39.3.7.6 SCR functions in port SCR_P3

This section describes the SCR functions of Port SCR_P3, which is mapped on P34.1-P34.5 and P35.3-P35.5.

The SCR has functions on Port lines SCR_P3.0 - SCR_P3.7, which can be alternatively used for UART, WCAN, SSC, T0/T1, T2CCU0/1, ADCOMP, PMS power-mode debug and External Interrupt input and output functions.

Following table summarizes the SCR I/O control selection functions of the 8 Port SCR_P3 lines.

Table 1705 Port P3 functions

Port pin	I/O	Pin functionality	Associated reg./I/O line	Port I/O control selection

39.3.7.7 General port control

There are a number of control registers for input pin selection:

- Selection of inputs for SSC, UART, T0, and T1 are made in:
  - SCUSCR_MODPISEL0
  - 1
- Inputs for T2 are selected in:
  - T2CCUx_T2_CON1.INSEL and .EXTINSEL
- WCAN input selection is made in:
  - WCAN_CFG.WCANRXDIS bit-field
- External interrupts are selected in:
  - IRSCR_PISEL0/1/2/3
- Inputs for I2CSCR are selected through:
  - I2CSCR_SRST.SCLSEL
  - I2CSCR_SRST.SDASEL

The following table provides an overview of these registers.

Table 1706 Registers overview - input pin selection (sorted by name)

Short name	Description	RMAP	PAGE	Offset address	Page number
IRSCR_PISEL0	External Interrupt Input Select Register 0	0	IRSCR_PAGE	$F7_H$	4
IRSCR_PISEL1	External Interrupt Input Select Register 1	0	IRSCR_PAGE	$F8_H$	4
IRSCR_PISEL2	External Interrupt Input Select Register 2	0	IRSCR_PAGE	$F9_H$	4
IRSCR_PISEL3	External Interrupt Input Select Register 3	0	IRSCR_PAGE	$F7_H$	5
SCUSCR_MODPISEL0	Peripheral Input Select Register 0 (UART,T0/1)	0	SCUSCR_PAGE	$F0_H$	2
SCUSCR_MODPISEL1	Peripheral Input Select Register 1 (PINRST, SSC)	0	SCUSCR_PAGE	$F1_H$	2
T2CCU0_T2_CON1.INSEL	Timer 2 Instance 0 Input Select	0	T2CCU0_PAGE	87_H	0

I2CSCR_SRST.SDASEL	I2CSCR data input select	0		FD_H	

39.3.8 Real time clock (RTCSCR)

39.3.8.1 Overview

One of the SCR's peripherals is the Real-Time Clock (RTCSCR) that, once started, can work independently of the state of the rest of the microcontroller.

Features

- Periodic wake-up mode using several possible clock sources
- Wake-up source during standby mode

39.3.8.2 RTCSCR operation

The real-time clock consists of a 41-bit timer (including 9-bit pre-scaler) which count up. It contains a set of 4 count registers, collectively know at RTCSCR_CNT register, that shows the current count value or the current time of the real-time clock. Another set of registers, RTCSCR_CR register, that consists of 4 registers can be used for interrupt generation. It can also be used to wake-up device from standby mode. The RTCSCR_CR register is also used to store the capture value when a capture event is triggered.

The RTCSCR starts counting after 1 PCLK + 4 RTCSCR Clock cycles after the RTCC is set.

***Note**: Before starting the RTCSCR counter, the compare value in registers RTCSCR_CRn must be set to a value unequal 0 (for example $FFFF_H$). Otherwise, the RTCSCR will not start, if it is initially 0, or stop after an overflow to 0.*

39.3.8.2.1 Periodic wake-up mode

The figure below shows the real-time clock. It consists of a 41-bit general purposes timer. The f_{RTCSCR} is selected through RTCSCR_CON.RTCCLKSEL.

Before real-time clock is started, RTCSCR_CNT register of the real-time clock can be written with any value. The value written is used as an initial value for the real-time clock timer, when it is started by setting bit RTCSCR_CON.RTCC to 1. This bit also enables the input clock into the real-time clock timer. RTCSCR_CNT register is protected by the PASSWD bit protection scheme as described in the SCUSCR chapter. The initial count value can only be updated when the protection scheme is being disabled in the stop mode (RTCSCR_CON.RTCC=0). The real-time clock's lower 9 bits, which serve as a pre-scaler into the 32-bit counters, RTCSCR_CNT, are set to an initial value of 000000000_B when the RTCSCR starts to run. The pre-scaler can be bypassed by setting bit RTCSCR_CON.RTPBYP to 1.

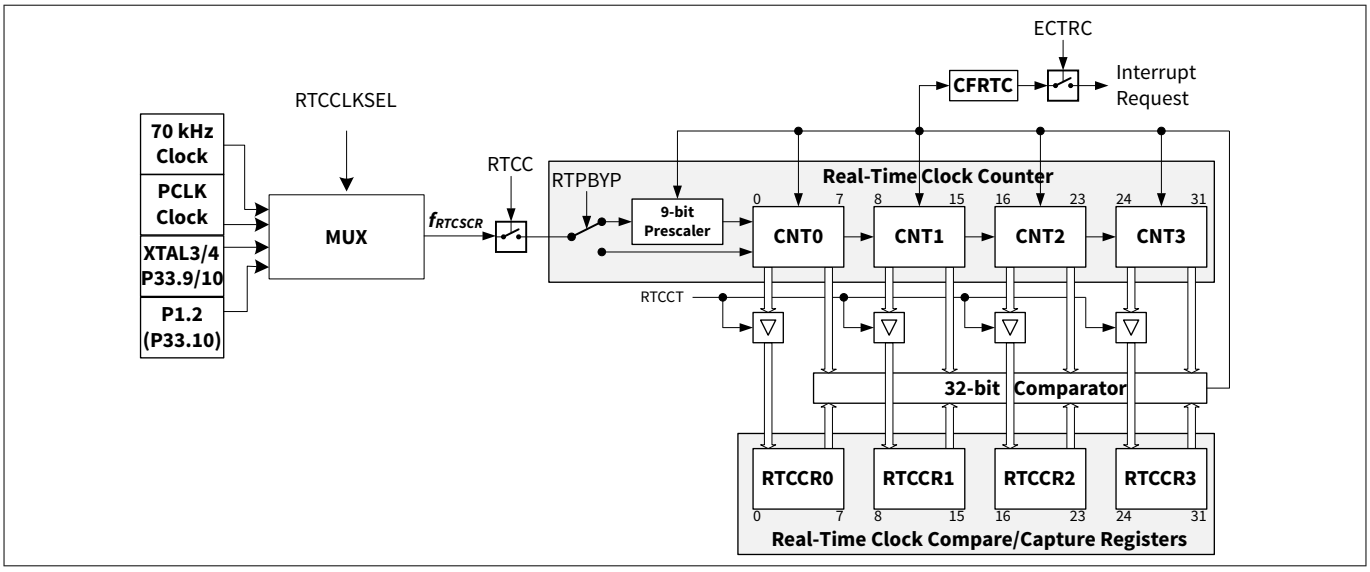

Figure 874 Real-time clock periodic wake-up mode with 9-bit pre-scaler

While the real-time clock is in operation, the contents of RTCSCR_CR register will be compared to the real-time clock counter (RTCSCR_CNT). An interrupt will be generated when the contents are equal if ECRTC is set to 1; bit RTCSCR_CON.CFRTCSCR will be set. The RTCSCR_CON.CFRTC flag can be monitored for the real-time clock wake-up request, but the flag has to be cleared to 0 by user software. In such situation, the real-time clock counter is reset and starts counting from zero again.

***Note**: Before starting the RTCSCR counter, the compare value in registers RTCSCR_CRn must be set to a value unequal 0 (for example $FFFF_H$). Otherwise, the RTCSCR will not start if it is initially 0, or stop after an overflow to 0.*

As RTCSCR still running in standby mode, it is able to wake-up at a fixed time by programming the number of count value that is equivalent to the length of time to wake-up in the RTCSCR_CR register. The real-time clock can generate a wake-up request to the main controller, if bit SCUSCR_WKPCON.RTCWKSEL is set to 1.

A capture event could be triggered by setting RTCSCR_CON.RTCCT bit to 1. The previous content in the RTCSCR_CR register will be overwritten with the captured RTCSCR_CNT values after a maximum of 9 f_{RTCSCR} cycles. An update of the actual compared value is necessary once a captured event is triggered. In SCR, it is recommended to trigger a capture event to read the value of the RTCSCR counter (RTCSCR_CNT). There is the potential of reading a wrong 32-bit real-time value while the RTCSCR is in running mode as only 8 bit of data could be fetched at one time.

The real-time clock stops counting and RTCSCR_CNT register holds the last value when the RTCSCR_CON.RTCC bit is set to 0. Setting this bit subsequently will start a new counting sequence which begin with the stop count.

***Note**: For the capture event to complete, up to 9 f_{RTCSCR} cycles are required. During this time window, the compare event is temporarily disabled and no compare match happens. Once, the capture is completed and the RTCSCR_CR is updated, the compare event is enabled again. In both cases- i.e.- pre-scaler bypassed or not bypassed - it is ensured that the next compare match happens only after the next overflow.*

***Note**: The RTCSCR single input pin for clock is limited to 32.768 kHz.*

39.3.8.2.2 Clock source

RTCSCR clock, f_{RTCSCR}, is selectable between 4 clock sources:

- 70 kHz clock
- (100 MHz)/DIV clock (PCLK)
- XTAL3/4 oscillator clock, forwarded from PMS
- Externally supplied clock on pin SCR_P1.2 (P33.10)

Selection is done through bit-field RTCSCR_CON.RTCCLKSEL, which is write-enable protected by bit-field RTCSCR_CON.RTCCLKSEL_P.

Once powered up, these clocks can operate irrespective of the state of the microcontroller. That is, it keeps running even when the SCR has entered idle or the device has entered standby mode.

In case of clock failure, the RTCSCR stops counting.

39.3.8.2.3 RTCSCR access delays and restrictions

When accessing the RTCSCR registers, the following delays and restrictions need to be obeyed:

- When the SCR is running and the clock is stable, RTCSCR_CON.RTCSCRC is allowed to be set/cleared
- When the RTCSCR clock is changed between available clocks, the waiting time of four old/current clock cycles and four clocks of the new/selected clock cycles need to be inserted before setting RTCSCR_CON.RTCSCRC. Upon each clock selection change, it is required to insert up to 9 RTCSCR Clock cycles to the waiting time mentioned in the previous sentence
- When an SCR reset is triggered, the RTCSCR clock is set to 70 kHz per default. After triggering the reset, software has to wait 2PCLK + 3RTCSCR clock cycles, before bit SCUSCR_PMCON0.RTC_DIS may be cleared
- When bit SCUSCR_PMCON0.RTC_DIS is cleared, a waiting time of four RTCSCR clock cycles needs to be inserted before any write access to RTCSCR registers may be performed

When bypassing the 9-bit pre-scaler (RTCSCR_CON.RTPBYP=1)and consecutively reading the RTCSCR count registers, the following delays need to be taken into account due to synchronization:

- When the RTCSCR is running with PCLK, a delay of 6 PCLK cycles is present between the read accesses, so the RTCSCR count value between two read operations may differ by 6 counts
- When the RTCSCR is running with 70 kHz, a delay of 5RTCSCR clock cycles is present between the read accesses, so the RTCSCR count value between two read operations will differ by 5 counts

39.3.8.2.4 Register overview

Overview of RTCSCR registers is given in the following table. More details are available in the "Registers" sub-chapter.

Table 1707 Overview of RTCSCR registers

Register short name	Description	Address
RTCSCR_CON	Control and status register	$E1_H$
RTCSCR_CNTn (n=0-3)	Upper 32-bits of the 41-bit counter value	$E2_H$-$E5_H$
RTCSCR_CRn (n=0-3)	Capture and compare register	$E6_H$-$E9_H$

39.3.8.3 RTCSCR interrupt request

Following table lists the interrupt event sources from the RTCSCR, and the corresponding event interrupt enable bit and flag bit.

Table 1708 RTCSCR interrupt events

Event	Event interrupt enable bit	Event flag bit
RTCSCR compare/wake-up	RTCSCR_CON.ECRTC	RTCSCR_CON.CFRTC

Next table shows the interrupt node assignment for each RTCSCR interrupt source.

Table 1709 RTC events' interrupt node control

Event	Interrupt node enable bit	Interrupt node flag bit	Vector address
RTC compare/wake-up	IEN1.ECCIP3	–	$6B_H$

The following figure illustrates the RTC interrupt request.

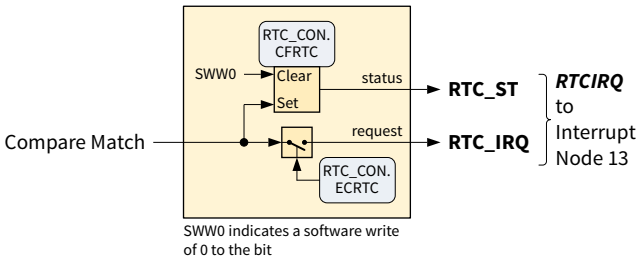

Figure 875 RTCSCR interrupt request

On a compare match event, if enabled through RTCSCR_CON.ECRTC, an RTC interrupt is signalized to the IRSCR through Interrupt Node 13. On the same event the status flag RTCSCR_CON.CFRTC is set. Once set, this flag should be cleared by software. For more details see also the section on "Interrupt Structure 2" in chapter "Interrupt System (IRSCR)".

39.3.8.4 Power saving mode

Once started, the real-time clock continues counting until the bit RTCSCR_CON.RTCC is cleared. The real-time clock is not affected by the idle mode of the SCR, and continues counting in standby mode provided the PCLK clock is available. In addition, the real-time clock will not automatically disable the operation when there is a clock failure.

39.3.8.4.1 Module suspend control

When the On-Chip Debug Support (OCDS) is in Monitor Mode (MMCR2.MMODE=1) and the Debug-Suspend signal is active (MMCR2.DSUSP=1), the timer/counter in RTCSCR module in the SCR can be suspended based on the settings of their corresponding module suspend bits in register SCUSCR_DBG_MODSUSP.

When suspended, only the timer stops counting as the counter input clock is gated off. The module is still clocked so that module registers are accessible.

39.3.9 PMS modules accessible from SCR

The SCR software can access certain sub-functions of the 64-bit Real-Time Clock (RTC) and Die-Temperature Sensor (DTS) located in PMS.

Besides RTC and DTS, the PMS HPOSC module also has the ability to be accessed by the SCR software through the SCU_PMSHPOSC_FTRIM registers (FTRIM7_0 and FTRIM8_8 are combined for 9-bits of value located inside PMS register PMS_HPOSCCON1.OSCFTRIM). This access can be used for temperature calibration of HPOSC from the SCR side, as a low-power alternative to doing calibration using software on the main SoC cores.

A detailed description of the 64-bit RTC as well as DTS modules are provided in respective PMS sub-chapter.

39.3.9.1 64-bit real-time clock

Besides the 41-bit RTCSCR located inside SCR sub-system, SCR software can also access certain subset functionality of 64-bit RTC located in the PMS module.

SCR can access PMS RTC only if the SCR is not in STANDBY1_70K state mode, meaning the SCR system clock (PCLK) is not 70 kHz. The SCR clock (PCLK) needs to be derived from the 100 MHz HPOSC clock. If the SCR clock is 70 kHz, reading to the below listed PMS RTC registers will always return zero and writing will be stalled until the 100 MHz clock is available. Shadow registers on the SCR side are available for write access even when SCR is operating at 70 kHz. However, PMS RTC registers will get updated only when the 100 MHz clock is available.

On the SCR side the following registers are available in the SCU address space:

Table 1710 PMS RTC bit-fields available for SCR software

PMS RTC bit-field name	SCR register name	Description	SCR software access
RTC_TIM1CAP[31:0] & RTC_TIM0[31:0]	SCUSCR_PMSRTC_TIM*	8 registers of 8-bits (TIM63_56, TIM55_48, …, TIM7_0) for a total of 64-bit timer value	Read-only
RTC_CON1.OFFSET[15:0]	SCUSCR_PMSRTC_OFFSET*	2 registers of 8-bits (OFFSET15_8 and OFFSET7_0) for a total of 16-bit offset value	Read and write
RTC_CMP1[31:0]	SCUSCR_PMSRTC_CMP1*	4 registers of 8-bits (CMP1_31_24, …, CMP1_7_0) for a total of 32-bits CMP1 value	Read and write
RTC_CON2.MSIZE1[4:0]	SCUSCR_PMSRTC_MSIZE1	5 least-significant bits of MSIZE1 value	Read and write
RTC_CON2.MSTART1[4:0]	SCUSCR_PMSRTC_MSTART1	5 least-significant bits of MSTART1 value	Read and write

Special notes on SCR access:

- While performing 8 read operations to read all 64-bits of TIM[63:0], the timer value can change in between those operations. It is recommended to read the most-significant byte first (SCUSCR_PMSRTC_TIM63_56) and then byte by byte toward least-significant byte (SCUSCR_PMSRTC_TIM7_0). If the value of the least significant byte is 00_H read again from SCUSCR_PMSRTC_TIM63_56 down to SCUSCR_PMSRTC_TIM15_8, as there is a chance that the lowest byte went from 0xFF to 0x00
- When writing MSIZE1 and MSTART1 values, the bit-fields in PMS RTC update with values provided by SCR software
- When writing OFFSET and CMP1 values, the bit-fields in PMS RTC update only after writing to the least-significant 8-bit register on SCR side
  - For example, writing SCUSCR_PMSRTC_CMP1_31_24 will be latched into SCR local shadow register, and it is copied to the respective RTC_CMP1[31:24] bit-field only after writing to

SCUSCR_PMSRTC_CMP1_7_0. It is not possible to read-back the value last written to local shadow register

***Note**: The PMS RTC registers are implemented in RTCSCR's clock domain (70 kHz/32 kHz), this is quite slow compared to the SCR's clock domain. Therefore, it takes some time for the PMS RTC registers to get updated with the new values. For example, if the RTC is clocked at 32 kHz it takes up to 62.5 µs until the registers are written and their new value can be read back. Therefore, the SCR software must wait until the PMS RTC registers are read back with their new value before a "standby 0" entry is requested. Otherwise the "standby 0" entry will invalidate the trimming of the RTC.*

PMS RTC outputs

Both CMP0 and CMP1 output lines (RTCCMP0 and RTCCMP1) are forwarded to the SCR as interrupt sources to interrupt node 7 and 8. The interrupt enable is located in IRSCR_MODIEN. The flags are located in the IRSCR_CON1 register. With these interrupt lines the SCR can fully utilize 64-bit PMS RTC as its own RTC.

In addition to the CMP outputs, the SCR also receives the 32 kHz clock from XTAL3/4 which also can be used by the PMS RTC.

39.3.9.2 Die-temperature sensor (DTS)

SCR software can also access some basic configuration and result registers of PMS DTS. Following registers are available in SCU address space:

Table 1711 PMS DTS bit-fields available for SCR software

PMS DTS bit-field name	SCR register name	Description	SCR software access
DTS_CON.START, DTS_CON.EN	SCUSCR_PMSDTS_CON.EN_START	DTS enable and start control is combined into a single bit	Read and write
DTS_STAT.RESULT[11:0]	SCUSCR_PMSDTS_RES*.VAL	Bit-fields in 2 registers combine for 12-bit result value	Read-only
DTS_STAT.READY	SCUSCR_PMSDTS_RES11_8.RES_READY	1-bit indication that temperature result is ready	Read-only

Special notes on SCR access:

***Note**: While performing 2 read operations to read all 12-bits of RESULT[11:0], the value can change in between those operations. It is recommended to read the lower 8-bits first, then the upper 4-bits and read again the lower 8-bits. If the new value of lower 8-bits is the same as on first read then keep the result, if not perform re-read of upper 4-bits.*

***Note**: Upon wake-up from STANDBY0, it is not possible to perform DTS calibration from SCR software side. This adds additional +-3LSB precision penalty on top of precision value listed in the datasheet.*

SCR only controls enabling and starting of the PMS DTS, and cannot explicitly disable it. But since DTS is located in the PMS1 domain it will be automatically switched off if the system transitions into STANDBY0 state.

SCR can enable and start the PMS DTS while in STANDBY1_70K mode. However, PMS DTS requires 100 MHz clock for its correct operation. Therefore, the SCR must select a PCLK faster than 70 kHz to use the DTS properly(SCR_SCUSCR_CLK.DIV_REQ!=DIV70kHz).

39.3.10 Timer 0 and timer 1 (T01)

39.3.10.1 Overview

Timer 0 and Timer 1 can function as both, timers or counters. When functioning as a timer, Timer 0 and Timer 1 are incremented at $f_{PCLK}/2$ (for example every 2 PCLKs). When functioning as a counter, Timer 0 and Timer 1 are incremented in response to a 1-to-0 transition (falling edge) at their respective external input pins, T0 or T1.

They are useful in many timing applications such as measuring the time interval between events, counting events and generating signals at regular intervals. In particular, Timer 1 can be used as the baudrate generator for the on-chip serial port.

Features:

- Four operational modes:
  - Mode 0: 13-bit timer/counter
  - Mode 1: 16-bit timer/counter
  - Mode 2: 8-bit timer/counter with auto-reload
  - Mode 3: Two 8-bit timers/counters

39.3.10.2 System information

This section provides system information relevant to the Timer 0 and 1.

39.3.10.2.1 Pinning

The following figure shows the connections and selections for the inputs to timers 0 and 1. Please see also the GPIO chapter (PORT8).

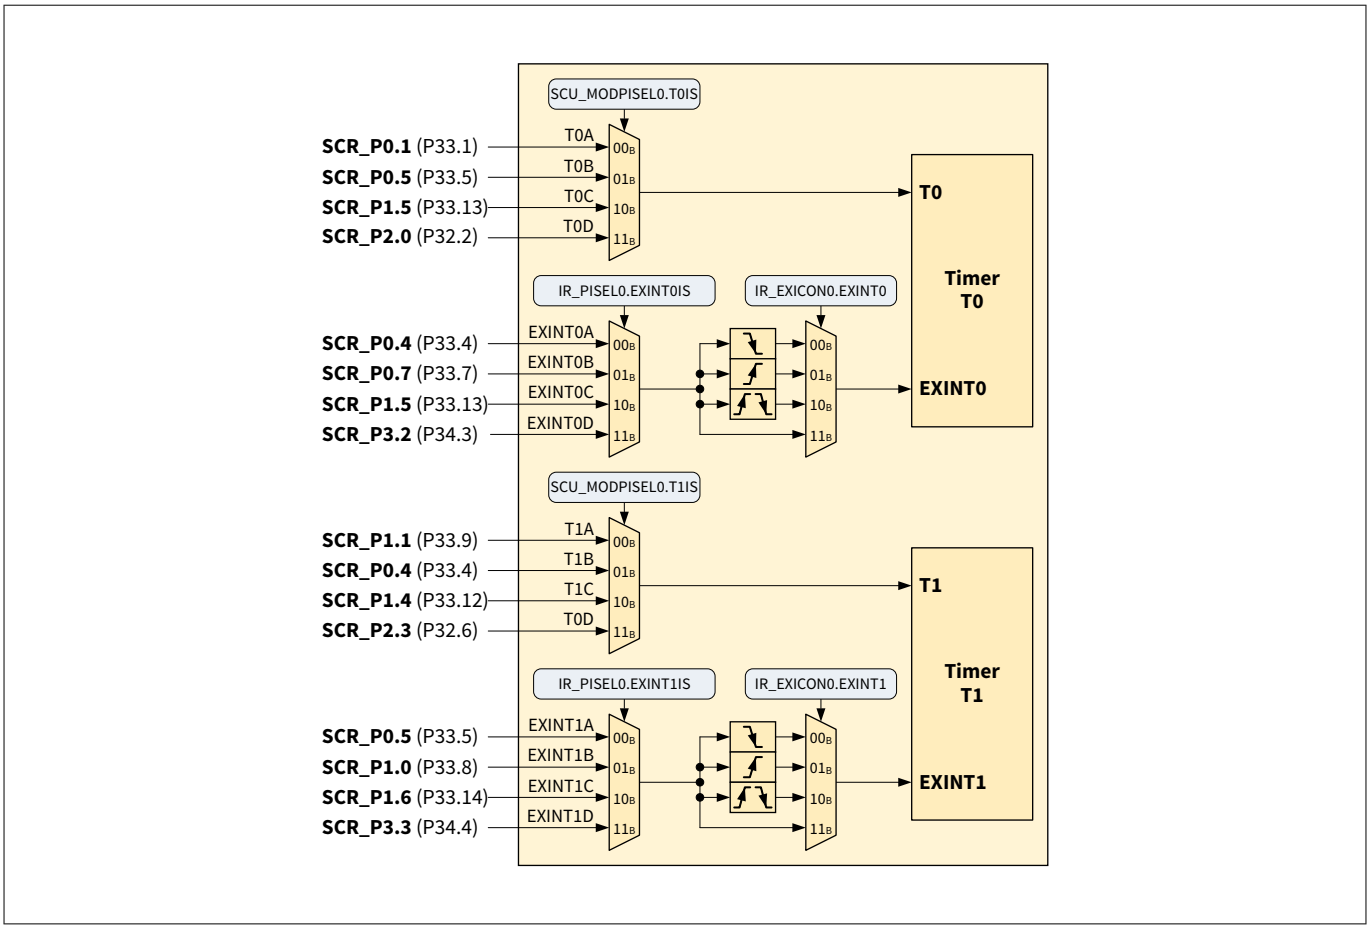

Figure 876 Timer 0 and 1 modules input signals

39.3.10.2.2 Clocking configuration

The Timer 0 and 1 run on the PCLK.

39.3.10.2.3 Interrupt events and assignment

The following table lists the interrupt event sources from Timer 0 and 1, and the interrupt node assignment for each Timer 0 and 1 interrupt source.

Table 1712 Timer 0 and 1 events' interrupt node control

Event	Interrupt node enable bit	Interrupt node flag bit	Vector address
External Interrupt 0	IEN0.EX0	T01_TCON.IE0	03_H
Timer 0 Overflow	IEN0.ET0	T01_TCON.TF0	$0B_H$
External Interrupt 1	IEN0.EX1	T01_TCON.IE1	13_H
Timer 1 Overflow	IEN0.ET1	T01_TCON.TF1	$1B_H$

39.3.10.3 Basic timer operations

The operations of the two timers are controlled using the Special Function Registers (SFRs) T01_TCON and T01_TMOD. To enable a timer, for example, to allow the timer to run, its control bit T01_TCON.TRx is set. To select the timer input to be either from internal system clock or external pin, the input selector bit T01_TMOD.TxS is used.

***Note**: The "x" (for example, T01_TCON.TRx) in this chapter denotes either 0 or 1.*

Each timer consists of two 8-bit registers - T01_TLx (low byte) and T01_THx (high byte) which defaults to $>00_H$ on reset. Setting or clearing T01_TCON.TRx does not affect the timer registers.

The timers 0 and 1 can be used as a counter, where the timer register is incremented in response to a 1-to-0 transition (falling edge) at the corresponding external input pin (T0 or T1). When the samples show a high for two PCLKs and a low in the next two PCLKs, the count is incremented. Since it takes four PCLKs to recognize a 1-to-0 transition, the maximum count rate is 1/4 of the PCLK frequency. There are no restrictions on the duty cycle of the external input signal, but it must be held at least two full PCLKs to ensure that a given level is sampled at least once before it changes.

Timer overflow

When a timer overflow occurs, the timer overflow flag, T01_TCON.TFx, is set, and an interrupt may be raised if the interrupt enable control bit, IEN0.ETx, is set. The overflow flag is automatically cleared when the interrupt service routine is entered. See also T0/T1 Interrupt Flags and Requests in related information..

When "Timer 0" operates in mode 3, the "Timer 1" control bits, TR1, TF1 and ET1 are reserved for TH0, see Mode 3 in related information.

External control

In addition to pure software control, the timers can also be enabled or disabled through external port control. When external port control is used, SFR EXICON0 must first be configured to bypass the edge detection circuitry for EXINTx to allow direct feed-through. When the timer is enabled (T01_TCON.TRx=1) and T01_TMOD.GATEx is set, the respective timer will only run if the core external interrupt EXINTx=1. This facilitates pulse width measurements. However, this is not applicable for "Timer 1" in mode 3.

If T01_TMOD.GATEx is cleared, the timer reverts to pure software control.

Related information

Mode 3 on page 6580

T0/T1 interrupt flags and requests on page 6581

39.3.10.4 Timer modes

Timers 0 and 1 are fully compatible and can be configured in four different operating modes, as shown in the following table. The bit-field TxM in register T01_TMOD selects the operating mode to be used for each timer.

In modes 0, 1 and 2, the two timers operate independently, but in mode 3, their functions are specialized.

Table 1713 Timer 0 and timer 1 modes

Mode	Operation
0	13-bit timer/counter The timer is essentially an 8-bit counter with a divide-by-32 prescaler. This mode is included solely for compatibility with Intel 8048 devices
1	16-bit timer/counter The timer registers, T01_TLx and T01_THx, are concatenated to form a 16-bit timer/ counter

(table continues...)

Table 1713 (continued) Timer 0 and timer 1 modes

Mode	Operation
2	8-bit timer/counter with auto-reload The timer register T01_TLx is reloaded with a user-defined 8-bit value in T01_THx upon overflow
3	Timer 0 operates as two 8-bit timers/counters The timer registers, T01_TL0 and T01_TH0, operate as two separate 8-bit counters. Timer 1 is halted and retains its count even if enabled

39.3.10.4.1 Mode 0

Putting either Timer 0 or Timer 1 into mode 0 configures it as an 8-bit timer/counter with a divide by 32 prescaler. The following figure shows the mode 0 operation.

In this mode, the timer register is configured as a 13-bit register. As the count rolls over from all '1's to all '0's, it sets the timer overflow flag TFx (see exception below). The overflow flag TFx can then be used to request an interrupt (see related information). The count input is enabled for the timer when TRx=1 and either GATEx=0 or EXINTx=1 (setting GATEx=1 allows the timer to be controlled by external input EXINTx to facilitate pulse width measurements). TRx is a control bit in the register TCON; bit GATEx is in register T01_TMOD.

The 13-bit register consists of all the 8 bits of T01_THx and the lower 5 bits of T01_TLx. The upper 3 bits of T01_TLx are indeterminate and should be ignored. Setting the run flag (TRx) does not clear the registers.

Mode 0 operation is the same for Timer 0 and Timer 1 (exception see below)

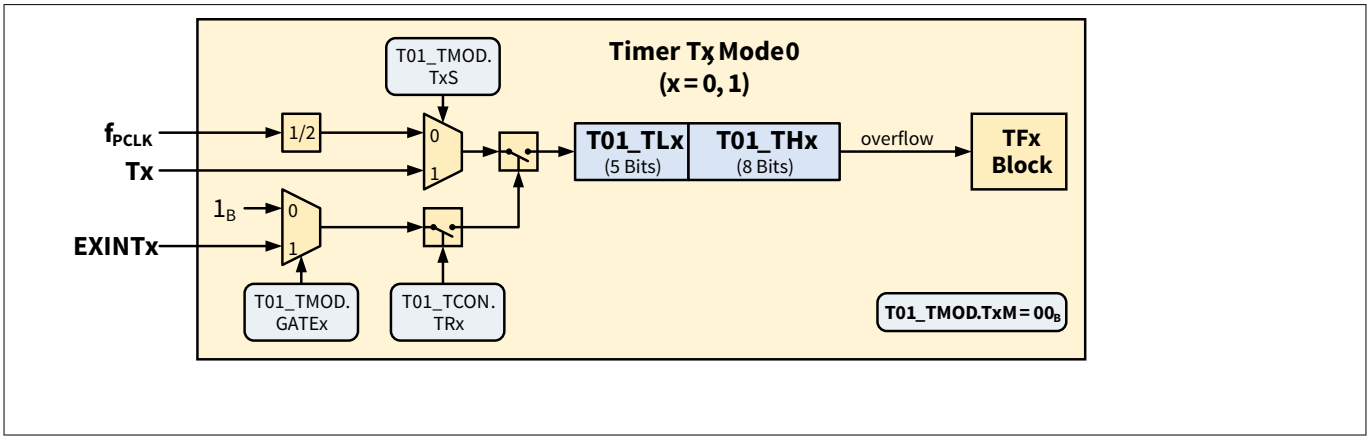

Figure 877 Timer x, mode 0: 13-bit timer/counter

The configuration shown in the figure above applies to Timer 1 as long as Timer 0 is NOT operating in mode 3. When Timer 0 is operating in mode 3, it uses resources from Timer 1; therefore, the mode 0 configuration of Timer 1 in this case is shown in the following figure.

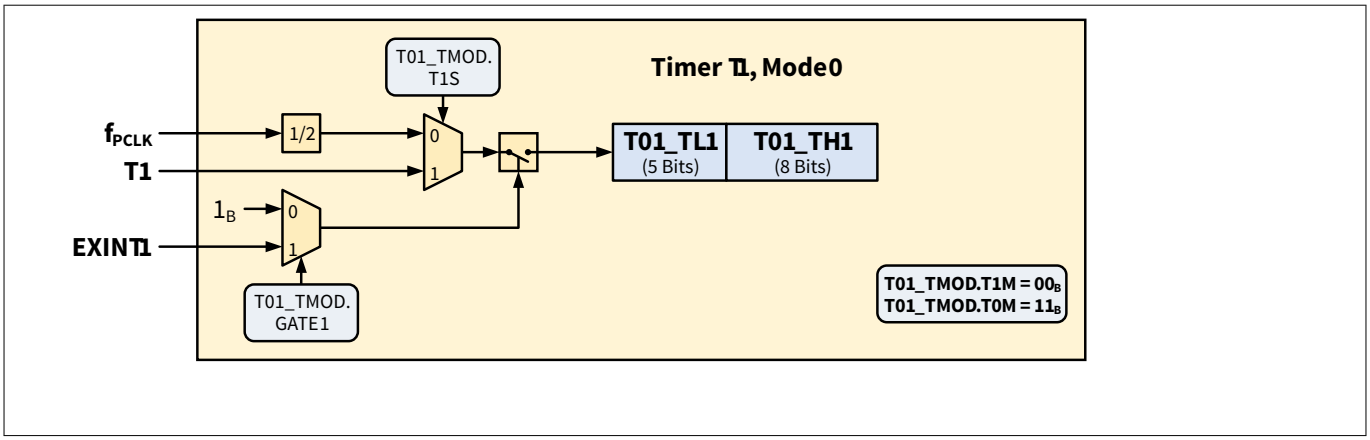

Figure 878 Timer 1 in mode 0 while timer 0 is in mode 3: 13-bit timer/counter

Related information

T0/T1 interrupt flags and requests on page 6581

39.3.10.4.2 Mode 1

Mode 1 operation is similar to that of mode 0, except that the timer register runs with all 16 bits. Mode 1 operation for Timer x is shown in the following figure.

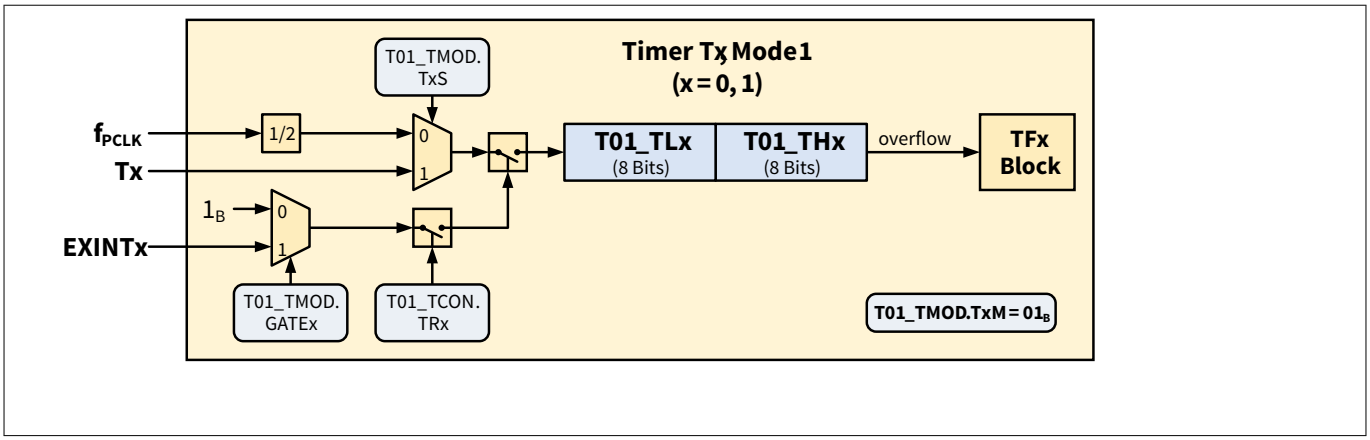

Figure 879 Timer x, mode 1: 16-bit timer/counter

The configuration shown in the figure above applies to Timer 1 as long as Timer 0 is NOT operating in mode 3. When Timer 0 is operating in mode 3, it uses resources from Timer 1; therefore, the mode 1 configuration of Timer 1 in this case is shown in the following figure.

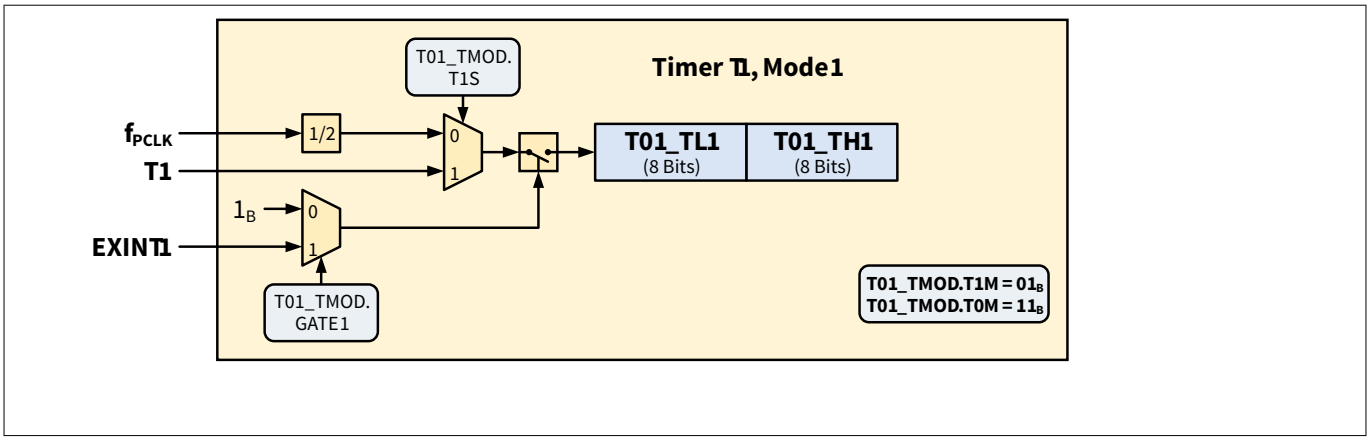

Figure 880 Timer 1 in mode 1 while timer 0 is in mode 3: 16-bit timer/counter

39.3.10.4.3 Mode 2

In Mode 2 operation, the timer is configured as an 8-bit counter (TLx) with automatic reload, as shown in the following figure.

An overflow from TLx not only sets TFx, but also reloads TLx with the contents of THx that has been preset by software. The reload leaves THx unchanged.

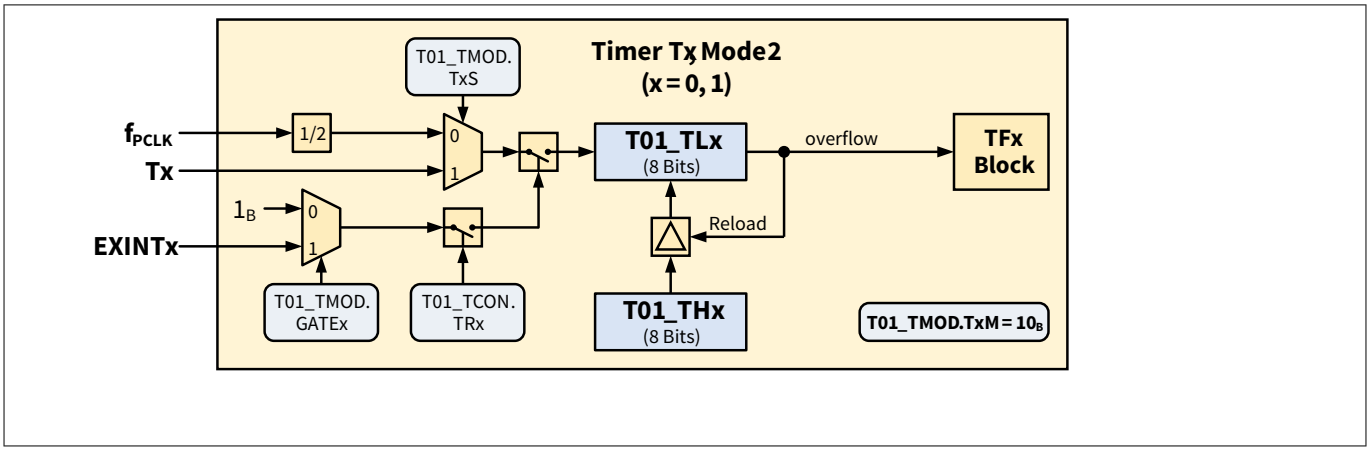

Figure 881 Timer x, mode 2: 8-bit timer/counter with auto-reload

The configuration shown in the figure above applies to Timer 1 as long as Timer 0 is NOT operating in mode 3. When Timer 0 is operating in mode 3, it uses resources from Timer 1; thus, the mode 2 configuration of Timer 1 in this case is shown in the following figure.

