AURIX™ TC4Dx user manual

About this document

Scope and purpose

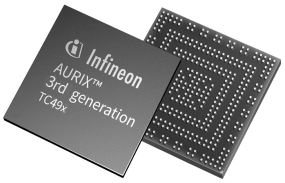
This document describes the Infineon AURIX™ TC4xx microcontrollers based on the Infineon TriCore™ architecture.

For a complete overview of the TriCore™ architecture, this document should be read in conjunction with the 'TriCore™ architecture manual'. Different derivatives of the AURIX™ may contain a different mix of functional blocks and features, but the TriCore™ architecture remains constant to preserve compatibility across all designs, and so it is described separately.

Intended audience

The primary intended audience are potential and actual users of a AURIX™ TC4xx platform product who need a detailed description and reference of the available functional blocks.

TC4xx overview



The AURIX™ TC4xx family of products is the 3rd generation of the Infineon multi-core microcontroller platform for automotive real-time applications in powertrain, chassis applications, safety applications, and advanced driver assistance systems.

This next generation of the AURIX™ platform delivers increased compute performance and a host of additional features to build on the success of the earlier platforms:

- Safe, real-time compute performance through the TriCore™ 1.8 multi-core architecture, up to 500 MHz and fully lock-stepped for ASIL-D safety level
- CPU virtualization and system virtualization support
- Up to 24 MB of on-chip non-volatile memory (NVM) and low-latency NVM access
- Support for software-over-the-air (SOTA) updates with extended A/B swap functionality
- Cyber security features and enhanced cyber security performance
- Low-latency, high-speed communication interfaces, 5 Gbps Ethernet and 8 Gbps PCIe, to address electrical and electronic (E/E) automotive architectures for domain control, gateway, and data fusion companion applications
- Enhanced signal processing performance for powertrain and sensor data fusion applications
- Low-latency real-time signal processing for powertrain and xEV (electric vehicle) applications
- Support for artificial intelligence algorithms, especially neural network inference algorithms
- Architecture enhancements to support the next generation of electrified powertrain applications
- All features designed to meet the functional safety standard ISO 26262
- Developed in 28 nm silicon technology to enable higher integration and lower power consumption

1 Using this document

Topics:

- Understanding the platform
- Understanding the document structure
- Functional block (FB) chapter structure
- Document conventions
- Registers: How are they documented?
- Register image linking
- Register bit-field access types

These topics provide important information on how to work with and understand this documentation collection.

***Note**:* *In this documentation there might be references to functional blocks which are not part of this device. All available functional blocks are shown in the table of contents.*

There could also be references to other devices than TC4Dx. This information is required to get the necessary overview and context.

1.1 Understanding the AURIX™ platform

The following graphic helps visualize the AURIX™ platform and explains some common terminology. Each platform generation consists of a product family of devices. Each device is made up of functional clusters. Each cluster is made up of functional blocks, and those blocks may contain separate functions (functional sub-blocks).

***Note**: In this documentation, TC4xx and TC4x are both used as family short name for AURIX™ 3rd generation.*

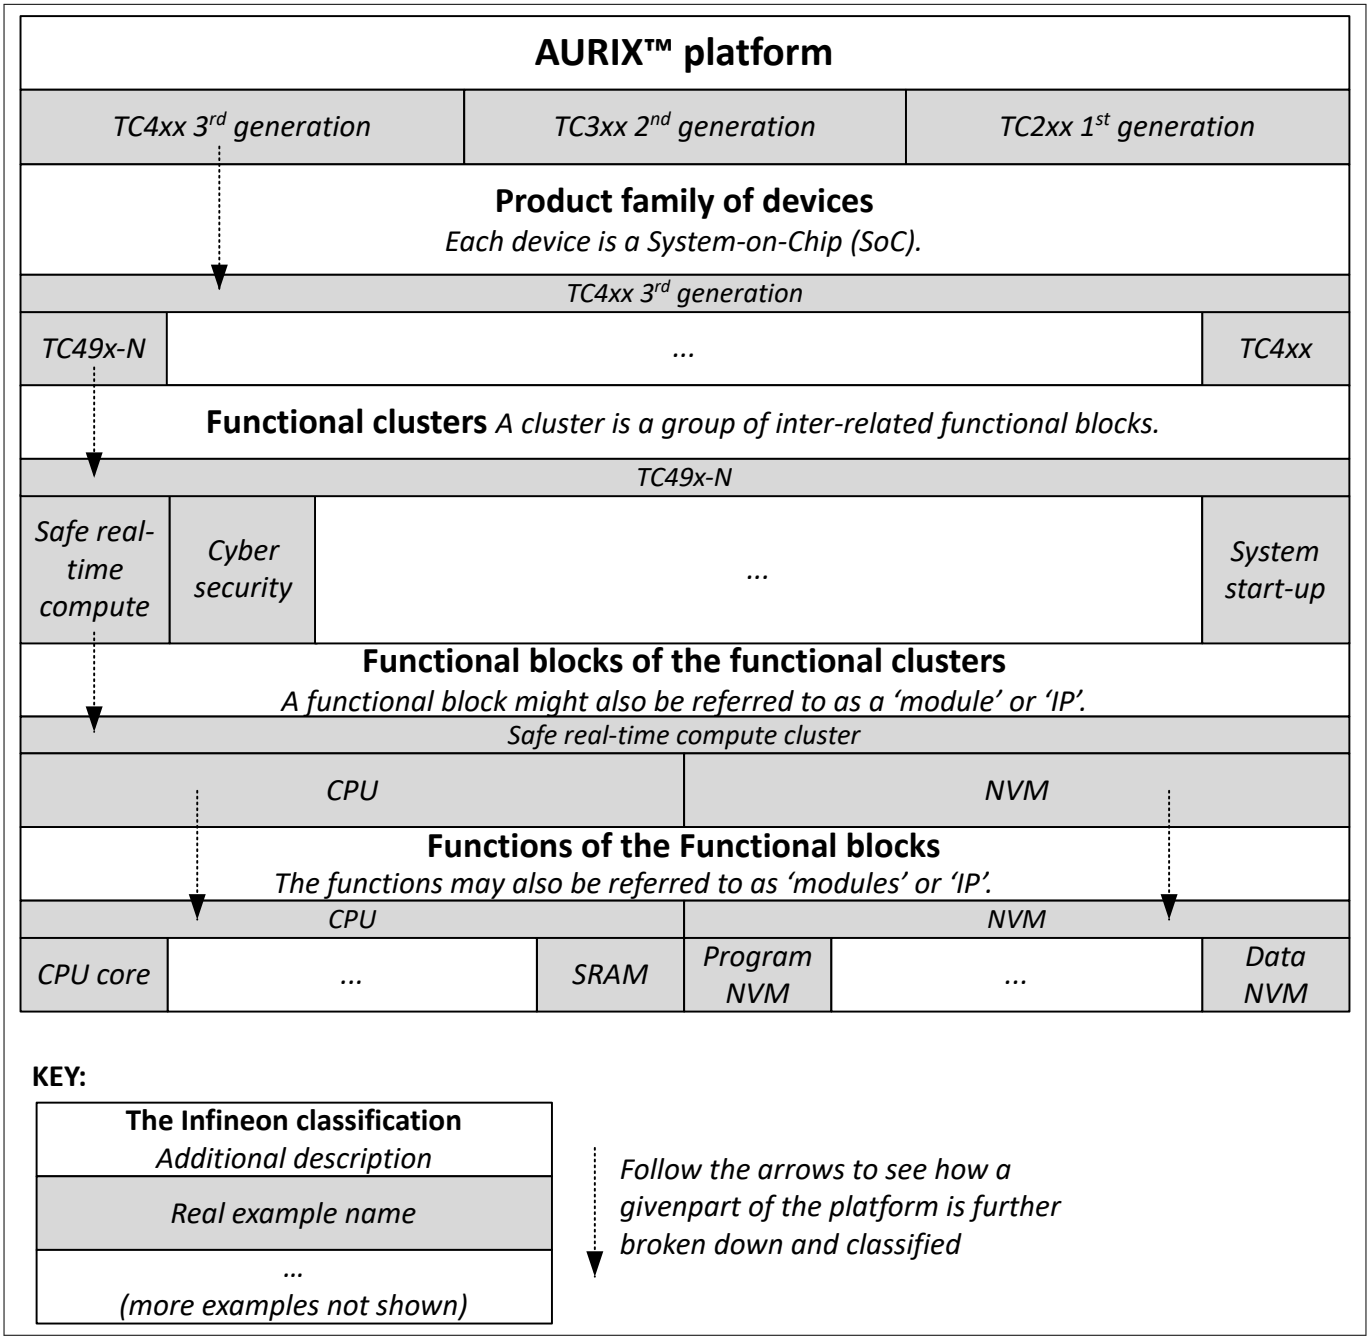

Figure 1 Visualizing the AURIX™ platform

1.2 Understanding the document structure

This document is divided up into the following major sub-sections:

- Preface
  - About this document
  - TC4xx overview
- Using this document
  - Understanding the AURIX™ platform
  - Understanding the document structure (this section)
  - Functional block (FB) chapter structure
  - Document conventions
  - Registers: How are they documented?
  - Register image linking
  - Register bit-field access types
- Features of the functional blocks
  - Up to 5 significant features of each functional block
- System address map
  - The 32-bit address ranges assigned to resources and reserved areas
  - The access capabilities of hardware masters
- Distributed functionality
  - Covers functionality that is shared by multiple functional blocks:
    - System interconnect connects the various master agents and slave agents in AURIX™ and allows them to communicate with each other
    - Software over the air (SOTA) enables software executing out of the application PFLASH (not PFLASHcs) to be updated without impacting the currently executing application
    - Resource access latencies describe CPU access times to various resources in SRI clock cycles
    - Module reset describes the kernel reset function
    - Debug and Trace shows an OTGB overview
- Functional blocks
  - Each functional block (module) has the same top-level topic structure. so for example an introduction paragraph is always followed by a feature list, then a functional overview that contains a block diagram
    - Exceptions to the standard Functional blocks
      - CSRM (only Feature list and overview are provided)
      - CSS (only feature list and overview are provided)
      - Debug and Trace (only feature list, overview, and description are provided)
- Product related documents
  - A list of related documentation that forms the complete document set for a given product
- Revision history
  - A list of major changes for the current document

***Note**:* *Each Functional block has its own revision history, once for the generic part and once for the device specific information*

1.3 Functional block (FB) chapter structure

The majority of functional block (also known as a module or IP) follow the same high-level chapter structure:

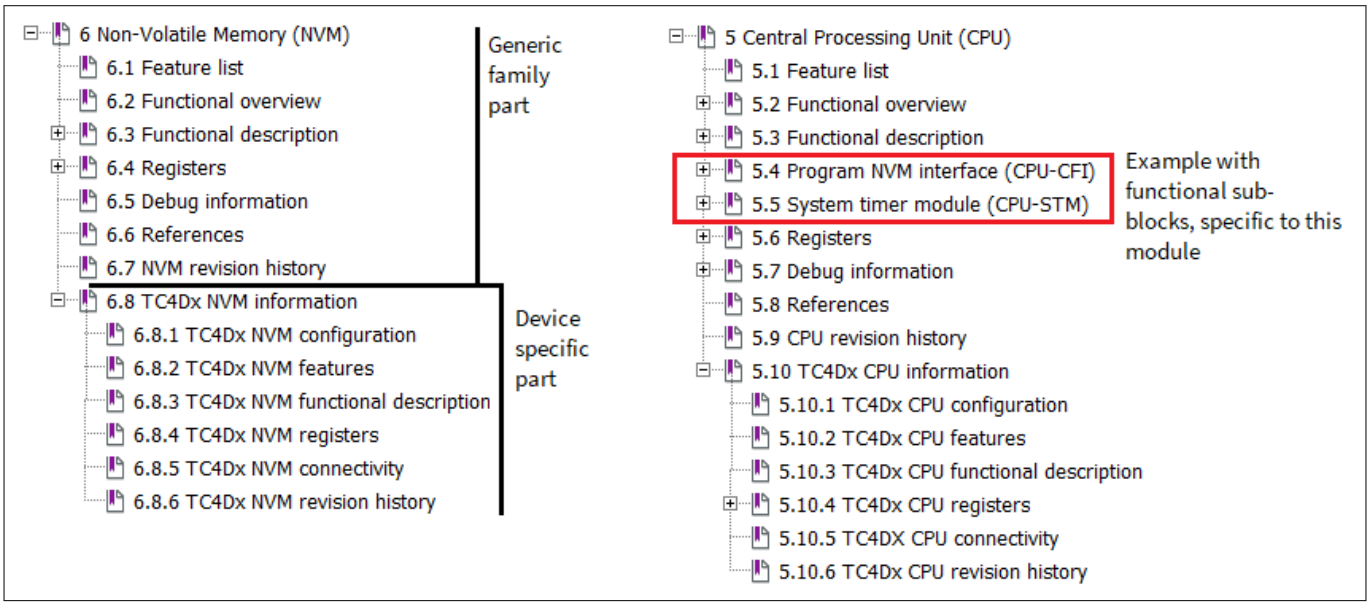

Figure 2 Standard functional block chapter structure

- Introduction paragraph under the functional block name written out in full. For example Central Processing Unit (CPU)
  - Feature list
    - A bullet list of significant features or functions of that block
  - Functional overview
    - A block diagram of the functional block
    - A brief summary intended to give a general understanding of the blocks capabilities and the capabilities of any of its functional sub-blocks (FSBs)
    - The information is generic and not device specific
  - Functional description
    - How to use the functional block. The description may include:
      - Data flow or transfer diagrams, functional timing diagrams, state transition and mode management, address modes, sequence or activity diagrams, alarms, interrupts, error management, triggers, bus interfaces
      - The information is generic and not device specific
  - Functional sub-blocks (FSBs)
    - Feature list
      - A list of the major technical features
    - Functional overview
      - A block diagram
      - A summary of the FSB capabilities
    - Functional description
      - Description of the FSB and how to use it, including information on bus interfaces, elements and signals
  - Registers
    - Register access mode glossary table
    - Register overview table with hyperlinks to each register
    - Description and definition of each register

- Debug information
- References
  - All referenced documents in the FB or FSB description
- Revision history for the sections above, which describe the generic functional block
- Device specific information for this functional block. Each heading is preceded by the device name TC4xx
  - Configuration
    - A list of major technical configuration changes for the current functional block in the context of the given device, as compared to the generic description (above), if applicable
  - Feature list
    - A list of device specific features, if applicable
  - Functional description
    - A description of any features that are listed in the feature list
  - Registers
    - Registers overview table with hyperlinks to the device specific register (if applicable) or to the generic register description
    - Device specific registers
      - This is a delta to the generic register part
  - Connectivity
    - Input and output signals
  - Device specific revision history for this sub-section

1.4 Document conventions

An overview of the common units, data formats, and other text conventions used in this document.

- Unit abbreviations:
  - MHz = Megahertz
    - 1 MHz is 1,000,000 Hz
  - µs = Microseconds
    - The 'µ' prefix scales by 0.000001
  - kBaud, kbit/s = 1,000 characters or bits per second
  - MBaud, Mbit/s = 1,000,000 characters or bits per second
  - Gbps = 1,000,000,000 characters or bits per second
  - Kbyte, KB = 1,024 bytes of memory
    - Synonymous term: Kibibyte, KiB
  - Mbyte, MB = 1,048,576 bytes of memory
    - Synonymous term: Mebibyte, MiB
  - Scaling summary
    - The 'k' prefix (lower case) scales a unit by 1,000. So the kBaud unit scales the preceding expression by 1,000
    - The 'K' prefix (upper case) scales a unit by 1,024. So the Kbyte unit scales the preceding expression by 1,024
    - The 'M' prefix scales by 1,000,000 or 1,048,576
      - 1 Mbyte is 1,024 x 1,024 bytes
      - 1 MBaud, Mbit/s are 1,000,000 characters/bits per second
- Data format quantities
  - Byte = 8-bit quantity
  - Half-word = 16-bit quantity
  - Word = 32-bit quantity
  - Double-word = 64-bit quantity
- Radix
  - The default radix is decimal
  - Hexadecimal constants are suffixed with a subscript letter 'H'. For example:
    - $AA80\ 0000_H$
  - Binary constants are suffixed with a subscript letter B. For example:
    - 1010_B
- Pins that use negative logic are indicated by an over-line. For example:
  - “The external reset pin $\overline{\text{ESR0}}$ has a dual function”
- Functional blocks (modules) are usually referenced by their abbreviation in plain upper case. For example:
  - “The QSPI supports full-duplex and half-duplex synchronous communication"”
- Registers
  - Bit-fields and bits in registers are in general referenced as either:
    - FunctionalBlock_register-name.bit-field

    - FunctionalBlock_register-name.bit
    - For example: “The current CPU priority number bit-field CPU_ICR.CCPN is cleared”
  - Most register names contain a functional block (module) abbreviation prefix which is separated from the actual register name by an underscore '_' character. For example:
    - “QSPI_GLOBALCON”
      - QSPI is the functional block abbreviation prefix
      - GLOBALCON is the kernel register name
        - In topics describing the kernels of peripherals, the registers are usually referenced by the kernel register name
  - Sets of registers may have a lower-case letter appended to indicate a value
    - “MOFCRn” for example, refers to multiple MOFCR registers of number 'n'
      - The bounds of the value 'n' are always defined where the register expression is first used, although the bounds may also be repeated throughout the text. For example:
        - “n = 0 - 255”
- Text conventions for register bit ranges, signals, and pins
  - Register fields, groups of register bits, and groups of pins are collectively referenced in the text in the format 'NAME[A:B]'. This indicates a range for the named group from A to B. For example:
    - CFG[2:0]
  - Individual bits, signals, or pins may be referenced as 'NAME[C]'. For example:
    - SRNP[0]

1.5 Registers: How are they documented?

In each functional block chapter, registers are grouped into both 'family' and 'device specific' sections. The family grouping provides a concise overview of all the registers available for that functional block in the product family. The device specific section gives detailed information on the applicable registers for the specific device.

***Note**: The exceptions to the description given here, are for CSRM, CSS, and Debug and Trace. CSRM and CSS are fully documented in separate documentation that is available on request. The Debug and Trace chapter follows conventions introduced in previous AURIX™ family documentation, and does not follow the standard format of other functional blocks.*

1.6 Register image linking

The register images contain hyperlinks from each bit-field, to the bit-field definition in the register description table that follows the image.

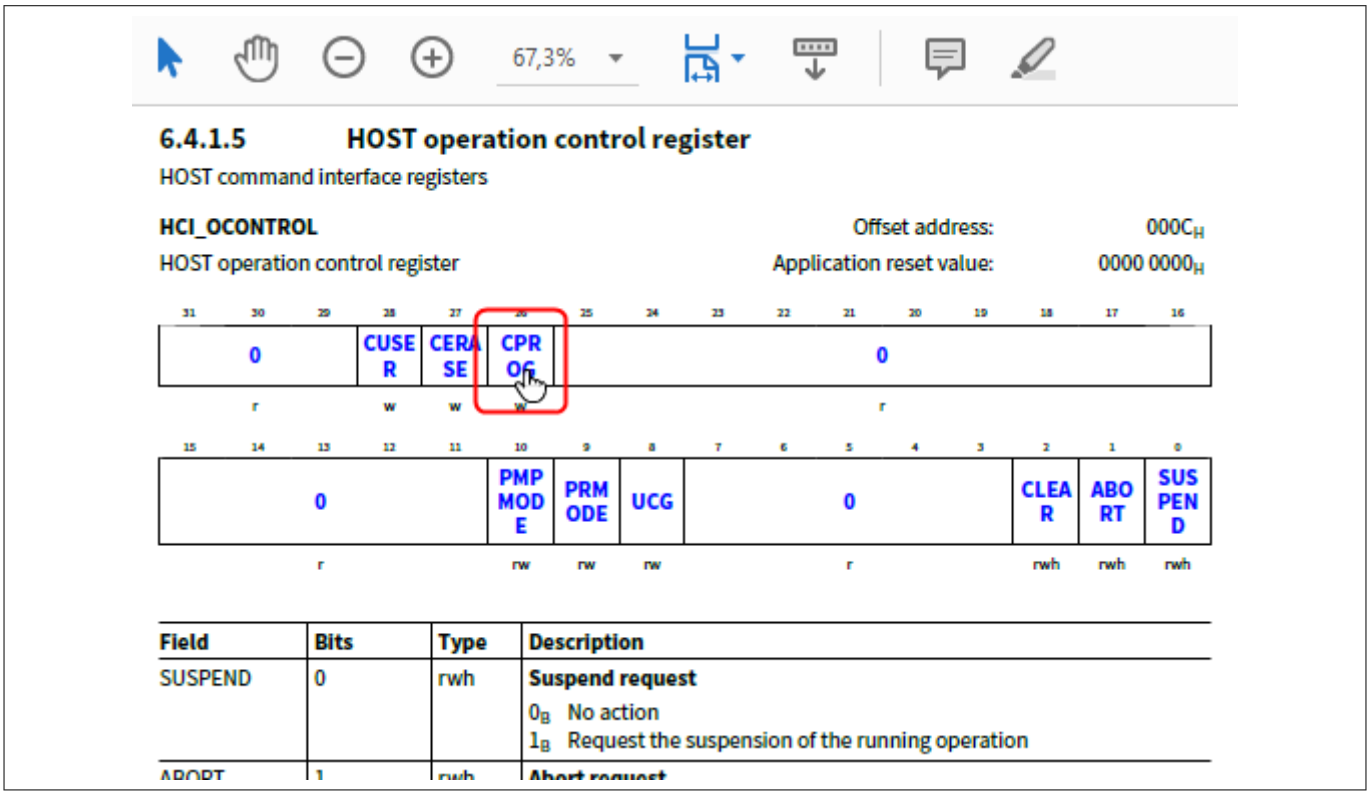

Figure 3 Bit-field hyperlink

If you have the PDF set to 'scroll' (the options to do this depend on the PDF viewer) then selecting the hyperlink will jump you to the corresponding row in the register description table. If the PDF is set to view 'per page' then the link will take you to the top of the page on which that link exists.

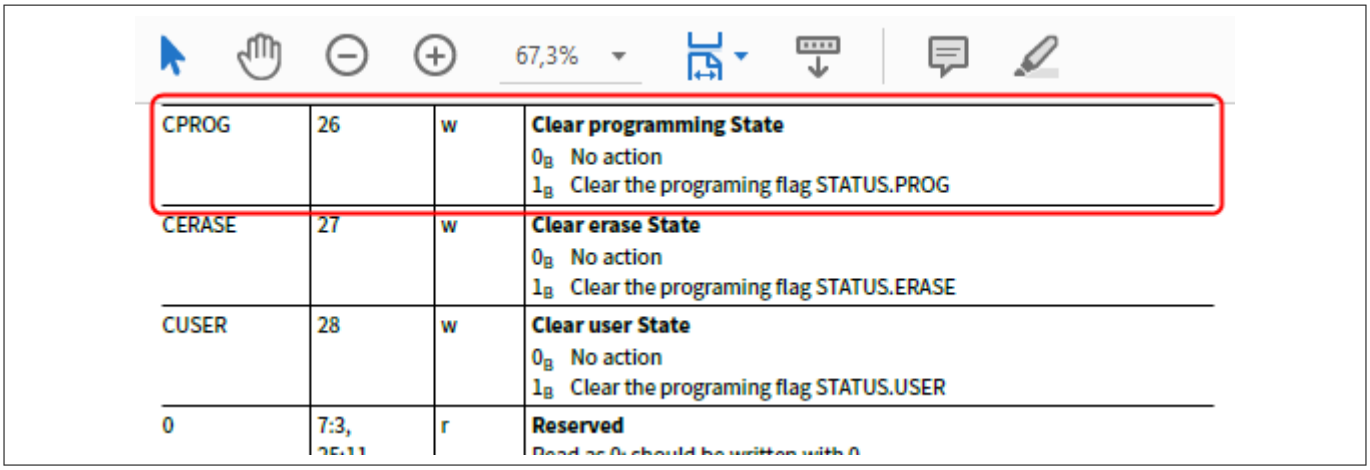

Figure 4 Hyperlink moves you to the correct bit-field

1.7 Register bit-field access types

Table 1 Access types

Access type	Description
r	Software can only read this bit-field. A software write will not change the value of the bit-field.
rh	Software can only read this bit-field. A software write will not change the value of the bit-field. Hardware can change the value of the bit-field.
rc	Reading returns the current value and clears the bit-field to '0'. A software write will not change the value of the bit-field.
w	Software can write this bit-field. Read returns 0 unless explicitly described differently.
wh[1)]	Software can only write this bit-field. Hardware can change the value of the bit-field. Read returns 0 unless explicitly described differently.
rw	Software can both read and write this bit-field.
rwh[1)]	Software can both read and write this bit-field. Hardware can change the value of the bit-field.
rw1s[2)]	Writing '1' to a bit inside this bit-field sets that bit to '1'. Writing '0' has no effect. Read returns the current value.
rw1sh[1)]	If the bit-field written value is '1', the corresponding bit-field is set to '1'. Otherwise, writing '0' has no effect. Hardware can change the value of the bit-field. Read returns the current value.
rw0c[2)]	Writing '0' to a bit inside this bit-field clears that bit to '0'. Otherwise, writing '1' has no effect. Read returns the current value.
rw0ch[1)]	If the bit-field written value is '0', the corresponding bit-field is cleared to ‘0’. Otherwise, writing '1' has no effect. Hardware can change the value of the bit-field. Read returns the current value.
rw1c[2)]	Writing '1' to a bit inside this bit-field clears that bit to '0'. Otherwise, writing '0' has no effect. Read returns the current value.
rw1ch[1)]	If the bit-field written value is '1', the corresponding bit-field is cleared to ‘0’. Otherwise, writing '0' has no effect. Hardware can change the value of the bit-field. Read returns the current value.

1) Performing a read-modify-write (RMW) operation on this bit-field should be avoided as hardware may change the values of the bit-field between READ and WRITE sub-operations of an RMW operation.

2) This access type is sometimes referred to as "sticky" or "write-once", because the bit-field value can be changed only once after each reset.

2 System address map

The system address map defines:

- The 32-bit address ranges assigned to resources and reserved areas
- The access capabilities of hardware masters

2.1 Address segments and accesses

In general, all hardware masters can address peripherals and memories at global addresses.

2.1.1 Acronyms and terms

Key terms used in the system address map.

Table 2 Address map related acronyms and terms

Acronym or term	Definition
Access	A bus access is allowed and is executed.
COMPBBE	A bus access is terminated with a bus error on the COMPB.
CPBBE	A bus access is terminated with a bus error on the CPB.
CSPBBE	A bus access is terminated with a bus error on the CSPB.
LLIBE	A bus access is terminated with a bus error on the LLI.
RCBBE	A bus access is terminated with a bus error on the RCB.
SPBBE	A bus access is terminated with a bus error on the SPB.
SRIBE	A bus access is terminated with a bus error on the SRI.
TPBBE	A bus access is terminated with a bus error on the TPB.

2.1.2 Overview of segments

The address space is divided into sixteen segments. Each segment has a defined purpose.

Segment 0

This segment is reserved.

Segments 1-7

These segments provide access to the following CPU memories:

- Program Scratch-Pad RAM (PSPR)
- Program Cache (PCACHE)
  - If the PCACHE is disabled and mapped into the address space then the PSPR (extension) is available
- Program Tag (PTAG) related to Program Cache (PCACHE)
  - If the PCACHE is disabled then the PTAG can be mapped into the address space
- Data Scratch-Pad RAM (DSPR)
- Data Cache (DCACHE)
  - If the DCACHE is disabled and mapped into the address space then the DSPR (extension) is available
- Data Tag (DTAG) related to Data Cache (DCACHE)
  - If the DCACHE is disabled then the DTAG can be mapped into the address space

Segment 8

This segment provides an alias for the cached access to the non-volatile memory in Segment 10.

Segment 9

This segment provides an alias for the cached access to the volatile memory in Segment 11.

Segment 10

This segment provides non-cached access to non-volatile memory.

Segment 11

This segment provides non-cached access to volatile memory.

Segment 12

This segment is not globally addressable and is reserved for certain compute agents.
Each CPUx has an internal access to CPUx.PSPR through segment C_H . Refer to the CPU chapter for further details.
The PPU has an internal access to PPU.VMEM through segment C_H . Refer to the PPU chapter for further details.

Segment 13

This segment is not globally addressable and is reserved for certain compute agents.
Each CPUx has an internal access to CPUx.DSPR through segment D_H . Refer to the CPU chapter for further details.

Segment 14

This segment provides access to peripheral space.

Segment 15

This segment provides access to peripheral space.

2.1.3 Memory accesses

Topics:

- Standard read-write memories
- Standard read-only memories
- Non-standard memories
- Dedicated memories

This section lists the memory access sizes to the following types of memory: standard read-write memories, standard read-only memories, non-standard memories, and dedicated memories.

Table 3 Key to memory access tables

Notation	Explanation
r	read
rmw	read modify write
w	write
y	'yes', access is supported
-	access is not supported

2.1.3.1 Standard read-write memories

Table 4 Standard read-write memories

Memory	1 Byte		2 Bytes		4 Bytes			8 Bytes		16 Bytes		32 Bytes		64 Bytes	
	r	w	r	w	r	w	rmw	r	w	r	w	r	w	r	w
SCR.XRAM [1]	y	y	y	y	y	y	y	-	-	-	-	-	-	-	-
CSS	y	y	y	y	y	y	-	y	y	y	y	y	y	y	y
CPUx.PSPR	y	y	y	y	y	y	y	y	y	y	y	y	y	y	y
CPUx.DSPR	y	y	y	y	y	y	y	y	y	y	y	y	y	y	y
CPUx.DLMU	y	y	y	y	y	y	y	y	y	y	y	y	y	y	y
CANx.SRAM	-	-	-	-	y	y	y	y	y	y	y	-	-	-	-
GETH0.RAM	-	-	-	-	-	-	-	y	y	y	y	y	y	y	y
PPU.CSM															
PPU.VMEM															
LMU	y	y	y	y	y	y	y	y	y	y	y	y	y	y	y

1) Accesses supported by software executed on a CPU.
2) Accesses are atomic for PPU internal accesses. CPU rmw accesses to PPU internal memories should only be executed when the PPU is not accessing the corresponding memory.

2.1.3.2 Standard read-only memories

Table 5 Standard read-only memories

Memory	1 Byte	2 Bytes	4 Bytes	8 Bytes	16 Bytes	32 Bytes	64 Bytes
	r	r	r	r	r	r	r
NVM.PFLASH	y	y	y	y	y	y	y[1]
NVM.EEPROM	y	y	y	y	-	-	-
NVM.UCB	y	y	y	y	-	-	-
NVM.BROM	y	y	y	y	y	y	-
xSPI	y	y	y	y	y	y	-

1) Only external accesses from the SRI interconnect.

2.1.3.3 Non-standard memories

Table 6 Non-standard memories

- The TAG memories (CPUx.PTAG and CPUx.DTAG) must not be used as general SRAMs
- To support memory testing, the TAG memories may be mapped into the system address map
- Test software must perform read and write accesses to a TAG memory using 64-bit aligned addresses and 32-bit data size
- The upper data bits of a TAG memory are not implemented

Memory	1 Byte		2 Bytes		4 Bytes			8 Bytes		16 Bytes		32 Bytes		64 Bytes	
	r	w	r	w	r	w	rmw	r	w	r	w	r	w	r	w
CPUx.PTAG	-	-	-	-	y	y	-	-	-	-	-	-	-	-	-
CPUx.DTAG	-	-	-	-	y	y	-	-	-	-	-	-	-	-	-

2.1.3.4 Dedicated memories

The following memories are dedicated resources:

- SCR.ROM is only accessible by the SCR
- CSROM is only accessible by the CPUcs

2.2 Address map

The address maps define which address ranges are valid or invalid for the respective segment. The access type column describes the error status location if the access is not permitted.

For the detailed address space of a specific functional block (module), please to the specific user manual chapter describing that block.

2.2.1 Segment 0

Table 7 Address map of segment 0

Address range	Size	Description	Access type	
			Read	Write
0000 0000$_H$ - 0FFF FFFF$_H$	-	Reserved	SRIBE [1]	SRIBE [1]

1) Any CPU load or store operation accessing 0000 0000$_H$ will trap

2.2.2 Segment 1

Table 8 Address map of segment 1

Address range	Size	Description	Access type	
			Read	Write
1000 0000$_H$ - 1003 BFFF$_H$	240 Kbyte	CPUcs.DSPR	Access	Access
1003 C000$_H$ - 1003 FFFF$_H$	16 Kbyte	CPUcs.DSPR (extension) or CPUcs.DCACHE (RAM)	Access [1] / SRIBE	Access [1] / SRIBE
1004 0000$_H$ - 100F FFFF$_H$	-	Reserved	SRIBE	SRIBE
1010 0000$_H$ - 1010 FFFF$_H$	64 Kbyte	CPUcs.PSPR	Access	Access
1011 0000$_H$ - 1011 7FFF$_H$	32 Kbyte	CPUcs.PSPR (extension) or CPUcs.PCACHE (RAM)	Access [1] / SRIBE	Access [1] / SRIBE
1011 8000$_H$ - 1011 FFFF$_H$	-	Reserved	SRIBE	SRIBE
1012 0000$_H$ - 1012 FFFF$_H$	64 Kbyte	Alias for CPUcs.PSPR	Access	Access
1013 0000$_H$ - 1013 7FFF$_H$	32 Kbyte	Alias for CPUcs.PSPR (extension)	Access	Access
1013 8000$_H$ - 1013 FFFF$_H$	-	Reserved	SRIBE	SRIBE
1014 0000$_H$ - 1014 FFFF$_H$	64 Kbyte	Alias for CPUcs.PSPR	Access	Access
1015 0000$_H$ - 1015 7FFF$_H$	32 Kbyte	Alias for CPUcs.PSPR (extension)	Access	Access
1015 8000$_H$ - 1015 FFFF$_H$	-	Reserved	SRIBE	SRIBE
1016 0000$_H$ - 1016 FFFF$_H$	64 Kbyte	Alias for CPUcs.PSPR	Access	Access
1017 0000$_H$ - 1017 7FFF$_H$	32 Kbyte	Alias for CPUcs.PSPR (extension)	Access	Access
1017 8000$_H$ - 1017 FFFF$_H$	-	Reserved	SRIBE	SRIBE
1018 0000$_H$ - 1018 FFFF$_H$	64 Kbyte	Alias for CPUcs.PSPR	Access	Access
1019 0000$_H$ - 1019 7FFF$_H$	32 Kbyte	Alias for CPUcs.PSPR (extension)	Access	Access

(table continues...)

Table 8 (continued) Address map of segment 1

Address range	Size	Description	Access type	
			Read	Write
$1019\ 8000_H$ - $1019\ FFFF_H$	-	Reserved	SRIBE	SRIBE
$101A\ 0000_H$ - $101A\ FFFF_H$	64 Kbyte	Alias for CPUcs.PSPR	Access	Access
$101B\ 0000_H$ - $101B\ 7FFF_H$	32 Kbyte	Alias for CPUcs.PSPR (extension)	Access	Access
$101B\ 8000_H$ - $101B\ FFFF_H$	-	Reserved	SRIBE	SRIBE
$101C\ 0000_H$ - $101C\ FFFF_H$	64 Kbyte	Alias for CPUcs.PSPR	Access	Access
$101D\ 0000_H$ - $101D\ 7FFF_H$	32 Kbyte	Alias for CPUcs.PSPR (extension)	Access	Access
$101D\ 8000_H$ - $101D\ FFFF_H$	-	Reserved	SRIBE	SRIBE
$101E\ 0000_H$ - $101E\ FFFF_H$	64 Kbyte	Alias for CPUcs.PSPR	Access	Access
$101F\ 0000_H$ - $101F\ 7FFF_H$	32 Kbyte	Alias for CPUcs.PSPR (extension)	Access	Access
$101F\ 8000_H$ - $101F\ FFFF_H$	-	Reserved	SRIBE	SRIBE
$1020\ 0000_H$ - $1020\ 17FF_H$	-	CPUcs.DTAG	Access [1] / SRIBE	Access [1] / SRIBE
$1020\ 1800_H$ - $102F\ FFFF_H$	-	Reserved	SRIBE	SRIBE
$1030\ 0000_H$ - $1030\ 2FFF_H$	-	CPUcs.PTAG	Access [1] / SRIBE	Access [1] / SRIBE
$1030\ 3000_H$ - $1FFF\ FFFF_H$	-	Reserved	SRIBE	SRIBE

1) PCACHE/PTAG and DCACHE/DTAG can be only accessed when mapped into the address space

2.2.3 Segment 2

Table 9 Address map of segment 2

Address range	Size	Description	Access type	
			Read	Write
$2000\ 0000_H$ - $2003\ BFFF_H$	240 Kbyte	CPU5.DSPR	Access	Access
$2003\ C000_H$ - $2003\ FFFF_H$	16 Kbyte	CPU5.DSPR (extension) or CPU5.DCACHE (RAM)	Access [1] / SRIBE	Access [1] / SRIBE

(table continues...)

Table 14 (continued) Address map of segment 7

Address range	Size	Description	Access type	
			Read	Write
$7030\ 0000_H$ - $7030\ 2FFF_H$	-	CPU0.PTAG	Access [1] / SRIBE	Access [1] / SRIBE
$7030\ 3000_H$ - $7FFF\ FFFF_H$	-	Reserved	SRIBE	SRIBE

1) PCACHE/PTAG and DCACHE/DTAG can be only accessed when mapped into the address space

2.2.9 Segments 8 and 10

The read address of the program flash and erase counters varies for the following modes:

- Linear address map
- SOTA address map A
- SOTA address map B

2.2.9.1 Segment 8 linear address map

Table 15 Linear address map of segment 8

Address range	Size	Description	Access type	
			Read	Write
$8000\ 0000_H$ - $801F\ FFFF_H$	2 Mbyte	NVM.PFLASH00 (Program Flash)	Access	SRIBE
$8020\ 0000_H$ - $803F\ FFFF_H$	2 Mbyte	NVM.PFLASH01 (Program Flash)	Access	SRIBE

2.2.11 Segment 12

Table 23 Address map of segment 12

Address range	Size	Description	Access type	
			Read	Write
$C000\ 0000_H$ - $CFFF\ FFFF_H$	-	Reserved [1) 2)]	SRIBE	SRIBE

1) See the CPU chapter Local and global addressing sub-chapter for details
2) See the PPU chapter for details

2.2.12 Segment 13

Table 24 Address map of segment 13

Address range	Size	Description	Access type	
			Read	Write
$D000\ 0000_H$ - $DFFF\ FFFF_H$	-	Reserved [1)]	SRIBE	SRIBE

1) See the CPU chapter Local and global addressing sub-chapter for details

2.2.13 Segment 14

Table 25 Address map of segment 14

Address range	Size	Unit	Access type	
			Read	Write
$E000\ 0000_H$ - $E97F\ FFFF_H$	–	Reserved	LLIBE	LLIBE
$E980\ 0000_H$ - $E980\ FFFF_H$	64 Kbyte	PPU.SFR	Access	Access
$E981\ 0000_H$ - $EBFF\ FFFF_H$	–	Reserved	LLIBE	LLIBE
$EC00\ 0000_H$ - $EFFF\ FFFF_H$	64 Mbyte	PCIe1.DATA	Access	Access

2.2.14 Segment 15

The address map of segment 15 includes the following module address ranges:

- Absolute Addressing Range
  - If a module is addressed in the first 16 Kbyte of segment 15, the CPU can access the module with absolute addressing mode
- Others
  - If a module is addressed above the first 16 Kbyte of segment 15, the CPU can access the module with base + offset

Table 26 Address map of segment 15

Address range	Size	Unit	Access type	
			Read	Write
$F000\ 0000_H$ - $F000\ 07FF_H$	2 Kbyte	WTU	Access	Access

2.3 System address map revision history

Reference	Description of change(s)
Date range: 2024-08-17 to 2025-04-08	
Segment 15	• SCR.PER.SFR removed from Segment 15

3 Distributed functionality

Topics:

- System interconnect
- Software Over The Air (SOTA)
- Resource access latencies
- Module reset

3.1 System interconnect

The system interconnect connects the various master agents and slave agents in AURIX™ and allows them to communicate with each other. It is tailored to meet the bandwidth and latency requirements of the various data flows between master and slave agents.

3.1.1 Functional overview

The system interconnect is composed of a number of interconnect segments and interconnect protocols. There are bridges implemented between the different interconnect segments such that any master agent in the system can access any slave agent in the system, except where explicitly disabled due to security or other reasons. The result is a uniform system address map, every part of which can be accessed by every master agent in the system[2]. These bridges and their capabilities are described further in the SRI chapter.

[2] There are a few exceptions to this uniform access as noted in the system address map chapter.

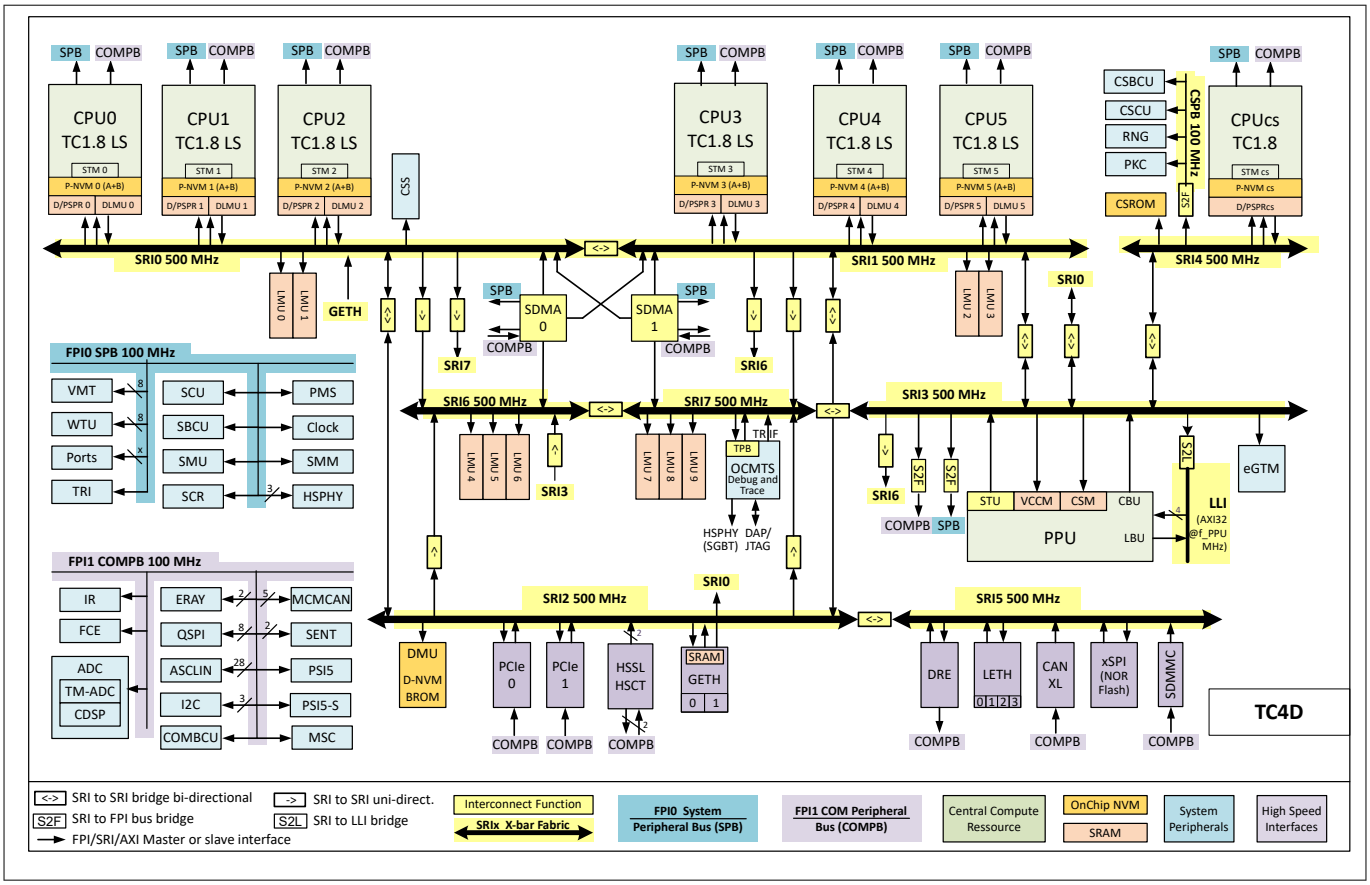

Figure 5 TC4Dx block diagram

3.1.2 Functional description

The system interconnect is implemented using the following interconnect segments and interconnect protocols.

- System Resource Interconnect (SRI) protocol
  - The SRI is a 64-bit interconnect used to connect the TriCore™ CPUs, the system DMA and other high bandwidth requestors to high bandwidth memories and other resources for instruction fetches and data accesses
  - The SRI fabric provides safety through end-to-end EDC and other safety mechanisms
  - The SRI fabric implements the SRI protocol and consists of multiple crossbars labeled SRIx (x = 0-7)
- Flexible Peripheral Interconnect (FPI) protocol
  - The FPI is a 32-bit multi-master interconnect
  - The FPI implementations provide safety through end-to-end EDC and other safety mechanisms
  - The following (device-specific) interconnect segments implement the FPI protocol
    - System peripheral bus (SPB): The SPB connects the TriCore™ CPUs, the system DMA and other SPB masters to medium and low bandwidth functional blocks
    - Converter peripheral bus (CPB): The CPB connects the TriCore™ CPUs and the system DMA to the GTM and related functional blocks
    - Communications peripheral bus (ComPB): The ComPB connects masters to the off-chip communications functional blocks

  - Cyber-security peripheral bus (CSPB): The CSPB connects the CPUcs to dedicated CSRM functional blocks
  - Tool peripheral bus (TPB): The TPB connects masters to the TRACE functional block and its associated functional blocks
  - Radar control bus (RCB): The RCB connects masters to the Radar functional blocks
- AMBA AXI protocol with user extensions
  - The Low Latency Interconnect (LLI) implements a 32-bit AXI interconnect which consists of a single crossbar with a limited number of master and slave agents
  - The LLI implementation provides safety through end-to-end EDC and other safety mechanisms, implemented as user extensions to the AMBA AXI protocol
  - The LLI provides a low latency path from the PPU and other SRI masters to the PPU configuration and debug registers, the eGTM, HRPWM (when present on the device) and the TMADC

3.1.2.1 Master agent function identifier

Each master agent function on the system interconnect is assigned a unique master agent function identifier (ID). The master agent function identifier is transmitted in the address phase of any system interconnect transaction. The master agent function identifier can be used at the slave function interface through the access protection mechanism to restrict the functions allowed read and write access to its internal resources. The master agent function ID in combination with the access protection in the slave agents is used for several system functions such as access protection, software encapsulation, hardware virtualization, software debug and trace.

The master agent function ID consists of:

- TAG-ID, master agent function TAG identifier (TAG ID), 6-bit
- VM, Virtual machine information (VM), 3-bit, optional information
- VM_VALID, signal which indicates whether the transmitted VM is to be used (VM validity indicator)
- PRS, Protection register information (PRS), 3-bit, optional information
- PRS_VALID, signal which indicates whether the transmitted PRS is to be used (PRS validity indicator)

Master agents which are not using the VM information for their master agent function ID drive the VM validity indicator to 0_B. Similarly, master agents which are not using the PRS information for their master agent function ID drive the PRS validity indicator to 0_B.

3.1.2.1.1 Master agent function TAG-ID assignments

The following table lists the master agent function TAG identifier for each master agent function in the microcontroller.

***Note**: Where TAG-IDs are assigned to multiple modules it is ensured that only one of the multiple modules is available in a dedicated device. Example: TAG-IDs assigned to SDMA1 and RIF0/1, RMEM, RDMA .*

Table 27 Master agent function TAG-ID assignments

3.1.2.2 Access protection

The system interconnect provides access protection mechanisms that enable application software to restrict read and write accesses to each slave function from a desired set of master agent functions.

These access protection mechanisms can be used to assign on chip resources like system functions, CPUs, volatile and non-volatile memories, communication functions, DMA resource partitions and Interrupt Router service request nodes to an application software instance. This can be used to partition the MCU resources between multiple applications and provide logical freedom from interference between these applications. In addition it supports CPU hypervisor functions with access protection control on VM ID and PRS granularity.

The system interconnect access protection mechanisms are an essential feature of the TC4xx safety and security architecture.

3.1.2.2.1 Feature list

- The PROT mechanism provides the ability to assign ownership of a set of registers to a single master agent function, known as the PROT owner
  - Once assigned, only the PROT owner is permitted to lock or unlock the protected registers and modify them
- The Access Protection Unit (APU) provides the ability to protect and restrict read and write access to a slave function
  - An APU can be configured to allow no access, read-only access, write-only access or read and write access to a slave function for each master agent function
  - The master agent function is identified by a master agent function identifier, which consists of a 6-bit TAG-ID, an optional 3-bit virtual machine (VM) ID and an optional 3-bit protection register set (PRS) ID
  - For system memories, the APU allows a smaller region of the memory region to be configured for protection by specifying the start and end addresses of the protection region

3.1.2.2.2 Functional overview

Access protection is implemented by gating accesses at the slave interface based on the master agent function that initiated the access. Each on chip resource with interconnect mastering capability has a unique master agent function identifier consisting of a TAG ID, VM ID and PRS ID that can be used to identify the origin of an on chip transaction. Each slave function implements register and memory access protection as necessary in order to provide freedom from interference between different application software instances attempting to access that slave function.

3.1.2.2.3 Functional description

Access protection in the slave interfaces is implemented using two functions which interact with each other.

1. The PROT mechanism allows a coarse-grained access protection to groups of registers
   a. It is usually used to protect registers that are not protected by an APU (for example, the APU registers themselves)
   b. It allows for a safe and secure assignment of resources to master agent functions. Each group of registers may be assigned to a single PROT owner master agent function
   c. It provides write protection to the group of registers
   d. It also allows software to lock control and configuration registers from further modification and then later unlock the registers in a safe and secure manner when required to do so
2. The Access Protection Unit (APU) provides fine-grained access protection to groups of registers related to a specific function or to volatile and non-volatile memories
   a. Each group of registers may be enabled for access from a configurable set of master agent functions
   b. It provides separate controls to allow sets of master agent functions read-only access, write-only access, read and write access or to disallow access from them
   c. It can also be used to provide access protection to configurable regions of a memory, allowing safe and secure partitioning of the memory between the different groups of master functions

The access protection logic (including PROT and APU) is reset on application reset and is not affected by either module or kernel reset.

Each functional block connected to the system interconnect implements access protection to its slave functions through one or more PROT and APU instances. The access protection details for each register in the functional block is provided in the functional block specific register overview table. This table contains columns specifying the read and write access protection mechanism for each register, including details of which PROT, APU or other mechanism provides the protection.

PROT mechanism

The "PROT" resource protection concept uses a PROT state machine, a PROT register and access gates to control access to the protected registers and hence to the protected resource itself.

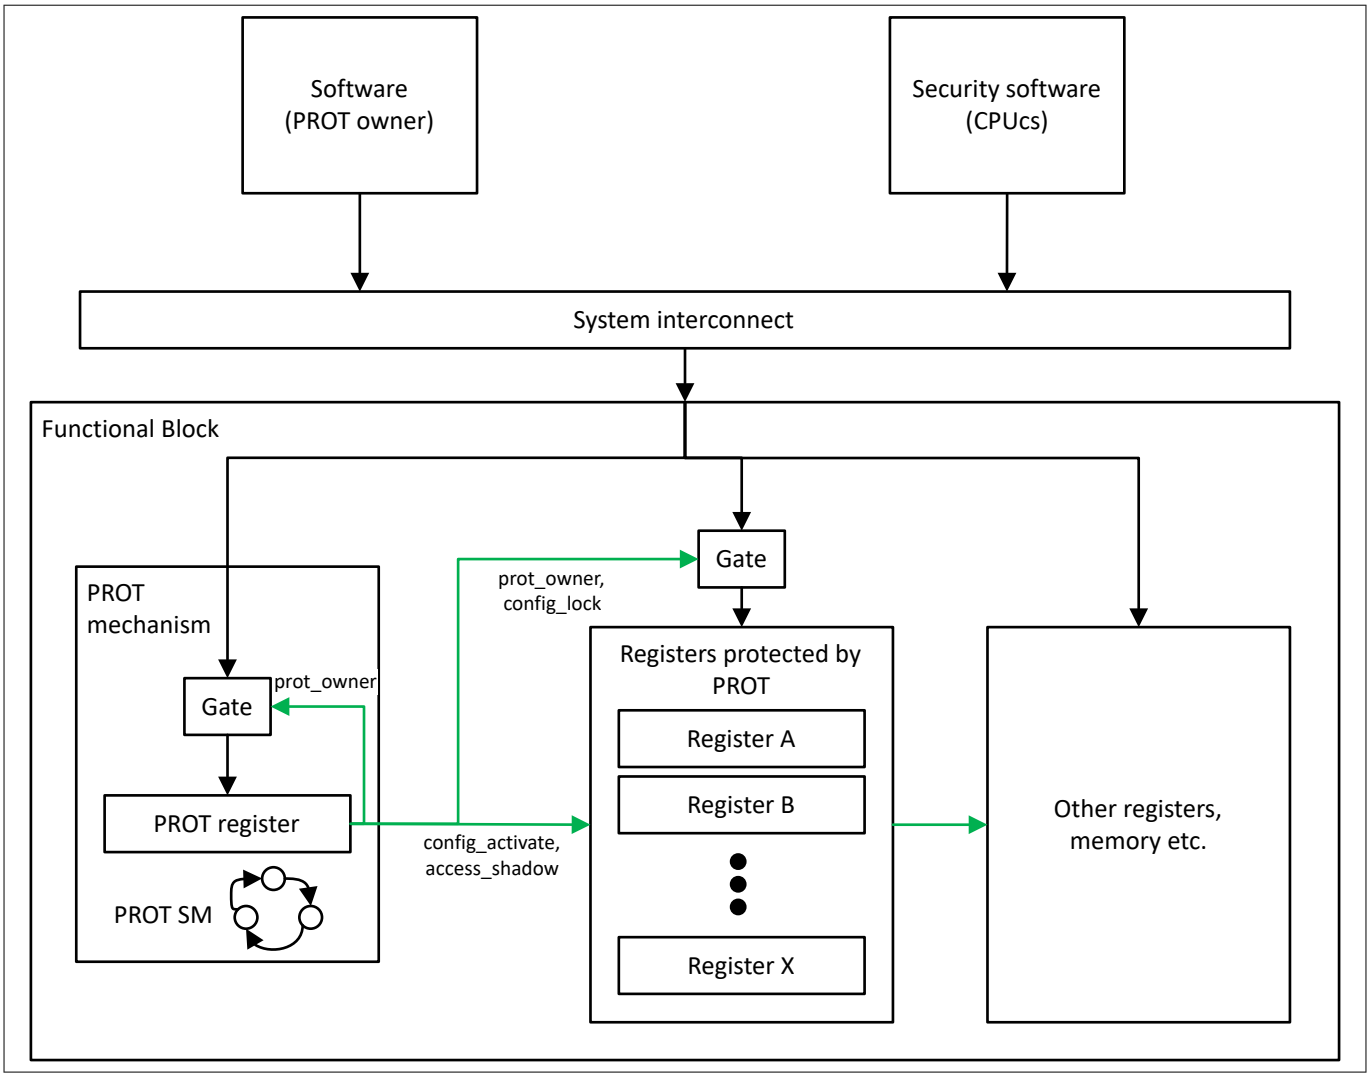

Figure 6 PROT concept

The software actors involved in the PROT concept are:

- The PROT owner: A configurable master agent function which is permitted to configure the PROT as well as the protected resource registers
- The secure master: A master agent function that is capable of generating CS transactions on the system interconnect. In particular, the CPUcs and a secure SDMA resource partition may generate CS transactions on the system interconnect which are marked by an asserted cs_valid bit on FPI buses and an asserted sri_sm bit on SRI interconnects.

The hardware blocks that interact to implement the PROT concept are:

- The PROT mechanism
  - The PROT state machine: A state machine that has a defined set of transitions supported in each state. The current state is used to control the access gates
  - The PROT register: Allows configuration and visibility of the PROT owner and the PROT state
  - The access gate to the PROT register: Controls access to the PROT register based on the PROT owner
- The protected registers: The set of registers which configure or control the protected function and which have to be protected against unsafe or non-secure modification
- The protected function: The module or logic which is configured or controlled by the protected registers
- The access gate to the protected registers: Uses information about the current PROT state and PROT owner to gate accesses to the protected registers to implement the protection

The "protection" aspect of the PROT concept is realized by ensuring that critical operations like configurations can only be done by the PROT owner in specified states which are not the normal operation states. These critical states can only be reached by specific PROT state transitions, triggered again by specified masters.

Resources that have their control shared between application software and security software are handled by having the (safe) PROT owner do the configuration and then having the security software check the configuration before it becomes active.

PROT state machine

The PROT state machine has a set of protection states and the possible transitions out of those states. Each transition is also annotated with the master agent function that is allowed to trigger that transition.

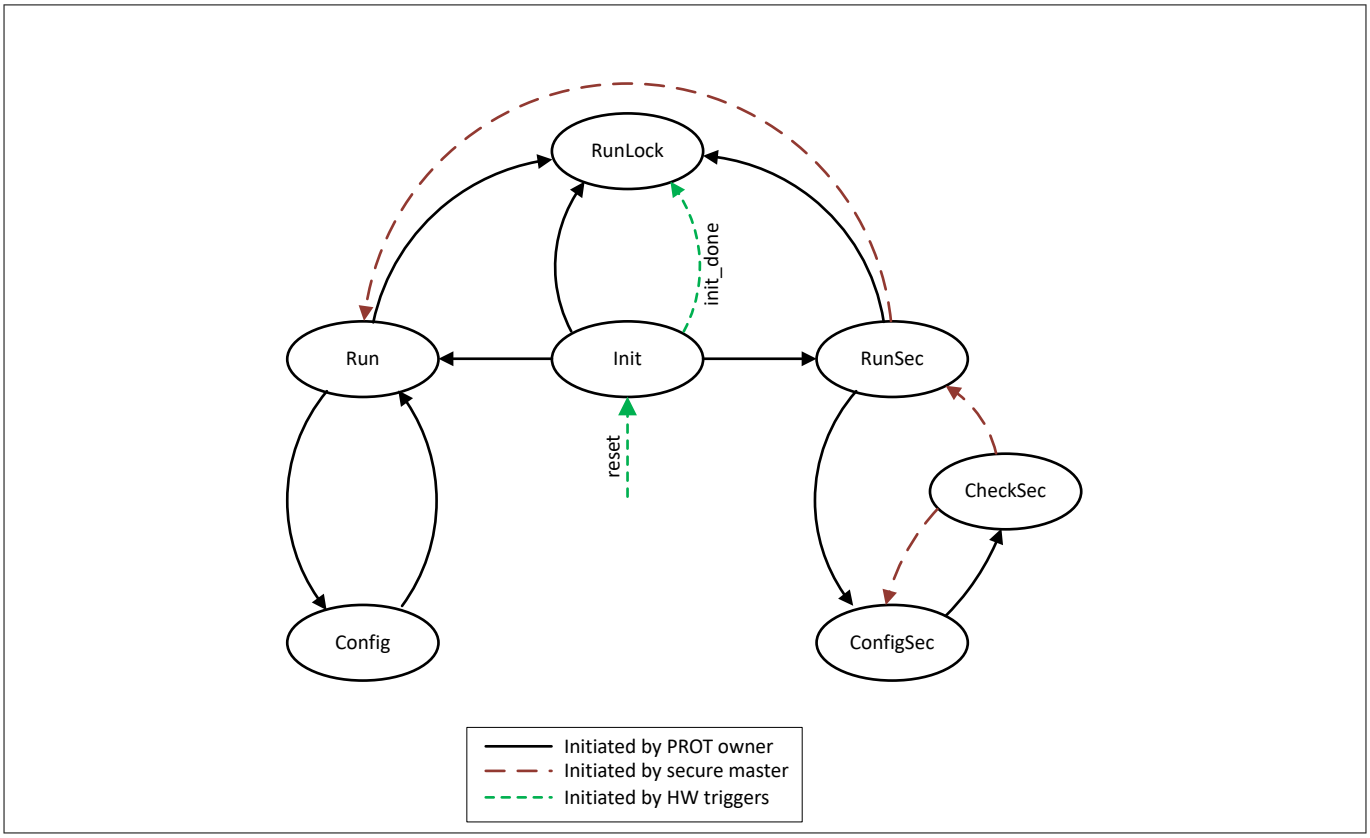

Figure 7 PROT state machine

State transitions are triggered by explicit software writes to the STATE field of the PROT register, except in the following cases:

1. PROT state machines will transition to the Init state on assertion of the application reset
2. PROT state machines which are in the Init state will transition to the RunLock state in response to the assertion of the init_done input signal
   - **a.** The assertion of the init_done input signal for cyber-security relevant PROT instances is controlled by the CSCU_INIT.DONE bit-field. See chapter CSRM for the list of PROT instances that are cyber-security relevant
   - **b.** The assertion of the init_done input signal for all other PROT instances is controlled by the SMM_PROTINIT.PINIT_DONE bit-field

Init state

The PROT state machine resets to the Init state. The protected function configuration may be modified in this state. The expected usage is that after reset, software does initial configuration of the protected function in the Init state, then sets the PROT owner and transitions to one of the Run, RunLock or RunSec states.

RunLock state

The RunLock state is used for functions which are configured once and do not need to be reconfigured until the next application reset.

The protected registers cannot be modified in the RunLock state and there are no transitions out of the RunLock state that permit later modification of the protected registers. Therefore the safety and security of the protected resource is ensured if the initial configuration is done safely and securely.

***Note**: There are two valid encodings of the RunLock state - 110_B and 111_B. Both these encodings may be used by the hardware or software and are indistinguishable from each other in terms of behavior.*

Run, config states

The Run state is the normal operation state of a PROT mechanism that is owned by a single master agent function. The protected registers cannot be modified in the Run state.

When the PROT owner wishes to reconfigure the protected registers, it transitions the PROT state to Config. The protected registers may be modified by the PROT owner in the Config state. Once the configuration is complete, the PROT owner transitions the PROT state back to Run, re-locking the protected registers.

RunSec, ConfigSec, CheckSec states

The RunSec state is similar to the Run state, except that it is used for functions that need shared control between application software and security software. The protected registers cannot be modified in the RunSec state.

When using the RunSec state, it is expected that software has configured the PROT owner to be a safe master agent function (for example, a lock-stepped CPU). A safe master agent function is one that is related to the safety task or safety application. The state transitions out of RunSec enforce a safe and secure interaction between the safe (though possibly malicious) PROT owner and the secure master. Note that if the PROT owner is malicious no safety can be guaranteed.

A configuration is always initiated by the PROT owner which writes the PROT state to transition to ConfigSec. This allows the PROT owner to then modify the protected registers. To ensure the security of the system, the modifications to the protected configuration registers should not immediately become active - they should only become active once security software has checked them for security issues and certified them. This is done by either:

- Disabling the protected function (access to the protected function, interconnect mastering by the protected function and so on) during reconfiguration such that any configuration that has not yet been checked by the security software is never used by the protected function
- Shadowing the protected registers so that the protected function can continue using the previous configuration while software is reconfiguring the shadow registers. The shadow registers are copied, moved or swapped to the active registers after the security checks have passed

***Note**: Shadowing of the protected registers is only implemented in a few functions like system memories where shared control between application software and security software is necessary. Details of the shadowing can be found in the respective functional block (module) chapters.*

Once the configuration is done, the PROT owner then writes the PROT state register to transition it to CheckSec. In this state, modification of the protected registers is no longer possible. This allows security software to check the new configuration before it is made active. If the security checks pass, the security software running on the secure master writes the PROT state register to transition back to the RunSec state. This transition from CheckSec to RunSec also triggers the activation of the new configuration of the protected registers. If the security checks fail, the security software running on the secure master writes the PROT state back to ConfigSec, indicating to the PROT owner that the security checks have failed and that it should fix the configuration. The PROT owner then takes further action to fix the configuration and retry the security checks or raises an alarm if the failure is unexpected.

The transition from RunSec back to Run state is only needed in special cases, for instance when a function is released from the secure domain back to a single-ownership usage model.

PROT access checks

PROT owner identification

The conditions for matching an incoming interconnect transaction to the PROT owner are as follows.

1. If PROT.ODEF is 0_B, the match condition is true regardless of the master agent function initiating the interconnect transaction. This means that any master agent function can behave as the PROT owner
2. If PROT.ODEF is 1_B
   a. The master agent function TAG ID on the interconnect transaction has to exactly match the value in the PROT.TAGID bit-field of the PROT register
   b. If PROT.VMEN is 0_B, the VM validity indicator and the VM ID in the interconnect transaction are ignored and not used in the match condition
   c. If PROT.VMEN is 1_B, the interconnect transaction has to have the VM validity indicator set and the VM ID in the interconnect transaction has to match the value in the PROT.VM bit-field of the PROT register
   d. If PROT.PRSEN is 0_B, the PRS validity indicator and the PRS in the interconnect transaction are ignored and not used in the match condition
   e. If PROT.PRSEN is 1_B, the interconnect transaction has to have the PRS validity indicator set and the PRS in the interconnect transaction has to match the value in the PROT.PRS bit-field of the PROT register

Secure master identification

Accesses from the secure master are identified through the cs_valid bit on FPI interconnects and the sri_sm bit on SRI interconnects.

PROT state transition checks

The state transitions in the PROT state machine can only be initiated by either the PROT owner, the secure master or by hardware. The following table describes the valid PROT state transitions, the master agent functions that can trigger each transition and the response to each type of trigger. Writes to the PROT.STATE bit-field with PROT.SWEN=1_B from a master agent function that is not allowed to initiate that state transition or that cause a state transition not listed in the table below (including self-state transitions) will not be executed and will terminate with an alarm or bus error.

***Note**: Where the secure master is also the PROT owner, writes from the secure master can effect the PROT state transitions allowed to either the PROT owner or the secure master.*

Table 28 PROT state transitions

PROT state transition	HW trigger	Response to PROT owner writes of STATE bit-field with SWEN=1_B	Response to secure master writes of STATE bit-field with SWEN=1_B	Response to other master agent function writes of STATE bit-field with SWEN=1_B
Any PROT state to Init	State transition on assertion of Application Reset	Alarm or Bus Error	Alarm or Bus Error	Alarm or Bus Error
Init to RunLock	State transition on assertion of init_done (through SCU/CSCU register)	State transition	Alarm or Bus Error	Alarm or Bus Error
Init to Run	N/A	State transition	Alarm or Bus Error	Alarm or Bus Error
Init to RunSec	N/A	State transition	Alarm or Bus Error	Alarm or Bus Error
Run to Config	N/A	State transition	Alarm or Bus Error	Alarm or Bus Error
Config to Run	N/A	State transition	Alarm or Bus Error	Alarm or Bus Error
Run to RunLock	N/A	State transition	Alarm or Bus Error	Alarm or Bus Error
RunSec to RunLock	N/A	State transition	Alarm or Bus Error	Alarm or Bus Error
RunSec to ConfigSec	N/A	State transition	Alarm or Bus Error	Alarm or Bus Error
ConfigSec to CheckSec	N/A	State transition	Alarm or Bus Error	Alarm or Bus Error
CheckSec to RunSec	N/A	Alarm or Bus Error	State transition	Alarm or Bus Error
CheckSec to ConfigSec	N/A	Alarm or Bus Error	State transition	Alarm or Bus Error
RunSec to Run	N/A	Alarm or Bus Error	State transition	Alarm or Bus Error

PROT register access rules

There are various conditions which have to be satisfied for a write access to a PROT register. A write which fails the required conditions below to update a PROT register will not update any of the bit-fields of the PROT register and will be terminated with an alarm or a bus error.

The following rules apply for accesses to the PROT register when ODEF is 0_B.

1. The PROT register can be read or written by any master agent function
2. A locked read-write sequence to the PROT register is not executed and terminates with an alarm or bus error
3. A write which represents an invalid PROT state transition is not executed and terminates with an alarm or bus error

The following rules apply for accesses to the PROT register when ODEF is 1_B.

1. The PROT register can be read by any master agent function
2. A locked read-write sequence to the PROT register is not executed and terminates with an alarm or bus error
3. A write to the PROT register from any master agent function other than the PROT owner or secure master is not executed and terminates with an alarm or bus error
4. Only the current PROT owner is allowed to modify the PROT owner fields. An attempt by any master agent function other than the PROT owner to update the PROT owner fields of the PROT register by

writing PROT.OWEN=1_B along with the other PROT owner fields is not executed and terminates with an alarm or bus error

5. A write by either the PROT owner or the secure master which represents an invalid PROT state transition is not executed and terminates with an alarm or bus error

***Note**: Certain functions only allow 32-bit accesses to their registers as indicated by the '32' in the access mode columns of the register overview tables in the respective functional block. Software shall follow this 32-bit access rule where a PROT register is marked as such.*

Protected registers access check

The following rules apply to accesses to the registers protected by a PROT mechanism.

- Registers protected by the PROT mechanism can be read by any master agent function, unless prevented by other access protection mechanisms like an APU
- The following PROT states are locked states: Run, RunLock, RunSec, CheckSec. When the PROT state machine is in a locked state, all write accesses to the registers protected by the PROT mechanism are not executed and terminate with an alarm or bus error
- The following PROT states are unlocked states: Init, Config, ConfigSec.
  - When the PROT state machine is in a unlocked state, only the PROT owner has write access to the registers protected by the PROT mechanism. Writes from disallowed master agent functions are not executed and terminate with an alarm or bus error
  - When the PROT state machine is in a unlocked state and no PROT owner is defined, all master agent functions have write access to the registers protected by the PROT mechanism, unless prevented by other access protection mechanisms like an APU

Related information

PROT state machine on page 66

PROT register

The PROT register allows software to define the PROT owner and provides the defined owner access to modify the PROT owner and state machine.

Each instance of the PROT mechanism may have implementation specific fields in the lower half of the PROT register. When such implementation specific fields are defined, they can only be written by the PROT owner when the PROT state is already unlocked or in the same write transaction that transitions the PROT state to unlocked (when the PROT state is Init, Config or ConfigSec or in the same write that changes the PROT state from Run to Config, RunSec to ConfigSec or CheckSec to ConfigSec). Writes from the PROT owner to the implementation specific fields when the PROT state is locked will be ignored and the implementation specific fields will not be updated. The PROT mechanism outputs the value of any implementation specific fields without any internal processing. See section "APU arrays to protect system memories" for an example of such an implementation specific field. Unused bits in this range are marked reserved, read-only zero.

After application reset, the PROT mechanism is in the Init state and ODEF is set to 0_B. This means that any master agent function can configure the PROT, as well as the protected registers immediately out of reset. Software will have to configure the PROT owner and switch to one of the Run states in order to secure the PROT mechanism.

***Note**: For functions related to cyber-security, the reset value of the PROT owner is instead be set to the CPUcs D TAG with ODEF=1_B.*

Interfaces

Table 30 PROT interfaces

Signal	Direction	Description
clock	in	Input clock
application_reset	in	Reset input to PROT mechanism.
init_done	in	On the rising edge of init_done, all PROT state machines which are in the Init state are transitioned to the RunLock state.
Interconnect interface	in-out	Interconnect slave interface (for example SRI, FPI) which is used to access registers in the functional block.
owner	out	PROT owner information for use in external access gates.
config_lock	out	Indicates when active that the protected registers cannot be modified by application software.

(table continues...)

Table 30 (continued) PROT interfaces

Signal	Direction	Description
config_activate	out	Indicates when active that the modified (shadow) configuration should now be made active.
access_shadow	out	Indicates when active that read and write accesses should be targeted to the shadow state rather than the active state.

The PROT mechanism does not generate any interrupts. It generates either an alarm or a bus error for invalid writes to the PROT register or the protected resource registers.

Lock signals

The PROT states are decoded to generate the config_lock, and access_shadow output signals.

The config_lock signal is used to ensure that registers protected by the PROT mechanism can only be modified when the PROT is in an unlocked state (Init, Config or ConfigSec).

Table 31 PROT outputs

PROT state	config_lock	access_shadow
Init	0	1
Run	1	0
RunLock	1	0
RunSec	1	0
Config	0	1
ConfigSec	0	1
CheckSec	1	1

Shadow access signals

For protected registers which are shadowed, the shadow state of the register is copied into the active state whenever the config_activate signal is set. The config_activate signal is kept asserted when the PROT state is Init. Any transition in the PROT state from a configuration or check state to a run state (Config to Run, CheckSec to RunSec) also generates a single cycle pulse in the config_activate signal.

The copy of state from shadow to active has to be done such that no transaction on the interconnect ever sees a partially updated active state. This can be ensured by either copying all shadow state into the active state in a single cycle or by holding off new interconnect transactions while the shadow state is being copied into the active state.

For protected registers that are shadowed, the access_shadow signal determines whether read and write accesses are directed to the active or shadow state. The desired behavior is described in the following table.

Table 32 Access destination for shadowed protected registers

PROT state	Read accesses	Write accesses
Init	Active state	Active state
Run/RunLock/RunSec	Active state	Disabled
Config/ConfigSec	Shadow state	Shadow state
CheckSec	Shadow state	Disabled

This behavior is implemented using the following rules for protected registers that are shadowed:

- When access_shadow is 0_B, read and write accesses to the protected registers are steered to the active copy. Write accesses are disabled when config_lock is 1_B
- When access_shadow is 1_B, read and write accesses to the protected registers are steered to the shadow copy. Write accesses are disabled when config_lock is 1_B
  - ***Note**:* *Even though access_shadow is set in the Init state and this means that read and write accesses are steered to the shadow state in Init, the config_activate signal is set in Init and causes the shadow state to be copied over into the active state on every write. This means that the shadow and active states are kept consistent throughout Init and the net effect to software is the same as if the active state were being directly accessed.*

Protecting APU registers on page 74

Use cases

A few high level examples of PROT usage in the system are presented below.

Protecting shadowed registers

When configuration or control registers affect both the safety and security of the module, any modifications to the registers has to be done in a safe and secure manner. This is achieved by applying the following measures:

- The affected registers are shadowed so that they may be modified without the changes taking immediate effect
- They are protected by a PROT mechanism that is operated by software, see chapter "RunSec, ConfigSec and CheckSec states"

When software accesses shadowed registers such as those described above, the accesses are steered to either the active state or the shadow state as described in the table below.

Table 33 Access destination for shadowed protected registers

PROT state	Read accesses	Write accesses
Init	Active state	Active state
Run/RunLock/RunSec	Active state	Disabled
Config/ConfigSec	Shadow state	Shadow state
CheckSec	Shadow state	Disabled

Related information

RunSec, ConfigSec, CheckSec states on page 67

Protecting APU registers

A common example of a set of protected registers is the APU register set. These are usually protected by a PROT mechanism and can only be configured by the PROT owner (when the PROT owner is defined).

If the APU configuration registers are shadowed, the previous APU configuration continues to be active until any re-configuration of the APU is complete.

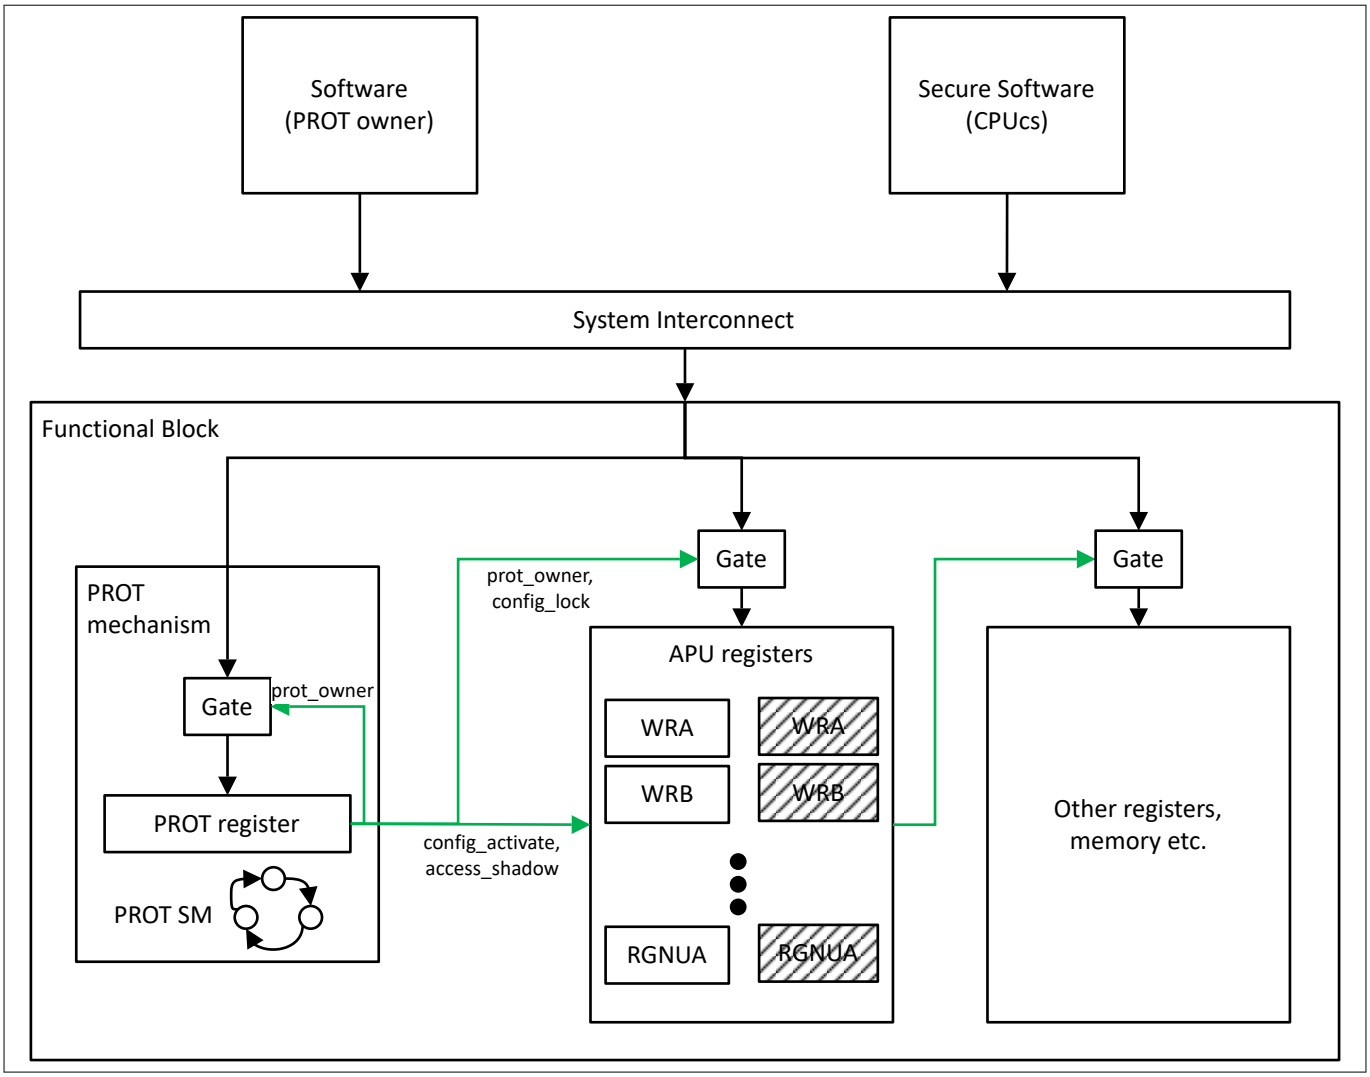

Figure 8 APU protection with shadowed state

Note that when a number of APUs together partition and protect a single function as is common in the system memories, it is not necessary that the state of all the APUs is shadowed. See chapter "APU arrays to protect system memories" for details.

Related information

APU arrays to protect system memories on page 77

Secure control of CSRM functions

There are several functions which are critical to the security of the MCU. The approach used to maximize security for these functions is that the reset state of related PROT and APU instances is set such that only the CPUcs has configuration access to these functions. After boot, the secure software can choose to open up access to these functions to other master agent functions as appropriate to the security of the application use case.

Reset state of security related PROT instances

- STATE = Init
- ODEF = 1
- TAGID = CPUCS.D

- VMEN = 0
- PRSEN = 0

Reset state of security related APU instances

- CPUCS TAG-IDs are enabled for read and write access
- All other TAG-IDs are disabled for read and write access
- All VM and PRS encodings are enabled for read and write access

Access protection unit (APU)

The access protection unit (APU) provides fine-grained control of the protection settings for a group of registers. Each APU can be set up to protect a set of registers or a memory region. The APU consists of a set of configurable registers (see "APU registers") and access checking logic which either allows or disallows each access from the bus interface to the intended target. Disallowed accesses are terminated with an alarm or bus error.

Related information

APU registers on page 78

Access protection check

The APU allows configuration software to enable or disable access to each master agent function in the MCU through the ACCEN_WRA/ACCEN_WRB and ACCEN_RDA/ACCEN_RDB registers. Each master agent function can be configured to have read-only access, write-only access, read and write access or can be disallowed access altogether

In addition, the APU supports virtualization by supporting access checks on the VM and PRS fields presented on the interconnect interface.

- When the interconnect interface presents a transaction with the VM validity indicator set, the access is only granted if the bit in ACCEN_VM corresponding to the VM number on the interconnect transaction is set. When the VM validity indicator on the transaction is not set (for example, when virtualization is disabled), the ACCEN_VM register is ignored
- When the interconnect interface presents a transaction with the PRS validity indicator set, the access is only granted if the bit in ACCEN_PRS corresponding to the PRS number on the interconnect transaction is set. When the PRS validity indicator on the transaction is not set, the ACCEN_PRS register is ignored

When the region registers (ACCEN_RGNLA, ACCEN_RGNUA) are implemented, they are used to restrict the APU instance to protect a subset of the memory region decoded by the slave.

An access operation (read or write) is executed if all of the following conditions are true:

- The bit corresponding to the master agent function TAG ID in the interconnect transaction is set in either the ACCEN_RDA/ACCEN_RDB or ACCEN_WRA/ACCEN_WRB register for read or write accesses respectively
- Either the VM validity indicator is not set in the interconnect transaction or the bit corresponding to the VM ID in the interconnect transaction is set in the ACCEN_VM register for read or write accesses respectively

- Either the PRS validity indicator is not set in the interconnect transaction or the bit corresponding to the PRS in the interconnect transaction is set in the ACCEN_PRS register for read or write accesses respectively
- Either the APU does not implement the ACCEN_RGNLA and ACCEN_RGNUA registers or the masked address in the interconnect transaction is such that $\text{ACCEN_RGNLA} \leq \text{masked_address} < \text{ACCEN_RGNUA}$. The masked address is defined as follows:
  - For addresses in segments 0-7 and 12-15, the masked address is the same as the address in the interconnect transaction
  - For addresses in segments 8-11, the masked address is the address in the interconnect transaction bitwise-ANDed with DFFFFFFF_H

***Note**: The ACCEN_RGNLA and ACCEN_RGNUA registers are usually only implemented in APUs protecting system memories to allow application software to partition the memory into smaller regions with different access protection rules.*

APU arrays to protect system memories

System memories such as DSPRs, PSPRs, DLMUs, LMUs, and PFLASHs are used to store data for many different software tasks and may therefore have to be partitioned into regions that can each have a different access protection configurations. This is implemented using an array of APU instances for each memory, with the ability to specify the region that each APU instance protects within that memory.

The region for each APU is configured by writing the lower and upper addresses of the desired region into the ACCEN_RGNLA and ACCEN_RGNUA registers respectively.

The APU configuration therefore is critical in partitioning the memory between different software tasks of various safety and security levels. The safety and security of the APU configuration is ensured through the following scheme:

- The array of APU registers is not directly writable by software; they are instead read-only
- There is a single additional shadow APU register set which is writable by software and protected by a PROT mechanism. The PROT register contains an implementation specific SEL field which allows the PROT owner to specify the target APU instance to be configured
- When the PROT owner wishes to modify the configuration of a certain target APU instance:
  - If the PROT state is currently Init:
    - The PROT owner writes the target APU instance number to the implementation specific SEL field of the PROT register
    - The PROT owner then writes the shadow APU's registers with the complete new configuration data
    - Since the PROT state is Init, this immediately updates the active state of the target APU instance
  - When the PROT state is not Init:
    - The PROT owner writes to the PROT register to unlock the configuration and writes the target APU instance number into the implementation specific SEL field in the PROT register (either in the same write or after the PROT state has been unlocked)
    - The PROT owner then writes the shadow APU's registers with the complete new configuration data
    - If some portion of the memory contains security related information, this configuration can then be checked by security software for security issues as described in the PROT mechanism chapter
    - When the PROT mechanism next transitions to a locked state, the new configuration is copied from the shadow registers into the target APU instances registers and becomes active

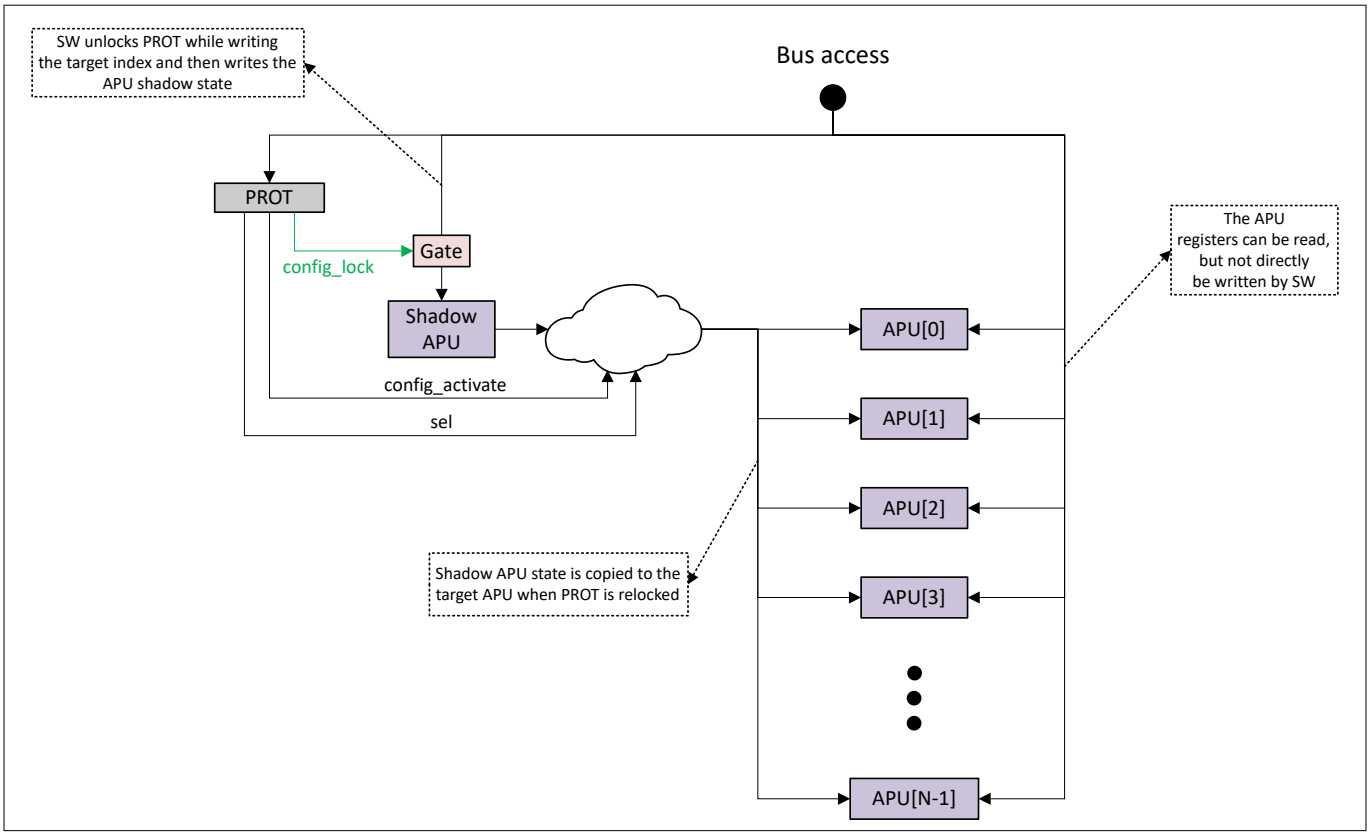

Figure 9 APU array configuration

PROT mechanism on page 64

APU registers

The APU registers are laid out as follows in a contiguous range of addresses.

The ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM and ACCEN_PRS registers are mandatory for every instantiation of the APU. The ACCEN_RGNLA and ACCEN_RGNUA registers are optionally present in APUs protecting system memories and allow the APU instance to protect a configurable subset of the memory region. When the ACCEN_RGNLA and ACCEN_RGNUA registers are not present, they shall be marked reserved and no other registers shall be overlaid on them.

The reset state of the APU is set to enable all master agent functions for read access and enable only CPU0 and Cerberus for write access. For security related functions like the CPUcs APU the reset value is instead set to allow only the CPUcs with read and write access.

Access protection of unused resources

When software does not intend to use a resource, it can choose not to configure the resource at all and leave any PROT and APU mechanisms in the resource in their reset states.

After all configuration by application startup software (ASSW) is complete, the ASSW writes to the SMM_PROTINIT.PINIT_DONE or CSCU_INIT.DONE register fields which causes all PROT mechanisms in that domain which are still in their Init states to transition to the RunLock state. No further modification of protected configuration is possible in the RunLock state until the next application reset. For unused modules which default to having their clocks turned off at reset, this disables the module entirely.

This mechanism thereby removes all access to any slave functions that are left unconfigured by software, effectively putting them in a safe and secure state.

Register access modes

Read and write access to registers and memory locations are sometimes . The terms defined in thetable bel ow may be used in memory and register access tables to indicate such restrictions on access. Eachfunction al block also defines additional terms in its access mode glossary table to indicate module specificrestrictio ns.

In general, if an access type is not permitted under these rules (for example, an attempted write to a read-only register or an attempted user mode access to a SV protected register) then a Bus Error will result, unless the access is also marked as nBE or otherwise stated in the specific module chapter. Where there are multiple access terms specified for a single register in a comma separated list, the access is only permitted if all of the conditions are satisfied when the access is executed.

Bit-fields access restrictions, where for example a write access is permitted or not depending on value of another bit-field in the same register, are described in separate "Access mode restrictions" tables for each register and its bit-fields. When violated, these bit-field restrictions do not generate a Bus Error unless specified differently.

Table 35 Access terms

Symbol	Description
BE	Always returns a Bus Error. This is used for example on a write access to indicate a read-only register.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.
nE	Indicates that no Error is generated when accessing this address or address range, even though the access is to an undefined address or address range. This is used for example on CPU accesses (MTCR or MFCR) to undefined addresses in the CSFR range.
TM	Access only when in test mode.
M	Indicates a module specific access condition. Refer to the register description for details of the specific access condition.
OEN	Access only when OCDS is enabled.
PW	Access only when the correct password is given.
STP	Access only during start-up, before start-up protection is set (SMM_STCON.ST_PROT=1).
CSSTP	Access only during secure start-up, before secure start-up protection is set (CSCU_STCON.CSSTP=1).
SV	Access only when supervisor mode is active on the interconnect.
PROT	Access restrictions as defined in the PROT register access rules.
16	Access when using 16-bit width or higher.
32	Access only when using 32-bit width.
64	Access only when using 64-bit width.
U	No access restrictions.

3.2 Software Over The Air (SOTA)

Software updates Over The Air (SOTA) is supported by providing the ability to split the PFLASH into two regions. The SOTA functionality enables software executing out of the application PFLASH (PFLASH other than the PFLASHcs) to be updated without impacting the currently executing application.

The application could be executing out of the active PFLASH region, while an update to the application code is downloaded and programmed into the inactive PFLASH region.

The SOTA functionality on the PFLASHcs is more in that a programming operation to the inactiveregion of the PFLASHcs cannot happen while the active region of the PFLASHcs is being accessed.

3.2.1 Feature list

- Ability to program the inactive application PFLASH region while retaining full read access to code and data in the active application PFLASH region
- Ability to swap the active PFLASH region by updating the SOTA swap configuration UCB. The updated configuration becomes active on the next system reset
- Ability to disable the SOTA mechanism and access all of the PFLASH in the MCU with a linear address map

3.2.2 Functional overview

The SOTA functionality can be enabled and configured independently for the application PFLASH and PFLASHcs through configuration in the SOTA UCBs. When SOTA is disabled, the MCU addresses the respective application PFLASH or PFLASHcs in the linear addressing mode. When SOTA is enabled, the MCU splits the respective application PFLASH or PFLASHcs into two address regions, one of which can be set as the active region as described below. See the system address map chapter for details of the PFLASH memory address ranges for each SOTA configuration.

Application PFLASH linear addressing mode

When SOTA is disabled for the application PFLASH, all the application PFLASH memory is available for instruction fetch and to read in a single contiguous memory region.

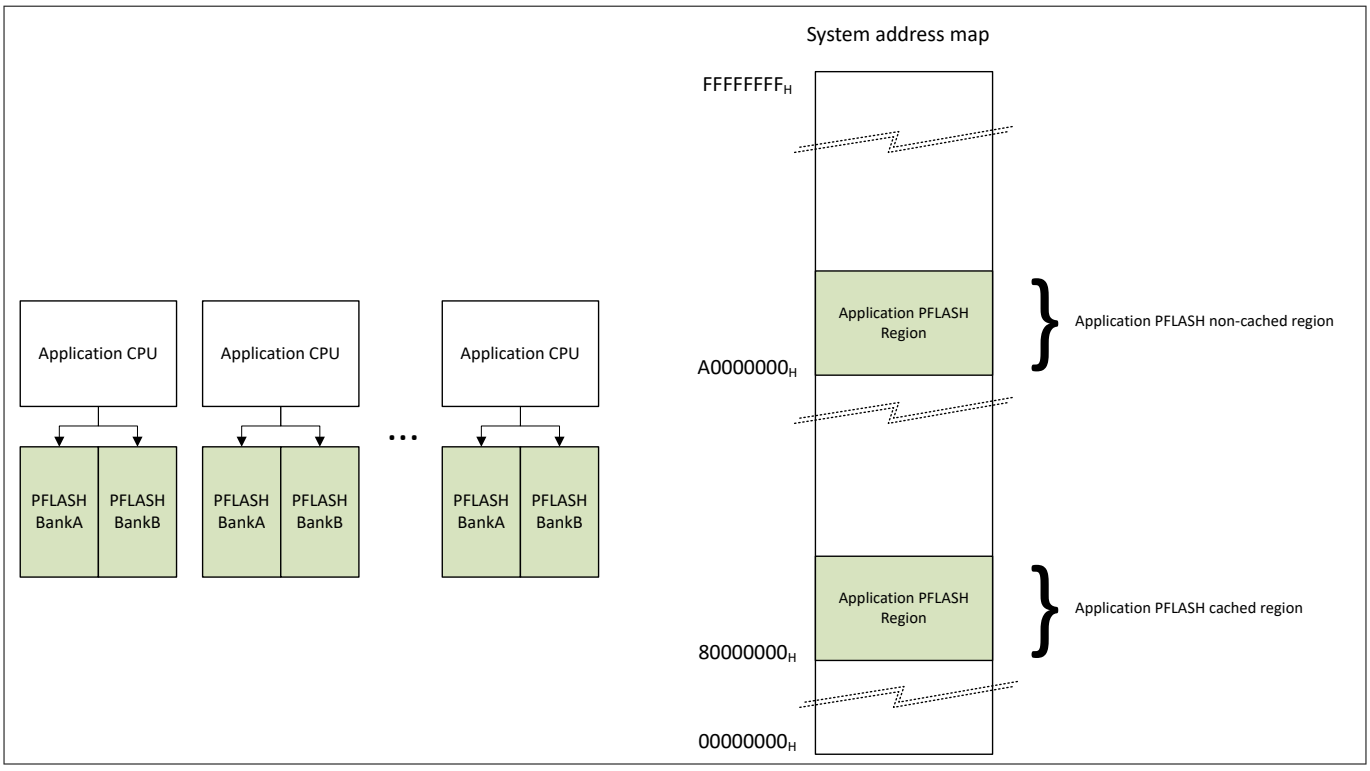

Figure 10 System address map with application PFLASH in linear addressing mode

Application PFLASH SOTA addressing mode

When SOTA is enabled for the application PFLASH, the application PFLASH is split into two equal regions.

- Application PFLASH region A: The memory available in one PFLASH bank of each of the application CPUs is available for instruction fetch and to read in a single contiguous memory region
- Application PFLASH region B: The memory available in the other PFLASH bank of each of the application CPUs is available for instruction fetch and to read in a single contiguous memory region

One of the application PFLASH regions A or B can be marked as an active region and this region is available for application software to read or execute from. The other region is marked as an inactive region and is available for programming operations such as to write a new software image. The programming operations to the inactive region can happen without any effect on instruction fetch or read accesses to the active region.

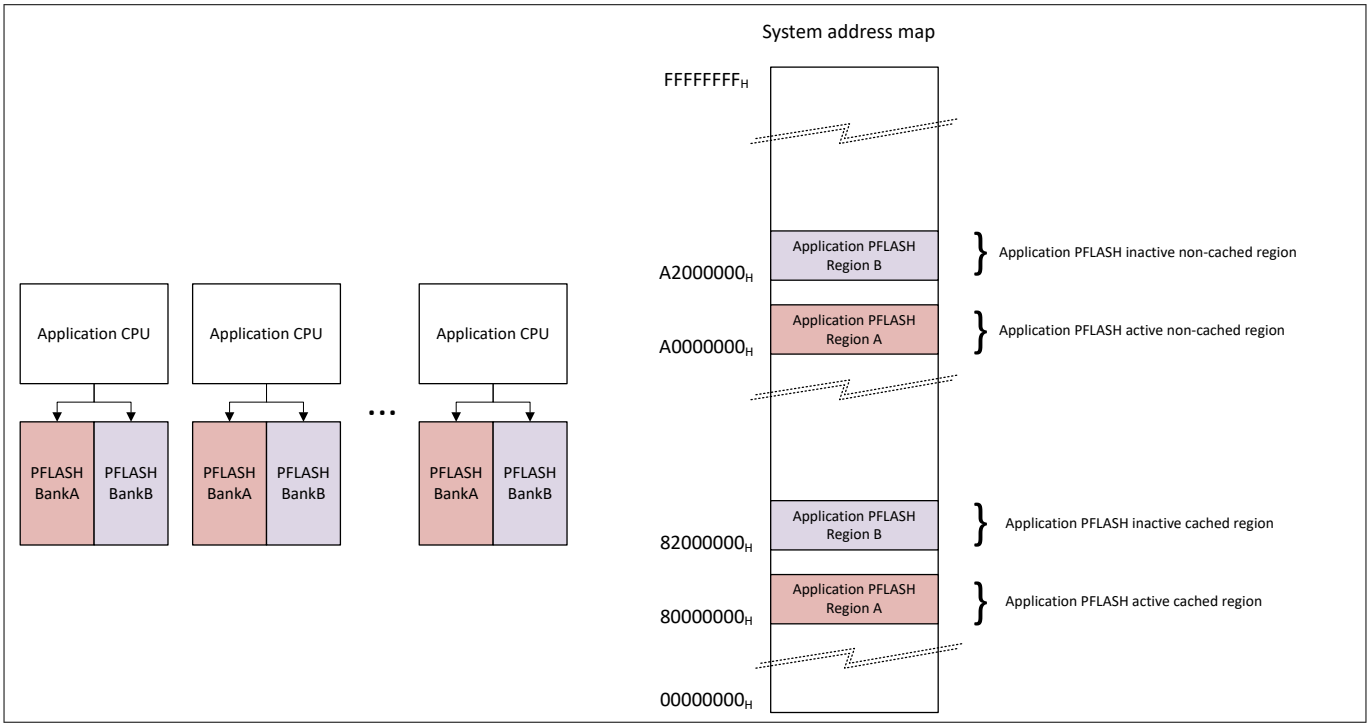

Figure 11 System address map with application PFLASH in SOTA-A mode

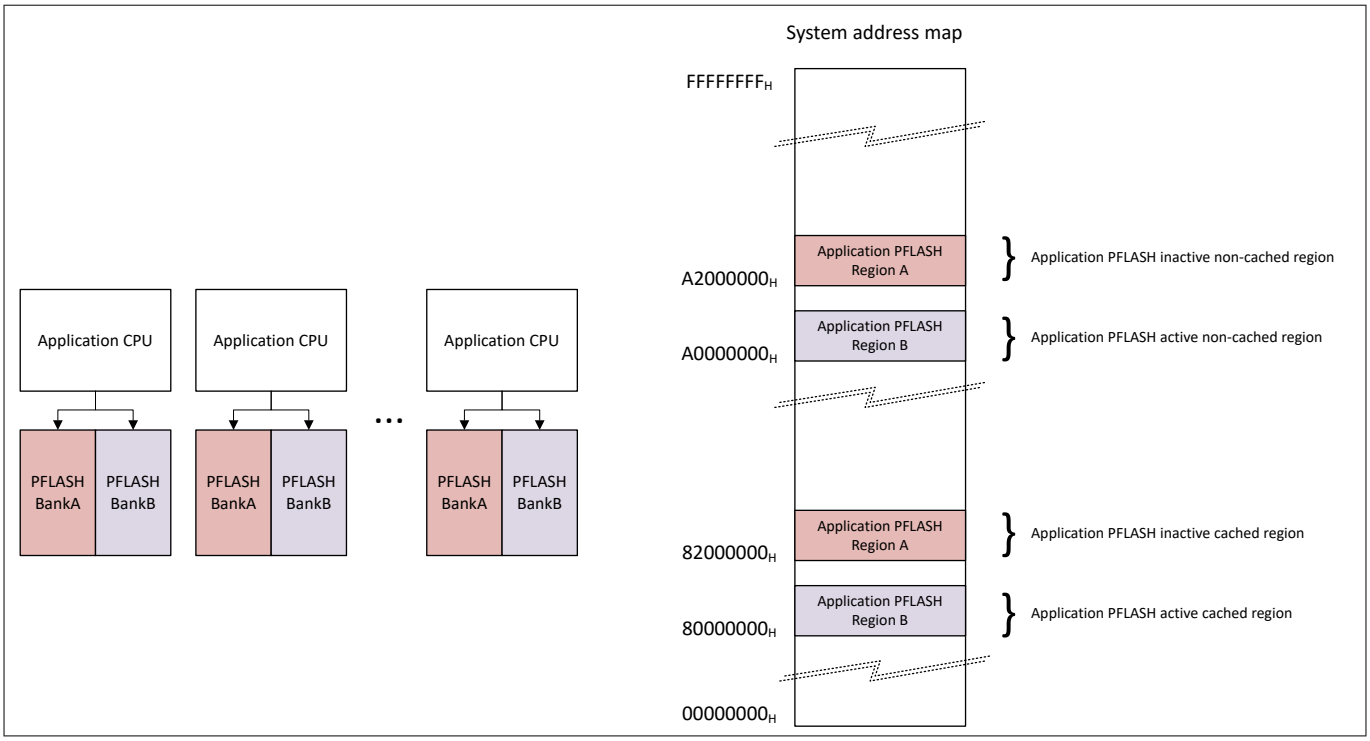

Figure 12 System address map with application PFLASH in SOTA-B mode

When SOTA is enabled for the application PFLASH, the active and inactive regions can be swapped by having application software update the SOTA swap configuration in the UCB. When a system reset is next applied, the MCU will boot up with the new SOTA swap configuration.

PFLASHcs linear addressing mode

When SOTA is disabled for the PFLASHcs, the PFLASHcs memory is available for instruction fetch and to read in a single contiguous memory region.

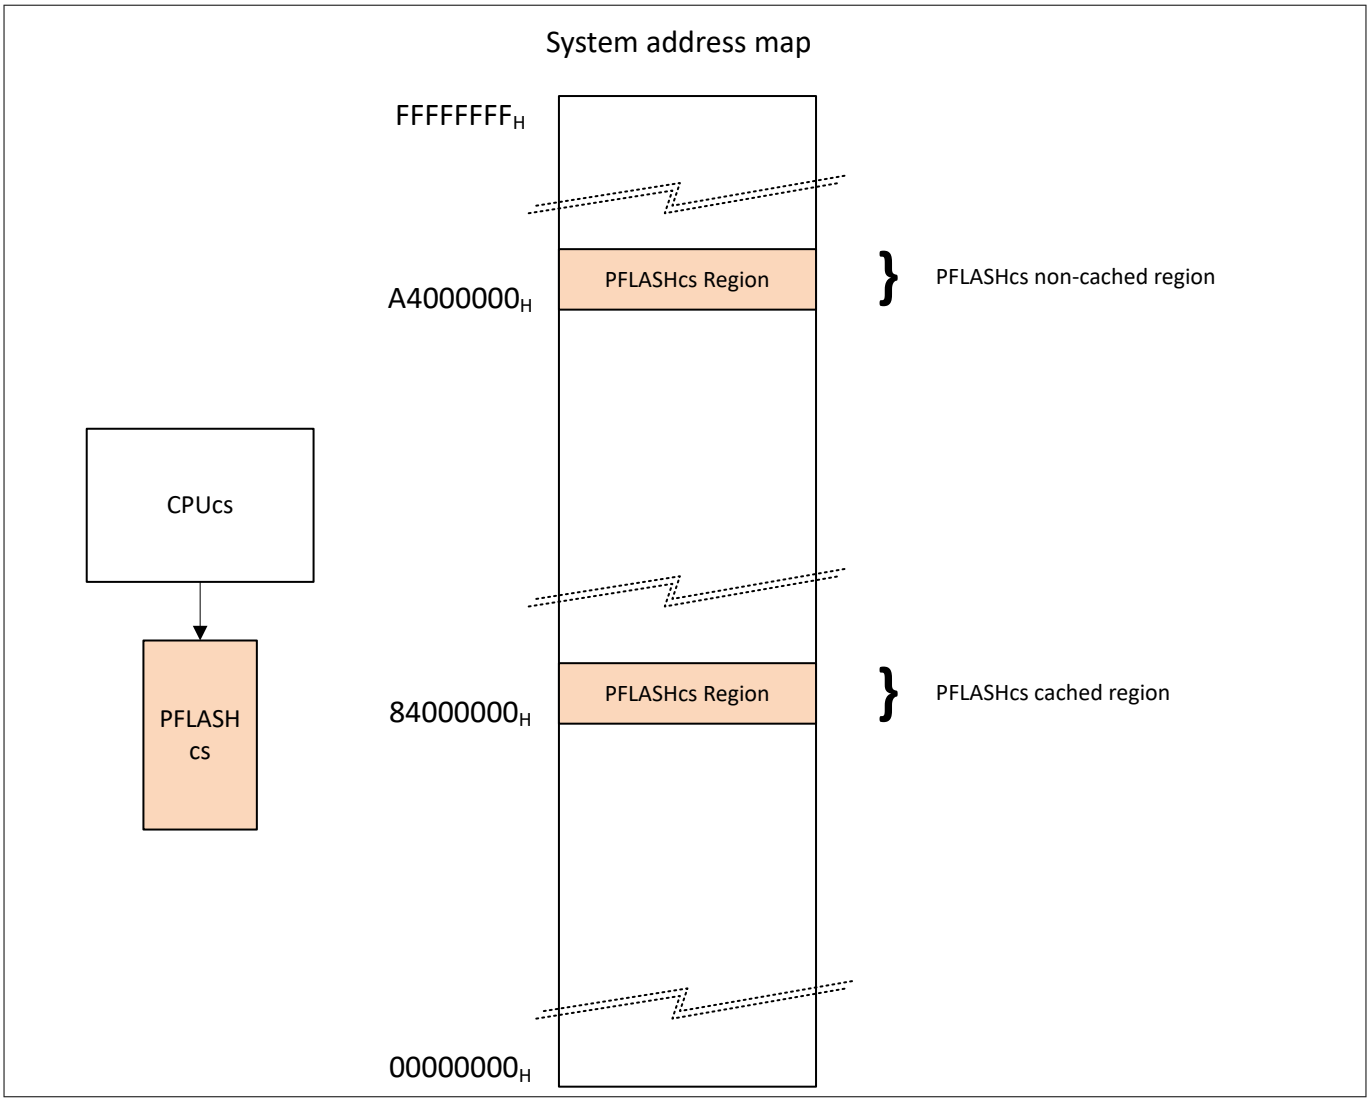

Figure 13 System address map with PFLASHcs in linear addressing mode

PFLASHcs SOTA addressing mode

When SOTA is enabled for the PFLASHcs, the PFLASHcs is split into two equal regions:

- PFLASHcs region A: One half of the PFLASHcs is denoted region A and is available for instruction fetch and to read in a single contiguous memory region
- PFLASHcs region B: One half of the PFLASHcs is denoted region B and is available for instruction fetch and to read in a single contiguous memory region

One of the PFLASHcs regions A or B can be marked as an active region and this region is available for application software to read or execute from. The other region is marked as an inactive region and is available for programming operations such as to write a new software image. Since both PFLASHcs regions physically map to a single PFLASH bank, programming accesses to the inactive region cannot happen at the same time as instruction fetch or read accesses to the active region.

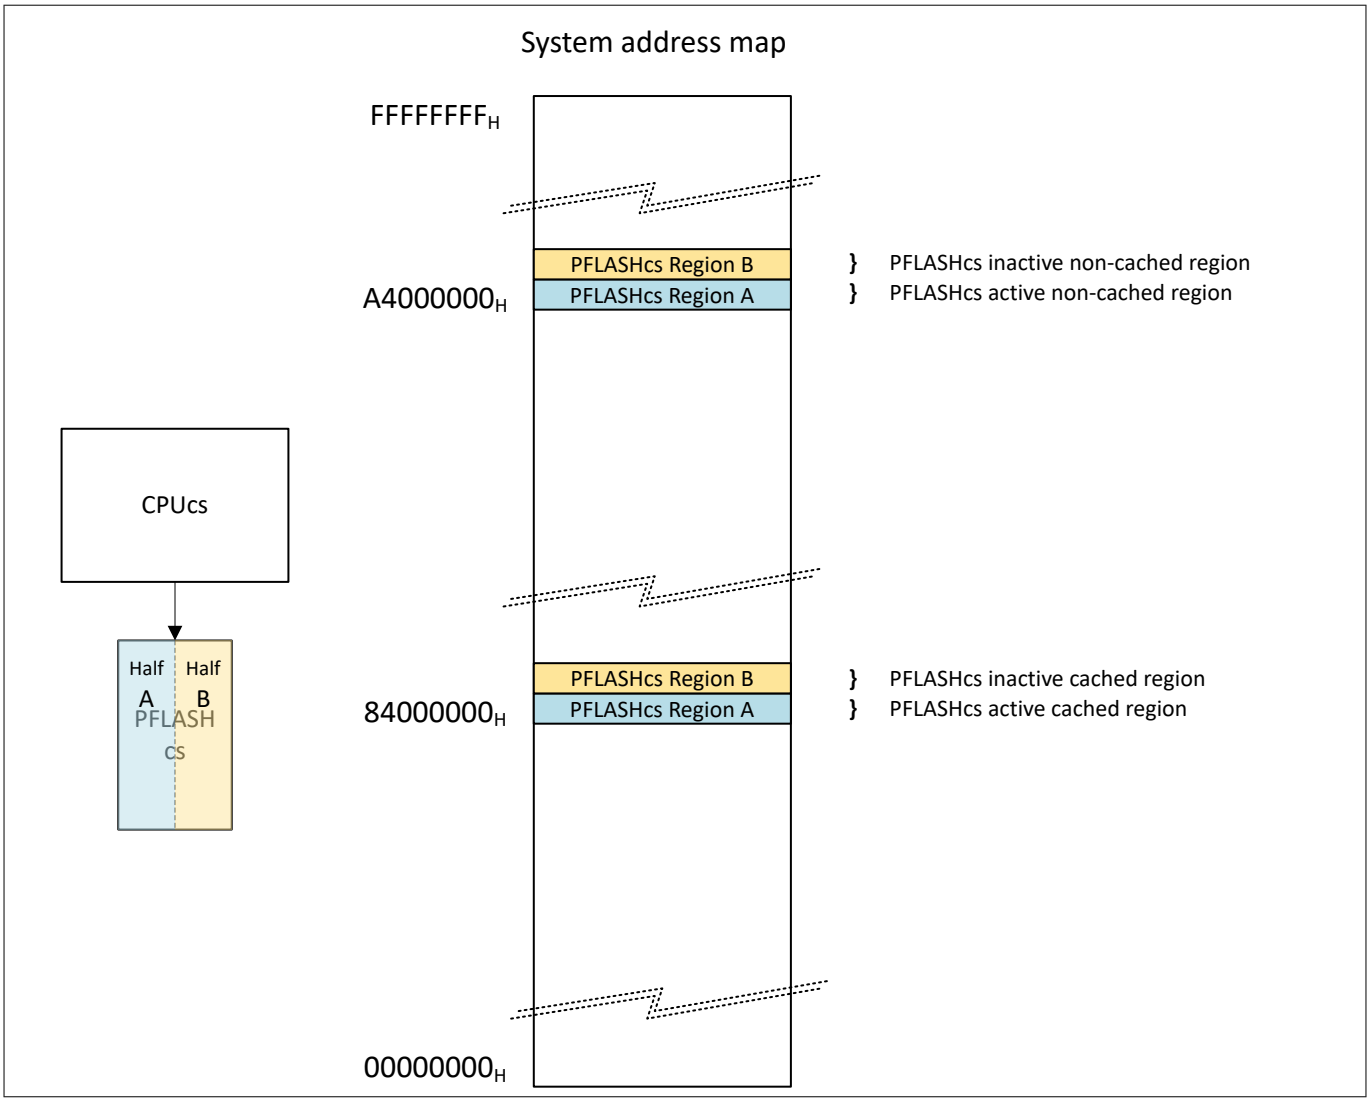

Figure 14 System address map with PFLASHcs in SOTA-A mode

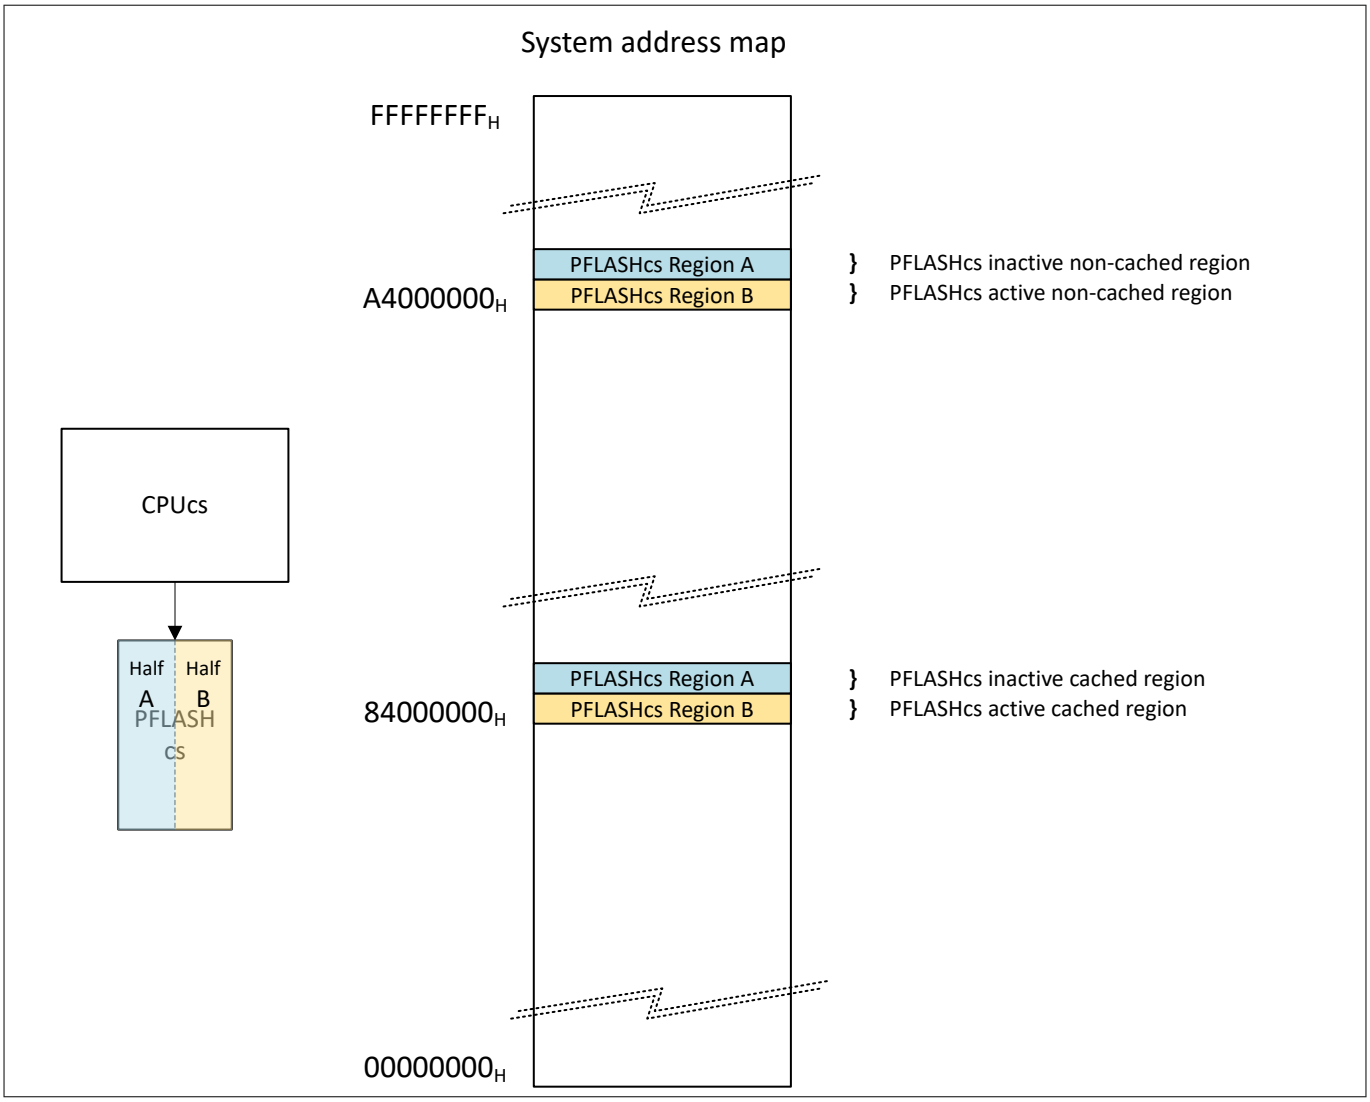

Figure 15 System address map with PFLASHcs in SOTA-B mode

When SOTA is enabled for the PFLASHcs, the active and inactive regions can be swapped by having secure software update the SOTA swap configuration in the UCB. When a system reset is next applied, the MCU will boot up with the new SOTA swap configuration.

3.2.3 Functional description

When SOTA is enabled, the active PFLASH region can be read or executed from, while programming or verification operations can be performed on the inactive PFLASH region. When a SOTA update has completed and the banks are swapped around, only the address mapping between the physical PFLASH modules and the system address map will change. This means that no data needs to be copied and the system address ranges being executed from are always the same.

***Note**: All NVM operations are performed using the physical system address of the PFLASH, so an NVM operation always uses the linear system address map regardless of SOTA or swap settings. 'NVM operation' is a term used for any command sequence such as a program or erase targeting a PFLASH and does not include reads.*

The parameters that control SOTA address map switching and related functions are configured in UCB and the hardware configuration is only updated during the subsequent system reset. This prevents unintentional changes during application execution.

Enabling SOTA on AURIX™ TC4xx devices takes effect with no loss of usable PFLASH memory apart from the partitioning of the memory into active and inactive PFLASH regions.

3.2.3.1 Performance considerations

The CPU access to its local Program Flash bank is optimized for maximum performance. In the AURIX™ TC4xx SOTA can be enabled with no impact on the performance of the application CPU access to the local PFLASH bank. This is achieved by providing each application CPU with two local PFLASH banks and simply switching between the two when a SOTA swap is requested.

3.2.3.2 Configuring SOTA

This section describes the configuration required to enable SOTA and swap between the active and inactive regions.

3.2.3.2.1 Configuration parameters

The SOTA functionality can be enabled and configured independently for the application PFLASH and PFLASHcs. The table below shows the UCB parameters which configure whether SOTA is enabled and which region is set to the active region.

Table 36 SOTA configuration parameters

Affected PFLASH	Parameter	Description	Configuration UCB
Application PFLASH	SOTA mode enable	If SWAPEN is set to enable, SOTA mode will be entered after the next system reset. Linear mode will be enabled otherwise.	UCB_RTC_USERCFG_ORIG.SWAP_ena, UCB_RTC_USERCFG_COPY.SWAP_ena
	Bank swap configuration	If SOTA mode is valid and enabled and the SWAP information configured in the UCB is valid, then after the next system reset the configured region A or B is made active.	UCB_RTC_SWAP_ORIG, UCB_RTC_SWAP_COPY
PFLASHcs	SOTA mode enable	If SWAPEN is set to enable, SOTA mode will be entered after the next system reset. Linear mode will be enabled otherwise.	UCB_CS_USERCFG_ORIG.SWAPCS_ena, UCB_CS_USERCFG_COPY.SWAPCS_ena
	Bank swap configuration	If SOTA mode is valid and enabled and the SWAP information configured in the UCB is valid, then after the next system reset the configured region A or B is made active.	UCB_CS_SWAP_ORIG, UCB_CS_SWAP_COPY

3.2.3.2.2 Initial device configuration for SOTA

There are some recommendations for installing the initial device configuration for a device which has SOTA enabled.

Starting from the delivery state, the initial execution image is programmed onto the active PFLASH region. If SOTA mode on PFLASHcs is required, the initial execution image should include the CSRM program code in the active PFLASHcs region. It is recommended that the sectors used are then protected by installing sector specific write protection in the UCB using the ORIG and COPY programming sequence as described in the 'UCB handling' section of the NVM chapter.

The start address of the initial image is programmed in UCB_RTC_BMHD and UCB_CS_BMHD and the standard programming of the Boot Mode Header UCBs is performed.

In order to select SOTA-A mode on the application PFLASH (PFLASH region A is active, PFLASH region B is inactive), the following values should be programmed into the UCB entry:

- Write the value 55_H into UCB_RTC_SWAP.SWAP_ORIG_MARKER0.MARKERx
- Write the system address of UCB_RTC_SWAP.SWAP_ORIG_SAL0 into UCB_RTC_SWAP.SWAP_ORIG_SAL0.SALx
- Write the confirmation code 43211234_H into UCB_RTC_SWAP.SWAP_ORIG_STATUS0.STATUSx
- Write the combined CRC32 value of SAL0, STATUS0, MARKER0 into UCB_RTC_SWAP.SWAP_ORIG_CRCSE0.CRCSEx
- Finally, UCB_RTC_USERCFG.SWAP_ena.SWAPEN is set to enabled, which enables SOTA mode for the application PFLASH with the next system reset

In order to select SOTA-A mode on the PFLASHcs (PFLASH region A is active, PFLASH region B is inactive), the following values should be programmed into the UCB entry:

- Write the value 44_H into UCB_CS_SWAP.SWAP_ORIG_MARKER0.MARKERx
- Write the system address of UCB_CS_SWAP.SWAP_ORIG_SAL0 into UCB_CS_SWAP.SWAP_ORIG_SAL0.SALx
- Write the confirmation code 43211234_H into UCB_CS_SWAP.SWAP_ORIG_STATUS0.STATUSx
- Write the combined CRC32 value of SAL0, STATUS0, MARKER0 into UCB_CS_SWAP.SWAP_ORIG_CRCSE0.CRCSEx
- Finally, UCB_CS_USERCFG.SWAP_ena.SWAPEN is set to enabled, which enables SOTA mode for the PFLASHcs with the next system reset

UCB_RTC_FLASH and UCB_RTC_PFLASH_OTPx are then programed with the necessary values to setup the required OTP and WOP settings on the application PFLASH. Similarly, UCB_CS_FLASH and UCB_CS_PFLASH_OTPx are programmed with the necessary values to setup the required OTP and WOP settings on the PFLASHcs bank.

***Note**: Any OTP or WOP protected sectors cannot be re-programmed with a new image.*

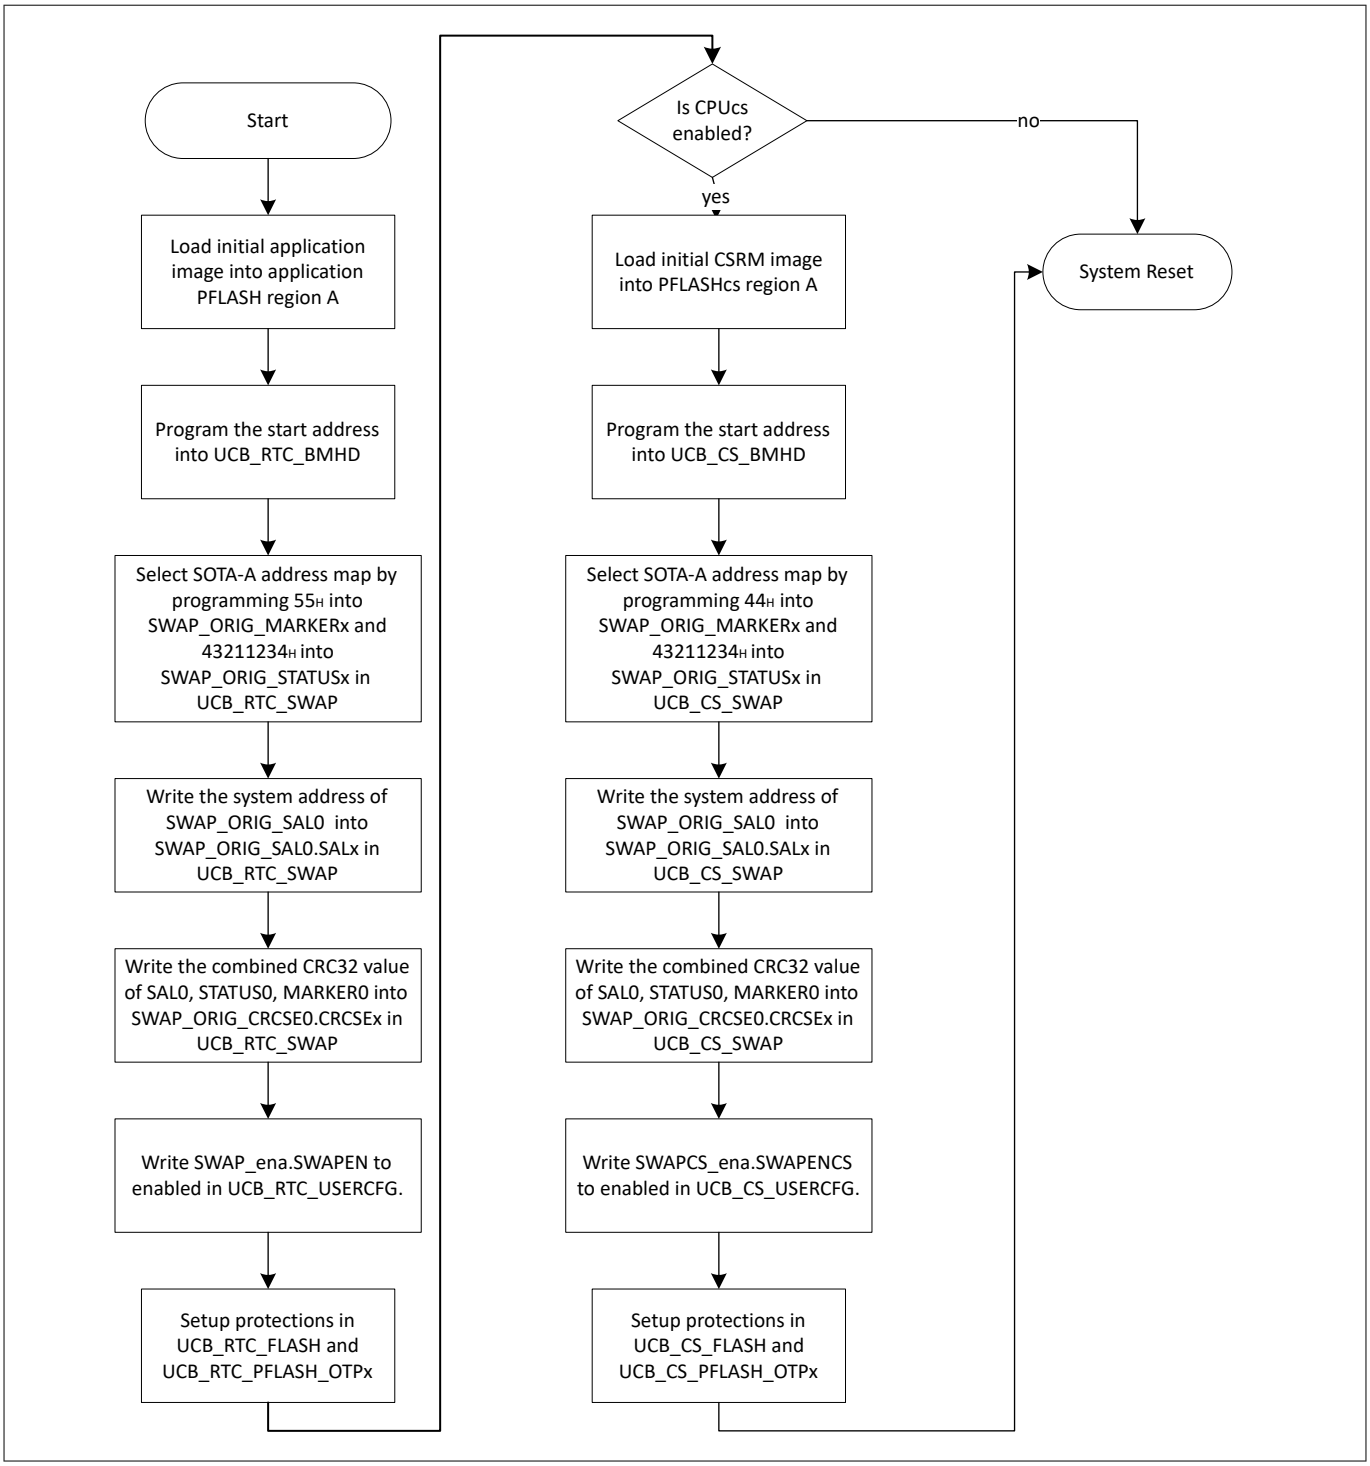

Figure 16 Initial SOTA configuration

3.2.3.2.3 Runtime SOTA configuration

Here we detail the recommendations for installing the new image during a running application and configuring the device to swap to the new image.

