0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														PB	INTX
r														rh	rw

Field	Bits	Type	Description
INTX	0	rw	**INTX interrupt** When this bit goes from low to high, the controller generates an Assert_INTx Message. When it goes from high to low, the controller generates a Deassert_INTx Message. The Interrupt Pin register for the corresponding function determines which INTx Message the controller generates (INTA, INTB, INTC, or INTD). Legacy and native PCIe devices capable of generating an interrupt must support both Assert_INTx/ Deassert_INTx and MSI or MSI-X.

(table continues...)

(continued)

Field	Bits	Type	Description
PB	1	rh	**Pending status of INTx interrupt request** Indicates if an INTx interrupt request is pending and the message is not yet sent. 1 means pending and 0 means not pending. 0_B No interrupt request pending 1_B Interrupt pending
0	31:2	r	**Reserved** Read as 0; should be written with 0.

19.4.2.44 Trigger status

After the decoding of the 5 bits, 32 interrupt requests are passed to the Bit control block that consist of three different registers namely EN, STAT and CLR. The Bit control block decides which interrupt is masked in the 32, indicates the current interrupt status and clears the interrupts after service. The above three registers are designed for these functionalities respectively. The 32 interrupt requests will then merged into 8 interrupts that will be handed over to IR and software interrupts are then triggered.

INT_TRIGSTAT Offset address: 0000358_H

Trigger status Kernel Reset value: $0000\ 0000_H$

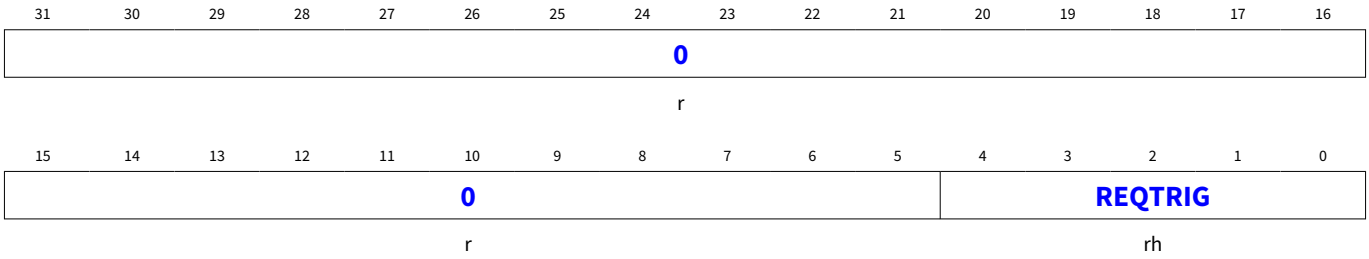
19.4.2.47 Receive incoming interrupt request, EP only.

INT_REQTRIG Offset address: 0000364_H

Receive incoming interrupt request, EP only. Kernel Reset value: $0000\ 0000_H$

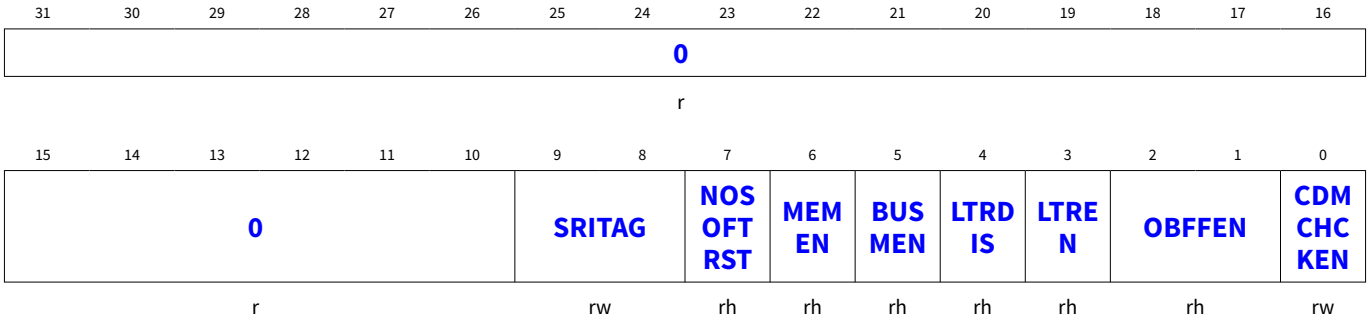


Field	Bits	Type	Description
REQTRIG	4:0	rh	**Receive incoming interrupt request** This field can only be written from wire. The received value is parsed as 32 interrupt requests.
0	31:5	r	**Reserved** Read as 0; should be written with 0.

19.4.2.48 Configuration information

CFG_INFO Offset address: 0000368_H

Configuration information Kernel Reset value: $0000\ 0080_H$



Field	Bits	Type	Description
CDMCHCKEN	0	rw	**Signal to enter test mode in the Register Checking Logic.** Asserted to enter test mode in the Register Checking Logic and disable writes to shadow CDM registers. Allows a value to be written to CDM registers to compare against the previous value in shadow CDM registers. If the value written to CDM is different to the value held in shadow CDM registers, comparison error is generated when the address is checked, indicating the Register Content Check function is working correctly. Note: In normal operation mode this bit should be driven to 0.
OBFFEN	2:1	rh	**The OBFF Enable field of the Device Control 2 register of function 0** Indicates The OBFF Enable field of the Device Control 2 register of function 0.

(table continues...)

(continued)

Field	Bits	Type	Description
LTREN	3	rh	**The LTR Mechanism Enable field of the Device Control 2 register of function 0.** Indicates the LTR Mechanism Enable field of the Device Control 2 register of function 0.
LTRDIS	4	rh	**Disable the autonomous generation of LTR clear message.**
BUSMEN	5	rh	**The state of the bus master enable bit in the PCI-compatible Command register.** Indicates the state of the bus master enable bit in the PCI-compatible Command register.
MEMEN	6	rh	**The state of the Memory Space Enable bit in the PCI-compatible** Indicates the state of the Memory Space Enable bit in the PCI-compatible Command register.
NOSOFTRST	7	rh	**No Soft Reset bit** This is the value of the No Soft Reset bit in the Power Management Control and Status Register. When set, you should not reset any controller registers when transitioning from D3hot to D0.
SRITAG	9:8	rw	**Selection of the VM or the PRS on the SRI** This bit selects which SRI tag (the VM or the PRS) is used to indicate the DMA index number, when an SRI bus transaction is initiated by the DMA. 00_B No VM/PRS tag used 01_B The VM tag is used in the SRI transaction 10_B The PRS tag is used in the SRI transaction 11_B Reserved, no VM/PRS tag used
0	31:10	r	**Reserved** Read as 0; should be written with 0.

19.4.2.49 Bus/device number

CFG_BUSNUM Offset address: $000036C_H$

Bus/device number Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SECBUSNUM			DEVNUM					PBUSNUM							
rh			rh					rh							

Field	Bits	Type	Description
PBUSNUM	7:0	rh	**The primary bus number assigned to the function.**
DEVNUM	12:8	rh	**The device number assigned to the function.**

(table continues...)

(continued)

Field	Bits	Type	Description
SECBUSNUM	20:13	rh	**Configured Secondary Bus Number.** The secondary bus number assigned to the device. When the host software detects the upstream switch port, it assigns a secondary bus number. This bus number is then used in configuration requests to detect the downstream ports. The switch controller must see this so that it can route configuration requests.
SUBBUSNUM	28:21	rh	**Configured Subordinate Bus Number.** When the switch controller receives a configuration request from the upstream port, it must see the secondary and subordinate bus number fields from the downstream ports to route the request.
0	31:29	r	**Reserved** Read as 0; should be written with 0.

19.4.2.50 Select device/port type

LNK_DVCTYP Offset address: 0000370_H

Select device/port type PowerOn Reset value: $0000\ 0000_H$

0											PWD	TYP			
r											rh	rw			

Field	Bits	Type	Description
TYP	3:0	rw	**Device/port type** Indicates the specific type of this PCI Express function. It is also used to set the 'Device/Port Type' field of the 'PCI Express Capabilities Register'. The controller uses this input to determine the operating mode of the controller at run time. Encodings except for the below ones are not supported. 0_H PCIe endpoint 4_H PCIe root complex
PWD	4	rh	**Power down status of the PCIe controller** Indicate the power-down status of the PCIe controler. The power-down status can be triggered by PERST# reset, SW kernal reset, the hot reset and link reset. The S2A bridge and the SPB slave interface will refuse to accept new bus request when this bit is asserted.
0	31:5	r	**Reserved** Read as 0; should be written with 0.

19.4.2.51 Indicate link status

LNK_STAT Offset address: 0000374_H

Indicate link status Kernel Reset value: $0000\ 0004_H$

r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0									PERSTINT	EQINT	BWINT	LINKINT	LINKRQRST	Res	LINKUP
r									rh	rh	rh	rh	rh	r	rh

Field	Bits	Type	Description
LINKUP	0	rh	**PHY Link up/down indicator** 0_B Link is down 1_B Link is up
LINKRQRST	2	rh	**Reset request** Reset request because the link has gone down or the controller received a hot-reset request. A low level indicates that the controller is requesting external logic to reset the controller because the PHY link is down. The link reset request is delayed until all pending bus transfers have completed.
LINKINT	3	rh	**Link Autonomous Bandwidth Interrupt. The interrupt can be triggered when the LNK_INTEN.LINKINTEN is asserted.** indicate that the Link Autonomous Bandwidth Status bit has been set. This bit is asserted when all of the following conditions are true When INTx is used • The INTx assertion disable bit in the Command register is 0, and • The Link Autonomous Bandwidth Interrupt Enable bit in the Link Control register is set to 1, and • The Link Autonomous Bandwidth Interrupt Status bit in the Link Status register is set to 1 Or when MSI is used: • MSI or MSI-X is enabled. • The Link Autonomous Bandwidth Status register (Link Status register bit 15) is updated. • The Link Autonomous Bandwidth Interrupt Enable (Link Control register bit 11) is set.

(table continues...)

(continued)

Field	Bits	Type	Description
BWINT	4	rh	**Link Bandwidth Management Interrupt. The interrupt can be triggered when the LNK_INTEN.BWINTEN is asserted.** Indicate that the Link Bandwidth Management Status bit has been set. This bit is asserted when all of the following conditions are true: When INTx is used • The INTx assertion disable bit in the Command register is 0, and • The Bandwidth Management Interrupt Enable bit in the Link Control register is set to 1, and • The Bandwidth Management Interrupt Status bit in the Link Status register is set to 1. Or when MSI is used: • MSI or MSI-X is enabled. • The Link Bandwidth Management Status register (Link Control Status register bit 14) is updated • The Link Bandwidth Management Interrupt Enable (Link Control register bit 10) is set..
EQINT	5	rh	**Link Equalization Request. The interrupt can be triggered when the LNK_INTEN.EQINTEN is asserted.** Interrupt indicating to your application that the Link Equalization Request bit in the Link Status 2 Register has been set and the Link Equalization Request Interrupt Enable (Link Control 3 Register bit 1) is set.
PERSTINT	6	rh	**Interrupt status of the PERST#. The interrupt can be triggered when the LNK_INTEN.PERSTEN is asserted.** It indicates the PERST# interrupt (detecting PERST# become active 0) arrives.
0	31:7	r	**Reserved** Read as 0; should be written with 0.

19.4.2.52 Controller control

LNK_CORECTRL Offset address: 0000378_H

Controller control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0														CLKREQEN	WAKEN
r														rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CLKREQ		WAKE		PERST		PERSTCLR	PERSTOVR	PERSTVAL	PERSTSTA	HOTRST	0	PFRQRTYEN	RQRTYEN	LTSSMEN	SRISMD
rw		rw		rw		w	rw	rw	rh	w	r	rw	rw	rw	rw

Field	Bits	Type	Description
SRISMD	0	rw	**SRIS operating mode** 0_B non-SRIS mode 1_B SRIS mode
LTSSMEN	1	rw	**Start link training.** Driven low default after cold, warm or hot reset to hold the LTSSM in the Detect state until your application is ready for the link training to begin. 0_B Hold LTSSM and delay link training 1_B Start link training
RQRTYEN	2	rw	**Defer incoming configuration requests** Provides a capability to defer incoming configuration requests until initialization is complete. When this bit is asserted, the controller completes incoming configuration requests with a configuration request retry status. Other incoming requests complete normally. When the Readiness Notification mechanism is supported, DRS messaging is blocked when RQRTYEN=1. When RQRTYEN=0 and MSG_INFO.DRSRDY=1, the controller autonomously transmits a DRS message when the link transitions from DL_Down to DL_Up.
PFRQRTYEN	3	rw	**Per Physical Function (PF) to defer incoming configuration requests** Provides a per Physical Function (PF) capability to defer incoming configuration requests until initialization is complete. When PFRQRTYEN is asserted for a certain PF, the controller completes incoming configuration requests with a configuration request retry status only for that particular PF; other incoming requests complete normally. When RQRTYEN is also asserted, the controller completes incoming configuration requests with a configuration request retry status for ALL PFs and VFs, regardless of the status of PFRQRTYEN. When the Readiness Notification mechanism is supported, DRS messaging is blocked when PFRQRTYEN =1 for at least one PF. The same applies when PFRQRTYEN =0 for all PFs, but RQRTYEN is asserted. When PFRQRTYEN =0 for a certain PF, and RQRTYEN =0, and MSG_INFO.DRSRDY=1, the controller autonomously transmits a DRS message when the link transitions from DL_Down to DL_Up.
HOTRST	5	w	**Request from your application to send a hot reset to the upstream port, RC only.** A downstream port (DSP) can hot reset an upstream port (USP) by sending two consecutive TS1 ordered sets with the hot reset bit asserted. This field requests from your application to send a hot reset to the upstream port. In an upstream port, you should not use this bit. Note: This bit is not used by the controller to set the SBR field in the BRIDGE_CTRL_INT_PIN_INT_LINE_REG register. During the transition from DL_Active to DL_inactive, assertion of this bit indicates a Surprise Down Error, but setting of SBR field in the BRIDGE_CTRL_INT_PIN_INT_LINE_REG register through FPI does not trigger a Surprise Down Error.
PERSTSTA	6	rh	**PERST# pin status** Indicate the PERST# pin status. 0_B Asserted (active low) 1_B Deasserted (active low)

(table continues...)

(continued)

Field	Bits	Type	Description
PERSTVAL	7	rw	**PERST# override value** This value decides the override value of the PERST# when the PERSTOVR is enabled. 0_B Asserted (active low) 1_B Deasserted (active low)
PERSTOVR	8	rw	**PERST# override enable** When this bit is enabled, the PERSTVAL bit will override the PERST# pin value in the controller.
PERSTCLR	9	w	**Clear the interrupt status of the PERSTINT.** Clear the interrupt status of the PERSTINT. 0_B Keep the status 1_B Clear the interrupt status
PERST	11:10	rw	**Alternate Input Select** Selects the alternate input for PERST#. 00_B Alternate Input A PERSTA_N 01_B Alternate Input B PERSTB_N 10_B Alternate Input A PERSTA_N 11_B Alternate Input A PERSTA_N
WAKE	13:12	rw	**Alternate input and output select** Selects the alternate input and output for WAKE#. 00_B Alternate input and output A WAKEA_IN_N 01_B Alternate input and output B WAKEB_IN_N 10_B Alternate input and output A WAKEA_IN_N 11_B Alternate input and output A WAKEA_IN_N
CLKREQ	15:14	rw	**Alternate input and output select** Selects the alternate input and output for CLKREQ#. 00_B Alternate input and output A CLKREQA_IN_N 01_B Alternate input and output B CLKREQB_IN_N 10_B Alternate input and output A CLKREQA_IN_N 11_B Alternate input and output A CLKREQA_IN_N
WAKEN	16	rw	**WAKE# enable control.** Enable the WAKE# input and output. If this bit is disabled, the alternative selection of the WAKE bit will have no effect 0_B WAKE# disable. None of the alternative pins is driven. 1_B WAKE# enable. One of the alternative pins is driven.
CLKREQEN	17	rw	**CLKREQ# enable control.** Enable the CLKREQ# input and output. If this bit is disabled, the alternative selection of the CLKREQ bit will have no effect 0_B CLKREQ# disable. None of the alternative pins is driven. 1_B CLKREQ# enable. One of the alternative pins is driven.
0	4, 31:18	r	**Reserved** Read as 0; should be written with 0.

19.4.2.53 Enable the interrupt requests to SRC_PCIELNK

CORERR	16	rh	**Sent Correctable Error, EP only.** Core has sent a message towards the Root Complex indicating that an Rx TLP that contained an error, and that can be corrected, was received by the EndPoint.
NONFAT	17	rh	**Sent Non-Fatal Error, EP only.** Controller has sent a message towards the Root Complex indicating that an Rx TLP that contained an non-fatal error, and that can not be corrected, was received by the EndPoint.
FATERR	18	rh	**Sent Fatal Error, EP only.** Controller has sent a message towards the Root Complex indicating that an Rx TLP that contained a fatal error, and that can not be corrected, was received by the EndPoint
SURPDWN	19	rh	**Indicates that a surprise down event is occurring in the controller.**
DRSRDY	21	rw	**Defers DRS messaging when set to '0', EP only.**
DRSSTAT	22	rh	**DRS Message Received Interrupt, RC only. The interrupt can be triggered when the DRSEN is asserted.** The DSP controller asserts this bit when all of the following are true: • It receives a DRS message • PCIE_CAP_DRS_SIGNALING_CONTROL in LINK_CONTROL_LINK_STATUS_REG is 2'b01 • MSI or MSI-X is enabled
DRSCLR	23	w	**Clear the DRS state, RC only.** 0_B Keep the status 1_B Clear the interrupt status

(table continues...)

(continued)

Field	Bits	Type	Description
DRSEN	24	rw	**Enable the DRS interrupt, RC only.** 0_B Disable interrupt 1_B Enable interrupt
0	20, 31:25	r	**Reserved** Read as 0; should be written with 0.

19.4.2.59 Power management control

PM_CTRL Offset address: 0000398_H

Power management control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0														TRN	TRN ACK
r														rh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PME MSG	TUR NOFF	0				CLK RM	PMEI NT	CLKP MEN	CLK REQ	XFER PND	REQ EXIT L1	RDYE NTR L23	REQ ENT RL1	AUX PWR DET	WKU PCM D
rh	w	r				rw	rh	rw	rh	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
WKUPCMD	0	rw	**Wake Up.** Wake Up. If PME is enabled and PME support is configured for current PMCSR D-state asserting this signal causes the controller to wake from either L1 or L2 state.
AUXPWRDET	1	rw	**Auxiliary Power Detected.** Used to report to the host software that auxiliary power (Vaux) is present.
REQENTRL1	2	rw	**Application request to Enter L1 ASPM state.** This bit is for use by applications that need to control L1 entry instead of using the L1 entry timer as defined in the PCI Express Specification. It is only effective when L1 is enabled. The controller latches this request when in L0 or L0s; to be acted upon later. Note: The controller ignores this input in RC mode
RDYENTRL23	3	rw	**Application Ready to Enter L23.** Indication from your application that it is ready to enter the L23 state. This bit is provided for applications that must control L23 entry (in case certain tasks must be performed before going into L23). The controller delays sending PM_Enter_L23 (in response to PM_Turn_Off) until this signal becomes active. When this signal has been asserted by the application, it must be kept asserted until L2 entry has completed.

(table continues...)

(continued)

Field	Bits	Type	Description
REQEXITL1	4	rw	**Application request to Exit L1.** Request from your application to exit L1. It is only effective when L1 is enabled.
XFERPND	5	rw	**Indicates that your application has transfers pending** If the entry into L1 is already in progress, assertion of app_xfer_pending causes an exit from L1. This is a level signal used to inform the controller about the state of external queues and pipeline stages that contain transactions to be transmitted by the controller. The controller uses this information to determine when to enter/exit L1. When this signal is asserted, it indicates that there are transactions outside the controller that the controller needs to transmit. When de-asserted, it indicates that there are no transactions outside the controller. The controller responds to an assertion on this signal as follows: • Upstream Ports: Prevents generation of requests to enter L1. Triggers exit if already in L1. • Downstream Ports: Triggers exit if already in L1.
CLKREQ	6	rh	**Status of the CLKREQ#** Status of the CLKREQ# bidirectional CMOS board-level signal. This should be connected to the GPIO. Used by the controller to determine when to enter and exit L1 Substates when using the CLKREQ#-based mechanism. For more details, see 'L1 Substates'.
CLKPMEN	7	rw	**Clock PM feature enabled by application.** Used to inhibit the programming of the Clock PM in Link Control Register.
PMEINT	8	rh	**PME interrupt received. The interrupt can be triggered when the PM_INTEN.PMEINTEN is asserted.** The controller asserts this bit when all of the following conditions are true: • The INTx Assertion Disable bit in the Command register is 0. • The PME Interrupt Enable bit in the Root Control register is set to 1. • The PME Status bit in the Root Status register is set to 1. Or • MSI or MSI-X is enabled. • The PME Interrupt Enable bit in the Root Control register is set to 1. • The PME Status bit in the Root Status register is set to 1.
CLKRM	9	rw	**Indicates that the application is ready to have reference clock removed.** The application should set this bit to 1'b1 if it supports reference clock removal. If the application does not want to remove reference clock it should set this bit to 1'b0. This bit should be asserted or de-asserted when L1 CPM or L1 Sub-states are being configured, it should not be changed dynamically during L1.
TURNOFF	14	w	**Request from your application to generate a PM_Turn_Off message.** You must assert this signal for one clock cycle. You must not assert the same bit again, until the previous message has been transmitted.

(table continues...)

(continued)

Field	Bits	Type	Description
PMEMSG	15	rh	**The controller received a PM_PME message.The interrupt can be triggered when the PM_INTEN.PMEMSGEN is asserted.**
TRNACK	16	rh	**The controller received a PME_TO_Ack message. Upstream port: Reserved. The interrupt can be triggered when the PM_INTEN.TOACKEN is asserted.**
TRN	17	rh	**The controller received a PME Turnoff message. The interrupt can be triggered when the PM_INTEN.TOEN is asserted.**
0	13:10, 31:18	r	**Reserved** Read as 0; should be written with 0.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
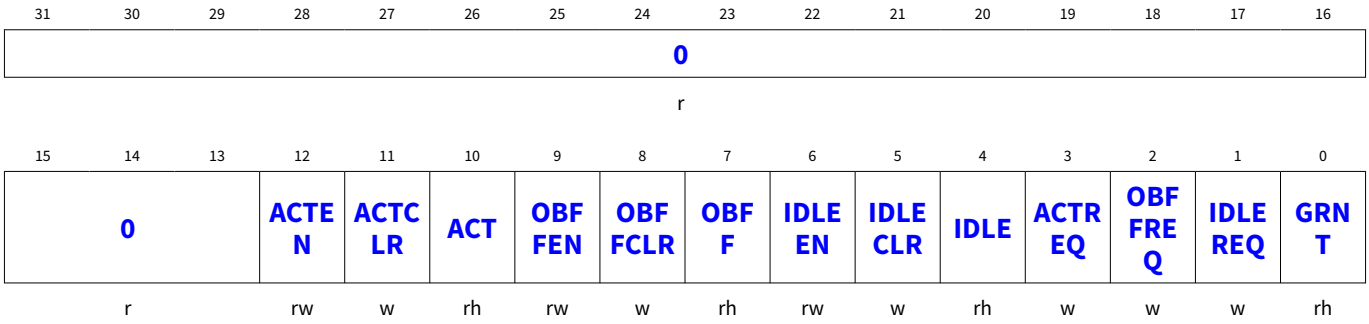
0												HPINTCLR	HPINTEN	HPINT	HPPME
r												w	rw	rh	rh

Field	Bits	Type	Description
HPPME	0	rh	**The controller asserts hp_pme when all of the following conditions are true:** • The PME Enable bit in the Power Management Control and Status register is set to 1. • Any bit in the Slot Status register transitions from 0 to 1 and the associated event notification is enabled in the Slot Control register. The controller does not check if the PM state is D1, D2, or D3hot. It is up to your application to check the value pm_dstate to make sure the device is in D1, D2, or D3hot. There is one bit of HPPME for each configured function. The controller pulses this bit output only when any hot plug status bit changes from 0 to 1 (as is HPINT). hp_int stays asserted as long as the status bit is set. In addition, it asserts HPPME only if PME is enabled, but it does not matter if hot-plug interrupts are enabled.
HPINT	1	rh	**The controller asserts hp_int when all of the following conditions are true:** • The INTx Assertion Disable bit in the Command register is 0. • Hot-Plug interrupts are enabled in the Slot Control register. • Any bit in the Slot Status register is equal to 1, and the associated event notification is enabled in the Slot Control register. Or • MSI or MSI-X is enabled. • Hot-Plug interrupts are enabled in the Slot Control register. • Any bit in the Slot Status register transitions from 0 to 1 and the associated event notification is enabled in the Slot Control register.
HPINTEN	2	rw	**Hot plug enable** 0_B Disable interrupt 1_B Enable interrupt
HPINTCLR	3	w	**Clear the HPINT bit.** 0_B Keep the status 1_B Clear the interrupt status
0	31:4	r	**Reserved** Read as 0; should be written with 0.

19.4.2.76 OBFF message control

OBFFMSG Offset address: $00003F0_H$

OBFF message control Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
GRNT	0	rh	**Request accepted to generate an OBFF message**
IDLEREQ	1	w	**To generate an 'IDLE' OBFF message.** Request from your application to generate an 'IDLE' OBFF message. Only usable in a downstream port.
OBFFREQ	2	w	**Request to generate an 'OBFF' OBFF message.** Request from your application to generate an 'OBFF' OBFF message. Only usable in a downstream port.
ACTREQ	3	w	**Request to generate a 'CPU Active' OBFF message.** Request from your application to generate a 'CPU Active' OBFF message. Only usable in a downstream port.
IDLE	4	rh	**The controller received an 'IDLE' OBFF message. The interrupt can be triggered when the IDLEEN is asserted.** Indicating that the controller received an 'IDLE' OBFF message. Only usable in an upstream port
IDLECLR	5	w	**Clear the IDLE bit** 0_B Keep the status 1_B Clear the interrupt status
IDLEEN	6	rw	**Enable the idle bit.** 0_B Disable interrupt 1_B Enable interrupt
OBFF	7	rh	**The controller received an 'OBFF' OBFF message. The interrupt can be triggered when the OBFFEN is asserted.** Indicating that the controller received an 'OBFF' OBFF message. Only usable in an upstream port.
OBFFCLR	8	w	**Clear the OBFFbit** 0_B Keep the status 1_B Clear the interrupt status
OBFFEN	9	rw	**Enable the OBFFbit.** 0_B Disable interrupt 1_B Enable interrupt
ACT	10	rh	**Received a 'CPU Active' OBFF message. The interrupt can be triggered when the ACTEN is asserted.** Indicating that the controller received a 'CPU Active' OBFF message. Only usable in an upstream port.

(table continues...)

(continued)

Field	Bits	Type	Description
ACTCLR	11	w	**Clear the ACT bit** 0_B Keep the status 1_B Clear the interrupt status
ACTEN	12	rw	**Enable the ACT bit.** 0_B Disable interrupt 1_B Enable interrupt
0	31:13	r	**Reserved** Read as 0; should be written with 0.

19.4.2.77 OBFF WAKE control

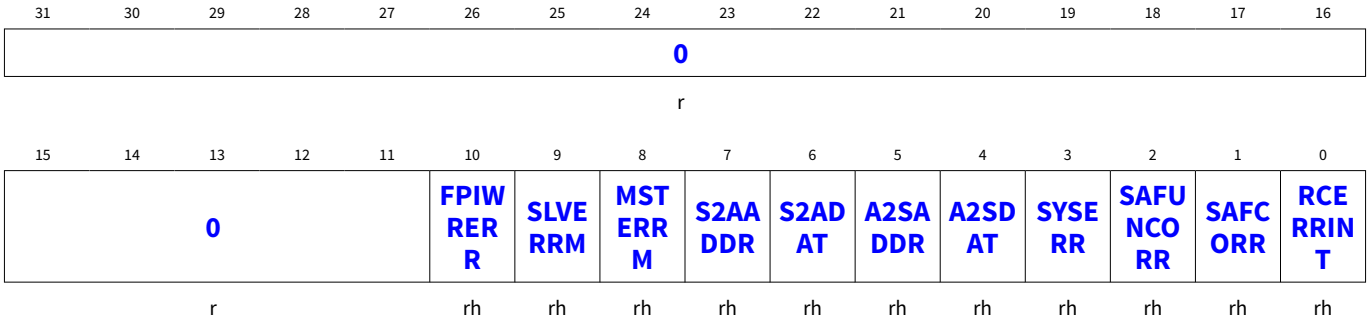
19.4.2.82 Interrupt/alarm status

ALARM_STAT Offset address: 0000424_H

Interrupt/alarm status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RCERRINT	0	rh	**Error reported. The interrupt can be triggered when the ALARM_INTEN.RCERREN is asserted.** Asserted when a reported error condition causes a bit to be set in the Root Error Status register and the associated error message reporting enable bit is set in the Root Error Command register. This bit is set when the RC internally generates an error or when an error message is received by the RC. Because the RC itself generates it, this needs to be propagated up to the system software which would then need to read the error registers to see which error occurred.
SAFCORR	1	rh	**Indicate correctable error. The interrupt can be triggered when the ALARM_INTEN.SAFCORREN is asserted.** The controller asserts this bit when a PCIe protocol correctable error or a Data Path protection correctable error is indicated and the associated mask for that event is not set.
SAFUNCORR	2	rh	**Indicate uncorrectable error. The interrupt can be triggered when the ALARM_INTEN.SAFUNCORR is asserted.** The controller asserts this bit when any of the internal safety mechanisms reports an uncorrectable error and the associated mask for that event is not set.
SYSERR	3	rh	**System error detected. The interrupt can be triggered when the ALARM_INTEN.SYSERREN is asserted.** Assertion of this bit indicates if any device in the hierarchy reports any of the following errors and the associated enable bit is set in the Root Control register: ERR_COR, ERR_FATAL, ERR_NONFATAL. Also asserted when an internal error is detected.
A2SDAT	4	rh	**Error detected during the data phase in the A2S bridge. The interrupt can be triggered when the ALARM_INTEN.A2SDEN is asserted.**
A2SADDR	5	rh	**Error detected during the address phase in the A2S bridge. The interrupt can be triggered when the ALARM_INTEN.A2SAEN is asserted.**
S2ADAT	6	rh	**Error detected during the data phase in the S2A bridge. The interrupt can be triggered when the ALARM_INTEN.S2ADEN is asserted.**
S2AADDR	7	rh	**Error detected during the address phase in the S2A bridge. The interrupt can be triggered when the ALARM_INTEN.S2AAEN is asserted.**
MSTERRM	8	rh	**The controller has entered RASDP error mode at the master interface of AXI.** The controller enters RASDP error mode (if the ERROR_MODE_EN register field =1) upon detection of the first uncorrectable error. During this mode: • Controller sets SLVERRM=1 • Controller sets MSTERRM=1 • Rx TLPs that are forwarded to your application are not guaranteed to be correct; you must discard them.

(table continues...)

(continued)

Field	Bits	Type	Description
SLVERRM	9	rh	**The controller has entered RASDP error mode at the slave interface of AXI.** The controller enters RASDP error mode (if the ERROR_MODE_EN register field =1) upon detection of the first uncorrectable error. During this mode: • Controller sets SLVERRM=1 • Controller sets MSTERRM=1 • Rx TLPs that are forwarded to your application are not guaranteed to be correct; you must discard them.
FPIWRERR	10	rh	**FPI write error status** Status to indicate write returned an error on the FPI interface
0	31:11	r	**Reserved** Read as 0; should be written with 0.

19.4.2.83 Interrupt/alarm clear

19.4.2.85 iATU Region i Control 1 Register Outbound

This register controls the iATU outbound region access based on the optional iATU outbound features enabled using iATU Region Control 2 Register.

IATU_REGION_CTRL_1_OFF_OUTBOUND_i (i=0-7) Offset address: $0003000_H+i*200_H$

iATU Region i Control 1 Register Outbound Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0									CTRL_1_FUNC_NUM			0			
r									rw			r			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		Res	0		ATTR		TD	TC			TYPE				
r		r	r		rw		rw	rw			rw				

Field	Bits	Type	Description
TYPE	4:0	rw	**When the address of an outbound TLP is matched to this region, then the TYPE field of the TLP is changed to the value in this register** Note: This register field is sticky.
TC	7:5	rw	**When the address of an outbound TLP is matched to this region, then the TC field of the TLP is changed to the value in this register** Note: This register field is sticky.
TD	8	rw	**This is a reserved field** Do not use. Note: This register field is sticky.
ATTR	10:9	rw	**When the address of an outbound TLP is matched to this region, then the ATTR field of the TLP is changed to the value in this register** Note: This register field is sticky.
CTRL_1_FUNC_NUM	22:20	rw	**Function Number** The value in this register must be 0x0 as only one function is supported by this controller. . When the address of an outbound TLP is matched to this region and the FUNC_BYPASS field in the "iATU Region Control 2 Register" is '0', then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register. This field is swapped before AXI decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used. Note: This register field is sticky
0	12:11, 19:14, 31:23	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.86 iATU Region i Control 2 Register Outbound

Using this register you can enable/disable the outbound iATU optional features.

IATU_REGION_CTRL_2_OFF_OUTBOUND_i (i=0-7) Offset address: $0003004_H+i*200_H$

iATU Region i Control 2 Register Outbound Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REGION_EN	0	INVERT_MODE	Res	DMA_BYPASS	0			HEADER_SUBSTITUTE_EN	INHIBIT_PAYLOAD	Res		FUNC_BYPASS	0		TAG_SUBSTITUTE_EN
rw	r	rw	r	rw	r			rw	rw	r		rw	r		rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAG								MSG_CODE							
rw								rw							

Field	Bits	Type	Description
MSG_CODE	7:0	rw	**MSG TLPs (Message Code)** When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. Note: This register field is sticky.
TAG	15:8	rw	**TAG** The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. Note: This register field is sticky.
TAG_SUBSTITUTE_EN	16	rw	**TAG Substitute Enable** When enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
FUNC_BYPASS	19	rw	**Function Number Translation Bypass** In this mode, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "iATU Region Control 1 Register" Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
INHIBIT_PAYLOAD	22	rw	**Inhibit TLP Payload Data for TLP's in Matched Region; assign iATU region to be TLP without data** When enabled and region address is matched, the iATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0b. Encoding are define as above. Note: This register field is sticky. 0_B **SUPPORT_DATA_TLP**: Fmt[1] =0/1 so that TLPs with or without data can be sent 1_B **NO_SUPPORT_FOR_DATA_TLP**: Fmt[1] =0 so that only TLP type without data is sent For example, a Msg instead of MsgD will be sent.
HEADER_SUBSTITUTE_EN	23	rw	**Header Substitute Enable** When enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i. Encodings are as above. Note: This register field is sticky. 0_B **FORM_ADDR**: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register forms the new address of the translated region 1_B **FILL_BYTES**: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header

(table continues...)

(continued)

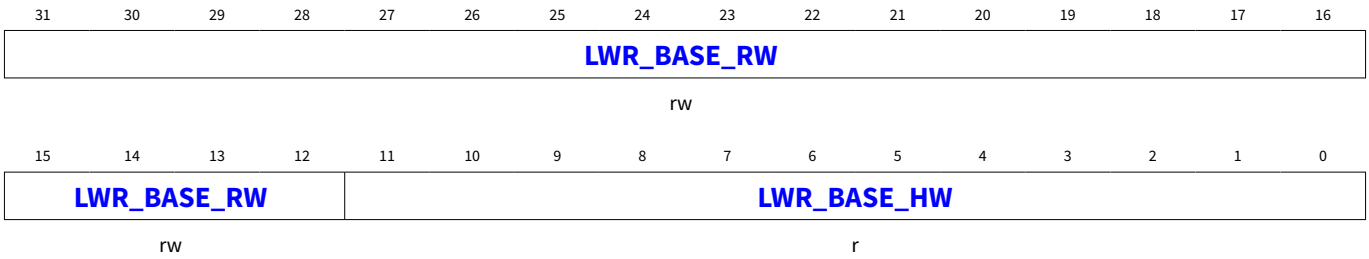
Field	Bits	Type	Description
DMA_BYPASS	27	rw	**DMA Bypass Mode** Allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
INVERT_MODE	29	rw	**Invert Mode** When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
REGION_EN	31	rw	**Region Enable** This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
0	18:17, 26:24, 30	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.87 iATU i Lower Base Address Register Outbound

The CX_ATU_MIN_REGION_SIZE configuration parameter (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower log2(CX_ATU_MIN_REGION_SIZE) bits are zero.

IATU_LWR_BASE_ADDR_OFF_OUTBOUND_i (i=0-7) Offset address: $0003008_H+i*200_H$

iATU i Lower Base Address Register Outbound Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
LWR_BASE_HW	11:0	r	**Forms bits of the start address of the address region to be translated** The start address must be aligned to a 4 kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller.
LWR_BASE_RW	31:12	rw	**Forms bits of the start address of the address region to be translated** Note: This register field is sticky.

19.4.2.88 iATU i Upper Base Address Register Outbound

This register holds the upper 32-bits of the start (and end) address of the address region to be translated.

IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_i (i=0-7) Offset address: $000300C_H+i*200_H$

iATU i Upper Base Address Register Outbound Kernel Reset value: $0000\ 0000_H$

LIMIT_ADDR_RW				LIMIT_ADDR_HW								CBUF_INCR			
rw				r								r			

Field	Bits	Type	Description
CBUF_INCR	3:0	r	**Circular Buffer** Note: This register field is sticky.
LIMIT_ADDR_HW	11:4	r	**Forms lower bits of the end address of the address region to be translated** The end address must be aligned to a 4 kB boundary, so these bits are always all ones. A write to this location is ignored by the PCIe controller. Note: This register field is sticky.
LIMIT_ADDR_RW	31:12	rw	**Forms upper bits of the end address of the address region to be translated** Note: This register field is sticky.

19.4.2.90 iATU i Lower Target Address Register Outbound

This register holds the Lower Target part of the new address of the translated region, or the outbound TLP header information, depending on the setting of HEADER_SUBSTITUTE_EN field of IATU_REGION_CTRL_2_VIEWPORT_OFF_OUTBOUND_i register.

IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i (i=0-7) Offset address: $0003014_H+i*200_H$

iATU i Lower Target Address Register Outbound Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LWR_TARGET_RW_OUTBOUND															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LWR_TARGET_RW_OUTBOUND															
rw															

Field	Bits	Type	Description
LWR_TARGET_RW_OUTBOUND	31:0	rw	**Containing the Lower Target part of the new address of the translated region, or the outbound TLP header information** When HEADER_SUBSTITUTE_EN is 0, for lower target address, the start address must be aligned to a 4 kB boundary, so the lower bits of the start address of the new address of the translated region (bits 11:0) are always '0'. When HEADER_SUBSTITUTE_EN in IATU_REGION_CTRL_2_OFF_OUTBOUND_i is '1': - this field forms bytes 8-11 (for 3 dword header) or bytes 12-15 (for 4 dword header) of the outbound TLP header. Note: This register field is sticky.

19.4.2.91 iATU i Upper Target Address Register Outbound

This register holds the upper 32 bits of the start address (Upper Target part) of the new address of the translated region.

IATU_UPPER_TARGET_ADDR_OFF_OUTBOUND_i (i=0-7) Offset address: $0003018_H+i*200_H$

iATU i Upper Target Address Register Outbound Kernel Reset value: $0000\ 0000_H$

UPPER_TARGET_RW															
rw															

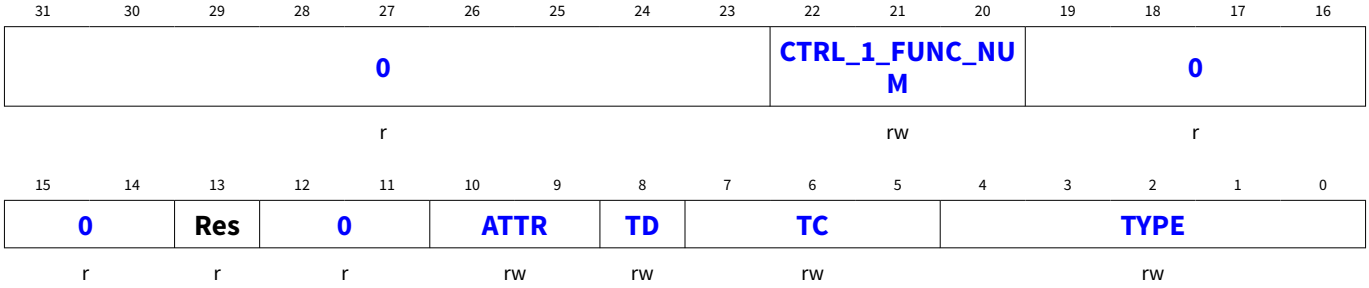
Field	Bits	Type	Description
UPPER_TARGET_RW	31:0	rw	**Forms bits [63:32] of the start address (Upper Target part) of the new address of the translated region** Note: This register field is sticky.

19.4.2.92 iATU Region i Control 1 Register Inbound

This register controls the iATU inbound region access based on the optional iATU inbound features enabled using iATU Region Control 2 Register.

IATU_REGION_CTRL_1_OFF_INBOUND_i (i=0-7) Offset address: $0003100_H+i*200_H$

iATU Region i Control 1 Register Inbound Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TYPE	4:0	rw	**When the TYPE field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful)** Note: This register field is sticky.
TC	7:5	rw	**When the TC field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful)** This check is only performed if the "TC Match Enable" bit of the "iATU Region Control 2 Register" is set. Note: This register field is sticky.
TD	8	rw	**When the TD field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful)** This check is only performed if the "TD Match Enable" bit of the "iATU Region Control 2 Register" is set. Note: This register field is sticky.
ATTR	10:9	rw	**When the ATTR field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful)** This check is only performed if the "ATTR Match Enable" bit of the "iATU Region Control 2 Register" is set. Note: This register field is sticky.
CTRL_1_FUNC_NUM	22:20	rw	**Function Number** - MEM-I/O: When the Address and BAR matching logic in the controller indicate that a MEM-I/O transaction matches a BAR in the function corresponding to this value, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Region Control 2 Register" is set. - CFG0/CFG1: When the destination function number as specified in the routing ID of the TLP header matches the function, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Region Control 2 Register" is set. Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
0	12:11, 19:14, 31:23	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.93 iATU Region i Control 2 Register Inbound

Using this register you can enable/disable the inbound iATU optional features.

IATU_REGION_CTRL_2_OFF_INBOUND_i (i=0-7) Offset address: $0003104_H+i*200_H$

iATU Region i Control 2 Register Inbound Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	r		rw			rw							

Field	Bits	Type	Description
MSG_CODE	7:0	rw	**MSG TLPs: (Message Code)** When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Message Code Match Enable" bit of the "iATU Region Control 2 Register" is set. Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
BAR_NUM	10:8	rw	**BAR Number** When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "iATU Region Control 2 Register" is set. IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. Note: This register field is sticky. 000_B **BAR0**: BAR0 001_B **BAR1**: BAR1 010_B **BAR2**: BAR2 011_B **BAR3**: BAR3 100_B **BAR4**: BAR4 101_B **BAR5**: BAR5 110_B **ROM**: ROM 111_B **RSVD**: reserved
MSG_TYPE_MATCH_MODE	13	rw	**Message Type Match Mode** When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the IATU_REGION_CTRL_1_OFF_INBOUND_i register (TYPE[4:3]=2'b10) will be translated. Message type match mode overrides any value of MATCH_MODE field in this register. Usage scenarios for this are translation of VDM or ATS messages when AXI bridge is configured on client interface. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
TC_MATCH_EN	14	rw	**TC Match Enable** Ensures that a successful TC TLP field comparison match (see TC field of the "iATU Region Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky. 0_B **DISABLE**: TC Match Disable 1_B **ENABLE**: TC Match Enable
TD_MATCH_EN	15	rw	**TD Match Enable** Ensures that a successful TD TLP field comparison match (see TD field of the "iATU Region Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky. 0_B **DISABLE**: TD Match Disable 1_B **ENABLE**: TD Match Enable
ATTR_MATCH_EN	16	rw	**ATTR Match Enable** Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "iATU Region Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky. 0_B **DISABLE**: ATTR Match Disable 1_B **ENABLE**: ATTR Match Enable

(table continues...)

(continued)

Field	Bits	Type	Description
FUNC_NUM_MATCH_EN	19	rw	**Function Number Match Enable** Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "iATU Region Control 1 Register") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. Note: This register field is sticky. 0_B **DISABLE**: Function Number Match Disable 1_B **ENABLE**: Function Number Match Enable
MSG_CODE_MATCH_EN	21	rw	**Message Code Match Enable (Msg TLPS)** Ensures that a successful message Code TLP field comparison match (see Message Code field of the "iATU Region Control 2 Register") occurs (in MSG transactions) for address translation to proceed. Note: This register field is sticky. 0_B **DISABLE**: Virtual Function Number Match Disable 1_B **ENABLE**: Message Code Match Enable (for Msg TLPS) or ST Match Enable (for Mem TLPs)
SINGLE_ADDR_LOC_TRANS_EN	23	rw	**Single Address Location Translate Enable** When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the iATU region. The main usage scenario is translation of Messages to MWr TLPs when the AXI bridge is enabled. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
RESPONSE_CODE	25:24	rw	**Response Code** Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. Note: This register field is sticky. 00_B **NORMAL_RADM**: Normal RADM filter response is used 01_B **UNSUP_REQ**: Unsupported request (UR) 10_B **COMPL_ABORT**: Completer abort (CA) 11_B **NOT_USED**: Not used / undefined / reserved
INVERT_MODE	29	rw	**Invert Mode Enable** When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). When set all regions of that type must use address match mode. Note: This register field is sticky. 0_B **DISABLE**: Invert Mode Disable 1_B **ENABLE**: Invert Mode Enable

(table continues...)

(continued)

Field	Bits	Type	Description
MATCH_MODE	30	rw	**Match Mode** Determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received as follows: For MEM-I/O TLPs, this field is interpreted as follows: • 0: Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. • 1: BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as follows: • 0: Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed • 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number For MSG/MSGD TLPs, this field is interpreted as follows: • 0: Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers • 1: Vendor ID Match Mode. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1 AND MSG_TYPE_MATCH_MODE =1, then Match Mode is ignored. Note: This register field is sticky. 0_B **ZERO**: The interpretation is dependent on TLP type, that is, MEM/IO, CFG0, or MSG/MSGD TLPs 1_B **ONE**: The interpretation is dependent on TLP type, that is, MEM/IO, CFG0, or MSG/MSGD TLPs
REGION_EN	31	rw	**Region Enable** This bit must be set to '1' for address translation to take place. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable

(table continues...)

(continued)

Field	Bits	Type	Description
0	12:11, 18:17, 20, 22, 26	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.94 iATU i Lower Base Address Register Inbound

The CX_ATU_MIN_REGION_SIZE configuration parameter (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower log2(CX_ATU_MIN_REGION_SIZE) bits are zero.

IATU_LWR_BASE_ADDR_OFF_INBOUND_i (i=0-7) Offset address: $0003108_H+i*200_H$

iATU i Lower Base Address Register Inbound Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
LWR_TARGET_HW	11:0	r	**Forms the LSB's of the Lower Target part of the new address of the translated region** The start address must be aligned to a 4 kB boundary (in address match mode); and to the Bar size boundary (in BAR match mode) so that these bits are always '0'. If the BAR is smaller than the iATU region size, then the iATU target address must align to the iATU region size; otherwise it must align to the BAR size. A write to this location is ignored by the PCIe controller. .
LWR_TARGET_RW	31:12	rw	**Forms MSB's of the Lower Target part of the new address of the translated region** These bits are always '0'. Note: This register field is sticky.

19.4.2.98 Device ID and Vendor ID Register

This register holds the device ID and vendor ID.

TYPE1_DEV_ID_VEND_ID_REG Offset address: 0004000_H

Device ID and Vendor ID Register Kernel Reset value: $ABCD\ FFFF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DEVICE_ID															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VENDOR_ID															
rw															

Field	Bits	Type	Description
VENDOR_ID	15:0	rw	**Vendor ID** The Vendor ID register identifies the manufacturer of the Function. Valid vendor identifiers are allocated by the PCI-SIG to ensure uniqueness. It is not permitted to keep this register populated with a value of FFFFh, which is an invalid value for Vendor ID. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
DEVICE_ID	31:16	rw	**Device ID** The Device ID register identifies the particular Function. This identifier is allocated by the vendor. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.2.99 Status and Command Register

This register provides the status and controls the behavior of a function.

TYPE1_STATUS_COMMAND_REG Offset address: 0004004_H

Status and Command Register Kernel Reset value: $0010\ 0000_H$

r					rw	r	rw	r	rw	r	r	r	rw	rwh	rwh

Field	Bits	Type	Description
IO_EN	0	rwh	**IO Space Enable** This bit controls a Function's response to I/O Space accesses received on its primary side. You cannot write to this register if your configuration has no IO BARs; that is, the internal signal has_io_bar =0. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: !has_io_bar ? RO : RW 0_B **CLEAR**: All received I/O accesses are caused to be handled as Unsupported Requests 1_B **SET**: The Function is enabled to decode the address and further process I/O Space accesses
MSE	1	rwh	**Memory Space Enable** This bit controls a Function's response to Memory Space accesses received on its primary side. You cannot write to this register if your configuration has no MEM BARs; that is, the internal signal has_mem_bar =0. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: !has_mem_bar ? RO : RW 0_B **CLEAR**: All received Memory Space accesses are caused to be handled as Unsupported Requests 1_B **SET**: The Function is enabled to decode the address and further process Memory Space accesses
BME	2	rw	**Bus Master Enable** This bit controls forwarding of Memory or I/O requests by a port in the Upstream direction. When this bit is 0b, Memory and I/O Requests received at a Root Port must be handled as Unsupported Requests (UR) For Non-Posted Requests a Completion with UR completion status must be returned. This bit does not affect forwarding of Completions in either the Upstream or Downstream direction. The forwarding of Requests other than Memory or I/O Requests is not controlled by this bit.
SCO	3	r	**Special Cycle Enable** This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
MWI_EN	4	r	**Memory Write and Invalidate** This bit was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b. For PCI Express to PCI/PCI-X Bridges, refer to the PCI Express to PCI/PCI-X Bridge Specification for requirements for this register.
VGAPS	5	r	**VGA Palette Snoop** This bit was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.

(table continues...)

(continued)

Field	Bits	Type	Description
PERREN	6	rw	**Parity Error Response** This bit controls the logging of poisoned TLPs in the Master Data Parity Error bit in the Status register. 0_B **DISABLE**: Parity Error Response disable 1_B **ENABLE**: Parity Error Response enable
IDSEL	7	r	**IDSEL Stepping/Wait Cycle Control** This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
SERREN	8	rw	**SERR# Enable** Note: - The errors are reported if enabled either through this bit or through the PCI Express specific bits in the Device Control register. - In addition, this bit controls transmission by the primary interface of ERR_NONFATAL and ERR_FATAL error Messages forwarded from the secondary interface. This bit does not affect the transmission of forwarded ERR_COR messages. 1_B **SET**: This bit enables reporting upstream of Non-fatal and Fatal errors detected by the Function
RSVDP_9	9	r	**Reserved for future use**
INT_EN	10	rw	**Interrupt Disable** Controls the ability of a Function to generate INTx emulation interrupts. Note: • Any INTx emulation interrupts already asserted by the Function must be deasserted when this bit is set. INTx interrupts use virtual wires that must, if asserted, be deasserted using the appropriate Deassert_INTx message(s) when this bit is set • Only the INTx virtual wire interrupt(s) associated with the Function(s) for which this bit is set are affected • For Functions that generate INTx interrupts on their own behalf, this bit is required. This bit has no effect on interrupts forwarded from the secondary side. 1_B **SET**: When set, Functions are prevented from asserting INTx interrupts
RESERV	15:11	r	**Reserved** 00_H **RESERVED**: Reserved **others,** Reserved
RSVDP_17	18:17	r	**Reserved for future use**
INT_STATUS	19	rh	**Interrupt Status** INTx emulation interrupts forwarded by Functions from the secondary side are not reflected in this bit. Setting the Interrupt Disable bit has no effect on the state of this bit. For Functions that do not generate INTx interrupts, the controller hardwires this bit to 0b. 1_B **SET**: Indicates that an INTx emulation interrupt is pending internally in the Function

(table continues...)

(continued)

Field	Bits	Type	Description
CAP_LIST	20	r	**Capabilities List** Indicates the presence of an Extended Capability list item. Since all PCI Express device Functions are required to implement the PCI Express Capability structure, the controller hardwires this bit to 1b.
FAST_66MHZ_CAP	21	r	**66 MHz Capable** This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
RSVDP_22	22	r	**Reserved for future use**
FAST_B2B_CAP	23	r	**Fast Back-to-Back Transactions Capable** This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
MASTER_DPE	24	rw1ch	**Master Data Parity Error** This bit is set by a Function if the Parity Error Response bit in the Command register is 1b and either of the following two conditions occurs: • Port receives a Poisoned Completion going downstream • Port transmits a Poisoned Request upstream If the Parity Error Response bit is 0b, this bit is never set.
DEV_SEL_TIMING	26:25	r	**DEVSEL Timing** This field was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires it to 00b.
SIGNALED_TARGET_ABORT	27	rw1ch	**Signaled Target Abort** This bit is set when a Function completes a Posted or Non-Posted Request as a Completer Abort error. This applies to a Function when the Completer Abort was generated by its primary side. Software write with 1 clears this bit-field.
RCVD_TARGET_ABORT	28	rw1ch	**Received Target Abort** This bit is set when a Requester receives a Completion with Completer Abort Completion status. The bit is set when the Completer Abort is received by a Function's primary side. Software write with 1 clears this bit-field.
RCVD_MASTER_ABORT	29	rw1ch	**Received Master Abort** This bit is set when a Requester receives a Completion with Unsupported Request Completion status. The bit is set when the Unsupported Request is received by a Function's primary side. Software write with 1 clears this bit-field.
SIGNALED_SYS_ERROR	30	rw1ch	**Signaled System Error** Software write with 1 clears this bit-field.. 1_B **SET**: This bit is set when a Function sends an ERR_FATAL or ERR_NONFATAL Message, and the SERR# Enable bit in the Command register is 1b

(table continues...)

(continued)

Field	Bits	Type	Description
DETECTED_PARITY_ERROR	31	rw1ch	**Detected Parity Error** The bit is set when the Poisoned TLP is received by a Function's primary side. Software write with 1 clears this bit-field. 1_B **SET**: This bit is set by a Function whenever it receives a Poisoned TLP, regardless of the state the Parity Error Response bit in the Command register
0	16	r	**Reserved** Read as 0; should be written with 0.

19.4.2.100 Class Code and Revision ID Register

This register specifies the class code and revision ID of a function.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PROGRAM_INTERFACE								REVISION_ID							
rw								rw							

Field	Bits	Type	Description
REVISION_ID	7:0	rw	**Revision ID** The value of this field specifies a Function specific revision identifier. The value is chosen by the vendor. Zero is an acceptable value. The Revision ID should be viewed as a vendor defined extension to the Device ID. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
PROGRAM_INTERFACE	15:8	rw	**Programming Interface** This field identifies a specific register level programming interface (if any) so that device independent software can interact with the Function. Encodings for interface are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are reserved. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
SUBCLASS_CODE	23:16	rw	**Sub-Class Code** Specifies a base class sub-class, which identifies more specifically the operation of the Function. Encodings for sub-class are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are reserved. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
BASE_CLASS_CODE	31:24	rw	**Base Class Code** A code that broadly classifies the type of operation the Function performs. Encodings for base class, are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are reserved. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.2.101 BIST, Header Type, Latency Timer, and Cache Line Size Register

This register provides the status and controls BIST. It also holds information regarding the header layout, latency timer, and cache line size.

TYPE1_BIST_HDR_TYPE_LAT_CACHE_LINE_SIZE_REG

Offset address: $000400C_H$

BIST, Header Type, Latency Timer, and Cache Line Size Register

Kernel Reset value: $0001\ 0000_H$

BIST								MULTI_FUNC	HEADER_TYPE						
r								r	r						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LATENCY_MASTER_TIMER								CACHE_LINE_SIZE							
r								rw							

Field	Bits	Type	Description
CACHE_LINE_SIZE	7:0	rw	**Cache Line Size** The Cache Line Size register is programmed by the system firmware or the operating system to system cache line size. However, legacy conventional PCI software may not always be able to program this register correctly especially in the case of Hot-Plug devices. This read-write register is implemented for legacy compatibility purposes but has no effect on any PCI Express device behavior.
LATENCY_MASTER_TIMER	15:8	r	**Latency Timer** This register is also referred to as Primary Latency Timer. The Latency Timer was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this register to 00h.
HEADER_TYPE	22:16	r	**Header Layout** This field identifies the layout of the second part of the predefined header. The controller uses 000 0001b encoding. The encoding 000 0010b is reserved. This encoding was originally described in the PC Card Standard Electrical Specification and is used in previous versions of the programming model. Careful consideration should be given to any attempt to re-purpose it.

(table continues...)

(continued)

Field	Bits	Type	Description
MULTI_FUNC	23	r	**Multi-Function Device** 0_B **CLEAR**: Software must not probe for Functions other than Function 0 1_B **SET**: Indicates that the device may contain multiple Functions, but not necessarily Software is permitted to probe for Functions other than Function 0.
BIST	31:24	r	**BIST** This register is used for control and status of BIST. Functions that do not support BIST must hardwire the register to 00h. A Function whose BIST is invoked must not prevent normal operation of the PCI Express Link. Bit descriptions: • [31]: BIST Capable. When set, this bit indicates that the Function supports BIST. When Clear, the Function does not support BIST • [30]: Start BIST. If BIST Capable is set, set this bit to invoke BIST. The Function resets the bit when BIST is complete. Software is permitted to fail the device if this bit is not Clear (BIST is not complete) 2 seconds after it had been set. Writing this bit to 0b has no effect. The controller hardwires this bit to 0b if BIST Capable is clear • [29:28]: Reserved • [27:24]: Completion Code. This field encodes the status of the most recent test. A value of 0000b means that the Function has passed its test. Non-zero values mean the Function failed. Function-specific failure codes can be encoded in the non-zero values. This field's value is only meaningful when BIST Capable is set and Start BIST is Clear. This field must be hardwired to 0000b if BIST Capable is clear.

19.4.2.102 BAR0 Register i

System software must build a consistent address map before booting the machine to an operating system. This means it has to determine how much memory is in the system, and how much address space the Functions in the system require. After determining this information, system software can map the Functions into reasonable locations and proceed with system boot. In order to do this mapping in a device-independent manner, the base registers for this mapping are placed in the predefined header portion of Configuration Space. It is strongly recommended that power-up firmware/software also support the optional Enhanced Configuration Access Mechanism (ECAM).

BARi_REG (i=0-1) Offset address: 0004010_H+i*4

BAR0 Register i Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
BAR0_MEM_IO	0	rwh	**BAR0 Memory Space Indicator** This bit is used to determine whether the register maps into Memory or I/O Space. Base Address registers that map to Memory Space must return a 0b. Base Address registers that map to I/O Space must return a 1b. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (BAR_ENABLED == 1) then (if [DBI_RO_WR_EN == 1] then R(Sticky)/W(Sticky) else R(Sticky)) else RO(Sticky) Note: This register field is sticky.
BAR0_TYPE	2:1	rwh	**BAR0 Type** • Memory Space: Base Address registers that map into Memory Space can be 32 bits or 64 bits wide (to support mapping into a 64-bit address space). The encodings defined in Values: apply • IO Space: Bit 1 is reserved and must return 0b on reads. Bits[31:2] are used to map the function into IO space. The encodings defined in Values: do not apply Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (BAR_ENABLED == 1) then (if [DBI_RO_WR_EN == 1] then R(Sticky)/W(Sticky) else R(Sticky)) else RO(Sticky) Note: This register field is sticky. 00_B **BAR_32**: Base register is 32 bits wide and can be mapped anywhere in the 32 address bit Memory Space 01_B **RSVD_1**: Reserved 10_B **BAR_64**: Base register is 64 bits wide and can be mapped anywhere in the 64 address bit Memory Space 11_B **RSVD_2**: Reserved
BAR0_PREFETCH	3	rwh	**BAR0 Prefetchable** • Memory Space: Set to one if data is prefetchable. A Function is permitted to mark a range as prefetchable. If there are no side effects on reads, the function returns all bytes on reads regardless of the byte enables, and host bridges can merge processor writes into this range without causing errors. Bit must me clear otherwise • IO Space: Not applicable Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (BAR_ENABLED == 1) then (if [DBI_RO_WR_EN == 1] then R(Sticky)/W(Sticky) else R(Sticky)) else RO(Sticky) Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
BAR0_START	31:4	rwh	**BAR0 Base Address** • Memory Space: Base Address • IO Space: bits[31:2] are used to map the function into IO space/ Base Address. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: R(Sticky)/W(Sticky) if enabled else R(Sticky) Note: This register field is sticky.

19.4.2.103 Secondary Latency Timer, Subordinate Bus Number, Secondary Bus Number, and Primary Bus Number Register

This register holds information regarding secondary latency timer, subordinate bus number, secondary bus number, and primary bus number.

SEC_LAT_TIMER_SUB_BUS_SEC_BUS_PRI_BUS_REG Offset address: 0004018_H

Secondary Latency Timer, Subordinate Bus Number, Secondary Bus Number, and Primary Bus Number Register

Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SEC_BUS								PRIM_BUS							
rw								rw							

Field	Bits	Type	Description
PRIM_BUS	7:0	rw	**Primary Bus Number** This register is not used by PCI Express Functions. It is implemented for compatibility with legacy software.
SEC_BUS	15:8	rw	**Secondary Bus Number** The Secondary Bus Number register is used to record the bus number of the PCI bus segment to which the secondary interface of the bridge is connected. Configuration software programs the value in this register. The bridge uses this register to determine when to respond to and convert a Type 1 configuration transaction on the primary interface into a Type 0 transaction on the secondary interface.
SUB_BUS	23:16	rw	**Subordinate Bus Number** The Subordinate Bus Number register is used to record the bus number of the highest numbered PCI bus segment which is behind (or subordinate to) the bridge. Configuration software programs the value in this register. The bridge uses this register in conjunction with the Secondary Bus Number register to determine when to respond to and pass on a Type 1 configuration transaction on the primary interface to the secondary interface.

(table continues...)

(continued)

Field	Bits	Type	Description
SEC_LAT_TIMER	31:24	r	**Secondary Latency Timer** This register does not apply to PCI Express. The controller hardwires it to 00h.

19.4.2.104 Secondary Status, and I/O Limit and Base Register

The I/O Limit and I/O Base registers are optional and define an address range that is used by the bridge to determine when to forward I/O transactions from one interface to the other. If a bridge does not implement an I/O address range, then both the I/O Limit and I/O Base registers must be implemented as read-only registers that return zero when read. If a bridge supports an I/O address range, then these registers must be initialized by configuration software so default states are not specified.

SEC_STAT_IO_LIMIT_IO_BASE_REG Offset address: $000401C_H$

IO_LIMIT				IO_RESERV1			IO_DECODE_BIT8	IO_BASE				IO_RESERV			IO_DECODE
rw				r			rwh	rw				r			rw

Field	Bits	Type	Description
IO_DECODE	0	rw	**I/O Addressing Encode (IO Base Address)** This bit encodes the IO addressing capability of the bridge. Note: • For 16bit I/O address decoding, the bridge must still perform a full 32-bit decode of the I/O address (that is, check that Address[31:16] are 0000h). In this case, the I/O address range supported by the bridge will be to the first 64 KB of I/O Space (0000 0000hto 0000 F FFFh) • For 16bit I/O address decoding, the bridge assumes that the upper 16 address bits, Address[31:16], of the I/O limit address (not implemented in I/O Limit register) are zero • For 32bit I/O address decoding, and the I/O Limit Upper 16 Bits hold the upper 16 bits, corresponding to Address[31:16], of the 32-bit Limit address. In this case, system configuration software is permitted to locate the I/O address range supported by the bridge anywhere in the 4-GB I/O Space • The 4-KB alignment and granularity restrictions still apply when the bridge supports 32-bit I/O addressing Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R 0_B **_16b_SUP_IO_ADDR**: The bridge supports only 16-bit I/O addressing (for ISA compatibility) 1_B **_32b_SUP_IO_ADDR**: The bridge supports 32-bit I/O addressing
IO_RESERV	3:1	r	**Reserved**
IO_BASE	7:4	rw	**I/O Base Address** These bits correspond to the address[15:12] of IO address range. For the purpose of address decoding, the bridge assumes that the lower 12 address bits, address[11:0], of the I/O base address (not implemented in the I/O Base register) are zero.

(table continues...)

(continued)

Field	Bits	Type	Description
IO_DECODE_BIT8	8	rwh	**I/O Addressing Encode (IO Limit Address)** This bit encodes the IO addressing capability of the bridge. Note: • For 16bit I/O address decoding, the bridge must still perform a full 32-bit decode of the I/O address (that is, check that Address[31:16] are 0000h). In this case, the I/O address range supported by the bridge will be to the first 64 KB of I/O Space (0000 0000hto 0000 F FFFh) • For 16bit I/O address decoding, the bridge assumes that the upper 16 address bits, Address[31:16], of the I/O limit address (not implemented in I/O Limit register) are zero • For 32bit I/O address decoding, and the I/O Limit Upper 16 Bits hold the upper 16 bits, corresponding to Address[31:16], of the 32-bit Limit address. In this case, system configuration software is permitted to locate the I/O address range supported by the bridge anywhere in the 4-GB I/O Space • The 4-KB alignment and granularity restrictions still apply when the bridge supports 32-bit I/O addressing Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: R 0_B **_16b_SUP_IO_ADDR**: The bridge supports only 16-bit I/O addressing (for ISA compatibility) 1_B **_32b_SUP_IO_ADDR**: The bridge supports 32-bit I/O addressing
IO_RESERV1	11:9	r	**Reserved**
IO_LIMIT	15:12	rw	**I/O Limit Address** These bits correspond to the address[15:12] of IO address range. For the purpose of address decoding, the bridge assumes that the lower 12 address bits, address[11:0], of the I/O limit address (not implemented in the I/O Limit register) are FFFh. The I/O Limit register can be programmed to a smaller value than the I/O Base register, if there are no I/O addresses on the secondary side of the bridge. In this case, the bridge will not forward any I/O transactions from the primary bus to the secondary and will forward all I/O transactions from the secondary bus to the primary bus.
SEC_STAT_RESERV	22:16	r	**Reserved**
RSVDP_23	23	r	**Reserved for future use**
SEC_STAT_MDPE	24	rw1ch	**Master Data Parity Error** This bit is set by a Function if the Parity Error Response Enable bit in the Bridge Control register is set, and either of the following two conditions occurs: • Port receives a Poisoned Completion coming Upstream • Port transmits a Poisoned Request Downstream If the Parity Error Response Enable bit is clear, this bit is never set
RSVDP_25	26:25	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
SEC_STAT_SIG_TRGT_ABRT	27	rw1ch	**Signaled Target Abort** This bit is set when the secondary side of the Function (for Requests completed by the Type 1 header Function itself) completes a Posted or Non-Posted request as a Completer Abort error. Software write with 1 clears this bit-field.
SEC_STAT_RCVD_TRGT_ABRT	28	rw1ch	**Received Target Abort** This bit is set when the secondary side of a Function (for requests initiated by the Type 1 header Function itself) receives a Completion with Completer Abort Completion status. Software write with 1 clears this bit-field.
SEC_STAT_RCVD_MSTR_ABRT	29	rw1ch	**Received Master Abort** This bit is set when the secondary side of a Function (for requests initiated by the Type 1 header Function itself) receives a Completion with Unsupported Request Completion status. Software write with 1 clears this bit-field.
SEC_STAT_RCVD_SYS_ERR	30	rw1ch	**Received System Error** This bit is set when the secondary side of a Function receives an ERR_FATAL or ERR_NONFATAL message. Software write with 1 clears this bit-field.
SEC_STAT_DPE	31	rw1ch	**Detected Parity Error** This bit is set by a Function when a Poisoned TLP is received by its secondary side, regardless of the state the Parity Error Response Enable bit in the Bridge Control register. Software write with 1 clears this bit-field.

Table 882 Reset values of SEC_STAT_IO_LIMIT_IO_BASE_REG

19.4.2.105 Memory Limit and Base Register

The Memory Limit and Memory Base registers define a memory mapped address range which is used by the bridge to determine when to forward memory transactions from one interface to the other. If there is no prefetchable memory space, and there is no memory-mapped space on the secondary side of the bridge, then the bridge will not forward any memory transactions from the primary bus to the secondary bus and will forward all memory transactions from the secondary bus to the primary bus.

MEM_LIMIT_MEM_BASE_REG Offset address: 0004020_H

Memory Limit and Base Register Kernel Reset value: $0000\ 0000_H$

MEM_BASE												MEM_BASE_RESERV			
rw												r			

Field	Bits	Type	Description
MEM_BASE_RESERV	3:0	r	**Reserved**
MEM_BASE	15:4	rw	**Memory Base Address** These bits correspond to the upper 12 address bits, Address[31:20], of 32-bit addresses. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, Address[19:0], of the memory base address (not implemented in the Memory Base register) are zero.
MEM_LIMIT_RESERV	19:16	r	**Reserved**
MEM_LIMIT	31:20	rw	**Memory Limit Address** These bits correspond to the upper 12 address bits, Address[31:20], of 32-bit addresses. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, Address[19:0], of the memory limit address (not implemented in the Memory Limit register) are F FFFFh. The Memory Limit register must be programmed to a smaller value than the Memory Base register if there is no memory-mapped address space on the secondary side of the bridge.

19.4.2.106 Prefetchable Memory Limit and Base Register

The Prefetchable Memory Limit and Prefetchable Memory Base registers must indicate that 64-bit addresses are supported. The Prefetchable Memory Limit and Prefetchable Memory Base registers are optional. They define a prefetchable memory address range which is used by the bridge to determine when to forward memory transactions from one interface to the other (see the PCI-to-PCI Bridge Architecture Specification for additional details).

PREF_MEM_LIMIT_PREF_MEM_BASE_REG Offset address: 0004024_H

r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVDP_8								CAP_POINTER							
r								rw							

Field	Bits	Type	Description
CAP_POINTER	7:0	rw	**Capabilities Pointer** This register is used to point to a linked list of capabilities implemented by this Function. Since all PCI Express Functions are required to implement the PCI Express Capability structure, this register must point to a valid capability structure and either this structure is the PCI Express Capability structure, or a subsequent list item points to the PCI Express Capability structure. The bottom two bits are Reserved and must be set to 00b. Software must mask these bits off before using this register as a pointer in Configuration Space to the first entry of a linked list of new capabilities. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
RSVDP_8	31:8	r	**Reserved for future use**

19.4.2.111 Bridge Control, Interrupt Pin, and Interrupt Line Register

This register provides many of the same controls for the secondary interface that are provided by the Command Register for the primary interface. This register also identifies the legacy interrupt Message(s) a Function uses and communicates interrupt line routing information.

BRIDGE_CTRL_INT_PIN_INT_LINE_REG Offset address: 000403C$_H$

Bridge Control, Interrupt Pin, and Interrupt Line Register — Kernel Reset value: 0000 01FF$_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INT_PIN								INT_LINE							
rw								rw							

Field	Bits	Type	Description
INT_LINE	7:0	rw	**Interrupt Line** The Interrupt Line register communicates interrupt line routing information. The register must be implemented by any Function that uses an interrupt pin. Values in this register are programmed by system software and are system architecture specific. The Function itself does not use this value; rather the value in this register is used by device drivers and operating systems.

(table continues...)

(continued)

Field	Bits	Type	Description
INT_PIN	15:8	rw	**Interrupt PIN** The Interrupt Pin register register that identifies the legacy interrupt Message(s) the Function uses. All encodings other than the defined encodings are reserved. - PCI Express defines one legacy interrupt Message for a single Function device and up to four legacy interrupt Messages for a multi-Function device. For a single Function device, only INTA may be used. - Any Function on a multi-Function device can use any of the INTx Messages. If a device implements a single legacy interrupt Message, it must be INTA; if it implements two legacy interrupt Messages, they must be INTA and INTB; and so forth. - For a multi-Function device, all Functions may use the same INTx Message or each may have its own (up to a maximum of four Functions) or any combination thereof. - A single Function can never generate an interrupt request on more than one INTx Message. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 00_H **NO_INT**: Indicates that the Function uses no legacy interrupt Message(s) 01_H **INTA**: Map to legacy interrupt Messages for INTA 02_H **INTB**: Map to legacy interrupt Messages for INTB 03_H **INTC**: Map to legacy interrupt Messages for INTC 04_H **INTD**: Map to legacy interrupt Messages for INTD **others,** Reserved
PERE	16	rw	**Parity Error Response Enable** This bit controls the logging of poisoned TLPs in the Master Data Parity Error bit in the Secondary Status register.
SERR_EN	17	rw	**SERR# Enable** This bit controls forwarding of ERR_COR, ERR_NONFATAL and ERR_FATAL from secondary to primary.
ISA_EN	18	rw	**ISA Enable** Modifies the response by the bridge to ISA I/O addresses. This applies only to I/O addresses that are enabled by the I/O Base and I/O Limit registers and are in the first 64 KB of I/O address space (0000 0000h to 0000 FFFFh). If this bit is set, the bridge will block any forwarding from primary to secondary of I/O transactions addressing the last 768 bytes in each 1-KB block. In the opposite direction (secondary to primary), I/O transactions will be forwarded if they address the last 768 bytes in each 1-KB block. 0_B **FRWD_DSP**: Forward downstream all I/O addresses in the address range defined by the I/O Base and I/O Limit registers 1_B **FRWD_USP**: Forward upstream ISA I/O addresses in the address range defined by the I/O Base and I/O Limit registers that are in the first 64 KB of PCI I/O address space (top 768 bytes of each 1-KB block

(table continues...)

(continued)

Field	Bits	Type	Description
VGA_EN	19	r	**VGA Enable** Modifies the response by the bridge to VGA compatible addresses. If the VGA Enable bit is set, the bridge will positively decode and forward the following accesses on the primary interface to the secondary interface (and, conversely, block the forwarding of these addresses from the secondary to primary interface): • Memory accesses in the range 000A 0000h to 000B FFFFh • I/O addresses in the first 64 KB of the I/O address space (Address[31:16] are 0000h) where Address[9:0] are in the ranges 3B0h to 3BBh and 3C0h to 3DFh (inclusive of ISA address aliases determined by the setting of VGA 16-bit Decode) If the VGA Enable bit is set, forwarding of these accesses is independent of the I/O address range and memory address ranges defined by the I/O Base and Limit registers, the Memory Base and Limit registers, and the Prefetchable Memory Base and Limit registers of the bridge. (Forwarding of these accesses is also independent of the setting of the ISA Enable bit (in the Bridge Control register) when the VGA Enable bit is set. Forwarding of these accesses is qualified by the I/O Space Enable and Memory Space Enable bits in the Command register.) For Functions that do not support VGA, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: R 0_B **NO_FRWD_VGA**: Do not forward VGA compatible memory and I/O addresses from the primary to the secondary interface (addresses defined above) unless they are enabled for forwarding by the defined I/O and memory address ranges 1_B **FRWD_VGA**: Forward VGA compatible memory and I/O addresses (addresses defined above) from the primary interface to the secondary interface (if the I/O Space Enable and Memory Space Enable bits are set) independent of the I/O and memory address ranges and independent of the ISA Enable bit
VGA_16B_DEC	20	r	**VGA 16 bit decode** This bit only has meaning if VGA Enable bit is set. This bit enables system configuration software to select between 10-bit and 16-bit I/O address decoding for all VGA I/O register accesses that are forwarded from primary to secondary. For Functions that do not support VGA, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: R 0_B **_10b_ADDR_DECODE**: Execute 10-bit address decodes on VGA I/O accesses 1_B **_16b_ADDR_DECODE**: Execute 16-bit address decodes on VGA I/O accesses
MSTR_ABORT_MODE	21	rh	**Master Abort Mode** This bit was originally described in the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
SBR	22	rw	**Secondary Bus Reset** Setting this bit triggers a hot reset on the corresponding PCI Express Port. Software must ensure a minimum reset duration (Trst) as defined in the PCI Local Bus Specification. Port configuration registers must not be changed, except as required to update Port status. Software and systems must honor first-access-following-reset timing requirements, unless the Readiness Notifications mechanism is used.
BRIDGE_CTRL_RESERV	31:23	r	**Reserved**

19.4.2.112 Power Management Capabilities Register

This register provides information refarding the Power Management Capabilities.

CAP_ID_NXT_PTR_REG Offset address: 0004040_H

Power Management Capabilities Register Reset values see: Table 883

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PM_NEXT_POINTER								PM_CAP_ID							
rw								r							

Field	Bits	Type	Description
PM_CAP_ID	7:0	r	**Capability ID** This field returns 01h to indicate that this is the PCI Power Management Capability. Each function may have only one item in its capability list with Capability ID set to 01h.
PM_NEXT_POINTER	15:8	rw	**Next Capability Pointer** This field provides an offset into the function's configuration space pointing to the location of next item in the capabilities list. If there are no additional items in the capabilities list, this field is set to 00h. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
PM_SPEC_VER	18:16	rw	**Version** This field provides the Power Management specification version. The controller hardwires this field to 011b for functions compliant to PCI Express Base Specification, Revision 4.0, Version 1.0>. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
PME_CLK	19	r	**PME Clock** Does not apply to PCI Express, the controller hardwires it to 0b. Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
DSI	21	rw	**Device Specific Initialization** The DSI bit indicates whether special initialization of this function is required. When set, indicates that the function requires a device specific initialization sequence following a transition to the D0uninitialized state. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. DSI capability is not supported in this implementation
AUX_CURR	24:22	rw	**Aux_Current** This 3 bit field reports the Vaux auxiliary current requirements for the function. If this function implements the Data Register, the controller hardwires this field to 000b. If PME_Support is 0 xxxxb (PME assertion from D3cold is not supported), the controller hardwires this field to 0000b. For functions where PME_Support is 1 xxxxb (PME assertion from D3cold is supported), and which do not implement the Data field, the encodings defined in Values: apply: Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 000_B **SELF_**: 0 self powered 001_B **_055mA_**: 55mA Vaux Max Current Required 010_B **_100mA_**: 100mA Vaux Max Current Required 011_B **_160mA_**: 160mA Vaux Max Current Required 100_B **_220mA_**: 220mA Vaux Max Current Required 101_B **_270mA_**: 270mA Vaux Max Current Required 110_B **_320mA_**: 320mA Vaux Max Current Required 111_B **_370mA_**: 375mA Vaux Max Current Required
D1_SUPPORT	25	rw	**D1_Support** If this bit is set, this function supports the D1 Power Management state. Functions that do not support D1 must always return a value of 0b for this bit. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. D1-support capability is not supported in this implementation
D2_SUPPORT	26	rw	**D2_Support** If this bit is set, this function supports the D2 Power Management state. Functions that do not support D2 must always return a value of 0b for this bit. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. D2-support capability is not supported in this implementation

(table continues...)

(continued)

Field	Bits	Type	Description
PME_SUPPORT	31:27	rwh	**PME_Support** This 5-bit field indicates the power states in which the function may generate a PME and/or forward PME messages. A value of 0b for any bit indicates that the function is not capable of asserting PME while in that power state. • bit(27) X XXX1b - PME can be generated from D0 • bit(28) X XX1Xb - PME can be generated from D1 • bit(29) X X1XXb - PME can be generated from D2 • bit(30) X 1XXXb - PME can be generated from D3hot • bit(31) 1 XXXXb - PME can be generated from D3cold Bit 31 (PME can be asserted from D3cold) represents a special case. Functions that set this bit require some sort of auxiliary power source. Implementation specific mechanisms are recommended to validate that the power source is available before setting this bit. Each bit that corresponds to a supported D-state must be set for PCI-PCI Bridge structures representing Ports on Root Complexes/Switches to indicate that the Bridge will forward PME Messages. Bit 31 must only be set if the Port is still able to forward PME Messages when main power is not available. The read value from this field is the write value && (sys_aux_pwr_det, 1'b1, D2_SUPPORT, D1_SUPPORT, 1'b1), where D1_SUPPORT and D2_SUPPORT are fields in this register. The reset value PME_SUPPORT_n && (sys_aux_pwr_det, 1'b1, D2_SUPPORT, D1_SUPPORT, 1'b1), where PME_SUPPORT_n is a configuration parameter. Note: The access attributes of this field are as follows: - Wire: R - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
0	20	r	**Reserved** Read as 0; should be written with 0.

Table 883 Reset values of CAP_ID_NXT_PTR_REG

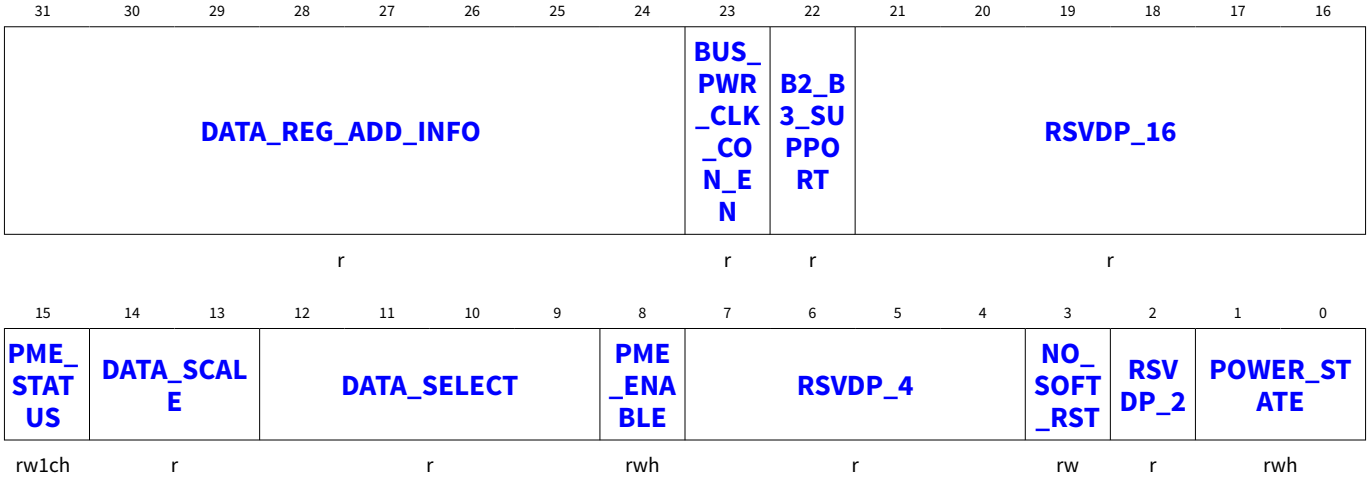
Reset	Reset value	Note
Kernel Reset	XXXX X001 1100 0011 0101 0000 0000 0001_B	

19.4.2.113 Power Management Control and Status Register

This register is used to manage the PCI function's power management state as well as to enable/monitor PMEs.

CON_STATUS_REG Offset address: 0004044_H

Power Management Control and Status Register Reset values see: Table 884



Field	Bits	Type	Description
POWER_STATE	1:0	rwh	**PowerState** This 2-bit field is used both to determine the current power state of a function and to set the function into a new power state. You can write to this register; however, the read-back value is the actual power state, not the write value. If you attempt to write an unsupported, optional state to this field, the write operation completes normally; however, the data is discarded and no state change occurs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 00_B **D0**: D0 power state 01_B **D1**: D1 power state 10_B **D2**: D2 power state 11_B **D3hot**: D3hot D3hot power state
RSVDP_2	2	r	**Reserved for future use**
NO_SOFT_RST	3	rw	**No_Soft_Reset** This bit indicates the state of the function after writing the PowerState field to transition the function from D3hot to D0. • When set, this transition preserves internal function state. The function is in D0Active and no additional software intervention is required • When clear, this transition results in undefined internal function state Regardless of this bit, functions that transition from D3hot to D0 by Fundamental Reset will return to D0Uninitialized with only PME context preserved if PME is supported and enabled. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
RSVDP_4	7:4	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
PME_ENABLE	8	rwh	**PME_En** • When set, the function is permitted to generate a PME • When clear, the function is not permitted to generate a PME. If PME_Support is 1 xxxxb (PME generation from D3cold) or the function consumes Aux power and Aux power is available this bit is RWS and the bit is not modified by Conventional Reset If PME_Support is 0 xxxxb, this field is not sticky (RW). If PME_Support is 0 0000b, the controller hardwires this bit to 0b. Note: This register field is sticky.
DATA_SELECT	12:9	r	**Data_Select** This 4-bit field is used to select which data is to be reported through the Data and Data_Scale field. If the Data field is not implemented, this field must be hardwired to 0000b.
DATA_SCALE	14:13	r	**Data_Scale** This field indicates the scaling factor to be used when interpreting the value of the Data field. The value and meaning of this field varies depending on which data value has been selected by the Data_Select field. For more details, see 7.5.2.3 section of PCI Express Base Specification.
PME_STATUS	15	rw1ch	**PME_Status** This bit is set when the function normally generates a PME signal. The value of this bit is not affected by the value of the PME_En bit. If PME_Support bit 31 of the Power Management Capabilities register is clear, this bit is permitted to be hardwired to 0b. Functions that consume Aux power must preserve the value of this sticky register when Aux power is available. In such functions, this register value is not modified by Conventional Reset . Note: This register field is sticky. Software write with 1 clears this bit-field.
RSVDP_16	21:16	r	**Reserved for future use**
B2_B3_SUPPORT	22	r	**B2B3 Support for D3hot** If this field is set, B2B3 support for D3hot is available.
BUS_PWR_CLK_CON_EN	23	r	**Bus Power/Clock Control Enable** If this field is set, Bus Power/Clock Control is Enable.
DATA_REG_ADD_INFO	31:24	r	**Data** This field is used to report the state dependent data requested by the Data_Select field. The value of this field is scaled by the value reported by the Data_Scale field.

Table 884 Reset values of CON_STATUS_REG

PCI_MSI_CAP_NEXT_OFFSET								PCI_MSI_CAP_ID							
rw								r							

Field	Bits	Type	Description
PCI_MSI_CAP_ID	7:0	r	**Capability ID** Indicates the MSI Capability structure. This field returns a Capability ID of 05h indicating that this is an MSI Capability structure.
PCI_MSI_CAP_NEXT_OFFSET	15:8	rw	**Next Capability Pointer** This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of Capabilities. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
PCI_MSI_ENABLE	16	rw	**MSI Enable** • If set and the MSI-X Enable bit in the MSI-X Message Control register is clear, the function is permitted to use MSI to request service and is prohibited from using INTx interrupts. System configuration software sets this bit to enable MSI. A device driver is prohibited from writing this bit to mask a function's service request. For more details on control of INTx interrupts, see section 7.5.1.1 of PCI Express Base Specification. • If clear, the function is prohibited from using MSI to request service Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
PCI_MSI_MULTIPLE_MSG_CAP	19:17	rw	**Multiple Message Capable** System software reads this field to determine the number of requested vectors. The number of requested vectors must be aligned to a power of two (if a function requires three vectors, it requests four by initializing this field to 010b). All encodings other than the defined encodings are reserved. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 000_B **_1_VECTOR**: 1 vector requested 001_B **_2_VECTOR**: 2 vectors requested 010_B **_4_VECTOR**: 4 vectors requested 011_B **_8_VECTOR**: 8 vectors requested 100_B **_16_VECTOR**: 16 vectors requested 101_B **_32_VECTOR**: 32 vectors requested **others,** Reserved
PCI_MSI_MULTIPLE_MSG_EN	22:20	rw	**Multiple Message Enable** Software writes to this field to indicate the number of allocated vectors (equal to or less than the number of requested vectors). The number of allocated vectors is aligned to a power of two. If a function requests four vectors (indicated by a Multiple Message Capable encoding of 010b), system software can allocate either four, two, or one vector by writing a 010b, 001b, or 000b to this field, respectively. When MSI is enabled, a function will be allocated at least 1 vector. All encodings other than the defined encodings are reserved. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 000_B **_1_VECTOR**: 1 vector allocated 001_B **_2_VECTOR**: 2 vectors allocated 010_B **_4_VECTOR**: 4 vectors allocated 011_B **_8_VECTOR**: 8 vectors allocated 100_B **_16_VECTOR**: 16 vectors allocated 101_B **_32_VECTOR**: 32 vectors allocated **others,** Reserved
PCI_MSI_64_BIT_ADDR_CAP	23	rw	**64 bit address capable** • If set, the function is capable of sending a 64-bit message address • If clear, the function is not capable of sending a 64-bit message address. This bit must be set if the function is a PCI Express Endpoint Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
PCI_PVM_SUPPORT	24	r	**Per-Vector Masking Capable** • If set, the function supports MSI Per-Vector Masking • If clear, the function does not support MSI Per-Vector Masking

(table continues...)

(continued)

Field	Bits	Type	Description
PCI_MSI_EXT_DATA_CAP	25	rw	**Extended Message Data Capable** • If set, the function is capable of providing Extended Message Data • If clear, the function does not support providing Extended Message Data Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. Extended Message Data Capability is not supported in the current implementation
PCI_MSI_EXT_DATA_EN	26	rw	**Extended Message Data Enable** • If set, the function is enabled to provide Extended Message Data • If clear, the function is not enabled to provide Extended Message Data Note: The access attributes of this field are as follows: • Wire: PCI_MSI_CAP_ID_NEXT_CTRL_REG.PCI_MSI_EXT_DATA_CAP ? RW : RO • Dbi: PCI_MSI_CAP_ID_NEXT_CTRL_REG.PCI_MSI_EXT_DATA_CAP ? RW : RO
RSVDP_27	31:27	r	**Reserved for future use**

19.4.2.115 Message Address Register for MSI (Offset 04h)

This register holds the system specified message address for an MSI transaction.

MSI_CAP_OFF_04H_REG Offset address: 0004054_H

Message Address Register for MSI [Offset 04h) Kernel Reset value: $0000\ 0000_H$

PCI_MSI_CAP_OFF_04H	31:2	rw	**Message Address - System-specified message address** If the Message Enable bit (bit 16 of the PCI_MSI_CAP_ID_NEXT_CTRL_REG register) is set, the contents of this field specify the DWORD-aligned address (Address[31:02]) for the MSI transaction. Address[1:0] are set to 00b. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.116 Message Address Register for MSI (Offset 08h)

This register represents the Message Upper Address Register for MSI (Offset 08h). It specifies the Message Upper Address (System-specified message upper address). This register is required for PCI Express Endpoints and is optional for other function types. If the Message Enable bit (bit 0 of the Message Control register) is set, the contents of this register (if non-zero) specify the upper 32-bits of a 64-bit message address (Address[63:32]). If the contents of this register are zero, the Function uses the 32 bit address specified by the Message Address register.

PCI_MSI_CAP_OFF_08H															
rw															

Field	Bits	Type	Description
PCI_MSI_CAP_OFF_08H	15:0	rw	**For a function that supports a 32-bit message address, this field contains Message Data (System-specified message data)** If the Message Enable bit (bit 16 of the PCI_MSI_CAP_ID_NEXT_CTRL_REG) is set, the function sends a DWORD Memory Write transaction using Message Data for the lower 16 bits. All 4 Byte Enables are set. The Multiple Message Enable field (bits 22:20 of the PCI_MSI_CAP_ID_NEXT_CTRL_REG) defines the number of low order message data bits the function is permitted to modify to generate its system software allocated vectors. For example, a Multiple Message Enable encoding of 010b indicates the function has been allocated four vectors and is permitted to modify message data bits 1 and 0 (a function modifies the lower message data bits to generate the allocated number of vectors). If the Multiple Message Enable field is 000b, the Function is not permitted to modify the message data. For a function that supports a 64-bit message address, it contains lower 16 bits of the Message Upper Address. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
PCI_MSI_CAP_OFF_0AH	31:16	rw	**For a function that supports a 32-bit message address, this field contains Extended Message Data (System-specified message data)** Extended Message Data Capability is not supported in the current implementation For the MSI Capability structures without per-vector masking, it must be implemented if the Extended Message Data Capable bit is set; otherwise, it is outside the MSI Capability structure and undefined. For the MSI Capability structures with Per-vector Masking, it must be implemented if the Extended Message Data Capable bit is set; otherwise, it is RsvdP. If the Extended Message Data Enable bit (bit 26 of the PCI_MSI_CAP_ID_NEXT_CTRL_REG) is set, the DWORD Memory Write transaction uses Extended Message Data for the upper 16 bits; otherwise, it uses 0000h for the upper 16 bits. For a function that supports a 64-bit message address, it contains upper 16 bits of the Message Upper Address. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.117 Message Address Register for MSI (Offset 0Ch)

This register contains Message Data.

MSI_CAP_OFF_0CH_REG Offset address: $000405C_H$

Message Address Register for MSI [Offset 0Ch) Kernel Reset value: $0000\ 0000_H$

PCI_MSI_CAP_OFF_14H	31:0	r	**Pending Bits** For each pending bit that is set, the function has a pending associated message.

19.4.2.120 PCI Express Capabilities, ID, Next Pointer Register

This is the PCI Express Capabilities, ID, and Next Pointer Register.

PCIE_CAP_ID_PCIE_NEXT_CAP_PTR_PCIE_CAP_REG Offset address: 0004070_H

PCI Express Capabilities, ID, Next Pointer Register Kernel Reset value: $0042\ B010_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSVDP_31	RSVD	PCIE_INT_MSG_NUM					PCIE_SLOT_IMP	PCIE_DEV_PORT_TYPE				PCIE_CAP_REG			
r	r	rw					rw	rh				r			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PCIE_CAP_NEXT_PTR								PCIE_CAP_ID							
rw								r							

Field	Bits	Type	Description
PCIE_CAP_ID	7:0	r	**Capability ID** Indicates the PCI Express Capability structure. This field must return a Capability ID of 10h indicating that this is a PCI Express Capability structure.
PCIE_CAP_NEXT_PTR	15:8	rw	**Next Capability Pointer** This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of Capabilities. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
PCIE_CAP_REG	19:16	r	**Capability Version** Indicates PCI-SIG defined PCI Express Capability structure version number. A version of the specification that changes the PCI Express Capability structure in a way that is not otherwise identifiable (for example, through a new Capability field) is permitted to increment this field. All such changes to the PCI Express Capability structure must be software-compatible. Software must check for Capability Version numbers that are greater than or equal to the highest number defined when the software is written, as functions reporting any such Capability Version numbers will contain a PCI Express Capability structure that is compatible with that piece of software. The controller hardwires this field to 2h for functions compliant to PCI Express Base Specification, Revision 4.0, Version 1.0. Note: This register field is sticky.

(table continues...)

(continued)

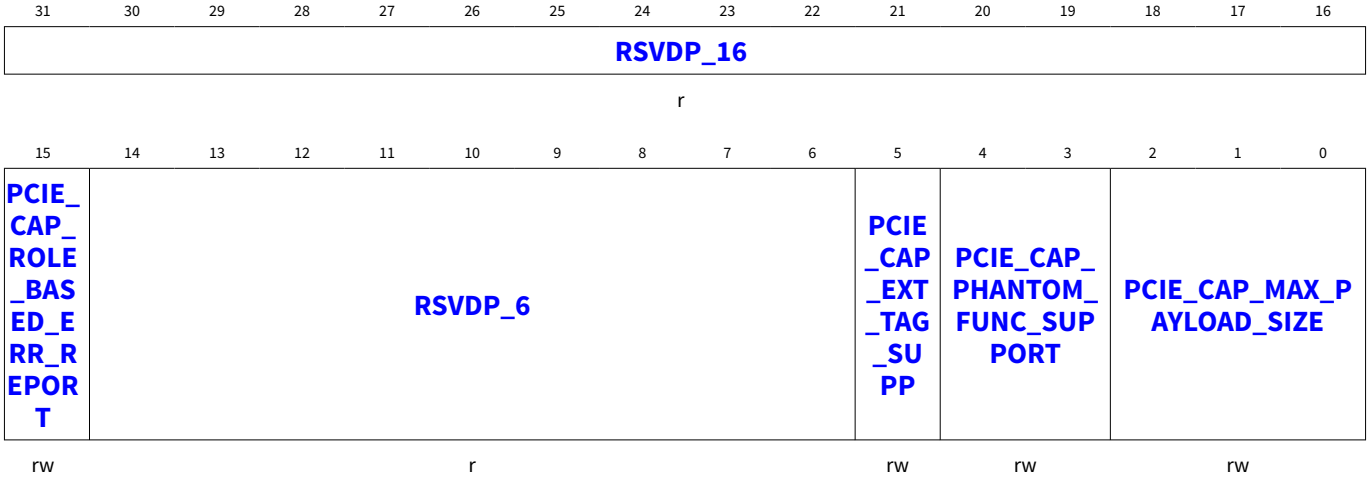
Field	Bits	Type	Description
PCIE_DEV_PORT_TYPE	23:20	rh	**Device/Port Type** Indicates the specific type of this PCI Express function. Note: Different functions in a Multi-Function Device can generally be of different types. Defined encodings for functions that implement a Type 00h PCI Configuration Space header are: Defined encodings for functions that implement a Type 01h PCI Configuration Space header are: All other encodings are Reserved. Note: Different Endpoint types have notably different requirements in Section 1.3.2 of PCI Express Base Specification regarding I/O resources, Extended Configuration Space, and other capabilities. 0_H **PCIE_EP**: PCI Express Endpoint 1_H **PCIE_LEGACY_EP**: Legacy PCI Express Endpoint 4_H **ROOT_PORT_PCIE_RC**: Root Port of PCI Express Root Complex 5_H **USP_PCIE_SWITCH**: Upstream Port of PCI Express Switch 6_H **DSP_PCIE_SWITCH**: Downstream Port of PCI Express Switch **others,** Reserved
PCIE_SLOT_IMP	24	rw	**Slot Implemented** When set, this bit indicates that the Link associated with this Port is connected to a slot (as compared to being connected to a system-integrated device or being disabled). This bit is valid for Downstream Ports. This bit is undefined for Upstream Ports. Note: The access attributes of this field are as follows: - Wire: HWINIT - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
PCIE_INT_MSG_NUM	29:25	rw	**PCIE Interrupt Message Number** Interrupt Message Number. This field indicates which MSI/MSI-X vector is used for the interrupt message generated in association with any of the status bits of this Capability structure. For MSI, the value in this field indicates the offset between the base Message Data and the interrupt message that is generated. Hardware is required to update this field so that it is correct if the number of MSI Messages assigned to the Function changes when software writes to the Multiple Message Enable field in the MSI Message Control register. For MSI-X, the value in this field indicates which MSI-X Table entry is used to generate the interrupt message. The entry must be one of the first 32 entries even if the Function implements more than 32 entries. For a given MSI-X implementation, the entry must remain constant. If both MSI and MSI-X are implemented, they are permitted to use different vectors, though software is permitted to enable only one mechanism at a time. If MSI-X is enabled, the value in this field must indicate the vector for MSI-X. If MSI is enabled or neither is enabled, the value in this field must indicate the vector for MSI. If software enables both MSI and MSI-X at the same time, the value in this field is undefined. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
RSVD	30	r	**Reserved**
RSVDP_31	31	r	**Reserved for future use**

19.4.2.121 Device Capabilities Register

The Device Capabilities register identifies PCI Express device function specific capabilities.

DEVICE_CAPABILITIES_REG Offset address: 0004074_H

Device Capabilities Register Kernel Reset value: $0000\ 8001_H$



Field	Bits	Type	Description
PCIE_CAP_MAX_PAYLOAD_SIZE	2:0	rw	**Max_Payload_Size Supported** This field indicates the maximum payload size that the function can support for TLPs. All encodings other than the defined encodings are reserved. The functions of a Multi-Function Device are permitted to report different values for this field. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 000_B **MAX_128B_SIZE**: 128 bytes max payload size 001_B **MAX_256B_SIZE**: 256 bytes max payload size 010_B **MAX_512B_SIZE**: 512 bytes max payload size 011_B **MAX_1024B_SIZE**: 1024 bytes max payload size 100_B **MAX_2048B_SIZE**: 2048 bytes max payload size 101_B **MAX_4096B_SIZE**: 4096 bytes max payload size **others,** Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_PHANTOM_FUNC_SUPPORT	4:3	rw	**Phantom Functions Supported** For functions that do not implement this capability (Phantom function capability is not available in this implementation), this bit will be hardwired to 0b. This field indicates the support for use of unclaimed function numbers to extend the number of outstanding transactions allowed by logically combining unclaimed function numbers (called Phantom Functions) with the Tag identifier (see Section 2.2.6.2 of PCI Express Base Specification for a description of Tag Extensions). With every Function in an ARI Device, the Phantom Functions Supported field must be set to 00b. The remainder of this field description applies only to non-ARI Multi-Function Devices. This field indicates the number of most significant bits of the Function Number portion of Requester ID that are logically combined with the Tag identifier. Note: Phantom Function support for the function must be enabled by the Phantom Functions Enable field in the Device Control register before the Function is permitted to use the Function Number field in the Requester ID for Phantom Functions. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 00_B **NO_PHNATOM_FUNC**: No Function Number bits are used for Phantom Functions Multi-Function Devices are permitted to implement up to 8 independent functions. 01_B **MAX_1_PHANTOM_PER_FUNC**: The most significant bit of the Function number in Requester ID is used for Phantom Functions; a Multi-Function Device is permitted to implement Functions 0-3 Functions 0, 1, 2, and 3 are permitted to use Function Numbers 4, 5, 6, and 7 respectively as Phantom Functions. 10_B **MAX_3_PHANTOM_PER_FUNC**: The two most significant bits of Function Number in Requester ID are used for Phantom Functions; a Multi-Function Device is permitted to implement Functions 0-1 Function 0 is permitted to use Function Numbers 2, 4, and 6 for Phantom Functions. Function 1 is permitted to use Function Numbers 3, 5, and 7 as Phantom Functions. 11_B **SINGLE_FUNC_MAX_7_PHANTOM_FUNC**: All 3 bits of Function Number in Requester ID used for Phantom Functions The device must have a single Function 0 that is permitted to use all other Function Numbers as Phantom Functions.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_EXT_TAG_SUPP	5	rw	**Extended Tag Field Supported** This bit, in combination with the 10-Bit Tag Requester Supported bit in the Device Capabilities 2 register, indicates the maximum supported size of the Tag field as a Requester. This bit must be set if the 10-Bit Tag Requester Supported bit is set. Note: 8-bit Tag field generation must be enabled by the Extended Tag Field Enable bit in the Device Control register of the Requester Function before 8-bit Tags can be generated by the Requester. See Section 2.2.6.2 of PCI Express Base Specification for interactions with enabling the use of 10-Bit Tags. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 0_B **_5b_TAG**: 5-bit Tag field supported 1_B **_8b_TAG**: 8-bit Tag field supported
RSVDP_6	14:6	r	**Reserved for future use**
PCIE_CAP_ROLE_BASED_ERR_REPORT	15	rw	**Role-Based Error Reporting** When set, this bit indicates that the function implements the functionality originally defined in the Error Reporting ECN for PCI Express Base Specification, Revision 1.0a, and later incorporated into PCI Express Base Specification, Revision 1.1. This bit must be set by all functions conforming to the ECN, PCI Express Base Specification, Revision 1.1., or subsequent PCI Express Base Specification revisions. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
RSVDP_16	31:16	r	**Reserved for future use**

19.4.2.122 Device Control and Device Status Register

This register controls PCI Express device specific parameters and provides information about PCI Express device (function) specific parameters.

DEVICE_CONTROL_DEVICE_STATUS Offset address: 0004078_H

Device Control and Device Status Register Reset values see: Table 885

r	rw			rw	rwh	rh	rh	rw			rw	rw	rw	rw	rw

Field	Bits	Type	Description
PCIE_CAP_CORR_ERR_REPORT_EN	0	rw	**Correctable Error Reporting Enable** This bit, in conjunction with other bits, controls sending ERR_COR Messages (for more details, see section 6.2.5, section 6.2.6, and section 6.2.10.2 of PCI Express Base Specification). For a Multi-Function device, this bit controls error reporting for each function from point-of-view of the respective function. For a Root Port, the reporting of correctable errors is internal to the root. No external ERR_COR Message is generated.
PCIE_CAP_NON_FATAL_ERR_REPORT_EN	1	rw	**Non-Fatal Error Reporting Enable** This bit, in conjunction with other bits, controls sending ERR_NONFATAL Messages (for more details, see section 6.2.5 and Section 6.2.6 of PCI Express Base Specification). For a Multi-Function Device, this bit controls error reporting for each function from point-of-view of the respective Function. For a Root Port, the reporting of Non-fatal errors is internal to the root. No external ERR_NONFATAL Message is generated.
PCIE_CAP_FATAL_ERR_REPORT_EN	2	rw	**Fatal Error Reporting Enable** This bit, in conjunction with other bits, controls sending ERR_FATAL Messages (for more details, see section 6.2.5 and section 6.2.6 of of PCI Express Base Specification). For a Multi-Function device, this bit controls error reporting for each function from point-of-view of the respective function. For a Root Port, the reporting of Fatal errors is internal to the root. No external ERR_FATAL Message is generated.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_UNSUPPORT_REQ_REP_EN	3	rw	**Unsupported Request Reporting Enable** This bit, in conjunction with other bits, controls the signaling of Unsupported Request Errors by sending error Messages (for more details, see section 6.2.5 and section 6.2.6 of PCI Express Base Specification). For a Multi-Function Device, this bit controls error reporting for each Function from point-of-view of the respective Function.
PCIE_CAP_EN_REL_ORDER	4	rw	**Enable Relaxed Ordering** If this bit is set, the function is permitted to set the Relaxed Ordering bit in the Attributes field of transactions it initiates that do not require strong write ordering (for more details, see section 2.2.6.4 and section 2.4 of PCI Express Base Specification). For a function that never sets the Relaxed Ordering attribute in transactions it initiates as a Requester, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
PCIE_CAP_MAX_PAYLOAD_SIZE_CS	7:5	rw	**Max_Payload_Size** This field sets maximum TLP payload size for the Function. As a Receiver, the Function must handle TLPs as large as the set value. As a Transmitter, the Function must not generate TLPs exceeding the set value. Permissible values that can be programmed are indicated by the Max_Payload_Size Supported field (PCIE_CAP_MAX_PAYLOAD_SIZE) in the Device Capabilities (DEVICE_CAPABILITIES_REG) register (for more details, see section 7.5.3.3 of PCI Express Base Specification). This field sets the maximum Read Request size for the function as a Requester. The function must not generate Read Requests with a size exceeding the set value. For Functions that support only the 128-byte max payload size, the controller hardwires this field to 000b. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 000_B **MAX_128B_SIZE**: 128 bytes maximum Read Request size 001_B **MAX_256B_SIZE**: 256 bytes maximum Read Request size 010_B **MAX_512B_SIZE**: 512 bytes maximum Read Request size 011_B **MAX_1024B_SIZE**: 1024 bytes maximum Read Request size 100_B **MAX_2048B_SIZE**: 2048 bytes maximum Read Request size 101_B **MAX_4096B_SIZE**: 4096 bytes maximum Read Request size 110_B **RESERVED1**: RESERVED 111_B **RESERVED2**: RESERVED

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_EXT_TAG_EN	8	rh	**Extended Tag Field Enable** This bit, in combination with the 10-Bit Tag Requester Enable bit in the Device Control 2 register, determines how many Tag field bits a Requester is permitted to use. When the 10-Bit Tag Requester Enable bit is clear, • If the Extended Tag Field Enable bit is set, the function is permitted to use an 8-bit Tag field as a Requester • If the Extended Tag Field Enable bit is clear, the Function is to a 5-bit Tag field See section 2.2.6.2 of PCI Express Base Specification for required behavior when the 10-Bit Tag Requester Enable bit is set. If software changes the value of the Extended Tag Field Enable bit while the function has outstanding Non-Posted Requests, the result is undefined. For functions that do not implement this capability, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: DEVICE_CAPABILITIES_REG.PCIE_CAP_EXT_TAG_SUPP ? RW : RO - Dbi: DEVICE_CAPABILITIES_REG.PCIE_CAP_EXT_TAG_SUPP ? RW : RO
PCIE_CAP_PHANTOM_FUNC_EN	9	rh	**Phantom Functions Enable** For functions that do not implement this capability (Phantom function capability is not available in this implementation), this bit will be hardwired to 0b. This bit, in combination with the 10-Bit Tag Requester Enable bit in the Device Control 2 register, determines how many Tag field bits a Requester is permitted to use. When the 10-Bit Tag Requester Enable bit is clear, • If this bit is set, it enables a function to use unclaimed functions as Phantom functions to extend the number of outstanding transaction identifiers • If this bit is clear, the function is not allowed to use Phantom functions For more details, see section 2.2.6.2 of PCI Express Base Specification. Software should not change the value of this bit while the function has outstanding Non-Posted Requests; otherwise, the result is undefined.Note: The access attributes of this field are as follows: • Wire: DEVICE_CAPABILITIES_REG.PCIE_CAP_PHANTOM_FUNC_SUPPORT ? RW : RO • Dbi: DEVICE_CAPABILITIES_REG.PCIE_CAP_PHANTOM_FUNC_SUPPORT ? RW : R

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_AUX_POWER_PM_EN	10	rwh	**Aux Power PM Enable** This bit is derived by sampling the sys_aux_pwr_det input. When set this bit, enables a function to draw Aux power independent of PME Aux power. Functions that require Aux power on legacy operating systems should continue to indicate PME Aux power requirements. Aux power is allocated as requested in the Aux_Current field of the Power Management Capabilities register (PMC), independent of the PME_En bit in the Power Management Control/Status register (PMCSR). For Multi-Function devices, a component is allowed to draw Aux power if at least one of the functions has this bit set. Note: Functions that consume Aux power must preserve the value of this sticky register when Aux power is available. In such functions, this bit is not modified by Conventional Reset. For functions that do not implement this capability, the controller hardwires this bit to 0b. Note: This register field is sticky.
PCIE_CAP_EN_NO_SNOOP	11	rw	**Enable No Snoop** If this bit is set, the function is permitted to Set the No Snoop bit in the Requester Attributes of transactions it initiates that do not require hardware enforced cache coherency (see section 2.2.6.5 in PCI Express Base Specification). Note: Setting this bit to 1b should not cause a function to set the No Snoop attribute on all transactions that it initiates. Even when this bit is set, a function is only permitted to set the No Snoop attribute on a transaction when it can guarantee that the address of the transaction is not stored in any cache in the system. The controller hardwires this bit 0b if a function would never set the No Snoop attribute in transactions it initiates. Note: The access attributes of this field are as follows: - Wire: R - Dbi: R
PCIE_CAP_MAX_READ_REQ_SIZE	14:12	rw	**Max_Read_Request_Size** This field sets the maximum Read Request size for the function as a Requester. The function must not generate Read Requests with a size exceeding the set value. For functions that do not generate Read Requests larger than 128 bytes and functions that do not generate Read Requests on their own behalf, the controller implements this field as Read Only (RO) with a value of 000b. 000_B **MAX_128B_SIZE**: 128 bytes maximum Read Request size 001_B **MAX_256B_SIZE**: 256 bytes maximum Read Request size 010_B **MAX_512B_SIZE**: 512 bytes maximum Read Request size 011_B **MAX_1024B_SIZE**: 1024 bytes maximum Read Request size 100_B **MAX_2048B_SIZE**: 2048 bytes maximum Read Request size 101_B **MAX_4096B_SIZE**: 4096 bytes maximum Read Request size 110_B **RESERVED1**: RESERVED 111_B **RESERVED2**: RESERVED
PCIE_CAP_CORR_ERR_DETECTED	16	rw1ch	**Correctable Error Detected** This bit indicates status of correctable errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For functions supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the Correctable Error Mask register. Software write with 1 clears this bit-field.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_NON_FATAL_ERR_DETECTED	17	rw1ch	**Non-Fatal Error Detected** This bit indicates status of Non-fatal errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For functions supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the Uncorrectable Error Mask register. Software write with 1 clears this bit-field.
PCIE_CAP_FATAL_ERR_DETECTED	18	rw1ch	**Fatal Error Detected** This bit indicates status of Fatal errors detected. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. For Functions supporting Advanced Error Handling, errors are logged in this register regardless of the settings of the Uncorrectable Error Mask register. Software write with 1 clears this bit-field.
PCIE_CAP_UNSUPPORTED_REQ_DETECTED	19	rw1ch	**Unsupported Request Detected** This bit indicates that the function received an Unsupported Request. Errors are logged in this register regardless of whether error reporting is enabled or not in the Device Control register. Software write with 1 clears this bit-field.
PCIE_CAP_AUX_POWER_DETECTED	20	rh	**AUX Power Detected** Functions that require Aux power report this bit as set if Aux power is detected by the function. .
PCIE_CAP_TRANS_PENDING	21	r	**Transactions Pending** Endpoints: When set, this bit indicates that the function has issued Non-Posted Requests that have not been completed. A Function reports this bit cleared only when all outstanding Non-Posted Requests have completed or have been terminated by the Completion Timeout mechanism. Root and Switch Ports: The controller hardwires this bit to 0b.
RSVDP_22	31:22	r	**Reserved for future use**
0	15	r	**Reserved** Read as 0; should be written with 0.

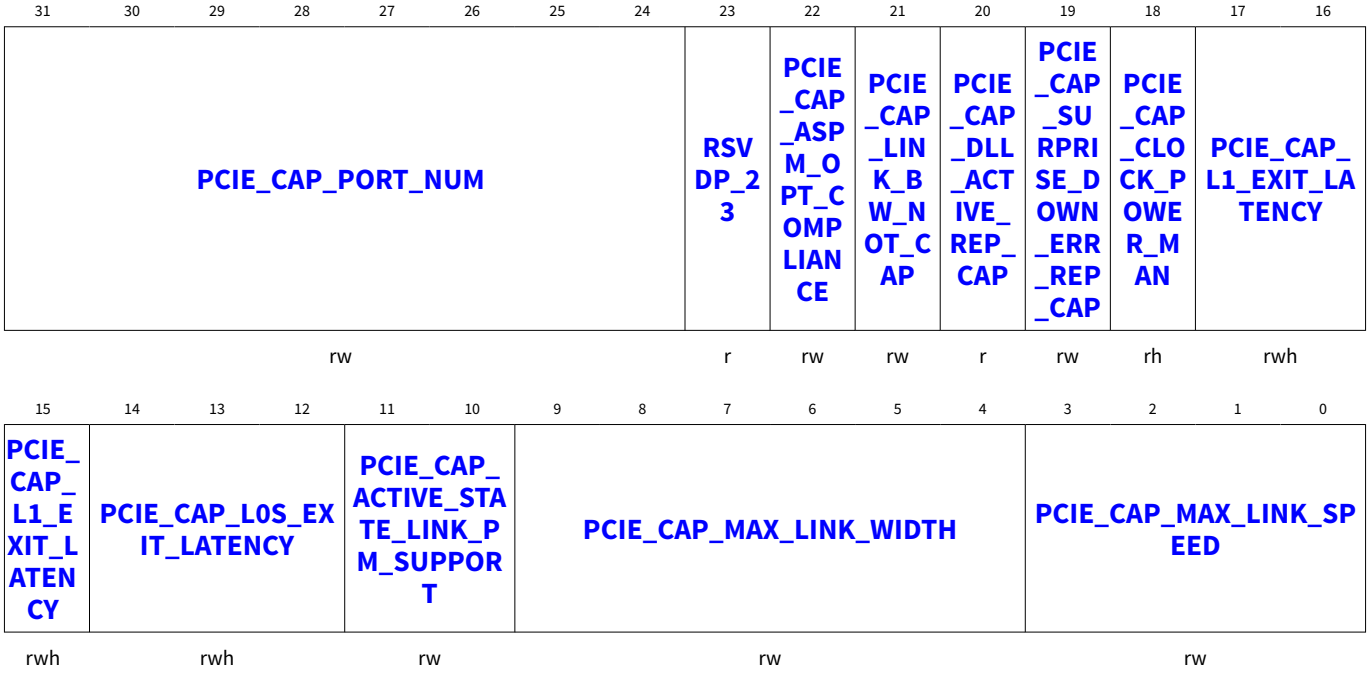
19.4.2.123 Link Capabilities Register

The Link Capabilities register identifies PCI Express Link specific capabilities.

LINK_CAPABILITIES_REG Offset address: $000407C_H$

Link Capabilities Register Reset values see: Table 886

19 Peripheral Component Interconnect Express (PCIe)



Field	Bits	Type	Description
PCIE_CAP_MAX_LINK_SPEED	3:0	rw	**Max Link Speed** This field indicates the maximum Link speed of the associated Port. The encoded value specifies a bit location in the Supported Link Speeds Vector (in the Link Capabilities 2 register) that corresponds to the maximum Link speed. All encodings other than the defined encodings are reserved. Multi-Function Devices associated with an Upstream Port must report the same value in this field for all functions. In M-PCIe mode, the reset and dynamic values of this field are calculated by the controller. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 1_H **SUP_LINK_SPEED_FIELD_BIT_0**: Supported Link Speeds Vector field bit 0 2_H **SUP_LINK_SPEED_FIELD_BIT_1**: Supported Link Speeds Vector field bit 1 3_H **SUP_LINK_SPEED_FIELD_BIT_2**: Supported Link Speeds Vector field bit 2 4_H **SUP_LINK_SPEED_FIELD_BIT_3**: Supported Link Speeds Vector field bit 3 5_H **SUP_LINK_SPEED_FIELD_BIT_4**: Supported Link Speeds Vector field bit 4 6_H **SUP_LINK_SPEED_FIELD_BIT_5**: Supported Link Speeds Vector field bit 5 7_H **SUP_LINK_SPEED_FIELD_BIT_6**: Supported Link Speeds Vector field bit 6 **others,** Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_MAX_LINK_WIDTH	9:4	rw	**Maximum Link Width** This field indicates the maximum Link width (xN - corresponding to N Lanes) implemented by the component. This value is permitted to exceed the number of Lanes routed to the slot (Downstream Port), adapter connector (Upstream Port), or in the case of component-to-component connections, the actual wired connection width. All encodings other than the defined encodings are reserved. Multi-Function devices associated with an Upstream Port must report the same value in this field for all functions. In M-PCIe mode, the reset and dynamic values of this field are calculated by the controller. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 01_H **X1**: x1 02_H **X2**: x2 04_H **X4**: x4 08_H **X8**: x8 $0C_H$ **X12**: x12 10_H **X16**: x16 20_H **X32**: x32 **others,** Reserved
PCIE_CAP_ACTIVE_STATE_LINK_PM_SUPPORT	11:10	rw	**Active State Power Management (ASPM) Support** This field indicates the level of ASPM supported on the given PCI Express Link. For more details on ASPM support requirements, see section 5.4.1 of PCI Express Base Specification. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 00_B **NO_ASPM_SUP**: No ASPM Support 01_B **L0S_SUP**: L0s Supported 10_B **L1_SUP**: L1 Supported 11_B **L0S_L1_SUP**: L0s and L1 Supported

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_L0S_EXIT_LATENCY	14:12	rwh	**L0s Exit Latency** This field indicates the L0s exit latency for the given PCI Express Link. The value reported indicates the length of time this Port requires to complete transition from L0s to L0. If L0s is not supported, the value is undefined; however, see the Implementation Note "Potential Issues With Legacy Software When L0s is Not Supported" in section 5.4.1.1 of PCI Express Base Specification for the recommended value. Note: Exit latencies may be influenced by PCI Express reference clock configuration depending upon whether a component uses a common or separate reference clock. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 000_B **LESS_THAN_64NS**: Less than 64 ns 001_B **_64NS_TO_128NS**: 64 ns to less than 128 ns 010_B **_128NS_TO_256NS**: 128 ns to less than 256 ns 011_B **_256NS_TO_512NS**: 256 ns to less than 512 ns 100_B **_512NS_TO_1US**: 512 ns to less than 1 µs 101_B **_1US_TO_2US**: 1 µs to less than 2 µs 110_B **_2US_TO_4US**: 2 µs to 4 µs 111_B **GREATER_THAN_4US**: More than 4 µs
PCIE_CAP_L1_EXIT_LATENCY	17:15	rwh	**L1 Exit Latency** This field indicates the L1 exit latency for the given PCI Express Link. The value reported indicates the length of time this Port requires to complete transition from ASPM L1 to L0. If ASPM L1 is not supported, the value is undefined. Note: Exit latencies may be influenced by PCI Express reference clock configuration depending upon whether a component uses a common or separate reference clock. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 000_B **LESS_THAN_1US**: Less than 1 µs 001_B **_1US_TO_2US**: 1 µs to less than 2 µs 010_B **_2US_TO_4US**: 2 µs to less than 4 µs 011_B **_4US_TO_8US**: 4 µs to less than 8 µs 100_B **_8US_TO_16US**: 8 µs to less than 16 µs 101_B **_16US_TO_32US**: 16 µs to less than 32 µs 110_B **_32US_TO_64US**: 32 µs to 64 µs 111_B **GREATER_THAN_64US**: More than 64 µs

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_CLOCK_POWER_MAN	18	rh	**Clock Power Management** For Upstream Ports, a value of 1b in this bit indicates that the component tolerates the removal of any reference clock(s) via the "clock request" (CLKREQ#) mechanism when the Link is in the L1 and L2/L3 Ready Link states. A value of 0b indicates the component does not have this capability and that reference clock(s) must not be removed in these Link states. L1 PM Substates defines other semantics for the CLKREQ# signal, which are managed independently of Clock Power Management. This Capability is applicable only in form factors that support "clock request" (CLKREQ#) capability. The reset value of this bit field is decided by the value of PM_CTRL.CLKPMEN. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
PCIE_CAP_SURPRISE_DOWN_ERR_REP_CAP	19	rw	**Surprise Down Error Reporting Capable** For a Downstream Port, this bit must be set if the component supports the optional capability of detecting and reporting a Surprise Down error condition. For Upstream Ports and components that do not support this optional capability, the controller hardwires this bit to 0b. Note: This register field is sticky.
PCIE_CAP_DLL_ACTIVE_REP_CAP	20	r	**Data Link Layer Link Active Reporting Capable** For a Downstream Port, the controller hardwires this bit to 1b if the component supports the optional capability of reporting the DL_Active state of the Data Link Control and Management State Machine. For a hot-plug capable Downstream Port (as indicated by the Hot-Plug Capable bit of the Slot Capabilities register) or a Downstream Port that supports Link speeds greater than 5.0 GT/s, the controller hardwires this bit to 1b. For Upstream Ports and components that do not support this optional capability, the controller hardwires this bit to 0b.
PCIE_CAP_LINK_BW_NOT_CAP	21	rw	**Link Bandwidth Notification Capability** A value of 1b indicates support for the Link Bandwidth Notification status and interrupt mechanisms. This capability is required for all Root Ports and Switch Downstream Ports supporting Links wider than x1 and/or multiple Link speeds. This field is not applicable and is Reserved for Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches. For functions that do not implement the Link Bandwidth Notification Capability the controller hardwires this bit to 0b. Note: This register field is sticky.
PCIE_CAP_ASPM_OPT_COMPLIANCE	22	rw	**ASPM Optionality Compliance** This field must be set to 1b in all functions. Components implemented against certain earlier versions of this specification will have this bit set to 0b. Software is permitted to use the value of this bit to help determine whether to enable ASPM or whether to run ASPM compliance tests. Note: The access attributes of this field are as follows: - Wire: HWINIT (hardware initialized) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
RSVDP_23	23	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_PORT_NUM	31:24	rw	**Port Number** This field indicates the PCI Express Port number for the given PCI Express Link. Multi-Function Devices associated with an Upstream Port must report the same value in this field for all functions. Note: The access attributes of this field are as follows: - Wire: HWINIT - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

rw		r		rwh	rwh	rw	rwh	rwh	rw	rwh	rwh	rw	r	rw	

Field	Bits	Type	Description
PCIE_CAP_ACTIVE_STATE_LINK_PM_CONTROL	1:0	rw	**Active State Power Management (ASPM) Control** This field controls the level of ASPM enabled on the given PCI Express Link. See section 5.4.1.3 of PCI Express Base Specification for requirements on when and how to enable ASPM. Note: "L0s Entry Enabled" enables the Transmitter to enter L0s. If L0s is supported, the Receiver must be capable of entering L0s even when the Transmitter is disabled from entering L0s (00b or 10b). ASPM L1 must be enabled by software in the Upstream component on a Link prior to enabling ASPM L1 in the Downstream component on that Link. When disabling ASPM L1, software must disable ASPM L1 in the Downstream component on a Link prior to disabling ASPM L1 in the Upstream component on that Link. ASPM L1 must only be enabled on the Downstream component if both components on a Link support ASPM L1. Software must not enable L0s in either direction on a given Link unless components on both sides of the Link each support L0s; otherwise, the result is undefined. 00_B **DISABLED**: Disabled 01_B **L0S_ENTRY_EN**: L0s Entry Enabled 10_B **L1_ENTRY_En**: L1 Entry Enabled 11_B **L0S_L1_ENTRY_EN**: L0s and L1 Entry Enabled
RSVDP_2	2	r	**Reserved for future use**
PCIE_CAP_RCB	3	rw	**Read Completion Boundary (RCB)** Root Ports: Indicates the RCB value for the Root Port. Refer to section 2.3.1.1 of PCI Express Base Specification for the definition of the parameter RCB. The controller hardwires this bit for a Root Port and returns its RCB support capabilities. Endpoints and Bridges: Optionally set by configuration software to indicate the RCB value of the Root Port Upstream from the Endpoint or Bridge. Refer to Section 2.3.1.1 of PCI Express Base Specification for the definition of the parameter RCB is same as Root Port. Configuration software must only set this bit if the Root Port Upstream from the Endpoint or Bridge reports an RCB value of 128 bytes (a value of 1b in the Read Completion Boundary bit). For functions that do not implement this feature, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_B **_64B**: 64 byte 1_B **_128B**: 128 byte
PCIE_CAP_LINK_DISABLE	4	rwh	**Link Disable** This bit disables the Link by directing the LTSSM to the Disabled state when set; this bit is Reserved on Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches. Writes to this bit are immediately reflected in the value read from the bit, regardless of actual Link state. After clearing this bit, software must honor timing requirements defined in Section 6.6.1 with respect to the first Configuration Read following a Conventional Reset. Note: The access attributes of this field are as follows: - Wire: dsp=1 ? RW : RO - Dbi: dsp=1? RW : RO

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_RETRAIN_LINK	5	rwh	**Retrain Link** A write of 1b to this bit initiates Link retraining by directing the Physical Layer LTSSM to the Recovery state. If the LTSSM is already in Recovery or Configuration, re-entering Recovery is permitted but not required. Reads of this bit always return 0b. It is permitted to write 1b to this bit while simultaneously writing modified values to other fields in this register. If the LTSSM is not already in Recovery or Configuration, the resulting Link training must use the modified values. If the LTSSM is already in Recovery or Configuration, the modified values are not required to affect the Link training that's already in progress. This bit is not applicable and is Reserved for Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches. This bit always returns 0b when read.
PCIE_CAP_COMMON_CLK_CONFIG	6	rw	**Common Clock Configuration** When set, this bit indicates that this component and the component at the opposite end of this Link are operating with a distributed common reference clock. A value of 0b indicates that this component and the component at the opposite end of this Link are operating with asynchronous reference clock. Components utilize this common clock configuration information to report the correct L0s and L1 Exit Latencies. After changing the value in this bit in both components on a Link, software must trigger the Link to retrain by writing a 1b to the Retrain Link bit of the Downstream Port.
PCIE_CAP_EXTENDED_SYNCH	7	rwh	**Extended Synch** When set, this bit forces the transmission of additional Ordered Sets when exiting the L0s state (see section 4.2.4.5 of PCI Express Base Specification) and when in the Recovery state (see section 4.2.6.4.1 of PCI Express Base Specification). This mode provides external devices (for example, logic analyzers) monitoring the Link time to achieve bit and Symbol lock before the Link enters the L0 state and resumes communication. For Multi-Function devices if any function has this bit set, then the component must transmit the additional Ordered Sets when exiting L0s or when in Recovery.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_EN_CLK_POWER_MAN	8	rwh	**Enable Clock Power Management** Applicable only for Upstream Ports and with form factors that support a "Clock Request" (CLKREQ#) mechanism, this bit operates as follows: . For Downstream Ports and components that do not support Clock Power Management (as indicated by a 0b value in the Clock Power Management bit of the Link Capabilities register), the controller hardwires this bit to 0b. The write value is gated with the PCIE_CAP_CLOCK_POWER_MAN field in LINK_CAPABILITIES_REG. Note: The access attributes of this field are as follows: • Wire: LINK_CAPABILITIES_REG.PCIE_CAP_CLOCK_POWER_MAN ? RWS : ROS • Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_CLOCK_POWER_MAN ? RWS : ROS Note: This register field is sticky 0_B **PM_DISABLE_LOW_CLKREQ**: Clock power management is disabled and device must hold CLKREQ# signal low 1_B **CLKREQ_IN_USE**: When this bit is set, the device is permitted to use CLKREQ# signal to power manage Link clock according to protocol defined in appropriate form factor specification
PCIE_CAP_HW_AUTO_WIDTH_DISABLE	9	rw	**Hardware Autonomous Width Disable** When set, this bit disables hardware from changing the Link width for reasons other than attempting to correct unreliable Link operation by reducing Link width. For components that do not implement the ability autonomously to change Link width, the ciontroller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
PCIE_CAP_LINK_BW_MAN_INT_EN	10	rwh	**Link Bandwidth Management Interrupt Enable** When set, this bit enables the generation of an interrupt to indicate that the Link Bandwidth Management Status bit has been set. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG. This bit is not applicable and is Reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges, and Upstream Ports of Switches. For functions that do not implement the Link Bandwidth Notification Capability, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: • Wire: LINK_CAPABILITIES_REG.PCIE_CAP_LINK_BW_NOT_CAP ? RW : RO • Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_LINK_BW_NOT_CAP ? RW : RO

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_LINK_AUTO_BW_INT_EN	11	rwh	**Link Autonomous Bandwidth Management Interrupt Enable** When set, this bit enables the generation of an interrupt to indicate that the Link Autonomous Bandwidth Status bit has been set. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG. This bit is not applicable and is Reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges, and Upstream Ports of Switches. For functions that do not implement the Link Bandwidth Notification Capability, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: • Wire: LINK_CAPABILITIES_REG.PCIE_CAP_LINK_BW_NOT_CAP ? RW : RO • Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_LINK_BW_NOT_CAP ? RW : RO
RSVDP_12	13:12	r	**Reserved for future use**
PCIE_CAP_DRS_SIGNALING_CONTROL	15:14	rw	**DRS Signaling Control** Indicates the mechanism used to report reception of a DRS message. Must be implemented for Downstream Ports with the DRS Supported bit Set in the Link Capabilities 2 Register. Encodings are: • If DRS Supported is set, receiving a DRS Message will set DRS Message Received in the Link Control 2 and Status 2 Register Register but will otherwise have no effect • If the DRS Message Received bit in the Link Control 2 and Status 2 Register Register transitions from 0 to 1, and either MSI or MSI-X is enabled, an MSI or MSI-X interrupt is generated using the vector in Interrupt Message Number (section 7.5.3.2) Behavior is undefined if this field is set to 10b as the FRS capability is not Supported. Behavior is undefined if this field is set to 11b. For Downstream Ports with the DRS Supported bit clear in the Link Capabilities 2 register, the controller hardwires this field to 00b. This field is Reserved for Upstream Ports. 00_B **DRS_NOT_REPORTED**: DRS not Reported 01_B **DRS_INTRRUPT_EN**: DRS Interrupt Enabled 10_B **FRS_EN**: DRS to FRS Signaling Enabled **others,** Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_LINK_SPEED	19:16	rh	**Current Link Speed** This field indicates the negotiated Link speed of the given PCI Express Link. The encoded value specifies a bit location in the Supported Link Speeds Vector (in the Link Capabilities 2 register) that corresponds to the current Link speed. All encodings other than the defined encodings are reserved. The value in this field is undefined when the Link is not up. 1_H **SUP_LINK_SPEED_FIELD_BIT_0**: Supported Link Speeds Vector field bit 0 2_H **SUP_LINK_SPEED_FIELD_BIT_1**: Supported Link Speeds Vector field bit 1 3_H **SUP_LINK_SPEED_FIELD_BIT_2**: Supported Link Speeds Vector field bit 2 4_H **SUP_LINK_SPEED_FIELD_BIT_3**: Supported Link Speeds Vector field bit 3 5_H **SUP_LINK_SPEED_FIELD_BIT_4**: Supported Link Speeds Vector field bit 4 6_H **SUP_LINK_SPEED_FIELD_BIT_5**: Supported Link Speeds Vector field bit 5 7_H **SUP_LINK_SPEED_FIELD_BIT_6**: Supported Link Speeds Vector field bit 6 **others,** Reserved
PCIE_CAP_NEGO_LINK_WIDTH	25:20	rh	**Negotiated Link Width** This field indicates the negotiated width of the given PCI Express Link. All encodings other than the defined encodings are reserved. The value in this field is undefined when the Link is not up. 01_H **X1**: x1 02_H **X2**: x2 04_H **X4**: x4 08_H **X8**: x8 $0C_H$ **X12**: x12 10_H **X16**: x16 20_H **X32**: x32 **others,** Reserved
RSVDP_26	26	r	**Reserved for future use**
PCIE_CAP_LINK_TRAINING	27	rh	**Link Training** This read-only bit indicates that the Physical Layer LTSSM is in the Configuration or Recovery state, or that 1b was written to the Retrain Link bit but Link training has not yet begun. Hardware clears this bit when the LTSSM exits the Configuration/Recovery state. This bit is not applicable and Reserved for Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches, and the controller hardwires it to 0b. Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: R

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_SLOT_CLK_CONFIG	28	rw	**Slot Clock Configuration** This bit indicates that the component uses the same physical reference clock that the platform provides on the connector. If the device uses an independent clock irrespective of the presence of a reference clock on the connector, this bit must be clear. For a Multi-Function Device, each Function must report the same value for this bit. Note: The access attributes of this field are as follows: - Wire: HWINIT - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
PCIE_CAP_DLL_ACTIVE	29	rh	**Data Link Layer Link Active** This bit indicates the status of the Data Link Control and Management State Machine. It returns a 1b to indicate the DL_Active state, 0b otherwise. This bit must be implemented if the Data Link Layer Link Active Reporting Capable bit is 1b. Otherwise, the controller hardwires it to 0b.
PCIE_CAP_LINK_BW_MAN_STATUS	30	rw1ch	**Link Bandwidth Management Status** This bit is set by hardware to indicate that either of the following has occurred without the Port transitioning through DL_Down status: • A Link retraining has completed following a write of 1b to the Retrain Link bit. Note: This bit is set following any write of 1b to the Retrain Link bit, including when the Link is in the process of retraining for some other reason • Hardware has changed Link speed or width to attempt to correct unreliable Link operation, either through an LTSSM timeout or a higher level process. This bit must be set if the Physical Layer reports a speed or width change was initiated by the Downstream component that was not indicated as an autonomous change. This bit is not applicable and is Reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges, and Upstream Ports of Switches. The default value of this bit is 0b. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: R Software write with 1 clears this bit-field.
PCIE_CAP_LINK_AUTO_BW_STATUS	31	w1c	**Link Autonomous Bandwidth Status** This bit is set by hardware to indicate that hardware has autonomously changed Link speed or width, without the Port transitioning through DL_Down status, for reasons other than to attempt to correct unreliable Link operation. This bit must be set if the Physical Layer reports a speed or width change was initiated by the Downstream component that was indicated as an autonomous change. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG. This bit is not applicable and is Reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges, and Upstream Ports of Switches. For functions that do not implement the Link Bandwidth Notification Capability, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: R Note: This register field is sticky. Software write with 1 clears this bit field.

Field	Bits	Type	Description
PCIE_CAP_ATTENTION_INDICATOR_BUTTON	0	rw	**Attention Button Present** Slot attention capability is not present in this implementation. When set, this bit indicates that an Attention Button for this slot is electrically controlled by the chassis. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
PCIE_CAP_POWER_CONTROLLER	1	rw	**Power Controller Present** Slot power controller capability is not present in this implementation. When set, this bit indicates that a software programmable Power Controller is implemented for this slot/adapter (depending on form factor). Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_MRL_SENSOR	2	rw	**MRL Sensor Present** When set, this bit indicates that an MRL Sensor is implemented on the chassis for this slot. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
PCIE_CAP_ATTENTION_INDICATOR	3	rw	**Attention Indicator Present** Power attention indicator capability is not supported in this implementation. When set, this bit indicates that an Attention Indicator is electrically controlled by the chassis. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
PCIE_CAP_POWER_INDICATOR	4	rw	**Power Indicator Present** Power Indicator capability is not supported in this implementation. When set, this bit indicates that a Power Indicator is electrically controlled by the chassis for this slot. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
PCIE_CAP_HOT_PLUG_SURPRISE	5	rw	**Hot-Plug Surprise** Hot-Plug surprise capability is not supported in this implementation. When set, this bit indicates that an adapter present in this slot might be removed from the system without any prior notification. This is a form factor specific capability. This bit is an indication to the operating system to allow for such removal without impacting continued software operation. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
PCIE_CAP_HOT_PLUG_CAPABLE	6	rw	**Hot-Plug Capable** Hot plug capabilities are not supported in this implementation. When set, this bit indicates that this slot is capable of supporting hot-plug operations. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
PCIE_CAP_SLOT_POWER_LIMIT_VALUE	14:7	rw	**Slot Power Limit Value** In combination with the Slot Power Limit Scale value, specifies the upper limit on power supplied by the slot (for more detais, see Section 6.9 of PCI Express Base Specification) or by other means to the adapter. Power limit (in Watts) is calculated by multiplying the value in this field by the value in the Slot Power Limit Scale field except when the Slot Power Limit Scale field equals 00b (1.0x) and Slot Power Limit Value exceeds EFh, the alternative encodings defined in Values: are used. Value F3h to FFh are Reserved for Slot Power Limit values above 300 W. This register must be implemented if the Slot Implemented bit is set. Writes to this register also cause the Port to send the Set_Slot_Power_Limit Message. The default value prior to hardware/ firmware initialization is 0000 0000b. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R $F0_H$ **_250W_LIMIT**: 250 W Slot Power Limit $F1_H$ **_275W_LIMIT**: 275 W Slot Power Limit $F2_H$ **_300W_LIMIT**: 300 W Slot Power Limit **others,** Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_SLOT_POWER_LIMIT_SCALE	16:15	rw	**Slot Power Limit Scale** Specifies the scale used for the Slot Power Limit Value (for more details, see Section 6.9 of PCI Express Base Specification). This register must be implemented if the Slot Implemented bit is set. Writes to this register also cause the Port to send the Set_Slot_Power_Limit Message. The default value prior to hardware/firmware initialization is 00b. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R 00_B **_1_0X**: 1.0x 01_B **_0_1X**: 0.1x 10_B **_0_01X**: 0.01x 11_B **_0_001X**: 0.001x
PCIE_CAP_ELECTROMECH_INTERLOCK	17	rw	**Electromechanical Interlock Present** Electromechanical Interlock capability is not supported in this implementation. When set, this bit indicates that an Electromechanical Interlock is implemented on the chassis for this slot. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
PCIE_CAP_NO_CMD_CPL_SUPPORT	18	rw	**No Command Completed Support** When set, this bit indicates that this slot does not generate software notification when an issued command is completed by the Hot-Plug Controller. This bit is only permitted to be set if the hot-plug capable Port is able to accept writes to all fields of the Slot Control register without delay between successive writes. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
PCIE_CAP_PHY_SLOT_NUM	31:19	rw	**Physical Slot Number** This field indicates the physical slot number attached to this Port. This field must be hardware initialized to a value that assigns a slot number that is unique within the chassis, regardless of the form factor associated with the slot. This field must be initialized to zero for Ports connected to devices that are either integrated on the system board or integrated within the same silicon as the Switch device or Root Port. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

19.4.2.126 Slot Control and Status Register

This register controls and provides information about PCI Express Slot specific parameters.

SLOT_CONTROL_SLOT_STATUS Offset address: 0004088_H

Slot Control and Status Register Reset values see: Table 888

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r		r	rw	rwh	rw	rw		rw		rw	rwh	rw	rw	rw	rw

Field	Bits	Type	Description
PCIE_CAP_ATTENTION_BUTTON_PRESSED_EN	0	rw	**Attention Button Pressed Enable** When set to 1b, this bit enables software notification on an attention button pressed event (for more details, see Section 6.7.3 of PCI Express Base Specification). If the Attention Button Present bit in the Slot Capabilities register is 0b, this bit is permitted to be read-only with a value of 0b.
PCIE_CAP_POWER_FAULT_DETECTED_EN	1	rw	**Power Fault Detected Enable** When set, this bit enables software notification on a power fault event (for more details, see Section 6.7.3 of PCI Express Base Specification). If a Power Controller that supports power fault detection is not implemented, this bit is permitted to be read-only with a value of 0b.
PCIE_CAP_MRL_SENSOR_CHANGED_EN	2	rw	**MRL Sensor Changed Enable** When set, this bit enables software notification on a MRL sensor changed event (for more details, see Section 6.7.3 of PCI Express Base Specification). If the MRL Sensor Present bit in the Slot Capabilities register is Clear, this bit is permitted to be read-only with a value of 0b.
PCIE_CAP_PRESENCE_DETECT_CHANGE_EN	3	rw	**Presence Detect Changed Enable** When set, this bit enables software notification on a presence detect changed event (for more details, see Section 6.7.3 of PCI Express Base Specification). If the Hot-Plug Capable bit in the Slot Capabilities register is 0b, this bit is permitted to be read-only with a value of 0b.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_CMD_CPL_INT_EN	4	rwh	**Command Completed Interrupt Enable** If Command Completed notification is supported (if the No Command Completed Support bit in the Slot Capabilities register is 0b), when set, this bit enables software notification when a hot-plug command is completed by the Hot-Plug Controller. If Command Completed notification is not supported, the controller hardwires this bit must to 0b. Write value is gated with PCIE_CAP_NO_CMD_CPL_SUPPORT field in SLOT_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: SLOT_CAPABILITIES_REG.PCIE_CAP_NO_CMD_CPL_SUPPORT ? RO : RW
PCIE_CAP_HOT_PLUG_INT_EN	5	rw	**Hot-Plug Interrupt Enable** When set, this bit enables generation of an interrupt on enabled hot-plug events. Since the Hot-Plug capable bit in the Slot Capabilities register is clear, this bit is to be considered as read-only with a value of 0b.
PCIE_CAP_ATTENTION_INDICATOR_CTRL	7:6	rw	**Attention Indicator Control** If an Attention Indicator is implemented, writes to this field set the Attention Indicator to the written state. Reads of this field must reflect the value from the latest write, even if the corresponding hot-plug command is not complete, unless software issues a write without waiting, if required to, for the previous command to complete in which case the read value is undefined. Note: The default value of this field must be one of the non-Reserved values. If the Attention Indicator Present bit in the Slot Capabilities register is 0b, this bit is permitted to be read-only with a value of 00b. 00_B **RESERVED**: Reserved 01_B **ON**: On 10_B **BLINK**: Blink 11_B **OFF**: Off
PCIE_CAP_POWER_INDICATOR_CTRL	9:8	rw	**Power Indicator Control** If a Power Indicator is implemented, writes to this field set the Power Indicator to the written state. Reads of this field must reflect the value from the latest write, even if the corresponding hot-plug command is not complete, unless software issues a write without waiting, if required to, for the previous command to complete in which case the read value is undefined. Note: The default value of this field must be one of the non-Reserved values. If the Power Indicator Present bit in the Slot Capabilities register is 0b, this bit is permitted to be read-only with a value of 00b. 00_B **RESERVED**: Reserved 01_B **ON**: On 10_B **BLINK**: Blink 11_B **OFF**: Off

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_POWER_CONTROLLER_CTRL	10	rw	**Power Controller Control** If a Power Controller is implemented, this bit when written sets the power state of the slot per the defined encodings. Reads of this bit must reflect the value from the latest write, even if the corresponding hot-plug command is not complete, unless software issues a write, if required to, without waiting for the previous command to complete in which case the read value is undefined. Note: In some cases the power controller may autonomously remove slot power or not respond to a power-up request based on a detected fault condition, independent of the Power Controller Control setting. If the Power Controller Present bit in the Slot Capabilities register is clear, then writes to this bit have no effect and the read value of this bit is undefined. 0_B **PWR_ON**: Power On 1_B **PWR_OFF**: Power Off
PCIE_CAP_ELECTROMECH_INTERLOCK_CTRL	11	rwh	**Electromechanical Interlock Control** If an Electromechanical Interlock is implemented, a write of 1b to this bit causes the state of the interlock to toggle. A write of 0b to this bit has no effect. A read of this bit always returns a 0b.
PCIE_CAP_DLL_STATE_CHANGED_EN	12	rw	**Data Link Layer State Changed Enable** If the Data Link Layer Link Active Reporting capability is 1b, this bit enables software notification when Data Link Layer Link Active bit is changed. If the Data Link Layer Link Active Reporting Capable bit is 0b, this bit is permitted to be read-only with a value of 0b.
RSVDP_14	15:14	r	**Reserved for future use**
PCIE_CAP_ATTENTION_BUTTON_PRESSED	16	w1c	**Attention Button Pressed** If an Attention Button is implemented, this bit is set when the attention button is pressed. If an Attention Button is not supported, this bit must not be set.
PCIE_CAP_POWER_FAULT_DETECTED	17	w1c	**Power Fault Detected** If a Power Controller that supports power fault detection is implemented, this bit issSet when the Power Controller detects a power fault at this slot. Note: Depending on hardware capability, it is possible that a power fault can be detected at any time, independent of the Power Controller Control setting or the occupancy of the slot. If power fault detection is not supported, this bit must not be set.
PCIE_CAP_MRL_SENSOR_CHANGED	18	w1c	**MRL Sensor Changed** If an MRL sensor is implemented, this bit is set when a MRL Sensor state change is detected. If an MRL sensor is not implemented, this bit must not be set.
PCIE_CAP_PRESENCE_DETECTED_CHANGED	19	w1c	**Presence Detect Changed** This bit is set when the value reported in the Presence Detect State bit is changed.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_CMD_CPLD	20	w1c	**Command Completed** If Command Completed notification is supported (if the No Command Completed Support bit in the Slot Capabilities register is 0b), this bit is set when a hot-plug command has completed and the Hot-Plug Controller is ready to accept a subsequent command. The Command Completed status bit is set as an indication to host software that the Hot-Plug Controller has processed the previous command and is ready to receive the next command; it provides no guarantee that the action corresponding to the command is complete. If Command Completed notification is not supported, the controller hardwires this bit to 0b.
PCIE_CAP_MRL_SENSOR_STATE	21	r	**MRL Sensor State** This bit reports the status of the MRL sensor if implemented. Encodings are define as above. 0_B **MRL_CLOSED**: MRL Closed 1_B **MRL_OPEN**: MRL Open
PCIE_CAP_PRESENCE_DETECT_STATE	22	rh	**Presence Detect State** This bit indicates the presence of an adapter in the slot, reflected by the logical "OR" of the Physical Layer in-band presence detect mechanism and, if present, any out-of-band presence detect mechanism defined for the slot's corresponding form factor. Note that the in-band presence detect mechanism requires that power be applied to an adapter for its presence to be detected. Consequently, form factors that require a power controller for hot-plug must implement a physical pin presence detect mechanism. This bit must be implemented on all Downstream Ports that implement slots. For Downstream Ports not connected to slots (where the Slot Implemented bit of the PCI Express Capabilities register is 0b), the controller hardwires this bit to 1b. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: R 0_B **EMPTY_SLOT**: Slot Empty 1_B **ADAPTER_PRESENT_IN_SLOT**: Adapter Present in slot
PCIE_CAP_ELECTROMECH_INTERLOCK_STATUS	23	r	**Electromechanical Interlock Status** If an Electromechanical Interlock is implemented, this bit indicates the status of the Electromechanical Interlock. 0_B **DISENGAGED**: Electromechanical Interlock Disengaged 1_B **ENGAGED**: Electromechanical Interlock Engaged
PCIE_CAP_DLL_STATE_CHANGED	24	w1c	**Data Link Layer State Changed** This bit is set when the value reported in the Data Link Layer Link Active bit of the Link Status register is changed. In response to a Data Link Layer State Changed event, software must read the Data Link Layer Link Active bit of the Link Status register to determine if the Link is active before initiating configuration cycles to the hot plugged device.
RSVDP_25	31:25	r	**Reserved for future use**
0	13	r	**Reserved** Read as 0; should be written with 0.

r											rw	rw	rw	rw	rw

Field	Bits	Type	Description
PCIE_CAP_SYS_ERR_ON_CORR_ERR_EN	0	rw	**System Error on Correctable Error Enable** If set, this bit indicates that a System Error should be generated if a correctable error (ERR_COR) is reported by any of the devices in the Hierarchy Domain associated with this Root Port, or by the Root Port itself. The mechanism for signaling a System Error to the system is system specific.
PCIE_CAP_SYS_ERR_ON_NON_FATAL_ERR_EN	1	rw	**System Error on Non-Fatal Error Enable** If set, this bit indicates that a System Error should be generated if a Non-fatal error (ERR_NONFATAL) is reported by any of the devices in the Hierarchy Domain associated with this Root Port, or by the Root Port itself. The mechanism for signaling a System Error to the system is system specific.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_SYS_ERR_ON_FATAL_ERR_EN	2	rw	**System Error on Fatal Error Enable** If set, this bit indicates that a System Error should be generated if a Fatal error (ERR_FATAL) is reported by any of the devices in the Hierarchy Domain associated with this Root Port, or by the Root Port itself. The mechanism for signaling a System Error to the system is system specific.
PCIE_CAP_PME_INT_EN	3	rw	**PME Interrupt Enable** When set, this bit enables PME interrupt generation upon receipt of a PME Message as reflected in the PME Status bit (for more details, see Table 7-29 of PCI Express Base Specification). A PME interrupt is also generated if the PME Status bit is set when this bit is changed from clear to set.
PCIE_CAP_CRS_SW_VISIBILITY_EN	4	rw	**CRS Software Visibility Enable** When set, this bit enables the Root Port to return Configuration Request Retry Status (CRS) Completion Status to software (for more details, see section 2.3.1 of PCI Express Base Specification). For Root Ports that do not implement this capability, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: ROOT_CONTROL_ROOT_CAPABILITIES_REG.PCIE_CAP_CRS_SW_VISIBILITY ? RW : RO
RSVDP_5	15:5	r	**Reserved for future use**
PCIE_CAP_CRS_SW_VISIBILITY	16	rw	**CRS Software Visibility Capable** When set, this bit indicates that the Root Port is capable of returning Configuration Request Retry Status (CRS) Completion Status to software (for more details, see section 2.3.1 of PCI Express Base Specification). Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W (Sticky) else R (Sticky) Note: This register field is sticky.
RSVDP_17	31:17	r	**Reserved for future use**

19.4.2.128 Root Status Register

The Root Status register provides information about PCI Express device specific parameters.

ROOT_STATUS_REG Offset address: 0004090_H

Root Status Register Kernel Reset value: $0000\ 0000_H$

PCIE_CAP_PME_REQ_ID															
r															

Field	Bits	Type	Description
PCIE_CAP_PME_REQ_ID	15:0	r	**PME Requester ID** This field indicates the PCI Requester ID of the last PME Requester. This field is only valid when the PME Status bit is set.
PCIE_CAP_PME_STATUS	16	w1c	**PME Status** This bit indicates that PME was asserted by the PME Requester indicated in the PME Requester ID field. Subsequent PMEs are kept pending until the status register is cleared by software by writing a 1b.
PCIE_CAP_PME_PENDING	17	r	**PME Pending** This bit indicates that another PME is pending when the PME Status bit is s et. When the PME Status bit is cleared by software; the PME is delivered by hardware by setting the PME Status bit again and updating the PME Requester ID field appropriately. The PME Pending bit is cleared by hardware if no more PMEs are pending.
RSVDP_18	31:18	r	**Reserved for future use**

19.4.2.129 Device Capabilities 2 Register

This register identifies PCI Express device specific capabilities; in addition to the Device Capabilities Register.

DEVICE_CAPABILITIES2_REG Offset address: 0004094_H

Device Capabilities 2 Register Kernel Reset value: $000C\ 0C1F_H$

r		r	r	rw	r	r	r	r	r	r	r	r			

Field	Bits	Type	Description
PCIE_CAP_CPL_TIMEOUT_RANGE	3:0	r	**Completion Timeout Ranges Supported** This field indicates device Function support for the optional Completion Timeout programmability mechanism. This mechanism allows system software to modify the Completion Timeout value. This field is applicable only to Root Ports, Endpoints that issue Requests on their own behalf, and PCI Express to PCI/PCI-X Bridges that take ownership of Requests issued on PCI Express. For all other Functions this field is Reserved and must be hardwired to 0000b. Four time value ranges are defined: • Range A: 50 µs to 10 ms • Range B: 10 ms to 250 ms • Range C: 250 ms to 4 s • Range D: 4 s to 64 s Bits are set according to the list below to show timeout value ranges supported. All encodings other than the defined encodings are reserved. It is strongly recommended that the Completion Timeout mechanism not expire in less than 10 ms. 0_H **NOT_SUP**: Completion Timeout programming not supported, the Function must implement a timeout value in the range 50 µs to 50 ms 1_H **RANGE_A**: Range A 2_H **RANGE_B**: Range B 3_H **RANGE_A_B**: Ranges A and B 6_H **RANGE_B_C**: Ranges B and C 7_H **RANGE_A_B_C**: Ranges A, B, and C E_H **RANGE_B_C_D**: Ranges B, C, and D F_H **RANGE_A_B_C_D**: Ranges A, B, C, and D
PCIE_CAP_CPL_TIMEOUT_DISABLE_SUPPORT	4	r	**Completion Timeout Disable Supported** A value of 1b indicates support for the Completion Timeout Disable mechanism. The Completion Timeout Disable mechanism is required for Endpoints that issue Requests on their own behalf and PCI Express to PCI/PCI-X Bridges that take ownership of Requests issued on PCI Express. This mechanism is optional for Root Ports. For all other Functions this field is Reserved and the controller hardwires this bit to 0b.
PCIE_CAP_ARI_FORWARD_SUPPORT	5	r	**ARI Forwarding Supported** Alternate routing ID capability is not available in this implementation. Applicable only to Switch Downstream Ports and Root Ports; must be 0b for other Function types. This bit must be set to 1b if a Switch Downstream Port or Root Port supports this optional capability. For more details, see section 6.13 of PCI Express Base Specification.
PCIE_CAP_ATOMIC_ROUTING_SUPP	6	r	**AtomicOp Routing Supported** Applicable only to Switch Upstream Ports, Switch Downstream Ports, and Root Ports; must be 0b for other Function types. This bit must be set to 1b if the Port supports this optional capability. For more details, see section 6.15 of PCI Express Base Specification.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_32_ATOMIC_CPL_SUPP	7	r	**32-bit AtomicOp Completer Supported** Applicable to Functions with Memory Space BARs as well as all Root Ports; must be 0b otherwise. Includes FetchAdd, Swap, and CAS AtomicOps. This bit must be set to 1b if the Function supports this optional capability. For more details on additional RC requirements, see section 6.15.3.1 of PCI Express Base Specification.
PCIE_CAP_64_ATOMIC_CPL_SUPP	8	r	**64-bit AtomicOp Completer Supported** Applicable to Functions with Memory Space BARs as well as all Root Ports; must be 0b otherwise. Includes FetchAdd, Swap, and CAS AtomicOps. This bit must be set to 1b if the Function supports this optional capability. For more details on additional RC requirements, see section 6.15.3.1 of PCI Express Base Specification.
PCIE_CAP_128_CAS_CPL_SUPP	9	r	**128-bit CAS Completer Supported** Applicable to Functions with Memory Space BARs as well as all Root Ports; must be 0b otherwise. This bit must be set to 1b if the Function supports this optional capability. For more details, see section 6.15 of PCI Express Base Specification.
PCIE_CAP_NO_RO_EN_PR2PR_PAR	10	r	**No RO-enabled PR-PR Passing** If this bit is set, the routing element never carries out the passing permitted by Table 2-39 of PCI Express Base Specification entry A2b that is associated with the Relaxed Ordering Attribute field being Set. This bit applies only for Switches and RCs that support peer-to-peer traffic between Root Ports. This bit applies only to Posted Requests being forwarded through the Switch or RC and does not apply to traffic originating or terminating within the Switch or RC itself. All Ports on a Switch or RC must report the same value for this bit. For all other functions, this bit must be 0b.
PCIE_CAP_LTR_SUPP	11	rw	**LTR Mechanism Supported** A value of 1b indicates support for the optional Latency Tolerance Reporting (LTR) mechanism. Root Ports, Switches and Endpoints are permitted to implement this capability. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(Sticky) else R(Sticky) Note: This register field is sticky.
PCIE_CAP_TPH_CMPLT_SUPPORT_0	12	r	**TPH Completer Supported Bit 0** TLP Processing Hints(TPH) is not supported in this implementation. Value of this bit along with TPH Completer Supported Bit 1 indicates Completer support for TPH or Extended TPH. Applicable only to Root Ports and Endpoints. For all other Functions, this field is Reserved. For more details, see section 6.17 of PCI Express Base Specification. 0_B **TPH_EXT_TPH_CMPL_NOT_SUP_OR_RSVD**: TPH and Extended TPH Completer not supported (if TPH Completer Supported Bit is 0) or Reserved ((if TPH Completer Supported Bit is 1) 1_B **TPH_SUP_EXT_TPH_NOT_SUP_OR_BOTH_SUPP**: TPH Completer supported; Extended TPH Completer not supported(if TPH Completer Supported Bit is 0) or Both TPH and Extended TPH Completer supported ((if TPH Completer Supported Bit is 1)
PCIE_CAP_TPH_CMPLT_SUPPORT_1	13	r	**TPH Completer Supported Bit 1** TLP Processing Hints(TPH) is not supported in this implementation

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP2_10_BIT_TAG_COMP_SUPPORT	16	r	**10-Bit Tag Completer Supported** If this bit is set, the Function supports 10-Bit Tag Completer capability; otherwise, the Function does not. For more details, see section 2.2.6.2. of PCI Express Base Specification.
PCIE_CAP2_10_BIT_TAG_REQ_SUPPORT	17	r	**10-Bit Tag Requester Supported** If this bit is set, the Function supports 10-Bit Tag Requester capability; otherwise, the Function does not. This bit must not be set if the 10-Bit Tag Completer Supported bit is clear. Note: 10-Bit Tag field generation must be enabled by the 10-Bit Tag Requester Enable bit in the Device Control 2 register of the Requester Function before 10-Bit Tags can be generated by the Requester. For more details, see section 2.2.6.2. of PCI Express Base Specification.
PCIE_CAP_OBFF_SUPPORT	19:18	rw	**OBFF Supported** This field indicates if OBFF is supported and, if so, what signaling mechanism is used. The value reported in this field must indicate support for WAKE# signaling only if: • for a Downstream Port, driving the WAKE# signal for OBFF is supported and the connector or component connected Downstream is known to receive that same WAKE# signal • for an Upstream Port, receiving the WAKE# signal for OBFF is supported and, if the component is on an add-in-card, that the component is connected to the WAKE# signal on the connector. Root Ports, Switch Ports, and Endpoints are permitted to implement this capability. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(Sticky) else R(Sticky) Note: This register field is sticky. 00_B **NOT_SUP**: OBFF Not Supported 01_B **SUP_USING_MSG**: OBFF supported using Message signaling only 10_B **SUP_USING_WAKE**: OBFF supported using WAKE# signaling only 11_B **SUP_USING_MSG_AND_WAKE**: OBFF supported using WAKE# and Message signaling
RSVDP_24	30:24	r	**Reserved for future use**
0	15:14, 23:20, 31	r	**Reserved** Read as all 0's; should be written with all 0's.

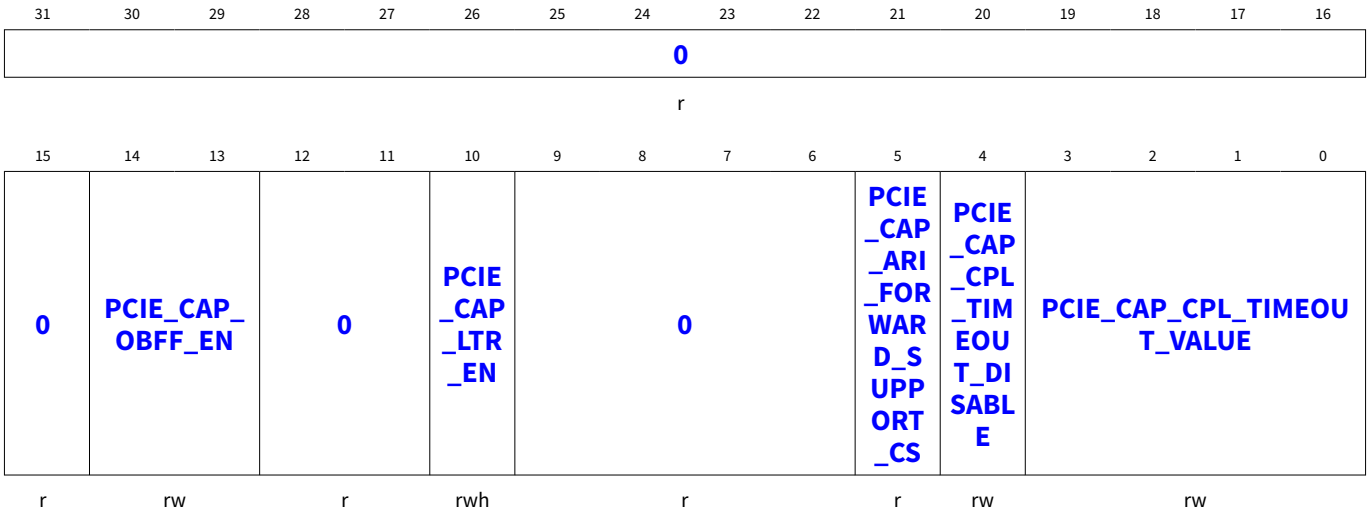
19.4.2.130 Device Control 2 and Status 2 Register

This register controls PCI Express device specific parameters and provides information about PCI Express device (function) specific parameters; in addition to the Device Control and Device Status Register.

DEVICE_CONTROL2_DEVICE_STATUS2_REG Offset address: 0004098_H

Device Control 2 and Status 2 Register Reset values see: Table 889

19 Peripheral Component Interconnect Express (PCIe)



Field	Bits	Type	Description
PCIE_CAP_CPL_TIMEOUT_VALUE	3:0	rw	**Completion Timeout Value** In device Functions that support Completion Timeout programmability, this field allows system software to modify the Completion Timeout value. This field is applicable to Root Ports, Endpoints that issue Requests on their own behalf. Functions that support Completion Timeout programmability must support the values given below corresponding to the programmability ranges indicated in the Completion Timeout Ranges Supported field. All encodings other than the defined encodings are reserved. It is strongly recommended that the Completion Timeout mechanism not expire in less than 10 ms. Software is permitted to change the value in this field at any time. For Requests already pending when the Completion Timeout Value is changed, hardware is permitted to use either the new or the old value for the outstanding Requests, and is permitted to base the start time for each Request either on when this value was changed or on when each request was issued. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_H **DEFAULT**: Default range: 50 µs to 50 ms 1_H **_50_TO_100_US**: 50 µs to 100 µs 2_H **_1_TO_10_MS**: 1 ms to 10 ms 5_H **_16_TO_55_MS**: 16 ms to 55 ms 6_H **_65_TO_210_MS**: 65 ms to 210 ms 9_H **_260_TO_900_MS**: 260 ms to 900 ms A_H **_1_TO_3_5_S**: 1 s to 3.5 s D_H **_4_TO_13_S**: 4 s to 13 s E_H **_17_TO_64_S**: 17 s to 64 s **others,** Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_CPL_TIMEOUT_DISABLE	4	rw	**Completion Timeout Disable** When set, this bit disables the Completion Timeout mechanism. This bit is required for all Functions that support the Completion Timeout Disable Capability. Functions that do not support this optional capability are permitted to hardwire this bit to 0b Software is permitted to set or clear this bit at any time. When set, the Completion Timeout detection mechanism is disabled. If there are outstanding Requests when the bit is cleared, it is permitted but not required for hardware to apply the completion timeout mechanism to the outstanding Requests. If this is done, it is permitted to base the start time for each Request on either the time this bit was cleared or the time each Request was issued.
PCIE_CAP_ARI_FORWARD_SUPPORT_CS	5	r	**ARI Forwarding Enable** Alternate routing ID capability is not available in this implementation. When set, the Downstream Port disables its traditional Device Number field being 0 enforcement when turning a Type 1 Configuration Request into a Type 0 Configuration Request, permitting access to Extended Functions in an ARI Device immediately below the Port. For more details, see Section 6.13 of PCI Express Base Specification.
PCIE_CAP_LTR_EN	10	rwh	**LTR Mechanism Enable** When set to 1b, this bit enables Upstream Ports to send LTR messages and Downstream Ports to process LTR Messages. For Downstream Ports, this bit must be reset to the default value if the Port goes to DL_Down status. The write value is gated with the PCIE_CAP_LTR_SUPP field of DEVICE_CAPABILITIES2_REG. Note: RW for function #0 and RsdvP for all other functions. Note: The access attributes of this field are as follows: - Wire: if (pf=0 && DEVICE_CAPABILITIES2_REG.PCIE_CAP_LTR_SUPP) then R/W else R - Dbi: if (pf=0 && DEVICE_CAPABILITIES2_REG.PCIE_CAP_LTR_SUPP) then R/W else R
PCIE_CAP_OBFF_EN	14:13	rw	**OBFF Enable** This field enables the OBFF mechanism and selects the signaling method. For more details on these encodings, see section 6.19 of PCI Express Base Specification. This field is required for all Ports that support the OBFF Capability. Note: RW for function #0 and RsdvP for all other functions. Note: The access attributes of this field are as follows: • Wire: if (DEVICE_CAPABILITIES2_REG.PCIE_CAP_OBFF_SUPPORT) then R/W else R • Dbi: if (DEVICE_CAPABILITIES2_REG.PCIE_CAP_OBFF_SUPPORT) then R/W else R 00_B **DISABLED**: Disabled 01_B **EN_USING_MSG_SIG_A**: Enabled using Message signaling [Variation A] 10_B **EN_USING_MSG_SIG_B**: Enabled using Message signaling [Variation B] 11_B **EN_USING_WAKE_SIG**: Enabled using WAKE# signaling

Field	Bits	Type	Description
PCIE_CAP_SUPPORT_LINK_SPEED_VECTOR	7:1	rh	**Supported Link Speeds Vector** This field indicates the supported Link speed(s) of the associated Port. For each bit, a value of 1b indicates that the corresponding Link speed is supported; otherwise, the Link speed is not supported. For more details, see section 8.2.1 of PCI Express Base Specification. Bit definitions within this field are: • Bit 0 2.5 GT/s • Bit 1 5.0 GT/s • Bit 2 8.0 GT/s • Bit 3 16.0 GT/s • Bit 4 32.0 GT/s • Bits 6:5 RsvdP This field has a default of (PCIE_CAP_MAX_LINK_SPEED == 0101) ? 0011111 : (PCIE_CAP_MAX_LINK_SPEED == 0100) ? 0001111 : (PCIE_CAP_MAX_LINK_SPEED == 0011) ? 0000111 : (PCIE_CAP_MAX_LINK_SPEED == 0010) ? 0000011 : 0000001 where PCIE_CAP_MAX_LINK_SPEED is a field in the LINK_CAPABILITIES_REG register.
PCIE_CAP_CROSS_LINK_SUPPORT	8	r	**Crosslink Supported** When set to 1b, this bit indicates that the associated Port supports crosslinks (for more details, see section 4.2.6.3.1 of PCI Express Base Specification). When set to 0b on a Port that supports Link speeds of 8.0 GT/s or higher, this bit indicates that the associated Port does not support crosslinks. When set to 0b on a Port that only supports Link speeds of 2.5 GT/s or 5.0 GT/s, this bit provides no information regarding the Port's level of crosslink support. It is recommended that this bit be Set in any Port that supports crosslinks even though doing so is only required for Ports that also support operating at 8.0 GT/s or higher Link speeds. Note: Software should use this bit when referencing fields whose definition depends on whether or not the Port supports crosslinks (for more details, see section 7.7.3.4 of PCI Express Base Specification). Multi-Function Devices associated with an Upstream Port must report the same value in this field for all Functions.No crosslink capability in this implementation
RSVDP_9	22:9	r	**Reserved for future use**
RSVDP_25	30:25	r	**Reserved for future use**
DRS_SUPPORTED	31	rw	**DRS Supported** When set, indicates support for the optional Device Readiness Status (DRS) capability. Must be Set in Downstream Ports that support DRS. Must be Set in Downstream Ports that support FRS. For Upstream Ports that support DRS, it is strongly recommended that this bit be Set in Function 0. For all other Functions associated with an Upstream Port, this bit must be Clear.127 Must be Clear in Functions that are not associated with a Port. RsvdP in all other Functions. Note: The access attributes of this field are as follows: - Wire: HWINIT - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

rwh				rwh	rw	rwh			rw	rw	rwh	rw			

Field	Bits	Type	Description
PCIE_CAP_TARGET_LINK_SPEED	3:0	rw	**Target Link Speed** For Downstream Ports, this field sets an upper limit on Link operational speed by restricting the values advertised by the Upstream component in its training sequences. The encoded value specifies a bit location in the Supported Link Speeds Vector (in the Link Capabilities 2 register) that corresponds to the desired target Link speed. All encodings other than the defined encodings are reserved. . If a value is written to this field that does not correspond to a supported speed (as indicated by the Supported Link Speeds Vector), the result is undefined. If either of the Enter Compliance or Enter Modified Compliance bits are implemented, then this field must also be implemented. The default value of this field is the highest Link speed supported by the component (as reported in the Max Link Speed field of the Link Capabilities register) unless the corresponding platform/form factor requires a different default value. For both Upstream and Downstream Ports, this field is used to set the target compliance mode speed when software is using the Enter Compliance bit to force a Link into compliance mode. For Upstream Ports, if the Enter Compliance bit is Clear, this field is permitted to have no effect. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky 1_H **SUP_LINK_SPEED_VECTOR_BIT_0**: Supported Link Speeds Vector field bit 0 2_H **SUP_LINK_SPEED_VECTOR_BIT_1**: Supported Link Speeds Vector field bit 1 3_H **SUP_LINK_SPEED_VECTOR_BIT_2**: Supported Link Speeds Vector field bit 2 4_H **SUP_LINK_SPEED_VECTOR_BIT_3**: Supported Link Speeds Vector field bit 3 5_H **SUP_LINK_SPEED_VECTOR_BIT_4**: Supported Link Speeds Vector field bit 4 6_H **SUP_LINK_SPEED_VECTOR_BIT_5**: Supported Link Speeds Vector field bit 5 7_H **SUP_LINK_SPEED_VECTOR_BIT_6**: Supported Link Speeds Vector field bit 6 **others,** Reserved
PCIE_CAP_ENTER_COMPLIANCE	4	rwh	**Enter Compliance** Software is permitted to force a Link to enter Compliance mode (at the speed indicated in the Target Link Speed field and the de-emphasis/ preset level indicated by the Compliance Preset/De-emphasis field) by setting this bit to 1b in both components on a Link and then initiating a hot reset on the Link. Default value of this bit following Fundamental Reset is 0b. Components that support only the 2.5 GT/s speed are permitted to hardwire this bit to 0b. This bit is intended for debug, compliance testing purposes only. System firmware and software is allowed to modify this bit only during debug or compliance testing. In all other cases, the system must ensure that this bit is set to the default value. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_HW_AUTO_SPEED_DISABLE	5	rw	**Hardware Autonomous Speed Disable** When set, this bit disables hardware from changing the Link speed for device-specific reasons other than attempting to correct unreliable Link operation by reducing Link speed. Initial transition to the highest supported common link speed is not blocked by this bit. Functions that do not implement the associated mechanism are permitted to hardwire this bit to 0b. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky.
PCIE_CAP_SEL_DEEMPHASIS	6	rw	**Selectable De-emphasis** When the Link is operating at 5.0 GT/s speed, this bit is used to control the transmit de-emphasis of the link in specific situations. For more details, see section 4.2.6 of PCI Express Base Specification. When the Link is not operating at 5.0 GT/s speed, the setting of this bit has no effect. Components that support only the 2.5 GT/s speed are permitted to hardwire this bit to 0b. This bit is not applicable and Reserved for Endpoints, PCI Express to PCI/PCI-X bridges, and Upstream Ports of Switches. Note: This register field is sticky. 0_B **_6_DB**: -6 dB 1_B **_3_5_DB**: -3.5 dB
PCIE_CAP_TX_MARGIN	9:7	rwh	**Transmit Margin, This field controls the value of the non-deemphasized voltage level at the Transmitter pins** This field is reset to 000b on entry to the LTSSM Polling.Configuration substate (see Chapter 4 of PCI Express Base Specification for details of how the Transmitter voltage level is determined in various states). - 001b-111b: As defined in Section 8.3.4 not all encodings are required to be implemented. For components that support only the 2.5 GT/s speed, the controller hardwires this bit to 000b. This field is intended for debug, compliance testing purposes only. System firmware and software is allowed to modify this field only during debug or compliance testing. In all other cases, the system must ensure that this field is set to the default value. Note: This register field is sticky. 000_B **NORMAL_RANGE**: Normal operating range **others,** Reserved
PCIE_CAP_ENTER_MODIFIED_COMPLIANCE	10	rw	**Enter Modified Compliance** When this bit is set to 1b, the device transmits Modified Compliance Pattern if the LTSSM enters Polling.Compliance substate. Components that support only the 2.5 GT/s speed are permitted to hardwire this bit to 0b. This bit is intended for debug, compliance testing purposes only. System firmware and software is allowed to modify this bit only during debug or compliance testing. In all other cases, the system must ensure that this bit is set to the default value. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_COMPLIANCE_SOS	11	rwh	**Compliance SOS** When set to 1b, the LTSSM is required to send SKP Ordered Sets between sequences when sending the Compliance Pattern or Modified Compliance Pattern. This bit is applicable when the Link is operating at 2.5 GT/s or 5.0 GT/s data rates only. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky.
PCIE_CAP_COMPLIANCE_PRESET	15:12	rwh	**Compliance Preset/De-emphasis** • For 8.0 GT/s and higher Data Rate: This field sets the Transmitter Preset in Polling.Compliance state if the entry occurred due to the Enter Compliance bit being 1b. The encodings are defined in section 4.2.3.2 of PCI Express Base Specification . Results are undefined if a reserved preset encoding is used when entering Polling.Compliance in this way. • For 5.0 GT/s Data Rate: This field sets the de-emphasis level in Polling.Compliance state if the entry occurred due to the Enter Compliance bit being 1b • When the Link is operating at 2.5 GT/s, the setting of this field has no effect. Components that support only 2.5 GT/s speed are permitted to hardwire this field to 0000b This field is intended for debug and compliance testing purposes. System firmware and software is allowed to modify this field only during debug or compliance testing. In all other cases, the system must ensure that this field is set to the default value. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_H **_6_DB**: -6 dB (for 5.0 GT/s Data Rate) 1_H **_3_5_DB**: -3.5 dB (for 5.0 GT/s Data Rate) **others,** Reserved
PCIE_CAP_CURR_DEEMPHASIS	16	rh	**Current De-emphasis Level** When the Link is operating at 5.0 GT/s speed, this bit reflects the level of de-emphasis. The value in this bit is undefined when the Link is not operating at 5.0 GT/s speed. 0_B **_6DB**: -6 dB 1_B **_3_5DB**: -3.5 dB
PCIE_CAP_EQ_CPL	17	rh	**Equalization 8.0 GT/s Complete** When set to 1b, this bit indicates that the Transmitter Equalization procedure at the 8.0 GT/s data rate has completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in section 4.2.6.4.2 of PCI Express Base Specification. For Multi-Function Upstream Port, this bit must be implemented in Function 0 and RsvdZ in other Functions. For components that only support speeds below 8.0 GT/s, the controller hardwires this bit to 0b. Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
PCIE_CAP_EQ_CPL_P1	18	rh	**Equalization 8.0 GT/s Phase 1 Successful** When set to 1b, this bit indicates that Phase 1 of the 8.0 GT/s Transmitter Equalization procedure has successfully completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in section 4.2.6.4.2 of PCI Express Base Specification. Note: This register field is sticky.
PCIE_CAP_EQ_CPL_P2	19	rh	**Equalization 8.0 GT/s Phase 2 Successful** When set to 1b, this bit indicates that Phase 2 of the 8.0 GT/s Transmitter Equalization procedure has successfully completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in section 4.2.6.4.2 of PCI Express Base Specification. Note: This register field is sticky.
PCIE_CAP_EQ_CPL_P3	20	rh	**EEqualization 8.0 GT/s Phase 3 Successful** When set to 1b, this bit indicates that Phase 3 of the 8.0 GT/s Transmitter Equalization procedure has successfully completed. Details of the Transmitter Equalization process and when this bit needs to be set to 1b is provided in section 4.2.6.4.2 of PCI Express Base Specification. Note: This register field is sticky.
PCIE_CAP_LINK_EQ_REQ	21	rw1ch	**Link Equalization Request 8.0 GT/s** This bit is set by hardware to request the 8.0 GT/s Link equalization process to be performed on the Link. For more details, see sections 4.2.3 and 4.2.6.4.2 of PCI Express Base Specification. Note: This register field is sticky. Software write with 1 clears this bit-field.
RSVDP_26	27:26	r	**Reserved for future use**

(table continues...)

(continued)

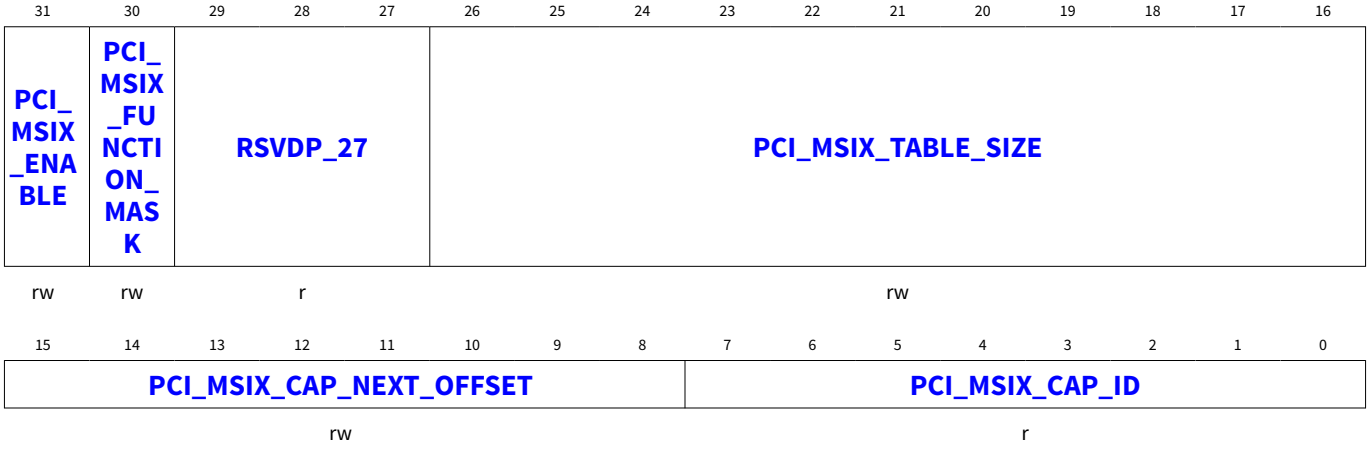
Field	Bits	Type	Description
DOWNSTREAM_COMPO_PRESENCE	30:28	r	**Downstream Component Presence** This field indicates the presence and DRS status for the Downstream Component, if any, connected to the Link. All encodings other than the defined encodings are reserved. Component Presence state must be determined by the logical "OR" of the Physical Layer in-band presence detect mechanism and, if present, any out-of-band presence detect mechanism implemented for the Link. If no out-of-band presence detect mechanism is implemented, then Component Presence state must be determined solely by the Physical Layer in-band presence detect mechanism. This field must be implemented in any Downstream Port where the DRS Supported bit is Set in the Link Capabilities 2 register. This field is RsvdZ for all other Functions. 000_B **LINK_DN_NOT_DETERMINED**: Link Down - Presence Not Determined 001_B **LINK_DN_DSP_NOT_PRESENT**: Link Down - Component Not Present indicates the Downstream Port (DP) has determined that a Downstream Component is not present 010_B **LINK_DN_DLL_NOT_ACTIVE**: Link Down - Component Present indicates the DP has determined that a Downstream Component is present, but the Data Link Layer is not active 100_B **LINK_UP_DRS_NOT_RECEIVED**: Link Up - Component Presentindicates the DP has determined that a Downstream Component is present, but no DRS Message has been received since the Data Link Layer became active 101_B **LINK_UP_DRS_RECEIVED**: Link Up - Component Present and DRS Received indicates the DP has received a DRS Message since the Data Link Layer became active **others,** Reserved
DRS_MESSAGE_RECEIVED	31	rw1ch	**DRS Message Received** This bit must be set whenever the Port receives a DRS Message. This bit must be cleared in DL_Down. This bit must be implemented in any Downstream Port where the DRS Supported bit is Set in the Link Capabilities 2 register. This bit is RsvdZ for all other Functions. Software write with 1 clears this bit-field.
0	25:22	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.133 MSI-X Capability ID, Next Pointer, Control Register

This Register holds MSI-X Capability ID, Next Capability pointer. It also controls the MSI-X behaviour.

PCI_MSIX_CAP_ID_NEXT_CTRL_REG Offset address: $00040B0_H$

MSI-X Capability ID, Next Pointer, Control Register Kernel Reset value: $0040\ 0011_H$



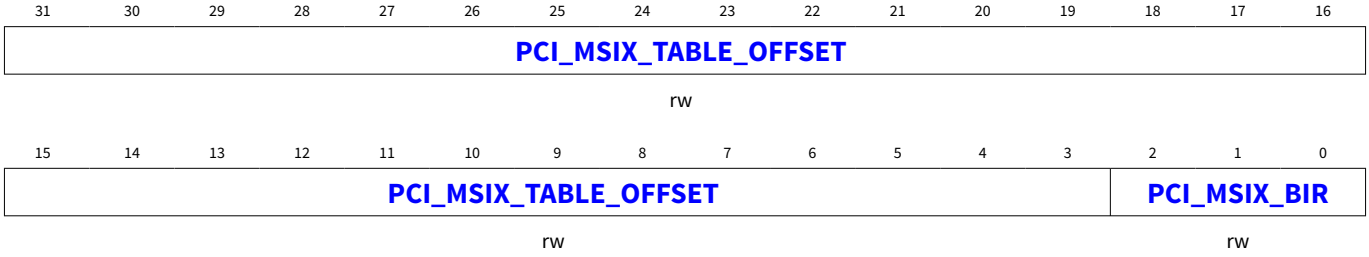
Field	Bits	Type	Description
PCI_MSIX_CAP_ID	7:0	r	**MSI-X Capability ID** This field indicates the MSI-X Capability structure. This field must return a Capability ID of 11h indicating that this is an MSI-X Capability structure.
PCI_MSIX_CAP_NEXT_OFFSET	15:8	rw	**MSI-X Next Capability Pointer** This field contains the offset to the next PCI Capability structure or 00h if no other items exist in the linked list of Capabilities. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
PCI_MSIX_TABLE_SIZE	26:16	rw	**MSI-X Table Size** System software reads this field to determine the MSI-X Table Size N, which is encoded as N-1. For example, a returned value of 000 0000 0011b indicates a table size of 4. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
RSVDP_27	29:27	r	**Reserved for future use**
PCI_MSIX_FUNCTION_MASK	30	rw	**Function Mask** If Set, all of the vectors associated with the Function are masked, regardless of their per-vector Mask bit values. If Clear, each vector's Mask bit determines whether the vector is masked or not. Setting or Clearing the MSI-X Function Mask bit has no effect on the value of the per-vector Mask bits. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
PCI_MSIX_ENABLE	31	rw	**MSI-X Enable** If Set and the MSI Enable bit in the MSI Message Control Register for MSI is Clear, the Function is permitted to use MSI-X to request service and is prohibited from using INTx interrupts (if implemented). System configuration software Sets this bit to enable MSI-X. A device driver is prohibited from writing this bit to mask a Function's service request. If Clear, the Function is prohibited from using MSI-X to request service.

19.4.2.134 MSI-X Table Offset and BIR Register

This register provides Table BIR and MSI-x Table offset select.

MSIX_TABLE_OFFSET_REG Offset address: $00040B4_H$

MSI-X Table Offset and BIR Register Kernel Reset value: $0000\ 0A00_H$



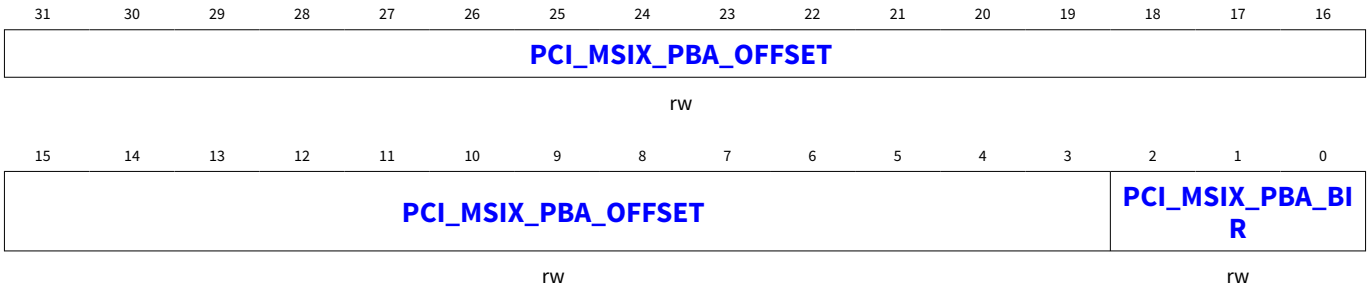
Field	Bits	Type	Description
PCI_MSIX_BIR	2:0	rw	**MSI-X Table BAR Indicator Register Field** This field indicates which one of a Function's Base Address Registers , located beginning at 10h in Configuration Space, or entry in the Enhanced Allocation capability with a matching BEI , is used to map the Function's MSI-X Table into Memory Space. All encodings other than the defined encodings are reserved. For a 64-bit Base Address Register , the Table BIR indicates the lower DWORD. For Functions with Type 1 Configuration Space headers, BIR values 2 through 5 are also Reserved. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky. 000_B **BAR_10**: Base Address Register 10h 001_B **BAR_14**: Base Address Register 14h 010_B **BAR_18**: Base Address Register 18h 011_B **BAR_1C**: Base Address Register 1Ch 100_B **BAR_20**: Base Address Register 20h 101_B **BAR_24**: Base Address Register 24h **others,** Reserved
PCI_MSIX_TABLE_OFFSET	31:3	rw	**MSI-X Table Offset** Used as an offset from the address contained by one of the Function's Base Address Registers to point to the base of the MSI-X Table. The lower 3 Table BIR bits are masked off (set to zero) by software to form a 32-bit QWORD-aligned offset. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

19.4.2.135 MSI-X PBA Offset and BIR Register

This register provides PBA Offset and PBA BIR value.

MSIX_PBA_OFFSET_REG Offset address: $00040B8_H$

MSI-X PBA Offset and BIR Register Kernel Reset value: $0000\ 0E10_H$



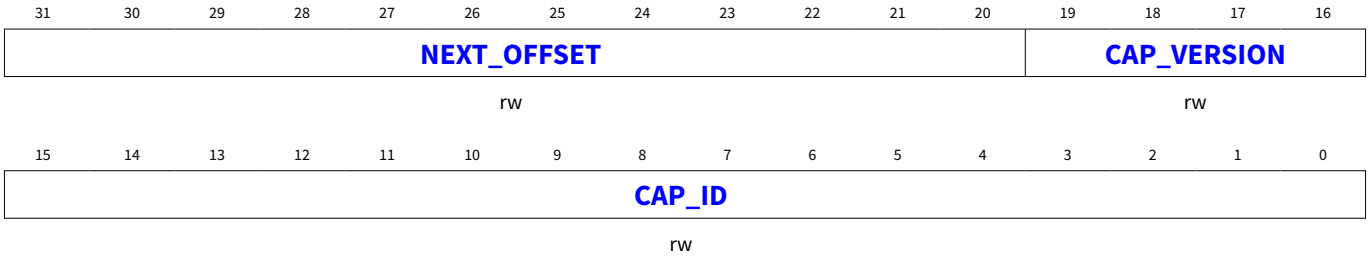
Field	Bits	Type	Description
PCI_MSIX_PBA_BIR	2:0	rw	**MSI-X PBA BIR** This field indicates which one of a Function's Base Address Registers , located beginning at 10h in Configuration Space, or entry in the Enhanced Allocation capability with a matching BEI, is used to map the Function's MSI-X PBA into Memory Space. The PBA BIR value definitions are identical to those for the Table BIR . Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
PCI_MSIX_PBA_OFFSET	31:3	rw	**MSI-X PBA Offset** Used as an offset from the address contained by one of the Function's Base Address Registers to point to the base of the MSI-X PBA. The lower 3 PBA BIR bits are masked off (set to zero) by software to form a 32-bit QWORD-aligned offset. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

19.4.2.136 Advanced Error Reporting Extended Capability Header

Advanced Error Reporting Extended Capability Header provides information about Capability ID, Version, and next offset.

AER_EXT_CAP_HDR_OFF Offset address: 0004100_H

Advanced Error Reporting Extended Capability Header Kernel Reset value: $1482\ 0001_H$



Field	Bits	Type	Description
CAP_ID	15:0	rw	**AER Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. The Extended Capability ID for the Advanced Error Reporting Capability is 0001h. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
CAP_VERSION	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. This field must be 2h if the End-End TLP Prefix Supported bit is set and must be 1h or 2h otherwise. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.2.137 Uncorrectable Error Status Register

The Uncorrectable Error Status Register (Offset 04h) indicates error detection status of individual errors on a PCI Express device Function. An individual error status bit that is Set indicates that a particular error was detected; software may clear an error status by writing a 1b to the respective bit. Register bits not implemented by the Function are hardwired to 0b.

UNCORR_ERR_STATUS_OFF Offset address: 0004104_H

Uncorrectable Error Status Register Reset values see: Table 891

19.4.2.138 Uncorrectable Error Mask Register

The Uncorrectable Error Mask Register controls reporting of individual errors by the device Function to the PCI Express Root Complex through a PCI Express error Message. A masked error (respective bit Set in the mask register) is not recorded or reported in the Header Log, TLP Prefix Log, or First Error Pointer, and is not reported to the PCI Express Root Complex by this Function. There is a mask bit per error bit of the Uncorrectable Error Status register. Register fields for bits not implemented by the Function are hardwired to 0b.

19.4.2.140 Correctable Error Status Register

The Correctable Error Status register reports error status of individual correctable error sources on a PCI Express device Function. When an individual error status bit is Set, it indicates that a particular error occurred; software may clear an error status by writing a 1b to the respective bit. Register bits not implemented by the Function are hardwired to 0b by the controller.

0	11	r	**Reserved** Read as 0; should be written with 0.

19.4.2.143 Header i Log Register 0

The Header Log Register 0 contains the header for the TLP corresponding to a detected error; The header is captured such that, when read using DW accesses, the fields of the header are laid out in the same way the headers are presented in the specification. Therefore, byte 0 of the header is located in byte 3 of the Header Log Register 0, byte 1 of the header is in byte 2 of the Header Log Register 0, and so forth. For 12-byte headers, only bytes 0 through 11 of the Header Log Register are used and values in bytes 12 through 15 are undefined. In certain cases where a Malformed TLP is reported, the Header Log Register may contain TLP Prefix information.

19.4.2.145 Root Error Status Register

The Root Error Status Register reports status of error Messages (ERR_COR, ERR_NONFATAL, and ERR_FATAL) received by the Root Port, and of errors detected by the Root Port itself(The Root Port had sent an error Message to itself). In order to update this register, error Messages received by the Root Port and/or internally generated error Messages must be enabled for “transmission” by the primary interface of the Root Port.

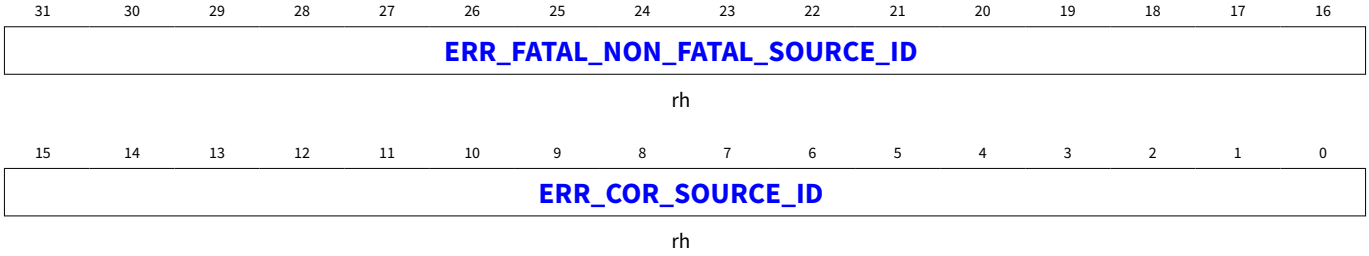
ADV_ERR_INT_MSG_NUM	31:27	rw	**Advanced Error Interrupt Message Number** This register indicates which MSI/MSI-X vector is used for the interrupt message generated in association with any of the status bits of this Capability. For MSI, the value in this register indicates the offset between the base Message Data and the interrupt message that is generated. For MSI-X, the value in this register indicates which MSI-X Table entry is used to generate the interrupt message. The entry must be one of the first 32 entries even if the Function implements more than 32 entries. For a given MSI-X implementation, the entry must remain constant. If MSI-X is enabled, the value in this register must indicate the vector for MSI-X. If MSI is enabled or neither is enabled, the value in this register must indicate the vector for MSI. If software enables both MSI and MSI-X at the same time, the value in this register is undefined. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.2.146 Error Source Identification Register

The Error Source Identification Register identifies the source (Requester ID) of first correctable and uncorrectable (Non-fatal/Fatal) errors reported in the Root Error Status Register. This register is updated regardless of the settings of the Root Control register and the Root Error Command Register.

AERCAP_ERR_SRC_ID_OFF Offset address: 0004134_H

Error Source Identification Register Kernel Reset value: $0000\ 0000_H$



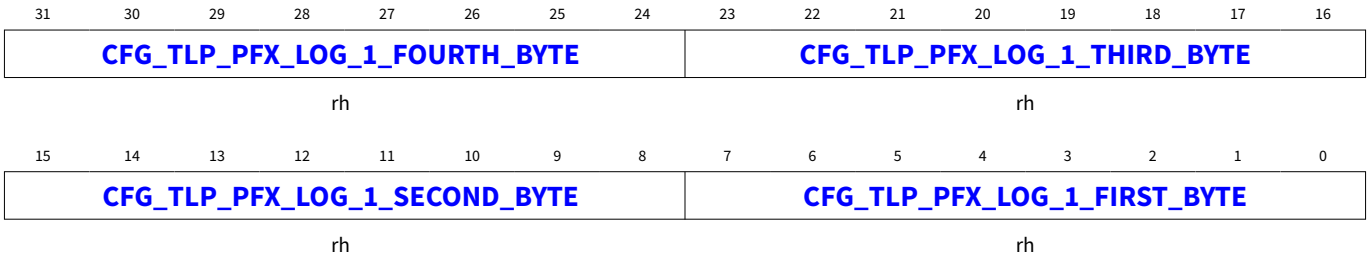
Field	Bits	Type	Description
ERR_COR_SOURCE_ID	15:0	rh	**Source of Correctable Error** Loaded with the Requester ID indicated in the received ERR_COR Message when the ERR_COR Received bit is not already set. Note: This register field is sticky.
ERR_FATAL_NON_FATAL_SOURCE_ID	31:16	rh	**Source of Fatal/Non-Fatal Error** Loaded with the Requester ID indicated in the received ERR_FATAL or ERR_NONFATAL Message when the ERR_FATAL/NONFATAL Received bit is not already set. Note: This register field is sticky.

19.4.2.147 TLP Prefix i Log Register 1

The First TLP Prefix Log Register contains the first End-End TLP Prefix from the TLP corresponding to the detected error. The TLP Prefix Log Register is only meaningful when the TLP Prefix Log Present bit is Set. The TLP Prefixes are captured such that, when read using DW accesses, the fields of the TLP Prefix are laid out in the same way the fields of the TLP Prefix are described. Therefore, byte 0 of a TLP Prefix is located in byte 3 of the associated TLP Prefix Log Register; byte 1 of a TLP Prefix is located in byte 2; and so forth. The TLP Prefix Log Registers beyond the number supported by the Function are hardwired to zero by controller. If the End-End TLP Prefix Supported bit is Clear, the TLP Prefix Log Register is not required to be implemented.

TLP_PREFIX_LOG_i_OFF (i=0-3) Offset address: 0004138_H+i*4

TLP Prefix i Log Register 1 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CFG_TLP_PFX_LOG_1_FIRST_BYTE	7:0	rh	**Byte 0 of Error TLP Prefix Log 1** This field contains first byte of First DW of TLP Prefix. Note: This register field is sticky.
CFG_TLP_PFX_LOG_1_SECOND_BYTE	15:8	rh	**Byte 1 of Error TLP Prefix Log 1** This field contains second byte of First DW of TLP Prefix. Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
CFG_TLP_PFX_LOG_1_THIRD_BYTE	23:16	rh	**Byte 2 of Error TLP Prefix Log 1** This field contains third byte of First DW of TLP Prefix. Note: This register field is sticky.
CFG_TLP_PFX_LOG_1_FOURTH_BYTE	31:24	rh	**Byte 3 of Error TLP Prefix Log 1** This field contains fourth byte of First DW of TLP Prefix. Note: This register field is sticky.

19.4.2.148 Device Serial Number Extended Capability Header

The Device Serial Number Extended Capability is an optional Extended Capability that may be implemented by any PCI Express device Function. This register provides Capability Id, Capability version, and Next offset of Capability structure.

SN_BASE Offset address: 0004148_H

Device Serial Number Extended Capability Header Kernel Reset value: $1581\ 0003_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SN_NEXT_OFFSET												SN_CAP_VERSION			
rw												rw			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SN_PCIE_EXTENDED_CAP_ID															
rw															

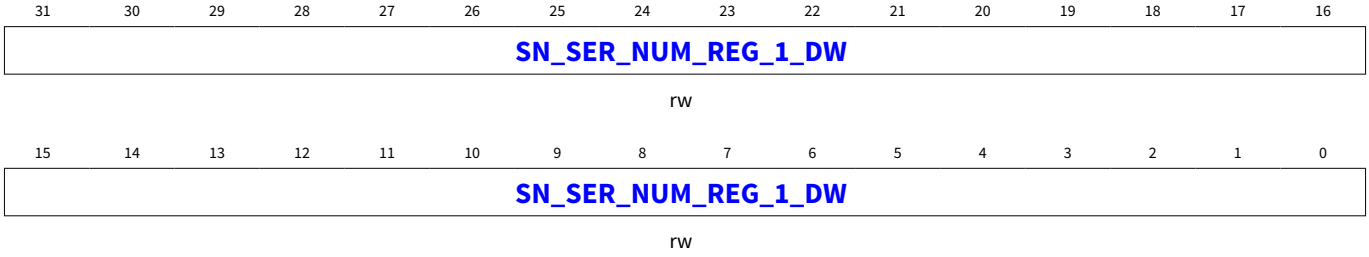
Field	Bits	Type	Description
SN_PCIE_EXTENDED_CAP_ID	15:0	rw	**Serial Number Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for the Device Serial Number Extended Capability is 0003h. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
SN_CAP_VERSION	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. This field is depends on the version of specification. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
SN_NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.2.149 Serial Number 1 Register

The Serial Number register is a 64-bit field that contains the IEEE defined 64-bit extended unique identifier.

SER_NUM_REG_DW_1 Offset address: $000414C_H$

Serial Number 1 Register Kernel Reset value: $0000\ 0000_H$



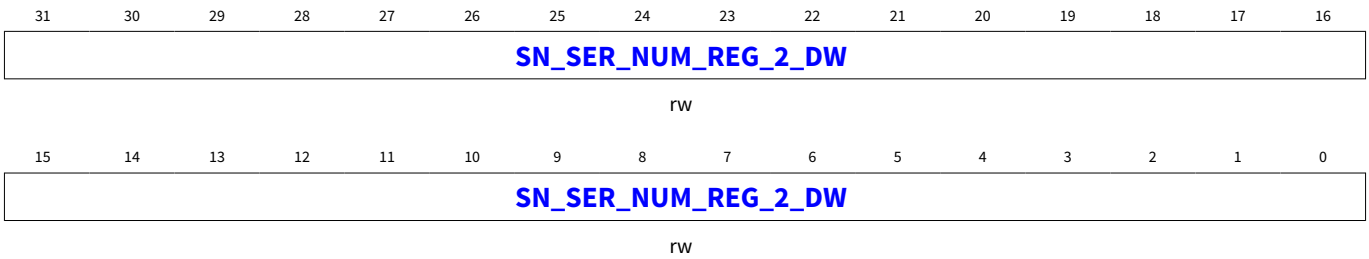
Field	Bits	Type	Description
SN_SER_NUM_REG_1_DW	31:0	rw	**IEEE 64 bit Device Serial Number (DW 1)** This field contains the IEEE defined 64-bit Extended Unique Identifier [EUI-64]. This identifier includes a 24-bit company id value assigned by IEEE registration authority and a 40-bit extension identifier assigned by the manufacturer. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.2.150 Serial Number 2 Register

The Serial Number register is a 64-bit field that contains the IEEE defined 64-bit extended unique identifier.

SER_NUM_REG_DW_2 Offset address: 0004150_H

Serial Number 2 Register Kernel Reset value: $0000\ 0000_H$



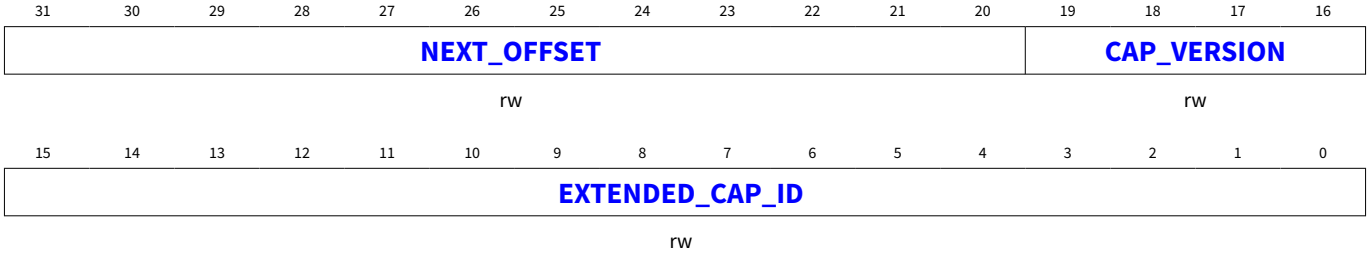
Field	Bits	Type	Description
SN_SER_NUM_REG_2_DW	31:0	rw	**IEEE 64 bit Device Serial Number (DW 2)** This field contains the IEEE defined 64-bit Extended Unique Identifier [EUI-64]. This identifier includes a 24-bit company id value assigned by IEEE registration authority and a 40-bit extension identifier assigned by the manufacturer. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.2.151 SPCIE Capability Header

This Register provides Capability Id, Capability Version, and next Offset of SPCIE Structure.

SPCIE_CAP_HEADER_REG Offset address: 0004158_H

SPCIE Capability Header Kernel Reset value: $1701\ 0019_H$



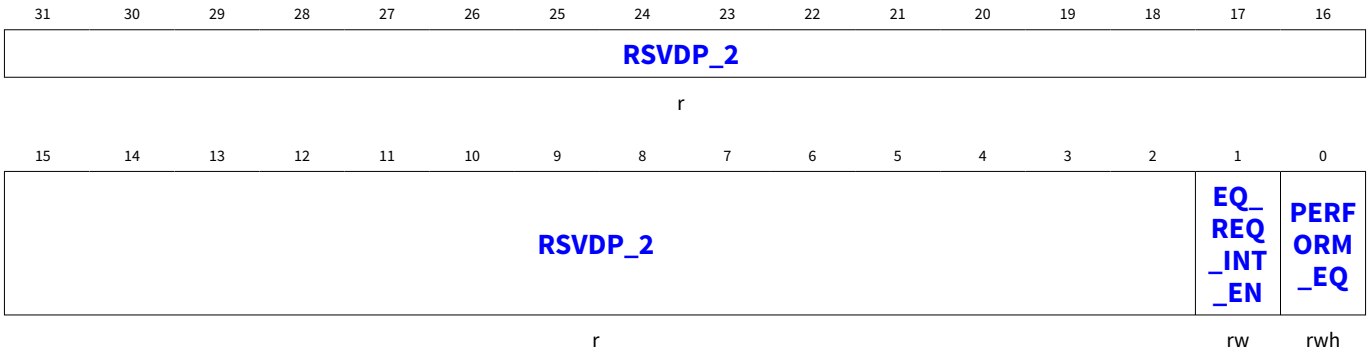
Field	Bits	Type	Description
EXTENDED_CAP_ID	15:0	rw	**Secondary PCI Express Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. PCI Express Extended Capability ID for the Secondary PCI Express Extended Capability is 0019h. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
CAP_VERSION	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of Capabilities. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value

19.4.2.152 Link Control 3 Register

This Register controls equilization and equilization interrupt.

LINK_CONTROL3_REG Offset address: $000415C_H$

Link Control 3 Register Reset values see: Table 892



Field	Bits	Type	Description
PERFORM_EQ	0	rwh	**Perform Equalization** This bit is RW for Downstream Ports and for Upstream Ports when Crosslink Supported is 1b. This bit is not applicable and is RsvdP for Upstream Ports when the Crosslink Supported bit is 0b. Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: RSVDP 0_B **CLEAR**: Clear 1_B **SET**: When this bit is 1b and a 1b is written to the Retrain Link bit with the Target Link Speed field set to 8.0 GT/s or higher, the Downstream Port must perform Link Equalization
EQ_REQ_INT_EN	1	rw	**Link Equalization Request Interrupt Enable** This bit is RW for Downstream Ports and for Upstream Ports when Crosslink Supported is 1b. This bit is not applicable and is RsvdP for Upstream Ports when the Crosslink Supported bit is 0b. Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: RSVDP 0_B **CLEAR**: Clear 1_B **SET**: When Set, this bit enables the generation of an interrupt to indicate that the Link Equalization Request 8.0 GT/s bit, the Link Equalization Request 16.0 GT/s bit, or the Link Equalization Request 32.0 GT/s bit has been set
RSVDP_2	31:2	r	**Reserved for future use**

Table 892 Reset values of LINK_CONTROL3_REG

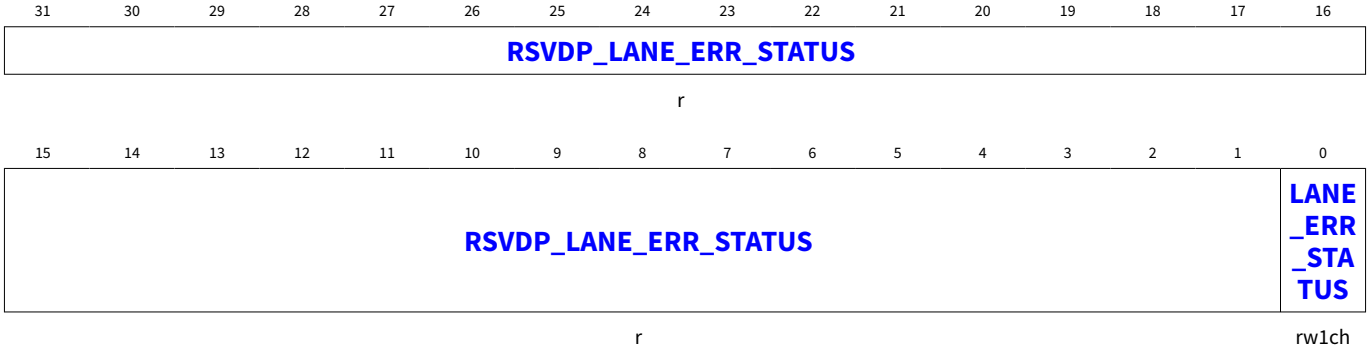
Reset	Reset value	Note
Kernel Reset	0000 0000 0000 0000 0000 0000 0000 000X_B	

19.4.2.153 Lane Error Status Register

This Register contains Lane Error Status Bits per Lane.