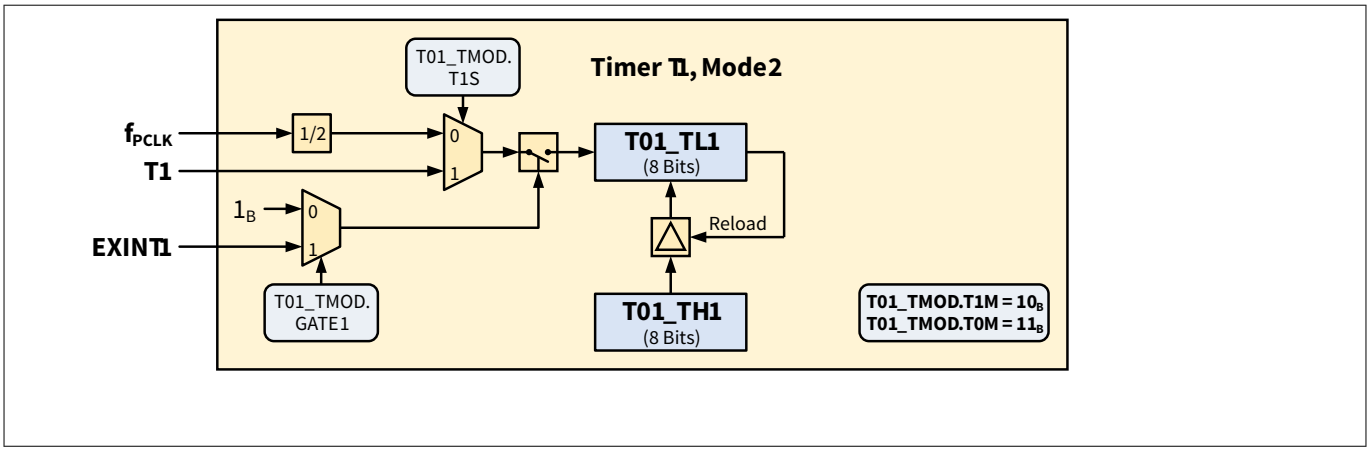

Figure 882 Timer 1 in mode 2 while timer 0 is in mode 3: 8-bit timer/counter

39.3.10.4.4 Mode 3

In mode 3, Timer 0 and Timer 1 behave differently. Timer 0 in mode 3 establishes T01_TL0 and T01_TH0 as two separate counters. Timer 1 in mode 3 simply holds its count. The effect is the same as setting TR1=0.

The logic for mode 3 operation for Timer 0 is shown in the following figure. T01_TL0 uses the Timer0 control bits GATE0, TR0 and TF0, while T01_TH0 is locked into a timer function (counting $f_{PCLK}/2$) and takes over the use of TR1 and TF1 from Timer 1 . T01_TH0 now sets TF1 upon overflow and generates an interrupt if ET1 is set (see also related information).

Mode 3 is provided for applications requiring an extra 8-bit timer. When Timer 0 is in mode 3 and TR1 is set, Timer 1 can be turned on by switching it to any of the other modes and turned off by switching it into mode 3.

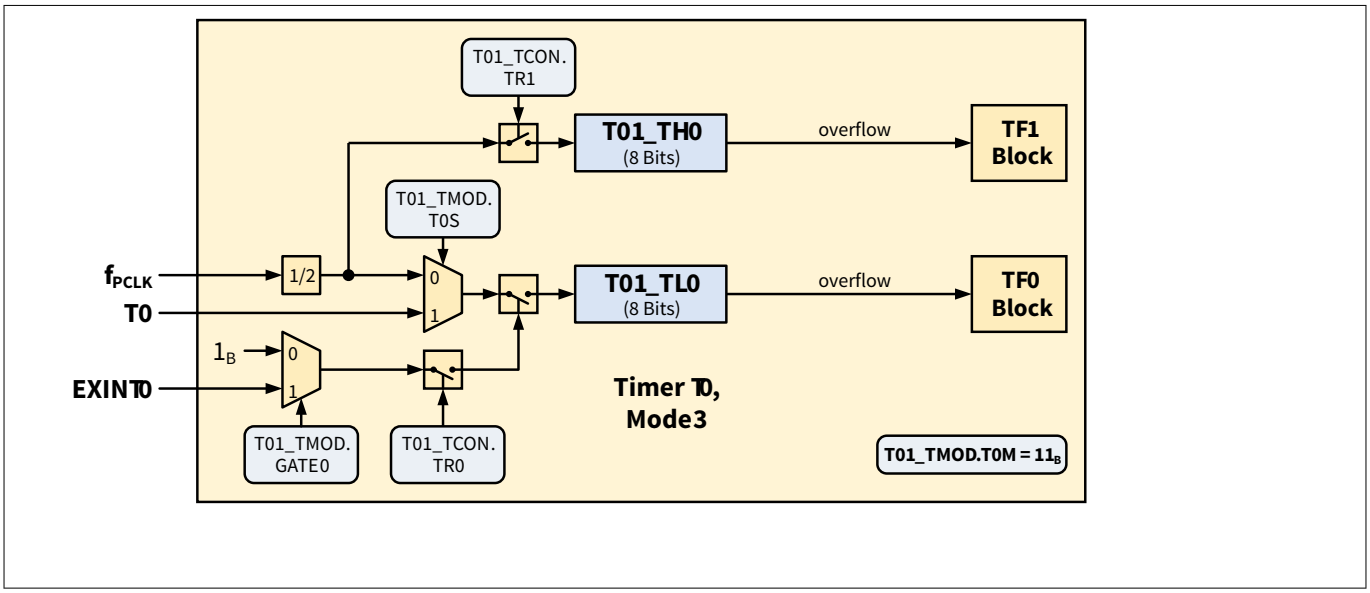

Figure 883 Timer0, mode 3: two 8-bit timers/counters

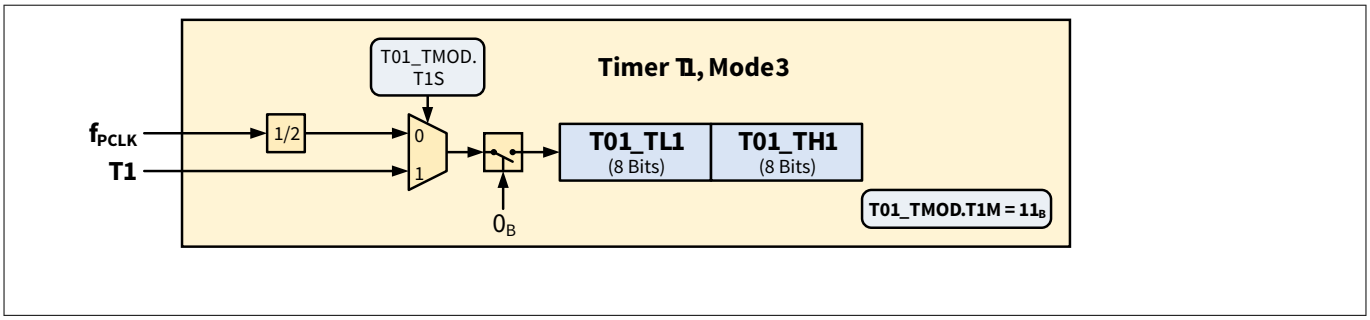

Figure 884 Timer 1 in mode 3: timer stops

Related information

T0/T1 interrupt flags and requests on page 6581

39.3.10.5 T0/T1 interrupt flags and requests

The following figure illustrates the T0/T1 interrupt requests. Besides the overflow interrupts, the T0/T1 module also handles the control for the two external interrupts EXINT0 and EXINT1.

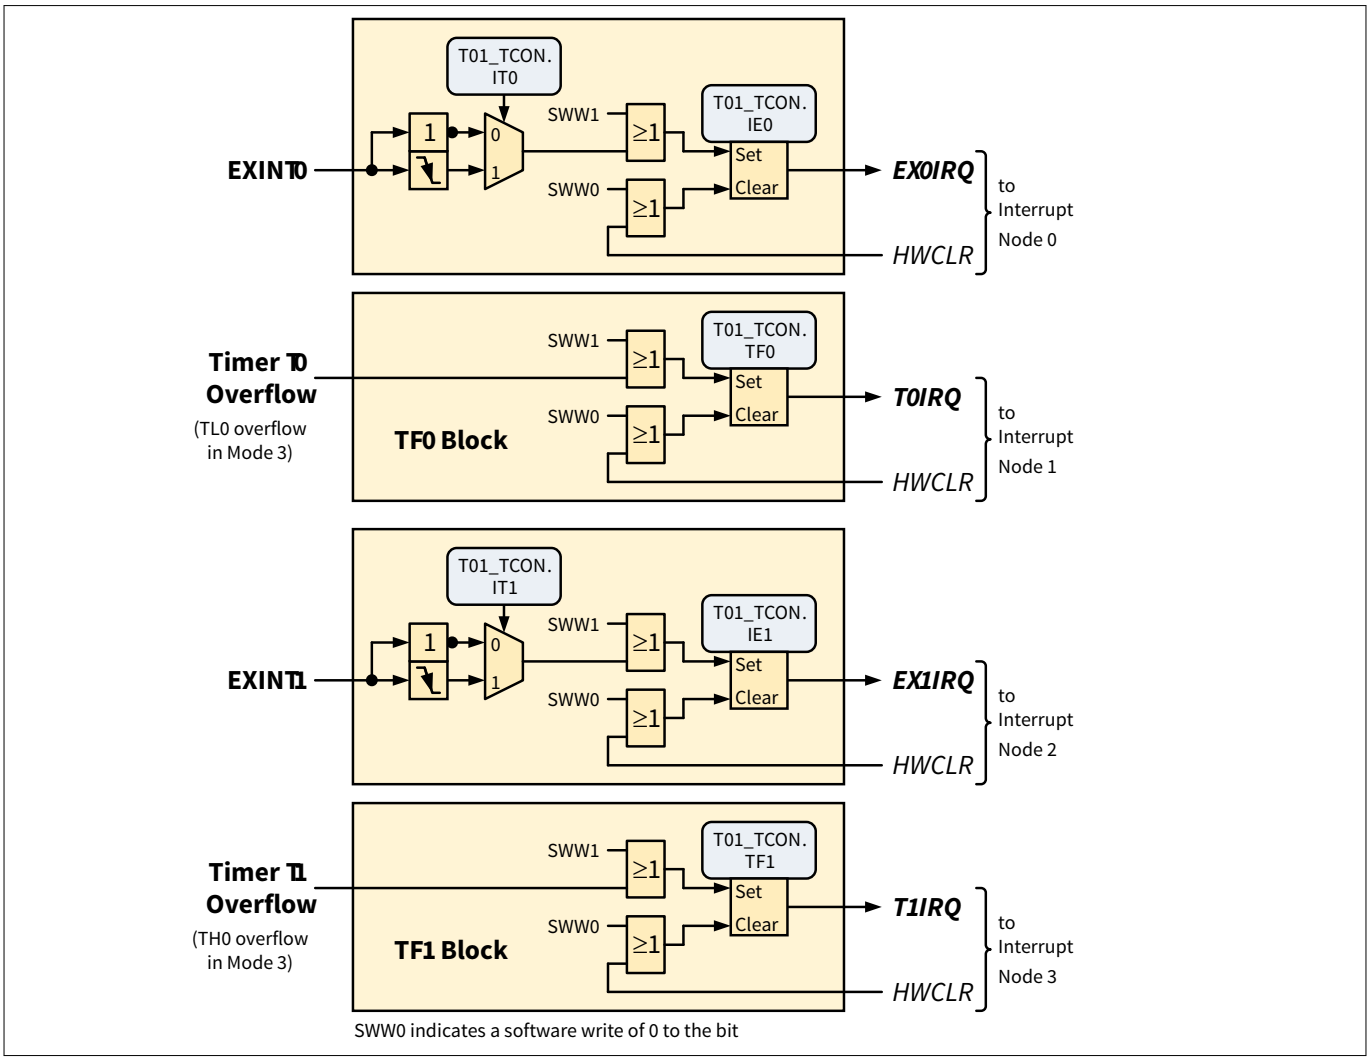

Figure 885 T0/T1 interrupt requests

Note that when timer T0 operates in Mode 3, flag TF0 is set by an overflow of the 8-bit timer part T01_TL0, while flag TF1 is set by an overflow of the 8-bit timer part T01_TH0. Besides being set by hardware, the flags can also be set by software (triggering an interrupt request).

The interrupt flags are automatically cleared by the CPU on entry into the respective service routine. They can also be cleared by software. See also the section on “Interrupt Structure 1” in “Interrupt System” chapter.

Related information

Interrupt structure 1 on page 6521

39.3.10.6 Register overview

Seven SFRs control the operations of Timer 0 and Timer 1. They can be accessed from both the standard (non-mapped) and mapped SFR area.

The following table lists the addresses of these SFRs.

Table 1714 Registers overview - T0/T1 (sorted by name)

Short name	Description	RMAP	PAGE	Offset address
IEN0	Interrupt Enable Register 0	X	X	$D8_H$
T01_TCON	Timer 0/1 Control Register	X	X	CA_H
T01_TMOD	Timer Mode Register	X	X	CB_H
T01_TL0	Timer 0 Low Byte	X	X	CC_H
T01_TL1	Timer 1 Low Byte	X	X	CD_H
T01_TH0	Timer 0 High Byte	X	X	CE_H
T01_TH1	Timer 1 High Byte	X	X	CF_H

The low bytes (T01_TL0,, T01_TL1) and high bytes (T01_TH0, T01_TH1) of both Timer 0 and Timer 1 can be combined to a one-timer configuration depending on the mode used. Register T01_TCON controls the operations of Timer 0 and Timer 1. The operating modes of both timers are selected using register T01_TMOD. Register IEN0 contains bits that enable interrupt operations in Timer 0 and Timer 1.

39.3.11 Timer 2 and capture-compare module (T2CCU0/1)

The T2CCU module is a flexible timing unit with two 16-bit timers and a 6-channel Capture/Compare Unit (CCU). There are two T2CCU modules instantiated in SCR: T2CCU0 and T2CCU1.

***Note**: In following sections if the index 0 or 1 is omitted in terms like T2CCU, T2EX, EXF2 then the statement applies generally to both instantiated T2CCU modules.*

39.3.11.1 Overview

The block diagram of the T2CCU module is shown in the following figure. It consists of the Timer 2, the Capture/Compare Timer (CCT), and a Capture/Compare Unit (CCU). Control is available in the CCU, for each of its 16-bit capture/compare channels, to individually select either Timer 2 or the Capture/Compare Timer (CCT) as the time base. Both timers have a resolution of 16 bits. The clock frequency of T2CCU, f_{T2CCU}, is set at PCLK frequency.

The T2CCU can be used for various digital signal generation and event capturing like pulse generation, pulse width modulation, pulse width measuring etc. Target applications include various automotive control as well as industrial applications (frequency generation, digital-to-analog conversion, process control etc.).

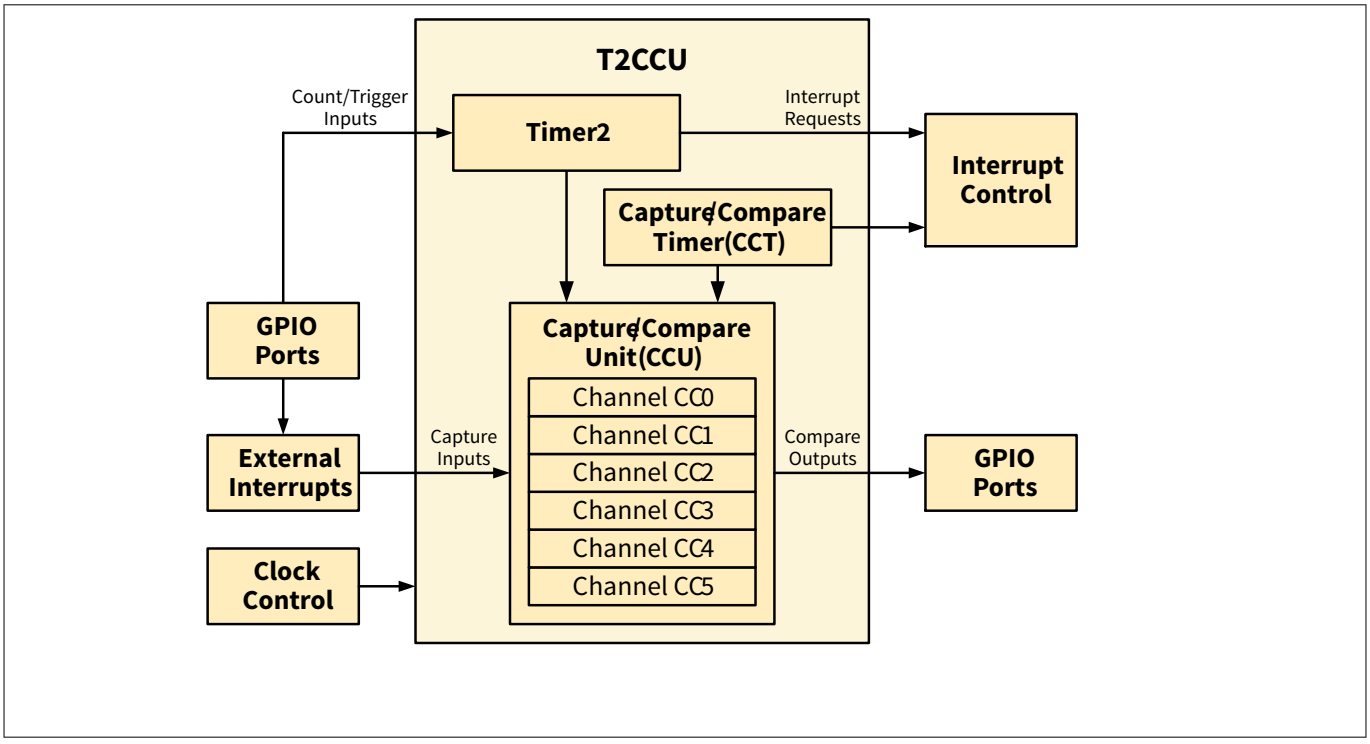

Figure 886 T2CCU module block diagram

39 Stand-by Controller (SCR)

The T2CCU has the following features:

Timer 2

- 16-bit resolution
- Timer or counter operation
- 16-bit auto-reload mode
- Selectable up or down counting
- One channel, 16-bit capture mode
- Baudrate generator for U(S)ART
- Usable as base timer for the CCU

Capture/Compare Timer (CCT)

- 16-bit resolution
- Timer operation
- 16-bit reload mode
- Extremely flexible Capture/Compare Timer count rate by cascading with Timer 2
- Capture/Compare Timer may be ‘reset’ immediately by triggering overflow event

Capture/Compare Unit (CCU)

- 16-bit resolution
- Option to individually select either Timer 2 or the CCT as base timer for a channel
- Six compare channels in total
  - Shadow register for each compare register: Transfer through software control or on timer overflow
  - Compare Mode 0: Compare output signal changes from the inactive level to active level on compare match. Returns to inactive level on timer overflow. Compare Mode 0 can be configured with or without dead-time generation. Active level can be defined by register bit for channel groups A and B. Support of 0% to 100% duty cycle in Compare Mode 0
  - Compare Mode 1: Full control of the software on the compare output signal level, for the next compare match
  - Concurrent Compare Mode with channel 0
- Four capture channels, shared with the compare channels
  - Capture Mode 0: Capture on any external event (rising/falling/both edge) at the 4 pins T2CC0 to T2CC3
  - Capture Mode 1: Capture upon writing to the low byte of the corresponding channel capture register
  - Capture Mode 0 or 1 can be established independently on the 4 capture channels

39.3.11.2 Timer 2

The Timer 2 of the T2CCU has the following features:

- 16-bit auto-reload mode
- Selectable up or down counting
- One channel, 16-bit capture mode
- Timer 2 can be used as a stand-alone timer, aside of the CCU, or can be used as a base timer for the CCU

39.3.11.2.1 Basic timer 2 operations

The following sections describe the basic functions of Timer 2.

Timer 2 start/stop and count control

The count input to Timer 2 is controlled by the run bit T2CCU1_T2_CON.TR2. timer 2 can be started by setting run bit T2CCU1_T2_CON.TR2 either through hardware or software. The timer can only be stopped through software by clearing bit T2CCU1_T2_CON.TR2.

The run bit T2CCU1_T2_CON.TR2 can be set by various events:

- By software: Write ’1’ to bit T2_CON.TR2
- By hardware:
  - A selectable transition at input T2EX. This input is enabled/disabled through bit T2_MOD.T2RHEN. The active transition of the input, either a rising or a falling edge, is selected through bit T2_MOD.REGS. Note that input T2EX can also be used for the capture/reload control of Timer 2 (see following sections)
  - Through the synchronous start signal from the capture/compare timer CCT. This event is enabled/ disabled through bit TIMSYN in register T2CCU_CCTCON. This option can be used to trigger a synchronous start of both timers, timer 2 and timer CCT. See Synchronized Start of Timer 2 and CCT Timer in related information for details

All of these actions set the run bit TR2 to 1. Its output controls the count input to the Timer 2. The state of the run bit can be read by software. To stop the timer, clear the run bit TR2 by writing a ‘0’ to it.

Following figure illustrates the start/stop and count control of timer 2. The count input selection is described in the next section. In the further diagrams of Timer 2, the start/stop control is shown as a block, together with the count input control. For the details, please refer to the following figure.

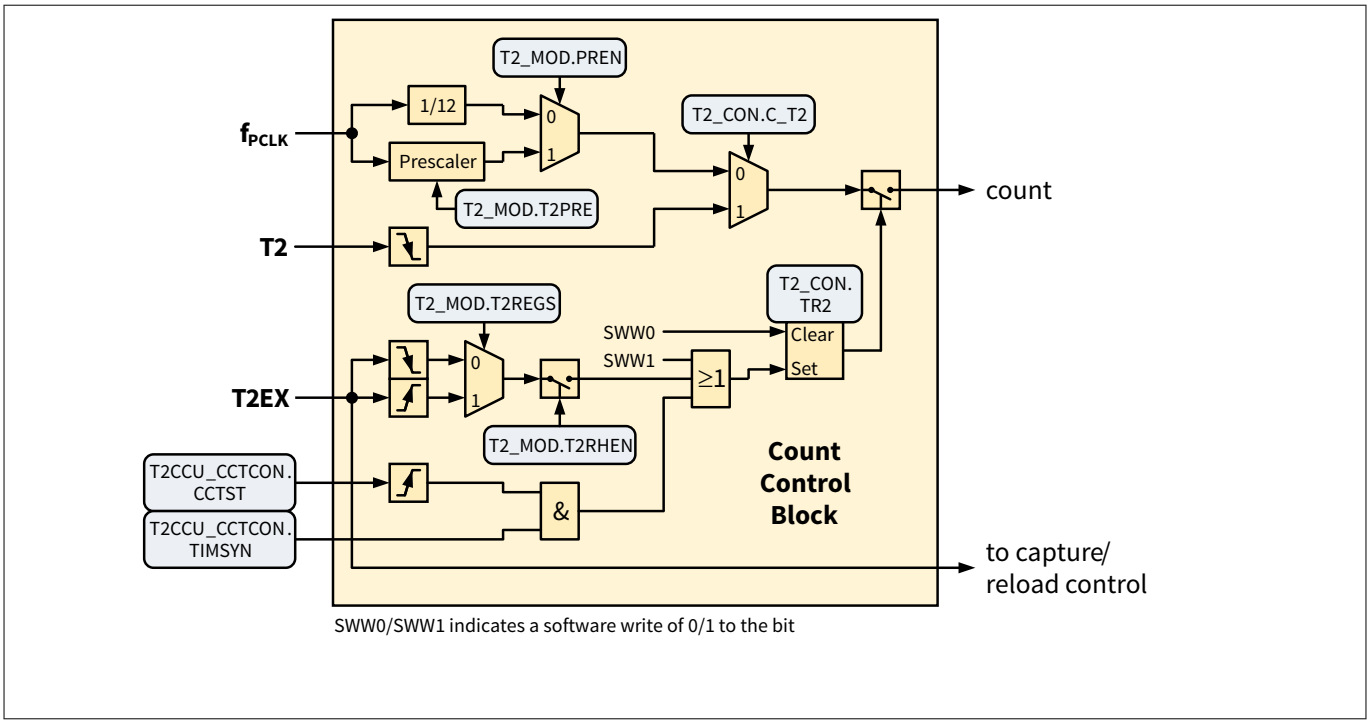

Figure 887 Timer 2 start/stop and count control

Related information

Synchronized start of timer 2 and CCT timer on page 6595

Count clock options

Timer 2 can either operate as a timer or as a counter. The selection is made through bit T2_CON.C_T2.

- Timer mode (C_T2=0):

  Either $f_{PCLK}/12$ or f_{PCLK} divided by a programmable pre-scaler can be selected as input clock to Timer 2. The selection is made through bit T2_MOD.PREN. The divide factor for the programmable pres-caler is chosen through bit-field T2_MOD.T2PRE
- Counter mode ((C_T2=1):

  Timer 2 counts in response to a 1-to-0 transition at input T2. Input T2 is sampled over 2 PCLK clock cycles. If a 1 was detected during the first clock and a 0 was detected in the following clock, then a count clock for Timer 2 is generated. Therefore, the input levels should be stable for at least 1 PCLK clock cycle

39.3.11.2.2 Timer 2 operating modes

The following sections describe the various operating modes of Timer 2.

***Note**: In order to simplify the diagrams, the connection of the Timer 2 contents to the Capture/Compare Unit (CCU) is not shown in the following figures.*

Reload Mode of timer 2

In reload mode of Timer 2 (bit T2_CON.CP_RL2 is 0), the RC2 register (register pair T2_RC2H|T2_T2_RC2L) is used to hold a reload/trigger value for Timer 2:

- When down counting is disabled, the value in RC2 is loaded into Timer 2 either on overflow or in response to an external signal transition
- When down counting is enabled, the value in RC2 is used as a trigger value to load $FFFF_H$ into Timer 2

In the following sections, these operations are described in detail.

***Note**: For a description of the interrupt request and flag logic "TF2 Block" and "EXF2 Block", please see related information.*

Related information

Timer 2 interrupt requests on page 6590

Reload operation in up-counting mode

When bit T2_MOD.DCEN is 0, Timer 2 can only count up, and the RC2 register is used to hold a reload value. The following figure shows an operational block diagram of Timer 2 in this configuration.

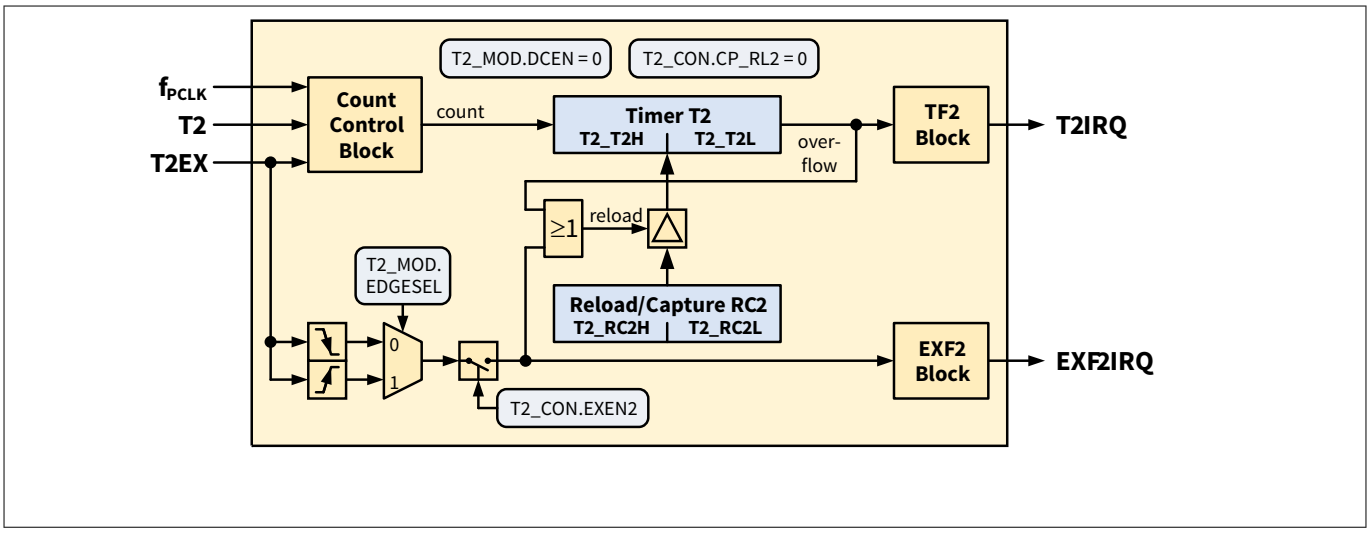

Figure 888 Reload operation in up-counting mode (T2_MOD.DCEN=0)

Depending on bit T2_CON.EXEN2, two options exist:

- EXEN2=0: Reload on overflow only (auto-reload):
  - Once the timer is started, it counts up to its maximum value $FFFF_H$
  - The next count clock pulse leads to an overflow condition: Timer 2 is loaded with the contents of register RC2, and flag T2_CON.TF2 is set to 1 (can be used to generate an interrupt request)
  - With the next count clock pulse(s), the timer continues to count up from the reloaded value
- EXEN2=1: Reload on overflow or on external signal edge:
  - Once the timer is started, it counts up
  - A reload of Timer 2 is performed either on an overflow condition (auto-reload, see above) or by a selected signal edge on input T2EX (external reload). With the next count clock pulse(s), the timer continues to count up from the reloaded value
  - The signal edge can either be a positive (0-to-1), or a negative (1-to-0) transition at input T2EX. The selection is done through bit T2_MOD.EDGESEL
  - The selected signal transition also sets flag T2_CON.EXF2 to 1 (can be used to generate an interrupt request)

Note that the input signal T2EX can be used for both, the timer count control and the external reload function.

When bit T2RHEN is set, Timer 2 is started by first falling edge/rising edge at pin T2EX, which is defined by bit T2REGS. If bit T2_CON.EXEN2 is set, bit T2_CON.EXF2 is also set at the same point when Timer 2 is started with the same falling edge/rising edge at pin T2EX, which is defined by bit T2_MOD.EDGESEL. The reload will happen with the following negative/positive transitions at pin T2EX, which is defined by bit T2_MOD.EDGESEL.

***Note**: In counter mode, if the reload via T2EX and the count clock T2 are detected simultaneously, the reload takes precedence over the count. The counter increments its value with the following T2 count clock.*

Reload operation in up/down-counting mode

When bit T2_MOD.DCEN is set to 1, the up/down count selection is enabled for Timer 2. The count direction is determined by the level at input pin T2EX. The following figure shows an operational block diagram of Timer 2 in this configuration.

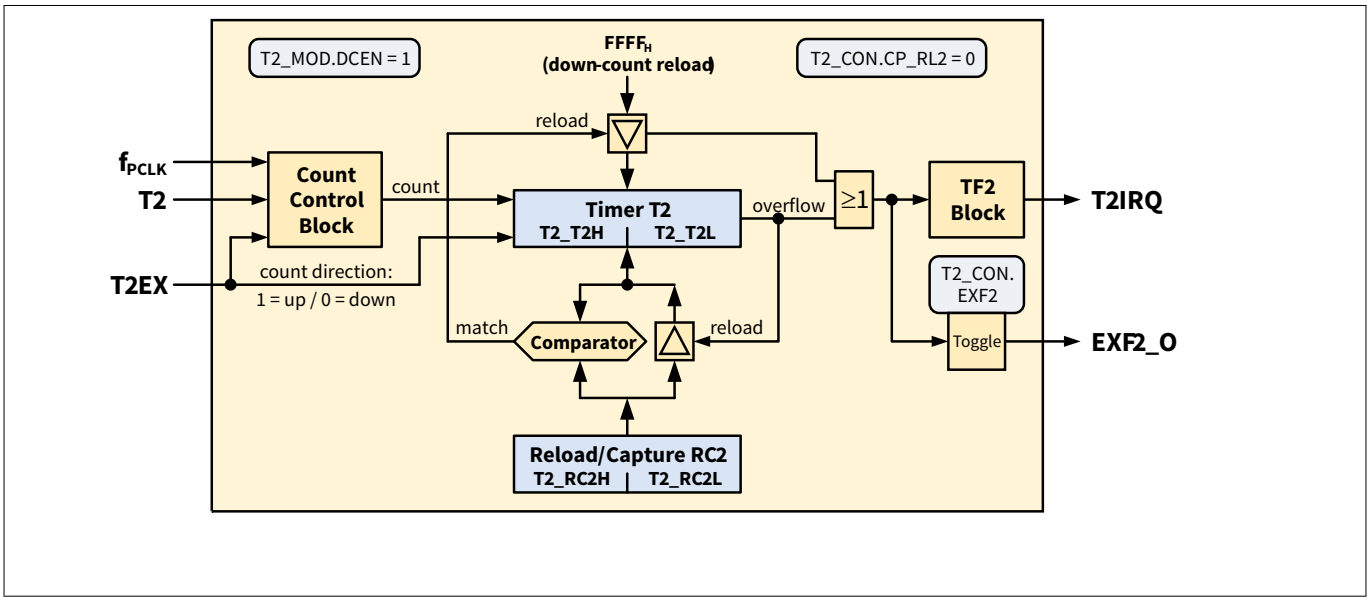

Figure 889 Reload operation in up/down-counting mode (T2_MOD.DCEN=1)

The operation in this mode is as follows:

- A logic 1 at pin T2EX sets the Timer 2 to up-counting mode:
  - Once the timer is started, it counts up to its maximum value FFFF$_H$
  - The next count clock pulse leads to an overflow condition: Timer 2 is loaded with the contents of register RC2, and flag T2_CON.TF2 is set to 1 (can be used to generate an interrupt request)
  - With the next count clock pulse(s), the timer continues to count up from the reloaded value
- A logic 0 at pin T2EX sets the Timer 2 to down-counting mode:
  - Once the timer is started, it counts down
  - When the timer contents match the value stored in register RC2, an underflow condition is generated. Timer 2 is loaded with the value FFFF$_H$, and flag T2_CON.TF2 is set to 1 (can be used to generate an interrupt request)
  - With the next count clock pulse(s), the timer continues to count down from FFFF$_H$

If bit T2RHEN is set, Timer 2 can be started either by rising edge (T2REGS=1) at pin T2EX and then proceed with the up counting, or be started by falling edge (T2REGS=0) at pin T2EX and then proceed with the down counting.

In this mode, bit T2_CON.EXF2 toggles whenever an overflow or an underflow condition is detected. This flag, however, does not generate an interrupt request.

Capture mode of timer 2

In capture mode of Timer 2 (bit T2_CON.CP_RL2 is 1), the RC2 register (register pair T2_RC2H|T2_RC2L) is used to latch the current contents of the timer in response to an external event.

The following figure shows an operational block diagram of Timer 2 in this configuration.

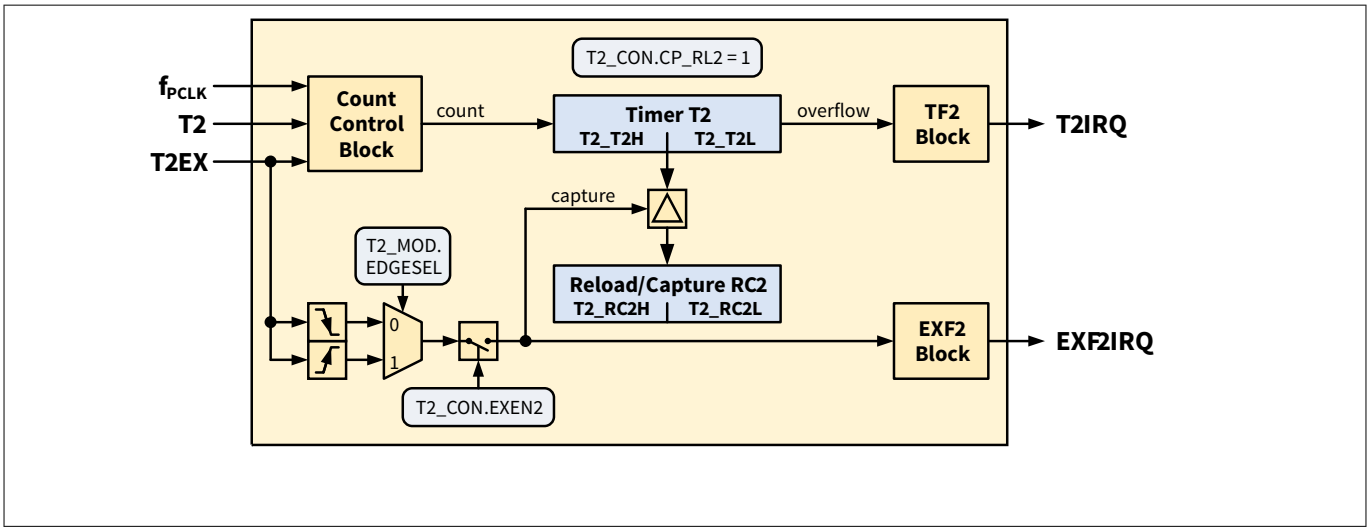

Figure 890 Capture mode of timer 2

To operate the timer in capture mode, the following settings must be made:

- Enable capture mode: Set bit T2_CON.CP_RL2 to 1
- Disable the down-count function: Clear bit T2_MOD.DCEN to 0
- Enable the external input T2EX: Set bit T2_CON.EXEN2 to 1

The timer functions as a 16-bit timer and always counts up to $FFFF_H$. With the next clock pulse, an overflow condition occurs; bit TF2 is set (which can generate an interrupt request), and the timer registers are loaded with 0000_H. The counting continues with the next clock pulse(s).

With a falling or rising edge (chosen by T2_MOD.EDGESEL) at input T2EX, the contents of the timer register are captured into the RC2 register. At the same time, bit T2_CON.EXF2 is set to 1. The external input is sampled in every PCLK clock cycle. When a sample shows a low (high) level in one PCLK clock cycle, and a high (low) in the next PCLK clock cycle, a transition is recognized. If the capture signal is detected while the timer is being incremented, the timer is first incremented before the capture operation is performed. This ensures that always the latest value of the timer register is captured.

Note that the input signal T2EX can be used for both, the timer count control and the external capture function.

If bit T2RHEN is set, Timer 2 is started by first falling edge/rising edge at pin T2EX, which is defined by bit T2REGS. If bit T2_CON.EXEN2 is set, bit T2_CON.EXF2 is also set at the same point when Timer 2 is started with the same falling edge/rising edge at pin T2EX, which is defined by bit T2_MOD.EDGESEL. The capture will happen with the following negative/positive transitions at pin T2EX, which is defined by bit T2_MOD.EDGESEL.

39.3.11.2.3 Timer 2 interrupt requests

Timer 2 can generate two different interrupt requests to the CPU:

- An interrupt request on timer overflow
- An interrupt request on an external transition at input T2EX

These interrupt requests are detailed in the following sections.

Timer overflow interrupt request

The following figure shows a functional diagram of the overflow interrupt request generation. The flag T2_CON.TF2 is set on an overflow of the timer (in certain modes), or it can be set by software. When enabled through bit T2_CON1.TF2EN, the signal which sets the T2_CON1.TF2EN flag will generate an interrupt request to the CPU.

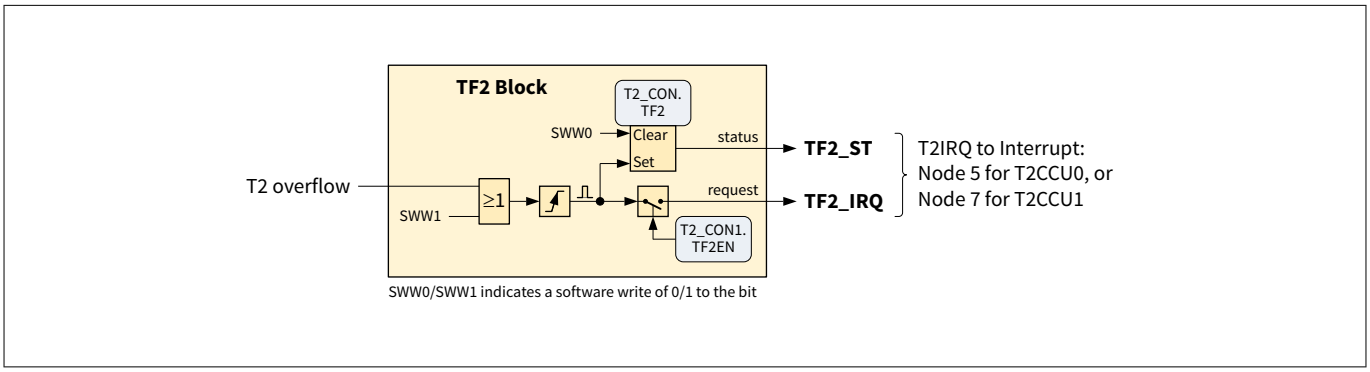

Figure 891 TF2 flag block

The overflow flag and the corresponding overflow interrupt request (if enabled) will be set/generated in the following cases:

- By software: By writing a 1 to flag T2_CON.TF2, the flag will be set and an interrupt request (if enabled) will be generated
- Reload Operation in Up-Counting Mode (T2_MOD.DCEN = 0, T2_CON.CP_RL2 = 0): When an overflow of Timer 2 occurs
- Reload Operation in Up/Down-Counting Mode (T2_MOD.DCEN = 1, T2_CON.CP_RL2 = 0): When an overflow of Timer 2 occurs, or when an underflow (timer contents match the value stored in register RC2) occurs
- Capture Mode of Timer 2 (T2_MOD.DCEN = 0, T2_CON.CP_RL2 = 1): When an overflow of Timer 2 occurs

Flag TF2 must be cleared by software.