In order to swap to the new image, the new program image needs to be loaded into the inactive PFLASH region. In order to do this, the sector specific write protection must be disabled for those banks by presenting the UCB_RTC_PFLASH or UCB_CS_PFLASH password for the ‘Disable Protection’ DMU command sequence in the

NVM. The master performing the update must also be enabled with write access to the inactive PFLASH region in the respective APU in the NVM.

Since concurrent NVM operations (like a program or erase) to PFLASH and DFLASH are not supported, PFLASH operations must either be scheduled for times when no DFLASH operation is taking place or any ongoing DFLASH operation must be suspended to allow the PFLASH operation to occur. Therefore there needs to be some synchronization between the EEPROM driver running in the application and the Secure Flash Bootloader which is performing the update. An alternative is to allocate all PFLASH banks to the CSRM command interface in the CSRM_ALL_PFLASH mode and have the CSRM perform all PFLASH programming while the host can continue accessing the host DFLASH through the host command interface.

The newly written image must have any errors identified and corrected before write protection is re-enabled as described in the safety manual.

In the case of a hard failure during SOTA re-programming or erasing of PFLASH, the Replace Logical Sector feature can be used (See NVM chapter for more details). This feature allows you to map a failing logical sector to a redundant sector using the ‘Replace Logical Sector’ DMU command sequence.

The next step is to configure the SWAP information by configuring the address map to be selected in the UCB_RTC_SWAP or UCB_CS_SWAP. After disabling the sector specific write protection as described above, UCB_RTC_SWAP.SWAP_ORIG_MARKERx is changed to either:

- 55_H, selecting the SOTA-A address map, if application PFLASH region A contains the new image
- AA_H, selecting the SOTA-B address map, if application PFLASH region B contains the new image

Similarly, after disabling the CS sector specific write protection as described above, UCB_CS_SWAP.SWAP_ORIG_MARKERx is changed to either:

- 44_H, selecting the SOTA-A address map, if PFLASHcs region A contains the new image
- Either 11_H or 22_H, selecting the SOTA-B address map, if PFLASHcs region B contains the new image. The value programmed depends on the size of the PFLASHcs bank in the device being programmed

The other fields in the UCB_RTC_SWAP or UCB_CS_SWAP entry - SWAP_ORIG_SALx.SALx, SWAP_ORIG_STATUSx.STATUSx and SWAP_ORIG_CRCSEx.CRCSEx are then programmed as with the initial configuration. The previous (x-1) UCB_RTC_SWAP or UCB_CS_SWAP entry is invalidated by over-programming all-1 into SWAP_ORIG_STATUS(x-1) and SWAP_ORIG_SAL(x-1) (over-programming with all-1 delivers an ECC correct result for UCB and DFLASH). For all of these, 'x' should be increased by one each time images are swapped, starting from 1 the first time after the initial configuration.

If UCB_RTC_SWAP or UCB_CS_SWAP is full (that is 'x' has reached 31), the whole UCB may be erased and 'x' set back to 0 before a new entry is added. The write protection is then re-enabled by using the ‘Resume Protection’ DMU command sequence and updating the master access protection in the relevant APU to detect and prevent accidental writes.

***Note**: The last valid entry of the SWAP information (that is SWAP information stored at the highest value of ‘x’) is used by the Startup Software for configuring SOTA in the system.*

It is possible to configure 32 SWAPs in UCB_RTC_SWAP or UCB_CS_SWAP before an erase is required. The maximum number of SWAPs possible during the lifetime of the device is dependent on the datasheet parameter for PFLASH erase or program cycles. To perform 1000 application PFLASH SWAP configurations, a total of at least 62 UCB erase or program cycles are required during the lifetime (two UCB erases are required per 32 SWAP updates as both UCB_RTC_SWAP_ORIG and UCB_RTC_SWAP_COPY need to be erased and updated). This needs to be taken into account while updating the other UCBs in order to adhere to the datasheet parameter for UCB program or erase cycles.

To begin running with the new image, a system reset needs to be triggered (application resets have no effect).

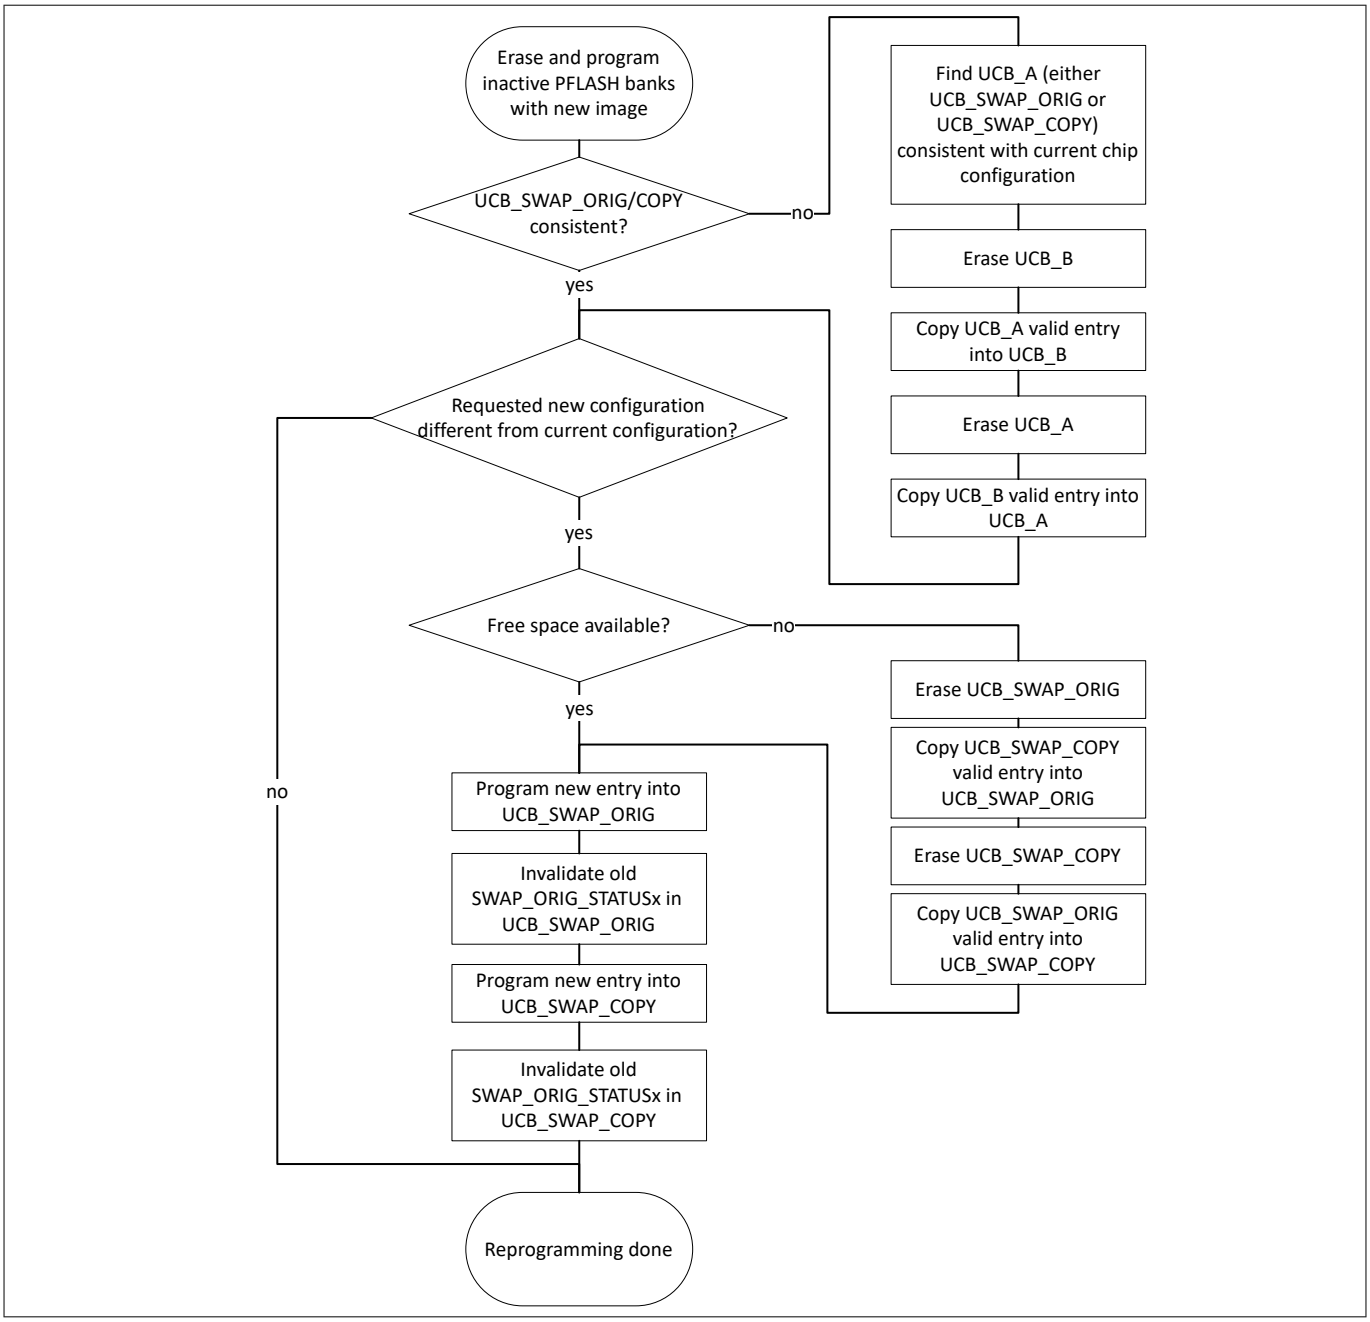

Figure 17 Runtime SWAP configuration

3.2.3.3 Safety

If SOTA is disabled, the entire PFLASH region should be protected by appropriate APU configuration in the DMU which prevents unintentional changes to the contents. If SOTA is enabled, APU protection for the inactive PFLASH region should be configured to allow them to be updated by enabled software masters.

However, even for the active PFLASH region, the requirement for safety application software to be checked before execution remains. More details on the APU protection features in the DMU are available in the ‘Protection’ section of the NVM chapter.

3.2.3.4 Security

The security protection offered to an NVM operation on the PFLASH remains the same as defined in the ‘Protection’ section of the NVM chapter irrespective of the active or inactive nature of the PFLASH region.

3.3 Resource access latencies

The following tables describe the CPU access times to various resources in SRI clock cycles.

- For the values of data access or instruction fetch accesses, the access times are the minimum number of CPU stall cycles to complete the access
- If there is a conflict for the resource accessed, there may be additional stall cycles till the conflicting access completes
- For write access, the access times are the maximum for a sequence of such access (non-conflicting). In many cases for a single access or a short sequence, write buffering reduces the stall effect seen by a CPU, sometimes to 0. However, as with loads and fetches, if there is a conflict for the resource accessed, there may be additional stall cycles till the conflicting access completes
- For data accesses, the access times listed are for 32-bit accesses. The access times for 64-bit write accesses to DLMU or LMU memories can be lower than the numbers listed below due to the SRAM organization

Access latency for FPI bus peripherals

Access to critical module registers is implemented with 1 wait-state (for example QSPI, ASCLIN, EVADC, DSADC result registers and DMA). Some modules may implement additional wait-states as for example in the following instances:

- Access to module internal SRAMs (for example MCAN, DMA, ERAY, GTM, SCR, GETH)
- System infrastructure modules (for example VMT, DMA)
- Access to control registers in large and complex modules that require internal registers stages to meet the timing (for example GTM)

Access latency for PFlash and DFlash accesses

The PFlash and DFlash wait-states are described in the NVM section of the documentation. The wait-states are configured through the following registers:

- PFLASH(HOST): DMU_GP_HOST_PFWAIT
- PFLASH(CSRM): DMU_GP_CSRM_PFWAIT
- DFLASH(HOST): DMU_GP_HOST_DFWAIT
- DFLASH(CSRM): DMU_GP_CSRM_DFWAIT

In all cases the values programmed in the registers are 1 less than the actual value. For example, DMU_GP_HOST_PFWAIT.RFLASH=7 corresponds to 8 read cycles.

For example, the number of stall cycles for a data read from a PFlash instance with DMU_GP_HOST_PFWAIT.RFLASH=7 accessed on the local SRI is as follows.

```
PWS           = (PFLASH READ CYCLES)
              = (DMU_GP_HOST_PFWAIT.RFLASH + 1)
              = 8

Stall cycles  = 5 + PWS
              = 13
```

3.3.1 TC4Dx resource access latencies

Access latency for FPI bus peripherals

The following table lists the stall cycles for CPU accesses to FPI peripherals.

Table 37 Access latency for FPI peripherals (TC4Dx)

CPU access type	Stall cycles for SPB peripheral access[1]	Stall cycles for ComPB peripheral access[1]
CPU0-5 data read[2]	$n \times (4 + \text{Module wait–states})$, where $\left(n = \frac{f_{CPU}}{f_{SPB}}\right)$	$n \times (4 + \text{Module wait–states})$, where $\left(n = \frac{f_{CPU}}{f_{SPB}}\right)$
CPU0-5 data write[2]	$n \times (4 + \text{Module wait–states})$, where $\left(n = \frac{f_{CPU}}{f_{SPB}}\right)$	$n \times (4 + \text{Module wait–states})$, where $\left(n = \frac{f_{CPU}}{f_{SPB}}\right)$
PPU data read[2]	50	50
PPU data write	17	17

1) The number of wait-states for read and for write accesses is >= 1 and depends on the accessed module and its configuration.
2) The final number of stall cycles will depend on the real number of wait-states generated by the target resource.

***Note**: Due to the various bridges between the PPU and the peripherals no generic formula can be given. The numbers documented are for the following frequency ratio PPU/Peripheral bus: 450 MHz/100 MHz*

Access latency for CPU local resources

The following table lists the stall cycles for CPU instruction fetch, read, and write accesses to internal memories.

Table 38 CPU accesses: Stall cycles for local resources

	Local CPU
Data read from DSPR	0
Data write to DSPR	0
Instruction fetch from DSPR	See SRI resources tables[1]
Data read from DLMU	1
Data write to DLMU	4 (2 for 64-bit write accesses)
Instruction fetch from DLMU	See SRI resources tables[1]
Data read from PSPR	See SRI resources tables[1]
Data write to PSPR	See SRI resources tables[1]
Instruction fetch from PSPR	0
Data read from PFlash	5 + PWS[2]
Instruction fetch from PFlash (buffer miss)	2 + PWS[2]
Instruction fetch from PFlash (buffer hit)	3

1) Data access to code side memories or code accesses to data side memories are made through the SRI interconnect.
2) PWS: Configured PFlash wait-states (Includes cycles for PFlash access cycles only). ECC correction latency is only incurred when the incoming data requires ECC correction.

Access latency for SRI resources

The following tables list the stall cycles for CPU read and write accesses over the SRI interconnect to various target memories.

Table 39 CPU accesses: Stall cycles for reads to SRI resources (TC4Dx)

	DSPR	DSPR	DLMU	DLMU	LMU	LMU	LMU	PFlash	PFlash	PPU	PPU
	0-2	3-5	0-2	3-5	0-1	2-3	4-9	0-2	3-5	CSM	VMEM
CPU0-2	7	14	7	14	8	15	15	$PWS + 9$	$PWS + 16$	36	38
CPU3-5	14	7	14	7	15	8	15	$PWS + 16$	$PWS + 9$	36	38
PPU	31	31	31	31	32	32	30	$\lceil PWS \times 0.9 \rceil + 33$	$\lceil PWS \times 0.9 \rceil + 33$	N.A.	N.A.

***Note**: The PPU is running asynchronous to the rest of the system. The documented numbers represent the average access latency in PPU clocks for accesses originating from the PPU. Individual accesses may see different access latencies. They are representative for SRI frequency of 500 and PPU frequency of 450, represented by a scaling factor of 0.9. PFlash access latency could change between random and sequential access.*

***Note**: The CPU stall cycles do not apply to the local PFlash path, for example CPU0 to PFlash0. Those stall cycles are listed in the local resources table.*

Table 40 CPU accesses: Stall cycles for non-pipelined writes to SRI resources (TC4Dx)

	DSPR	DSPR	DLMU	DLMU	LMU	LMU	LMU	PPU	PPU
	0-2	3-5	0-2	3-5	0-1	2-3	4-9	CSM	VMEM
CPU0-2	4	7	4	7	5	7	7	13	13
CPU3-5	7	4	7	4	7	5	7	13	13
PPU	7	7	7	7	7	7	6	N.A.	N.A.

Table 41 CPU accesses: Stall cycles for pipelined writes to SRI resources (TC4Dx)

	DSPR	DSPR	DLMU	DLMU	LMU	LMU	LMU	PPU	PPU
	0-2	3-5	0-2	3-5	0-1	2-3	4-9	CSM	VMEM
CPU0-2	3	5	4	5	4	5	5	13	13
CPU3-5	5	3	5	4	5	4	5	13	13
PPU	7	7	7	7	7	7	6	N.A.	N.A.

***Note**: The PPU is running asynchronous to the rest of the system. The documented numbers represent the average access latency, individual accesses may see different access latencies. They are representative for SRI frequency of 500 and PPU frequency of 450*

***Note**: Although the table lists DSPR access latencies, the PSPR access latencies will be equivalent to the listed DSPR latencies for data access through SRI*

A CPU's fetch latency from another CPU's PFlash either on the local or remote crossbar is influenced by the executing CPU's overall pipeline state. Additionally, it interacts with the pre-fetch mechanism when pre-fetch buffers are enabled on the PFlash path. The front end of the CPU pipeline operates on fetches which are equivalent to cache line size, even when the cache is disabled. The summary is indicative of the access latency assuming one pre-fetch buffer of the other CPU is assigned to the fetch CPU's P side SRI TAG-ID. Even though the instruction fetch and execution are decoupled, the actual stall cycles will depend on execution of fetched instructions. The following stall cycles apply when executing all instruction from the previously fetched line assuming they are all 32_B, can be dual issued and is devoid of exceptions, dependencies and hazards:

Table 42 CPU stall cycles due to line fetch(256b) over SRI from PFlash of another CPU

Fetch conditions	Pflash on local crossbar	Pflash on other crossbar
Instruction fetch (buffer miss)	$PWS + 9$	$PWS + 16$
Instruction fetch (buffer hit)[1)]	$\max(PWS + 2, 11) - 4$	$\max(PWS + 2, 18) - 4$

1) The reduction by 4 accounts for the 4 cycles to execute 8 instructions delivered in the fetch packet

3.3.2 TC4Dx SDMA throughput

The following tables describe the achieved SDMA throughput moving data from and to various system memories.

- The throughput is measured at the following clock frequencies: f_{SRI} = 500 MHz, f_{SPB} = 100 MHz
- The throughput is measured as the Gbyte/s (rounded-down) achieved by the SDMA instance while moving 32 KB of data from the source memory to a destination memory using a 512-bit move size
- When there are multiple DMA channels accessing a common memory location, the DMA channels are configured with addresses greater than 64 KB apart such that the DMA move requests to the memory are not pipelined
  - If the two DMA channels happen to target addresses within the same 64 KB region on source or destination memories, the throughput achieved will be better than the results below
- If there is a conflict for the resource accessed, there may be a drop in the throughput achieved till the conflicting access completes

Table 43 TC4Dx SDMA0 single channel throughput (Gbyte/s)

3.4 Module reset

It is proposed to stop all participants that have read or write access to the functional block (FB) kernel registers during the normal application, before a functional block module reset is started by application software, through the functional block KRST registers.

This means that for example DMA channels and software tasks that access the kernel are to be stopped, and the last write accesses by bridges must be waited for.

To detect unexpected write accesses during or after functional block kernel access, the kernel can also be switched off through the CLC register before a kernel reset.

Accesses to the kernel that is switched-off are normally terminated with an SRI or FPI error and signaled as an alarm to the SMU.

Many functional blocks support a reset of their kernel function.

If available, the kernel reset can be started and controlled with the registers:

- RST_CTRLA
- RST_CTRLB
- RST_STAT

There are also functional blocks with several kernel functions that have their own kernel reset function, such as ADC for example.

Which functional block registers are reset by a kernel reset function is described in the respective functional block register overview table.

Registers that are not normally reset by a kernel reset are PROTs, APUs, OCS, and CLC.

4 Central Processing Unit (CPU)

The TriCore™ 1.8 central processing unit (TC1.8 CPU) is a superscalar implementation of the version 1.8 of the TriCore™ architecture. TriCore™ is a 32-bit microcontroller-DSP architecture optimized for real-time embedded systems.

The TriCore™ instruction set architecture (ISA) combines the real-time capability of a microcontroller, the computational power of a Digital Signal Processor (DSP), and the high performance and features of a Reduced instruction set computer (RISC) load-store architecture, in a compact re-programmable core.

The ISA supports a uniform, 32-bit address space and memory-mapped Input/Output (IO). The architecture supports both 16-bit (reduced code space and low memory requirement) and 32-bit instruction formats. Real-time responsiveness is supported by low interrupt latency and fast-context-switching. The high performance architecture minimizes interrupt latency by avoiding long multi-cycle instructions and by providing a flexible hardware-supported interrupt scheme.

Compared to version 1.6, version 1.8 of the TriCore™ architecture includes virtualization support and a double precision IEEE-754-2019 Floating-point unit.

Please note that TriCore™ architectural information is defined in the TriCore™ 1.8 architecture manual. Topics covered by that manual include:

- Architecture overview
- Programming model
- CPU registers
- Tasks and functions
- Interrupt handling
- Traps
- Memory protection system
- Temporal protection system
- Floating-point operations
- Debug
- Instruction set
- Virtualization

***Note**: The optional MMU extension is not implemented in this product family.*

4.1 Feature list

The real-time core implementations have the following features:

- 32-bit load store little-endian architecture
- 16-bit and 32-bit instructions for reduced code size
- Single and double-precision floating-point unit (IEEE-754-2019)
- Virtualization
  - Dual virtual machine support per core with three hardware resource partitions replicating most state
  - Support for one hypervisor, one real-time virtual machine, and up to 6 other virtual machines
- Temporal protection system allowing time-bounded real-time operation
- 4 Gbyte address range (2^{32})
- Multiple data types
  - Boolean, integer with saturation, bit array, signed fraction, character, double-word integers, quad-word integers, signed integers and unsigned integers
- Multiple data formats
  - Bit, byte (8-bit), half-word (16-bit), word (32-bit), double-word (64-bit) and quad-word (128-bit)

- Byte and bit addressing
- Multiply and accumulate (MAC) instructions
  - Single 32 x 32 and dual 16 × 16, 16 × 32 architecture
- Integer arithmetic with saturation
- Packed data
- Addressing modes
  - Absolute, circular, bit reverse, long + short, base + offset with pre-update and post-update
- Instruction types
  - Arithmetic, address arithmetic, comparison, address comparison, logical, MAC, shift, coprocessor, bit logical, branch, bit-field, load and store, packed data and system
- General Purpose Register Set (GPRS):
  - Sixteen 32-bit data registers
  - Sixteen 32-bit address registers
  - Three 32-bit status and program counter registers (PSW, PC, PCXI)
- Debug support
- Flexible memory protection system providing multiple protection sets with multiple protection ranges per set
- Dedicated system timer with extensions for virtualization

4.2 Functional overview

The central processing unit implements version 1.8 of the TriCore™ architecture. A device specific number of instances can be used to run the application software. The CPU operation is supported by local SRAMs, a local NVM connection and configuration registers. The TC1.8 CPU block diagram is shown in the figure below:

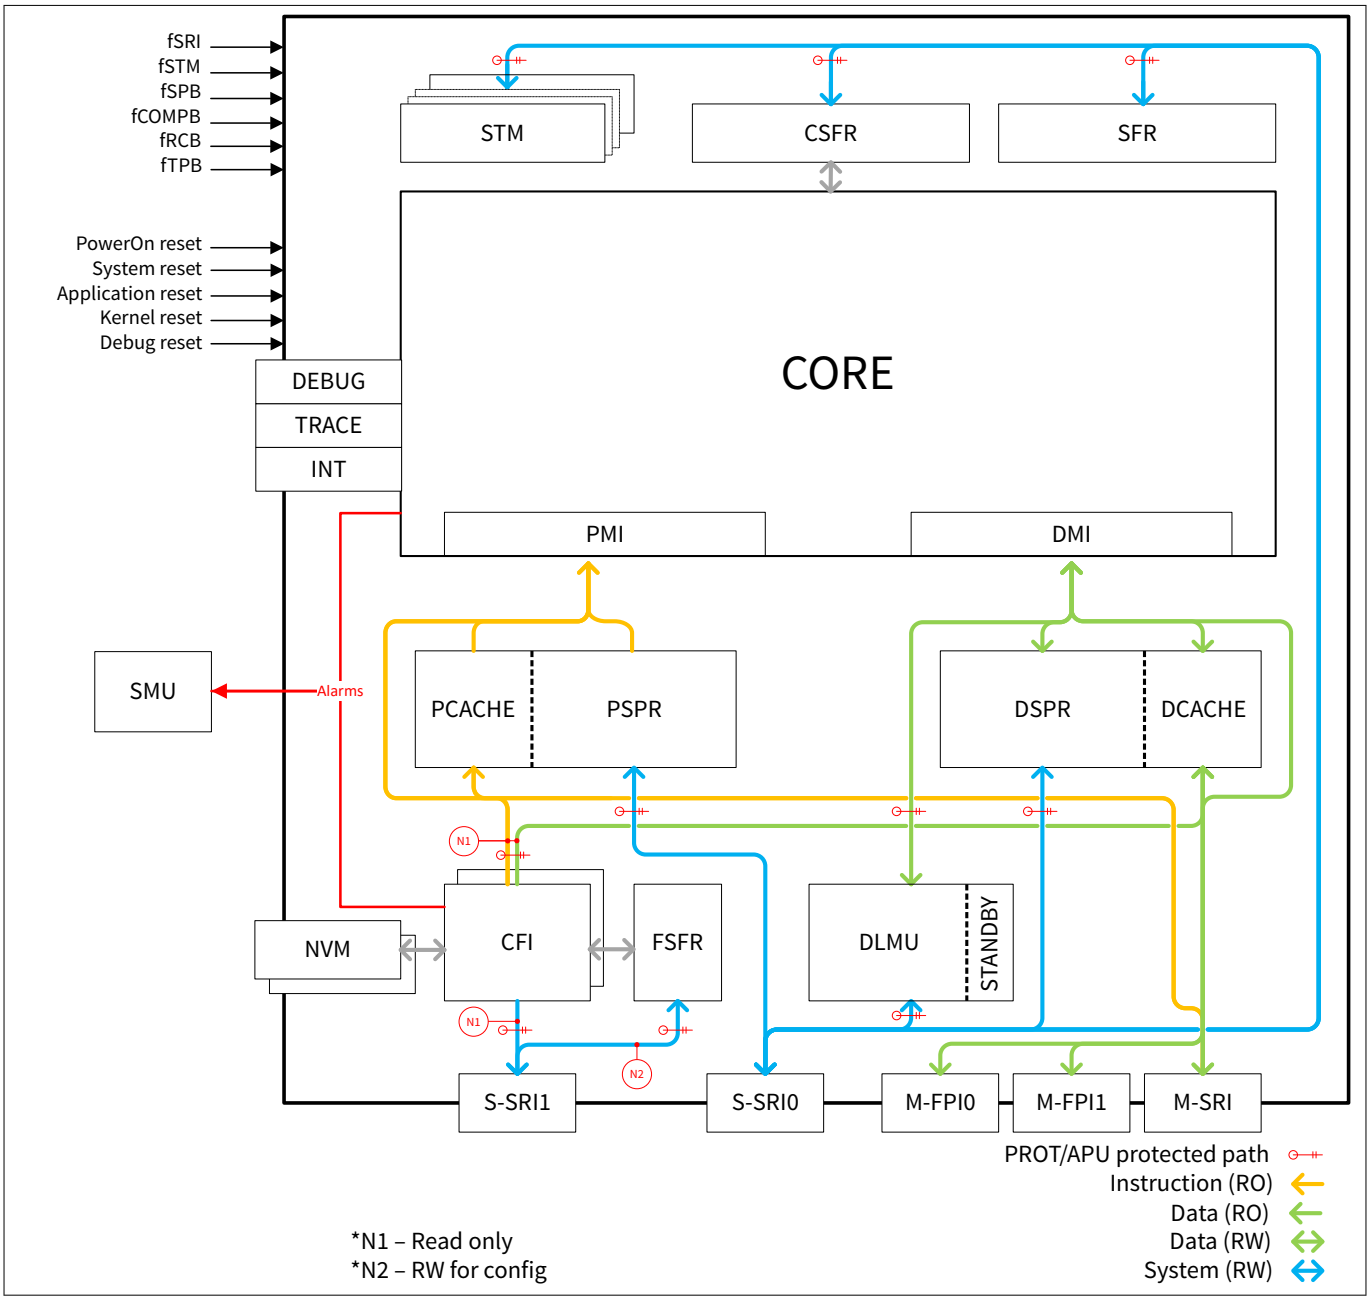

Figure 18 CPU block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

TC1.8 CPU connections

The TC1.8 CPU contains interfaces to the following memories, interconnect, and bus interfaces:

- Data scratchpad SRAM (DSPR)
- Program scratchpad SRAM (PSPR)
- Data cache (DCache)

- Program cache (PCache)
- Distributed LMU memory (DLMU)
- Local NVM bank (x2 some instances) through the NVM interface (CFI)
- SRI slave interface for other resources (S-SRI0)
- SRI slave interface for Local NVM (S-SRI1)
- SRI master interface (M-SRI)
- FPI master interface (M-FPI0)
  - FPI0 is always connected to the SPB
- FPI master interface (M-FPI1)
  - FPI1 can connect to other FPI buses depending on the device and the core instance

The protected paths are:

- S-SRI0 accesses to PSPR, DSPR, DLMU, SFR, CSFR, or STM
- S-SRI1 (if present) accesses to CFI, or FSFR
- PMI or PCACHE accesses to CFI
- DMI or DCACHE accesses to CFI
- DMI accesses to local DLMU

TC1.8 CPU units

The TC1.8 CPU comprises of the following units:

- TriCore™ based processing unit (CORE)
  - Program memory interface (PMI)
  - Data memory interface (DMI)
- Special function registers (SFR)
- Core special function registers (CSFR)
- NVM special function registers (FSFR)
- System timer (STM)

4.2.2 CPU block diagram

The processor core comprises of:

- An Instruction Fetch Unit
- An Execution Unit
- A General Purpose Register File (GPR)
- A CPU Slave interface (CPS)
- Optional Floating-Point Unit (FPU)
  - Single and double-precision floating-point units,
  - or single precision floating-point unit only
  - or no FPU

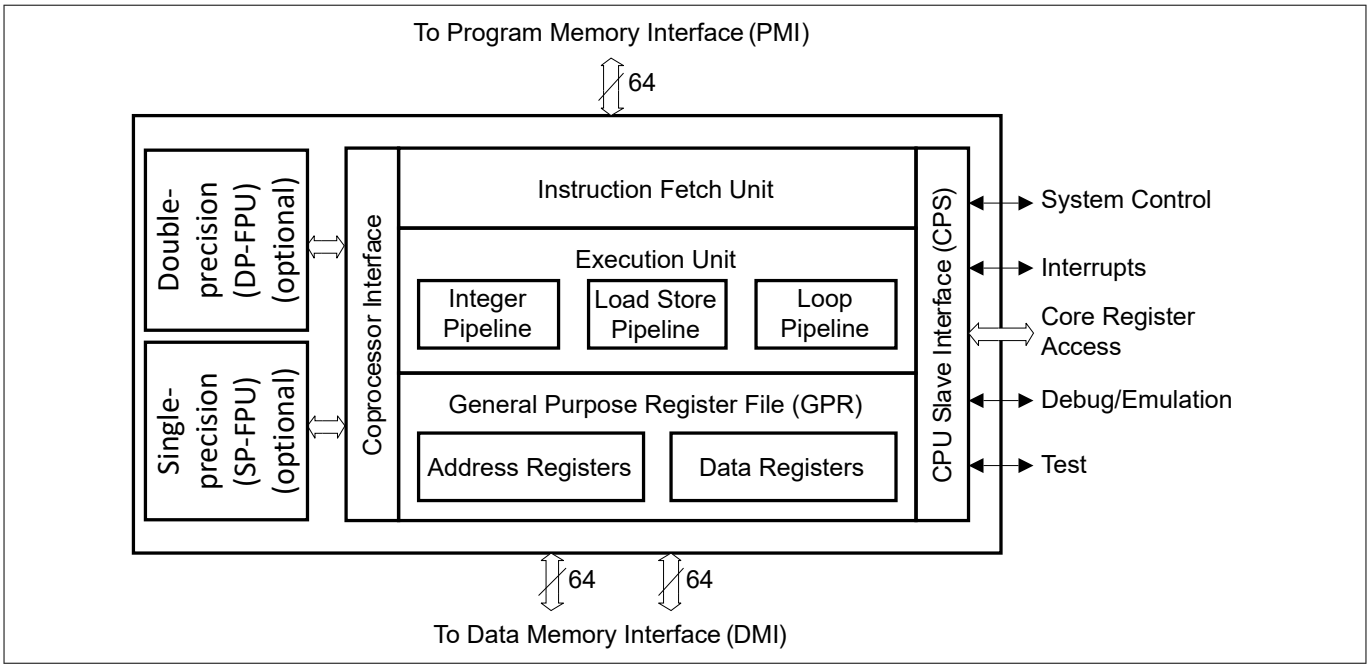

Figure 19 CPU block diagram

4.2.3 Instruction fetch unit

The Instruction Fetch Unit pre-fetches and aligns incoming instructions from the 64-bit wide Program Memory Interface (PMI). Instructions are placed in predicted program order in the Issue unit (FIFO).

The Instruction Protection Unit checks the validity of accesses to the PMI and the integrity of incoming instructions fetched from the PMI.

The branch unit (Prefetch) examines the fetched instructions for branch conditions and predicts the most likely execution path based on previous branch behavior. The Program Counter Unit (PC) is responsible for updating the program counter.

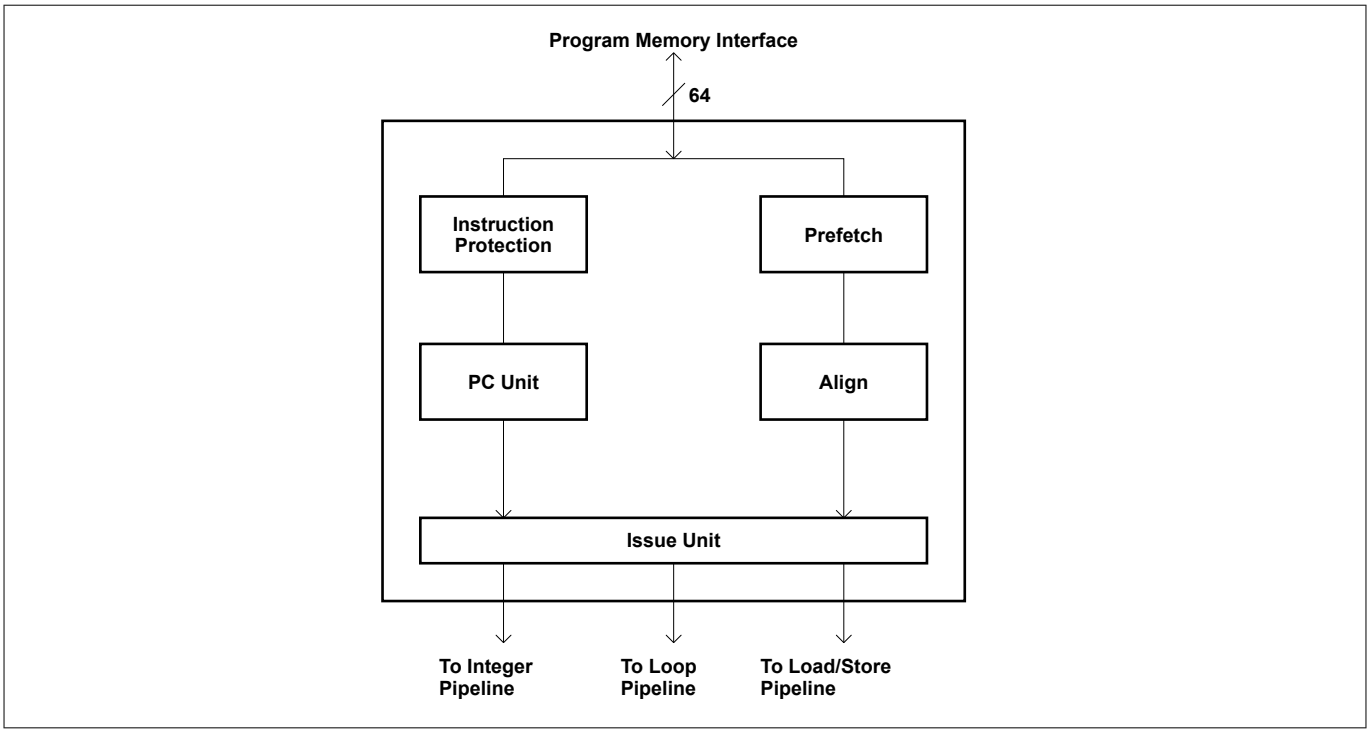

Figure 20 Instruction fetch unit

4.2.4 Execution unit

The Execution Unit contains the Integer Pipeline (IP), the Load/Store (LS) Pipeline and the Loop Pipeline (LP). All three pipelines operate in parallel, permitting up to three instructions to be executed in one clock cycle. In the execution unit all instructions pass through a decode stage followed by two execute stages (three for multiply-accumulate (MAC)). Pipeline hazards (stalls) are minimized by the use of forwarding paths between pipeline stages allowing the results of one instruction to be used by a following instruction as soon as the result becomes available.

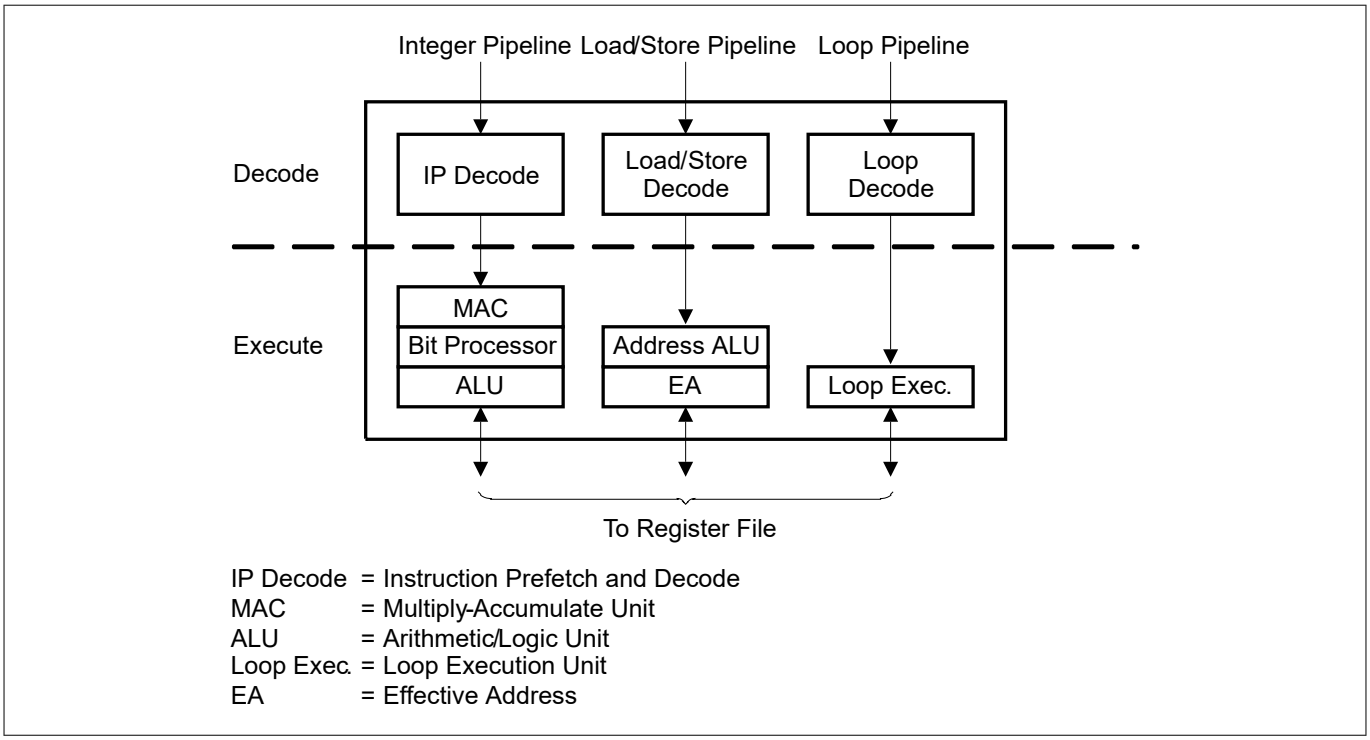

Figure 21 Execution unit

4.2.5 General purpose register file

The CPU has a General Purpose Register (GPR) file, divided into an Address Register File (registers A0 through A15) and a Data Register File (registers D0 through D15).

The data flow for instructions issued to the Load/Store Pipeline is steered through the Address Register File.

The data flow for instructions issued to the Integer Pipeline and for data load/store instructions issued to the Load/Store Pipeline is steered through the Data Register File.

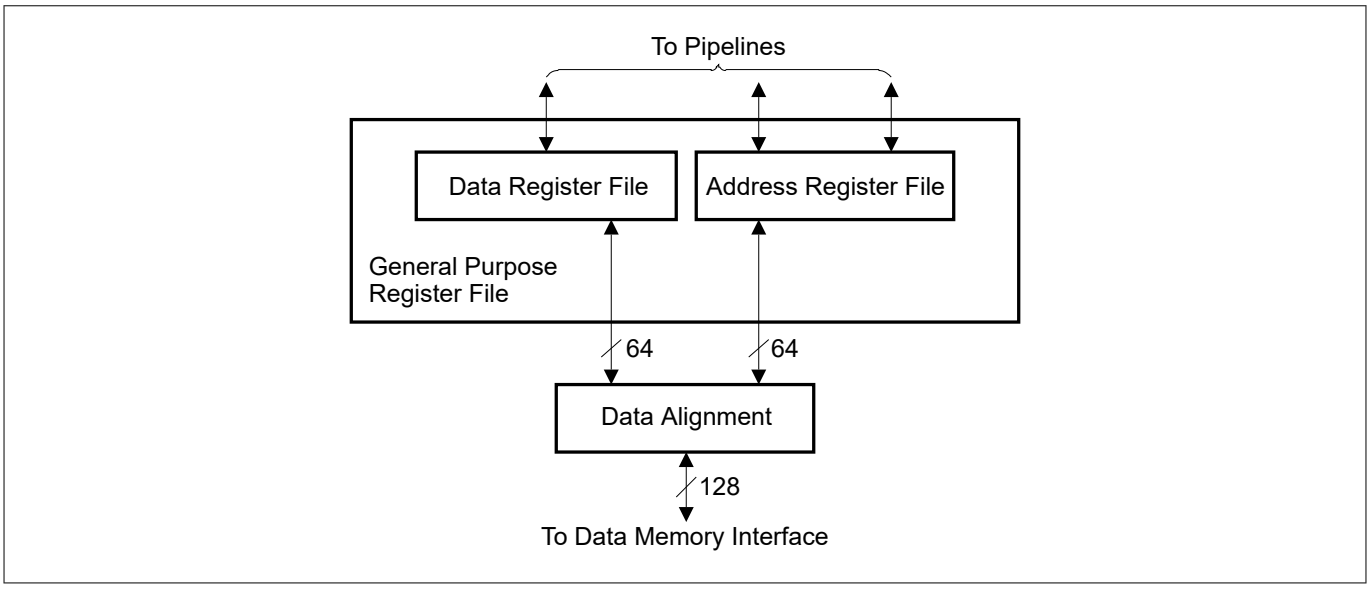

Figure 22 General purpose register file

4.3 Functional description

This sections describes the architectural choices made where there are allowed options, the implementation features such as instruction timing and memory hierarchy and system features implemented in the TC1.8 CPU like overlay support for calibration.

4.3.1 CPU implementation specific features

A description of those properties of the TC1.8 CPU which are allowed by version 1.8 of the TriCore™ architecture for an implementation to determine.

4.3.1.1 Configurability

Hardware support for several optional extensions is provided on specific TriCore™ instances. Refer to the TCCON register for a runtime accessible definition of the instance hardware features. Cores in some members of the product family or even some cores within a product might not have the same hardware features.

4.3.1.2 Context save areas and context operations

The CPU uses a uniform context-switching method for function calls, interrupts, and traps. In all cases the Upper Context of the task is automatically saved and restored by hardware. Saving and restoring of the Lower Context may be optionally performed by software.

Please refer to the TriCore™ architecture manual volume 1 for more details. The Context Save Areas (CSA) and addresses targeted by explicit context load or store instructions, such as LDLCX for example, may be placed in DSPR, DLMU, or non-peripheral SRI memory (cached or uncached).

CSA placement in DSPR or DLMU

The actual timing of context operations is dependent upon the placement of the Context Save Areas. Maximum performance is achieved when the Context Save Area is placed in DSPR.

In this case all context save and restore operations take four cycles (using DSPR assuming no external interference).

If the CSA is placed in the DLMU, context save and restore operations take eight cycles.

CSA placement in cached external memory

In this situation the timing is also dependent on the state of the data cache. The best case for CSA operations using the data cache occurs when context saves do not incur a cache line writeback, and context restores hit in the data cache (best case for a cache hit is four cycles).

CSA placement in non-cached external memory

CSA placement in non cached external memory is allowed, but not recommended for performance reasons. The execution time will be dependent on the system memory used.

4.3.1.3 Program counter (PC) register

The Program Counter (PC) holds the address of the instruction that is currently fetched and forwarded to the CPU pipelines. The CPU handles updates of the PC automatically.

Software can use the current value of the PC for various tasks, such as performing code address calculations.

Reading the PC through software executed by the CPU must only be done with an MFCR instruction. Such a read will return the PC of the MFCR instruction itself.

Explicit writes to the PC through an MTCR instruction must not be done due to possible unexpected behavior of the CPU. The PC may be written by an external agent only when the CPU is halted.

The CPU will not perform Load or Store instructions to the mapped address of any of the CSFR's in segment 15 (including the PC). A MEM trap will be generated if such an access is attempted.

Bit 0 of the PC register is read-only and is hard-wired to 0.

4.3.1.4 Store buffers

To increase performance, the TC1.8 CPUs implement store buffering to decouple memory write operations from CPU instruction execution. All stores from the CPU are placed in the store buffer prior to being written to local memory or transferred through the system interconnect.

Write data is taken from the store buffers and written when the target memory or interface becomes available.

In normal operation, with bit SMACON.IODT=0_B (default after reset), non-dependent loads may bypass store operations. When both a store and a load operation are present in the pipeline, the CPU will prioritize load operations over store operations in order to improve performance unless:

- The store buffer is full
- The load is to peripheral space and a store to peripheral space exists in the store buffer (in order access to peripheral space is guaranteed)
- The access belongs to an atomic operation
  - Atomic operations require an empty store buffer, this ensures that any buffered state is written to memory prior to the atomic operation
- The in-order data transfer is enabled (SMACON.IODT)
  - Memory operations are performed in program order when the SMACON.IODT bit is set. This should only be performed by test routines at start-up or shut-down as it will severely limit performance

To improve the performance of load operations, the CPU will snoop the content of the store buffer for a matching address. If a match is found, the load data is retrieved from the store buffer before the store is committed to memory.

To improve performance the store buffer will merge consecutively addressed[3)] data elements to reduce the number of memory accesses required. The following operations are merged in the store buffer:

- Consecutive byte writes to the same half-word memory location
- Consecutive half-word writes to the same word memory location
- Consecutive word writes to the same double-word memory location

For snooping and merging operations the properties of the load or store operation are checked against properties of the store contained in the store buffer. In such case the store buffer entry is flushed before the load completes. Snooping and merging do not happen when:

- The load or store belongs to a different virtual machine
- The load or store belongs to a task executed with a different protection set
- The load and store operations do not use the same master agent function identifier

The TC1.8 CPU store buffer can hold the data for up to 6 operations.

For TC1.8, the store buffers are implemented as a FIFO. An item at the head of the FIFO can be commenced on a distinct target as long as the previous head item has commenced even if it has not completed. The distinct targets are:

- Local DSPR
- Local DLMU
- SRI
- FPI (FPI0/FPI1 where present)

[3] Since loads can bypass stores, two store operations to be merged may not be consecutive in the instruction flow

This allows an item to be removed from the head of the FIFO, every clock cycle, to commence access to each free target without stalling the entire FIFO.

If there is a requirement that data is written to local memory prior to execution of a subsequent instruction then a LSYNC or a DSYNC instruction may be used to flush the store buffers. A DSYNC instruction must be used to guarantee that a write is completed at the target destination.

4.3.1.5 Interrupt system

An interrupt request can be generated by on-chip peripheral units, or it can be generated by external sources. Requests can be targeted to any CPU (please refer to the interrupt system described in the Interrupt Router (IR) chapter).

The interrupt system evaluates service requests for priority and to identify whether the CPU should receive the request. The highest-priority service request is then presented to the CPU.

On taking an interrupt the CPU will vector to a unique PC generated from the interrupt priority number and the Base Interrupt Vector (BIV). The spacing between the vector PCs in the interrupt vector table may be selected to be either 32 Bytes or 8 Bytes using BIV.VSS.

The TC1.8 CPU implements a fast interrupt mechanism for consecutive interrupts which avoids some context save and restore operations and therefore speeds up interrupt routine entry. The fast interrupt mechanism operates when:

- An Interrupt is pending
- A Return From exception (RFE) instruction is being executed
- The priority of the pending interrupt is greater than the priority level that would be returned to should the RFE be executed (ICR.PIPN > PCXI.PCPN)
- Interrupts will be enabled after RFE is executed (PCXI.PIE == 1)

The fast Interrupt mechanism will operate unless a MTCR, or MTDCR, instruction targeting PCXI, PSW, PC, CORECON, CPU_ID, CORE_ID, BIV, BTV, ISP, ICR, PPRS, FCX, LCX, BOOTCON, CCON, DMS, DCX, DBGTCR, HRHV_VMn_ICR and DBGCFG executes before the RFE.

The fast interrupt mechanism will operate unless context instruction executes before the RFE. These instructions are: call (CALL, CALLA, CALLA), return (RET), begin interrupt service routine (BISR), save lower context (SVLCX), restore lower context (RSLCX), load upper or lower context (LDUCX, LDLCX), and store upper or lower context (STUCX, STLCX).

In the absence of the fast interrupt mechanism, an interrupt immediately following an RFE would cause a restore of the upper context immediately followed by a save of the same upper context back to exactly the same memory location.

The fast interrupt mechanism replaces this redundant restore and save sequence with a load of PCXI, or PSW, or A10, or A11 from the saved context. System state at the end of the fast interrupt is the same as if the standard RFE or interrupt sequence had been performed.

Related information

Interrupt Router (IR) on page 6857

4.3.1.6 Trap system

The following traps have implementation-specific properties.

- MPX Memory Protection Execute (Class 1 TIN 4)
  - The MPX trap is raised whenever a program attempts to execute an instruction from a memory area for which it does not have execute permission and memory protection is enabled

- UOPC - Unimplemented Opcode (Class 2 TIN 2)
  - The UOPC trap is raised on optional half-precision and single-precision FPU instructions (coprocessor 1) when hardware support is not provided
  - The UOPC trap is raised on optional double-precision FPU instructions (coprocessor 2) when hardware support is not provided
  - The UOPC trap is raised on optional MMU instructions and coprocessor three instructions, neither are implemented in TC1.8
- OPD - Invalid Operand (Class 2 TIN 3)
  - The OPD trap is raised for instructions that take even-odd register pairs as an operand where the operand specifier is odd
  - The OPD trap is also raised for instructions that take a quad data register as an operand where the operand specifier is not [0, 4, 8, 12]
  - The OPD trap is also raised when a MTCR, MFCR, MTDCR, or MFDCR targets a GPR, a non-existing CSFR (virtualization disabled), or uses a misaligned offset
  - When virtualization is not present or disabled, the OPD trap is also raised for MTCR or MTDCR targeting CSFRs protected with PROTSFRE (virtualization disabled)
- DSE - Data Access Synchronous Error (Class 4 TIN 2)
  - The DSE trap is generated by the DMI module for an out-of-range access to DSPR
  - The DSE trap is also generated when a load access from the CPU encounters certain error conditions, such as an interconnect error
  - When a DSE trap is generated, the exact cause of the error can be determined by reading the Data Synchronous Trap Register, DSTR. Details of possible error conditions and the corresponding flag bits are found in that register
- DAE - Data Access Asynchronous Error (Class 4 TIN 3)
  - The DAE is generated by the DMI module when a store or cache management access from the CPU encounters certain error conditions, such as an interconnect error
  - When a DAE trap is generated, the exact cause of the error can be determined by reading the Data Asynchronous Trap Register, DATR. Details of possible error conditions and the corresponding flag bits are found in that register
- PIE Program Memory Integrity Error (Class 4 TIN 5)
  - The PIE trap is raised whenever an uncorrectable memory integrity error is detected in an instruction fetch from a local memory or the SRI
  - Program memories are protected from memory integrity errors on a 64-bit basis. A PIE trap is raised when an attempt is made to execute an instruction from any fetch group containing a memory integrity error
  - The PIEAR and PIETR registers may be interrogated to determine the source of any error more precisely. PIEAR and PIETR are only updated if PIETR.IED is not set
- DIE Data Memory Integrity Error (Class 4 TIN 6)
  - The DIE trap is raised whenever an uncorrectable memory integrity error is detected in a data access to a local memory or the SRI
  - DIE traps are always asynchronous independent of the operation which encountered the error
  - DSPR memories are protected from memory integrity errors on a 16-bit basis. DLMU memories are protected from memory integrity errors on a 64-bit basis
  - A DIE trap is raised if any memory half-word (local DSPR) or double-word (local DLMU or SRI) accessed by a load or store operation contains an uncorrectable error and no other DIE trap have been raised since the clearing of the DIETR.IED bit

- The DIEAR and DIETR registers may be interrogated to determine the source of any error more precisely
- Subsequent DIE traps are inhibited if DIETR.IED is set

4.3.1.7 WAIT instruction

The WAIT instruction will suspend the execution of instructions until the occurrence of one of the following events:

- Enabled Interrupt
- Non-Maskable Interrupt
- Asynchronous Trap
- Idle Request
- Suspend Request
- Asynchronous Debug Halt or Trap Request
- Hypervisor and VM switch

4.3.1.8 Speculation extent

The TC1.8 CPU may perform both necessary and speculative accesses:

- Necessary accesses
  - Those accesses that the CPU is required to make to correctly compute the program
- Speculative accesses
  - Those accesses that the CPU may make in order to improve performance either in correct or incorrect anticipation of a necessary access

The following speculative accesses are performed by the TC1.8 CPU:

- Speculative fetch accesses
  - The processor may speculatively fetch up to 64 bytes of instruction on the predicted execution path
- Speculative data read accesses
  - For cached data locations the processor will read an entire cache line containing data read for a required access

The processor does not perform:

- Speculative instruction execution
- Speculative write accesses
- Speculative accesses to peripheral space

4.3.1.9 Instruction memory range limitations

To ensure the processor cores are provided with a constant stream of instructions the Instruction Fetch Units will speculatively fetch instructions from up to 64 bytes ahead of the current PC.

If the current PC is within 64 bytes of the top of an instruction memory the Instruction Fetch Unit may attempt to speculatively fetch instructions from beyond the physical memory range. This may then lead to error conditions and alarms being triggered by the bus and memory systems.

The processor will not attempt a prefetch if memory protection is enabled, and the region is not declared as executable by the MPU. Thus in systems that are not using memory protection the upper 64 bytes of any memory should therefore not be used for instruction storage. This memory area should be initialized with NOP instructions.

4.3.1.10 Atomicity of data accesses

The data alignment rules along with the number of bus transactions for each access type are detailed in the following tables.

Table 48 Alignment rules for non-peripheral space

Access type	Access size	Alignment of address in memory	Min/Max number of SRI transactions
Load, Store Data Register	Byte	Byte (1_H)	1/1
	Half-Word	2 bytes (2_H)	1/1
	Word	2 bytes (2_H)	1/2*
	Double-Word	2 bytes (2_H)	1/3*
	Quad-Word	4 bytes (4_H)	1/3*
Load, Store Address Register	Word	4 bytes (4_H)	1/1
	Double-Word	4 bytes (4_H)	1/2*
SWAP, LDMST, CMPSWAP.W, SWAPMSK.W	Word	4 bytes (4_H)	1/1
ST.T	Word[1)]	4 bytes (4_H)[2)]	1/1
Context operations	16 x 32-bit registers	64 bytes (40_H)	2/2*

1) The architecture is supported through the use of a word access.
2) The implementation takes the byte address and uses the word enclosing address to perform the access.

Table 49 Alignment rules for peripheral space

Access type	Access size	Alignment of address in memory	Number of SRI/FPI transactions
Load, Store Data Register	Byte	Byte (1_H)	1
	Half-Word	2 bytes (2_H)	1
	Word	4 bytes (4_H)	1
	Double-Word	8 bytes (8_H)	1
	Quad-Word	16 bytes (10_H)	1/2*
Load, Store Address Register	Word	4 bytes (4_H)	1
	Double-Word	8 bytes (4_H)	1
SWAP.W, LDMST, CMPSWAP.W, SWAPMSK.W	Word	4 bytes (4_H)	1
ST.T	Word[1)]	4 bytes (4_H)[2)]	1/1
Context operations	16 x 32 bit registers	Not permitted	-

Please note the following cases:

- Where a single access results in a single transaction, atomicity of the data is preserved when viewed from any external master

- Where a single access leads to multiple transactions (marked as "*" in the tables above) then atomicity is not guaranteed. In these accesses it is possible for another master to read or write some of the target memory locations between the transactions required to complete the access
- In the case of word and double word access to the SRI, the number of transactions will be 1 for naturally aligned data values and therefore atomicity is preserved

The atomicity of data accesses to CPU CSFR registers is not guaranteed if the local processor is performing a MTCR or MTDCR instruction to the same CSFR register.

The instructions SWAP.W, LDMST, CMPSWAP.W, SWAPMSK.W, and ST.T are always atomic in operation. They perform a word read followed by a word write to a word aligned memory location. Both read and write access permissions must exist for the word aligned address.

4.3.1.11 A11 usage

In normal usage A11 will always contain the target of the next RET, RFE, or RFH instruction. The processor uses this fact to speculatively load the return target ahead of the execution of the RET, RFE, or RFH instruction. Code that modifies the A11 (for example test code) should be aware that any value stored in A11 may be used as the target of such speculation. If the value in A11 is not a valid address the speculation may lead to error conditions and alarms being triggered by the bus and memory systems.

It is therefore recommended that A11 should only ever contain a valid address value. This can be achieved by ensuring that the modification of A11 is either followed by an ISYNC or by using another address general purpose register, when the computation leads to partial results, before transferring the complete result back to A11.

4.3.1.12 Independent core kernel reset

The CPU core may be reset while the rest of the system remains operational. A module reset can be triggered by the safety management unit (SMU) or by writing '1' into both of the module reset registers CPU_KRST1.RST and register CPU_KRST0.RST.

The cause of the last reset to occur is indicated by the CPU_KRST0.RSTSTAT[0] or CPU_KRST0.RSTSTAT[1] bits. The status bits may be cleared by writing KRSTCLR.CLR to one.

The KRSTCLR, KRST1 and KRST0 registers are protected by PROTRSTE.

Registers related to the Debug Reset (Class 1), and STM registers are not influenced by the kernel reset.

Related information

Safety and security alarm Management Unit (SMU) on page 7056

4.3.1.13 CPU clock control

The effective CPU execution frequency may be reduced by programming the associated CCON.DIV. The effective execution frequency seen by the processor is given by the following equation:

$$f_{CPU} = f_{SRI}\frac{(64 - \text{CCON.DIV})}{64}$$

Where:

- f_{CPU} is the effective frequency seen by the processor
- f_{SRI} is the base SRI frequency

A CCON.DIV value of 0 results in the core being clocked at the SRI frequency (no frequency reduction).

To avoid synchronization issues typically associated with clock division, the clock control mechanism stalls the issue of instructions into the processor pipeline rather than modifying the actual applied clock. An incoming instruction fetch packet is stalled for the number of cycles required to approximate the required execution

frequency. The stall is seen by the processor as a stall in the instruction stream in the same way a stalling instruction memory would be seen.

In most scenarios, this mechanism provides a good approximation to clock division based control. The actual reduction in effective frequency will be dependent on the executed code. TPS_TIMERn (n=0-2) and CCNT count rate is not affected by CCON.DIV.

4.3.1.14 CPU memory protection registers

The TC1.8 CPU implements eight Memory Protection Register Sets. The sets specify memory protection ranges and permissions for code and data. The PSW.PRS bit field determines which of these sets is currently in use by the CPU. Note that the three bit PRS field is composed as PRS[2:0] === {PSW[15], PSW[13], PSW[12]}.

The CPUs each implement 24 data and 16 code range comparators. These may be flexibly shared amongst the protection sets to provide a maximum of 24 data ranges and 16 code ranges per set.

The protection registers protect the whole address space. The granularity of the protection ranges is 8 bytes for data and 32 bytes for code.

Code protection ranges define from which memory areas the CPU is allowed to fetch instructions. Instruction fetches from an area outside a valid code protection range will lead to a trap condition.

Data protection ranges define which memory areas the CPU may access for read and/or write operations. Each range may be separately enabled for read and/or write access. Data read accesses from an area outside a valid data protection range with read permissions will lead to a trap condition. Data write accesses to an area outside a valid data protection range with write permissions will lead to a trap condition.

There are no implementation specific features of the Memory Protection Registers. They are described in detail in the TriCore™ architecture manual.

Crossing protection boundaries

When protection is enabled the TC1.8 CPU checks the base address of instruction fetch and data access operations against the enabled MPU protection ranges. If this base address is outside of the enabled protection ranges a trap will be raised.

The TC1.8 CPU does check the full extent of instruction fetch. An instruction fetch that starts at the very top of an enabled region that extends into a non-enabled region triggers a trap condition.

The TC1.8 CPU does not check the full extent of data access. A data access that starts at the very top of an enabled region may therefore extend into a non-enabled region without triggering a trap condition.

In the following example a 4-byte instruction “DCBA” is placed at a valid location at the end of “A” in protection Region-B but extends into invalid Region-A. Execution of this instruction will lead to an MPX trap condition because a portion of the instruction resides in an invalid region.

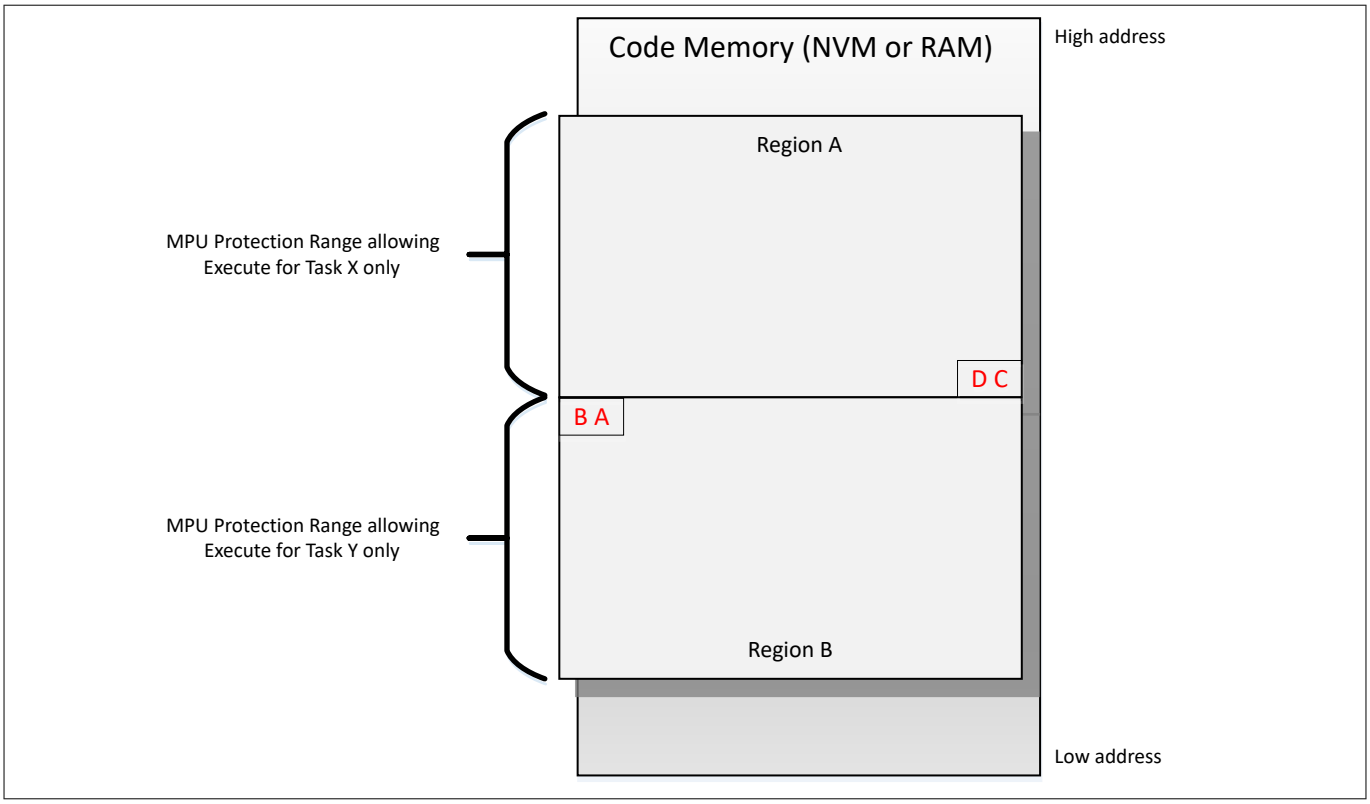

Figure 23 Crossing protection boundaries

To maintain separation between protection regions the following buffers regions should be placed between each memory protection region.

Code protection regions

- No buffer is required

Level 1 data protection

General case:

- Align protection boundaries to 64 bytes
- Minimum 12-byte[4)] buffer between "allowed" and "not allowed" data areas

Special case for regions not containing STLCX or STUCX context data:

- Minimum 12-byte[4)] buffer between "allowed" and "not allowed" data areas

***Note**: "Data areas" are not the same as “protection ranges”*

Virtualization - Level 2 data protection regions (for devices with CPU hardware support for virtualization)

The hypervisor must always allow for context operation in guest VMs.

- Align protection boundaries to 64 bytes
- Minimum 12-byte[4)] buffer between "allowed" and "not allowed" data areas

4 The gap is derived from the alignment rules for load/store instructions. The worst case is a word aligned load or store quad (LD.DD or ST.DD) when the first word falls in the first range, while the remaining 12 bytes cross into the next region

4.3.1.15 Memory integrity registers

Registers are provided which allow monitoring and debug of memory integrity errors experienced by code on the CPU and for capturing APU access violations by external masters.

Program integrity error and APU access violation information registers

Two registers allow software to localize the source of the last detected program memory integrity error or the last APU access violation:

- Program Integrity Error Trap Register (PIETR)
- Program Integrity Error Address Register (PIEAR)

These registers are updated when a program integrity error condition, or an APU access violation, is detected and the PIETR.IED bit is zero. On update the PIETR.IED bit is set to one and remains set until cleared by software. Whilst PIETR.IED is set further hardware updates of PIETR and PIEAR are inhibited. The various error scenarios are defined below.

Program integrity errors occurring on a program instruction fetch from local program memory

When a memory integrity error is detected during a local program fetch from a program memory, the IE_S, IE_C, IE_T, IE_LPB bits of PIETR are updated to denote in which memory structure the error was detected. If the IE_C bit is set the E_INFO field will be updated with the cache way. The PIEAR register is updated with the address of the access. If the error detected is an uncorrectable bit error the IE_UNC bit is set. The IED bit is set and all other PIETR register bits are set to zero. Since instruction fetches are speculative, the PIETR and PIEAR registers may be updated without a corresponding PIE trap.

Program integrity errors occurring on an access to program memory by an external master

When a memory integrity error is detected during an external read from program scratchpad memory, the IE_S, IE_C bits are updated to denote in which memory structure the error was detected. The IE_BS is set and E_INFO updated. The PIEAR register is updated with the address of the access. If the error detected is an uncorrectable error the IE_UNC bit is set. The IED bit is set and all other PIETR register bits are set to zero. Note that a memory read can be generated by a sub-word write operation. The IE_C bit can only be set if the cache is mapped into memory in SIST mode. In this case the E_INFO field indicates the tag of the requesting master.

PIExR register updates due to APU access violations

When an APU access violation is detected during an access to the CPU registers, the IE_SP, IE_BS bits are set and the E_INFO field of PIETR is updated. The E_VMN and E_VMN_EN fields are updated if VMN_EN is set or cleared otherwise. The E_PRS and E_PRS_EN fields are updated if PRS_EN is set or cleared otherwise. The PIEAR register is updated with the address of the access. The IED bit is set and all other PIETR register bits are set to zero. If virtualization is present and enabled only HRHV_PIETR and HRHV_PIEAR will be updated.

Program integrity errors caused by interconnect EDC errors

For a program fetch which accesses the interconnect and experiences an EDC error the IE_BI bit is set and the IE_BS bit is clear. The PIEAR register is updated with the address of the access.

For read by an external master which is received with an EDC error the IE_BI bit is set and the IE_BS bit is set and the E_INFO field is updated. The PIEAR register is updated with the address of the access.

For uncorrectable errors, IE_UNC bit is also set.

For an access by an external master which is received with an address phase EDC error, the IE_ADDR and IED bits are set, all other bits are cleared.

Program integrity error - memory test mode violation

The PIETR.IE_MTMV bit is set if the cache controller attempt to access the PSPR and PCache or PTAG memories while they are in a test mode.

Data integrity error and APU access violation information registers

Two architecturally visible registers allow software to localize the source of the last detected uncorrectable data memory integrity error or the last APU access violation:

- Data Integrity Error Trap Register (DIETR)
- Data Integrity Error Address Register (DIEAR)

These registers are updated when an uncorrectable data integrity error condition, or an APU access violation, is detected and the DIETR.IED bit is zero. On update the DIETR.IED bit is set to one and remains set until cleared by software. While DIETR.IED is set, further hardware updates of DIETR and DIEAR are inhibited. The various error scenarios are defined below.

Data integrity errors occurring on a load from local data memory

When a memory integrity error is detected during a load from a local data memory, the IE_S, IE_C, IE_T and IE_LPB, IE_DLMU bits of DIETR are updated to denote in which memory structure the error was detected. If the IE_C bit is set the E_INFO field will be updated with the cache way. The DIEAR register is updated with the address of the access. If the error detected is an uncorrectable error, the IE_UNC bit is set. The IED bit is set and all other DIETR register bits are set to zero. Note that a memory read may also be generated by a sub-word write operation or a cache line eviction.

Data integrity errors occurring on an access to data memory by an external access

When a memory integrity error is detected during an external bus read from data memory, the IE_S, IE_C, IE_DLMU bits of DIETR are updated to denote in which memory structure the error was detected. The IE_BS is set and E_INFO updated. The DIEAR register is updated with the address of the access. If the error detected is an uncorrectable error, the IE_UNC bit is set. The IED bit is set and all other DIETR register bits are set to zero. Note that a memory read may also be generated by a sub-word write operation or a cache line eviction. The IE_C bit can only be set if the cache is mapped into memory in SIST mode. In this case the E_INFO field indicates the tag of the requesting master.

DIExR register updates due to APU access violations

When an APU access violation is detected during a data memory access, the IE_SP, IE_BS bits are set and the E_INFO field updated. The E_VMN and E_VMN_EN fields are updated if VMN_EN is set or cleared otherwise. The E_PRS and E_PRS_EN fields are updated if PRS_EN is set or cleared otherwise. The DIEAR register is updated with the address of the access. The IED bit is set and all other DIETR register bits are set to zero.

Data integrity errors caused by interconnect EDC errors

For a local data access which accesses the interconnect and experiences an EDC error the IE_BI bit is set and the IE_BS bit is clear. The DIEAR register is updated with the address of the access.

For read by an external master which is received with an EDC error the IE_BI bit is set and the IE_BS bit is set and the E_INFO field is updated. The DIEAR register is updated with the address of the access.

For uncorrectable errors, IE_UNC bit is also set.

When an ECC error is detected at the data bus interface (either master or slave), the IE_BI bit is set. If the error is during an external access the IE_BS bit is set and the E_INFO field is updated. The DIEAR register is updated with the address of the access. If the error detected is an uncorrectable error the IE_UNC bit is set. The IED bit is set and all other DIETR register bits are set to zero.

Data integrity error - memory test mode violation

The DIETR.IE_MTMV bit is set if the cache controller attempt to access the DSPR and DCache, or DTAG, or DLMU memories while they are in a test mode.

4.3.2 Virtualization

Some instances of the TC1.8 CPU support the TriCore™ real-time virtualization extensions as described in the TriCore™ architecture manual. The presence of virtualization is core specific. The TCCON register can be used to identify cores with virtualization hardware support. Implementation specific details are described in the following sections.

4.3.2.1 Number of supported virtual machines

This section is described in the TriCore™ architecture manual volume 1.

4.3.2.2 Replicated state

Each hardware resource[5)] has a dedicated set of fully replicated CSFR (this does not include SFRs such as Overlay and FSFRs) registers, with the following exceptions:

- The Interrupt Control Register is replicated per virtual machine not per hardware resource. These CSFR registers will be identified by the prefix VM0_, VM1_, VM2_, VM3_, VM4_, VM5_, VM6_, and VM7_
- Read only state is not replicated (that is ID registers)
- CSA managed state is not replicated
- The debug and trace registers are only accessible by the Hypervisor
- The overlay registers are not replicated (SFR)
- The FLASHCON registers are not replicated (FSFR)

Each CSFR register is identified by the prefix HRHV_, HRA_ or HRB_. So FCX for example, is replicated and renamed as HRHV_FCX, HRA_FCX, HRB_FCX.

- Software running in HRHV has access to all registers
- Software running in HRA has access to HRA registers only
- Software running in HRB has access to HRB registers only

Table 50 Replicated state per HR (z = A/B/HV)

Name	Name	Name	Name

1) Replicated per VM (n=0..7)

Non-replicated registers are aliased in each of the hardware resources.

4.3.2.3 CSFR access from the local core

Access to CSFR state is performed from the local core through the MTCR or MFCR instructions, and the MTDCR or MFDCR instructions. These instructions use a 16-bit constant for their access address.

For MTDCR and MFDCR operations const[2] should always be “0” otherwise the operation is accessing a misaligned location and will lead to an OPD trap.

For version 1.8 of the TriCore™ architecture, offset bits [1:0] are used by VM0 to access CSFRs in its own or other hardware resources. See the TriCore™ architecture manual for more details.

A MTCR or MFCR operation in VM1-VM7 that targets an undefined CSFR location or a MTDCR or MFDCR operation in VM1-VM7 that targets an undefined double CSFR register location will result in a HV trap (Class 4 HVCSFR) if virtualization is configured and enabled. In all other cases an OPD trap is raised.

Table 54 CSFR access hardware resource selection rules from the local core

Currently active hardware resource	Const[1:0] == 00_B	Const[1:0] == 01_B	Const[1:0] == 10_B	Const[1:0] == 11_B
HRHV	Access to own CSFR register set	Access to HRA CSFR register set[1]	Access to HRB CSFR register set[2]	Misaligned CSFR access, OPD trap
HRA		Misaligned CSFR access, OPD Trap		
HRB

1) With regards to the operand granularity
2) Protection applies to writes to own space
3) Excludes HRA/B global registers

Related information

Non Replicated CSFRs supported through HV traps on page 126

4.3.2.3.1 Global address registers and GPRs

The global address registers (A0, A1, A8, and A9) are not saved and restored as part of the context save area. They therefore are replicated per hardware resource.

Accessing GPRs through the MTCR, MFCR, MTDCR, or MFDCR instructions is an illegal operation in the TriCore™ architecture. This remains the case for accesses to the GPRs of the currently executing VM. The hypervisor may access the Global Address GPRs (A0, A1, A8, or A9) of HRA, HRB using MTCR, MFCR, MTDCR, or MFDCR.

4.3.2.3.2 Hypervisor register offsets

SFR	HRA	HRB	HRHV	Offset	Description
			X	$3B000_H$	VCON0
			X	$3B004_H$	VCON1

			X	$3B008_H$	VCON2
			X	$3B010_H$	BHV
			X	$3B100_H + x*4_H$	VMn_ICR
			X	$3B200_H + x*4_H$	VMn_PETHRESH

4.3.2.3.3 Non Replicated CSFRs supported through HV traps

Some VM state needs to be under control of the hypervisor. To allow this, Guest VM accesses (read or write) to the following CSFRs will cause a trap to the hypervisor (Class 4 - HVCSFR).

Table 56 CSFRs requiring HV support

Register name	Function	Address
SEGEN	SRI Error Generation Control	1030_H
LCLTEST	Lockstep Test Register	1040_H
COMPAT	Compatibility Register	9400_H
All debug registers	All debug registers	Ranges $F000_H$ and $FD00_H$ (performance counters are replicated per HR and are decoupled from debug and therefore do not fall in this category)
PMA0/ PMA1/ PMA2	Physical memory attributes	8100_H / 8104_H / 8108_H
DCON0	Data Control Register 0[1)]	9040_H
DCON2	Data Control Register 2	9000_H
PCON0	Program Control Register 0[1)]	$920C_H$
PCON2	Program Control Register 2	9208_H
LCLCON	Lockstep Control Register	$FE64_H$
CCON	Clock Control Register	$FE68_H$
All undefined register locations[2)]		

1) Guest VMs requiring different cache configurations must be handled in the hypervisor software
2) Details of operation when virtualization is not configured or is configured but not enabled can be found in the section titled "CSFR access from the local core".

Related information

CSFR access from the local core on page 124

4.3.2.3.4 MTCR, MTDCR targeting HRA/HRB CSFR's

To support the Hypervisor in restoring the complete state of a non-resident VM, the operation of MTCR and MTDCR executed in the Hypervisor context will override hardware writeable fields (normally read only for the application) when the target CSFR belongs to either HRA or HRB.

A Hypervisor targeting the guest VM hardware resources of a different TC1.8 CPU (HRA or HRB CSFR's) can also override the hardware writeable fields of the target CPU if the access passes the target CPU APU checks.

***Note**: A guest VM operation targeting another CPU would be to only update the softwarewriteable fields of the target CPU.*

Related information

Instruction operation updates on page 136

4.3.2.3.5 MTCR/MFCR, MTDCR/MFDCR to non-existent or protected locations

A MTCR or MFCR operation by a guest VM that targets a non-existent CSFR location, or a MTDCR or MFDCR operation by a guest VM that targets a non-existent double CSFR register location will result in a HV trap (Class 4 HVCSFR).

A MTDCR to a non-existent register in either (not both) locations will be ignored.

A MFDCR from a non-existent register in either (not both) location will return 00000000_H for that location.

In all other cases (VM0 execution or virtualization not configured or enabled) an OPD trap is raised.

A MTCR operation by a guest VM that targets a CSFR location protected by PROTSFRE or PROTSFRSE will result in a HV trap (Class 4 HVCSFR).

A MTDCR operation by a guest VM that targets a double CSFR location where either of the CSFRs is protected by PROTSFRE or PROTSFRSE will result in a HV trap (Class 4 HVCSFR).

In all other cases (VM0 execution or virtualization not configured or enabled) an OPD trap is raised.

Related information

Instruction operation updates on page 136

4.3.2.3.6 PROT usage with virtualization present and enabled

The HV needs to be able to change the state of a guest VM's protected register during a VM swap without the time overhead of an unlock or lock operation. The HV is therefore allowed write access to all HRA, and HRB CSFRs without requiring a PROTSFRE unlock or lock sequence.

- Accesses to HRHV CSFRs and SFRs are protected by PROTSFRE and PROTSFRSE. A move to a HRHV CSFR that is protected will generate an OPD trap
- In the case where virtualization is not configured or not enabled, endinit like protection is maintained for the relevant registers. In this case a move to a CSFR that is protected will generate an OPD trap
- MTCR/MTDCR to protected CSFRs in a guest VM will generate a HV trap (Class 4 HVCSFR)

Table 57 PROT for configurations with virtualization present and enabled

Instance	Registers covered	Notes

4.3.2.4 Hypervisor traps

This section is described in the TriCore™ architecture manual volume 1.

4.3.2.5 Interrupts for the hypervisor

This section is described in the TriCore™ architecture manual volume 1.

4.3.2.5.1 Hypervisor context examples

This section is described in the TriCore™ architecture manual volume 1.

4.3.2.6 Interrupts

4.3.2.6.1 Interrupt interface

Each Interrupt SRN is extended to store a Virtual Machine Number (VMN) 0-7 alongside the TOS and SRPN. The SRN requests an interrupt at priority SRPN on the Service provider identified by the TOS and on the virtual machine identified by the VMN.

The VM value is presented to the processor alongside the interrupt request and PIPN. This allows incoming interrupts to be directed to the correct machine.

Each virtual machine has a separate ICR register and so a separate PIPN, IE, and CCPN. The interrupt state of each VM is independent of the other VMs.

The Interrupt router provides an indication of the presence or not of a valid interrupt request for a given VM. This information will be used by the CPU to update the PIPN for the VM presented. When the request is not valid, VMx_ICR.PIPN will be set to 0.

4.3.2.6.2 Interrupt pre-emption by other VMs

This section is described in the TriCore™ architecture manual volume 1.

4.3.2.6.3 Interrupt flow diagrams

The PIPN and VMN are presented to the CPU and compared against the CCPN and IE value for that machine in the standard way. In addition a pre-emption check will be performed if the requested VM is not currently running.

If the incoming interrupt is not for the currently running VM then a pre-emption check is performed to determine whether a VM switch should be performed.

If the pre-emption check passes then the Hypervisor will be called to perform a VM switch.

In the case where hardware has decided to “keep pending” the interrupt will simply be left pending. This situation will continue until the hardware state changes to a state in which the interrupt can be taken. This

significantly simplifies the hardware in that there is no need for mechanisms to allow the interrupt to be deferred to a later point in time.

For a taken interrupt, if the currently running machine is the same as the machine requested by the interrupt then the interrupt will be passed directly to the running machine.

In all cases a software swap of a virtual machine to or from memory is only required if the VM state is not currently held in one of the hardware resources sets. If the state is already held in one of the HR sets then a hardware switch is all that is required.

Use cases

In the case where there is a single executing VM (VM1) interrupts will be taken in VM1 unless targeted at the hypervisor (VM0). In this case a switch to the hypervisor will only be initiated if the incoming interrupt is above the preemption threshold of the hypervisor and if the hypervisor is in a state to receive interrupts.

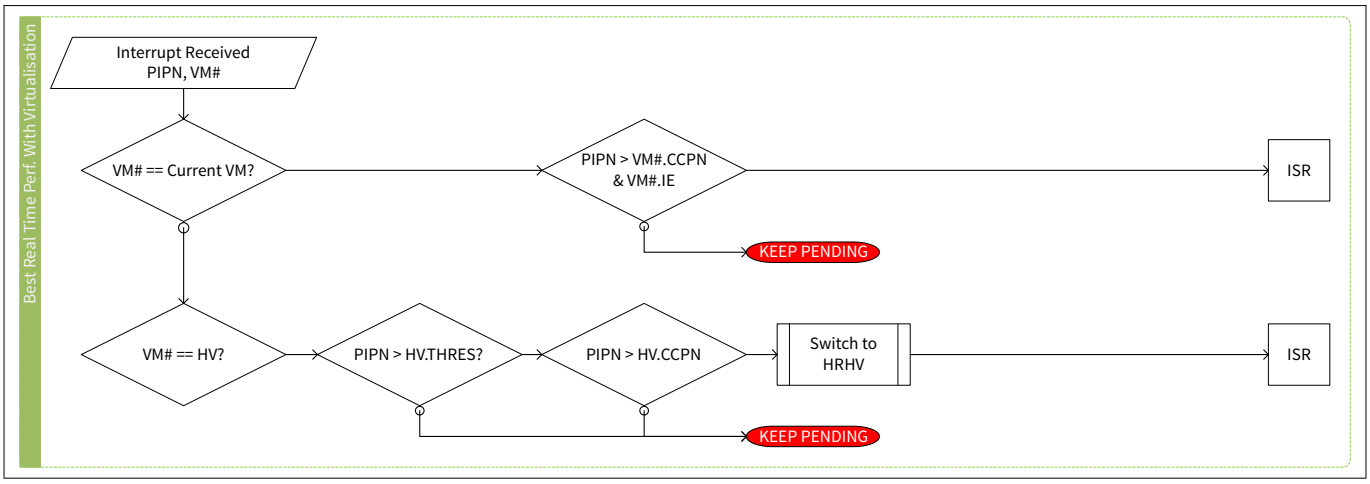

Figure 24 Interrupt flow diagram for 1 hypervisor and 1 real-time virtual machine

In the case where there are two active VMs (VM1, 2) interrupts targeted at the currently executing VM will be taken in that VM. Interrupts targeted at the other VM or the hypervisor (VM0) will initiate a switch to the target machine only if the incoming interrupt is above the preemption threshold of the target VM or hypervisor, and if that VM or hypervisor is in a state to receive interrupts.

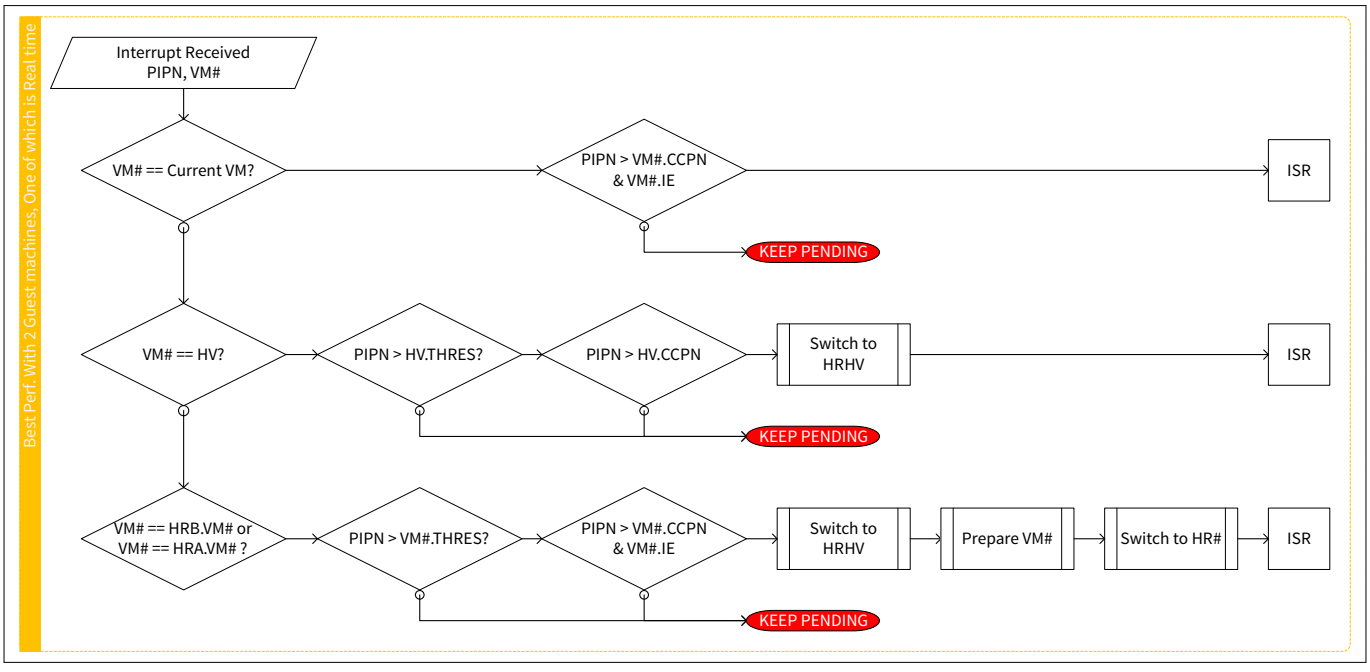

Figure 25 Interrupt flow diagram for 1 hypervisor and 2 resident virtual machines

When more than 2 VMs are required, the hypervisor software will be required to swap the content of hardware resource 2 to/from memory in order to place the targeted virtual machine in the hardware resource prior to the execution of the RFH instruction.

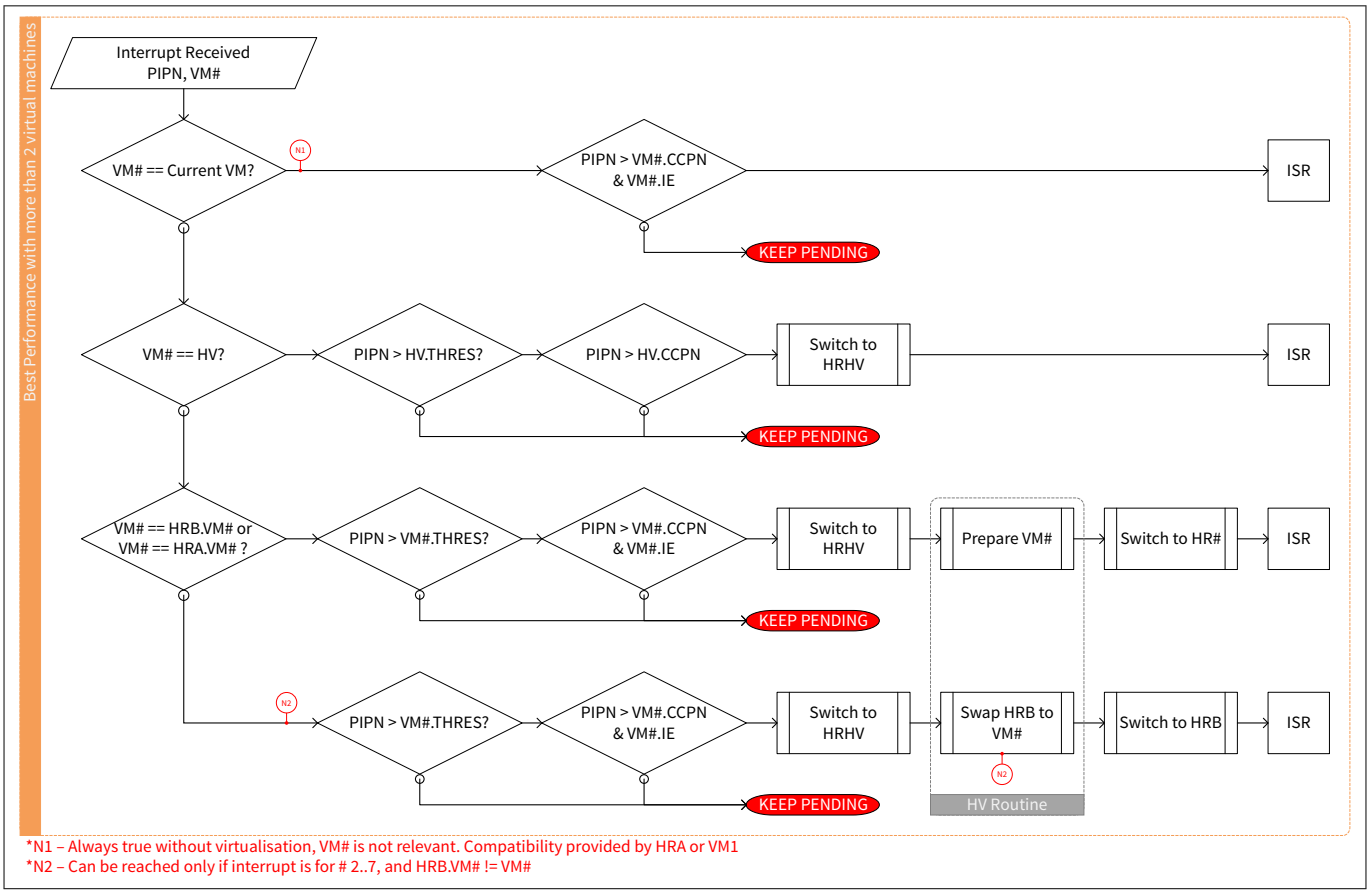

Figure 26 Interrupt flow diagram – 3 to 7 virtual machines

4.3.2.6.4 Interrupt corner cases

Configuration of the IR for each specific CPU should match the managed number of VMs. However, if there is a mismatch between the IR configuration and the use of virtualization or the number of supported guest VMs then this can be dealt with by SW.

Virtualization enabled and presentation of an interrupt to a non-enabled VM. There are two logical options that a system must choose:

- All unused VMs should have interrupts disabled. An interrupt to such a VM will be ignored by the HW
- All unused VMs should have interrupts enabled and their priority and threshold set to 0. An interrupt to such a VM will result in a HV switch. The HV would then flag this as a detected error

Virtualization disabled and presentation of an interrupt to a VM:

- The CPU will ignore the VMN field of the incoming interrupt and take the interrupt due to the standard ICR.IE and PIPN > CCPN tests

4.3.2.6.5 Hypervisor interrupt entry sequence

This section is described in the TriCore™ architecture manual volume 1.

4.3.2.6.6 Interrupt ack and interrupt enter

Enter

An interrupt enter should be sent to the IR once the conditions are met for that interrupt to be taken. For interrupts to the current VM this means passing the PIPN > CCPN check. For interrupts to the hypervisor or to other virtual machines, enter will be raised before switching to HRHV.

Acknowledge

Interrupt acknowledge should be sent before executing the first instruction of the ISR. This corresponds to the “Take Interrupt” box in the interrupt diagrams.

4.3.2.7 Virtualization instructions

Hypervisor call (HVCALL) and return (RFH) instructions are required.

Cache instructions which are not constrained by the virtual machine number are also required.

4.3.2.8 Boot operation

In version 1.8 of the TriCore™ architecture, the BHALT bit is available in a dedicated CSFR BOOTCON. BHALT. (Bit0)

The required boot sequence varies depending on whether the virtualization extension is present or not (see TCCON).

CPU instance with hardware virtualization

At boot the TC1.8 CPU starts in VM0/Hypervisor with virtualization enabled. All registers in all hardware resources, are visible and are accessible. This allows boot code to initialize the HV state along with other processor state as required.

A write to VCON0.VEN is required to set the virtualization operation of the core. This should be done prior to executing the first RFH instruction. This is not enforced in hardware but execution of a RFH prior to the first VCON0.VEN write is an illegal operation from an architectural viewpoint leading to undefined results.

CPU instance without hardware virtualization

A CPU that is configured without hardware virtualization will boot directly into VM1 with all virtualization extensions unavailable.

4.3.2.9 Disabling hypervisor

This section is described in the TriCore™ architecture manual volume 1.

4.3.2.10 Memory protection

HRHV, HRA, and HRB each have replicated memory protection sets with the following configurations.

Table 58 Number of memory protection ranges and sets

Hardware resource	Data protection ranges	Code protection ranges	Protection sets
HRHV	24	16	8
HRA	24	16	8
HRB	24	16	8

4.3.2.11 Protection state on entering hypervisor

On any entry to the hypervisor the PSW.PRS is set to 0.

Protection is enabled if HRHV_CORECON.PROTEN ==1.

4.3.2.12 Watchdogs

If the run-time monitoring function of the watchdog (WDT) functionality is required by one VM (VM0/HV or VM1) then it can be directly allocated. If WDT functionality is required by more than one guest VM (that is VM1..VM7) then the HV must provide the Program Flow Monitoring features through para-virtualization.

4.3.2.13 NMI virtualization

This section is described in the TriCore™ architecture manual volume 1.

4.3.2.14 Traps

This section is described in the TriCore™ architecture manual volume 1.

4.3.2.15 Asynchronous traps

For all asynchronous traps taken in HV, to allow software to determine whether an RFE or RFH should be used to terminate the exception handler, bit D15[31] is set whenever the trap entry requires a switch of VM. A simple conditional jump can be used to select the operation required to complete the trap handler.

```
        // return from handler
        JZ.T D15, 31, rfe_target
        RFH;
rfe_target:
        RFE;
```

DAE - data access asynchronous error (TIN 3)

The Data Access Asynchronous Error Trap (DAE) is generated by the DMI module when a store or cache management access from the CPU encounters certain error conditions, such as a Bus error. Since the source of the DAE trap is not directly linked to the current instruction, for example cache eviction, or even to the current VM, a DAE will lead to a switch to the Hypervisor.

When a DAE trap is generated, the exact cause of the error can be determined by reading the Data Asynchronous Trap Register, HRA_DATR. For the TC1.8 CPU HRA_DATR is extended to capture VMN, VMN_EN, PRS, PRS_EN and the value of the S bit used for the transaction.

DIE - data memory integrity error (TIN 6)

The DIE trap is raised whenever an uncorrectable memory integrity error is detected in a data access to a local memory or the SRI. The trap is of Class-4 and has a TIN of 6.

DIE traps are always asynchronous independent of the operation which encountered the error.

A DIE trap is raised if any memory half-word (local memory) or double-word (SRI) accessed by a load or store operation contains an uncorrectable error and no other DIE trap have been raised since the clearing of the DIETR.IED bit. The DIEAR and DIETR registers may be interrogated to determine the source of any error more precisely. Subsequent DIE traps are inhibited if DIETR.IED is set.

DIE will lead to a switch to the Hypervisor. For the TC1.8 CPU DIETR is extended to capture VMN, VMN_EN, PRS, and PRS_EN used for the transaction..

CAE - coprocessor asynchronous error (TIN 4)

Coprocessor errors relate to the software execution and are taken in the VM that triggered them. If the exception arises while the VM is being switched, the exception will remain pending until the hardware returns to that VM.

TAE - temporal asynchronous error (TIN 7)

Temporal traps guard against task run-time overrun and are taken in the VM that triggered them. If the exception arises while the VM is being switched, the exception will remain pending until the hardware returns to that VM.

4.3.2.16 Context save area (CSA) protection

In both version 1.8 of the TriCore™ architecture and earlier TriCore™ architectures, the memory accesses generated by CSA save and restore operations do not undergo level 1 protection checks. In version 1.8 of the TriCore™ architecture all Guest VM accesses, including CSA save and restore operations, are checked by the level 2 protection checks (L2 MPU).

When a guest VM is running the L2 MPU will check the base address accesses generated by CSA save and restore operations. If this address is outside of the enabled protection ranges a hypervisor trap will be raised. Since only the base address is being checked it is possible for an access to start at the top of an enabled region and to extend into a non-enabled region without triggering a trap condition. To maintain separation between protection regions of the L2 MPU, each data protection region should be aligned to 64-bytes and a buffer register of 12-bytes should be placed between data regions with different level of protection or different guest VMs. Due to the above CSA handling, it is not necessary for the HV to check the specific values of the CSA pointers within a VM.

CSA save and restore operations performed by the hypervisor do not undergo protection checks.

L2 MPU traps for CSA are synchronous to the event that triggered the error. When an L2 memory protection violation due to a CSA access, HRHV_DSTR will be updated.

4.3.2.17 Virtualization and caches

Cache bypass

Caches are bypassed after reset. Enabling of the caches is done through the DCON0 and PCON0 CSFRs.

Guest VM access (read or write) to DCON0 and PCON0 will cause a trap to the hypervisor to allow consistent policy control of these shared resources.

Cache write-back

When a cacheline write-back is required, the line is presented to the interconnect with the same VM information that allocated the line in the cache.

Cache invalidation

Cache invalidation of clean cache lines can be achieved in an efficient way using the DCON1 and PCON1 CSFRs. Since caches are shared and eviction of clean data related to a non-running VM, or to a different PRS, will naturally happen while executing another VM, no restriction is added for access, read and write, to DCON1 and PCON1 registers. These can be accessed by any VM.

CACHEA.*, CACHEI.* instructions

When operating with virtualization enabled these instructions are to invalidating cache entries forthe virtual machine defined in VCON2.VMN. This allows the HV to selectively operate on a particular VM's cachelines if re quired. This also ensures that a VM can only operate on its own entries.

CACHEA.*.VM, CACHEI.*.VM instructions

New versions of the CACHEA.*.VM and CACHEI.*.VM instructions are introduced to provide a mechanism for the hypervisor to operate on lines from all VMs.

***Note**: These instructions operate on any valid data tag entry regardless of PSW.PRS, and PSW.S. bit.*

Cache architecture on page 151

4.3.2.18 Virtualization and overlay

Virtualization provides two levels of MPU within the CPU. Overlay address modification only happens after the address has passed both MPU checks. The APU on all overlay memories is a final check which redirected accesses must pass to succeed.

The overlay mechanism does not restrict itself to a VM. If the NVM region is overlayed and allowed by MPU checks the overlay address substitution occurs. The destination APU check must still be passed by the access. Overlay is implemented using SFRs which are not replicated. Overlay is expected to be used for a whole system (or not). If finer granularity is required then it must be provided through some software layer.

4.3.2.19 System timer extensions for virtualization

To support virtualization it is required that interrupts can be generated per VM based on either Absolute Time or Relative time. To support the following changes are made to the STM:

- 64-bit relative time is implemented per VM, clocked from the same source as the existing timer (STM_RELTIM[63:0]) to hold the relative time value of the machine when it is not currently active:
  - This timer is loaded/unloaded on a VM switch/swap
  - This timer should be readable in the same way as the existing timer
- The compare registers (STM_CMP0, STM_CMP1) are replicated per VM:
  - STM_CMPc
- The compare match control register is duplicated per VM:
  - STM_CMCON
- Each comparator may be selected to compare against either the absolute or relative time:
  - New RELCOMP bits added to STM_CMCON [31,15]
- The interrupt control registers are replicated per VM:
  - STM_ICR
- The interrupt ISCR registers are replicated per VM:
  - STM_ISCR
- The interrupt ISR registers are replicated per VM:
  - STM_ISR
- The support of per VM system timers means an increase in the number of timer interrupts per core to 16
- A guest VM's access to the STM register is independent of the VM's number:
  - This is managed by the CPU redirecting guest VM STM accesses to the relevant STM registers
  - Hypervisor software can address any VM specific STM register

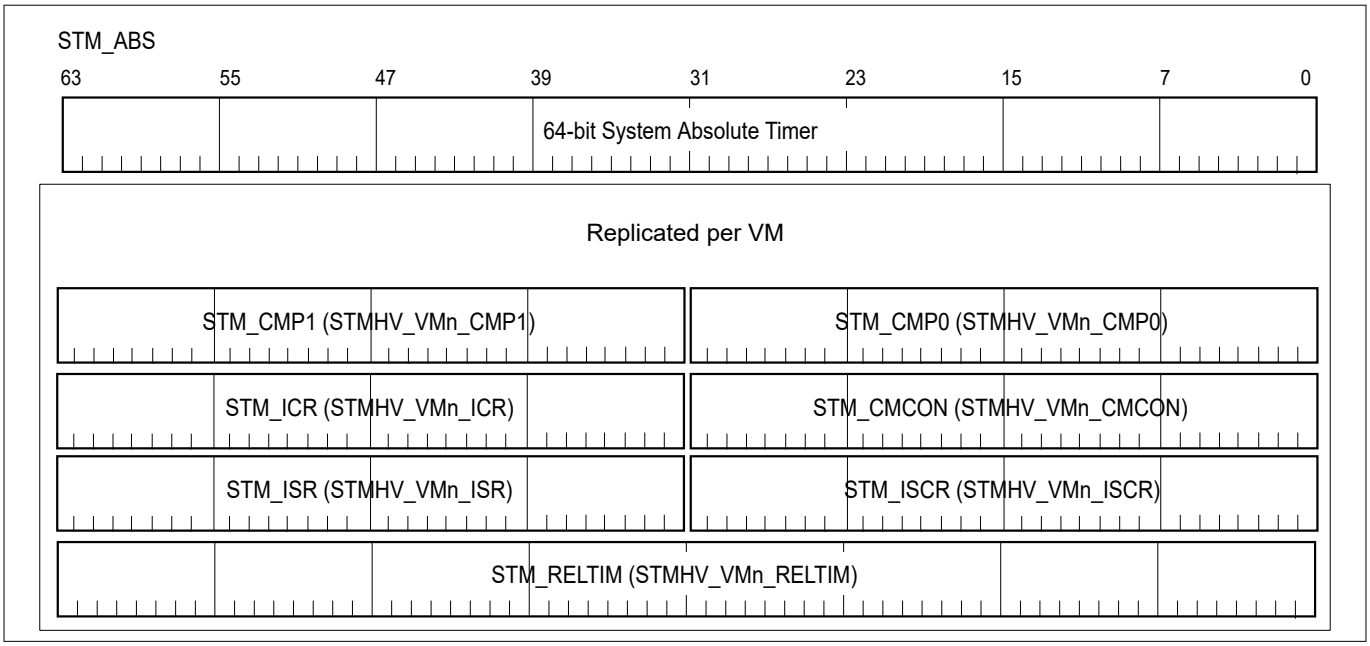

Figure 27 STM registers

4.3.2.20 STM register access (access virtualization)

The STM registers are located in the CPU SFR address space. To minimize the need for para-virtualization of the STM function, all guest virtual machines access their STM instance at the same offset. The same offset is also used if virtualization is disabled or not present. The hardware will then compute the offset corresponding to the requesting guest VM prior to performing the access. The access virtualization only applies to guest virtual machines and not to the hypervisor which will be able to access any of the virtual STM instances at their actual offset.

```
STMHV_VMx: 0xF8800000 + (CORE_ID << 18) + STM register offset
```

Guest VM example: CPU0 VM2 STM_CMP0 will be accessed in software at address 0xF8800120 (using the CPU0_STM_CMP0 address) which will result in an access at 0xF8800140 on the system interconnect (CPU0_STMHV_VM2_CMP0 address).

Hypervisor example: CPU0 VM0 STM_CMP0 must be accessed by the hypervisor software using CPU0_STMHV_VM0_CMP0 address.

Other masters attempting to access a CPU STM register must use the specific address corresponding to the targeted VM.

To provide isolation one additional PROT and 8 APUs are provided for the STM functionality (see section STM protection).

4.3.2.21 Temporal protection system timers (TPS) extensions for virtualization

The temporal protection system is replicated per hardware resource, and HRz_TPS_TIMERn only decrement while that hardware resource is active.

4.3.2.22 Para-virtualization and integrators tasks

This section details the modifications required to software to allow it to run as a virtual machine on the TC1.8 CPU.

4.3.3 Instructions that are new for version 1.8 of the TriCore™ architecture

The following instructions are new in version 1.8 of the TriCore™ architecture compared to version 1.6, and will not be available on CPUs implementing earlier architectures.

New instructions (see TriCore™ architecture manual for details):

- Hypervisor call and return from hypervisor (HVCALL, RFH)
- Load/Store quad data word (LD.DD, ST.DD)
- Move to or from core register pair (MTDCR, MFDCR)
- Carry-less multiplication (MULP.B)
- Call indirect variant (CALLI 16-bit)
- Jump relative indirect (JRI)
- 64-bit integer divide and remainder (DIV64, DIV64.U, REM64, REM64.U)
- Local data synchronization (LSYNC)
- New single-precision floating-point instructions (ABS.F, MAX.F, MIN.F, NEG.F)
- New double-precision floating-point coprocessor (ABS.DF, ADD.DF, CMP.DF, DFTOF, DFTOI, DFTOIN, DFTOIZ, DFTOU, DFTOUZ, DFTOL, DFTOLZ, DFTOUL, DFTOULZ, FTODF, ITODF, LTODF, MADD.DF, MAX.DF, MIN.DF, MSUB.DF, MUL.DF, NEG.DF, QSEED.DF, SUB.DF, ULTODF, UTODF)

4.3.4 Instruction operation updates

The operation of some instructions has been updated compared to previous implementations.

MTCR/MFCR, MTDCR/MFDCR to non-existent or protected locations on page 127

4.3.4.1 MSUB.Q

AURIX™ TC3xx implementations of the MSUB.Q instruction favored a slightly more accurate result during internal rounding. For better bit compatibility, the MSUB instruction in AURIX™ TC4xx returns the same result as a MUL.Q followed by a SUB.

4.3.4.2 CACHEI.* instruction input operands

The CACHEI.* instructions require a 'way' and an index value to be supplied in a valid address, where a valid address is an address that will pass memory protection and null pointer checks. The CACHEI.* instructions also require an address to be cacheable. The local portion of DLMU (even when accessed through segment 9_H) is not cacheable. The local DSPR's global address (segment $[7\text{-CORE_ID}]_H$, that is 0x700xxxxx, 0x600xxxxx and so on) is not cacheable either.

The location of these bits in the 32-bit address is as follows.

Table 59 Way, and index location

Function	Address bits
Way	[0]
Index	[12:5]

4.3.5 CPU instruction timing

This section gives information on CPU instruction timing by execution units.

Common timing assumptions:

- All targets yield a full instruction in one access. That is, not 16-bit of a 32-bit instruction
- All code fetches take a single cycle

Definition of terms:

Repeat rate: Assuming the same instruction is being issued sequentially, repeat is the minimum number of clock cycles between two consecutive issues. There may be additional delays described elsewhere due to internal pipeline effects when issuing a different subsequent instruction.

Result latency: The number of clock cycles from the cycle when the instruction is issued to the cycle when the result value is available to be used as an operand to a subsequently issued instruction or written into a GPR. Result latency is not meaningful for instructions that do not write a value into a GPR.

Address latency: The number of clock cycles from the cycle when the instruction is issued to the cycle when the addressing mode updated value is available as an operand to a subsequently issued instruction or written into an Address Register.

Flow latency: The number of clock cycles from the cycle when the instruction is issued to the cycle when the next instruction (located at the target location or the next sequential instruction if the control change is conditional) is issued.

4.3.5.1 Integer pipeline instructions

These tables define the TC1.8 CPU integer pipeline instruction timings.

Simple arithmetic instruction timings

Table 60 Simple arithmetic instruction timing: Arithmetic instructions

Instruction	Result latency	Repeat rate	Instruction	Result latency	Repeat rate
ABS	1	1	MAX.H	1	1
ABS.B	1	1	MAX.HU	1	1
ABS.H	1	1	MAX.U	1	1
ABSDIF	1	1	MIN	1	1
ABSDIF.B	1	1	MIN.B	1	1
ABSDIF.H	1	1	MIN.BU	1	1
ABSDIFS	2	1	MIN.H	1	1
ABSDIFS.H	2	1	MIN.HU	1	1
ABSS	2	1	MIN.U	1	1
ABSS.H	2	1	RSUB	1	1

SH.AND.T	1	1	SH.NOR.T	1	1
SH.ANDN.T	1	1	SH.OR.T	1	1
SH.EQ	1	1	SH.ORN.T	1	1
SH.GE	1	1	SH.XNOR.T	1	1
SH.GE.U	1	1	SH.XOR.T	1	1
SH.H	1	1	SHA	1	1
SH.LT	1	1	SHA.H	1	1
SH.LT.U	1	1	SHAS	2	1
SH.NAND.T	1	1			

Table 67 Simple arithmetic instruction timing: Coprocessor 0 instructions

Instruction	Result latency	Repeat rate	Instruction	Result latency	Repeat rate
BMERGE	2	1	IXMIN	2	1
BSPLIT	2	1	UNPACK	2	1
PARITY	2	1	IXMAX	2	1
PACK	2	1	IXMAX.U	2	1
IXMIN.U	2	1	CRC32B.W	2	1
CRC32L.W	2	1	CRC32.B	2	1
CRCN	2	1	MULP.B	2	1

Table 68 Simple arithmetic instruction timing: Integer divide instructions

Instruction	Result latency	Repeat rate	Instruction	Result latency	Repeat rate
DVADJ	2	1			
DIV[1)]	4-11	3-9	DIV.U[1)]	4-11	3-9
DVINIT	2	1	DVINIT.U	2	1
DVINIT.B	2	1	DVSTEP	2	1
DVINIT.H	2	1	DVINIT.HU	2	1
DVSTEP	6	4	DVSTEP.U	6	4
DIV64[1)]	4-19	3-17	DIV64.U[1)]	4-19	3-17
REM64[1)]	4-19	3-17	REM64.U[1)]	4-19	3-17

1) The latency and repeat rate values listed for the DIV, DIV.U, DIV64, DIV64.U, REM64, and REM64.U instructions are the minimum and maximum values. The pipeline provides early termination of the instruction once the full result is available.

Multiply instruction timings

Table 69 Multiply instruction timing

Instruction	Result latency	Repeat rate	Instruction	Result latency	Repeat rate
MUL	2	1	MUL.Q	3	1
MUL.U	2	1	MULM.H	3	1
MULS	3	1	MULR.H	3	1
MULS.U	3	1	MULR.Q	3	1
MUL.H	3	1			

Multiply accumulate (MAC) instruction timings

Table 70 Multiply accumulate instruction timing

Instruction	Result latency	Repeat rate	Instruction	Result latency	Repeat rate
MADD	3	1	MSUB	3	1
MADD.U	3	1	MSUB.U	3	1
MADDS	3	1	MSUBS	3	1
MADDS.U	3	1	MSUBS.U	3	1
MADD.H	3	1	MSUB.H	3	1
MADD.Q	3	1	MSUB.Q	3	1
MADDM.H	3	1	MSUBM.H	3	1
MADDMS.H	3	1	MSUBMS.H	3	1
MADDR.H	3	1	MSUBR.H	3	1
MADDR.Q	3	1	MSUBR.Q	3	1
MADDRS.H	3	1	MSUBRS.H	3	1
MADDRS.Q	3	1	MSUBRS.Q	3	1
MADDS.H	3	1	MSUBS.H	3	1
MADDS.Q	3	1	MSUBS.Q	3	1
MADDSU.H	3	1	MSUBAD.H	3	1
MADDSUM.H	3	1	MSUBADM.H	3	1
MADDSUMS.H	3	1	MSUBADMS.H	3	1
MADDSUR.H	3	1	MSUBADR.H	3	1
MADDSURS.H	3	1	MSUBADRS.H	3	1
MADDSUS.H	3	1	MSUBADS.H	3	1

For All MADD, MSUB, and MUL type instructions the result latency is reduced to 1 for accumulator forwarding between similar instructions. Instructions with 32-bit result forwarding to 32-bit accumulate and 64-bit results forwarding to 64-bit accumulate are considered to be similar.

4.3.5.2 Load-store pipeline instructions

These tables define the TC1.8 CPU load-store pipeline instruction timings.

Table 71 Load store arithmetic instructions

Instruction	Result latency	Repeat rate	Instruction	Result latency	Repeat rate
ADD.A	1	1	GE.A	1	1
ADDIH.A	1	1	LT.A	1	1
ADDSC.A	2	1	NE.A	1	1
ADDSC.AT	2	1	NEZ.A	1	1
EQ.A	1	1	SUB.A	1	1
EQZ.A	1	1	NOP	1	1

Table 72 Trap and interrupt instructions

Instruction	Result latency	Repeat rate	Instruction	Result latency	Repeat rate
DEBUG	–	1	TRAPSV[1)]	–	1
DISABLE	–	1	TRAPV[1)]	–	1
ENABLE	–	1	RSTV	–	1
RESTORE	–	1	WAIT	-	1
TRAPINV[2)]	-	-			

1) Execution cycles when no TRAP is taken. The execution timing in the case of raising these TRAPs is the same as other TRAPs such as SYSCALL.
2) The execution timing is the same as an IOPC TRAP

Table 73 Address move instructions

Instruction	Result latency	Repeat rate	Instruction	Result latency	Repeat rate
MFCR	2	1	MOV.A	1	1
MTCR	-	1	MOV.AA	1	1
MOVH.A	1	1	MOV.D	1	1

Table 74 Sync instructions

Instruction	Result latency	Repeat rate	Instruction	Result latency	Repeat rate
DSYNC	-	1[1)]	ISYNC[2)]	-	1
LSYNC	-	1[1)]			

1) Repeat rate assumes the store buffer is empty and all stores completed.
2) Repeat rate assumes that code fetch takes a single cycle.

Load instruction timing

Table 75 Load instruction timing

Instruction	Address latency	Result latency	Repeat rate	Instruction	Address latency	Result latency	Repeat rate
LD.A	1	3	1	LD.Q	1	2	1
LD.B	1	2	1	LD.W	1	2	1
LD.BU	1	2	1	LDLCX	-	5-9	5-9
LD.D	1	2	1	LDUCX	-	5-9	5-9
LD.DA	1	3	1	SWAP.W	2	3	6
LD.DD	2	2	2	LEA[1)]	–	1	1
LD.H	1	2	1	CMPSWAP.W	2	3	6
LD.HU	1	2	1	LHA	-	1	1
SWAPMSK.W	2	3	6				

1) The addressing mode returning an updated address is not relevant for this instruction.

Store instruction timing

Cache and Store instructions as with Load instructions will have a result for the pre-increment, post-increment, circular, or bit-reverse addressing modes, but do not produce a ‘register’ result.

- The memory references is naturally aligned
- The memory accessed takes a single cycle to accept a data item, or is snooped from the store buffer
- Timing is best case; no cache misses, no pending stores

Table 76 Cache instructions

Instruction	Result latency	Repeat rate	Instruction	Result latency	Repeat rate
CACHEA.I	1	1	CACHEA.WI[1)]	1	1
CACHEA.W[1)]	1	1	CACHEI.W[1)]	1	1
CACHEI.WI[1)]	1	1	CACHEI.I[1)]	1	1
CACHEA.W.VM[1)]	1	1	CACHEI.W.VM[1)]	1	1
CACHEI.WI.VM[1)]	1	1	CACHEI.I.VM[1)]	1	1
CACHEA.I.VM[1)]	1	1	CACHEA.WI.VM[1)]	1	1

1) Repeat rate assumes that no memory writeback operation occurs. Otherwise the repeat rate will depend upon the time for the castout buffers to clear.

Table 77 Store instructions

Instruction	Address latency	Repeat rate	Instruction	Address latency	Repeat rate
ST.A	1	1	ST.T	-	6
ST.B	1	1	ST.W	1	1
ST.D	1	1	STLCX	-	5-9
ST.DD	2	2	STUCX	-	5-9

(table continues...)

Table 77 (continued) Store instructions

Instruction	Address latency	Repeat rate	Instruction	Address latency	Repeat rate
ST.DA	1	1	LDMST	-	6
ST.H	1	1	-	-	-
ST.Q	1	1			

4.3.5.3 Load-store and integer conditional control flow instructions

Conditional control flow instructions generally do not produce any result value and only affect the next program counter value.

However, there are three exceptions. These are the LOOP instruction which produces an address register result, and the integer pipeline instructions JNED and JNEI, which produce a data register result.

Table 78 LOOP, JNED, and JNEI result latency

Instruction	Result latency
LOOP	4[1)]
JNED/JNEI	1

1) For LOOP result forwarding to non-LOOP instructions. For LOOP to LOOP the result latency is 1 clock

The remaining conditional control flow instructions are the integer pipeline conditional instructions (IP columns in table below)– JEQ, JGE, JGE.U, JGEZ, JGTZ, JLEZ, JLT, JLT.U, JLTZ, JNE, JNZ, JNZ.T, JZ and the load-store pipeline conditional instructions (LS columns in table below) - JEQ.A, JNE.A, JNZ.A, JZ.A.

Control flow instruction timing for the TC1.8 CPU can vary due to the state of branch target buffers and fetch FIFOs. The LOOP instruction (LP columns in table below) has the same penalties as a load-store conditional control flow instruction:

- Correctly predicted not taken branches incur no penalty
- Correctly predicted taken branches incur a penalty of up to two cycles depending on the state of the fetch FIFOs and the branch target buffer
- Incorrectly predicted LS instructions incur a three-cycle branch recovery penalty
- Incorrectly predicted IP instructions incur a four-cycle branch recovery penalty

Timing assumptions:

- All targets yield a full instruction in one access. That is, not 16-bit of a 32-bit instruction
- All code fetches take a single cycle

Table 79 Control flow timing

Prediction-result	Flow latency (LS, LP)	Repeat rate (LS, LP)	Flow latency (IP)	Repeat rate (IP)
Correct not-taken	1	1	1	1
Correct taken	1-3	1-3	1-3	1-3
Incorrect not-taken	3	4	4	4
Incorrect taken	3	4	4	4

Branch prediction

The TC1.8 CPU branch prediction system contains a dedicated loop buffer for nested loops, along with a branch target buffer and a branch history buffer.

4.3.5.4 Unconditional non CSA control flow instruction timing

Unconditional control flow changing instructions incur a penalty of up to two cycles depending on the state of branch target buffers and fetch FIFOs.

With the exception of the LOOPU instruction executed on the loop pipeline, the remainder - FCALL*, FRET, J, JA, JI, JL*I, JRI are all load-store instructions.

Timing Assumptions:

- All targets yield a full instruction in one access. That is, not 16-bit of a 32-bit instruction
- All code fetches take a single cycle

The following FCALL*/FRET control flow instructions all provide results to the implicit address register pair P[10] (A[10],A[11]).

Table 80 Unconditional FCALL/FRET control flow timing

Instruction	Flow latency	P[10] result latency	Repeat rate
FCALL	1-3	1	1-3
FCALLA	1-3	1	1-3
FCALLI	1-3	1	1-3
FRET	1-3	1	1-3

Some of following unconditional control flow instructions provide results to the implicit address register A[11].

Table 81 Unconditional jump control flow timing

Instruction	Flow latency	A[11] result latency	Repeat rate
J	1-3	-	1-3
JA	1-3	-	1-3
JI	1-3	-	1-3
JL	1-3	1	1-3
JLA	1-3	1	1-3
JLI	1-3	1	1-3
JRI	1-3	-	1-3

4.3.5.5 Load-store CSA instruction timing

This section summarizes the timing of the TC1.8 CPU CSA Control Flow instructions. Most change control flow, although some (BISR, SVLCX, and RSLCX) do not, and only update the CSA structures.

Timing assumptions:

- All targets yield a full instruction in one access. That is, not 16-bit of a 32-bit instruction
- All code fetches take a single cycle
- Timing is best case; no data cache misses for context operations, no pending stores

Some of the following instructions also provide a result to the implicit address register A[11]

Table 82 Load-store CSA control flow instruction timing

Instruction	Flow latency	A[11] result latency	Repeat rate
BISR	-	-	4/8[1)]
CALL	4/8[1)]	1	4/8[1)]
CALLA	4/8[1)]	1	4/8[1)]
CALLI	4/8[1)]	1	4/8[1)]
RET	4/8[1)]	-	4/8[1)]
RFE	4/8[1)]	-	4/8[1)]
RFM	4/8[1)]	-	4/8[1)]
RSLCX	-	-	4/8[1)]
SVLCX	-	-	4/8[1)]
SYSCALL	4/8[1)]	-	4/8[1)]
HVCALL	5/9[1)]	-	5/9[1)]
RFH	5/9[1)]	-	5/9[1)]

1) DSPR or cache hit/DLMU

4.3.5.6 Floating-point pipeline timing

This table defines the TC1.8 CPU floating point pipeline instruction timings.

Table 83 Floating-point instructions

Instruction	Result latency	Repeat rate	Instruction	Result latency	Repeat rate
ABS.F	1	1	ABS.DF	2	1
ADD.F	2	1	ADD.DF	2	1
CMP.F	1	1	CMP.DF	1	1
DIV.F	8	6	DIV.DF	16	14
FTOI	2	1	DFTOI	2	1
FTOIN	2	1	DFTOIN	2	1
FTOIZ	2	1	DFTOIZ	2	1
-	-	-	DFTOL	2	1
-	-	-	DFTOLZ	2	1
FTOQ31	2	1	-	-	-
FTOQ31Z	2	1	-	-	-
FTOU	2	1	DFTOU	2	1
FTOUZ	2	1	DFTOUZ	2	1
-	-	-	DFTOUL	2	1
-	-	-	DFTOULZ	2	1

(table continues...)

Table 83 (continued) Floating-point instructions

Instruction	Result latency	Repeat rate	Instruction	Result latency	Repeat rate
FTOHP	2	1	DFTOF	2	1
HPTOF	2	1	FTODF	2	1
ITOF	2	1	ITODF	2	1
-	-	-	LTODF	2	1
MADD.F	3	1	MADD.DF	4	2
MAX.F	1	1	MAX.DF	2	1
MIN.F	1	1	MIN.DF	2	1
MSUB.F	3	1	MSUB.DF	4	2

NEG.F	1	1	NEG.DF	2	1
Q31TOF	2	1	-	-	-
QSEED.F	1	1	QSEED.DF	2	1
SUB.F	2	1	SUB.DF	2	1
UPDFL	–	1	-	-	-
UTOF	2	1	UTODF	2	1
-	-	-	ULTODF	2	1

1) Double-Precision MUL.DF takes 3 cycles if any operand or the result is subnormal.

4.3.6 Local memory details

This section describes the features of the local memories of the TC1.8 CPU.

The processor implementation includes the following local memories:

- Data Scratch Pad Ram (DSPR)
  - Single cycle memory for local data operations, with code access through SRI
- Data Cache (DCache)
  - Single cycle memory for data operations
  - DCache can optionally be used as additional DSPR
- Distributed LMU (DLMU)
  - Two-cycle memory for local data operations, with code access through SRI
  - Contiguous with other DLMU memory in the system
  - The DLMU may be implemented as a standard SRAM or as a Standby SRAM. Where standby SRAM is available the DLMU contents will be maintained during standby power saving mode
- Program Scratch Pad Ram (PSPR)
  - Single cycle memory for local code fetch, with data access through SRI

- Program Cache (PCache)
  - Single cycle memory for code fetch
- Local PNVM Bank (LPB)
  - None, one, or two PNVM modules with multi-cycle NVM memory, local code and data read operations are direct access

The sizes of each of these memories is detailed in the CPU configurations section in the device specific manual.

Related information

NVM prefetch buffer (FPB) on page 173

TC4Dx CPU configuration on page 396

4.3.6.1 Data scratchpad RAM (DSPR)

The DSPR provides fast, deterministic data access to the CPU for use by performance critical code sequences.

The DSPR is organized as multiple memory “towers”. This organization allows the CPU to access 64-bit of data from any 16-bit aligned address

The DSPR may also be accessed from the SRI Slave interface by another bus master, with both read and write transactions supported. The DSPR may be accessed by the SRI Slave interface using any SRI transaction type, including burst transfers. In accordance with the SRI protocol, accesses to the SRI Slave interface must be naturally aligned.

The data scratchpad RAM is ECC protected across 16-bit data. Byte writes to the DSPR will be performed as read-modify-write operations at the memory interface. Any read-modify-write operation that detects an error on the read phase will not perform the write phase of operation. Byte writes to uninitialized memory always result in an ECC error being detected on the read phase and therefore no data will be written to the memory.

4.3.6.2 Distributed LMU (DLMU)

The DLMU provides fast, deterministic data access to a segment of the global LMU, ideally for use by the local CPU for global data.

The DLMU is organized as a 64-bit wide memory with ECC protection implemented on a 64-bit granularity. Within a double-word, sub-double-word write accesses are performed as internal read-modify-write operations.

The DLMU may also be accessed by an external master, with read, write, and atomic read-write sequence. The DLMU may be accessed using any SRI transaction type, including burst transfers.

The DLMU is not cached for data accesses by the local CPU regardless of the address segment. This is the same as for the DSPR.

Errors detected at the ECC decoders are signaled to the SMU through the SSH logic of the associated SRAM.

Any read-modify-write operation that detects an error on the read phase will not perform the write phase of operation. Sub 64-bit writes to un-initialized memory will always result in an ECC error being detected on the read phase and so no data will be written to the memory.

The TC1.8 CPU DLMU memory:

- Runs at half the frequency of the TC1.8 CPU and will introduce stalls into the CPU pipeline for load operations and store operations when the store buffers are full
- Contains a section of standby RAM (refer to the device specific CPU configuration)
- Does not implement data pacing to support burst read BTR transfers in cases when no ECC error is encountered. When a burst read encounters an ECC error in the memory, each beat of the burst that has an error will be delayed by 1 cycle using the data pacing feature of the SRI

4.3.6.3 Program Scratchpad RAM (PSPR)

The Program scratchpad RAM provides a fast, deterministic program fetch access from the CPU for use by performance critical code sequences.

***Note**: CPU program fetch accesses to scratchpad RAM are never cached in the program cache and are always directly targeted to the scratchpad RAM*

The CPU fetch interface will generate aligned accesses (64-bit), which will result in 64-bits of instruction being returned to the CPU.

Note that the CPU Fetch Unit can only read from the scratchpad RAM and can never write to it.

The scratchpad RAM may also be accessed from the SRI Slave interface by another bus master, such as the Data Memory Interface (DMI). The scratchpad RAM may be both read and written from the SRI. The SRI Slave interface supports all SRI transaction types.

The Program scratchpad RAM is ECC protected across 64-bit data. Writes to the PSPR that are less than 64 bits, or which are 64 bits but not naturally aligned will be performed as read-modify-write operations at the memory interface. Any read-modify-write operation that detects an error on the read phase will not perform the write phase of operation. Sub-64 bit writes to uninitialized memory always result in an ECC error being detected on the read phase and therefore no data will be written to the memory.

4.3.6.4 Local and global addressing

The TriCore™ architecture supports closely coupled program and data SRAM memories known as Program Scratch Pad RAM (PSPR) and Data Scratch Pad RAM (DSPR). The local addressing of the PSPR memory is always located at $C0000000_H$. The local addressing of the DSPR is always located at $D0000000_H$.

In a multiprocessor system the scratch pad memories appear in the global address map in the following locations:

Table 84 Global address locations

CORE_ID value	PSPR base	DSPR base
0	70100000_H	70000000_H
1	60100000_H	60000000_H
2	50100000_H	50000000_H
3	40100000_H	40000000_H
4	30100000_H	30000000_H
5	20100000_H	20000000_H
6 (CPUcs)	10100000_H	10000000_H

The CPUs always use the global addresses for SRI transactions. Therefore a data load from $C0000000_H$ (a CPUs local PSPR) will result in a SRI transaction with an address in the range 10100000_H - $701FFFFF_H$ dependent on the CORE_ID value of the processor.

Similarly a code fetch form $D0000000_H$ (a CPUs local DSPR) will result in a bus transaction with an address in the range 10000000_H - $700FFFFF_H$ dependent on the CORE_ID value of the processor.

4.3.6.5 PSPR address aliasing

In some situations the software in the PSPR is not static but dynamically loaded. For debugging this is hard to handle in ELF files and for breakpoints and trace. To assist debugging, knowledge of which code image is resident would ideally be available to the debug tooling.

When the option to enable the PSPR aliasing is enabled in COMPAT.PSPRALIAS==0, the TC1.8 CPU implements 8 mirrors of the physical PSPR regions per core. This means that 8 different code images can be easily distinguished by address for local code fetches and for accesses via the SRI slave interface. The run-time software still needs to ensure that the right code is loaded, but for debug and trace, for the MPU and within the ELF file, the different code can be easily distinguished.