LANE_ERR_STATUS_REG Offset address: 0004160_H

Lane Error Status Register Kernel Reset value: $0000\ 0000_H$



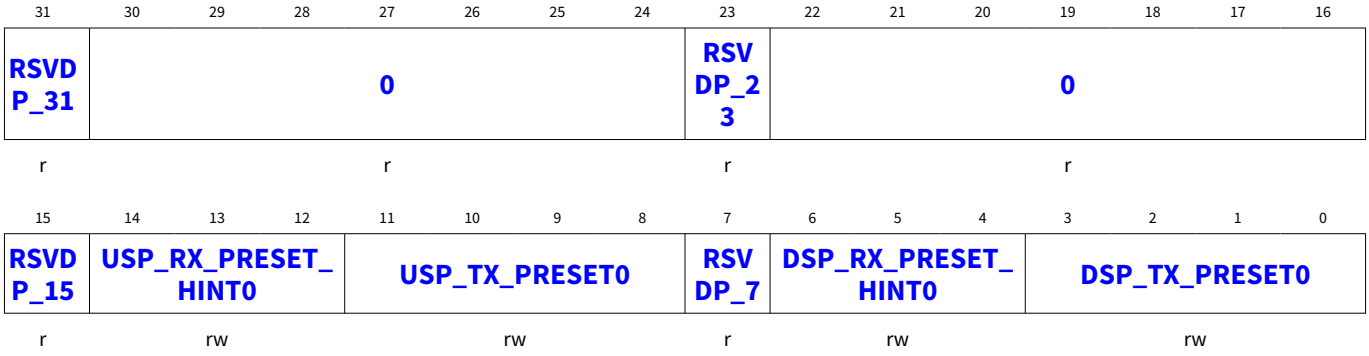
Field	Bits	Type	Description
LANE_ERR_STATUS	0	rw1ch	**Lane Error Status Bits per Lane** Each bit indicates if the corresponding Lane detected a Lane-based error. A value of 1b indicates that a Lane based-error was detected on the corresponding Lane Number. For Ports that are narrower than 32 Lanes, the unused upper bits [31: Maximum Link Width] are RsvdZ. Note: This register field is sticky. Software write with 1 clears this bit-field.
RSVDP_LANE_ERR_STATUS	31:1	r	**Reserved for future use**

19.4.2.154 Lane Equalization Control Register for lanes 1 and 0

This register provides Transmitter Preset and Receiver Preset Hint for Downstream Port and Upstream Port.

SPCIE_CAP_OFF_0CH_REG Offset address: 0004164_H

Lane Equalization Control Register for lanes 1 and 0 Kernel Reset value: $0000\ 7777_H$



Field	Bits	Type	Description
DSP_TX_PRESET0	3:0	rw	**Downstream Port 8.0 GT/s Transmitter Preset 0** Transmitter preset 0 value used for 8.0 GT/s equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. For an Upstream Port if Crosslink Supported is 0b, this field is RsvdP. Otherwise, this field is HwInit. Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: RSVDP

(table continues...)

(continued)

Field	Bits	Type	Description
DSP_RX_PRESET_HINT0	6:4	rw	**Downstream Port 8.0 GT/s Receiver Preset Hint 0** Receiver preset hint 0 value that may be used as a suggested setting for 8.0 GT/s receiver equalization by this Port when the Port is operating as a Downstream Port. This field is ignored when the Port is operating as an Upstream Port. For an Upstream Port if Crosslink Supported is 0b, this field is RsvdP. Otherwise, this field is HwInit. Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: RSVDP
RSVDP_7	7	r	**Reserved for future use**
USP_TX_PRESET0	11:8	rw	**Upstream Port 8.0 GT/s Transmitter Preset 0** The write value is gated with the PCIE_CAP_CROSS_LINK_SUPPORT field of LINK_CAPABILITIES2_REG. Field contains the Transmitter preset 0 value sent or received during 8.0 GT/s Link Equalization. • Case A: When Operating port is Downstream port and whether the Crosslink is supported or not, this field representss the value sent on Lane 0 during 8.0 GT/s equalization • Case B: When Operating port is Upstream port and Crosslink Supported bit is 0, this field is intended for debug and diagnostics. It contains the value captured from Lane 0 during Link Equalization • Case C: When Operating port is Upstream port and Crosslink Supported bit is 1, Field is not used or affected by the current Link Equalization. Field value will be used if a future crosslink negotiation switches the Operating Port Direction so that case A applies For case A and C, Field is HwInit. For case B, Field is RO. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: R (sticky) Note: This register field is sticky.
USP_RX_PRESET_HINT0	14:12	rw	**Upstream Port 8.0 GT/s Receiver Preset Hint 0** The write value is gated with the PCIE_CAP_CROSS_LINK_SUPPORT field of LINK_CAPABILITIES2_REG. Field contains the Receiver preset hint 0 value sent or received during 8.0 GT/s Link Equalization. • Case A: When Operating port is Downstream port and whether the Crosslink is supported or not, this field representss the value sent on Lane 0 during 8.0 GT/s equalization • Case B: When Operating port is Upstream port and Crosslink Supported bit is 0, this field is intended for debug and diagnostics. It contains the value captured from Lane 0 during Link Equalization • Case C: When Operating port is Upstream port and Crosslink Supported bit is 1, Field is not used or affected by the current Link Equalization. Field value will be used if a future crosslink negotiation switches the Operating Port Direction so that case A applies For case A and C, Field is HwInit. For case B, Field is RO. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: R (sticky) Note: This register field is sticky.
RSVDP_15	15	r	**Reserved for future use**
RSVDP_23	23	r	**Reserved for future use**
RSVDP_31	31	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
0	22:16, 30:24	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.155 L1 Substates Extended Capability Header

L1 Substates Extended Capability Header provides capability ID, capability version and next offset value for L1 Substates.

L1SUB_CAP_HEADER_REG Offset address: 0004170_H

L1 Substates Extended Capability Header Kernel Reset value: $1801\ 001E_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw												rw			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EXTENDED_CAP_ID															
rw															

Field	Bits	Type	Description
EXTENDED_CAP_ID	15:0	rw	**L1SUB Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for L1 PM Substates is 001Eh. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
CAP_VERSION	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. This field is depends on version of the specification. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Capability structure or 000h, if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. The bottom 2 bits of this offset are Reserved and must be implemented as 00b although software must mask them to allow for future uses of these bits. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.2.156 L1 Substates Capability Register

This register provides extended capability of L1 Substates.

L1SUB_CAPABILITY_REG Offset address: 0004174_H

L1 Substates Capability Register Kernel Reset value: $0038\ 0A1F_H$

(table continues...)

(continued)

Field	Bits	Type	Description
COMM_MODE_SUPPORT	15:8	rw	**Port Common Mode Restore Time** Time (in µs) required for this Port to re-establish common mode. Required for all Ports for which either the PCI-PM L1.2 Supported bit is Set, ASPM L1.2 Supported bit is Set, or both are Set, otherwise this field is of type RsvdP. Note: The access attributes of this field are as follows: - Wire: HWINIT - Dbi: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT|| L1SUB_CAPABILITY_REG.L1_2_PCIPM_SUPPORT ? RWS : RSVDP
PWR_ON_SCALE_SUPPORT	17:16	rw	**Port T Power On Scale** Specifies the scale used for the Port T_POWER_ON_VALUE field in the L1 PM Substates Capabilities register. Range of values are given below. Required for all Ports for which either the PCI-PM L1.2 Supported bit is Set, ASPM L1.2 Supported bit is Set, or both are Set, otherwise this field is of type RsvdP. Note: The access attributes of this field are as follows: - Wire: HWINIT - Dbi: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT|| L1SUB_CAPABILITY_REG.L1_2_PCIPM_SUPPORT ? RWS : RSVDP 00_B **_2us**: Scale is 2 µs 01_B **_10us**: Scale is 10 µs 10_B **_100us**: Scale is 100 µs 11_B **Reserved**: Reserved
RSVDP_18	18	r	**Reserved for future use**
PWR_ON_VALUE_SUPPORT	23:19	rw	**Port T Power On Value** Along with the Port T_POWER_ON_SCALE field in the L1 PM Substates Capabilities register sets the time (in µs) that this Port requires the port on the opposite side of Link to wait in L1.2.Exit after sampling CLKREQ# asserted before actively driving the interface. The value of Port T_POWER_ON is calculated by multiplying the value in this field by the scale value in the Port T_POWER_ON_SCALE field in the L1 PM Substates Capabilities register. Required for all Ports for which either the PCI-PM L1.2 Supported bit is Set, ASPM L1.2 Supported bit is Set, or both are Set, otherwise this field is of type RsvdP. Note: The access attributes of this field are as follows: • Wire: HWINIT • Dbi: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT|| L1SUB_CAPABILITY_REG.L1_2_PCIPM_SUPPORT ? RWS : RSVDP

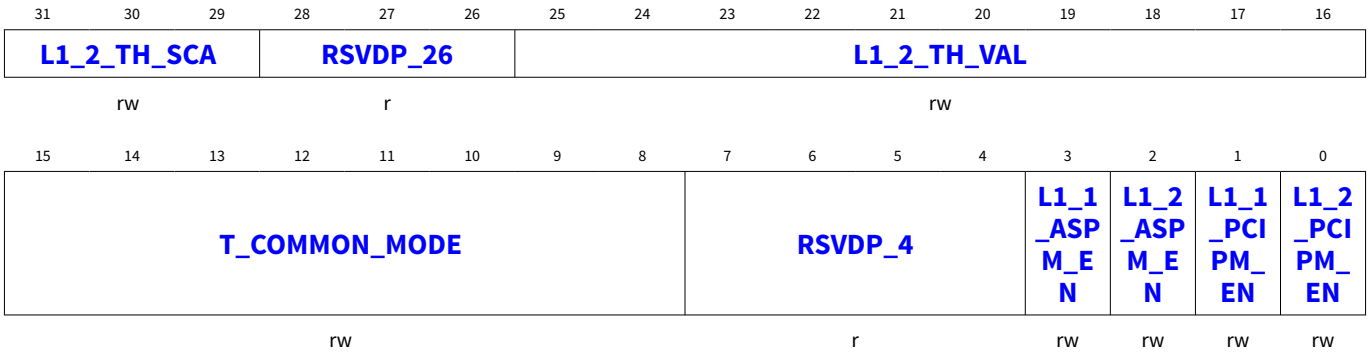
19.4.2.157 L1 Substates Control 1 Register

This register Controls that the individual extended capability is enabled ot not.

L1SUB_CONTROL1_REG Offset address: 0004178_H

L1 Substates Control 1 Register Kernel Reset value: $0000\ 0A00_H$



Field	Bits	Type	Description
L1_2_PCIPM_EN	0	rw	**PCI-PM L12 Enable** When Set this field, enables PCI-PM L1.2. For Ports for which the PCI-PM L1.2 Supported bit is clear, this bit is permitted to be hardwired to 0. Required for both Upstream and Downstream Ports. For compatibility with possible future extensions, software must not enable L1 PM Substates unless the L1 PM Substates Supported field in the L1 PM Substates Capabilities Register is Set.
L1_1_PCIPM_EN	1	rw	**PCI-PM L11 Enable** When Set this field, enables PCI-PM L1.1. Required for both Upstream and Downstream Ports. For compatibility with possible future extensions, software must not enable L1 PM Substates unless the L1 PM Substates Supported field in the L1 PM Substates Capabilities Register is Set.
L1_2_ASPM_EN	2	rw	**ASPM L12 Enable** When Set this field, enables ASPM L1.2. For Ports for which the ASPM L1.2 Supported bit is clear, this bit is permitted to be hardwired to 0. Required for both Upstream and Downstream Ports. For compatibility with possible future extensions, software must not enable L1 PM Substates unless the L1 PM Substates Supported field in the L1 PM Substates Capabilities Register is Set.
L1_1_ASPM_EN	3	rw	**ASPM L11 Enable** When Set this field, enables ASPM L1.1. For Ports for which the ASPM L1.1 Supported bit is clear, this bit is permitted to be hardwired to 0. Required for both Upstream and Downstream Ports. For compatibility with possible future extensions, software must not enable L1 PM Substates unless the L1 PM Substates Supported field in the L1 PM Substates Capabilities Register is Set.
RSVDP_4	7:4	r	**Reserved for future use**
T_COMMON_MODE	15:8	rw	**Common Mode Restore Time** Sets value of TCOMMONMODE (in µs), which must be used by the Downstream Ports for timing the re-establishment of common mode. This field is of type RsvdP for Upstream Ports.

(table continues...)

(continued)

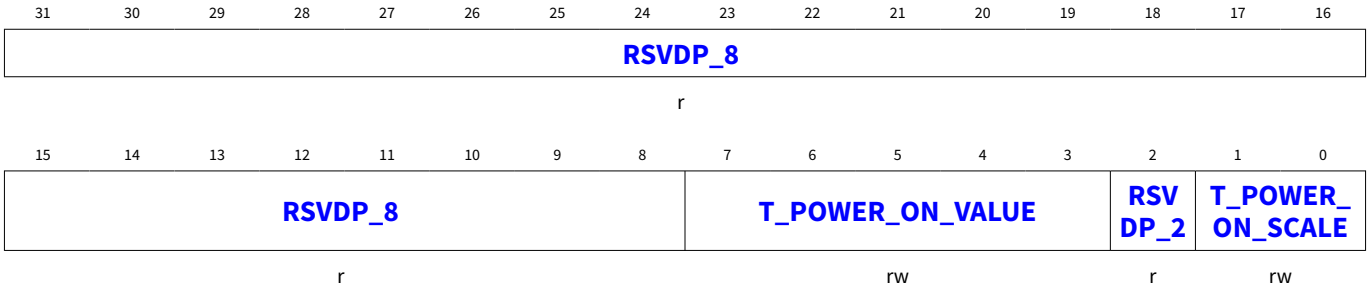
Field	Bits	Type	Description
L1_2_TH_VAL	25:16	rw	**LTR L12 Threshold Value** Along with the LTR_L1.2_THRESHOLD_Scale, this field indicates the LTR threshold used to determine if entry into L1 results in L1.1 (if enabled) or L1.2 (if enabled). Required for all Ports for which the ASPM L12 Supported bit is Set, otherwise this field is of type RsvdP. Note: The access attributes of this field are as follows • Wire: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT ? RW : RSVDP • Dbi: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT ? RW : RSVDP
RSVDP_26	28:26	r	**Reserved for future use**
L1_2_TH_SCA	31:29	rw	**LTR L12 Threshold Scale** This field provides a scale for the value contained within the LTR_L1.2_THRESHOLD_Value. Hardware operation is undefined if software writes a Not-Permitted value to this field. Required for all Ports Ports for which the ASPM L12 Supported bit is Set, otherwise this field is of type RsvdP. Note: The access attributes of this field are as follows: • Wire: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT ? RW : RSVDP • Dbi: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT ? RW : RSVD

19.4.2.158 L1 Substates Control 2 Register

This register Controls that the individual extended capability is enabled ot not.

L1SUB_CONTROL2_REG Offset address: $000417C_H$

L1 Substates Control 2 Register Kernel Reset value: $0000\ 0028_H$



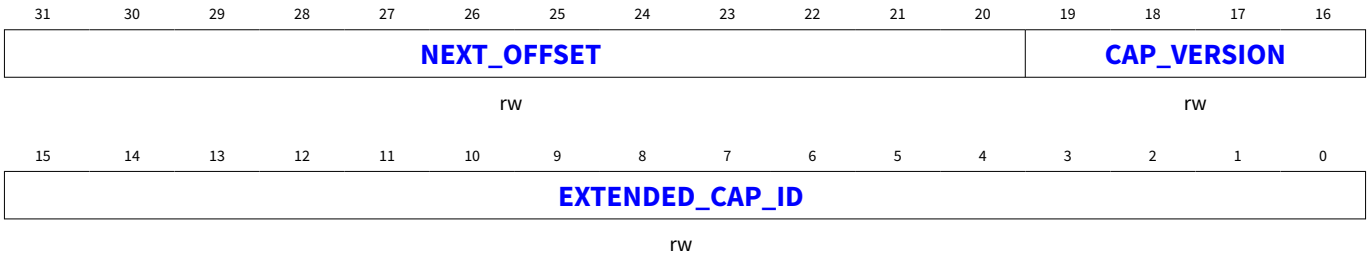
Field	Bits	Type	Description
T_POWER_ON_SCALE	1:0	rw	**T Power On Scale** Specifies the scale used for T_POWER_ON_VALUE. Range of values are given below. Required for all Ports that support L1.2, otherwise this field is of type RsvdP. This field must only be modified when the ASPM L1.2 Enable and PCI-PM L1.2 Enable bits are both Clear. The Port behavior is undefined if this field is modified when either the ASPM L1.2 Enable and/or PCI-PM L1.2 Enable bit(s) are set. Note: The access attributes of this field are as follows: • Wire: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT|| L1SUB_CAPABILITY_REG.L1_2_PCIPM_SUPPORT ? RWS : RSVDP • Dbi: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT|| L1SUB_CAPABILITY_REG.L1_2_PCIPM_SUPPORT ? RWS : RSVDP 00_B **_2us**: Scale is 2 µs 01_B **_10us**: Scale is 10 µs 10_B **_100us**: Scale is 100 µs 11_B **Reserved**: Reserved
RSVDP_2	2	r	**Reserved for future use**
T_POWER_ON_VALUE	7:3	rw	**T Power On Value** Along with the T_POWER_ON_SCALE sets the minimum amount of time (in µs) that the Port must wait in L1.2.Exit after sampling CLKREQ# asserted before actively driving the interface. T_POWER_ON is calculated by multiplying the value in this field by the value in the T_POWER_ON_SCALE field. Required for all Ports that support L1.2, otherwise this field is of type RsvdP.This field must only be modified when the ASPM L1.2 Enable and PCI-PM L1.2 Enable bits are both Clear. The Port behavior is undefined if this field is modified when either the ASPM L1.2 Enable and/or PCI-PM L1.2 Enable bit(s) are set. Note: The access attributes of this field are as follows: • Wire: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT|| L1SUB_CAPABILITY_REG.L1_2_PCIPM_SUPPORT ? RWS : RSVDP • Dbi: L1SUB_CAPABILITY_REG.L1_2_ASPM_SUPPORT|| L1SUB_CAPABILITY_REG.L1_2_PCIPM_SUPPORT ? RWS : RSVDP
RSVDP_8	31:8	r	**Reserved for future use**

19.4.2.159 Vendor-Specific Extended Capability Header

The Vendor-Specific Extended Capability (VSEC Capability) is an optional Extended Capability that is permitted to be implemented by any PCI Express Function or RCRB. This Register contains Capability Id, Capability Version and Next Offset value for Vendor-Specific Extended Capability.

RAS_DES_CAP_HEADER_REG Offset address: 0004180_H

Vendor-Specific Extended Capability Header Kernel Reset value: $2801\ 000B_H$



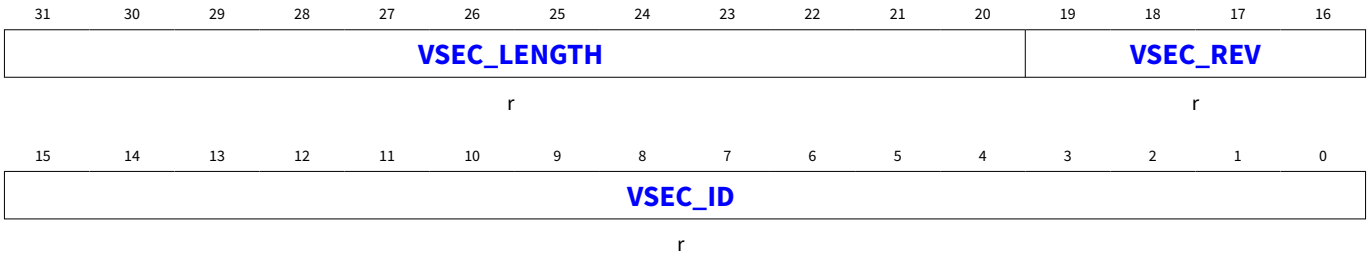
Field	Bits	Type	Description
EXTENDED_CAP_ID	15:0	rw	**PCI Express Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Extended Capability ID for the Vendor-Specific Extended Capability is 000Bh. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
CAP_VERSION	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. Value of this field is depends on the version of the specification. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value

19.4.2.160 Vendor-Specific Header

This Register field provides VSEC Length, VSEC ID and VSEC Rev(Version Number). Vendor-specific software must qualify the associated Vendor ID of the PCI Express Function or RCRB before attempting to interpret the values in the VSEC ID or VSEC Rev fields.

VENDOR_SPECIFIC_HEADER_REG Offset address: 0004184_H

Vendor-Specific Header Kernel Reset value: $1004\ 0002_H$



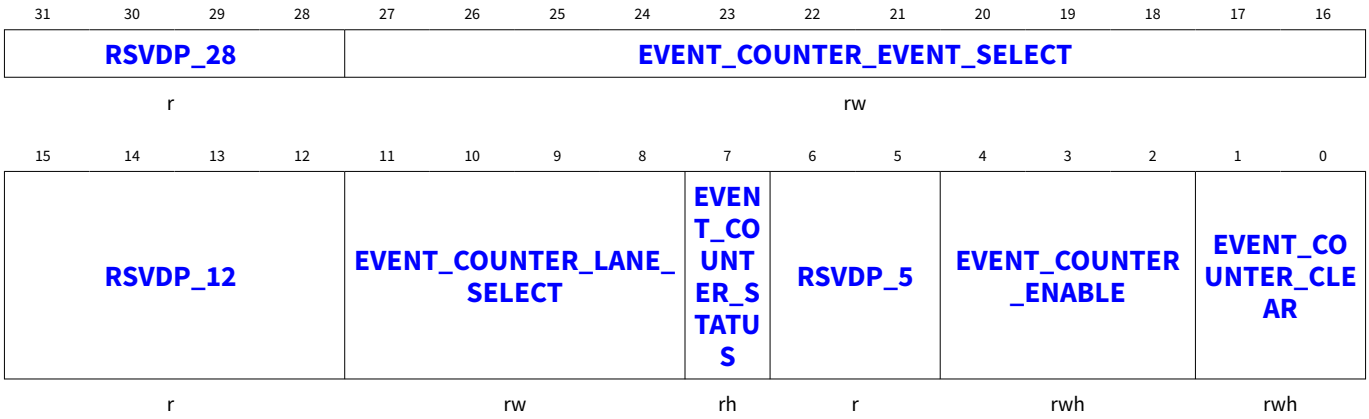
Field	Bits	Type	Description
VSEC_ID	15:0	r	**VSEC ID** This field is a vendor-defined ID number that indicates the nature and format of the VSEC structure. Software must qualify the Vendor ID before interpreting this field. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
VSEC_REV	19:16	r	**VSEC Rev** This field is a vendor-defined version number that indicates the version of the VSEC structure. Software must qualify the Vendor ID and VSEC ID before interpreting this field. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
VSEC_LENGTH	31:20	r	**VSEC Length** This field indicates the number of bytes in the entire VSEC structure, including the Vendor-Specific Extended Capability Header, the Vendor-Specific Header, and the vendor-specific registers. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value

19.4.2.161 Event Counter Control

This is a viewport control register. - Setting the EVENT_COUNTER_EVENT_SELECT and EVENT_COUNTER_LANE_SELECT fields in this register determine the Event Counter data returned by the EVENT_COUNTER_DATA_REG viewport register. - Setting the EVENT_COUNTER_ENABLE field in this register enables the Event Counter selected by the EVENT_COUNTER_EVENT_SELECT and EVENT_COUNTER_LANE_SELECT fields in this register. - Setting the EVENT_COUNTER_CLEAR field in this register clears the Event Counter selected by the EVENT_COUNTER_EVENT_SELECT and EVENT_COUNTER_LANE_SELECT fields in this register. - Reading the EVENT_COUNTER_STATUS field in this register returns the Enable status of the Event Counter selected by the EVENT_COUNTER_EVENT_SELECT and EVENT_COUNTER_LANE_SELECT fields in this register.

EVENT_COUNTER_CONTROL_REG Offset address: 0004188_H

Event Counter Control Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EVENT_COUNTER_CLEAR	1:0	rwh	**Event Counter Clear** Clears the Event Counter selected by the EVENT_COUNTER_EVENT_SELECT and EVENT_COUNTER_LANE_SELECT fields in this register. You can clear the value of a specific Event Counter by writing the 'per clear' code and you can clear all event counters at once by writing the 'all clear' code. The read value is always '0'. Other values are reserved. 00_B **NO_CHANGE**: no change 01_B **PER_CLEAR**: per clear 10_B **NO_CHANGE_2**: no change 11_B **ALL_CLEAR**: all clear
EVENT_COUNTER_ENABLE	4:2	rwh	**Event Counter Enable** Enables/disables the Event Counter selected by the EVENT_COUNTER_EVENT_SELECT and EVENT_COUNTER_LANE_SELECT fields in this register. By default, all event counters are disabled. You can enable/disable a specific Event Counter by writing the 'per event off' or 'per event on' codes. You can enable/disable all event counters by writing the 'all on' or 'all off' codes. The read value is always '0'. For other values no change. 001_B **PER_EVENT_OFF**: per event off 011_B **PER_EVENT_ON**: per event on 101_B **ALL_OFF**: all off 111_B **ALL_ON**: all on
RSVDP_5	6:5	r	**Reserved for future use**
EVENT_COUNTER_STATUS	7	rh	**Event Counter Status** This register returns the current value of the Event Counter selected by the following fields: - EVENT_COUNTER_EVENT_SELECT - EVENT_COUNTER_LANE_SELECT Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Set

(table continues...)

(continued)

Field	Bits	Type	Description
EVENT_COUNTER_LANE_SELECT	11:8	rw	**Event Counter Lane Select** This field in conjunction with EVENT_COUNTER_EVENT_SELECT indexes the Event Counter data returned by the EVENT_COUNTER_DATA_REG register. Note: This register field is sticky. 0_H **MIN_VAL**: Lane0 F_H **MAX_VAL**: Lane15
RSVDP_12	15:12	r	**Reserved for future use**
EVENT_COUNTER_EVENT_SELECT	27:16	rw	**Event Counter Data Select** This field in conjunction with the EVENT_COUNTER_LANE_SELECT field indexes the Event Counter data returned by the EVENT_COUNTER_DATA_REG register • 27-24: Group number(4-bit: 0..0x7) • 23-16: Event number(8-bit: 0..0x13) within the Group Note: This register field is sticky. 000_H **EBUF_OVERFLOW**: Ebuf Overflow 001_H **EBUF_UNDERRUN**: Ebuf Underrun 700_H **TX_MEM_WRITE**: Tx Memory Write 713_H **RX_MSG_TLP**: Rx Message TLP **others,** Reserved
RSVDP_28	31:28	r	**Reserved for future use**

19.4.2.162 Event Counter Data

This viewport register returns the data selected by the following fields: - EVENT_COUNTER_EVENT_SELECT in EVENT_COUNTER_CONTROL_REG - EVENT_COUNTER_LANE_SELECT in EVENT_COUNTER_CONTROL_REG

EVENT_COUNTER_DATA_REG Offset address: $000418C_H$

Event Counter Data Kernel Reset value: $0000\ 0000_H$

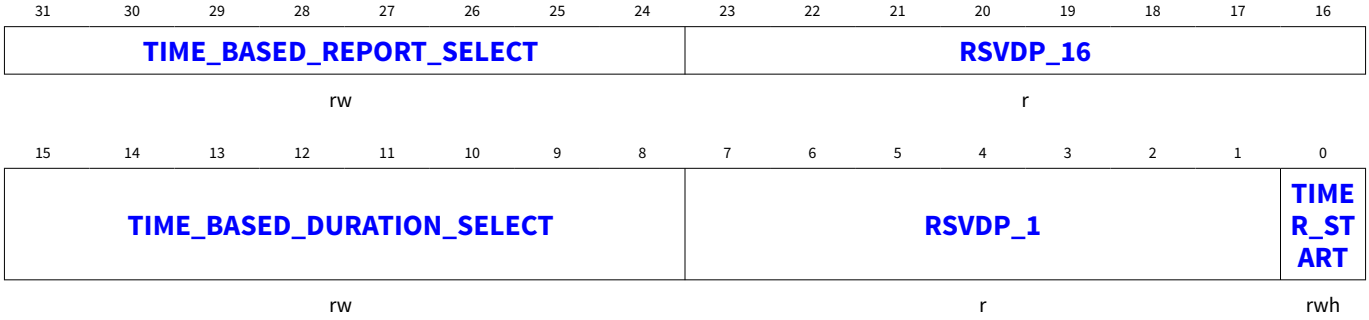
19.4.2.163 Time-based Analysis Control

Used for controlling the measurement of RX/TX data throughput and time spent in each low-power LTSSM state.

TIME_BASED_ANALYSIS_CONTROL_REG Offset address: 0004190_H

Time-based Analysis Control Kernel Reset value: $0000\ 0100_H$



Field	Bits	Type	Description
TIMER_START	0	rwh	**Timer Start** This bit will be cleared automatically when the measurement is finished. Note: This register field is sticky. 0_B **STOP**: Stop 1_B **START_RESTART**: Start/Restart
RSVDP_1	7:1	r	**Reserved for future use**
TIME_BASED_DURATION_SELECT	15:8	rw	**Time-based Duration Select** Selects the duration of time-based analysis. When "manual control" is selected and TIMER_START is set to '1', this analysis never stops until TIMER_STOP is set to '0'. All encodings other than the defined encodings are reserved. Note: This register field is sticky. 00_H **MANUAL**: Manual control 01_H **_1_MS**: 1ms 02_H **_2_MS**: 10ms 03_H **_100_MS**: 100ms 04_H **_1_S**: 1s 05_H **_2_S**: 2s 06_H **_4_S**: 4s FF_H **_4_US**: 4 µs (Debug purpose)
RSVDP_16	23:16	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
TIME_BASED_REPORT_SELECT	31:24	rw	**Time-based Report Select** Selects what type of data is measured for the selected duration (TIME_BASED_DURATION_SELECT), and returned in TIME_BASED_ANALYSIS_DATA. Each type of data is measured using one of three types of units: • Core_clk Cycles for 2.5GT/s, 5.0GT/s, 8.0GT/s. Total time in ps is [Value of TIME_BASED_ANALYSIS_DATA returned when TIME_BASED_REPORT_SELECT=0x00] * TIME_BASED_ANALYSIS_DATA. Values 0x0-0x4 and 0x7-0x8 correspond to Core_clk Cycles for 2.5GT/s, 5.0GT/s, 8.0GT/s. • Aux_clk Cycles. Total time in ps is [Period of platform specific clock] * TIME_BASED_ANALYSIS_DATA. Values 0x5, 0x6, and 0x9 correspond to aux_clk Cycles • Data Bytes. Actual amount of bytes is 16 * TIME_BASED_ANALYSIS_DATA. Values 0x20-0x23 correspond to data bytes All encodings other than the defined encodings are reserved. Note: This register field is sticky. 00_H **ONE_CYCLE**: Duration of 1 cycle 01_H **TX_L0S**: TxL0s 02_H **RX_L0S**: RxL0s 03_H **L0**: L0 04_H **L1**: L1 05_H **L1_1**: L1.1 06_H **L1_2**: L1.2 07_H **CFG_RCVRY**: Configuration/Recovery 08_H **TX_RX_L0S**: TxL0s and RxL0s 09_H **L1_AUX**: L1 aux 10_H **_1_CYCLE**: Duration of 1 cycle 11_H **TX_L0S_**: TxL0s 12_H **RX_L0S_**: RxL0s 13_H **L0_**: L0 14_H **L1_**: L1 17_H **CFG_RCVRY_**: Configuration/Recovery 18_H **TX_RX_L0S_**: TxL0s and RxL0s 20_H **TX_PCIE_TLP**: Tx PCIe TLP data payload Bytes 21_H **RX_PCIE_TLP**: Rx PCIe TLP data payload Bytes 22_H **TX_CCIX_TLP**: Tx CCIX TLP data payload Bytes 23_H **RX_CCIX_TLP**: Rx CCIX TLP data payload Bytes **others,** Reserved

19.4.2.164 Time-based Analysis Data

Contains the measurement results of RX/TX data throughput and time spent in each low-power LTSSM state. This viewport register returns the data selected by the TIME_BASED_REPORT_SELECT field in TIME_BASED_ANALYSIS_CONTROL_REG.

TIME_BASED_ANALYSIS_DATA_REG Offset address: 0004194_H

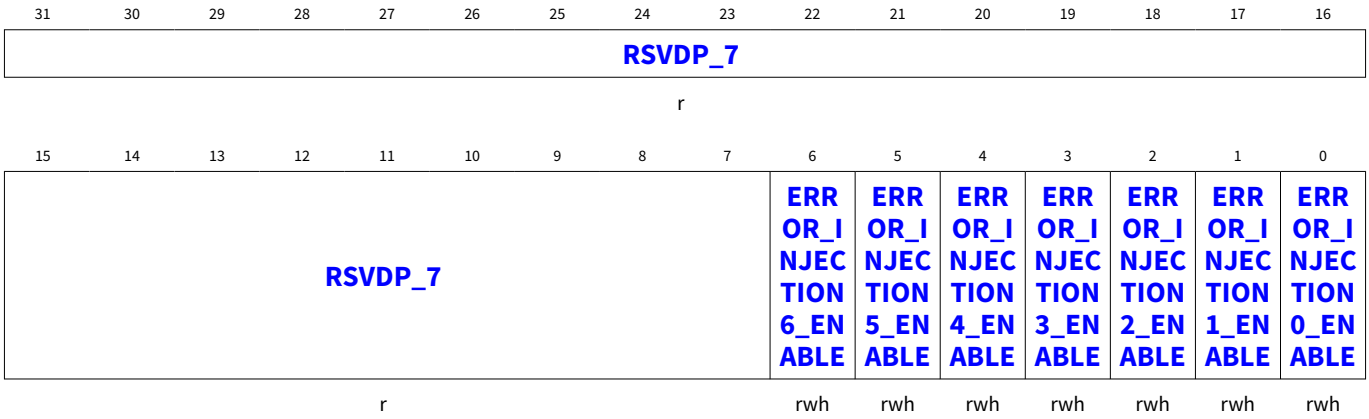
19.4.2.166 Error Injection Enable

Each type of error insertion is enabled by the corresponding bit in this register. The specific injection controls for each type of error are defined in the following registers: - 0: CRC Error: EINJ0_CRC_REG - 1: Sequence Number Error: EINJ1_SEQNUM_REG - 2: DLLP Error: EINJ2_DLLP_REG - 3: Symbol DataK Mask Error or Sync Header Error: EINJ3_SYMBOL_REG - 4: FC Credit Update Error: EINJ4_FC_REG - 5: TLP Duplicate/Nullify Error: EINJ5_SP_TLP_REG - 6: Specific TLP Error: EINJ6_COMPARE_*_REG/EINJ6_CHANGE_*_REG/EINJ6_TLP_REG After the errors have been inserted by controller, it will clear each bit here.

EINJ_ENABLE_REG Offset address: $00041B0_H$

Error Injection Enable Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ERROR_INJECTION0_ENABLE	0	rwh	**Error Injection0 Enable (CRC Error)** Enables insertion of errors into various CRC. For more details, see the EINJ0_CRC_REG register. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
ERROR_INJECTION1_ENABLE	1	rwh	**Error Injection1 Enable (Sequence Number Error)** Enables insertion of errors into sequence numbers. For more details, see the EINJ1_SEQNUM_REG register. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
ERROR_INJECTION2_ENABLE	2	rwh	**Error Injection2 Enable (DLLP Error)** Enables insertion of DLLP errors. For more details, see the EINJ2_DLLP_REG register. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
ERROR_INJECTION3_ENABLE	3	rwh	**Error Injection3 Enable (Symbol DataK Mask Error or Sync Header Error)** Enables DataK masking of special symbols or the breaking of the sync header. For more details, see the EINJ3_SYMBOL_REG register. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
ERROR_INJECTION4_ENABLE	4	rwh	**Error Injection4 Enable (FC Credit Update Error)** Enables insertion of errors into UpdateFCs. For more details, see the EINJ4_FC_REG register. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
ERROR_INJECTION5_ENABLE	5	rwh	**Error Injection5 Enable (TLP Duplicate/Nullify Error)** Enables insertion of duplicate/nullified TLPs. For more details, see the EINJ5_SP_TLP_REG register. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable

(table continues...)

(continued)

Field	Bits	Type	Description
ERROR_INJECTION6_ENABLE	6	rwh	**Error Injection6 Enable (Specific TLP Error)** Enables insertion of errors into the packets that you select. For more details, see the EINJ6_COMPARE_*_REG/EINJ6_CHANGE_*_REG/ EINJ6_TLP_REG registers. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
RSVDP_7	31:7	r	**Reserved for future use**

19.4.2.167 Error Injection Control 0 (CRC Error)

Controls the insertion of errors into the CRC, and parity of ordered sets for the selected type of the packets as follows: - LCRC. Bad TLP will be detected at the receiver side; receiver responds with NAK DLLP; Data Link Retry starts. - 16-bit CRC of ACK/NAK DLLPs. Bad DLLP occurs at the receiver side; Replay NUM Rollover occurs. - 16-bit CRC of UpdateFC DLLPs. Error insertion continues for the specific time; LTSSM transitions to the Recovery state because of the UpdateFC timeout (if the timeout is implemented at the receiver of the UpdateFCs). - ECRC. If ECRC check is enabled, ECRC error is detected at the receiver side. - FCRC. Framing error will be detected, TLP is discarded, and the LTSSM transitions to Recovery state. - Parity of TSOS. Error insertion continues for the specific time; LTSSM Recovery/Configuration timeout will occur. - Parity of SKPOS. Lane error will be detected at the receiver side.

EINJ0_CRC_REG Offset address: $00041B4_H$

Error Injection Control 0 [CRC Error) Kernel Reset value: $0000\ 0000_H$

RSVDP_12				EINJ0_CRC_TYPE				EINJ0_COUNT							
r				rw				rwh							

Field	Bits	Type	Description
EINJ0_COUNT	7:0	rwh	**Error injection count** Indicates the number of errors. This register is decremented when the errors have been inserted. - If the counter value is 0x01 and error is inserted, ERROR_INJECTION0_ENABLE in EINJ_ENABLE_REG returns 0b. - If the counter value is 0x00 and ERROR_INJECTION0_ENABLE=1, the errors are inserted until ERROR_INJECTION0_ENABLE is set to '0'. Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
EINJ0_CRC_TYPE	11:8	rw	**Error injection type** Selects the type of CRC error to be inserted. All encodings other than the defined encodings are reserved. Note: This register field is sticky. 0_H **TLP_LCRC_ERR**: (TX Path) New TLP's LCRC error injection 1_H **_16b_CRC_ERR_ACK_NAK_DLLP**: (TX Path) 16bCRC error injection of ACK/NAK DLLP 2_H **_16b_CRC_ERR_UPD_FC**: (TX Path) 16bCRC error injection of Update-FC DLLP 3_H **TLP_ECRC_ERR**: (TX Path) New TLP's ECRC error injection 4_H **FCRC_ERR_TLP**: (TX Path) TLP's FCRC error injection (128b/130b) 5_H **PARITY_TSOS_ERR**: (TX Path) Parity error of TSOS (128b/130b) 6_H **PARITY_SKPOS_ERR**: (TX Path) Parity error of SKPOS (128b/130b) 8_H **LCRC_ERR**: (RX Path) LCRC error injection B_H **ECRC_ERR**: (RX Path) ECRC error injection **others,** Reserved
RSVDP_12	31:12	r	**Reserved for future use**

19.4.2.168 Error Injection Control 1 (Sequence Number Error).

Controls the sequence number of the specific TLPs and ACK/NAK DLLPs. Data Link Protocol Error will be detected at the Rx side of ACK/NAL DLLPs when one of these conditions is true: - ((NEXT_TRANSMIT_SEQ -1) - AckNak_Seq_Num) mod 4096 > 2048 - (AckNak_Seq_Num - ACKD_SEQ) mod 4096 >= 2048 TLP is treated as Duplicate TLP at the Rx side when all these conditions are true: - Sequence Number != NEXT_RCV_SEQ - (NEXT_RCV_SEQ - Sequence Number) mod 4096 <= 2048 TLP is treated as Bad TLP at the Rx side when all these conditions are true: - Sequence Number != NEXT_RCV_SEQ and - (NEXT_RCV_SEQ - Sequence Number) mod 4096 > 2048

EINJ1_SEQNUM_REG Offset address: $00041B8_H$

Error Injection Control 1 [Sequence Number Error).
 Kernel Reset value: $0000\ 0000_H$

r							rw	rwh							

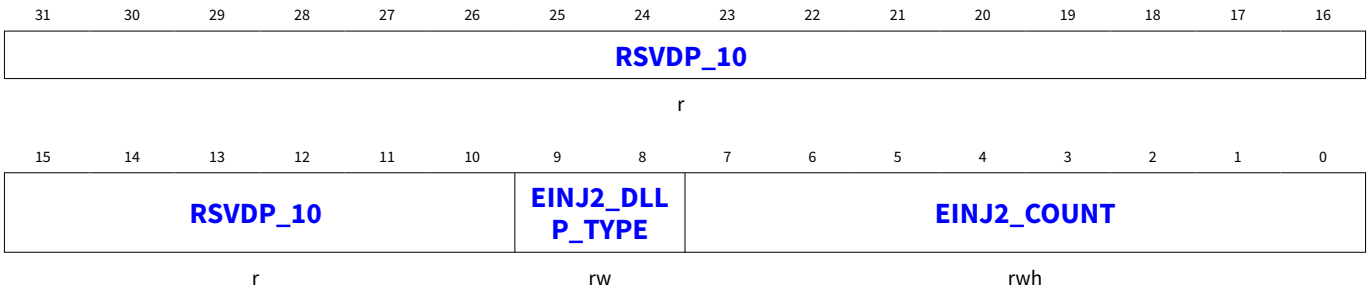
Field	Bits	Type	Description
EINJ1_COUNT	7:0	rwh	**Error injection count** Indicates the number of errors. This register is decremented as the errors are being inserted. - If the counter value is 0x01 and error is inserted, ERROR_INJECTION1_ENABLE in EINJ_ENABLE_REG returns '0'. - If the counter value is 0x00 and ERROR_INJECTION1_ENABLE=1, the errors are inserted until ERROR_INJECTION1_ENABLE is set to '0'. Note: This register field is sticky.
EINJ1_SEQNUM_TYPE	8	rw	**Sequence number type** Selects the type of sequence number. Note: This register field is sticky. 0_B **TLP_ERR**: Insertion of New TLP's SEQ# error 1_B **ACK_NAK_DLLP_ERR**: Insertion of ACK/NAK DLLP's SEQ# Error
RSVDP_9	15:9	r	**Reserved for future use**
EINJ1_BAD_SEQNUM	28:16	rw	**Bad sequence number** Indicates the value to add/subtract from the naturally-assigned sequence numbers. This value is represented by two's complement. For example: - Set Type, SEQ# and Count -- EINJ1_SEQNUM_TYPE =0 (Insert errors into new TLPs) -- EINJ1_BAD_SEQNUM =0x1FFD (represents -3) -- EINJ1_COUNT =1 - Enable Error Injection -- ERROR_INJECTION1_ENABLE =1 - Send a TLP From the Core's Application Interface -- Assume SEQ#5 is given to the TLP. - The SEQ# is Changed to #2 by the Error Injection Function in Layer2. -- 5 + (-3) = 2 - The TLP with SEQ#2 is Transmitted to PCIe Link. Note: This register field is sticky. $0FFF_H$ **MAX_VAL**: +4095 1001_H **MIN_VAL**: -4095 **others,** Reserved
RSVDP_29	31:29	r	**Reserved for future use**

19.4.2.169 Error Injection Control 2 (DLLP Error)

Controls the transmission of DLLPs and inserts the following errors: - If "ACK/NAK DLLP's transmission block" is selected, replay timeout error will occur at the transmitter of the TLPs and then Data Link Retry will occur. - If "Update FC DLLP's transmission block" is selected, LTSSM will transition to the Recovery state because of the UpdateFC timeout (if the timeout is implemented at the receiver of the UpdateFCs). - If "Always Transmission for NAK DLLP" is selected, Data Link Retry will occur at the transmitter of the TLPs. Furthermore, Replay NUM Rollover will occur when the transmitter has been requested four times to send the TLP with the same sequence number.

EINJ2_DLLP_REG Offset address: $00041BC_H$

Error Injection Control 2 [DLLP Error) Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EINJ2_COUNT	7:0	rwh	**Error injection count** Indicates the number of errors. This register is decremented as the errors are being inserted. - If the counter value is 0x01 and the error is inserted, ERROR_INJECTION2_ENABLE in EINJ_ENABLE_REG returns '0'. - If the counter value is 0x00 and ERROR_INJECTION2_ENABLE =1, the errors are inserted until ERROR_INJECTION2_ENABLE is set to '0'. This register is affected only when EINJ2_DLLP_TYPE =2'10b. Note: This register field is sticky.
EINJ2_DLLP_TYPE	9:8	rw	**DLLP Type** Selects the type of DLLP errors to be inserted. Note: This register field is sticky. 00_B **ACK_NACK_DLLP**: ACK/NAK DLLP's transmission block 01_B **UPD_FC_DLLP**: Update FC DLLP's transmission block 10_B **NAK_DLLP**: Always Transmission for NAK DLLP 11_B **RSVD**: Reserved
RSVDP_10	31:10	r	**Reserved for future use**

19.4.2.170 Error Injection Control 3 (Symbol Error)

When 8b/10b encoding is used, this register controls error insertion into the special (K code) symbols. - If TS1/TS2/FTS/E-Idle/SKP is selected, it affects whole of the ordered set. It might cause timeout of the LTSSM. - If END/EDB/STP/SDP is selected, TLP/DLLP will be discarded at the receiver side. When 128b/130b encoding is used, this register controls error insertion into the sync-header.

19.4.2.171 Error Injection Control 4 (FC Credit Error)

Controls error insertion into the credit value in the UpdateFCs. It is possible to insert errors for any of the following types: - Posted TLP Header credit - Non-Posted TLP Header credit - Completion TLP Header credit - Posted TLP Data credit - Non-Posted TLP Data credit - Completion TLP Data credit These errors are not correctable while error insertion is enabled. Receiver buffer overflow error might occur.

EINJ4_FC_REG Offset address: $00041C4_H$

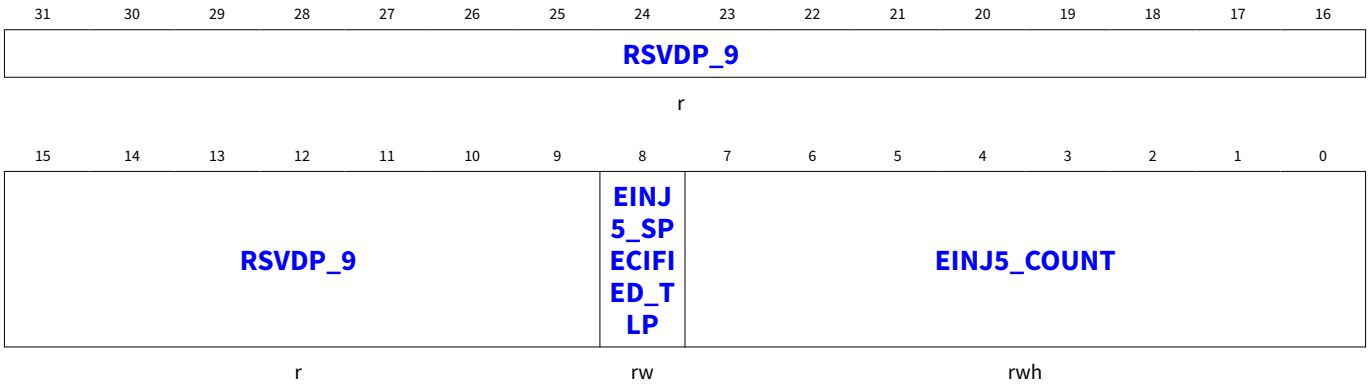
19.4.2.172 Error Injection Control 5 (Specific TLP Error)

Controls the generation of specified TLPs. Correctable errors will occur which will be fixed by the PCIe protocol. - For Duplicate TLP, the controller initiates Data Link Retry by handling ACK DLLP as NAK DLLP. These TLPs will be duplicate TLPs at the receiver side. - For Nullified TLP, the TLPs that the controller transmits are changed into nullified TLPs and the original TLPs are stored in the retry buffer. The receiver of these TLPs will detect the lack of seq# and send NAK DLLP at the next TLP. Then the original TLPs are sent from retry buffer and the data controls are recovered. For 128 bit controller or more than 128 bit, the controller inserts errors the number of times of EINJ5_COUNT but doesn't ensure that the errors are continuously inserted into TLPs.

EINJ5_SP_TLP_REG Offset address: $00041C8_H$

Error Injection Control 5 [Specific TLP Error) Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EINJ5_COUNT	7:0	rwh	**Error injection count** Indicates the number of errors. This register is decremented as the errors are being inserted. - If the counter value is 0x01 and error is inserted, ERROR_INJECTION5_ENABLE in EINJ_ENABLE_REG returns '0'. - If the counter value is 0x00 and ERROR_INJECTION5_ENABLE =1, the errors are inserted until ERROR_INJECTION5_ENABLE is set to '0'. Note: This register field is sticky.
EINJ5_SPECIFIED_TLP	8	rw	**Specified TLP** Selects the specified TLP to be inserted. Note: This register field is sticky. 0_B **DUPLICATE_DLLP**: Generates duplicate TLPs by handling ACK DLLP as NAK DLLP 1_B **NULLIFIED_TLP**: Generates Nullified TLP (Original TLP will be stored in retry buffer)
RSVDP_9	31:9	r	**Reserved for future use**

19.4.2.173 Error Injection Control 6 (Compare Point Header DWORD #0) i

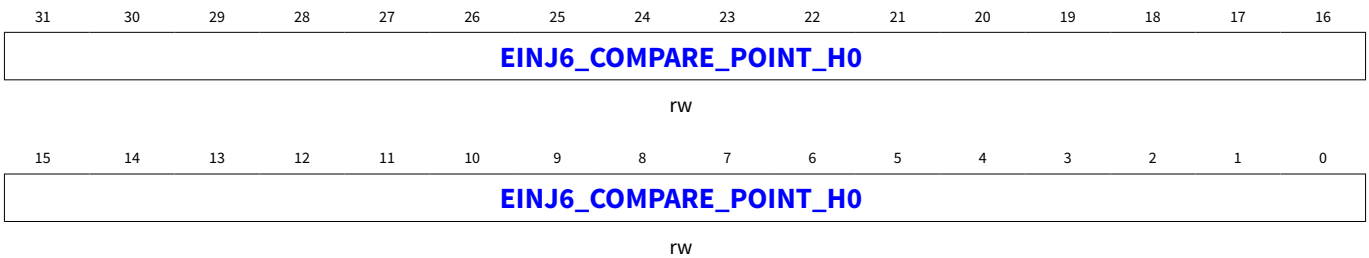
Program this register for the 1st DWORD of TLP header/prefix. It is necessary to carefully consider the endianness when you program this register. Bits [31:0] = TLP_DW0[7:0], TLP_DW0[15:8], TLP_DW0[23:16], TLP_DW0[31:24] The Packet Compare Point registers (EINJ6_COMPARE_POINT*) specify which Tx TLP header bits to compare with the corresponding bits in the Packet Compare Value registers (EINJ6_COMPARE_VALUE*). When all specified bits (in the Tx TLP header and EINJ6_COMPARE_VALUE*) match, the controller inserts errors into the TLP. The type and number of errors are specified by the EINJ6_TLP_REG register.

EINJ6_COMPARE_POINT_Hi_REG (i=0-3)

Error Injection Control 6 [Compare Point Header DWORD #0) i

Offset address: $00041CC_H+i*4$

Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EINJ6_COMPARE_POINT_H0	31:0	rw	**Packet Compare Point: 1st DWORD** Specifies which Tx TLP header DWORD#0 bits to compare with the corresponding bits in the Packet Compare Value registers (EINJ6_COMPARE_VALUE*). When all specified bits (in the Tx TLP header and EINJ6_COMPARE_VALUE*) match, the controller inserts errors into the TLP. Note: This register field is sticky.

19.4.2.174 Error Injection Control 6 (Compare Value Header DWORD #0) i

Program this register for the 1st DWORD of TLP header/prefix. It is necessary to carefully consider the endianness when you program this register. Bits [31:0] = TLP_DW0[7:0], TLP_DW0[15:8], TLP_DW0[23:16], TLP_DW0[31:24] The Packet Compare Point registers (EINJ6_COMPARE_POINT*) specify which Tx TLP header bits to compare with the corresponding bits in the Packet Compare Value registers (EINJ6_COMPARE_VALUE*). When all specified bits (in the Tx TLP header and EINJ6_COMPARE_VALUE*) match, the controller inserts errors into the TLP. The type and number of errors are specified by the EINJ6_TLP_REG register.

EINJ6_COMPARE_VALUE_Hi_REG (i=0-3) Offset address: $00041DC_H+i*4$

Field	Bits	Type	Description
EINJ6_CHANGE_VALUE_H0	31:0	rw	**Packet Change Value: 1st DWORD** Specifies replacement values for the Tx TLP header DWORD#0 bits defined in the Packet Change Point registers (EINJ6_CHANGE_POINT*). Only applies when the EINJ6_INVERTED_CONTROL field in EINJ6_TLP_REG is '0'. Note: This register field is sticky.

19.4.2.177 Error Injection Control 6 (Packet Error)

The Packet Compare Point registers (EINJ6_COMPARE_POINT*) specify which Tx TLP header bits to compare with the corresponding bits in the Packet Compare Value registers (EINJ6_COMPARE_VALUE*). When all specified bits (in the Tx TLP header and EINJ6_COMPARE_VALUE*) match, the controller inserts errors into the TLP. The type and number of errors are specified by the this register. The Packet Change Point registers (EINJ6_CHANGE_POINT*) specify which Tx TLP header bits to replace with the corresponding bits in the Packet Change Value registers (EINJ6_CHANGE_VALUE*). The type and number of errors are specified by the this register. Only applies when EINJ6_INVERTED_CONTROL in this register =0. The TLP into that errors are injected will not arrive at the transaction layer of the remote device when all of the following conditions are true. - Using 128b/130b encoding - Injecting errors into TLP Length field / TLP digest bit

Field	Bits	Type	Description
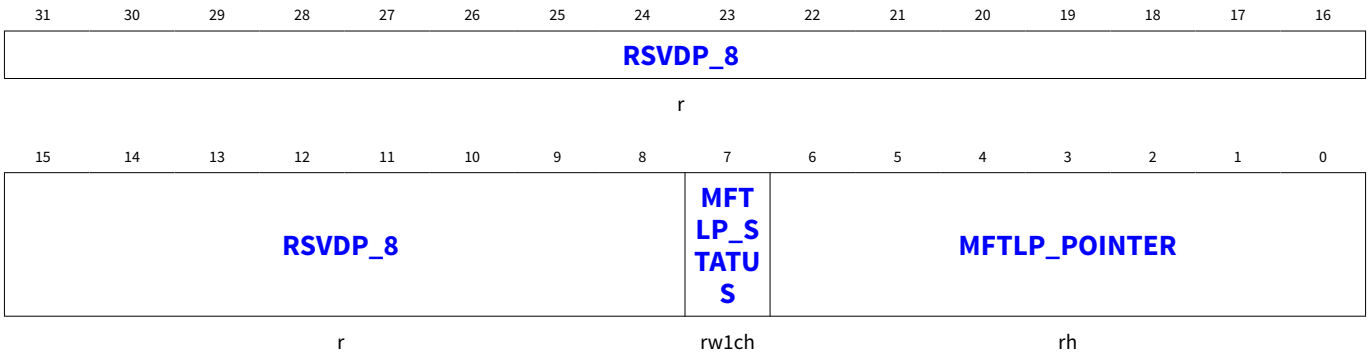
CREDIT_DATA0	19:8	rh	**Credit Data0** Current FC credit data selected by the CREDIT_SEL_VC, CREDIT_SEL_CREDIT_TYPE, CREDIT_SEL_TLP_TYPE, and CREDIT_SEL_HD viewport-select fields. - Rx: Credit Received Value - Tx: Credit Consumed Value Note: This register field is sticky.
CREDIT_DATA1	31:20	rh	**Credit Data1** Current FC credit data selected by the CREDIT_SEL_VC, CREDIT_SEL_CREDIT_TYPE, CREDIT_SEL_TLP_TYPE, and CREDIT_SEL_HD viewport-select fields. - Rx: Credit Allocated Value - Tx: Credit Limit Value. This value is valid when DLCMSM=0x3(DL_ACTIVE). Note: This register field is sticky.

19.4.2.185 Silicon Debug Status(Layer3)

Silicon Debug Status(Layer3).

SD_STATUS_L3_REG Offset address: 0004244_H

Silicon Debug Status[Layer3] Kernel Reset value: $0000\ 0000_H$



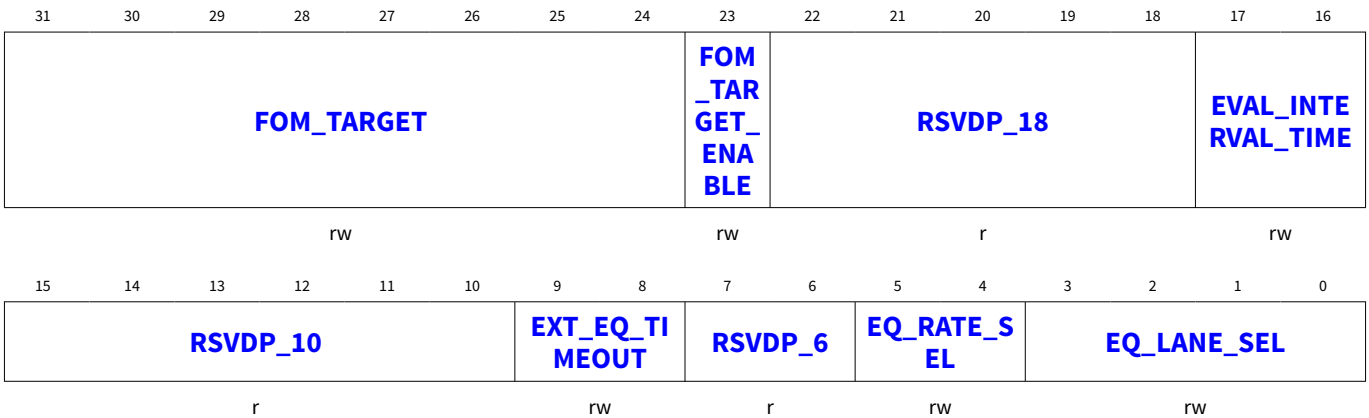
Field	Bits	Type	Description
MFTLP_POINTER	6:0	rh	**First Malformed TLP Error Pointer** Indicates the element of the received first malformed TLP. This pointer is validated by MFTLP_STATUS. All encodings other than the defined encodings are reserved. Note: This register field is sticky. 01_H **ATMC_OP_ALIGN**: AtomicOp address alignment 02_H **ATMC_OP_OPERAND**: AtomicOp operand 03_H **ATMC_OP_BYTE_EN**: AtomicOp byte enable 04_H **TLP_LENGTH_MISMATCH**: TLP length miss match 05_H **MAX_PAYLOAD_SIZE**: Max payload size 06_H **TLP_WITHOUT_TC0**: Message TLP without TC0 07_H **INVALID_TC**: Invalid TC 08_H **UNXPCTD_ROUTE_BIT_MSG_TLP**: Unexpected route bit in Message TLP 09_H **UNXPCTD_CRS_STATUS_CMPL_TLP**: Unexpected CRS status in Completion TLP $0A_H$ **BYTE_ENABLE**: Byte enable $0B_H$ **MEM_ADDR_4KB_BOUNDARY**: Memory Address 4KB boundary $0C_H$ **TLP_PREFIX_RULES**: TLP prefix rules $0D_H$ **TRANSLATION_RULES**: Translation request rules $0E_H$ **INVALID_TLP_TYPE**: Invalid TLP type $0F_H$ **CMPL_RULES**: Completion rules $7F_H$ **APPLICATION**: Application
MFTLP_STATUS	7	rw1ch	**Malformed TLP Status** Indicates malformed TLP has occurred. Note: This register field is sticky. Software write with 1 clears this bit-field.
RSVDP_8	31:8	r	**Reserved for future use**

19.4.2.186 Silicon Debug EQ Control 1

This is a viewport control register. Setting the EQ_RATE_SEL and EQ_LANE_SEL fields in this register determine the per-lane Silicon Debug EQ Status data returned by the SD_EQ_STATUS[1/2/3] viewport registers.

SD_EQ_CONTROL1_REG Offset address: 0004250_H

Silicon Debug EQ Control 1 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EQ_LANE_SEL	3:0	rw	**EQ Status Lane Select** Setting this field in conjunction with the EQ_RATE_SEL field determines the per-lane Silicon Debug EQ Status data returned by the SD_EQ_CONTROL[2/3] and SD_EQ_STATUS[1/2/3] viewport registers. Note: This register field is sticky. 0_H **MIN_VAL**: Lane0 F_H **MAX_VAL**: Lane15
EQ_RATE_SEL	5:4	rw	**EQ Status Rate Select** Setting this field in conjunction with the EQ_LANE_SEL field determines the per-lane Silicon Debug EQ Status data returned by the SD_EQ_CONTROL[2/3] and SD_EQ_STATUS[1/2/3] viewport registers. Note: This register field is sticky. 00_B **_8GT**: 8.0GT/s Speed (include ESM data rate) 01_B **_16GT**: 16.0GT/s Speed (include ESM data rate) 10_B **_32GT**: 32.0GT/s Speed **others,** Reserved
RSVDP_6	7:6	r	**Reserved for future use**
EXT_EQ_TIMEOUT	9:8	rw	**Extends EQ Phase2/3 Timeout** This field is used when the LTSSM is in Recovery.EQ2/3. When this field is set, the value of EQ2/3 timeout is extended. Note: This register field is sticky. 00_B **_24MS_OR_32MS**: [EQ Master(DSP in EQ Phase3/USP in EQ Phase2)] 24ms (default) or [EQ Slave(DSP in EQ Phase2/USP in EQ Phase3)] 32ms (default) 01_B **_48MS_OR_56MS**: [EQ Master(DSP in EQ Phase3/USP in EQ Phase2)] 48ms (x2) or [EQ Slave(DSP in EQ Phase2/USP in EQ Phase3)] 56ms (32ms+24ms) 10_B **_240MS_OR_248MS**: [EQ Master(DSP in EQ Phase3/USP in EQ Phase2)] 240ms (x10) or [EQ Slave(DSP in EQ Phase2/USP in EQ Phase3)] 248ms (32ms +9*24ms) 11_B **NO_TIMEOUT**: [EQ Master(DSP in EQ Phase3/USP in EQ Phase2)] No timeout or [EQ Slave(DSP in EQ Phase2/USP in EQ Phase3)] No timeout
RSVDP_10	15:10	r	**Reserved for future use**
EVAL_INTERVAL_TIME	17:16	rw	**Eval Interval Time** Indicates interval time of RxEqEval assertion. This field is used for EQ Master(DSP in EQ Phase3/USP in EQ Phase2). Note: This register field is sticky. 00_B **_500NS**: 500 ns 01_B **_1US**: 1 µs 10_B **_2US**: 2 µs 11_B **_4US**: 4 µs
RSVDP_18	22:18	r	**Reserved for future use**
FOM_TARGET_ENABLE	23	rw	**FOM Target Enable** Enables the FOM_TARGET fields. Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
FOM_TARGET	31:24	rw	**FOM Target** Indicates figure of merit target criteria value of EQ Master(DSP in EQ Phase3/USP in EQ Phase2). This field is only valid when GEN3_EQ_FB_MODE is 0001b(Figure Of Merit). Note: This register field is sticky.

19.4.2.187 Silicon Debug EQ Control 2

This viewport register returns the value for the rate and lane selected by the EQ_RATE_SEL and EQ_LANE_SEL fields in the SD_EQ_CONTROL1_REG register.

SD_EQ_CONTROL2_REG Offset address: 0004254_H

Silicon Debug EQ Control 2 Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
EQ_SEQUENCE	0	rh	**EQ Sequence** Indicates that the controller is starting the equalization sequence. Note: This register field is sticky.

(table continues...)

(continued)

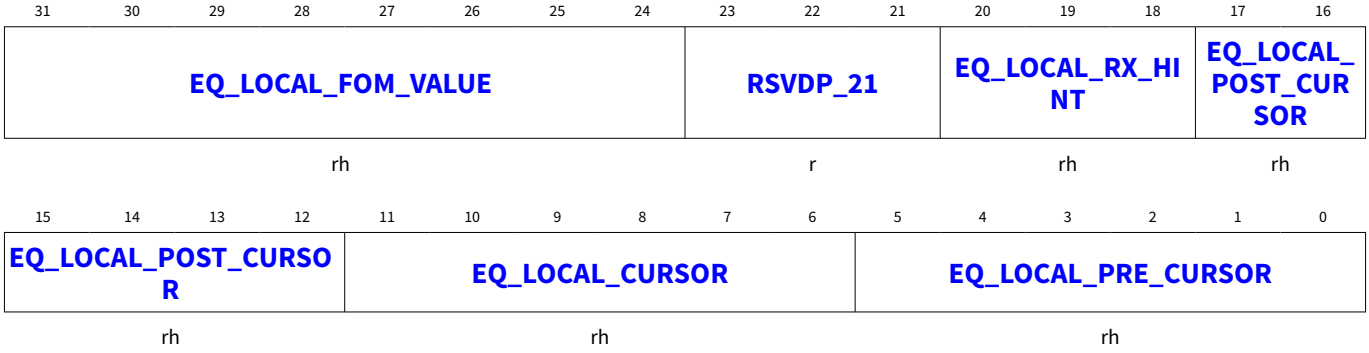
Field	Bits	Type	Description
EQ_CONVERGENCE_INFO	2:1	rh	**EQ Convergence Info** Indicates equalization convergence information. This bit is automatically cleared when the controller starts EQ Master phase again. Note: This register field is sticky. 00_B **EQ_NOT_ATTEMPTED**: Equalization is not attempted 01_B **EQ_SUCCESSFUL**: Equalization finished successfully 10_B **EQ_UNSUCCESSFUL**: Equalization finished unsuccessfully 11_B **RSVD**: Reserved
RSVDP_3	3	r	**Reserved for future use**
EQ_RULEA_VIOLATION	4	rh	**EQ Rule A Violation** Indicates that coefficients rule A violation is detected in the values provided by PHY using direction change method during EQ Master phase(DSP in EQ Phase3/USP in EQ Phase2). The coefficients rules A correspond to the rules a) from section "Rules for Transmitter Coefficents" in the PCI Express Base Specification. This bit is automatically cleared when the controller starts EQ Master phase again. Note: This register field is sticky.
EQ_RULEB_VIOLATION	5	rh	**EQ Rule B Violation** Indicates that coefficients rule B violation is detected in the values provided by PHY using direction change method during EQ Master phase(DSP in EQ Phase3/USP in EQ Phase2). The coefficients rules B correspond to the rules b) from section "Rules for Transmitter Coefficents" in the PCI Express Base Specification. This bit is automatically cleared when the controller starts EQ Master phase again. Note: This register field is sticky.
EQ_RULEC_VIOLATION	6	rh	**EQ Rule C Violation** Indicates that coefficients rule C violation is detected in the values provided by PHY using direction change method during EQ Master phase(DSP in EQ Phase3/USP in EQ Phase2). The coefficients rule C correspond to the rules c) from section "Rules for Transmitter Coefficents" in the PCI Express Base Specification. This bit is automatically cleared when the controller starts EQ Master phase again. Note: This register field is sticky.
EQ_REJECT_EVENT	7	rh	**EQ Reject Event** Indicates that the controller receives two consecutive TS1 OS w/ Reject=1b during EQ Master phase(DSP in EQ Phase3/USP in EQ Phase2). This bit is automatically cleared when the controller starts EQ Master phase again. Note: This register field is sticky.
RSVDP_8	31:8	r	**Reserved for future use**

19.4.2.190 Silicon Debug EQ Status 2

This viewport register returns the second of three words of Silicon Debug EQ Status data for the rate and lane selected by the EQ_RATE_SEL and EQ_LANE_SEL fields in the SD_EQ_CONTROL1_REG register. Each field is available when Equalization finished successfully(EQ_CONVERGENCE_INFO=1).

SD_EQ_STATUS2_REG Offset address: 0004264_H

Silicon Debug EQ Status 2 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EQ_LOCAL_PRE_CURSOR	5:0	rh	**EQ Local Pre-Cursor** Indicates Local pre cursor coefficient value. Note: This register field is sticky.
EQ_LOCAL_CURSOR	11:6	rh	**EQ Local Cursor** Indicates Local cursor coefficient value. Note: This register field is sticky.
EQ_LOCAL_POST_CURSOR	17:12	rh	**EQ Local Post-Cursor** Indicates Local post cursor coefficient value. Note: This register field is sticky.
EQ_LOCAL_RX_HINT	20:18	rh	**EQ Local Receiver Preset Hint** Indicates Local Receiver Preset Hint value. If select rate in the EQ_RATE_SEL field is other than 8.0GT/s Speed, this feature is not available. Note: This register field is sticky.
RSVDP_21	23:21	r	**Reserved for future use**
EQ_LOCAL_FOM_VALUE	31:24	rh	**EQ Local Figure of Merit** Indicates Local maximum Figure of Merit value. Note: This register field is sticky.

19.4.2.191 Silicon Debug EQ Status 3

This viewport register returns the third of three words of Silicon Debug EQ Status data for the rate and lane selected by the EQ_RATE_SEL and EQ_LANE_SEL fields in the SD_EQ_CONTROL1_REG register. Each field is available when Equalization finished successfully(EQ_CONVERGENCE_INFO=1).

SD_EQ_STATUS3_REG Offset address: 0004268_H

Silicon Debug EQ Status 3 Kernel Reset value: $0000\ 0000_H$

rw															

Field	Bits	Type	Description
ID	15:0	rw	**PCI Express Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value

(table continues...)

(continued)

Field	Bits	Type	Description
CAP	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. A version of the specification that changes the Extended Capability in a way that is not otherwise identifiable (e.g., through a new Capability field) is permitted to increment this field. All such changes to the Capability structure must be software-compatible. Software must check for Capability Version numbers that are greater than or equal to the highest number defined when the software is written, as Functions reporting any such Capability Version numbers will contain a Capability structure that is compatible with that piece of software. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. The bottom 2 bits of this offset are Reserved and must be implemented as 00b although software must mask them to allow for future uses of these bits. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value

19.4.2.193 Vendor Specific Header

This Register provides VSEC Length, VSEC ID and VSEC Rev (Version Number). Vendor-specific software must qualify the associated Vendor ID of the PCI Express Function or RCRB before attempting to interpret the values in the VSEC ID or VSEC Rev fields.

RASDP_VENDOR_SPECIFIC_HDR_OFF Offset address: 0004284_H

Vendor Specific Header Kernel Reset value: $0381\ 0001_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

VSEC_ID															
r															

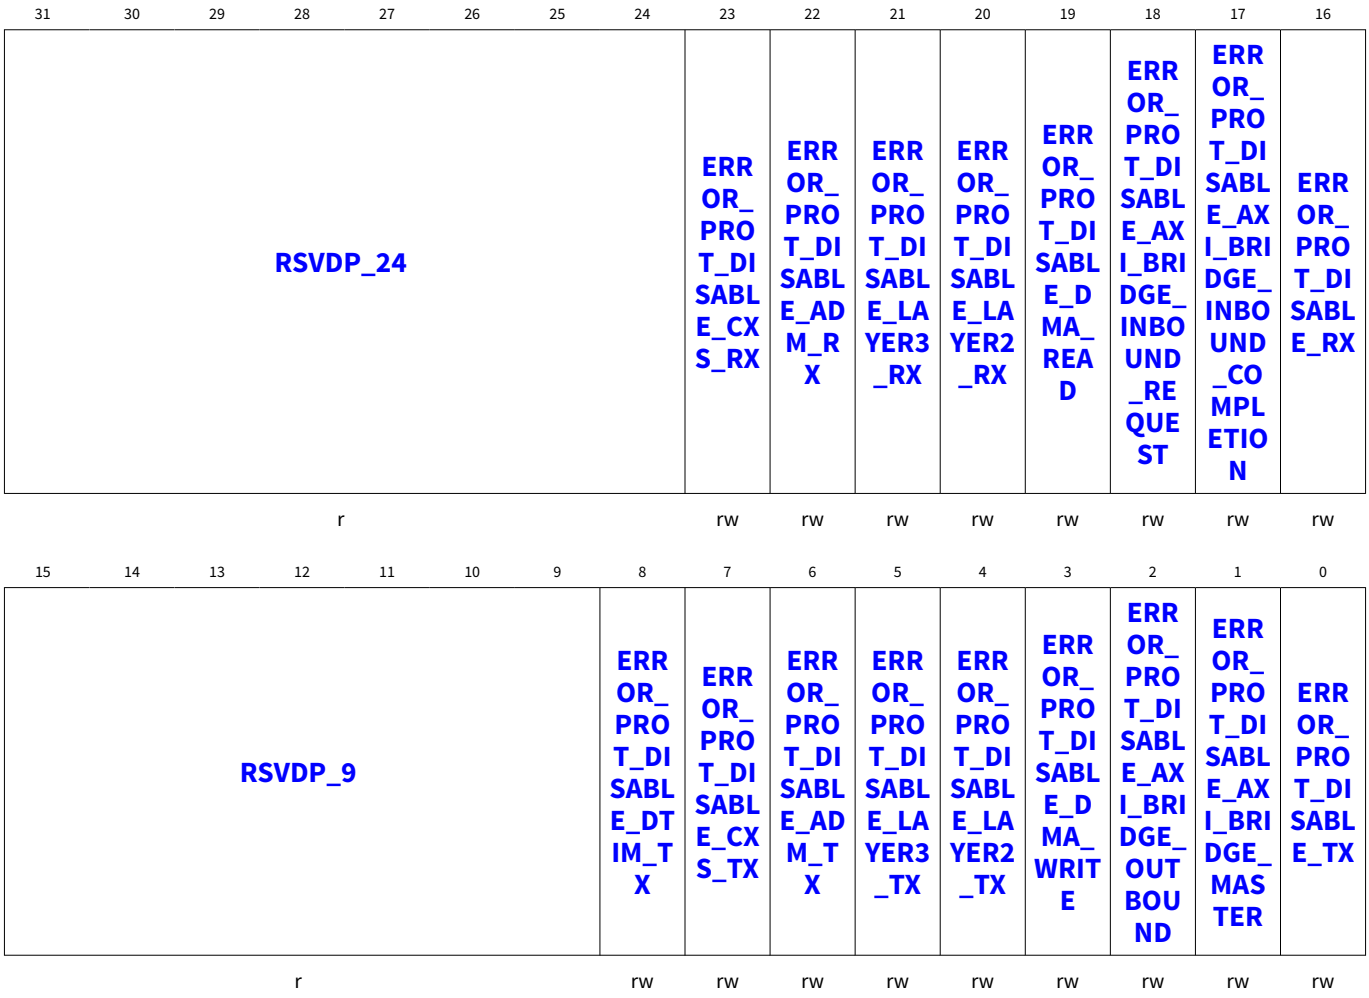
Field	Bits	Type	Description
VSEC_ID	15:0	r	**VSEC ID** This field is a vendor-defined ID number that indicates the nature and format of the VSEC structure. Software must qualify the Vendor ID before interpreting this field. Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
VSEC_REV	19:16	r	**VSEC Rev** This field is a vendor-defined version number that indicates the version of the VSEC structure. Software must qualify the Vendor ID and VSEC ID before interpreting this field. Note: This register field is sticky. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
VSEC_LENGTH	31:20	r	**VSEC Length** This field indicates the number of bytes in the entire VSEC structure, including the Vendor-Specific Extended Capability Header, the Vendor-Specific Header, and the vendor-specific registers. Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value

19.4.2.194 ECC Error Correction and Control Register

Allows you to disable ECC error correction for RAMs and datapath. When the AXI Bridge Module is implemented and the master / slave clocks are asynchronous to the PCIe native controller clock (core_clk), you must not write this register while operations are in progress in the AXI master / slave interface.

RASDP_ERROR_PROT_CTRL_OFF Offset address: 0004288_H

ECC Error Correction and Control Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ERROR_PROT_DISABLE_TX	0	rw	**Global error correction disable for all Tx layers** Does not disable the error detection reporting for 1-bit and 2-bit ECC errors. Note: This register field is sticky.
ERROR_PROT_DISABLE_AXI_BRIDGE_MASTER	1	rw	**Error correction disable for AXI bridge master completion buffer** Note: This register field is sticky.
ERROR_PROT_DISABLE_AXI_BRIDGE_OUTBOUND	2	rw	**Error correction disable for AXI bridge outbound request path** Note: This register field is sticky.
ERROR_PROT_DISABLE_DMA_WRITE	3	rw	**Error correction disable for DMA write engine** Note: This register field is sticky.
ERROR_PROT_DISABLE_LAYER2_TX	4	rw	**Error correction disable for layer 2 Tx path** Note: This register field is sticky.

(table continues...)

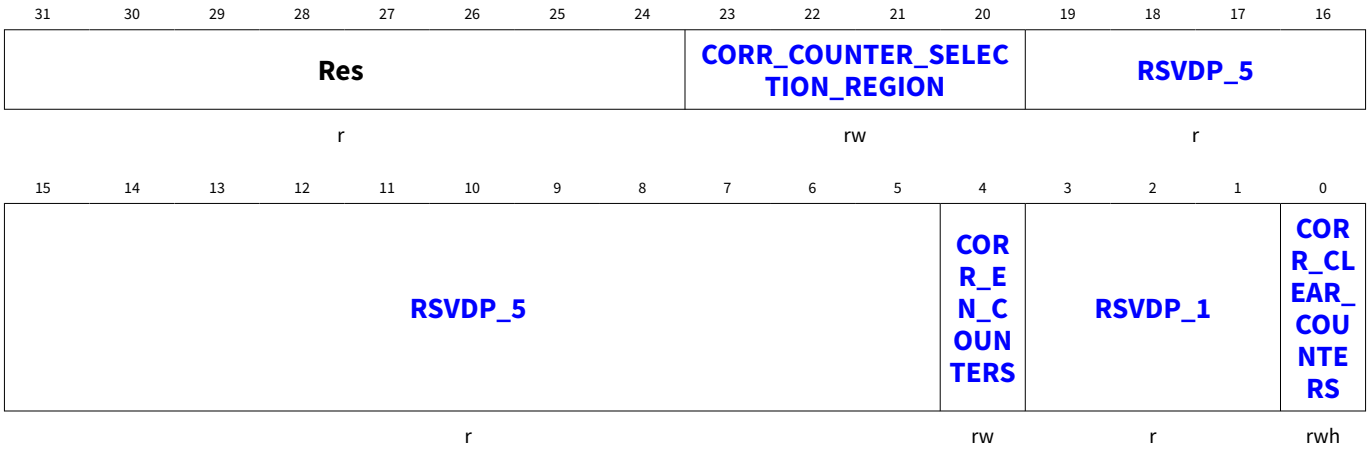
(continued)

Field	Bits	Type	Description
ERROR_PROT_DISABLE_LAYER3_TX	5	rw	**Error correction disable for layer 3 Tx path** Note: This register field is sticky.
ERROR_PROT_DISABLE_ADM_TX	6	rw	**Error correction disable for Adm Tx path** Note: This register field is sticky.
ERROR_PROT_DISABLE_CXS_TX	7	rw	**Error correction disable for CXS Rx path (PCIe Tx path)** Note: This register field is sticky.
ERROR_PROT_DISABLE_DTIM_TX	8	rw	**Error correction disable for DTIM Tx path** Note: This register field is sticky.
RSVDP_9	15:9	r	**Reserved for future use**
ERROR_PROT_DISABLE_RX	16	rw	**Global error correction disable for all Rx layers** Note: This register field is sticky.
ERROR_PROT_DISABLE_AXI_BRIDGE_INBOUND_COMPLETION	17	rw	**Error correction disable for AXI bridge inbound completion composer** Does not disable the error detection reporting for 1-bit and 2-bit ECC errors. Note: This register field is sticky.
ERROR_PROT_DISABLE_AXI_BRIDGE_INBOUND_REQUEST	18	rw	**Error correction disable for AXI bridge inbound request path** Note: This register field is sticky.
ERROR_PROT_DISABLE_DMA_READ	19	rw	**Error correction disable for DMA read engine** Note: This register field is sticky.
ERROR_PROT_DISABLE_LAYER2_RX	20	rw	**Error correction disable for layer 2 Rx path** Note: This register field is sticky.
ERROR_PROT_DISABLE_LAYER3_RX	21	rw	**Error correction disable for layer 3 Rx path** Note: This register field is sticky.
ERROR_PROT_DISABLE_ADM_RX	22	rw	**Error correction disable for ADM Rx path** Note: This register field is sticky.
ERROR_PROT_DISABLE_CXS_RX	23	rw	**Error correction disable for CXS Tx path (PCIe Rx path)** Note: This register field is sticky.
RSVDP_24	31:24	r	**Reserved for future use**

19.4.2.195 Corrected Error (1-bit ECC) Counter Selection and Control Register

This is a viewport control register. Setting the CORR_COUNTER_SELECTION_REGION and CORR_COUNTER_SELECTION fields in this register determine the counter data returned by the RASDP_CORR_COUNT_REPORT_OFF viewport data register.

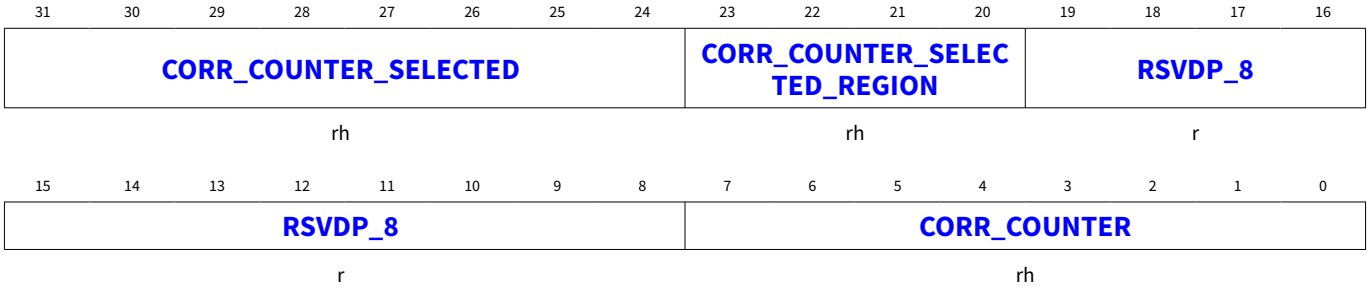
19 Peripheral Component Interconnect Express (PCIe)



Field	Bits	Type	Description
CORR_CLEAR_COUNTERS	0	rwh	**Clear all correctable error counters** Reading register field always returns a '0'.
RSVDP_1	3:1	r	**Reserved for future use**
CORR_EN_COUNTERS	4	rw	**Enable correctable errors counters** The counters are enabled by default. Note: This register field is sticky. 0_B **COUNTER_FROZEN**: Counters are frozen 1_B **COUNTER_EN**: Counters increment when the controller detects a correctable error
RSVDP_5	19:5	r	**Reserved for future use**
CORR_COUNTER_SELECTION_REGION	23:20	rw	**Select correctable counter region** All encodings other than the defined encodings are reserved. Note: This register field is sticky. 0_H **ADM_RX_PATH**: Region select for Adm Rx path 1_H **L3_RX_PATH**: Region select for layer 3 Rx path 2_H **L2_RX_PATH**: Region select for layer 2 Rx path 3_H **DMA_INBOUND_PATH**: Region select for DMA inbound path 4_H **AXI_INBOUND_REQ_PATH**: Region select for AXI bridge inbound request path 5_H **AXI_INBOUND_CMPL_PATH**: Region select for AXI bridge inbound completion composer path 6_H **ADM_TX_PATH**: Region select for Adm Tx path 7_H **L3_TX_PATH**: Region select for layer 3 Tx path 8_H **L2_TX_PATH**: Region select for layer 2 Tx path 9_H **DMA_OUTBOUND_PATH**: Region select for DMA outbound path A_H **AXI_OUTBOUND_REQ_PATH**: Region select for AXI bridge outbound request path B_H **AXI_OUTBOUND_CMPL_PATH**: Region select for AXI bridge outbound master completion buffer path C_H **CXS_TX_RX_PATH**: Region select for CXS Tx/Rx path D_H **DTIM_TX_RX_PATH**: Region select for DTIM Tx/Rx path **others,** Reserved

19.4.2.196 Corrected Error (1-bit ECC) Counter Data Register

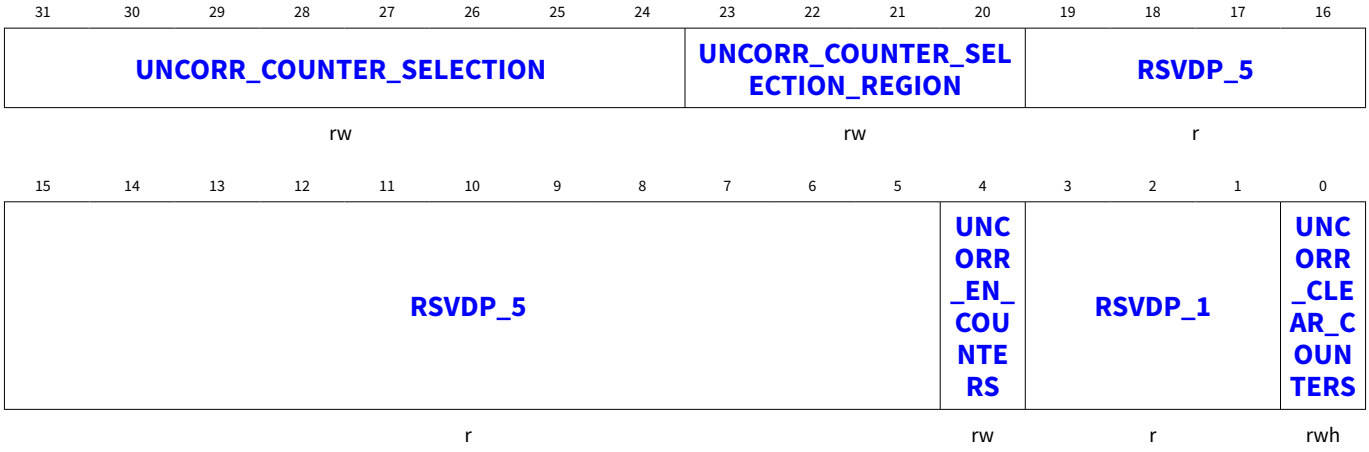
This viewport register returns the counter data selected by the CORR_COUNTER_SELECTION_REGION and CORR_COUNTER_SELECTION fields in the RASDP_CORR_COUNTER_CTRL_OFF register.



Field	Bits	Type	Description
CORR_COUNTER	7:0	rh	**Current corrected error count for the selected counter** Note: This register field is sticky.
RSVDP_8	19:8	r	**Reserved for future use**
CORR_COUNTER_SELECTED_REGION	23:20	rh	**Selected correctable counter region** All encodings other than the defined encodings are reserved. Note: This register field is sticky. 0_H **ADM_RX_PATH**: Region select for Adm Rx path 1_H **L3_RX_PATH**: Region select for layer 3 Rx path 2_H **L2_RX_PATH**: Region select for layer 2 Rx path 3_H **DMA_INBOUND_PATH**: Region select for DMA inbound path 4_H **AXI_INBOUND_REQ_PATH**: Region select for AXI bridge inbound request path 5_H **AXI_INBOUND_CMPL_PATH**: Region select for AXI bridge inbound completion composer path 6_H **ADM_TX_PATH**: Region select for Adm Tx path 7_H **L3_TX_PATH**: Region select for layer 3 Tx path 8_H **L2_TX_PATH**: Region select for layer 2 Tx path 9_H **DMA_OUTBOUND_PATH**: Region select for DMA outbound path A_H **AXI_OUTBOUND_REQ_PATH**: Region select for AXI bridge outbound request path B_H **AXI_OUTBOUND_CMPL_PATH**: Region select for AXI bridge outbound master completion buffer path C_H **CXS_TX_RX_PATH**: Region select for CXS Tx/Rx path D_H **DTIM_TX_RX_PATH**: Region select for DTIM Tx/Rx path **others,** Reserved
CORR_COUNTER_SELECTED	31:24	rh	**Counter selection** Returns the value set in the CORR_COUNTER_SELECTION field of the RASDP_CORR_COUNTER_CTRL_OFF register. Note: This register field is sticky.

19.4.2.197 Uncorrected Error (2-bit ECC and parity) Counter Selection and Control Register

This is a viewport control register. Setting the UNCORR_COUNTER_SELECTION_REGION and UNCORR_COUNTER_SELECTION fields in this register determine the counter data returned by the RASDP_UNCORR_COUNT_REPORT_OFF viewport data register.



Field	Bits	Type	Description
UNCORR_CLEAR_COUNTERS	0	rwh	**Clear uncorrectable errors counters** When asserted causes all counters tracking the uncorrectable errors to be cleared. Reading register field always returns a '0'.
RSVDP_1	3:1	r	**Reserved for future use**
UNCORR_EN_COUNTERS	4	rw	**Enable uncorrectable errors counters** The counters are enabled by default. Note: This register field is sticky. 0_B **COUNTER_FROZEN**: Counters are frozen 1_B **ENABLE_COUNTER**: Enables the counters to increment on detected correctable errors
RSVDP_5	19:5	r	**Reserved for future use**

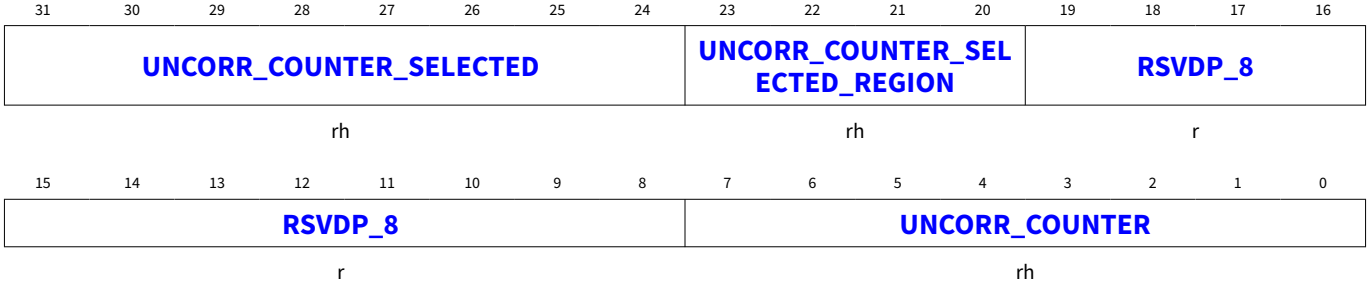
(table continues...)

(continued)

Field	Bits	Type	Description
UNCORR_COUNTER_SELECTION_REGION	23:20	rw	**Select uncorrectable counter region** All encodings other than the defined encodings are reserved. Note: This register field is sticky. 0_H **ADM_RX_PATH**: Region select for Adm Rx path 1_H **L3_RX_PATH**: Region select for layer 3 Rx path 2_H **L2_RX_PATH**: Region select for layer 2 Rx path 3_H **DMA_INBOUND_PATH**: Region select for DMA inbound path 4_H **AXI_INBOUND_REQ_PATH**: Region select for AXI bridge inbound request path 5_H **AXI_INBOUND_CMPL_PATH**: Region select for AXI bridge inbound completion composer path 6_H **ADM_TX_PATH**: Region select for Adm Tx path 7_H **L3_TX_PATH**: Region select for layer 3 Tx path 8_H **L2_TX_PATH**: Region select for layer 2 Tx path 9_H **DMA_OUTBOUND_PATH**: Region select for DMA outbound path A_H **AXI_OUTBOUND_REQ_PATH**: Region select for AXI bridge outbound request path B_H **AXI_OUTBOUND_CMPL_PATH**: Region select for AXI bridge outbound master completion buffer path C_H **CXS_TX_RX_PATH**: Region select for CXS Tx/Rx path D_H **DTIM_TX_RX_PATH**: Region select for DTIM Tx/Rx path **others,** Reserved
UNCORR_COUNTER_SELECTION	31:24	rw	**Counter selection** This field selects the counter ID (within the region defined by UNCORR_COUNTER_SELECTION_REGION) whose contents can be read from the RASDP_UNCORR_COUNT_REPORT_OFF register. You can cycle this field value from 0 to 255 to access all counters according to the detailed report of check points at http://www.synopsys.com/dw/doc.php/iip/DWC_pcie/latest/doc/RASDP_CheckPoints.pdf Note: This register field is sticky.

19.4.2.198 Uncorrected Error (2-bit ECC and parity) Counter Data Register

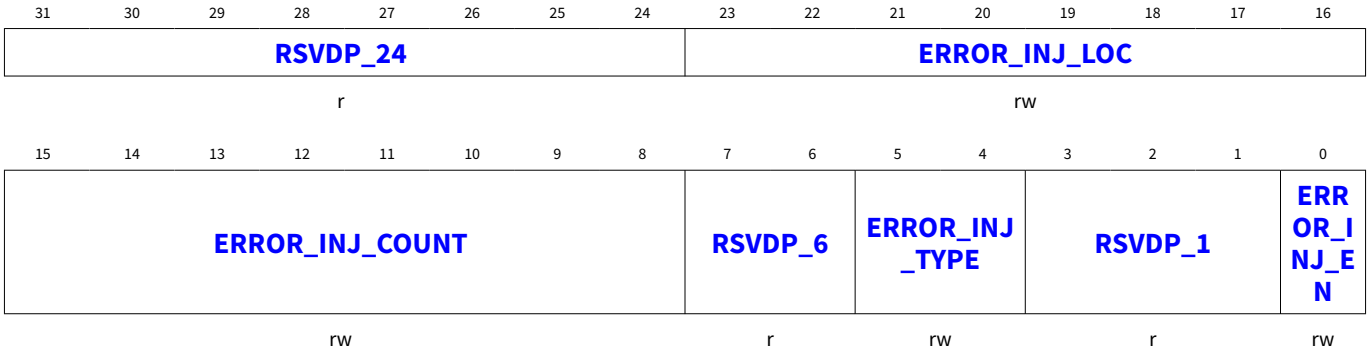
This viewport register returns the counter data selected by the UNCORR_COUNTER_SELECTION_REGION and UNCORR_COUNTER_SELECTION fields in the RASDP_UNCORR_COUNTER_CTRL_OFF register.



Field	Bits	Type	Description
UNCORR_COUNTER	7:0	rh	**Current uncorrected error count for the selected counter** Note: This register field is sticky.
RSVDP_8	19:8	r	**Reserved for future use**
UNCORR_COUNTER_SELECTED_REGION	23:20	rh	**Selected uncorrectable counter region** All encodings other than the defined encodings are reserved. Note: This register field is sticky. 0_H **ADM_RX_PATH**: Region select for Adm Rx path 1_H **L3_RX_PATH**: Region select for layer 3 Rx path 2_H **L2_RX_PATH**: Region select for layer 2 Rx path 3_H **DMA_INBOUND_PATH**: Region select for DMA inbound path 4_H **AXI_INBOUND_REQ_PATH**: Region select for AXI bridge inbound request path 5_H **AXI_INBOUND_CMPL_PATH**: Region select for AXI bridge inbound completion composer path 6_H **ADM_TX_PATH**: Region select for Adm Tx path 7_H **L3_TX_PATH**: Region select for layer 3 Tx path 8_H **L2_TX_PATH**: Region select for layer 2 Tx path 9_H **DMA_OUTBOUND_PATH**: Region select for DMA outbound path A_H **AXI_OUTBOUND_REQ_PATH**: Region select for AXI bridge outbound request path B_H **AXI_OUTBOUND_CMPL_PATH**: Region select for AXI bridge outbound master completion buffer path C_H **CXS_TX_RX_PATH**: Region select for CXS Tx/Rx path D_H **DTIM_TX_RX_PATH**: Region select for DTIM Tx/Rx path **others,** Reserved
UNCORR_COUNTER_SELECTED	31:24	rh	**Counter selection** Returns the value set in the UNCORR_COUNTER_SELECTION field of the RASDP_UNCORR_COUNTER_CTRL_OFF register. Note: This register field is sticky.

19.4.2.199 Error Injection Control Register

Error injection control for the following features: - 1-bit or 2-bit injection - Continuous or fixed-number (n) injection modes - Global enable/disable - Selectable location where injection occurs



Field	Bits	Type	Description
ERROR_INJ_EN	0	rw	**Error injection global enable** When set, enables the error insertion logic.
RSVDP_1	3:1	r	**Reserved for future use**
ERROR_INJ_TYPE	5:4	rw	**Error injection type** Note: This register field is sticky. 00_B **NONE**: none 01_B **_1_BIT**: 1-bit 10_B **_2_BIT**: 2-bit **others,** Reserved
RSVDP_6	7:6	r	**Reserved for future use**
ERROR_INJ_COUNT	15:8	rw	**Error injection count** If value is n, n amount of errors injected. Note: This register field is sticky. 00_H **ERR_INJ_EVERY_TLP**: Errors are inserted in every TLP until you clear ERROR_INJ_EN 01_H **ERR_INJ_1**: One errors injected 02_H **ERR_INJ_2**: Two errors injected **others,** Reserved
ERROR_INJ_LOC	23:16	rw	**Error injection location** Selects where error injection takes place. You can cycle this field value from 0 to 255 to access all locations according to the detailed report of check points at RASDP_CheckPoints.pdf Note: This register field is sticky.
RSVDP_24	31:24	r	**Reserved for future use**

19.4.2.200 Corrected Errors Location Register

Corrected errors locations.

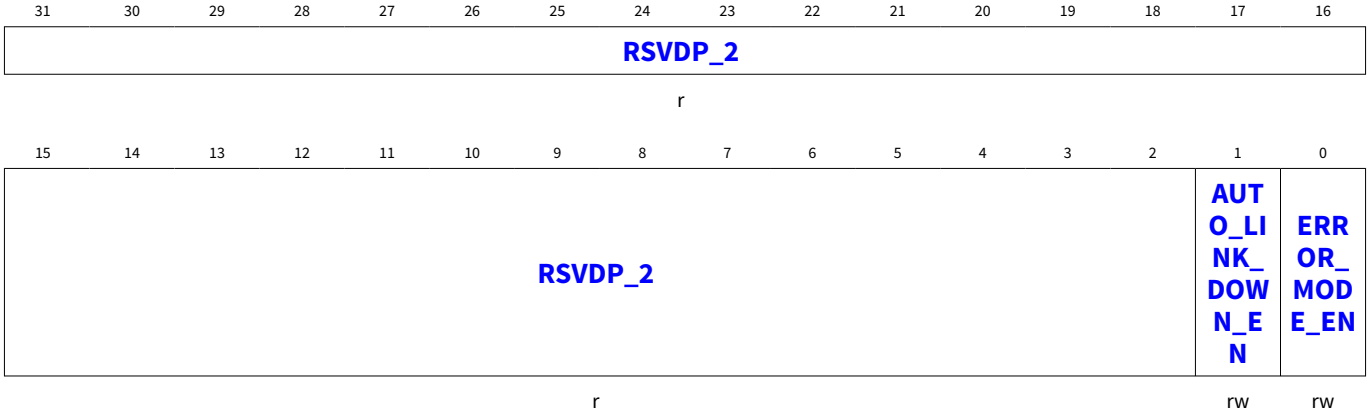
19.4.2.202 RASDP error mode enable.

RASDP error mode enable. The controller enters RASDP error mode (if ERROR_MODE_EN =1) upon detection of the first uncorrectable error. During this mode: - Rx TLPs that are forwarded to your application are not guaranteed to be correct; you must discard them. For more details, see the RAS Data Protection (DP) section in the Core Operations chapter of the user manual.

RASDP_ERROR_MODE_EN_OFF Offset address: $00042A8_H$

RASDP error mode enable. Kernel Reset value: $0000\ 0001_H$



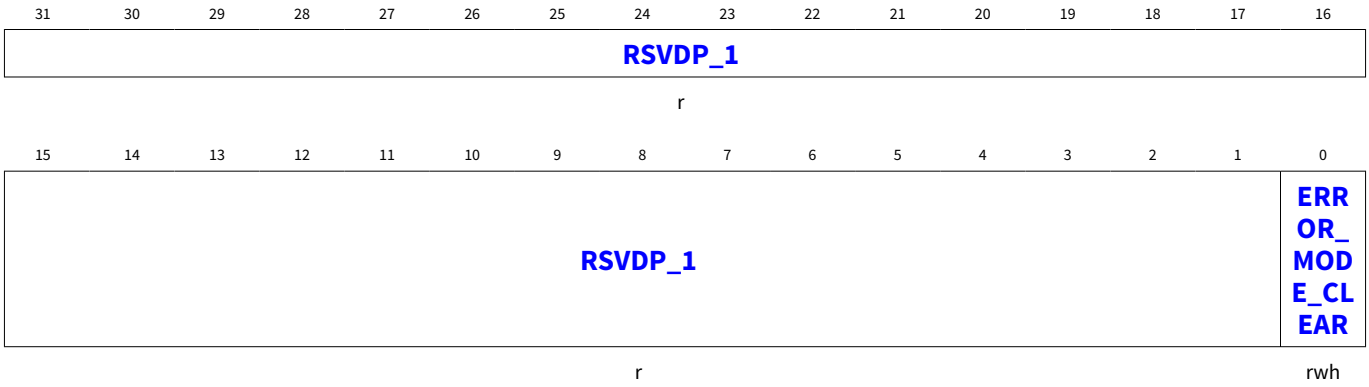
Field	Bits	Type	Description
ERROR_MODE_EN	0	rw	**Write '1' to enable the controller enter RASDP error mode when it detects an uncorrectable error** Note: This register field is sticky.
AUTO_LINK_DOWN_EN	1	rw	**Write '1' to enable the controller to bring the link down when the controller enters RASDP error mode** Note: This register field is sticky.
RSVDP_2	31:2	r	**Reserved for future use**

19.4.2.203 RASDP Error Mode Clear Register

Exit RASDP error mode. For more details, see the RAS Data Protection (DP) section in the Core Operations chapter of the user manual.

RASDP_ERROR_MODE_CLEAR_OFF Offset address: $00042AC_H$

RASDP Error Mode Clear Register Kernel Reset value: $0000\ 0000_H$



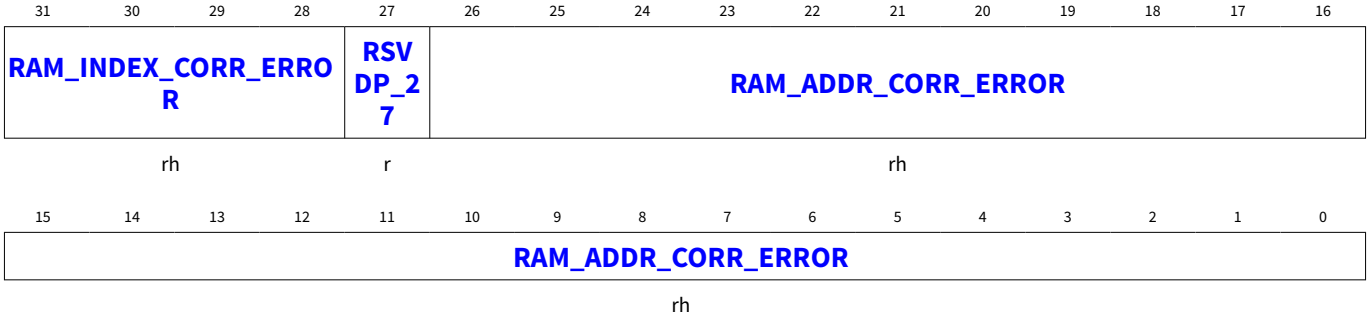
Field	Bits	Type	Description
ERROR_MODE_CLEAR	0	rwh	**Write '1' to take the controller out of RASDP error mode** The controller will then report uncorrectable errors (through AER internal error reporting) and also stop nullifying/discarding TLPs. Reading register field always returns a '0'.
RSVDP_1	31:1	r	**Reserved for future use**

19.4.2.204 RAM Address where a corrected error (1-bit ECC) is detected

For more details, see the RAS Data Protection (DP) section in the Core Operations chapter of the user manual.

RASDP_RAM_ADDR_CORR_ERROR_OFF Offset address: $00042B0_H$

RAM Address where a corrected error [1-bit ECC) is detected Kernel Reset value: $0000\ 0000_H$



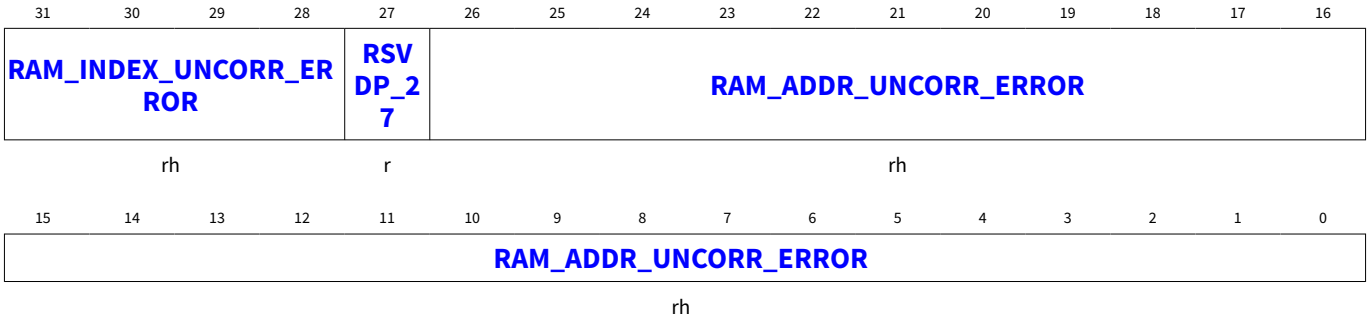
Field	Bits	Type	Description
RAM_ADDR_CORR_ERROR	26:0	rh	**RAM Address where a corrected error (1-bit ECC) is detected** Note: This register field is sticky.
RSVDP_27	27	r	**Reserved for future use**
RAM_INDEX_CORR_ERROR	31:28	rh	**RAM index where a corrected error (1-bit ECC) is detected** Note: This register field is sticky.

19.4.2.205 RAM Address where an uncorrected error (2-bit ECC) is detected

For more details, see the RAS Data Protection (DP) section in the Core Operations chapter of the user manual.

RASDP_RAM_ADDR_UNCORR_ERROR_OFF Offset address: $00042B4_H$

RAM Address where an uncorrected error [2-bit ECC) is detected Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RAM_ADDR_UNCORR_ERROR	26:0	rh	**RAM Address where an uncorrected error (2-bit ECC) is detected** Note: This register field is sticky.
RSVDP_27	27	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
RAM_INDEX_UNCORR_ERROR	31:28	rh	**RAM index where an uncorrected error (2-bit ECC) is detected** Note: This register field is sticky.

19.4.2.206 Precision Time Measurement Capability Header

This Register provides Capability ID, Cabability Version, and Next Offset of Precision Time Measurement Capability structure.

PTM_EXT_CAP_HDR_OFF Offset address: $00042B8_H$

Precision Time Measurement Capability Header Kernel Reset value: $2C41\ 001F_H$

PTM_CAP_ID															
rw															

Field	Bits	Type	Description
PTM_CAP_ID	15:0	rw	**Precision Time Measurement PCI Express Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. PCI Express Extended Capability ID for the Precision Time Measurement Capability is 001Fh. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
PTM_CAP_VERSION	19:16	rw	**Precision Time Measurement PCI Express Extended Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. This bit depends on the version of the specification. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
PTM_NEXT_OFFSET	31:20	rw	**Precision Time Measurement PCI Express Extended Capability Next Offset** This field contains the offset to the next PCI Express Extended Capability structure or 000h if no other items exist in the linked list of Capabilities. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value

19.4.2.207 PTM Capability Register

This register describes a Function's support for Precision Time Measurement. Not all fields within this register apply to all Functions capable of implementing PTM.

PTM_CAP_OFF Offset address: $00042BC_H$

PTM Capability Register Kernel Reset value: $0000\ 040F_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rwh								r				rw	rw	rwh	rw

Field	Bits	Type	Description
PTM_REQ_CAPABLE	0	rw	**PTM Requester Capable** Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Endpoints and RCiEPs are permitted to, and Switches supporting PTM must, set this bit to 1b to indicate they implement the PTM Requester role
PTM_RES_CAPABLE	1	rwh	**PTM Responder Capable** Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Root Ports and RCRB's are permitted to, and Switches supporting PTM must, set this bit to 1b to indicate they implement the PTM Responder role If PTM Root Capable is Set, this bit must be Set to 1b.
PTM_ROOT_CAPABLE	2	rw	**PTM Root Capable** Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Root Ports, RCRBs and Switches are permitted to set this bit to 1b, if they implement a PTM Time Source Role and are capable of serving as the PTM Root

(table continues...)

(continued)

Field	Bits	Type	Description
EPTM_CAPABLE	3	rw	**ePTM Capable** Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Indicates Enhanced Precision Time Management (ePTM) is supported Defaults to 0x1.
RSVDP_4	7:4	r	**Reserved for future use**
PTM_CLK_GRAN	15:8	rwh	**PTM Local Clock Granularity** For other than this value (between b00000001-b111111110) indicates the period of this Time Source's local clock in ns. If the PTM Root Select bit is Set, this local clock is used to provide PTM Master Time. Otherwise, the Time Source uses this local clock to locally track PTM Master Time received from further Upstream within a PTM Hierarchy. This field is reserved for Functions that do not implement the PTM Time Source role. Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) 00_H **No_local_clock**: Time Source does not implement a local clock It simply propagates timing information obtained from further Upstream in the PTM Hierarchy when responding to PTM Request messages. FF_H **Greater_than_254ns**: Indicates the period of this Time Source's local clock is greater than 254 ns
RSVDP_16	31:16	r	**Reserved for future use**

19.4.2.208 PTM Control Register

This register controls a Function's participation in the Precision Time Measurement mechanism. Not all fields within this register apply to all Functions capable of implementing PTM.

PTM_CONTROL_OFF Offset address: $00042C0_H$

PTM Control Register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
PTM_ENABLE	0	rw	**PTM Enable** 0_B **CLEAR**: Clear 1_B **SET**: When Set, this Function is permitted to participate in the PTM mechanism according to its selected role(s)
ROOT_SELECT	1	rw	**PTM Root Select** If the value of the PTM Root Capable bit is 0b, this bit is permitted to be hardwired to 0b by the controller. Within each PTM Hierarchy, it is recommended that system software select only the furthest Upstream Time Source to be the PTM Root. Note: The access attributes of this field are as follows: - Wire: HWINIT - Dbi: HWINIT 0_B **CLEAR**: Clear 1_B **SET**: When Set, if the PTM Enable bit is also Set, this Time Source is the PTM Root
RSVDP_2	7:2	r	**Reserved for future use**
EFF_GRAN	15:8	rh	**PTM Effective Granularity** For Functions implementing the PTM Requester Role, this field provides information relating to the expected accuracy of the PTM clock, but does not otherwise affect the PTM mechanism. For Endpoints, system software must program this field to the value representing the maximum Local Clock Granularity reported by the PTM Root and all intervening PTM Time Sources. For RCiEPs, system software must set this field to the value reported in the Local Clock Granularity field by the associated PTM Time Source. For other than this value (between b00000001-b111111110) indicates the effective PTM granularity in ns. Note: The access attributes of this field are as follows: - Wire: HWINIT - Dbi: HWINIT 00_H **No_local_clock**: Unknown PTM granularity - one or more Switches between this Function and the PTM Root reported a Local Clock Granularity value of 0000 0000b FF_H **Greater_than_254ns**: Indicates the effective PTM granularity is greater than 254 ns
RSVDP_16	31:16	r	**Reserved for future use**

19.4.2.209 Precision Time Measurement Responder Capability Header (VSEC)

For more details, see the PTM section in the Databook.

PTM_RES_CAP_HDR_OFF Offset address: $00042C4_H$

Precision Time Measurement Responder Capability Header [VSEC] Kernel Reset value: $32C1\ 000B_H$

Field	Bits	Type	Description
PTM_RES_EXT_CAP_ID	15:0	rw	**Precision Time Measurement Responder VSEC ID** For more details, see the PTM section in the Databook. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
PTM_RES_EXT_CAP_VER	19:16	rw	**Precision Time Measurement Responder VSEC Version** For more details, see the PTM section in the Databook. RSVDP_2														PTM_RES_REQUEST_RECEIVED	PTM_RES_CONTEXT_VALID
r														rh	rh

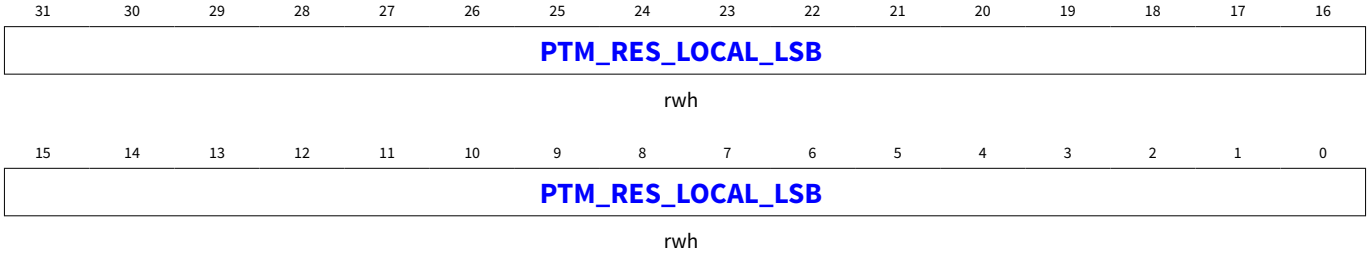
Field	Bits	Type	Description
PTM_RES_CONTEXT_VALID	0	rh	**PTM Responder Status Context Valid** PTM Local Timing Context is Valid. Value set from upstream port Requester in a Switch. Shadows the same in the control register in all other products. For more details, see the PTM section in the Databook. Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Set
PTM_RES_REQUEST_RECEIVED	1	rh	**PTM 1st Request Received** PTM Responder has received the first PTM Request Message. Upon receipt of a second PTM Request Message a ResponseD message with timing information will be sent from the Responder, if the context is valid. If the context is invalid a Response message will be sent instead. For more details, see the PTM section in the Databook. Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Set
RSVDP_2	31:2	r	**Reserved for future use**

19.4.2.213 PTM Responder Local Clock LSB

For more details, see the PTM section in the Databook.

PTM_RES_LOCAL_LSB_OFF Offset address: $00042D4_H$

PTM Responder Local Clock LSB Kernel Reset value: $0000\ 0000_H$



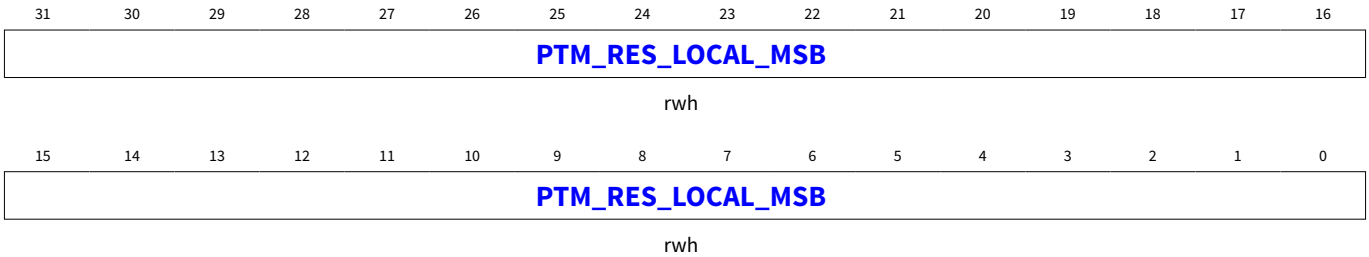
Field	Bits	Type	Description
PTM_RES_LOCAL_LSB	31:0	rwh	**PTM Responder Local Clock LSB** Lower 32 bits of local timer value. For more details, see the PTM section in the Databook. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.214 PTM Responder Local Clock MSB

For more details, see the PTM section in the Databook.

PTM_RES_LOCAL_MSB_OFF Offset address: $00042D8_H$

PTM Responder Local Clock MSB Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PTM_RES_LOCAL_MSB	31:0	rwh	**PTM Responder Local Clock MSB** Upper 32 bits of local timer value. For more details, see the PTM section in the Databook. Note: The access attributes of this field are as follows: - Wire: No access. - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.215 PTM Responder T2 Timestamp LSB

For more details, see the PTM section in the Databook.

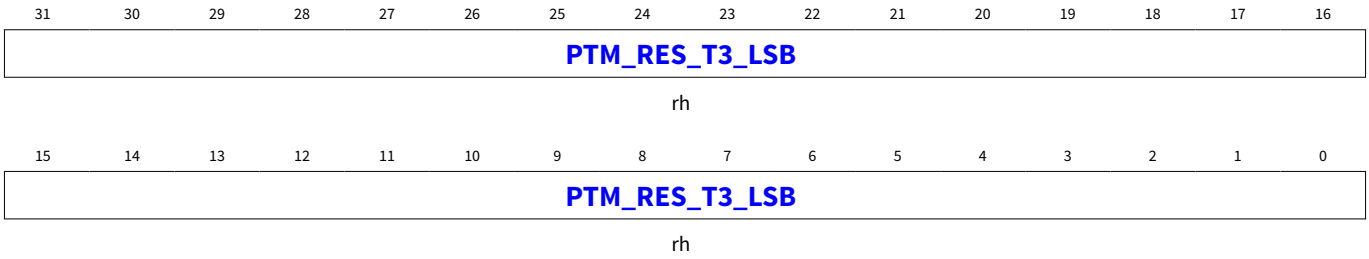
19.4.2.219 PTM Responder T3 Timestamp LSB

For more details, see the PTM section in the Databook.

PTM_RES_T3_LSB_OFF Offset address: $00042EC_H$

PTM Responder T3 Timestamp LSB Kernel Reset value: $0000\ 0000_H$



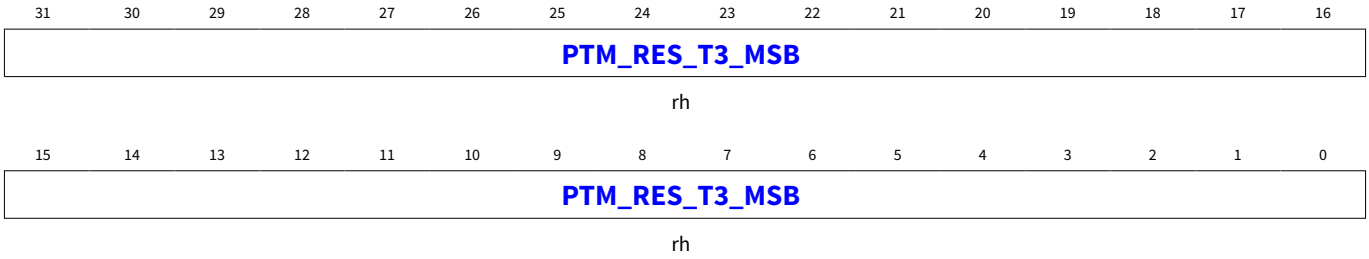
Field	Bits	Type	Description
PTM_RES_T3_LSB	31:0	rh	**PTM Responder T3 Timestamp LSB** Lower 32 bits of the T3 Timestamp value. For more details, see the PTM section in the Databook. Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.220 PTM Responder T3 Timestamp MSB

For more details, see the PTM section in the Databook.

PTM_RES_T3_MSB_OFF Offset address: $00042F0_H$

PTM Responder T3 Timestamp MSB Kernel Reset value: $0000\ 0000_H$



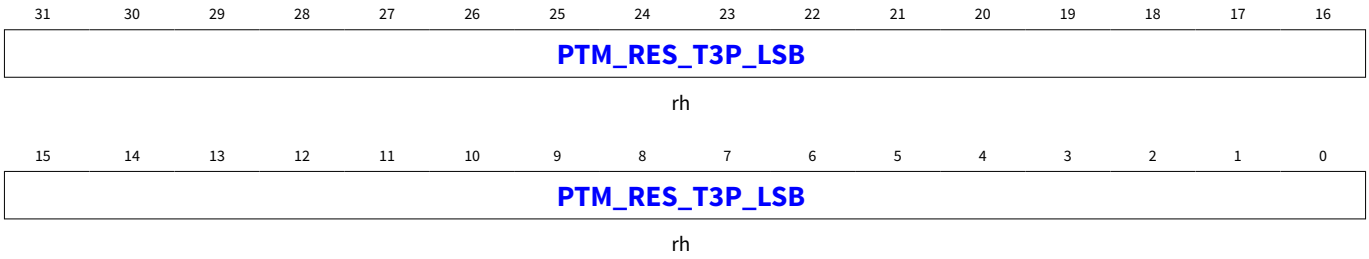
Field	Bits	Type	Description
PTM_RES_T3_MSB	31:0	rh	**PTM Responder T3 Timestamp MSB** Upper 32 bits of the T2 Timestamp value. For more details, see the PTM section in the Databook. Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.221 PTM Responder T3 Previous Timestamp LSB

For more details, see the PTM section in the Databook.

PTM_RES_T3P_LSB_OFF Offset address: $00042F4_H$

PTM Responder T3 Previous Timestamp LSB Kernel Reset value: $0000\ 0000_H$



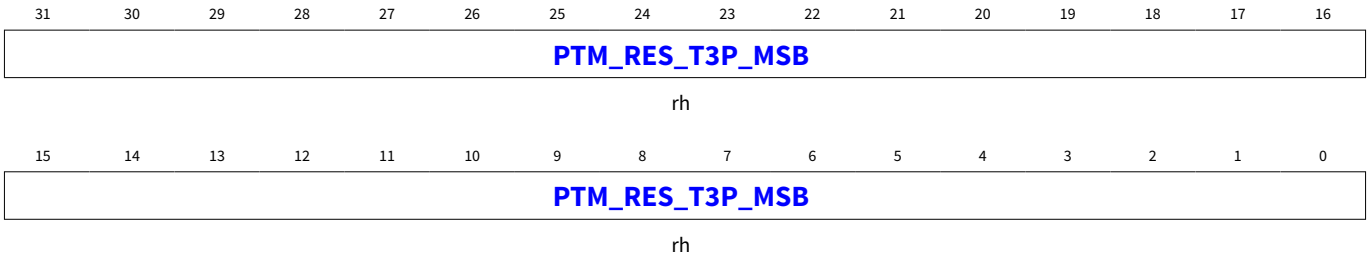
Field	Bits	Type	Description
PTM_RES_T3P_LSB	31:0	rh	**PTM Responder T3 Previous Timestamp LSB** Lower 32 bits of the previously stored T3 Timestamp value. For more details, see the PTM section in the Databook. Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.222 PTM Responder T3 Previous Timestamp MSB

For more details, see the PTM section in the Databook.

PTM_RES_T3P_MSB_OFF Offset address: $00042F8_H$

PTM Responder T3 Previous Timestamp MSB Kernel Reset value: $0000\ 0000_H$



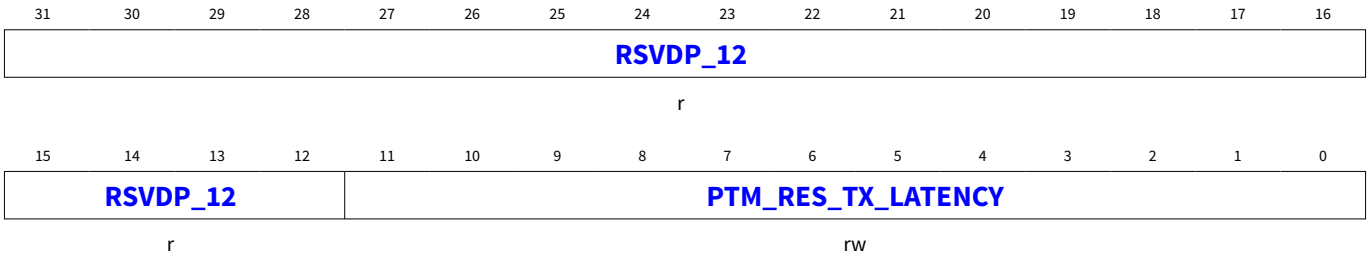
Field	Bits	Type	Description
PTM_RES_T3P_MSB	31:0	rh	**PTM Responder T3 Previous Timestamp MSB** Upper 32 bits of the previously stored T3 Timestamp value. For more details, see the PTM section in the Databook. Note: This register field is sticky. 00000000_H **MIN_VAL**: Min value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.223 PTM Responder TX Latency

For more details, see the PTM section in the Databook.

PTM_RES_TX_LATENCY_OFF Offset address: $00042FC_H$

PTM Responder TX Latency Kernel Reset value: $0000\ 000E_H$



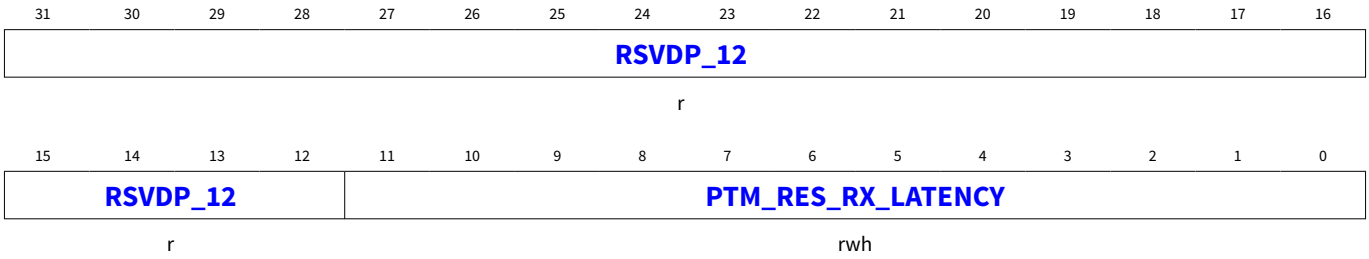
Field	Bits	Type	Description
PTM_RES_TX_LATENCY	11:0	rw	**PTM Responder TX Latency** Responder Transmit path latency viewport register. A register is provided for each supported link speed, and the value used for timestamp adjustment is automatically selected based on the current speed. The PTM Responder Latency Register Select register specifies the register to be written or read. For more details, see the PTM section in the Databook. Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value
RSVDP_12	31:12	r	**Reserved for future use**

19.4.2.224 PTM Responder RX Latency

For more details, see the PTM section in the Databook.

PTM_RES_RX_LATENCY_OFF Offset address: 0004300_H

PTM Responder RX Latency Kernel Reset value: $0000\ 002A_H$



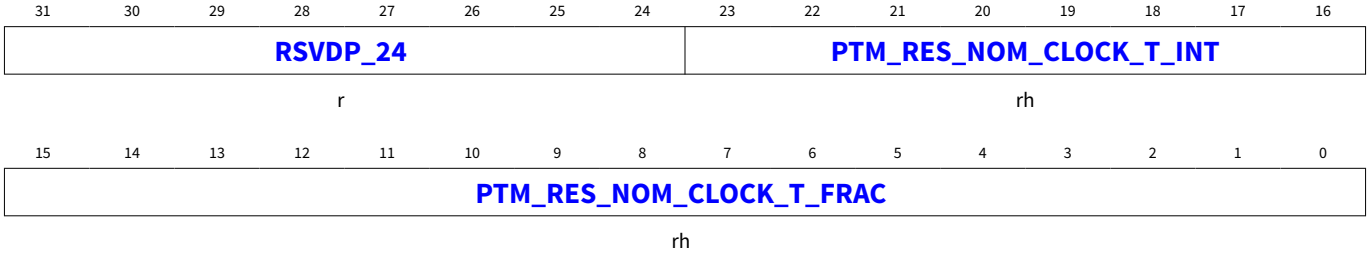
Field	Bits	Type	Description
PTM_RES_RX_LATENCY	11:0	rwh	**PTM Responder RX Latency** Responder Receive path latency viewport register. A register is provided for each supported link speed, and the value used for timestamp adjustment is automatically selected based on the current speed. The PTM Responder Latency Register Select register specifies the register to be written or read. For more details, see the PTM section in the Databook. Note: This register field is sticky. 000_H **MIN_VAL**: Min value FFF_H **MAX_VAL**: Max value
RSVDP_12	31:12	r	**Reserved for future use**

19.4.2.225 PTM Responder Nominal Clock Period

For more details, see the PTM section in the Databook.

PTM_RES_NOM_CLOCK_T_OFF Offset address: 0004304_H

PTM Responder Nominal Clock Period Kernel Reset value: $0000\ 0000_H$



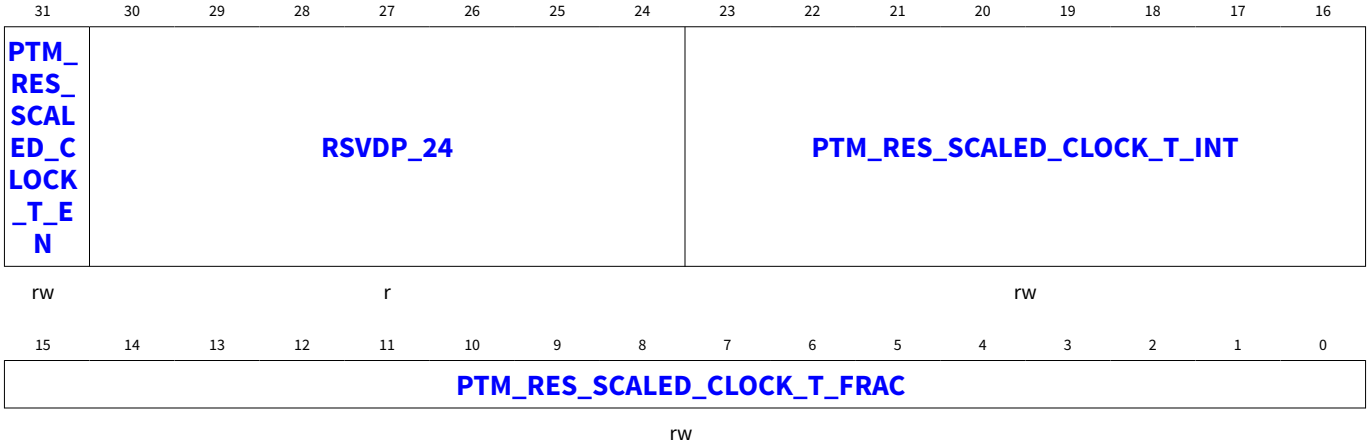
Field	Bits	Type	Description
PTM_RES_NOM_CLOCK_T_FRAC	15:0	rh	**PTM Responder Nominal Clock Period Fractional** Fractional part of the nominal PTM local clock period. LSB is 1/(2^16) nanoseconds. For more details, see the PTM section in the Databook. Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
PTM_RES_NOM_CLOCK_T_INT	23:16	rh	**PTM Responder Nominal Clock Period Integral – Integral part of the nominal PTM local clock period, in nanoseconds** For more details, see the PTM section in the Databook. Note: This register field is sticky. 00_H **MIN_VAL**: Min value $0F_H$ **MAX_VAL**: Max value **others,** Reserved
RSVDP_24	31:24	r	**Reserved for future use**

19.4.2.226 PTM Responder Scaled Clock Period

For more details, see the PTM section in the Databook.

PTM_RES_SCALED_CLOCK_T_OFF Offset address: 0004308_H

PTM Responder Scaled Clock Period Kernel Reset value: $0000\ 0000_H$



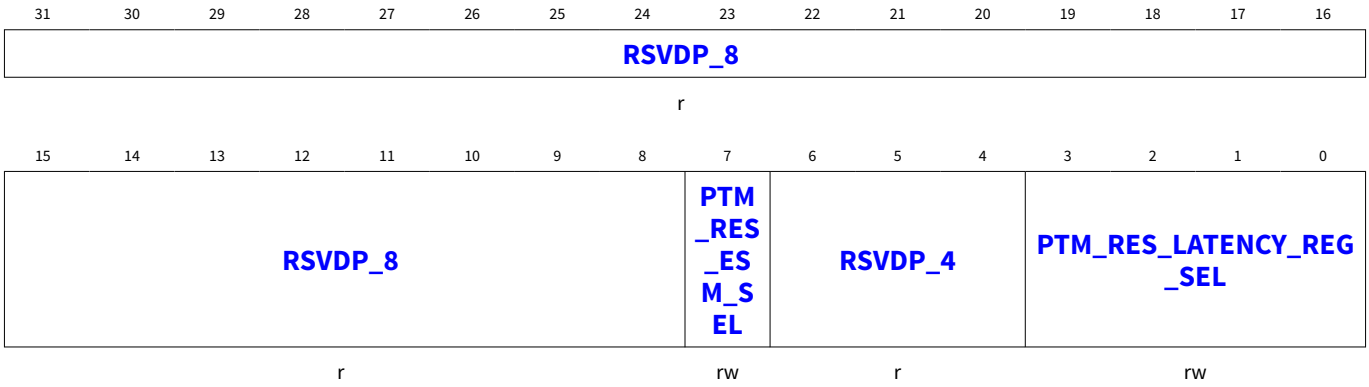
Field	Bits	Type	Description
PTM_RES_SCALED_CLOCK_T_FRAC	15:0	rw	**PTM Responder Scaled Clock Period Fractional** Fractional part of the nominal PTM local clock period. LSB is 1/(2^16) nanoseconds. For more details, see the PTM section in the Databook. Note: This register field is sticky. 0000_H **MIN_VAL**: Min value $FFFF_H$ **MAX_VAL**: Max value
PTM_RES_SCALED_CLOCK_T_INT	23:16	rw	**PTM Responder Scaled Clock Period Integral** Integral part of the nominal PTM local clock period, in nanoseconds. For more details, see the PTM section in the Databook. Note: This register field is sticky. 00_H **MIN_VAL**: Min value $0F_H$ **MAX_VAL**: Max value **others,** Reserved
RSVDP_24	30:24	r	**Reserved for future use**
PTM_RES_SCALED_CLOCK_T_EN	31	rw	**PTM Responder Scaled Clock Period Enable** Use the programmed scaled PTM clock period rather than the nominal values. This bit is cleared when the core_clk rate starts to change and can only be set when the clock period change is complete. For more details, see the PTM section in the Databook. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable

19.4.2.227 PTM Responder Latency Viewport Register Select

For more details, see the PTM section in the Databook.

PTM_RES_LATENCY_REG_SEL_OFF Offset address: $000430C_H$

PTM Responder Latency Viewport Register Select Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PTM_RES_LATENCY_REG_SEL	3:0	rw	**Selects the PTM Responder Tx and Rx Latency Viewport register to be written or read, together with the PTM_RES_ESM_SEL field** For more details, see the PTM section in the Databook. Note: This register field is sticky.
RSVDP_4	6:4	r	**Reserved for future use**
PTM_RES_ESM_SEL	7	rw	**Selection Mode for PTM Responder Tx and Rx Latency Viewport register to be written or read** For more details, see the PTM section in the Databook. Note: This register field is sticky. 0_B **SEL_PCIE_REGS**: write or read latency registers for PCIe rates 1_B **SEL_CCIX_ESM_REGS**: write or read latency registers for additional ESM rates
RSVDP_8	31:8	r	**Reserved for future use**

19.4.2.228 PCIe Extended Capability ID, Capability Version, and Next Capability Offset Register

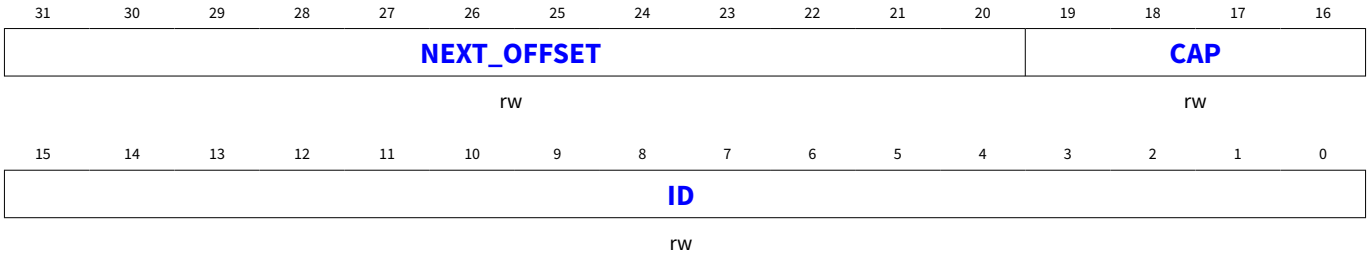
This register provides capability ID, capability version, and next capability offset for PCIe extended capability structure.

VSECDMA_EXT_CAP_HDR_OFF

PCIe Extended Capability ID, Capability Version, and Next Capability Offset Register

Offset address: $000432C_H$

Kernel Reset value: $0001\ 000B_H$



Field	Bits	Type	Description
ID	15:0	rw	**PCI Express Extended Capability ID** This field is a PCI-SIG defined ID number that indicates the nature and format of the Extended Capability. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
CAP	19:16	rw	**Capability Version** This field is a PCI-SIG defined version number that indicates the version of the Capability structure present. A version of the specification that changes the Extended Capability in a way that is not otherwise identifiable (that is, through a new Capability field) is permitted to increment this field. All such changes to the Capability structure must be software-compatible. Software must check for Capability Version numbers that are greater than or equal to the highest number defined when the software is written, as Functions reporting any such Capability Version numbers will contain a Capability structure that is compatible with that piece of software. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
NEXT_OFFSET	31:20	rw	**Next Capability Offset** This field contains the offset to the next PCI Express Capability structure or 000h if no other items exist in the linked list of Capabilities. For Extended Capabilities implemented in Configuration Space, this offset is relative to the beginning of PCI-compatible Configuration Space and thus must always be either 000h (for terminating list of Capabilities) or greater than 0FFh. The bottom 2 bits of this offset are Reserved and must be implemented as 00b although software must mask them to allow for future uses of these bits. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

19.4.2.229 Vendor Specific Header Register

This Register provides VSEC Length, VSEC ID, and VSEC Rev(Version Number). Vendor-specific software must qualify the associated Vendor ID of the PCI Express Function or RCRB before attempting to interpret the values in the VSEC ID or VSEC Rev fields.

VSECDMA_VENDOR_SPECIFIC_HDR_OFF Offset address: 0004330_H

Vendor Specific Header Register Kernel Reset value: $0180\ 0006_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r												r			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VSEC_ID															
r															

Field	Bits	Type	Description
VSEC_ID	15:0	r	**VSEC ID** This field is a vendor-defined ID number that indicates the nature and format of the VSEC structure. Software must qualify the Vendor ID before interpreting this field.
VSEC_REV	19:16	r	**VSEC Rev** This field is a vendor-defined version number that indicates the version of the VSEC structure. Software must qualify the Vendor ID and VSEC ID before interpreting this field.
VSEC_LENGTH	31:20	r	**VSEC Length** This field indicates the number of bytes in the entire VSEC structure, including the Vendor-Specific Extended Capability Header, the Vendor-Specific Header, and the vendor-specific registers.

19.4.2.230 DMA and related AXI Bridge Implementation Information

This register provides DMA and AXI Bridge implementation-specific information: - DMA Architecture: Legacy DMA or Hyper DMA (HDMA). - Register Location: Port-logic or Mapped to a Function and BAR. - Register Map: Legacy DMA or HDMA. - Channel Separation: Address distance between read and write channels. - AXI Bridge: Used or Not Used - AXI Master Bus Specification: AXI Master Bus Width, Burst Length, and Boundary Pointer Width You must use this information along with the IP version registers: - PCIE_VERSION_NUMBER_OFF - PCIE_VERSION_TYPE_OFF

VSECDMA_DEVICE_INFORMATION_OFF Offset address: 0004334_H

DMA and related AXI Bridge Implementation Information Kernel Reset value: $3498\ 0001_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PFN					BARN			RSVDP_3					MAP_FORMAT		
r					r			r					r		

Field	Bits	Type	Description
MAP_FORMAT	2:0	r	**Defines the register map format and features to be one of the following values: Other values are reserved** 000_B **EDMA_LEGACY_PL**: Legacy DMA register map accessed by the port-logic registers 001_B **EDMA_LEGACY_UNROLL**: Legacy DMA register map, mapped to a PF/BAR 101_B **HDMA_COMPATIBILITY_MODE**: HDMA compatibility mode (CC_LEGACY_DMA_MAP =1) register map, mapped to a PF/BAR 111_B **HDMA_NATIVE**: HDMA native (CC_LEGACY_DMA_MAP =0) register map, mapped to a PF/BAR
RSVDP_3	7:3	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
BARN	10:8	r	**Bar Number** This field provides information regarding the DMA register and BAR number mapping.
PFN	15:11	r	**Physical Function Number** This field provides information regarding the DMA register and physical function mapping.
CHANNEL_SEPARATION	18:16	r	**If the MAP_FORMAT is set to HDMA_NATIVE, this field specifies the read write channel address separation** Other values are reserved. 000_B **CHSEP_256**: 256 separated 001_B **CHSEP_512**: 512 separated 010_B **CHSEP_1K**: 1k separated 011_B **CHSEP_2K**: 2k separated 100_B **CHSEP_4K**: 4k separated 101_B **CHSEP_8K**: 8k separated 110_B **CHSEP_16K**: 16k separated 111_B **CHSEP_32K**: 32k separated
AXI	19	r	**This field provides information about AXI interface usage** It reports the value of AXI_POPULATED configuration parameter.
MASTER_BUS_WIDTH	22:20	r	**This field provides information regarding the AXI master data bus width** It reports the value of width of the AXI master databus. 000_B **MSTR_BUSWD_32**: 32 bits 001_B **MSTR_BUSWD_64**: 64 bits 010_B **MSTR_BUSWD_128**: 128 bits 011_B **MSTR_BUSWD_256**: 256 bits 100_B **MSTR_BUSWD_512**: 512 bits **others,** Reserved
MASTER_BURST_LENGTH	25:23	r	**Reports the maximum burst length (in beats) of an AXI transfer at the master interface** 000_B **MSTR_BRSTLEN_8**: 8 bits 001_B **MSTR_BRSTLEN_16**: 16 bits 010_B **MSTR_BRSTLEN_32**: 32 bits 011_B **MSTR_BRSTLEN_64**: 64 bits 100_B **MSTR_BRSTLEN_128**: 128 bits 101_B **MSTR_BRSTLEN_256**: 256 bits **others,** Reserved
MASTER_PAGE_BOUNDARY_POINTER_WIDTH	29:26	r	**This field provides address page boundary information** It reports the value of the page boundary of 128, 256, 512, 1K, 2K or 4K (bytes). .
RSVDP_30	31:30	r	**Reserved for future use**

19.4.2.231 Number of Implemented Channels Register

This register specifies the number of read and write channels implemented.

VSECDMA_NUM_CHAN_OFF Offset address: 0004338_H

Number of Implemented Channels Register Kernel Reset value: $0004\ 0004_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
UNROLL_ADDR_OFFSET_LOW															
r															

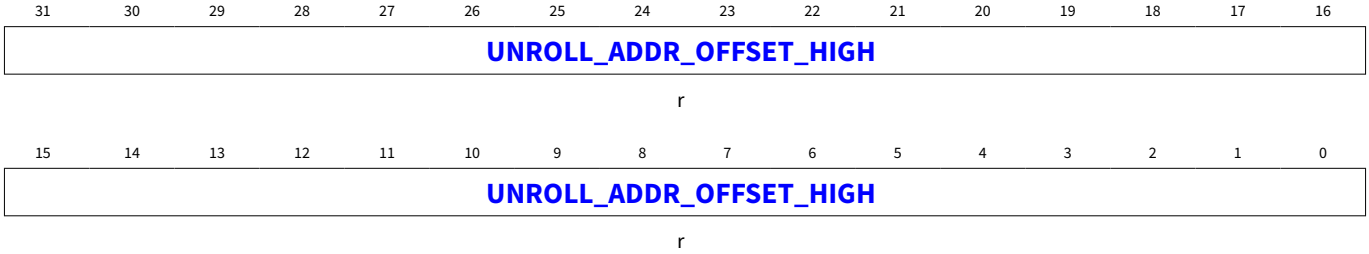
Field	Bits	Type	Description
UNROLL_ADDR_OFFSET_LOW	31:0	r	**BAR address offset, 32-bit LSB**

19.4.2.233 DMA Register Map Start Address Offset High Register

This register specifies the upper 32 bits of the offset of the start address of the DMA register map.

VSECDMA_UNROLL_ADDR_OFFSET_HIGH_OFF Offset address: 0004340_H

DMA Register Map Start Address Offset High Register Kernel Reset value: $0000\ 0000_H$



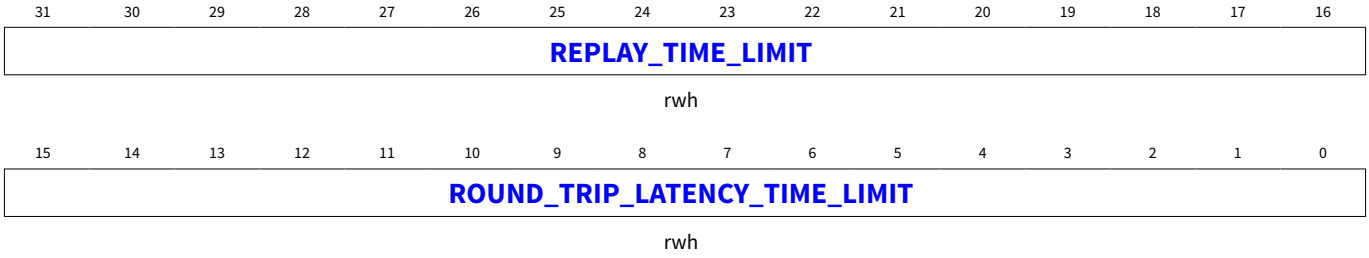
Field	Bits	Type	Description
UNROLL_ADDR_OFFSET_HIGH	31:0	r	**BAR address offset, 32-bit MSB**

19.4.2.234 Ack Latency Timer and Replay Timer Register

This register holds the ack latency timer limit and replay timer limit values.

ACK_LATENCY_TIMER_OFF Offset address: 0004700_H

Ack Latency Timer and Replay Timer Register Kernel Reset value: $0C23\ 040B_H$



Field	Bits	Type	Description
ROUND_TRIP_LATENCY_TIME_LIMIT	15:0	rwh	**Ack Latency Timer Limit** The Ack latency timer expires when it reaches this limit. - You can modify the effective timer limit through the TIMER_MOD_ACK_NAK field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register. - After reset, the controller updates the default according to the Negotiated Link Width, Max_Payload_Size, and speed. The value is determined from Tables 3-7, 3-8, and 3-9 of the PCI Express Base Specification. - The limit must reflect the round trip latency from requester to completer. - If there is a change in the payload size or link width, the controller overrides any value that you have written to this register field, and resets the field back to the specification-defined value. The controller does not change the value in the TIMER_MOD_ACK_NAK field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register.

(table continues...)

(continued)

Field	Bits	Type	Description
REPLAY_TIME_LIMIT	31:16	rwh	**Replay Timer Limit** The replay timer expires when it reaches this limit. The controller initiates a replay upon reception of a NAK or when the replay timer expires. - You can modify the effective timer limit through the TIMER_MOD_REPLAY_TIMER field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register. - After reset, the controller updates the default according to the Negotiated Link Width, Max_Payload_Size, and speed. The value is determined from Tables 3-4, 3-5, and 3-6 of the PCI Express Base Specification. - If there is a change in the payload size or link speed, the controller overrides any value that you have written to this register field, and resets the field back to the specification-defined value. The controller does not change the value in the TIMER_MOD_REPLAY_TIMER field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register.

19.4.2.235 Vendor Specific DLLP Register

This register holds the vendor specific DLLP.

VENDOR_SPEC_DLLP_OFF Offset address: 0004704_H

Vendor Specific DLLP Register Kernel Reset value: $FFFF\ FFFF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VENDOR_SPEC_DLLP															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VENDOR_SPEC_DLLP															
rw															

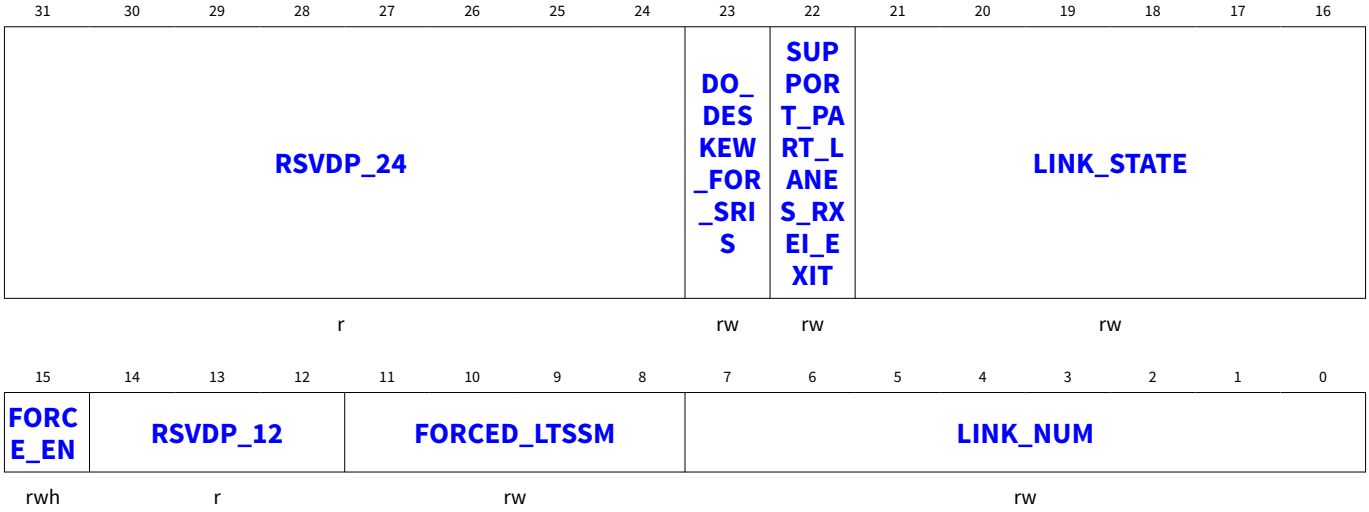
Field	Bits	Type	Description
VENDOR_SPEC_DLLP	31:0	rw	**Vendor Specific DLLP Register** You can use this register to send a specific PCI Express DLLP. Your application can write 8-bit DLLP Type and 24-bit Payload data into this register, and set the VENDOR_SPECIFIC_DLLP_REQ field of the PORT_LINK_CTRL_OFF, to send the DLLP. - Bits[7:0]: DLLP Type - Bits[31:8]: Vendor Defined Payload (24 bits) Note: This register field is sticky. 00000000_H **ZERO**: Zero value $FFFFFFFF_H$ **MAX**: Max value

19.4.2.236 Port Force Link Register

This register can be used for testing and debugging the link.

PORT_FORCE_OFF Offset address: 0004708_H

Port Force Link Register Kernel Reset value: $0080\ 0001_H$



Field	Bits	Type	Description
LINK_NUM	7:0	rw	**Link Number** Not used for endpoint. Note: This register field is sticky.
FORCED_LTSSM	11:8	rw	**Forced Link Command** The link command that the controller is forced to transmit when you set FORCE_EN bit (Force Link). Link command encoding is defined by the ltssm_cmd variable in workspace/src/Layer1/smlh_ltssm.v. Note: This register field is sticky.
RSVDP_12	14:12	r	**Reserved for future use**
FORCE_EN	15	rwh	**Force Link** The controller supports a testing and debug capability to allow your software to force the LTSSM state machine into a specific state, and to force the controller to transmit a specific Link Command. Asserting this bit triggers the following actions: • Forces the LTSSM to the state specified by the Forced LTSSM State field • Forces the controller to transmit the command specified by the Forced Link Command field This is a self-clearing register field. Reading from this register field always returns a '0'. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
LINK_STATE	21:16	rw	**Forced LTSSM State** The LTSSM state that the controller is forced to when you set the FORCE_EN bit (Force Link). . Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
SUPPORT_PART_LANES_RXEI_EXIT	22	rw	**Support LTSSM transition from Polling.Active to Polling.Config based on Rx 8 TSs on any lanes which are Rx EI exit too from base spec after 24ms timeout** This prevents some lanes detected but not Rx EI exit and LTSSM cannot move to Polling.Config. Note: This register field is sticky. 0_B **UNSUPPORT**: Any lanes receives 8 consecutive TS OS and all predetermined lanes have Rx ElecIdle exit, LTSSM moves from Polling.Active to Polling.Config This is legacy mode from Base Spec. Any predetermined lanes are still on Rx ElecIdle, LTSSM moves from Polling.Active to Polling.Compliance. 1_B **SUPPORT**: Any lanes receives 8 consecutive TS OSs, LTSSM moves from Polling.Active to Polling.Config If all lanes do not receive 8 consecutive TS OSs and any predetermined lanes are still on Rx ElecIdle, LTSSM moves from Polling.Active to Polling.Compliance.
DO_DESKEW_FOR_SRIS	23	rw	**Use the transitions from TS2 to Logical Idle Symbol, SKP OS to Logical Idle Symbol, EIEOS to Logical Idle Symbol, and FTS Sequence to SKP OS to do deskew instead of using received SKP OS or TS1 to TS2 transition if DO_DESKEW_FOR_SRIS is set to '1'** Note: This register field is sticky.
RSVDP_24	31:24	r	**Reserved for future use**

19.4.2.237 Ack Frequency and L0-L1 ASPM Control Register

This register is used to control ack frequency and L0-L1 ASPM behaviour.

ACK_F_ASPM_CTRL_OFF Offset address: $000470C_H$

Ack Frequency and L0-L1 ASPM Control Register Kernel Reset value: $09B4\ B400_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSVDP_31	ENTER_ASPM	L1_ENTRANCE_LATENCY			L0S_ENTRANCE_LATENCY			COMMON_CLK_N_FTS							
r	rw	rw			rw			r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ACK_N_FTS								ACK_FREQ							
rw								rw							

Field	Bits	Type	Description
ACK_FREQ	7:0	rw	**Ack Frequency** The controller accumulates the number of pending ACKs specified here (up to 255) before scheduling an ACK DLLP • 0: Indicates that this Ack Frequency Counter feature is turned off. The controller generates a low-priority ACK request for every TLP that it receives. The controller waits until the ACK Latency Timer expires, then converts the current low-priority ACK request to a high-priority ACK request and schedules the DLLP for transmission to the remote link partner • 1-255: Indicates that the controller will schedule a high-priority ACK after receiving this number of TLPs. It might schedule the ACK before receiving this number of TLPs if the ACK Latency Timer expires, but never later For a typical system, you do not have to modify the default setting. For more details, see "ACK/NAK Scheduling" in the user manual. Note: This register field is sticky. 00_H **MIN_VAL**: The value '0' indicates that this Ack Frequency Counter feature is turned off FF_H **MAX_VAL**: Any value between 1 and 255 indicates that the controller will schedule a high-priority ACK after receiving the specified number of TLPs
ACK_N_FTS	15:8	rw	**The number of Fast Training Sequence(N_FTS) ordered sets to be transmitted when transitioning from L0s to L0** Note: This register field is sticky. 00_H **ZERO**: The controller does not support a value of zero; a value of zero can cause the LTSSM to go into the recovery state when exiting from L0s FF_H **MAX_VAL**: The maximum number of FTS ordered-sets that a component can request is 255
COMMON_CLK_N_FTS	23:16	r	**Common Clock N_FTS** This is the N_FTS when common clock is used. The number of Fast Training Sequence ordered sets to be transmitted when transitioning from L0s to L0. Note: The access attributes of this field are as follows: - Wire: R - Dbi: R 00_H **ZERO**: The controller does not support a value of zero; a value of zero can cause the LTSSM to go into the recovery state when exiting from L0s FF_H **MAX_VAL**: The maximum number of FTS ordered-sets that a component can request is 255

(table continues...)

(continued)

Field	Bits	Type	Description
L0S_ENTRANCE_LATENCY	26:24	rw	**L0s Entrance Latency** Note: This register field is sticky. 000_B **_1_US**: 1 µs 001_B **_2_US**: 2 µs 010_B **_3_US**: 3 µs 011_B **_4_US**: 4 µs 100_B **_5_US**: 5 µs 101_B **_6_US**: 6 µs 110_B **_7_US**: 7 µs 111_B **_7US_**: 7 µs
L1_ENTRANCE_LATENCY	29:27	rw	**L1 Entrance Latency** Note: Programming this timer with a value greater that 32 µs has no effect unless extended sync is used, or all of the credits are infinite. Note: This register field is sticky. 000_B **_1_US**: 1 µs 001_B **_2_US**: 2 µs 010_B **_4_US**: 4 µs 011_B **_8_US**: 8 µs 100_B **_16_US**: 16 µs 101_B **_32_US**: 32 µs 110_B **_64_US**: 64 µs 111_B **_64US_**: 64 µs
ENTER_ASPM	30	rw	**ASPM L1 Entry Control** Note: This register field is sticky. 0_B **L0S_TO_L1**: Controller enters ASPM L1 only after idle period during which both receive and transmit are in L0s 1_B **IDLE_TO_L1**: Controller enters ASPM L1 after a period in which it has been idle
RSVDP_31	31	r	**Reserved for future use**

19.4.2.238 Port Link Control Register

Using this register you can control the port link behaviour.

PORT_LINK_CTRL_OFF Offset address: 0004710_H

Port Link Control Register Kernel Reset value: $0001\ 0120_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r				rw				r	rw	rw	r	rw	rw	rw	rw1ch

Field	Bits	Type	Description
VENDOR_SPECIFIC_DLLP_REQ	0	rw1ch	**Vendor Specific DLLP Request** Reading from this self-clearing register field always returns a '0'. Software write with 1 clears this bit-field. 0_B **CLEAR**: This is a self clearing register 1_B **SET**: When software writes a '1' to this bit, the controller transmits the DLLP contained in the VENDOR_SPEC_DLLP field of VENDOR_SPEC_DLLP_OFF
SCRAMBLE_DISABLE	1	rw	**Scramble Disable** Turns off data scrambling. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
LOOPBACK_ENABLE	2	rw	**Loopback Enable** Turns on loopback. For more details, see "Loopback" in the user manual. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
RESET_ASSERT	3	rw	**Reset Assert** Triggers a recovery and forces the LTSSM to the hot reset state (downstream port only). Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Set
RSVDP_4	4	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
DLL_LINK_EN	5	rw	**DLL Link Enable** Note: This register field is sticky. 0_B **DISABLE**: The controller does not transmit InitFC DLLPs and does not establish a link 1_B **ENABLE**: Enables link initialization
LINK_DISABLE	6	rw	**LINK DISABLE is an internally reserved field** Do not use. this register field is sticky
LINK_RATE	11:8	rw	**LINK_RATE is an internally reserved field** Do not use. Note: This register field is sticky.
RSVDP_12	15:12	r	**Reserved for future use**
LINK_CAPABLE	21:16	rw	**Link Mode Enable** Sets the number of lanes in the link that you want to connect to the link partner.Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 01_H **X1**: x1 03_H **X2**: x2 07_H **X4**: x4 $0F_H$ **X8**: x8 $1F_H$ **X16**: x16 $3F_H$ **X32**: x32 (not supported)
BEACON_ENABLE	24	rw	**BEACON_ENABLE is an internally reserved field** Do not use. Note: This register field is sticky.
CORRUPT_LCRC_ENABLE	25	rw	**CORRUPT_LCRC_ENABLE is an internally reserved field** Do not use. Note: This register field is sticky.
EXTENDED_SYNCH	26	rw	**EXTENDED_SYNCH is an internally reserved field** Do not use. Note: This register field is sticky.
TRANSMIT_LANE_REVERSALE_ENABLE	27	rw	**TRANSMIT_LANE_REVERSALE_ENABLE is an internally reserved field** Do not use. Note: This register field is sticky.
RSVDP_28	31:28	r	**Reserved for future use**
0	23:22	r	**Reserved** Read as all 0's; should be written with all 0's.

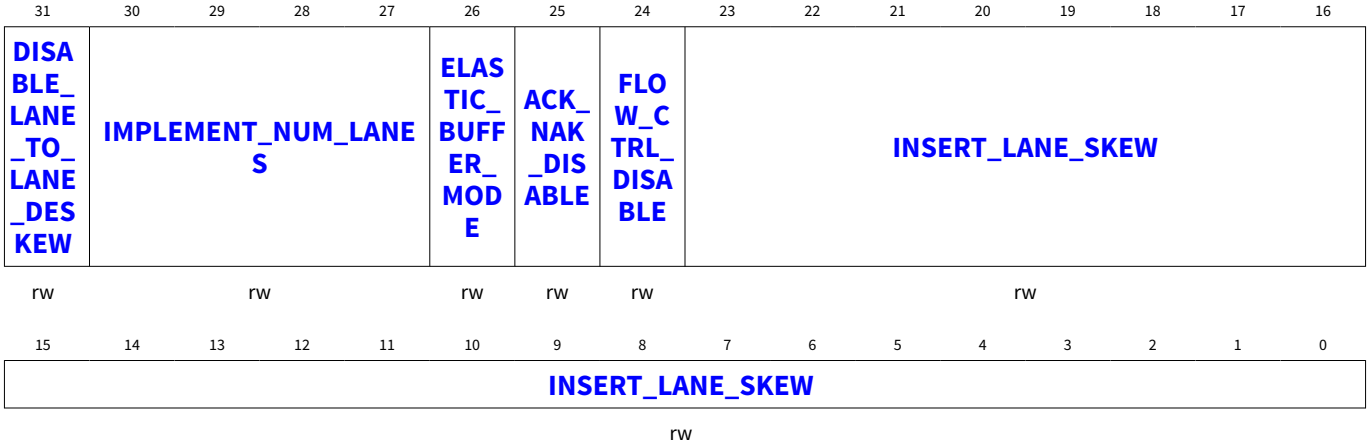
19.4.2.239 Lane Skew Register

This register is used to control the lane skew behaviour.

LANE_SKEW_OFF Offset address: 0004714_H

Lane Skew Register Kernel Reset value: $0400\ 0000_H$

19 Peripheral Component Interconnect Express (PCIe)



Field	Bits	Type	Description
INSERT_LANE_SKEW	23:0	rw	**INSERT_LANE_SKEW is an internally reserved field** Do not use. Note: This register field is sticky. 000000_H **MIN**: Zero value $0000FF_H$ **MAX**: Max value **others,** Reserved
FLOW_CTRL_DISABLE	24	rw	**Flow Control Disable** Prevents the controller from sending FC DLLPs. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
ACK_NAK_DISABLE	25	rw	**Ack/Nak Disable** Prevents the controller from sending ACK and NAK DLLPs. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
ELASTIC_BUFFER_MODE	26	rw	**Selects Elasticity Buffer operating mode:** Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **HALF_FULL**: Nominal Half Full Buffer mode 1_B **EMPTY**: Nominal Empty Buffer Mode

(table continues...)

(continued)

Field	Bits	Type	Description
IMPLEMENT_NUM_LANES	30:27	rw	**Implementation-specific Number of Lanes** Set the implementation-specific number of lanes. The number of lanes to be used when in Loopback Master. The number of lanes programmed must be equal to or less than the valid number of lanes set in LINK_CAPABLE field. You must configure this field before initiating Loopback by writing in the LOOPBACK_ENABLE field. The controller will transition from Loopback.Entry to Loopback.Active after receiving two consecutive TS1 Ordered Sets with the Loopback bit asserted on the implementation specific number of lanes configured in this field. Note: This register field is sticky. 0_H **_1_LANE**: 1 lane 1_H **_2_LANE**: 2 lanes 3_H **_4_LANE**: 4 lanes 7_H **_8_LANE**: 8 lanes F_H **_16_LANE**: 16 lanes
DISABLE_LANE_TO_LANE_DESKEW	31	rw	**Disable Lane-to-Lane Deskew** Causes the controller to disable the internal Lane-to-Lane deskew logic. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable

19.4.2.240 Timer Control and Max Function Number Register

This register holds the ack frequency, latency, replay, and max function number values.

TIMER_CTRL_MAX_FUNC_NUM_OFF Offset address: 0004718_H

Timer Control and Max Function Number Register Reset values see: Table 893

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSVDP_31	Res		UPDATE_FREQ_TIMER					TIMER_MOD_ACK_NAK					TIMER_MOD_REPLAY_TIMER		
r	r		rw					rw					rwh		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIMER_MOD_REPLAY_TIMER			RSVDP_8					MAX_FUNC_NUM							
rwh			r					rw							

Field	Bits	Type	Description
MAX_FUNC_NUM	7:0	rw	**Maximum function number that can be used in a request** Configuration requests targeted at function numbers above this value are returned with UR (unsupported request). Note: This register field is sticky. 00_H **MIN**: Zero value FF_H **MAX**: Max value
RSVDP_8	13:8	r	**Reserved for future use**
TIMER_MOD_REPLAY_TIMER	18:14	rwh	**Replay Timer Limit Modifier** Increases the time-out value for the replay timer in increments of 64 clock cycles at Gen1 or Gen2 speed, and in increments of 256 clock cycles at Gen3 speed. A value of '0' represents no modification to the timer limit. For more details, see the REPLAY_TIME_LIMIT field of the ACK_LATENCY_TIMER_OFF register. At Gen3 speed, the controller automatically changes the value of this field to DEFAULT_GEN3_REPLAY_ADJ. Note: This register field is sticky.
TIMER_MOD_ACK_NAK	23:19	rw	**Ack Latency Timer Modifier** Increases the timer value for the Ack latency timer in increments of 64 clock cycles. A value of '0' represents no modification to the timer value. For more details, see the ROUND_TRIP_LATENCY_TIME_LIMIT field of the ACK_LATENCY_TIMER_OFF register. Note: This register field is sticky.
UPDATE_FREQ_TIMER	28:24	rw	**UPDATE_FREQ_TIMER is an internally reserved field** Do not use. Note: This register field is sticky.
RSVDP_31	31	r	**Reserved for future use**

Reset	Reset value	Note
Kernel Reset	0100 0000 0000 0XXX XX00 0000 0000 0000_B	

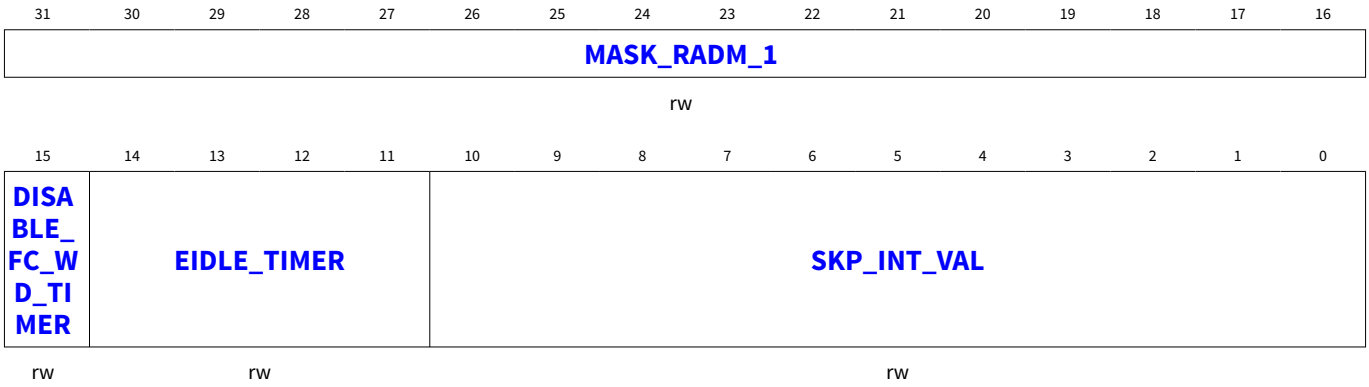
19.4.2.241 Symbol Timer Register and Filter Mask 1 Register

The Filter Mask 1 Register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule.

SYMBOL_TIMER_FILTER_1_OFF Offset address: $000471C_H$

Symbol Timer Register and Filter Mask 1 Register Kernel Reset value: $0000\ 0140_H$

19 Peripheral Component Interconnect Express (PCIe)



Field	Bits	Type	Description
SKP_INT_VAL	10:0	rw	**SKP Interval Value** The number of symbol times to wait between transmitting SKP ordered sets. The controller waits the number of symbol times in this register plus 1, between transmitting SKP ordered sets. Your application must program this register accordingly. For example, if 384 were programmed into this register (62.5 MHz for GEN 1, 4 symbols/cycle), then the controller actually transmits SKP ordered sets once every 1537 (384*4+1) symbol times. The value programmed to this register is actually clock ticks and not symbol times. Note: This value is not used at Gen3 speed; the skip interval is hardcoded to 370 blocks. Note: This register field is sticky.
EIDLE_TIMER	14:11	rw	**EIDLE_TIMER is an internally reserved field** Do not use. Note: This register field is sticky.
DISABLE_FC_WD_TIMER	15	rw	**Disable FC Watchdog Timer** Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable

(table continues...)

(continued)

Field	Bits	Type	Description
MASK_RADM_1	31:16	rw	**Filter Mask 1** The Filter Mask 1 Register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule. • [31]: CX_FLT_MASK_RC_CFG_DISCARD - 0: For RADM RC filter to not allow CFG transaction being received - 1: For RADM RC filter to allow CFG transaction being received • [30]: CX_FLT_MASK_RC_IO_DISCARD - 0: For RADM RC filter to not allow IO transaction being received - 1: For RADM RC filter to allow IO transaction being received • [29]: CX_FLT_MASK_MSG_DROP - 0: Drop MSG TLP (except for Vendor MSG). Send decoded message on the SII - 1: Do not Drop MSG (except for Vendor MSG). Send message TLPs to your application on TRGT1 and send decoded message on the SII - The default for this bit is the inverse of FLT_DROP_MSG. That is, if FLT_DROP_MSG =1, then the default of this bit is '0' (drop message TLPs). This bit only controls message TLPs other than Vendor MSGs. Vendor MSGs are controlled by Filter Mask Register 2, bits [1:0]. The controller never passes ATS Invalidate messages to the SII interface regardless of this filter rule setting. The controller passes all ATS Invalidate messages to TRGT1 (or AXI bridge master), as they are too big for the SII • [28]: CX_FLT_MASK_CPL_ECRC_DISCARD - Only used when completion queue is advertised with infinite credits and is in store-and-forward mode. - 0: Discard completions with ECRC errors - 1: Allow completions with ECRC errors to be passed up - Reserved field for SW • [27]: CX_FLT_MASK_ECRC_DISCARD - 0: Discard TLPs with ECRC errors - 1: Allow TLPs with ECRC errors to be passed up • [26]: CX_FLT_MASK_CPL_LEN_MATCH - 0: Enforce length match for completions; a violation results in cpl_abort, and possibly AER of unexp_cpl_err - 1: Mask length match for completions • [25]: CX_FLT_MASK_CPL_ATTR_MATCH - 0: Enforce attribute match for completions; a violation results in a malformed TLP error, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask attribute match for completions • [24]: CX_FLT_MASK_CPL_TC_MATCH - 0: Enforce Traffic Class match for completions; a violation results in a malformed TLP error, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask Traffic Class match for completions • [23]: CX_FLT_MASK_CPL_FUNC_MATCH - 0: Enforce function match for completions; a violation results in cpl_abort, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask function match for completions • [22]: CX_FLT_MASK_CPL_REQID_MATCH - 0: Enforce Req. Id match for completions; a violation result in cpl_abort, and possibly AER of

(table continues...)

(continued)

Field	Bits	Type	Description
			unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask Req. Id match for completions • [21]: CX_FLT_MASK_CPL_TAGERR_MATCH - 0: Enforce Tag Error Rules for completions; a violation result in cpl_abort, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask Tag Error Rules for completions • [20]: CX_FLT_MASK_LOCKED_RD_AS_UR - 0: Treat locked Read TLPs as UR for EP; Supported for RC - 1: Treat locked Read TLPs as Supported for EP; UR for RC • [19]: CX_FLT_MASK_CFG_TYPE1_REQ_AS_UR - 0: Treat CFG type1 TLPs as UR for EP; Supported for RC - 1: Treat CFG type1 TLPs as Supported for EP; UR for RC • [18]: CX_FLT_MASK_UR_OUTSIDE_BAR - 0: Treat out-of-bar TLPs as UR - 1: Do not treat out-of-bar TLPs as UR • [17]: CX_FLT_MASK_UR_POIS - 0: Treat poisoned request TLPs as UR - 1: Do not treat poisoned request TLPs as UR - The native controller always passes poisoned completions to your application except when you are using the DMA read channel • [16]: CX_FLT_MASK_UR_FUNC_MISMATCH - 0: Treat Function MisMatched TLPs as UR - 1: Do not treat Function MisMatched TLPs as UR. CX_FLT_MASK_UR_FUNC_MISMATCH is not allowed to be set unless CONFIG_LIMIT_REG =0 and TARGET_ABOVE_CONFIG_LIMIT_REG =2 in MISC_CONTROL_1_OFF register or CFG_TLP_BYPASS_EN_REG =1 and TARGET_ABOVE_CONFIG_LIMIT_REG =2 in MISC_CONTROL_1_OFF register Note: This register field is sticky.

19.4.2.242 Filter Mask 2 Register

This register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule.

FILTER_MASK_2_OFF Offset address: 0004720_H

Filter Mask 2 Register Kernel Reset value: $0000\ 0000_H$

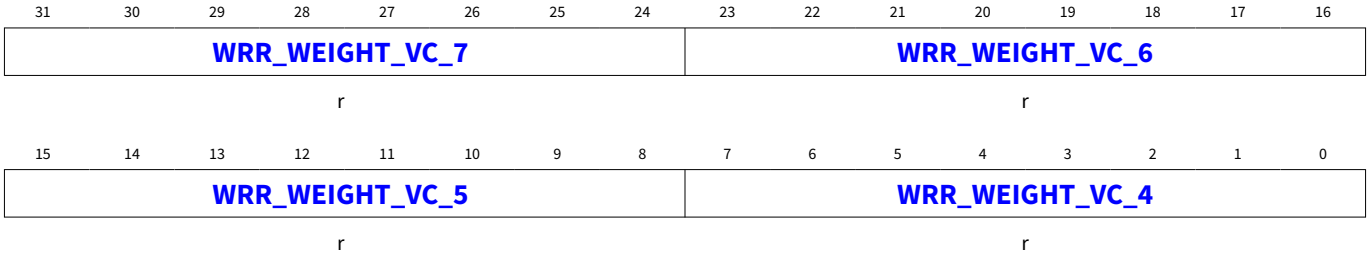
WRR_WEIGHT_VC_3	31:24	r	**WRR Weight for VC3** Note: The access attributes of this field are as follows: - Wire: R - Dbi: R

19.4.2.251 VC Transmit Arbitration Register 2

This register is used for setting the WRR weights for VC4 - VC7.



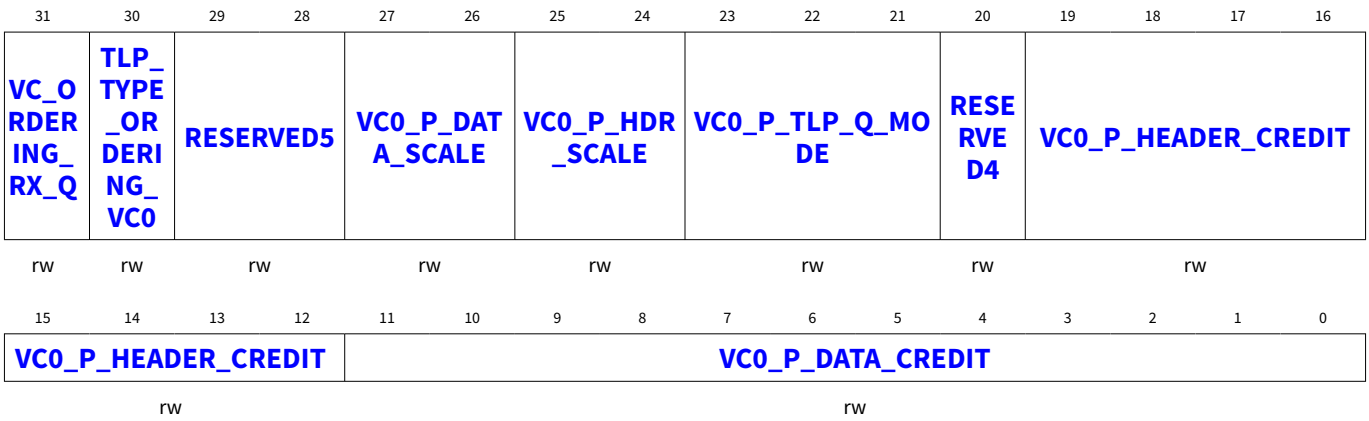
Field	Bits	Type	Description
WRR_WEIGHT_VC_4	7:0	r	**WRR Weight for VC4** Note: The access attributes of this field are as follows: - Wire: R - Dbi: R
WRR_WEIGHT_VC_5	15:8	r	**WRR Weight for VC5** Note: The access attributes of this field are as follows: - Wire: R - Dbi: R
WRR_WEIGHT_VC_6	23:16	r	**WRR Weight for VC6** Note: The access attributes of this field are as follows: - Wire: R - Dbi: R
WRR_WEIGHT_VC_7	31:24	r	**WRR Weight for VC7** Note: The access attributes of this field are as follows: - Wire: R - Dbi: R

19.4.2.252 Segmented-Buffer VC0 Posted Receive Queue Control

This register controls segmented-buffer VC0 posted receive queue operation.

VC0_P_RX_Q_CTRL_OFF Offset address: 0004748_H

Segmented-Buffer VC0 Posted Receive Queue Control Kernel Reset value: $C522\ 2050_H$



Field	Bits	Type	Description
VC0_P_DATA_CREDIT	11:0	rw	**VC0 Posted Data Credits** The number of initial posted data credits for VC0, used only in the segmented-buffer configuration. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: R (sticky) Note: This register field is sticky. 000_H **MIN_VAL**: Zero value FFF_H **MAX_VAL**: Max value
VC0_P_HEADER_CREDIT	19:12	rw	**VC0 Posted Header Credits** The number of initial posted header credits for VC0, used only in the segmented-buffer configuration. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: R (sticky) Note: This register field is sticky. 00_H **MIN_VAL**: Zero value FF_H **MAX_VAL**: Max value
RESERVED4	20	rw	**Reserved** Note: This register field is sticky.
VC0_P_TLP_Q_MODE	23:21	rw	**Reserved** Note: This register field is sticky.
VC0_P_HDR_SCALE	25:24	rw	**VC0 Scale Posted Header Credits** Note: This register field is sticky. 00_B **MIN_VAL**: Zero value 11_B **MAX_VAL**: Max value
VC0_P_DATA_SCALE	27:26	rw	**VC0 Scale Posted Data Credits** Note: This register field is sticky. 00_B **MIN_VAL**: Zero value 11_B **MAX_VAL**: Max value
RESERVED5	29:28	rw	**Reserved** Note: This register field is sticky.
TLP_TYPE_ORDERING_VC0	30	rw	**TLP Type Ordering for VC0** Determines the TLP type ordering rule for VC0 receive queues, used only in the segmented-buffer configuration: Note: This register field is sticky. 0_B **STRICT_ORDERING**: Strict ordering: posted, completion, then non-posted 1_B **PCIE_ORDERING_RULE**: PCIe ordering rules (recommended)
VC_ORDERING_RX_Q	31	rw	**VC Ordering for Receive Queues** Determines the VC ordering rule for the receive queues, used only in the segmented-buffer configuration: Note: This register field is sticky. 0_B **ROUND_ROBIN**: Round robin 1_B **STRICT_ORDERING**: Strict ordering, higher numbered VCs have higher priority

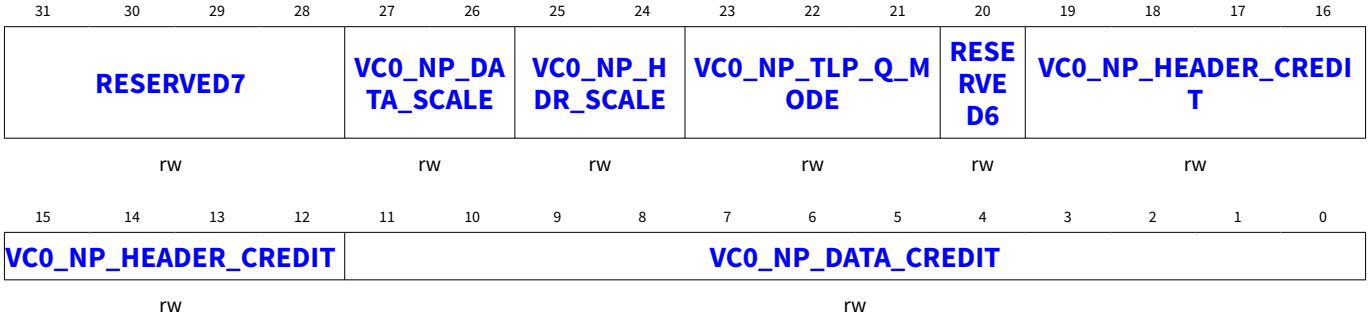
19.4.2.253 Segmented-Buffer VC0 Non-Posted Receive Queue Control

This register controls the segmented-buffer VC0 non-posted receive queue operation.

VC0_NP_RX_Q_CTRL_OFF Offset address: $000474C_H$

Segmented-Buffer VC0 Non-Posted Receive Queue Control

Kernel Reset value: $0522\ 2008_H$



Field	Bits	Type	Description
VC0_NP_DATA_CREDIT	11:0	rw	**VC0 Non-Posted Data Credits** The number of initial non-posted data credits for VC0, used only in the segmented-buffer configuration. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: R (sticky) Note: This register field is sticky. 000_H **MIN_VAL**: Zero value FFF_H **MAX_VAL**: Max value
VC0_NP_HEADER_CREDIT	19:12	rw	**VC0 Non-Posted Header Credits** The number of initial non-posted header credits for VC0, used only in the segmented-buffer configuration. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: R (sticky) Note: This register field is sticky. 00_H **MIN_VAL**: Zero value FF_H **MAX_VAL**: Max value

RESERVED7	31:28	rw	**Reserved** Note: This register field is sticky.

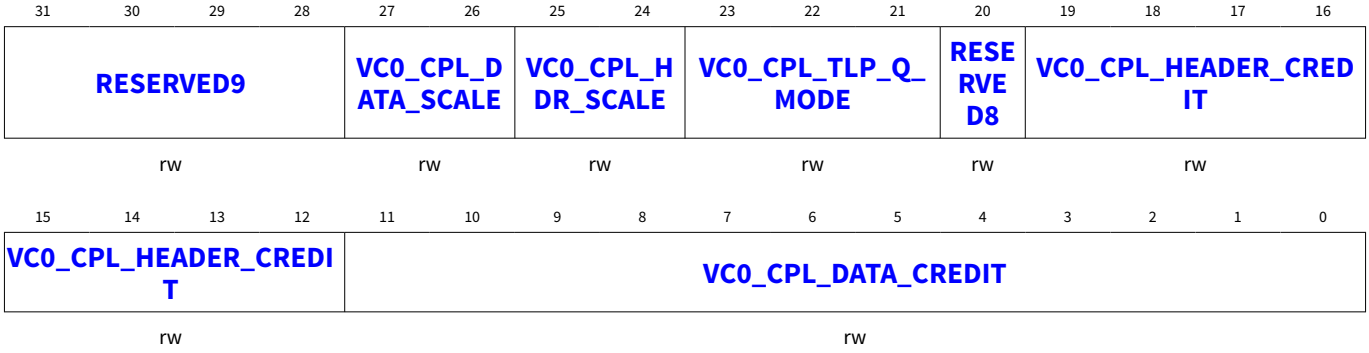
19.4.2.254 Segmented-Buffer VC0 Completion Receive Queue Control

This register controls the segmented-buffer VC0 completion receive queue operation.

VC0_CPL_RX_Q_CTRL_OFF Offset address: 0004750_H

Segmented-Buffer VC0 Completion Receive Queue Control

Kernel Reset value: $0520\ 0000_H$



Field	Bits	Type	Description
VC0_CPL_DATA_CREDIT	11:0	rw	**VC0 Completion Data Credits** The number of initial Completion data credits for VC0, used only in the segmented-buffer configuration. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: R (sticky) Note: This register field is sticky. 000_H **MIN_VAL**: Zero value FFF_H **MAX_VAL**: Max value
VC0_CPL_HEADER_CREDIT	19:12	rw	**VC0 Completion Header Credits** The number of initial Completion header credits for VC0, used only in the segmented-buffer configuration. Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: R (sticky) Note: This register field is sticky. 00_H **MIN_VAL**: Zero value FF_H **MAX_VAL**: Max value
RESERVED8	20	rw	**Reserved** Note: This register field is sticky.

VC0_CPL_HDR_SCALE	25:24	rw	**VC0 Scale CPL Header Credits** Note: This register field is sticky. 00_B **MIN_VAL**: Zero value 11_B **MAX_VAL**: Max value
VC0_CPL_DATA_SCALE	27:26	rw	**VC0 Scale CPL Data Credits** Note: This register field is sticky. 00_B **MIN_VAL**: Zero value 11_B **MAX_VAL**: Max value
RESERVED9	31:28	rw	**Reserved** Note: This register field is sticky.

19.4.2.255 Link Width and Speed Change Control Register

This register controls various functions of the controller related to link training, lane reversal, and equalization.

GEN2_CTRL_OFF Offset address: 000480C$_H$

Link Width and Speed Change Control Register Kernel Reset value: 0002 01B4$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								SELECTABLE_DEEMPH_BIT_MUX	SELECT_DEEMPH_VAR_MUX	GEN1_EI_INFERENCE	SEL_DEEMPHASIS	CONFIG_TX_COMP_RX	Res	DIRECT_SPEED_CHANGE	AUTO_LANE_FLIP_CTRL_EN
r								rw	rw	rw	rw	rw	r	rwh	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PRE_DET_LANE			NUM_OF_LANES					FAST_TRAINING_SEQ							
rw			rw					rw							

Field	Bits	Type	Description
FAST_TRAINING_SEQ	7:0	rw	**Sets the Number of Fast Training Sequences (N_FTS) that the controller advertises as its N_FTS during Gen2 or Gen3 link training** This value is used to inform the link partner about the PHY's ability to recover synchronization after a low power state. Do not set N_FTS to zero; doing so can cause the LTSSM to go into the recovery state when exiting from L0s. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky.
NUM_OF_LANES	12:8	rw	**Predetermined Number of Lanes** Defines the number of lanes which are connected and not bad. Used to limit the effective link width to ignore 'broken" or "unused" lanes that detect a receiver. Indicates the number of lanes to check for exit from Electrical Idle in Polling.Active and L2.Idle. It is possible that the LTSSM might detect a receiver on a bad or broken lane during the Detect Substate. However, it is also possible that such a lane might also fail to exit Electrical Idle and therefore prevent a valid link from being configured. This value is referred to as the "Predetermined Number of Lanes" in section 4.2.6.2.1 of the PCI Express Base Specification. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 01_H **_1_LANE**: 1 lane 02_H **_2_LANE**: 2 lanes 03_H **_3_LANE**: 3 lanes **others,** Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
PRE_DET_LANE	15:13	rw	**Predetermined Lane for Auto Flip** This field defines which physical lane is connected to logical Lane0 by the flip operation performed in Detect. This field is used to restrict the receiver detect procedure to a particular lane when the default detect and polling procedure performed on all lanes cannot be successful. A notable example of when it is useful to program this field to a value different from the default, is when a lane is asymmetrically broken, that is, it is detected in Detect LTSSM state but it cannot exit Electrical Idle in Polling LTSSM state. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 000_B **LANE0**: Connect logical Lane0 to physical lane 0, depending on which lane is detected 001_B **LANE1**: Connect logical Lane0 to physical lane 1 010_B **LANE3**: Connect logical Lane0 to physical lane 3 011_B **LANE7**: connect logical lane0 to physical lane 7 100_B **LANE15**: Connect logical Lane0 to physical lane 15 **others,** Reserved
AUTO_LANE_FLIP_CTRL_EN	16	rw	**Enable Auto flipping of the lanes** This feature is not supported by hardware. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
DIRECT_SPEED_CHANGE	17	rwh	**Directed Speed Change** When the speed change occurs, the controller will clear the contents of this field; and a read to this field by your software will return a '0'. To manually initiate the speed change: • Write to LINK_CONTROL2_LINK_STATUS2_REG.PCIE_CAP_TARGET_LINK_SPEED in the local device • Deassert this field • Assert this field If you set the default of this field using the DEFAULT_GEN2_SPEED_CHANGE configuration parameter to '1', then the speed change is initiated automatically after link up, and the controller clears the contents of this field. If you want to prevent this automatic speed change, then write a lower speed value to the Target Link Speed field of the Link Control 2 register (LINK_CONTROL2_LINK_STATUS2_OFF.PCIE_CAP_TARGET_LINK_SPEED) through the DBI before link up. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_B **CLEAR**: Clear 1_B **SET**: Writing '1' to this field instructs the LTSSM to initiate a speed change to Gen2 or Gen3 after the link is initialized at Gen1 speed

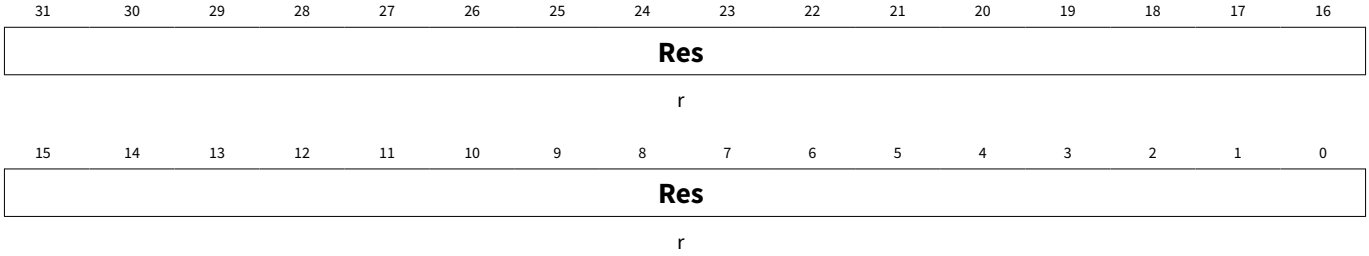
(table continues...)

(continued)

Field	Bits	Type	Description
CONFIG_TX_COMP_RX	19	rw	**Config Tx Compliance Receive Bit** Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: When set to 1, signals LTSSM to transmit TS ordered sets with the compliance receive bit assert (equal to '1')
SEL_DEEMPHASIS	20	rw	**Used to set the de-emphasis level for upstream ports** This bit selects the level of de-emphasis the link operates at. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **N_6DB**: -6 dB 1_B **N_3_5DB**: -3.5 dB
GEN1_EI_INFERENCE	21	rw	**Electrical Idle Inference Mode at Gen1 Rate** Programmable mode to determine inferred electrical idle (EI) in Recovery.Speed or Loopback.Active (as slave) state at Gen1 speed by looking for a '1' value on RxElecIdle instead of looking for a '0' on RxValid. If the PHY fails to deassert the RxValid signal in Recovery.Speed or Loopback.Active (because of corrupted EIOS for example), then EI cannot be inferred successfully in the controller by just detecting the condition RxValid=0. Note: This register field is sticky. 0_B **RXELECIDLE_TO_INFER**: Use RxElecIdle signal to infer Electrical Idle 1_B **RXVALID_TO_INFER**: Use RxValid signal to infer Electrical Idle
SELECT_DEEMPH_VAR_MUX	22	rw	**The select_deemphasis variable for DSP on entry to Recovery.RcvrCfg state is muxed between the Selectable De-emphasis field in the Link Control 2 register and the value requested by the Upstream Port in the eight consecutive TS1 Ordered Sets it received** Note: This register field is sticky. 0_B **REQUESTED_BY_USP**: The value requested by USP in Recovery.RcvrLock state through Tx TS1s from USP 1_B **FROM_LINK_CTRL_2_REG**: The value from the Selectable De-emphasis field in the Link Control 2 register
SELECTABLE_DEEMPH_BIT_MUX	23	rw	**The selectable deemphasis bit (Symbol 4 bit 6) of the transmitted TS2 Ordered Sets for DSP in Recovery.RcvrCfg state is muxed between the Selectable De-emphasis field in the Link Control 2 register and the value requested by USP in Recovery.RcvrLock state through Tx TS1s from USP** Note: This register field is sticky. 0_B **FROM_LINK_CTRL_2_REG**: The value from the Selectable De-emphasis field in the Link Control 2 register 1_B **REQUESTED_BY_USP**: The value requested by USP in Recovery.RcvrLock state through Tx TS1s from USP
0	31:24	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.256 PHY Status Register

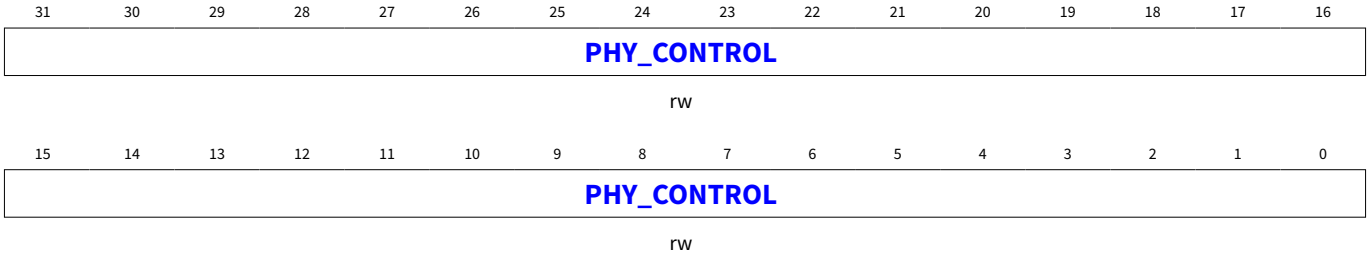
Memory mapped register from phy_cfg_status GPIO input pins.



Field	Bits	Type	Description

19.4.2.257 PHY Control Register

Memory mapped register to cfg_phy_control GPIO output pins.



Field	Bits	Type	Description
PHY_CONTROL	31:0	rw	**PHY Control** Data sent directly to the cfg_phy_control bus. This is a GPIO register driving the values on the static cfg_phy_control output signals, and does not in any way influence controller functionality. It can be used for any static sideband control signaling requirements that you have for your PHY. Usage of this register and the associated GPIO bus is RESERVED when the controller is connected to a Synopsys PHY. Note: This register field is sticky. 00000000_H **MIN_VAL**: Zero value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.258 Programmable Target Map Control Register

This register controls the target map.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TARGET_MAP_RESERVED_21_31											TARGET_MAP_INDEX

TARGET_MAP_RESERVED_13_15			0						TARGET_MAP_ROM	TARGET_MAP_PF					
r			r						rwh	rwh					

Field	Bits	Type	Description
TARGET_MAP_PF	5:0	rwh	**Target Values for each BAR on the PF Function selected by the index number** This register does not respect the Byte Enable setting, any write will affect all register bits.
TARGET_MAP_ROM	6	rwh	**Target Value for the ROM page of the PF Function selected by the index number** This register does not respect the Byte Enable setting, any write will affect all register bits.
TARGET_MAP_RESERVED_13_15	15:13	r	**Reserved** Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: R (sticky)
TARGET_MAP_INDEX	20:16	rwh	**The number of the PF Function on which the Target Values are set** This register does not respect the Byte Enable setting, any write will affect all register bits.
TARGET_MAP_RESERVED_21_31	31:21	r	**Reserved** Note: The access attributes of this field are as follows: - Wire: RSVDP - Dbi: R (sticky)
0	12:7	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.259 Integrated MSI Reception Module (iMRM) Address Register

This register holds the integrated MSI reception module address.

MSI_CTRL_ADDR_OFF Offset address: 0004820_H

Integrated MSI Reception Module [iMRM) Address Register

Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSI_CTRL_ADDR															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSI_CTRL_ADDR															
rw															

Field	Bits	Type	Description
MSI_CTRL_ADDR	31:0	rw	**Integrated MSI Reception Module Address** System specified address for MSI memory write transaction termination. Within the AXI Bridge, every received Memory Write request is examined to see if it targets the MSI Address that has been specified in this register; and also to see if it satisfies the definition of an MSI interrupt request. When these conditions are satisfied the Memory Write request is marked as an MSI request. Note: This register field is sticky. 00000000_H **MIN_VAL**: Zero value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.260 Integrated MSI Reception Module Upper Address Register

This register holds the integrated MSI reception module upper address.

MSI_CTRL_UPPER_ADDR_OFF Offset address: 0004824_H

Integrated MSI Reception Module Upper Address Register — Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSI_CTRL_UPPER_ADDR															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSI_CTRL_UPPER_ADDR															
rw															

Field	Bits	Type	Description
MSI_CTRL_UPPER_ADDR	31:0	rw	**Integrated MSI Reception Module Upper Address** System specified upper address for MSI memory write transaction termination. Allows functions to support a 64-bit MSI address. Note: This register field is sticky. 00000000_H **MIN_VAL**: Zero value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.261 Integrated MSI i Reception Module Interrupt0 Enable Register

This register enables integrated MSI reception module interrupt0.

MSI_CTRL_INT_i_EN_OFF (i=0-7) Offset address: 0004828_H+i*12

Integrated MSI i Reception Module Interrupt0 Enable Register — Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSI_CTRL_INT_0_EN															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSI_CTRL_INT_0_EN															
rw															

Field	Bits	Type	Description
MSI_CTRL_INT_0_EN	31:0	rw	**MSI Interrupt0 Enable** Specifies which interrupts are enabled. When an MSI is received from a disabled interrupt, no status bit gets set in MSI controller interrupt status register. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky. 00000000_H **MIN_VAL**: Zero value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.262 Integrated MSI i Reception Module Interrupt0 Mask Register

This register provides information regarding the MSI Interrupt0 mask.

MSI_CTRL_INT_i_MASK_OFF (i=0-7) Offset address: $000482C_H$+i*12

Integrated MSI i Reception Module Interrupt0 Mask Register — Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSI_CTRL_INT_0_MASK															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSI_CTRL_INT_0_MASK															
rw															

Field	Bits	Type	Description
MSI_CTRL_INT_0_MASK	31:0	rw	**MSI Interrupt0 Mask** Allows enabled interrupts to be masked. When an MSI is received for a masked interrupt, the corresponding status bit gets set in the interrupt status register but the msi_ctrl_int output is not set HIGH. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

19.4.2.263 Integrated MSI i Reception Module Interrupt0 Status Register

This register provides the MSI Interrupt0 status.

MSI_CTRL_INT_i_STATUS_OFF (i=0-7) Offset address: 0004830_H+i*12

Integrated MSI i Reception Module Interrupt0 Status Register — Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSI_CTRL_INT_0_STATUS															
rw1ch															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSI_CTRL_INT_0_STATUS															
rw1ch															

Field	Bits	Type	Description
MSI_CTRL_INT_0_STATUS	31:0	rw1ch	**MSI Interrupt0 Status** When an MSI is detected for EP#i, one bit in this register is set. The decoding of the data payload of the MSI Memory Write request determines which bit gets set. Each bit corresponds to a single MSI Interrupt Vector. Software write with 1 clears this bit-field. 00000000_H **MIN_VAL**: Zero value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.264 Integrated MSI Reception Module General Purpose IO Register

The contents of this register drive the top-level GPIO msi_ctrl_io[31:0].

MSI_GPIO_IO_OFF Offset address: 0004888_H

Integrated MSI Reception Module General Purpose IO Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSI_GPIO_REG															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSI_GPIO_REG															
rw															

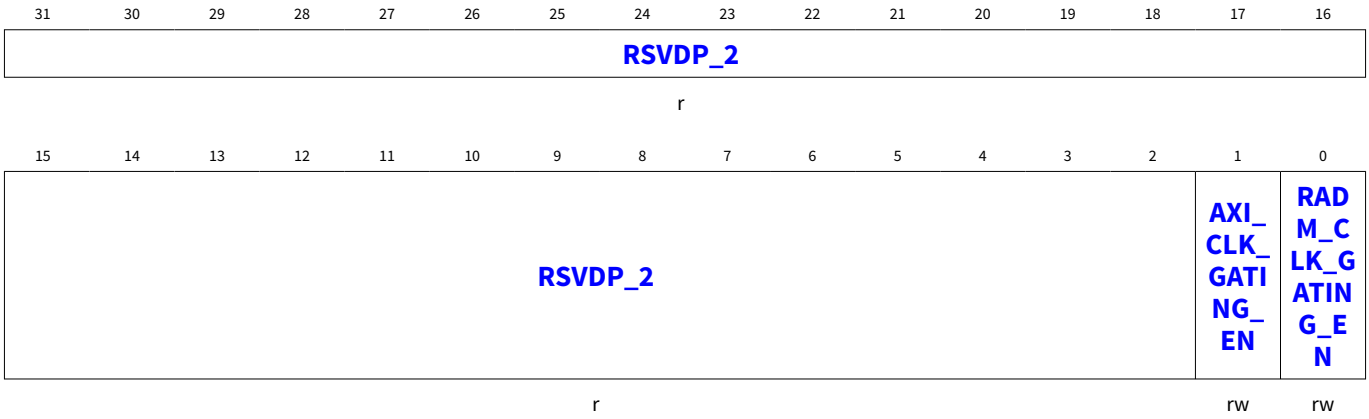
Field	Bits	Type	Description
MSI_GPIO_REG	31:0	rw	**MSI GPIO Register** The contents of this register drive the top-level GPIO msi_ctrl_io[31:0]. Note: This register field is sticky. 00000000_H **MIN_VAL**: Zero value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.265 Clock Gating Control Register

This register enables you to disable dynamic clock gating. By default dynamic clock gating is on, allowing the controller to autonomously enable and disable its clocks. The clock gating is performed in the clock and reset module, and is initiated by the controllers clock enable signals. The following modules support dynamic clock gating: - AXI Bridge - RADM

CLOCK_GATING_CTRL_OFF Offset address: $000488C_H$

Clock Gating Control Register Kernel Reset value: $0000\ 0003_H$



Field	Bits	Type	Description
RADM_CLK_GATING_EN	0	rw	**RADM Clock Gating Enable** This register, if set, enables the RADM to autonomously enable and disable its clock. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable (default)
AXI_CLK_GATING_EN	1	rw	**AXI Clock Gating Enable** This register enables the AXI Bridge to autonomously enable and disable the AXI Master clock, the AXI Slave clock and the AXI DBI slave clock. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable (default)
RSVDP_2	31:2	r	**Reserved for future use**

19.4.2.266 Gen3 Control Register

There is no Gen3-specific N_FTS field. The N_FTS field in the "Link Width and Speed Change Control Register" is used for both Gen2 and Gen3 speed modes. There is no Gen3-specific "Directed Speed Change" field. The "Directed Speed Change" field in the "Link Width and Speed Change Control Register" is used to change to Gen2 or Gen3 speed. A speed change to Gen3 occurs if (1) the "Directed Speed Change" field is set to '1' and (2) the "Target Link Speed" field in the Link Control 2 Register is set to Gen3. Gen3 support is advertised by both sides of the link during link training.

GEN3_RELATED_OFF Offset address: 0004890_H

Gen3 Control Register Kernel Reset value: $0000\ 2001_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSVDP_26						0		GEN3_EQ_INVREQ_EVAL_DIFF_DISABLE	0		RSVDP_19		GEN3_DC_BALANCE_DISABLE	GEN3_DLLP_XMT_DELAY_DISABLE	GEN3_EQUALIZATION_DISABLE
r						r		rw	r		r		rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVDP_14		RXEQ_RGRDLESS_RXTS	RXEQ_PH01_EN	EQ_REDO	EQ_EIEOS_CNT	EQ_PHASE_2_3	DISABLE_SCRAMBLER_GEN_3	RSVDP_2						NO_SEED_VALUE_CHANGE	GEN3_ZRXDC_NONCOMPL
r		rw	rw	rw	rw	rw	rw	r						rw	rw

Field	Bits	Type	Description
GEN3_ZRXDC_NONCOMPL	0	rw	**Gen3 Receiver Impedance ZRX-DC Not Compliant** Receivers that operate at 8.0 GT/s with an impedance other than the range defined by the ZRX-DC parameter for 2.5 GT/s (40-60 Ohms) must meet additional behavior requirements in the following LTSSM states: Polling, Rx_L0s, L1, L2, and Disabled. Note: This register field is sticky. 0_B **RCVR_COMPLIES**: The receiver complies with the ZRX-DC parameter for 2.5 GT/s when operating at 8 GT/s or higher 1_B **RCVR_NOT_COMPLIES**: The receiver does not comply with the ZRX-DC parameter for 2.5 GT/s when operating at 8 GT/s or higher
NO_SEED_VALUE_CHANGE	1	rw	**If this bit is set to 1, the seed value of LFSR for scrambler at Gen3 rate does not change after LinkUp = 1** This feature is not supported. Note: this register is shared for Gen3 and Gen4/Gen5 data rates. Note: This register field is sticky. 1_B **NO_CHANGE**: Not Change
RSVDP_2	7:2	r	**Reserved for future use**
DISABLE_SCRAMBLER_GEN_3	8	rw	**Disable Scrambler for Gen3 and Gen4 Data Rate** The Gen3 and Gen4 scrambler/descrambler within the controller needs to be disabled when the scrambling function is implemented outside of the controller (for example within the PHY). Note: This register field is sticky.
EQ_PHASE_2_3	9	rw	**Equalization Phase 2 and Phase 3 Disable** This applies to downstream ports only. Note: The access attributes of this field are as follows: - Wire: see description - Dbi: see description Note: This register field is sticky. 0_B **NO_TX_EQ_RX_EQ_PH01**: Rx equalization in phase 0/1 1_B **TX_EQ_23_RX_EQ_PH01**: No Rx equalization

(table continues...)

(continued)

Field	Bits	Type	Description
EQ_EIEOS_CNT	10	rw	**Equalization EIEOS Count Reset Disable** Disable requesting reset of EIEOS count during equalization. Note: This register field is sticky. 1_B **DISABLE**: Disable
EQ_REDO	11	rw	**Equalization Redo Disable** Disable autonomous mechanism for requesting to redo the equalization process. The received presets or coefficients mismatch in Recovery.RcvrLock after Recovery EQ phases causes the EQ redo requests. If the EQ redo is infinite or you do not want eq requests and redo, setting this bit to 1 will stop the EQ requests and EQ redo so that the link can go ahead to L0 state for packet trasmissions. Note: This register field is sticky.
RXEQ_PH01_EN	12	rw	**Rx Equalization Phase 0/Phase 1 Hold Enable** When this bit is set the upstream port holds phase 0 (the downstream port holds phase 1) for 10ms. Holding phase 0 or phase 1 can be used to allow sufficient time for Rx Equalization to be performed by the PHY. This bit is used during Virtex-7 Gen3 equalization. The programmable bits [RXEQ_PH01_EN, EQ_PHASE_2_3] can be used to obtain the following variations of the equalization procedure: Note: The access attributes of this field are as follows: - Wire: see description - Dbi: see description Note: This register field is sticky. 0_B **TX_EQ_23**: Tx equalization only in phase 2/3 1_B **NO_TX_EQ_NO_RX_EQ**: No Tx equalization
RXEQ_RGRDLESS_RXTS	13	rw	**When set to '1', the controller as Gen3 EQ master asserts RxEqEval to instruct the PHY to do Rx adaptation and evaluation after a 500ns timeout from a new preset request** . Note: The access attributes of this field are as follows: - Wire: see description - Dbi: see description Note: This register field is sticky. 0_B **ASSERT_1US**: mac_phy_rxeqeval asserts after 1 µs and 2 TS1 received from remote partner 1_B **ASSERT_500NS**: mac_phy_rxeqeval asserts after 500ns regardless of TS's received or not
RSVDP_14	15:14	r	**Reserved for future use**
GEN3_EQUALIZATION_DISABLE	16	rw	**Equalization Disable** Disable equalization feature. This bit cannot be changed once the LTSSM starts link training. Note: This register field is sticky.
GEN3_DLLP_XMT_DELAY_DISABLE	17	rw	**DLLP Transmission Delay Disable** Disable delay transmission of DLLPs before equalization. Note: This register field is sticky.
GEN3_DC_BALANCE_DISABLE	18	rw	**DC Balance Disable** Disable DC Balance feature. Note: This register field is sticky.
RSVDP_19	20:19	r	**Reserved for future use**
GEN3_EQ_INVREQ_EVAL_DIFF_DISABLE	23	rw	**Eq InvalidRequest and RxEqEval Different Time Assertion Disable** Disable the assertion of Eq InvalidRequest and RxEqEval at different time. Note: This register field is sticky.