***Note**: The overflow interrupt request logic of Timer 2 is basically of type “interrupt structure 2” (see section “Interrupt Structure” in chapter “Interrupt System”), however, the status signal does not have an individual enable control. Therefore, in order to clear the pending request flag in the interrupt system, it is necessary to clear all status flags assigned to that interrupt node, even if the respective interrupt request is not enabled.*

***Note**: Although two signals, TF2_IRQ and TF2_ST are connected to the respective interrupt node, the general signal name T2IRQ is used to represent both signals (interrupt structure 2).*

Related information

Interrupt structure on page 6521

Timer external interrupt request

The following figure shows a functional diagram of the external interrupt request generation. The flag T2_CON.EXF2 is set on an external transition at input T2EX (in certain modes), or it can be set by software. When enabled through bit T2_CON1.EXF2EN, the signal which sets the T2_CON.EXF2 flag will generate an interrupt request to the CPU.

The output of flag T2_CON.EXF2 is also connected to certain GPIO port lines.

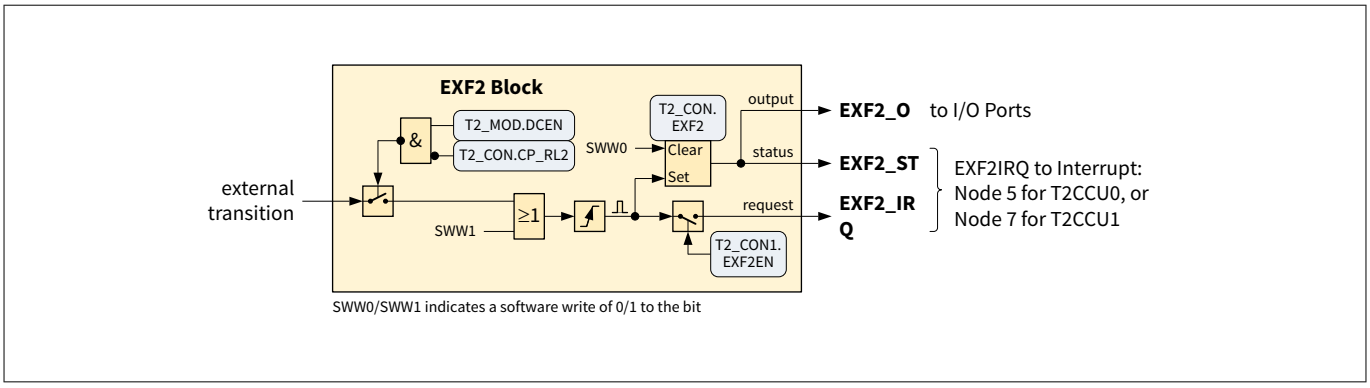

Figure 892 EXF2 flag block

The external transition flag T2_CON.EXF2 and the corresponding external interrupt request (if enabled) will be set/generated in the following cases:

- By software: By writing a 1 to flag T2_CON.EXF2, the flag will be set and an interrupt request (if enabled) will be generated
- Reload Operation in Up-Counting Mode (T2_MOD.DCEN = 0, T2_CON.CP_RL2 = 0): When bit T2_CON.EXEN2 is set and the selected transition at input T2EX occurs
- Reload Operation in Up/Down-Counting Mode (T2_MOD.DCEN = 1, T2_CON.CP_RL2 = 0): In this mode, flag T2_CON.EXF2 will toggle on each overflow or underflow (timer contents match the value stored in register RC2) of Timer 2. No interrupt request will be generated (this is not shown in the figure above)
- Capture Mode of Timer 2 (T2_MOD.DCEN = 0, T2_CON.CP_RL2 = 1): When bit T2_CON.EXEN2 is set and the selected transition at input T2EX occurs

Flag EXF2 must be cleared by software.

Note that while the timer/counter function is disabled (TR2=0), it is still possible to generate a Timer 2 interrupt to the core through an external event at input T2EX, as long as Timer 2 remains enabled (SCUSCR_PMCON0.T2CCU_DIS=0). To achieve this, bit T2_CON.EXEN2 must be set. As a result, any transition on T2EX will cause either a dummy reload or a dummy capture, depending on the T2_CON.CP_RL2 bit selection.

***Note**: The external interrupt request logic of Timer 2 is basically of type "interrupt structure 2" (see section "Interrupt Structure" in chapter "Interrupt System"), however, the status signal does not have an individual enable control. In order to clear the pending request flag in the interrupt system, it is necessary to clear all status flags assigned to that interrupt node, even if the respective interrupt request is not enabled.*

***Note**: Although two signals, EXF2_IRQ and EXF2_ST are connected to the respective interrupt node, the general signal name EXF2IRQ is used to represent both signals (interrupt structure 2).*

39.3.11.2.4 Input selection for timer 2

Timer 2 can be used as an event counter which counts 1-to-0 transitions at the external input T2. This input is selected from four different sources, T2A, T2B, T2C and T2D. The selection is performed by the SFR bits T2_CON1.INSEL. In addition, there are sixteen sources for the input T2EX. They can be selected by respective T2CCUx_T2_CON1.EXTINSEL. In case of T2CCU0 12 are coming from SCR.P0-3 ports. For T2CCU1 13 are coming from SCR.P0-3 ports In addition:

- T20EX has four more sources:
  - PINA, ESR1, PMS RTC CMP0, PMS RTC CMP1
- T21EX has three more sources:
  - PMS RTC clock, 70 kHz clock, external clock from pin SCR_P1.2(P33.10)

Detailed pin assignment for both T2CCU modules is shown in the GPIO chapter of the SCR.

39.3.11.3 Capture/compare timer of T2CCU

The Capture/Compare Timer (CCT) is part of the T2CCU, and is a dedicated time base for the CCU capture/compare operations. The following figure shows a block diagram of the CCT timer.

***Note**: In order to simplify the diagrams, the connection of the CCT contents to the Capture/Compare Unit (CCU) is not shown in the following figures.*

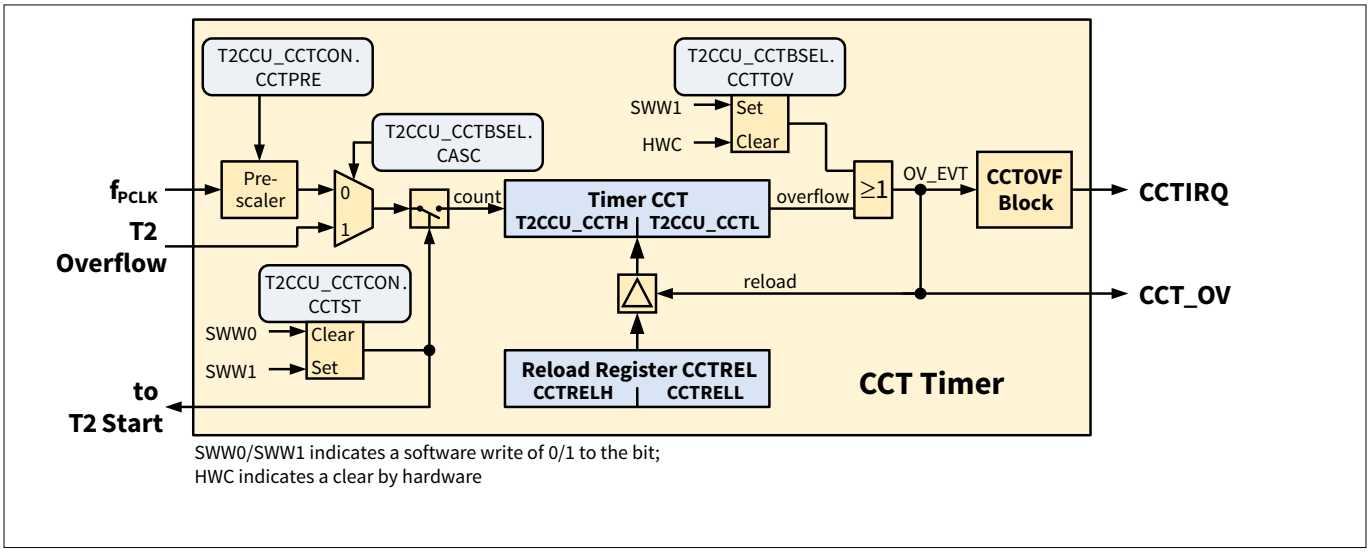

Figure 893 CCT timer block diagram

39.3.11.3.1 CCT timer basic operation

The features of the CCT are:

- 16-bit timer, comprised of register pair T2CCU_CCTH|T2CCU_CCTL (in the following simply called CCT)
- 16-bit reload register, comprised of register pair T2CCU_CCTRELH|T2CCU_CCTRELL (in the following simply called CCTREL)
- Start or stop controlled by software
- Input clock pre-scaler with 12 selectable stages (*input clock range from* f_{PCLK} to $f_{PCLK}/2048$)
- Once started, the CCT counts up from the initial value stored in its count register to $FFFF_H$. With the next clock pulse, it overflows and gets loaded with the value stored in register CCTREL. The counting continues from this value with the following clock pulse(s)
- CCT can be concatenated with Timer 2
- Optional synchronous start of CCT and Timer 2 possible
- CCT overflow event is generated either on CCT timer overflow or triggered by software. CCT overflow event performs the following:
  - Reloads CCT with contents of register CCTREL
  - Sets flag CCTOVF to 1 (can generate an interrupt request)
  - Pulses output line CCT_OV

When writing to the CCT timer register pair T2CCU_CCTH|T2CCU_CCTL, the following rules have to be obeyed:

- When the CCT is not running (CCTCON.CCTST=0), a write to the byte registers T2CCU_CCTH/T2CCU_CCTL updates the corresponding byte of the CCT timer
- When the CCT is running (CCTCON.CCTST=1), register T2CCU_CCTH has to be written first (this value is held in a shadow register). With the following write to register T2CCU_CCTL, both actual timer registers are updated, and the timer continues counting up from the written value

The CCT may be stopped at any time by clearing bit CCTST to 0. The timer registers will hold the last count value.

39.3.11.3.2 Software-triggered CCT timer overflow

A special feature of the CCT timer is the possibility to ‘reset’ the timer immediately by a Software-Triggered Timer Overflow event. By ‘reset’, the CCT timer is reloaded and starts counting from the value from the reload registers, while all actions associated with the operation mode of the timer channels on base timer overflow will be executed. When setting bit T2CCU_CCTBSEL.CCTTOV by software, the CCT timer overflow event is triggered asynchronously to the timer count operation. Bit T2CCU_CCTBSEL.CCTTOV is held at '1' for one PCLK cycle, then it is automatically cleared by hardware.

An example usage for a channel operating in compare mode 0 is illustrated in the following figure. For more details on compare mode 0, refer to Compare Operation in related information.

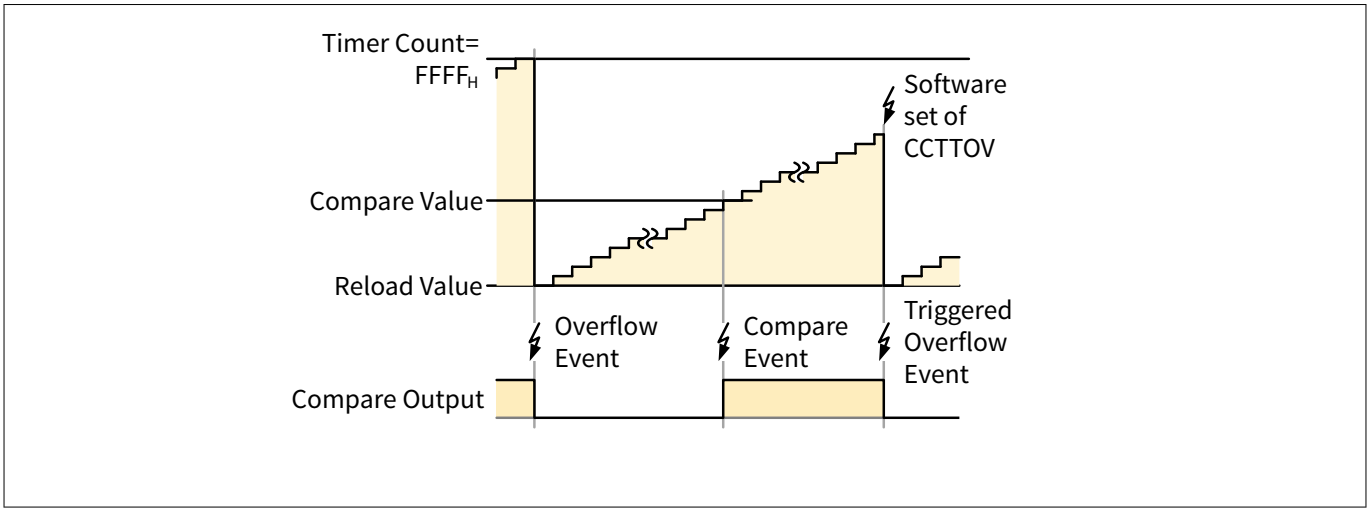

Figure 894 Example of channel in compare mode 0 on ‘triggered timer overflow’ event

39.3.11.3.3 Synchronized start of timer 2 and CCT timer

As described in the previous sections, the two timers of the T2CCU are usually started or stopped individually: timer 2 through bit TR2, and the CCT through bit CCTCON.CCTST.

However, it is also possible to start both timers synchronously. The procedure required to perform this is listed below:

1. Ensure CCT timer is not already running
2. Clear bit TR2 (stop timer 2) and ensure timers are properly initialized
3. Set bit T2CCU0 capture/compare timer control register.TIMSYN to enable synchronized timer starts
4. Set bit CCTCON.CCTST; this will also set bit TR2

Steps 3 and 4 can be combined in a single write operation to SFR T2CCU_CCTCON.

To stop the timers, the respective timer bits need to be cleared independently.

39.3.11.3.4 Cascading timer 2 and CCT timer for flexible count rate

Especially for applications requiring the base timer to run at a flexible count rate, it is possible to cascade Timer 2 with the CCT timer. When bit T2CCU_CCTBSEL.CASC is set, the CCT timer will increment its count with every

overflow of Timer 2. In this mode, Timer 2 acts as a pre-scaler for timer CCT. See following figure for a block diagram of this option.

***Note**: Timer 2 may be configured in timer mode or as an external event counter through input T2.*

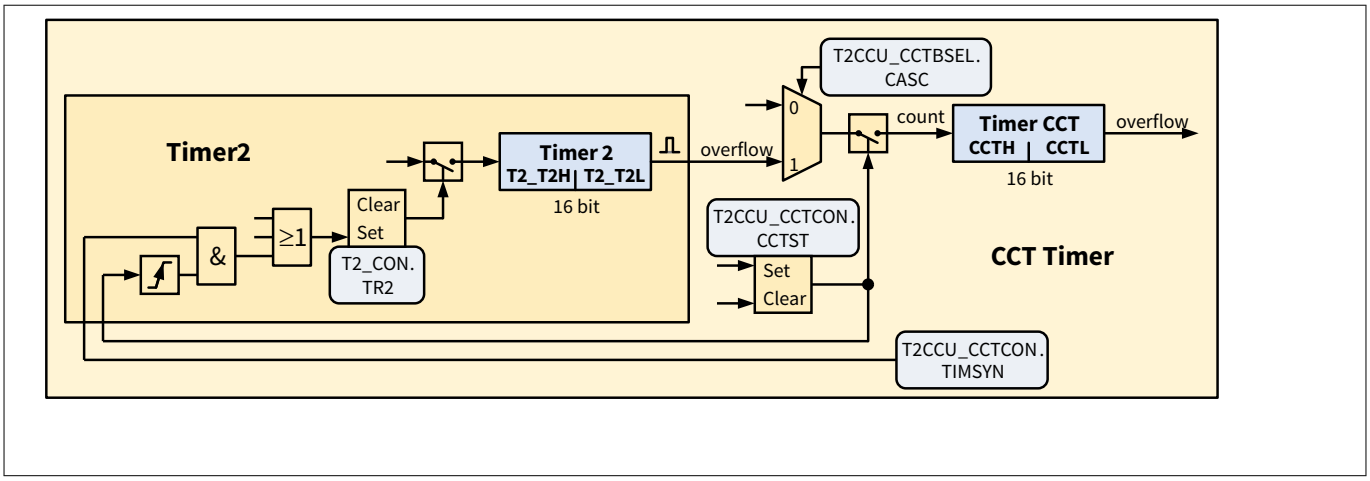

Figure 895 Cascading timer 2 with the CCT timer

39.3.11.3.5 CCT overflow flag and interrupt request

The overflow flag and the corresponding overflow interrupt request (if enabled) will be set/generated in the following cases:

- By software:
  - By writing a 1 to flag T2CCU_CCTCON.CCTOVF
  - By writing a 1 to bit T2CCU_CCTBSEL.CCTTOV (Software-Triggered Timer Overflow, see related information)
- By hardware, when an overflow of the CCT timer occurs

An interrupt request to the CPU is enabled when the enable bit T2CCU_CCTCON.CCTOVEN is set to 1.

Note that flag T2CCU_CCTCON.CCTOVF must be cleared by software.

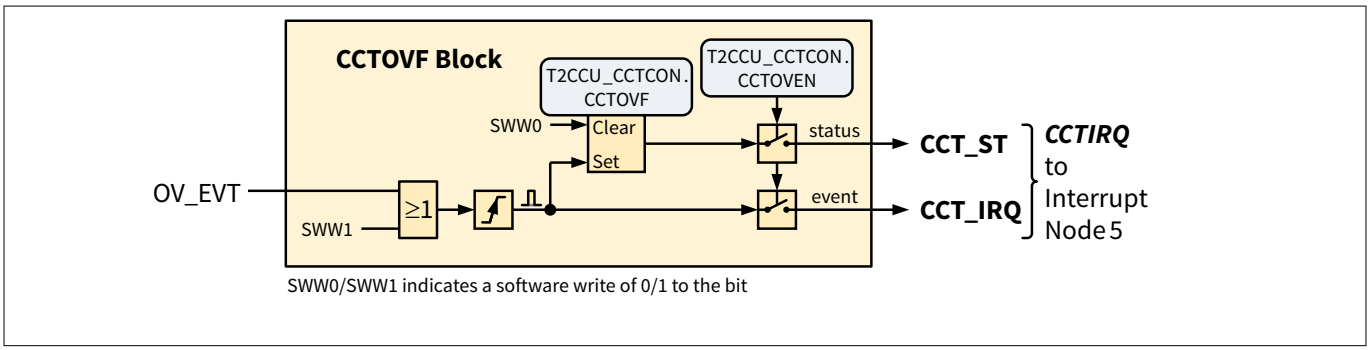

Figure 896 CCT overflow flag block

***Note**: Although two signals, CCT_IRQ and CCT_ST are connected to the respective interrupt node, the general signal name CCTIRQ is used to represent both signals (interrupt structure 2).*

39.3.11.4 Capture/Compare Unit (CCU) of the T2CCU

The Capture/Compare Unit (CCU) of the T2CCU consists of four 16-bit capture/compare channels (CC0-CC3) and two 16-bit compare-only channels (CC4-CC5), illustrated in the following figure.

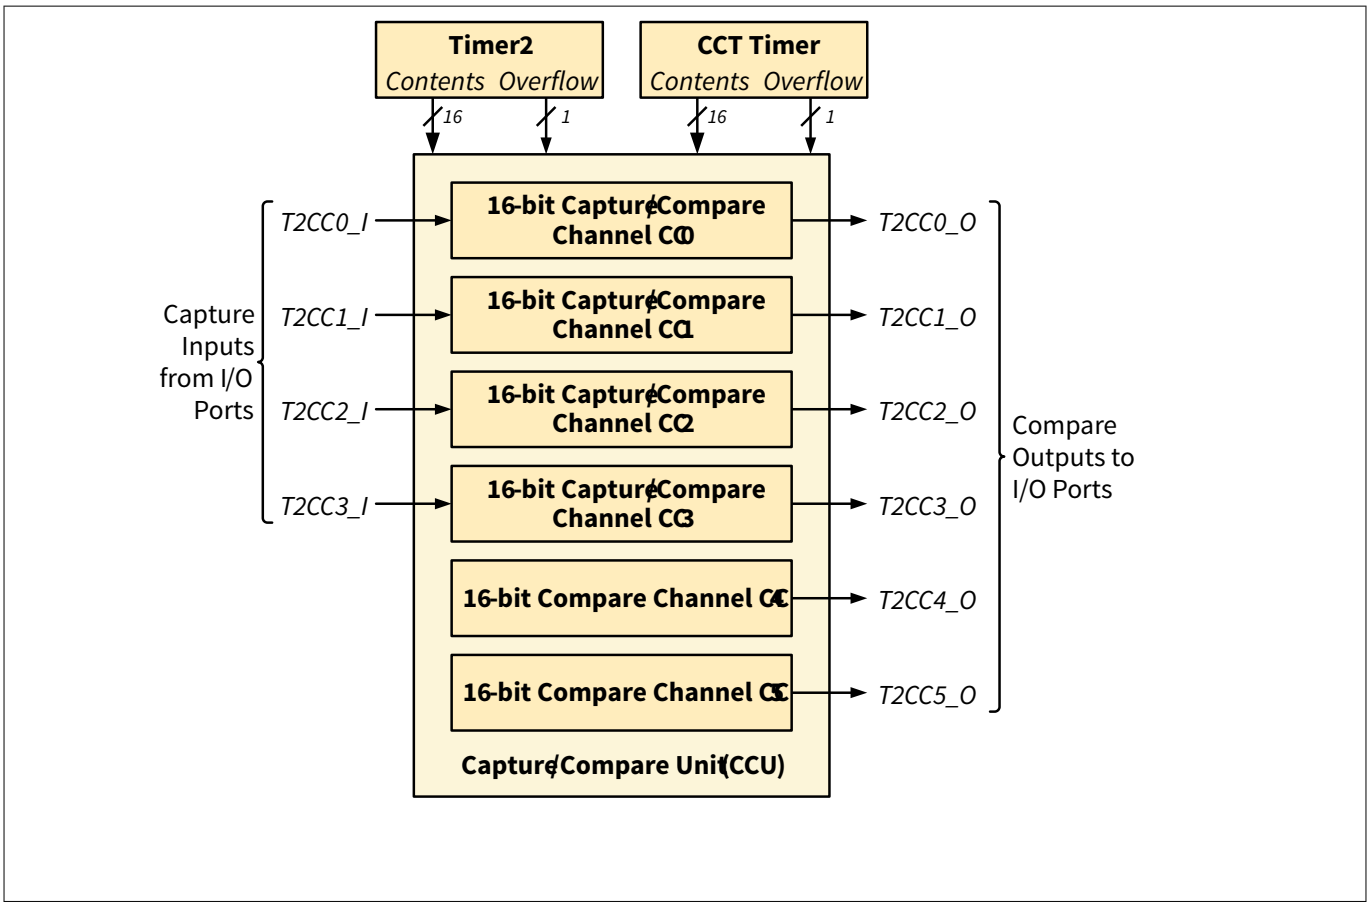

Figure 897 T2CCU Capture/Compare Unit (CCU) overview

The main features of the CCU are:

- 4 channels (CC0-CC3), which can be used for Capture or Compare Operation
- 2 channels (CC4-CC5), which can be used for Compare Operation
- Each capture channel (CC0-CC3) has a capture input T2CCx_I, coming from the I/O pins
- Each compare channel (CC0-CC5) has a compare output signal T2CCx_O, leading to the I/O pins
- Each channel can individually select either Timer 2 or the CCT as a base timer (using the contents and the overflow signal of the selected timer). The capture/compare resolution for a channel is determined by the operating frequency of the selected base timer
- Compare Operation: Various compare modes are available:
  - Compare Mode 0 without dead-time generation
  - Compare Mode 0 with dead-time generation
  - Compare Mode 1
  - Concurrent Compare Mode
- Capture Operation: Two modes are available:
  - Hardware-triggered capture
  - Software-triggered capture

The input/output signals of the CCU are assigned as alternate functions of general-purpose I/O ports. The compare outputs share the same pins as the capture inputs, and the ports are (partly) shared with External

Interrupt Inputs, see the following tables. The corresponding external interrupt request flags are set for the capture/compare function. See also CCU Interrupt and I/O Connections.

Table 1715 Input/output signals of the CCU0

Output/input	Function

39.3.11.4.1 Capture/Compare operation

The following sections describe the compare and capture operations of the CCU in detail.

***Note**: For defined behavior, it is required of the user to initialize properly all the T2CCU related SFRs before enabling any T2CCU capture or compare mode.*

39.3.11.4.2 Compare operation

In compare operation, the contents of a compare register can be regarded as a “time stamp”, at which the corresponding output reacts in a predefined way (with either a positive or negative transition). Variation of this “time stamp” changes the waveform of a rectangular output signal at the pin. As a variation of the duty cycle of a periodic signal, this may be used for pulse width modulation as well as for a continually controlled generation of any kind of square waveforms. Various compare modes are available to cover a wide range of possible applications.

The value stored in a compare register is constantly compared to the current value of the selected base timer. When the timer value is equal to or higher than the compare value, a “compare match” is detected, and appropriate actions are taken.

The following figure illustrates the configuration of the CCU for compare operation. The following items are important for the compare operation:

- Each 16-bit compare register CCx (x=0..5) is represented by two 8-bit registers, named T2CCU_CCxH (high-byte register) and T2CCU_CCxL (low-byte register)

- The desired compare mode is selected by bit T2CCU_COCON.COMOD and applies to all enabled compare channels
- For output polarity control and the dead-time generation, the channels are organized into two groups. GroupA comprises channels CC0, CC2, and CC4, while GroupB comprises channels CC1, CC3, and CC5
- In all compare modes, the new output value arrives at the port pin within the same PCLK cycle in which the internal compare signal is activated
- The compare output is only actively driven when the compare function is enabled. When the compare function is enabled by writing to a channel's CCMx bits, the respective compare output is latched (as initial value) based on the settings of the channel's registers and bit
- The rising edge of the compare match signal is the active edge for all compare match operations
- Each compare register has a shadow transfer mechanism which allows glitch-free pulse width modulation; see detailed description below

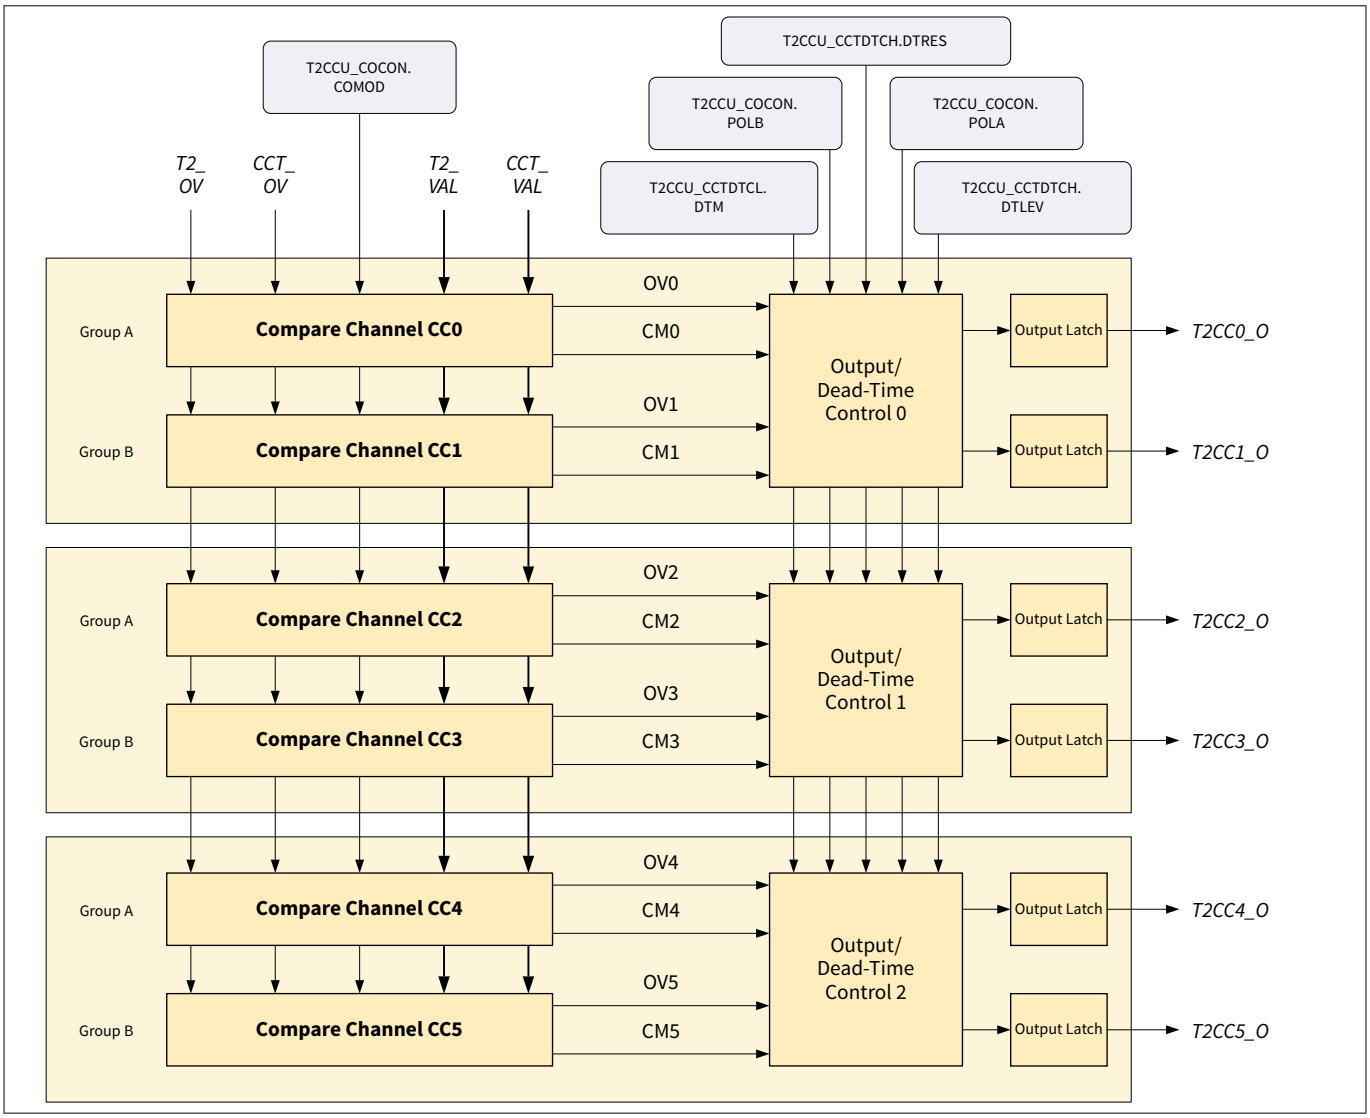

Figure 898 CCU compare channel configuration overview

Shadow registers for compare registers

To update a 16-bit compare value, two write accesses are required because of the two 8-bit registers of a compare channel. To allow for a glitch free update of a compare value without an intermediate "wrong" value, shadow registers are implemented. Software write accesses do not target the actual compare register, but the

respective shadow register. After the write access, the value is transferred from the shadow register into the actual compare register via one of two options:

1. Hardware Control: The transfer from the shadow register into the compare register is triggered by the overflow signal of the selected base timer. In this case, the update of the compare registers is controlled by hardware and is therefore independent from any service delay. This option is selected by setting bit T2CCU_COSHDW.TXOV to 1
2. Software Control: The transfer from the shadow register into the compare register is triggered by setting the corresponding bit T2CCU_COSHDW.COOUTx through software. Bit T2CCU_COSHDW.COOUTx will be cleared automatically by hardware at the next PCLK, after being set. This option is selected by setting bit T2CCU_COSHDW.ENSHDW to 1

In both cases, the rising edge of the event pulse signal is the active edge for the transfer from shadow register to compare register.

Note that it is not allowed to set both bits, T2CCU_COSHDW.TXOV and T2CCU_COSHDW.ENSHDW, at the same time. If bit T2CCU_COSHDW.TXOV is set to enable shadow transfer on timer overflow, bit T2CCU_COSHDW.ENSHDW will be cleared by internal hardware to disable shadow transfer by software.

The following figure illustrates the shadow transfer mechanism.

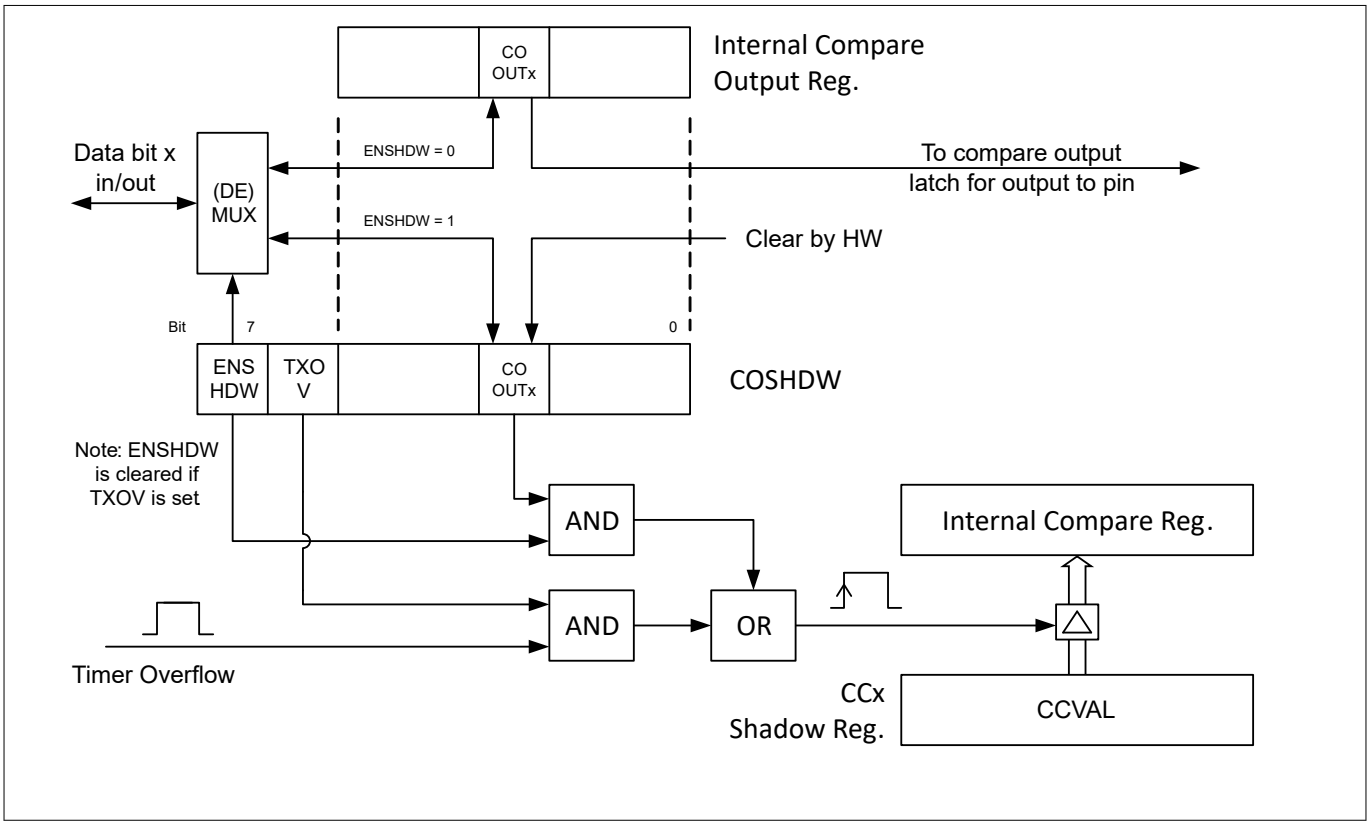

Figure 899 Compare value shadow transfer mechanism and the dual function of bits COOUTx

Mapped compare output bits

In 'Compare Mode 1' and 'Concurrent Compare Mode', bits T2CCU_COSHDW.COOUTx are used to set the polarity of the respective compare output. To select between the two functions of the T2CCU_COSHDW.COOUTx bits (shadow transfer versus output polarity), the state of bit T2CCU_COSHDW.ENSHDW is used (see figure above):

- When T2CCU_COSHDW.ENSHDW=1, bits T2CCU_COSHDW.COOUTx can be directly accessed to trigger the shadow transfer of the compare value
- When T2CCU_COSHDW.ENSHDW=0, writing or reading to the T2CCU_COSHDW.COOUTx bits actually accesses an internal compare output register instead of theT2CCU_COSHDW. COOUTx bits

The following compare modes are available, described in detail in the following sections:

Related information

Compare mode 0 (without dead-time control) on page 6601
Compare mode 0 with dead-time control on page 6603
Compare mode 1 on page 6606
Concurrent compare mode on page 6607

Compare mode 0 (without dead-time control)

In Compare Mode 0 without dead-time control, the output signal is affected by a compare match and by the overflow of the associated timer. A compare match sets the output to active level, while the timer overflow resets the output to the inactive level.

Compare Mode 0 is ideal for generating pulse width modulated output signals, which in turn can be used for digital-to-analog conversion through a filter network or by the controlled device (for example the inductance of a DC or AC motor). Compare Mode 0 may also be used for providing output clocks with initially defined period and duty cycle. This usage needs the least CPU time. Once set up, the output goes on oscillating without any CPU intervention.

The next figure shows a timing diagram example of Compare Mode 0, followed by a functional diagram of this mode. Please see figure Output & Dead-Time Generation Block for the output control.