The TC1.8 CPU supports 8 aliased 128K PSPR regions between 1 Mb and 2 Mb in each CPU segment. When the PCACHE is not required, the PSPR extension also supports the aliasing. Mapped TAGs are relocated to a different offset.

Table 85 PSPR address locations

Memory region alias	Start offset	End offset
0	100000_H	$11FFFF_H$
1	120000_H	$13FFFF_H$
2	140000_H	$15FFFF_H$
3	160000_H	$17FFFF_H$
4	180000_H	$19FFFF_H$
5	$1A0000_H$	$1BFFFF_H$
6	$1C0000_H$	$1DFFFF_H$
7	$1E0000_H$	$1FFFFF_H$

The 8 alias regions are supported for both local and global addressing.

Concurrent use of two aliases for the same physical locations is not supported. Multiple ELF images can be dynamically managed in non-overlapping subsets of the PSPR. When different images are loaded into overlapping portions of the PSPR, then the software should ensure that the store buffer is flushed in case the PSPR is used as a shared data location.

4.3.6.6 Cache and tag storage addressing

For the purposes of testing the storage arrays, or if the caches are not functionally required, the cache and tag memories may be mapped into the system address space. When mapped the cache memories are contiguous with the DSPR/PSPR memories respectively as detailed in the following table.

When mapped into the address space the cache memories behave as extensions to the PSPR/DSPR memories and may be used as such.

The mapping of cache and tag memories to the TriCore™ address space is controlled by the MEMMAP register in the VMT module.

The base address of the cache storage when mapped as SPR extension is detailed in the following table:

Table 86 Cache storage addressing when mapped

Memory	Base local address	Base global address
Program cache as PSPR extension	$C0000000_H$+PSPR memory size	PSPR base + PSPR memory size
Data cache as DSPR extension	$D0000000_H$+DSPR memory size	DSPR base + DSPR memory size

When mapped as PSPR extension, it will also be accessible in each aliased PSPR region.

The mapping of the Tag memories is provided for test purposes only. They may not be used as standard memory.

The base address of the tag storage when mapped into the address space is detailed in the following table:

Table 87 TAG storage addressing when mapped

Memory	Base local address	Base global address
Program TAG	$C0200000_H$	PSPR base + 200000_H
Data TAG	$D0200000_H$	DSPR base + 200000_H

4.3.6.7 Cache architecture

The TC1.8 CPU implements both a 2-way set-associative instruction cache and a 2-way set-associative data cache.

The data cache is a writeback cache with allocation on read and write.

Caches and PSW.S

Only one copy of an address will exist in the cache at any one time. An attempt to access an existing address with a different master TAG ID (based on PSW.S) will result in the eviction (writeback of dirty data) or invalidation of the current entry and a refetch using the new access information.

Caches and VMN

Only one copy of an address will exist in the cache at any one time. An attempt to access an existing address with a new VM number will result in the eviction or invalidation of the current entry and a refetch using the new access information.

Caches and PRS

When the option to capture the PRS in data cache is enabled COMPAT.TAGPRS, an attempt to load an existing address with a different PRS will result in the eviction or invalidation of the existing entry. When COMPAT.TAGPRS is disabled, all dirty cache data will be written back with no PRS value (PRS=0 and PRS_EN=0).

***Note**: This is independent of the value of* CORECON.PROTEN

Data cache invalidate

To enable the fast removal of clean data from the data cache, the 'data cache invalidate' control bit is provided in the DCON1 CSFR. The register bit DCON1.DCINV operates in a similar way to the bit PCON1.PCINV. When the bit is set to 1 all clean data lines within the data cache are invalidated.

Related information

Virtualization and caches on page 133

4.3.6.8 Data cache (DCACHE)

The DCache is a two-way set-associative cache with a Least-Recently-Used (LRU) replacement algorithm. Each line contains 256 bits of data along with ECC bits. A single valid bit and a single dirty bit are associated with each line.

CPU data accesses to a cacheable memory segment target the DCache. If the requested address and its associated data are found in the cache (Cache Hit), the data is passed to/from the CPU Load-Store Unit without

incurring any wait states. If the address is not found in the cache (Cache Miss), the DMI cache controller issues a cache refill sequence and wait states are incurred whilst the cache line is refilled. The CPU load-store interface will generate unaligned accesses (16-bit aligned), which will result in up to 64-bits of data being transferred to or from the CPU (for non-context operations). If the data access is made within a DCache line, no matter the alignment, and a cache hit is detected then the requested data is returned to the CPU in a single cycle. If the data access is made to the end of a DCache line, such that the requested data would span two DCache lines, a single wait cycle is incurred (if both cache lines are present in the cache, otherwise a refill sequence is required for the missing cache line(s)).

The data cache is of the writeback type. When the CPU writes to a cacheable location the data is merged with the corresponding cache line and not written to main memory immediately. Associated with each cache line is a single ‘dirty’ bit, to denote that the data in the cache line has been modified. Whenever a CPU load-store access results in a cache miss, and each of the potential cache ways that could hold the requested cache line are valid, one of the cache lines is chosen for eviction based upon the LRU replacement algorithm. The line selected for eviction is then checked to determine if it has been modified using its dirty bit. If the line has not been modified the line is discarded and the refill sequence started immediately. If the line has been modified then the dirty data is first written back to main memory before the refill is initiated. Due to the single dirty bit per cache line, 256 bits of data will always be written back, resulting in a SRI Burst-4 Transfer (BTR4) transactions.

Data Cache refills always result in the full cache line being refilled, with the critical double-word of the DCache line being fetched first. A refill sequence will always affect only one cache line. There is no prefetching of the next cache line. Due to the uniform size of DCache refill sequences, such refills are always implemented using SRI Burst Transfer 4 (BTR4) transactions.

All Cache SRAMs are ECC protected.

All TAG SRAMs are ECC protected

Data cache bypass

The Data Cache may be bypassed, under control of DCON0.DCBYP, to provide a direct data access path to memory. The default value of DCON0.DCBYP is such that the data cache is bypassed after reset.

Whilst the data cache bypass is enabled, a data access request by the CPU to a cacheable address will result in a forced cache miss. Any valid cache lines within the data cache will remain valid and unchanged whilst the data cache is bypassed. As such data accesses to cacheable addresses with the data cache bypass enabled behave identically to data accesses to non-cacheable addresses.

4.3.6.9 Program cache (PCACHE)

The program Cache is a two-way set-associative cache with a Least-Recently-Used (LRU) replacement algorithm. Each PCACHE line contains 256 bits of instruction and associated ECC bits.

CPU program fetch accesses which target a cacheable memory segment (and where the PCACHE is not bypassed) target the PCACHE. If the requested address and its associated instruction are found in the cache (Cache Hit), the instruction is passed to the CPU Fetch Unit without incurring any wait states. If the address is not found in the cache (Cache Miss), the PMI cache controller issues a cache refill sequence and wait states are incurred whilst the cache line is refilled. The fetch request always returns an aligned packet to the CPU.

The program cache is ECC protected on 64-bit data.

The program TAG Ram is ECC protected on 22-bit data.

Program Cache Refill Sequence

Program Cache refills are performed using a critical double-word first strategy with cache line wrapping such that the refill size is always 4 double-words. PCACHE refills are always performed in 64-bit quantities. A refill sequence will always affect only one cache line. There is no prefetching of the next cache line.

PCACHE refills are therefore implemented using an SRI Burst Transfer 4 (BTR4) transfers. The program cache supports instruction streaming, meaning that it can deliver available instruction half-words to the CPU Fetch Unit whilst the refill operation is ongoing.

Program Cache Bypass

The Program Cache may be bypassed, under control of PCON0.PCBYP, to provide a direct instruction fetch path for the CPU Fetch Unit. The default value of PCON0.PCBYP is such that the PCACHE is bypassed after reset.

Whilst PCACHE bypass is enabled, a fetch request by the CPU to a cacheable address will result in a forced cache miss, such that the cache controller issues a standard refill sequence and supplies instruction half-words to the CPU using instruction streaming, without updating the cache contents. Any valid cache lines within the PCACHE will remain valid and unchanged whilst the PCACHE is bypassed. As such, instruction fetch requests to cacheable addresses with PCACHE bypass enabled behave identically to instruction fetch requests to non-cacheable addresses.

Program Cache Invalidation

The PMI does not have automatic cache coherency support. Changes to the contents of memory areas external to the PMI that may have already been cached in the PCACHE are not detected. Software must provide the cache coherency in such a case. The PMI supports this via the cache invalidation function. The PCACHE contents may be globally invalidated by writing a ‘1’ to PCON1.PCINV. The PCACHE invalidation is performed over 64 cycles by a hardware state machine which cycles through the PCACHE entries marking each as invalid. During an invalidate sequence the CPU may continue to fetch instructions from non-cacheable memory. Any attempt to fetch instructions from a cacheable memory location during an invalidation sequence will result in the CPU stalling until the sequence completes. The status of the PCACHE invalidation sequence may be determined by reading the PCON1.PCINV bit.

4.3.6.10 DSPR access timing

The TC1.8 CPU implements a DSPR such that memory access are optimized for data aligned to the EABI rules. Data aligned to these rules is returned in a single cycle. Data not aligned to these rules may be returned in two cycles.

To maximize throughput for LD.DD and ST.DD instructions targeting the DSPR memory, they should use addresses with 16-byte alignment (the architecturally supported alignment may be no faster than a pair of LD.D & ST.D accesses).

Non-EABI aligned accesses to the DSPR can be counted by the performance counters.

4.3.7 CSFR, SFR and FSFR state

The internal processor state in the CPUs is split into two distinct groups. The majority of the registers are core special function registers (CSFRs). These registers are architecturally defined and must be accessed using MTCR/MFCR/MTDCR/MFDCR instructions (for access by the local processor). The remainder are SFRs and are implementation specific.

These SFR registers are accessed using load and store instructions through the system interconnect.

The TC1.8 CPU's FLASHCON (NVM control) registers are located in the FSFR address region to ensure separation between CPU and NVM access path.

4.3.7.1 CSFR, SFR, and FSFR address map and external access

Each CPU has a dedicated set of control and status registers accessed at the addresses detailed in this section. These registers are distinguished as Core Special Function Registers (CSFRs), Special Function Registers (SFRs), and NVM Special Function Registers (FSFRs).

CSFRs are usually registers defined in the architecture to support features required by an operating system (OS), real time operating system (RTOS), or hypervisor. A CPU must access its own CSFR registers using MTCR, MFCR, MTDCR, and MFDCR instructions. The CSFR registers of other CPUs may be accessed using load and store

instructions to their system addresses. The update of CSFRs of other CPUs is only well defined if that CPU is halted.

SFRs are registers that implement system features that are not usually part of the TriCore™ architecture. SFR registers of any CPU may only be accessed using load and store instructions. The system timer, kernel reset, overlay control, PROT, and APU registers of a CPU are mapped into its SFR address range.

PNVM control and status registers for the local NVM banks are located in the FSFR address range.

The CSFR space for each Hardware resource (HRHV,A,B) and the SFR space each occupy a separate 64 KB access region in Segment 15 for each processor.

The FSFR space is non-contiguous with the SFR/CSFR space and occupies another 64 KB region in segment 15 for each processor.

TC18 - Physical address of any CPU CSFR or SFR or FSFR

```
FSFR       : 0xF8400000 + (CORE_ID << 18) + FSFR offset
SFR        : 0xF8800000 + (CORE_ID << 18) + SFR offset
CSFR HRA   : 0xF8810000 + (CORE_ID << 18) + CSFR offset
CSFR HRB6) : 0xF8820000 + (CORE_ID << 18) + CSFR offset
CSFR HRHV6) : 0xF8830000 + (CORE_ID << 18) + CSFR offset
```

SFR, CSFR and FSFR bus access width

Accesses to SFR, CSFR, and FSFR registers from the system will support accesses widths of 32 and 64-bit.

Related information

FSFR range on page 172

4.3.7.2 SFR and CSFR partitioning

All new hypervisor registers will be added at offset $B000_H$ (Only in HRHV).

SFR	HRA	HRB	HRHV	Offset	Type
X				0000_H	STM
X				1000_H	Test registers
X				$D000_H$	Kernel reset SFRs
X				$E000_H$	APU SFRs
X				$FB00_H$	Overlay SFRs
	X	X	X	8100_H	PMA CSFRs
	X	X	X	9000_H	DMI CSFRs (including integrity error)
	X	X	X	9200_H	PMI CSFRs (including integrity error)
	X	x	X	$A000_H$	FPU CSFRs
			X	$B000_H$	Hypervisor registers
	X	X	X	$C000_H$	MPU Data protection ranges CSFRs
	X	X	X	$D000_H$	MPU Code protection ranges CSFRs
	X	X	X	$E000_H$	MPU (Code, Data) control CSFRs

6 only accessible when virtualization is present and enabled

SFR	HRA	HRB	HRHV	Offset	Type
	X	X	X	$E400_H$	Temporal protection CSFRs
				$F000_H$ & $FD00_H$	Debug registers
	X				Virtualization disabled
	X	X	X		Virtualization enabled (registers not replicated, trap to hypervisor when in HRA/B)
	X	X	X	$FC00_H$	Performance counters
	X	X	X	$FE00_H$	Main CSFRs 00 PCXI, PSW, PC, ----, 10 ----, CORECON, CPU_ID, CORE_ID, 20 BIV, BTV, ISP, ICR, 30 ----, PPRS, FCX, LCX, 40 SWID 50 CUS_ID 60 BOOTCON, LCLCON, CCON, TCCON Not replicated => PCXI, PSW, PPRS, PC, xxxID BOOTCON, LCLCON, CCON, TCCON
	X	X	X	$FF00_H$	GPRs - Only partially replicated (A0, A1, A8, A9).

***Note**: With the exception of hypervisor registers, non-replicated CSFRs are aliased in the memory map. For example, PCXI can be accessed at $1FE00_H$, $2FE00_H$ and $3FE00_H$.*

4.3.7.3 CORECON (SYSCON replacement)

In the AURIX™ TC4xx family the SYSCON register is renamed CORECON. This removes name clashes with the SYSCON register in the SCU which does control the system.

In order to make CORECON fully virtualized, both ESDIS and BHALT bits are relocated to COMPAT.ESEN and BOOTCON.BHALT.

The usage of (PROTSFRSE protection of the CPU core control register (CORECON) is configurable by the application software. From system reset, as well as after any kernel reset, the register is not subject to PROTSFRSE protection. Clearing the compatibility control register safety protection field (COMPAT.SP=$0B_B$) enables the PROTSFRSE protection of the register.

Related information

System Control Unit (SCU) on page 5872

4.3.7.4 Emulator space disable

The emulator space control bit (ESDIS) was previously held in the CORECON register (SYSCON.ESDIS/ CORECON.ESDIS). For version 1.8 of the TriCore™ architecture this control is moved to the COMPAT register bit[8]. To provide a compatible behavior from reset, the polarity of the bit is inverted and the control becomes the emulator space enable (COMPAT.ESEN).

4.3.7.5 Boot control: Boot halt

A new register BOOTCON ($FE60_H$) is introduced to hold the BHALT bit.

Following a system reset, both CPU0 and CPUcs will start their boot sequences. All other cores will be placed in the boot-halt state. In the boot-halt state the core is halted, and the instruction fetch system stalled. All traps and interrupts are ignored by a core in this state, but all memories and registers associated with the core are available for access through the system interconnect.

A core in boot-halt has BOOTCON.BHALT set. The core will remain halted until the BOOTCON.BHALT bit is written to “0”, when it will start to fetch from the PC defined in the PC CSFR. This will be the boot PC unless otherwise updated. A write to “1” of the BOOTCON.BHALT will be ignored.

4.3.7.6 Floating-point error registers

The following floating point error registers are updated in respect to previous TriCore™ implementations:

```
FPU_TRAP_OPC: Bit[9] – Double/single precision identifier
```

The following FPU trap registers are renamed and contain the lower 32-bit of input operand SRC registers for single and double precision floating-point operations. In order to improve software handling, the registers offsets are not compatible with previous versions of the architecture to allow reading of a complete operand in one instruction using the new MFDCR instruction.

```
FPU_TRAP_SRC1 -> FPU_TRAP_SRC1_L (0xa010)
FPU_TRAP_SRC2 -> FPU_TRAP_SRC2_L (0xa018 was previously 0xa014)
FPU_TRAP_SRC3 -> FPU_TRAP_SRC3_L (0xa020 was previously 0xa018)
```

The following FPU trap registers are new for version 1.8 of the TriCore™ architecture, and contain the upper 32-bit of input operand SRC registers for double precision floating-point operations.

```
FPU_TRAP_SRC1_U (0xa014)
FPU_TRAP_SRC2_U (0xa01C)
FPU_TRAP_SRC3_U (0xa024)
```

4.3.7.7 BTV, BHV reset values

BTV and BHV reset values are computed using fixed offsets from the base address of the ROM associated with the CPU instance.

For host CPUs the base address of the system BOOTROM will be used, while for the Secure CPU instance (CPUcs) the base address of the CSROM will be used.

BTV reset value = ROMADDR_base[31:16], 16’hFE00

BHV reset value = ROMADDR_base[31:16], 16’hFD00

4.3.7.8 Performance counters

The performance counters are decoupled from the debug system and can now be enabled on any device without requiring the use of the debug system. This allows performance to be monitored by/within applications.

Table 88 Counter source details

Counter name	Function
IP_DISPATCH_STALL	The counter is incremented on every cycle in which the Integer dispatch unit is stalled for whatever reason
LS_DISPATCH_STALL	The counter is incremented on every cycle in which the Load-Store dispatch unit is stalled for whatever reason
LP_DISPATCH_STALL	The counter is incremented on every cycle in which the Loop dispatch unit is stalled for whatever reason
PCACHE_HIT	The counter is incremented whenever the target of a cached fetch request from the fetch unit is found in the program cache
PCACHE_MISS	The counter is incremented whenever the target of a cached fetch request from the fetch unit is not found in the program cache and hence a bus fetch is initiated
MULTI_ISSUE	The counter is incremented in any cycle where more than one instruction is issued
DCACHE_HIT	The counter is incremented whenever the target of a cached request from the Load-Store unit is found in the data cache
DCACHE_MISS_CLEAN	The counter is incremented whenever the target of a cached request from the Load-Store unit is not found in the data cache and hence a bus fetch is initiated with no dirty cache line eviction
DCACHE_MISS_DIRTY	The counter is incremented whenever the target of a cached request from the Load-Store unit is not found in the data cache and hence a bus fetch is initiated with the writeback of a dirty cache line
TOTAL_BRANCH	The counter is incremented in any cycle in which a branch instruction is in a branch resolution stage of the pipeline (IP_EX1, LS_DEC, LP_DEC). This counter is also incremented for ISYNC, CALL, RET, RFE, RFM, FCALL/FRET and RFH instructions
PMEM_STALL	The counter is incremented whenever the fetch unit is requesting an instruction and the Instruction memory is stalled for whatever reason
DMEM_STALL	The counter is incremented whenever the Load-Store unit is requesting a data operation and the data memory is stalled for whatever reason

Performance counter registers

The various counter sources listed above may be selected for counting by programming the M1, M2 and M3 fields in the CCTRL register. (See the TriCore™ architecture manual for register details). The mappings are listed below.

Table 89 Performance counter registers

Name	Description	Offset address
CCTRL	Counter Control Register	$FC00_H$
CCNT	CPU Clock Count Register	$FC04_H$
ICNT	Instruction Count Register	$FC08_H$
M1CNT	Multi Count Register 1	$FC0C_H$
M2CNT	Multi Count Register 2	$FC10_H$
M3CNT	Multi Count Register 3	$FC14_H$

Table 90 Multi count configuration

CCTRL M1/M2/M3	M1CNT count function	M2CNT count function	M3CNT count function
000	IP_DISPATCH_STALL	LS_DISPATCH_STALL	LP_DISPATCH_STALL
001	PCACHE_HIT	PCACHE_MISS	MULTI_ISSUE
010	DCACHE_HIT	DCACHE_MISS_CLEAN	DCACHE_MISS_DIRTY
011	TOTAL_BRANCH	PMEM_STALL	DMEM_STALL

4.3.8 Data access overlay (OVC)

The data overlay provides the capability to redirect selected data accesses to the overlay memory. Data accesses made by the TriCore™ to Program NVM or Online Data Acquisition space can be redirected.

The presence of overlay is core specific. The TCCON register can be used to identify cores with overlay hardware support.

***Note**: The CPUcs instance does not have overlay support.*

Overlay memory may be located in the Local Memory (if present), in the DPSR/PSPR memory, or in another Program NVM bank[7].

Overlay functionality makes it possible for example, to modify the application's test and calibration parameters, which are typically stored in NVM memory, during the run-time of a program.

Only read and write data accesses are redirected. The access redirection is executed without performance penalty.

***Attention**: As the address translation is implemented in the DMI it is only effective for data accesses. Instruction fetches by the PMI or accesses by any other master, including the debug interface, are not effected*

***Warning**: Overlay address modification only happens after the address has passed all the MPU checks. The APU on all overlay memories is a final check which redirected accesses must pass to succeed*

Summary of features and functions

- Redirecting data accesses addressed to Program NVM and OLDA
- Support redirection to overlay memory located in:
  - Program NVM[7]
  - Local Memory Unit (LMU), if present, including DLMU
  - DSPR or PSPR memory
- Individual overlay system per processor core
- Up to 32 overlay ranges ("blocks") available in each TriCore™ instance
- Two levels of priority:
  - 2 low priority ranges with block sizes of 32 bytes up to 4 MB
  - 30 high priority ranges with block sizes of 32 bytes up to 512 KB
- Redirected address range span within an overlay memory of up to 16 MB/4 MB (low priority/high priority blocks)
  - Low priority blocks have a span of up to 16 MB for emulation devices, and are limited to a span of up to 4 MB in production devices
- Overlay memory location and block size selected individually for every overlay block
- Multiple overlay blocks can be enabled or disabled with one register write access
- Programmable flush (invalidate) control for data cache in DMI
- Overlay start/stop synchronized against data load

7 emulation devices only

4.3.8.1 Data access redirection

The principle of redirecting data access from the original target memory (“Target Address”) to overlay memory (“Redirected Address”) is shown here.

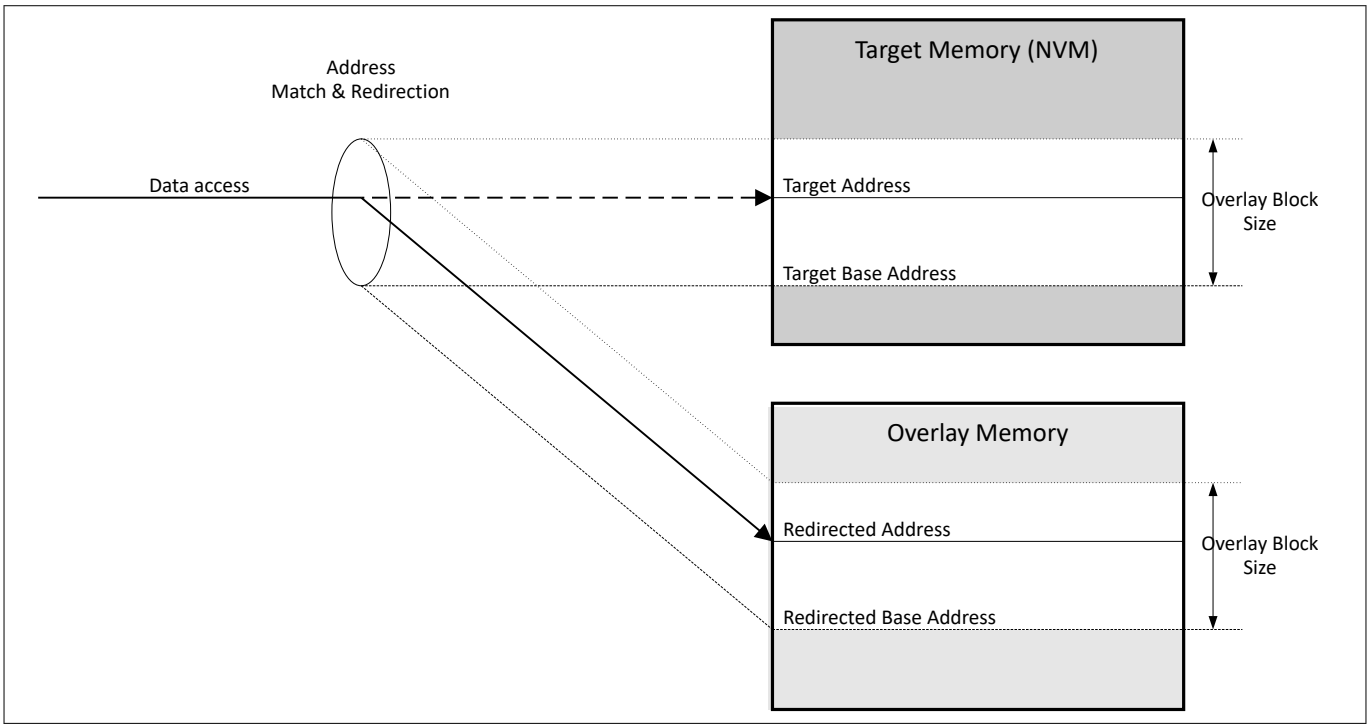

Figure 28 Data access redirection

Data access overlay is defined using overlay ranges (“overlay blocks”).

Each overlay block defines one continuous range of address space for which the accesses are redirected.

Each overlay block is configured with the following parameters:

- Overlay Block Target Base Address
  - The start address for the range of the target addresses to be redirected
- Overlay Block Size
  - The size of the range of the addresses to be redirected
- Overlay Block Redirection Base Address
  - The start address for redirection

In AURIX™ up to 32 overlay ranges can be used in each TriCore™ instance.

Each overlay block has 3 associated registers for independent configuration of these parameters.

The overlay parameters are configured as follows:

- Target Base Address is configured with OTARi register
- Overlay Block Size is configured with OMASKi register
- Redirection Base Address is configured with RABRi register

The size of the overlay memory blocks depends on the block index.

The size for the low priority set (block 0 and 1) can be 2^n x 32 bytes, with n = 0 to 17. This gives the block size range from 32 bytes to 4 Mbytes.

For the high priority set (blocks 2 to 31) n = 0 to 14. This gives the block size range from 32 bytes to 512 Kbytes.

The start address of the block can only be an integer multiple of the programmed block size (natural alignment boundary). If the OTARi register value, or RABRi register value is not aligned with the block size, the least significant bit values are ignored and treated as zero.

The Redirection Base Address is determined by two fields in the RABRi register:

- RABRi.OMEM selecting the Overlay Memory
- RABRi.OBASE selecting the base address within this memory

Each overlay block can be activated or deactivated with its RABRi.OVEN bit. Overlay blocks can be activated and deactivated independently, by directly accessing the RABRi register, or in groups, where multiple configured blocks are activated of deactivated concurrently. For information on concurrent block activation see the chapter "Global Overlay Control Synchronization".

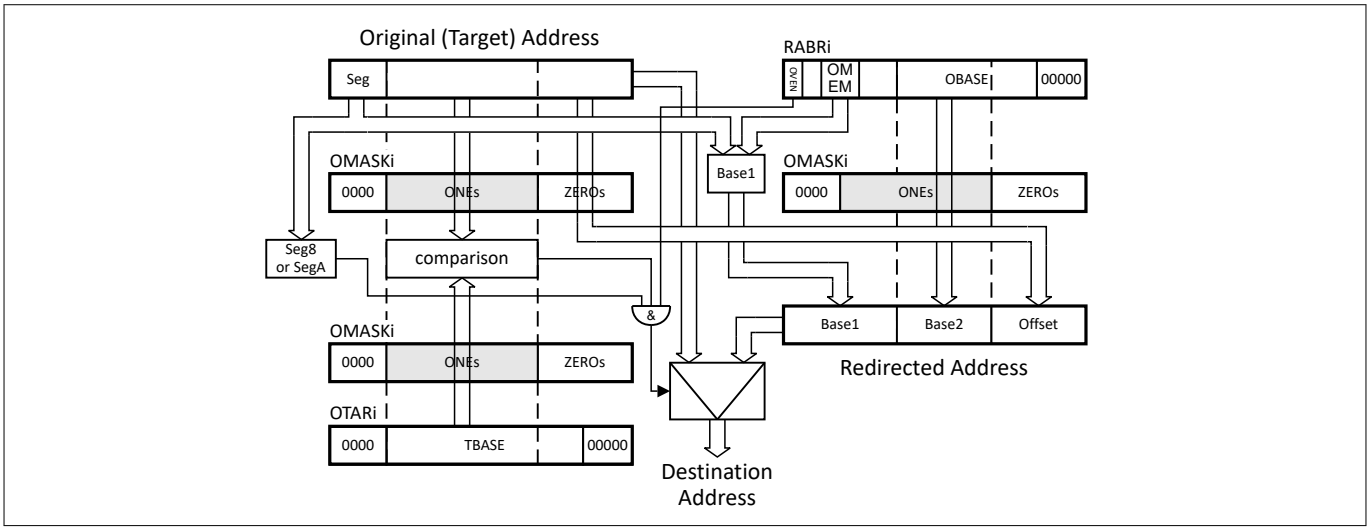

Figure 29 Address redirection process

Any data access to segment 8_H or segment A_H is checked against all the activated overlay blocks.

For each activated overlay block, address bits 27..5 are compared with the target base address (OTARi), and this bit-wise comparison is qualified by the content of OMASKi register.

Address bits participate in the comparison if the corresponding OMASKi bits are set to one. The access is redirected, if all the address bits selected by OMASKi equal to the corresponding bits in OTARi register.

The address for redirection is constructed as follows:

- Low priority ranges
  - Address bits 31..24 are set according to the Overlay Memory Selection (RABRi.OMEM) and the cache-ability of the original address
  - For address bits 23..5:
    - If the corresponding OMASKi bit is set, the address bit value is taken from RABRi.OBASE field
    - If the corresponding OMASKi bit is cleared, the address bit value is taken from the original address
  - Address bits 4..0 are always taken directly from the original address
- High priority ranges
  - Address bits 31..22 are set according to the Overlay Memory Selection (RABRi.OMEM) and the cache-ability of the original address
  - For address bits 21..5:
    - If the corresponding OMASKi bit is set, the address bit value is taken from RABRi.OBASE field;
    - If the corresponding OMASKi bit is cleared, the address bit value is taken from the original address
  - Address bits 4..0 are always taken directly from the original address

If there is no redirection, the original address is used to perform the access.

Overlapping redirections

Overlay ranges are split into two sets:

- Ranges 0 and 1 form the low priority set
- Ranges 2 to 31 form the high priority set

In order to minimize the number of descriptors used, the overlay supports the configuration of a low priority range as a wide overlay window, while using one of the high priority ranges to refine the redirection. An active high priority range takes precedence during block comparison.

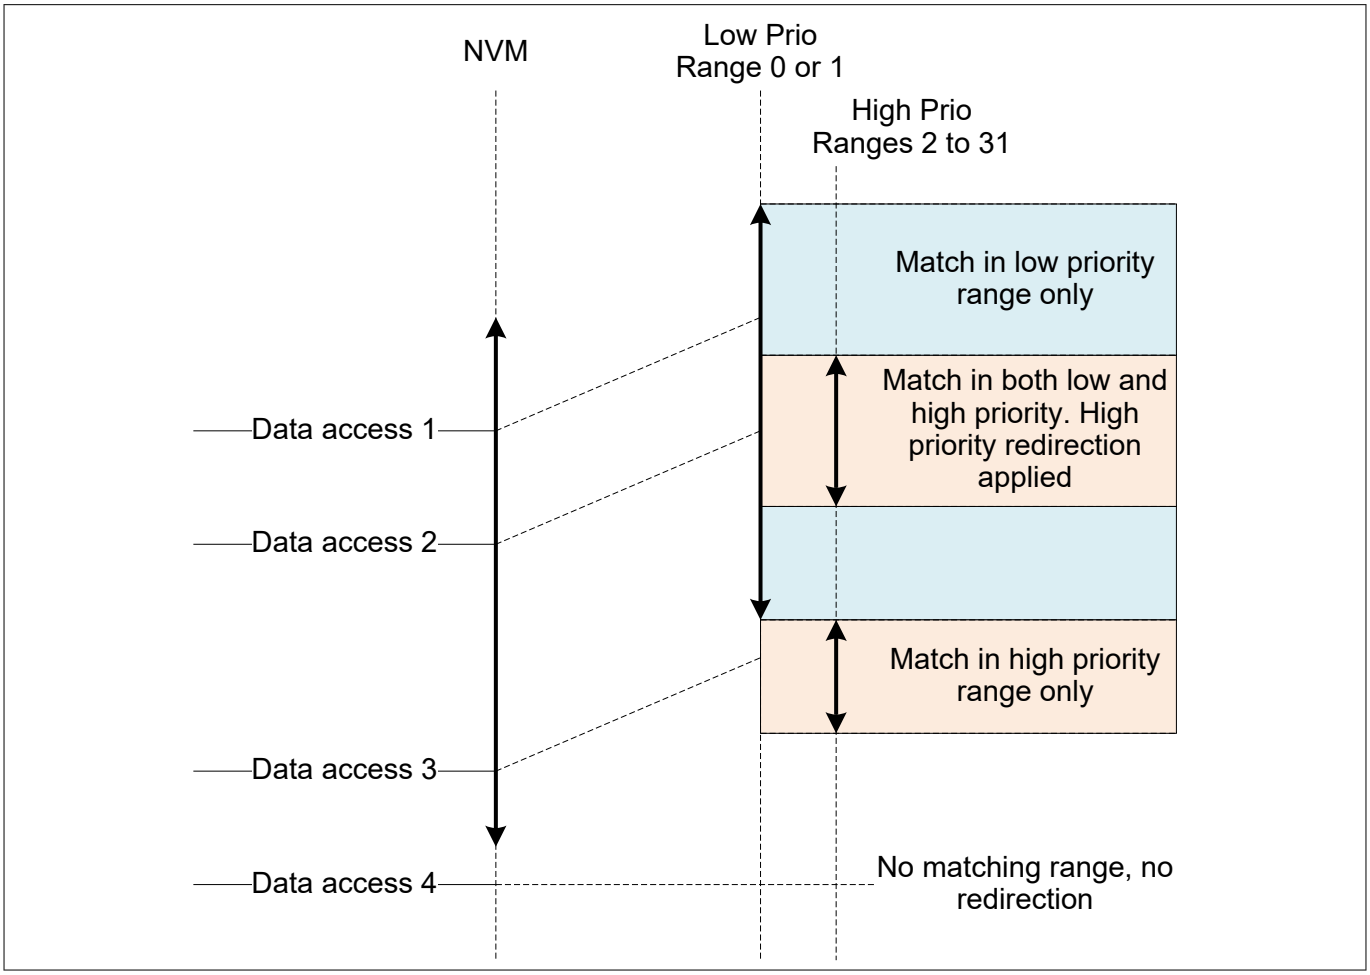

Figure 30 Two levels of priority

Target address ranges for activated overlay blocks in the same priority level should not overlap or an exception may occur. See the chapter "Access Protection, Attributes, Concurrent Matches".

Related information

Global overlay control synchronization on page 165

Access protection, attributes, concurrent matches on page 166

4.3.8.2 Target memories

Data access to any memory within the segment 8_H or segment A_H may be redirected to overlay memory. In particular, access to the following memories may be redirected:

- Program NVM
- Data NVM
- OLDA space

4.3.8.2.1 Online data acquisition (OLDA) space

Calibration is additionally supported by a virtual OLDA memory range. The base address of the virtual OLDA memory range is defined in the system address map.

4.3.8.3 Overlay memories

Here all the supported overlay memories are described. Depending on the device type, only a subset of the listed overlay memories are available. Overlay memory is selected independently for each block through the RABRi.OMEM field value.

4.3.8.3.1 Local memory

If present, the local memory (LMU) can be selected for overlay. The local memory is selected for overlay block 'i' redirection if the RABRi.OMEM value is either 8_H, 9_H or A_H. Values 9_H and A_H are reserved in production devices and only usable in emulation devices

LMU low - range 0 to 4 MB

The base address of the LMU is B/9000 0000_H.

During address translation, the upper 10 address bits are set to:

- $B0_H00_B$ (for target segment A_H)

or to

- 90_H00_B (for target segment 8_H)

LMU mid - range 4 MB to 8 MB

The base address of the LMU is B/9040 0000_H.

During address translation, the upper 10 address bits are set to:

- $B0_H01_B$ (for target segment A_H)

or to

- 90_H01_B (for target segment 8_H)

LMU high - range 8 MB to 12 MB

The base address of the LMU is B/9080 0000_H.

During address translation, the upper 10 address bits are set to:

- $B0_H10_B$ (for target segment A_H)

or to

- 90_H10_B (for target segment 8_H)

4.3.8.3.2 OWN

NVM to NVM redirection can be selected for overlay. The overlay to NVM (OWN) space is selected for overlay block 'i' redirection if the RABRi.OMEM value is C_H, D_H or E_H. These values are reserved in production devices and only usable in emulation devices.

PNVM low - range 0 to 16 MB

The base address of this space is A/8000 0000_H.

During address translation:

- For ranges 0 and 1, the upper 8 address bits are set to$A0_H$ (for target segment A_H) or to 80_H (for target segment 8_H)
- For ranges 2 to 31, the upper 10 address bits are set to$A0_H00_B$ (for target segment A_H) or to 80_H00_B (for target segment 8_H)

PNVM high - range 16 MB to 32 MB

The base address of this space is A/8100 0000_H.

During address translation:

- For ranges 0 and 1, the upper 8 address bits are set to$A1_H$ (for target segment A_H) or to 81_H (for target segment 8_H)
- For ranges 2 to 31, the upper 10 address bits are set to$A1_H00_B$ (for target segment A_H) or to 81_H00_B (for target segment 8_H)

PNVM SOTA alternate bank

The base address of this space is A/8200 0000_H.

During address translation:

- For ranges 0 and 1, the upper 8 address bits are set to$A2_H$ (for target segment A_H) or to 82_H (for target segment 8_H)
- For ranges 2 to 31, the upper 10 address bits are set to$A2_H00_B$ (for target segment A_H) or to 82_H00_B (for target segment 8_H)

4.3.8.3.3 DSPR and PSPR memory

Data scratch memory (DSPR) or program scratch memory (PSPR), from any application core, can be selected for overlay by configuring the block RABRi.OMEM value. During address translation, the upper 10 address bits are set to the target PSPR or DSPR target address.

Depending on the value set in RABRi.OBASE either DSPR memory (starting at offset 0_H) or PSPR memory (starting at offset 10 0000_H) can be used.

4.3.8.4 Global overlay control

Overlay can be disabled or enabled individually for each core with the SCU OVCENABLE register. If OVCENABLE.OVENx bit is cleared no address redirection is permitted on Core-x regardless of the remaining register settings. A write to the OVCENABLE register does not change any of the remaining register values.

While each overlay block can be activated and deactivated individually by writing its RABRi.OVEN bit, dedicated functionality is provided for concurrently activating and deactivating multiple blocks. This can be useful in maintaining data consistency across several memory regions.

For the purpose of concurrent activation and deactivation overlay blocks are selected in two stages:

- The individual blocks for activation and deactivation are selected with CPUx_OSEL registers for each core 'x' independently
- The set of cores is selected with OVCCON.CSEL field

Multiple overlay blocks can be simultaneously activated or deactivated with OVCCON.OVSTRT bit. When OVCCON.OVSTRT bit is written with one:

- If the OVCCON.CSELx bit is written with one, and the CPUx_OSEL.SHOVENi bit value is one, overlay block 'i' in core 'x' is activated, and CPUx_RABRi.OVEN bit is set
- If OVCCON.CSELx bit is written with one, and CPUx_OSEL.SHOVENi bit value is zero, overlay block 'i' in core 'x' is deactivated, and CPUx_RABRi.OVEN bit is cleared
- If OVCCON.CSELx bit is written with zero, the overlay configuration in core 'x' is not effected

The actions listed above are executed concurrently. The overlay configuration is not changed otherwise. With this function it is possible to switch directly from one set of overlay blocks to another set of overlay blocks.

Multiple overlay blocks can be simultaneously deactivated with OVCCON.OVSTP bit. When OVCCON.OVSTP is written with one:

- If OVCCON.CSELx bit is one, all the overlay blocks in core 'x' are deactivated, and all CPUx_RABRi.OVEN bits are cleared
- If OVCCON.CSELx bit is zero, the overlay configuration in core 'x' is not effected

The actions listed above are executed concurrently. The overlay configuration is not changed otherwise.

***Note**: Overlay should not be enabled or disabled using global OVCENABLE register if any of the blocks are enabled with RABRi.OVEN. Instead, OVSTRT or OVSTP should be used if concurrent block enabling or disabling is required.*

When OVCCON.DCINVAL is written with one, all the unmodified (clean) data cache lines in the selected cores are invalidated. The data cache lines containing modified (dirty) data are not effected. The cores not selected with OVCCON.CSEL field are not effected. Data cache invalidation can be combined with OVSTRT or OVSTP action. This function helps to assure that the CPU can access the new data after the overlay blocks have been activated or deactivated.

***Note**: OVCCON.CSEL field is written together with OVSTRT, OVSTP and DCINVAL bits in the same register, and only impacts any action triggered by the same write. CSEL, OVSTRT, OVSTP and DCINVAL do not retain the written value and always read as zero.*

The OVCCON.OVCONF user control flag is provided, together with its protection bit OVCCON.OVCONF_P. These bits do not impact the overlay functionality.

When the OVCCON register is written with CSELx set and either OVSTRT or OVSTP set, and at the same time CPUx_RABRi register is written, the resulting value of CPUx_RABRi.OVEN bit is not defined. Possibility of such simultaneous access should be avoided.

OVSTRT, OVSTP, and DCINVAL actions are not performed when TriCore™ is in idle state.

4.3.8.4.1 Global overlay control synchronization

When OVSTRT, OVSTP, or DCINVAL action is requested, its execution may be delayed to prevent changing overlay configuration during an ongoing data load.

Sufficient time should be allowed after an action request, before another action is requested. If a new action is requested while a previous action is still pending, due to synchronization with CPU loads, some actions may be lost.

4.3.8.5 Overlay configuration change

The overlay block should be disabled by clearing its RABRi.OVEN bit, before any changes are made to the OTARi, OMASKi, or RABRi registers. If not, unintended access redirection may occur.

The overlay block should only be enabled if the target address, the overlay memory selection, the redirection address, and the mask have all been configured with intended values.

***Note**: The overlay control does not prevent configuring the translation logic incorrectly. In particular, redirection to not implemented or forbidden address range is not prevented.*

Special care needs to be taken to synchronize overlay redirection change to the executed instruction stream if data consistency is required.

External accesses may be buffered in the CPU. External accesses that have not been completed may still be affected by overlay configuration changes. Therefore it is advised to ensure completion of all pending accesses, for example by executing a DSYNC instruction, before any overlay range is activated or deactivated.

When the overlay block is enabled and the same memory location is written through the target address space and read through the redirected address space, or vice-versa, the access synchronization needs to be enforced with a DSYNC and data cache writeback, if applicable.

4.3.8.6 Access protection, attributes, concurrent matches

When data access is redirected by overlay, access protection is applied as follows:

- Target address is subject to CPU Memory Protection (MPU) validation
- Redirected address is subject to APU validation

Physical memory attributes for the redirected access are determined based on the target address segment (see the CPU Physical Memory Attributes chapter).

Concurrent matches are only permitted between one of the overlay ranges 0,1 and one of the overlay ranges 2..31.

When an address matches two of the enabled ranges 0,1 or two or more of enabled overlay ranges 2..31, an exception is raised and the memory access is not performed.

A load operation with multiple matches on overlay ranges raises a data access synchronous error (DSE) trap, and a store operation raises a data access asynchronous error (DAE) trap. In such cases the relevant trap information registers are updated. The relevant registers are: data synchronous trap register (DSTR), data asynchronous trap register (DATR), and data error address register (DEADD). Please see the DMI Registers chapter for more information.

4.3.8.7 Overlay control registers

Overlay block control registers are located in each CPU that supports data access overlay. Overlay global control registers are located in the SCU. Overlay register access can be by APU register protection.

Per core overlay register

- CPUx_RABRi
- CPUx_OTARi
- CPUx_OMASKi
- CPUx_OSEL

Where 'x' is the core number and 'i' is the block number.

The overlay blocks are organized into two groups:

- Low priority group: Block numbers 0 and 1
- High priority group: Block numbers 2 to 31

Global overlay registers

- OVCENABLE
- OVCCON

These registers are described in the SCU chapter.

4.3.8.7.1 Block control registers

For each of the 32 overlay memory blocks, indicated by index i, three registers control the overlay operation and the memory selection:

- Redirected address base register RABRi, which selects the overlay memory, holds the block base address within this memory and contains block enable bit
- Overlay target address register OTARi, which holds the base address of the memory block being overlaid
- Overlay mask register OMASKi, which determines which bits from RABRi are used for the base address of the overlay memory and block, and which bits of the original data address are directly used as offset within the block

Additionally, the overlay range select register OSEL determines which blocks are to be enabled and which blocks are to be disabled when the OVCCON.OVSTRT bit is set.

All overlay block control registers are reset to their default values with the application reset. A special debug reset is not considered.

4.3.8.8 Global overlay control registers

Two registers globally control the overlay operation for all the cores:

- Overlay enable register OVCENABLE can be used to disable or enable data access overlay individually for each core
- Overlay control register OVCCON can be used to perform the following actions on a selected set of cores:
  - Concurrently enable or disable selected overlay blocks
  - Concurrently disable overlay blocks
  - Invalidate data cache

4.3.9 CPU timers

This section describes the TC1.8 CPU specific details of the temporal protection system.

4.3.9.1 Temporal protection system timers (TPS)

To assist in task run-time monitoring, the TC1.8 CPU implements a temporal protection system. This consists of three independent decrementing counters (TPS_TIMERn) arranged to generate a temporal asynchronous error trap (TAE - Class-4, Tin-7) on decrement to zero. A control register (TPS_CON) contains status and control bits for the temporal protection system.

The temporal protection system is enabled by the CORECON.TPROTEN register bit. The temporal protection registers are core special function registers (CSFRs), and are described in detail in the TriCore™ architecture manual.

The TC1.8 CPU decrements the TPS_TIMERn on each CPU clock. CPU clock control until either the count value reaches zero, or the timer is de-activated by writing zero to the TPS_TIMERn register. (CCON.DIV) has no effect on TPS_TIMERs decrement frequency. While the CPU clock is stopped (as happens in the CPU suspend state) then no decrementing occurs for this period.

4.3.10 Access protection and ENDINIT replacement

The TC1.8 CPU implements several access protection units (APUs), also known as safety protection, to provide protection against illegal or unintended bus access to the local memory system and control registers.

In order to provide access to the resources while reconfiguration is in progress, all APU instances in the TC1.8 CPU are configured through shadow registers. Each APU has an associated PROT. The shadow APU registers and their associated PROT are the only writeable registers in the APU.

Please refer to the Access Protection chapter for details on APU register configuration.

Table 91 Summary of APUs

Instance	Resource protected	AURIX™ TC3xx equivalent
ACCENDLMU	Ranged based APU protection with shadow configuration APU. 16 ranges can be configured to restrict accesses to the local DLMU to specific TAG, VMN and PRS	DLMU_SPROT_*
ACCENSPR	Ranged based APU protection with shadow configuration APU. 16 ranges can be configured to restrict accesses to the local DSPR/PSPR to specific TAG, VMN and PRS	SPR_SPROT_*
ACCENSFR	Range-less based APU protection with shadow configuration APU	SFR_SPROT_*
ACCENSTM	Virtualization not present or disabled only. Range-less based APU protection with shadow configuration APU	STM_ACCEN*
ACCENSTMVMx	Virtualization enabled only. Range-less based APU protection with shadow configuration APU	STM_ACCEN*
ACCENPFSFR	Range-less APU protection with shadow configuration APU	SFR_SPROT_*
ACCENPF	Ranged based APU protection with shadow configuration APU. 8 ranges can be configured to restrict accesses to the local PNVM to specific TAG, VMN and PRS. This APU will only provide read protection. Write to PNVM is not possible from this interface	LPB_SPROT_* (Previously range-less)

4.3.10.1 ENDINIT replacement

TC1.8 CPU PROT implementation

In AURIX™ TC4xx the control of the ENDINIT functionality is provided locally to the CPU by PROT instances (Please see the Access Protection chapter for background on the PROT functionality). With local control, the concepts of system wide ENDINIT and CPU ENDINIT, are no longer applicable.

PROT usage with no virtualization (or virtualization disabled)

To allow distinct resource control, resources are split across the following PROT instances:

Table 92 PROT for configurations without virtualization or with virtualization disabled

Instance	Registers covered	
PROTRSTE	KRST0, KRST1	Previously system ENDINIT. Separated from other PROT as the owner is likely to be a remote master
PROTSFRE	PMA0, PMA1, DCON0, PCON0, SEGEN, BIV, BTV, ISP	Previously CPU ENDINIT
PROTSFRE	STM_CLC	Previously system ENDINIT STM is now part of the CPU
PROTSFRSE	COMPAT, SMACON, CORECON, ACCENSFRCFG (APU)	Previously safety ENDINIT
PROTSTMSE	ACCENSTMCFG (APU)	Previously safety ENDINIT
PROTDLMUSE	ACCENDLMUCFG (APU)	Previously safety ENDINIT
PROTSPRSE	ACCENSPRCFG (APU)	Previously safety ENDINIT
PROTPFSFRE	PFIy_FLASHCON0, PFIy_FLASHCON1	Previously system ENDINIT
PROTPFSFRSE	ACCENPFSFRCFG (APU)	Previously safety ENDINIT
PROTPFSE	ACCENPFCFG (APU)	Previously safety ENDINIT

4.3.10.2 SPR protection

The TC1.8 CPU implements one PROTSPRSE, an ACCENSPRCFG APU, and 16 ACCENSPR range based APUs. To configure the APU, the implementation field of the PROTSPRSE is populated with a SEL index field to allow the software to select the range to be configured.

PROTSPRSE[11:8] = SEL.

All ACCENSPR registers are therefore read only.

4.3.10.3 DLMU protection

The TC1.8 CPU implements one PROTDLMUSE, an ACCENDLMUCFG APU, and 16 ACCENDLMU range based APUs. To configure the APU, the implementation field of the PROTDLMUSE is populated with a SEL index field to allow the software to select the range to be configured.

PROTDLMUSE[11:8] = SEL

All ACCENDLMU registers are therefore read only.

The DLMU is accessible both in segment 9_H and B_H.

In order to give the same protection to both addresses, the ACCENDLMUy_RGNUA and ACCENDLMUy_RGNLA registers will capture the segment 9_H address (bit 29 of the range registers is read-only).

4.3.10.4 SFR protection

The TC1.8 CPU implements one PROTSFRE, a PROTSFRSE, an ACCENSFRCFG APU, and one ACCENSFR range-less APU.

All ACCENSFR registers are therefore read only.

4.3.10.5 RESET protection

The TC1.8 CPU implements one PROTRSTE to protect from involuntary writes to the kernel reset registers. The registers external access is also protected by the ACCENSFR. A master must have access to the resource and disable the PROTRSTE lock in order to trigger a kernel reset.

4.3.10.6 STM protection

The TC1.8 CPU STM_ABS is protected by PROTSFRSE. The rest of the STM configuration is protected by its own PROT and APU.

Virtualization not present

In this configuration there is only one STM instance. The TC1.8 CPU provides a PROTSTMSE, an ACCENSTMCFG APU and one ACCENSTM range-less APU. The PROTSTMSE does not have a SEL field when virtualization is not present.

All ACCENSTM registers are therefore read only.

Virtualization present and enabled (for devices with CPU hardware support for virtualization)

In this configuration there is one STM instance per virtual machine. To provide a level of flexibility a separate APU is provided for each VM STM register set. The configuration of these VM specific APUs is achieved through a unique PROTSTMSE. The implementation specific field of the PROTSTMSE is populated with a SEL index field to allow the hypervisor software to select the VM specific ACCENSTM to be configured.

PROTSTMSE[10:8] = SEL.

All ACCENSTM registers are read only.

Virtualization present and disabled (for devices with CPU hardware support for virtualization)

In this configuration there is only one STM instance. The TC1.8 CPU provides a PROTSTMSE, an ACCENSTMCFG APU and one ACCENSTM range-less APU. The PROTSTMSE.SEL index must be set to 1 by the application software for the ACCENSTM to be configured.

PROTSTMSE[10:8] = 1.

All ACCENSTM registers are read only.

4.3.10.7 NVM protection

All external accesses to any local NVM resources are directed to the CPU S-SRI1 slave port. This includes NVM and registers. The TC1.8 CPU provides separate protections for these.

Register accesses

The TC1.8 CPU implements PROTPFSFRE , PROTPFSFRSE , ACCENPFSFRCFG and ACCENPFSFR to protect the configuration of the FLASHCON SFRs and accesses to the user and test registers associated with the local NVM banks.

NVM and erase counters

The TC1.8 CPU implements PROTPFSE, ACCENPFCFG and 8 ACCENPF range based APU to protect from read access to the local portions of the NVM, shared between both banks, as well as the erase counter sections. To

configure the APU, the implementation field of the PROTPFSE is populated with a SEL index field to allow the software to select the range to be configured.

PROTPFSE[10:8] = SEL

The NVM is accessible both in segment 8_H and A_H. In order to give the same protection to both addresses, the ACCENPFy_RGNLA and ACCENPFy_RGNUA registers will capture the segment 8_H address (bit 29 of the range registers is read-only).

All ACCENSFRPF and ACCENPF registers are therefore read only.

4.3.10.8 VM number

To enable a slave device to differentiate between different master VMs the bus fabric is extended to send the current VM number with all accesses. The VM number will be stored in the data tag to provide the correct VM number in the case of dirty data being written back.

4.3.10.9 PRS value

To enable a slave device to differentiate between different masters executing with different PRS values the bus fabric is extended to send the current PRS value with all accesses. All dirty cache data will be written back with a default PRS value (PRS=0 and PRS_EN=0) when COMPAT.TAGPRS is set or with the captured PRS and PRS_EN=1 when the bit is cleared.

4.3.10.10 Secure master value

To enable the correct programming of the PROT state machine, the bus fabric is extended with a secure_master indicator. This is additional to the master TAG ID. The application instances of the TriCore™ CPU will drive the secure master to a value of 0.

The CPUcs instance will be configurable and will drive secure_master to the value configured by the CSSCU.

4.3.11 FPI interfaces

The TC1.8 CPU implements a maximum of two FPI interfaces. It is a device specific feature for each CPU. The allocation of addresses to the FPI interfaces is fixed for a device.

If the second FPI is not implemented, accesses to the address region will be sent to the SRI interconnect.

4.4 Program NVM interface (CPU-CFI)

The TC1.8 CPU processor provides high bandwidth interfaces to the banks of NVM allocated to the processor instance.

4.4.1 Feature list

- Double program NVM interface for increased performance
- Homogenous SOTA A/B swap performance

4.4.2 Functional overview

The following sections give an overview of the TC1.8 CPU program NVM interface Implementation.

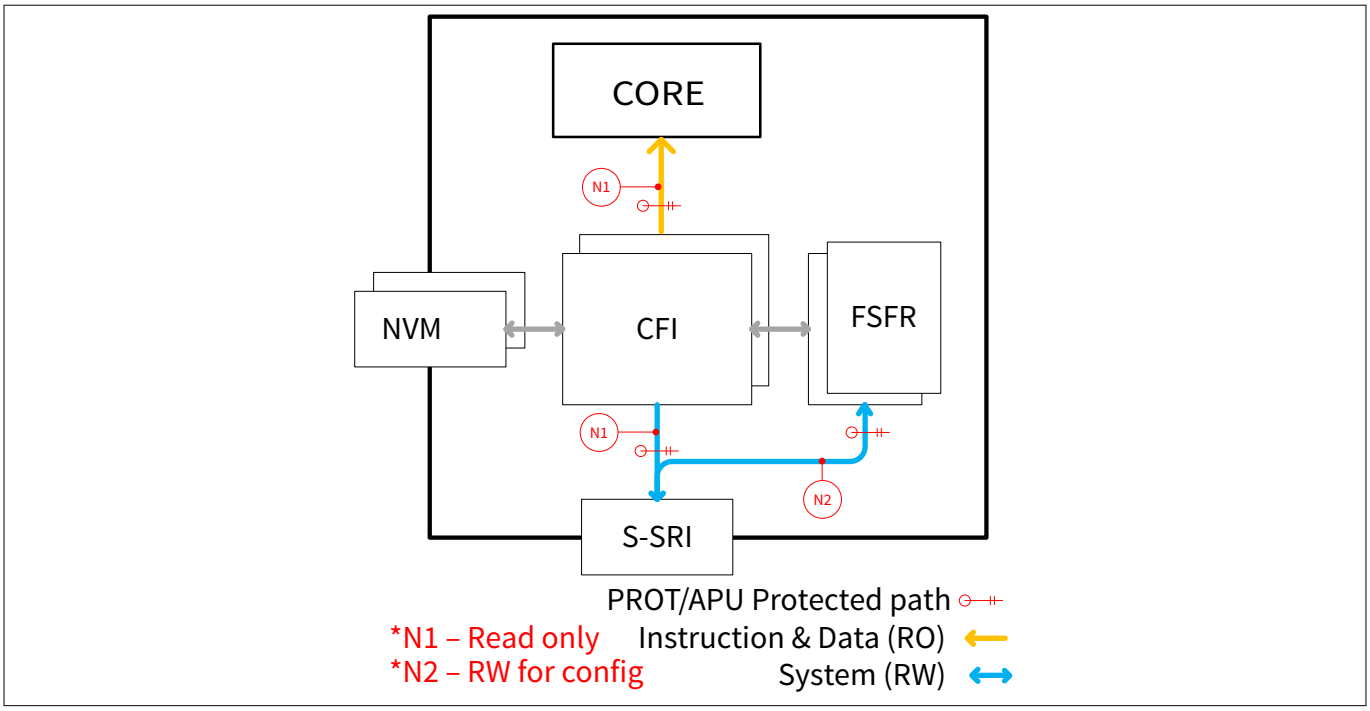

Figure 31 CPU-PFI block diagram

The program NVM interface connects the core and interconnect to the local portion of NVM and FSRS's.

4.4.3 Functional description

This section details the implementation specific features of the program NVM interface.

4.4.3.1 Program NVM interface

***Note**: For naming compatibility with earlier devices the historical names FLASHCON, PFI and FPB are preserved, despite being NVM technology agnostic*

4.4.3.1.1 FSFR range

All registers related to the function of the NVM attached to a CPU are located in the FSFR range. All the registers are SFR's and can be configured using load store instructions.

Table 93 FSFR address ranges

Address range	Size	Function
$F8400000_H$ – $F8400FFF_H$	4096 bytes	CPU0.FSFR (NVM Interface SFR)

Related information

CSFR, SFR, and FSFR address map and external access on page 153

4.4.3.1.2 FLASHCON renaming and relocation

Some CPU instances have more than one NVM interface therefore FLASHCON0 and FLASHCON1 are provided by NVM interface (PFI) and are renamed accordingly PFIy_FLASHCON0 and PFIy_FLASHCON1.

Table 94 ADDRCONFIG

Short name	Offset	Description
PFIy_FLASHCON0	200_H+y*8	CPU NVM Interface y Configuration register 0
PFIy_FLASHCON1	204_H+y*8	CPU NVM Interface y Configuration register 1

4.4.3.1.3 NVM prefetch buffer (FPB)

The prefetch path instantiates prefetch buffer(s) to speculatively fetch data. If the address of an access matches any of the FPBs then the data is returned from this FPB.

FPB configuration

The CPU contains a set of FLASHCON registers for configuring its local PFI. Each PFI instantiates five FPBs. An FPB may be assigned to an on chip master (see table below) by software programming the 6-bit master TAG identification number to the appropriate fields of the PFIy_FLASHCON0 register.

Table 95 FPB assignment

FPB	Description
0	Permanently assigned to the local CPU PMBI master TAG identification number
1-4	Assigned to an on chip master by software programming the PFIy_FLASHCON0 register with the appropriate 6-bit master TAG identification number. ***Note**: To reduce power consumption prefetching from NVM, an individual FPB may be disabled by software assigning the FPB to the reserved 6-bit master TAG identification number* ***Note**: The role of the FPB is to attempt to request the most likely NVM entry that could be requested by a certain master. The PFIy_FLASHCON0 is used to associate the FPB with the master TAG IDs that need to make use of the FPB. This means that each buffer can only be updated/filled by a matching TAG request, but the data is usable by any master asking for a particular address.*

Performance may be optimized by assigning a maximum of two FPBs to one on chip master. If two FPBs are assigned then adjacent FPBs must be assigned, for example:

- Local CPU PMBI on chip master: FPB0 assigned by default and software may additionally assign FPB1 for optimal local CPU performance
- Other on chip masters: software may assign FPB1 and FPB2, FPB2 and FPB3, or FPB3 and FPB4

Related information

Local memory details on page 147
TC4Dx CPU configuration on page 396

4.4.3.1.4 Erase counter and register accesses

The PFI to CPU point-to-point connection may be used to read the erase counter (NVM Flash devices), PFRWB registers (NVM Flash devices), or PMUR registers (NVM RRAM devices).

The access size must be an 32-bit word else the access will error.

4.4.3.1.5 NVM interface error capture registers

To monitor and debug violations of PROT and or APU protection during accesses to the CPU NVM interface, two registers (CFIERR and CFIERRAR) are provided. These registers allow the software to localize the source of the last error detected by the CFI. The registers are updated when an APU violation is detected and the CFIERR.ED bit is zero. On update the CFIERR.ED bit is set to one and remains set until cleared by software.

Table 96 Error capture registers

Short name	Offset	Description
CFIERR	250_H	CFI Error register
CFIERRAR	254_H	CFI Error address register

Error due to PROT and APU violation.

A PROT or APU error detected during an access to the local NVM range or to the FSFR range will result in the update of the CFIERR register. The register will capture the properties of the erroring transaction. E_TAG field is updated with the transaction master TAG ID. The E_VMN and E_VMN_EN fields are updated if VMN_EN is set or cleared otherwise. The E_PRS and E_PRS_EN fields are updated if PRS_EN is set or cleared otherwise. The CFIERR.ED bit is set. The CFIERRAR register is updated with the address of the access.

Integrity error due to ECC error during request address phase

When an ECC error is detected during a request address phase then the CFIERR.ED bit is set. The CFIERRAR register is updated with address 00000000_H.

Integrity error due to ECC error during a write access to the FSFR

When an ECC error is detected during a write data phase then the CFIERR.ED bit is set. The CFIERRAR register is updated with address of the access.

4.4.3.1.6 Power domain switch

Apart from CPU0, some CPUs may be capable of being powered down in order to reduce power consumption in parts of the system. The local banks of NVM associated with such CPUs will be available regardless of the CPU being powered up or down.

4.5 System timer module (CPU-STM)

Each TC1.8 CPU includes a System Timer (STM). The STM is designed for system timing applications requiring both high precision and a long period.

4.5.1 Feature list

The STM has the following features:

- Free-running 64-bit counter
- All 64-bits can be read synchronously
- Flexible service request generation based on compare match with partial ABS_TIMER or REL_TIMER fields
- Counting starts automatically after an system reset
- Support for virtualization with eight relative timers to support eight virtual machines

4.5.2 Functional overview

The following sections give an overview of the TC1.8 CPU STM implementation.

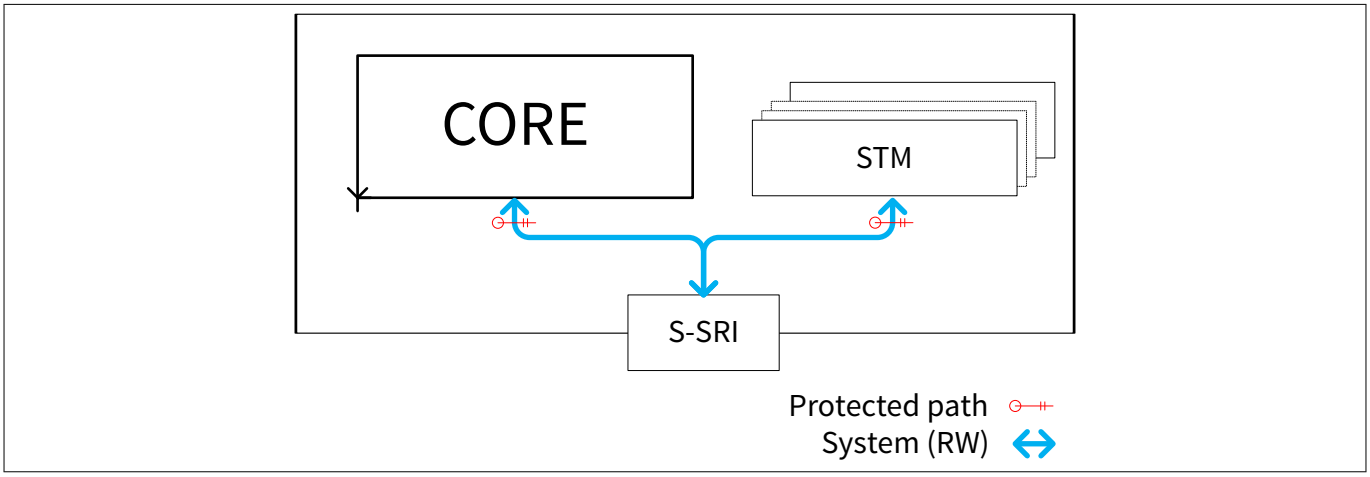

Figure 32 CPU-STM block diagram

The STM is accessed via the SRI slave interface.

4.5.3 Functional description

In AURIX™ TC4xx, the STM is part of the CPU and its addresses are contained within the CPU SFR space.

When migrating from previous generations the following aspects should be considered:

- STM is connected to system reset (therefore it is not affected by CPU kernel reset functionality)
- The STM ID register is removed
- The existing 64-bit timer is renamed STM_ABS[63:0]
- The interrupt control and status register is split into two registers
  - STM_ISCR – Interrupt set/clear register
  - STM_ISR – Interrupt status register
- The STM is clocked at f_{stm} to allow the timer to be consistent independently of the CPU frequency variation

4.5.3.1 Reading the timers

The entire 64-bit timer can only be read coherently using a 64-bit access (for example a LD.D instruction, or DMA single data transfer double word access). This avoids the need to have non-interruptible code if reading two component fields, which provides a performance benefit for real-time systems.

The STM can be optionally disabled for power-saving purposes, or suspended for debugging purposes. In suspend mode, the STM clock is stopped but all registers are still readable.

4.5.3.2 Compare register operation

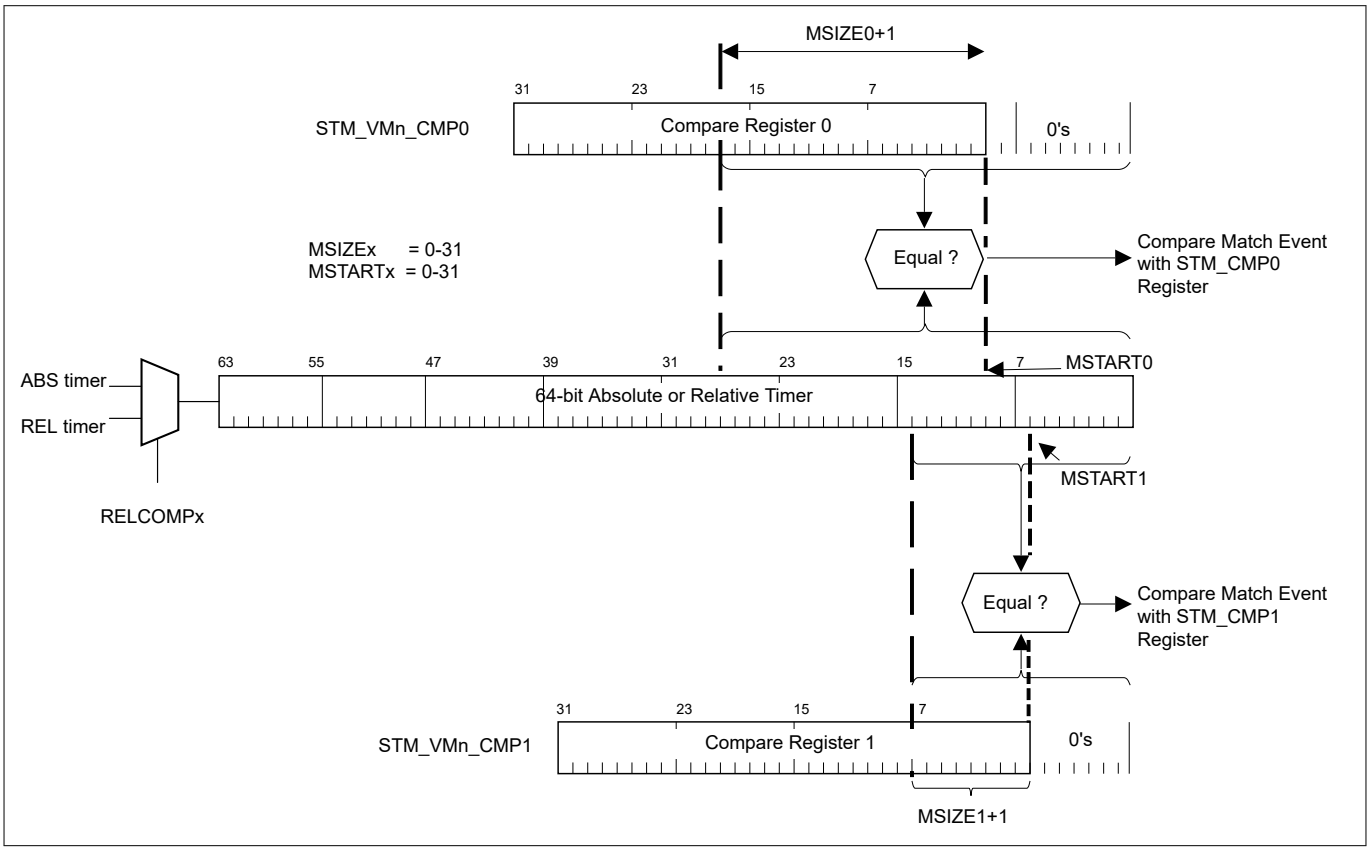

Figure 33 Compare mode operation

A compare operation with MSIZE not equal 11111_B always implies that the compared value as stored in the CMP register is right-extended with zeros. The timer value STM is taken either from STM_ABS or STM_RELTIM depending on the value of RELCOMP. This means that in the example of the figure above, the compare register content CMP0[17:0] plus ten zero bits right-extended is compared with STM[27:0] with STM[9:0] compared against 000_H. In case of register CMP1, STM[14:0] with STM[6:0] compared against 00_H are compared with CMP1[7:0] plus seven zero bits right-extended.

4.5.3.3 Compare match interrupt control

The compare match interrupt control logic is shown in the figure below. Each STM_CMPc (c=0-1) register has its compare match interrupt request flag (ICR.CMPxIR) that is set by hardware on a compare match event. The interrupt request flags can be set (ISCR.CMPxIRS) or cleared (ISCR.CMPxIRR) by software. Note that setting ICR.CMPxIR by writing a 1 into ISCR.CMPxIRS does not generate an interrupt at STMIRx. The compare match interrupts from CMP0 and CMP1 can be further directed by ICR.CMPxOS to either output signal STMIR0 or STMIR1.

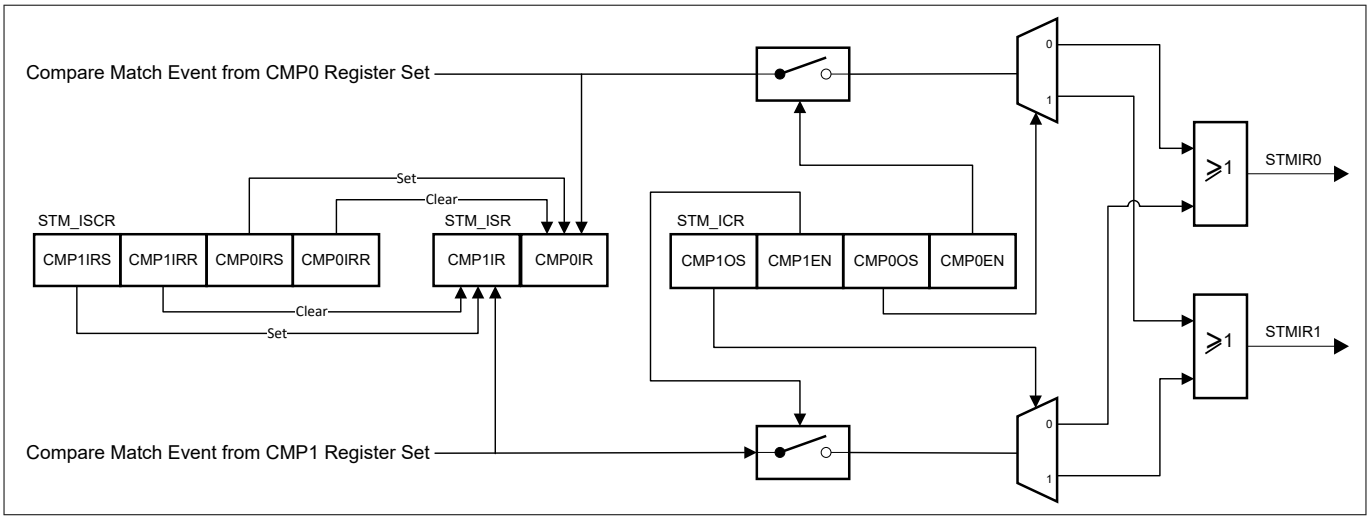

Figure 34 Interrupt Control

The compare match interrupt flags ICR.CMPxIR are immediately set after an STM reset operation, caused by a compare match event with the reset values of the STM_ABS and the compare registers STM_CMPc. This does not directly generate compare match interrupts because the compare match interrupts are automatically disabled after an STM reset operation (ICR.CMPxEN = 0). Therefore, before enabling a compare match interrupt after an STM system reset, the software should configure the STM and modify the reset values of the compare registers. Otherwise, undesired compare match interrupt events are triggered. The ISR.CMPxIR flags which are set after an STM reset can be cleared by writing register ISCR with CMPxIRR set.

4.5.3.4 STM as reset trigger

A compare match triggered by an CMP0 or CMP1 event can generate a reset in the system. The reset has to be enabled for each STM module individually in register SMM_RSTTRIGCTRLB. In case the STM compare match is used to trigger an application reset, the STM comparator time duration should be chosen adequately large enough that the application can service the STM after reset release (for example 5 ms). This is to avoid consecutive application resets being triggered by STM as it was not serviced after reset.

4.5.3.5 STM service request mapping

The STM supports two timer interrupts per VM. When virtualization is present and enabled, this results in 16 timer interrupts. When virtualization is not present, or disabled, only 2 timer interrupts are used. The following table maps the timer interrupts to their respective service request register

Table 97 Service request register mapping

Virtual machine number	Interrupt number	Corresponding IR SRC register
VM0	Service request 0 (STMIR0) Service request 1 (STMIR1)	IR_SRC_STMCPUwSR0 (w=0-5) IR_SRC_STMCPUwSR1 (w=0-5)
VM1[1)]	Service request 0 (STMIR0) Service request 1 (STMIR1)	IR_SRC_STMCPUwSR2 (w=0-5) IR_SRC_STMCPUwSR3 (w=0-5)
VM2	Service request 0 (STMIR0) Service request 1 (STMIR1)	IR_SRC_STMCPUwSR4 (w=0-5) IR_SRC_STMCPUwSR5 (w=0-5)

(table continues...)

Table 97 (continued) Service request register mapping

Virtual machine number	Interrupt number	Corresponding IR SRC register
VM3	Service request 0 (STMIR0) Service request 1 (STMIR1)	IR_SRC_STMCPUwSR6 (w=0-5) IR_SRC_STMCPUwSR7 (w=0-5)
VM4	Service request 0 (STMIR0) Service request 1 (STMIR1)	IR_SRC_STMCPUwSR8 (w=0-5) IR_SRC_STMCPUwSR9 (w=0-5)
VM5	Service request 0 (STMIR0) Service request 1 (STMIR1)	IR_SRC_STMCPUwSR10 (w=0-5) IR_SRC_STMCPUwSR11 (w=0-5)
VM6	Service request 0 (STMIR0) Service request 1 (STMIR1)	IR_SRC_STMCPUwSR12 (w=0-5) IR_SRC_STMCPUwSR13 (w=0-5)
VM7	Service request 0 (STMIR0) Service request 1 (STMIR1)	IR_SRC_STMCPUwSR14 (w=0-5) IR_SRC_STMCPUwSR15 (w=0-5)

1) When virtualization is not present or disabled, only SR2 and SR3 are used

4.5.3.6 STM register offsets and virtualization support

This section provides an overview of the location of the STM register offsets.

Table 98 Virtualization not present or disabled (1 STM instance), or guest VM software

SFR	HRA	HRB	HRHV	Offset	Description
X				00000_H	STM_CLC
X				00004_H	STM_OCS
X				00020_H	STM_ABS
X				00120_H	STM_CMP0
X				00124_H	STM_CMP1
X				00128_H	STM_CMCON
X				$0012C_H$	STM_ICR
X				00130_H	STM_ISCR
X				00134_H	STM_ISR
X				00138_H	STM_RELTIM[1)]

1) Provided for software compatibility. When virtualization is disabled, the STM_RELTIM and STM_ABS are aliased.

When virtualization is enabled there is one STM instance per guest virtual machine plus another instance for the hypervisor (8 instances in total). Only the hypervisor requires knowledge of the bus addresses of the different instances. Guest VM software must use the fact that the hardware provides address morphing.

Table 99 Virtualization enabled (8 VMn STM instances), hypervisor software or other master

HRHV_BTV	CPUx HR specific base trap vector table pointer	$3FE24_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	252
HRHV_ISP	CPUx HR specific interrupt stack pointer	$3FE28_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	253
HRHV_ICR	CPUx interrupt control register	$3FE2C_H$	P0, 32	P0, SV, 32	Kernel Reset	242
HRHV_PPRS	CPUx previous PRS	$3FE34_H$	P0, 32	P0, SV, 32	Kernel Reset	244
HRHV_FCX	CPUx HR specific free CSA list head pointer	$3FE38_H$	P0, 32	P0, SV, 32	Kernel Reset	254
HRHV_LCX	CPUx HR specific free CSA list limit pointer	$3FE3C_H$	P0, 32	P0, SV, 32	Kernel Reset	255
HRHV_SWID	CPUx software identification	$3FE40_H$	P0, 32	P0, SV, 32	Kernel Reset	244
HRHV_CUS_ID	CPUx customer ID register	$3FE50_H$	P0, 32	P0, SV, 32	Kernel Reset	245
HRHV_BOOTCON	CPUx core boot configuration register	$3FE60_H$	P0, 32	P0, SV, 32	Kernel Reset	246
HRHV_LCLCON	CPUx lockstep control register	$3FE64_H$	P0, 32	STP, SFRSE, P0, SV, 32	Cold PowerOn Reset	247
HRHV_CCON	CPUx clock control register	$3FE68_H$	P0, 32	P0, SV, 32	Kernel Reset	248
HRHV_TCCON	CPUx hardware configuration	$3FE6C_H$	P0, 32	P0, SV, 32	Kernel Reset	248
HRHV_Ay	CPUx HR specific address general purpose register y	$3FF80_H$+ y*4	P0, 32	P0, SV, 32	Kernel Reset	274
HRHV_Ay	CPUx HR specific address general purpose register y	$3FFA0_H$+ (y-8)*4	P0, 32	P0, SV, 32	Kernel Reset	274

4.6.1.3 Register overview - CPU domain CSFR (ascending offset address)

Table 102 Register overview - CPU domain CSFR (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPU_SEGEN	CPUx SRI error generation register	01030_H	P0, 32	SFRE, P0, SV, 32	Application Reset	255
CPU_LCLTEST	CPUx lockstep test register	01040_H	P0, 32	P0, SV, 32	Cold PowerOn Reset	256
CPU_PMA0	CPUx data access cacheability register	08100_H	P0, 32	SFRE, P0, SV, 32	Kernel Reset	232
CPU_PMA1	CPUx code access cacheability register	08104_H	P0, 32	SFRE, P0, SV, 32	Kernel Reset	233
CPU_PMA2	CPUx peripheral space identifier register	08108_H	P0, 32	SFRE, P0, SV, 32	Kernel Reset	234
CPU_DCON2	CPUx data control register 2	09000_H	P0, 32	P0, SV, 32	Kernel Reset	257
CPU_DCON1	CPUx data control register 1	09008_H	P0, 32	P0, SV, 32	Kernel Reset	258
CPU_SMACON	CPUx SIST mode access control register	$0900C_H$	P0, 32	SFRSE, P0, SV, 32	Kernel Reset	234
CPU_DSTR	CPUx HR specific data synchronous trap register	09010_H	P0, 32	P0, SV, 32	Kernel Reset	259
CPU_HVHRA_DSTR	CPUx HR specific data synchronous trap register	09011_H	P0, 32	P0, SV, 32	Kernel Reset	259
CPU_HVHRB_DSTR	CPUx HR specific data synchronous trap register	09012_H	P0, 32	P0, SV, 32	Kernel Reset	259
CPU_DATR	CPUx HR specific data asynchronous trap register	09018_H	P0, 32	P0, SV, 32	Kernel Reset	261
CPU_HVHRA_DATR	CPUx HR specific data asynchronous trap register	09019_H	P0, 32	P0, SV, 32	Kernel Reset	261
CPU_HVHRB_DATR	CPUx HR specific data asynchronous trap register	$0901A_H$	P0, 32	P0, SV, 32	Kernel Reset	261
CPU_DEADD	CPUx HR specific data error address register	$0901C_H$	P0, 32	P0, SV, 32	Kernel Reset	262
CPU_HVHRA_DEADD	CPUx HR specific data error address register	$0901D_H$	P0, 32	P0, SV, 32	Kernel Reset	262
CPU_HVHRB_DEADD	CPUx HR specific data error address register	$0901E_H$	P0, 32	P0, SV, 32	Kernel Reset	262
CPU_DIEAR	CPUx data integrity error address register	09020_H	P0, 32	P0, SV, 32	Kernel Reset	279
CPU_HVHRA_DIEAR	CPUx data integrity error address register	09021_H	P0, 32	P0, SV, 32	Kernel Reset	279
CPU_HVHRB_DIEAR	CPUx data integrity error address register	09022_H	P0, 32	P0, SV, 32	Kernel Reset	279
CPU_DIETR	CPUx data integrity error trap register	09024_H	P0, 32	P0, SV, 32	Kernel Reset	280

(table continues...)

Table 102 (continued) Register overview - CPU domain CSFR (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPU_HVHRA_DIETR	CPUx data integrity error trap register	09025_H	P0, 32	P0, SV, 32	Kernel Reset	280
CPU_HVHRB_DIETR	CPUx data integrity error trap register	09026_H	P0, 32	P0, SV, 32	Kernel Reset	280
CPU_DCON0	CPUx data memory control register	09040_H	P0, 32	SFRE, P0, SV, 32	Kernel Reset	258
CPU_PSTR	CPUx HR specific program synchronous trap register	09200_H	P0, 32	P0, SV, 32	Kernel Reset	295
CPU_HVHRA_PSTR	CPUx HR specific program synchronous trap register	09201_H	P0, 32	P0, SV, 32	Kernel Reset	295
CPU_HVHRB_PSTR	CPUx HR specific program synchronous trap register	09202_H	P0, 32	P0, SV, 32	Kernel Reset	295
CPU_PCON1	CPUx program control 1	09204_H	P0, 32	P0, SV, 32	Kernel Reset	292
CPU_PCON2	CPUx program control 2	09208_H	P0, 32	P0, SV, 32	Kernel Reset	293
CPU_PCON0	CPUx program control 0	$0920C_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	294
CPU_PIEAR	CPUx HR specific program integrity error address register	09210_H	P0, 32	P0, SV, 32	Kernel Reset	281
CPU_HVHRA_PIEAR	CPUx HR specific program integrity error address register	09211_H	P0, 32	P0, SV, 32	Kernel Reset	281
CPU_HVHRB_PIEAR	CPUx HR specific program integrity error address register	09212_H	P0, 32	P0, SV, 32	Kernel Reset	281
CPU_PIETR	CPUx HR specific program integrity error trap register	09214_H	P0, 32	P0, SV, 32	Kernel Reset	282
CPU_HVHRA_PIETR	CPUx HR specific program integrity error trap register	09215_H	P0, 32	P0, SV, 32	Kernel Reset	282
CPU_HVHRB_PIETR	CPUx HR specific program integrity error trap register	09216_H	P0, 32	P0, SV, 32	Kernel Reset	282
CPU_COMPAT	CPUx compatibility control register	09400_H	P0, 32	SFRSE, P0, SV, 32	Kernel Reset	235
CPU_FPU_TRAP_CON	CPUx HR specific trap control register	$0A000_H$	P0, 32	P0, SV, 32	Kernel Reset	263
CPU_HVHRA_FPU_TRAP_CON	CPUx HR specific trap control register	$0A001_H$	P0, 32	P0, SV, 32	Kernel Reset	263
CPU_HVHRB_FPU_TRAP_CON	CPUx HR specific trap control register	$0A002_H$	P0, 32	P0, SV, 32	Kernel Reset	263
CPU_FPU_TRAP_PC	CPUx HR specific trapping instruction program counter register	$0A004_H$	P0, 32	P0, SV, 32	Kernel Reset	265

0		RNG	TYP	0				CNT		0		BBM	0		EN
r		rw	rw	r				rw		r		rw	r		rw

Field	Bits	Type	Description
EN	0	rw	**Trigger enable** Trigger enable. If enabled, the settings defined in debug action configuration register (DGBACT) will determine if the trigger is active or not. Once an even numbered comparator has been set to range, the EN settings of its associated upper neighbour will be ignored. 0_B Disabled 1_B Event enabled according to the settings defined in DBGACT
BBM	3	rw	**Break before make (BBM) or break after make (BAM) selection** Code triggers BBM or BAM selection. ***Note**: Data access and data/code combination access triggers can only create BAM Debug Events. When these triggers occur, TRnEVT.BBM is ignored.* 0_B Triggers break after make (BAM) 1_B Triggers break before make (BBM). Default to BAM for data or combined triggers regardless of this setting.
CNT	7:6	rw	**Counter** When this event occurs adjust the control of the performance counters in task mode as follows: 00_B No change 01_B Start the performance counters 10_B Stop the performance counters 11_B Toggle the performance counter control (i.e. start it if it is currently stopped, stop it if it is currently running)
TYP	12	rw	**Input selection** 0_B Address 1_B Program counter

(table continues...)

(continued)

Field	Bits	Type	Description
RNG	13	rw	**Compare type** Once an even numbered comparator has been set to range, the EN settings of its associated upper neighbour will be ignored. 0_B Equality 1_B Range
AST	27	rw	**Address store** Used in conjunction with TYP=0
ALD	28	rw	**Address load** Used in conjunction with TYP=0
0	2:1, 5:4, 11:8, 26:14, 31:29	r	**Reserved - RES** Read as 0; should be written with 0.

Table 103 Mirrors of HRA_TRnEVT (n=0-7)

HRHV_DBGTCR	CPUx debug trap control is an alias.	$3FD48_H$

4.6.1.15 CPUx debug configuration

The TC and TCP bits enable that a tool can reliably configure this register before or after it is configured by SW. The use case is that SW configures it for Trace Based Measurement (TBM) but a debug tool must still have all options. The simple rule is: SW will write the register with TC and TCP set to 0, a tool will always write with both bits set to 1.

For configurations without Virtualization or if Virtualization is disabled, the fields VMn are reserved and will read as 0.

4.6.1.26 CPUx data access cacheability register

The Physical Memory Attributes registers (PMA0, PMA1, PMA2) define the physical memory attribute for each segment in the physical address space. The register is protected by CPUx_PROTSFRE and can be read with the MFCR instruction and written by the MTCR instruction. Note that when changing the value of the registers both the instruction and data caches should be invalidated, a DSYNC instruction should be executed immediately prior to the MTCR with an ISYNC instruction executed immediately following. This is required to maintain coherency of the processors view of memory.

The register PMA0 defines the data access cacheability of the segment in the physical address space. If bit n in the register is set then segment-n will be seen as cacheable for data accesses.

PMA0 is freely programmable with the following restrictions:

- In PMA0 Segment-C and its global address equivalent (Segment[7-CORE_ID], that is 0x701xxxxx, 0x601xxxxx and so on) must have the same value

Irrespective of the setting of the PMA registers the following constraints are always enforced:

- Segments-F and segment-E are constrained to be Peripheral space and hence non-cacheable
- Segment-A is constrained to be non-cacheable memory
- Segment-D (local data memory) and its global address equivalent (Segment[7-CORE_ID], that is 0x700xxxxx, 0x600xxxxx and so on)) are constrained to be non-cacheable for data accesses

Note: CPUx data accesses to CPUy DSPR (x!=y) can be made cacheable by enabling DCn bit (n=0-7) corresponding CPUy DSPR global address.

4.6.1.27 CPUx code access cacheability register

The Physical Memory Attributes registers (PMA0,PMA1,PMA2) define the physical memory attribute for each segment in the physical address space. The register is protected by CPUx_PROTSFRE and can be read with the MFCR instruction and written by the MTCR instruction. Note that when changing the value of the registers both the instruction and data caches should be invalidated, a DSYNC instruction should be executed immediately prior to the MTCR with an ISYNC instruction executed immediately following. This is required to maintain coherency of the processors view of memory.

The register PMA1 defines the code access cacheability of the segment in the physical address space. If bit n in the register is set then segment-n will be seen as cacheable for code accesses.

PMA1 is freely programmable with the following restrictions:

- In PMA1 Segment-D and its global address equivalent (Segment[7-CORE_ID], that is 0x700xxxxx, 0x600xxxxx and so on) must have the same value

Irrespective of the setting of the PMA registers the following constraints are always enforced:

- Segments-F and segment-E are constrained to be Peripheral space and hence non-cacheable
- Segment-A is constrained to be non-cacheable memory
- Segment-C (local program memory) and its global address equivalent (Segment[7-CORE_ID], that is 0x701xxxxx, 0x601xxxxx and so on) are constrained to be non-cacheable for code accesses

Note: CPUx code accesses to CPUy PSPR (x!=y) can be made cacheable by enabling CCn bit (n=0-7) corresponding CPUy PSPR global address.

HRHV_PMA1	CPUx code access cacheability register is an alias.	38104_H

4.6.1.28 CPUx peripheral space identifier register

The Physical Memory Attributes registers (PMA0,PMA1,PMA2) define the physical memory attribute for each segment in the physical address space. The register is protected by CPUx_PROTSFRE and can be read with the MFCR instruction and written by the MTCR instruction. Note that when changing the value of the registers both the instruction and data caches should be invalidated, a DSYNC instruction should be executed immediately prior to the MTCR with an ISYNC instruction executed immediately following. This is required to maintain coherency of the processors view of memory.

The register PMA2 defines the peripheral space identifier of the segment in the physical address space. If bit n in the register is set then segment-n will be seen as a peripheral segment.PMA2 is a read-only register.

HRA_PMA2 Offset address: 18108_H

CPUx peripheral space identifier register Kernel Reset value: $0000\ C000_H$

4.6.1.30 CPUx compatibility control register

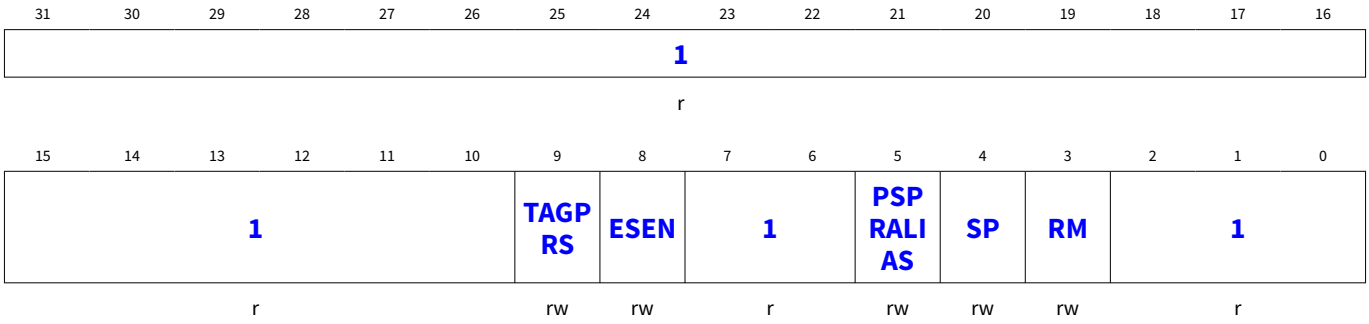
The Compatibility Control Register (COMPAT) is an implementation-specific CSFR which allows certain elements of backwards compatibility with earlier TriCore behavior to be forced. The reset value of the COMPAT register ensures that backwards compatibility with earlier TriCore is enabled by default. This register is protected by CPUx_PROTSFRSE.

HRA_COMPAT Offset address: 19400_H

CPUx compatibility control register Kernel Reset value: FFFF FFFF$_H$

CPU_COMPAT Offset address: 09400_H

Short address for domain CSFR Kernel Reset value: FFFF FFFF$_H$



Field	Bits	Type	Description
RM	3	rw	**Rounding mode compatibility** 0_B PSW.RM not restored by RET 1_B PSW.RM restored by RET (Compatibility mode)
SP	4	rw	**CORECON safety protection mode compatibility** 0_B CORECON[31:1] protected by PROTSFRSE 1_B CORECON[31:1] not protected (Compatibility mode)

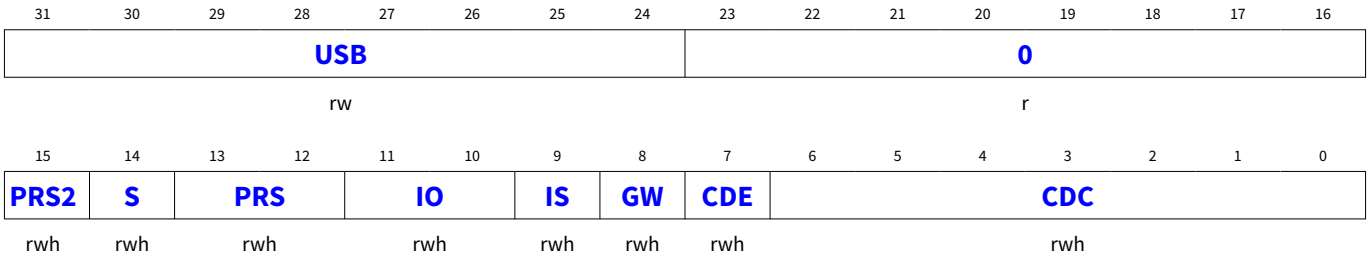
HRHV_PCXI	CPUx previous context information register is an alias.	$3FE00_H$

4.6.1.32 CPUx HR specific program status word

The Program Status Word register (PSW) is a 32-bit register that contains task-specific architectural state not captured in the General Purpose Register values. The lower half holds control values and parameters related to the protection system, including:

- The Protection Register Set (PRS)
- The I/O privilege level (IO)
- The Interrupt Stack flag (IS)
- The Global register Write permission flag (GW)
- The Call Depth Counter (CDC)
- The Call Depth Count Enable field (CDE)

HRA_PSW	Offset address:	$1FE04_H$
CPUx HR specific program status word	Kernel Reset value:	$0000\ 0B80_H$
CPU_PSW	Offset address:	$0FE04_H$
Short address for domain CSFR	Kernel Reset value:	$0000\ 0B80_H$



Field	Bits	Type	Description
CDC	6:0	rwh	**Call depth counter** Consists of two variable width subfields. The first subfield consists of a string of zero or more initial 1 bits, terminated by the first 0 bit. The remaining bits form the second subfield (CDC.COUNT) which constitutes the Call Depth Count value. The count value is incremented on each Call and is decremented on a Return. $0ccccc_B$: 6-bit counter; trap on overflow $10ccccc_B$: 5-bit counter; trap on overflow $110cccc_B$: 4-bit counter; trap on overflow $1110ccc_B$: 3-bit counter; trap on overflow $11110cc_B$: 2-bit counter; trap on overflow $111110c_B$: 1-bit counter; trap on overflow 1111110_B : Trap every call (Call Trace mode) 1111111_B : Disable Call Depth Counting When the call depth count (CDC.COUNT) overflows a trap (CDO) is generated. Setting the CDC to 1111110_B allows no bits for the counter and causes every call to be trapped. This is used for Call Depth Tracing. Setting the CDC to 1111111_B disables Call Depth Counting.
CDE	7	rwh	**Call depth count enable** Enables call-depth counting, provided that the PSW.CDC mask field is not all set to 1. If PSW.CDC = 1111111_B, call depth counting is disabled regardless of the setting on the PSW.CDE bit. 0_B Call depth counting is temporarily disabled It is automatically re-enabled after execution of the next Call instruction. 1_B Call depth counting is enabled

(table continues...)

(continued)

Field	Bits	Type	Description
GW	8	rwh	**Global address register write permission** Determines whether the current execution thread has permission to modify the global address registers.Most tasks and ISRs use the global address registers as ‘read only’ registers, pointing to the global literal pool and key data structures. However a task or ISR can be designated as the ‘owner’ of a particular global address register, and is allowed to modify it. The system designer must determine which global address variables are used with sufficient frequency and/or in sufficiently time-critical code to justify allocation to a global address register. By compiler convention, global address register A[0] is reserved as the base register for short form loads and stores. Register A[1] is also reserved for compiler use.Registers A[8] and A[9] are not used by the compiler, and are available for holding critical system address variables. 0_B Write permission to global registers A[0], A[1], A[8], A[9] is disabled 1_B Write permission to global registers A[0], A[1], A[8], A[9] is enabled
IS	9	rwh	**Interrupt Stack Control** Determines if the current execution thread is using the shared global (interrupt) stack or a user stack. 0_B USer stack If an interrupt is taken when the IS bit is 0, then the stack pointer register is loaded from the ISP register before execution starts at the first instruction of the Interrupt Service Routine (ISR). 1_B Shared Global Stack If an interrupt is taken when the PSW.IS bit is 1, then the current value of the stack pointer is used by the Interrupt Service Routine (ISR).
IO	11:10	rwh	**Access privilege level control (I/O privilege)** Determines the access level to special function registers and peripheral devices. 00_B User-0 mode No peripheral access. Access to memory regions with the peripheral space attribute are prohibited and results in a PSE or MPP trap. This access level is given to tasks that need not directly access peripheral devices. Tasks at this level do not have permission to enable or disable interrupts. 01_B User-1 mode Regular peripheral access. Enables access to common peripheral devices that are not specially protected, including read/write access to serial I/O ports, read access to timers, and access to most I/O status registers. Tasks at this level may disable interrupts. 10_B Supervisor mode Enables access to all peripheral devices. It enables read/write access to core registers and protected peripheral devices. Tasks at this level may disable interrupts. 11_B Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
PRS	13:12	rwh	**Protection register set** Selects the active Data and Code Memory Protection Register Set. The memory protection register values control load, store and instruction fetches within the current process.
S	14	rwh	**Alternate task identifier selector** Selects which of the master agent function TAG-ID to use for the load/ store accesses (CPUx.D or CPUx.DS)
PRS2	15	rwh	**Protection register set MSB** Selects the active Data and Code Memory Protection Register Set. The memory protection register values control load, store and instruction fetches within the current process.
USB	31:24	rw	**User status bits** The eight most significant bits of the PSW are designated as User Status Bits. These bits may be set or cleared as side effects of instruction execution. Refer to the TriCore Architecture manual for details.
0	23:16	r	**Reserved - RES** Read as 0; should be written with 0.

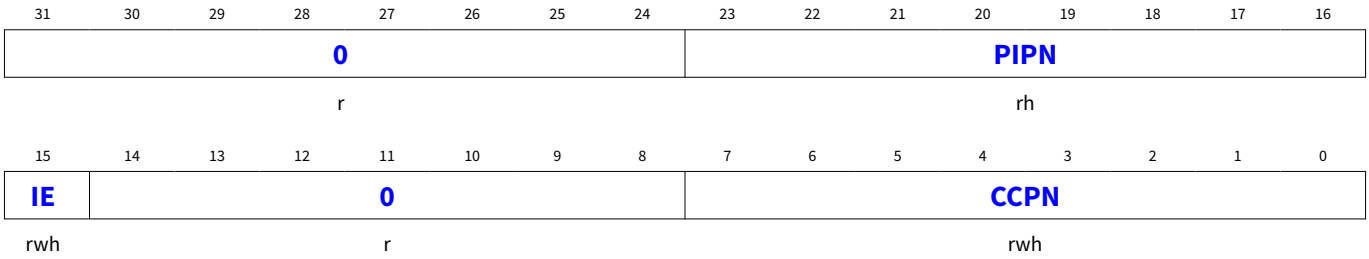
4.6.1.36 CPUx interrupt control register

HRA_ICR Offset address: $1FE2C_H$

CPUx interrupt control register Kernel Reset value: $0000\ 0000_H$

CPU_ICR Offset address: $0FE2C_H$

Short address for domain CSFR Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CCPN	7:0	rwh	**Current CPU priority number** The Current CPU Priority Number (CCPN) bit field indicates the current priority level of the CPU. It is automatically updated by hardware on entry or exit of Interrupt Service Routines (ISRs) and through the execution of a BISR instruction. CCPN can also be updated through an MTCR instruction.
IE	15	rwh	**Global interrupt enable bit** The interrupt enable bit globally enables the CPU service request system. Whether a service request is delivered to the CPU depends on the individual Service Request Enable Bits (SRE) in the SRNs, and the current state of the CPU. ICR.IE is automatically updated by hardware on entry and exit of an Interrupt Service Routine (ISR). ICR.IE is cleared to 0 when an interrupt is taken, and is restored to the previous value when the ISR executes an RFE instruction to terminate itself. ICR.IE can also be updated through the execution of the ENABLE, DISABLE, MTCR, and BISR instructions. 0_B Interrupt system is globally disabled 1_B Interrupt system is globally enabled
PIPN	23:16	rh	**Pending interrupt priority number** A read-only bit field that is updated by the ICU at the end of each interrupt arbitration process. It indicates the priority number of the pending service request. ICR.PIPN is set to 0 when no request is pending, and at the beginning of each new arbitration process. ... 00_H No valid pending request 01_H Request pending, lowest priority FF_H Request pending, highest priority
0	14:8, 31:24	r	**Reserved - RES** Read as 0; should be written as 0.

HRHV_TCCON	CPUx hardware configuration is an alias.	$3FE6C_H$

4.6.1.44 CPUx HR specific core configuration register

The Core Configuration Register provides the following functionality:

- Enable bit for temporal protection system
- Enable bit for memory protection system
- Bit for definition of the initial state of the PSW.S bit in interrupt handlers
- Bit for definition of the initial state of the PSW.S bit in trap handlers
- Enable for User-1 IO mode peripheral access as supervisor
- Disable for User-1 IO mode ability to enable and disable interrupts
- Status indicator of the Free Context List Depletion condition

HRA_CORECON	Offset address:	$1FE14_H$

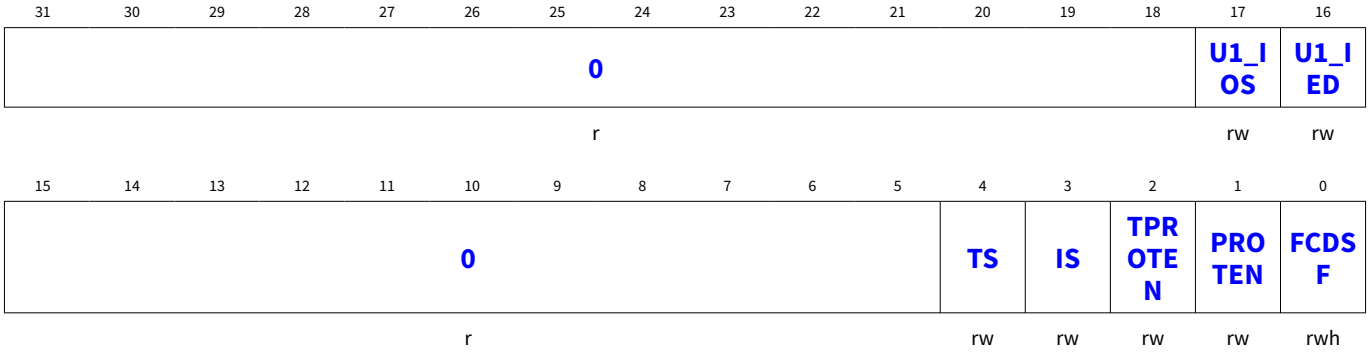
CPU_HVHRB_CORECON	Offset address:	$0FE16_H$
Short address for domain CSFR	Kernel Reset value:	$0000\ 0000_H$



Field	Bits	Type	Description
FCDSF	0	rwh	**Free context list depleted sticky flag** This sticky bit indicates that a FCD (Free Context List Depleted) trap occurred since the bit was last cleared by software. 0_B No FCD trap occurred since the last clear 1_B An FCD trap occurred since the last clear

(table continues...)

(continued)

Field	Bits	Type	Description
PROTEN	1	rw	**Memory protection enable** Enables the memory protection system. Memory protection is controlled through the memory protection register sets. Note: Initialize the protection register sets prior to setting PROTEN to one. 0_B Memory protection is disabled 1_B Memory protection is enabled
TPROTEN	2	rw	**Temporal protection enable** Enable the temporal protection system. 0_B Temporal protection is disabled 1_B Temporal protection is enabled
IS	3	rw	**Initial state interrupt** Value assigned to the PSW.S bit on interrupt entry
TS	4	rw	**Initial state trap** Value assigned to the PSW.S bit on trap entry
U1_IED	16	rw	**User-1 instruction execution disable** Disable the execution of User-1 mode instructions in User-1 IO mode. Disables User-1 ability to enable and disable interrupts.
U1_IOS	17	rw	**User-1 peripheral access as supervisor** Allow User-1 mode tasks to access peripherals as if in Supervisor mode. Enables User-1 access to all peripheral registers.
0	15:5, 31:18	r	**Reserved - RES** Read as 0; should be written with 0.

4.6.1.45 CPUx HR specific base interrupt vector table pointer

The BIV register contains the base address of the interrupt vector table. When an interrupt is accepted, the entry address into the interrupt vector table is generated from the priority number (taken from the PIPN) of that interrupt, left shifted by either three or five bits, and then ORd with the contents of the BIV register. The left-shift of the interrupt priority number results in a spacing of either eight bytes or 32 bytes between the individual entries in the vector table dependent on the vector spacing selected by the VSS bit.

HRA_BIV	Offset address:	$1FE20_H$

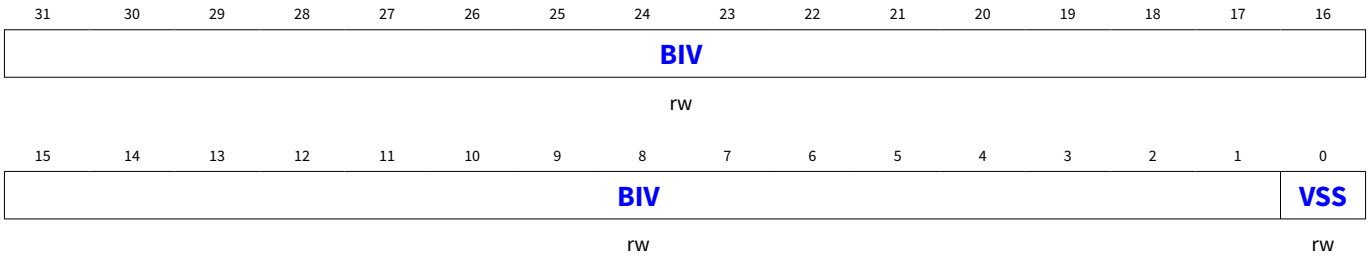
CPU_HVHRB_BIV	Offset address:	$0FE22_H$
Short address for domain CSFR	Kernel Reset value:	$0000\ 0000_H$



Field	Bits	Type	Description
VSS	0	rw	**Vector spacing select** 0_B 32 byte vector spacing 1_B 8 Byte vector spacing
BIV	31:1	rw	**Base address of interrupt vector table** The address in the BIV register must be aligned to an even byte address (halfword address). Because of the simple ORing of the left-shifted priority number and the contents of the BIV register, the alignment of the base address of the vector table must be to a power of two boundary, dependent on the number of interrupt entries used. For the full range of 256 interrupt entries an alignment to an 8 KByte boundary is required. If fewer sources are used, the alignment requirements are correspondingly relaxed.

4.6.1.46 CPUx HR specific base trap vector table pointer

The BTV contains the base address of the trap vector table. When a trap occurs, the entry address into the trap vector table is generated from the Trap Class of that trap, left-shifted by 5 bits and then ORd with the contents of the BTV register. The left-shift of the Trap Class results in a spacing of 8 words (32 bytes) between the individual entries in the vector table.

Note: This register is protected by CPUx_PROTSFRE.

HRA_BTV	Offset address:	$1FE24_H$
CPUx HR specific base trap vector table pointer	Kernel Reset value:	XXXX $FE00_H$
HRB_BTV	Offset address:	$2FE24_H$

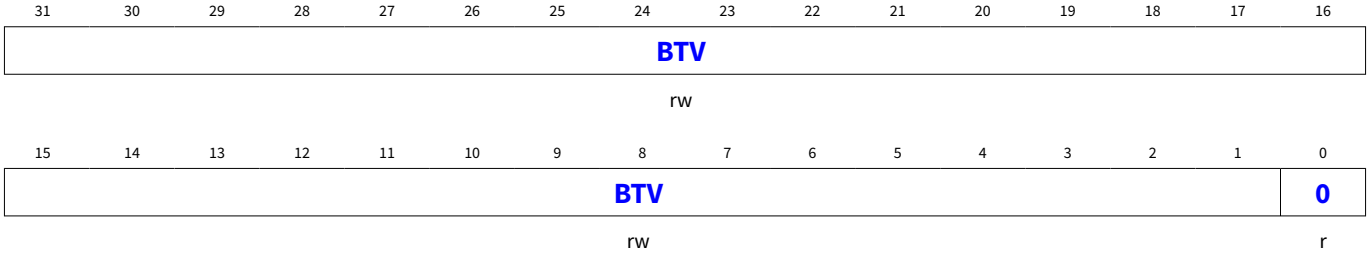
CPU_HVHRB_BTV	Offset address:	$0FE26_H$
Short address for domain CSFR	Kernel Reset value:	XXXX $FE00_H$



Field	Bits	Type	Description
BTV	31:1	rw	**Base address of trap vector table** The address in the BTV register must be aligned to an even byte address (halfword address). Also, due to the simple ORing of the left-shifted trap identification number and the contents of the BTV register, the alignment of the base address of the vector table must be to a power of two boundary. There are eight different trap classes, resulting in Trap Classes from 0 to 7. The contents of BTV should therefore be set to at least a 256 byte boundary (8 Trap Classes * 8 word spacing).
0	0	r	**Reserved - RES** Read as 0; should be written as 0.

4.6.1.47 CPUx HR specific interrupt stack pointer

HRA_ISP	Offset address:	$1FE28_H$

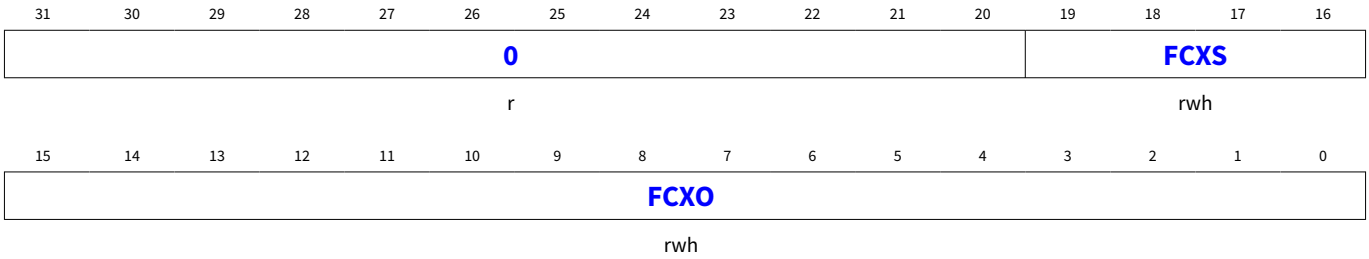
CPU_HVHRB_FCX	Offset address:	$0FE3A_H$
Short address for domain CSFR	Kernel Reset value:	$0000\ 0000_H$



Field	Bits	Type	Description
FCXO	15:0	rwh	**FCX offset address field** The FCXO and FCXS fields together form the FCX pointer, which points to the next available CSA.
FCXS	19:16	rwh	**FCX segment address field** Used in conjunction with the FCXO field.
0	31:20	r	**Reserved - RES** Read as 0; should be written as 0.

4.6.1.49 CPUx HR specific free CSA list limit pointer

The free CSA List Limit Pointer (LCX) register is used to recognize impending free CSA list depletion. If a context save operation occurs and the value of FCX matches LCX then the 'free context depletion' condition is recognized, which triggers an FCD trap immediately after completion of the operation causing the context save; i.e. the return address of the FCD trap is the first instruction of the trap/interrupt/called routine, or the instruction following an SVLCX or BISR instruction.

Note: Please refer to the FCD trap description for details on the use and setting of LCX.

HRA_LCX	Offset address:	$1FE3C_H$
CPUx HR specific free CSA list limit pointer	Kernel Reset value:	$0000\ 0000_H$

4.6.1.56 CPUx HR specific data asynchronous trap register

The DATR contains asynchronous trap information for the data memory system. The register is updated with trap information for DAE traps to aid the localisation of faults.

The register is updated whenever a valid trap is detected and the register has no bits already set. It is cleared by a write (independent of data value).

DAE traps are inhibited if the DATR register is non-zero.

4.6.1.57 CPUx HR specific data error address register

DEADD contains trap address information for the Data memory system. The register is updated with trap information for MEM, ALN, DSE or DAE traps to aid the localisation of faults.

The register is only set whenever a trap is detected and either the DATR or DSTR registers have no bits already set.

The register contents are only valid when either the DATR or DSTR register is non-zero and hence should be read prior to clearing these registers.

4.6.1.71 CPUx virtualization control register 0

The virtualization extension can be enabled or disabled by writing the bit VCON0.VEN (bit0). This bit is "write once" in that the value is locked following a write until the next reset, subsequent writes will be ignored and have no effect.

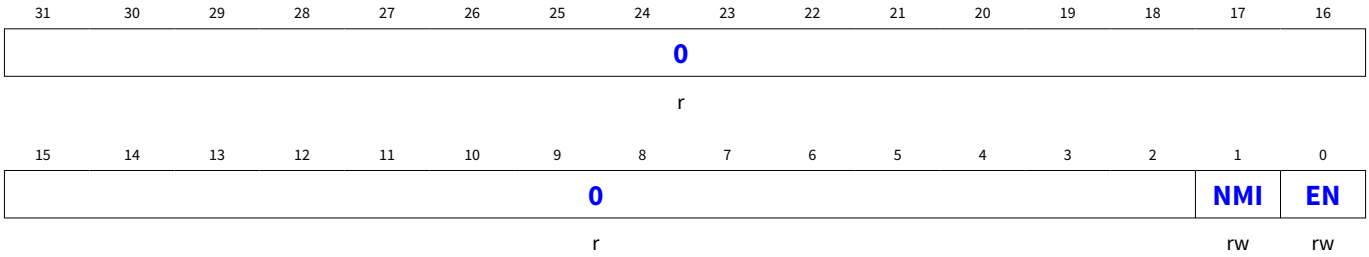
If VCON0.VEN==0 then HVCALL and all other methods of switching to the hypervisor are disabled.

HRHV_VCON0 — Offset address: $3B000_H$

CPUx virtualization control register 0 — Kernel Reset value: $0000\ 0001_H$

CPU_VCON0 — Offset address: $0B000_H$

Short address for domain CSFR — Kernel Reset value: $0000\ 0001_H$



Field	Bits	Type	Description
EN	0	rw	**Virtualization Enable** 0_B Virtualization disabled 1_B Virtualization enabled
NMI	1	rw	**NMI handling** 0_B NMI handled by the currently running VM 1_B NMI handled by the hypervisor
0	31:2	r	**Reserved - RES** Read as 0; should be written with 0.

4.6.1.72 CPUx virtualization control register 1

VCON1 contains the number of the currently running virtual machine. This status register is updated from VCON2.VMN on execution of the Return from Hypervisor (RFH) instruction or by a switch to the Hypervisor from some other virtual machine.

HRHV_VCON1 Offset address: $3B004_H$

CPUx virtualization control register 1 Kernel Reset value: $0000\ 0000_H$

CPU_VCON1 Offset address: $0B004_H$

0	31:3	r	**Reserved - RES** Read as 0; should be written with 0.

4.6.1.73 CPUx virtualization control register 2

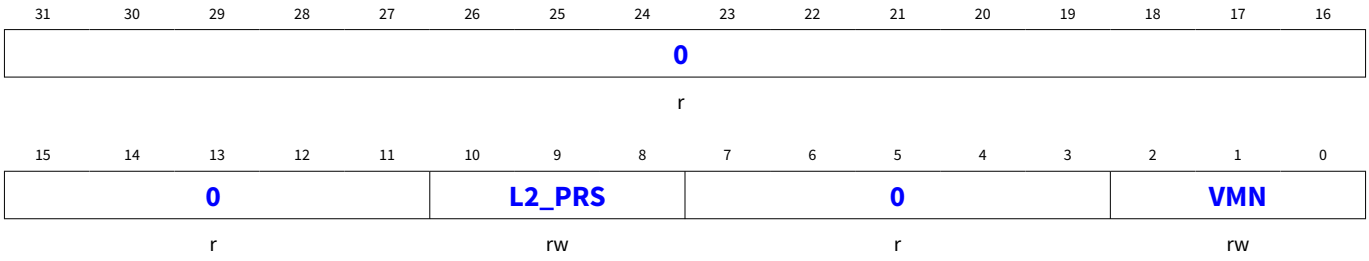
VCON2 is used by the Return from Hypervisor instruction (RFH) to change the execution from VM0 (hypervisor) to a target virtual machine selected by the hypervisor. It provides both the target virtual machine number and the protection register set to be used for the level 2 MPU. VCON2.VMN is also used by the CACHE[A/I].[I/W/WI] instructions to selectively operate on the data cache entries only encached by VM[VCON2.VMN].

HRHV_VCON2 Offset address: $3B008_H$

CPUx virtualization control register 2 Kernel Reset value: $0000\ 0001_H$

CPU_VCON2 Offset address: $0B008_H$

Short address for domain CSFR Kernel Reset value: $0000\ 0001_H$



Field	Bits	Type	Description
VMN	2:0	rw	**VMN** Target virtual machine number. Used by certain CACHE instructions and by the RFH instruction.

(table continues...)

(continued)

Field	Bits	Type	Description
L2_PRS	10:8	rw	**Level 2 MPU PRS** Selection of the protection register set for the level 2 MPU.
0	7:3, 31:11	r	**Reserved - RES** Read as 0; should be written with 0.

4.6.1.74 CPUx base hypervisor vector table pointer

The BHV contains the base address of the hypervisor trap vector table. When a hypervisor trap occurs, the entry address into the hypervisor trap vector table is generated from the hypervisor trap class number (HVTCN) of that trap, left-shifted by 5-bits and then ORd with the contents of the BHV register. The left-shift of the HVTCN results in a spacing of 8-words (32-bytes) between the individual entries in the vector table.

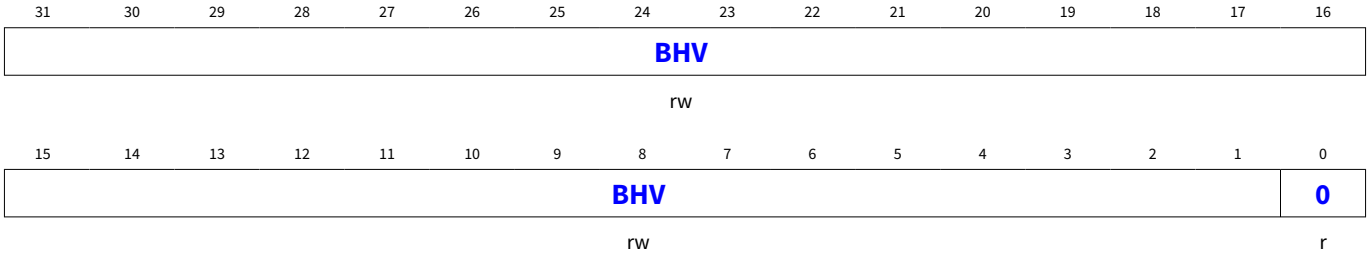
Note: This register is protected by CPUx_PROTSFRE.

HRHV_BHV Offset address: $3B010_H$

CPUx base hypervisor vector table pointer Kernel Reset value: $XXXX\ FD00_H$

CPU_BHV Offset address: $0B010_H$

Short address for domain CSFR Kernel Reset value: $XXXX\ FD00_H$



Field	Bits	Type	Description
BHV	31:1	rw	**Base address of hypervisor trap vector table** The address in the BHV register must be aligned to an even byte address (half-word address). Also, due to the simple ORing of the left-shifted trap identification number and the contents of the BHV register, the alignment of the base address of the vector table must be to a power of two boundary. There are six different hypervisor trap classes, resulting in Trap Classes from 0 to 5. The contents of BHV should therefore be set to at least a 256 byte boundary (8 Trap Classes * 8-word spacing, with 8 being the nearest power of two for 6).
0	0	r	**Reserved - RES** Read as 0; should be written as 0.

4.6.1.75 CPUx Virtual machine n interrupt state

The VMn_ICR registers allow the CPU to evaluate whether an incoming interrupt request can be serviced by a virtual machine (irrespective of its current execution status).

HRHV_VMn_ICR (n=0-7) — Offset address: $3B100_H$+n*4

CPUx Virtual machine n interrupt state — Kernel Reset value: $0000\ 0000_H$

CPU_VMn_ICR (n=0-7) — Offset address: $0B100_H$+n*4

4.6.1.94 CPUx HR specific program synchronous trap register

PSTR contains synchronous trap information for the program memory system. The register is updated with trap information for PSE traps to aid the localisation of faults. The register is only set whenever a trap is detected and the register has no bits already set. It is cleared by a CSFR write (independent of data value).

HRA_PSTR	Offset address:	19200_H

Field	Bits	Type	Description
FRE	0	rwh	**Fetch range error** A Fetch Range Error occurs whenever an access to the Program Scratch is outside the range of the SRAM.
FBE	2	rwh	**Fetch bus error** A Fetch bus error will be set whenever the SRI flags an error due a fetch from external memory. This will be set for both direct fetches from the bus and for cache refills.
FPE	12	rwh	**Fetch peripheral error** A Fetch peripheral error will be flagged whenever a fetch is attempted to peripheral space.
FME	14	rwh	**Fetch MSIST error** During SIST mode, a fetch from the PTAG will cause a PSE trap to occur.
0	1, 11:3, 13, 31:15	r	**Reserved - RES** Read as 0; should be written with 0.

4.6.1.95 CPUx HR specific temporal protection system control register

Definition of the temporal protection system control register.

HRA_TPS_CON — Offset address: $1E400_H$
CPUx HR specific temporal protection system control register — Kernel Reset value: $0000\ 0000_H$

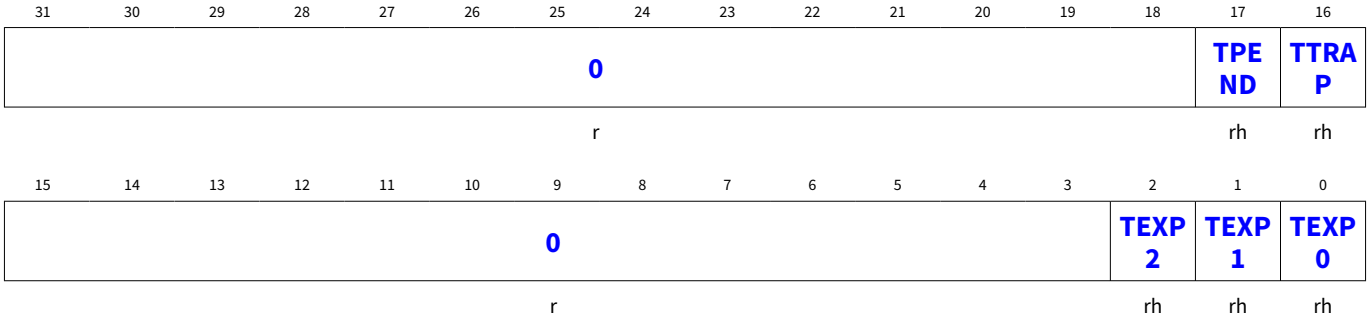
HRB_TPS_CON — Offset address: $2E400_H$
CPUx HR specific temporal protection system control register — Kernel Reset value: $0000\ 0000_H$

HRHV_TPS_CON — Offset address: $3E400_H$
CPUx HR specific temporal protection system control register — Kernel Reset value: $0000\ 0000_H$

CPU_TPS_CON — Offset address: $0E400_H$
Short address for domain CSFR — Kernel Reset value: $0000\ 0000_H$

CPU_HVHRA_TPS_CON — Offset address: $0E401_H$
Short address for domain CSFR — Kernel Reset value: $0000\ 0000_H$

CPU_HVHRB_TPS_CON — Offset address: $0E402_H$
Short address for domain CSFR — Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TEXPn (n=0-2)	n	rh	**Timer n expired flag** Set when the corresponding timer expires. Cleared on any write to the TPS_TIMERn register.
TTRAP	16	rh	**Temporal protection trap** If set, indicates that a TAE trap has been taken. Any subsequent TAE traps requests are disabled. Any write to the register clears the flag and re-enables TAE traps.
TPEND	17	rh	**TAE pending flag** If set, indicates that a TAE trap has been requested but not yet taken. Any subsequent TAE traps are disabled. TPEND is automatically cleared when TTRAP is set.
0	15:3, 31:18	r	**Reserved - RES** Read as 0; should be written with 0.

4.6.1.96 CPUx HR specific temporal protection system timer register n

Definition of the temporal protection system timer register n.

HRA_TPS_TIMERn (n=0-2) — Offset address: $1E404_H$+n*4

CPUx HR specific temporal protection system timer register n — Kernel Reset value: $0000\ 0000_H$

HRB_TPS_TIMERn (n=0-2) — Offset address: $2E404_H$+n*4

CPUx HR specific temporal protection system timer register n — Kernel Reset value: $0000\ 0000_H$

HRHV_TPS_TIMERn (n=0-2) — Offset address: $3E404_H$+n*4

CPUx HR specific temporal protection system timer register n — Kernel Reset value: $0000\ 0000_H$

CPU_TPS_TIMERn (n=0-2) — Offset address: $0E404_H$+n*4

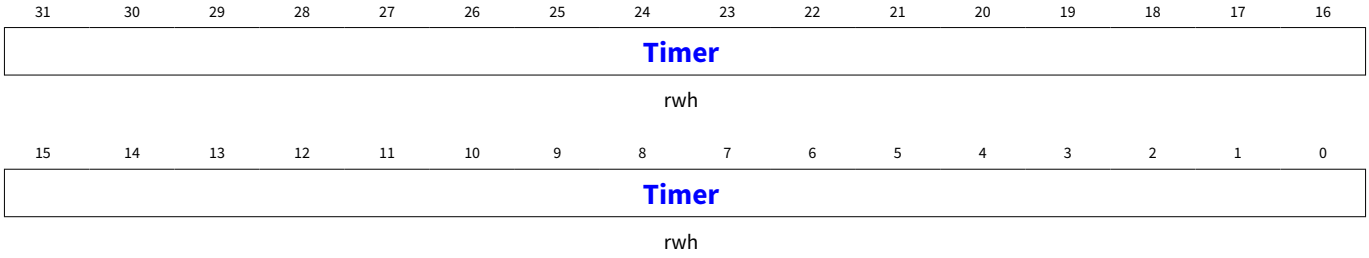
Short address for domain CSFR — Kernel Reset value: $0000\ 0000_H$

CPU_HVHRA_TPS_TIMERn (n=0-2) — Offset address: $0E405_H$+n*4

Short address for domain CSFR — Kernel Reset value: $0000\ 0000_H$

CPU_HVHRB_TPS_TIMERn (n=0-2) — Offset address: $0E406_H$+n*4

Short address for domain CSFR — Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
Timer	31:0	rwh	**Temporal protection timer** Writing zero de-activates the Timer. Writing a non-zero value starts the Timer. Any write clears the corresponding TPS_CON.TEXPn flag. Read returns the current value of Timer.

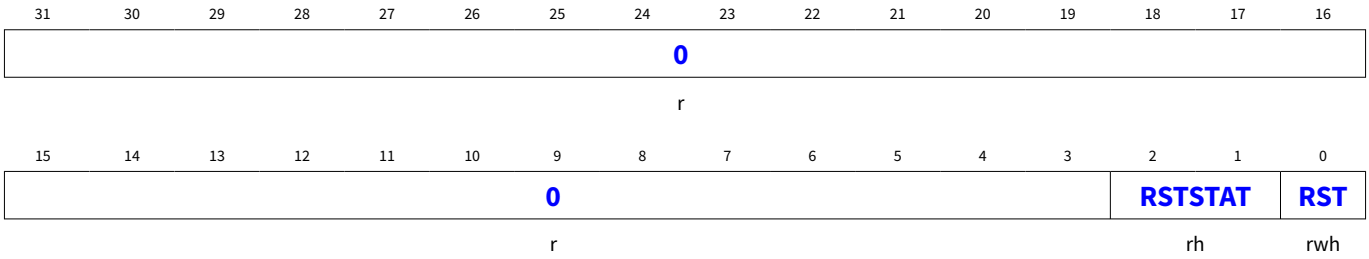
4.6.1.97 CPUx reset register 0

The CPU Kernel Reset Register 0 is used to reset the CPU kernel. CPU registers related to the Debug Reset (Class 1), STM registers and CFI registers (FSFR range) are not influenced. To reset a module kernel it is necessary to set the RST bits by writing with ´1´ in both CPU Kernel Reset Registers. The RST bits will be re-set at the end of the kernel reset sequence.

CPU Kernel Reset Register 0 includes a kernel reset status bits that is set to ´1´ at the start of the reset sequence. These bit can be used to detect that a kernel reset was processed. These bits can be re-set to ´0´ by writing ´1´ to the related KRSTCLRx.CLR register bit.