(table continues...)

(continued)

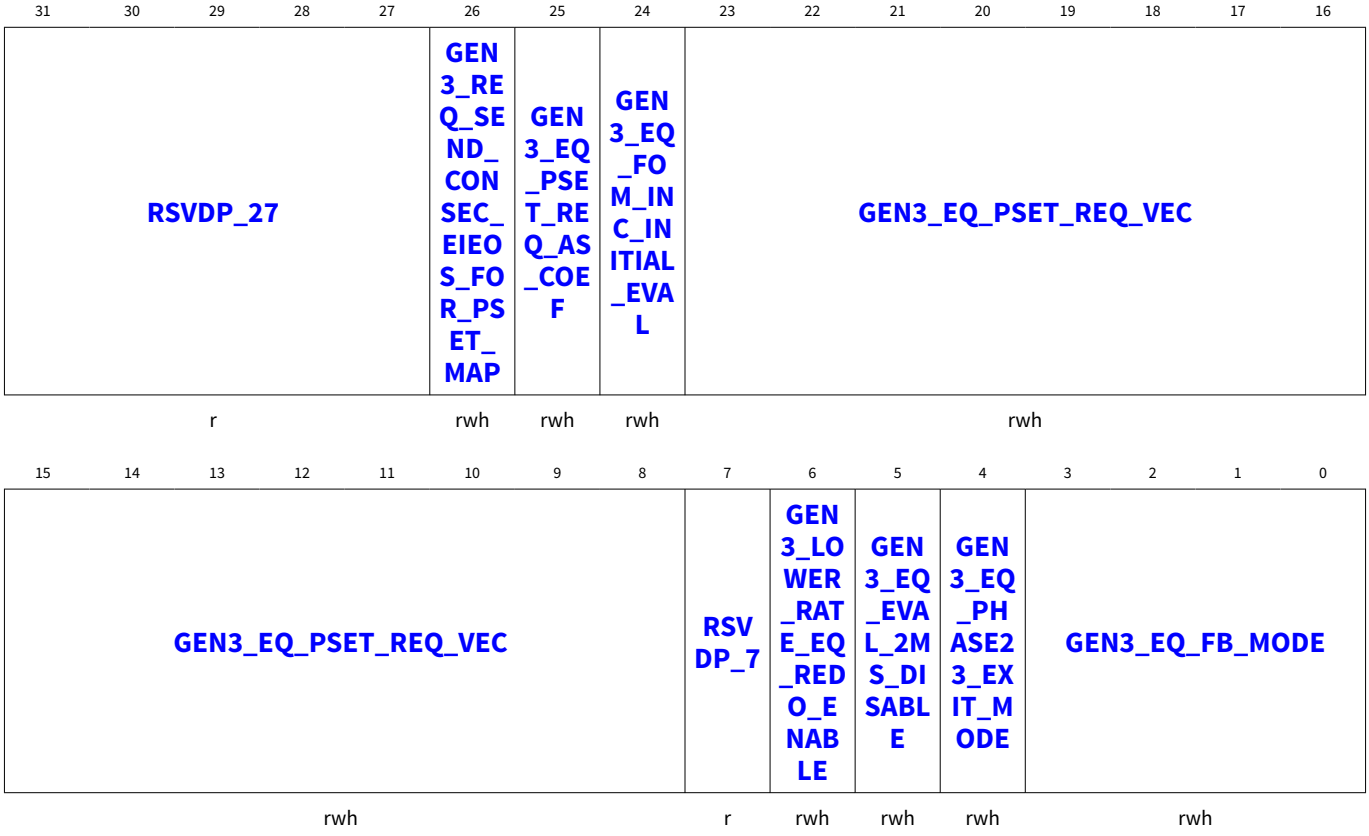
Field	Bits	Type	Description
RSVDP_26	31:26	r	**Reserved for future use**
0	22:21, 25:24	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.267 Gen3 EQ Control Register

This register controls equalization for Phase2 in an upstream port (USP), or Phase3 in a downstream port (DSP).

GEN3_EQ_CONTROL_OFF Offset address: $00048A8_H$

Gen3 EQ Control Register Kernel Reset value: $0501\ 7271_H$



Field	Bits	Type	Description
GEN3_EQ_FB_MODE	3:0	rwh	**Feedback Mode** Other values are reserved. Note: This register field is sticky. 0_H **DIR_CHG**: Direction Change 1_H **FOM**: Figure Of Merit **others,** Reserved

(table continues...)

(continued)

Field	Bits	Type	Description
GEN3_EQ_PHASE23_EXIT_MODE	4	rwh	**Behavior After 24 ms Timeout (when optimal settings are not found)** For a USP: Determine next LTSSM state from Phase2 after 24ms Timeout • 0: Recovery.Speed • 1: Recovery.Equalization.Phase3 When optimal settings are not found then: • Equalization Phase 2 Successful status bit is not set in the "Link Status Register 2" when GEN3_EQ_PHASE23_EXIT_MODE = 0 • Equalization Phase 2 Successful status bit is set in the "Link Status Register 2" when GEN3_EQ_PHASE23_EXIT_MODE = 1 • Equalization Phase 2 Complete status bit is set in the "Link Status Register 2" For a DSP: Determine next LTSSM state from Phase3 after 24ms Timeout • 0: Recovery.Speed • 1: Recovery.Equalization.RcvrLock When optimal settings are not found then: • Equalization Phase 3 Successful status bit is not set in the "Link Status Register 2" when GEN3_EQ_PHASE23_EXIT_MODE = 0 • Equalization Phase 3 Successful status bit is set in the "Link Status Register 2" when GEN3_EQ_PHASE23_EXIT_MODE = 1 • Equalization Phase 3 Complete status bit is set in the "Link Status Register 2" Note: GEN3_EQ_PHASE23_EXIT_MODE = 1 affects Direction Change feed back mode. EQ requests for Figure Of Merit mode complete before 24 ms timeout. Please see GEN3_EQ_PSET_REQ_VEC Register for more. Note: This register field is sticky. 0_B **RCVRY_SPEED**: Recovery.Speed 1_B **RCVRY_EQ**: USP: Recovery.Equalization.Phase3; DSP: Recovery.Equalization.RcvrLock
GEN3_EQ_EVAL_2MS_DISABLE	5	rwh	**Phase2_3 2 ms Timeout Disable** Determine behavior in Phase2 for USP (Phase3 if DSP) when the PHY does not respond within 2ms to the assertion of RxEqEval. Note: This register field is sticky. 0_B **ABORT_CURRENT_EVA**: Abort the current evaluation, stop any attempt to modify the remote transmitter settings, Phase2 is terminated by the 24ms timeout 1_B **IGNORE_2MS_TIMEOUT**: Ignore the 2ms timeout and continue as normal This is used to support PHYs that require more than 2ms to respond to the assertion of RxEqEval.
GEN3_LOWER_RATE_EQ_REDO_ENABLE	6	rwh	**Support EQ redo and lower rate change** To access this field, RATE_SHADOW_SEL should be set to 0. Note: This register field is sticky. 0_B **NO_SUP**: Not supported 1_B **SUP**: Supported
RSVDP_7	7	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
GEN3_EQ_PSET_REQ_VEC	23:8	rwh	**Preset Request Vector** Requesting of Presets during the initial part of the EQ Master Phase. Encoding scheme is as follows: Bit [15:0] =0x0: No preset is requested and evaluated in EQ Master Phase. Bit [i] =1: "Preset=i" is requested and evaluated in EQ Master Phase. • 0000000000000000: No preset be requested and evaluated in EQ Master Phase • 000000xxxxxxxxx1: Preset 0 is requested and evaluated in EQ Master Phase • 000000xxxxxxxx1x: Preset 1 is requested and evaluated in EQ Master Phase • 000000xxxxxxx1xx: Preset 2 is requested and evaluated in EQ Master Phase • 000000xxxxxx1xxx: Preset 3 is requested and evaluated in EQ Master Phase • 000000xxxxx1xxxx: Preset 4 is requested and evaluated in EQ Master Phase • 000000xxxx1xxxxx: Preset 5 is requested and evaluated in EQ Master Phase • 000000xxx1xxxxxx: Preset 6 is requested and evaluated in EQ Master Phase • 000000xx1xxxxxxx: Preset 7 is requested and evaluated in EQ Master Phase • 000000x1xxxxxxxx: Preset 8 is requested and evaluated in EQ Master Phase • 00000x1xxxxxxxxx: Preset 9 is requested and evaluated in EQ Master Phase • 000001xxxxxxxxxx: Preset 10 is requested and evaluated in EQ Master Phase • All other encodings: Reserved Note: This register field is sticky.
GEN3_EQ_FOM_INC_INITIAL_EVAL	24	rwh	**Include Initial FOM** Include or not the FOM feedback from the initial preset evaluation performed in the EQ Master, when finding the highest FOM among all preset evaluations. Note: This register field is sticky. 0_B **DO_NOT_INCLUDE**: Do not include 1_B **INCLUDE**: Include
GEN3_EQ_PSET_REQ_AS_COEF	25	rwh	**GEN3_EQ_PSET_REQ_AS_COEF is an internally reserved field** Do not use. Note: This register field is sticky.

(table continues...)

(continued)

Field	Bits	Type	Description
GEN3_REQ_SEND_CONSEC_EIEOS_FOR_PSET_MAP	26	rwh	**Request controller to send back-to-back EIEOS in Recovery.RcvrLock state until presets to coefficients mapping is complete** Note: Gen3 and Gen4 share the same register bit and have the same feature. Note: This register field is sticky. 0_B **DO_NOT_REQ**: Do not request 1_B **REQ**: Request
RSVDP_27	31:27	r	**Reserved for future use**

19.4.2.268 Gen3 EQ Direction Change Feedback Mode Control Register

Equalization controls to be used in Phase2 (USP) or Phase 3 (DSP), when you set the Feedback Mode in "Gen3 EQ Control Register" to "Direction Change." These fields allow control over the initial starting point for the search of optimal coefficient settings, and allow control over the criteria used to determine when the optimal settings have been achieved. The values are applied to all the lanes.

GEN3_EQ_FB_MODE_DIR_CHANGE_OFF — Offset address: $00048AC_H$

Gen3 EQ Direction Change Feedback Mode Control Register — Kernel Reset value: $0000\ 0040_H$

rw								rw	rw	rw	rw	rw	rw	rw	rwh

Field	Bits	Type	Description
DBI_RO_WR_EN	0	rwh	**Write to RO Registers Using DBI** This bit field protects the access to the registers to avoid intended modifications.. Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Your application can write to some RO and HwInit register fields through the DBI when you set this field to '1'
DEFAULT_TARGET	1	rw	**Default target for an IO or MEM request with UR/CA/CRS received** Based on the value of this field the controller either drops or forwards these requests to your application. Note: This register field is sticky. 0_B **DROP_IO_MEM_REQ**: The controller drops all incoming I/O or MEM requests (after corresponding error reporting) A completion with UR status is generated for non-posted requests. 1_B **FWD_IO_MEM_UR_CA_CRS**: The controller forwards all incoming I/O or MEM requests with UR/CA/CRS status to your application
UR_CA_MASK_4_TRGT1	2	rw	**When this field is set to '1', the controller suppresses error logging, error message generation, and CPL generation for non-posted requests TLPs (with UR filtering status) forwarded to your application (that is, when DEFAULT_TARGET =1)** Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Set

(table continues...)

(continued)

Field	Bits	Type	Description
SIMPLIFIED_REPLAY_TIMER	3	rw	**Enables Simplified Replay Timer (Gen4)** Simplified Replay Timer can have the following Values: • A value from 24,000 to 31,000 Symbol Times when Extended Synch is 0b • A value from 80,000 to 100,000 Symbol Times when Extended Synch is 1b The Simplified Replay Timer value must not be changed while the link is in use. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
DISABLE_AUTO_LTR_CLR_MSG	4	rw	**Disable the autonomous generation of LTR clear message in upstream port** This field can have the following values. Note: This register field is sticky. 0_B **ALLOW**: Allow the autonomous generation of LTR clear message 1_B **DISABLE**: Disable the autonomous generation of LTR clear message
ARI_DEVICE_NUMBER	5	rw	**When ARI is enabled, this field enables use of the device ID** Note: This register field is sticky. ARI capability is not available in this implementation 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
CPLQ_MNG_EN	6	rw	**This field enables the Completion Queue Management feature** Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
CFG_TLP_BYPASS_EN_REG	7	rw	**Setting of this field defines how to decide the destination of Configuration requests** Note: When LNK_CORECTRL.RQRTYEN is asserted, the setting of this field is ignored. Note: This register field is sticky. 0_B **ZERO**: Configuration TLPs are routed according to the setting of TARGET_ABOVE_CONFIG_LIMIT_REG, depending on the setting of CONFIG_LIMIT_REG Refer to the definition of CONFIG_LIMIT_REG for details. 1_B **ONE**: Configuration TLPs are routed according to the setting of TARGET_ABOVE_CONFIG_LIMIT_REG, regardless the value of CONFIG_LIMIT_REG

(table continues...)

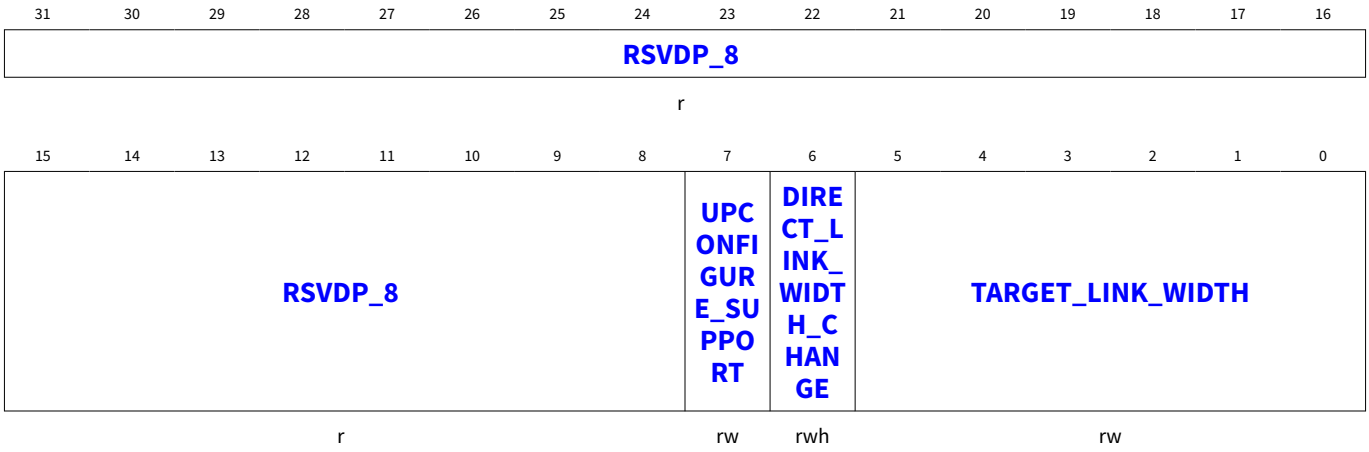
(continued)

Field	Bits	Type	Description
CONFIG_LIMIT_REG	17:8	rw	**Configuration requests are directed either to CDM or ELBI/RTRGT1 based on the value of this field** • Configuration requests with an address less CONFIG_LIMIT_REG are directed to the CDM • Configuration requests with an address greater than CONFIG_LIMIT_REG are directed to either ELBI or TRGT1 interface based on the setting of TARGET_ABOVE_CONFIG_LIMIT_REG field Your application must set a proper value for this field based on your extended configuration registers. Note: This register field is sticky.
TARGET_ABOVE_CONFIG_LIMIT_REG	19:18	rw	**Configuration requests with an address greater than CONFIG_LIMIT_REG are directed to either ELBI or TRGT1 interface based on the setting of this field** This field can have the following values: Note: This register field is sticky. 01_B **ELBI**: ELBI 10_B **TRGT1**: TRGT1 **others,** Reserved
P2P_TRACK_CPL_TO_REG	20	rw	**Determines whether to track completion of transmitted Non-Posted TLPs in P2P mode** Note: This register field is sticky. 0_B **DO_NOT_TRACk**: Do not track completion 1_B **TRACK**: Track completion
P2P_ERR_RPT_CTRL	21	rw	**Determines whether to enable Peer to Peer (P2P) error reporting** Note: This register field is sticky. 0_B **DISABLE**: Disable P2P error reporting 1_B **ENABLE**: Enable P2P error reporting
PORT_LOGIC_WR_DISABLE	22	rw	**Disable port logic register write from wire side** Note: The access attributes of this field are as follows: - Wire: R (sticky) - Dbi: R/W (sticky) Note: This register field is sticky.
RSVDP_23	31:23	r	**Reserved for future use**

19.4.2.272 UpConfigure Multi-lane Control Register

Used when upsizing or downsizing the link width through Configuration state without bringing the link down.

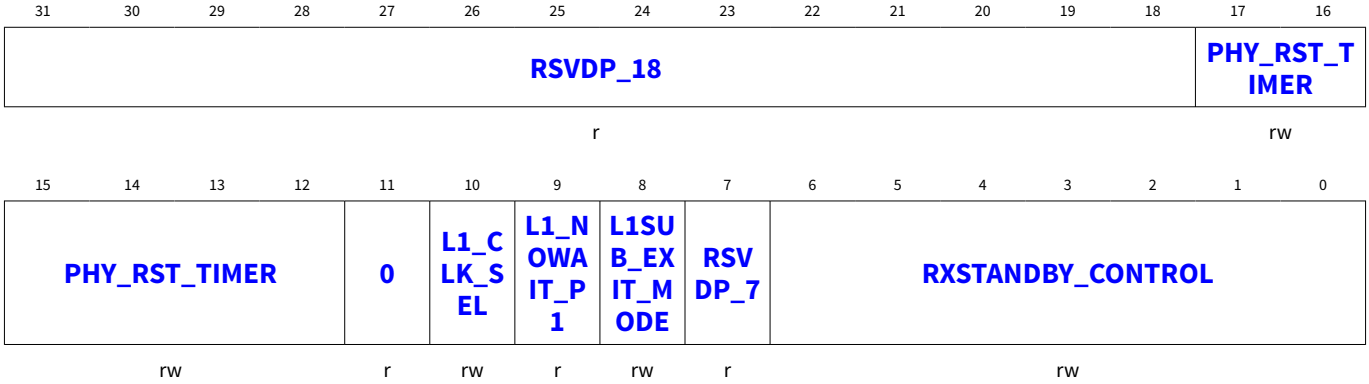
19 Peripheral Component Interconnect Express (PCIe)



Field	Bits	Type	Description
TARGET_LINK_WIDTH	5:0	rw	**Target Link Width** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 00_H **NOT_START**: Controller does not start upconfigure or autonomous width downsizing in the Configuration state 01_H **X1**: x1 02_H **X2**: x2 04_H **X4**: x4 08_H **X8**: x8 10_H **X16**: x16 20_H **X32**: x32 **others,** Reserved
DIRECT_LINK_WIDTH_CHANGE	6	rwh	**Directed Link Width Change** • If the upconfigure_capable variable is '1' and the PCIE_CAP_HW_AUTO_WIDTH_DISABLE bit in LINK_CONTROL_LINK_STATUS_REG is '0', the controller starts upconfigure or autonomous width downsizing (to the TARGET_LINK_WIDTH value) in the Configuration state • If TARGET_LINK_WIDTH value is 0x0, the controller does not start upconfigure or autonomous width downsizing in the Configuration state The controller self-clears this field when the controller accepts this request. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_B **CLEAR**: Clear 1_B **SET**: The controller always moves to Configuration state through Recovery state when this bit is set to '1'
UPCONFIGURE_SUPPORT	7	rw	**Upconfigure Support** The controller sends this value as the Link Upconfigure Capability in TS2 Ordered Sets in Configuration.Complete state. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky.
RSVDP_8	31:8	r	**Reserved for future use**

19.4.2.273 PHY Interoperability Control Register

This register controls the PHY interoperability.



Field	Bits	Type	Description
RXSTANDBY_CONTROL	6:0	rw	**Rxstandby Control** Bits 0..5 determine if the controller asserts the RxStandby signal (mac_phy_rxstandby) in the indicated condition. Bit 6 enables the controller to perform the RxStandby/RxStandbyStatus handshake. This field is reserved for internal use. You should not write to this field and change the default unless specifically instructed by Synopsys support. • [0]: Rx EIOS and subsequent T TX-IDLE-MIN • [1]: Rate Change • [2]: Inactive lane for upconfigure/downconfigure • [3]: PowerDown=P1orP2 • [4]: RxL0s.Idle • [5]: EI Infer in L0 • [6]: Execute RxStandby/RxStandbyStatus Handshake Note: This register field is sticky.
RSVDP_7	7	r	**Reserved for future use**
L1SUB_EXIT_MODE	8	rw	**L1 Exit Control Using phy_mac_pclkack_n** This field is reserved for internal use. You should not write to this field and change the default unless specifically instructed by Synopsys support. If PCLK as PHY input is selected, you should not write to this field and change the default value since PCLK as PHY input doesn't support any value other than the default. Note: This register field is sticky. 0_B **WAIT_FOR_PCLKACK**: Controller waits for the PHY to assert phy_mac_pclkack_n before exiting L1 1_B **NO_WAIT_FOR_PCLKACK**: Controller exits L1 without waiting for the PHY to assert phy_mac_pclkack_n

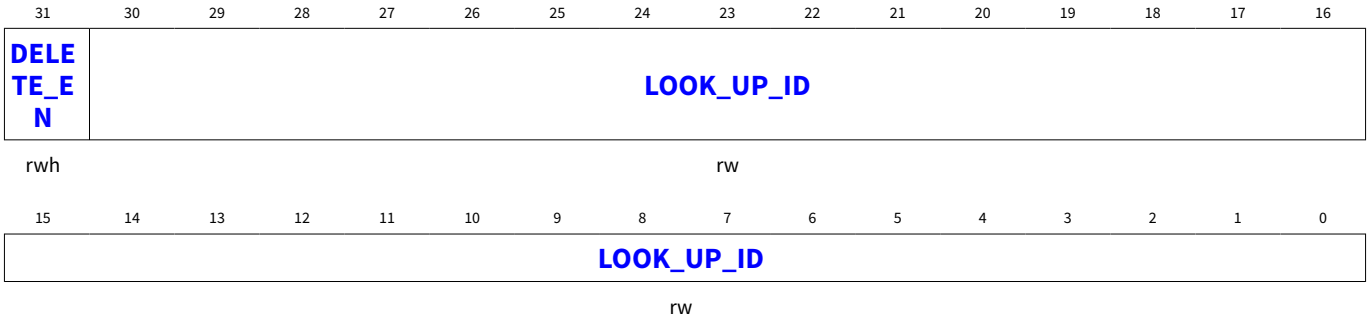
(table continues...)

(continued)

Field	Bits	Type	Description
L1_NOWAIT_P1	9	r	**L1 entry control bit** This field is reserved for internal use. You should not write to this field and change the default unless specifically instructed by Synopsys support. Note: The access attributes of this field are as follows: - Wire: R/W (sticky) - Dbi: R/W (sticky) Note: This register field is sticky. 0_B **WAIT_FOR_ACK**: Controller waits for the PHY to acknowledge transition to P1 before entering L1 1_B **NO_WAIT_FOR_ACK**: Controller does not wait for PHY to acknowledge transition to P1 before entering L1
L1_CLK_SEL	10	rw	**L1 Clock control bit** This field is reserved for internal use. You should not write to this field and change the default unless specifically instructed by Synopsys support. Note: This register field is sticky. 0_B **CAN_REQ**: Controller requests aux_clk switch and core_clk gating in L1 1_B **NO_REQ**: Controller does not request aux_clk switch and core_clk gating in L1
PHY_RST_TIMER	17:12	rw	**Decide how many aux clock cycles the PHY reset lasts (0 to 63 aux clock cycles)** Note: This register field is sticky. 00_H **MIN_VAL**: Zero value $3F_H$ **MAX_VAL**: Max value
RSVDP_18	31:18	r	**Reserved for future use**
0	11	r	**Reserved** Read as 0; should be written with 0.

19.4.2.274 TRGT_CPL_LUT Delete Entry Control register

Using this register you can delete one entry in the target completion LUT. You should only use this register when you know that your application will never send the completion because of an FLR or any other reason. Note:: The target completion LUT (and associated target completion timeout event) is watching for completions (from your application on XALI0/1/2 or AXI master read channel) corresponding to previously received non-posted requests from the PCIe wire.



Field	Bits	Type	Description
LOOK_UP_ID	30:0	rw	**This number selects one entry to delete of the TRGT_CPL_LUT**

(table continues...)

(continued)

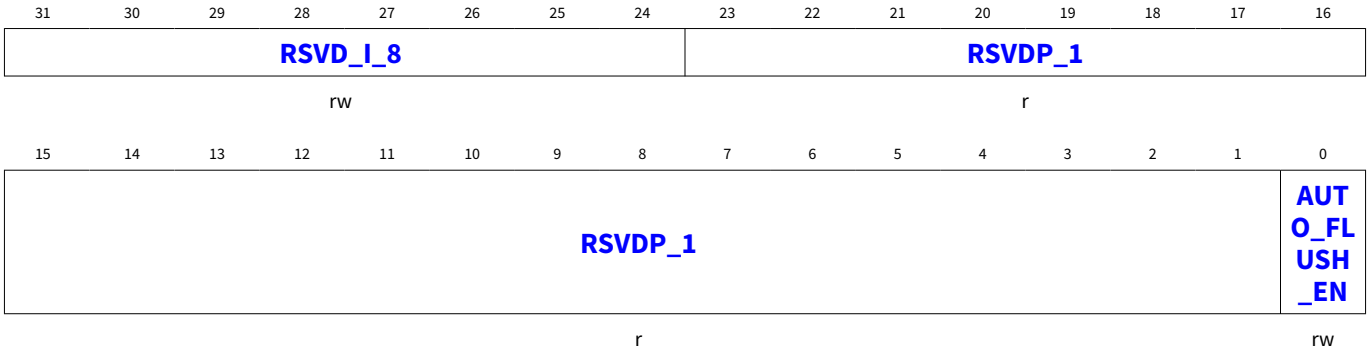
Field	Bits	Type	Description
DELETE_EN	31	rwh	**This is a one-shot bit** This is a self-clearing register field. Reading from this register field always returns a '0'. 0_B **CLEAR**: Clear 1_B **SET**: A '1' write to this bit triggers the deletion of the target completion LUT entry that is specified in the LOOK_UP_ID field

19.4.2.275 Link Reset Request Flush Control Register

This register controls link reset request flush behaviour.

LINK_FLUSH_CONTROL_OFF Offset address: $00048CC_H$

Link Reset Request Flush Control Register Kernel Reset value: $FF00\ 0001_H$



Field	Bits	Type	Description
AUTO_FLUSH_EN	0	rw	**Enables automatic flushing of pending requests before sending the reset request to the application logic to reset the PCIe controller and the AXI Bridge** The flushing process is initiated if any of the following events occur: • Hot reset request. A downstream port (DSP) can "hot reset" an upstream port (USP) by sending two consecutive TS1 ordered sets with the hot reset bit asserted • Warm (Soft) reset request. Generated when exiting from D3 to D0 and CFG_INFO.NOSOFTRST=0 • Link down reset request. A high to low transition on LNK_STAT.LINKRQRST indicates the link has gone down and the controller is requesting a reset If you disable automatic flushing, your application is responsible for resetting the PCIe controller and the AXI Bridge. Note: This register field is sticky. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
RSVDP_1	23:1	r	**Reserved for future use**
RSVD_I_8	31:24	rw	**This is an internally reserved field** Do not use. Note: This register field is sticky.

19.4.2.276 AXI Bridge Slave Error Response Register

This register holds the AXI bridge slave error responses.

AMBA_ERROR_RESPONSE_DEFAULT_OFF Offset address: 00048D0$_H$

AXI Bridge Slave Error Response Register Kernel Reset value: 0000 9C00$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
AMBA_ERROR_RESPONSE_MAP						RSVDP_5					AMBA_ERROR_RESPONSE_CRS		AMBA_ERROR_RESPONSE_VENDORID	RSVDP_1	AMBA_ERROR_RESPONSE_GLOBAL
rw						r					rw		rw	r	rw

Field	Bits	Type	Description
AMBA_ERROR_RESPONSE_GLOBAL	0	rw	**Global Slave Error Response Mapping** Determines the AXI slave response for all error scenarios on non-posted requests. Note: This register field is sticky. 0_B **OK_**: OKAY (with FFFF data for non-posted requests) 1_B **ERR_**: SLVERR/DECERR (the AMBA_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping)
RSVDP_1	1	r	**Reserved for future use**
AMBA_ERROR_RESPONSE_VENDORID	2	rw	**Vendor ID Non-existent Slave Error Response Mapping** Determines the AXI slave response for errors on reads to non-existent Vendor ID register. Note: This register field is sticky. 0_B **_OK_**: OKAY (with FFFF data) 1_B **_ERR_**: SLVERR/DECERR (the AMBA_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping)
AMBA_ERROR_RESPONSE_CRS	4:3	rw	**CRS Slave Error Response Mapping** Determines the AXI slave response for CRS completions. Note: This register field is sticky. 00_B **OK_**: OKAY 01_B **OK_CRS_CMPL**: OKAY with all FFFF_FFFF data for all CRS completions 10_B **OK_READ_REQ**: OKAY with FFFF_0001 data for CRS completions to vendor ID read requests, OKAY with FFFF_FFFF data for all other CRS completions 11_B **SLVERR_DECERR**: SLVERR/DECERR (the AMBA_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping)
RSVDP_5	9:5	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
AMBA_ERROR_RESPONSE_MAP	15:10	rw	**AXI Slave Response Error Map** Allows you to selectively map the errors received from the PCIe completion (for non-posted requests) to the AXI slave responses, slv_rresp or slv_bresp. The recommended setting is SLVERR. CRS is always mapped to OKAY. • [0] -- 0: UR (unsupported request) -> DECERR -- 1: UR (unsupported request) -> SLVERR • [1] -- 0: CRS (configuration retry status) -> DECERR -- 1: CRS (configuration retry status) -> SLVERR • [2] -- 0: CA (completer abort) -> DECERR -- 1: CA (completer abort) -> SLVERR • [3]: RESERVED (0x0) • [4]: RESERVED (0x0) • [5] -- 0: Completion Timeout -> DECERR -- 1: Completion Timeout -> SLVERR. The AXI bridge internally drops (processes internally but not passed to your application) a completion that has been marked by the Rx filter as UC or MLF, and does not pass its status directly down to the slave interface. It waits for a timeout and then signals "Completion Timeout" to the slave interface. The controller sets the AXI slave read databus to 0xFFFF for all error responses. Note: This register field is sticky.
RSVDP_16	31:16	r	**Reserved for future use**

19.4.2.277 Link Down AXI Bridge Slave Timeout Register

If your application issues outbound requests to the AXI bridge slave interface before the PCIe link is operational, the controller starts a "flush" timer. The timeout value of the timer is set by this register. If the timer times out before the PCIe link is operational, the bridge TX request queues are flushed.

AMBA_LINK_TIMEOUT_OFF Offset address: $00048D4_H$

Link Down AXI Bridge Slave Timeout Register Kernel Reset value: $0000\ 0032_H$

Field	Bits	Type	Description
RSVDP_0	0	r	**Reserved for future use**
AX_SNP_EN	1	rw	**AXI Serialize Non-Posted Requests Enable** This field enables the AXI Bridge to serialize same ID Non-Posted Read/Write Requests on the wire. Serialization implies one outstanding same ID NP Read or Write on the wire and used to avoid AXI RAR and WAW hazards at the remote link partner. 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
RSVDP_2	2	r	**Reserved for future use**

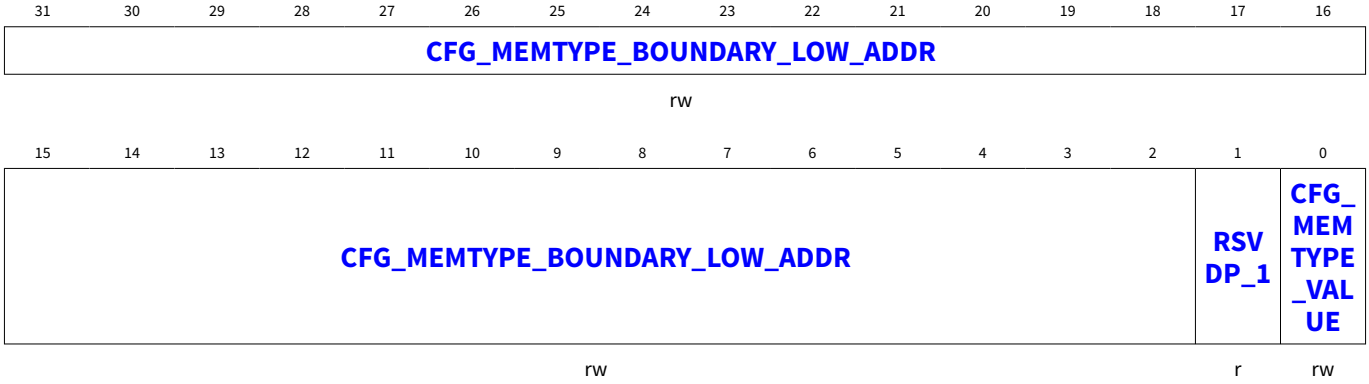
(table continues...)

(continued)

Field	Bits	Type	Description
AX_MSTR_ORDR_P_EVENT_SEL	4:3	rw	**AXI Master Posted Ordering Event Selector** This field selects how the master interface determines when a P write is completed when enforcing the PCIe ordering rule, "NP must not pass P" at the AXI Master Interface. The AXI protocol does not support ordering between channels. Therefore, NP reads can pass P on your AXI bus fabric. This can result in an ordering violation when the read overtakes a P that is going to the same address. Therefore, the bridge master does not issue any NP requests until all outstanding P writes reach their destination. It does this by waiting for the all of the write responses on the B channel. This can affect the performance of the master read channel. For scenarios where the interconnect serializes the AXI master "AW", "W" and "AR" channels,you can increase the performance by reducing the need to wait until the complete Posted transaction has effectively reached the application slave. Note: This setting will not affect: • MSI interrupt catcher and P data ordering. This is always driven by the B'last event • DMA read engine TLP ordering. This is always driven by the B'last event • NP write transactions which are always serialized with P write transactions 00_B **B**: B'last event: wait for the all of the write responses on the B channel thereby ensuring that the complete Posted transaction has effectively reached the application slave (default) 01_B **AW**: AW'last event: wait until the complete Posted transaction has left the AXI address channel at the bridge master 10_B **W**: W'last event: wait until the complete Posted transaction has left the AXI data channel at the bridge master 11_B **RSVD**: Reserved
RSVDP_5	6:5	r	**Reserved for future use**
AX_MSTR_ZEROLREAD_FW	7	rw	**AXI Master Zero Length Read Forward to the application** The AXI bridge is able to terminate in order with the Posted transactions the zero length read, implementing the PCIe express flush semantics of the Posted transactions. 0_B **_0_LN_RD_TERMINATE**: The zero length Read is terminated at the DW PCIe AXI bridge master 1_B **_0_LN_RD_FWD**: The zero length Read is forward to the application
RSVDP_8	31:8	r	**Reserved for future use**

19.4.2.279 ACE Cache Coherency Control Register 1

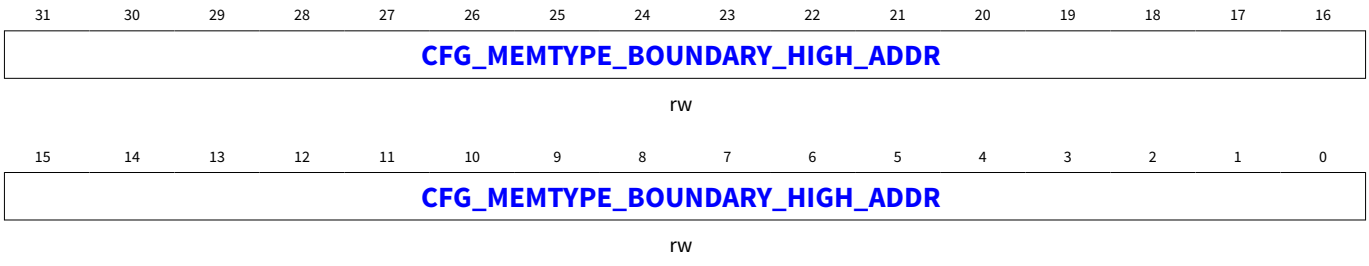
This register controls the ACE cache coherency operation.



Field	Bits	Type	Description
CFG_MEMTYPE_VALUE	0	rw	**Sets the memory type for the lower and upper parts of the address space:** Note: This register field is sticky. 0_B **LOWER_PREPH**: lower = Peripheral; upper = Memory 1_B **LOWER_MEM**: lower = Memory type; upper = Peripheral
RSVDP_1	1	r	**Reserved for future use**
CFG_MEMTYPE_BOUNDARY_LOW_ADDR	31:2	rw	**Boundary Lower Address For Memory Type** Bits [31:0] of dword-aligned address of the boundary for Memory type. The two lower address LSBs are '00'. Addresses up to but not including this value are in the lower address space region; addresses equal or greater than this value are in the upper address space region. Note: This register field is sticky.

19.4.2.280 ACE Cache Coherency Control Register 2

This register controls the ACE cache coherency operation.



Field	Bits	Type	Description
CFG_MEMTYPE_BOUNDARY_HIGH_ADDR	31:0	rw	**Boundary Upper Address For Memory Type** Bits [63:32] of the 64-bit dword-aligned address of the boundary for Memory type. Note: This register field is sticky.

19.4.2.281 ACE Cache Coherency Control Register 3

This register controls the ACE cache coherency operation.

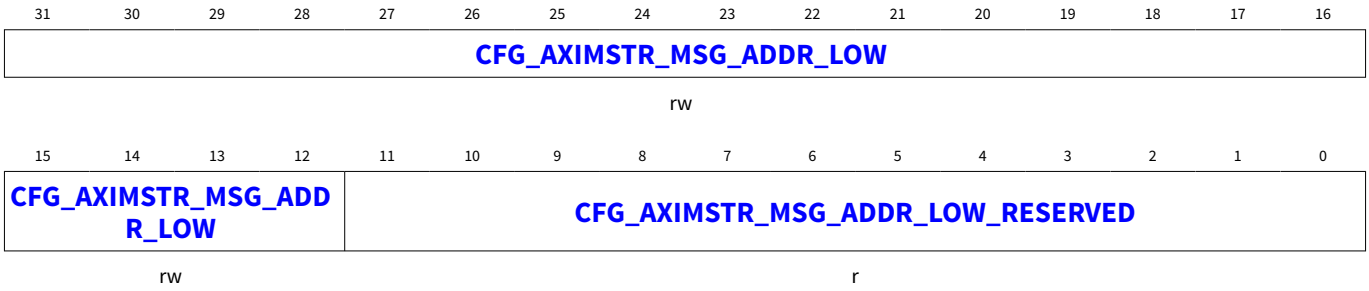
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	CFG_MSTR_AWCACHE_VALUE				0				CFG_MSTR_ARCACHE_VALUE				0		
r	rw				r				rw				r		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	CFG_MSTR_AWCACHE_MODE				0				CFG_MSTR_ARCACHE_MODE				0		
r	rw				r				rw				r		

Field	Bits	Type	Description
CFG_MSTR_ARCACHE_MODE	6:3	rw	**Master Read CACHE Signal Behavior** Defines how the individual bits in mstr_arcache are controlled. Note: This register field is sticky. 0_H **SET_BY_AXI_MASTER**: set automatically by the AXI master 1_H **SET_BY_FIELD**: set by the value of the corresponding bit of the CFG_MSTR_ARCACHE_VALUE field **others,** Reserved
CFG_MSTR_AWCACHE_MODE	14:11	rw	**Master Write CACHE Signal Behavior** Defines how the individual bits in mstr_awcache are controlled. Note: for message requests the value of mstr_awcache is always "0000" regardless of the value of this bit. Note: This register field is sticky. 0_H **SET_BY_AXI_MASTER**: set automatically by the AXI master 1_H **SET_BY_FIELD**: set by the value of the corresponding bit of the CFG_MSTR_AWCACHE_VALUE field **others,** Reserved
CFG_MSTR_ARCACHE_VALUE	22:19	rw	**Master Read CACHE Signal Value** Value of the individual bits in mstr_arcache when CFG_MSTR_ARCACHE_MODE is '1'. Note: This register field is sticky.
CFG_MSTR_AWCACHE_VALUE	30:27	rw	**Master Write CACHE Signal Value** Value of the individual bits in mstr_awcache when CFG_MSTR_AWCACHE_MODE is '1'. Note: Not applicable to message requests; for message requests the value of mstr_awcache is always '0000'. Note: This register field is sticky.
0	2:0, 10:7, 18:15, 26:23, 31	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.282 Lower 32-bits of the Programmable AXI Address

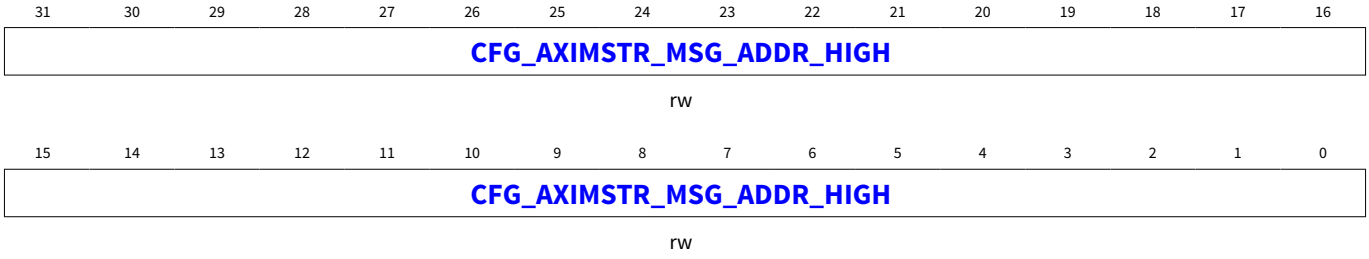
Lower 20 bits of the programmable AXI address to which Messages coming from wire are mapped. Bits [11:0] of the register are tied to zero for the address to be 4k-aligned. In previous releases, the third and fourth DWORDs of a message (Msg/MsgD) TLP header were delivered though the AXI master address bus (mstr_awaddr). These DWORDS are now supplied through the mstr_awmisc_info_hdr_34dw[63:0] output; and the value on mstr_awaddr is driven to the value you have programmed into the AXI_MSTR_MSG_ADDR_LOW_OFF and AXI_MSTR_MSG_ADDR_HIGH_OFF registers.



Field	Bits	Type	Description
CFG_AXIMSTR_MSG_ADDR_LOW_RESERVED	11:0	r	**Reserved for future use** Note: This register field is sticky.
CFG_AXIMSTR_MSG_ADDR_LOW	31:12	rw	**Lower 20-bits of the programmable AXI address for Messages** Note: This register field is sticky.

19.4.2.283 Upper 32-bits of the Programmable AXI Address

Upper 32 bits of the programmable AXI address to which Messages coming from wire are mapped.



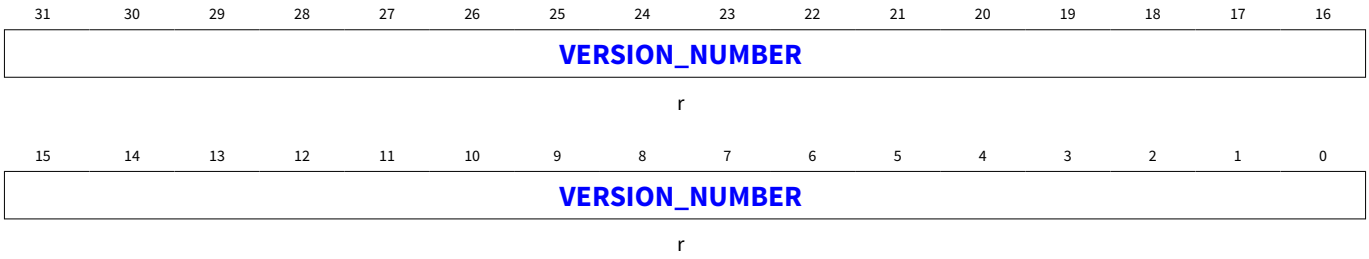
Field	Bits	Type	Description
CFG_AXIMSTR_MSG_ADDR_HIGH	31:0	rw	**Upper 32 bits of the programmable AXI address for Messages** Note: This register field is sticky.

19.4.2.284 PCIe Controller IIP Release Version Number

The version number is given in hex format. You should convert each pair of hex characters to ASCII to interpret. Using 4.70a (GA) as an example: - VERSION_NUMBER = 0x3437302a which translates to 470* - VERSION_TYPE = 0x67612a2a which translates to ga** Using 4.70a-ea01 as an example: - VERSION_NUMBER = 0x3437302a which translates to 470* - VERSION_TYPE = 0x65613031 which translates to ea01 GA is a general release available on www.designware.com EA is an early release available on a per-customer basis.

PCIE_VERSION_NUMBER_OFF Offset address: $00048F8_H$

PCIe Controller IIP Release Version Number Kernel Reset value: $3537\ 312A_H$



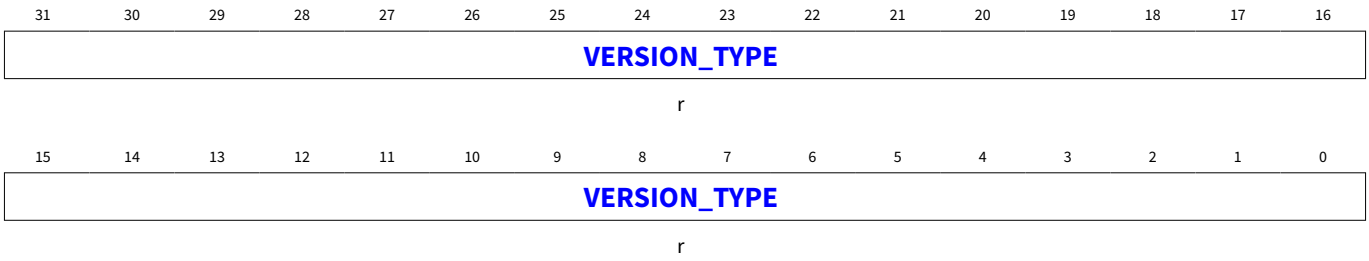
Field	Bits	Type	Description
VERSION_NUMBER	31:0	r	**Version Number** 00000000_H **MIN_VAL**: Zero value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.285 PCIe Controller IIP Release Version Type

The type is given in hex format. You should convert each pair of hex characters to ASCII to interpret. Using 4.70a (GA) as an example: - VERSION_NUMBER = 0x3437302a which translates to 470* - VERSION_TYPE = 0x67612a2a which translates to ga** Using 4.70a-ea01 as an example: - VERSION_NUMBER = 0x3437302a which translates to 470* - VERSION_TYPE = 0x65613031 which translates to ea01 GA is a general release available on www.designware.com EA is an early release available on a per-customer basis.

PCIE_VERSION_TYPE_OFF Offset address: $00048FC_H$

PCIe Controller IIP Release Version Type Kernel Reset value: $6C70\ 3031_H$



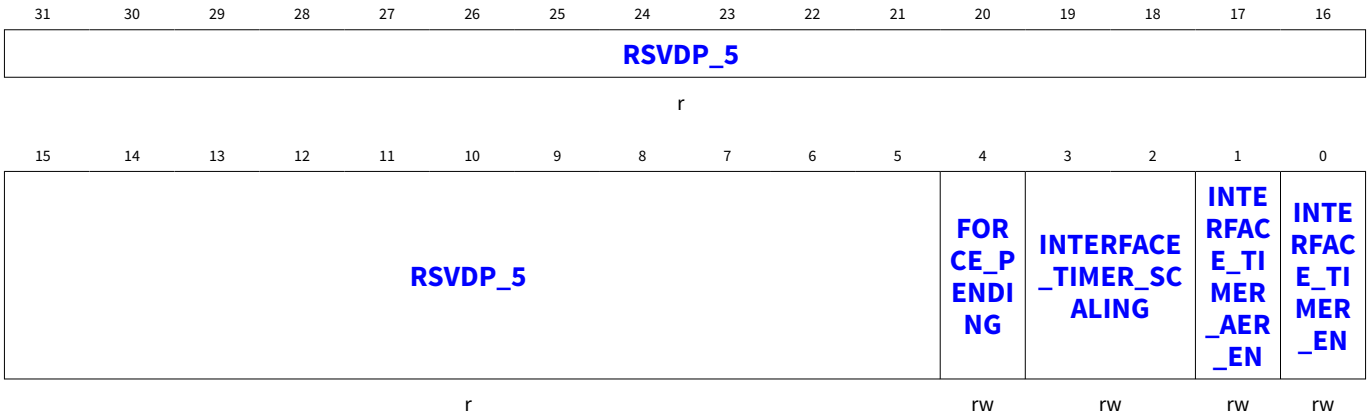
Field	Bits	Type	Description
VERSION_TYPE	31:0	r	**Version Type** 00000000_H **MIN_VAL**: Zero value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.286 Interface Timer Control Register

This register controls the interface timer.

INTERFACE_TIMER_CONTROL_OFF Offset address: 0004930_H

Interface Timer Control Register Kernel Reset value: $0000\ 0000_H$



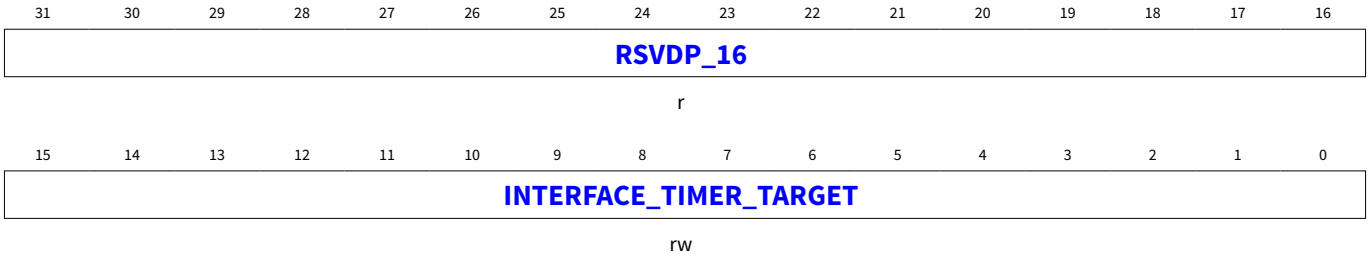
Field	Bits	Type	Description
INTERFACE_TIMER_EN	0	rw	**Interface timer enable** Note: This register field is sticky.
INTERFACE_TIMER_AER_EN	1	rw	**When set to 1 the Interface timer internal uncorrectable error generation is enabled** Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: The Interface timer internal uncorrectable error generation is enabled
INTERFACE_TIMER_SCALING	3:2	rw	**Interface timer scaling** This field can be used to reduce the timer duration. This field should only be programmed when the INTERFACE_TIMER_EN bit is set to 1'b0. Note: This register field is sticky.
FORCE_PENDING	4	rw	**Writing to this bit forces the value of the pending flags** Note: This register field is sticky.
RSVDP_5	31:5	r	**Reserved for future use**

19.4.2.287 Interface Timer Target Register

This is the interface timer target register.

INTERFACE_TIMER_TARGET_OFF Offset address: 0004934_H

Interface Timer Target Register Kernel Reset value: $0000\ 0032_H$



Field	Bits	Type	Description
INTERFACE_TIMER_TARGET	15:0	rw	**Interface timer target value** This field should only be programmed when the INTERFACE_TIMER_EN bit is set to 1'b0. Note: This register field is sticky.
RSVDP_16	31:16	r	**Reserved for future use**

19.4.2.288 Interface Timer Status Register

This is the interface timer status register.

INTERFACE_TIMER_STATUS_OFF Offset address: 0004938_H

Interface Timer Status Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

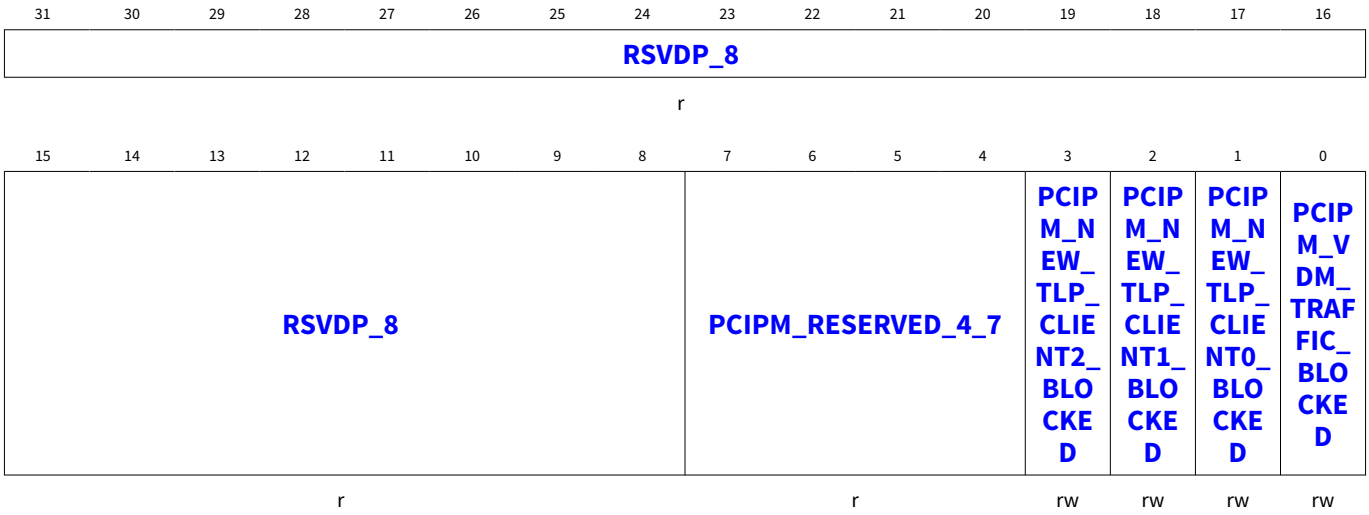
19.4.2.296 TLP Traffic during Non-D0 State Control Register

This register provides control over TLP Traffic during Non-D0 States.



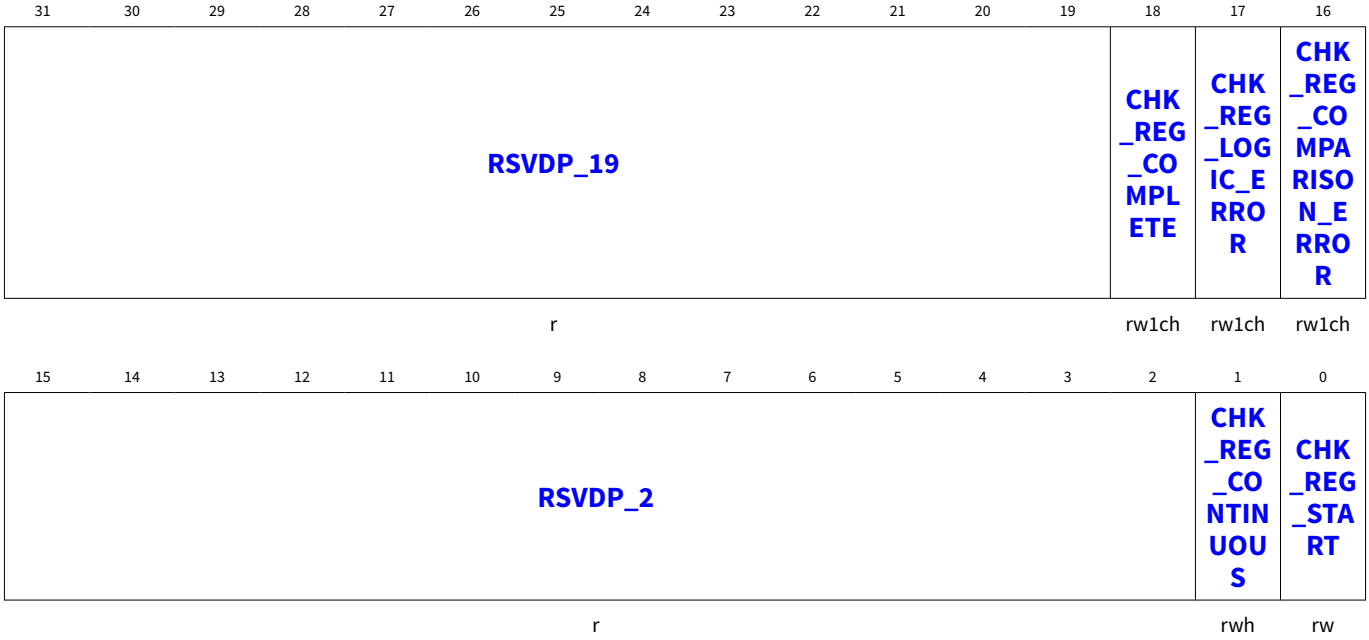
Field	Bits	Type	Description
PCIPM_VDM_TRAFFIC_BLOCKED	0	rw	**This field indicates that VDM Message TLPs are blocked during non-D0 states** Note: This register field is sticky.
PCIPM_NEW_TLP_CLIENT0_BLOCKED	1	rw	**This field indicates that all TLPs transmitted by Client 0 interface are blocked during non-D0 states** Note: This register field is sticky.
PCIPM_NEW_TLP_CLIENT1_BLOCKED	2	rw	**This field indicates that all TLPs transmitted by Client 1 interface are blocked during non-D0 states** Note: This register field is sticky.
PCIPM_NEW_TLP_CLIENT2_BLOCKED	3	rw	**This field indicates that all TLPs transmitted by Client 2 interface are blocked during non-D0 states** Note: This register field is sticky.
PCIPM_RESERVED_4_7	7:4	r	**Reserved** Note: This register field is sticky.
RSVDP_8	31:8	r	**Reserved for future use**

19.4.2.297 CDM Register Checking Control and Status Register

Controls register checking and displays status of register checking.

PL_CHK_REG_CONTROL_STATUS_OFF Offset address: $0004B20_H$

CDM Register Checking Control and Status Register Kernel Reset value: $0000\ 0000_H$



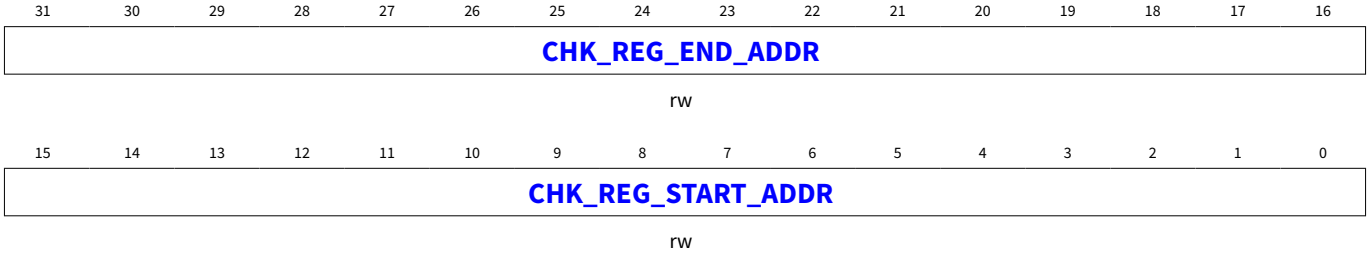
Field	Bits	Type	Description
CHK_REG_START	0	rw	**Begins a checking sequence** Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Set
CHK_REG_CONTINUOUS	1	rwh	**Set Continuous Checking Sequence** Note: This register field is sticky. 0_B **CLEAR**: Clear 1_B **SET**: Set
RSVDP_2	15:2	r	**Reserved for future use**
CHK_REG_COMPARISON_ERROR	16	rw1ch	**The system has detected that there is a bit error in the CDM Register Data** Note: This register field is sticky. Software write with 1 clears this bit-field. 0_B **CLEAR**: Clear 1_B **SET**: Indicates comparison error
CHK_REG_LOGIC_ERROR	17	rw1ch	**The system has detected an error in its own checking logic** Note: This register field is sticky. Software write with 1 clears this bit-field. 0_B **CLEAR**: Clear 1_B **SET**: Indicates an error in comparison logic
CHK_REG_COMPLETE	18	rw1ch	**The system has completed a checking cycle** Note: This register field is sticky. Software write with 1 clears this bit-field. 0_B **CLEAR**: Clear 1_B **SET**: Indicates the system has completed a checking cycle
RSVDP_19	31:19	r	**Reserved for future use**

19.4.2.298 CDM Register Checking First and Last address to check

This register holds the first and last address to check.

PL_CHK_REG_START_END_OFF Offset address: $0004B24_H$

CDM Register Checking First and Last address to check Kernel Reset value: $0BFF\ 0000_H$



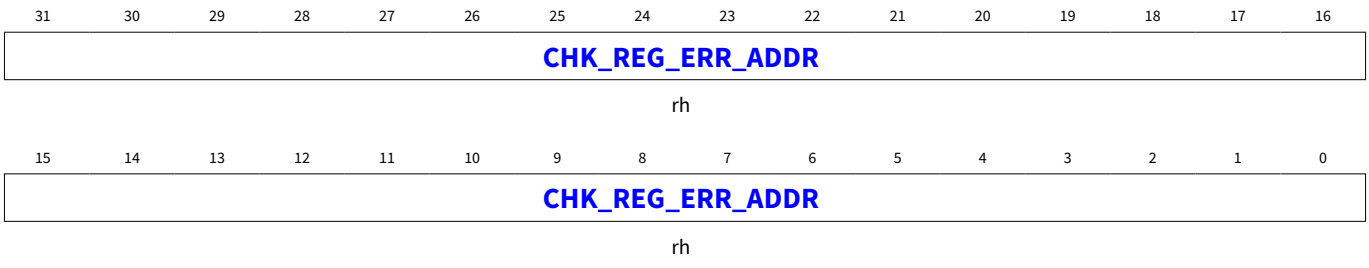
Field	Bits	Type	Description
CHK_REG_START_ADDR	15:0	rw	**The first address that is checked by the system** Note: This register field is sticky. 0000_H **MIN_VAL**: Zero value $FFFF_H$ **MAX_VAL**: Max value
CHK_REG_END_ADDR	31:16	rw	**The last address that is checked by the system** Note: This register field is sticky. 0000_H **MIN_VAL**: Zero value $FFFF_H$ **MAX_VAL**: Max value

19.4.2.299 CDM Register Checking Error Address

This register holds the CDM register checking error address.

PL_CHK_REG_ERR_ADDR_OFF Offset address: $0004B28_H$

CDM Register Checking Error Address Kernel Reset value: $0000\ 0000_H$



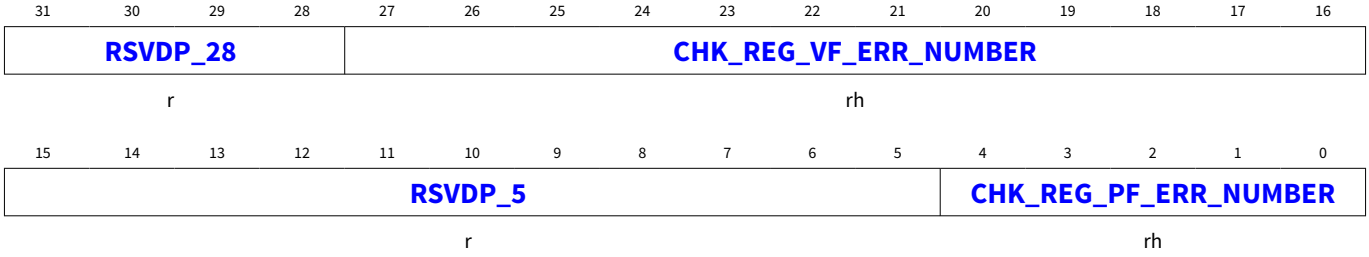
Field	Bits	Type	Description
CHK_REG_ERR_ADDR	31:0	rh	**The address at which an error has been detected** Valid only when the CDM Register Checker Comparison Error bit is set in the status register. Note: This register field is sticky. 00000000_H **MIN_VAL**: Zero value $FFFFFFFF_H$ **MAX_VAL**: Max value

19.4.2.300 CDM Register Checking error PF Numbers

This register holds the CDM Register checking error PF numbers.

PL_CHK_REG_ERR_PF_VF_OFF Offset address: $0004B2C_H$

CDM Register Checking error PF Numbers Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CHK_REG_PF_ERR_NUMBER	4:0	rh	**The PF number at which the error was detected** Valid only when the CDM Register Checker Comparison Error bit is set in the status register. Note: This register field is sticky. 00_H **MIN_VAL**: Zero value $1F_H$ **MAX_VAL**: Max value
RSVDP_5	15:5	r	**Reserved for future use**
CHK_REG_VF_ERR_NUMBER	27:16	rh	**The VF number at which the error was detected** Valid only when the CDM Register Checker Comparison Error bit is set in the status register. Note: This register field is sticky. 000_H **MIN_VAL**: Zero value $7FF_H$ **MAX_VAL**: Max value **others,** Reserved
RSVDP_28	31:28	r	**Reserved for future use**

19.4.2.301 LTR Latency Register

The function of this register field (and all other fields in this register) differs between an upstream port and a downstream port. For an upstream port, the register fields capture the corresponding fields in the LTR messages that are transmitted by the port. For a downstream port, the register fields capture the corresponding fields in the LTR messages that are received by the port.

PL_LTR_LATENCY_OFF Offset address: $0004B30_H$

LTR Latency Register Kernel Reset value: $0000\ 0000_H$

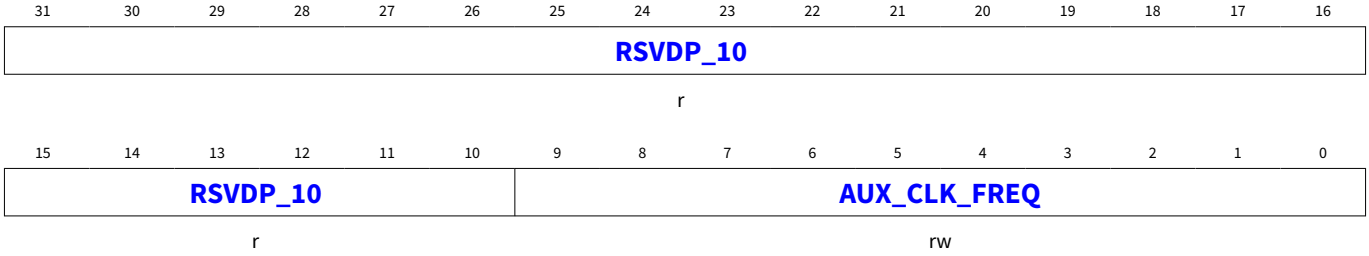
19.4.2.302 Auxiliary Clock Frequency Control Register

This register controls the auxiliary clock frequency.

AUX_CLK_FREQ_OFF Offset address: $0004B40_H$

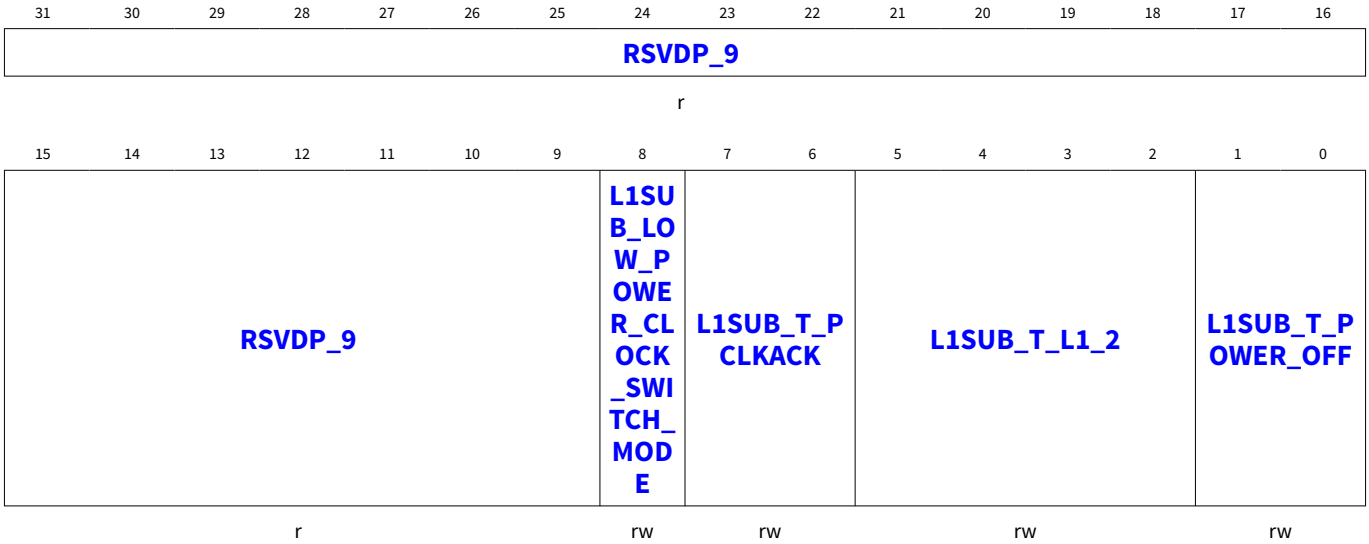
Auxiliary Clock Frequency Control Register Kernel Reset value: $0000\ 000A_H$



Field	Bits	Type	Description
AUX_CLK_FREQ	9:0	rw	**The aux_clk frequency in MHz** This value is used to provide a 1 µs reference for counting time during low-power states with aux_clk when the PHY has removed the pipe_clk. If the actual frequency (f) of aux_clk does not exactly match the programmed frequency (f_prog), then there is an error in the time counted by the controller that can be expressed in percentage as: err% = (f_prog/f-1)*100. For example if f=2.5 MHz and f_prog=3 MHz, then err% =(3/2.5-1)*100 =20%, meaning that the time counted by the controller on aux_clk will be 20% greater than the time in µs programmed in the corresponding time register (for example T_POWER_ON). Note: This register field is sticky.
RSVDP_10	31:10	r	**Reserved for future use**

19.4.2.303 L1 Substates Timing Register

This register holds L1 substates timing information.



Field	Bits	Type	Description
L1SUB_T_POWER_OFF	1:0	rw	**Duration (in 1 µs units) of L1.2.Entry** Range is 1..4. Note: This register field is sticky. 00_B **MIN_VAL**: Min value 11_B **MAX_VAL**: Max value

(table continues...)

(continued)

Field	Bits	Type	Description
L1SUB_T_L1_2	5:2	rw	**Duration (in 1 µs units) of L1.2** Range is 1..16. Note: This register field is sticky. 0_H **MIN_VAL**: Min value F_H **MAX_VAL**: Max value
L1SUB_T_PCLKACK	7:6	rw	**Max delay (in 1 µs units) between a MAC request to remove the clock and a PHY response** If the PHY does not respond within this time the request is aborted. Range is 1..4 Note: This register field is sticky. 00_B **MIN_VAL**: Min value 11_B **MAX_VAL**: Max value
L1SUB_LOW_POWER_CLOCK_SWITCH_MODE	8	rw	**If the bit is set to 1'b1 the controller will delay the switching of aux_clk to the slow platform clock until it detects that the link partner has de-asserted CLKREQ#** Note: This register field is sticky. 0_B **CLEAR**: The reference clock may be gated off when CLKREQ# is de-asserted 1_B **SET**: The reference clock shall be kept running regardless of the CLKREQ# setting
RSVDP_9	31:9	r	**Reserved for future use**

19.4.2.304 Powerdown Control and Status Register

This is the Powerdown Control and Status register.

POWERDOWN_CTRL_STATUS_OFF Offset address: $0004B48_H$

Powerdown Control and Status Register Kernel Reset value: $0000\ 0220_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

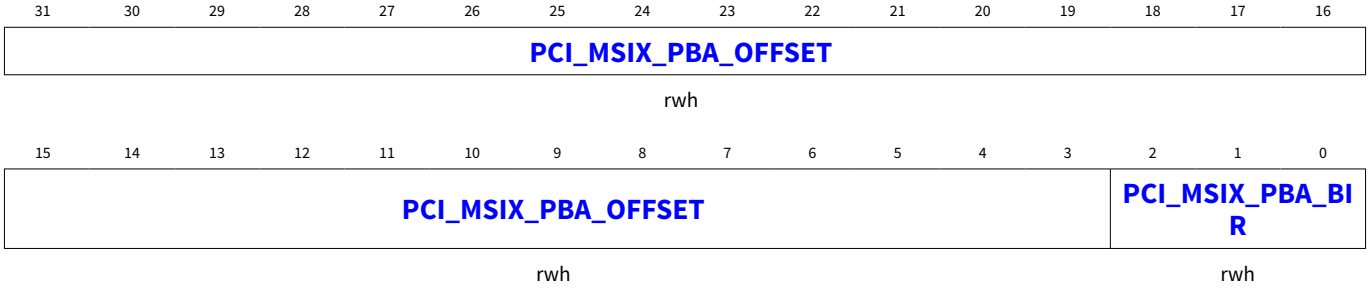
PCI_MSIX_TABLE_OFFSET													PCI_MSIX_BIR		
rwh													rwh		

Field	Bits	Type	Description
PCI_MSIX_BIR	2:0	rwh	**MSI-X Table BAR Indicator Register Field** This field indicates which one of a Function's Base Address Registers , located beginning at 10h in Configuration Space, or entry in the Enhanced Allocation capability with a matching BEI , is used to map the Function's MSI-X Table into Memory Space. All encodings other than the defined encodings are reserved. For a 64-bit Base Address Register , the Table BIR indicates the lower DWORD. For Functions with Type 1 Configuration Space headers, BIR values 2 through 5 are also Reserved. Note: The access attributes of this field are as follows: - Wire: No access - Dbi: if (DBI_RO_WR_EN == 1 && MSIX_CAP_ENABLE=1) then R/W else R Note: This register field is sticky. 000_B **BAR_10**: Base Address Register 10h 001_B **BAR_14**: Base Address Register 14h 010_B **BAR_18**: Base Address Register 18h 011_B **BAR_1C**: Base Address Register 1Ch 100_B **BAR_20**: Base Address Register 20h 101_B **BAR_24**: Base Address Register 24h **others,** Reserved
PCI_MSIX_TABLE_OFFSET	31:3	rwh	**MSI-X Table Offset** Used as an offset from the address contained by one of the Function's Base Address Registers to point to the base of the MSI-X Table. The lower 3 Table BIR bits are masked off (set to zero) by software to form a 32-bit QWORD-aligned offset. Note: The access attributes of this field are as follows: - Wire: No access - Dbi: if (DBI_RO_WR_EN == 1 && MSIX_CAP_ENABLE=1) then R/W else R Note: This register field is sticky.

19.4.2.309 MSI-X PBA Offset and BIR Register

This register provides PBA Offset and PBA BIR value.



Field	Bits	Type	Description
PCI_MSIX_PBA_BIR	2:0	rwh	**MSI-X PBA BIR** This field indicates which one of a Function's Base Address Registers , located beginning at 10h in Configuration Space, or entry in the Enhanced Allocation capability with a matching BEI, is used to map the Function's MSI-X PBA into Memory Space. The PBA BIR value definitions are identical to those for the Table BIR . Note: The access attributes of this field are as follows: • Wire: No access • Dbi: if (DBI_RO_WR_EN == 1 && MSIX_CAP_ENABLE=1) then R/W else R Note: This register field is sticky.
PCI_MSIX_PBA_OFFSET	31:3	rwh	**MSI-X PBA Offset** Used as an offset from the address contained by one of the Function's Base Address Registers to point to the base of the MSI-X PBA. The lower 3 PBA BIR bits are masked off (set to zero) by software to form a 32-bit QWORD-aligned offset. Note: The access attributes of this field are as follows: • Wire: No access • Dbi: if (DBI_RO_WR_EN == 1 && MSIX_CAP_ENABLE=1) then R/W else R Note: This register field is sticky.

19.4.2.310 DMA Arbitration Scheme for TRGT1 Interface

This register is used to control traffic priorities among various sources that are delivered to your application through TRGT1 where 0x0 represents the highest priority. - Non-DMA Rx Requests - DMA Write Channel MRd Requests (DMA data requests and LL element/descriptor access) - DMA Read Channel MRd Requests (LL element/descriptor access) - DMA Read Channel MWr Requests Concurrent traffic from channels with same priority are sorted according to Round-Robin arbitration rules. The arbitration priority defaults to Non-DMA requests (highest), Write Channel MRd, Read Channel MRd, Read Channel MWr.

DMA_CTRL_DATA_ARB_PRIOR_OFF Offset address: 0007000_H

DMA Arbitration Scheme for TRGT1 Interface Kernel Reset value: $0000\ 0688_H$

RSVDP_1															DMA_WRITE_ENGINE
r															rwh

Field	Bits	Type	Description
DMA_WRITE_ENGINE	0	rwh	**DMA Write Engine Enable** For normal operation, you must initially set this bit to '1', before any other software setup action. You do not need to toggle or rewrite to this bit during normal operation. You should set this bit to '0' when you want to "Soft Reset" the DMA controller write logic. There are three possible reasons for resetting the DMA controller write logic • The "Abort Interrupt Status" bit is set in the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF), and any of the bits in the DMA Write Error Status Register (DMA_WRITE_ERR_STATUS_OFF) are set. Resetting the DMA controller write logic re-initializes the control logic, ensuring that the next DMA write transfer is executed successfully. • You have executed the procedure outlined in "Stop Bit", after which, the "Abort Interrupt Status" bit is set and the Channel Status(CS) field of the DMA Write Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_i) is set to "Stopped". Resetting the DMA controller write logic re-initializes the control logic ensuring that the next DMA write transfer is executed successfully • During software development, when you incorrectly program the DMA write engine To "Soft Reset" the DMA controller write logic, you must: • De-assert the DMA write engine enable bit. • Wait for the DMA to complete any in-progress TLP transfer, by waiting until a read on the DMA write engine enable bit returns a '0'. • Assert the DMA write engine enable bit. This "Soft Reset" does not clear the DMA configuration registers. The DMA write transfer does not start until you write to the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_B **DISABLE**: Disable (Soft Reset) 1_B **ENABLE**: Enable
RSVDP_1	15:1	r	**Reserved for future use**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVDP_3													WR_DOORBELL_NUM		
r													rwh		

Field	Bits	Type	Description
WR_DOORBELL_NUM	2:0	rwh	**Doorbell Number** You must write the channel number to this register to start the DMA write transfer for that channel. The DMA detects a write to this register field even if the value of this field does not change. You do not need to toggle or write any other value to this register to start a new transfer. The range of this field is 0x0 to 0x7, where 0x0 corresponds to channel 0. Note: A write to this field triggers the controller to exit L1 substates. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_3	30:3	r	**Reserved for future use**

(table continues...)

(continued)

Field	Bits	Type	Description
WR_STOP	31	rwh	**Stop** Set in conjunction with the Doorbell Number field. The DMA write channel stops issuing requests, sets the channel status to "Stopped", and asserts the "Abort" interrupt if it is enabled. Before setting the Stop bit, you must read the channel Status field (CS) of the DMA Write Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) to ensure that the write channel is "Running" (transferring data). For more information, see "Stopping the DMA Transfer (Software Stop)". Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.314 DMA Write Engine Channel Arbitration Weight Low Register

The 5-bit channel weight (for write channels 0-3) specifies the maximum number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached or DMA channel request transfer size reaches zero, the WWR arbiter selects the next channel to be processed. Your software must initialize this register before ringing the doorbell. Value range is (0-0x1F) corresponding to (1-32) transaction requests.

DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF Offset address: 0007018_H

DMA Write Engine Channel Arbitration Weight Low Register — Kernel Reset value: $0000\ 8421_H$

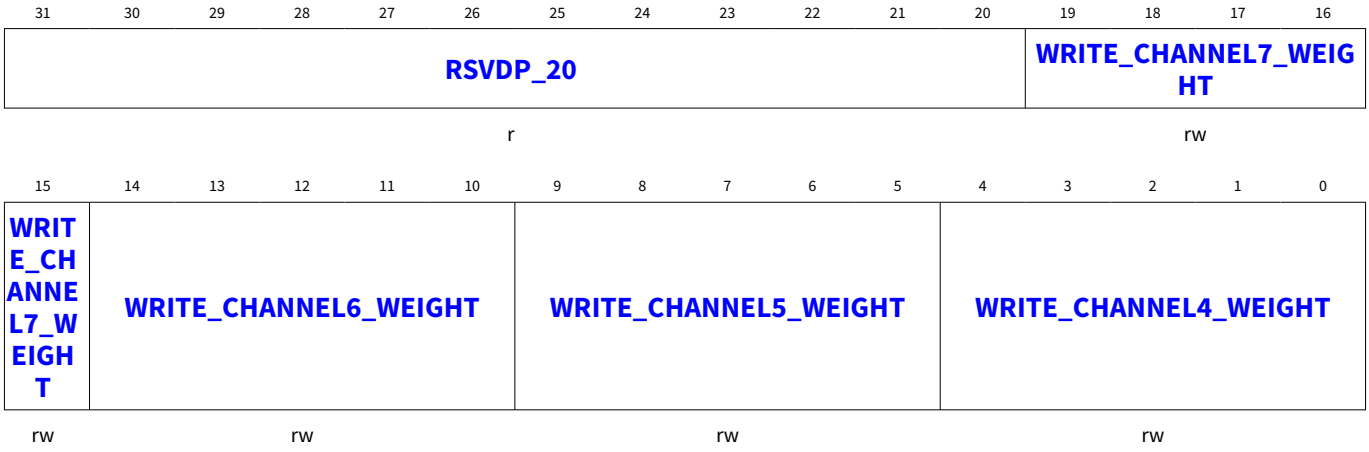
WRITE_CHANNEL2_WEIGHT	14:10	rw	**Channel 2 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
WRITE_CHANNEL3_WEIGHT	19:15	rw	**Channel 3 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_20	31:20	r	**Reserved for future use**

19.4.2.315 DMA Write Engine Channel Arbitration Weight High Register

The 5-bit channel weight (for write channels 4-7) specifies the maximum number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached or DMA channel request transfer size reaches zero, the WWR arbiter selects the next channel to be processed. Your software must initialize this register before ringing the doorbell. For more details, see "Multichannel Arbitration". Value range is (0-0x1F) corresponding to (1-32) transaction requests.



Field	Bits	Type	Description
WRITE_CHANNEL4_WEIGHT	4:0	rw	**Channel 4 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
WRITE_CHANNEL5_WEIGHT	9:5	rw	**Channel 5 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
WRITE_CHANNEL6_WEIGHT	14:10	rw	**Channel 6 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
WRITE_CHANNEL7_WEIGHT	19:15	rw	**Channel 7 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_20	31:20	r	**Reserved for future use**

19.4.2.316 DMA Read Engine Enable Register

This register indicates the status of DMA read engine and the status of DMA read engine handshake feature (per-channel).

DMA_READ_ENGINE_EN_OFF Offset address: $000702C_H$

DMA Read Engine Enable Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVDP_1															DMA_READ_ENGINE
r															rwh

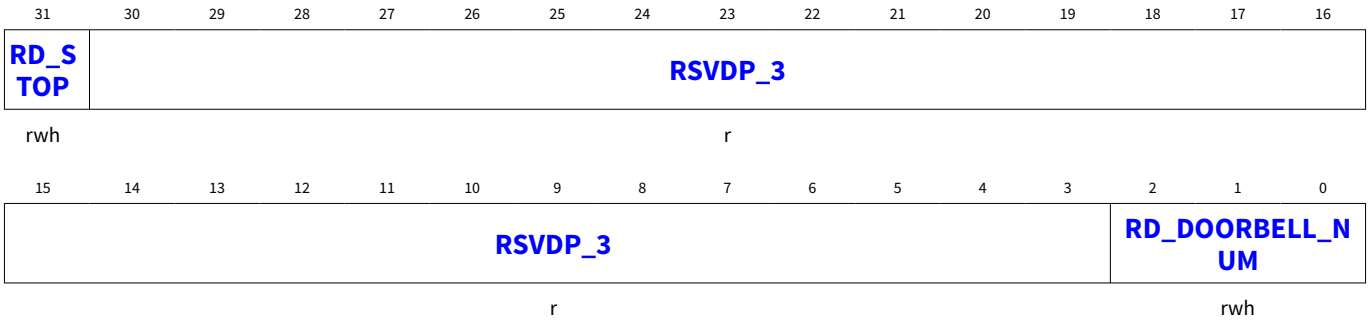
Field	Bits	Type	Description
DMA_READ_ENGINE	0	rwh	**DMA Read Engine Enable** For normal operation, you must initially set this bit to '1', before any other software setup action. You do not need to toggle or rewrite to this bit during normal operation. You should set this field to '0' when you want to "Soft Reset" the DMA controller read logic. There are three possible reasons for resetting the DMA controller read logic: - The "Abort Interrupt Status" bit is set in the DMA Read Interrupt Status Register (DMA_READ_INT_STATUS_OFF), and any of the bits in the DMA Read Error Status Low Register (DMA_READ_ERR_STATUS_LOW_OFF) is set. Resetting the DMA controller read logic re-initializes the control logic, ensuring that the next DMA read transfer is executed successfully. - You have executed the procedure outlined in "Stop Bit", after which, the "Abort Interrupt Status" bit is set and the channel Status field (CS) of the DMA Read Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_i) is set to "Stopped". Resetting the DMA controller read logic re-initializes the control logic ensuring that the next DMA read transfer is executed successfully. - During software development, when you incorrectly program the DMA read engine. To "Soft Reset" the DMA controller read logic, you must: - De-assert the DMA read engine enable bit. - Wait for the DMA to complete any in-progress TLP transfer, by waiting until a read on the DMA read engine enable bit returns a '0'. - Assert the DMA read engine enable bit. This "Soft Reset" does not clear the DMA configuration registers. The DMA read transfer does not start until you write to the DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF). Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_B **DISABLE**: Disable (Soft Reset) 1_B **ENABLE**: Enable
RSVDP_1	15:1	r	**Reserved for future use**
DMA_READ_ENGINE_EN_HSHAKE_CH0	16	rw	**Enable Handshake for DMA Read Engine Channel 0** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_READ_ENGINE_EN_HSHAKE_CH1	17	rw	**Enable Handshake for DMA Read Engine Channel 1** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_READ_ENGINE_EN_HSHAKE_CH2	18	rw	**Enable Handshake for DMA Read Engine Channel 2** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_READ_ENGINE_EN_HSHAKE_CH3	19	rw	**Enable Handshake for DMA Read Engine Channel 3** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_24	31:24	r	**Reserved for future use**

19.4.2.317 DMA Read Doorbell Register

This register controls the DMA read channel doorbell.

DMA_READ_DOORBELL_OFF Offset address: 0007030_H

DMA Read Doorbell Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RD_DOORBELL_NUM	2:0	rwh	**Doorbell Number** You must write 0x0 to this register to start the DMA read transfer for that channel. The DMA detects a write to this register field even if the value of this field does not change. The range of this field is 0x0 to 0x7, where 0x0 corresponds to channel 0. Note: A write to this field triggers the controller to exit L1 substates. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_3	30:3	r	**Reserved for future use**
RD_STOP	31	rwh	**Stop** Set in conjunction with the Doorbell Number field. The DMA read channel stops issuing requests, sets the channel status to "Stopped", and asserts the "Abort" interrupt if it is enabled. Before setting the Stop bit, you must read the channel Status field (CS) of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_RDCH_i) to ensure that the read channel is "Running" (transferring data). For more information, see "Stopping the DMA Transfer (Software Stop)". Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

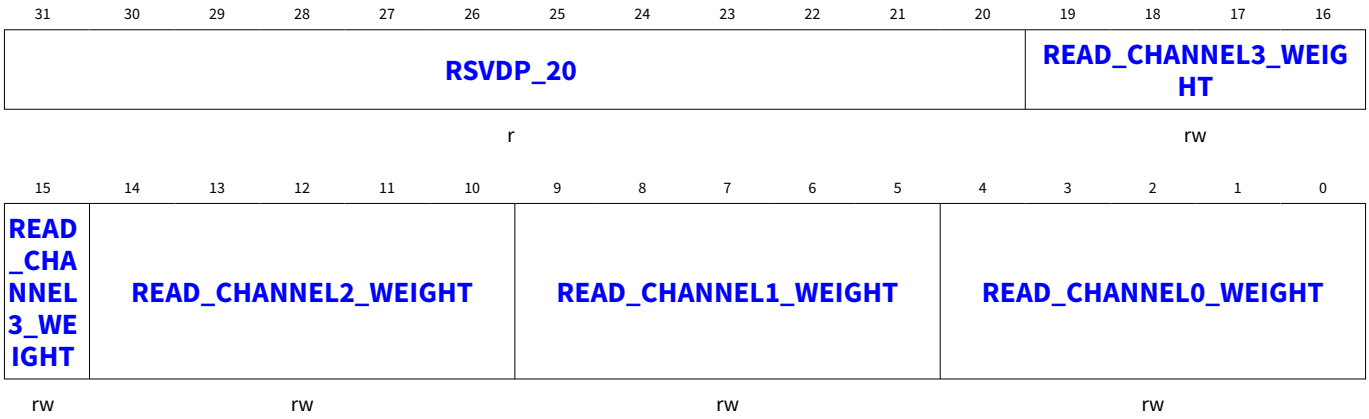
19.4.2.318 DMA Read Engine Channel Arbitration Weight Low Register

The 5-bit channel weight (for read channels 0-3) specifies the maximum number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached or DMA channel request transfer size reaches zero, the WWR arbiter selects the next channel to be processed. Your software must initialize this register before ringing the doorbell. For more details, see "Multichannel Arbitration". Value range is (0-0x1F) corresponding to (1-32) transaction requests.

DMA_READ_CHANNEL_ARB_WEIGHT_LOW_OFF Offset address: 0007038_H

DMA Read Engine Channel Arbitration Weight Low Register

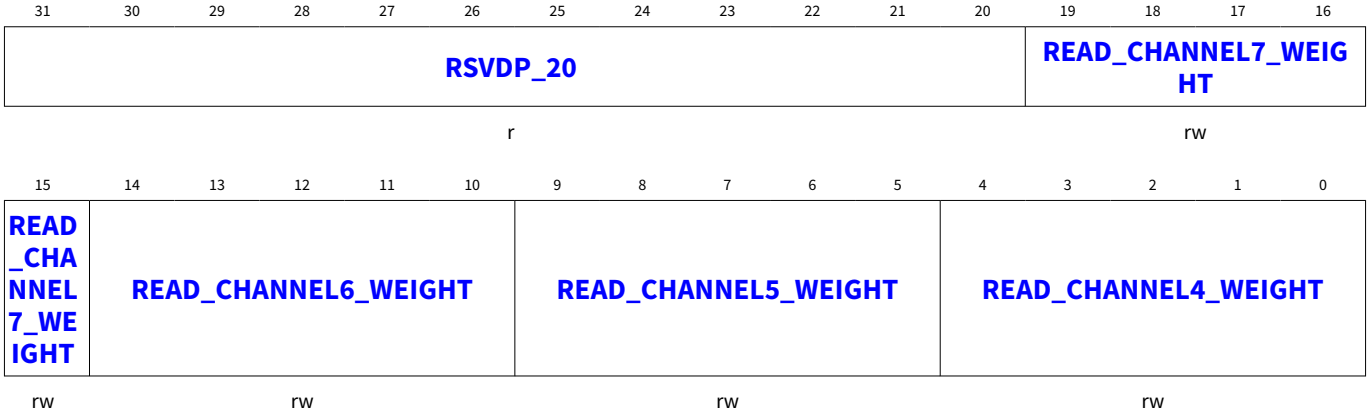
Kernel Reset value: $0000\ 8421_H$



Field	Bits	Type	Description
READ_CHANNEL0_WEIGHT	4:0	rw	**Channel 0 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
READ_CHANNEL1_WEIGHT	9:5	rw	**Channel 1 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
READ_CHANNEL2_WEIGHT	14:10	rw	**Channel 2 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
READ_CHANNEL3_WEIGHT	19:15	rw	**Channel 3 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_20	31:20	r	**Reserved for future use**

19.4.2.319 DMA Read Engine Channel Arbitration Weight High Register

The 5-bit channel weight (for read channels 4-7) specifies the maximum number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached or DMA channel request transfer size reaches zero, the WWR arbiter selects the next channel to be processed. Your software must initialize this register before ringing the doorbell. For more details, see "Multichannel Arbitration". Value range is (0-0x1F) corresponding to (1-32) transaction requests.



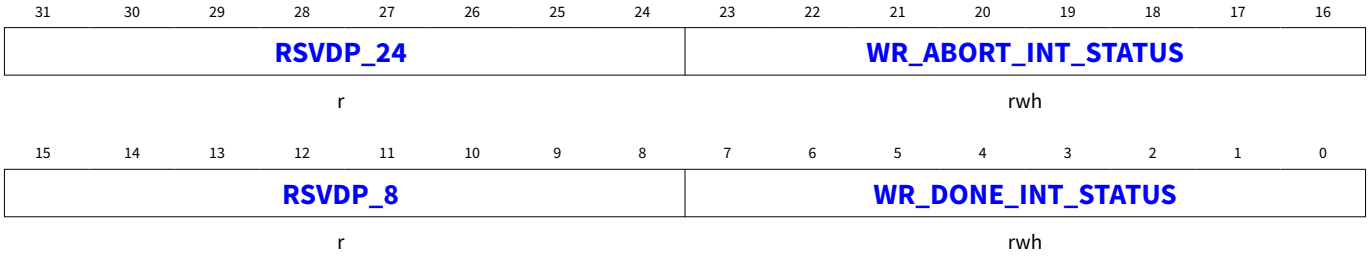
Field	Bits	Type	Description
READ_CHANNEL4_WEIGHT	4:0	rw	**Channel 4 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
READ_CHANNEL5_WEIGHT	9:5	rw	**Channel 5 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
READ_CHANNEL6_WEIGHT	14:10	rw	**Channel 6 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
READ_CHANNEL7_WEIGHT	19:15	rw	**Channel 7 Weight** The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_20	31:20	r	**Reserved for future use**

19.4.2.320 DMA Write Interrupt Status Register

This register indicates the status of Abort and Done interrupts for the DMA write channels.

DMA_WRITE_INT_STATUS_OFF Offset address: $000704C_H$

DMA Write Interrupt Status Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
WR_DONE_INT_STATUS	7:0	rwh	**Done Interrupt Status** The DMA write channel has successfully completed the DMA transfer. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA write interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA write interrupt Clear register to clear this interrupt bit. Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register . Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_8	15:8	r	**Reserved for future use**
WR_ABORT_INT_STATUS	23:16	rwh	**Abort Interrupt Status** The DMA write channel has detected an error, or you manually stopped the transfer as described in "Error Handling Assistance by Remote Software". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA write interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA write interrupt Clear register to clear this interrupt bit Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_24	31:24	r	**Reserved for future use**

19.4.2.321 DMA Write Interrupt Mask Register

This register holds the Abort and Done DMA write interrupt mask.

DMA_WRITE_INT_MASK_OFF Offset address: 0007054_H

DMA Write Interrupt Mask Register Kernel Reset value: $000F\ 000F_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSVDP_24								0				WR_ABORT_INT_MASK			
r								r				rw			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVDP_8								0				WR_DONE_INT_MASK			
r								r				rw			

Field	Bits	Type	Description
WR_DONE_INT_MASK	3:0	rw	**Done Interrupt Mask** Prevents the Done interrupt status field in the DMA write interrupt status register from asserting the edma_int output. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_8	15:8	r	**Reserved for future use**
WR_ABORT_INT_MASK	19:16	rw	**Abort Interrupt Mask** Prevents the Abort interrupt status field in the DMA write interrupt status register from asserting the edma_int output. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_24	31:24	r	**Reserved for future use**
0	7:4, 23:20	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.322 DMA Write Interrupt Clear Register

You can write to this register to clear the Abort and Done write interrupts.

DMA_WRITE_INT_CLEAR_OFF Offset address: 0007058_H

DMA Write Interrupt Clear Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSVDP_24								0				WR_ABORT_INT_CLEAR			
r								r				rwh			

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVDP_8								0				WR_DONE_INT_CLEAR			
r								r				rwh			

Field	Bits	Type	Description
WR_DONE_INT_CLEAR	3:0	rwh	**Done Interrupt Clear** You must write a 1'b1 to clear the corresponding bit in the Done interrupt status field of the DMA write interrupt status register. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Note: Reading from this self-clearing register field always returns a '0'.
RSVDP_8	15:8	r	**Reserved for future use**
WR_ABORT_INT_CLEAR	19:16	rwh	**Abort Interrupt Clear** You must write a 1'b1 to clear the corresponding bit in the Abort interrupt status field of the DMA write interrupt status register. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Note: Reading from this self-clearing register field always returns a '0'.
RSVDP_24	31:24	r	**Reserved for future use**
0	7:4, 23:20	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.323 DMA Write Error Status Register

This register provides information pertaining to errors incurred during write channel operation.

DMA_WRITE_ERR_STATUS_OFF Offset address: 000705C$_H$

DMA Write Error Status Register Kernel Reset value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVDP_8								APP_READ_ERR_DETECT							
r								rh							

Field	Bits	Type	Description
APP_READ_ERR_DETECT	7:0	rh	**Application Read Error Detected** The DMA write channel has received an error response from the AXI bus while reading data from it. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA write interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the DMA Write Interrupt Clear Register (DMA_WRITE_INT_CLEAR_OFF) to clear this error bit.
RSVDP_8	15:8	r	**Reserved for future use**
LINKLIST_ELEMENT_FETCH_ERR_DETECT	23:16	rh	**Linked List Element Fetch Error Detected** The DMA write channel has received an error response from the AXI bus while reading a linked list element from local memory. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA write interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the DMA Write Interrupt Clear Register (DMA_WRITE_INT_CLEAR_OFF) to clear this error bit.
RSVDP_24	31:24	r	**Reserved for future use**

19.4.2.324 DMA Write Done IMWr Address Low Register

This register holds the lower 32 bits of the Done IMWr TLP address.

DMA_WRITE_DONE_IMWR_LOW_OFF Offset address: 0007060$_H$

DMA Write Done IMWr Address Low Register Kernel Reset value: 0000 0000$_H$

RSVDP_8								0				WR_CHANNEL_LLRAIE			
r								r				rw			

Field	Bits	Type	Description
WR_CHANNEL_LLRAIE	3:0	rw	**Write Channel LL Remote Abort Interrupt Enable (LLRAIE)** You enable the write channel remote abort interrupt through this bit. The LIE and RIE bits in the LL element enable the write channel done interrupts. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only. For more details, see "Interrupt Handling". Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_8	15:8	r	**Reserved for future use**
WR_CHANNEL_LLLAIE	19:16	rw	**Write Channel LL Local Abort Interrupt Enable (LLLAIE)** You enable the write channel local abort interrupt through this bit. The LIE and RIE bits in the LL element enable the write channel done interrupts. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only. For more details, see "Interrupt Handling". Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_24	31:24	r	**Reserved for future use**
0	7:4, 23:20	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.333 DMA Read Interrupt Status Register

This register indicates the status of Abort and Done interrupts for the DMA read channels.

DMA_READ_INT_STATUS_OFF Offset address: $00070A0_H$

DMA Read Interrupt Status Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSVDP_24								RD_ABORT_INT_STATUS							
r								rwh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVDP_8								RD_DONE_INT_STATUS							
r								rwh							

Field	Bits	Type	Description
RD_DONE_INT_STATUS	7:0	rwh	**Done Interrupt Status** The DMA read channel has successfully completed the DMA read transfer. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA read interrupt Clear register to clear this interrupt bit Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_8	15:8	r	**Reserved for future use**
RD_ABORT_INT_STATUS	23:16	rwh	**Abort Interrupt Status** The DMA read channel has detected an error, or you manually stopped the transfer as described in "Stopping the DMA Transfer (Software Stop)". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. You can read the DMA Read Error Status Low Register (DMA_READ_ERR_STATUS_LOW_OFF) and DMA Read Error Status High Register (DMA_READ_ERR_STATUS_HIGH_OFF) to determine the source of the error. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA read interrupt Clear register to clear this interrupt bit. Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_24	31:24	r	**Reserved for future use**

19.4.2.334 DMA Read Interrupt Mask Register

This register holds the Abort and Done DMA read interrupt mask.

DMA_READ_INT_MASK_OFF Offset address: $00070A8_H$

DMA Read Interrupt Mask Register Kernel Reset value: $000F\ 000F_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RSVDP_24								0				RD_ABORT_INT_MASK

RSVDP_8								0				RD_DONE_INT_MASK			
r								r				rw			

Field	Bits	Type	Description
RD_DONE_INT_MASK	3:0	rw	**Done Interrupt Mask** Prevents the Done interrupt status field in the DMA read interrupt status register from asserting the edma_int output. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_8	15:8	r	**Reserved for future use**
RD_ABORT_INT_MASK	19:16	rw	**Abort Interrupt Mask** Prevents the Abort interrupt status field in the DMA read interrupt status register from asserting the edma_int output. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RSVDP_24	31:24	r	**Reserved for future use**
0	7:4, 23:20	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.335 DMA Read Interrupt Clear Register

You can write to this register to clear the Abort and Done read interrupts.

DMA_READ_INT_CLEAR_OFF Offset address: $00070AC_H$

DMA Read Interrupt Clear Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVDP_8								RD_DONE_INT_CLEAR							
r								rwh							

Field	Bits	Type	Description
RD_DONE_INT_CLEAR	7:0	rwh	**Done Interrupt Clear** You must write a 1'b1 to clear the corresponding bit in the Done interrupt status field of the DMA read interrupt status register. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Note: Reading from this self-clearing register field always returns a '0'.
RSVDP_8	15:8	r	**Reserved for future use**
RD_ABORT_INT_CLEAR	23:16	rwh	**Abort Interrupt Clear** You must write a 1'b1 to clear the corresponding bit in the Abort interrupt status field of the DMA read interrupt status register. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Note: Reading from this self-clearing register field always returns a '0'.
RSVDP_24	31:24	r	**Reserved for future use**

19.4.2.336 DMA Read Error Status Low Register

This register provides information pertaining to linked list element fetch error and application write error.

DMA_READ_ERR_STATUS_LOW_OFF Offset address: $00070B4_H$

DMA Read Error Status Low Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVDP_8								APP_WR_ERR_DETECT							
r								rh							

Field	Bits	Type	Description
APP_WR_ERR_DETECT	7:0	rh	**Application Write Error Detected** The DMA read channel has received an error response from the AXI bus while writing data to it. This error is fatal. You must restart the transfer from the beginning, as the channel context is corrupted, and the transfer is not rolled back. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit Note, this clears all bits in this register, and also the DMA Read Error Status High register (DMA_READ_ERR_STATUS_HIGH_OFF).
RSVDP_8	15:8	r	**Reserved for future use**
LINK_LIST_ELEMENT_FETCH_ERR_DETECT	23:16	rh	**Linked List Element Fetch Error Detected** - The DMA read channel has received an error response from the AXI bus while reading a linked list element from local memory. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the DMA Read Interrupt Clear Register (DMA_READ_INT_CLEAR_OFF) to clear this error bit Note, this clears all bits in this register, and also the DMA Read Error Status High register (DMA_READ_ERR_STATUS_HIGH_OFF).
RSVDP_24	31:24	r	**Reserved for future use**

19.4.2.337 DMA Read Error Status High Register

This register provides information pertaining to completion errors.

DMA_READ_ERR_STATUS_HIGH_OFF Offset address: $00070B8_H$

DMA Read Error Status High Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rh								rh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CPL_ABORT								UNSUPPORTED_REQ							
rh								rh							

Field	Bits	Type	Description
UNSUPPORTED_REQ	7:0	rh	**Unsupported Request** The DMA read channel has received a PCIe unsupported request completion status from the remote device in response to the MRd request. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the DMA Read Interrupt Clear Register (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
CPL_ABORT	15:8	rh	**Completer Abort** The DMA read channel has received a PCIe completer abort completion status from the remote device in response to the MRd request. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the DMA Read Interrupt Clear Register (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.

(table continues...)

(continued)

Field	Bits	Type	Description
CPL_TIMEOUT	23:16	rh	**Completion Time Out** The DMA read channel has timed-out while waiting for the remote device to respond to the MRd request, or a malformed CplD has been received. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the DMA Read Interrupt Clear Register (DMA_READ_INT_CLEAR_OFF) to clear this error bit Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
DATA_POISIONING	31:24	rh	**Data Poisoning** The DMA read channel has detected data poisoning in the completion from the remote device (in response to the MRd request). The DMA read channel will drop the completion and then be halted. The CX_FLT_MASK_UR_POIS filter rule does not affect this behavior. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. • Enabling: For more details, see "Interrupts and Error Handling" • Masking: The DMA read interrupt Mask register has no effect on this register • Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the DMA Read Interrupt Clear Register (DMA_READ_INT_CLEAR_OFF) to clear this error bit Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.

19.4.2.338 DMA Read Linked List Error Enable Register

The LIE and RIE bits in the LL element enable the channel "done" interrupts (local and remote). The LLLAIE and LLRAIE bits enable the channel "abort" interrupts (local and remote).

DMA_READ_LINKED_LIST_ERR_EN_OFF Offset address: $00070C4_H$

DMA Read Linked List Error Enable Register Kernel Reset value: $0000\ 0000_H$

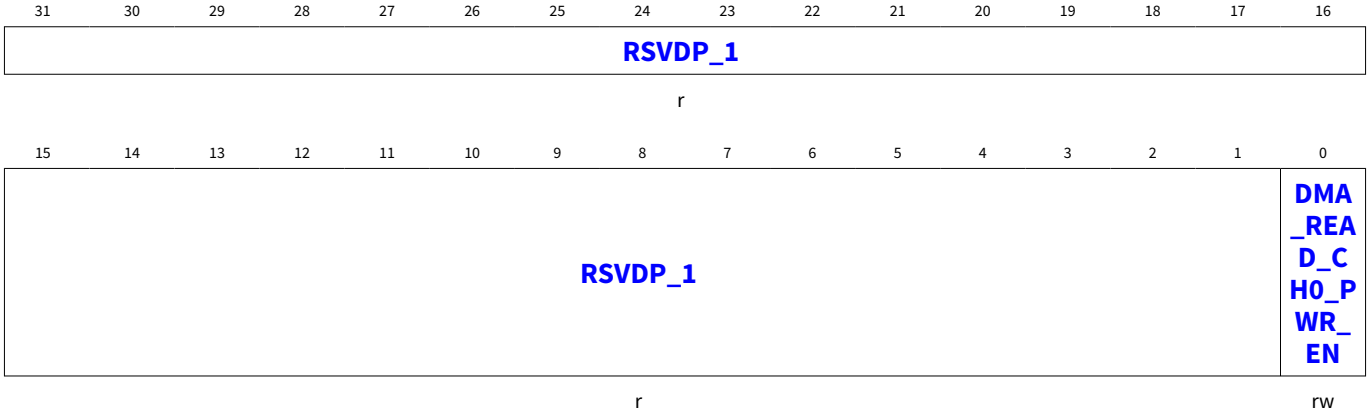
DMA_WRITE_CH0_PWR_EN	0	rw	**DMA Write Channel 0 Power enable/disable** 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
RSVDP_1	31:1	r	**Reserved for future use**

19.4.2.352 DMA Read Channel i Power Enable Register

This register controls power enable/disable for read channel 0.

DMA_READ_CHi_PWR_EN_OFF (i=0-3) Offset address: 0007168_H+i*4

DMA Read Channel i Power Enable Register Kernel Reset value: $0000\ 0000_H$



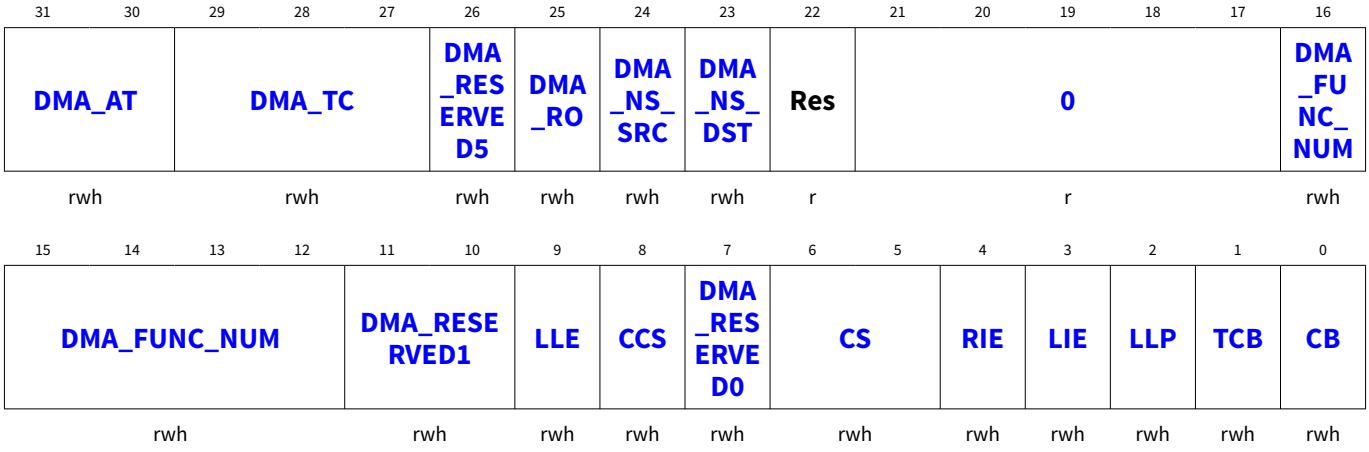
Field	Bits	Type	Description
DMA_READ_CH0_PWR_EN	0	rw	**DMA Read Channel 0 Power enable/disable** 0_B **DISABLE**: Disable 1_B **ENABLE**: Enable
RSVDP_1	31:1	r	**Reserved for future use**

19.4.2.353 DMA Write Channel i Control 1 Register

This register controls the DMA write channel operation.

DMA_CH_CONTROL1_OFF_WRCH_i (i=0-3) Offset address: 0007200_H+i*200_H

DMA Write Channel i Control 1 Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CB	0	rwh	**Cycle Bit (CB)** Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the CB of the linked list element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
TCB	1	rwh	**Toggle Cycle Bit (TCB)** Indicates to the DMA to toggle its interpretation of the CB. Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the TCB of the linked list element. this field is not defined in a data LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
LLP	2	rwh	**Load Link Pointer (LLP)** Used in linked list mode only. Indicates that this linked list element is a link element, and its LL element pointer dwords are pointing to the next (non-contiguous) element. The DMA loads this field with the LLP of the linked list element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
LIE	3	rwh	**Local Interrupt Enable (LIE)** You must set this bit to enable the generation of the Done or Abort Local interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the LIE of the LL element. The LIE bit in a LL element only enables the Done interrupt. In non-LL mode, the LIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
RIE	4	rwh	**Remote Interrupt Enable (RIE)** You must set this bit to enable the generation of the Done or Abort Remote interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the RIE of the LL element. The RIE bit in a LL element only enables the Done interrupt. In non-LL mode, the RIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
CS	6:5	rwh	**Channel Status (CS)** The channel status bits identify the current operational state of the DMA channel. The operation state encoding for each DMA channel is a s follows: 00_B **RESERVED**: Reserved 01_B **RUNNING**: This channel is active and transferring data 10_B **HALTED**: An error condition has been detected, and the DMA has stopped this channel 11_B **STOPPED**: The DMA has transferred all data for this channel, or you have prematurely stopped this channel by writing to the Stop field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF)
DMA_RESERVED0	7	rwh	**Reserved** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
CCS	8	rwh	**Consumer Cycle State (CCS)** Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". You must initialize this bit. The DMA updates this bit during linked list operation. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
LLE	9	rwh	**Linked List Enable (LLE)** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_B **DISABLE**: Disable linked list operation 1_B **ENABLE**: Enable linked list operation
DMA_RESERVED1	11:10	rwh	**Reserved** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_FUNC_NUM	16:12	rwh	**DMA Channel Physical Function Number** This field indicates the physical function associated with the DMA channel. The controller uses this field to form the requester ID of the generated MRd/MWr DMA TLPs. Note: The behavior is undefined if any value outside of the valid range is set for this field Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 00_H **Min_Val**: Physical Channel Function Number starts at 0 $1F_H$ **Max_Val**: The maximum number of Physical Functions, so the maximum value of this field is 0
DMA_NS_DST	23	rwh	**Destination No Snoop TLP Header Bit** The DMA uses this TLP header field when generating MWr (DAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_NS_SRC	24	rwh	**Source No Snoop TLP Header Bit** The DMA uses this TLP header field when generating MRd (SAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_RO	25	rwh	**Relaxed Ordering TLP Header Bit (RO)** DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_RESERVED5	26	rwh	**Reserved** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_TC	29:27	rwh	**Traffic Class TLP Header Bit (TC)** The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
DMA_AT	31:30	rwh	**Address Translation TLP Header Bit (AT)** The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
0	21:17	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.354 DMA CH i Write Transfer Size Register

This register holds the DMA write transfer size.

DMA_TRANSFER_SIZE_OFF_WRCH_i (i=0-3) Offset address: $0007208_H+i*200_H$

DMA CH i Write Transfer Size Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMA_TRANSFER_SIZE															
rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DMA_TRANSFER_SIZE															
rwh															

Field	Bits	Type	Description
DMA_TRANSFER_SIZE	31:0	rwh	**DMA Transfer Size** You program this register with the size of the DMA transfer. The maximum DMA transfer size is 4Gbytes. The minimum transfer size is one byte (0x1). This field is automatically decremented by the DMA as the DMA write channel transfer progresses. This field indicates the number bytes remaining to be transferred. When all bytes are successfully transferred the current transfer size is zero. In LL mode, the DMA overwrites this register with the corresponding dword of the LL element. You can read this register to monitor the transfer progress, however in some scenarios this register is updated after a delay. For example, when less than 3 channels are doorbelled, this register is updated only after a descriptor finishes(linked list mode), or the transfer ends (non-linked list mode). Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.355 DMA CH i Write SAR Low Register

This register holds the lower 32 bits of the Source Address Register (SAR).

DMA_SAR_LOW_OFF_WRCH_i (i=0-3) Offset address: $000720C_H+i*200_H$

DMA CH i Write SAR Low Register Kernel Reset value: $0000\ 0000_H$

rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SRC_ADDR_REG_LOW															
rwh															

Field	Bits	Type	Description
SRC_ADDR_REG_LOW	31:0	rwh	**Source Address Register (lower 32 bits)** Indicates the next address to be read from. The DMA increments the SAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding dword of the LL element. - DMA Read: The SAR is the address of the remote memory. - DMA Write: The SAR is the address of the local memory. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.356 DMA CH i Write SAR High Register

This register holds the higher 32 bits of the Source Address Register (SAR).

DMA_SAR_HIGH_OFF_WRCH_i (i=0-3) Offset address: $0007210_H+i*200_H$

DMA CH i Write SAR High Register Kernel Reset value: $0000\ 0000_H$

rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SRC_ADDR_REG_HIGH															
rwh															

Field	Bits	Type	Description
SRC_ADDR_REG_HIGH	31:0	rwh	**Source Address Register (higher 32 bits)** In LL mode, the DMA overwrites this with the corresponding dword of the LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.357 DMA CH i Write DAR Low Register

This register holds the lower 32 bits of the Destination Address Register (DAR).

DMA_DAR_LOW_OFF_WRCH_i (i=0-3) Offset address: $0007214_H+i*200_H$

DMA CH i Write DAR Low Register Kernel Reset value: $0000\ 0000_H$

rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DST_ADDR_REG_LOW															
rwh															

Field	Bits	Type	Description
DST_ADDR_REG_LOW	31:0	rwh	**Destination Address Register (lower 32 bits)** Indicates the next address to be written to. The DMA increments the DAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding dword of the LL element. - DMA Read: The DAR is the address of the local memory. - DMA Write: The DAR is the address of the remote memory. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.358 DMA CH i Write DAR High Register

This register holds the higher 32 bits of the Destination Address Register (DAR).

DMA_DAR_HIGH_OFF_WRCH_i (i=0-3) Offset address: $0007218_H+i*200_H$

DMA CH i Write DAR High Register Kernel Reset value: $0000\ 0000_H$

rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DST_ADDR_REG_HIGH															
rwh															

Field	Bits	Type	Description
DST_ADDR_REG_HIGH	31:0	rwh	**Destination Address Register (Higher 32 bits)** In LL mode, the DMA overwrites this with the corresponding dword of the LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.359 DMA CH i Write Linked List Pointer Low Register

This register holds the lower 32 bits of the DMA write linked list pointer.

DMA_LLP_LOW_OFF_WRCH_i (i=0-3) Offset address: $000721C_H+i*200_H$

DMA CH i Write Linked List Pointer Low Register Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
LLP_LOW	31:0	rwh	**Lower bits of the address of the linked list transfer list in local memory** Used in linked list mode only. When to point to the next element in the transfer list after the previous element is consumed. • When the current element is a data element; this field is incremented by 6 DWORDs. • When the current element is a link element; this field is overwritten by the LL Element Pointer of the element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.360 DMA CH i Write Linked List Pointer High Register

This register holds the higher 32 bits of the DMA write linked list pointer.

DMA_LLP_HIGH_OFF_WRCH_i (i=0-3) Offset address: $0007220_H+i*200_H$

DMA CH i Write Linked List Pointer High Register Kernel Reset value: $0000\ 0000_H$

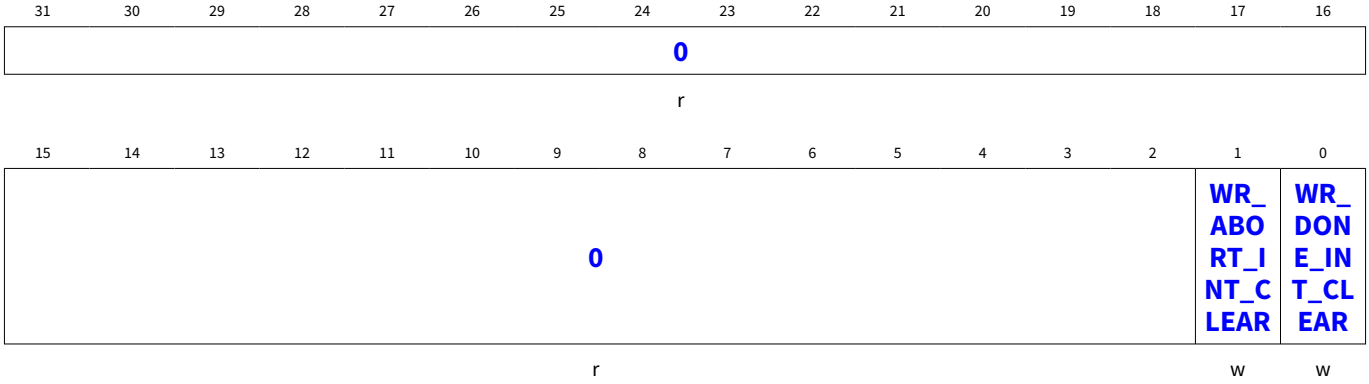
Field	Bits	Type	Description
LLP_HIGH	31:0	rwh	**Higher 32 bits of the address of the linked list transfer list in local memory** Used in linked list mode only. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.361 Interrupt clear for DMA write channel i

This register has dedicated control over a DMA channel and it has the same functionality as DMA Write Interrupt Clear Register.

DMACAP_CHi_WRCHN_WR_INT_CLEAR (i=0-3) Offset address: $0007224_H+i*200_H$

Interrupt clear for DMA write channel i Kernel Reset value: $0000\ 0000_H$



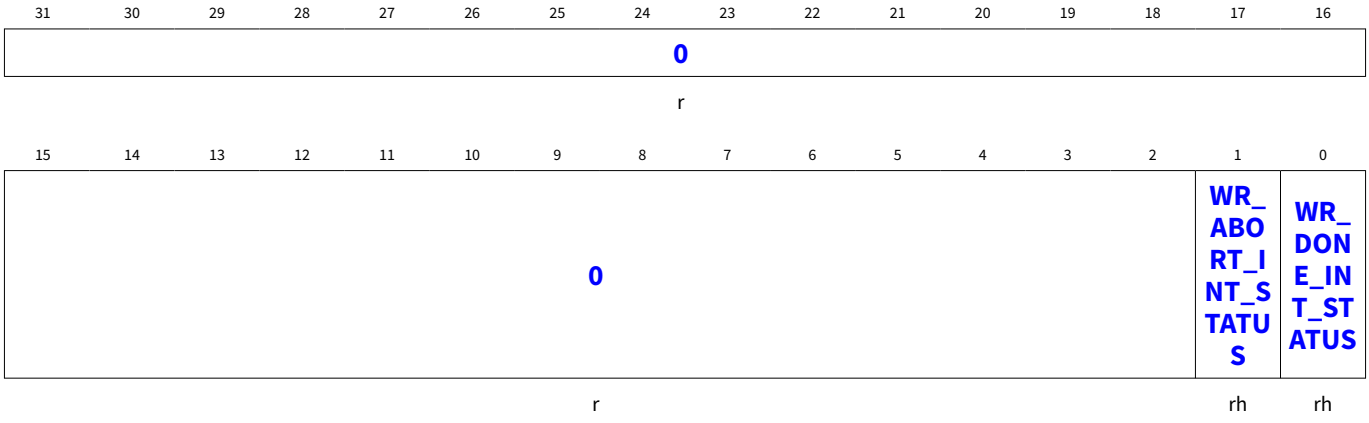
Field	Bits	Type	Description
WR_DONE_INT_CLEAR	0	w	**Done Interrupt Clear for the DMA channel i** You must write a 1'b1 to clear the corresponding bit in the Done interrupt status field of the DMA write interrupt status register. Note: Reading from this self-clearing register field always returns a '0'. 0_B No effect 1_B Clear status
WR_ABORT_INT_CLEAR	1	w	**Abort Interrupt Clear for the DMA channel i** You must write a 1'b1 to clear the corresponding bit in the Abort interrupt status field of the DMA write interrupt status register. Note: Reading from this self-clearing register field always returns a '0'. 0_B No effect 1_B Clear status
0	31:2	r	**Reserved** Read as 0; should be written with 0.

19.4.2.362 Interrupt status for DMA write channel i

This register has dedicated control over a DMA channel and it has the same functionality as DMA Write Interrupt Status Register.

DMACAP_CHi_WRCHN_WR_INT_STATUS (i=0-3) Offset address: $0007228_H+i*200_H$

Interrupt status for DMA write channel i Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
WR_DONE_INT_STATUS	0	rh	**Done Interrupt Status for the DMA channel i** The DMA write channel has successfully completed the DMA transfer.
WR_ABORT_INT_STATUS	1	rh	**Abort Interrupt Status for the DMA channel i** The DMA write channel has detected an error, or you manually stopped the transfer.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

19.4.2.363 Error status for DMA write channel i

This register has dedicated control over a DMA channel and it has the same functionality as DMA Write Error Status Register.

DMACAP_CHi_WRCHN_WR_ERR_STATUS (i=0-3) Offset address: $000722C_H+i*200_H$

Error status for DMA write channel i Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0														LINKLIST_ELEMENT_FETCH_ERR_DETECT	APP_READ_ERR_DETECT
r														rh	rh

Field	Bits	Type	Description
APP_READ_ERR_DETECT	0	rh	**Application Read Error Detected for the DMA channel i** The DMA write channel has received an error response from the AXI bus while reading data from it. . - Clearing: You must write a 1'b1 to the WR_ABORT_INT_CLEAR to clear this error bit.
LINKLIST_ELEMENT_FETCH_ERR_DETECT	1	rh	**Linked List Element Fetch Error Detected for the DMA channel i** The DMA write channel has received an error response from the AXI bus while reading a linked list element from local memory.- Clearing: You must write a 1'b1 to the corresponding channel bit in the WR_ABORT_INT_CLEAR to clear this error bit.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

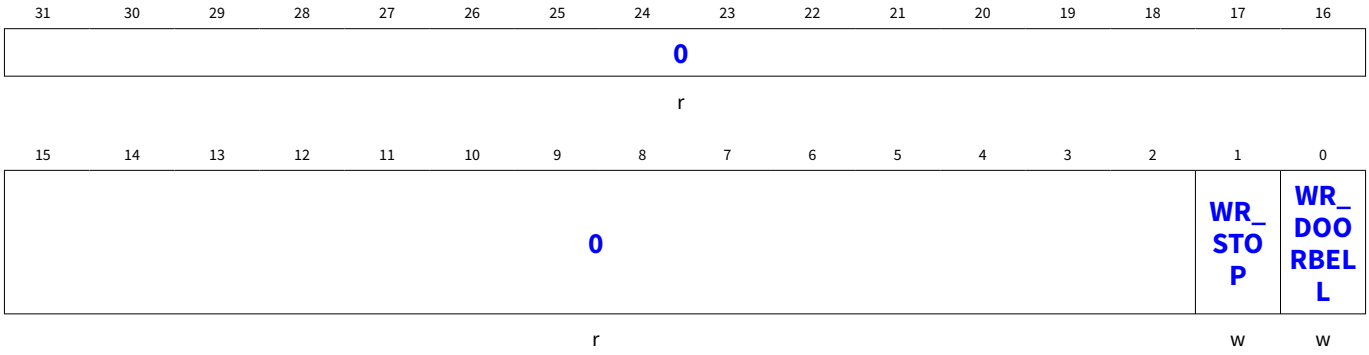
19.4.2.364 Doorbell for DMA write channel i

This register has dedicated control over a DMA channel and it has the same functionality as DMA Write Doorbell Register.

Note: This register is strictly a write only register. Reading this register may result in undefined behavior.

DMACAP_CHi_WRCHN_WR_DOORBELL (i=0-3) Offset address: $0007230_H+i*200_H$

Doorbell for DMA write channel i Kernel Reset value: $0000\ 0000_H$



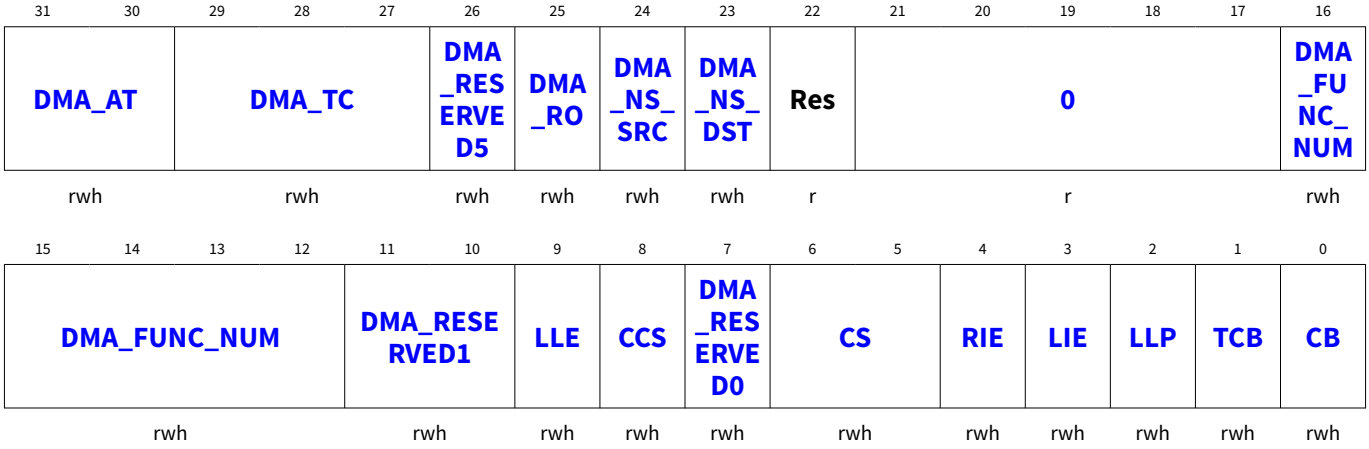
Field	Bits	Type	Description
WR_DOORBELL	0	w	**Doorbell Number for the DMA channel i** You must write the channel number 1'b1 to this register to start the DMA write transfer for that channel. Note: A write to this field triggers the controller to exit L1 substates 0_B No effect 1_B Start DMA transfer
WR_STOP	1	w	**Stop for the DMA channel i** The DMA write channel stops issuing requests, sets the channel status to "Stopped", and asserts the "Abort" interrupt if it is enabled. Before setting the Stop bit, you must read the channel Status field (CS) of the DMA Write Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) to ensure that the write channel is "Running" (transferring data). Note: Use this feature with caution. DMA stop feature is not meant to be used in operational mode. It is only a debug feature and has associated hazards. 0_B No effect 1_B Stop the DMA
0	31:2	r	**Reserved** Read as 0; should be written with 0.

19.4.2.365 DMA Read Channel i Control 1 Register

This register controls the DMA read channel operation.

DMA_CH_CONTROL1_OFF_RDCH_i (i=0-3) Offset address: $0007300_H+i*200_H$

DMA Read Channel i Control 1 Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CB	0	rwh	**Cycle Bit (CB)** Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the CB of the linked list element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
TCB	1	rwh	**Toggle Cycle Bit (TCB)** Indicates to the DMA to toggle its interpretation of the CB. Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the TCB of the linked list element. This field is not defined in a data LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
LLP	2	rwh	**Load Link Pointer (LLP)** Used in linked list mode only. Indicates that this linked list element is a link element, and its LL element pointer dwords are pointing to the next (non-contiguous) element. The DMA loads this field with the LLP of the linked list element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
LIE	3	rwh	**Local Interrupt Enable (LIE)** You must set this bit to enable the generation of the Done or Abort Local interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the LIE of the LL element. The LIE bit in a LL element only enables the Done interrupt. In non-LL mode, the LIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
RIE	4	rwh	**Remote Interrupt Enable (RIE)** You must set this bit to enable the generation of the Done or Abort Remote interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the RIE of the LL element. The RIE bit in a LL element only enables the Done interrupt. In non-LL mode, the RIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
CS	6:5	rwh	**Channel Status (CS)** The channel status bits identify the current operational state of the DMA channel. The operation state encoding for each DMA channel is a s follows: 00_B **RSVD**: Reserved 01_B **RUN**: Running This channel is active and transferring data. 10_B **HALT**: Halted An error condition has been detected, and the DMA has stopped this channel. 11_B **STOP**: Stopped The DMA has transferred all data for this channel, or you have prematurely stopped this channel by writing to the Stop field of the DMA Read Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF).
DMA_RESERVED0	7	rwh	**Reserved** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
CCS	8	rwh	**Consumer Cycle State (CCS)** Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". You must initialize this bit. The DMA updates this bit during linked list operation. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
LLE	9	rwh	**Linked List Enable (LLE)** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 0_B **DISABLE**: Disable linked list operation 1_B **ENABLE**: Enable linked list operation
DMA_RESERVED1	11:10	rwh	**Reserved** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

(table continues...)

(continued)

Field	Bits	Type	Description
DMA_FUNC_NUM	16:12	rwh	**DMA Channel Physical Function Number** This field indicates the physical function associated with the DMA channel. The controller uses this field to form the requester ID of the generated MRd/MWr DMA TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W 00_H **Min_Val**: Physical Channel Function Number starts at 0 $1F_H$ **Max_Val**: The maximum number of Physical Functions, so the maximum value of this field is 0
DMA_NS_DST	23	rwh	**Destination No Snoop TLP Header Bit** The DMA uses this TLP header field when generating MWr (DAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_NS_SRC	24	rwh	**Source No Snoop TLP Header Bit** The DMA uses this TLP header field when generating MRd (SAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_RO	25	rwh	**Relaxed Ordering TLP Header Bit (RO) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_RESERVED5	26	rwh	**Reserved** Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_TC	29:27	rwh	**Traffic Class TLP Header Bit (TC)** The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
DMA_AT	31:30	rwh	**Address Translation TLP Header Bit (AT)** The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W
0	21:17	r	**Reserved** Read as all 0's; should be written with all 0's.

19.4.2.366 DMA Read CH i Transfer Size Register

This register holds the DMA read transfer size.

DMA_TRANSFER_SIZE_OFF_RDCH_i (i=0-3) Offset address: $0007308_H+i*200_H$

DMA Read CH i Transfer Size Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMA_TRANSFER_SIZE															
rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DMA_TRANSFER_SIZE															
rwh															

Field	Bits	Type	Description
DMA_TRANSFER_SIZE	31:0	rwh	**DMA Transfer Size** You program this register with the size of the DMA transfer. The maximum DMA transfer size is 4Gbytes. The minimum transfer size is one byte (0x1). This field is automatically decremented by the DMA as the DMA read channel transfer progresses. This field indicates the number bytes remaining to be transferred. When all bytes are successfully transferred the current transfer size is zero. In LL mode, the DMA overwrites this register with the corresponding dword of the LL element. You can read this register to monitor the transfer progress, however in some scenarios this register is updated after a delay. For example, when less than 3 channels are doorbelled, this register is updated only after a descriptor finishes(linked list mode), or the transfer ends (non-linked list mode). Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.367 DMA Read CH i SAR Low Register

This register holds the lower 32 bits of the Source Address Register (SAR).

DMA_SAR_LOW_OFF_RDCH_i (i=0-3) Offset address: $000730C_H+i*200_H$

DMA Read CH i SAR Low Register Kernel Reset value: $0000\ 0000_H$

rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SRC_ADDR_REG_LOW															
rwh															

Field	Bits	Type	Description
SRC_ADDR_REG_LOW	31:0	rwh	**Source Address Register (Lower 32 bits)** Indicates the next address to be read from. The DMA increments the SAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding dword of the LL element. • DMA Read: The SAR is the address of the remote memory • DMA Read: The SAR is the address of the local memory Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.368 DMA Read CH i SAR High Register

This register holds the higher 32 bits of the Source Address Register (SAR).

DMA_SAR_HIGH_OFF_RDCH_i (i=0-3) Offset address: $0007310_H+i*200_H$

DMA Read CH i SAR High Register Kernel Reset value: $0000\ 0000_H$

rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SRC_ADDR_REG_HIGH															
rwh															

Field	Bits	Type	Description
SRC_ADDR_REG_HIGH	31:0	rwh	**Source Address Register (higher 32 bits)** In LL mode, the DMA overwrites this with the corresponding dword of the LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.369 DMA Read CH i DAR Low Register

This register holds the lower 32 bits of the Destination Address Register (DAR).

DMA_DAR_LOW_OFF_RDCH_i (i=0-3) Offset address: $0007314_H+i*200_H$

DMA Read CH i DAR Low Register Kernel Reset value: $0000\ 0000_H$

rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DST_ADDR_REG_LOW															
rwh															

Field	Bits	Type	Description
DST_ADDR_REG_LOW	31:0	rwh	**Destination Address Register (Lower 32 bits)** Indicates the next address to be written to. The DMA increments the DAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding dword of the LL element. • DMA Read: The DAR is the address of the local memory • DMA Read: The DAR is the address of the remote memory Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.370 DMA Read CH i DAR High Register

This register holds the higher 32 bits of the Destination Address Register (DAR).

DMA_DAR_HIGH_OFF_RDCH_i (i=0-3) Offset address: $0007318_H+i*200_H$

DMA Read CH i DAR High Register Kernel Reset value: $0000\ 0000_H$

rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DST_ADDR_REG_HIGH															
rwh															

Field	Bits	Type	Description
DST_ADDR_REG_HIGH	31:0	rwh	**Destination Address Register (higher 32 bits)** In LL mode, the DMA overwrites this with the corresponding dword of the LL element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.371 DMA Read CH i Linked List Pointer Low Register

This register holds the lower 32 bits of the DMA read linked list pointer.

DMA_LLP_LOW_OFF_RDCH_i (i=0-3) Offset address: $000731C_H+i*200_H$

DMA Read CH i Linked List Pointer Low Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LLP_LOW															
rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LLP_LOW															
rwh															

Field	Bits	Type	Description
LLP_LOW	31:0	rwh	**Lower bits of the address of the linked list transfer list in local memory** Used in linked list mode only. When using DMA to point to the next element in the transfer list after the previous element is consumed. • When the current element is a data element; this field is incremented by 6 DWORDs • When the current element is a link element; this field is overwritten by the LL Element Pointer of the element. Note: The access attributes of this field are as follows: - Wire: R/W - Dbi: R/W

19.4.2.372 DMA CH i Read Linked List Pointer High Register

This register holds the higher 32 bits of the DMA read linked list pointer.

DMA_LLP_HIGH_OFF_RDCH_i (i=0-3) Offset address: $0007320_H+i*200_H$

DMA CH i Read Linked List Pointer High Register Kernel Reset value: $0000\ 0000_H$

0														RD_ABORT_INT_STATUS	RD_DONE_INT_STATUS
r														rh	rh

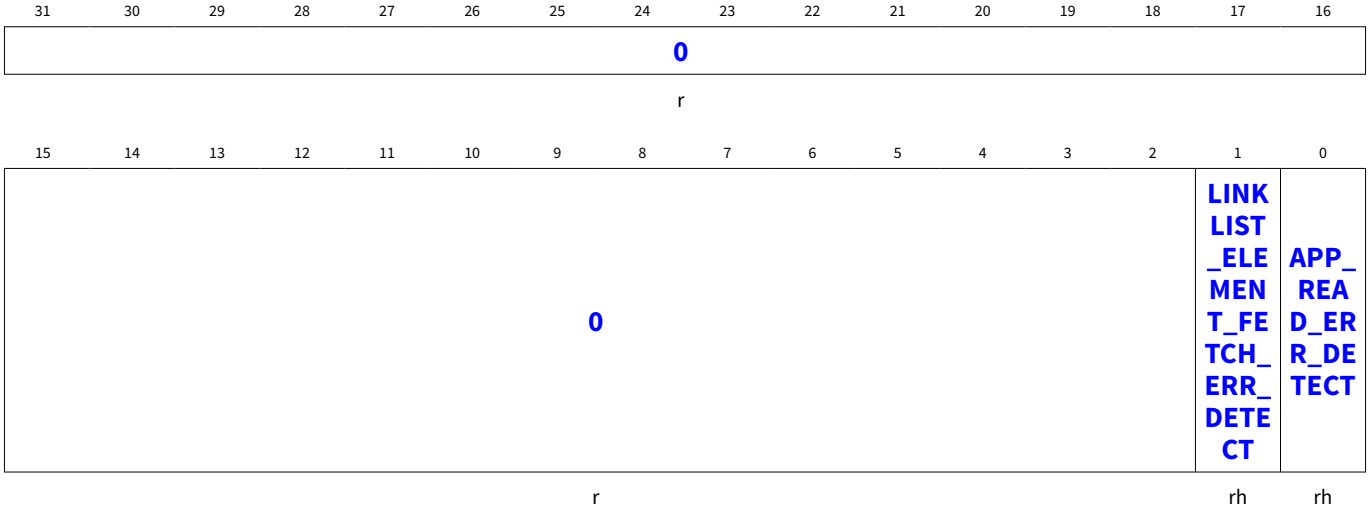
Field	Bits	Type	Description
RD_DONE_INT_STATUS	0	rh	**Done Interrupt Status for the DMA channel i** The DMA read channel has successfully completed the DMA transfer.
RD_ABORT_INT_STATUS	1	rh	**Abort Interrupt Status for the DMA channel i** The DMA read channel has detected an error, or you manually stopped the transfer.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

19.4.2.375 Error status for DMA read channel i

This register has dedicated control over a DMA channel and it has the same functionality as DMA Read Error Status Low Register.

DMACAP_CHi_RDCHN_RD_ERR_STATUS (i=0-3) Offset address: $000732C_H+i*200_H$

Error status for DMA read channel i Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
APP_READ_ERR_DETECT	0	rh	**Application Read Error Detected for the DMA channel i** The DMA read channel has received an error response from the AXI bus while reading data from it. . - Clearing: You must write a 1'b1 to the RD_ABORT_INT_CLEAR to clear this error bit.
LINKLIST_ELEMENT_FETCH_ERR_DETECT	1	rh	**Linked List Element Fetch Error Detected for the DMA channel i** The DMA read channel has received an error response from the AXI bus while reading a linked list element from local memory.- Clearing: You must write a 1'b1 to the corresponding channel bit in the RD_ABORT_INT_CLEAR to clear this error bit.
0	31:2	r	**Reserved** Read as 0; should be written with 0.

19.4.2.376 Higher error status for DMA read channel i

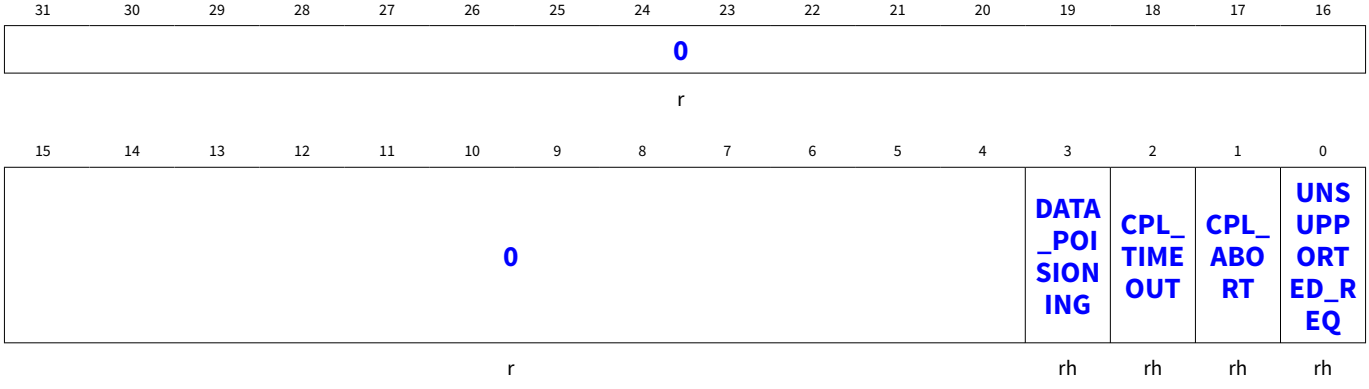
This register has dedicated control over a DMA channel and it has the same functionality as DMA Read Error Status High Register.

DMACAP_CHi_RDCHN_RD_ERR_STATUS_HIGH (i=0-3)

Offset address: $0007330_H+i*200_H$

Higher error status for DMA read channel i

Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
UNSUPPORTED_REQ	0	rh	**Unsupported Request for the DMA channel i** The DMA read channel has received a PCIe unsupported request completion status from the remote device in response to the MRd request. . - Clearing: You must write a 1'b1 to RD_ABORT_INT_CLEAR to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
CPL_ABORT	1	rh	**Completer Abort for the DMA channel i** The DMA read channel has received a PCIe completer abort completion status from the remote device in response to the MRd request.- Clearing: You must write a 1'b1 to the corresponding channel bit in the RD_ABORT_INT_CLEAR to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
CPL_TIMEOUT	2	rh	**Completion Time Out for the DMA channel i** The DMA read channel has timed-out while waiting for the remote device to respond to the MRd request, or a malformed CplD has been received. - Clearing: You must write a 1'b1 to the RD_ABORT_INT_CLEAR to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
DATA_POISIONING	3	rh	**Data Poisoning for the DMA channel i** The DMA read channel has detected data poisoning in the completion from the remote device (in response to the MRd request). The DMA read channel will drop the completion and then be halted. - Clearing: You must write a 1'b1 to the RD_ABORT_INT_CLEAR to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

19.4.2.377 Doorbell for DMA read channel i

This register has dedicated control over a DMA channel and it has the same functionality as DMA Read Doorbell Register.

Note: This register is strictly a write only register. Reading this register may result in undefined behavior.

DMACAP_CHi_RDCHN_RD_DOORBELL (i=0-3) Offset address: $0007334_H+i*200_H$

Doorbell for DMA read channel i Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0														RD_STOP	RD_DOORBELL
r														w	w

Field	Bits	Type	Description
RD_DOORBELL	0	w	**Doorbell Number for the DMA channel i** You must write the channel number 1'b1 to this register to start the DMA write transfer for that channel. Note: A write to this field triggers the controller to exit L1 substates 0_B No effect 1_B Start DMA transfer
RD_STOP	1	w	**Stop for the DMA channel i** The DMA read channel stops issuing requests, sets the channel status to "Stopped", and asserts the "Abort" interrupt if it is enabled. Before setting the Stop bit, you must read the channel Status field (CS) of the DMA Write Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) to ensure that the write channel is "Running" (transferring data). Note: Use this feature with caution. DMA stop feature is not meant to be used in operational mode. It is only a debug feature and has associated hazards. 0_B No effect 1_B Stop the DMA
0	31:2	r	**Reserved** Read as 0; should be written with 0.

19.4.2.378 Write access enable register A

This register defines which master agent function TAG identifier (TAG-ID) encodings are enabled or disabled for write accesses to the access protected region.

S2A_ACCENy_WRA (y=0-7) Offset address: $3FFFE00_H+y*20_H$

r								rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
RDq (q=00-07)	q	rw	**Read access enable for VM ID q** This bit enables read access to the access protected region for transactions with the VM ID q. 0_B Disabled for read access 1_B Enabled for read access

(table continues...)

(continued)

Field	Bits	Type	Description
WRq (q=00-07)	q+16	rw	**Write access enable for VM ID q** This bit enables write access to the access protected region for transactions with the VM ID q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

19.4.2.383 PRS access enable register

This register defines which protection register set encodings are enabled or disabled for accesses to the access protected region. There is one RDx and WRx bit for each PRSx.

S2A_ACCENy_PRS (y=0-7) Offset address: $3FFFE14_H+y*20_H$

PRS access enable register Application Reset value: $00FF\ 00FF_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0								RD07	RD06	RD05	RD04	RD03	RD02	RD01	RD00
r								rw	rw	rw	rw	rw	rw	rw	rw

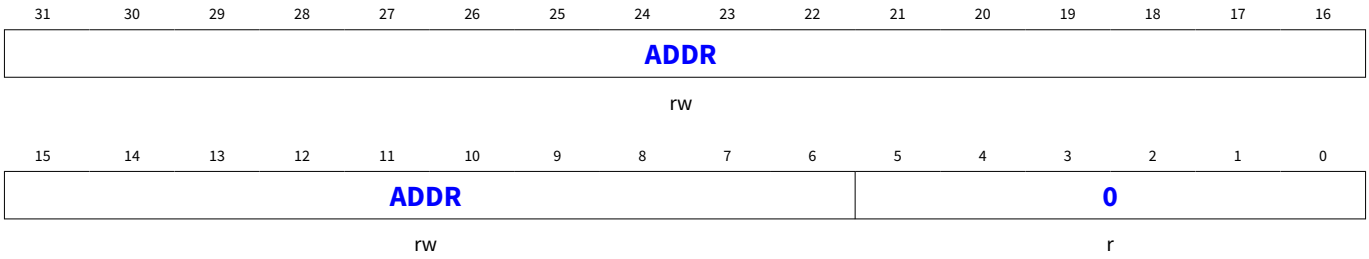
Field	Bits	Type	Description
RDq (q=00-07)	q	rw	**Read access enable for PRS q** This bit enables read access to the access protected region for transactions with the PRS q. 0_B Disabled for read access 1_B Enabled for read access
WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

19.4.2.384 Region lower address register

This register sets the lower bound of the access protected region. Addresses greater than or equal to the lower bound are considered part of the access protected region.

S2A_ACCENy_RGNLA (y=0-7) Offset address: $3FFFE18_H+y*20_H$

Region lower address register Application Reset value: $0000\ 0000_H$



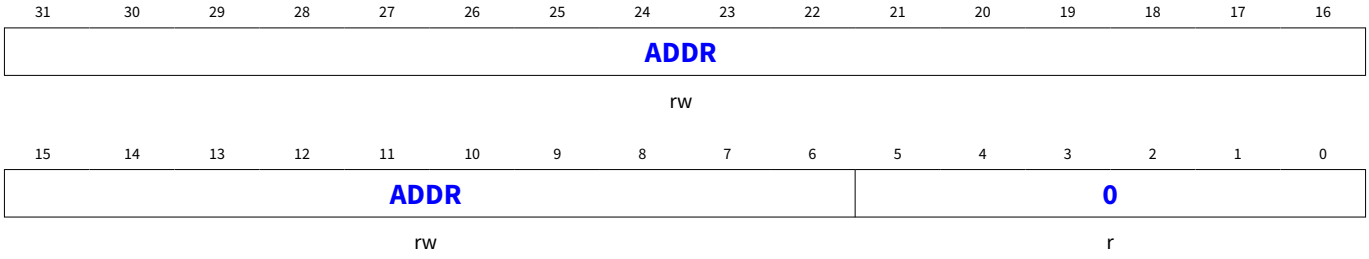
Field	Bits	Type	Description
ADDR	31:6	rw	**Bits 31:6 of the lower bound of the access protected region**
0	5:0	r	**Reserved** Read as 0; should be written with 0.

19.4.2.385 Region upper address register

This register sets the upper bound of the access protected region. Addresses stricly less than the upper bound are considered part of the access protected region.

S2A_ACCENy_RGNUA (y=0-7) Offset address: $3FFFE1C_H+y*20_H$

Region upper address register Application Reset value: $FFFF\ FFC0_H$



Field	Bits	Type	Description
ADDR	31:6	rw	**Bits 31:6 of the upper bound of the access protected region**
0	5:0	r	**Reserved** Read as 0; should be written with 0.

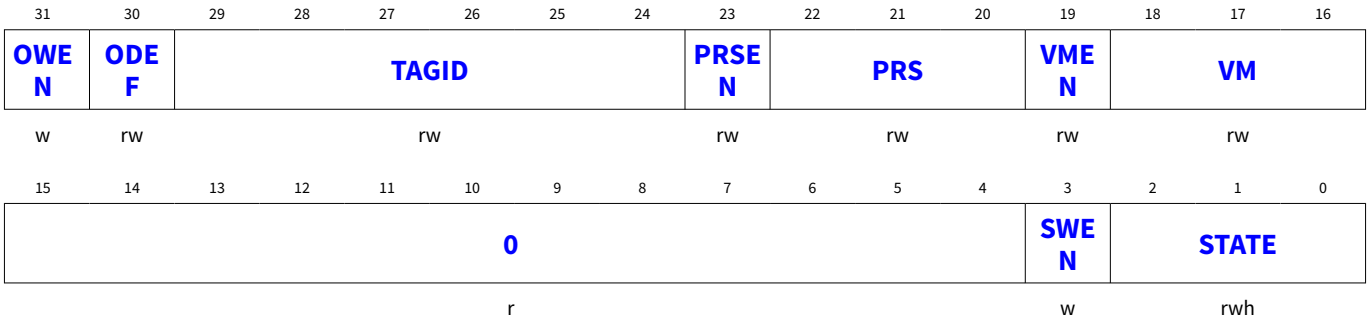
19.4.2.386 PROT Register Safe Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

S2A_PROTSE Offset address: $3FFFF04_H$

PROT Register Safe Endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 895 Access types of S2A_PROTSE in order of evaluation

Condition	Type		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
otherwise	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

19.5 Debug information

OTGB0[15:0] and OTGB1[15:0] can be used for tracing a lot of debug information for PCIe. Trigger sets are created to define which signals are traced. Different colors stand for different trigger sets. For the current plan, PCIe has three trigger sets. The third trigger set TS3 is tied to 0. Two trigger sets can be traced to OTGB0 and OTGB1 in parallel, as shown below .

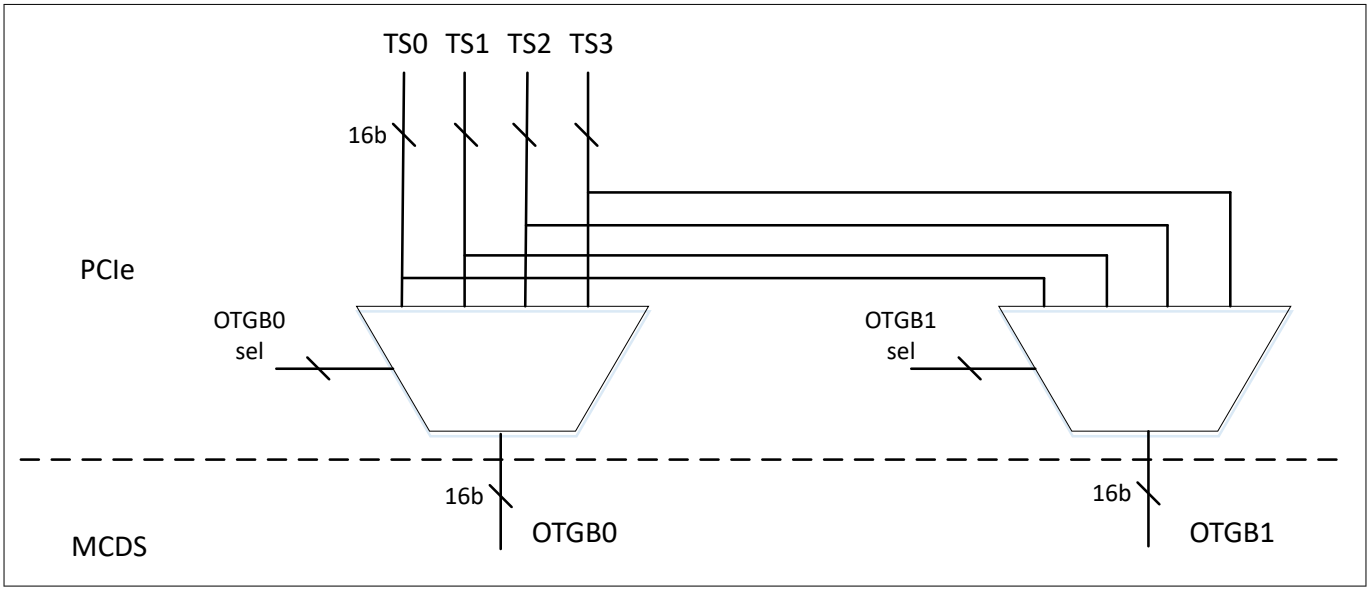


Figure 324 OTGB trigger sets selection logic

Table 896 TS16_PCIe0: Link information

Bits	Description
[0:5]	smlh_ltssm_state: LTSSM current state. Encoding is same as the dedicated smlh_ltssm_state
[6]	rmlh_rcvd_idle[0]: Receiver is receiving logical idle
[7]	smlh_ts2_rcvd: TS2 training sequence received (pulse)
[8]	smlh_ts1_rcvd: TS1 training sequence received (pulse)
[9]	smlh_inskip_rcv: Receiver reports skip reception
[10]	smlh_link_up: LTSSM reports PHY link up or LTSSM is in Loopback.Active for Loopback Master
[11]	xmtbyte_skip_sent: A skip ordered set has been transmitted
[12]	app_init_rst: Application request to initiate training reset
[13]	smlh_ltssm_in_pollconfig: LTSSM is in Polling.Configuration state
[14]	smlh_link_in_training: LTSSM performing link training
[15]	smlh_link_disable: TSSM in DISABLE state. Link inoperable

Table 897 TS16_PCIe1: LTSSM stats

Bits of cxpl_debug_info_ei	Description
[0]	EIOS detected
[1]	L1
[2]	L2

(table continues...)

Table 897 (continued) TS16_PCIe1: LTSSM stats

Bits of cxpl_debug_info_ei	Description
[3]	RxL0s
[4]	Disabled
[5]	Detect.Quiet
[6]	Polling.Active
[7]	Polling.Compliance
[8]	LTSSM is in a transitory state prior to L1 or L2
[9]	LTSSM is in a transitory state prior to Disabled
[10]	LTSSM is in Loopback.Active as a Slave at Gen1
[11]	LTSSM is in Polling.Active
[12]	LTSSM enters Recovery from L0 with EI inferred
[13]	LTSSM enters Recovery.Speed from Recovery.RcvrCfg with EI inferred
[14]	EI inferred while LTSSM in Recovery.Speed
[15]	EI inferred while LTSSM in Loopback.Active as a slave

Table 898 TS16_PCIe2: Power management and controller status

Bits	Description
[0:2]	pm_l1sub_state: PM L1 sub states
[3:5]	pm_curnt_state: PM current link states
[6:8]	pm_dstate: PM current device states
[9]	radm_q_not_empty: level indicating that the receive queues containTLP header and data.
[10]	rtlh_rfc_upd: indicates that the controller received a flowcontrol update DLLP.
[11]	radm_xfer_pending: receive request pending status.
[12]	edma_xfer_pending: DMA transfer pending status.
[13]	brdg_slv_xfer_pending: AXI Slave non-DBI transfer pending status.
[14]	rdlh_link_up: data link layer up or down indicator.
[15]	Reserved

19.5.1 Error injection

The controller provides support for your application to inject the following types of errors:

- CRC Error
- Sequence Number Error
- DLLP Error
- Symbol DataK Mask Error or Sync Header Error
- FC Credit Update Error
- TLP Duplicate/Nullify Error
- Specific TLP Error

Your application can use the registers to set up error injection.

Table 899 Error injection vendor specific extended capability (VSEC) registers

Register	Description
RAS_DES_CAP_HEADER_REG	Vendor-Specific Extended Capability Header.
VENDOR_SPECIFIC_HEADER_REG	Vendor-Specific Header.
.....other registers (for example, Event Counter, Time-based Analysis, Error Injection)	
EINJ_ENABLE_REG	Error Injection Enable.
EINJ0_CRC_REG	Error Injection Control 0 (CRC Error)
EINJ1_SEQNUM_REG	Error Injection Control 1 (SeqNum Error)
EINJ2_DLLP_REG	Error Injection Control 2 (DLLP Error)
EINJ3_SYMBOL_REG	Error Injection Control 3 (Symbol Error)
EINJ4_FC_REG	Error Injection Control 4 (FC Credit Error)
EINJ5_SP_TLP_REG	Error Injection Control 5 (Specific TLP Error)

19.5.2 Statistics

To facilitate collection of statistics the controller provides the following features:

- Time Based Analysis (RX/TX data throughput and time spent in each low-power LTSSM state)
- Event counters (Error and Non-Error)

Time based analysis

Using this feature you can obtain information regarding RX/TX data throughput and time spent in each low-power LTSSM state by the controller. Your application can use the outputs in Table 900 and registers in Table 902.

Table 900 Time-based analysis signals

Signal name	
app_ras_des_tba_ctrl	This bus controls the start/end of time based analysis
cdm_ras_des_tba_info_common	This is common event signal bus that provides RAS D.E.S. time based analysis information.

Table 901 Time-based analysis RAM signals

Signal name	
cdm_ras_des_tb_ram_*	This signal bus provides RAS D.E.S. time based analysis information for the RAMs.

Table 902 Time-based analysis vendor specific extended capability (VSEC) registers

Register	Description
RAS_DES_CAP_HEADER_REG	Vendor-Specific Extended Capability Header
VENDOR_SPECIFIC_HEADER_REG	Vendor-Specific Header.
.....other registers (for example, Event Counter).....	
TIME_BASED_ANALYSIS_CONTROL_REG	Time-based Analysis Control.
TIME_BASED_ANALYSIS_DATA_REG	Time-based Analysis Data.

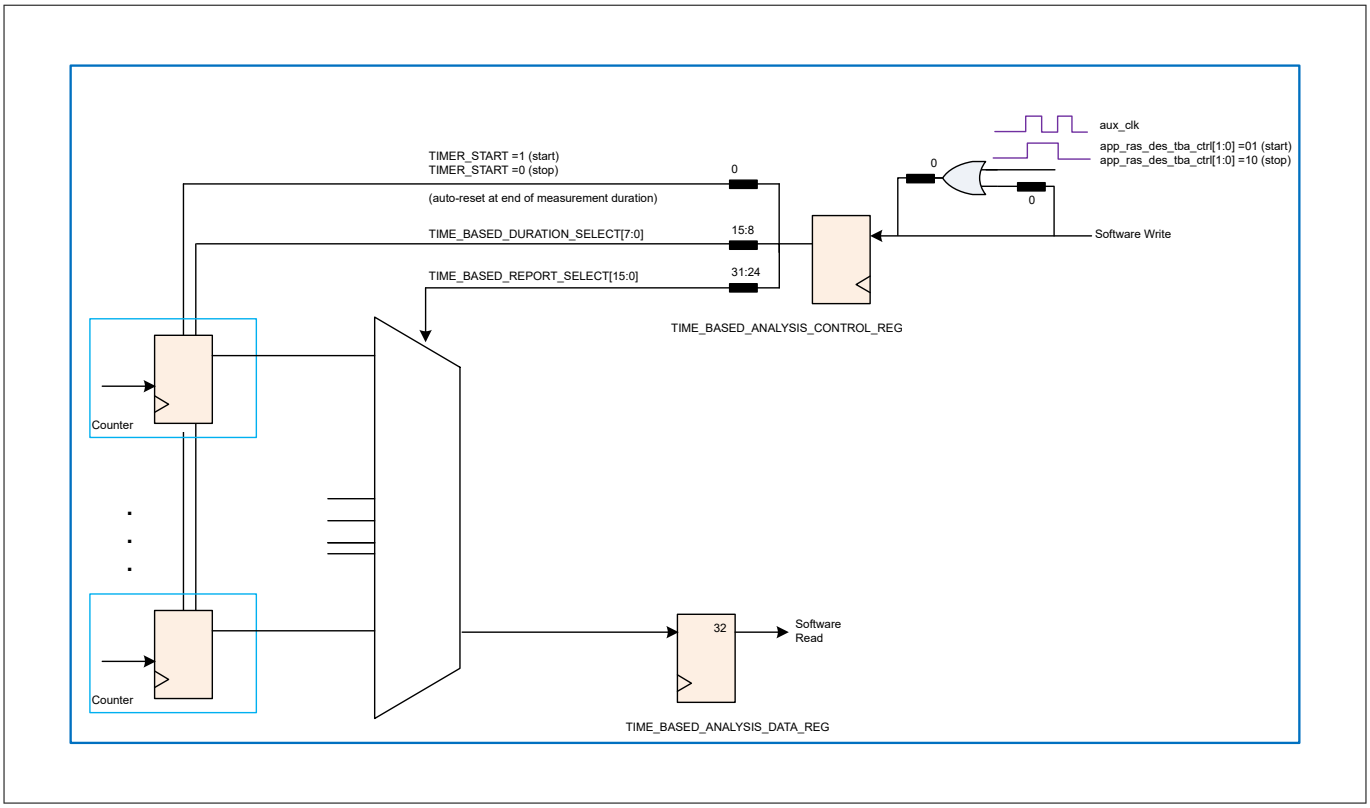

Figure 325 Time-based analysis register access

The counters measure, for example, what percentage of time does the controller stay in L0 in a one second window (configurable through TIME_BASED_DURATION_SELECT field). The measurement range of each Event in Group#0 is shown in Figure 326.

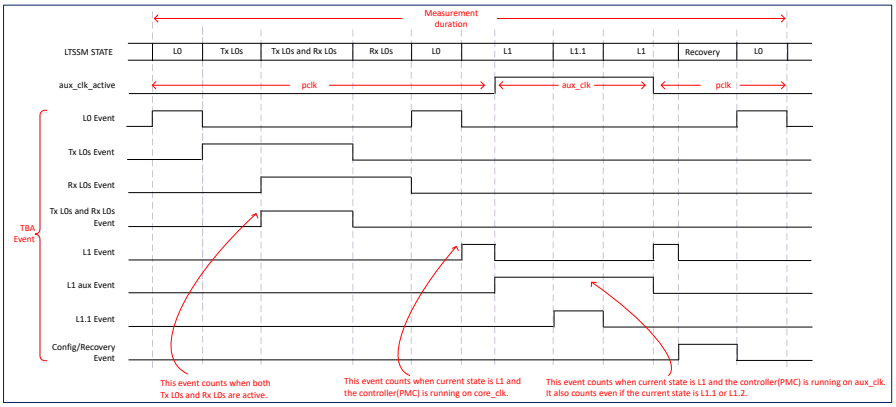

Figure 326 Measurement ranges of time-based analysis events in group #0

Table 903 Time-based analysis counter group #0 (32-bit low-power cycle counter (RAM)

Event #	% of measurement window spent in LTSSM state	Note
0x01	Tx L0s	-
0x02	Rx L0s	-
0x03	L0	-

(table continues...)

Table 903 (continued) Time-based analysis counter group #0 (32-bit low-power cycle counter (RAM)

Event #	% of measurement window spent in LTSSM state	Note
0x04	L1	The controller (PMC) is running on core_clk
0x05	L1.1	-
0x06	L1.2	-
0x07	Configuration/Recovery	-
0x08	L1 aux	The controller (PMC) is running on aux_clk
0x09	Tx L0s and Rx L0s	-

Table 904 Time-based analysis counter group #1 (32-bit throughput 4-DWORD counter)

Event #	Amount of data processed (units of 16 Bytes)	Note
0x00	Tx PCIe TLP Data Payload	-
0x01	Rx PCIe TLP Data Payload	-

L2 Exit: All RASDES analysis results are cleared when the controller exits from L2.

Event counters

Your application can use the outputs in Table 905 and registers in Table 907.

Table 905 Event counter signals

Output	Description
cdm_ras_des_ec_info_common	This is a common signal bus that provides RAS D.E.S. event counter information.
cdm_ras_des_ec_info_i(for i = 0; i <CX_NL))	This is Lane*i* event signal bus that provides RAS D.E.S. event counter information.

Table 906 Event counter RAM signals

Signal names	Description
cdm_ras_des_ec_ram_*	This signal bus provides RAS D.E.S. Event Counter information for the RAMs.

Table 907 Event counter VSEC registers

Register	Description
RAS_DES_CAP_HEADER_REG	Vendor-Specific Extended Capability Header.
VENDOR_SPECIFIC_HEADER_REG	Vendor-Specific Header.
EVENT_COUNTER_CONTROL_REG	Event Counter Control.
EVENT_COUNTER_DATA_REG	Event Counter Data.

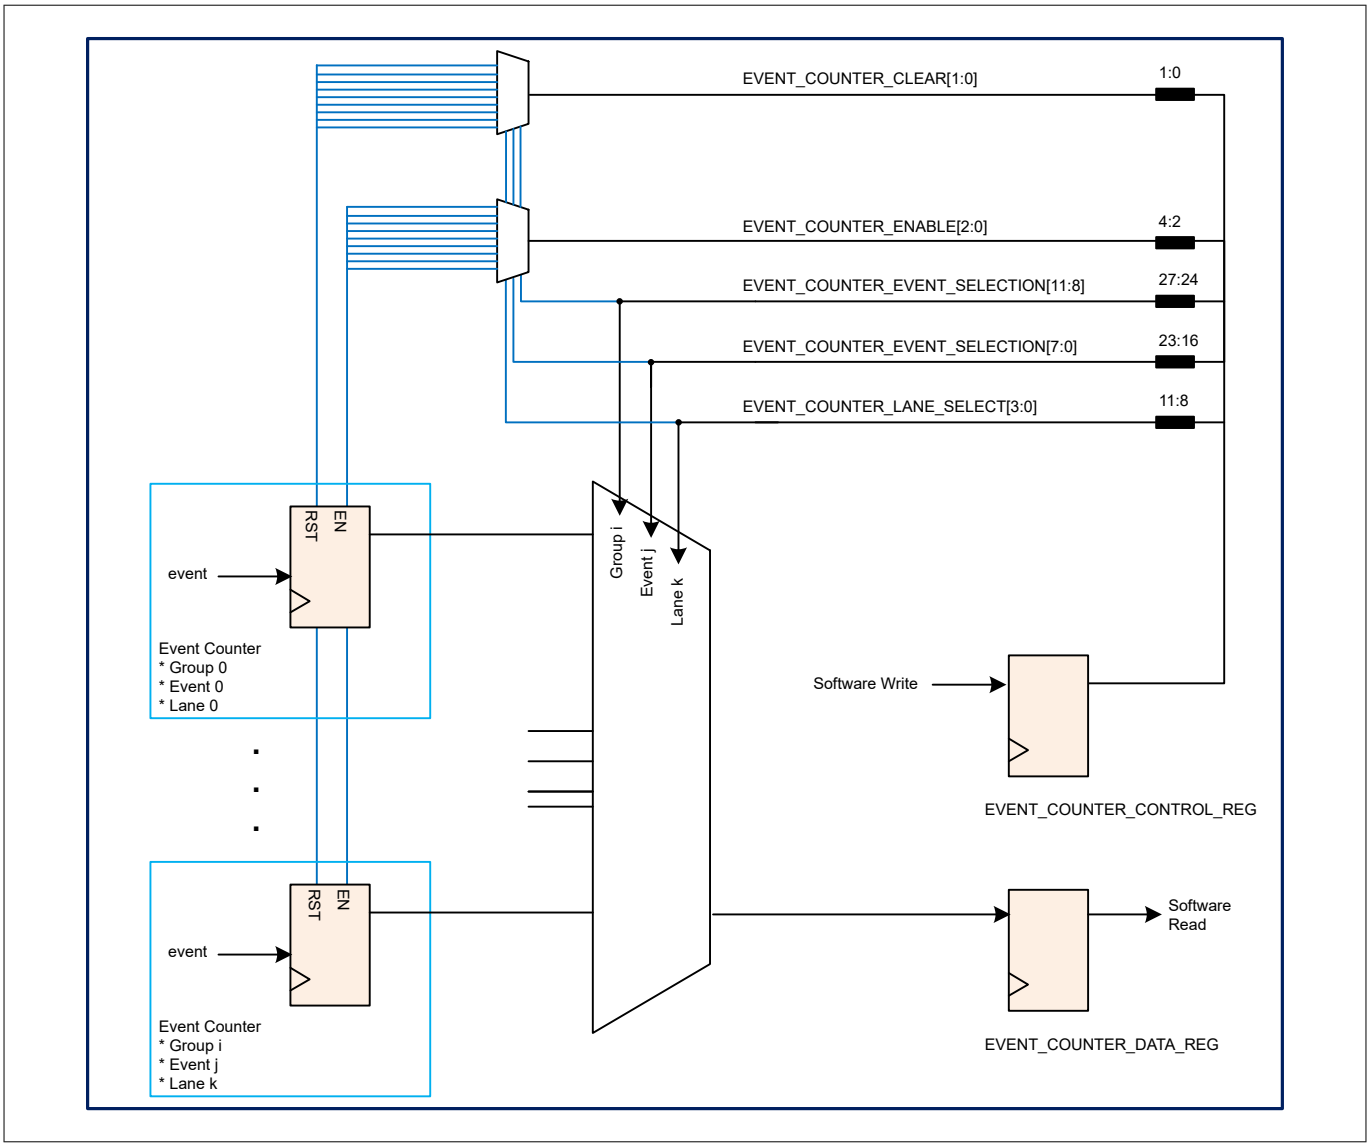

Figure 327 Event counter register access

Event counter data details

The following tables provide the Group/Event numbers which are required when using the EVENT_COUNTER_CONTROL_REG viewport control register to read each of the event counters. Some of the event counters only exist for specific configurations. Groups 5-7 are implemented in RAM as indicated. The group # is set by EVENT_COUNTER_EVENT_SELECTION[11:8]and the event # is set by EVENT_COUNTER_EVENT_SELECTION[7:0]

Table 908 Event counter group #0 (4-bit layer1 error counter per-lane)

Event #	Description	Note
0x00	EBUF Overflow	-
0x01	EBUF Under-run	-

0x12	Rx Completion w data	-
0x13	Rx Message TLP	PCIe VC only
0x14	Rx Atomic	-
0x15	Rx TLP with Prefix	-

Limitations

If the controller (PMC) is running on `aux_clk` during the measurement:

- The measurement timers (`TIME_BASED_DURATION_SELECT`: 1 ms, 10 ms, …, 2 s, 4 s) have measurement error less than 4 µs
- The measurement timers and event timers of all the events are stopped temporarily when `aux_clk_active` or `pm_sel_aux_clk` are controlled. Figure 328 describes the timing details when `aux_clk_active` or `pm_sel_aux_clk` are controlled

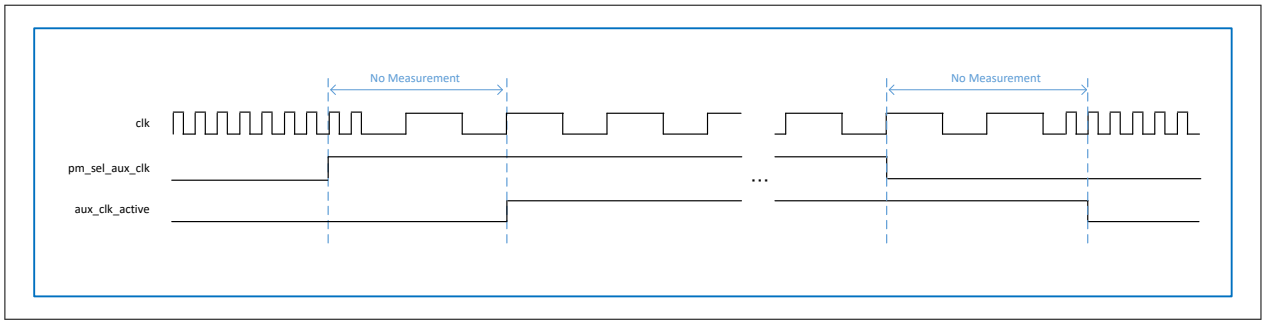

Figure 328 No measurement period

Table 920 (continued) Register overview - access mode glossary

Keyword	Description
APU-P_DMAy (y=0-3)	Protection group consisting of registers PCIE0_USP_DMA_ACCENy_WRA , PCIE0_USP_DMA_ACCENy_WRB , PCIE0_USP_DMA_ACCENy_RDA , PCIE0_USP_DMA_ACCENy_RDB , PCIE0_USP_DMA_ACCENy_VM , PCIE0_USP_DMA_ACCENy_PRS or PCIE1_USP_DMA_ACCENy_WRA , PCIE1_USP_DMA_ACCENy_WRB , PCIE1_USP_DMA_ACCENy_RDA , PCIE1_USP_DMA_ACCENy_RDB , PCIE1_USP_DMA_ACCENy_VM , PCIE1_USP_DMA_ACCENy_PRS .
P_DMAy	Access protection using *APU-P_DMAy* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

19.8.4.4 Register overview - PCIE0_USP domain FPI (ascending offset address)

Table 921 Register overview - PCIE0_USP domain FPI (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
PCIE0_USP_CLC	Clock control register	0000000H	P	P, SV, E	Application Reset	2822
PCIE0_USP_OCS	OCDS control and status register	0000004H	P	SV, P	Debug Reset	2823
PCIE0_USP_ID	Module identification register	0000008H	P	BE	PowerOn Reset	2823
PCIE0_USP_RST_CTRLA	Reset control register A	000000CH	P	P, SV, E	Application Reset	2824
PCIE0_USP_RST_CTRLB	Reset control register B	0000010H	P	P, SV, E	Application Reset	2825
PCIE0_USP_RST_STAT	Reset status register	0000014H	P	BE	Application Reset	2825
PCIE0_USP_PROTE	PROT register endinit	0000020H	U	SV, PROT	Application Reset	2826
PCIE0_USP_PROTSE	PROT register safe endinit	0000024H	U	SV, PROT	Application Reset	2828
PCIE0_USP_ACCEN_WRA	Write access enable register A	0000040H	U	SE, SV	Application Reset	2829
PCIE0_USP_ACCEN_WRB	Write access enable register B	0000044H	U	SE, SV	Application Reset	2830
PCIE0_USP_ACCEN_RDA	Read access enable register A	0000048H	U	SE, SV	Application Reset	2830
PCIE0_USP_ACCEN_RDB	Read access enable register B	000004CH	U	SE, SV	Application Reset	2831

20 Data Routing Engine (DRE)

The DRE is a hardware accelerator used to route Controller Area Network (CAN) frames and Ethernet frames.

The DRE routes CAN frames between Ethernet interfaces. Additionally, it can assist in routing CAN frames from one CAN interface to another CAN interface or to a user-configured memory location, and in forwarding Ethernet frames between Ethernet interfaces.

The DRE is aligned to the AVTP Control frame format defined by IEEE 1722-2016.

In this chapter the following notations from IEEE 1722-2016 are used:

- AVTP frame refers to an Ethernet frame containing Audio Video Transport Protocol
- ACF (AVTP Control Format) frame refers to an AVTP frame containing control frames
- ACF_CAN_BRIEF message refers to CAN frames contained within an ACF frame

  The following chapters describe the core elements of the DRE, their role in routing/forwarding and the configuration possibilities

20.1 Feature list

- Routes Controller Area Network (CAN) frames to or from Ethernet interfaces using IEEE 1722 ACF frames
  - Supports different Ethernet transmit trigger modes
  - User-configured Ethernet MAC Header (Layer 2) for ACF transmit frames
  - Automatic Ethernet DMA transmit and receive descriptor handling
  - Configurable AVTP stream-ID
  - CAN-ID based CAN interface destination search
  - Filtering of CAN frames tunneled over Ethernet
  - User-configured CAN Routing Table to identify the destination CAN interface for a CAN frame tunneled over Ethernet
- Assists CAN Routing Engine (CRE) to perform inter-MCMCAN transfer of CAN frames from a CAN interface to another CAN interface
- Assists CRE to perform routing of received CAN frame(s) or CAN I-PDU(s) from a CAN interface to a configurable internal memory address location
  - Automatic memory address increment and wrap around
  - User-configured watermark interrupt generation for CPU notification
- Supports 1:1 uni-cast routing and 1:4 multi-cast Ethernet to CAN routing
- Provides non-starving arbitration between routing transfer requests
- Supports 1:1 uni-cast or 1:6 multi-cast forwarding of Ethernet frames between interfaces
- Provides non-starving arbitration between routing and forwarding requests
- Provides error monitoring mechanisms for accelerated detection of faults

20.2 Functional overview

The DRE block diagram is shown in the following figure:

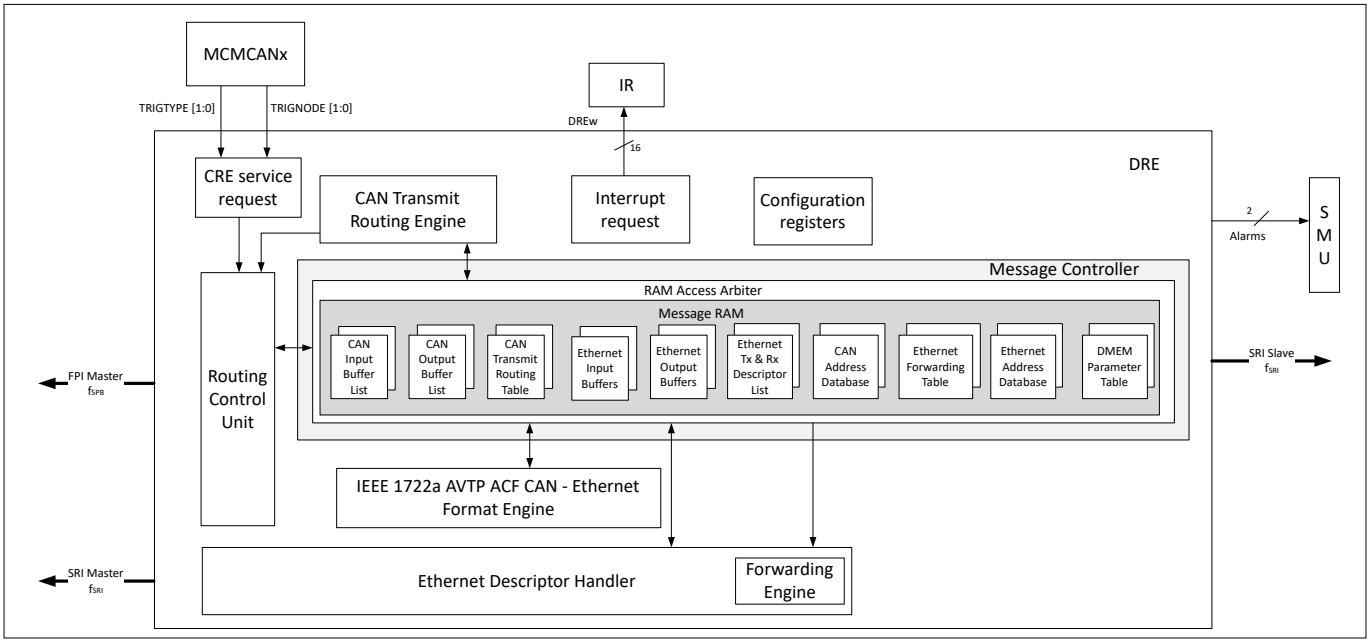

Figure 329 DRE block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

- The DRE contains a central message storage RAM which buffers the CAN frames and the Ethernet frames
- The Routing Control Unit assists in the transfer of received CAN frames from the MCMCAN module to the internal message RAM. The Routing Control Unit also transfers the CAN frame to the identified CAN interface for transmission
- The ACF CAN - Ethernet Format Engine performs the translation of CAN frames to ACF frame format and vice versa
- The CAN Transmit Routing Engine, along with a user-configured Routing Table, decides the destination CAN interface from which a CAN frame has to be transmitted. The Routing Control Unit also transfers the CAN frame to the identified CAN interface for transmission
- The Ethernet Descriptor Handler maintains the Ethernet Transmit (Tx) and Receive (Rx) descriptors which will then be used by Ethernet DMA or the software to transmit or receive Ethernet frames
- The Forwarding Engine, along with a user-configured Forwarding Table, decides the destination Ethernet interface(s) to which the Ethernet frame has to be forwarded

20.3 Functional description

The following sections describe in detail the functions of the DRE.

20.4 Message controller

The Message Controller manages the CAN and Ethernet frame buffers in the Message RAM and arbitrates the RAM accesses.

The image in the chapter Functional overview below shows the Message Controller relative to the DRE Message RAM.

The Message RAM stores control information and CAN and Ethernet data. The SRI Slave accesses are always given the highest priority followed by the MCMCAN module accesses. All the RAM accesses by other control logic

of the DRE are arbitrated with equal priority. Read and write accesses to the Message RAM are of up to 64-bit data width.

20.4.1 Feature list

- Message RAM is of size 32 Kbytes (4 kwords x 64 bits) for buffering frame data and control information as follows:
  - CAN frames received from CAN interface - CAN Input Buffer List to buffer maximum of 20 CAN frames (as there are a total of 20 CAN interfaces)
  - CAN Address Database for address and control configuration of CAN Receive Host Buffers and CAN Transmit Host Buffers
  - Ethernet Address Database for address configuration of LETH and GETH DMA channels
  - Ethernet Input Buffers having 192 double words each can be used to store Ethernet frames received from Ethernet interfaces
  - CAN frames to be transmitted to CAN interface in CAN Output Buffer List; stores a maximum of 64 CAN frames
  - Ethernet Output Buffers having 192 double words each can be used to store Ethernet frames received from Ethernet interfaces
  - CAN Transmit Routing Tables (1 to 4); each routing table can accommodate a maximum of 128 routing rules
  - Ethernet Transmit (Tx) and Receive (Rx) Descriptor List
  - Ethernet Forwarding Table with a maximum of 128 forwarding rules
  - DMEM Parameter Table that consists of configuration of 28 memory destinations
- Management of message buffers and routing control information
- Allows direct access of Message RAM for application software through SRI Slave interface for monitoring
- Arbitration of RAM accesses

20.4.2 Functional overview

This chapter describes the contents of the DRE Message RAM.

Message RAM

The contents of the Message RAM and its interfaces are shown in the figure below.

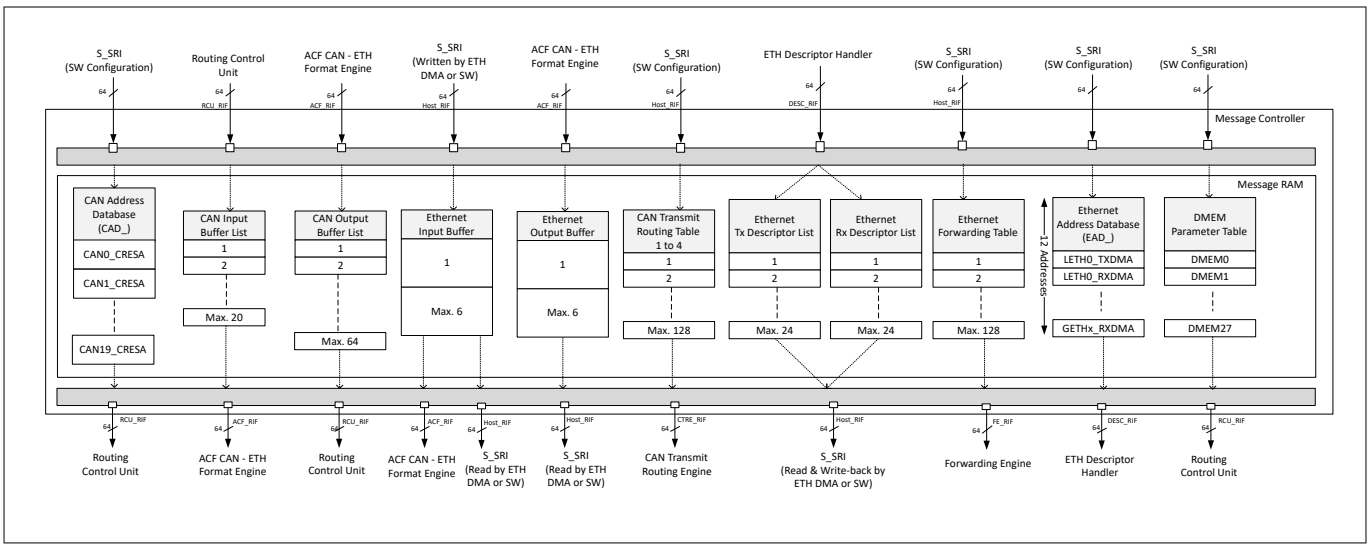

Figure 330 Message RAM block diagram

20 Data Routing Engine (DRE)

The Message RAM contains the following buffers and control information:

- CAN Address Database (CAD)
- CAN Input Buffer List (CIBL)
- CAN Output Buffer List (COBL)
- Ethernet Input Buffers (EIBUF)
- Ethernet Output Buffers (EOBUF)
- CAN Transmit Routing Tables (1 to 4)
- Ethernet Descriptor Lists (Tx and Rx)
- Ethernet Forwarding Table
- Ethernet Address Database (EAD)
- DMEM Parameter Table

20.4.3 Functional description

The following section describes the configuration and contents of DRE Message RAM.

Fixed setup of Message RAM layout

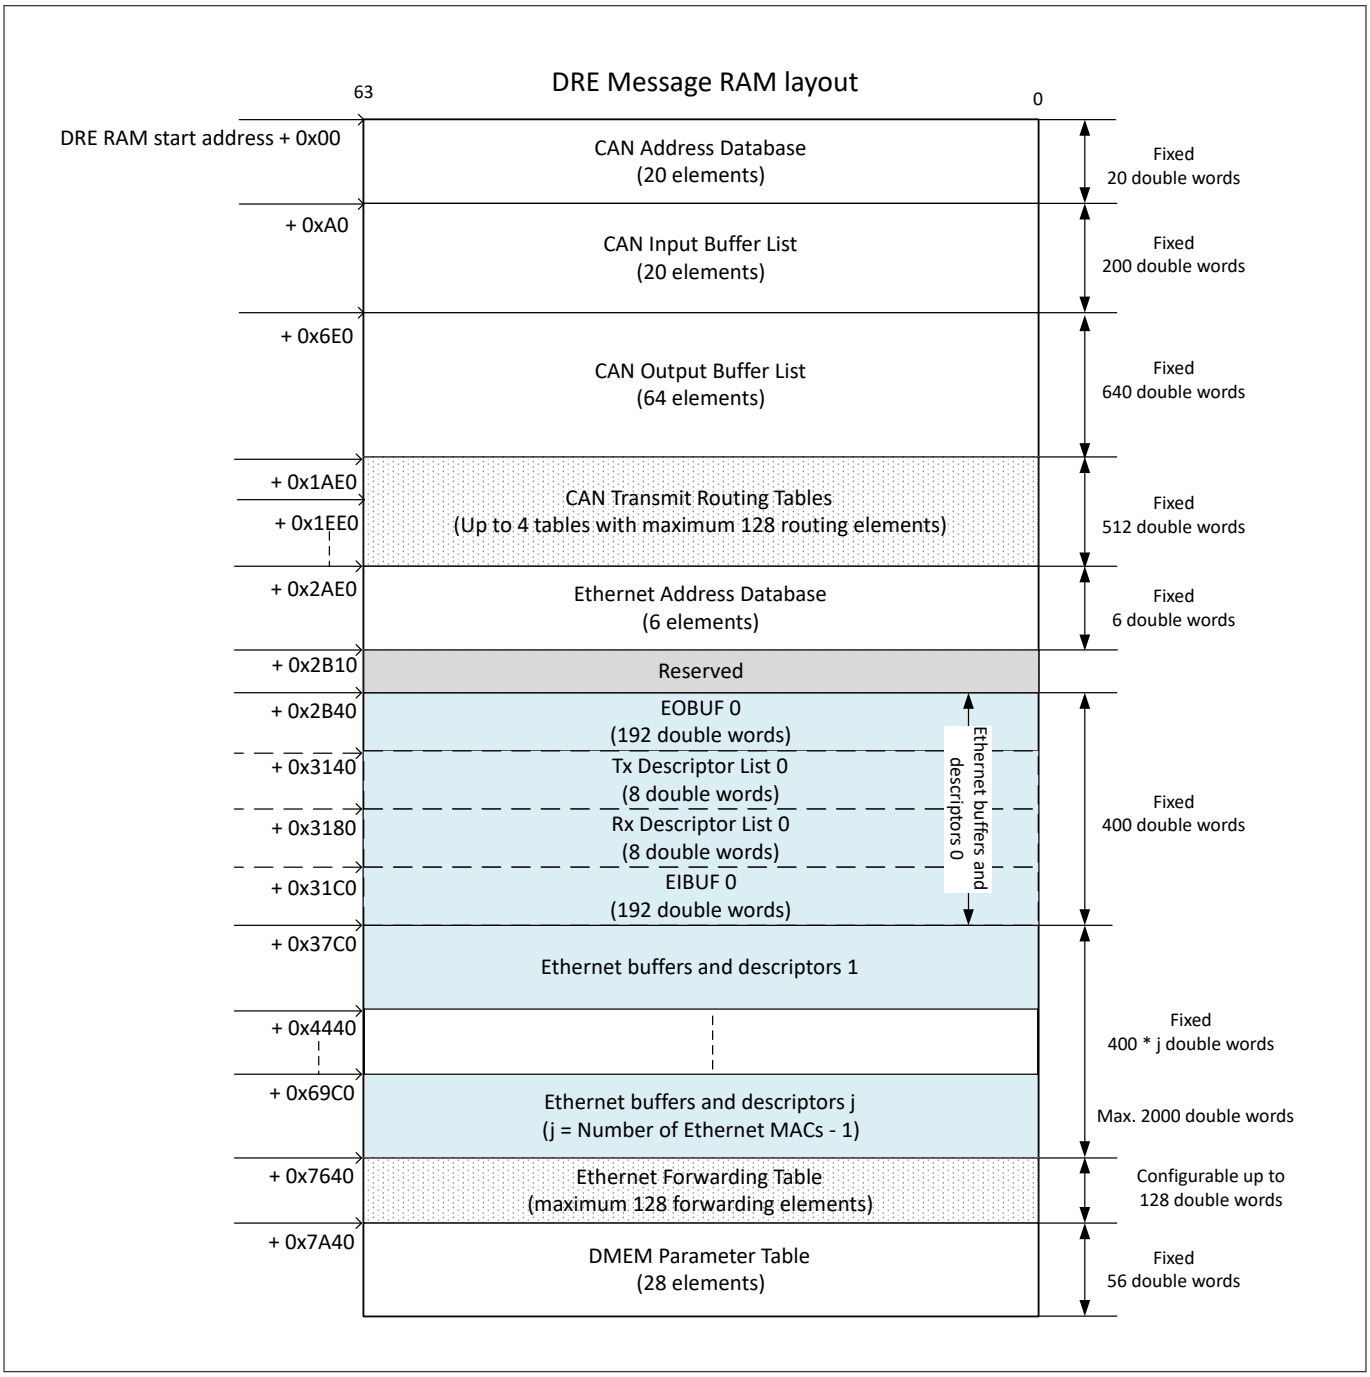

Figure 331 Setup of Message RAM layout

***Note**: The Message RAM is not accessible during Kernel reset*

20.4.3.1 CAN address database

The CAN Address Database (CAD) contains the control and address configuration of the CRE Receive host buffers and the Transmit Host Buffers.

The CRE of the CAN peripherals (refer to CAN chapter for detailed information) contains host buffers for Receive and Transmit CAN frames. The CAD needs to be configured by the user in order for the DRE to perform routing operations to or from CAN peripherals. The database is stored in the Message RAM of the DRE and always starts at the offset 0_H. The structure of the database is given in the figure below.

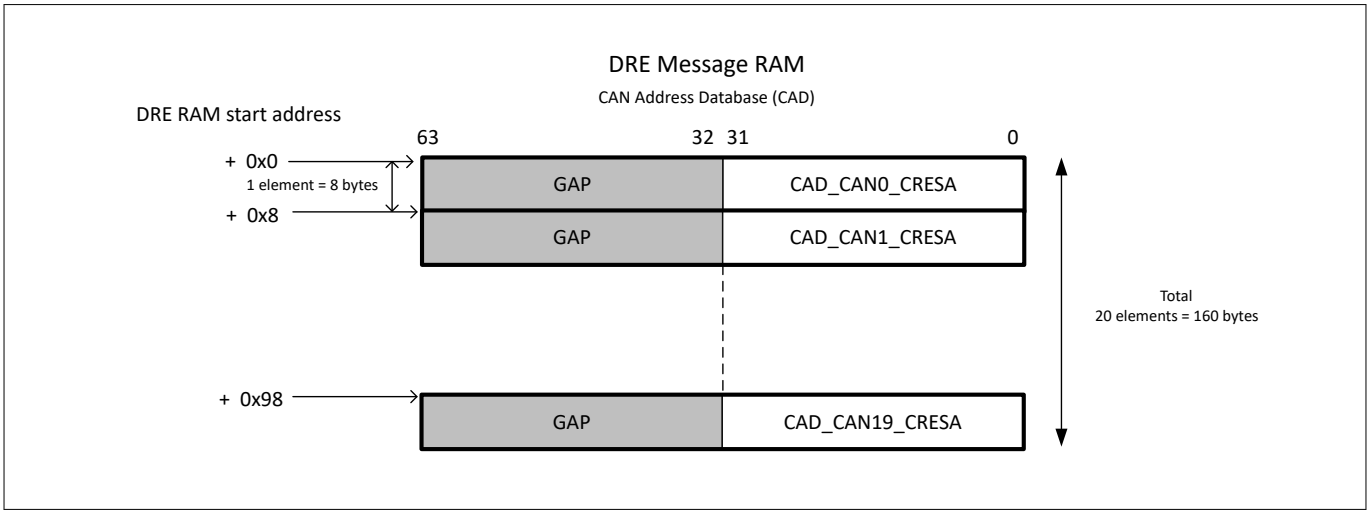

Figure 332 CAN address database RAM structure

Each CAD element contains the following configurations for the corresponding CAN peripheral:

- The absolute start address of the CRE address space (CAD_CANi_CRESA.ADR)

Related information

CAN output buffer list on page 3728
Routing control unit on page 3760

20.4.3.2 CAN input buffer list

The CAN Input Buffer List stores the CAN frames received by CAN interfaces which are to be transmitted through ACF Ethernet frames. The Routing Control Unit transfers the received CAN frames with destination $\mathrm{ID} = 18_H$ to $\mathrm{ID} = 1\mathrm{D}_H$ from MCMCAN to the CAN Input Buffer List.

The start address of the CAN Input Buffer List is DRE RAM start address + 0xA0. There are a total of 20 CAN input buffers. Each buffer stores 16 bytes of header data and 64 CAN data bytes. The structure of the buffers is shown in the figure below.

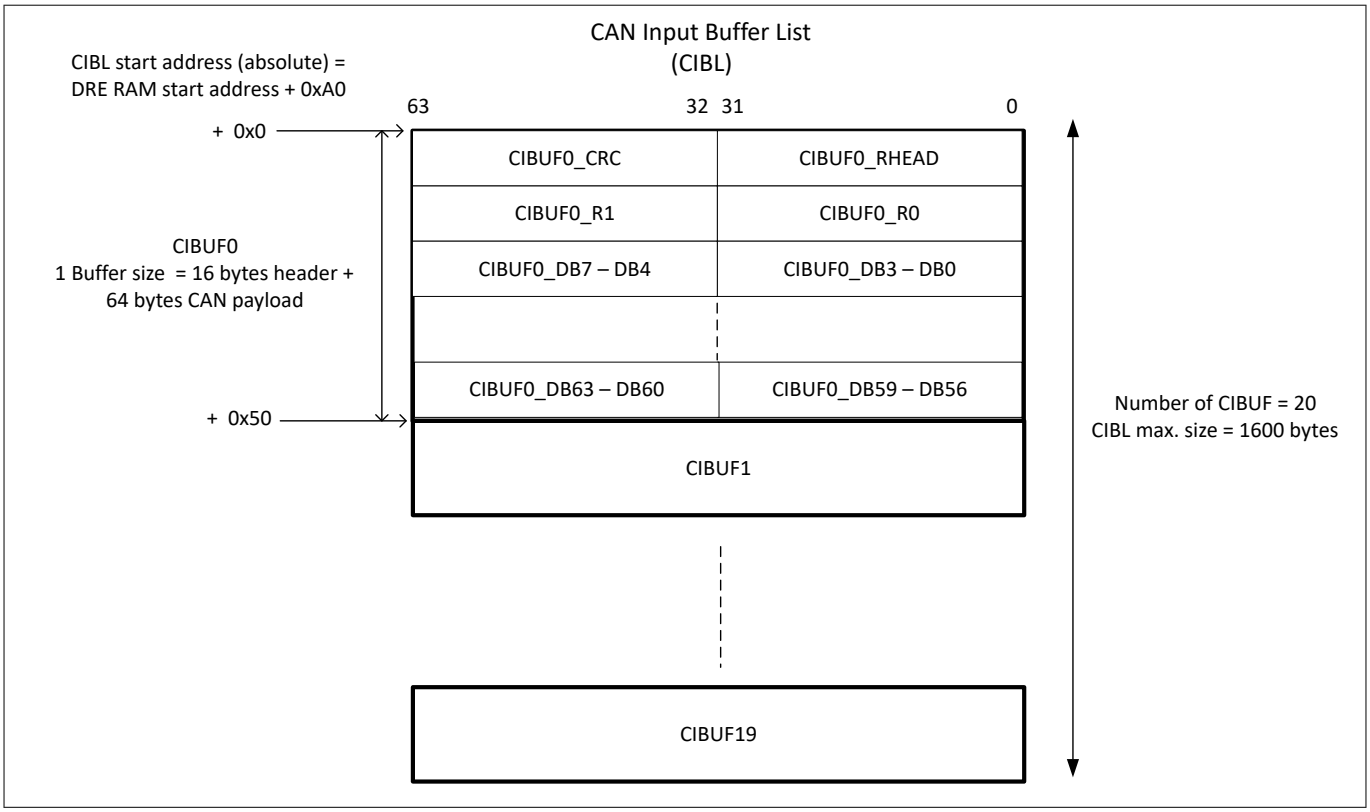

Figure 333 RAM structure of CAN input buffer list

The buffers are organized in the form of a circular list. The list contains a Put Index (CIBL_STATUS.PIDX).

The Put Index is controlled by the Message Controller. A new CAN frame is stored in the buffer indexed by the Put Index. The Put Index is incremented to the next free buffer after storing the CAN frame. The Put Index wraps around to the next free buffer starting from index 0 after it has reached the maximum number of assigned buffers in the list. The buffer pending request (BPR) in CIBL_BPR is set by hardware to indicate that the CAN buffer contains a frame yet to be processed by the ACF CAN-Ethernet Format Engine.

The pending requests are scanned by the ACF CAN-Ethernet Format Engine to identify the CAN frame to be processed. After processing the identified CAN frame, the pending request is cleared by the ACF CAN-Ethernet Format Engine.

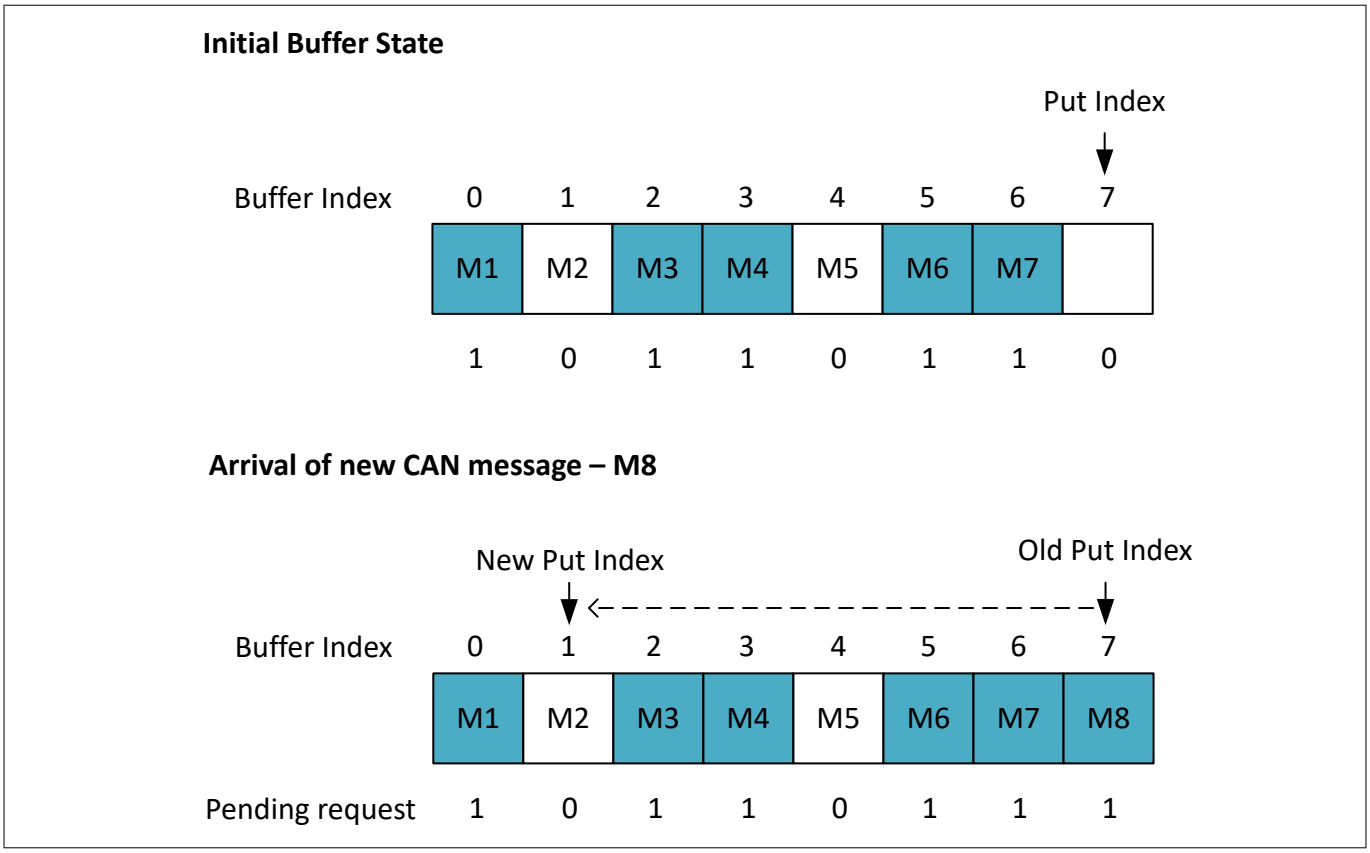

Figure 334 Example of CAN input buffer list handling with 8 CAN input buffers

In the example figure:

- The Put Index is currently at buffer 7
- When a new CAN frame (M8) is fetched by the data Move Engine, it stores it in buffer 7 as indicated by the Put Index
- The Put Index is then circularly incremented to the next free buffer location, which is buffer index 1

The Buffer Full flag (CIBL_STATUS.BF) is set by the Message Controller when the EOBUF is not available to store the incoming CAN frame and an interrupt is triggered. It is cleared by hardware after the frame is fetched from the EOBUF.

The Buffer Empty flag (CIBL_STATUS.BE) is set by the Message Controller when no pending requests are set. It is cleared by hardware when at least 1 buffer has a pending request set.

CAN address database on page 3726
Ethernet output buffer on page 3730

20.4.3.3 CAN output buffer list

The CAN Output Buffer List stores the CAN frames which are to be transmitted through CAN interfaces.

After the CAN Transmit Routing Engine decides the routing destination of a CAN frame to be transmitted, the ACF CAN-Ethernet Format Engine writes the CAN frame into the CAN Output Buffer List. The Routing Control Unit transfers the CAN frame from the output buffers to their corresponding destinations.

The start address of the CAN Output Buffer List is DRE RAM start address + 0x6E0. There are a total of 64 CAN output buffers. Each buffer stores 16 bytes of header data and 64 CAN data bytes. The structure of the buffers is shown in figure below.

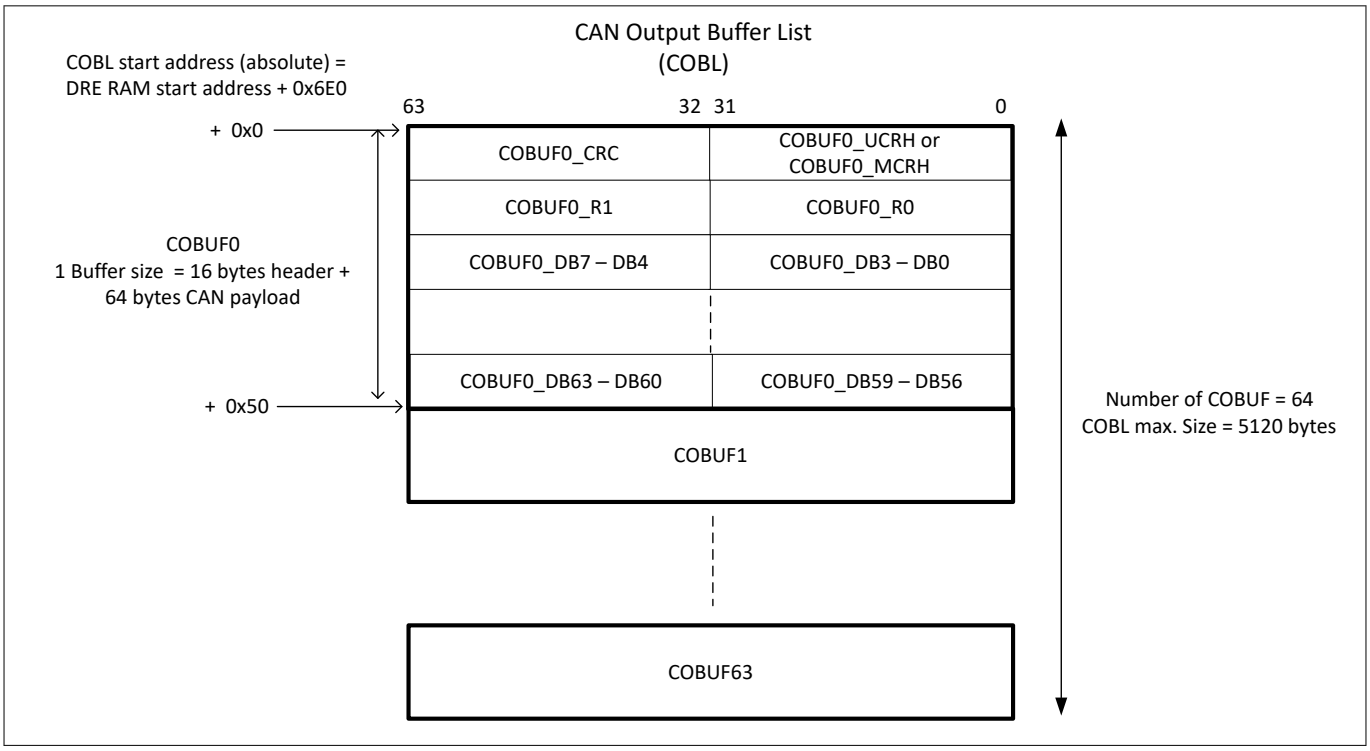

Figure 335 RAM structure of CAN output buffer list

The CAN output buffers are organized in the form of a circular list. The list contains a Put Index (COBL_STATUS.PIDX).

The Put Index is controlled by the Message Controller. A new transmit CAN frame is stored in the buffer indexed by the Put Index. The Put Index is incremented to the next free buffer after storing the CAN frame. The Put Index wraps around to the next free buffer starting from index 0 after the configured maximum number of buffers.

A pending request (COBL_BPR0.PRj (j=0-31) and COBL_BPR1.PRj (j=32-63)) is set by the ACF CAN-Ethernet Format Engine to indicate that the CAN buffer contains a frame yet to be transferred to its corresponding destination. The pending requests are scanned by the Routing Control Unit to identify the CAN frames to be transferred. After transfer of the fetched CAN frame to its corresponding destination, the pending request is cleared by the Routing Control Unit.