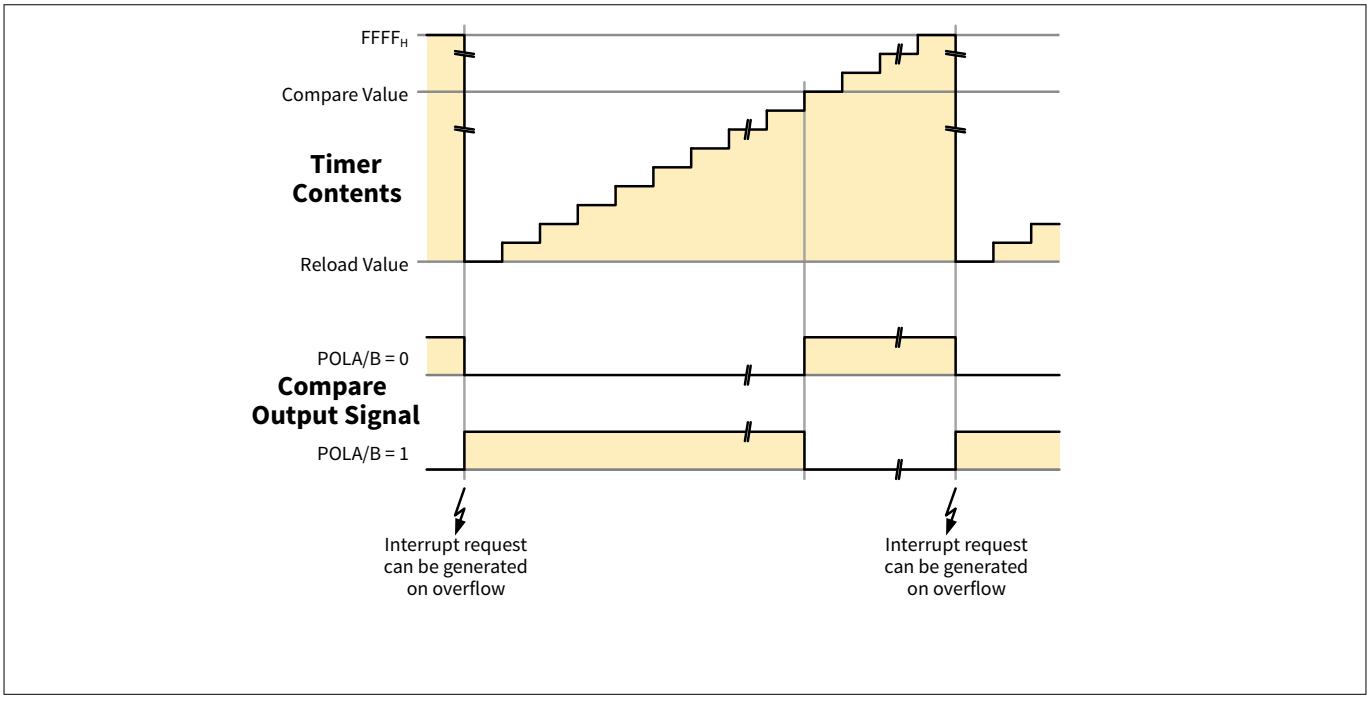

Figure 900 Channel output example in compare mode 0 (without dead-time control)

To configure Compare Mode 0, the following steps need to be done:

- Set bit-field T2CCU_COCON.COMOD to 00_B to select Compare Mode 0
- Set bit T2CCU_COSHDW.TXOV to 1_B (the usual way to perform the compare shadow value transfer in Compare Mode 0 is through the timer overflow)
- Configure the desired output polarity of the compare outputs through bits T2CCU_COCON.POLA and T2CCU_COCON.POLB. Bit T2CCU_COCON.POLA applies to channels 0, 2, and 4 (channel group A), while T2CCU_COCON.POLB applies to channels 1, 3, and 5 (channel group B)

***Note**: The two steps listed above can be done in one write access to register T2CCU_COCON. However, the enabling of compare channels 4 and 5 (see following step) must be done in a separate write access to register T2CCU_COCON, to ensure a glitch-free compare output level.*

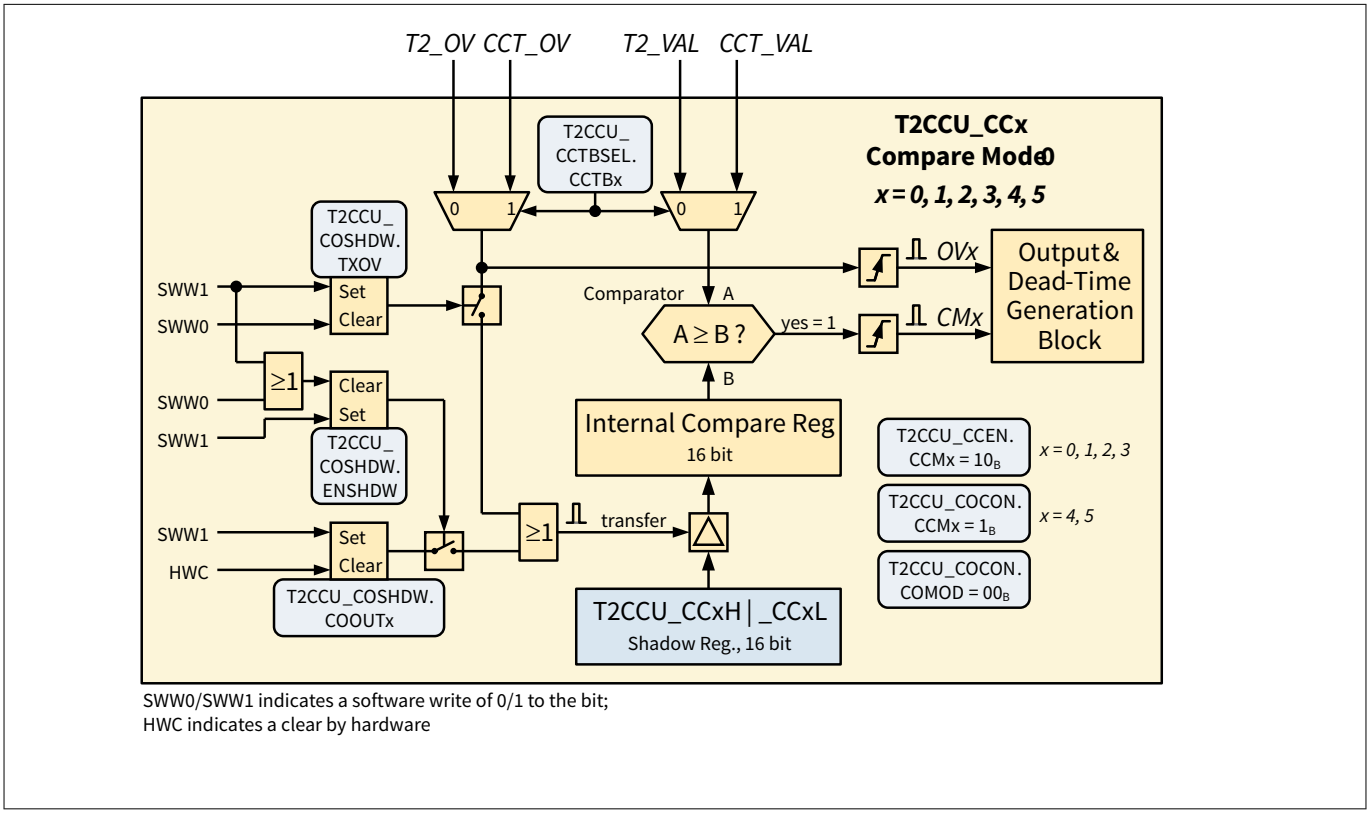
- For compare channels 0 through 3, individually enable the compare mode for the desired compare registers by setting bit T2CCU_CCEN.CCMx to 10_B. For compare channels 4 and 5, individually enable the compare mode for the desired compare registers by setting bit T2CCU_COCON.CCMx to 1_B

The compare output is immediately set to the appropriate level when the associated compare register is enabled through bit/bit-field T2CCU_COCON.CCMx:

- It is set to the active level if the base timer contents are equal to or greater than the compare register contents
- It is set to the inactive level if the base timer contents are less than the compare register contents

Either Timer 2 or the CCT timer can be used as base timer in Compare Mode 0. The shadow transfer of a new compare value is usually triggered by the overflow of the selected base timer (set bit T2CCU_COSHDW.TXOV to 1_B).

Note that no interrupt is generated when a compare match occurs. See CCU Interrupt and I/O Connections. for further information.



SWW0/SWW1 indicates a software write of 0/1 to the bit;
HWC indicates a clear by hardware

Figure 901 Functional diagram of compare mode 0 (without dead-time control)

Operation in the first timer period after initialization

The following needs to be regarded concerning the compare output level for the first timer period after initialization:

- Although a compare value might have been written to the compare shadow register before enabling the compare operation, the actual compare register will contain 0000_H (if no transfer from the shadow register to the actual compare register has been forced through software, see below)
- In this case, the value of the timer will be greater than or equal to the value in the compare register (whether the timer contains the initial value of 0x0 or has been programmed to another value)

- Thus, the condition of a “compare match” is true (timer ≥ compare value) and the compare output level will be set to the active level
- On the following timer overflow, the first compare value shadow transfer takes place (bit T2CCU_COSHDW.TXOV = 1_B) and the output will go to its inactive level if the programmed compare value is > 0000_H
- From this second timer period on, the output will switch from inactive to active level on compare match and vice verse on timer overflow

In order to get a proper compare operation already during the first timer period, a compare value shadow transfer must be forced by software. This can only be done after compare mode is enabled

- After enabling the compare mode and before starting the timer, a compare value shadow transfer must be forced by software
- Write a value greater than the timer value to the compare shadow register
- Set bit T2CCU_COSHDW.ENSHDW to 1_B (clear bit T2CCU_COSHDW.TXOV to 0_B with the same write access), and set T2CCU_COSHDW.COOUTx to 1_B
- After this, clear bit T2CCU_COSHDW.ENSHDW to 0_B and set bit T2CCU_COSHDW.TXOV to 1_B with the same write access (bit T2CCU_COSHDW.COOUTx is automatically cleared by hardware)
- Now the actual compare register contains the programmed value (> timer value) and the compare output goes to inactive level
- The timer can now be started for its first period

PWM signal from 0% to 100% duty cycle in compare mode 0

The active level of a PWM signal refers to the compare output signal level from the time of compare match until the next timer overflow. To generate signals with duty cycles of 100% or 0%, the following methods can be used:

- To support a 100% duty cycle for a compare channel with T2CCU_COCON.POLA/B=0 (active level = high), the compare value must be set equal to the timer reload value. In this case, the internal hardware will not cause the compare output signal to the inactive level on timer overflow and the output stays at the active level until the next timer overflow when the compare value is no more equal to the timer reload value
- To support a 0% duty cycle for a compare channel with T2CCU_COCON.POLA/B=0, the compare value must be smaller than the timer overflow reload value. In this case, the timer reload value must not be zero. The compare match event will not happen and the compare output stays at the inactive level (low)

The mechanisms described above apply correspondingly for the case that the chosen active level=low (T2CCU_COCON.POLA/B=1).

Compare mode 0 with dead-time control

Compare Mode 0 offers an additional feature for the generation of complementary signals with a so-called dead-time between the deactivation of one signal and the activation of the other signal.

The generation of (complementary) signals with dead-time for the high-side and the low-side switches of a power inverter phase is based on twin grouping of the consecutive compare channels – one from group A and the other from group B. The three compare channel pairs therefore are comprised of channel 0 with 1, channel 2 with 3, and channel 4 with 5.

The Compare Mode 0 with dead-time generation can be used under the following conditions:

- All involved compare channels must use the CCT timer
- Both channels of a channel pair must have the same compare value (CC0 = CC1; CC2 = CC3; CC4 = CC5)
- All used channels must have the dead-time generation enabled (bit T2CCU_CCTDTCH.DTEy = 1)

- All high-side and low-side switches must have the same active polarity. For example, if the high-side switch should be active while the CCT timer value is above the compare value, then the low-side switch should be active while the CCT timer value is below the compare value
- The active signal polarity is controlled by the bits T2CCU_COCON.POLA (for compare channel group A) and T2CCU_COCON.POLB (for compare channel group B). T2CCU_COCON.POLA and T2CCU_COCON.POLB must be set to complementary values

The following figure illustrates the dead-time generation. This logic is implemented three times, one for each compare channel pair. It mainly consists of an 8-bit down-counter (dead-time counter, clocked with the CCT count rate), and a logic to manipulate the output signals.

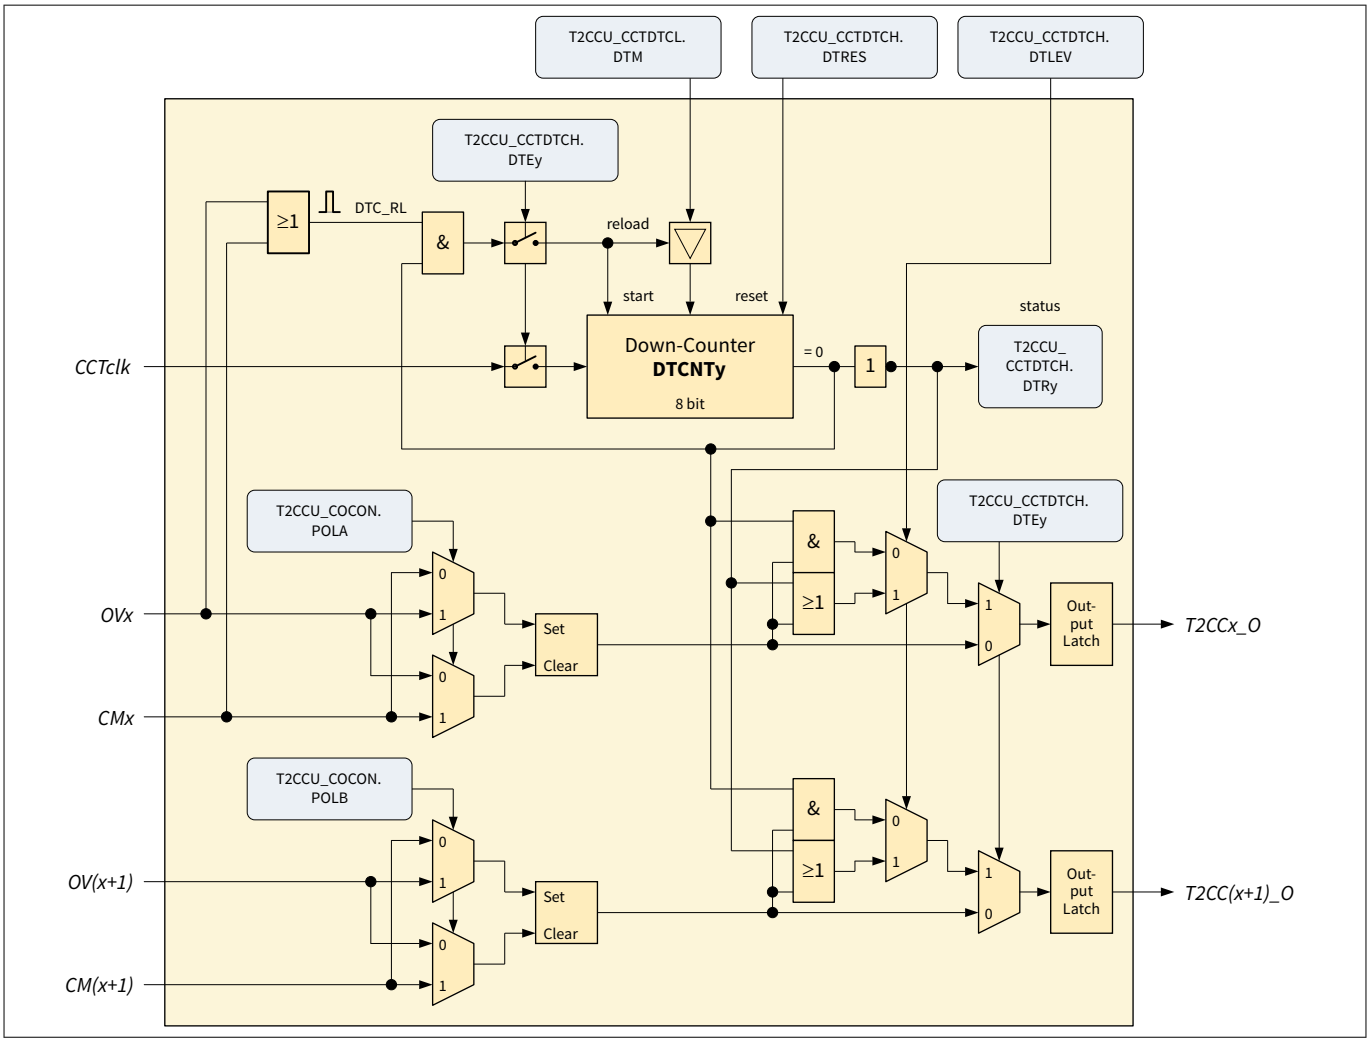


Figure 902 Output and dead-time generation block

The following list describes the detailed operation:

- If dead-time is not enabled for a channel (bit T2CCU_CCTDTCH.DTEy = 0), the output signal polarity is solely controlled by bits T2CCU_COCON.POLA/POLB
- If dead-time is enabled for a channel (bit T2CCU_CCTDTCH.DTEy = 1), the output signal polarity is controlled by bits T2CCU_COCON.POLA/POLB and the dead-time control logic:
  - As long as the dead-time counter is not running (signal '=0' is active, status flag T2CCU_CCTDTCH.DTRy=0), the output signals are determined by bits T2CCU_COCON.POLA/POLB
  - Each instance of the CCT timer overflow or a compare match event (of channel from group A, rising edge) triggers the corresponding dead-time counter. The trigger pulse (DTC_RL) reloads the dead-time

counter with the value programmed in bit-field T2CCU_CCTDTCL.DTM, and starts it. This can only take place if the dead-time feature is enabled by bit T2CCU_CCTDTCH.DTEx and while the counter is zero

- Once started, the dead-time counter counts down until it reaches 0. Then it stops counting
- As long as the dead-time counter is running, the output signals are forced to their programmed dead-time level. This level is determined by bit T2CCU_CCTDTCH.DTLEV. T2CCU_CCTDTCH.DTLEV must be set such that the outputs a forced to the inactive level during the dead-time

Please see also the section 'Operation in the first timer period after initialization' in related information, which applies in a similar manner for the dead-time operation.

The following figure illustrates the resulting signal waveforms for the dead-time operation (example with T2CCU_COCON.POLA= 0 and T2CCU_COCON.POLB=1).

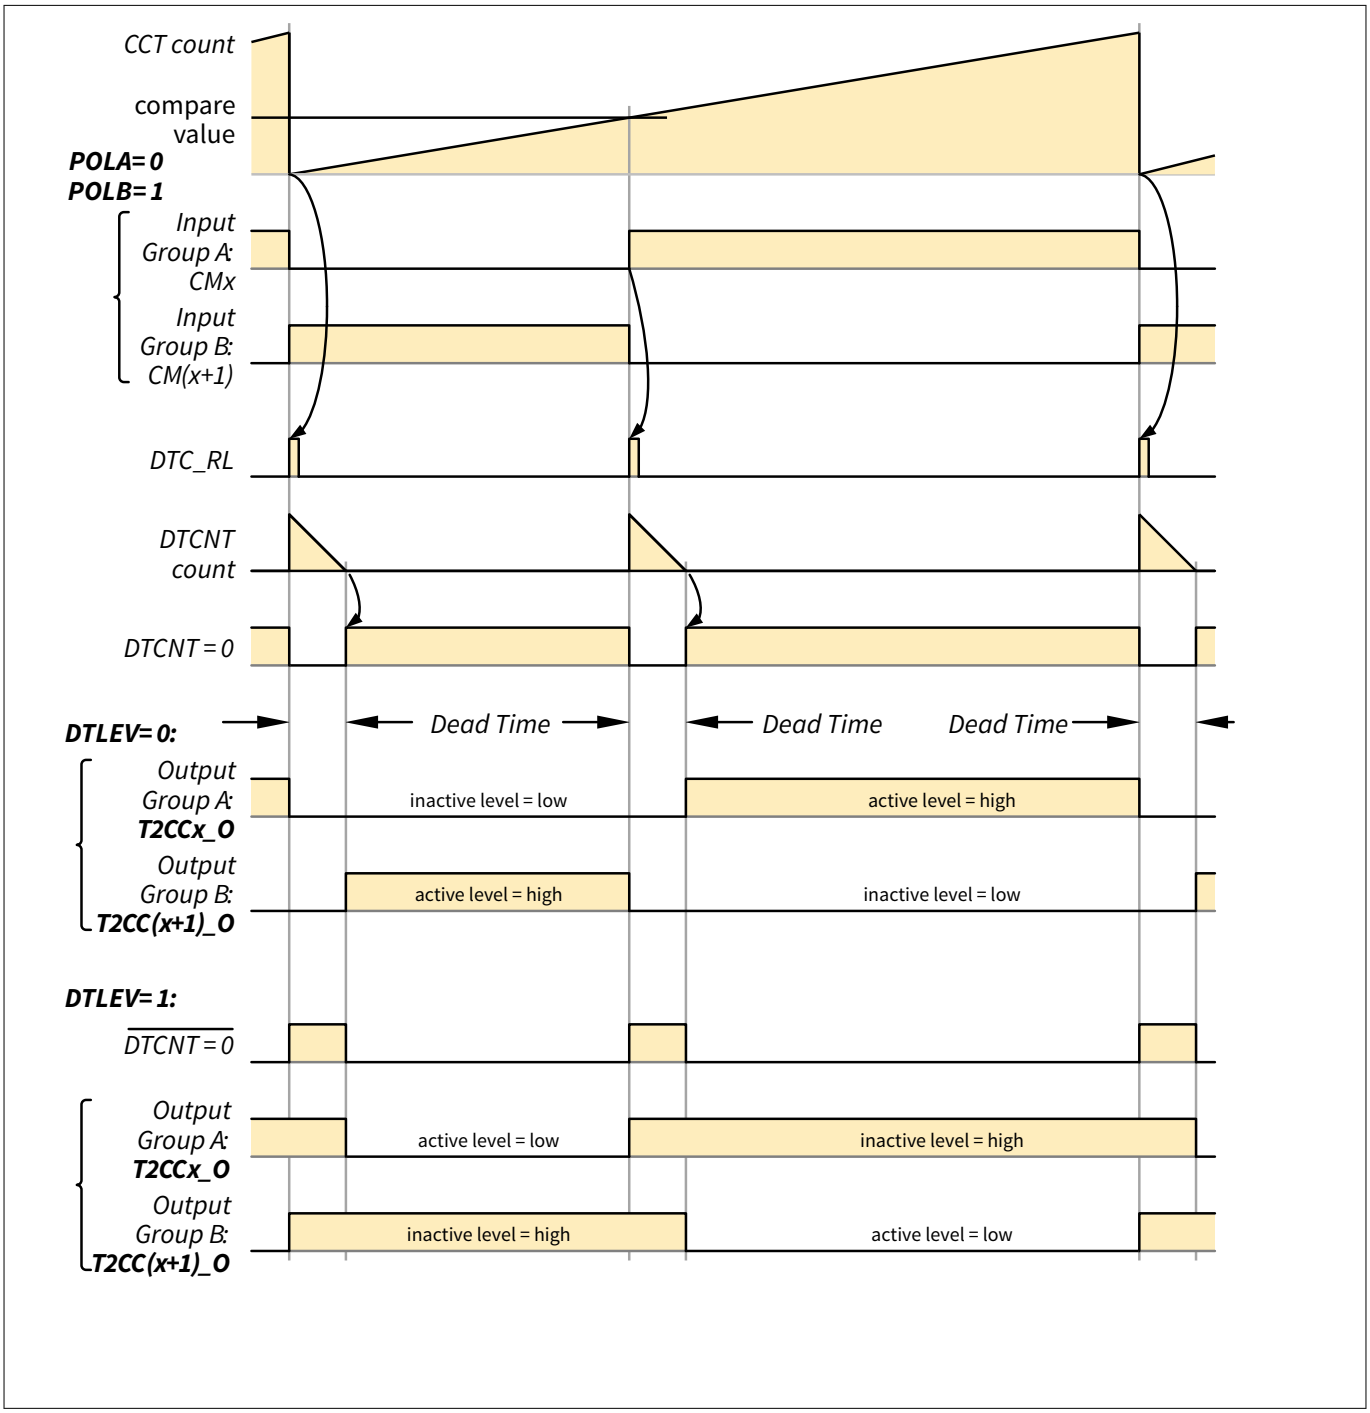

Figure 903 PWM-signals with dead-time generation (illustrated for one channel pair)

***Note**: While the channels pairs can be individually enabled or disabled for dead-time generation through their DTEy bits, the dead-time (DTM) and the dead-time level (DTLEV) apply to all channels. In addition, the reset control (DTRES) applies to all three dead-time counters.*

***Note**: The dead-time logic is designed for the application case in which one and only one compare event is generated within one timer period. If more than one compare event happens within one timer period or if two or more timer overflows happen without a compare event in between, proper functionality of the dead-time logic is not assured. In addition, the timer must not be disabled while the dead-time is in progress or between a timer overflow and a compare match.*

***Note**: When the dead-timeT2CCU_CCTDTCL. DTM is set to 0_H, no dead-time will be generated. This is equivalent as if the dead-time function is not enabled (for example DTEy = 0_B).*

Related information

Compare mode 0 (without dead-time control) on page 6601

Compare mode 1

In Compare Mode 1, the output signal is only updated on a compare match, but not by the respective timer overflow (as in Compare Mode 0). In Compare Mode 1, the software adaptively determines the transition of the output signal. It is commonly used when output signals are not related to a constant signal period (as in a standard PWM Generation), but must be controlled very precisely with high resolution and without jitter. In Compare Mode 1, the compare output signal level is under the full control of the software.

The following figure shows a functional diagram of Compare Mode 1.

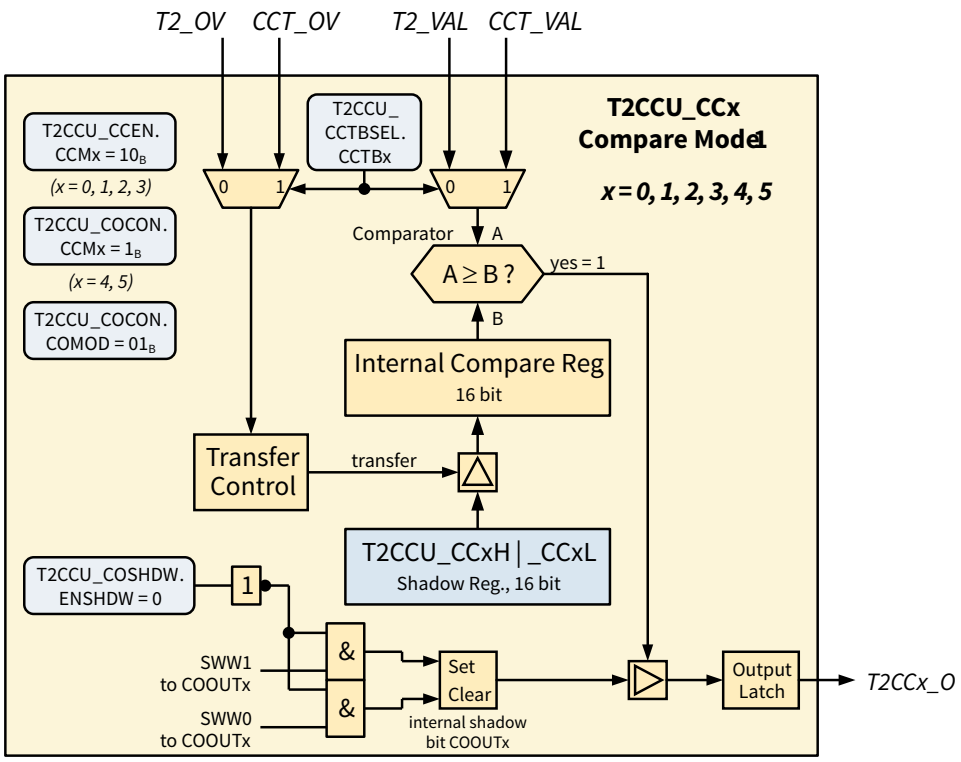

Figure 904 Functional diagram of compare mode 1

To configure Compare Mode 1, the following steps need to be done:

- Set bit-field T2CCU_COCON.COMOD to 01_B to select Compare Mode 1
- For compare channels 0 through 3, individually enable the compare mode for the desired compare registers by setting bit-field T2CCU_CCEN.CCMx to 10_B. For compare channels 4 and 5, individually enable the compare mode for the desired compare registers by setting bit T2CCU_COCON.CCMx to 1_B
- The shadow transfer of a new compare value is triggered by the overflow of the selected base timer (T2CCU_COSHDW.TXOV=1)
- The software writes the desired output level for the next compare match to the T2CCU_COSHDW.COOUTx bit(s) of the internal compare output register (in this case, bit T2CCU_COSHDW.ENSHDW must be cleared to 0). This new value will not appear at the output until the next compare match occurs. Thus, it is possible to choose, independently for each compare channel, whether the output signal is to toggle (1-to-0 or 0-to-1) or to remain at the same level, when a compare match occurs

The compare output is immediately set to the value initialized to bit T2CCU_COSHDW.COOUTx (of the internal compare output register), when the associated compare register is enabled through bitT2CCU_CCEN.CCMx.

Either Timer 2 or the CCT timer can be used as base timer in Compare Mode 0. The shadow transfer of a new compare value must be triggered by the overflow of the selected base timer.

Note that no interrupt is generated when a compare match occurs. See CCU Interrupt and I/O Connections for further information.

Concurrent compare mode

Concurrent Compare Mode allows to manipulate more than one output with the same compare event. Up to all six compare outputs can be updated concurrently when a compare channel 0 event occurs.

Concurrent compare is an ideal and effective mode for applications where more than one synchronous output signal is to be generated. Such applications could include, for example, a multiple-phase stepper motor control, or control of ignition coils of a car engine. These applications generally require predefined bit-patterns to be put to an output port at precisely predefined moments.

The following figure illustrates the function of Concurrent Compare Mode.

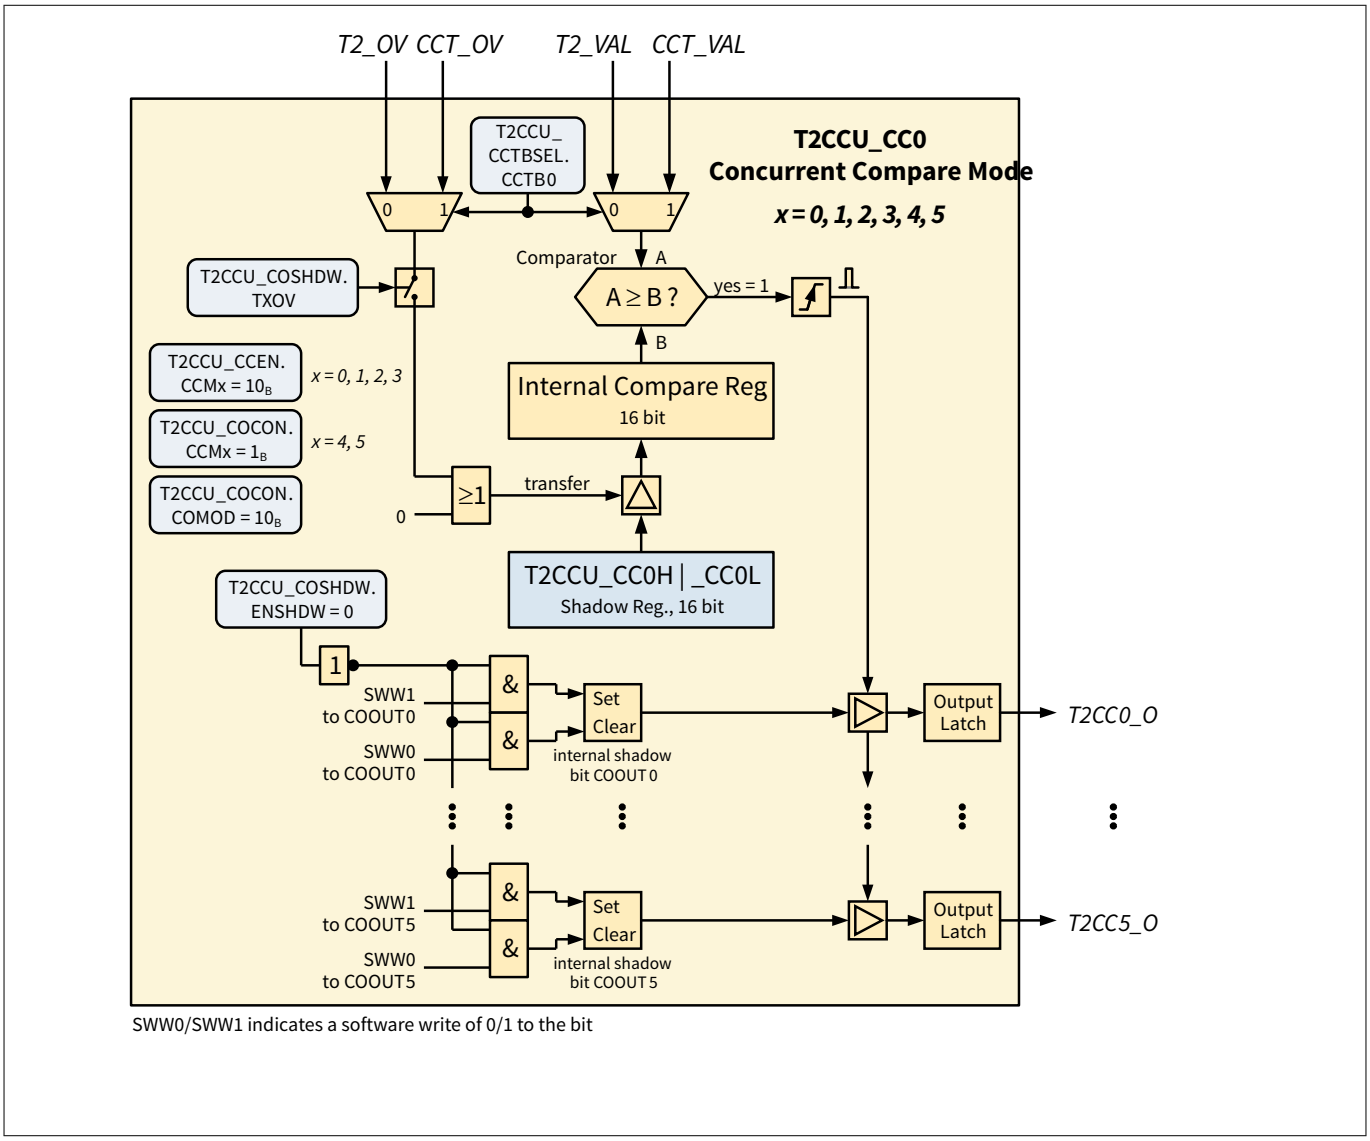

Figure 905 Functional diagram of concurrent compare mode

To operate the CCU in Concurrent Compare Mode, the following configurations must be made:

- Bit T2CCU_COSHDW.ENSHDW must be cleared to 0
- The shadow transfer is triggered by the overflow of the selected base timer; set bit T2CCU_COSHDW.TXOV to 1_B
- Set the compare mode to Concurrent Compare Mode, by setting bitfield T2CCU_COCON.COMOD to 10_B
- Write the initial output values to the internal compare output bits T2CCU_COSHDW.COOUTx of the desired outputs
- Only Compare Channel 0 is used for the outputs. Write the required compare value to T2CCU_CC0H and T2CCU_CC0L
- Enable the desired output signals through their individual enable bits (for channels 0 to 3: Set bit-field T2CCU_CCEN.CCMx to 10_B; for channels 4 and 5: Set bit T2CCU_COCON.CCMx to 1_B)

***Note**: The compare outputs are latched with the corresponding values initialized to the T2CCU_COSHDW.COOUTx bits of the internal compare output register when setting the CCMx enable control for the desired outputs (make sure to first select Concurrent Compare Mode through T2CCU_COCON.COMOD, and to program the desired values into the T2CCU_COSHDW.COOUTx bits).*

- During steady operation, write the new compare value to register pair T2CCU_CC0H and T2CCU_CC0L, and the new output values to bits T2CCU_COSHDW.COOUTx
- With the following timer overflow, the new compare value will be used during the new timer period, and the new output values will appear at the outputs when the compare match occurs

The following figure illustrates two examples of how four rectangular waveforms can be generated at the port using a pattern table. The patterns are written to the internal compare output register (with T2CCU_COSHDW.ENSHDW=0) before the corresponding timer count is reached. The (future) timer count at which the pattern shall be available at the port must be loaded to the compare shadow registers T2CCU_CC0H and T2CCU_CC0L, and transferred to the internal compare registers. To manage the waveform generation, one example uses a time schedule table with list of compare values, the other example makes use of a fixed compare value (such as $FFF0_H$) with shorter timer period. In these ways, each channel can be controlled at predefined time(s) by the user on whether to toggle or not.

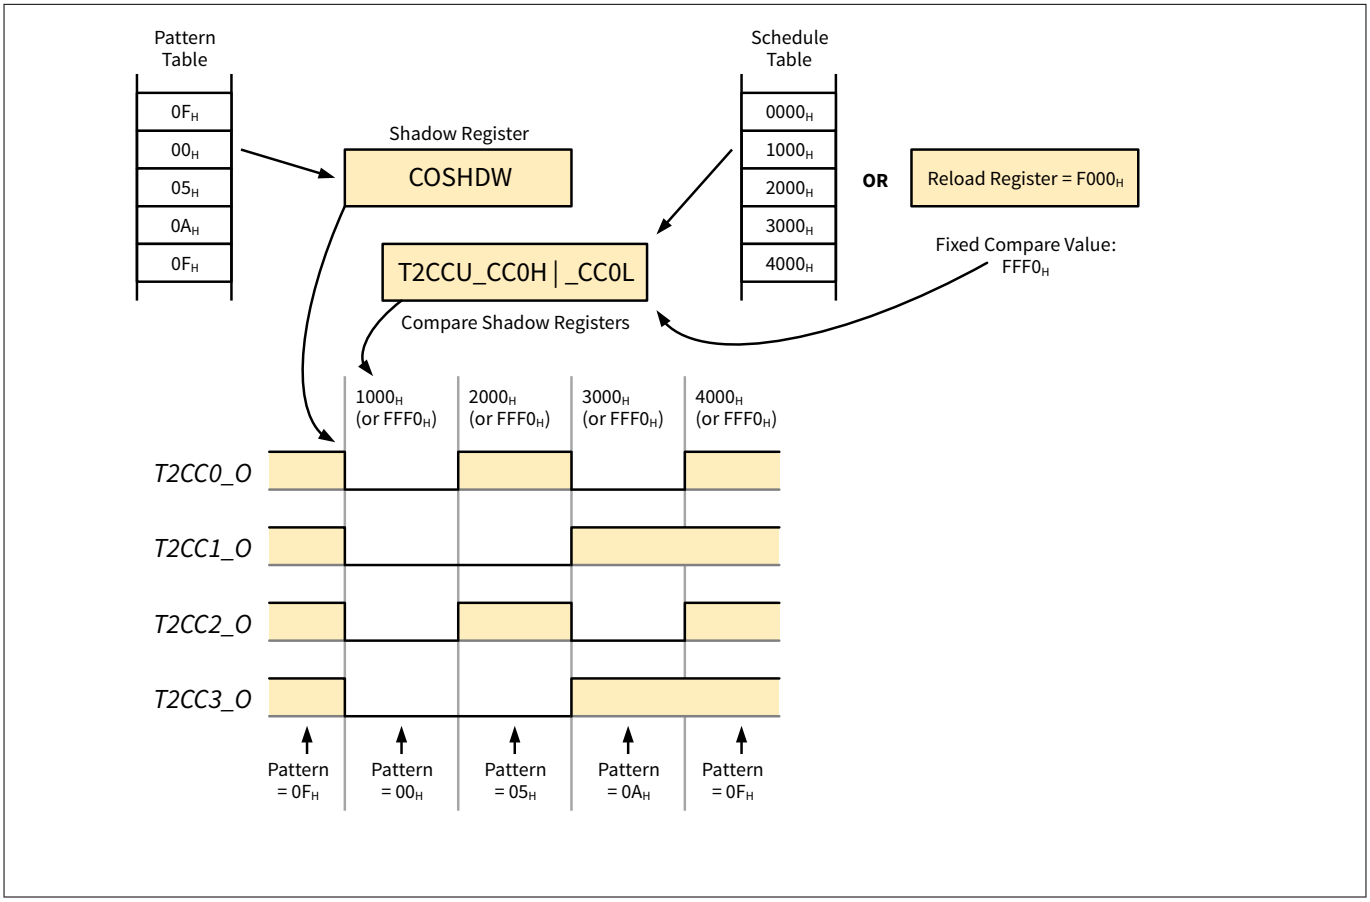

Figure 906 Two examples of waveform generation in concurrent compare mode (by schedule table of compare values or fixed compare value)

Using interrupts in combination with the compare function

There are no interrupt requests generated within the CCU on a compare match. Thus, it is not possible to directly trigger an interrupt service routine on a compare match to handle the programming of new compare and/or output values.

There are two options to overcome this:

- In many cases, the overflow interrupt request of the associated base timer can be used
- Since the compare outputs are connected to the same pins which serve as external interrupt inputs (and CCU capture inputs), these interrupts can be used

These options offer the following possibilities:

- Compare Mode 0 (with or without dead-time): In this mode, a compare match will always show a defined signal edge at the compare output. This signal edge will also appear on the associated input line for the external interrupt input. By appropriately programming the external interrupt configuration, an interrupt request to the CPU can be generated. In the associated service routine, the next compare value can be written to the compare shadow register
- Compare Mode 1 and Concurrent Compare Mode: In these modes, the shadow transfer of compare and output value is always triggered with the overflow of the selected base timer. So, the associated overflow interrupt of the timer is the right trigger for a respective service routine to set up new compare and output values

See also related information for more information for configuring the external interrupt input.

39.3.11.4.3 Capture function

The capture modes of the CCU allow the measurement of external signal pulse widths or the latching of time-stamps via the capture/compare registers CC0 through CC3. Each of the 16-bit registers can be used to latch the current 16-bit count value of the selected base timer. Two capture modes are provided for this function, a hardware- and a software-triggered capture:

- In Capture Mode 0, an external event at input T2CCUx_I latches the contents of the selected base timer into the associated capture register
- In Capture Mode 1, a software write to the low byte of a capture register latches the contents of the selected base timer into the associated capture register

The two capture modes can be established individually for each capture channel. That means, in contrast to the compare modes, it is possible to simultaneously select Mode 0 for one capture channel and Mode 1 for another channel. The following figure shows the capture operation a capture/compare channel.

