filter event.
0	7:1, 15:12, 16, 28:17, 31:29	r	**Reserved** Read as 0; should be written with 0.

14.6.300 Port j MAC VPCSel IndReg2

This register contains policing counter number corresponding to each VLAN filter event.

Portj_MAC_VPCSel_IndReg2 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC VPCSel IndReg2 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PCEN	0	rw	**Policing Counter Enable** When set enables the policing counter indicated by the PCNUM field

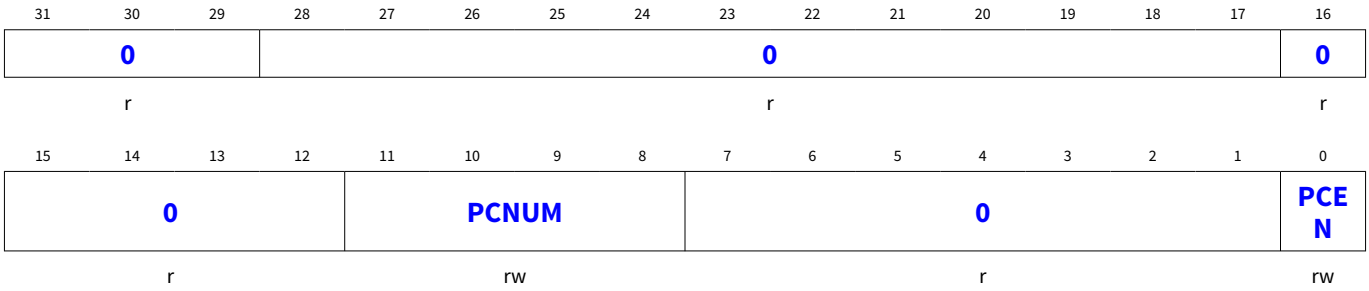
14.6.305 Port j MAC VPCSel IndReg7

This register contains policing counter number corresponding to each VLAN filter event.

Portj_MAC_VPCSel_IndReg7 (j=0-1) Offset address: $10704_H+j*2000_H$

Port j MAC VPCSel IndReg7 Kernel Reset value: $0000\ 0000_H$



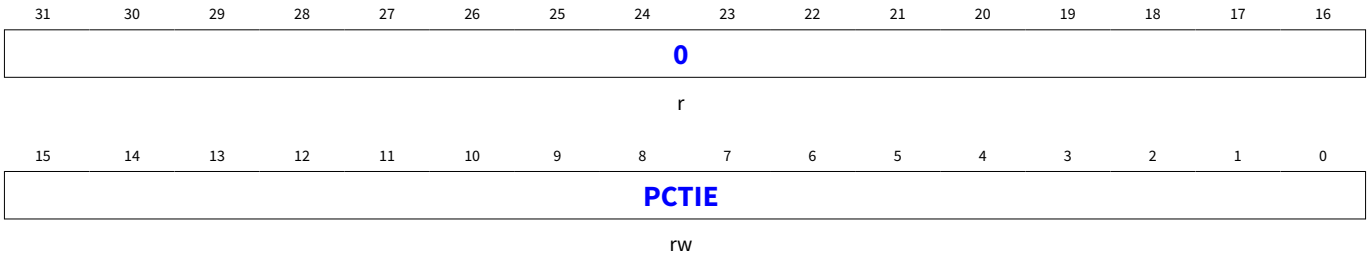
Field	Bits	Type	Description
PCEN	0	rw	**Policing Counter Enable** When set enables the policing counter indicated by the PCNUM field
PCNUM	11:8	rw	**Policing Counter Number** This field specifies the counter number selected for corresponding VLAN filter event.
0	7:1, 15:12, 16, 28:17, 31:29	r	**Reserved** Read as 0; should be written with 0.

14.6.306 Port j MAC PCTH Intr Enable

This register contains threshold based interrupt enable for corresponding policing counters.

Portj_MAC_PCTH_Intr_Enable (j=0-1) Offset address: $10708_H+j*2000_H$

Port j MAC PCTH Intr Enable Kernel Reset value: $0000\ 0000_H$



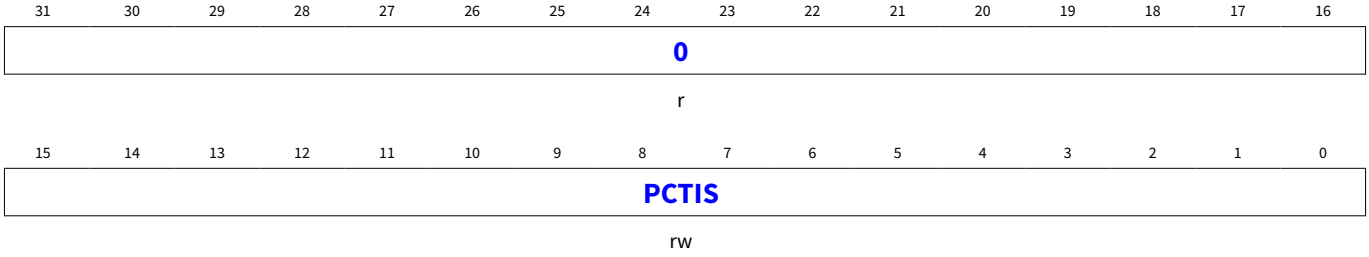
Field	Bits	Type	Description
PCTIE	15:0	rw	**Policing Counter Threshold Interrupt Enable** When set indicates the assertion of the interrupt is enabled for corresponding policing counters.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.307 Port j MAC PCTH Intr Status

This register contains threshold based interrupts for corresponding policing counters.

Portj_MAC_PCTH_Intr_Status (j=0-1) Offset address: $1070C_H+j*2000_H$

Port j MAC PCTH Intr Status Kernel Reset value: $0000\ 0000_H$



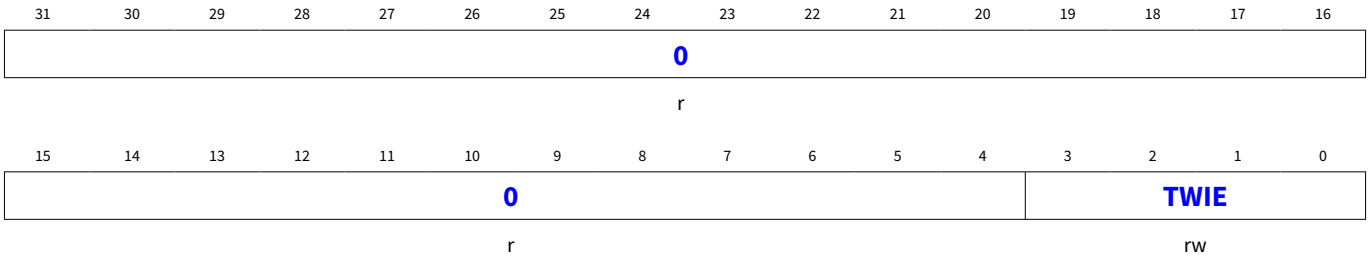
Field	Bits	Type	Description
PCTIS	15:0	rw	**Policing Counter Threshold Interrupt Status** This field is set when corresponding threshold-based interrupt is generated in corresponding policing counter Access restriction applies. This field is cleared when read (or written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set).
0	31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.308 Port j MAC PCTW Intr Enable

This register contains enable bits for Time based interrupt.

Portj_MAC_PCTW_Intr_Enable (j=0-1) Offset address: $10730_H+j*2000_H$

Port j MAC PCTW Intr Enable Kernel Reset value: $0000\ 0000_H$



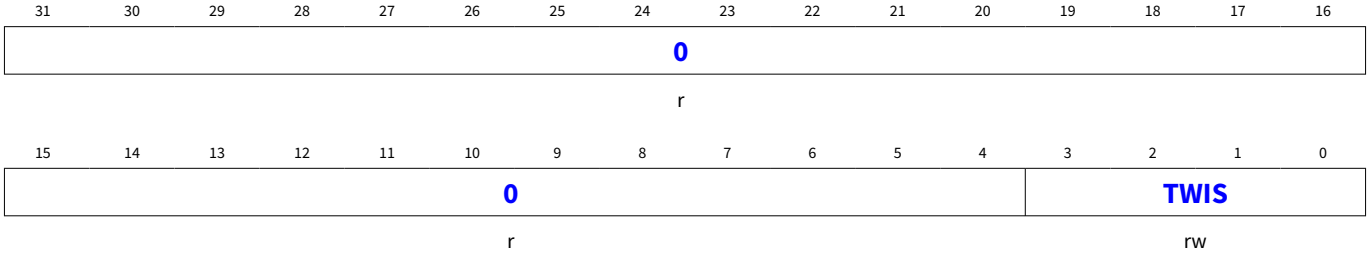
Field	Bits	Type	Description
TWIE	3:0	rw	**Time window Interrupt Enable** When set indicates the assertion of the interrupt is enabled for corresponding Time window.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

14.6.309 Port j MAC PCTW Intr Status

This register contains Time window based interrupt status.

Portj_MAC_PCTW_Intr_Status (j=0-1) Offset address: $10734_H+j*2000_H$

Port j MAC PCTW Intr Status Kernel Reset value: $0000\ 0000_H$



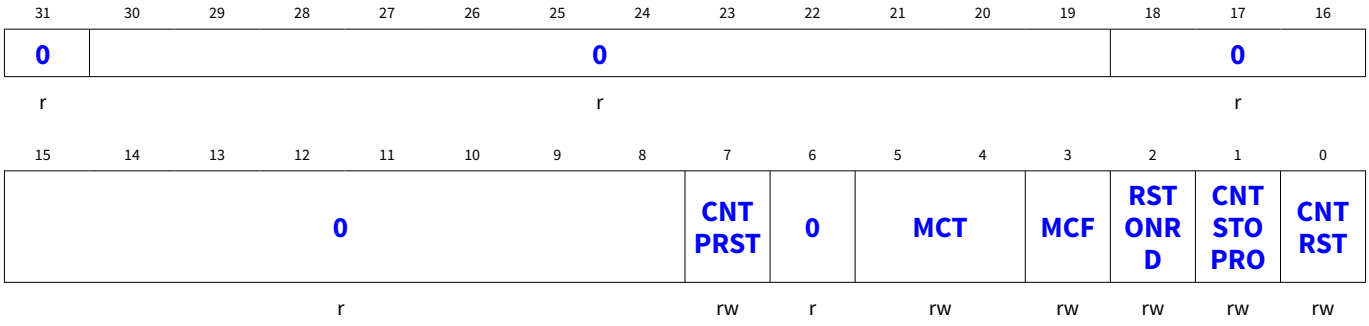
Field	Bits	Type	Description
TWIS	3:0	rw	**Time window Interrupt Status** This field is set when corresponding end of time window is detected. Access restriction applies. This field is cleared when read (or written to 1 when RCWE bit of MAC_CSR_SW_Ctrl register is set).
0	31:4	r	**Reserved** Read as 0; should be written with 0.

14.6.310 Port j MMC Control

The MMC Control register establishes the operating mode of the management counters.

Portj_MMC_Control (j=0-1) Offset address: $10800_H+j*2000_H$

Port j MMC Control Kernel Reset value: $0000\ 0020_H$



Field	Bits	Type	Description
CNTRST	0	rw	**Counters Reset** When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle.

(table continues...)

(continued)

Field	Bits	Type	Description
CNTSTOPRO	1	rw	**Counter Stop Rollover** When this bit is set, no MMC counter rolls over to zero after reaching the maximum count value. The counters are cleared when the least significant byte lane (bits[7:0]) is read after reaching the maximum count value. When the MMC module is enabled for the 64-bit counter mode, the lower and upper counters are cleared only when the least significant byte lane (bits[7:0]) of the upper counter is read after reaching the maximum count value.
RSTONRD	2	rw	**Reset on Read** When this bit is set, the MMC counters are reset to zero after a read. The counters are cleared when the least significant byte lane (bits[7:0]) is read. When the MMC module is enabled for the 64-bit counter mode, the lower and upper counters are cleared only when the least significant byte lane (bits[7:0]) of the corresponding counter is read. Note: When 64-bit counter mode is selected and RSTONRD is set, read the lower counter first followed by the corresponding upper counter. This is to ensure that only the lower 32-bit counter is updated after the first read operation and the software gets the original higher 32-bit counter and gets a consistent value.
MCF	3	rw	**MMC Counter Freeze** When set, this bit freezes the MMC counters to their current value. No MMC counter is updated for subsequent packet transmission or reception until this bit is reset to 0. If any MMC counter is read with the Reset on Read bit set, that counter is also cleared when this bit is set.
MCT	5:4	rw	**MMC Counter Threshold** Threshold value for the counter which, when crossed, causes the interrupt to be scheduled - 2'b00: Reserved - 2'b01: One-quarter the maximum value - X - 2'b10: One-half of the maximum value - X - 2'b11: Three-quarters of the maximum value - X Here, - X = 16 for all the Packet counters and - X = 2048 for all the Octet/Byte counters
CNTPRST	7	rw	**Counters Preset** When this bit is set, all counters are initialized or preset to a value depending on Bits [5:4]. This bit is cleared after 1 clock cycle. This bit, along with Bits [5:4], is useful for debugging and testing the assertion of interrupts because of MMC counter becoming one-quarter-full/half-full/three-quarter-full. If this bit is set along with CNTRST bit, CNTRST bit has precedence.
0	6, 15:8, 18:16, 30:19, 31	r	**Reserved** Read as 0; should be written with 0.

14.6.311 Port j MMC Rx Interrupt

The MMC Receive Interrupt Status register maintains the interrupts generated when receive statistic counters reach the threshold programmed in the MMC control register. When the MMC counter that caused the interrupt is read, the corresponding interrupt status bit is cleared. The least significant byte lane (bits[7:0]) of the counter must be read to clear the interrupt status bit. When the MMC module is enabled for 64-bit counter mode, the least significant byte lane (bits[7:0]) of the upper counter must be read to clear the interrupt status bit.

Portj_MMC_Rx_Interrupt (j=0-1) Offset address: $10804_H+j*2000_H$

Port j MMC Rx Interrupt Kernel Reset value: $0000\ 0000_H$

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Field	Bits	Type	Description
RXGBPKTIS	0	r	**Rx Good Bad Packet Counter Interrupt Status** The bit is set when the 64-bit Rx_Packet_Count_Good_Bad_High and Rx_Packet_Count_Good_Bad_Low counter or 32-bit Rx_Packet_Count_Good_Bad_Low counter reaches the threshold value programmed in the MMC control register.
RXGBOCTIS	1	r	**Rx Good Bad Octet Counter Interrupt Status** The bit is set when the Rx_Octet_Count_Good_Bad_High and Rx_Octet_Count_Good_Bad_Low counter reaches the threshold value programmed in the MMC control register.
RXGOCTIS	2	r	**Rx Good Octet Counter Interrupt Status** The bit is set when the Rx_Octet_Count_Good_High and Rx_Octet_Count_Good_Low counter reaches the threshold value programmed in the MMC control register.
RXBCGPIS	3	r	**Rx Good Broadcast Packet Counter Interrupt Status** The bit is set when the 64-bit Rx_Broadcast_Packets_Good_High and Rx_Broadcast_Packets_Good_Low counter or 32-bit Rx_Broadcast_Packets_Good_Low counter reaches the threshold value programmed in the MMC control register.
RXMCGPIS	4	r	**Rx Good Multicast Packet Counter Interrupt Status** The bit is set when the 64-bit Rx_Multicast_Packets_Good_High and Rx_Multicast_Packets_Good_Low counter or 32-bit Rx_Multicast_Packets_Good_Low counter reaches the threshold value programmed in the MMC control register.

(table continues...)

(continued)

Field	Bits	Type	Description
RXCRCERPIS	5	r	**Rx CRC Error Packet Counter Interrupt Status** The bit is set when the 64-bit Rx_CRC_Error_Packets_High and Rx_CRC_Error_Packets_Low counter or 32-bit Rx_CRC_Error_Packets_Low reaches the threshold value programmed in the MMC control register.
RXRUNTPIS	6	r	**Rx Runt Error Packet Counter Interrupt Status** This bit is set when the Rx_Runt_Error_Packets counter reaches the threshold value programmed in the MMC control register.
RXJABERPIS	7	r	**Rx Jabber Error Packet Counter Interrupt Status** The bit is set when the Rx_Jabber_Error_Packets counter reaches the threshold value programmed in the MMC control register.
RXUSIZEGPIS	8	r	**Rx Good Undersize Packet Counter Interrupt Status** The bit is set when the Rx_Undersize_Packets_Good counter reaches the threshold value programmed in the MMC control register.
RXOSIZEGPIS	9	r	**Rx Good Oversize Packet Counter Interrupt Status** The bit is set when the Rx_Oversize_Packets_Good counter reaches the threshold value programmed in the MMC control register.

14.6.312 Port j MMC Tx Interrupt

The MMC Transmit Interrupt Status register maintains the interrupts generated when the transmit statistic counters reach the threshold value programmed in MMC control register (for example, the counter's MSB is set). This register is 32 bits wide. When the MMC counter that caused the interrupt is read, the corresponding interrupt status bit is cleared. The least significant byte lane (bits[7:0]) of the corresponding counter must be read to clear the interrupt status bit. When the MMC module is enabled for 64-bit counter mode, the least significant byte lane (bits[7:0]) of the upper counter must be read to clear the interrupt status bit.

Portj_MMC_Tx_Interrupt (j=0-1) Offset address: $10808_H+j*2000_H$

Field	Bits	Type	Description
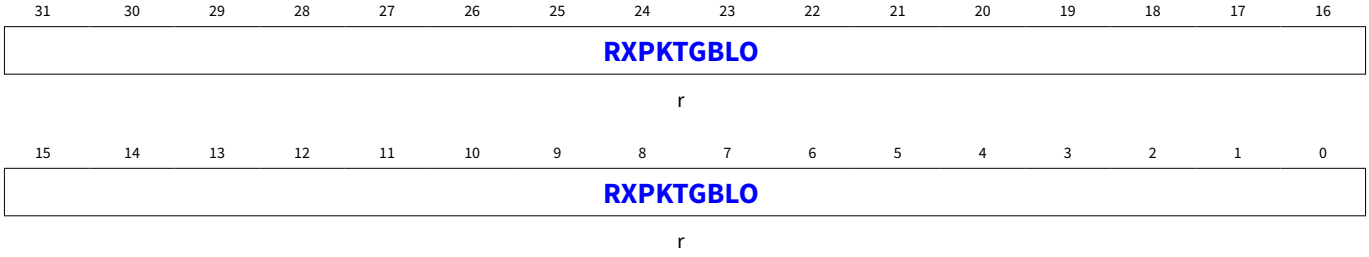
TXLPITRC	31:0	r	**Tx LPI Transition Count** This field indicates the number of times DWC_xgmac entered to Tx LPI state.

14.6.337 Port j Rx Packet Count Good Bad Low

This register provides lower 32 bits of received good and bad packets count.

Portj_Rx_Packet_Count_Good_Bad_Low (j=0-1) Offset address: $10900_H+j*2000_H$

Port j Rx Packet Count Good Bad Low Kernel Reset value: $0000\ 0000_H$



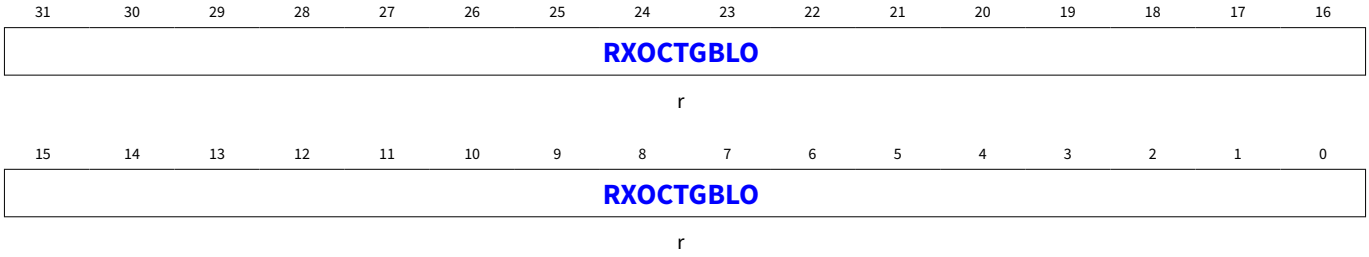
Field	Bits	Type	Description
RXPKTGBLO	31:0	r	**Rx Good Bad Packet Count Low** This field indicates lower 32 bits of the counter that counts the number of good and bad packets received.

14.6.338 Port j Rx Octet Count Good Bad Low

This register provides lower 32 bits of received octet count, excluding preamble, in good and bad packets.

Portj_Rx_Octet_Count_Good_Bad_Low (j=0-1) Offset address: $10908_H+j*2000_H$

Port j Rx Octet Count Good Bad Low Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RXOCTGBLO	31:0	r	**Rx Good Bad Octet Count Low** This field indicates the lower 32 bits of received octet count, where octet count is the number of bytes received, excluding preamble, in good and bad packets.

14.6.339 Port j Rx Octet Count Good Bad High

This register provides upper 32 bits of received octet count, excluding preamble, in good and bad packets.

Portj_Rx_Octet_Count_Good_Bad_High (j=0-1) Offset address: $1090C_H+j*2000_H$

Port j Rx Octet Count Good Bad High Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RXCRCERLO	31:0	r	**Rx CRC Error Packet Count Low** This field indicates lower 32 bits of the counter that counts the number of packets received with a CRC error.

14.6.345 Port j Rx Runt Error Packets

This register provides received packets with Runt error count.

Portj_Rx_Runt_Error_Packets (j=0-1) Offset address: $10930_H+j*2000_H$

Port j Rx Runt Error Packets Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RXRUNTER															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RXRUNTER															
r															

Field	Bits	Type	Description
RXRUNTER	31:0	r	**Rx Runt Error Packet Count** This field indicates number of shorter-than-64-byte packets received with a CRC error.

14.6.346 Port j Rx Jabber Error Packets

This register provides received packets with Jabber error count.

Portj_Rx_Jabber_Error_Packets (j=0-1) Offset address: $10934_H+j*2000_H$

Port j Rx Jabber Error Packets Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RXJABERER															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RXJABERER															
r															

Field	Bits	Type	Description
RXJABERER	31:0	r	**Rx Jabber Error Packet Count** This field indicates number of giant (including CRC) packets received with a CRC error. The giant packet status is generated as per the programming described in MAC_Rx_Configuration.

14.6.347 Port j Rx Undersize Packets Good

This register provides count of received good undersize packets.

Portj_Rx_Undersize_Packets_Good (j=0-1) Offset address: $10938_H+j*2000_H$

Port j Rx Undersize Packets Good Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RXUSIZEG															
r															

Field	Bits	Type	Description
RXUSIZEG	31:0	r	**Rx Good Undersize Packet Count** This field indicates number of shorter-than-64-byte packets received without any errors.

14.6.348 Port j Rx Oversize Packets Good

This register provides count of received good oversize packets.