The Buffer Full flag (COBL_STATUS.BF) is set by the Message Controller when there are no free buffers to store the incoming CAN frame and an interrupt is triggered. It is cleared by hardware when there are free buffers available. The Buffer Empty flag (COBL_STATUS.BE) is set by the Message Controller when no pending requests are set. It is cleared by hardware when at least one buffer has a pending request set.

20.4.3.4 CAN transmit routing tables (1 to 4)

The CAN Transmit Routing Tables store the routing elements which identify the CAN interface to which a CAN frame is to be transmitted. The routing tables are used by the CAN Transmit Routing Engine to identify the transmit CAN interface.

Up to 4 routing tables with a maximum of 128 routing elements per routing table can be configured. The start address of the first routing table is DRE RAM start address + 0x1AE0. The start address of the consecutive routing tables are at fixed offsets of 0x400 from the previous table. The number of routing elements in each routing table is configured using RTi_CONFIG.NRULES.

Each routing element contains:

1. CAN ID filter (RT_REj_CIDFC (j = 0-127)) and
2. Routing rule with CAN destinations (RT_REj_UCR or MCR (j = 0-127))

The CAN ID filter conditions are used by the CAN Transmit Routing Engine to identify the routing rule corresponding to a CAN frame based on the configured CAN ID filters.

The routing rule configuration is used by the CAN Transmit Routing Engine to identify the destination CAN interface.

Related information

CAN acceptance filters on page 3759

20.4.3.5 Ethernet output buffer

The Ethernet Output Buffer stores the transmit ACF frames containing one or more ACF_CAN_BRIEF messages. There are six EOBUFs available but usability depends on the number of Ethernet interfaces available in the device.

The start address of Ethernet Output Buffer j (j = 0 - 5) is configured at DRE RAM start address + 0x2B40 + j*0xC80. The buffers have the following three sections:

1. IEEE 802.3 MAC header
2. NTSCF header
3. ACF payload

The structure of the Ethernet Output Buffer is shown in the figure below.

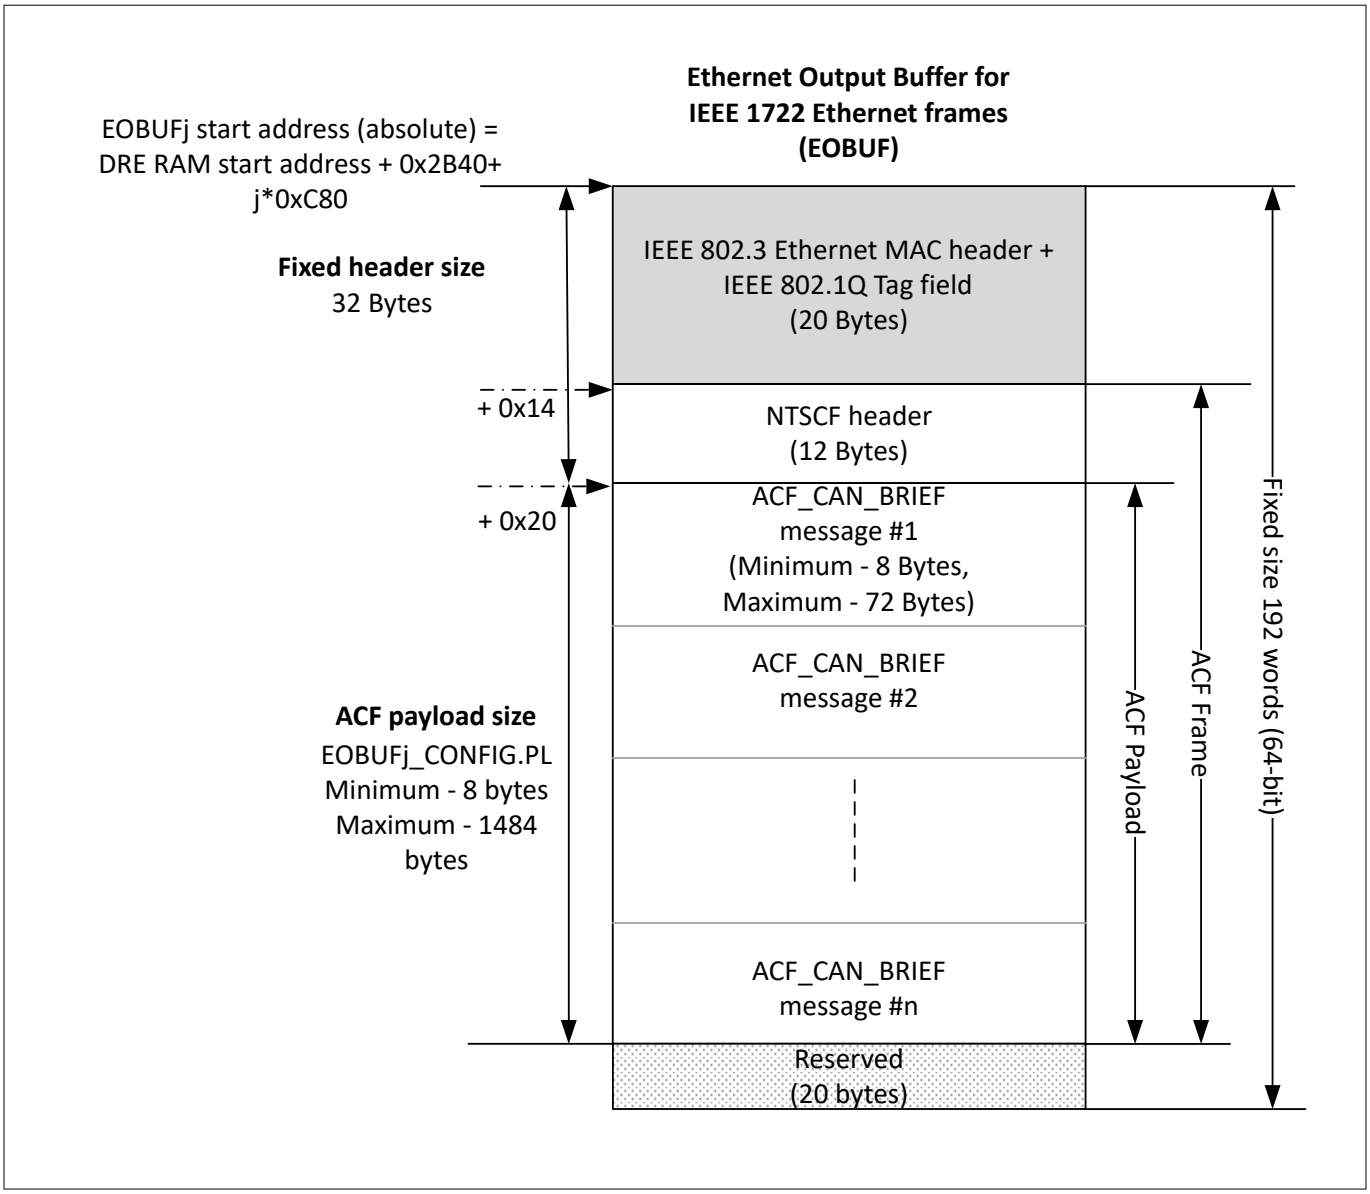

Figure 336 Ethernet output buffer structure

IEEE 802.3 MAC header

This section contains the user-configured Ethernet MAC header with optional IEEE 802.1Q tag field. The header always starts at the offset of 2_H from the start address of the buffer. The MAC header is configured in EOBUFj_MAC_H0, EOBUFj_MAC_H1, EOBUFj_MAC_H2, EOBUFj_MAC_H3 and EOBUFj_MAC_H4. The header is assembled by the ACF CAN-Ethernet Format Engine when an Ethernet frame transmit trigger condition occurs. The structure of the IEEE 802.3 MAC header is shown in the figure below.

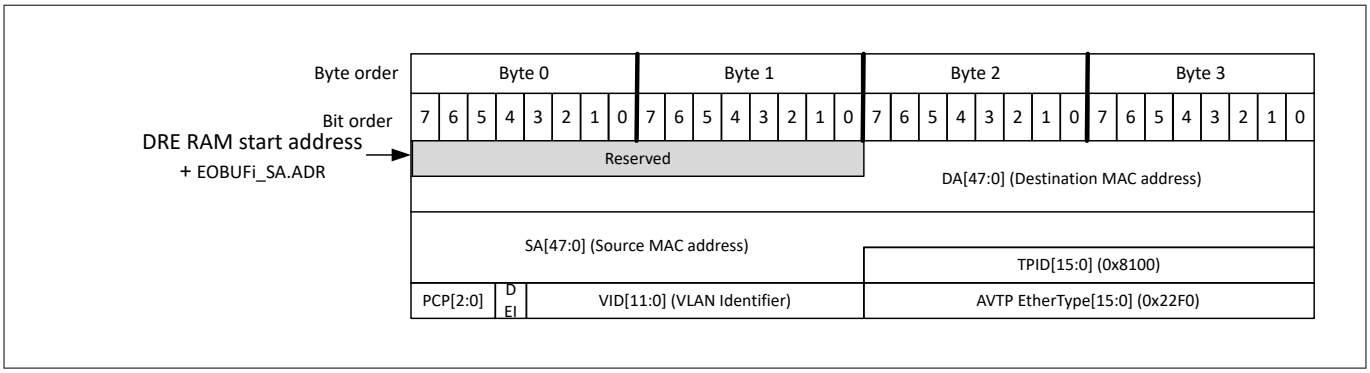

Figure 337 IEEE 802.3 MAC header

NTSCF header

This section contains the NTSCF header of the transmit Ethernet frame. The header always starts at the offset of 14_H from the start address of the buffer. The header information is shown in EOBUFj_NTSCF_H0. The header is assembled by the ACF CAN-Ethernet Format Engine when an Ethernet frame transmit trigger condition occurs. The structure of the NTSCF header is shown in the figure below.

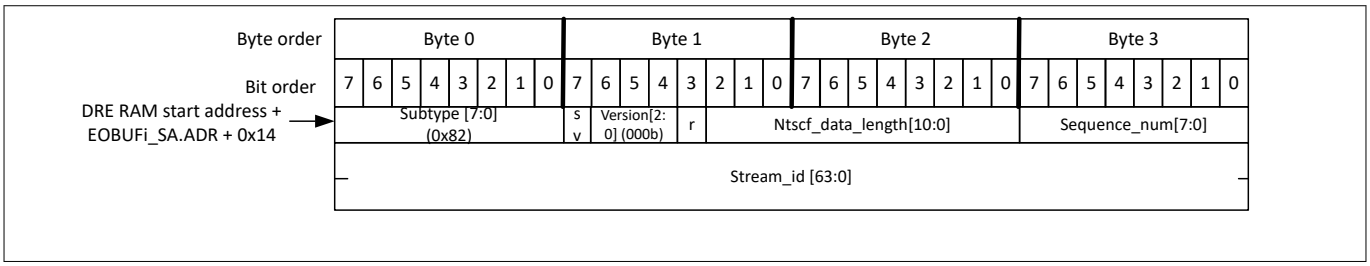

Figure 338 NTSCF header

ACF payload

This section contains one or more ACF_CAN_BRIEF messages. The ACF payload section always starts at the offset of 20_H from the start address of the buffer. The length of the ACF payload section is configured by the user at EOBUFj_CONFIG.PL. The structure of the ACF_CAN_BRIEF message is shown in the figure below.

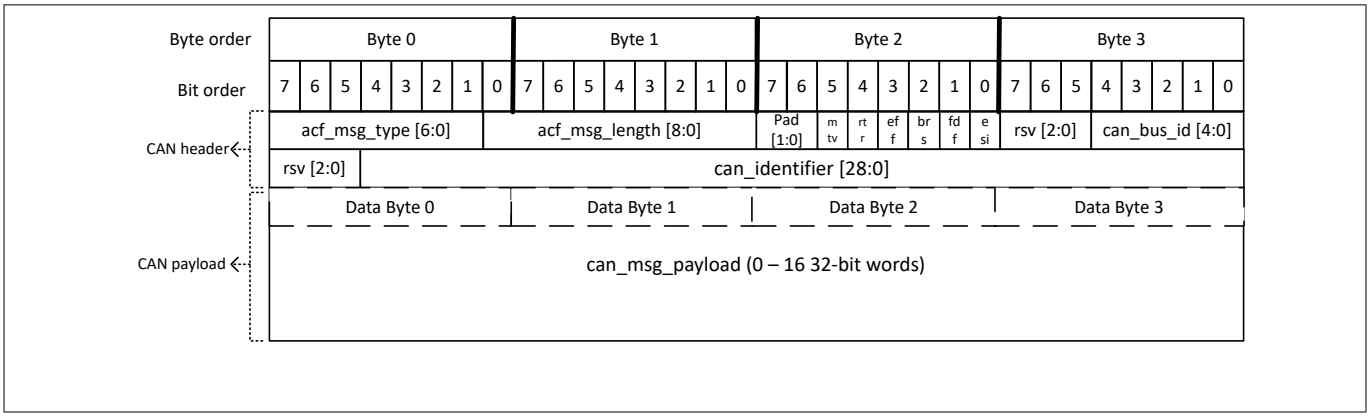

Figure 339 ACF_CAN_BRIEF message

Tx descriptor handler on page 3781
CAN input buffer list on page 3726

20.4.3.6 Ethernet input buffer

The Ethernet Input Buffer stores the received Ethernet frames from the Ethernet module. The ACF CAN-Ethernet Format Engine disassembles CAN frames from the ACF frames. Alternatively, the Ethernet Descriptor Handler forwards the Ethernet frame if the destination is an Ethernet interface.

The Ethernet Input Buffer stores the Ethernet frames received from Ethernet interfaces which are to be transmitted to CAN interfaces or forwarded to a different Ethernet interface. There are six EIBUFs available but usability depends on the number of Ethernet interfaces available in the device. The start address of Ethernet Input Buffer j (j = 0 - 5) is configured at DRE RAM start address + 0x31C0 + j*0xC80 . The size of the buffer is 192 double words which include the complete Ethernet frame (including MAC header, NTSCF header and ACF payload) plus some additional padding bytes to achieve 64-byte alignment. The state machine gets the size of the frame from the Rx descriptor in the case of Ethernet to Ethernet forwarding or the NTSCF header in the case of Ethernet to CAN routing. The structure of the header and the payload is the same as that of the Ethernet Output Buffer.

20.4.3.7 Ethernet descriptor lists

The Ethernet descriptor lists consist of a set of Rx or Tx descriptors to receive and transmit Ethernet frames.

The Ethernet descriptors are updated by the Ethernet Descriptor Handler (Read format) and the Ethernet DMA channels (Write-back format). The ETH Descriptor Handler consists of 6 Transmit Descriptor Lists (0-5) and 6 Receive Descriptor Lists (0-5) but usability depends on the number of Ethernet interfaces available in the device. There is one Tx list and one Rx list per Tx/Rx DMA channel respectively. The Message RAM consists of 4 Rx descriptors and 4 Tx descriptors per Ethernet interface. Each descriptor list contains 4 descriptors, and each descriptor is made up of 4 32-bit words.

The descriptors are used to exchange packet data and packet control or status information between the DRE and Ethernet DMA channel.

The start address of Ethernet Tx descriptor list j (j = 0 - 5) is configured at DRE RAM start address + 0x3140 + j*0xC80.

The start address of Ethernet Rx descriptor list j (j = 0 - 5) is configured at DRE RAM start address + 0x3180 + j*0xC80.

Related information

Tx descriptor handler on page 3781
Rx descriptor handler on page 3784
Forwarding table on page 3739

20.4.3.7.1 Descriptor structure configuration

This section describes the configuration of descriptors for use in the DRE.

In the ring structure, each descriptor is made of 4 32-bit words. The descriptor structure is configured by the user by configuring the following registers:

- The Rx and Tx descriptor lists can be assigned to an Ethernet interface by setting RETHDLi_CTRL.EIF and RETHDLi_CTRL.EIFID. For example, if EIBUF0 is used for receiving Ethernet frames from GETH0 Rx DMA channel 1:
  - RETHDL0_CTRL.EIF = 0
  - RETHDL0_CTRL.EIFID = 0
  - RETHDL0_CTRL.DMACH = 1

  Note: *Bit-fields RETHDLi_CTRL.DMACH and TETHDLi_CTRL.DMACH should be the same. Irrespective of the value configured in this bit-field, the DRE receives/transmits frames only from/to the Ethernet DMA channel whose Tail Pointer address is configured in the Ethernet Address Database (EAD) at the corresponding index RETHDLi_CTRL.EIF and RETHDLi_CTRL.EIFID. Bit-field RETHDLi_CTRL.DMACH is used in generating the FWDID while forwarding and bit-field TETHDLi_CTRL.DMACH is only for status information*

- RETHDLi_CTRL.TRIG and TETHDLi_CTRL.TRIG set the type of trigger from the Descriptor Handler. When a TRIG is set, Ethernet frames are sent to and received from software by triggering an interrupt. In this case, the descriptors are not prepared by the DRE

The user must pre-configure the descriptor structure of the DRE within the Ethernet DMA channel by updating the registers with the start addresses of the Tx and Rx descriptor list within the Message RAM:

- For GETH, DMA_CHj_TxDesc_List_LAddress and DMA_CHj_RxDesc_List_LAddress
- For LETH, DMA_CHy_TxDesc_List_Address and DMA_CHy_RxDesc_List_Address

The user must also update the registers with the total number Tx and Rx descriptors per respective DMA channel:

- For GETH, DMA_CHj_Tx_Control2.TDRL and DMA_CHj_Rx_Control2.RDRL
- For LETH, DMA_CHy_TxDesc_Ring_Length.TDRL and DMA_CHy_Rx_Control2.RDRL

20.4.3.7.2 Tx descriptors

This chapter describes the use of Tx descriptors in the DRE.

Whenever a new Ethernet frame is to be transmitted to a Tx DMA channel of an Ethernet interface, transmit descriptors (TDESC_RD0-3) are prepared by the DRE in Read format in the Message RAM. The Tx DMA reads the descriptor prepared by the DRE and then overwrites it with the Write-back format (TDESC_WR0-3) after reading the frame from the Ethernet Output Buffer. The following figures give an overview of the Read and Write-back formats. A detailed description can be found in the chapter Registers of this manual.

Read format

The following image shows an example of the structure of a Tx descriptor. Each Read format descriptor contains 4 TDESCi_RD descriptor words (i=0-3). Each Tx descriptor list in Read format contains 4 descriptors, giving 16 words for each list in total.

Words marked reserved contain no valid input.

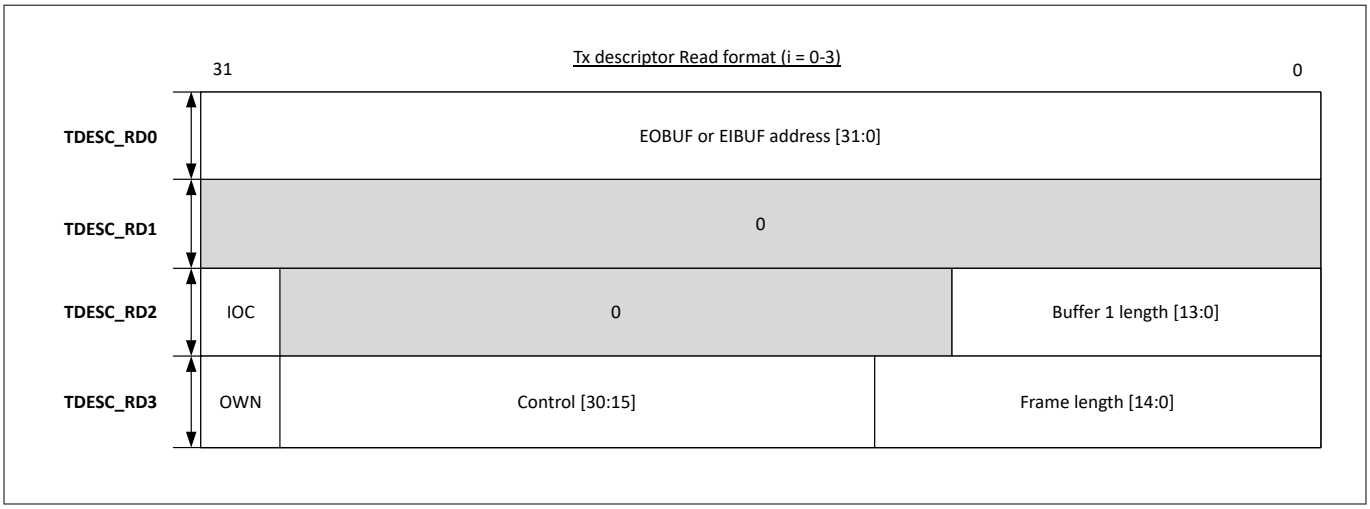

Figure 340 Tx descriptor - read format

The 4 descriptor words prepared by the DRE are: TDESCi_RD0, TDESCi_RD1, TDESCi_RD2 and TDESCi_RD3

Write-back format

The following image shows an example of the structure of a Tx descriptor. Each Write-back format descriptor contains 4 TDESCi_WR descriptor words (i=0-3). Each Tx descriptor list in Write-back format contains 4 descriptors, giving 16 words for each list in total.

Words marked reserved contain no valid input.

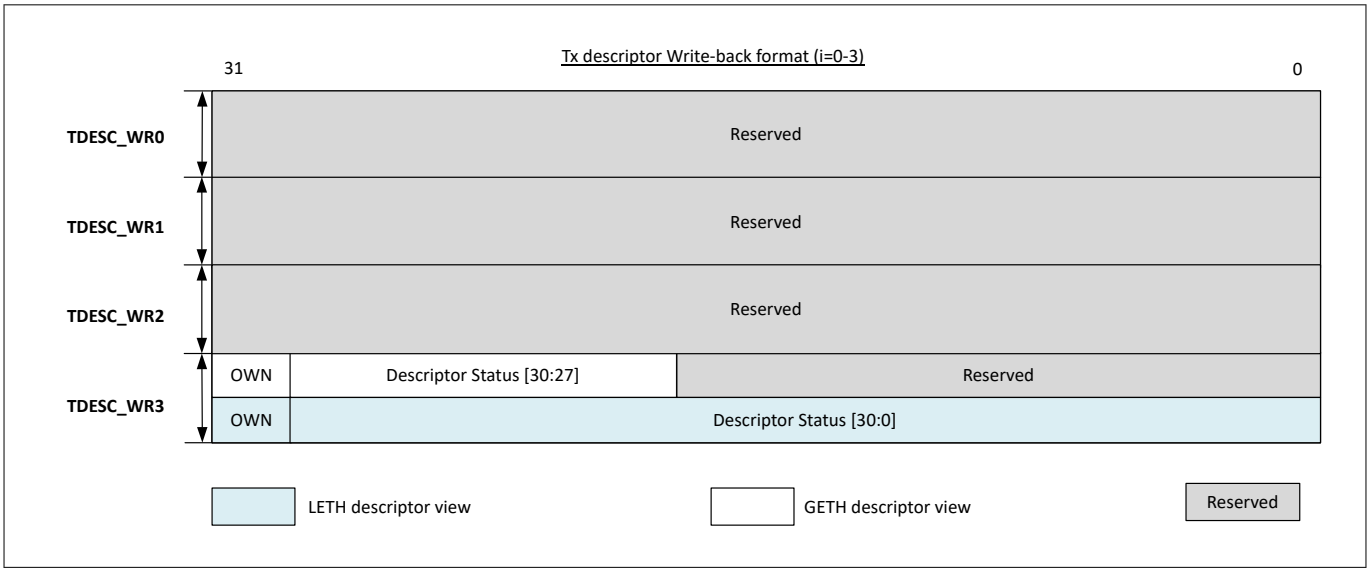

Figure 341 Tx descriptor - write-back format

- The GETH Tx DMA channel prepares the 4 descriptor words: TDESCi_WR0, TDESCi_WR1, TDESCi_WR2 and TDESCi_WR3G
- The LETH Tx DMA channel prepares the 4 descriptor words: TDESCi_WR0L, TDESCi_WR1L, TDESCi_WR2 and TDESCi_WR3L

20.4.3.7.3 Rx descriptors

This chapter describes the use of Rx descriptors in the DRE.

Whenever a free EIBUF is available to receive an Ethernet frame from an Ethernet interface, receive descriptors (RDESC_RD0-3) are prepared by the DRE in Read format in the Message RAM. The Rx DMA reads the descriptor and then overwrites it with the Write-back format (RDESC_RD0-3) after writing the frame to the Ethernet Input buffer. The following figures give an overview of the Read and Write-back formats. A detailed description can be found in the chapter Registers in this manual.

Read format

The following image shows an example of the structure of an Rx descriptor. Each Read format descriptor contains 4 TDESCi_RD descriptor words (i=0-3). Each Rx descriptor list in Read format contains 4 descriptors, giving 16 words for each list in total.

Words marked reserved contain no valid input.

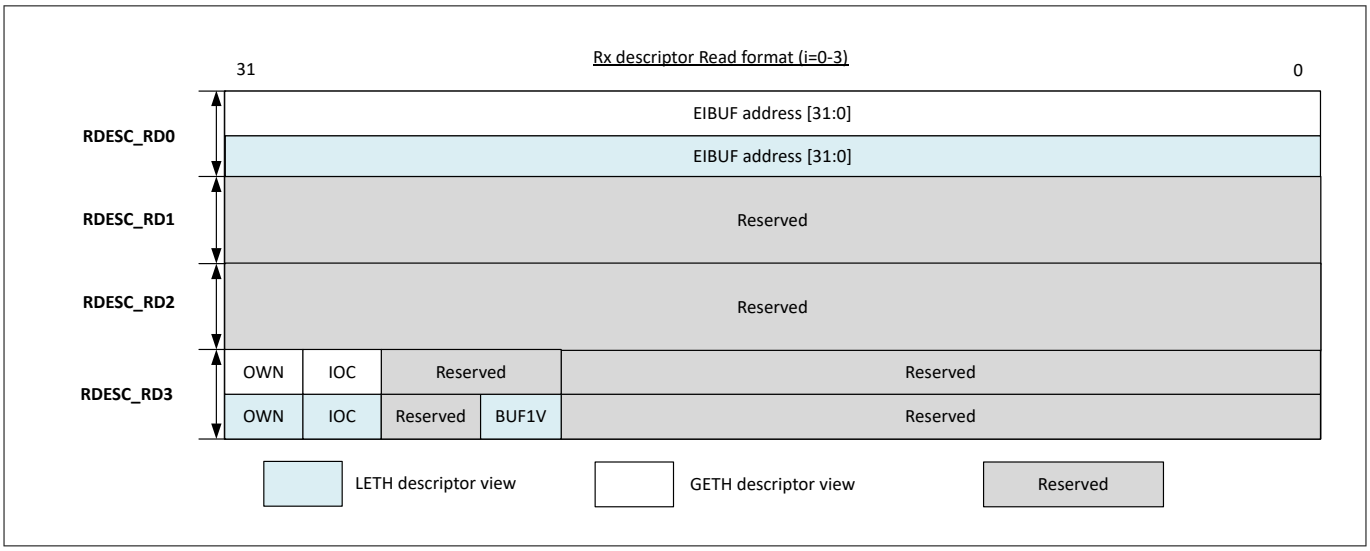

Figure 342 Rx descriptor - read format

The 4 descriptor words prepared by the DRE are: RDESCi_RD0, RDESCi_RD1, RDESCi_RD2, and RDESCi_RD3G for GETH or RDESCi_RD3L for LETH.

Write-back format

The following image shows an example of the structure of an Rx descriptor. Each Write-back format descriptor contains 4 TDESCi_WR descriptor words (i=0-3). Each Rx descriptor list in Write-back format contains 4 descriptors, giving 16 words for each list in total.

Words marked reserved contain no valid input.

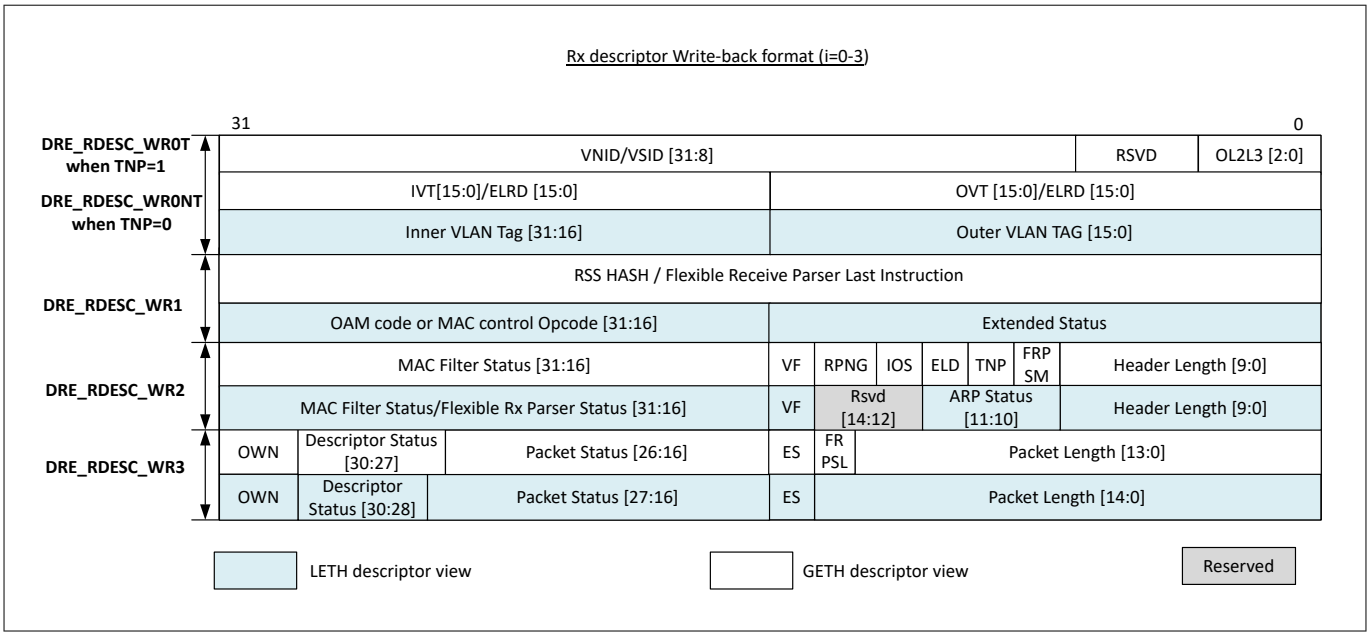

Figure 343 Rx descriptor - write-back format

The image above shows the differences for tunneled and non-tunneled frames for RDESCi_WR0. When TNP=1, RDESCi_WROT applies to both GETH and LETH interfaces. When TNP=0, RDESCi_WR0NT applies for LETH and GETH as shown by the colors in the image.

- The GETH Rx DMA channel prepares the 4 descriptor words: RDESCi_WR0T (for tunneled frames) or RDESCi_WR0NT (for non-tunneled frames), RDESCi_WR1G, RDESCi_WR2G and RDESCi_WR3G
- The LETH Rx DMA channel prepares the 4 descriptor words: RDESCi_WR0NT, RDESCi_WR1L, RDESCi_WR2L and RDESCi_WR3L

20.4.3.8 Message RAM access protection

The Ethernet section is organized such that each EOBUF, it's corresponding EIBUF and the corresponding Tx and RX descriptor lists are located together in a consecutive RAM address range, as shown in the diagram below. Each address range has it's own Access Protection Unit (APU) associated to it, so each address range can be individually protected. Each APU corresponds to a Ethernet interface (SRI master) as shown in the image below. The start address of the APU is the same as the EOBUF start address. The owner of the APU is determined based on which master requires write access to the EIBUF and the descriptors (RETHDLi_CTRL.EIF, EIFID). While the owner of the APU must have read and write access, the other masters must have only read access.

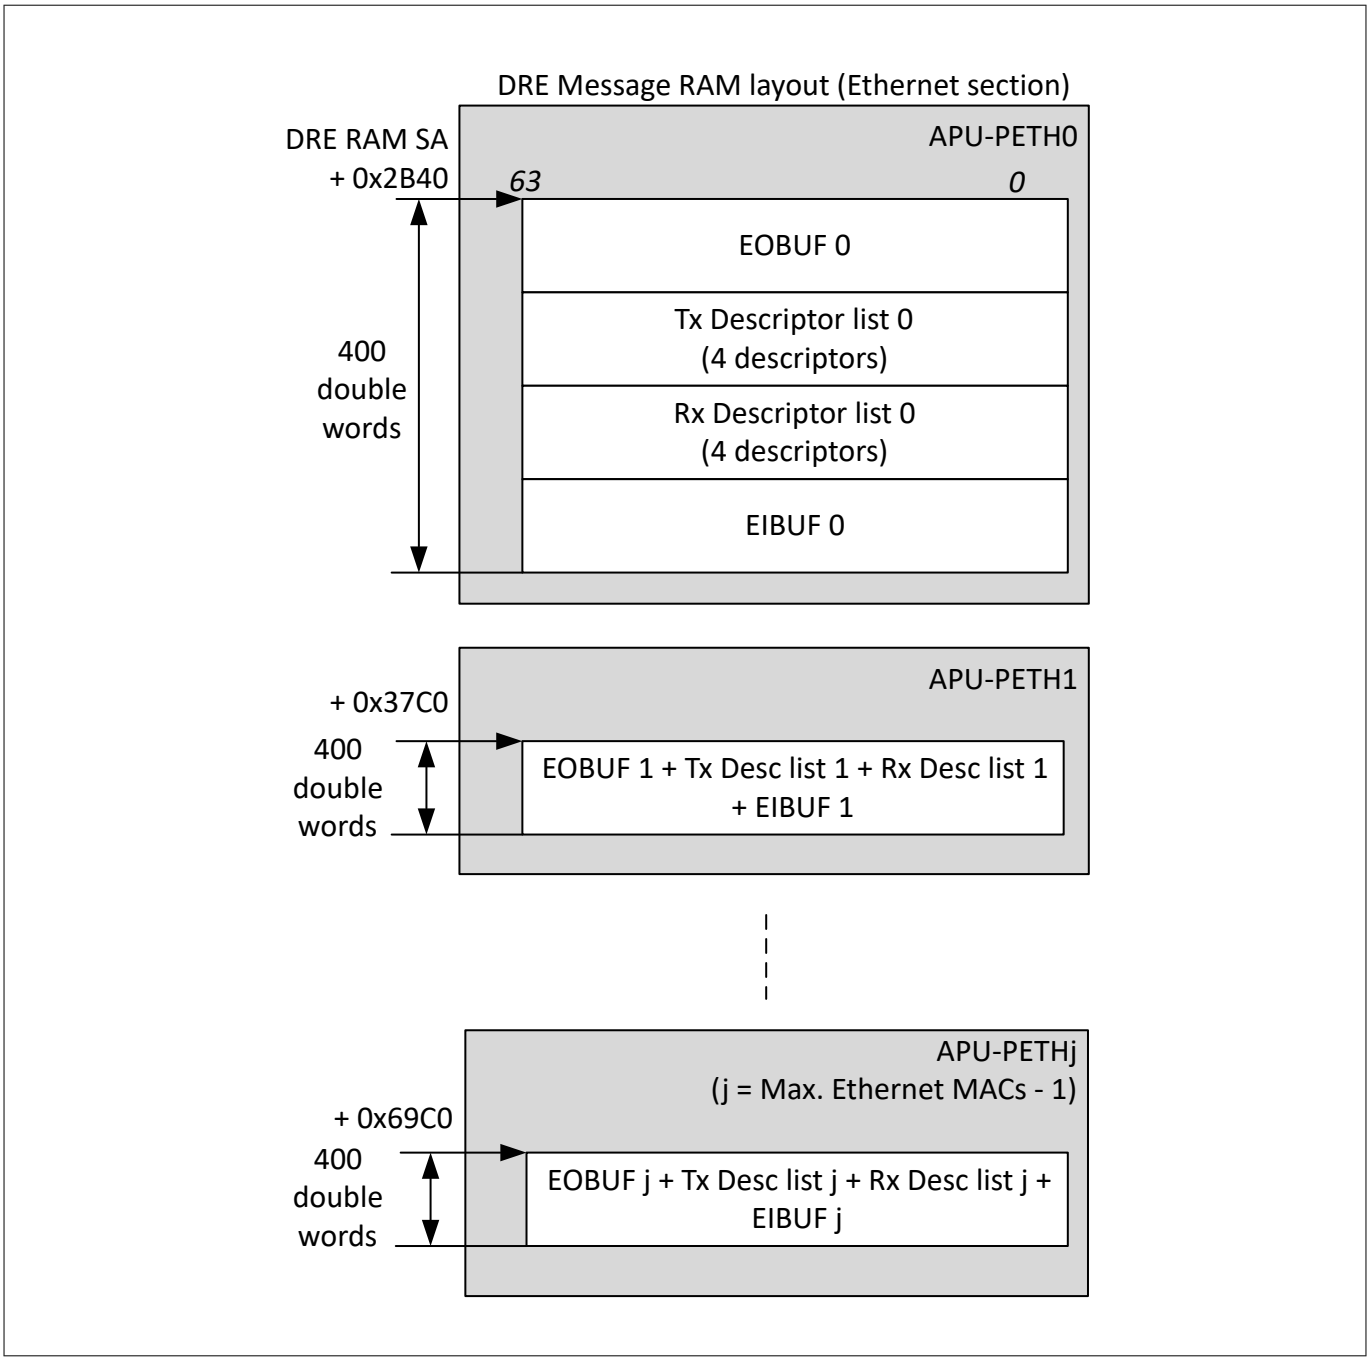

Figure 344 DRE message RAM layout for Ethernet

Example access matrices for GETH and LETH are given in Table 1 and Table 2 below. The APUs can be configured using the APU-PETHj (ETHj_ACCEN) registers (refer to the Registers chapters for details).

Table 933 Example access matrix (APU owned by GETH0)

Read access	Write access
• GETH0 • LETH interfaces	GETH0

Table 934 Example access matrix (APU owned by LETH0)

Read access	Write access
• LETH0 • GETH interfaces	LETH0

20.4.3.9 Forwarding table

The forwarding table is used by the Forwarding Engine to identify the transmit Ethernet interface.

The forwarding table stores the forwarding rules which identify the Ethernet interface to which an Ethernet frame is to be forwarded.

Up to a maximum of 128 forwarding elements can be configured. The start address of the forwarding table is DRE RAM start address + 0x7640. The number of forwarding elements can be configured through FTCFG.NRULES as shown in the figure below.

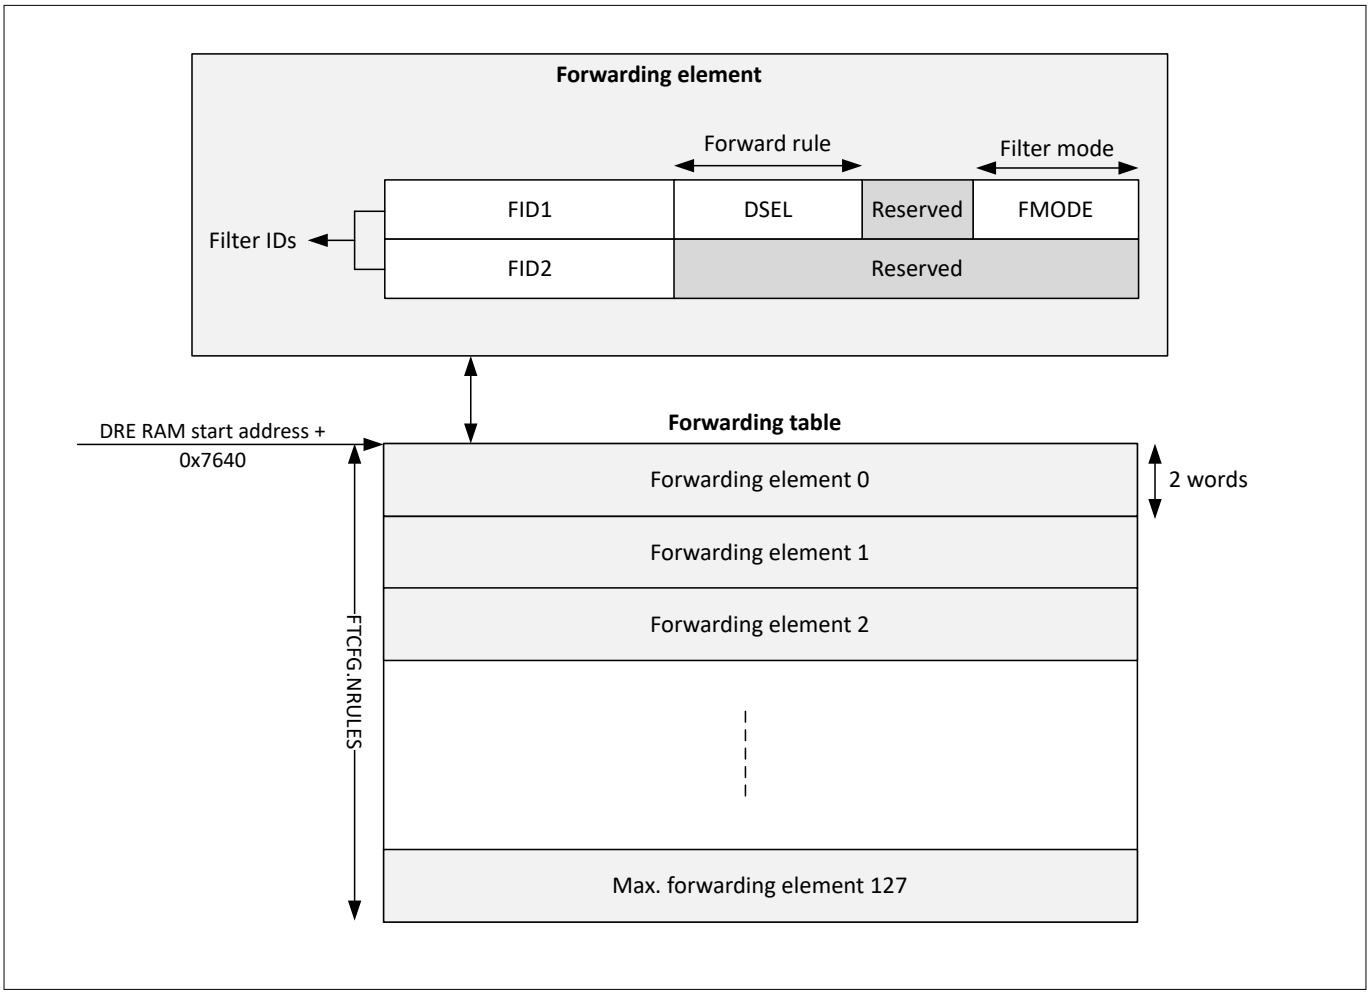

Figure 345 Forwarding table

Each forwarding element contains:

1. Uni-cast or multi-cast Forward ID filters Filter ID1 in bit-field FT_FEj_FRULE.FID1 and Filter ID2 in bit-field FT_FEj_FID2.FID2
2. Forwarding rule FT_FEj_FRULE.DSEL. The forwarding rule is bit-encoded. Single bit is set in the case of uni-cast and multiple bits are set in the case of multi-cast forwarding
3. Filter mode FT_FEj_FRULE.FMODE

The FWD ID filter conditions are used by the Forwarding Engine to identify the forwarding rule corresponding to an Ethernet frame based on the configured FWD ID based filters.

The forwarding rule configuration is used by the Forwarding Engine to identify the destination Ethernet interface of the corresponding Ethernet frame.

20.4.3.10 Ethernet address database (EAD)

The Ethernet Descriptor Handler receives Ethernet frames from or transmits them to Ethernet DMA channels.

The Ethernet Address Database (EAD) needs to be configured by the user in order for the DRE to perform routing and forwarding operations to or from Ethernet DMA channels. The database is stored in the Message RAM of the DRE and always starts at address DRE RAM start address + 0x2AE0. The EAD is indexed based on RETHDLi_CTRL.EIF and EIFID configured. The Ethernet address database stores the addresses of the following Rx and Tx Tail Pointer registers of each Ethernet DMA channel, as shown in the figure below:

- DMA_CHy_RxDesc_Tail_Pointer (y=0-7) and DMA_CHy_TxDesc_Tail_Pointer (y=0-7) for LETH
- DMA_CHj_RxDesc_Tail_LPointer (j=0-7) and DMA_CHj_TxDesc_Tail_LPointer (j=0-7) for GETH

***Note**: One Tx and one Rx DMA channel per Ethernet MAC is configured to receive and/or transmit Ethernet frames from/to the DRE*

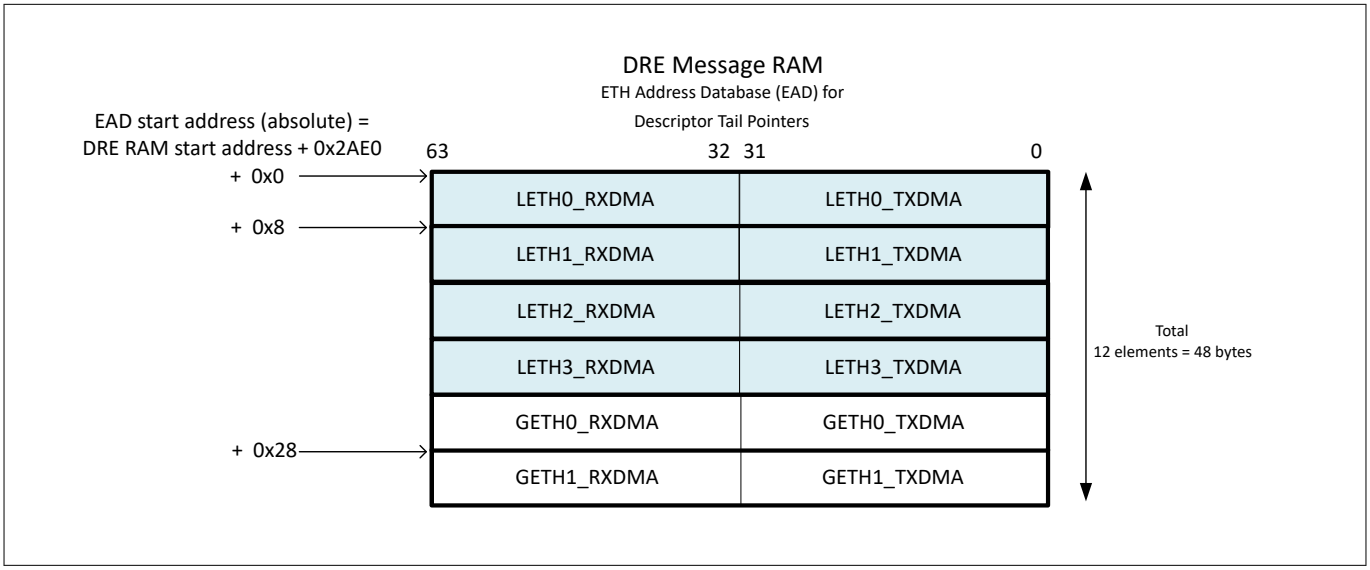

Figure 346 Ethernet address database structure

The Ethernet Descriptor Handler reads the Ethernet DMA Status register DMA_CH_Status during error or polls it to determine the status of the DMA. The bits highlighted in the figure below are checked by the Descriptor Handler to determine the status.

1. GETH DMA_CHj_Status (j=0-7) register address = DMA_CHj_RxDesc_Tail_LPointer (j=0-7) + EADCFG.GOV
2. LETH DMA_CHy_Status (y=0-7) register address = DMA_CHy_RxDesc_Tail_Pointer (y=0-7) + EADCFG.LOV

20.4.3.11 DMEM parameter table

The DMEM parameter table contains the control and address configuration of the destination memories used for CAN to system memory routing.

The start address of the DMEM parameter table is DRE RAM start address + 0x7A40. The DMEM parameter table consists of 28 elements. Each element corresponds to an individual destination memory (DMEMi) configuration. This way 28 independent destination memories can be configured. The DMEM parameter table layout is shown in the following figure.

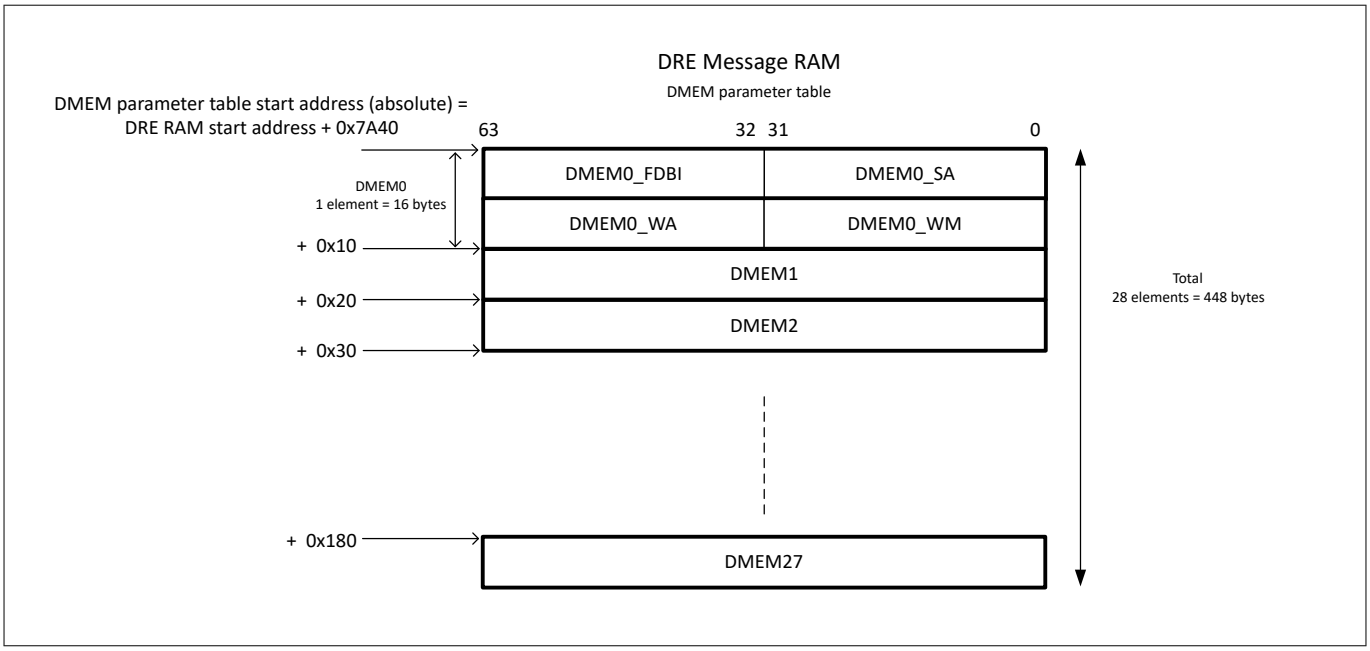

Figure 348 DMEM parameter table layout

The DMEM table is configured by the user with the following parameters:

1. DMEMi_SA defines the start address of DMEMi (i= 0 to 27)
2. DMEMi_WM defines the watermark level of DMEMi (i= 0 to 27). The watermark level is configured as number of CAN messages or number of words depending on the trigger mode.
3. DMEMi_WA defines the wraparound level of DMEMi (i= 0 to 27). The wraparound level is configured as number of CAN messages or number of words depending on the trigger mode.

The DMEM table also consists of DMEMi_FDBI, which is updated by the DRE after each CAN message is transferred to the destination memory.

20.5 ACF CAN-Ethernet format engine

This section describes the CAN-to-ACF and ACF-to-CAN frame formatting.

20.5.1 Feature list

- Concurrent assembly and disassembly of CAN (FD) frames into and from ACF frames according to IEEE 1722-2016
  - Supports Non-Time-Synchronous Control Format header (NTSCF)
  - Supports Abbreviated CAN/CAN FD message type (ACF_CAN_BRIEF)
- Support of different ACF frame transmission modes
  - Frame Count transmit mode
  - Buffer Fill Level transmit mode
  - Time-Triggered transmit mode
  - Software-Triggered transmit mode
- User-configurable stream ID for the ACF transmit frames
- Optional user configuration for Ethernet 802.3 MAC header and 802.1Q tag field corresponding to ACF frames contained in Layer 2 Ethernet frame

- Automatic stream ID-based sequence number generation and validation for ACF transmit and receive frames respectively
- Flexible identification of AVTP EtherType field start offset address in received ACF frames
- Stream ID-based acceptance filters for received ACF frames
- Support of the following error detections
  - Invalid NTSCF sub-type received
  - Invalid CAN/CAN FD message type received
  - ACF received frame length error

20.5.2 Functional overview

The block diagram of the ACF CAN-to-Ethernet Format Engine is shown in the following figure. It contains four blocks:

- Transmit Trigger Unit
- CAN-to-Ethernet ACF Assembler
- Ethernet ACF-to-CAN Disassembler
- Stream ID Filter

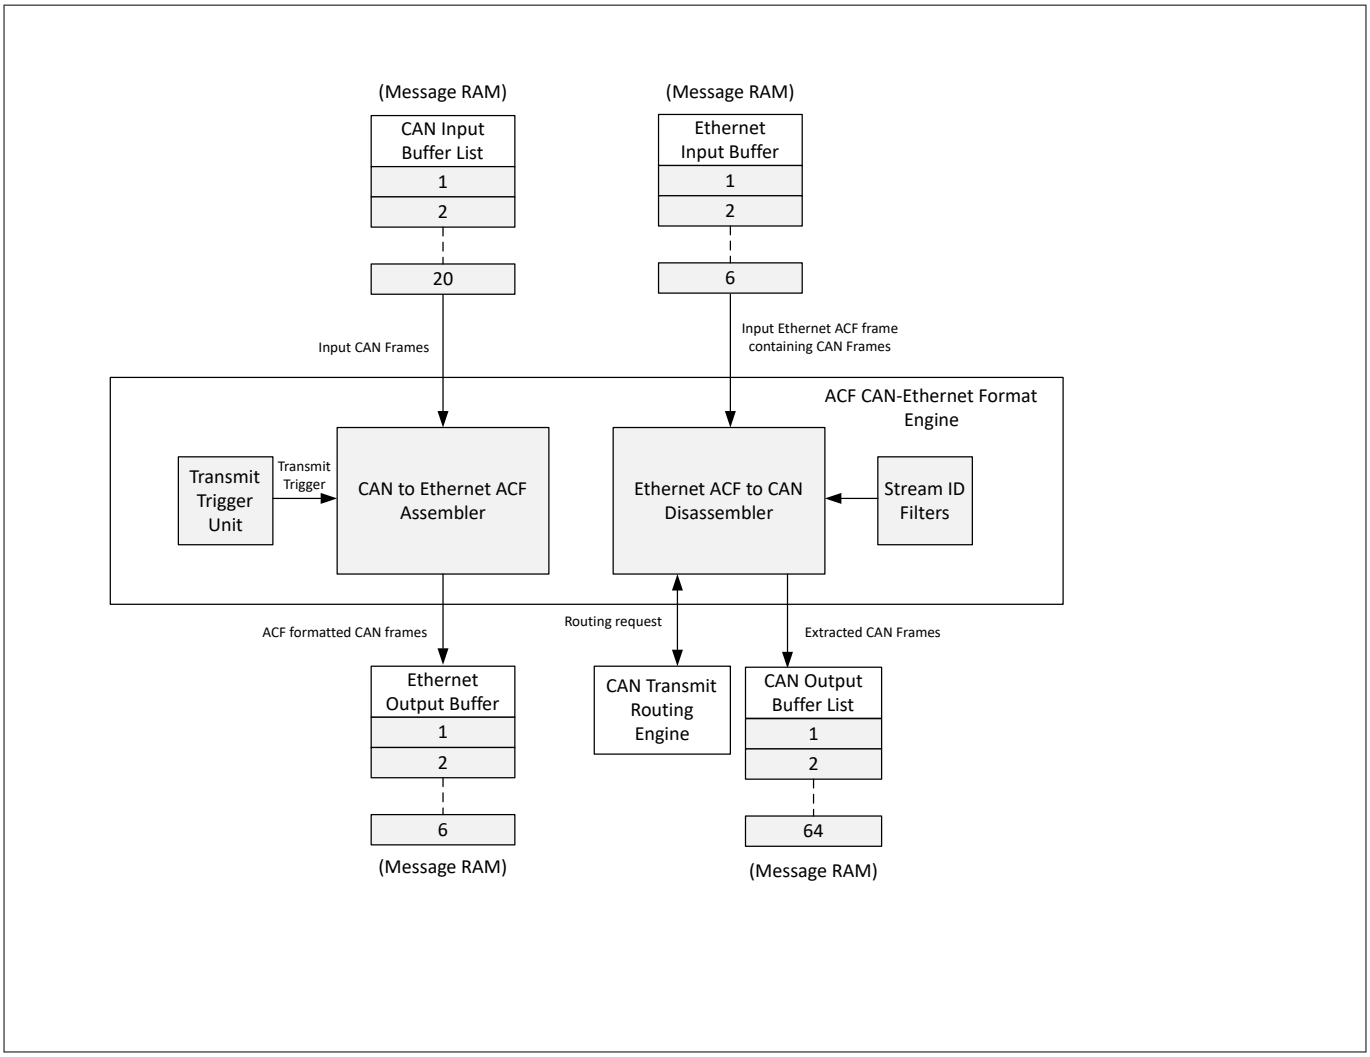

Figure 349 IEEE 1722a ACF format engine block diagram

Transmit Trigger Unit

The Transmit Trigger Unit controls the completion criteria of assembling the CAN-over-Ethernet frame which is performed by the CAN-to-Ethernet ACF Assembler. Based on the configuration of the Transmit Trigger Unit, a transmit trigger is sent to the CAN-to-Ethernet ACF Assembler, which marks that the corresponding Ethernet Output Buffer is ready for transmission to an Ethernet interface. The Transmit Trigger Unit supports 4 modes of operation:

- Frame Count transmit mode
- Buffer Fill Level transmit mode
- Time-Triggered transmit mode
- Software-Triggered transmit mode

CAN-to-Ethernet ACF Assembler

The CAN-to-Ethernet ACF Assembler performs the formatting of the CAN frame to Abbreviated CAN/CAN FD message type (ACF_CAN_BRIEF) format as specified by the IEEE 1722-2016 standard. The CAN frames are fetched from the CAN Input Buffer List and the formatted CAN frames are written to the Ethernet Output Buffer corresponding to the destination ID contained in the routing header of the input CAN frame. In addition to the ACF payload, it also prepares the NTSCF header.

Ethernet ACF-to-CAN Disassembler

The Ethernet ACF-to-CAN Disassembler performs the extraction of Abbreviated CAN/CAN FD messages (ACF_CAN_BRIEF) from an ACF frame in the Ethernet Input Buffer and formats it to the CAN frame transmit format. The extracted and formatted transmit CAN frames are handed to the CAN Transmit Routing Engine to determine the destination CAN interface.

Stream ID Filter

The Stream ID Filters contain the configuration for accepted Stream IDs of the input ACF frames. They also contain routing table indexes for each Stream ID filter. The routing table index is used by the CAN Transmit Routing Engine to select a corresponding CAN Transmit Routing Table which is compared to extracted CAN frames to identify the destination CAN interface.

20.5.3 Functional description

In this section, the packing and un-packing of CAN frames to or from ACF frames are described in detail.

20.5.3.1 Transmit trigger unit

The Transmit Trigger Unit enables the user to configure the transmit condition of the ACF frame. The following transmit modes are supported and can be configured with EOBUFj_CONFIG.TTM:

- Frame Count
- Buffer Fill Level
- Time-Triggered
- Software-Triggered

20.5.3.1.1 Frame count transmit mode

The transmission of the ACF frame is triggered when the number of ACF_CAN_BRIEF messages in an Ethernet Output Buffer has reached the user-configured frame count value in the EOBUFj_TTC.TFL bit-field.

The Frame Count transmit mode is enabled when EOBUFj_CONFIG.TTM = 01_B. The current number of CAN frames packed in an Ethernet Output Buffer is seen at EOBUFj_STATUS.ACFL. When it reaches the EOBUFj_TTC.TFL of an Ethernet Output Buffer, the EOBUFj_STATUS.TXRDY flag is set.

20.5.3.1.2 Buffer fill level transmit mode

The transmission of the ACF frame is triggered when the ACF payload size is greater than or equal to the configured Buffer Fill level in EOBUFj_TTC.BUFT.

The Buffer Fill Level transmit mode is enabled when EOBUFj_CONFIG.TTM = 10_B. The current ACF payload size of an Ethernet Output Buffer is shown in EOBUFj_NTSCF_H0.NTSCFDL. When the ACF payload size is greater than or equal to the configured Buffer Fill level (EOBUFj_TTC.BUFT), the Transmit Ready flag (EOBUFj_STATUS.TXRDY) is set.

20.5.3.1.3 Time-triggered transmit mode

The transmission of the ACF frame is triggered after a configured time interval.

The Time-Triggered transmit mode is enabled when EOBUFj_CONFIG.TTM = 11_B. The clock source of the timer is fSRI. The pre-scaler value for the timer is configured in EOBUFj_TTC.TP. Writing a non-zero value to the Timer Reload Value (EOBUFj_TTS.TRV) starts the timer. At the start of the timer, the TRV value is loaded to the Current Timer Value (EOBUFj_TTC.CTV) and it is decremented at the frequency of the clock source fSRI (pre-scaled by EOBUFj_TTC.TP). When EOBUFj_TTC.CTV reaches 00_H, the Transmit Ready flag (EOBUFj_STATUS.TXRDY) is set. Upon a trigger condition, when the corresponding Ethernet Output Buffer is empty, the Transmit Ready flag is not set and the Transmit Trigger Lost flag (EOBUFj_STATUS.TTL) is set.

20.5.3.1.4 Software-triggered transmit mode

The transmission of the ACF Ethernet frame is triggered from the application software.

When EOBUFj_CONFIG.TTM = 0_B, the application software can trigger the transmission of the ACF frame by setting EOBUFj_STATUS.TXRDY. When the TXRDY flag is set and the corresponding EOBUF is empty, the Transmit Trigger Lost flag (EOBUFj_STATUS.TTL) is set.

20.5.3.2 CAN-to-Ethernet ACF assembler

The CAN-to-Ethernet ACF Assembler:

1. Formats the CAN frames in CIBUF from CAN Input Buffer format to ACF_CAN_BRIEF format
2. Writes the ACF_CAN_BRIEF messages to the Ethernet Output Buffer
3. Writes the Ethernet header and NTSCF header to the Ethernet Output Buffer

The state machine of the CAN-to-Ethernet ACF Assembler is shown in the figure below.

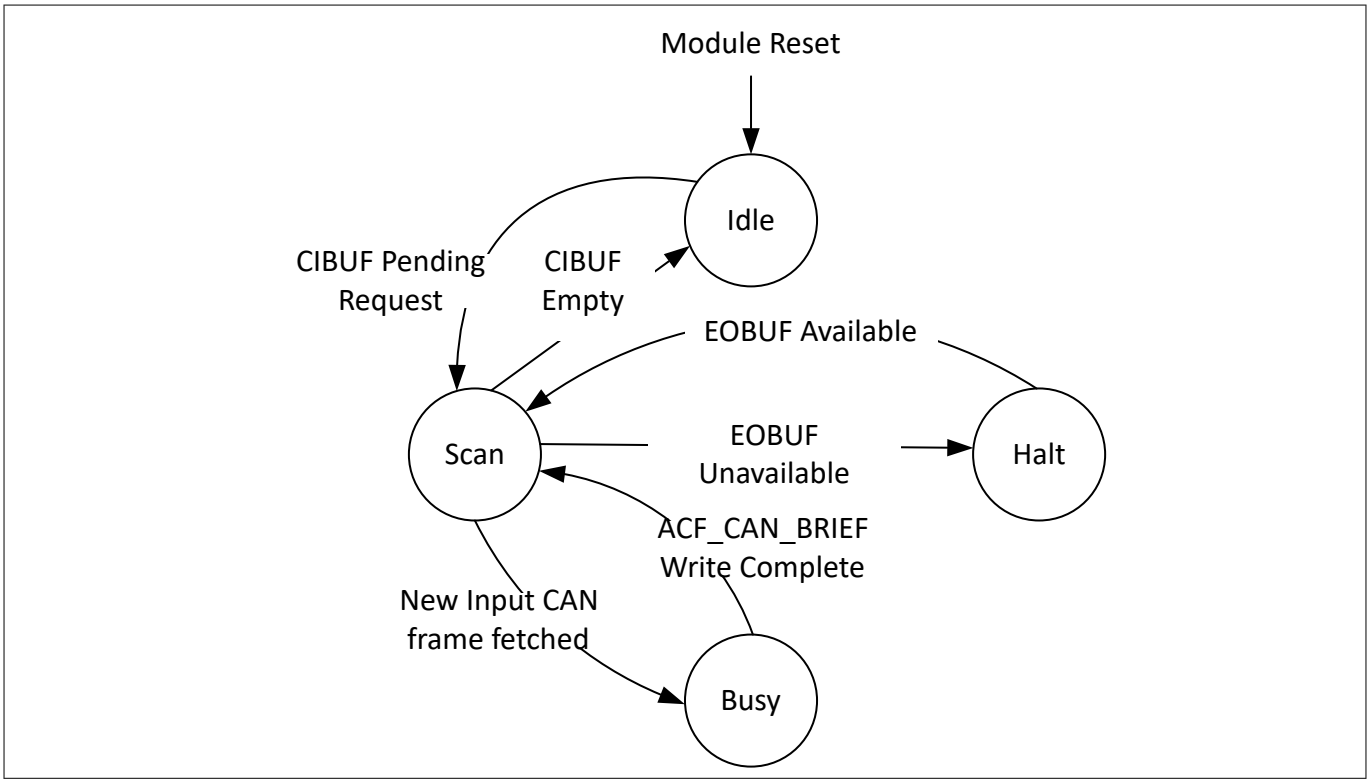

Figure 350 CAN-to-Ethernet state machine diagram

The transition conditions are described in the following table.

Table 935 CAN-to-Ethernet state transition condition

Current state	Next state	Transition condition
Any	Idle	Module Reset triggered
Idle	Scan	Pending Request of CAN Input Buffer
Scan	Idle	CAN Input Buffer List is empty
Scan	Busy	New CAN frame from CAN Input Buffer is ready to be processed
Busy	Scan	Assembling CAN frame in Ethernet Output Buffer is completed
Scan	Halt	No relevant Ethernet Output Buffer is available
Halt	Scan	An Ethernet Output Buffer becomes available

Related information

CAN input buffer list on page 3726
Ethernet output buffer on page 3730

20.5.3.2.1 Fetch input CAN frame

The Pending Request bit (CIBL_BPR) is used to identify the CAN frames to be processed from the CAN Input Buffer List. Upon a new CAN Input Buffer pending request, the state machine transits from Idle to Scan state. In this state, the pending requests of the CAN Input Buffers are scanned from CAN Input Buffer Index 0 up to Index 19. A CAN frame from a CAN Input Buffer is processed when the following conditions are satisfied:

1. The CAN Input Buffer has a pending request set, and
2. All destination Ethernet Output Buffer(s) are enabled and there is a free Ethernet Output Buffer (EOBUFj_STATUS.TXRDY = 0 and EOBUFj_STATUS.TXREQ = 0)

The destination Ethernet Output Buffer(s) is determined by the Routing header of the input CAN frame (CIBUFj_RHEAD). When an Ethernet destination(s) is enabled in CIBUFj_RHEAD, the corresponding Ethernet Destination IDs are compared with configured matching Destination IDs of the Ethernet Output Buffers 0 to 5 (EOBUFj_CONFIG.DID). The EOBUF with the matching Destination ID is used as the destination Ethernet Output Buffer. When no match is found, the Invalid Routing Destination Error flag (ME_ERR.IRDE) is set.

The CAN frame satisfying the above-mentioned conditions is then formatted with the ACF_CAN_BRIEF frame structure. The CAN Input Buffer Index which matches the conditions is reflected in the CIBL_STATUS.CBI bit-field and the state is set to Busy. In case the above conditions are not met by a CAN Input Buffer and the corresponding CAN frame, the next CAN Input Buffer is scanned, until the configured maximum number of buffers is reached. A transition from Scan to Idle state is performed when the Buffer Empty flag (CIBL_STATUS.BE) is set. A transition from Scan to Halt state is performed when no CAN frame with pending request has destination Ethernet Output Buffer(s) free.

***Note**: The order of the ACF_CAN_BRIEF messages assembled in the EOBUF is not maintained as per the order of incoming CAN requests*

20.5.3.2.2 ACF_CAN_BRIEF message format encoder

ACF_CAN_BRIEF message format encoder

The input CAN frame is converted to the ACF_CAN_BRIEF format as defined by IEEE 1722-2016. The format of the ACF_CAN_BRIEF message type is shown in figure below.

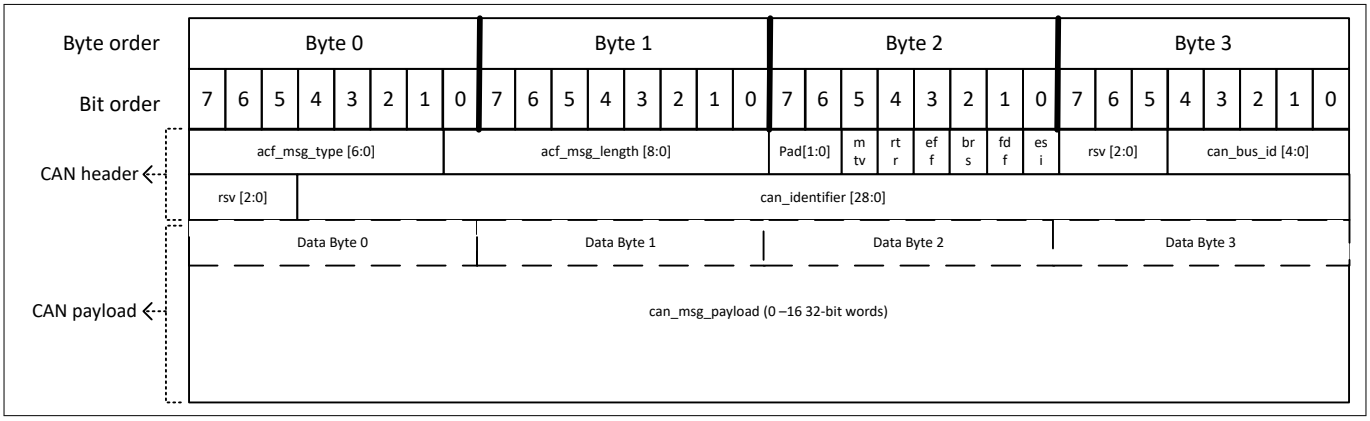

Figure 351 ACF_CAN_BRIEF frame format

The ACF_CAN_BRIEF message has the following fields:

- acf_msg_type: 7 bits
- acf_msg_length: 9 bits
- pad (padding length): 2 bits
- mtv (message_timestamp valid): 1 bit
- rtr (remote transmission request): 1 bit

- eff (extended frame format): 1 bit
- brs (bit rate switch): 1 bit
- fdf (CAN Flexible Data-rate Format): 1 bit
- esi (error state indicator): 1 bit
- rsv (reserved): 3 bits
- can_bus_id: 5 bits
- can_identifier: 29 bits
- rsv: 3 bits
- can_msg_payload: 0 to 16 (32-bit) words

acf_msg_type field

The acf_msg_type field describes the type of message contained in the ACF message payload. The ACF_CAN_BRIEF frames have a fixed acf_msg_type value of 0x02.

acf_msg_length field

The acf_ msg_length field indicates the number of words contained in the ACF_CAN_BRIEF frame. It includes the number of words in the CAN header and in the CAN payload. The length of the input CAN frame payload is indicated in the DLC field of the CAN Input Buffer. The acf_msg_length field always represents the number of 32-bit words in the frame. The minimum length is always 2, that is, when a CAN message contains no payload, then the acf_msg_length contains a value of 2 representing only the words occupied by the CAN header. When a CAN frame has a payload length which is not an integral multiple of 32-bit words, then the remaining bytes of the can_msg_payload are padded with zero (0) to reach an integral multiple of 32-bit words. This is described in detail below in the pad field description.

pad (padding length) field

The pad field indicates the length of padding at the end of the CAN message payload in bytes. Padding is added to the payload of the input CAN frame so that the can_msg_payload ends on a word boundary. A value of zero (0) is used in case there is no padding required for the CAN message payload. The table below shows the encoding of the acf_msg_length and pad fields values for corresponding input CAN message length (DLC) values.

Table 936 CAN message payload length transformation

Input CAN message data length code (DLC)	Input CAN message data length (in bytes)	can_message_payload length (in words)	Pad value (in bytes)	acf_msg_length value (in words)
0_H	0_D	0_D	0_D	2_D
1_H	1_D	1_D	3_D	3_D
2_H	2_D	1_D	2_D	3_D
3_H	3_D	1_D	1_D	3_D
4_H	4_D	1_D	0_D	3_D
5_H	5_D	2_D	3_D	4_D
6_H	6_D	2_D	2_D	4_D
7_H	7_D	2_D	1_D	4_D
8_H	8_D	2_D	0_D	4_D
9_H	12_D	3_D	0_D	5_D
A_H	16_D	4_D	0_D	6_D

(table continues...)

Table 936 (continued) CAN message payload length transformation

Input CAN message data length code (DLC)	Input CAN message data length (in bytes)	can_message_payload length (in words)	Pad value (in bytes)	acf_msg_length value (in words)
B_H	20_D	5_D	0_D	7_D
C_H	24_D	6_D	0_D	8_D
D_H	32_D	8_D	0_D	10_D
E_H	48_D	12_D	0_D	14_D
F_H	64_D	16_D	0_D	18_D

mtv (message_timestamp_valid) field

The mtv field is always set to zero (0) for the ACF_CAN_BRIEF message format.

rtr (remote_transmission_request) field

The rtr field contains the CAN message Remote Transmission Request bit. The value of this bit-field corresponds to CIBUFj_R0.RTR bit-field of the CAN Input Buffer. In case of Remote frames, there is no payload data copied and the frame ends at R1.

eff (extended_frame_format) field

The eff field contains the CAN message Extended Frame Format bit. The value of this bit-field corresponds to the CIBUFj_R0.XTD bit-field of the CAN Input Buffer.

Input CAN frames with standard 11-bit CAN identifier have their eff bit set to zero (0).

Input CAN frames with extended 29-bit CAN identifier have their eff bit set to one (1).

brs (bit_rate_switch) field

The brs field contains the CAN message Bit Rate Switch bit. The value of this bit-field corresponds to the CIBUFj_R1.BRS bit-field of the CAN Input Buffer.

fdf (CAN Flexible Data-rate [FD] Format) field

The fdf field contains the CAN message Flexible Data-rate Format bit. The value of this bit-field corresponds to the CIBUFj_R1.FDF bit-field of the CAN Input Buffer.

If the fdf bit is set to zero (0), then it is a classical CAN message and the valid lengths for data in the can_msg_payload field are 0 through 8 bytes.

If the fdf bit is set to one (1), then it is a CAN FD message and the valid lengths for data in the can_msg_payload field are 0 through 8, 12, 16, 20, 24, 32, 48 and 64 bytes.

esi (error_state_indicator) field

The esi field contains the CAN message Error State Indicator bit. The value of this bit-field corresponds to the CIBUFj_R0.ESI bit-field of the CAN Input Buffer.

can_bus_id field

The can_bus_id field contains an identifier for the CAN bus on which this frame is received. The value of this bit-field corresponds to the bits CIBUFj_RHEAD.SCBID[4:0] of the CAN Input Buffer.

can_identifier field

The can_identifier field contains the CAN frame identifier. The CAN frame identifier is either 11 or 29 bits in length. The length of the can_identifier is indicated by the eff field. 11-bit CAN message identifiers CIBUFj_R0.ID[28:18] are stored in byte 2, bits 2 through 0 and byte 3, bits 7 through 0. The remaining bits of the field are set to zero (0). 29-bit CAN frame identifiers CIBUFj_R0.ID[28:0] occupy the entire 29-bit-field length of the can_identifier field. The mapping of the CAN ID from the CAN Input Buffer to the ACF can_identifier field is shown in the figure below. Valid CAN ID bits are marked as 'v' in the figure.

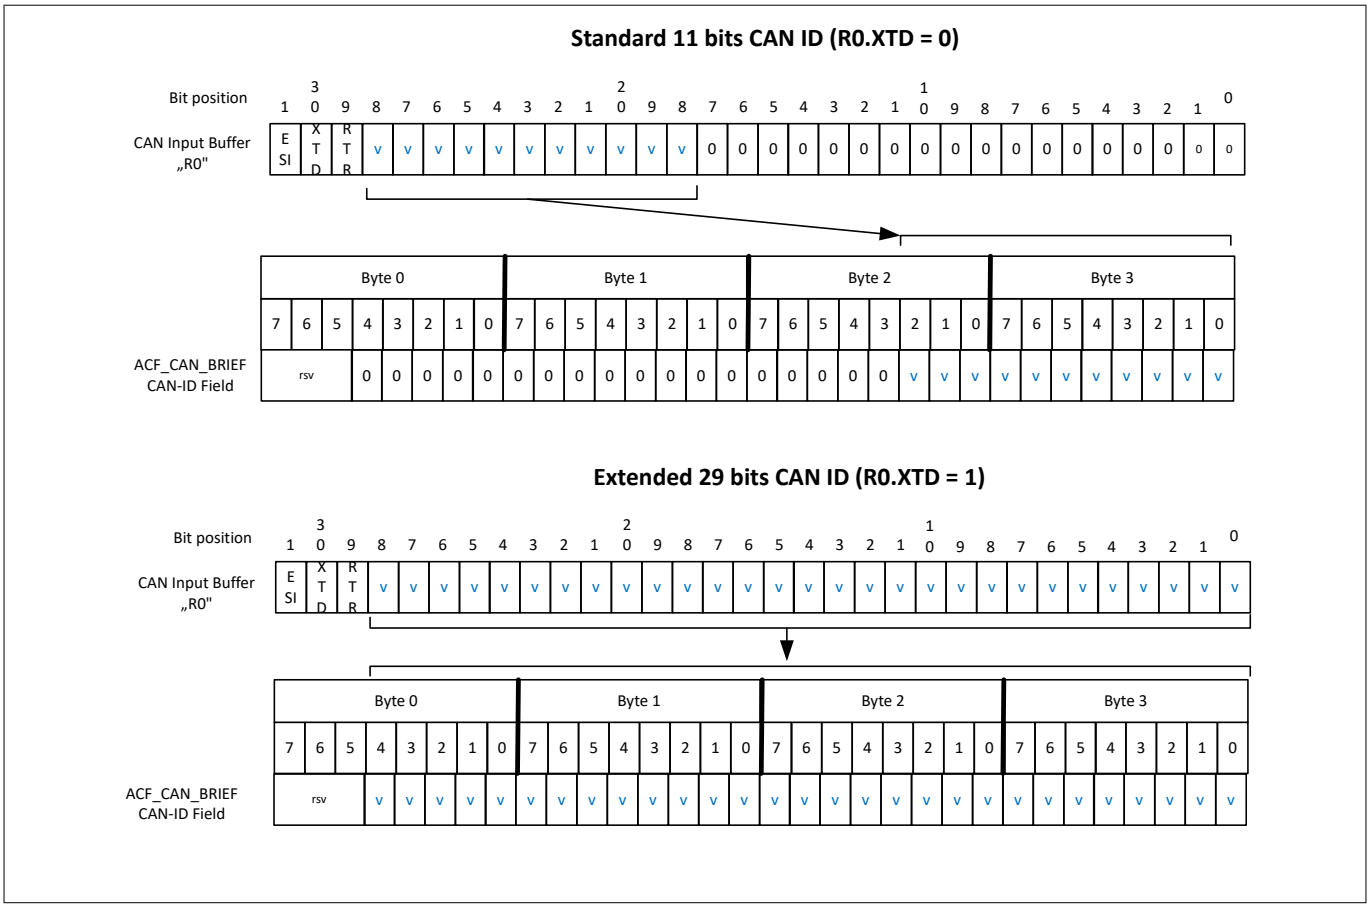

Figure 352 CAN ID mapping

can_msg_payload field

The can_msg_payload field contains the CAN frame payload data. The size of this field can be from 0 to 16 words, depending on the DLC (Data Length Code) of the input CAN frame. Only the data bytes of length corresponding to CIBUFj_R1.DLC from the CAN Input Buffer are written to the can_msg_payload field. The overall size of the can_msg_payload field is always an integral multiple of words (one word is of 4-bytes). If the data length is not word aligned, padding is always added at the end of the CAN frame payload to satisfy the length condition as shown in the previous table.

20.5.3.2.3 Assembling the CAN frame

This section describes the steps performed by the CAN-to-Ethernet ACF Assembler to assemble CAN frames.

Identification of the destination Ethernet Output Buffer

The destination of the input CAN frame is identified through the Destination ID in the Routing header of the CAN frame (CIBUFj_RHEAD.ETHDID). Valid Destination ID values for Ethernet are from 18_H until $1D_H$. The Ethernet Output Buffer corresponding to the Destination ID values are configured in EOBUFj_CONFIG.DID. The Ethernet Output Buffer that matches the Destination ID of the input CAN frame is chosen to store the corresponding ACF_CAN_BRIEF message. In case the Ethernet Output buffer configurations contain the same Destination ID values, Ethernet Output Buffer 0 is given the highest priority followed by the other buffers, provided that the Buffer 0 is free to accept a new CAN frame.

Write operation to the ACF payload section

The input CAN frames which are encoded in the ACF_CAN_BRIEF message format are written to the ACF Payload section of the Ethernet Output Buffer. The ACF Payload section starts at an offset address of 0x20 from the Ethernet Output Buffer start address. The offset address at which the current ACF_CAN_BRIEF message is to

be written is indicated in EOBUFj_STATUS.ACF_CAN_ADDR. The ACF_CAN_BRIEF message is written to the indicated payload address. Then following occurs after completion of the write operation:

1. The EOBUFj_STATUS.ACF_CAN_ADDR is incremented by $\text{can_msg_payload} \times 4$ (multiple of 4 is done to convert the size from 32-bit words to bytes)
2. The ntscf_data_length (EOBUFj_NTSCF_H0.NTSCFDL) of the NTSCF header is incremented by $\text{can_msg_payload} \times 4$

The Assembler verifies the 16-bit CRC (CIBUFj_CRC) which is calculated by the CRE over R0, R1 (except ESI, ANMF, RXTS, FIDX and BRS which are considered as zero), safety critical CAN payload and the DID (which is padded with zeros to make it 32-bits) which is part of the input CAN frame in the CIBUF before it writes the final block of data into the EOBUF. The CRC is calculated over 16 bits of data at a time starting with the MSB. It uses the CCITT CRC16 polynomial: 0x1021 $x^{16} + x^{12} + x^5 + 1$. If there is a mismatch in the CRC, the CRC Error flag (CIBL_STATUS.CRCE) is set and an error interrupt is triggered but the CAN frame is still processed by the DRE.

***Note**: In case of CAN to CAN routing, the DRE does not calculate the CRC. It only copies the CRC from the source CAN node to the destination CAN node.*

Acknowledgement of the CAN Input Buffer

After finishing the write operation of the completed ACF_CAN_BRIEF message to the Ethernet Output Buffer, the pending request of the corresponding CAN Input Buffer is cleared by the hardware. EOBUFj_STATUS.ACFL is incremented after the ACF_CAN_BRIEF message is assembled inside the EOBUF. The CAN-to-Ethernet ACF Assembler then proceeds to fetch the next available input CAN frame.

The DRE monitors for delayed processing of the CAN frame in CIBUF by the engine. The watchdog timer counter starts incrementing when the Timeout Enable (CWDCFG.EN) is set. The CAN watchdog timer triggers periodic events E1, E2,…,En after a user-configured timeout prescaler CWDCFG.CTO. If the start condition is true and the end condition is not true within two events Ei and Ei+1, the CAN watchdog Timeout Error flag CIBL_STATUS.WDTE is set and the error interrupt INT_8 is triggered if CWDCFG.WTOE is enabled. The buffer with the Timeout error is indicated by the CITO register. Whenever there is a timeout, the corresponding CIBUF is taken out of the arbitration. The software shall clear the Timeout status within the CITO register and also clear the pending request if needed after reading the frame. In case the same CIBUF is to be reused (included again in the next arbitration), the software shall clear only the Timeout status.

The Timeout period between the events Ei is calculated as follows:

- Default Timeout period: $T_{def} = \frac{16}{f_{SRI}}$
- User-configured Timeout period: $T_{out} = T_{def} * (CWDCFG.CTO + 1)$

The table below shows the conditions which trigger a Timeout interrupt.

Table 937 Timeout interrupt trigger

Timeout check	Timeout interrupt trigger
End condition is true within a single event Ei	No Timeout error. No Timeout interrupt triggered
End condition is true within two consecutive events Ei and Ei+1	If the presence of start condition is detected at Ei, then the end condition is expected to happen before Ei+1. If not, the Timeout interrupt is triggered
End condition is true after two consecutive events Ei and Ei+1	Timeout interrupt is triggered

The table below shows the start and end conditions for the CIBUF.

Table 938 CIBUF : Start and end condition list

Start condition	End condition
Pending request is set for the CAN frame in an individual buffer CIBUF. The CIBL_BPR.PRj indicates the pending requests	Pending request is cleared for the CIBUF

Checking the Ethernet Output Buffer full condition

The maximum size of the ACF Payload section is configured at EOBUFj_CONFIG.PL. Before storing a new ACF_CAN_BRIEF frame into an Ethernet Output Buffer, if the EOBUFj_NTSCF_H0.NTSCFDL will exceed the configured EOBUF payload size (EOBUFj_CONFIG.PL), the Buffer Full flag (EOBUFj_STATUS.BF) is set by the hardware and an interrupt is triggered. There is no transmit ready from the DRE in case of Buffer Full scenario. The software shall use the Buffer Full interrupt to set the TXRDY.

The hardware then checks for the next available Ethernet Output Buffer with a matching Destination ID. If available, the ACF_CAN_BRIEF message is stored in that buffer, otherwise the ACF_CAN_BRIEF message processing is aborted and the pending request flag (CIBL_BPR.PRj) of the corresponding CAN Input Buffer is not cleared.

Write operation to the Ethernet header section

The Transmit Trigger Unit controls the Transmit Ready (EOBUFj_STATUS.TXRDY) condition of each Ethernet Output Buffer. The CAN-to-Ethernet ACF Assembler continues to stack ACF_CAN_BRIEF messages to the Ethernet Output Buffer until EOBUFj_STATUS.TXRDY is set by the Transmit Trigger Unit. When EOBUFj_STATUS.TXRDY is set, the CAN-to-Ethernet ACF Assembler prepares the Ethernet header section of the Ethernet Output Buffer as follows:

1. When EOBUFj_CONFIG.HE is set, the contents of the Ethernet header (EOBUFj_MAC_H0, EOBUFj_MAC_H1, EOBUFj_MAC_H2, EOBUFj_MAC_H3 and EOBUFj_MAC_H4) are written to the header section of the Ethernet Output Buffer, starting at offset address of 0_H from the EOBUF start address
2. The NTSCF header (EOBUFj_NTSCF_H0, EOBUFj_NTSCF_STREAM0_ID and EOBUFj_NTSCF_STREAM1_ID) is written to the NTSCF header section of the Ethernet Output Buffer, starting at an offset address of 14_H from the EOBUF start address
3. The Sequence Number (EOBUFj_NTSCF_H0.SN) is incremented by 1. Upon overflow, the Sequence Number is wrapped around to 0
4. The Ethernet Transmit Request bit for the corresponding EOBUF is set in EREQ.TXi_REQ
5. The assembled Ethernet frame is handed over to the Ethernet Descriptor Handler which triggers an interrupt to the Interrupt Router module or prepares the Tx descriptors depending on the TETHDLi_CTRL.TRIG

20.5.3.3 Ethernet ACF-to-CAN disassembler

This section describes the extraction of CAN frames from the input ACF frame.

Related information

Ethernet input buffer on page 3733

20.5.3.3.1 Ethernet input frame

The received Ethernet frames are stored in the Ethernet Input Buffer by the ETH DMA channel or the software. A new received Ethernet frame in the Ethernet Input Buffer is indicated by the pending request set by the ETH Descriptor Handler. The Ethernet Input Buffer with a pending request set is processed by the ACF-to-CAN Disassembler. The Buffer 0 has the highest priority while the Buffer 5 has the lowest priority.

Validation of the Ethernet input frame

The Ethernet input frame is checked for a valid subtype and stream_id in the NTSCF header.

Header type validation

The subtype field starts at offset 0 of the NTSCF header field and is 8 bits long. The value of the subtype field should be 82_H, which corresponds to the Non-Time-Synchronous Control format.

In case of a mismatch to the subtype field, it is checked if the Ethernet frame needs to be forwarded to an Ethernet destination by performing the Forward ID filtering within the forwarding table (refer to the Forwarding Engine chapter). When there is no match, the NTSCF Header Format Error flag is set. It is considered an Ethernet Frame error (EIBUFi_STATUS.FE=1), as the Ethernet input frame cannot be processed further. In this case, the FE flag is set and the pending request is cleared by the hardware.

Stream ID validation

The stream_id field starts at offset 04_H from the start of the NTSCF header and is 64 bits long. The stream_id value is checked against the Stream-ID filter configuration for acceptance of the Ethernet frame and to determine the CAN Transmit Routing Table to be used for the routing operation of the CAN frames contained within the Ethernet input ACF frame. The CAN Transmit Routing Table is identified by the SIDFi_FC.RTI configuration.

The Stream ID filters support up to 8 filter configurations. The filter mode can be configured as Range filter or Mask filter using SIDFi_FC.MODE. In Range filter mode, the Stream ID of the Ethernet input frame must fall within the values between Filter 1 (SIDFi_FIL1_L, SIDFi_FIL1_H) and Filter 2 (SIDFi_FIL2_L, SIDFi_FIL2_H) in order to pass. In Mask filter mode, the Stream ID of the Ethernet input frame is checked for a match with the Filter 1 configuration and the Filter 2 value is used as mask for the compare operation. The filtering operation is terminated with the first matching filter element. When no configured filter is matched, the Ethernet input frame is checked if it needs to be forwarded to an Ethernet destination by performing the Forward ID filtering within the Forwarding Table (refer to the Forwarding Engine chapter). When there is still no match, the Invalid Destination ID flag (EIBUFi_STATUS.IDID) is set and an interrupt INT_10 is triggered. The software fetches the Ethernet frame from the buffer and clears the pending request.

***Note**: In case RETHDLi_CTRL.TRIG is set to 1, the Forward ID filtering is not performed when the Stream ID filtering returns no match. The Invalid Destination ID flag (EIBUFi_STATUS.IDID) is set and an interrupt INT_10 is triggered.*

Related information

Forwarding engine on page 3787

20.5.3.3.2 ACF_CAN_BRIEF message format decoder

The ACF_CAN_BRIEF messages contained in the Ethernet input frame ACF payload are extracted and formatted to the CAN frame format of the CAN Output Buffer. In addition, the routing destination of each extracted CAN frame is requested from the CAN Transmit Routing Engine.

Fetch ACF_CAN_BRIEF

ACF_CAN_BRIEF messages start at offset C_H from the NTSCF start address. Initially, the offset address of the ACF_CAN_BRIEF message to be fetched is indicated in EIBUFi_STATUS.ACF_CAN_ADR. After the fetched ACF_CAN_BRIEF message is processed, the offset address of the next ACF_CAN_BRIEF message is determined by the acf_msg_length value of the last fetched message.

$$\text{New ACF_CAN_ADDR} = \text{ACF_CAN_ADDR} + \text{acf_msg_length} << 2_H$$

For each fetched ACF_CAN_BRIEF message, the length of the ACF payload is incremented as follows:

$$\text{ACF_Payload_Length} = \text{ACF_Payload_Length} + \text{acf_msg_length} << 2_H$$

ACF_CAN_BRIEF messages are fetched from the Ethernet Input Buffer until the calculated ACF_Payload_Length is equal to the Ntscf_data_length value of the NTSCF header. If it is greater, then the fetched ACF_CAN_BRIEF message is discarded, the AVTP Length Mismatch Error flag (EIBUFi_STATUS.LME) is set, the Ethernet input frame is discarded and the EIBUF pending request is cleared.

Validation of ACF_CAN_BRIEF

Each fetched ACF_CAN_BRIEF message is validated for Frame Format and Remote Frame errors before it is decoded.

Frame format error

The acf_msg_type value of the ACF_CAN_BRIEF message shall be 02_H. In case of a mismatch, the CAN Frame Format Error flag is triggered, the corresponding Ethernet input frame is dropped and the Pending Request flag is reset.

Remote frame error

When Reject Remote Frame is configured as 1_B and the RTR field of the ACF_CAN_BRIEF frame is 1_B and FDF is set to 0_B, the EIBUFi_STATUS.RFE flag is set and the next ACF_CAN_BRIEF message is fetched (if available). When Reject Remote Frame is configured as 0_B , the frame is copied without any data bytes.

As there are no remote frames in case of CAN FD format, the DRE_COBUFj_R0.RTR bit is ignored if the FDF bit is set to 1_B.

Routing request

The CAN Identifier field of the validated ACF_CAN_BRIEF message and the Routing Table Index is used to request the CAN Transmit Routing Engine in order to identify the destination of the CAN frames.

A new routing request is performed when RREQ_CONFIG.REQ bit is cleared. The CAN Identifier and eff values of the ACF_CAN_BRIEF frame are written to RREQ_CID. The SIDFi_FC.RTI of the matched Stream ID filter is written to the RREQ_CONFIG.RTI. A routing request is initiated by setting the RREQ_CONFIG.REQ bit by hardware.

The CAN Transmit Routing Engine, after identifying a matching routing rule for the requested CAN frame, writes the corresponding routing rule in the Routing header (UCRH or MCRH SFR). The index of the Routing Element used by the CAN Transmit Routing Engine is written to RS.RE. The CAN Transmit Routing Engine acknowledges back the completion of the routing request by clearing the RREQ_CONFIG.REQ bit.

Frame decoder

The ACF_CAN_BRIEF frame is decoded and written to the CAN Output Buffer.

The ACF_CAN_BRIEF message is formatted and written to the available CAN Output Buffer indicated by the Put Index of CAN Output Buffer List.

The ACF_CAN_BRIEF message is formatted as follows:

- **Routing header**

  The Routing header as given by the CAN Transmit Routing Engine is copied to COBUFj_UCRH, COBUFj_MCRH
- **CAN identifier**

  The value of the CAN_ID field of the ACF_CAN_BRIEF message is copied to COBUFj_R0.ID
- **Remote transmit request**

  The value of the RTR field of the ACF_CAN_BRIEF message is copied to COBUFj_R0.RTR
- **Extended CAN identifier**

  The value of the EFF field of the ACF_CAN_BRIEF message is copied to COBUFj_R0.XTD
- **Error state indicator**

  The value of the EDI field of the ACF_CAN_BRIEF message is copied to COBUFj_R0.ESI

- **Data length code**

  The acf_msg_length and pad bit values are translated to a CAN Data Length Code as specified in the ACF_CAN_BRIEF message format encoder section. The translated Data Length Code is written to COBUFj_R1.DLC. In case of an invalid Data Length Code, the CAN Frame Length Error is set and the CAN frame is dropped
- **Bit-rate switch**

  The value of the BRS field of the ACF_CAN_BRIEF message is copied to COBUFj_R1.BRS
- **Frame format**

  The value of the FDF field of the ACF_CAN BRIEF message is copied to COBUFj_R1.FDF
- **CAN payload data**

  The can_msg_payload data bytes as determined by the calculated DLC of the ACF_CAN_BRIEF message are copied to the COBUFj_DB fields. The padded bytes are not written to the CAN Output Buffer

Related information

ACF_CAN_BRIEF message format encoder on page 3748

CAN frame completion

The ACF_CAN_BRIEF message decoder also computes a 16-bit CRC (COBUFj_CRC) over the R0, R1 (except ESI, ANMF, RXTS, FIDX and BRS which are considered as zero), safety critical CAN payload and the DID (which is padded with zeros to make it 32-bits) of the CAN frame stored in the CAN Output Buffer. It uses the CCITT CRC16 polynomial: 0x1021 $x^{16} + x^{12} + x^5 + 1$. The CRC is calculated over 16 bits of data at a time starting with the MSB.

After successful completion of the write operation of the CRC and the CAN frame to the CAN Output Buffer, the corresponding Transmit Request bit is set by hardware. The next ACF_CAN_BRIEF message is fetched and decoded.

The DRE monitors for delayed processing of the CAN frame in COBUF by the Routing Control Unit. The watchdog timer counter starts incrementing when the Timeout Enable (CWDCFG.EN) is set. The CAN watchdog timer triggers periodic events E1, E2,…, En after a user-configured timeout prescaler CWDCFG.CTO. If the start condition is true and the end condition is not true within two events E_i and E_{i+1}, the CAN watchdog Timeout Error flag COBL_STATUS.WDTE is set and error interrupt INT_9 is triggered if CWDCFG.WTOE is enabled. The buffer with the Timeout error is indicated by the COTO0 and COTO1 registers. Whenever there is a timeout, the corresponding COBUF is taken out of the arbitration. The software shall clear the Timeout status within the COTO0 and COTO1 registers and also clear the pending request if needed after reading the frame. In case the same COBUF is to be reused (included again in the next arbitration), the software shall clear only the Timeout status.

The Timeout period between the events E_i is calculated as follows:

- Default Timeout period: $T_{def} = \frac{16}{f_{SRI}}$
- User-configured Timeout period: $T_{out} = T_{def} * (CWDCFG.CTO + 1)$

The table below shows the conditions which trigger a Timeout interrupt.

Table 939 Timeout interrupt trigger

Timeout check	Timeout interrupt trigger
End condition is true within a single event E_i	No Timeout error. No Timeout interrupt triggered

(table continues...)

Table 939 (continued) Timeout interrupt trigger

Timeout check	Timeout interrupt trigger
End condition is true within two consecutive events E_i and E_{i+1}	If the presence of start condition is detected at Ei, then the end condition is expected to happen before Ei+1. If not, the Timeout interrupt is triggered
End condition is true after two consecutive events E_i and E_{i+1}	Timeout interrupt is triggered

The table below shows the start and end conditions for the COBUF.

Table 940 COBUF : Start and end condition list

Start condition	End condition
Pending request is set for the CAN frame in an individual buffer COBUF. The COBL_BPR0 and COBL_BPR1 indicate the pending requests	Pending request is cleared for the COBUF

Fetch ACF_CAN_BRIEF on page 3754

20.5.3.3.3 Completion of the Ethernet frame

All CAN frames contained within the input ACF frame are considered to be processed when the calculated ACF payload length matches with the NTSCF_data_length value of the NTSCF header. Upon successful completion, the pending request of the Ethernet Input Buffer (EIBUFi_STATUS.BPR) is cleared by hardware.

20.6 CAN transmit routing engine and routing control unit

The CAN Transmit Routing Engine and the Routing Control Unit are responsible for the routing of CAN frames to CAN peripherals.

20.6.1 Feature list

- Up to 4 user-configurable CAN Transmit Routing Tables
- Up to 128 user-configurable routing rules per CAN Transmit Routing Table
- The following routing modes are supported:
  - Uni-cast
  - Multi-cast (up to 4 configurable destination CAN interfaces)
- Up to 128 user-configurable CAN ID-based acceptance or rejection filters per CAN Transmit Routing Table
- Processing of multiple routing requests:
  - Requests from source CAN nodes
  - Requests from the CAN Output Buffer List
- Non-starving arbitration of routing requests
- CAN routing transfer to the following destinations:
  - CAN nodes
  - ACF Ethernet frames
  - System memory
- FPI and SRI transactions by the Move Engine

20.6.2 Functional overview

The figure below shows the block diagram of the CAN Transmit Routing Engine and the Routing Control Unit.

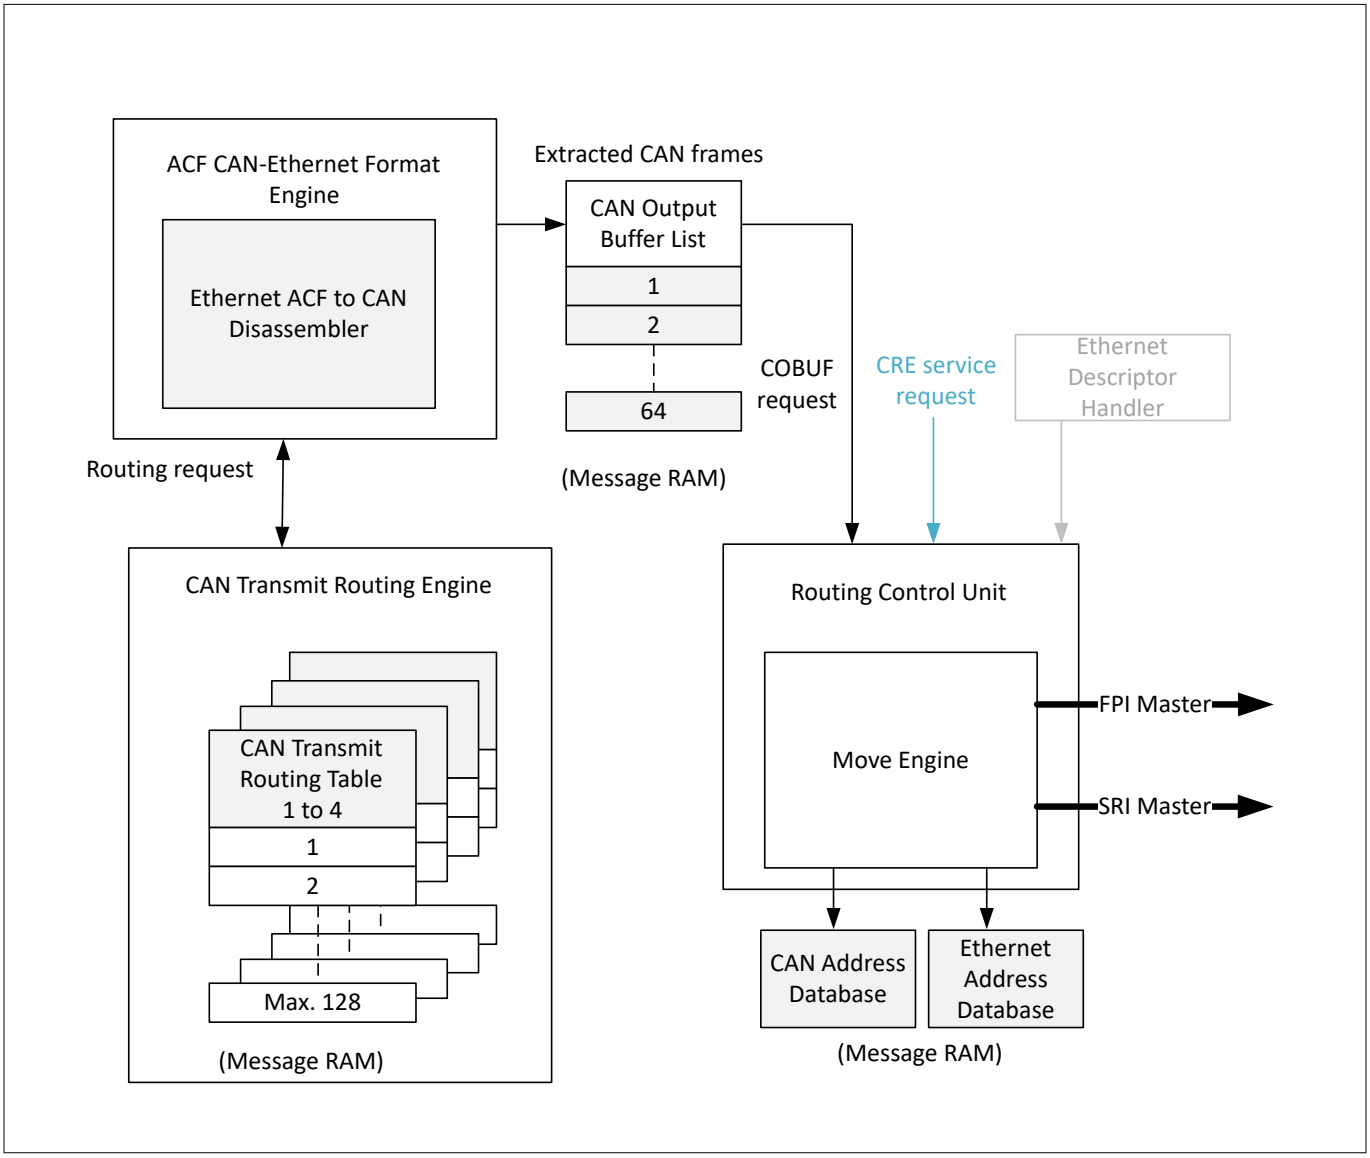

Figure 353 CAN Transmit Routing Engine and Routing Control Unit block diagram

The CAN Transmit Routing Engine is responsible for identifying the transmit destination of a CAN frame in the CAN Output Buffer List (Ethernet to CAN routing use case), whereas the Routing Control Unit assists, together with the Move Engine, in the transfer of CAN frames and Ethernet frames.

20.6.3 Functional description

In this section, the routing of transmit CAN frames and the functions of the CAN Transmit Routing Engine and the Routing Control Unit are described in detail.

20.6.3.1 CAN transmit routing engine

The CAN Transmit Routing Engine is responsible for identifying the transmit destination CAN interface of a CAN frame.

20.6.3.1.1 Initiating routing operation

The routing function of the CAN Transmit Routing Engine is initiated when a CAN Routing Request is set. When the CAN Routing Request is set, the CAN Transmit Routing Engine uses the following registers to identify the destination of the CAN frame:

- RREQ_CONFIG.RTI to identify the CAN Transmit Routing Table (1 to 4)
- RREQ_CID.ID and XTD for acceptance filter scanning

20.6.3.1.2 CAN acceptance filters

Each routing element in a CAN Transmit Routing Table contains the following:

- CAN ID filter (RT_REj_CIDFC (j = 0-127))
- Routing rule (RT_REj_UCR or RT_REj_MCR (j = 0-127))

The CAN ID filter contains the acceptance condition for a given CAN ID. The CAN ID (RREQ_CID.ID) and the Extended Identifier (RREQ_CID.XTD) of the CAN Routing Request are scanned through the CAN ID filters of each routing element. When a match occurs, the corresponding routing rule is used to identify the destination of the requested CAN frame. Disabled routing rules are not used for the filter operation. The scanning operation is performed starting from routing element 0 and ends with the routing element with the first matching CAN ID filter.

The CAN ID filter supports 3 modes of operation (RT_REj_CIDFC.MODE):

- Classical ID filter (MODE = 00_B):
  - RT_REj_CIDFC.CANID1 is used as the CAN ID filter and RT_REj_CIDFC.CANID2 is used as the mask. A mask value with bit positions having "0b" causes the corresponding bits of CAN ID1 to be ignored for matching with the requested CAN ID (RREQ_CID.ID). A mask value of all 1 causes a successful match only if the requested CAN ID is exactly same as the RT_REj_CIDFC.CANID1 value. Similarly, a mask value of all 0 causes any CAN ID value to match
- Dual ID filter (MODE = 01_B):
  - RT_REj_CIDFC.CANID1 or RT_REj_CIDFC.CANID2 is used as the CAN ID filter. The requested CAN ID must exactly match to either RT_REj_CIDFC.CANID1 or RT_REj_CIDFC.CANID2. No masking bits are used
- Range ID filter (MODE = 10_B):
  - The range of IDs between RT_REj_CIDFC.CANID1 and RT_REj_CIDFC.CANID2, inclusive, are used as CAN ID filters. The requested CAN ID must be between RT_REj_CIDFC.CANID1 (inclusive) and RT_REj_CIDFC.CANID2 (inclusive) for a match

On successful identification of the routing element with a matching CAN ID filter, the corresponding routing rule (RT_REj_UCR or RT_REj_MCR) is written to the routing header (UCRH or MCRH) of the CAN frame and the Routing Request flag (RREQ_CONFIG.REQ) is reset to 0. The corresponding routing element index is written to the RS.RE bit-field.

CAN transmit routing tables (1 to 4) on page 3730

20.6.3.1.3 Error scenarios

Invalid routing table error

When the CAN Transmit Routing Table indexed by the routing request (RREQ_CONFIG.REQ) is disabled or reserved, then the Invalid Routing Table flag (RS.IRT) is set.

Non-matched filter element error

When no matching CAN ID filter is found in the indexed CAN Transmit Routing Table, the Non-Matching Filter Element Error flag (RS.NMFE) is set.

20.6.3.2 Routing control unit

This section describes the handing of the CAN routing operation.

Related information

CAN address database on page 3726

20.6.3.2.1 CAN trigger request

The MCMCAN module generates Receive and Transmit Host Buffer triggers for the DRE.

The trigger request from a CAN node consists of the following signals:

- **TRIGTYPE(0:1):** Indicates the host buffer (Receive Host Buffer 0/1 or Transmit Host Buffer 0) related to the trigger request
- **TRIGNODE(0:1):** Indicates the CAN node within the MCMCAN module related to the trigger request

The table below shows the encoding of the TRIGTYPE trigger.

Table 941 TRIGTYPE description

TRIGTYPE(1)	TRIGTYPE(0)	Description
0_B	0_B	No trigger or idle
0_B	1_B	Transmit Host Buffer 0 free
1_B	0_B	New Receive Host Buffer 0
1_B	1_B	New Receive Host Buffer 1

Although the MCMCAN module provides two Transmit Host Buffers, only the Transmit Host Buffer 0 can be configured to trigger the DRE. CAN Receive Host Buffer 0 or 1 requests from the MCMCAN module indicates to the DRE that a new Receive CAN frame from the corresponding CAN node is pending to be fetched. The DRE in this case sets a pending Receive Request flag for the corresponding CAN node (CANRXR0, CANRXR1). A CAN Transmit Host Buffer 0 request from MCMCAN module indicates to the DRE that the corresponding CAN node has a free Transmit Host Buffer. The DRE in this case sets a pending Transmit Request flag for the corresponding CAN node (CANTXR).

The table below shows the encoding of the TRIGNODE trigger.

Table 942 TRIGNODE description

TRIGNODE(1)	TRIGNODE(0)	Description
0_B	0_B	CANx_N0
0_B	1_B	CANx_N1
1_B	0_B	CANx_N2
1_B	1_B	CANx_N3

20.6.3.2.2 Routing requests

The Routing Control Unit receives routing requests from CAN nodes (through CAN trigger request inputs) and from CAN Output Buffers.

Routing requests from CAN nodes

CAN Receive Host Buffers pending requests (CANRXR0, CANRXR1) are processed by the Routing Control Unit in a round-robin (non-starving) priority scheme, starting with the MCMCAN0 Node 0 request until the maximum number of available CAN node requests is reached. Within a CAN node request, the Receive Host Buffer 0 (CANRXR0.Ci_RH0R, CANRXR1.Ci_RH0R) gets a higher priority than the Receive Host Buffer 1 (CANRXR0.Ci_RH1R, CANRXR1.Ci_RH1R).

CAN node address decoding

The CAN Address Database in the DRE RAM always starts at the DRE RAM base address. The CAN Address Database is configured by the user with the CRE start address (CAD_CANi_CRESA.ADR). An overview of the Receive and Transmit Host Buffers structure and address decoding is given in the figure below. Refer to the CAN chapter for detailed description.

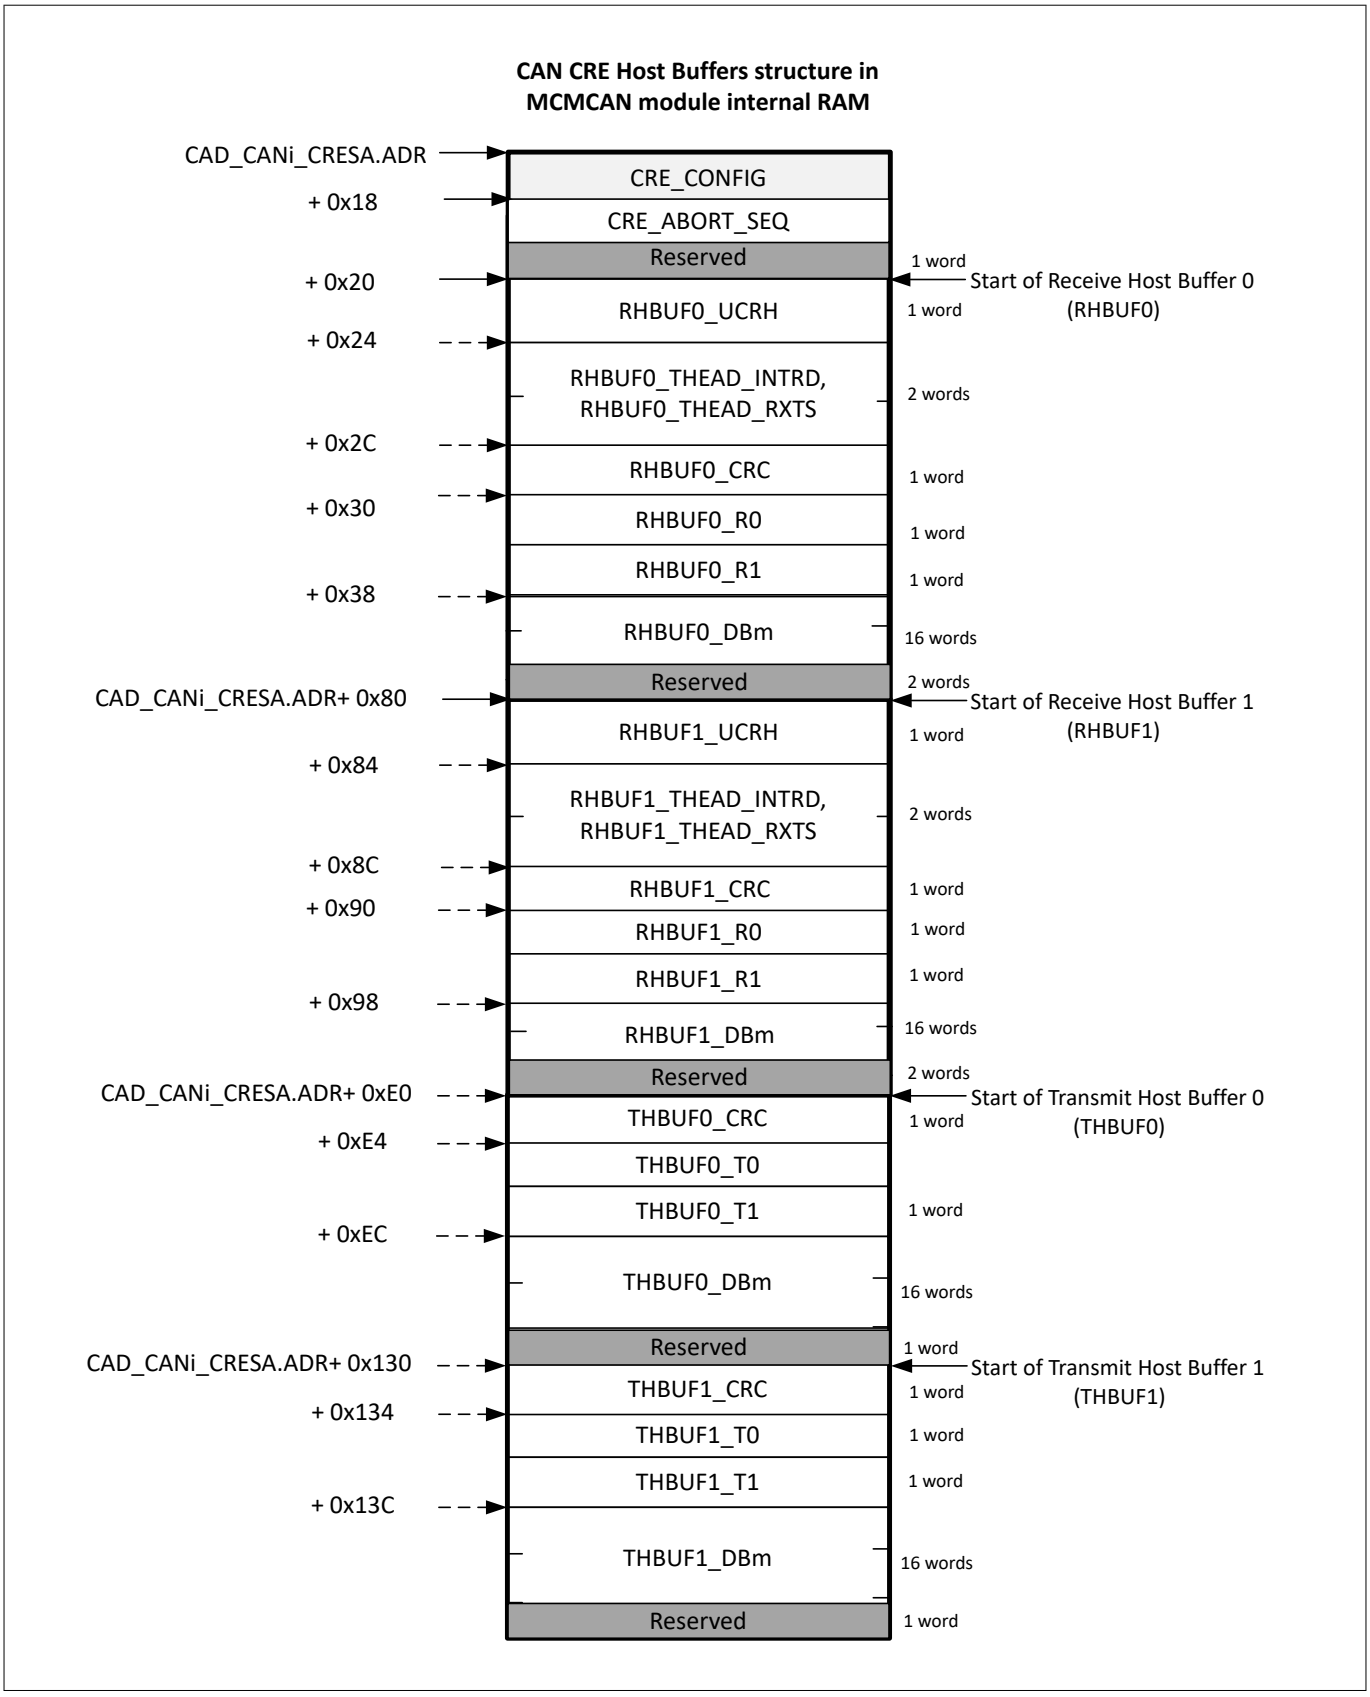

Figure 354 CAN CRE host buffer structure

When a new request from a CAN node is received, the DRE Move Engine transfers the CAN frame from the respective CAN Receive Host Buffer to the corresponding destination(s) as indicated in the routing header (RHBUFk_UCRH).

Requests from RHBUF0

The DRE performs the following after receiving a request from RHBUF0 of a CAN node CANi:

- The Routing header is read from the user-configured CAD_CANi_CRESA.ADR + 20_H address
- The Timing header (2 words) is read from the CAD_CANi_CRESA.ADR +24_H address
- The CRC header (1 word) is read from the CAD_CANi_CRESA.ADR +$2C_H$ address
- The CAN header or PDU header (2 words) RHBUF0_R0 and R1 are read from the CAD_CANi_CRESA.ADR +30_H address
- The CAN data bytes RHBUF0_DBm are read from the CAD_CANi_CRESA.ADR +38_H address. The number of data bytes to be read is defined by the Data Length Code (DLC) of the CAN frame (RHBUF0_R1.DLC)

Requests from RHBUF1

The DRE performs the following after receiving a request from RHBUF1 of CAN Node CANi:

- The Routing header is read from the user-configured CAD_CANi_CRESA.ADR +80_H address
- The Timing header (2 words) is read from the CAD_CANi_CRESA.ADR +84_H address
- The CRC header (1 word) is read from the CAD_CANi_CRESA.ADR +$8C_H$ address
- The CAN header or PDU header (2 words) RHBUF1_R0 and R1 are read from the CAD_CANi_CRESA.ADR +90_H address
- The CAN data bytes RHBUF1_DBm are read from the CAD_CANi_CRESA.ADR +98_H address. The number of data bytes to be read is defined by the Data Length Code (DLC) of the CAN frame (RHBUF1_R1.DLC)

The fetched CAN frame is routed to the assigned destination(s) as described in the chapter Routing transfer. After a successful routing transfer, the CAN Receive Host Buffer pending requests (CANRXR0.Ci_RH0R, Ci_RH1R, CANRXR1.Ci_RH0R, Ci_RH1R) are cleared by hardware.

Related information

Routing transfer on page 3765

Routing requests from CAN output buffers

CAN Output Buffers store CAN frames to be transmitted to CAN nodes. Pending CAN frames in the CAN Output Buffer are indicated by COBL_BPR0 or COBL_BPR1. Among pending CAN frames, the highest priority CAN frame which has all its destinations available is selected for routing transfer. The priority of the CAN frame is defined by the corresponding CAN ID. CAN frames with the lowest CAN ID value have the highest priority as defined by ISO 11898-1. When multiple buffers have CAN frames of equal priority with the same CAN ID, the CAN frame in the buffer with the lowest index is selected for routing transfer.

The Routing Control Unit determines the availability of a destination according to the following:

- A CAN node as a destination is said to be available when the corresponding Transmit Host Buffer request bit (CANTXR.Ci_THR) is set. The DRE always writes only into the Transmit Host Buffer 0 (CAD_CANi_CRESA.ADR +$E0_H$)

  ***Note**:* *In the MCMCAN module, the CRE Tx Host Buffer 0 has to be configured to trigger the DRE by setting Ni_CRE_HBUF_TX0_CONFIG.INTEN to 0_B*

- An Ethernet frame as a destination is said to be available when the CAN Input Buffer List has free buffers (CIBL_STATUS.BF = 0)
- A memory destination is said to be available when enabled in DMEMi_CONFIG.EN = 1

After successful routing transfer, the pending request of the CAN Output Buffer (COBL_BPR0.PRj, COBL_BPR1.PRj) is cleared by hardware.

Related information

CAN output buffer pending request 0 on page 3816
CAN output buffer list on page 3728

Priority between requests from CAN nodes and CAN output buffers

When CAN Receive Host Buffers and CAN Output Buffers have pending requests at the same time, the routing requests are serviced alternately between them, giving them equal priority. The following figure shows an example with 4 CAN nodes (C0 to C3) with 2 pending receive requests and 4 CAN Output Buffers with 3 pending requests.

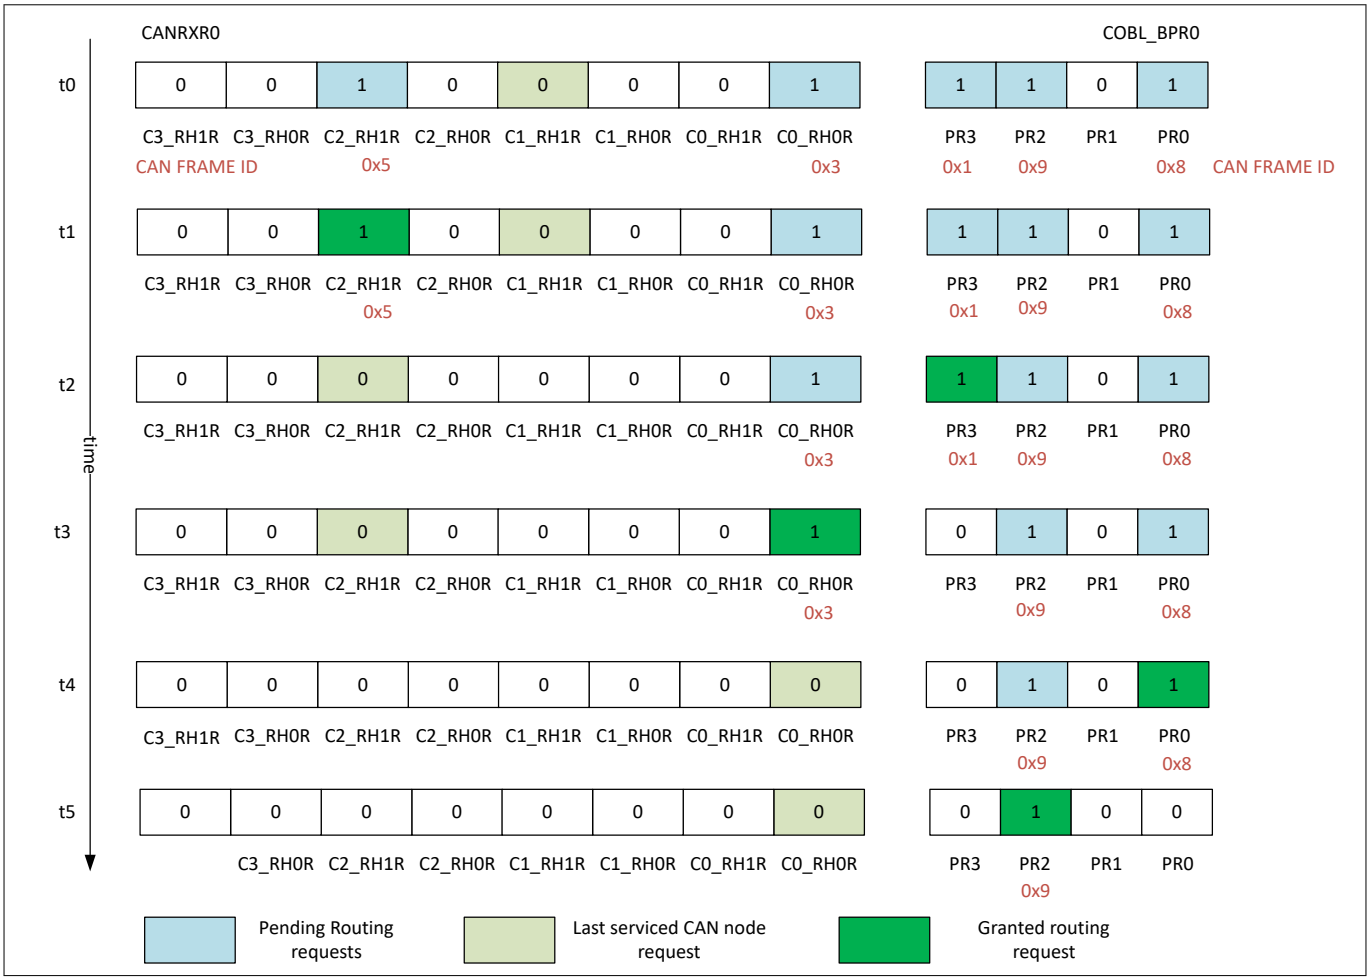

Figure 355 An example of priority handling between CAN receive requests and CAN output buffer requests

In the previous figure, it can be assumed that before time 't0', the pending request PR1 in the CAN Output Buffer List is serviced, then at 't1', the CAN Receive Host Buffer pending requests are granted an opportunity to perform routing transfer. Since the last serviced CANRXR0 is C1_RH1R, the next pending request in the round-robin scan is C2_RH1R. Therefore, the C2_RH1R routing request is serviced at 't1'. After successful routing operation, the CAN Output Buffer List pending requests are handled. At time 't2', the PR3 request is granted since the corresponding CAN frame has the highest priority CAN ID (ID=0x1) among the pending requests in the CAN Output Buffer List (PR0 & PR2). Similarly, at 't3' and 't4' CAN receive requests and CAN Output Buffer

pending requests are serviced alternately. At 't5', since there are no more pending CAN receive requests, the CAN Output Buffer List pending request PR2 is chosen again for routing transfer.

In case of any error (such as bus error, IRDE or DBOE), where the ongoing transaction has to be canceled by the DRE, the DRE writes into the CRE_ABORT_SEQ at the CAD_CANi_CRESA.ADR + 18_H address. The abort sequence is triggered by the DRE only after it starts reading the CAN payload and before the last read or write operation is launched.

Related information

Routing requests from CAN nodes on page 3761

Routing requests from CAN output buffers on page 3763

20.6.3.2.3 Routing transfer

The routing transfer function moves CAN frames from a source to their corresponding destination(s).

CAN routing header

The destination of a CAN frame is indicated by the routing header of the corresponding CAN frame. When a routing transfer request for a pending CAN frame is received, the routing header is read by the Routing Control Unit to identify the destination of the CAN frame.

The following CAN routing header types are supported:

- Uni-cast routing: In the case of CAN to CAN routing, CAN to Ethernet routing and vice versa
- Multi-cast routing: In the case of Ethernet to CAN routing (by the DRE). The multi-cast routing of CAN frames is performed as a sequence of uni-cast routing operations by the CRE
- PDU routing: In the case of CAN to memory routing

Uni-cast routing

In uni-cast routing, the CAN frame is routed to only a single destination. It is indicated in the routing header with MODE = 00_B.

Multi-cast routing

In multi-cast routing, the CAN frame is routed to up to 4 destinations. It is indicated in the routing header with MODE = 01_B.

Multi-cast routing is supported by the DRE for Ethernet to CAN routing. Multi-cast routing for CAN frames is handled by the CRE.

The multi-cast rule must follow the below configuration rules:

- Unused DIDs are set to zero
- At least DID0 and DID1 should have valid destination IDs (1_H to 14_H)
  - Invalid configuration: DID0 or/and DID1 are set to zero
- All valid DIDs are different. If the DIDs are the same, the CAN frame is routed only once
- No gaps are allowed between valid DIDs. For example:
  - Valid configuration: DID0, DID1 and DID2 are valid
  - Invalid configuration: DID0, DID1 and DID3 are valid. DID2 is set to zero

The routing transfer is performed in order from destination 1 to destination 4. The CAN frame is routed only when all relevant destinations are available. Destinations with DID=0 are ignored. The IRDE bit-field is set when there are no valid DIDs for a CAN frame and the routing operation is aborted. The DRE writes into the

CRE_ABORT_SEQ at the CAD_CANi_CRESA.ADR + 18_H address. The abort sequence is triggered by the DRE only after it starts reading the CAN frame and before the last read or write operation is launched. The DRE cancels the ongoing read sequence by writing 1_B to CRE_ABORT_SEQ.CRHBUF0 or CRHBUF1 if it has already started reading the CAN frame (R0, R1, DBm) after the error has occurred. The DRE cancels the ongoing write sequence to Tx Host Buffer 0 by writing 1_B to CRE_ABORT_SEQ.CTHBUF0 if it has already started writing the CAN frame (T0, T1, DBm) after the error has occurred.

In multi-cast routing, the Ethernet ACF-to-CAN Disassembler computes a 16-bit CRC over the R0, R1 (except ESI, ANMF, RXTS, FIDX and BRS which are considered as zero) and the safety critical CAN payload (without DID). This intermediate CRC is stored in the COBUF. While writing the frame from the COBUF to the Tx Host Buffer 0, at the moment of writing the CRC, the CRC is re-computed by the DRE including the DID0. The same is done for all 4 DIDs (DID0 to DID3) before the corresponding write operations.

PDU routing

In PDU routing, the CAN I-PDU is routed to a single destination. It is indicated in the uni-cast routing header with MODE = 10_B. The CAN I-PDU is routed to the system memory location indicated by the DID bit in the routing header.

Routing destinations

This section describes the possible routing destinations for a CAN frame.

A CAN frame can have the following routing destinations:

- CAN node
- ACF Ethernet frame
- User-configured memory location

Each destination is allocated with a 6-bit unique ID. The table below shows the IDs relevant for each destination type and the respective routing transfer destinations.

Table 943 Routing destinations ID

Destination	ID (6 bits)	Transfer destination
Destination disabled	0_H	-
MCMCAN0_Ni (i=0:3)	1_H to 4_H	CAN Transmit Host Buffer 0 (MCMCAN0_Ni_THBUF0)
MCMCAN1_Ni (i=0:3)	5_H to 8_H	CAN Transmit Host Buffer 0 (MCMCAN1_Ni_THBUF0)
MCMCAN2_Ni (i=0:3)	9_H to C_H	CAN Transmit Host Buffer 0 (MCMCAN2_Ni_THBUF0)
MCMCAN3_Ni (i=0:3)	D_H to 10_H	CAN Transmit Host Buffer 0 (MCMCAN3_Ni_THBUF0)
MCMCAN4_Ni (i=0:3)	11_H to 14_H	CAN Transmit Host Buffer 0 (MCMCAN4_Ni_THBUF0)
ACF Ethernet frames	18_H to $1D_H$	DRE CAN Input Buffer List
System memory locations (1 to 28)	20_H to $3B_H$	User-configured by DMEM (0-27)
Reserved for future extension	Others	-

When the DID in the routing header from the CRE does not belong to any valid destination, the IRDE bit is set by the DRE and an interrupt is triggered.

CAN node as destination (ID = 1_H to 14_H)

When the destination of the CAN frame is a CAN node (Destination ID = 1_H to 14_H), then the CAN frame is transferred to the CAN Transmit Host Buffer 0 of the destination CAN node that is configured for the DRE.

The following requests can have a CAN node as destination:

- Requests from a source CAN node
- Requests from the CAN Output Buffer List

Requests from a source CAN node

The following occurs if the source request is from a CAN node (CANRXR0, CANRXR1):

1. The pending request of the Transmit Host Buffer 0 (CANTXR) of the destination CAN node is checked
2. If a pending request for the destination CAN node is set (CANTXR), the CAN frame starting from RHBUFk_R0 until the data bytes defined by DLC is read from the source and written to the destination CAN frame Transmit Host Buffer 0 (the length of data bytes to be written is defined by DLC). The source CAN node request (CANRXR0, CANRXR1) is cleared when the DRE starts reading the RHBUFk_R0
3. After a successful transfer to the destination CAN Transmit Host Buffer 0, the destination Transmit Host Buffer 0 request (CANTXR.Ci_THR) is cleared
4. If the destination CAN node has its Transmit Host Buffer 0 pending request cleared, and if a CAN Output Buffer is free (COBL_STATUS.BF = 0), then the CAN frame along with the routing header is transferred to the CAN Output Buffer and the corresponding COBL_BPR1 and COBL_BPR0 pending request is set. In this case, the source request (CANRXR0, CANRXR1) is cleared after the CAN frame is written successfully to the CAN Output Buffer. Otherwise, the source CAN frame is aborted from the routing transfer, without clearing the source request
5. During a routing transfer, if the length of the source CAN frame is bigger than the destination buffer (Transmit Host Buffer 0 size or CAN Output Buffer size), the source CAN frame is dropped with the Destination Buffer Overflow Error flag set (ME_ERR.DBOE). In this case, the corresponding source request is cleared

Requests from the CAN output buffer list

The following occurs if the source request is from the CAN Output Buffer List (COBL_BPR1 and COBL_BPR0):

1. The pending request of the Transmit Host Buffer 0 (CANTXR) of the destination CAN node is checked
2. If a pending request for a destination CAN node is set (CANTXR), the CAN frame starting from COBUFj_R0 until the data bytes defined by COBUFj_R1.DLC are read from the source and written to the destination CAN node Transmit Host Buffer 0
3. After a successful transfer to the destination CAN Transmit Host Buffer 0, the source request (CAN Output Buffer request) and the destination Transmit Host Buffer 0 request (CANTXR.Ci_THR) are cleared
4. If the destination CAN node has the Transmit Host Buffer 0 pending request cleared, the source CAN frame is aborted from routing transfer without clearing the source request

ACF Ethernet frame as destination (ID = 18_H to $1D_H$)

When the destination of the CAN frame is an ACF Ethernet frame (Destination ID = 18_H to $1D_H$), then the CAN frame is transferred to an available CAN Input Buffer indexed by CIBL_STATUS.PIDX. The CAN frame starting from the RHBUFk_CRC, RHBUFk_R0 until the data bytes defined by RHBUFk_R1.DLC is read from the source and written to the CAN Input Buffer. After a successful transfer, the source request (CANRXR0 and CANRXR1) is cleared and the pending request in the corresponding CAN Input Buffer (CIBL_BPR) is set.

If the CAN Input Buffer List is full (CIBL_STATUS.BF=1), then the source CAN frame is aborted from routing transfer without clearing the source request.

System memory as destination (ID = 20_H to $3B_H$)

When the destination of the CAN message is a system memory location (Destination ID = 20_H to $3B_H$) and the corresponding destination memory (DMEMi) is enabled (DMEMi_CONFIG.EN1=1_B), then the CAN message is transferred to the system memory location with the starting address (DMEMi_SA.ADR) configured by the user in the DMEM parameter table. The index i of DMEMi is derived from the destination ID (i = destination ID - 20_H).

The user should configure the following levels for each DMEM in the DMEM parameter table:

- Watermark (DMEMi_WM) if required
- Wraparound (DMEMi_WA)

The user should also configure the CAN message type being received by a DMEM (DMEMi_CONFIG.CTYP). The following CAN message types are supported:

- CAN frames (DMEMi_CONFIG.CTYP = 0_B)
- CAN I-PDUs (DMEMi_CONFIG.CTYP = 1_B)

Related information

DMEM parameter table on page 3741

CAN message buffer layout

The user can create a circular list of CAN Message Buffers to store CAN messages in the DMEM. The following figure shows the CAN Message Buffer layout for CAN frames (DMEMi_CONFIG.CTYP = 0) within the DMEMi.

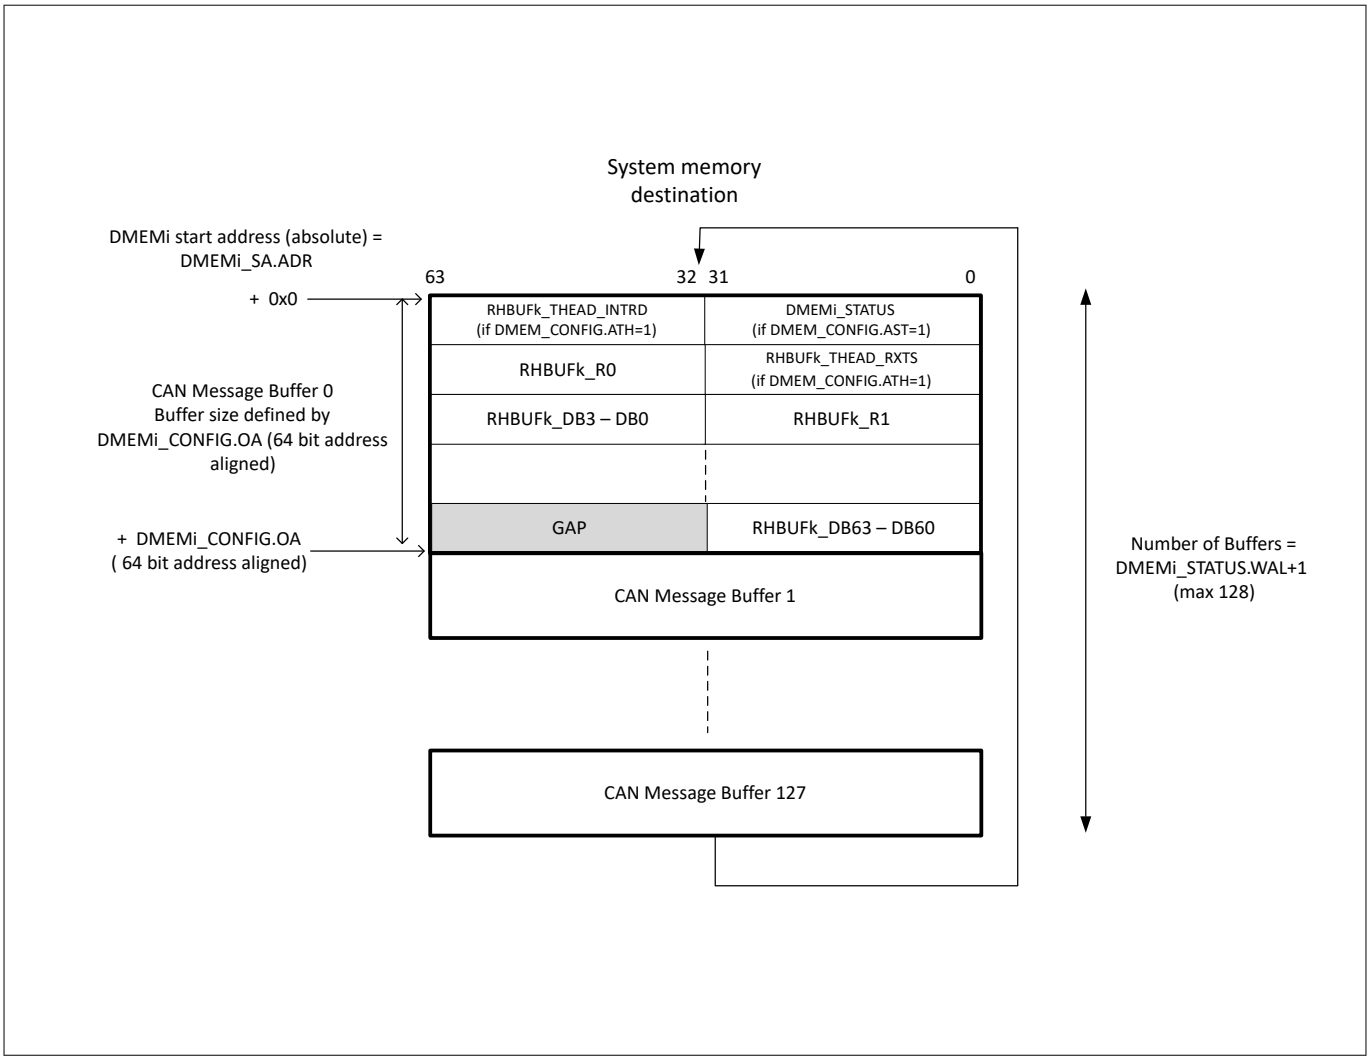

Figure 356 CAN Message Buffer layout for CAN frames

The CAN Message Buffer layout must have the following characteristics:

- The size of the CAN Message Buffers is defined by DMEMi_CONFIG.OA
- The total number of CAN Message Buffers in the circular list is defined by the configured Wraparound level (DMEMi_WA.WAL+1)
- The CAN Message Buffer Index at which the next CAN message is to be stored is shown in DMEMi_STATUS.BC
- The start address of each CAN Message Buffer can be identified as DMEMi_SA.ADR + (DMEMi_STATUS.BC * DMEMi_CONFIG.OA)

***Note**: The Watermark level (DMEMi_WM) must always be smaller than the Wraparound level.*

CAN message buffer layout mode

The user can configure DMEMi_MODE.BUF to set the layout mode of the CAN Message Buffer. The following layout modes are supported:

- Single (DMEMi_MODE.BUF = 0_B)
- Continuous (DMEMi_MODE.BUF = 1_B)

These layout modes apply for DMEMs configured for both CAN message types, CAN frames (DMEMi_CONFIG.CTYP = 0_B) and CAN I-PDUs (DMEMi_CONFIG.CTYP = 1_B).

Single mode

In Single mode (SINGLE, DMEMi_MODE.BUF = 0_B), the CAN Message Buffer is split into the following two buffers:

- Frame Data Buffer 1 (based on the Watermark level DMEMi_WM)
- Frame Data Buffer 2 (based on the Wraparound level DMEMi_WA)

Both Frame Data Buffers always start at the 64-bit aligned address. The DRE triggers a Watermark and a Wraparound interrupt when the set DMEMi_WM and DMEMi_WA levels are reached.

Single mode supports the following trigger modes:

- Index-based trigger (INDEX, DMEMi_MODE.TRIG = 0_B): This mode is valid only for CAN I-PDUs. For CAN frames this bit is ignored and the Count-based trigger mode is used. In the Index-based trigger mode, the Watermark and Wraparound interrupts are triggered based on the DMEMi_FDBI value. The DMEMi_WM and DMEMi_WA levels are configured as words in this case
- Count-based trigger (COUNT, DMEMi_MODE.TRIG = 1_B): In this mode, the Watermark and Wraparound interrupts are triggered based on the DMEMi_STATUS.BC value. The DMEMi_WM and DMEMi_WA levels are configured as number of CAN frames or CAN I-PDUs. The size of Frame Data Buffer 1 and Frame Data Buffer 2 are allocated based on DMEMi_WM, DMEMi_WA and DMEMi_CONFIG.OA

Continuous mode

In Continuous mode (CONT, DMEMi_MODE.BUF = 1_B), the CAN Message Buffer is considered as a whole buffer and the CAN messages are assembled continuously until the Wraparound level (DMEMi_WA) is reached.

Continuous mode supports the following trigger modes:

- Index-based trigger (INDEX, DMEMi_MODE.TRIG = 0_B): This mode is valid only for CAN I-PDUs. For CAN frames this bit is ignored and the Count-based trigger mode is used. In the Index-based trigger mode, the Wraparound interrupt is triggered based on the DMEMi_FDBI value. The DMEMi_WA level is configured as words in this case
- Count-based trigger (COUNT, DMEMi_MODE.TRIG = 1_B): In this mode, the Wraparound interrupt is triggered based on the DMEMi_STATUS.BC value. The DMEMi_WA level is configured as number of CAN frames or CAN I-PDUs. The size of Frame Data Buffer 1 is allocated based on DMEMi_WA and DMEMi_CONFIG.OA

CAN message buffer packing

DMEMi_MODE.TYP enables the user to configure the CAN Message Buffer packing type. The following packing types can be configured:

- Multiplexing disabled (MUXDIS, DMEMi_MODE.TYP = 0_B): The CAN messages (CAN frames or CAN I-PDUs) are packed in the same way as shown in the figure CAN Message Buffer layout for CAN frames (see above). The size of the CAN Message Buffer is defined by DMEMi_CONFIG.OA. In this case, there will be padding bits between the CAN messages as each CAN message starts at a 32-bit aligned address and no FDBI is present to indicate the exact length
- Multiplexing enabled (MUXEN, DMEMi_MODE.TYP = 1_B): This mode is valid only for CAN I-PDUs. The CAN I-PDUs are packed without any padding bits in between them. This mode can be used when the CAN I-PDUs are to be multiplexed into a frame, for example, an Ethernet frame. The size of the assembled frame is defined by DMEMi_FDBI which is incremented by the size of the CAN I-PDU after each CAN I-PDU is transferred to the DMEM

Related information

CAN message buffer layout on page 3768

Destination memory transfer mode configurations

The following table shows a summary with the possible applicable DMEMi transfer mode configurations (DMEMi_MODE) depending on the CAN message type being received by the DMEMi (DMEMi_CONFIG.CTYP).

Table 944 Applicable DMEMi transfer mode configurations

DMEMi_MODE			DMEMi_CONFIG.CTYP		Description
TYP	TRIG	BUF	CAN frame[1)]	CAN I-PDU[1)]	
MUXDIS	COUNT	CONT	✔	✔	• Space between CAN frames/CAN I-PDUs depending on the DLC • Interrupt trigger based on the number of CAN frames/CAN I-PDUs • CAN frames/CAN I-PDUs are assembled continuously with no DMEMi division
MUXDIS	COUNT	SINGLE	✔	✔	• Space between CAN frames/CAN I-PDUs depending on the DLC • Interrupt trigger based on the number of CAN frames/CAN I-PDUs • DMEMi divided into FDB1 and FDB2. CAN frames/CAN I-PDUs are assembled first in FDB1 followed by FDB2
MUXDIS	INDEX	CONT	✔	✔	• Space between CAN frames/CAN I-PDUs depending on the DLC • Interrupt trigger based on the index (FDBI) • CAN frames/CAN I-PDUs are assembled continuously with no DMEMi division
MUXDIS	INDEX	SINGLE	✔	✔	• Space between CAN frames/CAN I-PDUs depending on the DLC • Interrupt trigger based on the index (FDBI) • DMEMi divided into FDB1 and FDB2. CAN frames/CAN I-PDUs are assembled first in FDB1 followed by FDB2
MUXEN	COUNT	CONT	✘	✔	• No space between CAN I-PDUs • Interrupt trigger based on the number of CAN I-PDUs • CAN I-PDUs are assembled continuously with no DMEMi division
MUXEN	COUNT	SINGLE	✘	✔	• No space between CAN I-PDUs • Interrupt trigger based on the number of CAN I-PDUs • DMEMi divided into FDB1 and FDB2. CAN I-PDUs are assembled first in FDB1 followed by FDB2

(table continues...)

Table 944 (continued) Applicable DMEMi transfer mode configurations

DMEMi_MODE			DMEMi_CONFIG.CTYP		Description
TYP	TRIG	BUF	CAN frame[1)]	CAN I-PDU[1)]	
MUXEN	INDEX	CONT	✘	✔	• No padding bytes between CAN I-PDUs • Interrupt trigger based on the index (FDBI) • CAN I-PDUs are assembled continuously with no DMEMi division
MUXEN	INDEX	SINGLE	✘	✔	• No space between CAN I-PDUs • The interrupt trigger is based on the index (FDBI) • DMEMi divided into FDB1 and FDB2. CAN I-PDUs are assembled first in FDB1 followed by FDB2

1) ✔ = applicable, ✘ = not applicable

CAN frames to system memory

For every CAN frame routing where DMEMi_CONFIG.CTYP is set to 0_B (CAN frame) by the user, the following tasks are performed:

1. If DMEMi_CONFIG.ATH = 1, the CAN frame Timing headers (RHBUFk_THEAD_INTRD and RHBUFk_THEAD_RXTS) are copied as the first two words of the current CAN Message Buffer
2. If both DMEMi_CONFIG.AST=1 and DMEMi_CONFIG.ATH = 1 are set, DMEMi_STATUS and the Timing headers are copied
3. The CAN frame is then transferred to destination memory starting from RHBUFk_R0 until the end of the CAN data bytes defined by RHBUFk_R1.DLC and aligned to 32-bit words
4. The following occurs after a successful transfer:
   a. If DMEMi_WM.WML = DMEMi_STATUS.BC (except when WML=0), the Watermark flag is set (DMEMi_STATUS.WMF = 1) and an interrupt is triggered
   b. If DMEMi_WA = DMEMi_STATUS.BC, the Wraparound flag is set (DMEMi_STATUS.WAF = 1) and an interrupt is triggered. After the wraparound event, the next CAN frame is stored again at the start address DMEMi_SA.ADR, making the destination a circular list
   c. The buffer counter (DMEMi_STATUS.BC) is increased by 1. When a Wraparound event occurs, the buffer counter is reset to 0. The BC value is still zero within the DMEMi after the first message is transferred. The register DMEMi_STATUS indicates the correct count value
   d. The message counter (DMEMi_STATUS.MC) is increased by 1. After overflow of the counter, the counter is reset to 0
5. DMEMi_STATUS.SID is updated with the source ID of the CAN frame and the New Message bit (DMEMi_STATUS.NM) is set to 1
6. If only DMEMi_CONFIG.AST = 1 is set, DMEMi_STATUS is copied as the first word of the current virtual CAN buffer after the frame is copied

Consider the following when transferring CAN frames to the system memory:

- The message counter (DMEMi_STATUS.MC) resets to 0 either after a counter overflow or after a software write with a non-zero value
- If the CAN frame (including Status and Timing headers, if enabled) does not fit the destination buffer size defined by DMEMi_CONFIG.OA, the Destination Buffer Overflow Error flag (ME_ERR.DBOE) is set and the source CAN request is cleared. The ongoing transaction has to be canceled by the DRE by writing into the CRE_ABORT_SEQ at the CAD_CANi_CRESA.ADR + 18_H address.

- If a CAN I-PDU is received instead of a CAN frame where DMEMi_CONFIG.CTYP is set to 0_B, the CAN I-PDU is discarded, the Invalid Routing Destination Error flag (ME_ERR.IRDE) is set and the source CAN request is cleared. The ongoing transaction has to be canceled by the DRE by writing into the CRE_ABORT_SEQ at the CAD_CANi_CRESA.ADR + 18_H address. The abort sequence is triggered by the DRE only after it starts reading the CAN frame and before the last read or write operation is launched. The DRE cancels the ongoing read sequence by writing 1_B to CRE_ABORT_SEQ.CRHBUF0 or CRHBUF1 if it has already started reading the CAN frame (R0, R1, DBm) after the error has occurred.
- The DRE locks the buffer by setting DMEMi_CONFIG.EN1 or EN2 to 0_B after a Wraparound or Watermark event. It is up to the software to unlock the buffer again by setting the DMEMi_CONFIG.EN1 or EN2 to 1_B

CAN I-PDUs to system memory with multiplexing enabled

If DMEMi_MODE.TYP is set to 1_B (MUXEN), the CAN I-PDUs in the data buffers are assembled with no padding between them. The SRI transactions are broken down based on the payload length which is part of the PDU header in order to avoid padding, as shown in the alignment of CAN message 1 - 3 in the figure below.

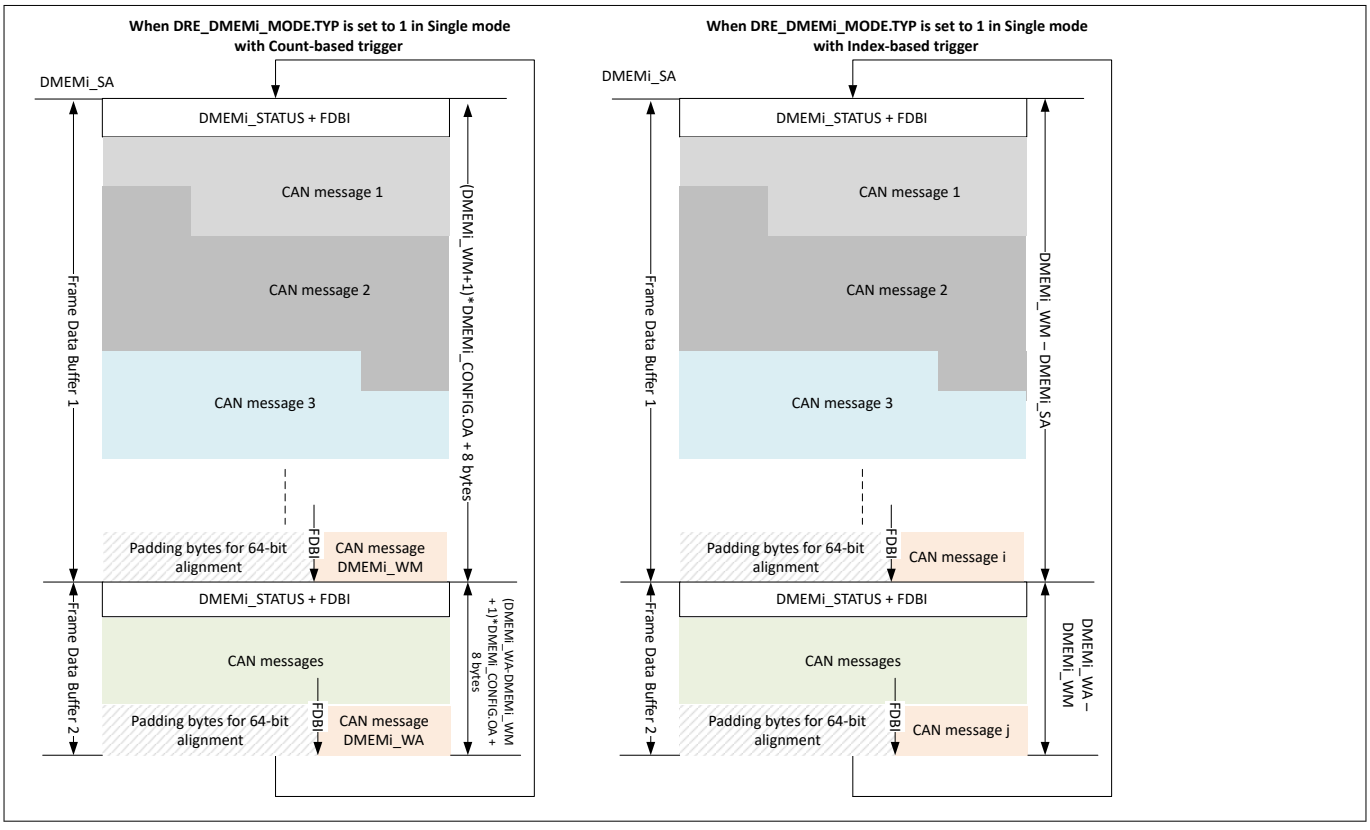

Figure 357 Trigger modes comparison

The DMEMi_FDBI denotes where the next CAN I-PDU is to be stored in the Frame Data Buffer.

When the first CAN I-PDU is received, it is copied at the index DMEMi_SA as long as the WML is large enough to accommodate a whole CAN I-PDU including the status and header information. The FDBI is then updated as follows:

$$FDBI(bytes) = 4\,bytes\,DMEMi_STATUS\,(optional) + 4\,bytes\,DMEMi_FDBI + 8\,bytes\,THEAD\,(optional) + Short\ \ or\ \ Long\,PDU\ \ header\,(4\,or\,8\,bytes) + Data\ \ (bytes)$$

The second CAN I-PDU is then copied starting from the index FDBI as shown in the figure below.

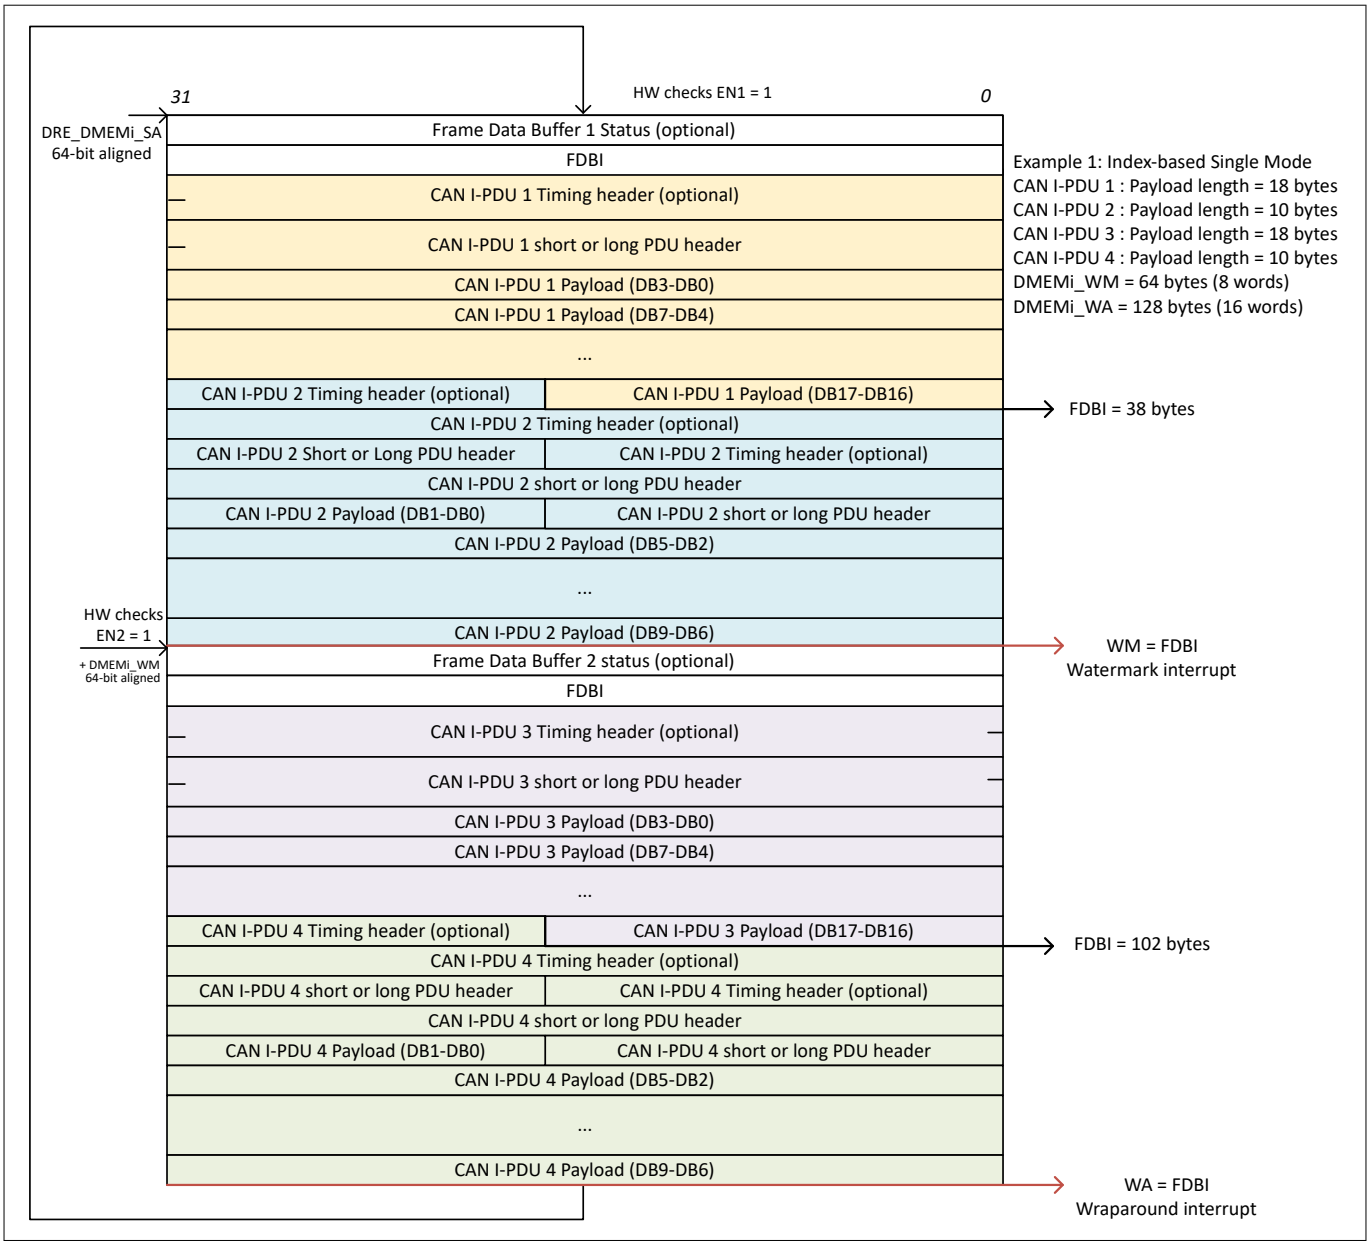

Figure 358 Example 1: Index-based trigger in Single mode

The following occurs if the new CAN I-PDU (including Timing header, if enabled) does not fit to the destination buffer size or if the buffer becomes unavailable:

- If DMEMi_MODE.FOM is set to 0_B, the CAN I-PDU is stored in the next available Frame Data Buffer 1, or Frame Data Buffer 2 when the corresponding EN bit is set to 1_B. When the EN bit is set to 0_B, this means that the Frame Data Buffer is disabled or that the software has not read the data yet. The CAN I-PDU is discarded, the Destination Buffer Overflow Error flag (ME_ERR.DBOE) is set and the source CAN request is cleared
- If DMEMi_MODE.FOM is set to 1_B, the CAN I-PDU is discarded, the Destination Buffer Overflow Error flag (ME_ERR.DBOE) is set and the source CAN request is cleared

  The ongoing transaction has to be canceled by the DRE in the case of error by writing into CRE_ABORT_SEQ at the CAD_CANi_CRESA.ADR + 18_H address. The abort sequence is triggered by the DRE only after it starts reading the CAN frame and before the last read or write operation is launched. The DRE cancels the ongoing read sequence by writing 1_B to CRE_ABORT_SEQ.CRHBUF0 or CRHBUF1 if it has already started reading the CAN frame (R0, R1, DBm) after the error has occurred

For each CAN request, the DRE reads the Routing header RHBUFk_UCRH from the Rx Host Buffer to determine the destination DMEMi and performs the following tasks:

1. Checks if the bit DMEMi_CONFIG.EN1 is 1_B
2. If DMEMi_CONFIG.ATH = 1 is set, then the Timing header (THEAD of two 32-bit words in size) of the CAN I-PDU is copied after DMEMi_FDBI
3. The CAN I-PDU is transferred to the destination memory starting from the PDU header (always two 32-bit words in size) until end of CAN data bytes defined by DLC in the PDU header
4. DMEMi_FDBI is updated with the index where the next CAN I-PDU is to be stored. DMEMi_STATUS.BC is incremented by 1. The BC value is still zero within the DMEMi after the first message is transferred. The register DMEMi_STATUS indicates the correct count value
5. The next CAN I-PDU is fetched. The following occurs depending on the configured layout mode:
   a. **Single mode**: Steps 4 to 6 are repeated until the Watermark level is reached. The DRE proceeds with Step 9 for the Frame Data Buffer 1. The DRE repeats Steps 1 to 6 (if DMEMi_CONFIG.EN2 is 1_B) until the Wraparound level is reached for the Frame Data Buffer 2. See the previous figure Example 1: Index-based trigger in Single mode
   b. **Continuous mode**: Steps 5 to 7 are repeated until the Wraparound level is reached, as shown in the figure below:

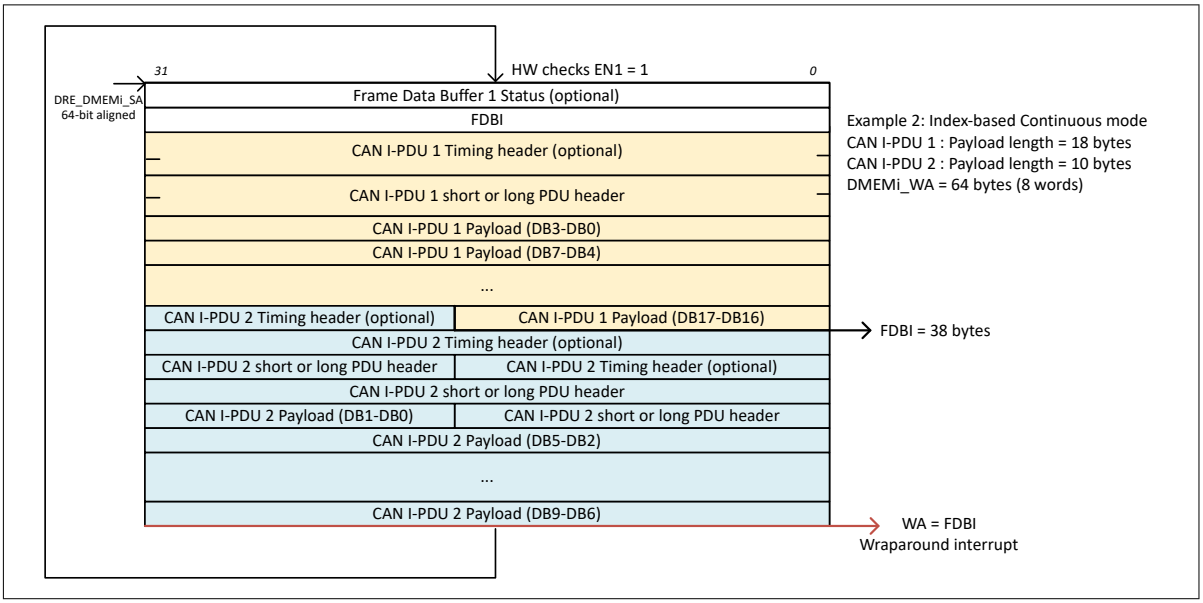

Figure 359 Example 2: Index-based trigger in Continuous mode

6. The DRE then locks the buffer by setting DMEMi_CONFIG.EN1 or EN2 to 0_B. DMEMi_STATUS.WMF or DMEMi_STATUS.WAF is set and interrupt is triggered. The message counter (DMEMi_STATUS .MC) is increased by 1 to indicate a message transfer to the DMEM. Upon overflow of the counter, the counter is reset to 0
7. If DMEMi_CONFIG.AST = 1, then DMEMi_STATUS is copied as the first word of the destination memory just before the Watermark or Wraparound interrupt is triggered
8. DMEMi_FDBI is copied as the 2nd word (or first word) just before the Watermark or Wraparound interrupt is triggered
9. The software initiates the frame processing in the DMEMi until the configured Watermark or Wraparound level is reached. FDBI indicates the exact length of the frame in the buffer. It is up to the software to unlock the buffer again by setting the DMEMi_CONFIG.EN1 or EN2 to 1_B

***Note**: The start addresses of Frame Data Buffer 1 and Frame Data Buffer 2 are always 64-bit aligned. If the configured DMEMi_WM is not 64-bit aligned, there are padding bits added to the end of Frame Data Buffer 1. Even in Count-based trigger mode, when FDBI is not 64-bit aligned at the watermark, there are padding bits added to the end of Frame Data Buffer 1. Nevertheless, the exact length of the frame is indicated by the FDBI*

Handling buffer overflow and unavailability for CAN I-PDUs

In Continuous mode (DMEMi_MODE.BUF = 1_B), the CAN I-PDU is discarded when DMEMi_CONFIG.EN1 is not set, the CAN request is cleared and the DBOE interrupt is triggered. In Single mode (DMEMi_MODE.BUF = 0_B), the DRE handles CAN I-PDUs depending on the buffer availability DMEMi_CONFIG.EN1 and DMEMi_CONFIG.EN2, and the set buffer overflow mode (DMEMi_MODE).

The following table shows how the DRE handles CAN requests in Single mode when the EN bits are not set or when a buffer overflow scenario occurs where the size of the incoming CAN I-PDU exceeds the configured Watermark (DMEMi_WM) or Wraparound (DMEMi_WA) level.

Table 945 Buffer overflow or buffer unavailability (Single mode)

Scenario	Condition	EN1	EN2	FOM	Result
Buffer available	PDU for Frame Data Buffer 1	1	-	-	Copy PDU to Frame Data Buffer 1
	PDU for Frame Data Buffer 2	-	1	-	Copy PDU to Frame Data Buffer 2
Buffer unavailable	PDU for Frame Data Buffer 1 or 2	0	0	1	PDU is discarded, CAN request cleared and DBOE interrupt triggered
	PDU for Frame Data Buffer 1	0 (buffer full)	1	0	Copy PDU to Frame Data Buffer 2
	PDU for Frame Data Buffer 2	1	0 (buffer full)	0	Copy PDU to Frame Data Buffer 1
Buffer overflow	Size of PDU for Frame Data Buffer 1 exceeds DMEMi_WM	1	1	0	Copy PDU to Frame Data Buffer 2 and trigger Watermark interrupt
		1	0	0	PDU is discarded, CAN request cleared and DBOE interrupt triggered
		1	-	1	
	Size of PDU for Frame Data Buffer 2 exceeds DMEMi_WA	1	1	0	Copy PDU to Frame Data Buffer 1 and trigger Wraparound interrupt
		0	1	0	PDU is discarded, CAN request cleared and DBOE interrupt triggered
		-	1	1	

***Note**: The DMEMi_STATUS that is copied to the DMEMi (if DMEMi_CONFIG.AST = 1) is only updated in the buffer that receives a message. In case the FOM bit is set in order to copy the message to the spare Frame data buffer, the DMEMi_STATUS is not updated for the buffer which is full but is updated for the Frame data buffer to which the CAN message is copied to. In case of buffer overflow, the software shall read the error information from the DMEMi_STATUS register and not from the DMEMi*

Summary of allowed scenarios during CAN message transfer to system memory

Scenarios that lead to a message being stored in the configured DMEM. The following table shows a summary of allowed scenarios for CAN frame or CAN I-PDU transfer to the system memory.

Table 946 Summary of allowed CAN node to memory cases

Configured mode in DMEMi_MODE (TYP_TRIG_BUF)[1]	Operating mode	Condition[2]	EN 1	EN 2	Result
-	-	CTYP matches	-	-	Message stored, WMF and WAF flags set accordingly, FDBI updated, EN1 cleared if WML reached
MUXEN_COUNT_SINGLE	MUXEN_COUNT_SINGLE	Message destined for FDB1	1	x	Message stored, WMF and WAF flags set accordingly, FDBI updated, EN1 cleared if WML reached
		Message destined for FDB2	x	1	Same handling as FDB1
MUXEN_COUNT_CONT MUXEN_COUNT_SINGLE with WM>=WA	MUXEN_COUNT_CONT	Message destined for DMEM	1	x	Message stored, WMF and WAF flags set accordingly, FDBI updated, EN1 cleared if WAL reached[3]
MUXEN_INDEX_SINGLE	MUXEN_INDEX_SINGLE	Message destined for FDB1	1	x	Message accepted in FDB1, WMF flag set if WML reached, FDBI set to end of messaged(+1) delivered in FDB1, EN1 cleared if at WML
		Message destined for FDB2	x	1	Same handling as FDB1
MUXEN_INDEX_CONT MUXEN_INDEX_SINGLE with WM>=WA	MUXEN_INDEX_CONT	Message destined for DMEM	1	x	Message stored and flags set accordingly, FDBI updated
MUXDIS_*	MUXDIS_COUNT_CONT	Message destined for DMEM	1	x	Message stored[4] , WMF and WAF flags set accordingly, EN1 cleared if wrap around reached, EN2 untouched

1) Configuration should be static
2) The requirement is that the WML/WAL set to at least one maximum frame size plus some bytes
3) WMF always set according to the programmed levels, independent of the mode, but no WM interrupt triggered
4) General rule is that a message coming to a buffer whose EN is 0 is dropped, BO is triggered, and status is unchanged

***Note**: Other scenarios not included in this table are illegal or cause the message to be dropped and trigger the corresponding interrupt or error.*

20.6.3.2.4 Move engine

The Move Engine performs the FPI and SRI transactions as required by the routing transfer operation. The Move Engine also has direct read and write access to the DRE internal RAM. The read/write operation is directed to the corresponding interface based on the address map.

The current status of the routing transfer operation and the bus access is shown in ME_STATE SFR. The read and write address of a ME transaction is shown in ME_SRCA and ME_DESTA. In case of an FPI or SRI transaction error, the corresponding error flags are set in ME_ERR. After an error, the first error status is shown in ME_ERR.FESID, FEDID, ME_FESRCA and ME_FEDESTA. In case of an error, the current routing transfer is aborted and the Move Engine continues to perform the next routing transfer request from the Routing Control Unit. The DRE writes into the CRE_ABORT_SEQ at the CAD_CANi_CRESA.ADR + 18_H address to indicate the CRE about the abort of the routing transfer.

Resource partition configuration

CAN nodes and system memory destinations can be assigned to one of the Resource Partitions (RP) using the registers CANi_RP, DMEMi_RP and DMAi_RP. These registers point to the RP configuration MODEr that defines the DRE Move Engine access condition to the on-chip buses when performing a routing transfer. The Move Engine inherits the RP configuration of CAN nodes during read/write access to CAN nodes. Similarly, it inherits the RP configuration of system memory destinations, during write access to the same.

While accessing the Ethernet DMA channels, the DRE inherits the RP configuration pointed to by the DMAi_RP register. DMA0_RP and DMA1_RP indicates the index of RP configuration of GETH0 and GETH1 respectively. DMA2_RP to DMA5_RP indicates the index of RP configuration of LETH0 to LETH3 respectively.

The RP has a master tag identifier driven onto the on-chip bus during the Move Engine access to the corresponding resource. The master tag identifier for a RP is derived from the DRE base master tag ID and corresponding MODEr.TAG_OFF bit-field.

Each RP may further be assigned to a virtual machine number and protection set (PRS). The virtual machine number and the PRS programmed in the RP MODEr SFR will be driven on the bus during read or write access to the corresponding resource.

MODEr.MODE determines if the DRE performs the corresponding bus accesses in supervisor mode or user mode.

20.7 Ethernet descriptor handler

The ETH Descriptor Handler prepares the normal Transmit and Receive ETH descriptors within the Message RAM to exchange ETH frames and descriptors that contain control or status information between the DRE and ETH MAC.

20.7.1 Feature list

- Offloads CPU by preparing the Rx and Tx descriptors
- A maximum of 24 Rx descriptors can be configured (4 per Ethernet Rx DMA channel) to receive an Ethernet frame in the EIBUF. One Rx descriptor is used to receive one Ethernet frame in EIBUF
- A total of 24 Tx descriptors can be configured (4 per Ethernet Tx DMA channel) and used to transmit or forward an Ethernet frame:
  - Transmit an IEEE 1722 ACF Ethernet frame from EOBUF or
  - Forward an Ethernet frame received in EIBUF
- Consists of a Forwarding Engine to forward Ethernet frames between Ethernet interfaces

20.7.2 Functional overview

The block diagram of the Ethernet Descriptor Handler is shown in the following figure. It contains three blocks:

- Tx Descriptor Handler
- Rx Descriptor Handler
- Forwarding Engine

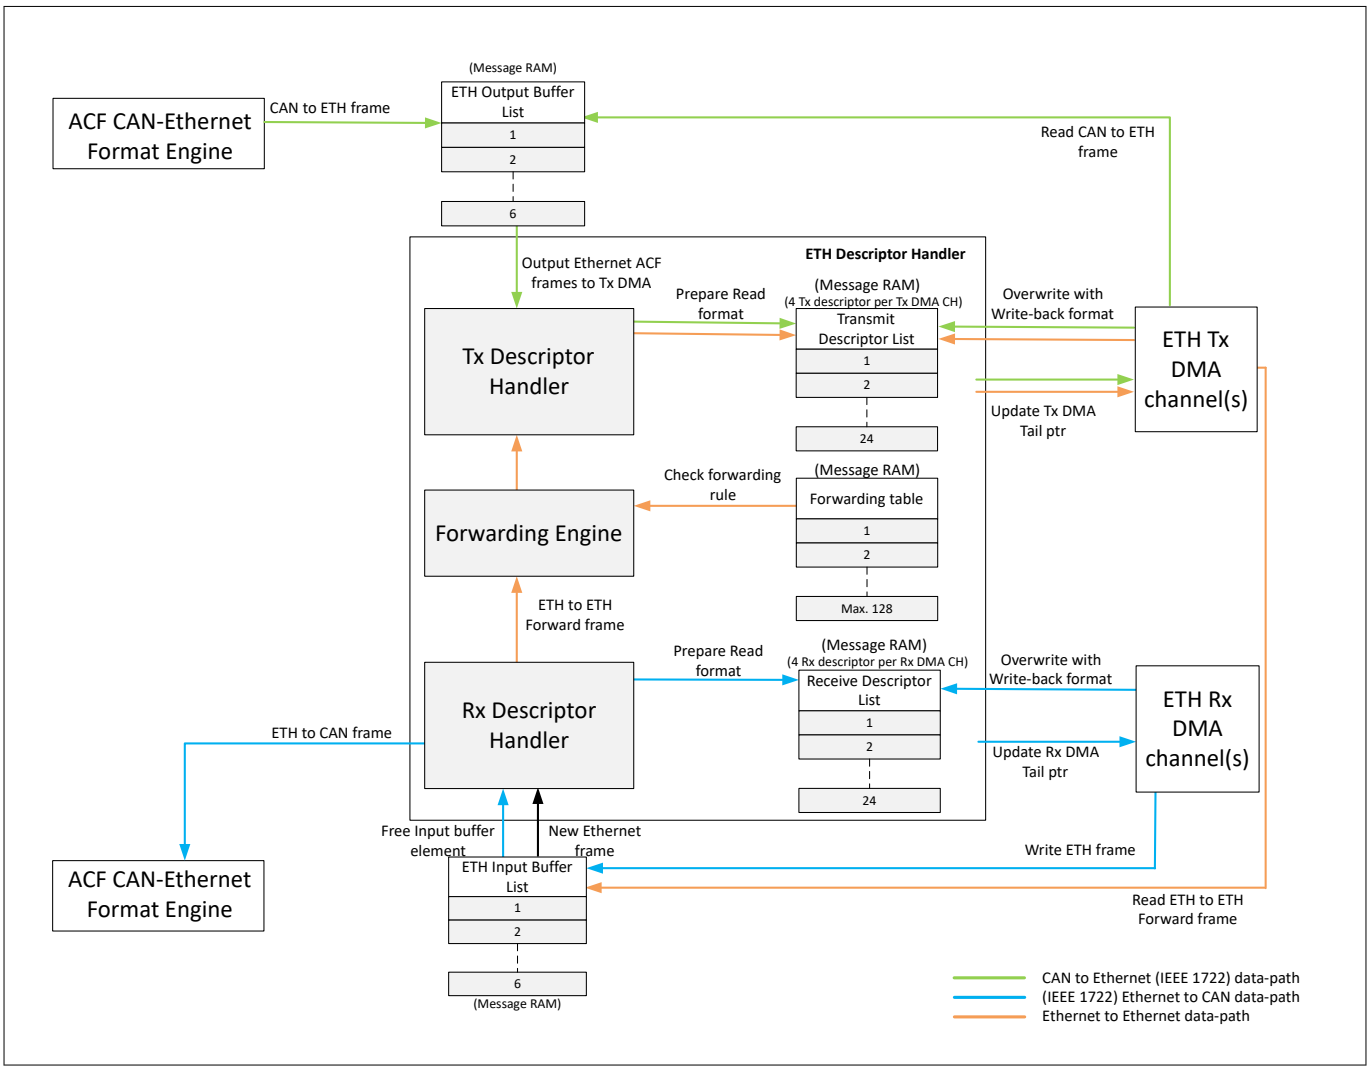

Figure 360 Ethernet descriptor handler block diagram

Tx Descriptor Handler

The Tx Descriptor Handler prepares the Tx descriptor(s) in Read format within the Message RAM for each Ethernet frame that is to be routed or forwarded to an Ethernet interface through an Ethernet Tx DMA channel.

- CAN to Ethernet frame: IEEE 1722 ACF Ethernet frame in EOBUF
- Ethernet to Ethernet frame: Ethernet forward frame in EIBUF

It also updates the DMA Tail Pointer registers of LETH (DMA_CHy_TxDesc_Tail_Pointer (y=0-7)) and GETH (DMA_CHj_TxDesc_Tail_LPointer (j=0-7)) Tx DMA channels. For the LETH Tx address register, see RAM LETH Tx DMA channel address. For the GETH Tx address register, see RAM GETH Tx DMA channel address . The DMA channel overwrites the descriptor with the Write-back format after reading the Ethernet frame from the buffer. The Tx Descriptor Handler also checks the status within the Write-back format of the Tx descriptor and triggers an interrupt in the event of any errors.

Rx Descriptor Handler

The Rx Descriptor Handler prepares the Rx descriptor(s) in Read format within the Message RAM whenever there is a free EIBUF element to receive an Ethernet frame from an Ethernet Rx DMA channel.

It also updates the DMA Tail Pointer registers of the LETH (DMA_CHy_RxDesc_Tail_Pointer (y=0-7)) and GETH (DMA_CHj_RxDesc_Tail_LPointer (j=0-7)) Rx DMA channels. For the LETH Rx address register, see RAM LETH Rx DMA channel address. For the GETH Rx address register, see RAM GETH Rx DMA channel address. The DMA channel overwrites the descriptor with the Write-back format after writing the Ethernet frame to the buffer. The Rx Descriptor Handler also checks the status within the Write-back format of the Rx descriptor and triggers an interrupt in the event of any errors.

The Rx Descriptor Handler also separates the Ethernet to CAN traffic and the Ethernet to Ethernet forward traffic.

Forwarding Engine

The Forwarding Engine generates the FTCFG.FID from the Write-back format of the Rx descriptor. It performs the Forward ID filtering to determine the forwarding destination of the Ethernet frame.

20.7.3 Functional description

In this section, the transmit, receive and forward functions of the Ethernet frames are described in detail.

20.7.3.1 Tx descriptor handler

The Tx Descriptor Handler transmits ACF Ethernet frames from the EOBUF and also forwards an Ethernet frame from the EIBUF to an Ethernet Tx DMA channel.

Whenever there is an Ethernet frame to be transmitted or forwarded, the corresponding EREQ.TXi_REQ or EREQ.FWDi_REQ request bit is set.

When TETHDLi_CTRL.TRIG is set to 1, it sets EOBUFj_STATUS.TXREQ and triggers an Ethernet output frame transmit request interrupt to the IR indicating that the software can read the Ethernet frame from the buffer. When TETHDLi_CTRL.TRIG is set to 0, the following happens:

1. The Tx Descriptor Handler prepares the 4 words of all Tx descriptors in Read format:
   a. For the ACF Ethernet frame in the EOBUF
   b. For the Ethernet frame in the EIBUF in the case of Ethernet frame forwarding
2. The Tx Descriptor Handler sets the following bits:
   a. TDESCi_RD3.FD bit is set to indicate to the DMA that this is the first Tx descriptor of the Ethernet frame
   b. TDESCi_RD3.LD bit is set to indicate to the DMA that this is the last Tx descriptor of the Ethernet frame

   The Tx Descriptor Handler prepares the remaining unused Tx descriptors as well with buffer pointers to EOBUF. If a forwarding request arrives, then the Tx descriptors are used for the frame in EIBUF by changing the buffer pointers. The OWN bit is not set for these descriptors as unused Tx descriptors are still owned by the DRE.
3. After preparing the Tx descriptor, the Tx Descriptor Handler sets the TDESCi_RD3.OWN bit in the descriptor, indicating that the DMA channel TETHDLi_CTRL.DMACH owns the descriptor. The OWN bit of the second Tx descriptor is set for the second frame, the OWN bit of the third descriptor is set for the third frame, and so on. After the fourth frame, the first descriptor is used again
4. The Tx Descriptor Handler then reads the address of the DMA Tail Pointer from the Ethernet address database and updates the Tail Pointer DMA_CHj_TxDesc_Tail_LPointer or DMA_CHy_TxDesc_Tail_Pointer of the Ethernet DMA channel TETHDLi_CTRL.DMACH, indicating the total number of Tx descriptors. The Tx Descriptor Tail LPointer register has the 32-bit end address of the Transmit descriptor list. This is the Transmit Poll Demand from the DRE.
   a. $DMA_CHj_TxDesc_Tail_LPointer = Start\ address\ of\ TETHDLi + 10_H$ for GETH if the first descriptor has OWN bit set
   b. $DMA_CHy_TxDesc_Tail_Pointer = Start\ address\ of\ TETHDLi + 10_H$ for LETH if the first descriptor has OWN bit set

   The Tail Pointer is updated until the descriptor which has the OWN bit set
5. While in Run state, the Ethernet DMA selects the next Tx DMA channel from which the packets requiring transmission should be processed. The Ethernet DMA channel fetches each Tx descriptor (DRE_TDESC) and performs the following actions:
   a. Reads the buffer address and payload length from the Tx descriptor and fetches the ACF Ethernet frame from the EOBUF. In case of forwarding it fetches the Ethernet frame from the EIBUF
   b. Clears OWN bit and overwrites the Tx descriptors with the Write-back format. The TDESCi_WR3G.LD bit or TDESCi_WR3L.LD must be set by DMA once the last descriptor is processed instructing the Tx Descriptor Handler to release the DRE_TDESC to be used by another frame

c. It then fetches the next descriptor and if the OWN bit is not set, it goes into Suspend state

d. The DMA comes out of Suspend state and goes into Run state with the next Transmit Poll Demand from the DRE

***Note**: The DRE issues only one Transmit poll demand at a time. Any new request for the same Tx DMA channel would be considered only after the write-back format is written by the DMA channel for the previous request*

6. If there is no error in the Write-back format, the Tx Descriptor Handler clears the following bits, indicating buffer free:

- EREQ.TXi_REQ, after the entire frame is read from the EOBUF
- EREQ.FWDi_REQ, after the entire frame is read from the EIBUF

7. When there is a new frame to be transmitted or forwarded, the Tx Descriptor Handler then issues another Transmit Poll Demand after setting the OWN bit of the next Tx descriptor pointed to by the TETHDLi_CTRL.PTR. The PTR is always pointing to the next descriptor following the last word write-back format write operation from the Tx DMA channel. This Transmit Poll Demand brings the DMA out of Suspend state. If the DMA does not read the descriptor pointed to by TETHDLi_CTRL.PTR, error flag EOBUFj_ERROR.TDESE is set and Transmit descriptor error interrupt INT_14 is triggered

8. After the successful routing and forwarding of each Ethernet frame, EDLSTAT.TXCNT is incremented

9. The transmit of an Ethernet frame is complete upon the detection of the write of the last word of the descriptor Write-back format TDESCi_WR3 (RAM TDESC word 3 Write-back format for GETH or RAM TDESC word 3 Write-back format for LETH). The Tx DMA updates the Write-back descriptor error status TDESCi_WR3G.DERR in most error scenarios. In the case of LETH, TDESCi_WR3L.DE and ES bits indicate error. But when an AXI bus error occurs (refer GETH or LETH chapters) while writing the Write-back format, the transaction is aborted immediately by the Tx DMA channel and the last word TDESCi_WR3 might not be updated. When Ethernet Transmit Timeout Monitoring is enabled and the last word is not written before the timer expires, a timeout interrupt is triggered. When Ethernet Transmit Timeout Monitoring is disabled, the Tx Descriptor Handler polls the GETH DMA_CHj_Status (j=0-7) and LETH DMA_CHy_Status (y=0-7) registers every 200 clock cycles in order to monitor the status of the DMA channel. The polling starts at the first word read of the descriptor Read format and is done in a round-robin fashion for each DMA channel. If the DMA detects one of the following conditions, the transmission from that channel is suspended or stopped and the Tx DMA proceeds to go into Suspend state or Stop state.

Tip: As Suspend state is considered an abnormal event by Ethernet, it triggers AIS interrupt. It is recommended that this interrupt is disabled when the DMA channel is configured to route or forward frames using DRE

Bit TBU (bit 2) of the Status register of the corresponding DMA channel is set in the event that transmission is suspended:

a. The descriptor is flagged as owned by the DRE (OWN bit is cleared): In this case the DRE Tx Descriptor Handler gives the ownership to the DMA by setting the OWN bit and then issues a Poll Demand command by writing to the Tail Pointer register

b. The descriptor Tail Pointer is equal to the current descriptor pointer in Ring Descriptor list mode: In this case the DRE Tx Descriptor Handler modifies the Tail Pointer such that the following condition is true:

Current Descriptor Pointer < Descriptor Tail Pointer

c. An error condition occurs because of transmit underflow: The packet transmission is aborted and TDESCi_WR3.DERR (in the case of GETH) or TDESCi_WR3.DE (in the case of LETH) is set accordingly by the DMA channel. DRE Tx Descriptor Handler triggers a Transmit descriptor error interrupt INT_14

d. In the event of a bus error, the DMA proceeds to Stop state, bit FBE is set and the bit-field TPS of the Status register is set accordingly. In this case, the packet transmission is aborted, TDESE is set and Transmit descriptor error interrupt INT_14 is triggered

e. The software can reset the TETHDLi_CTRL.PTR if required by setting the TETHDLi_CTRL.STOP bit. The software must wait for the DRE to set the TETHDLi_CTRL.STOPACK before resetting the PTR. The software must then clear the STOP bit. Clearing of this STOP bit will trigger DRE to clear STOPACK and set OWN bit of the TDESCi pointed to by the new updated TETHDLi_CTRL.PTR and trigger a Transmit Poll Demand to the Tx DMA channel

***Note**: The software can ensure that the Ethernet DMA current pointer in this case is also pointing to the same descriptor by resetting the Ethernet DMA current pointer or by restarting the DMA*

Requests arbitration

All the requests to forward or transmit Ethernet frames are processed in a round-robin fashion. A requests arbitration example is shown in the image below. The priority is as follows:

1. Write-back format processing
2. If the previous processed request was TXi_REQ, then FWDi_REQ is processed
3. If the previous processed request was FWDi_REQ, then TXi_REQ is processed

   This ensures a non-starving arbitration of TXi_REQ and FWDi_REQ

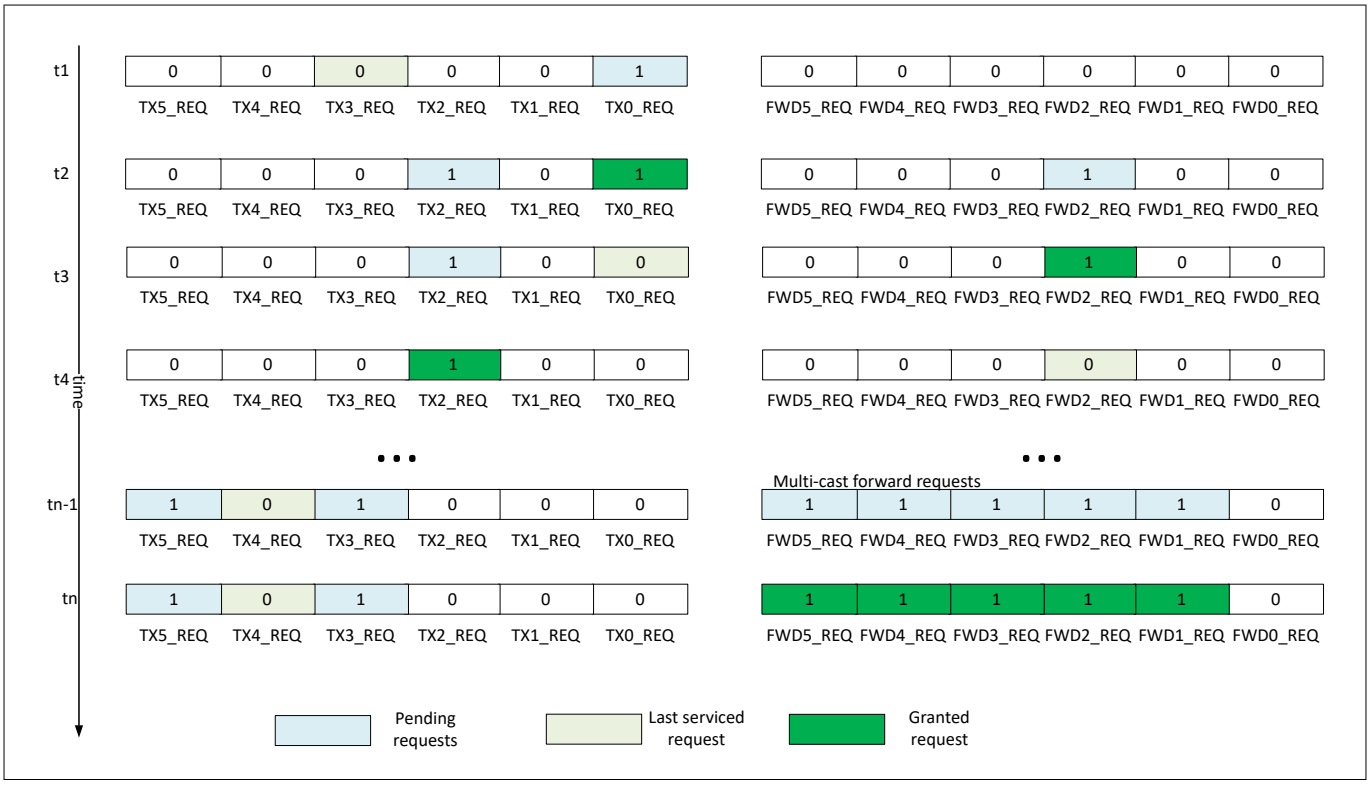

Figure 361 Requests arbitration example

Ethernet transmit timeout monitoring

The DRE monitors for delayed Ethernet frame availability to transmit within the EOBUF and also monitors for delayed read of Ethernet frames from EOBUF by the Ethernet DMA channel. The Ethernet watchdog counter starts incrementing when the Ethernet watchdog timeout is enabled in EWDCFG.EN. The watchdog timer triggers periodic events E1, E2, …, En after a user-configured Ethernet timeout period EWDCFG.ETO. The Ethernet timeout period is configured by the user based on the use-case. If the start condition is true and the

end condition is not true within two events E_i and E_{i+1}, the Ethernet watchdog timeout error flag EOBUFj_ERROR.WDTE is set and error interrupt INT_14 is triggered if EWDCFG.WTOE is enabled. The software can read the frame in the event of such a timeout and must clear the error flag. Once the error flag is cleared, the EOBUF is used for the next frame.

The timeout period between the events E_i is calculated as follows:

- Default timeout period: $T_{def} = \frac{16}{f_{SRI}}$
- User-configured timeout period: $T_{out} = T_{def} * (EWDCFG.ETO + 1)$

Table 947 Timeout interrupt trigger

Timeout check	Timeout interrupt trigger
End condition is true within a single event E_i	No Timeout error. No timeout interrupt triggered
End condition is true within two consecutive events E_i and E_{i+1}	If the presence of start condition is detected at Ei, then the end condition is expected to happen before Ei+1. If not, timeout interrupt is triggered
End condition is true after two consecutive events E_i and E_{i+1}	Timeout interrupt is triggered

Table 948 EOBUF : Start and end condition list

Start condition	End condition
EOBUF full (ready for transmit). EREQ.TXi_REQ is set to indicate this	EOBUF empty (read complete by Ethernet DMA channel or software). EREQ.TXi_REQ is cleared
EOBUF not empty (partially full)	EOBUF full (ready for transmit). EREQ.TXi_REQ is set

20.7.3.2 Rx descriptor handler

The Rx Descriptor Handler receives an Ethernet frame in the EIBUF from an ETH Rx DMA channel.

Whenever there is a free EIBUF available to receive an ETH frame, the EIBUFi_STATUS.BPR is 0 indicating buffer empty.

When RETHDLi_CTRL.TRIG is set to 1, the Descriptor Handler sets EIBUFi_STATUS.RXREQ and triggers an Ethernet Frame Receive Request Interrupt INT_11 to the IR indicating that the software can write an Ethernet frame to the free buffer. The software writes the Ethernet frame to the EIBUF and clears the RXREQ. The handler sets the Buffer Pending Request (BPR) bit after the Ethernet frame is received in the EIBUF. When RETHDLi_CTRL.TRIG is set to 0, the following actions are performed:

1. The Rx Descriptor Handler prepares the 4 words of all Rx descriptors in Read format for the ETH frame to be stored in EIBUF but only sets the OWN bit of the first Rx descriptor. The OWN bit of the second Rx descriptor is set for the second frame, the OWN bit of the third descriptor is set for the third frame, and

so on. After the fourth frame, the first descriptor is used again. RDESC_RD0.BUF1AP points to the EIBUF start address

2. After preparing the Rx descriptors, the Rx Descriptor Handler sets the RDESCi_RD3.OWN bit (GETH) or RDESCi_RD3.OWN bit (LETH) in the first descriptor, indicating that the DMA channel RETHDLi_CTRL.DMACH owns the descriptor
3. The Rx Descriptor Handler reads the address of the DMA Tail Pointer from the Ethernet address database and updates the Tail Pointer DMA_CHj_RxDesc_Tail_LPointer (GETH) or DMA_CHy_RxDesc_Tail_Pointer (LETH) of the Ethernet DMA channel RETHDLi_CTRL.DMACH indicating the total number of Rx descriptors. The Rx Descriptor Tail LPointer register has the 32-bit end address of the Receive descriptor list. This is the Receive Poll Demand from the DRE:
   a. $DMA_CHj_RxDesc_Tail_LPointer = Start\ address\ of RETHDLi + 10_H$ for GETH if the first descriptor has OWN bit set
   b. $DMA_CHy_RxDesc_Tail_Pointer = Start\ address\ of RETHDLi + 10_H$ for LETH if the first descriptor has OWN bit set

   The Tail Pointer is updated up to the descriptor which has the OWN bit set
4. While in Run state, the Ethernet DMA channel fetches each Rx descriptor (DRE_RDESC) and performs the following actions:
   a. Reads the buffer address from the Rx descriptor and writes the Ethernet frame to this address in the EIBUF
   b. Clears OWN bit and overwrites the Rx descriptor with the Write-back format which includes the packet length RDESCi_WR3G.PL (GETH) or RDESCi_WR3L.PL (LETH). The RDESCi_WR3G.LD bit (GETH) or RDESCi_WR3L.LD (LETH) must be set by the DMA once the last descriptor is processed, indicating to the DRE to release the DRE_RDESCi to be used by another frame. If the LD bit is not set, the error flag EIBUFi_ERROR.RDESE is set and error interrupt INT_10 is triggered
   c. The Ethernet DMA starts to process the next Rx descriptor but goes into Suspend state as the second descriptor is still owned by the DRE
   d. The DMA comes out of Suspend state and goes into Run state with the next Receive Poll Demand from the DRE
5. If there is no error in the Write-back format, after the last word write to the Write-back format Rx descriptor DRE_RDESCi_WR3 (RDESCi_WR3G for GETH or RDESCi_WR3L for LETH), the OWN bit is checked if cleared and BPR bit is set to 1 by the Rx Descriptor Handler indicating buffer full
6. The DRE then begins processing the new frame in EIBUF. After the frame in EIBUF is successfully processed and once the buffer is empty, the Rx Descriptor Handler sets the OWN bit of the next Rx descriptor pointed to by the RETHDLi_CTRL.PTR and issues a Receive Poll Demand . The PTR is always pointing to the next descriptor following the last word Write-back format write operation from the Rx DMA channel. This Receive Poll Demand brings the DMA out of Suspend state to start processing the next descriptor. If the DMA does not read the descriptor pointed to by RETHDLi_CTRL.PTR, error flag EIBUFi_ERROR.RDESE is set and Receive descriptor error interrupt INT_10 is triggered
7. After successful forwarding of each Ethernet frame, EDLSTAT.RXCNT is incremented
8. The reception of an Ethernet frame is complete upon the detection of the write of the last word of the descriptor Write-back format RDESCi_WR3 (RAM RDESC word 3 Write-back format GETH or RAM RDESC word 3 Write-back format LETH). The Rx DMA updates the Write-back descriptor error summary RDESCi_WR3G.ES bit or RDESCi_WR3L.ES bit in most error scenarios. But when an AXI bus error (refer LETH or GETH chapters) occurs while writing the Write-back format, the transaction is aborted immediately by the Rx DMA channel and the last word RDESCi_WR3 might not be updated. When Ethernet Receive Timeout Monitoring is enabled and the last word is not written before the timer expires, a timeout interrupt will be triggered. When Ethernet Receive Timeout Monitoring is disabled, the Rx Descriptor Handler polls the GETH DMA_CHj_Status (j=0-7) and LETH DMA_CHy_Status (y=0-7) registers every 200 clock cycles in order to monitor the status of the DMA channel. The polling starts at the first word read of descriptor Read format and is done in a round-robin fashion for each DMA channel.

If the DMA detects one of the following conditions, the transmission from that channel is suspended or stopped and the Rx DMA proceeds to go into Suspend state or Stop state

a. The Ethernet DMA enters Suspend state when there are no free descriptors (based on Rx current descriptor and descriptor Tail Pointer register values). Bit RBU (bit 7) of the Status register of the corresponding DMA channel is set in the event that transmission is suspended. It exits the suspend state on a Receive Poll Demand from the DRE after it advances the Tail Pointer of the channel.

Tip: As Suspend state is considered an abnormal event by Ethernet, it triggers AIS interrupt. It is recommended that this interrupt is disabled when the DMA channel is configured to route or forward frames using DRE

b. If there is an error indication by RDESCi_WR3G.ES or RDESCi_WR3L.ES bit, the Rx Descriptor Handler stores the frame in the EIBUF, sets the error flag EIBUFi_ERROR.RDESE and triggers a Receive descriptor error interrupt INT_10

c. In the event of a bus error, the DMA proceeds to Stop state, bit FBE is set and the bit-field RPS of the Status register is set accordingly. In this case, the transaction is aborted, RDESE is set and Receive descriptor error interrupt INT_10 is triggered

d. The software can reset the RETHDLi_CTRL.PTR if required by setting the RETHDLi_CTRL.STOP bit. The software must wait for the DRE to set the RETHDLi_CTRL.STOPACK before resetting the PTR. The software must then clear the STOP bit. Clearing of this STOP bit will trigger DRE to clear STOPACK and set OWN bit of the RDESCi pointed to by the new updated RETHDLi_CTRL.PTR and trigger a Receive Poll Demand to the Rx DMA channel

***Note**: The software can ensure that the Ethernet DMA current pointer in this case is also pointing to the same descriptor by resetting the Ethernet DMA current pointer or by restarting the DMA*

Ethernet receive timeout monitoring

The DRE monitors for a delayed write of an Ethernet frame by the Ethernet DMA channel or software to the EIBUF and also monitors for delayed processing of the Ethernet frame by the ACF Format Engine or by the Tx Descriptor Handler in the case of Ethernet forwarding. The Ethernet watchdog counter starts incrementing when the Ethernet watchdog timeout is enabled in EWDCFG.EN is set. The watchdog timer triggers periodic events E1, E2, …, En after a user-configured Ethernet timeout period EWDCFG.ETO. The Ethernet timeout period is configured by the user based on the use-case. If the start condition is true and the end condition is not true within two events E_i and E_{i+1}, the Ethernet watchdog timeout error flag EIBUFi_ERROR.WDTE is set and error interrupt INT_10 is triggered if EWDCFG.WTOE is enabled. The software can read the frame in the event of such a timeout and must clear the error flag. Once the error flag is cleared, the EIBUF is used for the next frame.

The timeout period between the events E_i is calculated as follows:

- Default timeout period: $T_{def} = \frac{16}{f_{SRI}}$
- User-configured timeout period: $T_{out} = T_{def} * (EWDCFG.ETO + 1)$

Table 949 Timeout interrupt trigger

Timeout check	Timeout interrupt trigger
End condition is true within a single event E_i	No timeout error. No timeout interrupt triggered
End condition is true within two consecutive events E_i and E_{i+1}	If the presence of start condition is detected at Ei, then the end condition is expected to happen before Ei+1. If not, timeout interrupt is triggered

(table continues...)

Table 949 (continued) Timeout interrupt trigger

Timeout check	Timeout interrupt trigger
End condition is true after two consecutive events E_i and E_{i+1}	Timeout interrupt is triggered

Table 950 EIBUF : Start and end condition list

Start condition	End condition
EIBUF empty (EIBUFi_STATUS.BPR is 0)	EIBUF full (EIBUFi_STATUS.BPR is 1). In the event of an error scenario such as overflow, the EIBUFi_STATUS bit BPR, Buffer Pending Request, is not set by the DRE, which triggers a timeout. In this case, two error interrupts (Buffer full and timeout) are triggered. If the end condition and the timeout occur at the same time, INT_10 is triggered even if the Ethernet frame is processed successfully
EIBUF full	EIBUF empty (processed by the Ethernet to CAN Disassembler or by the Tx Descriptor Handler in the case of forwarding)

20.7.3.3 Forwarding engine

The Forwarding Engine assists in forwarding Ethernet frames between Ethernet interfaces.

The Rx Descriptor Handler decides the path of the Ethernet frame in the EIBUF. The Rx Descriptor Handler can give control of the Ethernet frame to the ACF CAN-Ethernet Format Engine (to the Ethernet ACF to CAN Disassembler) in the case of ETH to CAN routing or to the Forwarding Engine in the case of Ethernet forwarding. It gives control to the ACF CAN-Ethernet Format Engine under the following scenarios:

1. In the case of an IEEE 1722 Ethernet frame containing AV tagged data,
   a. For GETH, RDESCi_WR2G bit AVTDP or AVTCP is set

      ***Note**: The DRE does not support split header feature. The DRE identifies the frame to be AV tagged when AVTDP or AVTCP is set irrespective of L34T value. If the frame is not AV tagged but AVTDP or AVTCP is still set, the subtype check or failed StreamID filtering described below would give control to the Forwarding Engine*

   b. For LETH, RDESCi_WR1L bits 2:0 (Payload Type) are 110_B or 111_B
2. If the frame is identified to be an IEEE 1722 Ethernet frame (refer to the section Validation of the Ethernet input frame):
   a. Subtype = 0x82
   b. StreamID filtering passed

In all other scenarios, the Rx Descriptor Handler gives control of the Ethernet frame to the Forwarding Engine.

The Forwarding Engine assists in forwarding Ethernet frames between Ethernet interfaces. The Ethernet MAC consists of a built-in Ethernet packet filtering which consists of L2, L3, L4 filters and a Flexible Receive Parser (FRP). Acceptance and rejection of packets is based on the configuration of these filters:

- For LETH, the L3L4FM (3 bits) is not included in filtering
- For GETH, the L3L4FM (3 bits) is not included in filtering when both L34M and L4M are zero

The DRE_RDESCi Write-back format consists of the packet filtering and FRP status information. This is used by the Forwarding Engine to create a FTCFG.FID as shown in the following figure.