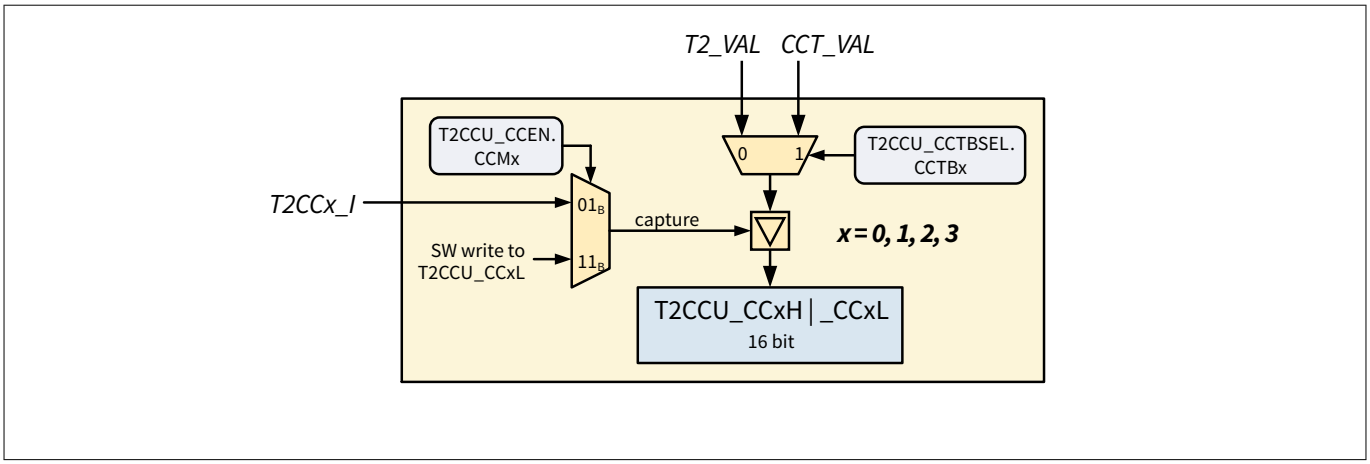

Figure 907 Functional diagram of capture mode

Capture mode 0

In Capture Mode 0, any selected external event (rising/falling/both edge) at the associated input (T2CC0_I through T2CC3_I) latches the channel timer contents to the corresponding channel capture register. The capture edge is defined by the corresponding external interrupt set up (each capture input shares the same pin with an external interrupt). The timer contents are latched into the corresponding capture register in the PCLK cycle following the one in which the external transition was recognized.

To configure Capture Mode 0, the following steps need to be done:

- Configure the external input signal (and interrupt request) associated with the desired capture channel (see related information)
- Select the base timer for the desired capture register through T2CCU_CCTBSEL.CCTBx
- Set bit-field T2CCU_CCEN.CCMx to 01_B (Capture Mode 0)

Related information

Configuring the external capture input on page 6611

Capture mode 1

In Capture Mode 1, a capture will occur upon writing to the low byte of the corresponding channel capture register. Thus, the software is able to read the contents of the channel timer “on-the-fly”. The value written to the capture register is irrelevant for this function. The timer contents will be latched into the channel capture register following the write instruction. In this mode, no interrupt request will be generated.

To configure Capture Mode 1, the following steps need to be done:

- Select the base timer for the desired capture register through T2CCU_CCTBSEL.CCTBx
- Set bit-field T2CCU_CCEN.CCMx to 11_B (Capture Mode 1)
- Write any value to the low-byte register T2CCU_CCxL to trigger the capture operation

Configuring the external capture input

Each capture input shares the same pin with an external interrupt. In fact, the capture input T2CCUx_I is derived from the external interrupt input such that it is connected from the edge selection multiplexer for the external interrupt to the CCU of the T2CCU. This is exemplary illustrated in next figure for capture input T2CCU0_0_I.

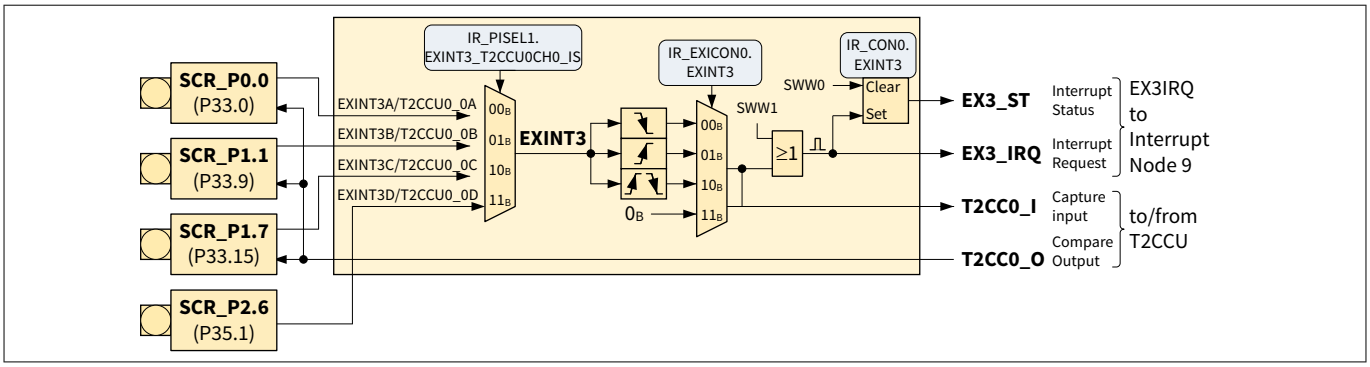

Figure 908 Capture input configuration

An external interrupt input is sampled in every PCLK cycle. When a sample shows a low (high) level in one PCLK cycle and a high (low) in the next PCLK cycle, a transition is recognized. The corresponding external interrupt request flag(s) (EXINT3 to EXINT6 for T2CCU0, or EXINT8 to EXINT11 for T2CCU1) is set. If the interrupt(s) is enabled, the CPU will vector to the appropriate interrupt service routine.

When a hardware capture mode is programmed for a CCU capture channel, the edge selected for the associated external interrupt input is also used as the relevant capture trigger. The timer contents are latched to the corresponding capture register in the PCLK cycle following the one in which the transition was identified.

When configuring an external capture input, the following points are relevant:

- The desired input pin is selected through bit IR_PISEL1.EXINTy_T2CCU0CHx_IS, or IR_PISEL2.EXINTz_T2CCU1CHx_IS
- The external interrupt inputs EXINT3 through EXINT6, share one interrupt node, XINTR9, with common enable bit for this interrupt node IEN1.EXM
- The external interrupt inputs EXINT8 through EXINT11, are on two interrupt nodes, XINTR10-11, with IEN1.ECCIP0-1 as enable bits
- The active edge is selected through bit-fields EXINTx (x=3 to 6, 8 to 11) in registers IR_EXICON0-2
- The interrupt status flags are: EXINT3 through EXINT6 in register IR_CON0, and EXINT8 through EXINT11 in register IR_CON2

Compare match interrupts

Since a compare match does not directly generate an interrupt request, the external interrupt inputs, which are shared with the compare outputs, can be used to generate an appropriate interrupt request, if required.

For this, the measures described in the section above for the capture inputs are taken. Since the channel is programmed for one of the compare modes, the capture input line has no effect.

The change of the compare output signal on a compare match is then used to trigger the associated interrupt request.

The main advantage in using compare match interrupts is to avoid unintentional overwriting of compare/ compare output registers before a match has been reached. This could happen when the CPU writes to the compare registers without knowing about the actual timer count.

***Note**: As an alternative, the timer overflow interrupt may be used in place of the compare match interrupt.*

39.3.11.5 CCU Interrupt and I/O Connections

This section describes the connections of the capture/compare channels to interrupts, as well as to the I/O ports (and other modules).

Usually, the interrupt request blocks are used which also provide the respective capture input T2CCx_I. However, since the capture/compare I/O lines are connected to more than on port pin, alternative interrupt requests can be used. In addition, the connection to other SCR modules is shown.

39.3.11.5.1 Capture/Compare Channel 0

The picture below illustrates (for both T2CCU0 and T2CCU1) the connections of capture/compare channel 0 to the ports, interrupt request blocks, and other SCR modules.

39.3.11.6 T2CCU clocking configuration

If the T2CCU0/1 functionality is not required at all, it can be completely disabled by gating off its clock input for maximal power reduction. This is done by setting bit SCUSCR_PMCON0.T2CCU0_DIS or SCUSCR_PMCON0.T2CCU1_DIS.

39.3.11.7 Interfaces of the T2CCU

The following figure gives an overview of the interconnections of the T2CCU.

The interrupt lines of the T2CCU0/1 are connected to the CPU interrupt controller.

The General Purpose IO (GPIO) Ports provide the interface from the T2CCU0/1 to the external world.

The T2CCU timers can be suspendedwhen OCDS enters Monitor Mode and has the Debug-Suspend signal activated, provided the respective timer suspend bit (SCUSCR_DBG_MODSUSP.T2CCUnSUSP) is set. Refer to the OCDS chapter.

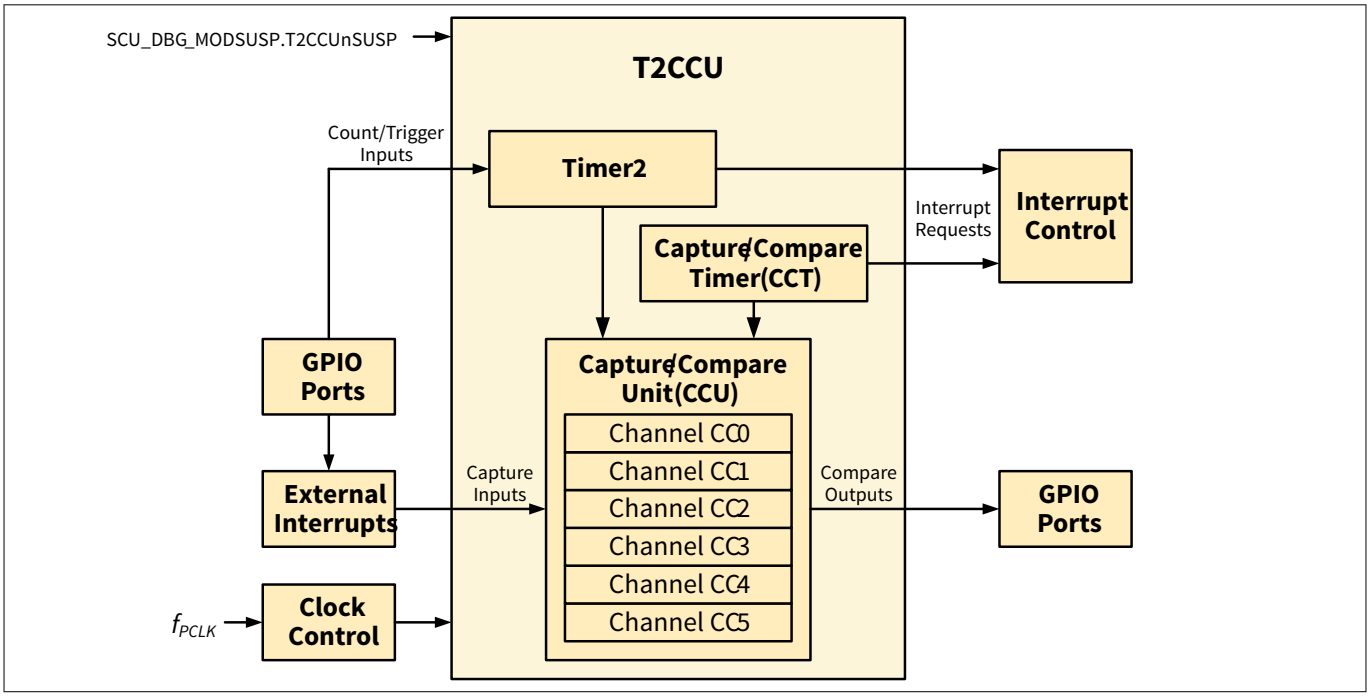

Figure 915 Interconnections of T2CCU

39.3.11.7.1 Interrupt events and assignment

The following table lists the interrupt event sources from the T2CCU, and the corresponding event interrupt enable bit and flag bit.

Table 1717 T2CCU interrupt events

Event	Event interrupt enable bit	Event flag bit
Timer 2 Overflow	T2_CON1.TF2EN	T2_CON.TF2
Timer 2 External Input	T2_CON1.EXF2EN	T2_CON.EXF2
CCT Timer Overflow	T2CCU_CCTCON.CCTOVEN	T2CCU_CCTCON.CCTOVF

Following tables show the interrupt node assignment for each T2CCU0/1 interrupt source.

Table 1718 T2CCU0 events' interrupt node control

Event	Interrupt node enable bit	Interrupt node flag bit	Vector address
Timer 2 Overflow	IEN0.ET2	–	$2B_H$
Timer 2 External Input			
CCT Timer Overflow			

Table 1719 T2CCU1 events' interrupt node control

Event	Interrupt node enable bit	Interrupt node flag bit	Vector address
Timer 2 Overflow	IEN1.ESSC	–	$3B_H$
Timer 2 External Input			
CCT Timer Overflow			

39.3.11.7.2 Module suspend control

When the On-Chip Debug Support (OCDS) is in Monitor Mode (DBG_MMCR2.MMODE=1) and the Debug-Suspend signal is active (DBG_MMCR2.DSUSP=1), the timers in the T2CCU module can be suspended based on the settings of their corresponding module suspend bits in register SCUSCR_DBG_MODSUSP. When suspended, only the timer stops counting, since the counter input clock is gated off. The module is still clocked, so that module registers are accessible.

39.3.12 Universal Asynchronous Receiver/Transmitter (UART)

39.3.12.1 Overview

The UART provides a full-duplex asynchronous receiver/transmitter, i.e., it can transmit and receive simultaneously. It is also receive-buffered, i.e., it can commence reception of a second byte before a previously received byte has been read from the receive register. However, if the first byte still has not been read by the time reception of the second byte is complete, one of the bytes will be lost.

***Note**: A module cycle of the UART consists of 2 PCLK cycles.*

***Note**: In this chapter, the input and output signals from/to the GPIO ports are referred to with their generic name, such as TXD and RXD. "RXD" assumes an input direction, "RXD_O" assumes an output direction, and "TXD" assumes an output direction.*

UART Features:

- Full-duplex asynchronous modes
  - 8-bit or 9-bit data frames, LSB first
  - fixed or variable baudrate
- Receive buffered
- Multiprocessor communication
- Interrupt generation on the completion of a data transmission or reception

39.3.12.2 UART modes

The UART can be used in four different modes. In mode 0, it operates as an 8-bit shift register. In mode 1, it operates as an 8-bit serial port. In modes 2 and 3, it operates as a 9-bit serial port. The only difference between mode 2 and mode 3 is the baud rate, which is fixed in mode 2 but variable in mode 3. The variable baudrate is set by the underflow rate on the dedicated baud rate generator.

The different modes are selected by setting bits UART_SCON.SM0 and UART_SCON.SM1, , to their corresponding values, as shown in following table:

Table 1720 UART modes

SM0	SM1	Operating mode	Baud rate
0	0	Mode 0: 8-bit shift register	$f_{PCLK}/2$
0	1	Mode 1: 8-bit shift UART	Variable
1	0	Mode 2: 9-bit shift UART	$f_{PCLK}/64$ or $f_{PCLK}/32$
1	1	Mode 3: 9-bit shift UART	Variable

39.3.12.2.1 Mode 0, 8-bit shift register, fixed baudrate

In mode 0, the serial port behaves as an 8-bit shift register. Data is shifted in through RXD, and out through RXD_O, while the TXD line is used to provide a shift clock which can be used by external devices to clock data in and out.

The transmission cycle is activated by a write to SBUF. One module cycle later, the data has been written to the transmit shift register with a 1 at the 9th bit position. For the next seven module cycles, the contents of the transmit shift register are shifted right one position and a zero shifted in from the left so that when the MSB of

the data byte is at the output position, it has a 1 and a sequence of zeros to its left. The control block then executes one last shift before setting the SCON.TI bit. If SCON.TI is set, the next data can be written to SBUF, without destroying the ongoing transmission. If SCON.TI is not set, the ongoing transmission maybe corrupted.

Reception is started by the condition REN=1 and SCON.RI=0. At the start of the reception cycle, 11111110_B is written to the receive shift register. In each module cycle that follows, the contents of the shift register are shifted left one position and the value sampled on the RXD line in the same module cycle is shifted in from the right. When the 0 of the initial byte reaches the leftmost position, the control block executes one last shift, loads SBUF and sets the SCON.RI bit.

The baudrate for the transfer is fixed at $f_{PCLK}/2$, where f_{PCLK} is the input clock frequency, that means one bit per module cycle.

***Note**: The bit SCON.RI is set at the beginning of the 8th bit.*

39.3.12.2.2 Mode 1, 8-bit UART, variable baudrate

In mode 1, the UART behaves as an 8-bit serial port. A start bit (0), 8 data bits, and a stop bit (1) are transmitted on TXD or received on RXD at a variable baudrate.

The transmission cycle is activated by a write to SBUF. The data is transferred to the transmit register and a 1 is loaded to the 9th bit position (as in mode 0). At phase 1 of the module cycle after the next rollover in the divide-by-16 counter, the start bit is copied to TXD, and data is activated one bit time later. One bit time after the data is activated, the data starts getting shifted right with zeros shifted in from the left. When the MSB gets to the output position, the control block executes one last shift and sets the SCON.TI bit.

Reception is started by a high to low transition on RXD (sampled at 16 times the baudrate). The divide-by-16 counter is then reset and 11111111_B is written to the receive register. If a valid start bit (0) is then detected (based on two out of three samples), it is shifted into the register followed by 8 data bits. If the transition is not followed by a valid start bit, the controller goes back to looking for a high to low transition on RXD. When the start bit reaches the leftmost position, the control block executes one last shift, then loads SBUF with the 8 data bits, loads RB8 (SCON.2) with the stop bit, and sets the SCON.RI bit, provided SCON.RI=0, and either SM2=0 (see related information) or the received stop bit=1. If none of these conditions is met, the received byte is lost.

The associated timings for transmit/receive in mode 1 are illustrated in the following figure.

***Note**: The bit SCON.RI is set at the end of the 8th bit.*

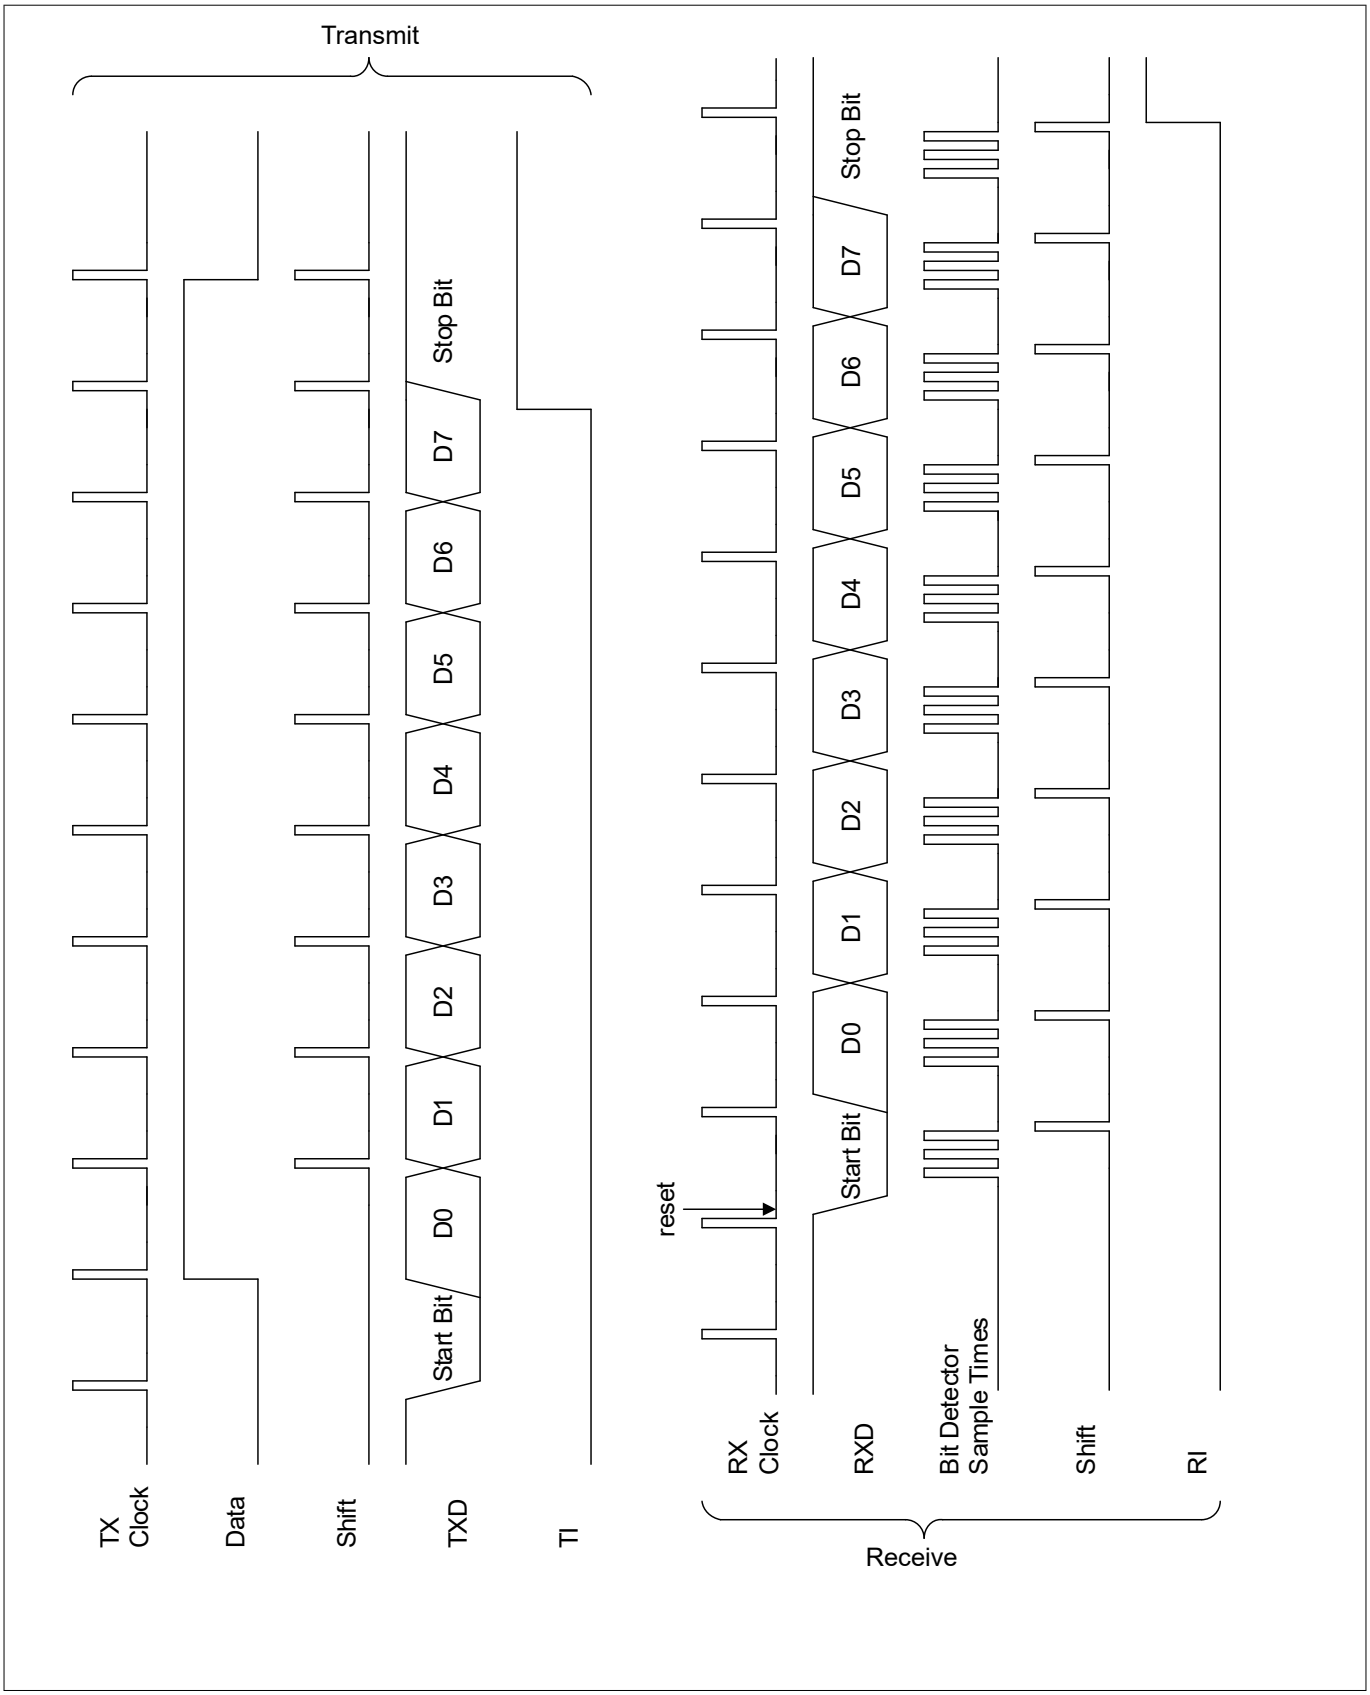

Figure 916 Serial interface, mode 1, timing diagram

Related information

Multiprocessor communication on page 6626

39.3.12.2.3 Mode 2, 9-bit UART, fixed baudrate

In mode 2, the UART behaves as a 9-bit serial port. A start bit (0), 8 data bits plus a programmable 9th bit and a stop bit (1) are transmitted on TXD or received on RXD. The 9th bit for transmission is taken from TB8 (SCON.3) while for reception, the 9th bit received is placed in RB8 (SCON.2).

The transmission cycle is activated by a write to SBUF. The data is transferred to the transmit register and TB8 is copied into the 9th bit position. At phase 1 of the module cycle following the next rollover in the divide-by-16 counter, the start bit is copied to TXD and data is activated one bit time later. One bit time after the data is activated, the data starts shifting right. For the first shift, a stop bit (1) is shifted in from the left and for subsequent shifts, zeros are shifted in. When the TB8 bit gets to the output position, the control block executes one last shift and sets the SCON.TI bit.

Reception is started by a high to low transition on RXD (sampled at 16 times the baudrate). The divide-by-16 counter is then reset and 11111111_B is written to the receive register. If a valid start bit (0) is then detected (based on two out of three samples), it is shifted into the register followed by 8 data bits. If the transition is not followed by a valid start bit, the controller goes back to looking for a high to low transition on RXD. When the start bit reaches the leftmost position, the control block executes one last shift, then loads SBUF with the 8 data bits, loads RB8 (SCON.2) with the 9th data bit, and sets the SCON.RI bit, provided SCON.RI=0, and either SM2=0 (see related information) or the 9th bit=1. If none of these conditions is met, the received byte is lost.

The baudrate for the transfer is either $f_{PCLK}/64$ or $f_{PCLK}/32$, depending on the setting of the top bit (PCON .SMOD) of the PCON (Power Control) register, which acts as a double baudrate selector.

***Note**: The bit SCON.RI is set at the end of the 9th bit.*

Related information

Multiprocessor communication on page 6626

39.3.12.2.4 Mode 3, 9-bit UART, variable baudrate

Mode 3 is the same as mode 2 in all respects except that the baudrate is variable.

In all modes, transmission is initiated by any instruction that uses SBUF as a destination register. A reception is initiated in the modes by the incoming start bit if REN=1.

The serial interface also provides interrupt requests when transmission or reception of the frames has been completed. The corresponding interrupt request flags are SCON.TI or SCON.RI, respectively. If the serial interrupt is not used (i.e., serial interrupt not enabled), SCON.TI and SCON.RI can also be used for polling the serial interface.

The associated timings for transmit/receive in modes 2 and 3 are illustrated in the following figure.

***Note**: The bit SCON.RI is set at the end of the 9th bit.*

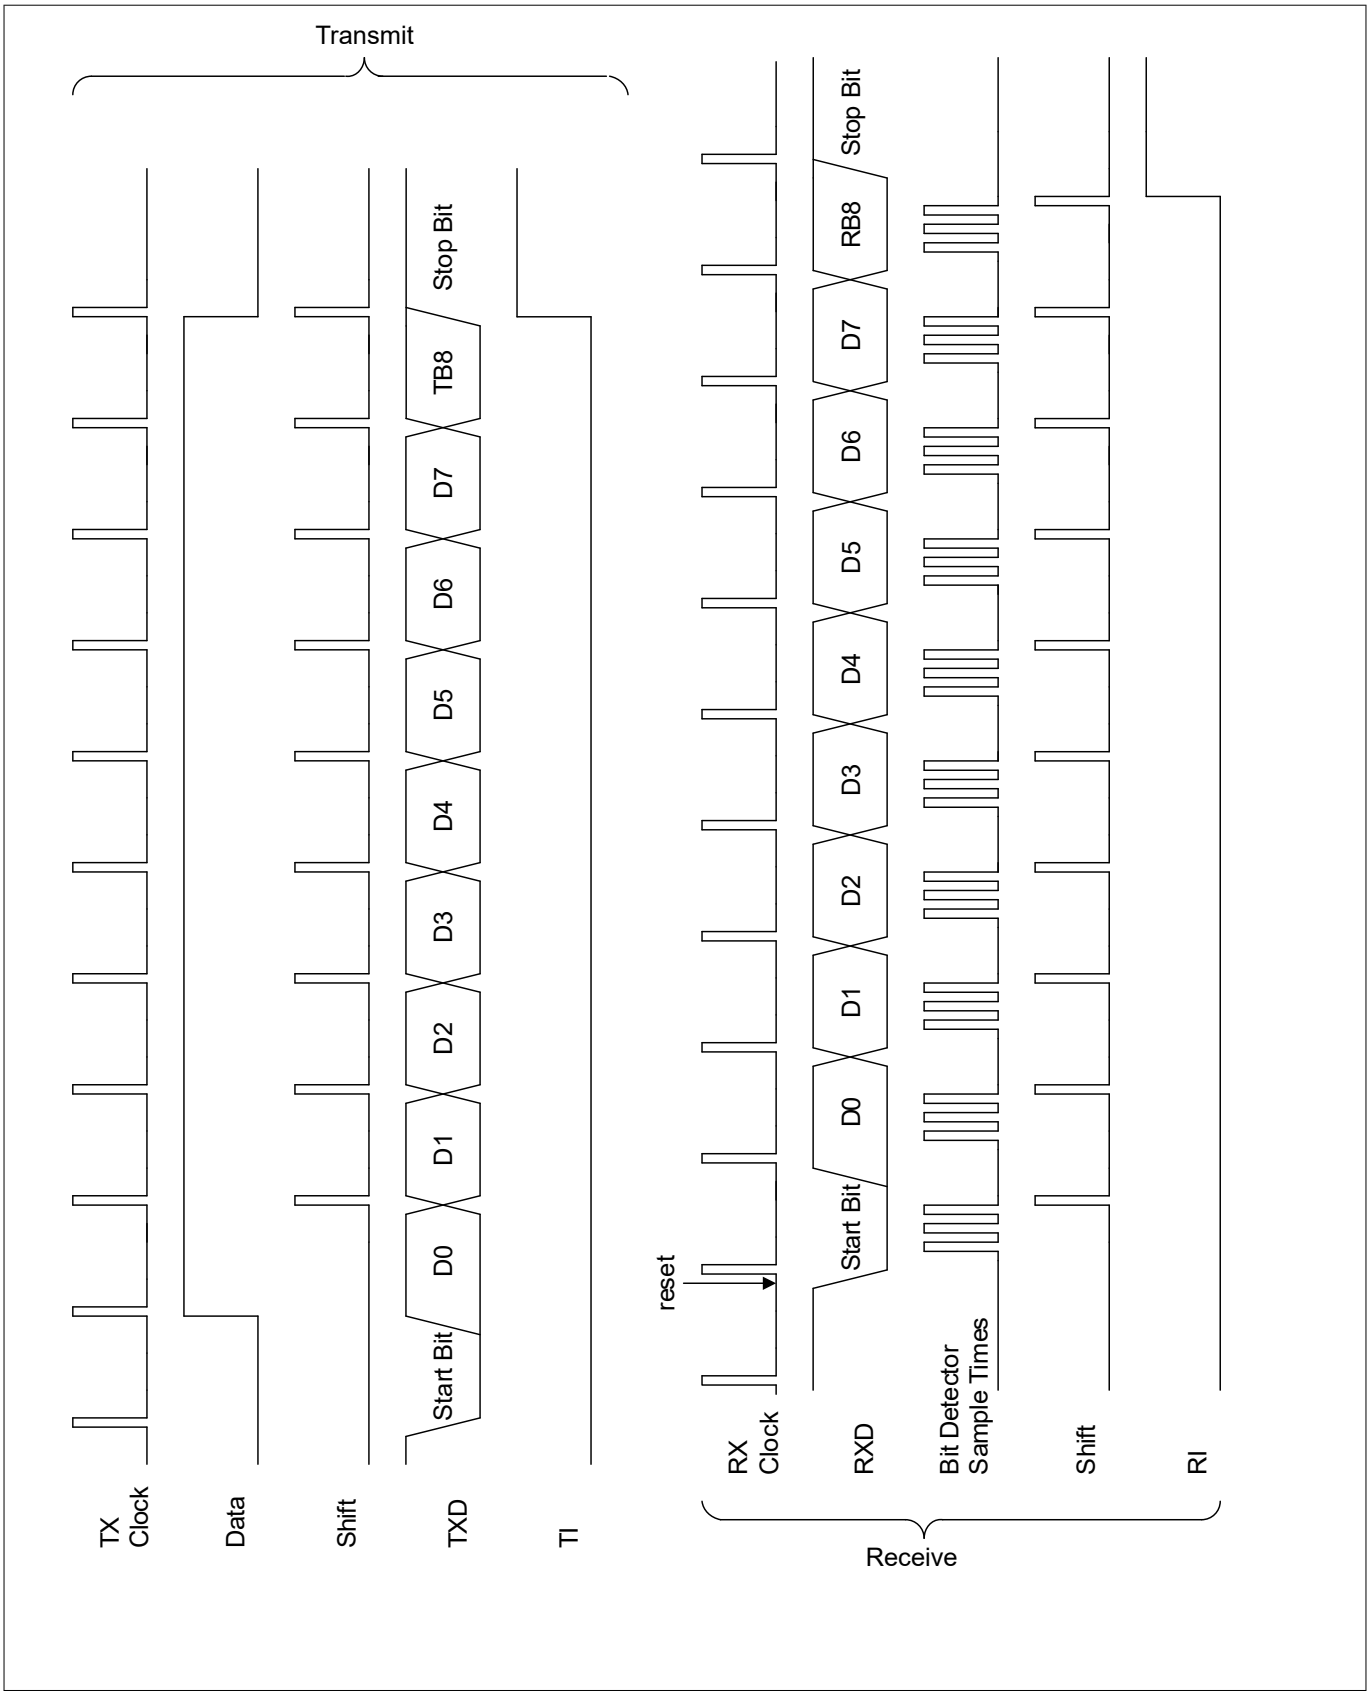

Figure 917 Serial interface, modes 2 and 3, timing diagram

39.3.12.3 Multiprocessor communication

Modes 2 and 3 have a special provision for multiprocessor communication using a system of address bytes with bit 9=1 and data bytes with bit 9=0. In these modes, 9data bits are received. The 9th data bit goes into RB8. The communication always ends with one stop bit. The port can be programmed such that when the stop bit is received, the serial port interrupt will be activated only if RB8=1.

This feature is enabled by setting bit SCON.SM2. One of the ways to use this feature in multiprocessor systems is described in the following paragraph.

When the master processor wants to transmit a block of data to one of several slaves, it first sends out an address byte that identifies the target slave. An address byte differs from a data byte in that the 9th bit is 1 in an address byte and 0 in a data byte. With SCON.SM2=1, no slave will be interrupted by a data byte. An address byte, however, will interrupt all slaves, so that each slave can examine the received byte and see if it is being addressed. The addressed slave will clear its SCON.SM2 bit and prepare to receive the data bytes that will be coming. The slaves that were not being addressed retain their SCON.SM2s as set and ignore the incoming data bytes.

Bit SCON.SM2 has no effect in mode 0. SCON.SM2 can be used in mode 1 to check the validity of the stop bit. In a mode 1 reception, if SCON.SM2=1, the receive interrupt will not be activated unless a valid stop bit is received.

39.3.12.4 Baudrate generation

There are several ways to generate the baudrate clock for the serial ports, depending on the mode in which they are operating.

The baudrates in modes 0 and 2 are fixed, so they use the fixed clock, (see Fixed Clock in related information). In modes 1 and 3, the variable baudrate is generated using the UART baudrate generator (see UART Baudrate Generator in related information).

“Baudrate clock” and “baudrate” must be distinguished from each other. The serial interface requires a clock rate that is 16 times the baudrate, to accommodate for the 16-times oversampling on reception. Therefore, the UART baudrate generator must provide a “baudrate clock” to the serial interface, where it is divided by 16 to obtain the actual “baudrate”. The abbreviation f_{PCLK} refers to the input clock frequency.

Related information

Fixed clock on page 6626

UART baudrate generator on page 6627

39.3.12.4.1 Fixed clock

The baudrates in modes 0 and 2 are fixed. However, while the baudrate in mode 0 can only be $f_{PCLK}/2$, the baudrate in mode 2 can be selected as either $f_{PCLK}/64$ or $f_{PCLK}/32$ depending on bit PCON.SMOD.

Bit PCON.SMOD acts as a double baudrate selector, as shown in the following figure. If PCON.SMOD=0 (value after reset), the baudrate is 1/64 of the input clock frequency f_{PCLK}. If PCON.SMOD=1, the baudrate is 1/32 of f_{PCLK}.

$$Mode\ 2\ Baudrate = \frac{2^{SMOD}}{64} \times f_{PCLK} \tag{63}$$

Mode 2 baudrate

39.3.12.4.2 UART baudrate generator

The UART baudrate generator is used to generate the variable baudrate for the UART in modes 1 and 3. It has programmable 11-bit reload value, 3-bit pre-scaler, and 5-bit fractional divider. It is configured through bit-fields stored in registers: LIN_BCON, LIN_BGL, LIN_BGH.

The baudrate generator is clocked derived through a pre-scaler (f_{DIV}) from the input clock f_{PCLK}. The baudrate timer counts downwards and can be started or stopped through the baudrate control run bit LIN_BCON.R. Each underflow of the timer provides one clock pulse to the serial channel. The timer is reloaded with the 11-bit BR_VALUE stored in its reload register LIN_BGH/LIN_BGL each time it underflows. The duration between underflows depends on the 'n' value in the fractional divider, which can be selected by the bits LIN_BGL.FD_SEL. 'n' times out of 32, the timer counts one cycle more than specified by BR_VALUE. The pre-scaler is selected by the bits LIN_BCON.BRPRE.

Register LIN_BGH/LIN_BGL is the dual-function baudrate Generator/Reload register. Reading LIN_BGH/LIN_BGL returns the contents of the timer, while writing to LIN_BGH/LIN_BGL always updates the reload register.

Registers LIN_BGH/LIN_BGL may be written only when LIN_BCON.R is 0. An auto-reload of the timer with the contents of the reload register is performed one instruction cycle after the next time LIN_BCON.R is set. Any write to LIN_BGH/LIN_BGL, while LIN_BCON.R is set, is not allowed.

The baudrate of the baudrate generator depends on the following bits and register values:

- Input clock f_{PCLK}
- Value of bit-field LIN_BCON.BRPRE
- Value of bit-field BG.FD_SEL
- Value of the 11-bit reload value BR_VALUE in registers LIN_BGH/LIN_BGL

The following figure shows a simplified block diagram of the baudrate generator. Note that f_{BR} is 16 times the configured baudrate, due to synchronization and oversampling needs.

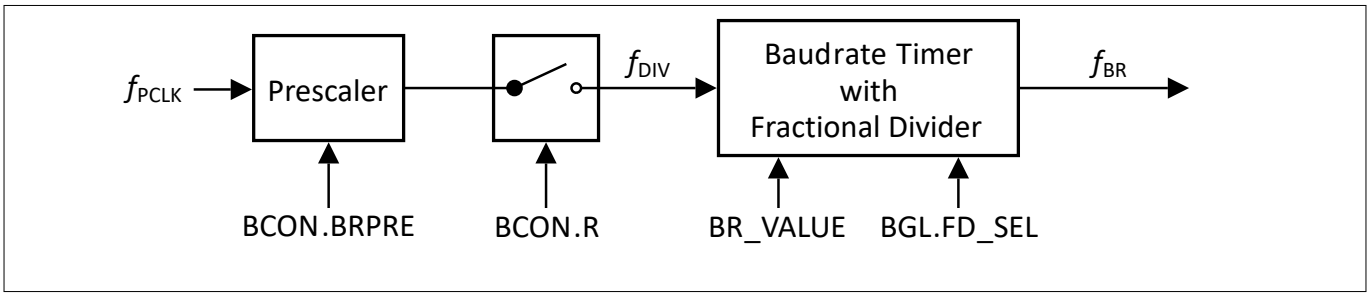

Figure 918 Simplified baudrate generator block diagram

The following equation calculates the final baudrate.

$$Baudrate = \frac{f_{BR}}{16} = \frac{f_{PCLK}}{16 \times \mathrm{Pr}\,escaler \times \left(BR_VALUE + \frac{n}{32}\right)} = \frac{f_{PCLK}}{16 \times \left(2^{BCON.BRPRE}\right) \times \left(BR_VALUE + \left(\frac{BGL.FD_SEL}{32}\right)\right)} \quad (64)$$

Baudrate calculation

The value of the pre-scaler is chosen by the bit-field LIN_BCON.BRPRE. BR_VALUE represents the contents of the reload value, taken as unsigned 11-bit integer from the two bit fields BR_VALUE in registers LIN_BGH and LIN_BGL. n/32 is defined by the fractional divider selection in bit-field LIN_BGL.FD_SEL.