Portj_Rx_Oversize_Packets_Good (j=0-1) Offset address: $1093C_H+j*2000_H$

Port j Rx Oversize Packets Good Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RXOSIZEG															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RXOSIZEG															
r															

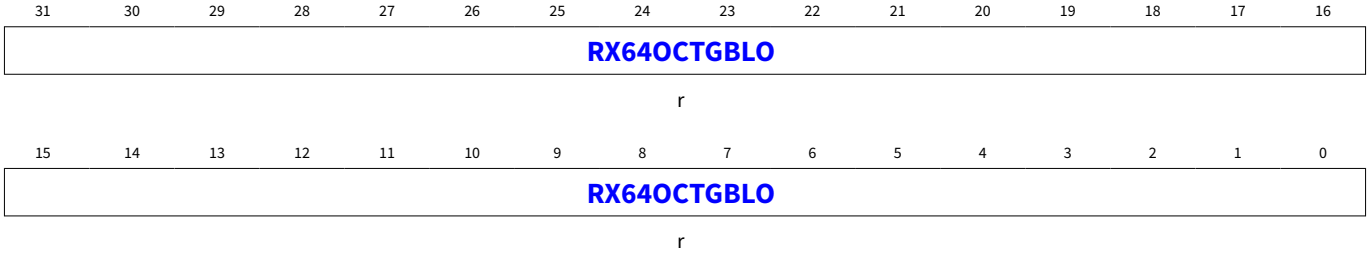
Field	Bits	Type	Description
RXOSIZEG	31:0	r	**Rx Good Oversize Packet Count** This field indicates number of greater than the maxsize packets received without errors. In other words, the number of good giant packets.

14.6.349 Port j Rx 64Octets Packets Good Bad Low

This register provides lower 32 bits of received 64 octet size good and bad packets count.

Portj_Rx_64Octets_Packets_Good_Bad_Low (j=0-1) Offset address: $10940_H+j*2000_H$

Port j Rx 64Octets Packets Good Bad Low Kernel Reset value: $0000\ 0000_H$



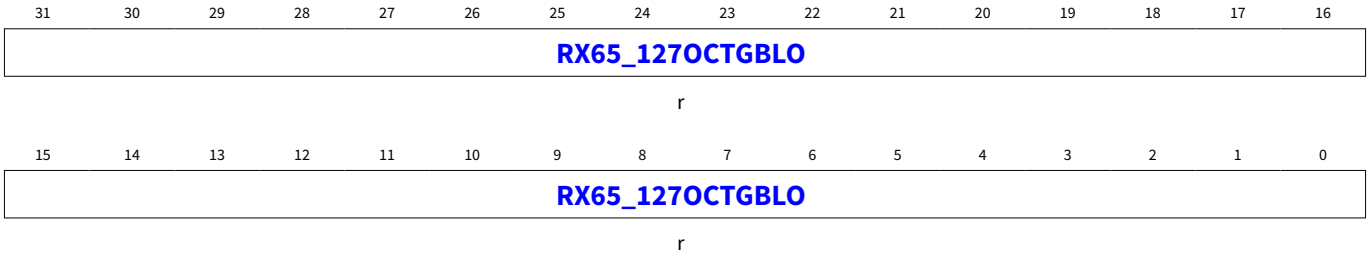
Field	Bits	Type	Description
RX64OCTGBLO	31:0	r	**Rx Good Bad 64 Octet Size Packet Count Low** This field indicates lower 32 bits of the counter that counts the number of good and bad packets received that are of size 64 bytes, excluding preamble.

14.6.350 Port j Rx 65To127Octets Packets Good Bad Low

This register provides lower 32 bits of received 65-to-127 octet size good and bad packets count.

Portj_Rx_65To127Octets_Packets_Good_Bad_Low (j=0-1) Offset address: $10948_H+j*2000_H$

Port j Rx 65To127Octets Packets Good Bad Low Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RX65_127OCTGBLO	31:0	r	**Rx Good Bad 65-to-127 Octet Size Packet Count Low** This field indicates lower 32 bits of the counter that counts the number of 65-to-127-byte good and bad packets received, excluding preamble.

14.6.351 Port j Rx 128To255Octets Packets Good Bad Low

This register provides lower 32 bits of received 128-to-255 octet size good and bad packets count.

Portj_Rx_128To255Octets_Packets_Good_Bad_Low (j=0-1) Offset address: $10950_H+j*2000_H$

Port j Rx 128To255Octets Packets Good Bad Low Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RX256_511OCTGBLO	31:0	r	**Rx Good Bad 256-to-511 Octet Size Packet Count Low** This field indicates lower 32 bits of the counter that counts the number of 256-to-511-byte good and bad packets received, excluding preamble.

14.6.353 Port j Rx 512To1023Octets Packets Good Bad Low

This register provides lower 32 bits of received 512-to-1023 octet size good and bad packets count.

Portj_Rx_512To1023Octets_Packets_Good_Bad_Low (j=0-1) Offset address: $10960_H+j*2000_H$

Port j Rx 512To1023Octets Packets Good Bad Low Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RX512_1023OCTGBLO	31:0	r	**Rx Good Bad 512-to-1023 Octet Size Packet Count Low** This field indicates lower 32 bits of the counter that counts the number of 512-to-1023-byte good and bad packets received, excluding preamble.

14.6.354 Port j Rx 1024ToMaxOctets Packets Good Bad Low

This register provides lower 32 bits of received 1024-tomaxsize octet size good and bad packets count.

Portj_Rx_1024ToMaxOctets_Packets_Good_Bad_Low (j=0-1) Offset address: $10968_H+j*2000_H$

Port j Rx 1024ToMaxOctets Packets Good Bad Low Kernel Reset value: $0000\ 0000_H$

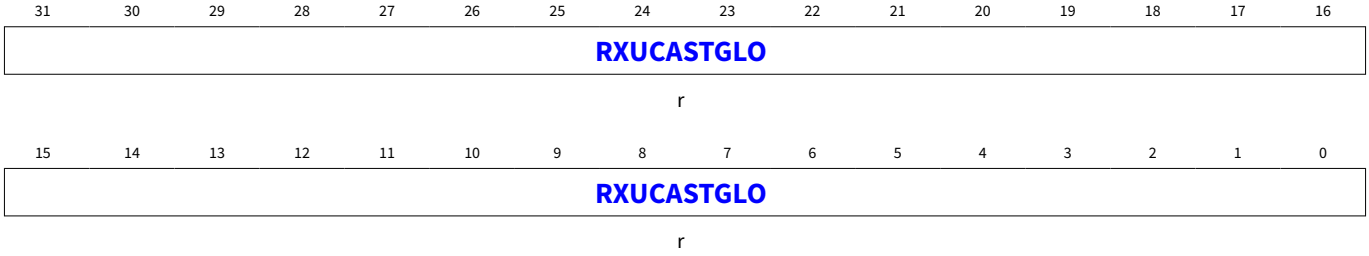
Field	Bits	Type	Description
RX1024_MAXOCTGBLO	31:0	r	**Rx Good Bad 1024-tomaxsize Octet Size Packet Count Low** This field indicates lower 32 bits of the counter that counts the number of 1024-tomaxsize-byte (inclusive) good and bad packets received, excluding preamble.

14.6.355 Port j Rx Unicast Packets Good Low

This register provides lower 32 bits of received good unicast packets count.

Portj_Rx_Unicast_Packets_Good_Low (j=0-1) Offset address: $10970_H+j*2000_H$

Port j Rx Unicast Packets Good Low Kernel Reset value: $0000\ 0000_H$



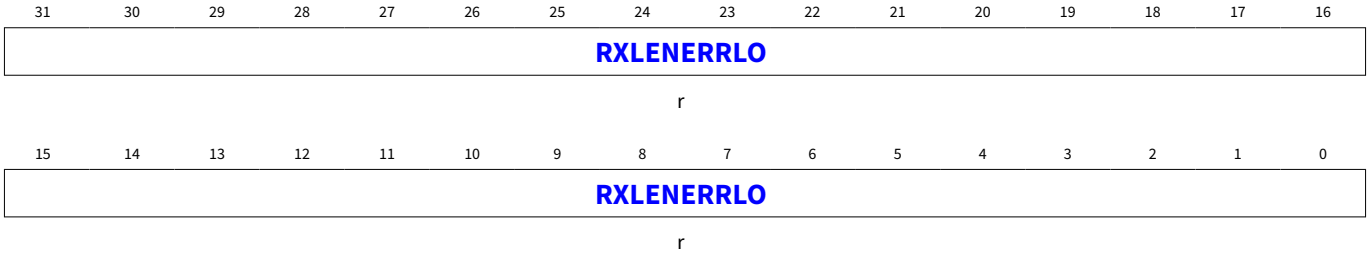
Field	Bits	Type	Description
RXUCASTGLO	31:0	r	**Rx Good Unicast Packet Count Low** This field indicates lower 32 bits of the counter that counts the number of good unicast packets received.

14.6.356 Port j Rx Length Error Packets Low

This register provides lower 32 bits of received packets with Length error count.

Portj_Rx_Length_Error_Packets_Low (j=0-1) Offset address: $10978_H+j*2000_H$

Port j Rx Length Error Packets Low Kernel Reset value: $0000\ 0000_H$



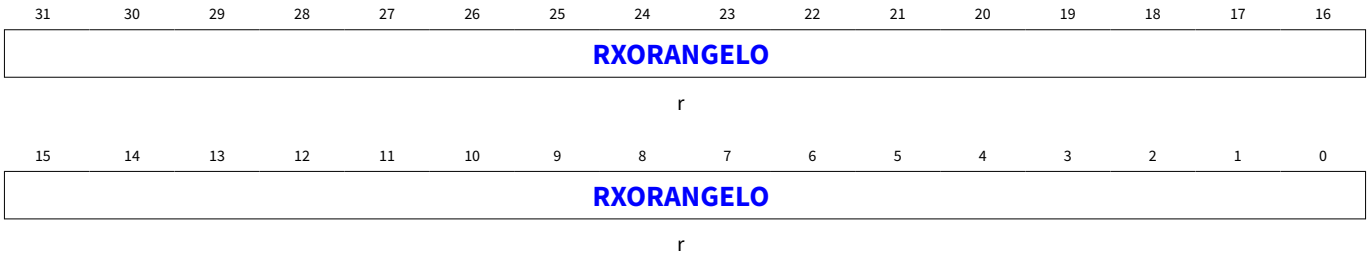
Field	Bits	Type	Description
RXLENERRLO	31:0	r	**Rx Length Error Packet Count Low** This field indicates lower 32 bits of the counter that counts the number of packets received with a Length error (Length field not equal to packet size), for all packets with valid Length field.

14.6.357 Port j Rx OutofRange Packets Low

This register provides lower 32 bits of received packets with out of range length field count.

Portj_Rx_OutofRange_Packets_Low (j=0-1) Offset address: $10980_H+j*2000_H$

Port j Rx OutofRange Packets Low Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RXORANGELO	31:0	r	**Rx Out of Range Packet Count Low** This field indicates lower 32 bits of the counter that counts the number of packets received with Length field not equal to the valid packet size (greater than 1500).

14.6.358 Port j Rx Pause Packets Low

This register provides lower 32 bits of received Pause packets count.

Portj_Rx_Pause_Packets_Low (j=0-1) Offset address: $10988_H+j*2000_H$

Port j Rx Pause Packets Low Kernel Reset value: $0000\ 0000_H$

r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RXDPCNTGBLO															
r															

Field	Bits	Type	Description
RXDPCNTGBLO	31:0	r	**Rx Good Bad Discard Packet Count Low** This field indicates the number of packets received and discarded due to Filter Fail. This represents the lower 32 bits of the counter. When a packet is dropped due to filtering and not counted in the normal RMON counters, this counter is incremented. This counter is incremented irrespective of whether it is a good or bad packet.

14.6.365 Port j Rx Discard Octets Good Bad Low

This register provides lower 32 bits of received good bad octets count that were discarded due to filter fail.

Portj_Rx_Discard_Octets_Good_Bad_Low (j=0-1) Offset address: $109B4_H+j*2000_H$

Port j Rx Discard Octets Good Bad Low Kernel Reset value: $0000\ 0000_H$

14.6.370 Port j MMC FPE Tx Interrupt

This register maintains the interrupts generated from all FPE related Transmit statistics counters. The MMC FPE Transmit Interrupt register maintains the interrupts generated when the transmit statistic counters reach the threshold value programmed in MMC control register (for example, the counter's MSB is set). This register is 32 bits wide. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits[7:0]) of the corresponding counter must be read to clear the interrupt status bit.

Portj_MMC_FPE_Tx_Interrupt (j=0-1) Offset address: $10A00_H+j*2000_H$

Port j MMC FPE Tx Interrupt Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
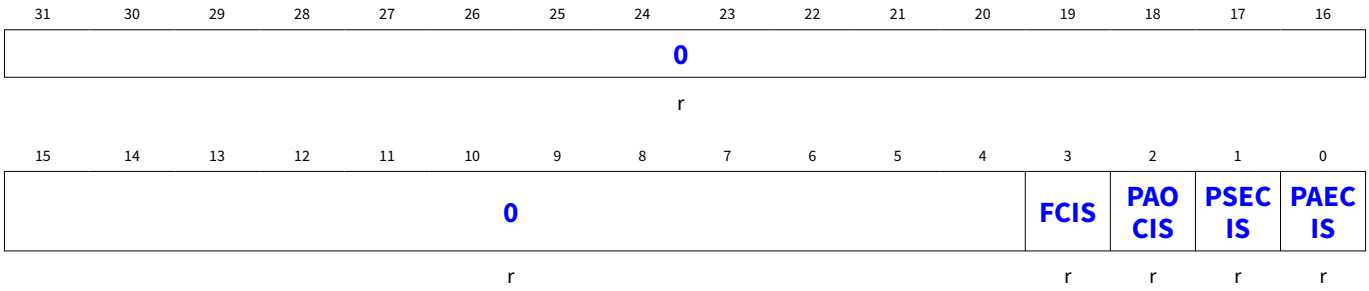
TXGOCH	31:0	r	**Tx Gate/Window Overrun Counter High** This field indicates the upper 32-bits of counter that counts the number of of times packets overrun the transmission gate/window. In FPE mode, the counter is updated based on pre-empt packet overrunning in Hold window. In EST mode, the counter is updated based on any packet of the queue overrunning after gate closed for the Tx Queue. When both enabled together, the counter is updated based on both the conditions.

14.6.376 Port j MMC FPE Rx Interrupt

This register maintains the interrupts generated from all FPE related Receive statistics counters. The MMC FPE Receive Interrupt register maintains the interrupts generated when receive statistic counters reach the threshold value programmed in MMC control register (for example, the counter's MSB is set). The MMC FPE Receive Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

Portj_MMC_FPE_Rx_Interrupt (j=0-1) Offset address: $10A20_H+j*2000_H$

Port j MMC FPE Rx Interrupt Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PAECIS	0	r	**MMC Rx Packet Assembly Error Counter Interrupt Status** This bit is set when the Rx_Packet_Assemble_Err_Cntr counter reaches the threshold value programmed in MMC control register. Access restriction applies. Clears on read. Self-set to 1 on internal event. Exists when any one of the Rx/Tx MMC counters are enabled during FPE Enabled configuration. 0_B **INACTIVE**: MMC Rx Packet Assembly Error Counter Interrupt Status not detected 1_B **ACTIVE**: MMC Rx Packet Assembly Error Counter Interrupt Status detected
PSECIS	1	r	**MMC Rx Packet SMD Error Counter Interrupt Status** This bit is set when the Rx_Packet_SMD_Err_Cntr counter reaches the threshold value programmed in MMC control register. Access restriction applies. Clears on read. Self-set to 1 on internal event. Exists when any one of the Rx/Tx MMC counters are enabled during FPE Enabled configuration. 0_B **INACTIVE**: MMC Rx Packet SMD Error Counter Interrupt Status not detected 1_B **ACTIVE**: MMC Rx Packet SMD Error Counter Interrupt Status detected
PAOCIS	2	r	**MMC Rx Packet Assembly OK Counter Interrupt Status** This bit is set when the Rx_Packet_Assemble_Ok_Cntr counter reach the threshold value programmed in MMC control register. Access restriction applies. Clears on read. Self-set to 1 on internal event. Exists when any one of the Rx/Tx MMC counters are enabled during FPE Enabled configuration. 0_B **INACTIVE**: MMC Rx Packet Assembly OK Counter Interrupt Status not detected 1_B **ACTIVE**: MMC Rx Packet Assembly OK Counter Interrupt Status detected

Field	Bits	Type	Description
TXEXSDEF	31:0	r	**Tx Excessive Deferral Error** This field indicates the number of packets aborted because of excessive deferral error (deferred for more than two max-sized packet times).

14.6.389 Port j MMC IPC Rx Interrupt Mask

This register maintains the mask for the interrupt generated from the receive IPC statistic counters. The MMC Receive Checksum Off load Interrupt Mask register maintains the masks for the interrupts generated when the receive IPC (Checksum Off load) statistic counters reach half their maximum value, and when they reach their maximum values. This register is 32 bits wide.

Portj_MMC_IPC_Rx_Interrupt_Mask (j=0-1) Offset address: $10A5C_H+j*2000_H$

Port j MMC IPC Rx Interrupt Mask Kernel Reset value: $0000\ 0000_H$

14.6.390 Port j MMC IPC Rx Interrupt

This register maintains the interrupt that the receive IPC statistic counters generate. The MMC Receive Checksum Offload Interrupt register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000_0000_0000 for 64 bit counter and 0x8000_0000 for 32 bit counter), and when they cross their maximum values (0xFFFF_FFFF_FFFF_FFFF for 64 bit counter and 0xFFFF_FFFF for 32 bit counter). When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.

The MMC Receive Checksum Offload Interrupt register is 32 bit wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (Bits[7:0]) must be read to clear the interrupt bit.

Portj_MMC_IPC_Rx_Interrupt (j=0-1) Offset address: $10A60_H+j*2000_H$

Field	Bits	Type	Description
RXIPV4NOPAYPKTLO	31:0	r	**RxIPv4 Payload Packets** This field indicates lower 32 bits of IPv4 datagram packets received that did not have a TCP, UDP, or ICMP payload.

14.6.394 Port j RxIPv4 Fragmented Packets Low

This register provides lower 32 bits of good IPv4 datagrams received by DWC_xgmac with fragmentation.

Portj_RxIPv4_Fragmented_Packets_Low (j=0-1) Offset address: $10A7C_H+j*2000_H$

Port j RxIPv4 Fragmented Packets Low Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RXIPV4FRAGPKTLO	31:0	r	**RxIPv4 Fragmented Packets** This field indicates lower 32 bits of good IPv4 datagrams received with fragmentation.

14.6.395 Port j RxIPv4 UDP Checksum Disabled Packets Low

This register provides lower 32 bits of good IPv4 datagrams received by DWC_xgmac that had a UDP payload with checksum disabled.

Portj_RxIPv4_UDP_Checksum_Disabled_Packets_Low (j=0-1) Offset address: $10A84_H+j*2000_H$

Port j RxIPv4 UDP Checksum Disabled Packets Low Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
RXIPV4UDSBLPKTLO	31:0	r	**RxIPv4 UDP Checksum Disabled Packets** This field indicates lower 32 bits of good IPv4 datagrams received that had a UDP payload with checksum disabled.

14.6.396 Port j RxIPv6 Good Packets Low

This register provides lower 32 bits of good IPv6 datagrams received by DWC_xgmac with the TCP, UDP, or ICMP payload.

Portj_RxIPv6_Good_Packets_Low (j=0-1) Offset address: $10A8C_H+j*2000_H$

Port j RxIPv6 Good Packets Low Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
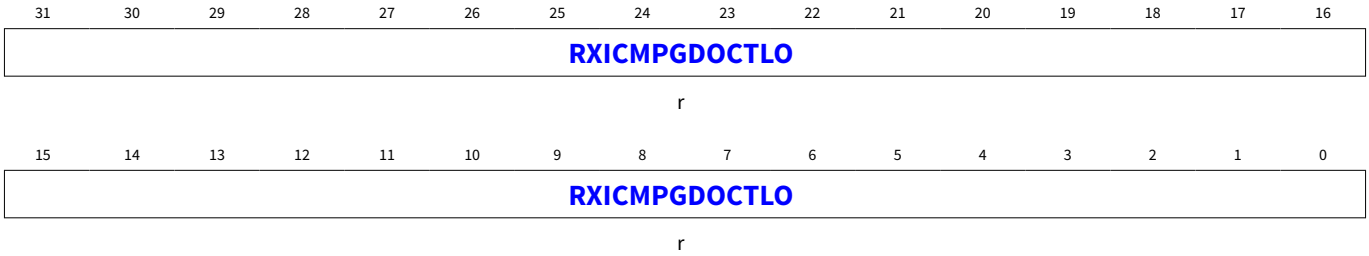
RXTCPERROCTLO	31:0	r	**RxTCP Error Octets** This field indicates lower 32 bits of bytes received in a TCP segment that had checksum errors. This counter does not count IP header bytes.

14.6.417 Port j RxICMP Good Octets Low

This register provides lower 32 bits of bytes received by DWC_xgmac in a good ICMP segment. This counter does not count IP header bytes.

Portj_RxICMP_Good_Octets_Low (j=0-1) Offset address: $10B34_H+j*2000_H$

Port j RxICMP Good Octets Low Kernel Reset value: $0000\ 0000_H$



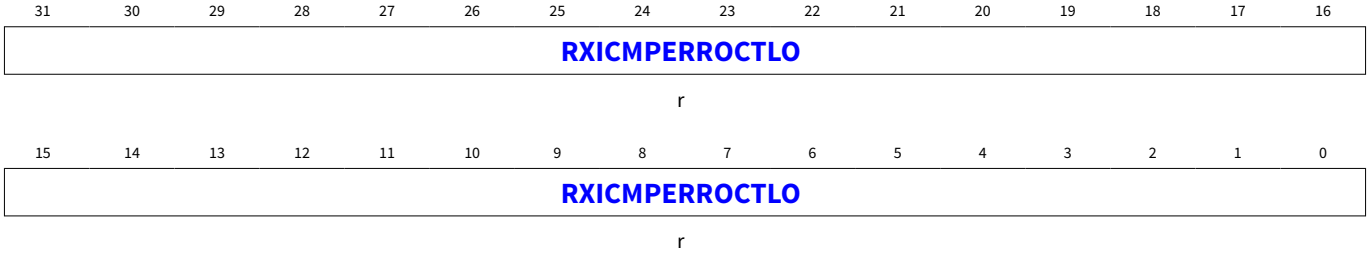
Field	Bits	Type	Description
RXICMPGDOCTLO	31:0	r	**RxICMP Good Octets** This field indicates lower 32 bits of bytes received in a good ICMP segment. This counter does not count IP header bytes.

14.6.418 Port j RxICMP Error Octets Low

This register provides lower 32 bits of bytes received by DWC_xgmac in a ICMP segment that had checksum errors. This counter does not count IP header bytes.

Portj_RxICMP_Error_Octets_Low (j=0-1) Offset address: $10B3C_H+j*2000_H$

Port j RxICMP Error Octets Low Kernel Reset value: $0000\ 0000_H$



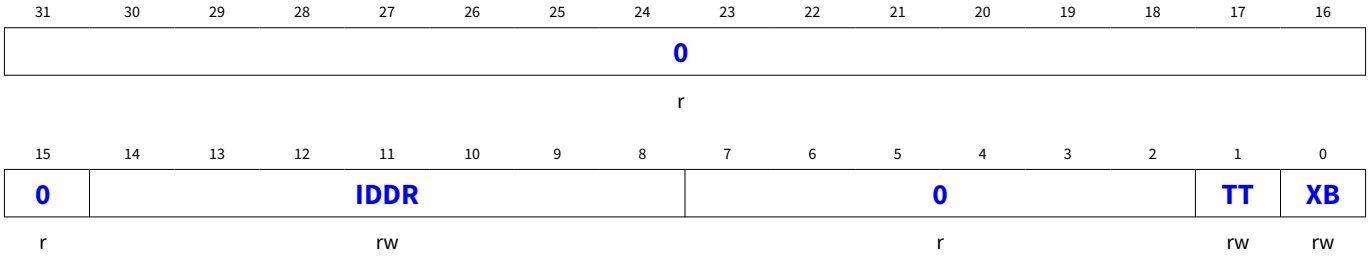
Field	Bits	Type	Description
RXICMPERROCTLO	31:0	r	**RxICMP Error Octets** This field indicates lower 32 bits of bytes received in a ICMP segment that had checksum errors. This counter does not count IP header bytes.