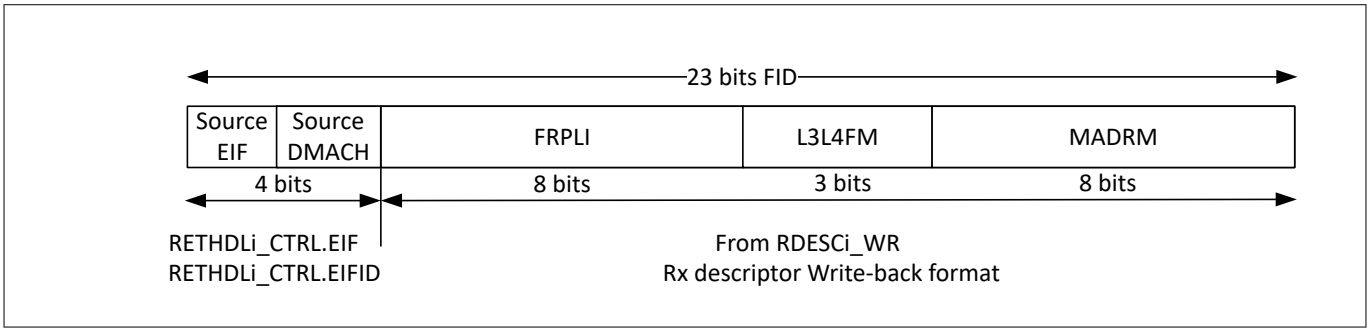

Figure 362 Forwarding ID

The Forwarding Engine determines the destination of the Ethernet frame using this FID within the Forwarding table. The Forwarding table consists of a set of user-configurable forward filter IDs FT_FEj_FRULE.FID1, FT_FEj_FID2.FID2 and a bit-encoded forward rule FT_FEj_FRULE.DSEL consisting of 6 bits. The forward rule is used to select the Tx descriptor list of the corresponding destination DMA channel. The Forwarding Engine performs the following operations:

1. **Forward ID filtering:** Each filter element is executed until the first matching element is found. Forward ID filtering stops at the first matching element. The remaining filter elements are not evaluated for this frame. The following types of filtering mode can be configured by setting FT_FEj_FRULE.FMODE accordingly:
   a. Classic ID filter: FID1 used as the filter ID and FID2 used as mask
   b. Dual ID filter: FID1 or FID2 used as filter ID and FTCFG.FID should be an exact match
   c. Range ID filter: Range of IDs between FID1 and FID2 are used as filter IDs. The FTCFG.FID should be between FID1 and FID2
2. **Frame forwarding:** When there is a matching filter element, the Forwarding Engine sets the EREQ.FWDi_REQ of the corresponding Tx descriptor list FT_FEj_FRULE.DSEL. It gives control of the Ethernet frame in the EIBUF to the Tx Descriptor Handler. The Tx Ethernet Descriptor Handler then prepares the Tx descriptors for the frame in EIBUF depending on the configured forward rule FT_FEj_FRULE.DSEL

20.7.3.4 Descriptor error handling

The Ethernet DMA channel signals an error through the status information within the Write-back format of the descriptors.

During any SRI bus error while sending the Transmit or Receive Poll demand, the EOBUFj_ERROR.TDESE or EIBUFi_ERROR.RDESE is set for transmit and receive respectively. ME_ERR.SRIBE is set and FEDID and FESID bits are set accordingly.

Error in Tx descriptors

- In the case of GETH, error in Tx descriptors is indicated by bit TDESCi_WR3G.DERR
- In the case of LETH, error in Tx descriptors is indicated by bit TDESCi_WR3L.DE and bit TDESCi_WR3L.ES indicates the type of error

In the event of a Tx descriptor error, the Tx Descriptor Handler retains the Tx descriptors and the frame in EOBUF or EIBUF. It sets the error flag EOBUFj_ERROR.TDESE and EIBUFi_STATUS.FE (in the case of FWDi_REQ from EIBUF) and triggers an interrupt. The software then fixes the root cause of the error, it fetches the Ethernet frame from the buffer, clears the request TXi_REQ or FWDi_REQ and then clears the TDESE or RDESE.

Meanwhile, the Tx Descriptor Handler processes the remaining requests in round-robin fashion, as described in the chapter Tx Descriptor Handler. During any Tx descriptor error caused by a FWDi_REQ, the TXi_REQ is blocked until the TDESE belonging to the EOBUFi is cleared by the software as the Tx descriptors are mapped to the same Tx DMA channel.

Error in Rx descriptors

- In the case of GETH, error in Rx descriptors or in the received packet is indicated by bit RDESCi_WR3G.ES
- In the case of LETH, error in Rx descriptors or in the received packet is indicated by RDESCi_WR3L.ES

In the event of an Rx descriptor error, the Rx Descriptor Handler retains the Rx descriptor Write-back format and the frame in the EIBUF. It sets the error flag EIBUFi_ERROR.RDESE, EIBUFi_STATUS.FE and triggers an interrupt. The software then fetches the Ethernet frame from the buffer and clears the error flag. Once the error flag is cleared, the EIBUF is used for the next frame.

Meanwhile, the Rx Descriptor Handler processes the next free EIBUF as described in the chapter Rx Descriptor Handler.

Rx descriptor handler on page 3784

20.7.3.5 Interrupt grouping

DRE generates status and error events on 16 interrupt lines (INT_0 until INT_15) to the Interrupt Router.

The corresponding interrupt lines are enabled by configuring the IE register. A trigger event on an interrupt line is shown in the INTSIG register even if the interrupt is disabled. INT_i (i= 0 to 15) output will be a pulse when a trigger event for interrupt i happens even if INTSIG[i] is already set at that point in time. The 16 interrupt lines are mapped to the following status and error events:

Table 951 Interrupt grouping table

Interrupt line	Interrupt type	Status and error events mapped
INT_0 to INT_7	Watermark and Wraparound Interrupts	Groups watermark and wraparound events of destination memory routing operations. DMEMi_STATUS.WAF and WMF status events are mapped to one of INT[0:7] as selected by DMEMi_CONFIG.INP
INT_8	CAN Input Buffer List Interrupts	Groups the following CIBL error interrupts: • CIBL_STATUS.BF • CIBL_STATUS.CRCE • CIBL_STATUS.WDTE
INT_9	CAN Output Buffer List Interrupts	Groups the following COBL error interrupts: • COBL_STATUS.BF • COBL_STATUS.WDTE
INT_10	EIBUF Frame Error Interrupts	Groups the following EIBUF error interrupts: • EIBUFi_STATUS.FE • EIBUFi_STATUS.IFT • EIBUFi_STATUS.LME • EIBUFi_STATUS.RFE • EIBUFi_STATUS.IDID • EIBUFi_STATUS.CFE • EIBUFi_ERROR.WDTE • EIBUFi_ERROR.RDESE • EIBUFi_ERROR.BF
INT_11	Ethernet Frame Receive Request Interrupt	EIBUFi_STATUS.RXREQ
INT_12	Routing Table Error Interrupts	Groups RS.IRT and NMFE
INT_13	ME Routing Transaction Lost Interrupts	Groups the following ME error interrupts: • ME_ERR.DBOE • ME_ERR.SRIBE • ME_ERR.SPBBE • ME_ERR.IRDE

(table continues...)

Table 951 (continued) Interrupt grouping table

Interrupt line	Interrupt type	Status and error events mapped
INT_14	EOBUF Frame Error Interrupts	Groups the following EOBUF error interrupts: • EOBUFj_STATUS.BF • EOBUFj_ERROR.WDTE • EOBUFj_ERROR.TDESE
INT_15	Ethernet Frame Transmit Request Interrupt	EOBUFj_STATUS.TXREQ

When multiple events are mapped to the same interrupt lines, the corresponding interrupt line is triggered when at least one of the relevant status or error events has occurred (logical OR operation on status or error event).

20.8 Registers

20.8.1 Register overview - access mode glossary

Table 952 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-PETHj (j=0-5)	Protection group consisting of registers ETHj_ACCEN_WRA, ETHj_ACCEN_WRB, ETHj_ACCEN_RDA, ETHj_ACCEN_RDB, ETHj_ACCEN_VM, ETHj_ACCEN_PRS.
PETHj	Access protection using *APU-PETHj* registers.
APU-PG	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
PG	Access protection using *APU-PG* registers.
32	Access only when using 32-bit width.
SV	Access only when supervisor mode is active on the interconnect.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
P	Description can be found in global access mode definition.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.

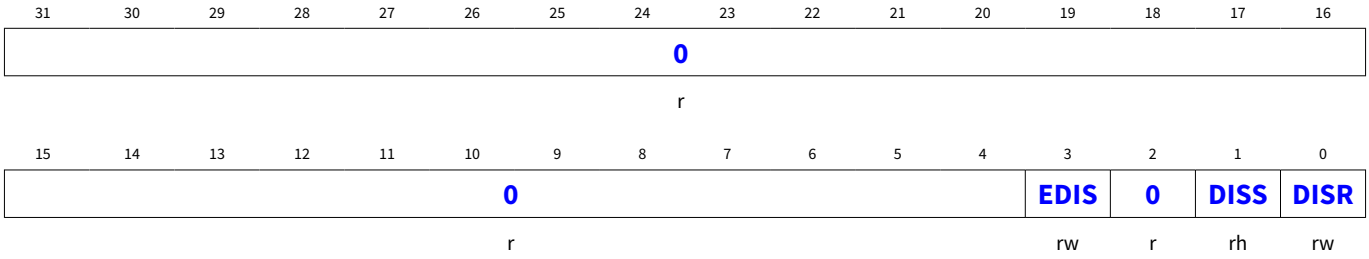
20.8.11 Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 00000_H

Clock Control Register Application Reset value: $0000\ 0003_H$



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. 0_B On request: enable the module clock 1_B Off request: stop the module clock

(table continues...)

(continued)

Field	Bits	Type	Description
DISS	1	rh	**Module Disable Status Bit** When CLC.DISS=1B, registers CLC, OCS, ID, RST_CTRLA, RST_CTRLB, PROTE, PROTSE, ACCEN* and ETH_ACCEN* are still accessible. Accesses to other DRE registers are not executed and will result in a bus error. 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. Note: Sleep mode should not be enabled when there are ongoing or pending transactions between the DRE and Ethernet 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

20.8.12 OCDS Control and Status Register

The OCDS Control and Status register OCS controls the debug and trace behavior by selecting suspend modes and OTGB trigger sets. When OCDS is disabled the suspend control is ineffective.

OCS Offset address: 00004_H

OCDS Control and Status Register Debug Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0															
r															

Field	Bits	Type	Description
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) Not listed combinations are reserved. 0_H Will not suspend 1_H Reserved, Do not use 2_H Soft suspend mode Clocks will be disabled after kernel acknowledge. The DRE waits for the onging transactions on the SRI and FPI Master interfaces to finish. SRI access remains operational. Read accesses are allowed on the SRI slave interface for the entire SFR space and the RAM memory. Write access are allowed on the SRI slave interface for the RAM memory and the registers on the application domain (common registers). Write access to Kernel domain registers will have no effect. The DRE resumes operation from the point where it was stopped upon a suspend request. Note: Suspend mode should not be enabled when there are ongoing or pending transactions. Rapid sequence of suspend requests should be avoided in order to avoid false acknowledge. **others,** Reserved, do not use
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:0, 31:30	r	**Reserved** Read as 0; should be written with 0.

Table 962 Access mode restrictions of OCS sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SUS_P**	rw	SUS	Set SUS_P during write access
(default)	r	SUS	

20.8.13 Module Identification Register

ID Offset address: 00008_H

r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOD_TYPE								MOD_REV							
r								r							

Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** The bit-field is set to $C0_H$ which defines the module as a 32-bit module.
MOD_NUM	31:16	r	**Module Number Value** This bit-field defines a module identification number.

20.8.14 Reset Control Register A

RST_CTRLA Offset address: $0000C_H$

Reset Control Register A Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0

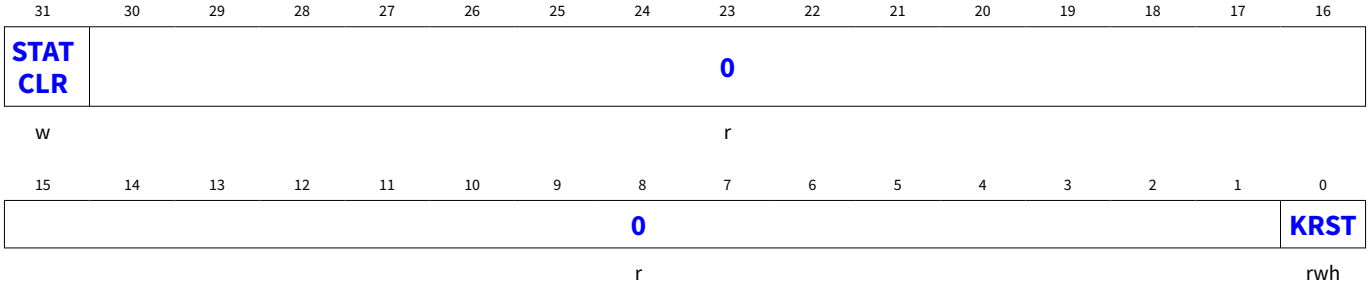
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				GRSTEN3	GRSTEN2	GRSTEN1	GRSTEN0	0							KRST
r				rw	rw	rw	rw	r							rwh

Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The reset is executed if the reset bits of both kernel reset registers are set. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for Global Module Reset Group x** 0_B Global module reset group x does not have any effect 1_B Global module reset group x results in a kernel reset
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

20.8.15 Reset Control Register B

RST_CTRLB Offset address: 00010_H

Reset Control Register B Application Reset value: $0000\ 0000_H$



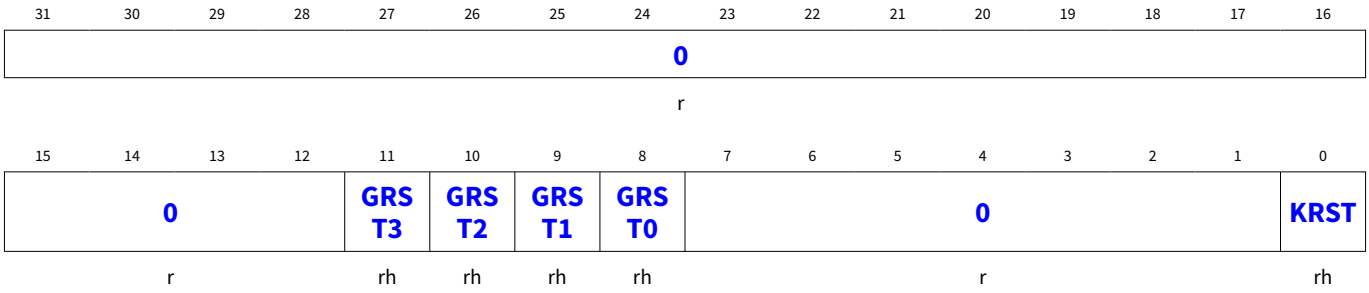
Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The reset is executed if the reset bits of both kernel reset registers are set. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
STATCLR	31	w	**Kernel Reset Status Clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits STAT.GRSTx and bit STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

20.8.16 Reset Status Register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: 00014_H

Reset Status Register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rh	**Kernel Reset Status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.

(table continues...)

(continued)

Field	Bits	Type	Description
GRSTx (x=0-3)	x+8	rh	**Status for Global Module Reset Group x** 0_B Reset was not triggered by global reset group x 1_B Reset was triggered by global reset group x
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

20.8.17 PROT Register Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 00018_H

PROT Register Endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OWEN	ODEF	TAGID						PRSEN	PRS			VMEN	VM

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												SWEN	STATE		
r												w	rwh		

Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.

(table continues...)

(continued)

Field	Bits	Type	Description
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 963 Access mode restrictions of PROTE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN

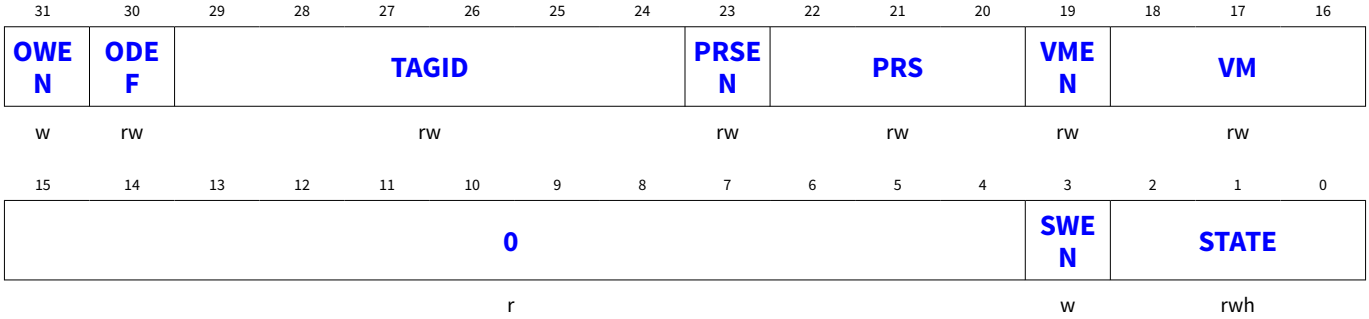
20.8.18 PROT Register Safe Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: $0001C_H$

PROT Register Safe Endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 964 Access mode restrictions of PROTSE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN

0		CBI						0		PIDX					
r		rh						r		rh					

Field	Bits	Type	Description
PIDX	5:0	rh	**Put Index** This bit-field shows the index corresponding to the buffer at which a new CAN frame will be stored. When Buffer Full flag (BF) is set, value of this bit-field is ignored.
CBI	13:8	rh	**Current CAN Input Buffer Index** This bit-field indicates that CAN input buffer index currently processed by the ACF CAN-Ethernet Format Engine. Valid values are 1 to 20.

(table continues...)

(continued)

Field	Bits	Type	Description
BF	16	rh	**Buffer Full** This bit-field shows the buffer full status. This flag is set by hardware when all the buffers have pending requests set. The flag is cleared by hardware when there is a free buffer available Note: When all the EOBUFs corresponding to the DIDs of the CAN frames in the CIBL are disabled, it leads to a buffer full condition. The software shall enable the EOBUF based on the buffer full interrupt 0_B Free buffers available 1_B CAN Input Buffer List is full
BE	17	rh	**Buffer Empty** This flag shows the buffer empty condition. The flag is set by hardware when there are no buffers with a pending request. The flag is cleared by hardware when atleast one buffer has a pending request set. 0_B Buffer not empty Buffers have pending requests set. 1_B Buffer empty Buffers have no pending requests set
CRCE	18	rwh	**CRC error flag** This bit is set by the hardware to indicate an CRC mismatch while verifying the 16-bit CRC part of the CAN frame in the CIBUF before writing the final block of data into the EOBUF. The software write with 1 clears this bit.
WDTE	19	rwh	**Watchdog timeout error flag** This bit is set by the hardware to indicate an CAN Watchdog timeout error in case of delayed processing of the CAN frame in CIBUF by the ACF CAN-ETH assembler. Software write with 1 clears this bit
0	7:6, 15:14, 31:20	r	**Reserved** Read as 0; should be written with 0.

20.8.35 CAN output buffer pending request 0

The pending requests for CAN output buffers from index 0 to 31 are set by hardware in this register.

COBL_BPR0 — Offset address: $010C8_H$

CAN output buffer pending request 0 — Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
PIDX	6:0	rh	**Put Index** This bit-field shows the index corresponding to the buffer at which a new CAN frame is stored. When Buffer Full (BF) flag is set, value of this bit-field is ignored.
BF	16	rh	**Buffer Full** This bit-field shows the buffer full status. This flag is set by hardware when all the buffers have pending requests set. The flag is cleared by hardware when there is a free buffer available. 0_B Free buffers available 1_B CAN Output Buffer List is full
BE	17	rh	**Buffer Empty** This flag shows the buffer empty condition. The flag is set by hardware when there are no buffers with a pending request. The flag is cleared by hardware when atleast one buffer has a pending request set. 0_B Buffers have pending requests set 1_B Buffers have no pending requests set
WDTE	19	rwh	**Watchdog timeout error flag** This bit is set by the hardware to indicate an CAN Watchdog timeout error in case of delayed processing of the CAN frame in COBUF by the Routing control unit. Software write with 1 clears this bit
0	15:7, 18, 31:20	r	**Reserved** Read as 0; should be written with 0.

20.8.38 Ethernet input buffer i configuration

EIBUFi_CONFIG (i=0-5) Offset address: $010D8_H+i*14_H$

Ethernet input buffer i configuration Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
NTSCF_SA	7:2	rw	**Start Address of the NTSCF Header** This bit-field defines the bits [7:2] of the offset address from EIBUF start address which the NTSCF header starts. Note: The start address offset is always 32 bit aligned.
RRF	28	rw	**Reject Remote Frame** When this bit-field is set, ACF_CAN_BRIEF messages with RTR = 1 are not processed. When this bit is not set, there is no CAN payload data copied by the DRE. The frame is copied until R1
0	1:0, 26:8, 27, 31:29	r	**Reserved**

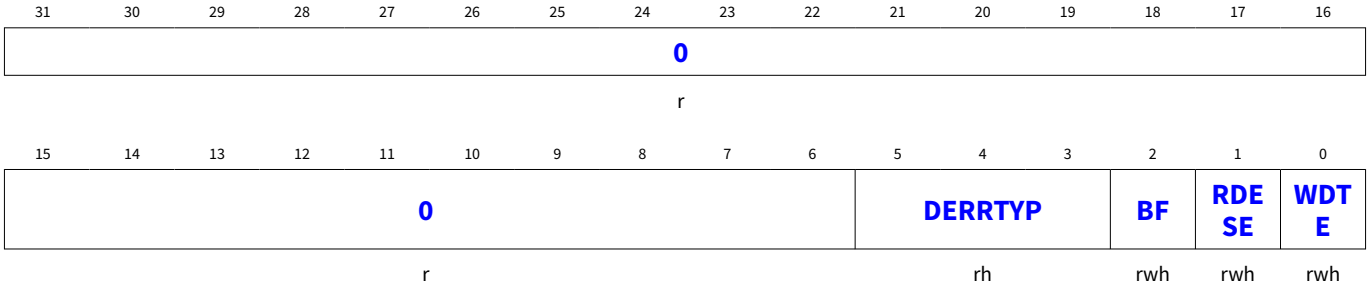
20.8.39 Ethernet input buffer i error

EIBUFi_ERROR (i=0-5)

Ethernet input buffer i error

Offset address: $010E0_H+i*14_H$

Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
WDTE	0	rwh	**Ethernet watchdog timeout error** This bit is set by the hardware to indicate an Ethernet Watchdog timeout error in case of delayed processing of the Ethernet frame in EIBUF by the ACF engine or by the Tx Descriptor Handler. The software shall read the frame directly from the EIBUF and clear this flag. Software write with 1 clears this bit. In case a WDTE event occurs during a forwarding request, the software identifies the EIBUF by checking the EREQ.CBIi and EREQ.FWDi_REQ bits. Clearing the EREQ.FWDi_REQ would automatically clear the EIBUF_STATUS.BPR bit. EIBUF_STATUS.BPR bit could already be cleared by DRE in some cases even after the WDTE error occurs as the forwarding request could be already processed within the time the WDTE error is triggered When there is a watchdog timeout error, the software has to restart the Tx Descriptor Handler by setting the TETHDLi_CTRL.STOP request in order to avoid the Tx Descriptor Handler waiting indefinitely for the Write-back format
RDESE	1	rwh	**Rx descriptor error** This bit is also set by hardware under following scenarios: Error in Rx descriptor is indicated by bits RDESCi_WR3L.ES, RDESCi_WR3G.ES, and RDESCi_WR3G.ETLT. The software shall read the frame directly from the EIBUF and clear this flag. Software write with 1 clears this bit. This bit shall be cleared by the software only after clearing the corresponding TXi_REQ or FWDi_REQ
BF	2	rwh	**Buffer full** This bit is set by the hardware to indicate that the EIBUF is full. It is set by the DRE when the calculated size of the Ethernet frame from the NTSCF header or the packet length from the receive descriptor Write-back format RDESCi_WR3.PL exceeds the maxumum size of the EIBUF. The software shall read the frame directly from the EIBUF and clear this flag. Software write with 1 clears the bit. 0_B Free buffer 1_B EIBUF full

(table continues...)

(continued)

Field	Bits	Type	Description
DERRTYP	5:3	rh	**Descriptor error type** This bit-field indicates the reason for RDESE error. This is set by the hardware when RDESE error occurs and cleared by hardware when the software clears RDESE 000_B No error 001_B Rx Poll Demand error Bus error while Rx Tail Pointer register update 010_B Rx DMA state error The Rx DMA channel is in STOP state 011_B Incorrect OWN bit In case the OWN bit is not set while the Rx DMA channel is reading the Rx descriptor read format 100_B PTR mismatch read Mismatch between the Read format Rx descriptor pointed to by RETHDLi_CTRL.PTR and the descriptor being read by Rx DMA channel 101_B PTR mismatch Write-back Mismatch between the Rx descriptor pointed to by RETHDLi_CTRL.PTR and the descriptor being written back by Rx DMA channel 110_B Write-back error Write-back error in GETH Rx descriptor is indicated by bits RDESCi_WR3G.ES and LETH Rx descriptor is indicated by RDESCi_WR3L.ES. Write-back error also occurs when the Write-back format has the OWN bit set and LD bit not set 111_B Reserved
0	31:6	r	**Reserved** Read as 0; should be written with 0.

20.8.40 Ethernet input buffer i status

EIBUFi_STATUS (i=0-5) Offset address: $010E4_H+i*14_H$

Ethernet input buffer i status Kernel Reset value: $2003\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BPR	BPRC	RXREQ	0	MSFE			ACF_CAN_ADDR

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FC	RFE	CFE	LME	IDID	IFT	FE	LE_ACF_CAN_ADDR								
rwh	rwh	rwh	rwh	rwh	rwh	rwh	rh								

Field	Bits	Type	Description
LE_ACF_CAN_ADDR	8:0	rh	**Last Error ACF CAN Address Pointer** This bit-field indicates the latest ACF_CAN_ADDR (bits 10 to 2 of the 32-bit aligned address) of the ACF_CAN_BRIEF message which had either a Remote Frame Error (RFE) or a CAN Format Error (CFE). The value of this bit-field is valid only when either RFE or CFE error status bits are set. This bit-field is reset by the hardware once the BPR is set again for the next request
FE	9	rwh	**Input Ethernet Frame Error** This flag is set in case of Ethernet frame error and the frame cannot be processed by the ACF CAN-Ethernet Format Engine or the Forwarding engine. This bit-field is set when any of the IFT, IDID, CFE,LME, WDTE, RDESE or BF flags are set. Hardware sets the flag and software write with 1 clears the flag.
IFT	10	rwh	**Invalid Frame Type** This flag is set when the "Subtype" field of NTSCF header has a value other than 0x82. Hardware sets the flag and a software write with 1b clears the flag. In case the descriptor mode is used, this bit is set only when IDID is set to indicate the software the type of frame that caused the error
IDID	11	rwh	**Invalid destination ID** This bit-field is set when there is no matching Stream ID Filter element corresponding to the "Stream ID" of the input frame and there is also no matching FWDID Filter element. Hardware sets the flag and a software write with 1b clears the flag. Once set, the IDID status bit is sticky until SW clears it. The next incoming forwarding frame shall be forwarded irrespective of this bit being set unless there is again an IDID error for this frame.
LME	12	rwh	**AVTP Length Mismatch Error** This bit-field indicates if the calculated ACF_PAYLOAD_LENGTH is greater than the "Ntscf_data_length" value of the NTSCF header of input Ethernet frame. Hardware sets the flag and a software write with 1b clears the flag.
CFE	13	rwh	**CAN Format Error** This bit-field is set when the "ACF_MSG_TYPE" of the CAN frame contained in the input Ethernet frame has a value other than 0x2. Hardware sets the flag and a software write with 1b clears the flag.
RFE	14	rwh	**Remote Frame Error** This bit-field is set when EIBUF_CONFIG.RRF = 1 and a CAN frame has RTR = 1. Hardware sets the flag and a software write with 1b clears the flag.
FC	15	rwh	**Ethernet Frame Complete** This flag is set when the input Ethernet frame is processed by ACF CAN-Ethernet Format Engine that is when EIBUFi_STATUS.BPR bit-field is cleared by hardware. Software write with 1 clears the bit-field. Note: The SW should clear this bit when the RETHDLi_CTRL.TRIG mode is changed from interrupt to Rx descriptor mode

(table continues...)

(continued)

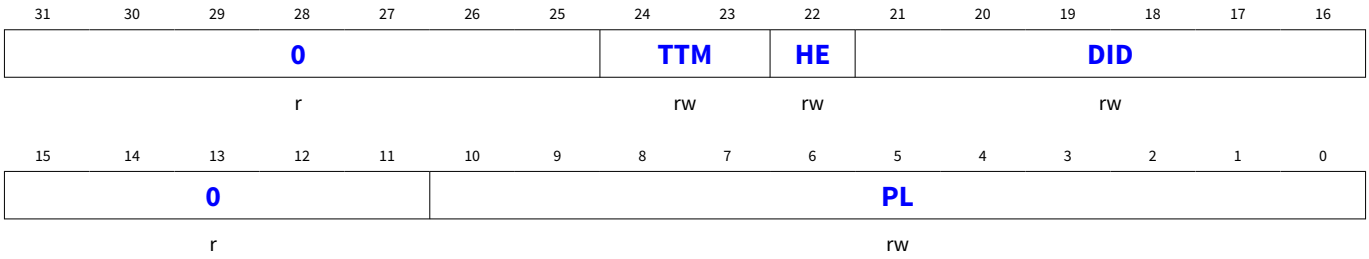
Field	Bits	Type	Description
ACF_CAN_ADDR	24:16	rh	**ACF CAN Address Pointer** This bit-field indicates the bits 10 to 2 of offset address from the NTSCF header start address of the Ethernet Input Buffer from which a new ACF_CAN_BRIEF message is to be read from. The bits 1 and 0 of the physical address to be considered as 0, as the address is always 32-bit aligned. The first ACF_CAN_BRIEF message is always read from offset of 0xC. The address is modified to the start of next ACF_CAN_BRIEF message after processing the fetch ACF_CAN_BRIEF message by the ACF CAN-Ethernet Format Engine. The bit-field is reset to 0x3 (32-bit aligned address representation of the offset address 0xC) when EIBUFi_STATUS.BPR is set again for the next request. BPR is cleared by hardware (when frame processing is completed) or by software setting BPRC = 1 (software abort).
MSFE	27:25	rh	**Matched Stream ID Filter Element** This bit-field indicates the index of the matched Stream-ID filter element. Valid match indicated only when IDID = 0. In case there is no Stream-ID match found, this bit-field is set to 7 and IDID is set to 1 if there is no forwarding filter match
RXREQ	29	rwh	**Ethernet receive request** This bit-field indicates a free Ethernet Input Buffer available to receive a Ethernet frame. 1_B - The bit-field is set by hardware and cleared by software with write of 1B after a frame is written to the EIBUF. The software to clear the bit after reset or after writing the Ethernet frame into the EIBUF. 0_B - A software write of 0B has no effect
BPRC	30	rwh	**Buffer Pending Request Clear** This bit-field allows software to clear the BPR of EIBUF. Software write with 1b clears the BPR bit-field of EIBUF. This bit-field is cleared at once the BPR bit-field is cleared by hardware. A software write with 0b has no effect.
BPR	31	rh	**Buffer Pending Request** This bit-field indicates a pending request for the EIBUF. The Ethernet Descriptor Handler writes 1b to indicate a new input Ethernet frame in EIBUF. The ACF CAN-Ethernet Format Engine clears the bit-field by hardware after completing extraction all CAN Frames from the input Ethernet frame. Software can also clear the flag (example: Software abort) by setting the BPRC bit-field to 1b.
0	28	r	**Reserved** Read as 0; Written as 0

20.8.41 Ethernet output buffer j configuration

EOBUFj_CONFIG (j=0-5) Offset address: 01150_H+j*38_H

Ethernet output buffer j configuration Kernel Reset value: $0032\ 0000_H$

20 Data Routing Engine (DRE)



Field	Bits	Type	Description
PL	10:0	rw	**ACF Payload Length** This bit-field configures the size in bytes of the ACF payload of Ethernet Output Buffer. Only the value of bits PL[10:2] is considered and PL[1:0] is always considered by hardware as 00b, so that the payload size is always an integral multiple of 32-bits. The minimum value is 8 bytes and maximum value can be 1484 bytes. 0 - Ethernet Output Buffer is disabled 4 - Considered as 8 bytes 8 to 1484 - Specifies the configured number of bytes (always a multiple of 4) >1484 - Considered as 1484 Note: When PL is not configured according to the Transmit trigger mode TTM and configuration TTC, the Buffer full flag BF is set when the EOBUF cannot accomodate the incoming CAN frame. The PL shall be configured such that there is at least a single ACF_CAN_BRIEF message within the EOBUF. There is no TXREQ triggered if the EOBUF is empty
DID	21:16	rw	**Destination ID of the Buffer** This bit-field assigns a routing destination ID for the Ethernet Output Buffer. The input CAN frames with a matching destination ID with this bit-field value are assembled to the Ethernet Output Buffer. Valid values are from 0x18 till 0x1D. Other values are reserved. Only consecutive EOBUFs can be configured with similar DIDs. For e.g.: EOBUF0, EOBUF1 can have DID=18H. But if the configurations of DIDs is EOBUF0=18H, EOBUF1=19H and EOBUF2=18H, then it is incorrect.
HE	22	rw	**Header Enable** This bit-field enables the Ethernet header content of the buffer. 0_B Ethernet header insertion is disabled 1_B Ethernet header insertion is enabled

(table continues...)

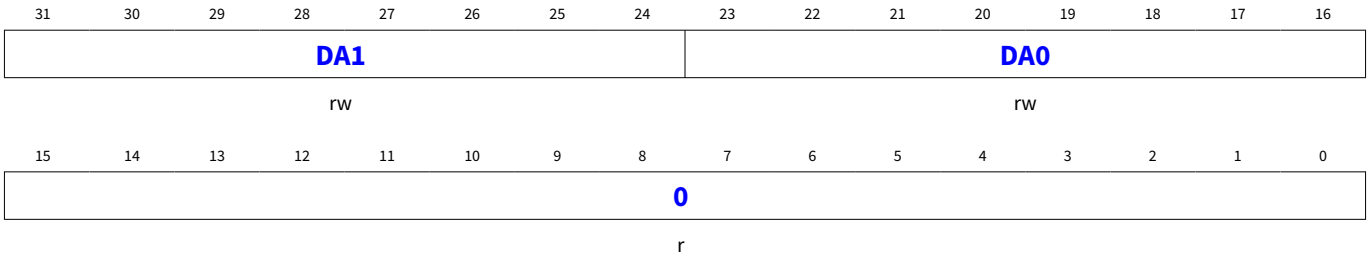
(continued)

Field	Bits	Type	Description
TTM	24:23	rw	**Transmit Trigger Mode** This bit-field configures the AVTP frame transmit trigger modes. Note : When Buffer full flag BF is set, the DRE forces a SW transmit trigger mode for that EOBUF irrespective of the trigger mode configured. The software shall set the TXRDY flag based on the Buffer full interrupt. When Buffer full flag BF is set in descriptor mode, the Tx descriptors are prepared and there is no transmit trigger generated In case of SW trigger mode, the TXRDY bit should not be set when the TXREQ bit or TXi_REQ bit is already set 00_B **SWTM**: Software Triggered Transmit Mode Transmit trigger is initiated when software sets EOBUFj_STATUS.TXRDY. 01_B **FCTM**: Frame Count Transmit Mode The transmit trigger is based on configured number of CAN frames (EOBUFj_TTC.TFL) in a transmit Ethernet frame. 10_B **BFTM**: Buffer Fill Level Transmit Mode The transmit trigger condition is based on the fill size of the Ethernet Output Buffer as configured in EOBUFj_TTC.BUFT. 11_B **TTTM**: Time Triggered Transmit Mode The transmit trigger condition is based on a timer as configured in EOBUFj_TTC and EOBUFj_TTS.
0	15:11, 31:25	r	**Reserved** Read as 0; should be written with 0.

20.8.42 Ethernet output buffer j MAC header 0

EOBUFj_MAC_H0 (j=0-5) Offset address: 01154_H+j*38_H

Ethernet output buffer j MAC header 0 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
DA0	23:16	rw	**MAC Destination Address 0** This bit-field corresponds to bits 47 to 40 of the MAC destination address of the transmit Ethernet frame.
DA1	31:24	rw	**MAC Destination Address 1** This bit-field corresponds to bits 39 to 32 of the MAC destination address of the transmit Ethernet frame.
0	15:0	r	**Reserved** Read as 0; should be written with 0.

20.8.43 Ethernet output buffer j MAC header 1

EOBUFj_MAC_H1 (j=0-5) Offset address: 01158_H+j*38_H

Field	Bits	Type	Description
SUBTYP	7:0	r	**Subtype of AVTP Frame** This bit-field is used to identify the format being carried by AVTP frame. Non-Time Synchronous Control frames (NTSCF) has subtype value of 0x82.

(table continues...)

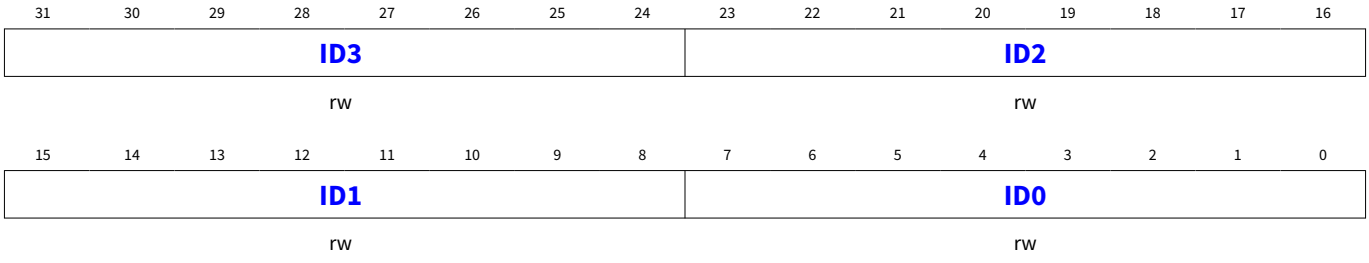
(continued)

Field	Bits	Type	Description
NTSCFDL_H	10:8	rh	**NTSCF Data Length High** This bit-field contains bits 10 to 8 of NTSCF data length field of the ACF payload data in bytes. The ACF CAN-Ethernet Format Engine updates the length on every ACF_CAN_BRIEF message written to the ACF payload section of Ethernet Output Buffer. It is reset to 0 when EOBUFj_STATUS.TXREQ is cleared to 0.
SV	15	rw	**Stream ID Valid** This bit-field indicates whether the STREAM_ID field contains an ID for a stream with a valid stream reservation.
NTSCFDL_L	23:16	rh	**NTSCF Data Length Low** This bit-field contains bits 7 to 0 of NTSCF data length field of the ACF payload data in bytes. The ACF CAN-Ethernet Format Engine updates the length on every ACF_CAN_BRIEF message written to the ACF payload section of Ethernet Output Buffer.
SN	31:24	rwh	**Sequence Number** This bit-field indicates the sequence of AVTP frames in a stream. Software can configure an initial value for a stream and the sequence number if incremented by the ACF CAN-Ethernet Format engine for every new transmit AVTP frame. Upon overflow, the value is wrapped around to 0x00 by hardware.
0	14:11	r	**Reserved** Read as 0; should be written with 0.

20.8.48 Ethernet output buffer j Stream ID configuration 0

EOBUFj_NTSCF_STREAM0_ID (j=0-5) Offset address: $0116C_H+j*38_H$

Ethernet output buffer j Stream ID configuration 0 Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ID0	7:0	rw	**Stream ID** This bit-field defines bits 63 to 56 of the identifier for stream identification. User must configure a valid Stream ID as defined in subclause 35.2.2.8.2 of IEEE Std 802.1Q - 2014.
ID1	15:8	rw	**Stream ID** This bit-field defines bits 55 to 48 of the identifier for stream identification. User must configure a valid Stream ID as defined in subclause 35.2.2.8.2 of IEEE Std 802.1Q - 2014.

(table continues...)

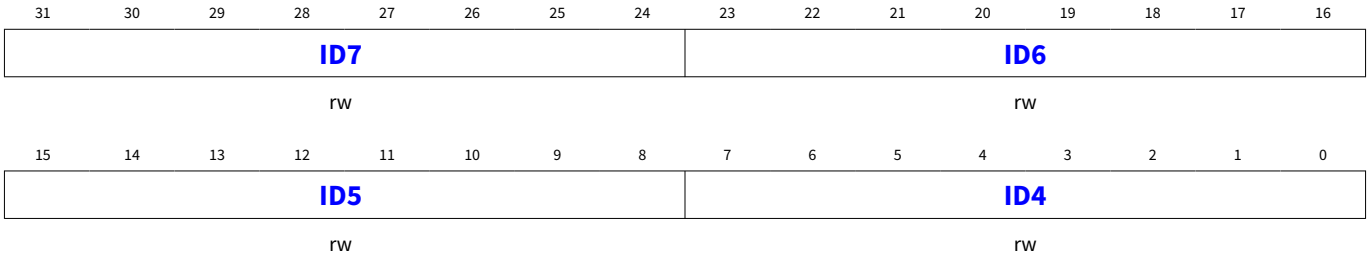
(continued)

Field	Bits	Type	Description
ID2	23:16	rw	**Stream ID** This bit-field defines bits 47 to 40 of the identifier for stream identification. User must configure a valid Stream ID as defined in subclause 35.2.2.8.2 of IEEE Std 802.1Q - 2014.
ID3	31:24	rw	**Stream ID** This bit-field defines bits 39 to 32 of the identifier for stream identification. User must configure a valid Stream ID as defined in subclause 35.2.2.8.2 of IEEE Std 802.1Q - 2014.

20.8.49 Ethernet output buffer j Stream ID configuration 1

EOBUFj_NTSCF_STREAM1_ID (j=0-5) Offset address: 01170_H+j*38_H

Ethernet output buffer j Stream ID configuration 1 Kernel Reset value: $0000\ 0000_H$

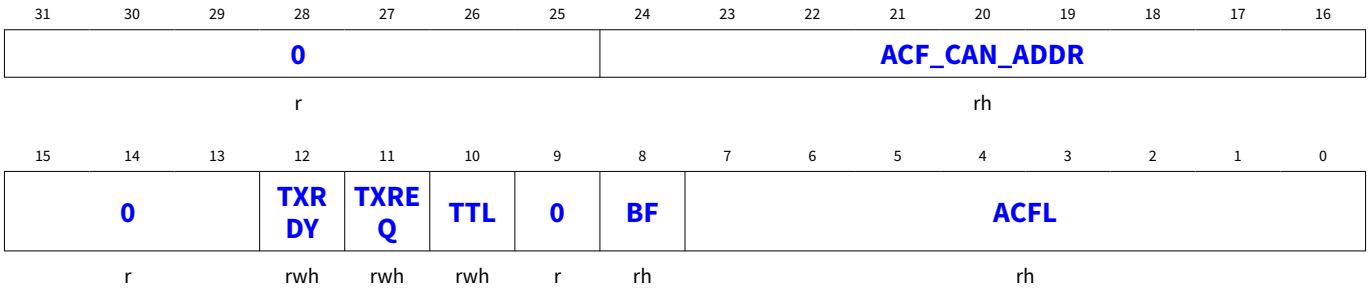


Field	Bits	Type	Description
ID4	7:0	rw	**Stream ID** This bit-field defines bits 31 to 24 of the identifier for stream identification. User must configure a valid Stream ID as defined in subclause 35.2.2.8.2 of IEEE Std 802.1Q - 2014.
ID5	15:8	rw	**Stream ID** This bit-field defines bits 23 to 16 of the identifier for stream identification. User must configure a valid Stream ID as defined in subclause 35.2.2.8.2 of IEEE Std 802.1Q - 2014.
ID6	23:16	rw	**Stream ID** This bit-field defines bits 15 to 8 of the identifier for stream identification. User must configure a valid Stream ID as defined in subclause 35.2.2.8.2 of IEEE Std 802.1Q - 2014.
ID7	31:24	rw	**Stream ID** This bit-field defines bits 7 to 0 of the identifier for stream identification. User must configure a valid Stream ID as defined in subclause 35.2.2.8.2 of IEEE Std 802.1Q - 2014.

20.8.50 Ethernet output buffer j status

EOBUFj_STATUS (j=0-5) Offset address: 01174_H+j*38_H

Ethernet output buffer j status Kernel Reset value: $0008\ 0000_H$



Field	Bits	Type	Description
ACFL	7:0	rh	**ACF CAN Fill Level** This bit-field indicates the number of CAN frames assembled in the Ethernet Output Buffer. The field is reset to 0x0 when EOBUFj_STATUS.TXREQ is cleared to 0.
BF	8	rh	**Buffer Full** This flag is set the EOBUF cannot accommodate the currently processed CAN frame. This bit shall only be cleared by hardware after TXREQ (in case of interrupt trigger) is cleared by software. In case the descriptor mode is used, this bit shall be cleared by hardware simultaneously while clearing EREQ.TXi_REQ. Note : The EOBUFj_CONFIG.PL needs to be configured according the Transmit trigger mode TTM and configuration TTC 0_B Free buffer 1_B EOBUF full
TTL	10	rwh	**Transmit Trigger Lost** This status bit is set by hardware when a transmit trigger condition is skipped as the corresponding Ethernet Output Buffer is empty (ACFL = 0). A software write with 1b clears the bit-field. A write with 0b has no effect.
TXREQ	11	rwh	**Ethernet Output Buffer Transmit Request** This bit-field indicates a valid transmit Ethernet frame in the Ethernet Output Buffer. The bit-field is set by hardware and cleared by software with write of 1b. A software write of 0b has no effect.
TXRDY	12	rwh	**Ethernet Output Buffer Transmit Ready** This bit-field is set by hardware when an Ethernet Output Buffer has a transmit trigger as configured in EOBUFj_CONFIG.TTM. When TTM = 0, the software write of 1b to this bit-field marks the transmit trgger condition. The flag is cleared by hardware, when the transmit Ethernet frame is prepared. A software write of 0b has no effect.
ACF_CAN_ADDR	24:16	rh	**ACF CAN Address Offset** This bit-field indicates the bits 10 to 2 of offset address from the start address of the Ethernet Output Buffer at which a new ACF_CAN_BRIEF message is to be stored. The bits 1 and 0 of the physical address to be considered as 0, as the address is always 32-bit aligned. The first ACF_CAN_BRIEF message is always stored at the offset address of 0x20. This field is reset to 0x8 (32-bit aligned representation of the offset address 0x20) when EOBUFj_STATUS.TXREQ is cleared to 0.

(table continues...)

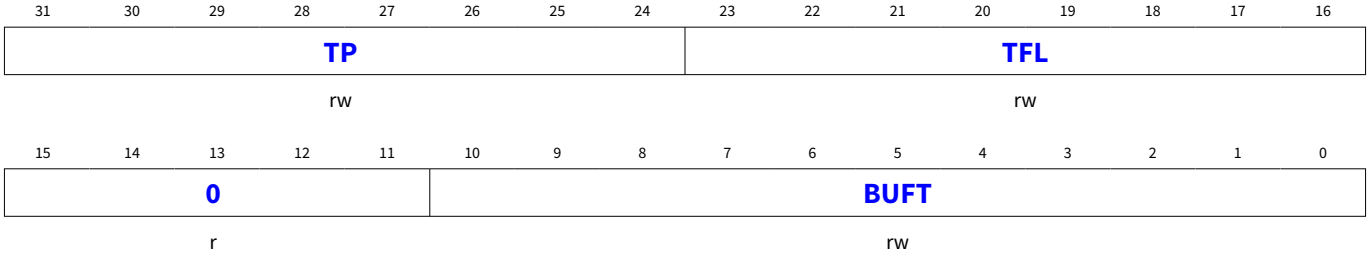
(continued)

Field	Bits	Type	Description
0	9, 15:13, 31:25	r	**Reserved** Read as 0. should be written with 0.

20.8.51 Ethernet output buffer j Transmit trigger configuration

EOBUFj_TTC (j=0-5) Offset address: 01178_H+j*38_H

Ethernet output buffer j Transmit trigger configuration Kernel Reset value: $0000\ 0000_H$

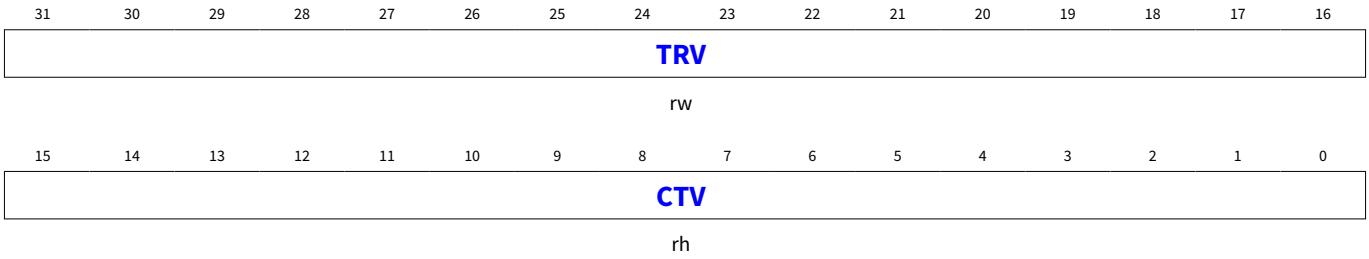


Field	Bits	Type	Description
BUFT	10:0	rw	**Buffer Threshold** When EOBUFj_CONFIG.TTM = 0x2, this bit-field configures the threshold size of the Ethernet Output Buffer ACF payload for transmit trigger. A valid value of this bit-field is between 0x1 till the maximum size of the Ethernet Output Buffer ACF payload as configured in EOBUFj_CONFIG.PL
TFL	23:16	rw	**Trigger Fill Level** When EOBUFj_CONFIG.TTM = 0x1, this bit-field defines the threshold for number of CAN frames in an Ethernet Output Buffer for transmit trigger condition. This bit-field cannot be zero. Note: This value has to be set based on the size of the incoming CAN frames and the size of the EOBUF. If this value is set too high, there might not be a transmit trigger
TP	31:24	rw	**Pre-scale for Timer** This bit-field defines the divider factor of the clock frequency used for transmit trigger. The prescaler used is (TP+1).
0	15:11	r	**Reserved** Read as 0; should be written with 0.

20.8.52 Ethernet output buffer j Timer threshold and status

EOBUFj_TTS (j=0-5) Offset address: $0117C_H+j*38_H$

Ethernet output buffer j Timer threshold and status Kernel Reset value: $0000\ 0000_H$

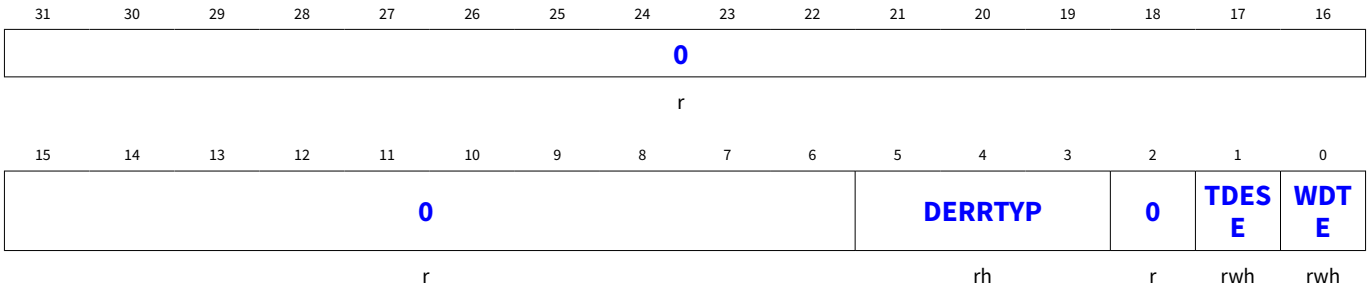


Field	Bits	Type	Description
CTV	15:0	rh	**Current Timer Value** This bit-field shows the current timer value. It is reloaded with the value of TRV upon a non-zero write to TRV bit-field and is decremented at the timer frequency. Transmit trigger condition occurs when it reaches 0. The timer is halted when TRV is written with 0.
TRV	31:16	rw	**Timer Reload Value** This bit-field defines the reload value of the transmit timers. It is configured by the software. A non-zero TRV value indicates that the timer is running. When TRV transitions from zero to non-zero value, the timer is started. The first transmit trigger is generated immediately. All subsequent transmit triggers would be at the intervals of the value configured. When the timer is already running and the SW changes the TRV to a different non-zero value, the timer automatically adjusts the time period without generating any surplus transmit trigger

20.8.53 Ethernet output buffer j error

EOBUFj_ERROR (j=0-5) Offset address: 01180_H+j*38_H

Ethernet output buffer j error Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
WDTE	0	rwh	**Ethernet watchdog timeout error** This bit is set by the hardware to indicate an Ethernet Watchdog timeout error in case of delayed availability of Ethernet frame to transmit within the EOBUF and delayed read of the Ethernet frame from EOBUF. Software write with 1 clears this bit

(table continues...)

(continued)

Field	Bits	Type	Description
TDESE	1	rwh	**Tx descriptor error** This bit is also set by hardware under following scenarios: Error in Tx descriptor is indicated by bit TDESCi_WR3G.DERR or TDESCi_WR3L.DE. Software write with 1 clears this bit. This bit shall be cleared by software only after clearing the corresponding TXi_REQ or FWDi_REQ
DERRTYP	5:3	rh	**Descriptor error type** This bit-field indicates the reason for TDESE error. This is set by the hardware when TDESE error occurs and cleared by hardware when the software clears TDESE 000_B No error 001_B Tx Poll Demand error Bus error during the Tx Tail Pointer register update 010_B Tx DMA state error The Tx DMA channel is in STOP state 011_B Incorrect OWN bit In case the OWN bit is not set while the Tx DMA channel is reading the Tx descriptor read format 100_B PTR mismatch read Mismatch between the Read format Tx descriptor pointed to by TETHDLi_CTRL.PTR and the descriptor being read by Tx DMA channel 101_B PTR mismatch Write-back Mismatch between the Tx descriptor pointed to by TETHDLi_CTRL.PTR and the descriptor being written back by Tx DMA channel 110_B Write-back error Write-back error in GETH Tx descriptor is indicated by bits TDESCi_WR3G.DERR and LETH Tx descriptor is indicated by TDESCi_WR3L.DE. Write-back error also occurs when the Write-back format has the OWN bit set and LD bit not set 111_B Reserved
0	2, 31:6	r	**Reserved** Read as 0; should be written with 0.

20.8.54 Stream ID filter i configuration

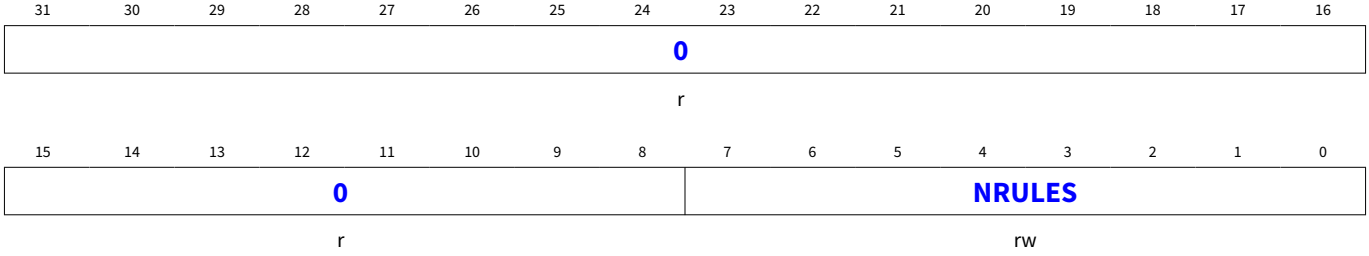
20.8.59 CAN transmit routing table i configuration

RTi_CONFIG (i=0-3) Offset address: 01340_H+i*8

CAN transmit routing table i configuration Kernel Reset value: $0000\ 0000_H$

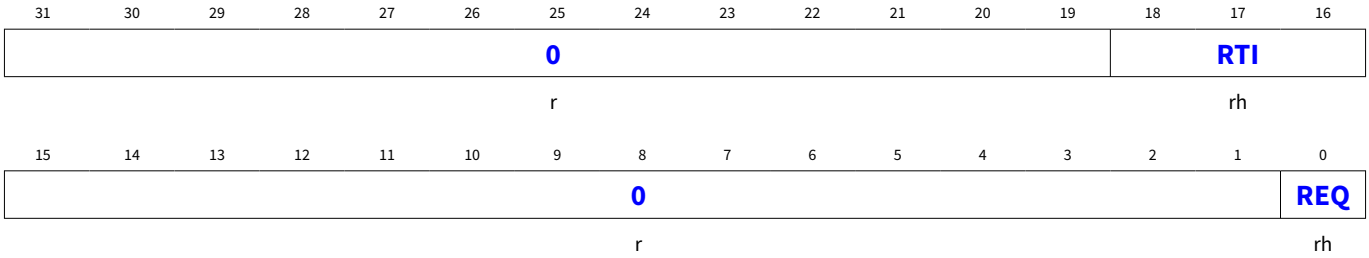


Field	Bits	Type	Description
NRULES	7:0	rw	**Number of routing rules** This bit-field configures the number of routing rules contained in the CAN Transmit Routing Table (RTi). Valid values are from 0 to 128. 0 - CAN Transmit Routing Table is disabled 1 to 128 - Number of routing rules in the CAN Transmit Routing Table >128 - Invalid configuration
0	31:8	r	**Reserved** Read as 0; should be written with 0.

20.8.60 Routing request configuration

RREQ_CONFIG Offset address: $0135C_H$

Routing request configuration Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
REQ	0	rh	**New Routing Request** This bit-field indicates a new routing request for CAN Transmit Routing Engine.
RTI	18:16	rh	**Routing Table Index** This bit-field indicates the CAN Transmit Routing Table to be used for the routing search done by the CAN Transmit Routing Engine. Valid values are 0 to 3.
0	15:1, 31:19	r	**Reserved** Read as 0; should be written with 0.

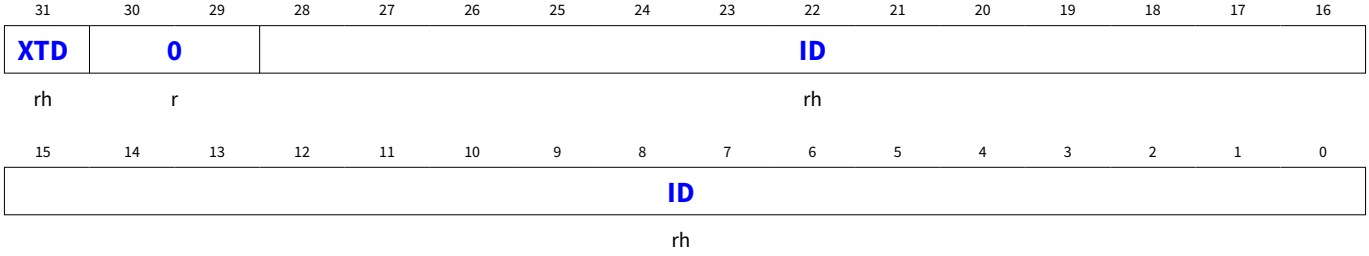
20.8.61 CAN ID request

RREQ_CID

CAN ID request

Offset address: 01360_H

Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ID	28:0	rh	**CAN Identifier** This bit-field indicates the CAN ID for which the routing request is initiated.
XTD	31	rh	**Extended Identifier** This bit-field indicates the ID format of the CAN ID. 0_B Standard 11-bit ID 1_B Extended 29-bit CAN ID
0	30:29	r	**Reserved** Read as 0; should be written with 0.

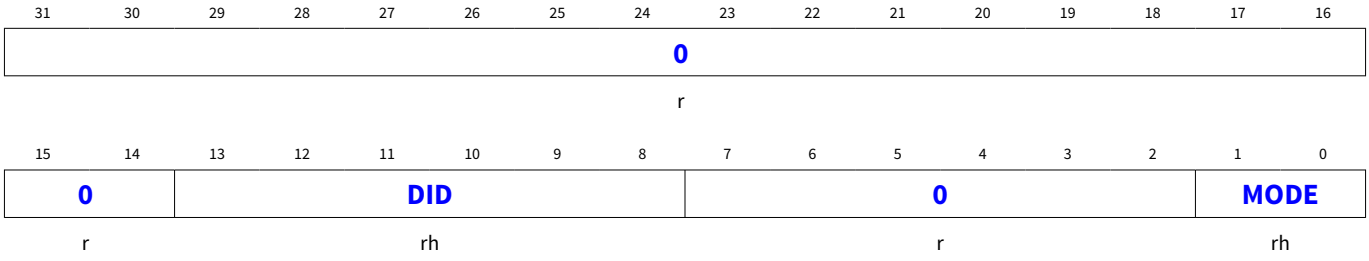
20.8.62 Uni-cast routing header

UCRH

Uni-cast routing header

Offset address: 01364_H

Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
MODE	1:0	rh	**Routing Rule Mode** It defines the type of the routing rule 0 - Uni-cast rule 1 - Multi-cast rule other - Reserved, considered as Uni-cast rule

(table continues...)

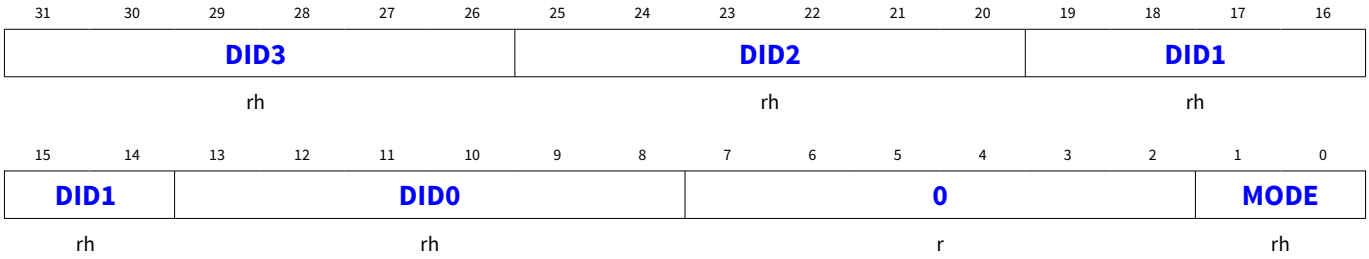
(continued)

Field	Bits	Type	Description
DID	13:8	rh	**Destination ID** This bit-field indicates the destination CAN node to which the received CAN frame has to be transferred. The destination CAN node is referenced using a unique ID as given in the Routing destination ID table.
0	7:2, 31:14	r	**Reserved** Read as 0; should be written with 0.

20.8.63 Multi-cast routing header

MCRH Offset address: 01364_H

Multi-cast routing header Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
MODE	1:0	rh	**Routing Rule Mode** It defines the type of the routing rule 0 - Uni-cast rule 1 - Multi-cast rule other - Reserved, considered as Uni-cast rule
DID0	13:8	rh	**Destination ID 1** This bit-field indicates the 1st destination CAN node to which the received CAN frame has to be transferred. The destination CAN node is referenced using a unique ID as given in the Routing destination ID table.
DID1	19:14	rh	**Destination ID 2** This bit-field indicates the 2nd destination CAN node to which the received CAN frame has to be transferred. The destination CAN node is referenced using a unique ID as given in the Routing destination ID table.
DID2	25:20	rh	**Destination ID 3** This bit-field indicates the 3rd destination CAN node to which the received CAN frame has to be transferred. The destination CAN node is referenced using a unique ID as given in the Routing destination ID table.

(table continues...)

(continued)

Field	Bits	Type	Description
DID3	31:26	rh	**Destination ID 4** This bit-field indicates the 4th destination CAN node to which the received CAN frame has to be transferred. The destination CAN node is referenced using a unique ID as given in the Routing destination ID table.
0	7:2	r	**Reserved** Read as 0; should be written with 0.

20.8.64 Routing status

RS Offset address: 01368_H

Routing status Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
Ci_THR (i=0-19)	i	rh	**CANi Transmit Host Buffer 0 Request** This bit-field indicates a free transmit buffer available in CANi interface
0	31:20	r	**Reserved** Read as 0; should be written with 0.

20.8.68 Destination memory i configuration

DMEMi_CONFIG (i=0-27) Offset address: $0137C_H+i*20_H$

Destination memory i configuration Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															CTYP
r															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OA								INP				ATH	AST	EN2	EN1
rw								rw				rw	rw	rwh	rwh

Field	Bits	Type	Description
EN1	0	rwh	**Enable Memory Destination 1** This bit-field is used to enable or disable the corresponding memory destination by the software. The software sets this bit by writing 1 to indicate that the buffer is ready for the CAN frame or CAN I-PDU to be stored. Software write with 0 has no effect. The hardware clears this bit after the CAN frames or CAN I-PDUs are assembled till the waternark level. 0_B DMEM not available 1_B DMEM available

(table continues...)

(continued)

Field	Bits	Type	Description
EN2	1	rwh	**Enable Memory Destination 2** This bit-field is used to enable or disable the corresponding memory destination by the software. The software sets this bit by writing 1 to indicate that the buffer is ready for the CAN frame or CAN I-PDU to be stored. Software write with 0 has no effect. The hardware clears this bit after the CAN frames or CAN I-PDUs are assembled till the wraparound level. 0_B DMEM not available 1_B DMEM available
AST	2	rw	**Append Status Information** When set to 1, the DMEMi_STATUS register content is appended along with the CAN message in the memory destination 0_B **DIS**: DMEMi_STATUS not appended 1_B **EN**: DMEMi_STATUS appended
ATH	3	rw	**Append Timing Header** When set to 1, the CAN timing header is appended to the CAN message at the memory destination 0_B **DIS**: THEAD not appended 1_B **EN**: THEAD appended
INP	7:4	rw	**Interrupt Node Pointer** This bit-field configures the interrupt line to be triggered in case of a watermark or address wraparound event. Valid values are 0 till 7. Other values are reserved and will be considered as 0.
OA	15:8	rw	**Offset Address** The offset address by which the destination address is incremented after every routing operation to the destination memory. It defines the size of each buffer at the destination memory. OA[0:2] is considered always as 000b so that the calculated absolute destination address is always 64-bit aligned. In case of CAN I-PDU routing, the OA is considered for the count based trigger mode to calculate the size of the frame data buffers 1 and 2. The OA should be configured by the user based upon the number of I-PDUs (DMEMi_WM and DMEMi_WA levels) and the size of the I-PDUs that are to be assembled within the DMEMi. The OA value should also include the Timing header (optional) and I-PDU header. It is illegal to configure the OA smaller than the combined sizes of the incoming CAN messages Note: Configuring the OA for Classical CAN I-PDU (Timing header (optional) + PDU header + Payload), but incoming CAN FD I-PDUs into the DMEMi would lead to buffer overflow as the size would be too small Note: Avoid setting OA as 0x20 for CAN frames with larger payload of more than 8 bytes. Such frames are rejected and an error is triggered but the status flags WAF, WMF and BC are updated even though the frame is rejected

(table continues...)

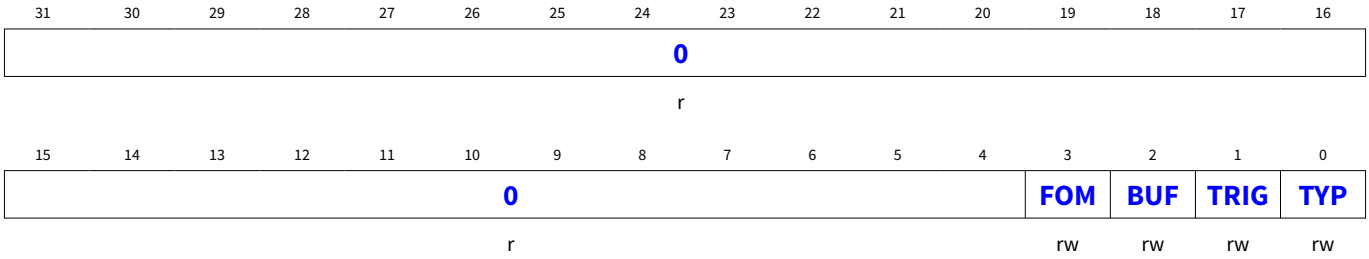
(continued)

Field	Bits	Type	Description
CTYP	16	rw	**Type of CAN message** This bit indicates the type of CAN message that is stored in the DMEM. When the incoming CAN frame has the DID which is configured to accept CAN I-PDU or vice-versa, the CAN message is discarded and Invalid destination ID error is triggered 0_B CAN Frame 1_B CAN I-PDU
0	31:17	r	**Reserved**

20.8.69 Destination memory i transfer mode configuration

DMEMi_MODE (i=0-27) Offset address: 01380_H+i*20_H

Destination memory i transfer mode configuration Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TYP	0	rw	**PDU Mode enabled** The bit-field configures the destination memory in the case of a CAN frame or CAN I-PDU 0_B **MUXDIS**: Padding Padding bits are present between CAN messages 1_B **MUXEN**: No padding No padding bits present between CAN messages
TRIG	1	rw	**Trigger Mode** This bit-field selects between two interrupt trigger modes 0_B **INDEX**: Index-based interrupt trigger This index based trigger is valid only for CAN I-PDUs. The watermark and wraparound interrupts are triggered based on the DMEMi_FDBI 1_B **COUNT**: Count-based interrupt trigger The watermark and wraparound interrupts are triggered based on the buffer count DMEMi_STATUS.BC

(table continues...)

(continued)

Field	Bits	Type	Description
BUF	2	rw	**Buffer Mode** This bit configures the buffer split of the DMEM 0_B **SINGLE**: Single buffer mode The DMEM is divided into two parts Frame data buffer 1 and Frame data buffer 2 based on the Watermark level and Wraparound levels respectively. Note: Both the Frame data buffers always starts at a 64-bit aligned address. 1_B **CONT**: Continuous buffer mode The DMEM is treated as a continuous buffer. Only wraparound level is considered
FOM	3	rw	**FDBI overflow mode** This bit controls the data path of the new CAN frame or CAN I-PDU in case of no space in the Frame data buffer 0_B Continue If frame or I-PDU is received that does not fit in the current part of the DMEM Frame data buffer, it is placed into the other buffer when the EN bit is set. Otherwise there is a buffer overflow error triggered. 1_B Overflow The frame or I-PDU is discarded and an overflow error is triggered
0	31:4	r	**Reserved** Read as 0; should be written as 0

20.8.70 Destination memory i status

DMEMi_STATUS (i=0-27) Offset address: 01390_H+i*20_H

Destination memory i status Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MC												0	BO	WAF	WMF
rwh												r	rwh	rwh	rwh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BC								0	SID						NM
rh								r	rh						rwh

Field	Bits	Type	Description
NM	0	rwh	**New Message** This bit indicates a new message is transferred to destination memory. Hardware sets this bit and software write with 1 clears the bit. Software write with 0 has no effect.
SID	6:1	rh	**Source ID** This bit-field indicates the source from which the message is fetched.

(table continues...)

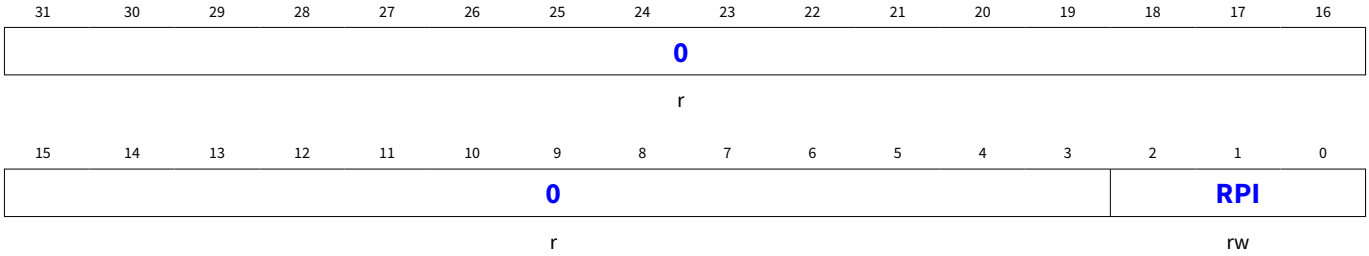
(continued)

Field	Bits	Type	Description
BC	15:8	rh	**Buffer Counter** This bit-field is incremented on every transfer of message to the destination memory. The counter is reset to 0 when a wraparound event has occurred. Note: In index mode, if CAN messages with zero payload or less payload are received, the count could exceed 255 depending on the configuration. In this case, the counter wraps around to 0
WMF	16	rwh	**Watermark Flag** This bit-field indicates watermark event. Hardware sets the flag and a software write with 1b clears the flag.
WAF	17	rwh	**Wraparound Flag** This bit-field is set when address wraparound has occurred. Hardware sets the flag and a software write with 1b clears the flag.
BO	18	rwh	**Buffer Overflow** This bit indicates a buffer overflow. This bit is set by hardware in case of an buffer overflow error (DBOE) and cleared by software by writing 1. Writing 0 has no effect.
MC	31:20	rwh	**Message Counter** This bit-field is incremented on every message transfer to the destination. A software write with a non zero value resets the counter value to 0. The counter wraps around to 0 upon overflow.
0	7, 19	r	**Reserved** Read as 0; should be written as 0

20.8.71 Destination memory i resource partition

DMEMi_RP (i=0-27) Offset address: 01394_H+i*20_H

Destination memory i resource partition Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RPI	2:0	rw	**Resource Partition Index** This bit-field indicates the Resource Partition allocated to the destination memory i.
0	31:3	r	**Reserved** Read as 0; should be written with 0.

20.8.72 Move engine source address

This SFR indicates the first address the Move Engine is reading from.

ME_SRCA Offset address: $016F8_H$

Move engine source address Kernel Reset value: $0000\ 0000_H$

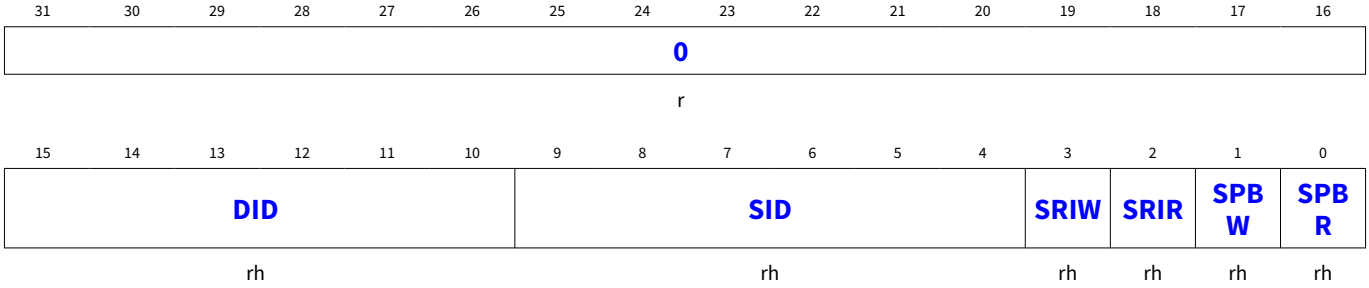
ADR	31:0	rh	**Destination Address** This bit-field indicates the current address which the Move Engine is writing to.

20.8.74 Move engine state

ME_STATE Offset address: 01700_H

Move engine state Kernel Reset value: $0000\ 0000_H$



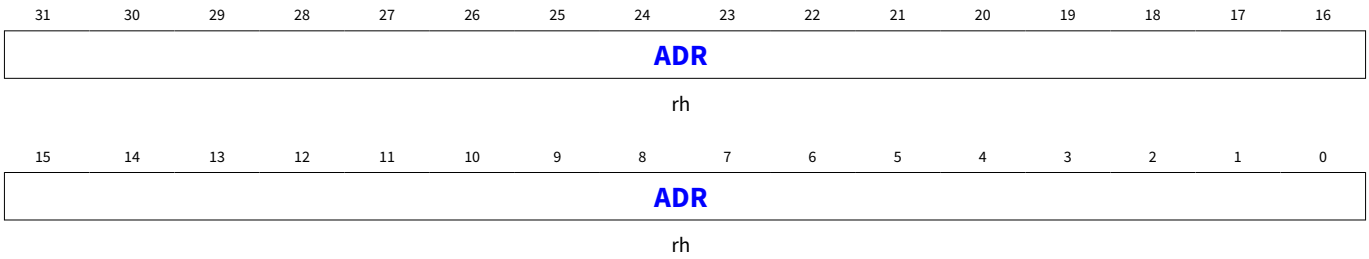
Field	Bits	Type	Description
SPBR	0	rh	**SPB Read** This bit-field is set when an FPI/SPB read operation is currently performed by the Move Engine
SPBW	1	rh	**SPB Write** This bit-field is set when an FPI/SPB write operation is performed by the Move Engine
SRIR	2	rh	**SRI Read** This bit-field is set when a SRI read operation is currently performed by the Move Engine
SRIW	3	rh	**SRI Write** This bit-field is set when a SRI write operation is performed by the Move Engine
SID	9:4	rh	**Source ID** This bit-field indicates the source ID of the current routing operation
DID	15:10	rh	**Destination ID** This bit-field indicates the destination ID of the current routing operation.
0	31:16	r	**Reserved** Read as 0; Write with 0

20.8.75 Move engine first error source address

This SFR indicates the first read address at which the Move Engine has an error.

ME_FESRCA Offset address: 01704_H

Move engine first error source address Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ADR	31:0	rh	**First Error Source Address** This bit-field indicates the source address (that is start address of CAN Receive Host Buffer or CAN Output Buffer) for the routing request which has at least one of the IRDE, DBOE, SPBBE, SRIBE errors. The value of this bit-field is frozen once any of the aforementioned error flags are set. The value of this bit-field is ignored when there is no error (all Move Engine error status flags IRDE, DBOE, SPBBE, SRIBE are 0).

20.8.76 Move engine first error destination address

This SFR indicates the first write address at which the Move Engine has an error.

ME_FEDESTA Offset address: 01708_H

Move engine first error destination address Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADR															
rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADR															
rh															

Field	Bits	Type	Description
ADR	31:0	rh	**First Error Destination Address** This bit-field indicates the destination address (that is start address of virtual CAN buffer at memory destination or CAN Input Buffer or CAN Output Buffer) for the routing request which has at least one of the DBOE, SPBBE, SRIBE errors. The value of this bit-field is frozen once any of the aforementioned error flags are set. The value of this bit-field is ignored when there is no error (Move Engine error status flags DBOE, SPBBE, SRIBE are 0) or when FEDID has reserved destination ID values.

20.8.77 Move engine error register

ME_ERR Offset address: $0170C_H$

Move engine error register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FEDID						FESID						FEDIR	FEC		
rh						rh						rh	rh		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0											IRDE	DBOE	SRIBE	SPBBE	0
r											rwh	rwh	rwh	rwh	r

Field	Bits	Type	Description
SPBBE	1	rwh	**SPB Bus Transaction error** This bit-field indicates an error occurred during an FPI/SPB transaction performed by Move Engine. Hardware sets the flag and a software write with 1b clears the flag.
SRIBE	2	rwh	**SRI Transaction Error** This bit-field indicates an error occurred during an SRI transaction performed by the Move Engine. Hardware sets the flag and a software write with 1b clears the flag. Note: The hardware sets this bit and triggers interrupt INT_13 also in the event of read data error detection and correction (EDC) error and read data transaction ID error on SRI master interface (MIF)
DBOE	3	rwh	**Destination Buffer Overflow Error** This bit-field indicates the destination buffer overflow condition that is, the CAN frame size is larger than the buffer size of the corresponding destination (shown in FEDID). Hardware sets the flag and a software write with 1b clears the flag.
IRDE	4	rwh	**Invalid Routing Destination Error** This bit-field indicates in case of routing requests with a destination ID value corresponding to a reserved value or when the corresponding destination is disabled. Hardware sets the flag and a software write with 1b clears the flag.
FEC	18:16	rh	**First error code** This bit-field is bit encoded to indicate which error first occurred. This denotes that the FEDIR, FESID and FEDID corresponds to the error indicated by this bit-field 000_B No error 001_B IRDE 010_B DBOE 011_B SRIBE 100_B SPBBE **others,** Reserved
FEDIR	19	rh	**First Error Direction** This bit indicates whether access error was for read or write access 0_B Read 1_B Write

(table continues...)

(continued)

Field	Bits	Type	Description
FESID	25:20	rh	**First Error Source ID** This bit-field indicates the source ID of the first routing operation which has at least one of IRDE, DBOE, SPBBE or SRIBE errors. The value of this bit-field is ignored when there is no error (all Move Engine error status flags IRDE, DBOE, SPBBE or SRIBE are 0). The value of this bit-field is frozen once any of the aforementioned error flags are set. When the source ID of the routing or forwarding request is known for the corresponding transaction, this bit-field is updated with the SID. Otherwise in the case of the following scenarios where the source ID is unknown, this bit-field is set to: b111100 when a bus transaction error occurs during the write operation of the Rx descriptor Tail Pointer. RDESE is set and interrupt INT_10 triggered b111101 when a bus transaction error occurs during the write operation of the Tx descriptor Tail Pointer. TDESE is set and interrupt INT_14 triggered b111110 when a bus transaction error occurs during the read operation of the DMA status register.
FEDID	31:26	rh	**First Error Destination ID** This bit-field indicates the destination ID of the first routing operation which has at least one of IRDE, DBOE, SPBBE or SRIBE errors. The value of this bit-field is ignored when there is no error (all Move Engine error status flags IRDE, DBOE, SPBBE or SRIBE are 0). The value of this bit-field is frozen once any of the aforementioned error flags are set. When the destination ID of the routing or forwarding request is known for the corresponding transaction, this bit-field is updated with the DID. Otherwise in the case of the following scenarios when the destination ID is unknown, this bit-field is set to: b111111 when a bus transaction error occurs during the read operation of the routing header (RHEAD). b111100 when a bus transaction error occurs during the write operation of the Rx descriptor Tail Pointer. RDESE is set and interrupt INT_10 triggered b111101 when a bus transaction error occurs during the write operation of the Tx descriptor Tail Pointer. TDESE is set and interrupt INT_14 triggered b111110 when a bus transaction error occurs during the read operation of the DMA status register.
0	0, 15:5	r	**Reserved** Read as 0; should be written as 0

20.8.78 Interrupt signal

DRE signals events to the Interrupt Router module through 16 interrupt lines INT[15:0]. This register shows the status of interrupt signalled for the events grouped to an interrupt line. It means at least one status event has occurred within an interrupt line. The bit-fields value is purely OR-ing of the status bits corresponding to the interrupt line.

INTSIG Offset address: 01710_H

Interrupt signal Kernel Reset value: $0000\ 0800_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0							FCS	TRIG	0	EIFID		DMACH			EIF
r							rw	rw	r	rw		rw			rw

Field	Bits	Type	Description
EIF	0	rw	**Ethernet Interface** This bit-field selects between the LETH and GETH interface to which the Rx and Tx descriptor list is mapped. One descriptor list consists of 4 descriptors 0_B GETH 1_B LETH
DMACH	3:1	rw	**DMA channel number** This bit-field configures the Ethernet DMA CH to which the Rx descriptor list belongs. Two Rx descriptor lists cannot be mapped to the same Rx DMA channel. This bit-field is used by the hardware only to generate the FWD ID and not in identifying the DMA channel mapped. Note: Irrespective of the value configured in this bit-field, the DRE only receives/transmits frames from/to the Ethernet DMA channel whose Tail Pointer address is configured in the Ethernet Address Database (EAD) at the corresponding index RETHDLi_CTRL.EIF and EIFID

(table continues...)

(continued)

Field	Bits	Type	Description
EIFID	5:4	rw	**Ethernet interface ID** This bit-field indicates the source or destination Ethernet Interface ID. x is determined by bit EIF Note: When EIFID > 1, EIF will be LETH by default 00_B **xETH0**: xETH0 interface 01_B **xETH1**: xETH1 interface 10_B **xETH2**: xETH2 interface EIF shall be LETH 11_B **xETH3**: xETH3 interface EIF shall be LETH
TRIG	7	rw	**Trigger type** This bit-field configures the type of trigger from the Ethernet Descriptor Handler. This bit-field is cleared by software only at the end, after the configuration of the Rx DMA channel, in order for the DRE to start preparing the Rx descriptors 0_B **DMA**: Rx from Ethernet DMA This is the descriptor mode where Rx descriptors are prepared by the DRE. Ethernet frame is received from Ethernet DMA. The Ethernet Descriptor Handler gives a Receive Poll Demand by updating the Ethernet Rx DMA channel Tail Pointer. 1_B **IR**: Trigger interrupt An interrupt is triggerd to the IR. The SW shall write an Ethernet frame into the EIBUF based on the interrupt. The software shall clear the TRIG bit only at the end, after the configuration of the Rx descriptor list, in order to trigger the DRE to start preparing the Rx descriptors.
FCS	8	rw	**Receive Ethernet packet has FCS field** This bit-field indicates if the Ethernet frame received by the corresponding Rx descriptor has FCS field included or not. This bit-field must be configured by SW during the initialization phase of DRE and shall not be changed during run-time. This bit-field value is used by DRE only for Ethernet-to-Ethernet forwarding use-case, to configure the TDESCi_RD3.CPC bit-field of the corresponding Transmit descriptor. If FCS = 0, then the corresponding TDESCi_RD3.CPC bit-field is set to b00 (Enable CRC and PAD insertion) or else TDESCi_RD3.CPC bit-field is set to b10 (Disable CRC insertion).
IOC	26	rw	**Interrupt on completion** This bit is the static configuration for Rx descriptors RDESCi_RD3G.IOC for GETH and RDESCi_RD3L.IOC for LETH

(table continues...)

(continued)

Field	Bits	Type	Description
STOPACK	27	rh	**STOP acknowledge** This bit is set by the hardware in case the STOP bit is set by the software. The Rx Descriptor Handler sets this bit after it finishes the ongoing processes and goes into IDLE state. The software must then update the RETHDLi_CTRL.PTR after STOPACK is set. The RETHDLi_CTRL.STOP bit must be cleared by software after updating the RETHDLi_CTRL.PTR. Clearing of STOP bit will trigger DRE to clear STOPACK and set OWN bit of the RDESCi pointed to by the new updated RETHDLi_CTRL.PTR and trigger a Receive Poll Demand to the Rx DMA channel. Note: All writes to RETHDLi_CTRL.PTR bit while the STOPACK bit is 0 are ignored and have no effect
STOP	28	rw	**STOP bit** This bit is set by the software in the event that the descriptor pointer RETHDLi_CTRL.PTR needs to be reset. The Rx Descriptor Handler sets the RETHDLi_CTRL.STOPACK after it finishes the ongoing processes and goes into IDLE state. The software must then update the RETHDLi_CTRL.PTR after STOPACK is set. The STOP bit must be cleared by software after updating the RETHDLi_CTRL.PTR. Clearing of STOP bit will trigger DRE to clear STOPACK and set OWN bit of the RDESCi pointed to by the newly updated RETHDLi_CTRL.PTR and trigger a Receive Poll Demand to the Rx DMA channel.
PTR	31:29	rwh	**Descriptor pointer** This bit-field points to the index of the next Rx descriptor to be prepared and whose OWN bit should be set by the Ethernet Descriptor Handler. Valid values are 0 to 3. This bit-field wraps around after 3 Note: For descriptors owned by the DRE, the OWN bit of RDESCi_WR3G for GETH or RDESCi_WR3L for LETH is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1 All writes to this bit-field are ignored when RETHDLi_CTRL.STOPACK is not set to 1
0	6, 25:9	r	**Reserved** Read as 0; should be written with 0.

20.8.81 Tx Ethernet descriptor list i configuration and control

TETHDLi_CTRL (i=0-5) Offset address: $0174C_H+i*10_H$

Tx Ethernet descriptor list i configuration and control Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PTR			STOP	STOPACK	IOC	SAIC			SLOTNUM				0		
rwh			rw	rh	rw	rw			rw				r		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0									TRIG	0		DMACH			0
r									rw	r		rw			r

Field	Bits	Type	Description
DMACH	3:1	rw	**DMA channel number** This bit-field is redundant to RETHDLi_CTRL.DMACH and indicates the Ethernet DMA CH to which the Tx descriptor list belongs. Two Tx descriptor lists cannot be mapped to the same Tx DMA channel. This bit-field acts as status information only. The hardware considers that Rx and Tx DMA channels have the same ID. For example, LETH0 has Rx DMA channel 0 and Tx DMA channel 0 mapped to DRE. Note: Irrespective of the value configured in this bit-field, the DRE only receives/transmits frames from/to the Ethernet DMA channel whose Tail Pointer address is configured in the Ethernet Address Database (EAD) at the corresponding index RETHDLi_CTRL.EIF and EIFID
TRIG	6	rw	**Trigger type** This bit-field configures the type of trigger from the Ethernet Descriptor Handler 0_B **DMA**: Tx to Ethernet DMA This is the descriptor mode where Tx descriptors are prepared by DRE. Ethernet frame is transmitted to Ethernet DMA. The Ethernet Descriptor Handler gives a Transmit Poll Demand by updating the Ethernet Tx DMA channel Tail Pointer. 1_B **IR**: Trigger interrupt An interrupt is triggerd to the IR. The SW shall read the Ethernet frame from the EOBUF/EIBUF based on the interrupt
SLOTNUM	22:19	rw	**Slot Number configuration** This bit is the static configuration for all Tx descriptors TDESCi_RD3.SLOTNUM.
SAIC	25:23	rw	**SA insertion control configuration** This bit is the static configuration for all Tx descriptors TDESCi_RD3.SAIC. • 2'b00: Do not include the source address • 2'b01: Reserved • 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses • 2'b11: Reserved
IOC	26	rw	**Interrupt on completion** This bit is the static configuration for all Tx descriptors TDESCi_RD2.IOC
STOPACK	27	rh	**STOP acknowledge** This bit is set by the hardware in case the STOP bit is set by the software. The Tx Descriptor Handler sets this bit after it finishes the ongoing processes and goes into IDLE state. The software must then update the TETHDLi_CTRL.PTR after STOPACK is set. The TETHDLi_CTRL.STOP bit must be cleared by software after updating the TETHDLi_CTRL.PTR. Clearing of STOP bit will trigger DRE to clear STOPACK and set OWN bit of the TDESCi pointed to by the new updated TETHDLi_CTRL.PTR and trigger a Transmit Poll Demand to the Tx DMA channel. Note: All writes to TETHDLi_CTRL.PTR bit while the STOPACK bit is 0 are ignored and have no effect

(table continues...)

(continued)

Field	Bits	Type	Description
STOP	28	rw	**STOP bit** This bit is set by the software in case the descriotor pointer TETHDLi_CTRL.PTR needs to be reset. The Tx Descriptor Handler sets the TETHDLi_CTRL.STOPACK after it finishes the ongoing processes and goes into IDLE state. The software must then update the TETHDLi_CTRL.PTR after STOPACK is set. The STOP bit must be cleared by software after updating the TETHDLi_CTRL.PTR. Clearing of STOP bit will trigger DRE to clear STOPACK and set OWN bit of the TDESCi pointed to by the new updated TETHDLi_CTRL.PTR and trigger a Transmit Poll Demand to the Tx DMA channel.
PTR	31:29	rwh	**Descriptor pointer** This bit-field points to the index of index of the next Tx descriptor to be prepared and whose OWN bit should be set by the Ethernet Descriptor Handler Valid values are 0 to 3. This bit-field wraps around after 3 Note : For descriptors owned by the DRE, the OWN bit of TDES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1 All writes to this bit-field is ignored when TETHDLi_CTRL.STOPACK is not set to 1
0	0, 5:4, 18:7	r	**Reserved** Read as 0; should be written with 0

rh			r	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
TXi_REQ (i=0-5)	i	rwh	**Tx request** This bit-field is set by hardware whenever there is an ACF Ethernet frame to be transmitted in the EOBUF. It is cleared by hardware after the Ethernet frame is sucessfully transmitted and there is no error Write-back format of the descriptor. In the case of an interrupt (INT_15), this bit is cleared by the hardware after the frame is read from EOBUF by the software. In the case of error, this bit is cleared by software after reading the frame from the buffer. If there is a buffer full condition, this would be cleared by hardware together with the EOBUFj_STATUS.BF flag. Software write with 1 clears this flag. Software write with 0 has no effect
FWDi_REQ (i=0-5)	i+6	rwh	**Forward request** This bit-field is set by the Forwarding engine whenever there is an Ethernet frame to be forwarded in the EIBUF. When there is a matching filter element, the Forwarding engine sets the EREQ.FWDi_REQ of the corresponding Tx descriptor list FT_FEj_FRULE.DSEL. It is cleared by the Descriptor Handler after the Ethernet frame is sucessfully forwarded and there is no error Write-back format of the descriptor. In case of error, this bit is cleared by software after reading the frame from the buffer. Software write with 1 clears this flag. Software write with 0 has no effect

(table continues...)

(continued)

Field	Bits	Type	Description
CBI0	15:13	rh	**Current buffer index 0** Indicates the buffer index of EIBUF for which the Tx descriptors of Tx descriptor list 0 are being prepared in case of forwarding

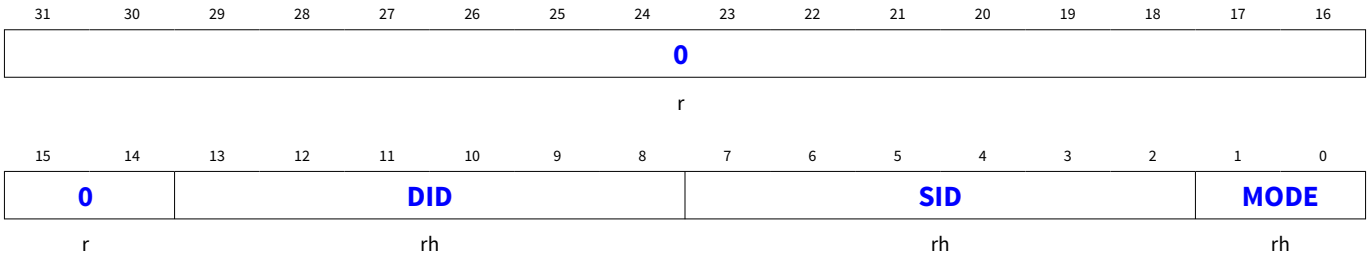
20.8.94 CAN Output Buffer List RAM interface

20.8.94.1 RAM uni-cast routing header

The CAN Output Buffer List is stored in DRE RAM starting from DRE RAM base address + 0x6E0. The number of buffers in the list is 64.

COBUFj_UCRH (j=0-63) Offset address: $006E0_H+j*50_H$

RAM uni-cast routing header RAMInit value: $XXXX\ XXXX_H$



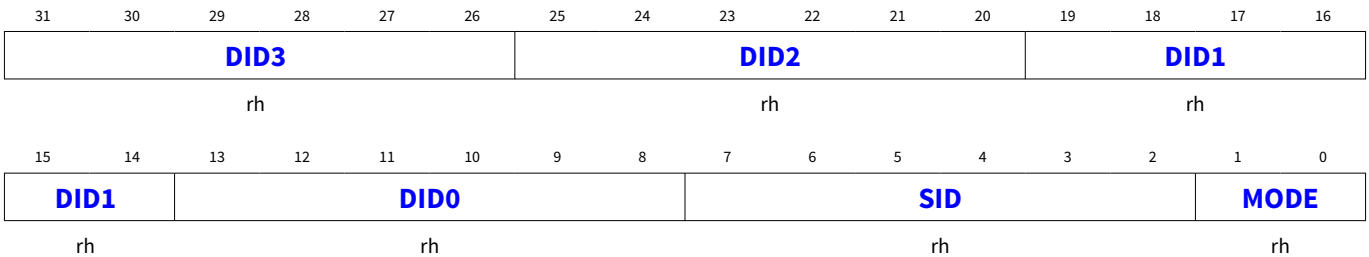
Field	Bits	Type	Description
MODE	1:0	rh	**Routing Rule Mode** It defines the type of the routing rule 0 - Uni-cast rule 1 - Multi-cast rule other - Reserved, considered as Uni-cast rule
SID	7:2	rh	**Source ID** This bit-field indicates the source from which the CAN frame is received. The source module are referenced using a unique ID as given in the Routing destination ID table. • EIBUF0 : 0x18 • EIBUF1 : 0x19 • EIBUF2 : 0x1A • EIBUF3 : 0x1B • EIBUF4 : 0x1C • EIBUF5 : 0x1D
DID	13:8	rh	**Destination ID** This bit-field indicates the destination CAN node to which the received CAN frame has to be transferred. The destination CAN node are referenced using a unique ID as given in the Routing destination ID table.
0	31:14	r	**Reserved** Read as 0; should be written with 0.

20.8.94.2 RAM multi-cast routing header

The CAN Output Buffer List is stored in DRE RAM starting from DRE RAM base address + 0x6E0. The number of buffers in the list is 64.

COBUFj_MCRH (j=0-63) Offset address: $006E0_H+j*50_H$

RAM multi-cast routing header RAMInit value: $XXXX\ XXXX_H$



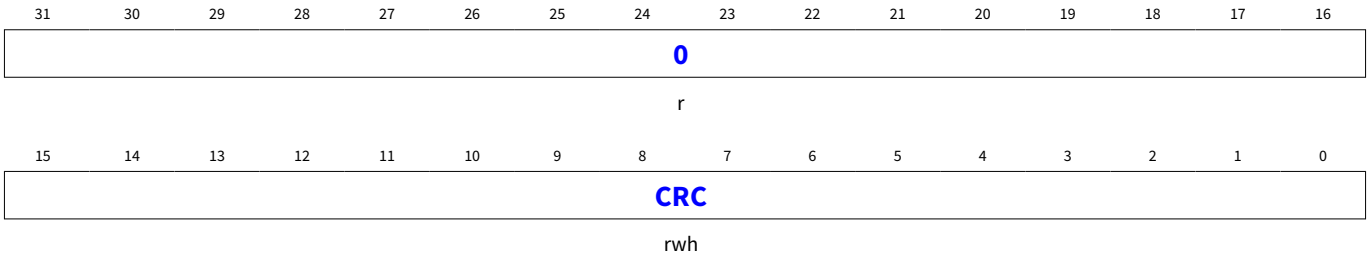
Field	Bits	Type	Description
MODE	1:0	rh	**Routing Rule Mode** It defines the type of the routing rule 0 - Uni-cast rule 1 - Multi-cast rule other - Reserved, considered as Uni-cast rule
SID	7:2	rh	**Source ID** This bit-field indicates the source from which the CAN frame is received. The source module are referenced using a unique ID as given in the Routing destination ID table. • EIBUF0 : 0x18 • EIBUF1 : 0x19 • EIBUF2 : 0x1A • EIBUF3 : 0x1B • EIBUF4 : 0x1C • EIBUF5 : 0x1D
DID0	13:8	rh	**Destination ID 1** This bit-field indicates the 1st destination CAN node to which the received CAN frame has to be transferred. The destination CAN node is referenced using a unique ID as given in the Routing destination ID table.
DID1	19:14	rh	**Destination ID 2** This bit-field indicates the 2nd destination CAN node to which the received CAN frame has to be transferred. The destination CAN node is referenced using a unique ID as given in the Routing destination ID table.
DID2	25:20	rh	**Destination ID 3** This bit-field indicates the 3rd destination CAN node to which the received CAN frame has to be transferred. The destination CAN node is referenced using a unique ID as given in the Routing destination ID table.
DID3	31:26	rh	**Destination ID 4** This bit-field indicates the 4th destination CAN node to which the received CAN frame has to be transferred. The destination CAN node is referenced using a unique ID as given in the Routing destination ID table.

20.8.94.3 RAM COBUF CRC computed by DRE

The CAN Output Buffer List is stored in DRE RAM starting from DRE RAM base address + 0x6E0. The number of buffers in the list is 64.

COBUFj_CRC (j=0-63) Offset address: $006E4_H+j*50_H$

RAM COBUF CRC computed by DRE RAMInit value: $XXXX\ XXXX_H$



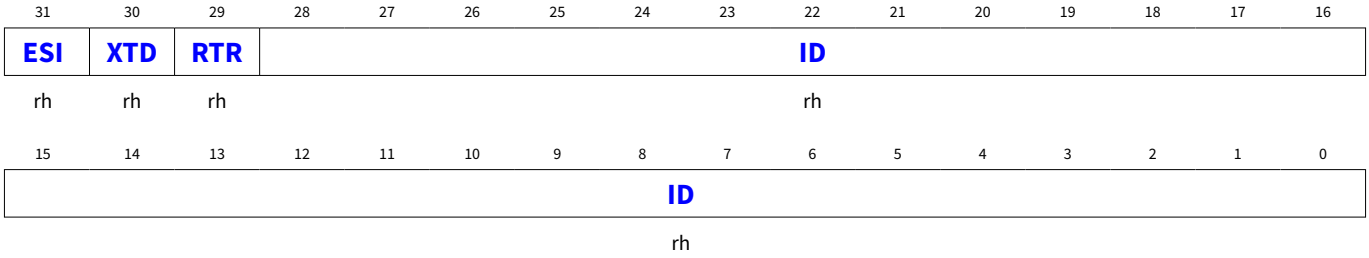
Field	Bits	Type	Description
CRC	15:0	rwh	**CRC** CRC computed by DRE Note: In case of Multi-cast, an intermediate CRC calculated over R0, R1 (except ANMF, RXTS, FIDX and BRS which are considered as zero), safety critical CAN payload (without DID) is stored
0	31:16	r	**Reserved**

20.8.94.4 RAM COBUF register 0

The CAN Output Buffer List is stored in DRE RAM starting from DRE RAM base address + 0x6E0. The number of buffers in the list is 64.

COBUFj_R0 (j=0-63) Offset address: $006E8_H+j*50_H$

RAM COBUF register 0 RAMInit value: $XXXX\ XXXX_H$



Field	Bits	Type	Description
ID	28:0	rh	**CAN Identifier** Standard or extended identifier depending on bit XTD. A standard identifier is stored into ID[28:18].
RTR	29	rh	**Remote Transmission Request** This bit-field indicates that the CAN frame is a remote frame. There are no remote frames in CAN FD format. In case of CAN FD frame (FDF = 1), this bit-field is ignored. 0_B Received frame is a data frame 1_B Received frame is a remote frame
XTD	30	rh	**Extended Identifier** Indicates whether the CAN frame has a standard or extended identifier. 0_B 11-bit standard identifier 1_B 29-bit extended identifier

(table continues...)

(continued)

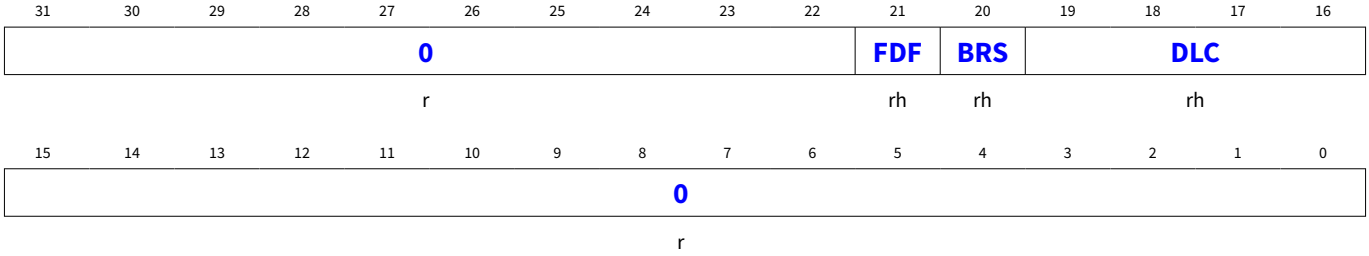
Field	Bits	Type	Description
ESI	31	rh	**Error State Indicator** 0_B Transmitting node is error active 1_B Transmitting node is error passive

20.8.94.5 RAM COBUF register 1

The CAN Output Buffer List is stored in DRE RAM starting from DRE RAM base address + 0x6E0. The number of buffers in the list is 64.

COBUFj_R1 (j=0-63) Offset address: $006EC_H+j*50_H$

RAM COBUF register 1 RAMInit value: $XXXX\ XXXX_H$



Field	Bits	Type	Description
DLC	19:16	rh	**Data Length Code** 0_H CAN + CAN FD: received frame has 0 data bytes … 8_H CAN + CAN FD: received frame has 8 data bytes 9_H CAN FD: received frame has 12 (9*4-24) data bytes CAN: received frame has 8 data bytes … C_H CAN FD: received frame has 24 (12*4-24) data bytes CAN: received frame has 8 data bytes D_H CAN FD: received frame has 32 (13*16-176) data bytes CAN: received frame has 8 data bytes … F_H CAN FD: received frame has 64 (15*16-176) data bytes CAN: received frame has 8 data bytes
BRS	20	rh	**Bit Rate Switch** 0_B Frame received without bit rate switching 1_B Frame received with bit rate switching
FDF	21	rh	**Frame Data Format** 0_B Standard frame format 1_B CAN FD frame format (new DLC-coding and CRC)
0	15:0, 31:22	r	**Reserved** Read as 0; should be written with 0.

20.8.94.6 RAM COBUF data byte m

This register indicates value of CAN payload data byte m.

COBUFj_DB (j=0-63;m=0-63) Offset address: $006F0_H+j*50_H+m$

RAM COBUF data byte m RAMInit value: XX_H

7	6	5	4	3	2	1	0
DB							
rh							

Field	Bits	Type	Description
DB	7:0	rh	**Data Byte m**

20.8.95 CAN Transmit Routing Table RAM interface

20.8.95.1 RAM routing table CAN ID filter configuration

The CAN Transmit Routing Table i elements are stored in DRE RAM starting from DRE RAM base address + 0x1AE0 + i*RTi_CONFIG.NRULES. The number of routing elements within each routing table is configured in RTi_CONFIG.NRULES.

RT_REj_CIDFC (j=0-127) Offset address: $01AE0_H+j*8$

RAM routing table CAN ID filter configuration RAMInit value: $XXXX\ XXXX_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0	MODE		CANID2												
r	rw		rw												

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDS			CANID1												
rw			rw												

Field	Bits	Type	Description
CANID1	12:0	rw	**CAN ID 1** The first CAN identifier used for filter operation. The function of CAN ID 1 depends on the configured "MODE" bit-field. For standard CAN IDs (RREQ_CID.XTD = 0b) only bits 10 to 0 are considered. For extended CAN IDs (RREQ_CID.XTD = 1b) all 13 bits are considered.
IDS	15:13	rw	**ID Shift** This bit-field is used only when RREQ_CID.XTD = 1b. The extended ID is shifted left by this bit-field value and the most significant 13 bits of the shifted CAN ID are used for filtering operation.
CANID2	28:16	rw	**CAN ID 2** The second CAN identifier used for filter operation. The function of CAN ID 2 depends on the configured "MODE" bit-field. For standard CAN IDs (RREQ_CID.XTD = 0b) only bits 10 to 0 are considered. For extended CAN IDs (RREQ_CID.XTD = 1b) all 13 bits are considered.

(table continues...)

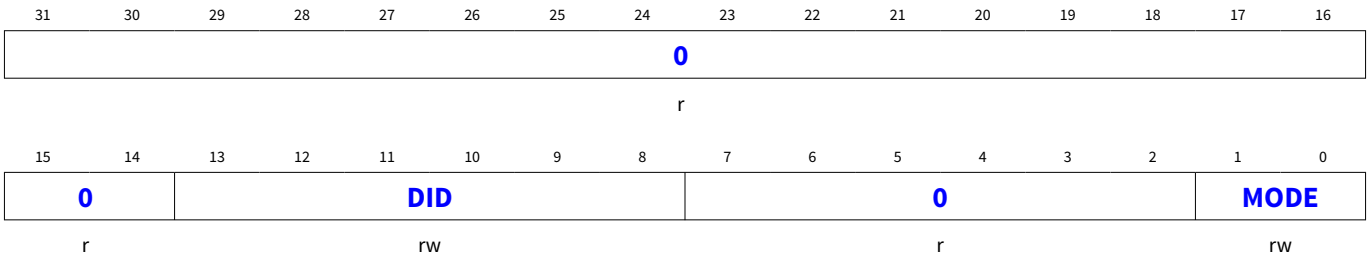
(continued)

Field	Bits	Type	Description
MODE	30:29	rw	**Filter Mode** This bit-field configures the filter mode. 00_B Classical ID Filter "CAN ID 1" is used as the filter ID and "CAN ID 2" is used as mask 01_B Dual ID Filter "CANID1" or "CANID2" is used as the filter ID. No masking is done. 10_B Range ID Filter The range of IDs from "CANID1" till "CANID2" are used as filter IDs. It has to be ensured by the user that "CANID1" < "CANID2" 11_B Reserved Reserved; not to be used
0	31	r	**Reserved** Read as 0; should be written with 0.

20.8.95.2 RAM routing table uni-cast routing

RT_REj_UCR (j=0-127) Offset address: $01AE4_H+j*8$

RAM routing table uni-cast routing RAMInit value: $XXXX\ XXXX_H$



Field	Bits	Type	Description
MODE	1:0	rw	**Routing Rule Mode** It defines the type of the routing rule 0 - Uni-cast rule 1 - Multi-cast rule other - Reserved, considered as Uni-cast rule
DID	13:8	rw	**Destination ID** This bit-field indicates the destination CAN node to which the received CAN frame has to be transferred. The destination CAN node is referenced using a unique ID as given in the Routing destination ID table.
0	7:2, 31:14	r	**Reserved** Read as 0; should be written with 0.

20.8.95.3 RAM routing table multi-cast routing

RT_REj_MCR (j=0-127) Offset address: $01AE4_H+j*8$

RAM routing table multi-cast routing RAMInit value: $XXXX\ XXXX_H$

20.8.97 Ethernet descriptors RAM interface

20.8.97.1 RAM TDESC word 0 read format

The Ethernet Transmit descriptor list j is stored in DRE RAM at DRE RAM base address + 0x3140 + j*0xC80
There are 4 descriptors (each of which is made up of four 32-bit words) within each descriptor list.

TDESCi_RD0 (i=0-3) Offset address: 03140_H+i*10_H

RAM TDESC word 0 read format RAMInit value: $XXXX\ XXXX_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BUF1AP															
rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BUF1AP															
rwh															

Field	Bits	Type	Description
BUF1AP	31:0	rwh	**Ethernet Buffer Address Pointer 1** These bits indicate the physical address of the frame in EOBUF or EIBUF. Bit FD shall be set.

20.8.97.2 RAM TDESC word 0 Write-back format

The Ethernet Transmit descriptor list j is stored in DRE RAM at DRE RAM base address + 0x3140 + j*0xC80
There are 4 descriptors (each of which is made up of four 32-bit words) within each descriptor list.

TDESCi_WR0 (i=0-3) Offset address: 03140_H+i*10_H

RAM TDESC word 0 Write-back format RAMInit value: $XXXX\ XXXX_H$

rwh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BUF2AP															
rwh															

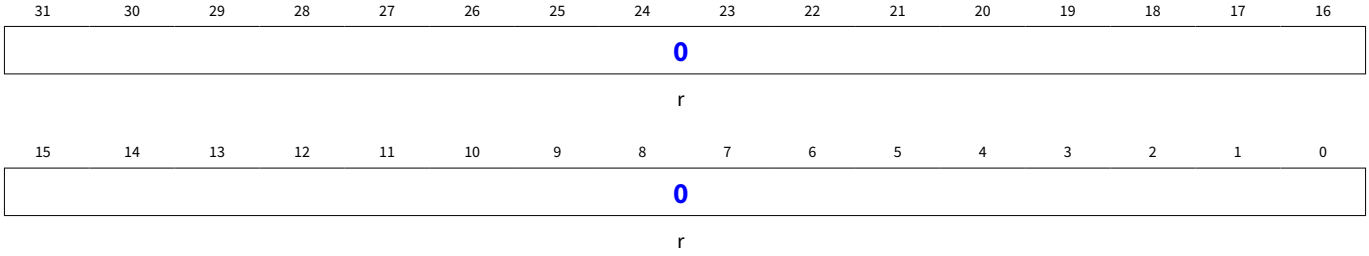
Field	Bits	Type	Description
BUF2AP	31:0	rwh	**Ethernet Buffer Address Pointer 2** Shall be 0 as there is no segmentation of frame

20.8.97.4 RAM TDESC word 1 Write-back format

The Ethernet Transmit descriptor list j is stored in DRE RAM at DRE RAM base address + 0x3140 + j*0xC80
There are 4 descriptors (each of which is made up of four 32-bit words) within each descriptor list.

TDESCi_WR1 (i=0-3) Offset address: 03144_H+i*10_H

RAM TDESC word 1 Write-back format RAMInit value: $XXXX\ XXXX_H$



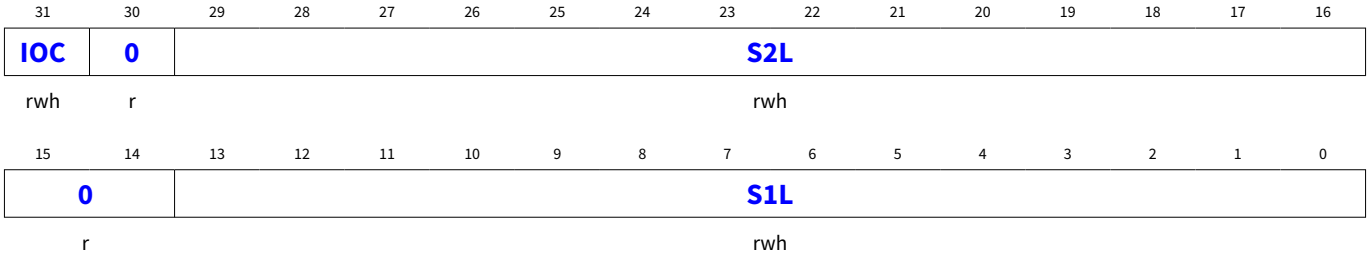
Field	Bits	Type	Description
0	31:0	r	**Reserved** Read as 0; should be written as 0

20.8.97.5 RAM TDESC word 2 read format

The Ethernet Transmit descriptor list j is stored in DRE RAM at DRE RAM base address + 0x3140 + j*0xC80
There are 4 descriptors (each of which is made up of four 32-bit words) within each descriptor list.

TDESCi_RD2 (i=0-3) Offset address: 03148_H+i*10_H

RAM TDESC word 2 read format RAMInit value: $XXXX\ XXXX_H$



Field	Bits	Type	Description
S1L	13:0	rwh	**Size of buffer 1** Indicates the size of the frame EOBUF/EIBUF (in bytes)
S2L	29:16	rwh	**Size of buffer 2** Shall be 0 as there is no second buffer in DRE

(table continues...)

(continued)

Field	Bits	Type	Description
IOC	31	rwh	**Interrupt on Completion** This bit sets the TI bit in the DMA_CH(#i)_Status register after the present packet has been transmitted.
0	15:14, 30	r	**Reserved** Read as 0; should be written as 0

20.8.97.6 RAM TDESC word 2 Write-back format

The Ethernet Transmit descriptor list j is stored in DRE RAM at DRE RAM base address + 0x3140 + j*0xC80
There are 4 descriptors (each of which is made up of four 32-bit words) within each descriptor list.

TDESCi_WR2 (i=0-3) Offset address: 03148_H+i*10_H

RAM TDESC word 2 Write-back format RAMInit value: $XXXX\ XXXX_H$

20.8.97.7 RAM TDESC word 3 read format

The Ethernet Transmit descriptor list j is stored in DRE RAM at DRE RAM base address + 0x3140 + j*0xC80
There are 4 descriptors (each of which is made up of four 32-bit words) within each descriptor list.

TDESCi_RD3 (i=0-3) Offset address: $0314C_H+i*10_H$

RAM TDESC word 3 read format RAMInit value: $XXXX\ XXXX_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OWN	CTXT	FD	LD	CPC		SAIC			SLOTNUM				0	CIC	
rwh	rwh	rwh	rwh	rwh		rwh			rwh				r	rwh	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	FL														
r	rwh														

Field	Bits	Type	Description
FL	14:0	rwh	**Packet Length** Length of the packet to be transmitted in bytes. This equals the total length of the packet to be transmitted: Header length + Payload length

(table continues...)

(continued)

Field	Bits	Type	Description
CIC	17:16	rwh	**Checksum Insertion control** Checksum insertion is disabled. Shall be set to 0
SLOTNUM	22:19	rwh	**Slot Number** Holds the static value configured in TETHDLi_CTRL.SLOTNUM. These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by D0 or D1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH(#i)_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels.
SAIC	25:23	rwh	**SA insertion control** Holds the static value configured in TETHDLi_CTRL.SAIC These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. If the Source Address field is modified in a packet, the MAC automatically recalculates and replaces the CRC bytes. Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of bits [24:23]: • 2'b00: Do not include the source address • 2'b01: Reserved • 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses • 2'b11: Reserved
CPC	27:26	rwh	**CRC Pad Control** This field controls the CRC and Pad Insertion for TX packet. This field is valid only when the first descriptor bit (TDESCi_RD3[29]) is set • 2'b10 Disable CRC Insertion: The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer • 2'b00 CRC and Pad Insertion: The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically adds padding and CRC to a frame shorter than 60 bytes In case of Ethernet frames to be forwarded from EIBUF, this bit is configured based on the RETHDLi_CTRL.FCS bit. If FCS = 0, then the corresponding TDESCi_RD3.CPC bit-field is set to b00 (Enable CRC and PAD insertion) or else TDESCi_RD3.CPC bit-field is set to b10 (Disable CRC insertion) This field shall be set to 0 in case the Ethernet frame is in EOBUF
LD	28	rwh	**Last Descriptor** When this bit is set, it indicates that the buffer contains last segment of the packet

(table continues...)

(continued)

Field	Bits	Type	Description
FD	29	rwh	**First Descriptor** When this bit is set, it indicates that the buffer contains first segment of the packet.
CTXT	30	rwh	**Context Type** Shall be set to 0 for Normal descriptor
OWN	31	rwh	**OWN bit** When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the DRE owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffers.
0	15, 18	r	**Reserved** Read as 0; should be written as 0

20.8.97.8 RAM TDESC word 3 Write-back format for GETH

The Ethernet Transmit descriptor list j is stored in DRE RAM at DRE RAM base address + 0x3140 + j*0xC80
There are 4 descriptors (each of which is made up of four 32-bit words) within each descriptor list.

TDESCi_WR3G (i=0-3) Offset address: $0314C_H+i*10_H$

RAM TDESC word 3 Write-back format for GETH RAMInit value: $XXXX\ XXXX_H$

rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh				rwh	rwh	rwh	rwh

Field	Bits	Type	Description
IHE	0	rwh	**IP Header Error** When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when Tx Checksum Offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload. In full duplex mode, when EST/Qbv is enabled and this bit is set, it indicates the frame drop status due to Frame Size error or Schedule Error.
DB	1	rwh	**Deferred Bit** This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
UF	2	rwh	**Underflow Error** This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: • The DMA encountered an empty Transmit Buffer while transmitting the packet • The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the suspended state and sets the underflow bit corresponding to a queue in the MTL_Interrupt_Status register.

(table continues...)

(continued)

Field	Bits	Type	Description
ED	3	rwh	**Excessive Deferral** This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbps mode or Jumbo Packet enabled mode) if DC bit is set in the MAC_Configuration register. When TBS is enabled in full duplex mode and this bit is set, it indicates that the frame has been dropped after the expiry time has reached.
CC	7:4	rwh	**Collision Count** This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.
EC	8	rwh	**Excessive Collision** This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is aborted.
LC	9	rwh	**Late Collision** This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode and 512 byte times including Preamble and Carrier Extension in GMII mode). This bit is not valid if Underflow Error is set.
NC	10	rwh	**No Carrier** This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
LOC	11	rwh	**Loss of Carrier** This bit indicates that Loss of Carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
PCE	12	rwh	**Payload Checksum Error** This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when Bus Error is detected during packet transfer. When the Full Checksum Offload engine is not enabled, this bit is reserved.
FF	13	rwh	**Packet Flushed** This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.

(table continues...)

(continued)

Field	Bits	Type	Description
JT	14	rwh	**Jabber Timeout** This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC_Configuration register is not set.
ES	15	rwh	**Error Summary** This bit indicates the logical OR of the following bits: • TDES3[0]: IP Header Error • TDES3[14]: Jabber Timeout • TDES3[13]: Packet Flush • TDES3[12]: Payload Checksum Error • TDES3[11]: Loss of Carrier • TDES3[10]: No Carrier • TDES3[9]: Late Collision • TDES3[8]: Excessive Collision • TDES3[3]: Excessive Deferral • TDES3[2]: Underflow Error This bit is also set when EUE (bit 16) is set.
EUE	16	rwh	**ECC Uncorrectable Error Status** Indicates the ECC uncorrectable error in the TSO memory. Uncorrectable error in Transmit FIFO memory is reported with (Bit 13) FF = 1. This is because, all such packets are flushed by LETH.
TTSS	17	rwh	**Tx Timestamp Status** This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES0 and TDES1 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is set. This bit is valid only when IEEE 1588 timestamping feature is enabled; otherwise, it is reserved.
DE	23	rwh	**Descriptor Error** When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during Write-back while closing the descriptor.
LD	28	rwh	**Last Descriptor** When this bit is set, it indicates that the buffer contains last segment of the packet
FD	29	rwh	**First Descriptor** When this bit is set, it indicates that the buffer contains first segment of the packet.
CTXT	30	rwh	**Context Type** Shall be set to 0 for Normal descriptor
OWN	31	rwh	**OWN bit** When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the DRE owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffers.

rwh	rwh	rwh	rwh	rwh				rwh	rwh	rwh	rwh	rwh	rwh		

Field	Bits	Type	Description
PT	2:0	rwh	**Payload type** These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE): • 3'b000: Unknown type or IP/AV payload not processed • 3'b001: UDP • 3'b010: TCP • 3'b011: ICMP • 3'b110: AV Tagged Data Packet • 3'b111: AV Tagged Control Packet • 3'b101: AV Untagged Control Packet • 3'b100: IGMP if IPV4 Header Present bit is set else DCB (LLDP) Control Packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 3'b000.
IPHE	3	rwh	**IP Header Error** When this bit is set, it indicates either of the following: • The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes. • The IP datagram version is not consistent with the Ethernet Type value. • Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either bit 5 or bit 4 is set. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
IPV4	4	rwh	**IPV4 Header Present** This bit indicates that an IPV4 header is detected. When the SPH bit of RDESCi_WR3 is set, the IPV4 header is available in the header buffer area to which RDESCi_WR0 is pointing.
IPV6	5	rwh	**IPV6 Header Present** This bit indicates that an IPV6 header is detected. When the Enable Split Header Feature option is selected and the SPH bit of Control Register of a channel is set, the IPV6 header is available in the header buffer area to which RDES0 is pointing.
IPCB	6	rwh	**IP Checksum Bypassed** This bit indicates that the checksum offload engine is bypassed. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.

(table continues...)

(continued)

Field	Bits	Type	Description
IPCE	7	rwh	**IP Payload Error** When this bit is set, it indicates either of the following: • The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment. • The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. • The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDESCi_WR3 is not set when this bit is set.
PMT	11:8	rwh	**PTP Message Type** These bits are encoded to give the type of the message received: • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011 to 1110: Reserved • 1111: PTP packet with Reserved message type These bits are available only when you select the Timestamp feature.
PFT	12	rwh	**PTP Packet Type** This bit indicates that the PTP message is sent directly over Ethernet. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
PV	13	rwh	**PTP Version** This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
TSA	14	rwh	**Timestamp Available** When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDESCi_WR2) and word 1 (RDESCi_WR1). This is valid only when the Last Descriptor bit (RDESCi_WR3 [28]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.

(table continues...)

(continued)

Field	Bits	Type	Description
TD	15	rwh	**Timestamp Dropped** This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
OPC	31:16	rwh	**OAM Sub-Type Code, or MAC Control Packet opcode** • OAM Sub-Type Code If bits[18:16] of RDESCi_WR3 are set to 3'b111, this field contains the OAM sub-type and code fields. • MAC Control Packet opcode If bits[18:16] of RDESCi_WR3 are set to 3'b110, this field contains the MAC Control packet opcode field.

20.8.97.16 RAM RDESC word 2 read format

The Ethernet Receive descriptor list j is stored in DRE RAM at DRE RAM base address + 0x3180 + j*0xC80

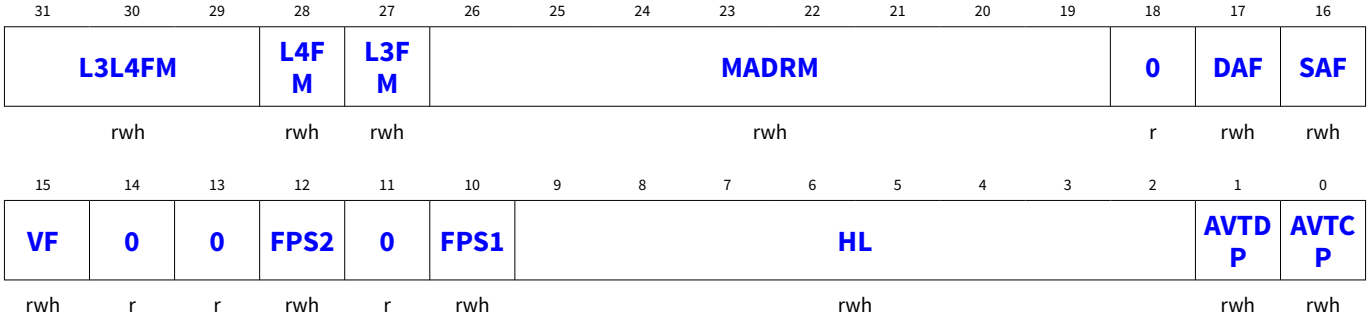
20.8.97.17 RAM RDESC word 2 Write-back format GETH

The Ethernet Receive descriptor list j is stored in DRE RAM at DRE RAM base address + 0x3180 + j*0xC80
There are 4 descriptors (each of which is made up of four 32-bit words) within each descriptor list.

RDESCi_WR2G (i=0-3) Offset address: 03188_H+i*10_H

RAM RDESC word 2 Write-back format GETH RAMInit value: $XXXX\ XXXX_H$



Field	Bits	Type	Description
AVTCP	0	rwh	**AV Tagged Control Packet** When L34T=0b0000, this bit is set to 1 when AV Tagged Control packet is received. When L34T is non-zero, this bit is HL[0] for packet split by the MAC at L3 or L4 header. Note: The DRE does not support split header feature. The DRE identifies the frame to be AV tagged when AVTDP or AVTCP is set irrespective of L34T value.
AVTDP	1	rwh	**AV Tagged Data Packet** When L34T=0b0000, this bit is set to 1 when AV Tagged Data packet is received. When L34T is non-zero, this bit is HL[1] for packet split by the MAC at L3 or L4 header Note: The DRE does not support split header feature. The DRE identifies the frame to be AV tagged when AVTDP or AVTCP is set irrespective of L34T value.
HL	9:2	rwh	**L3/L4 Header Length** This field contains the length of the header of the packet split by the MAC at L3 or L4 header boundary as identified by the MAC receiver. This field is valid only when the first descriptor bit is set (FD = 1). The header data is written to the Buffer 1 address of corresponding descriptor. If header length is zero, it implies that the MAC did not identify and split the header and both Buffer 1 and Buffer 2 are used for storing the packet.
FPS1	10	rwh	**Flexible Receive Parser bit 1**
FPS2	12	rwh	**Flexible Receive Parser bit 2**
VF	15	rwh	**VLAN Filter Status** When this bit is set, it indicates that the VLAN Tag of received packet passed the VLAN filter. For a tunneled packet, only the outer Ethernet header fields are used for filtering
SAF	16	rwh	**SA Address Filter Fail** When this bit is set, it indicates that the packet failed the SA Filter in the MAC. For a tunneled packet, only the outer Ethernet header fields are used for filtering
DAF	17	rwh	**Destination Address Filter Fail** When this bit is set, it indicates that the packet failed the DA Filter in the MAC. For a tunneled packet, only the outer Ethernet header fields are used for filtering.

(table continues...)

(continued)

Field	Bits	Type	Description
MADRM	26:19	rwh	**MAC Address Match or Hash Value** This field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset. This bit-field is used by the DRE to generate the forward ID.
L3FM	27	rwh	**Layer 3 Filter Match** When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: • All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed • All enabled filter fields match When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by bits[31:29]. For a tunneled packet, only the outer L3-L4 header fields are used for filter comparison
L4FM	28	rwh	**Layer 4 Filter Match** When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: • Layer 3 fields are not enabled and all enabled Layer 4 fields match • All enabled Layer 3 and Layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by bits[31:29] For a tunneled packet, only the outer L3-L4 header fields are used for filter comparison.
L3L4FM	31:29	rwh	**Layer 3 and Layer 4 Filter Number Matched** This bit-field is used by the DRE to generate the forward ID. These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet: • 000: Filter 0 • 001: Filter 1 • 010: Filter 2 • 011: Filter 3 • 100: Filter 4 • 101: Filter 5 • 110: Filter 6 • 111: Filter 7 This field is valid only when bit 28 or bit 27 is set high. When more than one filter matches, these bits give the number of lowest filter. For a tunneled packet, only the outer L3-L4 header fields are used for comparison

rwh	rwh	r			rwh	rwh									

Field	Bits	Type	Description
HL	9:0	rwh	**L3/L4 Header Length** This field contains the length of the header of the packet split by the MAC at L3 or L4 header boundary as identified by the MAC receiver. This field is valid only when the first descriptor bit is set (FD = 1). The header data is written to the Buffer 1 address of corresponding descriptor. If header length is zero, this field is not valid. It implies that the MAC did not identify and split the header. This field is valid when the Enable Split Header Feature option is selected.
ARPNR	10	rwh	**ARP Reply Not Generated** When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). This bit is reserved when the Enable IPv4 ARP Offload option is not selected.
ITS	14	rwh	**Inner VLAN Tag Filter Status** This bit is valid only when DWC_EQOS_ERVFE is enabled. This bit is valid only for Double VLAN Tagged frames, when Double VLAN Processing is enabled. For more information, see the Filter Status topic of LETH.

(table continues...)

(continued)

Field	Bits	Type	Description
OTS	15	rwh	**VLAN Filter Status** When set, this bit indicates that the VLAN Tag of the received packed passed the VLAN filter. This bit is valid only when DWC_EQOS_ERVFE is not enabled. If DWC_EQOS_ERVFE is enabled, the bit is redefined as Outer VLAN Tag Filter Status (OTS). This bit is valid for both Single and Double VLAN Tagged frames
SAF	16	rwh	**SA Filter Fail or Packet dropped** SA Address Filter Fail When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the SA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet is dropped (RXPD) by the parser. Note: When this bit is set, ES bit of RDESCi_WR3 is also set.
DAF	17	rwh	**DA Filter Fail or Packet parsing incomplete** Destination Address Filter Fail When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the DA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet parsing is incomplete (RXPI) due to ECC error. Note: When this bit is set, ES bit of RDESCi_WR3 is also set.
HF	18	rwh	**Hash Filter Status** When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits[26:19] indicate the hash value. Note: This status is not available when Flexible RX Parser is enabled.
MADRM	26:19	rwh	**MAC Address Match or Hash Value** When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset. When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register. Note: This status is not available when Flexible RX Parser is enabled.
L3FM	27	rwh	**Layer 3 Filter Match** When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: • All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed • All enabled filter fields match When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by bits[31:29]. Note: This status is not available when Flexible RX Parser is enabled.

(table continues...)

(continued)

Field	Bits	Type	Description
L4FM	28	rwh	**Layer 4 Filter Match** When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: • Layer 3 fields are not enabled and all enabled Layer 4 fields match • All enabled Layer 3 and Layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by bits[31:29]. Note: This status is not available when Flexible RX Parser is enabled.
L3L4FM	31:29	rwh	**Layer 3 and Layer 4 Filter Number Matched** These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet: • 000: Filter 0 • 001: Filter 1 • 010: Filter 2 • 011: Filter 3 • 100: Filter 4 • 101: Filter 5 • 110: Filter 6 • 111: Filter 7 This field is valid only when bit 28 or bit 27 is set high. When more than one filter matches, these bits give the number of lowest filter. Note: This status is not available when Flexible RX Parser is enabled.

0															
r															

Field	Bits	Type	Description
BUF1V	24	rwh	**Buffer 1 address valid** When this bit is set, it indicates the DMA that the EIBUF address specified in the RDESCi_RD0.BUF1AP is valid.
IOC	30	rwh	**Interrupt on Completion** This bit sets the TI bit in the DMA_CH(#i)_Status register after the present packet has been transmitted.
OWN	31	rwh	**OWN bit** When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the DRE owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffers.
0	23:0, 29:25	r	**Reserved** Read as 0; should be written as 0

20.8.97.21 RAM RDESC word 3 Write-back format GETH

The Ethernet Receive descriptor list j is stored in DRE RAM at DRE RAM base address + 0x3180 + j*0xC80
There are 4 descriptors (each of which is made up of four 32-bit words) within each descriptor list.

RDESCi_WR3G (i=0-3) Offset address: $0318C_H+i*10_H$

RAM RDESC word 3 Write-back format GETH RAMInit value: $XXXX\ XXXX_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ES	FRPSL	PL													
rwh	rwh	rwh													

Field	Bits	Type	Description
PL	13:0	rwh	**Packet length** These bits indicate the byte length of the received packet that was transferred to system memory. This does not include the VLAN/Pad/CRC bytes if VLAN/Pad/CRC stripping is enabled. This field is valid when the LD (bit[28]) is set and ES (bit[15]) is reset. Note: Only this bit-field is checked by the DRE for the packet length. So this value should include the complete length including the headers
FRPSL	14	rwh	**Flexible Receive Parser Status LSB bit** Indicates the status of the Flexible receive parser. For details see, GETH/LETH specification
ES	15	rwh	**Error Summary** This bit indicates that the received packet has an error. The type of error is indicated by bits [19:16]. This field is valid only when the LD bit of RDESCi_WR3 is set. When this bit is set, INT_10 is triggered • Bit[0]: IP Header Error • Bit[14]: Jabber Timeout • Bit[13]: Packet Flush • Bit[12]: Payload Checksum Error • Bit[11]: Remote Fault • Bit[10]: Local Fault • Bit[2]: Underflow Error
ETLT	19:16	rwh	**Error Type or L2 Type** When the 15th bit of this descriptor (ES) is set to 1, this field indicates the Error Type. When the 15th bit of this descriptor (ES) is set to 0, this field indicates the L2 Packet Type. Refer GETH/LETH UM for the encoding

(table continues...)

(continued)

Field	Bits	Type	Description
L34T	23:20	rwh	**Layer3/ Layer4 packet Type** These bits indicate the type of payload encapsulated in the IP datagram and processed by the Receive Checksum Offload Engine
ETMNCP	24	rwh	**Ether Type Match or No Coagulation Packet** When L34T=0b0000, this bit is set to 1 (ETM Status) when the Type field of the received packet matches the value programmed in the MAC_Rx_Eth_Type_Match register. When L34T has any value other than zero and this bit is set to 1 (NCP Status), it indicates that the DMA has received a packet that must not be kept holding for TCP packet coagulation. It must be forwarded to the TCP/IP stack immediately even though it may be in sequence with respect to the previous packet. NCP Status is valid only when the OoS function is enabled in the MAC_RSS_Control register. For a tunneled packet, ETM refers to the Type Match of the Inner Ethernet Header. NCP is not supported for a tunneled packet.
CDA	27	rwh	**Context Descriptor Available** The DRE does not support context descriptors
LD	28	rwh	**Last Descriptor** When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
FD	29	rwh	**First Descriptor** When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet. CTXT, FD, and LD bits together indicate Descriptor Definition Error. During Write-back, all three bits are set to 1 {CTXT, FD, LD} = 3'b111 to indicate Descriptor Definition Error in the Rx Descriptor. Descriptor Definition Error for Rx Descriptor is indicated when both Buffer-1 and Buffer-2 are all 1s.
CTXT	30	rwh	**Receive Context Descriptor** When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 1'b0 to this bit for normal receive descriptor.
OWN	31	rwh	**OWN bit** When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the DRE owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffers.
0	26:25	r	**Reserved** Read as 0; should be written as 0

20.8.97.22 RAM RDESC word 3 Write-back format LETH

The Ethernet Receive descriptor list j is stored in DRE RAM at DRE RAM base address + 0x3180 + j*0xC80
There are 4 descriptors (each of which is made up of four 32-bit words) within each descriptor list.

RDESCi_WR3L (i=0-3) Offset address: $0318C_H+i*10_H$

RAM RDESC word 3 Write-back format LETH RAMInit value: $XXXX\ XXXX_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ES	PL														
rwh	rwh														

Field	Bits	Type	Description
PL	14:0	rwh	**Packet length** These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDESCi_WR3 is set and ES bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDESCi_WR3 is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet. Note: Only this bit-field is checked by the DRE for the packet length. So this value should include the complete length including the headers
ES	15	rwh	**Error Summary** When this bit is set, it indicates the logical OR of the following bits: • RDESCi_WR3[24]: CRC Error • RDESCi_WR3[19]: Dribble Error • RDESCi_WR3[20]: Receive Error • RDESCi_WR3[22]: Watchdog Timeout • RDESCi_WR3[21]: Overflow Error • RDESCi_WR3[23]: Giant Packet • RDESCi_WR2[17]: Destination Address Filter Fail, when Flexible RX Parser is enabled • RDESCi_WR2[16]: SA Address Filter Fail, when Flexible RX Parser is enabled This field is valid only when the LD bit of RDESCi_WR3 is set.

(table continues...)

(continued)

Field	Bits	Type	Description
LT	18:16	rwh	**Length/Type Field** This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: • 3'b000: The packet is a length packet • 3'b001: The packet is a type packet. • 3'b011: The packet is a ARP Request packet type • 3'b100: The packet is a type packet with VLAN Tag • 3'b101: The packet is a type packet with Double VLAN Tag • 3'b110: The packet is a MAC Control packet type • 3'b111: The packet is a OAM packet type • 3'b010: Reserved
DE	19	rwh	**Dribble Bit Error** When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode.
RE	20	rwh	**Receive Error** When this bit is set, it indicates that the gmii_rxer_i signal is asserted while the gmii_rxdv_i signal is asserted during packet reception. This error also includes carrier extension error in the GMII and half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
OE	21	rwh	**Overflow Error** When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO. Note: This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO. NCP Status is valid only when the OoS function is enabled in the MAC_RSS_Control register. For a tunneled packet, ETM refers to the Type Match of the Inner Ethernet Header. NCP is not supported for a tunneled packet.
RWT	22	rwh	**Receive Watchdog Timeout** When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.
GP	23	rwh	**Giant Packet** When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set). Note: Giant packet indicates only the packet length. It does not cause any packet truncation.
CE	24	rwh	**CRC Error** When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDESCi_WR3 is set.

(table continues...)

(continued)

Field	Bits	Type	Description
RS0V	25	rwh	**Receive Status RDESCi_WR0 Valid** When this bit is set, it indicates that the status in RDESCi_WR0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDESCi_WR3 is set.
RS1V	26	rwh	**Receive Status RDESCi_WR1 Valid** When this bit is set, it indicates that the status in RDESCi_WR1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDESCi_WR3 is set.
RS2V	27	rwh	**Receive Status RDESCi_WR2 Valid** When this bit is set, it indicates that the status in RDESCi_WR2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDESCi_WR3 is set.
LD	28	rwh	**Last Descriptor** When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
FD	29	rwh	**First Descriptor** When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet. See the CTXT bit description for details of using the CTXT bit and FD bit together.
CTXT	30	rwh	**Receive Context Descriptor** When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 1'b0 to this bit for normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD} • 00: Intermediate Descriptor • 01: First Descriptor • 10: Reserved • 11: Descriptor Error (due to all 1s)
OWN	31	rwh	**OWN bit** When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the DRE owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffers.

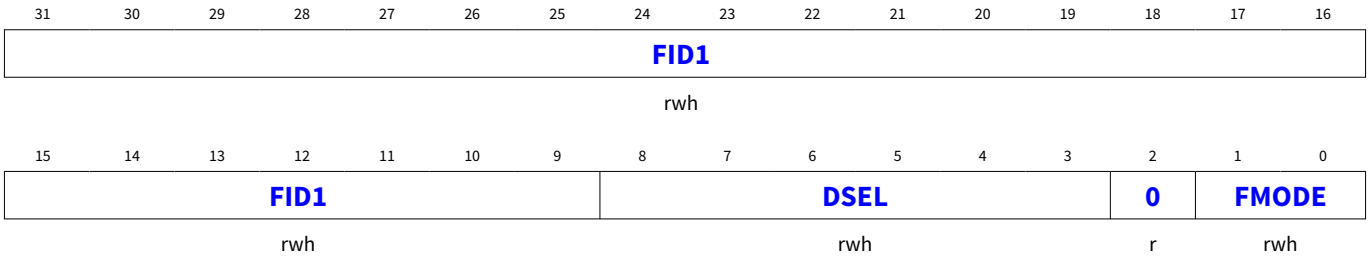
20.8.98 Forwarding table RAM interface

20.8.98.1 RAM Forwarding rule and FID1

Consists of the forwarding rule and Filter ID.

FT_FEj_FRULE (j=0-127) Offset address: 07640_H+j*8

RAM Forwarding rule and FID1 RAMInit value: $XXXX\ XXXX_H$



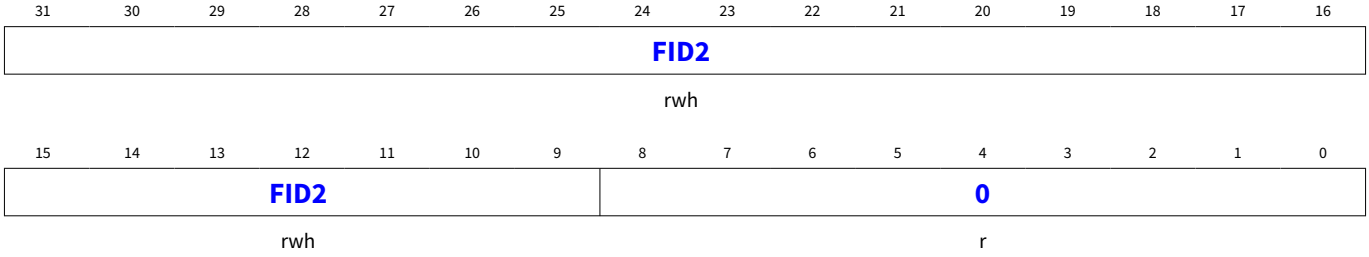
Field	Bits	Type	Description
FMODE	1:0	rwh	**Filter mode** Forwarding filter modes 00_B **CLASSIC**: Classic filter Filter ID 1 used as the filter and ID 2 used as Mask 01_B **DUAL**: Dual ID filter Filter ID1 or Filter ID2 used as filter and FWD ID should be exact match with one of the Filter ID 10_B **RANGE**: Range ID filter Range of IDs between Filter ID1 and Filter ID2 are used as Filter IDs. The FWD ID must match the values between Filter ID1 and Filter ID2. 11_B **OTHER**: Other Treated as Classsic Filter
DSEL	8:3	rwh	**Destination select** Bit encoded destination Tx descriptor list select. The Ethernet desriptor handler prepares the corresponding Tx descriptors for the frame in EIBUF • Bit[0] : Tx desc list 0 • Bit[1] : Tx desc list 1 • Bit[2] : Tx desc list 2 • Bit[3] : Tx desc list 3 • Bit[4] : Tx desc list 4 • Bit[5] : Tx desc list 5 In case of uni-cast forward only one bit is set. In case of multi-cast forward, multiple bits can be set. If the Tx descriptor list selected has TETHDLi_CTRL.TRIG bit set, the frame is not forwarded to that particular destination and this particular DSEL bit is treated as cleared When no bit is set, the frame is not forwarded and a IDID bit is set and INT_10 is triggered
FID1	31:9	rwh	**Forward filter ID1** Forward filter ID 1
0	2	r	**Reserved** Read as 0; should be written as 0

20.8.98.2 RAM Forward filter ID2

Forward filter ID2

FT_FEj_FID2 (j=0-127) Offset address: 07644_H+j*8

RAM Forward filter ID2 RAMInit value: $XXXX\ XXXX_H$



Field	Bits	Type	Description
FID2	31:9	rwh	**Forward filter ID2** Forward filter ID 2
0	8:0	r	**Reserved** Read as 0; should be written as 0

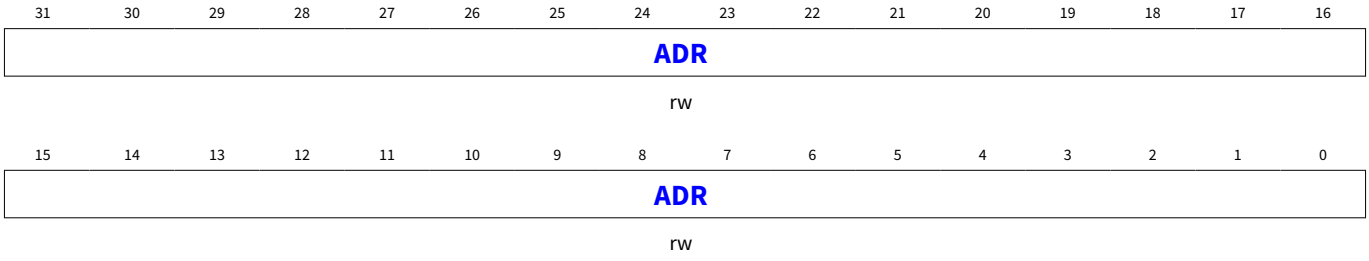
20.8.99 DMEM parameter table RAM interface

20.8.99.1 RAM Destination memory start address

The DMEM parameter table elements are stored in DRE RAM starting from DRE RAM base address + 0x7A40. This register configures the start address of the destination memory region

DMEMi_SA (i=0-27) Offset address: $07A40_H+i*10_H$

RAM Destination memory start address RAMInit value: $XXXX\ XXXX_H$



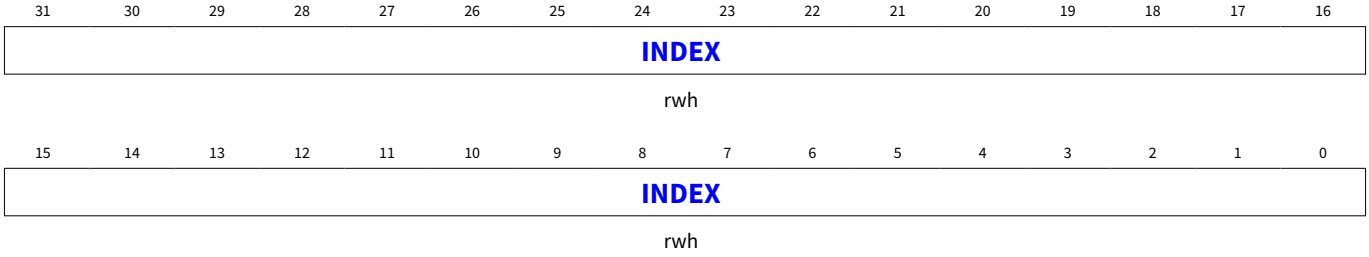
Field	Bits	Type	Description
ADR	31:0	rw	**Absolute Start Address** The start address of the destination memory. Only ADR[31:3] are considered for address decoding, ADR[2:0] are by default 000b. Note: The start address offset is always 64 bit aligned.

20.8.99.2 RAM Destination memory frame data buffer index

The DMEM parameter table elements are stored in DRE RAM starting from DRE RAM base address + 0x7A40.

DMEMi_FDBI (i=0-27) Offset address: $07A44_H+i*10_H$

RAM Destination memory frame data buffer index RAMInit value: $XXXX\ XXXX_H$



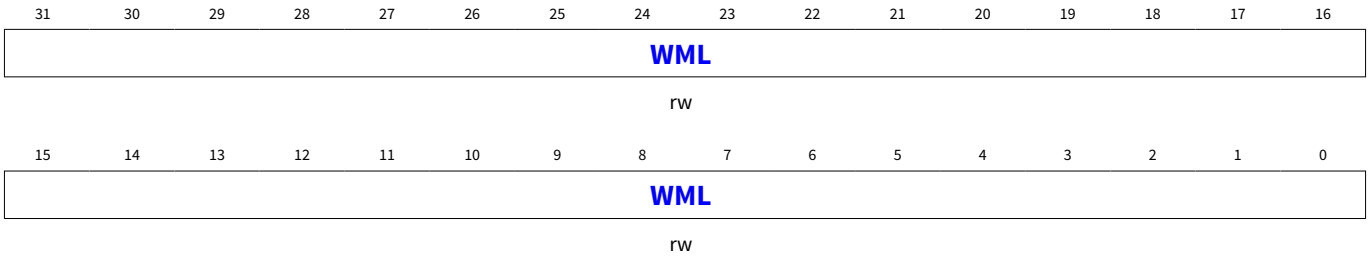
Field	Bits	Type	Description
INDEX	31:0	rwh	**Data buffer index** This bit-field is calculated by the hardware on every transfer of message to the destination memory. It denotes where the next CAN message is to be stored in the Frame data buffer. The counter is reset to 0 when a wraparound event has occurred.

20.8.99.3 RAM Destination memory watermark level

The DMEM parameter table elements are stored in DRE RAM starting from DRE RAM base address + 0x7A40.
This bit-field configures the Watermark level in case of Single Mode
When WML= WAL, the behaviour is as observed in Continuos mode.

DMEMi_WM (i=0-27) Offset address: $07A48_H+i*10_H$

RAM Destination memory watermark level RAMInit value: $XXXX\ XXXX_H$



Field	Bits	Type	Description
WML	31:0	rw	**Watermark level** • Index-based trigger mode : This is only valid for CAN I-PDU. The watermark level is configured as absolute address from the DMEMi_SA. The watermark flag DMEMi_STATUS.WMF is set (after successful transfer of CAN I-PDU to destination memory) when this address value is reached. This bit-field has to be configured to a value higher than the size of a single CAN message (plus headers) • Count-based trigger mode : The watermark level is configured in terms of number of frames or I-PDUs. The watermark flag DMEMi_STATUS.WMF is set (after successful transfer of CAN frame or CAN I-PDU to destination memory) when the DMEMi_STATUS.BC value of current CAN frame equals to the configured WML bit-field value. When WML is configured 0, the Watermark interrupt would be triggered after 1 CAN message is copied to DMEMi. When WML>=WAL, the behaviour is as observed in Continuos mode. In order to disable watermark, the user shall set WML>=WAL

20.8.99.4 RAM Destination memory wraparound level

The DMEM parameter table elements are stored in DRE RAM starting from DRE RAM base address + 0x7A40.
Wraparound level for both Single and Continuos mode

DMEMi_WA (i=0-27) Offset address: $07A4C_H+i*10_H$

RAM Destination memory wraparound level RAMInit value: $XXXX\ XXXX_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WAL															
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WAL															
rw															

Field	Bits	Type	Description
WAL	31:0	rw	**Wraparound level** • Index-based trigger mode : This is only valid for CAN I-PDU. The wraparound level is configured as absolute address from the DMEMi_WM. The wraparound flag DMEMi_STATUS.WAF is set (after successful transfer of CAN I-PDU to destination memory) when this address value is reached. This bit-field has to be configured to a value higher than the size of a single CAN message (plus headers) • Count-based trigger mode : The wraparound level is configured in terms of number of frames or I-PDUs. The watermark flag DMEMi_STATUS.WAF is set (after successful transfer of CAN frame or CAN I-PDU to destination memory) when the DMEMi_STATUS.BC value of current CAN frame equals to the configure WAL bit-field value.

20.9 Debug information

This section is not applicable for the module being described.

Reference	Description of change(s)
Date range: 2024-08-17 to 2024-10-25	
Registers	• Changed representation of register base addresses and offsets (no change of physical register addresses)

20.12 TC4Dx DRE information

20.12.1 TC4Dx DRE configuration

There is no device specific DRE configuration

20.12.2 TC4Dx DRE features

Forwarding between Ethernet interfaces include:

1. GETH to LETH forwarding
2. LETH to GETH forwarding

20.12.3 TC4Dx DRE functional description

1. DRE acts as a Master on the ComPB bus and uses the system clock frequency f_{SPB}. In TC4Dx, the ComPB also uses this clock

20.12.4 TC4Dx DRE registers

There are no deviations from the generic specification.

20.12.6 TC4Dx DRE revision history

Initial release of the chapter.

21 Controller Area Network interface (CAN)

The CAN module provides a communication interface according to the ISO 11898-1 standard, supporting both classical CAN and CAN FD communication. It provides the CAN Routing Engine as an extension which is used to route data within different CAN nodes based on the CAN-ID, and it also provides a virtual host interface to the RxFIFOs and TxQueues/TxFIFO of CAN nodes. The CAN module in this document is referred as MCMCAN. The CAN nodes in this document is referred as M_CAN.

21.1 Feature list

- Compatibility to ISO 11898-1
- CAN Error Logging
- AUTOSAR optimized
- SAE J1939 optimized
- Direct Message RAM access for Host CPU
- Multiple M_CANs share the same Message RAM
- Maskable module interrupts
- Power-down support
- Debug on CAN support
- CAN Routing Engine (CRE)
  - Abstraction of RxFIFO, TxFIFO/TxQueue operation with virtual buffers
  - Hardware accelerated CAN to CAN routing within the same MCMCAN module
  - Assists Data Routing Engine (DRE) to perform hardware accelerated
    - CAN to CAN routing between different MCMCAN Modules
    - CAN to Ethernet (in IEEE 1722 ACF frame) routing
    - CAN to a user-configurable System RAM location transfer
    - CAN PDU to a user configurable system RAM location transfer
  - Consists of a measurement unit for Intrusion Detection (IDMU)

21.2 Functional overview

This figure gives an overview of the MCMCAN block.

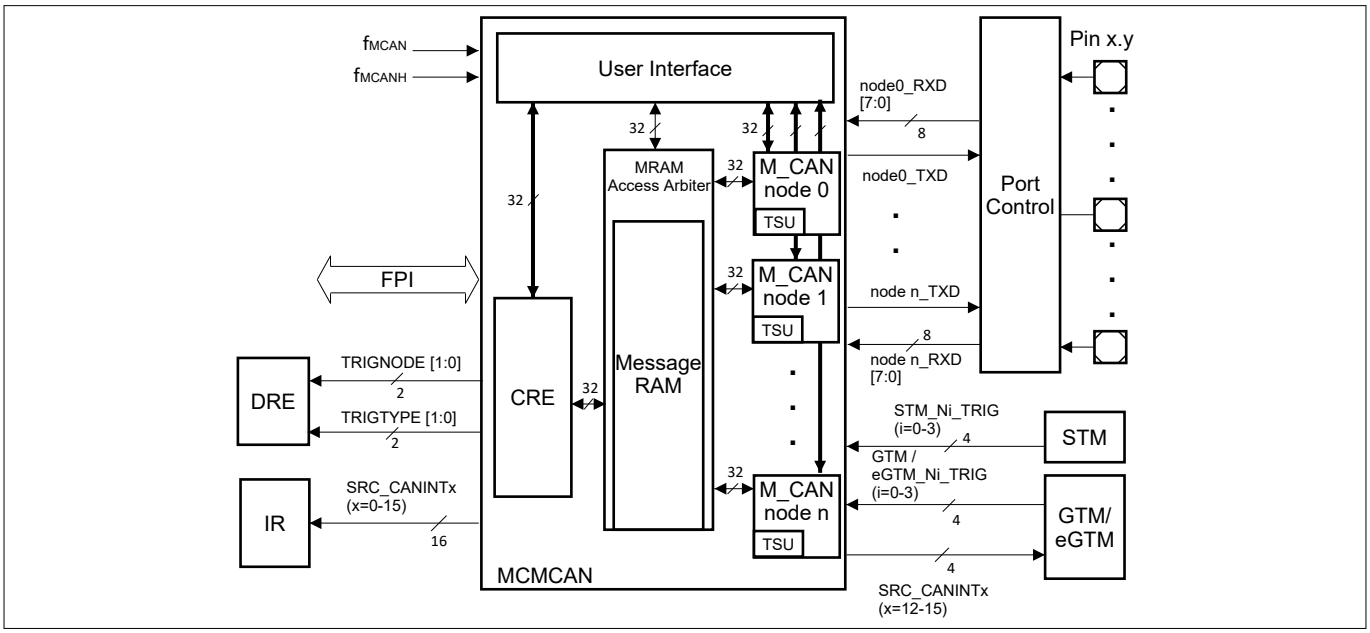

Figure 363 MCMCAN block diagram

The MCMCAN contains of the following sub blocks: User Interface, M_CAN nodes, the CAN routing engine and the Message RAM.

21.3 Functional description

Please refer to each of the CAN functional sub-blocks for the functional description.

21.4 User interface (UI)

The user interface is the wrapper which provides the interface for control of the M_CAN, CRE and MRAM to the user and to the CPU. It contains configuration for clocks, trigger signal, interrupts, timers and the modules connection to the outside world.

21.4.1 Feature list

- Clock selection and generation through Clock Control Block
  - Up to 160 MHz input clock for CAN baud rate generation
- Flexible interrupt structure generation available
  - Interrupt groups
- Timer based transmission of CAN frame and timeouts for reception of CAN frames
- Read and write access protection for Message RAM

21.4.2 Functional overview

The overview of the User Interface is shown in the following figure. The clock generation is handled in Clock Control Block, where the required frequencies are derived from the f_{MCAN} and f_{MCANH} inputs.

The Timing functions module is used for calculating the delays and generating triggers when automatic transmission of messages is needed.

The Interrupt Generation module consists of the interrupt grouping logic for interrupt triggers and the node specific transmit trigger.

For test purposes, the user can connect the nodes to an CAN internal bus, this mode is also referred as loop back mode. Additionally, the user can select the node in the loop back mode out, where a connection between the internal CAN bus and an external CAN bus is possible. This is provided from the Test functions module.

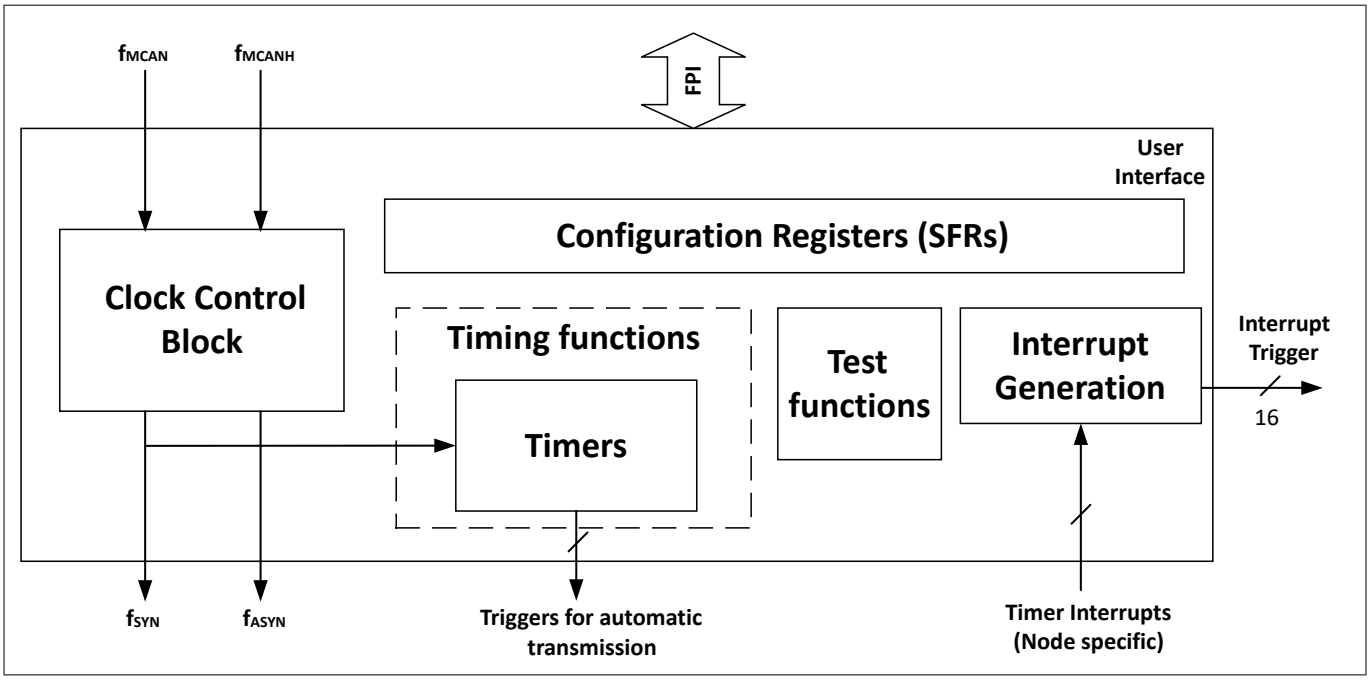

Figure 364 UI block diagram

21.4.3 Functional description

The MCMCAN User Interface describes about the clock generation, grouping of interrupts, external connections to the module and IO configurations.

21.4.3.1 MCMCAN clockpaths

A general overview of clocks within the MCMCAN module.

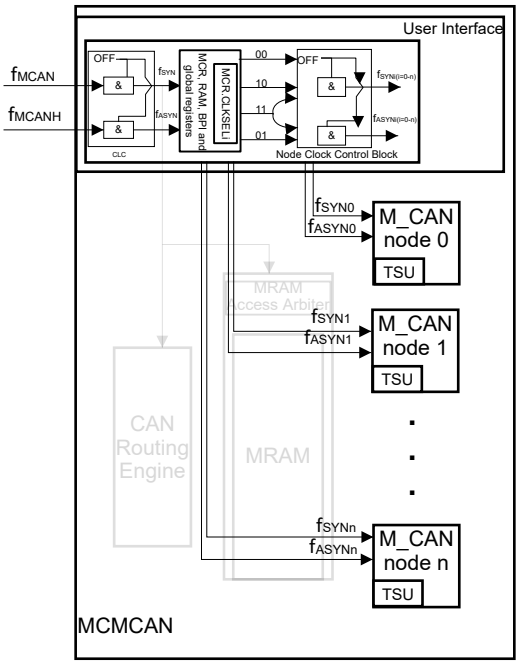

Figure 365 MCMCAN clock interconnects and clock control unit

The MCMCAN module clock inputs are connected to the clock control unit (CCU). The CLC setting supplies the global module registers with its clocks. To supply the M_CAN nodes with the corresponding clocks, the MCR.CLKSELi registers have to be set.

In the figure above the clock switch through CLC and clock control for single nodes is shown. The asynchronous clock (f_{ASYN}) as well as the synchronous clock (f_{SYN})of each single M_CAN node can be switched on and off through MCR.CLKSELi register bit-fields.

The f_{SYN} is supplied from f_{MCANH} and f_{ASYN} is supplied from f_{MCAN} from CCU. The f_{SYN} is used as the clock source for registers and RAM interface, f_{ASYN} is used to generate the nominal and fast CAN FD baudrates. It is recommended to use f_{ASYN} as 20 MHz, 40 MHz, 80 MHz, or 160 MHz from the Peripheral clock or also from f_{OSC}, in order to achieve commonly used nominal and fast CAN FD baudrates. The condition that $f_{SYN} >= f_{ASYN}$ is essential for proper functioning of MCMCAN.

Table 971 MCMCAN clock interconnects

CAN clock inputs	Connected to	Description
f_{MCAN}	CCU	f_{MCAN} of the MCMCAN module is one of the clock inputs of the Clock Control Block, providing the MCMCAN with the clock for the asynchronous clock path f_{ASYN}
f_{MCANH}	CCU	f_{MCANH} of the MCMCAN module is the clock input of the Clock Control Block, providing the main kernel clock f_{SYN}
f_{SYN}	CLC	f_{MCANH} becomes f_{SYN} within the module
f_{ASYN}	CLC	f_{MCAN} becomes f_{ASYN} within the module
f_{SYNi}	MCR.CLKSELi	f_{SYN} becomes f_{SYNi} clocking the synchronous part of M_CAN node i (Nodes can be switched on or off individually)
f_{ASYNi}	MCR.CLKSELi	f_{ASYN} becomes f_{ASYNi} clocking the asynchronous part of M_CAN node i (Nodes can be switched on or off individually)

Clock selection

The asynchronous clock part of the M_CAN and the rest of the MCMCAN module are separate frequency domains and can be driven by separate independent frequencies. The clocks for the module are chosen within the clock control unit. The asynchronous clock can be chosen in the CCU among the Peripheral clock f_{PLL} or with direct drive from the oscillator f_{OSC}.

The purpose of supplying the asynchronous clock part with a direct oscillator clock is to avoid the clock jitter added by the PLL, necessary when the chip is driven by a low cost ceramic resonator instead of by a high precision quartz crystal.

As shown in the figure above the clock signals for the MCMCAN module are generated and controlled by a clock control unit. This clock control unit is responsible for the enable or disable control, the clock frequency adjustment.

Clock control register

The Module clock is enabled using the CLC register. The module control clock f_{SYN} is used inside the MCMCAN module for control purposes such as clocking of control logic and register operations. The frequency of f_{SYN} is sourced by f_{MCANH} from CCU module. This clock is independent to f_{SPB} and allows M_CAN to continue operation when f_{SPB} is reduced in frequency, therefore enabling pretended networking. The clock control register CLC makes it possible to enable or disable f_{SYN} and f_{ASYN} under certain conditions.

21.4.3.2 Interrupt groups

Interrupt grouping is fixed, as shown in the following figures. For the complete module, 16 interrupt nodes are existing. The interrupt groups can be freely assigned to the interrupt line by using Ni_G0INTR (i=0-3), Ni_G1INTR (i=0-3) and Ni_G2INTR (i=0-3) .

21.4.3.2.1 Mapping of interrupts

The mapping of interrupt from the interrupt registers into groups, out of which only enabled interrupt sources are forwarded, is as following:

- REINT - Receive Interrupt
- RxF0F - Rx FIFO 0 Full
- RxF1F - Rx FIFO 1 Full
- RxF0N - Rx FIFO 0 New Message
- RxF1N - Rx FIFO 1 New Message
- RXTI - Receive Timeout
- TRAQ - Transmission Queue
- TRACO - Transmission Control
- TEFIFO - Tx Event FIFO incident
- HPE - High Priority Event
- WATI - Watermark Interrupt
- ALRT - Alert
- MOER - Module Error
- SAFE - Safety
- BOFF - Bus Off
- LOI - Last Error Interrupt

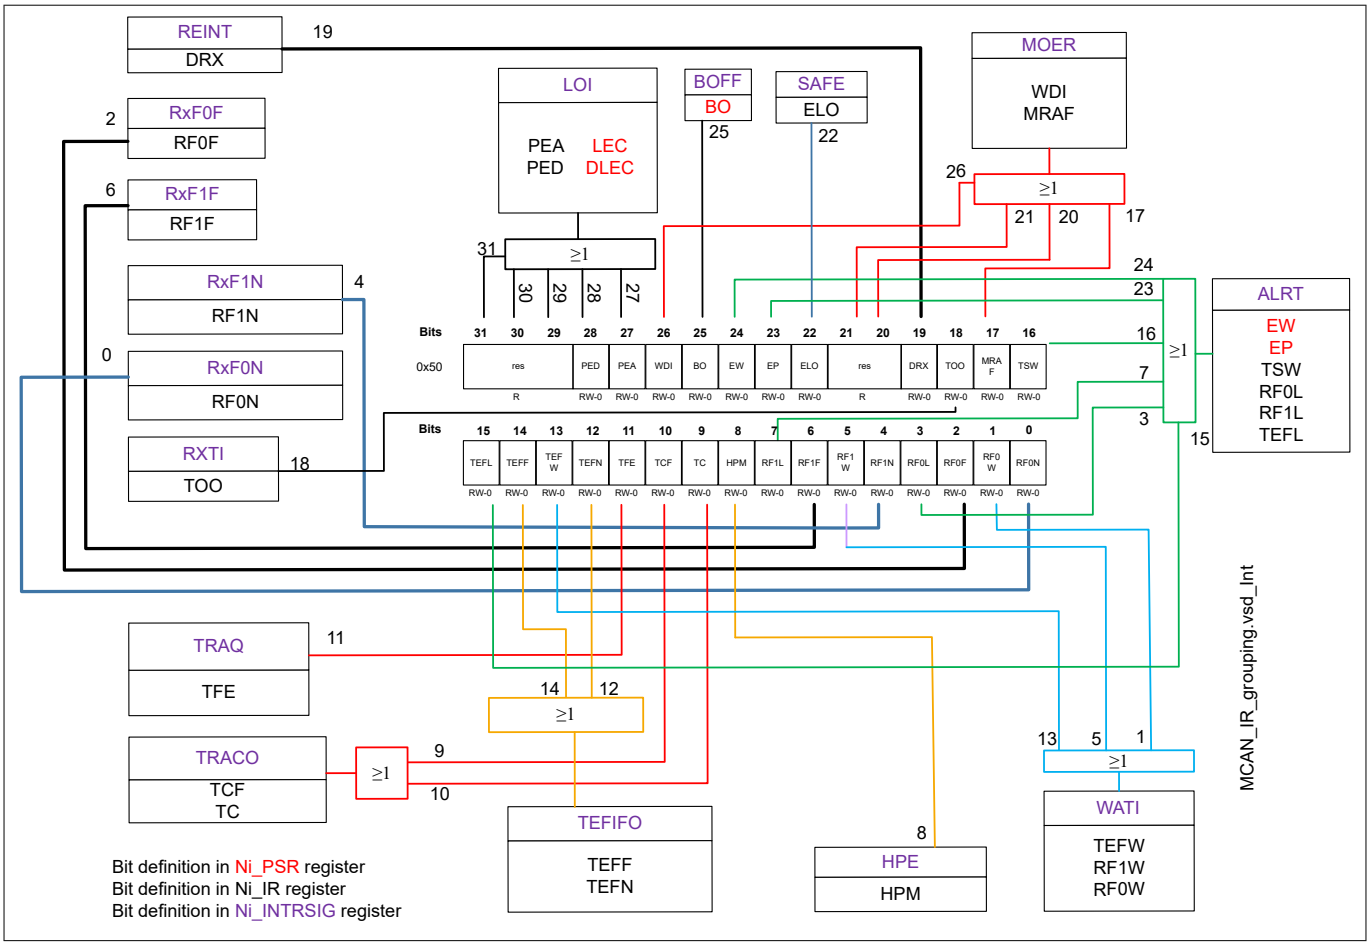

Figure 366 Mapping of interrupts into groups

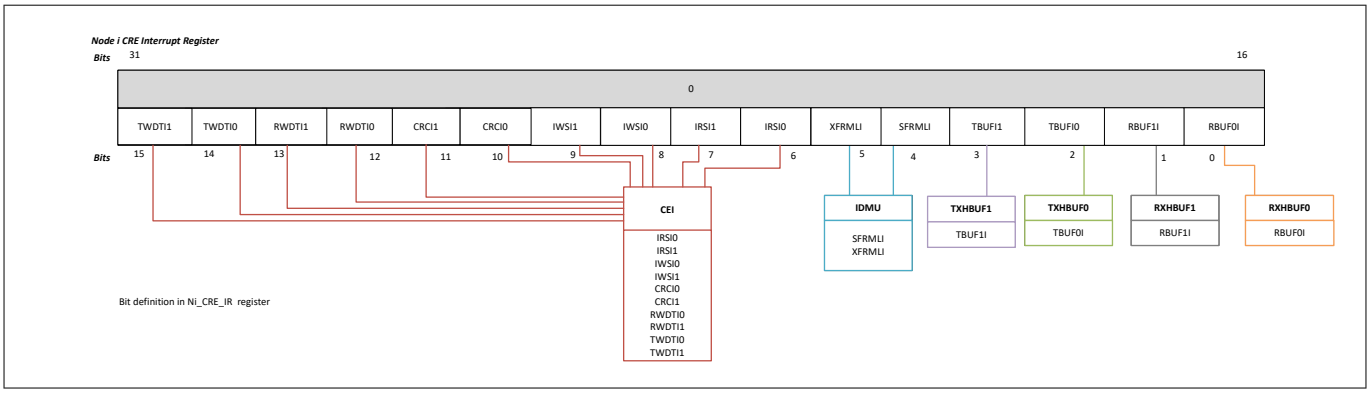

Figure 367 Mapping of CRE interrupts into groups

21.4.3.2.2 Signalling interrupts of groups

The groups defined in the previous paragraph are also shown in Ni_INTRSIG (i=0-3). For each group, 0 in the corresponding bit-field means that no interrupt is pending and 1 means pending interrupt.

21.4.3.2.3 Interrupt control

The general interrupt structure is shown in the following figure:

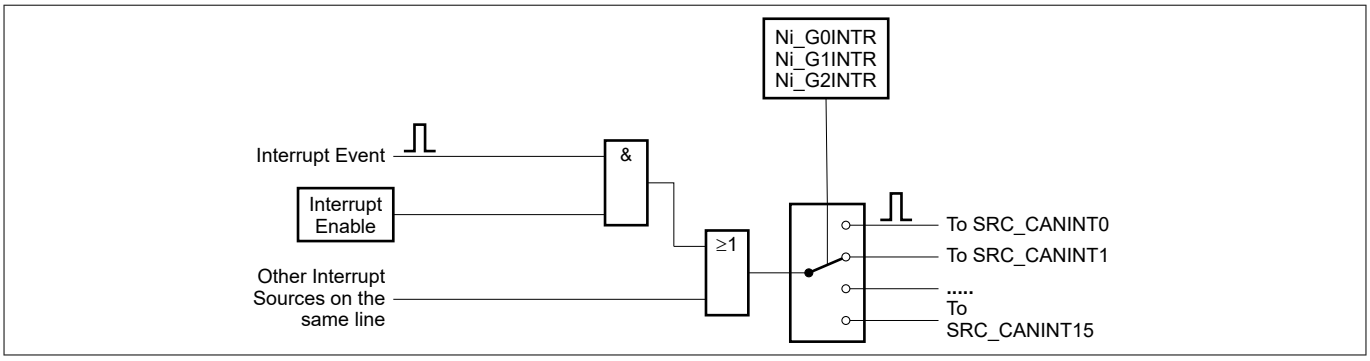

Figure 368 General interrupt structure

The interrupt event can trigger the interrupt generation. The interrupt pulse is generated based on the interrupt flag and the interrupt enable bit. The interrupt flag registers are: Ni_IR (i=0-3) and Ni_CRE_IR (i=0-3). The interrupts are enabled at Ni_IE (i=0-3) and CRE configuration registers. The pulse generation is purely based on AND logic between the interrupt flags and interrupt enable bit-fields. The interrupt flag can be reset by software by writing a '1' to the Ni_IR and Ni_CRE_IR respective bit-field.

If enabled by the related interrupt enable bit in the corresponding interrupt enable register (Ni_IE (i=0-3), Ni_TIMER_RXTOUT (i=0-3).TEIE and CRE configuration registers), an interrupt pulse can be generated at one of the 16 interrupt output lines SRC_CANINTn of the module using Ni_G0INTR (i=0-3), Ni_G1INTR (i=0-3) and Ni_G2INTR (i=0-3). If more than one interrupt source is connected to the same interrupt line the requests are combined to one common line.

The interrupt groups are only OR - ing the interrupts of the corresponding CAN nodes. The interrupt request has to be reset in the node.

***Note**: Enabling an interrupt in Interrupt Enable register when the corresponding flag is already set in Interrupt Register will also generate an interrupt pulse. Hence it is recommended to clear the interrupt flags before enabling the corresponding interrupts.*

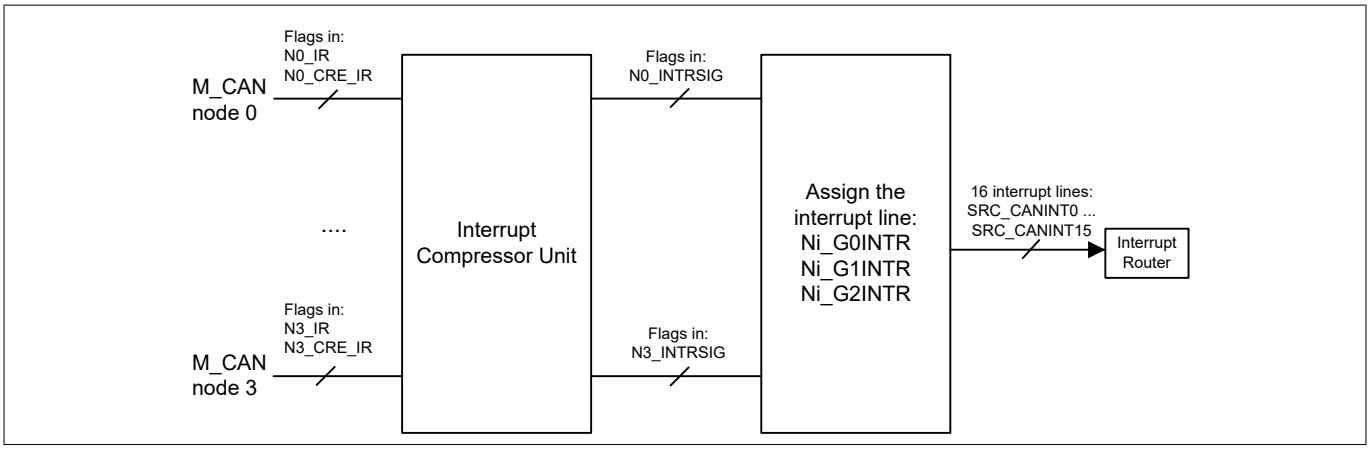

Figure 369 Interrupt compression Unit

21.4.3.3 Connecting the module to the outside world

Each node in the MCMCAN module can be connected to an internal or external CAN bus via configuring the Ni_PORTCTRL (i=0-3).LBM.

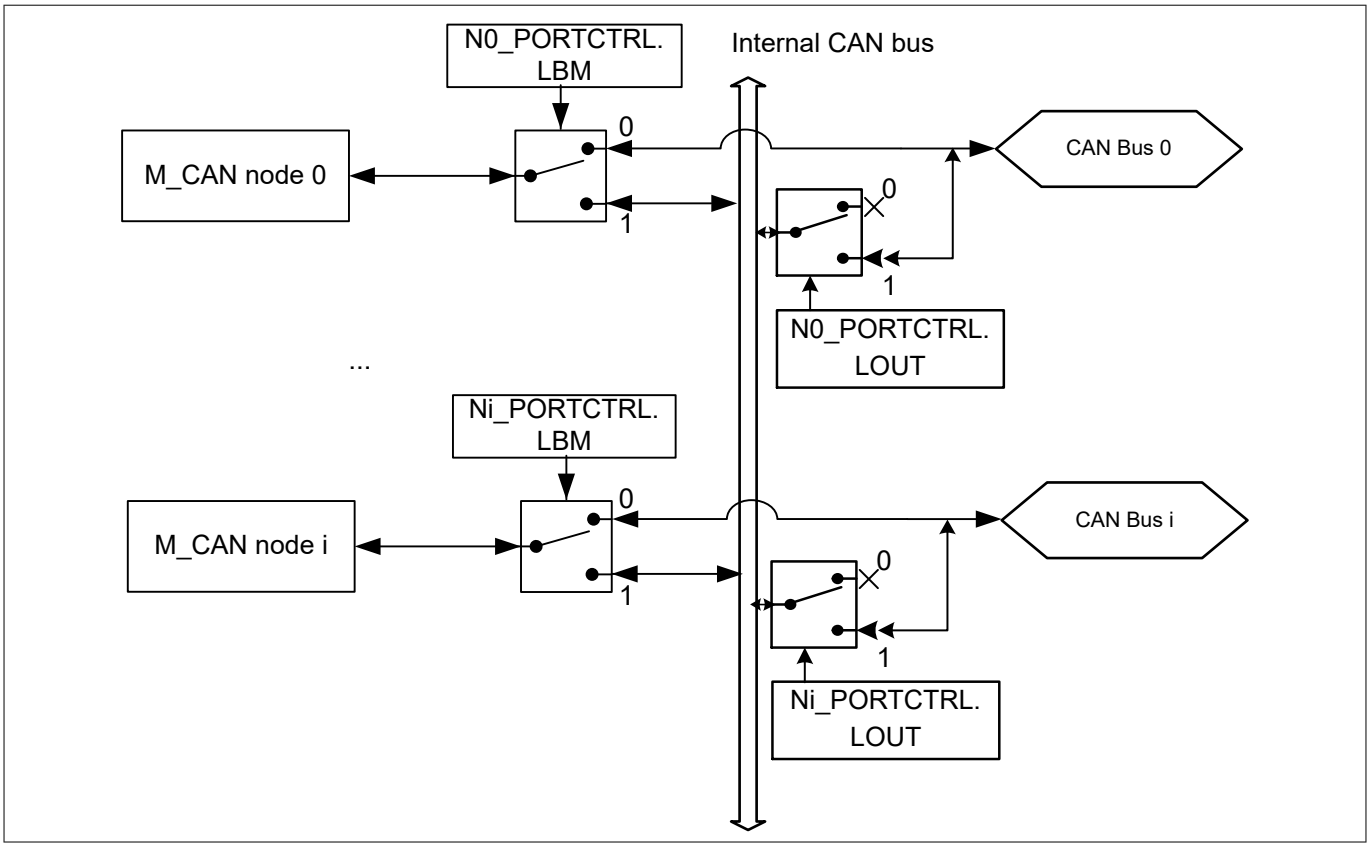

Figure 370 Module internal loop-back mode and loop-back mode out

21.4.3.3.1 Module internal loop-back mode

The MCMCAN module provides a module internal loop-back mode to enable an in-system test of the MCMCAN module as well as the development of CAN driver software without access to an external CAN bus.

The loop-back feature consists of an internal CAN bus (inside the MCMCAN module) and a bus select switch for each CAN node. With the switch, each CAN node can be connected either to the internal CAN bus (internal loop-back mode activated) or the external CAN bus, respectively to transmit and receive pins (normal operation). The CAN bus that is not currently selected is driven recessive; this means the transmit pin is held at 1, and the receive pin is ignored by the CAN nodes that are in Loop-Back Mode.

The internal loop-back mode is selected for CAN node x by setting the Node x Port Control Register bit Ni_PORTCTRL (i=0-3).LBM. All CAN nodes that are in loop-back mode may communicate together through the internal CAN bus without affecting the normal operation of the other CAN nodes that are not in Loop-Back Mode.

21.4.3.3.2 Module loop back mode out

Setting Ni_PORTCTRL (i=0-3).LOUT bit will send the signals from the internal loop back bus to the corresponding pins of the CAN node and vice versa. Therefore a receive and transmit between internal loop back bus and a bus system outside is possible. When Ni_PORTCTRL (i=0-3).LOUT is set to one, the internal loop back bus and the external bus will be communicating with each other. The table below explains the behavior of the CAN module for different combinations Ni_PORTCTRL (i=0-3).LOUT and Ni_PORTCTRL (i=0-3).LBM.

Table 972 Combinations of internal loop back mode and loop back mode out

Ni_PORTCTRL.LOUT	Ni_PORTCTRL.LBM	Description
0	0	Normal CAN operation. Internal and loop back out mode deactivated
0	1	Internal Loop Back mode
1	0	Loop Back Mode Out
1	1	Reserved

21.4.3.4 Setting the address protection for the CAN nodes

Inside the Register User Interface, the address protection is defined. Here the nodes become protectable, as well as the control area. More information regarding the protection scheme is found in the PROT chapter.

MCMCAN has 5 APU set of registers to protect read/write access condition of separate parts of the module. APU with ID 0-3, shown in Register overview chapter as PNi(i=0-3) controls CAN node i(i=0-3) read/write access protection. APU with ID 4 is used for other registers read/write protection (shared by all CAN nodes). Therefore each node has isolated read and write access protection configuration for its configuration registers. Individual masters could be configured for each and every CAN node.

The Node Start Address (Ni_STARTADR (i=0-3)) and Node End Address (Ni_ENDADR (i=0-3)) registers, give the possibility to define a range within CAN and CRE RAM, belonging to a node, which can only be written and read by masters configured in CAN node APU register. The specified RAM area is write and read protected. An overlap of the protected areas, is not found by the hardware.

21.4.3.5 Node timing functions

A CAN node offers the following timing functions:

- A receive timeout mode that can detect the reception within message buffers. The timeout expires, when no message has been received
- Without CPU involvement, a selectable message buffer can be transmitted periodically, triggered by a timer, the System Timer (STM), the General Timer Module (GTM) or the Enhanced General Timer Module (eGTM)

The clocking options for the node timer is controlled by Node Timer Clock Control Register, Ni_TIMER_CCR (i=0-3), the node timing functions for Receive Timeout Mode is controlled by Ni_TIMER_RXTOUT (i=0-3) and for Transmit Trigger Mode is controlled by Node i Timer 0/1/2 Transmit Trigger Registers (Ni_TIMER_TXTRIG0 (i=0-3), Ni_TIMER_TXTRIG1 (i=0-3), Ni_TIMER_TXTRIG2 (i=0-3)). The timers will start running after setting the STRT bit and setting the RELOAD value, to a value different than 0.

Modes with timer usage

A CAN node timer is driven by the synchronous clock or by the corresponding clock sources, divided by a prescaler selected through bit-field Ni_TIMER_CCR (i=0-3).TPSC in the corresponding timer control register. The timers are enabled by writing to the RELOAD bits in the relevant node timer registers. Then it decrements from its initial value. The further behavior depends on the selected timer mode:

- Receive Timeout Mode: The receive timeout function is valid for the receive buffers. A receive time-out check is enabled, which may be a received frame or remote data frame. If any of the message buffers receives before the timer is 0, the timer will be reloaded. When the timer reaches 0, it will stop. Bit TE in Ni_TIMER_RXTOUT (i=0-3) register will be set. With bit Ni_TIMER_RXTOUT (i=0-3).TEIE = 1, an interrupt will be generated.

***Note**: To avoid unintended receive timeout interrupts, the corresponding receive interrupts shall be enabled via bits Ni_IE.RF0NE, Ni_IE.RF1NE or Ni_IE.DRXE depending on the usage of RxFIFO0/1 or dedicated Rx buffers for proper function of the receive timeout interrupt*

- Transmit Trigger Mode: When the timer reaches 0, the TXRQ of the corresponding message buffer is selected

Transmit trigger by system timer or general timer module

For Node i Timer the trigger for transmission of a message can also be set by a System Timer (STM) trigger event, the General Timer Module (GTM), or the Enhanced General Timer Module (eGTM) trigger event, see the following figure. The bit-field Ni_TIMER_CCR (i=0-3).TRIGSRC in the timer clock control register enables this feature and the timer is started once values are written to the RELOAD bits of the relevant Ni_TIMER_TXTRIG0 (i=0-3), Ni_TIMER_TXTRIG1 (i=0-3) or Ni_TIMER_TXTRIG2 (i=0-3) registers. In transmit trigger mode, when a trigger event occurs (STM, GTM or eGTM), the node timer will be decremented per trigger event timing prescaled by (TPSC+1). The transmit request is set for the corresponding transmit message buffer one trigger event after the RELOAD value reaches zero.

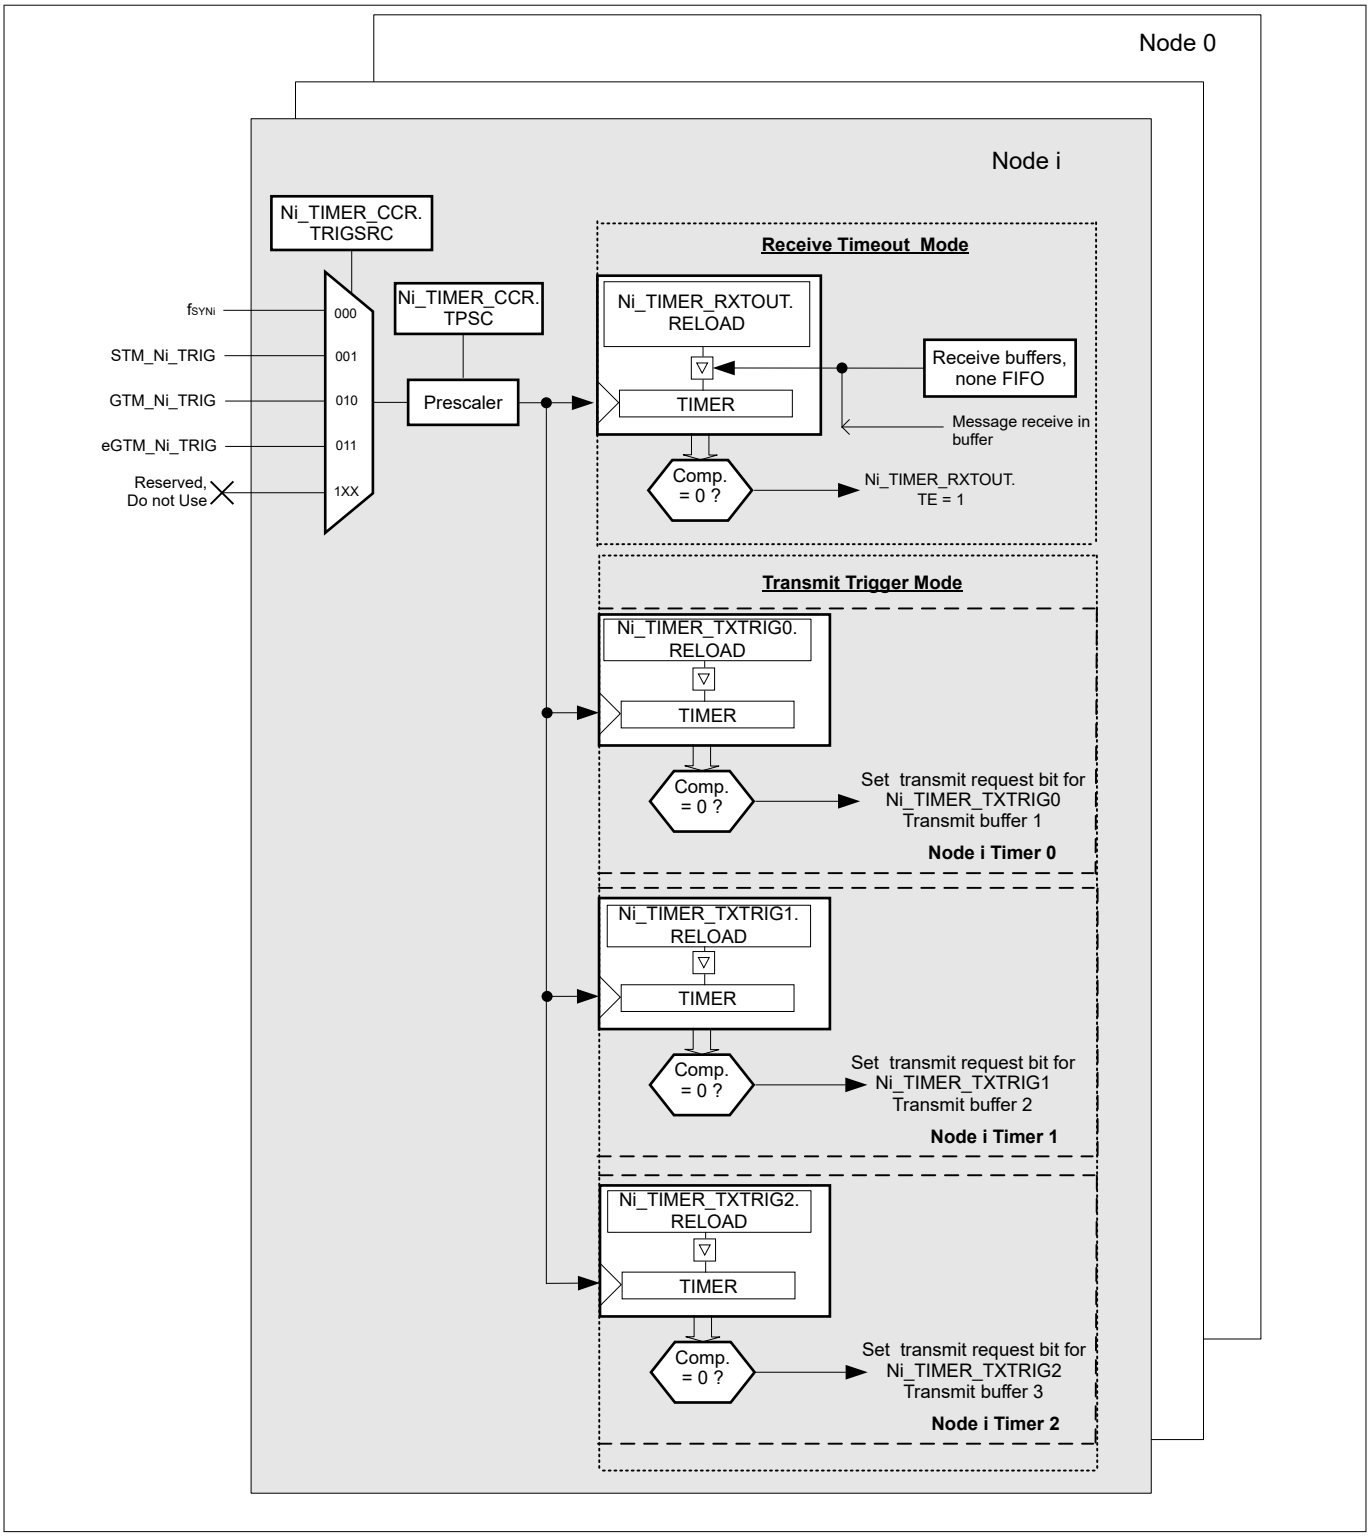

Figure 371 CAN node timing modes

21.4.3.5.1 Automatic transferring of messages

Ni_TIMER_TXTRIG0 (i=0-3), Ni_TIMER_TXTRIG1 (i=0-3), Ni_TIMER_TXTRIG2 (i=0-3) registers enable the M_CAN to trigger messages on timer events. The timer per module have one clock source. The counting events can take place on an STM interrupt, a GTM, an eGTM interrupt or by f_{SYNi}. These timers can be used to enable Pretended Networking, or to have hardware support for a gateway functionality. This functionality needs a receive

interrupt or a watermark interrupt within a FIFO, triggering a DMA transfer. The transmit objects will be automatically triggered to transfer the message buffer, through timer underflow. As the transmit triggers are fixed to message RAM buffers 1-3, this feature only works if these buffers are available.

21.4.3.6 Message RAM

The Message RAM is shared by all the CAN nodes within the module. The elements of the message RAM are configured per CAN node. When operated in CAN FD mode the required Message RAM size strongly depends on the element size configured for Rx FIFO0, Rx FIFO1, Rx Buffers, and Tx Buffers through Ni_RXESC.F0DS, Ni_RXESC.F1DS, Ni_RXESC.RBDS, and Ni_TXESC.TBDS.

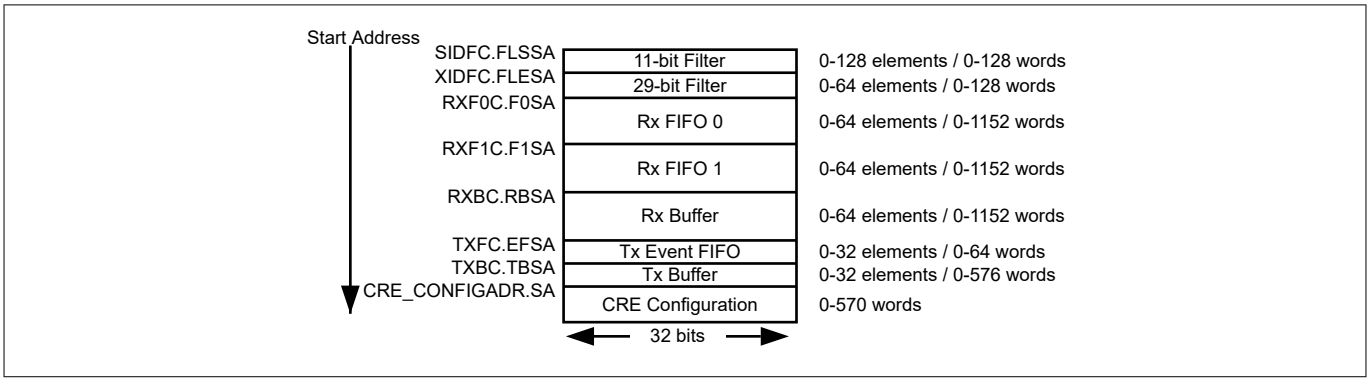

Figure 372 Message RAM configuration

When the M_CAN addresses the Message RAM it addresses 32-bit words, not single bytes. The configurable start addresses are 32-bit word addresses this means only bits 15 to 2 are evaluated, the two least significant bits are ignored.

The CRE part of RAM structure is shown in the figure above.

***Note**: The M_CAN does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.*

21.4.3.6.1 Rx buffer and FIFO element

Up to 64 Rx buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx buffer/FIFO element is shown in the table below. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field through register Ni_RXESC (i=0-3).

RXMSGk_R1A(k=0-63): When no TSU is used (Ni_CCCR (i=0-3).UTSU = '0'), R1A.RXTS[15:0] holds the 16-bit timestamp generated by the M_CAN's internal timestamp logic.

RXMSGk_R1B (k=0-63): When a TSU is used (Ni_CCCR (i=0-3).UTSU = '1') and when bit SSYNC/ESYNC of the matching filter element is set, R1B .TSC = '1' and R1B .RXTSP [3:0] holds the number of the TSU's Timestamp registers which holds the 32-bit timestamp captured by the TSU. Else RXMSGk_R1B(k=0-63).TSC= '0' and RXMSGk_R1B (k=0-63).RXTSP[3:0] is not valid.

Table 973 Message layout - Rx buffer and FIFO element

***Note**: Depending on the configuration of the element size (RXESC), between two and sixteen 32-bit words are used for storage of a CAN message's data field.*

21.4.3.6.2 Tx buffer element

The Tx buffers section can be configured to hold dedicated Tx buffers as well as a Tx FIFO/Tx Queue. If the Tx buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx buffers start at the beginning of the Tx buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx buffers and Tx FIFO/Tx Queue by evaluating the Tx buffer configuration Ni_TXBC.TFQS and Ni_TXBC.NDTB. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field through register Ni_TXESC.

***Note**: Depending on the configuration of the element size (TXESC), between two and sixteen 32-bit words are used for storage of a CAN message's data field.*

21.4.3.6.3 Tx event FIFO element

Each element stores information about transmitted messages. By reading the Tx event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx event FIFO can be obtained from register Ni_TXEFS.

E1A: When Ni_CCCR.WMM ='0' and no TSU is used (Ni_CCCR.UTSU = '0'). E1A.TXTS[15:0] holds the 16-bit timestamp generated by the M_CAN's internal timestamping logic.

E1B: When 16-bit Message Marker are enabled (Ni_CCCR.WMM = '1') or when Ni_CCCR.UTSU = '1', E1B.MM1[15:8] holds the upper 8 bit of the Wide Message Marker. When a TSU is used (Ni_CCCR.UTSU = '1') and when bit TSCE of the related Tx_Buffer element is set, E1B.TSC = '1' and E1B .TXTSP[3:0] holds the number of the TSU's Timestamp register which holds the 32-bit timestamp captured by the TSU. Else E1B.TSC = '0' and E1B.TXTSP[3:0] is not valid.

21.4.3.6.4 Standard message ID filter element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a standard message ID Filter element, its address is the filter list standard start address SIDFCi.FLSSA plus the index of the filter element (0…127).

Table 976 Message layout - standard message ID Filter element

21.4.3.7 Debug over CAN (DXCM feature)

The MCMCAN controller supports debugging using standard CAN tool access in parallel to regular CAN bus traffic. This is achieved by transmitting DAP telegrams and replies as regular CAN messages (DXCM DAP over CAN Messages). DXCM uses the lowest message buffers and it is strongly recommended to use also the same CAN pins as for DXCPL (DAP over CAN Physical Layer). DXCM is enabled with the MCR.DXCM bit. Please refer to the Debug and Trace chapter for more information about DAP, DXCM and DXCPL.

Debug over CAN shall be only available on CAN0. TX Buffer 0 will be the sending transmit object. For receive at least one message buffer has to be configured. Meaning that RX Buffer 0 will be used for receiving DAP telegrams. The starting address of the message buffer and the receiving address of the message buffer have to be configured within BUFADR register.

21.5 Modular CAN (M_CAN)

This section describes the Modular CAN nodes.

21.5.1 Feature list

- Transmit and receive CAN frames with compatibility to ISO 11898-1
  - CAN FD with up to 64 data bytes supported
- Improved acceptance filtering
- Separate event signaling on reception of high priority messages
- Flexible functional configuration for software
  - Configurable transmit FIFO
  - Configurable transmit queue
  - Configurable transmit event FIFO
  - Programmable loopback test mode
  - Two configurable receive FIFOs
- Data storage:
  - Up to 64 dedicated receive buffers
  - Up to 32 dedicated transmit buffers
  - Up to sixteen 32-bit timestamps supported
- Timestamping:
  - Hardware timestamping according to CiA 603
  - AUTOSAR synchronization method supported

21.5.2 Functional overview

This part gives a overview of the M_CAN module.

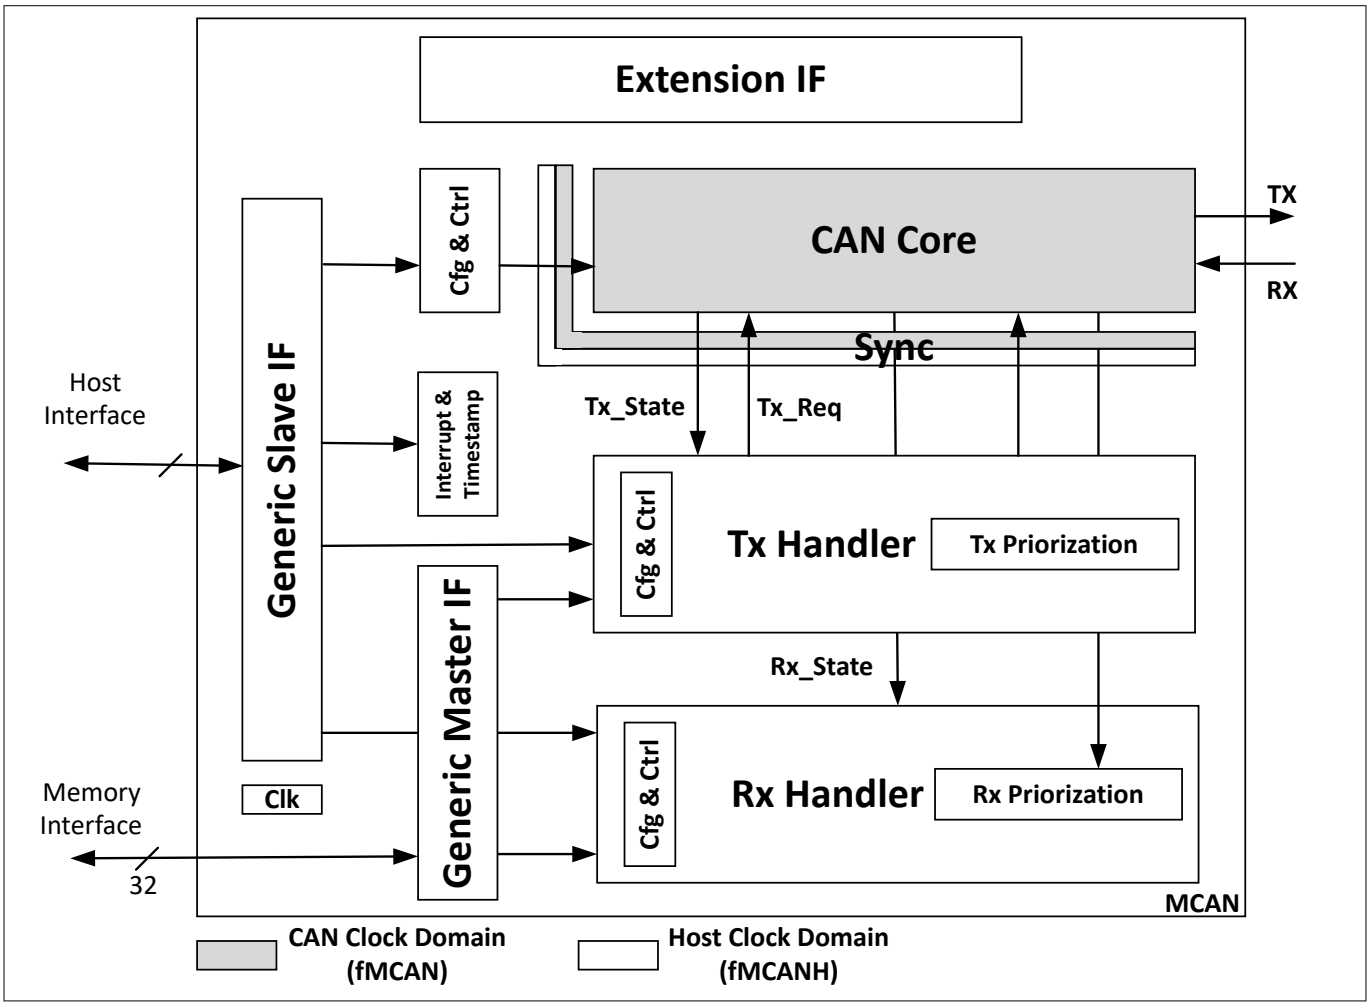

Figure 373 M_CAN block diagram

CAN core

CAN Protocol Controller and Rx or Tx Shift register. Handles all ISO 11898-1 protocol functions. Supports 11-bit and 29-bit identifiers.

Sync

Synchronizes signals from the Host clock domain to the CAN clock domain and vice versa.

Clk

Synchronizes reset signal to the Host clock domain and to the CAN clock domain.

Cfg and Ctrl

CAN core related configuration and control bits.

Interrupt and timestamp

Interrupt control and 16-bit CAN bit time counter for receive and transmit timestamp generation. An externally generated 16-bit vector may substitute the integrated 16-bit CAN bit time counter for receive and transmit timestamp generation.

Tx handler

Controls the message transfer from the external message RAM to the CAN core. A maximum of 32 Tx buffers can be configured for transmission. Tx buffers can be used as dedicated Tx buffers, as Tx FIFO, part of a Tx queue, or as a combination of them. A Tx event FIFO stores Tx timestamps together with the corresponding message ID. Transmit cancellation is also supported.

The Tx Handler also implements the Frame Synchronization Entity (FSE) which controls time-triggered communication according to ISO11898-4. It synchronizes itself to the reference messages on the CAN bus, controls cycle time and global time, and handles transmissions according to the predefined message schedule, the system matrix. It also handles the time marks of the system matrix that are linked to the messages in the Message RAM. Stop Watch Trigger, Event Trigger, and Time Mark Interrupt are synchronization interfaces.

Rx handler

Controls the transfer of received messages from the CAN core to the external message RAM. The Rx Handler supports two receive FIFOs, each of configurable size, and up to 64 dedicated Rx buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx buffer, in contrast to a receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs.

Generic slave interface

Connects the M_CAN to a customer specific Host CPU.

Generic master interface

Connects the M_CAN access to an external 32-bit message RAM.

Extension interface

All flags from the interrupt register (Ni_IR SFR) and selected internal status and control signals are routed to this interface.

21.5.3 Functional description

The CAN module consists of four M_CAN nodes. Each M_CAN node represents a CAN channel interface, which is configured individually. The functional description of a M_CAN node is given in this chapter.

21.5.3.1 Operating modes

This chapter provides the details of configuration options for a M_CAN operation, which includes: software initialization, CAN and CAN FD operation, sleep mode and test modes.

21.5.3.1.1 Software initialization

Software initialization is started by setting bit Ni_CCCR (i=0-3).INIT, either by software or by a hardware reset, or by going Bus_Off. While Ni_CCCR (i=0-3).INIT is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus output TXD is recessive (HIGH). The counters of the Error Management Logic EML are unchanged. Setting Ni_CCCR (i=0-3).INIT does not change any configuration register. Resetting Ni_CCCR (i=0-3).INIT finishes the software initialization. Afterwards the Bit Stream Processor BSP synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (Bus_Idle) before it can take part in bus activities and start the message transfer.

Access to the M_CAN configuration registers is only enabled when both bits Ni_CCCR (i=0-3).INIT and Ni_CCCR (i=0-3).CCE are set (protected write).

Ni_CCCR (i=0-3).CCE can only be set/reset while Ni_CCCR (i=0-3).INIT = 1. Ni_CCCR (i=0-3).CCE is automatically reset, when Ni_CCCR (i=0-3).INIT is cleared.

The following registers are reset when Ni_CCCR (i=0-3).CCE is set

- Ni_HPMS (i=0-3) - High Priority Message Status
- Ni_RXF0S (i=0-3) - Rx FIFO 0 Status
- Ni_RXF1S (i=0-3) - Rx FIFO 1 Status
- Ni_TXFQS (i=0-3) - Tx FIFO/Queue Status
- Ni_TXBRP (i=0-3) - Tx Buffer Request Pending
- Ni_TXBTO (i=0-3) - Tx Buffer Transmission Occurred
- Ni_TXBCF (i=0-3) - Tx Buffer Cancellation Finished
- Ni_TXEFS (i=0-3) - Tx Event FIFO Status

The Timeout Counter value Ni_TOCV (i=0-3).TOC is preset to the value configured by Ni_TOCC (i=0-3).TOP when Ni_CCCR (i=0-3).CCE is set.

In addition the state machines of the Tx Handler and Rx Handler are held in idle state while Ni_CCCR (i=0-3).CCE = 1.