Note that the maximum baudrate that can be generated in this implementation is limited to f_{PCLK}/48. For a module clock of 20 MHz, the maximum achievable baudrate is 416.67 kBaud.

The following table lists various commonly used baudrates together with their corresponding parameter settings and the deviation errors compared to the intended baudrate.

Table 1721 Typical baudrates of UART, example f_{PCLK} = 20 MHz

Baudrate (f_{PCLK} = 20 MHz)	BCON.BRPRE	Reload value (BR_VALUE)	Numerator of fractional value (BGL.FD_SEL)	BG value[1]	Deviation error
115.2 kBaud	000_B (pre-scaler = 1)	$0A_H$	$1B_H$	$015B_H$	+0.06%
20 kBaud	000_B (pre-scaler = 1)	$3E_H$	10_H	$07D0_H$	+0.00%
19.2 kBaud	000_B (pre-scaler = 1)	41_H	03_H	0823_H	+0.02%
9600 Baud	001_B (pre-scaler = 2)	65_H	03_H	0823_H	+0.02%
4800 Baud	010_B (pre-scaler = 4)	41_H	03_H	0823_H	+0.02%
2400 Baud	011_B (pre-scaler = 8)	41_H	03_H	0823_H	+0.02%

1) The BG value is obtained by concatenating the 11-bit BR_VALUE and 5-bit FD_SEL value to a 16-bit value, which represents the contents of the register pair BGH|BGL.

39.3.12.5 UART interrupt requests

The following figure illustrates the UART receive and transmit interrupt requests. Note that the SCON.RI/ SCON.TI flags are not automatically cleared by the CPU on entry into the respective service routine. They must be cleared by software. See also the section on “Interrupt Structure 1” in chapter “Interrupt System”.

39.3.12.6 LIN support in UART

The UART module can be used to support the Local Interconnect Network (LIN) protocol for both master and slave operations. The LIN baudrate detection feature, which consists of the hardware logic for Break and Synch Field detection, provides the capability to detect the baudrate within LIN protocol using one of the available Timer 2 units. This allows the UART module to be synchronized to the LIN baudrate for data transmission and reception. Timer 2 will be used for BREAK detection and generation.

***Note**: Both T2CCU0 Timer 2 and T2CCU1 Timer 2 could be used for this feature. Which one of the two will be used depends on selected input pins - requirement is that UART/LIN RXD input is on the same pin as Timer 2 EX input (T20EX or T21EX).*

39.3.12.6.1 LIN protocol

LIN is a holistic communication concept for local interconnected networks in vehicles. The communication is based on the SCI (UART) data format, a single-master/multiple-slave concept, a clock synchronization for nodes without stabilized time base. An attractive feature of LIN is self-synchronization of the slave nodes without a crystal or ceramic resonator, which significantly reduces the cost of hardware platform. The baudrate must be calculated and returned with every message frame.

The structure of a LIN frame is shown in the following figure. The frame consists of the:

- Header, which comprises a Break (13-bit time low), Synch Byte (55_B), and ID field
- Response time
- Data bytes (according to UART protocol)
- Checksum

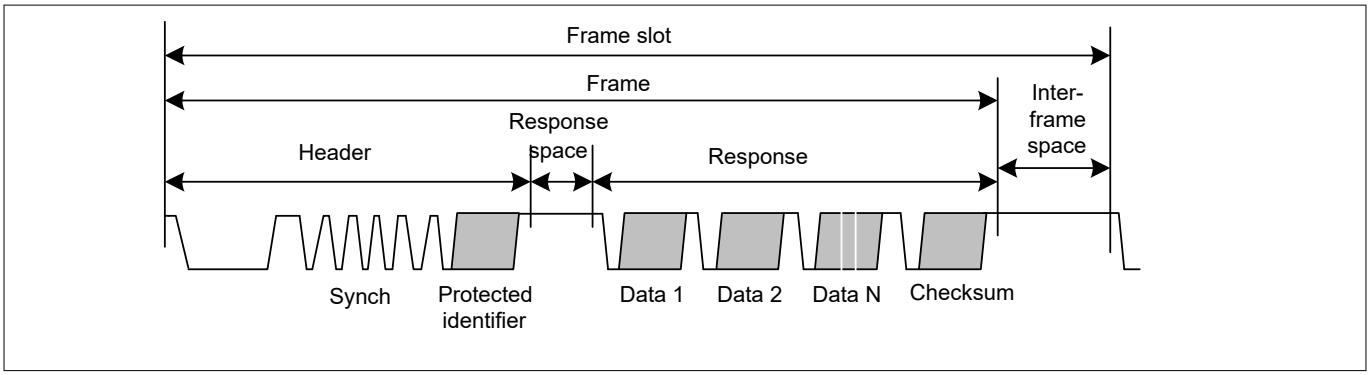

Figure 920 The structure of LIN frame

Each byte field is transmitted as a serial byte, as shown in the following figure. The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and the stop bit is encoded as a bit with value one (recessive).

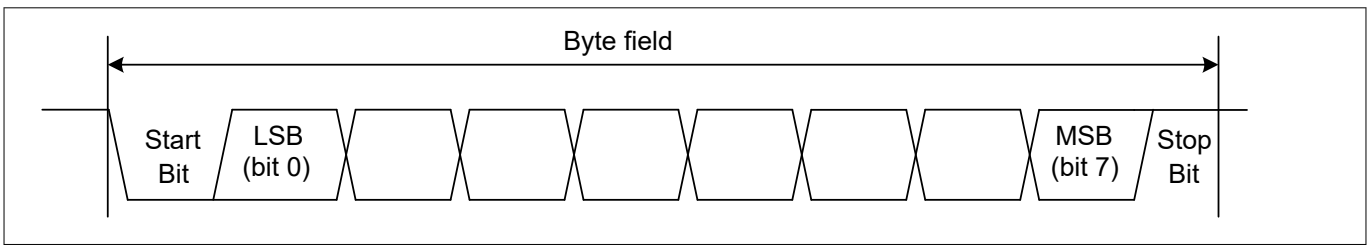

Figure 921 The structure of byte field

The break is used to signal the beginning of a new frame. It is the only field that does not comply with the previous figure. A break is always generated by the master task (in the master mode) and it must be at least

13 bits of dominant value, including the start bit, followed by a break delimiter, as shown in the following figure. The maximum length is 26.6 bit times. The break delimiter will be at least one nominal bit time long.

A slave node will use a break detection threshold of 11 nominal bit times.

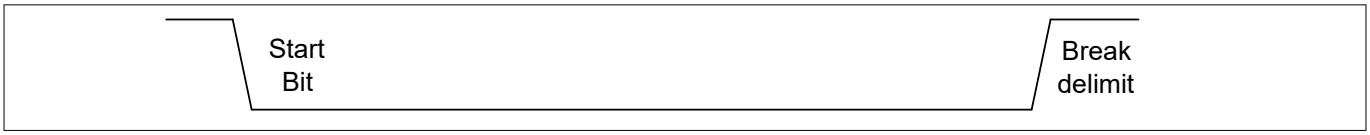

Figure 922 The break field

Synch Byte is a specific pattern for determination of time base. The byte field is with the data value 55_H, as shown in the following figure.

A slave task is always able to detect the Break/Synch sequence, even if it expects a byte field (assuming the byte fields are separated from each other). If this happens, detection of the Break/Synch sequence will abort the transfer in progress and processing of the new frame will commence.

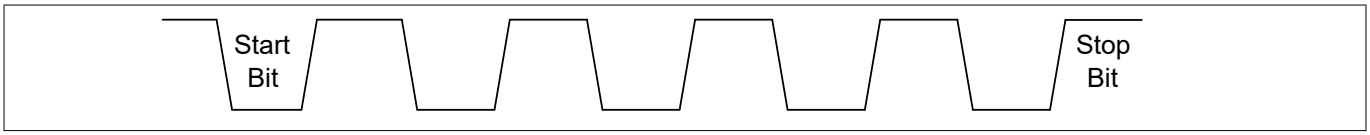

Figure 923 The synch byte field

The slave task will receive and transmit data when an appropriate ID is sent by the master:

1. Slave waits for Synch Break
2. Slave synchronizes on Synch Byte
3. Slave snoops for ID
4. According to ID, slave determines whether to receive or transmit data or to do nothing
5. When transmitting, the slave sends 2, 4 or 8 data bytes, followed by check byte

39.3.12.6.2 LIN header transmission

LIN header transmission is only applicable in master mode. In LIN communication, a master task decides when and which frame is to be transferred on the bus. It also identifies a slave task to provide the data transported by each frame. The information needed for the handshaking between the master and slave tasks is provided by the master task through the header portion of the frame.

The header consists of a "break and synch" pattern followed by an identifier. Among these three fields, only the break pattern cannot be transmitted as normal 8-bit UART data. The break must contain a dominant value of 13 bits or more to ensure proper synchronization of slave nodes.

In LIN communication, a slave task is required to be synchronized at the beginning of the protected identifier field of frame. For this purpose, every frame starts with a sequence consisting of a break field followed by a "synch" byte field. This sequence is unique and provides enough information for any slave task to detect the beginning of a new frame and be synchronized at the start of the identifier field.

39.3.12.6.3 Automatic synchronization to the host

Upon entering LIN communication, a connection is established and the transfer speed (baudrate) of the serial communication partner (host) is automatically synchronized in the following steps that are to be included in user software:

STEP 1: Initialize interface for reception and timer for baudrate measurement

STEP 2: Wait for an incoming LIN frame from host

STEP 3: Synchronize the baudrate to the host

STEP 4: Enter for Master Request Frame or for Slave Response Frame

The related section provides some hints on setting up the microcontroller for baudrate detection of LIN.

***Note**: Re-synchronization and setup of baudrate are always done for every Master Request Header or Slave Response Header LIN frame.*

Related information

Initialization of break/synch field detection logic on page 6631

39.3.12.6.4 Initialization of break/synch field detection logic

***Note**: Both T2CCU0 and T2CCU1 can be used to implement this feature. Which one of the two will be used depends on selected input pins - the requirement is that a UART/LIN RXD input is on the same pin as a Timer 2 EX input (T20EX or T21EX). In the text below it is only referred to as "Timer 2" without index 0 or 1.*

The LIN baudrate detection feature provides measures to detect the baudrate within the LIN protocol using Timer 2 (T2CCU) and UART, within the LIN user software. Initialization consists of:

- Serial port of the microcontroller to be configured to Mode 1 (8-bit UART, variable baudrate) for communication
- Provide the baudrate range by configuring the bit-field LIN_BCON.BGSEL
- Write LIN_BCON.BRDIS = 1
- Write LIN_BCON.BRDIS = 0 to initialize the Break / synch detection logic
- Clear all status flags LIN_STAT.BRK, LIN_STAT.EOFSYN and LIN_STAT.ERRSYN to 0
- Configure Timer 2 to capture mode with falling edge trigger input T2xEX (x can be 0 or 1). Bit T2CCUn_T2_MOD.EDGESEL is set to 0 by default, and bit T2CCUn_T2_CON.CP_RL2 is set to 1
- Enable external events for Timer 2 by setting T2CCUn_T2_CON. EXEN2 to 1 (EXF2 flag is set when a negative transition occurs at input T2xEX)

The baudrate calculation using the T2 result can be done with the following:

- The UART baudrate is given by the previous Equation 2
- The baudrate measured by the T2 is:

$$BRmeasured\ T2 = \frac{f_{PCLK} \times N_{measured\ bits}}{T2\ prescaler \times T2\ capture\ value} \quad (65)$$

- With the assumption T2 pre-scaler = UART pre-scaler, we can say:

$$BR_VALUE + \frac{BGL.FD_SEL}{32} = \frac{T2\ capture\ value}{16 \times N_{measured\ bits}} \quad (66)$$

With following bits and register values:

- Input clock f_{PCLK}
- Number of measured bits Nmeasured bits
- Value of bit-field T2 capture value, 16 bit value in registers T2CCUn_T2_RC2H/T2CCUn_T2_RC2L
- Value of bit-field LIN_BGL.FD_SEL
- Value of the UART pre-scaler is configured in LIN_BCON.BRPRE

- Value of the T2 pre-scaler is configured in T2CCUn_T2_MOD.T2PRE
- Value of the 11-bit reload value BR_VALUE in registers LIN_BGH/LIN_BGL

***Note**: f_{T2} can be configured by bit-field T2CCUn_T2_MOD.T2PRE*

***Note**: The baudrate must be calculated and returned with every message frame.*

***Note**: It is also recommended to toggle the LIN_BCON.BRDIS bit after the reception of each LIN frame (complete or erroneous frame) to avoid a wrong Break field detection in noisy environments (i.e. spikes on the LIN bus).*

***Note**: The baudrate is the number of times the signal can switch states in one second. To calculate the actual byte transfer rate simply divide the baudrate by the number of bits that must be transferred for each byte of data.*

39.3.12.6.5 Break detection

The Break/Synch Field detection logic supports a maximum number of bits in the Break field as defined by the conformance test 26.6 bits.

39.3.12.6.6 Baudrate range selection

$$Maximum\ number\ of\ bits = Baudrate \times \frac{7262}{SampleFrequency} \tag{67}$$

Maximum number of bits in break field

$$Sample\ frequency = \frac{f_{PCLK}}{8 \times 2^{BGSEL}} \tag{68}$$

Sample frequency equation

If the maximum number of bits in the Break field is exceeded, the internal counter will overflow, which results in a baudrate detection error. Therefore, an appropriate LIN_BCON.BGSEL value has to be selected for the required baudrate detection range.

The baudrate range defined by different LIN_BCON.BGSEL settings is shown in the next table. Each LIN_BCON.BGSEL setting supports a range of baudrate for detection. If the baudrate used is outside the defined range, the baudrate may not be detected correctly.

Table 1722 BGSEL bit-field definition for different input frequencies

f_{PCLK}	BGSEL	Baudrate selection for detection $f_{PCLK}/(2184*2^{BGSEL})$ to $f_{PCLK}/(74*2^{BGSEL})$
20 MHz	00_B	9.2 kHz to 270.2 kHz
	01_B	4.6 kHz to 135.1 kHz
	10_B	2.3 kHz to 67.5 kHz
	11_B	1.1 kHz to 33.7 kHz

(table continues...)

Table 1722 (continued) BGSEL bit-field definition for different input frequencies

f_{PCLK}	BGSEL	Baudrate selection for detection $f_{PCLK}/(2184*2^{BGSEL})$ to $f_{PCLK}/(74*2^{BGSEL})$
100 MHz	00_B	45.8 kHz to 1451.3 kHz
	01_B	22.9 kHz to 675.6 kHz
	10_B	11.5 kHz to 337.8 kHz
	11_B	5.8 kHz to 168.9 kHz

If f_{PCLK}=20 MHz, the baudrate range between 1.1 kHz to 270.2 kHz can be detected. The following examples serve as a guide to select the BGSEL value:

- If the baudrate falls in the range of 1.2 kHz to 2.3 kHz, the selected BGSEL value is 11_B
- If the baudrate falls in the range of 2.3 kHz to 4.6 kHz, the selected BGSEL value is 10_B
- If the baudrate falls in the range of 4.6 kHz to 9.2 kHz, the selected BGSEL value is 01_B
- If the baudrate falls in the range of 9.2 kHz to 270.2 kHz, the selected BGSEL value is 00_B. If the baudrate is 20 kHz, the possible values of BGSEL that can be selected are 00_B, 01_B, 10_B, and 11_B. However, it is advisable to select 00_B for better detection accuracy

For PCLK at 100 MHz, BGSEL can be chosen at 11_B.

39.3.12.6.7 LIN baudrate detection

The configuration has to take place in software. The baudrate detection for LIN is shown in the following figure, the Header LIN frame consists of:

- SYN(CH) Break (13-bit times low)
- SYN(CH) byte (55_H)
- Protected ID field

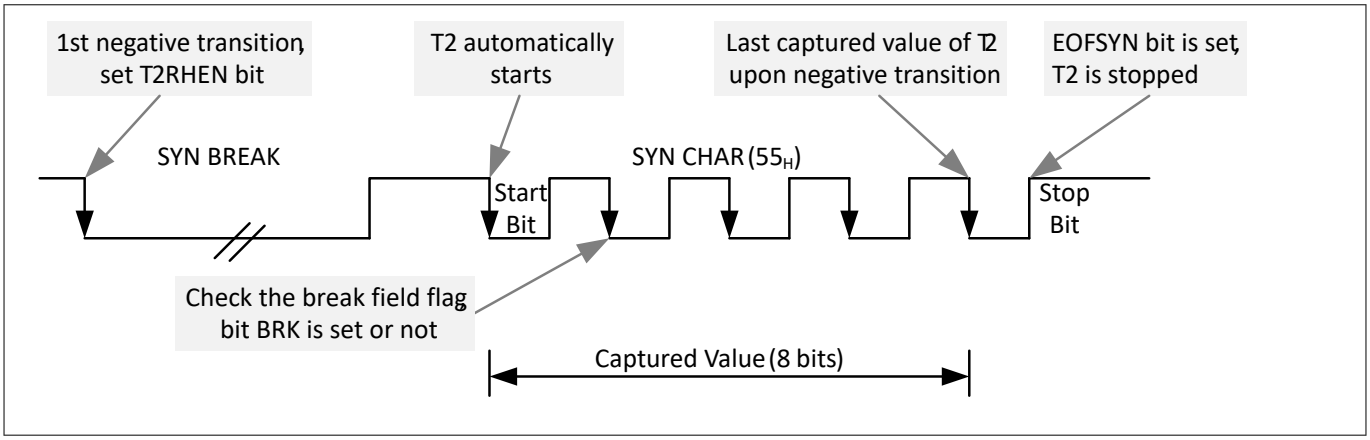

Figure 924 LIN baudrate detection

***Note**: Both T2CCU0 Timer 2 and T2CCU1 Timer 2 could be used for this feature. Which one of the two will be used depends on selected input pins - requirement is that UART/LIN RXD input is on the same pin as Timer 2 EX input (T20EX or T21EX). In the text below it is only referred to as "Timer 2" without index 0 or 1.*

With the first falling edge:

- The Timer 2 External Start Enable bit (T2CCU0_T2_MOD.T2RHEN) is set. The falling edge at input T2EX is selected by default for Timer 2 External Start (bit T2CCU0_T2_MOD.T2REGS is 0)

With the second falling edge:

- Start Timer 2 by the hardware

With the third falling edge:

- Timer 2 captures the timing of 2 bits of SYN byte
- Check the Break Field Flag bit LIN_STAT.BRK

If the Break Field Flag LIN_STAT.BRK is set, software may continue to capture 4/6/8 bits of SYN byte. The End of SYN Byte Flag (LIN_STAT.EOFSYN) is set, Timer 2 is stopped. T2 Reload/Capture register (T2CCUn_T2_RC2H/ T2CCUn_T2_RC2L) is the time taken for 2/4/6/8 bits according to the implementation. Then the LIN user software routine calculates the actual baudrate, sets the LIN_BCON.BRPRE and LIN_BGH/LIN_BGL values if the UART module uses the baudrate generator for baudrate generation.

After the third falling edge, the software may discard the current operation and continue to detect the next header LIN frame if the following conditions were detected:

- The Break Field Flag LIN_STAT.BRK is not set, or
- The SYN Byte Error Flag LIN_STAT.ERRSYN is set, or
- The Break Field Flag LIN_STAT.BRK is set, but the end of SYN Byte Flag LIN_STAT.EOFSYN and the SYN Byte Error Flag LIN_STAT.ERRSYN is not set

39.3.12.6.8 LIN interrupt requests

The following figure illustrates the LIN interrupt requests. Note that the flags must be cleared by software. See also the section on “Interrupt Structure 2” in chapter “Interrupt System”.

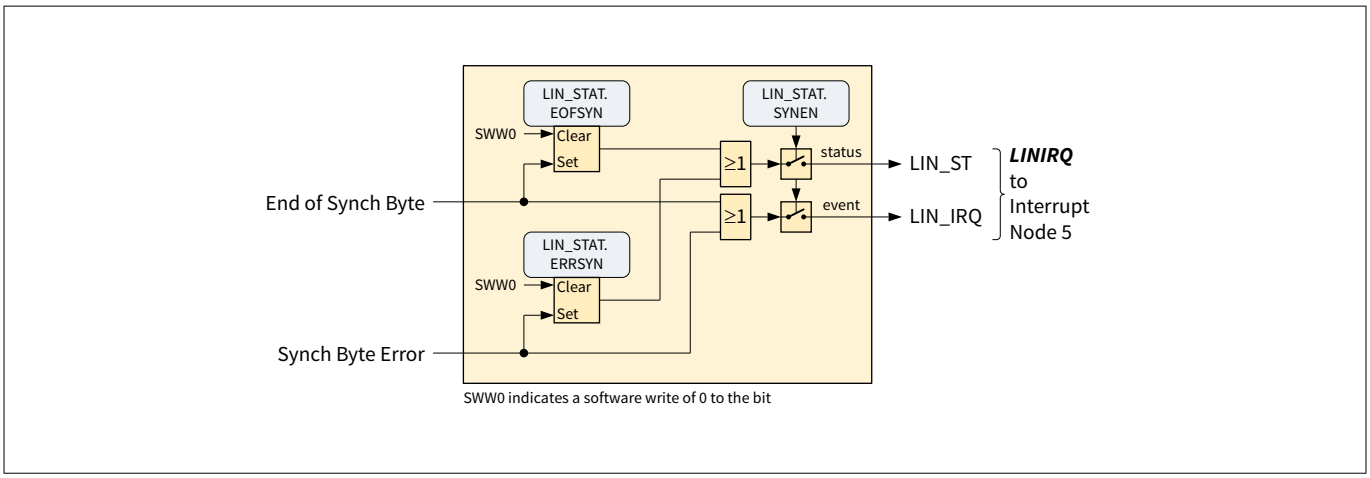

Figure 925 LIN interrupt requests

39.3.12.7 UART connections to GPIO

The following figure illustrates the signal connections of the UART to the GPIO ports.

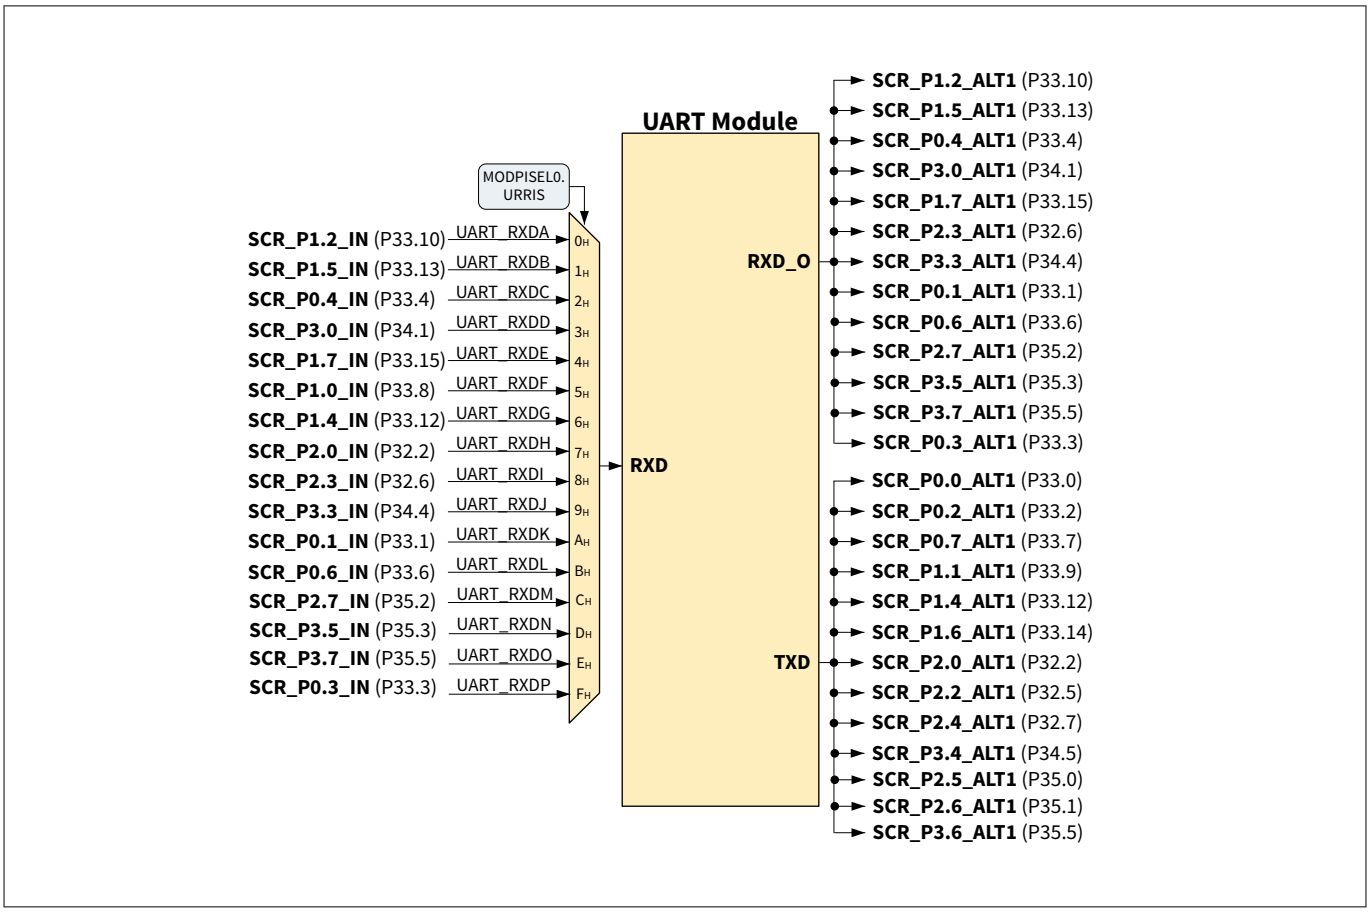

Figure 926 UART connections to GPIO ports

39.3.12.8 Register overview

The UART/LIN registers can be accessed from both the standard (non-mapped) and mapped SFR area.

UART contains the two Special Function Registers (SFRs), UART_SCON and UART_SBUF. UART_SCON is the control register and UART_SBUF is the data register. On reset, both UART_SCON and UART_SBUF return 00_H. The serial port control and status register is the UART_SCON . This register contains not only the mode selection bits, but also the 9th data bit for transmit and receive (TB8 and RB8) and the serial port interrupt bits (SCON.TI and SCON.RI).

UART_SBUF is the receive and transmit buffer of the serial interface. Writing to UART_SBUF loads the transmit register and initiates transmission. This register is used for both transmit and receive data. Transmit data is written to this location and receive data is read from this location, but the two paths are independent.

Reading out UART_SBUF accesses a physically separate receive register.

Other registers are prefixed with "LIN" even though they are used for both UART and LIN functionality: LIN_BCON, LIN_BGL/BGH, LIN_STAT.

The low (LIN_BGL) and high byte (LIN_BGH) of the baudrate timer/reload register BG (consisting out of high and low byte) contain the 11-bit reload value for the Baudrate timer and the 5-bit fractional divider selection. Reading the low byte of BG LIN_BGL returns the content of the lower three bits of the baudrate timer and the FD_SEL setting, while reading the high byte LIN_BGH returns the content of the upper 8 bits of the baudrate timer.

Writing to register BG loads the baudrate timer with the reload and fractional divider values from the BG registers, the first instruction cycle after LIN_BCON.R is set.

BG may only be written if BCON.R = 0.

39.3.13 Synchronous Serial Channel (SSC)

This chapter describes the Synchronous Serial Channel (SSC).

39.3.13.1 Overview

The Synchronous Serial Channel (SSC) supports both full-duplex and half-duplex serial synchronous communication. The serial clock signal can be generated by the SSC itself (Master Mode) through its own 16-bit baudrate generator, or can be received from an external master (Slave Mode). Data width, shift direction, clock polarity, and phase are programmable. This allows communication with SPI - compatible devices using other synchronous serial channel. Transmission and reception of data is double-buffered. In slave mode, the SSC is limited to 1 MBit/s.

Features

- Master and Slave Mode operation
  - Full-duplex or half-duplex operation
- Transmit and receive buffered
- Flexible data format
  - Programmable number of data bits: 4 to 8 bits (1, 2 and 3 bit transfers are programmable, but forbidden)
  - Programmable shift direction: Least Significant Bit (LSB) or Most Significant Bit (MSB) shift first
  - Programmable clock polarity: idle low or high state for the shift clock
  - Programmable clock/data phase: data shift with leading or trailing edge of the shift clock
- Compatible with Serial Peripheral Interface (SPI)
- Interrupt generation
  - On a transmitter empty condition
  - On a receive condition
  - On a receiver FIFO full and empty condition
  - On an error condition (receive, baudrate, transmit error)

The following figure shows the block diagram of the SSC.

***Note**: In this chapter, the input and output signals from/to the GPIO ports are referred to with their generic name, such as MTSR, MRST, or SCLK. However, the actual input and output signals use separate lines from/to the GPIO, since they are connected in different ways to the pin logic (pin input line; alternate data output line). Only where explicitly applicable, the generic signal names are extended with an "_I" (input line) or "_O" (output line) identifier.*

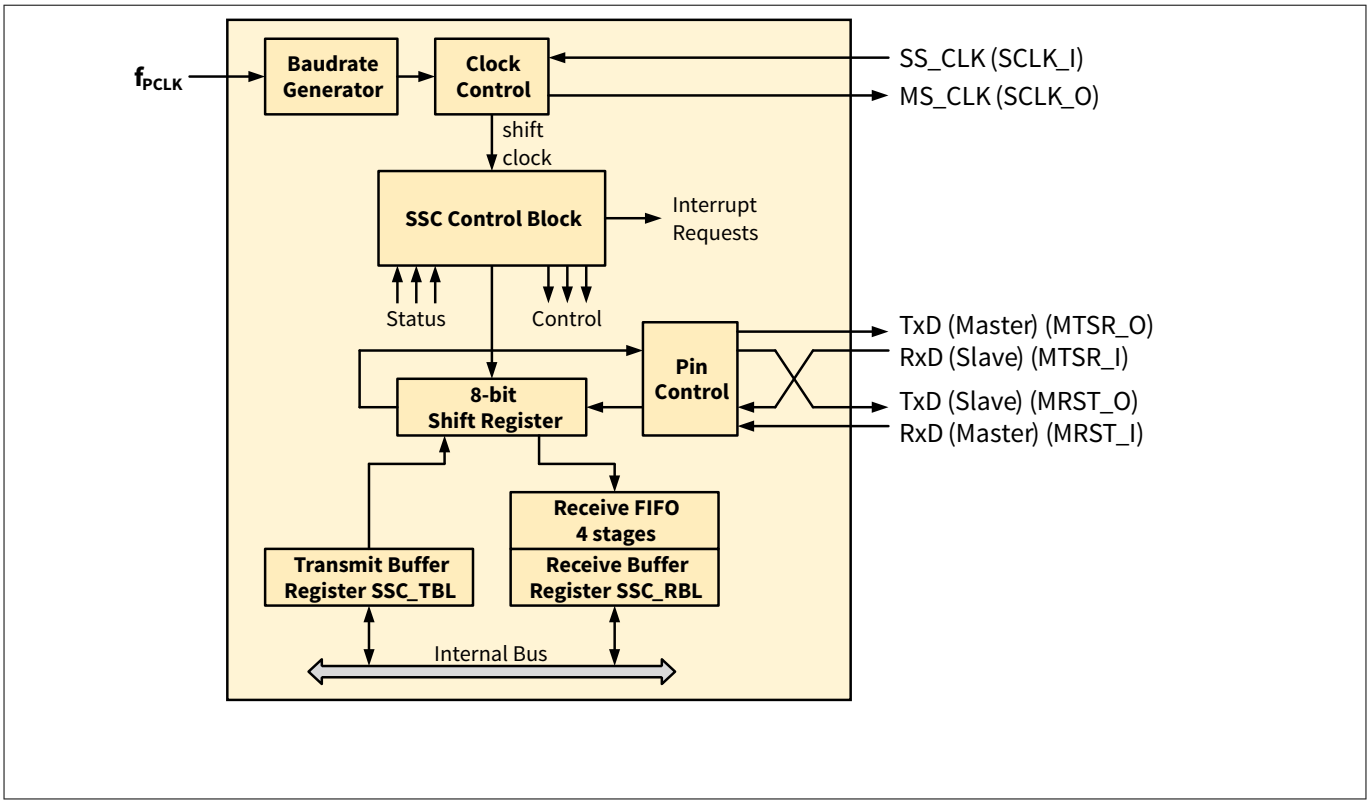

Figure 927 SSC block diagram

39.3.13.2 General operation

The SSC supports full-duplex and half-duplex synchronous communication of 3.33 MBaud (@20 MHz module clock). The serial clock signal can be generated by the SSC itself (Master Mode) or can be received from an external master (Slave Mode). Data width, shift direction, clock polarity, and phase are programmable. This allows communication with SPI devices. The data, which is transmitted and received is stored in is double-buffered registers. A 16-bit baudrate generator provides the SSC with a separate serial clock signal.

The SSC can be configured in a very flexible way, so it can be used with other synchronous serial channels, can serve for master/slave or multi-master interconnections, or can operate compatible with the popular SPI interface. Thus, the SSC can be used to communicate with shift registers (I/O expansion), peripherals (for example EEPROMs, etc.) or other controllers (networking). The SSC supports half-duplex and full-duplex communication. Data is transmitted or received on lines TXD and RXD, normally connected with pins MTSR (Master Transmit/Slave Receive) and MRST (Master Receive/Slave Transmit). The clock signal is output through line MS_CLK (Master Serial Shift Clock) or input through line SS_CLK (Slave Serial Shift Clock). Both lines are normally connected to pin SCLK.

39.3.13.2.1 Operating mode selection

The operating mode of the serial channel SSC is controlled by two register pairs, sharing the same addresses:

- During programming (SSC disabled SSC_CONPH.EN=0), access to register pair SSC_CONPH/SSC_CONPL is available, providing access to a set of control bits
- During operation (SSC enabled SSC_CONOH.EN=1), access to register pair SSC_CONOH/SSC_CONOL is available, providing access to a set of control/status flags

The two register pairs share the same two addresses. The selection between the registers is depending on the state of the enable bit SSC_CONPH.EN prior to an access to the register pairs.

The shift register of the SSC is connected to both the transmit lines and the receive lines via the pin control logic. Transmission and reception of serial data are synchronized and take place at the same time, that is the same number of transmitted bits is also received. Transmit data is written into the Transmit Buffer (SSC_TBL) and it is moved, on the next shifting edge, to the shift register as soon as this is empty. An SSC master (SSC_CONOH.MS=1) immediately begins transmitting, while an SSC slave (SSC_CONOH.MS=0) will wait for an active shift clock. When the transfer starts, the busy flag SSC_CONOH.BSY is set and the Transmit Interrupt Request line TIR will be activated within the timeframe of the first bit to indicate that register SSC_TBL may be reloaded again. When the programmed number of bits (4…8) has been transferred, the contents of the shift register are moved to the Receive FIFO and the Receive Interrupt Request line RIR will be activated for the first received frame. If no further transfer is to take place (SSC_TBL is empty), SSC_CONOH.BSY will be cleared (Master Mode). In Slave Mode, SSC_CONOH.BSY will always be cleared after a single transfer. Software shall not modify SSC_CONOH.BSY, as this flag is hardware controlled. If the mode of SSC is changed from operating to programming after the Transmit Interrupt Request line is set, the last byte of SSC data will not be transmitted. It is important to wait for SSC_CONOH.BSY to get cleared before changing the mode from operating to programming.

***Note**:* *The SSC starts transmission and sets SSC_CONOH.BSY minimum two clock cycles after transmit data is written into SSC_TBL. Therefore, it is not recommended to poll SSC_CONOH.BSY to check for the start and end of a single transmission. Instead, interrupt service routines should be used if interrupts are enabled, or the interrupt flags IRSCR_IRCON1.TIR and IRSCR_IRCON1.RIR should be polled if interrupts are disabled.*

***Note**:* *Only one serial interface can be master at a given time.*

The transfer of serial data bits can be programmed in many respects:

- The data width can be specified from 4 bits to 8 bits
- A transfer may start with either the LSB or the MSB
- The shift clock may be idle low or idle high
- The data bits may be shifted with the leading edge or the trailing edge of the shift clock signal
- The baudrate may be set from 152.59 Baud up to 3.33 MBaud (@20 MHz module clock)
- The shift clock can be generated (MS_CLK) or can be received (SS_CLK)

These features allow the adaptation of the SSC to a wide range of applications requiring serial data transfer.

The Data Width Selection supports the transfer of frames of any data length, from 4-bit “characters” up to 8-bit “characters”. Starting with the LSB (SSC_CONPL.HB=0) allows communication with SSC devices in Synchronous Mode or with 8051-like serial interfaces, for example. Starting with the MSB (SSC_CONPL.HB=1) allows operation compatible with the SPI interface.

Regardless of the data width selected and whether the MSB or the LSB is transmitted first, the transfer data is always right-aligned in registers SSC_TBL and SSC_RBL, with the LSB of the transfer data in bit 0 of these registers. The data bits are rearranged for transfer by the internal shift register logic. The unselected bits of SSC_TBL are ignored; the unselected bits of SSC_RBL will not be valid and should be ignored by the receiver service routine.

The Clock Control allows the adaptation of transmit and receive behavior of the SSC to a variety of serial interfaces. A specific shift clock edge (rising or falling) is used to shift out transmit data, while the other shift clock edge is used to latch in receive data. Bit SSC_CONPL.PH selects the leading edge or the trailing edge for each function. Bit SSC_CONPL.PO selects the level of the shift clock line in the idle state. Therefore, for an idle-high clock, the leading edge is a falling one, a 1-to-0 transition (see following figure).

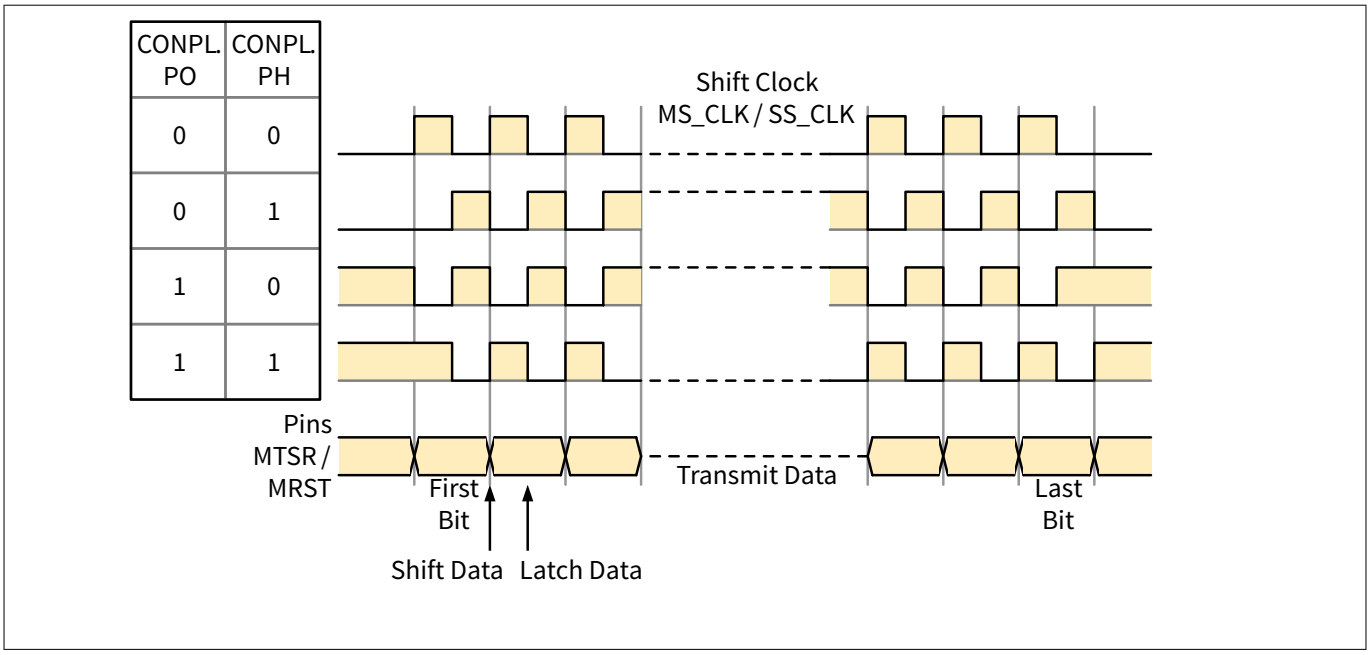

Figure 928 Serial clock phase and polarity options

39.3.13.2.2 Full-duplex operation

The various devices are connected through three lines. The definition of these lines is always determined by the master: the line connected to the master's data output line TXD is the transmit line; the receive line is connected to its data input line RXD; the shift clock line is either MS_CLK or SS_CLK. Only the device selected for master operation generates and outputs the shift clock on line MS_CLK. Since all slaves receive this clock, their pin SCLK must be switched to input mode. The output of the master's shift register is connected to the external transmit line, which in turn is connected to the slaves' shift register input. The output of the slaves' shift register is connected to the external receive line in order to enable the master to receive the data shifted out of the slave. The external connections are hard-wired, the function and direction of these pins is determined by the master or slave operation of the individual device.