14.6.419 Port j MAC L3 L4 Address Control

This register has the indirect address and control for accessing the Layer 3 and Layer 4 Filter registers.

Portj_MAC_L3_L4_Address_Control (j=0-1) Offset address: $10C00_H+j*2000_H$

Port j MAC L3 L4 Address Control Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
XB	0	rw	**Transfer Busy** When set, initiates a read or write transaction (as indicated by TT) is initiated to the L3_L4 Filter register. When reset, indicates that read or write transaction to L3-L4 Filter register is complete. You must read and confirm that this bit is 0 (previous transfer is completed) before setting this bit again.
TT	1	rw	**Transfer Type** When set, a read transfer from the L3_L4 Filter register addressed by IDDR is executed. The data read from the register is available in the MAC_L3_L4_Data register. When reset, a write transfer to the L3_L4 Filter register addressed by IDDR is executed. The data is transferred from the MAC_L3_L4_Data register and written to the respective L3_L4 Filter register. You must write the MAC_L3_L4_Data register before initiating the write transaction.

Field	Bits	Type	Description
IDDR	14:8	rw	**L3_L4 Filter Address** This field contains the indirect address to the L3_L4 Filter registers. The IDDR[3:0] indicates the type of L3_L4 Filter register while bits[8:4] indicate the Filter number (0 to 7). IDDR[3:0] Values: - 0: MAC_L3_L4_Control - 1: MAC_Layer4_Address - 2-3: Reserved - 4: MAC_Layer3_Addr0_Reg - 5: MAC_Layer3_Addr1_Reg - 6: MAC_Layer3_Addr2_Reg - 7: MAC_Layer3_Addr3_Reg - 8 to 15: Reserved
0	7:2, 31:15	r	**Reserved** Read as 0; should be written with 0.

14.6.420 Port j MAC L3 L4 Data

This register has the indirect data and control for accessing the Layer 3 and Layer 4 Filter registers.

Portj_MAC_L3_L4_Data (j=0-1) Offset address: $10C04_H+j*2000_H$

Port j MAC L3 L4 Data Kernel Reset value: $0000\ 0000_H$

L3HDBM0					L3HSBM0					L3DAIM0	L3DAM0	L3SAIM0	L3SAM0	0	L3PEN0
rw					rw					rw	rw	rw	rw	r	rw

Field	Bits	Type	Description
L3PEN0	0	rw	**Layer 3 Protocol Enable** When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set.
L3SAM0	2	rw	**Layer 3 IP SA Match Enable** When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When the L3PEN0 bit is set, you must set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering.
L3SAIM0	3	rw	**Layer 3 IP SA Inverse Match Enable** When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when the L3SAM0 bit is set.
L3DAM0	4	rw	**Layer 3 IP DA Match Enable** When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When the L3PEN0 bit is set, you must set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering.
L3DAIM0	5	rw	**Layer 3 IP DA Inverse Match Enable** When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when the L3DAM0 bit is set high.

Field	Bits	Type	Description
L3HSBM0	10:6	rw	**Layer 3 IP SA Higher Bits Match** IPv4 Packets: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked. - 1: Lsb[0] is masked - 2: Two Lsbs [1:0] are masked - ... - 31: All bits except Msb are masked. IPv6 Packets: This field contains Bits[4:0] of L3HSBM0. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high.
L3HDBM0	15:11	rw	**Layer 3 IP DA Higher Bits Match** IPv4 Packets: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. The following list describes the values of this field: - 0: No bits are masked. - 1: LSB[0] is masked - 2: Two Lsbs [1:0] are masked - ... - 31: All bits except Msb are masked. IPv6 Packets: Bits[12:11] of this field correspond to Bits[6:5] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits: - 0: No bits are masked. - 1: LSB[0] is masked. - 2: Two Lsbs [1:0] are masked - ... - 127: All bits except Msb are masked. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.
L4PEN0	16	rw	**Layer 4 Protocol Enable** When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching. The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set.

(table continues...)

(continued)

Field	Bits	Type	Description
L4SPM0	18	rw	**Layer 4 Source Port Match Enable** When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching.
L4SPIM0	19	rw	**Layer 4 Source Port Inverse Match Enable** When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4SPM0 bit is set high.
L4DPM0	20	rw	**Layer 4 Destination Port Match Enable** When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching.
L4DPIM0	21	rw	**Layer 4 Destination Port Inverse Match Enable** When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when the L4DPM0 bit is set high.
DMCHN	26:24	rw	**DMA Channel Number** When DMCHEN is set high, this field selects the DMA Channel number to which the packet passed by this filter is routed. The width of this field depends on the number of the DMA channels present in your configuration.
DMCHEN	31	rw	**DMA Channel Select Enable** When set, this bit enables the selection of the DMA channel number for the packet that is passed by this L3_L4 filter. The DMA channel is indicated by the DMCHN bits. When the bit is reset, the DMA channel is not decided by the filter.
0	1, 17, 22, 23, 29:27, 30	r	**Reserved** Read as 0; should be written with 0.

14.6.422 Port j MAC L3 L4 Control1

The Layer 3 and Layer 4 Control register controls the operations of filter 0 of Layer 3 and Layer 4.

rw					rw					rw	rw	rw	rw	r	rw

Field	Bits	Type	Description
L3PEN4	0	rw	**Layer 3 Protocol Enable** When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets. The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set.
L3SAM4	2	rw	**Layer 3 IP SA Match Enable** When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When the L3PEN0 bit is set, you must set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering.
L3SAIM4	3	rw	**Layer 3 IP SA Inverse Match Enable** When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when the L3SAM0 bit is set.
L3DAM4	4	rw	**Layer 3 IP DA Match Enable** When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When the L3PEN0 bit is set, you must set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering.
L3DAIM4	5	rw	**Layer 3 IP DA Inverse Match Enable** When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when the L3DAM0 bit is set high.

L4SP7	15:0	rw	**Layer 4 Source Port Number Field** When the L4PEN0 bit is reset and the L4DPM0 bit is set in the MAC_L3_L4_Control7 register, this field contains the value to be matched with the TCP Source Port Number field in the IPv4 or IPv6 packets. When the L4PEN0 and L4DPM0 bits are set in MAC_L3_L4_Control7 register, this field contains the value to be matched with the UDP Source Port Number field in the IPv4 or IPv6 packets.
L4DP7	31:16	rw	**Layer 4 Destination Port Number Field** When the L4PEN0 bit is reset and the L4DPM0 bit is set in the MAC_L3_L4_Control7 register, this field contains the value to be matched with the TCP Destination Port Number field in the IPv4 or IPv6 packets. When the L4PEN0 and L4DPM0 bits are set in MAC_L3_L4_Control7 register, this field contains the value to be matched with the UDP Destination Port Number field in the IPv4 or IPv6 packets.

14.6.469 Port j MAC Timestamp Control

This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.

Portj_MAC_Timestamp_Control (j=0-1) Offset address: $10D00_H+j*2000_H$

Port j MAC Timestamp Control Kernel Reset value: $0000\ 2000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	r	rw	rw	r	rw	rw	rw	rw

Field	Bits	Type	Description
TSENA	0	rw	**Enable Timestamp** When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the Receive side, the MAC processes the 1588 packets only if this bit is set.
TSCFUPDT	1	rw	**Fine or Coarse Timestamp Update** When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp.
TSINIT	2	rw	**Initialize Timestamp** When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers. This bit must be zero before it is updated. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled during controller configuration) can only be initialized. When Media Clock Generation and Recovery is configured (DWCXG_FLEXI_PPS_OUT_EN) and enabled MAC_Presn_Time_Updt should also be updated before setting this field. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

(table continues...)

(continued)

Field	Bits	Type	Description
TSUPDT	3	rw	**Update Timestamp** When this bit is set, the system time is updated (added or subtracted) with the value specified in MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update. This bit must be zero before updating it. This bit is reset when the update is complete in hardware. The Timestamp Higher Word register (if enabled during controller configuration) is not updated. When Media Clock Generation and Recovery is configured (DWCXG_FLEXI_PPS_OUT_EN) and enabled MAC_Presn_Time_Updt should also be updated before setting this field. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
TSADDREG	5	rw	**Update Addend Register** When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit must be zero before it is set.
PTGE	6	rw	**Presentation Time Generation Enable** When this bit is set the Presentation Time generation is enabled.
TSENALL	8	rw	**Enable Timestamp for All Packets** When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC.
TSCTRLSSR	9	rw	**Timestamp Digital or Binary Rollover Control** When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit.
TSVER2ENA	10	rw	**Enable PTP Packet Processing for Version 2 Format** When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in "PTP Processing and Control" section.
TSIPENA	11	rw	**Enable Processing of PTP over Ethernet Packets** When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets.
TSIPV6ENA	12	rw	**Enable Processing of PTP Packets Sent over IPv6-UDP** When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets.
TSIPV4ENA	13	rw	**Enable Processing of PTP Packets Sent over IPv4-UDP** When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default.

(table continues...)

(continued)

Field	Bits	Type	Description
TSEVNTENA	14	rw	**Enable Timestamp Snapshot for Event Messages** When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling.
TSMSTRENA	15	rw	**Enable Snapshot for Messages Relevant to Master** When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.
SNAPTYPSEL	17:16	rw	**Select PTP packets for Taking Snapshots** These bits, along with Bits 15 and 14, decide the set of PTP packet types for which snapshot needs to be taken.
TSENMACADDR	18	rw	**Enable MAC Address for PTP Packet Filtering** When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet. Note: When this bit is set, the PTP Offload function qualifies received PTP packet with unicast DA matching MAC Address 0 register (in addition to received PTP packet with unicast DA matching PTP special multicast addresses) for PTP response generation.
CSC	19	rw	**Enable checksum correction during OST for PTP over UDP/IPv4 packets** When this bit is set, the last two bytes of PTP message sent over UDP/IPv4 is updated to keep the UDP checksum correct, for changes made to origin timestamp and/or correction field as part of one step timestamp operation. The application must form the packet with these two dummy bytes. When reset, no updates are done to keep the UDP checksum correct. The application must form the packet with UDP checksum set to 0.
ESTI	20	rw	**External System Time Input** When this bit is set, the MAC uses the external 64-bit reference System Time input for the following: - To take the timestamp provided as status - To insert the timestamp in transmit PTP packets When this bit is reset, the MAC uses the internal reference System Time.
TXTSSTSM	24	rw	**Transmit Timestamp Status Mode** - When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSTSMIS bit of the MAC_TxTimestamp_Status_Nanoseconds register. - When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSTSHI bit of the MAC_TxTimestamp_Status_Seconds register.

(table continues...)

(continued)

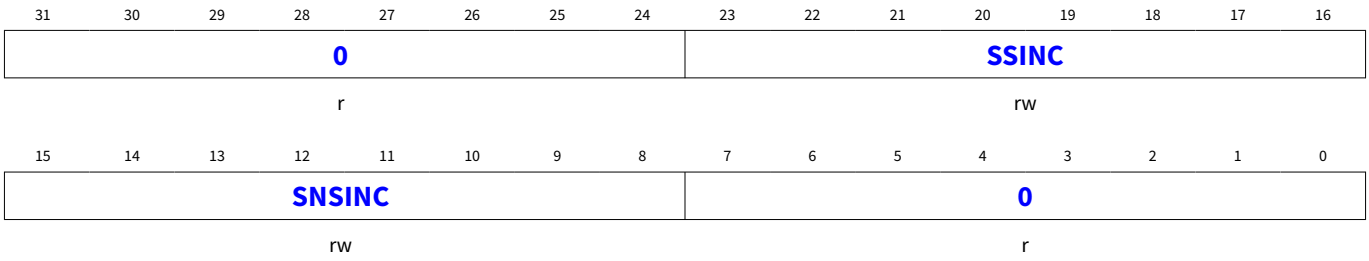
Field	Bits	Type	Description
AV8021ASMEN	28	rw	**AV IEEE 802.1AS Mode Enable** When this bit is set, the MAC processes only untagged PTP over Ethernet packets for providing PTP status and capturing timestamp snapshots, that is, IEEE 802.1AS mode of operation.
0	4, 7, 23:21, 25, 27:26, 29, 31:30	r	**Reserved** Read as 0; should be written with 0.

14.6.470 Port j MAC Sub Second Increment

In Coarse Update mode [Bit 1 in MAC_Timestamp_Control register], the value in this register is added to the system time every clock cycle of clk_ptp_ref_i. In Fine Update mode, the value in this register is added to the system time when the Accumulator gets an overflow.

Portj_MAC_Sub_Second_Increment (j=0-1) Offset address: $10D04_H+j*2000_H$

Port j MAC Sub Second Increment Kernel Reset value: $0000\ 0000_H$



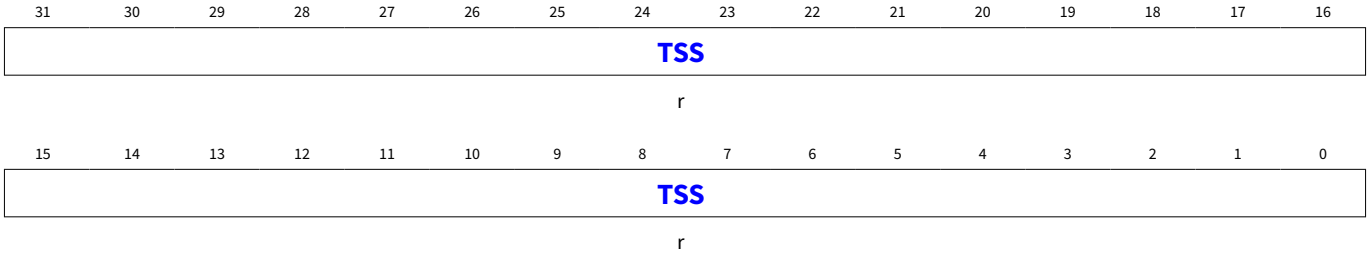
Field	Bits	Type	Description
SNSINC	15:8	rw	**Sub-nanosecond Increment Value** This field contains the sub-nanosecond increment value, represented in nanoseconds multiplied by 28. This value is accumulated with the sub-nanoseconds field of the sub-second register. For example, when TSCTRLSSR field in the MAC_Timestamp_Control register is set. and if the required increment is 5.3ns, then SSINC must be 0x05 and SNSINC must be 0x4C.
SSINC	23:16	rw	**Sub-second Increment Value** The value programmed in this field is accumulated with the contents of the sub-second register. For example, when the PTP clock is 50 MHz (period is 20 ns), you must program 20 (0x14) when the System Time-Nanoseconds register has an accuracy of 1 ns [Bit 9 (TSCTRLSSR) is set in MAC_Timestamp_Control]. When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you must program a value of 43 (0x2B) which is derived by 20 ns/0.465.
0	7:0, 31:24	r	**Reserved** Read as 0; should be written with 0.

14.6.471 Port j MAC System Time Seconds

The System Time-Seconds register, along with System Time-Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

Portj_MAC_System_Time_Seconds (j=0-1) Offset address: $10D08_H+j*2000_H$

Port j MAC System Time Seconds Kernel Reset value: $0000\ 0000_H$



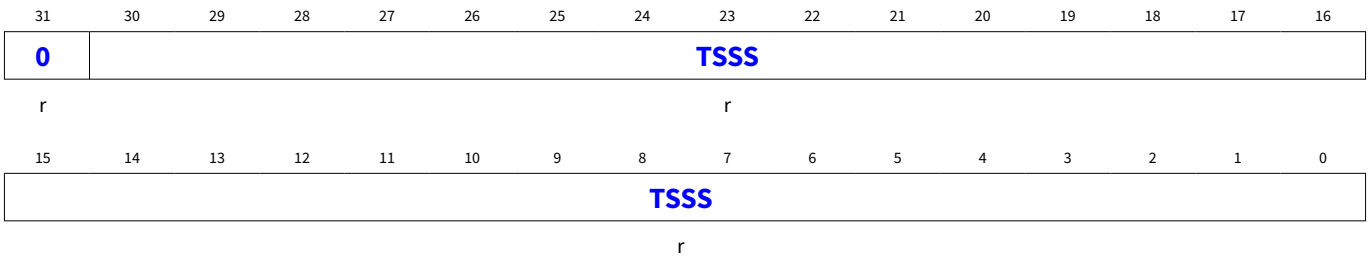
Field	Bits	Type	Description
TSS	31:0	r	**Timestamp Second** The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

14.6.472 Port j MAC System Time Nanoseconds

The System Time-Nanoseconds register, along with System Time-Seconds register, indicates the current value of the system time maintained by the MAC.

Portj_MAC_System_Time_Nanoseconds (j=0-1) Offset address: $10D0C_H+j*2000_H$

Port j MAC System Time Nanoseconds Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TSSS	30:0	r	**Timestamp Sub Seconds** The value in this field has the sub-second representation of time, with an accuracy of 0.46 ns. When Bit 9 is set in MAC_Timestamp_Control, each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls-over to zero.
0	31	r	**Reserved** Read as 0; should be written with 0.

14.6.473 Port j MAC System Time Seconds Update

The System Time-Seconds Update register, along with the System Time-Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both registers before setting the TSINIT or TSUPDT bits in MAC_Timestamp_Control register.

Portj_MAC_System_Time_Seconds_Update (j=0-1) Offset address: $10D10_H+j*2000_H$

Port j MAC System Time Seconds Update Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
TSSS	30:0	rw	**Timestamp Sub Seconds** The value in this field is the sub-second part of the update. - When ADDSUB is reset, this field must be programmed with the sub-second part of the update value, with an accuracy based on the TSCTRLSSR bit of the MAC Timestamp Control register. - When ADDSUB is set, this field must be programmed with the complement of the sub-second part of the update value, as follows. - When TSCTRLSSR is set, the programmed value must be 10^9 - (sub-second value). When TSCTRLSSR is reset, the programmed value must be 2^31 - (sub-second_value). For example, when TSCTRLSSR bit is set and if 2.000000001 second needs to be subtracted with the system time, the TSS field in the MAC Timestamp Seconds update register must be 0xFFFF_FFFE (for instance, 2^32 - 2), ADDSUB bit in this register must be set, and the TSSS field must be 0x3B9A_C9FF (for instance, 10^9 - 1).
ADDSUB	31	rw	**Add or Subtract Time** When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register.

14.6.475 Port j MAC Timestamp Addend

This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the MAC_Timestamp_Control register). The content of this register is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated when the accumulator overflows.

Portj_MAC_Timestamp_Addend (j=0-1) Offset address: $10D18_H+j*2000_H$

Port j MAC Timestamp Addend Kernel Reset value: $0000\ 0000_H$

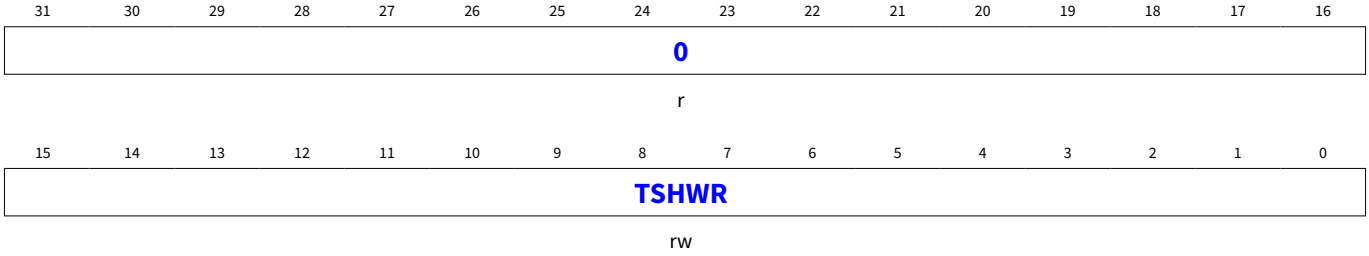
Field	Bits	Type	Description
TSAR	31:0	rw	**Timestamp Addend Register** This field indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

14.6.476 Port j MAC System Time Higher Word Seconds

This register contains the most-significant 16-bits of timestamp seconds value.

Portj_MAC_System_Time_Higher_Word_Seconds (j=0-1) Offset address: $10D1C_H+j*2000_H$

Port j MAC System Time Higher Word Seconds Kernel Reset value: $0000\ 0000_H$



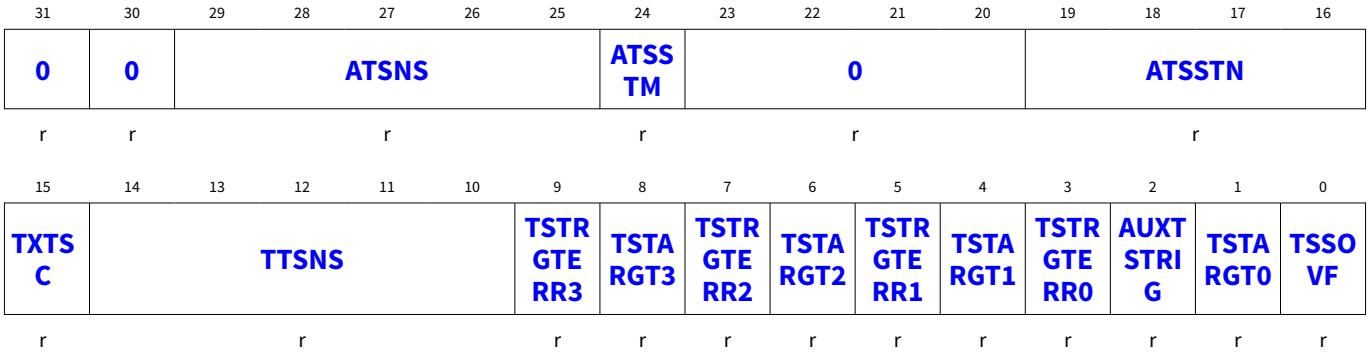
Field	Bits	Type	Description
TSHWR	15:0	rw	**Timestamp Higher Word Register** This field contains the most-significant 16-bits of timestamp seconds value. This register is optional. This register is directly written to initialize the value and it is incremented when there is an overflow from 32-bits of the System Time - Seconds register.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.477 Port j MAC Timestamp Status

The Timestamp Status register All bits except Bits[29:25] gets cleared when the application reads this register.

Portj_MAC_Timestamp_Status (j=0-1) Offset address: $10D20_H+j*2000_H$

Port j MAC Timestamp Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TSSOVF	0	r	**Timestamp Seconds Overflow** When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.

(table continues...)