KRST0 — Offset address: $0D000_H$

CPUx reset register 0 — Kernel Reset value: $0000\ 0000_H$



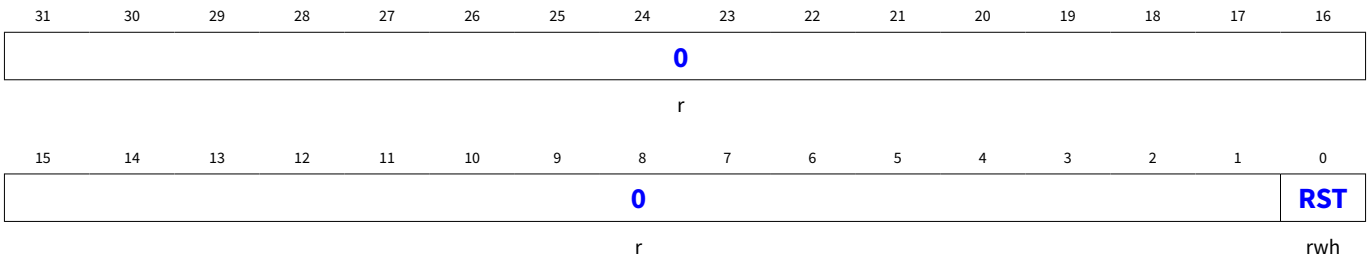
Field	Bits	Type	Description
RST	0	rwh	**Kernel reset** This reset bit can be used to request a kernel reset. The kernel reset will be executed if the reset bits of both kernel registers are set. The RST bit will be cleared (re-set to ´0´) by the BPI_FPI after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
RSTSTAT	2:1	rh	**Kernel reset status** This bit indicates whether a kernel reset was executed or not. This bit is set immediately after the execution of a kernel reset. These bits can be cleared by writing ´1´ to the CLR bit in the related KRSTCLR register. 00_B No kernel reset was executed 01_B Kernel reset was requested by hardware since last clear (SMU) 10_B Kernel reset was requested by software since last clear (KRST)
0	31:3	r	**Reserved - RES** Read as 0; should be written with 0.

4.6.1.98 CPUx reset register 1

The CPU kernel reset register 1 is used to reset the CPU kernel. To reset the CPU kernel it is necessary to set the RST bits by writing with ´1´ in both Kernel Reset Registers CPU_KRSTx1.RST and CPU_KRSTx0.RST. The RST bit will be re-set at end of the reset sequence.

KRST1 Offset address: $0D004_H$

CPUx reset register 1 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RST	0	rwh	**Kernel reset** This reset bit can be used to request a kernel reset. The kernel reset will be executed if the reset bits of both kernel reset registers is set. The RST bit will be cleared (re-set to ´0´) after the kernel reset was executed. 0_B No kernel reset was requested 1_B A kernel reset was requested
0	31:1	r	**Reserved - RES** Read as 0; should be written with 0.

4.6.1.99 CPUx reset clear register

The kernel reset register clear register is used to clear the Kernel Reset Status bits (CPU_KRST0.RSTSTAT).

KRSTCLR Offset address: $0D008_H$

CPUx reset clear register Kernel Reset value: $0000\ 0000_H$

0	4:0, 31:28	r	**Reserved - RES** Corresponding address bits are not used in the address comparison. Corresponding final address bits are taken from the original data address.
1	27:19	r	**Fixed 1 Values (High Priority) - ONE** Corresponding address bits are participating in the address comparison. Corresponding final address bits are taken from RABRi.

4.6.1.106 CPUx PROTSPR register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSPRSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers allocated to the SPR resources.

PROTSPRSE Offset address: $0E008_H$

CPUx PROTSPR register safe endinit Reset values see: Table 152

Field	Bits	Type	Description
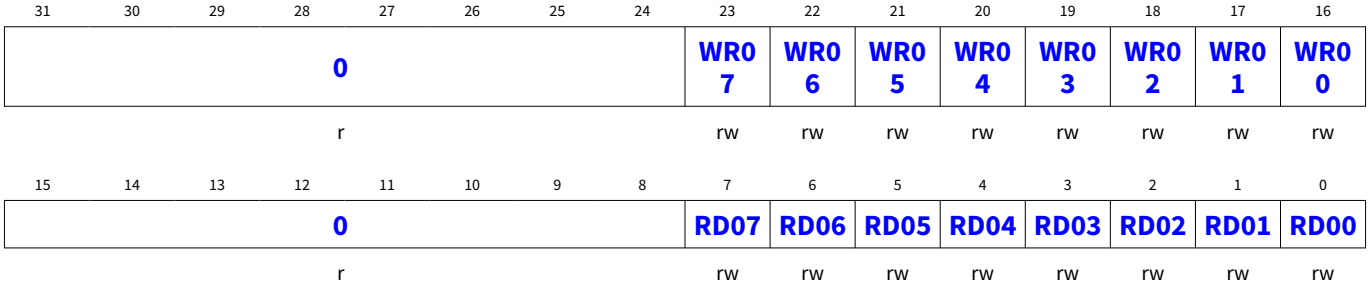
RDq (q=00-07)	q	rw	**Read access enable for VM ID q** This bit enables read access to the access protected region for transactions with the VM ID q. 0_B Disabled for read access 1_B Enabled for read access
WRq (q=00-07)	q+16	rw	**Write access enable for VM ID q** This bit enables write access to the access protected region for transactions with the VM ID q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

4.6.1.112 CPUx shadow SPR, PRS access enable register

This register defines which protection register set encodings are enabled or disabled for accesses to the access protected region. There is one RDx and WRx bit for each PRSx.

ACCENSPRCFG_PRS Offset address: 0E034$_H$

CPUx shadow SPR, PRS access enable register Application Reset value: 00FF 00FF$_H$



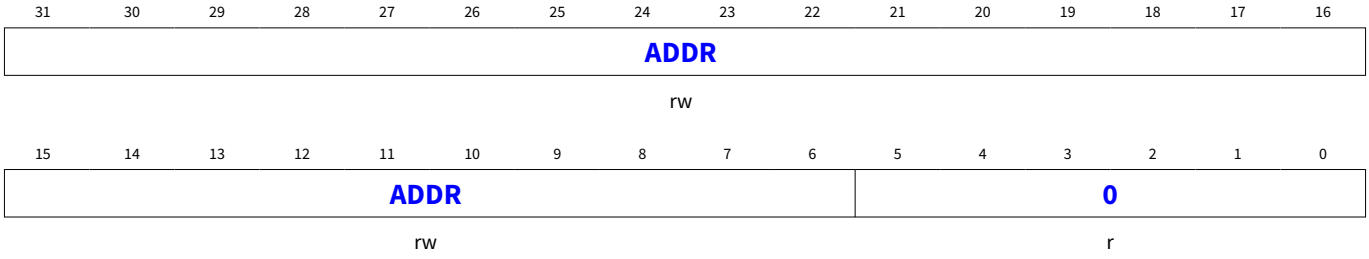
Field	Bits	Type	Description
RDq (q=00-07)	q	rw	**Read access enable for PRS q** This bit enables read access to the access protected region for transactions with the PRS q. 0_B Disabled for read access 1_B Enabled for read access
WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

4.6.1.113 CPUx shadow SPR, region lower address register

This register sets the lower bound of the access protected region. Addresses greater than or equal to the lower bound are considered part of the access protected region.

ACCENSPRCFG_RGNLA Offset address: $0E038_H$

CPUx shadow SPR, region lower address register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ADDR	31:6	rw	**Defines bits 31:6 of the lower bound of the access protected region**
0	5:0	r	**Reserved** Read as 0; should be written with 0.

4.6.1.114 CPUx shadow SPR, region upper address register

This register sets the upper bound of the access protected region. Addresses stricly less than the upper bound are considered part of the access protected region.

ACCENSPRCFG_RGNUA Offset address: $0E03C_H$

CPUx shadow SPR, region upper address register Application Reset value: $FFFF\ FFC0_H$

Field	Bits	Type	Description
ADDR	31:6	rw	**Defines bits 31:6 of the upper bound of the access protected region**
0	5:0	r	**Reserved** Read as 0; should be written with 0.

4.6.1.115 CPUx PROTDLMU register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTDLMUSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers allocated to the DLMU resources.

PROTDLMUSE Offset address: $0E048_H$

CPUx PROTDLMU register safe endinit Application Reset value: $0000\ 0000_H$

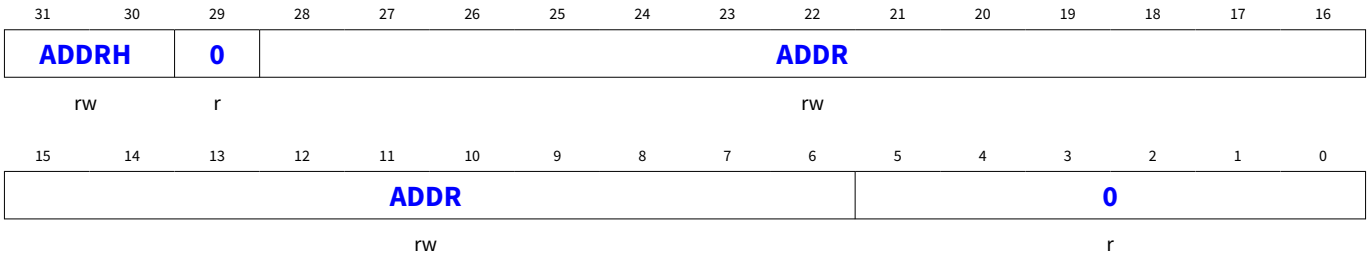
4.6.1.122 CPUx shadow DLMU, region lower address register

This register sets the lower bound of the access protected region. Addresses greater than or equal to the lower bound are considered part of the access protected region.

ACCENDLMUCFG_RGNLA Offset address: $0E078_H$

CPUx shadow DLMU, region lower address register Application Reset value: $0000\ 0000_H$



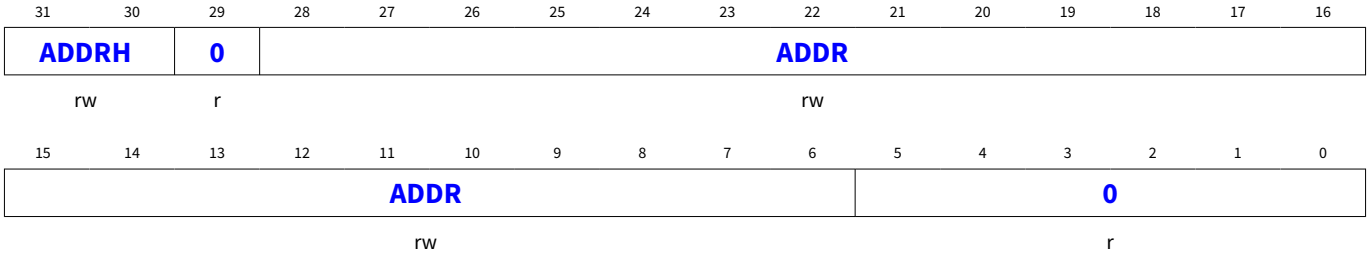
Field	Bits	Type	Description
ADDR	28:6	rw	**Defines bits 28:6 of the lower bound of the access protected region**
ADDRH	31:30	rw	**Defines bits 31:30 of the lower bound of the access protected region**
0	5:0, 29	r	**Reserved** Read as 0; should be written with 0.

4.6.1.123 CPUx shadow DLMU, region upper address register

This register sets the upper bound of the access protected region. Addresses stricly less than the upper bound are considered part of the access protected region.

ACCENDLMUCFG_RGNUA Offset address: $0E07C_H$

CPUx shadow DLMU, region upper address register Application Reset value: $DFFF\ FFC0_H$



Field	Bits	Type	Description
ADDR	28:6	rw	**Defines bits 28:6 of the upper bound of the access protected region**
ADDRH	31:30	rw	**Defines bits 31:30 of the upper bound of the access protected region**
0	5:0, 29	r	**Reserved** Read as 0; should be written with 0.

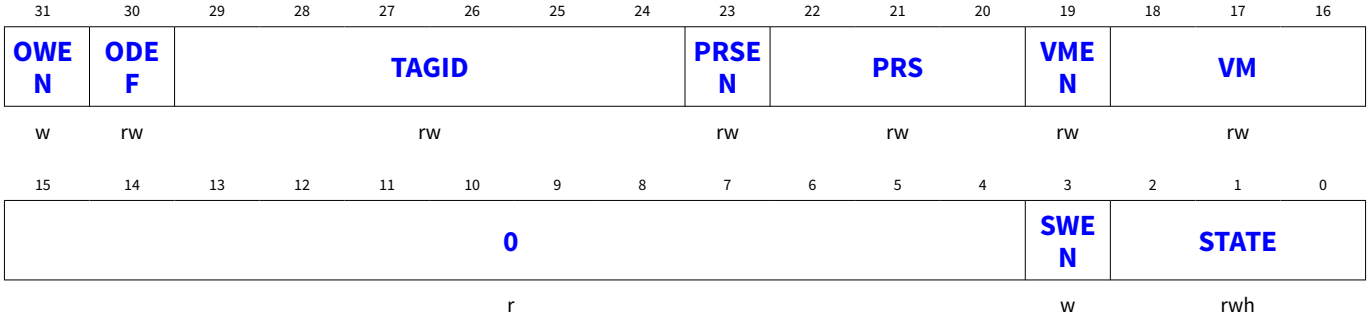
4.6.1.124 CPUx PROTSFR register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSFRE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTSFRE Offset address: $0E080_H$

CPUx PROTSFR register endinit Reset values see: Table 159



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 158 Access mode restrictions of PROTSFRE sorted by descending priority

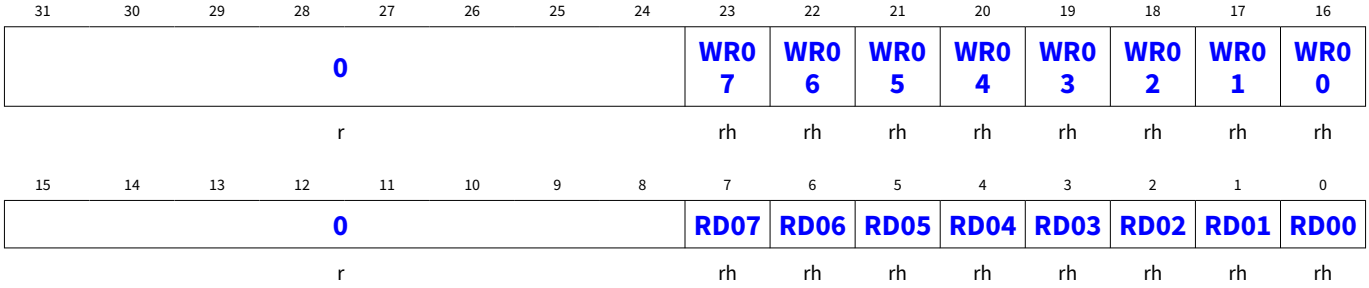
CPUx STM, PRS access enable register Application Reset value: $00FF\ 00FF_H$

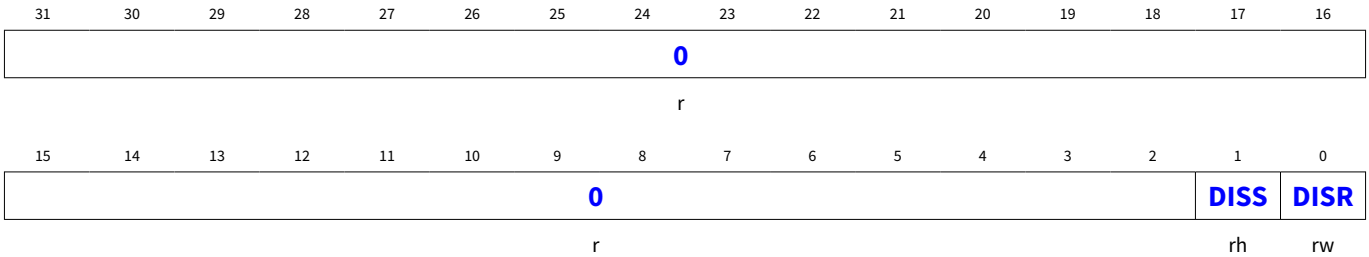


Field	Bits	Type	Description
RDq (q=00-07)	q	rh	**Read access enable for PRS q** This bit enables read access to the access protected region for transactions with the PRS q. 0_B Disabled for read access 1_B Enabled for read access
WRq (q=00-07)	q+16	rh	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

4.6.1.168 CPUx system timer clock control register

The STM clock control register is used to switch the STM on or off and to control its input clock rate. After reset, the STM is always enabled and starts counting. The STM can be disabled by setting bit DISR to 1.

STM_CLC	Offset address:	00000_H
CPUx system timer clock control register	System Reset value:	$0000\ 0000_H$
STMHV_CLC	Offset address:	00000_H
CPUx system timer clock control register, hypervisor view	System Reset value:	$0000\ 0000_H$



Field	Bits	Type	Description
DISR	0	rw	**Module disable request bit** Used for enable and disable control of the STM module. ***Note:*** *f_{STM} is generated by the CCU.* 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module disable status bit** When STM_CLC.DISS=1_H, registers STM_CLC, PROTSTMSE, and ACCENSTMCFG are still accessible. Accesses to other STM registers are not executed. 0_B STM module is enabled 1_B STM module is disabled
0	31:2	r	**Reserved** Read as 0; should be written with 0.

4.6.1.169 CPUx OCDS control and status register

The OCDS control and status register OCS controls the debug behavior by selecting suspend modes.

Register OCS is cleared by Debug Reset. It can only be written when Debug is enabled.

If Debug is being disabled, the OCS register value will not change. When Debug is disabled the OCS suspend control is ineffective.

If the virtualization extension is not present or disabled:

- Debug is enabled when both DBGSR.DE==1 and DBGCFG.EN==1

If the virtualization extension is present and enabled:

- Debug is enabled when DBGSR.DE==1, DBGCFG.EN==1, and DBGCFG.VMn==1 for the currently active virtual machine

STM_OCS Offset address: 00004_H

CPUx OCDS control and status register Debug Reset value: $0000\ 0000_H$

STMHV_OCS Offset address: 00004_H

CPUx OCDS control and status register, hypervisor view Debug Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RELCOMP0	0		MSTART0					0			MSIZE0				
rw	r		rw					r			rw				

Field	Bits	Type	Description
MSIZE0	4:0	rw	**Compare register size for CMP0** This bit field determines the number of bits in register CMP0 (starting from bit 0) that are used for the compare operation with the System Timer. 00_H CMP0[0] used for compare operation 01_H CMP0[1:0] used for compare operation 10_H ... $1E_H$ CMP0[30:0] used for compare operation $1F_H$ CMP0[31:0] used for compare operation
MSTART0	12:8	rw	**Start bit location for CMP0** This bit field determines the lowest bit number of the 64-bit STM that is compared with the content of register CMP0 bit 0. The number of bits to be compared is defined by bit field MSIZE0. 00_H STM[0] is the lowest bit number 01_H STM[1] is the lowest bit number 10_H ... $1E_H$ STM[30] is the lowest bit number $1F_H$ STM[31] is the lowest bit number
RELCOMP0	15	rw	**Relative timer comparison** CMP0 may be selected to compare against either the absolute or the relative timer. A comparator that is set to compare absolute time is constantly active. A comparator that is set to compare relative time is only active when its associated VM is active. 0_B Compare against absolute timer 1_B Compare against relative timer

(table continues...)

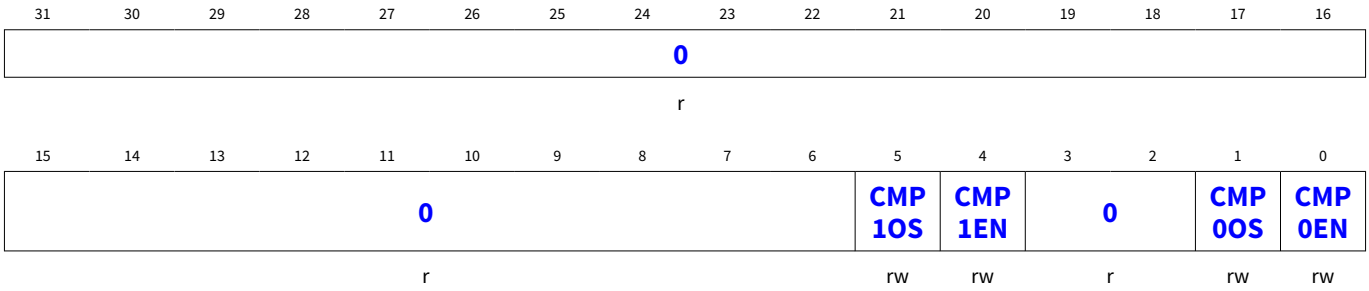
(continued)

Field	Bits	Type	Description
MSIZE1	20:16	rw	**Compare register size for CMP1** This bit field determines the number of bits in register CMP1 (starting from bit 0) that are used for the compare operation with the System Timer. 00_H CMP1[0] used for compare operation 01_H CMP1[1:0] used for compare operation 10_H ... $1E_H$ CMP1[30:0] used for compare operation $1F_H$ CMP1[31:0] used for compare operation
MSTART1	28:24	rw	**Start bit location for CMP1** This bit field determines the lowest bit number of the 64-bit STM that is compared with the content of register CMP1 bit 0. The number of bits to be compared is defined by bit field MSIZE1. 00_H STM[0] is the lowest bit number 01_H STM[1] is the lowest bit number 10_H ... $1E_H$ STM[30] is the lowest bit number $1F_H$ STM[31] is the lowest bit number
RELCOMP1	31	rw	**Relative timer comparison** CMP0 may be selected to compare against either the absolute or the relative timer. A comparator that is set to compare absolute time is constantly active. A comparator that is set to compare relative time is only active when its associated VM is active. 0_B Compare against absolute timer 1_B Compare against relative timer
0	7:5, 14:13, 23:21, 30:29	r	**Reserved** Read as 0; should be written with 0.

4.6.1.173 CPUx system timer interrupt control register

The two compare match interrupts of the STM are controlled by the STM Interrupt Control Register.

STM_ICR	Offset address:	$0012C_H$
CPUx system timer interrupt control register	System Reset value:	$0000\ 0000_H$
STMHV_VMn_ICR (n=0-7)	Offset address:	$0010C_H+n*20_H$
CPUx VMn system timer interrupt control register, hypervisor view	System Reset value:	$0000\ 0000_H$



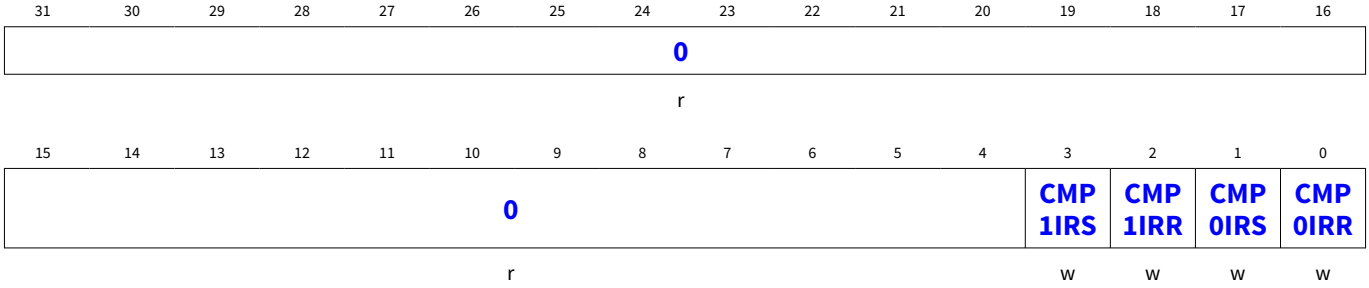
Field	Bits	Type	Description
CMP0EN	0	rw	**Compare register CMP0 interrupt enable control** This bit enables the compare match interrupt with compare register CMP0. 0_B Interrupt on compare match with CMP0 disabled 1_B Interrupt on compare match with CMP0 enabled
CMP0OS	1	rw	**Compare register CMP0 interrupt output selection** This bit determines the interrupt output that is activated on a compare match event of compare register CMP0. 0_B Interrupt output STMIR0 selected 1_B Interrupt output STMIR1 selected
CMP1EN	4	rw	**Compare register CMP1 interrupt enable control** This bit enables the compare match interrupt with compare register CMP1. 0_B Interrupt on compare match with CMP1 disabled 1_B Interrupt on compare match with CMP1 enabled
CMP1OS	5	rw	**Compare register CMP1 interrupt output selection** This bit determines the interrupt output that is activated on a compare match event of compare register CMP1. 0_B Interrupt output STMIR0 selected 1_B Interrupt output STMIR1 selected
0	3:2, 31:6	r	**Reserved** Read as 0; should be written with 0.

4.6.1.174 CPUx system timer interrupt set/clear register

The bits in the STM Interrupt Set/Clear Register make it possible to set or cleared the compare match interrupt request status flags of register ICR.

***Note**: Reading register ISCR always returns 0000 0000$_H$.*

STM_ISCR	Offset address:	00130_H
CPUx system timer interrupt set/clear register	System Reset value:	$0000\ 0000_H$
STMHV_VMn_ISCR (n=0-7)	Offset address:	00110_H+n*20_H
CPUx VMn system timer interrupt set/clear register, hypervisor view	System Reset value:	$0000\ 0000_H$



Field	Bits	Type	Description
CMP0IRR	0	w	**Reset compare register CMP0 interrupt flag** 0_B Bit ISR.CMP0IR is not changed 1_B Bit ISR.CMP0IR is cleared
CMP0IRS	1	w	**Set compare register CMP0 interrupt flag** 0_B Bit ISR.CMP0IR is not changed 1_B Bit ISR.CMP0IR is set. The state of bit CMP0IRR is "don't care" in this case
CMP1IRR	2	w	**Reset compare register CMP1 interrupt flag** 0_B Bit ISR.CMP1IR is not changed 1_B Bit ISR.CMP1IR is cleared.
CMP1IRS	3	w	**Set compare register CMP1 interrupt flag** 0_B Bit ISR.CMP1IR is not changed 1_B Bit ISR.CMP1IR is set. The state of bit CMP1IRR is "don't care" in this case
0	31:4	r	**Reserved** Read as 0; should be written with 0.

4.6.1.175 CPUx system timer interrupt status register

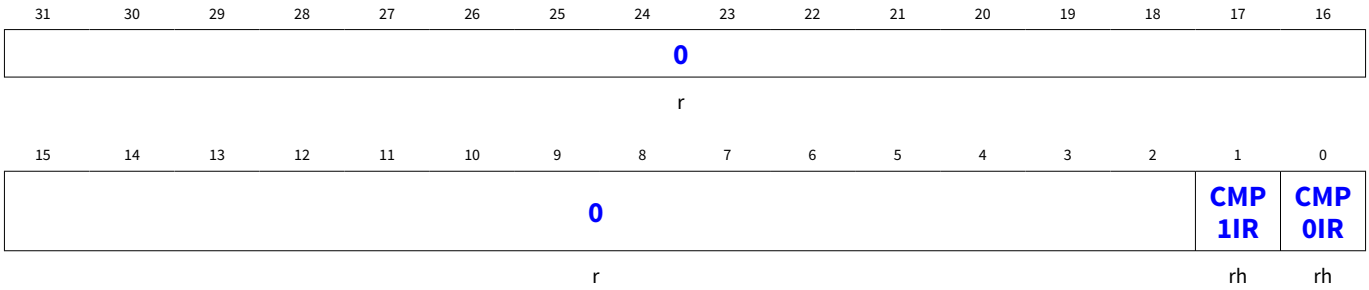
The status of the two compare match interrupts of the STM is provided by the STM Interrupt Status Register.

STM_ISR — Offset address: 00134_H

CPUx system timer interrupt status register — System Reset value: $0000\ 0000_H$

STMHV_VMn_ISR (n=0-7) — Offset address: 00114_H+n*20_H

CPUx VMn system timer interrupt status register, hypervisor view — System Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CMP0IR	0	rh	**Compare register CMP0 interrupt request flag** This bit indicates whether or not a compare match event of compare register CMP0 has occured. CMP0IR can be cleared by software and can be set by software, too (see ISCR register). After a STM reset operation, CMP0IR is immediately set as a result of a compare match event with the reset values of the STM and the compare register CMP0. ***Note**: This flag does not gate the interrupt generation. i.e., even if this flag is not cleared, compare match event interrupts are forwarded if CMPxEN is set.* 0_B A compare match event has not been detected since the bit was last cleared 1_B A compare match event has been detected
CMP1IR	1	rh	**Compare register CMP1 interrupt request flag** This bit indicates whether or not a compare match event of compare register CMP1 has occured. CMP1IR can be cleared by software and can be set by software, too (see ISCR register). After a STM reset operation, CMP1IR is immediately set as a result of a compare match event with the reset values of the STM and the compare register CMP1. ***Note**: This flag does not gate the interrupt generation. i.e., even if this flag is not cleared, compare match event interrupts are forwarded if CMPxEN is set.* 0_B A compare match event has not been detected since the bit was last cleared 1_B A compare match event has been detected
0	31:2	r	**Reserved** Read as 0; should be written with 0.

4.6.1.176 CPUx system timer relative timer

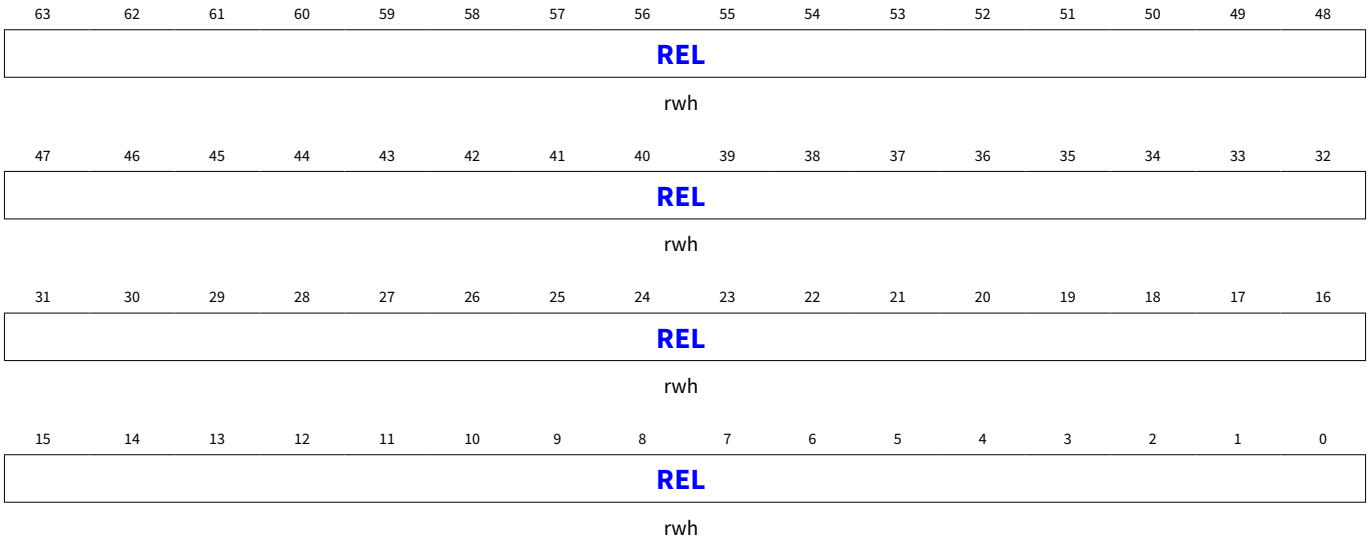
Alias for STM_ABS.

STM_RELTIM — Offset address: 00138_H

CPUx system timer relative timer — System Reset value: 0000 0000 0000 0000_H

STMHV_VMn_RELTIM (n=0-7) — Offset address: 00118_H+n*20_H

CPUx VMn system timer relative timer, hypervisor view — System Reset value: 0000 0000 0000 0000_H



Field	Bits	Type	Description
REL	63:0	rwh	**System timer bits [63:0]** This bit field contains the relative value of the 64-bit STM.

4.6.2 Registers of CPU CFI interface

4.6.2.1 Register overview - access mode glossary

Table 185 Register overview - access mode glossary

Keyword	Description
PFSE	Access protection using PROT register PROTPFSE.
PFSFRE	Access protection using PROT register PROTPFSFRE.
PFSFRSE	Access protection using PROT register PROTPFSFRSE.
APU-P4	Protection group consisting of registers ACCENPFSFRCFG_WRA, ACCENPFSFRCFG_WRB, ACCENPFSFRCFG_RDA, ACCENPFSFRCFG_RDB, ACCENPFSFRCFG_VM, ACCENPFSFRCFG_PRS, ACCENPFSFR_WRA, ACCENPFSFR_WRB, ACCENPFSFR_RDA, ACCENPFSFR_RDB, ACCENPFSFR_VM, ACCENPFSFR_PRS.
P4	Access protection using *APU-P4* registers.
APU-P5	Protection group consisting of registers ACCENPFCFG_RDA, ACCENPFCFG_RDB, ACCENPFCFG_VM, ACCENPFCFG_PRS, ACCENPFCFG_RGNLA, ACCENPFCFG_RGNUA, ACCENPFy_RDA, ACCENPFy_RDB, ACCENPFy_VM, ACCENPFy_PRS, ACCENPFy_RGNLA, ACCENPFy_RGNUA.
P5	Access protection using *APU-P5* registers.
32	Access only when using 32-bit width.
PROT	Access restrictions as defined in the PROT register access rules.

4.6.2.3 CPUx PROTPFSFR register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTPFSFRE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTPFSFRE Offset address: 00000_H

CPUx PROTPFSFR register endinit Reset values see: Table 188

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Application Reset	0000 0000_H	Instance specific: Non secure NVM
Application Reset	4C00 0000_H	Instance specific: Secure NVM

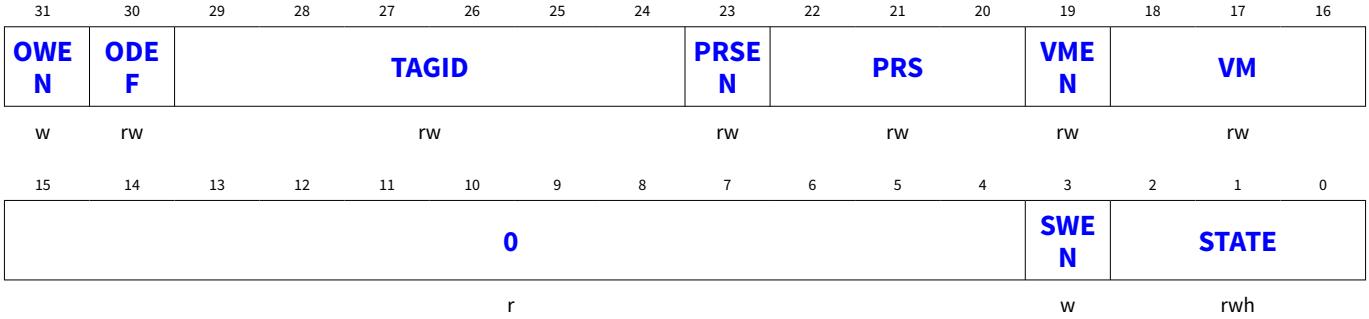
4.6.2.4 CPUx PROTPFSFR register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTPFSFRSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTPFSFRSE Offset address: 00008_H

CPUx PROTPFSFR register safe endinit Reset values see: Table 190



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 189 Access mode restrictions of PROTPFSFRSE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE

WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

4.6.2.11 CPUx PROTPF register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTPFSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers allocated to the local NVM resources.

PROTPFSE Offset address: 00048_H

CPUx PROTPF register safe endinit Reset values see: Table 196

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OWEN	ODEF	TAGID						PRSEN	PRS			VMEN	VM

After Boot-FW Value	$0000\ 0000_H$	PFI0

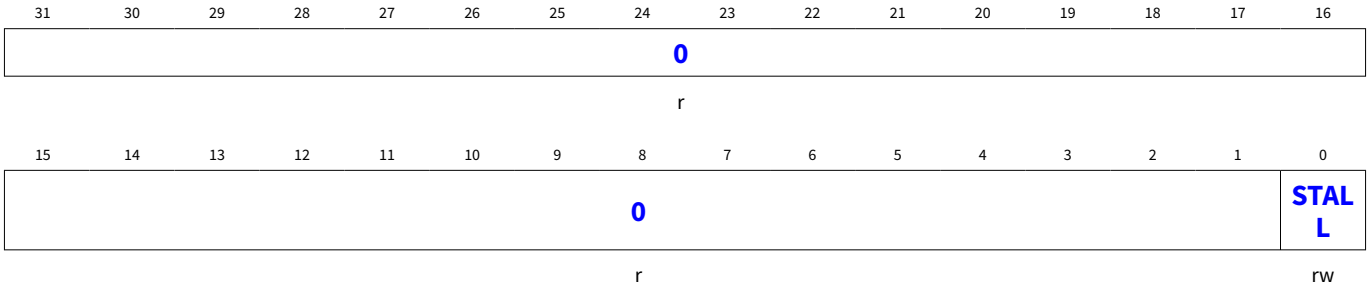
4.6.2.31 CPUx NVM interface y configuration register 1

The CPU NVM Interface Configuration Register 1 controls the stall response.

If a CPU instance does not have a local NVM bank then the FLASHCON1 register associated with that instance will have no functionality.

PFIy_FLASHCON1 (y=0-1) Offset address: 00204_H+y*8

CPUx NVM interface y configuration register 1 Application Reset value: $0000\ 0000_H$

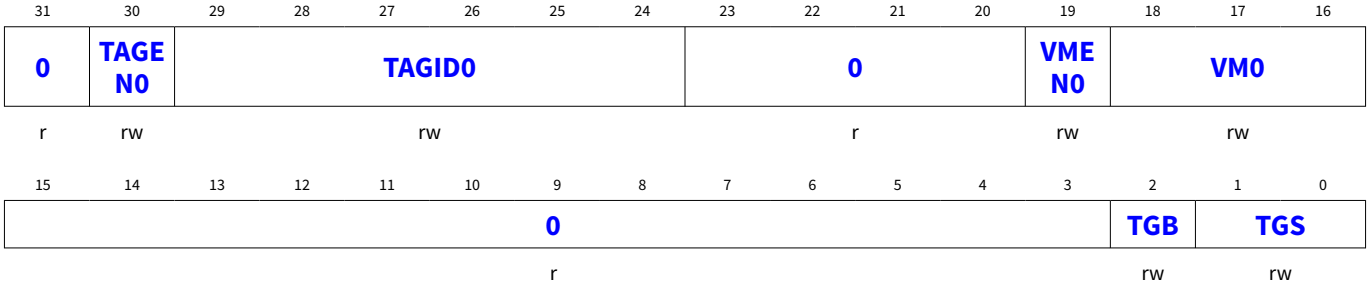


Field	Bits	Type	Description
STALL	0	rw	**Stall Bus Request** This field must not be changed while any bank is busy. The results are unpredictable. It is strongly recommended to configure this field once and avoid changing it during operation. Reading a NVM bank, erase counter (NVM Flash devices), or special sectors (NVM RRAM devices), in Sleep Mode must result in a bus error independent of this field (although it reports "busy"). Reading a status register is possible even while a bank is busy. Writing a user status register while a bank is busy is not possible and results in an error regardless of the value of the STALL field. 0_B **Error**: Reading local NVM bank, erase counter (NVM Flash devices), or special sectors (NVM RRAM devices, when DMU_HCI_STATUS.PxBUSY is set, generates a bus error. 1_B **Stall**: Reading local NVM bank, erase counter (NVM Flash devices), or special sectors (NVM RRAM devices, when DMU_HCI_STATUS.PxBUSY is set delays the response by inserting additional wait cycles until PxBUSY is cleared.
0	31:1	r	**Reserved - RES** Read as 0; should be written with 0.

4.6.2.32 CPUx NVM interface y MCDS performance counter control register 0

TS16PNVMy_CTRL0 (y=0-1) Offset address: 00210_H+y*8

CPUx NVM interface y MCDS performance counter control register 0 Debug Reset value: $0000\ 0000_H$

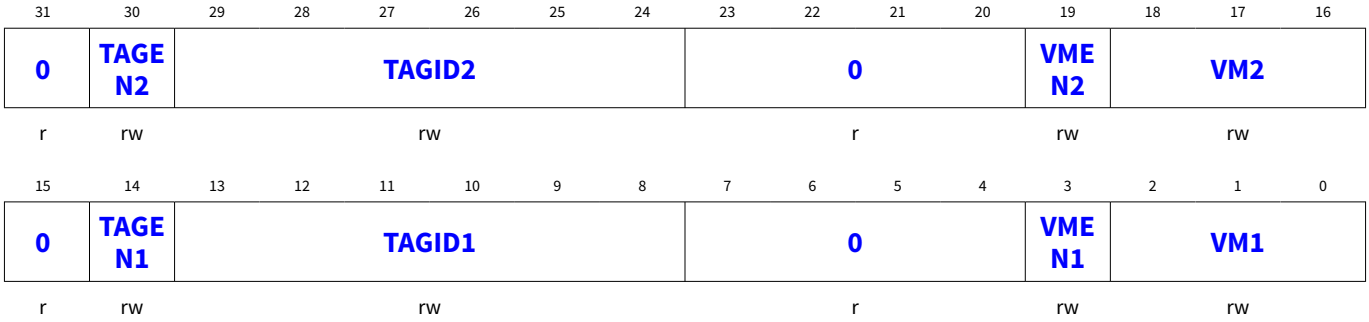


Field	Bits	Type	Description
TGS	1:0	rw	**Trigger set for OTGB0/1** 00_B No trigger set output 01_B Trigger set 'TS16P_NVM' selected **others,** Reserved
TGB	2	rw	**OTGB0/1 bus select** 0_B Trigger set output on OTGB0 1_B Trigger set output on OTGB1
VM0	18:16	rw	**Virtual machine definition for TAG0** Restricts the VM for TAG0. This field is ignored if VMEN0=0_B
VMEN0	19	rw	**Enable for TAG0 virtual machine definition** 0_B Any VM 1_B Only the virtual machine defined by VM0
TAGID0	29:24	rw	**TAG-ID definition for TAG0** Restricts the TAG-ID for TAG0. This field is ignored if TAGEN0=0_B
TAGEN0	30	rw	**Enable for TAG0 TAG-ID definition** 0_B Any master 1_B Only the master defined by TAGID0
0	15:3, 23:20, 31	r	**Reserved** Read as 0; should be written with 0.

4.6.2.33 CPUx NVM interface y MCDS performance counter control register 1

TS16PNVMy_CTRL1 (y=0-1) Offset address: 00214_H+y*8

CPUx NVM interface y MCDS performance counter control register 1 Debug Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
VM1	2:0	rw	**Virtual machine definition for TAG1** Restricts the VM for TAG1. This field is ignored if VMEN1=0_B
VMEN1	3	rw	**Enable for TAG1 virtual machine definition** 0_B Any VM 1_B Only the virtual machine defined by VM1
TAGID1	13:8	rw	**TAG-ID definition for TAG1** Restricts the TAG-ID for TAG1. This field is ignored if TAGEN1=0_B
TAGEN1	14	rw	**Enable for TAG1 TAG-ID definition** 0_B Any master 1_B Only the master defined by TAGID1
VM2	18:16	rw	**Virtual machine definition for TAG2** Restricts the VM for TAG2. This field is ignored if VMEN2=0_B
VMEN2	19	rw	**Enable for TAG2 virtual machine definition** 0_B Any VM 1_B Only the virtual machine defined by VM2

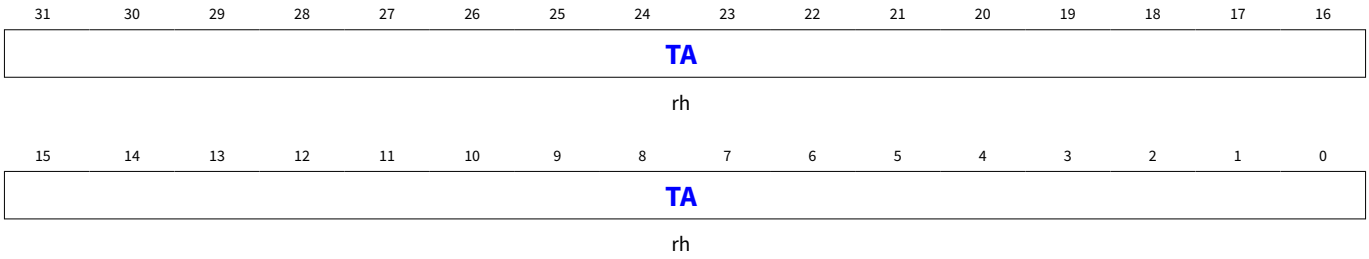
4.6.2.37 CPUx CFI error address register

CFIERRAR Offset address: 00254_H

CPUx CFI error address register Application Reset value: $0000\ 0000_H$



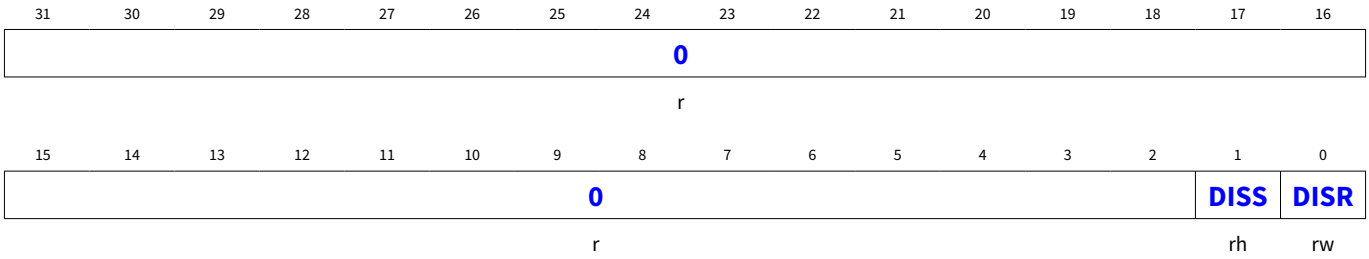
Field	Bits	Type	Description
TA	31:0	rh	**Transaction address** Address being accessed by operation that encountered the error.

4.6.2.38 CPUx PFI buffer disable

A number of buffers (prefetch buffers, data read line buffer) are implemented to reduce the access time of subsequent NVM accesses. When an access, targeting the NVM, is required to read the memory (for example for test), the buffers need to be bypassed to ensure that the data is not retrieved from the buffers. When requested (PFIBUFDIS.DISR=1), PFIBUFDIS.DISS is set, all buffers are invalidated and bypassed ensuring that subsequent accesses, even to the same address are not buffered. The buffers remain disabled until the request is remove (PFIBUFDIS.DISR=0). After reset the buffers are not bypassed.

PFIBUFDIS Offset address: 00320_H

CPUx PFI buffer disable Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DISR	0	rw	**Prefetch and data read line buffers disable request bit** 0_B Enable request: Enable the prefetch and data read line buffers 1_B Bypass request: Disable the prefetch and data read line buffers
DISS	1	rh	**Prefetch and data read line buffers disable status bit** 0_B Pretch buffers and data read line buffers are enabled 1_B Pretch buffers and data read line buffers are invalidated and bypassed. Next access will trigger a new request to the NVM
0	31:2	r	**Reserved - RES** Always read as 0; should be written with 0.

4.7 Debug information

Topics:

- Debug restrictions
- Filtering support for trace based measurement
- Trace bandwidth limiting
- Enabling and disabling the trace using TRCCFG
- TC1.8 CPU and local NVM performance measurement
- System timer suspend

4.7.1 Debug restrictions

For context operations and operations using circular addressing the base address of the operation is used for debug range comparison, rather than the effective address.

When the program cache (PCACHE) is mapped into address space, PCACHE operation can only be enabled when debug is enabled. When the data cache (DCACHE) is mapped into address space DCACHE operation can only be enabled when debug is enabled.

External writes to the processor's GPR registers are not supported unless the processor is in Boot-Halt, Debug-Halt or idle state.

External writes to the processor's PSW and PC registers are not supported unless the processor is in Boot-Halt, Debug-Halt or idle state.

4.7.2 Filtering support for trace based measurement

The current MCDS system produces large amount of trace data. The TC1.8 CPU implements two configuration registers to qualify the data to be traced. Load/Store operations can be filtered on the following conditions in the TRCFILT register:

- Indicate based on a particular base address register used by the Load/Store instruction
- Based on type of load store instruction used 10-bit/16-bit

Additional qualification of trace output required:

- Exclude CSA operations
- Exclude Stack operations from trace

The trace can be further configured to apply to a particular virtual machine or to the whole CPU via the TRCCFG register.

4.7.3 Trace bandwidth limiting

When tracing large amounts of date the MCDS data trace unit (DTU) trace FIFO may saturate. To better match the CPU bandwidth with that of the trace system the CPU implements a mechanism to limit trace output by stalling instruction execution. This feature is controlled through the TRCLIM register.

4.7.4 Enabling and disabling the trace using TRCCFG

The TriCore™ architecture defines multiple multi-cycle operations (for example CALL, Return, …) which can have an effect on the trace data over multiple cycles. When using the TRCCFG register to enable or disable the trace in software, the application should ensure that all previous multi-cycle operation have completed. Configuration of the TRCCFG register is achieved using the MTCR instruction. The architecture requires that an

ISYNC should be placed after the MTCR for the effects to be seen by the CPU. This is not enough in the case of changing the trace configuration.

Enabling the trace

Before enabling the trace, the application software should ensure that the previous instruction is completed and that the store buffers are flushed. The following sequence is recommended in order to avoid instructions being traced partially:

- ISYNC
- DSYNC
- TRCCFG configuration using MTCR
- ISYNC

Disabling the trace

Before disabling the trace, the application software should ensure that the previous instruction is completed and that the store buffers are flushed. The following sequence is recommended in order to avoid incomplete trace of instructions already completed:

- ISYNC
- DSYNC
- TRCCFG configuration using MTCR
- ISYNC

4.7.5 TC1.8 CPU and local NVM performance measurement

Real-time measurement of the core and local NVM performance provides useful insights to system developers. The TC1.8 CPU provides a set of relevant events to the MCDS that can be used to measure different performance aspects without real-time effect on execution.

The performance events that can be measured are described in the following two sections. The 'OTGB core performance counter' and the 'OTGB NVM performance counter' are configured independently and share the same OTGB interfaces. The hardware allows the measurement of a maximum of two sources (out of a maximum of three for CPU instances with two NVM interfaces).

When multiple sources are redirected to the same OTGB interface, the interface will prioritize the core performance over the local NVM0 and over local NVM1 by default.

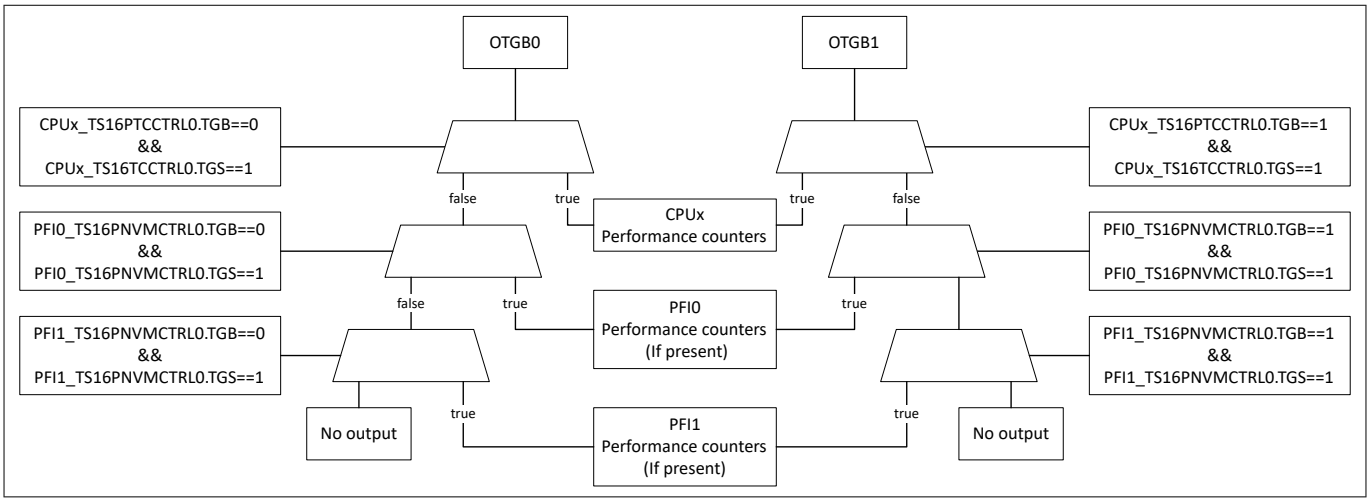


Figure 35 OTGB selection logic

4.7.5.1 OTGB core performance counters

The following table describes the TC1.8 CPU events that can be mapped to counters in MCDS module. Before they can be used in MCDS, they must be activated using the OCS.OTGM function. The list also describes how the event affects a counter selected in the MCDS.

Details of the MCDS counter functions, for example counter width, counter overflow, linkage of counters, are described in the OCMTS chapter.

The OTGB interface is controlled using the HRA_TS16PTCCTRL register which can be used to enable the counters, select the OTGB target and restrict the event to a specific virtual machine number or to the complete TC1.8 CPU instance.

Table 207 TS16P_TC performance counter scheme

Bit	Event function	Resolution [1)]	Description
[1:0]	Instructions executed	2 instructions	Bit 0 indicates that 2 instructions have been executed Bit 1 indicates that 4 instructions have been executed
2	Stall cycles	2 stall cycles	Indication that either the fetch unit or the Load-Store unit are requesting data and are respectively stalled.
3	Correctly predicted branch	2 branches	Indication that a conditional branch instruction is in a branch resolution stage of the pipeline (IP_EX1, LS_DEC, LP_DEC) and is correctly predicted
4	Incorrectly predicted branch	2 branches	Indication that a conditional branch instruction is in a branch resolution stage of the pipeline (IP_EX1, LS_DEC, LP_DEC) and is mispredicted
5	Taken branch	2 branches	Indication that a conditional branch instruction is in a branch resolution stage of the pipeline (IP_EX1, LS_DEC, LP_DEC)
6	Instruction cache hits	2 hits	Indication that the target of a cached fetch request from the fetch unit is found in the program cache
7	Instruction cache misses	2 misses	Indication that the target of a cached fetch request from the fetch unit is not found in the program cache and hence a bus fetch is initiated
8	Data cache hits	2 hits	Indication that the target of a cached request from the Load-Store unit is found in the data cache
9	Data cache misses	2 misses	Indication that the target of a cached request from the Load-Store unit is not found in the data cache and hence a bus fetch is initiated. (This includes clean and dirty misses)
10	PSPR access	2 accesses	Indication of an access to the program scratch pad RAM
11	DSPR access	2 accesses	Indication of an access to the data scratch pad RAM
12	DLMU access	2 accesses	Indication of an access to the local distribute local memory unit RAM
13	0 (not used)	-	
14	Interrupt acknowledge	1 interrupt	Indication that an interrupt request was acknowledged by the local CPU

(table continues...)

Table 207 (continued) TS16P_TC performance counter scheme

Bit	Event function	Resolution [1]	Description
15	Clock indicator	-	This bit is active for one TPB clock cycle every 2 active CPU clock cycles and does consider the CPU‘s fractional divider. This allows a tool to determine the effective clock rate ratio to MCDS considering the CPU‘s fractional divider

1) A resolution of 2 means that the OTGB bit is active for N = E/2 OTGB clock cycles. E is the number of active cycles of the event. Considering also the phase a tool has an uncertainty of +/- 1 event: E = N*2 +/- 1

4.7.5.2 OTGB NVM performance counter

The following table describes the local NVM events that can be mapped to counters in MCDS module. Before they can be used in MCDS, they must be activated using the OCS.OTGM function. The list also describes how the event affects a counter selected in the MCDS.

Details of the MCDS counter functions, for example counter width, counter overflow, linkage of counters, are described in the OCMTS chapter.

The OTGB interface is configured separately per NVM interface (where implemented) using the PFIy_TS16PNVMCTRL0 and PFIy_TS16PNVMCTRL1 registers. These registers can be used to enable the counters, select the OTGB target and restrict the events to a specific virtual machine number, specific master TAG-ID identifiers or to the complete set of transactions of the TC1.8 CPU NVM instance.

Table 208 TS16P_NVM performance counter scheme

Bit	Event function	Resolution [1]	Description
0	TAG0 read access	2 accesses	Indication of a read access from TAG0
1	TAG0 waits for prefetch	2 accesses	Indication that a request from TAG0 waits for a NVM prefetch buffer to complete a prefetch request
2	TAG0 prefetch buffer hit	2 hits	Indication that a request from TAG0 is present in the prefetch buffer
3	TAG0 read line buffer hit	2 hits	Indication that a request from TAG0 is present in the read line buffer
4	TAG1 read access	2 accesses	Indication of a read access from TAG1
5	TAG1 waits for prefetch	2 accesses	Indication that a request from TAG1 waits for a NVM prefetch buffer to complete a prefetch request
6	TAG1 prefetch buffer hit	2 hits	Indication that a request from TAG1 is present in the prefetch buffer
7	TAG1 read line buffer hit	2 hits	Indication that a request from TAG1 is present in the read line buffer
8	TAG2 read access	2 accesses	Indication of a read access from TAG2
9	TAG2 waits for prefetch	2 accesses	Indication that a request from TAG0 waits for a NVM prefetch buffer to complete a prefetch request
10	TAG2 prefetch buffer hit	2 hits	Indication that a request from TAG2 is present in the prefetch buffer

(table continues...)

Table 208 (continued) TS16P_NVM performance counter scheme

Bit	Event function	Resolution [1]	Description
11	TAG2 read line buffer hit	2 hits	Indication that a request from TAG2 is present in the read line buffer
12-14	0 (not used)	-	
15	Clock indicator	-	This bit is active for one TPB clock cycle every 2 CPU clock cycles and does not consider the CPU‘s fractional divider. This allows a tool to determine the clock rate ratio to MCDS

1) A resolution of 2 means that the OTGB bit is active for N = E/2 OTGB clock cycles. E is the number of active cycles of the event. Considering also the phase a tool has an uncertainty of +/- 1 event: E = N*2 +/- 1

4.7.6 System timer suspend

Different configurations of the debug system may be needed in order to ensure synchronicity a CPU and its local STM instance, or between different STM instances.

Single-stepping a single CPU while maintaining local STM synchronicity

In order to ensure the tight coupling of the executing software and the values of the STM timer, the CPU debug system should be configured with DBGACT.SUSP=1. With this setting DBGSR.SUSOUT is set when a debug event is taken. This ensures that as soon as CPUx is suspended, its associated CPUx.STM is also suspended.

***Note**: In this configuration, a small timer drift will be noticed in the other STM instances due to the propagation of the suspend request to the other cores. That is, if CPUx is being single-stepped, STMx is stopped earlier than STMy (y != x) as each breakpoint are taken.*

Debug while maintaining the same time base across all STM instances

In order to ensure common time base across all STM instances, the CPU debug system must be configured with DBGACT.SUSP=0. With this setting, DBGSR.SUSOUT retain its value when a debug event is taken. This ensures that the suspend request is received by all STM instances at the same time, keeping the timebase common across all instances.

***Note**: In this configuration, all STM instances keep the same time base but a small time drift is introduced between CPUx and its STMx instance. That is CPUx will suspend while STMx (and all other STM instances) may keep counting for a few cycles.*

4.9 CPU revision history

Reference	Description of change(s)
Date range: 2024-08-17 to 2025-02-07	
Functional overview	• Clarified location of the APU protection
HRA_DBGSR	• Replaced incorrect mention of PSW.CDC with "core debug controller"

Reference	Description of change(s)
Erase counter and register accesses	• Added clarification that erase counters are only available for NVM Flash based devices
PFIy_FLASHCON1	• Added clarification that erase counters are only available for NVM Flash based devices
PFIBUFDIS	• PFIBUDIS register now visible in all devices. The register was previously hidden
Online data acquisition (OLDA) space	• Removed incorrect OLDA address and added reference to the system address map
PROTSPRSE, PROTDLMUSE, PROTSTMSE, PROTPFSE	• Removed SEL bit-field from the Access mode restrictions table as the bit-field is not protected by .OWEN

4.10 TC4Dx CPU information

4.10.1 TC4Dx CPU configuration

The different CPU and local memory configurations for the AURIX™ TC4xx family of devices are defined in the following table:

	SRI	$B0200000_H$	$B027FFFF_H$	DLMU RAM interface (non-cached)
CPU4	SRI	$F8900000_H$	$F893FFFF_H$	SRI slave interface for SFR+CSFR
(CPU5)	SRI	20000000_H	$2003BFFF_H$	Data ScratchPad RAM interface
	SRI	$2003C000_H$	$2003FFFF_H$	Data Cache RAM interface
	SRI	20100000_H	$2010FFFF_H$	Program ScratchPad RAM interface
	SRI	20110000_H	$20117FFF_H$	Program Cache RAM interface
	SRI	20200000_H	$202017FF_H$	Data Cache Tag RAM interface
	SRI	20300000_H	$20302FFF_H$	Program Cache TAG RAM interface
	SRI	90200000_H	$9027FFFF_H$	DLMU RAM interface (cached)
	SRI	$B0280000_H$	$B02FFFFF_H$	DLMU RAM interface (non-cached)
CPU5	SRI	$F8940000_H$	$F897FFFF_H$	SRI slave interface for SFR+CSFR

(table continues...)

Table 212 (continued) Registers address space - CPU domain SRI

Key: The module name in brackets () indicates a memory section name. Without brackets the reference is to a functional block.

Module	Domain	Base address	End address	Note
(CPUCS)	SRI	10000000_H	$1003BFFF_H$	Data ScratchPad RAM interface
	SRI	$1003C000_H$	$1003FFFF_H$	Data Cache RAM interface
	SRI	10100000_H	$1010FFFF_H$	Program ScratchPad RAM interface
	SRI	10110000_H	$10117FFF_H$	Program Cache RAM interface
	SRI	10200000_H	$102017FF_H$	Data Cache Tag RAM interface
	SRI	10300000_H	$10302FFF_H$	Program Cache TAG RAM interface
CPUCS	SRI	$F8980000_H$	$F89BFFFF_H$	SRI slave interface for SFR+CSFR

4.10.4.1.3 Register address space - CPU domain CSFR

Table 213 Registers address space - CPU domain CSFR

Module	Domain	Base address	End address	Note
CPU	CSFR	0000_H	$FFFF_H$	Short addresses for MxCR/MxDCR instructions

4.10.4.1.4 Register overview - access mode glossary

Table 214 Register overview - access mode glossary

Keyword	Description
DLMUSE	Access protection using PROT register CPU0_PROTDLMUSE or CPU1_PROTDLMUSE or CPU2_PROTDLMUSE or CPU3_PROTDLMUSE or CPU4_PROTDLMUSE or CPU5_PROTDLMUSE .
RSTE	Access protection using PROT register CPU0_PROTRSTE or CPU1_PROTRSTE or CPU2_PROTRSTE or CPU3_PROTRSTE or CPU4_PROTRSTE or CPU5_PROTRSTE or CPUCS_PROTRSTE.
SFRE	Access protection using PROT register CPU0_PROTSFRE or CPU1_PROTSFRE or CPU2_PROTSFRE or CPU3_PROTSFRE or CPU4_PROTSFRE or CPU5_PROTSFRE or CPUCS_PROTSFRE.
SFRSE	Access protection using PROT register CPU0_PROTSFRSE or CPU1_PROTSFRSE or CPU2_PROTSFRSE or CPU3_PROTSFRSE or CPU4_PROTSFRSE or CPU5_PROTSFRSE or CPUCS_PROTSFRSE.
SPRSE	Access protection using PROT register CPU0_PROTSPRSE or CPU1_PROTSPRSE or CPU2_PROTSPRSE or CPU3_PROTSPRSE or CPU4_PROTSPRSE or CPU5_PROTSPRSE or CPUCS_PROTSPRSE.
STMSE	Access protection using PROT register CPU0_PROTSTMSE or CPU1_PROTSTMSE or CPU2_PROTSTMSE or CPU3_PROTSTMSE or CPU4_PROTSTMSE or CPU5_PROTSTMSE or CPUCS_PROTSTMSE.

(table continues...)

Table 214 (continued) Register overview - access mode glossary

Keyword	Description
APU-P0	Protection group consisting of registers CPU0_ACCENSFRCFG_WRA, CPU0_ACCENSFRCFG_WRB, CPU0_ACCENSFRCFG_RDA, CPU0_ACCENSFRCFG_RDB, CPU0_ACCENSFRCFG_VM , CPU0_ACCENSFRCFG_PRS , CPU0_ACCENSFR_WRA, CPU0_ACCENSFR_WRB, CPU0_ACCENSFR_RDA, CPU0_ACCENSFR_RDB, CPU0_ACCENSFR_VM , CPU0_ACCENSFR_PRS or CPU1_ACCENSFRCFG_WRA, CPU1_ACCENSFRCFG_WRB, CPU1_ACCENSFRCFG_RDA, CPU1_ACCENSFRCFG_RDB, CPU1_ACCENSFRCFG_VM , CPU1_ACCENSFRCFG_PRS , CPU1_ACCENSFR_WRA, CPU1_ACCENSFR_WRB, CPU1_ACCENSFR_RDA, CPU1_ACCENSFR_RDB, CPU1_ACCENSFR_VM , CPU1_ACCENSFR_PRS or CPU2_ACCENSFRCFG_WRA, CPU2_ACCENSFRCFG_WRB, CPU2_ACCENSFRCFG_RDA, CPU2_ACCENSFRCFG_RDB, CPU2_ACCENSFRCFG_VM , CPU2_ACCENSFRCFG_PRS , CPU2_ACCENSFR_WRA, CPU2_ACCENSFR_WRB, CPU2_ACCENSFR_RDA, CPU2_ACCENSFR_RDB, CPU2_ACCENSFR_VM , CPU2_ACCENSFR_PRS or CPU3_ACCENSFRCFG_WRA, CPU3_ACCENSFRCFG_WRB, CPU3_ACCENSFRCFG_RDA, CPU3_ACCENSFRCFG_RDB, CPU3_ACCENSFRCFG_VM , CPU3_ACCENSFRCFG_PRS , CPU3_ACCENSFR_WRA, CPU3_ACCENSFR_WRB, CPU3_ACCENSFR_RDA, CPU3_ACCENSFR_RDB, CPU3_ACCENSFR_VM , CPU3_ACCENSFR_PRS or CPU4_ACCENSFRCFG_WRA, CPU4_ACCENSFRCFG_WRB, CPU4_ACCENSFRCFG_RDA, CPU4_ACCENSFRCFG_RDB, CPU4_ACCENSFRCFG_VM , CPU4_ACCENSFRCFG_PRS , CPU4_ACCENSFR_WRA, CPU4_ACCENSFR_WRB, CPU4_ACCENSFR_RDA, CPU4_ACCENSFR_RDB, CPU4_ACCENSFR_VM , CPU4_ACCENSFR_PRS or CPU5_ACCENSFRCFG_WRA, CPU5_ACCENSFRCFG_WRB, CPU5_ACCENSFRCFG_RDA, CPU5_ACCENSFRCFG_RDB, CPU5_ACCENSFRCFG_VM , CPU5_ACCENSFRCFG_PRS , CPU5_ACCENSFR_WRA, CPU5_ACCENSFR_WRB, CPU5_ACCENSFR_RDA, CPU5_ACCENSFR_RDB, CPU5_ACCENSFR_VM , CPU5_ACCENSFR_PRS or CPUCS_ACCENSFRCFG_WRA, CPUCS_ACCENSFRCFG_WRB, CPUCS_ACCENSFRCFG_RDA, CPUCS_ACCENSFRCFG_RDB, CPUCS_ACCENSFRCFG_VM , CPUCS_ACCENSFRCFG_PRS , CPUCS_ACCENSFR_WRA, CPUCS_ACCENSFR_WRB, CPUCS_ACCENSFR_RDA, CPUCS_ACCENSFR_RDB, CPUCS_ACCENSFR_VM , CPUCS_ACCENSFR_PRS .
P0	Access protection using *APU-P0* registers.

(table continues...)

Table 214 (continued) Register overview - access mode glossary

Keyword	Description
APU-P1	Protection group consisting of registers CPU0_ACCENSTMCFG_WRA, CPU0_ACCENSTMCFG_WRB , CPU0_ACCENSTMCFG_RDA, CPU0_ACCENSTMCFG_RDB, CPU0_ACCENSTMCFG_VM , CPU0_ACCENSTMCFG_PRS , CPU0_ACCENSTMVMy_WRA, CPU0_ACCENSTMVMy_WRB , CPU0_ACCENSTMVMy_RDA, CPU0_ACCENSTMVMy_RDB, CPU0_ACCENSTMVMy_VM , CPU0_ACCENSTMVMy_PRS or CPU1_ACCENSTMCFG_WRA, CPU1_ACCENSTMCFG_WRB , CPU1_ACCENSTMCFG_RDA, CPU1_ACCENSTMCFG_RDB, CPU1_ACCENSTMCFG_VM , CPU1_ACCENSTMCFG_PRS , CPU1_ACCENSTMVMy_WRA, CPU1_ACCENSTMVMy_WRB , CPU1_ACCENSTMVMy_RDA, CPU1_ACCENSTMVMy_RDB, CPU1_ACCENSTMVMy_VM , CPU1_ACCENSTMVMy_PRS or CPU2_ACCENSTMCFG_WRA, CPU2_ACCENSTMCFG_WRB , CPU2_ACCENSTMCFG_RDA, CPU2_ACCENSTMCFG_RDB, CPU2_ACCENSTMCFG_VM , CPU2_ACCENSTMCFG_PRS , CPU2_ACCENSTMVMy_WRA, CPU2_ACCENSTMVMy_WRB , CPU2_ACCENSTMVMy_RDA, CPU2_ACCENSTMVMy_RDB, CPU2_ACCENSTMVMy_VM , CPU2_ACCENSTMVMy_PRS or CPU3_ACCENSTMCFG_WRA, CPU3_ACCENSTMCFG_WRB , CPU3_ACCENSTMCFG_RDA, CPU3_ACCENSTMCFG_RDB, CPU3_ACCENSTMCFG_VM , CPU3_ACCENSTMCFG_PRS , CPU3_ACCENSTMVMy_WRA, CPU3_ACCENSTMVMy_WRB , CPU3_ACCENSTMVMy_RDA, CPU3_ACCENSTMVMy_RDB, CPU3_ACCENSTMVMy_VM , CPU3_ACCENSTMVMy_PRS or CPU4_ACCENSTMCFG_WRA, CPU4_ACCENSTMCFG_WRB , CPU4_ACCENSTMCFG_RDA, CPU4_ACCENSTMCFG_RDB, CPU4_ACCENSTMCFG_VM , CPU4_ACCENSTMCFG_PRS , CPU4_ACCENSTMVMy_WRA, CPU4_ACCENSTMVMy_WRB , CPU4_ACCENSTMVMy_RDA, CPU4_ACCENSTMVMy_RDB, CPU4_ACCENSTMVMy_VM , CPU4_ACCENSTMVMy_PRS or CPU5_ACCENSTMCFG_WRA, CPU5_ACCENSTMCFG_WRB , CPU5_ACCENSTMCFG_RDA, CPU5_ACCENSTMCFG_RDB, CPU5_ACCENSTMCFG_VM , CPU5_ACCENSTMCFG_PRS , CPU5_ACCENSTMVMy_WRA, CPU5_ACCENSTMVMy_WRB , CPU5_ACCENSTMVMy_RDA, CPU5_ACCENSTMVMy_RDB, CPU5_ACCENSTMVMy_VM , CPU5_ACCENSTMVMy_PRS or CPUCS_ACCENSTMCFG_WRA, CPUCS_ACCENSTMCFG_WRB , CPUCS_ACCENSTMCFG_RDA, CPUCS_ACCENSTMCFG_RDB, CPUCS_ACCENSTMCFG_VM , CPUCS_ACCENSTMCFG_PRS , CPUCS_ACCENSTM_WRA, CPUCS_ACCENSTM_WRB , CPUCS_ACCENSTM_RDA, CPUCS_ACCENSTM_RDB, CPUCS_ACCENSTM_VM , CPUCS_ACCENSTM_PRS .
P1	Access protection using *APU-P1* registers.

(table continues...)

Table 214 (continued) Register overview - access mode glossary

Keyword	Description
APU-P2	Protection group consisting of registers CPU0_ACCENSPRCFG_WRA, CPU0_ACCENSPRCFG_WRB, CPU0_ACCENSPRCFG_RDA, CPU0_ACCENSPRCFG_RDB, CPU0_ACCENSPRCFG_VM , CPU0_ACCENSPRCFG_PRS , CPU0_ACCENSPRCFG_RGNLA , CPU0_ACCENSPRCFG_RGNUA , CPU0_ACCENSPRy_WRA, CPU0_ACCENSPRy_WRB, CPU0_ACCENSPRy_RDA, CPU0_ACCENSPRy_RDB, CPU0_ACCENSPRy_VM , CPU0_ACCENSPRy_PRS , CPU0_ACCENSPRy_RGNLA , CPU0_ACCENSPRy_RGNUA or CPU1_ACCENSPRCFG_WRA, CPU1_ACCENSPRCFG_WRB, CPU1_ACCENSPRCFG_RDA, CPU1_ACCENSPRCFG_RDB, CPU1_ACCENSPRCFG_VM , CPU1_ACCENSPRCFG_PRS , CPU1_ACCENSPRCFG_RGNLA , CPU1_ACCENSPRCFG_RGNUA , CPU1_ACCENSPRy_WRA, CPU1_ACCENSPRy_WRB, CPU1_ACCENSPRy_RDA, CPU1_ACCENSPRy_RDB, CPU1_ACCENSPRy_VM , CPU1_ACCENSPRy_PRS , CPU1_ACCENSPRy_RGNLA , CPU1_ACCENSPRy_RGNUA or CPU2_ACCENSPRCFG_WRA, CPU2_ACCENSPRCFG_WRB, CPU2_ACCENSPRCFG_RDA, CPU2_ACCENSPRCFG_RDB, CPU2_ACCENSPRCFG_VM , CPU2_ACCENSPRCFG_PRS , CPU2_ACCENSPRCFG_RGNLA , CPU2_ACCENSPRCFG_RGNUA , CPU2_ACCENSPRy_WRA, CPU2_ACCENSPRy_WRB, CPU2_ACCENSPRy_RDA, CPU2_ACCENSPRy_RDB, CPU2_ACCENSPRy_VM , CPU2_ACCENSPRy_PRS , CPU2_ACCENSPRy_RGNLA , CPU2_ACCENSPRy_RGNUA or CPU3_ACCENSPRCFG_WRA, CPU3_ACCENSPRCFG_WRB, CPU3_ACCENSPRCFG_RDA, CPU3_ACCENSPRCFG_RDB, CPU3_ACCENSPRCFG_VM , CPU3_ACCENSPRCFG_PRS , CPU3_ACCENSPRCFG_RGNLA , CPU3_ACCENSPRCFG_RGNUA , CPU3_ACCENSPRy_WRA, CPU3_ACCENSPRy_WRB, CPU3_ACCENSPRy_RDA, CPU3_ACCENSPRy_RDB, CPU3_ACCENSPRy_VM , CPU3_ACCENSPRy_PRS , CPU3_ACCENSPRy_RGNLA , CPU3_ACCENSPRy_RGNUA or CPU4_ACCENSPRCFG_WRA, CPU4_ACCENSPRCFG_WRB, CPU4_ACCENSPRCFG_RDA, CPU4_ACCENSPRCFG_RDB, CPU4_ACCENSPRCFG_VM , CPU4_ACCENSPRCFG_PRS , CPU4_ACCENSPRCFG_RGNLA , CPU4_ACCENSPRCFG_RGNUA , CPU4_ACCENSPRy_WRA, CPU4_ACCENSPRy_WRB, CPU4_ACCENSPRy_RDA, CPU4_ACCENSPRy_RDB, CPU4_ACCENSPRy_VM , CPU4_ACCENSPRy_PRS , CPU4_ACCENSPRy_RGNLA , CPU4_ACCENSPRy_RGNUA or CPU5_ACCENSPRCFG_WRA, CPU5_ACCENSPRCFG_WRB, CPU5_ACCENSPRCFG_RDA, CPU5_ACCENSPRCFG_RDB, CPU5_ACCENSPRCFG_VM , CPU5_ACCENSPRCFG_PRS , CPU5_ACCENSPRCFG_RGNLA , CPU5_ACCENSPRCFG_RGNUA , CPU5_ACCENSPRy_WRA, CPU5_ACCENSPRy_WRB, CPU5_ACCENSPRy_RDA, CPU5_ACCENSPRy_RDB, CPU5_ACCENSPRy_VM , CPU5_ACCENSPRy_PRS , CPU5_ACCENSPRy_RGNLA , CPU5_ACCENSPRy_RGNUA or CPUCS_ACCENSPRCFG_WRA, CPUCS_ACCENSPRCFG_WRB, CPUCS_ACCENSPRCFG_RDA, CPUCS_ACCENSPRCFG_RDB, CPUCS_ACCENSPRCFG_VM , CPUCS_ACCENSPRCFG_PRS , CPUCS_ACCENSPRCFG_RGNLA , CPUCS_ACCENSPRCFG_RGNUA , CPUCS_ACCENSPRy_WRA, CPUCS_ACCENSPRy_WRB, CPUCS_ACCENSPRy_RDA, CPUCS_ACCENSPRy_RDB, CPUCS_ACCENSPRy_VM , CPUCS_ACCENSPRy_PRS , CPUCS_ACCENSPRy_RGNLA , CPUCS_ACCENSPRy_RGNUA .
P2	Access protection using *APU-P2* registers.

(table continues...)

Table 214 (continued) Register overview - access mode glossary

Keyword	Description
APU-P3	Protection group consisting of registers CPU0_ACCENDLMUCFG_WRA , CPU0_ACCENDLMUCFG_WRB , CPU0_ACCENDLMUCFG_RDA , CPU0_ACCENDLMUCFG_RDB , CPU0_ACCENDLMUCFG_VM , CPU0_ACCENDLMUCFG_PRS , CPU0_ACCENDLMUCFG_RGNLA , CPU0_ACCENDLMUCFG_RGNUA , CPU0_ACCENDLMUy_WRA , CPU0_ACCENDLMUy_WRB , CPU0_ACCENDLMUy_RDA , CPU0_ACCENDLMUy_RDB , CPU0_ACCENDLMUy_VM , CPU0_ACCENDLMUy_PRS , CPU0_ACCENDLMUy_RGNLA , CPU0_ACCENDLMUy_RGNUA or CPU1_ACCENDLMUCFG_WRA , CPU1_ACCENDLMUCFG_WRB , CPU1_ACCENDLMUCFG_RDA , CPU1_ACCENDLMUCFG_RDB , CPU1_ACCENDLMUCFG_VM , CPU1_ACCENDLMUCFG_PRS , CPU1_ACCENDLMUCFG_RGNLA , CPU1_ACCENDLMUCFG_RGNUA , CPU1_ACCENDLMUy_WRA , CPU1_ACCENDLMUy_WRB , CPU1_ACCENDLMUy_RDA , CPU1_ACCENDLMUy_RDB , CPU1_ACCENDLMUy_VM , CPU1_ACCENDLMUy_PRS , CPU1_ACCENDLMUy_RGNLA , CPU1_ACCENDLMUy_RGNUA or CPU2_ACCENDLMUCFG_WRA , CPU2_ACCENDLMUCFG_WRB , CPU2_ACCENDLMUCFG_RDA , CPU2_ACCENDLMUCFG_RDB , CPU2_ACCENDLMUCFG_VM , CPU2_ACCENDLMUCFG_PRS , CPU2_ACCENDLMUCFG_RGNLA , CPU2_ACCENDLMUCFG_RGNUA , CPU2_ACCENDLMUy_WRA , CPU2_ACCENDLMUy_WRB , CPU2_ACCENDLMUy_RDA , CPU2_ACCENDLMUy_RDB , CPU2_ACCENDLMUy_VM , CPU2_ACCENDLMUy_PRS , CPU2_ACCENDLMUy_RGNLA , CPU2_ACCENDLMUy_RGNUA or CPU3_ACCENDLMUCFG_WRA , CPU3_ACCENDLMUCFG_WRB , CPU3_ACCENDLMUCFG_RDA , CPU3_ACCENDLMUCFG_RDB , CPU3_ACCENDLMUCFG_VM , CPU3_ACCENDLMUCFG_PRS , CPU3_ACCENDLMUCFG_RGNLA , CPU3_ACCENDLMUCFG_RGNUA , CPU3_ACCENDLMUy_WRA , CPU3_ACCENDLMUy_WRB , CPU3_ACCENDLMUy_RDA , CPU3_ACCENDLMUy_RDB , CPU3_ACCENDLMUy_VM , CPU3_ACCENDLMUy_PRS , CPU3_ACCENDLMUy_RGNLA , CPU3_ACCENDLMUy_RGNUA or CPU4_ACCENDLMUCFG_WRA , CPU4_ACCENDLMUCFG_WRB , CPU4_ACCENDLMUCFG_RDA , CPU4_ACCENDLMUCFG_RDB , CPU4_ACCENDLMUCFG_VM , CPU4_ACCENDLMUCFG_PRS , CPU4_ACCENDLMUCFG_RGNLA , CPU4_ACCENDLMUCFG_RGNUA , CPU4_ACCENDLMUy_WRA , CPU4_ACCENDLMUy_WRB , CPU4_ACCENDLMUy_RDA , CPU4_ACCENDLMUy_RDB , CPU4_ACCENDLMUy_VM , CPU4_ACCENDLMUy_PRS , CPU4_ACCENDLMUy_RGNLA , CPU4_ACCENDLMUy_RGNUA or CPU5_ACCENDLMUCFG_WRA , CPU5_ACCENDLMUCFG_WRB , CPU5_ACCENDLMUCFG_RDA , CPU5_ACCENDLMUCFG_RDB , CPU5_ACCENDLMUCFG_VM , CPU5_ACCENDLMUCFG_PRS , CPU5_ACCENDLMUCFG_RGNLA , CPU5_ACCENDLMUCFG_RGNUA , CPU5_ACCENDLMUy_WRA , CPU5_ACCENDLMUy_WRB , CPU5_ACCENDLMUy_RDA , CPU5_ACCENDLMUy_RDB , CPU5_ACCENDLMUy_VM , CPU5_ACCENDLMUy_PRS , CPU5_ACCENDLMUy_RGNLA , CPU5_ACCENDLMUy_RGNUA .
P3	Access protection using *APU-P3* registers.
32	Access only when using 32-bit width.
STP	Access only during start-up, before start-up protection is set (SMM_STCON.ST_PROT=1).
PROT	Access restrictions as defined in the PROT register access rules.
DEN	Description can be found in global access mode definition.
64	Access only when using 64-bit width.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.

4.10.4.1.5 Register overview - CPU0 domain SRI (ascending offset address)

Table 215 Register overview - CPU0 domain SRI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPU0_STM_CLC	CPU0 system timer clock control register	00000_H	P0, 32	P0, SV, SFRE, 32	System Reset	351
CPU0_STMHV_CLC	CPU0 system timer clock control register, hypervisor view	00000_H	P0, 32	P0, SV, SFRE, 32	System Reset	351
CPU0_STM_OCS	CPU0 OCDS control and status register	00004_H	P0, 32	P0, SV, 32, DEN	Debug Reset	352
CPU0_STMHV_OCS	CPU0 OCDS control and status register, hypervisor view	00004_H	P0, 32	P0, SV, 32, DEN	Debug Reset	352
CPU0_STM_ABS	CPU0 system timer absolute timer	00020_H	(P0, 32)| (P0, 64)	P0, SV, 64, SFRSE	System Reset	353
CPU0_STMHV_ABS	CPU0 system timer absolute timer, hypervisor view	00020_H	(P0, 32)| (P0, 64)	P0, SV, 64, SFRSE	System Reset	353
CPU0_STMHV_VMn_CMPc (c=0-1;n=0-7)	CPU0 VMn system timer compare register c, hypervisor view	00100_H+ n*20_H+c *4	P1, 32	P1, SV, 32	System Reset	354
CPU0_STMHV_VMn_CMCON (n=0-7)	CPU0 VMn system timer compare match control register, hypervisor view	00108_H+ n*20_H	P1, 32	P1, SV, 32	System Reset	355
CPU0_STMHV_VMn_ICR (n=0-7)	CPU0 VMn system timer interrupt control register, hypervisor view	$0010C_H$+ n*20_H	P1, 32	P1, SV, 32	System Reset	356
CPU0_STMHV_VMn_ISCR (n=0-7)	CPU0 VMn system timer interrupt set/clear register, hypervisor view	00110_H+ n*20_H	P1, 32	P1, SV, 32	System Reset	357
CPU0_STMHV_VMn_ISR (n=0-7)	CPU0 VMn system timer interrupt status register, hypervisor view	00114_H+ n*20_H	P1, 32	P1, SV, 32	System Reset	358
CPU0_STMHV_VMn_RELTIM (n=0-7)	CPU0 VMn system timer relative timer, hypervisor view	00118_H+ n*20_H	(P1, 32)| (P1, 64)	P1, SV, 64	System Reset	359
CPU0_STM_CMPc (c=0-1)	CPU0 system timer compare register c	00120_H+ c*4	P1, 32	P1, SV, 32	System Reset	354
CPU0_STM_CMCON	CPU0 system timer compare match control register	00128_H	P1, 32	P1, SV, 32	System Reset	355
CPU0_STM_ICR	CPU0 system timer interrupt control register	$0012C_H$	P1, 32	P1, SV, 32	System Reset	356

Table 215 (continued) Register overview - CPU0 domain SRI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPU0_HRHV_DBGSR	CPU0 debug status register	$3FD00_H$	P0, 32	P0, SV, 32	Debug Reset	211
CPU0_HRHV_EXEVT	CPU0 external event register	$3FD08_H$	P0, 32	P0, SV, 32	Debug Reset	212
CPU0_HRHV_CREVT	CPU0 core register access event	$3FD0C_H$	P0, 32	P0, SV, 32	Debug Reset	213
CPU0_HRHV_SWEVT	CPU0 software debug event	$3FD10_H$	P0, 32	P0, SV, 32	Debug Reset	214
CPU0_HRHV_DBGACT	CPU0 debug action configuration	$3FD14_H$	P0, 32	P0, SV, 32	Debug Reset	215
CPU0_HRHV_TRIG_ACC	CPU0 trigger event accumulator	$3FD30_H$	P0, 32	P0, SV, 32	Debug Reset	217
CPU0_HRHV_DMS	CPU0 debug monitor start address	$3FD40_H$	P0, 32	P0, SV, 32	Debug Reset	534
CPU0_HRHV_DCX	CPU0 debug context save area pointer	$3FD44_H$	P0, 32	P0, SV, 32	Debug Reset	536
CPU0_HRHV_DBGTCR	CPU0 debug trap control	$3FD48_H$	P0, 32	P0, SV, 32	Application Reset	219
CPU0_HRHV_DBGCFG	CPU0 debug configuration	$3FD4C_H$	P0, 32	P0, SV, 32	Debug Reset	220
CPU0_HRHV_TRCCFG	CPU0 trace configuration	$3FD50_H$	P0, 32	P0, SV, 32	Debug Reset	221
CPU0_HRHV_TRCFILT	CPU0 trace filter	$3FD54_H$	P0, 32	P0, SV, 32	Debug Reset	222
CPU0_HRHV_TRCLIM	CPU0 trace bandwidth limiter	$3FD58_H$	P0, 32	P0, SV, 32	Debug Reset	224
CPU0_HRHV_TS16PTCCTRL	CPU0 MCDS performance counter control register	$3FD60_H$	P0, 32	P0, SV, 32	Debug Reset	225
CPU0_HRHV_PCXI	CPU0 previous context information register	$3FE00_H$	P0, 32	P0, SV, 32	Kernel Reset	236
CPU0_HRHV_PSW	CPU0 HR specific program status word	$3FE04_H$	P0, 32	P0, SV, 32	Kernel Reset	237
CPU0_HRHV_PC	CPU0 program counter	$3FE08_H$	P0, 32	P0, SV, 32	Kernel Reset	538
CPU0_HRHV_CORECON	CPU0 HR specific core configuration register	$3FE14_H$	P0, 32	SFRSE, P0, SV, 32	Kernel Reset	250
CPU0_HRHV_CPU_ID	CPU0 identification register	$3FE18_H$	P0, 32	P0, SV, 32	Kernel Reset	540
CPU0_HRHV_CORE_ID	CPU0 core identification register	$3FE1C_H$	P0, 32	P0, SV, 32	Kernel Reset	542
CPU0_HRHV_BIV	CPU0 HR specific base interrupt vector table pointer	$3FE20_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	251

(table continues...)

Table 215 (continued) Register overview - CPU0 domain SRI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPU0_HRHV_BTV	CPU0 HR specific base trap vector table pointer	$3FE24_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	555
CPU0_HRHV_ISP	CPU0 HR specific interrupt stack pointer	$3FE28_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	253
CPU0_HRHV_ICR	CPU0 interrupt control register	$3FE2C_H$	P0, 32	P0, SV, 32	Kernel Reset	242
CPU0_HRHV_PPRS	CPU0 previous PRS	$3FE34_H$	P0, 32	P0, SV, 32	Kernel Reset	244
CPU0_HRHV_FCX	CPU0 HR specific free CSA list head pointer	$3FE38_H$	P0, 32	P0, SV, 32	Kernel Reset	254
CPU0_HRHV_LCX	CPU0 HR specific free CSA list limit pointer	$3FE3C_H$	P0, 32	P0, SV, 32	Kernel Reset	255
CPU0_HRHV_SWID	CPU0 software identification	$3FE40_H$	P0, 32	P0, SV, 32	Kernel Reset	544
CPU0_HRHV_CUS_ID	CPU0 customer ID register	$3FE50_H$	P0, 32	P0, SV, 32	Kernel Reset	546
CPU0_HRHV_BOOTCON	CPU0 core boot configuration register	$3FE60_H$	P0, 32	P0, SV, 32	Kernel Reset	548
CPU0_HRHV_LCLCON	CPU0 lockstep control register	$3FE64_H$	P0, 32	STP, SFRSE, P0, SV, 32	Cold PowerOn Reset	550
CPU0_HRHV_CCON	CPU0 clock control register	$3FE68_H$	P0, 32	P0, SV, 32	Kernel Reset	248
CPU0_HRHV_TCCON	CPU0 hardware configuration	$3FE6C_H$	P0, 32	P0, SV, 32	Kernel Reset	552
CPU0_HRHV_Ay (y=0-1)	CPU0 HR specific address general purpose register y	$3FF80_H$+ y*4	P0, 32	P0, SV, 32	Kernel Reset	274
CPU0_HRHV_Ay (y=8-9)	CPU0 HR specific address general purpose register y	$3FFA0_H$+ (y-8)*4	P0, 32	P0, SV, 32	Kernel Reset	274

4.10.4.1.6 Register overview - CPU1 domain SRI (ascending offset address)

Table 216 Register overview - CPU1 domain SRI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See

Table 217 (continued) Register overview - CPU2 domain SRI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPU2_HRA_SWID	CPU2 software identification	$1FE40_H$	P0, 32	P0, SV, 32	Kernel Reset	544
CPU2_HRA_CUS_ID	CPU2 customer ID register	$1FE50_H$	P0, 32	P0, SV, 32	Kernel Reset	546
CPU2_HRA_BOOTCON	CPU2 core boot configuration register	$1FE60_H$	P0, 32	P0, SV, 32	Kernel Reset	548
CPU2_HRA_LCLCON	CPU2 lockstep control register	$1FE64_H$	P0, 32	STP, SFRSE, P0, SV, 32	Cold PowerOn Reset	550
CPU2_HRA_CCON	CPU2 clock control register	$1FE68_H$	P0, 32	P0, SV, 32	Kernel Reset	248
CPU2_HRA_TCCON	CPU2 hardware configuration	$1FE6C_H$	P0, 32	P0, SV, 32	Kernel Reset	552
CPU2_Dy (y=0-15)	CPU2 data general purpose register y	$1FF00_H$+ y*4	P0, 32	P0, SV, 32	Kernel Reset	274
CPU2_Ay (y=0-15)	CPU2 address general purpose register y	$1FF80_H$+ y*4	P0, 32	P0, SV, 32	Kernel Reset	274
CPU2_HRB_SEGEN	CPU2 SRI error generation register	21030_H	P0, 32	SFRE, P0, SV, 32	Kernel Reset	255
CPU2_HRB_LCLTEST	CPU2 lockstep test register	21040_H	P0, 32	P0, SV, 32	Cold PowerOn Reset	256
CPU2_HRB_PMA0	CPU2 data access cacheability register	28100_H	P0, 32	SFRE, P0, SV, 32	Kernel Reset	232
CPU2_HRB_PMA1	CPU2 code access cacheability register	28104_H	P0, 32	SFRE, P0, SV, 32	Kernel Reset	233
CPU2_HRB_PMA2	CPU2 peripheral space identifier register	28108_H	P0, 32	SFRE, P0, SV, 32	Kernel Reset	234
CPU2_HRB_DCON2	CPU2 data control register 2	29000_H	P0, 32	P0, SV, 32	Kernel Reset	558
CPU2_HRB_DCON1	CPU2 data control register 1	29008_H	P0, 32	P0, SV, 32	Kernel Reset	258
CPU2_HRB_SMACON	CPU2 SIST mode access control register	$2900C_H$	P0, 32	SFRSE, P0, SV, 32	Kernel Reset	234
CPU2_HRB_DSTR	CPU2 HR specific data synchronous trap register	29010_H	P0, 32	P0, SV, 32	Kernel Reset	259
CPU2_HRB_DATR	CPU2 HR specific data asynchronous trap register	29018_H	P0, 32	P0, SV, 32	Kernel Reset	261
CPU2_HRB_DEADD	CPU2 HR specific data error address register	$2901C_H$	P0, 32	P0, SV, 32	Kernel Reset	262
CPU2_HRB_DIEAR	CPU2 data integrity error address register	29020_H	P0, 32	P0, SV, 32	Kernel Reset	279

(table continues...)

Table 217 (continued) Register overview - CPU2 domain SRI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPU2_HRB_DIETR	CPU2 data integrity error trap register	29024_H	P0, 32	P0, SV, 32	Kernel Reset	280
CPU2_HRB_DCON0	CPU2 data memory control register	29040_H	P0, 32	SFRE, P0, SV, 32	Kernel Reset	258
CPU2_HRB_PSTR	CPU2 HR specific program synchronous trap register	29200_H	P0, 32	P0, SV, 32	Kernel Reset	295
CPU2_HRB_PCON1	CPU2 program control 1	29204_H	P0, 32	P0, SV, 32	Kernel Reset	292
CPU2_HRB_PCON2	CPU2 program control 2	29208_H	P0, 32	P0, SV, 32	Kernel Reset	561
CPU2_HRB_PCON0	CPU2 program control 0	$2920C_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	294
CPU2_HRB_PIEAR	CPU2 HR specific program integrity error address register	29210_H	P0, 32	P0, SV, 32	Kernel Reset	281
CPU2_HRB_PIETR	CPU2 HR specific program integrity error trap register	29214_H	P0, 32	P0, SV, 32	Kernel Reset	282
CPU2_HRB_COMPAT	CPU2 compatibility control register	29400_H	P0, 32	SFRSE, P0, SV, 32	Kernel Reset	235
CPU2_HRB_FPU_TRAP_CON	CPU2 HR specific trap control register	$2A000_H$	P0, 32	P0, SV, 32	Kernel Reset	263
CPU2_HRB_FPU_TRAP_PC	CPU2 HR specific trapping instruction program counter register	$2A004_H$	P0, 32	P0, SV, 32	Kernel Reset	265
CPU2_HRB_FPU_TRAP_OPC	CPU2 HR specific trapping instruction opcode register	$2A008_H$	P0, 32	P0, SV, 32	Kernel Reset	266
CPU2_HRB_FPU_TRAP_SRC1_L	CPU2 HR specific trapping instruction operand register	$2A010_H$	P0, 32	P0, SV, 32	Kernel Reset	267
CPU2_HRB_FPU_TRAP_SRC1_U	CPU2 HR specific trapping instruction operand register	$2A014_H$	P0, 32	P0, SV, 32	Kernel Reset	268
CPU2_HRB_FPU_TRAP_SRC2_L	CPU2 HR specific trapping instruction operand register	$2A018_H$	P0, 32	P0, SV, 32	Kernel Reset	268
CPU2_HRB_FPU_TRAP_SRC2_U	CPU2 HR specific trapping instruction operand register	$2A01C_H$	P0, 32	P0, SV, 32	Kernel Reset	269
CPU2_HRB_FPU_TRAP_SRC3_L	CPU2 HR specific trapping instruction operand register	$2A020_H$	P0, 32	P0, SV, 32	Kernel Reset	270

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPU2_HRB_FPU_TRAP_SRC3_U	CPU2 HR specific trapping instruction operand register	$2A024_H$	P0, 32	P0, SV, 32	Kernel Reset	270
CPU2_HRB_FPU_SYNC_TRAP_CON	CPU2 HR specific synchronous trap control register	$2A030_H$	P0, 32	P0, SV, 32	Kernel Reset	271
CPU2_HRB_FPU_SYNC_TRAP_OPC	CPU2 HR specific trapping instruction opcode register	$2A034_H$	P0, 32	P0, SV, 32	Kernel Reset	273
CPU2_HRB_DPRy_L (y=0-23)	CPU2 HR specific data protection range y, lower bound register	$2C000_H$+y*8	P0, 32	P0, SV, 32	Kernel Reset	283
CPU2_HRB_DPRy_U (y=0-23)	CPU2 HR specific data protection range y, upper bound register	$2C004_H$+y*8	P0, 32	P0, SV, 32	Kernel Reset	284
CPU2_HRB_CPRy_L (y=0-15)	CPU2 HR specific code protection range y, lower bound register	$2D000_H$+y*8	P0, 32	P0, SV, 32	Kernel Reset	285
CPU2_HRB_CPRy_U (y=0-15)	CPU2 HR specific code protection range y, upper bound register	$2D004_H$+y*8	P0, 32	P0, SV, 32	Kernel Reset	286
CPU2_HRB_CPXE_y (y=0-3)	CPU2 HR specific code protection execute enable register set y	$2E000_H$+y*4	P0, 32	P0, SV, 32	Kernel Reset	287
CPU2_HRB_DPRE_y (y=0-3)	CPU2 HR specific data protection read enable register set y	$2E010_H$+y*4	P0, 32	P0, SV, 32	Kernel Reset	288
CPU2_HRB_DPWE_y (y=0-3)	CPU2 HR specific data protection write enable register set y	$2E020_H$+y*4	P0, 32	P0, SV, 32	Kernel Reset	289
CPU2_HRB_CPXE_y (y=4-7)	CPU2 HR specific code protection execute enable register set y	$2E040_H$+(y-4)*4	P0, 32	P0, SV, 32	Kernel Reset	287
CPU2_HRB_DPRE_y (y=4-7)	CPU2 HR specific data protection read enable register set y	$2E050_H$+(y-4)*4	P0, 32	P0, SV, 32	Kernel Reset	288
CPU2_HRB_DPWE_y (y=4-7)	CPU2 HR specific data protection write enable register set y	$2E060_H$+(y-4)*4	P0, 32	P0, SV, 32	Kernel Reset	289
CPU2_HRB_TPS_CON	CPU2 HR specific temporal protection system control register	$2E400_H$	P0, 32	P0, SV, 32	Kernel Reset	296

(table continues...)

Table 217 (continued) Register overview - CPU2 domain SRI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPU2_HRB_TPS_TIMERn (n=0-2)	CPU2 HR specific temporal protection system timer register n	$2E404_H$+ n*4	P0, 32	P0, SV, 32	Kernel Reset	297
CPU2_HRB_TRnEVT (n=0-7)	CPU2 trigger event n	$2F000_H$+ n*8	P0, 32	P0, SV, 32	Debug Reset	209
CPU2_HRB_TRnADR (n=0-7)	CPU2 trigger address n	$2F004_H$+ n*8	P0, 32	P0, SV, 32	Debug Reset	210
CPU2_HRB_CCTRL	CPU2 HR specific counter control	$2FC00_H$	P0, 32	P0, SV, 32	Kernel Reset	226
CPU2_HRB_CCNT	CPU2 HR specific CPU clock cycle count	$2FC04_H$	P0, 32	P0, SV, 32	Kernel Reset	227
CPU2_HRB_ICNT	CPU2 HR specific instruction count	$2FC08_H$	P0, 32	P0, SV, 32	Kernel Reset	228
CPU2_HRB_M1CNT	CPU2 HR specific multi-count register 1	$2FC0C_H$	P0, 32	P0, SV, 32	Kernel Reset	229
CPU2_HRB_M2CNT	CPU2 HR specific multi-count register 2	$2FC10_H$	P0, 32	P0, SV, 32	Kernel Reset	230
CPU2_HRB_M3CNT	CPU2 HR specific multi-count register 3	$2FC14_H$	P0, 32	P0, SV, 32	Kernel Reset	231
CPU2_HRB_DBGSR	CPU2 debug status register	$2FD00_H$	P0, 32	P0, SV, 32	Debug Reset	211
CPU2_HRB_EXEVT	CPU2 external event register	$2FD08_H$	P0, 32	P0, SV, 32	Debug Reset	212
CPU2_HRB_CREVT	CPU2 core register access event	$2FD0C_H$	P0, 32	P0, SV, 32	Debug Reset	213
CPU2_HRB_SWEVT	CPU2 software debug event	$2FD10_H$	P0, 32	P0, SV, 32	Debug Reset	214
CPU2_HRB_DBGACT	CPU2 debug action configuration	$2FD14_H$	P0, 32	P0, SV, 32	Debug Reset	215
CPU2_HRB_TRIG_ACC	CPU2 trigger event accumulator	$2FD30_H$	P0, 32	P0, SV, 32	Debug Reset	217
CPU2_HRB_DMS	CPU2 debug monitor start address	$2FD40_H$	P0, 32	P0, SV, 32	Debug Reset	534
CPU2_HRB_DCX	CPU2 debug context save area pointer	$2FD44_H$	P0, 32	P0, SV, 32	Debug Reset	536
CPU2_HRB_DBGTCR	CPU2 debug trap control	$2FD48_H$	P0, 32	P0, SV, 32	Application Reset	219
CPU2_HRB_DBGCFG	CPU2 debug configuration	$2FD4C_H$	P0, 32	P0, SV, 32	Debug Reset	220

(table continues...)

Table 217 (continued) Register overview - CPU2 domain SRI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPU2_HRB_TRCCFG	CPU2 trace configuration	$2FD50_H$	P0, 32	P0, SV, 32	Debug Reset	221
CPU2_HRB_TRCFILT	CPU2 trace filter	$2FD54_H$	P0, 32	P0, SV, 32	Debug Reset	222
CPU2_HRB_TRCLIM	CPU2 trace bandwidth limiter	$2FD58_H$	P0, 32	P0, SV, 32	Debug Reset	224
CPU2_HRB_TS16PTCCTRL	CPU2 MCDS performance counter control register	$2FD60_H$	P0, 32	P0, SV, 32	Debug Reset	225
CPU2_HRB_PCXI	CPU2 previous context information register	$2FE00_H$	P0, 32	P0, SV, 32	Kernel Reset	236
CPU2_HRB_PSW	CPU2 HR specific program status word	$2FE04_H$	P0, 32	P0, SV, 32	Kernel Reset	237
CPU2_HRB_PC	CPU2 program counter	$2FE08_H$	P0, 32	P0, SV, 32	Kernel Reset	538
CPU2_HRB_CORECON	CPU2 HR specific core configuration register	$2FE14_H$	P0, 32	SFRSE, P0, SV, 32	Kernel Reset	250
CPU2_HRB_CPU_ID	CPU2 identification register	$2FE18_H$	P0, 32	P0, SV, 32	Kernel Reset	540
CPU2_HRB_CORE_ID	CPU2 core identification register	$2FE1C_H$	P0, 32	P0, SV, 32	Kernel Reset	542
CPU2_HRB_BIV	CPU2 HR specific base interrupt vector table pointer	$2FE20_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	251
CPU2_HRB_BTV	CPU2 HR specific base trap vector table pointer	$2FE24_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	555
CPU2_HRB_ISP	CPU2 HR specific interrupt stack pointer	$2FE28_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	253
CPU2_HRB_ICR	CPU2 interrupt control register	$2FE2C_H$	P0, 32	P0, SV, 32	Kernel Reset	242
CPU2_HRB_PPRS	CPU2 previous PRS	$2FE34_H$	P0, 32	P0, SV, 32	Kernel Reset	244
CPU2_HRB_FCX	CPU2 HR specific free CSA list head pointer	$2FE38_H$	P0, 32	P0, SV, 32	Kernel Reset	254
CPU2_HRB_LCX	CPU2 HR specific free CSA list limit pointer	$2FE3C_H$	P0, 32	P0, SV, 32	Kernel Reset	255
CPU2_HRB_SWID	CPU2 software identification	$2FE40_H$	P0, 32	P0, SV, 32	Kernel Reset	544
CPU2_HRB_CUS_ID	CPU2 customer ID register	$2FE50_H$	P0, 32	P0, SV, 32	Kernel Reset	546
CPU2_HRB_BOOTCON	CPU2 core boot configuration register	$2FE60_H$	P0, 32	P0, SV, 32	Kernel Reset	548
CPU2_HRB_LCLCON	CPU2 lockstep control register	$2FE64_H$	P0, 32	STP, SFRSE, P0, SV, 32	Cold PowerOn Reset	550

CPU3_HRB_M3CNT	CPU3 HR specific multi-count register 3	$2FC14_H$	P0, 32	P0, SV, 32	Kernel Reset	231
CPU3_HRB_DBGSR	CPU3 debug status register	$2FD00_H$	P0, 32	P0, SV, 32	Debug Reset	211
CPU3_HRB_EXEVT	CPU3 external event register	$2FD08_H$	P0, 32	P0, SV, 32	Debug Reset	212
CPU3_HRB_CREVT	CPU3 core register access event	$2FD0C_H$	P0, 32	P0, SV, 32	Debug Reset	213
CPU3_HRB_SWEVT	CPU3 software debug event	$2FD10_H$	P0, 32	P0, SV, 32	Debug Reset	214
CPU3_HRB_DBGACT	CPU3 debug action configuration	$2FD14_H$	P0, 32	P0, SV, 32	Debug Reset	215
CPU3_HRB_TRIG_ACC	CPU3 trigger event accumulator	$2FD30_H$	P0, 32	P0, SV, 32	Debug Reset	217
CPU3_HRB_DMS	CPU3 debug monitor start address	$2FD40_H$	P0, 32	P0, SV, 32	Debug Reset	534
CPU3_HRB_DCX	CPU3 debug context save area pointer	$2FD44_H$	P0, 32	P0, SV, 32	Debug Reset	536
CPU3_HRB_DBGTCR	CPU3 debug trap control	$2FD48_H$	P0, 32	P0, SV, 32	Application Reset	219
CPU3_HRB_DBGCFG	CPU3 debug configuration	$2FD4C_H$	P0, 32	P0, SV, 32	Debug Reset	220
CPU3_HRB_TRCCFG	CPU3 trace configuration	$2FD50_H$	P0, 32	P0, SV, 32	Debug Reset	221
CPU3_HRB_TRCFILT	CPU3 trace filter	$2FD54_H$	P0, 32	P0, SV, 32	Debug Reset	222
CPU3_HRB_TRCLIM	CPU3 trace bandwidth limiter	$2FD58_H$	P0, 32	P0, SV, 32	Debug Reset	224
CPU3_HRB_TS16PTCCTRL	CPU3 MCDS performance counter control register	$2FD60_H$	P0, 32	P0, SV, 32	Debug Reset	225
CPU3_HRB_PCXI	CPU3 previous context information register	$2FE00_H$	P0, 32	P0, SV, 32	Kernel Reset	236

(table continues...)

Table 218 (continued) Register overview - CPU3 domain SRI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPU3_HRB_PSW	CPU3 HR specific program status word	$2FE04_H$	P0, 32	P0, SV, 32	Kernel Reset	237
CPU3_HRB_PC	CPU3 program counter	$2FE08_H$	P0, 32	P0, SV, 32	Kernel Reset	538
CPU3_HRB_CORECON	CPU3 HR specific core configuration register	$2FE14_H$	P0, 32	SFRSE, P0, SV, 32	Kernel Reset	250
CPU3_HRB_CPU_ID	CPU3 identification register	$2FE18_H$	P0, 32	P0, SV, 32	Kernel Reset	540
CPU3_HRB_CORE_ID	CPU3 core identification register	$2FE1C_H$	P0, 32	P0, SV, 32	Kernel Reset	542
CPU3_HRB_BIV	CPU3 HR specific base interrupt vector table pointer	$2FE20_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	251
CPU3_HRB_BTV	CPU3 HR specific base trap vector table pointer	$2FE24_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	555
CPU3_HRB_ISP	CPU3 HR specific interrupt stack pointer	$2FE28_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	253
CPU3_HRB_ICR	CPU3 interrupt control register	$2FE2C_H$	P0, 32	P0, SV, 32	Kernel Reset	242
CPU3_HRB_PPRS	CPU3 previous PRS	$2FE34_H$	P0, 32	P0, SV, 32	Kernel Reset	244
CPU3_HRB_FCX	CPU3 HR specific free CSA list head pointer	$2FE38_H$	P0, 32	P0, SV, 32	Kernel Reset	254
CPU3_HRB_LCX	CPU3 HR specific free CSA list limit pointer	$2FE3C_H$	P0, 32	P0, SV, 32	Kernel Reset	255
CPU3_HRB_SWID	CPU3 software identification	$2FE40_H$	P0, 32	P0, SV, 32	Kernel Reset	544
CPU3_HRB_CUS_ID	CPU3 customer ID register	$2FE50_H$	P0, 32	P0, SV, 32	Kernel Reset	546
CPU3_HRB_BOOTCON	CPU3 core boot configuration register	$2FE60_H$	P0, 32	P0, SV, 32	Kernel Reset	548
CPU3_HRB_LCLCON	CPU3 lockstep control register	$2FE64_H$	P0, 32	STP, SFRSE, P0, SV, 32	Cold PowerOn Reset	550
CPU3_HRB_CCON	CPU3 clock control register	$2FE68_H$	P0, 32	P0, SV, 32	Kernel Reset	248
CPU3_HRB_TCCON	CPU3 hardware configuration	$2FE6C_H$	P0, 32	P0, SV, 32	Kernel Reset	552
CPU3_HRB_Ay (y=0-1)	CPU3 HR specific address general purpose register y	$2FF80_H$+ y*4	P0, 32	P0, SV, 32	Kernel Reset	274
CPU3_HRB_Ay (y=8-9)	CPU3 HR specific address general purpose register y	$2FFA0_H$+ (y-8)*4	P0, 32	P0, SV, 32	Kernel Reset	274

CPU4_HRA_TRCFILT	CPU4 trace filter	$1FD54_H$	P0, 32	P0, SV, 32	Debug Reset	222
CPU4_HRA_TRCLIM	CPU4 trace bandwidth limiter	$1FD58_H$	P0, 32	P0, SV, 32	Debug Reset	224
CPU4_HRA_TS16PTCCTRL	CPU4 MCDS performance counter control register	$1FD60_H$	P0, 32	P0, SV, 32	Debug Reset	225
CPU4_HRA_PCXI	CPU4 previous context information register	$1FE00_H$	P0, 32	P0, SV, 32	Kernel Reset	236

(table continues...)

Table 219 (continued) Register overview - CPU4 domain SRI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPU4_HRA_PSW	CPU4 HR specific program status word	$1FE04_H$	P0, 32	P0, SV, 32	Kernel Reset	237
CPU4_HRA_PC	CPU4 program counter	$1FE08_H$	P0, 32	P0, SV, 32	Kernel Reset	538
CPU4_HRA_CORECON	CPU4 HR specific core configuration register	$1FE14_H$	P0, 32	SFRSE, P0, SV, 32	Kernel Reset	250
CPU4_HRA_CPU_ID	CPU4 identification register	$1FE18_H$	P0, 32	P0, SV, 32	Kernel Reset	540
CPU4_HRA_CORE_ID	CPU4 core identification register	$1FE1C_H$	P0, 32	P0, SV, 32	Kernel Reset	542
CPU4_HRA_BIV	CPU4 HR specific base interrupt vector table pointer	$1FE20_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	251
CPU4_HRA_BTV	CPU4 HR specific base trap vector table pointer	$1FE24_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	554
CPU4_HRA_ISP	CPU4 HR specific interrupt stack pointer	$1FE28_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	253
CPU4_HRA_ICR	CPU4 interrupt control register	$1FE2C_H$	P0, 32	P0, SV, 32	Kernel Reset	242
CPU4_HRA_PPRS	CPU4 previous PRS	$1FE34_H$	P0, 32	P0, SV, 32	Kernel Reset	244
CPU4_HRA_FCX	CPU4 HR specific free CSA list head pointer	$1FE38_H$	P0, 32	P0, SV, 32	Kernel Reset	254
CPU4_HRA_LCX	CPU4 HR specific free CSA list limit pointer	$1FE3C_H$	P0, 32	P0, SV, 32	Kernel Reset	255
CPU4_HRA_SWID	CPU4 software identification	$1FE40_H$	P0, 32	P0, SV, 32	Kernel Reset	544
CPU4_HRA_CUS_ID	CPU4 customer ID register	$1FE50_H$	P0, 32	P0, SV, 32	Kernel Reset	546
CPU4_HRA_BOOTCON	CPU4 core boot configuration register	$1FE60_H$	P0, 32	P0, SV, 32	Kernel Reset	548
CPU4_HRA_LCLCON	CPU4 lockstep control register	$1FE64_H$	P0, 32	STP, SFRSE, P0, SV, 32	Cold PowerOn Reset	550
CPU4_HRA_CCON	CPU4 clock control register	$1FE68_H$	P0, 32	P0, SV, 32	Kernel Reset	248
CPU4_HRA_TCCON	CPU4 hardware configuration	$1FE6C_H$	P0, 32	P0, SV, 32	Kernel Reset	552
CPU4_Dy (y=0-15)	CPU4 data general purpose register y	$1FF00_H$+ y*4	P0, 32	P0, SV, 32	Kernel Reset	274
CPU4_Ay (y=0-15)	CPU4 address general purpose register y	$1FF80_H$+ y*4	P0, 32	P0, SV, 32	Kernel Reset	274

(table continues...)

Table 219 (continued) Register overview - CPU4 domain SRI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPU4_HRB_SEGEN	CPU4 SRI error generation register	21030_H	P0, 32	SFRE, P0, SV, 32	Kernel Reset	255
CPU4_HRB_LCLTEST	CPU4 lockstep test register	21040_H	P0, 32	P0, SV, 32	Cold PowerOn Reset	256
CPU4_HRB_PMA0	CPU4 data access cacheability register	28100_H	P0, 32	SFRE, P0, SV, 32	Kernel Reset	232
CPU4_HRB_PMA1	CPU4 code access cacheability register	28104_H	P0, 32	SFRE, P0, SV, 32	Kernel Reset	233
CPU4_HRB_PMA2	CPU4 peripheral space identifier register	28108_H	P0, 32	SFRE, P0, SV, 32	Kernel Reset	234
CPU4_HRB_DCON2	CPU4 data control register 2	29000_H	P0, 32	P0, SV, 32	Kernel Reset	558
CPU4_HRB_DCON1	CPU4 data control register 1	29008_H	P0, 32	P0, SV, 32	Kernel Reset	258
CPU4_HRB_SMACON	CPU4 SIST mode access control register	$2900C_H$	P0, 32	SFRSE, P0, SV, 32	Kernel Reset	234
CPU4_HRB_DSTR	CPU4 HR specific data synchronous trap register	29010_H	P0, 32	P0, SV, 32	Kernel Reset	259
CPU4_HRB_DATR	CPU4 HR specific data asynchronous trap register	29018_H	P0, 32	P0, SV, 32	Kernel Reset	261
CPU4_HRB_DEADD	CPU4 HR specific data error address register	$2901C_H$	P0, 32	P0, SV, 32	Kernel Reset	262
CPU4_HRB_DIEAR	CPU4 data integrity error address register	29020_H	P0, 32	P0, SV, 32	Kernel Reset	279
CPU4_HRB_DIETR	CPU4 data integrity error trap register	29024_H	P0, 32	P0, SV, 32	Kernel Reset	280
CPU4_HRB_DCON0	CPU4 data memory control register	29040_H	P0, 32	SFRE, P0, SV, 32	Kernel Reset	258
CPU4_HRB_PSTR	CPU4 HR specific program synchronous trap register	29200_H	P0, 32	P0, SV, 32	Kernel Reset	295
CPU4_HRB_PCON1	CPU4 program control 1	29204_H	P0, 32	P0, SV, 32	Kernel Reset	292
CPU4_HRB_PCON2	CPU4 program control 2	29208_H	P0, 32	P0, SV, 32	Kernel Reset	561
CPU4_HRB_PCON0	CPU4 program control 0	$2920C_H$	P0, 32	SFRE, P0, SV, 32	Kernel Reset	294
CPU4_HRB_PIEAR	CPU4 HR specific program integrity error address register	29210_H	P0, 32	P0, SV, 32	Kernel Reset	281
CPU4_HRB_PIETR	CPU4 HR specific program integrity error trap register	29214_H	P0, 32	P0, SV, 32	Kernel Reset	282

CPUCS_STM_CLC	CPUcs system timer clock control register	00000_H	P0, 32	P0, SV, SFRE, 32	System Reset	351
CPUCS_STM_OCS	CPUcs OCDS control and status register	00004_H	P0, 32	P0, SV, 32, DEN	Debug Reset	352
CPUCS_STM_ABS	CPUcs system timer absolute timer	00020_H	(P0, 32)| (P0, 64)	P0, SV, 64, SFRSE	System Reset	353

(table continues...)

Table 221 (continued) Register overview - CPUCS domain SRI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPUCS_STM_CMPc (c=0-1)	CPUcs system timer compare register c	00120_H+c*4	P1, 32	P1, SV, 32	System Reset	354
CPUCS_STM_CMCON	CPUcs system timer compare match control register	00128_H	P1, 32	P1, SV, 32	System Reset	355
CPUCS_STM_ICR	CPUcs system timer interrupt control register	$0012C_H$	P1, 32	P1, SV, 32	System Reset	356
CPUCS_STM_ISCR	CPUcs system timer interrupt set/clear register	00130_H	P1, 32	P1, SV, 32	System Reset	357
CPUCS_STM_ISR	CPUcs system timer interrupt status register	00134_H	P1, 32	P1, SV, 32	System Reset	358
CPUCS_STM_RELTIM	CPUcs system timer relative timer	00138_H	(P1, 32)| (P1, 64)	P1, SV, 64	System Reset	359
CPUCS_KRST0	CPUcs reset register 0	$0D000_H$	P0, 32	RSTE, P0, SV, 32	Kernel Reset	297
CPUCS_KRST1	CPUcs reset register 1	$0D004_H$	P0, 32	RSTE, P0, SV, 32	Kernel Reset	298
CPUCS_KRSTCLR	CPUcs reset clear register	$0D008_H$	P0, 32	RSTE, P0, SV, 32	Kernel Reset	299
CPUCS_PROTSPRSE	CPUcs PROTSPR register safe endinit	$0E008_H$	32	SV, 32, PROT	Application Reset	562
CPUCS_ACCENSPRCFG_WRA	CPUcs shadow SPR, write access enable register A	$0E020_H$	32	SPRSE, SV, 32	See 565	565
CPUCS_ACCENSPRCFG_WRB	CPUcs shadow SPR, write access enable register B	$0E024_H$	32	SPRSE, SV, 32	See 566	566
CPUCS_ACCENSPRCFG_RDA	CPUcs shadow SPR, read access enable register A	$0E028_H$	32	SPRSE, SV, 32	See 567	567
CPUCS_ACCENSPRCFG_RDB	CPUcs shadow SPR, read access enable register B	$0E02C_H$	32	SPRSE, SV, 32	Application Reset	568
CPUCS_ACCENSPRCFG_VM	CPUcs shadow SPR, VM access enable register	$0E030_H$	32	SPRSE, SV, 32	Application Reset	310
CPUCS_ACCENSPRCFG_PRS	CPUcs shadow SPR, PRS access enable register	$0E034_H$	32	SPRSE, SV, 32	Application Reset	310
CPUCS_ACCENSPRCFG_RGNLA	CPUcs shadow SPR, region lower address register	$0E038_H$	32	SPRSE, SV, 32	Application Reset	311
CPUCS_ACCENSPRCFG_RGNUA	CPUcs shadow SPR, region upper address register	$0E03C_H$	32	SPRSE, SV, 32	Application Reset	312
CPUCS_PROTSFRE	CPUcs PROTSFR register endinit	$0E080_H$	32	SV, 32, PROT	Application Reset	569
CPUCS_PROTSFRSE	CPUcs PROTSFR register safe endinit	$0E088_H$	32	SV, 32, PROT	Application Reset	571

(table continues...)

Table 221 (continued) Register overview - CPUCS domain SRI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CPUCS_ACCENSFRCFG_WRA	CPUcs shadow SFR, write access enable register A	$0E0A0_H$	32	SFRSE, SV, 32	See 573	573
CPUCS_ACCENSFRCFG_WRB	CPUcs shadow SFR, write access enable register B	$0E0A4_H$	32	SFRSE, SV, 32	See 574	574
CPUCS_ACCENSFRCFG_RDA	CPUcs shadow SFR, read access enable register A	$0E0A8_H$	32	SFRSE, SV, 32	See 575	575
CPUCS_ACCENSFRCFG_RDB	CPUcs shadow SFR, read access enable register B	$0E0AC_H$	32	SFRSE, SV, 32	See 576	576
CPUCS_ACCENSFRCFG_VM	CPUcs shadow SFR, VM access enable register	$0E0B0_H$	32	SFRSE, SV, 32	Application Reset	325
CPUCS_ACCENSFRCFG_PRS	CPUcs shadow SFR, PRS access enable register	$0E0B4_H$	32	SFRSE, SV, 32	Application Reset	325
CPUCS_PROTRSTE	CPUcs PROTRST register endinit	$0E0C0_H$	32	SV, 32, PROT	Application Reset	577
CPUCS_PROTSTMSE	CPUcs PROTSTM Register Safe Endinit	$0E0D8_H$	32	SV, 32, PROT	Application Reset	579
CPUCS_ACCENSTMCFG_WRA	CPUcs shadow STM, write access enable register A	$0E0E0_H$	32	STMSE, SV, 32	Application Reset	582
CPUCS_ACCENSTMCFG_WRB	CPUcs shadow STM, write access enable register B	$0E0E4_H$	32	STMSE, SV, 32	Application Reset	330
CPUCS_ACCENSTMCFG_RDA	CPUcs shadow STM, read access enable register A	$0E0E8_H$	32	STMSE, SV, 32	Application Reset	583
CPUCS_ACCENSTMCFG_RDB	CPUcs shadow STM, read access enable register B	$0E0EC_H$	32	STMSE, SV, 32	Application Reset	584
CPUCS_ACCENSTMCFG_VM	CPUcs shadow STM, VM access enable register	$0E0F0_H$	32	STMSE, SV, 32	Application Reset	332
CPUCS_ACCENSTMCFG_PRS	CPUcs shadow STM, PRS access enable register	$0E0F4_H$	32	STMSE, SV, 32	Application Reset	333
CPUCS_ACCENSPRy_WRA (y=0-15)	CPUcs SPR range y, write access enable register A	$0E200_H$+ y*20_H	32	SPRSE, SV, 32	See 585	585
CPUCS_ACCENSPRy_WRB (y=0-15)	CPUcs SPR range y, write access enable register B	$0E204_H$+ y*20_H	32	SPRSE, SV, 32	See 586	586
CPUCS_ACCENSPRy_RDA (y=0-15)	CPUcs SPR range y, read access enable register A	$0E208_H$+ y*20_H	32	SPRSE, SV, 32	See 587	587
CPUCS_ACCENSPRy_RDB (y=0-15)	CPUcs SPR range y, read access enable register B	$0E20C_H$+ y*20_H	32	SPRSE, SV, 32	Application Reset	588

4.10.4.1.14 CPU0 program counter

The 32-bit Program Counter (PC) shown below, holds the address of the instruction that is currently running. The Program Counter is part of a task's state information. The PC should only be written via the Core Debug Controller when the core is halted. If the core is not in halt a write will have no effect.

CPU0_HRA_PC	Offset address:	$1FE08_H$
CPU0 program counter	Kernel Reset value:	$AFFF\ FF00_H$
CPU1_HRA_PC	Offset address:	$1FE08_H$
CPU1 program counter	Kernel Reset value:	$0000\ 0000_H$

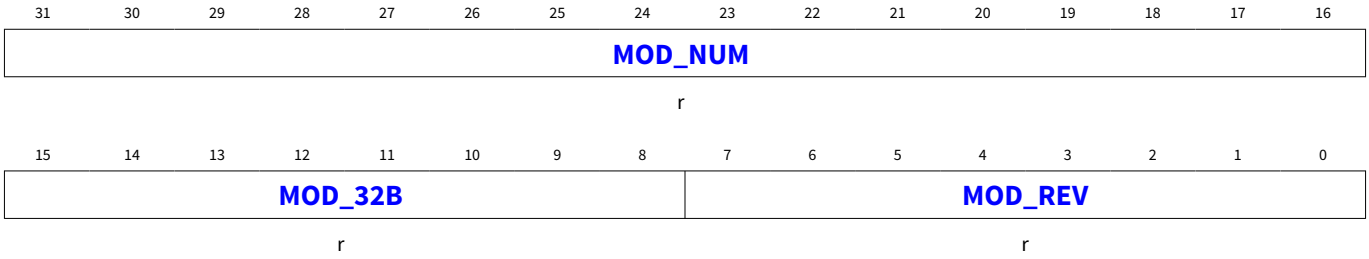
4.10.4.1.15 CPU0 identification register

The CPU Identification Register identifies the CPU type and revision.

CPU0_HRA_CPU_ID	Offset address:	$1FE18_H$
CPU0 identification register	Kernel Reset value:	$00C0\ C031_H$
CPU1_HRA_CPU_ID	Offset address:	$1FE18_H$
CPU1 identification register	Kernel Reset value:	$00C0\ C031_H$
CPU2_HRA_CPU_ID	Offset address:	$1FE18_H$
CPU2 identification register	Kernel Reset value:	$00C0\ C031_H$
CPU3_HRA_CPU_ID	Offset address:	$1FE18_H$
CPU3 identification register	Kernel Reset value:	$00C0\ C031_H$
CPU4_HRA_CPU_ID	Offset address:	$1FE18_H$
CPU4 identification register	Kernel Reset value:	$00C0\ C031_H$
CPU5_HRA_CPU_ID	Offset address:	$1FE18_H$
CPU5 identification register	Kernel Reset value:	$00C0\ C031_H$
CPUCS_HRA_CPU_ID	Offset address:	$1FE18_H$
CPUcs identification register	Kernel Reset value:	$00C0\ C031_H$
CPU_CPU_ID	Offset address:	$0FE18_H$
Short address for domain CSFR	Kernel Reset value:	$00C0\ C031_H$



Field	Bits	Type	Description
MOD_REV	7:0	r	**Revision number**
MOD_32B	15:8	r	**Module type** A value of $C0_H$ in this field indicates a 32-bit module with a 32-bit module ID register
MOD_NUM	31:16	r	**Module identification number**

Table 243 Mirrors of CPU0_HRA_CPU_ID

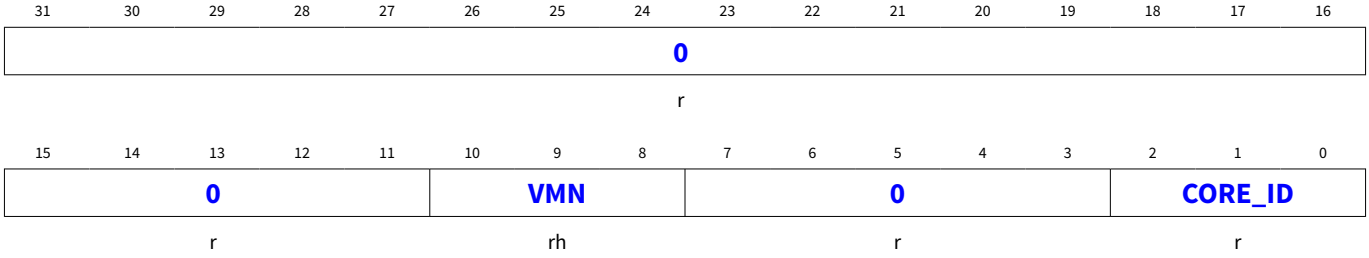
CPU5_HRHV_CPU_ID	CPU5 identification register is an alias.	$3FE18_H$

4.10.4.1.16 CPU0 core identification register

In a multiprocessor system each logical processor core is given a unique identification number. In a system supporting virtualization each logical processor core can be used to run multiple virtual machines. The Core Identification Register holds both the core identification number and the current virtual machine number.

CPU0_HRA_CORE_ID	Offset address:	$1FE1C_H$
CPU0 core identification register	Kernel Reset value:	$0000\ 0000_H$
CPU1_HRA_CORE_ID	Offset address:	$1FE1C_H$
CPU1 core identification register	Kernel Reset value:	$0000\ 0001_H$
CPU2_HRA_CORE_ID	Offset address:	$1FE1C_H$
CPU2 core identification register	Kernel Reset value:	$0000\ 0002_H$
CPU3_HRA_CORE_ID	Offset address:	$1FE1C_H$
CPU3 core identification register	Kernel Reset value:	$0000\ 0003_H$
CPU4_HRA_CORE_ID	Offset address:	$1FE1C_H$
CPU4 core identification register	Kernel Reset value:	$0000\ 0004_H$
CPU5_HRA_CORE_ID	Offset address:	$1FE1C_H$
CPU5 core identification register	Kernel Reset value:	$0000\ 0005_H$
CPUCS_HRA_CORE_ID	Offset address:	$1FE1C_H$
CPUcs core identification register	Kernel Reset value:	$0000\ 0006_H$
CPU_CORE_ID	Offset address:	$0FE1C_H$
Short address for domain CSFR	Reset values see:	Table 249



Field	Bits	Type	Description
CORE_ID	2:0	r	**Core identification number** The identification number of the core.
VMN	10:8	rh	**Virutal machine number** The current virutal machine number. When virtualization is disabled or not present this field will read as 1.
0	7:3, 31:11	r	**Reserved - RES** Read as 0.

4.10.4.1.22 CPU0 HR specific base trap vector table pointer

The BTV contains the base address of the trap vector table. When a trap occurs, the entry address into the trap vector table is generated from the Trap Class of that trap, left-shifted by 5 bits and then ORd with the contents of the BTV register. The left-shift of the Trap Class results in a spacing of 8 words (32 bytes) between the individual entries in the vector table.

Note: This register is protected by CPUx_PROTSFRE.

4.10.4.1.26 CPU0 base hypervisor vector table pointer

The BHV contains the base address of the hypervisor trap vector table. When a hypervisor trap occurs, the entry address into the hypervisor trap vector table is generated from the hypervisor trap class number (HVTCN) of that trap, left-shifted by 5-bits and then ORd with the contents of the BHV register. The left-shift of the HVTCN results in a spacing of 8-words (32-bytes) between the individual entries in the vector table.