***Note**: The shift direction shown in the figure applies for MSB-first operation as well as for LSB-first operation.*

When initializing the devices in this configuration, one device must be selected for master operation while all other devices must be programmed for slave operation. Initialization includes the operating mode of the device's SSC and also the function of the respective port lines.

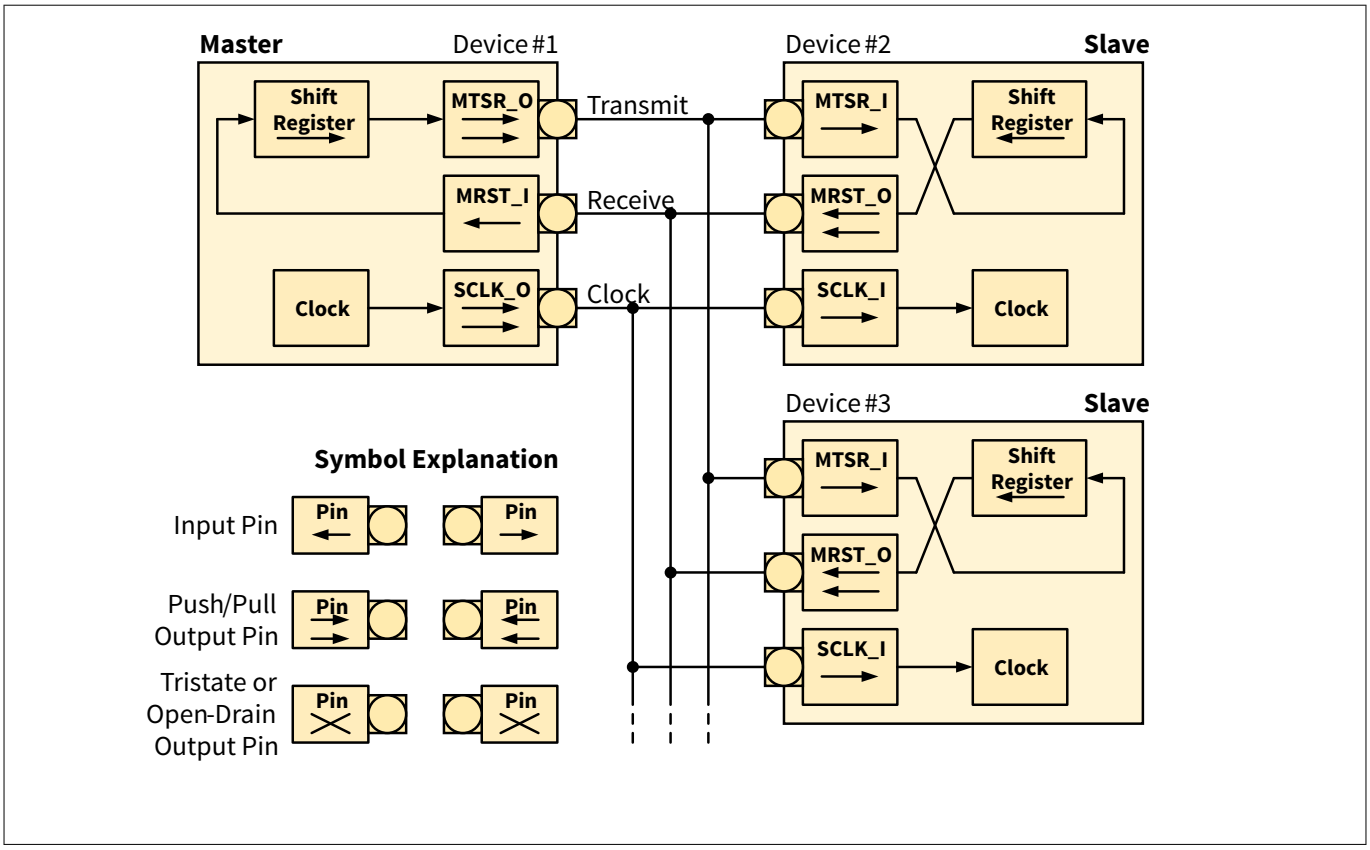

Figure 929 SSC full-duplex configuration

The data output pins MRST of all slave devices are connected together onto the one receive line in the configuration shown in the figure above. During a transfer, each slave shifts out data from its shift register. There are two ways to avoid collisions on the receive line due to different slave data:

- Only one slave drives the line, that is to say it enables the driver of its MRST pin. All the other slaves must have their MRST pins programmed as input so only one slave can put its data onto the master's receive line. It is possible to only receive data from the master. The master selects the slave device from which it expects data either by separate select lines or by sending a special command to this slave. The selected slave then switches its MRST line to output until it gets a de-selection signal or command. This option is applicable only if the pin has output driver disabling capability
- The slaves use open-drain output on MRST. This forms a wired-AND connection. The receive line needs an external pull-up in this case. Corruption of the data on the receive line sent by the selected slave is avoided when all slaves not selected for transmission to the master only send ones (1 s). Because this high level is not actively driven onto the line, but only held through the pull-up device, the selected slave can pull this line actively to a low-level when transmitting a zero bit. The master selects the slave device from which it expects data either by separate select lines or by sending a special command to this slave

After performing the necessary initialization of the SSC, the serial interfaces can be enabled. For a master device, the alternate clock line will now go to its programmed polarity. The alternate data line will go to either 0 or 1 until the first transfer starts.

When the serial interfaces are enabled, the master device can initiate the first data transfer by writing the transmit data into register SSC_TBL. This value is copied into the shift register (assumed to be empty at this time), and the selected first bit of the transmit data will be placed onto the TXD line before the next clock from the baudrate generator (transmission starts only if SSC_CONPH.EN=1).

Depending on the selected clock phase, a clock pulse will also be generated on the MS_CLK line. At the same time, with the opposite clock edge, the master latches and shifts in the data detected at its input line RXD. This “exchanges” the transmit data with the receive data. Because the clock line is connected to all slaves, their shift

registers will be shifted synchronously with the master's shift register — shifting out the data contained in the registers, and shifting in the data detected at the input line. After the pre-programmed number of clock pulses (via the data width selection), the data transmitted by the master is contained in all the slaves' shift registers, while the master's shift register holds the data of the selected slave. In the master and all slaves, the contents of the shift register are copied into the receive FIFO and the receive interrupt line RIR is activated for the first received frame.

When a slave device is transmitting its data, the bit SSC_CONOH.BSY is not set until the first clock edge at SS_CLK appears. The slave device will not wait for the next clock from the baudrate generator, as the master does. The reason for this is that, depending on the selected clock phase, the first clock edge generated by the master may already be used to clock in the first data bit. Thus, the slave's first data bit must already be valid at this time.

***Note**: For Master and Slave Mode the following applies: In the case SSC_CONPL.PH=1, the value is placed immediately on the bus, while for SSC_CONPL.PH=0, it is placed on the output with the first shifting edge. Besides, the value is not immediately copied into the shift register, but with the first shifting edge.*

***Note**: On the SSC, a transmission and a reception takes place at the same time, regardless of whether valid data has been transmitted or received.*

***Note**: The initialization of the SCLK pin on the master requires some attention in order to avoid undesired clock transitions, which may disturb the other devices. Before the clock pin is switched to output mode, the clock output level should be selected in the control register SSC_CONPL, and the alternate output be prepared via the appropriate GPIO register, or the output latch must be loaded with the clock idle level.*

39.3.13.2.3 Half-duplex operation

In a Half-Duplex Mode, only one data line is necessary for both receiving and transmitting of data (see following figure).

The master device controls the data transfer by generating the shift clock, while the slave devices receive it. Due to the fact that all transmit and receive pins are connected to the one data exchange line, serial data may be moved between arbitrary stations.

Similar to Full-Duplex Mode, there are two ways to avoid collisions on the data exchange line:

- Only the transmitting device may enable its transmit pin driver. This option is applicable only if the pin has output driver disabling capability
- The non-transmitting devices use open-drain output and send only ones

Because the data inputs and outputs are connected together, a transmitting device will clock in its own data at the input pin (MRST for a master device, MTSR for a slave). By this method, any corruptions on the common data exchange line are detected if the received data is not equal to the transmitted data.

The Half-Duplex Mode port configuration using three pins is shown in the following figure.

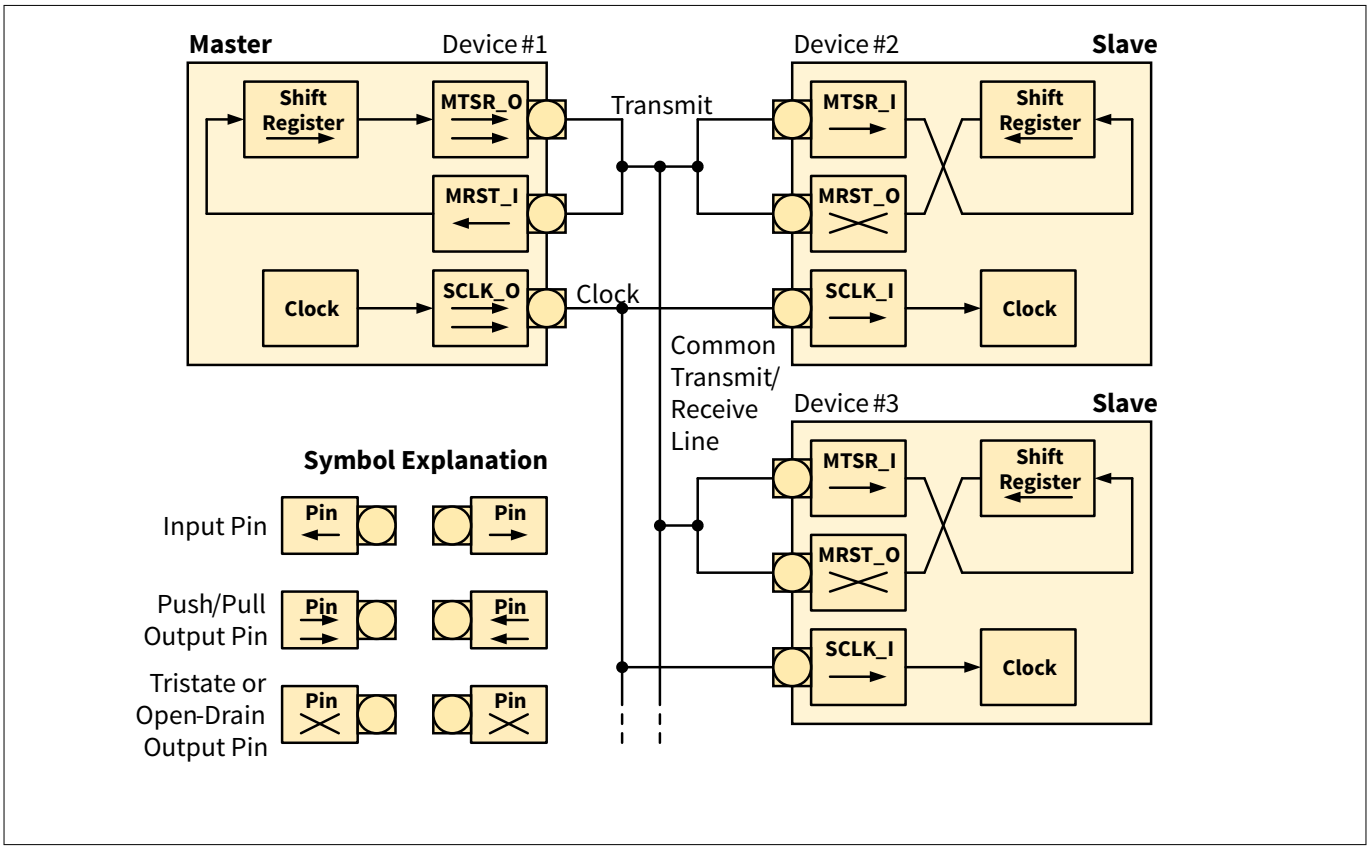

Figure 930 SSC half-duplex configuration

39.3.13.2.4 Loop back mode

To aid debugging, it is useful to receive back the data which is sent out. When SSC_CONPL.LB is set, the receive input is connected to the transmit output. Hence, the data which is sent out is automatically received back. Loop-back mode is supported only in master mode.

39.3.13.2.5 Continuous transfers (master mode only)

When the transmit interrupt request flag is set, it indicates that the transmit buffer SSC_TBL is empty and ready to be loaded with the next transmit data. If SSC_TBL has been reloaded by the time the current transmission is finished (at least 2 PCLK cycles before the last latching edge), the data is immediately transferred to the shift register and the next transmission will start without any additional delay. In such a case, there is no gap between the two successive frames on the data line. For example, two byte transfers looks the same as one word transfer. This feature can be used to interface with devices that can operate with or require more than 8 data bits per transfer. It is just a matter of software, how long a total data frame length can be. This option can also be used to interface to byte-wide and word-wide devices on the same serial bus, for instance.

***Note**: Of course, this can happen only in multiples of the selected basic data width, because it requires disabling/enabling of the SSC to reprogram the basic data width on-the-fly. Additionally, if the next data is now written any time after 2 PCLK cycles before the last latching edge, then there may be up to a half SCLK clock delay to start transmission of the new word.*

***Note**: In slave mode, when SSC_CONPL.PH = 0, if the data is written into the transmit buffer at least 4 PCLK cycles before the first SS_CLK edge of the next transfer (whether shifting or latching), then continuous transfer occurs and no transmit error is generated. Otherwise, a transmit error is generated. If SSC_CONPL.PH = 1, then the data has to be provided 7 PCLK cycles before the first SS_CLK edge of the next transfer. Otherwise, a transmit error is generated.*

39.3.13.2.6 Baudrate generation

The serial channel SSC has its own dedicated 16-bit Baudrate generator with 16-bit reload capability, allowing Baudrate generation independent of the timers. Next figure shows the Baudrate generator.

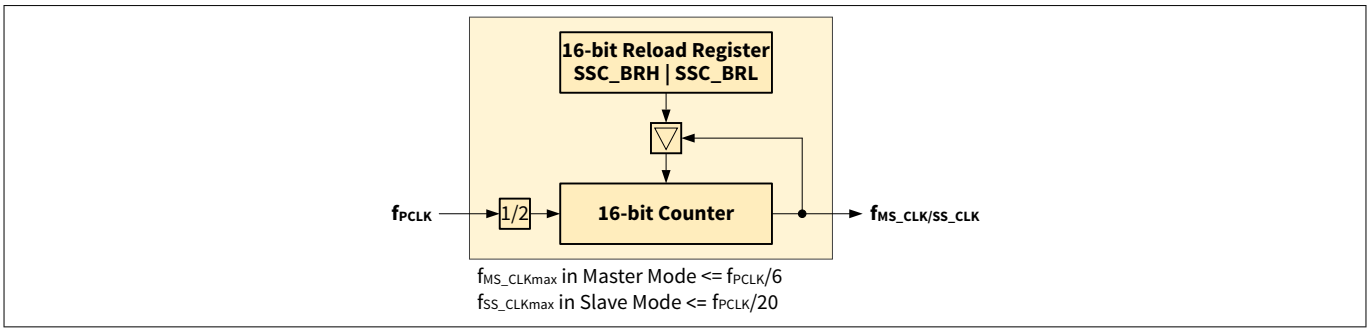

Figure 931 SSC baud-rate generator

The Baudrate generator is clocked with the module clock f_{PCLK}. The timer counts downwards. On underflow, it is reloaded with the 16-bit value BR contained in register pair SSC_BRH|SSC_BRL.

***Note**: Never write to BR while the SSC is enabled. The desired value shall be written to BR only when SSC is disabled.*

The formulas below calculate either the resulting Baudrate for a given reload value, or the required reload value for a given Baudrate:

***Note**: For the SSC module in the SCR, f_{hw_clk} is the PCLK (f_{PCLK}).*

$$Baudrate = \frac{f_{hw_clk}}{2 \times (< BR > + 1)}$$
$$BR = \frac{f_{hw_clk}}{2 \times Baudrate} - 1 \quad (69)$$

SSC baud rate calculation

BR represents the contents of the reload register pair, taken as an unsigned 16-bit integer, while Baudrate is equal to f_{MS_CLK/SS_CLK} as shown in the equation above.

The maximum Baudrate that can be achieved when using a module clock of 100 MHz is 16.67 MBaud in Master Mode (with BR=0002_H) (the theoretical value is 50 MBaud, but not guaranteed) or 5 MBaud (the theoretical value is 25 MBaud, but this value is not guaranteed) in Slave Mode (with BR=0009_H).

The table below lists some possible Baudrates together with the required reload values and the resulting bit times, assuming a module clock of 20 MHz.

Table 1723 Typical Baudrates of the SSC (f_{hw_clk}=20 MHz)

Reload value	Baudrate (= $f_{MS_CLK}/_{ss_clk}$)	Deviation
0000_H	Not allowed	0.0%
0001_H	Not allowed	0.0%
0004_H	2 MBaud (only in master mode)	0.0%
0009_H	1 MBaud	0.0%
0013_H	500 kBaud	0.0%
0063_H	100 kBaud	0.0%
$FFFF_H$	152.59 Baud	0.0%

39.3.13.2.7 Error detection mechanisms

The SSC is able to detect three different error conditions. Receive Error is detected in all modes; "Transmit Error" and "Baudrate Error" apply only to Slave Mode. When an error is detected, the respective error flag is/can be set and an error interrupt request will be generated if enabled (see following figure). The error interrupt handler may then check the error flags to determine the cause of the error interrupt. The error flags are not reset automatically, but must be cleared by software after servicing. This allows servicing of some error conditions via interrupt, while the others may be polled by software.

***Note**: The error interrupt handler must clear the associated (enabled) error flag(s) to prevent repeated interrupt requests.*

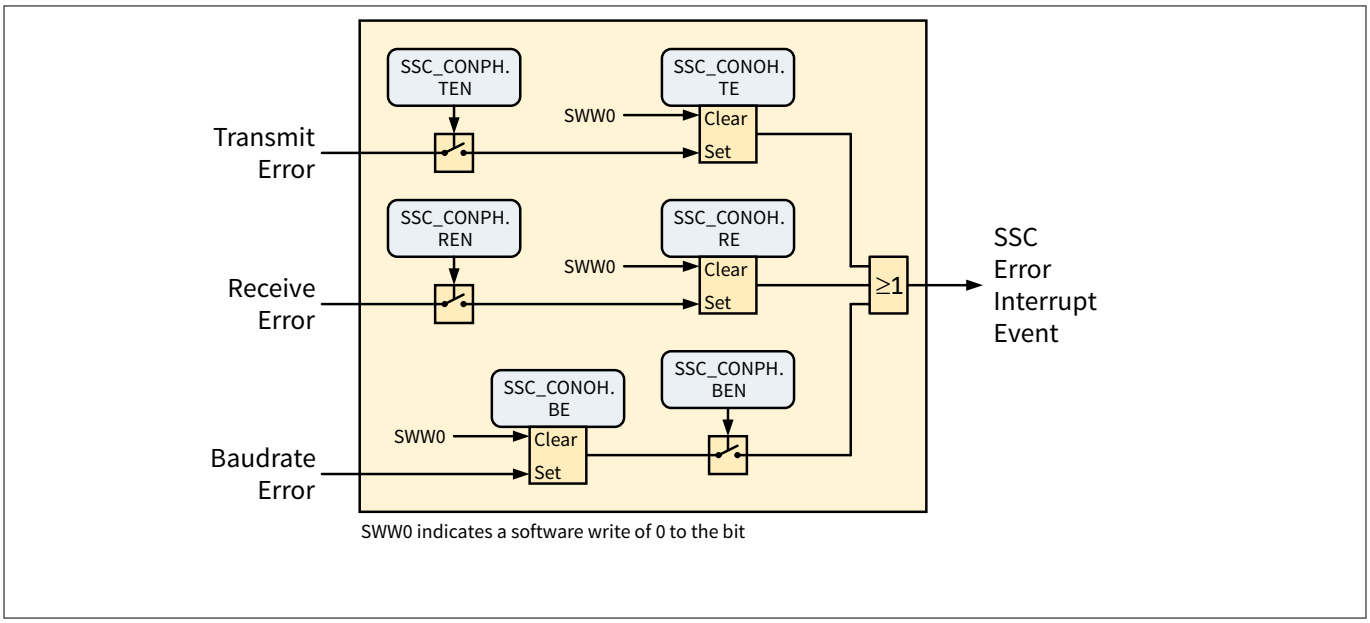

Figure 932 SSC error interrupt control (interrupt pulse no signal)

A Receive Error (Master or Slave Mode) is detected when the FIFO is full (FIFO full already set) and another frame is completely received, but the previous data was not read out of the receive FIFO. This condition sets the error flag SSC_CONOH.RE and the error interrupt request line, when enabled via SSC_CONPH.REN. The FIFO has four elements, afterwards, the reception is stopped. FIFO full will be raised. When Receive Error is raised, an additional reception was intended, but as the FIFO is full it is lost.

A "Baudrate Error" (Slave Mode) is detected when the incoming clock signal deviates from the programmed Baudrate by more than 100%, that means it is either more than double or less than half the expected baudrate.

This condition sets the error flag SSC_CONOH.BE and, when enabled via SSC_CONPH.BEN , the error interrupt request line. Using this error detection capability requires that the slave's baudrate generator is programmed to the same baudrate as the master device. This feature detects false additional, or missing pulses on the clock line (within a certain frame).

A Transmit Error (Slave Mode) is detected when a transfer was initiated by the master (SS_CLK gets active) but the transmit buffer SSC_TBL of the slave was not updated since the last transfer. This condition sets the error flag SSC_CONOH.TE and the error interrupt request line, when enabled via SSC_CONPH.TEN. If a transfer starts while the transmit buffer is not updated, the slave may shift out invalid data. This may lead to corruption of the data on the transmit/receive line in half-duplex mode (open-drain configuration) if this slave is not selected for transmission. This mode requires that slaves not selected for transmission only shift out ones; that is, their transmit buffers must be loaded with $FFFF_H$ prior to any transfer.

***Note**: In order to avoid possible conflicts or misinterpretations, it is recommended to always load the slave's transmit buffer prior to any transfer.*

The cause of an error interrupt request (receive, baudrate, transmit error) can be identified by the error status flags in control register SSC_CONOH.

***Note**: The error status flags SSC_CONOH.TE, SSC_CONOH.RE, and SSC_CONOH.BE are not reset automatically upon entry into the error interrupt service routine, but must be cleared by software.*

39.3.13.3 SSC interrupts

The five SSC interrupts can be separately enabled or disabled by setting or clearing their corresponding enable bits in SFR IR_MODIEN.

For a detailed description of the various interrupts see General Operation in related information. An overview is given in the following table.

Table 1724 SSC interrupt sources

Interrupt	Signal	Description
Transmission starts	TIR	Indicates that the transmit buffer can be reloaded with new data
Transmission ends	RIR	The configured number of bits has been transmitted and shifted to the receive buffer. This is only the case for the first reception after FIFO empty
Receive FIFO full	RFFIR	The receive FIFO is full and will stop reception. Further information is lost
Receive FIFO empty	RFEIR	The receive FIFO is empty, further access will provide junk data
Receive Error	EIR	This interrupt occurs if a new data frame is completely received while the FIFO is full
Baud-Rate Error (Slave Mode only)	EIR	This interrupt is generated when the incoming clock signal deviates from the programmed baud-rate by more than 100%
Transmit Error (Slave Mode only)	EIR	TE is generated in case corrupted data is sent. This can be an empty transmit buffer or corrupted data on the serial bus (in case the transmit buffer is overwritten round about transmission start)

Following figure shows a diagram of the interrupt request handling of the SSC.

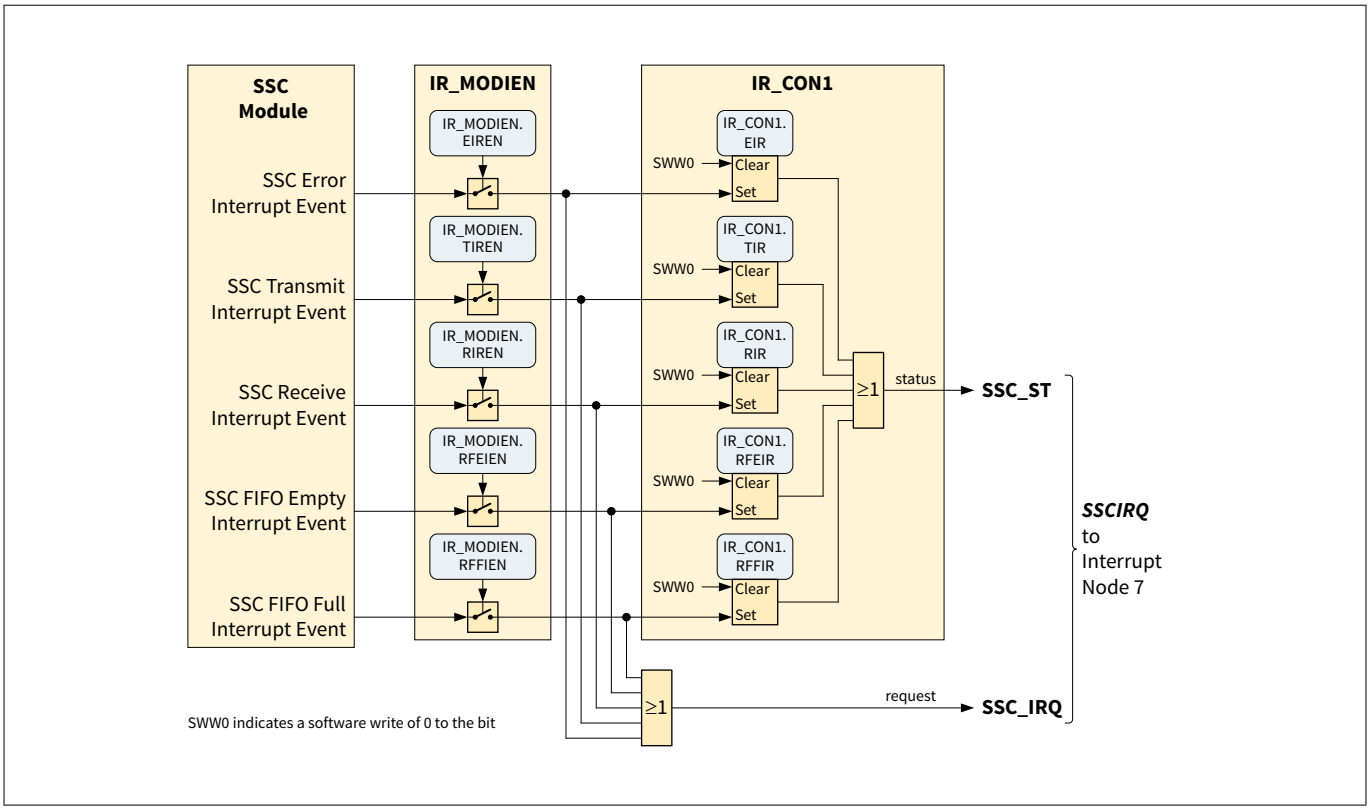

Figure 933 SSC interrupt request overview

39.3.13.4 SSC connections to GPIO

The following figure illustrates the signal connections of the SSC to the GPIO ports.

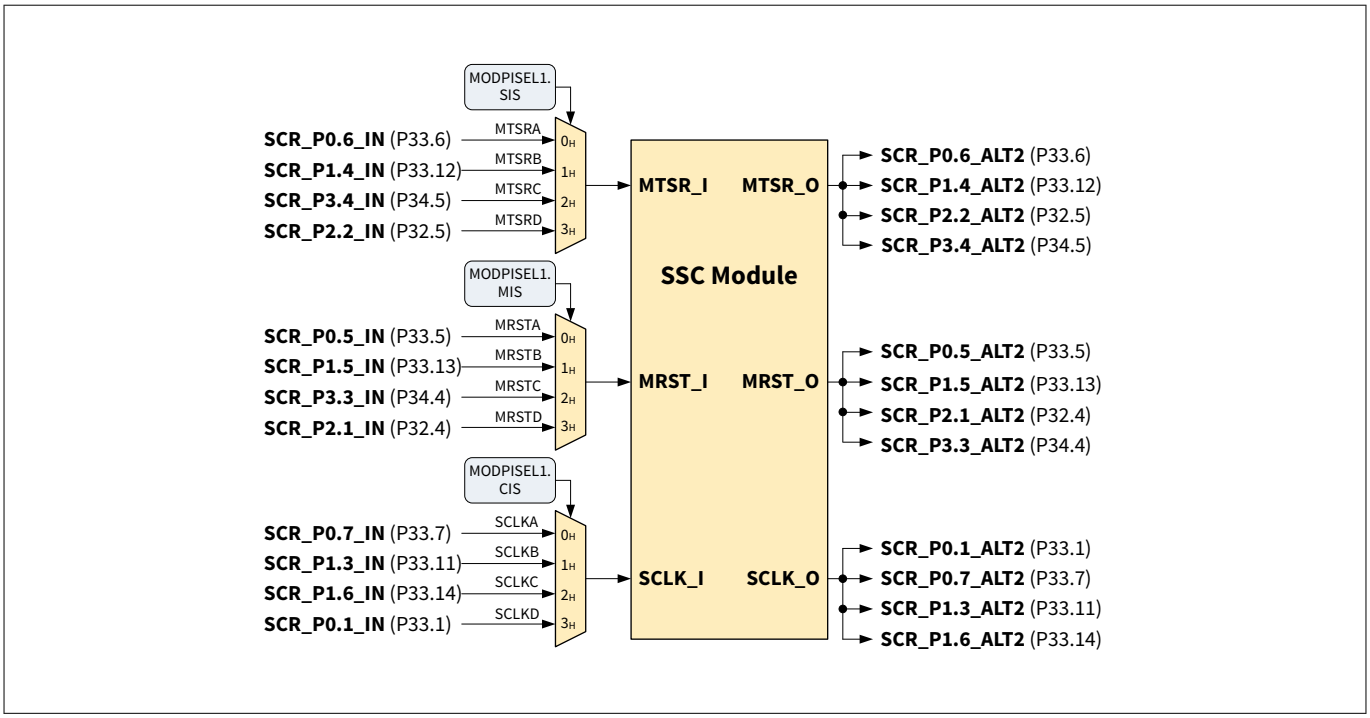

Figure 934 SSC connections to GPIO ports

39.3.13.5 Register overview

The SSC Special Function Registers are accessed from the standard (non-mapped) SFR area.

Configuration register

The operating mode of the serial channel SSC is controlled by two register pairs, sharing the two same addresses:

- Register pair SSC_CONPH/SSC_CONPL provides access to a set of control bits and is accessible in Programming Mode
- Register pair SSC_CONOH/SSC_CONOL provides access to a set of control/status flags and is accessible in Operating Mode

The selection between the register pairs is depending on the state of the enable bit EN prior to an access to the register. This bit is available at the MSB position in both registers, SSC_CONPH and SSC_CONOH:

- When EN=0 (Programming Mode), registers SSC_CONPH and SSC_CONPL are accessible
- When EN=1 (Operating Mode), registers SSC_CONOH and SSC_CONOL are accessible

Since the selection is dependent on the state of the EN bit prior to an access, writing, for example, 11000000_B to SSC_CONPH in programming mode (SSC_CONPH.EN = 0) will initialize the SSC (SSC_CONPH.EN was 0) and then turn it on. Then, register pair SSC_CONOH|SSC_CONOL is accessible, with SSC_CONOH.EN = 1.

***Note**: Between programming SSC_CONPH.EN=1 and writing into SSC_TBL a minimum delay of 4 cycles has to be kept. (see SSC_TBL)*

Baud rate timer reload register

The SSC baudrate timer reload register pair SSC_BRH|SSC_BRL contains the 16-bit reload value BR for the baudrate timer.

Transmit buffer register

***Note**: Before writing to SSC_TBL a minimum delay of 4 PCLK cycles has to be regarded after writing,SSC_CONPH.EN=1. for example:*

SSC_CONPH.EN=1;
for (i=0;i<4;i++)
nop();
SSC_TBL=Byte to be transferred.
Instead of nop() more useful code can be used, as long as a delay of 4 cycles is guaranteed.

It is recommended to use the transmit interrupt as signal to write the next piece of information to the transmit buffer register. This way, it is guaranteed, that the module has the information on time (in slave mode) to guarantee the transmission.

Receive buffer register

The SSC receive buffer register SSC_RBL contains the received data value. It is the access point to the FIFO. The FIFO depth is 4 bytes. The FIFO stops receiving, when full. Warning flags for FIFO full (RFF) and FIFO empty (RFE) exist in SSC_CONOH.

39.3.14 ADC Comparator Unit (ADCOMP)

The ADCOMP constitutes an 11-bit successive approximation (SAR) Analog-to-Digital converter, supporting up to 16 channels. The ADCOMP unit can be periodically activated by the SCR to measure certain analog inputs. The ADCOMP unit can be quickly activated, followed by few measurements, after which the unit is powered off to keep the overall Standby current to the minimum.

The conversion control involves enabling the ADC Comparator unit, selecting the channel, selecting sampling time and subsequently issuing start of conversion through software. After conversion is completed, end of conversion event is indicated and an interrupt may be generated.

39.3.14.1 Features

The ADCOMP has the following features:

- 11-bit resolution
- Periodic monitoring of up to 16 ADC channels
- Operating frequency 50 MHz (100 MHz/2)
- Configurable sampling times

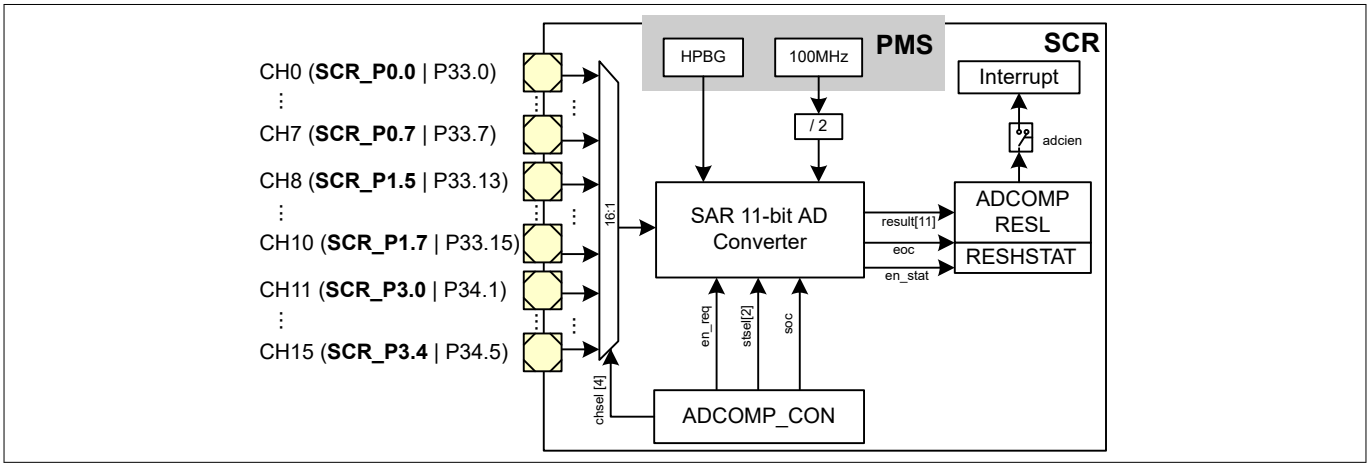

Figure 935 ADC comparator overview

For detailed mapping of SCR Ports to ADCOMP input channels, please refer to the SCR GPIO chapter.

***Note**: A pad should be in a tristate configuration in order to be used as an analog input.*

For detailed electrical characteristics of ADCOMP please refer to device datasheet.

39.3.14.2 Overview

The ADC unit is clocked with 50 MHz clock derived from the HPOSC 100 MHz clock. The reference voltage for the conversion is derived from the high-precision bandgap HPBG. The analog channels are selected through a 16:1 multiplexer. The ADCOMP unit is enabled through ADCOMP_CON.EN_REQ. The conversion control and result handling part is encapsulated in the SCR digital domain, and is clocked by PCLK.

39.3.14.3 ADC comparator (ADCOMP) operation

This single ADC comparator can be operated by SCR independent from PMS.

Before an ADC conversion is triggered, HPBG band-gap, ADC unit and 100 MHz back-up clock have to be enabled:

- If backup clock is disabled (by having SCR_SCUSCR_CLK.DIV_REQ = DIV70K) the clock source has to be enabled from SCR side by setting SCUSCR_CLK.DIV_REQ to a different value than DIV70K
- ADCOMP is by default disabled, so starting ADC is triggered by setting ADCOMP_CON.EN_REQ
- The activation of the ADCOMP unit triggers the activation of the band gap HPBG

After enabling ADCOMP unit a certain stabilization time needs to be waited – time will be in range of 50 µs, and it will depend if HPBG was enable or not before enabling ADCOMP.

In most cases,

- if the system was in "RUN mode" prior to setting ADCOMP_CON.EN_REQ, HPBG is enabled and this stabilization time is shorter (around 15 µs),
- and if the system was in STBY0 or STBY1_70kHz mode prior to setting ADCOMP_CON.EN_REQ, HPBG is disabled and it will take longer (around 65 µs)
- Once the ADCOMP components are initialized and ready to use, the bit ADCOMP_RESHSTAT.EN_STAT is set showing that the ADCOMP is ready. This allows a start of conversion (SOC) to be triggered, as shown in the figure below
- Start of conversion (SOC) can be requested even if ADCOMP_RESHSTAT.EN_STAT is not set. In this case, the conversion will be started as soon as the ADCOMP_RESHSTAT.EN_STAT is set and the ADCOMP is up and running

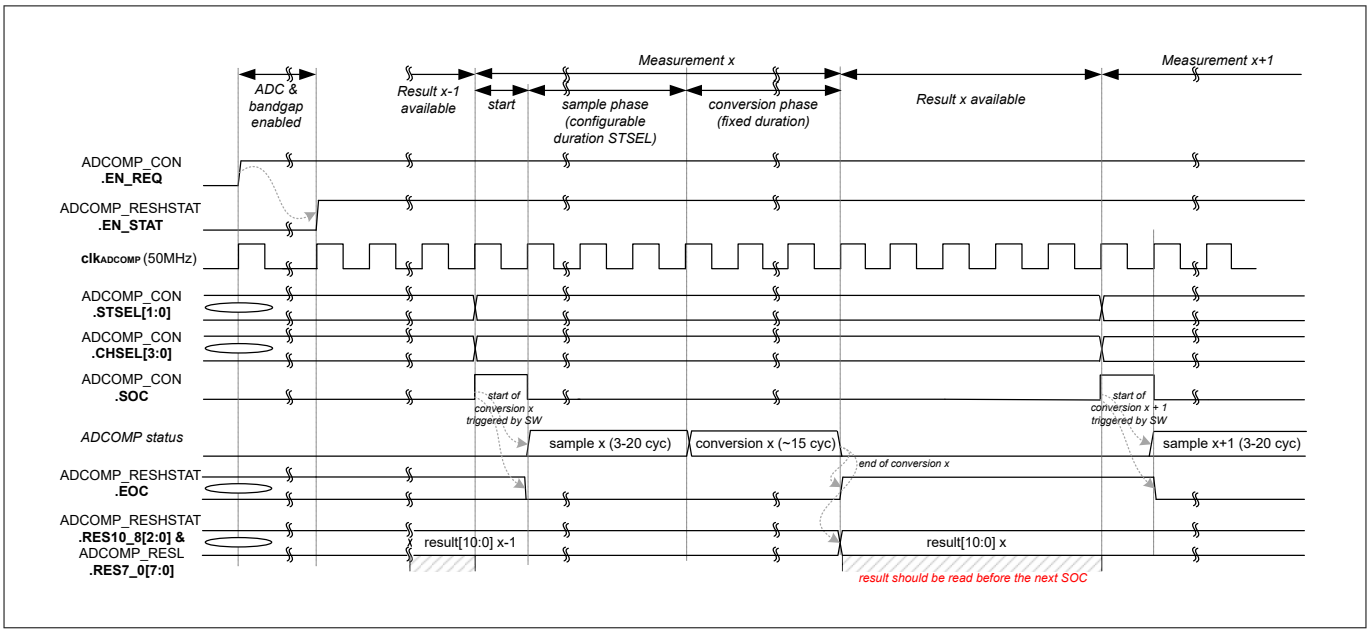

Figure 936 ADC comparator signal diagram

After ADCOMP is enabled each measurement is carried with following steps:

1. Start of conversion (SOC) is initiated by SCR software through ADCOMP_CON.SOC bit

- When the "Start of Conversion" is requested, the "End of Conversion" (EOC) bit is cleared. End of Conversion is set, when the requested conversion is finished. Start of Conversion can be set at anytime irrespective of the "EOC" flag. If Start of Conversion is requested while the conversion is ongoing that means End of Conversion flag is not set, the next conversion will be started immediately after the current conversion has ended. End of Conversion flag will be set only when the second conversion has finished

- The sampling and conversion phases are carried out back to back
- The required channel and sample time duration are selected through ADCOMP_CON.CHSEL (channel-select) and ADCOMP_CON.STSEL (sample-time-select)
  - Both ADCOMP_CON.CHSEL and ADCOMP_CON.STSEL can be set after the ADCOMP is enabled, and even in the same write access as when SOC is set to '1'
  - The sample time duration ADCOMP_CON.STSEL can be one of the four predefined values Conversion time is not configurable
  - In order to get a valid measurement the ADCOMP_CON.CHSEL value shall not be changed before end of conversion is reached

2. After each conversion phase is completed, bit ADCOMP_RESHSTAT.EOC is set

- An interrupt is triggered if enabled through IRSCR_MODIEN.ADCIEN enable bit
- The converted 11-bit result is transferred to ADCOMP_RESL.RES7_0 (lower 8 bits) and ADCOMP_RESHSTAT.RES10_8 (upper 3 bits). Result should be read before the subsequent SOC conversion event
- EOC bit serves also as a valid indication

Once the sample and conversion time (Conversion time = 15 cycles) have elapsed, a new measurement can be triggered by software. If a measurement is triggered before the end of conversion is reached, the EOC will not be signaled.