(continued)

Field	Bits	Type	Description
TSTARGT0	1	r	**Timestamp Target Time Reached** When this bit is set and MCGREN0 of MAC_PPS_Control register is reset, it indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers. When this bit is set and MCGREN0 of MAC_PPS_Control register is set, it indicates that mcgr_dma_req_o[0] is asserted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
AUXTSTRIG	2	r	**Reserved**
TSTRGTERR0	3	r	**Timestamp Target Time Error** This bit is set when the latest target time programmed in the MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds registers has already elapsed. The bit is also set when the PPS command programmed cannot be executed as the earlier programmed target time has already elapsed. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
TSTARGT1	4	r	**Timestamp Target Time Reached for Target Time PPS1** When this bit is set and MCGREN1 of MAC_PPS_Control register is reset, it indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS1_Target_Time_Seconds and MAC_PPS1_Target_Time_Nanoseconds registers. When this bit is set and MCGREN1 of MAC_PPS_Control register is set, it indicates that mcgr_dma_req_o[1] is asserted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
TSTRGTERR1	5	r	**Timestamp Target Time Error** This bit is set when the latest target time programmed in the MAC_PPS1_Target_Time_Seconds and MAC_PPS1_Target_Time_Nanoseconds registers has already elapsed. The bit is also set when the PPS command programmed cannot be executed as the earlier programmed target time has already elapsed. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
TSTARGT2	6	r	**Timestamp Target Time Reached for Target Time PPS2** When this bit is set and MCGREN2 of MAC_PPS_Control register is reset, it indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS2_Target_Time_Seconds and MAC_PPS2_Target_Time_Nanoseconds registers. When this bit is set and MCGREN2 of MAC_PPS_Control register is set, it indicates that mcgr_dma_req_o[2] is asserted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.

(table continues...)

(continued)

Field	Bits	Type	Description
TSTRGTERR2	7	r	**Timestamp Target Time Error** This bit is set when the latest target time programmed in the MAC_PPS2_Target_Time_Seconds and MAC_PPS2_Target_Time_Nanoseconds registers has already elapsed. The bit is also set when the PPS command programmed cannot be executed as the earlier programmed target time has already elapsed. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
TSTARGT3	8	r	**Timestamp Target Time Reached for Target Time PPS3** When this bit is set and MCGREN3 of MAC_PPS_Control register is reset, it indicates that the value of system time is greater than or equal to the value specified in the MAC_PPS3_Target_Time_Seconds and MAC_PPS3_Target_Time_Nanoseconds registers. When this bit is set and MCGREN3 of MAC_PPS_Control register is set, it indicates that mcgr_dma_req_o[3] is asserted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
TSTRGTERR3	9	r	**Timestamp Target Time Error** This bit is set when the latest target time programmed in the MAC_PPS3_Target_Time_Seconds and MAC_PPS3_Target_Time_Nanoseconds registers has already elapsed. The bit is also set when the PPS command programmed cannot be executed as the earlier programmed target time has already elapsed. This bit is cleared when the application reads this bit. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.
TTSNS	14:10	r	**Number of Tx Timestamp Snapshots** This field indicates the number of Tx Timestamp Snapshots available in the FIFO. A value equal to the selected depth of FIFO (2, 4, 8, or 16) indicates that the Tx Timestamp Snapshot FIFO is full. The Tx Timestamp Snapshot FIFO is implemented as synchronous FIFO in the CSR clock domain. This field is incremented along with the Tx Timestamp Snapshot write command to the FIFO. This field is decremented along with the Tx Timestamp Snapshot read command (issued when byte 3 or byte 0 of MAC_TxTimestamp_Status_Seconds register is read in little or big endian mode respectively) to the FIFO. If both write and read command is issued simultaneously, this field is not changed. This field is valid only if the "Enable IEEE 1588 Timestamp Support" option is selected.

(table continues...)

(continued)

Field	Bits	Type	Description
TXTSC	15	r	**Tx Timestamp Captured** When set, this bit indicates that a timestamp of the current packet being transmitted by the MAC is available in MAC_TxTimestamp_Status_Seconds and MAC_TxTimestamp_Status_Nanoseconds registers. This bit is cleared on reading (byte 3 or byte 0 in little or big endian mode respectively) the MAC_TxTimestamp_Status_Seconds register. When Tx Timestamp Status FIFO depth selected is more than 1, this bit is set as long as Tx Timestamp status FIFO has Tx Timestamp status entries. It is cleared when Seconds field corresponding to last entry is read (byte 3 or byte 0 in little or big endian mode respectively) from MAC_TxTimestamp_Status_Seconds register. Access restriction applies.This bit is cleared on reading (byte 3 or byte 0 in little or big endian mode respectively) the MAC_TxTimestamp_Status_Seconds register (or write to corresponding byte of MAC_Tx_Timestamp_Status_Seconds register when RCWE bit of MAC_CSR_SW_Ctrl register is set).
ATSSTN	19:16	r	**Reserved**

Field	Bits	Type	Description
TXSNS	15:8	rw	**Transmit Domain Time Increment Value in Sub-Nanoseconds** This field indicates the Sub-Nanosecond part of the increment value of the PTP time maintained in Transmit clock domain that is used for timestamping. This field has granularity of 1/256 ns. When both TXSNS and TXNS fields are all-zeros, the fixed value based on operating speed is used for PTP time increment in Transmit clock domain.

(table continues...)

(continued)

Field	Bits	Type	Description
TXNS	31:16	rw	**Transmit Domain Time Increment Value in Nanoseconds** This field indicates the Nanosecond part of the increment value of the PTP time maintained in Transmit clock domain that is used for timestamping. For example, when operating in 2.5G XGMII speed the clock period is 12.8ns, so for Digital Rollover mode the TXNS and TXSNS fields must be programmed with 12 and (0.8*256)=205 respectively. In Binary Rollover mode, 12/0.466=25.75 and 0.8+0.75=1.55, so TXNS and TXSNS fields must be programmed with (25+1)=26 and (0.55*256)=141 respectively. When both TXSNS and TXNS fields are all-zeros, the fixed value based on operating speed is used for PTP time increment in Transmit clock domain.
0	7:0	r	**Reserved** Read as 0; should be written with 0.

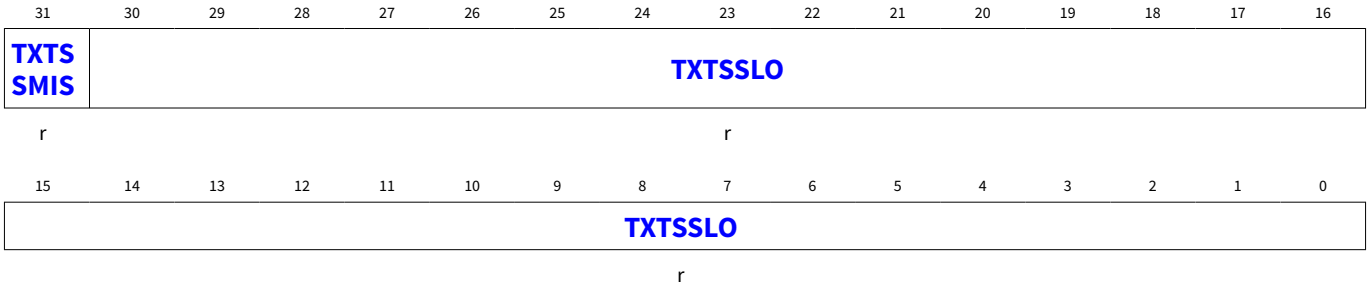
14.6.480 Port j MAC Tx Timestamp Status Nanoseconds

The MAC_TxTimestamp_Status_Nanoseconds register, along with MAC_TxTimestamp_Status_Seconds, gives the 64-bit timestamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte of MAC_Tx_Timestamp_Status_Seconds is read. In the little-endian mode, this means bits[31:24] are read; in big-endian mode, bits[7:0] are read.

If the application does not read these registers and timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the setting of the TXTSSTSM bit of the MAC_Timestamp_Control register. The status bit TXTSC bit [15] in MAC_Timestamp_Status register is set when the MAC transmitter captures the timestamp.

Portj_MAC_Tx_Timestamp_Status_Nanoseconds (j=0-1) Offset address: $10D30_H+j*2000_H$

Port j MAC Tx Timestamp Status Nanoseconds Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TXTSSLO	30:0	r	**Transmit Timestamp Status Low** This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp.

(table continues...)

(continued)

Field	Bits	Type	Description
TXTSSMIS	31	r	**Transmit Timestamp Status Missed** When this bit is set, it indicates one of the following: - The timestamp of the current packet is ignored if TXTSSTSM bit of the MAC_Timestamp_Control register is reset - The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the MAC_Timestamp_Control register is set.

14.6.481 Port j MAC Tx Timestamp Status Seconds

The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

Portj_MAC_Tx_Timestamp_Status_Seconds (j=0-1) Offset address: $10D34_H+j*2000_H$

Port j MAC Tx Timestamp Status Seconds Kernel Reset value: $0000\ 0000_H$

TXTSSTSHI															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TXTSSTSHI															
r															

Field	Bits	Type	Description
TXTSSTSHI	31:0	r	**Transmit Timestamp Status High** This field contains the lower 32 bits of the Seconds field of Transmit packet's captured timestamp.

14.6.482 Port j MAC Tx Timestamp Status PktID

This register contains the PTP packet ID corresponding to the Tx Timestamp Status in MAC_TxTimestamp_Status_Nanoseconds and MAC_TxTimestamp_Status_Seconds registers. This register is available when IEEE 1588 Tx Timestamp Status FIFO Depth is greater than 1.

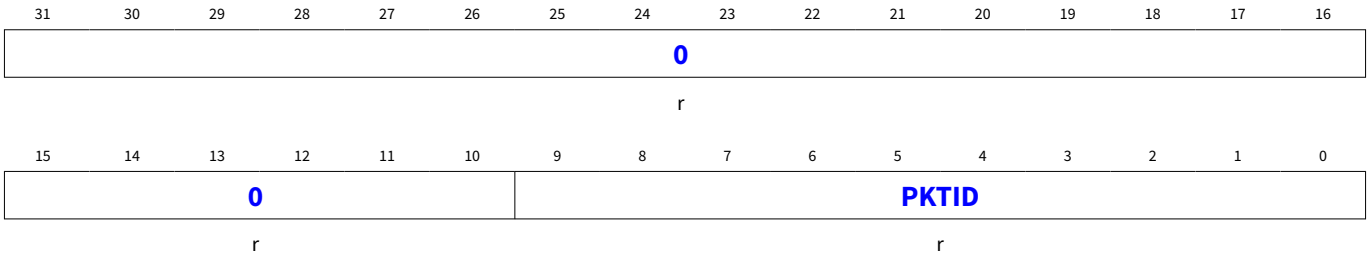
The correct reading sequence of these registers is as follows:

- MAC_TxTimestamp_Status_PktID register
- MAC_TxTimestamp_Status_Nanoseconds register
- MAC_TxTimestamp_Status_Seconds register

This is because, all the 3 registers are updated to a new value when the application reads the last byte of the MAC_TxTimestamp_Status_Seconds register.

Portj_MAC_Tx_Timestamp_Status_PktID (j=0-1) Offset address: $10D38_H+j*2000_H$

Port j MAC Tx Timestamp Status PktID Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PKTID	9:0	r	**Packet ID** The field contains the packet ID corresponding to the Tx Timestamp status in MAC_TxTimestamp_Status_Nanoseconds and MAC_TxTimestamp_Status_Seconds registers. Note: The value of 0 for Packet ID is reserved, it is used by DWC_xgmac for indicating timestamp status of packets for which Packet ID was not provided by Software or for PTP response packets generated by the hardware PTP Offload engine.
0	31:10	r	**Reserved** Read as 0; should be written with 0.

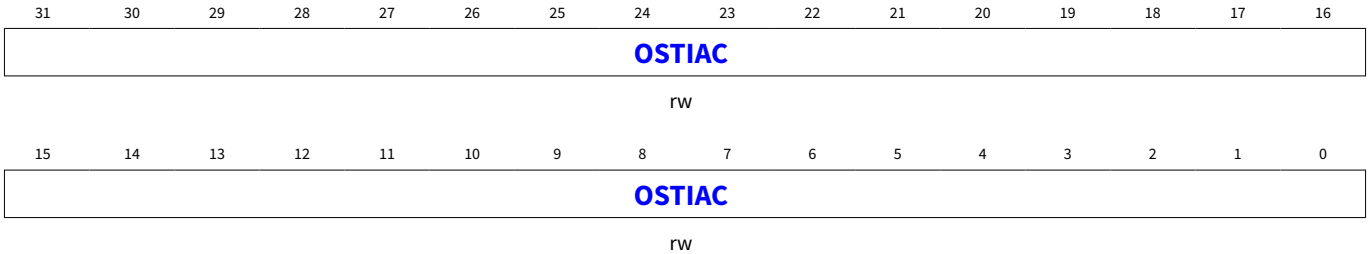
14.6.483 Port j MAC Timestamp Ingress Asym Corr

The MAC Timestamp Ingress Asymmetry Correction register contains the Ingress Asymmetry Correction value to be used while updating correction field in some PTP messages. Ideally, Ingress Asymmetry correction needs to be done in the receive side, when the corresponding packet is received. But when one-step time stamping is enabled, the controller performs ingress asymmetry correction on the transmit (egress) side, which still holds good for packets that are received and transmitted on the same port (for example, Pdelay Resp, which is sent for a Pdelay Request received in the same port).

In other cases (for example, transparent bridge), this feature can still be used if all receive ports have the same ingress correction value. If not, then OSTIAC must be programmed to 0x0.

Portj_MAC_Timestamp_Ingress_Asym_Corr (j=0-1) Offset address: $10D50_H+j*2000_H$

Port j MAC Timestamp Ingress Asym Corr Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
OSTIAC	31:0	rw	**One-Step Timestamp Ingress Asymmetry Correction** This field contains the ingress path asymmetry value to be added to correctionField of Sync and Pdelay_Resp PTP packet. The programmed value must be in units of nanoseconds and multiplied by 2^16. For example, 2.5 ns is represented as 0x00028000. The value can also be negative and then is represented in twos complement form with bit 31 representing the sign bit.

14.6.484 Port j MAC Timestamp Egress Asym Corr

The MAC Timestamp Egress Asymmetry Correction register contains the Egress Asymmetry Correction value to be used while updating the correction field in for some PTP message types.

Portj_MAC_Timestamp_Egress_Asym_Corr (j=0-1) Offset address: $10D54_H+j*2000_H$

Port j MAC Timestamp Egress Asym Corr Kernel Reset value: $0000\ 0000_H$

OSTEAC															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OSTEAC															
rw															

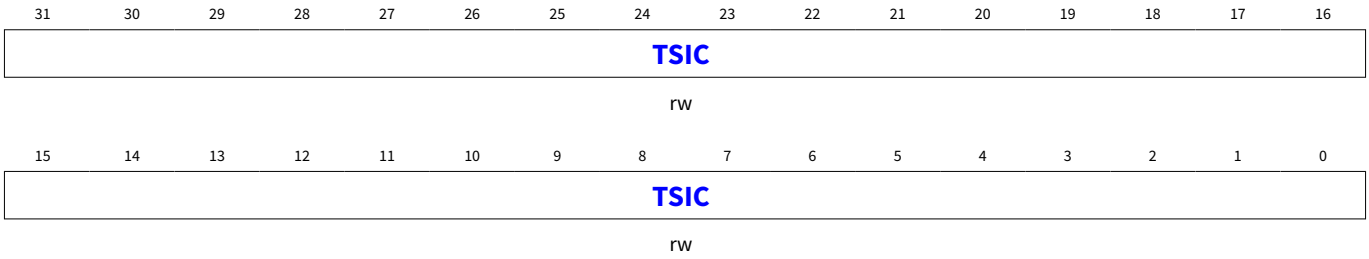
Field	Bits	Type	Description
OSTEAC	31:0	rw	**One-Step Timestamp Egress Asymmetry Correction** This field contains the egress path asymmetry value to be subtracted from correctionField of Delay_Req and Pdelay_Req PTP packet. The programmed value must be the negated value in units of nanoseconds multiplied by 2^16. For example, if the required correction is +2.5 ns, then the programmed value must be 0xFFFD_8000, which is twos complement of 0x0002_8000 (2.5 * 2^16). Similarly, if the required correction is -3.3 ns, then the programmed value is 0x0003_4CCC (3.3 * 2^16).

14.6.485 Port j MAC Timestamp Ingress Corr Nanosecond

The MAC Timestamp Ingress Correction Nanosecond register contains the correction value to be used with the captured timestamp value in the ingress path. This is used to compensate the errors due to timestamp synchronization from the PTP clock domain to the MAC Rx clock domain, and the latency incurred between the message timestamp point and the point at which the timestamp snapshot is taken.

Portj_MAC_Timestamp_Ingress_Corr_Nanosecond (j=0-1) Offset address: $10D58_H+j*2000_H$

Port j MAC Timestamp Ingress Corr Nanosecond Kernel Reset value: $0000\ 0000_H$



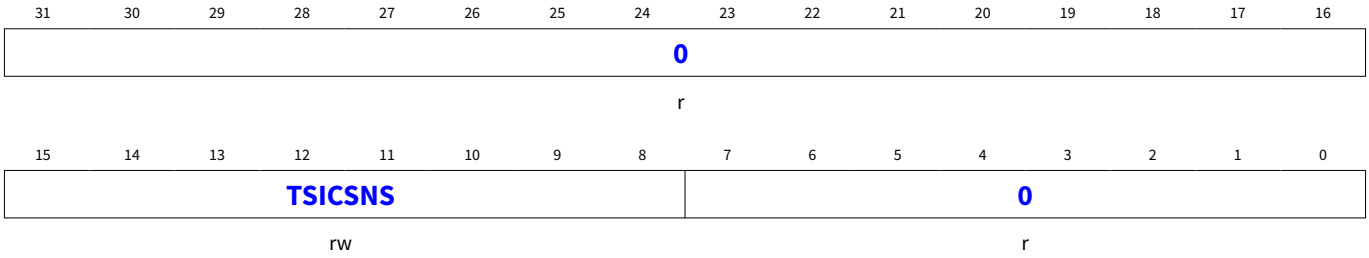
Field	Bits	Type	Description
TSIC	31:0	rw	**Timestamp Ingress Correction** This field contains the ingress path correction value in nanoseconds as defined by the "Ingress Correction" expression.

14.6.486 Port j MAC Timestamp Ingress Corr Subnanosecond

The MAC Timestamp Ingress Correction Sub-Nanosecond register contains the sub-nanosecond part of the correction value to be used with the captured timestamp value, for ingress directions.

Portj_MAC_Timestamp_Ingress_Corr_Subnanosecond (j=0-1) Offset address: $10D5C_H+j*2000_H$

Port j MAC Timestamp Ingress Corr Subnanosecond Kernel Reset value: $0000\ 0000_H$



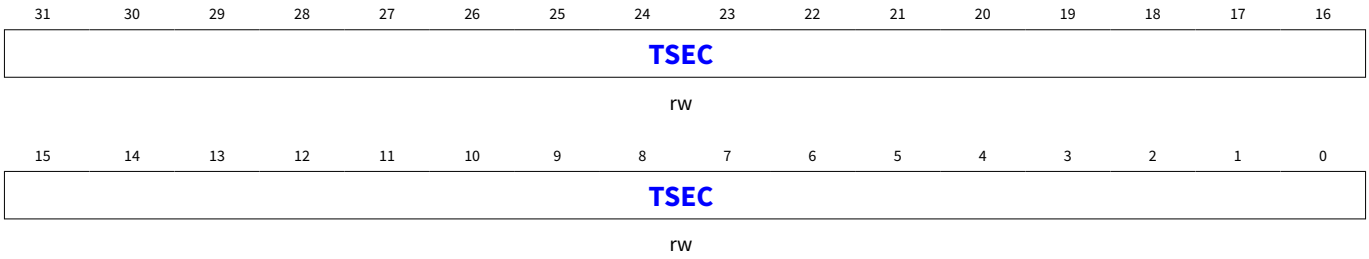
Field	Bits	Type	Description
TSICSNS	15:8	rw	**Timestamp Ingress Correction, sub-nanoseconds** This field contains the sub-nanoseconds part of the ingress path correction value as defined by the "Ingress Correction" expression.
0	7:0, 31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.487 Port j MAC Timestamp Egress Corr Nanosecond

The MAC Egress Timestamp Correction Nanosecond register contains the correction value to be used with the captured timestamp value in the egress path. This is used to compensate the errors due to timestamp synchronization from PTP clock domain to MAC Tx clock domain, and the latency incurred between the point at which the timestamp snapshot is taken and the message timestamp point.

Portj_MAC_Timestamp_Egress_Corr_Nanosecond (j=0-1) Offset address: $10D60_H+j*2000_H$

Port j MAC Timestamp Egress Corr Nanosecond Kernel Reset value: $0000\ 0000_H$



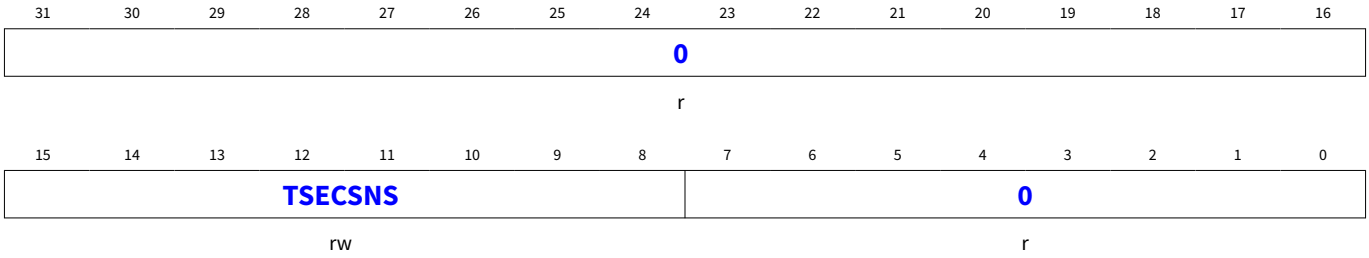
Field	Bits	Type	Description
TSEC	31:0	rw	**Timestamp Egress Correction** This field contains the nanoseconds part of the egress path correction value as defined by the "Egress Correction" expression,

14.6.488 Port j MAC Timestamp Egress Corr Subnanosecond

The MAC Timestamp Correction Egress Sub-nanosecond register contains the sub-nanosecond part of the correction value to be used with the captured timestamp value, for egress directions.

Portj_MAC_Timestamp_Egress_Corr_Subnanosecond (j=0-1) Offset address: $10D64_H+j*2000_H$

Port j MAC Timestamp Egress Corr Subnanosecond Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TSECSNS	15:8	rw	**Timestamp Egress Correction, sub-nanoseconds** This field contains the sub-nanoseconds part of the egress path correction value as defined by the "Egress Correction" expression.
0	7:0, 31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.489 Port j MAC PPS Control

. . Bits[22:16] are valid only when three or more Flexible PPS outputs are selected. Bits[14:8] are valid only when two or more Flexible PPS outputs are selected. Bits[6:4] are valid.

Portj_MAC_PPS_Control (j=0-1) Offset address: $10D70_H+j*2000_H$

Port j MAC PPS Control Kernel Reset value: $0000\ 0000_H$

MCGREN1	TRGTMODSEL1	PPSEN1	PPSCMD1	MCGREN0	TRGTMODSEL0	PPSEN0	PPSCTRL0_PPSCMD0
rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
PPSCTRL0_PPSCMD0	3:0	rw	**PPSCMD0: Flexible PPS Output (ptp_pps_o[0]) Control** Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software must ensure that these bits are programmed only when they are all-zero. The following list describes the values of PPSCMD0: - 0000: No Command - 0001: START Single Pulse This command generates a single pulse rising at the start point defined in Target Time registers and of a duration defined in the PPS0 Width register. - 0010: START Pulse Train This command generates the train of pulses rising at the start point defined in the Target Time registers and of a duration defined in the PPS0 Width register and repeated at interval defined in the PPS Interval register. By default, the PPS pulse train is free-running unless stopped by the "Stop Pulse train at time" or "Stop Pulse Train immediately" commands. - 0011: Cancel START This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. - 0100: STOP Pulse train at time This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. - 0101: STOP Pulse Train immediately This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). - 0110: Cancel STOP Pulse train This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command. - 0111-1111: Reserved or Presentation Time Control When MCGREN0 is 1, these bits are treated as Presentation time control bits. The following list describes the values of PPSCMD0: - 0000: MCGR operation is not carried out. If set to this value in the mid of clock recovery or generation, all the processing inputs are flushed - 0001: Capture the Presentation time at the rising edge of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0010: Capture the Presentation time at the falling edge of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0011: Capture the Presentation time at both edges of mcg_pst_trig_i[0] into the MAC_PPS0_Target_Time_Seconds register - 0100-1000: Reserved - 1001: Toggle output on compare

(table continues...)