Note: This register is protected by CPUx_PROTSFRE.

4.10.4.1.28 CPU0 PROTSPR register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSPRSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers allocated to the SPR resources.

CPU0_PROTSPRSE	Offset address:	$0E008_H$

4.10.4.1.39 CPU0 PROTRST register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTRSTE register controls lock / unlock of the local Endinit (E) protected control registers associated with the kernel reset resource.

Field	Bits	Type	Description
ENq (q=32-63)	q-32	rh	**Read access enable for TAG-ID q** This bit enables read access to the access protected region for transactions with the TAG-ID q. 0_B Disabled for read access 1_B Enabled for read access

Table 329 Reset values of CPUCS_ACCENSFR_RDB

Reset type	Reset value	Note
Application Reset	$0000\ 0000_H$	CPUcs, CSRM debug disabled
After Boot-FW Value	$0000\ 4000_H$	CPUcs, CSRM debug enabled

4.10.4.1.52 CPU0 VMy STM, write access enable register A, virtualization view

This register defines which master agent function TAG identifier (TAG-ID) encodings are enabled or disabled for write accesses to the access protected region.

CPU0_ACCENSTMVMy_WRA (y=0-7) — Offset address: $0E700_H+y*20_H$

CPU0 VMy STM, write access enable register A, virtualization view — Application Reset value: $1000\ 0003_H$

CPU1_ACCENSTMVMy_WRA (y=0-7) — Offset address: $0E700_H+y*20_H$

CPU1 VMy STM, write access enable register A, virtualization view — Application Reset value: $1000\ 0003_H$

CPU2_ACCENSTMVMy_WRA (y=0-7) — Offset address: $0E700_H+y*20_H$

CPU2 VMy STM, write access enable register A, virtualization view — Application Reset value: $1000\ 0003_H$

CPU3_ACCENSTMVMy_WRA (y=0-7) — Offset address: $0E700_H+y*20_H$

CPU3 VMy STM, write access enable register A, virtualization view — Application Reset value: $1000\ 0003_H$

CPU4_ACCENSTMVMy_WRA (y=0-7) — Offset address: $0E700_H+y*20_H$

CPU4 VMy STM, write access enable register A, virtualization view — Application Reset value: $1000\ 0003_H$

CPU5_ACCENSTMVMy_WRA (y=0-7) — Offset address: $0E700_H+y*20_H$

CPU5 VMy STM, write access enable register A, virtualization view — Application Reset value: $1000\ 0003_H$

CPUCS_ACCENSTM_WRA — Offset address: $0E720_H$

CPUcs STM, write access enable register A — Application Reset value: $0000\ 1000_H$

4.10.4.2.10 CPU0 PROTPFSFR register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTPFSFRE register controls lock / unlock of the local Endinit (E) protected control registers.

CPU_CFI0_PROTPFSFRE	Offset address:	00000_H

Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

4.10.4.2.16 CPU0 PROTPF register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTPFSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers allocated to the local NVM resources.

CPU_CFI0_PROTPFSE Offset address: 00048$_H$

4.10.4.2.25 CPU0 NVM interface y configuration register 0

Software may configure a NVM Prefetch Buffer with a master TAG ID stored in NVM Interface Configuration Register 0.

If a CPU instance does not have a local NVM bank then the FLASHCON0 register associated with that instance will have no functionality.

CPU_CFI0_PFIy_FLASHCON0 (y=0-1)	Offset address:	00200_H+y*8
CPU0 NVM interface y configuration register 0	Reset values see:	Table 350
CPU_CFI1_PFIy_FLASHCON0 (y=0-1)	Offset address:	00200_H+y*8
CPU1 NVM interface y configuration register 0	Reset values see:	Table 351
CPU_CFI2_PFIy_FLASHCON0 (y=0-1)	Offset address:	00200_H+y*8
CPU2 NVM interface y configuration register 0	Reset values see:	Table 352
CPU_CFI3_PFIy_FLASHCON0 (y=0-1)	Offset address:	00200_H+y*8
CPU3 NVM interface y configuration register 0	Reset values see:	Table 353
CPU_CFI4_PFIy_FLASHCON0 (y=0-1)	Offset address:	00200_H+y*8
CPU4 NVM interface y configuration register 0	Reset values see:	Table 354
CPU_CFI5_PFIy_FLASHCON0 (y=0-1)	Offset address:	00200_H+y*8
CPU5 NVM interface y configuration register 0	Reset values see:	Table 355
CPU_CFICS_PFI0_FLASHCON0	Offset address:	00200_H
CPUcs NVM interface 0 configuration register 0	Reset values see:	Table 356

0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LSEN	0														LS
r	r														r

Field	Bits	Type	Description
LS	0	r	**Lockstep mode status** This bit indicates whether the CPU NVM interface is currently running in lockstep monitor mode. 0_B Not in lockstep mode 1_B Running in lockstep mode
LSEN	15	r	**Lockstep enable** Enable lockstep CPU monitoring for the CPU NVM interface. This lockstep is always enabled. 0_B Lockstep is disabled 1_B Lockstep enabled (Default after Cold Power-On Reset)
0	14:1, 31:16	r	**Reserved** Read as 0; should be written with 0.

4.10.5 TC4Dx CPU connectivity

The table below lists interfaces to and from this functional block to other blocks in the device.

Table 357 List of CPU interface signals

Interface signals	I/O	Description
CLOCK_CPU_fSRI	In	fSRI
CLOCK_CPU_fSPB	In	FPI0 is always clocked at fSPB
CLOCK_CPU_fFPI1	In	FPI1 is device specific. Refer to FPI chapter for device specific interconnect type. Refer to CPU configuration section for number of FPI master connection for each CPU instances
CLOCK_CPU_fSTM	In	fSTM
SMM_CPU_ApplicationReset	In	Application Reset
SMM_CPU_SystemReset	In	System Reset
SMM_CPU_DebugReset	In	Debug Reset
SMU_CPU1_RESET	In	Kernel Reset
SMU_CPU2_RESET	In	Kernel Reset
SMU_CPU3_RESET	In	Kernel Reset
SMU_CPU4_RESET	In	Kernel Reset

4.10.6 TC4Dx CPU revision history

Reference	Description of change(s)
Date range: 2024-08-17 to 2025-02-07	
HRA_DBGSR	• Replaced incorrect mention of PSW.CDC with "core debug controller"
PFIy_FLASHCON1	• Added clarification that erase counters are only available for NVM Flash based devices
PFIBUFDIS	• PFIBUDIS register now visible in all devices. The register was previously hidden
PROTSPRSE, PROTDLMUSE, PROTSTMSE, PROTPFSE	• Removed SEL bit-field from the Access mode restrictions table as the bit-field is not protected by .OWEN

5 Non-Volatile Memory (NVM)

This sub-system provides non-volatile memory for code and data.

The memory is divided into separate Program Flash (PFLASH) Banks to allow parallel read operations and read-while-write functions. For frequent data updates there is a Data Flash (DFLASH) memory region available, which allows a high number of program or erase cycles to emulate an EEPROM.

The NVM also provides User Configuration Blocks (UCB) where System and NVM configuration settings can be stored. For startup the NVM also contains a BootROM to store the startup software.

For further details about NVM and UCB, please refer to the AURIX™ TC4Dx user manual, under the chapters NVM and Firmware.

5.1 Feature list

- Storage of CPU code and data in several Program Flash (PFLASH) banks with fast read access
  - Independent read access to the banks
  - Read-while-Write capability between the banks
- Storage of EEPROM data in dedicated Data Flash (DFLASH) banks
  - High write or erase cycling endurance
  - DFLASH write or erase while PFLASH read possible
- Security code and data can be stored in separate banks with access protection to the security CPU
- User Configuration Block (UCB) for microcontroller and application specific configuration storage
- Write and erase operations include a verify operation to check the correct cell distribution of programmed and erased bits after the operation
- Two different write operations:
  - Write page with minimum Error Correction Code (ECC) width
  - Write burst for high throughput: more data with one operation
- Erase operation with adjustable range from minimum logical sector size of 16 KB PFLASH and 2 KB DFLASH, up to 512 KB PFLASH and 256 KB DFLASH
- Write (burst) and erase operations may be aborted to allow the start of an other operation
- Replace Logical Sector (RLS) repair function usable by application software in the field to replace a failing logical sector by a free redundant sector
- Separate erase counter for each PFLASH bank: each erase operation in the PFLASH bank is counted and up to 500 entries are possible
- Data integrity check operations
- BootROM for microcontroller start-up software (SSW)

5.2 Functional overview

Blocks of the NVM sub-system

The following figure shows the NVM sub-system and the interfaces to CPU and SRI.

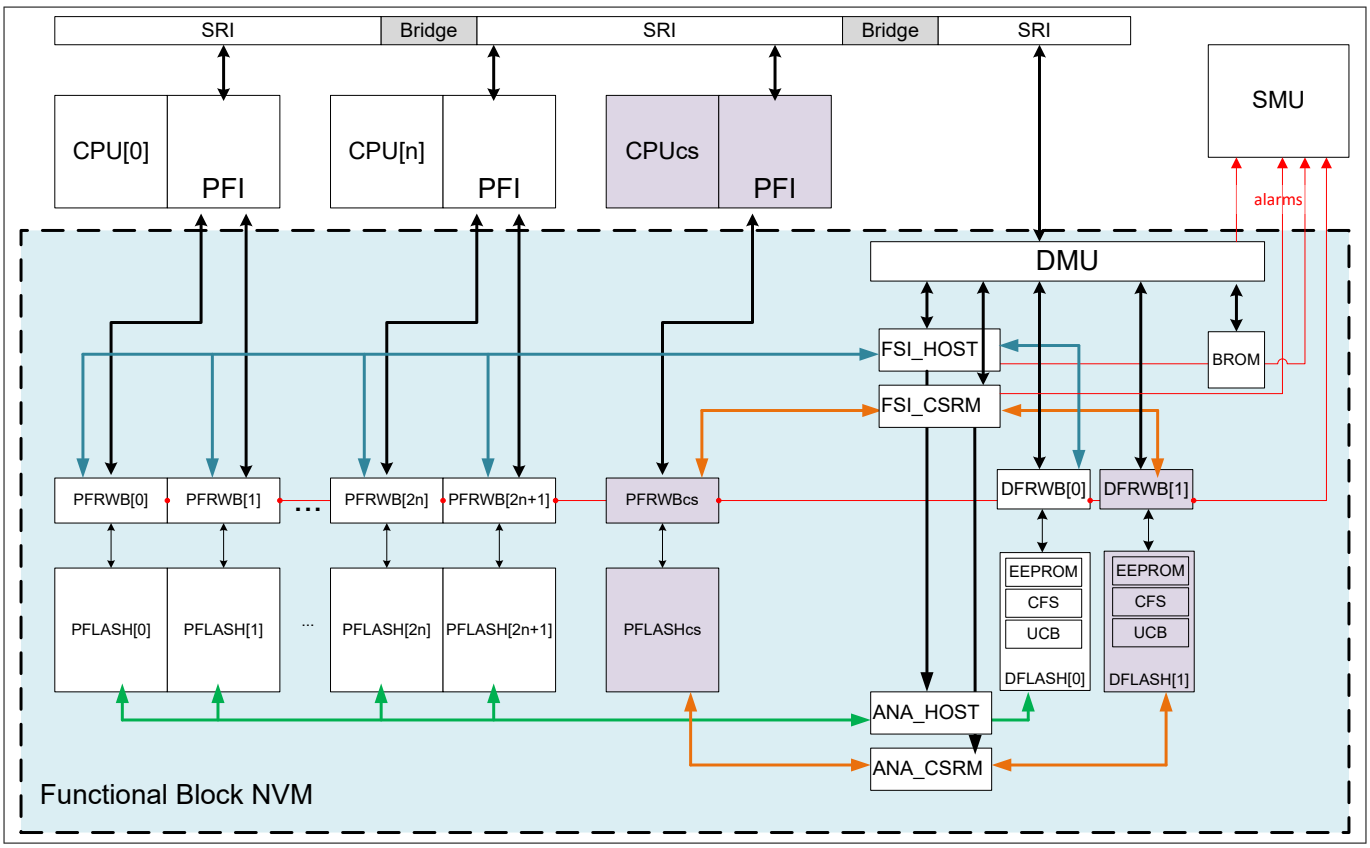

Figure 36 NVM block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

Block descriptions

Table 358 Blocks within the NVM sub-system

Sub-system block	Sub-function	Description
DMU	-	Command Interface Block to System: • Command Decoding of Flash Operation Requests from CPU or other SRI Bus masters • Check of write, read, write_once, and OTP protection • Check of security settings of memory regions • Flash operations to protected memory regions will be prevented Read port and access control for: DFLASH Banks, UCB and BootROM
FSI_x	-	NVM internal CPU for execution of Flash Operation commands such as program, erase, or verify. It has its own storage for firmware for Flash operations
ANALOG_x	-	Central hardmacro block containing chargepumps mainly used for program or erase operation
PFLASH[x]	-	PFLASH bank. A bank containing memory cells for code or data storage of the CPUs, and also containing peripheral circuitry for read, write, or erase operations, 278-bit data output (256-bit data and 22-bit ECC checkbits). Each Bank has a separate address or read path and one bank can be programmed or erased while the other banks are being read (read-while-write support)
PFLASHcs	-	PFLASH bank (as above). Can be set to be exclusively readable, programmable, or erasable by the security CPU
PFRWB[x]	-	PFLASH Read Write Buffers. Digital Interface to the hardmacro PFLASH banks containing address muxes, read buffers, ECC correction, and also control registers for the PFLASH bank
DFLASH[0]	-	Bank containing memory cells for the EEPROM, UCB, and CFS sub-functions. Shared bitline and other read, program or erase peripheral circuitry for operation
	EEPROM	For the storage of data which needs to be frequently updated during its lifetime
	Config Sector (CFS)	Internal parameters and settings of the NVM and the system. Not accessible by the application software
	User Configuration Blocks (UCB)	Infineon and user settings. Part of it can be changed by customer production equipment or application software
DFLASH[1]	-	Separate bank for the EEPROM, UCB, and CFS sub-functions, which can be set to be exclusively readable, programmable, or erasable by the security CPU
	EEPROM	For the storage of data which needs to be frequently updated during its lifetime

(table continues...)

Table 358 (continued) Blocks within the NVM sub-system

Sub-system block	Sub-function	Description
	Config Sector (CFS)	NVM and system internal parameters and settings. Not accessible by the application or security software
	User Configuration Blocks (UCB)	Infineon and user settings. Part of it can be changed by customer production equipment, application and security software
DFRWB[x]	-	DFLASH Read Write Buffers. Digital Interface to the hardmacro DFLASH Banks containing address muxes, read buffers, ECC correction and also control registers for the DFLASH Bank
BROM	-	ROM containing the startup software (SSW)

5.3 Functional description

The following chapters describe the NVM architecture and functions.

5.3.1 NVM sub-functions

Main sub-functions

1. PFLASH safety critical code and data fetch
2. DFLASH data read
3. PFLASH and DFLASH security critical code and data fetch
4. Support of MCU boot
5. Change of NVM content
6. Change of system and NVM configuration

PFLASH safety critical code and data fetch

- Direct fetch path from CPU through CPU PFI Interface to one of the attached PFLASH Bank PFLASH[x]
- Fetch path from CPU to the PFLASH Banks attached to other CPUs through SRI – CPU – CPU PFI

DFLASH data read

- CPU and DMA can read DFLASH[0] EEPROM memory region

PFLASH and DFLASH security critical code and data fetch

- Direct fetch path from CSRM TriCore™ CPU to the attached PFLASH Bank PFLASH[Cx]
- DFLASH[1] can be configured to be only accessible by the CSRM CPU

Support of MCU boot

- BootROM contains the system start-up software which can be read through the SRI connection of the DMU during the system boot phase
- Critical system settings or configurations and trimming values are stored within the config sector and the UCBs and can be read by the start-up software during system boot
- Subset of the UCBs can also be read by the application

Change of NVM content

- Always using a dedicated command sequence through the SRI bus to an allocated memory region (see memory map) which is then decoded in the DMU as a command:
  - Program operations
  - Erase operations
  - Data integrity check operations
  - Replace logical sector operation
- DMU checks the protection or security settings before the execution of a command:
  - If security memory regions have been configured as exclusive then they can be only changed by the security CPU
  - For each logical sector in the PFLASH it is possible to set write, write-once, OTP protection

Change of system and NVM configuration

- During test, the Infineon internal settings and configurations are programmed to config sector and UCB
- Customer production equipment, application or security software changes customer configuration settings like write protection in dedicated UCBs

5.3.2 NVM general terms

Some definitions of terms that are useful to know when reading the NVM chapters.

Table 359 General NVM terms

Application programming interface
Describes all inputs and outputs as well as necessary communication protocols of a software component or a software unit.
Assembly buffer
A special memory area to store data to be programmed into the Flash memory. We distinguish between the FSI SRAM ASB (assembly buffer in the FSI SRAM) and the flash ASB (assembly buffer located in the hardmarco).
Confirmation code
The 32-bit value stored in a predefined NVM memory region, such as a UCB for example, used to identify the state of that memory region. A change of the confirmation value becomes effective after boot or test mode connect. The states that can expressed by the Confirmation Code are: • ERRORED - The state of the confirmation code if it is not CONFIRMED or UNLOCKED. This state indicates that the content of the memory region is somehow corrupted and therefore shall not be used • UNLOCKED - The state where the entire memory region is accessible by read or any NVM operation. In this state the content of that memory region can be modified. The UNLOCKED confirmation code value is 4321_1234_H • CONFIRMED - The state where the content of that memory region is valid and can be used. The access to that memory region is in some way . For example, it is not allowed to modify the memory content. The type of restriction might differ from memory region to memory region. The CONFIRMED confirmation code value is $57B5_327F_H$
Configurable write protection
The removable protection of PFLASH Logical Sector against any NVM operation that can change its content. The write protection is configured in a special UCB and can be removed by software using the password stored in this special UCB. The granularity of the configurable write protection can be selected to be entire PFLASH region or individual PFLASH Banks.
CSRM channel, CSRM command interface
The request channel to execute NVM operations (excluding read operation). Per reset it is exclusive for the CSRM CPU unless the protection is bypassed by UCB setting. The CSRM channel requests are handled by the FSI_{CSRM}
Endurance
The maximum number of program or erase cycles of each flash cell is called "endurance". It is a statistical figure that depends on operating conditions, the use of the Flash cells, and the required quality level.
Erase counter
A special memory region to record the erase events.

(table continues...)

Table 359 (continued) General NVM terms

Erasing
The process of forcing a programmed Flash memory cell to the erased state. The erased state of the Flash cell is logical 0_B. The erased state is not necessarily an ECC codeword. Reading an erased page might result in ECC failures and an ECC correction might by applied. Complete Logical Sectors are erased. All Flash cells in this area incur one "cycle" that counts for the "endurance".
Flash embedded RISC (FLER)
A small processor in the FSI to control FSI operations. The µCode is executed on this processor.
Flash interface - flash standard interface (FSI)
The digital control logic to control the read accesses and any write or erase accesses to the NVM.
HOST channel, HOST command interface
The request channel to execute NVM operations (excluding read operation) mainly for the HOST standard processor(s) [or TriCore™s]. Per reset the HOST command channel access is set to CPU(0) but this can be changed to allow several other CPUs (including the CSRM CPU) access. The HOST channel requests are handled by the FSI_{HOST}
NVM bank idle state
The state where no read and no operation on that NVM Bank is running, and any new read or operation on that bank is possible.
NVM idle state
The state where no NVM read and no NVM operation is running and any new NVM read or new NVM operation is possible.
NVM operation
An operation that is targeting or ongoing at either: **1.** modifying **2.** analyzing the contents of the NVM **3.** changing the redundancy configuration of the NVM **4.** changing the state of the NVM Whenever a NVM operation is executed the FSI and the µCode are involved. ***Note**: 'Operation' means every function of the NVM except the read. Examples are Program and Erase, but also Verify, memory bit counting, integrity checks, or changing redundancy. It also means any operation that changes the status such as start-up, sleep, wake up, or shutdown for example.*
Program erase (p/e) cycle
A sequence consisting of one program and one erase (or vice-versa) in the NVM.
Programming
The programmed state of a Flash cell is logical 1_B. Changing an erased Flash cell to this state is called "programming".
Retention
This is the time during which the data of a Flash cell can be read reliably. The retention time is a statistical figure that depends on the operating conditions of the device (such as temperature profile) and is affected by operations on other flash cells in the same Wordline and physical sector. With an increased number of p/e cycles (see endurance) the retention may be impacted.

(table continues...)

Table 359 (continued) General NVM terms

Test mode
A special set of NVM operations to support the NVM test. Test mode operations are not available to the customer.
Test Pass Marker
The 32-bit value stored in the UCB_TEST; it is programmed to 80658383_H when all Infineon's production tests are passed. A production device with a Test Pass Marker value different than 80658383_H, is specified to be discarded. This is to prevent any possibility of an unknown fault in Infineon production or customer procurement process, resulting in an invalid device used by the customer. In such cases Infineon appreciates a notification.
µCode
Software that is executed on the FSI.
User mode
A well defined set of NVM operations that are provided to support common Flash functions like erase or program. In contrast to the Test Mode operations, all user mode functions are delivered to the custome r,although some user mode functions might be by the DMU. The (full set of) user mode NVM operations are available after NVM boot phase.
Verify
A process to check the programmed and erased state of Flash cells against a given p/e criteria. Different verify operations (Program Verify, Erase Verify, or Tight Margin Reads for example) are possible. This term shall be used as a collection term for all of these verify options.

5.3.3 NVM architecture terms

Definitions of some special terms related to the NVM architecture.

Table 360 NVM architecture terms

Flash module
A module that contains a Non-Volatile Memory (NVM) with its own digital control logic.
Block
A Block consists of multiple (but at least one) Banks physically grouped together. All Banks of a Block share a common "Block analog" region.
Bank
An NVM memory region with own address and read path. A Bank consists of *b* Physical Sectors. The whole NVM is divided into Banks. There are two different bank types: • PFLASH Bank: used for code or data • DFLASH Bank: used for data which is continuously changed during the application run (EEPROM emulation) Both Bank types have different configurations in terms of LOGSEC size, WL size, Page size, and ECC capabilities for example.
Segment
A segment consists of *s* Physical Sectors with the same Bitline redundancy.
Physical sector
A contiguous memory region within a Bank which has separate local bitlines. A Physical Sector consists of *m* Logical Sectors for code and data storage (where *m* depends on the Flash Bank type). A Physical Sector also contains *r* additional Logical Sectors for special purpose: • Redundant Logical Sectors • PFLASH: Erase Counter Logical Sector (only in one Physical Sector of a Bank)
Logical sector
The smallest erasable contiguous memory region within a Physical Sector. It consists of *w* consecutive Wordlines (where *w* depends on the Flash Bank type). In AURIX™ TC4xx a Logical Sector is equal to a Mini Sector. The Logical Sector, Mini Sector and Sector are effectively synonymous terms.
Mini sector
The Logical Sector, Mini Sector, and Sector are synonymous terms in AURIX™ TC4xx.
Sector
The Logical Sector, Mini Sector, and Sector are synonymous terms in AURIX™ TC4xx.
Wordline
A set of *p* consecutive Pages, where *p* depends on the Flash Bank type.
Page
A set of *b* consecutive bytes, where *b* depends on the Flash Bank type. It is the smallest unit that can be programmed. A Page consists of: • Data part that stores the customer data • ECC part that stores an Flash Bank type specific ECC checksum • A well-defined number of spare bits that can be used to repair defect bits within a Page (so-called Bitline redundancy) The exact dimension of these parts depend on the Flash Bank type.

The following figure depicts the relationship between the NVM architecture terms.

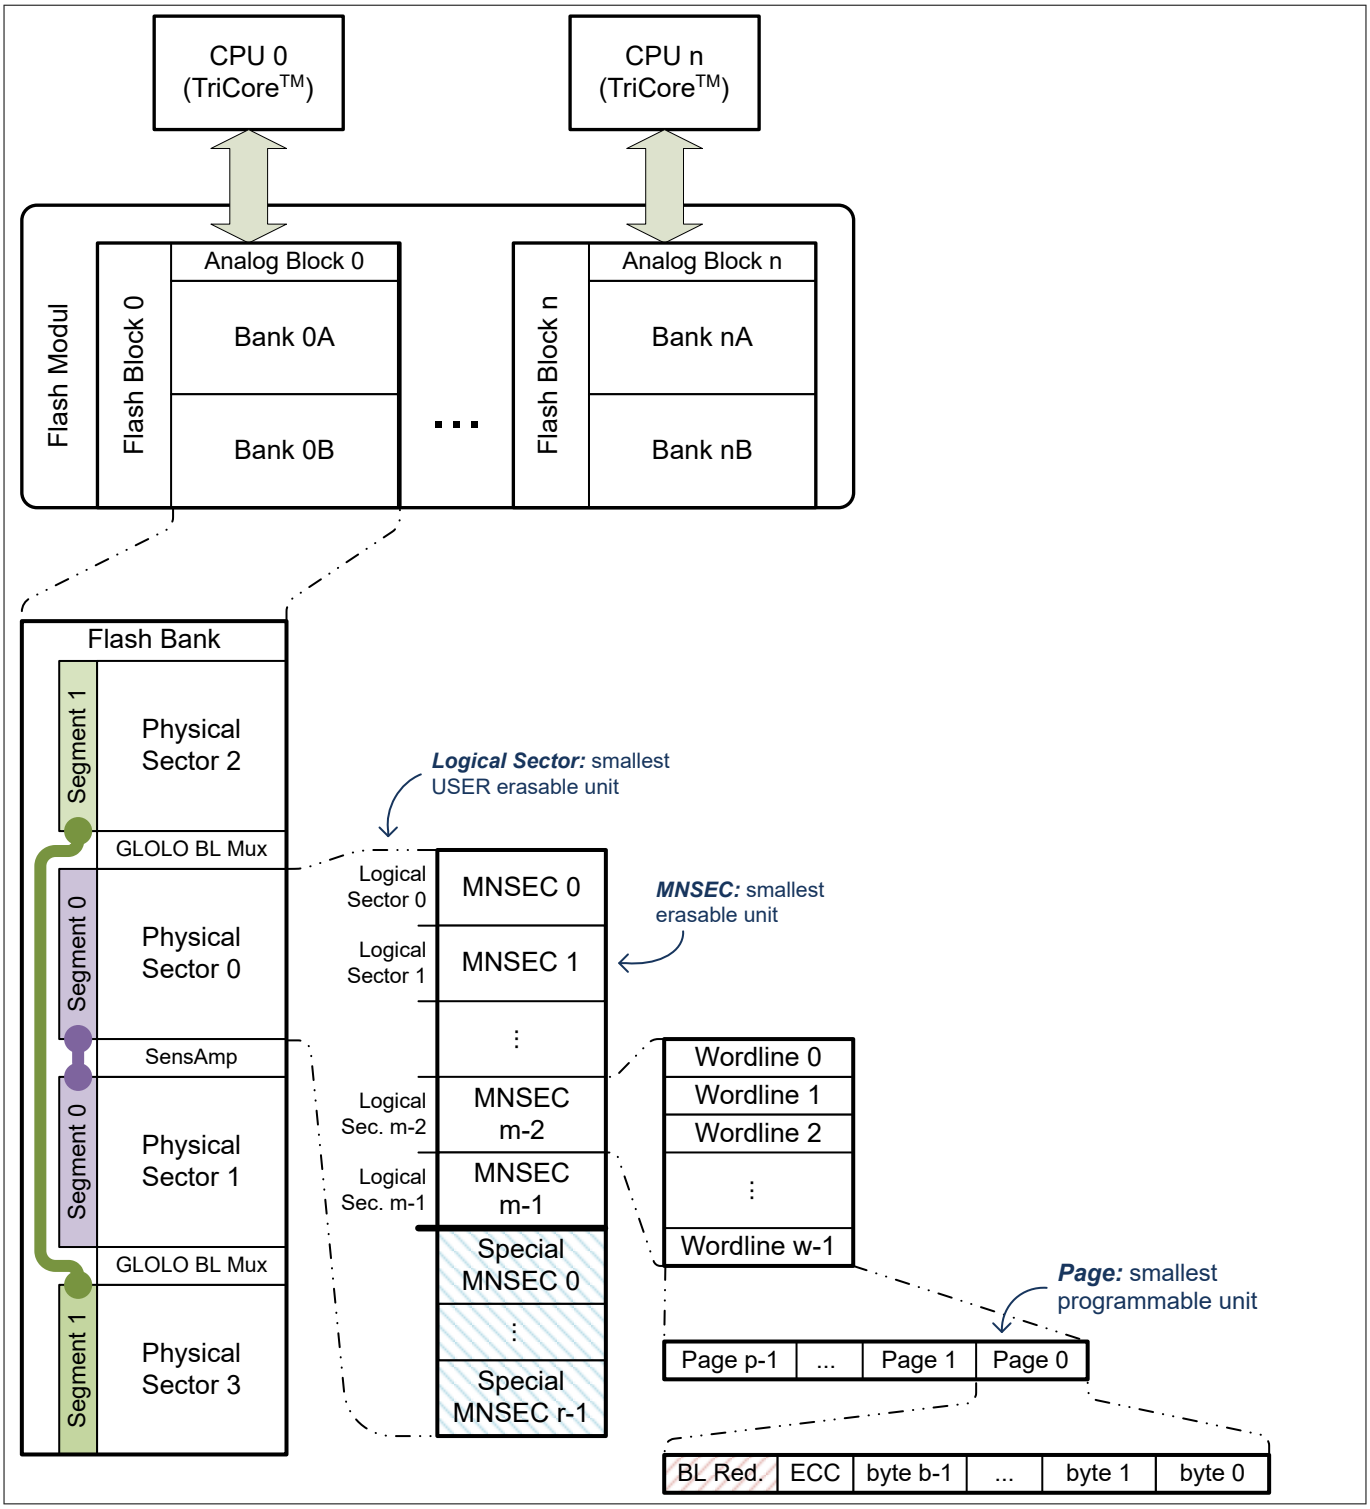

Figure 37 Logical structure of flash memory

CFTM
CPU Flash Test Mode
CSRM
Cyber Security Real Time Module
DECTED
Double Error Correcting, Triple Error Detecting
DF or DFLASH
Data Flash or Data Memory In the AURIX™ 3rd Generation family of products, the NVM distinguishes between HOST and CSRM Data Flashes, so the following refinement is introduced: • $DFLASH_{CSRM}$ or CSRM DFLASH or csDFLASH - Describes a DFLASH that belongs to the CSRM domain • $DFLASH_{HOST}$ or HOST DFLASH - A DFLASH that belongs to the HOST domain Using the abbreviation DF or DFLASH without an additional domain extension addresses both domains. Enumeration of Data Flashes is performed using the following syntax: • DFLASH(x) or $DFLASH_{CSRM}$(x), where *x* is either a placeholder for all available Data Flashes or a dedicated decimal number that identifies a specific Flash Bank. The following figure illustrates the enumeration using the current POR. Since only one Bank is planned per domain, most of the names are equivalent

Table 361 (continued) NVM abbreviations

PF or PFLASH
Program Flash or Program Memory In the AURIX™ 3rd Generation product family, the NVM functional block distinguishes between HOST and CSRM Program Flashes, so the following refinement is introduced: • $PFLASH_{CSRM}$/CSRM PFLASH/csPFLASH - Describes a PFLASH that belongs to the CSRM domain • $PFLASH_{HOST}$/HOST PFLASH - A PFLASH that belongs to the HOST domain Using the abbreviation PF or PFLASH without an additional domain extension addresses both domains. Enumeration of Program Flashes is carried out using the following syntax: • PFLASH(x) or $PFLASH_{HOST}$(x): where *x* is either a placeholder for all available Program Flashes or a dedicated identifier that identifies a specific Flash Bank. Since a PFLASH Bank is part of a Flash Block that usually consists of two Banks *A* and *B*, the unique identifier shall be expressed by *x=x'{A|B}*, where *x'* defines the unique ID of a Flash Block (corresponds to CPU ID). Example: $PFLASH_{HOST}$(x) means all HOST Program Flashes while $PFLASH_{HOST}$(0B) means the second PFLASH Bank of the first PFLASH Bock of the HOST domain

5.3.5 Flash structure

The following chapters describe the sector structure and addresses of the PFLASH - and DFLASH - Banks. Please also refer to chapter NVM architecture terms for a description of the micro-architecture within a Logical Sector (wordlines, pages, bitlines).

Related information

NVM architecture terms on page 650

5.3.5.1 Program flash banks

Sector structure

All PFLASH Banks PFp are based on the same sector structure.

There are different sizes of PFp Banks available. The PFp Banks implement the following sector structure:

- 2 Mbyte Program Flash Bank PFp implements logical sectors S0 to S127
- 1 Mbyte Program Flash Bank PFp implements logical sectors S0 to S63

Table 362 Sector structure of PFp

Logical sector	Physical sector	Offset address	Size	Total
S0	PS0	$00'0000_H$	16 Kbyte	16 Kbyte
S1		$00'4000_H$	16 Kbyte	32 Kbyte
S2		$00'8000_H$	16 Kbyte	48 Kbyte
...		...	...	...
S30		$07'8000_H$	16 Kbyte	496 Kbyte
S31		$07'C000_H$	16 Kbyte	512 Kbyte
S32	PS1	$08'0000_H$	16 Kbyte	528 Kbyte
S33		$08'4000_H$	16 Kbyte	544 Kbyte
S34		$08'8000_H$	16 Kbyte	560 Kbyte
...		...	...	...
S62		$0F'8000_H$	16 Kbyte	1008 Kbyte
S63		$0F'C000_H$	16 Kbyte	1024 Kbyte
S64	PS2	$10'0000_H$	16 Kbyte	1040 Kbyte
S65		$10'4000_H$	16 Kbyte	1056 Kbyte
...		...	...	...
S94		$17'8000_H$	16 Kbyte	1520 Kbyte
S95		$17'C000_H$	16 Kbyte	1536 Kbyte
S96	PS3	$18'0000_H$	16 Kbyte	1552 Kbyte
S97		$18'4000_H$	16 Kbyte	1568 Kbyte
...		...	...	...
S126		$1F'8000_H$	16 Kbyte	2032 Kbyte
S127		$1F'C000_H$	16 Kbyte	2048 byte

***Note**: As option there are also 512 Kbyte Banks planned for certain products.*

Please refer to the system memory map for an overview of how many 2 Mbyte and 1 Mbyte Banks are available for a product and the Bank addresses.

Security code PFLASH bank

There is a separate Program Flash Bank for the Cyber Security CPU.

5.3.5.2 Data flash banks

The AURIX™ TC4x has 2 different Data Flash Banks which are used for different purposes. The following table shows the two banks and namings which can be used as synonyms.

Table 363 Data flash banks

Bank	Synonyms	Available sizes	Used for
DFLASH(0)	DFLASH(HOST), DF(0)	1024 Kbyte, 512 Kbyte, 128 Kbyte	Data, EEPROM emulation for the HOST application
DFLASH(1)	DFLASH(CSRM), DF(1)	128 Kbyte	Data, EEPROM emulation for the CSRM security application

***Note**: The size of a DFLASH Bank is set according to its EEPROM region size (see below).*

***Note**: Access rights for the DFLASH(1) Bank are usually set to the security CPU only. For initial factory programming this can be bypassed by UCB but shall be set for normal operation. Please refer to the description of the chapter about protection for further details.*

A data flash bank consists of 3 parts, which are explained in the following table.

Table 364 Data flash bank parts

Memory region	Description
EEPROM Region	Data flash region which can be used to store data during application run and to emulate an EEPROM
UCB Region	User Configuration Blocks
Config Sector Region (CFS)	Storage of device configuration data (recovered during start-up), not accessible for normal operation

There are different sizes of DFp Banks available. The size of UCB and CFS regions are always the same but the size of the actual EEPROM region differs and is use as classifier of the Bank; for example: a "1 MB" DFLASH Bank contains an EEPROM region of 1 MB but contains also additional regions for UCB and CFS (for the UCB sizes please refer to the UCB description).

The EEPROM region of the DFp Banks implement the following sector structure:

- 1 Mbyte data flash bank DFp implement logical sectors EEPROM0 to EEPROM511
- 512 Kbyte data flash bank DFp implement logical sectors EEPROM0 to EEPROM255

Data flash banks ≥ 256 Kbyte have 128 Kbyte physical sectors and 2 Kbyte logical sectors. Smaller data flash banks have 64 Kbyte physical sectors and 2 Kbyte logical sectors.

Table 365 Sector structure of EEPROM region of a DFLASH bank of 1 Mbyte

Logical sector	Physical sector (128 Kbyte)	Offset address EEPROM region	Size	Total
EEPROM0	PS0	$00'0000_H$	2 Kbyte	2 Kbyte

5.3.5.3 Logical sector

A logical sector is the smallest erasable contiguous memory region within a Physical Sector. It consists of *w* consecutive wordlines. Each wordline has *p* consecutive Pages; a Page is the smallest unit that can be programmed using the `Write Page` command. The size of the logical sector, its number of wordlines and pages per wordline depend on the Bank type (PFLASH or DFLASH).

Table 368 Logical sector structure

Bank type	Logical sector size [Kbyte]	Number of wordlines	Wordline size [Byte]	Number of pages per wordline
PFLASH	16	16	1024	32
DFLASH	2	4	512	64

***Note**: one UCB in DFLASH has the same structure as a Logical Sector in DFLASH.*

Table 369 PFLASH logical sector offset addresses

Wordline	Offset address	Total size [Kbyte]
0	0000_H	1
1	0400_H	2
2	0800_H	3
..	...	
14	3800_H	15
15	$3C00_H$	16

Table 370 DFLASH logical sector offset addresses

Wordline	Offset address	Total size [Kbyte]
0	0000_H	0.5
1	0200_H	1
2	0400_H	1.5
3	0600_H	2

Table 371 PFLASH wordline offset addresses

Page	Offset address	Total size [Byte]
0	0000_H	32
1	0020_H	64
2	0040_H	96
..	...	
30	$03C0_H$	992
31	$03E0_H$	1024

Table 372 DFLASH wordline offset addresses

Page	Offset address	Total size [Byte]
0	0000_H	8
1	0008_H	16
2	0010_H	24
..	...	
62	$01F0_H$	504
63	$01F8_H$	512

5.3.5.4 Erase counters

For each PFLASH(PFp) Bank there is a dedicated Erase Counter(EC), which is an additional 16 Kbyte logical sector within each PFLASH(PFp) Bank, but belongs to a separate system address region (see system memory map). The erase counter is read-only in the application.

Erase logging

For every call of an “Erase Logical Sector Range” command sequence the NVM automatically records the logical sector start address and the number of logical sectors in a 256-bit log in the corresponding Erase Counter (ECp) memory region. The sector start address is not the system address, but the address of the selected logical sector in the local PFLASH Bank. For the address of the erase counter region please refer to the system memory map: the entry is "NVM.PFLASHxy (Erase Counter)" with x for CPU number and y = 0 or 1 for one of the 2 local PFLASH banks of a CPU.

The ECp 16 Kbyte erase counter supports the recording of 2 x 250 x 256-bit log entries. The Erase Counter area in each PFLASH is divided into two areas supporting 250 entries each - of which the first entry is pre-programmed and the remaining 249 entries are used to record erase operations. The first 250 entries from the Erase Counter base address is the Low priority area and the remaining is the High priority area. The user can assign priority to a logical sector in the PFLASH using the UCB_RTC_ECPRIO. When an erase encompassing at least one high priority logical sector is triggered, it is recorded in the high priority area of the Erase Counter. Otherwise, the erase is recorded in the low priority area. The first entry of each area is a pre-programmed ECC valid entry, and cannot be used for Erase Counter entries.

For TC4xx the erase counter region does not start at the start address of a 16 Kbyte logical sector but at page with offset address 0180_H (rationale: the memory range from offset address 0000_H to 0160_H is reserved).

Table 373 Erase counter logical sector structure

Page	Offset address	Purpose
0	0000_H	Reserved
1	0020_H	
..	..	..
3		
...		
10	0140_H	
11	0160_H	
12	0180_H	Erase Counter LowPrio Entry 0 (dummy entry to have valid ECC)
13	$01A0_H$	Erase Counter LowPrio Entry 1
		..
260	2080_H	Erase Counter LowPrio Entry 248
261	$20A0_H$	Last possible Erase Counter LowPrio Entry 249
262	$20C0_H$	Erase Counter HighPrio Entry 0 (dummy entry to have valid ECC)
263	$20E0_H$	Erase Counter HighPrio Entry 1
..	..	..
510	$3FC0_H$	Erase Counter HighPrio Entry 248
511	$3FE0_H$	Last possible Erase Counter HighPrio Entry 249

Each EC entry (including the first pre-programmed entry) has a 4 byte log marker. The marker is used to indicate the last valid EC entry. If the marker value of the entry is not equal to 0x00000000, the next EC entry is valid and can be read. If the marker value of entry is equal to 0x00000000, the last valid EC entry is reached. Thus, the next entry on address is empty (erased state) and shall not be read (would generate in most cases an uncorrectable error).

This is the reason why the first entry of a erase counter region is pre-programmed by Infineon during product test and cannot be used for erase counting. The next figure shows the erase counter structure and an application use case where a part of the erase counter entries has already been written due to customer or application erase requests.

Table 374 256-bit erase counter logging entry structure

Bits	Description
[31:0]	Marker (4 byte)
[55:32]	Start address of the first PFp logical sector (3 byte)
[63:56]	Number of logical sectors erased (1 byte)
[255:64]	Reserved

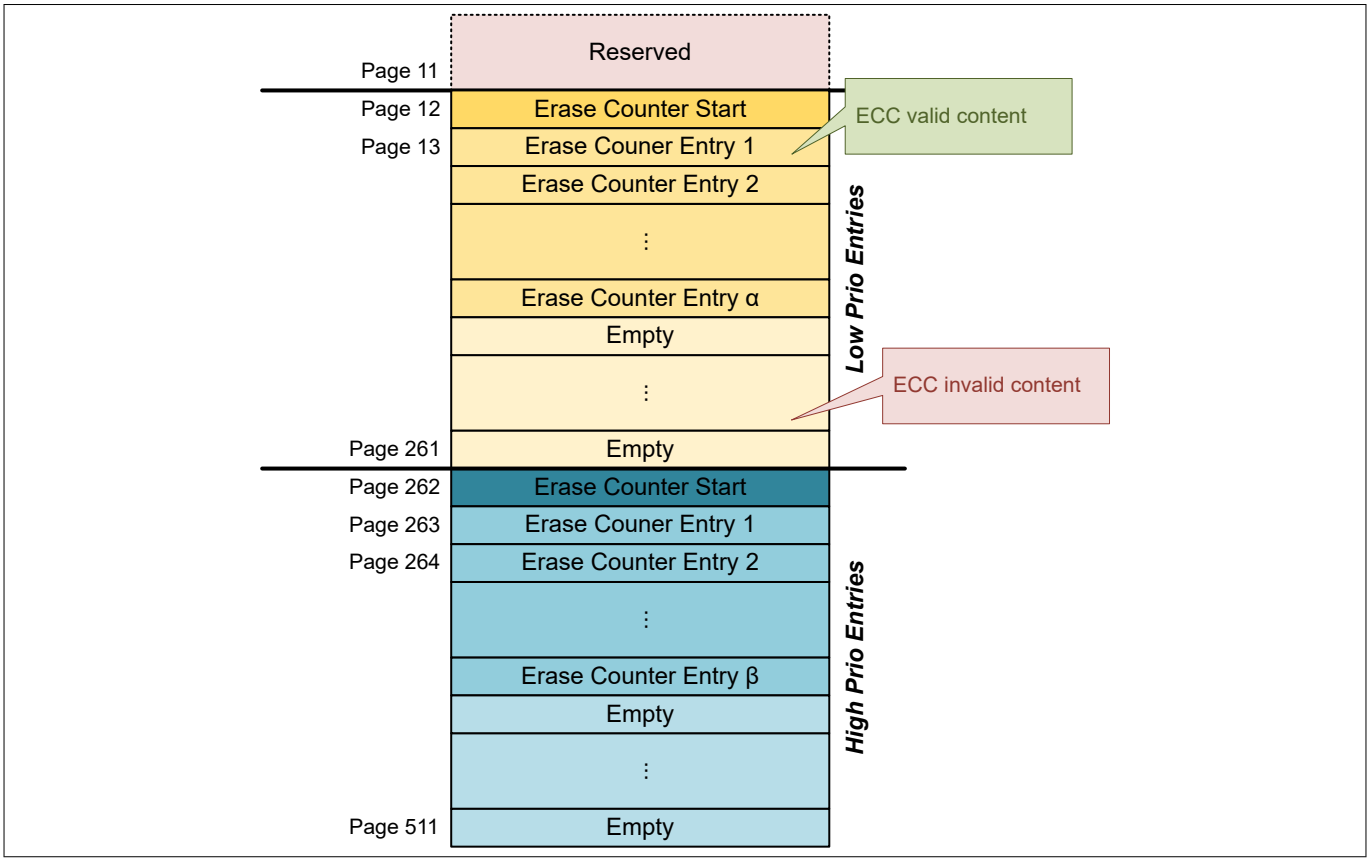

Figure 40 Erase counter structure and use case

Erase counter access

Erase counters can be read by any bus master that has the rights to read the associated PFLASH bank. All reads are performed by the local CPU through the connected flash interface. All other flash operations on the Erase Counter regions fail with an ERROR (see command sequence chapter for more details).

Erase counter registers and configuration

For each logical sector of a PFLASH Bank it is possible to configure it as "low"- or "high"-priority sector for erase counter monitoring. The DMU registers DMU_GP_HOST_PFECPRIOpXn show the settings. The following table explains the "pXn" indexing of the registers:

Table 375 Indexing of bank registers

Index	Description
p	Number of CPU
X	= A or =B for Bank A or Bank B of a CPU
n	Number of physical sector: for a 2 MB Bank n = (0..3) for 4 physical sectors with each having 32 logical sectors (=> 32 bits of register)

The registers DMU_GP_HOST_PFECPRIOpXn are read only and are read after a reset by the DMU from the UCB_RTC_ECPRIO_ORIG or UCB_RTC_ECPRIO_COPY. It is possible to change these UCBs by write or erase commands if the correct password has been applied using the `Disable Protection` command. Please refer to the UCB address map overview chapter for the offset address of UCB and the offset addresses of UCB content, confirmation codes and passwords.

The following table shows an example for the erase counter priority registers for the Bank B of CPU(1):

Table 376 Example of ECPRIO registers for bank B of CPU(1)

Register	High or Low priority settings for
DMU_GP_HOST_PFECPRIO1B0	logical sectors 0..31
DMU_GP_HOST_PFECPRIO1B1	logical sectors 31..63
DMU_GP_HOST_PFECPRIO1B2	logical sectors 64..95
DMU_GP_HOST_PFECPRIO1B3	logical sectors 96..127

CSRM specific erase counter registers and UCB

The erase counter settings for the PFLASH Bank of the CSRM are stored in the registers DMU_GP_CSRM_PFECPRIOn with n = (0..3). These registers are read only and are read after a reset by the DMU from the UCB_CS_ECPRIO_ORIG or UCB_CS_ECPRIO_COPY.

5.3.5.5 UCB

The AURIX™ TC4xx has two regions of UCB (User Configuration Blocks): one region in DFLASH(HOST) Bank and one region in DFLASH(CSRM) Bank.

Table 377 UCB memory regions

DFLASH bank	UCB	Size
DF(0):DFLASH(HOST)	NVM.UCB0	80 Kbyte
DF(1):DFLASH(CSRM)	NVM.UCB1	52 Kbyte

***Note**: please refer to the system memory map for the addresses of the UCB using the references NVM.UCBx mentioned in the table*

Master access restrictions

The following table lists the master access protections for the two UCB regions based on reset values of the APU registers.

Table 378 Master access protections of UCB memory regions

UCB	Read	Write
NVM.UCB0	all	CPU0
NVM.UCB1	CPUcs	CPUcs

***Note**: for a write access it is also necessary that the command interface (HOST or CSRM) may also be accessed by the master*

The access restriction may be bypassed by a specific setting of the APUBYPASS set within the UCB_CS_PFLASH_OTP0 of NVM.UCB1 which is recovered during startup by the DMU.

UCB specific access restrictions

In addition to the master access restrictions there are also additional restrictions concerning read and or write, which are UCB specific; for example UCB with passwords do not allow the read access to password region or UCB for permanent write protection do not allow erase once the UCB is in CONFIRMED state. Please refer to the description of the UCB for UCB specific read and write restrictions.

References to detailed UCB description

Please see the following reference for a detailed description of the UCB offset addresses and content: Chapter **Firmware → Registers**.

References to UCB handling and NVM UCB usage

The following list contains references to chapters describing the handling of the UCB and the usage of UCBs to store NVM block configuration settings like sector protection.

5.3.6 Read access

If the Flash Banks are in Read Mode then all flash read accesses are memory mapped reads. Read protection can be used to block a read.

5.3.6.1 Transaction types

Program flash

The transaction types for **local** CPU and **remote** CPU read accesses to a PFLASH are as follows:

Table 379 Local CPU read accesses to PFLASH

Local CPU access	Bus	Code fetch	Data constant
Cacheable address	DPI	Block Transfer 4 (BTR4)	Block Transfer 4 (BTR4)
Non-cacheable address	DPI	Block Transfer 4 (BTR4)	Minimum width

Table 380 Remote CPU read accesses to PFLASH

CPU access	Bus	Code fetch	Data constant
Cacheable address	SRI	Block Transfer 4 (BTR4)	Block Transfer 4 (BTR4)
Non-cacheable address	SRI	Block Transfer 4 (BTR4)	Minimum width

Data flash

Read accesses to DFLASH must be single transfers made across the SRI and are available only in the non-cacheable address range. A Block Transfer will result in a bus error.

5.3.6.2 Configuring read access cycles

Configuring PFLASH read access cycles

Read accesses to the PFLASH have an access delay setting counted with the f_{SRI} clock. The setting is defined in the DMU_GP_HOST_PFWAIT register.

In the datasheet the parameter t_{PF} defines the read access time to a PFLASH Bank in [ns]. This needs to be converted into a number of read cycles based on the actual **SRI** frequency using the formula mentioned in the table below.

Table 381 PFLASH read access cycle calculation

	Minimum value[1)]
PFLASH read cycles	Ceiling(t_{PF} * f_{SRI})

1) The Ceiling(r) function rounds up a real number, i.e., the result is the smallest integer not less than the real argument.

The "number of read cycles - 1" has to be programmed into the following register bit field: DMU_GP_HOST_PFWAIT.RFLASH

***Attention**: In case of using the frequency modulation of the clock the maximum frequency of the f_{SRI} clock has to enter the calculation. This could mean an additional wait cycle in worst case.*

PFLASH read cycles example

Example configurations with different SRI clock frequencies are shown in the table below.

Table 382 Example configurations for PFLASH read access time in DMU_GP_HOST_PFWAIT.RFLASH

Read access time t_{PF}	**f_{SRI} MAX [MHz]**	**Frequency modulation (MA = 2%)**	**Read cycles**	**Wait states**
15	400	OFF	6	5
15	408	ON	7	6
15	450	OFF	7	6
15	459	ON	7	6
15	500	OFF	8	7
15	510	ON	8	7

***Attention**: Values mentioned in the previous table are meant as examples. Please refer to the actual product datasheet for applicable values of t_{PF} and f_{SRI}.*

Configuring DFLASH read access cycles

Read accesses to the DFLASH have an access delay setting counted with the f_{FSI} clock. The setting is defined in the DMU_GP_HOST_DFWAIT register.

In the datasheet the parameter t_{DF} defines the read access time to a DFLASH Bank in [ns]. This needs to be converted into a number of read cycles based on the actual **FSI** frequency using the formula mentioned in the table below.

Table 383 DFLASH read access cycle calculation

	Minimum value[1)]
DFLASH read cycles	Ceiling(t_{DF} * f_{FSI})

1) The Ceiling(r) function rounds up a real number, i.e., the result is the smallest integer not less than the real argument.

The "number of read cycles - 1" has to be programmed into the following register bit field: DMU_GP_HOST_DFWAIT.RFLASH

***Attention**: In case of using the frequency modulation of the clock the maximum frequency of the f_{SRI} clock has to enter the calculation. This could mean an additional wait cycle in worst case.*

DFLASH read cycles example

Example configurations with different FSI clock frequencies are shown in the table below.

Table 384 Example configurations for DFLASH read access time in DMU_GP_HOST_DFWAIT.RFLASH

Read access time t_{DF}	**f_{FSI} MAX [MHz]**	**Frequency modulation (MA = 2%)**	**Read cycles**	**Wait states**
50	100	OFF	5	4
50	102	ON	6	5
50	112.5	OFF	6	5
50	114.75	ON	6	6

***Attention**: Values mentioned in the previous table are meant as examples. Please refer to the actual product datasheet for applicable values of t_{DF} and f_{FSI}.*

Separate wait state settings for the security memory banks

For the security memory Banks there is a separate setting of wait states necessary in the following registers:

Table 385 Wait state settings for the security memory banks

Bank	**Wait state setting in register**
CSRM PFLASH	DMU_GP_CSRM_PFWAIT
CSRM DFLASH (DF(1))	DMU_GP_CSRM_DFWAIT

***Attention**: please check the SRI clock settings for the cyber security real time module (CSRM) from which the applicable wait state settings for the CSRM PFLASH can then be derived. For the CSRM DFLASH this is not an issue because the reference clock for CSRM -DFLASH reading is the FSI clock (same clock as used for HOST DFLASH reading).*

5.3.6.3 PFLASH ECC

Features

The ECC checksum is calculated over 256 data bits and the address bits. The ECC has the following features:

- Correction of 1-bit and 2-bit errors
- Detection of 100% of 1-bit, 2-bit and 3-bit errors
- Detection of >99% of all error vectors in the white noise error model
- Detection of >99% of all-0 and all-1 cases
- Detection of addressing errors

Per safety requirement the error correcting code detects all-0 and all-1 data as uncorrectable errors. Therefore reading from an erased Flash range results in uncorrectable error and also over-programming of Flash ranges with all-1 would create entries with uncorrectable ECC errors.

Please always refer to the device specific safety manual to find out which safety mechanisms of this functional block need to be considered for safety relevant applications.

PFLASH ECC control and error flags

The control and the status of the PFLASH ECC is done by the following PFRWB control and status registers:

- UR_FLASHCON2
- UR_ECCR
- UR_ECCS
- UR_SBABx
- UR_DBABx
- UR_UBABx

For each PFLASH Bank there is a separate set of these registers. The registers can be accessed by CPU; the base address can be found in the system address map at NVM.PFRWB**xy**.UR with:

- **x** = number of the CPU where these PFLASH Bank belongs to
- **y** = 0 for PFLASH Bank 0(A) or **y** = 1 for PFLASH Bank 1(B)

For the offset address of the register please refer to the Registers Overview - PFRWB chapter.

The ECC is automatically generated when programming the Flash. This can be disabled with bit field UR_FLASHCON2.ECCCORDIS. The disabling of the error correction can be selected per Bank as described above.

The ECC is automatically evaluated when reading data. Errors are only reported for 256-bit data blocks for which at least one byte is read by the CPU port.

An internal prefetch with ECC errors (1-bit, 2-bit or uncorrectable) is discarded and is not stored in the prefetch buffer. The ECC errors will not be recorded in status and error address buffer registers. Also a (potential) SMU alarm will not be triggered.

Besides the prefetch the flash interface does not know if the master uses the requested data or discards it (for example due to speculatively fetching code). Therefore speculatively fetched code or data gets an error response in case of a ECC error. This means an error flag setting in the ECC status registers and potentially also an SMU alarm (depending on error number and configuration).

Error reporting and ECC disabling:

- Single-bit error:
  - Is noted in register bit field UR_ECCS.SBER
  - Single Bit Error (SBER) alarm is generated
  - If UR_FLASHCON2.RECDIS = 0_B then the affected address is stored uniquely in the SBAB (see section below), if the SBAB buffer is full an additional safety alarm is generated
  - If UR_FLASHCON2.RECDIS = 1_B then no recording is done and no alarm is generated
  - Data and ECC value are corrected if this is not disabled with UR_FLASHCON2.ECCCORDIS[8)]

[8] Disabling the correction of errors with ECCCORDIS is a test feature. During application run-time the correction must be enabled.

- Double-bit error:
  - Is noted in register bit field UR_ECCS.DBER
  - Double Bit Error (DBER) alarm is generated
  - If UR_FLASHCON2.RECDIS = 0_B then the affected address is stored uniquely in the DBAB (see section below), if the DBAB buffer is full an additional safety alarm is generated
  - If UR_FLASHCON2.RECDIS = 1_B then no recording is done and no alarm is generated
  - Data and ECC value are corrected if this is not disabled UR_FLASHCON2.ECCCORDIS
- Uncorrectable error:
  - Is noted in register bit field UR_ECCS.UCER
  - Causes a bus error
  - If UR_FLASHCON2.RECDIS = 0_B then the affected address is stored uniquely in the UBAB (see section below), if the UBAB buffer is full an additional safety alarm is generated
  - If UR_FLASHCON2.RECDIS = 1_B then no recording is done and no alarm is generated

***Note**: In the UR_ECCS register there are additional status bits available: for example all-0 bit error or accumulated single bit error; please refer to the description of the register for further details.*

Error address buffers SBAB, DBAB and UBAB

If UR_FLASHCON2.RECDIS = 0_B then the affected address is stored uniquely in one of the error address buffers:

Table 386 PFLASH ECC error address buffers

Address buffer	Description
SBABx	address storage for page(s) with correctable single bit errors
DBABx	address storage for page(s) with correctable double bit errors
UBABx	address storage for page(s) with uncorrectable double bit errors

For a description of the address buffers please refer to the register descriptions in the Registers Overview - PFRWB chapter.

For a description of the safety alarms and how to handle these alarms please refer to the safety description: safety mechanism: SM[HW]:NVM:PFLASH_ERROR_MANAGEMENT

Related information

Write page on page 696

5.3.6.4 DFLASH ECC

Features

The ECC is calculated over 64 data bits. Addressing faults (correct data is read from an incorrect address) cannot be detected. The ECC has the following features:

- Correction of 1-bit, 2-bit and 3-bit errors
- Detection of 100% of 1-bit, 2-bit, 3-bit and 4-bit errors
- Detection of >90% of all error vectors in the white noise error model
- All-0 and all-1 data is a valid ECC word

An erased Flash range delivers ECC correct all-0 data. Over-programming with all-1 results in ECC correct all-1 data.

***Attention**: over-programming already existing data in DFLASH is allowed but only to a limited number; please refer to the datasheet parameters ND_PAGE_OVERWR and ND_LOGSEC_BL_PROG.*

DFLASH ECC control and error flags

The control and the status of the DFLASH ECC is done by the following DMU control and status registers:

- HOST DFLASH (DFLASH(0))
  - DMU_GP_HOST_DFECCC
  - DMU_GP_HOST_DFECCS
  - DMU_GP_HOST_DFECCR
  - DMU_GP_HOST_DFECCW
- CSRM DFLASH (DFLASH(1))
  - DMU_GP_CSRM_DFECCC
  - DMU_GP_CSRM_DFECCS
  - DMU_GP_CSRM_DFECCR
  - DMU_GP_CSRM_DFECCW

The registers can be accessed by CPU; the base address can be found in the system address map at NVM.DMU.

For the offset address of the register please refer to the Registers Overview - DMU .

The ECC is automatically generated when programming the Flash. This can be disabled with bit field GP_HOST_DFECCC.ECCCORDIS and GP_CSRM_DFECCC.ECCCORDIS.

The ECC is automatically evaluated when reading data. Errors are only reported for 64-bit data blocks for which at least one byte is read.

Error reporting:

The following ECC error flags are available:

Table 387 DFLASH ECC error flags

Error flag	Description
SBER	Single Bit ECC error
DBER	Double Bit ECC error
TBER	Triple Bit ECC error
UCER	Uncorrectable ECC error
ANER	Any ECC error

In addition for all of these flags also an "accumulated" error flag is available, for example the flag **A**SBER, which reports that at least one single bit error was found in the read accesses since the last reset or clear.

Related information

DFLASH read configuration protection on page 769

5.3.7 Command interfaces

All Flash operations except memory mapped reads are performed with command sequences.

A command sequence is done by a sequence of write accesses to a dedicated memory range of system address segment 15. The DMU has two command interfaces which can be accessed at two different addresses of segment 15:

- Host command interface
- CSRM command interface

Command sequences consist of 1 to 9 command cycles. The command sequence interpreter checks that a command cycle is correct in the current state of command interpretation, else a *Sequence Error (SQER)* is reported.

Triggering an NVM operation using the command sequences takes the DMU into **COMMAND MODE**. The DMU_HCI_STATUS .REQACK is set on the first cycle of a command sequence to acknowledge that a request was received (for CSRM Flash Banks see DMU_CSCI_STATUS.REQACK). During the execution of the command the DMU_HCI_STATUS.BUSYx of the Banks under operation are set (for CSRM Flash Banks see DMU_CSCI_STATUS.BUSYx). In this mode read accesses to a Flash Bank are refused with a *Bus Error* or the ready is suppressed until BUSY clears (see section about "stall function" below).

Upon BUSY assertion the PFI of the CPU invalidates all prefetch and data buffer.

Code that performs any NVM operation on a PFLASH Bank must be executed from an other PFLASH Bank or from SRAM. This is valid for any command executed by the DMU: not only for program or erase commands but also for data integrity check commands like `Verify Erased Logical Sector Range`.

At the end of a flash operation the Flash bank clears the BUSY bit and read accesses are enabled.

The end of the command sequence is signaled by the bit DMU_HCI_STATUS.REQDONE set to 1_B (HOST command interface). Only after this it is possible to apply a new command sequence. For the CSRM command interface the bit DMU_CSCI_STATUS.REQDONE need to be checked.

The command sequence interpreter reports a *sequence error* by setting SQER bit or a *protection error* by setting PROER bit in the command interface error registers DMU_HCI_ERR (for HOST command interface) or DMU_CSCI_ERR (for CSRM command interface). Then the command sequence interpreter is in **ERROR MODE** and a `Reset to Read` command is necessary to reset the command interpreter.

***Note**: In the following chapters the terms "command interface" and "command channel" will be used interchangeably.*

Using CPU stall function

Using the CPU register PFIy_FLASHCON1.STALL = 1_B is not recommended for normal use because the stalled CPU is inoperable. This feature shall only be used under controlled conditions by a Flash loader.

Attention**: **Using the CPU register PFIy_FLASHCON1.STALL = 1_B together with Flash Sleep (on affected Banks) is forbidden as it might lead to device hang-up.

Command sequences on page 689
Host command interface on page 679
CSRM command interface on page 679

5.3.7.1 Host command interface

- The host command sequence interpreter is accessed by write accesses to the NVM.DMU (Host command sequence interpreter) F808 0000_H - F808 $FFFF_H$ address range in the memory map segment 15
- A on chip bus master may perform command sequences using the host command interface if this is allowed by the access enable protection settings (APU)
- Reports status and errors in DMU_HCI_STATUS and DMU_HCI_ERR
- Own assembly buffer for programming data

Related information

Command interfaces on page 678

5.3.7.2 CSRM command interface

- The CSRM command sequence interpreter is accessed by write accesses to the NVM.DMU (CSRM command sequence interpreter) F80C 0000_H - F80C $FFFF_H$ address range in the memory map segment 15
- A on chip bus master may perform command sequences via the CSRM command interface if this is allowed by the access enable protection settings (APU). Per RESET value these protection settings only allow access by the CSRM CPU
- Reports status and errors in DMU_CSCI_STATUS and DMU_CSCI_ERR
- Own assembly buffer for programming data

Related information

Command interfaces on page 678

5.3.7.3 Concurrent operations

Both command interfaces are independent from each other. They can issue command sequences independently and they have their "own" registers with status-, control- and error-flags.

TC4xx allows a **true** parallel operation on both command interfaces. The following example is a possible concurrent operation scenario:

- Write page on DFLASH(HOST)
- Erase on DFLASH(CSRM)

Attention**: **two parallel NVM operations lead to increased current consumption on the VDDEXT supply. It is possible to reduce the current consumption in field while still taking benefit of this true parallel operation capability by using write operations which split the program pulse into several pulses (see the description in the related information).

Write settings on page 739

5.3.7.4 Allocation of banks to command interfaces

Each Command Interface allows NVM Operations on a subset of NVM PFLASH and DFLASH **Banks**. The following table shows this allocation.

Table 388 Allocation of NVM banks to the command interfaces

DMU command interface mode	Host command interface	CSRM command interface
Domain Mode	HOST PFLASH PFx HOST DFLASH DF(0)	CSRM PFLASH CSRM DFLASH DF(1)
CSRM_ALL_PFLASH Mode	HOST DFLASH DF(0)	CSRM PFLASH CSRM DFLASH DF(1) HOST PFLASH PF(x)

***Note**: The DEFAULT mode after start-up is domain mode.*

***Note**: A change of the modes can be done by the `Bank Reallocation` command sequence.*

A Bank may only be allocated to one command interface. The modes shown above are the only allowed settings.

Command sequences on allocated memory banks

A NVM operation by a command interface is possible to those Banks which are allocated to that command interface.

The access to the command interface alone is not sufficient. In addition it is necessary that the accen registers for the memory banks are also set to enable the master access. For further details please refer to the Access Protection chapter.

The following sections show graphical representations of the table above. Please note that the access lines from HOST and from CSRM CPUs to the command interfaces show examples for allowed accesses. For an overview of the protection settings and how to change them please refer to the related information mentioned at the end of the chapter.

Domain mode

This is the default mode after start-up. The allocation of the banks to the command interfaces matches with the separation of the domains:

- All HOST memories are allocated to the HOST command interface
- All security memories are allocated to the CSRM command interface

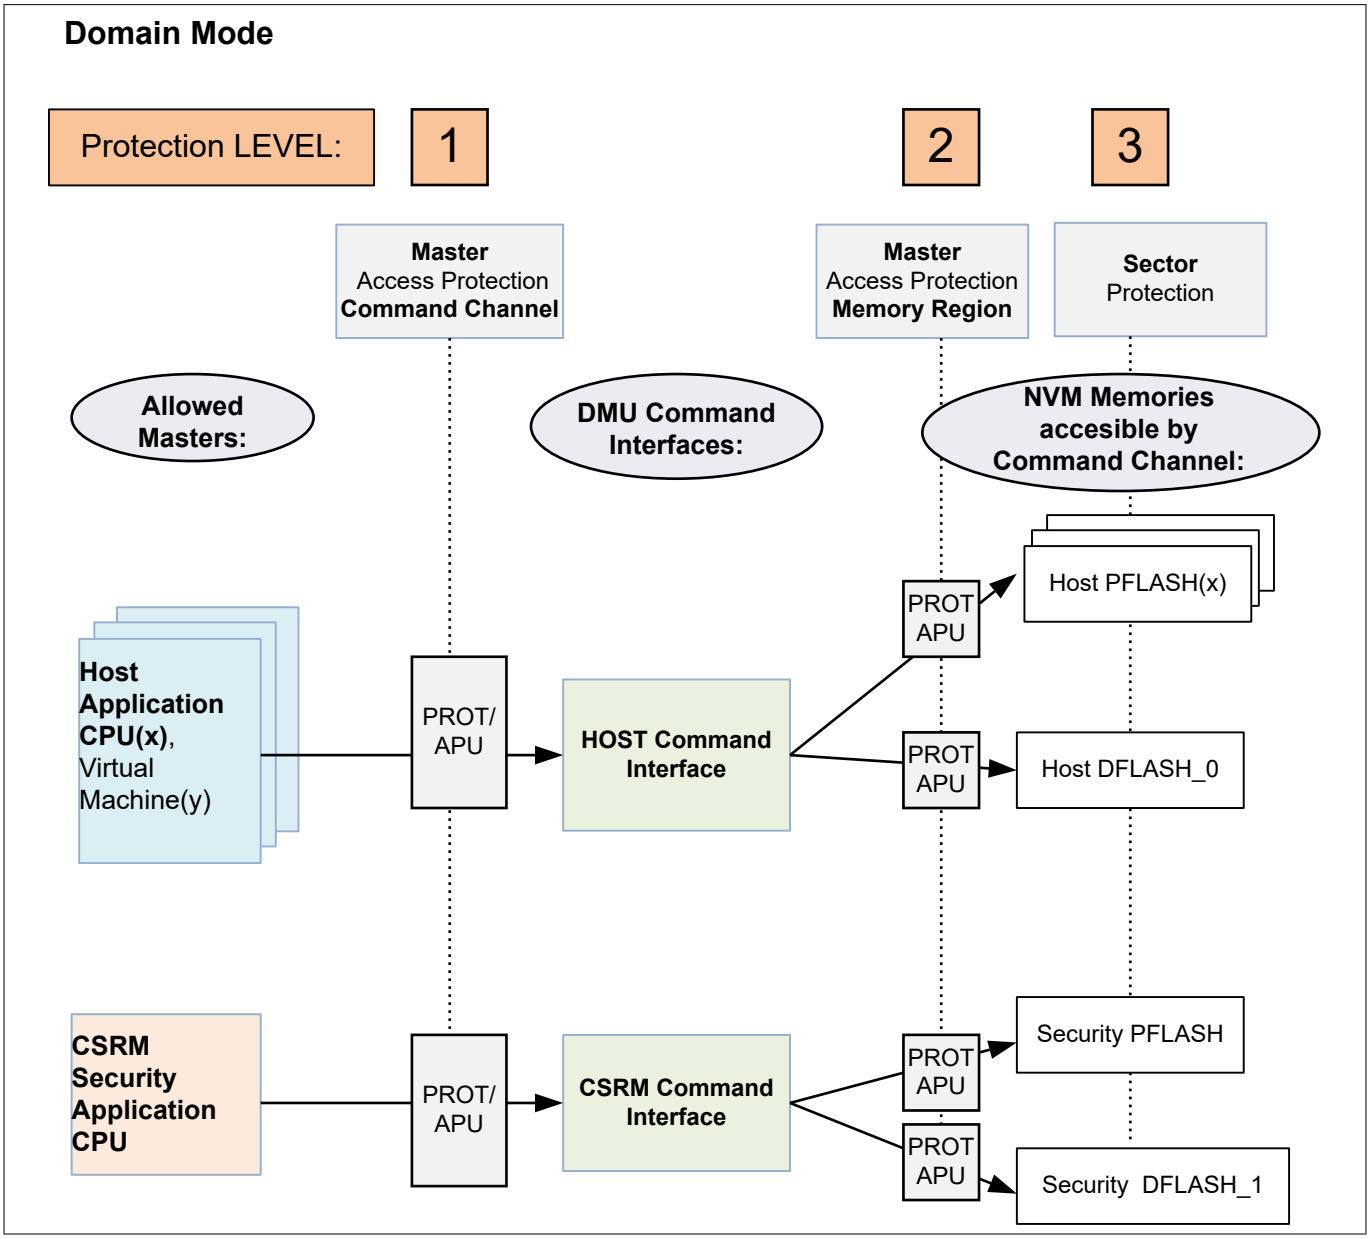

Figure 41 Domain mode

The preceding figure shows the default allocation of memory banks to the command interfaces. The access from different CPUs to the command interfaces is also shown. This CPU → command interface access is not a hardware configuration but is possible to adapt by setting the APU or accen registers.

CSRM_ALL_PFLASH mode

In this mode only the DFLASH(HOST) is allocated to the HOST command interface. All the other Banks are allocated to the CSRM command interface.

This mode is beneficial for concurrent operations on different Bank types. A possible use case is the EEPROM emulation on DFLASH(HOST)) and concurrent updates of PFLASH (HOST) for SOTA purpose. For this use case the security software running on CSRM CPU could do the prog or erase operations on the PFLASH Banks while the EEPROM software may be operated on a HOST CPU and perform prog or erase operations on the DFLASH(HOST) by the HOST command interface.

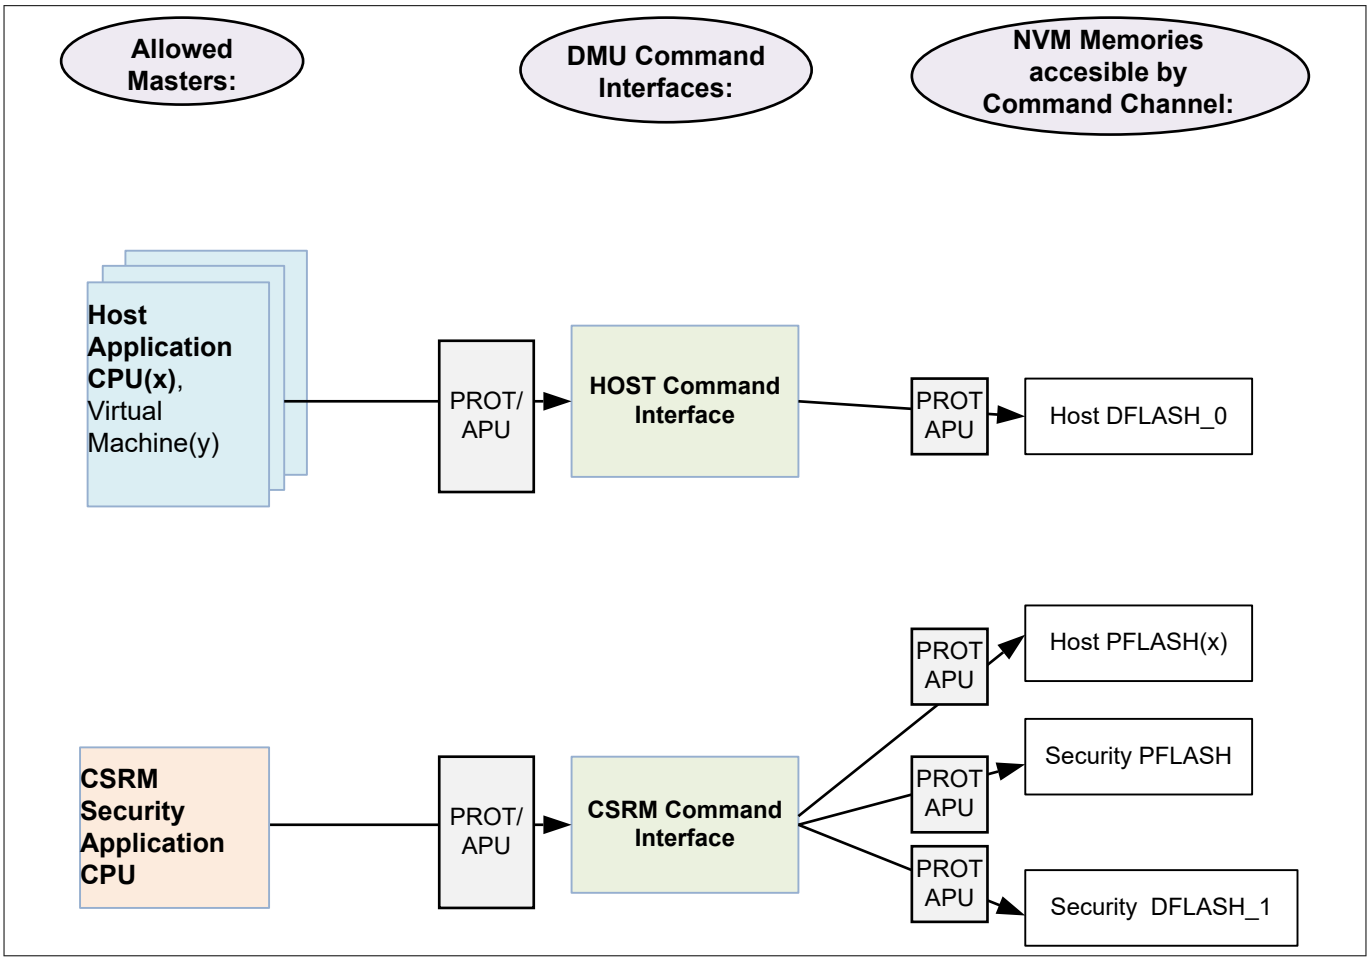

Figure 42 CSRM_ALL_PFLASH mode

Status bits of PFLASH(HOST) banks during the CSRM_ALL_PFLASH mode

If the PFLASH(HOST) Banks are allocated to the CSRM command interface then the status bits for BUSY and SLEEP states for these Banks are updated only in the CSRM status registers (see the following table). Status bits of these Banks in the HOST status registers are not updated.

To enable an interrupt correlated with a NVM operation on the PFLASH (HOST) banks it is also necessary to use the CSCI_INTEN register.

Also any other control setting or error status information for operations on PFLASH(HOST) memories shall be set or checked in the corresponding CSRM control or status registers (for example CSCI_ERR or CSCI_OCONTROL.

Table 389 CSRM command interface registers

Register	Use
DMU_CSCI_STATUS	Status, BUSY indication
DMU_CSCI_ERR	Error flags

CPUcs access to HOST memories

There are two possibilities to grant the CPUcs command access to the HOST memories:

1. CSRM_ALL_PFLASH mode
2. DOMAIN Mode and CPUcs gets access to the HOST command interface

Access to the command interface alone is not sufficient. In addition it is necessary that the accen registers for the PFLASH (HOST) are also set to enable CPUcs access.

Bank reallocation on page 735
Operation protection overview on page 759

5.3.7.5 Command interface modes

A command interface may be in one of the following states (also called "modes" in other chapters):

- IDLE MODE
- COMMAND MODE
- PAGE MODE
- ERROR MODE

IDLE MODE

During this mode there is no NVM operation ongoing. All NVM Banks may be read (with the exception of Banks which had been sent to SLEEP). A new command sequence may be applied to the command interface.

COMMAND MODE

This mode is started by a command sequence to the NVM. During this mode a NVM operation like write or erase is performed on NVM Bank(s). During the operation on a Bank the BUSY flag of that Bank is set and that Bank cannot be read. The CPU stall setting determines the behavior if a BUSY PFLASH Bank is read. Read access to a BUSY DFLASH Bank always generates a bus error.

PAGE MODE

The command interface must be in PAGE MODE to:

- Load write data in an assembly buffer
- Support a `Write` command to write assembly buffer data in the Flash

The PAGE MODE is started by a `Enter Page Mode` command sequence.

The PAGE MODE is left by any `Write` command sequence; for example `Write Page` command. The PAGE MODE is also left if the subsequent Write command is aborted. The PAGE MODE is also aborted by a `Reset to Read` command.

ERROR MODE

The command interface is in ERROR MODE if a *Sequence Error (SQER)* or a *Protection Error (PROER)*occurs. In this mode the command interface does not accept new commands except `Reset to Read`..

It is necessary to perform a `Reset to Read` command to get the command interface back to IDLE MODE.

OPERATION ERROR MODE

OPERATION ERROR MODE is entered when there is an *Operation Error (OPER)*. In this case the following happens:

- An on-going NVM operation is aborted
- The BUSY flags of bank(s) under operation stay HIGH
- The read of the other banks is not impaired
- All further commands are rejected with *Sequence Error (SQER)*.

The OPERATION ERROR MODE can only be left by a SYSTEM RESET.

Freedom of interference between both command interfaces

Both command interfaces (HOST, CSRM) are independent from each other which means that the one command interface may be in mode or state A while the other command interface may be in mode or state B; for example: HOST command interface may be IDLE while CSRM command interface is in PAGE MODE.

Error handling on page 685

5.3.7.6 Error handling

This chapter describes:

- Fault conditions
- New state or mode of NVM
- Proposed handling by software

for the following errors:

- *Sequence Error (SQER)*
- *Operation Error (OPER)*
- *Protection Error (PROER)*
- *Erase Verify Error (EVER)*
- *Program Verify Error (PVER)*
- *Original Error (ORIER)*

These errors are reported by the NVM by setting the corresponding bit in the command interface error registers:

- HOST command interface error register DMU_HCI_ERR
- CSRM command interface error register DMU_CSCI_ERR

Sequence error (SQER)

Fault conditions:

- Improper command cycle address or data, that means incorrect command sequence
- New `Enter Page Mode` in **PAGE MODE**
- `Load Page` and not in **PAGE MODE**
- `Load Page` with mixed 32-bit or 64-bit transfers
- `Load Page` with invalid operation code (operation code must be SDTD or SDTW)
- For a 32-bit transfer the first `Load Page` addresses the upper 32-bit word
- Write commands when the assembly buffer contains no data, to few data or too much data was transferred
- Write commands not in **PAGE MODE**
- All commands to unavailable Flash range (for example: Flash range does not physically exist)
- Command sequence with address not aligned to a legal start address (for example page, UCB or logical sector)
- Command sequence not pointing to a PFLASH, DFLASH0(EEPROM), DFLASH0(UCB) or DFLASH1(EEPROM), DFLASH1(UCB) address
- A command sequence to the Configuration Sector (CFS)
- A command sequence to the Erase Counters
- `Write Page Once` targeting DFLASH
- `Write Burst Once` targeting DFLASH
- `Erase Logical Sector Range` or `Verify Erased Logical Sector Range` with range violating the Bank address boundaries
- Any command to a Bank in SLEEP state except a Bank wake-up command
- Unsupported command sequence for ERROR MODE

New state:

The command interface enters **ERROR MODE** and does not accept new commands except `Reset to Read`.

Proposed handling by software:

Usually this bit is only set due to a bug in the software. Therefore in development code the responsible error tracer shall be notified. In production code this error shall not occur.

It is necessary to perform the command `Reset to Read` to get the command interface back to **IDLE MODE**.

Operation error (OPER)

Fault conditions:

The FSI may report an OPER at any time. Possible causes include:

- Double-bit ECC error detected while executing microcode out of FSI SRAM
- Transient event due to alpha-particles or illegal operating conditions
- Permanent error due to a hardware defect

The probability for these faults is very low.

New state:

The Flash operation is aborted and **OPERATION ERROR MODE** is entered.

Proposed handling by software:

The last operation can be determined from the flags in the status registers (for example PROG) flag. In case of an erase operation the affected physical sector must be assumed to be in an invalid state, in case of a program operation only the affected page (or pages in case of `Write Burst` commands. Other physical sectors can still be read. New program or erase commands must not be issued before the next reset.

A system reset must be applied to perform a new Flash startup with initialization of the FSI SRAM and clear the OPER flag. The application must determine from the context which operation failed and react accordingly: it is recommended to erase and rewrite the logical sector which was under operation when the OPER occurred.

Only in case of a permanent defective FSI SRAM or control logic the next operation after system reset will incur again this error.

Protection error (PROER)

Fault conditions:

- Password failure
- Erase or Write to protected sector
- Replace Logical Sector command to a protected sector
- `Erase Logical Sector Range` of UCB with active protection
- Write commands to UCB with active protection
- Verify commands to a protected sector:
  - `Verify Erased Page`, `Verify Erased Wordline`, `Verify Erased Logical Sector Range`
- User commands to a protected sector:
  - `User Margin Count`, `User Vth Count`, `User Content Count`
- During ramp-up if for any single and dual UCB both the ORIG and COPY confirmation codes are **ERRORED**

New state:

The protection violating command is not executed.

The command interface enters **ERROR MODE** and does not accept new commands except `Reset to Read`.

Proposed handling by software:

System integrator to select appropriate further action. It is necessary to perform the command `Reset to Read` to get the command interface back to **IDLE MODE**.

Erase verify error (EVER)

Fault conditions:

This flag is set in one of the following cases:

- `Erase Logical Sector Range` operation was not successful
- Standalone `Verify Erased Logical Sector Range`, `Verify Erased Page`, `Verify Erased Wordline` functions found errors
- `Replace Logical Sector` command did not find a free redundant sector to be used for repair
- `Write Page Once` or `Write Burst Once` functions found that targeted memory range is not erased

New state:

No state change. Just the EVER bit is set.

Proposed handling by software:

This flag can be cleared with the `Clear Status` command.

There are several possible reasons for the failure of an erase operation.

- Permanent or temporal voltage condition below the minimum specification (VDDEXT or VDD Core supply)
- Wrong device configuration
- Hard breakdown of an oxide within the NVM
- Erase in principle functional but the number of weakly erased cells is above a defined fault tolerance threshold level

The operating conditions shall always be checked with regards to voltage and temperature. A stable voltage supply during the whole time of the erase command must be maintained.

It is also recommended to repeat the Erase operation at least one time.

The following advice assumes that a repetition of the erase operation still shows an EVER flag and that the operating conditions and device configuration was correct.

It is possible to "repair" a failing logical sector by using the `Replace Logical Sector` command. For this 2 things are necessary:

- Ensure that there is still a free redundant mini sector for repair
- Identify the address of the failing logical sector

The `Count Free Redundant Sectors` command may be used to check if there are free redundant mini sectors available for a repair.

It is also necessary to identify the failing logical sector address. Usually an erase is done over a wider range: for example up to 256 KB erase size are allowed for Data Flash. It is possible to repeat the erase on smaller regions to make sure that all logical sectors are erased properly and the failing logical sector can be identified.

Once the failing logical sector is identified it is possible to repair this sector by applying the `Replace Logical Sector` command together with the logical sector address.

If the DFLASH EEPROM emulation software is not designed to use the `Replace Logical Sector` command or cannot use it due to whatever reason then the software must be able to "jump" over a logical sector during the operation.

For additional information about a "robust EEPROM emulation" algorithm please refer to the chapter EEPROM emulation with DFLASH.

***Note**:* *It is recommended to clear the EVER flag at the end of the command. Otherwise all following operations — including “sleep” — could trigger an interrupt even when they are successful.*

Program verify error (PVER)

Fault conditions:

This flag is set in one of the following cases:

- `Write Page`, `Write Page Once`, `Write Burst`, or `Write Burst Once` operation was not successful
- Error during the programming of the new redundancy mapping information during the `Replace Logical Sector` command operation
- During the application of the `Erase Logical Sector Range` command on a PFLASH region when it was not possible to write a new erase counter entry

New state:

No state change. Just the PVER bit is set.

Proposed handling by software:

This can be cleared with the `Clear Status` command.

There are several possible reasons for the failure of an program operation.

- Permanent or temporal voltage condition below the minimum specification (VDDEXT or VDD Core supply)

- Wrong device configuration
- Hard breakdown of an oxide within the NVM
- Program in principle functional but the number of weakly programmed cells is above a defined "fault tolerance threshold" level

The operating conditions shall always be checked with regards to voltage and temperature. A stable voltage supply during the whole time of the write command must be maintained.

It is also recommended to repeat the write operation at least one time.

The following advice assumes that a repetition of the write operation still shows a PVER flag and that the operating conditions and device configuration was correct.

All write operations (for example `Write Page`, `Write Page Once`) contain the check of the programmed bits under very tight conditions to have sufficient retention margin for the full operating lifetime. Therefore there could be a *Program Verify Error (PVER)* but a normal read of this data does not show an (ECC) error. But the PVER indicates that the retention of the data may not be sufficient.

***Note**:* *After the write operation the number of failing bits may be read out, see the command sequence description of the `Write Page` command.*

Shall the PVER error flag not disappear after a repetition of the write command then it is recommended to either skip the use of the wordline or repair the logical sector where the error occurred by the `Replace Logical Sector` command. Please refer to the application hints given in the previous section for EVER and the hints given in the chapter EEPROM emulation with DFLASH.

***Note**:* *It is recommended to clear the PVER flag at the end of the command. Otherwise all following operations — including “sleep” — could trigger an interrupt even when they are successful.*

Original error (ORIER)

Fault conditions:

This bit is set by hardware, if during startup, the DMU detects an **ERRORED** value or an uncorrectable ECC error in the ORIG confirmation code of a single UCB (one UCB containing both ORIG and COPY confirmation codes).

Proposed handling:

The start of the MCU is still possible as long as the COPY confirmation code of the UCB is still correct. It is recommended to rewrite this UCB in a stable environment (for example at next inspection).

Replace logical sector on page 702

5.3.8 Command sequences

The command sequence interpreter checks for the correctness of request and execution. In case of any error a Sequence Error (SQER) is generated.

The command sequence descriptions use the following nomenclature (symbolic assembly language) STaddr, data. Symbolic representation of a command cycle moving "data" to "addr". The parameter "addr" is defined as follows:

- $CCCC_H$: The "addr" must point into any of the address regions of the Command Sequence Interpreter used. The last 16 address bits must match $CCCC_H$

The parameter "data" can be one of the following attributes:

- **PA**: Absolute start address of the Flash page. It must be aligned to burst size for "Write Burst" or to the page size for "Write Page"
- **WA**: Absolute start address of the Flash word line
- **SA**: Absolute start address of a Flash sector. Allowed are the PFlash sectors S*x* and the DFlash sectors EEPROM*x* and UCB*x*
- **BS**: Bank selection coded as 32-bit vector (refer to the command description to see the allowed combinations):
  - Bit 0: HOST PFLASH0A
  - Bit 1: HOST PFLASH0B
  - Bit 2 : HOST PFLASH1A
  - ..
  - Bit 11: HOST PFLASH5B
  - Bit 12 -15 : reserved - 0
  - Bit 16 : HOST DFLASH (includes UCB)
  - Bit 17: CSRM DFLASH (includes UCB)
  - Bit 18: CSRM PFLASH
  - Bit 19-31 : reserved - 0

  ***Note**: For products with less PFLASH (HOST) Banks, it is necessary to adapt the BS accordingly. Example: a product with 10 PFLASH (HOST) banks would make use of bits 0 to 9 (i.e. HOST PFLASH0A to PFLASH4B) and would have bits 10 - 15 as reserved.*

- **WD64** and **WD32**: 64-bit or 32-bit **write data** to be loaded into the page assembly buffer
- xx**YY**: 8-bit write data as part of a command cycle. Only the byte "YY" is used for command interpretation. The higher order bytes "xx" are ignored
  - xx**5y**: "y" can be 0_H for selecting the PFlash or D_H for DFlash
  - xx**ww**: "ww" defines the number of pages and must not cross a word line border
  - xx**nn**: "nn" defines the number of logical sectors that are erased or verified. This number underlies certain restrictions
- **UC**: Identification of the UCB*x* for which the password checking shall be performed:
  - **HOST command sequence interpreter**
    - xx00H for UCB_RTC_BMHD*n* (n=0 - 3)
    - xx01H for UCB_RTC_USERCFG_ORIG and UCB_RTC_USERCFG_COPY
    - xx02H for UCB_RTC_SWAP_ORIG and UCB_RTC_SWAP_COPY
    - xx03H for UCB_RTC_ECPRIO_ORIG and UCB_RTC_ECPRIO_COPY
    - xx04H for UCB_USER_DATA0
    - xx05H for UCB_USER_DATA1

- xx10H for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read and write protection for HOST DFLASH and all HOST PFLASHs
- xx20H for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read protection for HOST DFLASH
- xx21H for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read protection for HOST PFLASH
- xx30H for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read protection, and sector specific write protection for HOST PFLASH0A
- xx31H for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read protection, and sector specific write protection for HOST PFLASH0B
- xx32H for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read protection, and sector specific write protection for HOST PFLASH1A
- xx33H for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read protection, and sector specific write protection for HOST PFLASH1B
- xx34H for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read protection, and sector specific write protection for HOST PFLASH2A
- xx35H for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read protection, and sector specific write protection for HOST PFLASH2B
- xx36H for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read protection, and sector specific write protection for HOST PFLASH3A
- xx37H for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read protection, and sector specific write protection for HOST PFLASH3B
- xx38H for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read protection, and sector specific write protection for HOST PFLASH4A
- xx39H for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read protection, and sector specific write protection for HOST PFLASH4B
- xx3AH for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read protection, and sector specific write protection for HOST PFLASH5A
- xx3BH for UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY to disable global read protection, and sector specific write protection for HOST PFLASH5B

  ***Note**:* *For products with less PFLASH (HOST) Banks, it is necessary to adapt the UC accordingly. Example: a product with 10 PFLASH (HOST) banks would not make use of UCs xx34H and xx3BH for PFLASH5A and PFLASH5B.*

- **CSRM command sequencer**
  - xx80H for UCB_CS_BMHD*n* (n=0 - 3)
  - xx81H for UCB_CS_USERCFG_ORIG and UCB_CS_USERCFG_COPY
  - xx82H for UCB_CS_SWAP_ORIG and UCB_CS_SWAP_COPY
  - xx83H for UCB_CS_ECPRIO_ORIG and UCB_CS_ECPRIO_COPY
  - xx84H for UCB_CS_USER_DATA0
  - xx85H for UCB_CS_USER_DATA1
  - xx8DH for UCB_DBGCS_ORIGand UCB_DBGCS_COPY
  - xx90H for UCB_CS_FLASH_ORIG and UCB_CS_FLASH_COPY to disable read and write protection for CSRM DFLASH, and to disable sector specific write protection for CSRM PFLASH

- xxA0H for UCB_CS_FLASH_ORIG and UCB_CS_FLASH_COPY to disable read and write protection for CSRM DFLASH
- xxB0H for UCB_CS_FLASH_ORIG and UCB_CS_FLASH_COPY to disable sector specific write protection for CSRM PFLASH

- **PW**x: 32-bit word of a 256-bit password. Note that the entire password consists of 256 bits. During the execution of the command sequence “disable protection”, the password is split into eight transfers of 32 bits each

Several command sequences are supported by the DMU. These are summarized in the following table :

Table 390 Command sequences supported by the DMU

Command sequence		Cycle								
		1	2	3	4	5	6	7	8	9
Reset to Read	Addr	.5554								
	Data	xxF0

DFLASH global read protection on page 771

5.3.8.1 Reset to read

Calling

- ST 5554_H, xx$F0_H$

Function

This function resets the addressed command sequence interpreter to its initial state (i.e. the next command cycle must be the 1st cycle of a sequence). A **PAGE MODE** is aborted.

This command is the only one that is accepted without *Sequence Error (SQER)* when the command sequence interpreter has already received command cycles of a different sequence. Thus `Reset to Read` can cancel every command sequence before its last command cycle has been received.

A system reset will re-initialize the NVM control circuits.

Host Command Sequence Interpreter

Host command sequence interpreter is reset. The following flags are cleared:

- Command sequence error flag: DMU_HCI_ERR.SQER
- Protection error flag: DMU_HCI_ERR.PROER
- PAGE MODE flags: DMU_HCI_STATUS.DFPAGE and DMU_HCI_STATUS.PFPAGE
- Request acknowledgment : DMU_HCI_STATUS.REQACK and DMU_HCI_STATUS.REQDONE

CSRM Command Sequence Interpreter

CSRM command sequence interpreter is reset. The following flags are cleared:

- Command sequence error flag: DMU_CSCI_ERR.SQER
- Protection error flag: DMU_CSCI_ERR.PROER
- PAGE MODE flags: DMU_CSCI_STATUS.DFPAGE and DMU_CSCI_STATUS.PFPAGE
- Request acknowledgment : DMU_CSCI_STATUS.REQACK and DMU_CSCI_STATUS.REQDONE

5.3.8.2 Enter page mode

Calling

- ST 5554_H, xx5**y**$_H$

Function

The PFLASH or the DFLASH assembly buffer enter **PAGE MODE** selected by the parameter "**y**":

Table 391 Page Mode memory selection

y	Memory which enters Page Mode
0_H	PFLASH
D_H	DFLASH

The write pointer of the page assembly buffer is set to 0, its previous content is maintained.

If a new `Enter Page Mode` command sequence is received while any Flash is already in **PAGE MODE**, then *Sequence Error (SQER)* is set.

PAGE MODE is exited when the next `Write Page` or `Write Burst` command sequence terminates.

If the DMU is in **ERROR MODE** then the command fails with a *Sequence Error (SQER)*.

Host Command Sequence Interpreter

PAGE MODE is signaled by the flags DMU_HCI_STATUS.DFPAGE and DMU_HCI_STATUS.PFPAGE for DFLASH and PFLASH respectively.

CSRM Command Sequence Interpreter

PAGE MODE is signaled by the flags DMU_CSCI_STATUS.DFPAGE and DMU_CSCI_STATUS.PFPAGE for DFLASH and PFLASH respectively. .

5.3.8.3 Load page

Calling

- ST $55F0_H$, **WD64** (for 64-bit transfers)
- ST $55F4_H$, **WD32** (for 32-bit transfers)

Function

Loads the data **WDxx** into the page assembly buffer of the chosen HOST or CSRM channel and increments the write pointer to the next position.

All **WDxx** transfers for one page must have the same width (either all 32-bit or all 64-bit). Else the transfer is refused with *Sequence Error (SQER)*.

The following table shows the number of necessary `Load Page` commands before a `Write` operation depending on Page or Burst mode and PFLASH or DFLASH memory.

Table 392 Number of `Load Page` commands

Command	Data [Byte]	Number of `Load Page` (32 Bit)	Number of `Load Page` (64 Bit)
PFLASH `Write Page`	32	8	4
PFLASH `Write Burst`	512	128	64
DFLASH `Write Page`	8	2	1

(table continues...)

Table 392 (continued) Number of `Load Page` commands

Command	Data [Byte]	Number of `Load Page` (32 Bit)	Number of `Load Page` (64 Bit)
DFLASH `Write Burst`	32	8	4

***Attention**: for 32-bit transfers always use address $55F4_H$, this is different to the command specification in previous product generations.*

If the number of `Load Page` data transfers does not result in the correct data amount for a write operation as specified in the table above, then the following `Write Page` or `Write Burst` command will not execute and show a *Sequence Error (SQER)*.

If `Load Page` is called more often than allowed for the required data, then the overflow data is discarded and **PAGE MODE** is not left. This overflow is reported by the following `Write Page` or `Write Burst` command with *Sequence Error (SQER)* and the write operation to Flash will not be executed (example for this error type: data for Burst is written but a Write Page command is requested)

If the DMU is in ERROR MODE then the command fails with an *Sequence Error (SQER)*.

5.3.8.4 Write page

Calling

- ST $AA50_H$, **PA**
- ST $AA58_H$, $xx00_H$
- ST $AAA8_H$, $xxA0_H$
- ST $AAA8_H$, $xxAA_H$

Function

This function starts the programming process for one page with the data transferred previously by `Load Page` commands. Upon executing the command, **PAGE MODE** is exited (indicated by clearing the corresponding PAGE flag) and the BUSY flag of the bank is set.

This command is refused with *Sequence Error (SQER)* when the addressed Flash is not in **PAGE MODE**.

Sequence Error (SQER) is also issued when **PA** addresses an unavailable Flash range or when **PA** does not point to a correct page start address.

If after `Enter Page Mode` no data, too few data or too much data was transferred to the assembly buffer with `Load Page` then the execution of `Write Page` fails, no data is programmed and *Sequence Error (SQER)* is set.

When the page **PA** is located in a sector with active write protection or the Flash module has an active global read protection the execution fails and *Protection Error (PROER)* is set.

When the programming process incurs an error the flag *Program Verify Error (PVER)* is set (both: '0' and '1' bits are verified). The flag is set when the number of incorrect bits is bigger than a memory region dependent threshold. This threshold is of course below the error correction capability of the memory region.

The same applies to the CSRM command sequence interpreter which maintains its own assembly buffer. After programming to the CSRM sectors the assembly buffer is automatically erased.

If the DMU is in **ERROR MODE** then the command fails with a *Sequence Error (SQER)*.

Additional information

After the execution of the command there is additional information about the number of failing bits ('0' and '1') available. This is described in the following table.

Table 393 Additional information after write page execution

NVM part	Register	Range	Description
FSI	COMM0	0 .. 255	Returns the number of fails detected during program verify. Both ('0' and '1' bits are checked and the value is the sum of the failing bits). This result is reported independently from the *Program Verify Error (PVER)* and may be not equal 0 even in case that *PVER* = 0_B.

The maximum allowed number of failing bits (fault tolerance) for the *Program Verify Error (PVER)* is at least one bit less than the number of bits which can be corrected by the error correcting circuitry. This means that with a *Program Verify Error (PVER)* = 1_B there are two possibilities:

1. number of failing bits is lower or equal the number of bits which can be corrected
2. number of failing bits is higher than the number of bits which can be corrected

By using the failcount available in the COMM0 register it is possible to distinguish the two cases. This information can be used by the software to decide on further appropriate actions depending on the type of data and the memory region (for example: waive of error, write data again, erase and write data again, apply replace logical sector command,..),

Table 394 PFLASH: Examples for fault tolerant PVER assertions

Failing Bits (COMM0)	Fault Tolerance	=> PVER	ECC correctable ?
1	1	0	YES
2	1	1	YES
≥ 3	1	1	NO

Notes for safety critical memory regions

Built in fault tolerance of the Write page command is necessary to support fail operational usage in case of few single bit hard errors. Single bit errors up to a certain threshold may be tolerated. The readout of the COMM0 register provides an immediate check of failing bits. The readout of the whole PFLASH memory region together with the check of the error buffers SBABx, DBABx and UBAB (see related information) allows to monitor the overall state of the memory and perform appropriate action if necessary.

Table 395 DFLASH: Examples for fault tolerant PVER assertions in case of fault tolerance = 1

Failing Bits (COMM0)	Fault Tolerance	=> PVER	ECC correctable ?
1	1	0	YES
2	1	1	YES
3	1	1	YES
≥ 4	1	1	NO

FSI_COMMx register addresses

There are separate FSI_COMMx registers for the HOST and for the CSRM command interface:

- FSI_HOST.COMMx
- FSI_CSRM.COMMx

These COMMx registers do not belong to the standard DMU register region. To access those registers please refer to:

Table 396 FSI COMMx registers

Address	Chapter
Register Base Address FSI_HOST.COMM0	System address map
Register Base Address FSI_CSRM.COMM0	
Register offset addresses for COMMx Registers Note: The offset addresses for FSI_HOST.COMMx and for FSI_CSRM.COMMx are the same	Register Overview - FSI

Related information

PFLASH ECC on page 674

5.3.8.5 Write page once

Calling

- ST $AA50_H$, **PA**
- ST $AA58_H$, $xx00_H$
- ST $AAA8_H$, $xxA0_H$
- ST $AAA8_H$, $xxA8_H$

Function

This function starts the programming process for one page as the normal `Write Page` does. But before programming it checks if the page is erased. If the page is not erased (allowing one correctable error) the command fails with *Erase Verify Error (EVER)*.

When the programming itself incurs an error the flag *Program Verify Error (PVER)* is set.

The `Write Page Once` command is only possible on PFLASH Banks. When applied to DFLASH the command fails with *Sequence Error (SQER)*.

Execution time of the write by the `Write Page Once` command is longer then a normal write command (the adder is defined by the datasheet parameter t_{ADD}).

On sectors with “write-once” protection only the `Write Page Once` and the `Write Burst Once` commands are accepted by DMU.

Other than the specific function features mentioned above the same features and constraints as mentioned for `Write Page` apply.

Related information

Write operation hints on page 739

5.3.8.6 Write burst

Calling

- ST $AA50_H$, **PA**
- ST $AA58_H$, $xx00_H$
- ST $AAA8_H$, $xxA0_H$
- ST $AAA8_H$, $xxA6_H$

Function

This function starts the programming process for an aligned group of pages. The programming process is more efficient than for a single page, achieving a significantly higher throughput (see data sheet).

In the PFLASH 16 pages (512bytes) are programmed and in DFLASH 4 pages (32bytes). The pages are programmed one after the other with increasing addresses.

For further details see the `Write Page` command description.

A *Sequence Error (SQER)* is returned and the execution fails as well if:

- The **PA** is not aligned to a burst address (512bytes PFLASH and 32bytes DFLASH)

Host command sequence interpreter

For disabled ECC generation:

- If DMU_GP_HOST_PFECCW.ENCDIS = '11_B' then the user must not perform a Write Burst to PFLASH
- If DMU_GP_HOST_DFECCW.ENCDIS = '11_B' then the user must not perform a Write Burst to DFLASH

CSRM command sequence interpreter

For disabled ECC generation:

- If DMU_GP_CSRM_PFECCW.ENCDIS = '11_B' then the user must not perform a Write Burst to PFLASH
- If DMU_GP_CSRM_DFECCW.ENCDIS = '11_B' then the user must not perform a Write Burst to DFLASH

Related information

Write operation hints on page 739

5.3.8.7 Write burst once

Calling

- ST $AA50_H$, **PA**
- ST $AA58_H$, $xx00_H$
- ST $AAA8_H$, $xxA0_H$
- ST $AAA8_H$, $xxA4_H$

Function

This function starts the programming process for an aligned group of pages as the normal `Write Burst` does. But before programming it checks if all the target pages are erased. If one page is not erased (allowing one correctable error) the command fails with *Erase Verify Error (EVER)*.

When the programming itself incurs an error the flag *Program Verify Error (PVER)* is set.

The `Write Burst Once` command is only possible on PFLASH Banks. When applied to DFLASH the command fails with *Sequence Error (SQER)*.

Execution time of the write by the `Write Burst Once` command is longer then a normal `Write Burst` command (adder by number of pages x t_{ADD}).

On sectors with “write-once” protection only the `Write Page Once` and the `Write Burst Once` commands are accepted by DMU.

For further details see `Write Burst`.

Host Command Sequence Interpreter

For disabled ECC generation:

- If DMU_GP_HOST_PFECCW.ENCDIS = ‘11_B’ then the user must not perform a Write Burst to PFLASH
- If DMU_GP_HOST_DFECCW.ENCDIS = ‘11_B’ then the user must not perform a Write Burst to DFLASH

HSM Command Sequence Interpreter

For disabled ECC generation:

- If DMU_GP_CSRM_PFECCW.ENCDIS = ‘11_B’ then the user must not perform a Write Burst to PFLASH
- If DMU_GP_CSRM_DFECCW.ENCDIS = ‘11_B’ then the user must not perform a Write Burst to DFLASH

Related information

Write operation hints on page 739

5.3.8.8 Count free redundant sectors

Calling

- ST $AAC0_H$, **BS**

Use Case

This command sequence can be used to retrieve the number of free redundant sector in a Bank before executing a `Replace Logical Sector` to replace failing logical sectors.

Function

The argument "**BS**" is used to select the Bank in which the number of free redundant sectors shall be counted.

Only one bank at a time is accepted, other values for **BS** will fail with a *Sequence Error (SQER)*.

The number of free redundant sectors will be returned in the FSI HOST or FSI CSRM COMM0 register. This number will be comprised between 0 and the number of maximum available redundant sectors described in the following tables :

Table 397 PFLASH maximum number of available redundant sectors

PFLASH Bank size	Maximum number of free redundant sectors
1MB	3
2MB	7

Table 398 DFLASH maximum number of available redundant sectors

DFLASH Bank size	Maximum number of free redundant sectors
128kB	7
0.5MB	15
1MB	31

If the `Count Free Redundant Sectors` returns 0, it is useless to execute a `Replace Logical Sector` in this Bank as no redundant sectors are available anymore and thus the device cannot be repaired anymore.

FSI_COMMx register addresses

There are separate FSI_COMMx registers for the HOST and for the CSRM command interface:

- FSI_HOST.COMMx
- FSI_CSRM.COMMx

These COMMx registers do not belong to the standard DMU register region. To access those registers please refer to:

Table 399 FSI COMMx registers

Address	Chapter
Register Base Address FSI_HOST.COMM0	System address map
Register Base Address FSI_CSRM.COMM0	
Register offset addresses for COMMx Registers Note: The offset addresses for FSI_HOST.COMMx and for FSI_CSRM.COMMx are the same	Register Overview - FSI

5.3.8.9 Replace logical sector

Calling

- ST $AA50_H$, **PA**
- ST $AA58_H$, $xx00_H$
- ST $AAA8_H$, $xxA0_H$
- ST $AAA8_H$, $xxAC_H$

Use case

`Replace Logical Sector` is a command sequence that enables the replacement of a logical sector with hard fails with an available redundant logical sector. It can be used if a sector fails during an erase or program.

The AURIX™ TC4xx allows the replacements of logical sectors in PFLASH and in DFLASH Banks.

Every Bank has a certain number of redundant logical sectors. This number depends on the type (PFLASH, DFLASH) and on the size (2 MB, 1 MB, … 128 KB.). The redundant logical sectors are available both for production test, and for the application. Depending on the number of redundant logical sectors used for production test there may be a reduced number of sectors free for repair by the application. The number of already used sectors may be different for different Banks. In worst case there are no more free redundant sectors available. The probability for this is low and might happen rather for smaller Banks than for large Banks. The number of available free redundant sectors can be retrieved by using the `Count Free Redundant Sectors` command.

A failure in a logical sector that has already been replaced cannot be repaired. If the application software uses Replace Logical Sector on a sector that has already been replaced, no error will be reported, but the replacement will not occur, and a redundant sector will be consumed.

After the successful execution of the `Replace Logical Sector` command the previously failing logical sector is mapped to a free redundant functional logical sector which is accessible at the same address. In addition the mapping information of the replacement is programmed into a non volatile memory region so that also at the next reset the mapping information is recovered.

If the DMU is in **ERROR MODE** then the command fails with an *Sequence Error (SQER)*

Function

The argument “**PA**” is used to select a page address aligned to the start of the logical sector (in PFLASH or in DFLASH) to be re-mapped.

Status and error flags

The *Sequence Error (SQER)* is set when the **PA** is not aligned to the start address of a logical sector page address or when **PA** addresses an unavailable Flash range. Logical sectors of the following Flash ranges cannot be repaired:

- UCB
- Erase Counter

The *Protection Error (PROER)* is set when there is an attempt to re-map a logical sector with enabled Write Protection or when the master requesting the command is not allowed to do so.

During the execution of the command the BUSY bit of the Bank under operation is set.

An *Erase Verify Error (EVER)* is generated if there is no free redundant logical sector available in that Bank anymore.

A *Program Verify Error (PVER)* is generated if there is a programming error during the programming of the redundancy information.

Related information

Error handling on page 685

5.3.8.10 Verify erased page

Calling

- ST $AA50_H$, **PA**
- ST $AA58_H$, $xx00_H$
- ST $AAA8_H$, $xx80_H$
- ST $AAA8_H$, $xx56_H$

Function

This command verifies if one page addressed by **PA** is correctly erased, i.e. contain 0 data and ECC bits. Upon executing the command, the BUSY flag of the corresponding bank is set.

As the PFLASH has Safety ECC, the PFLASH cannot be checked for “0” content by direct reads.

The *Erase Verify Error (EVER)* is set in case of an erase verification error.

Sequence error

A *Sequence Error (SQER)* is returned and the execution fails for the following conditions:

- The **PA** is not aligned to a page address
- The DMU is in **ERROR MODE**

5.3.8.11 Verify erased wordline

Calling

- ST $AA50_H$, **WA**
- ST $AA58_H$, $xx00_H$
- ST $AAA8_H$, $xx80_H$
- ST $AAA8_H$, $xx58_H$

Function

This command verifies if one wordline addressed by **WA** is correctly erased, i.e. contain 0 data and ECC bits. Upon executing the command, the BUSY flag of the corresponding bank is set.

As the PFLASH has Safety ECC, the PFLASH cannot be checked for “0” content by direct reads.

The *Erase Verify Error (EVER)* is set in case of an erase verification error.

Sequence error

A *Sequence Error (SQER)* is returned and the execution fails for the following conditions:

- The **WA** is not aligned to a wordline address
- The DMU is in **ERROR MODE**

5.3.8.12 Verify erased logical sector range

Calling

- ST $AA50_H$, **SA**
- ST $AA58_H$, xx**nn**$_H$
- ST $AAA8_H$, $xx80_H$
- ST $AAA8_H$, $xx5F_H$

Function

This command verifies if **nn** sectors starting at the sector addressed by **SA** are correctly erased, i.e. contain 0 data and ECC bits. Upon executing the command, the BUSY flag of the corresponding bank is set.

As the PFLASH has Safety ECC, the PFLASH cannot be checked for “0” content by direct reads.

The *Erase Verify Error (EVER)* is set in case of an erase verification error.

A *Sequence Error (SQER)* is returned and the execution fails for the following conditions:

- The **SA** is not within the logical sector range and not page aligned or it points to an unavailable sector
- For DFLASH, if the range of logical sectors exceeds 256 KByte addressable memory
- For PFLASH, if the range of logical sectors exceeds 512 KByte
- For UCB, if the range of logical sectors exceeds 1
- If the range of logical sector is not contained in a bank
- The DMU is in **ERROR MODE**

A *Protection Error (PROER)* is returned and the execution fails for the following conditions:

- If **SA** or any of the following (**nn** - 1) logical sectors has an active write protection
- If **SA** or any of the following (**nn** - 1) logical sectors belong to a memory region where the APU does not allow access to the master requesting the Erase
- If the Erase request is given to a command interface where the APU does not allow access to the master requesting the Erase
- The Flash module has an active global read protection set

Additional Information in case of erase verify error

In case of *Erase Verify Error (EVER)* there is additional information available. This is described in the following table.

Table 400 Additional information in case of erase verify error

NVM part	Register	Range	Description
FSI	COMM1	0 .. 255	Offset address of first failing logical sector within the sector range: 0: 1st logical sector has erase verify error 1: 2nd logical sector has erase verify error ...

FSI_COMMx register addresses

There are separate FSI_COMMx registers for the HOST and for the CSRM command interface:

- FSI_HOST.COMMx
- FSI_CSRM.COMMx

These COMMx registers do not belong to the standard DMU register region. To access those registers please refer to:

Table 401 FSI COMMx registers

Address	Chapter
Register Base Address FSI_HOST.COMM0	System address map
Register Base Address FSI_CSRM.COMM0	
Register offset addresses for COMMx Registers Note: The offset addresses for FSI_HOST.COMMx and for FSI_CSRM.COMMx are the same	Register Overview - FSI

5.3.8.13 Erase logical sector range

Calling

- ST $AA50_H$, **SA**
- ST $AA58_H$, xx**nn**$_H$
- ST $AAA8_H$, $xx80_H$
- ST $AAA8_H$, $xx50_H$

Function

This command erases **nn** logical sectors starting at the sector addressed by **SA**. Upon executing the command, the BUSY flag of the corresponding bank is set.

A *Sequence Error (SQER)* is returned and the execution fails for the following conditions:

- For PFLASH, if the range of logical sectors exceeds 512 KByte
- For DFLASH, if the range of logical sectors exceeds 256 KByte addressable memory
- For UCB, if the range of logical sectors exceeds 1
- If the range of logical sector is not contained in a bank
- If **SA** is not within the logical sector range and not page aligned
- If **SA** aligns to an unavailable sector
- If **nn** logical sectors is set to 0
- If the DMU is in **ERROR MODE**

A *Protection Error (PROER)* is returned and the execution fails for the following conditions:

- If **SA** or any of the following (**nn** - 1) logical sectors has an active write protection
- If **SA** or any of the following (**nn** - 1) logical sectors belong to a memory region where the APU does not allow access to the master requesting the Erase
- If the erase request is given to a command interface where the APU does not allow access to the master requesting the erase
- The Flash module has an active global read protection set

The *Erase Verify Error (EVER)* is set to indicate an error during the erase process.

The *Program Verify Error (PVER)* is set when the erase counter programming incurs an error (only for PFLASH erase).

***Note**: The duration of an erase command can be much shorter than documented in the datasheet when the range is already erased or partly erased.*

Additional Information in case of erase verify error

In case of *Erase Verify Error (EVER)* there is additional information available. This is described in the following table.

Table 402 Additional information in case of erase verify error

NVM part	Register	Range	Description
FSI	COMM0	0 .. 255	Number of failing logical sectors
	COMM1	0 .. 255	Offset address of first failing logical sector within the sector range: 0: 1st logical sector has erase verify error 1: 2nd logical sector has erase verify error ...

FSI_COMMx register addresses

There are separate FSI_COMMx registers for the HOST and for the CSRM command interface:

- FSI_HOST.COMMx
- FSI_CSRM.COMMx

These COMMx registers do not belong to the standard DMU register region. To access those registers please refer to:

5.3.8.14 User margin count

Calling

- ST $AA50_H$, **WA**
- ST $AA58_H$, $xx00_H$
- ST $AAA8_H$, $xx60_H$
- ST $AAA8_H$, $xx11_H$

Function

Attention**: **This command is mainly for characterization and analysis purpose.

With this command the distribution of NVM cell currents can be investigated. The scope is either a single page or a complete wordline; this can be selected by the DMU_HCI_OCONTROL.UCG (or DMU_CSCI_OCONTROL.UCG for CSRM command channel). Depending on the scope the argument **WA** must then be used to select a page or wordline aligned address.

The result of this function is the number N_dv of logic 1 bits in the selected wordline or page which have less cell current than the selected reference current. Calling this function with different reference currents allows calculation of the cell current distribution (please refer to the 2 figures below).

The reference current can be specified by setting an **REF_CURRENT_OFFSET** by bits [6:0] of the FSI_COMM0 register (for register address see section at the end of chapter).

The actual reference current used within the function is calculated using the following formulas:

- PFLASH: reference_current_pflash:= default_current_pflash + **REF_CURRENT_OFFSET**
- DFLASH: reference_current _dflash := default_current_dflash + **REF_CURRENT_OFFSET**

Attention**: **Default values base on characterization and qualification. Please contact your local Infineon representative to check for latest values.

The values for **REF_CURRENT_OFFSET**are used as signed integer (two's complement) to either increase or decrease the default current values; please refer to the following table for reference:

Table 404 Setting table for reference current

REF_CURRENT_OFFSET		Offset Value
hex	bin	[µA]
3F	0111111	15,75
...	...	...
9	0001001	2,25
8	0001000	2
7	0000111	1,75
6	0000110	1,5
5	0000101	1,25
4	0000100	1
3	0000011	0,75
2	0000010	0,5
1	0000001	0,25

...	...	...
40	1000000	-16

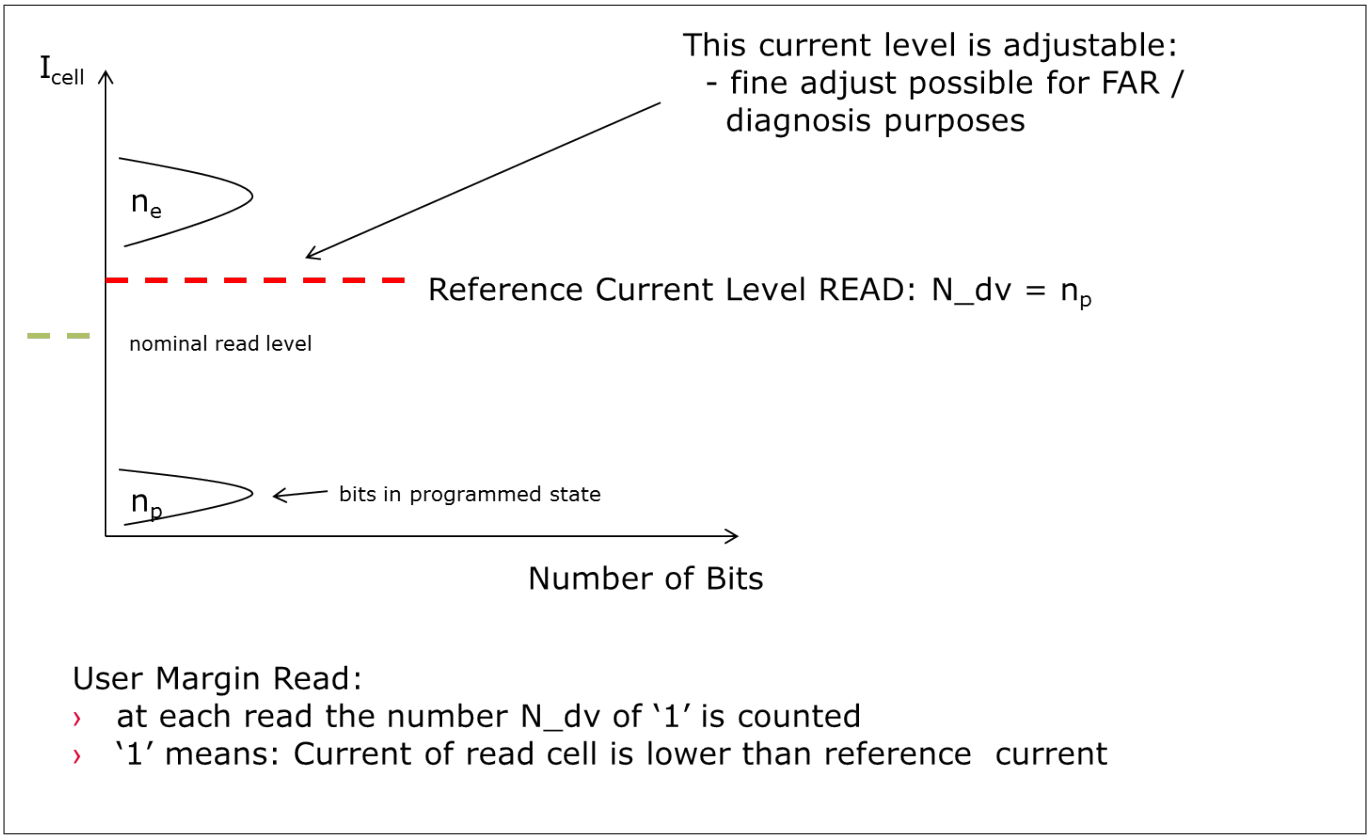

Figure 43 Basic principle of user margin count

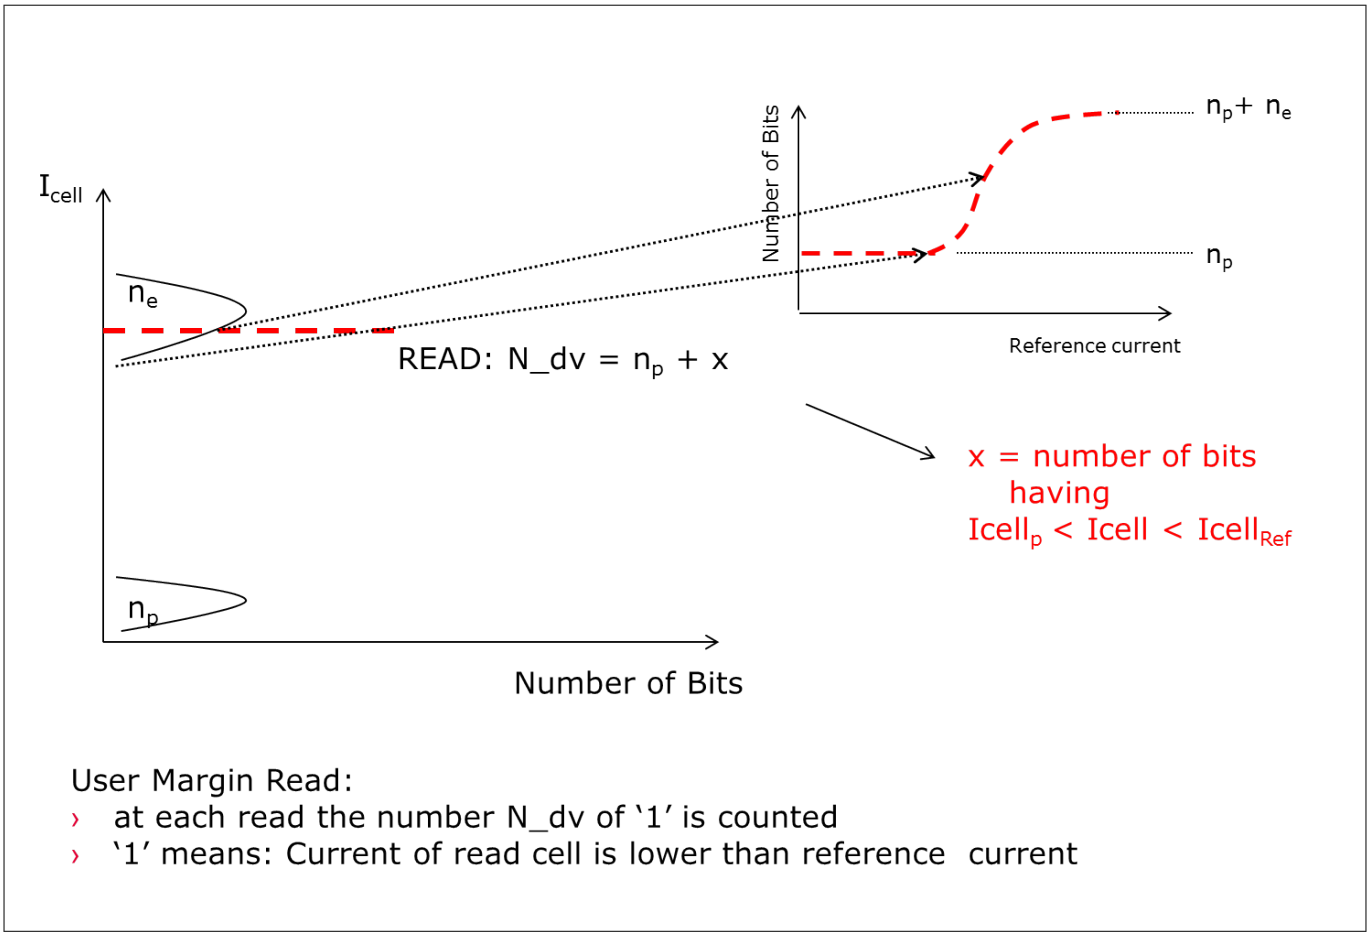

Figure 44 Example of shifted reference current of user margin count

Results

- DFLASH
  - The result is returned as 13-bit unsigned integer with bits [7:0] in FSI_COMM0 [7:0] and bits [12:8] in FSI_COMM1[4:0]
  - The ECC errors are evaluated and stored in FSI_COMM1 bit 5 for triple bit error, bit 6 for double bit error, bit 7 for uncorrectable error
- PFLASH
  - The result is returned as 14-bit unsigned integer with bits [7:0] in FSI_COMM0 [7:0] and bits [13:8] in FSI_COMM1 [5:0]
  - The ECC errors are evaluated and stored in FSI_COMM1 bit 6 for double bit error, bit 7 for uncorrectable error

***Note**: The registers FSI_COMM0 and FSI_COMM1 support only byte wide accesses. Other access sizes generate a bus error. For register address see section at the end of the chapter.*

Error flags

A *Sequence Error (SQER)* is set if **WA** address alignment does not fit to the scope selected (wordline or page).

A *Protection Error (PROER)* is set if:

- Write protection for target memory area is active
- PROT/APU access protection forbids an access of the requesting master

FSI_COMMx register addresses

There are separate FSI_COMMx registers for the HOST and for the CSRM command interface:

- FSI_HOST.COMMx
- FSI_CSRM.COMMx

These COMMx registers do not belong to the standard DMU register region. To access those registers please refer to:

Table 405 FSI COMMx registers

Address	Chapter
Register Base Address FSI_HOST.COMM0	System address map
Register Base Address FSI_CSRM.COMM0	
Register offset addresses for COMMx Registers Note: The offset addresses for FSI_HOST.COMMx and for FSI_CSRM.COMMx are the same	Register Overview - FSI

Application hints

- During the execution of a `User Margin Count`, `User Vth Count` or `User Content Count` command the BUSY flag of the corresponding bank is set in the status registers DMU_HCI_STATUS (HOST) or DMU_CSCI_STATUS (CSRM)
- The COMMx registers must not be changed during the execution of the commands
- The default content 0 of the COMM0 and COMM1 registers shall be set after the end of the execution

5.3.8.15 User Vth count

Calling

- ST $AA50_H$, **WA**
- ST $AA58_H$, $xx00_H$
- ST $AAA8_H$, $xx60_H$
- ST $AAA8_H$, $xx12_H$

Function

Attention: ***This command is ONLY for characterization and analysis purpose. If this command is used many times on the same memory location then a disturb may occur.***

With this command the distribution of the cell threshold voltage Vth of erased cells can be investigated. The scope is either a single page or a complete wordline; this can be selected by the DMU_HCI_OCONTROL.UCG (or DMU_CSCI_OCONTROL.UCG for CSRM command channel). Depending on the scope the argument **WA** must then be used to select a page or wordline aligned address.

The result of this function is the number N_pv of logic 1 bits in the selected wordline or page having a threshold voltage Vth higher than the selected wordline voltage. Calling this function with different wordline voltages allows the calculation of the Vth distribution (please refer to the following figures for examples).