The following registers are only writeable while Ni_CCCR (i=0-3).CCE = ‘0’

- Ni_TXBAR (i=0-3) - Tx Buffer Add Request
- Ni_TXBCR (i=0-3) - Tx Buffer Cancellation Request

Ni_CCCR (i=0-3).TEST and Ni_CCCR (i=0-3).MON can only be set by the Host while Ni_CCCR (i=0-3).INIT = 1 and Ni_CCCR (i=0-3).CCE = 1. Both bits may be reset at any time. Ni_CCCR (i=0-3).DAR can only be set/reset while Ni_CCCR (i=0-3).INIT = 1 and Ni_CCCR (i=0-3).CCE = 1.

21.5.3.1.2 Normal operation

The M_CAN's default operating mode after hardware reset is event-driven CAN communication.

Once the M_CAN is initialized and Ni_CCCR (i=0-3).INIT is reset to zero, the M_CAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including Message ID and DLC are stored into a dedicated Rx Buffer or into Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

21.5.3.1.3 CAN FD operation

There are two variants in the CAN FD frame transmission:

- The CAN FD frame without bit-rate switching
- The CAN FD frame where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers will now be decoded as FDF bit. If FDF is equal to:

- Recessive: It signifies a CAN FD frame
- Dominant It signifies a Classical CAN frame

In a CAN FD frame, the two bits following FDF, res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. The coding of res = recessive is reserved for future expansion of the protocol.

In case the M_CAN receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting bit Ni_PSR (i=0-3).PXE. When Protocol Exception Handling is:

- Enabled (Ni_CCCR (i=0-3).PXHD = 0): This causes the operation state to change from Receiver (Ni_PSR (i=0-3).ACT = "10") to Synchronizing (Ni_PSR (i=0-3).ACT = "00") at the next sample point
- Disabled (Ni_CCCR (i=0-3).PXHD = 1): The M_CAN will treat a recessive res bit as an form error and will respond with an error frame

CAN FD operation is enabled by programming Ni_CCCR (i=0-3).FDOE. In case Ni_CCCR (i=0-3).FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of classical CAN frames is always possible. Whether a CAN FD frame or a classical CAN frame is transmitted can be configured through bit FDF in the respective Tx Buffer element. With Ni_CCCR (i=0-3).FDOE = 0, received frames are interpreted as classical CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if bit FDF of a Tx Buffer element is set. Ni_CCCR (i=0-3).FDOE and Ni_CCCR (i=0-3).BRSE can only be changed while Ni_CCCR (i=0-3).INIT and Ni_CCCR (i=0-3).CCE are both set. With Ni_CCCR (i=0-3).FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in Classical CAN format. With Ni_CCCR (i=0-3).FDOE = 1 and Ni_CCCR (i=0-3).BRSE = 0, only bit FDF of a Tx Buffer element is evaluated. With Ni_CCCR (i=0-3).FDOE = 1 and Ni_CCCR (i=0-3).BRSE = 1, transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significantly higher than in the CAN FD arbitration phase. In this case, disable the CAN FD bit rate switching option for transmissions
- During system start-up all nodes are transmitting Classical CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation
- Wake-up messages in CAN partial networking have to be transmitted in classical CAN format
- End-of-line programming in case not all nodes are CAN FD capable. Non-CAN FD nodes are held in silent mode until programming has completed. Then all nodes switch back to classical CAN communication

In the CAN FD format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN. The DLC codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to the table below.

Table 978 Coding of DLC in CAN FD

DLC	9	10	11	12	13	14	15
Number of data bytes	12	16	20	24	32	48	64

In CAN FD frames, the bit timing will be switched inside the frame, after the BRS (Bit Rate Switch) bit, if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the standard CAN bit timing is used as defined by the Nominal Bit Timing and Prescaler Register Ni_DBTP (i=0-3). In the following CAN FD data phase, the data phase bit timing is used as defined by the Data Bit Timing and Prescaler Register Ni_DBTP (i=0-3). The bit timing is switched back from the fast timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the CAN clock frequency (asynchronous clock). Example: with a CAN clock frequency of 20 MHz and the shortest configurable bit time of 4 tq, the bit rate in the data phase is 5 Mbit/s.

***Note**: MCMCAN supports up to 5 Mbit/s considering the physical medium CAN-FD timing requirements from ISO 11898-2:2016. At fM_CAN = 80 MHz, CAN-FD data phase bit rate can be extended to 8 Mbit/s, while the bit asymmetry effect from CAN-FD transceiver, physical layer network topology and any other dependencies, has to be considered by the user.*

In both data frame formats, CAN FD long and CAN FD fast, the value of the bit ESI (Error Status Indicator) is determined by the transmitter's error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is transmitted dominant.

21.5.3.1.4 Bus off recovery

The M_CAN enters Bus off state according to CAN protocol conditions specified in ISO 11898-1. The Bus off state is reported by setting Ni_PSR.BO. Additionally, the M_CAN sets Ni_CCCR.INIT to stop all CAN operation.

To restart CAN operation, the application software needs to clear Ni_CCCR.INIT. After Ni_CCCR.INIT is cleared, the M_CAN's CAN state machine waits for the completion of the Bus off recovery Sequence according to CAN protocol (at least 128 occurrences of Bus Idle Condition, which is the detection of 11 consecutive recessive bits).

The M_CAN uses its Receive Error Counter to count the occurrences of the Bus Idle Condition. If need be, that can be monitored at Ni_ECR.REC. Additionally, each occurrence of the Bus Idle condition is flagged by Ni_PSR.LEC = 5 = Bit0Error, which triggers an interrupt (Ni_IR.PEA) when Ni_IE.PEAE is enabled.

While the Bus off recovery proceeds, the CAN activity is reported as "Synchronizing", Ni_PSR.ACT = 0 and Ni_PSR.BO remains set. The time from resetting Ni_CCCR.INIT to the clearing of Ni_PSR.BO will be (in the absence of dominant bits on the CAN bus) 1420 (11 * 129 + 1) CAN bit times plus synchronization delay between clock domains.

During Bus off recovery, the M_CAN does not receive or start transmission of messages. When a transmission is requested while the Bus off recovery proceeds, it will be started after the recovery has completed and CAN activity entered Idle state, Ni_PSR.ACT = 1.

When the Bus off recovery has completed, Ni_PSR.BO, Ni_ECR.TEC, and Ni_ECR.REC are cleared, and one CAN bit time later Ni_PSR.ACT is set to Idle.

After Ni_PSR.ACT reaches Idle, it will remain in Idle for at least one CAN bit time. The M_CAN's CAN state machine will become receiver (Ni_PSR.ACT = 2) when it samples a dominant bit during Idle state or it will become transmitter (Ni_PSR.ACT = 3) when it detects a pending transmission request during Idle state.

21.5.3.1.5 Transmitter delay compensation

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting through pin TXD the protocol controller receives the transmitted data from its local CAN transceiver through pin RXD. The received data is delayed by the CAN transmitter delay. In case this delay is greater than TSEG1 (time segment before sample point), a bit error is detected. In order to enable a data phase bit time that is even shorter than the transmitter delay, the delay compensation is introduced. Without transmitter delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transmitter delay.

Configuration

The CAN FD protocol unit has implemented a delay compensation mechanism to compensate the CAN transceiver's loop delay, the transmitter delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver and port delay.

For the transmitter delay compensation the following boundary conditions have to be considered:

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the Secondary Sample Point (SSP). If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in the ISO11898-1. It is enabled by setting bit Ni_DBTP (i=0-3).TDC. The received bit is compared against the transmitted bit at the Secondary Sample Point. The Secondary Sample Point position is defined as the sum of the measured delay from the M_CAN's transmit output TX through the transceiver to the receive input RX plus the transmitter delay compensation offset as configured by Ni_TDCR (i=0-3).TDCO. The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (for example half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of minimum time quanta "mtq". Ni_PSR.TDCV shows the actual transmitter delay compensation value. Ni_PSR (i=0-3).TDCV is cleared when Ni_CCCR.INIT is set and is updated at each transmission of an FD frame while Ni_DBTP (i=0-3).TDC is set.

The following boundary conditions have to be considered for the transmitter delay compensation implemented in the M_CAN:

- The sum of the measured delay from TX to RX and the configured transmitter delay compensation offset Ni_TDCR (i=0-3).TDCO has to be less than 6-bit times in the data phase. The sum of the measured delay from RX to RX and the configured transmitter delay compensation offset Ni_TDCR (i=0-3).TDCO has to be less than or equal to 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation. The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the secondary sample points

Measurement

If transmitter delay compensation is enabled by programming Ni_DBTP (i=0-3).TDC = '1', the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the receive input RX of the transmitter. The resolution of this measurement is one mtq.

The figure below describes how the transmitter loop delay is measured.

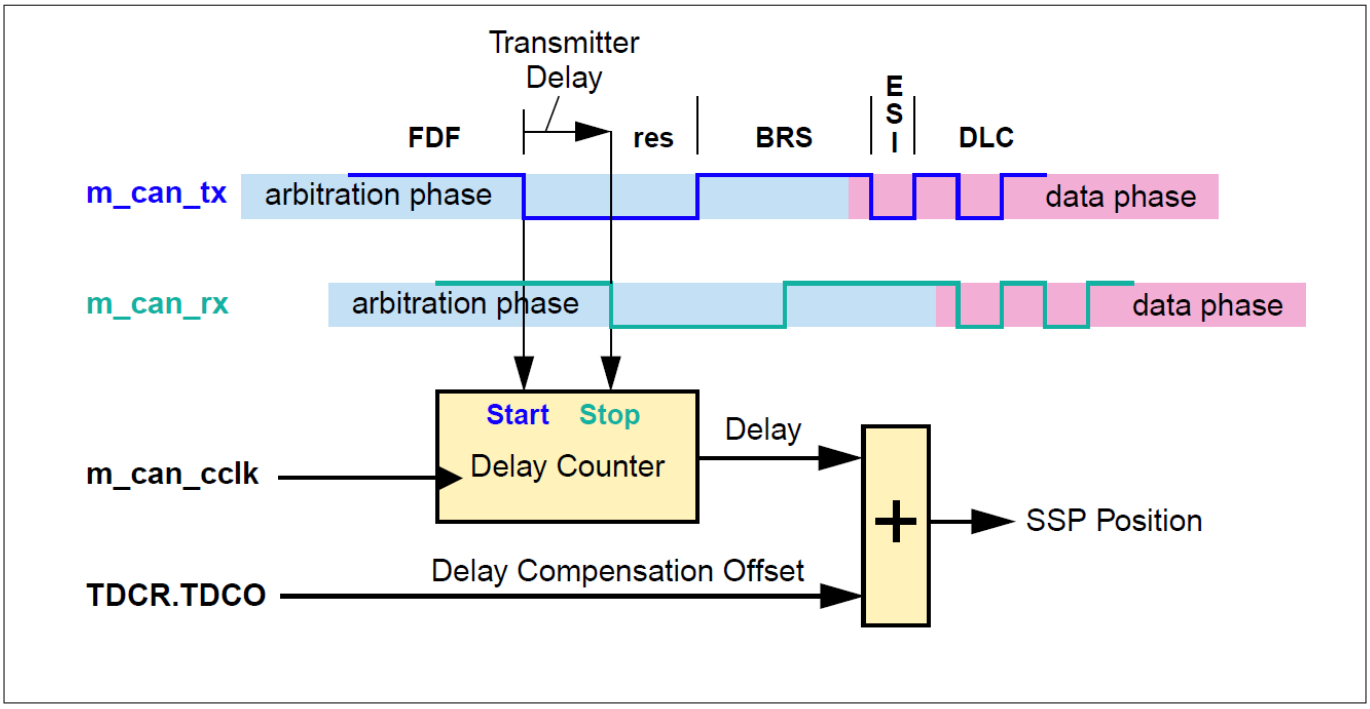

Figure 374 Transmitter delay measurement

To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received “res” bit, resulting in a to early Secondary Sample Point position, the use of a transmitter delay compensation filter window can be enabled by programming Ni_TDCR (i=0-3).TDCF. This defines a minimum value for the Secondary Sample Point position. Dominant edges on RX, that would result in an earlier Secondary Sample Point position are ignored for transmitter delay measurement. The measurement is stopped when the Secondary Sample Point position is at least Ni_TDCR (i=0-3).TDCF AND TX is low.

21.5.3.1.6 Restricted operation mode

In operation mode the node is able to:• Rece

ive data

- Receive remote frames, and
- Give acknowledge to valid frames

The node does not send:

- Data frames
- Remote frames
- Active error frames, or
- Overload frames

In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle to resynchronize itself to the CAN communication. The error counters (Ni_ECR (i=0-3).REC and Ni_ECR (i=0-3).TEC) are frozen while Error Logging (Ni_ECR (i=0-3).CEL) is active. The Host can set the M_CAN into Restricted Operation mode by setting bit Ni_CCCR (i=0-3).ASM. The bit can only be set by the Host when both Ni_CCCR (i=0-3).CCE and Ni_CCCR (i=0-3).INIT are set to ‘1’. The bit can be reset by the Host at any time.

Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset Ni_CCCR (i=0-3).ASM.

The Restricted Operation Mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

21.5.3.1.7 Bus monitoring mode

The M_CAN is set in bus monitoring mode by programming Ni_CCCR (i=0-3).MON to one. In bus monitoring mode (see ISO11898-1, 10.12 Bus monitoring), the M_CAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus, if the M_CAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the M_CAN monitors this dominant bit, although the CAN bus may remain in recessive state. In bus monitoring mode register TXBRP is held in reset state.

The bus monitoring mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. The following figure shows the connection of signals TXD and RXD to the M_CAN in bus monitoring mode.

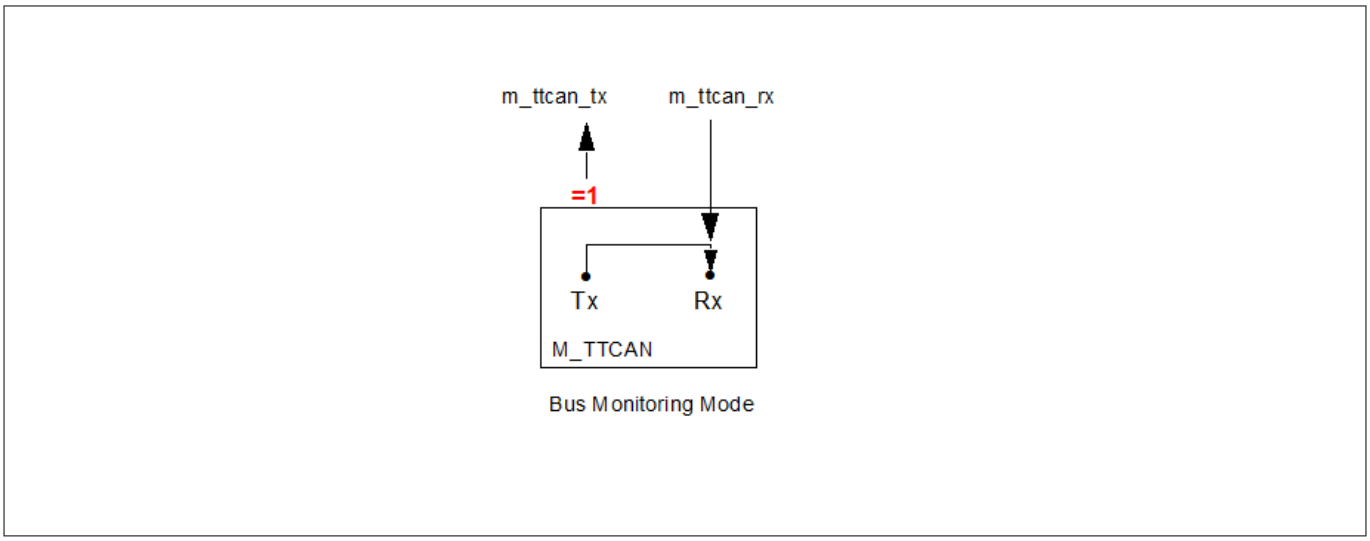

Figure 375 Pin control in bus monitoring mode

21.5.3.1.8 Disabled automatic retransmission

According to the CAN Specification (see ISO11898-1, 6.3.3 Recovery Management), the M_CAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled. To support time-triggered communication as described in ISO 11898-1 in Chapter 9.2, the automatic retransmission may be disabled through Ni_CCCR (i=0-3).DAR.

Frame transmission in DAR mode

In DAR mode all transmissions are automatically canceled after they started on the CAN bus. A Tx Buffer's Tx Request Pending bit Ni_TXBRP (i=0-3).TRPx is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- Successful transmission:
  - Corresponding Tx Buffer Transmission Occurred bit Ni_TXBTO (i=0-3).TOx set
  - Corresponding Tx Buffer Cancellation Finished bit Ni_TXBCF (i=0-3).CFx not set

- Successful transmission in spite of cancellation:
  - Corresponding Tx Buffer Transmission Occurred bit Ni_TXBTO (i=0-3.TOx set
  - Corresponding Tx Buffer Cancellation Finished bit Ni_TXBCF (i=0-3).CFx set
- Arbitration lost or frame transmission disturbed:
  - Corresponding Tx Buffer Transmission Occurred bit Ni_TXBTO (i=0-3.TOx not set
  - Corresponding Tx Buffer Cancellation Finished bit Ni_TXBCF (i=0-3).CFx set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = “10” (transmission in spite of cancellation).

21.5.3.1.9 Power down (sleep mode)

The M_CAN can be set into power down mode controlled by input signal clock stop request or by CC Control Register Ni_CCCR (i=0-3).CSR. As long as the clock stop request signal is active, bit Ni_CCCR (i=0-3).CSR is read as one.

When all pending transmission requests have completed, the M_CAN waits until bus idle state is detected. Then the M_CAN sets then Ni_CCCR (i=0-3).INIT to one to prevent any further CAN transfers. Now the M_CAN acknowledges that it is ready for power down by setting Ni_CCCR (i=0-3).CSA to one. In this state, before the clocks are switched off, further register accesses can be made. A write access to Ni_CCCR (i=0-3).INIT will have no effect. Now the module clocks may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting CC Control Register flag Ni_CCCR (i=0-3).CSR. The M_CAN will acknowledge this by resetting Ni_CCCR (i=0-3).CSA. Afterwards, the application can restart CAN communication by resetting bit Ni_CCCR (i=0-3).INIT.

21.5.3.1.10 Test modes

To enable write access to register TEST (see Ni_TEST (i=0-3)), bit Ni_CCCR (i=0-3).TEST has to be set to one. This allows the configuration of the test modes and test functions.

Four output functions are available for the CAN transmit pin TXD by programming Ni_TEST (i=0-3).TX. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the M_CAN’s bit timing and it can drive constant dominant or recessive values. The actual value at pin RXD can be read from Ni_TEST (i=0-3).RX. Both functions can be used to check the CAN bus’ physical layer.

Due to the synchronization mechanism between CAN clock and Host clock domain, there may be a delay of several Host clock periods between writing to Ni_TEST (i=0-3).TX until the new configuration is visible at output pin TXD. This applies also when reading input pin RXD through Ni_TEST (i=0-3).RX.

***Note**: Test modes should be used for production tests or self test only. The software control for pin TXD interferes with all CAN protocol functions. It is not recommended to use test modes for application.*

Node external loop back mode

The M_CAN can be set in external loop back Mode by programming Ni_TEST (i=0-3).LBCK to one. In loop back mode, the M_CAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into an Rx Buffer or an Rx FIFO0/1. The following figure shows the connection of TXD and RXD to the M_CAN in external loop back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the M_CAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data or remote frame) in loop back mode. In this mode the M_CAN performs an internal feedback from its Tx output to its Rx input. The actual value of the RXD input pin is disregarded by the M_CAN. The transmitted messages can be monitored at the TXD pin.

Node internal loop back mode

Internal loop back mode is entered by programming bits Ni_TEST (i=0-3).LBCK and Ni_CCCR (i=0-3).MON to one. This mode can be used for a “Hot Selftest”, meaning the M_CAN can be tested without affecting a running CAN system connected to the pins TXD and RXD. In this mode pin RXD is disconnected from the M_CAN and pin TXD is held recessive. The following figure shows the connection of TXD and RXD to the M_CAN in case of internal loop back mode.

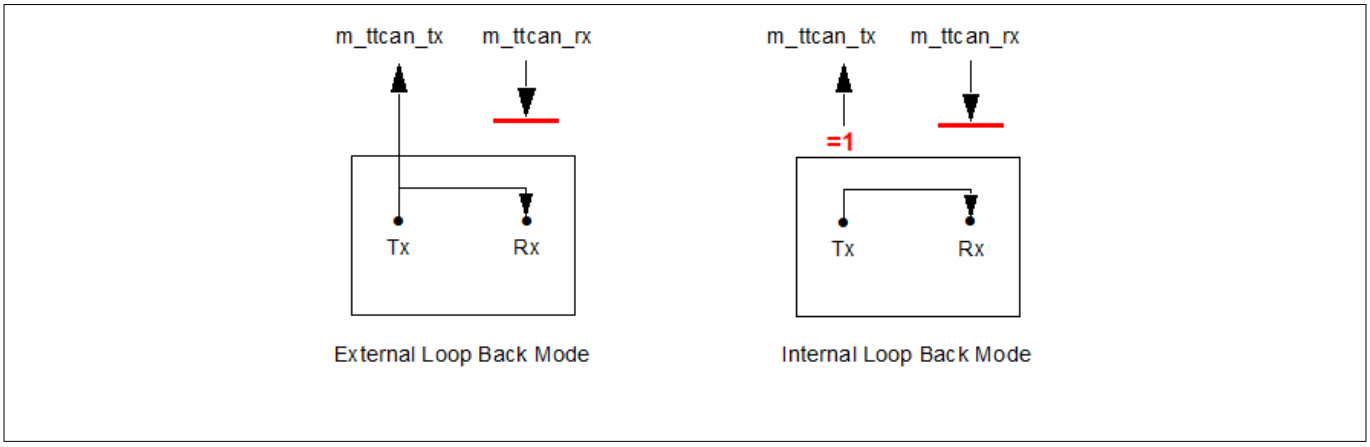

Figure 376 Pin control in loop back modes

21.5.3.2 Timestamp generation

M_CAN supports two methods for frame timestamping:

1. Internal M_CAN timestamping feature 16-bit wide timestamps, using a selectable clock source, compatible with previous versions of MCMCAN module
2. Hardware timestamping 32-bit wide timestamps using TSU module, according to CiA 603

21.5.3.2.1 Internal timestamp generation

For timestamp generation the M_CAN supplies a 16-bit wrap-around counter. A prescaler Ni_TSCC (i=0-3).TCP can be configured to clock the counter in multiples of CAN bit times (1…16). The counter is readable through Ni_TSCV (i=0-3).TSC. A write access to register TSCV resets the counter to zero. When the timestamp counter wraps around interrupt flag Ni_IR (i=0-3).TSW is set.

On start of frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer/Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

By programming bit Ni_TSCC (i=0-3).TSS an external 16-bit timestamp can be used. The external timer can be controlled using the Ni_TIMER_CCR (i=0-3) register. The external source for the timer is selected by programming the Ni_TIMER_CCR (i=0-3).TRGIGSRC. The external timer can be started by setting Ni_TIMER_CCR (i=0-3).STSTART. It can be reset to zero by setting Ni_TIMER_CCR (i=0-3).STRESET. A write of ‘1b’ to Ni_TIMER_CCR (i=0-3).STSTART is effective only when Ni_TIMER_CCR (i=0-3).STRESET is ‘0b’ that is, the external timer cannot be started when Ni_TIMER_CCR (i=0-3).STRESET is ‘1b’.

21.5.3.2.2 Timestamping unit (TSU)

This section gives a description of configuring and using the timestamping unit for hardware captured timestamps of received or transmitted frames.

To enable hardware timestamping together with the TSU, M_CAN’s configuration bit Ni_CCCR (i=0-3).UTSU has to be configured to 1. In case Ni_CCCR (i=0-3).UTSU = ‘0’ (default value), the M_CAN’s internal 16-bit timestamp counter is used, if enabled.

TSU Configuration

The TSU is configured by Ni_TSU_TSCFG. This register is only writable while Ni_CCCR (i=0-3).CCE = ‘1’. With Ni_TSU_TSCFG.TSUE the TSU is enabled. Both Ni_CCCR (i=0-3).UTSU and Ni_TSU_TSCFG.TSUE shall be set to '1', for proper functioning of timestamping using TSU. By default the TSU is disabled. The Timebase Prescaler Ni_TSU_TSCFG.TBPRE[7:0] is used to adapt the count rate of the TSU’s internal counter, if enabled, to the requirements of the application.

The TSU provides the user the possibility of using an internal timebase or an external timebase input for timestamping, selected through Ni_TSU_TSCFG (i=1-3).TBCS. When this bit is set to ‘0’, the internal free running timebase counter is used, and if this bit is set to ‘1’, the timestamp value is taken from the external timebase input. CAN node 0 has no external timebase input. CAN node 1-3 external timebase input is the output of the CAN node 0 internal timebase. This gives the possibility of synchronized timestamping accross the nodes. The following figure shows the connection and its configuration.

Ni_TSU_TSCFG.SCP configures the point in time when a timestamp is captured for Sync messages (0: at EOF, 1: at SOF of the received or transmitted Sync message).

When Ni_TSU_TSCFG.SCP = '0', the timestamp is captured directly from the Actual Timebase Ni_TSU_ATB (i=0-3) to the timestamp register Ni_TSU_TSm (i=0-3;m=0-15) when the message gets valid at EOF. This configuration is intended for AUTOSAR conformant applications.

When Ni_TSU_TSCFG.SCP = '1', the Actual Timebase Ni_TSU_ATB (i=0-3) is captured into a temporary buffer at each SOF. When the message gets valid at EOF the timestamp is copied from the temporary buffer to the timestamp register Ni_TSU_TSm (i=0-3;m=0-15).

The Timestamp Pointer is incremented after capturing the timestamp.

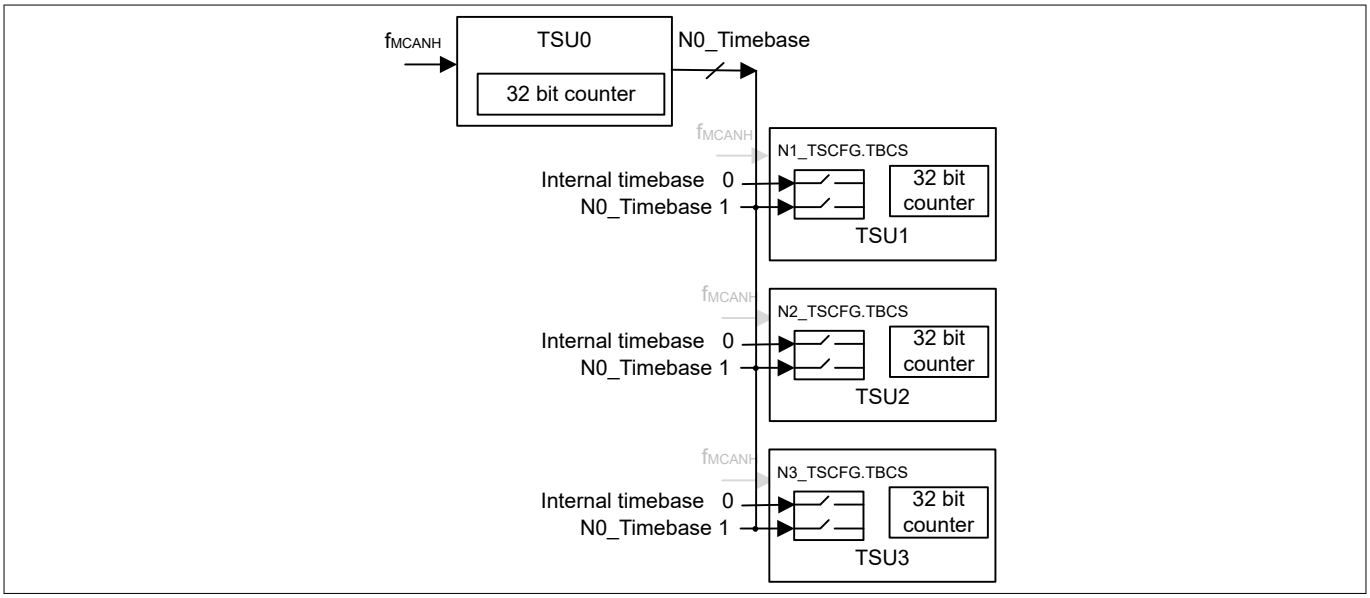

Figure 377 TSU connectivity across the nodes

Reception of timestamped messages

To configure the M_CAN for reception of timestamped messages, a Standard/Extended Message ID Filter Element has to be set up by configuration of STDMSGk_S0.SSYNC = ‘1’ respectively EXTMSGk_F1.ESYNC = ‘1’. In case the filter element matches the received frame and the received frame is valid, M_CAN output at the EOF triggers the storage of the value of the TSU’s Actual Timebase ATB to the TSU's timestamp register selected by the Timestamp Pointer Ni_TSU_TSS2 (i=0-3).TSP[3:0]. At the same pulse, the M_CAN captures the Timestamp Pointer value and this value is written to the M_CAN’s RXMSGk_R1B.RXTSP[3:0] of the related Rx Buffer or Rx FIFO element. R1B.TSC is set to ‘1’ when a timestamp has been captured by the TSU and RXMSGk_R1B.RXTSP[3:0] holds a valid timestamp pointer.

Transmission of timestamped messages

In case bits TXMSGk_T1.TSCE and TXMSGk_T1.EFC of a Tx Buffer element are set, a successful transmission of that Tx Buffer generates a pulse that triggers the storage of the value of the TSU's Actual Timebase ATB to the TSU's timestamp register selected by the Timestamp Pointer Ni_TSU_TSS2 (i=0-3).TSP[3:0]. At the same pulse, the M_CAN captures the Timestamp Pointer value and this value is written to the M_CAN's TXEVENTk_E1B.TXTSP[3:0] of the related Tx Event FIFO. TXEVENTk_E1B.TSC is set to '1' when a timestamp has been captured by the TSU and TXEVENTk_E1B.TXTSP[3:0] holds a valid timestamp pointer element.

Handling of timestamps

The TSU stores sixteen 32-bit timestamps. They are written to TS0 to TS15 in a cyclic manner.

Each timestamp register has assigned two status bits:

- Ni_TSU_TSS1 (i=0-3).TSNn is set whenever a timestamp was stored to the related timestamp register Ni_TSU_TSm (i=0-3;m=0-15)
- Ni_TSU_TSS1 (i=0-3).TSLn is set when a new timestamp was stored to the related timestamp register TSn before the previously store timestamp has been read out

Reading a Timestamp register resets the related TSS1 bits, if Ni_PORTCTRL(i=0-3).DELE is set.

21.5.3.3 Timeout counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO the M_CAN supplies a 16-bit Timeout Counter. It operates as down-counter and uses the same prescaler controlled by Ni_TSCC (i=0-3).TCP as the Timestamp Counter. The Timeout Counter is configured by register Ni_TOCC (i=0-3). The actual counter value can be read from Ni_TOCV (i=0-3).TOC.

The Timeout Counter can only be started while Ni_CCCR (i=0-3).INIT = '0'. It is stopped when Ni_CCCR (i=0-3).INIT = '1', for example when the M_CAN enters Bus_Off state.

The operation mode is selected by Ni_TOCC (i=0-3).TOS. When operating in Continuous Mode, the counter starts when Ni_CCCR.INIT is reset. A write to Ni_TOCV (i=0-3) presets the counter to the value configured by Ni_TOCC (i=0-3).TOP and continues down-counting.

When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by Ni_TOCC (i=0-3).TOP. Down-counting is started when the first FIFO element is stored. Writing to Ni_TOCV (i=0-3) has no effect.

When the counter reaches zero, interrupt flag Ni_IR (i=0-3).TOO is set. In Continuous Mode, the counter is immediately restarted at Ni_TOCC (i=0-3).TOP.

***Note**: The clock signal for the Timeout Counter is derived from the CAN Core's sample point signal. Therefore the point in time where the Timeout Counter is decremented may vary due to the synchronization/ re-synchronization mechanism of the CAN Core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.*

21.5.3.4 Rx handling

The Rx Handler controls the acceptance filtering, the transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs, as well as the Rx FIFO's Put and Get Indices.

21.5.3.4.1 Acceptance filtering

The M_CAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to an Rx Buffer or to Rx FIFO 0,1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as:
  - Range filter (from - to)
  - Filter for one or two dedicated IDs, or
  - Classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled and disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration Ni_GFC (i=0-3)
- Standard ID Filter Configuration Ni_SIDFC (i=0-3)
- Extended ID Filter Configuration Ni_XIDFC (i=0-3)
- Extended ID AND Mask Ni_XIDAM (i=0-3)

Depending on the configuration of the filter element (STDMSGk_S0.SFEC or EXTMSGk_F0.EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx Buffer
- Store received frame in Rx Buffer
- Reject received frame
- Set High Priority Message interrupt flag Ni_IR (i=0-3).HPM
- Set High Priority Message interrupt flag Ni_IR (i=0-3).HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx Buffer or Rx FIFO has been found, the Message Handler starts writing the received message data in portions of 32 bits to the matching Rx Buffer or Rx FIFO. If the CAN protocol controller has detected an error condition (for example CRC error), this message is discarded with the following impact on the affected Rx Buffer or Rx FIFO:

Rx Buffer New Data flag of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data.

Rx FIFO Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in Rx FIFO Overwrite Mode (see related information) have to be considered.

For error type see Ni_PSR (i=0-3).LEC respectively Ni_PSR (i=0-3).FLEC.

***Note**: When an accepted message is written to one of the two Rx FIFOs, or into an Rx Buffer, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.*

Related information

Rx FIFO overwrite mode on page 3952

Range filter

The filter matches for all received frames with Message IDs in the range defined by STDMSGk_S0.SFID1/SFID2 respectively EXTMSGk_F0.EFID1/EFID2.

There are two possibilities when range filtering is used together with extended frames:

- EXTMSGk_F1.EFT = 00: The Message ID of received frames is ANDed with the Extended ID AND Mask (Ni_XIDAM) before the range filter is applied
- EXTMSGk_F1.EFT = 11: The Extended ID AND Mask (Ni_XIDAM) is not used for range filtering

Filter for specific IDs

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with STDMSGk_S0.SFID1 = STDMSGk_S0.SFID2 respectively EXTMSGk_F0.EFID1 = EXTMSGk_F1.EFID2.

Classic bit mask filter

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering STDMSGk_S0.SFID1/EXTMSGk_F0.EFID1 is used as Message ID filter, while STDMSGk_S0.SFID2/EXTMSGk_F1.EFID2 is used as filter mask.

A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, for example the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering.

In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

Standard message ID filtering

The following figure shows the flow for standard message ID (11-bit identifier) filtering. The standard message ID Filter element is described in related information.

Controlled by the global filter configuration Ni_GFC (i=0-3) and the standard ID filter configuration Ni_SIDFC message ID, remote transmission request bit (RTR), and the identifier extension bit (IDE) of received frames are compared against the list of configured filter elements.

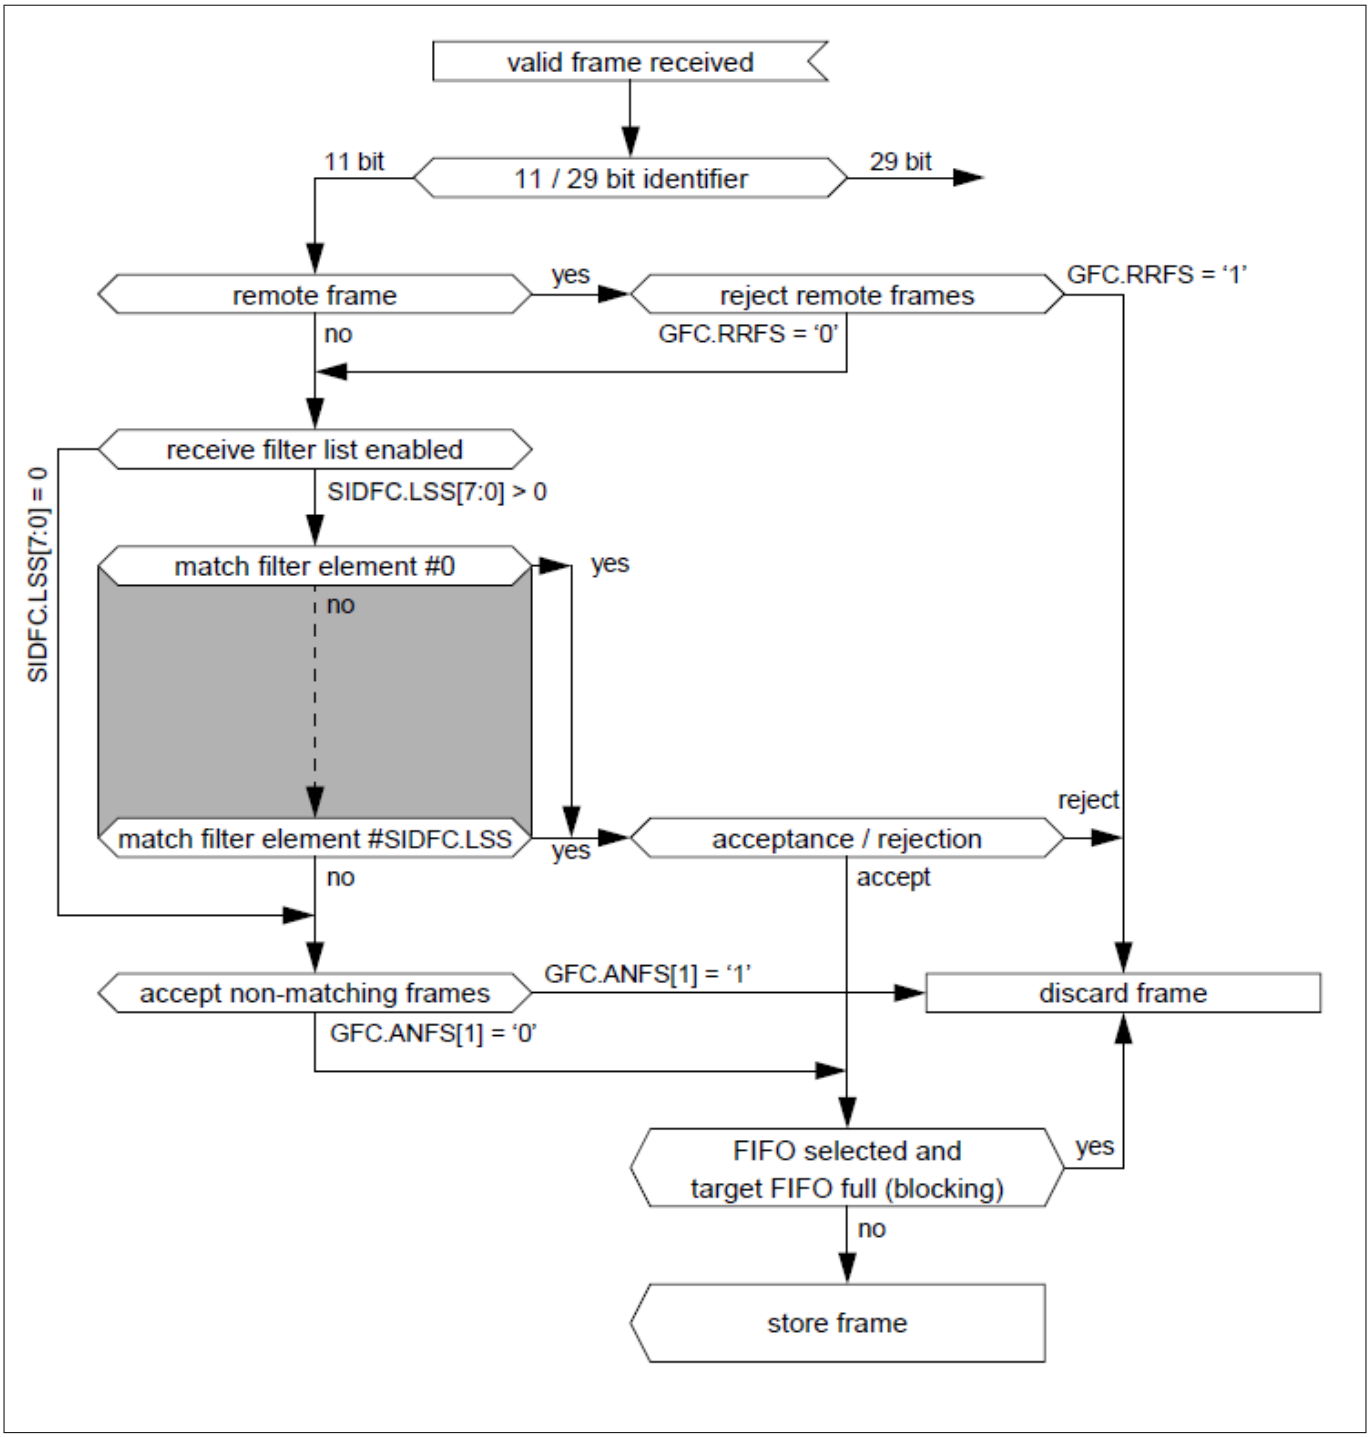

Figure 378 Standard message ID filter path

Related information

Standard message ID filter element on page 3932

Extended message ID filtering

The following figure shows the flow for extended message ID (29-bit identifier) filtering. The extended message ID filter element is described in related information.

Controlled by the Global Filter Configuration Ni_GFC and the Extended ID Filter Configuration Ni_XIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

The Extended ID AND Mask Ni_XIDAM is ANDed with the received identifier before the filter list is executed.

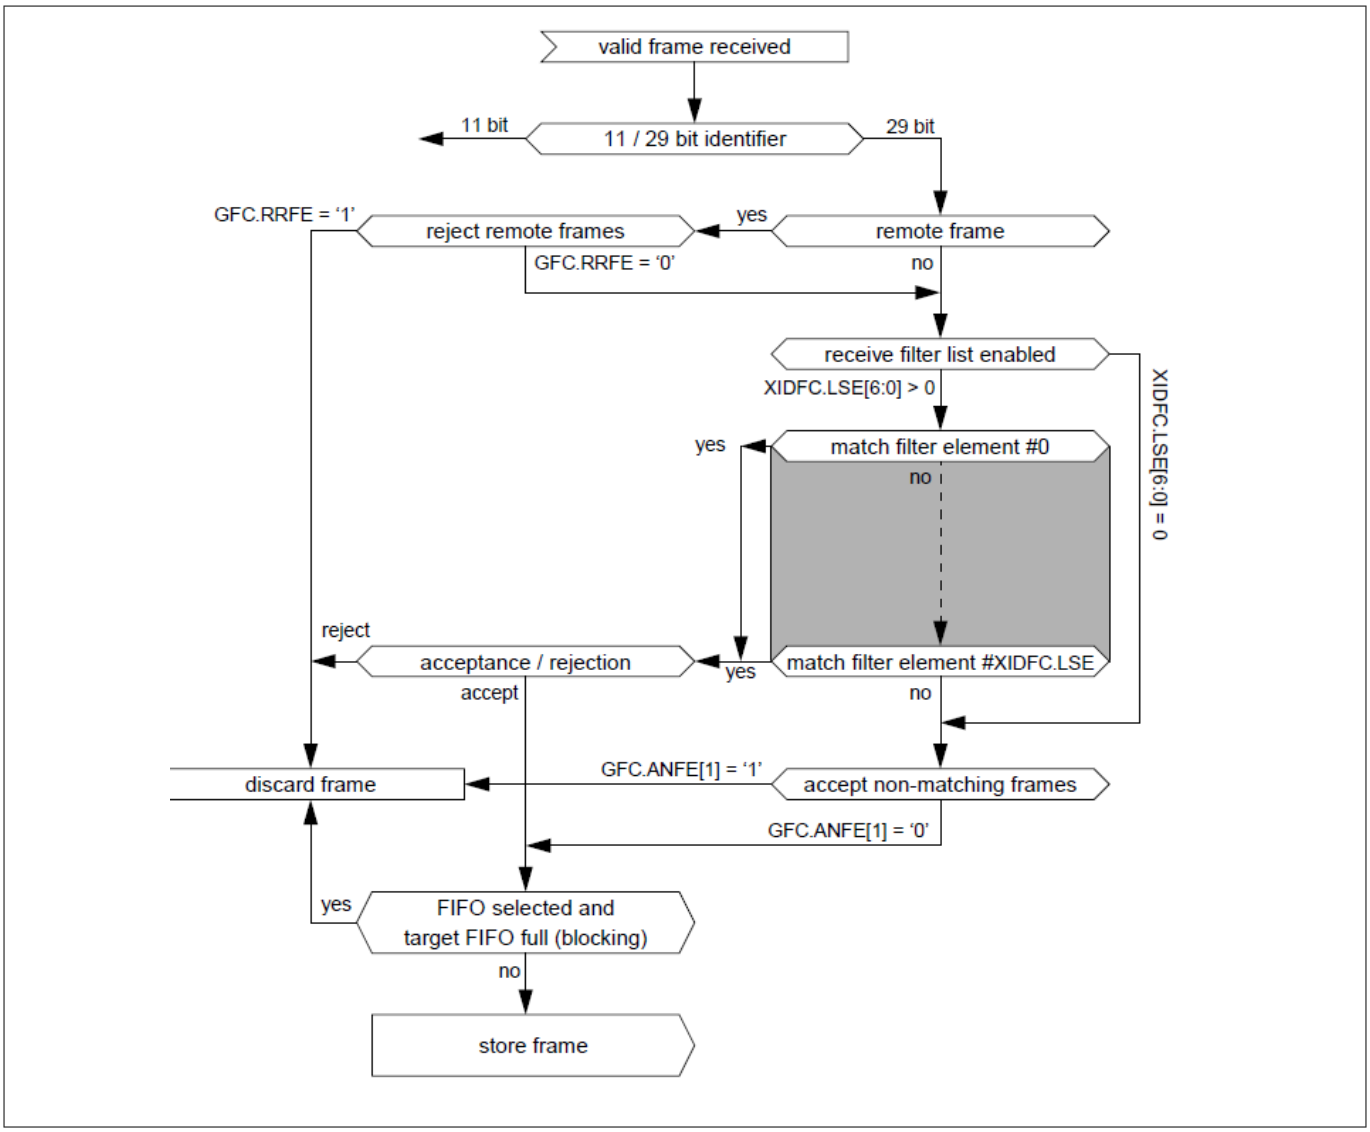

Figure 379 Extended message ID filter path

Related information

Standard message ID filter element on page 3932

21.5.3.4.2 Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done by registers Ni_RXF0C (i=0-3) and Ni_RXF1C (i=0-3).

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1 see Acceptance Filtering in related information. The Rx FIFO element is described in Rx Buffer and FIFO Element in related information.

To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by RXFnC.FnWM, interrupt flag Ni_IR.RFnW is set. When the Rx FIFO Put Index

reaches the Rx FIFO Get Index an Rx FIFO Full condition is signalled by Ni_RXFnS.FnF. In addition interrupt flag Ni_IR (i=0-3).RFnF is set.

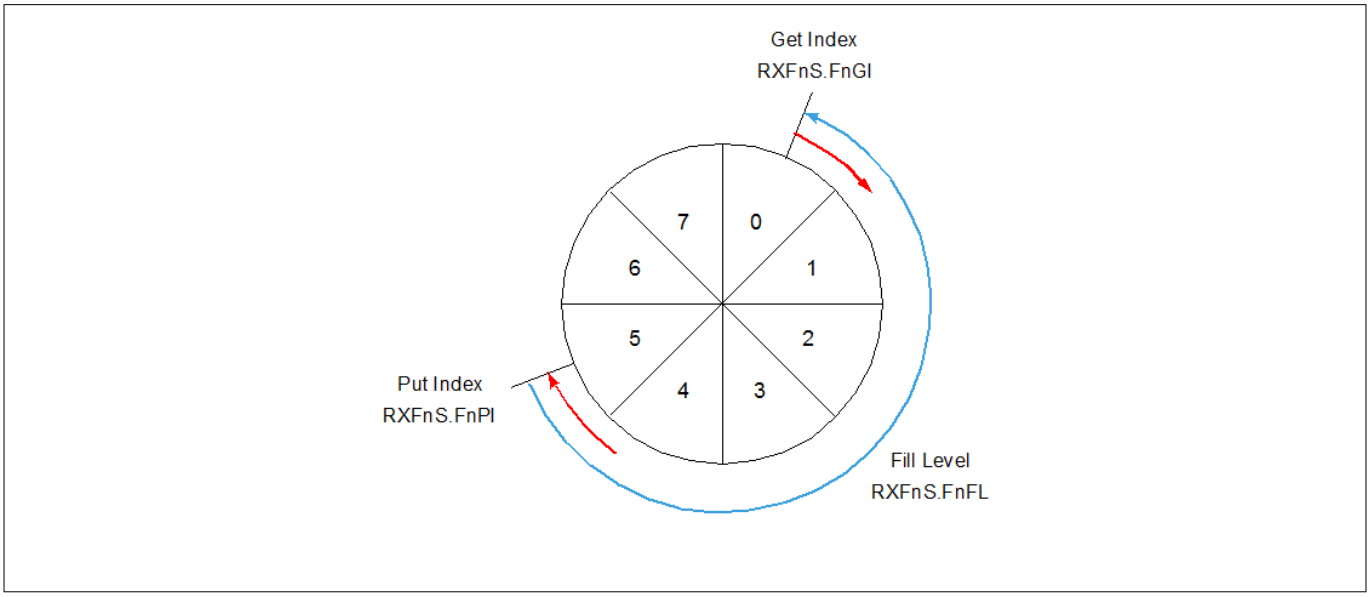

Figure 380 Rx FIFO status

When reading from an Rx FIFO, Rx FIFO Get Index Ni_RXFnS.FnGI • FIFO Element Size has to be added to the corresponding Rx FIFO start address Ni_RXFnC.FnSA.

Table 979 Rx buffer/FIFO element size

Ni_RXESC.RBDS[2:0] Ni_RXESC.FnDS[2:0]	Data field [bytes]	FIFO element size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

Related information

Acceptance filtering on page 3946
Rx buffer and FIFO element on page 3929

Rx FIFO blocking mode

The Rx FIFO blocking mode is configured by Ni_RXFnC.FnOM = '0'. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached (Ni_RXFnS.FnPI = Ni_RXFnS.FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by Ni_RXFnS.FnF = '1'. In addition interrupt flag Ni_IR (i=0-3).RFnF is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signalled by Ni_RXFnS.RFnL = ‘1’. In addition interrupt flag Ni_IR (i=0-3).RFnL is set.

Rx FIFO overwrite mode

The Rx FIFO overwrite mode is configured by Ni_RXFnC.FnOM = ‘1’.

When an Rx FIFO full condition (Ni_RXFnS.FnPI = RXFnS.FnGI) is signalled by Ni_RXFnS.FnF = ‘1’, the next message accepted for the FIFO will overwrite the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (put index) while the CPU is reading from the Message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO. The following figure shows an offset of two with respect to the get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

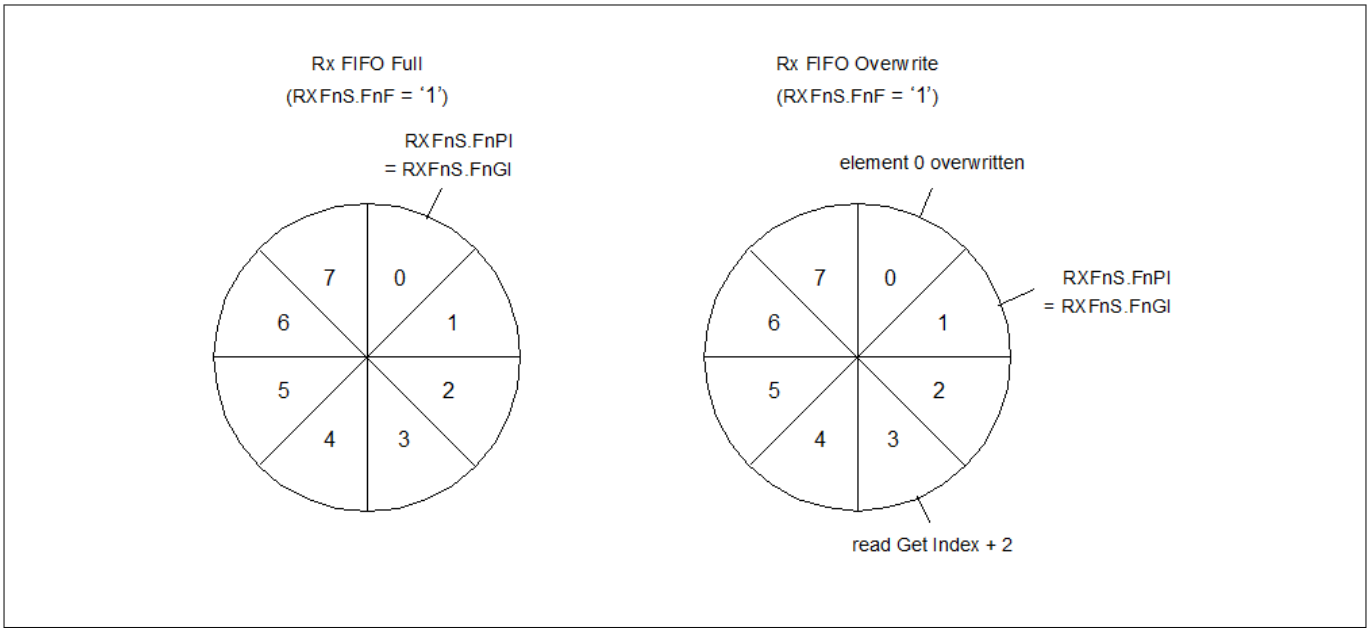

Figure 381 Rx FIFO overflow handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index Ni_RXFnA.FnA. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (Ni_RXFnS.FnF = ‘0’).

21.5.3.4.3 Dedicated Rx buffers

The M_CAN supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured by Ni_RXBC (i=0-3).RBSA.

For each Rx Buffer a Standard or Extended Message ID Filter Element with STDMSGk_S0.SFEC/ EXTMSGk_F0.EFEC = “111” and STDMSGk_S0.SFID2/EXTMSGk_F1.EFID2[10:9] = “00” has to be configured (see related information).

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag Ni_IR.DRX (Message stored in dedicated Rx Buffer) in the interrupt register is set.

Table 980 Example filter configuration for Rx buffers

Filter element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register Ni_NDAT1 (i=0-3),Ni_NDAT2 (i=0-3) is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host by writing a '1' to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

Extended message ID filter element on page 3932

Rx buffer handling

- Reset interrupt flag Ni_IR (i=0-3).DRX
- Read new data registers
- Read messages from Message RAM
- Reset new data flags of processed messages

21.5.3.5 Tx handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN Core, the Put and Get Indices, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The CAN mode for transmission (Classic CAN or CAN FD) can be configured separately for each Tx Buffer element. The Tx Buffer element is described in related information. The following table describes the possible configurations for frame transmission.

Table 981 Possible configuration for frame transmission

CCCR		Tx buffer element		Frame transmission
BRSE	FDOE	FDF	BRS	
Ignored	0	Ignored	Ignored	Classical CAN
0	1	0	Ignored	Classical CAN
0	1	1	Ignored	FD without bit rate switching
1	1	0	Ignored	Classical CAN
1	1	1	0	FD without bit rate switching
1	1	1	1	FD with bit rate switching

***Note**: AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation*

The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register Ni_TXBRP (i=0-3) is updated, or when a transmission has been started.

Related information

Tx buffer element on page 3930

21.5.3.5.1 Transmit pause

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority should be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If for example CAN ECU-1 has the transmit pause feature enabled and is requested by its application software to transmit four messages, it will, after the first successful message transmission, wait for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The transmit pause feature is controlled by bit Ni_CCCR (i=0-3).TXP. If the bit is set, the M_CAN will, each time it has successfully transmitted a message, pause for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is transmit pause disabled (Ni_CCCR (i=0-3).TXP = '0').

This feature loosens up burst transmissions coming from a single node and it protects against "babbling idiot" scenarios where the application program erroneously requests too many transmissions.

21.5.3.5.2 Dedicated Tx buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. Each dedicated Tx Buffer is configured with a specific Message ID. In case that multiple dedicated Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first. These Tx buffers shall be requested in ascending order with lowest buffer number first. Alternatively all Tx buffers configured with the same Message ID can be requested simultaneously by a single write access to Ni_TXBAR (i=0-3).

If the data section has been updated, a transmission is requested by an "Add Request" through Ni_TXBAR (i=0-3).ARn. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

A dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM (see related information). Therefore the start address of a dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index (0…31) • Element Size to the Tx Buffer Start Address Ni_TXBC (i=0-3).TBSA.

Table 982 Tx buffer/FIFO/queue element size

Ni_TXESC.TBDS[2:0]	Data field [bytes]	Element size [RAM words]

111	64	18

Related information

Tx FIFO on page 3956

21.5.3.5.3 Tx FIFO

Tx FIFO operation is configured by programming Ni_TXBC (i=0-3).TFQM to '0'. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index Ni_TXFQS (i=0-3).TFGI. After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The M_CAN calculates the Tx FIFO Free Level Ni_TXFQS (i=0-3).TFFL as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index Ni_TXFQS (i=0-3).TFQPI. An "Add Request" increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (Ni_TXFQS (i=0-3).TFQF = '1') is signalled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing a '1' to the TXBAR bit related to the Tx Buffer referenced by the Tx FIFO's Put Index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested by Ni_TXBAR (i=0-3). The Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level.

When a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see table in related information). Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index Ni_TXFQS (i=0-3).TFQPI (0…31) • Element Size to the Tx Buffer Start Address Ni_TXBC (i=0-3).TBSA.

Related information

Dedicated Tx buffers on page 3954

21.5.3.5.4 Tx queue

Tx Queue operation is configured by programming Ni_TXBC (i=0-3).TFQM to '1'. Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Tx Queue buffers are configured with the same Message ID, the transmission order depends on numbers of the buffers where the messages were stored for transmission. As these buffer numbers depend on the then current states of the Put Index, a prediction of the transmission order is not possible.

New messages have to be written to the Tx Buffer referenced by the Put Index Ni_TXFQS (i=0-3).TFQPI. The Put Index always points to that free buffer of the Tx Queue with the lowest buffer number. In case that the Tx Queue is full (Ni_TXFQS (i=0-3).TFQF = "1"), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use register TXBRP instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see table in related information). Therefore the start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index Ni_TXFQS (i=0-3).TFQPI (0…31) • Element Size to the Tx Buffer Start Address Ni_TXBC (i=0-3).TBSA.

Related information

Dedicated Tx buffers on page 3954

21.5.3.5.5 Mixed dedicated Tx buffers/Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of dedicated Tx Buffers and a Tx FIFO. The number of dedicated Tx Buffers is configured by Ni_TXBC (i=0-3).NDTB. The number of Tx Buffers assigned to the Tx FIFO is configured by Ni_TXBC (i=0-3).TFQSi. In case Ni_TXBC (i=0-3).TFQS is programmed to 0x0, only dedicated Tx Buffers are used.

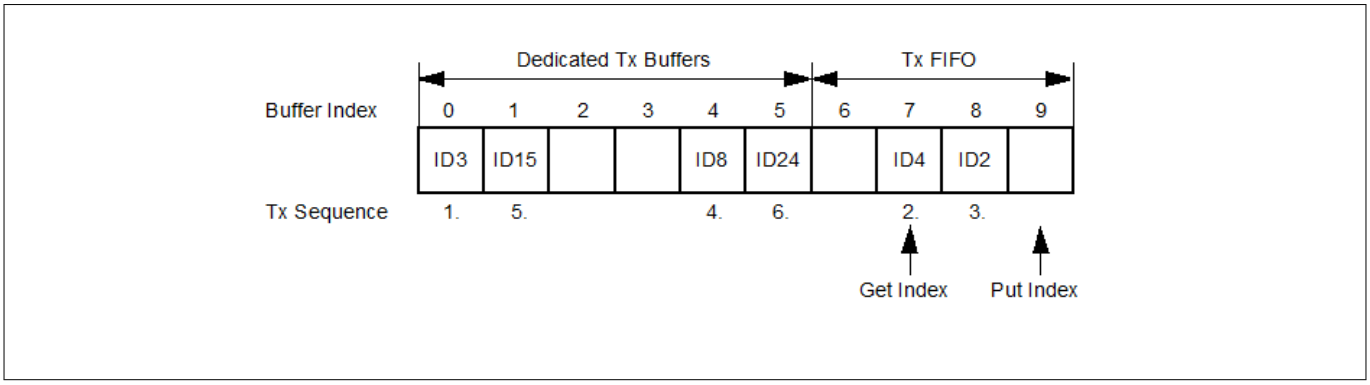

Figure 382 Example of mixed configuration dedicated Tx buffers/Tx FIFO

Tx prioritization:

- Scan dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by Ni_TXFQS (i=0-3).TFGI)
- Buffer with lowest Message ID gets highest priority and is transmitted next

21.5.3.5.6 Mixed dedicated Tx buffers/Tx queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of dedicated Tx Buffers and a Tx Queue. The number of dedicated Tx Buffers is configured by Ni_TXBC (i=0-3).NDTB. The number of Tx Queue Buffers is configured by Ni_TXBC (i=0-3).TFQSi. In case Ni_TXBC (i=0-3).TFQS is programmed to zero, only dedicated Tx Buffers are used.

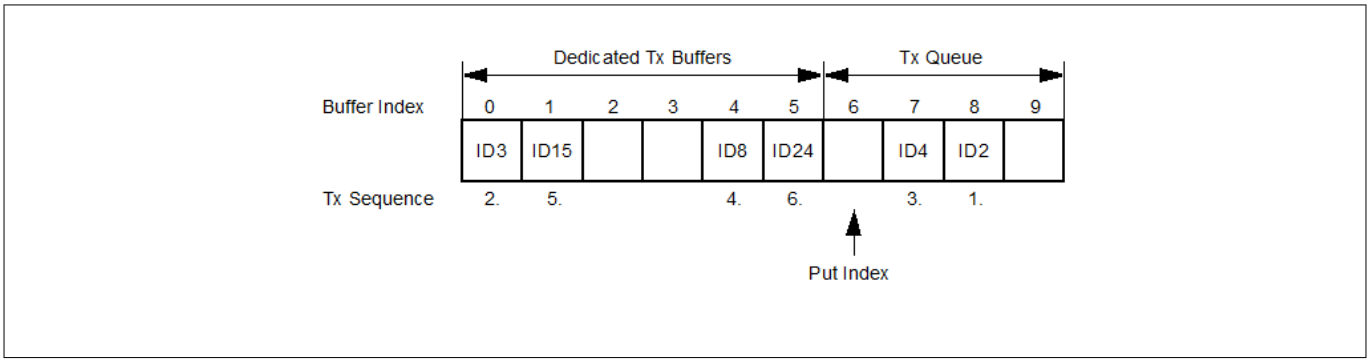

Figure 383 Example of mixed configuration dedicated Tx buffers/Tx queue

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

21.5.3.5.7 Transmit cancellation

This feature is especially intended for gateway applications and AUTOSAR based applications. To cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue buffer the Host has to write a '1' to the corresponding bit position (=number of Tx Buffer) of register Ni_TXBCR (i=0-3). Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of register TXBCF to '1'.

In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

***Note**: In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.*

21.5.3.5.8 Tx event handling

To support Tx event handling the M_CAN has implemented a Tx Event FIFO. After the M_CAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

The Tx Event FIFO can be configured to a maximum of 32 elements. The Tx Event FIFO element is described in related information.

The purpose of the Tx Event FIFO is to decouple handling transmit status information from transmit message handling that is a Tx Buffer holds only the message to be transmitted, while the transmit status is stored separately in the Tx Event FIFO. This has the advantage, especially when operating a dynamically managed transmit queue, that a Tx Buffer can be used for a new message immediately after successful transmission. There is no need to save transmit status information from a Tx Buffer before overwriting that Tx Buffer.

When a Tx Event FIFO full condition is signalled by Ni_IR (i=0-3).TEFF, no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag Ni_IR (i=0-3).TEFL is set.

To avoid a Tx Event FIFO overflow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by Ni_TXEFC (i=0-3).EFWM, interrupt flag Ni_IR.TEFW is set.

When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index Ni_TXEFS (i=0-3).EFGI has to be added to the Tx Event FIFO start address Ni_TXEFC (i=0-3).EFSA.

Related information

Tx event FIFO element on page 3931

21.5.3.6 FIFO acknowledge handling

The Get Indices of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see Ni_RXF0A, Ni_RXF1A and Ni_TXEFA). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index.

When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFO's Get Index.

Due to the fact that the CPU has free access to the M_CAN's Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also alters the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

***Note**: The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The M_CAN does not check for erroneous values.*

21.6 CAN Routing Engine (CRE)

The CAN Routing Engine (CRE) is an extension of MCMCAN which is used to route CAN frames by determining the destination(s) of a received CAN frame based on the received CAN-ID.

The destination of the CAN frame can be another CAN interface or Ethernet interface or a System RAM location. The CRE standalone routes the CAN frames with destination within the MCMCAN it belongs to. For CAN frames with destination outside the MCMCAN, CRE writes the frame to respective Host Buffer and triggers the Data Routing Engine (DRE) or an interrupt to the Interrupt Router based on the configuration. The CRE provides a virtual host interface to the RxFIFOs and TxQueues/TxFIFO of M_CAN, for ease of reading the received CAN frame and writing the transmit CAN frame without any additional processing by host to perform address calculation/acknowledge for CAN RxFIFO and TxQueue/TxFIFO. The CRE also consists of a Intrusion Detection Measurement Unit (IDMU) which provides parameters that can be used by intrusion detection software.

The CRE is enabled by setting Ni_CRE_CONFIG.EN to 1. When CRE is enabled, the virtual host interfaces RX and TX Host Buffers are also enabled. In this case, the received frames are read from the receive Host Buffer RHBUF by the FPI master instead of the RxFIFO. Frames are written to the Transmit Host Buffer THBUF by the FPI master instead of TxQueue/TxFIFO. The CRE must be enabled before enabling routing or IDMU.

***Note**: When CRE is disabled, both routing and IDMU are disabled. The host buffers are disabled and the frames are written to or read from TxQueue/TxFIFO and RxFIFO.*

The routing operation is enabled by setting both Ni_CRE_CONFIG.EN and Ni_CRE_CONFIG.REN to 1. This CRE should be enabled both at the source and the destination nodes for a successful routing operation.

The IDMU is enabled by setting both Ni_CRE_CONFIG.EN and Ni_CRE_CONFIG.IDMUEN to 1.

21.6.1 Feature list

The following are the features of CRE:

- Offloads CPU by hardware accelerated routing of received CAN frames to a user configured destination(s)
- Hardware accelerated CAN to CAN routing within the same MCMCAN module
- Assists Data Routing Engine (DRE) to perform hardware accelerated
  - CAN to CAN routing between different MCMCAN module
  - CAN to Ethernet (in IEEE 1722 ACF Frame) routing
  - CAN frame to a user configurable system RAM location transfer
  - CAN PDU to a user configurable system RAM location transfer
- Supports DRE in multi-cast routing, that is routing of a received CAN frame to a maximum of up to four destinations
- Provides a configurable routing table to define the rules of the routing operation

- Abstracts the M_CAN RxFIFOs and TxFIFO/TxQueues operation to the host interface by providing virtual buffers
  - Enables system DMA, CPU software or DRE to write transmitted CAN frames and to read received CAN frames with ease
- Consists of a measurement unit for Intrusion Detection (IDMU)

21.6.2 Functional overview

The CAN Routing Engine is shared by all four CAN interfaces in a MCMCAN module as shown in the figure below.

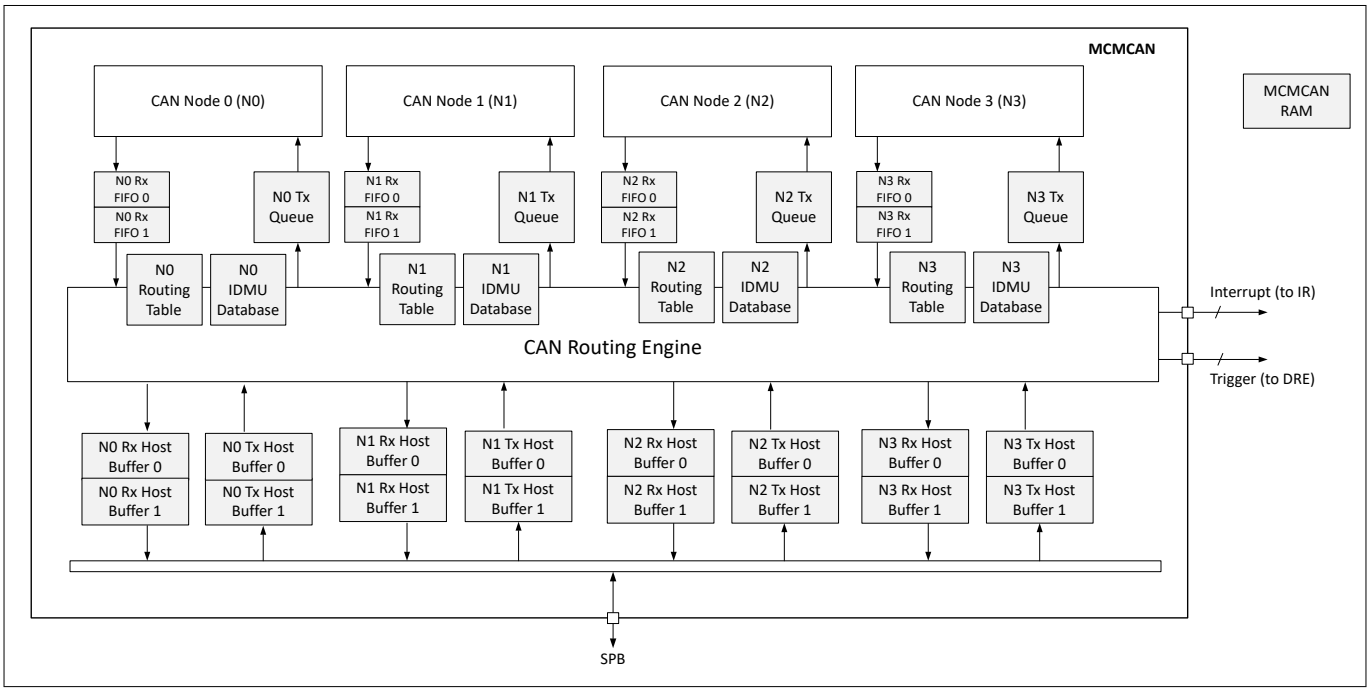

Figure 384 CRE interfaces to CAN nodes

Routing table

The Routing Table contains the rules which decide the routing path of the received CAN frame. It also has other configuration parameters related to its destination. The CAN Routing Engine uses the Routing Table to perform all the routing operations.

IDMU

The Intrusion Detection Measurement Unit (IDMU) contains a Timestamp database and a Frame Rate Measure table, which provide measures that can be used for intrusion detection. The CAN Routing Engine uses the Timestamp database to calculate the Inter Arrival Measure (IAM) of frames. The Frame Rate Measure table consists of counters that increment with reception of each frame.

Receive host buffer

The Receive Host Buffer 0/1 contains the pending received CAN frame from RxFIFO0/RxFIFO1. The CRE identifies the routing destination of the newly received CAN frame from RxFIFO0 or RxFIFO1. If the Routing Destination is not one of the CAN Nodes belonging to the CRE (within the same MCMCAN the CRE belongs to), then CRE writes the CAN frame to the respective Receive Host Buffer. If the destination of the CAN frame is within the same MCMCAN the CRE belongs to, the frame is not written to respective Receive Host Buffer. The CRE transmit interface writes the CAN frame directly to the destination CAN node TxQueue or TxFIFO.

Event Notification: Each new frame on the Rx Host Buffer triggers either an interrupt to IR or a trigger to DRE, as configured by the user.

Transmit host buffer

The Tx Host Buffer0/1 contains the CAN frame to be transmitted. Upon detecting a valid CAN frame, the CRE copies the frame to TxQueue or to TxFIFO and initiates transmission by setting Transmit request (Ni_TXBAR).

Event Notification: When a free element in TxQueue/TxFIFO is available, triggers either an interrupt to IR or a trigger to DRE, indicating the possibility to initiate transmission of a new CAN frame through the Tx Host Buffer.

21.6.3 Functional description

The block diagram of CRE is shown in Figure below

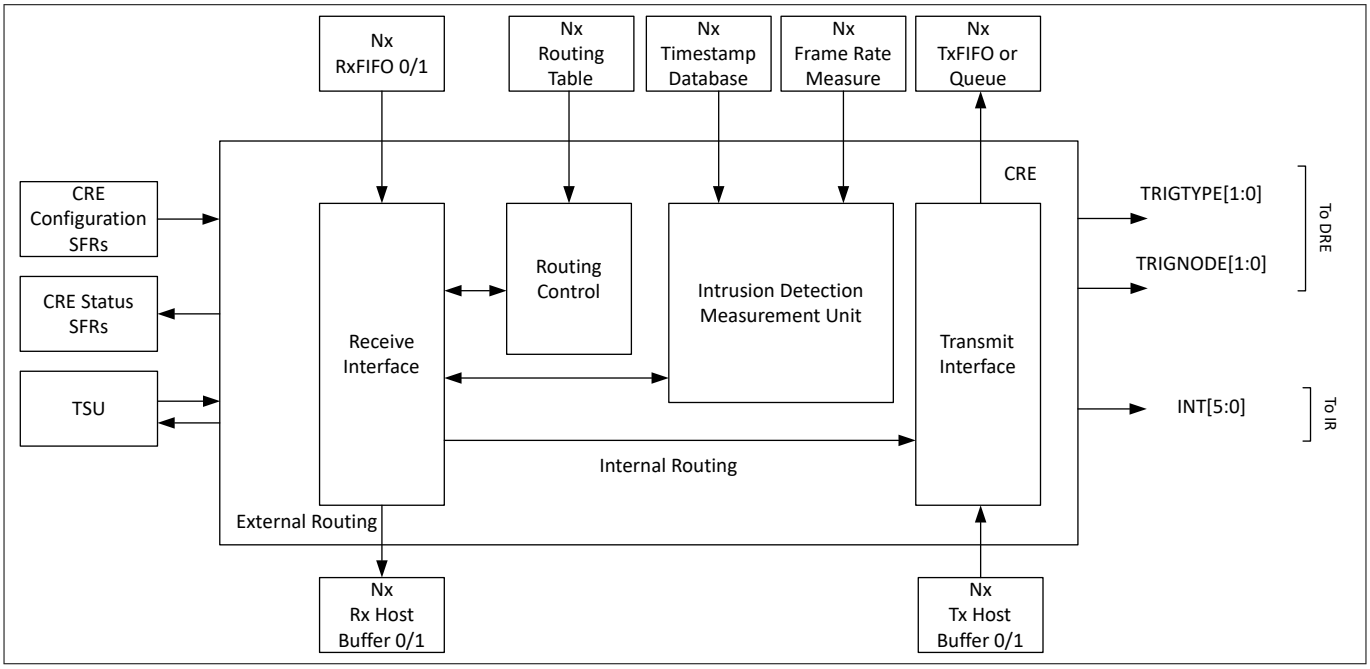

Figure 385 CRE block diagram

The CRE consists of four major blocks:

- Receive Interface
- Routing Control
- Intrusion Detection Measurement Unit (IDMU)
- Transmit Interface

In addition to it, the CRE Host Buffers, Routing Tables, IDMU Tables and databases are stored in the MCMCAN RAM. Total RAM size of 36KBytes or 20KBytes (Refer to Device specific CAN configuration chapter for the total RAM size for the CAN module) is shared between CRE and CAN. Based on the use case, user shall do the RAM configuration for CRE and CAN. For example, 4KB for CRE and 32 KB of RAM can be configured for MCMCAN0. Ni_CRE_CONFIGADR.SA defines the start address of the CRE configurations in the RAM. The start addresses and size of the tables are part of the CRE tables specific configuration parameters as shown in the following figure.

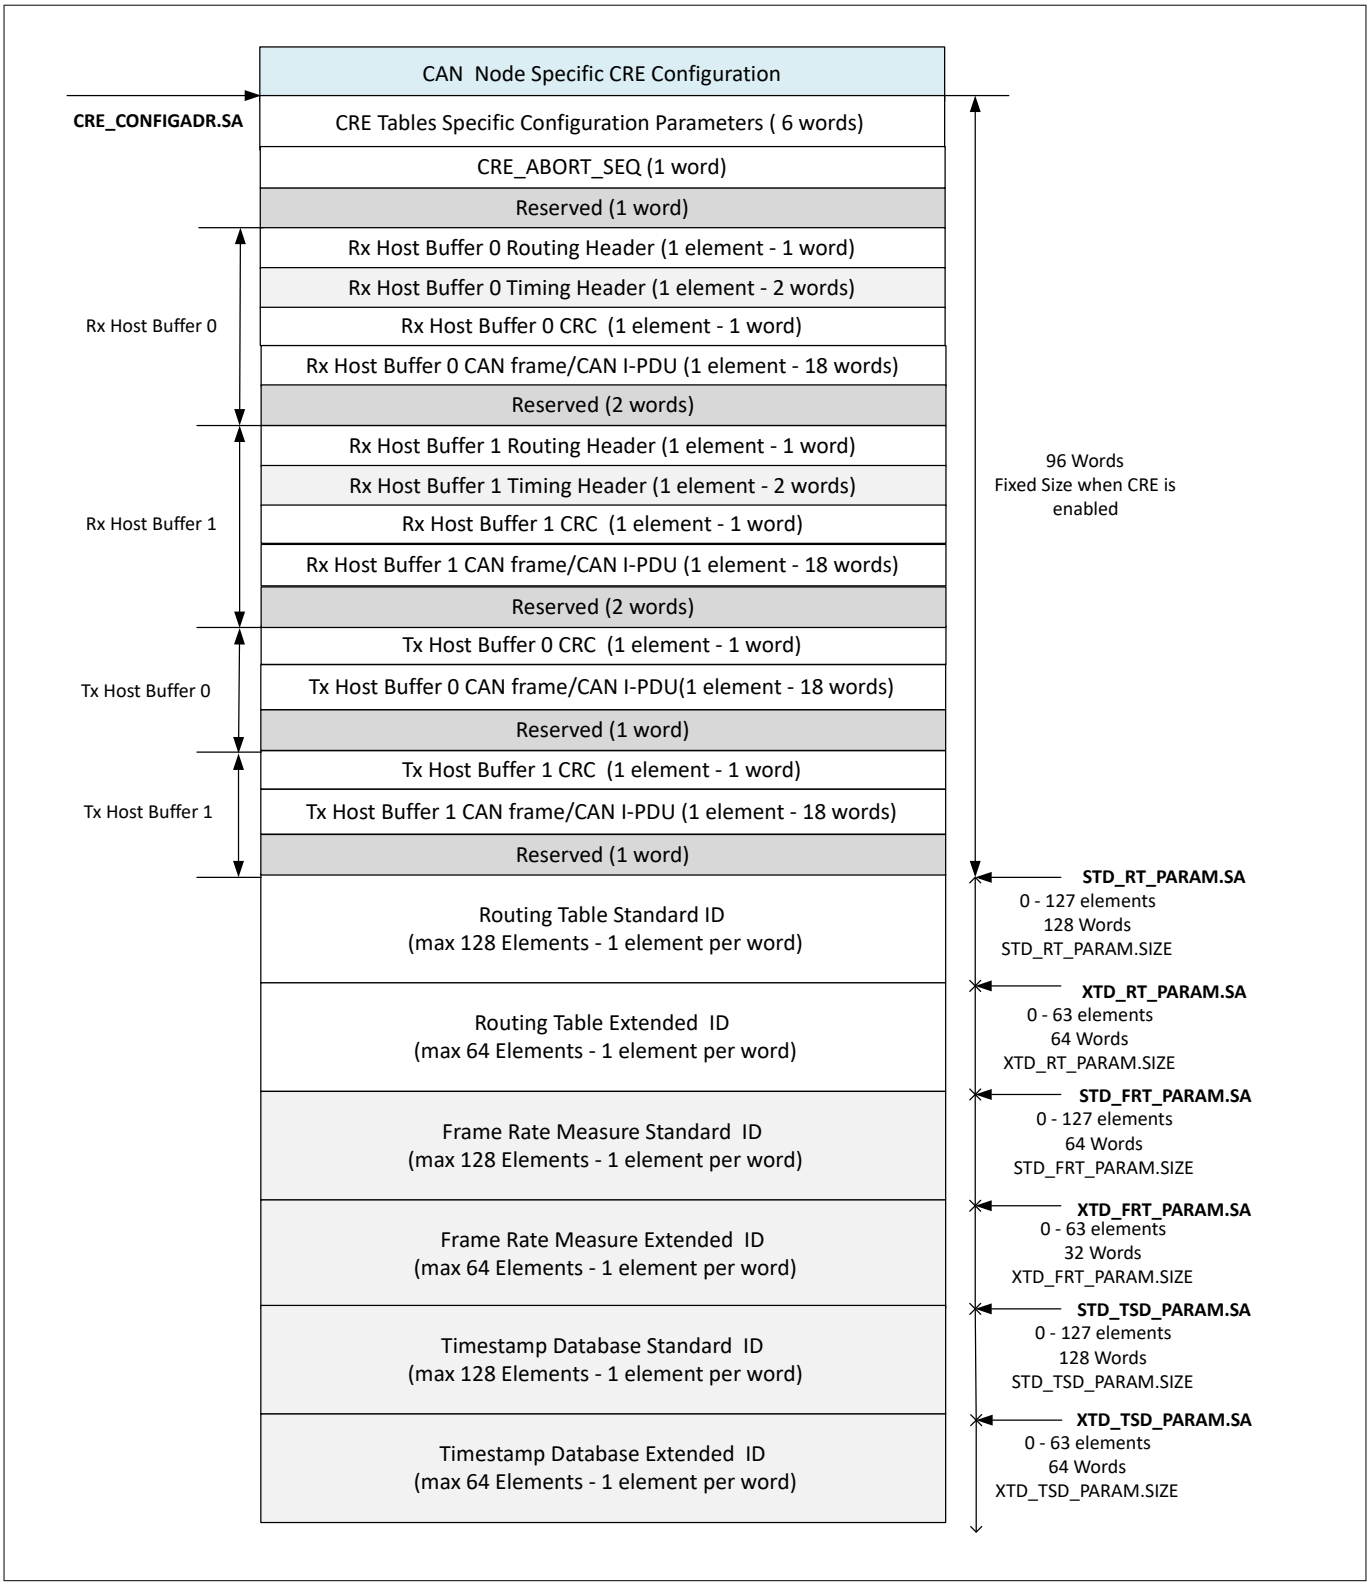

Figure 386 Message RAM layout for CRE

***Note**: Offset addresses for the CRE Standard Routing Table, CRE Extended Routing Table, CRE Standard Frame Rate Table, CRE Extended Frame Rate Table, CRE Standard Timestamp Database and CRE Extended Timestamp Database are relative to the configured start address by the user in the appropriate CRE configuration table. These configured start addresses are absolute in the CAN message RAM and not relative to the start of the CRE RAM section.*

In following sections, detailed functionality of CRE with respect to transmit and receive CAN frames are described.

21.6.3.1 Receive interface

The Receive Interface abstracts the following operations relating to RxFIFO for the user:

- Address calculation to identify the pending RxFIFO0/1 element
- Acknowledge the RxFIFO 0/1 after the read operation
- Fetching the external 32-bit timestamp from the TSU
- Fetching the internally generated 16-bit timestamp from RXMSGk_R1A (k=0-63).RXTS[15:0]

When Ni_CRE_CONFIG (i=0-3).EN = 1, a master of FPI can always read a pending received CAN frame only from the Rx Host Buffer 0/1 instead of accessing from the RxFIFO0/1. The CRE assists the read operation by providing a interrupt/trigger for each newly available CAN frame stored in Rx Host Buffer 0/1. The Receive Interface interacts with the Routing Control to identify the destination of a corresponding received CAN frame. It fetches the receive timestamp from the Timestamping Unit (TSU) (external timestamp) or from RXMSGk_R1A (k=0-63).RXTS[15:0] (internal timestamp). It interacts with the IDMU to calculate the intrusion detection measures. The Receive Interface also updates the timing header with the received timestamp.

Identify a new received frame from RxFIFO

The Receive Interface monitors the RxFIFO fill level Ni_RXF0S (i=0-3).F0FL (or) Ni_RXF1S (i=0-3).F1FL. When the F0FL or F1FL is not 0, then CRE reads the newly received CAN frame as indicated by RxFIFO Get index Ni_RXF0S.F0GI or Ni_RXF1S.F1GI. The corresponding Get index of the RxFIFO is also indicated in Ni_CRE_HBUF_RXz_STAT (i=0-3;z=0-1).INDEX.

Fetching the receive timestamp

Every frame consists of a 16-bit internal (Internal Timestamp Generation, see related information) or 32-bit external timestamp (Timestamping Unit (TSU), see related information). Receive Interface first checks if the TSU is enabled (CCCR.UTSU = 1 and TSUE = 1) and then if RXMSGk_R1B (k=0-63).TSC is set. R1B.TSC is set when a timestamp has been captured by the TSU and RXMSGk_R1B (k=0-63).RXTSP holds a valid timestamp pointer. If R1B.TSC is set and the TSU is enabled, the Receive Interface fetches the 32-bit timestamp captured by the TSU using the RXMSGk_R1B (k=0-63).RXTSP which holds the pointer of the TSU's timestamp register.

The Timing Header (THEAD) is composed of two words (32-bit each) as shown in the figure above. RHBUFk_THEAD_RXTS (k=0-1) holds the timestamp and RHBUFk_THEAD_INTRD (k=0-1) consists of status flags (TSCLEN, TSC and TSL) associated with the THEAD_RXTS. The Receive Interface updates the THEAD with the timestamp received in the following manner:

- Case 1: When a 16-bit internal timestamp is used, Timing Header (THEAD) RHBUFk_THEAD_RXTS (k=0-1) is updated with RXMSGk_R1A (k=0-63).RXTS[15:0]. TSCLEN and TSC are set to 0 by the hardware
- Case 2: When a 32-bit external timestamp is used, Timing Header (THEAD) RHBUFk_THEAD_RXTS (k=0-1) is updated with the timestamp from TSU pointed to by RXMSGk_R1B (k=0-63).RXTSP[3:0]. TSCLEN and TSC are set to 1 by the hardware. The TSC bit is set to 1 by the hardware to indicate that the 32-bit timestamp RHBUFk_THEAD_RXTS (k=0-1) is valid. The timestamp is only valid when bits Ni_CCCR.UTSU, TSUE, SSYNC/ESYNC, RXMSGk_R1B.TSC and Ni_TSU_TSS1.TSN are set. TSL bit is set in the THEAD when there is a loss of timestamp in the TSU (Ni_TSU_TSS1.TSLn = 1)

***Note**: The Intrusion Detection Measurement Unit (IDMU) (see related information) updates the THEAD further with the intrusion detection measure IAM and IAMSTAT*

Relevance for routing operation

When the routing operation is enabled for a CAN node (Ni_CRE_CONFIG (i=0-3).REN), then the Receive Interface decides if the received CAN frame is relevant for routing operation or not, based on the Acceptance Filter from which the CAN frame has been received. REN should be enabled at the source CAN node. Enabling REN makes the CAN node a routing source. The frame is routed to the destination DID irrespective of the REN bit at the destination node.

The CRE Receive Interface checks the Acceptance Filter ID (RXMSGk_R1A (k=0-63).FIDX) and Accept Non-Matching Frame (RXMSGk_R1A (k=0-63).ANMF) in the Rx FIFO element of the received CAN frame.

- Case 1: When R1.ANMF = 1, then the Rx frame is not relevant for routing
- Case 2: When R1.ANMF = 0, and R1.FIDX < CRE_STD_RT_PARAM.SIZE (when R0.XTD = 0) or CRE_XTD_RT_PARAM.SIZE (when R0.XTD = 1), the Rx frame is relevant for routing. Otherwise, the Rx frame is not relevant for routing

In case routing is disabled (REN is 0), all the frames are considered as routing non-relevant. REN bit is checked only at the source CAN node of the Routing operation.

Case 1: Routing non-relevant Rx CAN frame

The Received CAN frame is processed according to Table 984 without performing a Routing operation. Ni_CRE_HBUF_RXz_STAT (i=0-3;z=0-1).VRH is set to 0, to indicate the corresponding CAN frame stored in Rx Host Buffer does not have a Routing Header (Routing non-relevant).

Case 2: Routing relevant Rx CAN frame

The CRE Receive Interface passes the CAN frame over to the Routing Control. Routing Control consists of Routing Tables for both standard ID and extended ID CAN frames. The Routing Tables should be configured by the user with routing rules (standard ID: SRTk_UCR or SRTk_MCR and extended ID: XRTk_UCR or XRTk_MCR) that give the destination ID (DID) of CAN frames. The routing destination ID (DID) map is shown in the following table. After Routing Control has identified the destination of the CAN frame, the Receive Interface performs an internal CAN routing or external CAN routing depending on the DID.

1. Internal routing of CAN frames: If the DID belongs to the IDs of the CAN node belonging to the same MCMCAN as that of the CRE, the CRE Receive Interface provides the CAN frame along to the Transmit Interface. For example, if the Ni_CRE_CONFIG (i=0-3).ID = 1_H and corresponding routing rule configured in the Routing Table SRTk_UCR (k=0-127).DID = 2_H, the frame is routed internally within MCMCAN0 from CAN node with ID 1_H to CAN node with ID 2_H

   ***Note**: No Routing header is generated and CAN frame is not written to the respective RHBUF (Rx Host Buffer) in case of internal routing.*

2. External routing of CAN frames: If the DID does not belong to the IDs of the CAN node belonging to the same MCMCAN as that of the CRE (Ni_CRE_CONFIG (i=0-3).ID), then CRE Receive Interface generates a Routing Header (RHBUFk_UCRH (k=0-1) or RHBUFk_MCRH (k=0-1)), writes the Routing Header and the modified CAN frame to the corresponding Rx Host Buffer. Table 985 explains the processing of external routing relevant frames. VRH is set to 1, to indicate the corresponding CAN frame stored in Rx Host Buffer has a valid Routing Header (Routing relevant). When the DID does not belong to any valid destination, the VRH is not set. The format of the Routing Header is described in RHBUFk_UCRH (k=0-1) or RHBUFk_MCRH (k=0-1)

The CRE Receive Interface also computes an 16-bit CRC over the CAN headers R0 and R1 (except ESI, ANMF, RXTS and FIDX which are considered zero for CRC calculation), the safety critical CAN payload and the DID of CAN frame stored in the Rx Host Buffer. The CRC is calculated over 16-bit data at a time starting with the MSB. The 32-bit RAM word is divided into two 16-bit words and the highest 16 bits (31:16) is taken first for the CRC calculation followed by the lower 16 bits (15:0). The CRC calculation and verification is always enabled when

Ni_CRE_HBUF_RXz_CONFIG (i=0-3;z=0-1).TRIGEN is enabled. The CRC calculation and verification can be enabled or disabled using Ni_CRE_HBUF_RXz_CONFIG (i=0-3;z=0-1).CRCEN. In case of DIDs belonging to system memory locations (20_H till $3B_H$), the CRC calculation is not valid and it is ignored by the DRE. The CRC should be read exactly once as the first element from the Rx Host Buffer by the DRE or by the application. The Receive Interface stores the computed CRC along with the CAN frame in the Rx Host Buffer. The CRE uses CCITT CRC16 polynomial: 0x1021 $x^{16} + x^{12} + x^5 + 1$.

Table 983 Routing destination IDs

Destination	ID (6 bits)	Transfer destination
Destination disabled	0_H	-
MCMCAN0_Ni (i=0:3)	1_H till 4_H	CAN0 Transmit Host Buffer 0 (MCMCAN0_Ni_THBUF0)
MCMCAN1_Ni (i=0:3)	5_H till 8_H	CAN1 Transmit Host Buffer 0 (MCMCAN1_Ni_THBUF0)
MCMCAN2_Ni (i=0:3)	9_H till C_H	CAN2 Transmit Host Buffer 0 (MCMCAN2_Ni_THBUF0)
MCMCAN3_Ni (i=0:3)	D_H till 10_H	CAN3 Transmit Host Buffer 0 (MCMCAN3_Ni_THBUF0)
MCMCAN4_Ni (i=0:3)	11_H till 14_H	CAN4 Transmit Host Buffer 0 (MCMCAN4_Ni_THBUF0)
ACF Ethernet frames	18_H till $1D_H$	DRE CAN Input Buffer List
System memory locations (1 to 28)	20_H till $3B_H$	User configured by DMEMi (i=0:27)
Reserved for future extension	Others	-

In case of a routing non-relevant frames as shown in Case 1 above or for CAN frames with invalid destination ID, for example, in case of PDU routing with DID outside the range of System memory locations 20_H till $3B_H$, the behavior would be as follows:

Table 984 Behavior in case of routing non-relevant frames and invalid DID

Ni_CRE_HBUF_RXz_CONFIG.TRIGEN	Ni_CRE_HBUF_RXz_CONFIG.INTEN	Behavior
0	0	Invalid configuration. The frame just remains in the Receive Host Buffer.
1	0	The frame is discarded from the routing operation and there is no trigger to the DRE
0	1	The frame is written to the Receive Host Buffer and interrupt is triggered
1	1	The frame is written to the Receive Host Buffer and interrupt is triggered. There is no trigger to the DRE

Table 985 Behavior in case of external routing relevant frames

Ni_CRE_HBUF_RXz_CONFIG.TRIGEN	Ni_CRE_HBUF_RXz_CONFIG.INTEN	Behavior
0	0	Invalid configuration. The frame just remains in the Rx Host Buffer.
1	0	The frame is written to Rx Host Buffer and there is a trigger to the DRE
0	1	The frame is written to the Rx Host Buffer and interrupt is triggered
1	1	The frame is written to Rx Host Buffer and there is a trigger to the DRE. There is an interrupt trigger as well. The application needs to ensure it does not read any message content that is covered by the sequence checker in order not to disrupt the reading of message by the DRE

Event generation

After the Receive Interface writes the complete frame to the Receive Host Buffer (RHBUF), it generates the new event by triggering either the DRE or an interrupt to the IR.

- Trigger to DRE is done through TRIGTYPE[1:0] and TRIGNODE[1:0] interfaces when Ni_CRE_HBUF_RXz_CONFIG (i=0-3;z=0-1).TRIGEN is set
- Interrupt to IR Ni_CRE_IR (i=0-3).RBUFzI is triggered when Ni_CRE_HBUF_RXz_CONFIG (i=0-3;z=0-1).INTEN is set

After the trigger, the Rx Host Buffer New Event (Ni_CRE_HBUF_RXz_STAT (i=0-3;z=0-1).RHREQ) flag is set to 1 by hardware indicating a frame is ready to be read from the RHBUF. The software can also trigger the DRE by setting Ni_CRE_HBUF_RXz_STAT (i=0-3;z=0-1).SWTRIG to 1 after writing a frame into the RHBUF. The hardware clears the SWTRIG flag after trigger to DRE.

Multi-cast routing

In case of 1 up to 4 multi-cast routing, the Receive Interface hands over the frame to the Transmit interface in case of an internal routing. In case of destinations outside the same MCMCAN, the Receive Interface writes the complete frame to the respective Receive Host Buffer and triggers the DRE. The multi-cast routing with up to 4 DIDs outside the same MCMCAN is broken down into 4 individual uni-cast routing by the CRE. In this case, the CRE overwrites the Routing header with a new DID and triggers the DRE. The CRE clears the Receive Host Buffer (RHBUF) contents only after the DRE forwards the frames to the corresponding DID specified in the Routing Headers. The multi-cast routing rule SRTk_MCR or XRTk_MCR should follow the below configuration rules:

- At least DID0 and DID1 should have valid destination IDs (1_H till 14_H or 20_H till $3B_H$)
- All valid DIDs are different
- Unused DIDs are set to zero
- No gaps allowed between valid DIDs. For example,
  - Valid configuration: DID0, DID1 and DID2 are valid
  - Invalid configuration: DID0, DID1 and DID3 are valid. DID2 is set to zero

PDU routing

PDU routing is handled together by CRE and DRE. In case of PDU routing, the CRE Receive Interface:

- Converts the CAN frame into an CAN I-PDU (Interaction layer Protocol Data Unit) by generating a PDU Header along with the Routing and Timing Headers. The PDU Header is of two 32-bit RAM words and consists of the PDU ID and Payload length.

  ***Note**:* *PDU Header has the same size of 2 32-bit RAM words as that of R0 and R1 of the CAN frame so that data location remains the same*

- Writes the CAN I-PDU to the Rx Host Buffer
- Triggers the DRE

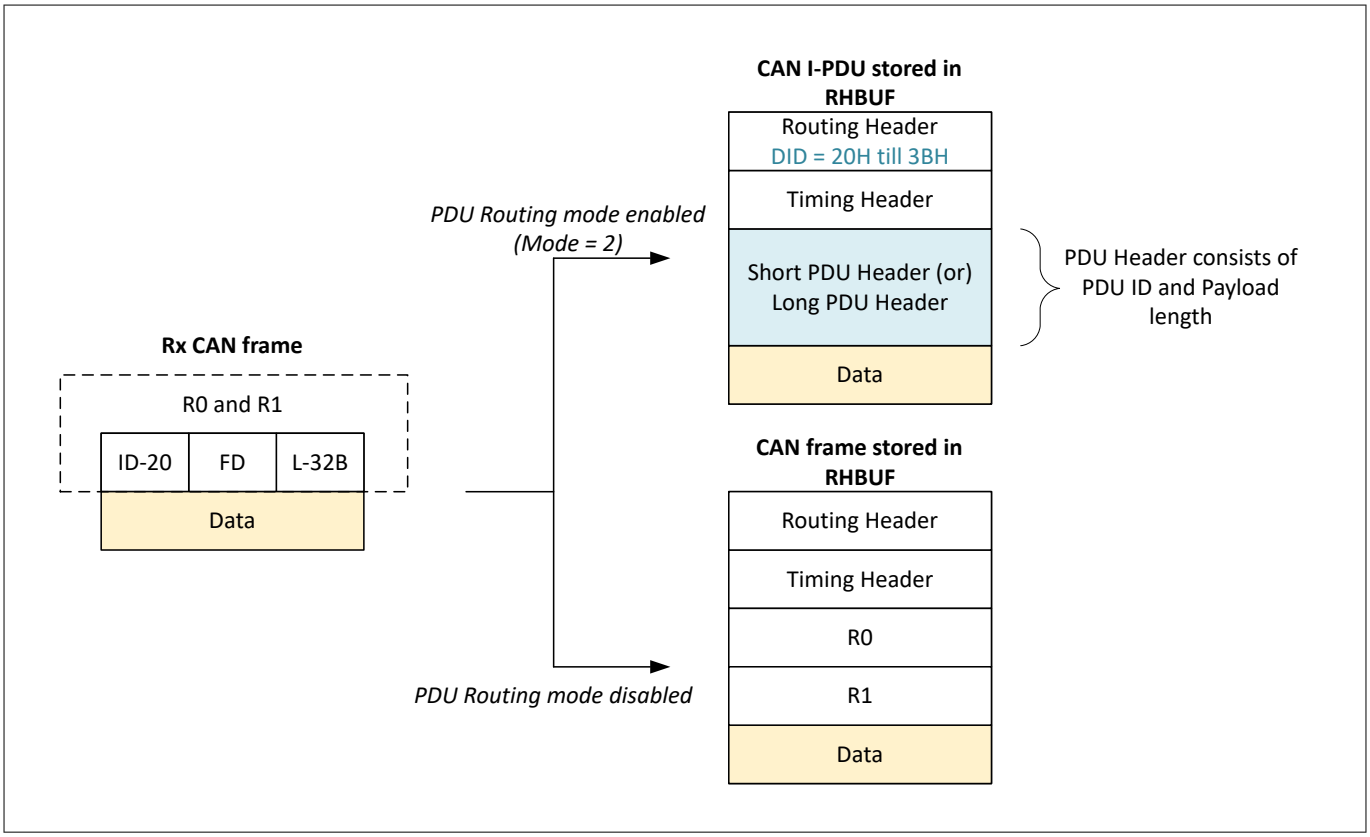

Figure 387 CAN frame to CAN I-PDU conversion

Read completion event

The Receive Host Buffer interrupt or trigger can be used by a master of FPI to read the CAN frame (R0, R1 and data) from the Receive Host Buffer. The Receive Interface also monitors the address of the Last Word of data to be read from FPI interface. The 'Last Word' can be configured either as Dynamic Data Length (based on DLC) or Fixed Data Length through Ni_CRE_HBUF_RXz_CONFIG (i=0-3;z=0-1).LEN. The DRE always reads the Rx Host Buffer in Dynamic Data Length mode. Fixed Data Length mode is only for software. One data word (DW) corresponds to 4 bytes.

For example, If the CAN Message has DLC = 4, and the Rx Host Buffer LEN = 2, then:

- - Dynamic Data Length
    - The last read operation is DW0 (RHBUFk_RHBUF_DBm (k=0-1;m=0-63))
  - Fixed Data Length
    - The last read operation is DW1 (RHBUFk_RHBUF_DBm (k=0-1;m=0-63))

***Note**:* *When the RTR bit is set, the frame ends at R1 because it has no data. Remote frames configured for PDU routing are rejected.*

On the 'Last Word' read completion event (the entire CAN frame is read from the Rx Host Buffer), the Receive Interface performs the following actions:

1. The Rx Host Buffer New Event (Ni_CRE_HBUF_RXz_STAT (i=0-3;z=0-1).RHREQ) flag is cleared by hardware
2. Acknowledge the corresponding RxFIFO by updating the Ni_RXF0A or Ni_RXF1A.FA with the index of the FIFO element currently processed
3. On each successful read completion of a frame from the Receive Host Buffer, the Receive Host Buffer counter (Ni_CRE_HBUF_RXz_STAT (i=0-3;z=0-1).COUNT) is incremented by 1 (resets to 0 on overflow)
4. The Receive Interface starts processing the next received CAN frame

   In case the DRE Move Engine has an error, it cancels the ongoing read sequence by writing 1 to CRE_ABORT_SEQ(i=0-3).CRHBUF0 or CRHBUF1 as long as the last read has not been started. A read sequence error is triggered in this case. Ni_CRE_IR(i=0-3).IRSI0 or IRSI1 error flag (depending on Rx Host Buffer) is set and interrupt is triggered when Ni_ERRCTRL.IRSIE is enabled. There is no re-trigger to the DRE. The SW clears the error flags and could read the frame from the respective Rx Host Buffer, or set the Ni_CRE_HBUF_RXz_STAT.SWTRIG in order to re-trigger the DRE, or write '1' into Ni_CRE_HBUF_RXz_STAT.RHREQ to free Rx Host Buffer for new frame and discard existing one from Rx Host Buffer.

Error monitoring

1. **Sequence check:** The CRE Receive Interface monitors the incorrect read access to the Rx Host buffer by an FPI master by checking the sequence in which the message is being read from the Rx Host Buffer (R0, R1 and DBm). The Routing header, Timing header and CRC are not part of the sequence check. The sequence checking starts once the FPI master starts reading the first word of the CAN frame or CAN I-PDU from the Rx Host buffer.

   If the message is read in an incorrect sequence, the Ni_CRE_IR(i=0-3).IRSI0 or IRSI1 (depending on Rx Host Buffer) error flag is set and interrupt is triggered when Ni_ERRCTRL.IRSIE is enabled. DRE is not re-triggered in this scenario. The SW clears the error flags and could read the frame from the respective Rx Host Buffer, or set the Ni_CRE_HBUF_RXz_STAT.SWTRIG in order to re-trigger the DRE, or write '1' into Ni_CRE_HBUF_RXz_STAT.RHREQ to free Rx Host Buffer for new frame and discard existing one from Rx Host Buffer.
2. **Timeout monitoring:**

   The CRE Receive Interface also monitors for a delayed read operation by master of FPI. The watchdog timer counter starts incrementing when timeout enable WDT.EN is set. The watchdog timer triggers periodic events E1, E2, …, En after a user configured timeout prescaler WDT.FWDP and SWDP. The FWDP pre-scaler is configured by user for monitoring fast events as shown in Table below. The SWDP prescaler is configured by user for monitoring slow events as shown in Table below. If FWDP or SWDP are set to zero, then a default value of 16 is used for the corresponding prescaler. The fast timeout prescaler and slow timeout prescaler is configured by the user based on the usage of both the RHBUF and THBUF. If the presence of start condition is detected at Ei, then the end condition is expected to happen before Ei+1. If not, the corresponding watchdog timeout error flag Ni_CRE_IR(i=0-3).RWDTI0 or RWDTI1 is set and interrupt is triggered whenNi_ERRCTRL(i=0-3).RWD0IE or RWD1IE is enabled. DRE is not re-triggered in this scenario. The SW clears the error flags and could read the frame from the respective Rx Host Buffer, or set the Ni_CRE_HBUF_RXz_STAT.SWTRIG in order to re-trigger the DRE, or write '1' into Ni_CRE_HBUF_RXz_STAT.RHREQ to free Rx Host Buffer for new frame and discard existing one from Rx Host Buffer.

   The watchdog counter is running at the host clock frequency f_{MCANH} . The timeout period between the events Ei is calculated as follows:

   - Default timeout period : $T_{def} = \frac{16}{f_{MCANH}}$

- Fast timeout period : $T_{fast} = T_{def} * (FWDP + 1)$
- Slow timeout period : $T_{slow} = T_{def} * (SWDP + 1)$

Table 986 Timeout interrupt trigger

Timeout check	Timeout interrupt trigger
End condition is true within a single event Ei	No timeout error. No timeout interrupt triggered
End condition is true within two consecutive events Ei	If the presence of start condition is detected at Ei, then the end condition is expected to happen before Ei+1. If not, timeout interrupt is triggered
End condition is true after two consecutive events Ei	Timeout interrupt is triggered

Table 987 RHBUF : Start and end condition list

Start condition (SC)	End condition (EC)	Direction	Event type	Enable
RxFIFO not empty	RxFIFO processing done	Source	Fast event	When Ni_ERRCTRL.WDG1 is enabled
RHBUF empty	RHBUF full	Source	Slow event	When Ni_ERRCTRL.WDG2 is enabled
RHBUF full	RHBUF empty	Source	Slow event	When Ni_ERRCTRL.WDG3 is enabled

***Note**: Timeout monitoring does not apply to routing non-relevant frames*

21.6.3.2 Routing control

The Routing Control along with the Routing Table decides the destination location of the received CAN frame and formats the CAN frame as defined by the Routing rule.

Routing table

The Routing Table contains a number of user configured Routing rules. The Routing rules define the destination of the CAN frame. The destination can be another CAN interface or Ethernet interface or a system memory location. It also provides the possibility to change the CAN Frame Format Classical/CAN FD Frame, Data Length and ID of the CAN frame.

Each CAN node can have two Routing Tables

- Standard ID Routing Table - Containing the routing rules for Rx CAN frames with standard 11-bit CAN ID
- Extended ID Routing Table - Containing the routing rules for Rx CAN frames with extended 29-bit CAN ID

The start address of the Routing Table is configured in CRE_STD_RT_PARAM.SA and number of Routing rules for standard CAN IDs is configured using CRE_STD_RT_PARAM.SIZE. Similarly for extended CAN IDs at CRE_XTD_RT_PARAM.SA and CRE_XTD_RT_PARAM.SIZE.

Each Routing rule, supports three modes of routing:

- Uni-cast Routing rule (Mode = 0)
  - Only one configurable destination
  - CAN frame modification is possible
- Multi-cast Routing rule (Mode = 1)
  - Up to 4 configurable destinations
  - CAN frame modification not possible
- PDU Routing rule (Mode = 2)
  - Only one configurable destination
  - PDU header generation and automatic PDU ID creation is based on the PDU header type configuration
  - Optional software configurable "Metadata"

The format of the standard ID Uni-cast and Multi-cast Routing rules are given in SRT_UCR and SRT_MCR respectively.

The format of the extended ID Uni-cast and Multi-cast Routing rules are given in XRT_UCR and XRT_MCR respectively.

CAN frame modifiers

When Uni-cast Routing mode is used (Mode = 0), then the CRE can modify the following properties of the received CAN frame based on the following configuration parameters of the Uni-cast Routing rule.

1. FDF (CAN FD Format)
   a. If SRT_UCR.FDFM = 0, the FDF bit is ignored and the CAN frame format is not changed. The frame format is kept same as that of the received CAN frame
   b. If SRT_UCR.FDFM = 1, the CAN frame format is changed to either Classical CAN frame (FDF = 0) or CAN FD frame format (FDF = 1)

   ***Note**: When a CAN-FD frame of more than 8 bytes is configured to be changed to classic CAN format, only the first 8 bytes will be transmitted and remaining data is truncated*

2. DLC (Data Length Code)
   a. If SRT_UCR or XRT_UCR.DLC = 0, the Destination CAN frame length is same as the source CAN frame
   b. If SRT_UCR or XRT_UCR.DLC != 0, the Destination CAN frame length is as defined by ISO 11898-1. The DLC configured in the routing rule must be smaller than the actual frame DLC. When DLC configured in the Routing rule is larger than the frame DLC, the additional bytes will contain undefined values in the Rx Host Buffer

3. IDXOR (CAN ID Modifier)
   a. For Standard ID, the Destination CAN Frame ID = SRT_UCR.IDXOR (XORed) Rx_CANID
   b. For Extended ID, the Destination CAN frame ID = [XRT_UCR.IDXOR << XRT_UCR.IDSHIFT] (XORed) Rx_CANID

***Note**: Both the source and destination nodes in the system should be aware of the frame modifications so that any potential truncation or modification of the safety critical payload can be avoided or properly handled by the system integrator.*

Routing table index

The indexing of the Routing Table is done based upon the receive acceptance filter ID. The Acceptance Filter ID is stored along with the CAN frame in the Receive Buffer, RXMSGk_R1A or RXMSGk_R1B.FIDX. The Rx CAN frames which are accepted by Acceptance Filter ID0 has the corresponding Routing rule stored at address (in words)

Offset ’0’ from the start of the Routing Table, similarly Acceptance Filter ID1 corresponds to address (in words) Offset '1' of Routing Table and so on.

Desired Routing Index:

Standard ID Routing rule Address = CRE_STD_RT_PARAM.SA + $(R1.\mathrm{FIDX} \times 4)$

Extended ID Routing rule Address = CRE_XTD_RT_PARAM.SA + $(R1.\mathrm{FIDX} \times 4)$

Hence it is essential to consider during the Acceptance Filter (AF) configuration, that AF configuration corresponding to the CAN Frames which are to be routed should start with the first AF element 0. A total of up to 128 standard ID Routing rules and 64 extended ID Routing rules can be configured.

PDU routing rule

The PDU routing mode is enabled, when SRTk_PR.Mode is configured as 0x2. The user shall configure the Routing rule "DID" to one of the System memory locations (20_H till $3B_H$). The Routing rule also consists of the "PDU header type", which is used to configure the PDU header contents. Short PDU Header is of 1 RAM word and Long PDU Header is of 2 RAM words.

- Type 1: 11-bit Standard CAN ID with no Metadata
- Type 2: 11-bit Standard CAN ID with Metadata
- Type 3: 11-bit Standard CAN ID with optional Metadata
- Type 4: 29-bit Extended CAN ID with no Metadata
- Type 5: 29-bit Extended CAN ID with no Metadata and no Source ID

***Note**:* *Type 5: If the CAN ID is unique per CAN node, the system can identify the CAN node without the Source ID. Last 3 bits are reserved*

Type 4: Only first 27 bits of the 29-bit ID are used

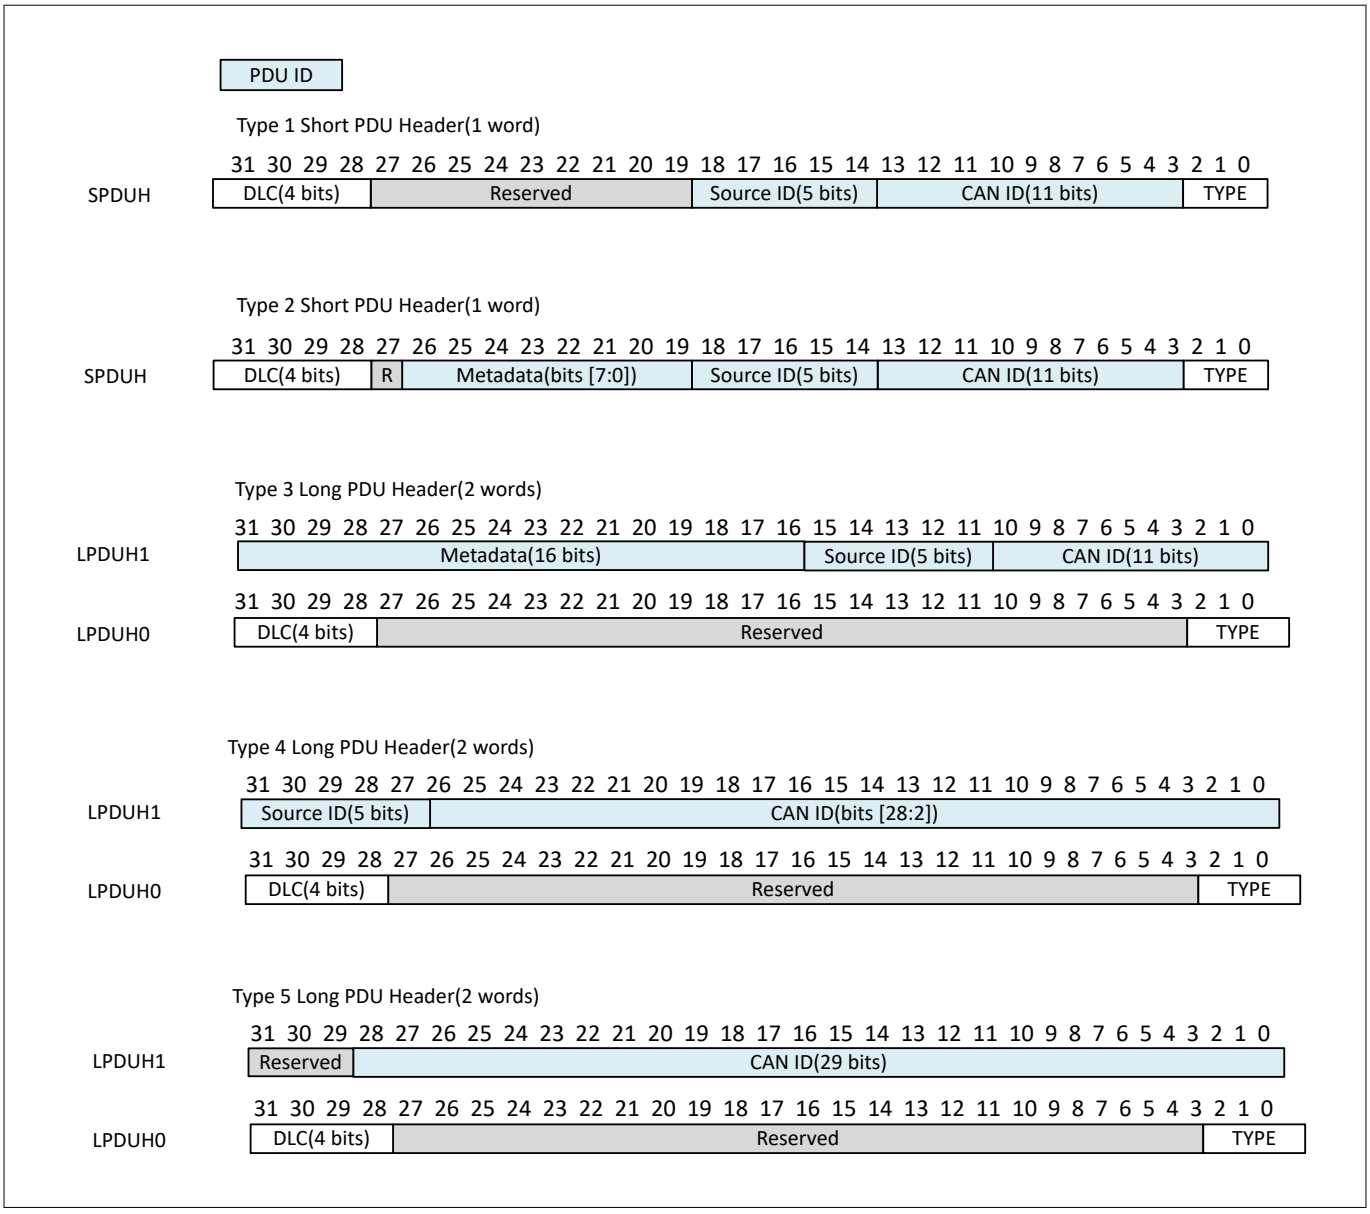

Figure 388 PDU Header types

21.6.3.3 Transmit Interface

The Transmit Interface abstracts the following operation related to TxFIFO or TxQueue for the user

- Address calculation to identify the available TxFIFO (or Tx Queue) element
- Setting a new transmit request for the corresponding TxFIFO (or Tx Queue) element

The Transmit Interface can get two types of transmit requests

- External transmit requests - a master of FPI initiates transmission of a new CAN frame.

  A master of FPI can write a CAN frame to be transmitted to the CAN Tx Host Buffer (THBUF) instead of the TxFIFO(Queue). The CRE assists the writing by providing a interrupt/trigger for each free TxFIFO(Queue) element
- Internal transmit requests - the CRE Receive Interface initiates transmission of a CAN frame due to internal CAN routing operation.

Transmit Interface can also get a new CAN frame from the CRE Receive Interface, if the destination of the CAN frame is configured by the Routing Table as another CAN Node belonging to the same MCMCAN module. The Transmit Interface identifies the destination CAN Node, with the help of DID in Routing Header

External transmit request

The CRE Transmit Interface first identifies a free element in the TxFIFO or Tx Queue based on the Put Index.

Identify free Tx buffer element in TxFIFO or Tx Queue

If the TxFIFO/TxQueue is not full, that is, Ni_TXFQS (i=0-3).TFQF = 0, then Tx FIFO Put Index Ni_TXFQS (i=0-3).TFQPI, points to the next Free Transmit Buffer in the Tx FIFO/TxQueue. The Ni_CRE_HBUF_TXz_STAT (i=0-3;z=0-1).INDEX points to the identified Put Index of TxFIFO/Tx Queue. Upon identifying a free transmit buffer element,

- Checks for a pending frame in the Tx Host Buffer (Ni_CRE_HBUF_TXz_STAT (i=0-3;z=0-1).THREQ is set to 1_B)
- In case of a pending frame in the Tx Host Buffer, the Transmit Interface
  - Copies the CAN frame from the Tx Host Buffer to the identified Tx Buffer element in TxFIFO or Tx Queue
  - Set transmit request (Ni_TXBAR (i=0-3).AR) of the corresponding Tx buffer element
  - On each successful write completion of a new transmit frame to the TxFIFO or Tx Queue, the Ni_CRE_HBUF_TXz_STAT (i=0-3;z=0-1).COUNT is incremented by 1_B(resets to 0 upon overflow)
  - Sets Ni_CRE_HBUF_TXz_STAT (i=0-3;z=0-1).THREQ to 0_B. Then it starts identifying the next available Tx Buffer element in the TxFIFO or TxQueue
- In case a Tx Host Buffer is empty, the Transmit Interface triggers either
  - Trigger to DRE: TRIGTYPE[1:0], TRIGNODE[1:0] or
  - Interrupt to IR: Ni_CRE_IR.TBUF0I or TBUF1I

  correspondingly based on the configuration of Ni_CRE_HBUF_TXz_CONFIG (i=0-3;z=0-1).INTEN.

***Note**: Only Tx Host Buffer 0 shall be configured to trigger to DRE.*

At the destination CAN node, Ni_CRE_CONFIG (i=0-3).DEN is checked by the CRE before the CAN frame is written to the TxFIFO.

Table 988 Routing behavior based on DEN configuration

Use-case	Ni_CRE_CONFIG.EN	Ni_CRE_CONFIG.DEN	Behavior
Internal	0	0	No routing enabled. Frame is discarded
Internal	0	1	Frame is routed to the destination TxFIFO
Internal	1	0	Frame is discarded
Internal	1	1	Frame is routed to the destination TxFIFO
External	0	0	No routing enabled. No triggers
External	0	1	No routing enabled. No triggers
External	1	0	Frame remains in the Tx Host buffer. No re-trigger is performed.
External	1	1	Frame is routed to the destination TxFIFO

***Note**: DEN=0 is used to isolate a CAN node in case of any bus error where the CAN frame is not expected to be written to the TxFIFO by the CRE*

The CRE should be enabled and the Host Buffers need to be configured after the DRE is enabled. A free Tx Host Buffer is indicated by Ni_CRE_HBUF_TXz_STAT (i=0-3;z=0-1).THREQ = 0_B. The trigger or the interrupt is used by master of FPI to write a new Transmit CAN frame to the Tx Host Buffer.

Tx Host Buffer 1 shall be configured to trigger interrupt to IR. Based on the interrupt, Tx Host Buffer 1 can be dedicated for System DMA. One System DMA channel is configured per CAN node. The interrupt Ni_CRE_IR(i=0-3).TBUF0/1I indicates the System DMA that the THBUF is ready to receive a new CAN frame. The software then writes the CAN frame to the system memory in dedicated buffers per CAN node. The System DMA reads each CAN frame from the system memory location and writes the CAN frame to the corresponding THBUF. The number of CAN frames transmitted is indicated in the Ni_CRE_HBUF_TXz_STAT (i=0-3;z=0-1).COUNT bit-field.

The Transmit Interface identifies the start of Transmit frame (T0, T1 and DBm) write by a FPI master by monitoring the write to the First Word of the Tx Host Buffer. The format of the Transmit Host Buffer is given in THBUFk_T0, THBUFk_T1 and THBUFk_DBm (m=0-63).

Write completion event

The Transmit Interface monitors the address of the "Last Word" of the Tx Host Buffer to be written by master of FPI interface. The "Last Word" can be configured either as Dynamic Data Length (based on DLC) or Fixed Data Length (Ni_CRE_HBUF_TXz_CONFIG.LEN). The configuration of last word can be done by programming Ni_CRE_HBUF_TXz_CONFIG (i=0-3;z=0-1).LWM. The DRE always writes into the Tx Host Buffer 0 in Dynamic Data Length mode. Fixed Data Length mode is only for the software. One data word (DW) corresponds to 4 bytes.

For example: If the Tx CAN frame has DLC = 4 and the Tx Host Buffer LEN = 2, then

- Dynamic Data Length: The last write operation is "DW0" (THBUFk_DBm (m=0-63))
- Fixed Data Length (8 bytes): The last write operation is "DW1" (THBUFk_DBm (m=0-63))

Upon the "the Last Word" write completion event (the entire CAN frame is written to the Tx Host Buffer), the Transmit Interface performs the following actions

1. Sets Ni_CRE_HBUF_TXz_STAT (i=0-3;z=0-1).THREQ to 1_B indicating Tx Host Buffer full
2. Copies the CAN frame from the Tx Host Buffer to the identified Tx Buffer element in TxFIFO or Tx Queue
3. Set transmit request (Ni_TXBAR (i=0-3).AR) of the corresponding Tx buffer element
4. On each successful write completion of a new transmit frame to the TxFIFO or Tx Queue, the Ni_CRE_HBUF_TXz_STAT (i=0-3;z=0-1).COUNT is incremented by 1_B(resets to 0 upon overflow)
5. The Transmit Interface sets Ni_CRE_HBUF_TXz_STAT (i=0-3;z=0-1).THREQ to 0_B. Then it starts identifying the next available Tx Buffer element in the TxFIFO or TxQueue

   In case the DRE Move Engine has an error, it cancels the ongoing write sequence by writing 1 to CRE_ABORT_SEQ(i=0-3).CTHBUF as long as the last write has not been launched. A write sequence error is launched in this case. Ni_CRE_IR.IWSI0 error flag is set and interrupt is triggered when Ni_ERRCTRL.IWSIE is enabled. There is no re-trigger to the DRE. The SW clears the error flags and could read the frame from the respective Tx Host Buffer, or set the Ni_CRE_HBUF_TXz_STAT.SWTRIG in order to re-trigger the DRE, or write '1' into Ni_CRE_HBUF_TXz_STAT.THREQ to free Tx Host Buffer for new frame and discard existing one from Tx Host Buffer.

Internal transmit request

The Transmit Interface gets the CAN frame along with a Routing Header from the Receive Interface in case of internal MCMCAN routing. The Transmit Interface identifies the destination CAN Node from the DID in the Routing Header. The Transmit Interface identifies a free Tx FIFO/Queue Element from the corresponding CAN node. It writes the CAN frame to the identified Tx FIFO/Queue element and sets the corresponding Transmit Request (Ni_TXBAR.AR). The Transmit Interface then acknowledges back the Receive Interface to indicate that the internal routing is performed. After the acknowledge, the Receive Interface performs the following operation

1. Acknowledge the corresponding RxFIFO by updating the Ni_RXF0A or Ni_RXF1A.FA with the index of the FIFO element currently processed
2. Clear RxFIFO New Message Flag Ni_IR (i=0-3).RF0N or RF1N

The Transmit Interface after setting the Transmit Request (Ni_TXBAR.AR), it starts identifying the next available Tx Buffer element in the TxFIFO or TxQueue.

Error monitoring

1. **Sequence check:** The CRE Transmit Interface monitors the incorrect write access to the Tx Host Buffer by an FPI master by checking the sequence in which the message is being written to the Tx Host Buffer(T0, T1 and DBm). The sequence checking starts once the FPI master starts writing the first word of the CAN frame to the Tx Host buffer.

   If the message is later written in an incorrect sequence, the Ni_CRE_IR.IWSI0 or IWSI1 (depending on the Tx Host Buffer) error flag is set and interrupt is triggered when Ni_ERRCTRL.IWSIE is enabled. There is no re-trigger of the DRE. The SW clears the error flags and could read the frame from the respective Tx Host Buffer, or set the Ni_CRE_HBUF_TXz_STAT.SWTRIG in order to re-trigger the DRE, or write '1' into Ni_CRE_HBUF_TXz_STAT.THREQ to free Tx Host Buffer for new frame and discard existing one from Tx Host Buffer.
2. **CRC verification:** The DRE or application generates an 16-bit CRC over the CAN headers R0 and R1 (except ESI, ANMF, RXTS and FIDX), the safety critical CAN payload and the DID using CCITT CRC16 polynomial: 0x1021 $x^{16} + x^{12} + x^5 + 1$. The CRC is calculated over 16 bits of data at a time starting with the MSB. The DRE or the application should write the CRC along with the CAN frame into the Tx Host Buffer. After the CAN frame is written to the Tx Host Buffer, CRE Transmit Interface verifies the CRC and the DID before writing the CAN frame to the Tx FIFO/Tx Queue. If there is a mismatch between the calculated CRC and the received CRC, the Ni_CRE_IR.CRCI0 or CRCI1 (depending on the Tx Host Buffer) interrupt is triggered when the CRC error interrupt is enabled in Ni_ERRCTRL.CRCIE. The processing of the frame is based on the Ni_CRE_HBUF_TXz_CONFIG.CRCG. In case the CRCG is set to 0, the CAN frame is processed further and written to the TxFIFO. In case the CRCG is set to 1, the CAN frame is discarded in the Host buffer. There is no re-trigger of the DRE. The SW clears the error flags and could read the frame from the respective Tx Host Buffer, or set the Ni_CRE_HBUF_TXz_STAT.SWTRIG in order to re-trigger the DRE. The user must ensure that the size of the TxFIFO or TxQueue is large enough to store the data from the Tx Host Buffer in order to avoid unwanted CRC error.
3. **Timeout monitoring:** The CRE Transmit Interface monitors for a delayed write operation by master of FPI. The watchdog timer counter starts incrementing when timeout enable WDT.EN is set. The watchdog timer triggers periodic events E1, E2, …, En after a user configured timeout prescaler WDT.FWDP or SWDP. The FWDP pre-scaler is configured by user for monitoring fast events as shown in Table below. The SWDP pre-scaler is configured by user for monitoring slow events as shown in Table below. If FWDP or SWDP are set to zero, then a default value of 16 is used for the corresponding prescaler. The fast timeout prescaler and slow timeout prescaler is configured by the user based on the usage of both the RHBUF and THBUF. If the presence of start condition is detected at Ei, then the end condition is expected to happen before Ei+1. If not, the corresponding watchdog timeout error flag Ni_CRE_IR.TWDTI0 or TWDT1 is set and interrupt triggered when Ni_ERRCTRL.TWD0IE or TWD1IE is enabled. There is no re-trigger of the DRE. The SW clears the error flags and could read the frame from the respective Tx Host Buffer, or set the Ni_CRE_HBUF_TXz_STAT.SWTRIG in order to re-trigger the DRE, or write '1' into Ni_CRE_HBUF_TXz_STAT.THREQ to free Tx Host Buffer for new frame and discard existing one from Tx Host Buffer.

The watchdog counter is running at the host clock frequency f_{MCANH} . The timeout period between the events Ei is calculated as follows:

- Default timeout period : $T_{def} = \frac{16}{f_{MCANH}}$
- Fast timeout period : $T_{fast} = T_{def} * (FWDP + 1)$
- Slow timeout period : $T_{slow} = T_{def} * (SWDP + 1)$

Table 989 Timeout interrupt trigger

Timeout check	Timeout interrupt trigger
End condition is true within a single event Ei	No timeout error. No timeout interrupt triggered
End condition is true within two consecutive events Ei	If the presence of start condition is detected at Ei, then the end condition is expected to happen before Ei+1. If not, timeout interrupt is triggered
End condition is true after two consecutive events Ei	Timeout interrupt is triggered

Table 990 THBUF : Start and end condition list

Start condition	End condition	Direction	Event type	Enable
THBUF empty	THBUF full	Destination	Slow event	When Ni_ERRCTRL.WDG2 is enabled
THBUF full	THBUF empty	Destination	Fast event	When Ni_ERRCTRL.WDG1 is enabled

21.6.3.4 Trigger function

The CRE can generate triggers to DRE for Rx Host Buffers and Tx Host Buffers. The trigger events are encoded as given in the following tables.

The signal TRIGTYPE[1:0] indicates a new trigger event corresponding to a Host Buffer. The signal TRIGNODE[1:0] indicates the CAN Node which the Host Buffer belongs to. Initially, the TRIGTYPE[1:0] and TRIGNODE[1:0] are 00b. The CRE, upon detecting the trigger event of a Host Buffer, sets the TRIGTYPE[1:0] and TRIGNODE[1:0] to corresponding level.

Table 991 TRIGTYPE description

TRIGTYPE(1)	TRIGTYPE(0)	Description
0_B	0_B	No Trigger or Idle
0_B	1_B	Transmit Host Buffer 0 free
1_B	0_B	New Receive Host Buffer 0
1_B	1_B	New Receive Host Buffer 1

Table 992 TRIGNODE description

TRIGNODE(1)	TRIGNODE(0)	Description
0_B	0_B	CANx_N0
0_B	1_B	CANx_N1
1_B	0_B	CANx_N2
1_B	1_B	CANx_N3

21.6.3.5 Intrusion detection measurement unit (IDMU)

The IDMU assists with intrusion detection by measuring the following timing parameters and updating the Timing Header (THEAD) for each received frame that has the routing destination outside the MCMCAN.

- Inter Arrival Measure (RHBUFk_THEAD_INTRD (k = 0-1).IAM)
- Frame Rate Measure (SFRk_FR (k = 0-63) or XFRk_FR (k = 0-31))
- Rx Throughput Measure (Ni_IDMU_RXTPCFG (i = 0-3).TP)

The IDMU consists of a Timestamp Database and Frame Rate Measure Table as shown in the following figure. All the IDMU Tables are part of the CRE RAM as shown in table CRE RAM Structure, see related information. The Timestamp Database stores the previous received timestamp (Reference Timestamp) of CAN frame(s) corresponding to a Acceptance Filter ID. The Frame Rate Measure Table consists of frame counters for each Acceptance Filter ID, that increment with reception of each frame accepted by the filter.

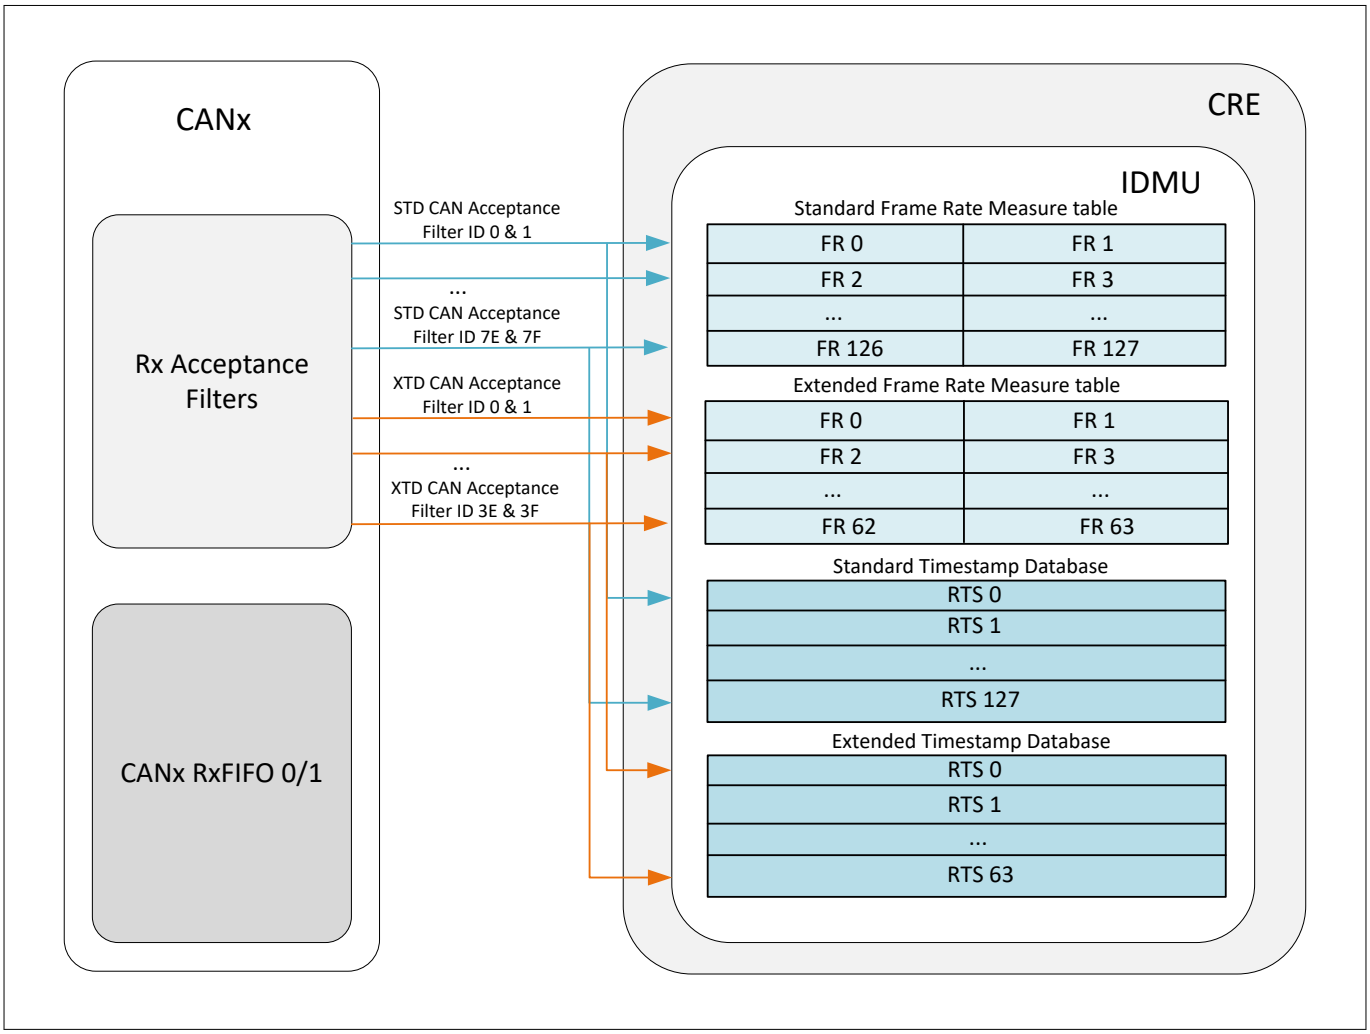

Figure 389 IDMU

Inter arrival measure

When there is valid timestamp available, the IAM is calculated for each frame by calculating the difference between the current received timestamp RHBUFk_THEAD_RXTS (k=0-1) and the Reference Timestamp STSDk_RTS (k=0-127) or XTSDk_RTS (k=0-63) which is fetched from the Reference Timestamp Database for the corresponding Acceptance Filter ID. The Reference Timestamp Database is updated with the last timestamp to compute the IAM of the next frame. Similar to the routing table, the indexing of the Reference Timestamp Database and Frame Rate Measure Table are done based upon the receive Acceptance Filter ID as shown in the figure above.

The IAM of each frame is part of the Timing Header THEAD.

For Standard ID CAN frame(s) :

$$RHBUF\text{k_THEAD_INTRD.IAM} = RHBUF\text{k_THEAD_RXTS.RXTS} - \text{STSDk_RTS.TS}$$

For Extended ID CAN frame(s) :

$$RHBUF\text{k_THEAD_INTRD.IAM} = RHBUF\text{k_ THEAD_RXTS.RXTS} - \text{XTSDk_RTS.TS}$$

When there is an overflow of the timebase counter and the current timestamp is smaller than the Reference Timestamp,

$$RHBUF\text{k_THEAD_INTRD.IAM} = (\text{MaxValue Of Timestamp} - \text{STSDk_RTS.TS}) + (RHBUF\text{k_THEAD_RXTS.RXTS} + 1)$$

The value of "MaxValueOfTimestamp" is computed based on the maximum value of TSCLEN.

The calculated IAM is written to the Timing Header RHBUFk_THEAD_INTRD (k=0-1).IAM and RHBUFk_THEAD_INTRD (k=0-1).IAMSTAT is set to 1.

If there was a loss of timestamp the RHBUFk_THEAD_INTRD (k=0-1).TSL is set. But the IAM is calculated with the latest available valid timestamp.

The Receive Interface fetches only valid timestamps. In case of no valid timestamp available or in case of the first frame received which will not have a Reference Timestamp to calculate the IAM, there is no IAM calculated and RHBUFk_THEAD_INTRD (k=0-1).IAMSTAT = 0.

Frame rate measure

The Frame Rate Measures SFRk_FR (k=0-63) are counters associated with each Acceptance Filter ID, which increment with reception of each frame. The start address of the Frame Rate Measure table and the size can be configured in CRE_STD_FRT_PARAM. Similarly for extended CAN IDs at CRE_XTD_FRT_PARAM.

Each entry of the Frame Rate Measure Table consists of two Frame Rate Measure counters FR1 and FR2, corresponding to two Acceptance Filter IDs (FID). The indexing of the Frame Rate Measures are based on the LSB of the FID. Each Frame Rate Measure counter is of 16 bits. The Frame Rate Measure counters are controlled by Ni_IDMU_FRTCONFIG (i=0-3).STDLOCK or XTDLOCK. Reading of the frame rate is recommended to be done in a timer-based interrupt service routine which sets the STDLOCK or XTDLOCK is '1' correspondingly . The Frame Rate Measures freeze whenever the STDLOCK/XTDLOCK is set to 1. The Frame Rate Measure counters and the STDLOCK/XTDLOCK bit must be reset to 0 by software after reading. The Frame Rate Measure counters start incrementing again with the reception of the next frame.

If frames are received while the STDLOCK/XTDLOCK bit is set, there is a loss of Frame Rate Measure count and an interrupt SFRMLI or XFRMLI is triggered when Ni_IDMU_FRTCONFIG.INTEN0 or Ni_IDMU_FRTCONFIG.INTEN1 is enabled.

Rx throughput measure

The Rx Throughput Measure Ni_IDMU_RXTPCFG (i=0-3).TP is a counter per CAN node. The Receive Interface identifies newly received CAN frames based on the RxFIFO fill level Ni_RXF0S (i=0-3).F0FL (or) Ni_RXF1S (i=0-3).F1FL. The Rx Throughput Measure counter TP increments whenever there is a new message. Reading of the Rx Throughput Measure counter is recommended to be done in a timer-based interrupt service routine. TP can be reset to 0 by software after reading.

21.7 Registers

21.7.1 Register overview - access mode glossary

Table 993 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-PNi (i=0-3)	Protection group consisting of registers Ni_ACCEN_WRA, Ni_ACCEN_WRB, Ni_ACCEN_RDA, Ni_ACCEN_RDB, Ni_ACCEN_VM, Ni_ACCEN_PRS.
PNi	Access protection using *APU-PNi* registers.
APU-P4	Protection group consisting of registers ACCEN_WRA, ACCEN_WRB, ACCEN_RDA, ACCEN_RDB, ACCEN_VM, ACCEN_PRS.
P4	Access protection using *APU-P4* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.
M	Indicates a module specific access condition. Refer to the register description for details of the specific access condition.

21.7.17 Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 00000_H

Clock Control Register Reset values see: Table 1009

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												EDIS	0	DISS	DISR
r												rw	r	rh	rw

Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. The synchronous and asynchronous clock is switched on/off. Note that no register access is possible to any register while module is disabled. A disable request is granted, if the M_CAN clock is disabled, or all M_CAN nodes acknowledge the disable request. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

Table 1009 Reset values of CLC

Reset type	Reset value	Note
Application Reset	0000 0003$_H$	
After Boot-FW Value	0000 0000$_H$	After CAN BSL execution

21.7.18 OCDS Control and Status Register

The OCDS Control and Status register OCS controls the debug and trace behavior by selecting suspend modes and OTGB trigger sets. When OCDS is disabled the suspend control is ineffective.

OCS Offset address: 00004$_H$

OCDS Control and Status Register Debug Reset value: 0000 0000$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0		SUSSTA	SUS_P	SUS				0							
r		rh	w	rw				r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0												TG_P	TGB	TGS	
r												w	rw	rw	

Field	Bits	Type	Description
TGS	1:0	rw	**Trigger Set for OTGB0/1** 00_B No Trigger Set output 01_B TS16_CAN 10_B Reserved 11_B Reserved
TGB	2	rw	**OTGB0/1 Bus Select** 0_B Trigger Set is output on OTGB0 1_B Trigger Set is output on OTGB1
TG_P	3	w	**TGS, TGB Write Protection** TGS and TGB are only written when TG_P is 1, otherwise unchanged. Read as 0.
SUS	27:24	rw	**OCDS Suspend Control** Controls the sensitivity to the suspend signal coming from the OCDS Trigger Switch (OTGS) Not listed combinations are reserved. 0_H Will not suspend 1_H Hard suspend. Clock is off immediately. Do not use this mode in normal CAN applications, this mode is meant for debugging the peripheral IP. 2_H Soft suspend mode Soft suspend of CAN nodes. **others,** Reserved, do not use

(table continues...)

(continued)

Field	Bits	Type	Description
SUS_P	28	w	**SUS Write Protection** SUS is only written when SUS_P is 1, otherwise unchanged. Read as 0.
SUSSTA	29	rh	**Suspend State** 0_B Module is not (yet) suspended 1_B Module is suspended
0	23:4, 31:30	r	**Reserved** Read as 0; should be written with 0.

Table 1010 Access mode restrictions of OCS sorted by descending priority

Mode name	Access mode		Description
write 1 to .**TG_P**	rw	TGB, TGS	Set TG_P during write access
write 1 to .**SUS_P**	rw	SUS	Set SUS_P during write access
(default)	r	SUS, TGB, TGS	

21.7.19 Module Identification Register

ID Offset address: 00008_H

Module Identification Register PowerOn Reset value: $00B8\ C004_H$

r															

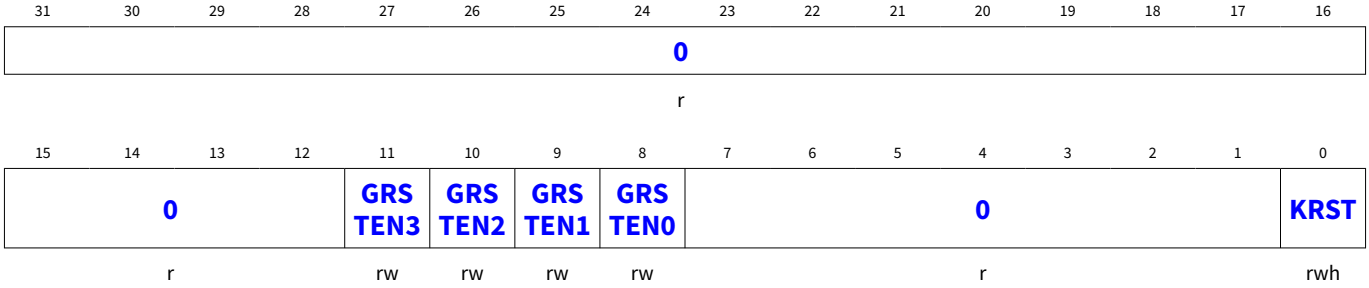
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOD_TYPE								MOD_REV							
r								r							

Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to C0.
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number (00B8 = CAN).

21.7.20 Reset Control Register A

RST_CTRLA Offset address: $0000C_H$

Reset Control Register A Application Reset value: $0000\ 0000_H$

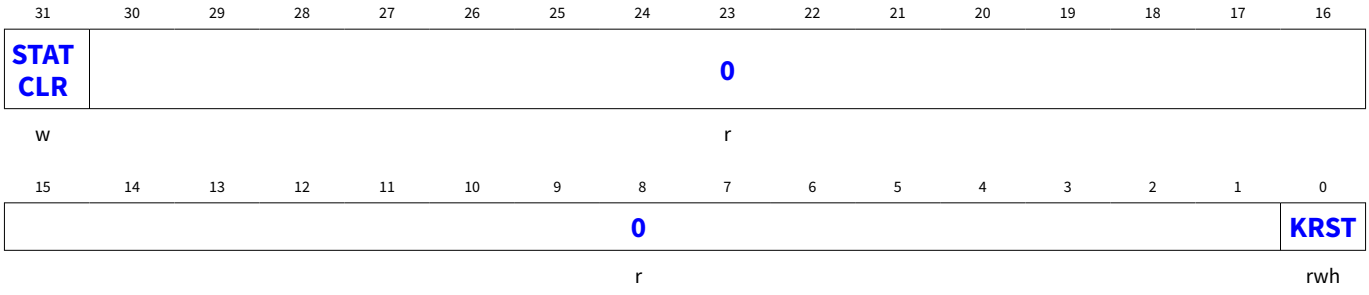


Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The reset is executed if the reset bits of both kernel reset registers are set. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for Global Module Reset Group x** 0_B global module reset group x does not have any effect 1_B global module reset group x results in a kernel reset
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

21.7.21 Reset Control Register B

RST_CTRLB Offset address: 00010_H

Reset Control Register B Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The reset is executed if the reset bits of both kernel reset registers are set. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested

(table continues...)

(continued)

Field	Bits	Type	Description
STATCLR	31	w	**Kernel Reset Status Clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with ´1´ clears bits STAT.GRSTx and bit STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

21.7.22 Reset Status Register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: 00014_H

Reset Status Register Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				GRST3	GRST2	GRST1	GRST0	0							KRST
r				rh	rh	rh	rh	r							rh

Field	Bits	Type	Description
KRST	0	rh	**Kernel Reset Status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.
GRSTx (x=0-3)	x+8	rh	**Status for Global Module Reset Group x** 0_B Reset was not triggered by global reset group x 1_B Reset was triggered by global reset group x
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

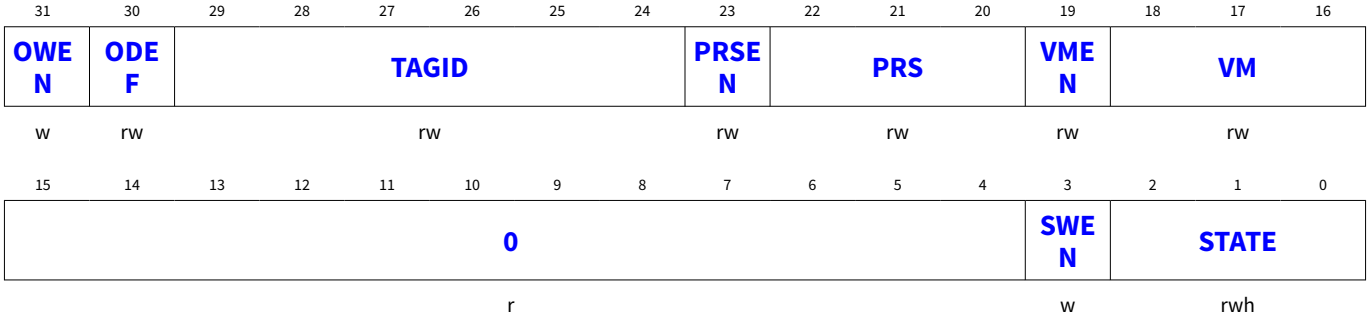
21.7.23 PROT Register Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock / unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 00018_H

PROT Register Endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1011 Access mode restrictions of PROTE sorted by descending priority

Mode name	Access mode		Description
write 1 to .**SWEN**	rwh	STATE	
write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

21.7.24 PROT Register Safe Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: $0001C_H$

PROT Register Safe Endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

21.7.31 Module Control Register

The Module Control Register MCR contains basic settings that determine the operation of the MCMCAN module.

The write access to the lowest byte of the MCR register becomes only valid, if and only if, MCR.CCCE and MCR.CI are already set during write access. To switch the clocks on or off, the bits of MCR.CCCE and MCR.CI have to be reset afterwards. Before this sequence hasn't taken place, no write access to the corresponding nodes, can be done.

***Note**: If the baud rate logic is supplied from an unstable clock source, or no clock at all, the CAN functionality is not guaranteed.*

To be able to change the clock settings the following programming sequence needs to be met:
uwTemp = CANn_MCR.U;
uwTemp |= (0xC0000000 | CLKSELx);
CANn_MCR.U = uwTemp;
uwTemp &= ~0xC0000000;
CANn_MCR.U = uwTemp;
The clock settings for CAN nodes becomes active.
To be able to start the RAM initialization, the following programming sequence need to be met:
CANn_MCR |= 0xC0000000;
Wait until CANn_MCR.RBUSY is 0b
Set CANn_MCR.RINIT to 0b
Set CANn_MCR.RINIT to 1b
Dummy read CANn_MCR
Wait until CANn_MCR.RBUSY is 0b
Set CANn_MCR.RINIT to 0b
CANn_MCR &= ~0xC0000000;
RAM initialization is finished

MCR Offset address: 00070_H

Module Control Register Reset values see: Table 1013

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r								rw		rw		rw		rw	

Field	Bits	Type	Description
CLKSEL0	1:0	rw	**Clock Select 0** This bit-field is MCR.CI and MCR.CCCE protected. 00_B No clock supplied 01_B The asynchronous clock source is switched on 10_B The synchronous clock source is switched on 11_B Both clock sources are switched on

(table continues...)

(continued)

Field	Bits	Type	Description
CLKSEL1	3:2	rw	**Clock Select 1** This bit-field is MCR.CI and MCR.CCCE protected. 00_B No clock supplied 01_B The asynchronous clock source is switched on 10_B The synchronous clock source is switched on 11_B Both clock sources are switched on
CLKSEL2	5:4	rw	**Clock Select 2** This bit-field is MCR.CI and MCR.CCCE protected. 00_B No clock supplied 01_B The asynchronous clock source is switched on 10_B The synchronous clock source is switched on 11_B Both clock sources are switched on
CLKSEL3	7:6	rw	**Clock Select 3** This bit-field is MCR.CI and MCR.CCCE protected. 00_B No clock supplied 01_B The asynchronous clock source is switched on 10_B The synchronous clock source is switched on 11_B Both clock sources are switched on
NODE	26:24	rw	**Node** This bit-field determines the M_CAN node i which is used for debug over M_CAN. This bit-field only exists on CAN module 0. 000_B M_CAN0 … 011_B M_CAN3
DXCM	27	rw	**Debug Over CAN Messages Enable** This bit enables the debug over serial connections between DAP and CAN module 0. If enabled the lowest receive/transmit message buffer is reserved for debugger communication. DXCM is described in detail in the OCDS chapter. This bit only exists on CAN module 0. 0_B DXCM disabled 1_B DXCM enabled
RBUSY	28	rh	**RAM BUSY** This bit shows that the RAM Initialization is running. This bit is set back to 0b by hardware when the RAM intialization is completed.
RINIT	29	rw	**RAM Init** This bit is MCR.CI and MCR.CCCE protected. This bit starts the initialization of the RAM block to all 0x0. The RAM initialization is started only when this bit is changed from 0b to 1b and also RBUSY is 0b.

(table continues...)

(continued)

Field	Bits	Type	Description
CI	30	rw	**Change Init** Needs to be set to enable and disable clocks. 0_B Change Init disabled 1_B Change Init enabled (takes effect with CCCE:=1)
CCCE	31	rw	**Clock and RAM Change Enable** Needs to be set to enable and disable the clocks. 0_B Clock and RAM Change disabled 1_B Clock and RAM Change enabled (takes effect with CI:=1)
0	23:8	r	**Reserved** Shall read 0; shall be written with 0.

Table 1013 Reset values of MCR

Reset type	Reset value	Note
Kernel Reset	$0000\ 0000_H$	
After Boot-FW Value	$0000\ 000C_H$	After CAN BSL execution

21.7.32 Buffer receive address and transmit address

This register is used only when Debug over CAN Messages feature is used. This register assigns the start address to all features needing the message buffers inside the corresponding M_CAN, which are for receive and transmit

BUFADR Offset address: 00074_H

Buffer receive address and transmit address Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
TXBUF	13:0	rw	**Transmit Buffer start address** This is the start address of the first dedicated transmit buffer.
RXBUF	29:16	rw	**Receive Buffer start address** This is the start address of the first dedicated receive buffer.
0	15:14, 31:30	r	**Reserved** Read as 0; should be written with 0.

21.7.33 Measure Control Register

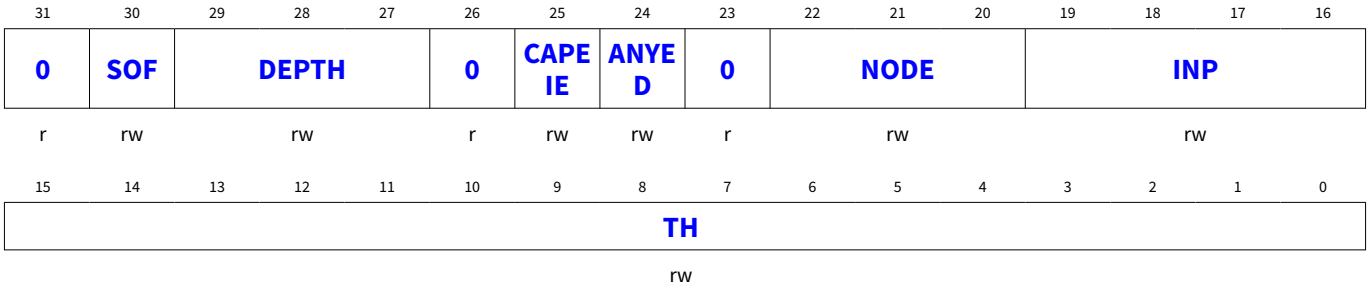
The Measure Control Register MECR controls the CAN edge timing measurement function for calibration purposes. This feature only exists on CAN module 0.

Oscillator calibration

This register supports the oscillator calibration on which the decision is taken to increase or decrease the frequency.

MECR Offset address: 00080_H

Measure Control Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TH	15:0	rw	**Threshold** This bit-field contains the threshold value for the measurement timer. If TH = 0000, the timer is stopped and the capture function is disabled.
INP	19:16	rw	**Interrupt Node Pointer** INP selects the interrupt output line SRC_CANINTx (x = 0-15) for a capture event interrupt. 0_H Interrupt output line SRC_CANINT0 is selected … F_H Interrupt output line SRC_CANINT15 is selected
NODE	22:20	rw	**Node** This bit-field determines the CAN node i whose input line RXDCANi is used for start and capture of the measurement timer. 000_B Node 0 … 011_B Node 3
ANYED	24	rw	**Any Edge** This bit enables capture on any edge of CAN input line specified by NODE. 0_B Capture on falling (dominant) edge only 1_B Capture on rising (recessive) or falling (dominant) edge
CAPEIE	25	rw	**Capture Event Interrupt Enable** This bit enables the capture event interrupt. Bit-field INP selects the interrupt output line which becomes activated at this type of interrupt. 0_B Capture event interrupt is disabled 1_B Capture event interrupt is enabled

(table continues...)

(continued)

Field	Bits	Type	Description
DEPTH	29:27	rw	**Digital Glitch Filter Depth** DEPTH determines the number of input samples clocked with f_{SYNi} that are taken into account for the calculation of the floating average. The higher DEPTH is chosen to be, the longer the glitches that are suppressed and the longer the delay of the input signal introduced by this filter. 000_B off, default 001_B Filter depth of 8 cycles 010_B Filter depth of 16 cycles 011_B Filter depth of 32 cycles 100_B Filter depth of 64 cycles 101_B Filter depth of 128 cycles 110_B Filter depth of 255 cycles 111_B not allowed, reserved
SOF	30	rw	**Start Of Frame** This bit selects falling edge or any edge as measurement for start of frame detection. 0_B Measurement starts with any falling edge 1_B Measurement starts with falling Start of Frame edge. i.e any falling edge that occurs while the CAN node is in idle state
0	23, 26, 31	r	**Reserved** Read as 0; should be written with 0.

21.7.34 Measure Status Register

The Measure Status Register MESTAT contains the status information of the CAN edge timing measurement. This feature only exists on CAN module 0.

MESTAT Offset address: 00084_H

Measure Status Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0														CAPE	CAPRED
r														rwh	rh

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CAPT															
rh															

Field	Bits	Type	Description
CAPT	15:0	rh	**Captured Timer** This bit-field contains the captured measurement timer content. The timer itself is cleared and started by the first falling (dominant) edge of a CAN frame on the input line of the CAN node specified by MECR.NODE. The timer is incremented by the module control clock f_{SYNi} and will be stopped when $FFFF_H$ is reached. If MECR.TH = 0000, the timer is always stopped. A capture will take place if all the following conditions are met: **1.** MECR.TH > 0000 **2.** Timer is cleared and started by new frame **3.** Timer reaches MECR.TH **4.** This node is not sending and first edge (as specified by MECR.ANYED) after 3. occurs on input line Capture will be repeated for the following CAN frames until MECR.TH is cleared.
CAPRED	16	rh	**Captured Rising Edge** This bit indicates the type of edge that caused the last capture event. 0_B Capture occurred on falling (dominant) edge 1_B Capture occurred on rising (recessive) edge
CAPE	17	rwh	**Capture Event** This flag is set on a capture event. It must be reset by software. An interrupt request is generated if MECR.CAPEIE = 1. If CAPE=1, then no further measurement results are posted to MESTAT.CAPT and MESTAT.CAPRED. CAPE bit has to be cleared to re-enable update of MESTAT.CAPT and MESTAT.CAPRED. 0_B No capture event has occurred since last flag reset 1_B Capture event has occurred since last flag reset
0	31:18	r	**Reserved** Read as 0; should be written with 0.

21.7.35 CRE Watchdog timer register

The CRE Watchdog timer register to monitor timeout.

WDT Offset address: 00088_H

CRE Watchdog timer register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

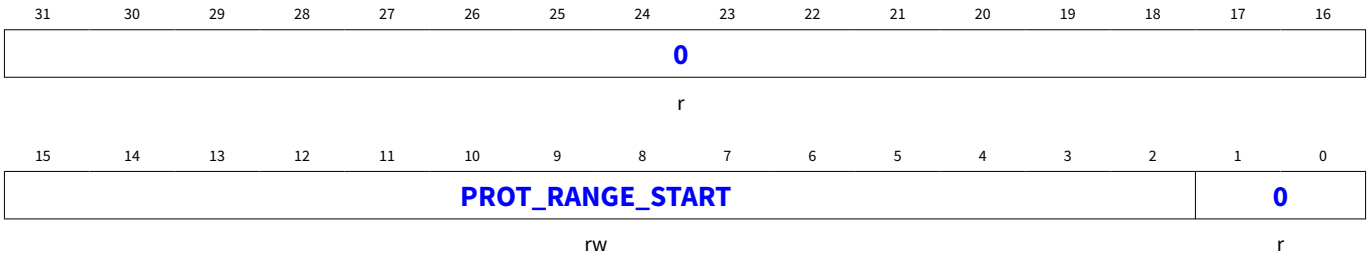
21.7.42 Node i Start Address

In case the RAM shall not be protected, the STARTADR has to be higher than the corresponding ENDADR of the node.

Ni_STARTADR (i=0-3) Offset address: $00120_H+i*400_H$

Node i Start Address Application Reset value: $0000\ 0000_H$

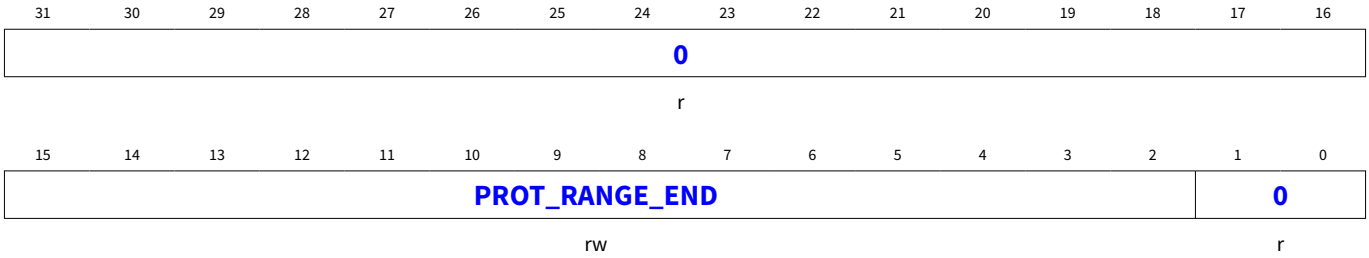


Field	Bits	Type	Description
PROT_RANGE_START	15:2	rw	**Message RAM start - START** The address within the RAM area of the MCMCAN, of node i, where the message RAM to be protected starts
0	1:0, 31:16	r	**Reserved** Read as 0; should be written with 0.

21.7.43 Node i End Address

Ni_ENDADR (i=0-3) Offset address: $00124_H+i*400_H$

Node i End Address Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
PROT_RANGE_END	15:2	rw	**Message RAM end - END** The address within the RAM area of the MCMCAN, of node i, where the message RAM to be protected ends
0	1:0, 31:16	r	**Reserved** Read as 0; should be written with 0.

21.7.44 Node i Interrupt Signalling Register

The groups by the Ni_G0INTR, Ni_G1INTR and G2INTR registers are also shown inside the INTRSIG (interrupt signalling register) register. Inside the interrupt signalling register a 1 means, that one of the corresponding bits inside the interrupt (status) register of the corresponding M_CAN node, at least one group member is showing an interrupt. Ni_INTRSIG is purely OR-ing the interrupt status bits of the group to enable SW to have proper handling of the bits. Writing to Ni_INTRSIG has no effect.

If Ni_INTRSIG is written, this shall have no effect on the interrupt status inside the M_CAN nodes. The bits have to be reset inside the corresponding M_CAN nodes, see register Ni_IR.

Ni_INTRSIG (i=0-3) Offset address: $00128_H+i*400_H$

Node i Interrupt Signalling Register Kernel Reset value: $0000\ 0000_H$

0	31:22	r	**Reserved** Read as 0; should be written with 0.

21.7.45 Node i Interrupt routing for Group 0

Ni_G0INTR is the first of three grouping registers. In this register, the interrupt line within the module is fixed. Please be reminded, that the interrupt sources need to be enabled to be mapped. The total module has 16 interrupts and the interrupt node can be chosen within Ni_G0INTR, Ni_G1INTR and Ni_G2INTR.

Meaning:

0000_B Interrupt output line SRC_CANINT0 is selected.

0001_B Interrupt output line SRC_CANINT1 is selected.

…B…

1110_B Interrupt output line SRC_CANINT14 is selected.

1111_B Interrupt output line SRC_CANINT15 is selected.

Note: MCMCAN has 22 interrupt groups and 16 interrupt lines, and the user can decide how the interrupt lines are shared within the groups.

Ni_G0INTR (i=0-3) Offset address: $0012C_H+i*400_H$

Node i Interrupt routing for Group 0 Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOI				BOFF				SAFE				MOER

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ALRT				WATI				HPE				TEFIFO			
rw				rw				rw				rw			

Field	Bits	Type	Description
TEFIFO	3:0	rw	**Transmit Event FIFO Incidents** are mapped here. Ni_IR.TEFF (Transmit Event FIFO Full) and Ni_IR.TEFN (Transmit Event FIFO New Entry)
HPE	7:4	rw	**High Priority Events** are mapped here, giving Ni_IR.HPM an interrupt level
WATI	11:8	rw	**Watermark interrupts** are mapped here: Ni_IR.TEFW (Transmit FIFO warning interrupt reached), Ni_IR.RF1W (Receive FIFO 1 warning interrupt reached). Ni_IR.RF0W (Receive FIFO 0 warning interrupt reached)
ALRT	15:12	rw	**ALERTS** All kind of alerts are mapped here. Ni_IR.EW (warning status), Ni_IR.EP (error passive), Ni_IR.TSW (timestamp wrap around), Ni_IR.TEFL (Transmit Event FIFO Element Lost), Ni_IR.RF0L (Receive FIFO 0 Message Lost), Ni_IR.RF1L (Receive FIFO 1 Message Lost).
MOER	19:16	rw	**Module errors** Ni_IR.WDI (watchdog interrupt) and Ni_IR.MRAF (message RAM access failure) are mapped here.
SAFE	23:20	rw	**Safety counter overflow** The interrupt node for Ni_IR.ELO showing a safety counter overflow

(table continues...)

(continued)

Field	Bits	Type	Description
BOFF	27:24	rw	**Bus Off has been reached** Mapped to Ni_IR.BO flag indication the change in Bus_Off status. To get out of bus off, the Ni_CCCR.INIT bit has to be reset.
LOI	31:28	rw	**Last Error Interrupts** The interrupt sources Ni_IR.PED (Protocol Error in Data Phase) and Ni_IR.PEA (Protocol Error in Arbitration Phase) are signalled here.

21.7.46 Node i Interrupt routing for Group 1

Ni_ G1INTR has the same functionality as Ni_ G0INTR, but for other interrupt sources. The interrupt sources need to be enabled to be mapped.

Ni_G1INTR (i=0-3) Offset address: $00130_H+i*400_H$

Node i Interrupt routing for Group 1 Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Bits	Type	Description
REINT	3:0	rw	**Message stored in dedicated receive buffer interrupt (Ni_IR.DRX)** is assigned to interrupt node.
RxF1F	7:4	rw	**IR.RF1F** Receive FIFO1 full interrupt assigned to an interrupt node
RxF0F	11:8	rw	**IR.RF0F** Receive FIFO0 full interrupt assigned to an interrupt node
RxF1N	15:12	rw	**IR.RF1N** Receive FIFO1 new message assigned to an interrupt node
RxF0N	19:16	rw	**IR.RF0N** Receive FIFO0 new message assigned to an interrupt node
RETI	23:20	rw	**Receive Timeouts** can be assigned here. Ni_IR.TOO (time-out event) and TE (Timer Event)
TRAQ	27:24	rw	**Transmission Queue Events** can be assigned here. Ni_IR.TFE Transmission FIFO Empty
TRACO	31:28	rw	**Interrupts of the transmission control** can be assigned here. Ni_IR.TCF (Transmission Cancellation Finished) and Ni_IR.TF (Transmission Completed).

21.7.47 Node i Interrupt routing for Group 2

Ni_ G2INTR has the same functionality as Ni_ G0INTR, but for other interrupt sources. The interrupt sources need to be enabled to be mapped.

Ni_G2INTR (i=0-3) Offset address: $00134_H+i*400_H$

Node i Interrupt routing for Group 2 Kernel Reset value: $0000\ 0000_H$

RXHBUF1	7:4	rw	**CRE Rx host buffer 1 interrupt** are mapped here: Ni_CRE_IR.RBUF0I (Receive Host Buffer 1 interrupt)
TXHBUF0	11:8	rw	**CRE Tx host buffer interrupt** are mapped here: Ni_CRE_IR.TBUFI 0 (Transmit Host Buffer 0 interrupt)
TXHBUF1	15:12	rw	**CRE Tx host buffer interrupt** are mapped here: Ni_CRE_IR.TBUFI 1 (Transmit Host Buffer 1 interrupt)
IDMU	19:16	rw	**IDMU relevant interrupts** are mapped here: Ni_CRE_IR.SFRMLI, Ni_CRE_IR.XFRMLI (Frame rate measure lost interrupts)
CEI	23:20	rw	**CRE error interrupts** are mapped here: Ni_CRE_IR.IRSI, Ni_CRE_IR.IWSI, Ni_CRE_IR.CRCI, Ni_CRE_IR.RWDTI, Ni_CRE_IR.TWDTI (Error interrupts)
0	31:24	r	**Reserved** Read as 0; should be written with 0.

21.7.48 Node i Timer Clock Control Register

The Node i Timer Clock Control Register Ni_TIMER_CCR controls the functions of the node timer.

Ni_TIMER_CCR (i=0-3) Offset address: $00138_H+i*400_H$

Node i Timer Clock Control Register Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

STSTART	STRESET	0		TPSC				0							
rw	rw	r		rw				r							

Field	Bits	Type	Description
TPSC	11:8	rw	**Timer Prescaler** The duration of one timer clock is given by Ni_TIMER_CCR.TRIGSRC frequency divided by (TPSC + 1).
STRESET	14	rw	**Stamping Reset** This bit gives the possibility to reset the time stamp for CAN FD messages.
STSTART	15	rw	**Stamping Start** This bit starts the external timer used for CAN FD messages. The source and the prescaler are identical to the Ni_TIMER_CCR(i=0-3).
TRIGSRC	20:18	rw	**Trigger Source** This bit selects the trigger source for the different modes in the node timer. 000_B Node i Timer is decremented per f_{SYNi} prescaled by (TPSC + 1) timing to 0. 001_B System Timer (STM) trigger event enabled Node i Timer is decremented per STM trigger event prescaled by (TPSC + 1). 010_B General Timer (GTM) trigger event enabled Node i Timer is decremented per GTM trigger event prescaled by (TPSC + 1). 011_B Enhanced General Timer (eGTM) trigger event enabled Node i Timer is decremented per eGTM trigger event prescaled by (TPSC + 1). **others,** Reserved, do not use
0	7:0, 13:12, 17:16, 31:21	r	**Reserved** Read as 0; should be written with 0.

21.7.49 Node i Timer Transmit Trigger 0 Register

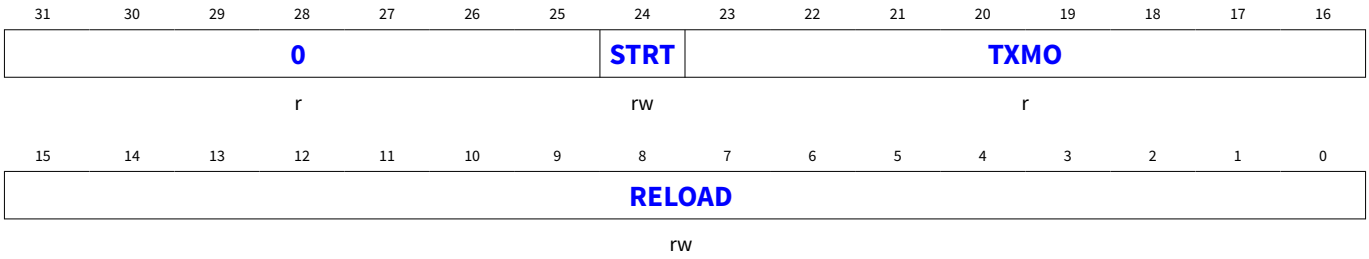
The Node i Timer Transmit Trigger 0 Register Ni_TIMER_TXTRIG0 controls the node timing functions for Transmit Trigger Mode.

Pretended Networking

The timer registers are intended to support Pretended Networking. As an application example, the SPB bus is clocked at 40MHz. The asynchronous module part is clocked either with 40MHz as well or even more power saving with direct drive from the oscillator. The cores are in idle mode. Messages can be received and a receive interrupt can be generated. It is possible to trigger messages with or without changing the content by the timers provided. For example the network management message and two related messages can be triggered without any CPU interaction. As mostly the operating system is still running, messages can be changed without any problem during the time, where the operating system is active.

Ni_TIMER_TXTRIG0 (i=0-3) Offset address: $0013C_H+i*400_H$

Node i Timer Transmit Trigger 0 Register Kernel Reset value: $0001\ 0000_H$



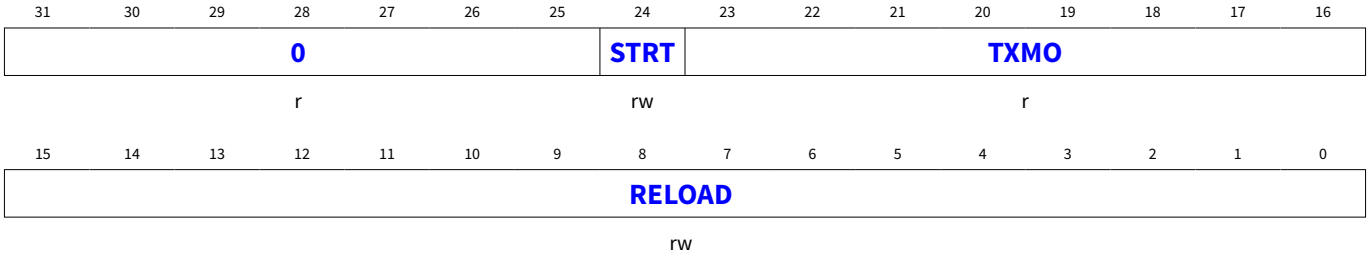
Field	Bits	Type	Description
RELOAD	15:0	rw	**Reload Value** This bit-field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	23:16	r	**Transmit Message Object** This transmit trigger is fixed to transmit buffer 1
STRT	24	rw	**Timer Start** This bit-field controls the operation of the timer. 0_B Timer is stopped. 1_B Timer is started.
0	31:25	r	**Reserved** Read as 0; should be written with 0.

21.7.50 Node i Timer Transmit Trigger 1 Register

The Node i Timer Transmit Trigger 1 Register Ni_TIMER_TXTRIG1 controls the node timing functions for Transmit Trigger Mode.

Ni_TIMER_TXTRIG1 (i=0-3) Offset address: $00140_H+i*400_H$

Node i Timer Transmit Trigger 1 Register Kernel Reset value: $0002\ 0000_H$



Field	Bits	Type	Description
RELOAD	15:0	rw	**Reload Value** This bit-field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	23:16	r	**Transmit Message Object** This transmit object is fixed to transmit buffer 2

(table continues...)

(continued)

Field	Bits	Type	Description
STRT	24	rw	**Timer Start** This bit-field controls the operation of the timer. 0_B Timer is stopped. 1_B Timer is started.
0	31:25	r	**Reserved** Read as 0; should be written with 0.

21.7.51 Node i Timer Transmit Trigger 2 Register

The Node i Timer Transmit Trigger 2 Register Ni_TIMER_TXTRIG2 controls the node timing functions for Transmit Trigger Mode.

Ni_TIMER_TXTRIG2 (i=0-3) Offset address: $00144_H+i*400_H$

Node i Timer Transmit Trigger 2 Register Kernel Reset value: $0003\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0							STRT	TXMO							
r							rw	r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RELOAD															
rw															

Field	Bits	Type	Description
RELOAD	15:0	rw	**Reload Value** This bit-field contains the reload value for the timer. The timer will restart when RELOAD is written.
TXMO	23:16	r	**Transmit Message Object** This transmit trigger is fixed to transmit buffer 3
STRT	24	rw	**Timer Start** This bit-field controls the operation of the timer. 0_B Timer is stopped. 1_B Timer is started.
0	31:25	r	**Reserved** Read as 0; should be written with 0.

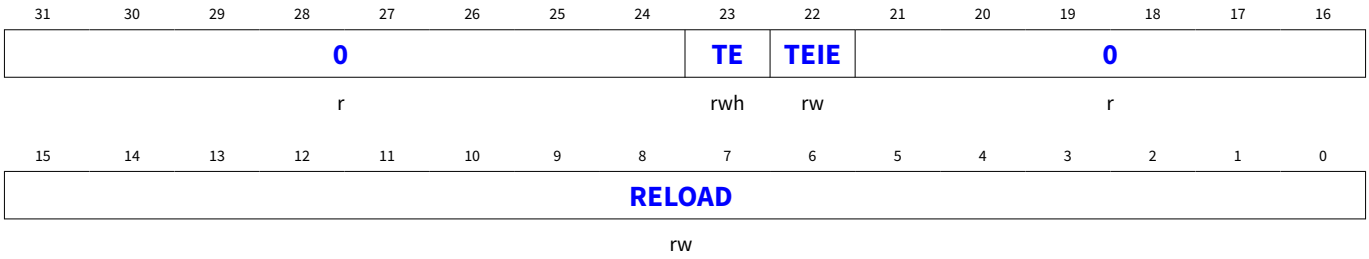
21.7.52 Node i Timer Receive Timeout Register

The Node i Timer Receive Timeout Register Ni_TIMER_RXTOUT controls the node timing functions for Receive Timeout Mode. This feature is independent of Classical CAN and CAN FD.

This mode exists, to have for example network management supervision.

Ni_TIMER_RXTOUT (i=0-3) Offset address: $00148_H+i*400_H$

Node i Timer Receive Timeout Register Kernel Reset value: $0000\ 0000_H$



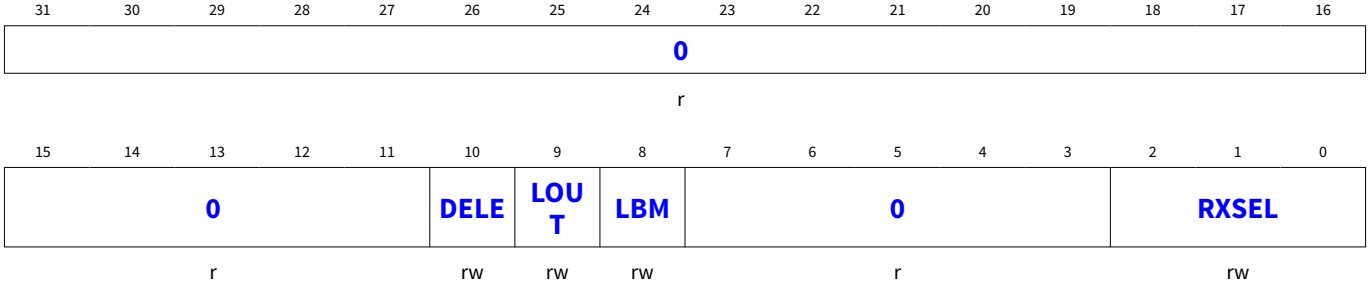
Field	Bits	Type	Description
RELOAD	15:0	rw	**Reload Value** This bit-field contains the reload value for the timer. The timer will start when RELOAD ≠ 0 is written. After half the time of the RELOAD value, the interrupt flags of the receive buffers will be cleared automatically, to ensure, that no message receive will be missed.
TEIE	22	rw	**Timer Event Interrupt Enable** This bit enables the node timer event interrupt of CAN node i. Bit-field Ni_G1INTR.RETI selects the interrupt output line which becomes activated at this type of interrupt. 0_B Timer event interrupt is disabled 1_B Timer event interrupt is enabled
TE	23	rwh	**Timer Event** This flag is set on a node timer transition from 1 to 0 in Receive Timeout Mode. This bit must be reset (i.e Write to '0') by software, writing a '1' has no effect. An interrupt request is generated if TEIE = 1. 0_B No timer event has occurred since last flag reset 1_B Timer event has occurred since last flag reset
0	21:16, 31:24	r	**Reserved** Read as 0; should be written with 0.

21.7.53 Node i Port Control Register

The Node Port Control Register Ni_PORTCTRL configures the CAN bus transmit/receive ports.

Ni_PORTCTRL (i=0-3) Offset address: $0014C_H+i*400_H$

Node i Port Control Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
RXSEL	2:0	rw	**Receive Select** RXSEL selects one out of 8 possible receive inputs. The CAN receive signal is performed by the selected input.
LBM	8	rw	**Loop-Back Mode** 0_B Loop-Back Mode is disabled. 1_B Loop-Back Mode is enabled. This node is connected to an internal (virtual) loop-back CAN bus. All CAN nodes which are in Loop-Back Mode are connected to this virtual CAN bus so that they can communicate with each other internally. The external transmit line is forced recessive in Loop-Back Mode.
LOUT	9	rw	**Loop Back Mode Out** The loop back bus is switched to the external CAN bus of the node.
DELE	10	rw	**Enable destructive read on Ni_ECR.CEL** If this bit is set, the destructive read on Ni_ECR.CEL and on the PSR register takes place. Meaning, that with read access on Ni_ECR, the CEL is reset. The same is true for the Ni_PSR register, for the bits PXE, RFDF, RBRS, RESI, LEC and DLEC. When this bitfield is set, reading the timestamp value from Ni_TSU_TSn register resets the related Ni_TSU_TSS1 bits. After the destructive read it is advised to reset the bit again.
0	7:3, 31:11	r	**Reserved** Read as 0; should be written with 0.

21.7.54 Node i CRE Configuration Register

The Node i CRE Configuration Register Ni_CRE_CONFIG configures the Routing Engine functionality.

Ni_CRE_CONFIG (i=0) Offset address: $00150_H+i*400_H$

Node i CRE Configuration Register Kernel Reset value: $0000\ 0100_H$

Ni_CRE_CONFIG (i=1) Offset address: $00150_H+i*400_H$

Node i CRE Configuration Register Kernel Reset value: $0000\ 0200_H$

Ni_CRE_CONFIG (i=2) Offset address: $00150_H+i*400_H$

Node i CRE Configuration Register Kernel Reset value: $0000\ 0300_H$

Ni_CRE_CONFIG (i=3) Offset address: $00150_H+i*400_H$

Node i CRE Configuration Register Kernel Reset value: $0000\ 0400_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0		ID						0				DEN	IDM UEN	REN	EN
r		r						r				rw	rw	rw	rw

Field	Bits	Type	Description
EN	0	rw	**Enable** Note: When the EN is set, the respective host buffers are enabled. The RxFIFO0/1 and Tx FIFO/Queues shall not be used in this case. The frames are read/written from/to CRE host buffers instead. 0_B **DIS**: CRE function is disabled 1_B **EN**: CRE function is enabled. When CRE is enabled, then RxFIFO0/1 and TxFIFO/Queue host interface handling is also enabled when corresponding FIFO/Queue are enabled by CAN node
REN	1	rw	**Routing Enable** This bit indicates that the Routing is enabled for the Source node. This bit is checked only at the Source node. This bit-field can be written only when Ni_CRE_CONFIG.EN = 1. Note: This bit should be enabled at the source node for correct routing 0_B **DIS**: Routing Disable The Routing function of CRE is disabled. Note: If Ni_CRE_CFG.EN is set, the corresponding host buffers are still enabled. 1_B **EN**: Routing Enable The Routing function of CRE is enabled for the Source CAN node
IDMUEN	2	rw	**IDMU Enable** This bit-field can be written only when Ni_CRE_CFG.EN = 1 0_B **DIS**: IDMU Disable The Intrusion detection measurement unit (IDMU) of CRE is disabled 1_B **EN**: IDMU Enable The Intrusion detection measurement unit (IDMU) of CRE is enabled
DEN	3	rw	**Destination Enable** This bit is checked only at the Destination node. This bit controls the CRE write of the CAN frame to TxFIFO Note: In case of external routing, the CAN frame remains in the Tx Host Buffer and there will be no re-trigger to the DRE if DEN is set to 0 after there has already been a trigger to the DRE. In case of internal routing, the CAN frame would be discarded if DEN is set to 0 0_B **DIS**: Destination Disable The CAN frame is discarded 1_B **EN**: Destination Enable The CRE will write the CAN frame to the TxFIFO
ID	13:8	r	**Unique ID** A Unique ID of the CAN Node i 1_H till 4_H - MCMCAN 0 CAN Node 0-Node 3 respectively 5_H till 8_H - MCMCAN 1 CAN Node 0-Node 3 respectively 9_H till C_H - MCMCAN 2 CAN Node 0-Node 3 respectively D_H till 10_H - MCMCAN 3 CAN Node 0-Node 3 respectively 11_H till 14_H - MCMCAN 4 CAN Node 0-Node 3 respectively

(table continues...)

(continued)

Field	Bits	Type	Description
0	7:4, 31:14	r	**Reserved** Read as 0; shall be written with 0.

21.7.55 Node i CRE Configuration Start Address

This register defines the CRE RAM start address of CRE Configurations

Ni_CRE_CONFIGADR (i=0-3) Offset address: $00154_H+i*400_H$

Node i CRE Configuration Start Address Kernel Reset value: $0000\ 0000_H$

0					CRCEN	INTEN	TRIGEN	0	LEN						LRM
r					rw	rw	rw	r	rw						rw

Field	Bits	Type	Description
LRM	0	rw	**Last Read Mode** This bit-field defines the last word of the CAN payload data expected to be read by the host from Rx Host Buffer 0_B Dynamic Data Length: The last word to be read by the host is defined by the DLC of the received CAN frame 1_B Fixed Data Length The last word to be read by the host is defined by LEN bit-field of this register
LEN	6:1	rw	**Fixed Data Length** This bit-field contains the length of CAN Data field in words (4 bytes) which is stored in the Receive Host Buffer. It defines the last word to be read by the host when LRM=1. This bit-field is ignored when LRM=0. 0 - No payload data 1 - Data length of 4 bytes or 1 word 2 - Data length of 8 bytes or 2 words . . 16 - Data length of 64 bytes or 16 words others - Incorrect (shall not be more than 16)
TRIGEN	8	rw	**Enable Trigger** This bit-field enables / disables the generation of Trigger signal when a new CAN frame is stored in Receive Host Buffer. 0_B Disable The Receive Host Buffer z trigger signal is disabled 1_B Enabled The Receive Host Buffer z trigger signal is enabled
INTEN	9	rw	**Interrupt Enable** This bit-field enables / disables the generation of interrupt when a new CAN frame is stored in Receive Host Buffer. 0_B Disable The Receive Host Buffer z interrupt is disabled 1_B Enabled The Receive Host Buffer z interrupt is enabled
CRCEN	10	rw	**CRC calculation enable** This bit controls inclusion of CRC in the sequence check 0_B CRC not included 1_B CRC included
0	7, 31:11	r	**Reserved** Read as 0; should be written with 0.

21.7.57 Node i Receive Host Buffer z Status

This register provides the status information of the Receive Host buffer.

Ni_CRE_HBUF_RXz_STAT (i=0-3;z=0-1) Offset address: $0015C_H+i*400_H+z*8$

Node i Receive Host Buffer z Status Kernel Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

WEG		INDEX						0		SWTRIG	VTH	RHREQ	VRH	0	
rwh		rh						r		rwh	rh	rwh	rh	r	

Field	Bits	Type	Description
VRH	2	rh	**Valid Routing Header** This bit-field indicates if there is a valid routing header stored in Routing Header for the current CAN frame. 0 - No routing header (routing non-relevant) 1 - Valid routing header
RHREQ	3	rwh	**New Receive Host Buffer z Transfer Request** This bit-field indicates a pending transfer request of Receive Host buffer. It is set to 1 by hardware, when there is a new CAN frame stored in the Receive Host Buffer. After successful read operation of the host from the RX Host Buffer, this bit is reset to 0 by hardware. SW write to 1 also clears the bit. A SW write by 0 has no effect. A transition of 0 to 1 triggers RHBUF_INT when enabled in Ni_CRE_HBUF_RXz_CONFIG.INTEN=1.
VTH	4	rh	**Valid Timing Header** This bit-field indicates if there is a valid timing header stored in Timing Header for the current CAN frame. 0 - No Timing header (Intrusion parameters not available) 1 - Valid Timing header
SWTRIG	5	rwh	**Software DRE Tigger** SW trigger to the DRE. SW writes 1 to request trigger to DRE. HW clears it after trigger to DRE. SW write with 0 has no effect
INDEX	13:8	rh	**RxFIFOz Index** This bit-field indicates the Get Index of RxFIFOz, from which the current CAN frame is fetched form.

(table continues...)

(continued)

Field	Bits	Type	Description
WEG	15:14	rwh	**Watchdog Event Group** Set by hardware when there is a watchdog timeout error. This bit-field indicates which event group has watchdog timeout error. Write operation of any non-zero value resets the value to 0. Writing 0 does not change the value of the bit-field 00_B No Error 01_B WDG1 Error 10_B WDG2 Error 11_B WDG3 Error
COUNT	23:16	rwh	**Counter** The count field increments by 1 for every successful read of a CAN frame by host from the Receive Host Buffer. The Counter wraps around to 0 by hardware upon overflow. A write operation of any non zero value resets the counters value to 0. Writing of 0 does not change the value
0	1:0, 7:6, 31:24	r	**Reserved** Reserved. Read as 0; should be written with 0

21.7.58 Node i Transmit Host Buffer z Configuration

This register configures the Host Buffer for TxFIFO / TxQueue

Ni_CRE_HBUF_TXz_CONFIG (i=0-3;z=0-1) Offset address: $00168_H+i*400_H+z*8$

Node i Transmit Host Buffer z Configuration Kernel Reset value: $0000\ 0000_H$

0				CRCG	CRCEN	INTEN	0		LEN						LWM
r				rw	rw	rw	r		rw						rw

Field	Bits	Type	Description
LWM	0	rw	**Last Write Mode** This bit-field defines the last word of the CAN payload data expected to be written by the host to Tx Host Buffer 0_B Dynamic Data Length: The last word to be read by the host is defined by the DLC of the transmit CAN frame 1_B Fixed Data Length The last word to be written by the host is defined by Ni_CRE_HBUF_TXz_CONFIG.LEN. Ni_CRE_HBUF_TXz_CONFIG.LEN shall be configured greater than 0

(table continues...)

(continued)

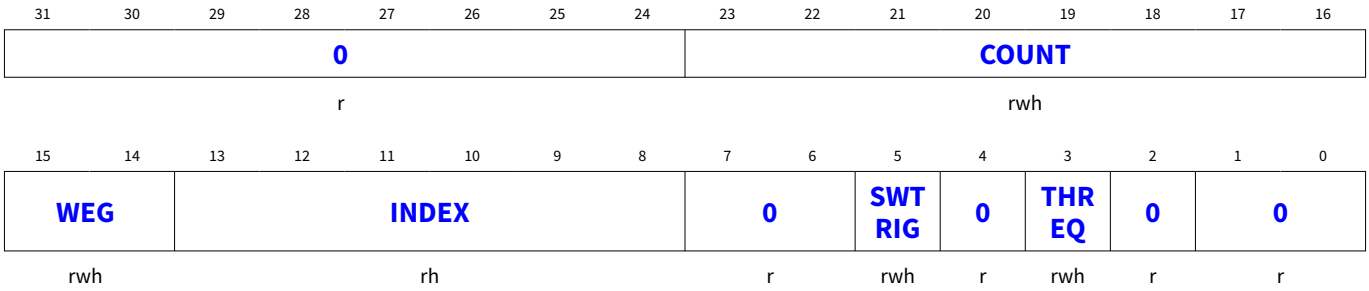
Field	Bits	Type	Description
LEN	6:1	rw	**Fixed Data Length** This bit-field contains the length of CAN Data field in words (4 bytes) which is stored in the Transmit Host Buffer. It defines the last word to be written by the host when LWM=1. This bit-field is ignored when LWM=0. 0 - No payload data 1 - Data length of 4 bytes or 1 word 2 - Data length of 8 bytes or 2 words . . 16 - Data length of 64 bytes or 16 words others - Incorrect (shall not be more than 16)
INTEN	9	rw	**Interrupt or Trigger Enable** This bit-field enables the generation of trigger signal to DRE/interrupt to IR when the Transmit Host Buffer is available to transmit a new CAN frame. Only Tx Host Buffer 0 shall be used to trigger DRE. In case the Tx Host Buffer 1 INTEN is set to 0, there is no trigger to DRE nor an interrupt Note: The interrupt is triggered only when the Tx Host Buffer is emptied after being filled. 0_B TRIG Enabled The Transmit Host Buffer trigger signal is enabled 1_B Interrupt Enabled The Transmit Host Buffer interrupt is enabled
CRCEN	10	rw	**CRC calculation enable** This bit controls enable and disable of CRC calculation when INTEN is 1 CRC calculation is always enabled when INTEN is 0 0_B CRC calculation disabled 1_B CRC calculation enabled
CRCG	11	rw	**CRC gate** This bit controls whether the CAN frame with CRC error is processed further or discarded by the CRE 0_B CAN frame is not discarded 1_B CAN frame discarded
0	8:7, 31:12	r	**Reserved** Read as 0; should be written with 0.

21.7.59 Node i Transmit Host Buffer z Status

This register provides the status information of the Transmit Host buffer.

Ni_CRE_HBUF_TXz_STAT (i=0-3;z=0-1) Offset address: $0016C_H+i*400_H+z*8$

Node i Transmit Host Buffer z Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
THREQ	3	rwh	**Free Transmit Host Buffer z** This bit-field indicates a pending transfer request of Transmit Host Buffer. It is set to 0 by hardware, when the Transmit Host Buffer is free to accept a new transmit CAN frame. Upon "last word" write completion event to the Tx Host Buffer the HW sets this bit to 1 indicating buffer full. SW write to 1 also clears the bit. A SW write by 0 has no effect. An interrupt TXHBUF_INT is triggered when enabled in Ni_CRE_HBUF_TXz_CONFIG.INTEN=1 to indicate free buffer element..
SWTRIG	5	rwh	**Software DRE Tigger** SW trigger to the DRE. SW writes 1 to request trigger to DRE. HW clears it after trigger to DRE. SW write with 0 has no effect. Note: Write to this bit is valid only for Tx Host buffer 0. SW write has no effect for Tx Host buffer 1
INDEX	13:8	rh	**TxFIFO/Queue Index** This bit-field indicates the Put Index of TxFIFO / Queue, to which the current CAN frame will be written to.
WEG	15:14	rwh	**Watchdog Event Group** Set by hardware when there is a watchdog timeout error. This bit-field indicates which event group has watchdog timeout error. Write operation of any non-zero value resets the value to 0. Writing 0 does not change the value of the bit-field 00_B No Error 01_B WDG1 Error 10_B WDG2 Error 11_B WDG3 Error
COUNT	23:16	rwh	**Counter** The count field increments by 1 for every successful write of a CAN frame by host to the Transmit Host Buffer. The Counter wraps around to 0 by hardware upon overflow. A write operation of any non zero value resets the counters value to 0. Writing of 0 does not change the value
0	1:0, 2, 4, 7:6, 31:24	r	**Reserved** Reserved. Read as 0; should be written with 0

21.7.60 Node i CRE Interrupt Register

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect.

Ni_CRE_IR (i=0-3) Offset address: $0018C_H+i*400_H$

Node i CRE Interrupt Register Kernel Reset value: $0000\ 0000_H$

r					rw	r	rwh	r					rw	r	rwh

Field	Bits	Type	Description
STDLOCK	0	rwh	**Lock STD ID Frame Rate Measures** Lock bit to freeze the Standard ID Frame Rate Measures. This bit is set by the user (eg. in a timer-based interrupt service routine) to read the STD ID frame rate measure counters
INTEN0	2	rw	**STD ID Frame rate measure Interrupt Enable** This bit-field enables / disables the generation of interrupt when a frame is received while the Frame Rate Measure counters (FRMs) are frozen i.e when the STDLOCK is set and there is a loss of frame count. 0_B Disable The STD ID Frame rate measure interrupt is disabled 1_B Enabled The STD ID Frame rate measure interrupt is enabled
XTDLOCK	8	rwh	**Lock XTD ID Frame Rate Measures** Lock bit to freeze the Extended ID Frame Rate Measures. This bit is set by the user (eg. in a timer-based interrupt service routine) to read the XTD ID frame rate measure counters
INTEN1	10	rw	**XTD ID Frame rate measure Interrupt Enable** This bit-field enables / disables the generation of interrupt when a frame is received while the Frame Rate Measure counters (FRMs) are frozen i.e when the XTDLOCK is set and there is a loss of frame count. 0_B Disable The XTD ID Frame rate measure interrupt is disabled 1_B Enabled The XTD ID Frame rate measure interrupt is enabled
0	1, 7:3, 9, 31:11	r	**Reserved** Read as 0; should be written with 0

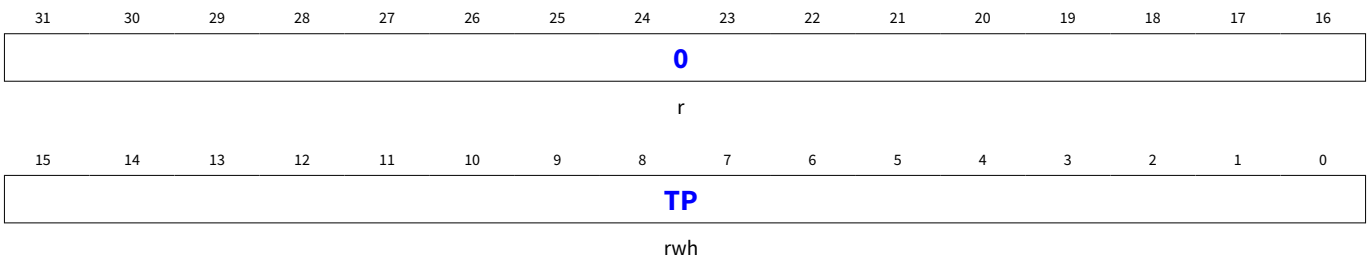
21.7.62 Node i Rx Throughput Measure configuration

Configuration registers for IDMU

This register provides the Rx Throughput Measured over a set of frames of the MCAN and its corresponding control bits

Ni_IDMU_RXTPCFG (i=0-3) Offset address: $00194_H+i*400_H$

Node i Rx Throughput Measure configuration Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TP	15:0	rwh	**Rx Throughput Measure** Rx Throughput Measure is relevant for Intrusion detection. It indicates the total number of frames received by the MCMCAN.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

21.7.63 Node i CRE Error control register

The CRE error control register is used to enable particular monitoring group of start and end conditions and control the interrupt enable.

Ni_ERRCTRL (i=0-3) Offset address: $00198_H+i*400_H$

Node i CRE Error control register Kernel Reset value: $0000\ 0000_H$

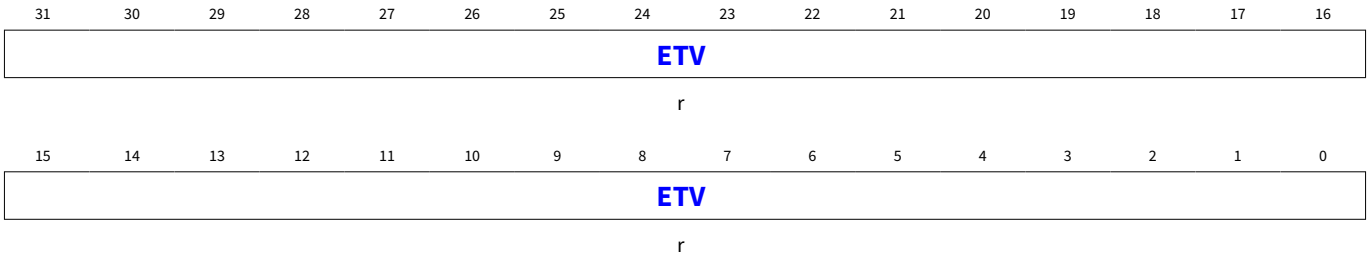
21.7.65 Node i Endian Register

Ni_ENDN (i=0-3) Offset address: $00204_H+i*400_H$

Node i Endian Register Kernel Reset value: $8765\ 4321_H$



Field	Bits	Type	Description
ETV	31:0	r	**Endianness Test Value** The endianness test value is 0x87654321.

21.7.66 Node i Data Bit Timing & Prescaler Register

This register is only writable if bits Ni_CCCR.CCE and Ni_CCCR.INIT are set. The CAN bit time may be programmed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 clock cycles. t_q = (DBRP + 1) clock cycles.

DTSEG1 is the sum of Prop_Seg and Phase_Seg1. DTSEG2 is Phase_Seg2.

Therefore the length of the bit time is (programmed values) [DTSEG1 + DTSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

***Note**: With a CAN clock of 8 MHz, the reset value of 0x00000A33 configures the M_CAN for a fast bit rate of 500 kbit/s.*

The bit rate configured for the CAN FD data phase via DBTP must be higher or equal to the bit rate configured for the arbitration phase via NBTP.

Ni_DBTP (i=0-3) Offset address: $0020C_H+i*400_H$

Node i Data Bit Timing & Prescaler Register Reset values see: Table 1015

21.7.67 Node i Test Register

Write access to the Test Register has to be enabled by setting bit Ni_CCCR.TEST to ‘1’. All Test Register functions are set to their reset values when bit Ni_CCCR.TEST is reset.

Loop Back Mode and software control of transmit pin are hardware test modes. Programming of Ni_TEST.TX ≠ “00” may disturb the message transfer on the CAN bus.

Ni_TEST (i=0-3) Offset address: $00210_H+i*400_H$

Node i Test Register Reset values see: Table 1016

21.7.68 Node i RAM Watchdog

The RAM Watchdog monitors the READY output of the Message RAM. A Message RAM access via the M_CAN’s Generic Master Interface starts the Message RAM Watchdog Counter with the value configured by Ni_RWD.WDC. The counter is reloaded with RWD.WDC when the Message RAM signals successful completion. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag Ni_IR.WDI is set. The RAM Watchdog Counter is clocked by the Host clock.

Ni_RWD (i=0-3) Offset address: $00214_H+i*400_H$

Node i RAM Watchdog Kernel Reset value: $0000\ 0000_H$

With the reset value of “00” the counter is disabled. 00_H Watchdog disabled **others,** Start value of the Message RAM Watchdog Counter
WDV	15:8	rh	**Watchdog Value** Actual Message RAM Watchdog Counter Value.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

21.7.69 Node i CC Control Register

The Ni_CCCR register enables and disables CAN bus participation and basic protocol functions. Due to synchronization mechanisms between the clock domains, after a write operation to Ni_CCCR, the register shall be read back, until the set values are written to the register. Please keep in mind, that the register also includes hardware influenced bits.

***Note**: After enabling the CAN clocks in MCR register, the application software has to wait for 10 host clock cycles before accessing the kernel registers.*

***Note**: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for rwh bits in this register.*

Ni_CCCR (i=0-3) Offset address: $00218_H+i*400_H$

Node i CC Control Register Reset values see: Table 1017

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rh	rwh	rw	rwh

Field	Bits	Type	Description
INIT	0	rwh	**Initialization** ***Note**: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.* 0_B Normal Operation 1_B Initialization is started
CCE	1	rw	**Configuration Change Enable** 0_B The CPU has no write access to the protected configuration registers 1_B The CPU has write access to the protected configuration registers (while CCCR.INIT = '1')
ASM	2	rwh	**Restricted Operation Mode** Bit ASM can only be set by the Host when both CCE and INIT are set to '1'. In can also be set by the M_CAN. The bit can be reset by the Host at any time. For a description of the Restricted Operation Mode see paragraph Restricted Operation Mode. 0_B Normal CAN operation 1_B Restricted Operation Mode active
CSA	3	rh	**Clock Stop Acknowledge** 0_B No clock stop acknowledged 1_B M_CAN may be set in power down by stopping the synchronous and the asynchronous clock source
CSR	4	rw	**Clock Stop Request** 0_B No clock stop is requested 1_B Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle.
MON	5	rw	**Bus Monitoring Mode** Bit MON can only be set by the Host when both CCE and INIT are set to '1'. The bit can be reset by the Host at any time. 0_B Bus Monitoring Mode is disabled 1_B Bus Monitoring Mode is enabled
DAR	6	rw	**Disable Automatic Retransmission** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Automatic retransmission of messages not transmitted successfully enabled 1_B Automatic retransmission disabled

(table continues...)

(continued)

Field	Bits	Type	Description
TEST	7	rw	**Test Mode Enable** The TEST register can only be set, if CCE, INIT and TEST are set. Writes to test will only have effect, if all three bits are set. 0_B Normal operation, register TEST holds reset values 1_B Test Mode, write access to register TEST enabled
FDOE	8	rw	**FD Operation Enable** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B CAN FD frame format disabled. 1_B CAN FD frame format enabled.
BRSE	9	rw	**Bit Rate Switch Enable** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Bit rate switching for transmission disabled. 1_B Bit rate switching for transmission enabled.
UTSU	10	rw	**Use Timestamping register** When UTSU is set, 16-bit Wide Message Markers are also enabled regardless of the value of WMM. 0_B Internal time stamping 1_B External time stamping by TSU
WMM	11	rw	**Wide Message Marker** Enables the use of 16-bit Wide Message Markers. When 16-bit Wide Message Markers are used (WMM = '1'), 16-bit internal timestamping is disabled for the Tx Event FIFO. 0_B 8-bit Message Marker used 1_B 16-bit Message Marker used, replacing 16-bit timestamps in Tx Event FIFO
PXHD	12	rw	**Protocol Exception Handling Disable** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Protocol exception handling enabled. 1_B Protocol exception handling disabled. (When protocol exception handling is disabled, the M_CAN will transmit an error frame when it detects a protocol exception condition.
EFBI	13	rw	**Edge Filtering during Bus Integration** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Edge filter disabled 1_B Two consecutive dominant tq required to detect an edge for hard synchronization.

(table continues...)

(continued)

Field	Bits	Type	Description
TXP	14	rw	**Transmit Pause** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. If this bit is set, the M_CAN pauses for two CAN bit times before starting the next transmission after itself has successfully transmitted a frame. 0_B Transmit pause disabled 1_B Transmit pause enabled
NISO	15	rw	**Non ISO Operation** If this bit is set, the M_CAN uses the CAN FD frame format as specified by the Bosch CAN FD Specification V1.0. 0_B CAN FD frame format according to ISO11898-1 1_B CAN FD frame format according to Bosch CAN FD Specification V1.0
0	31:16	r	**Reserved** Read as 0; should be written with 0.

21.7.70 Node i Nominal Bit Timing & Prescaler Register

This register is only writable if bits Ni_CCCR.CCE and Ni_CCCR.INIT are set.

The CAN bit time may be programmed in the range of 4 to 385 time quanta. The CAN time quantum may be programmed in the range of 1 to 512 clock periods. t_q = (NBRP + 1) clock periods.

NTSEG1 is the sum of Prop_Seg and Phase_Seg1. NTSEG2 is Phase_Seg2.

Therefore the length of the bit time is (programmed values) [NTSEG1 + NTSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

***Note**: With a CAN clock of 8 MHz, the reset value of 0600_H0A03 configures the M_CAN for a bit rate of 500 kbit/s.*

Ni_NBTP (i=0-3) Offset address: $0021C_H+i*400_H$

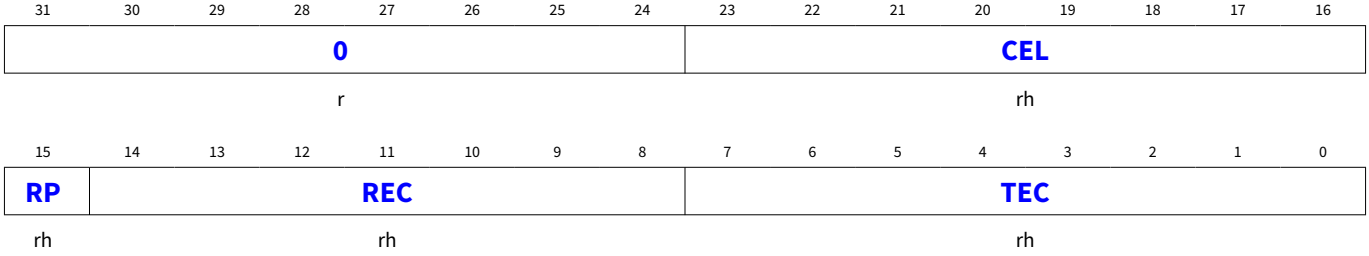
TOC															
rwh															

Field	Bits	Type	Description
TOC	15:0	rwh	**Timeout Counter** The Timeout Counter is decremented in multiples of CAN bit times [1…16] depending on the configuration of Ni_TSCC.TCP. When decremented to zero, interrupt flag Ni_IR.TOO is set and the Timeout Counter is stopped. Start and reset/restart conditions are configured via Ni_TOCC.TOS. Any write access will lead to clearing of the counter.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

21.7.75 Node i Error Counter Register

Ni_ECR (i=0-3) Offset address: $00240_H+i*400_H$

Node i Error Counter Register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
TEC	7:0	rh	**Transmit Error Counter** Actual state of the Transmit Error Counter, values between 0 and 255 ***Note**: When CCCR.ASM is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.*
REC	14:8	rh	**Receive Error Counter** Actual state of the Receive Error Counter, values between 0 and 127 ***Note**: When CCCR.ASM is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.*
RP	15	rh	**Receive Error Passive** 0_B The Receive Error Counter is below the error passive level of 128 1_B The Receive Error Counter has reached the error passive level of 128
CEL	23:16	rh	**CAN Error Logging** The counter is incremented each time when a CAN protocol error causes the Transmit Error Counter or the Receive Error Counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag Ni_IR.ELO. The counter is reset on read, if the bit Ni_PORTCTRL.DELE is set for the node.
0	31:24	r	**Reserved** Read as 0; should be written with 0.