(continued)

Field	Bits	Type	Description
			- 1010: Pulse output low on compare for one PTP-clock cycle - 1011: Pulse output high on compare for one PTP-clock cycle - 1100-1111: Reserved This field can be the PPS Output Frequency Control (PPSCTRL0) or the Flexible PPS Output (ptp_pps_o[0]) Control (PPSCMD0) PPSCTRL0: PPS Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_ref_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: - 0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. - 0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. - 0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. - 0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. - ... - 1111: The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz. In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example: When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of: - One clock of 50 percent duty cycle and 537 ms period - Second clock of 463 ms period (268 ms low and 195 ms high) When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of: - Three clocks of 50 percent duty cycle and 268 ms period - Fourth clock of 195 ms period (134 ms low and 61 ms high) This behavior is because of the non-linear toggling of bits in the digital rollover mode in the MAC_System_Time_Nanoseconds register.
PPSEN0	4	rw	**Flexible PPS Output Mode Enable** When this bit is set, Bits[3:0] function as PPSCMD. When this bit is reset, Bits[3:0] function as PPSCTRL (Fixed PPS mode).

(table continues...)

(continued)

Field	Bits	Type	Description
TRGTMODSEL0	6:5	rw	**Target Time Register Mode for PPS0 Output** This field indicates the Target Time registers mode for PPS0 output signal: - 00: Target Time registers are programmed only for generating the Target Time Reached interrupt event. The Flexible PPS function must not be enabled in this mode, otherwise spurious transitions might be observed on the corresponding ptp_pps_o output port - 01: Reserved - 10: Target Time registers are programmed for generating the Target Time Reached interrupt event and starting or stopping the PPS0 output signal generation. - 11: Target Time registers are programmed only for starting or stopping the PPS0 output signal generation. No Target Time Reached interrupt is asserted.
MCGREN0	7	rw	**MCGR Mode Enable for PPS0 Output** This field enables the 0th PPS instance to operate in PPS or MCGR mode. When set it operates in MCGR mode and on reset it operates in PPS mode.
PPSCMD1	11:8	rw	**Flexible PPS1 Output Control** This field controls the flexible PPS1 output (ptp_pps_o[1]) signal. This field is similar to the PPSCMD0 field. - When MCGREN1 is 1, PPSCMD1 indicated by the 4 bits [11:8] are taken as Presentation Time Control bits for media clock generation and recovery for comparator instance 1. This field is similar to the PPSCMD0 Presentation Time Control bits. - When MCGREN1 is 0, only 3 bits from [10:8] are used as PPSCMD1 and the 4th bit must be set as 0. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.
PPSEN1	12	rw	
TRGTMODSEL1	14:13	rw	**Target Time Register Mode for PPS1 Output** This field indicates the Target Time registers mode for PPS1 output signal. This field is similar to the TRGTMODSEL0 field.
MCGREN1	15	rw	**MCGR Mode Enable for PPS1 Output** This field enables the 1st PPS instance to operate in PPS or MCGR mode. - 1: Operates in MCGR mode - 0: Operates in PPS mode

(table continues...)

(continued)

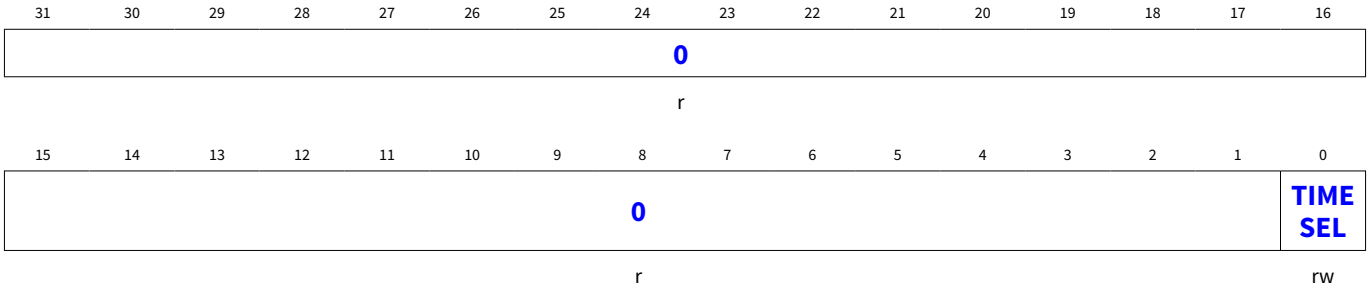
14.6.490 Port j MAC PPS Extnd Ctrl

.

Portj_MAC_PPS_Extnd_Ctrl (j=0-1) Offset address: $10D74_H+j*2000_H$

Port j MAC PPS Extnd Ctrl Kernel Reset value: $0000\ 0000_H$



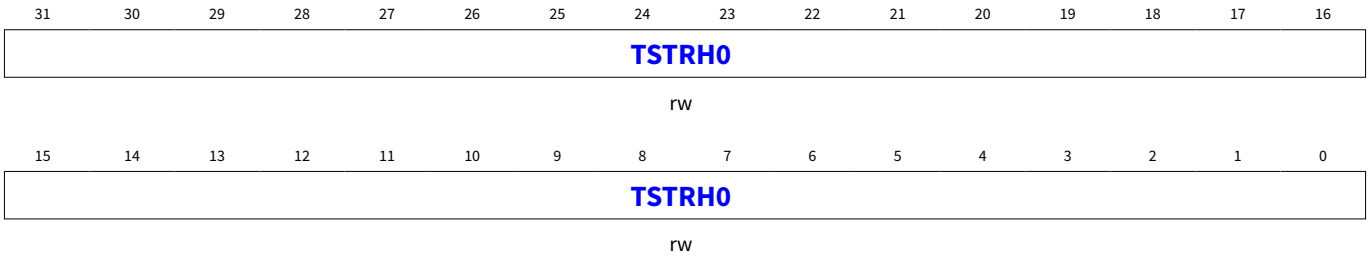
Field	Bits	Type	Description
TIMESEL	0	rw	
0	31:1	r	**Reserved** Read as 0; should be written with 0.

14.6.491 Port j MAC PPS0 Target Time Seconds

The PPS0 Target Time Seconds register, along with PPS0 Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of MAC_Timestamp_Status] when the system time exceeds the value programmed in these registers.

Portj_MAC_PPS0_Target_Time_Seconds (j=0-1) Offset address: $10D80_H+j*2000_H$

Port j MAC PPS0 Target Time Seconds Kernel Reset value: $0000\ 0000_H$



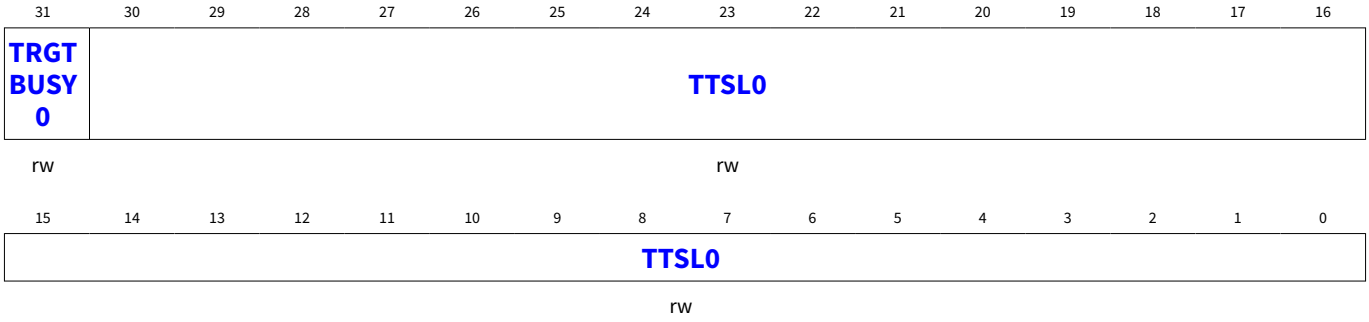
Field	Bits	Type	Description
TSTRH0	31:0	rw	**PPS0 Target Time Seconds Register** This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Bits[6:5] of MAC_PPS_Control register. If DWCXG_FLEXI_PPS_OUT_EN is enabled in the configuration and PTGE field of MAC_Timestamp_Control Register is set with Presentation time control set in recovery mode, then these bits indicate the TPT being programmed by the application and in generation mode it indicates the CPT generated at the sampled trigger.

14.6.492 Port j MAC PPS0 Target Time Nanoseconds

The PPS0 Target Time Nanoseconds register is present only when more than one Flexible PPS output is selected.

Portj_MAC_PPS0_Target_Time_Nanoseconds (j=0-1) Offset address: $10D84_H+j*2000_H$

Port j MAC PPS0 Target Time Nanoseconds Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TTSL0	30:0	rw	**Target Time Low for PPS0 Register** This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output or generates a Target Time Reached interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in MAC_PPS_Control. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, this value must not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output might have an error margin up to one unit of sub-second increment value.
TRGTBUSY0	31	rw	**PPS0 Target Time Register Busy** The MAC sets this bit when the PPSCMD0 field in the MAC_PPS_Control register is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time registers to the PTP clock domain The application must not update the Target Time registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted.

14.6.493 Port j MAC PPS0 Interval

The PPS0 Interval register contains the number of units of sub-second increment value between the rising edges of PPS0 signal output (ptp_pps_o[0]).

Portj_MAC_PPS0_Interval (j=0-1) Offset address: $10D88_H+j*2000_H$

Port j MAC PPS0 Interval Kernel Reset value: $0000\ 0000_H$

PPSINT0															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PPSINT0															
rw															

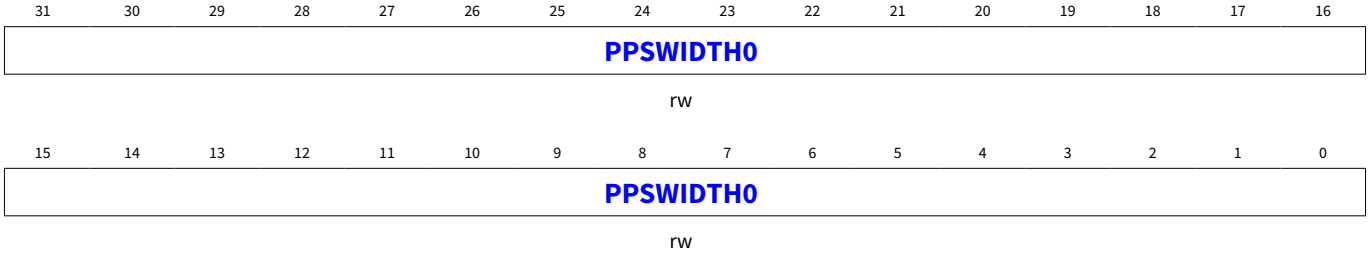
Field	Bits	Type	Description
PPSINT0	31:0	rw	**PPS0 Output Signal Interval** These bits store the interval between the rising edges of PPS0 signal output. The interval is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS0 signal output is 100 ns (that is, five units of sub-second increment value), you must program value 4 (5 - 1) in this register.

14.6.494 Port j MAC PPS0 Width

The PPS0 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of PPS0 signal output (ptp_pps_o[0]).

Portj_MAC_PPS0_Width (j=0-1) Offset address: $10D8C_H+j*2000_H$

Port j MAC PPS0 Width Kernel Reset value: $0000\ 0000_H$



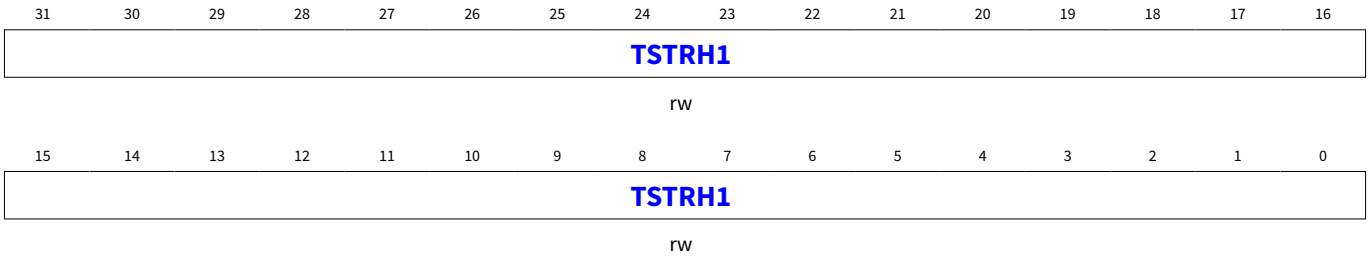
Field	Bits	Type	Description
PPSWIDTH0	31:0	rw	**PPS0 Output Signal Width** These bits store the width between the rising edge and corresponding falling edge of PPS0 signal output. The width is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS0 signal output is 80 ns (that is, four units of sub-second increment value), you must program value 3 (4 - 1) in this register. Note: The value programmed in this register must be lesser than the value programmed in MAC_PPS0_Interval.

14.6.495 Port j MAC PPS1 Target Time Seconds

The PPS1 Target Time Seconds register, along with PPS1 Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of MAC_Timestamp_Status] when the system time exceeds the value programmed in these registers.

Portj_MAC_PPS1_Target_Time_Seconds (j=0-1) Offset address: $10D90_H+j*2000_H$

Port j MAC PPS1 Target Time Seconds Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TSTRH1	31:0	rw	**PPS1 Target Time Seconds** This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Bits[14:13] of MAC_PPS_Control register. If DWCXG_FLEXI_PPS_OUT_EN is enabled in the configuration and PTGE field of MAC_Timestamp_Control Register is set with Presentation time control set in recovery mode, then these bits indicate the TPT being programmed by the application and in generation mode it indicates the CPT generated at the sampled trigger.

14.6.496 Port j MAC PPS1 Target Time Nanoseconds

The PPS1 Target Time Nanoseconds register, along with PPS1 Target Time Seconds register, is used to schedule an interrupt event [Bit 1 of MAC_Timestamp_Status] when the system time exceeds the value programmed in these registers.

Portj_MAC_PPS1_Target_Time_Nanoseconds (j=0-1) Offset address: $10D94_H+j*2000_H$

Port j MAC PPS1 Target Time Nanoseconds Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
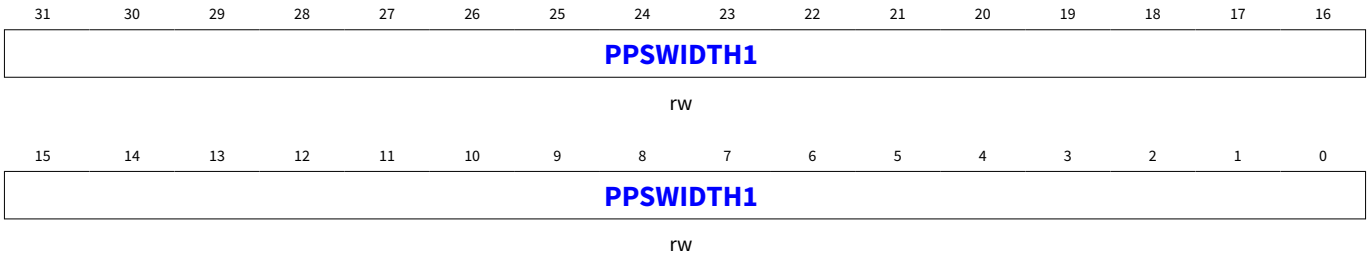
PPSINT1	31:0	rw	**PPS1 Output Signal Interval** These bits store the interval between the rising edges of PPS1 signal output. The interval is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS1 signal output is 100 ns (that is, five units of sub-second increment value), you must program value 4 (5 - 1) in this register.

14.6.498 Port j MAC PPS1 Width

The PPS1 Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of PPS1 signal output (ptp_pps_o[1]).

Portj_MAC_PPS1_Width (j=0-1) Offset address: $10D9C_H+j*2000_H$

Port j MAC PPS1 Width Kernel Reset value: $0000\ 0000_H$



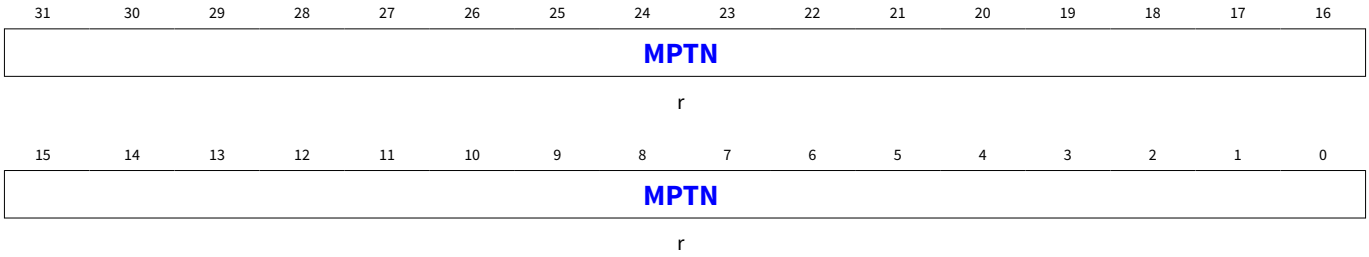
Field	Bits	Type	Description
PPSWIDTH1	31:0	rw	**PPS1 Output Signal Width** These bits store the width between the rising edge and corresponding falling edge of PPS1 signal output. The width is stored in terms of number of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS1 signal output is 80 ns (that is, four units of sub-second increment value), you must program value 3 (4 - 1) in this register. Note: The value programmed in this register must be lesser than the value programmed in MAC_PPS1_Interval.

14.6.499 Port j MAC Presn Time ns

This register contains the 32-bit binary rollover equivalent time of the PTP System Time in ns.

Portj_MAC_Presn_Time_ns (j=0-1) Offset address: $10DE0_H+j*2000_H$

Port j MAC Presn Time ns Kernel Reset value: $0000\ 0000_H$



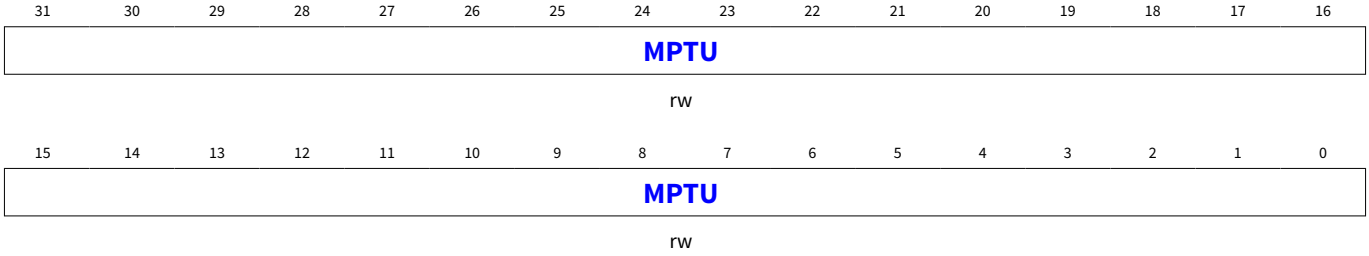
Field	Bits	Type	Description
MPTN	31:0	r	**MAC 1722 Presentation Time in ns** These bits indicate the value of the 32-bit binary rollover equivalent time of the PTP System Time in ns.

14.6.500 Port j MAC Presn Time Updt

This field holds the 32-bit value of MAC 1722 Presentation Time in ns, that should be added to the Current Presentation Time Counter value. Init happens when TSINIT is set, and update happens when the TSUPDT bit is set (TSINIT and TSINIT defined in MAC_Timestamp_ Control register).

Portj_MAC_Presn_Time_Updt (j=0-1) Offset address: $10DE4_H+j*2000_H$

Port j MAC Presn Time Updt Kernel Reset value: $0000\ 0000_H$



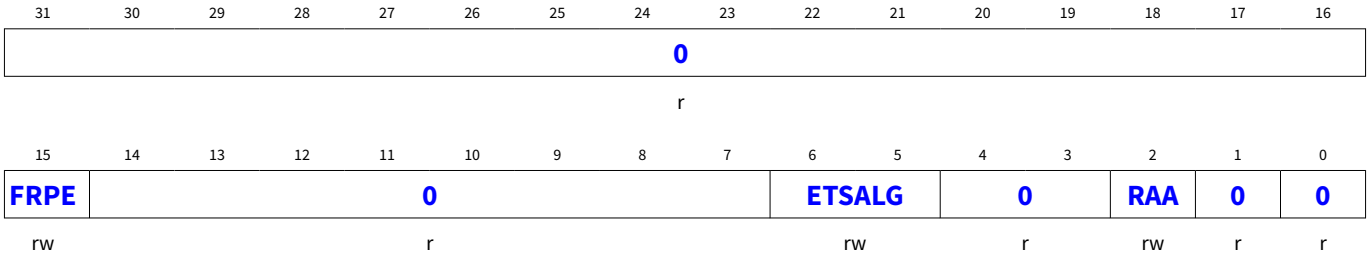
Field	Bits	Type	Description
MPTU	31:0	rw	**MAC 1722 Presentation Time Update** This field holds the init value or the update value for the presentation time. When used for update, this field holds the 32-bit value in ns, that should be added to the Current Presentation Time Counter value. Init happens when TSINIT is set, and update happens when the TSUPDT bit is set (TSINIT and TSINIT defined in MAC_Timestamp_ Control register). When ADDSUB field of MAC_System_Time_Nanoseconds_Update is set, this value is directly used for subtraction.

14.6.501 Port j MTL Operation Mode

The Operation Mode register establishes the Transmit and Receive operating modes and commands.

Portj_MTL_Operation_Mode (j=0-1) Offset address: $11000_H+j*2000_H$

Port j MTL Operation Mode Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RAA	2	rw	**Receive Arbitration Algorithm** This field is used to select the arbitration algorithm for the Rx side. - 0: Strict Priority (SP) - 1: Weighted Strict Priority (WSP) Queue 0 has the lowest priority and the last queue has the highest priority. RXQ_WEGT field of MTL_RxQ(#i)_Control register controls the weight assigned to receive queue.
ETSALG	6:5	rw	**ETS Algorithm** This field selects the type of ETS algorithm to be applied for traffic classes whose transmission selection algorithm (TSA) is set to ETS: - 2'b00: WRR algorithm - 2'b11: Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
FRPE	15	rw	**Flexible Receive Parser Enable** When this bit is set, Flexible Receive Parser is enabled for packet filtering and classification. When this bit is reset, Flexible Receive Parser is disabled for packet filtering and classification. Note: If the flexible receive parser is in the middle of the parsing then, FRPE programming change is applicable from next immediate packet. 0_B **DISABLE**: Flexible Rx parser is disabled 1_B **ENABLE**: Flexible Rx parser is enabled
0	0, 1, 4:3, 14:7, 31:16	r	**Reserved** Read as 0; should be written with 0.