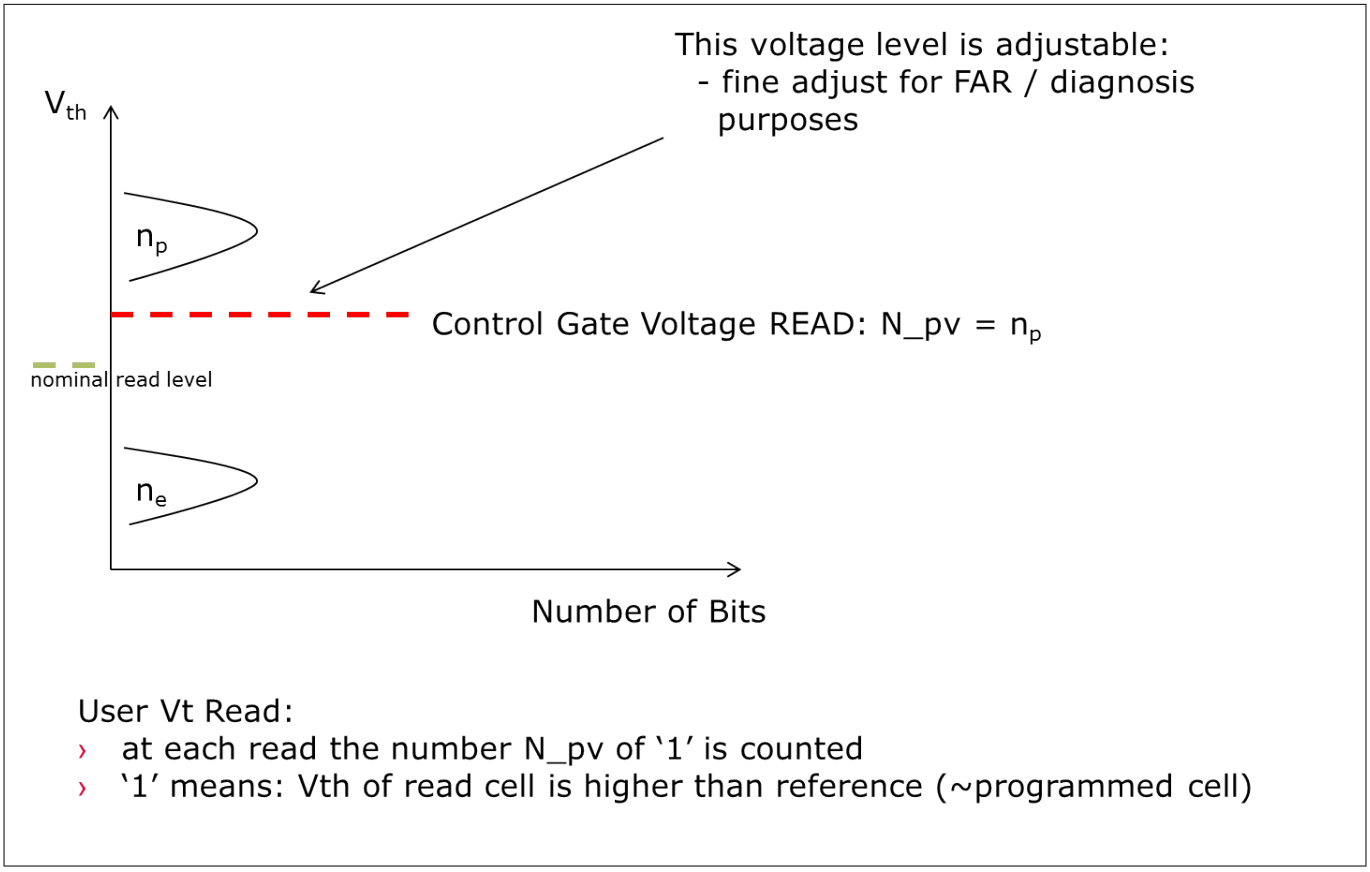

Figure 45 Basic principle of user Vth count

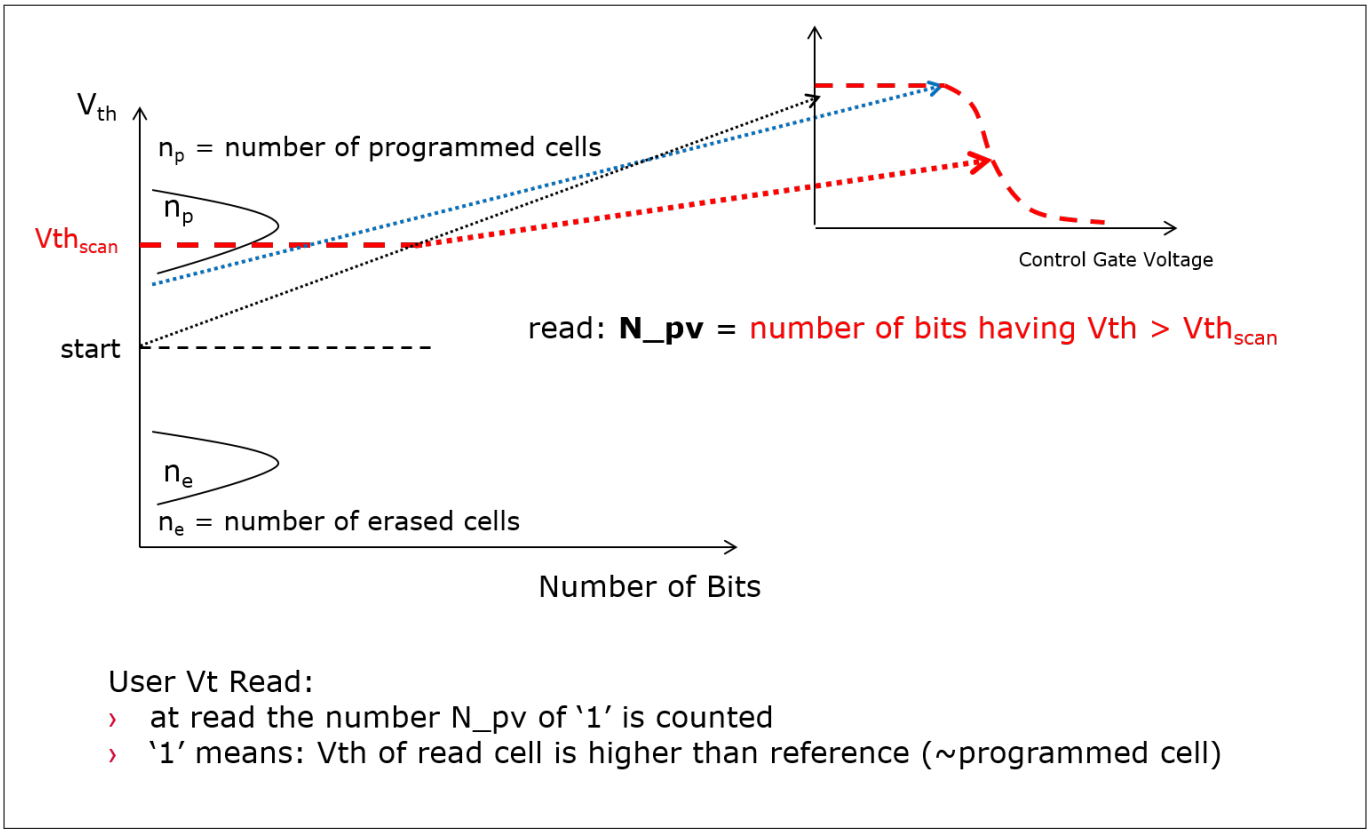

Figure 46 Example of shifted wordline voltage of user Vth count

The **wordline voltage** can be specified by bits [5:0] of FSI_COMM0.
The valid settings are described in the table below.

Table 406 Wordline voltage settings

Hex	Dec	Bin	Voltage
00	0	000000	2,1
01	1	000001	2,2
02	2	000010	2,3
03	3	000011	2,4
04	4	000100	2,5
05	5	000101	2,6
06	6	000110	2,7
07	7	000111	2,8
08	8	001000	2,9
09	9	001001	3,0
0A	10	001010	3,1
0B	11	001011	3,2
0C	12	001100	3,3
0D	13	001101	3,4
0E	14	001110	3,5

(table continues...)

Table 406 (continued) Wordline voltage settings

Hex	Dec	Bin	Voltage
0F	15	001111	3,6
10	16	010000	3,7
11	17	010001	3,8
12	18	010010	3,9
13	19	010011	4,0
14	20	010100	4,1
15	21	010101	4,2
16	22	010110	4,3
17	23	010111	4,4
18	24	011000	4,5
19	25	011001	4,6
1A	26	011010	4,7
1B	27	011011	4,8
1C	28	011100	4,9
1D	29	011101	5,0
1E	30	011110	5,1
1F	31	011111	5,2
20	32	100000	5,3
21	33	100001	5,4
22	34	100010	5,5

Results

- DFLASH
  - The result is returned as 13-bit unsigned integer with bits [7:0] in FSI_COMM0 [7:0] and bits [12:8] in FSI_COMM1[4:0]
  - The ECC errors are evaluated and stored in FSI_COMM1 bit 5 for triple bit error, bit 6 for double bit error, bit 7 for uncorrectable error
- PFLASH
  - The result is returned as 14-bit unsigned integer with bits [7:0] in FSI_COMM0 [7:0] and bits [13:8] in FSI_COMM1 [5:0]
  - The ECC errors are evaluated and stored in FSI_COMM1 bit 6 for double bit error, bit 7 for uncorrectable error

***Note**: The registers FSI_COMM0 and FSI_COMM1 support only byte wide accesses. Other access sizes generate a bus error. For register address see section at the end of the chapter.*

Disturbs by Vth count

Frequent use of the `User Vth Count` Function on one wordline might lead to a disturb of the data within the wordline; especially if high voltages are used. In a worst case this disturb might lead to a change for some cells. However occasional use for characterization or analysis (about 10 times a wordline with the max voltage of 5.5 V) will not lead to a problem. Please consult your local Infineon technical customer service in case of questions.

Error flags

A *Sequence Error (SQER)* is set if **WA** address alignment does not fit to the scope selected (wordline or page).

A *Protection Error (PROER)* is set if:

- Write protection for target memory area is active
- PROT/APU access protection forbids an access of the requesting master

FSI_COMMx register addresses

There are separate FSI_COMMx registers for the HOST and for the CSRM command interface:

- FSI_HOST.COMMx
- FSI_CSRM.COMMx

These COMMx registers do not belong to the standard DMU register region. To access those registers please refer to:

Table 407 FSI COMMx registers

Address	Chapter
Register Base Address FSI_HOST.COMM0	System address map
Register Base Address FSI_CSRM.COMM0	
Register offset addresses for COMMx Registers Note: The offset addresses for FSI_HOST.COMMx and for FSI_CSRM.COMMx are the same	Register Overview - FSI

Application hints

- During the execution of a `User Margin Count`, `User Vth Count` or `User Content Count` command the BUSY flag of the corresponding bank is set in the status registers DMU_HCI_STATUS (HOST) or DMU_CSCI_STATUS (CSRM)

- The COMMx registers must not be changed during the execution of the commands
- The default content 0 of the COMM0 and COMM1 registers shall be set after the end of the execution

5.3.8.16 User content count

Calling

[Function description is not yet complete]

- ST $AA50_H$, **WA**
- ST $AA58_H$, $xx00_H$
- ST $AAA8_H$, $xx60_H$
- ST $AAA8_H$, $xx14_H$

Function

Attention**:* ***This command is mainly for characterization and analysis purpose. Limited use during run-time for data integrity checks may be possible but applicable disturb parameters and default configuration need to be taken into account. Please check with your local Infineon representative in case that it is intended to use this command during runtime

The result of the User Content Count function is the difference of the logic 1 bits counted by the User Vth Count and the User Margin Count functions:

result:= N_dv - N_pv

The User Content Count function is a data integrity check which detects bits with a cell current level between the erase verify- and an adjustable wordline verify- level (please refer to the following figures). This function may be called by setting different wordline (control gate) voltages. Changing of the erase verify level is not possible; the current level is the same as used for the `Verify Erased Logical Sector Range` function.

The scope is either a single page or a complete wordline; this can be selected by the DMU_HCI_OCONTROL.UCG (or DMU_CSCI_OCONTROL.UCG for CSRM command channel). Depending on the scope the argument **WA** must then be used to select a page or wordline aligned address.

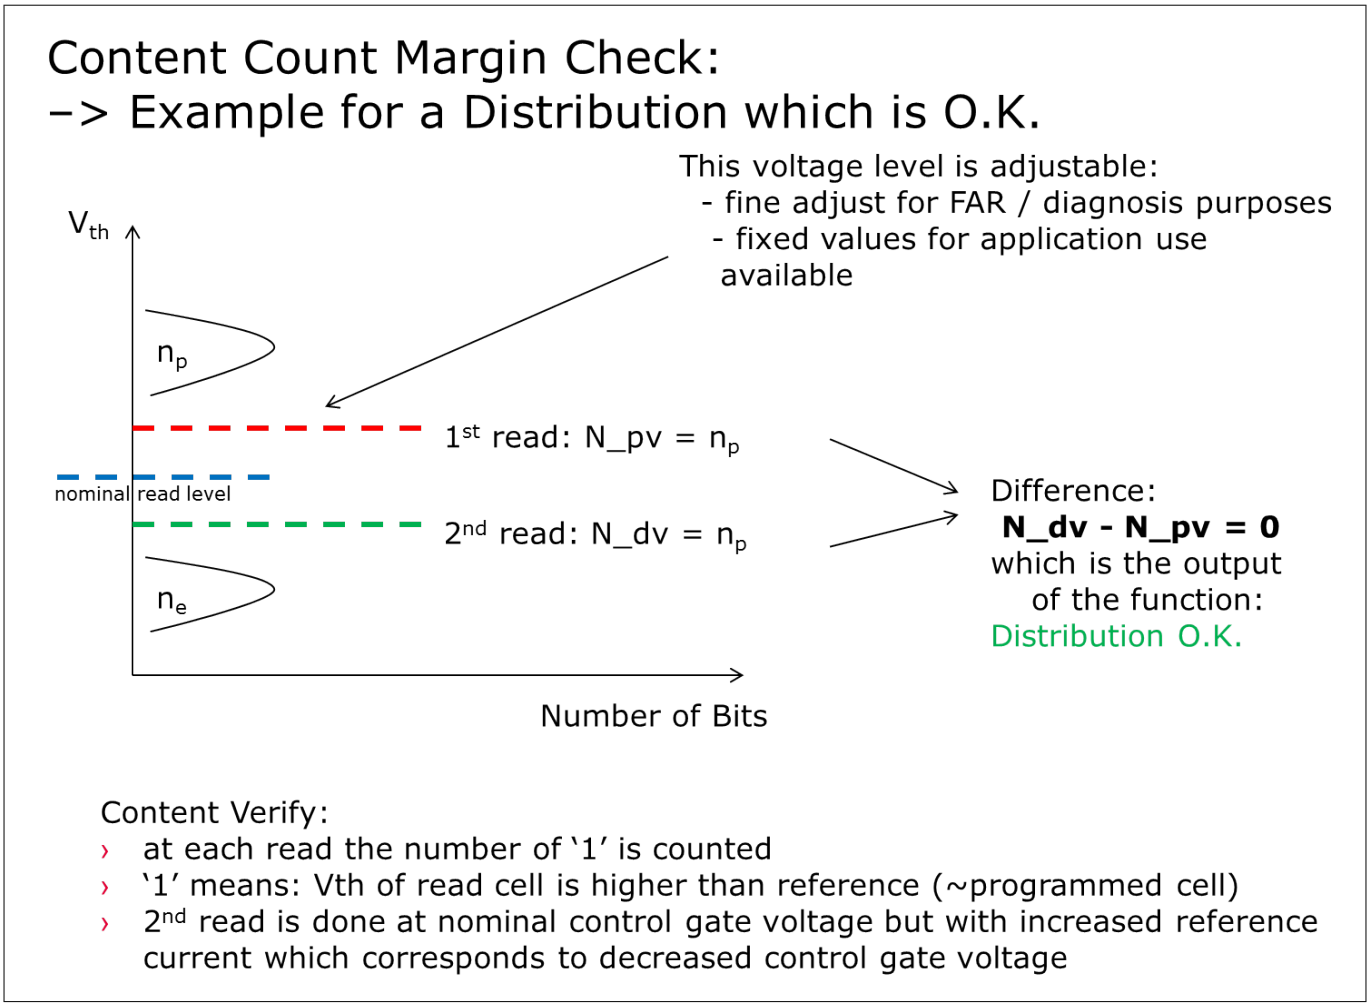

Figure 47 Basic principle of user content count

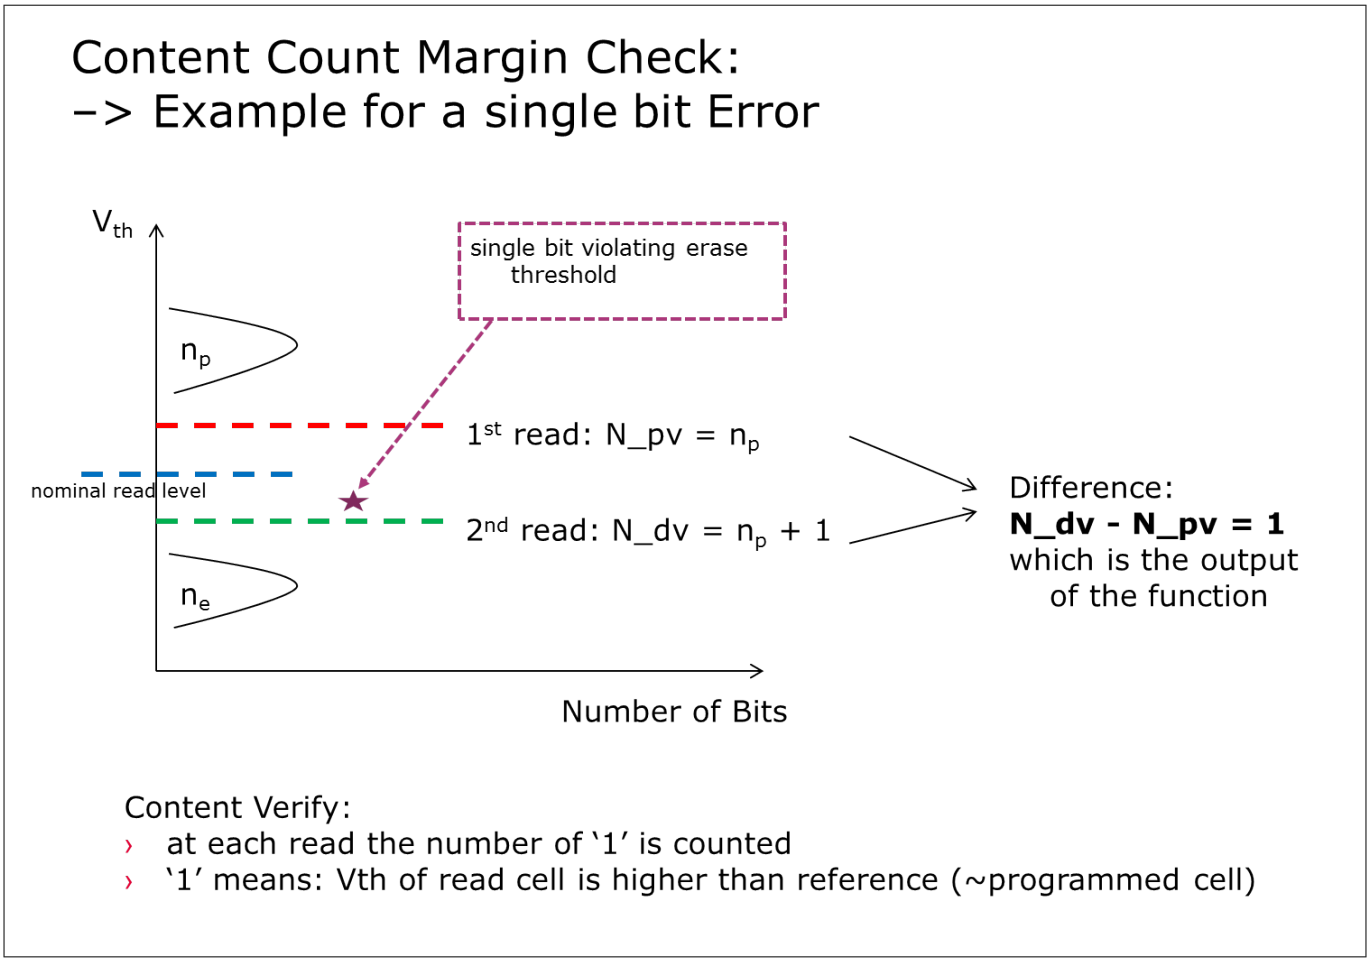

Figure 48 Example of user content count with 1 bit error

The **wordline voltage** can be specified by bits [5:0] of FSI_COMM0.
The valid settings are described in the table below.

Table 408 Wordline voltage settings

hex	dec	bin	voltage
00	0	000000	2,1
01	1	000001	2,2
02	2	000010	2,3
03	3	000011	2,4
04	4	000100	2,5
05	5	000101	2,6
06	6	000110	2,7
07	7	000111	2,8
08	8	001000	2,9
09	9	001001	3,0
0A	10	001010	3,1
0B	11	001011	3,2

(table continues...)

Table 408 (continued) Wordline voltage settings

hex	dec	bin	voltage
0C	12	001100	3,3
0D	13	001101	3,4
0E	14	001110	3,5
0F	15	001111	3,6
10	16	010000	3,7
11	17	010001	3,8
12	18	010010	3,9
13	19	010011	4,0

1F	31	011111	5,2
20	32	100000	5,3
21	33	100001	5,4
22	34	100010	5,5

Results

- DFLASH
  - The result is returned as 13-bit unsigned integer with bits [7:0] in FSI_COMM0 [7:0] and bits [12:8] in FSI_COMM1[4:0]
  - The ECC errors are evaluated and stored in FSI_COMM1 bit 5 for triple bit error, bit 6 for double bit error, bit 7 for uncorrectable error
- PFLASH
  - The result is returned as 14-bit unsigned integer with bits [7:0] in FSI_COMM0 [7:0] and bits [13:8] in FSI_COMM1 [5:0]
  - The ECC errors are evaluated and stored in FSI_COMM1 bit 6 for double bit error, bit 7 for uncorrectable error

***Note**: The registers FSI_COMM0 and FSI_COMM1 support only byte wide accesses. Other access sizes generate a bus error. For register address see section at the end of the chapter.*

Disturbs by user content count

Frequent use of the `User Content Count` function on one wordline might lead to a disturb of the data within the wordline; especially if high voltages are used. In a worst case this disturb might lead to a change for some cells. However occasional use for characterization or analysis (about 10 times a wordline with the max voltage of 5.5 V) will not lead to a problem. Please consult your local Infineon technical customer service in case of questions.

Error flags

A *Sequence Error (SQER)* is set if **WA** address alignment does not fit to the scope selected (wordline or page).

A *Protection Error (PROER)* is set if:

- Write protection for target memory area is active
- PROT/APU access protection forbids an access of the requesting master

FSI_COMMx register addresses

There are separate FSI_COMMx registers for the HOST and for the CSRM command interface:

- FSI_HOST.COMMx
- FSI_CSRM.COMMx

These COMMx registers do not belong to the standard DMU register region. To access those registers please refer to:

Table 409 FSI COMMx registers

Address	Chapter
Register Base Address FSI_HOST.COMM0	System address map
Register Base Address FSI_CSRM.COMM0	
Register offset addresses for COMMx Registers Note: The offset addresses for FSI_HOST.COMMx and for FSI_CSRM.COMMx are the same	Register Overview - FSI

Application hints

- During the execution of a `User Margin Count`, `User Vth Count` or `User Content Count` command the BUSY flag of the corresponding bank is set in the status registers DMU_HCI_STATUS (HOST) or DMU_CSCI_STATUS (CSRM)

- The COMMx registers must not be changed during the execution of the commands
- The default content 0 of the COMM0 and COMM1 registers shall be set after the end of the execution

User of user content count during runtime

The User Content Count function may be used during runtime for data integrity checks with a fixed single value for the wordline voltage. For this purpose recommended values for PFLASH and DFLASH (HOST or CSRM) are available.

Attention**: **Recommended values for use during runtime may be changed based on final characterization and qualification results. Please contact your local Infineon representative.

5.3.8.17 Disable protection

Calling

- ST $553C_H$, **UC**
- ST.W $553C_H$, **PW0**
- ST.W $553C_H$, **PW1**
- ST.W $553C_H$, **PW2**
- ST.W $553C_H$, **PW3**
- ST.W $553C_H$, **PW4**
- ST.W $553C_H$, **PW5**
- ST.W $553C_H$, **PW6**
- ST.W $553C_H$, **PW7**

Function

The password protection of the selected UCB (if this UCB offers this feature) is temporarily disabled and the respective bit in GP_HOST_PROTECT or GP_CSRM_PROTECT is set. when all the passwords **PW0** .. **PW7** match their configured values in the corresponding UCB.

The following protections may be disabled temporarily by using the Disable Protection command:

- "Global" Read and "Global" Write Protection
- Write Protection of a specific Bank

The following protections cannot be disabled anymore:

- Permanent Write ("OTP") Protection
- Permanent Write Once Protection

This command sequence generates a PROER if

1. any supplied **PWx** is incorrect or
2. if the confirmation code of the target UCB is not in UNLOCKED or CONFIRMED state (see UCB confirmation code registers CONFIRMA, CONFIRMB, and CONFIRMC)

In such cases, an application reset is needed before trying this command sequence again. Otherwise, all further calls of the Disable Protection will fail with a PROER regardless of the supplied password.

Before comparing passwords, the DMU reads again the confirmation codes from DF and if necessary, it updates the corresponding registers GP_HOST_CONFIRMA, GP_HOST_CONFIRMB, GP_HOST_CONFIRMC, GP_CSRM_CONFIRMA, GP_CSRM_CONFIRMB or GP_CSRM_CONFIRMC.

***Note**:* *Host and CSRM BHMDs have a specific handling.*

Every disable protection sequence issued on the BMHDs shall prompt the DMU to read the BMHDs confirmation codes (CC) in ascending order, from BMHD0 to BMHD3, regardless of their CC values.

The overall status of the BMHDs, that ultimately controls their access and protection, is evaluated based on the status of the first valid BMHD. The table below describes the status of the BMHD UCBs after the programming phase and following a reset.

***Note**:* *during the UCBs programming phase, it is recommended to avoid any resets.*

***Note**:* *the ERASED CC is a special case of ERRORED and therefore the behavior is the same. ERRORED can mean ERASED or virgin, that is never been written*

Table 410 Handling of BMHDs CC and PWD combination

BMHD0 CC	BMHD1 CC	BMHD2 CC	BMHD3 CC	BMHDs overall status	Access	PWD protection
UNLOCKED	Any state	Any state	Any state	UNLOCKED	Full read and write access on all BMHDs, regardless of their status.	Disabled
CONFIRMED	Any state	Any state	Any state	CONFIRMED	BMHDs PWDs not readable. Content of all BMHDs can be read but it cannot be written.	Enabled
ERRORED	UNLOCKED	Any state	Any state	UNLOCKED	Full read and write access on all BMHDs, regardless of their status.	Disabled
ERRORED	CONFIRMED	Any state	Any state	CONFIRMED	BMHDs PWDs not readable. Content of all BMHDs can be read but it cannot be written.	Enabled
ERRORED	ERRORED	UNLOCKED	Any state	UNLOCKED	Full read and write access on all BMHDs, regardless of their status.	Disabled
ERRORED	ERRORED	CONFIRMED	Any state	CONFIRMED	BMHDs PWDs not readable. Content of all BMHDs can be read but it cannot be written.	Enabled
ERRORED	ERRORED	ERRORED	UNLOCKED	UNLOCKED	Full read and write access on all BMHDs, regardless of their status.	Disabled
ERRORED	ERRORED	ERRORED	CONFIRMED	CONFIRMED	BMHDs PWDs not readable. Content of all BMHDs can be read but it cannot be written.	Enabled

(table continues...)

Table 410 (continued) Handling of BMHDs CC and PWD combination

BMHD0 CC	BMHD1 CC	BMHD2 CC	BMHD3 CC	BMHDs overall status	Access	PWD protection
ERRORED	ERRORED	ERRORED	ERRORED	Braindead	None of the BMHDs PWDs can be read. No write access.	Enabled

***Note**: the PWD protection column in the table above indicates the protection status following a reset. It is evaluated based on the GP_HOST_PROTECT or GP_CSRM_PROTECT registers and of the BMHDs overall status. During the programming phase, changing the confirmation code of the UCBs does not enable or disable the protection.*

***Note**: the value of the CCs does not reflect their protection status. A disable protection command sequence does not change the CC value but changes the relevant status bit in the GP_HOST_PROTECT or GP_CSRM_PROTECT registers.*

To disable the protection of all BHMDs, the disable protection command sequence shall be issued with the password of the first CONFIRMED BMHD, providing that the preceding BMHD (where applicable) is not UNLOCKED.

A disable protection issued with the correct PWD on an BMHD with UNLOCKED CC shall set the BMHD dedicated bit in the GP_HOST_PROTECT or GP_CSRM_PROTECT register, providing that the preceding BMHDs (where applicable) are not UNLOCKED or CONFIRMED and that BMHDs PWDs differ. Otherwise, a PROER shall be returned.

A disable protection issued with the correct PWD on the second or subsequent valid BMHD shall return a PROER providing that all BMHDs PWDs differ.

***Note**: successfully disabling the protection of the BMHDs allows full read and write access to them, regardless of their confirmation code.*

In addition, it is advised that the confirmation code of the first valid BMHD shall always be set to CONFIRMED to prevent reads of the BMHDs password that would otherwise remove the protection to all BMHDs

In the current implementation of the design, every disable protection sequence issued on the dual UCBs shall prompt the DMU to read the ORIG CC first followed by the COPY CC, regardless of their CC values.

The overall status of the dual UCBs, that ultimately controls their access and protection, is evaluated based status of the first valid dual UCB. The table below describes the status of the dual UCBs after the programming phase and following a reset.

***Note**: during the dual UCBs programming phase, it is recommended to avoid any resets.*

Table 411 Handling of dual UCBs CC and PWD combination

ORIG UCB CC	COPY UCB CC	UCB overall status	Access	PWD protection
UNLOCKED	UNLOCKED	UNLOCKED	Full read and write access on both ORIG and COPY, regardless of their status.	Disabled

(table continues...)

Table 411 (continued) Handling of dual UCBs CC and PWD combination

ORIG UCB CC	COPY UCB CC	UCB overall status	Access	PWD protection
UNLOCKED	CONFIRMED	UNLOCKED	Full read and write access on both ORIG and COPY, regardless of their status. The protection on COPY UCB shall not be enabled because the main UCB is ORIG	
UNLOCKED	ERRORED	UNLOCKED	Full read and write access on both ORIG and COPY, regardless of their status.	
CONFIRMED	UNLOCKED	CONFIRMED	Neither ORIG nor COPY PWDs can be read. Content of ORIG and COPY can be read but it cannot be written. Disabling the protection on ORIG allows write access to both UCBs regardless of the status of the COPY UCB.	Enabled
CONFIRMED	CONFIRMED	CONFIRMED		
CONFIRMED	ERRORED	CONFIRMED		
ERRORED	UNLOCKED	UNLOCKED	Full read and write access on both ORIG and COPY, regardless of their status.	Disabled
ERRORED	CONFIRMED	CONFIRMED	PWD of neither ORIG nor COPY can be read. Content of ORIG and COPY can be read but it cannot be written. Disabling the protection on COPY allows write access to both UCBs.	Enabled
ERRORED	ERRORED	ERRORED	UCBs PWDs cannot be read. No write access	Enabled

To disable the protection of the dual UCBs, when the ORIG CC is CONFIRMED, the disable protection command sequence shall be issued with the password of the ORIG UCB, regardless of the value of the COPY CC.

Otherwise, disabling the protection of the dual UCBs when the ORIG CC is ERRORED and the COPY CC is CONFIRMED, the disable protection command sequence shall be issued with the password of the COPY UCB.

In either case, the ERRORED UCB shall be provided full read and write access.

***Note**: PWD protection is evaluated based on the GP_HOST_PROTECT or GP_CSRM_PROTECT registers and of the dual UCBs overall status. The value of the dual UCBs CCs does not reflect their protection status. A disable protection command sequence does not change the CC value but changes the relevant status bit in the GP_HOST_PROTECT or GP_CSRM_PROTECT registers.*

***Note**: Limitations in the AURIX™ 3rd Generation*

- *Single-UCBs: UCB_USER_DATA0, UCB_USER_DATA1, UCB_CS_USER_DATA0, and UCB_CS_USER_DATA1*
  - *If the UCB is in ERRORED state, the UCB cannot be recovered*

***Note**: In order to avoid this shortcoming, during the programming phase the following shall not occur:*

- *writing the incorrect confirmation code in the UCBs*
- *brownout or voltage losses*
- *resets while writing confirmation codes*

but also ensure that:

- *setups with compiler generating the binary files are generated correctly*
- *no issues with the debug tools present*

5.3.8.18 Resume protection

Calling

- ST 5554_H, xxF5$_H$

Function

This command clears all DMU_GP_HOST_PROTECT (Host Command Interface) or DMU_GP_CSRM_PROTECT (CSRM Command Interface) and enables again the Flash protection as it was configured.

5.3.8.19 Clear status

Calling

- ST 5554_H, xxFA_H

Function

Clear operation and error flags.
Clearing of error flags will not solve the underlying problem that caused the error flag.

Host Command Sequence interpreter

The following flags of the register DMU_HCI_STATUS are cleared:
- PROG
- ERASE
- USER
- REQACK
- REQDONE

The following flags of the register DMU_HCI_ERR are cleared:
- PVER
- EVER

CSRM Command Sequence interpreter

The following flags of the register DMU_CSCI_STATUS are cleared:
- PROG
- ERASE
- USER
- REQACK
- REQDONE

The following flags of the register DMU_CSCI_ERR are cleared:
- PVER
- EVER

5.3.8.20 Bank sleep

Calling

- ST $AA00_H$, **BS**

Function

Sets all banks defined by **BS** into an off - state ("`Sleep`") for power reduction during which no read or operation on these banks is possible.

- **BS**: Bank selection coded as 32-bit vector:
  - Bit 0: HOST PFLASH0A
  - Bit 1: HOST PFLASH0B
  - Bit 2 : HOST PFLASH1A
  - ...
  - Bit 11: HOST PFLASH5B
  - Bit 12 -15 : reserved - 0
  - Bit 16 : HOST DFLASH (includes UCB)
  - Bit 17: CSRM DFLASH (includes UCB)
  - Bit 18: CSRM PFLASH
  - Bit 19-31 : reserved - 0

***Note**: For products with less PFLASH (HOST) Banks, it is necessary to adapt the BS accordingly. Example: a product with 10 PFLASH (HOST) banks would make use of bits 0 to 9 (i.e. HOST PFLASH0A to PFLASH4B) and would have bits 10 - 15 as reserved.*

Please note the following hints:

- The command interface can only set to `Sleep` those Banks which are allocated to this command channel
- A bank under operation (for example erase) cannot be set into `Sleep` mode[9].
- A Bank in `Sleep` mode gets a BUSY indication in the status register DMU_HCI_STATUS or DMU_CSCI_STATUS
- A bank in `Sleep` mode gets an indication in the status register DMU_HCI_SLEEP or DMU_CSCI_SLEEP

The command fails with an error flag in the following situations:

- A part of the addressed banks is already in sleep → *Sequence Error (SQER)*
- An invalid bank is selected (for example, reserved bits), → *Sequence Error (SQER)*
- An operation is running → *Bus Error (BE)*
- Master is not allowed to operate on the command interface → *Bus Error (BE)*

***Note**: If all banks of both command interfaces are set to `Sleep` then the NVM will enter a "deep sleep" state during which also common analog resources are switched off.*

HOST command interface registers

Table 412 HOST command interface registers

Register	Use
DMU_HCI_STATUS	Status, BUSY indication
DMU_HCI_ERR	Error flags
DMU_HCI_SLEEP	Sleep status indication

[9] application of sleep would only be possible if the NVM operation was aborted

CSRM command interface registers

Table 413 CSRM command interface registers

Register	Use
DMU_CSCI_STATUS	Status, BUSY indication
DMU_CSCI_ERR	Error flags
DMU_CSCI_SLEEP	Sleep status indication

5.3.8.21 Bank wake-up

Calling

- ST $AAF0_H$, **BS**

Function

Wakes up all (sleeping) banks defined by **BS** into an idle state during which a read or operation on these banks is possible.

- **BS**: Bank selection coded as 32-bit vector:
  - Bit 0: HOST PFLASH0A
  - Bit 1: HOST PFLASH0B
  - Bit 2 : HOST PFLASH1A
  - …
  - Bit 11: HOST PFLASH5B
  - Bit 12 -15 : reserved - 0
  - Bit 16 : HOST DFLASH (includes UCB)
  - Bit 17: CSRM DFLASH (includes UCB)
  - Bit 18: CSRM PFLASH
  - Bit 19-31 : reserved - 0

***Note**: For products with less PFLASH (HOST) Banks, it is necessary to adapt the BS accordingly. Example: a product with 10 PFLASH (HOST) banks would make use of bits 0 to 9 (i.e. HOST PFLASH0A to PFLASH4B) and would have bits 10 - 15 as reserved.*

Please note the following hints:

- The command interface can only wake up those banks which are allocated to this command channel
- A Bank under read or operation cannot be waken up

The command fails with an error flag in the following situations:

- A part of the banks is already in read or operation state → *Sequence Error (SQER)*
- An invalid bank is selected (for example, reserved bits), → *Sequence Error (SQER)*
- An operation is running → *Bus Error (BE)*
- Master is not allowed to operate on the command interface → *Bus Error (BE)*

Attention**: **For waking up n banks it is necessary to apply the command n times.

***Note**: If the NVM is in Deep Sleep then the wake up timing of the first bank is longer because first the common analog resources are switched on, then the Bank is woken up.*

HOST command interface registers

Table 414 HOST command interface registers

Register	Use
DMU_HCI_STATUS	Status, BUSY indication
DMU_HCI_ERR	Error Flags
DMU_HCI_SLEEP	Sleep status indication

CSRM command interface registers

Table 415 CSRM command interface registers

Register	Use
DMU_CSCI_STATUS	Status, BUSY indication
DMU_CSCI_ERR	Error Flags
DMU_CSCI_SLEEP	Sleep status indication

5.3.8.22 Bank reallocation

Calling

- ST $AA90_H$, **BS**

Function

Moves all Banks defined by **BS** to the other command interface.

- **BS**: Bank selection coded as 32-bit vector:
  - Bit 0: HOST PFLASH0A
  - Bit 1: HOST PFLASH0B
  - Bit 2 : HOST PFLASH1A
  - ..
  - Bit 11: HOST PFLASH5B
  - Bit 12 -15 : reserved - 0
  - Bit 16 : HOST DFLASH (includes UCB)
  - Bit 17: reserved - 0
  - Bit 18: reserved - 0
  - Bit 19-31 : reserved - 0

***Note**: For products with less PFLASH (HOST) Banks, it is necessary to adapt the BS accordingly. Example: a product with 10 PFLASH (HOST) banks would make use of bits 0 to 9 (i.e. HOST PFLASH0A to PFLASH4B) and would have bits 10 - 15 as reserved.*

Please note the following hints:

- A command interface can only move those banks to the other command interface which currently belong to the interface executing the move command
- Security memory banks cannot be moved
- Only two different modes (allocation sets) are possible
- If one or more of the banks selected to move are under operation (for example erase) then a reallocation is not possible
- If one or more of the banks selected to move are in `Sleep` then a reallocation is not possible
- Banks with ongoing read - accesses may be re-allocated without impact on the reading
- It is only possible to move all PFLASH HOST Banks together but not a subset of it

Table 416 Allowed BS settings

BS Setting for products with 12 PFLASH HOST Banks	Selection
0000 $0FFF_H$	All HOST PFLASH Banks selected

***Note**: For products with less PFLASH (HOST) Banks it is necessary to adapt the **BS**. Example: A product with 8 PFLASH(HOST) banks would need **BS** = 0000 $00FF_H$ to select all PFLASH(HOST) Banks .*

Table 417 Allocation of NVM banks to the command interfaces

DMU Command interface mode	Host command interface	CSRM command interface
Domain mode	HOST PFLASH PFx HOST DFLASH DF(0)	CSRM PFLASH CSRM DFLASH DF(1)
CSRM_ALL_PFLASH mode	HOST DFLASH DF(0)	CSRM PFLASH CSRM DFLASH DF(1) HOST PFLASH PF(x)

The following table and picture shows the allowed transitions between the different Bank allocation; the table also mentions which command interface (CI: HOST or CSRM) may execute the command.

Table 418 Possible transitions

Initial allocation	Command interface involved (CI)	Final allocation
Domain	HOST CI: reallocate PFLASH(HOST) → CSRM CI	CSRM_ALL_PFLASH
CSRM_ALL_PFLASH	CSRM CI: reallocate PFLASH(HOST) → HOST CI	Domain

***Note**: A mode with DFLASH(HOST) on CSRM CI but PFLASH(HOST) on HOST CI is not possible.*

The command fails with an error flag in the following situations:

- A wrong **BS** selection → *Sequence Error (SQER)*
- One or several banks selected for reallocation are under operation (for example `Erase` ongoing) → *Sequence Error (SQER)*
- One or several banks selected for reallocation are in `Sleep` → *Sequence Error (SQER)*
- Master is not allowed to operate on one or several banks selected for reallocation → *Protection Error (PROER)*

Common bank allocation register

The following register shows the current allocation of the memory banks: DMU_GP_BKALLOC

Status bits of PFLASH(HOST) banks during the CSRM_ALL_PFLASH mode

If the PFLASH(HOST) Banks are allocated to the CSRM command interface then the status bits for BUSY and SLEEP states for these Banks are updated only in the CSRM status registers (see the following table). Status bits of these Banks in the HOST status registers are not updated.

To enable an interrupt correlated with a NVM operation on the PFLASH (HOST) banks it is also necessary to use the CSCI_INTEN register.

Also any other control setting or error status information for operations on PFLASH(HOST) memories shall be set or checked in the corresponding CSRM control or status registers (for example CSCI_ERR or CSCI_OCONTROL.

Table 419 CSRM command interface registers

Register	Use
DMU_CSCI_STATUS	Status, BUSY indication
DMU_CSCI_ERR	Error flags

Concurrent NVM operations

Concurrent Operations in Domain Mode:

In Domain Mode the NVM shall provide the software actors with the ability to perform each of the concurrent operation combinations mentioned in the columns of the following table.

HOST channel	HOST PF (bankx)	read	read	read	operation	read	read	read	operation	read	read	read	operation
	HOST PF (banky)	read	read	operation	read	read	read	operation	read	read	read	operation	read
	HOST DF / UCB / CFS	read*	operation	read*	read*	read	operation	read	read	read*	operation	read*	read*
CSRM channel	CSRM PF	read	read	read	read	read	read	read	read	operation	operation	operation	operation
	CSRM DF / UCB / CFS	read*	read	read*	read*	operation	operation	operation	operation	read*	read	read*	read*

Figure 49 Domain Mode Concurrent Operations

Notes:

- "read*" read may be delayed on system to the single SRI port
- "operation" means all ucode controlled sequences, so also a read for a prog verify is included here

Concurrent Operations in CSRM ALL PFLASH Mode:

In CSRM ALL PFLASH mode the NVM shall provide the software actors with the ability to perform each of the concurrent operation combinations mentioned in the columns of the following table.

HOST channel	HOST DF / UCB / CFS	read*	read	operation	read*	operation	read*	operation	read*	operation
CSRM channel	HOST PF (bankx)	read	read	read	read	read	read	read	operation	operation
	HOST PF (banky)	read	read	read	read	read	operation	operation	read	read
	CSRM PF	read	read	read	operation	operation	read	read	read	read
	CSRM DF / UCB / CFS	read*	operation	operation	read*	read	read*	read*	read*	read*

Figure 50 CSRM ALL PFLASH Mode Concurrent Operations

Notes:

- "read*" read may be delayed on system to the single SRI port
- "operation" means all ucode controlled sequences, so also a read for a prog verify is included here

Allocation of banks to command interfaces on page 680

5.3.9 Clocks relevant for NVM

The SRI and FSI clocks are relevant for the NVM functions.

SRI clock

SRI clock is relevant for:

- Counting of wait states during a PFLASH read access
- Duration of data transfers to NVM for write
- Duration of read data transfer from DataFlash

Changing SRI clock

In addition to possible other constraints (see other module chapters and SRI description) it must be ensured that before, during and after the divider change the configured number of PFLASH wait cycles is sufficient for the selected clock frequency. For a change to a higher SRI clock it is necessary to change wait states first to a higher value necessary for the higher clock; then a clock increase can be done.

Attention**: **the SRI clock for the cyber security real time module (CSRM) might be different to the SRI clock of the HOST CPU SRI clusters. This need to be taken into account when configuring the PFLASH read wait states for the CSRM PFLASH Bank. Therefore please check the SRI clock settings for the CSRM from which the applicable wait state settings for the CSRM PFLASH can then be derived.

FSI clock

FSI clock is relevant for:

- Counting of wait states during a DFLASH read access
- Duration of command sequences like `Write Burst` or `Erase Logical Sector Range`

Attention**: **All the command timing parameters in the datasheet (for example: erase timing) are specified for the condition that f_{FSI} = 100 MHz.

Changing FSI clock

It must be ensured that before, during and after the divider change the configured number of DFLASH wait cycles is sufficient for the selected clock frequency. For a change to a higher FSI clock it is necessary to change wait states first to a higher value necessary for the higher clock; then a clock increase can be done.

Attention**: **a FSI clock change during a running NVM operation is NOT possible.

Write burst once on page 699
Error handling on page 685

5.3.10.1 Write settings

Overview

The write operation to the NVM may be controlled by the following settings:

1. Page or Burst mode
2. Program pulse width: 256 bit or 4 x 64 bit

Page versus burst mode

In page mode there is only one page written to the NVM (PFLASH: 32 bytes, DFLASH: 8 bytes).

In the burst mode there are 512 bytes (PFLASH) and 32 bytes (DFLASH) written to the NVM.

The benefit of the burst mode is a higher program throughput because internal NVM voltages do not need to be changed so many times.

- The burst mode is available for PFLASH and DFLASH
- Burst or page mode are selected by choosing the dedicated commands
  - Page mode: `Write Page` or `Write Page Once`
  - Burst mode: `Write Burst` or `Write Burst Once`

Write pulse width

For the PFLASH there is an additional option available to increase the program throughput: this can be done by increasing the number of bits which are written with one program pulse to the memory.

Normally only 64 bits are programmed. So a page write for PFLASH would need four program pulses to write the page size of 256 bits (4 x 64 bits). Also for the burst mode there would be 16 x 4 = 64 pulses to achieve 512 bytes.

When the 256 bit pulse register bit is set to 1_B the program pulse for the page mode would be one pulse only with 256 bits being programmed.

Consequences:

- Higher program throughput
- Higher current consumption

The write pulse width increase is only available for PFLASH and can be selected by the following settings:

- Host command interface: set DMU_HCI_OCONTROL.PRMODE to 1_B
- CSRM command interface: set DMU_CSCI_OCONTROL.PRMODE to 1_B

***Note**: The reset value is 0_B which means that per default four pulses are necessary per page.*

***Note**: Once changed the selection stays valid also for the next write commands until it is changed again.*

For the timings please refer to the following datasheet parameters:

Table 420 PFLASH program timing parameters

Parameter	Program pulse	Page or burst
$t_{PRG_P64_P}$	4 x 64 bit	Page (256 bit)
$t_{PRG_P256_P}$	1 x 256 bit	Page (256 bit)
$t_{PRG_P64_B}$	4 x 64 bit	Burst (16 x 256 bit)
$t_{PRG_P256_B}$	1 x 256 bit	Burst (16 x 256 bit)

Attention**: **Please refer to the datasheet for potential additional restrictions for the 256 bit one pulse programming.

***Note**: Selection of 256 bit one pulse programming cause a higher VDDEXT current consumption than the default 4 x 64 bit pulse program mode.*

Use case: High program throughput

To achieve a high program throughput the following settings shall be used:

- Write burst commands
- 256 bit write pulse

This mode may be beneficial for fast programming during fabrication or garage updates. Applicable restrictions (VDDEXT minimum voltage and current consumption) can be taken into account.

Use case: Low VDDEXT current consumption

In order to achieve a low current consumption at the cost of longer execution timing the following settings shall be used:

- Write burst commands
- 4 x 64 bit write pulse setting

This mode may be beneficial to reduce the VDDEXT current consumption for cases where two concurrent write operations occur: for example a PFLASH-Write together with a DFLASH-Write.

Related information

Concurrent operations on page 679

5.3.10.2 Write sequence

Recommended write sequence

The following sequence is recommended for the write operation.

- `Clear Status` command to clear flags
- `Enter Page Mode` command
- Wait until DMU_HCI_STATUS.PFPAGE = ‘1’ or DMU_HCI_STATUS.DFPAGE = ‘1’ depending upon the Flash target, or fail if DMU_HCI_ERR.SQER = ‘1’ or DMU_HCI_ERR.PROER = ‘1’’
- `Clear Status` command to clear flags
- Repeat `Load Page` command until the page is filled (check HCI_ERR.SQER)
- `Clear Status` command to clear flags
- `Write Page` command
- information: the NVM sets DMU_HCI_STATUS.REQACK = ‘1’ as soon as the NVM receives the first cycle of the command sequence
- Wait until DMU_HCI_STATUS.REQDONE = ‘1’
- Error Flag Checks:
  - Fail if DMU_HCI_ERR.PVER flag
  - Fail if DMU_HCI_ERR.OPER = ‘1’
  - Fail if DMU_HCI_ERR.SQER = ‘1’
  - Fail if DMU_HCI_ERR.PROER = ‘1’
- For information about how to handle the errors refer to Error handling
- Recommended: read programmed content and evaluate it by CRC and or error flags of the memory error correction circuit (ECC)
- Clear error flags either with “Clear Status” or by directly writing to DMU_HCI_CLRERR register

***Note**:* *The steps may also be done when using the CSRM command interface; in this case use the registers DMU_CSCI_STATUS, DMU_CSCI_ERR and DMU_CSCI_CLRERR.*

Program Verify Error (PVER)

There are different ways to react on a *Program Verify Error (PVER)*. Please refer to the following two chapters for further information:

- Write page (Write page)
- Error handling (Error handling)

Critical section

The following commands shall be applied by the software in a sequence which is not interrupted by another software accessing the same command interface:

- `Clear Status`
- `Enter Page Mode`
- `Load Page` as often as necessary to fill buffer
- `Clear Status`
- `Write Page` (or `Write Burst`)

Alternative write sequence using several interrupts

The following sequence is a possible alternative to the write sequence. For this alternative several interrupts are used.

- `Clear Status` command to clear flags

- `Enter Page Mode` command
- Wait until DMU_HCI_STATUS.PFPAGE = ‘1’ or DMU_HCI_STATUS.DFPAGE = ‘1’ depending upon the Flash target, or fail if DMU_HCI_ERR.SQER = ‘1’ or DMU_HCI_ERR.PROER = ‘1’’
- `Clear Status` command to clear flags
- Repeat `Load Page` command until the page is filled
- `Write Page` command
- Wait until one of the following interrupts[10]:
  - Sequence error interrupt
  - Protection error interrupt
  - Operation error interrupt
  - End of busy interrupt
- Error Flag Checks:
  - Fail if DMU_HCI_ERR.PVER flag
  - Fail if DMU_HCI_ERR.OPER = ‘1’
  - Fail if DMU_HCI_ERR.SQER = ‘1’
  - Fail if DMU_HCI_ERR.PROER = ‘1’
- For information about how to handle the errors refer to Error handling, see also the remarks given in the previous section about the handling of PVER.
- Recommended: read programmed content and evaluate it either CRC, error flags of the memory error correction circuit (ECC) or both
- Clear error flags either with “Clear Status” or by directly writing to DMU_HCI_CLRERR register

***Note**: The steps may also be done when using the CSRM command interface; in this case use the registers DMU_CSCI_STATUS, DMU_CSCI_ERR and DMU_CSCI_CLRERR.*

Timeout

The datasheet parameters (for example $t_{PRG_P256_B}$) can be used for a timeout check after the application of the `Write Page` command. To account for potential system related additional timing (for example command transfer from CPU via SRI to DMU) it is recommended to use: (datasheet value) + (5 µs) as timeout value.

Further notes

At the end of the write operation the busy flag of a bank is set back to "0" which indicates that all operations on the bank are finished and a read from the bank is possible again. The "end of busy" interrupt is asserted by the falling edge transition of the busy flag in DMU_HCI_STATUS or DMU_CSCI_STATUS.

However the command sequence might not yet been finished: for example there may be a write of FSI_COMMx registers ongoing. The real end of the command sequence execution is signaled by DMU_HCI_STATUS.REQDONE = ‘1’

Related information

Write page on page 696

10 prerequisite: all of these interrupts are enabled before the start of the write sequence

5.3.11 Erase operation hints

The following chapters describe applicable erase sizes and show an example sequence for erase, which also includes the use of status and error flags.

Related information

Erase logical sector range on page 707

5.3.11.1 Erase range sizes

PFLASH erase range sizes

Table 421 PFLASH erase range sizes

Size	Description	Size [Kbyte]
Minimum size	Logical Sector	16
Maximum size	Contiguous Range of Logical Sectors	512

***Note**: For the AURIX™ TC4xx products it is allowed that the range of logical sectors may cross a physical sector boundary.*

DFLASH erase range sizes

Table 422 DFLASH erase range sizes

Size	Description	Size [Kbyte]
Minimum size	Logical Sector	2
Maximum size	Contiguous Range of Logical Sectors	256

***Note**: For the AURIX™ TC4xx products it is allowed that the range of logical sectors may cross a physical sector boundary.*

***Note**: One UCB comprise also a logical sector with 2 Kbyte.*

5.3.11.2 Erase sequence

Recommended erase sequence

The following sequence is recommended for the erase operation.

- `Clear Status` command to clear flags
- `Erase Logical Sector Range` command
- information: the NVM sets DMU_HCI_STATUS.REQACK = '1' as soon as the NVM receives the first cycle of the command sequence
- Wait until DMU_HCI_STATUS.REQDONE = '1'
- Error Flag Checks:
  - Optional: Check for DMU_HCI_ERR.PVER flag (PFLASH: Erase counter program fail, would not block the erase)
  - Fail if DMU_HCI_ERR.EVER flag
  - Fail if DMU_HCI_ERR.OPER = '1'
  - Fail if DMU_HCI_ERR.SQER = '1'
  - Fail if DMU_HCI_ERR.PROER = '1'
- For information about how to handle the errors refer to Error handling
- Clear error flags either with "Clear Status" or by directly writing to DMU_HCI_CLRERR register

***Note**: The steps may also be done when using the CSRM command interface; in this case use the registers DMU_CSCI_STATUS, DMU_CSCI_ERR and DMU_CSCI_CLRERR.*

Alternative erase sequence using several interrupts

The following sequence is a possible alternative to the erase sequence. For this alternative several interrupts are used.

- `Clear Status` command to clear flags
- `Erase Logical Sector Range` command
- Wait until one of the following interrupts[11]:
  - Sequence error interrupt
  - Protection error interrupt
  - Operation error interrupt
  - End of busy interrupt
- Error Flag Checks:
  - Optional: Check for DMU_HCI_ERR.PVER flag (PFLASH: Erase counter program fail, would not block the erase)
  - Fail if DMU_HCI_ERR.EVER flag
  - Fail if DMU_HCI_ERR.OPER = '1'
  - Fail if DMU_HCI_ERR.SQER = '1'
  - Fail if DMU_HCI_ERR.PROER = '1'
- For information about how to handle the errors refer to Error handling
- Clear error flags either with "Clear Status" or by directly writing to DMU_HCI_CLRERR register

***Note**: The steps may also be done when using the CSRM command interface; in this case use the registers DMU_CSCI_STATUS, DMU_CSCI_ERR and DMU_CSCI_CLRERR.*

11 prerequisite: all of these interrupts are enabled before the start of the erase sequence

Timeout

The datasheet parameters (for example t_{RANGE_ERP}) can be used for a timeout check after the application of the `Erase Logical Sector Range` command. To account for potential system related additional timing (for example command transfer from CPU via SRI to DMU) it is recommended to use: (datasheet value) + (5 µs) as timeout value.

Further notes

At the end of the write operation the busy flag of a bank is set back to "0" which indicates that all operations on the bank are finished and a read from the bank is possible again. The "end of busy" interrupt is asserted by the falling edge transition of the busy flag in DMU_HCI_STATUS or DMU_CSCI_STATUS.

However the command sequence might not yet been finished: for example there may be a write of FSI_COMMx registers ongoing. The real end of the command sequence execution is signaled by DMU_HCI_STATUS.REQDONE = ‘1’

5.3.12 Abort

This section details the use of the abort command.

5.3.12.1 Command overview

This chapter describes the general concept of the abort feature.

Table 423 NVM abbreviations

Abort
A running NVM operation can be aborted. This means that the operation is terminated immediately . ***Note**: An aborted NVM operation might result in an undefined Flash memory content (with respect to the operation range of the aborted operation).* Software may abort a running NVM operation by writing 1_B to DMU_HCI_OCONTROL.ABORT (HOST command interface) or DMU_CSCI_OCONTROL.ABORT (CSRM command interface) ***Note**: Abort may need a certain time until read or another operation is possible. The maximum time is defined by the datasheet parameter t_{SPNDP} for PFLASH or t_{SPNDD} for DFLASH.*

5.3.12.2 Command interface states

The commands described above are possible for each command interface. The state of one command interface is independent from the state of the other command interface.

The state of a command interface can be modeled as *m* with *m* ϵ {*'idle'*, *'active'*}. The value of *m* denotes the current operation mode of the channel.

Table 424 Command interfaces stack and active or idle states

State	m (operation mode)	Description
A	Idle	• No abort command • No command is currently executed, any new command may be started
B	Active	• Abort is possible • A command is currently executed

Example: A running ERASE request on PFLASH Bank can be expressed by the state (active)

The following figure shows the state transition graph.

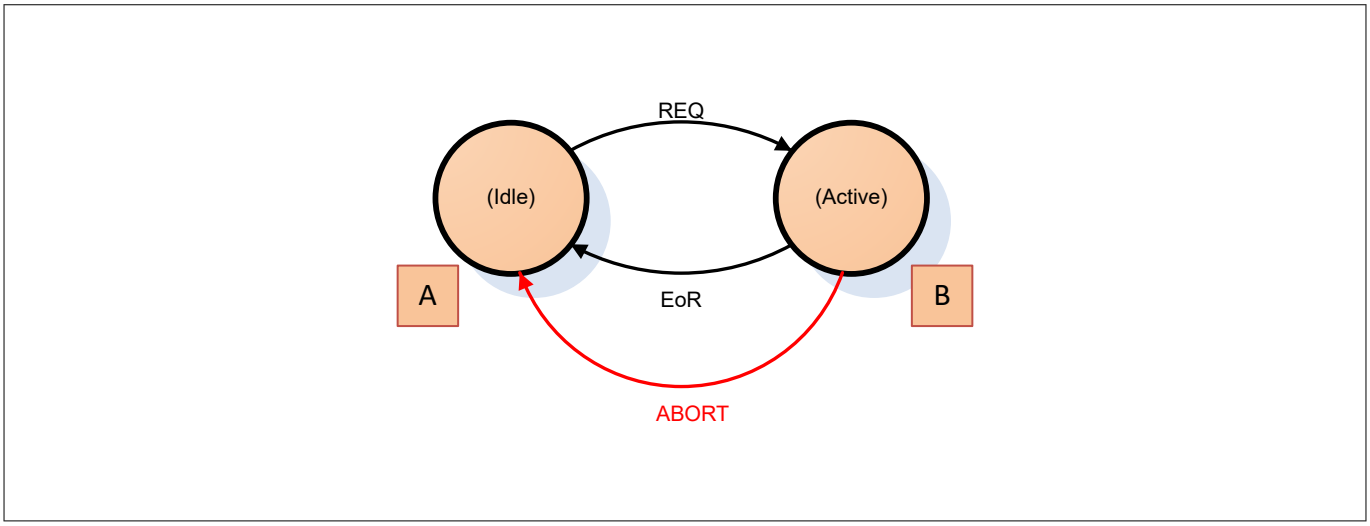

Figure 51 Command interface state transitions

Table 425 Abbreviations used in previous figure

Abbreviation	Description
REQ	Request for operation is applied on command interface (for example: Write Page sequence)
EoR	The operation is finished
ABORT	The operation is aborted

The new feature of AURIX™ TC4xx NVM, namely *Abort* is also shown in the figure. As already mentioned in a previous section an *Abort* terminates any running operation. Thus, an *Abort* creates a state transition from state *('active')*to state *('idle')*. These transitions are highlighted in red.

5.3.12.3 Abort operation

List of operations which may be aborted

The following operations may be aborted:

- `Write Page, Write Page Once, Write Burst, Write Burst Once`
- `Erase Logical Sector Range`
- `Verify Erased Page, Verify Erased WL, Verify Erased Logical Sector Range`
- `User Margin Count, User Vth Count, Content Count`

Erroneous abort requests are detected and prevented by the DMU.

Abort

Software may abort a NVM operation by writing 1_B to DMU_HCI_OCONTROL.ABORT.

- The command interface checks if there is a flash operation requested or ongoing
  - If not, then the abort request is ignored and DMU_HCI_OCONTROL.ABORT is cleared
- The command interface checks if the ongoing flash operation may be aborted
  - If not, then the DMU:
    - Reports an abort error (DMU_HCI_ERR.ABER = 1_B)
    - Waits for the flash operation to be finished
    - Then clears the abort request (DMU_HCI_OCONTROL.ABORT = 0_B)
- In the case of a valid abort request, the DMU executes the abort and proceeds as follows:
  - The DMU waits for the NVM operation to reach a state where an abort can be done
  - The running operation is aborted and the bank which was under operation is set back to read state
  - Then the busy flag of the bank is cleared
  - DMU_HCI_OCONTROL.ABORT is cleared
- After a command has been aborted:
  - A new NVM operation may be started

***Note**: The abort of a `Write` command leads to an exit of the PAGE MODE*

CSRM command Interface

The Abort operation is also possible on the CSRM command interface for operations which are operated by this interface. Abort on the CSRM command interface is completely independent from the Abort on the Host command interface. For operation please use the following registers of the CSRM Command Interface:

- DMU_CSCI_OCONTROL.ABORT
- DMU_CSCI_ERR.ABER

5.3.12.4 Abort application hints

Abort operation => undefined memory state

Aborting a write or erase operation leaves the target memory range of this operation in an **undefined state**. Reading this range may deliver unpredictable results.

Minimum time between start and abort recommendation

There is no minimum time necessary if a restart of the operation after the abort is not planned. If however the abort is used to start a new operation "B" and after the completion of "B" there is a restart of the aborted operation planned then the time between the start of a Flash operation and the abort request shall be ~10 ms. Timings mentioned above are valid for f_{FSI} = 100 MHz and need to be scaled up accordingly when using a lower FSI frequency.

Abort an ongoing NVM operation

- Check if the corresponding BUSY flag has already been cleared
  - If BUSY = 0_B:
    - the command was finished already
- Request abort with the control flag DMU_HCI_OCONTROL.ABORT set to 1_B
- Wait until the corresponding BUSY flag clears
- Now, a new Flash operation is allowed

Attention**: **by using the abort feature the complete information about the aborted command is deleted. Instead a new command sequence is necessary if the aborted operation need to be done.

CSRM command Interface

The same guidance is applicable for CSRM Command Interface using the following registers:

- DMU_CSCI_OCONTROL.ABORT
- DMU_CSCI_ERR.ABER

5.3.13 UCB handling

This chapter details the handling of UCBs during startup and re-programming.

Attention**: **The Erase operation of the UCB takes more time than the 'normal' Erase operation of a logical sector in the DFLASH(EEPROM) region, for UCB erase please refer to the datasheet timing $t_{SECTOR_ERDM_LC_UCB}$.

Related information

UCB on page 668

5.3.13.1 UCB confirmation code and UCB state evaluation

The state of a UCB is determined by the evaluation of the confirmation codes.

Table 426 UCB confirmation codes

Confirmation code	Value	Description
ERASED	0000 0000$_H$	Erased State The UCB confirmation code was erased. The behavior is the same as for the **ERRORED** state. ***Note**: The **ERASED** state is considered a special case of **ERRORED** and will not be used in the rest of the UCB state descriptions.*
UNLOCKED	4321 1234$_H$	Delivery State The UCB confirmation code is programmed with the **UNLOCKED** value.
CONFIRMED	57B5 327F$_H$	Operational State The UCB confirmation code is programmed with the **CONFIRMED** value. ***Note**: The **UNLOCKED** value can be over programmed with the **CONFIRMED** value.*
ERRORED	Others	Errored State The UCB confirmation code stored is not the **CONFIRMED** or **UNLOCKED** value.

The erased state is considered as **ERRORED** to ensure that a complete loss of UCB content is not leading to the installation of wrong configurations and wrong or no protections.

The device is delivered with UCBs in **UNLOCKED** state. After user configuration, the UCBs shall be changed to **CONFIRMED** state by over-programming the **UNLOCKED** confirmation code value with the **CONFIRMED** confirmation code value (keeping the 4 bytes following the confirmation code to 0000 0000$_H$ to ensure an ECC clean page).

In fact the state of the UCBs is determined by evaluating a pair of confirmation codes called ORIG and COPY confirmation codes.

Single UCB

A single UCB contains full content and a pair of ORIG and COPY confirmation codes in the same UCB.
The state of the UCB is evaluated as follow :

Table 427 Evaluation of the pair of confirmation codes in single UCB

ORIG confirmation code	COPY confirmation code	UCB state
UNLOCKED without uncorrectable ECC error	any state	Only ORIG is evaluated. The UCB is considered **UNLOCKED** and the content can be used.
CONFIRMED without uncorrectable ECC error	any state	Only ORIG is evaluated. The UCB is considered **CONFIRMED** and the content can be used.
ERRORED or uncorrectable ECC error detected	**UNLOCKED**	ORIG and COPY are evaluated. The UCB is considered **UNLOCKED** and the content can be used. An *original error (ORIER)* is set.
ERRORED or uncorrectable ECC error detected	**CONFIRMED**	ORIG and COPY are evaluated. The UCB is considered **CONFIRMED** and the content can be used. An *original error (ORIER)* is set.
ERRORED or uncorrectable ECC error detected	**ERRORED** or uncorrectable ECC error detected	ORIG and COPY are evaluated The UCB is considered **ERRORED** and the content can not be used. An *original error (ORIER)* is set.

Note the *original error (ORIER)* is visible per channel in the respective registers : DMU_HCI_ERR for HOST UCBs or DMU_CSCI_ERR for CSRM UCBs.

***Note**: to increase UCB's security, it is recommended to set both ORIG and COPY confirmation codes to CONFIRMED to avoid unexpected changes to the UCB's state when UCERs occur on the ORIG confirmation code.*

Dual UCB

A dual UCB is a pair of UCBs containing redundant content. The UCBs are called ORIG and COPY UCBs. In this case the ORIG UCB contains a ORIG confirmation code and the COPY UCB the COPY confirmation code.

The state of the dual UCB is evaluated as follow :

Table 428 Evaluation of the pair of confirmation codes in dual UCBs

ORIG confirmation code from the ORIG UCB	COPY confirmation code from the COPY UCB	UCB state
UNLOCKED without uncorrectable ECC error	any state	Only ORIG is evaluated. The UCB is considered **UNLOCKED** and the content of the ORIG UCB can be used. ***Note**: COPY UCB has full read and write access, regardless of its state.*
CONFIRMED without uncorrectable ECC error	any state	Only ORIG is evaluated. The UCB is considered **CONFIRMED** and the content of the ORIG UCB can be used. ***Note**: when COPY UCB is ERRORED, it can be fully recoverable, providing that the password protection is disabled on ORIG UCB.*
ERRORED or uncorrectable ECC error detected	**UNLOCKED**	ORIG and COPY are evaluated. The UCB is considered **UNLOCKED** and the content of the COPY UCB can be used. ***Note**: ORIG UCB is fully recoverable.*
ERRORED or uncorrectable ECC error detected	**CONFIRMED**	ORIG and COPY are evaluated. The UCB is considered **CONFIRMED** and the content of the COPY UCB can be used. ***Note**: ORIG UCB is fully recoverable, providing that the password protection is disabled on COPY UCB.*
ERRORED or uncorrectable ECC error detected	**ERRORED** or uncorrectable ECC error detected	ORIG and COPY are evaluated The UCB is considered **ERRORED** and the content can not be used.

***Note**: to increase UCBs' security, it is recommended to set the confirmation code of both ORIG and COPY UCBs to CONFIRMED to avoid unexpected changes to the UCB's state when UCERs occur on the UCB ORIG confirmation code.*

Related registers

After evaluation of the confirmation codes while startup the DMU will store the status of the HOST UCBs in the DMU_GP_HOST_CONFIRMA, DMU_GP_HOST_CONFIRMB, DMU_GP_HOST_CONFIRMC and the status of the CSRM UCBs in the DMU_GP_CSRM_CONFIRMA, DMU_GP_CSRM_CONFIRMB, DMU_GP_CSRM_CONFIRMC.

Note after an update of the content or the state of a UCB a reset is necessary for the DMU to recover the new information.

***Note**: while in delivery state and during the programming phase of the UCBs, any reset is to be avoided until all UCBs have been programmed to prevent inconsistencies in the life cycle state.*

5.3.13.2 UCB COPY and ORIG update procedure

Dual UCB with password: ORIG and COPY reprogramming

The data stored in the ORIG and COPY of a UCB pair shall be identical. If there is a need to change the data then the following sequence shall be followed:

- Check if UCB ORIG is either **UNLOCKED** or **CONFIRMED**:
  - The data and *password* are recovered from the UCB ORIG
- If UCB ORIG is **ERRORED** then:
  - The data and *password* are recovered from the UCB COPY, but only if UCB COPY is either **UNLOCKED** or **CONFIRMED**
  - If UCB COPY was also **ERRORED** then there was a startup error
- Apply the *password* with the command sequence `Disable Protection`. This disables protection for both: ORIG and COPY UCBs
- Erase COPY UCB - the confirmation code is treated as **ERRORED** for the installation
- Program in COPY UCB the data and the confirmation code to **CONFIRMED**
- Erase ORIG UCB - the confirmation code is treated as **ERRORED** for the installation
  - After a reset the data and the confirmation code would be sourced now from the COPY UCB
- Program in ORIG UCB the data and the confirmation code to **CONFIRMED**
  - After a reset the data and the confirmation code will be sourced from the ORIG UCB
- Enabling of protection can be done either by:
  - Command sequence Resume Protection
  - Or MCU reboot (system reset)

The ORIG UCB is always evaluated. The above sequence ensures that the new data is confirmed in COPY before the ORIG is re-programmed. It avoids a scenario where the ORIG confirmation state is **ERRORED** and the COPY confirmation state is also **ERRORED**.

The following flowchart details the flow for use cases where one of both UCBs is errored.

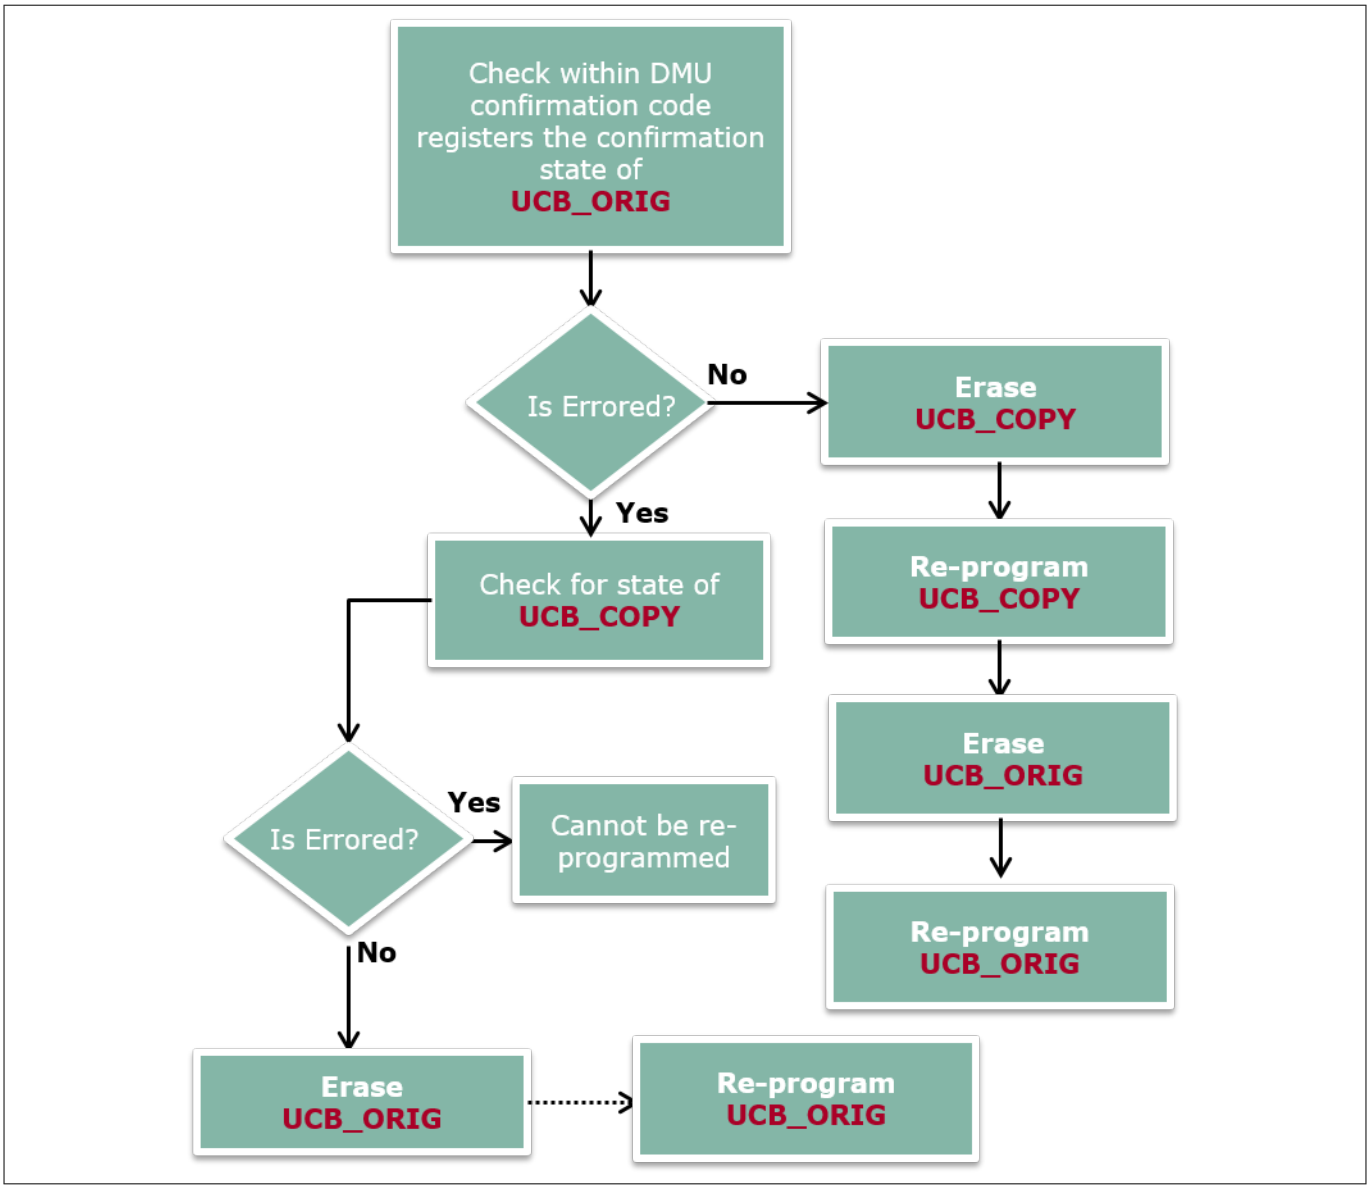

Figure 52 Dual password UCB update flow

Dual UCB without password: OTPx ORIG and COPY reprogramming

The normal use case of the UCB OTPx is different to the standard password protection UCBs: UCB OTPx are normally programmed in a sequential manner and the final protection setting is an OR function of all OTPxy protection sets.

There is no password protection but once a single OTPxy protection set gets his confirmation code to **CONFIRMED** programmed then this UCB OTPxy set cannot be programmed again any longer and the whole UCB OTPx cannot be erased anymore.

So as long as all OTPxy sets have confirmation code in **UNLOCKED** state it is possible to erase the UCB OTPx and re-program it.

Beside these constraints the flow of updating the UCB OTPx ORIG and COPY is the same as mentioned in the previous section for the password protected UCBs.

UCB1_7	UCB_CS_PFLASH_OTP0_ORIG	UNLOCKED
UCB1_8	UCB_CS_ECPRIO_ORIG	UNLOCKED
UCB1_9	UCB_CS_PFLASH_OTP0_COPY	UNLOCKED
UCB1_10	UCB_CS_ECPRIO_COPY	UNLOCKED
UCB1_11	UCB_CS_FLASH_ORIG	UNLOCKED
UCB1_12	UCB_CS_SWAP_ORIG	UNLOCKED
UCB1_13	UCB_CS_SWAP_COPY	UNLOCKED

(table continues...)

Table 429 (continued) Device state table

UCB Number	UCB Name	Delivery State
UCB1_14	UCB_CS_FLASH_COPY	UNLOCKED
UCB1_15	UCB_CSRM_ORIG	UNLOCKED
UCB1_16	UCB_CSRM_COPY	UNLOCKED
UCB1_24	UCB_CS_USER_DATA0	UNLOCKED
UCB1_25	UCB_CS_USER_DATA1	UNLOCKED

***Note**: The detailed description of the UCB is available in the Firmware chapter of this manual.*

Attention**: **For a secure operation in field it is mandatory to set to CONFIRMED state at least one of those UCBs which cannot be changed back to UNLOCKED state by using Disable Protection Command and erase+write operation. Examples for UCBs being unchangeable with CONFIRMED state are: UCB_RTC_PFLASH_OTP0_ORIG or UCB_CS_PFLASH_OTP0_ORIG.

5.3.14 Access protection

This section details the use of protection for NVM memory ranges, command interfaces and configuration registers.

5.3.14.1 Operation protection

A change of the NVM content is done by performing a NVM operation like `Write Page` or `Erase Logical Sector Range`. It is necessary to protect the NVM memory regions against accidental and unauthorized changes. For this there are different protection mechanisms available, which are described in the following chapters.

If activated the operation protection mechanisms block **any** NVM operation on a specific memory region. This also includes operations which may not (directly) change the content of the NVM but are used for other purpose: for example data integrity check operations like `Verify Erased Wordline` or the `Replace Logical Sector` function. Only masters which are allowed to perform a change of the memory may analyze the memory or perform a replacement of a sector.

5.3.14.1.1 Operation protection overview

The following figure shows an overview of the three protection levels used during normal operation in field.

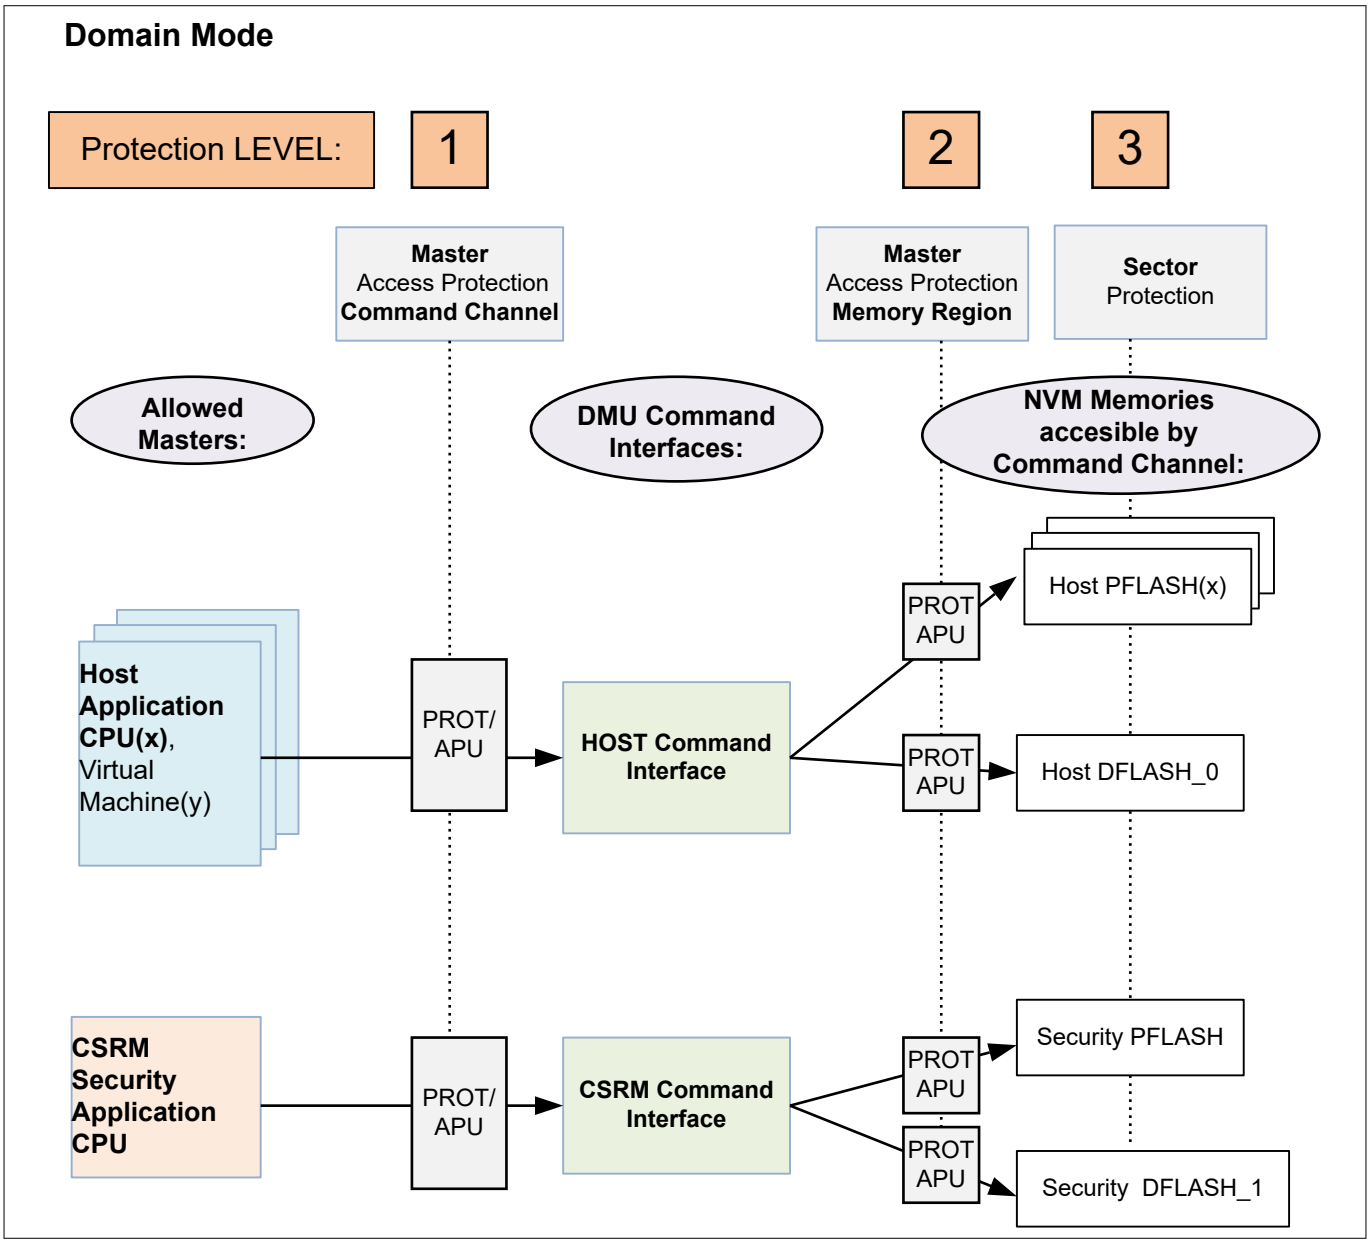

Figure 53 Protection levels for NVM operation

Table 430 Brief description of the three protection levels

Level	Name	Description	Usage examples
1	Master Acces Protection on Command Channel	Master → Resource[1)] Protection	One Command Channel exclusive for CSRM CPU operating on secure memories
2	Master Access Protection on Memory Region	Master → Memory Region Protection	Blocking of accidental PFLASH(Host) Writes, Access Protection to secure memories
3	Sector Protection	Master independent Protection of individual (PFLASH) logical sectors or regions	Write protection of selected PFLASH logical sectors independent from a master
		Master independent Protection of the whole PFLASH (HOST) region and DFLASH (HOST)	Write protection of the whole PFLASH with one password

1) Command Channel

The NVM shall perform a NVM Operation only if all of the three protection levels allow this:

1. Augmented Master ID matches with the IDs allowed by the APU of the command channel used
2. Augmented Master ID matches with the IDs allowed by the APU for the addressed memory region
3. Protection of all sectors of the memory region targeted by the NVM Operation is either not set or disabled

***Note**: in addition to the restrictions mentioned above there are certain memory regions which never can be changed by the application, for example: erase counter regions, certain UCBs with Infineon configuration, customer UCBs for Permanent Write (OTP) protection after program of confirmation code. Please refer to the description of a memory or function for a check whether a change of this memory is possible or not.*

Data flash banks on page 658
Error handling on page 685
Allocation of banks to command interfaces on page 680

5.3.14.1.2 Master access protection on command channels

Each command channel has a separate set of PROT and APUs to configure the access protection.

Table 431 Command channel access protections

Resource	Function	Number of PROT	Number of APU
HOST Command Channel	NVM Operation	1	1
HOST Command Channel Configuration Registers	Read or Write Register		
CSRM Command Channel	NVM Operation	1	1
CSRM Command Channel Configuration Registers	Read or Write Register		

There is a common protection for the **command channel** itself and its **configuration registers**.

The setting for WRITE access means:

- A master may perform a NVM Operation using this command channel
- A master may change the command channel configuration registers

The setting for READ access means:

- A master can read the command channel configuration registers

Upper or lower address region definition registers in the APU are not used here. The protection is valid for both: command channel and all configuration registers for this channel.

The following list contains examples for command channel configuration registers which are protected by this mechanism:

- Command configuration registers (for example program modes)
- Status registers (for example: busy)
- Program and erase error registers (for example: program verify error)
- Communication registers (for example: communication registers used for data integrity check commands)

Use Case: Different settings for register read and write

Within one domain (for example: HOST domain) there is normally no need to restrict the READ access to the registers of the command channel. On the other hand the WRITE access to registers is usually only needed for those masters which are also allowed to write a memory range and to use this command channel for the write operation to the memory range.

Different PROT/APU for HOST and CSRM command channel and register protection ensure that the read or write access to CSRM command channel configuration registers can be limited to secure masters.

5.3.14.1.3 Master access protection on memory regions

For each memory region there is an independent set of PROT/APU available; please refer to the following table.

Table 432 Memory protections by PROT/APU

Memory	Function	Number of PROT	Number of APU
PFLASH (HOST) Banks	NVM Operation	1	product dependent: = number of Banks
PFLASH (CSRM) Bank	NVM Operation	1	4
DFLASH (HOST)	Read and NVM Operation	1	8
UCB of DFLASH (HOST)	Read and NVM Operation		1
DFLASH (CSRM)	Read and NVM Operation	1	4
UCB of DFLASH (CSRM)	Read and NVM Operation		1

***Note**: The access protection for PFLASH (HOST and CSRM) READ is within the CPU; please refer to the description of the CPU.*

DFLASH and UCB protection

For the DFLASH (HOST) Bank there is one common PROT but different APUs:

- 8 APUs for the DFLASH (HOST) EEPROM Memory Range (APU upper and lower address registers can be used)
- 1 APU which is dedicated solely for the UCBs of the DFLASH (HOST), no address range definition necessary

For the DFLASH (CSRM) Bank there is one common PROT but different APUs:

- 4 APUs for the DFLASH (CSRM) EEPROM Memory Range (APU upper and lower address registers can be used)
- 1 APU which is dedicated solely for the UCBs of the DFLASH (CSRM), no address range definition necessary

Attention**: **In addition the UCB dependent access restrictions are still valid: if a UCB cannot be read or changed (for example UCB OTP in confirmed state) then the setting of PROT/APU is irrelevant. On the other hand if a read or write access to a UCB is possible then also the APU settings for the UCBs need to allow the master to do this.

Related information

DFLASH master read protection on page 769

5.3.14.1.4 Sector protection

For each logical sector of the PFLASH it is possible to set one of 3 different write protection levels. These protection levels are independent from the master accessing the memory: even if a master is allowed to access a memory range the NVM may refuse the request with protection error (PROER) if at least one logical sector has a write protection which forbids this operation.

The protection levels may be set by writing the information into a specific UCB. During startup and after application reset the protections will be read out from the UCB and be set into the protection registers.

The following table describes the 3 protection levels.

Table 433 Sector protection levels

Level	Blocked	Allowed	Disable Protection during run-time?
Write Protection	All `Erase` and `Write` commands `Replace Logical Sector` command	-	Yes, temporarily possible by `Disable Protection` command
Permanent Write Once Protection	All `Erase` commands All standard `Write` commands `Replace Logical Sector` command	`Write Once` commands (page and burst)	Not possible
Permanent Write Protection (synonym: OTP)	All `Erase` and `Write` commands `Replace Logical Sector` command	-	Not possible

Attention**: **the table above describes the possible operations and changes during runtime. The actual protection setting is defined by the UCB. If a UCB for Write Once Protection or Permanent Write Protection has a confirmation code written to CONFIRMED then this protection cannot be changed anymore

***Note**: the write once commands may also be applied to sectors without any sector protection set: in this case the command does the same function as it does on write-once protected sectors.*

***Note**: The sector protections are available for the PFLASH(HOST) and the PFLASH(CSRM) banks (see the related information for a description).*

PFLASH (HOST) global write protection

It is possible to disable the write access to **all** PFLASH(HOST) Banks. For this the UCB bit has to be programmed as described in the table below. The UCB will be recovered during the startup and after an application reset and the register bit will indicate if the global write protection is set.

Table 434 Register and UCB for global PFLASH read protection

Domain	Register	UCB	UCB_Offset_Address
HOST	DMU_GP_HOST_PFPROCON.RWPRO	DFLASH(HOST): UCB_RTC_FLASH	refer to UCB overview

The global write protection may be temporarily removed by using the `Disable Protection` command with the correct **UC** setting as described in the chapter "Command Sequences".

***Note**: the RWPRO bit shall be also be used if the read from PFLASH shall be blocked in case that the MCU startup is NOT from the internal Flash (please refer to the related information for more details).*

DFLASH (HOST) write protections

It is possible to disable the write access to the complete DFLASH(HOST) bank. For this the UCB bits have to be programmed as described in the table below. The UCB will be recovered during the startup and after an application reset and the register bits will indicate if the write protection is enabled.

Table 435 Register and UCB for global DFLASH read protection

Domain	Register	UCB	UCB_Offset_Address
HOST	DMU_GP_HOST_DFPROCON.WP	DFLASH(HOST): UCB_RTC_FLASH	refer to UCB overview
	DMU_GP_HOST_DFPROCON.RWPRO		

The write protection is enabled if WP or RWPRO is set to 1_B.

Difference between RWPRO and WP: the RWPRO is also the configuration for the DFLASH(HOST) read protection in case that the MCU startup is NOT from the internal Flash, whereas the WP is only a configuration of the write protection.

The write protection may be temporarily removed by using the `Disable Protection` command with the correct **UC** setting as described in the chapter "Command Sequences".

DFLASH (CSRM) write protections

It is possible to disable the write access to the complete DFLASH(CSRM) bank. For this the UCB bits have to be programmed as described in the table below. The UCB will be recovered during the startup and after an application reset and the register bits will indicate if the write protection is enabled.

Table 436 Register and UCB for global DFLASH read protection

Domain	Register	UCB	UCB_Offset_Address
CSRM	DMU_GP_CSRM_DFPROCON.WP	DFLASH(CSRM): UCB_CS_FLASH	refer to UCB overview

The write protection is enabled if WP is set to 1_B.

The write protection may be temporarily removed by using the `Disable Protection` command with the correct **UC** setting as described in the chapter "Command Sequences".

PFLASH global read protection on page 767

DFLASH global read protection on page 771

5.3.14.1.5 Error signaling

If a master requests an access but is not allowed to do the following error signaling is available.

Table 437 Error signaling

Blocked access	Error
Master → Command Channel	Bus Error
Master → Command Channel - Configuration Register Change	Bus Error
Master → Memory Region	Protection Error (see DMU_HCI_ERR.PROER)

***Note**: Protection error on PFLASH(CSRM) is signaled as: DMU_CSCI_ERR.PROER.*

If a master is allowed by the access enable registers (APU) to perform an access but the target memory region has an additional (master independent) active **sector protection** there is also a *Protection Error (PROER)* set.

5.3.14.2 Read protection

The following chapters describe the master access protection on read from NVM memories and on the read configuration (for example wait state settings).

5.3.14.2.1 PFLASH master read protection

The PFLASH read access is controlled by the CPU to which the PFLASH Bank is allocated. Each CPU contains PROT/APU registers for the master access protection on the PFLASH read access.

Related information

PFLASH global read protection on page 767

5.3.14.2.2 PFLASH read configuration protection

The PFLASH read configuration settings can be split into two groups:

- Local PFLASH Bank specific settings like ECC ON and OFF control
- Global PFLASH settings like wait state settings

Local PFLASH bank specific read configuration protection

The local read configuration of a PFLASH Bank is done by PFRWB Flash configuration registers. The following overview lists some of the Bank specific critical read configurations for PFLASH.

- ECC correction ON and OFF
- ECC trap disable
- ECC status register clear
- Tight read margin settings for robustness checks

***Note**: This list contains only examples, for a list of registers please refer to the NVM PFRWB register overview.*

The access to these registers is protected by one PROT and one APU per CPU, please refer to the access protection description of the CPU.

Global PFLASH read configuration protection

There is a central setting of the PFLASH read wait states in the DMU. As a consequence it is necessary to have PROT/APU registers in the DMU for the master access protection on these settings. For this purpose are used the same PROT/APU as for the DFLASH read configuration protection.

Related information

DFLASH read configuration protection on page 769

5.3.14.2.3 PFLASH global read protection

It is possible to disable the read access to **all** PFLASH(HOST) Banks to prevent the readout of NVM content, for example by downloaded code. For this the UCB has to be programmed as described in the tables below. The UCB will be recovered during the startup and after application reset and the register bit will indicate if the global read protection is configured.

Table 438 Register and UCB for global PFLASH read protection

Domain	Register	UCB	UCB_Offset_Address
HOST	DMU_GP_HOST_PFPROCON.RWPRO	DFLASH(HOST): UCB_RTC_FLASH	refer to UCB overview

The register bit DMU_HCI_BCONTROL.DDFP shows the setting:

- DDFP = 0_B: Read access enabled
- DDFP = 1_B: Read access blocked

The following 2 conditions must be met to switch the global read protection on:

1. UCB_RTC_FLASH for DMU_GP_HOST_PFPROCON.RWPRO = 1_B
2. Startup Mode is NOT from internal Flash

The following table shows the possible settings. The next section explains how the protection may be disabled temporarily by the `Disable Protection` command.

Table 439 Global read protection based on RWPRO and internal boot

UCB RWPRO	Boot from Internal Flash	DDFP	Read possible ?	Comment
0	YES	0	YES	
0	NO	0	YES	Fab-configuration: to be used only for initial programming of the device
1	YES	0	YES	**Recommended Default**
1	NO	1	NO	Not recommended for productive devices

Disabling of global read protection if RWPRO = 1 and DDFP = 1

To allow read access it is necessary to change the DDFP register bit to 0_B. The following steps are necessary to do that:

1. Apply the `Disable Protection` command sequence
2. Change the DDFP register bit from 1_B to 0_B

All of the following command sequence must be issued to disable the global read protection:

- Disable the global read protection for all PFLASH HOST Banks
- Disable the global read protection for all PFLASH HOST Banks and for DFLASH HOST
- Disable the read protection and the write protection of a specific PFLASH Bank pAx or pBx

These options can be selected by the **UC** parameter of the `Disable Protection` command; for the description of the possible **UC** settings please refer to chapter Command Sequences.

Please note that even if the global protection is disabled there may be additional APU protections set.

Resume and lock of global read protection if RWPRO = 1

By setting the DDFP register bit to 1_B the read protection is enabled. The bit access can then be locked by the `Resume Protection` command.

Enabling global read protection if RWPRO = 1 and DDFP = 0

In case of RWPRO = 1 and boot from internal Flash the value of DDFP is 0_B to enable the read from PFLASH.
It is possible to activate the global read protection by setting DMU_HCI_BCONTROL.DDFP = 1.
After this a disable of the Global Read Protection is only possible with the Disable Protection Command as described above.

Change of Global Read Protection if RWPRO = 0

If RWPRO is 0 then the direct register access to DMU_HCI_BCONTROL.DDFP is possible to do the following changes:

- Change 0 → 1 (protection enabled)
- Change 1 → 0 (protection disabled)

Summary of direct HCI_BCONTROL register change

The following table summarizes the possibilities for a change of the DMU_HCI_BCONTROL.DDFP.

Table 440 Direct Change of DDFP

RWPRO	DDFP 0 → 1 ?	DDFP 1 → 0 ?
0	YES	YES
1	YES	after Disable Protection

Use of RWPRO for other purpose

The RWPRO configuration is also used to activate a global write protection for all PFLASH Banks which is effective in any case independent from the boot and access mode. The write protection may also be disabled temporarily by the `Disable Protection` command.

Notes on PFLASH(CSRM)

PFLASH(CSRM) does not have a configurable global read and write protection by RWPRO. Per reset the PFLASH(CSRM) has master access control set to CPUcs for read and write. It is also possible to configure sector write protections for the PFLASH (CSRM) per UCB.
In addition it is possible to block the PFLASH (CSRM) reading by setting the DMU_CSCI_BCONTROL.DDFP = 1_B.

***Note**: once set, DMU_CSCI_BCONTROL.DDFP can only be cleared by the next start up.*

Related information

Command sequences on page 689
PFLASH master read protection on page 766
DFLASH global read protection on page 771
Sector protection on page 763

5.3.14.2.4 DFLASH master read protection

The DFLASH read access is controlled by the DMU. For the master access protection on the DFLASH **read** access the same PROT/APU register sets as for the memory region **operation** protection are used.

These APU registers allow to configure the read and the write access by separate settings. Read access means the actual read from the DFLASH memory region and write access means the command operation on the DFLASH memory region (for example: `Write Page`).

Related information

Master access protection on memory regions on page 762
Data flash banks on page 658
DFLASH global read protection on page 771

5.3.14.2.5 DFLASH read configuration protection

The read configuration of DFLASH is done by DMU registers. The following overview lists some of the critical read configurations for DFLASH.

- ECC correction ON and OFF
- ECC trap disable
- ECC status register clear
- Tight read margin settings for robustness checks
- Wait state settings

***Note**: This list contains examples, for a list of registers please refer to the chapters about the functions and the chapter of DMU register overview for the description of the read and write access modes.*

For each DFLASH Bank (HOST, CSRM) there is a **separate** PROT/APU set as described in the table below.

Table 441 Access protection to DFLASH bank read configurations

Resource	Function	Number of PROT	Number of APU
DFLASH (0) (HOST) Read Configuration Registers	Read and write of registers	1	1
PFLASH (HOST) Wait State Setting (see section below)			
DFLASH (1) (CSRM) Read Configuration Registers	Read and write of registers	1	1
PFLASH(CSRM) Wait State Setting (see section below)			

***Note**: Wait state settings shall be configured during software startup and not be changed anymore. Therefore it is recommended to enable the access only during software startup and then lock any access to protect the settings against accidental changes.*

***Note**: APU allows to configure read access to read configuration registers for many actors whereas the write access may be limited to few masters.*

Use of DFLASH read configuration protection for PFLASH wait state setting protection

There is a central setting of the PFLASH read wait states in the NVM.DMU (see related information). As a consequence it is necessary to have master access protection on these settings. For this purpose the same PROT/APU sets are used as for the DFLASH read configuration protection (see table above).

Related information

DFLASH ECC on page 676
Configuring read access cycles on page 671
PFLASH read configuration protection on page 766

5.3.14.2.6 DFLASH global read protection

It is possible to disable the read access to the DFLASH(HOST) Bank to prevent the readout of NVM content, for example by downloaded code. For this the UCB bit has to be programmed as described in the tables below. The UCB will be recovered during the startup and after the application reset and the register bit will indicate if the global read protection is configured.

Table 442 Register and UCB for global DFLASH read protection

Domain	Register	UCB	UCB_Offset_Address
HOST	DMU_GP_HOST_DFPROCON.RWPRO	DFLASH(HOST): UCB_RTC_FLASH	refer to UCB overview

The register bit DMU_HCI_BCONTROL.DDFD shows the setting:

- DDFD = 0_B: Read access enabled
- DDFD = 1_B: Read access blocked

The following 2 conditions must be met to switch the global read protection on:

1. DMU_GP_HOST_DFPROCON.RWPRO = 1_B
2. Startup Mode is NOT from internal Flash

The following table shows the possible settings. The next section explains how the protection may be disabled temporarily by the `Disable Protection` command.

Table 443 Global read protection based on RWPRO and internal boot

UCB RWPRO	Boot from Internal Flash	DDFD	Read possible ?	Comment
0	YES	0	YES	
0	NO	0	YES	Fab-configuration: to be used only for initial programming of the device
1	YES	0	YES	**Recommended Default**
1	NO	1	NO	Not recommended for productive devices

Disabling of global read protection if RWPRO = 1 and DDFD = 1

To allow read access it is necessary to change the DDFD register bit to 0_B. The following steps are necessary to do that:

1. Apply the `Disable Protection` command sequence
2. Change the DDFD register bit from 1_B to 0_B

There are the following possibilities to disable the global read protection:

- Disable the global read protection for DFLASH HOST Banks

These options can be selected by the **UC** parameter of the `Disable Protection` command; for the description of the possible **UC** settings please refer to chapter Command Sequences.

Please note that even if the global protection is disabled there may be additional APU protections set.

Resume and lock of global read protection if RWPRO = 1

By setting the DDFP register bit to 1_B the read protection is enabled. The bit access can then be locked by the `Resume Protection` command.

Enabling global read protection if RWPRO = 1 and DDFD = 0

In case of RWPRO = 1 and boot from internal Flash the value of DDFD is 0_B to enable the read from PFLASH.
It is possible to activate the global read protection by setting DMU_HCI_BCONTROL.DDFD = 1.
After this a disable of the Global Read Protection is only possible with the Disable Protection Command as described above.

Change of Global Read Protection if RWPRO = 0

If RWPRO is 0 then the direct register access to DMU_HCI_BCONTROL.DDFD is possible to do the following changes:

- Change 0 → 1 (protection enabled)
- Change 1 → 0 (protection disabled)

Summary of direct HCI_BCONTROL register change

The following table summarizes the possibilities for a change of the DMU_HCI_BCONTROL.DDFD.

Table 444 Direct Change of DDFD

RWPRO	DDFD 0 → 1 ?	DDFD 1 → 0 ?
0	YES	YES
1	YES	after Disable Protection

Use of RWPRO for other purpose

The RWPRO configuration is also used to activate a write protection for the DFLASH(HOST) which is effective in any case independent from the boot and access mode. The write protection may also be disabled temporarily by the `Disable Protection` command.

Notes on DFLASH(CSRM)

DFLASH(CSRM) does not have a configurable global read and write protection by RWPRO. Per reset the DFLASH(CSRM) has master access control set to CPUcs for read and write. It is also possible to configure a write protection for the DFLASH (CSRM) per UCB.
In addition it is possible to block the DFLASH (CSRM) reading by setting the DMU_CSCI_BCONTROL.DDFD = 1_B.

***Note**: once set, DMU_CSCI_BCONTROL.DDFD can only be cleared by the next start up.*

5.3.14.3 Protection configuration and registers

This section details the registers which contain the protection information. For those registers which are recovered from a UCB during device startup there is also a list of the UCBs.

5.3.14.3.1 Master access protection registers

The PROT and APU registers are all contained in the DMU_PROT register group.

The following table documents the relation between the PROT registers, ACCEN registers and the protected resources :

Table 446 Protection scheme

PROT	Related ACCEN	Related resource
PROTHCI	ACCENHCI	HOST command interface and registers
PROTCSCI	ACCENCSCI	CSRM command interface and registers
PROTHRDC	ACCENHRDC	HOST read configurations registers
PROTCSRDC	ACCENCSRDC	CSRM read configurations registers
PROTHPF	ACCENHPF	HOST PFLASH
PROTHDF	ACCENHDF ACCENHDFUCB	HOST DFLASH HOST UCB
PROTCSPF	ACCENCSPF	CSRM PFLASH
PROTCSDF	ACCENCDF ACCENCDFUCB	CSRM DFLASH CSRM UCB

Please see the address map overview of the registers to know which registers is protected by which ACCEN/APU. After a reset PROT and ACCEN registers have default values which can be changed by the masters having default access. In delivery state the ACCEN/APU are bypassed due to a setting within the APUBYPASS set of the UCB UCB_CS_PFLASH_OTP0. Further details about the life cycle and how to permanently enable the use of ACCEN/APU can be found in the chapter Master access protection life cycle.

Master access protection life cycle on page 779

5.3.14.3.2 Sector protection configuration and registers

During the device startup the DMU reads the sector protection settings from UCBs into the protection registers (which are read-only). The following table shows which registers and UCBs are used for the 3 different sector protections:

Table 447 Registers and UCBs for sector protection

Protection	Registers	UCB
Write protection	DMU_GP_HOST_PFPROCONWPpXn	UCB_RTC_FLASH_ORIG, UCB_RTC_FLASH_COPY
Permanent write once protection	DMU_GP_HOST_PFPROCONPWOPpXn	UCB_RTC_PFLASH_OTP0_ORIG, UCB_RTC_PFLASH_OTP0_COPY, UCB_RTC_PFLASH_OTP1_ORIG, UCB_RTC_PFLASH_OTP1_COPY
Permanent write protection	DMU_GP_HOST_PFPROCONPWPpXn	

The following table explains the indexing "pXn" of the registers:

Table 448 Indexing of bank registers

Index	Description
p	Number of CPU
X	= A or =B for Bank A or Bank B of a CPU
n	Number of physical sector: for a 2 MB Bank n = (0..3) for 4 physical sectors with each having 32 logical sectors (=> 32 bits of register)

The following table shows an example for the write protection registers for the Bank B of CPU(1):

Table 449 Example of DMU_GP_HOST_PFPROCONWPpXn registers for Bank B of CPU(1) if the Bank has 2 MB size

Register	write protection setting for
DMU_GP_HOST_PFPROCONWP1B0	logical sectors 0..31
DMU_GP_HOST_PFPROCONWP1B1	logical sectors 31..63
DMU_GP_HOST_PFPROCONWP1B2	logical sectors 64..95
DMU_GP_HOST_PFPROCONWP1B3	logical sectors 96..127

Table 450 Example of DMU_GP_HOST_PFPROCONWPpXn registers for Bank B of CPU(1) if the Bank has 1 MB size

Register	write protection setting for
DMU_GP_HOST_PFPROCONWP1B0	logical sectors 0..31
DMU_GP_HOST_PFPROCONWP1B1	logical sectors 31..63

***Attention**: The register description chapter always shows all possible registers for a maximum bank size of 2 MB. For Banks with a smaller size there are no registers for those logical sectors which do not exist. The UCB storage area for those registers is "do not care" and not recovered during the startup.*

Configuration of write protection in the UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY

The UCB_RTC_FLASH_ORIG and UCB_RTC_FLASH_COPY is password protected. Once the password protection is disabled by using the `Disable Protection` command with the correct password it is possible to erase or write content to the UCB. Please refer to the UCB address map overview chapter for the offset address of UCB and the offset addresses of UCB content, confirmation codes and passwords.

Note that the Disable Protection command does two things:

- Disables sector specific write protection of the Bank addressed with the command settings
- Disables the write protection of the UCB_RTC_FLASH

Configuration of permanent write once and permanent write protection in the UCB_RTC_PFLASH_OTP0_ORIG, UCB_RTC_PFLASH_OTP0_COPY, UCB_RTC_PFLASH_OTP1_ORIG and UCB_RTC_PFLASH_OTP1_COPY

The handling of the permanent write once protection and permanent write protection is different compared to the write protection handling. There is no password for the permanent write once and permanent write protection. Instead there are different "OTP_sets(y) with y = 1..6".

- UCB_RTC_PFLASH_OTP0 contains the OTP_sets 1-3
- UCB_RTC_PFLASH_OTP1 contains the OTP_sets 4-6

Each OTP_set contains storage place to define for all logical sectors of all PFLASH Banks:

- DMU_GP_HOST_PFPROCONPWPpXn
- DMU_GP_HOST_PFPROCONPWOPpXn

Each OTP_set has its own confirmation code. As long as the confirmation codes of all OTP_sets of a UCB are in **UNLOCKED** state it is possible to erase this UCB. If one or more OTP_sets have a confirmation code **CONFIRMED** it is no longer possible to erase the UCB. A write operation of a OTP_set(y) is possible if the confirmation code of this OTP_set is **UNLOCKED**. If the confirmation code of a OTP_set is **CONFIRMED** then a write is not possible.

The PFPROCON registers contain the OR'ed information of all OTP_set. If a OTP_set(y) is **CONFIRMED** then its content cannot be longer changed and the resulting permanent write (once) protection is set forever. By the combination of several OTP_sets it is only possible to add additional logical sectors to the protection. The following table shows some examples of the lifecycle for the UCB_RTC_PFLASH_OTP0.

Table 451 Example for OTP set life cycle of UCB_RTC_PFLASH_OTP0

OTP_set1	OTP_set2	OTP_set3	Erase UCB?	Write OTP sets?
UNLOCKED	UNLOCKED	UNLOCKED	yes	1,2,3
CONFIRMED	UNLOCKED	UNLOCKED	no	2,3
CONFIRMED	CONFIRMED	UNLOCKED	no	3

The status (**UNLOCKED**, **CONFIRMED**, **ERRORED**) information of each OTP_set**y** is available in the register DMU_GP_HOST_CONFIRMC.

HOST OTP protection installation

Initial protection

- If UCB_RTC_PFLASH_OTP0_**ORIG**:OTP_**Set_0** is **UNLOCKED** or **CONFIRMED** then:
  - GP_HOST_PFPROCONPWPpXn and GP_HOST_PFPROCONPWOPpXn registers are initialized to the UCB_RTC_PFLASH_OTP0_**ORIG**:OTP_**Set_0** configuration set
- Else if UCB_RTC_PFLASH_OTP0_**ORIG**:OTP_**Set_0** is **ERRORED** and UCB_RTC_PFLASH_OTP0_**COPY**:OTP_**Set_0** is **UNLOCKED** or **CONFIRMED** then:
  - GP_HOST_PFPROCONPWPpXn and GP_HOST_PFPROCONPWOPpXn registers are initialized to the UCB_RTC_PFLASH_OTP0_**COPY**:OTP_**Set_0** configuration set

Subsequent protection

- If UCB_RTC_PFLASH_OTP0_**ORIG**:OTP_**Set_1** is **UNLOCKED** or **CONFIRMED** then:
  - GP_HOST_PFPROCONPWPpXn and GP_HOST_PFPROCONPWOPpXn registers are set to the **OR** (UCB_RTC_PFLASH_OTP0_xxxx:OTP_**Set_0**, UCB_RTC_PFLASH_OTP0_ORIG:OTP_**Set_1**) configuration set
  - Note: OTP0_xxxx means either OTP0_ORIG or OTP0_COPY (see "Initial Protection")

- Else if UCB_RTC_PFLASH_OTP0_**ORIG**:OTP_**Set_1** is **ERRORED** and UCB_RTC_PFLASH_OTP0_**COPY**:OTP_**Set_1** is **UNLOCKED** or **CONFIRMED** then:
  - GP_HOST_PFPROCONPWPpXn and GP_HOST_PFPROCONPWOPpXn registers are set to the **OR** (UCB_RTC_PFLASH_OTP0_xxxx:OTP_**Set_0**, UCB_RTC_PFLASH_OTP0_**COPY**:OTP_**Set_1**) configuration set
  - Note: OTP0_xxxx means either OTP0_ORIG or OTP0_COPY (see "Initial Protection")
- If subsequent OTP_Set **y** is **UNLOCKED** or **CONFIRMED** then:
  - GP_HOST_PFPROCONPWPpXn and GP_HOST_PFPROCONPWOPpXn registers are set to the OR of all preceding OTP configuration sets including Set **y**

Error:

- If (for a common y) both OTP_set**y** of the ORIG and the COPY UCB are **ERRORED** then:
  - All sector protection bits of GP_HOST_PFPROCONPWPpXn and GP_HOST_PFPROCONPWOPpXn registers are set to 1_B which means that all sectors are protected

CSRM specific write protection registers and UCB

The write protection settings for the PFLASH Bank of the CSRM are stored in the following registers and UCB.

Table 452 Registers and UCBs for sector protection

Protection	Registers	UCB
Write protection	DMU_GP_CSRM_PFPROCONWPn	UCB_CS_FLASH_ORIG and UCB_CS_FLASH_COPY
Permanent write once protection	DMU_GP_CSRM_PFPROCONPWOPn	UCB_CS_PFLASH_OTP0_ORIG and UCB_CS_PFLASH_OTP0_COPY
Permanent write protection	DMU_GP_CSRM_PFPROCONPWPn	

There is only one PFLASH Bank for the CSRM and therefore only one index n is necessary. For the 1 MB PFLASH(CSRM) Bank n is 0 or 1.

The UCB_CS_PFLASH_OTP0_ORIG and UCB_CS_PFLASH_OTP0_COPY contain the OTP sets 1-3 (for CSRM PFLASH there are only 3 OTP sets available).

The status (**UNLOCKED**, **CONFIRMED**, **ERRORED**) information of each OTP_set **y** is available in the register DMU_GP_CSRM_CONFIRMC.

The configuration of CSRM OTP UCBs and the installation of the information from the UCBs into the registers is similar to the way described above for the HOST UCBs.

5.3.14.4 Master access protection life cycle

Master access protections are disabled at the delivery state to support an initial configuration of the NVM memory regions. During the code development phase it is possible to activate and deactivate the protections for debugging purpose. For a usage in field a secure protection can be permanently activated, for example the access to the security memories.

5.3.14.4.1 Overview life cycle

The following figure is a simplified view of the standard MCU life cycle.

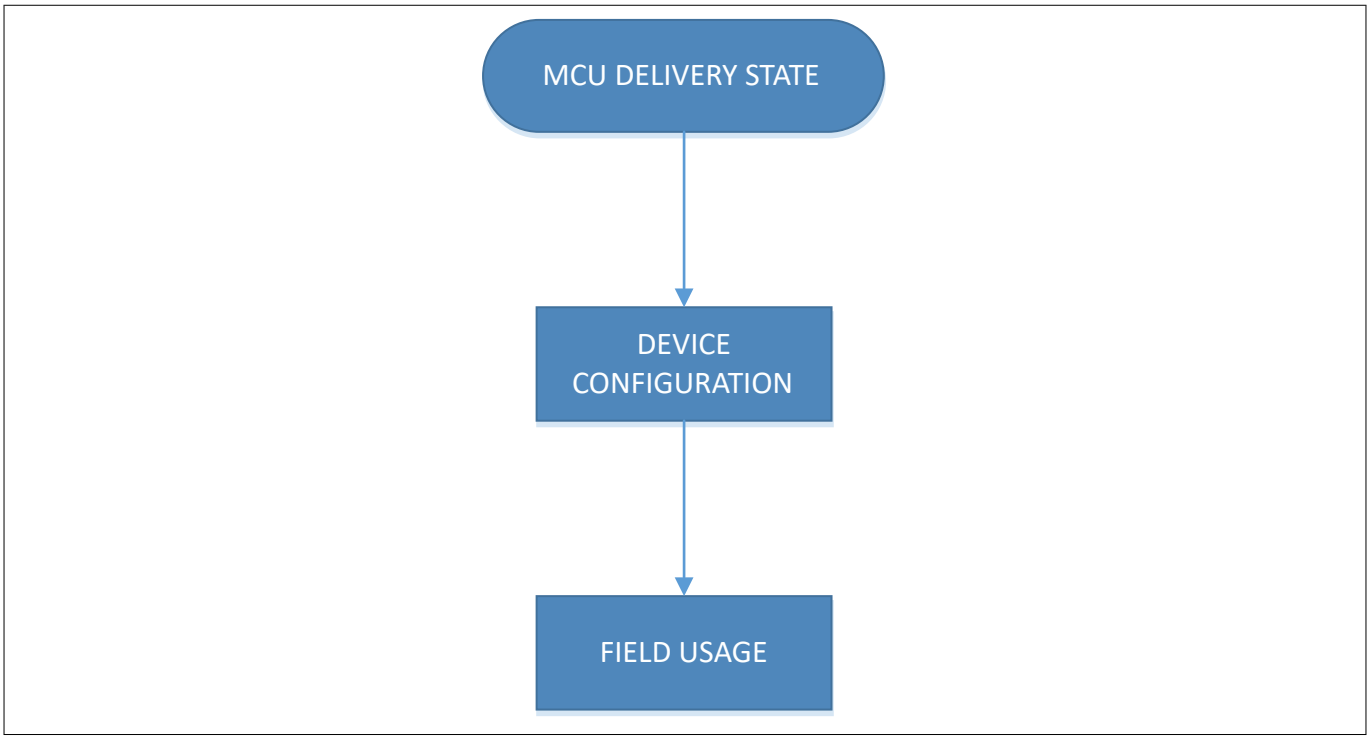

Figure 54 Standard MCU life cycle

Delivery state

In the delivery state, the APU protections are bypassed as described in the following chapter.

Device configuration

The device configuration is done at customer production environment. During this phase the bypass of the protection can be switched off by changing the UCB entry APUBYPASS in the UCB_CS_PFLASH_OTP0 to APU_USE so that the device is ready for field usage.

Field usage

The device has a safe and secure basic configuration after MCU startup or after Reset. Based on this, the application host software and the security software can do a refinement of the APU protections for the HOST and for the secure memories during their startup phase.

5.3.14.4.2 Delivery state APU bypass

The UCB entry APUBYPASS of the UCB_CS_PFLASH_OTP0 in DELIVERY state has the following content and confirmation code:

Table 453 Delivery state

UCB APUBYPASS confirmation code	UCB APUBYPASS content	Effect
UNLOCKED	APU_BYPASS	**1.** UCB may be changed **2.** APU protection is not used (this means it is bypassed)

Bypass of all APUs means:

- All masters have READ access to all NVM regions
- All masters can perform a NVM Operation to all NVM regions

The following restrictions apply under all circumstances (therefore there are also valid in the APU BYPASS situation):

- No read or write access to configuration sector
- No write access to erase counter
- No read or write access to certain UCBs (please refer to UCB description)

Attention**: **in DELIVERY state, the owner of the PROT for the security memories is the CPUcs, this means that a change of the APU (or the PROT) is only possible by a code executed on the CPUcs (either from secure SRAM or from PFLASH(CSRM)).

The purpose of this bypass mode is to enable an initial programming and read access to all memories before the access is locked to a subset of masters. The following chapters describe how this initial bypass state can be changed to support safe and secure operation by protecting the memories from unauthorized access by using the PROT and APU mechanisms.

The following figure shows a sketch of the bypass of the APU of the command channels and the memory region.

Attention**: **The BYPASS is only at the APU of the command channel and the memory region. In the delivery state the sector protection of the Banks is not set but once these sector protections are set they become valid. Since the sector protections are independent from the PROT/APU protections the BYPASS of the APU protections does not change the sector protection.

During the startup of the NVM the content of the UCB entry APUBYPASS is read and the following register field is set accordingly: DMU_PROT_APUBYPASS.BYPASS.

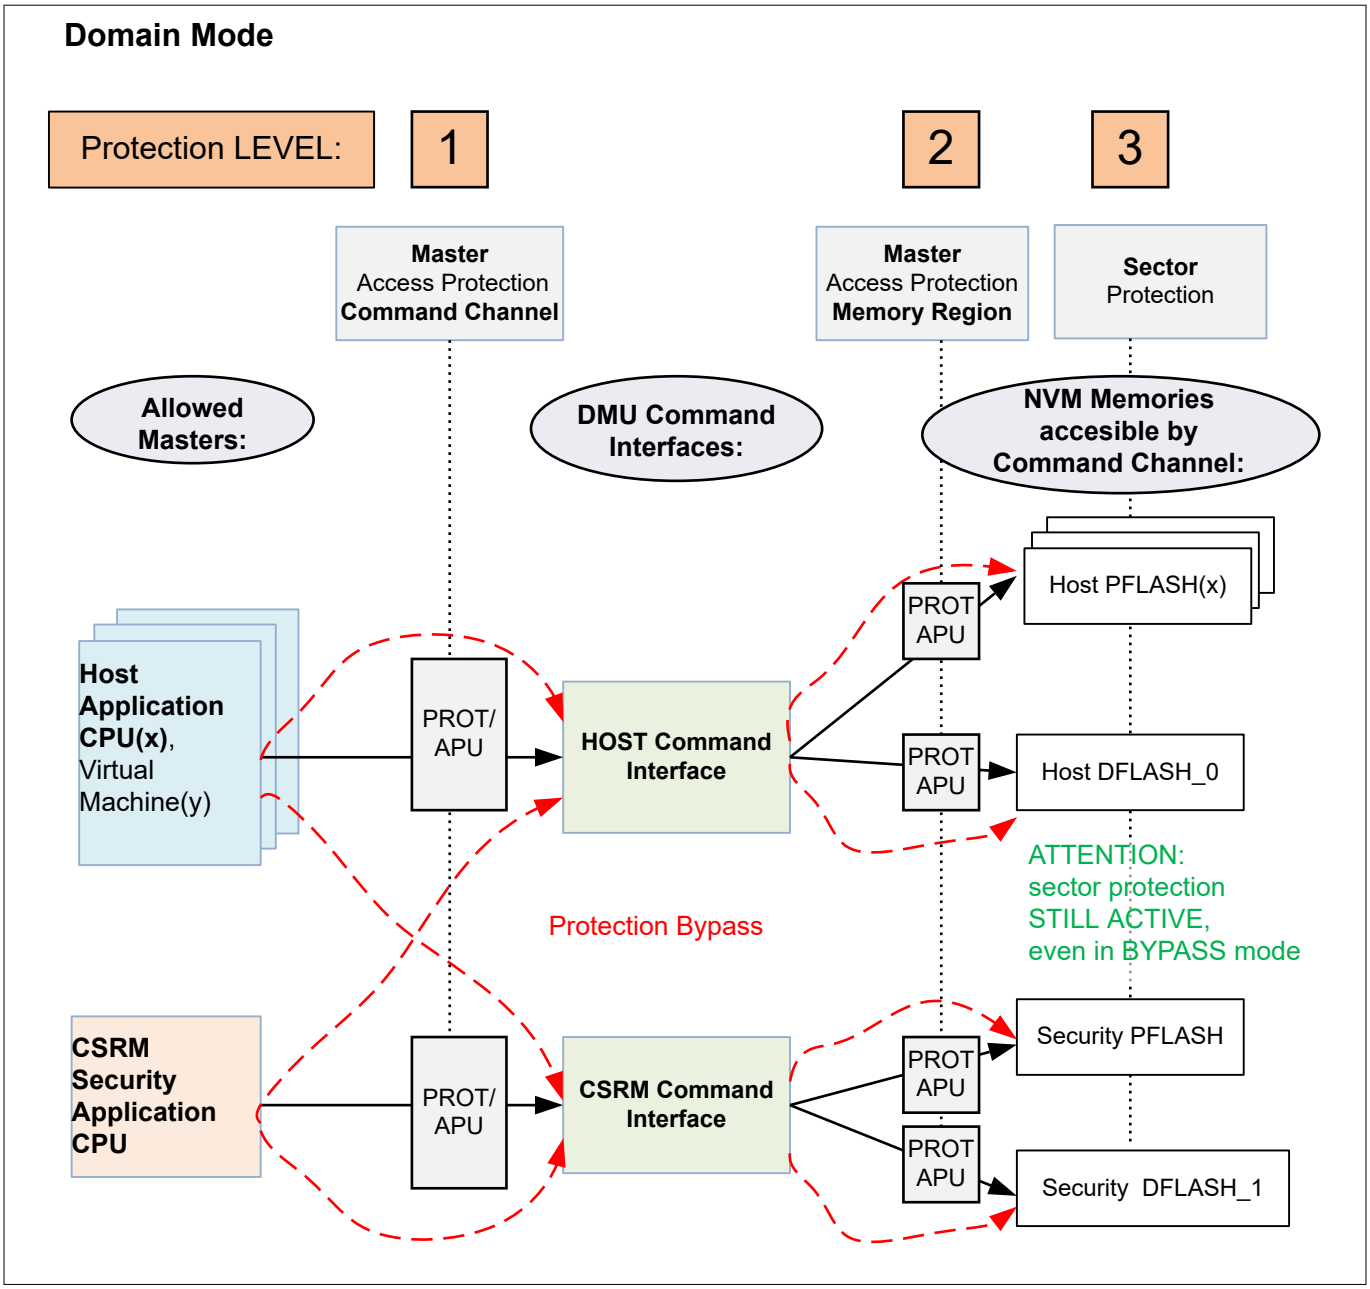

Figure 55 Bypass of APU

Related information

UCB for APU bypass on page 782

5.3.14.4.3 UCB for APU bypass

Overview

There is a UCB entry necessary to define if the APUs for the memories are used or bypassed. The UCB entry is named APUBYPASS and is part of the UCB_CS_PFLASH_OTP0. After UCB recovery the DMU register DMU_PROT_APUBYPASS contains the protection state APU_BYPASS or APU_USE.

***Note**: The access to the UCB_CS_PFLASH_OTP0 is if the APU is used because this UCB is part of theDFLASH(CSRM) UCB region.*

The UCB has a content and a place for status information. The status of the UCB may be:

- ERRORED:
  - UCB content errored
  - UCB confirmation code uncorrectable errored
  - invalid confirmation code values written
- UNLOCKED: unlock code is read
- CONFIRMED: confirmation code is read

The content of the UCB may have 2 states:

- APU_BYPASS
- APU_USE

Table 454 Definition of page for the UCB content

UCB entry APUBYPASS content	Pattern for one page (64 bit)
APU_BYPASS	DMU checks Byte 0: 55_H , Rest: 0
APU_USE	DMU checks Byte 0: FF_H ; overall pattern has to be 4 x $FFFF_H$ to get ECC valid 8 Byte word (can be achieved by over-programming the APU BYPASS pattern)

The UCB state is ERRORED if one of the following conditions occurs:

- Uncorrectable error when reading state or content
- Content different to the patterns mentioned in the previous table

APUBYPASS UCB State and Content Truth Table

The consequences of the UCB state and the UCB content are described in the following truth table.

Table 455 UCB entry APUBYPASS state and content => NVM APU use or bypass

UCB state	UCB content	=> NVM APU protection	=> UCB Change possible?
ERRORED	"do not care"	used	no
UNLOCKED	APU_BYPASS	bypassed	yes
	APU_USE	used	yes, but access may be restricted to CPUcs
	ECC uncorrectable error or any other pattern than APU_BYPASS	used	
CONFIRMED	APU_BYPASS	bypassed	NO, UCB content is OTP
	APU_USE	used	
	ECC uncorrectable error or any other pattern than APU_BYPASS	used	

***Attention**: If the UCB state for the APUBYASS is set to CONFIRMED then a change of this configuration is not possible anymore. Therefore for field usage the UCB content must be set to APU_USE before the confirmation code is set to CONFIRMED to make sure that the APU protections become effective.*

***Attention**: The UCB entry APUBYPASS is part of the UCB_CS_PFLASH_OTP0; therefore changes of this APUBYPASS entry may be limited to program only if one of the OTP sets are already confirmed. Please refer to the section "Use case scenarios" within this chapter.*

***Attention**: Once the APUBYPASS content is written to APU_USE (0xFF) then a change of this content is only possible by an erase of the UCB. If the erase of the UCB is not possible anymore due to an CONFIRMED OTP set then this APUBYPASS content becomes already fixed (even if the actual confirmation code is still UNLOCKED.*

Use case scenarios for the UCB_CS_PFLASH_OTP0

The UCB UCB_CS_PFLASH_OTP0 contains the following information:

- OTP sets: settings for OTP (permanent write) protection of PFLASH(CSRM) logical sectors
- APUBYPASS entry

Each OTP set and the APUBYPASS entry have their own confirmation code. This enables to lock each information independently from the other information.

If one (or several) of the OTP sets or the APUBYPASS entry have a confirmation code CONFIRMED then the following rules apply:

- It is not possible anymore to erase the UCB_CS_PFLASH_OTP0
- It is not possible anymore to program a UCB set content which has the confirmation code CONFIRMED
- It is possible to program a UCB set entry (content and confirmation code) which has the confirmation code UNLOCKED

The following figure describes possible use cases during the life cycle (please note that the table is only an example and describes a functional view, please refer to the UCB memory map for the number and the location (addresses) of the UCB entries).

Action/State	OTP set 1 content	OTP set 1 Confirmation code	OTP set 2 content	OTP set 2 Confirmation code	APUBYPASS content	APUBYPASS Confirmation code	=> UCB Overall State	=> PROG UCB possible ?	=> ERASE UCB possible ?
DELIVERY State	erased	UNLOCKED	erased	UNLOCKED	APU_BYPASS	UNLOCKED	UNLOCKED	YES	YES
Prog OTP_1 content	OTP-data	UNLOCKED	erased	UNLOCKED	APU_BYPASS	UNLOCKED	UNLOCKED	YES	YES
Prog Confirmation code OTP 1	OTP-data	CONFIRMED	erased	UNLOCKED	APU_BYPASS	UNLOCKED	CONFIRMED	only OTP set 2 and APUBYPASS	NO
Prog APUBYPASS content	OTP-data	CONFIRMED	erased	UNLOCKED	APU_USE	UNLOCKED	CONFIRMED	only OTP set 2	NO
Read Fail	uncorrectable data	wrong code or uncorrectable data	x	x	x	x	ERRORED	NO	NO

Figure 56 UCB_CS_PFLASH_OTP0 scenarios

***Note**: In the figure above the change as a result of an action is marked red.*

Development phase at customer

The following figure describes the different states of the UCB_APU during the life cycle.