21.7.76 Node i Protocol Status Register

Ni_PSR (i=0-3) Offset address: $00244_H+i*400_H$

Node i Protocol Status Register Kernel Reset value: $0000\ 0707_H$

21 Controller Area Network interface (CAN)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0									TDCV						
r									rh						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	PXE	RFDF	RBRS	RESI	DLEC			BO	EW	EP	ACT		LEC		
r	rh	rh	rh	rh	rh			rh	rh	rh	rh		rh		

Field	Bits	Type	Description
LEC	2:0	rh	**Last Error Code** The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. This bit-field is set to 0x7 on read, if Ni_PORTCTRL.DELE is set. ***Note**: The Bus_Off recovery sequence (see ISO11898-1) cannot be shortened by setting or resetting Ni_CCCR.INIT. If the device goes Bus_Off, it will set Ni_CCCR.INIT of its own accord, stopping all bus activities. Once Ni_CCCR.INIT has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of Ni_CCCR.INIT, each time a sequence of 11 recessive bits has been monitored, a Bit0 Error code is written to Ni_PSR.LEC, enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. Ni_ECR.REC is used to count these sequences.* 000_B No Error: No error occurred since LEC has been reset by successful reception or transmission. 001_B Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. 010_B Form Error: A fixed format part of a received frame has the wrong format. 011_B Ack Error: The message transmitted by the M_CAN was not acknowledged by another node. 100_B Bit1 Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 101_B Bit0 Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 110_B CRC Error: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data. 111_B No Change: Any read access to the Protocol Status Register re-initializes the LEC to '7'. When the LEC shows the value '7', no CAN bus event was detected since the last CPU read access to the Protocol Status Register.

(table continues...)

(continued)

Field	Bits	Type	Description
ACT	4:3	rh	**Activity** Monitors the module's CAN communication state. ***Note:*** *ACT is set to "00" by a Protocol Exception Event.* 00_B Synchronizing - node is synchronizing on CAN communication 01_B Idle - node is neither receiver nor transmitter 10_B Receiver - node is operating as receiver 11_B Transmitter - node is operating as transmitter
EP	5	rh	**Error Passive** 0_B The M_CAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected 1_B The M_CAN is in the Error_Passive state
EW	6	rh	**Warning Status** 0_B Both error counters are below the Error_Warning limit of 96 1_B At least one of error counter has reached the Error_Warning limit of 96
BO	7	rh	**Bus_Off Status** 0_B The M_CAN is not in Bus_Off[1)] 1_B The M_CAN is in Bus_Off state
DLEC	10:8	rh	**Data Phase Last Error Code** Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for LEC. This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error. This bit-field is set to 0x7 on read, if Ni_PORTCTRL.DELE is set. ***Note:*** *When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error.*
RESI	11	rh	**ESI flag of last received CAN FD Message** This bit is set together with REDF, independent of acceptance filtering. This bit is reset after read access, if Ni_PORTCTRL.DELE is set. 0_B Last received CAN FD message did not have its ESI flag set 1_B Last received CAN FD message had its ESI flag set
RBRS	12	rh	**BRS flag of last received CAN FD Message** This bit is set together with REDF, independent of acceptance filtering. This bit is reset after read access, if Ni_PORTCTRL.DELE is set. 0_B Last received CAN FD message did not have its BRS flag set 1_B Last received CAN FD message had its BRS flag set

(table continues...)

(continued)

Field	Bits	Type	Description
RFDF	13	rh	**Received a CAN FD Message** This bit is set independent of acceptance filtering. This bit is reset after read access, if Ni_PORTCTRL.DELE is set. 0_B Since this bit was reset by the CPU, no CAN FD message has been received 1_B Message in CAN FD format with FDF flag set, has been received
PXE	14	rh	**Protocol Exception Event** This bit is reset after read access, if Ni_PORTCTRL.DELE is set. 0_B No protocol exception event occurred since last read access 1_B Protocol exception event occurred
TDCV	22:16	rh	**Transmitter Delay Compensation Value** Position of the secondary sample point, defined by the sum of the measured delay from TX to RX and Ni_TDCR.TDCO. The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq.
0	15, 31:23	r	**Reserved** Read as 0; should be written with 0.

1) The Bus_Off recovery sequence (see ISO11898-1) cannot be shortened by setting or resetting CCCR.INIT. If the device goes Bus_Off, it will set CCCR.INIT of its own accord, stopping all bus activities. Once CCCR.INIT has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Error Management Counters will be reset. During the waiting time after the resetting of CCCR.INIT, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to PSR.LEC, enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. ECR.REC is used to count these sequences.

21.7.77 Node i Transmitter Delay Compensation Register

Ni_TDCR (i=0-3) Offset address: $00248_H+i*400_H$

Node i Transmitter Delay Compensation Register Kernel Reset value: $0000\ 0000_H$

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	TDCO							0	TDCF						
r	rw							r	rw						

Field	Bits	Type	Description
TDCF	6:0	rw	**Transmitter Delay Compensation Filter Window Length** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. Defines the minimum value for the Secondary Sample Point position, dominant edges on RX that would result in an earlier Secondary Sample Point position are ignored for transmitter delay measurement. This feature is enabled when TDCF is configured to a value greater than TDCO. Valid values are from 0 to 127 mtq.
TDCO	14:8	rw	**Transmitter Delay Compensation Offset** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. Offset value defining the distance between the measured delay from TX to RX and the secondary sample point. Valid values are 0 to 127 mtq. The duration of one mtq is equal to the fASYNi clock period.
0	7, 31:15	r	**Reserved** Read as 0; should be written with 0.

21.7.78 Node i Interrupt Register

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a “1” to the corresponding bit position. Writing a “0” has no effect. The configuration of Ni_IE controls whether an interrupt is generated.

***Note**: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all rwh bits in this register.*

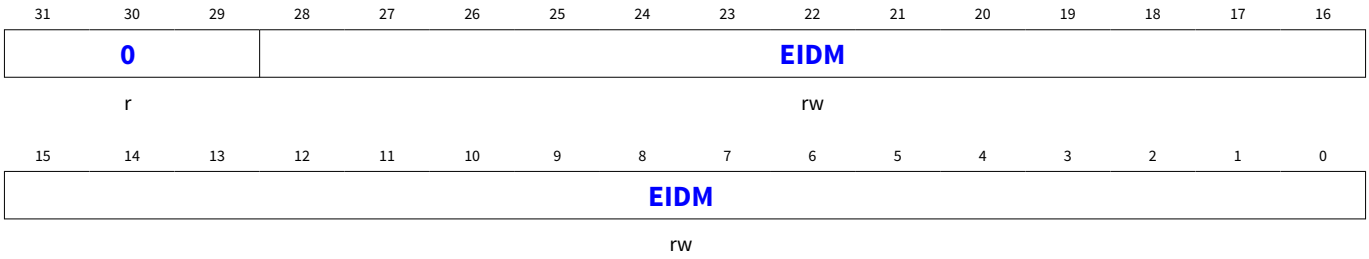
FLESA														0	
rw														r	

Field	Bits	Type	Description
FLESA	15:2	rw	**Filter List Extended Start Address** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. Start address of extended Message ID filter list (32-bit word addess).
LSE	22:16	rw	**List Size Extended** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. 00$_H$ No standard Message ID filter 01$_H$ 1 extended Message ID filter element … 40$_H$ 64 extended Message ID filter element **others,** 64 extended Message ID filter elements
0	1:0, 31:23	r	**Reserved** Read as 0; should be written with 0.

21.7.83 Node i Extended ID AND Mask

Ni_XIDAM (i=0-3) Offset address: 00290$_H$+i*400$_H$

Node i Extended ID AND Mask Kernel Reset value: 1FFF FFFF$_H$



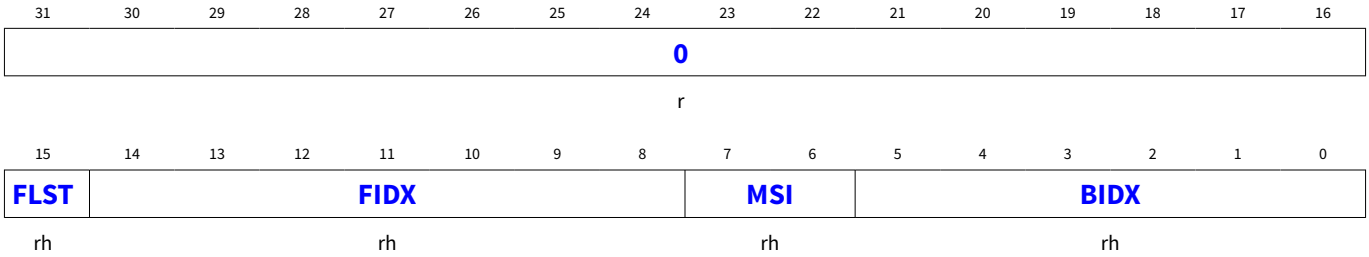
Field	Bits	Type	Description
EIDM	28:0	rw	**Extended ID Mask** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. For acceptance filtering of extended frames the Extended ID AND Mask is ANDed with the Message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. With the reset value of all bits set to one the mask is not active.
0	31:29	r	**Reserved** Read as 0; should be written with 0.

21.7.84 Node i High Priority Message Status

This register is updated every time a Message ID filter element configured to generate a priority event matches. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

Ni_HPMS (i=0-3) Offset address: $00294_H+i*400_H$

Node i High Priority Message Status Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
BIDX	5:0	rh	**Buffer Index** Index of Rx FIFO element to which the message was stored. Only valid when MSI[1] = '1'.
MSI	7:6	rh	**Message Storage Indicator** 00_B No FIFO selected 01_B FIFO message lost 10_B Message stored in FIFO 0 11_B Message stored in FIFO 1

(table continues...)

(continued)

Field	Bits	Type	Description
FIDX	14:8	rh	**Filter Index** Index of matching filter element. Range is 0 to Ni_SIDFC.LSS - 1 resp. Ni_XIDFC.LSE - 1.
FLST	15	rh	**Filter List** Indicates the filter list of the matching filter element. 0_B Standard Filter List 1_B Extended Filter List
0	31:16	r	**Reserved** Read as 0; should be written with 0.

21.7.85 Node i New Data 1

The register holds the New Data flags of Rx Buffers 0 to 31.

***Note**: LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all rwh bits in this register.*

Ni_NDAT1 (i=0-3) Offset address: $00298_H+i*400_H$

Node i New Data 1 Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
TBSA	15:2	rw	**Tx Buffers Start Address** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. Start address of Tx Buffers section in Message RAM (32-bit word address).

(table continues...)

(continued)

Field	Bits	Type	Description
NDTB	21:16	rw	**Number of Dedicated Transmit Buffers** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. ***Note:*** *Be aware that the sum of TFQS and NDTB may be not greater than 32. There is no check for erroneous configurations. The Tx Buffers section in the Message RAM starts with the dedicated Tx Buffers.* 00_H No Dedicated Tx Buffers 01_H 1 Dedicated Tx Buffers … 20_H 32 Dedicated Tx Buffers **others,** 32 Dedicated Tx Buffers
TFQS	29:24	rw	**Transmit FIFO/Queue Size** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. 00_H No Tx FIFO/Queue 01_H 1 Tx Buffers used for Tx FIFO/Queue … 20_H 32 Tx Buffers used for Tx FIFO/Queue **others,** 32 Tx Buffers used for Tx FIFO/Queue
TFQM	30	rw	**Tx FIFO/Queue Mode** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. 0_B Tx FIFO operation 1_B Tx Queue operation
0	1:0, 23:22, 31	r	**Reserved** Read as 0; should be written with 0.

Table 1021 Reset values of Ni_TXBC (i=0-3)

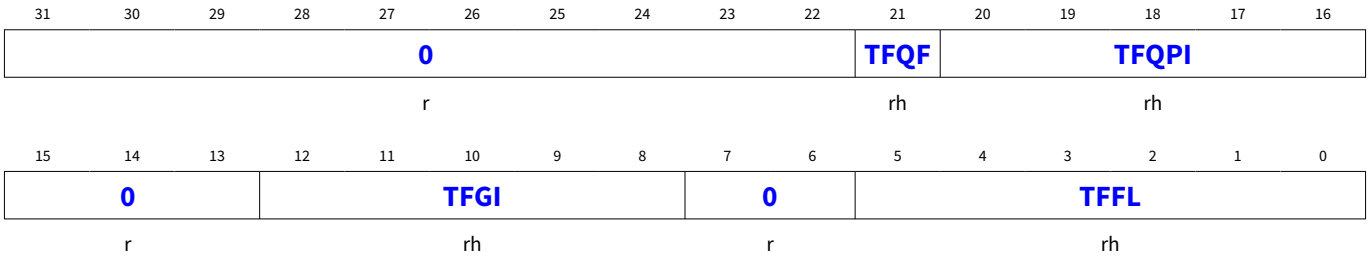
Reset type	Reset value	Note
Kernel Reset	$0000\ 0000_H$	
After Boot-FW Value	$0000\ 1208_H$	After CAN BSL execution (applicable only for CAN0 and Node 1)

21.7.96 Node i Tx FIFO/Queue Status

The Tx FIFO/Queue status is related to the pending Tx requests listed in register Ni_TXBRP. Therefore the effect of Add/Cancellation requests may be delayed due to a running Tx scan (Ni_TXBRP not yet updated).

Ni_TXFQS (i=0-3) Offset address: $002C4_H+i*400_H$

Node i Tx FIFO/Queue Status Kernel Reset value: $0000\ 0000_H$



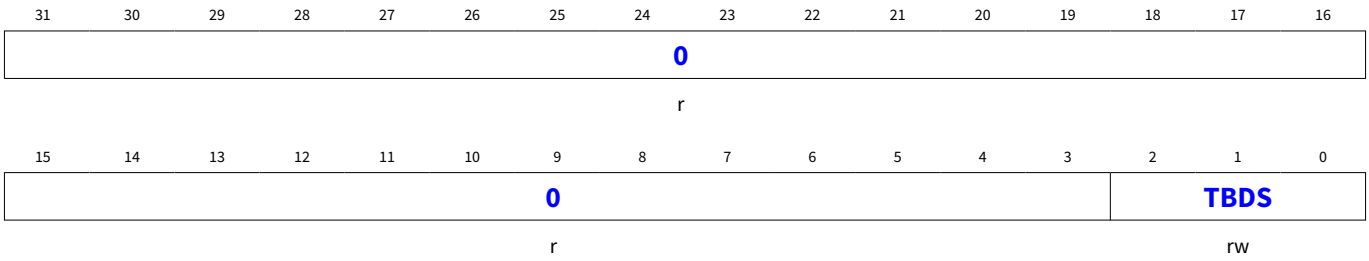
Field	Bits	Type	Description
TFFL	5:0	rh	**Tx FIFO Free Level** Number of consecutive free Tx FIFO elements starting from TFGI, range 0 to 32. Read as zero when Tx Queue operation is configured (Ni_TXBC.TFQM = '1') ***Note**: In case of mixed configurations where dedicated Tx Buffers are combined with a Tx FIFO or a Tx Queue, the Put and Get Indices indicate the number of the Tx Buffer starting with the first dedicated Tx Buffers. Example: For a configuration of 12 dedicated Tx Buffers and a Tx FIFO of 20 Buffers a Put Index of 15 points to the fourth buffer of the Tx FIFO.*
TFGI	12:8	rh	**Tx FIFO Get Index** Tx FIFO read index pointer, range 0 to 31. Read as zero when Tx Queue operation is configured (Ni_TXBC.TFQM = '1').
TFQPI	20:16	rh	**Tx FIFO/Queue Put Index** Tx FIFO/Queue write index pointer, range 0 to 31.
TFQF	21	rh	**Tx FIFO/Queue Full** 0_B Tx FIFO/Queue not full 1_B Tx FIFO/Queue full
0	7:6, 15:13, 31:22	r	**Reserved** Read as 0; should be written with 0.

21.7.97 Node i Tx Buffer Element Size Configuration

Configures the number of data bytes belonging to a Tx Buffer element. Data field sizes > 8 bytes are intended for CAN FD operation only.

Ni_TXESC (i=0-3) Offset address: $002C8_H+i*400_H$

Node i Tx Buffer Element Size Configuration Reset values see: Table 1022



Field	Bits	Type	Description
TBDS	2:0	rw	**Tx Buffer Data Field Size** This bit-field is CCE and INIT protected. Writes will only have effect, if both bits are set. ***Note**: In case the data length code DLC of a Tx Buffer element is configured to a value higher than the Tx Buffer data field size Ni_TXESC.TBDS, the bytes not defined by the Tx Buffer are transmitted as "0xCC" (padding bytes).* 000_B 8-byte data field 001_B 12-byte data field 010_B 16-byte data field 011_B 20-byte data field 100_B 24-byte data field 101_B 32-byte data field 110_B 48-byte data field 111_B 64-byte data field
0	31:3	r	**Reserved** Read as 0; should be written with 0.

Table 1022 Reset values of Ni_TXESC (i=0-3)

Reset type	Reset value	Note
Kernel Reset	$0000\ 0000_H$	
After Boot-FW Value	$0000\ 0007_H$	After CAN BSL execution (applicable only for CAN0 and Node 1)

21.7.98 Node i Tx Buffer Request Pending

Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register Ni_TXBAR. The bits are reset after a requested transmission has completed or has been cancelled via register Ni_TXBCR.

Ni_TXBRP bits are set only for those Tx Buffers configured via Ni_TXBC. After a TXBRP bit has been set, a Tx scan (Tx Handling) is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID).

A cancellation request resets the corresponding transmission request pending bit of register Ni_TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding TXBRP bit has been reset.

After a cancellation has been requested, a finished cancellation is signalled via Ni_TXBCF

- after successful transmission together with the corresponding Ni_TXBTO bit
- when the transmission has not yet been started at the point of cancellation
- when the transmission has been aborted due to lost arbitration
- when an error occurred during frame transmission

In "Disable Automatic Retransmission" mode all transmissions are automatically cancelled if they are not successful. The corresponding Ni_TXBCF bit is set for all unsuccessful transmissions.

***Note**: TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this "Add Request" is cancelled immediately, the corresponding Ni_TXBRP bit is reset.*

Ni_TXBRP (i=0-3) Offset address: $002CC_H+i*400_H$

Node i Tx Buffer Request Pending Kernel Reset value: $0000\ 0000_H$

TRPz (z=0-31)	z	rh	**Transmission Request Pending Tx Buffer z - TRP** 0_B No transmission request pending 1_B Transmission request pending

21.7.99 Node i Tx Buffer Add Request

Each Tx Buffer has its own "Add Request" bit. Writing a ‘1’ will set the corresponding "Add Request" bit; writing a ‘0’ has no impact. This enables the Host to set transmission requests for multiple Tx Buffers with one write to Ni_TXBAR. Ni_TXBAR bits are set only for those Tx Buffers configured via Ni_TXBC. When no Tx scan is running, the bits are reset immediately, else the bits remain set until the Tx scan process has completed.

***Note**: If an add request is applied for a Tx Buffer with pending transmission request (corresponding Ni_TXBRP bit already set), this add request is ignored. LDMST or SWAPMSK.W instructions should be used only with bit mask enabled for all rwh bits in this register.*

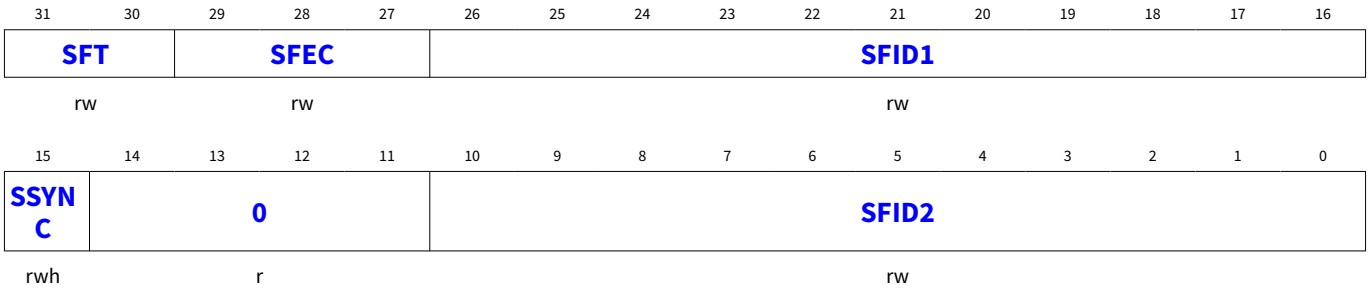
21.7.115 Standard Message ID Filter Element

21.7.115.1 Standard Message 0

STDMSGk_S0 (k=0-127) Offset address: $00000_H + k*4$

Standard Message 0 RAMInit value: $XXXX\ XXXX_H$



Field	Bits	Type	Description
SFID2	10:0	rw	**Standard Filter ID 2** This bit-field has a different meaning depending on the configuration of SFEC: 1) SFEC = “001”…”110” Second ID of standard ID filter element 2) SFEC = “111” Filter for Rx Buffers or for debug messages **SFID2[5:0]** defines the offset to the Rx Buffer Start Address Ni_RXBC.RBSA for storage of a matching message. **SFID2[8:6]** is used to control the filter event pins. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one host clock period in case the filter matches. **SFID2[10:9]** decides whether the received message is stored into an Rx Buffer or treated as message A, B, or C of the debug message sequence. 000_H Store message into an Rx Buffer … $1FF_H$ Store message into an Rx Buffer 200_H Debug Message A … $3FF_H$ Debug Message A 400_H Debug Message B … $5FF_H$ Debug Message B 600_H Debug Message C … $7FF_H$ Debug Message C
SSYNC	15	rwh	**Standard Sync Message** Only evaluated when Ni_CCCR.UTSU = '1'. 0_B Timestamping for the matching Sync message disabled. 1_B Timestamping for the matching Sync message enabled.
SFID1	26:16	rw	**Standard Filter ID 1** First ID of standard ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used.

(table continues...)

(continued)

Field	Bits	Type	Description
SFEC	29:27	rw	**Standard Filter Element Configuration** All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = “100”, “101” or “110”, a match sets interrupt flag Ni_IR.HPM and, if enabled, an interrupt is generated. In this case register Ni_HPMS is updated with the status of the priority match. 000_B Disable filter element 001_B Store in Rx FIFO 0 if filter matches 010_B Store in Rx FIFO 1 if filter matches 011_B Reject ID if filter matches 100_B Set priority if filter matches 101_B Set priority and store in FIFO 0 if filter matches 110_B Set priority and store in FIFO 1 if filter matches 111_B Store into Rx Buffer or as debug message, configuration of SFT[1:0] ignored
SFT	31:30	rw	**Standard Filter Type** ***Note**: With SFT = “11” the filter element is disabled and the acceptance filtering continues (same behavior as with SFEC = “000”)* 00_B Range filter from SF1ID to SF2ID (SF2ID ≥ SF1ID) 01_B Dual ID filter for SF1ID or SF2ID 10_B Classic filter: SF1ID = filter, SF2ID = mask 11_B Filter element disabled
0	14:11	r	**Reserved** Read as 0; should be written with 0.

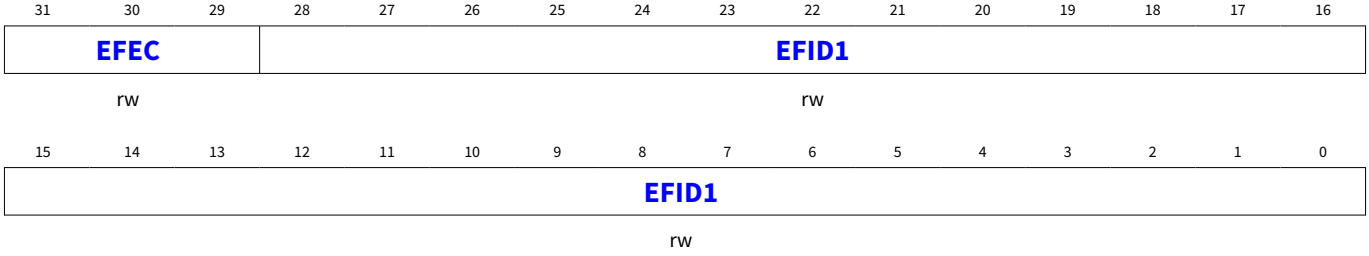
21.7.116 Extended Message ID Filter Element

21.7.116.1 Filter Element 0

See Message layout.

EXTMSGk_F0 (k=0-63) Offset address: 00000_H + k*8

Filter Element 0 RAMInit value: XXXX $XXXX_H$



Field	Bits	Type	Description
EFID1	28:0	rw	**Extended Filter ID 1** First ID of extended ID filter element. When filtering for Rx Buffers or for debug messages this field defines the ID of an extended message to be stored. The received identifiers must match exactly, only XIDAMi masking mechanism is used.
EFEC	31:29	rw	**Extended Filter Element Configuration** All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If EFEC = “100”, “101” or “110”, a match sets interrupt flag Ni_IR.HPM and, if enabled, an interrupt is generated. In this case register Ni_HPMS is updated with the status of the priority match. 000_B Disable filter element 001_B Store in Rx FIFO 0 if filter matches 010_B Store in Rx FIFO 1 if filter matches 011_B Reject ID if filter matches 100_B Set priority if filter matches 101_B Set priority and store in FIFO 0 if filter matches 110_B Set priority and store in FIFO 1 if filter matches 111_B Store into Rx Buffer or as debug message, configuration of EFT[1:0] ignored

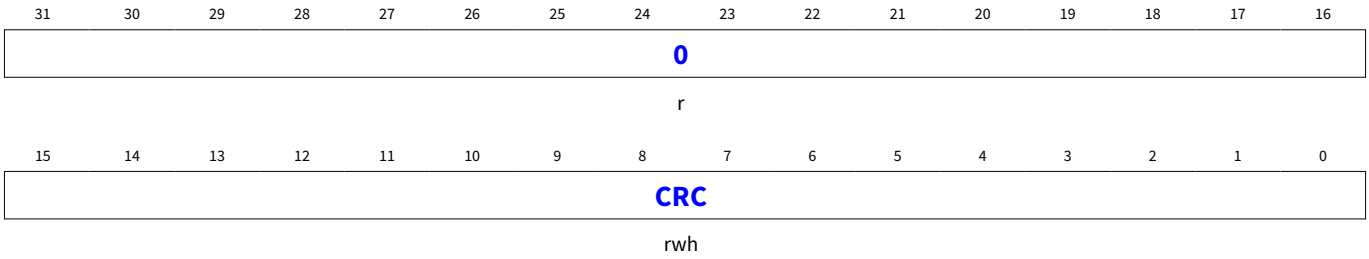
21.7.122 CRE Transmit Host Buffers

21.7.122.1 Tx Host Buffer CRC

CRC computed over the safety critical CAN payload of the CAN frame stored in the THBUF. This CRC is verified by the CRE before writing the CAN frame to the Tx FIFO/Queue

THBUFk_CRC (k=0-1) Offset address: $000E0_H+k*50_H$

Tx Host Buffer CRC RAMInit value: $XXXX\ XXXX_H$



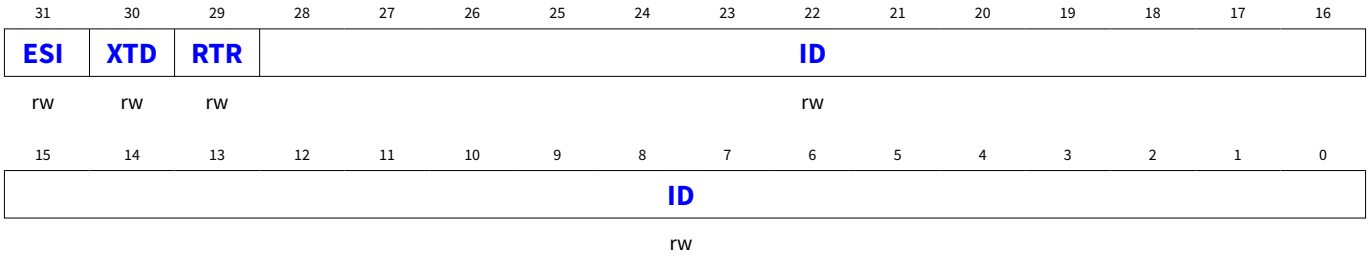
Field	Bits	Type	Description
CRC	15:0	rwh	**CRC** CRC to be verified by CRE
0	31:16	r	**Reserved**

21.7.122.2 Transmit Host Buffer Word 0

See Message layout.

THBUFk_T0 (k=0-1) Offset address: $000E4_H+k*50_H$

Transmit Host Buffer Word 0 RAMInit value: $XXXX\ XXXX_H$



Field	Bits	Type	Description
ID	28:0	rw	**Identifier** Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
RTR	29	rw	**Remote Transmission Request** ***Note**: When RTR = 1, the M_CAN transmits a remote frame according to ISO11898-1, even if Ni_CCCR.FDOE enables the transmission in CAN FD format.* 0_B Transmit data frame 1_B Transmit remote frame
XTD	30	rw	**Extended Identifier** 0_B 11-bit standard identifier 1_B 29-bit extended identifier

(table continues...)

(continued)

Field	Bits	Type	Description
ESI	31	rw	**Error State Indicator** ***Note**: The ESI bit of the transmit buffer is OR'ed with the error passive flag to decide the value of the ESI bit in the transmitted FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node will always transmit the ESI bit recessive.* 0_B ESI bit in CAN FD format depends only on error passive flag 1_B ESI bit in CAN FD format transmitted recessive

21.7.125 CRE Standard Frame Rate Table

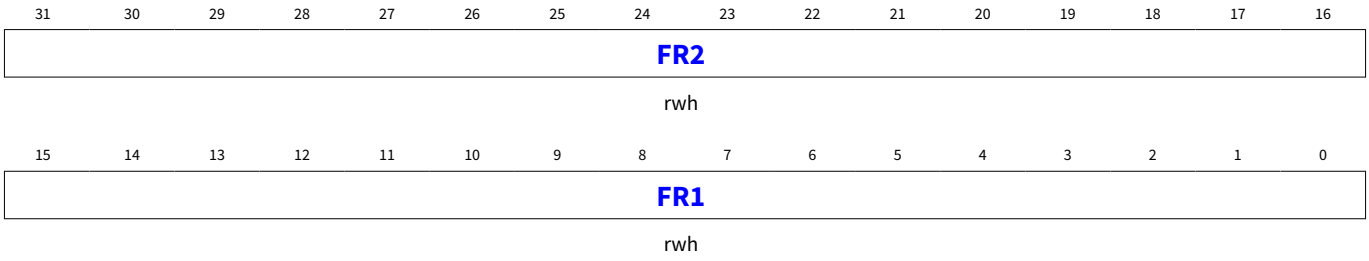
21.7.125.1 Standard ID Frame Rate Measure

Standard CAN ID Frame rate measure table

Consists of two Standard ID Frame rate measures

SFRk_FR (k=0-63) Offset address: 00468_H+k*4

Standard ID Frame Rate Measure RAMinit value: XXXX $XXXX_H$



Field	Bits	Type	Description
FR1	15:0	rwh	**Frame Rate Measure 1** Frame Rate Measure is relevant for Intrusion detection. It indicates the number of frames received
FR2	31:16	rwh	**Frame Rate Measure 2** Frame Rate Measure is relevant for Intrusion detection. It indicates the number of frames received

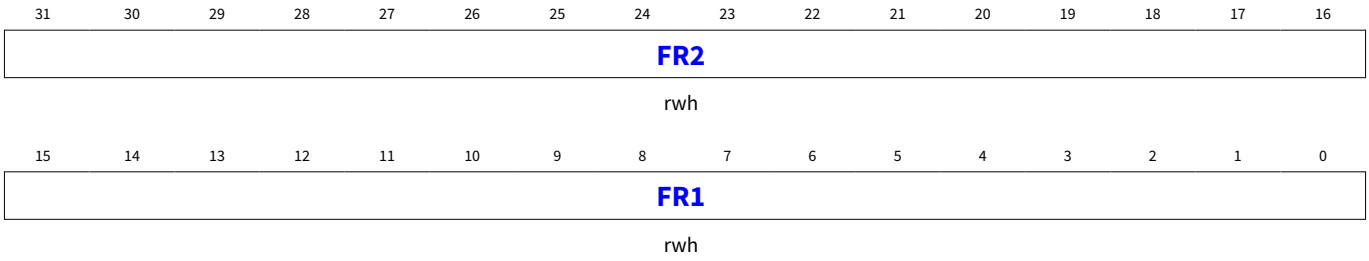
21.7.126 CRE Extended Frame Rate Table

21.7.126.1 Extended ID Frame Rate Measure

Extended CAN ID Frame Rate Mesaure table
Consists of two Extended ID Frame rate measures

XFRk_FR (k=0-31) Offset address: 00568_H+k*4

Extended ID Frame Rate Measure RAMInit value: XXXX $XXXX_H$



Field	Bits	Type	Description
FR1	15:0	rwh	**Frame Rate Measure 1** Frame Rate Measure is relevant for Intrusion detection. It indicates the number of frames received
FR2	31:16	rwh	**Frame Rate Measure 2** Frame Rate Measure is relevant for Intrusion detection. It indicates the number of frames received

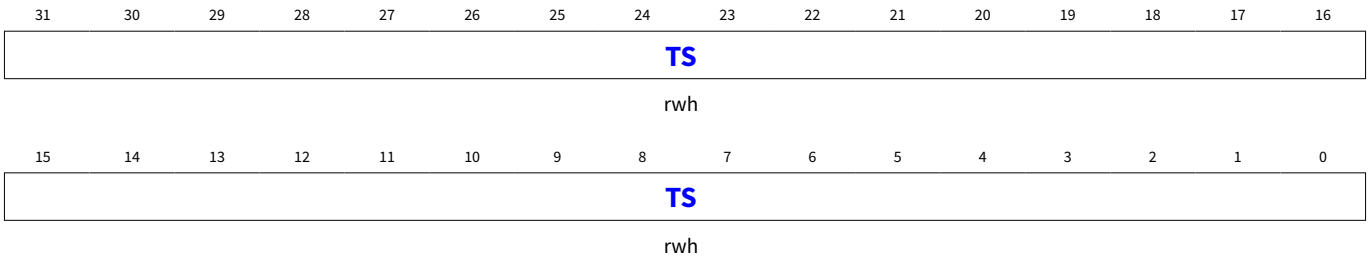
21.7.127 CRE Standard Timestamp Database

21.7.127.1 Standard ID Reference Timestamp

Standard ID Reference Timestamp which is used to calculate the RHBUFk_THEAD_INTRD. IAM
Note: The database needs to be initialized to 0

STSDk_RTS (k=0-127) Offset address: $005E8_H$+k*4

Standard ID Reference Timestamp RAMInit value: XXXX $XXXX_H$



Field	Bits	Type	Description
TS	31:0	rwh	**Reference Timestamp** This Reference Timestamp is the previous received Timestamp used for calculating the Inter Arrival Measure.

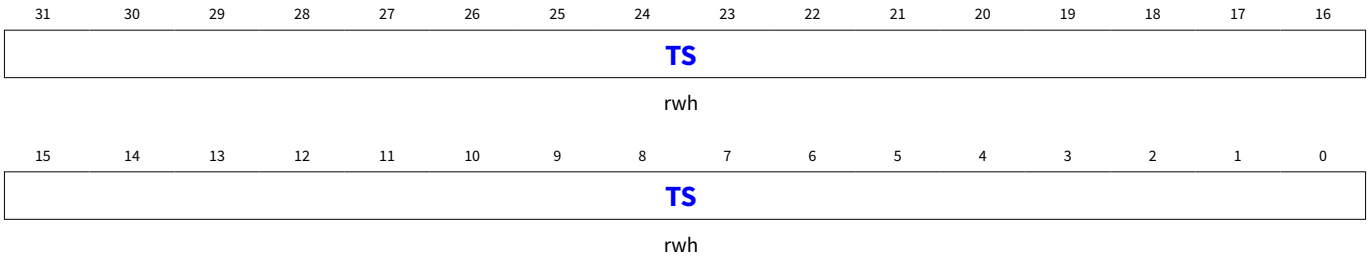
21.7.128 CRE Extended Timestamp Database

21.7.128.1 Extended ID Reference Timestamp

Extended ID Reference Timestamp which is used to calculate the RHBUFk_THEAD_INTRD. IAM
Note: The database needs to be initialized to 0

XTSDk_RTS (k=0-63) Offset address: $007E8_H+k*4$

Extended ID Reference Timestamp RAMInit value: $XXXX\ XXXX_H$



Field	Bits	Type	Description
TS	31:0	rwh	**Reference Timestamp** This Reference Timestamp is the previous received Timestamp used for calculating the Inter Arrival Measure.

21.8 Debug information

OCDS suspend behavior support

- Hard suspend
  - The clock is switched off to the MCMCAN module, and any ongoing transmission or reception event will be suspended immediately
- Soft suspend
  - The clock is switched off to the MCMCAN module after completion of the ongoing transmission and reception events. The Ni_CCCR.INIT bit will be set during the soft suspend. So, when leaving the soft suspend, the debugger has to ensure that the Ni_CCCR.INIT bit is cleared in order to continue normal CAN operation

Destructive debug

On destructive debug entry ie., when GP_CSRM_DBCFG.DESTDBG = 11b and GP_CSRM_DBGMODE.EDDM = 11b, the CAN transmit data output (TXD) is tied to “Recessive state” (logic ‘1b’). This blocks any further CAN transmission when the device has entered the Destructive Debug state.

OCDS trigger bus interface

The CAN trigger set is shown in table. Its output is on OTBG0 or OTGB1 controlled by the OCS register.

Table 1024 TS16_CAN trigger set

Values	Name	Description
i	AF	Acceptance filtering done for Node i
i + 4	MR	Message successfully received on Node i
i + 8	FDR	Fast Data Phase reception on Node i
i + 12	FDT	Fast Data Phase transmission on Node i

21.11 TC4Dx CAN information

21.11.1 TC4Dx CAN configuration

Table 1025 Device specific parameters

Parameters	CAN0	CAN1	CAN2	CAN3	CAN4
Number of CAN nodes	4	4	4	4	4
RAM size (in Kbytes)	36	20	20	20	20
Debug over CAN support	Yes (only in Node 0)	No	No	No	No

21.11.2 TC4Dx CAN features

There are no deviations from the generic specification.

21.11.3 TC4Dx CAN functional description

- In TC4Dx device, the CAN modules are connected to ComPB bus interface. The CAN chapter refers to it as FPI bus
- In TC4Dx, the reset domain for the Node Start Address (Ni_STARTADR (i=0-3)) and Node End Address (Ni_ENDADR (i=0-3)) registers is Kernel Reset and the reset value remains the same as specified in the family specification 4010

21.11.4 TC4Dx CAN registers

21.11.4.1 Memory overview tables of CAN domain SFR

Table 1026 Memory overview - CAN domain SFR (ascending address)

Short name	Long name	Address
CAN0_RAM	Embedded SRAM for messages (09000_H Byte)	$F4700000_H$
CAN1_RAM	Embedded SRAM for messages (05000_H Byte)	$F4720000_H$

Table 1028 (continued) Register overview - access mode glossary

Keyword	Description
APU-P4	Protection group consisting of registers CAN0_ACCEN_WRA , CAN0_ACCEN_WRB , CAN0_ACCEN_RDA , CAN0_ACCEN_RDB , CAN0_ACCEN_VM , CAN0_ACCEN_PRS or CAN1_ACCEN_WRA , CAN1_ACCEN_WRB , CAN1_ACCEN_RDA , CAN1_ACCEN_RDB , CAN1_ACCEN_VM , CAN1_ACCEN_PRS or CAN2_ACCEN_WRA , CAN2_ACCEN_WRB , CAN2_ACCEN_RDA , CAN2_ACCEN_RDB , CAN2_ACCEN_VM , CAN2_ACCEN_PRS or CAN3_ACCEN_WRA , CAN3_ACCEN_WRB , CAN3_ACCEN_RDA , CAN3_ACCEN_RDB , CAN3_ACCEN_VM , CAN3_ACCEN_PRS or CAN4_ACCEN_WRA , CAN4_ACCEN_WRB , CAN4_ACCEN_RDA , CAN4_ACCEN_RDB , CAN4_ACCEN_VM , CAN4_ACCEN_PRS .
P4	Access protection using *APU-P4* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.
M	Indicates a module specific access condition. Refer to the register description for details of the specific access condition.

21.11.4.4 Register overview - CAN0 domain SFR (ascending offset address)

Table 1029 Register overview - CAN0 domain SFR (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write

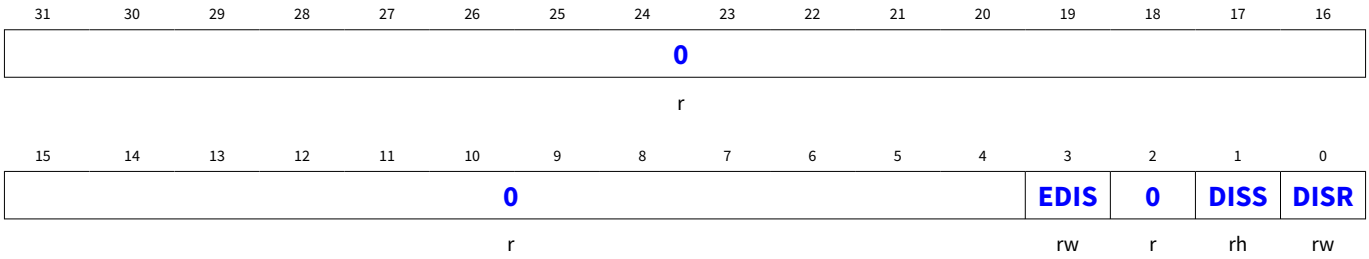
21.11.4.9 Clock Control Register (CANn=1-4)

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CAN1_CLC	Offset address:	00000_H
Clock Control Register	Application Reset value:	0000 0003_H
CAN2_CLC	Offset address:	00000_H
Clock Control Register	Application Reset value:	0000 0003_H
CAN3_CLC	Offset address:	00000_H
Clock Control Register	Application Reset value:	0000 0003_H
CAN4_CLC	Offset address:	00000_H
Clock Control Register	Application Reset value:	0000 0003_H



Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable/disable control of the module. The synchronous and asynchronous clock is switched on/off. Note that no register access is possible to any register while module is disabled. A disable request is granted, if the M_CAN clock is disabled, or all M_CAN nodes acknowledge the disable request. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

21.11.4.10 Module Control Register (CANn=1-4)

The Module Control Register MCR contains basic settings that determine the operation of the MCMCAN module.

The write access to the lowest byte of the MCR register becomes only valid, if and only if, MCR.CCCE and MCR.CI are already set during write access. To switch the clocks on or off, the bits of MCR.CCCE and MCR.CI have to be reset afterwards. Before this sequence hasn't taken place, no write access to the corresponding nodes, can be done.

***Note**: If the baud rate logic is supplied from an unstable clock source, or no clock at all, the CAN functionality is not guaranteed.*

To be able to change the clock settings the following programming sequence needs to be met:
uwTemp = CANn_MCR.U;
uwTemp |= (0xC0000000 | CLKSELx);
CANn_MCR.U = uwTemp;
uwTemp &= ~0xC0000000;
CANn_MCR.U = uwTemp;
The clock settings for CAN nodes becomes active.
To be able to start the RAM initialization, the following programming sequence need to be met:
CANn_MCR |= 0xC0000000;
Wait until CANn_MCR.RBUSY is 0b
Set CANn_MCR.RINIT to 0b
Set CANn_MCR.RINIT to 1b
Dummy read CANn_MCR
Wait until CANn_MCR.RBUSY is 0b
Set CANn_MCR.RINIT to 0b
CANn_MCR &= ~0xC0000000;
RAM initialization is finished

CAN1_MCR	Offset address:	00070_H
Module Control Register	Kernel Reset value:	$0000\ 0000_H$
CAN2_MCR	Offset address:	00070_H

22 Controller Area Network XL interface (CANXL)

The CANXL module provides a communication interface according to the ISO 11898-1:2024 standard, supporting Classical CAN, CAN FD and CAN XL communication. It supports CAN XL data baudrates of up to 20 Mbits/s.

22.1 Feature list

- Classical CAN, CAN FD and CAN XL communication according to ISO 11898-1:2024
- CAN XL payload size of up to 2048 data bytes
- CAN XL communication baud rate up to 20 Mbits/s
- Hardware-based 64-bit time stamping
- Integrated DMA for message transfers without CPU load
- 1 transmit priority queue with maximum of 32 slots for ID-based priority transmission of CAN frames
- Maximum of 8 TX FIFO queues
- Maximum of 8 RX FIFO queues
- TX message filtering with up to 16 filter elements
- RX message filtering with up to 255 filter elements (with 32-bit word compare)

22.2 Functional overview

The figure below shows the block diagram overview of the CANXL module.

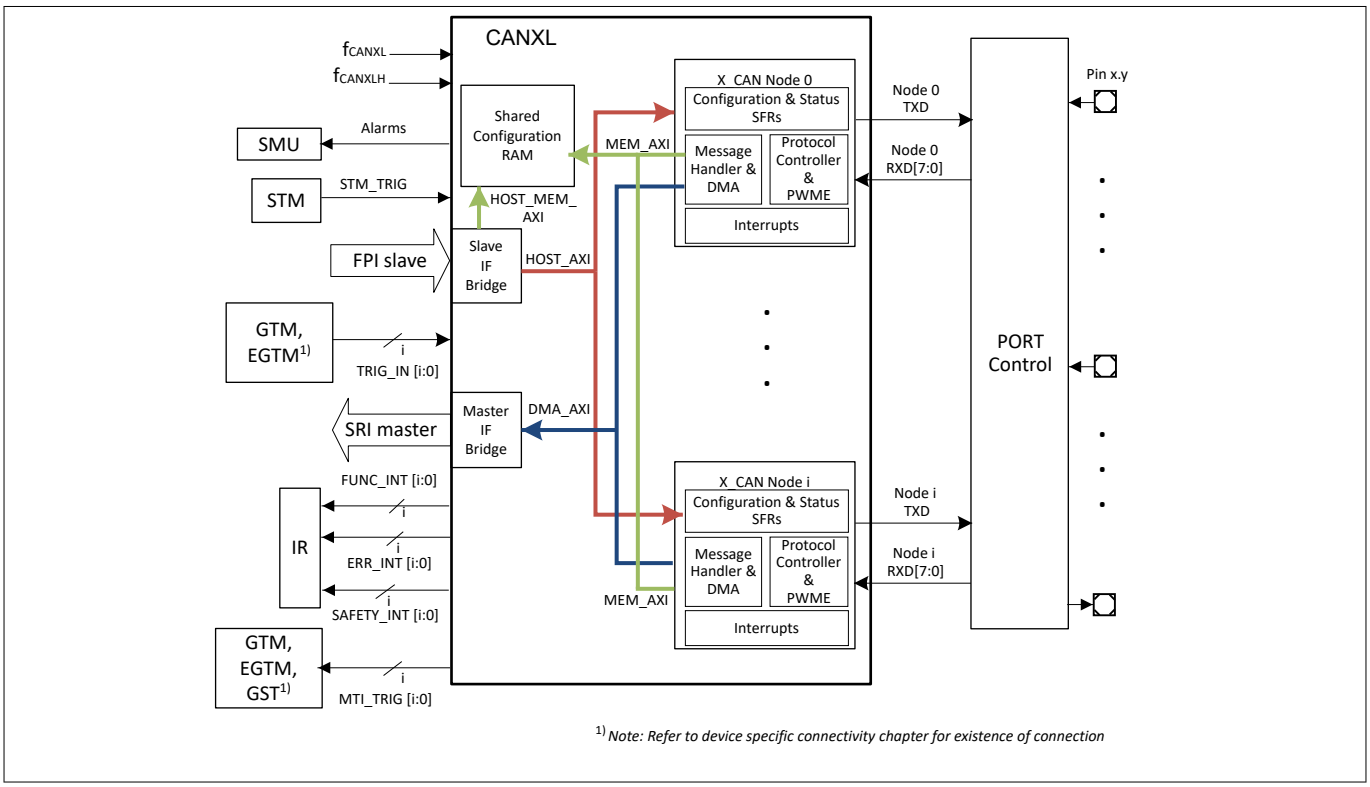

Figure 390 CANXL block diagram

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

The Node I are instances of X_CAN IP from Bosch. The Slave Interface Bridge contains the following functions

- Clock control
- Reset functions

- Access protection and
- Slave bus protocol conversion bridges for accessing SFRs and local memory RAM through the 32-bit FPI interface

The Master Interface Bridge contains the following function

- VM and PRS configuration
- Master bus protocol conversion bridges for data and control transfer through 64-bit SRI interface

22.3 Functional description

CANXL Glossary

The following table introduces some acronyms related to the CANXL functional block that are used in the rest of the chapter.

Table 1035 CANXL acronyms

Acronym	Description
CAN	Generic term for any controller area network protocol variant.
CCAN	Classical CAN protocol as per ISO 11898-1:2024.
CAN FD	CAN with flexible datarate protocol as per ISO 11898-1:2024.
CAN XL	CAN XL protocol as per ISO 11898-1:2024.
X_CAN	Bosch IP core that supports CCAN/CAN FD/CAN XL protocols and message handling on a single interface node.
CANXL	Functional block encapsulating multiple X_CAN.
MH	Message Handler module inside X_CAN responsible for DMA of CAN message data and message descriptor data to and from system memory.
PRT	Protocol Controller module inside X_CAN responsible for CAN protocol operation and interface to MH module.
L_MEM	Local Memory. It is also referred in the chapter as "Shared Configuration RAM"
S_MEM	System Memory. It refers to System RAM.
XCAND_MH_DESC	DESCRIPTOR MESSAGE HANDLER
XCAND_MH_DMA	DMA MESSAGE HANDLER

Clock control

The CANXL module has one global clock control special function register (SFR) and each X_CAN node has an independent clock control SFR. The clock control SFR (MODULE_CLC) controls the clock enable or disable of the entire CANXL module. The CLKEN SFR controls the clock enable or disable only for the corresponding X_CAN nodes. The node i clock control is a subset of module clock control, that is switching off the clocks using module clock control switches off all nodes clock domains as well.

***Note**: The clocks must be switched off by hardware only after the respective X_CAN node's Protocol Controller is stopped.*

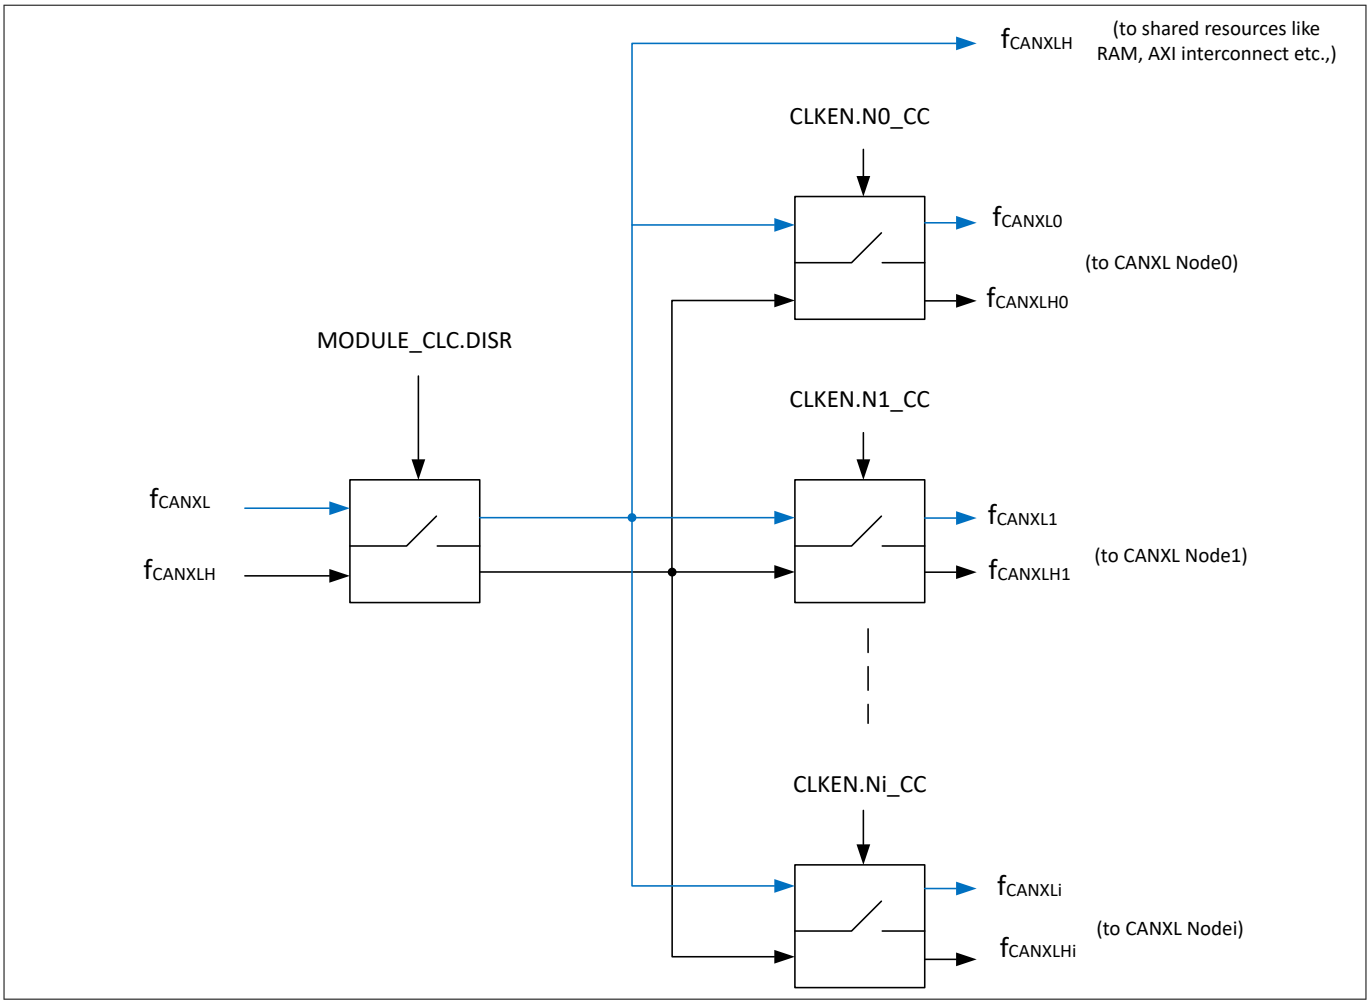

Figure 391 CANXL clock control

Reset control

The CANXL module has one global Reset Control Register set (MODULE_RST_CTRLA and MODULE_RST_CTRLB) and each X_CAN node has an independent Reset Control Register set (NODEi_RST_CTRLA and NODEi_RST_CTRLB). The module reset control SFRs controls the reset of entire CANXL module. The node i reset control SFRs control only for the corresponding X_CAN nodes reset. The node i reset control is a subset of module reset control, that is triggering reset using module reset control resets all nodes also.

***Note**: The kernel reset must be initiated by software only after the corresponding X_CAN node's Message Handler and Protocol Controller are stopped. In case of individual node i kernel reset, it is up to the software to ensure that X_CAN node i's Message Handler and Protocol Controller are stopped, before requesting the reset via node i KRST.*

Access protection

The CANXL module contains global access protection (MODULE_ACCEN SFRs) for access protection configuration to all SFRs which are shared by the X_CAN nodes. Each X_CAN node specific SFRs access protection is configured through the corresponding node specific access protection registers (NODEi_ACCENNODE). The access protection for node specific configuration RAM regions are configured through NODEi_ACCENNODE_RGNLA and NODEi_ACCENNODE_RGNUA registers. Refer to Register Overview table for access protection allocation to SFRs.

Master VM and PRS allocation

All X_CAN nodes within the module share a single SRI master interface and has a single Master TAG-ID assigned. In order to distinguish the SRI transactions initiated by each X_CAN node, NODEi_VMPRSCONFIG SFRs are used. Each X_CAN node DMA transactions can be assigned to a virtual machine number (VM) and protection set (PRS). The VM number and the PRS programmed in the NODEi_VMPRSCONFIG register will be driven on the SRI interconnect during read or write accesses to the corresponding resource (memory), if they are enabled respectively through configuration.

Shared Local Memory (L_MEM)

The shared L_MEM is a 32-bit RAM with allocation of 4kB per X_CAN node. The L_MEM is accessed both by software through HOST_MEM interface and MEM_AXI interface. Arbitration is done in round-robin basis when parallel access is requested through HOST_MEM and by hardware through MEM_AXI. The L_MEM stores the following data for each X_CAN node

- RX filter elements. The base address of the RX filter elements are configured through Ni_RX_FILTER_MEM_ADD register. The amount of RAM space allocated for the RX filter elements is strictly dependent on Ni_RX_FILTER_CTRL.NB_FE bit-field configuration and individual RX filter element configuration.
- Tx FIFO Queue Header and Next descriptors. The base address for TX FIFO Queue descriptors are configured through Ni_TX_DESC_MEM_ADD.FQ_BASE_ADDR bit-field. The amount of RAM space allocated for the Tx FIFO Queue descriptors is strictly dependent on number of active TX FIFO Queues.
- Tx Priority Queue Header descriptors. The base address for TX Priority Queue descriptors are configured through Ni_TX_DESC_MEM_ADD.PQ_BASE_ADDR bit-field. The amount of RAM space allocated for the Tx Priority Queue descriptors is strictly dependent on number of active TX Priority Queue elements.

Interrupt Control

The CANXL module reports status and error events through interrupts to the Interrupt Router module. Each X_CAN node generates following three interrupts

- SRC_CANXLiFUNC interrupt. Each X_CAN node's functional events as described in Ni_FUNC_RAW register can trigger this interrupt, if the corresponding events are enabled through Ni_FUNC_ENA register. The corresponding event flags can be cleared by software through Ni_FUNC_CLR register.
- SRC_CANXLiERR interrupt. Each X_CAN node's error events as described in Ni_ERR_RAW register can trigger this interrupt, if the corresponding events are enabled through Ni_ERR_ENA register. The corresponding event flags can be cleared by software through Ni_ERR_CLR register.
- SRC_CANXLiSAFETY interrupt. Each X_CAN node's error events as described in Ni_SAFETY_RAW register can trigger this interrupt, if the corresponding events are enabled through Ni_SAFETY_ENA register. The corresponding event flags can be cleared by software through Ni_SAFETY_CLR register.

Message transfer trigger to GTM, eGTM and GST

CANXL module provides MTI_TRIG[N_NODES-1:0] trigger output from each CAN XL node to GTM, eGTM and GST. Refer to device specific connectivity chapter for the availability of the trigger to GTM, eGTM and GST.

Each CAN XL node's message transfer relevant events as described in NODEi_MTI_RAW register can trigger this interrupt, if the corresponding events are enabled through NODEi_MTI_ENA register. The corresponding event flags can be cleared by software through NODEi_MTI_CLR register.

Timebase generation for hardware time stamping

Each X_CAN node can capture a 64-bit timestamp for every receive and transmit frames. The source for the timebase can be selected by configuring Ni_TS_CLOCK_CTL.SRC_SEL. One of the four following sources can be selected

1. fCANXLH clock
2. STM trigger
3. GTM trigger and
4. eGTM trigger

The selected source can be be prescaled by a 4-bit prescaler (Ni_TS_CLOCK_CTL.PRESCALER). The prescaled source is used as basis of tick to increment the 64-bit counter which is represented in Ni_TS_CNT_HI and Ni_TS_CNT_LO SFRs. The 64-bit counter is enabled through Ni_TS_CTL.ENABLED. The counter is cleared when Ni_TS_CMD.TS_CLEAR bit-field is written with 1_B.

The X_CAN node instances i with i>0 have an additional feature to synchronizes their time bases with Node 0 64-bit timebase. This can be enabled with Ni_TS_CLOCK_CTL.SYNC_SEL = 1_B. In this scenario, the synchronized nodes timebase is controlled by N0 timebase. The figure below shows the timebase generation and control for each instance of X_CAN node.

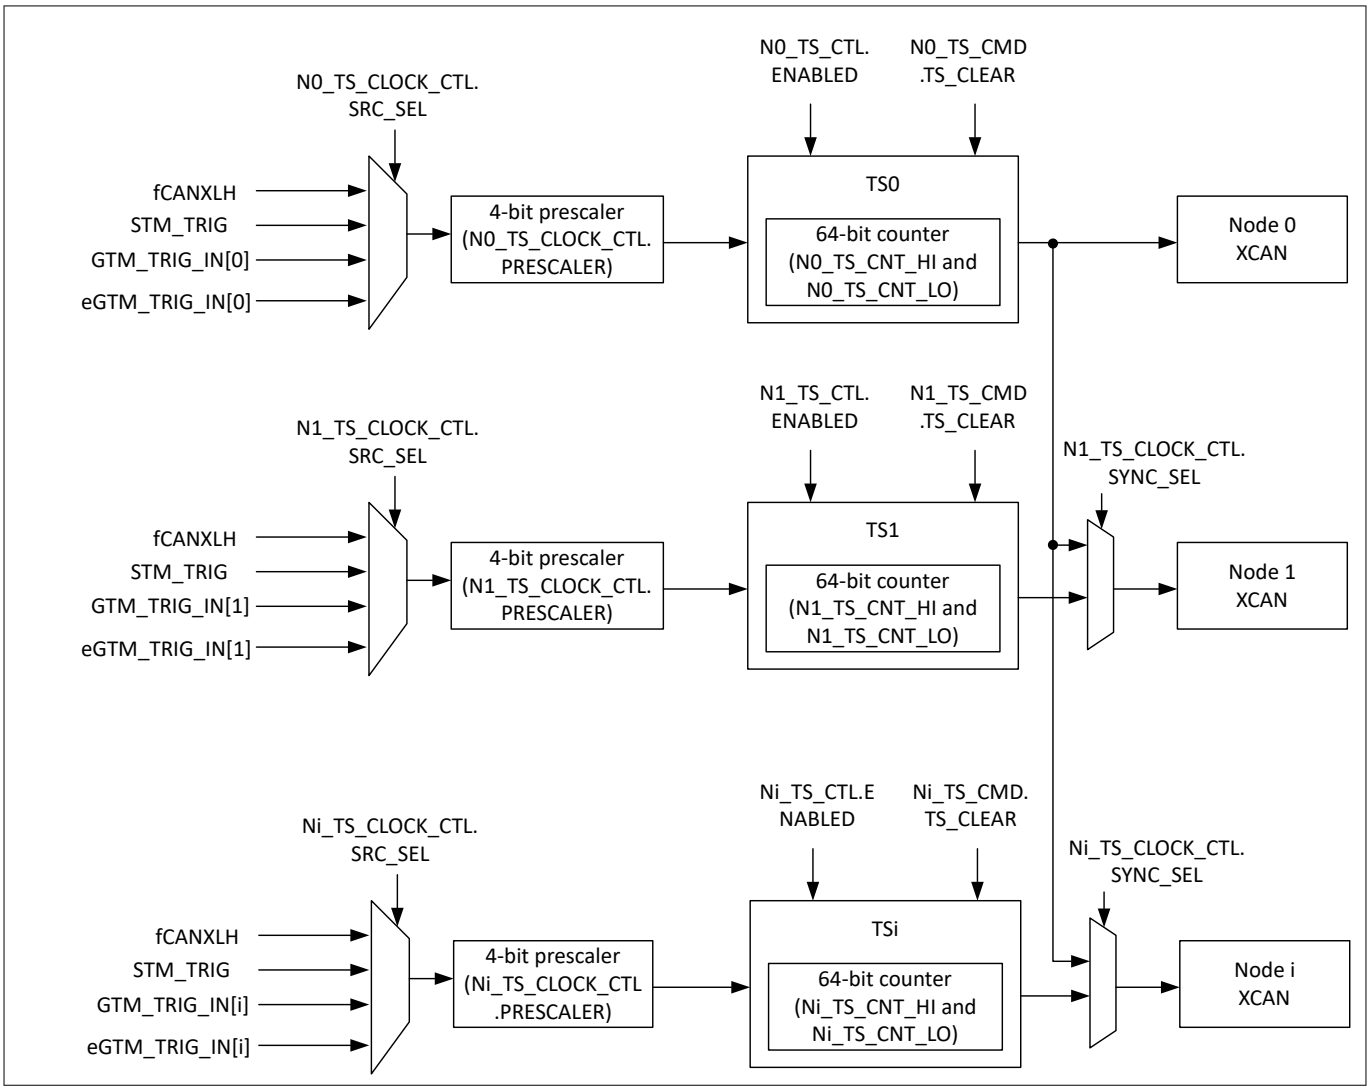

Figure 392 Timebase generation overview

***Note**: Check availability of signals (specially GTM triggers) in connectivity chapter*

Receive Port Selection

Each X_CAN node can select 1 out of 8 possible RX port interfaces. The RX port can be selected using NODEi_PORTCTRL.RXSEL.

22.4 X_CAN

The X_CAN is the new CAN Communication Controller IP supporting CAN XL protocol. The X_CAN performs communication according to ISO 11898-1:2024.

22.4.1 Feature list

- Conform with ISO 11898-1:2024
- Classical CAN with up to 8 data bytes
- CAN FD with up to 64 data bytes
- CAN XL with up to 2048 data bytes
- CAN Error Logging
- Fault Injection Module
- Programmable loop-back test mode
- 1 Priority Queue, up to 32 slots, priority based on the arbitration field of the CAN frame
- 8 TX FIFO queues
- 8 RX FIFO queues
- TX message filtering with up to 16 filter elements
- RX message filtering with up to 255 filter elements, while each can compare one 32-bit word (the actual usable number of filter elements depends on CAN clock frequency, CAN bit rate, and Local Memory performance)
- Maskable module interrupts with three categories: Functional, Functional Error and Safety
- Three clock domains (HOST, CAN, TIMEBASE clock domains)

22.4.2 Functional overview

The X_CAN is the new CAN Communication Controller IP from Bosch supporting CAN XL protocol. The X_CAN performs communication according to ISO 11898-1:2024. The following block diagram shows the internal structure of the X_CAN IP.

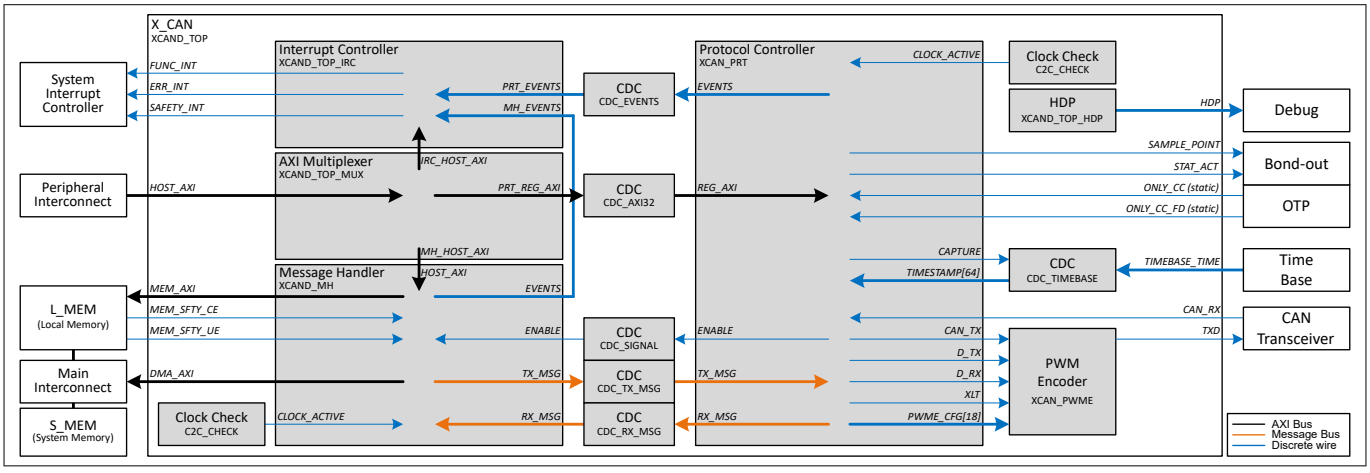

Figure 393 X_CAN block diagram

22.4.3 Functional description

The top level of the X_CAN IP embeds all digital blocks required for communication on one CAN bus.

To start up the X_CAN IP, the Message Handler and the Protocol Controller have to be configured beforehand. The Message Handler must be started first (writing a '1' to the Ni_MH_CTRL.START bit) and afterwards, the Protocol Controller has to be started by writing a ‘1’ to the Ni_CTRL.STRT bit.

22.4.3.1 AXI multiplexer

The X_CAN embeds three register banks, containing configuration, control, status and event information. They are located in the modules Message handler, Protocol controller and Interrupt controller and are accessible through the peripheral interconnect using the HOST_AXI interface and IP internal AXI multiplexer.

- When an access is performed to a non-mapped register in the address range, an access error response is provided
- When a read access to write-only registers or a write access to read-only registers is performed, an access error response is provided

22.4.3.2 Message handler

All functions concerning the storage and scheduling of CAN messages are implemented in the Message handler (MH). The TX path supports the storage of CAN messages in 8 TX FIFO Queues and one TX Priority Queue. The RX path provides 8 RX FIFO Queues.

FIFO data is physically stored in System Memory (S_MEM) and managed by descriptors. TX and RX Filters provide methods to accept or deny CAN Messages and (for RX only) to determine the target RX FIFO for data storage.

The MH will be configured and controlled by HOST CPU through HOST_AXI interface. CAN messages and descriptors are transported between System Memory and local memory autonomously by an internal DMA, which is connected to DMA_AXI. For fast access, the MH needs a Local Memory (L_MEM) which is connected via MEM_AXI interface.

22.4.3.3 Protocol controller

The Protocol Controller (PRT) performs CAN communication as specified in ISO 11898-1:2024. The bitrate can be configured to values up to 20 MBit/s at a clock speed of 160 MHz, depending on the semiconductor technology used. For the connection to the physical layer, additional transceiver hardware is required.

The PRT does not provide internal buffering of frames, so that data has to be transferred by IP internal Message Busses in 32-bit slices in real-time while (de)-serializing them on the CAN Bus. Thus, single data transfers at the internal Message Busses are closely time-synchronised to the schedule at the CAN bus.

22.4.3.4 PWME

The module PWME implements the PWM encoding as specified in ISO 11898-1:2024. When transceiver mode switching is enabled, the PWME encodes the CAN_TX input signal during a CAN XL frame's data phase and during ADH CAN XL bit-field, to generate the PWM encoded output signal TXD.

22.4.3.5 Hardware Debug Port

The X_CAN provides a 16-bit Hardware Debug Port (HDP) to enable debugging using the internal signals of the X_CAN.

The internal signals are organized in pre-defined sets which are selected by Ni_HDP.HDP_SEL. The following tables describe the signal sets.

Table 1036 Hardware Debug Port signal sets

HDP [15:0]	HDP_SEL = 0 (MH debug port)	HDP_SEL = 1 (PRT interface signals)
15	MH_HDP[15]	TX_DU
14	MH_HDP[14]	RX_DO
13	MH_HDP[13]	BUS_OFF

(table continues...)

Table 1036 (continued) Hardware Debug Port signal sets

HDP [15:0]	HDP_SEL = 0 (MH debug port)	HDP_SEL = 1 (PRT interface signals)
12	MH_HDP[12]	E_PASSIVE
11	MH_HDP[11]	E_ACTIVE
10	MH_HDP[10]	BUS_ERR
9	MH_HDP[9]	TX_EVT
8	MH_HDP[8]	RX_EVT
7	MH_HDP[7]	STAT_ACT[1]
6	MH_HDP[6]	STAT_ACT[0]
5	MH_HDP[5]	XLT
4	MH_HDP[4]	D_RX
3	MH_HDP[3]	D_TX
2	MH_HDP[2]	SAMPLE_POINT
1	MH_HDP[1]	CAN_TX
0	MH_HDP[0]	CAN_CLK

22.4.3.6 Interrupt controller

The X_CAN IP is equipped with a central interrupt controller (IRC). It captures all events of the MH and PRT and can be configured for each event individually to interrupt the HOST CPU.

22.5 Message handler (MH)

The Message Handler (MH) is located between the main interconnect and the Protocol Controller (PRT). It is used in transmit direction, to read TX CAN message data from System memory (S_MEM) and to send them to the PRT and in receive direction, to provides S_MEM with the RX CAN message data from PRT.

22.5.1 Feature list

- Functional and Error interrupts
- Safety interrupts
- Safety measures built-in:
  - Data path parity protection
  - Parity protection on address pointers
  - Linked list descriptor protected by CRC
  - Register bank protected by CRC
  - Interface timeout protection (PRT and AXI master interfaces)
- TX message priority based on ID and IDE and SRR and RTR
- Up to 8 TX FIFO queues can be defined
- Up to 8 RX FIFO queues can be defined
- 1 Priority Queue with a programmable number of slot, limited to 32
- TX message filtering with up to 16 filter definition
- RX message filtering with up to 255 filter definition
- Classic CAN and CAN FD supported
- CAN XL supported

22.5.2 Functional overview

The Message Handler (MH) is located between the main interconnect and the Protocol Controller (PRT). It is designed to read TX CAN message data from System memory (S_MEM) and to send them to the PRT.

In the other direction, it provides S_MEM with the RX CAN message data, when received by the PRT. A status feedback is given to the software for every CAN RX and TX messages directly in the S_MEM, avoiding register accesses.

All functions concerning the storage and scheduling of CAN messages are implemented in the Message Handler (MH). The TX path supports the storage of CAN messages in 8 TX FIFO queues and one TX priority queue. The RX path provides 8 RX FIFO queues. FIFO data is physically stored in system memory and managed by descriptors. TX and RX filters provide methods to accept or deny CAN messages and (for RX only) to determine the target RX FIFO for data storage.

The MH will be configured and controlled by software through HOST_AXI interface. CAN messages and descriptors are transported between system memory and local memory (L_MEM) autonomously by an internal DMA, which is connected to DMA_AXI interface. The MH needs a local memory which is connected through MEM_AXI interface.

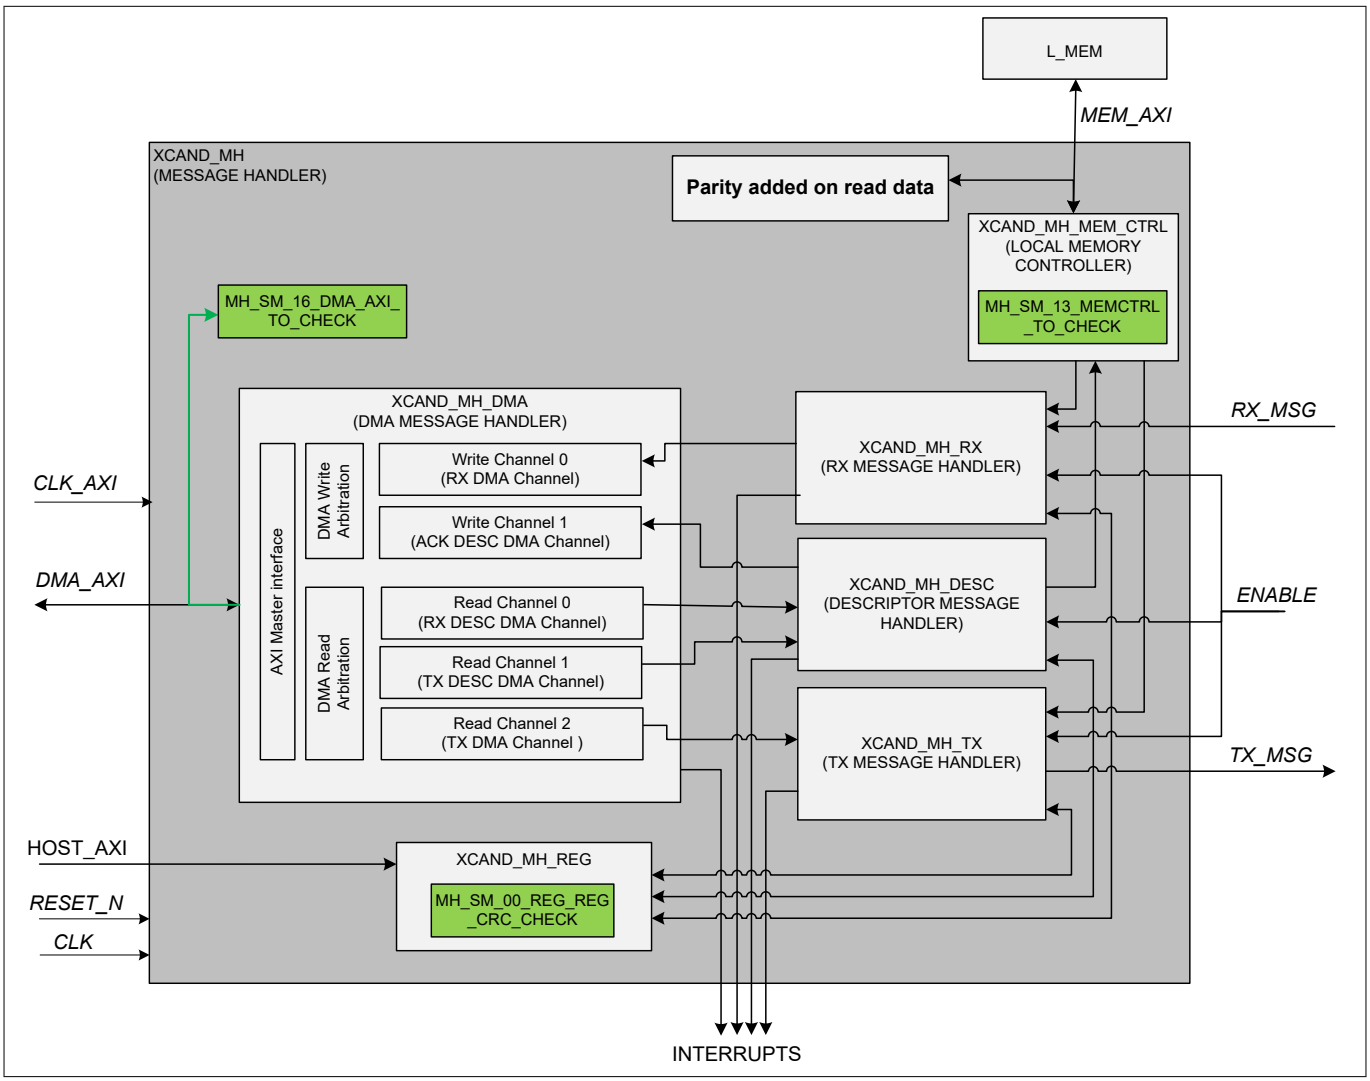

Figure 394 MH block diagram

22.5.3 Functional description

The MH can manage concurrently up to 8 TX FIFO Queues, up to 8 RX FIFO Queues and up to 32 slots defined in a TX Priority Queue. The message handler uses the principle of linked list to define RX and TX FIFO queues, as well as the TX priority queue.

The TX message is made of TX descriptors (see TX descriptor chapter for more information) which define the TX message header information and the address of its payload. The payload buffer can be defined in any location in memory.

An RX message is written to memory based on the information defined in RX descriptors (see RX descriptor chapter for more details) and/or configuration registers. All RX message data can be defined in any location in memory.

The RX FIFO queue can support classic CAN, CAN FD and CAN XL frame format.

The TX FIFO queues and TX priority queue slots can support classic CAN, CAN FD and CAN XL frame format.

The TX MESSAGE HANDLER is managing the TX messages while the RX MESSAGE HANDLER is taking care of RX messages. Both share the Descriptor Message Handler to get their TX and RX descriptors respectively. This module also updates the status at the TX/RX FIFO Queues and TX Priority Queue when a transfer is completed. A dedicated sub-module in the Descriptor Message Handler is assigned to the TX path and one for the RX path, that can run concurrently.

The selection of the highest priority TX message and the RX message filtering is done locally using the L_MEM. Therefore, the highest priority message to be sent is defined in a shorter time. Regarding the RX filtering, the RX filter elements are fetched from the L_MEM to reduce the processing time to accept or reject an RX message before a new one comes in.

The MH can drive only one protocol controller using the TX_MSG and RX_MSG interfaces.

Related information

RX descriptor on page 4194

22.5.3.1 TX MESSAGE HANDLER

The TX MESSAGE HANDLER is in charge of TX FIFO queues and TX priority queue management. Therefore, the TX message handler is requesting the TX descriptor whenever required, arbitrates the TX descriptors according to their IDs and selects the high priority TX message to be sent to the PRT.

Once a TX descriptor is selected and the PRT is winning the arbitration on CAN bus, it fetches the payload data assigned to that descriptor from the system memory.

The internal arbitration on TX descriptors is called TX-SCAN in order to avoid a conflict with the arbitration done on the CAN bus.

A TX filter is put in place to ensure only the relevant TX messages will be sent through the CAN bus.

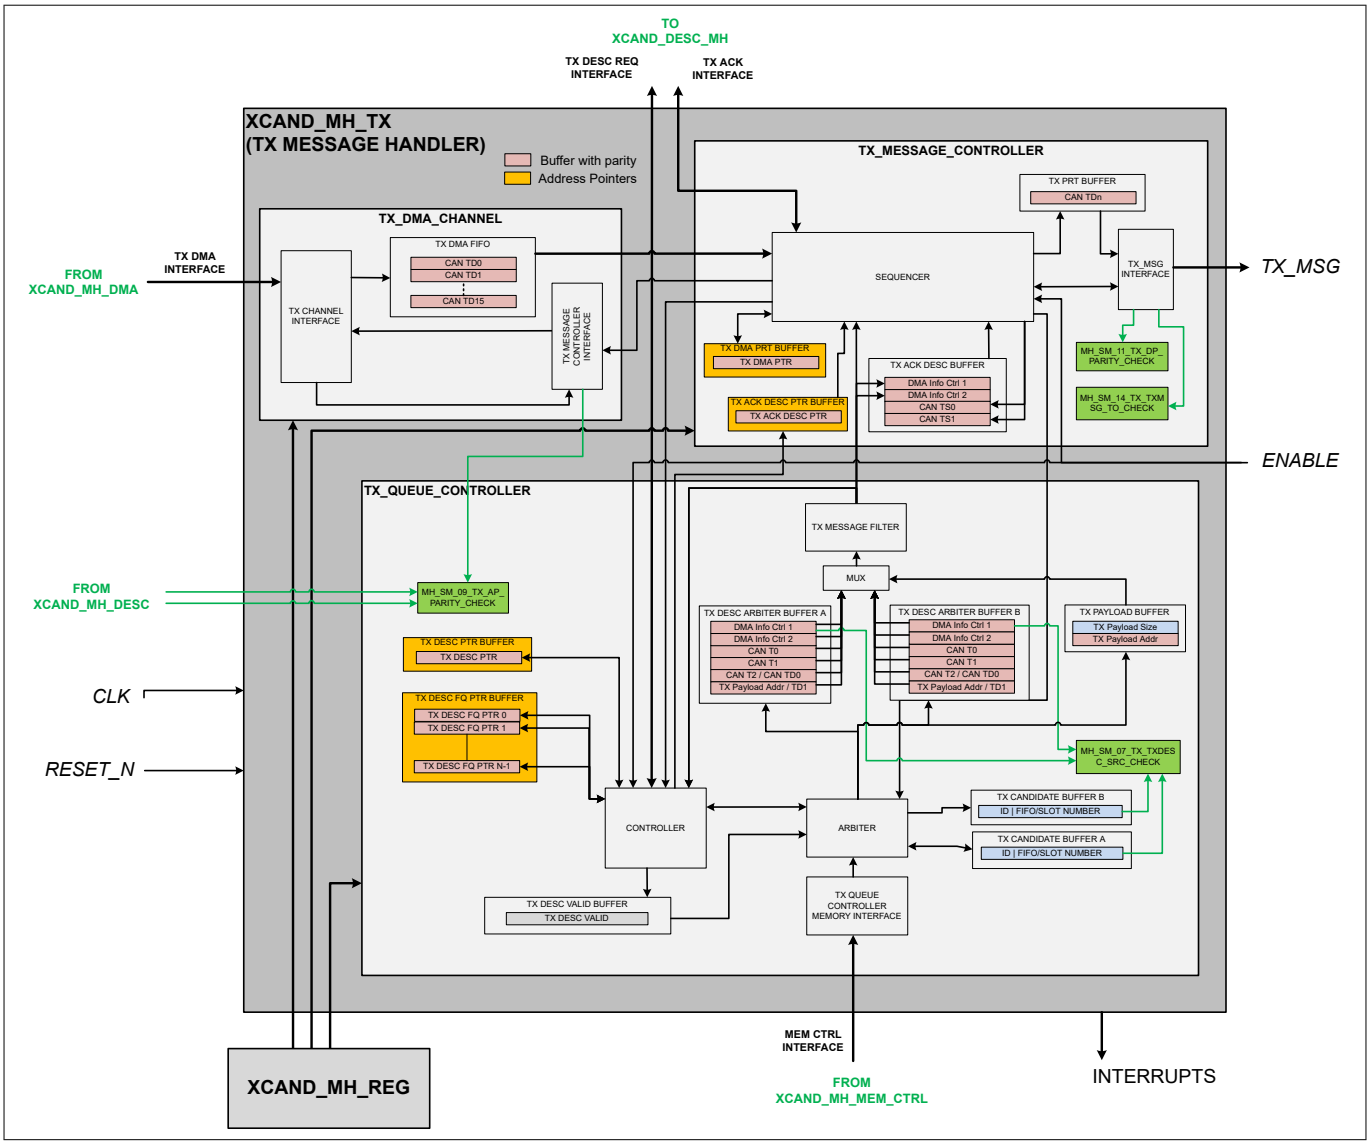

Figure 395 TX MESSAGE HANDLER block diagram

22.5.3.1.1 Block description

Several blocks are used to manage the TX message, TX FIFO Queues and the TX Priority Queue.

TX DMA channel interface

This block is interfacing the DMA MESSAGE HANDLER to send read commands to the system memory. It will also hold the payload data in a local TX DMA FIFO before sending the data to the TX MESSAGE CONTROLLER when available and complete.

The size of the payload data can be different from time to time, as low as 8 bytes for the Classic CAN up to 2048 bytes for the CAN XL.

Every TX descriptor defines the size of the data transfer to be executed. So, only one DMA transfer request is performed per TX descriptor. Every information related to the data transfer is set by the TX MESSAGE CONTROLLER. The TX DMA FIFO size is set to two maximum burst length to allow continuous execution of the data transfer. As soon as the TX DMA FIFO is having enough space to load a new burst the DMA MESSAGE HANDLER will initiate a new fetch from the system memory. Only one data transfer can be defined at a time. As a matter of fact, when the first defined data transfer is finished, meaning the data to be read are inside the TX

DMA FIFO, a second data transfer can be started. The remaining data from the first transfer are used to wait for the second DMA transfer data to be stored in the TX DMA FIFO.

Only the address pointer ADDR_PTR[31:0] to fetch the payload data and the SIZE[10:0] of the transfer are required. This fields can be found on the related TX descriptor.

The other data transfer parameter are static and defined using control registers.

The TX DMA CHANNEL can accept only one data transfer definition at a time in the TX DMA PTR BUFFER, so one data transfer can be performed at a time.

TX message controller

This block is in charge of sequencing the TX message data to the TX_MSG interface. Two sources of data are used to build the TX message. The first data comes from the TX descriptor, which contains the header and the first payload words of the CAN frame.

This TX descriptor comes from the TX QUEUE CONTROLLER and is provided by the ARBITER.

Once the TX descriptor is executed, the address pointer defined in the descriptor is used to fetch further payload data from the S_MEM using the TX DMA CHANNEL.

The TX MESSAGE CONTROLLER is in charge of managing new TX descriptor when several descriptors are used for one TX message. Any new TX message to be sent is provided only by the ARBITER, in all scenarios.

As all TX messages are managed by the TX MESSAGE CONTROLLER, once a message is sent (or not sent) successfully to the PRT, an acknowledge descriptor is provided to the DESC MESSAGE HANDLER to be written back to the source descriptor. If some issues are detected, the current message is canceled and all the traffic from the system memory is aborted. Once done, a new TX message can be considered and should be already provided by the ARBITER.

The PRT signalizes via ENABLE signal whether it requires message handling or not. When this signal goes low, the MH must stop its current activities. This means the TX FIFO Queues and TX Priority Queue are put on hold as well as all the relevant traffic from and to the S_MEM must be aborted.

TX queue controller

This block manages the TX FIFO Queues and the TX Priority Queue as well as the TX-SCAN. As soon as a TX FIFO Queue is started, and/or a TX Priority Queue slot is valid, the TX QUEUE CONTROLLER is fetching the appropriate TX descriptor from the system memory.

Those descriptors are stored in the L_MEM for further processing. The TX descriptors (only part of it) are fetched from the L_MEM and analyzed to find out the TX message having the highest priority.

The one selected is stored locally for the TX MESSAGE CONTROLLER to be read. This block is also computing the address to read the next TX descriptor for every TX FIFO Queues running once used and to manage the active slot from the TX Priority Queue for new one being declared.

All the relevant information to the TX MESSAGE CONTROLLER is provided by this block.

The TX filter uses configuration registers to select between TX messages to be sent to the CAN bus and TX messages to be discarded.

When the TX-SCAN (selection of the TX message with the highest priority) is done, the selected TX descriptor is read from the L_MEM. To ensure that it is the one already selected, some TX descriptor bit fields are checked against the expected value stored locally by the TX-Scan. In case one of the bit fields, listed below, does not match, a TX_DESC_REQ_ERR signal is triggered to the system and Ni_SFTY_INT_STS.TX_DESC_REQ_ERR is set to 1:

- The IN (instance number)
- The FQN (TX FIFO queue number) if PQ = 0
- The PQSN (TX Priority Queue slot number) if PQ = 1

- The PQ (Priority Queue flag)
- The Priority Value assigned to the TX message

22.5.3.2 RX MESSAGE HANDLER

The RX MESSAGE HANDLER is in charge of the RX FIFO queues. Every RX FIFO queue uses a linked list of RX descriptors to identify the exact location in S_MEM to store the message.

The RX MESSAGE HANDLER requests the RX descriptor as required, when for example the RX filter result of an accepted incoming RX Message becomes available.

The RX filter identifies any incoming RX messages and determines whether it has to be rejected (not stored) or accepted (stored into one of the RX FIFO queues, defined by the RX filter).

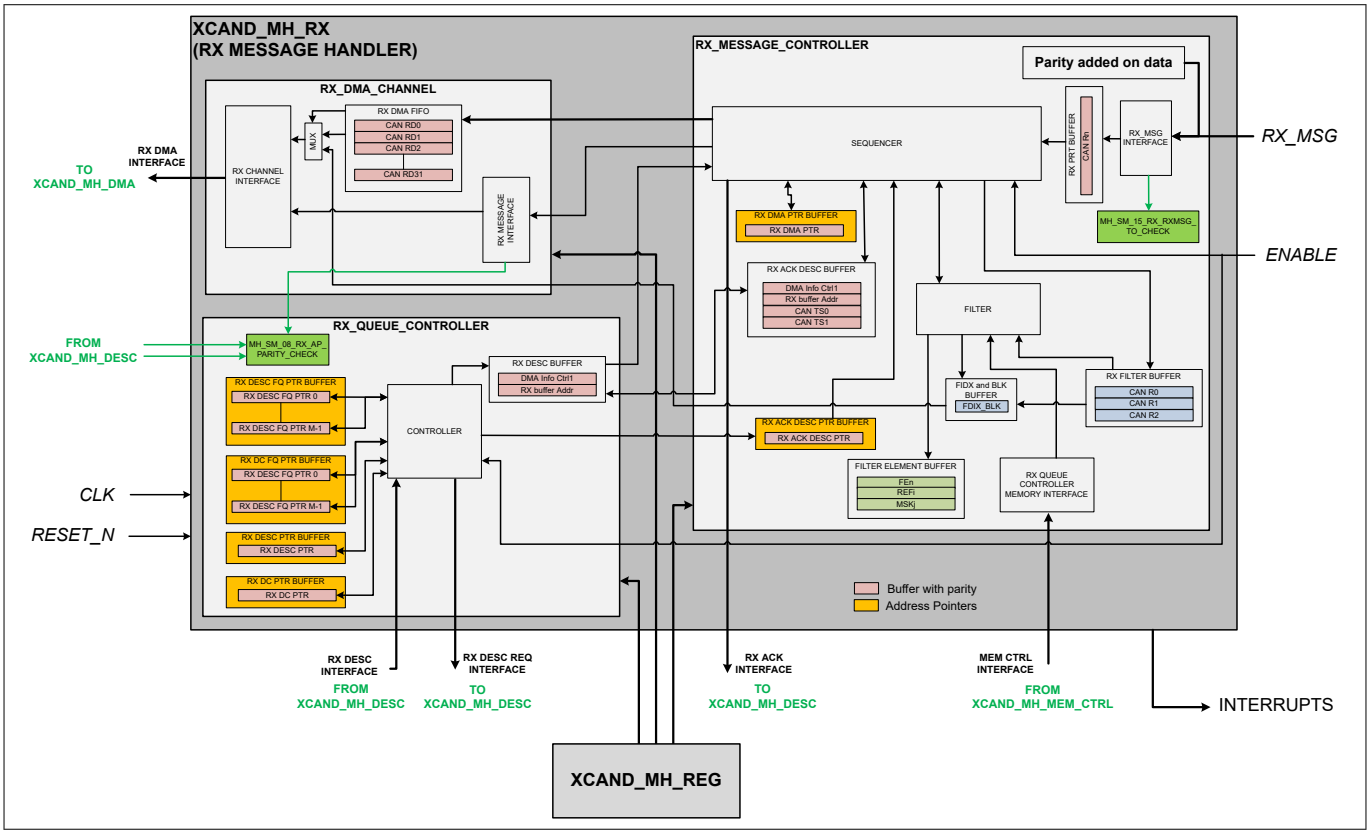

Figure 396 RX MESSAGE HANDLER block diagram

22.5.3.2.1 Block description

Several blocks are used to manage the RX FIFO Queues.

RX DMA channel

This block interfaces the DMA MESSAGE HANDLER to send write commands to the S_MEM. It will also buffer the RX message data in a local RX DMA FIFO before sending the data to the S_MEM.

The size of the payload data for a CAN frame can be the size of 8 bytes for Classical CAN and up to 2048 bytes for CAN XL.

Every RX descriptor of the same RX FIFO Queue has a fixed buffer size to hold data. The size of the overall transfers is stored locally to identify how many descriptors are required for the RX message and what the size of each DMA data transfer is.

As a matter of fact, when the RX message exceeds the maximum buffer pointed by the current descriptor, one or several DMA data transfers are executed. In other words, there are as many DMA data transfer as RX descriptors per RX message.

Only the address pointer ADDR_PTR[31:0] and the SIZE[10:0] (size of the transfer) are required to fetch the payload data. This fields can be found on the RX descriptor. The other data transfer parameters are static and are defined in control registers.

The RX DMA CHANNEL can accept only one data transfer definition in the RX DMA PTR BUFFER, so one data transfer can be performed at a time.

RX message controller

This block is in charge of sequencing the RX message data from the RX_MSG interface to the RX_DMA_CHANNEL and to filter the incoming messages.

The RX message is managed by the RX MESSAGE CONTROLLER. Once a message is received successfully, an acknowledge descriptor is provided to the DESCRIPTOR MESSAGE HANDLER to be written back to the first descriptor of the RX message. This first descriptor is used along the process of receiving a message and is the only one which is acknowledged and holds the header data.

If an error was detected, the current message will be canceled and the storage to the S_MEM will be aborted. Once done, a new RX message can be processed and the RX descriptors of the previously aborted message are reused.

To avoid duplication of buffers, the data from the PRT is stored directly into the RX DMA FIFO without waiting for the result of the filter. Once the result of the filter is known (RX message accepted or not accepted), the CAN data being received is stored in the S_MEM or discarded.

The PRT signals through ENABLE signal whether it is active and requires message handling or not. When this signal is going low, the MH stops current activities. This means that the RX FIFO queues are put on hold as well as the traffic from and to the S_MEM will be aborted.

Related information

RX filter on page 4243

RX queue controller

This block manages the RX FIFO queues and keeps track of the write pointers to use for each of them. As soon as an RX FIFO queue is started, the RX queue controller is allowed to request descriptors from the descriptor message handler.

The descriptor to be used is stored into the local RX desc buffer and is the result of a request to the descriptor message handler when the RX FIFO queue is identified by the FILTER. This block also computes the address to read the next RX descriptor for every RX FIFO queues running, once used. All the relevant information to write data to the S_MEM or to generate an interrupt when receiving a message is provided to the RX message controller.

In case that several descriptors are required for one message, the RX queue controller can request the next descriptor from the descriptor message handler as soon as RX message controller has taken over the current descriptor.

22.5.3.3 Descriptor message handler

This block is in charge of getting, from the S_MEM, the RX descriptors used by the RX MESSAGE HANDLER. For the TX path, it is also fetching all the descriptors for the TX path which will be used later on by the TX message handler.

On top of providing the appropriate descriptor to those sub-modules, as soon as an RX or TX message is received or sent, it will provide the acknowledge data relative to that message to the header descriptor.

This sub-module is only managing the RX or TX descriptors fetched and acknowledged on request from the two control sub-modules; TX MESSAGE HANDLER and RX MESSAGE HANDLER.

As the RX and TX and acknowledge paths are fully concurrent, it is up to the DMA_CONTROLLER managing traffic from or to the S_MEM to decide which request to serve first.

As the CAN bus is unidirectional there should be a low collision rate on the AXI bus interface of the same channel.

The parallel processing of TX/RX descriptors will decouple functions between the two paths. Such approach relaxes the constraints on those two concurrent data flows, considering use cases where both are active at the same time. Furthermore, while receiving a CAN Frame, TX descriptors can be fetched from the S_MEM on request or while executing RX FIFOs. This approach lowers the complexity of use case management.

Regarding the acknowledge of descriptors, the same strategy is used, the acknowledge path does not interfere with the RX and TX data path.

Any configuration register is defined into the main register bank of the message handler.

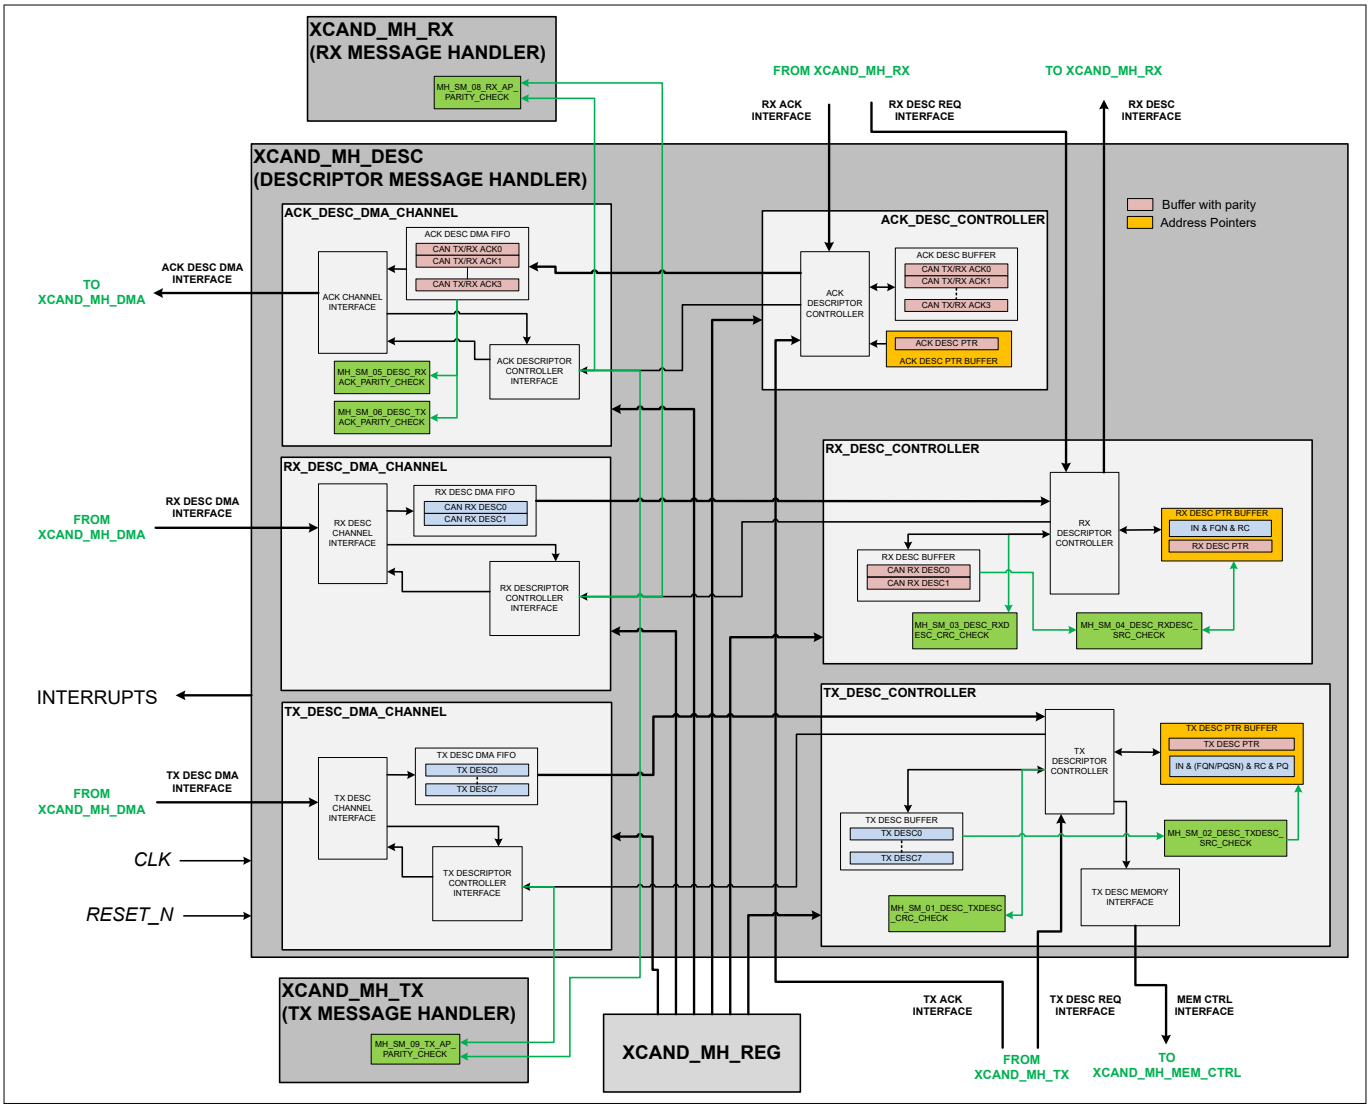

Figure 397 Descriptor message handler block diagram

22.5.3.3.1 Block description

TX_DESC_CONTROLLER

This block stores read descriptor requests from the TX MESSAGE HANDLER and sends them to the TX_DESC_DMA_CHANNEL. It is able to accept up to two requests when there is a need to pre-fetch TX descriptors.

In order to provide the request to the TX_DESC_DMA_CHANNEL, the block sends only the address of the TX descriptor ADDR_PTR[31:0] (the size of the TX descriptor is always identical). Other control signals manage the handshaking. On top of those information, an abort signal is provided to stop the current data transfer on the DMA channel, when requested by the TX MESSAGE HANDLER.

Once a TX descriptor is provided by the TX_DESC_DMA_CHANNEL, several checks are performed to ensure the correctness of the descriptor and its validity. These checks are (in the order):

1. The VALID bit in the TX descriptor is checked to ensure descriptor is valid. The following check is performed only if the VALID bit equals 1
2. A CRC check is done on the TX descriptor. In case a CRC error is detected, a CRC error is triggered to the system using the TX_DESC_REQ_ERR signal and Ni_SFTY_INT_STS.TX_DESC_CRC_ERR flag is set. The following check is performed only if there is no CRC issue
3. The instance number IN[2:0], either the TX FIFO Queue number FQN[3:0] or the TX FIFO Queue slot number PQSN[4:0], the rolling counter RC[4:0] bit fields of the TX descriptor and the Priority Queue bit PQ are checked against the expected values from the request (see TX descriptor definition chapter for more detail on those bit fields). In case that one of the bit fields does not match, a TX_DESC_REQ_ERR signal is triggered to the system and flag Ni_SFTY_INT_STS.TX_DESC_REQ_ERR set.

Whatever the result of the checks done on the TX descriptor, it is always written to the L_MEM. Doing so, the wrong TX descriptor can be read from the L_MEM, if required for debug purpose.

To store the TX descriptor, a write access is performed to the L_MEM through the memory controller interface. As the size of the TX descriptor to write does not change, the number of words to be written is identical for all descriptors. As soon as a TX descriptor is checked and no issue is identified, it is written to the L_MEM and a notification is sent to the TX MESSAGE HANDLER.

The TX descriptor from the S_MEM is stored locally for filtering. Once stored and accepted, it is written to the L_MEM. In case a Header Descriptor is rejected, the TX_FILTER_IRQ interrupt is triggered to the system. The TX MESSAGE CONTROLLER is notified that the requested TX descriptor is rejected and will not be provided. Refer to the TX Filter chapter for a detailed description.

TX descriptor on page 4187

TX_DESC_DMA_CHANNEL

This block is interfacing the DMA_CONTROLLER to send read commands to the S_MEM. It will also hold the TX descriptors in a local DMA FIFO before sending the data to the TX_DESC_CONTROLLER when available and complete. As the TX descriptor has a fixed size (8 words of 32 bits), the data transfer to be executed by the DMA channel will always be the same. Only the address pointer ADDR_PTR[31:0] to fetch the TX descriptor is required. The other data transfer parameter are static and defined using control registers. As the transmit FIFO can accept only one TX descriptor, only one data transfer can be performed at a time. There is no check performed by this block as everything is done by the TX_DESC_CONTROLLER holding the read request definition. For more details on the DMA_CONTROLLER interface see the relevant chapter.

Related information

DMA message handler on page 4182

RX_DESC_CONTROLLER

This block is in charge of storing read descriptor requests from the RX MESSAGE HANDLER and to send them to the RX_DESC_DMA_CHANNEL. It is possible to accept up to two requests when there is a need to pre-fetch RX descriptors for large payload data defined in RX messages.

In order to provide the request to the RX_DESC_DMA_CHANNEL the block is sending only the address of the RX descriptor ADDR_PTR[31:0] and a PRIORITY signal, other control signals are managing the handshaking. On top of those information an abort signal is provided to stop the current data transfer on the DMA channel when requested by the RX MESSAGE HANDLER.

Once an RX descriptor is providing by the RX_DESC_DMA_CHANNEL several checks are performed to ensure the correctness of the descriptor. These checks are:

1. The VALID bit in the RX descriptor is checked to ensure descriptor is valid. The following check is performed only if the VALID bit equals 1
2. A CRC check is done on the RX descriptor. When the CRC is valid, the RX descriptor is sent to the RX MESSAGE HANDLER, otherwise a CRC error is triggered to the system using the RX_DESC_REQ_ERR signal and flag Ni_SFTY_INT_STS.RX_DESC_REQ_ERR set. The following check is performed only if there is no CRC issue
3. The instance number IN[2:0], the RX FIFO Queue number FQN[3:0] and the rolling counter RC[4:0] bit fields of the RX descriptor are checked against the expected value mentioned in the request (see RX descriptor definition chapter for more detail on those bit fields). In case one of the bit field does not match, an RX_DESC_REQ_ERR signal is triggered to the system and flag Ni_SFTY_INT_STS.RX_DESC_REQ_ERR set.

Related information

RX descriptor on page 4194

RX_DESC_DMA_CHANNEL

This block interfaces the DMA_CONTROLLER to send read commands to the S_MEM. It will also hold the RX descriptors in a local DMA FIFO before sending the data to the RX_DESC_CONTROLLER when available and complete. As the RX descriptors have the same size (2 words of 32 bits), the data transfer to be executed by the DMA channel will always be the same. Only the address pointer ADDR_PTR[31:0], to fetch the RX descriptor, is required. The other data transfer parameters are static and defined using control registers. As the RX FIFO can accept only one RX descriptor, only one data transfer can be performed at a time. There is no check performed by this block as everything is done by the RX_DESC_CONTROLLER holding the read request definition. For more details on the DMA_CONTROLLER interface, see the relevant chapter.

Related information

DMA message handler on page 4182

ACK_DESC_CONTROLLER

This block manages the RX MESSAGE HANDLER and TX MESSAGE HANDLER request when an RX or TX descriptor being executed needs to be acknowledged. As soon as the RX MESSAGE HANDLER has completed its execution using one RX descriptor, the relevant information (transfer status and errors mainly) of that transfer must be sent back to the first descriptor. To do so, the RX MESSAGE HANDLER and TX MESSAGE HANDLER will send a request to the ACK_DESC_CONTROLLER to write acknowledge data into the respective Header Descriptor.

The ACK_DESC_CONTROLLER can only accept data when the ACK DESC DMA FIFO has enough data to store it. As long as this DMA FIFO cannot accept the data, it will hold any request from either RX MESSAGE HANDLER and/or TX MESSAGE HANDLER. Acknowledge data are build and stored in the RX MESSAGE HANDLER and TX MESSAGE HANDLER. This way, any updates along the reception or transmission of a TX message will

automatically be done locally on the sub-module. As the CAN bus is unidirectional, there should be no conflict regarding RX and TX descriptors being acknowledged at the same time. The only exception is when PRT is set in loopback mode. As soon as the ACK DESC DMA FIFO in ACK_DESC_DMA_CHANNEL provides the right FIFO level to receive one burst of data, the ACK_DESC_CONTROLLER will write those data and will push the address pointer of those data. Despite that RX and TX acknowledge requests may not occur at the same time, the higher priority is always given to the RX path. The ACK_DESC_CONTROLLER will always start writing the acknowledge data (always $4 \times 32\ bit$) to the DMA FIFO in ACK_DESC_DMA_CHANNEL whatever the request source is, either TX MESSAGE HANDLER or RX MESSAGE HANDLER. At last it will write the address pointer of that descriptor triggering at the same time a new DMA data transfer. The option, to provide a priority signal to define the urgency of the writing, exists.

ACK_DESC_DMA_CHANNEL

This block is interfacing the DMA_CONTROLLER to send write commands to the S_MEM. It also holds bursts to be sent over the interconnect into a local DMA FIFO before asking the DMA_CONTROLLER to send it to the S_MEM.

As the acknowledge data for RX and TX descriptors is having a fix size (4 words of 32 bits), the data transfer to be executed by the DMA channel will always be the same. Only the address pointer to write the burst is required and a PRIORITY signal to manage the urgency of the request. The other data transfer parameter are static and defined using control registers. As the transmit DMA FIFO can accept only one burst, one transfer can be performed at a time. For more details on the DMA_CONTROLLER interface see the relevant chapter.

22.5.3.4 DMA message handler

The DMA_CONTROLLER reads and writes bursts of data from and to the S_MEM through its AXI4 master interface DMA_AXI (compliant to AMBA 4 ARM™ protocol). The DMA_CONTROLLER manages request commands from the sub-module that is in charge of sending or receiving TX or RX messages, as well as fetching RX or TX descriptors.

It is in charge of providing data to the sub-module responsible to send CAN frames (TX MESSAGE HANDLER) as well as to the sub-module managing the RX and TX descriptors (DESC MESSAGE HANDLER). It is managing all data from a received CAN frames (RX MESSAGE HANDLER) as well as to write back information into RX/TX descriptors when required (DESC MESSAGE HANDLER).

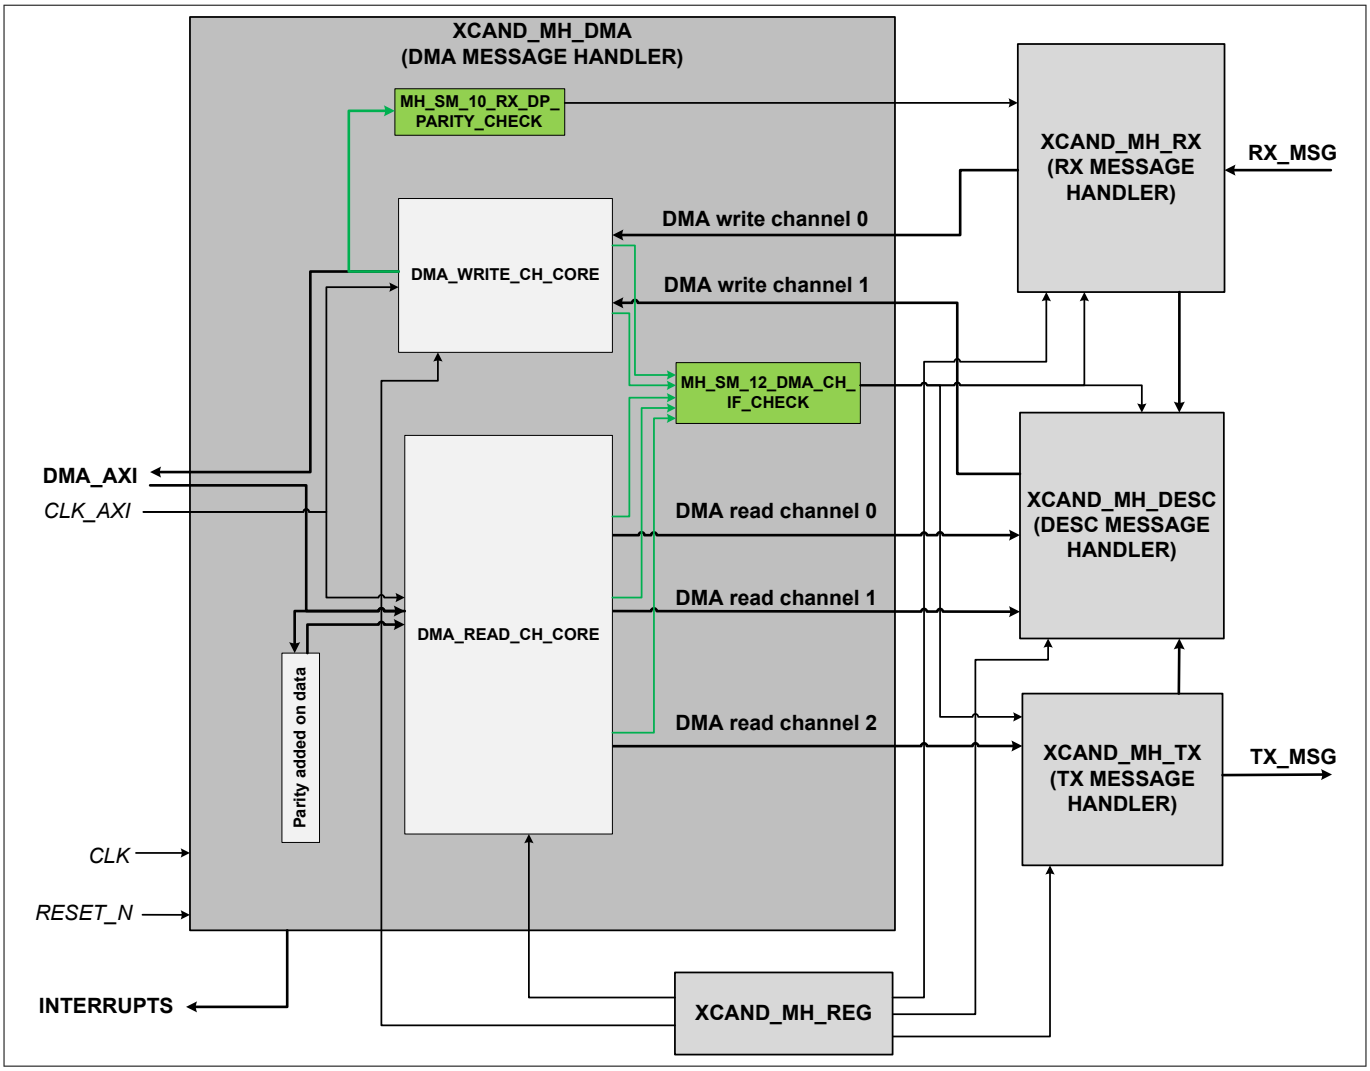

Figure 398 DMA message handler block diagram

22.5.3.4.1 Block description

The DMA build in the DMA MESSAGE HANDLER block has a static configuration, once the software has written the registers. They must not be changed except if all the DMA channels are stopped.

An arbitration process will take place to define which request command is to be served first.

As several concurrent read and write accesses can be foreseen, refer to Ni_AXI_PARAMS.AR_MAX_PEND[1:0] and Ni_AXI_PARAMS.AR_MAX_PEND[1:0] bit field registers.

To maximize the AXI throughput, whatever the number of data transfer to be done, the DMA_CONTROLLER ensures the usage of the maximum burst length whenever possible. To do so, the DMA_CONTROLLER is always trying to generate a burst length for the first transfer to get an aligned address burst size for the next data to be transferred (maximize the usage of maximum burst size for transfers).

The RESP_ERR[1:0] interrupts are used to trigger the system for any bus error, when reading or writing the S_MEM and L_MEM. Some status flags provide the interrupt source, see the Ni_SFTY_INT_STS register.

Before starting any transfer a DMA read/write channel must be enabled. The Ni_TX_FQ_CTRL2.ENABLE[n] and Ni_RX_FQ_CTRL2.ENABLE[n] and Ni_TX_PQ_CTRL2.ENABLE[n] bit-field registers are used to identify when the DMA channels are required. If none of those enable bit are set to 1, no data transfer can occur.

The DMA is intended to:

- Write all the received RX CAN frame data coming from the PRT to the system memory at a defined address location (specified into RX descriptors). This traffic does concern only the RX MESSAGE HANDLER
- Write the acknowledge of TX CAN frame message back to the relative TX descriptor. This traffic is owned by the DESC MESSAGE HANDLER
- Write the acknowledge of RX CAN frame message back to the appropriate RX descriptor. This traffic is owned by the DESC MESSAGE HANDLER
- Read TX descriptors where the TX CAN frame header is defined with some other relevant information like the address pointer of the payload data. This traffic is owned by the DESC MESSAGE HANDLER
- Read RX descriptors according to the RX CAN frame messages being filtered to identify which location to write the received data. This traffic is owned by the DESC MESSAGE HANDLER
- Read TX message payload data from the system memory when the corresponding message header is winning the CAN bus arbitration. This traffic does concern only the TX MESSAGE HANDLER

DMA_WRITE_CH_CORE

This block is in charge of the following:

- Writing data to the system memory and to have those transfers compliant to the AXI4 AMBA protocol
- Providing the appropriate write burst length for a maximum system bus efficiency according to the number of data to be sent
- Reading the relevant number of data from a defined DMA write channel through the read FIFO interface
- Arbitrating among the different DMA write command of those channels
- Stopping any AXI data transfer any time without locking the AXI write system bus interface

The DMA_WRITE_CH_CORE is storing and sending all the write commands to the system memory. As soon as a write command is granted, the required data is fetch from the read FIFO interface of the corresponding channel and written to the AXI write system bus interface.

A classic read FIFO interface is provided at the block interface to avoid embedded data FIFOs. This kind of implementation does allow to scale the data FIFO assigned to any DMA write channel without having to modify the DMA_CONTROLLER. Only the level of the FIFO to be read must be provide to ensure a proper handshaking. The read FIFO interface is defined as, a 32-bit data bus with a read enable and a FIFO level to ensure enough data are present into the FIFO to perform a new burst.

Once a command is received from a DMA write channel, the arbitration process is taking care of the right command to execute.

Any write command selected by the ARBITER must only be issue by a sub-module if all the relevant data of the burst are present into the local FIFO of the sub-module.

As long as the DMA FIFO level is not empty, AXI write commands will be issued according to the write outstanding value set in the Ni_AXI_PARAMS.AW_MAX_PEND[1:0] bit register.

It is not allowed to insert wait state in between data read from the FIFO interface.

DMA_READ_CH_CORE

This block is in charge of:

- Reading data from the system memory and to have those transfers compliant to the AXI4 AMBA protocol
- Providing the appropriate read burst length for a maximum system bus efficiency according to the number of data to be fetched
- Writing the relevant number of data to a defined DMA read channel through the write FIFO interface
- Arbitrating among the different DMA read command of those channels
- Stopping any AXI data transfer any time without locking the AXI read system bus interface

The DMA_READ_CH_CORE is storing and sending all the read commands to the system memory. As soon as a read command is granted, the required data is fetched from the AXI write system bus interface and written to the read FIFO interface of the corresponding channel.

A classic write FIFO interface is provided at the block interface to avoid embedded data FIFOs. This kind of implementation does allow to scale the data FIFO assigned to any DMA read channel without having to modify the DMA_CONTROLLER. Only the level of the FIFO to be written must be provide to ensure a proper handshaking. The write FIFO interface is defined as a 32-bit data bus with a write enable and a FIFO level to ensure enough place are present into the FIFO to receive a new burst.

A read command from the DMA read channel would need to define all the relevant information to describe the read data transfer to be executed, see the common list of signal defined previously.

Once a command is received from a DMA read channel, the arbitration process is taking care of the right command to be executed.

As long as the DMA FIFO level is not full, AXI read commands will be issued according to the read outstanding value set in the Ni_AXI_PARAMS.AR_MAX_PEND[1:0] bit register.

It is not allowed to insert wait state in between data written to the FIFO interface.

22.5.3.4.2 Data transfer mode

Several data transfer type can be defined:

No Transfer: When the register Ni_AXI_PARAMS.AW_MAX_PEND[1:0] is set to 0, no AXI write transfer is executed. Doing so, there is the option to have the MH fully active and running without the need of an external memory to receive RX messages. Acknowledges will not be written, so this mode is considered for debug purpose only. When the Ni_AXI_PARAMS.AR_MAX_PEND[1:0] is set to 0, no read access is performed and without TX/RX descriptor read, the MH will be waiting forever.

The Ni_AXI_PARAMS.AW_MAX_PEND[1:0] and Ni_AXI_PARAMS.AR_MAX_PEND[1:0] can set the maximum number of read/write outstanding commands on the DMA_AXI interface.

22.5.3.4.3 Data transfer description

Address bus

The DMA is able to address up to 4GB memory space (DMA_AXI_AWADDR[31:0] and DMA_AXI_ARADDR[31:0]).

Burst size

The maximum number of bytes to transfer in each data transfer is fixed and set to 4. Any read or write transfer is always using 32 bits.

When considering TX CAN frame for instance, the payload data being define as bytes must be 4 byte aligned when read from the system memory.

For the RX CAN frame, if data to be written to system memory is not properly aligned some padding needs to be added to complete a 4-byte word. The padding bytes are set to 00_H.

As a consequence, the write strobe signals are not managed by the DMA_CONTROLLER as all 4 bytes are always written.

Burst length

The DMA_CONTROLLER for the AXI read and write transfers supports INCR burst lengths from 1 to 8, considering an AXI 32 bits data bus width. The DMA_AXI_AWLEN[3:0] and DMA_AXI_ARLEN[3:0] are sized to support a

maximum burst length of 16 despite only 8 is possible. To be fully compliant with the AXI4 AMBA protocol [3] the DMA_AXI_AWLEN[7:4] and DMA_AXI_ARLEN[7:4] are considered as 0000_B.

The DMA_CONTROLLER will always try to align its burst address to make full benefit of the maximum allowed burst length. The address burst value must be always 32 byte aligned to ensure the maximum burst length ($8 \times 32\ bit$). Whatever the data transfer mode, the DMA engine will reduce (if needed) the size of the first burst to align the address to the maximum burst length. Depending on the amount of data to be transferred the last burst can be shorter.

It is important to optimize the access to the system memory, especially if a low number of data transfer is performed. As an example, if a data transfer of $12 \times 32\ bit$ needs to be executed and the start address is 32 byte aligned, it will result in two burst $8 \times 32\ bit$ and $4 \times 32\ bit$. In case the start address is not aligned and we are in the worst scenario it could lead to 3 bursts $3 \times 32\ bit$ and $8 \times 32\ bit$ and $1 \times 32\ bit$ or $2 \times 32\ bit$ and $8 \times 32\ bit$ and $2 \times 32\ bit$ or $1 \times 32\ bit$ and $8 \times 32\ bit$ and $3 \times 32\ bit$.

In case high latency is expected, it is essential to limit the number of burst and make sure whenever possible to align the start address to the maximum burst size.

The DMA_CONTROLLER provides variable burst length of data according to the sub-module command requests.

The burst lengths from/to sub-modules connected to the DMA_CONTROLLER are defined based on the data type of information to be used.

Here below are the expected burst length from/to the sub-modules:

- TX MESSAGE HANDLER: This sub-module does read the TX payload data from the system memory through the DMA read channel 2. The maximum burst length is limited to $8 \times 32\ bit$. There is no write access from this sub-module
- RX MESSAGE HANDLER: This sub-module writes the RX CAN frame data to the system memory through the DMA write channel 1. The maximum burst length is limited to $8 \times 32\ bit$. There is no read access from this sub-module
- DESCRIPTOR MESSAGE HANDLER: This sub-module performs a fixed burst read of $8 \times 32\ bit$ to read TX descriptors from the system memory through the DMA read channel 2. A fixed burst length of $2 \times 32\ bit$ is used instead to read RX descriptors through the DMA read channel 0. To acknowledge any transfer from and to the CAN bus, a fixed burst length of $4 \times 32\ bit$ is performed to either the RX descriptor for received frame or to the TX descriptor for TX message through the DMA write channel 1

Outstanding transactions

In order to support read and write outstanding commands and to limit the FIFO size, the maximum burst length is limited to $8 \times 32\ bit$. The maximum number of outstanding command/transactions expected at the DMA_AXI interface is programmable, see Ni_AXI_PARAMS.AR_MAX_PEND[1:0] and Ni_AXI_PARAMS.AR_MAX_PEND[1:0] bit field register. Up to 3 read and write outstanding transactions can be specified. Even if set to the maximum value, the maximum number of outstanding transactions performed by the MH will depend on many parameters like the system latency, the CAN Bus bit rate, the MH and PRT clock ratio.

Burst type

The only burst type supported is the burst incrementing INCR. Check [3] for more information

The WRAP/FIXED burst type is not supported.

Memory attributes

The memory attributes for the read or write accesses to memory are Normal, Non-modifiable (Non-cacheable in AXI3) and Non-Bufferable. No read-allocate nor Write-allocate are expected on this interface and would be set to 0_B.

As a reminder, Non-bufferable means:

- The write response must be obtained from the final destination
- Read data must be obtained from the destination
- Transactions are Non-Modifiable
- Read and write transactions from the same ID to addresses that overlap must remain ordered

Non-modifiable means:

- A Non-modifiable transaction must not be split into multiple transactions or merged with other transactions
- In a Non-modifiable transaction, the parameters AxADDR, AxSIZE, AxLEN, AxBURST and AxPROT must not be changed

Transaction ID

The DMA_CONTROLLER is building the ID of every burst access based on the number of channels defined. It provides a way to track on the system bus which DMA channel is doing the access at any time.

For the AXI read interface, the DMA_AXI_ARID[1:0] defines the channel number as follow:

00_B => RX descriptor fetch from S_MEM

01_B => TX descriptor fetch from S_MEM

10_B => TX data payload read from S_MEM

For the AXI write interface, the DMA_AXI_AWID[0] defines the channel number as follow:

0_B => TX/RX descriptor acknowledge to S_MEM

1_B => RX message data write (payload and header) to S_MEM

22.5.3.5 TX descriptor

TX descriptors are used for the TX FIFO Queues and the TX Priority Queue. They can be fetched with one AXI burst, as the overall size is only $8 \times 32\ bit$.

Many bit fields are common but some are different between TX FIFO Queue and TX Priority Queue. Details are provided in the following table.

Further information is provided by the chapter TX Message Header Definition.

Table 1037 TX descriptor description

Element number	Bit-field	Name	Managed by	Description/Constraints
0	[31]	VALID	SW/MH	Valid: The SW must set this bit to 1 to define a TX descriptor is valid for the MH. When the descriptor has been fully used, the MH will clear this bit when writing the acknowledge data information back to this descriptor. This update occurs only when the HD bit is set to 1. In case the descriptor is fetched when this bit is set to 0, an interrupt TX_FQ_IRQ is triggered to the system for the TX FIFO queue n having this descriptor
	[30]	HD	SW only	Must be set to 1

(table continues...)

Table 1037 (continued) TX descriptor description

Element number	Bit-field	Name	Managed by	Description/Constraints
	[29]	WRAP	SW only	Wrap: When set to 1 the next message descriptor is the one declared at the initial start address of the TX FIFO Queue (First Descriptor). This bit provides a way to the SW to keep the next TX message continuous in a memory buffer if less space is available at the end of a data container
	[28]	NEXT	SW only	Must be set to 0
	[27]	IRQ	SW only	Interrupt: when set to 1 an interrupt is triggered to the system when the descriptor execution is complete, meaning when the TX message has been sent to the CAN bus
	[26]	PQ	SW only	TX Priority Queue: when set to 1, the TX descriptor belongs to the TX Priority Queue TX FIFO Queue: must be set to 0
	[25]	END	SW only	For the TX FIFO Queue: when set to 1 the TX FIFO Queue defined its ending, it means, it is set as inactive. Once done, the TX FIFO Queue can be reprogrammed and started
				For the TX Priority Queue: must be set to 0
	[24:16]	CRC[8:0]	SW only	CRC: this CRC is computed by the SW for the current TX descriptor. It must consider all elements assuming this bit-field as set to 0. Any CRC error is triggering an interrupt to the system. The CRC is not evaluated if the Ni_MH_SFTY_CTRL.TX_DESC_CRC_EN bit is set to 0.
	[15:12]	FQN[3:0]	SW only	TX FIFO Queue: define the TX FIFO Queue number allocated to this TX descriptor. Despite being set to 4 bits, only the FQN[2:0] bit range is used
		PQSN[4:1]	SW only	TX Priority Queue: define the TX FIFO Queue slot number allocate to this descriptor
	[11]	Reserved	SW only	TX FIFO Queue: must be set to 0
		PQSN[0]	SW only	TX Priority Queue: Define the TX FIFO Queue slot number allocated to this descriptor
	[10:9]	Not used	SW only	Must be set to 0

(table continues...)

Table 1037 (continued) TX descriptor description

Element number	Bit-field	Name	Managed by	Description/Constraints
	[8:4]	RC[4:0]	SW only	Rolling Counter: use to track the order of TX descriptor fetched when a TX FIFO Queue or a TX Priority Queue slot is running. TX FIFO Queue: When a TX FIFO Queue is started for the first time, its first TX descriptor must have the RC[4:0] set to 00000_B. This value must be incremented for every new TX descriptor up to 11111_B and then back to 00000_B even in case of wrap. TX Priority Queue: This bit field must be set to 00000_B as the initial value for all TX Header descriptor defined in the different slots.
	[3:0]	STS[3:0]	MH only	Status: gives the status of the TX message transmitted. The MH writes back only the Header Descriptor (HD bit set to 1) for status report. The SW must always set it to 0. 0000_B: none 0001_B: message sent successfully 0010_B: message not sent after a number of trials 0011_B: message skipped due to HFI 0100_B: message rejected by TX filter 0101_B to 1110_B: reserved 1111_B: message acknowledge data with parity error
1	[31:27]	Not Used	SW only	Must be set to 0
	[26]	PLSRC	SW only	Payload Source: This bit provides to the MH the information about the need to fetch payload data in the data container when executing only a TX Header Descriptor. When set to 1: the TX descriptor is attached to a data container which would need to be accessed and the bit field SIZE[9:0] defines the number of TX data to send for this descriptor. For CAN XL, as no payload data can be defined in TX descriptor, this bit is always set to 1 for CAN XL. For CAN FD, this bit is set to 1 when the payload data is greater than 4 bytes. When set to 0: the payload data defined in the data container are not required. Therefore, the TX descriptor includes all data payload. For the Classical CAN, all payload data are always included, this bit must always be set to 0. In case of CAN FD it would be set to 0 only when the payload data is less or equal to 4 bytes. Nevertheless, the bit field SIZE[9:0] still defines the number of payload data to send per TX descriptor

(table continues...)

Table 1037 (continued) TX descriptor description

Element number	Bit-field	Name	Managed by	Description/Constraints
	[25:16]	SIZE[9:0]	SW only	Define the buffer size in words (32-bit) for the given TX descriptor to transmit to the PRT. As an example, a payload from 1 to 4 bytes requires SIZE to be set to 1. As only 32-bit read accesses are performed the buffer size containing the payload must be 32 bit aligned. When set to 0, there is no payload data attached to the TX descriptor (only valid for Classical CAN/CAN FD without payload or a Classical CAN remote frame) For CAN XL no data is defined in TX descriptor. The MH replies only on the address pointer defined in element 7 to fetch payload data from S_MEM. For CAN FD: SIZE > 1: The copy of the first data payload (aligned on 32 bits) is required in element 6. The address pointer in element 7 is used to fetch the payload data from S_MEM. SIZE = 1: The copy of the first data payload is required in element 6. The address pointer in element 7 is not used. Nevertheless, it is required to have it set to the address of the payload data in S_MEM SIZE = 0: Element 7 and 6 are not used
	[15:13]	IN[2:0]	SW only	Instance Number: define the X_CAN instance number using that descriptor. This bit field is relevant if several X_CAN are running concurrently. It provides a way to detect descriptor fetch issue between instances. The value defined must be equal to the one defined in the Ni_MH_CFG.INST_NUM bit field register.
	[12]	Not Used	SW only	Must be set to 0
	[11:2]	TDO[9:0]	SW only	For the TX Priority Queue: This bit field must be set to 0.
		NHDO[9:0]	SW only	For the TX FIFO Queue: This bit field must be set to 1.
	[2:0]	Not used	SW only	Must be set to 0
2	[31:0]	TS0[31:0]	MH only	Timestamp 0: LSB of the 64-bit timestamp of the successfully sent TX message (only valid when HD bit is set to 1)
3	[31:0]	TS1[31:0]	MH only	Timestamp 1: MSB of the 64-bit timestamp of the successfully sent TX message (only valid when HD bit is set to 1)
4	[31:0]	T0[31:0]	SW only	Define the TX message header information, see TX message header definition chapter

(table continues...)

Table 1037 (continued) TX descriptor description

Element number	Bit-field	Name	Managed by	Description/Constraints
5	[31:0]	T1[31:0]	SW only	Define the TX message header information, see TX message header definition chapter
6	[31:0]	TD0[31:0]	SW only	Classic CAN and CAN FD: define the first payload of the TX message
		T2[31:0]	SW only	CAN XL: Defined the TX message header information, see TX message header definition chapter
7	[31:0]	TD1[31:0]	SW only	Classical CAN with payload greater equal to 4 byte: define the last payload data of the TX message for the Classical CAN (in case payload data is greater than 4 bytes).
		TX_AP[31:0]	SW only	CAN XL and CAN FD with payload greater than 4 bytes: Address pointer to fetch the TX message payload data. This bit-field is mandatory for the CAN XL as no payload data can be defined into the descriptor. As the Classic CAN has only 8 bytes payload, the whole message can be defined using only one TX descriptor, see TD0 and TD1. As the address pointer must be 32 bit aligned the two LSB will not be considered and so must be set to 0 all time. In case the TX_AP is not used it must be set to 0.

22.5.3.5.1 TX descriptor CRC computation

A dedicated CRC is computed for every TX descriptor. When a CRC error is detected the DESC_ERR interrupt signal is triggered. This way the data transfer setting and description up to the DMA engine are fully protected.

The CRC covers all the relevant data, meaning the 247-bit data in the TX descriptor considering the CRC bit-field in the descriptor as equal to 9'b0. The CRC is part of the Element Number 0.

The CRC ($CRC-9_167$) is computed assuming the following elements in sequence:

Element Number 0[31:25] & 9'b0 & Element Number 0[15:0].

Element Number 1[31:0]

Element Number 2[31:0] set to 32’b0

Element Number 3[31:0] set to 32’b0

Element Number 4[31:0]

Element Number 5[31:0]

Element Number 6[31:0]

Element Number 7[31:0]

***Note**: The Koopman representation of the polynomial CRC-9_167is used to protect TX descriptors: $CRC-9_167=\left(x^9+x^7+x^6+x^3+x^2+x+1\right)$ (CRC polynomial in implicit "+1" hex format, meaning the trailing "+1" is omitted from the polynomial number)*

Using the Ni_MH_SFTY_CTRL.TX_DESC_CRC_EN bit register, the SW can decide to disable this check for all the TX descriptors fetched from S_MEM or L_MEM.

22.5.3.5.2 TX descriptors errors

When a TX descriptor error is detected, the relevant information are logged in the Ni_DESC_ERR_INFO1 register. Furthermore, the source address of the faulty TX descriptor is logged in the Ni_DESC_ERR_INFO0 register. This would help the SW to identify potential root causes when such error occurs. The Ni_DESC_ERR_INFO1.RX_TX bit is set to 0 when a TX descriptor gets an error.

22.5.3.6 TX message header definition

The TX descriptor contains the TX message header. The header data structure depends on the CAN Frame Format (Classical CAN, CAN FD, CAN XL) to be used for this message on the CAN Bus. It can be controlled by the

header bits T0.FDF, T0.XLF and T0.XTD. The following tables describe the three data structures used for the headers.

Table 1040 Classical CAN TX header definition

Tn	Bits	Name	Description/Constraints
T0	[31]	FDF	FD Format

22.5.3.7 RX descriptor

The RX descriptor definition for the RX FIFO is defined in table below. Only 4x32 bit are required to define an RX descriptor. Hence the overall RX descriptor can be fetched with one burst. Some bit field elements are defined in a separate table for the sake of simplicity.

Table 1043 RX descriptor description

Element number	Bit-field	Name	Managed by	Description/Constraints
0	[31]	VALID	SW/MH	Valid: The SW must set this bit to 0 to define an RX descriptor is pointing to a valid data container. As soon as the RX descriptor is executed the MH will set this bit to 1 to indicate to the SW valid data written to the S_MEM. In case the RX descriptor is fetched with this bit set to 1 and interrupt RX_FQ_IRQ is triggered to the system for the RX FIFO Queue having this non valid descriptor. The SW must clear this bit only when all the RX message data attached have been read

(table continues...)

Table 1043 (continued) RX descriptor description

Element number	Bit-field	Name	Managed by	Description/Constraints
	[30]	HD	MH only	Message header: when set to 1 the RX descriptor is defined as containing the header of the RX message. Any other RX descriptor, if several descriptors are used for the same RX message, will contain only payload data. In Continuous Mode HD is always set to 1 as only one RX descriptor is used per RX message
	[29]	reserved	SW only	Must be set to 0
	[28]	NEXT	MH only	Next: Set to 1 by the MH to indicate in the RX Header descriptor that more than one descriptor is used for the RX message. This information is only mentioned in the Header Descriptor, the RX Trailing Descriptors are not modified. This allows the SW to acknowledge only the RX Header Descriptor for any RX messages. In Continuous Mode NEXT is always set to 0 as only one RX descriptor is used per RX message
	[27]	IRQ	SW only	Interrupt: when set to 1, an interrupt is triggered to the system when the descriptor execution is complete and a correctly received RX message was written to it. This interrupt can provide point to the SW a synchronization point to monitor the RX FIFO Queue execution
	[26:25]	Not Used	SW only	Must be set to 0
	[24:16]	CRC[8:0]	SW only	CRC: this CRC is computed by the SW for the current RX descriptor. It must consider all elements assuming this bit-field as set to 0. Any CRC error is triggering an interrupt to the system. The CRC is not evaluated if the Ni_MH_STS.RX_DESC_CRC_EN bit is set to 0
	[15:12]	FQN[3:0]	SW only	RX FIFO Queue number: define the RX FIFO Queue number allocated to this RX descriptor
	[11:9]	IN[2:0]	SW only	Instance Number: define the XCAN instance number using that descriptor. This bit-field is relevant if several XCAN are running concurrently. It provides a way to detect descriptor fetch issue between instances. The value defined must be equal to the one defined in the Ni_MH_CFG.INST_NUM bit-field register.

(table continues...)

Table 1043 (continued) RX descriptor description

Element number	Bit-field	Name	Managed by	Description/Constraints
	[8:4]	RC[4:0]	SW only	Rolling Counter: use to track the order of RX descriptor fetched when an RX FIFO Queue is running. When an RX FIFO Queue is started for the first time, its first RX descriptor must have the RC[4:0] set to 5'b00000. This value must be incremented for every new RX descriptor up to 5'b11111 and then back to 5'b00000. Even if a wrap occurs at to the end of the RX FIFO Queue, there must be continuous. Therefore, the First RX descriptor may have a RC[4:0] different from 5'b00000.To have always RC[4:0] = 5'b00000 for the First RX descriptor, the RX FIFO Queue size must be a multiple of 32 RX descriptor size
	[3:0]	STS[3:0]	MH only	Status: gives the status of the RX message received. This bit-field is written back by the MH when the descriptor has been completed. This bit-field must be set to 0 by SW. 0000_B: none 0001_B: message received successfully 0010_B: message received but not filtered 0011_B to 1110_B: reserved 1111_B: message acknowledged with parity error
1	[31:0]	RX_AP	SW/MH	Normal Mode: the SW defines the address of the RX data container to write RX data Continuous Mode: The SW must set this bit field to 0 as default value. The MH writes this field with the address pointer to find the RX message attached to the RX descriptor. Only the RX Header Descriptor is having this bit field updated, with the RX message address in the data container. This address must be 32 bit aligned, the two LSB bits are assumed to be always 0
2	[31:0]	TS0[31:0]	MH only	Timestamp 0: LSB of the 64-bit timestamp of the successfully received RX message (only valid when HD bit is set to 1)
3	[31:0]	TS1[31:0]	MH only	Timestamp 1: MSB of the 64-bit timestamp of the successfully received RX message (only valid when HD bit is set to 1)

Here is the list of required elements for the various RX descriptor definition to be managed by the SW or the MH:

Table 1044 Element managed by SW

	SW to write information to MH	SW to read information from MH	
Element number	**RX Descriptor**	**Header descriptor**	**Trailing descriptor**
0	Mandatory	Mandatory	Mandatory in Normal mode
1	Mandatory in Normal mode NA in Continuous mode (must be set to 0)	Mandatory	Mandatory in Normal mode
2	NA (must be set to 0)	Mandatory	NA (must be equal to 0)
3	NA (must be set to 0)	Mandatory	NA (must be equal to 0)

Table 1045 Element managed by MH

	MH to write information to SW		MH to read information from SW
Element number	**Header descriptor**	**Trailing descriptor**	**RX descriptor**
0	Mandatory	Not updated	Mandatory
1	Not updated in Normal mode Mandatory in Continuous mode	Not updated	Mandatory in Normal mode NA in Continuous mode
2	Mandatory	Not updated	NA
3	Mandatory	Not updated	NA

When the Element´s content is mentioned as NA, the assumed default value must be 0.

22.5.3.7.1 CRC computation

A dedicated CRC is computed for every RX descriptor. When a CRC issue is detected, the DESC_ERR interrupt signal is triggered (see safety measures section). This way the data transfer setting and description up to the DMA engine are fully protected.

The CRC covers all the relevant data, meaning the 55 bits of data in the RX descriptor considering the CRC bit field in the descriptor as equal to 9'b0. The CRC is part of the Element Number 0.

The CRC (CRC-9_167) is computed assuming the following elements in sequence:

Element Number 0[31:25] & 9'b0 & Element Number 0[15:0]

Element Number 1[31:0]

***Note**: The Koopman representation of the polynomial CRC-9_167is used to protect RX descriptors: CRC-9_167 = ($x^9+x^7+x^6+x^3+x^2+x+1$) (CRC polynomial in implicit "+1" hex format, meaning the trailing "+1" is omitted from the polynomial number)*

Using the Ni_MH_SFTY_CTRL.RX_DESC_CRC_EN bit register, the SW can decide to disable this check for all the RX descriptors fetched from S_MEM or L_MEM.

22.5.3.7.2 RX Descriptor Errors

When an RX descriptor error is detected, the relevant information are logged in the Ni_DESC_ERR_INFO1 register. Furthermore, the source address of the faulty RX descriptor is logged in the Ni_DESC_ERR_INFO0 register. This would help the SW to identify potential root causes when such error occurs. The Ni_DESC_ERR_INFO1.RX_TX bit register is set to 1 when an RX descriptor gets an error.

22.5.3.8 RX message header definition

Messages received from the CAN Bus are stored in the S_MEM, each consisting of a header followed by the payload. The header data structure depends on the CAN Frame Format (Classical CAN, CAN FD, CAN XL) used for this message on the CAN Bus. It can be identified by the header bits FDF and XLF. The following tables describe the three data structures used for the headers, consisting of the words R0, R1 and R2.

Table 1046 Classical CAN RX header definition

Rn	Bits	Name	Source	Description/Constraints

22.5.3.9 TX message

For a better understanding while reading this chapter, read the TX descriptor chapter first.

A TX message is defined using one TX descriptor and a TX data container where the payload data buffer is defined.

The Header Descriptor (or the only one, in case of one descriptor per message) holds the header data information and for some CAN protocols, the data payload of the message. Such descriptor also provides some additional information to the MH: the interrupt to be triggered, where to write acknowledge data, where to fetch TX message data, etc.

A TX data container is a general term to name the memory space allocated by the SW. This data container is used to hold the payload data buffer. In most of the cases, this TX data container would be identical to the data buffer size to transmit, avoiding the loss of memory space.

A specific TX descriptor is used for the TX FIFO Queue and for the TX Priority Queue due to the structure of the two different implementations.

In order to optimize the fetch of the TX descriptor as well as data payload, a maximum burst length of 8x32 bit is used.

The buffer size which can be defined in a TX descriptor can go up to 2048 byte. This way, a TX message can be defined using a single TX descriptor and one data buffer.

As the maximum efficiency is reached when using the maximum burst length, it is highly recommended to define a data buffer size aligned on the maximum burst length.

If the TX payload data is not a multiple of the burst length, the remaining data in the data container won't be read. Nevertheless, the embedded DMA_CONTROLLER will use the maximum burst length to read the payload whenever possible and will adapt the latest burst length to complete its transfer. Only the relevant data are read from S_MEM when smaller than the maximum burst length.

The address pointer used to fetch the payload data is always 32 bit, despite that payload data is byte aligned.

Every TX descriptor holding the header of the TX message, once a TX message is transmitted, is acknowledged for status, error reporting and timestamping.

Here below are the different types of messages according to CAN protocols.

Related information

TX descriptor on page 4187

22.5.3.9.1 Single TX descriptor usage

A TX message can be defined using one single TX descriptor. This kind of choice requires to have the complete payload data defined in one data container in the S_MEM. In case of Classical CAN, the complete Classical CAN message is embedded in the TX descriptor. This means no payload buffer is required for Classical CAN messages. The NEXT bit in TX descriptor must be set to 0. In case of a TX Priority Queue, the TX descriptor TDO bit field must be set to 0. For the TX FIFO Queues, the NHDO is set to a value equal to 1 in order to define the next TX header descriptor.

For the TX Priority Queue and TX FIFO Queue the same description below applies.

Classical CAN with up to 8 bytes payload

As the Classical CAN payload data is only 8 bytes, it can be defined completely in the TX descriptor (see TD0 and TD1 in chapter TX descriptor). There is no need to define an address pointer to a payload buffer in that case. Despite a data container is mentioned, it is not used. This is to align with the other description in the next sections.

This approach provides a single and simple way to send any Classical CAN TX message in a straight forward manner. Using the T0, T1, TD0 and TD1 in the TX descriptor, the overall Classical CAN message can be defined, refer to the TX descriptor chapter for more details.

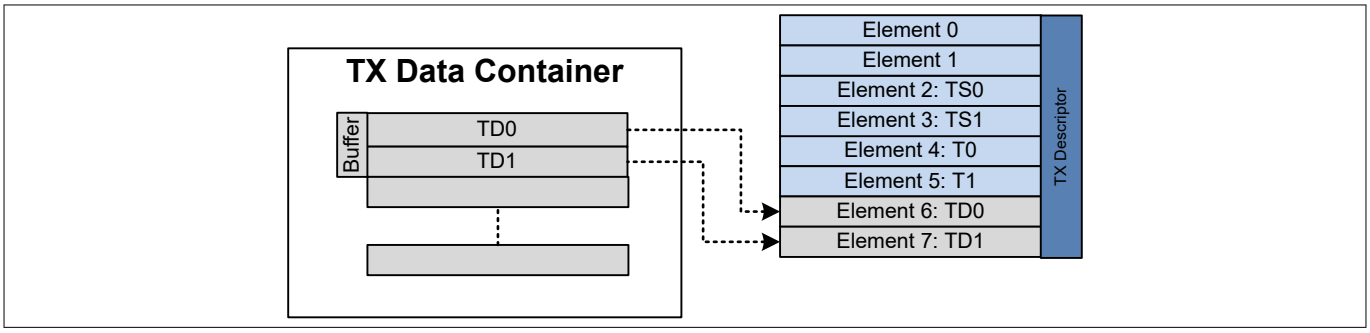

Figure 399 Classical CAN TX message with 8 bytes payload (single descriptor)

CAN FD

As the CAN FD protocol can provide up to 64 bytes, it is mandatory to define an address pointer to read the payload data from the S_MEM when the size is greater than 4 bytes. The first payload data defined in the payload data buffer also needs to be defined in the TX descriptor. For high latency system, the time to fetch the payload data, once the arbitration process is complete, can lead to a potential under-run. To solve this issue, TD0 is declared in the TX descriptor. By the time TD0 is sent through the CAN bus, the payload data will be read from the S_MEM. This approach avoids pre-fetching the payload data before having the arbitration result and to

throw away the complete burst when arbitration is not successful. The TD0 from the first read burst access will then be skipped.

The address pointer points to the buffer holding the overall payload data as depicted in figure below. In case only 4-byte payload data is required, there would be no need to define the address pointer (must be set to 0). For payload data above 4 bytes an address pointer is required. The minimum data container size is either 32 bytes (data payload lower or equal to 32 bytes) or 64 bytes (data payload greater than 32 bytes).

The size of the buffer to be fetched is always 32 bit aligned. When the data payload is lower than a multiple of 32 bits, padding is expected and will be discarded by the PRT.

Using the T0, T1, TD0 and the TX_AP fields, the overall CAN FD TX message can be defined, refer to the TX descriptor chapter for more details

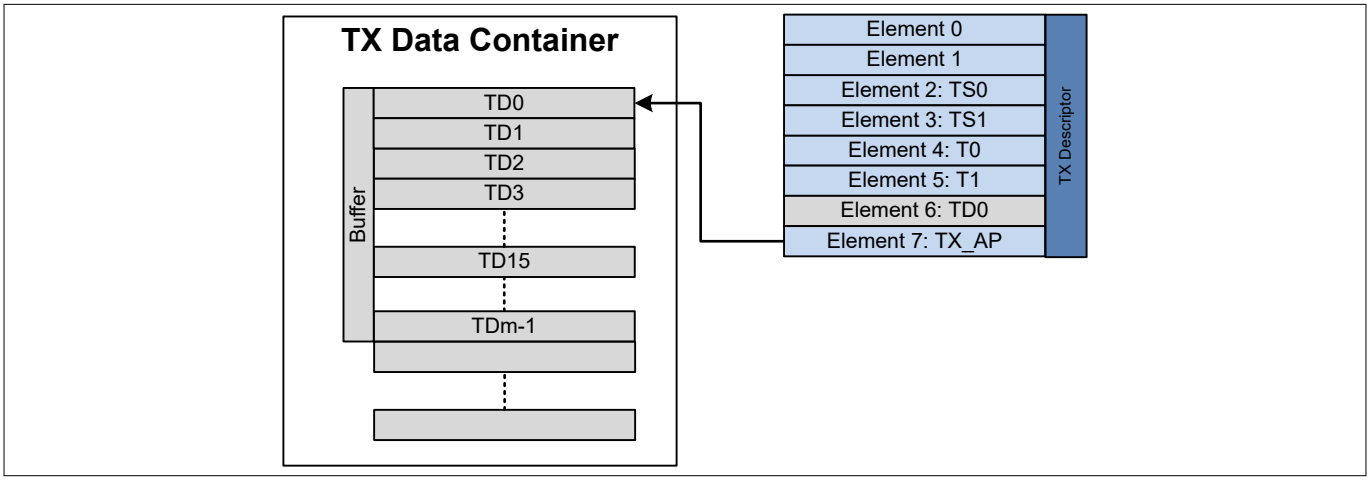

Figure 400 CAN FD TX message with more than 4 byte payload (single descriptor)

CAN XL

As the CAN XL header information requires 3 words of 32 bits, there is no payload data defined in the TX descriptor. T2 is required only when the arbitration on the CAN bus is successful, giving time for the MH to read the payload data from the S_MEM and to avoid the need of prefetching data.

Using the T0, T1, T2 and the TX_AP fields, the overall CAN XL TX message can be defined, refer to the TX descriptor chapter for more details.

The size of the buffer to be fetched is always 32 bit aligned. When the data payload is lower than a multiple of 32 bits, padding is expected and will be discarded by the PRT.

22.5.3.10 RX message in normal mode

In order to receive RX messages, an RX descriptor is required to define how the MH must behave and where to write the RX data in Normal mode.

Those RX descriptors are attached to RX FIFO Queues which are selected according to the RX filtering rules. It means, RX descriptors are concatenated and read in sequence.

An RX data container is a general term to name the memory space allocated by the SW. This data container is used to hold the RX message data. In most of the cases, this RX data container would not be fully filled with data, maximum data payload being different for CAN protocols.

Every RX descriptor is assigned to a data container to write incoming data to the S_MEM. The RX data container size is a multiple of the maximum burst length supported, 8x32 bit with a maximum of 4064 bytes (127*32 bytes) and a minimum of 32 bytes. This granularity does provide some flexibility to address several RX message size with only one data container. As defined previously, if an RX data container is smaller than an RX message, several RX descriptors will be assigned to that message.

Compared to the TX message, the header and the payload of the RX message are written together to the S_MEM. This approach gives the flexibility to pass address pointers of the overall message to the application and to avoid copies.

If the payload data does not cover a multiple of the burst length, some data won't be written to the data buffer in the container. The embedded DMA_CONTROLLER will use the maximum burst length whenever possible to write header and payload and will adapt the latest burst length to complete its transfer.

The address pointer used to write the RX message is always 32 bit aligned despite payload data is byte aligned.

The size of the data container defined into the RX descriptor is fixed for a given RX FIFO Queue and for all the RX descriptors of that queue. The smaller the size of data buffer the less RX descriptors a message would require.

As the data container is defined anywhere into the S_MEM, the SW can decide to allocate all the data containers into a continuous way in the S_MEM to ensure, the RX message is not split over several location. It will ease the reading of RX messages and simplify the management of data buffers, see RX FIFO Queue chapter for more details.

The NEXT bit defined into the RX Header Descriptor provides the information to the SW that one or several RX descriptors are used. On top of it, the RX Header Descriptor of an RX message will have the HD bit set to 1 to indicate that the data container got the header of the message.

Only the RX Header Descriptor holding the header data is acknowledged when an RX message is received. This way, despite receiving the timestamp at the end of the data received, it will be written with the header and status reporting.

Here below are the different types of RX messages according to the CAN protocol and some different structures when using one or several RX descriptors.

Related information

RX FIFO queue in normal mode on page 4217

22.5.3.10.1 Single RX descriptor

With such structure the size of the data container defined by the RX descriptor must be large enough to hold the maximum payload size of the expected RX message to receive.

Classical CAN

As depicted in the following figure, the Classical CAN header and payload data can be directly written into a 32 bytes data container ($N = 1$). If such data buffer size is defined then several RX descriptors would be required to support CAN FD (3 RX descriptors) or CAN XL (65 RX descriptors) frame size. It is important to note that according to the RX message type received, the whole message may be written into a bigger data container as every RX FIFO Queue is defining its own data container size.

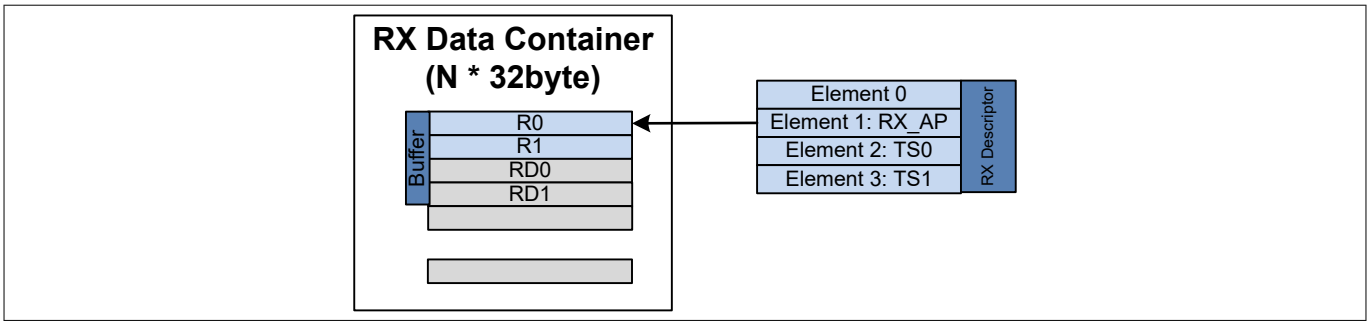

Figure 402 Classical CAN RX message (single descriptor)

CAN FD

Compared to Classical CAN, a larger data buffer is required to hold up to 64 bytes of payload data and the header message data. In this case a data container of 96 bytes ($N = 3$) is allocated to support CAN FD frame format. There will be no issue regarding Classical CAN message as it would fit entirely into the same data container. Doing so, the CAN XL message can be supported but would require up to 22 RX descriptors.

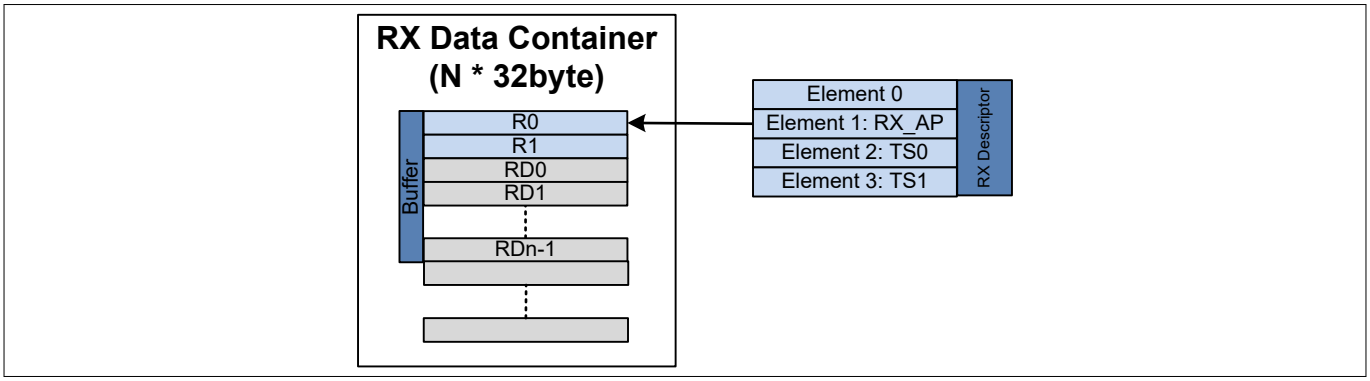

Figure 403 CAN FD RX message (single descriptor)

CAN XL

To ensure only one RX descriptor is pointing to one RX message a data container size of more than 2048 bytes is required ($N = 65$). With this setting, all the different CAN protocols are covered with a single data container per RX descriptor. However, quite some memory space is lost in the data container (when configure to support CAN XL payload size) when receiving Classical CAN or CAN FD messages. To solve this issue, multiple RX descriptors can be used, see next chapter.

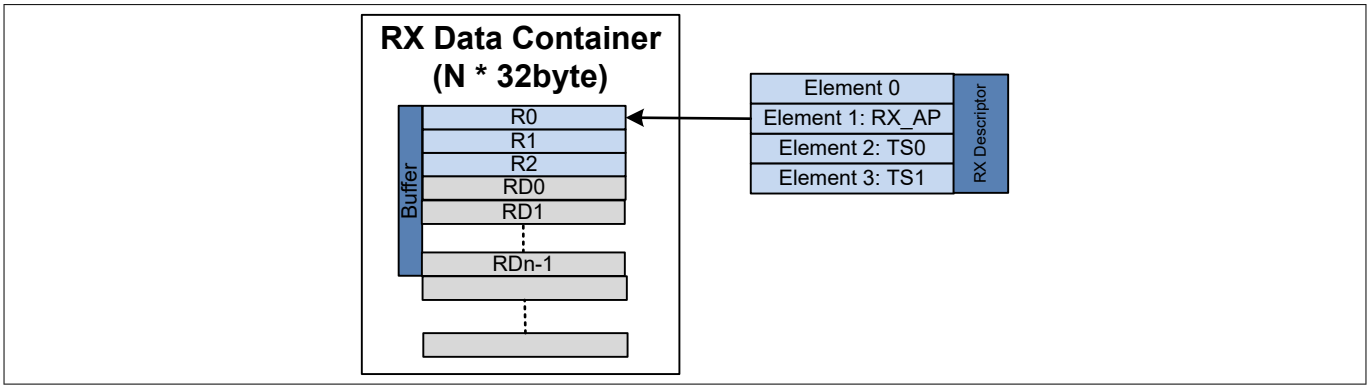

Figure 404 CAN XL RX message (single descriptor)

22.5.3.10.2 Multiple RX descriptors

To optimize the memory usage, regardless of the payload size of the RX message received, several RX descriptors can be assigned to one RX message. Doing so, the RX message is written in several data containers. When one is full, the RX message data is going to the next one. As depicted in the figure below, for a given size of data container (constant per RX FIFO Queue), the RX message can be written anywhere into the S_MEM. The MH takes care of filling the right data container with the RX message data whenever required. As a fixed memory allocation is defined per RX descriptor, the RX message data may be spread over several data containers and RX descriptors (depends on RX message payload data).

The figure below shows three RX descriptors and their assigned data container to hold the entire RX message. If a data container has a size of 96 bytes (N=3) and a CAN XL message payload of 270 bytes is received, then the RX message is depicted in figure below. Although the CAN XL message, in this example, is split over several RX descriptors, this configuration allows to support Classical CAN and CAN FD with only one RX descriptor.

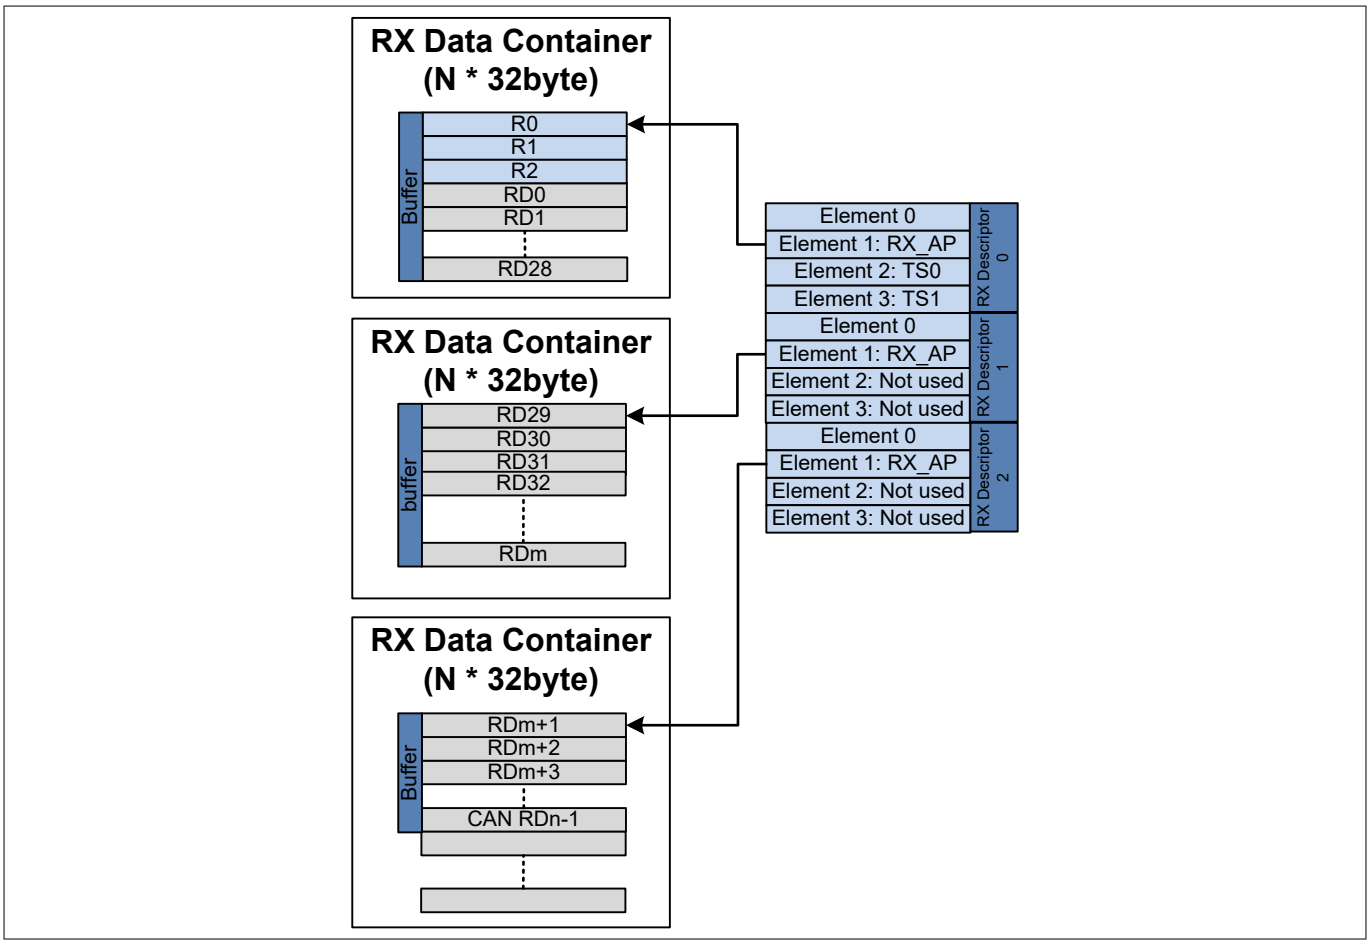

Figure 405 RX message (multiple descriptors)

22.5.3.11 RX message in continuous mode

For a better understanding of this section please read the RX Message in Normal mode chapter.

In the Continuous mode, the RX messages, instead of being split over several data container (see RX Message in Normal mode chapter), are merged in the same big data container one after the other. As depicted below only a single data container is defined per RX FIFO Queue and one RX descriptor is used per RX message.

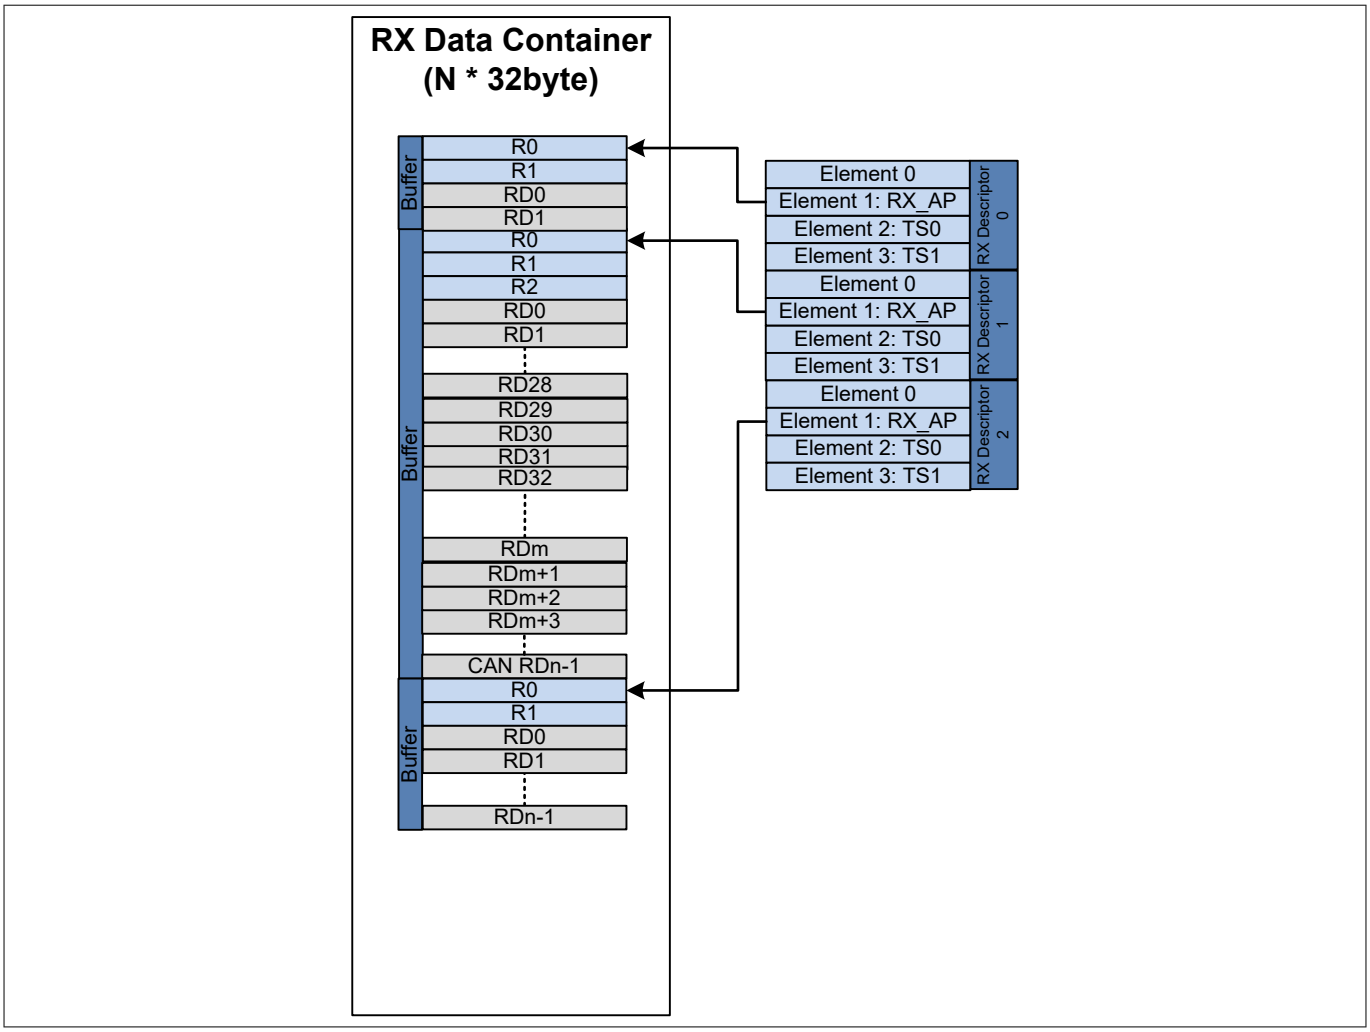

Figure 406 RX message (continuous mode)

The Continuous mode makes use of the already defined RX descriptor list to support the SW management of RX messages, see RX message Normal mode for more details.

It is important to note that the Continuous mode applies to all RX FIFO Queues when set. There is no option to make it available only to some queues.

The RX descriptors are attached to a defined RX FIFO Queue. The RX FIFO Queue, to write the RX message, is defined according to the RX filtering rules, see RX Filter chapter for more details. Once the RX FIFO Queue is identified, the latest RX descriptor (meaning the current one) is fetched from S_MEM. As the RX descriptors in a given FIFO Queue are concatenated, they will be read in sequence up to the end of the RX message.

Every RX descriptor is assigned to only one RX message in this large data container. This data container size is a multiple of the maximum burst lengths supported, 8x32 bit with a maximum of 131040 bytes (4095*32 byte) and a minimum of 32 bytes. Every RX FIFO Queue has its own data container (defined by a start address and a size).

The header and the payload of the RX message are written one after the other to the S_MEM. This approach gives the advantage to have the complete RX message data available in one place in the S_MEM. A copy of the RX message in the S_MEM can then be easily defined by a start address and a size.

Whenever it is possible, the embedded DMA_CONTROLLER uses the maximum burst length to write header and payload data and will adapt the latest burst length to complete its transfer.

The address pointer, used to write the RX message, is always 32 bit aligned despite payload data is byte aligned.

The data container is defined anywhere in the S_MEM. Being defined as a 32 bit address pointer, it can be defined in a 4 Gbyte memory area.

The NEXT bit defined in the RX Descriptor will never be set, as only one RX Descriptor is used per RX message. The RX Descriptor pointing to the RX message has the HD bit set to 1 as it is a Header Descriptor. No Trailing Descriptors are used for such mode, only one RX descriptor is required and it is a Header Descriptor.

Only the RX Header Descriptor holding the header data is acknowledged when an RX message is received, considering the Normal mode. The same applies for the Continuous mode, see RX message in Normal mode chapter for more details.

Compared to the Normal mode, there is no tradeoff to consider regarding the different CAN protocol payload data size. As the RX messages are written in a row, no loss of memory is expected in the data container assigned to an RX FIFO Queue.

This mode will also ensure that RX data are always linearly and continuously written in the S_MEM. At the beginning of the reception of an RX message header, a check is performed to ensure the RX data to be received can fit entirely in the data container. As the RX message cannot be written at the bottom and at the top of the data container, the MH will go to the start address of the data container before writing the first data. This would provide to the SW an easy way to perform memory copy, as one start address and a size can define the overall RX message.

22.5.3.12 Descriptor acknowledgement

For the TX and RX paths, the MH is providing data information back to the RX and TX Header Descriptor.

To do so, some place holders are defined in the RX and TX descriptors for the MH to write RX and TX message status, timestamping and error reporting.

As the CAN bus is not a full duplex interface, there should not be any collision on the acknowledge of RX and TX descriptors, with the exception of the PRT when in loopback mode. In such mode, all TX messages transmitted by the MH are send back by the PRT to the MH, refer to the PRT chapter for detailed description of the loopback.

The process of acknowledgment is completely separated from the reception or transmission of a CAN frame, a dedicated DMA channel is reserved for such purpose.

22.5.3.12.1 RX descriptor

For the RX path, one or several RX descriptors can be used to hold the complete RX message. Once an RX message is received successfully, an acknowledgement is written back to the Header Descriptor when the message is completed. If several descriptors are used per message (Trailing Descriptors), they are not changed by the MH. If the data container assigned to the RX descriptor is sized in such a way that any RX message can fit in entirely, then every RX descriptor (in fact Header descriptors in that case) will be acknowledged.

If several RX descriptors are used to store the RX message and an issue occurs while processing the message, all RX descriptors already used are then released for the next RX message.

Here below is the list of bit fields used by the MH to provide the acknowledgement information to the RX Header descriptor, see RX Descriptor chapter for details:

- VALID: The MH expects this bit to be set to 0 by the SW to ensure the data container is ready to be written again. This bit is written by the MH to 1, when an RX message is received successfully and the data are available in S_MEM. It is true only for the RX descriptor holding the RX message header data
- TS0[31:0] and TS1[31:0]: The MH writes the 64-bit timestamp (TS0 and TS1) in the RX descriptor when the RX message data is received successfully. Only the RX descriptor holding the data will have this bit-field updated
- NEXT: As soon as more than one RX descriptor is required for an RX message, the MH is setting this bit to 1 to indicate to the SW, more descriptors are used for this RX message. Only the RX Header descriptor will have this bit-field updated. The trailing descriptors are not updated. When in Continuous mode this bit will always be 0

- HD: In case several RX descriptors are used to define an RX message, the MH is setting this bit to 1 to identify which descriptor has the message header embedded into its data buffer
- STS[3:0]: This bit-field gets updated by the MH for any usage of RX descriptor. It provides information on the status of the RX message and on any related issue while RX FIFO Queues are running

22.5.3.12.2 TX descriptor

For the TX path, once a TX message is processed, the TX Header Descriptor is written back with the relevant information. The list of conditions to trigger an acknowledge is defined below:

- Message sent successfully
- Message rejected by the TX filter (see TX Filter chapter)
- Message discarded after several retransmission
- Message rejected by the PRT (see HFI codeword in PRT chapter)

Here below are the list of bit-field used by the MH to provide the acknowledgment information to the TX descriptor, see TX Descriptor chapter for details:

- VALID: The MH expects this bit to be set to 1 by SW to ensure the data buffer is ready to be sent, only the TX descriptors having this bit set to 1 are accepted and executed. This rule applies for every TX descriptor with or without the header data (when TX message is split over several descriptors). When the last data defined by this TX descriptor has been sent over the CAN bus, it will be set back to 0 by the MH only to the TX descriptor holding the header data
- TS0[31:0] and TS1[31:0]: When the TX message data is sent successfully a 64-bit timestamp is written back into to the TX descriptor holding the header data
- STS[3:0]: This bit-field gets updated by the MH for any usage of TX descriptor. It provides information on the status of the TX message and on any related issue while TX FIFO Queues are running

22.5.3.13 TX FIFO queue

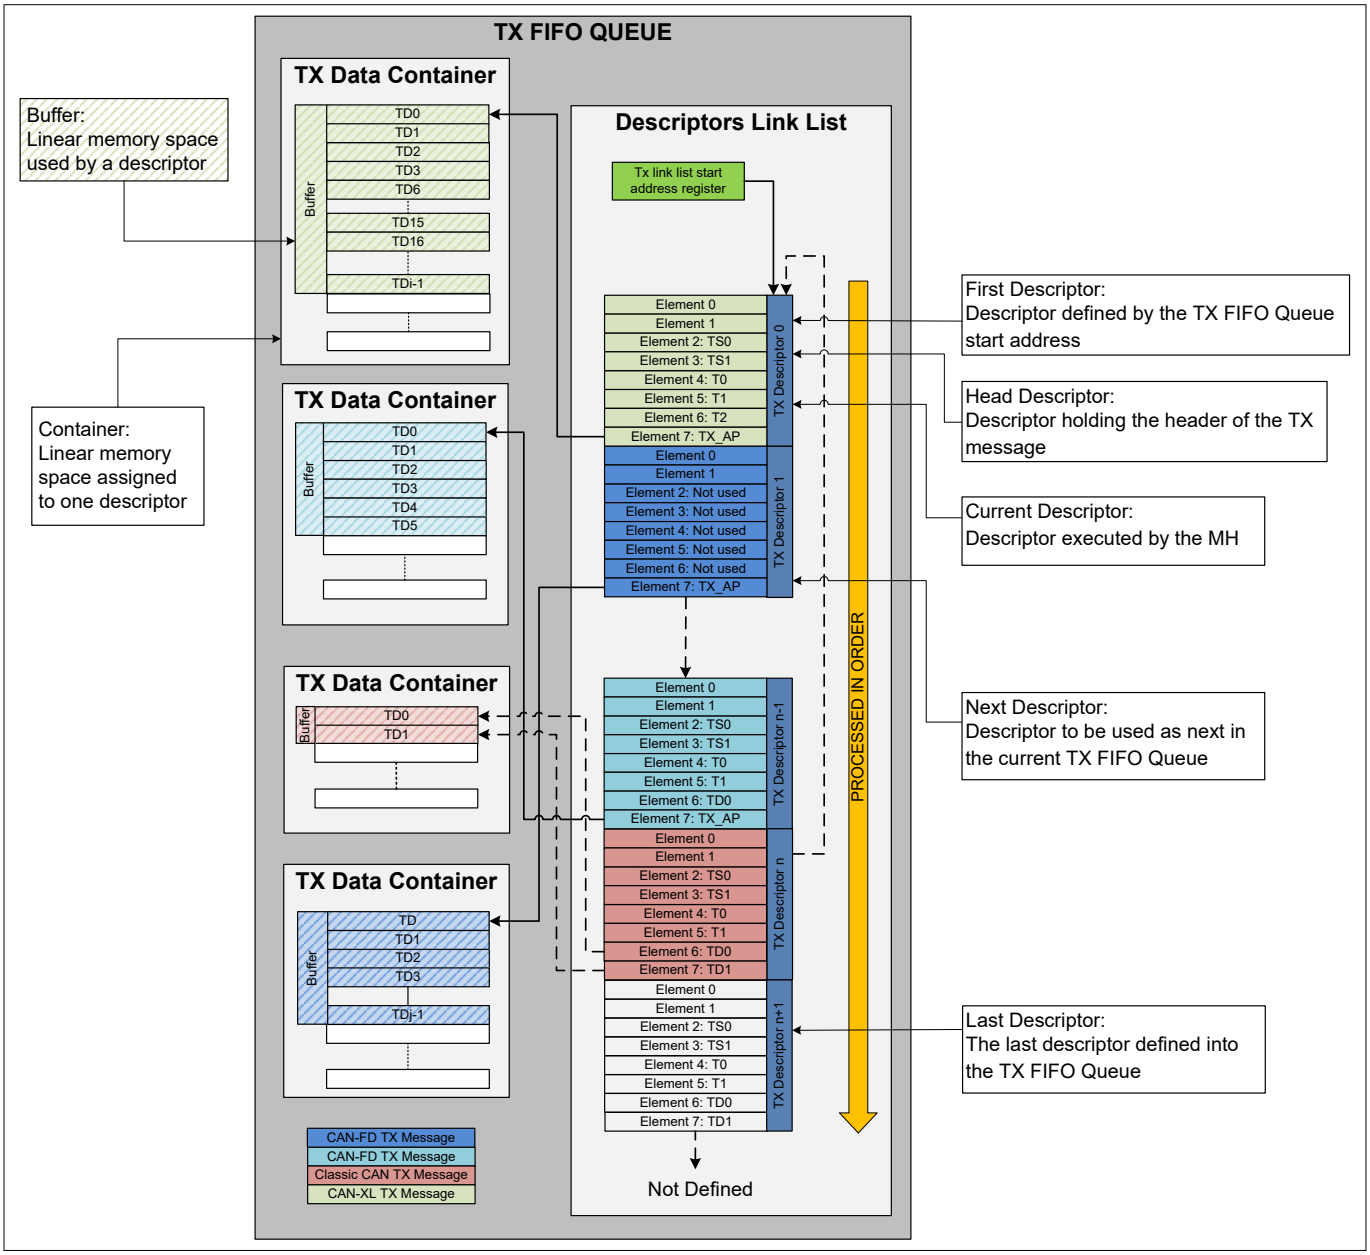

Figure 407 TX FIFO queue description

Up to 8 TX FIFO Queues can be defined and managed by the MH.

When the SW wants to configure N TX FIFO Queues, only the queue number from 0 to N-1 can be used.

A TX FIFO Queue is a list of TX messages to be sent in order to the PRT.

Each one being fully independent from the others, the SW can declare and add new messages to any of the FIFO Queue without stopping the execution of the others or the current one. In this sense, the TX FIFO Queues can be enabled or disabled individually. An abort mechanism is provided to stop and flush each TX FIFO Queue individually.

Prior to launch any TX FIFO Queue, the MH must be started (Ni_MH_CTRL.START written to 1 will drive the Ni_MH_STS.BUSY bit status to 1). To start the TX FIFO Queue n, write 1 to the Ni_TX_FQ_CTRL0.START[n]. Before launching a TX FIFO Queue n, it must be enabled by setting the Ni_TX_FQ_CTRL2.ENABLE[n] bit to 1. Once enabled and started, there is no way to disable it while it is running without a defined procedure. Instead, the abort bit Ni_TX_FQ_CTRL1.ABORT[n] provides a way to stop a TX FIFO Queue n running and to ensure a safe

stop and flush of ongoing data. For more detail on starting and stopping TX FIFO Queues, refer to the Application Information chapter.

To ensure no dead lock can occur at start, the ENABLE signal from the PRT must be set to high to allow any TX FIFO Queue to start. This signal status can be monitored in the Ni_MH_STS.ENABLE bit field.

There is also nothing preventing the SW to declare and run a TX FIFO Queue with a defined list of TX messages, assuming an interrupt at the end of the TX FIFO Queue execution.

However, the TX FIFO Queue can be used as a circular buffer when the Last Descriptor defines a wrap to the First Descriptor (WRAP bit set to 1 in TX descriptor). Doing so, the SW can add new messages in an endless manner over time.

The mechanism, used to manage TX FIFO Queues, is based on the concept of linked list. Any TX FIFO Queue is defined using a linked list of TX descriptors and data buffers to read TX message payload from the S_MEM.

A linked list is made of descriptors, where a descriptor is defined by several data elements of the same size, the element is a 32-bit word. Each element provides some information or would define some actions to perform. A descriptor is built by the SW but will be read and executed by the MH.

Every TX descriptor is of the same size, pointing to a data buffer and also to the next descriptor, as depicted in the figure above. The TX descriptors are continuous in memory (to ease and simplify implementation). Therefore, it is not required to declare or use a bit field to mention the position of the next descriptor as it is implicit.

The linked list is started by fetching the First Descriptor in the list, once it is fully read, it is executed and the data buffer assigned to it, is read. Other actions can be defined into the element data like triggering an interrupt or setting a flag. The linked list is processed one descriptor at a time, once a descriptor is completed, the next one is fetched into the list and the process repeats itself. The process keeps going up to the Last Descriptor of the link list and from this point in, may end or may wrap to the first descriptor in a circular buffer mode.

Every TX FIFO Queue defines its own order of TX messages to be send to the CAN bus, but as several queues are running concurrently, an arbitration process is performed between queues to select the highest priority message. Every TX message is filtered to ensure only the required ones can be sent. The SW builds those queues with messages and the MH takes care of sending them whenever appropriate.

For the TX FIFO Queues, data buffers hold the payload data of the TX message while the descriptor defines header information. In some cases, the first payload data may also be part of the Head Descriptor.

To give a status report and some information like timestamping, the MH is also able to write back some elements in the TX descriptors. Not all of them are written back but only the one having the Header Descriptor data are updated.

It is possible to wrap at the top of the TX FIFO Queue any time but with the following constraints:

- The WRAP bit must be set in the Header Descriptor to identify where is the next TX message

The descriptors are mainly defined on SRAM as they drive the actions to be taken. Nothing prevents the SW to declare and use the E_MEM instead but it can slow down the execution and may create real time issues. However, the data buffers can be either in E_MEM, which is usually the case, or in SRAM. As a matter of fact, if the next descriptor cannot be fetched before the relevant data are fully read or written, the link list execution speed would depend on the data access time. To solve this issue, read prefetchings are performed to hide the system latency whenever possible.

TX Data Containers can be defined at any location in S_MEM. But for performance reason and to optimize the burst access, it is highly recommended to have the TX buffer 32 byte aligned. Those containers are considered as memory space that is allocated by the Memory Management Unit to store buffer. Once a message is sent, the container can be de-allocated, so the memory space is released for further usage.

As soon as the TX FIFO Queue is started, the MH will fetch the First Descriptor and store it to L_MEM. When the TX descriptor is available in L_MEM, it will be part of the arbitration process. As long as the TX message defined by this TX descriptor is not sent to the CAN bus, it will remain for all the arbitration runs. When it is sent successfully, the next TX descriptor of that TX FIFO Queue is fetched automatically.

The MH will proceed with all TX FIFO Queues in the same way. As the TX message to be sent is based on its priority, the TX FIFO Queues will run at a different rate up to the point that all TX messages are sent successfully.

If the Last Descriptor of a TX FIFO Queue sets the END bit, the MH will end the FIFO execution as soon as the TX message defined is transmitted successfully on the CAN bus and the TX descriptor acknowledge is written to the S_MEM.

Up to 1023 TX descriptors can be defined for a TX FIFO Queue. When the maximum number of TX descriptor defined for a TX FIFO Queue is reached, the MH wraps automatically to its initial start address to fetch the next TX descriptor. Despite this default behavior, it is still possible at any time for the SW to mention a wrap using the WRAP bit in the Header Descriptor.

When the END bit is not set for the last TX descriptor, the TX FIFO Queue is considered as endless and any new TX descriptor can be appended to the already defined last descriptor. To allow such way of working, the last descriptor must always be not valid (VALID bit set to 0). This is very important as the detection of the non-valid TX descriptor triggers an interrupt to the system to declare that the TX FIFO Queue is stopped. It would then be up to the SW to append a new TX descriptor and restart the TX FIFO Queue.

If for some reasons a TX FIFO Queue has an error, it is still possible to abort the execution of that TX FIFO Queue. When such action is performed, the TX FIFO Queue will be considered as active as long as the current data transfer assigned to a TX descriptor is not finished. This means, the TX descriptor is not considered for the arbitration anymore, so no more fetches are done and the TX FIFO Queue is set inactive.

Any safety issue related to a TX descriptor executed by a TX FIFO Queue will stop it right away. The TX FIFO Queue is declared as no more valid and is stopped. To identify such issue, some interrupts are triggered to the system, TX_CRC_ERR and TX_SFTY_STS. Despite that the faulty TX FIFO queue is stopped, the others will keep going.

If a message has reached maximum number of retransmission or has declared an invalid header format, the message is skipped and the next one in the TX FIFO Queue is considered instead. The error mentioning such skip is written back to the report status bit field in the TX Header Descriptor.

In a context where a TX descriptor provides the definition of one TX message, the next TX message is the next TX descriptor, an offset of 1 (1x32byte) is required.

A TX FIFO Queue is controlled and monitored using several registers and bit registers:

- The Ni_TX_FQ_START_ADD{n} (where n is 0-7) register to define the start address of the TX FIFO Queue n
- The Ni_TX_FQ_CTRL0.START[n] (where n is 0-7) register to launch the TX FIFO Queue n
- The Ni_TX_FQ_SIZE{n} (where n is 0-7) register to define the maximum number of TX descriptor for the TX FIFO Queue n before looping back to the initial start address
- The Ni_TX_FQ_ADD_PT{n} (where n is 0-7) register to monitor the current address pointer of the TX FIFO Queue n
- The Ni_TX_DESC_ADD_PT register to monitor the current address pointer
- The Ni_TX_FQ_CTRL1.ABORT[n] (where n is 0-7) bit register to abort the execution of the TX FIFO Queue n
- The Ni_TX_FQ_CTRL2.ENABLE[n] (where n is 0-7) bit register to enable the TX FIFO Queue n prior to use it
- The Ni_TX_FQ_INT_STS.SENT[n] and Ni_TX_FQ_INT_STS.UNVALID[n] (where n is 0-7) bit registers to identify respectively, a message is transmitted and an invalid TX descriptor is detected
- The Ni_TX_FQ_STS0.BUSY[n] and Ni_TX_FQ_STS.STOP[n] (where n is 0-7}) bit registers to know respectively, the status of the TX FIFO Queue n, busy (TX FIFO Queue is active) and stopped or running
- The Ni_TX_FQ_STS1.ERROR[n] and Ni_TX_FQ_STS.UNVALID[n] (where n is 0-7) bit registers to identify the root cause of the TX FIFO Queue being stopped, an error is detected or an invalid TX descriptor is detected

A TX FIFO Queue is being controlled for any issue using common bit registers when receiving interrupts:

- The Ni_SFTY_INT_STS.TX_DESC_CRC_ERR and Ni_SFTY_INT_STS.TX_DESC_REQ_ERR bit registers to identify respectively, any CRC issue on TX descriptor running in the TX FIFO Queue n and non-expected TX descriptor

- The Ni_ERR_INT_STS.DP_TX_ACK_DO_ERR bit register to identify overflow on TX ACK data path for the TX FIFO Queues
- The Ni_ERR_INT_STS.DP_TX_SEQ_ERR bit register to identify if an issue occurs on the TX_MSG interface

22.5.3.13.1 Basic mode

The SW defines one TX descriptor per TX message payload data. Thus, a TX message would be:

- One TX descriptor to provide the complete header information
- One TX data container to hold the complete TX message payload data (only required for CAN FD and CAN XL when payload data is over 8 bytes)

Data containers holding the TX payload buffer can be declared anywhere in the S_MEM despite being attached to only one TX descriptor, as depicted in the following figure.

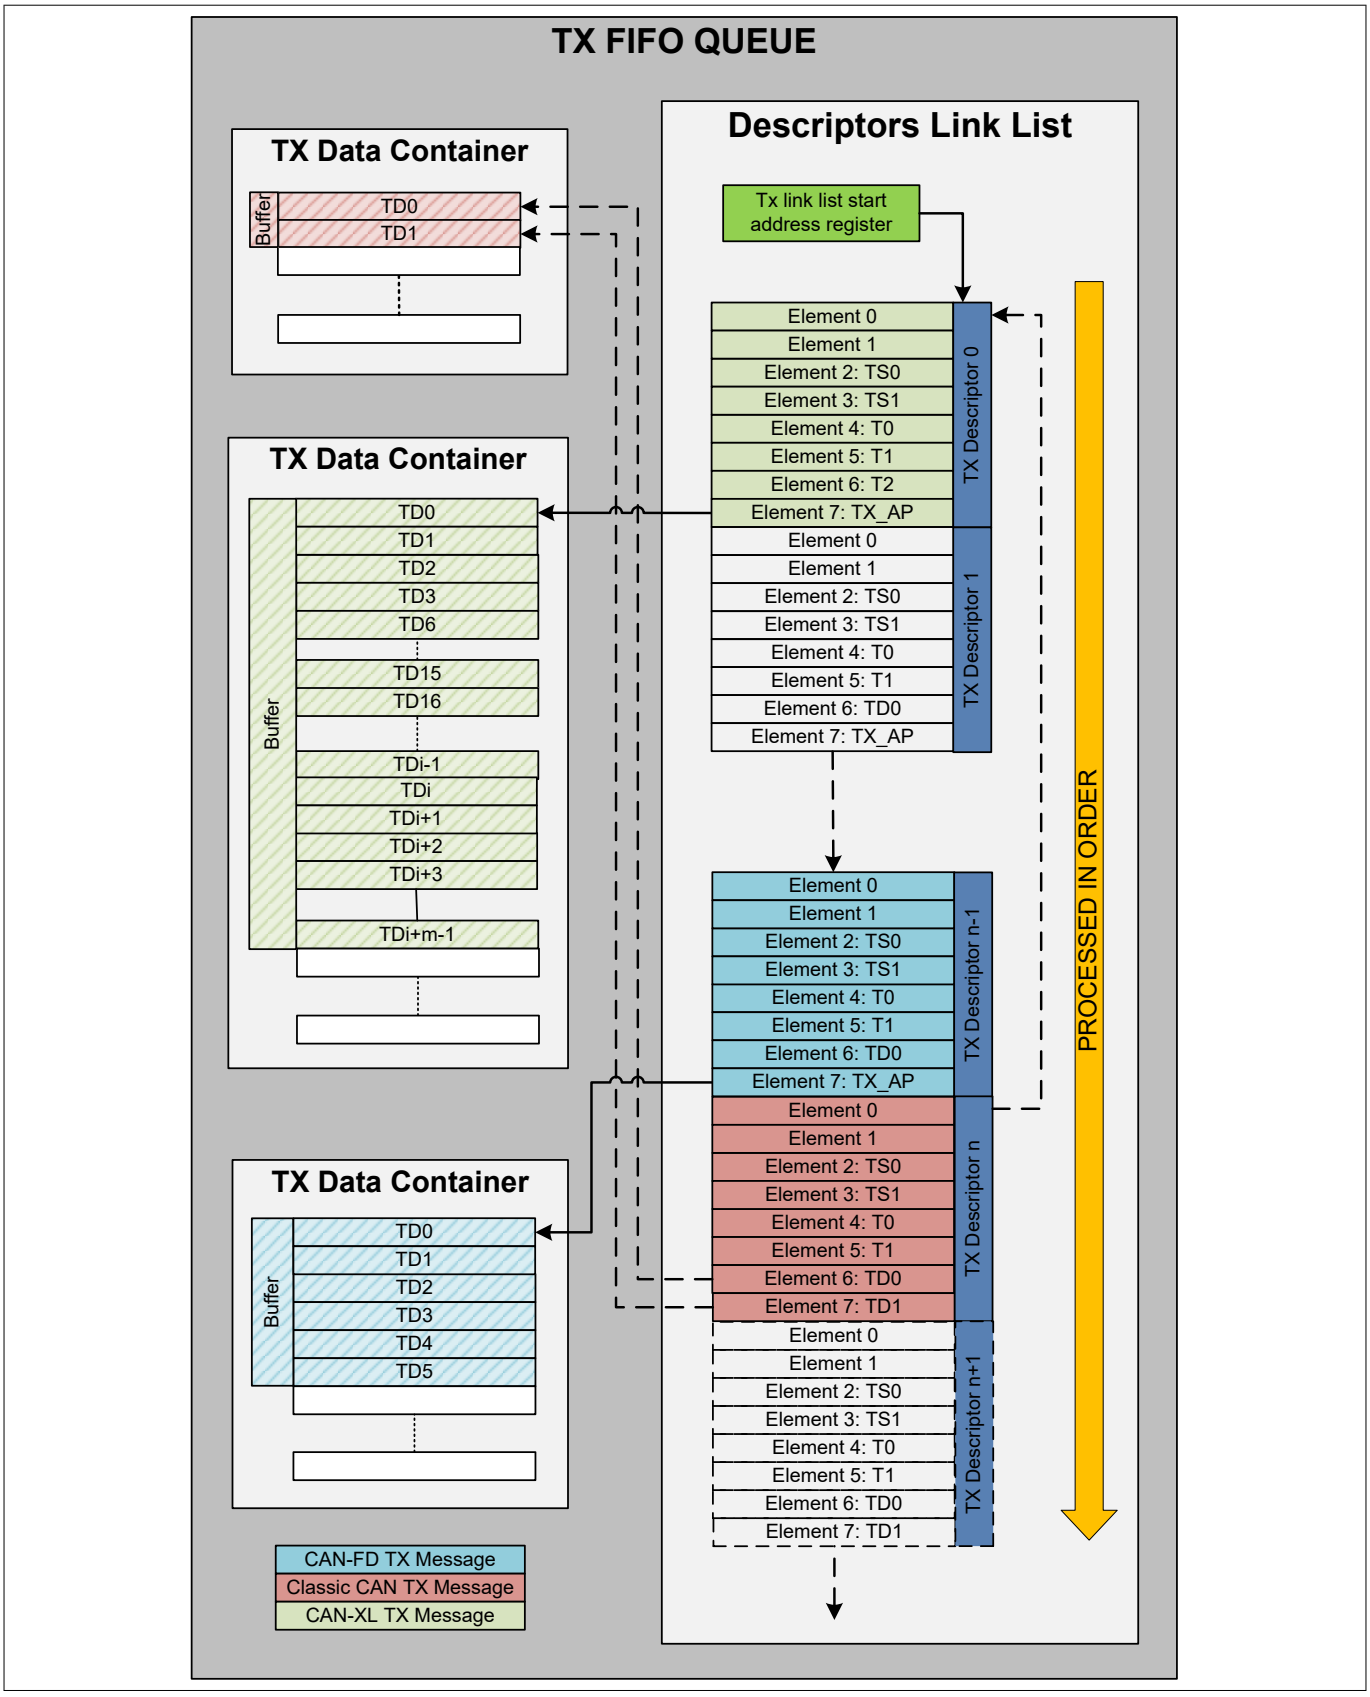

Figure 408 TX FIFO Queue (Basic Mode)

This approach does provide less constraints on system as only one TX descriptor needs to be fetched per TX message. It would be much more efficient in term of performances and memory allocation regarding linked list descriptors.

The only constraint for such configuration would be the memory space allocated to the payload data. As the CAN XL can support up to 2048 bytes, the size of the data container to hold the complete payload could be quite large.

22.5.3.14 TX priority queue

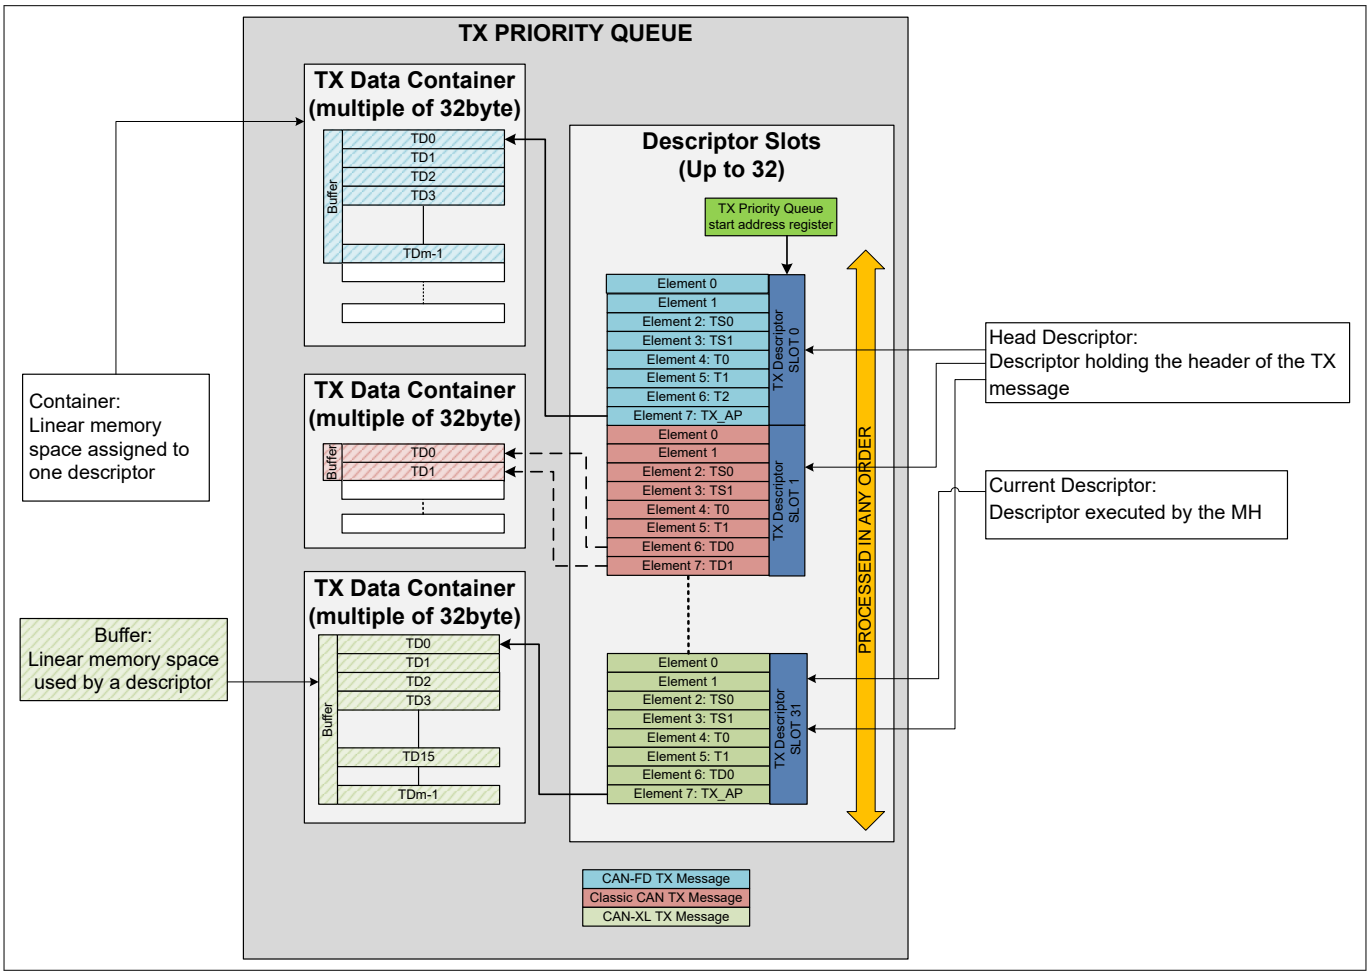

Figure 409 TX priority queue description

This kind of queue does not behave as the TX FIFO Queue but the way messages are defined and how the MH is reading the descriptor are identical.

A TX Priority Queue can be configured with a maximum of 32 slots.

When the SW wants to configure N TX Priority Queue slots, only the slot number from 0 to N-1 can be used.

Every slot is assigned one TX message from a SW point of view. Every slot can be enabled/disabled individually leaving the option to define any number of active slot or none in the SW. Compared to the TX FIFO Queue, there is no order of execution. Any message defined in the TX Priority queue can be selected and executed in any order, only the highest priority message is selected first. Those messages are evaluated against the one currently in use in all TX FIFO Queues.

The same principle is used to define a TX message, meaning some TX descriptors and TX data buffers to define a message. Like the TX FIFO Queues, data buffers hold the payload data of the TX message while descriptor defines header information. In some cases, the first payload data may also be part of the descriptor.

To give a status report and some information like timestamping, the MH writes back some bit field in the TX Header Descriptor. This way the SW is able to track back TX messages sent and identify those with issues.

The TX Priority Queue is using the same data path as the one defined and implemented for the TX FIFO Queue.

The main difference between the two queues is:

- The Priority Queue is managed in any order. As soon as a slot over the 32 is available, a new message can be defined
- The SW needs to trigger the MH to consider a new message in a slot
- The SW needs to read status register to identify which message has been sent

Prior to launch any TX Priority Queue slot, the MH must be started (Ni_MH_CTRL.START written to 1 will drive the Ni_MH_STS.BUSY bit status to 1). To start the TX Priority Queue slot n, write 1 to the Ni_TX_PQ_CTRL0.START[n]. Before launching a TX Priority Queue slot n, it must be enabled by setting the Ni_TX_PQ_CTRL2.ENABLE[n] bit to 1. Once enabled and started, there is no way to disable it while running without a defined procedure. Instead, the abort bit Ni_TX_PQ_CTRL1.ABORT[n] provides a way to stop a TX Priority Queue slot n running and to ensure a safe stop and flush of ongoing data. For more detail on starting and stopping TX Priority Queue slots, refer to the Application Information chapter.

To ensure that no dead lock can occur at start, the ENABLE signal from the PRT must be high to allow any TX Priority Queue to start. This signal status can be monitored in the Ni_MH_STS.ENABLE bit field.

As soon as one or several slots of the TX Priority Queue are started, the MH will fetch the relevant TX descriptors defined at those locations and stores them in L_MEM. When the TX descriptors are available in the L_MEM, they will be part of the arbitration process. As long as the TX messages defined by those TX descriptors are not sent to the CAN bus, they will remain for all the arbitration runs. It is important to note the TX FIFO Queue's messages are also part of this arbitration process.

When the TX message is sent successfully, the TX Priority Queue slot is released and set inactive. A TX_PQ_IRQ interrupt can be triggered to the SW when the last data of the TX message is sent. The other option would be to poll the corresponding status bit register, to identify when the transfer has completed. This last approach requires much more CPU time compare to the interrupt one.

As the TX message to select is based on an arbitration process, the TX Priority Queue execution will run at a different rate compared to the TX FIFO Queues. If TX messages are defined into the TX Priority and have highest priority they will go before TX FIFO Queues. The SW can add new messages at any time when a slot is available.

If for some reason a TX Priority Queue slot n needs to be stopped, it is still possible to abort the execution of that slot. When such action is performed, the TX Priority Queue slot n will be considered as no more active. If the TX message assigned to this slot is already in progress to the CAN bus or has been selected as the next message to be sent, it will not be canceled. By using a register status, it is possible to identify if the slot aborted has been done before or after the sending of the TX message.

Any safety issue related to a TX descriptor executed by a TX Priority Queue slot is declared as no more valid. This means, it will not be part of the arbitration process with the other slots but will not prevent the others to be executed. To identify such issue a TX_DESC_CRC_ERR is sent to the system. Despite this TX Priority Queue slot is stopped, the others will keep going with their own TX descriptors.

If some message does not go through for the two following reasons, maximum number of restart reached or invalid header format, the message is discarded. The error status being detected is written back to the TX descriptor holding the header data.

There is a way to keep track of the TX descriptors used for a given TX FIFO Queue, refer to the Trace and Debug chapter.