14.6.502 Port j MTL Debug Control

The MTL Debug Control register controls the operation mode of debug access to the TXFIFO, RXFIFO and Descriptor Cache memories connected to the DWC_xgmac. Note: Consecutive write or read to this register must be performed after at least 16 clock cycles of the slowest clock among MAC Transmitter/Receiver clock and Application/CSR clock.

Portj_MTL_Debug_Control (j=0-1) Offset address: $11008_H+j*2000_H$

Port j MTL Debug Control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0													EIEC	EIAE E	EIEE
r													rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

r	rw	rw		rw	rw	rw	rw	r	rw		r	rw		rw	rw

Field	Bits	Type	Description
FDBGEN	0	rw	**FIFO Debug Access Enable** When this bit is set, access is available to the memories selected by FIFOSEL. The type of access (Debug mode or Slave mode) is determined by DBGMOD. When this bit is reset, the memories are in mission mode and direct access to these memories are disabled..

(table continues...)

(continued)

Field	Bits	Type	Description
DBGMOD	1	rw	**Debug Mode Access to FIFO** When this bit is set and FDBGEN is set, direct access is enabled to the memories selected by FIFOSEL. The transfer of packets between the host interface and the MAC through the TXFIFO & RXFIFO memory are disabled. The CPU/software can perform direct write/read operations to the memories as determined by programming of FIFOWREN/ FIFORDEN bits. When this bit is reset and FDBGEN is set, the TXFIFO and RXFIFO memory are put in Slave mode. In this mode, packets can be directly written into the TXFIFO memory for transmission by MAC as well as the packets received by the MAC can be read directly. The transfer of packets between the FIFO memories and the host interface is stopped. In this mode, only the following access are allowed: Packet Write access to the Tx FIFO Packet Read access to the Rx FIFO
BYTEEN	3:2	rw	**Write Data Byte Enable** This field indicates the number of data bytes valid in the MTL_Debug_Data register during Write operation. This is valid only when PKTSTATE is 2'b11 (EOP) and Tx FIFO or Rx FIFO is selected. - 00: Byte 0 valid - 01: Byte 0 and Byte 1 are valid - 10: Byte 0, Byte 1, and Byte 2 are valid - 11: All four bytes are valid
PKTSTATE	6:5	rw	**Write Control Type** This field is used to decide the tag bits along with the data being written into the FIFO. When the TxFIFO is written in Slave mode or Debug mode, this field marks the type of data written as follows: - 00: Packet Data - 01: Control Word - 10: SOP Data - 11: EOP Data When the Rx FIFO is being written in Slave mode, this field marks the type of data written as follows: - 00: Packet Data - 01: Normal Status - 10: Last Status - 11: EOP
RSTALL	8	rw	**Reset All Pointers** When this bit is set, the address pointers to all FIFO memory in btoh Debug and Slave modes are reset. This bit is self cleared.
RSTSEL	9	rw	**Reset Pointers of Selected FIFO** When this bit is set, the address pointer of the memory selected by FIFOSEL is reset in both Debug and Slave modes. This bit is self cleared.

(table continues...)

(continued)

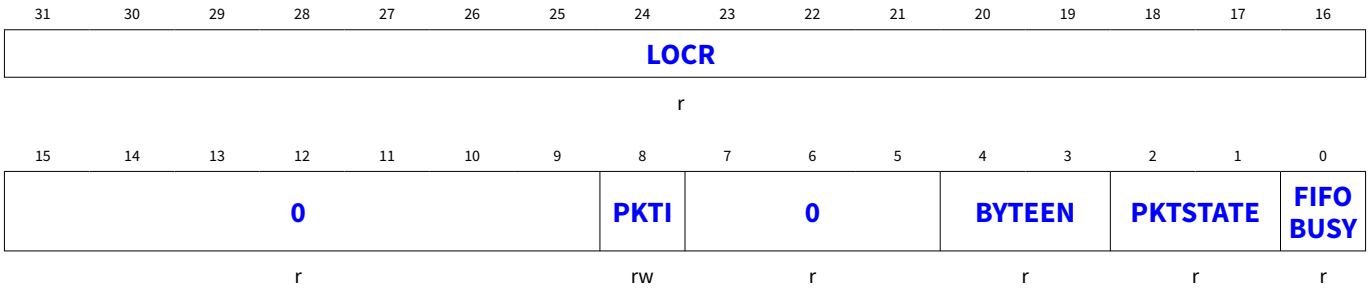
Field	Bits	Type	Description
FIFORDEN	10	rw	**FIFO Read Enable** When this bit is set, it enables the Read operation on the memory selected by FIFOSEL. If both FIFOWREN and FIFORDEN are set to 1 together, the behaviour is unpredictable.
FIFOWREN	11	rw	**FIFO Write Enable** When this bit is set, it enables the Write operation on the memory selected by FIFOSEL. If both FIFOWREN and FIFORDEN are set to 1 together, the behaviour is unpredictable.
FIFOSEL	13:12	rw	**FIFO Selected for Access** This field indicates the FIFO selected for debug access: - 00: Tx FIFO - 01: Descriptor cache (only when DBGMOD = 1) - 11: Rx FIFO
PKTIE	14	rw	**Receive Packet Available Interrupt Status Enable** When this bit is set, an interrupt is generated when EOP of received packet is written by the MAC to the Rx FIFO. This bit is applicable only when Slave mode is active.
EIEE	16	rw	**ECC Inject Error Enable** When set, enables the ECC error injection function in Debug mode. If EIAEE is set, enables the ECC Address Error Injection, otherwise, enables the ECC Data/Check Bits Error Injection (See EIM and BLEI field in MTL_DPP_ECC_EIC Register). When reset, disables the ECC error injection function.
EIAEE	17	rw	**ECC Inject Address Error Enable** When set, indicates that the ECC Debug error should be injected in Address Bits. When reset, indicates that the ECC Debug error should be injected in Data/Check Bits.
EIEC	18	rw	**ECC Inject Error Control** When EIEE bit of this register is set, errors are inserted in databus to memory based on the value encoded in this field. 0_B **M_1BIT**: Insert 1 bit error 1_B **M_2BIT**: Insert 2 bit errors
0	4, 7, 15, 31:19	r	**Reserved** Read as 0; should be written with 0.

14.6.503 Port j MTL Debug Status

The Debug Status register contains the state of the transactions to FIFO memory in Debug or Slave modes.
Note: Consecutive write or read to this register must be performed after at least 16 clock cycles of the slowest clock among MAC Transmitter/Receiver clock and Application/CSR clock.

Portj_MTL_Debug_Status (j=0-1) Offset address: $1100C_H+j*2000_H$

Port j MTL Debug Status Kernel Reset value: $0000\ 0018_H$



Field	Bits	Type	Description
FIFOBUSY	0	r	**FIFO Busy** When set, this bit indicates that a FIFO operation is in progress in the MAC and content of the following fields is not valid: - All other fields of this register - All fields of the MTL_FIFO_Debug_Data register
PKTSTATE	2:1	r	**Read Control Type** This field indicates the tag bits read along with the data being read from the selected FIFO. When the TxFIFO is read in Debug mode, this field marks the type of data read as follows: - 00: Packet Data - 01: Control Word - 10: SOP Data - 11: EOP Data When the RxFIFO is read in Debug or Slave mode, this field marks the type of data read as listed as follows: - 00: Packet Data - 01: Normal Status - 10: Last Status - 11: EOP
BYTEEN	4:3	r	**Read Data Byte Enable** This field indicates the number of data bytes valid in the MTL_FIFO_Debug_Data register during Read operation. This is valid only when PKTSTATE is 2'b11 (EOP). - 00: Byte 0 valid - 01: Byte 0 and Byte 1 are valid - 10: Byte 0, Byte 1, and Byte 2 are valid - 11: All four bytes are valid
PKTI	8	rw	**Receive Packet Available Interrupt Status** When set, this bit indicates that MAC layer has written the EOP of received packet to the Rx FIFO. This bit is reset when 1 is written to this bit.

(table continues...)

(continued)

Field	Bits	Type	Description
LOCR	31:16	r	**Remaining Locations in the FIFO** Slave Access Mode: This field indicates the space available in selected FIFO. Debug Access Mode: This field contains the Write or Read pointer value of the selected FIFO during Write or Read operation, respectively.
0	7:5, 15:9	r	**Reserved** Read as 0; should be written with 0.

14.6.504 Port j MTL FIFO Debug Data

The FIFO Debug Data register contains the data to be written to or read from the FIFOs. Note: Consecutive write or read to this register must be performed after at least 16 clock cycles of the slowest clock among MAC Transmitter/Receiver clock and Application/CSR clock.

Portj_MTL_FIFO_Debug_Data (j=0-1) Offset address: $11010_H+j*2000_H$

Port j MTL FIFO Debug Data Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
Q0IS	0	r	**Traffic Class/Queue 0 Interrupt Status** This bit indicates that there is an interrupt from Traffic Class/Queue 0. To reset this bit, the software must read Traffic Class/Queue 0 Interrupt Control and Status register to get the exact cause of the interrupt and clear its source.
Q1IS	1	r	**Traffic Class/Queue 1 Interrupt Status** This bit indicates that there is an interrupt from Traffic Class/Queue 1. To reset this bit, the software must read Traffic Class/Queue 1 Interrupt Control and Status register to get the exact cause of the interrupt and clear its source.
Q2IS	2	r	**Traffic Class/Queue 2 Interrupt Status** This bit indicates that there is an interrupt from Traffic Class/Queue 2. To reset this bit, the software must read Traffic Class/Queue 2 Interrupt Control and Status register to get the exact cause of the interrupt and clear its source.
Q3IS	3	r	**Traffic Class/Queue 3 Interrupt Status** This bit indicates that there is an interrupt from Traffic Class/Queue 3. To reset this bit, the software must read Traffic Class/Queue 3 Interrupt Control and Status register to get the exact cause of the interrupt and clear its source.
Q4IS	4	r	**Traffic Class/Queue 4 Interrupt Status** This bit indicates that there is an interrupt from Traffic Class/Queue 4. To reset this bit, the software must read Traffic Class/Queue 4 Interrupt Control and Status register to get the exact cause of the interrupt and clear its source.
Q5IS	5	r	**Traffic Class/Queue 5 Interrupt Status** This bit indicates that there is an interrupt from traffic Class/Queue 5. To reset this bit, the software must read traffic Class/Queue 5 Interrupt Control and Status register to get the exact cause of the interrupt and clear its source.
Q6IS	6	r	**Traffic Class/Queue 6 Interrupt Status** This bit indicates that there is an interrupt from Traffic Class/Queue 6. To reset this bit, the software must read Traffic Class/Queue 6 Interrupt Control and Status register to get the exact cause of the interrupt and clear its source.

(table continues...)

(continued)

Field	Bits	Type	Description
Q7IS	7	r	**Traffic Class/Queue 7 Interrupt Status** This bit indicates that there is an interrupt from Traffic Class/Queue 7. To reset this bit, the software must read Traffic Class/Queue 7 Interrupt Control and Status register to get the exact cause of the interrupt and clear its source.
MACIS	16	r	**MAC Interrupt Status** This bit indicates an interrupt event in the MAC. To reset this bit to 1'b0, the software must read the corresponding MAC_Interrupt_Status in the MAC to get the exact cause of the interrupt and clear its source.
DBGIS	17	r	**Debug Interrupt Status** This bit indicates an interrupt event during the slave access. To reset this bit, the software must read the MTL_Debug_Status register to get the exact cause of the interrupt and clear its source.
ESTIS	18	r	**EST (TAS- IEEE 802.1Qbv) Interrupt Status** This bit indicates an interrupt event during the operation of Time Aware Shaper for transmit traffic. To reset this bit, the application must clear the error/event that has caused the interrupt. The status bits that are set in MTL_EST_Status registers should be written to 1, to clear the ESTIS bit 0_B **INACTIVE**: EST (TAS- 802.1Qbv) Interrupt status not activated 1_B **ACTIVE**: EST (TAS- 802.1Qbv) Interrupt event activated
TINS	19	r	**TBS Interrupt Status** This bit is set when a frame is dropped in any of the TX queues in TBS mode due to the expiry of Launch time or transmission window. Access restriction applies. Clears on write of 1. 0_B **INACTIVE**: TBS Interrupt status not activated 1_B **ACTIVE**: TBS Interrupt event activated
SGFIS	20	r	**SGF Interrupt Status** This bit indicates an interrupt event during the operation of SGF. To reset this bit, the application must clear the source of the error/event that has caused the interrupt. The status bits that are set in MTL_SGF_Status registers should be written to 1, to clear the SGFIS bit. 0_B **INACTIVE**: SGF Interrupt status not activated 1_B **ACTIVE**: SGF Interrupt event activated
MTLPIS	23	r	**MTL Rx-Parser Interrupt Status** This bit indicates that there is an interrupt from Rx Parser Block. To reset this bit, the application must read the MTL_RXP_Interrupt_Control_Status register to get the exact cause of the interrupt and clear its source. 0_B **INACTIVE**: MTL Rx Parser Interrupt status not activated 1_B **ACTIVE**: MTL Rx Parser Interrupt event activated

Field	Bits	Type	Description
Q0MDMACH	2:0	rw	**Receive Queue 0 Mapped to DMA Channel** This field controls the routing of the packet received in Receive Queue 0 to the DMA channel. This field is valid when the Q0DDMACH field is reset. The encoding is the same as Q3MDMACH of this register.
Q0DDMACH	7	rw	**Receive Queue 0 Enabled for Dynamic DMA Channel Selection** When set, this bit indicates that each packet received in Receive Queue 0 is routed to a DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, the Ethernet DA address or VLAN filter registers. When reset, this bit indicates that all packets received in Receive Queue 0 are routed to the DMA Channel programmed in the Q0MDMACH field.

(table continues...)

(continued)

Field	Bits	Type	Description
Q1MDMACH	10:8	rw	**Receive Queue 1 Mapped to DMA Channel** This field controls the routing of the received packet in Receive Queue 1 to the DMA channel. This field is valid when the Q1DDMACH field is reset. The encoding is the same as Q3MDMACH of this register.
Q1DDMACH	15	rw	**Receive Queue 1 Enabled for Dynamic DMA Channel Selection** When set, this bit indicates that each packet received in Receive Queue 1 is routed to a DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, the Ethernet DA address registers or VLAN filter registers. When reset, this bit indicates that all packets received in Receive Queue 1 are routed to the DMA Channel programmed in the Q1MDMACH field.
Q2MDMACH	18:16	rw	**Receive Queue 2 Mapped to DMA Channel** This field controls the routing of the received packet in Receive Queue 2 to the DMA channel. This field is valid when the Q2DDMACH field is reset. The encoding is the same as Q3MDMACH of this register.
Q2DDMACH	23	rw	**Receive Queue 2 Enabled for Dynamic MA Channel Selection** When set, this bit indicates that each packet received in Receive Queue 2 is routed to a DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, the Ethernet DA address registers or VLAN filter registers. When reset, this bit indicates that all packets received in Receive Queue 2 are routed to the DMA Channel programmed in the Q2MDMACH field.
Q3MDMACH	26:24	rw	**Receive Queue 3 Mapped to DMA Channel** This field controls the routing of the received packet in Receive Queue 3 to the DMA channel. This field is valid when the Q3DDMACH field is reset. - 4'b0000: DMA Channel 0 - 4'b0001: DMA Channel 1 - 4'b0010: DMA Channel 2 - 4'b0011: DMA Channel 3 - 4'b0100: DMA Channel 4 - 4'b0101: DMA Channel 5 - 4'b0110: DMA Channel 6 - 4'b0111: DMA Channel 7
Q3DDMACH	31	rw	**Receive Queue 3 Enabled for Dynamic DMA Channel Selection** When set, each packet received in Receive Queue 3 is routed to a DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, the Ethernet DA address registers or VLAN filter registers. When reset, this bit indicates that all packets received in Receive Queue 3 are routed to the DMA Channel programmed in the Q3MDMACH field.
0	6:3, 14:11, 22:19, 30:27	r	**Reserved** Read as 0; should be written with 0.

14.6.507 Port j MTL RxQ DMA Map1

The Receive Queue and DMA Channel Mapping 1 register controls the static or dynamic mapping of Receive Queues 4-7 to Receive DMA Channels.

Portj_MTL_RxQ_DMA_Map1 (j=0-1) Offset address: $11034_H+j*2000_H$

Port j MTL RxQ DMA Map1 Kernel Reset value: $0000\ 0000_H$

rw	r				rw			rw	r				rw		

Field	Bits	Type	Description
Q4MDMACH	2:0	rw	**Receive Queue 4 Mapped to DMA Channel** This field controls the routing of the packet received in Receive Queue 4 to the DMA channel. This field is valid when the Q4DDMACH field is reset. The encoding is the same as Q3MDMACH of MTL_RxQ_DMA_Map0 register.
Q4DDMACH	7	rw	**Receive Queue 4 Enabled for Dynamic DMA Channel Selection** When set, this bit indicates that each packet received in Receive Queue 4 is routed to a DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, the Ethernet DA address or VLAN filter registers. When reset, this bit indicates that all packets received in Receive Queue 4 are routed to the DMA Channel programmed in the Q4MDMACH field.
Q5MDMACH	10:8	rw	**Receive Queue 5 Mapped to DMA Channel** This field controls the routing of the received packet in Receive Queue 5 to the DMA channel. This field is valid when the Q5DDMACH field is reset. The encoding is the same as Q3MDMACH of MTL_RxQ_DMA_Map0 register.
Q5DDMACH	15	rw	**Receive Queue 5 Enabled for Dynamic DMA Channel Selection** When set, this bit indicates that each packet received in Receive Queue 5 is routed to a DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, the Ethernet DA address registers or VLAN filter registers. When reset, this bit indicates that all packets received in Receive Queue 5 are routed to the DMA Channel programmed in the Q5MDMACH field.
Q6MDMACH	18:16	rw	**Receive Queue 6 Mapped to DMA Channel** This field controls the routing of the received packet in Receive Queue 6 to the DMA channel. This field is valid when the Q6DDMACH field is reset. The encoding is the same as Q3MDMACH of MTL_RxQ_DMA_Map0 register.

(table continues...)

(continued)

Field	Bits	Type	Description
Q6DDMACH	23	rw	**Receive Queue 6 Enabled for Dynamic MA Channel Selection** When set, this bit indicates that each packet received in Receive Queue 6 is routed to a DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, the Ethernet DA address registers or VLAN filter registers. When reset, this bit indicates that all packets received in Receive Queue 6 are routed to the DMA Channel programmed in the Q6MDMACH field.
Q7MDMACH	26:24	rw	**Receive Queue 7 Mapped to DMA Channel** This field controls the routing of the received packet in Receive Queue 7 to the DMA channel. This field is valid when the Q7DDMACH field is reset. The encoding is the same as Q3MDMACH of MTL_RxQ_DMA_Map0 register. The width of this field depends on the number of Receive DMA channels, therefore all values might not be valid in certain configurations. For example, if the number of Rx DMA channels selected is 2, the only valid values are 0 and 1. Other values are reserved.
Q7DDMACH	31	rw	**Receive Queue 7 Enabled for Dynamic DMA Channel Selection** When set, this bit indicates that each packet received in Receive Queue 7 is routed to a DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, the Ethernet DA address registers or VLAN filter registers. When reset, this bit indicates that all packets received in Receive Queue 7 are routed to the DMA Channel programmed in the Q7MDMACH field.
0	6:3, 14:11, 22:19, 30:27	r	**Reserved** Read as 0; should be written with 0.

14.6.508 Port j MTL TBS CTRL

This register controls the operation of Time Based Scheduling.

Portj_MTL_TBS_CTRL (j=0-1) Offset address: $11048_H+j*2000_H$

Port j MTL TBS CTRL Kernel Reset value: $0000\ 0000_H$

LEOS								0	LEGOS			0	TIEN	LEOV	ESTM
rw								r	rw			r	rw	rw	rw

Field	Bits	Type	Description
ESTM	0	rw	**EST offset Mode** When this bit is set, the Launch Time value used in Time Based Scheduling is interpreted as an EST offset value and is added to the Base Time Register (BTR) of the current list. When reset, the Launch Time value is used as an absolute value that must be compared with the System time [39:8]. 0_B **DISABLE**: EST offset Mode is disabled 1_B **ENABLE**: EST offset Mode is enabled
LEOV	1	rw	**Launch Expiry Offset Valid** When set indicates the LEOS field is valid. When not set, indicates the Launch Expiry Offset is not valid and the MTL must not check for Launch expiry time. 0_B **INVALID**: LEOS field is invalid 1_B **VALID**: LEOS field is valid
TIEN	2	rw	**TBS Interrupt Enable** When set indicates that TBS interrupt (occurs due to frame drop) is enabled. Value valid only when TIEN is set. 0_B **INVALID**: TBS interrupt is enabled 1_B **VALID**: TBS interrupt is disabled
LEGOS	6:4	rw	**Launch Expiry GSN Offset** The number of GSN slots that has to be added to the Launch GSN to compute the Launch Expiry time. Value valid only when LEOV is set.
LEOS	31:8	rw	**Launch Expiry Offset** The value in units of 256 nanoseconds that has to be added to the Launch time to compute the Launch Expiry time. A value of 0 means 256ns, 1 means 512ns and so on. Value valid only when LEOV is set. Max value: 999,999,999 ns, additionally must be smaller than CTR-1 value when ESTM mode is set, as this value is a modulo CTR value.
0	3, 7	r	**Reserved** Read as 0; should be written with 0.

14.6.509 Port j MTL TBS STATS

This register provides the One Hot encoded Queue numbers that have the frame drop related error.

Portj_MTL_TBS_STATS (j=0-1) Offset address: $1104C_H+j*2000_H$

Port j MTL TBS STATS Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
EDQN	7:0	rw	**Expiry drop Queue number** EDQN can have multiple bits set corresponding to the Queue numbers that have experienced error described in TINS field of MTL_Status register. Access restriction applies. Self-set to 1 on internal event. Clears on write of 1.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.510 Port j MTL EST Control

This register controls the operation of Time Aware Shaper conforming to Enhancements to Scheduled Transmission (IEEE 802.1Qbv) standard.

Portj_MTL_EST_Control (j=0-1) Offset address: $11050_H+j*2000_H$

Port j MTL EST Control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PTOV									CTOV						
rw									rw						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CTOV					TILS			LCSE		DFBS	DDBF	QHLBF	0	SSWL	EEST
rw					rw			rw		rw	rw	rw	r	rw	rw

Field	Bits	Type	Description
EEST	0	rw	**Enable EST** When this bit is set, the Time Aware Shaper algorithm gets activated in the Transmit scheduler. During the toggle from 0 to 1, the gate control list processing starts only after the SSWL bit is set. When this bit is reset, the EST function is disabled and all gates of teh GCL table are considered to be in Open state. If an uncorrectable error is detected in the GCL memory, DWC_xgmac resets this bit and disables the EST function. 0_B **DISABLE**: EST is disabled 1_B **ENABLE**: EST is enabled

(table continues...)