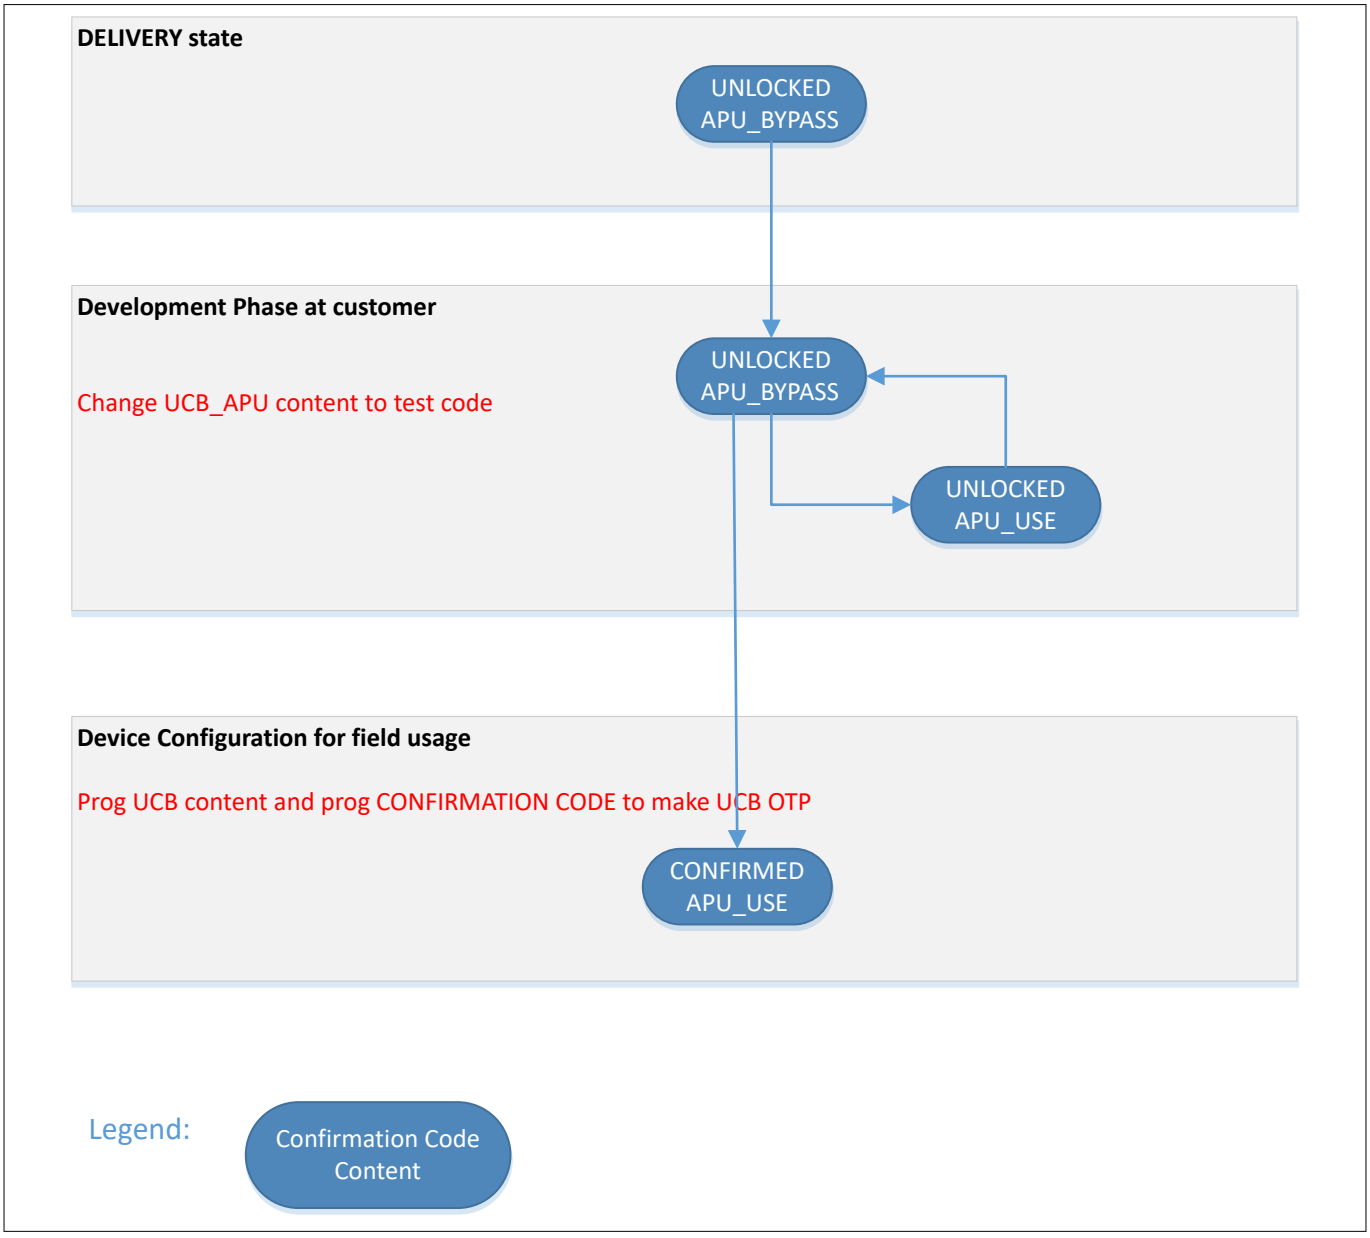

Figure 57 States of UCB_APU during the life cycle

For the development phase at customer, the UCB entry APUBYPASS may be programmed to UNLOCKED and its content be programmed to either APU_BYPASS or APU_USE to test both configurations. If the UCB content is APU_USE then the master access protection to the APU_UCB is active which means that a change of the UCB can only be done by:

- CPUcs executing code from PFLASH(CSRM) which rewrites the UCB entry APUBYPASS
- CPUcs having configured the APU for DFLASH(CSRM) so that another master can change the UCB entry APUBYPASS

***Note**: The delivery state of the microcontroller has all customer changeable UCBs in **UNLOCKED** state. In this delivery state the APU is automatically bypassed independent from the content of the APUBYPASS UCB. The content of the APUBYPASS UCB is relevant only if at least one UCB is **CONFIRMED**, because then the delivery state is left.*

***Note**: For the development phase it is recommended to set a UCB in **CONFIRMED** state which still can be changed, for example the setting of the UCB_RTC_FLASH (sector write protection) to **CONFIRMED** still allows a change of the write protection settings by the use of the Disable Protection command with the correct password.*

Delivery state on page 756

5.3.14.4.4 Device configuration

The device configuration is done at customer production environment. During this phase, the read and write access to all memories is possible as long as the UCB APUBYPASS content is APU_BYPASS.

After the final programming of code and data, the UCBBYPASS content may be changed to APU_USE.

After a program of the CONFIRMATION code to the UCB APUBYPASS this UCB will be locked forever and cannot be changed anymore.

The following tables assume:

1. APUBYPASS is in UNLOCKED state
2. MCU shall be configured for use in field

MCU PROT/APU initial device configuration

Table 456 HOST application: Command channel and memories

State and transition	Command channel(HOST)		PFLASH(HOST)		DFLASH(HOST)		UCB APUBYPASS entry: UCB state UCB content
	PROT	APU	PROT	APU	PROT	APU	
RESET Values	ALL	READ: ALL WRITE: CPU0,CBS	ALL	READ:ALL WRITE:CPU0,CBS	ALL	READ: ALL WRITE:CPU0,CBS	
UCB Recovery							UNLOCKED APU_BYPASS
After MCU Startup	ALL	BYPASS	ALL	BYPASS	ALL	BYPASS	UNLOCKED APU_BYPASS
Device Configuration: UCB_Change							CONFIRMED APU_USE
After Reset and MCU Startup	ALL	READ: ALL WRITE: CPU0,CBS	ALL	READ: ALL WRITE: CPU0,CBS	ALL	READ: ALL WRITE: CPU0,CBS	CONFIRMED APU_USE

Table 457 Abbreviations and terms

Abbreviation and term	Description
ALL	For PROT: ODEF = 0_B, for APU: all masters enabled
READ: ALL WRITE: CPU0,CBS	For APU: APU set so that READ is possible for all masters, WRITE is ONLY possible for CPU0 and Cerberus
BYPASS	APU is not used, memory access possible to all masters

Table 458 Secure application: Command channel and memories

State and transition	Command channel(CSRM)		PFLASH(CSRM)		DFLASH(CSRM)		UCB APUBYPASS entry: UCB state UCB content
	PROT	APU	PROT	APU	PROT	APU	
RESET Values	CPUcs	CPUcs	CPUcs	CPUcs	CPUcs	CPUcs	
UCB Recovery							UNLOCKED APU_BYPASS
After MCU Startup	CPUcs	BYPASS	CPUcs	BYPASS	CPUcs	BYPASS	UNLOCKED APU_BYPASS
Device Configuration: UCB_Change							CONFIRMED APU_USE
After Reset and MCU Startup	CPUcs	CPUcs	CPUcs	CPUcs	CPUcs	CPUcs	CONFIRMED APU_USE

Table 459 Abbreviations and terms

Abbreviation and term	Description
CPUcs	For PROT: CPUcs is the owner of PROT, for APU: CPUcs only has access to command channel and memories
BYPASS	APU is not used, memory access possible to all masters

The tables above only mean the transition by programming the UCB. In addition, there would be initial startup code be programmed into the HOST PFLASH and the CSRM PFLASH memories. This startup code is always executed after RESET and MCU startup and may do a specific setting of the APU registers according to the software structure being used. This is described in the next chapter.

In addition to the configurations described above there will also be configuration of the other UCBs to confirmed state which will determine the read and write access to these UCBs together with the applicable PROT/APU protections.

The following sequence is recommended:

1. Program PFLASH code into PFLASH(HOST) and PFLASH(CSRM)
2. Program initial DFLASH data into DFLASH(HOST) and DFLASH(CSRM)
3. Program content and confirmation codes to the user UCBs (see UCB documentation)
4. Program content and confirmation code to the UCB entry (APUBYPASS) which is part of the UCB_CS_PFLASH_OTP0
5. Device is ready for field usage

5.3.14.4.5 Field usage

Overview

The following tables describe a typical use case of a MCU which has been configured for safety and security during production and which is run in field.

The description focus on the NVM Operation like program or erase to a memory range; commonalities and differences with regards to a read access to the memory are explained at the end of the chapter.

MCU PROT/APU configuration during field usage

Table 460 Host application: Command channel and memories

Abbreviation and term	Description
CPUcs	For PROT: CPUcs is the owner of PROT, for APU: CPUcs only has access to command channel and memories
authorized_security	For APU: Secure Application Start Software may extend or limit further the access to (part of) security memories

Safety: Protections against accidental PFLASH programming

Accidental change of PFLASH(HOST) memories by programming or erasing must be avoided for a safe operation.

An easy way to achieve this is to block all masters for an NVM Operation access to PFLASH(HOST) memories during normal operation.

In case that a program or erase operation is needed for a sub range of the PFLASH(HOST):

- The safety owner changes the APU
  - Grant write access to the software component doing the PFLASH(HOST) change
  - On a dedicated memory range

This scheme is a replacement of the use of "safety_endinit" scheme of TC3xx. An example application may be to allow the prog or erase access to an (inactive) bank for SOTA updates or the prog or erase access to a PFLASH(HOST) Bank range during offline state for incremental updates.

PROT/APU for read access

The description in the previous sections is for a NVM Operation like `Write` or `Erase`. The principal scheme of PROT/APU setting for *reading* is the same but the following differences need to be taken into account:

- Command channel is not necessary for *reading*
- There are different PROT/APU sets to protect PFLASH *reading*
- PROT/APU for PFLASH (HOST and CSRM) *reading* is within the CPU

PROT/APU for read configuration registers

The description in the previous sections is for a NVM Operation like Prog or Erase. The principal scheme of PROT/APU setting for READ and WRITE of the Read Configuration registers is the same but the following differences need to be taken into account:

- Read configuration registers are independent from the command channel configuration registers

- There are different PROT/APU sets to protect the READ configuration registers
- A part of the Read configuration registers is accessible by CPU and therefore the PROT/APU for those registers is within the CPU

5.3.15 EEPROM emulation with DFLASH

The Data Flash can be used for the emulation of an EEPROM or the storage of "quasi static" data, which is seldom changed. This chapter describes parameters, flags and additional commands to achieve a reliable data storage.

EEPROM emulation purpose

The term “EEPROM Emulation” designates an algorithm with the following features:

- It maps a logical EEPROM memory address to a physical Flash address
- It increases the effective endurance by spreading the EEPROM write accesses over a larger range of Flash memory
- It ensures that all Flash cells incur a similar number of cycles independent of the update frequency of the EEPROM data (“wear leveling”)
- It manages the allocation of EEPROM data to Flash ranges so that stale data can be erased

Handling of quasi static data

For the AURIX™ TC4xx products a logical sector within the Data Flash does not get disturbed during the program or erase operations within other Data Flash ranges. Thus, 'quasi-static' data may be placed in the Data Flash without the need to include this in the EEPROM emulation data (which could cost storage place and update cycles).

However the retention of Data Flash cells may be lower then those of Program Flash cells (due to other algorithms being used).

Therefore it is necessary to use the following measures for quasi static data:

1. Definition of quasi-static data:
   - less than 1000 updates
2. Permanent partitioning of DFLASH EEPROM necessary:
   a. EEPROM region for data updated less than the maximum allowed number of cycles per logical sector (parameters N_{E_CSRM} and N_{E_EEPROM})
   b. Quasi static data region for data updated less than 1000 times
3. Before the start of product usage the partitioning must be fixed for the whole lifetime:
   - It is not allowed to change an EEPROM region with more than 1000 cycles done into a quasi static data region
   - It is not allowed to change a quasi static data region into an EEPROM region (quasi static data region only allows less than 1000 updates)
4. Use the `Erase Logical Sector Range` command with 'quasi static data' option as described below:
   - Set the FSI COMM0 register to 0x05
   - Start the `Erase Logical Sector Range` command
   - Set the FSI COMM0 register to 0x00
5. Use the `Write Page` or `Write Burst` command with 'quasi static data' option as described below:
   - Set the FSI COMM0 register to 0x05
   - Start the `Write Page` or `Write Burst` command
   - Set the FSI COMM0 register to 0x00

Attention**: **The Erase and Write commands with the 'quasi static data' option shall only be used for the low-cycled (< 1000 updates) data.

Attention**: **The Erase operation with the 'quasi static data' option takes more time than the 'normal' Erase operation, see the datasheet timings $t_{SECTOR_ERDM_LC_UCB}$ for one logical sector and $t_{RANGE_ERDM_LC}$ for the maximum allowed erase size. The abbreviation "LC" in the parameter name stands for "low cycle".

***Note**: For UCB erasing and programming the use of the 'quasi static data' option is not necessary because the NVM automatically detects a UCB operation and adapts the sequence accordingly (an unintentional use of the option would not do harm). The erase and write operation on a UCB uses the same sequence as the erase and write sequence on a 'quasi static data" logical sector (therefore the parameter name $t_{SECTOR_ERDM_LC_UCB}$ contains also "UCB").*

***Note**: During the maximum 1000 updates of quasi static data the probability of a failure is low; nevertheless it is possible to perform a sector replacement if a logical sector cannot be erased or programmed. For this purpose the Replace Logical Sector command can be used.*

FSI_COMMx register addresses

There are separate FSI_COMMx registers for the HOST and for the CSRM command interface:

- FSI_HOST.COMMx
- FSI_CSRM.COMMx

These COMMx registers do not belong to the standard DMU register region. To access those registers please refer to:

Table 464 FSI COMMx registers

Address	Chapter
Register Base Address FSI_HOST.COMM0	System address map
Register Base Address FSI_CSRM.COMM0	
Register offset addresses for COMMx Registers Note: The offset addresses for FSI_HOST.COMMx and for FSI_CSRM.COMMx are the same	Register Overview - FSI

5.3.15.1 Segmentation and parameters

Definition of parameters

The DFLASH supports "multi-sector" EEPROM emulation. Each of these "EEPROM sectors" may consist of a range of Flash logical sectors. Usually an "EEPROM sector" is erased completely during the EEPROM emulation; this is possible as long as the total size of the "EEPROM sector" is lower or equal to the maximum erase size of the Data Flash.

The number of erase operations in the Data Flash is limited by the two parameters shown in the table below:

Table 465 Limits for number of erase operations

Parameter HOST and CSRM	Description
NE_EEPROM or *NE_CSRM*	Total number of erase operations on a logical sector of DFLASH(HOST)(0) EEPROM or DFLASH(CSRM)(1)
NERD0S or *NERD1S*	Total number of erase operations on DFLASH(HOST) (0) or DFLASH(CSRM) (1) over lifetime

The parameter *NE_EEPROM* defines the maximum allowed erase operations per cell and must be observed in all cases. It is defined per logical sector but it is also valid for an "EEPROM sector", because the "EEPROM sector" is defined as a logical sector range which is always erased completely using the `Erase Logical Sector Range` command.

The parameter *NERD0S* is not memory cell related but relate to the memory periphery. Each erase operation uses high internal voltages, which induce a small stress on transistors in periphery switches or other circuits of the memory periphery. The overall accumulated stress within lifetime must not exceed a certain limit. Therefore the total number of erase operations must be limited.

Impact of parameters for different DFLASH segmentations

For the AURIX™ TC4xx the following formula is valid: *NERD0S* = 8 x *NE_EEPROM*.

This means that if DFLASH is split in 8 "EEPROM sectors", the total number of erase operations for each "EEPROM sector" is equal to *NE_EEPROM* and the total number of erase operations on the entire DFLASH is equal to *NERD0S*.

A division of the DFLASH region into a number of "EEPROM sectors" different than 8 is always possible, but the following equations must be observed:

- Number of erase operations of each "EEPROM sector" ≤ *NE_EEPROM*
- Number of "EEPROM sectors" **x** number of erase operation on each "EEPROM sectors" ≤ *NERD0S*

If the number of “EEPROM sectors” is less than 8, the limiting constrain is always *NE_EEPROM*..

If the number of “EEPROM sectors” is greater than 8, the limiting constraint is always *NERD0S*.

It is also possible to define "EEPROM sectors" of different sizes and with different number of updates as long as the limits *NE_EEPROM* and *NERD0S* are not violated.

Please note that the maximum size of each "EEPROM sector" must be less or equal the maximum allowed erase size for Data Flash.

Example for a "two sector emulation"

Example: If the 1 MB DFLASH is divided into two EEPROM regions; then the size of each EEPRPOM region would be 512 KB. Considering that the maximum erase size of the Data Flash is 256 KB, each EEPROM region needs two erase operations to be fully erased. For this reason, this case has the same behavior as the case where the DFLASH is divided in 4 “EEPROM sectors”.

Examples of possible segmentations

The following table shows an overview of different segmentations.

Table 466 Examples of possible segmentations for a 1 MB Data Flash EEPROM region

Number of "EEPROM_sectors"	Size of "EEPROM_sector"	Max number of "EEPROM sector" erase operations
4	256 KB	NE_EEPROM
8	128 KB	NE_EEPROM
16	64 KB	NERD0S/16

***Note**: In case of four "EEPROM_sectors" the parameter NE_EEPROM becomes the limiting constraint.*

***Note**: In case of sixteen "EEPROM_sectors" the parameter NERD0S is the limiting constraint.*

***Note**: Same constraints apply to the DFLASH(CSRM), for which the parameters NE_CSRM and NERD1S have to be used.*

5.3.15.2 Robust EEPROM emulation

A key requirement for an EEPROM emulation algorithm is the reliability of the stored data. This chapter provides information about possible faults and how to prevent and repair them.

Fault types and resulting failures

A memory array may have:

- Bitline oriented faults
- Wordline oriented faults
- Sector oriented faults

Bitline oriented faults mean a limited number of failing bits within the read data. The error correction circuit (ECC) can correct up to 3 failing bits within 64 bit and can detect all possible 4 failing bit patterns and an arbitrary amount of uncorrectable (multibit) errors with a detection coverage ~90%.

Wordline and sector oriented faults may result in a failure of:

- Reading from Wordline
- Write (Page or Burst) on Wordline
- Erase Logical sector

The ECC mechanism cannot correct wordline or sector oriented failures.

Wordline or sector oriented failures are most likely to occur during the high voltage conditions present during writing or erase operations. A hard breakdown of the following may occur:

- oxide between cell nodes
- oxide between contacts
- metal layer

Repair function

The AURIX™ TC4xx products offer a logical sector repair for the Data Flash: a failing logical sector may be replaced by a free redundant logical sector by the `Replace Logical Sector` command.

The `Replace Logical Sector` command needs to be started with the address of the failing logical sector; it replaces the complete logical sector (in Data Flash 2 KB, four wordlines) by an (erased) redundant logical sector, which is accessible at the same logical address after the command execution.

Repair after an erase operation

To detect a failure of an erase operation the check of the *Erase Verify Error (EVER)* flag is necessary (register for HOST command interface: DMU_HCI_ERR, register for CSRM command interface: DMU_CSCI_ERR).

Before repairing a logical sector it is necessary to ensure that no other reason for the erase failure exists: a stable voltage supply (VDDEXT) during the erase operation is mandatory.

It is recommended to repeat the erase operation at least one time. This may help to shift (potentially few) remaining cells to the target erase state.

If the *Erase Verify Error (EVER)* persists, then a repair of the failing logical sector shall be done, because otherwise write and read operations on the wordlines of the failing sector will likely fail. Furthermore a failing erase may have left the wordlines of the concerned logical sector in an undefined (erroneous) state or an old state with old data. The repair by the `Replace Logical Sector` command resolves these issues by providing an erased functional logical sector at the same address.

Usually during an erase in the Data Flash a contiguous range of n logical sectors is erased with one execution of the `Erase Logical Sector Range` command. It is necessary to identify the failing logical sector. This can be done by erase each logical sector in the range separately.

By doing so it is ensured that all the other logical sectors are erased sufficiently and the failing logical sector address is known.

The repair of a failing logical sector can then be done by performing the `Replace Logical Sector` command with the address of the failing sector.

***Note**: in order to speed up the operation it is possible to operate the Erase Logical Sector commands on half of the original region and continue on the failing region similar to a "binary search".*

***Note**: The erase command sequence checks the state of a logical sector before the start of the command execution. The actual erase does not start if a logical sector is already erased. Thus, unnecessary stress and execution time are avoided.*

Fault mitigation after a write operation

Based on the used cell voltage conditions it is expected that the likelihood of a hard fail during erase is significantly higher than the likelihood of a hard fail during a write operation. A quantitative assessment of this is only possible after product qualification with sufficient statistics.

It is therefore recommended that the EEPROM emulation algorithm is able to work with faulty wordlines and protect against data loss during a write operation.

The following mechanisms are possible to mitigate the effects of a faulty wordline.

Before writing a page in a wordline, save the content of those pages (of the wordline) which already contain valid data to SRAM.

To detect a failure of a write operation it is necessary to:

- Check the *Program Verify Error (PVER)* flag (see DMU_HCI_ERR or DMU_CSCI_ERR)
- Read pages of the wordline and compare with target content
- Correctable 1-bit and 2-bit errors may be accepted

***Note**: Erase and write operations have a built-in fault tolerance to prevent the repetition of needless operations in the case of a few "stuck-at programmed state or stuck-at erased state" bits. This means that after a write operation there may be a (correctable) single bit or double bit error.*

It is recommended to repeat a failing write operation at least one time. This may help to shift (potentially few) remaining cells to the target program state.

If the *Program Verify Error (PVER)* persists or there is a mismatch between read data and target data, there are three options:

1. Skip the failing wordline and write the wordline content in the next wordline
2. Skip the failing wordline and write the wordline content in the next wordline and store the logical sector address of the failing wordline for a later repair
3. Repair the whole logical sector containing the failing wordline immediately by the use of the `Replace Logical Sector` command

Writing the content in the next wordline leaves a faulty wordline which need to be excluded from further data processing.

Replacing the whole logical sector immediately (option 3) means that the faulty wordline is no longer visible. However such an immediate repair requires the temporary backup of the already existing content of the logical sector into SRAM, replace the sector and then write back the valid content (see the description in the next section). This takes a considerable amount of additional time. If a reset occurs during this process there may be a loss of data. Option 2 mitigates this risk by delaying the repair to a situation where the sector data is no more necessary, however in this case the application must be able to skip faulty wordlines until the repair is possible.

Repair after a write operation

It is necessary to make a backup of the already existing valid data pages within the sector before the application of the `Replace Logical Sector` command.

The repair sequence shall be as follows:

1. Read all valid data from the broken logical sector
   - Use backup data in SRAM in case the data from the failing wordline cannot be read anymore. Data from functional wordlines of the logical sectors can be read[12)]

2. Apply the *Replace Logical Sector* command, using the sector address of the logical sector where the write has failed
3. After successful command execution, the current logical sector is replaced by an (erased) redundant logical sector, which is accessible at the same logical address
4. Write the stored data at the same address again

Resets during EEPROM emulation

A reset during a prog or erase operation stops the running sequence and may leave the targeted memory range in an undefined state.

A detection of such an event can be done by performing two operations in sequence and determine after reset from the correctness of the second the completeness of the first operation.

Example: after erasing a Data Flash logical sector a page is programmed. After reset the existence of correct data in this page proves that the erase process was performed completely.

The detection of aborted programming processes can be handled similarly. After a successful programming of a data block an additional page is programmed as marker. When after reset the block of data is readable and the marker is existent it is ensured that the block of data was programmed without interruption.

Instead the use of a marker the rewrite of the last written page or burst after startup may be done. This is possible if the data can be read and has only correctable errors.

Attention**: **"Over-programming" already existing data in DFLASH again is allowed but only to a limited number; please refer to the datasheet parameters $N_{D_PAGE_OVERWR}$ and $N_{D_LOGSEC_BL_PROG}$.

The probability of aborting a programming process due to power on reset can be minimized by voltage monitoring: this can be used to get an under voltage warning early enough so that an ongoing programming process can be finished and no new one is started.

In addition to the means described above there is a `User Content Count` command which checks the data integrity of a wordline or page: the command checks that the programmed and erased cells are above or below critical threshold levels to make sure that a reading is possible and the retention of the cell state is sufficient.

For the check of erase state it is possible to use the `Verify Erase Page`, `Verify Erase Wordline` or `Verify Erase Logical Sector Range` commands.

Invalidation of data

A reliable invalidation of data is possible by "over-programming" a page with "all-1" data. The datasheet parameters $N_{D_PAGE_OVERWR}$ and $N_{D_LOGSEC_BL_PROG}$ need to be taken into account as limits for such "over-programming" activities within one logical sector. The dastasheet parameters need not to be taken into account if the purpose is only to "destroy" existing data and the whole data of the logical sector is not used anymore (for example invalidation of markers before erase).

12

5.3.16 Resets during flash operation

A reset or power failure during an ongoing Flash operation (i.e. program or erase) must be considered as a violation of stable operating conditions. However, the Flash was designed to prevent damage to non-addressed Flash ranges when the reset is applied as defined in the datasheet. The addressed Flash range is left in an undefined state.

When an erase operation is aborted the previously programmed bits (‘1’) in the addressed Flash range can be in any state between ‘0’ and ‘1’. When reading this range all-0 can be returned, the old data, or something in between. The result can be unstable. Due to the ECC correction there may even appear ‘1’ bits at positions which contained ‘0’ bits before erase start.

When a page programming operation is aborted the page can still appear as erased (but contain slightly programmed bits), it can appear as being correctly programmed (but the data has a lowered retention) or the page contains garbage data. It is also possible that the read data is unstable so that depending on the operating conditions different data is read.

When Flash processes are aborted by system resets or power-on resets, this is not indicated by any flags. It is not possible to detect an aborted operation simply by reading the Flash range (please note that the ECC is not a reliable means to detect an aborted Flash operation). Also the margin reads don’t offer a reliable indication.

When erasing or programming the PFlash usually an external instance can notice the reset and restart the operation by erasing the Flash range and programming it again.

In addition there is a `User Content Count` command which checks the data integrity of a wordline or page: the command checks that the programmed and erased cells are above or below critical threshold levels to make sure that a reading is possible and the retention of the cell state is sufficient. This command can be used to check the integrity of data if it is not sure whether this data has been erased or programmed properly.

5.3.17 Interrupts

The NVM can be configured to trigger interrupt service requests on certain events. Both command interfaces request independent interrupts as described below.

HOST command interface

The following events can trigger an interrupt service request from the HOST command interface to the interrupt router (IR):

- End of BUSY : if the interrupt is enabled on "end of BUSY" using DMU_HCI_INTEN.EOBM = 1_B and one of the BUSY flags in DMU_HCI_STATUS goes low, then the end of a command sequence is detected and a interrupt is requested
- *Protection Error (PROER)* : if DMU_HCI_INTEN.PROERM = 1_B and the DMU_HCI_ERR.PROER flag is set
- *Sequence Error (SQER)* : if DMU_HCI_INTEN.SQERM = 1_B and the DMU_HCI_ERR.SQER flag is set
- *Operation Error (OPER)* : at the end of the operation, if DMU_HCI_INTEN.OPERM = 1_B and the DMU_HCI_ERR.OPER flag is set
- *Erase Verify Error (EVER)* : at the end of the operation, if DMU_HCI_INTEN.EVERM = 1_B and the DMU_HCI_ERR.EVER flag is set
- *Program Verify Error (PVER)* : at the end of the operation, if DMU_HCI_INTEN.PVERM = 1_B and the DMU_HCI_ERR.PVER flag is set

In case several conditions are enabled, the source of the interrupt can be determined by reading the DMU_HCI_STATUS and DMU_HCI_ERR registers.

CSRM command interface

The following events can trigger an interrupt service request from the CSRM command interface to the interrupt router (IR):

- End of BUSY : if the interrupt is enabled on "end of BUSY" using DMU_CSCI_INTEN.EOBM = 1_B and one of the BUSY flags in DMU_CSCI_STATUS goes low, then the end of a command sequence is detected and a interrupt is requested
- *Protection Error (PROER)* : if DMU_CSCI_INTEN.PROERM = 1_B and the DMU_CSCI_ERR.PROER flag is set
- *Sequence Error (SQER)* : if DMU_CSCI_INTEN.SQERM = 1_B and the DMU_CSCI_ERR.SQER flag is set
- *Operation Error (OPER)* : at the end of the operation, if DMU_CSCI_INTEN.OPERM = 1_B and the DMU_CSCI_ERR.OPER flag is set
- *Erase Verify Error (EVER)* : at the end of the operation, if DMU_CSCI_INTEN.EVERM = 1_B and the DMU_CSCI_ERR.EVER flag is set
- *Program Verify Error (PVER)* : at the end of the operation, if DMU_CSCI_INTEN.PVERM = 1_B and the DMU_CSCI_ERR.PVER flag is set

In case several conditions are enabled, the source of the interrupt can be determined by reading the DMU_CSCI_STATUS and DMU_CSCI_ERR registers.

5.3.18 Traps

The following fatal errors create a bus error which is translated by the CPU into a trap.

The conditions for reporting a bus error are:

- Uncorrectable ECC error
- Write access to Boot ROM (BROM)
- Write access to read-only register
- Read or write access to unoccupied register address
- Register Read or Write using double word or Block Transfer
- Write access to an access controlled register or Flash address range by a master without allowance by the register access protection
- Not allowed write access to a protected register (for example supervisor, startup protected)
- Not allowed Flash read access with active read protection
- Command Sequence to not available Flash memory
- Command Sequence like Write, Erase to a Bank which is in Sleep state (only wake up is allowed for sleeping Banks)
- Command Sequence on a command interface which is already operating a command sequence
- Command Sequence using data size other than Word (except the Double-word option for the Load Page (64 bit) command options
- Read-modify-write access to the Flash memory
- Read access to a Bank which is in Sleep state
- Read access to not available Flash memory
- Read access to a busy PFLASH bank (if not disabled by with CPU register PFly_FLASHCON1.STALL)
- Read access to a busy DFLASH bank (DFLASH0 or DFLASH1 EEPROM,UCB)
- Block Transfer for reading from a DFLASH bank

5.4 Registers

5.4.1 DMU registers

5.4.1.1 Register overview - access mode glossary

Table 467 Register overview - access mode glossary

Keyword	Description
CSCI	Access protection using PROT register PROT_PROTCSCI.
CSDF	Access protection using PROT register PROT_PROTCSDF.
CSPF	Access protection using PROT register PROT_PROTCSPF.
CSRDC	Access protection using PROT register PROT_PROTCSRDC.
HCI	Access protection using PROT register PROT_PROTHCI.
HDF	Access protection using PROT register PROT_PROTHDF.
HPF	Access protection using PROT register PROT_PROTHPF.
HRDC	Access protection using PROT register PROT_PROTHRDC.
APU-PCSCI	Protection group consisting of registers PROT_ACCENCSCI_WRA, PROT_ACCENCSCI_WRB, PROT_ACCENCSCI_RDA, PROT_ACCENCSCI_RDB, PROT_ACCENCSCI_VM, PROT_ACCENCSCI_PRS.
PCSCI	Access protection using *APU-PCSCI* registers.
APU-PCSDFUCB	Protection group consisting of registers PROT_ACCENCSDFUCB_WRA, PROT_ACCENCSDFUCB_WRB, PROT_ACCENCSDFUCB_RDA, PROT_ACCENCSDFUCB_RDB, PROT_ACCENCSDFUCB_VM, PROT_ACCENCSDFUCB_PRS.
PCSDFUCB	Access protection using *APU-PCSDFUCB* registers.
APU-PCSDFd (d=0-3)	Protection group consisting of registers PROT_ACCENCSDFd_WRA, PROT_ACCENCSDFd_WRB, PROT_ACCENCSDFd_RDA, PROT_ACCENCSDFd_RDB, PROT_ACCENCSDFd_VM, PROT_ACCENCSDFd_PRS, PROT_ACCENCSDFd_RGNLA, PROT_ACCENCSDFd_RGNUA.
PCSDFd	Access protection using *APU-PCSDFd* registers.
APU-PCSPFp (p=0-3)	Protection group consisting of registers PROT_ACCENCSPFp_WRA, PROT_ACCENCSPFp_WRB, PROT_ACCENCSPFp_VM, PROT_ACCENCSPFp_PRS, PROT_ACCENCSPFp_RGNLA, PROT_ACCENCSPFp_RGNUA.
PCSPFp	Access protection using *APU-PCSPFp* registers.
APU-PCSRDC	Protection group consisting of registers PROT_ACCENCSRDC_WRA, PROT_ACCENCSRDC_WRB, PROT_ACCENCSRDC_RDA, PROT_ACCENCSRDC_RDB, PROT_ACCENCSRDC_VM, PROT_ACCENCSRDC_PRS.
PCSRDC	Access protection using *APU-PCSRDC* registers.
APU-PHCI	Protection group consisting of registers PROT_ACCENHCI_WRA, PROT_ACCENHCI_WRB, PROT_ACCENHCI_RDA, PROT_ACCENHCI_RDB, PROT_ACCENHCI_VM, PROT_ACCENHCI_PRS.
PHCI	Access protection using *APU-PHCI* registers.

0		0		BUSYP5B	BUSYP5A	BUSYP4B	BUSYP4A	BUSYP3B	BUSYP3A	BUSYP2B	BUSYP2A	BUSYP1B	BUSYP1A	BUSYP0B	BUSYP0A
r		r		rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
BUSYPxA (x=0-5)	2*x	rh	**HOST PFLASH PxA BUSY setting** HW-controlled status flag. Indication of busy state of PFxA because of active execution of an operation; PFxA busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the PFxA does not allow read access. 0_B Bank ready for read 1_B Bank busy; no read possible (NVM is not fully started or bank is under operation or bank is sleeping)
BUSYPxB (x=0-5)	2*x+1	rh	**HOST PFLASH PxB BUSY setting** HW-controlled status flag. Indication of busy state of PFxB because of active execution of an operation; PFxB busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the PFxB does not allow read access. 0_B Bank ready for read 1_B Bank busy; no read possible (NVM is not fully started or bank is under operation or bank is sleeping)
BUSYHOSTDF	16	rh	**HOST DFLASH BUSY setting** HW-controlled status flag. Indication of busy state of HOST DFLASH because of active execution of an operation; HOST DFLASH busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the HOST DFLASH does not allow read access. 0_B Bank ready for read 1_B Bank busy; no read possible (NVM is not fully started or bank is under operation or bank is sleeping)
FSIACTIVE	19	rh	**HOST FSI active** This register bit shows to the system if the FSI is active.
DFPAGE	24	rh	**Data Flash in Page Mode** HW-controlled status flag. Set with Enter Page Mode for DFLASH, cleared with Write Page command. Read accesses are allowed while in page mode. 0_B DFLASH not in page mode 1_B DFLASH in page mode

(table continues...)

(continued)

Field	Bits	Type	Description
PFPAGE	25	rh	**Program Flash in Page Mode** HW-controlled status flag. Set with Enter Page Mode for Flash, cleared with Write Page command. Read accesses are allowed while in page mode. 0_B PFLASH not in page mode 1_B PFLASH in page mode
PROG	26	rh	**Programming State** This bitfield indicates that the last received operation was a programming operation. This is set per HW once the programming operation is received and stays until cleared with DMU_HCI_OCONTROL.CPROG or with the "clear status" command. It is set with last cycle of write page or write burst and replace logical sector command sequences. 0_B Programming state is cleared (default) 1_B Program operation on going or finished.
ERASE	27	rh	**Erasing State** This bitfield indicates that the last received operation was an erase or a verify erase operation. This is set per HW once the erase or verify erase operation is received and stays until cleared with DMU_HCI_OCONTROL.CERASE or with the "clear status" command. It is set with last cycle of erase or verify erase command sequences. 0_B Erasing state is cleared (default) 1_B Erase operation on going or finished.
USER	28	rh	**User State** This bitfield indicates that the last received operation was an user operation. This is set per HW once the user operation is received and stays until cleared with DMU_HCI_OCONTROL.CUSER or with the "clear status" command. It is set with last cycle of user ommand sequences 0_B User state is cleared (default) 1_B User operation on going or finished.
REQACK	30	rh	**Request acknowledgement** This bitfield is set on the first cycle of a command sequence to acknowledge that a request was received. The request acknowledge information stays until cleared by "clear status" command. 0_B No request received (default) 1_B Request received

(table continues...)

(continued)

Field	Bits	Type	Description
REQDONE	31	rh	**Request done** This bitfield is set at the end of the execution of a command sequence to acknowledge that the request is executed. The request done information stays until cleared by "clear status" command. 0_B No request executed (default) 1_B Request execution done
0	15:14, 13:12, 18:17, 23:20, 29	r	**Reserved** Read as 0; shall be written with 0.

Field	Bits	Type	Description
CLEAR	2	rwh	**Clear Request** 0_B No action 1_B Request to clear
UCG	8	rw	**User Command Granularity** Granularity configuration of User commands. 0_B Wordline (default) 1_B Page
PRMODE	9	rw	**Programming mode** This bitfield configures the programming mode for the PFLASH. Note the DFLASH is always programmed in one pulse independently from this setting. 0_B Program in 4 pulses of 64 bits (default) 1_B Program in 1 pulse of 256 bits (please refer to the datasheet for potential additional restrictions)
PMPMODE	10	rw	**Pump mode** This bitfield configures the pump mode for the operations. 0_B Full mode (default) 1_B Half mode (test setting, do not use without clarification with Infineon FAE)
CPROG	26	w	**Clear programming State** 0_B No action 1_B Clear programming state flag STATUS.PROG
CERASE	27	w	**Clear erase State** 0_B No action 1_B Clear erase state flag STATUS.ERASE
CUSER	28	w	**Clear user State** 0_B No action 1_B Clear user state flag STATUS.USER
0	0, 7:3, 25:11, 31:29	r	**Reserved** Read as 0; shall be written with 0.

5.4.1.6 HOST command interface error register

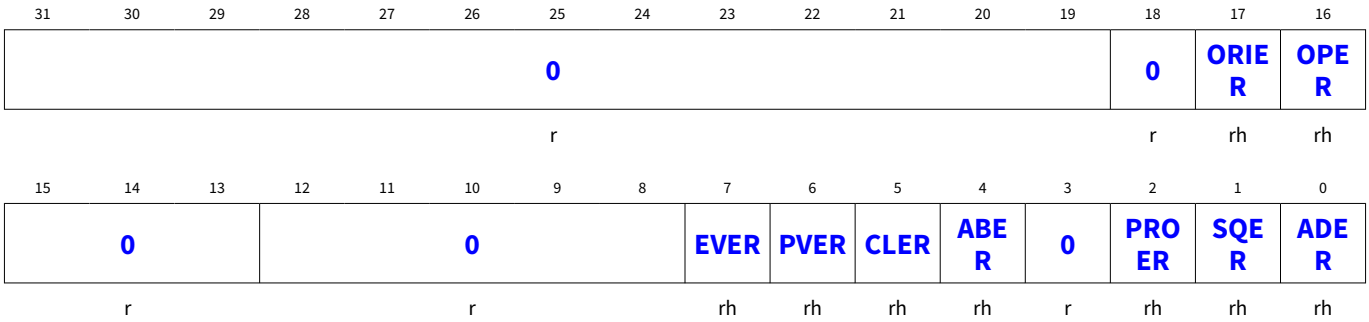
HOST command interface registers

This register stores the errors occuring while execution of NVM operations through the HOST command interface.

Note: the setting of any of these error bits takes priority over the clear operation performed using HCI_CLRERR.

HCI_ERR Offset address: 0010_H

HOST command interface error register Reset values see: Table 470



Field	Bits	Type	Description
ADER	0	rh	**SRI bus Address error** This bit is set when the DMU detects an ECC error in the address phase of the SRI transaction. *Note : Cleared with application reset or writting HCI_CLRERR.CADER=1$_B$.* 0_B No SRI address error was detected 1_B SRI address error detected
SQER	1	rh	**Command sequence error** This bit is set when the DMU detects a sequence error. *Note : Cleared with application reset, command "Reset to Read" or writing HCI_CLRERR.CSQER=1$_B$.* 0_B No sequence error was detected 1_B A sequence error was detected
PROER	2	rh	**Protection error** This bit is set when the DMU detects a protection error. *Note : Cleared with application reset, command "Reset to Read" or writing HCI_CLRERR.CPROER=1$_B$.* 0_B No protection error was detected 1_B A protection error was detected
ABER	4	rh	**Abort error** This bit is set when the DMU detects an abort error. *Note : Cleared with application reset or writting HCI_CLRERR.CABER=1$_B$.* 0_B No abort error was detected 1_B An abort error was detected
CLER	5	rh	**Clear error** This bit is set when the DMU detects a clear error. *Note : Cleared with application reset or writting HCI_CLRERR.CCLER=1$_B$.* 0_B No clear error was detected 1_B A clear error was detected

(table continues...)

(continued)

Field	Bits	Type	Description
PVER	6	rh	**Program verify error** This bit is set when, while execution of an NVM operation, the programming part failed, means the programmed data are not the expected ones. This includes error while write operations as well as hidden program operations for example : error in erase counter update while erase. The meaning of the error bits is detailed as well in the command sequence description. *Note : Cleared with application reset, command "Clear Status" or writting HCI_CLRERR.CPVER=1_B .* 0_B No program verify error was detected 1_B An program verify error was detected
EVER	7	rh	**Erase verify error** This bit is set when, while execution of an NVM operation, the expected data are not erased state. This includes error while erase operations as well as hidden erase verify checks. Example : no free entry found while replace logical sector. The meaning of the error bits is detailed as well in the command sequence description. *Note : Cleared with application reset, command "Clear Status" or writting HCI_CLRERR.CEVER=1_B .* 0_B No erase verify error was detected 1_B An erase verify error was detected
OPER	16	rh	**Flash operation error** This bit is set if a flash operation error occurred. *Note : Cleared with system reset.* 0_B No operation error was detected 1_B An operation error was detected
ORIER	17	rh	**Original error** This bit is set by hardware, if during startup, the DMU detects an ERRORED value or an uncorrectable ECC error in the ORIG confirmation code of a single UCB (one UCB containing both ORIG and COPY confirmation codes). *Note : Cleared with application reset.* 0_B No original error was detected 1_B An original error was detected
0	3, 12:8, 15:13, 18, 31:19	r	**Reserved** Read as 0; shall be written with 0.

Table 470 Reset values of HCI_ERR

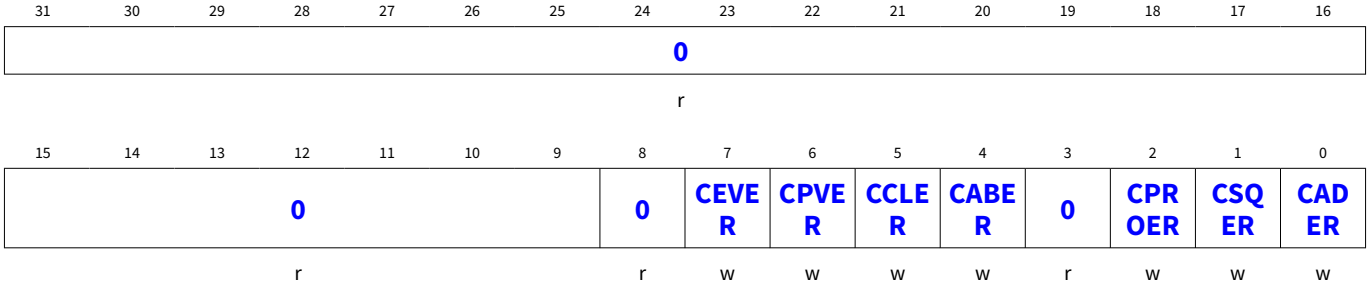
Reset type	Reset value	Note
Application Reset	0000 0000 0000 000X 0000 0000 0000 0000_B	Bit 16 (OPER) is only cleared with system reset

5.4.1.7 HOST command interface clear error register

HOST command interface registers

HCI_CLRERR Offset address: 0014_H

HOST command interface clear error register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CADER	0	w	**Clear SRI bus Address error** 0_B No action 1_B Clears the SRI address error flag DMU_HCI_ERR.ADER
CSQER	1	w	**Clears command sequence error** 0_B No action 1_B Clears the sequence error flag DMU_HCI_ERR.SQER
CPROER	2	w	**Clears protection error** 0_B No action 1_B Clears the protection error flag DMU_HCI_ERR.PROER
CABER	4	w	**Clears abort error** 0_B No action 1_B Clears the abort error flag DMU_HCI_ERR.ABER
CCLER	5	w	**Clear clear error** 0_B No action 1_B Clears the clear error flag DMU_HCI_ERR.CLER
CPVER	6	w	**Clear program verify error** 0_B No action 1_B Clears the program verify error flag DMU_HCI_ERR.PVER
CEVER	7	w	**Clear erase verify error** 0_B No action 1_B Clears the erase verify error flag DMU_HCI_ERR.EVER
0	3, 8, 31:9	r	**Reserved** Read as 0; shall be written with 0.

5.4.1.8 HOST command interface interrupt enable register

HOST command interface registers

HCI_INTEN Offset address: 0018_H

HOST command interface interrupt enable register Application Reset value: $0000\ 0000_H$

r		r		rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
BUSYPxA (x=0-5)	2*x	rh	**HOST PFLASH PxA BUSY setting** HW-controlled status flag. Indication of busy state of PFxA because of active execution of an operation; PFxA busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the PFxA does not allow read access. 0_B Bank ready for read 1_B Bank busy; no read possible (NVM is not fully started or bank is under operation or bank is sleeping)
BUSYPxB (x=0-5)	2*x+1	rh	**HOST PFLASH PxB BUSY setting** HW-controlled status flag. Indication of busy state of PFxB because of active execution of an operation; PFxB busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the PFxB does not allow read access. 0_B Bank ready for read 1_B Bank busy; no read possible (NVM is not fully started or bank is under operation or bank is sleeping)
BUSYHOSTDF	16	rh	**HOST DFLASH BUSY setting** HW-controlled status flag. Indication of busy state of HOST DFLASH because of active execution of an operation; HOST DFLASH busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the HOST DFLASH does not allow read access. 0_B Bank ready for read 1_B Bank busy; no read possible (NVM is not fully started or bank is under operation or bank is sleeping)
BUSYCSRMDF	17	rh	**CSRM DFLASH BUSY setting** HW-controlled status flag. Indication of busy state of CSRM DFLASH because of active execution of an operation; CSRM DFLASH busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the CSRM DFLASH does not allow read access 0_B Bank ready for read 1_B Bank busy; no read possible (NVM is not fully started or bank is under operation or bank is sleeping)
BUSYCSRMPF	18	rh	**CSRM PFLASH BUSY setting** HW-controlled status flag. Indication of busy state of CSRM PFLASH because of active execution of an operation; CSRM PFLASH busy state is also indicated during Flash startup after reset or in sleep mode; while in busy state the CSRM PFLASH does not allow read access 0_B Bank ready for read 1_B Bank busy; no read possible (NVM is not fully started or bank is under operation or bank is sleeping)
FSIACTIVE	19	rh	**CSRM FSI active** This register bit shows to the system if the FSI is active.

(table continues...)

(continued)

Field	Bits	Type	Description
DFPAGE	24	rh	**Data Flash in Page Mode** HW-controlled status flag. Set with Enter Page Mode for DFLASH, cleared with Write Page command. Read accesses are allowed while in page mode. 0_B DFLASH not in page mode 1_B DFLASH in page mode
PFPAGE	25	rh	**Program Flash in Page Mode** HW-controlled status flag. Set with Enter Page Mode for Flash, cleared with Write Page command. Read accesses are allowed while in page mode. 0_B PFLASH not in page mode 1_B PFLASH in page mode
PROG	26	rh	**Programming State** This bitfield indicates that the last received operation was a programming operation. This is set per HW once the programming operation is received and stays until cleared with DMU_CSCI_OCONTROL.CPROG or with the "clear status" command. It is set with last cycle of write page or write burst and replace logical sector command sequences. 0_B Programming state is cleared (default) 1_B Program operation on going or finished.
ERASE	27	rh	**Erasing State** This bitfield indicates that the last received operation was an erase or a verify erase operation. This is set per HW once the erase or verify erase operation is received and stays until cleared with DMU_CSCI_OCONTROL.CERASE or with the "clear status" command. It is set with last cycle of erase or verify erase command sequences. 0_B Erasing state is cleared (default) 1_B Erase operation on going or finished.
USER	28	rh	**User State** This bitfield indicates that the last received operation was an user operation. This is set per HW once the user operation is received and stays until cleared with DMU_CSCI_OCONTROL.CUSER or with the "clear status" command. It is set with last cycle of user ommand sequences 0_B User state is cleared (default) 1_B User operation on going or finished.

(table continues...)

(continued)

Field	Bits	Type	Description
REQACK	30	rh	**Request acknowledgement** This bitfield is set on the first cycle of a command sequence to acknowledge that a request was received. The request acknowledge information stays until cleared by "clear status" command. 0_B No request received (default) 1_B Request received
REQDONE	31	rh	**Request done** This bitfield is set at the end of the execution of a command sequence to acknowledge that the request is executed. The request done information stays until cleared by "clear status" command. 0_B No request executed (default) 1_B Request execution done
0	15:14, 13:12, 23:20, 29	r	**Reserved** Read as 0; shall be written with 0.

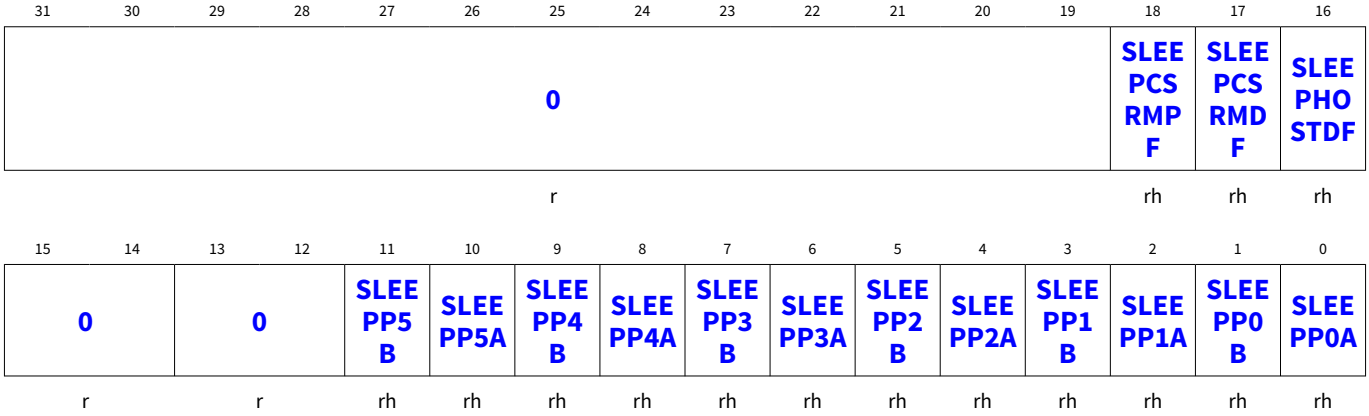
5.4.1.16 CSRM sleep register

CSRM command interface registers

CSCI_SLEEP Offset address: $009C_H$

CSRM sleep register Application Reset value: $0000\ 0000_H$

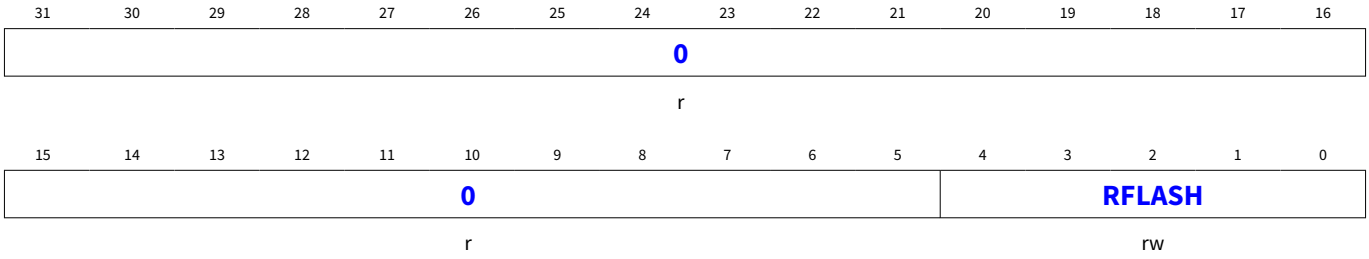


Field	Bits	Type	Description
SLEEPPxA (x=0-5)	2*x	rh	**HOST PFLASH PxA sleeping** HW-controlled status flag. Indication that PFxA is sleeping thus no read nor operation can be executed on that bank. 0_B Bank awake 1_B Bank sleeping; no read, no operation possible
SLEEPPxB (x=0-5)	2*x+1	rh	**HOST PFLASH PxB sleeping** HW-controlled status flag. Indication that PFxB is sleeping thus no read nor operation can be executed on that bank. 0_B Bank awake 1_B Bank sleeping; no read, no operation possible
SLEEPHOSTDF	16	rh	**HOST DFLASH sleeping** HW-controlled status flag. Indication that HOST DFLASH is sleeping thus no read nor operation can be executed on that bank 0_B Bank awake 1_B Bank sleeping; no read, no operation possible
SLEEPCSRMDF	17	rh	**CSRM DFLASH sleeping** HW-controlled status flag. Indication that CSRM DFLASH is sleeping thus no read nor operation can be executed on that bank 0_B Bank awake 1_B Bank sleeping; no read, no operation possible
SLEEPCSRMPF	18	rh	**CSRM PFLASH sleeping** HW-controlled status flag. Indication that CSRM PFLASH is sleeping thus no read nor operation can be executed on that bank 0_B Bank awake 1_B Bank sleeping; no read, no operation possible
0	15:14, 13:12, 31:19	r	**Reserved** Read as 0; shall be written with 0.

5.4.1.17 HOST DFLASH wait cycle register

GP_HOST_DFWAIT Offset address: 0100_H

HOST DFLASH wait cycle register Reset values see: Table 473



Field	Bits	Type	Description
RFLASH	4:0	rw	**Wait cycles for read** These registers defines the number of FSI clock cycles needed for a HOST DFLASH, UCB or CFS read access. 00_H Read access takes 1 fFSI clock cycles … $1F_H$ Read access takes 32 fFSI clock cycles
0	31:5	r	**Reserved** Read as 0; shall be written with 0.

Table 473 Reset values of GP_HOST_DFWAIT

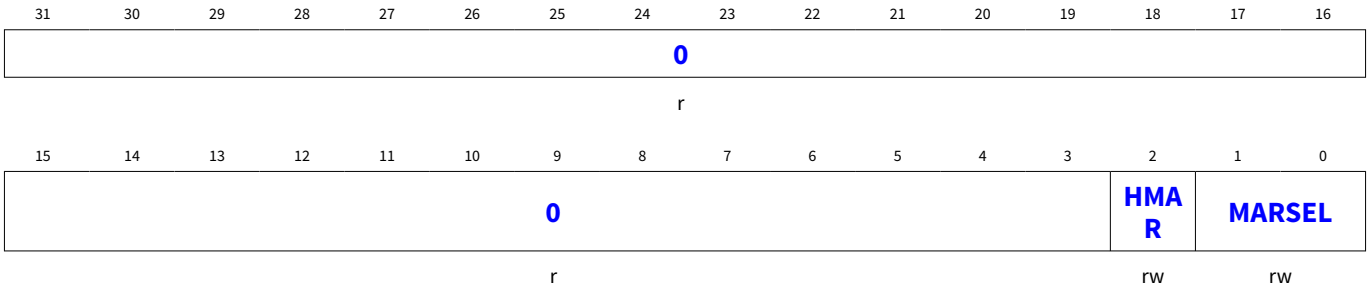
Reset type	Reset value	Note
System Reset	$0000\ 0005_H$	
After Boot-FW Value	$0000\ 0005_H$	

5.4.1.18 HOST DFLASH margin control register

If a change between the read margin settings is done using HMAR or MARSEL, the system must wait a delay time $t_{FL_MarginDel}$ until the next read is requested.

GP_HOST_DFMARGIN Offset address: 0104_H

HOST DFLASH margin control register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
MARSEL	1:0	rw	**Read margin selection** This register enables to use the hard margins to read out of the HOST DFLASH, UCB and CFS memory regions. 00_B Enables the standard read margins for reading the HOST DFLASH, UCB or CFS bank. ... 10_B Enables the standard read margins for reading the HOST DFLASH, UCB or CFS bank. 11_B Enables the read margins chosen by DMU_GP_HOST_DFMARGIN.HMAR for reading the HOST DFLASH, UCB or CFS bank
HMAR	2	rw	**Hard margin selection** These registers enable to chose between the thigh-0 and the tight-1 margin for reading out of the HOST DFLASH, UCB or CFS memory regions. This setting is effective only if DMU_GP_HOST_DFMARGIN.MARSEL=11_B. 0_B Enables the tight-0 read margins (sub-optimal 0 read as 1) for reading the HOST DFLASH, UCB or CFS bank. 1_B Enables the tight-1 read margins (sub-optimal 1 read as 0) for reading the HOST DFLASH, UCB or CFS bank.
0	31:3	r	**Reserved** Read as 0; shall be written with 0.

5.4.1.19 HOST DFLASH ECC read register

The ECC read register stores the ECC checksum corresponding to the last read on the HOST DFLASH, UCB or CFS bank when the read is initiated through the DMU SRI slave interface.

GP_HOST_DFECCR Offset address: 0108_H

HOST DFLASH ECC read register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RCODE															
rh															

Field	Bits	Type	Description
RCODE	21:0	rh	**Error correction code from the last read.** These registers contain the ECC checksum corresponding to the last HOST DFLASH, UCB or CFS read access.
RES	23:22	rh	**Reserved** Reserved. Internal
0	31:24	r	**Reserved** Read as 0; shall be written with 0.

5.4.1.20 HOST DFLASH ECC status register

The ECC status register stores the errors found by the ECC corresponding to the last read(s) on the HOST DFLASH, UCB or CFS bank when the read is initiated through the DMU SRI slave interface.

GP_HOST_DFECCS Offset address: $010C_H$

HOST DFLASH ECC status register Reset values see: Table 474

r							rh	r				rh	rh	rh	rh

Field	Bits	Type	Description
SBER	0	rh	**Single Bit ECC Error** This register reports a single bit error found in the last read access. 0_B No single bit error was detected by the ECC in the last read access. 1_B A single bit error was detected by the ECC in the last read access.
DBER	1	rh	**Double Bit ECC Error** This register reports a double bit error found in the last read access. 0_B No double bit error was detected by the ECC in the last read access. 1_B A double bit error was detected by the ECC in the last read access.
TBER	2	rh	**Triple Bit ECC Error** This register reports a triple bit error found in the last read access. 0_B No triple bit error was detected by the ECC in the last read access. 1_B A triple bit error was detected by the ECC in the last read access.
UCER	3	rh	**Uncorrectable ECC Error** This register reports an uncorrectable error found in the last read access. 0_B No uncorrectable error was detected by the ECC in the last read access. 1_B An uncorrectable error was detected by the ECC in the last read access.
ANER	8	rh	**Any ECC error** This register reports an error found in the last read access. 0_B No error was detected by the ECC in the last read access. 1_B An error was detected by the ECC in the last read access.

(table continues...)

(continued)

Field	Bits	Type	Description
ASBER	16	rh	**Accumulated Single Bit ECC Error** This register reports that at least one single bit error was found in the read accesses since the last reset or clear. 0_B No single bit error was detected by the ECC in the read accesses. 1_B A single bit error was detected by the ECC in the read accesses.
ADBER	17	rh	**Accumulated Double Bit ECC Error** This register reports that at least one double bit error was found in the read accesses since the last reset or clear. 0_B No double bit error was detected by the ECC in the read accesses. 1_B A double bit error was detected by the ECC in the read accesses.
ATBER	18	rh	**Accumulated Triple Bit ECC Error** This register reports that at least one triple bit error was found in the read accesses since the last reset or clear. 0_B No triple bit error was detected by the ECC in the read accesses. 1_B A triple bit error was detected by the ECC in the read accesses.
AUCER	19	rh	**Accumulated Uncorrectable ECC Error** This register reports that at least one uncorrectable error was found in the read accesses since the last reset or clear. 0_B No uncorrectable error was detected by the ECC in the read accesses. 1_B A uncorrectable error was detected by the ECC in the read accesses.
AANER	24	rh	**Accumulated Any ECC error** This register reports that at least one error was found in the read accesses since the last reset or clear. 0_B No error was detected by the ECC in the read accesses. 1_B An error was detected by the ECC in the read accesses.
0	7:4, 15:9, 23:20, 31:25	r	**Reserved** Read as 0; shall be written with 0.

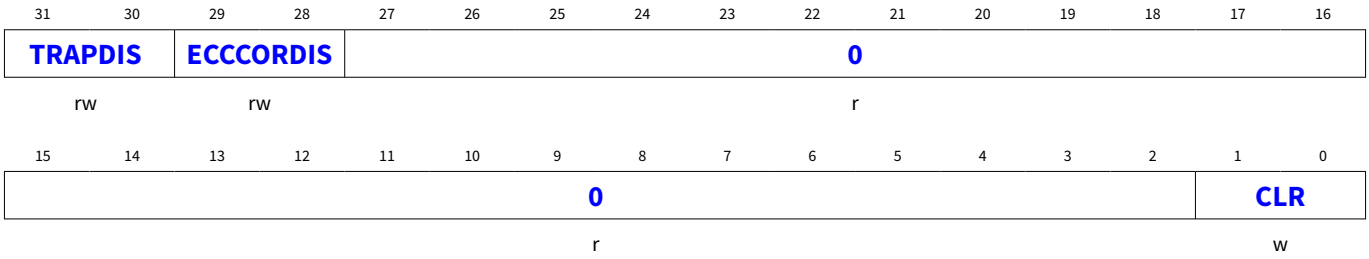
Table 474 Reset values of GP_HOST_DFECCS

Reset type	Reset value	Note
Application Reset	$0000\ 0000_H$	
After Boot-FW Value	$0000\ 0000_H$	

5.4.1.21 HOST DFLASH ECC control register

GP_HOST_DFECCC Offset address: 0110_H

HOST DFLASH ECC control register Application Reset value: $C000\ 0000_H$



Field	Bits	Type	Description
CLR	1:0	w	**Clear ECC status bits** These registers clears the DMU_GP_HOST_DFECCS registers. 00_B No action … 10_B No action 11_B Clears the DMU_GP_HOST_DFECCS
ECCCORDIS	29:28	rw	**ECC correction disable** These registers disable the ECC correction for the HOST DFLASH, UCB and CFS bank. 00_B ECC correction is enabled for HOST DFLASH, UCB and CFS … 10_B ECC correction is enabled for HOST DFLASH, UCB and CFS 11_B ECC correction is disabled for HOST DFLASH, UCB and CFS
TRAPDIS	31:30	rw	**ECC trap disable** These registers disable the bus error trap on ECC uncorrectable errors for the HOST DFLASH, UCB and CFS bank 00_B Bus error trap is enabled for HOST DFLASH, UCB and CFS uncorrectable ECC errors … 10_B Bus error trap is enabled for HOST DFLASH, UCB and CFS uncorrectable ECC errors 11_B Bus error trap is disabled for HOST DFLASH, UCB and CFS uncorrectable ECC errors
0	27:2	r	**Reserved** Read as 0; shall be written with 0.

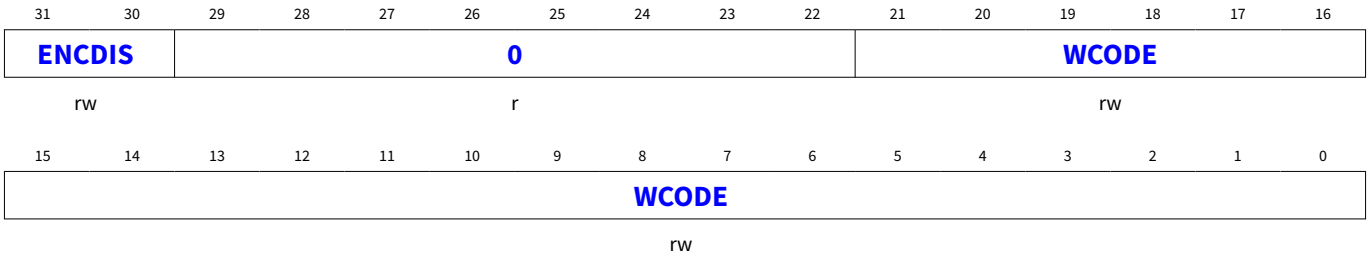
5.4.1.22 HOST DFLASH ECC write register

These registers control the behavior of the ECC for write.

When disabling the ECC encoding with DMU_GP_HOST_DFECCW.ENCDIS='11_B' the ECC code for the next 64-bit data block transferred from the DMU to the HOST DFLASH is taken from the DMU_GP_HOST_DFECCW.WCODE.

GP_HOST_DFECCW Offset address: 0114_H

HOST DFLASH ECC write register Application Reset value: $0000\ 0000_H$

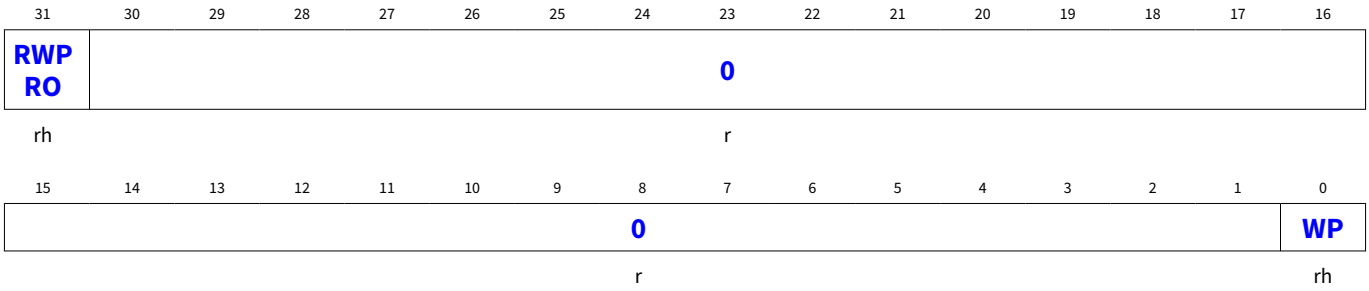


Field	Bits	Type	Description
WCODE	21:0	rw	**Error correction code for write** These registers contain the ECC checksum for the next write on HOST DFLASH.
ENCDIS	31:30	rw	**ECC encoding disable** 00_B The ECC code is calculated automatically. … 10_B The ECC code is calculated automatically. 11_B The ECC code is taken from WCODE
0	29:22	r	**Reserved** Read as 0; shall be written with 0.

5.4.1.23 HOST DFLASH protection register

GP_HOST_DFPROCON Offset address: 0118_H

HOST DFLASH protection register Reset values see: Table 475



Field	Bits	Type	Description
WP	0	rh	**Write protection** This bit indicates whether the HOST DFLASH is write protected. 0_B No write protection is configured for HOST DFLASH. 1_B Write protection is configured for HOST DFLASH.
RWPRO	31	rh	**Read and write protections configuration** This bit indicates whether read and write protection are configured for HOST DFLASH. 0_B No read and no write protection are configured for HOST DFLASH. 1_B Read and write protections are configured for HOST DFLASH.

(table continues...)

(continued)

Field	Bits	Type	Description
0	30:1	r	**Reserved** Read as 0; shall be written with 0.

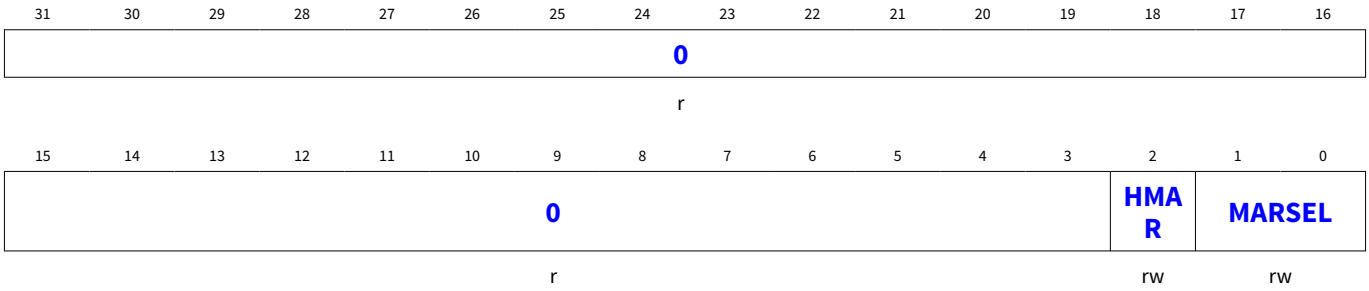
5.4.1.65 CSRM DFLASH margin control register

If a change between the read margin settings is done using HMAR or MARSEL, the system must wait a delay time $t_{FL_MarginDel}$ until the next read is requested.

GP_CSRM_DFMARGIN Offset address: 0904$_H$

CSRM DFLASH margin control register Application Reset value: 0000 0000$_H$



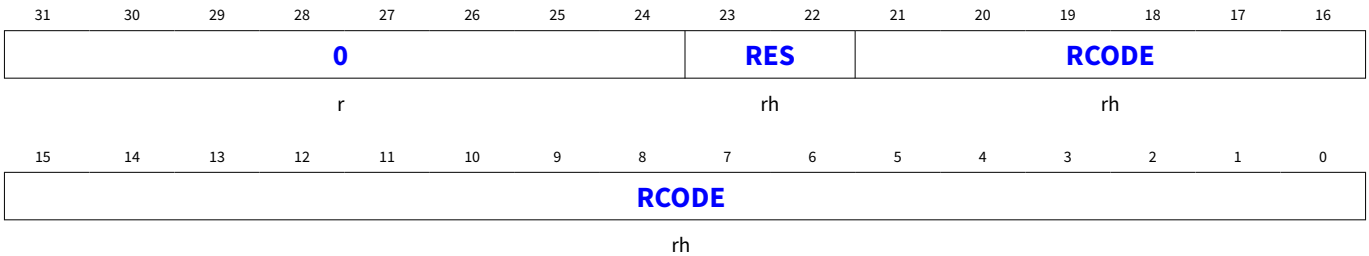
Field	Bits	Type	Description
MARSEL	1:0	rw	**Read margin selection** This register enables to use the hard margins to read out of the CSRM DFLASH, UCB and CFS memory regions. 00_B Enables the standard read margins for reading the CSRM DFLASH, UCB or CFS bank. … 10_B Enables the standard read margins for reading the CSRM DFLASH, UCB or CFS bank. 11_B Enables the read margins chosen by DMU_GP_CSRM_DFMARGIN.HMAR for reading the CSRM DFLASH, UCB or CFS bank
HMAR	2	rw	**Hard margin selection** These registers enable to chose between the thigh-0 and the tight-1 margin for reading out of the CSRM DFLASH, UCB or CFS memory regions. This setting is effective only if DMU_GP_CSRM_DFMARGIN.MARSEL=11_B. 0_B Enables the tight-0 read margins (sub-optimal 0 read as 1) for reading the CSRM DFLASH, UCB or CFS bank. 1_B Enables the tight-1 read margins (sub-optimal 1 read as 0) for reading the CSRM DFLASH, UCB or CFS bank.
0	31:3	r	**Reserved** Read as 0; shall be written with 0.

5.4.1.66 CSRM DFLASH ECC read register

The ECC read register stores the ECC checksum corresponding to the last read on the CSRM DFLASH, UCB or CFS bank when the read is initiated through the DMU SRI slave interface.

GP_CSRM_DFECCR Offset address: 0908_H

CSRM DFLASH ECC read register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RCODE	21:0	rh	**Error correction code from the last read.** These registers contain the ECC checksum corresponding to the last CSRM DFLASH, UCB or CFS read access.
RES	23:22	rh	**Reserved** Reserved. Internal
0	31:24	r	**Reserved** Read as 0; shall be written with 0.

5.4.1.67 CSRM DFLASH ECC status register

The ECC status register stores the errors found by the ECC corresponding to the last read(s) on the CSRM DFLASH, UCB or CFS bank when the read is initiated through the DMU SRI slave interface.

GP_CSRM_DFECCS Offset address: $090C_H$

CSRM DFLASH ECC status register Reset values see: Table 514

0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															WSERRINJ
r															w

Field	Bits	Type	Description
WSERRINJ	0	w	**CSRM PFLASH Wait State ECC error injection** Error injection into the ECC logic protecting PFlash Wait states to trigger an alarm. 0_B No action 1_B An error is injected in the ECC checksum protecting the PFLASH wait states
0	31:1	r	**Reserved** Read as 0; shall be written with 0.

5.4.1.73 CSRM PFLASH ECC write register

These registers control the behavior of the ECC for write.

When disabling the ECC correction with DMU_GP_CSRM_PFECCW.ENCDIS='11_B' the ECC code for the next 256-bit data block transferred from the DMU to the CSRM PFLASH is taken from the DMU_GP_CSRM_PFECCW.WCODE.

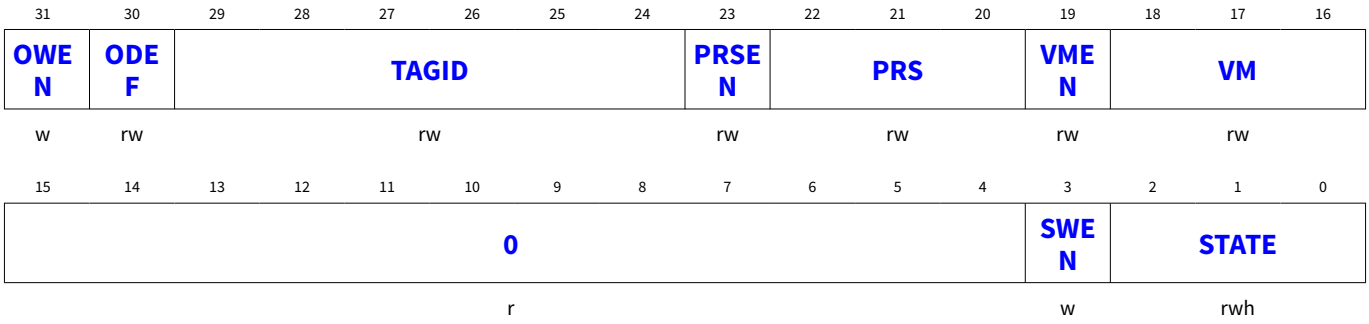
5.4.1.98 PROT register for HOST command interface and HCI registers

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTHCI register controls lock and unlock of the locally protected HOST command interface and HCI registers.

PROT_PROTHCI Offset address: $0B00_H$

PROT register for HOST command interface and HCI registers Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection Set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection Set definition Enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; shall be written with 0.

Table 539 Access mode restrictions of PROT_PROTHCI sorted by descending priority

Mode name	Access mode		Description
PROT_OWNER and write 1 to .**SWEN**	rwh	STATE	PROT owner can modify the PROT state (for allowed and valid transitions)
PROT_OWNER and write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	PROT owner can modify the existing PROT owner
SECURE_MASTER and write 1 to .**SWEN**	rwh	STATE	Secure master can modify the PROT state (for allowed and valid transitions)
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

5.4.1.99 HOST command interface and HCI registers, write access enable register A

This register defines which master TAG ID encodings are enabled or disabled for write accesses to the access protected region.

PROT_ACCENHCI_WRA

HOST command interface and HCI registers, write access enable register A

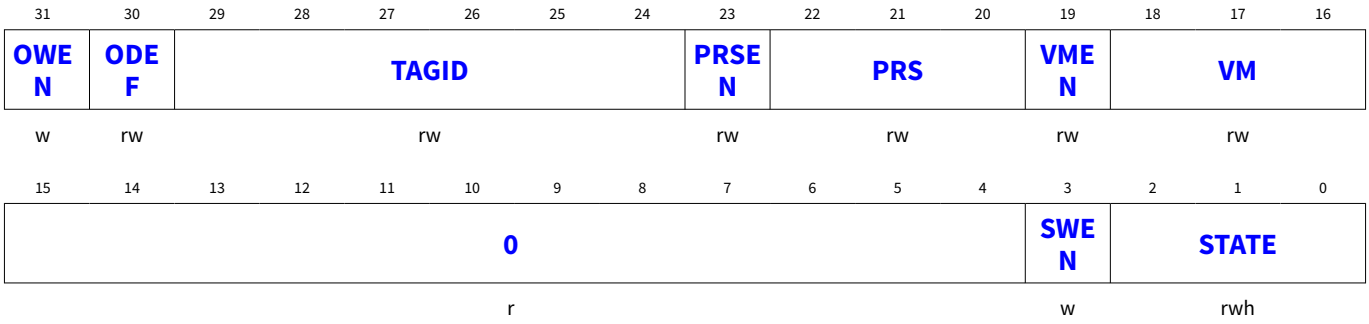
5.4.1.105 PROT register for CSRM command interface and CSCI registers

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTCSCI register controls lock and unlock of the locally protected CSRM command interface and CSCI registers.

PROT_PROTCSCI Offset address: $0B28_H$

PROT register for CSRM command interface and CSCI registers Application Reset value: $4C00\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection Set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection Set definition Enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; shall be written with 0.

r				rw											

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR								0							
rw								r							

Field	Bits	Type	Description
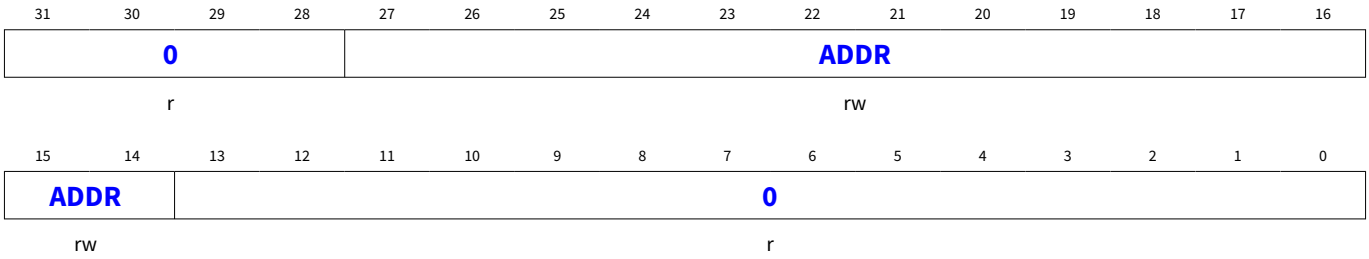
ADDR	27:14	rw	**Region lower address** Defines bits 27:14 of the lower bound of the access protected region in PFLASH.
0	13:0, 31:28	r	**Reserved** Read as 0; shall be written with 0.

5.4.1.132 HOST PFLASH memory Pp, region upper address register

This register sets the upper bound of the access protected region. Addresses stricly less than the upper bound are considered part of the access protected region.

PROT_ACCENHPFp_RGNUA (p=0-11) Offset address: $0BC4_H+p*20_H$

HOST PFLASH memory Pp, region upper address register Application Reset value: $0FFF\ C000_H$



Field	Bits	Type	Description
ADDR	27:14	rw	**Region upper address** Defines bits 27:14 of the upper bound of the access protected region in PFLASH.
0	13:0, 31:28	r	**Reserved** Read as 0; shall be written with 0.

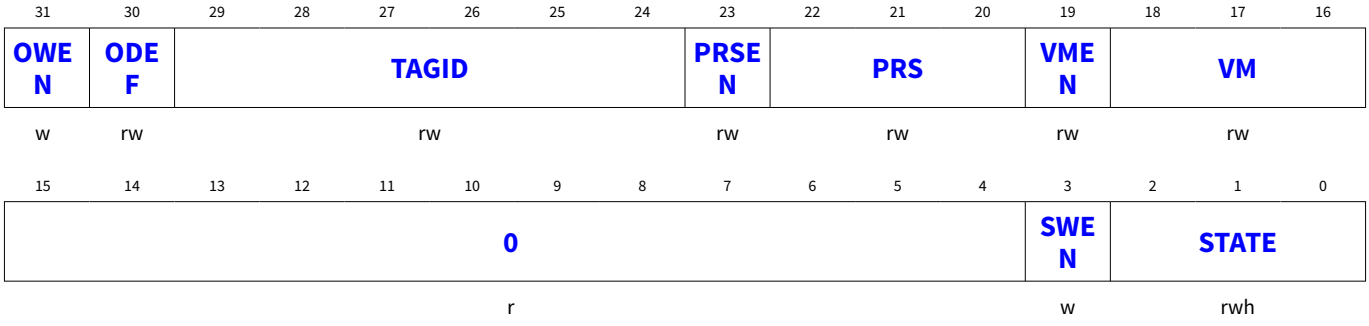
5.4.1.133 PROT register for HOST DFLASH (EEPROM) and HOST UCB memory

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner or CS master to update the PROT state as described in the PROT mechanism.

The PROTHDF register controls lock and unlock of the locally protected HOST DFLASH (EEPROM) and HOST UCB memory.

PROT_PROTHDF Offset address: $0DA8_H$

PROT register for HOST DFLASH [EEPROM) and HOST UCB memory Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection Set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection Set definition Enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; shall be written with 0.

Table 544 Access mode restrictions of PROT_PROTHDF sorted by descending priority

Mode name	Access mode		Description
PROT_OWNER and write 1 to .**SWEN**	rwh	STATE	PROT owner can modify the PROT state (for allowed and valid transitions)
PROT_OWNER and write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	PROT owner can modify the existing PROT owner
SECURE_MASTER and write 1 to .**SWEN**	rwh	STATE	Secure master can modify the PROT state (for allowed and valid transitions)
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

5.4.1.134 HOST DFLASH (EEPROM) memory Dd, write access enable register A

This register defines which master TAG ID encodings are enabled or disabled for write accesses to the access protected region.

PROT_ACCENHDFd_WRA (d=0-7) Offset address: $0DB0_H+d*20_H$

Field	Bits	Type	Description
COMM1	7:0	rwh	**Communication register 1** This 8 bit register can be written by the DMU and by the FSI and is used to transfer options for the command sequences to FSI or status information back to the system.

5.4.2.5 Communication register 2

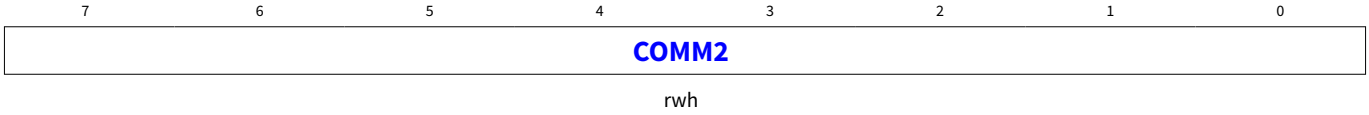
This 8 bit register can be written by the DMU and by the FSI and is used to transfer options for the command sequences to FSI or status information back to the system.

Properties:

[[NVM_MISR : NO]]
[[NVM_ROM : NO]]
[[NVM_RECOVER : NO]]
[[NVM_CRITICAL : NO]]
[[NVM_TYPE : FSI_SFR_REQ]]

COMM2 Offset address: 0002_H

Communication register 2 System Reset value: 00_H



Field	Bits	Type	Description
COMM2	7:0	rwh	**Communication register 2** This 8 bit register can be written by the DMU and by the FSI and is used to transfer options for the command sequences to FSI or status information back to the system.

5.4.3 PFRWB registers

5.4.3.1 Register overview - access mode glossary

Table 550 Register overview - access mode glossary

Keyword	Description
M	Indicates a module specific access condition. Refer to the register description for details of the specific access condition.
32	Access only when using 32-bit width.
BE	Always returns a Bus Error.

5.4.3.2 Registers overview - PFRWB (ascending offset address)

Table 551 Registers overview - PFRWB (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
UR_FLASHCON2	PFRWB FLASH configuration register 2	000000_H	M, 32	M, 32	Application Reset	956
UR_FLASHCON3	PFRWB FLASH configuration register 3	000004_H	M, 32	M, 32	Application Reset	958
UR_ECCR	ECC read register	002000_H	M, 32	BE	System Reset	960

(table continues...)

Table 551 (continued) Registers overview - PFRWB (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
UR_ECCS	ECC status register	002004_H	M, 32	BE	System Reset	960
UR_SBABx	Single bit error address buffer x	002080_H +x*4	M, 32	BE	System Reset	963
UR_DBABx	Double bit error address buffer x	002100_H +x*4	M, 32	BE	System Reset	964
UR_UBAB0	Uncorrectable error address buffer x	002180_H	M, 32	BE	System Reset	964

5.4.3.3 PFRWB FLASH configuration register 2

The Flash Configuration register 2 enables to control the read margins, the ECC behavior and the recording in the xBAB (ECC error address buffer) registers.

If a change between the read margin settings is done using HMAR or MARSEL, the system must wait a delay time $t_{FL_MarginDel}$ until the next read is requested.

UR_FLASHCON2 Offset address: 000000_H

PFRWB FLASH configuration register 2 Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	UBABCLR	0	DBABCLR	0	SBABCLR	0	ECCSCLR	0							RECDIS
r	w	r	w	r	w	r	w	r							rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0			TDISUDATA	0	MASKUECC	0	ECCCORDIS	0					HMAR	0	MARSEL
r			rw	r	rw	r	rw	r					rw	r	rw

Field	Bits	Type	Description
MARSEL	0	rw	**Margin Read Selection** This bitfield enables to use the hard margins to read out of the local PFLASH bank. This bitfield is protected by a SFF. 0_B Enables the standard read margins for reading the local PFLASH bank. 1_B Enables the read margins chosen by PFRWBx_FLASHCON2.HMAR for reading the local PFLASH bank.

(table continues...)

(continued)

Field	Bits	Type	Description
HMAR	2	rw	**Hard Margin Selection** This bitfield enables to chose between the thigh-0 and the tight-1 margin for reading out of the local PFLASH bank. This setting is effective only if PFRWBx_FLASCON2.MARSEL=1_B. This bitfield is protected by a SFF. 0_B Enables the tight-0 read margins (sub-optimal 0 read as 1) for reading the local PFLASH bank. 1_B Enables the tight-1 read margins (sub-optimal 1 read as 0) for reading the local PFLASH bank.
ECCCORDIS	8	rw	**ECC correction disable** This bitfield disables the ECC correction for the local PFLASH bank. This bitfield is protected by a SFF. 0_B Enable the ECC correction for reading the local PFLASH bank. 1_B Disable the ECC correction for reading the local PFLASH bank.
MASKUECC	10	rw	**Mask PFLASH ECC uncorrectable errors** This bitfield enables to mask the uncorrectable ECC errors. Note that the ECCS and UBAB registers will still store the uncorrectable error, and an alarm is generated but the master will not trap. This bitfield is protected by a SFF. 0_B Enable the propagation of the uncorrectable ECC error to any master reading the local PFLASH. 1_B Disable the propagation of the uncorrectable ECC error to any master reading the local PFLASH bank.
TDISUDATA	12	rw	**Trap disable and uncorrected data** Note: Test setting, do not use without clarification with Infineon FAE. This bitfield shall be set to 0_B in field and used only for test purpose. It disable the traps and always send uncorrected data to the CPU. This bitfield is protected by a SFF. Note that setting this bit leads to safety alarms from the ECC online monitor on correctable error and from the UBAB on uncorrectable error found. 0_B User mode : enable the propagation of ECC errors and always provide the corrected data when necessary to any master reading the local PFLASH. 1_B Test mode : disable the propagation of the any ECC error and always provide the uncorrected data to any master reading the local PFLASH bank.
RECDIS	16	rw	**Address Buffer Record Disable** These bitfield disables the recording in the xBaBs registers if set to 1_B. SBAB, DBAB and UBAB alarms will not be generated if RECDIS is 1_B This bitfield is protected by a SFF. 0_B Enable local PFlash bank ECC error recording in SBAB, DBAB, UBAB. 1_B Disable local PFLASH bank ECC error recording in SBAB, DBAB, and UBAB.

(table continues...)

(continued)

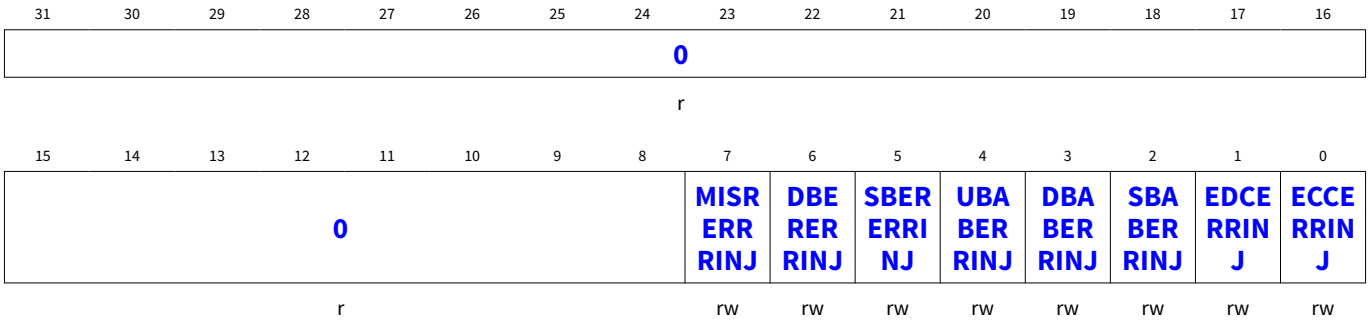
Field	Bits	Type	Description
ECCSCLR	24	w	**Clear ECCS status register** This bitfield enables to clear the ECC status register. This bitfield is protected by a SFF. 0_B No action. 1_B Clear the ECCS registers and the SBER and DBER alarms.
SBABCLR	26	w	**Clear SBAB record registers** This bitfield enables to clear the SBAB registers. This bitfield is protected by a SFF. 0_B No action. 1_B Clear the SBAB registers and the SBAB alarm.
DBABCLR	28	w	**Clear DBAB record registers** This bitfield enables to clear the DBAB registers, This bitfield is protected by a SFF. 0_B No action. 1_B Clear the DBAB registers and the DBAB alarm.
UBABCLR	30	w	**Clear UBAB record registers** This bitfield enables to clear the UBAB registers. This bitfield is protected by a SFF. 0_B No action. 1_B Clear the UBAB registers and the UBAB alarm.
0	1, 7:3, 9, 11, 15:13, 23:17, 25, 27, 29, 31	r	**Reserved** Read as 0; shall be written with 0.

5.4.3.4 PFRWB FLASH configuration register 3

The Flash Configuration register 3 enables to control the error injections to the PFRWB safety mechanisms.

UR_FLASHCON3 Offset address: 000004_H

PFRWB FLASH configuration register 3 Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ECCERRINJ	0	rw	**ECC Error Injection** Setting this bit enforces an error in the ECC error correction monitoring circuit. This can be used to check the alarm line to the SMU. 0_B No error injected, ECC monitor operates normally. 1_B An error is injected in the output of the ECC monitoring logic to mimic an alarm.
EDCERRINJ	1	rw	**EDC Error Injection** Setting this bit enforces an error in the EDC checker logic. This can be used to check the alarm line to the SMU. 0_B No error injected, EDC checker logic operates normally. 1_B An error is injected in the output of the EDC checker logic to mimic an alarm.
SBABERRINJ	2	rw	**SBAB Error Injection** Setting this bit generates a SBAB full SMU alarm, and can be used to check the correct function of this alarm. 0_B No error injected, SBAB logic operates normally. 1_B Inject a SBAB full alarm to the SMU.
DBABERRINJ	3	rw	**DBAB Error Injection** Setting this bit generates a DBAB full SMU alarm, and can be used to check the correct function of this alarm 0_B No error injected, DBAB logic operates normally. 1_B Inject a DBAB full alarm to the SMU.
UBABERRINJ	4	rw	**UBAB Error Injection** Setting this bit generates an UBAB full SMU alarm, and can be used to check the correct function of this alarm. 0_B No error injected, UBAB logic operates normally. 1_B Inject an UBAB full alarm to the SMU.
SBERERRINJ	5	rw	**ECC Single Bit error error injection** Setting this bit generates SBER SMU alarm, and can be used to check the correct function of this alarm 0_B No error injected, SBER logic operates normally. 1_B Inject a SBER alarm to the SMU.

(table continues...)

(continued)

Field	Bits	Type	Description
DBERERRINJ	6	rw	**ECC Double Bit error error injection** Setting this bit generates DBER SMU alarm, and can be used to check the correct function of this alarm 0_B No error injected, DBER logic operates normally. 1_B Inject a DBER alarm to the SMU.
MISRERRRINJ	7	rw	**MISR error injection** Setting this bit generates a MISR SMU alarm, and can be used to check the correct function of this alarm 0_B No error injected, MISR logic operates normally. 1_B Inject a MISR alarm to the SMU.
0	31:8	r	**Reserved** Read as 0; shall be written with 0.

5.4.3.5 ECC read register

The ECC Read register stores the ECC checksum corresponding to the last read on the local PFLASH bank.

UR_ECCR Offset address: 002000_H

ECC read register System Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r								r		rh					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RCODE															
rh															

Field	Bits	Type	Description
RCODE	21:0	rh	**Error Correction Code from the last read.** These registers contain the ECC checksum corresponding to the last local PFLASH bank read access.
0	23:22, 31:24	r	**Reserved** Read as 0; shall be written with 0.

5.4.3.6 ECC status register

The ECC status register stores the errors found by the ECC while reading the local PFLASH bank.

UR_ECCS Offset address: 002004_H

ECC status register System Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0							AANER	0		AALL1	AALL0	AUCER	0	ADBER	ASBER
r							rh	r		rh	rh	rh	r	rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0							ANER	0		ALL1	ALL0	UCER	0	DBER	SBER
r							rh	r		rh	rh	rh	r	rh	rh

Field	Bits	Type	Description
SBER	0	rh	**Single Bit ECC Error** This register reports a single bit error found in the last local PFLASH bank read access. 0_B No single bit error was detected by the ECC in the last local PFLASH bank read. 1_B A single bit error was detected by the ECC in the last local PFLASH bank read.
DBER	1	rh	**Double Bit ECC Error** This register reports a double bit error found in the last local PFLASH bank read access. 0_B No double bit error was detected by the ECC in the last local PFLASH bank read. 1_B A double bit error was detected by the ECC in the last local PFLASH bank read.
UCER	3	rh	**Uncorrectable ECC Error** This register reports an uncorrectable error found in the last local PFLASH bank read access. 0_B No uncorrectable error was detected by the ECC in the last local PFLASH bank read. 1_B An uncorrectable error was detected by the ECC in the last local PFLASH bank read.
ALL0	4	rh	**All 0 bit error** This register reports that all bits are zeros in the last local PFLASH bank read access. 0_B Not all zeros detected in the last local PFLASH bank read. 1_B All zeros detected in the last local PFLASH bank read.
ALL1	5	rh	**All 1 bit error** This register reports that all bits are ones in the last local PFLASH bank read access. 0_B Not all ones detected in the last local PFLASH bank read. 1_B All ones detected in the last local PFLASH bank read.

(table continues...)

(continued)

Field	Bits	Type	Description
ANER	8	rh	**Any ECC error** This register reports an error found in the last local PFLASH bank read access. 0_B No error was detected by the ECC in the last local PFLASH bank read. 1_B An error was detected by the ECC in the last local PFLASH bank read.
ASBER	16	rh	**Accumulated Single Bit ECC Error** This register reports that at least one single bit error was found in the local PFLASH bank read accesses since the last reset or clear. 0_B No single bit error was detected by the ECC in the local PFLASH bank read accesses. 1_B A single bit error was detected by the ECC in the local PFLASH bank read accesses.
ADBER	17	rh	**Accumulated Double Bit ECC Error** This register reports that at least one double bit error was found in the local PFLASH bank read accesses since the last reset or clear. 0_B No double bit error was detected by the ECC in the local PFLASH bank read accesses. 1_B A double bit error was detected by the ECC in the local PFLASH bank read accesses.
AUCER	19	rh	**Accumulated Uncorrectable ECC Error** This register reports that at least one uncorrectable error was found in the local PFLASH bank read accesses since the last reset or clear. 0_B No uncorrectable error was detected by the ECC in the local PFLASH bank read accesses. 1_B A uncorrectable error was detected by the ECC in the local PFLASH bank read accesses.
AALL0	20	rh	**Acumulated all 0 bit error** This register reports that at least one all zeros was found in the local PFLASH bank read accesses since the last reset or clear. 0_B Not all zeros detected in the local PFLASH bank read accesses. 1_B All zeros detected in the local PFLASH bank read accesses.
AALL1	21	rh	**Accumulated all 1 bit error** This register reports that at least one all ones was found in the local PFLASH bank read accesses since the last reset or clear. 0_B Not all ones detected in the local PFLASH bank read accesses. 1_B All ones detected in the local PFLASH bank read accesses.
AANER	24	rh	**Accumulated Any ECC error** This register reports that at least one error was found in the local PFLASH bank read accesses since the last reset or clea 0_B No error was detected by the ECC in the local PFLASH bank read accesses. 1_B An error was detected by the ECC in the local PFLASH bank read accesses.

(table continues...)

(continued)

Field	Bits	Type	Description
0	2, 7:6, 15:9, 18, 23:22, 31:25	r	**Reserved** Read as 0; shall be written with 0.

5.4.3.7 Single bit error address buffer x

These registers records the single bit error detected by the ECC in the local PFLASH bank reads. Once all entries are valid, the buffer is considered full and an alarm is generated.

UR_SBABx (x=0-16) Offset address: 002080_H+x*4

Single bit error address buffer x System Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
ADDR	20:5	rh	**Address** This register stores the address of the detected local PFLASH bank read error.
ECF	27	rh	**Erase Counter Flag** This register stores the information that the error was detected in the erase counter. 0_B The error was found in the PFLASH 1_B The error was found in the erase counter.
VLD	31	rh	**Valid** This register stores the information that this 32 bit entry of the SBAB is valid. This bitfield is protected by a SFF. 0_B Entry is not valid. 1_B A valid entry was recorded.
0	4:0, 26:21, 30:28	r	**Reserved** Read as 0; shall be written with 0.

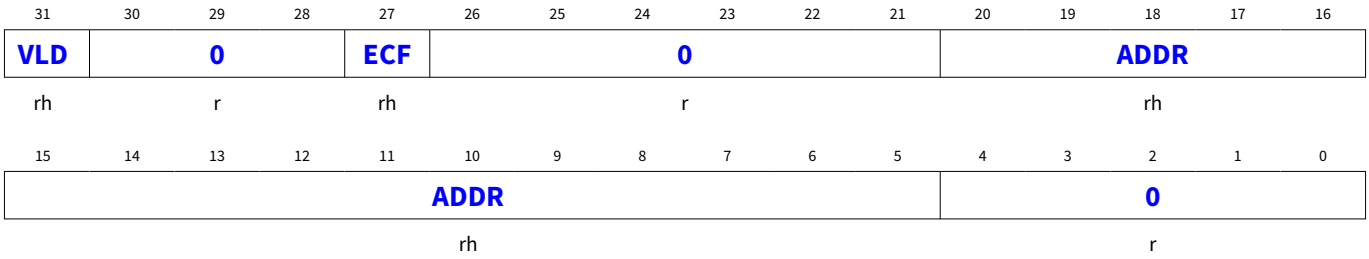
5.4.3.9 Uncorrectable error address buffer x

These registers records the uncorrectable bit error detected by the ECC in the local PFLASH bank reads. Once all entries are valid, the buffer is considered full and an alarm is generated.

UR_UBAB0 Offset address: 002180_H

Uncorrectable error address buffer x System Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ADDR	20:5	rh	**Address** This register stores the address of the detected local PFLASH bank read error.
ECF	27	rh	**Erase Counter Flag** This register stores the information that the error was detected in the erase counter. 0_B The error was found in the PFLASH 1_B The error was found in the erase counter.
VLD	31	rh	**Valid** This register stores the information that this 32 bit entry of the SBAB is valid. This bitfield is protected by a SFF. 0_B Entry is not valid. 1_B A valid entry was recorded.
0	4:0, 26:21, 30:28	r	**Reserved** Read as 0; shall be written with 0.

5.5 Debug information

This section is not applicable for the module being described.

5.6 References

This section is not applicable for the module being described.

5.7 NVM revision history

Initial release of the chapter.

5.8 TC4Dx NVM information

5.8.1 TC4Dx NVM configuration

The following tables details the NVM Bank configuration of the TC4Dx product.

Table 552 TC4Dx Program Flash Banks

CPU	PFLASH Bank	Size	System Address
CPU0	0A	2 Mbyte	NVM.PFLASH00 (Program Flash)
	0B	2 Mbyte	NVM.PFLASH01 (Program Flash)
CPU1	1A	2 Mbyte	NVM.PFLASH10 (Program Flash)
	1B	2 Mbyte	NVM.PFLASH11 (Program Flash)
CPU2	2A	1 Mbyte	NVM.PFLASH20 (Program Flash)
	2B	1 Mbyte	NVM.PFLASH21 (Program Flash)
CPU3	3A	2 Mbyte	NVM.PFLASH30 (Program Flash)
	3B	2 Mbyte	NVM.PFLASH31 (Program Flash)
CPU4	4A	2 Mbyte	NVM.PFLASH40 (Program Flash)
	4B	2 Mbyte	NVM.PFLASH41 (Program Flash)
CPU5	5A	1 Mbyte	NVM.PFLASH50 (Program Flash)
	5B	1 Mbyte	NVM.PFLASH51 (Program Flash)
CPUcs	CSRM	1 Mbyte	NVM.PFLASHcs (Program Flash)

***Note**: for the actual memory address please refer to the system address chapter. Each Program Flash Bank has also a separate erase counter (16 Kbyte) which is accessible at the system address NVM.PFLASHxx (Erase Counter).*

***Note**: PFLASH Banks for the CPU2 and for the CPU5 have a size of 1 MB. Therefore less write protection registers are necessary. The register description chapters and the UCB description always contain the maximum number of possible write protection registers (which is for a 2 MB Bank). Therefore for the PFLASH Banks for CPU2 and CPU5 only the write protection registers for up to 1 MB are available and the remaining UCB space is "do not care" and will not be recovered.*

Table 553 TC4Dx Data Flash Banks

DFLASH Bank	Memory Region	Size	System Address
DFLASH(0) - HOST	EEPROM Emulation HOST	1024 Kbyte	NVM.EEPROM0
	User Configuration Blocks UCB(0)	80 Kbyte	NVM.UCB0
	Configuration Sector(0)	80 Kbyte	NVM.CFS0 (not accessible in user mode)

(table continues...)

Table 553 (continued) TC4Dx Data Flash Banks

DFLASH Bank	Memory Region	Size	System Address
DFLASH(1) - CSRM	EEPROM Emulation CSRM	128 Kbyte	NVM.EEPROM1
	User Configuration Blocks UCB(1)	52 Kbyte	NVM.UCB1
	Configuration Sector(1)	44 Kbyte	NVM.CFS1 (not accessible in user mode)

***Note**: for the actual memory address please refer to the system address chapter.*

5.8.2 TC4Dx NVM features

There are no deviations from the generic specification.

5.8.3 TC4Dx NVM functional description

The number of APU for PFLASH (HOST) banks is 12.

5.8.4 TC4Dx NVM registers

PFLASH Banks for the CPU2 and for the CPU5 have a size of 1 MB. Therefore less write protection registers are necessary. The register description chapters and the UCB description always contain the maximum number of possible write protection registers (which is for a 2 MB Bank). Therefore for the PFLASH Banks for CPU2 and CPU5 only the write protection registers for up to 1 MB are available and the UCB memory for the upper 1 MB space is "do not care" and is not recovered during the startup phase. This concerns the following registers for the HOST and the CSRM command interfaces:

- GP_HOST_PFPROCONWPpXn (p=2 or p=5 (CPU2,5), X=A or B, n = 2,3 for upper 1 MB not existing))
- GP_HOST_PFPROCONPWPpXn (p=2 or p=5 (CPU2,5), X=A or B, n = 2,3 for upper 1 MB not existing))
- GP_HOST_PFPROCONPWOPpXn ((p=2 or p=5 (CPU2,5), X=A or B, n = 2,3 for upper 1 MB not existing))
- GP_HOST_PFECPRIOpXn ((p=2 or p=5 (CPU2,5), X=A or B, n = 2,3 for upper 1 MB not existing))

5.8.4.1 Register address space - DMU

Table 554 Registers address space - DMU

Module	Base address	End address	Note
DMU	$F8040000_H$	$F807FFFF_H$	

5.8.4.2 Register overview - access mode glossary

Table 555 Register overview - access mode glossary

Keyword	Description
CSCI	Access protection using PROT register DMU_PROT_PROTCSCI .

5.8.4.25 Device specific registers

There are no device specific register changes.

5.8.5 TC4Dx NVM connectivity

There are no deviations from the generic specification.

5.8.6 TC4Dx NVM revision history

Initial release of the chapter.

6 Shared Resource Interconnect (SRI)

The Shared Resource Interconnect (SRI) connects modules with native SRI interfaces such as TriCore™ CPUs and high performance modules such as the DMA with memories and peripherals. The SRI crossbar connects all the agents in one SRI domain with a deterministic performance objective. The fabric is extended with bridges, to connect one SRI domain to another as well as to other components and interconnects operating on different protocols.

The SRI crossbar supports concurrent transactions between different SRI master and SRI slave agents. When transacting to the same slave, the master can achieve very high utilization over the link by employing pipelining. In addition, a master can conduct read and write transfers to different slaves in parallel.

6.1 Feature list

- Single (8-bit, 16-bit, 32-bit and 64-bit) and block read and write transactions (blocks up to 8 x 64-bit beats)
- Atomic read write transaction sequence supported
- Pipelined transactions from SRI masters to SRI slaves
  - Improved read write parallelism compared to previous generations
- Arbiter for each SRI slave, with individual configuration
  - Two round-robin groups, high and low priority
  - Control of opportunity for the high priority group
- EDC (Error Detection Code) on all address, data and control information transferred between SRI masters and SRI slaves
  - EDC on all data and control information transferred from an SRI master to an SRI slave for a write
  - EDC on all data and control information transferred from an SRI slave to an SRI master for a read
- Device specific capability to monitor and record bandwidth utilization of resources for Quality of Service (QoS) purposes

6.2 Functional overview

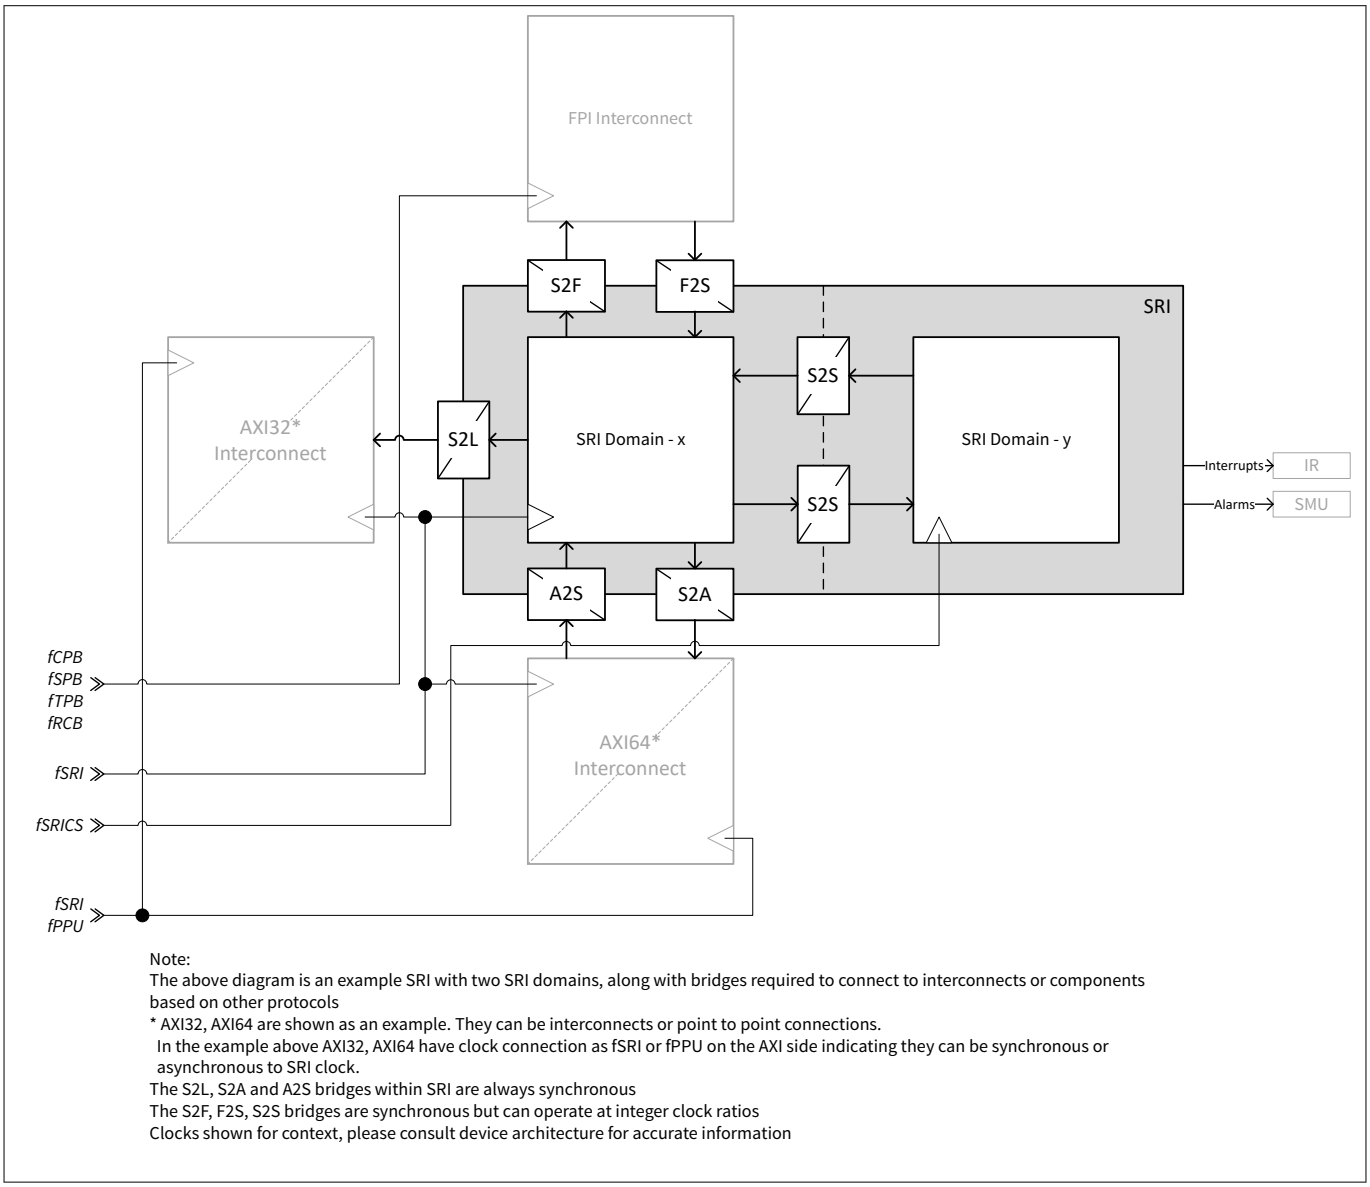

Figure 58 SRI block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

The ERAY consists of one or more crossbars implementing a high bandwidth, deterministic latency, on-chip fabric to interconnect master agents to slave agents through the SRI protocol. On complex systems with numerous masters and slaves, the SRI fabric is subdivided into domains. Each domain implements a crossbar to interconnect a subset of unique masters and slaves. SRI domains connect to other SRI domains, or other interconnects such as FPI and AXI (Advanced extensible interface) through bridges such as:

- S2S - SRI to SRI bridge
- S2A - SRI to AXI64 bridge
- S2L - SRI to AXI32 bridge
- S2F - SRI to FPI bridge
- A2S - AXI64 to SRI bridge
- F2S - FPI to SRI bridge

The bridges permit a master to reach all slaves if desired. Equally, masters may not be connected to all slaves within a single SRI domain if there is no functional need for them to communicate. The interconnected domains

all have clocks derived from the same root, therefore operate either on the same clock or a limited set of integer clock ratios. The bridges implement the clock domain crossing points within the interconnect. The number of SRI domains varies per device.

Related information

TC4Dx SMU alarm mapping tables on page 7233

6.3 Functional description

The SRI fabric includes one or more SRI domains each with an SRI crossbar, along with the bridges necessary to connect between interconnect domains.

6.3.1 Operational overview

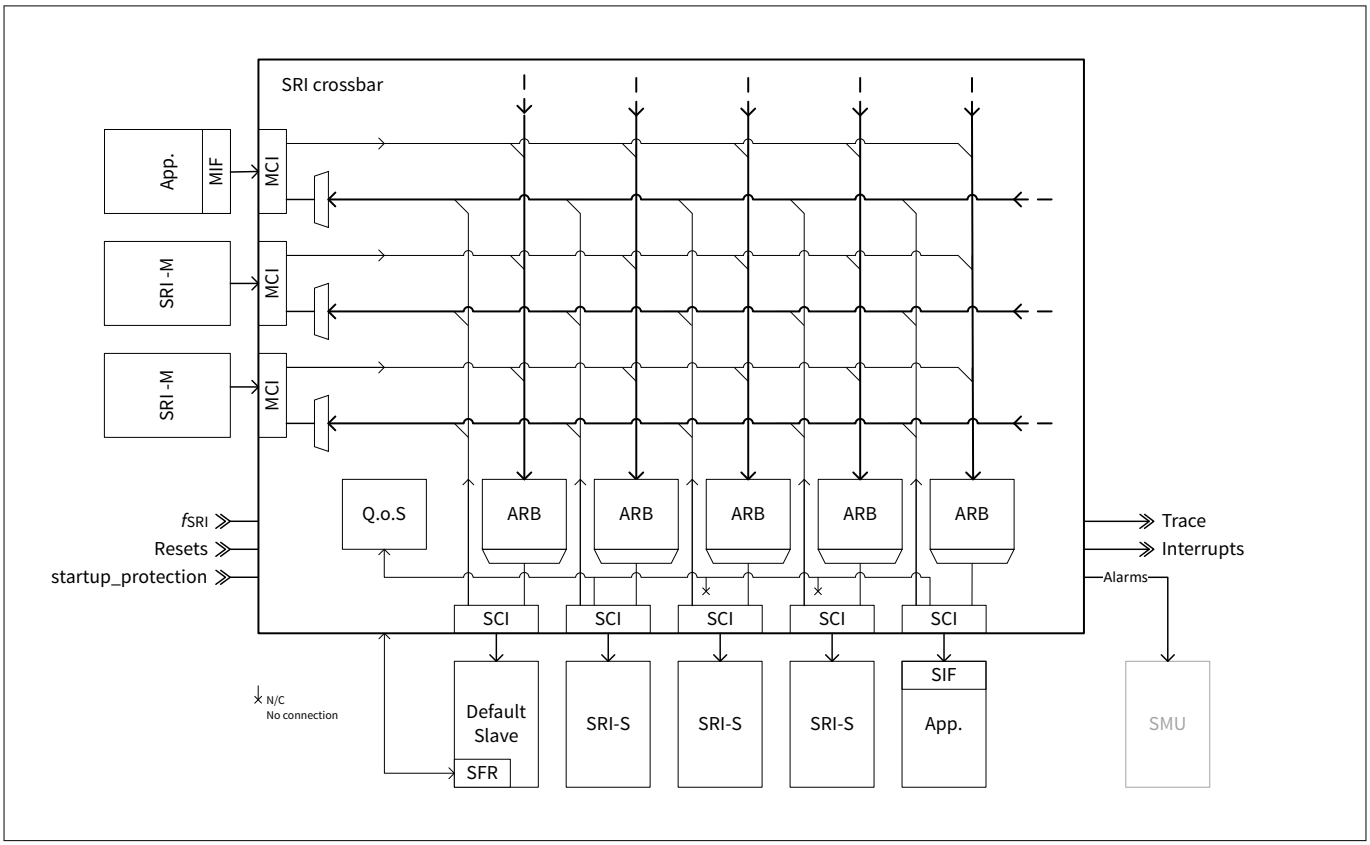

Figure 59 Example of an SRI crossbar

The SRI crossbar provides SRI master connection interfaces (MCIx) to connect SRI master modules and SRI slave connection interfaces (SCIx) to connect SRI slave modules to the SRI crossbar. There is one arbiter per connected SRI slave module and the infrastructure for the enabled read and write data paths.

Each SRI domain will always include at least one slave, called the default slave, to provide housekeeping functions such as:

- domain specific control and status registers
- sink transactions that are to reserved memory regions in the address map

The SRI domain provides arbitration that permits the independent configuration of SRI master priorities for every SRI slave. The SRI includes resources to capture and report various error conditions required for system level diagnostics. Quality of service (QoS) observation capability may also be provided within an SRI domain. The availability of QoS monitoring is device specific and not all connected resources implement QoS monitoring

Table 576 SRI fabric terms

Term	Description
Agent	An SRI agent is any master or slave interface which is connected to the SRI fabric.

(table continues...)

Table 576 (continued) SRI fabric terms

Term	Description
Master agent	An SRI master agent is able to initiate transactions on the SRI through an SRI master interface. More than one master agent function can drive through an SRI master agent. CPU or DMA for example. A master agent is identified as SRI-M in the SRI crossbar diagram.
App.	An application kernel which implements an application interface that connects to a MIF or SIF.
MIF	• Master Interface, abstracts the SRI protocol to an application interface simplifying the integration of master agents • A MIF with an application kernel (App.), also makes a master agent
Slave agent	An SRI slave agent is able to respond to transactions on the SRI received through an SRI slave interface. Memories or register interfaces for example. A slave agent is identified as SRI-S in the SRI crossbar diagram
SIF	• Slave Interface, abstracts the SRI protocol to an application interface simplifying the integration of slave agents • A SIF with an application kernel (App.), also makes a master agent
SRI crossbar	The SRI crossbar provides the connectivity between master and slave agents in the same domain. The SRI crossbar includes arbitration mechanisms and error capture capabilities.
MCI	Each master is connected through one master connection interface.
SCI	Each slave is connected through one slave connection interface. The SRI contains control registers which allow configuration for each SCI of the high or low priority of each MCI for arbitration.
Domain	An SRI domain consists of those agents which are connected to a specific SRI crossbar. There will be at least one master agent and at least one slave agent, and an instance of a crossbar providing full or partial connectivity between all the agents in the domain.
Arbiter	If two or more master agents attempt to access the same slave agent, the arbiter provides the order in which master agents are serviced. The order is determined by the two-level round-robin mechanism implemented by the arbiter and the configuration of master agent priority. The arbiter is identified as ARB in the SRI crossbar diagram.
Default slave	A slave agent which both provides error acknowledgment for unknown addresses and provides access to the configuration and error capture registers of the domain.
QoS	Quality of Service observation point. Provides a method to monitor the interconnect usage on a specific SCI port.

The SRI crossbar can perform multiple transactions from different master agents in parallel if the master agents are accessing different slave agents. A master can also carry out parallel read write transactions to different slaves. When multiple masters compete to access the same resource, an arbiter resolves the ensuing resource contention.

6.3.1.1 Master connection interface (MCI)

Each SRI master in the domain is mapped to master related control and status register bits and bit-fields through its MCI number.

The MCI number is completely distinct from the master tag(s) used by the SRI master connected to that MCI. However, the set of master tags presented by a specific MCI is fixed for a given device.

6.3.1.2 Slave connection interface (SCI)

Each SRI Slave in the system is mapped to slave related control and status register bits and bit-fields through its SCI number.

6.3.1.3 Slave arbiter

Each SCI has an associated arbiter which includes all the functionality for the following tasks:

- Address decoding
- Arbitration to permit a master to access a shared resource in a mult-master environment
- Error capture
  - Errors detected by a slave (some errors are detected by masters) will have transaction information captured where possible and the condition, if enabled, signaled to the system through the Interrupt Router (IR)

6.3.1.4 Default slave

A default slave is an SRI slave which implements necessary housekeeping functions. As an SRI slave, it has its own SCI and arbiter.

A default slave services a single domain. For an SRI fabric with multiple domains there will be one default slave per domain.

A default slave provides the following functions:

- Access to domain specific control and status registers
- Any transactions that fall into a reserved region as determined by the local decoders are directed to the default slave, which can record and complete the transaction
  - recording and reporting of such transactions is further controlled by the cyber security activity visibility (CSAV) attributes
- One default slave supports the online data acquisition (OLDA) feature for the complete interconnect

Each default slave is allocated its unique address space, which is used for accesses to its allocated fabric control and status registers. For accesses to the control and status registers, only single data transactions of word size (32-bit) are permitted. Unsupported transactions are acknowledged with an error.

A default slave completes SRI transactions to non-existent addresses (both reads and write) with an SRI error, which will activate the error capturing mechanism of the default slave's arbiter.

***Note**: A read by an SRI master to a non-existent address in another domain or interconnect (for example, the SPB) may be reported both by the other interconnect, and also reported in the local SRI domain by the bridge to the other interconnect. In the ERAY, this transaction information will be captured by the bridge's arbiter, rather than the default slave for the domain. A write by an SRI master to a non-existent address which is located in another domain or interconnect is posted. A posted write's error will only be reported directly or indirectly in the interconnect segment that generated the error.*

Related information

System address map on page 14
Online data acquisition (OLDA) on page 999

6.3.1.5 Online data acquisition (OLDA)

OLDA is a defined region in the address map, which can be used for data logging during debug and development. Additionally, a physical memory region can be mapped to the OLDA using the Data access

overlay feature of the TriCore™ CPUs. If the overlay feature is enabled, any system memory can be used as overlay memory. OLDA region is allocated to the default slave in domain 0.

When OLDA is enabled, while executing code without a physical memory mapped to the OLDA region, the designated default slave completes all write transfers to the OLDA region by silently dropping them. Therefore OLDA permits production code to incorporate logging and debug, enabling seamless transition between diagnostic and mission mode profiles with a common code base.

The OLDA region has the following characteristics:

- The base address of the OLDA memory range is defined in the system address map
- OLDA support is enabled by setting bit OLDAEN to 1 in the BRCON register
  - If OLDA support is enabled, write accesses do not generate an SRI error
  - If OLDA support is disabled, write accesses will generate an SRI error
  - Read access to an OLDA region will result in bus error when the overlay does not remap it to a physical memory
- OLDA address range is visible from both cached and un-cached segments
  - Reads due to write allocation on the cache, will generate bus errors when data overlay is not enabled

Switching on or off the OLDA function takes a number of system clock cycles after the BRCON register write completes. It is therefore possible for an immediately subsequent access to be pipelined to the OLDA address space, and be acknowledged with either the “on” or “off” behavior. A method of synchronization such as read back of BRCON or another enhanced method should be considered to ensure that the mode change has made effect. However in a multi master environment, more advanced synchronization methods may be required.

***Note**: If enabled in the device, any target address can be selected for redirection in the OTARx registers, including addresses in the OLDA range. However, the handling of direct accesses to the OLDA range is completely controlled by the accessed default slave.*

6.3.1.6 Control and status register access protection

The ERAY control and status registers are protected by a master agent function ID which consists of a unique 6-bit TAG-ID, the optional 3-bit VM information, and the optional 3-bit PRS information.

Each on-chip resource with direct or indirect bus master capability has a unique master TAG ID that can be used to identify the master of an on-chip bus transaction. The protection mechanism and requirements are described in the Access Protection chapter.

After application reset, the access protection mechanism must be configured to put the system into the state that is required by the application.

6.3.2 Arbitration details

An SRI crossbar provides a dedicated SRI arbiter for each connected slave agent. On the crossbar, multiple parallel requests for the same slave agent are arbitrated by the respective arbiter and executed in a sequence. The arbiters consider a request as a unit item, therefore ignore transaction sizes and disregard the actual claimed bandwidth from arbitration decisions.

6.3.2.1 Transaction request arbitration

The arbiter used in the SRI work on a work-conserving round robin (RR) scheme. Round robin provides a predictable starvation free mechanism wherein each request is chosen in a cyclical order. The work conserving scheme ensures that no arbitration slots are wasted when the nominal winner is inactive. Inactive masters are skipped in the current round and the next higher priority master is selected.

With the basic scheme as outlined above, arbitration is further broken down into two priority groups; high priority round robin group (HPRR) and low priority round robin group (LPRR). An arbitration cycle executes both rounds in parallel. The specific allocation of a master to a round robin group is configured by software in PRIORITYx.

A further refinement to the algorithm considers the outcome of both rounds. The high priority round share parameter (PRIORITYx.HPRS) monitors the number of successive HPRR winning slots, and inserts an LPRR slot if it has an active request. If there are no HPRR winners in a specific slot, the LPRR is the default winner. PRIORITYx.HPRS permits an asymmetric bandwidth distribution among the masters in a domain.

The arbitration scheme operates at the SRI request granularity. It does not take any other attribute of that request into consideration. Therefore any observation of bandwidth share between the masters may indicate a non-uniform bandwidth allocation.

Related information

Arbitration configuration on page 1001
Request latency on page 1001

6.3.2.2 Arbitration configuration

The arbitration configuration provides software with the ability to map an MCI (and therefore the master agents connected to it) to the HPRR or LPRR arbitration group. The configuration is domain and SCI specific. On a given domain, a certain master agent can be mapped to different levels in different SCI arbiters. PRIORITYx.MCIn_P configuration directs a request from an MCI with the corresponding index to HPRR or LPRR. The PRIORITYx.HPRS determines the high priority round share for the domain.

After reset most present MCIs are set to the low priority level, although bridges and DMAs are typically set to high priority.

For error diagnosis purposes, when permitted by CSAV configuration, the arbiter samples all the necessary transaction information and provides this in the ERRADDRx and ERRx registers if an SRI protocol error occurs.

Error tracking capability on page 1005

6.3.2.3 Request latency

If another transaction is not pending at the SCI, a transaction from an MCI will be granted in the next clock cycle after that master's request. If there are multiple requests pending, or arrive at the same time at the same SCI, then the latency depends on whether the MCI is in the HPRR or LPRR group at the slave agent, and how many other requests are in each round.

The following table shows an example of the worst case number of transactions that a master might have to wait before its transaction can commence in an example of a domain with 8 masters.

Table 577 Master request transactions

Number of high / low priority master agents	High priority round share(HPRS) for parallel requests to the same slave agent (FB or bridge)	Worst case delay in arbitration for a high priority master[1)]	Worst case delay in arbitration for a low priority master

8 / 0	(0)	7	N.A.

1) Refers to winning arbitration slots, and not directly clocks

The worst case number of transactions to wait for access to a slave with fewer masters can be computed as follows:

If there is only a single round of arbitration (high or low), then;

```
max_delay    = number_of_masters-1
```

If there are two rounds (high and low) of arbitration, then for a high priority master;

```
HP_max_delay    = number_of_high_priority_masters
```

and for a low priority master;

```
LP_max_delay    = ((HPRS+1) x number_of_low_priority_masters)-1
```

The worst case number of clock cycles a master waits will depend on the response time of the respective slave. So if for example the SRI Slave has a response time of 10 clocks, the worst case wait in clock cycles for a low priority master in a 2 high, 6 low configuration with a high priority share set to 7, is 470 clocks.

Usually each SRI slave will have a deterministic response time to transactions, although it might vary between read and write transactions, and the data width to be transferred. It is typically only in the case of off-chip accesses, such as the xSPI, where there might be high variation in transaction times.

6.3.3 SRI errors

SRI error conditions can be detected by both masters and slaves depending on the condition. Errors are always reported through alarms to the SMU and optionally interrupts, or signaled directly from a slave to the master within a domain. Some masters, such as the CPUs, can directly respond by taking a trap.

For some errors, a slave can signal to the corresponding master that an error has occurred, which results in an immediate termination of the current transaction (and the status is also captured in the interconnect). For other errors during a transaction, the transaction continues, but the error is captured by the SRI and signaled through an alarm and optionally an interrupt if enabled in both the SRI and interrupt router (IR). The following sections describe the behavior of each error type in detail.

There are three error types:

- SRI Protocol Errors
- SRI Transaction ID Errors
- SRI EDC Errors

SRI interrupts

A crossbar has two interrupt trigger outputs for errors, an SRI_IR_SRC_SRIx and SRI_IR_SRC_SRIxSM. These are only generated if enabled.

6.3.3.1 SRI protocol errors

The following error conditions are detected by SRI slaves and result in error termination of the transaction (SRI protocol error - signaled as an SRI error) to the SRI master and an alarm:

- Non-existent address region accessed by an SRI master
  - The accesses to non-existent address regions are checked by a default slave
- Reserved address within an existing memory region
- Unsupported or reserved op-codes for the addressed slave
- On detection of an access protection violation, such as a supervisor register accessed in user mode

- Access protection is configured to not allow the current SRI Master read access
- Access protection is configured to not allow the current SRI Master write access
  - Some slaves do not issue a bus error. In that case the write is prevented within the slave and an alarm is issued
- Special master indication is incorrect. On SRI, special master(SM) is the cyber security master(CS). For example a special master region accessed by a non-special master such as CPU0 accessing CSRM PFlash
- Unsupported operation to a specific register, such as a write to a read-only register for example
- EDC error detected for the address phase

For testing purposes, an SRI protocol error can be generated by the application software with an access to a reserved address (refer to the Memory Map chapter).

Those SRI Slaves which have detected a protocol error can be determined by inspection of the domain specific PESTAT register.

6.3.3.2 SRI transaction ID errors

A transaction ID is an identifier connected to all phases of a transaction, in order to make the transaction unique in the SRI during the transaction's lifetime.

The transaction ID is used by SRI Masters and SRI Slaves to identify errors in the SRI that might result in data packets received by a master or slave that do not correspond to the relevant transaction. If the read or write transaction identifier does not match the transaction identifier sent during the address phase, this is a transaction ID error and reported by the SRI crossbar.

In addition to SRI Fabric errors, forcing a transaction ID error is used in situations where at the data source side (the SRI master for write transactions and the SRI slave for read transactions), a data phase has to be invalidated (detection of an uncorrectable error from an accessed memory for example). In these situations, an invalid transaction ID is sent in order to invalidate the data phase.

For testing purposes an SRI transaction ID error condition can be generated by injecting a non-correctable error into one of the SRAMs (CPU scratch pad SRAM for example), and then reading the corrupted data by an SRI master.

Those SRI masters and SRI slaves which have detected a transaction ID error can be determined by inspection of the TIDSTAT register.

6.3.3.3 SRI EDC errors

The SRI provides EDC protection for the:

- Address and control signals of an SRI transaction
- Transmitted read and write data

SRI address phase EDC errors

- If an SRI Slave detects an SRI address EDC error, it finishes the transaction with SRI error (a protocol error) and does not process it further
- In addition to the SRI protocol error termination, each SRI Slave signals an address EDC error to the SMU as an alarm (Address Phase EDC Error Alarm)

SRI write data EDC errors

An SRI Slave will check each data beat of a write transaction for EDC validity.

If an SRI Slave detects an SRI write data EDC error, it is only signaled to the SMU as an alarm.

Whether an SRI Slave only monitors the EDC error condition or attempts to prevent the state update, is not defined by the SRI infrastructure, but is described in each SRI functional block or sub-block chapter.

SRI read data EDC errors

An SRI Master will check each received data beat of a read transaction for EDC validity.

If an SRI Master detects an SRI read data EDC error, it is only signaled to the SMU as an alarm.

Whether an SRI Master only monitors the EDC error condition or attempts to prevent the use of the returned data is not defined by the SRI infrastructure, but is described in each SRI functional block or sub-block chapter.

Because of their key role, the behavior of CPUs is reiterated here. A trap will be taken by the CPU if it receives a data item containing an EDC error and the data would be immediately used by the CPU. The data might not be used and no trap taken if a cache line is requested and the beat containing the EDC error is not required for the instruction stream or the data load instruction. If any part of a received memory line contains an EDC error, a possible cache update is prevented and the received data is discarded.