A TX Priority Queue is controlled and monitored using several registers and bit registers:

- The Ni_TX_PQ_START_ADD register to define the start address of the TX Priority Queue
- The Ni_TX_PQ_CTRL0.START[n] (where n is 0-31) bit register to launch the TX Priority Queue slot n
- The Ni_TX_PQ_CTRL1.ABORT[n] (where n is 0-31) bit register to abort the execution of the TX Priority Queue slot n

- The Ni_TX_PQ_CTRL2.ENABLE[n] (where n is 0-31) bit register to enable the TX Priority Queue slot n prior to use it
- The Ni_TX_DESC_ADD_PT register to monitor the current address pointer
- The Ni_TX_PQ_STS0.BUSY[n] (where n is 0-31) bit register to know the status of the TX Priority Queue slot n, either busy (TX Priority Queue Slot is having a TX message to send) or not busy (Slot is no more active for reasons like message sent, safety issue, ...)
- The Ni_TX_PQ_STS1.SENT[n] (where n is 0-31) bit register to know the status of the TX message assigned to the TX Priority Queue slot n, either sent (TX message assigned to slot n is sent) or not sent (could be for different reasons like safety issue, max retransmission counter reached, ...)
- The Ni_TX_PQ_INT_STS0.SENT[n]/ Ni_TX_PQ_INT_STS1.SENT[n] and Ni_TX_PQ_INT_STS0.UNVALID[n]/ Ni_TX_PQ_INT_STS1.UNVALID[n] (where n is 0-31) bit register to identify respectively, a message is transmitted or an invalid TX descriptor is detected

A TX Priority Queue is being controlled for any issue using common bit registers:

- The Ni_SFTY_INT_STS.TX_DESC_CRC_ERR and Ni_SFTY_INT_STS.TX_DESC_REQ_ERR bit registers to identify respectively, any CRC issue on TX descriptor running in the TX FIFO Queue n and non-expected TX descriptor
- The Ni_ERR_INT_STS.DP_TX_ACK_DO_ERR bit register to identify overflow on TX ACK data path for the TX FIFO Queues
- The Ni_ERR_INT_STS.DP_TX_SEQ_ERR bit register to identify if an issue occurs on the TX_MSG interface

22.5.3.15 RX FIFO queue in normal mode

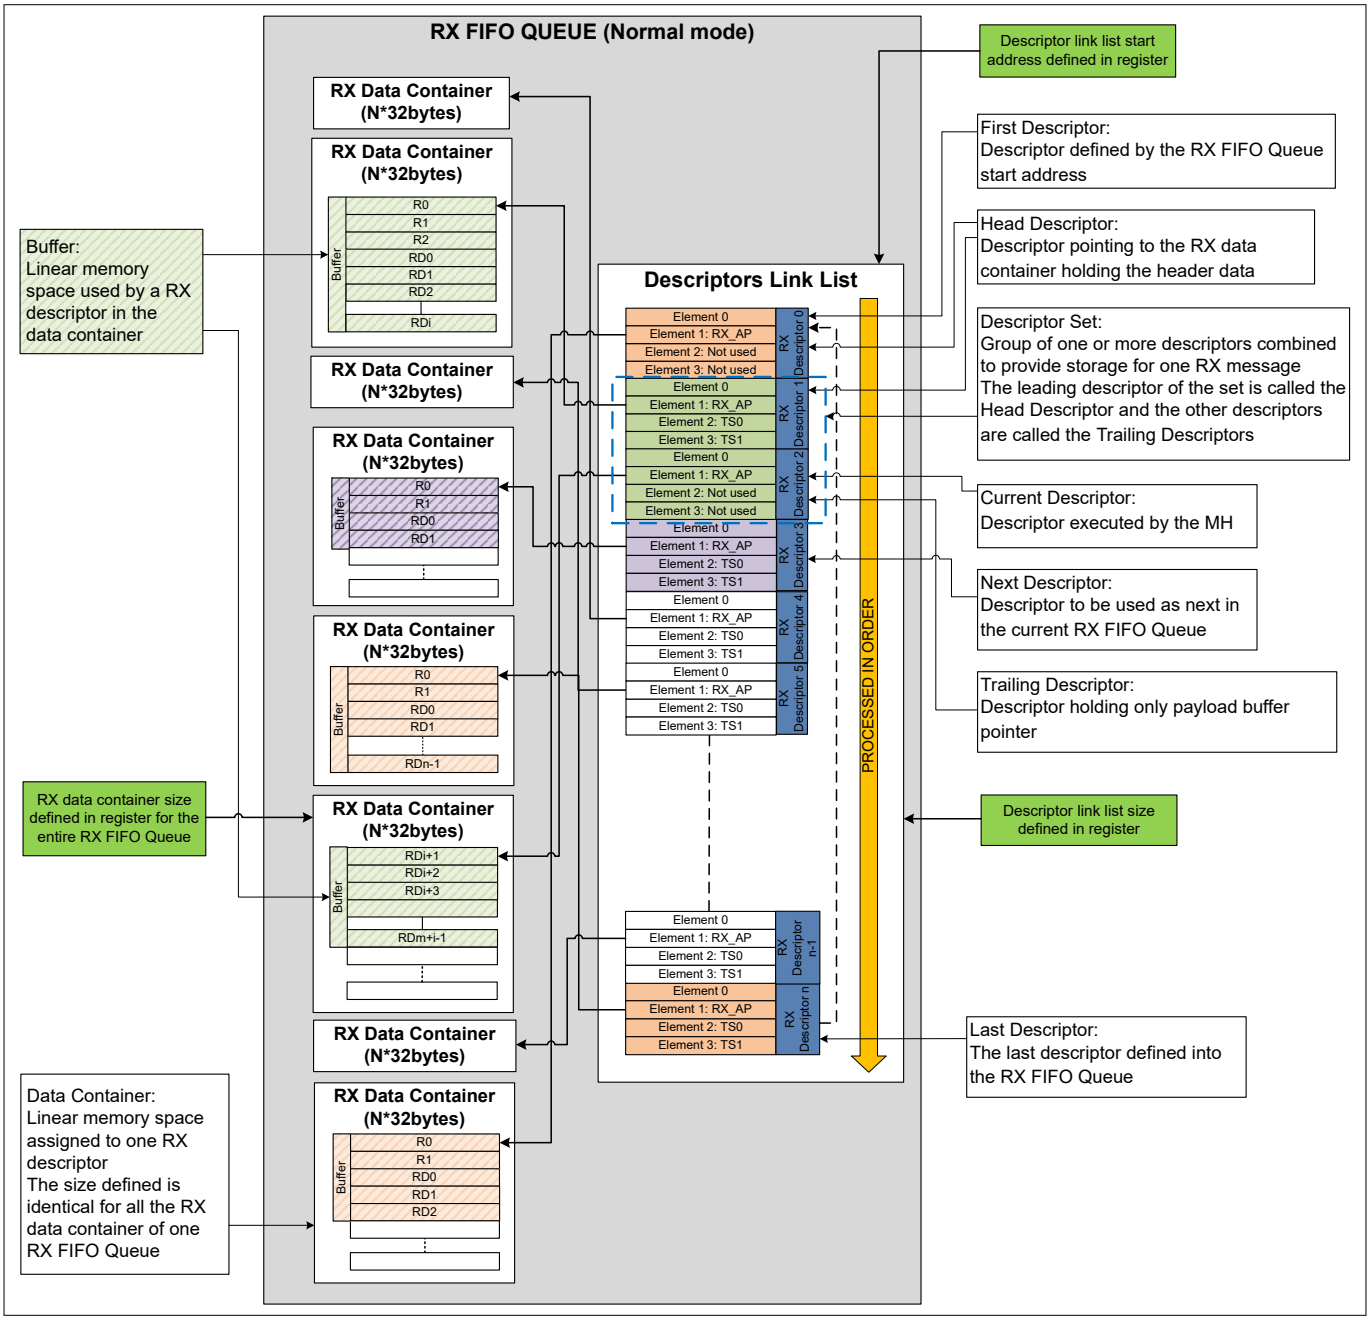

Figure 410 RX FIFO queue description

Up to 8 RX FIFO Queue can be defined and managed by the MH. An RX FIFO Queue is a list of RX descriptors pointing to RX data container to store the RX messages received by the PRT.

The RX filtering rules, programmed by the SW, define if a message is rejected or accepted and in case it is which RX FIFO Queue is receiving the message. If a message is rejected it will not appear in any of the FIFOs. Each one being fully independent from the others, the MH appends new RX message as they arrive on the CAN Bus.

The mechanism to manage RX FIFO Queues is based on the concept of link list. Any RX FIFO Queue is defined using a link list of RX descriptors and RX data container. Those containers are used to write the RX message data to the S_MEM and have fix size over the entire RX FIFO Queue. A different size could be defined per RX FIFO Queue but must always be a multiple of 32 byte.

The size of the data container is programmable to store small or large RX message payload data, if required. Up to Ni_RX_FQ_SIZE{n}.DC_SIZE[6:0] * 32byte data container size can be defined per RX descriptor in an RX FIFO Queue n. As the size is programmable per RX FIFO Queue, it is then possible to limit the memory footprint according to the expected message to be received.

A link list is made of descriptors, where a descriptor is defined by several data elements of the same size, the element is 32 bit word. Each element provides some information or would define some actions to perform. A descriptor is built by the SW but will be read and executed by the MH. Every descriptor is of the same size, pointing to a data container and also to the next descriptor. The link between descriptor is just a fix offset, as they are continuous in memory (to ease and simplify implementation). Therefore, it is not required to declare or use a bit field to mention the position of the next descriptor as it is implicit (dashed lines). As data containers have a fix size and the RX message received may change in size, several descriptors could be required.

As messages are received in a continuous way, the RX FIFO Queue are used in a circular buffer mode. This means when the Last Descriptor is reach the MH will consider the First Descriptor as the next descriptor. The Last Descriptor is defined by the size of the RX FIFO Queue and the start address of the RX FIFO Queue.

An RX filter in MH is used to accept or reject RX messages. If a message is accepted, it is then sent to a defined RX FIFO Queue. The RX filter builds over time those queues with messages based on the filtering result. It is up to the SW to read them in time.

The RX filter observes all the incoming RX messages to identify the right RX FIFO Queue. Once defined, the first RX descriptor attached to the selected RX FIFO Queue is fetched and used to write the incoming data to the S_MEM. As soon as the incoming RX data is increasing above the limit of the data buffer pointed by the current RX descriptor a new one is fetched to keep going. This process repeats up to last RX data received.

The MH will proceed with all the RX FIFO Queues the same way. As the RX FIFO Queue selected depends on the RX filtering result, the RX FIFO Queues will be fill up at a different rate.

Prior to launching any RX FIFO Queue, the MH must be started (Ni_MH_CTRL.START written to 1 will drive the Ni_MH_STS.BUSY bit status to 1). To start the RX FIFO Queue n, write 1 to the Ni_RX_FQ_CTRL0.START[n]. Before launching an RX FIFO Queue n, it must be enabled by setting the Ni_RX_FQ_CTRL2.ENABLE[n] bit to 1. Once enabled and started, there is no way to disable it while running without a defined procedure. Instead, the abort bit Ni_RX_FQ_CTRL1.ABORT[n] provides a way to stop an RX FIFO Queue n running and to ensure a safe stop and flush of on going data. For more detail on starting and stopping RX FIFO Queues, refer to the Application Information chapter. It is essential to configure and start the relevant RX FIFO Queues before starting the PRT. When the MH is not started and so no RX FIFO Queues are started, the MH will not accept any RX data, leading to a PRT data overflow.

Each RX FIFO Queue can be managed individually, SW can decide to enable or disable any queue according to the way RX messages must be managed. Once the RX filter is defined and the PRT is receiving messages any change on the RX FIFO Queue setting is not possible. There is still a mechanism to abort an flush an RX FIFO Queue while others are running.

Once a link list is started and an RX message needs to be written inside, the first descriptor in the list is read. It is executed and the data buffer assigned to it, written. Other actions could be defined into the element data like triggering an interrupt or setting flags. The link list is processed one descriptor at a time, if more RX descriptor is required for a given message, the next one into the list is fetched (or could have been fetched earlier) and the process repeats itself. The process keeps going up to the last descriptor of the link list, a wrap will occur automatically at this time.

If the size of the container is small, the RX message with few payload data may fit in but larger one would require several descriptors and containers. This approach optimizes the memory usage as the number of containers used is very close to the effective size of the RX message received. But on the other way, such strategy requires more descriptors and Data Container.

If we consider the other way round, large data container avoids splitting data buffers and limits the number of descriptors. The main disadvantage would be the usage of more memory per descriptor.

This is up to the SW to find the best tradeoff according to the CAN protocol and to the application required. There is also the option to size differently the data container for every RX FIFO Queue, leaving some flexibility of optimization.

Before receiving any RX message the RX FIFO Queues must be started. In case some messages are received and the RX FIFO Queue to write data is not active the RX message is rejected and an RX_ABORT_IRQ interrupt is triggered to the system.

To give a status report and some information like timestamping, the MH is also able to write back some elements in the RX or TX descriptors. Not all of them are written back but only the one having the header data defined.

The same remark regarding TX descriptors and TX data buffer location into memory applies for the RX descriptors and data buffers.

The SW must always ensure that some RX descriptors in the RX FIFO Queue are always valid (VALID bit set to 0). In case an RX descriptor is not valid the RX FIFO Queue n is stopped and an interrupt RX_FQ_IRQ is sent to the system. If the system provides a valid RX descriptor and restarts the RX FIFO Queue n in time the RX message could may be written into memory, otherwise the message is rejected and the interrupt RX_FQ_IRQ is triggered to the system.

Up to 1023 RX descriptors can be defined for an RX FIFO Queue. The size of the RX FIFO Queue is defined such a way when the Last Descriptor is reached, the MH wraps automatically to its initial start address to get the First Descriptor.

If for some reasons an RX FIFO Queue has an error, it is still possible to abort the execution of that FIFO Queue. When such action is performed, the RX FIFO Queue will be considered as active as long as the current data transfer assigned to an RX descriptor is not finished. This means no more fetches are done and the RX FIFO Queue is set inactive.

Any issue related to an RX descriptor executed by an RX FIFO Queue will stop it right away. To identify such issue some interrupts are triggered to the system, RX_DESC_CRC_ERR or RX_DESC_REQ_ERR. Despite this RX FIFO Queue is stopped, the others will keep going through their own RX descriptors.

An RX FIFO Queue is controlled and monitored using several registers and bit registers:

- The Ni_RX_FQ_START_ADD{n} (where n is 0-7}) bit register to define the start address of the RX FIFO Queue n
- The Ni_RX_FQ_CTRL0.START[n] (n € {0, 1, 2, …, 7}) bit register to launch the RX FIFO Queue n
- The Ni_RX_FQ_CTRL1.ABORT[n] (where n is 0-7}) bit register to abort the execution of the RX FIFO Queue n
- The Ni_RX_FQ_CTRL2.ENABLE[n] (where n is 0-7}) bit register to enable the RX FIFO Queue n prior to use it
- The Ni_RX_FQ_SIZE{n}.MAX_DESC and Ni_RX_FQ_SIZE{n}.DC_SIZE (where n is 0-7}) bit register to define respectively, the maximum number of RX descriptor before looping back to the initial start address and the Data Container size for the RX FIFO Queue n
- The Ni_RX_FQ_ADD_PT{n} (where n is 0-7}) register to monitor the current address pointer of the RX FIFO Queue n
- The Ni_RX_FQ_STS0.BUSY[n] and Ni_RX_FQ_STS0.STOP[n] (where n is 0-7}) bit registers to know respectively, the status of the RX FIFO Queue n, busy (RX FIFO Queue is active) and stopped or running or not started
- The Ni_RX_FQ_STS1.ERROR[n] and Ni_RX_FQ_STS1.UNVALID[n] (where n is 0-7}) bit registers to identify the root cause of the RX FIFO Queue being stopped, an error is detected or a RX descriptor is invalid
- The Ni_RX_FQ_INT_STS.RECEIVED[n] and Ni_RX_FQ_INT_STS.UNVALID[n] (where n is 0-7}) bit registers to identify respectively, a message is received and an invalid RX descriptor is detected

An RX FIFO Queue is being controlled for any issue using common bit registers:

- The Ni_SFTY_INT_STS.RX_DESC_CRC_ERR and Ni_SFTY_INT_STS.RX_DESC_REQ_ERR bit registers to identify respectively, any CRC issue on RX descriptor running in the RX FIFO Queue n and non-expected RX descriptor

- The Ni_ERR_INT_STS.DP_RX_ACK_DO_ERR bit register to identify overflow on RX ACK data path for the TX FIFO Queues
- The Ni_ERR_INT_STS.DP_RX_FIFO_DO_ERR bit register to identify overflow on RX DMA FIFO for the RX FIFO Queues
- The Ni_ERR_INT_STS.DP_RX_SEQ_ERR bit register to identify if an issue occurs on the RX_MSG interface

22.5.3.15.1 Fragmented data container

The RX Data Container can be defined into any location and so an RX message is split across several area in the S_MEM. With such approach, an address pointer is given to the application for any RX message data, no copy is performed. A new Data Container is then allocated to replace the one being sent to the application. It is important to note that in case of RX message received into several Data Container, several address pointers will need to be provided. It is assumed that Data Containers that belongs to the same message can only be released once all RX buffer data have been read.

When the MH has executed the Last Descriptor (the descriptor defined at the latest position in the Descriptor Link List), it wraps automatically to the First descriptor.

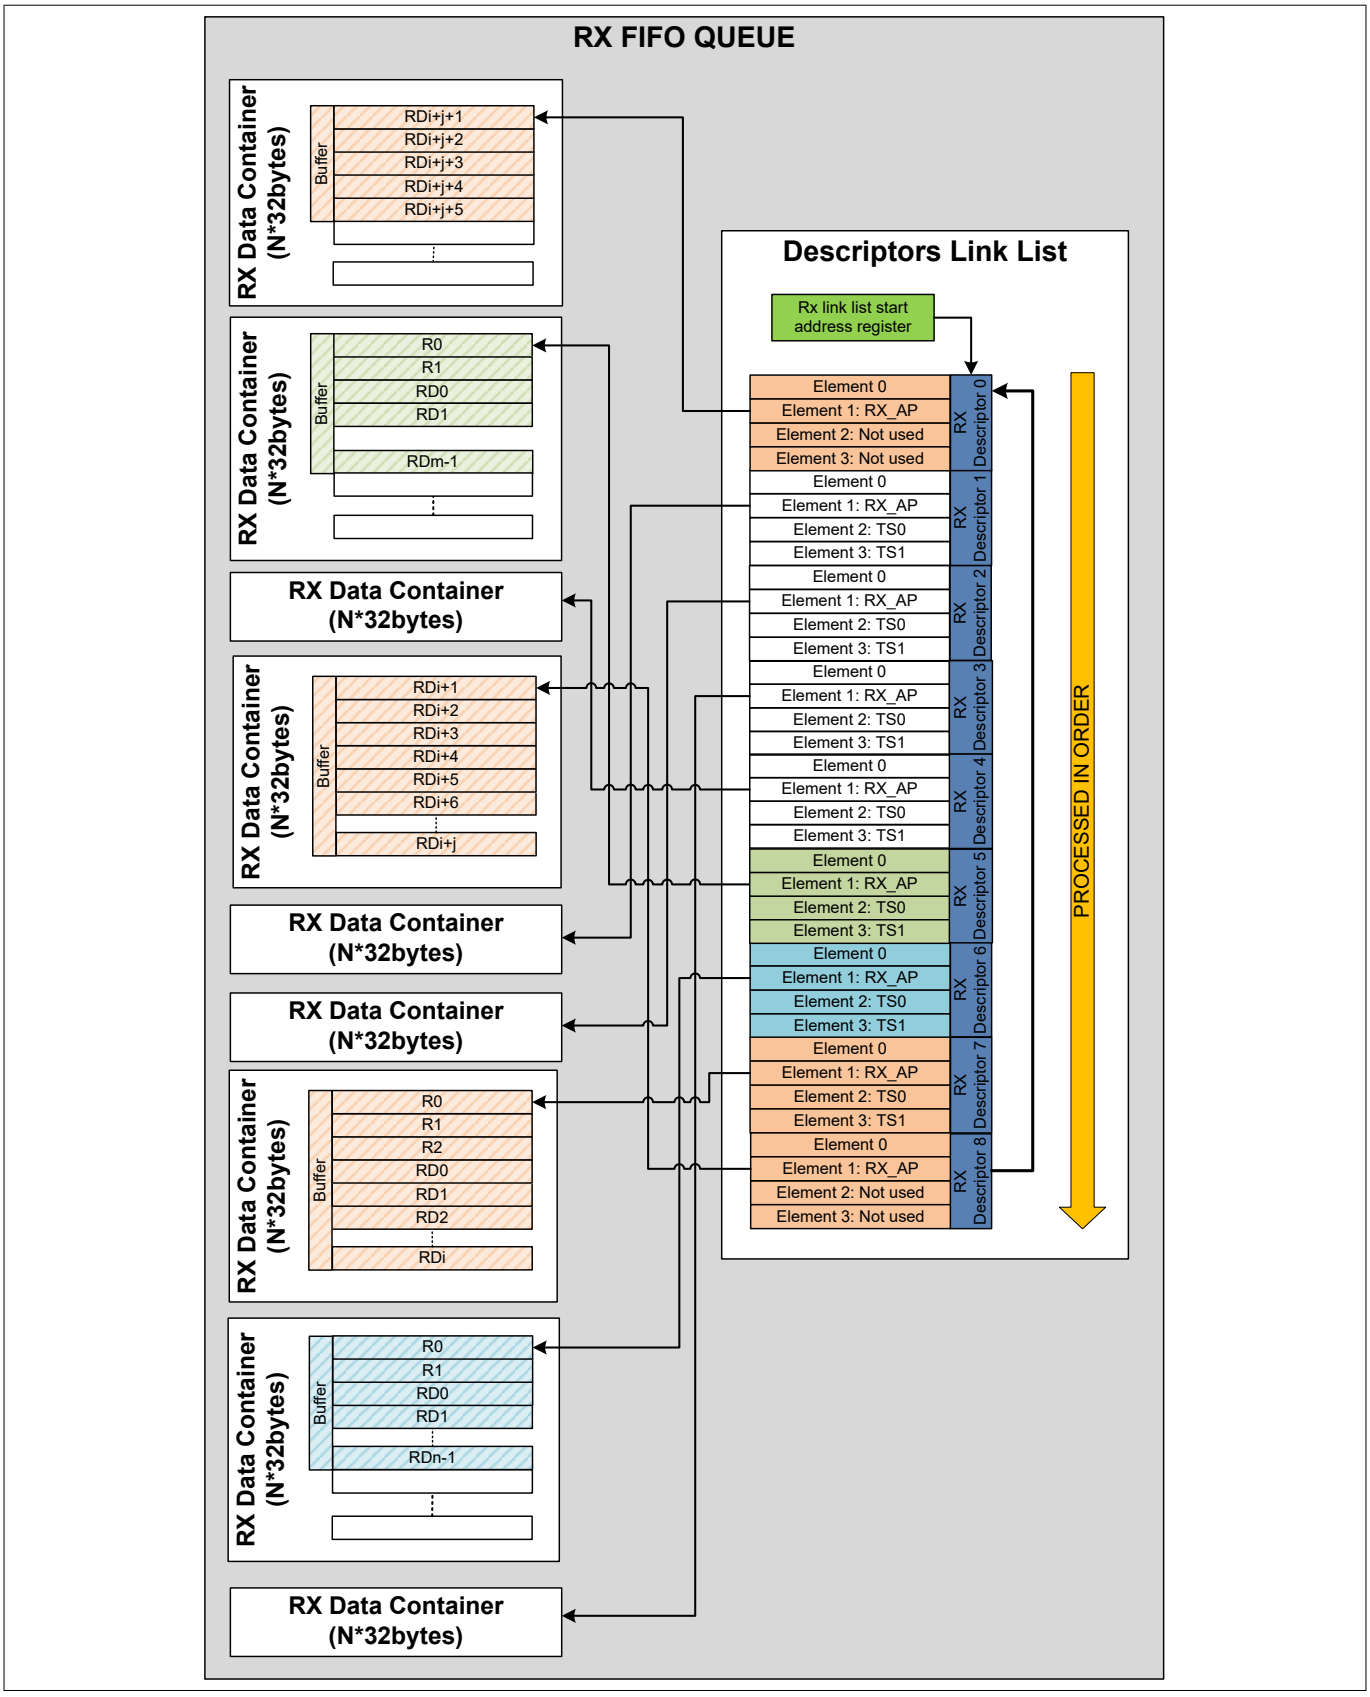

Figure 411 RX FIFO Queue in Normal mode (Fragmented data containers)

In some cases the RX message can then be split across RX descriptor being at the top and at the bottom of an RX FIFO Queue. This mode does make use of all the RX descriptors defined in a given RX FIFO Queue. It may

happen that SW would prefer to rely on linear RX message, having in mind a linear organization of data containers in S_MEM, see Continuous data container chapter.

22.5.3.15.2 Continuous data container

As the RX data containers of the same message are spread to different location in L_MEM, it will not be easy for the SW to read the entire message. To get around this issue, the SW can decide to declare the RX Data Container in a linear memory area and to have them continuous to each other as depicted below.

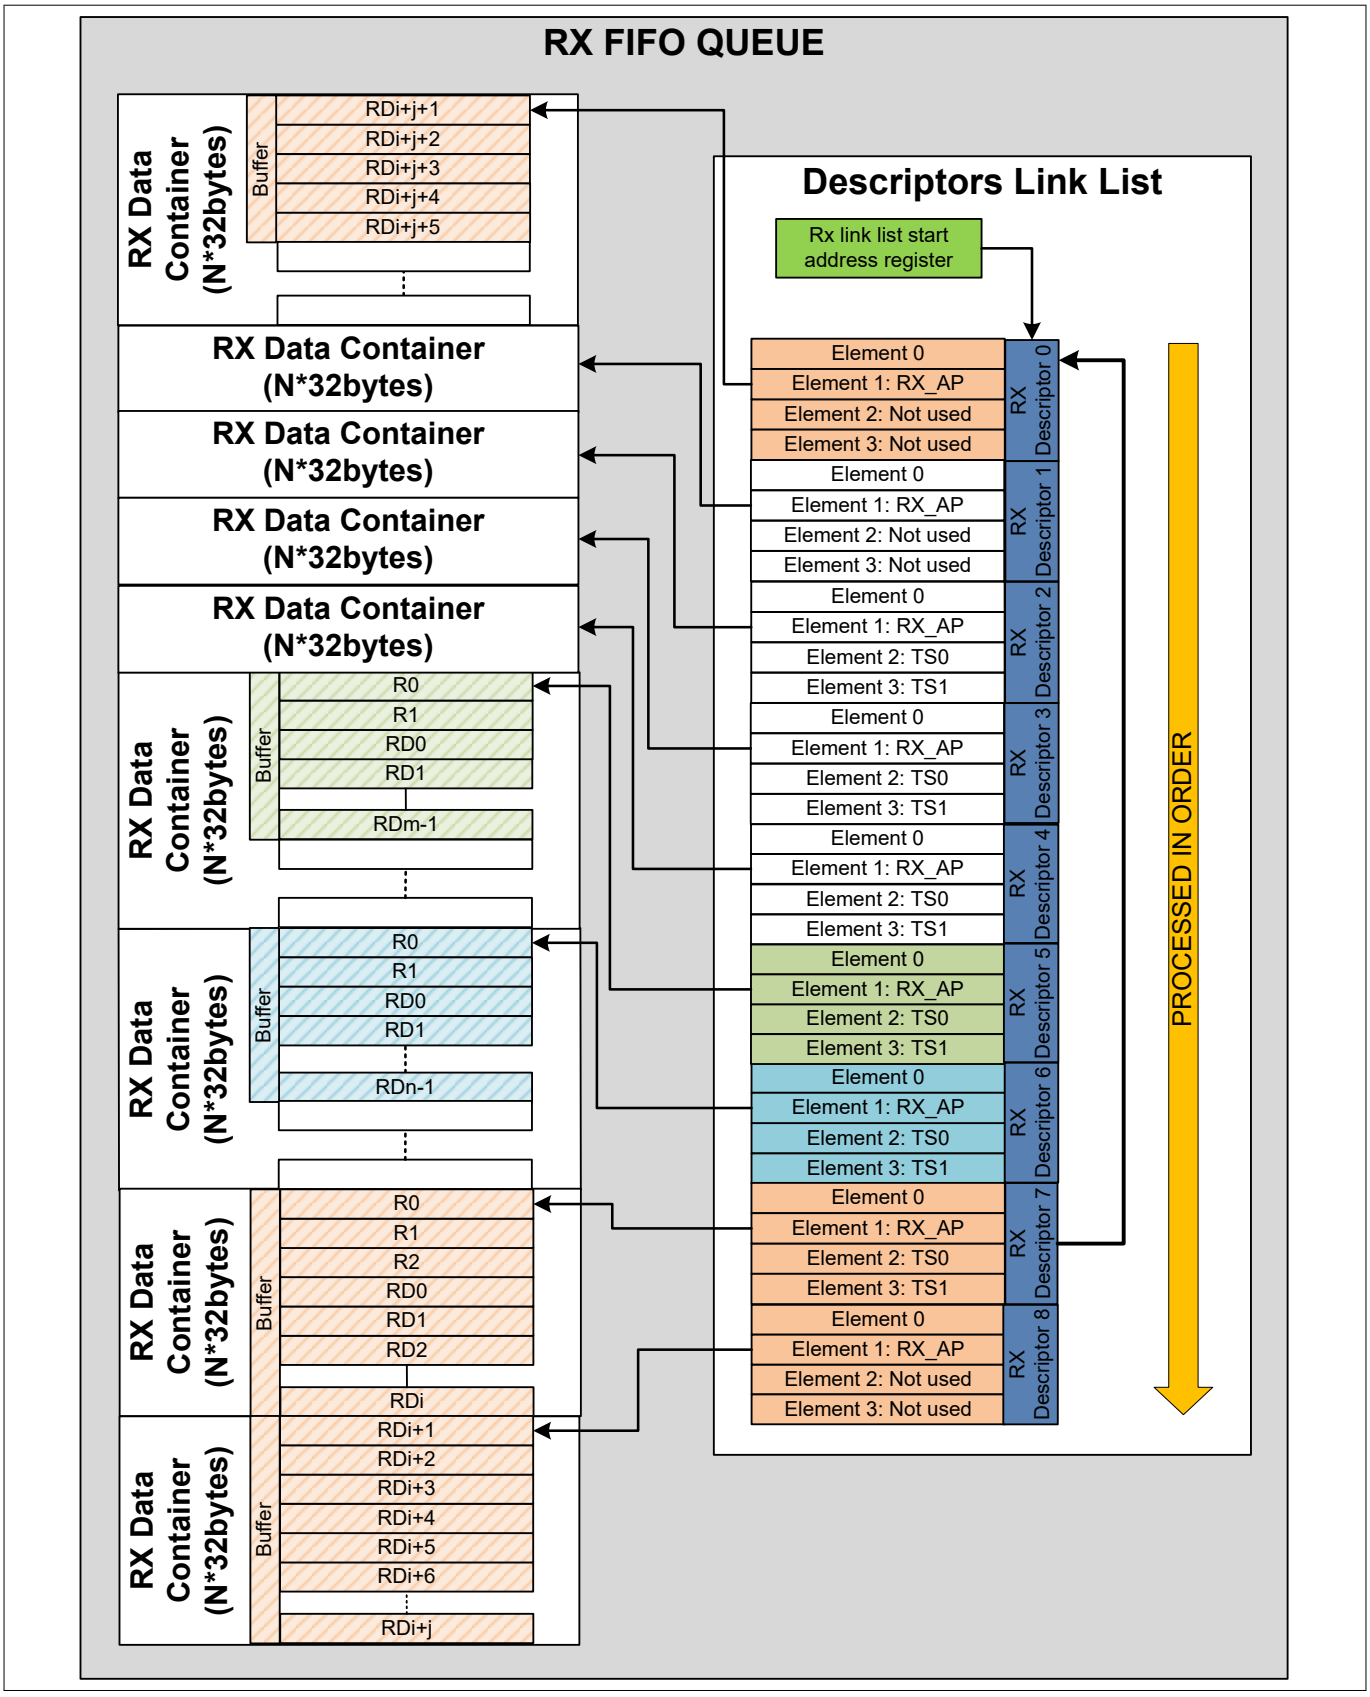

Figure 412 RX FIFO Queue in Normal Mode (Continuous Data Container)

This way of managing the RX message will have the main advantage to provide an RX message written in a linear memory area, despite being split in several data containers.

The only exception would be when the Last Descriptor is used and the message size exceed the Data Container. The MH wraps and uses the First Descriptor to keep going with the current RX message data. In this particular scenario the RX message data is split over the top and the bottom of the data container and the same applies for the link list holding the RX descriptor. This is normal behavior and it must not be an issue for the SW to read the RX message following the RX descriptor list from bottom to top.

This configuration provides a pseudo linearity for the RX messages in S_MEM, excepted at the borders. Doing so, the SW would need to perform a copy of the RX message data to free the memory area for the new incoming messages. Such configuration does not require any update on address pointer in the RX descriptors. Only the VALID bit needs to be written by the SW to acknowledge the reading of the RX message and the update of the read address pointer register.

22.5.3.16 RX FIFO queue in continuous mode

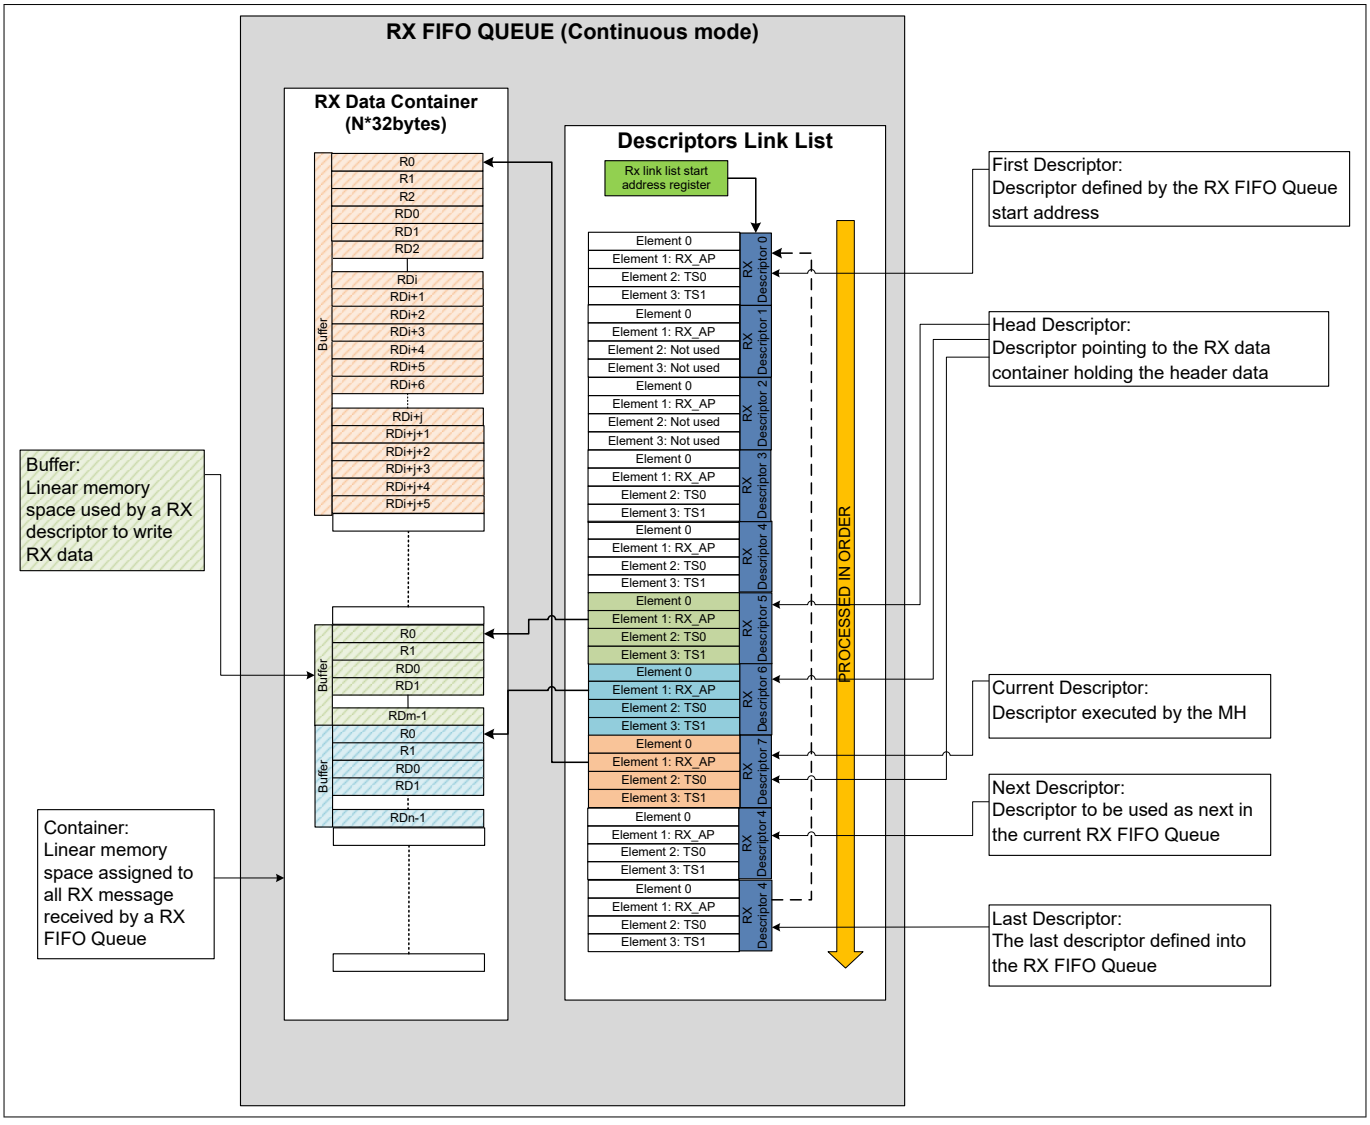

Figure 413 RX FIFO queue continuous mode

The same principle as defined in the RX FIFO Queue in Normal mode applies for the RX descriptors in this Continuous mode. The way they are used, managed and defined remain, see RX FIFO Queue in Normal mode chapter.

The main difference is coming from the structure of the RX message data being stored in the S_MEM. An RX FIFO Queue when in Continuous mode is a list of RX descriptors pointing to a large and single data container to store all the RX messages received by the PRT.

The RX filtering rules, programmed by the SW, define if a message is rejected or accepted, and in case it is which RX FIFO Queue is receiving the message. If a message is rejected it will not appear in any of the FIFOs. Each one being fully independent from the others, the MH appends to RX FIFO Queues new RX message as they arrive on the CAN Bus. The RX filter builds over time those queues with messages based on the filtering result. It is up to the SW to read them in time.

The mechanism to manage RX FIFO Queues is based on the concept of link list. Any RX FIFO Queue when in Continuous mode is defined using a link list of RX descriptors and a large data container.

As messages are received in a continuous way, the RX FIFO Queue are used in a circular buffer mode. This means when the Last Descriptor is reach the MH will consider the First Descriptor as the next descriptor. The Last Descriptor is defined by the size of the RX FIFO Queue and the start address of the RX FIFO Queue.

The RX filter observes all the incoming RX messages to identify the right RX FIFO Queue. Once defined, the current RX descriptor attached to the selected RX FIFO Queue is fetched and used to define the new incoming RX message data.

The MH will proceed with all the RX FIFO Queues the same way. As the RX FIFO Queue selected depends on the RX filtering result, the RX FIFO Queues will be fill up at a different rate.

Every RX FIFO Queue can be managed individually, SW can decide to enable or disable any queue according to the way RX messages must be managed. Once the RX filter is defined and the PRT is receiving messages any change on the RX FIFO Queue setting is not possible. There is still a mechanism to abort and flush an RX FIFO Queue while others are running.

Once an RX FIFO Queue is started and an RX message needs to be written in its corresponding data container, the First descriptor in the descriptor list is read. It is executed and the initial start address of the data container assigned to it. The link list is processed one descriptor at a time every time a new RX message is received by the same RX FIFO Queue. The process keeps going up to the Last descriptor of the link list before making a wrap. Other actions could be defined in the RX descriptor like triggering an interrupt or setting flags.

The MH writes messages as they arrive, to avoid overwritting. The SW needs to write the address value of the current message being read to a MH register. Therefore, the MH can compute the exact memory left to be used by the new RX message.

The size of the data container is programmable to store many CAN XL frames if required. Up to Ni_RX_FQ_SIZE{n}.DC_SIZE[11:0] * 32byte data container size can be defined for a data container assigned to an RX FIFO Queue. As the size is programmable per RX FIFO Queue, it is then possible to limit the memory footprint according to the expected message to be received.

Before receiving any RX message the RX FIFO Queues must be started. In case some messages are received and the RX FIFO Queue to write data is not active the RX message is rejected and an RX_ABORT_IRQ interrupt is triggered to the system.

To give a status report and some information like timestamping, the MH is also able to write back some elements in the RX or TX descriptors. Not all of them are written back but only the one having the header data defined.

The same remark regarding TX descriptors and TX data buffer location into memory applies for the RX descriptors and data buffers.

The SW must always ensure that some RX descriptors in the RX FIFO Queue are always valid (VALID bit set to 0). In case an RX descriptor is not valid the RX FIFO Queue n is stopped and an interrupt RX_FQ_IRQ is sent to the system. If the system provides a valid RX descriptor and restarts the RX FIFO Queue n in time the RX message could may be written into memory, otherwise the message is rejected and the interrupt RX_FQ_IRQ is triggered to the system.

In the Continuous mode, one RX descriptor is assigned to one message, thus, once the SW has read the message, the VALID bit can be set to 0 right away. The SW is in charge, once the message is read, to set the read

address pointer in the MH register. The MH uses this information to estimate if the incoming message data can be written safely in the data container.

Up to 1023 RX descriptors can be defined for an RX FIFO Queue. The size of the RX FIFO Queue is defined such that when the Last Descriptor is reached, the MH wraps to its initial start address to fetch the First Descriptor. As the RX FIFO Queue size for the RX descriptors is defined at first time and cannot be changed once the RX FIFO Queue is started, the MH wraps automatically to keep going.

If, for some reasons, an RX FIFO Queue has an error, it is still possible to abort the execution of that FIFO Queue. When such action is performed, the RX FIFO Queue will be considered as active, as long as the current data transfers, assigned to an RX descriptor, are not finished. This means, there is no pending transaction attached to the RX FIFO Queue, this includes the RX descriptor acknowledge when an RX message is received. The RX_FQ_IRQ interrupt is triggered to the system, if enable, once the last RX message is received by the aborted RX FIFO Queue n.

Any issue related to an RX descriptor that is executed by an RX FIFO Queue will stop it right away. To identify such issue, some interrupts are triggered to the system, RX_DESC_CRC_ERR or RX_DESC_REQ_ERR. Despite of having this RX FIFO Queue stopped, the other ones will keep going through their own RX descriptors.

An RX FIFO Queue is controlled and monitored using several registers and bit registers:

- See the all registers already defined for the Normal mode
- The Ni_RX_FQ_DC_START_ADDn (where n is 0-7) register to be written by the software to indicate to the MH the read address pointer in the data container for the RX FIFO Queue n
- The Ni_RX_FQ_STS2.DC_FULL[n] (where n is 0-7) bit register to identify the root cause of the RX FIFO Queue being stopped, there is no space left on the system memory to write new RX data. This issue may occur only if the MH is set to Continuous Mode
- In case of Continuous mode, the Ni_RX_FQ_RD_ADD_PTn (n € {0, 1, ..., 7}) register must be initialized to {Ni_RX_FQ_RD_ADD_PTn.VAL | 0b11} otherwise left to its default value

An RX FIFO Queue is being controlled for any issue using common bit registers:

- See the all registers already defined for the Normal mode

22.5.3.17 TX FIFO queue data flow

The SW defines the TX descriptors for every TX FIFO Queues to be used and declare the TX data buffers assigned to those TX descriptors.

As soon as the TX FIFO Queues are started the TX MH will process and fetch all the relevant TX descriptors and will store them into the L_MEM for arbitration.

Only the TX message having the highest priority ID is sent first. Those messages will compete against the one defined into the TX Priority Queue. Only the TX descriptor holding the header data is written back with status information of the data transfer and timestamp. As soon as one TX descriptor is used from a TX FIFO Queue it will be replaced by the next one of that queue. The TX MESSAGE HANDLER is managing on its own the request for a new descriptor whenever required.

The following data flow describes how the TX FIFO Queues are running in parallel. Here are the different steps when a TX message is selected and/or used:

1. After having sent a TX message from the TX FIFO queue n, the TX MESSAGE HANDLER is sending a request to the DESCRIPTOR MESSAGE HANDLER for the next TX descriptor from that queue
2. The relevant TX descriptor of the TX FIFO Queue is fetched by the DESCRIPTOR MESSAGE HANDLER and written to the L_MEM
3. As soon as the new TX descriptor is completely written into the L_MEM an arbitration run is performed. This arbitration will identify which TX descriptor is having the highest priority, looping through the current TX descriptor for every TX FIFO Queues and through all the slot of the TX Priority Queue declared as active. Once the two first candidates position (Priority Queue slot number or TX FIFO queue number) are defined, they are loaded in the TX MESSAGE HANDLER

4. The TX MESSAGE HANDLER is then trying to upload the TX message with the highest priority locally. If a TX message is in progress, the TX MESSAGE HANDLER will wait for the end of the current transmission to read from the L_MEM the complete TX descriptor. If nothing is preventing the upload of the next descriptor, it will be done right away. As soon as the TX descriptor is locally stored the first TX message data are sent to the PRT. The TX MESSAGE HANDLER will wait for the PRT to know if it has won the arbitration process. As long as no new TX descriptor is changing the arbitration result, the selected TX descriptor remains in the TX MESSAGE HANDLER for further arbitration trials. As soon as the TX message is winning the arbitration, all the data contained in the TX descriptor is sent to the PRT
5. The payload data assigned to the TX descriptor is fetched from the S_MEM.
6. If the TX message is sent successfully, an acknowledge request is sent to the DESCRIPTOR MESSAGE HANDLER with the status and information of the transfer. The DESCRIPTOR MESSAGE HANDLER writes back the acknowledge of that descriptor in the S_MEM. When the DESCRIPTOR MESSAGE HANDLER has finished writing the TX descriptor an interrupt TX_FQ_IRQ for the TX FIFO Queue n may be triggered to the system

As all TX FIFO Queue are processed the same way, the data flow of only one TX FIFO Queue is depicted in the following figure with the reference number for each step.

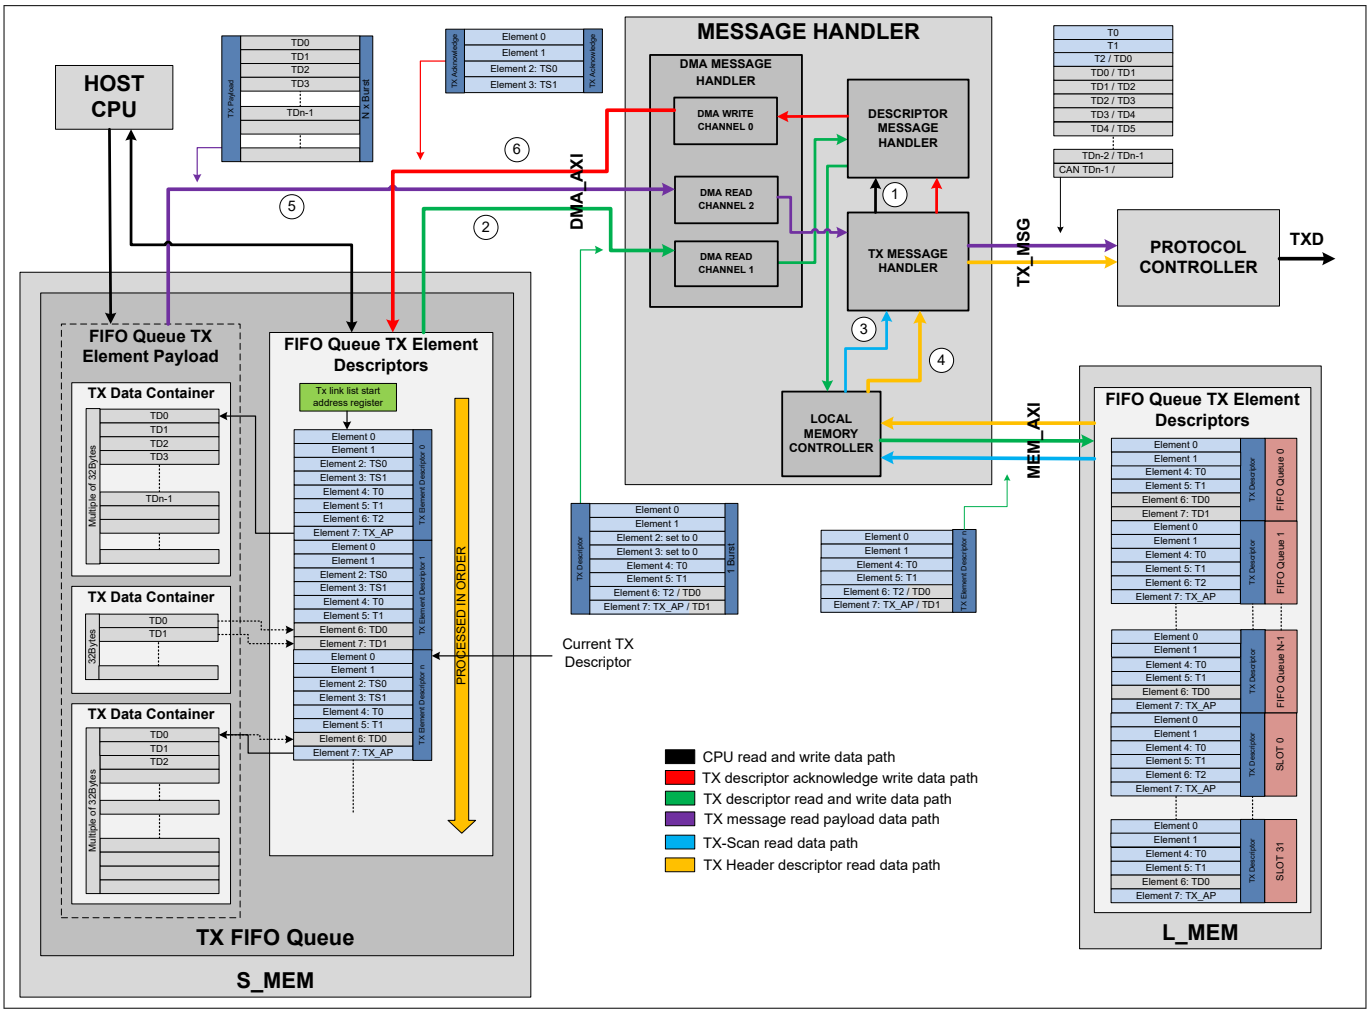

Figure 414 TX FIFO queue data flow

22.5.3.18 TX priority queue data flow

The SW defines the TX descriptors to be sent into the TX Priority Queue slot to be used and declare the TX data buffers assigned to those TX descriptors. Once done the SW triggers the TX MESSAGE HANDLER to have those

messages sent as soon as possible. Those messages will compete against the one defined into the TX FIFO Queues. Only the ID is relevant for the selection of TX messages.

As soon as the TX Priority Queue slots are started the TX MESSAGE HANDLER will process and fetch all the relevant TX descriptors and will store them into the L_MEM for arbitration.

When a TX message is sent, an acknowledge (status information and timestamp) is written back to the TX descriptor holding the header data. As soon as a TX descriptor slot is used from a TX Priority Queue slot, it will be considered as inactive and won't be considered afterwards.

There is a way to keep track of the TX descriptors used for the TX Priority Queue, refer to the Trace and Debug chapter.

The following data flow is relevant for all TX Priority Queue slots.

Here below are the different steps when a TX message is selected and or used:

1. To trigger the TX message defined into the TX Priority Queue, the SW must write the start bit of the corresponding slot. There is nothing preventing the SW to declared several TX message at the same time and to launch them at once. The TX MESSAGE HANDLER is sending requests to the DESCRIPTOR MESSAGE HANDLER for the TX descriptors to be fetched. If several TX descriptors need to be uploaded at once, they would be fetched in the order of their slot number, starting with 0
2. The relevant TX descriptors of the TX FIFO Queue is fetched by the DESCRIPTOR MESSAGE HANDLER and written to the L_MEM
3. As soon as the new TX descriptor is completely written into the L_MEM an arbitration run is performed and only the TX descriptor uploaded for the slot will be considered. This arbitration will identify which TX descriptor is having the highest priority, looping through the current TX descriptor for every TX FIFO Queue and through all slots of the TX Priority Queue declared as active. This selection is performed doing a single read on all defined TX descriptor in the L_MEM. Once the two first candidates are identified, either the TX Priority Queue Slot number and/or the TX FIFO queue number, they are stored locally in the TX MESSAGE HANDLER
4. The TX MESSAGE HANDLER is then trying to upload the TX descriptor with the highest priority locally. If a TX message is in progress, the TX MESSAGE HANDLER will wait for the end of the current transmission to read from the L_MEM the complete TX descriptor. If nothing is preventing the upload of the next descriptor, it will be done right away. As soon as the TX descriptor is stored locally the first TX message data are sent to the PRT. The TX MESSAGE HANDLER will wait for the PRT to know if it has won the arbitration process. As long as no new TX descriptor is changing the arbitration result, the selected TX descriptor remains into the TX MESSAGE HANDLER for further arbitration trials. As soon as the TX message is winning the arbitration, all the data contained into the TX descriptor is sent to the PRT
5. The payload data assigned to the TX descriptor is fetched from the S_MEM.
6. If the TX message is sent successfully, an acknowledge request is sent to the DESCRIPTOR MESSAGE HANDLER with the status and information of the transfer. The DESCRIPTOR MESSAGE HANDLER writes back the acknowledge of that descriptor in the S_MEM. When the DESCRIPTOR MESSAGE HANDLER has finished writing the TX descriptor an interrupt TX_PQ_IRQ for any of the TX Priority Queue slot may be triggered to the system. Once the acknowledge is written, the slot is considered as invalid and will not be used for the next arbitration run, up to the time the SW set it back to active

As all the TX Priority Queue slots are processed the same way, the data flow of one slot is depicted in the following figure with the reference number for each step.

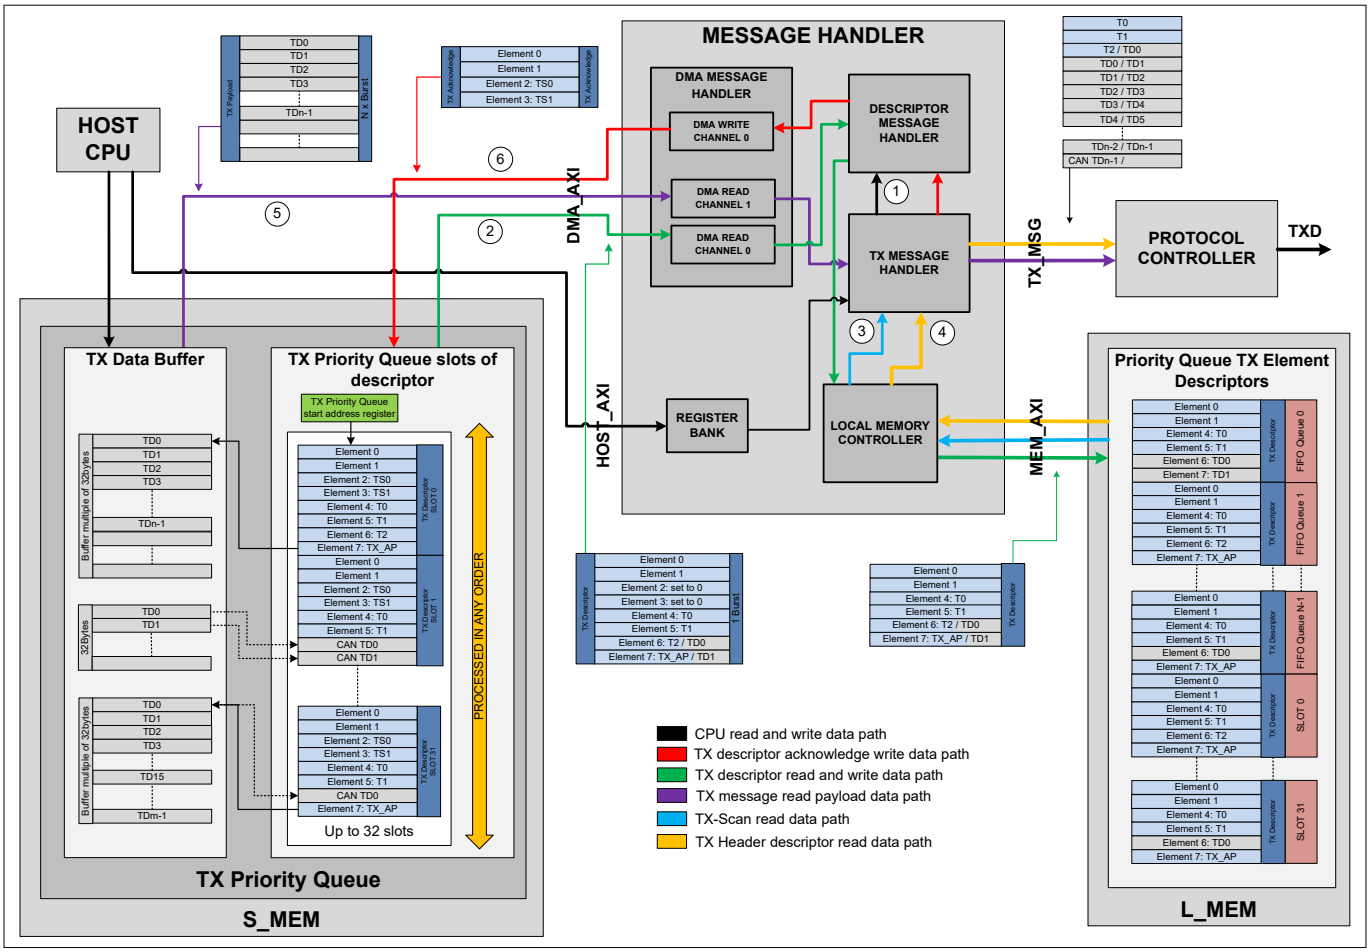

Figure 415 TX Priority queue data flow

22.5.3.19 RX FIFO queue data flow in Normal Mode

The SW needs to prepare into the S_MEM the RX filter elements. Once done the SW writes those elements to the L_MEM. The SW cannot access this memory directly in write mode through the HOST bus interface. As a consequence the L_MEM should provide a way to protect the memory space allocated to the RX filtering elements from being read by any other masters.

The SW defines the RX descriptors for every RX FIFO Queue to be used and allocated the RX data buffers assigned to those RX descriptors. As soon as the RX FIFO Queues are started any RX messages will be filtered, meaning rejected or accepted, and stored into the S_MEM when required.

Here below are the different steps when receiving an RX message:

1. As soon as the RX message data R0, R1 and R2 are received the RX filtering is started. All the incoming data are stored locally into the RX MESSAGE HANDLER waiting for the result of RX filtering. The RX MESSAGE HANDLER identifies RX FIFO Queue to be used
2. The RX MESSAGE HANDLER sends an RX descriptor request to the DESCRIPTOR MESSAGE HANDLER
3. The relevant RX descriptor of the queue identified and fetched by the DESCRIPTOR MESSAGE HANDLER is given to the RX MESSAGE HANDLER
4. The RX MESSAGE HANDLER is using the address pointer of the RX descriptor to write the message data to the S_MEM as soon as a complete burst is available. As long as the data buffer can accept message data, the process of writing can continue. In case the last data can be written into the data buffer pointed by the current RX descriptor, go to 6 otherwise the next RX descriptor of the same queue is requested to the DESCRIPTOR MESSAGE HANDLER

5. When the current RX descriptor is about to be complete, the new RX descriptor should be available for the next DMA data transfer and go to 3
6. The RX MESSAGE HANDLER gets the status of the last part of the RX message and the information of the latest data transfers. Those data are sent to the DESCRIPTOR MESSAGE HANDLER to be written back as acknowledge to RX descriptor into the S_MEM holding the header. The timestamp and report status of the RX message is written at the same time. When the DESCRIPTOR MESSAGE HANDLER has finished writing the RX descriptor an interrupt RX_FQ_IRQ for the RX FIFO Queue n may be triggered to the system

As all the RX FIFO Queues are processed the same way, the data flow of only one RX FIFO Queue is depicted in the following figure with the reference number for each step.

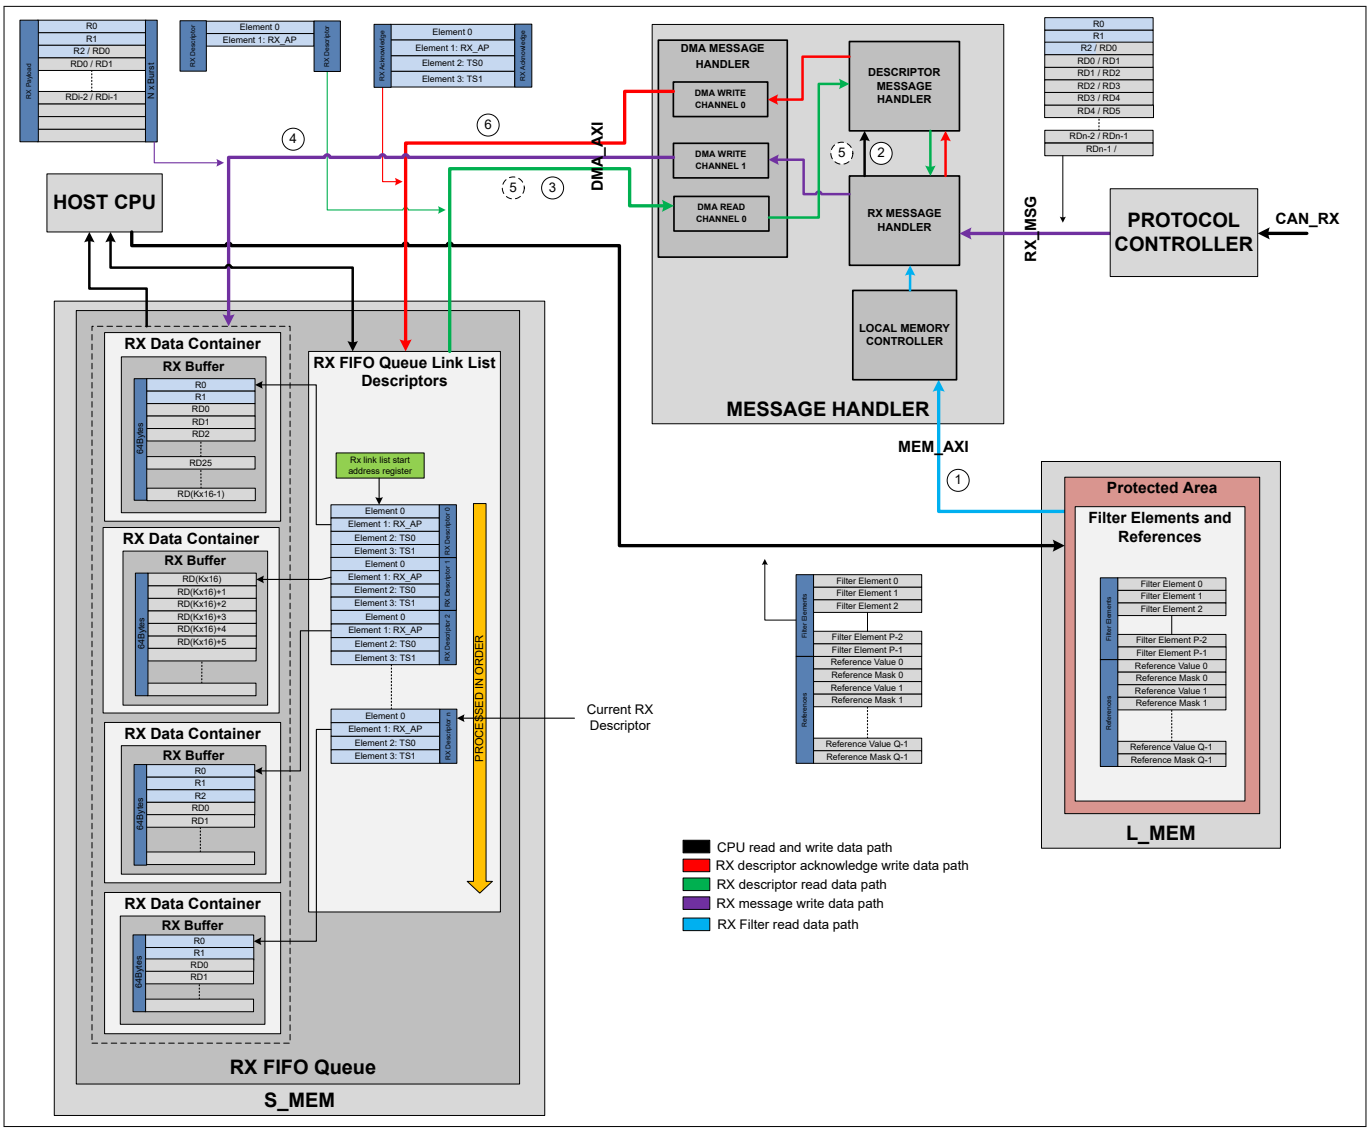

Figure 416 RX FIFO queue data flow in Normal Mode

22.5.3.19.1 RX FIFO Queue data flow in Continuous Mode

The SW needs to prepare the RX filter elements required to accept or reject RX messages. Once done, the SW writes those elements to the L_MEM. The SW cannot access this memory directly in write mode through the HOST bus interface. As a consequence the L_MEM must provide a way to protect the memory space allocated to the RX filtering elements from being read by any other masters.

The SW defines the RX descriptors for every RX FIFO Queue to be used and allocates the single data container for each of them.

As soon as the RX FIFO Queues are started, any RX messages will be filtered, meaning rejected or accepted, and stored into the S_MEM when required.

Here below are the different steps when receiving an RX message:

1. As soon as the RX message data R0, R1 and R2 are received, the RX filtering is started. All the incoming data are stored locally in the RX MESSAGE HANDLER waiting for the result of RX filtering. The RX MESSAGE HANDLER identifies RX FIFO Queue to be used
2. The RX MESSAGE HANDLER sends an RX descriptor request to the DESCRIPTOR MESSAGE HANDLER
3. The relevant RX descriptor of the queue identified and fetched by the DESCRIPTOR MESSAGE HANDLER is given to the RX MESSAGE HANDLER
4. The RX MESSAGE HANDLER holds the RX descriptor of that RX FIFO queue for futher purpose. In case the current RX message cannot fit in the remaining space of the data container, the message is automatically written at the top (if possible). The message data are written to the S_MEM starting after the last RX message stored in the data container. As soon as a complete burst is available, it is written and this process continues up to the last RX message data.
5. The RX MESSAGE HANDLER gets the status of the last part of the RX message and the information of the latest data transfers. Those data are sent to the DESCRIPTOR MESSAGE HANDLER to be written back as an acknowledge to the RX descriptor fetched earlier from the S_MEM. The timestamp, the address of the RX message inside the data container and a report status of the RX message are written at the same time. When the DESCRIPTOR MESSAGE HANDLER has finished writing the RX descriptor, an interrupt RX_FQ_IRQ for the RX FIFO Queue n may be triggered to the system.

As all the RX FIFO Queues are processed the same way, the data flow of only one RX FIFO Queue is depicted in the figure below with the reference number for each step.

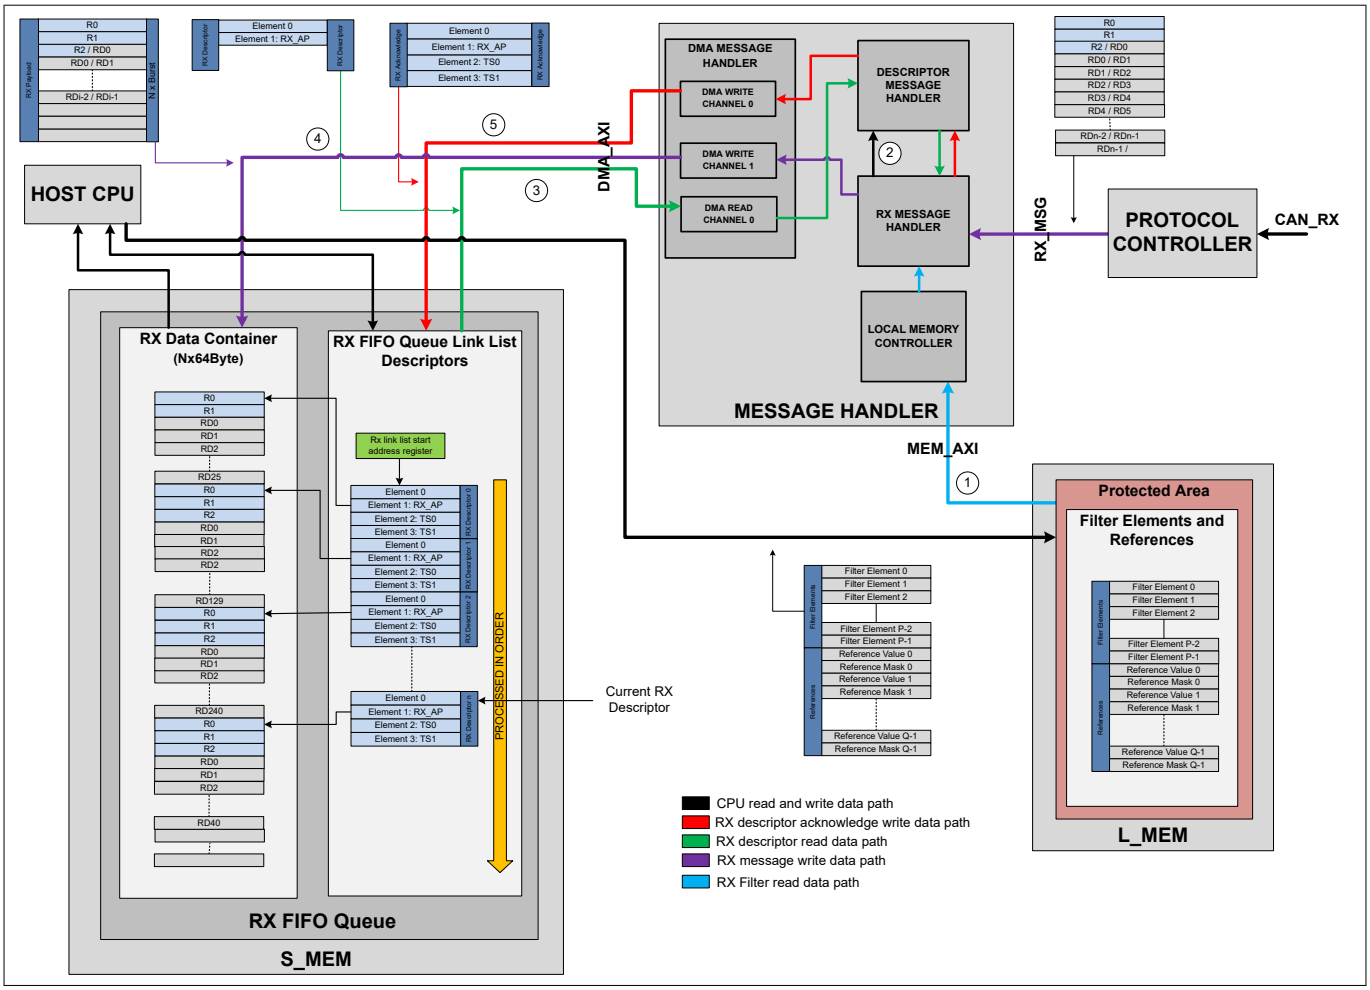

Figure 417 RX FIFO Queue data flow in Continuous Mode

22.5.3.20 TX-SCAN

To avoid any misunderstanding when talking about the selection of the next TX message to be sent to the PRT, the term TX-SCAN is used to define this process.

To arbitrate TX FIFO queues and cope with high latency in S_MEM, the TX Header Descriptor of every active TX FIFO Queues are stored into the L_MEM. The same applies for the TX Priority Queue slots when they are declared as active. It means up to 8 TX FIFO Queues Header Descriptor can be declared in L_MEM and up to 32 for the TX Priority Queue. Doing so, it becomes much easier to parse all the active TX Header Descriptors locally to identify which TX message has the highest priority. The TX-SCAN process would be very fast and the expected TX message order at CAN bus as close as possible to the one expected by the SW.

The TX-SCAN uses the list of TX descriptors available in L_MEM. When a new TX descriptor is added, a flag is set to indicate the availability of a new potential candidate. As long as the TX descriptor is not executed or discarded, it will remain as a valid candidate, see Ni_TX_FQ_DESC_VALID and Ni_TX_PQ_DESC_VALID registers.

Events to trigger a TX-SCAN run are:

- A new TX message written in a TX Priority Queue slot
- A TX message sent successfully
- A TX message discarded after N retransmissions
- A SW abort of a TX Priority Queue slot
- A SW abort of a TX FIFO Queue

- A TX message rejected by the TX Filter
- A TX message starting to be sent (in case of TX FIFO Queue, triggers the fetch of the next descriptor)

Any new TX message appended to a TX FIFO Queue does not trig a new TX-SCAN. The MH is only processing TX descriptor one after the other in every TX FIFO Queue, it does not know if a new message is added to one of them.

A re-transmission counter defines the number of re-transmissions allowed to the same TX message when this one is unsuccessful. For every trial of the same TX message, the re-transmission counter is incremented and compared to a maximum value defined in the Ni_MH_CFG.MAX_RETRANS[2:0]. If the counter exceeds the limit, the current TX message will no longer be considered and is skipped, the next TX message is taken instead. The re-transmission counter is set back to 0 when a new TX message is selected. There is the option to define an unlimited number of trials for TX messages.

The maximum number of re-transmission is defined by the register Ni_MH_CFG.MAX_RETRANS[2:0] and covers the maximum value defined in ISO 11898-1:2024.

Several options are defined:

- 0: No re-transmission
- 1 to 6: 1 to 6 re-transmission
- 7: Unlimited re-transmission (default value)

Here below is the definition of the 32bit priority value when considering Classical CAN, CAN FD and CAN XL. The fields XLF, FDF, XTD, RTR, SRR and ID (defined in CAN protocol [1]) are used to determine the priority value of a given TX message. The priority value is computed for every TX message and then compared with each other to identify the highest priority message (the lowest value gives the highest priority message to transmit).

Only the T0 of the TX Header Descriptor is used for the selection of the highest priority message. As the relevant bits are defined in T0 element, only a single read access from the L_MEM is required. In Classical frame format, a data frame and a remote frame with the same identifier have the same priority in the TX-Scan.

Table 1049 Definition of priority value

CAN Protocol	Protocol Selection			Priority Value						
	XLF	FDF	XTD	31 down to 19	20	19	18	17	16 downto 1	0
Classic CAN	0	0	0	T0[28:18] (Base ID[10:0])	0 (RTR)	0 (XTD)	0 (FDF)	0	16'b0	0
Classic CAN (extended ID)	0	0	1	T0[28:18] (Base ID[10:0])	1 (SRR)	1 (XTD)	T0[17:0] (Identifier Extension[17:0])			0 (RTR)
CAN FD	0	1	0	T0[28:18] (Base ID[10:0])	0 (RRS)	0 (XTD)	1 (FDF)	0	16'b0	0
CAN FD (extended ID)	0	1	1	T0[28:18] (Base ID[10:0])	1 (SRR)	1 (XTD)	T0[17:0] (Identifier Extension[17:0])			0 (RSS)

(table continues...)

Table 1049 (continued) Definition of priority value

CAN Protocol	Protocol Selection			Priority Value						
	XLF	FDF	XTD	31 down to 19	20	19	18	17	16 downto 1	0
CAN XL	1	X	X	T0[28:18] (Priority ID[10:0])	T0[17] (RRS)	0 (XTD)	1 (FDF)	1 (XLF)	16'b0	0

The selection of the TX message is done by looking at the queues in the following order, TX Priority Queue slots from 0 to 31, then the TX FIFO Queues are scanned from 0 to 7. The process of TX message selection will keep the two highest priority messages over the full scan.

When two or more TX messages have the same priority value, the first one will always be kept as the one to be sent first.

***Note**: At initial time, when several TX FIFO Queues are started at the same time, the first TX messages may not be in the right order. Due to the scanning order (TX FIFO Queue slots 0 to 31 and then TX FIFO Queue 0 to 7) and if the system memory latency is high, by the time the last TX descriptor is uploaded to the L_MEM, some TX messages may have been already scanned for the highest priority and sent to the PRT. This is normal behavior and will last only for the first TX messages.*

As soon as a new Header Descriptor is available in the L_MEM, it will be arbitrated automatically if the TX-Scan process is not running. In case that a new TX Header Descriptor is stored in the L_MEM while the TX-Scan is running, the TX-Scan goes up to the end and will restarted to take this new descriptor into account.

Before starting the TX-Scan, the list of all potential candidates (valid) on the L_MEM is stored locally. This process will ensure a proper definition of the best candidates after a complete scan at the time it is done.

The duration of the TX-Scan mainly depends on the access time to the L_MEM and the number of TX FIFO Queues and TX Priority Queue Slots. Here is the list of parameters that will drive the overall time:

- The number of TX FIFO Queues being active at the same time
- The number of TX Priority Queue slots active at the same time
- The L_MEM read latency to fetch one single word

The processing time for one TX -Scan run can be defined as:

$$TX\ Scan\ processing\ time\left(\mu s\right) = Lr * \left(Nbfq + Nbpqs\right) * \frac{1}{CLK(Mhz)}$$ where Nbfq = Number of TX FIFO Queues active, Nbpqs = Number of TX Priority Queue slots active and Lr = read latency from L_MEM defined in number of CLK clock cycles.

In any cases, when a new TX message is scheduled for transmission and it has the highest priority, the maximum delay to have this message selected by the TX-SCAN depends on, the maximum number of TX FIFO Queue and TX priority Queue running concurrently at that time. Considering a maximum of 8 TX FIFO Queues and 32 TX Priority Queue slots running at the same time this leads to (considering the previous formula):

$$Maximum TX\ SCAN\ duration\ \left(\mu s\right) = Lr * \left(\frac{1}{CLK(MHz)}\right) * 40$$

To ensure the continuity of a TX message, it is important to note that regarding TX FIFO Queues, the current and the next TX Header Descriptor for a given FIFO are loaded in the L_MEM. This assumption is valid only if the two TX descriptors are valid. Thus, if several TX messages in the same FIFO have the highest priority over the others, they will be sent back to back. For the TX priority Queue, things are different as one TX message is stored per slot. Only the TX message defined as active in a slot is taken into account at any time.

Two internal buffers are used to hold the TX descriptors in order to send TX messages in a row. One is holding the current TX descriptor to be sent right away to the PRT while the other stores the TX descriptor for the next message. It is important to note that the TX descriptors selected are the result of one TX-Scan. If any new events like, a message sent or a new message to be sent occurs, the two candidates may not be right ones. In this case the TX descriptors already buffered may need to be changed by some new ones. The change is performed step by step, to always have the highest priority message of one TX-Scan run available in one of the two local buffers. The previous TX descriptor with the highest priority is kept in one of the two local buffer while the new highest one is replacing the other. This procedure is repeated, if required, to change the second highest priority message.

The event of any new TX descriptor being loaded and available in the L_MEM triggers a TX-SCAN run. The TX descriptors describing TX messages can only be taken into account by the TX-SCAN if they are available in L_MEM, see Ni_TX_FQ_DESC_VALID and Ni_TX_PQ_DESC_VALID registers.

To prepare the next TX descriptor and to react properly according to some result of the data being sent, there will be several actions to perform:

- The TX-SCAN is computing the two next potential candidates, without considering the TX descriptor set as current in one of the two local buffers (the one with the highest priority). As soon as there are identified, the information related to the source of the two next highest priority messages is stored locally
- The first candidate is compared to the one already in local buffer and having the lowest priority. If the first candidate computed is already in one of the two local buffers, nothing needs to be done. If this is not the case, it is uploaded to provide the next highest priority TX message and will replace the one having the lowest priority in the local buffers. This is mandatory to ensure there is always a valid TX descriptor with high priority to provide to PRT, at any time. This is valid, even if the highest priority TX descriptor in local buffer may, at this time, not be the one with the highest priority. As soon as the first candidate is loaded in the local buffer, it may become the current one if it is having the highest priority or the next one otherwise. It may happen that while loading the first candidate, the current one is used as the next TX message. Nothing can prevent such scenario and either the one with the highest priority is sent first or at the second place
- The second candidate is compared with the one previously defined as current. If the second candidate computed is already in one of the two local buffers, nothing needs to be done. If this is not the case, it is uploaded to provide the second highest TX message. In this particular case the second candidate overwrites the other local buffer

Here below is the flow chart of the TX-SCAN process.

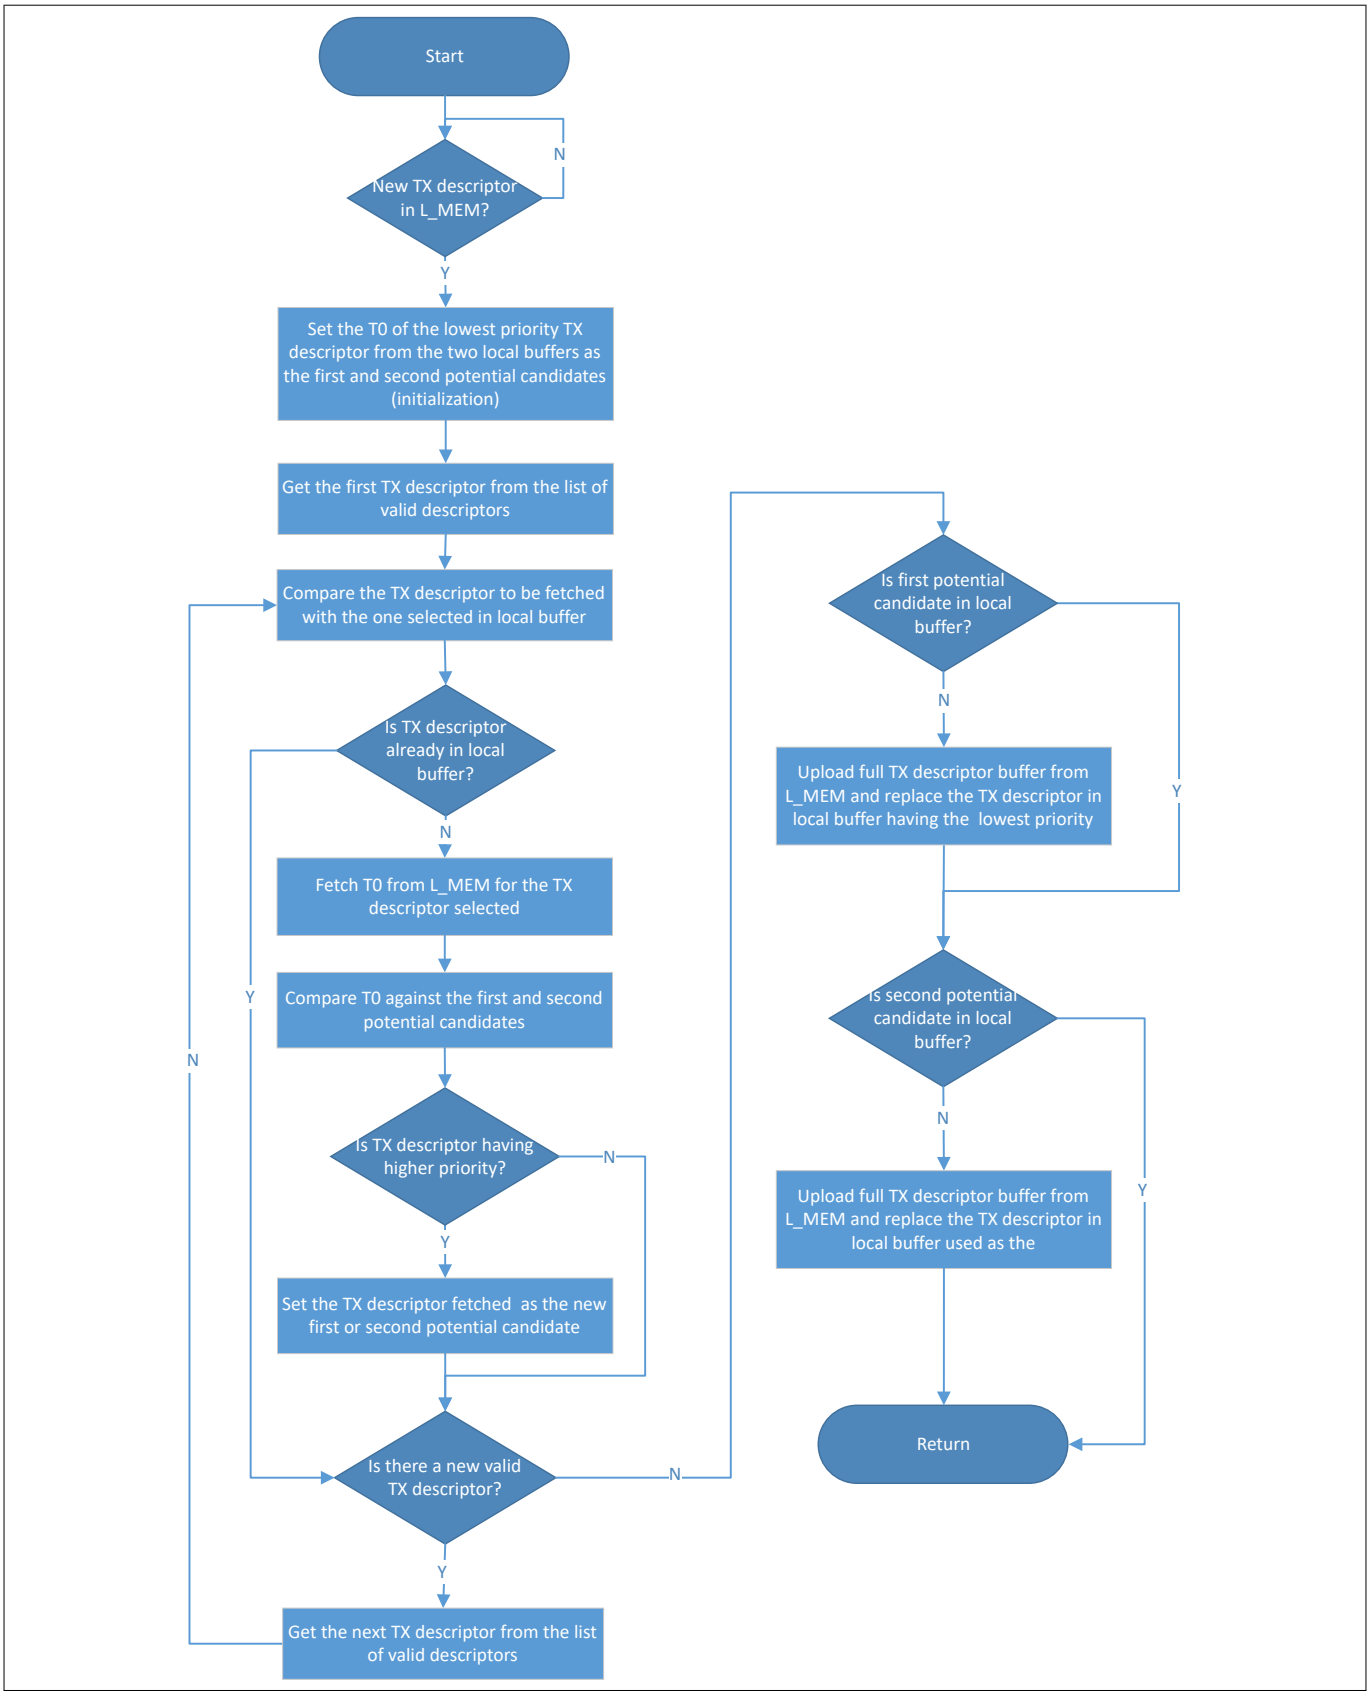

Figure 418 Flow chart of the TX-SCAN process

According to the status of the message sent, there will be two different actions:

- The TX message is sent successfully: the next candidate is considered as the current message. If no new TX descriptor is available in L_MEM, the next candidate to be fetched is already known, otherwise a new TX-SCAN run is launched
- The TX message is not sent successfully: The first next candidate is compare with the current one being not successful. If the current candidate is having a higher priority it will be considered as the one to select otherwise the other candidate is used instead. On top of it, the re-transmission counter defined in the Ni_MH_CFG register will limit the number of possible trials for the same message. If the counter exceeds the limit, the current candidate will no longer be considered, even it has the highest priority. The TX message is skipped and the next candidate is taken instead. If the counter does not reach the maximum value defined and a new message is taken instead, the counter is reset to 0

Some TX-SCAN scenarios are described here below with the following assumptions:

- Three TX FIFO Queues and 3 TX Priority Queue slots are defined
- The TX messages are sent without any pause (no RX message received)
- For the sake of simplicity, only the ID in T0 is used as the main criteria to select the TX message to be sent
- A TX message is defined per TX descriptor (only Header Descriptor are defined)

The first scenario describes the TX-SCAN based only on TX FIFO Queues running and considering every message as sent successfully.

Some debug registers are used to monitor the activity of the TX-Scan:

- The Ni_TX_SCAN_FC register provides the 2 best candidates selected from the previous TX-Scan run as well as the 2 best candidates for the current run
- The Ni_TX_SCAN_BC register gives all the relevant information (The TX FIFO Queue number and TX descriptor offset in that Queue or the TX Priority Queue slot number) regarding the two best candidates uploaded in the local buffer and ready to be sent to the PRT
- The Ni_TX_FQ_DESC_VALID register identifies which TX descriptor is valid, uploaded in the L_MEM and belonging to the list of potential candidate for the TX-Scan. The information displayed in that register covers for a given TX FIFO Queue, the current and the next TX descriptors of a queue that may be loaded in the L_MEM and valid
- The Ni_TX_PQ_DESC_VALID register provides the information of the slots of the TX Priority Queue loaded in the L_MEM and valid (ready for the TX-Scan)

22.5.3.21 TX filter

To ensure only declared TX messages can go through, the MH provides to the SW a way to define TX acceptance filters. Only the TX messages being filtered are considered for the arbitration process. There is the option to enable or disable this TX filtering process (see Ni_TX_FILTER_CTRL0.EN bit register) and so to leave all TX messages to go through or not. Several TX filter elements are defined and processed to determine if the TX message is accepted or rejected. The Ni_TX_FILTER_CTRL0 control register defines how the TX filter element are used, either standalone or combined.

A TX filter element uses reference values to compare with the TX message header data. The selection of the bit field to do the comparison can be configured for every TX filter element. Up to 16 TX filter elements can be defined and are applied to every TX messages when fetched from the L_MEM. There is no way to define those filters only for some specific queues. They apply to all TX messages whatever the TX FIFO Queues and TX Priority Queue slots.

When a TX filter error occurs, the faulty TX message is acknowledged with the status report "message rejected by TX filter". Thus, the SW is able to identify which one has been rejected, while scanning the TX descriptors from the TX FIFO Queues or TX Priority Queue slots. In order to determine the one being faulty and to avoid waiting for the TX descriptor, the Ni_TX_FILTER_ERR_INFO register provides the relevant information. The Ni_TX_FILTER_ERR_INFO.FQ when set to 1 defines a faulty TX message from a TX FIFO Queue otherwise from the TX Priority Queue. The FIFO Queue number is defined with the Ni_TX_FILTER_ERR_INFO.FQNS_PQS[3:0] bit field and the slot number with the Ni_TX_FILTER_ERR_INFO.FQNS_PQS[4:0] bit field.

22.5.3.21.1 Global configuration

To protect the setting of those TX filter elements, registers assigned to the configuration are protected, they can only be accessed while in privileged mode. Only the required application can modify the TX filter setting.

A global TX filter configuration register can be used to define, if the TX messages are accepted or rejected on match using the Ni_TX_FILTER_CTRL0.MODE bit register.

To notify the system that a TX message is rejected, a TX_FILTER_IRQ interrupt is generated. It is possible to enable and disable the TX filter interrupt using the Ni_TX_FILTER_CTRL0.IRQ_EN bit register. On top of it, the faulty TX descriptor is acknowledged immediately with the status rejected by TX filter.

The TX filter elements can be enabled or disabled independently from each other thanks to the Ni_TX_FILTER_CTRL1.VALID[15:0] bit registers.

In order to define the type of data to be compared with, either the VCID or SDT, the Ni_TX_FILTER_CTRL1.FIELD[15:0] is used. This register bit field is relevant for the CAN XL protocol only.

The definition of those TX filter elements is done through the setting of registers. Compared to the RX filter, the TX filter does not require to have access to the L_MEM, settings are done only in registers, see Ni_TX_FILTER_CTRL0, Ni_TX_FILTER_CTRL1, Ni_TX_FILTER_REFVAL{n} (n € {0, 1, 2, 3}). It is assumed that the TX filter elements once defined are statics and won’t change over time while the MH is running.

Refer to the TX filter registers for a more detailed description of the TX filter elements.

As the MH can support several CAN protocols, different options are possible on the TX filter, see the next sections for more details.

22.5.3.21.2 Classical CAN

All Classical CAN TX messages are either accepted or rejected, see Ni_TX_FILTER_CTRL0.CC_CAN bit register. There is no other option for such Classic CAN protocol. The TX filter elements are only used for the CAN XL protocol.

22.5.3.21.3 CAN FD

All CAN FD messages are either accepted or rejected, see Ni_TX_FILTER_CTRL0.CAN_FD bit register. There is no other option for such CAN FD protocol. The TX filter elements are only used for the CAN XL protocol.

22.5.3.21.4 CAN XL

Several options are possible to define the TX filter elements. Two global modes are defined for the overall TX filter elements, either Allow or Reject on match, see Ni_TX_FILTER_CTRL0.MODE bit-field register. When the Mode is configured to "Allow" (White List Approach), set by default, a frame is only transmitted, if there is a match on one of the TX filter elements. When the Mode is configured to "Reject" (Black List Approach) a frame is only transmitted, if there is no match at all.

Every TX filter elements is provided with a reference value to be compared with and which bit-field in the message header to be used, either VCID or SDT.

There is three different options on how to define a TX filter elements with the previous definition:

- Option 1:

  In normal mode, the reference value defined in Ni_TX_FILTER_REFVAL{n}.REF_VAL3, Ni_TX_FILTER_REFVAL{n}.REF_VAL2, Ni_TX_FILTER_REFVAL{n}.REF_VAL1 and Ni_TX_FILTER_REFVAL{n}.REF_VAL0 (n € {0, 1, 2, 3}) registers, is compared with either SDT or VCID. If e.g. Ni_TX_FILTER_REFVAL{n}.REF_VAL0 is defined to be compared to VCID and Ni_TX_FILTER_REFVAL{n}.REF_VAL1 to be compared to SDT than a CAN message will get a match if one of the two values matches.

  Any of the 16 TX filter elements can be used to compare the VCID or the SDT value, refer to the control bit register Ni_TX_FILTER_CTRL1.FIELD[n] (n € {0, 1, 2, 3, …, 15}) (when the bit n is set to 1, the SDT bit field is selected for the TX filter element n otherwise VCID).

  The Tx filter n is defined as valid or not valid using the Ni_TX_FILTER_CTRL1.VALID[n] (n € {0, 1, 2, 3, …, 15}) bit register. If the TX filter 1 is not considered, just set the Ni_TX_FILTER_CTRL1.VALID[1] to 0. An example of the option 1 is given in the table below.

  For such configuration, the Ni_TX_FILTER_CTRL0.MASK[n] (n € {0, 1, 2, …, 7}) bit register must be set to 0 for the given TX filter element pair (n and n+1 assuming n is even)

  To allow single compare value, meaning one reference value for one match, the Ni_TX_FILTER_CTRL0.COMB[n] must set to 0 for TX filter element n and n+1 (n being even). In this mode, there will be always TX filter element n and n+1 available.
- Option 2:

  Based on the normal mode and to increase the possible filtering options, two TX filter elements can be combined to allow VCID and SDT to be checked as only one filter. However, both values must be identical. As only a pair of TX filter elements reference values can be combined, Ni_TX_FILTER_REFVAL{n}.REF_VAL0 and Ni_TX_FILTER_REFVAL{n}.REF_VAL1 or Ni_TX_FILTER_REFVAL{n}.REF_VAL2 and Ni_TX_FILTER_REFVAL{n}.REF_VAL3 (n € {0, 1, 2, 3}) can be used.

  The selection of the bit field value to be compared with is defined by the Ni_TX_FILTER_CTRL1.FIELD[n] (n € {0, 1, 2, 3, …, 15}) bit register. The setting of this register is identical to the option 1.

  Only two adjacent TX filter elements can be configured as combined, using the Ni_TX_FILTER_CTRL0.COMB[n] (n € {0, 1, 2, …, 7}) bit register. When set to 1, TX filter n and n+1 (n being even) are combined. A an example, for the REF_VAL0/REF_VAL1 in the Ni_TX_FILTER_REFVAL0 register, the Ni_TX_FILTER_CTRL0.COMB[0] bit must be set to 1.

  For such configuration, the Ni_TX_FILTER_CTRL0.MASK[n] (n € {0, 1, 2, …, 7}) bit register must be set to 0 for the given TX filter element pair (n and n+1 assuming n is even).

  The TX filter element n and n+1 which are combined (n being even) need to be set as valid (set to 1) using the Ni_TX_FILTER_CTRL1.VALID[n] and Ni_TX_FILTER_CTRL1.VALID[n+1] (n € {0, 1, 2, 3, …, 15}) bit register. This means that combined TX filter elements require two bits to be set in the Ni_TX_FILTER_CTRL1 register.
- Option 3: In order to compare a range of values, a reference value and a mask are required. To provide such option, two TX filter elements TX filter n and n+ 1 (n is even) can be paired in a way that one is the value to be compared with while the other is the mask. As only a pair of TX filter elements reference values can be combined, Ni_TX_FILTER_REFVAL{n}.REF_VAL0 and Ni_TX_FILTER_REFVAL{n}.REF_VAL1 or Ni_TX_FILTER_REFVAL{n}.REF_VAL2 and Ni_TX_FILTER_REFVAL{n}.REF_VAL3 (n € {0, 1, 2, 3}) can be used.

  In order to set one of the two reference value as a mask, the appropriate bit in the Ni_TX_FILTER_CTRL0.MASK[n] (n € {0, 1, 2, …, 7}) bit register must be set to 1. As an eaxmple, the Ni_TX_FILTER_CTRL0.MASK[0] set to 1 is referring to the pair Ni_TX_FILTER_REFVAL0.REF_VAL0 and Ni_TX_FILTER_REFVAL0.REF_VAL1. In such configuration, the second reference value is the mask, hence the REF_VAL1 when considering the REF_VAL0/REF_VAL1 pair.

  The bit field to be compared with is defined by the Ni_TX_FILTER_CTRL0.FIELD bit field register. For the above example the Ni_TX_FILTER_CTRL0.FIELD[0] must be set either to 1 for SDT or 0 for VCID. When Ni_TX_FILTER_CTRL0.MASK[0]=1 then Ni_TX_FILTER_CTRL0.FIELD[1] is ignored by the MH, REF_VAL1 is interpreted as a mask only.

Only two adjacent TX filter elements can be configured as combined, using the Ni_TX_FILTER_CTRL0.COMB[n] (n € {0, 1, 2, …, 7}) bit register. When set to 1, TX filter n and n+1 (n being even) are combined. A an example, for the Ni_TX_FILTER_REFVAL0.REF_VAL0 and Ni_TX_FILTER_REFVAL0.REF_VAL1 bit field, the Ni_TX_FILTER_CTRL0.COMB[0] bit must be set to 1.

It is essential to enable this pair of TX filter element by setting the appropriate bits in the Ni_TX_FILTER_CTRL1 register. As an example the Ni_TX_FILTER_CTRL1.VALID[1:0] set to 2'b11 will enable the Ni_TX_FILTER_REFVAL0.REF_VAL0 (used as reference value) and Ni_TX_FILTER_REFVAL0.REF_VAL1 (used as a mask).

The following example shows 4 reference values defined in the Ni_TX_FILTER_REFVAL0 register, others behave the same.

Option 1 (single): A TX filter element uses only one reference value and one bit field (VCID or SDT)

Option 2 (Combined with matches): REF_VAL0 and REF_VAL1 are combined to provide a TX filter element that is able to compare VCID and SDT in the same filter. The same holds for REF_VAL2 and REF_VAL3.

Option 3 (Combined with mask and value): same as Option 2 with the difference that, REF_VAL0 is still the reference value to compare with (either VCID or SDT) but the REF_VAL1 is the mask to apply.

Table 1050 TX Filter Element options

Reference value	Option 1 (single)	Option 2 (Combined with matches)	Option 3 (Combined with mask and value)
REF_VAL0	REF_VAL0 = (VCID or SDT)	REF_VAL0 = VCID or SDT AND REF_VAL1 = VCID or SDT	REF_VAL0 (value) = REF_VAL1 (mask) AND (VCID or SDT)
REF_VAL1	REF_VAL1 = (VCID or SDT)		
REF_VAL2	REF_VAL2 = (VCID or SDT)	REF_VAL2 = VCID or SDT AND REF_VAL3 = VCID or SDT	REF_VAL2 (value)= REF_VAL3 (mask) AND (VCID or SDT)
REF_VAL3	REF_VAL3 = (VCID or SDT)		

22.5.3.22 RX filter

The RX filtering provides a way to reject or accept RX messages to the SW as well as to write those messages to a defined RX FIFO Queue.

Up to 255 RX filters can be defined. The RX filter is defined using an RX filter element (word of 32bit) associated with up to 2 pairs of reference(32bit)/mask(32bit) values. Those RX filter elements are continuous in the L_MEM and will be parsed one after the other. Regarding the reference/mask pairs they are defined after the RX filter element list in the L_MEM, up to 256 pairs can be declared.

To be flexible, an RX filter is made of up to 2 comparisons, each one using a reference value (32bit) and mask value (32bit) to apply on one of the incoming header message data word (R0, R1 or R3) from the PRT. A reference/mask pair can apply to any of the RX filter elements.

It is a SW task to define and write the RX filter elements and reference/mask pairs in the L_MEM. There is no direct access to it through the MH. The SW would need to access the L_MEM directly to program the relevant RX filter elements and reference/mask pairs.

The process of RX filtering is started as soon as the first 32bit word from the PRT is received, meaning R0. If the RX filter is fetching a filter element which requires R1, the process is on hold waiting for the 32bit word to be available. The same applies with R2 if only R0 and R1 are available.

The minimum time dedicated to the RX filtering is defined by the reception of an RX message when it is sent back to back. The timing window in this case is defined by the reception of two first 32bit word from the PRT (R0/R1) for the current RX message to the next two 32bit words (R0/R1) of the next message.

22.5.3.22.1 Global configuration

The register Ni_RX_FILTER_CTRL is used to set the general configuration for all RX Filters, a write access in Privileged mode is required. Once the MH is started (Ni_MH_CTRL.START = 1), the register is write protected. Here below are the list RX filter configuration setting:

- The number of RX filter elements is defined in the Ni_RX_FILTER_CTRL.NB_FE[7:0] bit field register
- Non-matching CAN frames can be accepted or rejected by configuring the Ni_RX_FILTER_CTRL.ANMF bit register to 1. If non-matching frames are accepted, they are stored in the default RX FIFO Queue defined by the Ni_RX_FILTER_CTRL.ANMF_FQ[2:0] bit field register
- If the RX filtering is not done in time, the data stored in the RX DMA FIFO may lead to an overflow. There is the option to allow the reception of such frames to the default RX FIFO Queue (defined by the Ni_RX_FILTER_CTRL.ANMF_FQ[2:0] bit field register). This feature is only enabled when setting the Ni_RX_FILTER_CTRL.ANFF bit field register to 1. The Ni_RX_FILTER_CTRL.THRESHOLD[4:0] defines the level in the RX DMA FIFO to reach before sending the non-filtered frames to the default RX FIFO Queue
- The default RX FIFO Queue number, to write RX message data when non-matching frames OR non-filtered frames are accepted, is defined in the Ni_RX_FILTER_CTRL.ANMF_FQ[2:0] bit field register. This default RX FIFO Queue value is considered if either the Ni_RX_FILTER_CTRL.ANMF bit or the Ni_RX_FILTER_CTRL.ANFF bit is set to 1. It is essential to enable and start this default RX FIFO Queue prior starting the PRT

22.5.3.22.2 Reference and Mask pair

Two comparisons in the RX Filter Element can be defined. Each comparison require a reference value (REFm) and a mask (MSKm) (m € {0, 1, 2, …, 255}). The reference and mask value are 32bit raw data. The 32bit reference value is compared with the first (R0), the second (R1) or the third (R3) word (32bit) of the RX message header (coming from the PRT) after applying the 32bit mask value.

The reference value and the mask are defined as a pair of two consecutive words of 32bit in L_MEM, starting with the REFm. Up to 256 pairs can be defined for the overall RX filter elements. All the pairs of reference value and mask are appended after the RX filter elements section in L_MEM, see MH Software Interface chapter. Any of the 256 reference/mask pairs can be selected for a given RX filter element.

The RX filter element will use an index to identify the position of the pairs to be used. The first pair is having the index 0, the second the index 1 and so on. The RX Filter Element is then referring to this index in the bit field CREFI0 and CREFI1 (see RX Filter Element Definition chapter), to identify the right pair to use.

22.5.3.22.3 RX Filter Element definition

For every filter element it is possible to:

- Define which RX FIFO Queue to use if RX message is accepted or rejected on match
- Generate an interrupt when a filter matches, triggering the signal RX_FILTER_IRQ to the system
- Define if the RX message expected is being defined into the black list (BLK bit-field)
- Define up to 2 comparisons with the option to:
  - Select the word index in the header message to look at (limited to R0, R1 and R2), see WI0 or WI1. It is important to note that R2 is a header data for the CAN XL while a payload data in case of Classic CAN and CAN FD. In case a remote frame is detected, any filter looking at R2 will be discarded
  - Define the reference value and mask index to perform the comparison, see CREFI0 or CREFI1 bit-field
  - Reject or accept on match, see AR0 and AR1
  - Perform two comparison for a match. When WI0 and WI1 are both different from 0, both comparisons are performed to know if there is a match. In such configuration, the AR0 and AR1 must be identical. In case they are not, only the comparison 0 is performed to check for a match

RX filter element is described in the following table:

Table 1051 RX filter element

Filter Element	Section	Bit-field	Name	Description
FEn	Control	FEn[31:28]	FIFO[3:0]	RX FIFO Queue number to store the receive CAN data
		FEn[27]	IRQ	Interrupt: When set to 1 an interrupt is triggered to the system when a match is detected
		FEn[26]	BLK	BlackList: When set to 1 the BLK bit defined in the RX message header is set to 1
		FEn[25:24]	Reserved	
	Comparison 1 (only considered with comparison 0)	FEn[23]	Reserved	
		FEn[22]	AR1	See AR0 bit-field description. Must always be equal to AR0.
		FEn[21:20]	WI1[1:0]	See WI0 bit-field description
		FEn[19:12]	CREFI1[7:0]	See CREFI0 bit-field description
	Comparison 0	FEn[11]	Reserved	
		FEn[10]	AR0	Accept or Reject on match: when set to 1 the RX message is rejected on match otherwise accepted on match

(table continues...)

Table 1051 (continued) RX filter element

Filter Element	Section	Bit-field	Name	Description
		FEn[9:8]	WI0[1:0]	Word Index: provide the index of the RX message header word to compare, 1 for R0, 2 for R1 and 3 for R2. R2 will not be considered as a valid index for remote frame or Classical CAN frame with no payload data or CAN FD frame without payload, the comparison is then canceled. When set to 0, no comparison is performed
		FEn[7:0]	CREFI0[7:0]	Comparison Reference Index: provide the index of the reference pair (value and mask) to be used for comparison

The RX filter element can be used in two different modes:

- Comparison 0 only ($WI0 > 0$ and $WI0 = 0$)
- Comparison 0 and comparison 1 ($WI0 > 0$ and $WI1 > 0$)

It is essential to understand that if the Comparison 1 is defined, this RX Filter element will not be considered if the Comparison 0 is not defined. In such case, the filter element is skipped.

Each time an RX message is received, the RX filtering is triggered and start the following sequence:

- Fetch the first filter element from L_MEM. The start address of this first filter element is defined in Ni_RX_FILTER_MEM_ADD.BASE_ADDR[15:0] register
- If the conditions listed below are met, the RX filter element will be discarded and the next filter element be fetched (if there is one available). In all other cases, go to next step:
  - $WI0 = 0$
  - $WI0 = 3$ and the frame is either a Classic CAN/CAN FD without payload or a Classic CAN remote frame
  - $WI1 = 3$ and the frame is either a Classic CAN/CAN FD without payload or a Classic CAN remote frame
  - $WI0 > 3$ and $WI1 > 3$ and AR0/AR1 not equal
- For the comparison 0, using the index CREFI0, the two words for the reference value and mask are fetched from L_MEM
- The comparison 0 is done between the word defined by the index WI0 and the reference value/mask fetched earlier. According to the WI1 bit several actions are taken:
  - WI1 set to 0 (Comparison 0 only): if there is a match, the RX filter will look at the AR0 bit to identify what to do with the RX message. It would then be accepted or rejected and the RX filter stops. If there

is no match, the RX filter keeps going with the next filter element, if there is one available, otherwise stops

- WI1 > 0 (Comparison 0 and Comparison 1 expected): if there is a match on the comparison 0, the RX filter will wait for the result of the comparison 1 to decide what to do with the RX message. If there is no match on comparison 0, the RX filter keeps going with the next filter element, if there is one available, otherwise stops

- The comparison 1 is done between the word defined by the index WI1 and the reference value/mask fetched earlier. If there is a match, the RX filter will look at the AR0 bit to identify what to do with the RX message. It would then be accepted or rejected and the RX filter stops. If there is no match, the RX filter keeps going with the next filter element, if there is one available, otherwise stops

22.5.3.22.4 RX Header Descriptor updates

When an RX message is accepted, the index of the RX filter element which has accepted the message on match is logged inside the RX Header Descriptor. In case the RX message is rejected, no information is provided to the SW.

The filtering process writes filtering information to three bit-fields of the header data (see RX Message header definition chapter):

- The BLK bit in the header data of the RX message can be set by an RX filter element to indicate to the SW a non expected messages. When the SW is parsing the RX message Header Descriptor it can easily identify them once available in S_MEM
- The FIDX[7:0] bit-field is used to provide the information of the filter element index which has been triggered for that message
- The FAB bit field when set to 1, indicates to the SW that there was not enough time to complete the RX filtering process. This bit will be set when such issue occurs and only if the Ni_RX_FILTER_CTRL.ANFF bit register is set to 1 and Ni_RX_FILTER_CTRL.THRESHOLD[4:0] bit field greater than 0 (threshold mechanism active)
- The FM bit-field when set to 1, notifies the SW that there was a match on the RX filtering. When the FAB and FM bit-fields are set to 0, the RX filtering process ending with no match

22.5.3.22.5 MH behavior according to RX Filter setting

The RX filter elements are sequentially read from the L_MEM. This process continues up to the point, where the RX filter result is known and the message can either be accepted or rejected.

In case the RX filter selects an RX FIFO Queue that is not enabled, the incoming frame is considered as a non-matching frame and is discarded, the RX_ABORT_IRQ is set to the system.

In a normal situation, when the RX filter result arrives in time, the RX message data are sent to the appropriate RX FIFO Queue or are rejected.

A default RX FIFO Queue can be defined for some configuration when Ni_RX_FILTER_CTRL.ANMF_FQ[2:0] is defined and Ni_RX_FILTER_CTRL.ANMF set to 1.

A threshold can be defined on the RX DMA FIFO to manage not filtered frames. The Ni_RX_FILTER_CTRL.ANFF must be set to 1 to activate the function and the Ni_RX_FILTER_CTRL.THRESHOLD[4:0] bit field defining the threshold value must be greater than 0. Once activated, those frames are sent to a default RX FIFO Queue, see Ni_RX_FILTER_CTRL.ANMF_FQ[2:0] bit field register.

Here below is the summary of the RX filter behavior when considering Ni_RX_FILTER_CTRL.NB_FE[7:0], Ni_RX_FILTER_CTRL.ANMF and Ni_RX_FILTER_CTRL.ANFF bit fields:

Table 1052 RX Filter behavior

ANMF	NBFE[7:0]	ANFF	RX Filter status
0	0	X	All RX frames are rejected
1	0	X	All RX messages are accepted and are going to the default RX FIFO Queue defined by Ni_RX_FILTER_CTRL.ANMF_FQ[2:0]
0	>0	0	Frames with match are going to RX FIFO Queues Frames with no match are rejected No threshold monitoring is performed during RX filtering
		1	Frames with match are going to RX FIFO Queues Frames with no match are rejected Frames reaching the RX DMA FIFO level set in the Ni_RX_FILTER_CTRL.THRESHOLD[4:0] register and not filtered, are going to the default RX FIFO Queue defined in Ni_RX_FILTER_CTRL.ANMF_FQ[2:0] register
1	>0	0	Frames with match are going to RX FIFO Queues Frames with no match are going to the default RX FIFO Queue defined by Ni_RX_FILTER_CTRL.ANMF_FQ[2:0] No threshold monitoring is performed during RX filtering

(table continues...)

Table 1052 (continued) RX Filter behavior

ANMF	NBFE[7:0]	ANFF	RX Filter status
		1	Frames with match are going to RX FIFO Queues Frames with no match are going to the default RX FIFO Queue defined by Ni_RX_FILTER_CTRL.ANMF_FQ[2:0] Frames reaching the RX DMA FIFO level set in the Ni_RX_FILTER_CTRL.THRESHOLD[4:0] register and not filtered, are going to the default RX FIFO Queue defined in Ni_RX_FILTER_CTRL.ANMF_FQ[2:0] register

The MH will manage the RX message differently if a default RX FIFO Queue is defined or not with or without a threshold defined. The configurations being able to use the two last options are described below:

Scenario 1:

Threshold mechanism is not active (Ni_RX_FILTER_CTRL.ANFF bit set to 0 and Ni_RX_FILTER_CTRL.NBFE[7:0] > 0).

Two scenarios can occur:

- The RX filtering result is not known before receiving the first word of the next RX message and the amount of the CAN frame data is lower than the RX DMA FIFO. The RX message is discarded with the RX_ABORT_IRQ interrupt and the RX_FILTER_ERR is also triggered to the system.
- In case the amount of data received, while waiting the RX filtering result, does exceed the maximum RX DMA FIFO size, the RX message is discarded with the RX_ABORT_IRQ interrupt. The DP_DO_ERR interrupt is triggered to notify an RX DMA FIFO overflow.

Scenario 2: Threshold mechanism is active (Ni_RX_FILTER_CTRL.ANNF bit set to 1 and Ni_RX_FILTER_CTRL.NBFE[7:0] > 0 and Ni_RX_FILTER_CTRL.THRESHOLD[4:0] value is greater than 0). This backup solution to avoid losing the RX message is possible due to the monitoring of the RX DMA FIFO level and a threshold configured in the Ni_RX_FILTER_CTRL.THRESHOLD[4:0] bit field register (see next section for more details).

Two scenarios can occur:

- The RX filtering result takes a very long time and the frame size is large. Once the threshold is reached, the RX descriptor from the default RX FIFO Queue is fetched from the S_MEM. Then, the RX buffer address pointer defined in the RX descriptor is used to write the first burst of data to the default RX FIFO Queue.
- The RX filtering result takes a very long time and the frame size does not reach the threshold value. As long as no new message is received, the RX filtering keeps going and a result could be expected in time. In case a new RX message is received, the current RX message is discarded with the RX_ABORT_IRQ interrupt. The RX_FILTER_ERR is also triggered to the system to identified a potential issue with the RX filter.

Here below is a table to summarize the different scenarios:

Table 1053 RX Filter scenarios

Frame length	Filter result when threshold is reached	Filter result when next RX message arrives	Action of MH	Comments
Short	Not possible	Available	Store frame in RX FIFO Queue defined by RX filter result	Normal behavior
Short	Not possible	Not available	Discard frame	The overall processing time is too long due to a high number of filters and/or a low core clock frequency,
Long	Available and ANFF = X	Not considered	Store frame in RX FIFO Queue defined by RX filter result	Normal behavior
Long	Not available and ANFF = 0	Not considered	Keeps waiting for the RX filter result	Within this case, the message is written in time to the right RX FIFO Queue or discarded due to data overflow on the RX DMA FIFO
Long	Not available and ANFF = 1	Not considered	Store frame in default RX FIFO Queue	Threshold must be set such a way there is enough time to fetch RX descriptor and to write burst data to S_MEM,

22.5.3.22.6 Threshold computation

The MH uses the Ni_RX_FILTER_CTRL.THRESHOLD[4:0] only when the Ni_RX_FILTER_CTRL.ANFF bit is set to 1 and the threshold value is greater than 0. The threshold value to be configured by the user depends on the S_MEM latency, the CAN protocols supported and the CAN XL data bit rate. The RX DMA FIFO has a size of 32 words (128 byte).

Case 1: Only Classical CAN and/or CAN FD messages are received: The RX DMA FIFO is capable of storing a complete Classical CAN or CAN FD message. The feature Ni_RX_FILTER_CTRL.ANFF should not be used.

Note: When Ni_RX_FILTER_CTRL.ANFF=1 and Ni_RX_FILTER_CTRL.THRESHOLD[4:0] is set to 19 or larger, then the threshold will never be reached. This implicitly disables the threshold, because it will be never be reached by a Classical CAN or CAN FD message.

Case 2: Also CAN XL messages are received: CAN XL messages can be much longer than the RX DMA FIFO size. When the fill level of the RX DMA FIFO reaches the threshold, the MH will fetch the RX descriptor from the default RX FIFO Queue and will write the first burst of data stored in the RX DMA FIFO. For the case, that no RX filter result is available at the point in time the threshold is reached, this mechanism prevents a data overflow that would occur on the RX DMA FIFO and allows the reception of the message. The threshold divides the time budget provided by the RX DMA FIFO into two parts: (1) time to do the RX Filtering, (2) Time to fetch the RX Descriptor from S_MEM and to write the first burst of data to S_MEM. The user should configure the threshold as large as possible, to give the RX Filtering enough time, but as low as necessary to be able to receive the message, in case RX Filtering is not finished yet.

22.5.3.22.7 RX Filter processing time

The number of accesses to evaluate an RX filter element is defined as follow:

Classical CAN and CAN FD:

One single word access (definition of the filter element) and 2 words for the mask and value to compare with

CAN XL:

same as Classical CAN / CAN FD or one single word and 2 reads of 2 words for the 2 mask and value to compare with

The RX filter element access time depends on the read latency Lr (defined in number of CLK clock cycles):

Classical CAN and CAN FD:

$$RXFilter\ \ element\ \ processing\ time\left(\mu s\right)\ \ =\ \ \left(\left(Lr+2\right)+\left(Lr+1+2\right)\right)*\left(\frac{1}{CLK(MHz)}\right)$$

CAN XL:

$$RXFilter\ \ element\ \ processing\ time\left(\mu s\right)\ \ =\ \ \left(\left(Lr+2\right)+\left(Lr+1+2\right)\right)*\left(\frac{1}{CLK(MHz)}\right)\ with\ one\ comparison$$

$$RXFilter\ \ element\ \ processing\ time\left(\mu s\right)\ \ =\ \ \left(\left(Lr+2\right)+2*\left(Lr+1+2\right)\right)*\left(\frac{1}{CLK(MHz)}\right)\ with$$

two $comparisons$

The overall RX filter time is computed as follow:

$$RX\ Filter\ processing\ time\left(\mu s\right)\ \ =\ \ \left(Nbfe1c*\left(\left(Lr+2\right)+\left(Lr+1+2\right)\right)+Nbfe2c*\left(\left(Lr+2\right)+2*\left(Lr+1+2\right)\right)\right)*\left(\frac{1}{CLK(MHz)}\right)$$

where Nbfe1c = Number of filter element with 1 comparison, Nbfe2c = Number of filter element with 2 comparisons and the read latency Lr (defined in number of CLK clock cycles).

22.5.3.23 Local Memory Controller

The XCAND_MH_MEM_CTRL block is in charge of reading and writing the L_MEM. The Local Memory Controller is managing all requests and data transfer for the different blocks running concurrently:

- The writes of TX descriptors from the XCAND_DESC block
- The read of RX filter elements from the XCAND_RX_PATH
- The read of TX descriptor from XCAND_TX_PATH when a message has to be sent
- The read of TX descriptor from XCAND_TX_PATH for TX SCAN (selection of the highest priority TX message)

22.5.3.23.1 Local Memory side band signals

It is assumes that the L_MEM provides safety measure to protect data. The safety protection implemented in the L_MEM could either report error when reading a data (Single Error Detection) or be able to correct it in some cases (Single Error Correction and Double Error Detection for example). To address those two options, two input side band signals denominated MEM_SFTY_CE and MEM_SFTY_UE, are provided with the MEM_AXI interface.

Here below are the expected behavior of those signals and the expected response on the MEM_AXI interface:

- Error Detection Only: When a corrupted data is read from the L_MEM, a pulse of one CLK clock cycle must be generated on the MEM_SFTY_UE input signal. The MEM_AXI interface must report a SLVERR response on the MEM_AXI bus. The MEM_SFTY_UE input signal can be fully asynchronous to the MEM_AXI interface.
- Error Detection and Correction: When a corrupted data is read from the L_MEM but is corrected, a pulse of one CLK clock cycle must be generated on the MEM_SFTY_CE input signal. The MEM_AXI interface must report an OKAY response on the MEM_AXI bus. The MEM_SFTY_UE input signal can be fully asynchronous to the MEM_AXI interface.

22.5.3.23.2 Address bus

The XCAND_MH_MEM_CTRL block is able to address up to 64 Kbytes memory space (MEM_AXI_AWADDR[15:0] and MEM_AXI_ARADDR[15:0]).

The address burst value is always 32 bit aligned.

22.5.3.23.3 Burst size

The maximum number of bytes to transfer in each data transfer is fixed and set to 4. Any read or write transfer is always using 32 bit.

As a consequence, the write strobe signals are not managed by the XCAND_MH_MEM_CTRL as all 4 bytes are always written.

22.5.3.23.4 Burst length

The Local Memory Controller for the AXI read and write transfers supports INCR burst length 1, 2 and 8 considering an AXI 32 bit data bus width.

The burst lengths from/to the L_MEM are defined based on the data type of information to be used. Here below are the expected burst length from/to the different sub-blocks:

- XCAND_MH_DESC: This sub-block writes the TX descriptor allocated to TX FIFO Queues and TX Priority Queue slots. The burst length is fixed and set to $8 \times 32\ bit$. There is no read access from this sub-module
- XCAND_MH_RX: This sub-block reads the RX filter elements and reference/mask values to perform the RX message filtering. The burst length is set to $1 \times 32\ bit$ for the RX filter element and $2 \times 32 bit$ for the reference/mask value. There is no write access from this sub module
- XCAND_MH_TX: This sub-block reads two type of information, the TX descriptor to be sent as the next candidate to the TX_MSG interface and part of the TX descriptors assigned to TX FIFO Queues and TX Priority Queue slots. A fixed burst length of $1 \times 32\ bit$ is used for the TX SCAN and $8 \times 32\ bit$ is for the TX descriptor

22.5.3.23.5 Outstanding

As the L_MEM can be shared across several X_CAN instances and many accesses are required for RX filtering and TX SCAN, 2 outstanding read transactions can supported. As only a few writes are required from the MH point of view, only 1 outstanding write transaction is supported.

22.5.3.23.6 Burst type

The only burst type supported is the burst incrementing INCR.

The WRAP/FIXED burst type is not supported.

22.5.3.23.7 Multi-region

The Local Memory Controller does not support multiple region interfaces.

22.5.3.23.8 Memory attributes

The memory attributes for the read or write accesses to the L_MEM are Normal, Non-modifiable (Non-cacheable in AXI3) and Non-bufferable. No read-allocate nor No Write-allocate are expected on this interface and would be set to 1'b0.

As a reminder, Non-bufferable means (See [3] for mode details):

- The write response must be obtained from the destination
- Read data must be obtained from the destination
- Transactions are Non-modifiable
- Read and write transactions from the same ID to addresses that overlap must remain ordered

As a reminder, Non-modifiable means:

- A Non-modifiable transaction must not be split into multiple transactions or merged with other transactions
- In a Non-modifiable transaction, the parameters AxADDR, AxSIZE, AxLEN, AxBURST and AxPROT must not be changed

22.5.3.23.9 Access permissions

It is considered that any access is always defined as a Data, Secure and the operating mode is Unprivileged, see [3] for more details. Those setting cannot be changed by SW.

Therefore, any access from the MH which needs to be non-secure, must be managed with an external and dedicated logic attached to the MEM_AXI interface.

As an example, the RX filter elements and reference/mask can be stored in a secure area in the L_MEM, as a consequence the MEM_AXI_ARPROT[1] and MEM_AXI_AWPROT[1] are set to 0_B. Doing so, the MH is able to read secure and non-secure data in the L_MEM, with the assumption that non-secure area is always accessible by a secure access. This means MEM_AXI_A(W/R)PROT[2:0] is set to 000_B.

22.5.3.23.10 Transaction ID

The L_MEM Controller builds the ID of every burst access based on the source of request. It provides a way to track which sub-block is doing the access at any time on the system bus.

For the AXI read interface, the MEM_AXI_ARID[1:0] defines the channel number as follow:

00_B => XCAND_MH_TX reads TX descriptor from L_MEM

2’b01 => XCAND_MH_TX read part of TX descriptor from L_MEM for TX SCAN

10_B => XCAND_MH_RX reads RX filter elements and reference/mask values from L_MEM

11_B => Reserved

For the AXI write interface, the MEM_AXI_AWID[0] defines the channel number as follow:

0_B => XCAND_MH_DESC writes TX descriptor to L_MEM

1_B => Reserved

22.5.3.24 Trace and debug

22.5.3.24.1 Interrupts

For integration verification it is possible to trig functional and safety interrupts by SW. Here is the procedure:

1. Unlock the Ni_DEBUG_TEST_CTRL register, see section Lock Mechanism Protection in Register Protection chapter
2. Write the Ni_DEBUG_TEST_CTRL.TEST_IRQ_EN bit to 1 in privileged mode
3. Once the access to the Ni_INT_TEST0 and Ni_INT_TEST1 registers are allowed (always accessible once opened), write 1 to the relevant bit to set the appropriate interrupt line.

Re-lock the access to the Ni_INT_TEST0 and Ni_INT_TEST1 registers. Step 1) and 2) needs to be done with Ni_DEBUG_TEST_CTRL.TEST_IRQ_EN bit set to 0 instead.

22.5.3.24.2 Hardware debug port

The 16bit HDP bus provides some visibility to internal signals to debug the MH. By default, there is no activity on the HDP bus.

To enable the toggling of the HW signal on the HDP bus, set the Ni_DEBUG_TEST_CTRL.HDP_EN bit to 1.

1) Unlock the Ni_DEBUG_TEST_CTRL register, see section Lock Mechanism Protection in Register Protection chapter

2) Write the Ni_DEBUG_TEST_CTRL.HDP_EN bit to 1 and the selected set to be monitored on the HDP using the Ni_DEBUG_TEST_CTRL.HDP_SEL[2:0]. This access must be done in privileged mode.

To disable the Hardware Debug Port monitoring, do the previous set with Ni_DEBUG_TEST_CTRL.HDP_EN bit to 0.

Up to 8 sets can be defined using the Ni_DEBUG_TEST_CTRL.HDP_SEL[2:0] bit field. When the value is set to n the set n is selected on the HDP bus.

INTERRUPTS:

The interrupt line assigned to the RX or TX FIFO Queue can be monitored individually. Therefore, it is possible to track the activity of the FIFO Queues while they are running. To allow the visibility of all MH interrupts, on the same HDP set, the TX FIFO Queues interrupt lines are gathered to only one single HW internal signal called TX_FQ_IRQ_ORED (the interrupts are 'ored'). The same is done on the RX FIFO Queues and so the interrupts are 'ored' to provide the HW internal signal RX_FQ_IRQ_ORED.

***Note**: There are two possible sources to trig an interrupt (valid for TX_FQ_IRQ[7:0], RX_FQ_IRQ[7:0] and TX_PQ_IRQ interrupt lines): one is related to functional and the other one is from the Ni_INT_TEST0 and Ni_INT_TEST1 registers (for integration test only). Only the functional interrupt source is displayed on the HDP set. Therefore, when an interrupt is triggered, by a write access to either Ni_INT_TEST0 or Ni_INT_TEST1 register, it will not be visible on the HDP. Nevertheless, the interrupt line is properly set at the MH interface.*

INTERFACES:

To ensure the traceability of the traffic going from and to the MH, the following interfaces can be monitored through one of the HDP sets:

- DMA_AXI interface (control signals) used to manage RX/TX descriptors and RX/TX message data
- MEM_AXI interface (control signals) used to manage TX descriptors for TX-Scan and RX filtering
- TX_MSG interface (control signals) used to transmit TX message from MH to PRT
- RX_MSG interface (control signals) used to receive RX message from PRT to MH

The table below shows the description of sets available on the MH HDP bus.

Table 1054 Signals available on the HDP bus

MH_HDP[15:0]	Set 0 (interrupts)	Set 1 (RX and TX path)	Set 2 (TX Scan)	Set 3 (MH_PRT Interface)	Set 4 (Write AXI DMA interface)	Set 5 (Read AXI DMA interface)	Set 6 (Write AXI MEM interface)	Set 7 (Read AXI MEM interface)
15	TX_FQ_IRQ[7]	CLK	FH_OFFSET[9]	CLK	CLK	CLK	CLK	CLK

22.5.3.24.3 TX-scan

In order to keep track of the TX-Scan process, some registers provide the relevant information to observe the selection of the next TX message, meaning, which TX FIFO Queue number and which message within this FIFO Queue is selected, or which TX Priority Queue slot number. The Ni_TX_SCAN_FC and Ni_TX_SCAN_BC registers are monitoring the TX-Scan activity, see Software Interface chapter for more details. The duration of a CAN frame is large enough to make it possible, to read those registers in time and get some valuable information.

The Ni_TX_SCAN_FC register provides the information of the source of the four first candidates selected by the TX-Scan., meaning the TX FIFO Queue number or the TX Priority Queue slot number. The source of the two first candidates are defined by:

- The Ni_TX_SCAN_FC.FQ_PQ{n} (n € {0, 1}) bit register: when set to 0, the first or second candidate is a TX FIFO Queue. In fact, Ni_TX_SCAN_FC.FQ_PQ0 = Ni_TX_SCAN_BC.FH_PQ and Ni_TX_SCAN_FC.FQ_PQ1 = Ni_TX_SCAN_BC.SH_PQ, see Ni_TX_SCAN_BC register description below
- The Ni_TX_SCAN_FC.FQN_PQSN{n} (n € {0, 1}) bit register: define either a TX FIFO Queue number or a TX Priority Queue slot number according to the Ni_TX_SCAN_FC.FQ_PQ{n} (n € {0, 1}) bit register. In fact, Ni_TX_SCAN_FC.FQN_PQSN0 = Ni_TX_SCAN_BC.FH_FQN_PQSN and Ni_TX_SCAN_FC.FQN_PQSN1 = Ni_TX_SCAN_BC.SH_FQN_PQSN, see Ni_TX_SCAN_BC register description below
- The two sources of the last two candidates are monitoring the selection of a TX-Scan. It is essential to note that the value in those registers is not stable, compare to the source of the two first candidate, and will change during a TX-Scan run. When the Ni_TX_SCAN_FC.FQ_PQ{n} (n € {0, 1, …, 3}) is set to 0, the candidate n is a TX FIFO Queue, looking at the Ni_TX_SCAN_FC.FQN_PQSN{n} (n € {0, 1, …, 3} bit field, provides the number. If the Ni_TX_SCAN_FC.FQ_PQ{n} (n € {0, 1, …, 3}) is set to 1, the candidate n is a TX Priority Queue and the slot number is defined by the Ni_TX_SCAN_FC.FQN_PQSN{n} (n € {0, 1, …, 3} bit field.

The value of the Ni_TX_SCAN_FC register is updated when a new TX Scan result is available, see TX-SCAN chapter.

The Ni_TX_SCAN_BC register gives the full reference of the first and second highest priority messages, defined and uploaded at the end of a TX-Scan run (see Buffer A and B in TX MESSAGE HANDLER chapter). The first highest candidate is the one selected and sent to the CAN bus. The second highest priority candidate is the TX message to be sent, once the transmission of the first highest candidate is completed. The register values provide full visibility of the two message candidates stored locally in Buffer A and B, see TX MESSAGE HANDLER chapter for more details. As such, those registers are stable over time and do change only after at the end of a TX-Scan.

The first best candidate is defined by:

- The Ni_TX_SCAN_BC.FH_PQ bit register: when set to 0, the candidate is a TX FIFO Queue
- The Ni_TX_SCAN_BC.FH_FQN_PQSN bit register: define either a TX FIFO Queue number or a TX Priority Queue slot number according to the Ni_TX_SCAN_BC.FH_PQ bit register
- The Ni_TX_SCAN_BC.FH_OFFSET bit register: define the offset (in 32byte) of the TX descriptor selected, starting from the initial start address of the TX FIFO Queue (defined in the Ni_TX_SCAN_BC.FH_FQN_PQS bit register) with TX descriptor address = TX FIFO Queue start address + offset * 32byte. When the candidate is a TX Priority Queue slot, the Ni_TX_SCAN_BC.FH_OFFSET register has no meaning and is set to 0.

The second best candidate is defined by:

- The Ni_TX_SCAN_BC.SH_PQ bit register: when set to 0, the candidate is a TX FIFO Queue
- The Ni_TX_SCAN_BC.SH_FQN_PQSN bit register: define either the TX FIFO Queue number or the TX Priority Queue slot number according to the Ni_TX_SCAN_BC.FH_PQ bit register
- The Ni_TX_SCAN_BC.SH_OFFSET bit register: define the offset (in 32byte) of the TX descriptor selected, starting from the initial start address of the TX FIFO Queue (defined in the Ni_TX_SCAN_BC.SH_FQN_PQSN bit register) with TX descriptor address = TX FIFO Queue start address + offset * 32byte. It is important to note that, when the TX FIFO queue selected for the first best candidate is identical to the one for the second, the offset would be also identical. In such scenario, the second best candidate is always the next

TX descriptor of that TX FIFO Queue. When the candidate is a TX Priority Queue slot, the Ni_TX_SCAN_BC.SH_OFFSET register has no meaning and is set to 0

22.5.3.24.4 TX Descriptor tracking in a TX FIFO Queue

The current and next TX descriptors for a given TX FIFO Queue n are stored in the L_MEM and can be identified in the Ni_TX_FQ_DESC_VALID.DESC_NC_VALID[n] and Ni_TX_FQ_DESC_VALID.DESC_CN_VALID[n] bit registers.

Here are the status for those bit register when progressing with the TX FIFO Queue n:

Initial start:

1. The current TX descriptor (first one in case this is an initial start) fetched from S_MEM and written to L_MEM is leading to Ni_TX_FQ_DESC_VALID.DESC_CN_VALID[n] = 1 and Ni_TX_FQ_DESC_VALID.DESC_NC_VALID[n] = 0.
2. If the current TX descriptor is about to be sent go to 3), otherwise stay in 2) and no updates are done on bit registers.
3. The next descriptor is fetched from S_MEM and written in L_MEM.
   a. If the next TX descriptor is not valid then the TX FIFO Queue n is put on hold. The Ni_TX_FQ_DESC_VALID.DESC_CN_VALID[n] set to 1, goes to 0 once the TX message is sent (Ni_TX_FQ_DESC_VALID.DESC_NC_VALID[n] =0).
   b. If the descriptor is valid, Ni_TX_FQ_DESC_VALID.DESC_CN_VALID[n] = 1 and Ni_TX_FQ_DESC_VALID.DESC_NC_VALID[n] =1, go to 4)
4. When the current TX message is fully sent, Ni_TX_FQ_DESC_VALID.DESC_CN_VALID[n] = 0 and Ni_TX_FQ_DESC_VALID.DESC_NC_VALID[n] =1.
5. If the current TX descriptor is about to be sent go to 6), otherwise stay in 5) and no updates are done on bit registers.
6. The next descriptor is fetched from S_MEM and written in L_MEM.
   a. If the next TX descriptor is not valid then the TX FIFO Queue n is put on hold. The Ni_TX_FQ_DESC_VALID.DESC_NC_VALID[n] set to 1, goes to 0 once the TX message is sent (Ni_TX_FQ_DESC_VALID.DESC_CN_VALID[n] =0).
   b. If the descriptor is valid, Ni_TX_FQ_DESC_VALID.DESC_NC_VALID[n] = 1 and Ni_TX_FQ_DESC_VALID.DESC_CN_VALID[n] =1, go to 7)
7. When the current TX message is fully sent, Ni_TX_FQ_DESC_VALID.DESC_NC_VALID[n] = 0 and Ni_TX_FQ_DESC_VALID.DESC_CN_VALID[n] =1, go to 2)

22.5.3.24.5 TX Descriptor tracking in TX Priority Queue

As soon as a TX Priority Queue slot n is started, the corresponding TX descriptor is fetched from the S_MEM and written to the L_MEM. When the TX descriptor assigned to the slot n is fully written in the L_MEM, the Ni_TX_PQ_DESC_VALID.DESC_VALID[n] is set to 1.

If the TX descriptor fetched is not valid or has any safety issue, the Ni_TX_PQ_DESC_VALID.DESC_VALID[n] is not set. In case the TX message of the slot n is discarded, the Ni_TX_PQ_DESC_VALID.DESC_VALID[n] is set back to 0.

22.5.3.25 RX and TX Statistics

22.5.3.25.1 RX statistic counters

Two 12bit counters are provided to keep track of how many messages have been received successfully/ unsuccessfully, see Ni_RX_STATISTICS register. When a counter has reached the maximum value, it will wrap to zero with the next increment. The counters can be cleared (set to 0) by writing 0 to the dedicated register bit

field. To identify when counters are wrapping, the STATS_IRQ interrupt line is triggered to the system. To identify the counter which has wrapped, a read to the Ni_STATS_INT_STS register is required. Writing a 1 to the corresponding bit will clear the bit.

Here are the list of root cause to increment Ni_RX_STATISTICS.SUCC[11:0] counter:

- When an RX message is stored in S_MEM and its RX Header descriptor is acknowledged

Here are the list of root cause to increment Ni_RX_STATISTICS.UNSUCC[11:0] counter.

Safety or Errors:

- When an RX data parity error is detected
- When an RX address pointer parity error is detected
- When an RX descriptor error (request, CRC or invalid) is detected and used for the current RX message

Functional:

- When an ABORT code word is received from the PRT
- When a DO code word is received from the PRT
- When the RX message cannot be written to the RX FIFO Queue (queue not enable and/or started)
- When the RX filtering has not finished in time before a new one
- When a data overflow occurs on the RX DMA FIFO
- When a new RX message is received while one is already in progress (filtered and RX descriptor already fetched from system memory)
- When the PRT ENABLE signal is going from High to Low when receiving an RX frame

22.5.3.25.2 TX statistic counters

Two 12bit counters are provided to keep track of how many messages have been transmitted successfully/ unsuccessfully, see Ni_TX_STATISTICS register. When a counter has reached the maximum value, it will wrap to zero with the next increment. The counters can be cleared (set to 0) by writing 0 to the dedicated register bit field. To identify when counters are wrapping, the STATS_IRQ interrupt line is triggered to the system. To identify the counter which has wrapped, a read to the Ni_STATS_INT_STS register is required. Writing a 1 to the corresponding bit will clear the bit.

Here are the list of root cause to increment Ni_TX_STATISTICS.SUCC[11:0] counter:

- When a TX message is fully sent to the PRT, and its TX Header descriptor is acknowledged

Here are the list of root cause to increment Ni_TX_STATISTICS.UNSUCC[11:0] counter.

Safety or Errors:

- Not applicable

Functional:

- When a HFI code word is received from the PRT
- When the maximum number of transmission allowed for a given TX message is reached
- When the TX filtering has rejected a TX message

22.5.3.26 Register access

The MH registers are accessible in read/write mode through its AXI4-Lite slave interface HOST_AXI (compliant to AMBA 4 ARM Ltd protocol, see [3]).

Any access to registers, either read or write, must use a 32bit aligned address, otherwise a SLVERR is provided as a response.

When an access is performed to a non-mapped register in the address range, a SLVERR is provided as a response.

When a read access to write-only registers or a write access to read-only registers is performed, a SLVERR is provided as a response.

When an access is performed to a write-only Privileged register in the address range, a SLVERR is provided as a response.

The phrase ‘SLVERR is provided as a response’ means that the HOST_AXI responds with RRESP = ‘SLVERR’ respective BRESP = ‘SLVERR’.

The error is only reported on the AXI4-Lite protocol, no interrupt is triggered for such issue. The register interface does not provide any access to the L_MEM. It would in charge of the integrator to provide a direct access to the L_MEM to write the relevant data for the MH.

22.5.3.27 Register protection

22.5.3.27.1 Lock mechanism protection

To secure the access to some of the critical registers, an unlock key sequence is required prior to any write-modified access. This procedure must be done before any write to the locked registers. As soon as the write is completed, the register is automatically set back to lock mode.

When an access is performed to a locked register, a SLVERR is provided as a response. The error is only reported on the AXI4-Lite protocol, no interrupt is triggered for such issue.

Two locks are provided for two different purposes:

- A lock is protecting the register in charge of stopping RX and TX FIFO Queues as well as TX Priority Queue slots
- A lock is protecting the MH to be set in debug mode

Functional lock

This sequence is based on three step as defined below:

1. Write 0x1234 to the Ni_LOCK.ULK[15:0] bit-field register
2. Write 0x4321 to the Ni_LOCK.ULK[15:0] bit-field register
3. Write to the unlocked register the expected value

Once the write is performed to the register, it will be automatically back to lock.

The following list of registers are using this protection:

- Ni_TX_FQ_CTRL1
- Ni_TX_PQ_CTRL1
- Ni_RX_FQ_CTRL1

Test mode lock

An unlock key sequence is required to access in write mode the registers assigned to debug and test purpose. This procedure must be done before any write to the locked registers.

This sequence is based on three step as defined below:

1. Write 0x6789 to the Ni_LOCK.TMK[15:0] bit-field register
2. Write 0x9876 to the Ni_LOCK.TMK[15:0] bit-field register
3. Write to the unlocked register the expected value

Once the write is performed to the register, it will be automatically back to a lock state. The only register using this specific key sequence is the Ni_DEBUG_TEST_CTRL register as it does control the debug mode.

22.5.3.27.2 Conditional access protection

Some registers can be written if a bit defined in another register allows the access. As long as this conditional bit is having the right value, any single or consecutive writes can be performed. Configuration registers are protected by such mechanism to avoid any changes while the logic is running.

When an access is performed to a write protected register, a SLVERR is provided as a response. The error is only reported on the AXI4-Lite protocol, no interrupt is triggered for such issue.

The registers with conditional accesses are defined in the following table.

Table 1055 Conditional access register list

Register Name	Condition to write access	Description/Constraints
Ni_MH_CFG	Ni_MH_STS.BUSY = 0	The register can be written if the MH is not running
Ni_MH_SFTY_CFG		
Ni_MH_SFTY_CTRL		
Ni_RX_FILTER_MEM_ADD		
Ni_TX_DESC_MEM_ADD		
Ni_AXI_ADD_EXT		
Ni_AXI_PARAMS		
Ni_TX_FILTER_CTRL0		
Ni_TX_FILTER_CTRL1		
Ni_TX_FILTER_REFVAL0		
Ni_TX_FILTER_REFVAL1		
Ni_TX_FILTER_REFVAL2		
Ni_TX_FILTER_REFVAL3		
Ni_RX_FILTER_CTRL		
Ni_TX_FQ_START_ADD{n}	Ni_TX_FQ_STS0.BUSY[n] = 0	The register can be written if the TX FIFO Queue n is not running (where n is 0-7)
Ni_TX_FQ_SIZE0{n}		
Ni_TX_PQ_START_ADD	Ni_TX_PQ_STS0 = 00000000_H	The register can be written if no TX Priority Queue slots are running
Ni_RX_FQ_START_ADD{n}	Ni_RX_FQ_STS0.BUSY[n] = 00_H	The register can be written if the RX FIFO Queue n is not running (where n is 0-7)
Ni_RX_FQ_SIZE{n}		
Ni_RX_FQ_DC_START_ADD{n}		
Ni_INT_TEST0	Ni_DEBUG_TEST_CTRL.TEST_IRQ_EN = 1	The interrupt lines can be trigger by SW if the interrupt test mode is enable
Ni_INT_TEST1		

22.5.3.27.3 Register CRC computation

To protect the MH configuration, control and configuration registers are protected using CRC. A reference CRC, computed by the SW, is set to a register, and compare with an internal CRC value computed by the MH. It is important to note that some of the registers won't be accessible once the MH is started, Ni_MH_STS.BUSY set to 1, refer to Conditional Access Protection and Lock Mechanism Protection sections for more details.

Once the overall MH setting is done and only when there are no more changes on the control and configuration register, do the following:

- The SW must provide the expected CRC for list of protected registers. The CRC reference value must be computed, only for the registers defined as CRC protected, starting from the lowest address offset. The order of the register to be considered for the CRC computation is defined below (all register values will be checked). The CRC is computed using the 32bit value of the register defined in the list
- Once the 32bit CRC value is computed by SW, it must be written to the Ni_CRC_REG register. The write access to this register does not trig a CRC check
- To check the CRC for the registers, set the Ni_CRC_CTRL.START bit to 1. The MH goes through the list of CRC protected registers and compute the global CRC. After a few cycles, the CRC reference value in the Ni_CRC_REG register is compared with the one already computed. If a CRC error is detected, the REG_CRC_ERR interrupt signal is triggered. As the check is only done and control by SW, there is no enable defined

SW can start a CRC check at regular time interval by setting the Ni_CRC_CTRL.START bit to 1. It is recommended to perform a register CRC check, for any new configuration, to ensure a proper setting before starting the MH.

Here below is the list of registers protected by CRC, in the order they need to be considered (refer to sections in Register Protection chapter for register accessibility):

- Ni_VERSION
- Ni_MH_CFG
- Ni_MH_SFTY_CFG
- Ni_MH_SFTY_CTRL
- Ni_RX_FILTER_MEM_ADD
- Ni_TX_DESC_MEM_ADD
- Ni_AXI_ADD_EXT
- Ni_AXI_PARAMS
- LOOP n from 0 to 7
  - Ni_TX_FQ_START_ADD{n}
  - Ni_TX_FQ_SIZE{n}
- END LOOP
- Ni_TX_PQ_START_ADD
- LOOP n from 0 to 7
  - Ni_RX_FQ_START_ADD{n}
  - Ni_RX_FQ_SIZE{n}
  - Ni_RX_FQ_DC_START_ADD{n}
- END LOOP
- Ni_TX_FILTER_CTRL0 (Privileged)
- Ni_TX_FILTER_CTRL1 (Privileged)
- LOOP n from 0 to 3
  - Ni_TX_FILTER_REFVAL{n} (Privileged)
- END LOOP
- Ni_RX_FILTER_CTRL (Privileged)
- Ni_DEBUG_TEST_CTRL (Privileged)
- Ni_INT_TEST0
- Ni_INT_TEST1

Here below is the normal polynomial representation and implementation of the CRC-32 used to protect the registers:

$$CRC - 32 = \left(x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x + 1\right)$$

```
Here below is the pseudo code to compute the CRC for the MH register bank:
The reg_table[] is the array of 32bit registers defined previously (in the order they are
listed):
static logic[31:0] rem32 = 32'hffffffff;
static logic[31:0] rem32_old = 32'hffffffff;
static logic[31:0] poly = 32'h4c11db7;
static logic[31:0] crc32;
// initialize CRC shift register
// This algorithm is indirect
rem32 = 32'hffffffff;
foreach (reg_table[i]) begin
for (int j = 31; j >= 0; j--) begin
// to decide whether reduction with polynomial will be required based on MSB before shift
rem32_old = rem32;
// shift out MSB of CRC
rem32 = rem32 << 1;
rem32[0] = reg_table[i].get()[j];
// perform reduction if required
if (rem32_old[31]) rem32 = rem32 ^ poly;
end
end
// processing 32 0s more
repeat(32) begin
// to decide whether reduction with polynomial will be required based on MSB before shift
rem32_old = rem32;
// shift out MSB of CRC
rem32 = rem32 << 1;
rem32[0] = 0;
// perform reduction if required
if (rem32_old[31]) rem32 = rem32 ^ poly;
end
crc32 = rem32;
```

22.5.3.28 Error and exception handling

Here is the list of potential issues the MH may have to handle and how it should react:

Table 1056 Potential issues of the MH

Error	Source	Interrupt	MH behavior
	MH		

(table continues...)

Table 1056 (continued) Potential issues of the MH

Error	Source	Interrupt	MH behavior
RX acknowledge path overflow	Acknowledge data not sent in time before new one needs to be stored	DP_DO_ERR	The current RX message is discarded and an RX_ABORT_IRQ is triggered to the system. The interrupt DP_DO_ERR is triggered to the system and the Ni_ERR_INT_STS.DP_RX_ACK_DO_ERR bit status register is set to 1. The MH finishes its current transactions and stops with Ni_MH_CTRL.BUSY = 0. The SW needs to restart it and the MH will keep going with its current task.
TX acknowledge path overflow	Acknowledge data not sent in time before the new one being stored	DP_DO_ERR	As soon as an acknowledge data locally stored and ready to be send cannot be done (due to some overflow) no new messages will be sent to the PRT. The DP_DO_ERR interrupt is triggered to the system and the Ni_ERR_INT_STS.DP_TX_ACK_DO_ERR bit status register is set to 1. The MH finishes its current transaction and stops with Ni_MH_CTRL.BUSY = 0. The SW needs to restart it and the MH will keep going with its current task.
RX DMA FIFO overflow	The FIFO overflow on the RX path	DP_DO_ERR	The current RX message is discarded and an RX_ABORT_IRQ is sent to the system. The already RX descriptors used are allocated for the next message. No status is sent back to the Header Descriptor. The MH keeps receiving RX message despite this temporary issue. The Ni_ERR_INT_STS.DP_RX_FIFO_DO_ERR bit status register is set to 1.

(table continues...)

Table 1056 (continued) Potential issues of the MH

Error	Source	Interrupt	MH behavior
RX DMA FIFO above threshold while RX filtering in progress	The RX filter has not completed in time to avoid a potential overflow	NONE	The current RX message is sent to the default RX FIFO Queue as backup solution if enable, see the Ni_RX_FILTER_CTRL register. The threshold is defined to provide enough time for the MH to write the message in S_MEM. The RX Header descriptor of that RX message will have its status report bit field set to “message received but not filtered”. The MH keeps receiving RX message.
RX descriptor CRC error when fetched from S_MEM	A CRC error is detected on RX descriptor	DESC_ERR	As the RX descriptor has a CRC error, the related RX FIFO Queue is stopped and the interrupt DESC_ERR is triggered to the system, see Ni_RX_FQ_STS1, Ni_RX_FQ_STS0 registers. The Ni_SFTY_INT_STS.RX_DESC_CRC_ERR bit status register is set to 1. Other RX FIFO Queues would still be running.
Wrong RX descriptor fetched from S_MEM	The expected descriptor is not the one coming back from S_MEM. Several issue on the address could lead to such result	DESC_ERR	As the RX descriptor is not the one expected, the related RX FIFO Queue is stopped and the interrupt DESC_ERR is triggered to the system, see Ni_RX_FQ_STS1, Ni_RX_FQ_STS0 registers. The Ni_SFTY_INT_STS.RX_DESC_REQ_ERR bit status register is set to 1. Other RX FIFO Queues would still be running.
TX descriptor CRC error when fetched from S_MEM	A CRC error is detected on TX descriptor when fetched from S_MEM	DESC_ERR	As the TX descriptor has a CRC error, the related TX FIFO Queue is stopped and the interrupt DESC_ERR is triggered to the system. The Ni_SFTY_INT_STS.TX_DESC_CRC_ERR bit status register is set to 1. Other TX FIFO Queues would still be running. TX priority Queue are managed differently. If an issue occurs on the TX descriptor the slot will have its busy and sent flags set to 0, see Ni_TX_PQ_STS0 and Ni_TX_PQ_STS1 registers.

(table continues...)

Table 1056 (continued) Potential issues of the MH

Error	Source	Interrupt	MH behavior
Wrong TX descriptor fetched from S_MEM	The expected descriptor is not the one coming back from S_MEM. Several issue on the address could lead to such result	DESC_ERR	As the TX descriptor is not the one expected, the related TX FIFO Queue is stopped and the interrupt DESC_ERR is triggered to the system. The Ni_SFTY_INT_STS.TX_DESC_REQ_ERR bit status register is set to 1. Other TX FIFO Queues would still be running. TX priority Queue are managed differently. If an issue occurs on the TX descriptor the slot will have its busy and sent flags set to 0, see Ni_TX_PQ_STS0 and Ni_TX_PQ_STS1 registers.
Wrong TX descriptor fetched from L_MEM	The expected descriptor is not the one coming back from L_MEM. Several issue on the address could lead to such result	DESC_ERR	The TX descriptor selected to be the next message candidate is corrupted. Either the related TX FIFO Queue is stopped (see Ni_TX_FQ_STS0 and Ni_SFTY_INT_STS registers) or the TX Priority Queue slot is set disable (busy flag set to 0), see Ni_TX_PQ_STS0 and Ni_SFTY_INT_STS registers). The interrupt DESC_ERR is triggered to the system. The Ni_SFTY_INT_STS.TX_DESC_REQ_ERR bit status register is set to 1. Other TX FIFO Queues would still be running as well as TX Priority Queue slots.
Parity error detected on TX address pointers	One of the address pointers managing the TX FIFO Queues or the TX Priority Queue is corrupted	AP_PARITY_ERR	As the source of parity issue, could lead to wrong memory accesses, the MH stops. The MH finishes all pending data transfers and then stops with Ni_MH_STS.BUSY = 0. The SW is notified through the AP_PARITY_ERR interrupt and the Ni_SFTY_INT_STS.AP_TX_PARITY_ERR status bit register is set to 1.

(table continues...)

Table 1056 (continued) Potential issues of the MH

Error	Source	Interrupt	MH behavior
Parity error detected on RX address pointers	One of the address pointers managing the RX FIFO Queues is corrupted	AP_PARITY_ERR	As the source of parity issue, could lead to wrong memory accesses, the MH stops. The MH finishes all pending data transfers and then stops with Ni_MH_STS.BUSY = 0. The SW is notified through the AP_PARITY_ERR interrupt and the Ni_SFTY_INT_STS.AP_RX_PARITY_ERR status bit register is set to 1.
Register CRC error	One of the configuration register protected by CRC is corrupted	REG_CRC_ERR	There is no way to define which register is corrupted and to evaluate which part of the logic would be impacted. The MH is stopped. When receiving an RX message, the current message is discarded and all RX FIFO Queues are stopped. When transmitting a message, it is aborted. All TX FIFO Queues are stopped and all TX Priority Queue slot are disabled. The interrupt REG_CRC_ERR is sent to system
TX data path sequence error	Any error sequence detected on the TX_MSG interface	DP_SEQ_ERR	If any code word reported by the PRT does not match the expected sequence the PRT and MH are no more synchronized. The MH finishes all pending data transfers and then stops with Ni_MH_STS.BUSY = 0. the DP_SEQ_ERR interrupt is triggered with the Ni_ERR_INT_STS.DP_TX_SEQ_ERR bit status register set to 1.
RX data path sequence error	Any error sequence detected on the RX_MSG interface	DP_SEQ_ERR	If any code word reported by the PRT does not match the expected sequence the PRT and MH are no more synchronized. The MH finishes all pending data transfers and then stops with Ni_MH_STS.BUSY = 0. the DP_SEQ_ERR interrupt is triggered with the Ni_ERR_INT_STS.DP_RX_SEQ_ERR bit status register set to 1.

(table continues...)

Table 1056 (continued) Potential issues of the MH

Error	Source	Interrupt	MH behavior
RX frame reception in progress when receiving a new RX message	Due to a high number of filter elements and a high latency on the memory, the RX filtering process may cover almost the shortest CAN frame, leading to an overlap on the current and new RX messages	RX_ABORT_IRQ	As the current RX message has not complete prior receiving the next frame, the new frame is discarded to provide the remaining time to complete the process on the current one. Therefore, any new RX message is aborted with an RX_ABORT_IRQ interrupt.
RX filter not done in time before a new RX frame	The RX filter does not complete in time its process to identify the RX FIFO Queue	RX_FILTER_ERR	When the RX filter is taking too much time and a new RX message is coming, the RX_FILTER_ERR interrupt is triggered. The new RX message is discarded, see Ni_RX_FILTER_CTRL register. The MH keeps running on its current frame. Such interrupt is a good indicator for SW to identify large RX filtering time on some frames.
RX FIFO Queue not enable for reception	The RX FIFO Queue selected to receive the RX message is not running, either not set or wrongly set	RX_ABORT_IRQ	The selected RX FIFO Queue defined after the RX filtering process is disable. The MH discards the RX message with the RX_ABORT_IRQ interrupt. Every RX message going to this disabled RX FIFO Queue will trigger this interrupt. The SW must ensure RX FIFO Queues are enable at first time.
	The RX Filter cannot send message to the RX FIFO Queue as it is disable	RX_FILTER_ERR	In case the RX Filter identifies an RX FIFO Queue to receive an RX message but this queue is disable, the RX_FILTER_ERR interrupt is triggered and the message is rejected
TX message rejected by TX filter	The Header Descriptor is filtered to ensure only well-defined TX message can go through	TX_FILTER_IRQ	When a TX message is rejected it will be skipped by the MH. When the Header descriptor is in a TX FIFO Queue, the next message in the FIFO is used instead. An acknowledge is sent to the TX descriptor with the status rejected. Regarding TX Priority Queue, the corresponding slot is disabled. The MH keeps running all other TX FIFO Queues or slots defined as valid

(table continues...)

Table 1056 (continued) Potential issues of the MH

Error	Source	Interrupt	MH behavior
DMA channel interface mixed up	Wrong data sent or received to DMA channel interface detected by the DMA	DMA_CH_ERR	As such issue would mean data are mixed up, there is no way to recover. The MH finishes all pending data transfers and then stops with Ni_MH_STS.BUSY = 0. The system is notified through the DMA_CH_ERR interrupt line. There is no status flag assigned to such interrupt as the DMA channel being faulty cannot be identified
Parity error on RX message data	A bit flip is detected on data from the RX_MSG to the AXI system bus interface	DP_PARITY_ERR	If such issue occurs while receiving data, the RX message would be discarded. No acknowledge data is sent. An interrupt DP_PARITY_ERR is triggered. The Ni_SFTY_INT_STS.DP_RX_PARITY_ERR bit status register is set to 1. As the RX message would be aborted, the RX_ABORT_IRQ interrupt would also be set. The MH keeps going with new messages.
Parity error on TX message data	A bit flip is detected on data from the AXI system bus interface to the TX_MSG	DP_PARITY_ERR	If such issue occurs while transmitting data, the TX message would be aborted. An interrupt DP_PARITY_ERR would be triggered. The Ni_SFTY_INT_STS.DP_TX_PARITY_ERR bit status register is set to 1. The TX_ABORT_IRQ interrupt is set.
Parity error on RX message acknowledge data	A bit flip is detected on data from the RX_MSG to the AXI system bus interface	DP_PARITY_ERR	If such issue occurs on the acknowledge data, the RX message would be discarded. No acknowledge data is sent. An interrupt DP_PARITY_ERR is triggered. The Ni_SFTY_INT_STS.ACK_RX_PARITY_ERR bit status register is set to 1. The MH keeps going with new messages.

(table continues...)

Table 1056 (continued) Potential issues of the MH

Error	Source	Interrupt	MH behavior
Parity error on TX message acknowledge data	A bit flip is detected on payload data from the AXI system bus interface to the TX_MSG	DP_PARITY_ERR	If such issue occurs while acknowledging the TX message. An interrupt DP_PARITY_ERR is triggered. The Ni_SFTY_INT_STS.ACK_TX_PARITY_ERR bit status register is set to 1. The SW can identify such issue reading the report status of that TX descriptor.
RX message received while MH not started	Ni_MH_CTRL.START bit wrongly set to 1	NONE	The MH does not accept RX message data from the PRT. As the PRT cannot sent data to the MH, a data overflow on the PRT will occur leading to an interrupt.
PRT			
RX data path overflow	DO code word received from PRT. . Several issues could lead to such issue for example, peak latency preventing write accesses in time or RX path being stopped and so on.	NA	The RX message is discarded. The already used RX descriptor are reused for the next message. Then, no status is sent back to the Header Descriptor in S_MEM.
RX message on CAN bus not successful	ABORT code word received from PRT. Invalid CAN message detected on CAN bus	NA	This is normal behavior. The RX message is discarded. The already used RX descriptors are allocated for the next message. No acknowledge data is sent back to the S_MEM

(table continues...)

Table 1056 (continued) Potential issues of the MH

Error	Source	Interrupt	MH behavior
TX data path underrun	DU code word received from PRT. TX message data not provided in time	NA	The current TX message, selected and started on the MH side, is aborted but the PRT keeps going with its current frame and will generated a wrong CRC to invalidate the frame at the receiver side. All data transfers from S_MEM is aborted. The issue may be the result of a peak latency. The TX message is still valid and will be part of the next TXScan. The MH can restart to transmit the same message according to the restart counter setting. The PRT is triggered an interrupt to the system when such code word is transmitted to the MH. It is essential to understand that the MH will still be active and fully functional. There is no message loss when such issue occurs
TX message on CAN bus not successful	RESTART code word received from PRT	NA	The current TX message, selected and started on the MH side, is aborted. All data transfers from S_MEM is aborted. The current TX message is still valid and will be part of the next TX-Scan. The MH can restart to transmit the same message according to the restart counter setting or use another one with highest priority.
TX message header invalid	HFI code word received from PRT	NA	The current TX message is discarded, and a data acknowledge is sent back to the Header Descriptor in S_MEM. The report status of the TX descriptor is updated with the issue. If the TX message was in a TX FIFO Queue, the MH keeps running and skips this TX message to fetch the next one. In case of a TX Priority Queue slot, the slot is set as done but not sent (see report status in TX descriptor)

(table continues...)

Table 1056 (continued) Potential issues of the MH

Error	Source	Interrupt	MH behavior
Unexpected Start Of Sequence (USOS) at the TX_MSG interface	When PRT detects USOS, it stops CAN protocol operation and sets ENABLE=0	STOP_IRQ	In case such code word is received, the MH or the PRT are no more synchronized. The MH finishes its current transfers and stops. The STOP_IRQ interrupt is set to notify MH is no more active. In such scenario the only action would be to reset the MH and PRT to recover
PRT entered CAN protocol's Bus-Off state	PRT stops CAN protocol operation and sets ENABLE=0	STOP_IRQ	MH finishes all pending data transfers and then stops (put on hold). All FSM in the MH go to idle. The STOP_IRQ interrupt is set to notify MH is no more active. A write to the Ni_MH_CTRL.START bit register allows the SW to restart everything at the point it was stopped, if required.
PRT stopped by SW	PRT stops CAN protocol operation and sets ENABLE=0	STOP_IRQ	
PRT TX_MSG interface not responding	PRT is having a deadlock and cannot answer to MH request or receive data	DP_TO_ERR	When the timeout assigned to the TX_MSG interface fires, the MH finishes all pending data transfers and then stops with Ni_MH_STS.BUSY = 0. The DP_TO_ERR interrupt is triggered to the system.with the Ni_ERR_INT_STS.DP_TX_TO_ERR bit status set to 1
PRT RX_MSG interface not responding	PRT is having a deadlock and cannot send data to MH	DP_TO_ERR	When the timeout assigned to the RX_MSG interface fires, the MH finishes all pending data transfers and then stops with Ni_MH_STS.BUSY = 0. The DP_TO_ERR interrupt is triggered to the system with the Ni_ERR_INT_STS.DP_RX_TO_ERR bit status set to 1
LOCAL MEMORY (L_MEM)			

(table continues...)

Table 1056 (continued) Potential issues of the MH

Error	Source	Interrupt	MH behavior
Local memory safety error while reading RX filter element. Corrupted data has been corrected	The L_MEM is providing a safety error on MEM_SFTY_CE input signal while reading a data	MEM_SFTY_ERR	As the corrupted data word is corrected, the RX filtering can be done on the current RX message. The MH keeps running and will be able to receive new messages. The interrupt MEM_SFTY_ERR is triggered to the system with the Ni_SFTY_INT_STS.MEM_SFTY_CE bit status register set to 1. It is essential for such issue that there is no error response on the memory interface while reading the corrected data.
Local memory safety error while reading TX descriptor. Corrupted data has been corrected	The L_MEM is providing a safety error on MEM_SFTY_CE input signal while reading a data	MEM_SFTY_ERR	As the TX descriptor selected to be the next message candidate is corrupted but corrected, the related TX FIFO Queue or the TX Priority Queue slot will run as normal. When the TX-Scan is reading a corrected TX descriptor, the all process will complete. The interrupt MEM_SFTY_ERR is triggered to the system with the Ni_SFTY_INT_STS.MEM_SFTY_CE bit status register set to 1. It is essential for such issue that there is no error response on the memory interface while reading the corrected data.
Local memory safety error while reading RX filter element. Corrupted data is not corrected	The L_MEM is providing a safety error on MEM_SFTY_UE input signal while reading a data with SLVERR response	MEM_SFTY_ERR	As no more filtering can be done on the current RX message, it is discarded. As it is not possible to keep going with a corrupted RX filter element, the MH stops The interrupt MEM_SFTY_ERR is triggered to the system with the Ni_SFTY_INT_STS.MEM_SFTY_UE bit status register set to 1. The MH finishes all pending data transfers and then stops with Ni_MH_STS.BUSY = 0. It is essential for such issue, to have the memory interface reporting a SLVERR when reading the corrupted data.

(table continues...)

Table 1056 (continued) Potential issues of the MH

Error	Source	Interrupt	MH behavior
Local memory safety error while reading TX descriptor. Corrupted data is not corrected	The L_MEM is providing a safety error on MEM_SFTY_UE input signal while reading a data with a SLVERR response	MEM_SFTY_ERR	As it is not possible to keep going with a corrupted TX descriptor, the MH stops The interrupt MEM_SFTY_ERR is triggered to the system if such issue occurs with the Ni_SFTY_INT_STS.MEM_SFTY_UE bit status register set to 1. The MH finishes all pending data transfers and then stops with Ni_MH_STS.BUSY = 0. It is essential for such issue, to have the memory interface reporting a SLVERR when reading the corrupted data.
Error response received on local memory write access. A safety issue is not considered here	The L_MEM is providing a DECERR/SLVERR error response on BRESP[1:0] for a write access	RESP_ERR[0]	The TX descriptor written to the L_MEM is not valid. In such cases as the L_MEM cannot be trusted anymore, the MH stops. The MH finishes all pending data transfers and then stops with the Ni_MH_STS.BUSY = 0. The RESP_ERR[0] interrupt is triggered to the system. To identify the issue the BRESP[1:0] and the ID of the transaction are logged in the Ni_AXI_ERR_INFO.MEM_ID[1:0] and Ni_AXI_ERR_INFO.MEM_RESP[1:0] bit status register.
Error response received on local memory read access. A safety issue is not considered here	The L_MEM is providing a DECERR/SLVERR error response on RRESP[1:0] for a read access	RESP_ERR[1]	The TX descriptor or RX Filter element read from the L_MEM is not valid. In such cases as the L_MEM cannot be trusted anymore, the MH stops. The MH finishes all pending data transfers and stops with the Ni_MH_STS.BUSY = 0. The RESP_ERR[0] interrupt is triggered to the system. To identify the issue the RRESP[1:0] and the ID of the transaction are logged in the Ni_AXI_ERR_INFO.MEM_ID[1:0] and Ni_AXI_ERR_INFO.MEM_RESP[1:0] bit status register.

(table continues...)

Table 1056 (continued) Potential issues of the MH

Error	Source	Interrupt	MH behavior
A read from the L_MEM cannot complete	The MH does not complete a read within a defined time frame	MEM_TO_ERR	When the timeout assigned to the L_MEM AXI read channel fires, the MH finishes all pending data transfers and then stops with Ni_MH_STS.BUSY = 0. The MEM_TO_ERR interrupt is triggered to the system and the Ni_SFTY_INT_STS.MEM_AXI_RD_TO_ERR bit status is set to 1
A write to the L_MEM cannot complete	The MH does not complete a write within a defined time frame	MEM_TO_ERR	When the timeout assigned to the L_MEM AXI write channel fires, the MH finishes all pending data transfers and then stops with Ni_MH_STS.BUSY = 0. The MEM_TO_ERR interrupt is triggered to the system and the Ni_SFTY_INT_STS.MEM_AXI_WR_TO_ERR bit status is set to 1
System			
Address decoding error on DMA write channels	Error response from AXI system bus interface, DECERR received on BRESP[1:0] for write access	RESP_ERR[0]	When the error is detected on the RX message data or acknowledge data being written, the interrupt RESP_ERR[0] interrupt is sent to the system. As the S_MEM is not reliable, the MH stops. The MH finishes all pending data transfers and stops with the Ni_MH_STS.BUSY = 0. To identify the issue the BRESP[1:0] and the ID of the transaction are logged in the Ni_AXI_ERR_INFO.DMA_ID[1:0] and Ni_AXI_ERR_INFO.DMA_RESP[1:0] bit status register.
Address decoding error on DMA read channels	Error response from AXI system bus interface, DECERR received on RRESP[1:] for read access	RESP_ERR[1]	When the error is detected on the TX message data, RX or TX descriptors, the interrupt RESP_ERR[1] is sent to the system. As the S_MEM is not reliable, the MH stops. The MH finishes all pending data transfers and stops with the Ni_MH_STS.BUSY = 0. To identify the issue the RRESP[1:0] and the ID of the transaction are logged in the Ni_AXI_ERR_INFO.DMA_ID[1:0] and Ni_AXI_ERR_INFO.DMA_RESP[1:0] bit status register.

(table continues...)

Table 1056 (continued) Potential issues of the MH

Error	Source	Interrupt	MH behavior
System memory CRC error or Access to wrong slave on DMA write channel	Error response from AXI system bus interface, SLVERR received on BRESP[1:0] for write access	RESP_ERR[0]	There is no way to identify the exact error source, either a CRC error or a wrong slave access. See “Address decoding error on DMA write channels” description in this table
System memory CRC error or Access to wrong slave on DMA read channel	Error response from AXI system bus interface, SLVERR received on RRESP[1:0] for read access	RESP_ERR[1]	There is no way to identify the exact source, either a CRC error or a wrong slave access. See “Address decoding error on DMA read channels” description in this table
A read from the S_MEM cannot complete	The MH does not complete a read within a defined time frame	DMA_TO_ERR	When the timeout assigned to the S_MEM AXI read channel fires, the MH finishes all pending data transfers and then stops with Ni_MH_STS.BUSY = 0. The DMA_TO_ERR interrupt is triggered to the system with the Ni_SFTY_INT_STS.DMA_AXI_RD_TO_ERR bit status set to 1
A write to the S_MEM cannot complete	The MH does not complete a write within a defined time frame	DMA_TO_ERR	When the timeout assigned to the S_MEM AXI write channel fires, the MH finishes all pending data transfers and then stops with Ni_MH_STS.BUSY = 0. The DMA_TO_ERR interrupt is triggered to the system with the Ni_SFTY_INT_STS.DMA_AXI_WR_TO_ERR bit status set to 1

22.5.3.29 Interrupts

Table 1057 Interrupts

Interrupt	Description
TX_FQ_IRQ[7:0]	When considering TX FIFO Queues there is a mean, thanks to the IRQ bit-field in TX descriptor, to trigger an interrupt to the system when a TX message is sent successfully or skipped. This interrupt can only be declared in a TX Header Descriptor (HD=1). When a TX descriptor has HD=0 and IRQ=1, no interrupt is generated A dedicated interrupt signal TX_FQ_IRQ[N] is provided per TX FIFO queue n (0 <= n <= 7). When a TX Header Descriptor is mentioning an interrupt (IRQ bit set to 1) and the message is successfully sent or skipped, the DESC_MESSAGE_HANDLER identifies the TX FIFO queue source number of that descriptor and triggers the relative line of the interrupt bus signal. When one or several TX descriptors are used for one TX message, the SW needs to define the interrupt (IRQ bit-field set to 1) only to the Header Descriptor. The interrupt will be effective only when the acknowledge data of that descriptor is fully written in S_MEM. It is then possible to define for a TX FIFO Queue n, having a fix number of messages to be sent, the interrupt TX_FQ_IRQ[N] only to the last Header Descriptor. Doing so, this approach will limit the number of interrupts to the system. The main purpose of the TX FIFO Queue is to append on the fly new messages. A race condition may occur between the SW and the Message Handler regarding the definition of valid TX message in that queue. In case a TX FIFO Queue n does not provide a valid TX descriptor, the MH notifies the SW with the TX_FQ_IRQ[n] that the TX FIFO Queue n is on hold, despite being active. The Ni_TX_FQ_INT_STS register provides the relevant information to detect the root cause. As a summary two different source of events can trig those interrupts: • This interrupt is triggered when the IRQ bit field in TX Header Descriptor is set to 1 and the TX message is sent successfully. The Ni_TX_FQ_INT_STS.SENT[n] bit register is set to 1 for the TX FIFO Queue n and the bit field STS[3:0] in the TX descriptor is set to 0’b0001 • This interrupt trigs when the TX message is skipped. The Ni_TX_FQ_INT_STS.SENT[n] bit register is set to 1 for the TX FIFO Queue n and the bit field STS[3:0] in the TX descriptor is set to 0’b0010 or 0’b0011 • The TX FIFO Queue n execution is stopped due to the fetch of an invalid TX descriptor in this queue (no more TX message defined, and no END bit set to 1 for the last TX message). The Ni_TX_FQ_INT_STS.UNVALID[n] bit register is set to 1 for the TX FIFO Queue n

(table continues...)

Table 1057 (continued) Interrupts

Interrupt	Description
RX_FQ_IRQ[7:0]	When considering RX FIFO Queues there is the option, thanks to the IRQ bit field in RX descriptor, to trigger an interrupt to the system when an RX message is received successfully. The interrupt bus signal RX_FQ_IRQ[n] provides an interrupt line for the RX FIFO queue n (0 <= n <=7). When the DESC_MESSAGE_HANDLER fetches an RX descriptor for a given RX message and identifies an IRQ bit set to 1 in one of them, it stores this information. Once the RX message is received successfully and a IRQ bit set has been detected in one RX descriptor, an interrupt is triggered. This interrupt is triggered only when the acknowledge data (written in the Header Descriptor) is fully written in the S_MEM. As a summary there are two options to define this interrupt bit in RX descriptors: • In case the SW requires an interrupt per RX message, the IRQ bit in all RX descriptors must be set to 1. This setting is valid for Normal and Continuous mode with the same effect. • The SW can set the IRQ bit in a regular interval along an RX FIFO Queue, avoiding interrupts at every RX message. Only the RX message covering the RX descriptor having this IRQ bit set will trigger an interrupt. In Continuous mode, it is then possible to set an interrupt every two, three or N messages. In Normal mode, the interrupt could be defined every two, three or N RX descriptors According to the RX message size, several RX descriptors will be used and so could trig the interrupt. It is important to note that RX messages are received with various bit rate, thus the interrupt time interval will not be identical. A race condition may occur between the SW and the Message Handler regarding the definition of valid RX descriptor in a queue. In case an RX FIFO Queue n does not provide a valid RX descriptor in time, the interrupt notifies the SW with the RX_FQ_IRQ[n] interrupt that the RX FIFO Queue n is on hold despite being active. The Ni_RX_FQ_INT_STS register provides the related information to identify the root cause. As a summary two different source of events can trig those interrupts: • This interrupt is triggered when the IRQ bit field in an RX Descriptor is set to 1 and the RX message is received successfully. The Ni_RX_FQ_INT_STS.RECEIVED[n] bit register is set to 1 for the RX FIFO Queue n and the bit field STS[3:0] in the RX descriptor is set to 0’b0001 • The RX FIFO Queue n execution is stopped due to the fetch of an invalid RX descriptor in this queue. The Ni_RX_FQ_INT_STS.UNVALID[n] bit register is set to 1 for the TX FIFO Queue n

(table continues...)

Table 1057 (continued) Interrupts

Interrupt	Description
TX_PQ_IRQ	A single TX_PQ_IRQ interrupt is assigned to all TX Priority Queue slots. Any TX Priority Queue slot can trigger an interrupt (IRQ = 1) when the relative TX message is successfully sent or skipped. Any TX Header Descriptor having the IRQ bit set and used by the TX Priority Queue trigs this interrupt line. As for the TX FIFO Queue, when a TX message is defined in a TX Priority Queue slot, all the TX descriptors used to define this message must be valid. When the message is sent, the slot is set to inactive and nothing else can occur. Whereas the TX FIFO Queue, which is processing up to the point a TX descriptor is invalid, the TX Priority Queue slot must not fetch any invalid descriptor. To protect the execution of TX message and to have a common TX Queue management, the TX priority Queue can also report invalid descriptor. The SW need to look at the interrupt status register Ni_TX_PQ_INT_STS0 and Ni_TX_PQ_INT_STS1 to identify which slot has generated the interrupt and for which reason. As a summary three different source of events can trig this interrupt: • This interrupt is triggered when the IRQ bit field in TX Header Descriptor is set to 1 and the TX message is sent successfully. The Ni_TX_PQ_INT_STS0.SENT[n] bit register is set to 1 for the TX Priority Queue slot n and the bit field STS[3:0] in the TX descriptor is set to 0’b0001 • This interrupt is triggered when the TX message is skipped. The Ni_TX_PQ_INT_STS0.SENT[n] bit register is set to 1 for the TX Priority Queue slot n and the bit field STS[3:0] in the TX descriptor is set to 0’b0010 or 0’b0011 • The TX Priority Queue slot n execution is stopped due to the fetch of an invalid TX descriptor in this queue (TX descriptor is not valid). The Ni_TX_PQ_INT_STS1.UNVALID[n] bit register is set to 1 for the TX Priority Queue slot n
STATS_IRQ	Four Statistic counters are used to monitor successful and unsuccessful RX and TX messages. As soon as one of those counters overflows the STATS_IRQ is triggers to the system, refer to the RX and TX Statistics chapter for more details. When looking at the Ni_STATS_INT_STS register, the SW can identify which counter has reached its maximum value: • When the number of unsuccessful RX message received has reached the maximum counter value, the Ni_STATS_INT_STS.RX_UNSUCC is set to 1 • When the number of successful RX message received has reached the maximum counter value, the Ni_STATS_INT_STS.RX_SUCC is set to 1 • When the number of unsuccessful TX message received has reached the maximum counter value, the Ni_STATS_INT_STS.TX_UNSUCC is set to 1 • When the number of successful TX message received has reached the maximum counter value, the Ni_STATS_INT_STS.TX_SUCC is set to 1

(table continues...)

Table 1057 (continued) Interrupts

Interrupt	Description
STOP_IRQ	When the PRT is stop (ENABLE signal goes from high to low), the MH finishes its current tasks. It puts all active RX/TX FIFO Queues on hold and discard all active TX Priority Queue slots. Once done, the MH notifies such state by triggering the STOP_IRQ interrupt. The interrupt STOP_IRQ is raised under the following conditions: • Ni_TX_FQ_STS0 = 0x0000 and Ni_RX_FQ_STS0 = 0x0000 and Ni_TX_PQ_STS0 = 0x00000000 • Ni_TX_FQ_STS0 = 0xXYXY and Ni_RX_FQ_STS0 = 0xWVWV and Ni_TX_PQ_STS0 = 0x00000000, where XY defined the active and on hold TX FIFO Queues and WV the active and on hold RX FIFO Queues
RX_FILTER_IRQ	In order to track RX filtering results, an interrupt can be defined when a match is detected on any defined RX filter element. The RX_FILTER_IRQ can only be triggered if the IRQ bit in the RX filter element is set to 1 AND there is a match. When a match is detected, the FM bit (set in RX message header) is set to 1 and the filter element index is defined in the FIDX[7:0] bit field (set in the RX message header). ***Note**: The BLK bit field in the RX Filter element is a side band information and is not considered for the interrupt generation*
TX_FILTER_IRQ	The interrupt is triggered when the TX filter is enabled, and a TX message is rejected. Despite being rejected, the TX descriptor used to define the TX message is acknowledged. To identify the TX descriptor allocated to the TX message rejected, the STS[3:0] bit field in the TX descriptor is set to 0'b0100. The Ni_TX_FILTER_ERR_INFO register provides the relevant information to identify which TX FIFO Queue or TX Priority Queue slot is impacted.
TX_ABORT_IRQ	This interrupt line is only triggered when the MH needs to abort a TX message being sent to the PRT. This interrupt does not have any status flags, as it will always be linked to functional or safety errors. Thus, another interrupt will provide the require information related to the issue. Several source of events can lead to this interrupt: • TX address pointer parity error (refer to AP_PARITY_ERR interrupt) • Timeout on S_MEM, L_MEM or PRT interface (refer to MEM_TO_ERR, DMA_TO_ERR or DP_TO_ERR interrupt) • DMA channel routing error (refer to DMA_CH_ERR interrupt) • A TX_MSG sequence error (refer to DP_SEQ_ERR interrupt) • A DMA AXI or MEM AXI error response (refer to RESP_ERR interrupt) • An uncorrectable error detected on the L_MEM (refer to MEM_SFTY_ERR interrupt) • A TX data parity error (refer to DP_PARITY_ERR interrupt) Aborting a TX FIFO Queue or a TX Priority Queue slot does not set this interrupt as no TX message abort is expected to occur (the MH will complete the current TX message before aborting the TX FIFO Queue).

(table continues...)

Table 1057 (continued) Interrupts

Interrupt	Description
RX_ABORT_IRQ	This interrupt line is triggered when the MH needs to abort an RX message is received from PRT. This interrupt does not have any status flags, as it will always be linked to functional or safety errors. Thus, another interrupt will provide the require information related to the issue. As a summary two different source of events can trig this interrupt: • An RX message is about to be sent to a disabled RX FIFO Queue. • An RX message is in progress and the MH receives a new RX message at the same time. If the RX filter has already completed or if the threshold in the RX DMA FIFO is reached, the new one is aborted to leave more time for the current one to complete. • RX address pointer parity error (refer to AP_PARITY_ERR interrupt) • Timeout on S_MEM, L_MEM or PRT interface (refer to MEM_TO_ERR, DMA_TO_ERR or DP_TO_ERR interrupt) • DMA channel routing error (refer to DMA_CH_ERR interrupt) • An RX_MSG sequence error (refer to DP_SEQ_ERR interrupt) • A DMA AXI or MEM AXI error response (refer to RESP_ERR interrupt) • An uncorrectable error detected on the L_MEM (refer to MEM_SFTY_ERR interrupt) • An RX data parity error (refer to DP_PARITY_ERR interrupt) • An RX descriptor error (refer to DESC_ERR interrupt) • An overflow on RX DMA FIFO or on the RX descriptor acknowledge path (refer to the DP_DO_ERR interrupt) Aborting an RX FIFO Queue will never set this interrupt, as the MH will complete its current reception before this action.
RX_FILTER_ERR	This interrupt line is triggered when the RX filter has not finished in time, to define the RX FIFO Queue number, before the reception of a new RX message. It provides information to the SW about large RX filtering time. Refer to the RX Filter chapter for detailed description. There is no status flag related to this interrupt, as the second source of event, defined below, is a programming issue and should never occur. Two different sources of events can trig this interrupt: • RX filtering not finished before a new RX frame • RX FIFO Queue to receive RX frame not running

(table continues...)

Table 1057 (continued) Interrupts

Interrupt	Description
MEM_SFTY_ERR	Safety error detected at the L_MEM interface. In fact, this interrupt is triggered when either the MEM_SFTY_CE or MEM_SFTY_UE input signal is active. To identify the root cause of such interrupt, refer to the Ni_SFTY_INT_STS register Two different sources of events can trigger this interrupt: • The MEM_SFTY_UE input signal, when set, to indicate an uncorrectable error from the L_MEM when reading (this signal must be generated by the L_MEM memory controller). The Ni_SFTY_INT_STS. MEM_SFTY_UE bit register is set to 1 in this case • The MEM_SFTY_CE input signal, when set, to indicate a correctable error from the L_MEM when reading (this signal must be generated by the L_MEM memory controller). The Ni_SFTY_INT_STS. MEM_SFTY_CE bit register is set to 1 in this case
REG_CRC_ERR	CRC error detected on the register bank. This interrupt is triggered after a few cycles if the CRC written in the Ni_CRC_REG.VAL[31:0], prior writing 1 to the Ni_CRC_CTRL.START bit, is not matching the one computed in hardware. Such interrupt event does not trig any actions in the MH. Therefore, it is a SW task to do the appropriate actions to stop the MH.
DESC_ERR	CRC error detected on RX/TX descriptor or unexpected RX/TX descriptor received. Status flags allow SW to identify the root cause of such interrupt, see Ni_SFTY_INT_STS register. Several source issues could lead to this interrupt: • When the Ni_SFTY_INT_STS.RX_DESC_CRC_ERR is set to 1, an RX descriptor is received and is having a CRC error • When the Ni_SFTY_INT_STS.RX_DESC_REQ_ERR is set to 1, an RX descriptor is received and is not compliant to the one requested (wrong RX FIFO Queue, wrong instance number, wrong position in the queue, …) • When the Ni_SFTY_INT_STS.TX_DESC_CRC_ERR is set to 1, a TX descriptor is received and is having a CRC error • When the Ni_SFTY_INT_STS.TX_DESC_REQ_ERR is set to 1, a TX descriptor is received and is not compliant to the one requested (wrong TX FIFO Queue, wrong instance number, wrong position in the queue, wrong TX Priority Queue slot…) The Ni_DESC_ERR_INFO0 and Ni_DESC_ERR_INFO1 registers provide a detailed description of the faulty RX/TX descriptor. Only the first RX/TX descriptor error will lead to an update of those registers, in case several ones occur. To capture the next descriptor error information, the SW must clear the interrupt source.

(table continues...)

Table 1057 (continued) Interrupts

Interrupt	Description
AP_PARITY_ERR	Address pointers used to manage TX FIFO Queues, RX FIFO Queues and TX Priority Queue are protected using parity bit (1bit per byte). Any issue detected trigs this interrupt. The parity bits are checked only when the address pointer is used for S_MEM accesses. Status flags allow SW to identify the root cause, see Ni_SFTY_INT_STS register. Several source issues could lead to this interrupt: • When the Ni_SFTY_INT_STS.AP_RX_PARITY_ERR is set to 1, an address pointer used to manage the RX path is having a parity error • When the Ni_SFTY_INT_STS.AP_TX_PARITY_ERR is set to 1, an address pointer used to manage the TX path is having a parity error
DP_PARITY_ERR	Parity error detected on RX message data received from PRT to AXI system bus or TX payload data transmitted from AXI system bus to PRT. Any issue detected trigs this interrupt. Status flags allow SW to identify the root cause, see Ni_SFTY_INT_STS register. Several source issues could lead to this interrupt: • When the Ni_SFTY_INT_STS.DP_RX_PARITY_ERR is set to 1, an RX message data is having a parity error • When the Ni_SFTY_INT_STS.DP_TX_PARITY_ERR is set to 1, a TX message data is having a parity error
DP_SEQ_ERR	The RX_MSG or TX_MSG interface used to synchronize the MH and PRT data exchange is not functional. A wrong PRT or MH behavior could lead to this issue. A problem on the logic managing the clock domain crossing on RX_MSG or TX_MSG interface may be one of the source issues. Status flags are available to identify the faulty interface, see Ni_ERR_INT_STS register. Several source issues could lead to this interrupt: • When the Ni_ERR_INT_STS.DP_RX_SEQ_ERR is set to 1, an issue is detected on the RX_MSG interface • When the Ni_ERR_INT_STS.DP_TX_SEQ_ERR is set to 1, an issue is detected on the TX_MSG interface

(table continues...)

Table 1057 (continued) Interrupts

Interrupt	Description
DP_DO_ERR	An overflow is detected on the RX data path or while acknowledging an RX/TX descriptor. Some status flags are provided to identify the interrupt source, see Ni_ERR_INT_STS register Several source issue could trigger this interrupt: • When the Ni_ERR_INT_STS.DP_RX_FIFO_DO_ERR is set to 1, an RX DMA FIFO overflow is detected. Several reasons could explain such issue: a very high system latency (over the expected limit considered for the MH), a system memory no more accessible and a wrong MH behavior. • When the Ni_ERR_INT_STS.DP_RX_ACK_DO_ERR is set to 1, an ACK DMA FIFO overflow is detected. Such issue occurs when the acknowledgment of an RX descriptor is not possible due to some pending ones. A system memory not accessible or a wrong MH behavior (DMA_CONTROLLER not functional, deadlock on RX/TX acknowledge path) could explain such issue. • When the Ni_ERR_INT_STS.DP_TX_ACK_DO_ERR is set to 1, an ACK DMA FIFO overflow is detected. Such issue occurs when the acknowledgment of a TX descriptor is not possible due to some pending ones. A system memory not accessible or a wrong MH behavior (DMA_CONTROLLER not functional, deadlock on RX/TX acknowledge path) could explain such issue
DP_TO_ERR	When the PRT is not responding after a certain amount of time, either on RX or on TX path, the DP_TO_ERR interrupt is triggered. The counter on RX_MSG or TX_MSG interface starts with the Start Of Frame and stop when receiving the timestamp. The timeout value is programmable by SW. Some status flags provide the interrupt source, see Ni_SFTY_INT_STS register. Several source issue could trigger this interrupt: • When the Ni_SFTY_INT_STS.DP_PRT_RX_TO_ERR is set to 1, the timeout value defined on the RX_MSG interface is over. The PRT or MH may be locked, preventing data reception • When the Ni_SFTY_INT_STS.DP_PRT_TX_TO_ERR is set to 1, the timeout value defined on the TX_MSG interface is over. The PRT or MH may be locked, preventing data transmission
DMA_TO_ERR	When the S_MEM is not responding after a defined time interval, the DMA_TO_ERR is triggered. The timeout value is programmable by SW. Some status flags provide the interrupt source, see Ni_SFTY_INT_STS register. Several source issue could trigger this interrupt: • When the Ni_SFTY_INT_STS.DMA_AXI_RD_TO_ERR is set to 1, the timeout value defined on the DMA AXI read channel interface is over. A system memory no more accessible or a DMA_CONTROLLER in deadlock could explain such issue. • When the Ni_SFTY_INT_STS.DMA_AXI_WR_TO_ERR is set to 1, the timeout value defined on the DMA AXI write channel interface is over. A system memory no more accessible or a DMA_CONTROLLER in deadlock could explain such issue.

(table continues...)

Table 1057 (continued) Interrupts

Interrupt	Description
MEM_TO_ERR	When the L_MEM is not responding after a defined time interval the MEM_TO_ERR is triggered. The timeout value is programmable by SW. Some status flags are provided to identify the interrupt source, see Ni_SFTY_INT_STS register. Several source issue could trigger this interrupt: • When the Ni_SFTY_INT_STS.MEM_AXI_RD_TO_ERR is set to 1, the timeout value defined on the MEM AXI read channel interface is over. A local memory no more accessible or a memory controller in deadlock could explain such issue. • When the Ni_SFTY_INT_STS.MEM_AXI_WR_TO_ERR is set to 1, the timeout value defined on the MEM AXI write channel interface is over. A local memory no more accessible or a memory controller in deadlock could explain such issue.
DMA_CH_ERR	Data received or sent are not routed to or from the right DMA channels. Such issue will lead to data corruption and wrong MH behavior. There are no status flags to identify the source channel being faulty.
RESP_ERR[1:0]	Any error response from the DMA AXI and MEM AXI interfaces can lead to a RESP_ERR[1:0] interrupts. Some status flags provide the interrupt source, see Ni_SFTY_INT_STS register. Several source issue could trigger those interrupts: • When the RESP_ERR[0] interrupt is set, a write access error is detected on either the DMA_AXI or MEM_AXI write channel. • When the RESP_ERR[1] interrupt is set, a read access error is detected on either the DMA_AXI or MEM_AXI read channel. The Ni_AXI_ERR_INFO register provides a detailed description of the faulty AXI interface, refer to the Ni_AXI_ERR_INFO.MEM_RESP[1:0] or Ni_AXI_ERR_INFO.DMA_RESP[1:0] bit field to determine which one (must be different from 0'b00). The traffic getting the error response is defined when looking at the Ni_AXI_ERR_INFO.MEM_ID[1:0] (if Ni_AXI_ERR_INFO.MEM_RESP[1:0] is different from 0'b00) or Ni_AXI_ERR_INFO.DMA_ID[1:0] bit field (if Ni_AXI_ERR_INFO.DMA_RESP[1:0] is different from 0'b00). In case several response errors occur on the same interface, only the AXI ID of the last one is captured.

22.5.3.30 Local memory map

In order to perform the RX filtering and the TX-SCAN, the MH requires a local memory. This local memory called L_MEM is addressable through the MEM_AXI interface. The MEM_AXI interface is able to address up to 64 KBytes with a 32 bit data bus width.

The L_MEM is storing all the RX filter elements, Header Descriptor for TX FIFO and Priority Queues, as well as a single Trailing Descriptor when considering TX message defined with several descriptors.

22.5.3.30.1 TX descriptors

The TX FIFO Queue descriptors are organized into the L_MEM starting at the base address defined in Ni_TX_DESC_MEM_ADD.fq_base_add[15:0]. Up to 8 memory location, of size $8 \times 32\ bit$, is required to hold the TX Header Descriptor of every TX FIFO Queues.

Every TX FIFO Queue, when active, has its current and next descriptor defined into the L_MEM for the TX-SCAN process. This means, for a given TX FIFO Queue, memory space must be double. The current and the next TX Header Descriptor are used for the TX-SCAN.

The TX Priority Queue descriptors are organized into the L_MEM starting at the base address defined in Ni_TX_DESC_MEM_ADD.PQ_BASE_ADDR[15:0]. Up to 32 memory location, of size $8 \times 32\ bit$, is required to hold the TX Header Descriptors of every slot. As there is only one TX message per slot, there is no need to allocate more space.

When a TX message is split over several descriptors, a temporary memory location is used to hold the Trailing Descriptor to retrieve payload data (see Temporary Descriptor below).

The TX descriptor element are organized in 32 bit word and so any offset would be a multiple of 8. Here below is the memory organization of the TX descriptors considering N TX FIFO Queues and M TX Priority Queue Slots:

Table 1058 Memory organization of the TX descriptors

Memory base address	Offset	Name	Bit field	Description
FQ_BASE_ADD[15:0]	0x0+0x40*n $0x0 + 0x40 \times n$	TX FIFO Queue n (current/next TX Header Descriptor) (0 <= n < N)	Element 0	TX Header Descriptor, see TX descriptor, TX Message and TX FIFO Queue chapters
	0x4+0x40*n $0x4 + 40 \times n$		Element 1	
	$0x8 + 0x40 \times n$		Element 2: TS0	
	$0xC + 0x40 \times n$		Element 3: TS1	
	$0x10 + 0x40 \times n$		Element 4: T0	
	$0x14 + 0x40 \times n$		Element 5: T1	
	$0x18 + 0x40 \times n$		Element 6: T2/TD0	
	$0x1C + 0x40 \times n$		Element 7: TX_AP/TD1	
	$0x20 + 0x40 \times n$	TX FIFO Queue n (next/current TX Header Descriptor) (0<= n < N)	Element 0	TX Header Descriptor, see TX descriptor, TX Message and TX FIFO Queue chapters
	$0x24 + 0x40 \times n$		Element 1	
	$0x28 + 0x40 \times n$		Element 2: TS0	
	$0x2C + 0x40 \times n$		Element 3: TS1	
	$0x30 + 0x40 \times n$		Element 4: T0	
	$0x34 + 0x40 \times n$		Element 5: T1	
	$0x38 + 0x40 \times n$		Element 6: T2/TD0	
	$0x3C + 0x40 \times n$		Element 7: TX_AP/TD1	
	$0x0 + 0x40 \times N$	Temporary TX Trailing Descriptor	Element 0	TX Trailing Descriptor, see TX descriptor, TX Message and TX FIFO Queue chapters
	$0x4 + 0x40 \times N$		Element 1	
	$0x8 + 0x40 \times N$		Element 2: TS0	
	$0xC + 0x40 \times N$		Element 3: TS1	
	$0x10 + 0x40 \times N$		Element 4: T0	

(table continues...)

Table 1058 (continued) Memory organization of the TX descriptors

Memory base address	Offset	Name	Bit field	Description
	$0x14 + 0x40 \times N$		Element 5: T1	
	$0x18 + 0x40 \times N$		Element 6: T2/TD0	
	$0x1C + 0x40 \times N$		Element 7: TX_AP/TD1	
PQ_BASE_ADD[15:0]	$0x0 + 0x20 \times m$	TX Priority Queue slot n (0<= m < M)	Element 0	TX Header Descriptor, see TX descriptor, TX Message and TX Priority Queue chapters
	$0x4 + 0x20 \times m$		Element 1	
	$0x8 + 0x20 \times m$		Element 2: TS0	
	$0xC + 0x20 \times m$		Element 3: TS1	
	$0x10 + 0x20 \times m$		Element 4: T0	
	$0x14 + 0x20 \times m$		Element 5: T1	
	$0x18 + 0x20 \times m$		Element 6: T2/TD0	
	$0x1C + 0x20 \times m$		Element 7: TX_AP/TD1	

As the L_MEM can be shared across several MH, the SW is having some flexibility to allocate TX FIFO/Priority Queue descriptors anywhere and also according to the usage of the application. As an example, if only 4 TX FIFO Queues is required with a TX Priority Queue with 16 slots the expected memory size would be half compare to the maximum configuration possible. It is obvious that this kind of configuration would assume TX FIFO Queues are continuous, meaning 0, 1, 2 and 3 AND TX Priority Queue slots 0, 1, ... and 15.

One must be careful if more TX FIFO Queue and TX Priority Queue slots are required as more memory space would then need to be allocated. As a matter of fact, if the SW is able to enable any TX FIFO Queue and/or TX Priority Queue slots, the worst configuration would be a memory space configured with 8 TX FIFO Queues and 32 TX Priority Queues.

22.5.3.30.2 RX filter elements

The filter elements to be parsed are stored into the local memory on 32 bit word. The global setting of the RX Filter is defined by the Ni_RX_FILTER_CTRL register and will apply to all filter elements. Up to n filter elements can be defined (where n is from 0 to 255) with up to m reference/mask pair (where m is from 0 to 255). The number of elements is defined in the Ni_RX_FILTER_CTRL.NB_FE[7:0] bit-field register.

Table 1059

Memory Base Address	Offset ($0 \leq n \leq 254$) ($0 < n < 255$)	Name ($0 \leq n \leq 254$) ($0 < n < 255$)	Description
RX_FILTER_ADD[15:0]	$0x0$	FE0	Define the RX filter element 0
	$0x4 \times n$	FEn	Define the RX filter element $n - 1$

(table continues...)

Table 1059 (continued)

Memory Base Address	Offset ($0 \leq n \leq 254$) ($0 < n < 255$)	Name ($0 \leq n \leq 254$) ($0 < n < 255$)	Description
RX_FILTER_ADD[15:0] $+0x4 \times n$	$0x0$	REF0	RX Filter Reference value 0
	0x4 $0x4$	MSK0	RX Filter Reference mask 0
	$0x0 + 0x4 \times m$	REFm	RX Filter Reference value m
	$0x4 + 0x4 \times m$	MSKm	RX Filter Reference mask m

As the local memory can be shared across several Message Handler, the SW is having some flexibility to allocate RX filter elements and references anywhere and also according to the usage of the application. As a memory space of 64 Kbytes is addressable, the start address of those elements is defined in the Ni_RX_FILTER_MEM_ADD.BASE_ADDR[15:0] bit-field register.

22.5.3.31 Application information

General information related to performances, starting and stopping RX/TX FIFO Queues as well as TX Priority Queue.

22.5.3.31.1 Queue status flags

The TX FIFO Queue status is defined according to the bit status in the Ni_TX_FQ_STS0 register, as shown in the table below:

Table 1060 TX FIFO Queue status

Ni_TX_FQ_STS0.BUSY[n]	Ni_TX_FQ_STS0.STOP[n]	Status for TX FIFO QUEUE n (n = 0 to 31)
0	0	Inactive: The TX FIFO Queue can be programmed and started if enabled
0	1	na
1	0	Active and running: The TX FIFO Queue is enabled and has been started. TX messages are sent whenever possible to the PRT
1	1	Active and on hold: When considering no functional or safety errors, this status is reached when an invalid TX descriptor is fetched from S_MEM.

The TX Priority Queue slot n status is defined according to the bit status in the Ni_TX_PQ_STS0 register, as shown in the table below

Table 1061 TX Priority Queue status

Ni_TX_PQ_STS0.BUSY[n]	Status for TX PRIORITY QUEUE slot n (n=0 to 31)
0	Inactive: The TX Priority Queue can be programmed and started if enabled
1	Active and running: The TX Priority Queue is enabled and has been started. TX message in the slot n can be transmitted whenever possible

Compared to the TX FIFO Queues, there is no STOP bits. Any errors related to a TX Priority Queue slot execution sets the slot as inactive.

Table 1062 RX FIFO Queue status

Ni_RX_FQ_STS0.BUSY[n]	Ni_RX_FQ_STS0.STOP[n]	Status for RX FIFO QUEUE n (n = 0 to 31)
0	0	Inactive: The RX FIFO Queue can be programmed and started if enabled
0	1	na
1	0	Active and running: The RX FIFO Queue is enabled and has been started. RX messages can be received from the PRT
1	1	Active and on hold: When considering no functional or safety errors, this status is reached when an invalid RX descriptor is fetched from S_MEM.

22.5.3.31.2 Cluster

The same L_MEM can be shared accross several Message Handler but several points need to be highlighted. A tradeoff needs to be found to ensure every MH will get enough time to complete their RX filter process as well as their TX-Scan for a given L_MEM bandwidth.

- The worst scenario on RX path is defined when all MH in a cluster are receiving an RX message at the same time. Therefore, it is essential to ensure the available bandwidth on the L_MEM is able to support the RX filter process from all concurrent MH. Several measures can be taken to lower the bandwidth for a given value: limit the number of RX filter elements and the number of comparison (1 or 2) per filter element.
- The worst scenario on TX path is defined by all TX FIFO queues active for every MH as well as new TX messages being added to all TX Priority Queue slots. As one message is added or sent at a time for every MH, the impact of the TX-Scan may be limited but may play an important role by generating more arbitration occurences
- The read latency to access the L_MEM is a common factor for all MH and should be as low as possible. This access time is driven the overall performances when in cluster mode

22.5.3.31.3 Performances

Several processing time have a direct impact on the overall MH performances, see sections below.

Core clock frequency

The minimum MH core clock frequency is driven by several parameters:

- The maximum number of RX filter elements to support
- The Classical CAN, CAN FD and CAN XL bit rates (Arbitration and Data Phase)
- The L_MEM read latency
- The maximum number of TX FIFO Queues

To estimate the minimum core clock frequency to set, please refer to excel file [6]. One must keep in mind that the computated value is a minimum. Other clock frequency constraints may require an higher clock speed on the MH.

TX-Scan

The TX-Scan does compute the highest priority message over the TX FIFO queues and the TX Priority Queue slots. The processing time is mainly link to the number of TX FIFO Queues active at the same time as well as the number of TX Priority Queue slots being set active. The higher the number of slots and TX FIFO queues active, the higher the bandwitdh from the L_MEM. The sooner the result is known the better the expected transmission order is. For more detail on TX-Scan refer to the TX-Scan chapter.

RX Filter

As the RX filter elements are defined and read from the L_MEM, any RX message received will generate many accesses. The number of RX filter elements and the number of comparisons per element drive the bandwidth from the L_MEM and so the processing time. The higher the number of filter elements the higher it takes to define if an RX message is accepted or rejected. Despite some measures are in place to avoid to discard the current RX message, the SW would need to sort the non dispatched messages later on. For more detail on RX Filter refer to the RX Filter chapter.

The process of filtering is started as soon as the first RX message header data is received. When an RX filter element expects an RX data word that is not already stored, the process stops and waits for the RX data word. As the RX filter element are fetched linearly from the L_MEM, it is required to have them organized in a specific way to optimize the filtering time. This means, the RX filter elements, having to be compared to the first header data word, must be stored at the beginning, the ones using the second header data word at the last position. The Classical CAN with a low bit rate does provide more margin to complete the RX filtering in time. The critical path is defined when receiving CAN FD frame with no payload data.

As a general rule, it is recommended to define RX filter elements in this order:

1. CAN FD, assuming that only one comparison with the first message header word is required
2. CAN XL, assuming either one or two comparisons could be defined
3. Classical CAN , assuming that only one comparison with the first message header word is required

Such RX filter elements organization will optimize the overall processing time.

RX or TX Descriptors memory organization

RX/TX descriptors are fetched from the S_MEM. The DMA_CONTROLLER is reading and writing data to the S_MEM using burst length of various sizes. As soon as the address to read or write data is aligned on burst length of 8, all the following burst transfer are using maximum burst length of 8. If the address to fetch the RX/TX descriptor does cross a burst of 8 boundary, two read accesses are required.

TX path

As the TX header descriptor is store locally in the MH there is no constraint regarding the access time from the S_MEM. Nevertheless, several recommendation will help to increase access performances and to limit power consumption:

- Align TX FIFO Queue start address on maximum burst length (8 word of 32 bit)
- Align TX Priority Queue start address on maximum burst length (8 word of 32 bit)
- Define TX FIFO and or Priority Queues (link list of TX descriptors) in SRAM to leave more time for payload data fetching. This is best pratice to declare TX descriptor in SRAM whenever possible

RX path

RX descriptors fetches are driving the RX messages write to S_MEM. On top of it, if the RX filtering is taking too much time, an RX DMA FIFO overflow may occur. Several recommendation will help to increase access performances and to limit power consumption:

- Align RX FIFO Queue start address on maximum burst length (8 word of 32 bit)
- Define RX FIFO Queues (link list of RX descriptors) in SRAM to leave more time for RX filtering. This is best practice to declare RX descriptor in SRAM whenever possible

Data payload buffer memory organization

Any accesses done from or to the S_MEM by the DMA will be fully optimized as the address is aligned on the maximum burst length (8x32bit).

TX path

- Align data container start address on maximum burst length (8 word of 32 bit)
- Use data container size multiple of maximum burst length (8 word of 32 bit)

RX path

- Align data container start address on maximum burst length (8 word of 32 bit), whatever the mode (Normal or Continuous)
- Use data container size multiple of maximum burst length (8 word of 32 bit)

High system memory latency

If the latency time to get the first payload data burst is greater than the computed value, an underrun will occur when starting to transmit a TX message to the PRT. As many DMA requests may occur to the system bus at the same time, some critical scenarios could lead to delay the fetch of the first payload data, providing underrun. If one of the TX descriptor DMA requests is preempting the access to the first payload data for the current TX message, the delay would be larger than the one expected. As an example, starting all TX FIFO Queues and TX Priority Queue slots at the same time may increase the probability to have an underrun.

Very high system latency may lead to underrun due to the high constraints on burst accesses. The data underrun is a warning and won't affect the MH behavior and the order of the TX messages. No TX message with underrun is dropped and it will still be considered in the next TX-Scan run.

Nevertheless, here below are a list of recommendations to avoid and limit issues in a system with high latency:

TX path

Every TX descriptor and its payload data are fetched from the S_MEM. The payload data is only read from the S_MEM when the TX message (defined by its TX descriptor) started to be transmitted on the CAN bus (meaning the message has won the CAN bus arbitration). Thus, in case of very high latency system, a data underrun may occur on the PRT. As a matter of fact, the critical path is defined by the first bunch of payload data to be fetched. Several actions can be done to cope with high system latency:

- Align data container start address on maximum burst length (8 word of 32bit)

- Align TX FIFO Queue start address on maximum burst length (8 word of 32bit)
- Align TX Priority Queue start address on maximum burst length (8 word of 32bit)
- Use data container size multiple of maximum burst length (8 word of 32bit)
- The usage of write outstanding transaction may not provide a significant improvement as the write accesses are somehow sequential. Nevertheless, it is recommended to set it to the maximum value, see Ni_AXI_PARAMS.AW_MAX_PEND[1:0] bit register
- Make use of read outstanding transaction (this is mandatory to avoid cases where DMA channel are competing against each other to read the S_MEM). The maximum value is recommended, see Ni_AXI_PARAMS.AR_MAX_PEND[1:0] bit register
- Define TX FIFO/Priority Queues (linked list of TX descriptors) in SRAM to leave more time for payload data fetching. This is best practice to declare descriptor in SRAM whenever possible

RX path