(continued)

Field	Bits	Type	Description
SSWL	1	rw	**Switch to software owned list** When this bit is set, the DWC_xgmac is instructed to switch to the new GCL list (SWOL) programmed in the GCL memory, at the start of new BTR. Hardware clears this bit when the switch to the SWOL is completed or an non-recoverable BTR error (BTRL = "11111111" indicates the iterations exceeded the value of 512 and DWC_xgmac was not able to update New BTR to be equal to or greater than Current Time.) is set. When BTRE is set this bit is cleared but SWOL is not updated as the switch was not successful. The write to this bit is effective only when EEST bit is set to 1 along with it or EEST bit is previously set to 1. Access restriction applies. Writing 1 sets the bit. Self-cleared. Writing 0 has no effect. 0_B **DISABLE**: Switch to S/W owned list is disabled 1_B **ENABLE**: Switch to S/W owned list is enabled
QHLBF	3	rw	**Quick Assertion of HLBF Error** When set, HLBF error is reported after the packet is not transmitted for 1 to 2 iterations of GCL list. When this bit is reset, the HLBF error is reported after the packet is not transmitted for 2 to 3 iterations of GCL list. 0_B **DISABLE**: Disable Quick assertion of HLBF error 1_B **ENABLE**: Quick Assertion of HLBF Error
DDBF	4	rw	**Do not Drop frames due to HLBF error** When this bit is set, frames that are not scheduled for transmission because its size is larger than the Gate Open time window, are not dropped. This can result in head-of-line blocking in the corresponding TX Queue. When this bit is reset, frames that do not get scheduled for transmission due to HLBF error after the completion of the number of GCL Table iterations as set in QHLBF. 0_B **DROP**: Drop frames due to HLBF error 1_B **DONT_DROP**: Do not Drop frames due to HLBF error
DFBS	5	rw	**Drop Frames causing Scheduling Error** When this bit is set, frames that do not get scheduled for transmission after the number of GCL iterations as set in LCSE, are dropped. When this bit is reset, frames are not dropped due to any TAS scheduling conflicts or delays (HLBS). This can create HOL (head-of-line) blocking in the transmit queue. 0_B **DONT_DROP**: Do not Drop Frames causing Scheduling Error 1_B **DROP**: Drop Frames causing Scheduling Error

(table continues...)

(continued)

Field	Bits	Type	Description
LCSE	7:6	rw	**Loop Count to report Scheduling Error** Programmable number of GCL list iterations before reporting an HLBS error defined in EST_Status register. 00_B **M_4_ITERNS**: 4 iterations 01_B **M_8_ITERNS**: 8 iterations 10_B **M_16_ITERNS**: 16 iterations 11_B **M_32_ITERNS**: 32 iterations
TILS	10:8	rw	**Time Interval Left Shift Amount** This field provides the left shift amount for the programmed Time Interval values used in the Gate Control Lists. - 000: No left shift needed (equal to x1ns) - 001: Left shift TI by 1 bit (equal to x2ns) - 010: Left shift TI by 2 bits (equal to x4ns) - ... - 111: Left shift TI by 7 bits (equal to x128ns) Based on the configuration, one or more bits of this field must be treated as Reserved/Read-Only.
CTOV	22:11	rw	**Current Time Offset Value** Provides a 12 bit time offset value in nanosecond that is added to the current time to compensate for all the implementation pipeline delays such as the CDC sync delay, buffering delays, data path delays, and so on. This offset helps to ensure that the impact of gate controls is visible on the line exactly at the pre-determined schedule (or as close to the schedule as possible).
PTOV	31:23	rw	**PTP Time Offset Value** The value of PTP Clock period multiplied by 9 in nanoseconds. This value is needed to avoid transmission overruns at the beginning of the installation of a new GCL.
0	2	r	**Reserved** Read as 0; should be written with 0.

14.6.511 Port j MTL EST Overhead

This register indicates the value of Overhead in bytes to be considered for EST Scheduling.

Portj_MTL_EST_Overhead (j=0-1) Offset address: $11054_H+j*2000_H$

Port j MTL EST Overhead Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0											ABYT				
r											rw				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0								OVHD							
r								rw							

Field	Bits	Type	Description
OVHD	7:0	rw	**Overhead Bytes Value** This field should be programmed with the delay in bytes between the point at which a packet is selected for transmission by the EST scheduler and time at which the Start of Packet appears on the XGMII/ GMII TX interface. This value differs based on the operating speed and configuration. The value to be programmed is provided in Table "Overheads to be Accounted in the EST Overhead Field".
ABYT	20:16	rw	**Bytes transmitted in 1 application clock** This field should be programmed with the number of bytes transmitted on XGMII/GMII interface in the time window corresponding to 1 application clock period. For Example: if Time period of Application clock is 6.4 ns and speed mode is XGMII 10G, the programmed value must be, ((6.4)/(3.2)* (Number of Bytes in 1 Tx clock =4) = 8. (for values greater 0.5, round it off to 1)
0	15:8, 31:21	r	**Reserved** Read as 0; should be written with 0.

14.6.512 Port j MTL EST Status

This register reports the events related to Enhancements to Scheduled Transmission (IEEE 802.1Qbv).

Portj_MTL_EST_Status (j=0-1) Offset address: $11058_H+j*2000_H$

Port j MTL EST Status Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0												CGSN			
r												r			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BTRL								SWOL	0		CGCE	HLBS	HLBF	BTRE	SWLC
r								r	r		rw	r	r	rw	rw

Field	Bits	Type	Description
SWLC	0	rw	**Switch to Software Owned List Complete** When this field is set, indicates that DWC_xgmac has successfully switched to the SWOL, and the SWOL bit is updated to that effect. This field is cleared when the SSWL field of EST_Control register transitions from 0 to 1, or when a 1 is written to this bit. Access restriction applies. Self-set to 1 on internal event. Clears on write of 1. Writing 0 has no effect. 0_B **INACTIVE**: Switch to S/W owned list Complete not detected 1_B **ACTIVE**: Switch to S/W owned list Complete detected

(table continues...)

(continued)

Field	Bits	Type	Description
BTRE	1	rw	**BTR Error** When this field is set, indicates a programming error in the BTR of SWOL where the programmed value is less than current time. If the BTRL = "11111111", SWOL is not updated and software must reprogram the BTR to a value greater than current time and set the SSWL bit to re-initiate the switch to SWOL. Access restriction applies. Self-set to 1 on internal event. Self clear or clears on write of 1. Writing 0 has no effect. 0_B **INACTIVE**: BTR Error not detected 1_B **ACTIVE**: BTR Error detected
HLBF	2	r	**Head-Of-Line Blocking due to Frame Size** This field is set when HOL Blocking is noticed on one or more Queues when none of the Time Intervals of open-gates in the GCL is greater than or equal to the duration needed for frame (or frame fragment size when preemption is enabled) transmission. The one-hot encoded Queue numbers that are experiencing HLBF are indicated in the MTL_EST_Frm_Size_Error register. Additionally, the first Queue number that experienced HLBF along with the frame size is captured in MTL_EST_Frm_Size_Capture register. Bit cleared when MTL_EST_Frame_Size_Error register is all zeros. 0_B **INACTIVE**: Head-Of-Line Blocking due to Frame Size not detected 1_B **ACTIVE**: Head-Of-Line Blocking due to Frame Size detected
HLBS	3	r	**Head-Of-Line Blocking due to Scheduling** When set, it indicates that a packet is not able to get scheduled by EST even after LCSE number of GCL iterations has elapsed. Indicates to software a potential programming error. The one-hot encoded values of the Queue Numbers that have such packets blocking the queue, are indicated in the MTL_EST_Sch_Error register. Bit cleared when MTL_EST_Sch_Error register is all zeros. Note: A single fixed reference or tic is generated at integral multiple of MTL_EST_Control.LCSE loops/iterations. The HLBS is generated after (MTL_EST_Control.LCSE + N) loops/iterations, where N is non-integral number of MTL_EST_Control.LCSE loops/iterations the packet could not be scheduled before the last 2 tics. 0_B **INACTIVE**: Head-Of-Line Blocking due to Scheduling not detected 1_B **ACTIVE**: Head-Of-Line Blocking due to Scheduling detected
CGCE	4	rw	**Constant Gate Control Error** This error occurs when the programmed Time Interval (TI) value after the optional Left Shifting is more than or equal to the Cycle Time (CTR). Programming a GCL row's time interval TI greater than CTR is equivalent of always closing or opening of certain Transmit queues which can be done by disabling or enabling the required open or closed queues without enabling EST. Due to this reason, such a programming is treated as Error. Access restriction applies. Self-set to 1 on internal event. Clears on write of 1. Writing 0 has no effect. 0_B **INACTIVE**: Constant Gate Control Error not detected 1_B **ACTIVE**: Constant Gate Control Error detected

(table continues...)

(continued)

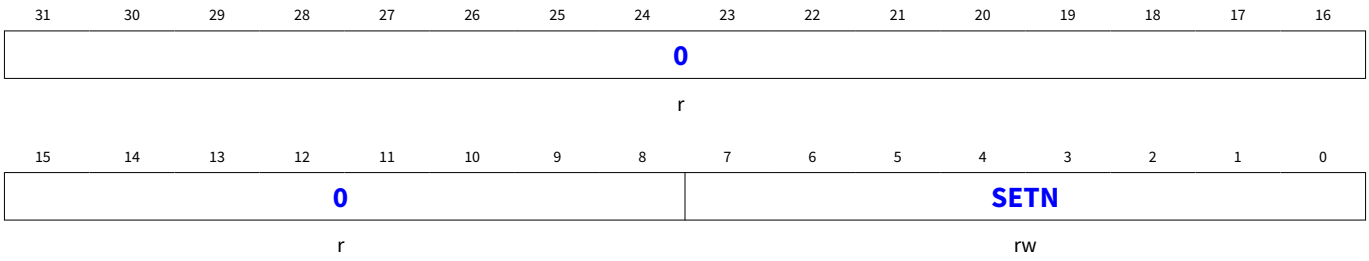
Field	Bits	Type	Description
SWOL	7	r	**Software Owned List** When this field is 0, indicates that the Gate control list number 0 is owned by software. When this field is 1, indicates that the Gate Control list 1 is owned by the software. Any reads/writes by the software (using indirect access through GCL_Control) is directed to the list indicated by this value. The inverse of this value is treated as HWOL. R/W operations performed by DWC_xgmac are directed to the list pointed by HWOL. Values: - 0x0: Gate control list number "0" is owned by software - 0x1: Gate control list number "1" is owned by software
BTRL	15:8	r	**BTR Loop Count** This field provides the number of GCL cycle times after which the switch to new SWOL GCL occurs after SSWL is set. It is determined by the value N which satisfies the equation "Current Time is less than or equal to New BTR + (N * 4 * New Cycle Time)". N = "11111111" indicates that the iterations exceeded the value of 512 and DWC_xgmac is unable to update New BTR to be equal to or greater than Current Time. Software intervention is needed to update the New BTR. This field is cleared when BTRE field of this register is cleared.
CGSN	19:16	r	**Current GCL Slot Number** Indicates the slot number of the GCL list. Slot number is a modulo 16 count of the GCL List loops executed so far. Even if a new GCL list is installed, the count is incremental.
0	6:5, 31:20	r	**Reserved** Read as 0; should be written with 0.

14.6.513 Port j MTL EST Sch Error

This register provides the Traffic Class numbers that have the GCL scheduling related error.

Portj_MTL_EST_Sch_Error (j=0-1) Offset address: $11060_H+j*2000_H$

Port j MTL EST Sch Error Kernel Reset value: $0000\ 0000_H$



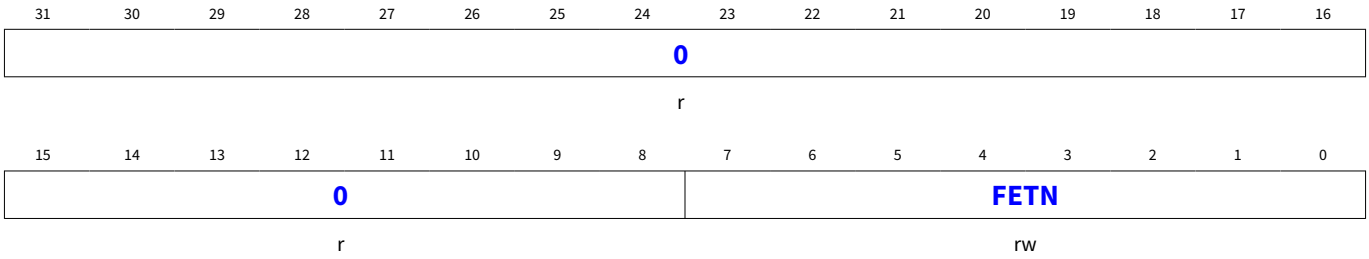
Field	Bits	Type	Description
SETN	7:0	rw	**Schedule Error TC Number** SETN can have multiple bits set corresponding to the TC numbers that have experienced error described in HLBS field of status register. Bit 0 corresponds to TC0, Bit 1 corresponds to TC1, and so on. Access restriction applies. Self-set to 1 on internal event. Clears on write of 1. Writing 0 has no effect.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.514 Port j MTL EST Frm Size Error

This register provides the Traffic Class numbers that have the Frame Size related scheduling error.

Portj_MTL_EST_Frm_Size_Error (j=0-1) Offset address: $11064_H+j*2000_H$

Port j MTL EST Frm Size Error Kernel Reset value: $0000\ 0000_H$



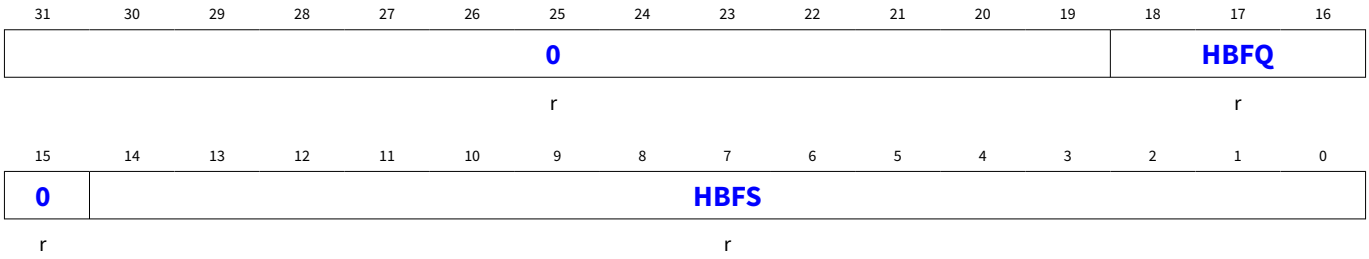
Field	Bits	Type	Description
FETN	7:0	rw	**Frame Size Error TC Number** FETN can have multiple bits set corresponding to the TC numbers that have experienced error described in HLBF field of status register. Bit 0 corresponds to TC0, Bit 1 corresponds to TC1, and so on. Access restriction applies. Self-set to 1 on internal event. Clears on write of 1. Writing 0 has no effect.
0	31:8	r	**Reserved** Read as 0; should be written with 0.

14.6.515 Port j MTL EST Frm Size Capture

This register captures the Frame Size and Traffic Class Number of the first occurrence of the Frame Size related error. Upon clearing, this register captures the data of the next occurrence of a similar error.

Portj_MTL_EST_Frm_Size_Capture (j=0-1) Offset address: $11068_H+j*2000_H$

Port j MTL EST Frm Size Capture Kernel Reset value: $0000\ 0000_H$



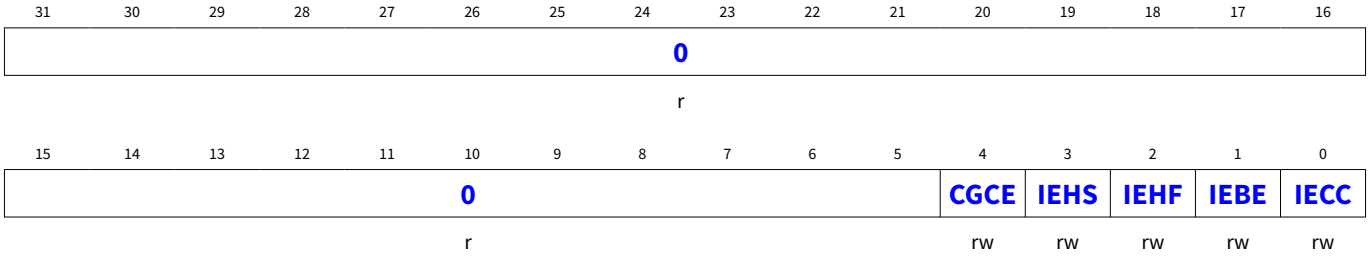
Field	Bits	Type	Description
HBFS	14:0	r	**Frame Size of HLBF** Captures the Frame Size of the frame present in the queue number indicated by HBFQ field of this register. Contents of this register must be considered invalid, if this field is zero. Cleared when MTL_EST_Frm_Size_Error register is all zeros.
HBFQ	18:16	r	**Transmit Queue Number of HLBF** Captures the binary value of the first Transmit Queue experiencing HLBF error (see HLBF field of MTL_EST_status register). Value once written is not altered by any subsequent queue errors of similar nature. Once cleared, the queue number of the next occurring HLBF error is captured. Cleared when MTL_EST_Frm_Size_Error register is all zeros.
0	15, 31:19	r	**Reserved** Read as 0; should be written with 0.

14.6.516 Port j MTL EST Intr Enable

This register implements the Interrupt Enable bits for the various events in the EST scheduler. Bit positions have a 1- to-1 correspondence with the status bit positions in MTL_EST_Status register.

Portj_MTL_EST_Intr_Enable (j=0-1) Offset address: $11070_H+j*2000_H$

Port j MTL EST Intr Enable Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
IECC	0	rw	**Interrupt Enable for Switch List** When set, generates interrupt when the GCL Table switch is successful. When reset, this event does not generate an interrupt. 0_B **DISABLE**: Interrupt for Switch List is disabled 1_B **ENABLE**: Interrupt for Switch List is enabled

(table continues...)

(continued)

Field	Bits	Type	Description
IEBE	1	rw	**Interrupt Enable for BTR Error** When set, generates interrupt when the BTR Error occurs and is indicated in the status. When reset, this event does not generate an interrupt. 0_B **DISABLE**: Interrupt for BTR Error is disabled 1_B **ENABLE**: Interrupt for BTR Error is enabled
IEHF	2	rw	**Interrupt Enable for HLBF** When set, generates interrupt when HLBS status bit is set. When reset, this event does not generate an interrupt. 0_B **DISABLE**: Interrupt for HLBF is disabled 1_B **ENABLE**: Interrupt for HLBF is enabled
IEHS	3	rw	**Interrupt Enable for HLBS** When set, generates interrupt when HLBS status bit is set. When reset, this event does not generate an interrupt. 0_B **DISABLE**: Interrupt for HLBS is disabled 1_B **ENABLE**: Interrupt for HLBS is enabled
CGCE	4	rw	**Interrupt Enable for CGCE** When set, generates interrupt when the Constant Gate Control Error occurs and is indicated in the status. When reset, this event does not generate an interrupt. 0_B **DISABLE**: Interrupt for CGCE is disabled 1_B **ENABLE**: Interrupt for CGCE is enabled
0	31:5	r	**Reserved** Read as 0; should be written with 0.

14.6.517 Port j MTL GCL Control

This register provides the control for reading/writing to the Gate Control lists.

Portj_MTL_GCL_Control (j=0-1) Offset address: $11080_H+j*2000_H$

Port j MTL GCL Control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								GCLEIEC	GCLEIAEE	GCLEIEE	0				
r								rw	rw	rw	r				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR								0		DBGB	DBGM	GCLS	GCRR	R1W0	SRWO
rw								r		rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
SRWO	0	rw	**Start Read/Write Op - When this field is set, indicates that a Read/ Write operation has started and is in progress** - When this field is reset by DWC_xgmac, indicates that the R/W operation is complete or an error has occurred. - Reads: Data can be read from MTL_GCL_Data register after this bit is reset. - Writes: MTL_GCL_Data must be programmed with write data before setting SRWO bit. Access restriction applies. Writing 1 sets the bit. Self-cleared. Writing 0 has no effect. 0_B **DISABLE**: Start Read/Write Op disabled 1_B **ENABLE**: Start Read/Write Op enabled
R1W0	1	rw	**Read 1, Write 0: - When set to 1: Read Operation - When set to 0: Write Operation** 0_B **WRITE**: Write Operation 1_B **READ**: Read Operation
GCRR	2	rw	**Gate Control Related Registers** When this field is set to 1, indicates that the R/W access is for the GCL related registers (BTR, CTR, TER, LLR) whose address is provided by GCRA. When 0, indicates that R/W must be directed to GCL from the address provided by GCLA.
GCLS	3	rw	**Gate Control/Address Select** When set to "1" indicates the SGF R/W access for the GCL related registers/GCL memory. When set to "0" indicates the EST R/W access for the GCL related registers/GCL memory.
DBGM	4	rw	**Debug Mode** When this field is set to 1, indicates R/W in debug mode where the memory bank (for GCL and Time related registers) is explicitly provided by DBGB value. When set to 0, SWOL bit is used to determine which bank to access. 0_B **DISABLE**: Debug Mode is disabled 1_B **ENABLE**: Debug Mode is enabled
DBGB	5	rw	**Debug Mode Bank Select** When this field is set to 0, indicates R/W in debug mode must be directed to Bank 0 (GCL0 and corresponding Time related registers). When set to 1, indicates R/W in debug mode must be directed to Bank 1 (GCL1 and corresponding Time related registers). This value is used when DBGM is set and overrides the value of SWOL, which is normally used. 0_B **BANK0**: R/W in debug mode should be directed to Bank 0 1_B **BANK1**: R/W in debug mode should be directed to Bank 1

(table continues...)

(continued)

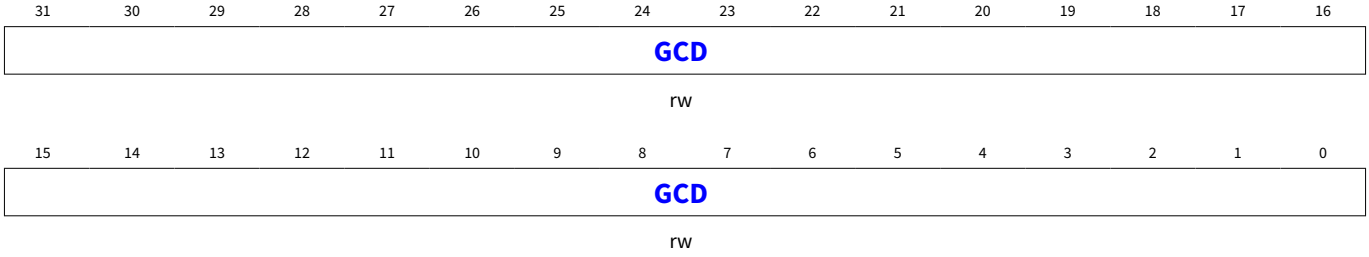
Field	Bits	Type	Description
ADDR	15:8	rw	**Gate Control List Address: (GCLA when GCRR is 0)** Provides the address (row number) of the Gate Control List at which the R/W operation has to be performed. By default the Gate Control List pointed by SWOL of MTL_EST_Status is selected for R/W. However, if the DBGM bit of this register is set, a debug mode access is given to R/W from DBGB. Gate Control list Related Registers Address: (GCRA when GCRR is 1). By default, the GCL related register set pointed by SWOL of MTL_EST_Status is selected for R/W. However, if the DBGM bit of this register is set, a debug mode access is given to R/W from DBGB. Only the lower 3 bits are used in this mode. Higher order bits are treated as dont care values. - 000: BTR Low (31:0) - 001: BTR High (63:31) - 010: CTR Low (31:0) - 011: CTR High (39:32) - 100: TER (30:0) - 101: LLR (8:0) - Others: Reserved Range Variable[x]:15
GCLEIEE	21	rw	**GCL ECC Inject Error Enable** When set along with EEST bit of MTL_EST_Control register, enables the ECC error injection feature. If GCLEIAEE is set, enables the ECC Address Error Injection, otherwise, error is injected in address bus, otherwise error is injected in Data/ECC bits to teh GCL memory. When reset, disables the ECC error injection feature. 0_B **DISABLE**: GCL ECC Inject Error is disabled 1_B **ENABLE**: GCL ECC Inject Error is enabled
GCLEIAEE	22	rw	**GCL ECC Inject Address Error** When this bit is set, error injection (when triggered by GCLEIEE) is done in Address bus to GCL memory. When this bit is reset, error is injected in the data bus to GCL memory.
GCLEIEC	23	rw	**ECC Inject Error Control for GCL Memory** When GCLEIEE bit of this register is set, ECC error is injected based on the value encoded in this field. 0_B **M_1BIT**: Insert 1 bit error 1_B **M_2BIT**: Insert 2 bit errors
0	7:6, 20:16, 31:24	r	**Reserved** Read as 0; should be written with 0.