6.3.3.4 Error tracking capability

The SRI crossbar tracks all SRI transactions for SRI protocol errors, and it tracks information about SRI transaction ID errors, but not EDC errors. This is done by all arbiters in parallel, since the SRI crossbar supports the processing of multiple transactions from masters and slaves in parallel, which can result in concurrent events at different SCIs.

When an arbiter recognizes that its associated SRI Slave has signaled an SRI protocol error for a transaction, the arbiter can sample all relevant information of the transaction in the diagnostic registers (ERRx and ERRADDRx). An indication of this error can be provided to the interrupt router (IR), and this indication can be controlled, through the PECONx.PEEN control bit. Only when this bit is set is the error information captured and the trigger condition signaled to the interrupt router.

***Notes**:*

1. *The two error registers ERRx and ERRADDRx in each arbiter are updated with the content of the currently processed transaction. The registers are only updated if they are not locked due to an earlier protocol error*
2. *No master with SM asserted/set will have information captured unless so enabled by CSAV. Transaction ID errors are exempt from CSAV filtering*
3. *SM accesses will be signaled through a separate trigger*

The error capture register field OPC contains information about the type of transaction for which information has been captured. For single data transactions, this field indicates the number of bytes. For block transactions, this field indicates the number of expected data beats. The encoding is shown in the following table.

Table 578 SRI operation code (opcode) encoding

OPC[3:0]	Identifier	Description
0000	SDTB	Single Data Transfer Byte (1 Byte)
0001	SDTH	Single Data Transfer Half-Word (2 Bytes)
0010	SDTW	Single Data Transfer Word (4 Bytes)
0011	SDTD	Single Data Transfer Double Word (8 Bytes)
0100-0111		Reserved
1000	BTR2	Block Transfer Request (2 Beats)
1001	BTR4	Block Transfer Request (4 Beats)
1010	BTR8	Block Transfer Request (8 Beats)
1011-1111		Reserved

The error capture registers will not be updated again until the indication is acknowledged to the slave arbiter module by software (set the respective PECONx.PEACK).

The error capture registers will be locked after the first error. This results in the non-capture of subsequent error information for this slave agent until the write releasing the lock is processed.

Further protocol errors will be ignored by an arbiter that has detected a protocol error until the capture mechanism is re-activated through the arbiter internal control register. A detected protocol error is signaled by the arbiter to the per-domain error status register PESTAT. Each error signal can be masked individually by the PECONx control registers in the arbiter modules for SCIx. In addition the ERRx and ERRADDRx registers are accessible in each SCIx.

A master or a slave can detect a transaction ID error. An indication of this error can be provided to the interrupt router (IR), and this indication can be controlled through the TIDEN.ENMCI and TIDEN.ENSCI control bits. Only if the relevant enable bit is set is the error condition captured in TIDSTAT, and the trigger condition signaled to the interrupt router.

For transaction ID errors of write transactions, the SCIs propagates errors to the associated bit in TIDSTAT.TIDSCIx. For transaction ID errors of read transactions, the MCIs propagate errors to the assigned bit inTIDSTAT.TIDMCIx.

Once an error is signaled from an arbiter to the system, the system can then perform more detailed diagnostics by reading out the error registers(as detailed above) in the respective arbiter . The error information captured for an SRI protocol error allows the identification of the master through the sampled master tag ID, and the final destination through the captured target address. In addition, the ERRx register captures the opcode and other control information about the transaction.

After reading all relevant error information, the error capture mechanism should be re-enabled by clearing the corresponding bits in PESTAT or TIDSTAT as appropriate.

***Notes**:*

1. *While a status bit for an error source is set in either the PESTAT or TIDSTAT register, a new error from this particular source does not generate a new trigger to the Interrupt Router (IR)*
2. *Each SRI agent in the system has two error conditions: protocol errors, and transaction ID errors. Protocol errors are classified as SM and non-SM, where as transaction ID errors are always classified as non-SM. All non-SM errors from an SRI domain share a single SRN in the interrupt router (IR). All SM errors from an SRI domain share a separate single SRN in the IR*

6.3.3.5 Indication event interactions

There are some interactions between indication events. In general, several indications from the same or a different source (arbiter, MCI, or SCI) can occur at the same time. One indication could occur several times before a service request routine services it.

The following examples describe the system behavior without re-arming from a service routine when all consecutive indications or events occur within the same domain.

Two consecutive protocol errors

The first protocol error is captured, together with the generation of an indication to the system. The second protocol error is not captured, since the registers ERR and ERRADDx are already locked, and no indication is generated.

Two consecutive transaction ID errors

The first transaction ID error generates an indication to the system. The second transaction ID error will not generate an indication to the system.

6.3.3.6 Releasing the lock from ERR and ERRADDR registers

When the ERR and ERRADDR registers are locked, the lock can be released by writing a 1 to PECONx.PEACK.

6.3.4 Quality of Service application interconnect usage observation

The QoS observation mechanism enables the system software to monitor the consumed interconnect cycles at key resources for up to 8 application partitions within a QoS time interval.

The application partitions can be defined by assigning master agent functions through its TAG-ID and PRS encoding to the application resource partition functions (ARPx).

For each ARP function:

- The system can define the usage threshold for it
- The interconnect cycles consumed by the assigned master agent functions within a QoS interval are logged
- If the consumed cycles within a QoS time interval reaches the defined usage threshold, an interrupt is signaled at the end of the interval for this ARP function, the cycles consumed until the end of the interval is stored in a capture register and the capture register is locked

***Note**: Setting the threshold value to 0 is considered illegal and should be avoided.*

QoS time interval

A QoS time interval starts as soon as QOS_ICTRL.QOSEN is enabled. At the start of a QoS time interval, QOS_ICNT.QOSICNT is initialized with the value from QOS_ICTRL.QOSINT and partition cycle counter registers are cleared and set to 0. As long as the QOS_ICTRL.QOSEN is set -QoS time intervals with the configured duration (QOS_ICTRL.QOSINT) are generated.

Measuring the cycle consumption during a QoS interval

During a QoS time interval each ARP mechanism counts for the master agent function IDs assigned to the ARP function the number of clocks the master agents occupies the observed resource within the time interval by counting the number of data phase clock cycles.

At the FPI the observed shared resource is the local FPI interconnect, at the SRI it is the SRI respective slave agent to which the ARP function belongs.

Interconnect usage includes the data phase along with wait states, where ongoing activity from a master prevents other masters from using the resource.

***Note**: The interconnect usage of CS-related transactions (with SM= 1) is only taken into account if CSAV = full or CSAV=limited.*

End of QoS interval

At the end of a QoS Interval (QOSICNT=0), the cycles consumed by the assigned master agent functions is copied into the Partition cycle count capture register of the respective ARP. For each ARP function where the interconnect cycles consumed by the assigned master agent functions is above the value configured in its Partition threshold register, an interrupt is signaled and the Partition cycle count capture register is locked after update.

The value of the locked partition cycle counter capture register is then not updated by the hardware until it is unlocked by software.

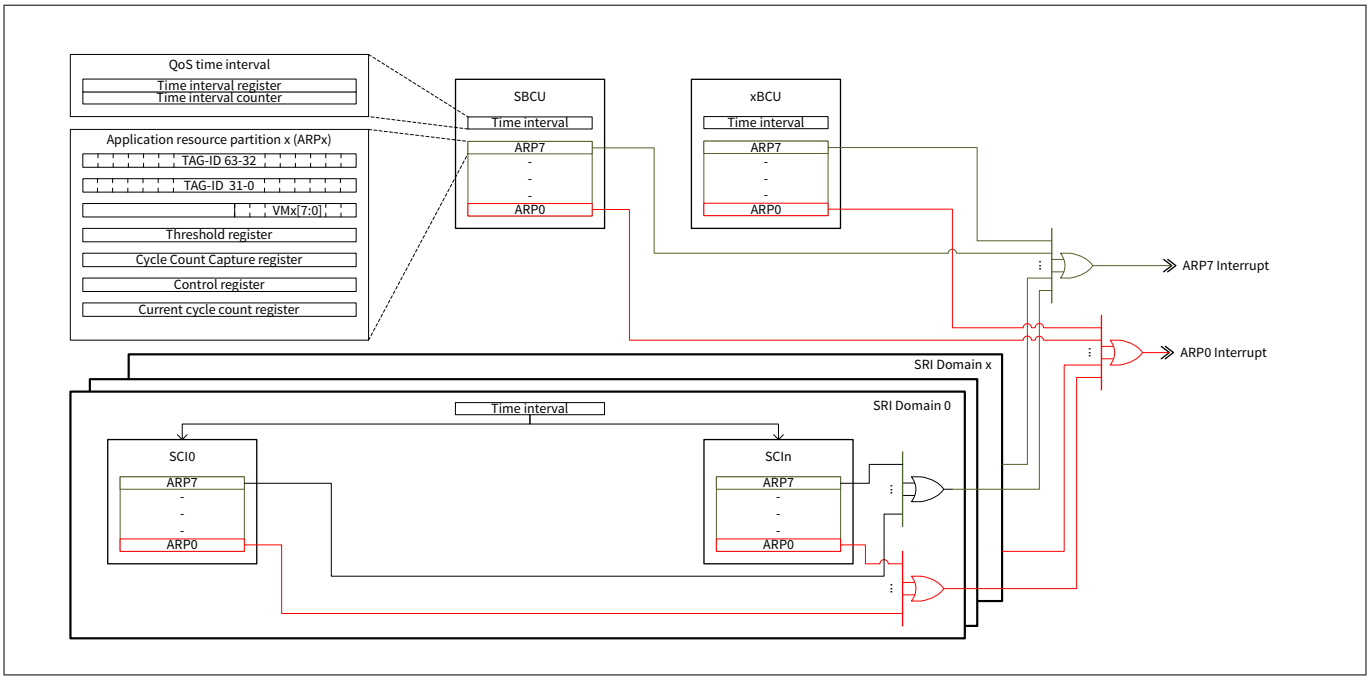

Figure 62 Hardware connection of the local ARP events to 8 ARP system interrupts

6.4 SRI to SRI bridge (S2S)

The S2S bridge facilitate master agents from one SRI domain to initiate transactions to slaves on another domain.

6.4.1 Feature list

- Bridges all transaction types from a master in one domain to a slave in another
- Implements posted writes
- Operates at fSRI frequency; with integer clock ratios of 1:1, 2:1, 1:2, between the source and destination

6.4.2 Functional overview

The S2S bridge facilitate master agents from one SRI domain to initiate transactions to slaves on another domain. The direction of a bridge refers to the request flow direction that is master to slave. Therefore to achieve connectivity between masters and slaves across two domains, two S2S bridges are required in opposite directions between the two SRI domains. The S2S bridge can carry both read and write transactions between the two domains.

S2S bridges transmit all SRI transactions transparently (without modifying either master agent function ID, transaction type including opcode or address).

6.4.3 Functional description

The S2S bridges transaction requests from masters in one domain(origin) to slaves in a target domain. It also bridges the transaction responses from the slaves in the target domain to the origin. The S2S bridge is special in its handling of errors, as it transmits most errors between the domains and does not raise alarms for them itself.

6.4.3.1 EDC errors

The S2S bridge does not perform EDC checks, instead the detection is implemented at the master or slave.

Address EDC errors are passed from the initiating domain and left to the receiving slave.

Read data with EDC errors are transferred from the slave domain to the initiating master.

Write data with EDC errors will be transferred from the initiating domain to the receiving slave.

6.4.3.2 Protocol errors

SRI read transaction protocol errors are transferred from the slave domain to the initiating master, to interrupt or raise alarms as configured.

As write transactions are posted, SRI write transaction protocol errors will not be signalled in the initiating SRI domain by the S2S bridge, as it has no knowledge of the error condition. In this instance, the receiving domain handles the error and signals an alarm.

6.4.3.3 Transaction errors for posted writes

Write transactions from one SRI domain to another SRI domain are handled as posted writes. This means that a write operation from a SRI Master through the S2S Bridge can finish on the source domain, and the S2S completes the write later on the destination SRI domain. If the S2S write transaction results in an error on the destination domain, the error information is not passed back to the source SRI domain.

This behavior occurs only for write operations over the S2S Bridge.

6.4.3.4 S2S clocking

The S2S can bridge two SRI domains which have a clock ratio of 1 or 2 between them.

6.5 FPI to SRI bridge (SFI_F2S)

The SFI_F2S bridge implements a uni-directional bridge that forwards transactions from an implementation of an FPI protocol bus to the SRI.

6.5.1 Feature list

- Bridges transactions from an FPI bus to an SRI domain
- Converts FPI transactions into one or more equivalent SRI transactions
- Signals EDC errors through system alarms
- Operates at f_{TPB} and f_{SRI} frequencies

6.5.2 Functional overview

The SFI_S2S bridge implements a uni-directional bridge that forwards transactions from an implementation of an FPI protocol bus to the SRI . The bridge supports all FPI transactions and that subset of transactions of the SRI required to implement them.

6.5.3 Functional description

The bridge is transparent for the address of a transaction and the master agent information of the FPI transaction. However, transaction types are mapped as described in the following table. For performance reasons, write transactions from FPI masters to SRI resources are handled as posted writes.

Table 579 FPI transaction to SRI transaction mapping

FPI transaction (32-bit data bus)	SRI transaction(s) (64-bit data bus)
Single Byte Transfer (8 bit)	Single Data Transfer Byte (SDTB) (8 bit)
Single Half-Word Transfer (16 bit)	Single Data Transfer Half-Word (SDTH) (16 bit)
Single Word Transfer (32 bit)	Single Data Transfer Word (SDTW) (32 bit)
2-Word Block Transfer	Single Data Transfer Double-Word (SDTD) (64 bit)
4-Word Block Transfer (aligned to 64 bit address boundary)	Block Transfer Request (BTR2) (2 transfers)
4-Word Block Transfer (starting address offset by 04_H,$0C_H$)	SDTW, SDTD, SDTW
8-Word Block Transfer (aligned to 64 bit address boundary)	Block Transfer Request (BTR4) (4 transfers)
8-Word Block Transfer (starting address offset by 04_H, 14_H)	SDTW, SDTD, BTR2, SDTW
8-Word Block Transfer (starting address offset by $0C_H$,$1C_H$)	SDTW, BTR2, SDTD, SDTW
Atomic Read Write 8/16/32 bit sequence	Atomic Read Write 8/16/32 bit sequence

6.5.4 Transaction errors for posted writes

Write transactions from FPI masters to SRI resources are handled as posted writes. This means that a write operation from an FPI master through the SFI_F2S bridge will finish on the FPI bus, and the SFI_F2S completes the write later on the SRI. If the SRI write transaction results in a SRI protocol error, the error information is not passed back to the FPI bus. The error condition will be processed by the receiving SRI slave or domain to interrupt or raise alarms as configured.

6.5.5 Data phase transaction ID errors

A transaction ID mismatch during the SRI read data phase may indicate the mis-steering of an SRI response or the presence of an uncorrectable ECC error at the source of that data. In either case, when a transaction ID error is observed on the read response to a SRI transaction type SDTx, the F2S bridge will convert that SRI read response to an FPI error.

When the read part of a read-with-intent-to-write transaction on the SRI receives such an error, the error is propagated to the FPI. As a consequence, the transaction will terminate on the FPI. The bridge will then complete the write phase on the SRI side as follows

- The data value received during the read data phase will be used as the write data
- The write data phase will be invalidated by transaction ID corruption

Such an error propagation will not happen for block transfers on SRI.

6.6 SRI to FPI bridge (SFI_S2F)

This section describes the functionality of the SFI_S2F bridge, a bridge from the SRI to an FPI based bus system.

6.6.1 Feature list

- Bridges transactions from an SRI domain to an FPI bus
- Converts SRI transactions, except for block transfers of 8 double words and atomic transactions of 64-bits, into equivalent FPI sequences
- Signals FPI EDC errors through system alarms
- Operates at f_{FPI} and f_{SRI} frequencies
  - f_{FPI} is one of f_{CPB}, f_{SPB}, f_{RCB}, f_{TPB}

6.6.2 Functional overview

The SFI_S2F bridge is implemented as a uni-directional bridge that forwards transactions from the SRI to an FPI bus. The bridge supports all SRI transactions on the SRI except for block transfers of 8 beats and atomic read write sequences of 64 bits.

6.6.3 Functional description

The bridge is transparent for the address of a transaction and the master agent information of the SRI transaction. However transactions are mapped as described in the following table. For performance reasons, write transactions from the SRI to FPI resources are handled as posted writes.

Table 580 SRI transaction to FPI transaction mapping

SRI transaction (64 bit data bus)	FPI transaction (32 bit data bus)
Single Data Transfer Byte (8 bit)	Single Byte Transfer (8 bit)
Single Data Transfer Half-Word (16 bit)	Single Half-Word Transfer (16 bit)
Single Data Transfer Word (32 bit)	Single Word Transfer (32 bit)
Single Data Transfer Double-Word (64 bit)	2-Word Block Transfer
Block Transfer Request (2 transfers)	4-Word Block Transfer
Block Transfer Request (4 transfers)	8-Word Block Transfer
Block Transfer Request (8 transfers)	Not converted - errored at the SRI interface.
Atomic Read Write 8/16/32 bit sequence	Atomic Read Write 8/16/32 bit sequence
Atomic Read Write 64 bit sequence	Not converted - errored at the SRI interface,

6.6.4 Transaction errors for posted writes

Write transactions from SRI masters to FPI resources are handled as posted writes. This means that a write operation from a SRI master through the SFI_S2F bridge can finish on the SRI, and the SFI_S2F completes the write later on the FPI. If the FPI write transaction results in an error on the FPI, the error information is not passed back to the SRI. The error condition is detected by the control logic of the FPI (BCU on the FPI), to interrupt or raise alarms as configured. This behavior occurs only for write operations through the SFI_S2F.

6.7 SRI to AXI bridge (S2A)

This section describes the functionality of the S2A bridge, a bridge from the ERAY to slaves using a 64-bit AXI interconnect.

6.7.1 Feature list

- Operates at fSRI frequency with the AXI interconnect at the same frequency
- 64-bit AXI interface support
  - All SRI transactions are converted to equivalent AXI transactions
  - Examples are used by the PCIe and PPU
- Provides PROT and ACCEN registers for the connected AXI slaves

6.7.2 Functional overview

This section describes the functionality of the S2A bridge, a bridge from the SRI to slaves on a 64-bit data AXI interconnect.

6.7.3 Functional description

The S2A bridge is implemented as a uni-directional bridge that forwards transactions from the SRI to a 64-bit data AXI interconnect. The bridge supports all SRI transactions on the SRI, and those transactions of the AXI interconnect required to implement them.

The bridge is transparent for the address of a transaction. Transactions are mapped as described in the table below. For performance reasons write transactions from the SRI to AXI resources are handled as posted writes.

***Note**: An INCR burst is a transaction of 1 or more beats where the address for each beat increments depending on the size of the transfer. A WRAP burst wraps around to a lower address if the transaction size boundary is reached.*

Table 581 SRI transaction to 64-bit data AXI transaction mapping

SRI transaction (64-bit data bus)	AXI transaction (64-bit data bus)
Single Data Transfer Byte (8 bit)	INCR Burst (Length=1, Size=1 byte)
Single Data Transfer Half-Word (16 bit)	INCR Burst (Length=1, Size=2 bytes)
Single Data Transfer Word (32 bit)	INCR Burst (Length=1, Size=4 bytes)
Single Data Transfer Double-Word (64 bit)	INCR Burst (Length=1, Size=8 bytes)
Block Transfer Request (2 transfers)	WRAP Burst (Length=2, Size=8 bytes)
Block Transfer Request (4 transfers)	WRAP Burst (Length=4, Size=8 bytes)
Block Transfer Request (8 transfers)	WRAP Burst (Length=8, Size=8 bytes)
Atomic Read Write sequence (8 bit)	INCR Burst Read followed by INCR Burst write (Length=1, Size=1 byte)[1)]

(table continues...)

Table 581 (continued) SRI transaction to 64-bit data AXI transaction mapping

SRI transaction (64-bit data bus)	AXI transaction (64-bit data bus)
Atomic Read Write sequence (16 bit)	INCR Burst Read followed by INCR Burst write (Length=1, Size=2 bytes) 1)
Atomic Read Write sequence (32 bit)	INCR Burst Read followed by INCR Burst write (Length=1, Size=4 bytes) 1)
Atomic Read Write sequence (64 bit)	INCR Burst Read followed by INCR Burst write (Length=1, Size=8 bytes) 1)

1) This sequence is not atomic on the AXI interconnect.

6.7.3.1 Transaction errors for posted writes

Write transactions from SRI masters to AXI resources are handled as posted writes. This means that a write operation from an SRI master through the S2A bridge can finish on the SRI, and the S2A completes the write later on the AXI interconnect. If the AXI write transaction results in an error on the AXI interconnect, the error information is not passed back to the SRI. The error condition is detected by the S2A bridge and an alarm is raised.

Note that this alarm behavior occurs only for write operations through the S2A bridge.

Any read or write response on the AXI interconnect which is not OKAY is an error.

6.7.3.2 Data phase EDC errors

The S2A bridge checks received write data for EDC correctness. If an EDC error is detected in the write data beats, a data phase alarm is raised. For the resulting AXI transaction the write strobes are all set disabled for the respective data beat and all remaining data beats, so that incorrect data is not written into the target slave.

If the S2A bridge receives read data from the AXI interface with an EDC error, the read transaction ID bits 7 and 6 returned to the SRI are inverted, to force an error at the receiving SRI master agent.

6.7.3.3 Parity errors

The S2A AXI interface implements parity across address and read and write data control signals. If a parity error is detected for a valid input, the S2A raises an alarm. Parity errors detected in the AXI read and write address channels result in an address phase alarm, any other parity error results in a data phase alarm.

6.7.3.4 Protection registers

The S2A provides the PROT and ACCEN registers for the connected AXI slaves. The registers are accessed from the SRI interface, and are used by the S2A to determine whether a master agent function is allowed to access the AXI target.

If an SRI master agent function is not allowed access to the target AXI slave, the transaction is acknowledged with an SRI error. One set of protection registers is provided for each slave target accessible by the S2A bridge. The registers, behavior and specific addresses for the PROT and APU registers implemented per slave are described in the individual slave module chapters accessed by an S2A bridge.

6.7.3.5 Target unavailability

If the target module is inaccessible through the AXI interface for any reason, including clock gated off or power gated off, the S2A will error all accesses to the address space allocated to the module. The SRI error indication will, as usual, raise an alarm and interrupt if enabled.

6.8 SRI to LLI bridge (S2L)

This section describes the functionality of the S2L bridge, a bridge from the SRI to the LLI.

6.8.1 Feature list

- 32-bit data AXI interface support
  - Single SRI transactions up to word size are converted to equivalent AXI transactions
- Provides PROT and ACCEN registers for connected LLI slaves
- Error injection support
- Supports SRI and LLI operating at the same frequency only

6.8.2 Functional overview

S2L is a bridge translating SRI transactions to equivalent AXI transactions for the AXI based LLI interconnect (see LLI chapter).

6.8.3 Functional description

The S2L bridge is implemented as a uni-directional bridge that forwards transactions from the SRI to the 32-bit data AXI LLI interconnect. The bridge supports all single SRI transactions on the SRI, and those transactions of the AXI interconnect required to implement them.

The bridge is transparent for the address and tag of an SRI transaction, and transactions are mapped as described in the table below. For performance reasons write transactions from the SRI to LLI resources are handled as posted writes.

Table 582 SRI transaction to 32-bit data AXI transaction mapping

SRI transaction (64-bit data bus)	AXI transaction (32-bit data bus)
Single Data Transfer Byte (8 bit)	INCR Burst (Length=1, Size=8 bits)
Single Data Transfer Half-Word (16 bit)	INCR Burst (Length=1, Size=16 bits)
Single Data Transfer Word (32 bit)	INCR Burst (Length=1, Size=32 bits)
Single Data Transfer Double-Word (64 bit)	Not converted - errored at the SRI interface.
Block Transfer Request (2 transfers)	Not converted - errored at the SRI interface.
Block Transfer Request (4 transfers)	Not converted - errored at the SRI interface.
Block Transfer Request (8 transfers)	Not converted - errored at the SRI interface.
Atomic Read Write sequence (8 bit)	INCR Burst Read followed by INCR Burst write (Length=1, Size=1 byte)[1)]
Atomic Read Write sequence (16 bit)	INCR Burst Read followed by INCR Burst write (Length=1, Size=2 bytes)[1)]
Atomic Read Write sequence (32 bit)	INCR Burst Read followed by INCR Burst write (Length=1, Size=4 bytes)[1)]
Atomic Read Write sequence (64 bit)	Not converted - errored at the SRI interface.

1) This sequence is not atomic on the AXI interconnect.

6.8.3.1 Transaction errors for posted writes

Write transactions from SRI masters to LLI resources are handled as posted writes. This means that a write operation from an SRI master through the S2L bridge will finish on the SRI, and the S2L completes the write later on the LLI interconnect. If the AXI write transaction results in an error on the LLI interconnect, the error

information is not passed back to the SRI. The error condition is detected by the S2L bridge and an alarm is raised.

Note that this alarm behavior occurs only for write operations through the S2L bridge.

Any read or write response on the AXI interconnect which is not OKAY is an error.

6.8.3.2 Data phase EDC errors

The S2L bridge checks received write data for EDC correctness. If an EDC error is detected in the write data beat, a data phase alarm is raised. For the resulting AXI transaction the write strobes are all set disabled, so that incorrect data is not written into the target slave.

6.8.3.3 Parity errors

The S2L AXI interface implements parity across address and read and write data control signals. If a parity error is detected for a valid input, the S2L raises an alarm. Parity errors detected in the AXI read and write address channels result in an address phase alarm, any other parity error results in a data phase alarm.

6.8.3.4 Protection registers

The S2L provides the PROT and ACCEN registers for the connected AXI slaves. The registers are accessed from the SRI interface, and are used by the S2L to determine whether a master agent function is allowed to access the AXI target. If an SRI master agent function is not allowed access to the target AXI slave, the transaction is acknowledged with an SRI error. One set of protection registers is provided for each slave target accessible by the S2L bridge. The registers behavior and specific addresses for the PROT and APU registers implemented per slave are described in the individual slave module chapters accessed by an S2L bridge.

6.8.3.5 Target unavailability

If the target module is inaccessible through the AXI interface for any reason, including clock gated off or power gated off, the S2L will error all accesses to the address space allocated to the module. The SRI error indication will, as usual, raise an alarm and interrupt if enabled.

6.9 AXI to SRI bridge (A2S)

This section describes the functionality of the A2S bridge, a bridge from a 64-bit AXI interconnect to the SRI.

6.9.1 Feature list

- Converts AXI transactions into one or more equivalent SRI transactions
- Signals EDC errors through system alarms
- Provides posted writes from AXI to the SRI fabric
- Supports SRI and LLI operating at the same frequency only

6.9.2 Functional overview

The A2S bridge is a uni-directional bridge that forwards transactions from a 64-bit data AXI interconnect to the SRI.

The bridge supports most transactions of the 64-bit AXI interconnect and all SRI transactions on the SRI Fabric required to implement them. A small subset of AXI transactions are not supported and receive a SLVERR error indication.

6.9.3 Functional description

The conversion of AXI read transactions which are‘regular’ is straightforward and described in the table below. In addition, the conversion of AXI write ‘regular transactions’; with the additional restriction for burst transactions that all bytes of a beat are written; is straightforward and also described in the table below. AXI transactions which are not ‘straightforward’ are described in the section non-straightforward transactions.

The A2S bridge is transparent for the address of a straightforward transaction, but not for the AxID of the AXI master. The AxID is mapped to an SRI tag in the SRI.

***Note**: For AXI write transactions, a master can use the low-order address lines to provide an unaligned start address or provide an aligned address and use the byte lane strobes to provide the unaligned start address. It is the provided address which is used for the converted transaction or first transaction of a sequence.*

Transactions are converted as described in the table below. For performance reasons write transactions from the AXI interconnect to SRI resources are handled as posted writes.

***Note**: An INCR burst is a transaction of 1 or more beats where the address for each beat increments depending on the size of the transfer. A WRAP burst wraps around to a lower address if the transaction size boundary is reached.*

Table 583 AXI ‘straightforward’ transaction to SRI transaction conversions

AXI 64-bit transaction	SRI transaction (64-bit data bus)
INCR (Length=1, Size=8 bits) (1 byte)	Single Data Transfer Byte (SDTB) (8-bit)
INCR (Length=1, Size=16 bits, Start address aligned to size) (2 bytes)	Single Data Transfer Half-Word (SDTH) (16-bit)
INCR (Length=1, Size=16 bits, Start address unaligned to size) (2 bytes)	Sequence SDTB, SDTB
INCR (Length=1, Size=32 bits, Start address aligned to size) (4 bytes)	Single Data Transfer Word (SDTW) (32-bit)
INCR (Length=1, Size=32 bits, Start address unaligned to size) (4 bytes)	Sequence SDTH, SDTH
INCR (Length=1, Size=32 bits, Start address unaligned to size) (4 bytes)	Sequence SDTB, SDTH, SDTB
INCR (Length=1, Size=64 bits, Start address unaligned to size) (8 bytes)	Single Data Transfer Double-Word (SDTD) (64-bit)
INCR (Length=1, Size=64 bits, Start address unaligned to size) (7 valid bytes)	Sequence SDTB, SDTH, SDTW
INCR (Length=1, Size=64 bits, Start address unaligned to size)(5 valid bytes)	Sequence SDTB, SDTW
INCR (Length=1, Size=64 bits, Start address unaligned to size)(3 valid bytes)	Sequence SDTB, SDTH
INCR (Length=1, Size=64 bits, Start address unaligned to size)(6 valid bytes)	Sequence SDTH, SDTW
Locked INCR Read followed by unlocked INCR write (Both length=1, both Byte/Half-Word/Word/Double-Word Aligned Transfer (1/2/4/8 bytes respectively)	Atomic Read Write SDTB/SDTH/SDTW/SDTD sequence

(table continues...)

Table 583 (continued) AXI 'straightforward' transaction to SRI transaction conversions

AXI 64-bit transaction	SRI transaction (64-bit data bus)
Locked Read Half-Word/Word/Double-Word Non-Aligned Transfer (2/4/8 bytes)	Not converted – errored at AXI interface
Locked INCR Write	Not converted – errored at AXI interface
Locked INCR or WRAP Burst (Length = 2-16)	Not converted – errored at AXI interface
INCR Burst regular = 16 byte aligned (Length=2, Size=8 bytes)	Block Transfer Request (BTR2) (2 transfers)
INCR Burst regular = 32 byte aligned (Length=4, Size=8 bytes)	Block Transfer Request (BTR4) (4 transfers)
INCR Burst regular = 64 byte aligned (Length=8, Size=8 bytes)	Block Transfer Request (BTR8) (8 transfers)
INCR Burst regular = 128 byte aligned (Length=16, Size=8 bytes)	Sequence BTR8, BTR8
WRAP Burst regular = 8 byte aligned (Length=2, Size=8 bytes)	Block Transfer Request (BTR2) (2 transfers)
WRAP Burst regular = 8 byte aligned (Length=4, Size=8 bytes)	Block Transfer Request (BTR4) (4 transfers)
WRAP Burst regular = 8 byte aligned (Length=8, Size=8 bytes)	Block Transfer Request (BTR8) (8 transfers)
WRAP Burst regular = 8 byte aligned (Length=16, Size=8 bytes)	Sequence BTR8, BTR8

6.9.3.1 Transaction errors for reads

When the A2S converts a read transaction which is errored in the SRI, it returns data beats to the AXI master with dummy read data and a read response of an error (RRESP=SLVERR).

When the A2S converts a read transaction which for a data beat receives a transaction ID error, or the A2S explicitly detects an EDC error, it returns the received (faulty) data and a read response of an error (RRESP=SLVERR) with each faulty beat or beats. In addition the A2S raises an EDC error alarm.

In addition, if the A2S in returning read data detects an EDC error in the data to be placed on the AXI interconnect, the A2S provides an error response (RRESP=SLVERR) with the faulty beat or beats of data. In addition the A2S raises an EDC error alarm.

6.9.3.2 Transaction errors for posted writes

Write transactions from AXI Masters to SRI resources are handled as posted writes. This means that a write operation from an AXI Master through the A2S Bridge will always have the data beats finished on the AXI interconnect, and the A2S completes the write later on the SRI.

If the SRI write transaction results in an error on the SRI, the error information is not passed back to the AXI interconnect. The error condition will be left to the receiving SRI slave to interrupt or raise alarms as configured.

This behavior occurs only for write operations using the A2S bridge.

If one or more of the AXI write data beats is detected as having an EDC error then the A2S returns an error to the AXI master (BRESP=SLVERR). As the transaction will be executed on the SRI, the corresponding beat in error is annotated with a transaction ID error so the slave is aware of the EDC condition.

6.9.3.3 Locked transfers

The only permitted sequence is a single locked Read of a particular size followed by a single Write of the same size. This pair of transactions occur in an uninterrupted sequence and provides a 1:1 map to the SRI atomic sequence.If the initial SRI read transaction of the read write sequence terminates on the SRI with an error, the error will be propagated to the AXI read. The counter part write transaction is still expected and will be terminated with an error and be not translated to the SRI.

The use of this locked sequence is reserved for the PPU master when it implements the EX instruction required to enable management of synchronization primitives. The use of this feature is discouraged in all other circumstances.

6.9.3.4 Parity errors

The A2S AXI interface implements parity across address and read and write data control signals. If a parity error is detected for a valid input, the A2S raises an alarm, but does not halt the transaction.

6.9.3.5 Non-straightforward transactions

AXI transactions which are not straightforward will require more than one separate SRI transactions for their conversion.

AXI transactions presented to the A2S which are not straightforward are:

- FIXED burst transactions
- INCR or WRAP bursts where the length is not 2, 4, 8, or 16, or the data in each beat is not 8-bytes
- INCR or WRAP bursts where the starting address is not naturally aligned

If the written bytes presented in any beat are discontiguous the AXI transaction will be errored and not presented on the SRI.

FIXED burst transactions of length ‘n’ will be converted to a sequence of ‘n’ element conversions. The element conversion may itself be a sequence of SRI transactions if the AXI transaction is not aligned. The element conversion will be one of the single transaction conversions described in the table “straightforward conversions”.

INCR or WRAP burst transactions will be mapped into sequences of SRI transactions which will vary in size and length depending on the length, alignment, and bytes presented during each beat. The SRI transactions resulting from the conversion will be the minimum required respecting the SRI natural alignment restrictions.

6.9.3.6 Converting AXI transaction IDs

This section describes how AXI transaction IDs are mapped onto transactions within the SRI.

The AXI interface will receive either an AwID or an ArID which identifies the originating master of the transaction. Each master agent which uses an A2S to access the SRI has an SRI master tag assigned to it, and the A2S will identify the driving master from the received ID. The A2S then drives the mapped transaction with the assigned SRI master tag.

***Note**: Most AXI masters only contain one master agent, and therefore have one tag assigned. The GETH DMA is one master, but has 9 master agents, one per read or write channel and descriptor, and therefore the A2S attached to this can drive any one of 9 SRI master tags.*

6.9.3.7 Low power capability

The AXI side of the bridge implements the low power capability as defined by the AXI3 low power interface. Only controller initiated wake up and sleep is required to be supported. An external controller can put the bridge into a low power state to isolate the AXI side from the SRI.

The clocks may be switched off after successfully entering low power mode.

6.10 GTM to SRI bridge (G2S)

The G2S bridge implements a uni-directional bridge that forwards transactions from a single beat 32-bit AXI master to the SRI.

6.10.1 Feature list

- Converts GTM AXI transactions into equivalent SRI transactions
- Signals EDC errors through system alarms
- Provides posted writes from AXI to the SRI Fabric
- Operates at f_{CPB} and f_{SRI} clock frequencies

6.10.2 Functional overview

The G2S bridge implements a uni-directional bridge that forwards transactions from the single beat 32-bit AXI master (GTM) to the SRI Fabric. The bridge supports the subset of AXI transactions that the GTM presents and that subset of transactions of the SRI required to implement them.

6.10.3 Functional description

The bridge is transparent for the address of a transaction, but not for the AxID of the AXI master. The AxID is mapped to an SRI tag in the SRI. Transactions are converted as described in the following table.

Table 584 AXI single fully enabled transaction to SRI transaction mapping

AXI transaction	SRI transaction (64-bit data bus)
Single Byte Transfer (8-bit)	Single Data Transfer Byte (8-bit)
Single Half-Word Transfer (16-bit)	Single Data Transfer Half-Word (16-bit)
Single Word Transfer (32-bit)	Single Data Transfer Word (32-bit)

6.10.3.1 Converting AXI transaction IDs

The AXI interface will receive an AXI ID which identifies the originating master of the transaction.

Each master agent which uses a G2S to access the SRI has an SRI master tag assigned to it, and the G2S will identify the driving master from the received ID. The G2S then drives the converted transaction with the assigned SRI master tag.

VM and PRS information on the SRI is populated with a 1:1 mapping from the information received on the designated AXI side user signals.

6.10.3.2 Transaction errors for posted writes

Write transactions from the GTM to SRI resources are handled as posted writes. This means that a write operation from the GTM through the G2S bridge can finish on the AXI bus, and the G2S completes the write later on the SRI.

If the SRI write transaction results in an error, the error information is not passed back to the AXI interconnect. The error condition will be left to the receiving SRI slave to interrupt or raise alarms as configured.

This behavior occurs only for write operations using the G2S bridge.

If the AXI write data beat is detected as having an EDC error then the G2S returns an error to the AXI master (BRESP=SLVERR). As the transaction will be executed on the SRI, the corresponding beat in error is annotated with a transaction ID error so the slave is aware of the EDC condition.

6.11 Set to use latency for access protection updates through S2A and S2L bridges

Additional considerations to update PROT and APU registers that are accessed through S2A and S2L bridges

- Some of the access protection checks for resources downstream of a bridge are implemented within the bridge itself
- PROT and APU register updates in the bridges can take up-to 5 clock cycles before they are used for subsequent permission checks
- When the access permissions are modified on-the-fly amidst live traffic scenarios, transactions closely following the update may be subjected to permission checks using the old configuration
- In order to avoid the ambiguous permission check around the time of the configuration change, the application software must suitably regulate the sensitive traffic through the bridge during that time

The affected slaves include eGTM.SIF, S2L, PPU.CSM, PPU.VCCM, GETH.SIF, LETH0/1.SIF, PCI0/1.SIF (not all slaves may be present in all devices).

6.12 Registers

6.12.1 Register overview - access mode glossary

Table 585 Register overview - access mode glossary

Keyword	Description
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P	Access protection using *APU-P* registers.
32	Access only when using 32-bit width.
SV	Access only when supervisor mode is active on the interconnect.
BE	Always returns a Bus Error.
STP	Access only during start-up, before start-up protection is set (SMM_STCON.ST_PROT=1).
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

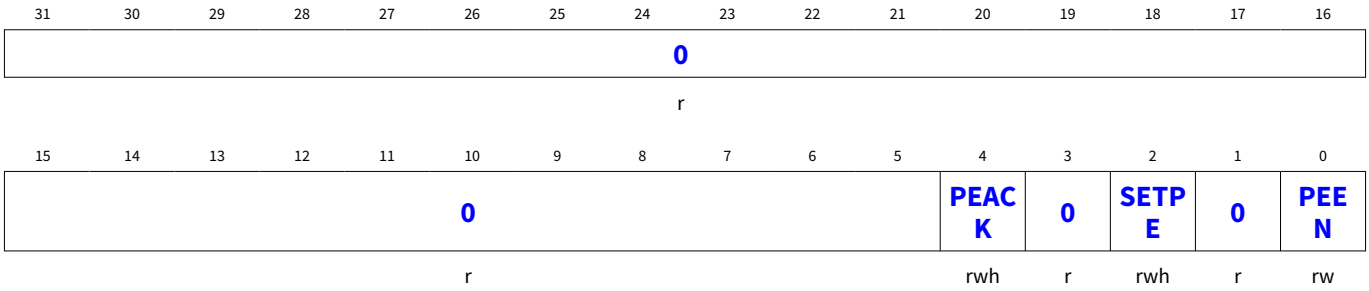
6.12.3 Protocol error control register x

PECONx (x=0-15) Offset address: 00000_H + x*20_H

Protocol error control register x Application Reset value: 0000 0001_H



Field	Bits	Type	Description
PEEN	0	rw	**Protocol error enable** 0_B Protocol errors are not indicated and no information is captured. 1_B Protocol errors are indicated and information is captured.
SETPE	2	rwh	**Set protocol error** This allows SW to mimic a protocol error and present an indication similar to a hardware detected error. After setting this bit, it is automatically cleared by the hardware in the cycle after the write. 0_B No protocol error indication is generated 1_B A protocol error indication is generated
PEACK	4	rwh	**Protocol error acknowledge** Writing a one to this bit while it's set has the following results: The error lock of the corresponding ERRADDRx and ERRx are released, and the registers will be updated for the next protocol error detected (see chapter "Error tracking capability"). After setting this bit, it is automatically cleared by the hardware in the cycle after the write. 0_B Default value 1_B A Protocol Error for this arbiter has been indicated. The corresponding ERRADDR and ERR registers are not updated for new errors.
0	1, 3, 31:5	r	**Reserved** Read as 0; should be written with 0.

6.12.4 SCIx arbiter priority register

Identical functionality can be achieved by setting all priorities to high compared with setting all priorities to low.

HPRS only affects arbitration when high priority requests arrive so frequently that there are no arbitration rounds with only low priority requests. When this occurs (no high priority free arbitration rounds), a maximum of HPRS grants are given to high priority masters, and then a single grant is given to the low priority round robin winner. An example configuration would be to assign the DMA to high priority and the CPUs to low priority so that the DMA does not have to wait too long for accesses and thus lose samples when moving data from RX/TX FIFOs.

***Note**: Only the MCIn_P bits assigned to implemented MCIs are present. Bits corresponding to unimplemented MCIs are treated as reserved bits.*

Reset values are device and instance specific. Refer to the device specific register table for reset values.

PRIORITYx (x=0-15) Offset address: 00008_H+x*20_H

TR_ID	15:8	rh	**Transaction ID** This field contains the Master's transaction ID of the erroneous transaction. The Transaction ID is built out of the Master's 6-bit unique TAG ID (TR_ID[5:0]), and a 2-bit running number TR_ID[7:6].
ADDR_EDC	23:16	rh	**Address phase error detection information** This field contains the Address Phase Error Detection Information of the erroneous transaction.
PRS	26:24	rh	**Protection register set** This field contains the Master's PRS number of the erroneous transaction
PRS_EN	27	rh	**PRS enable** This field contains the Master's PRS enable of the erroneous transaction
VM	30:28	rh	**Virtual machine** This field contains the Master's Virtual Machine number of the erroneous transaction
VM_EN	31	rh	**VM Enable** This field contains the Master's VM enable of the erroneous transaction

6.12.7 Identification register

The identification register identifies the module, and provides revision and type information. The table below describes the identification register, which is implemented per domain.

ID Offset address: 00408_H

Identification register Application Reset value: $0004\ D006_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MOD_NUM															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOD_TYPE								MOD_REV							
r								r							

Field	Bits	Type	Description
MOD_REV	7:0	r	**Module revision number** This bit field defines the module revision number. The value of a module revision starts with 01H (first revision).
MOD_TYPE	15:8	r	**Module type** The bit field is set to D0H which defines the module as a 64-bit module.
MOD_NUM	31:16	r	**Module number value** This bit field defines a module identification number. The value for the SRI SRI Fabric is 0004H.

6.12.8 Protocol error status register

***Note**: Only the bits assigned to implemented SCIs are present. Bits corresponding to unimplemented SCIs are treated as reserved bits, which will be read as 0, and should be written with 0.*

PESTAT Offset address: 00410_H

Protocol error status register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PESCI15	PESCI14	PESCI13	PESCI12	PESCI11	PESCI10	PESCI9	PESCI8	PESCI7	PESCI6	PESCI5	PESCI4	PESCI3	PESCI2	PESCI1	PESCI0
rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															
r															

Field	Bits	Type	Description
PESCIn (n=0-15)	n+16	rwh	**Protocol error status of SCIn** Writing 0 to the bit leaves the content unchanged, while writing 1 to the bit clears it. In case the bit is simultaneously cleared via software and set via hardware, the bit remains set and is not cleared. 0_B No protocol error has been indicated by SCIn 1_B A protocol error has been indicated by SCIn
0	15:0	r	**Reserved** Read as 0; should be written with 0.

6.12.9 Transaction ID status register

Only the bits assigned to implemented SCIs and MCIs are present. Bits corresponding to unimplemented SCIs and MCIs are treated as reserved bits, which will be read as 0, and should be written with 0. Reset values for bits/bit fields referencing MCIs or SCIs that are not implemented or enabled are 0.

TIDSTAT Offset address: 00418_H

Transaction ID status register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

6.12.18 Resource protection register

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

PROTSE Offset address: $004E0_H$

Resource protection register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OWEN	ODEF	TAGID						PRSEN	PRS			VMEN	VM		
w	rw	rw						rw	rw			rw	rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												SWEN	STATE		
r												w	rwh		

Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM portion of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection Set definition for PROT owner** Defines the PRS portion of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection Set definition Enable for PROT owner** 0_B **Disable**: PRS is part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition

(table continues...)

(continued)

Field	Bits	Type	Description
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID portion of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 587 Access mode restrictions of PROTSE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

6.12.19 QoS time interval control register

The QOSICTRL register allows the enabling and disabling of the QoS function and the defining of the QoS time interval for this interconnect.The four lower order bits are reserved and always zero so that the register as a whole provides the time interval at a granularity of 16 clocks.

QOS_ICTRL Offset address: 01000_H

QoS time interval control register Application Reset value: $0007\ FFF0_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
QOSEN	0								QOSINT						
rw	r								rw						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
QOSINT												0			
rw												r			

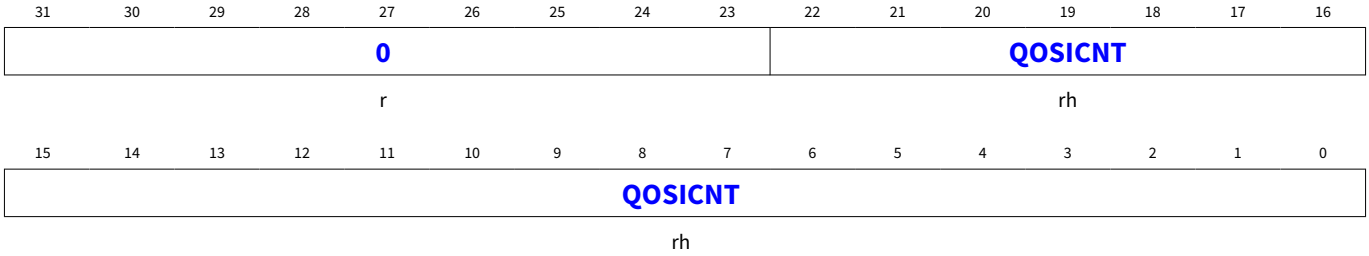
Field	Bits	Type	Description
QOSINT	22:4	rw	**QoS time interval** The bit field determines the QoS time interval in multiples of 16 local interconnect clock cycles. The lower order reserved bits within the register account for the 16 cycle granularity.
QOSEN	31	rw	**QoS enable** 0_B QoS function is disabled for the local interconnect 1_B QoS function is enabled for the local interconnect
0	3:0, 30:23	r	**Reserved** Read as 0; should be written with 0.

6.12.20 QoS time interval counter

Indicates the current value of the QoS time interval counter.

QOS_ICNT Offset address: 01004_H

QoS time interval counter Application Reset value: $007F\ FFFF_H$



Field	Bits	Type	Description
QOSICNT	22:0	rh	**QoS time interval counter** The bit field shows the current values of the QoS time interval counter. In QoS mode, the decrementing counter indicates the number of local clock cycles before the current time interval has expired. when the counter is counted down to 0, it is reloaded with the counter value at 16 cycle granularity as derived from QOS_ICTRL.
0	31:23	r	**Reserved** Read as 0; should be written with 0.

6.12.21 QOSx ARPp TAG-ID assignment register A

QOSx_ARPp_TAGIDA (p=0-7;x=1-15) Offset address: $01020_H+x*200_H+p*20_H$

QOSx ARPp TAG-ID assignment register A Application Reset value: $0000\ 0000_H$

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
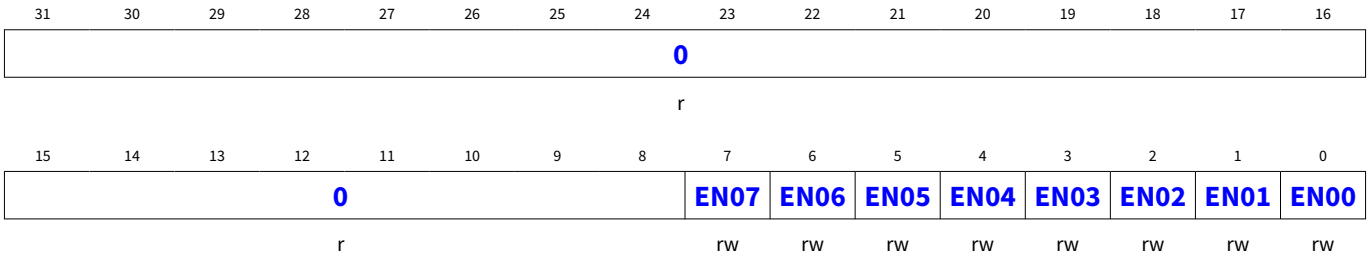
ENq (q=32-63)	q-32	rw	**TAG-ID q** This bit enables usage monitoring of master agent TAG-ID q 0_B TAG-ID not assigned to ARPp 1_B TAG-ID assigned to ARPp

6.12.23 QOSx ARPp VM assignment register

QOSx_ARPp_VM (p=0-7;x=1-15) Offset address: $01028_H+x*200_H+p*20_H$

QOSx ARPp VM assignment register Application Reset value: $0000\ 0000_H$



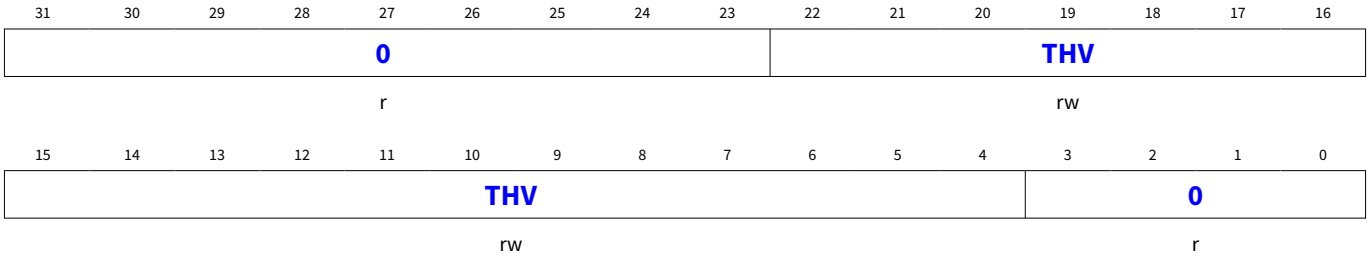
Field	Bits	Type	Description
ENq (q=00-07)	q	rw	**VM-ID q** This bit enables usage monitoring of master agent VM-ID q 0_B VM-ID not assigned to ARPp 1_B VM-ID assigned to ARPp
0	31:8	r	**Reserved** Read as 0; should be written with 0.

6.12.24 QOSx ARPp threshold register

Register defines the interconnect usage budget for the master agent functions mapped to ARPp. The four lower order bits are reserved and always read zero so that the register as a whole defines the cycle count budget at a granularity of 16 clocks.

QOSx_ARPp_THR (p=0-7;x=1-15) Offset address: $0102C_H+x*200_H+p*20_H$

QOSx ARPp threshold register Application Reset value: $0007\ FFF0_H$



Field	Bits	Type	Description
THV	22:4	rw	**ARPp threshold value** Bit field defines how many clock cycles the master agent functions assigned to ARPp can use the interconnect in the QoS time interval before it is identified as an ARPp usage violation. The bit field, along with the reserved lower order bits, defines the number in multiples of 16 local interconnect clock cycles.
0	3:0, 31:23	r	**Reserved** Read as 0; should be written with 0.

6.12.25 QOSx ARPp control register

Register provides control for the ARPp function and indicates the status of ARPp.

QOSx_ARPp_CTRL (p=0-7;x=1-15) Offset address: 01030_H+x*200_H+p*20_H

QOSx ARPp control register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
STAT	CLR	0													
rh	w	r													

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0															EN
r															rw

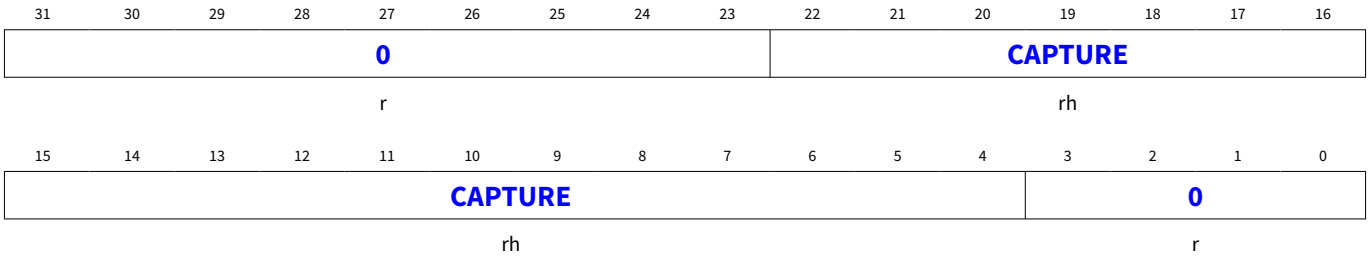
Field	Bits	Type	Description
EN	0	rw	**ARPp enable** 0_B ARPp function is disabled 1_B ARPp function is enabled
CLR	30	w	**ARPp status clear** Bit can be used to clear the ARPp status bit (STAT). Bit is always read as 0. 0_B No action 1_B STAT bit is cleared.
STAT	31	rh	**ARPp status** The STAT bit is set by the ARPp function at the end of a QoS interval if an ARPp interconnect usage violation was identified in the QoS interval. If the STAT bit is not already set at that time, the CAPTURE register is simultaneously updated and its contents are protected against being overwritten by the hardware until the STAT bit is reset by the application software. 0_B This partition has not had a usage violation 1_B This partition has had a usage violation
0	29:1	r	**Reserved-0** Read as 0; should be written with 0.

6.12.26 QOSx ARPp cycle count capture register

Register shows the interconnect cycles used by the master agent functions mapped to ARPp in a QoS interval. The four lower order bits are reserved and always read zero so that the register as a whole provides the cycle count usage at a granularity of 16 clocks.

QOSx_ARPp_CCC (p=0-7;x=1-15) Offset address: 01034_H+x*200_H+p*20_H

QOSx ARPp cycle count capture register Application Reset value: $0000\ 0000_H$



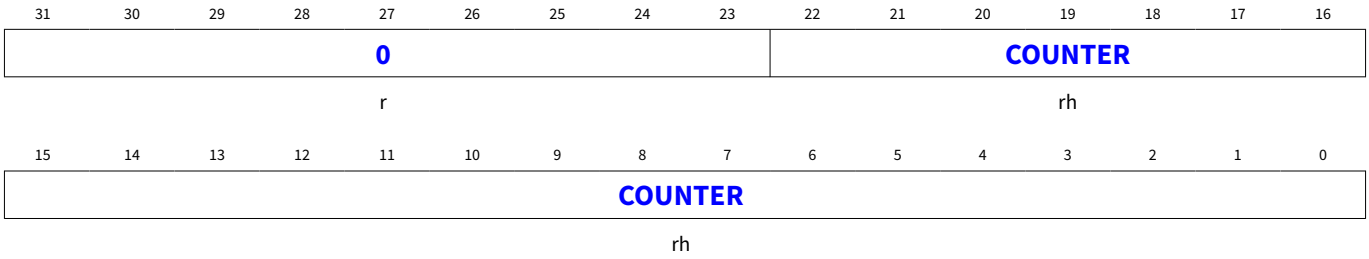
Field	Bits	Type	Description
CAPTURE	22:4	rh	**ARPp captured cycle count** Bit field indicates how many clock cycles the master agent functions assigned to the ARPp have used the interconnect in a QoS time interval. The register is updated at the end of a QoS time interval if the CTRL.STAT bit is not set. The bit field, along with the four lower order reserved bits from the register, provide the result in multiples of 16 local interconnect clock cycles.
0	3:0, 31:23	r	**Reserved-0** Read as 0; should be written with 0.

6.12.27 QOSx ARPp current counter value register

Register shows the state of the ARPp counter with which the clocks are counted in which ARPp master agent functions have used the interconnect in the current QoS interval.

QOSx_ARPp_CCV (p=0-7;x=1-15) Offset address: 01038_H+x*200_H+p*20_H

QOSx ARPp current counter value register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
COUNTER	22:0	rh	**ARPp cycle count** Bit field shows the current state of the ARPp clock cycle counter and thus how many clock cycles the master agent functions assigned to the ARPp have used the interconnect so far in the current QoS time interval. Note: the ARPp clock cycle counter counts only if ARPp is enabled.
0	31:23	r	**Reserved-0** Read as 0; should be written with 0.

6.13 Debug information

There are no deviations from the generic specification.

6.16.3 TC4Dx SRI functional description

6.16.3.1 Set to use latency for access protection updates through S2A and S2L bridges

Additional considerations to update PROT and APU registers that are accessed through S2A and S2L bridges

- Some of the access protection checks for resources downstream of a bridge are implemented within the bridge itself
- PROT and APU register updates in the bridges can take up-to 5 clock cycles before they are used for subsequent permission checks
- When the access permissions are modified on-the-fly amidst live traffic scenarios, transactions closely following the update may be subjected to permission checks using the old configuration
- In order to avoid the ambiguous permission check around the time of the configuration change, the application software must suitably regulate the sensitive traffic through the bridge during that time

The affected slaves include eGTM.SIF, S2L, PPU.CSM, PPU.VCCM, GETH.SIF, LETH0/1.SIF, PCI0/1.SIF (not all slaves may be present in all devices).

6.16.3.2 TC4Dx OLDA address space restrictions

The following restriction applies to the 512KB OLDA region

- OLDA region is split into 32 16KB sections
- In each 16KB section, 64B starting at offset 0x4C0 is not available for OLDA and writes should not be targeted to this region

Online data acquisition (OLDA) on page 999

6.16.3.3 TC4Dx incorrect write completion status from S2L following RMW write address EDC error

For SRI read with intent to write (RMW) transaction types, which are often the result of atomic CPU instructions , a soft error could affect the address phase of the write. On detecting such errors, the S2L will generate an alarm to signal an address phase EDC error to the SMU. The detection of the address phase EDC error terminates the transaction. Such terminated transaction should also be indicated as complete by the S2L. However, for the specific case as discussed above, the S2L would not indicate the completion of this transfer

back to the initiating master. Therefore, if a DSYNC appears in the instruction stream following the above soft error scenario, the CPU pipeline could stall indefinitely (which would eventually be detected by the expiration of a watchdog timer). Such a DSYNC may also appear within the interrupt service routine which is a direct response to the SMU alarm. If the ISR is executed on the same CPU as the one which triggered the S2L alarm, the ISR and therefore alarm reaction may not complete.

The recommendation is to handle S2L address phase EDC errors by invoking an application reset, or to execute the associated SMU initiated ISR on a CPU that does not normally access the S2L. Application reset is guaranteed to reinitialize the completion status at the S2L and also recover stalled CPUs.

6.16.3.4 TC4Dx transactions closely following a RMW may break strict round robin arbitration

For transaction sequences closely following RMW transactions as observed at the SRI crossbar arbiter, the arbiter might unfairly grant access to the same master even though other higher priority masters are pending. The exact sequence depends on the internal state of the arbiter and in the worst case the arbiter unfairly grants two additional transactions.

Therefore, when the arbiters witness a high density of RMW, the instantaneous worst case arbitration delay of other participating masters would be extended by up-to two arbitration delay slots, or the equivalent clock cycles.

6.16.3.5 Legend to connectivity matrix

Table 588 Legend to connectivity matrix

Name	Guide to naming convention
<FB>.MIF<*n*>	n^{th} master port instance belonging to the functional block(FB) where the FB has more than one master port. It is omitted when there is a single mater port.
<FB>.<named_port>	Where a unique name is associated with a FB master or slave, such as PPU.CBU, or PPU.VMEM, CPU.SSF(alternately P, S_SRI1), or CPU.SSX (alternately S, S_SRI0), for example.
<FB>.SIF<*n*>	n^{th} slave port instance belonging to the functional block(FB) where the FB has more than one slave port. It may be omitted when there is a single slave port, or alternately identified with n as *0*.
S2S_<*i*><*j*>_<*k*>	An S2S bridge from domain *i* to domain *j*. *k* stands for the instance of the bridge for the specified connection. *k* stands for the instance of the bridge when multiple bridges exist. *k* is normally 0, or only one bridge exists.
S2F_<*i*><named_fpi>_<*k*>	An SRI to FPI bridge from domain *i* to one of the FPI domains. *k* stands for the instance of the bridge. *k* stands for the instance of the bridge when multiple bridges exist. *k* is normally 0, or only one bridge exists.
F2S_<named_fpi><*j*>_<*k*>	An FPI to SRI bridge from one of the FPI domains to domain *j*. *k* stands for the instance of the bridge when multiple bridges exist. *k* is normally 0, or only one bridge exists.

6.16.4.11 SCIx arbiter priority register (x=0-14)

Identical functionality can be achieved by setting all priorities to high compared with setting all priorities to low.

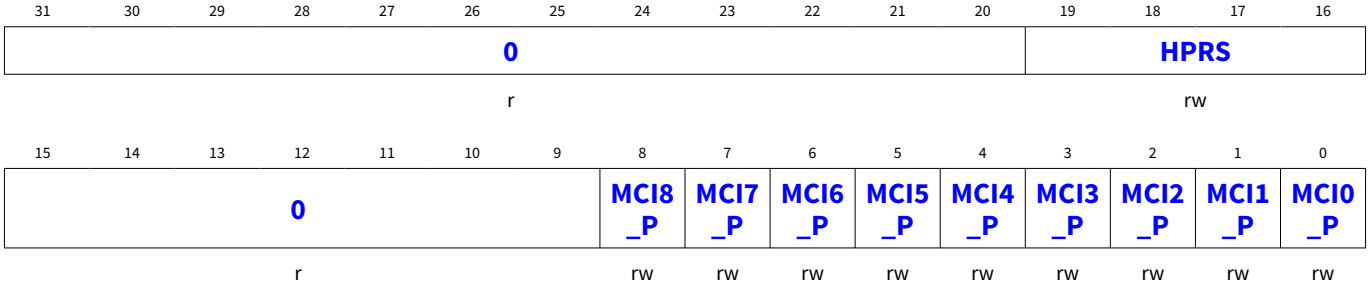
HPRS only affects arbitration when high priority requests arrive so frequently that there are no arbitration rounds with only low priority requests. When this occurs (no high priority free arbitration rounds), a maximum of HPRS grants are given to high priority masters, and then a single grant is given to the low priority round robin winner. An example configuration would be to assign the DMA to high priority and the CPUs to low priority so that the DMA does not have to wait too long for accesses and thus lose samples when moving data from RX/TX FIFOs.

***Note**: Only the MCIn_P bits assigned to implemented MCIs are present. Bits corresponding to unimplemented MCIs are treated as reserved bits.*

Reset values are device and instance specific. Refer to the device specific register table for reset values.

DOM0_PRIORITYx (x=0-14) Offset address: 00008_H+x*20_H

SCIx arbiter priority register Application Reset value: 0005 0171_H



Field	Bits	Type	Description
MCIn_P (n=0-8)	n	rw	**MCIn Priority** 0_B MCIn requests are arbitrated in the low priority round robin. 1_B MCIn requests are arbitrated in the high priority round robin.
HPRS	19:16	rw	**High priority round share** Number of transactions to give to the high priority round robin before a transaction from low priority round (when request saturated). This number may not be less than the number of high priority MCI programmed via. MCIn_P.
0	15:9, 31:20	r	**Reserved** Read as 0; should be written with 0.

6.16.6 TC4Dx SRI revision history

Initial release of the chapter.

7 Flexible Peripheral Interconnect (FPI)

The system on chip (SoC) communication is mainly based on three interconnect protocols: SRI, FPI, and AXI that used for the LLI interconnect.

The Flexible peripheral interconnect (FPI) is multi-master interconnect, 32-bit data width, based on FPI interconnect protocol. The FPI connects the high speed peripherals, such as the TC1.8 CPUs and DMA modules to the medium and low bandwidth functional blocks.

7.1 Feature list

- Optimized for high-speed and high-performance
  - Support of multiple master agents and back-to-back transaction execution
  - Transaction pipelining support to support up to 1 data transmission per cycle
  - 32-bit address and 32-bit data width
  - 8, 16, and 32-bit data transfers
  - 64, 128, and 256-bit block transfers with wrap around addressing
- Slave-controlled wait state and retry insertion
- Timeout detection and handling
- Support of atomic TriCore™ operations for example LDMST, ST.T, SWAP.W, CMPSWP, and SWPMSK
- Flexible arbitration schemes
  - Priority based, two round-robin groups and starvation prevention mechanism
- QoS master agent interconnect usage control mechanism
- QoS application interconnect usage observation mechanism
- Round-robin group control mechanism (round share mechanism)
- Starvation prevention mechanism that can take care that even low priority requests will be granted after a configurable number of arbitration cycles, permanently enabled
- Default slave mechanism that responds to a transactions to a not implemented addresses
- Debug support where transaction information are captured in case of a FPI timeout or FPI error
- Address phase includes master identifier, supervisor mode and security mode information
- All slave agents implemented with master agent identifier based access protection
- Transactions protected through end to end error detection code (EDC)

7.2 Functional overview

The Flexible Peripheral Interconnect (FPI) is a multi-master interconnect with a 32-bit interconnect supporting 8-, 16-, 32-, 64- 128- and 256-bit data transfers as well as atomic Read-Modify-Write transactions. Multi-master interconnect here means that exactly one data transfer between the connected function blocks can be executed at any time. The FPI connects the high speed functional blocks, such as the TC1.8 CPU´s and DMA modules to the medium and low bandwidth system and communication functional blocks.

The TC4x System interconnect architecture defines multiple FPI interconnect instances where each FPI interconnect instance provides a dedicated FPI Bus Control Unit (BCU):

- SBCU related to the system peripheral interconnect (SPB)
- CBCU related to the converter peripheral interconnect (CPB)
- COMBCU related to communication peripheral interconnect (COMPB)
- RBCU related to the radar control peripheral interconnect (RCB)
- CSBCU related to the cyber Security peripheral interconnect (CSPB)
- TBCU related to the tool peripheral interconnect (TPB)

***Note**: Which FPI instances are instantiated in the respective product is described in chapter 'Characteristic of FPI interconnect'. The distribution of FBs to SPB, COMPB and CPB is product-specific.*

***Note**: The distribution of FBs on SPB, COMPB and CPB is product-specific and visible through the product specific BCUs ALSTAT register bits. The product-specific BCU ALSTAT registers show which FBs are connected to the respective FPI with their FPI EDC alarm signals.*

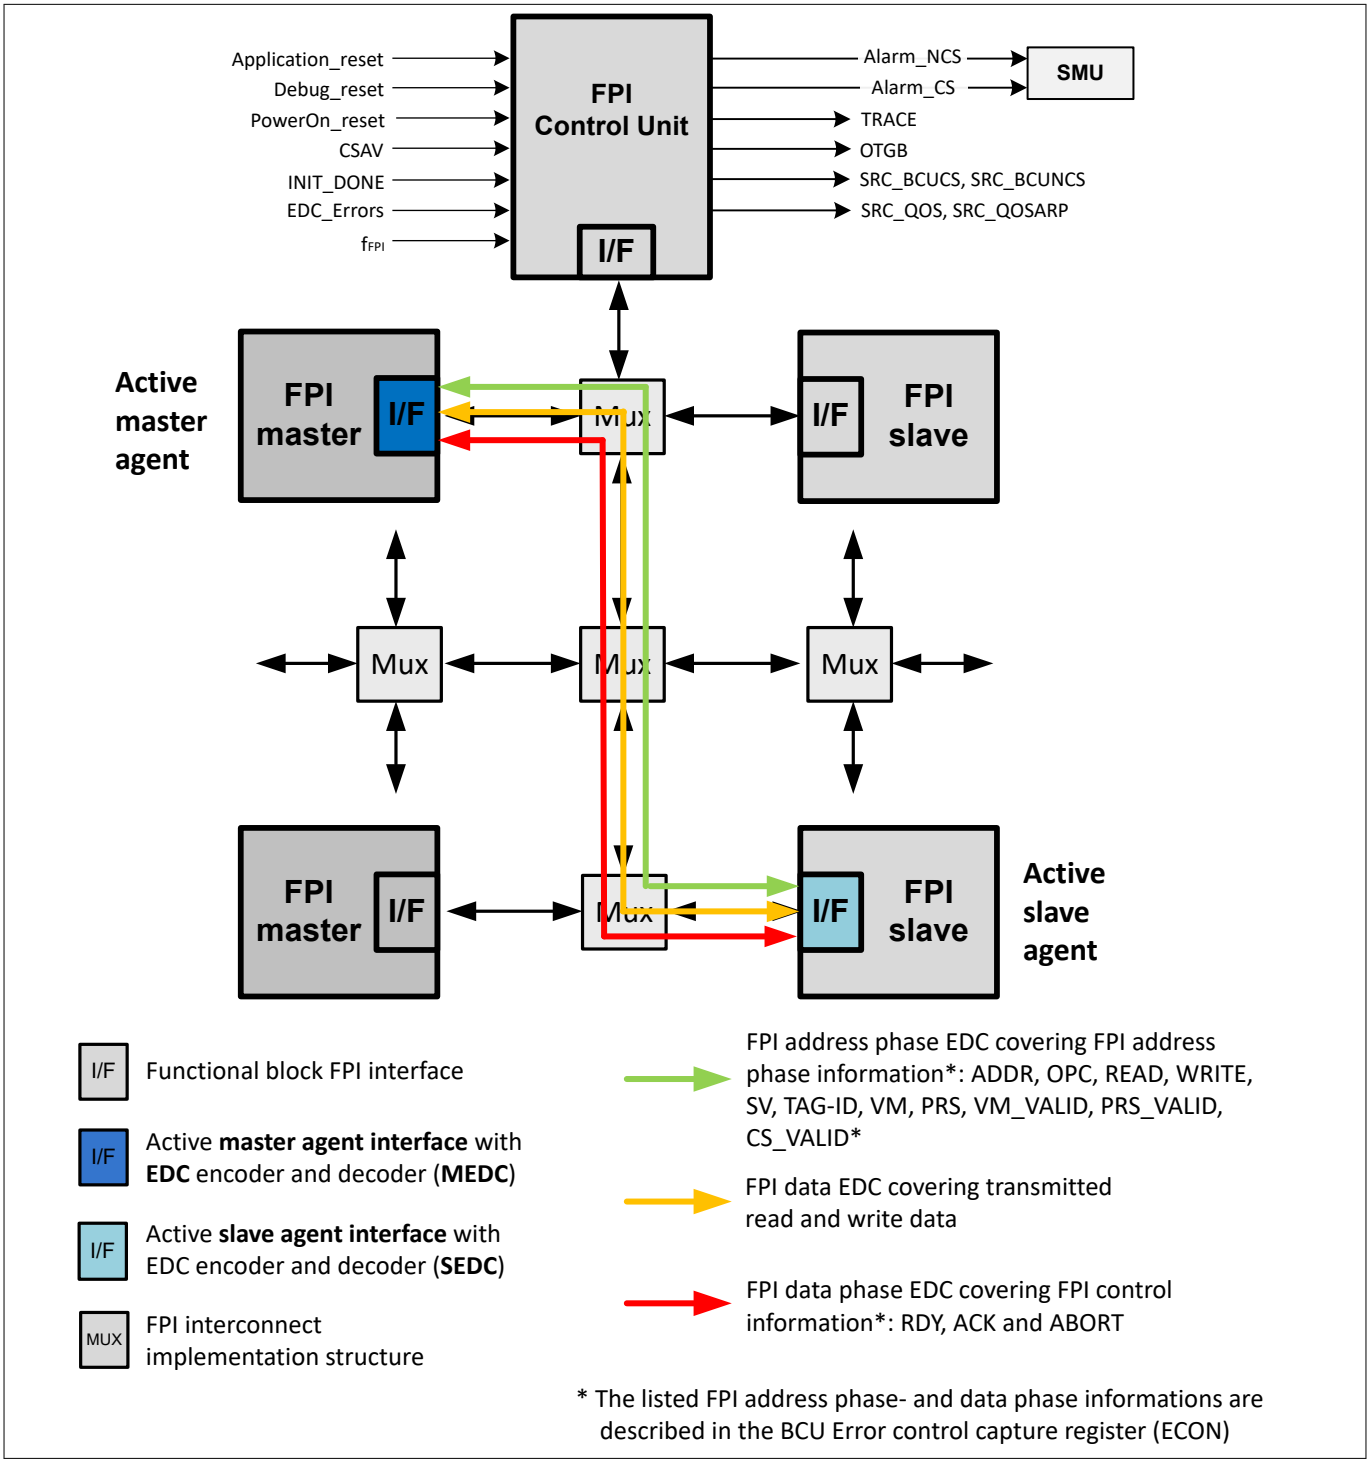

Figure 71 FPI block diagram

Functional blocks (FB) can be connected to an FPI interconnect through an FPI slave interface, also called a slave agent, and through FPI master interface that is also called the master agent. An FPI interconnect allows

the connected master agents to access the connected slave agents address range. In contrast to the SRI interconnect, which provides a cross-bar connection that supports parallel access between the connected master and slave agents, an FPI interconnect is a shared interconnect where all master and slave agents share the connections. Therefore an FPI interconnect is limited to only one connected master agent accessing one connected slave agent at a time.

There are two types of agents with which functional blocks are connected to an FPI interconnect:

- FPI master agent can request for access to the FPI interconnect, starting a FPI transaction when it is granted by the local BCU arbitration function
- FPI slave agent can only react and respond to FPI transactions initiated by FPI master agents in order to read or write internal registers of slave modules and for example memories

When an FPI master agent attempts to initiate a transaction on the FPI, it first signals a request for interconnect ownership to the local BCU. When the master agent is granted by the BCU it becomes the active master agent and starts the read or write transaction that consists of one or multiple address phase and data phase sequences. The slave agent addressed by the transaction address phase becomes the active FPI slave agent that responds with either the requested data transfer or with a transaction error.

FPI interconnect arbitration is performed by the BCU of the FPI. In case of a transaction error, the BCU signals an alarm to the Safety Management Unit (SMU) . Additionally it can generate an interrupt request and it can capture information about the transaction that lead to the transaction error.

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

Related information

TC4Dx SMU alarm mapping tables on page 7233

7.3 Functional description

This section gives an overview of the on-chip FPI interconnect which is necessary for understanding behavior and debug information. This chapter describes also the Bus Control Unit (BCU) modules including arbitration, scheduling, prioritizing, error conditions, and debugging support.

7.3.1 FPI transaction types

This section describes the FPI transaction types.

Single transfers

Single transfers are byte, half-word (16-bit) and word (32-bit) transactions that target any slave connected to the system interconnect.

Block transfers

The FPI also supports transactions with 64-, 128- and 256-bit transferred data bits. Since the FPI is a 32-bit (word) interconnect, these transactions are executed as block transfers that are also called burst transactions or multi beat transactions.

Block transfers operate in principle in the same way as single transfers do, but one address phase is followed by multiple data phases. Block transfers can be composed of 2-word, 4-word, or 8-word transfers.

***Note**: Block transfer that are not started with a block size aligned start address are executed in wrap around addressing mode. Linear addressing mode is not supported by the current FPI version .*

Block transfers can be initiated directly through for example DMA channel configuration but also indirectly through CPU instructions. For example by the following TriCore™ instructions: LD.D, LD.DA, LD.DD, MOV.D, ST.D, ST.DA, ST.DD.

Atomic read-modify-write transfers

Atomic read modify write (RMW) transfers are generated by some TriCore™ instructions like, for example, LDMST, ST.T and SWAP.W and are executed through the interconnect with two single transfers which is a read followed by a write transfer. The read and write transfers of an atomic transfer are always locked and cannot be interrupted by another FPI master agent. Atomic transfers are also referenced as read-modify-write transfers.

***Note**: See also chapter ´FPI error handling´ for available FPI transfer types.*

***Note**: For the complete list of TriCore™ instructions that are executed through the interconnect with read-modify-write please refer the TriCore™ architecture manual.*

7.3.2 Reaction of a busy slave agent

If an FPI slave agent is busy at an incoming FPI transaction request, it can delay the execution of the FPI transaction through two different methods: Retry and Wait states.

- Retry: If the slave agent answers a transaction with Retry, the current transaction without data transfer is finished and the FPI is free for other transactions. The requesting master agent that has received a retry must send another transaction request and repeat the transaction. Retry is used by an FPI2SRI bridge that is still occupied by a previous access and does not know how long it will be occupied. Other FPI slaves do not use retry during normal application flow
- Wait States: If a slave agent requires several clocks to deliver a read data or to accept a write data, it can use wait states to extend the data phase

7.3.3 FPI address alignment rules

FPI address generation is compliant with the following rules:

- Half-word transactions must have a half-word aligned address (A[0] = 0_B). Half-word accesses using byte lanes 1 and 2 to transfer data are illegal
- Word transactions must always have word-aligned addresses (A[1:0] = 00_B)
- Block transactions must always have word-aligned start address
- Block transactions are executed with wrap around addressing mode in case of a non-block aligned start address
- Read-Modify-Write transactions must always have a word aligned start address

7.3.4 FPI basic operations

This section describes some basic transactions on the FPI.

Each transaction consists of one or more data transfers. Each data transfer consists of 3 phases that are executed sequentially on the FPI interconnect:

1. Request and grant phase:
   - An FPI master agent attempts to perform a read or write transfer and requests for FPI access. If the FPI interconnect is available, it is granted in the same clock cycle by the Bus Control Unit (BCU)

2. Address phase:
   - After the request or grant phase, the master puts the address on the FPI interconnect and all connected FPI slave agents check whether they are addressed for the following data phase. The addressed slave agent becomes the active slave agent for this transaction
3. Data phase:
   - In the data phase, in case of a write data phase master puts write data on the FPI which is taken over by the active FPI slave agent, and in case of a read data phase the slave agent puts the read data on the FPI which is taken over at the end of the data phase by the active master agent

Up to three transfers can be executed parallel on the FPI interconnect with different transfer phases:

- The data phase of a first transfer
- The address phase of a second transfer, the next data phase belongs to this transfer
- The request/grant phase, at the end of which the BCU decides which master agent to assign next unless it is part of a burst or RMW transaction that has already started

On the FPI interconnect the three phases that are in parallel on the FPI interconnect are synchronized with the FPI_RDY signal. All three phases end together with the FPI clock cycle in which FPI_RDY=1. The FPI_RDY signal can be used by the active FPI slave agent to extend a data phase, and through this also the parallel address and request phase, with wait states by signaling FPI_RDY=0. If no slave agent is active FPI_RDY=1 is signaled by the FPI interconnect.

A maximum number of wait states, consecutive FPI clock cycles with FPI_RDY=0, before a transaction is terminated by the BCU with FPI Timeout can be configured in the BCU.

The figure below shows 3 fully pipelined transfers which means that there is no IDLE transfer in between these 3 transfers. Transfer 1 is granted. Transfers 2 and 3 show the conflict when two master agent requesting in parallel for FPI interconnect access and how the conflict is resolved. In the example, the FPI master agent of transfer 2 has a higher priority than the FPI master agent of transfer 3 and is therefore granted first.

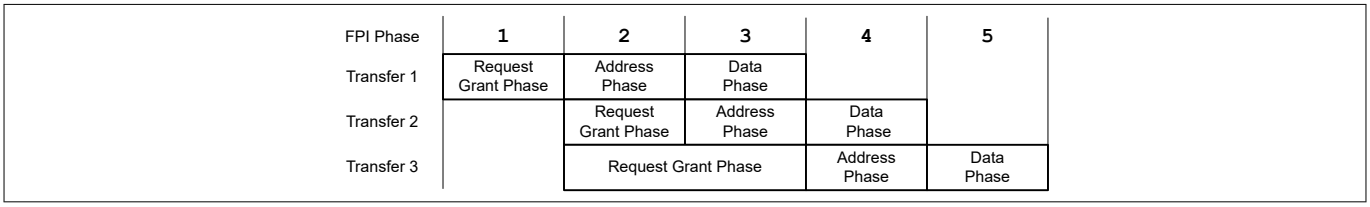

Figure 72 Basic FPI transactions

7.3.5 FPI interconnect arbitration

The arbitration unit of the BCU arbitrates among the master agents that are requesting for FPI access. The priority for each master agent connected to the FPI is defined in the BCU registers PRIOH and PRIOL. During arbitration, the FPI is granted to the requesting master agent with the highest priority. If no master agent request is pending, the FPI is granted to a default master.

The mapping of implemented master agents to the BCU registers PRIOH and PRIOL is described in the product specific BCU chapter.

The arbitration is implemented as a late arbitration scheme. This means that the decision which master agent will be granted next is always done at the last FPI clock cycle of a data phase, which is the cycle with FPI_RDY=1.

7.3.5.1 Configurable master agent priorities

Arbitration only becomes active if several master agents request interconnect access at the same time. If this happens the order of access is determined by the priority of the master agents or by the arbitration mechanisms.

- Each master agent connected to the FPI is assigned to a dedicated 4-bit priority bit field in the BCU registers PRIOH and PRIOL
- In addition, each PRIOH and PRIOL 4-bit field is assigned to an index in the range from 0 to 15:
  - PRIOL[3:0] → index 0 up to PRIOH[31:28] → index 15
  - The index is used to define the arbitration sequence within a round-robin group arbitration
- The value in a priority bit-field defines the related FPI master agent priority used for the priority driven FPI arbitration
- A lower priority number has a higher priority, 0 is the highest priority

7.3.5.2 Arbitration algorithms

The arbitration algorithm implemented in the BCU combines three layers of arbitration:

- Priority driven arbitration of master agents with a pending request with priority 0 - 15, 0 = highest priority
- Round-robin group arbitration mechanism on priority 4 covering all master agents assigned to priority 4
- Round-robin group arbitration mechanism on priority 8 covering all master agents assigned to priority 8
- Starvation Prevention mechanism that can increase master priorities during Starvation Prevention process

The default priority of each connected FPI master agent can be changed during run-time through its related bit-field in the registers PRIOH and PRIOL (see also section 'Changing master agent priorities' in this chapter).

Application software must be ensure that two FPI master agents do not have the same priority, with the exception of priority 8 and priority 4 which are the round-robin group priorities.

If more than one master agent is configured with the same priority but not with the round-robin group priorities 8 or 4, the arbitration will still work but the sequence how these master agents will be granted can not be guaranteed.

Priority driven arbitration (priority 0- priority 15)

The general arbitration algorithm is priority driven where priority 0 is the highest priority and 15 the lowest one. If multiple master agents are requesting, the master agent with the highest priority will win the next arbitration round (see also section 'Starvation prevention' in this chapter).

Round-robin groups (priority 4 and priority 8)

Priorities 8 and 4 are implemented as a round-robin groups. The two round-robin groups work independently from each other.

Example for round-robin group mechanism on priority 8, similar mechanism also applies to priority 4:

- The round-robin group algorithm arbitrates among all master agents configured with priority 8 that are requesting for interconnect access. The winner of the round-robin group arbitration will be treated as a normal master agent request with priority 8 within the priority driven arbitration algorithm
- Master agents assigned to priority 8 without pending request for interconnect access are not considered by the round robin mechanism and will not delay other master agents from being granted
- If only one master agent is mapped to a round-robin group priority, the master agent’s request will be treated as normal master agent request with priority 8 within the priority driven arbitration algorithm
- After the winner of a round-robin group has been granted, the requesting Master Agent configured on priority 8 with the next higher index number will be selected as the next winner of the round-robin group. If there is no requesting master agent with a higher index number in the round-robin group, the algorithm will start with the requesting master agent with the lowest index number in the round-robin group, going to the next higher index number and so on. The index numbers are defined in the registers PRIOH, PRIOL

Round-robin group control (round share mechanism)

Each round-robin group also provides a mechanism to prevent the master agents of the round-robin group in combination with master agents with a higher priority from excluding the master agents with low priority from arbitration for too long.

For this it can be configured per round-robin group after how many consecutive granted transactions in a round-robin group and from master agents with a higher priority one master agent request with low priority is granted.

This allows a fine granular adjustment to temporary interconnect overload situations to the application requirements. These are periods with a high master agent request density.

The round share mechanism of a round-robin group is disabled if the related register RRCTRL.RRx bit-field is configured with 0.

If not disabled, the Round Share mechanism of an round-robin group:

- Becomes active, starts to count, as soon as at least one master agent of the round-robin group or with a higher priority has a request pending AND at least one master agent with a lower priority has a request pending
- When active, it counts the consecutive granted transactions to the masters agents of the round-robin group and to master agents with higher priority
- Resets its grant counter if a master agent with lower priority than that of the round-robin group was granted
- Resets its grant counter if no master agent of the round-robin group or master agent with a higher priority has a request pending
- Allows a grant to a lower priority master agent when the configured number of successive granted transactions has been reached

In addition to the round share mechanism there is the starvation prevention mechanism that works independent of the round share mechanisms and provides a safety net for all non-granted master agents in a configured period of time.

Master agent priorities after reset

The default priority settings should be optimal for most applications. Where required, the arbitration setting can be adapted to the specific application needs (see also section 'Changing master agent priorities' in this chapter).

The master agent priorities are described in the device specific chapter, section BCU.

Changing master agent priorities

The FPI master agent priorities can be reconfigured at any time. The BCU arbitration mechanism always uses the current PRIOH and PRIOL configuration. This means that after a change in one of the PRIOH and PRIOL registers, the new master agent priorities take effect immediately and also affect the current pending master requests if more than one master agent requests access for the FPI.

Starvation prevention

Starvation prevention takes care that even requesting low priority master agents will be granted after a period, where the period length can be controlled by Bus control unit (BCU) control registers. Because of the priority driven arbitration algorithm, it is possible that a lower-priority master agent may never be granted if one or more higher-priority master agents continuously requesting for FPI access. To protect against starvation of lower-priority master agents, the starvation prevention mechanism of the BCU will detect such cases and momentarily raise the priority of the lower-priority requester to the highest priority (above all other priorities), thereby guaranteeing it access.

Starvation prevention employs a counter that is decremented with each clock cycle on the related FPI interconnect, for example on SPB with fSPB and CPB with fCPB. When the counter is counted down to zero it is always re-loaded with the starvation period value in the CON.SPC bit-field. When the counter is counted down

to zero, for each active master agent request a request flag is stored in the BCU. This flag is cleared automatically when a master agent is granted by the BCU.

When the next counter period is finished and not all request flags where cleared, a starvation event happened. These master agents related to the remaining request flags will now be set to the highest priority and will be granted in the order of their configured priority ranking.

If a master agent that is processing its transaction under starvation condition is retried by the addressed slave (means: slave was busy, transaction was not executed), its corresponding request flag is automatically set again.

Starvation protection is permanently enabled. The sample period of the counter is programmed through register bit-field CON.SPC. The configured value in the SPC bit-field must be larger than the number of master agents. Its reset value is FFF_H.

7.3.5.3 Default master mechanism

If no master agent is requesting for FPI access, the FPI master agent that was most recently granted will be granted as the default master. An exception is if the master agent that was most recently granted is now switched off or it is in Request delay mode. In this case, the BCU is the default master until another master has requested and was granted.

Any master agent can act as default master.

The BCU has no functional master agent interface and therefore has no request or grant signal. However, the BCU can act as the default master on the local interconnect. If the BCU acts as default master, it gives itself a default master grant internally that is not visible outside the BCU nor visible through the BCU error capture registers.

After a reset the BCU is the default master until a master agent is requesting for interconnect access.

A disabled master agent and a master agent in Request delay mode is not granted as default master. In this situation, the BCU becomes default master until a master agent is granted.

7.3.6 FPI error handling

When an FPI error occurs on an FPI interconnect, its BCU captures and stores information about the erroneous condition, signals an alarm to the SMU and generates an interrupt if enabled to do so. The FPI error conditions that force an error-capture are:

- Error acknowledge: A FPI transaction is terminated by the slave agent in a data phase with FPI error acknowledge. A slave agent may terminate a transaction with FPI Error acknowledge due to an access protection violation, access with an op-code not supported for this address or an access to a reserved system address that is not assigned to register or memory
- Access to a Reserved system address: No FPI slave agent responds to a transaction request
- Timeout: A slave does not respond to a transaction request within a certain time window. The number of interconnect clock cycles that can elapse until a FPI time-out is generated is defined by bit-field CON.TOUT

When a transaction causes an error, the address and data phase signals of the transaction causing the error can be captured by the BCU and traced through On chip multi tool support (OCMTS) if enabled for capturing and tracing.

Capturing and tracing of Cyber security real-time module (CSRM) transaction information (CS_VALID=1) is controlled by CSRM through the functional block Cyber security system control unit (CSCU). See also register CSSTAT.

- The Error Address Capture Register (EADD) stores the 32-bit FPI address information that has been captured during the erroneous FPI transaction

- The Error Data Capture Registers (EDAT) stores the 32-bit FPI data information that has been captured during the erroneous FPI transaction
- The Error Control Capture Register (ECON) stores status information of the error event

In case of an EDC error the BCU provides additional information in the ALSTAT registers to identify the connected FPI slave or master interface where the FPI EDC error was detected.

If more than one FPI transaction generates a error, only the first error is captured. After a error has been captured, the capture mechanism must be released again by software. The lock is removed by reading the register ECON which clears the ECON.ERRCNT bit-field.

***Note**: It is recommended to read in a debug session register ECON last as this removes the lock and a new error can already modify the content of the other two registers EDAT and EADD.*

If a write transaction from a master function that is not directly connected to an FPI instance causes an error on this FPI instance, for example a posted write transaction forwarded through an S2F bridge, the originating master is not informed about this error.

With each error-and error capture event,

- A service request can be generated if enabled and configured in the corresponding service request control register in the Interrupt Router function. In the interrupt router, the corresponding service request control registers are named SRC_<BCU>_NCS, SRC_<BCU>_CS where <BCU> is the placeholder for the respective BCU instance name: SBCU, CBCU, COMBCU, CSBCU, TBCU and RBCU
- An alarm is signaled to the SMU (Alarm_CS or Alarm_NCS)

7.3.6.1 Interpreting the BCU control register error information

Although the address and data values captured in registers EADD and EDAT, respectively, are self-explanatory, the captured FPI control information needs some more explanation.

Register ECON captures the state of the read (RDN), write (WRN), Supervisor Mode (SVM), acknowledge (ACK), ready (RDY), abort (ABT), timeout (TOUT), master identification lines (TAG, VM, PRS, VM_VALID, PRS_VALID), cyber security information (CS_VALID) and transaction operation code (OPC) lines of the FPI .

The SVM signal is set to 1 for an access in Supervisor Mode and set to 0 for an access in User Mode.

The timeout signal indicates when a slave agent has inserted more wait states than defined by BCU_TOUT in a data phase and the BCU has aborted the data phase with signaling TOUT=1.

An acknowledge code has to be driven by the selected slave agent during each data cycle of an access. These codes are listed below in table ´FPI acknowledge codes´.

Table 600 FPI acknowledge codes

Code (ACK)	Description
00_B	NSC: No special condition
01_B	Reserved
10_B	RTY: Retry. Slave can currently not respond to the access. Master agent must repeat the access later
11_B	ERR: Error, last data cycle is aborted

Transactions on the FPI are classified through a 4-bit operation code.

Table 601 FPI operation codes (OPC)

OPC	Description
0000_B	Single Byte Transfer (8-bit)

(table continues...)

Table 601 (continued) FPI operation codes (OPC)

OPC	Description
0001_B	Single Half-Word Transfer (16-bit)
0010_B	Single Word Transfer (32-bit)
0100_B	2-Word Block Transfer
0101_B	4-Word Block Transfer
0110_B	8-Word Block Transfer
1111	No operation
0011_B, 0111_B, 1000_B - 1110_B	Reserved

FPI error handling on page 1093

7.3.6.2 FPI error capture mechanism and BCU interrupts

The BCU provides two interfaces for observation and software debugging:

- A capture mechanism captures the first transaction with a fatal error and a trace port which sends trace information to the MCDS. Fatal error means that an intended transaction was not executed because it leads to an FPI Error, an FPI timeout or when no slave responding to an access. After a transaction information was captured, software can release the mechanism again
- A trace port which sends trace information to the MCDS

The visibility of CS related transactions through these interfaces is controlled by the CSRM through the CSAV signals. As long CSRM does not enable the capturing of CS related transactions through CSAV=Full or CSAV=Limited, only transactions with CS_VALID=0 can be captured in the BCU and traced through OCMTS.

The interfaces cover all relevant transaction information, including:

- Master agent grant signal status
- 32-bit address
- OP-code, Read and Write information
- TAG ID, VM, PRS
- Supervisor (SV) and Security (CS_VALID) information
- 32-bit data
- Slave agent acknowledge code
- FPI protocol control signals of the transactions address phase and data phase

CSRM control of the debug and trace interfaces:

The visibility of CS related transactions is controlled by CSRM tracing through a two bit enable signal (CSAV) driven from the CSRM block. The signal value decode is shown in the Table 602 table.

Table 602 CSAV Decode

Value	Meaning
0	No CSRM tracing (default reset value)
1	Limited CSRM tracing
2	Reserved - same behavior as 0
3	Full CSRM tracing

The definition of limited and full tracing for errored and non-errored transactions are shown in tables Table 603 and Table 604 .

Table 603 CSAV levels for the trace of the local FPI interconnect traffic

Level	Behavior for CS transactions
Full	Fully visible in the trace
Limited	Visible in the trace, but address and data are 0
No	Not visible in the trace

Table 604 CSAV levels for BCU error capturing on fatal transaction errors

Level	Behavior for CS transactions
Full	Transactions are captured
Limited	Transactions are not captured
No	Transactions are not captured

7.3.7 BCU interrupts

Each BCU provides multiple interrupts. The interrupts are signaled to the functional block Interrupt router (IR) where each interrupt is assigned to dedicated Service request control register in the interrupt router.

The names of the BCU related service request control registers in the IR for the BCU instance <BCU> :

- SRC_<BCU>CS: Transaction with CS_VALID = 1 that leads to an FPI error, FPI timeout or access to a reserved address
- SRC_<BCU>NCS: Transaction with CS_VALID = 0 that leads to an FPI error, FPI timeout or access to a reserved address
- SRC_<BCU>QOS: Interrupt is signaled whenever one or multiple of the QOSMx_STAT.MSB bits changes from 0 to 1. The QoS support is not implemented in all BCU instances
- SRC_QOSARPx; x=0-7: Interrupts signaled by a BCU with QoS ARP function whenever ARPx_CTRL.STAT bit changes from 0 to 1. The QOSARPx interrupt outputs from all BCUs and SRI interconnects with QoS observing function are bit-wise OR combined and the resulting interrupt trigger signals are mapped in the IR to SRC_QOSARPx, x=0-7. The QoS support is not implemented in all BCU instances

A BCU can be configured to generate interrupts for fatal errors of Secure (CS_VALID=1) and Non-Secure (CS_VALID=0) transaction on detection of an FPI error situation an FPI timeout situation or an FPI access to a reserved address.

***Note**: The product specific FPI chapters show the available FPI interconnects, the corresponding BCU control registers and the information which BCU is implemented with QoS functionality.*

Related information

BCU alarms to SMU on page 1096

7.3.8 BCU alarms to SMU

BCU alarm signals to SMU

Each instance of the FPI interconnect provides two alarm signals:

- Alarm_CS for an alarm event detected for a security related transaction with CS_VALID=1 in the transaction address phase
- Alarm_NCS for an alarm event related to a non security related transaction with CS_VALID=0 in the transaction address phase

On detection of a FPI transaction terminated with FPI error acknowledge or a FPI timeout on a security related transaction (CS_VALID = 1):

- Alarm_CS is signaled to the SMU_CS

On detection of a FPI transaction terminated with FPI error acknowledge or a FPI timeout on a non security related transaction (CS_VALID = 0):

- Alarm_NCS is signaled to the SMU_SAFEx

On detection of a FPI EDC error during a FPI transaction the CS_VALID signal can no longer be considered valid, safety related transaction is assumed:

- Alarm_NCS is signaled to the SMU_SAFEx

The alarm signals are covering the following three events:

- Alarm on detection of a FPI transaction finished with FPI error (e.g. access protection violation, access to reserved address)
- Alarm on detection of a FPI timeout situation
- Alarm on detection of a FPI EDC error

Each BCU enables the application software to test the EDC decoders of all connected FPI master and slave agents through the FPI Error Generation (FEGEN) register in the BCU. See also related information.

The Alarm_CS and Alarm_NCS signal paths to the SMU can be tested in different ways with access to an address related to the respective FPI instance. For example by an CPU access to reserved address that results in an FPI error and an Alarm_NCS and by a CPUcs access to reserved address that results in an FPI error and an Alarm_CS.

FPI error injection on page 1108

7.3.9 Interconnect performance measurement and analysis

Real-time measurement of the interconnect performance provides useful insights to system developers, architects, application developers.

The BCU provides a set of relevant events to the MCDS that can be used to measure different performance aspects of the local interconnect without any real-time effect on execution.

The performance events that can be measured are described in the table 'TS16_BCU,
BCU Performance Events' .

The forwarding of the BCU performance events is controlled by the OCS register. The signals are then forwarded to the MCDS module via the OTGB interface.

The performance measurement events can be used to measure basic parameters such as:

- Data Phase count. The counter is incremented on end of a data phases with NSC, ERR or RTY. NOP transactions not counted
- Local FPI clock cycles count. The counter is incremented with local FPI clock cycles
- Wait state cycle count. The counter is incremented on every wait state clock cycle
- Retry Phase count. The counter is incremented on every data phase ending with RTY
- Interconnect contention cycles. The counter is incremented on every clock cycle where x requests are pending in parallel to the actual transaction. Number of parallel requests X is configurable. A single request that is granted in a request phase is not counted
- Default master data phases. The counter is incremented with any data phase of transaction in default master mode. NOP transactions not counted

- Starvation prevention active. The counter is incremented with every interconnect clock cycle where starvation prevention is active
- Starvation prevention transaction. Can be used to count the number of transactions granted by starvation prevention mechanism

7.3.9.1 Typical performance event usage

The performance parameters can be mapped in the Multi Core Debug Support (MCDS) module to its counter functions.

Typically two parameters are always counted for base line measurement:

- Local FPI clock cycle count (CCNT)
- Data Phase count (TCNT)

Additional parameters can be counted to derive the desired performance values, for example:

- Interconnect load
- Transaction rate
- Wait states per transaction
- Transaction retry rate
- Interconnect contention rate
- Starvation prevention active rate

7.3.9.2 BCU performance parameters

The following list describes the local FPI interconnect events that can be mapped to counters in MCDS module. Before they can be used in MCDS, they must be activated using the OCS.OTGM function. The list also describes how the event affects a counter selected in the MCDS.

Details of the MCDS counter functions, for example counter width, counter overflow, linkage of counters, are described in the OCMTS chapter.

Table 605 TS16_BCU, BCU performance events

Bit	Event function	Description
0	Data_phase_count (DPC)	Counter is incremented whenever a transaction data phase ends with NSC, ERR or RTY. NOP transactions not counted. Aborted Data Phases are not counted
1	Waits_state_count (WSC)	Counter is incremented with any local FPI clock cycle where a transaction is delayed by wait state clock cycle
2	Transaction_count (TC)	Counter is incremented with any transaction. NOP transactions not counted
3	Transaction_retry_count (TRC)	Counter is incremented when a data phase is terminated with RTY by a slave agent which means that the slave agent was busy, transaction not executed

(table continues...)

Table 605 (continued) TS16_BCU, BCU performance events

Bit	Event function	Description
4	Transaction_default_master_count (TDMC)	Counter is incremented when a transaction is started in Default Master mode. NOP transactions not counted
5	Transaction_starvation_prevention_count (TSPC)	Counter is incremented when a transaction is granted by the starvation prevention mechanism
6	Transaction_aborted_count (TAC)	Counter is incremented when a transaction is aborted by master agent
7	Transaction_Error_Count (TEC)	Counter is incremented when a transaction is terminated with ERR
8	Interconnect_contention_cycles (ICC)	Counter is incremented on every clock cycle where >= x requests are pending in parallel to the actual transaction. Number of parallel requests x is configurable through register PSELECT.PMAR. A single request that is granted in a request phase is not counted
9	Starvation_prevention_active_cycles (SPAC)	Counter is incremented with every local FPI clock cycle at which the starvation prevention mechanism is active which means that one or more transactions are pending for grant by the starvation prevention mechanism
10	QOS_event_cycles (QEC)	Counter is incremented whenever one of the QOSMx_CTRL.MSB bits changes from 0 to 1. This means that master agent x is or was in Request Delay Mode because it has consumed its assigned FPI clock cycles in a QoS time interval.
11	Unused_FPI_cycles (UFC)	Counter is incremented with any local FPI clock cycle in which the local FPI interconnect is not used for a transfer.
12 - 13	Reserved	Counter is not counting.
14	PSELECT	The function of this bit will be defined by the register PSELECT.PSEL allows to map an event from this list to this bit
15	Local_FPI_clock (LFC)	This signal is active for one f_{TPB} clock cycle per local FPI clock cycle. It is used by the tool to determine the clock ratio between local FPI and MCDS to evaluate the other TS16_BCU event information.

7.3.10 QoS master agent interconnect usage control

The QoS control mechanism enables the application software to assign a master agent a number of interconnect clock cycles that it can consume in a QoS interval before its activities on the interconnect are until the end of the QoS interval. The way in which the master agent is is also configurableby the application software.

- For each FPI interconnect a QoS time interval (QOSICNT.QOSINT) can be defined with the QOSICTRL.QOSINT register in multiples of 16 local interconnect clock cycles. The time interval counter (QOSISTAT.QOSICNT) width is 20-bit
- For each connected master agent a master interconnect cycle count can be defined with the QOSMx_CTRL.MICC register in multiples of 16 local FPI clock cycles. The QOSMx_CTRL.MICC is used to define the number of FPI clock cycles a master agent can consume on the interconnect within a QoS time interval before the request delay mechanism becomes active for this master agent until the end of the QoS time interval. The master cycle counter (QOSMx_STAT.MCNT) width is 19-bit
- For each connected master agent a master request delay (QOSMx_CTRL.MRD) can be defined with the QOSMx_CTRL.MRD register (11-bit). The MRD defines the number of local clocks by which a request of the master is delayed in request delay mode before it is considered in the arbitration
- If the QoS control mechanism is available in a FPI interconnect instance, it can be activated there separately for each connected master agent
- Master agent transactions are considered independently of the transactions CS_VALID status. This means that CSAV has no influence here
- The FPI master agent of a SRI2FPI bridge is treated like any other FPI master agent. An FPI2SRI does not have its own transaction ID but transparently forwards the transaction ID of accesses through the bridge

QoS time interval

A QoS time interval starts as soon as QOSICTRL.QOSEN is enabled.

At the start of a QoS time interval, QOSISTAT.QOSICNT is initialized with the value from QOS_ICTRL.QOSINT.

As long as the QOSICTRL.QOSEN is set QoS time intervals with the configured duration (QOSICTRL.QOSINT) are generated.

At the start of a QoS time interval, for each master agent for which the QoS control feature is enabled through QOSMx_STAT.CTRL.MEN=1_B,

- QOSMx_STAT.MSTAT is set to0_B which means ´No request delay mode´
- QOSMx_CTRL.MICC register value is loaded into QOSMx_STAT.MCNT

***Note**: The assignment of the connected master agents to an index ´x´ is defined in the product-specific registers PRIOH, PRIOL*

Measuring the master agent FPI cycle consumption during a QoS interval

During a QoS time interval the mechanism counts for each connected master agent for which the QoS usage control function is enabled, the number of data phase FPI clock cycles the master agent uses the local FPI interconnect within the time interval. This includes also the data phase wait state clock cycles.

Usage here means that the FPI interconnect cannot be used by other master agents for data transmission. A master agent in the ´No request delay mode (QOSMx_STAT.MSTAT=0 while QOSMx_STAT.MCNT!=0) has not consumed the number of interconnect clock cycles assigned to it. Its requests for FPI access are taken into account without delay by the arbitration.

Master in request delay mode

As soon as a master agent has consumed its allocated interconnect cycles within the current QoS time interval, which means QOSISTAT.QOSICNT!=0_B and QOSMx_STAT.MCNT=0_B and QOSMx_STAT.MSTAT=0_B, the hardware sets QOSMx_STAT.MSTAT=1_B and the master agent is arbitrated in request delay mode until the end of the current QoS time interval (QOSISTAT.QOSICNT=0_B).

In request delay mode (QOSMx_STAT.MSTAT=1_B), each request of the master for interconnect access is delayed by the number of clocks configured in the master request delay register (QOSMx_CTRL.MRD) before the request is forwarded to the arbiter and there arbitrated according to configured master agents priority. This reduces the number of conflicts on the FPI interconnect of other master agents with the master agent in request delay

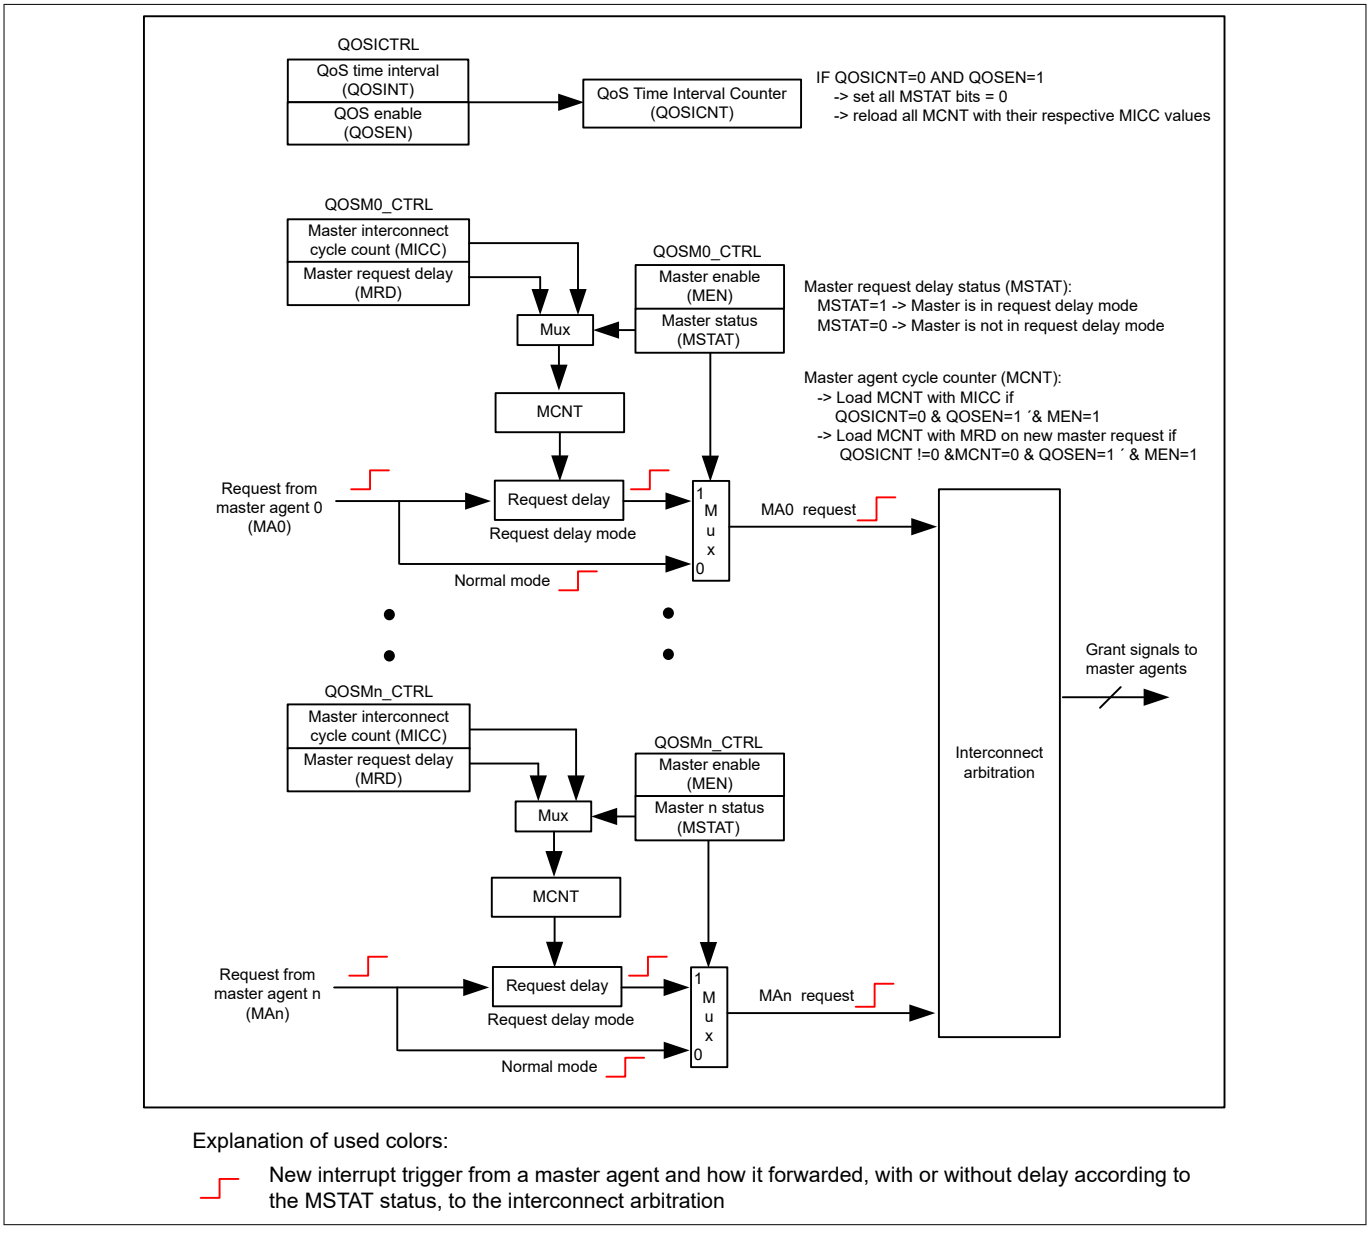
mode at the interconnect. Nevertheless, a reduced access rate at the interconnect can still be enabled for the master in request delay mode.

End of QoS interval

At the end of an QoS time interval (QOSISTAT.QOSICNT=0_B),

- all MSTAT bits are cleared (QOSMx_STAT.MSTAT=0_B)
- all master agents QOSMx_STAT.MCNT counters are re-loaded with the respective Master interconnect cycle count (QOSMx_CTRL.MICC) value
- the QoS time interval counter (QOSISTAT.QOSICNT) is loaded with the QOSICTRL.QOSINT value
- if QOSMx_STAT.MSTAT is set to 1_B at the end of the time interval, QOSMx_STAT.MSB is set to 1_B

A QoS control interrupt is signaled to the related SRC_BCUQOS service request node in the IR whenever a QOSMx_STAT.MSB bit changes from 0 to 1



Explanation of used colors:

New interrupt trigger from a master agent and how it forwarded, with or without delay according to the MSTAT status, to the interconnect arbitration

Figure 73 QoS: Structure of the request delay mechanism control registers

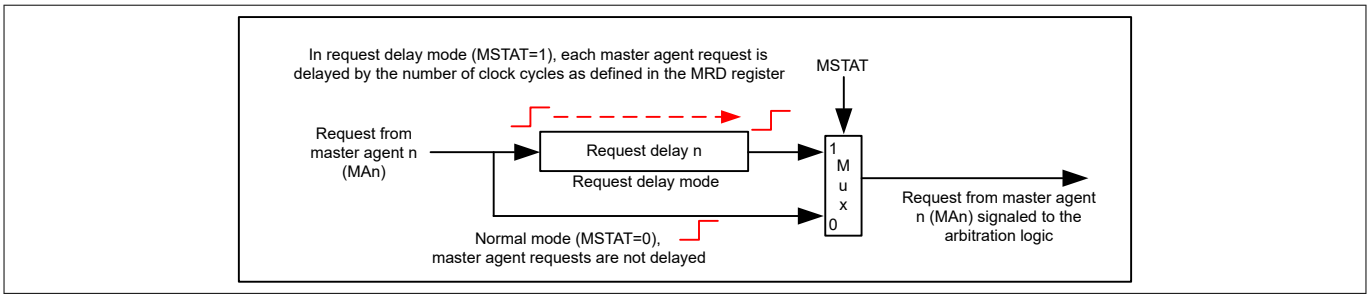


Figure 74 QoS: Structure of the request delay mode

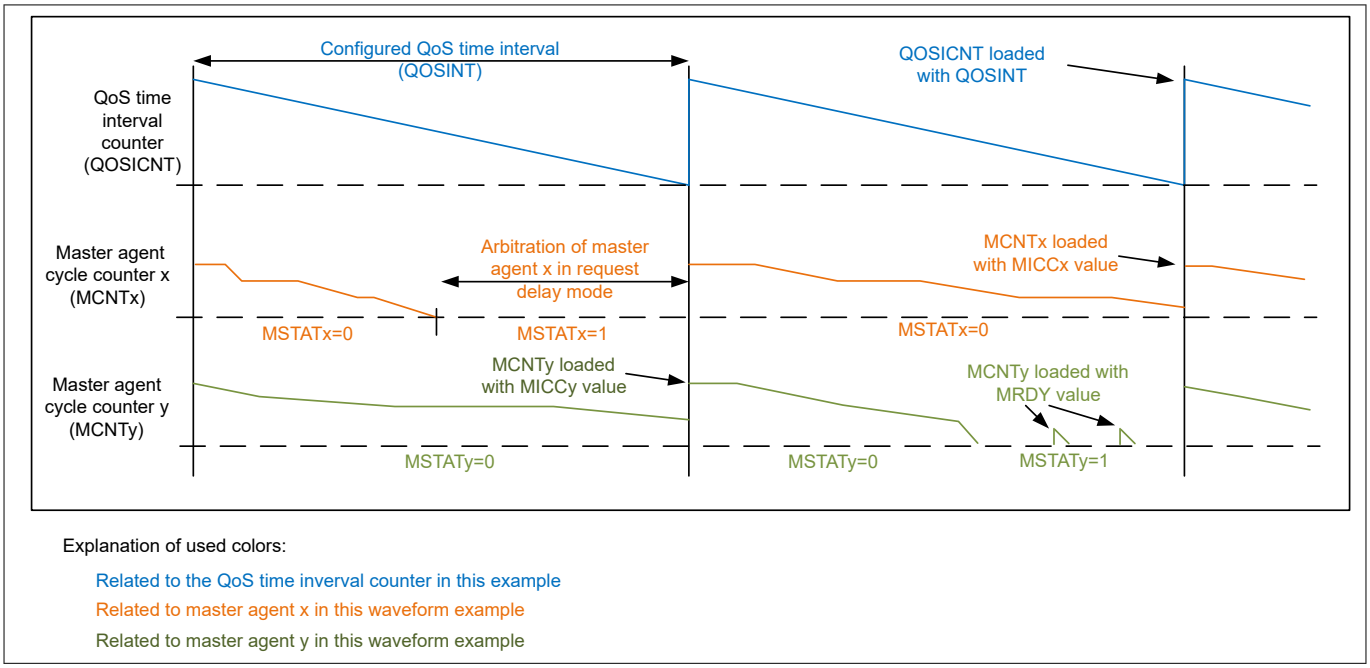

Figure 75 QoS: Temporal description of the request delay mechanism

7.3.11 Quality of Service application interconnect usage observation

The QoS observation mechanism enables the system software to monitor the consumed interconnect cycles at key resources for up to 8 application partitions within a QoS time interval.

The application partitions can be defined by assigning master agent functions through its TAG-ID and PRS encoding to the application resource partition functions (ARPx).

For each ARP function:

- The system can define the usage threshold for it
- The interconnect cycles consumed by the assigned master agent functions within a QoS interval are logged
- If the consumed cycles within a QoS time interval reaches the defined usage threshold, an interrupt is signaled at the end of the interval for this ARP function, the cycles consumed until the end of the interval is stored in a capture register and the capture register is locked

***Note**: Setting the threshold value to 0 is considered illegal and should be avoided.*

QoS time interval

A QoS time interval starts as soon as QOS_ICTRL.QOSEN is enabled. At the start of a QoS time interval, QOS_ICNT.QOSICNT is initialized with the value from QOS_ICTRL.QOSINT and partition cycle counter registers

are cleared and set to 0. As long as the QOS_ICTRL.QOSEN is set -QoS time intervals with the configured duration (QOS_ICTRL.QOSINT) are generated.

Measuring the cycle consumption during a QoS interval

During a QoS time interval each ARP mechanism counts for the master agent function IDs assigned to the ARP function the number of clocks the master agents occupies the observed resource within the time interval by counting the number of data phase clock cycles.

At the FPI the observed shared resource is the local FPI interconnect, at the SRI it is the SRI respective slave agent to which the ARP function belongs.

Interconnect usage includes the data phase along with wait states, where ongoing activity from a master prevents other masters from using the resource.

***Note**: The interconnect usage of CS-related transactions (with SM= 1) is only taken into account if CSAV = full or CSAV=limited.*

End of QoS interval

At the end of a QoS Interval (QOSICNT=0), the cycles consumed by the assigned master agent functions is copied into the Partition cycle count capture register of the respective ARP. For each ARP function where the interconnect cycles consumed by the assigned master agent functions is above the value configured in its Partition threshold register, an interrupt is signaled and the Partition cycle count capture register is locked after update.

The value of the locked partition cycle counter capture register is then not updated by the hardware until it is unlocked by software.

7.3.12 FPI integrity support

All transactions through the FPI interconnect are protected with an error detection mechanism (EDC). The mechanism is defined and implemented in order to detect errors on the signaled information in between active FPI master and slave agents during a transaction for example:

- Transaction address phase errors
- Transaction data phase errors
- Errors in the transmitted Data
- Situations where no slave agent, the wrong slave agent or multiple slave agents respond to a transaction
- Situations where multiple master agents are initiating transactions in parallel
- Situations where a granted master agent is not initiating a transaction

- Active master agent: master agent that initiates a transaction
- Active slave agent: slave agent that is selected in the Address Phase

The FPI EDC is distributed. Each master and slave agent performs the EDC check independently and signals a detected error to the interconnect fabric. The fabric can only forward one detected error per clock pulse to the BCU. If more than one error is signaled by the master and slave agents in a clock cycle, only the ALCTRL.PALOV bit is set. This scenario does not affect errors in address and data phases. However, it can be generated by errors in some FPI control signals.

The FPI implementation provides at any time the FPI address, data and control signals are driven by exactly one master agent or slave agent as required by the FPI specification. The active FPI slave and master agents drive the signals with its output enable signals. For the groups of the respective output enable signals, the BCU checks whether there are no or several active output enable signals at any time, reports this as an alarm and sets the corresponding ALSTAT register bits. This is done permanently by the BCU in parallel to the master and slave agents EDC checks. On detection of such an event (no or multiple output enables active), the related bits are set in the ALSTAT3 register:

- A_EN, no or multiple FPI address phase output enables active, mapped to ALSTAT3.AL0
- ABORT_EN, no or multiple FPI abort output enables active, mapped to ALSTAT3.AL1
- ACK_EN, no or multiple FPI acknowledge and FPI RDY output enables active, mapped to ALSTAT3.AL2
- D_EN, no or multiple FPI data phase output enables active, mapped to ALSTAT3.AL3

On detection of an FPI EDC error the Bus Control Unit (BCU) signals an Alarm_NCS to the functional block Safety management unit (SMU). The BCU ALSTAT registers provide detailed information about which FPI master or slave agent detected the EDC error.

The implemented solution ensures that only relevant errors will generate an alarm.

This includes:

- The interconnect signals from the active master agent through the interconnect
- The interconnect signals from the active slave through the interconnect
- General control signals during a transaction to detect erroneous active slave and master agent interfaces
- FPI_RDY = 1 is used as qualifier for valid Data Phase and Address Phase ECC information

***Note**:* *In this implementation, the FPI integrity support only offers error detection. Error correction codes (ECC) are used for extended error detection but not for error correction.*

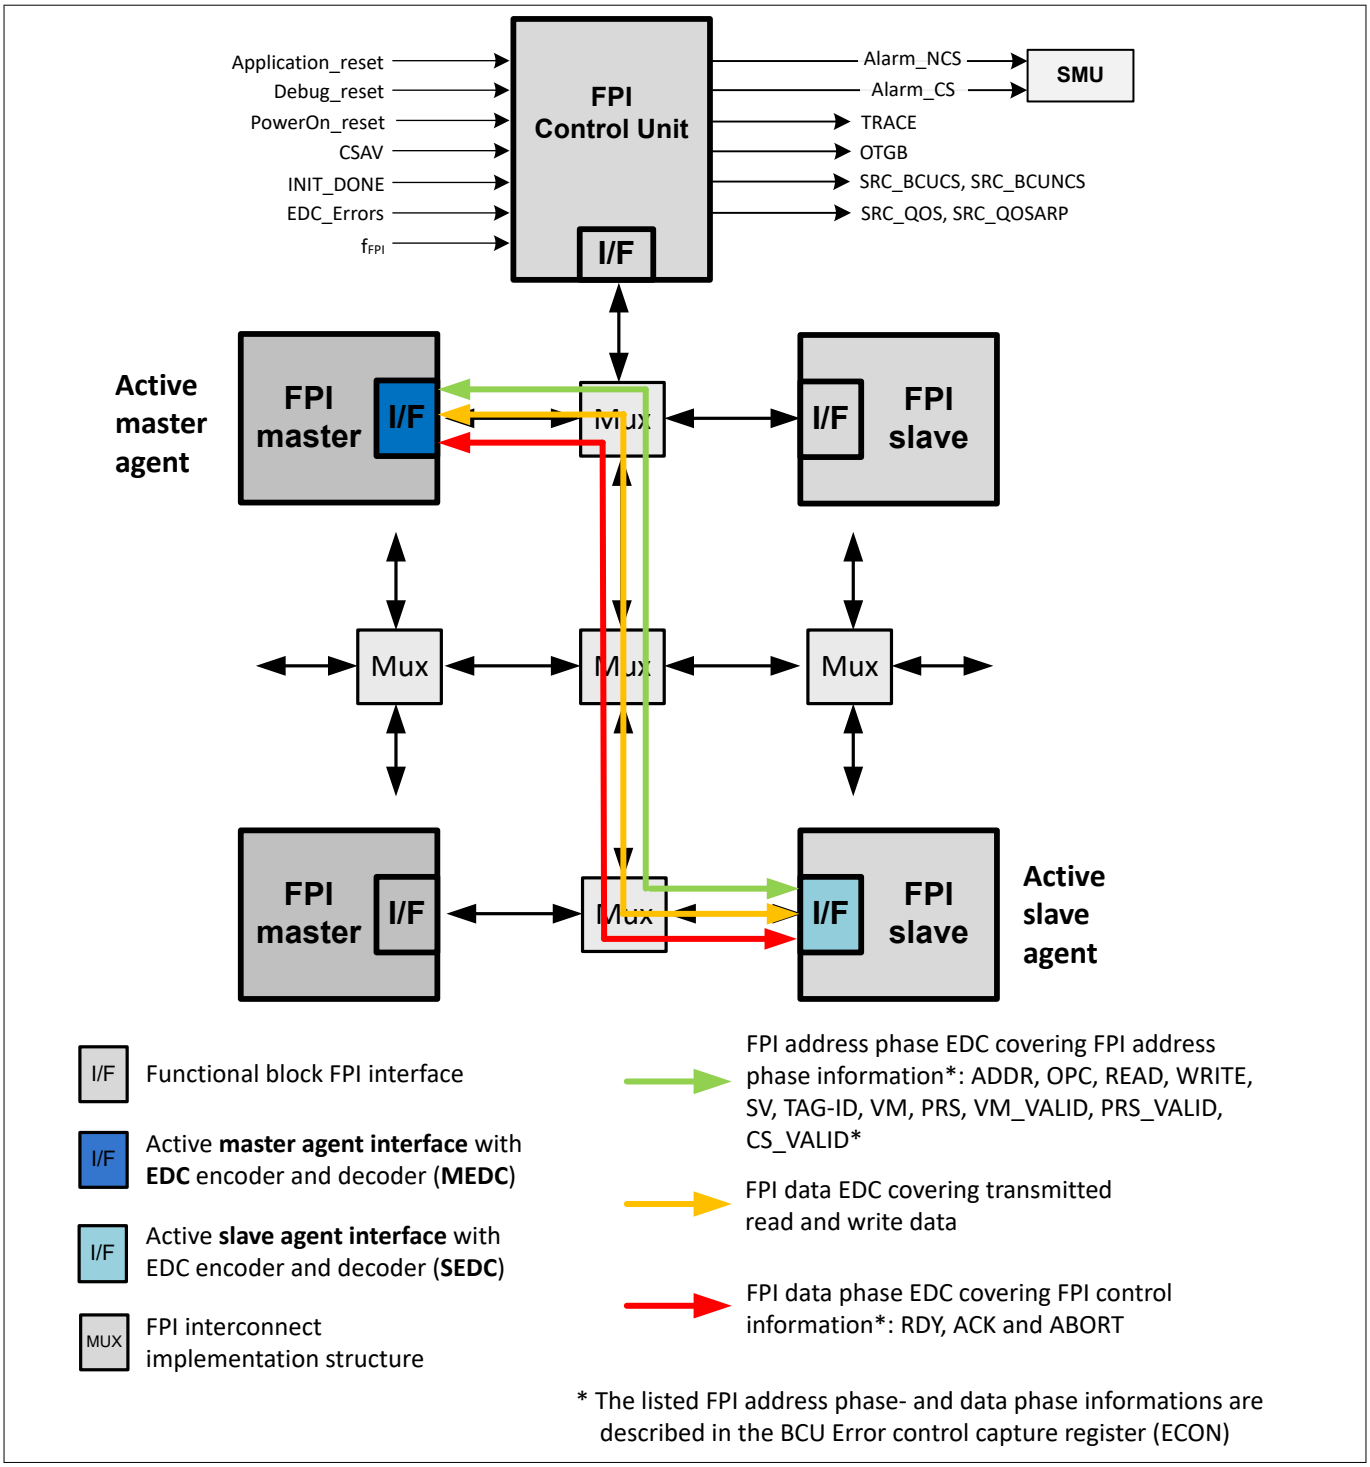

Figure 79 FPI EDC: Protection of active master agent to active slave data path through interconnect fabric

7.3.12.1 Safety support

BCU alarm and interrupts

Each FPI interconnect instances is implemented with one dedicated BCU. Each BCU provides:

- Two alarm signals ALARM_CS and ALARM_NCS to the functional block SMU

- Two interrupt signals SRC_CS and SRC_NCS to the functional block IR
- Additional 9 interrupt signals if the BCU is implemented with QoS support (SRC_QOS and SRC_QOSARP[7:0]). Each BCU with QoS support has a dedicated SRC_QOS service request node in the IR while the SRC_QOSARP[7:0] interrupts are combined with all other BCUs and SRI SCIs SRC_QOSARP[7:0] signals and mapped to one set of SRC_QOSARP[7:0] service request nodes in the IR

Capturing of FPI transaction error information

On detection of a FPI error and FPI timeout the BCU signals an alarm to the SMU. See chapter ´FPI error handling´.

FPI starvation prevention

The FPI arbitration algorithm in the BCU provides a starvation prevention mechanism. This feature of the BCU ensures that even requesting low priority master agents will be granted after a period, where the period length is defined through BCU control registers. See chapter ´Arbitration algorithmss´.

The starvation prevention is permanently enabled.

FPI Timeout

Each BCU provides a FPI timeout detection mechanism for its FPI interconnect instance. This mechanism detects if a slave agent does not finish a data phase within a configurable time window. The timeout mechanism is also implemented in the FPI protocol. A dedicated FPI TIMEOUT protocol signal forces the active master and active slave agent to release the FPI interconnect if the BCU has detected a timeout situation. On detection of timeout situation the BCU signals an alarm to the SMU (Alarm_NCS or Alarm_CS).

Register access protection

The BCU control registers are protected by the register access protection. On detection of an access protection violation the BCU terminates the transaction with FPI error and signals an Alarm_NCS or Alarm_CS to the SMU.

Access to reserved FPI address (default slave mechanism)

As long no slave agent is active, the FPI interconnect fabric implementation shows the following FPI slave agent control and EDC information:

- FPI_RDY = 1
- FPI_ACK = 11. This is equal to a slave FPI error acknowledge
- FPI_DP_ECC = 111. This is an invalid FPI EDC for the above RDY and ACK default information on the interconnect

This means that with these default values the following error situations can trigger an EDC alarm for the transaction of the active master agent although no EDC relevant signal error has occurred:

- The master agent access a reserved address where no slave agent becomes active. As a result the BCU signals alarm to the SMU
- The addressed FPI slave does not become active. As a result the BCU signals alarm to the SMU
- A master agent does not react to the default master grant and is not driving the data phase signals during the default master data phase while the next requesting and granted master agent looks at FPI_RDY to identify the start and end of its address phase. This means that an EDC error in a default master phase is only signaled as an alarm if it affects a following real transaction. This situation can result in FPI EDC alarms from the next transaction active master agent and from the active slave interface to BCU, where the BCU signals an Alarm_CS or Alarm_NCS to the SMU

In these cases two errors are displayed by the BCU: a FPI error acknowledge with the captured data and the EDC alarm in the respective ALSTAT register.

7.3.12.2 FPI EDC overview

The FPI EDC covers the FPI address, FPI data and control signals from a active FPI master agent output to the active FPI slave agent input during a transaction.

The FPI EDC is implemented as end to end protection in between the master agents and the slave agents connected to one FPI instance. The FPI EDC encoder and decoder functions are implemented in the master and slave agents:

- A Master EDC encoder and decoder module (MEDM) is implemented in each master agent
- A Slave EDC encoder decoder module (SEDM) is implemented in each slave agent

The active master agent and slave agent perform an EDC check of the received transaction information at the relevant times of the address phases and data phases of the transaction.

On detection of EDC error the master agent or slave agent signals an EDC alarm to the local BCU.

Each FPI interconnect and the related local Interconnect control unit (BCU) includes:

- A mechanism to inject EDC errors and to localize detected errors
- A mechanism to detect error situations where more than master agent or more than one slave agent becomes active at a time at the same FPI interconnect
- A mechanism to detect EDC error situations where a granted FPI master agent does not become active

***Note**: The FPI EDC is not working in the first 4 FPI clock cycles after a reset of the FPI interconnect.*