14.6.518 Port j MTL GCL Data

This register holds the read data or write data in case of reads and writes respectively.

Portj_MTL_GCL_Data (j=0-1) Offset address: $11084_H+j*2000_H$

Port j MTL GCL Data Kernel Reset value: $0000\ 0000_H$



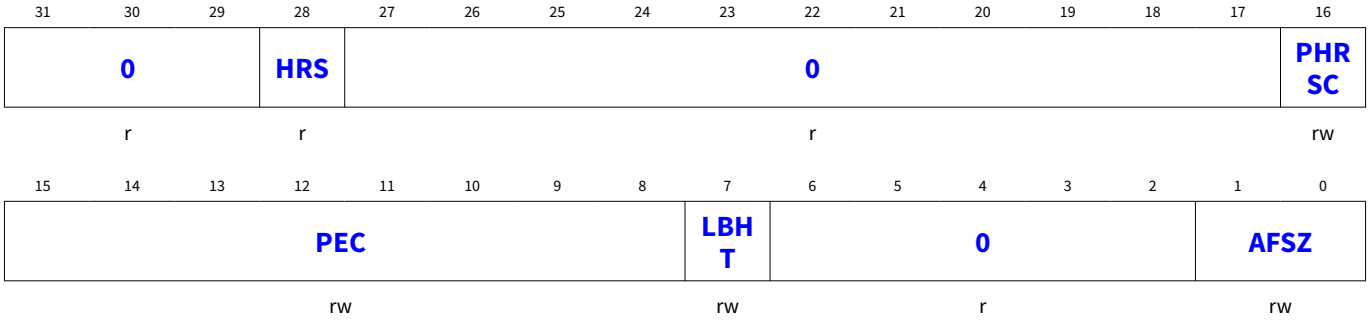
Field	Bits	Type	Description
GCD	31:0	rw	**Gate Control Data** The data corresponding to the address selected in the GCL_Control register. Used for both Read and Write operations.

14.6.519 Port j MTL FPE CTRL STS

This register controls the operation of, and provides status for Frame Preemption (IEEE 802.1Qbu/802.3br).

Portj_MTL_FPE_CTRL_STS (j=0-1) Offset address: $11090_H+j*2000_H$

Port j MTL FPE CTRL STS Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
AFSZ	1:0	rw	**Additional Fragment Size** Used to indicate, in units of 64 bytes, the minimum number of bytes over 64 bytes required in non-final fragments of preempted frames. The minimum non-final fragment size is (AFSZ +1) * 64 bytes
LBHT	7	rw	**Level Based Hold Transition** When set to 1, enables hold operation in second row of EST GCL during non-first loop even when hold request is set in first row, that is there is no release request to hold request transition. When set to 0, enables hold operation in second row of EST GCL only on transition from release request to hold request.

(table continues...)

(continued)

Field	Bits	Type	Description
PEC	15:8	rw	**Preemption Classification** This controls whether a traffic class is marked as preemptable or express. Each bit corresponds to a TC (Bit8 is TC0, Bit9 is TC1, and so on). When a bit is set, the corresponding TC is marked as preemptable. When bit is 0, that traffic class is marked as express packets. When both EST (Qbv) and Preemption are enabled, TC0 is always assumed to be preemptable. When EST (Qbv) is enabled, traffic class categorized as preemptable here are always assumed to be in "Open" state in the Gate Control List.
PHRSC	16	rw	**Preemption MAC Hold/Release Sideband Control Select - 1: Indicates that Set-Hold-and-Release-MAC operation is controlled by Sideband Signal sbd_pmac_hold_i** - 0: Indicates that Set-Hold-and-Release-MAC operation is controlled by IEEE 802.1Qbv Enhancement to Scheduled Traffic (EST) Gate Control List (GCL) entries.
HRS	28	r	**Hold/Release Status - 1: Indicates a Set-and-Hold-MAC operation was executed and the pMAC is in Hold State** - 0: Indicates a Set-and-Release-MAC operation was executed and the pMAC is in Release State. 0_B **SET_REL**: Indicates a Set-and-Release-MAC operation was executed and the pMAC is in Release State 1_B **SET_HOLD**: Indicates a Set-and-Hold-MAC operation was executed and the pMAC is in Hold State
0	6:2, 27:17, 31:29	r	**Reserved** Read as 0; should be written with 0.

14.6.520 Port j MTL FPE Advance

This register holds the Hold and Release Advance time.

Portj_MTL_FPE_Advance (j=0-1) Offset address: $11094_H+j*2000_H$

Port j MTL FPE Advance Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RADV															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HADV															
rw															

Field	Bits	Type	Description
HADV	15:0	rw	**Hold Advance** The maximum time in nanoseconds that can elapse between issuing a HOLD to the MAC and the MAC ceasing to transmit any preemptable frame that is in the process of transmission or any preemptable frames that are queued for transmission.
RADV	31:16	rw	**Release Advance** The maximum time in nanoseconds that can elapse between issuing a RELEASE to the MAC and the MAC being ready to resume transmission of preemptable frames, in the absence of there being any express frames available for transmission.

14.6.521 Port j MTL RXP Control Status

This is the Control and Status register for Flexible Receive Parser.

Portj_MTL_RXP_Control_Status (j=0-1) Offset address: $110A0_H+j*2000_H$

Port j MTL RXP Control Status Kernel Reset value: $40FF\ 00FF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RXPI	PIPE			0			0	NPE							
r	r			r			r	rw							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	FPE_RCH			OKI_DME	0	0	0	NVE							
r	rw			rw	r	r	r	rw							

Field	Bits	Type	Description
NVE	7:0	rw	**Number Valid Entries in the Instruction table** This field indicates the last valid entry in the Instruction Table. This is used by the Rx-Parser logic to detect programming errors. While parsing the table, if the address becomes greater than this entry, NVEOVIS bit in the MTL_RXP_Interrupt_Control_Status register is set. Note: - Value of 0 implies, 1st Instruction; a value of 255 implies 256th instruction. - Program this field with a value between 0 and 255. Read the value after programming this field.
OKI_DME	11	rw	**Instruction's OK Index Dual Meaning Enable** When this bit is set to 1, the OKI field in the Instruction can be interpreted also as Policing Counter Number/Valid or Gate ID/Valid when SGF or PC functions are enabled. For more detail refer respective feature section. When this bit is reset, the OKI field interpretation is always "OK Index".

(table continues...)

(continued)

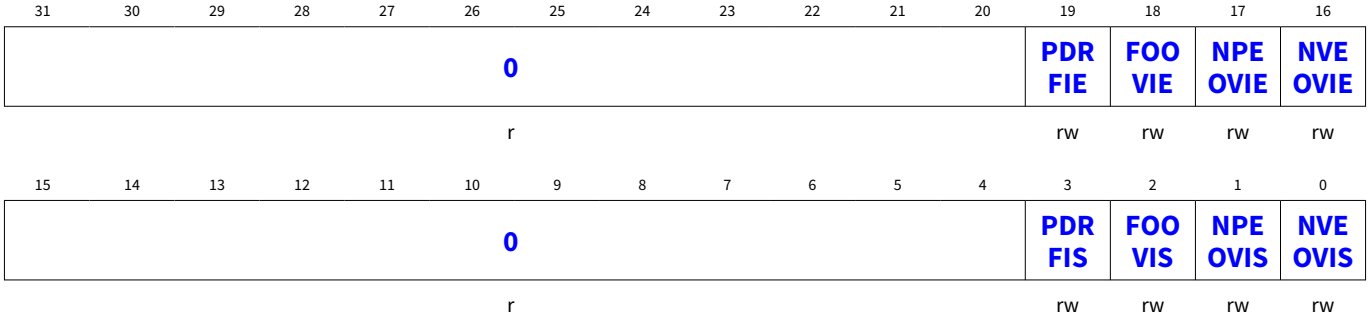
Field	Bits	Type	Description
FPE_RCH	14:12	rw	**Frame Preemption Residue Receive DMA Channel** This field holds the Rx Channel number to which the residual preemption frames must be forwarded. Preemption frames which pass Rx Parser filtering, are routed based on Instruction Table. All other frames are treated as residual frames and are routed to the channel number mentioned in this field. Channel-0 is used as a default Channel for express residual frames, so this field must not be programmed to a value 0.
NPE	23:16	rw	**Number of Parsable Entries in the Instruction Table** This field indicates the number of parsable entries in the Instruction Table. This field is used in Rx-Parser logic to detect programming error. If the number of parsed entries for a packet is more than this value, NPEOVIS bit in the MTL_RXP_Interrupt_Control_Status register is set. Note: - A value of 0 value implies 1 Instruction. Value of 255 implies 256 instructions. - Program this field with a value between 0 and 255.Read the value after programming this field.
PIPE	30:28	r	**Number of Parallel Instruction Processor Engines** This field is read-only.
RXPI	31	r	**Rx Parser is Active** This status bit is set to 1 when the Rx parser is in Active state. This bit can be used as a handshake with the software when the parser gets disabled/enabled. 0_B **INACTIVE**: Rx Parser is not Active 1_B **ACTIVE**: Rx Parser is Active
0	8, 9, 10, 15, 24, 27:25	r	**Reserved** Read as 0; should be written with 0.

14.6.522 Port j MTL RXP Interrupt Control Status

This is Interrupt Control and Status register for Flexible Receive Parser.

Portj_MTL_RXP_Interrupt_Control_Status (j=0-1) Offset address: $110A4_H+j*2000_H$

Port j MTL RXP Interrupt Control Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
NVEOVIS	0	rw	**Number of Valid Entries Overflow Interrupt Status** While parsing, if the instruction address is found to be more than NVE (Number of Valid Entries in MTL_RXP_Control register), this bit is set to 1. This bit is cleared when the software writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Clears on write of 1. Writing 0 has no effect. 0_B **INACTIVE**: Number of Valid Entries Overflow Interrupt Status not detected 1_B **ACTIVE**: Number of Valid Entries Overflow Interrupt Status detected
NPEOVIS	1	rw	**Number of Parsable Entries Overflow Interrupt Status** While parsing, if the number of parsed entries is found to be more than NPE[] (Number of Parsable Entries in MTL_RXP_Control register), this bit is set to 1. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Clears on write of 1. Writing 0 has no effect. 0_B **INACTIVE**: Number of Parsable Entries Overflow Interrupt Status not detected 1_B **ACTIVE**: Number of Parsable Entries Overflow Interrupt Status detected
FOOVIS	2	rw	**Frame Offset Overflow Interrupt Status** During parsing, if the Instruction table entry's 'Frame Offset' is found to be more than EOF offset, this bit is set. This bit is cleared when the software writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Clears on write of 1. Writing 0 has no effect. 0_B **INACTIVE**: Frame Offset Overflow Interrupt Status not detected 1_B **ACTIVE**: Frame Offset Overflow Interrupt Status detected
PDRFIS	3	rw	**Packet Dropped due to RF Interrupt Status** When the Rx-Parser requests a packet-drop (by setting RF=1 in the instruction table), this bit is set to 1. This bit is cleared when the software writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Clears on write of 1. Writing 0 has no effect. 0_B **INACTIVE**: Packet Dropped due to RF Interrupt Status not detected 1_B **ACTIVE**: Packet Dropped due to RF Interrupt Status detected

(table continues...)

(continued)

Field	Bits	Type	Description
NVEOVIE	16	rw	**Number of Valid Entries Overflow Interrupt Enable** When this bit is set, the interrupt is asserted when NVEOVIS bit is set. When this bit is reset, the interrupt is not asserted when NVEOVIS is set. 0_B **DISABLE**: Last valid instruction Overflow Interrupt is disabled 1_B **ENABLE**: Last valid instruction Overflow Interrupt is enabled
NPEOVIE	17	rw	**Number of Parsable Entries Overflow Interrupt Enable** When this bit is set, the interrupt is asserted when NPEOVIS bit is set. When this bit is reset, the interrupt is not asserted when NPEOVIS is set. 0_B **DISABLE**: Number of Parsable Instructions Overflow Interrupt is disabled 1_B **ENABLE**: Number of Parsable Instructions Overflow Interrupt is enabled
FOOVIE	18	rw	**Frame Offset Overflow Interrupt Enable** When this bit is set, the interrupt is asserted when FOOVIS bit is set. When this bit is reset, the interrupt is not asserted when FOOVIS is set. 0_B **DISABLE**: Frame Offset Overflow Interrupt is disabled 1_B **ENABLE**: Frame Offset Overflow Interrupt is enabled
PDRFIE	19	rw	**Packet Drop due to RF Interrupt Enable** When this bit is set, the interrupt is asserted when PDRFIS bit is set. When this bit is reset, the interrupt is not asserted when PDRFIS is set. 0_B **DISABLE**: Packet Drop due to RF Interrupt is disabled 1_B **ENABLE**: Packet Drop due to RF Interrupt is enabled
0	15:4, 31:20	r	**Reserved** Read as 0; should be written with 0.

14.6.523 Port j MTL Indirect Acc Control Status

This is Control register to access the MTL indirect registers/tables.

Portj_MTL_Indirect_Acc_Control_Status (j=0-1) Offset address: $110B0_H+j*2000_H$

Port j MTL Indirect Acc Control Status Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
STARTBUSY	0					ACCSEL		0	RXPEIEC		RXPEIEE	0	CRWEN	CRWSEL	WRRDN
rw	r					rw		r	rw		rw	r	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0						ADDR									
r						rw									

Field	Bits	Type	Description
ADDR	9:0	rw	**Indirect Access Write/Read Address** This field indicates the address of each 32-bit data/register of the selected ACCSEL. ACCSEL Value Usage of this Field - ACC_IT: used for Instruction Table's 32 bits data word address. - ACC_IFR: used for Indirect FRP Register Block. Indirect FRP Register Block Address Map. 1) 0x0 : For MTL_RXP_Drop_Cnt. 2) 0x1 : For MTL_RXP_Error_Cnt. 3) 0x2 : For MTL_RXP_Bypass_Cnt. 4) 0x40 + (0x10 * i + 0x0): For MTL_FRP_ACNTR, where i = 0 to DWCXG_FRP_NUM_AC-1. 5) 0x40 + (0x10 * i + 0x2): For MTL_FRP_ACNTR_CNFG, where i = 0 to DWCXG_FRP_NUM_AC-1. Note: Use valid address according to the ACCSEL selection. Software shall write this before issuing any Read/Write command.
WRRDN	16	rw	**Read Write Control** When this bit is set to 1, indicates the write operation is selected for ACCSEL. When this bit is set to 0, indicates the read operation is selected for ACCSEL. 0_B **READ**: Read operation to ACCSEL 1_B **WRITE**: Write operation to ACCSEL
CRWSEL	17	rw	**Continuous Read/Write Mode Select** This field is valid only when Instruction Table (ACC_IT), ACC_RCHLIST or ACC_MMC is selected in ACCSEL field. When CRWEN is set, CRWSEL is valid. Software can select which continuous mode to use, either Write or Read. 0_B **READ**: Continuous Read 1_B **WRITE**: Continuous Write
CRWEN	18	rw	**Continuous Read/Write Mode Enable** This field is valid only when Instruction Table (ACC_IT) or ACC_RCHLIST is selected in the ACCSEL field. When this bit is set, continuous read/write mode is enabled. CRWSEL selects either Read or Write continuous mode. In this mode, software has to set ADDR, STARTBUSY once. For subsequent write/read operations, it is not required to set ADDR and STARTBUSY. The hardware automatically triggers the read or write access to the next address when the MTL_Indirect_Acc_Data register is read or written. To disable this mode, set this bit to 0. Note: Byte-wise Write/Read is not supported. 0_B **DISABLE**: Disabled Continuous Read/Write Mode 1_B **ENABLE**: Enabled Continuous Read/Write Mode

(table continues...)

(continued)

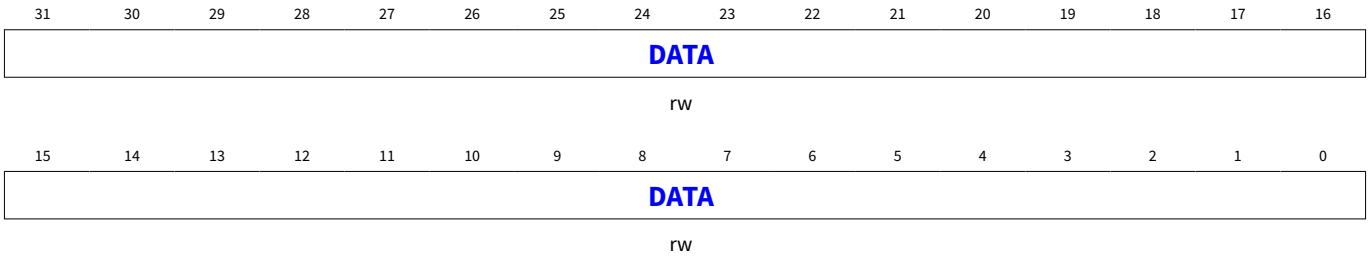
Field	Bits	Type	Description
RXPEIEE	20	rw	**ECC Inject Error Enable** This field is valid only when Instruction Table (ACC_IT) is selected in ACCSEL field. When set, enables the ECC error injection feature. When reset, disables the ECC error injection feature. Note: Hardware injects error when this bit is set and software initiates read access to Rx Parser Instruction Table. 0_B **DISABLE**: ECC Inject Error for ACCSEL is disabled 1_B **ENABLE**: ECC Inject Error for ACCSEL is enabled
RXPEIEC	22:21	rw	**ECC Inject Error Control** This field is valid only when Instruction Table (ACC_IT) is selected in the ACCSEL field. When RXPEIEE bit of this register is set, following errors are inserted based on the value encoded in this field. 00_B **D_1BIT**: Insert 1 bit ECC error in data or parity 01_B **D_2BIT**: Insert 2 bit ECC error in data or parity 10_B **A_1BIT**: Insert 1 bit ECC error in address 11_B **RSVD**: Reserved
ACCSEL	25:24	rw	**Indirect Access Selection** This field is used to select the indirect table/register block to access. Software can select what to access from following selection option: - 0x0: ACC_IT, Access FRP Instruction Table. - 0x1: ACC_IFR, Access Indirect FRP Register block. - 0x2: Reserved. - 0x3: Reserved.
STARTBUSY	31	rw	**Indirect Access Busy** When this bit is set to 1 by the software, it indicates to start the Read/ Write operation from/to selected ACCSEL. Software must read this bit as 0 before issuing read or write request to access the selected ACCSEL. This bit is cleared by DWC_xgmac when the the read/write transaction is completed. Software must not issue the next read or write operation, until this bit is cleared. 0_B **INACTIVE**: Read/Write transaction complete and Idle 1_B **ACTIVE**: Read/Write transaction is active
0	15:10, 19, 23, 30:26	r	**Reserved** Read as 0; should be written with 0.

14.6.524 Port j MTL Indirect Acc Data

This is the data register to Access MTL indirect registers/tables.

Portj_MTL_Indirect_Acc_Data (j=0-1) Offset address: $110B4_H+j*2000_H$

Port j MTL Indirect Acc Data Kernel Reset value: $0000\ 0000_H$



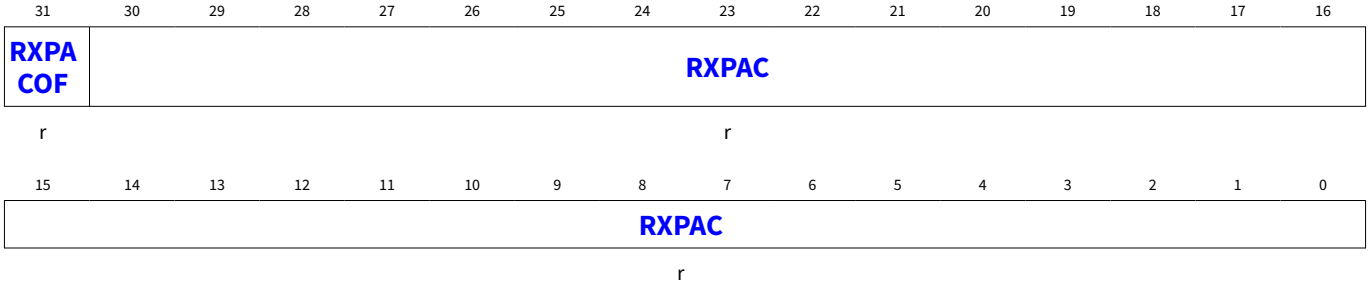
Field	Bits	Type	Description
DATA	31:0	rw	**Indirect Access Write/Read Data** Software must write this register before issuing any write command. DWC_xgmac provides the read data from selected ACCSEL for read operation when STARTBUSY =0 after read command.

14.6.525 Port j MTL FRP ACNTR0

The MTL_FRP_ACNTR(#i) registers are indirect and provide the count of the number of frames accepted by FRP particular to channel. Such accept counters mapping with receive channel is static, one to one, if supported number of receive channels are less than or equal to 16. Otherwise if it is more than 16 then, FRP implements fix number of accept counters and provides programmable option to application to map it to application-specific receive channel via corresponding MTL_FRP_ACNTR_CNFG(#i) indirect registers. These indirect registers can be accessible through MTL_Indirect_Acc_Control_Status and MTL_Indirect_Acc_Data registers.

Portj_MTL_FRP_ACNTR0 (j=0-1) Offset address: $110B4_H+j*2000_H$

Port j MTL FRP ACNTR0 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RXPAC	30:0	r	**Rx-Parser Accept Counter** This 31-bit counter is incremented whenever the Rx Parser accepts a packet due to AF = 1 and RF = 0. The packet must match the Rx Parser acceptance criteria irrespective of its type (length or type) and size (undersize/runt or oversize). The counter is cleared when the register is read.
RXPACOF	31	r	**Rx-Parser Accept Counter Overflow Bit** When set, this bit indicates that the RXPAC Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0_B **INACTIVE**: Rx Parser Accept Counter overflow not occurred 1_B **ACTIVE**: Rx Parser Accept Counter overflow occurred

14.6.526 Port j MTL FRP ACNTR1

The MTL_FRP_ACNTR(#i) registers are indirect and provide the count of the number of frames accepted by FRP particular to channel. Such accept counters mapping with receive channel is static, one to one, if supported number of receive channels are less than or equal to 16. Otherwise if it is more than 16 then, FRP implements fix number of accept counters and provides programmable option to application to map it to application-specific receive channel via corresponding MTL_FRP_ACNTR_CNFG(#i) indirect registers. These indirect registers can be accessible through MTL_Indirect_Acc_Control_Status and MTL_Indirect_Acc_Data registers.

Portj_MTL_FRP_ACNTR1 (j=0-1) Offset address: $110B4_H+j*2000_H$

Port j MTL FRP ACNTR1 Kernel Reset value: $0000\ 0000_H$