After the conversion is completed, ADCOMP unit may be disabled by clearing ADCOMP_CON.EN_REQ register bit. If ADCOMP_CON.EN_REQ is cleared during ongoing conversion, then the ADC is disabled only after the currently running conversion has ended, but the result is not saved.

In case of an LVD reset event during STANDBY1, the ADCOMP operation is aborted. Consequently, the SCR is switched off and ADC is disabled after that reset. In case of an SCR-only reset, the ADCOMP is disabled after finished conversion, similar to clearing ADCOMP_CON.EN_REQ.

39.3.14.4 ADCOMP interrupt request

Figure below illustrates the interrupt request handling of the ADCOMP module.

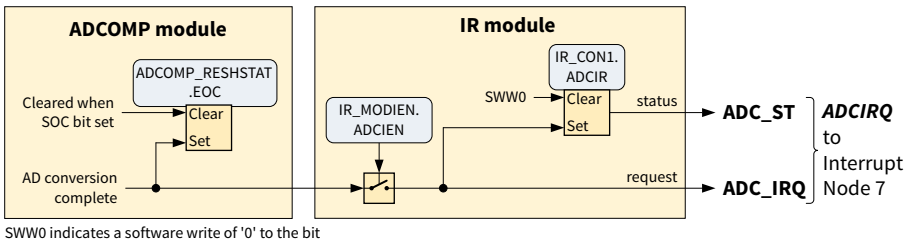

Figure 937 ADCOMP interrupt request overview

Upon completion of a conversion an interrupt is signaled to Interrupt Node 7, if ADC interrupt is enabled through IR_MODIEN.ADCIR bit. Information on interrupt request is also stored in IR_CON1.ADCIR, which should be cleared by software if set. Besides triggering an interrupt, end of conversion signal is also stored in a local ADC bit ADCOMP_RESHSTAT.EOC until the next start of conversion.

39.3.14.5 ADCOMP register overview

ADCOMP contains only 3 registers, as shown in the table below. Beside those, an interrupt enable bit ADCIEN is located inside IRSCR_MODIEN, and interrupt status flag ADCIR inside IRSCR_CON1 register.

Table 1725 Register overview - ADCOMP (sorted by name)

Short name	Description	Offset address RMAP=0, PAGE=X
ADCOMP_CON	ADCOMP control register	$C7_H$
ADCOMP_RESL	ADCOMP result register, lower 8-bits	$C8_H$
ADCOMP_RESHSTAT	ADCOMP result and status register, higher 3-bits of result	$C9_H$

39.3.15 Wake-up CAN filter (WCAN)

This chapter describes the WCAN controller of the SCR. It contains the following sections:

- Overview on the Wake-Up capabilities
- Functional description of the WCAN kernel
- WCAN Kernel register description
- Functional description on the CAN based kernel
- SCR implementation specific details and registers of the WCAN (port connections and control, interrupt control, address decoding, clock control)

39.3.15.1 Definitions and abbreviations

- WUF - Wake-Up Frame
- WUP - Wake-Up Pattern; Wake-Up Pattern detection has to be supported by external CAN transceiver and WUP detection has to be notified by transceiver to WCAN by a falling edge on RXD. To keep the context simple, the term Wake-Up Pattern is used in WCAN specification

39.3.15.2 Wake-up CAN filter implementation

39.3.15.2.1 Overview

This section describes the ISO 11898-6 datalink layer. The Wake-Up CAN module contains 1 CAN node, representing only the receive part of the communication interface. Furthermore, the Wake-Up CAN filter functionality and interfaces in TC4Dx.

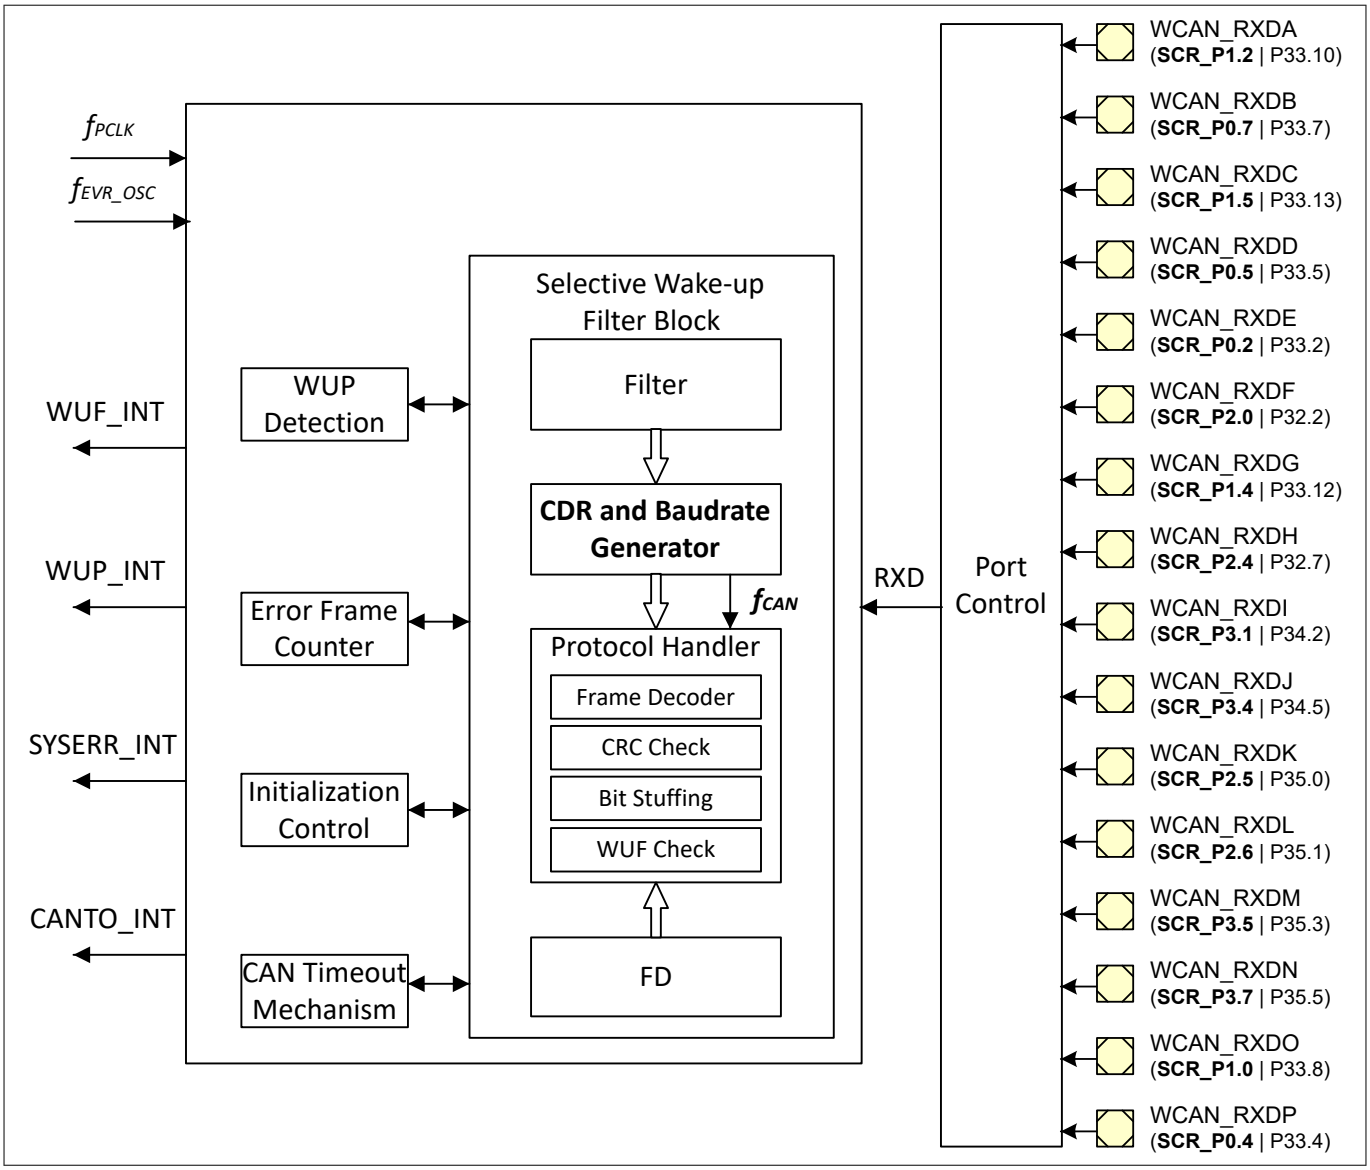

Figure 938 Wake-up CAN filter interfaces

39.3.15.2.2 WCAN filter features

The following are the feature list for WCAN module in SCR:

- Wake-Up CAN functionality similar to ISO 11898-6
- 1 Wake-Up CAN node
- Guaranteed data transfer rate up to 500 KBit/s. Default settings for 125 KBit/s, 250 KBit/s and 500 KBit/s are according to the given propagation delays
- 1 Wake-up frame configuration registers to the wake-up node:
  - Set up to handle frames with 11-bit and/or 29-bit identifiers
  - Programmable acceptance mask register for filtering
  - Programmable Wake-Up message ID, DLC and data
- Wake-Up CAN message time-out feature
- Power saving through Standby Mode on CAN message time-out
- WUP detection by monitoring falling edge on RXD when in Standby Mode

- Tolerant to CAN FD frames
- Error counter to de-bounce CAN protocol and Wake-Up function errors
- Interrupt generation on:
  - Successful Wake-Up message frame reception
  - Error recognition
  - Wake-Up CAN timeout
  - WUP (falling edge on RXD) detection

39.3.15.2.3 Introduction

Feature overview

Reception and evaluation of CAN frames is handled in like in CAN specification ISO 11898-2 (formally known as ISO11898-6) data link layer. The received messages will be compared against the programmed wake-up pattern and in case of pattern match, a wake-up will be issued. In case of an erroneous understanding or errors on the bus, the receive error counter can also reach a wake-up threshold. The node will be purely listening to the bus and will not communicate to the outside. The CAN node has Wake-Up Frame (WUF) configuration registers. In these WUF registers, the identifier including a bit-wise mask, the corresponding DLC as well as a data mask is included. Only (outside the erroneous case), if all criteria match, a wake-up will be initiated. The bit timings for the CAN nodes are derived from the CAN clock (f_{CAN}) and are programmable up to a data rate of 1 MBit/s, nonetheless guaranteed wake-up is only given for special configurations according to the propagation delay defined by the German OEMs.

Features:

- Similar to ISO 11898-2
- Receive operation similar to ISO 11898-2
- Tolerant to CAN FD frames
- Dedicated control registers for the CAN node. Data transfer rates are guaranteed until 500 kBit/s, in case of higher baudrates, more wake-up frames might be needed. Transmitter tolerances up to 0.4% are calculated and guaranteed with CDR enabled. Higher transmitter tolerances are not pretested
  - The message buffer can be configured to accept only standard or only extended Classical frames as valid Wake-Up frame
- Four interrupt sources do exist, wake-up frame found, $t_{SILENCE}$ expired, error overflow and WUP detected

39.3.15.2.4 WCAN initialization sequence

In order to initialize the WCAN module, the following sequence has to be performed:

- Enable WCAN module by setting SCUSCR_PMCON0.WCAN_DIS = 1
- Enable WCAN input pin SCR_Pn_PDISC.PDISm = 0
- Set WCAN_CFG.WCAN_EN = 1
- Set WCAN_CFG.CCE = 1
- Configure CDR,CAN FD and baudrate configuration registers
- Reset WCAN_CFG.CCE = 0
- Reset WCAN_CFG.SELWK_EN = 0
- Configure WUF configuration registers
- Set WCAN_CFG.SELWK_EN = 1
- Wait until WCAN_INTESTAT0.SWACK = 1

In order to perform only reconfiguration of the WUF configuration registers, the following sequence has to be performed

- Set WCAN_CFG.WCAN_EN = 1
- Reset WCAN_CFG.SELWK_EN = 0
- Wait until WCAN_INTESTAT0.SWACK = 0
- Configure WUF configuration registers
- Set WCAN_CFG.SELWK_EN = 1b
- Wait until WCAN_INTESTAT0.SWACK = 1

After the initialization/WUF reconfiguration sequence is performed, the application software has to check the WCAN_INTESTAT1.SWKSET bit-field to verify if the Selective Wake-Up feature is successfully enabled or not. The WCAN_INTESTAT1.SWKSET bit-field is set to 1 if all of the below mentioned conditions are true, and it is cleared if any of the conditions is not met.

- WCAN_CFG.WCAN_EN = 1b
- WCAN_CFG.CCE = 0b
- WCAN_INTESTAT0.SWACK = 1b
- WCAN_INTESTAT0.MODE = 0b
- f_{BACK} is switched on

***Note**: If application software writes either WCAN_CFG.CCE = 1 or WCAN_CFG.SELWK_EN = 0b when WCAN is already active, then any ongoing reception will be lost. If WCAN_CFG.WCAN_EN = 0 when WCAN is already active, then the selective wake-Up filter block will be in halt state and the application software has to perform re-initialization based on the sequence given above.*

39.3.15.2.5 Wake-up frame configuration and detection

The received frame is compared to the configured wake-up frame and in case a match is detected a wake-up request is issued. The wake-up request sets the WCAN_INTESTAT1.WUF flag and issues WUF_INT interrupt if not masked by WCAN_INTMRSLT.WUFMASK. Only a matched Classical CAN frame can lead to WUF detection.

***Note**: In addition to the message object configuration registers (i.e. WCAN_DLC_CTRL, IDn_CTRL(n=0-3), MASK_IDn_CTRL(n=0-3), WCAN_DATAn_CTRL) the node bit timing configuration is configured in the BTLn_CTRL(n=1-2) register.*

Configuration of wake-up frame filter

The message object configuration of the wake-up frame is done in the following registers:

- Register IDn_CTRL(n=0-3)) contains the CAN identifier filter bits
- Register MASK_IDn_CTRL(n=0-3) contains the ID mask bits
- Register WCAN_DLC_CTRL are the data length code filter bits
- Register WCAN_DATAn_CTRL are the data filter bits

Detection of wake-up frame filter

The compare mechanisms are different according to the information field inside the CAN frame:

- The identifier programmed inside IDn_CTRL(n=0-3) and MASK_IDn_CTRL(n=0-3) has to match the data in the received frame and the logic seen in Figure 939, a wake-up condition is detected
- The DLC programmed in WCAN_DLC_CTRL together with the data filter bits in WCAN_DATAn_CTRL will be compared to the DLC and data inside the received frame, in case a single ‘1’ match in WCAN_DATAn_CTRL,

a wake-up condition within the data is detected. DLC values greater than 8 will be treated as 8. See following figure

If and only if, identifier and masking, the WCAN_DLC_CTRL and the WCAN_DATAn_CTRL will lead to a match, a valid wake-up Frame (WUF) is detected and a wake-up interrupt will be issued if WCAN_CFG.SELWK_EN is enabled.

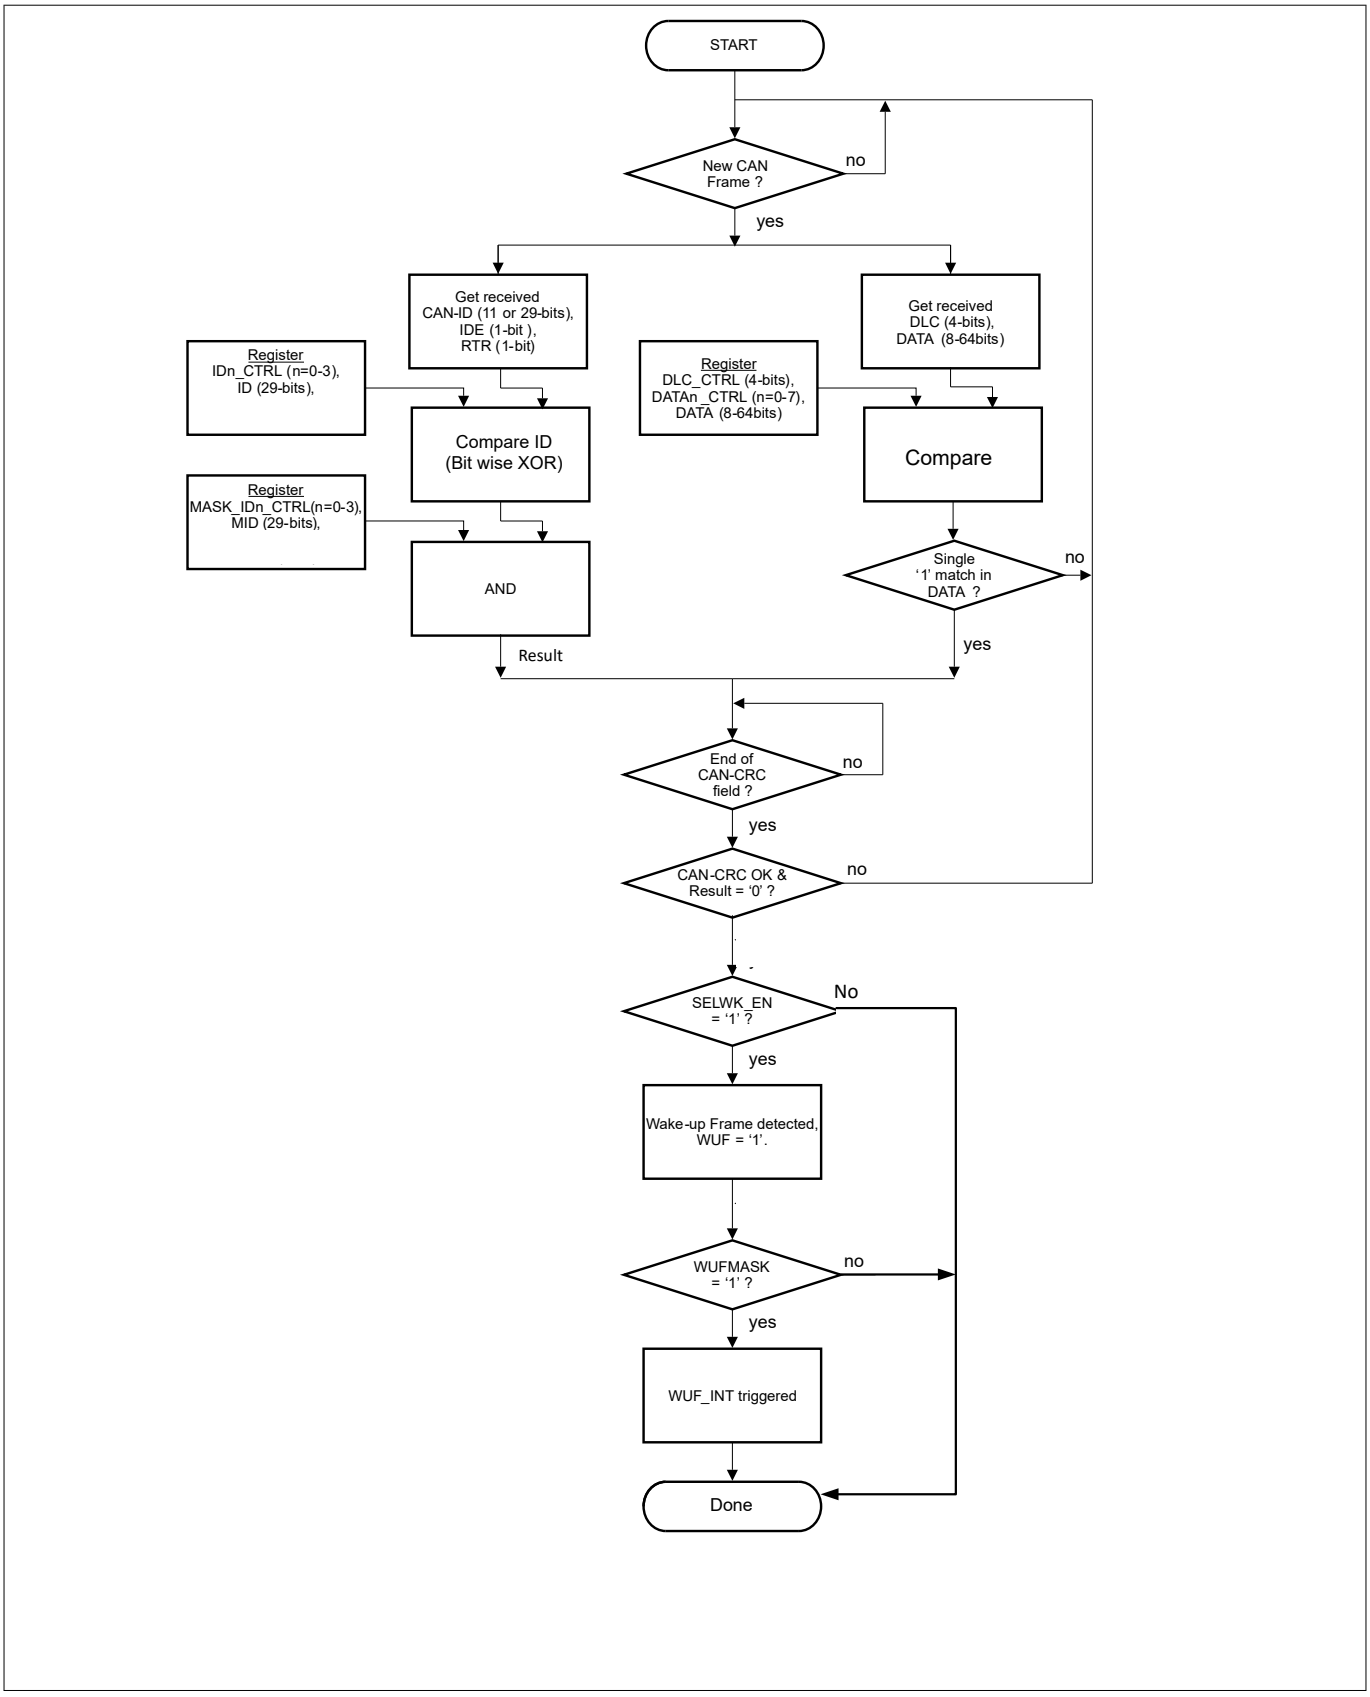

Figure 939 Wake-up frame detection

39.3.15.2.6 CAN message timeout

A timeout mechanism to monitor CAN bus activity is available on the WCAN. The timeout mechanism monitors the RXDC0 pin. When the RXDC0 pin is inactive for a $t_{SILENCE}$ time of 750 ms, both CAN bus silent bit (WCAN_INTESTAT1.CANSIL) and if selective Wake-Up is enabled, CAN timeout bit (WCAN_INTESTAT0.CANTO) will be set with a CAN time out interrupt (CANTO_INT). An occurrence of CAN Timeout will clear the error counter.

The CAN bus silent bit (WCAN_INTESTAT1.CANSIL) is reset when there is activity on the CAN bus where else the CAN timeout bit can be reset by setting CAN time out clear bit (WCAN_INTESCLR0.CANTOCLR). When WCAN_CFG.WCAN_EN = 0, the timeout counter remains in the reset state. The WCAN_INTESTAT1.CANSIL can also be cleared by setting WCAN_INTESCLR1.CANSILCLR.

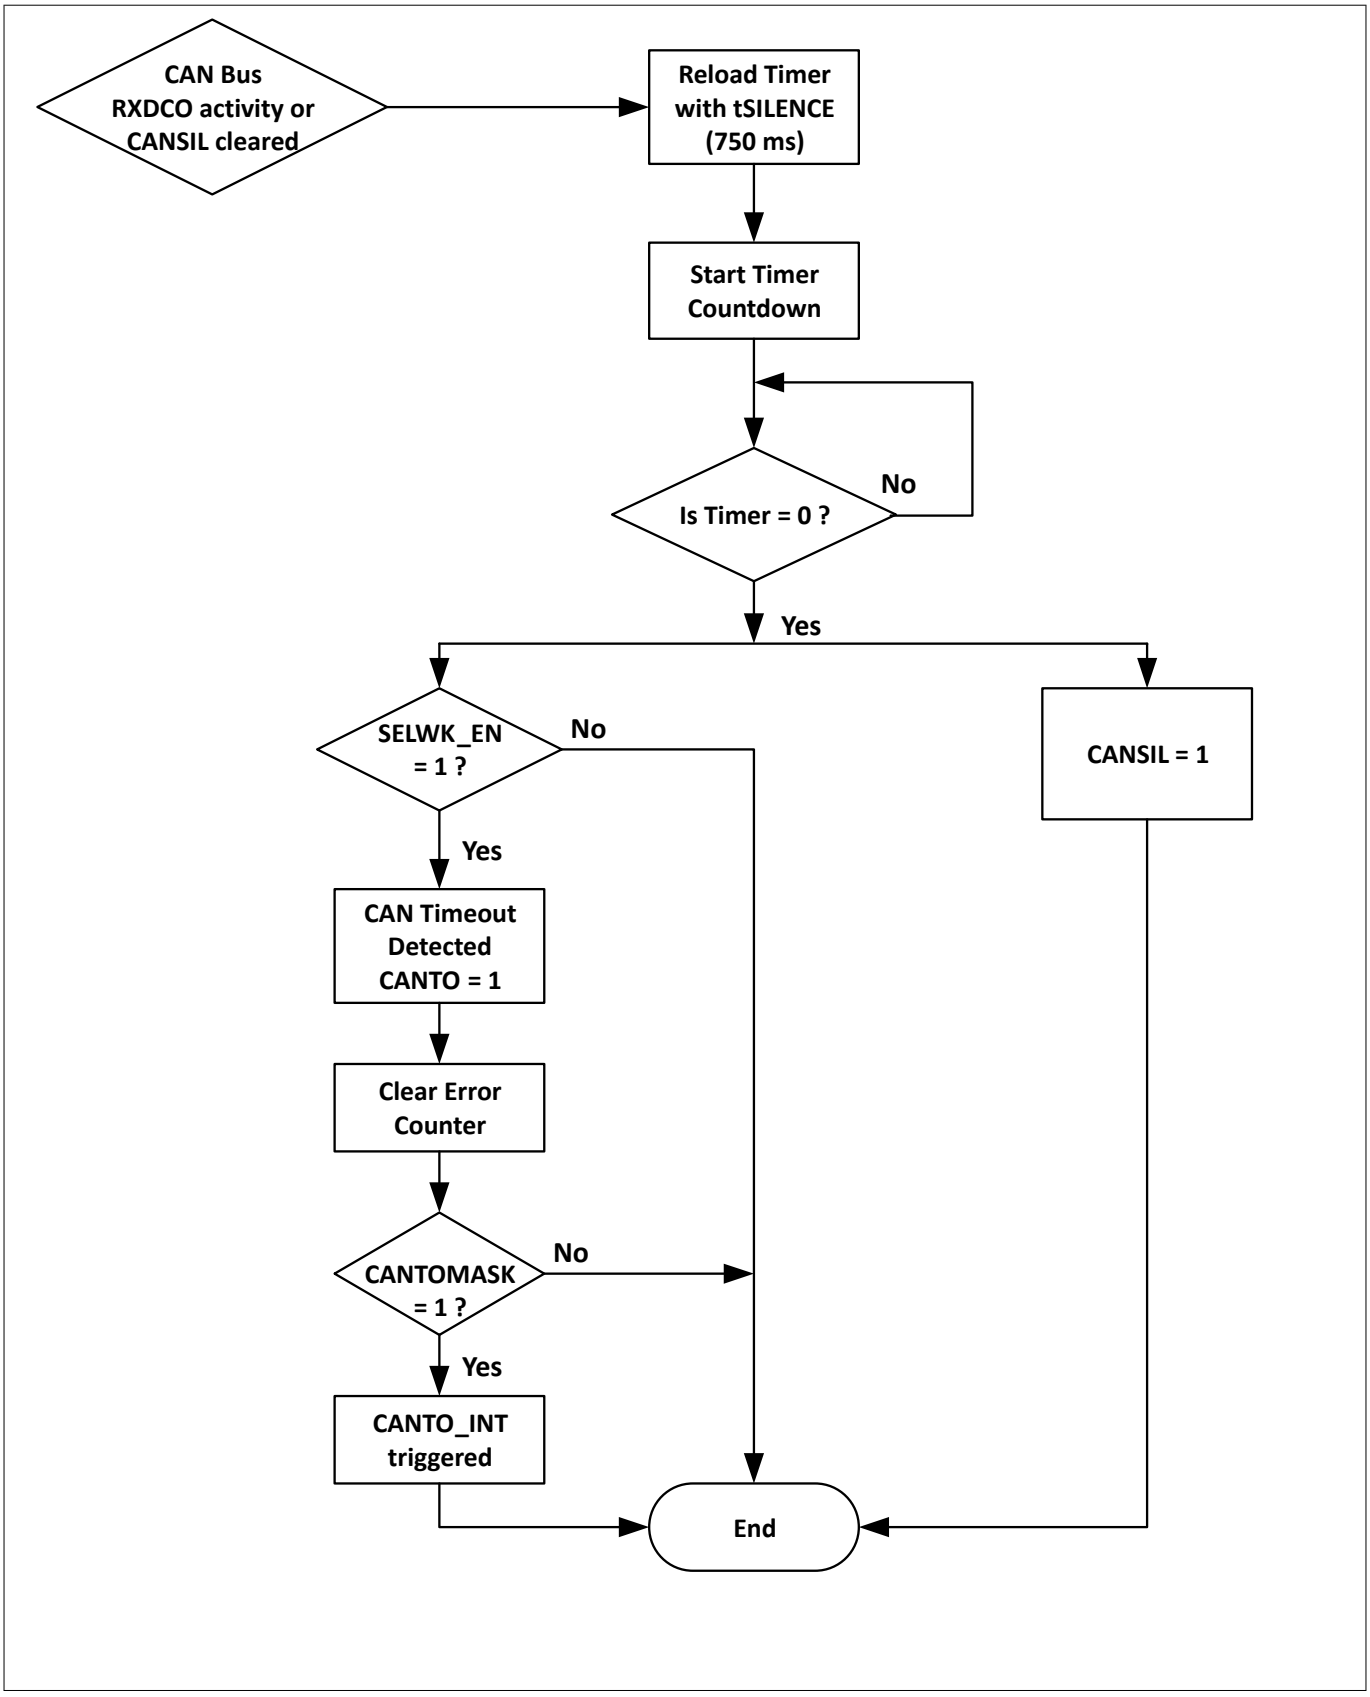

Figure 940 CAN timeout

39.3.15.2.7 Error counter

The error counting mechanism in ISO 11898-6 is different to ISO 11898-1. As the device is only receiving messages and never transmitting it could never get into a bus-off situation. Therefore an ISO11898-6 implementation is incrementing its error counter on a Form, Stuff and a CRC error. In case of a correct message, the error counter will be decremented, if it is greater than 0. In case the error counter is greater than 31 an overflow occurs and a wake-up will be initiated. This shall enable the software to correct the situation. In case of overflow the WCAN_INTESTAT0.SYSERR and WCAN_INTESTAT0.ECOFL flags are set. The error counter is cleared when timeout has occurred or when WCAN_CFG.SELWK_EN is re-enabled (from '0' to '1'). If the CAN FD tolerance feature is enabled and a CAN FD frame is received, the error monitoring is done only until WCAN_INTESCLR1.FDF bit-field. The behavior of the error counter for CAN FD frames is based on WCAN_FRMERRCNT.FDEC_DIS bit-field. The conditions at which error counter is incremented or decremented is given in the table below. The WCAN_INTESTAT0.ECOFL flags can be cleared by writing WCAN_INTESCLR0.ECOFLCLR to '1'.

***Note**: If ECNTCLR is written to '1' and at the same time an error in received frame has occurred, the error counter will remain cleared and it will not be incremented.*

Table 1726 Error counter conditions

WCAN_FD_CTRL.**FDEN**	WCAN_FRMERRCNT.**FDEC_DIS**	**Behavior of error counter**
0	X	Decrement on: • Valid classical CAN frame Increment on: • Corrupt classical CAN frame • CAN FD frame
1	0	Decrement on: • Valid classical or CAN FD frame Increment on: • Corrupt CAN FD frame • Corrupt classical CAN frame
1	1	Decrement on: • Valid classical CAN frame Increment on: • Corrupt classical CAN frame No action: • CAN FD frame

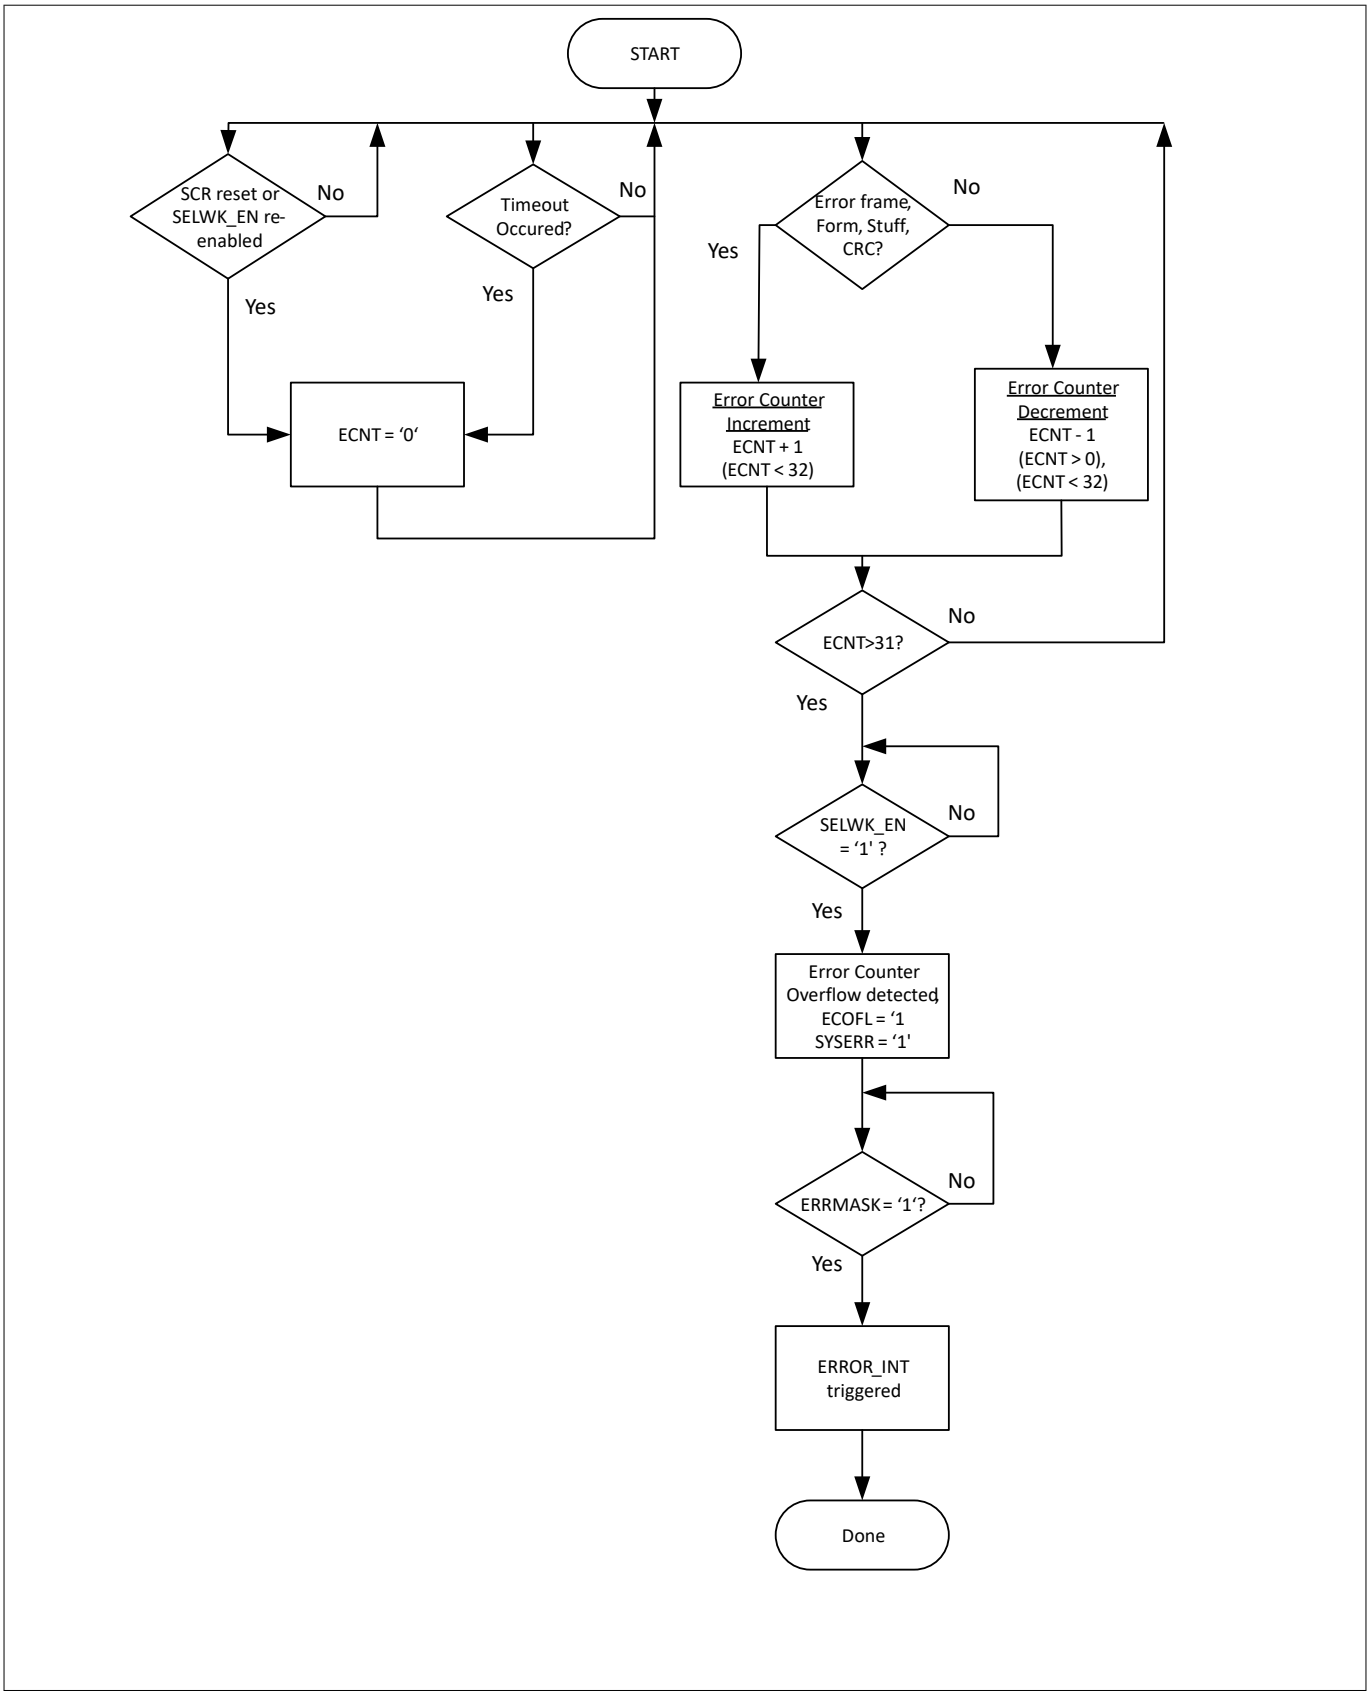

Figure 941 Error counter

39.3.15.3 WUP detection

WCAN supports WUP detection by waking up on a low level detected on RXD when a wake-up is sent on the bus. The WUP is detected by the CAN Transceiver. In case the CAN Transceiver does not support Wake-Up Pattern detection, then WCAN considers any low level on RXD as WUP. In WCAN, the WUP detection is active only when the Selective Wake-Up feature is enabled and CAN timeout has occurred. On occurrence of "CAN Timeout", WCAN enters into a Standby mode.

When WCAN is in Standby Mode:

- The Protocol Handler is reset and Selective Wake-Up feature is disabled
- The Clock to the Protocol Handler is switched off to save power
- WUP detection is active, waiting for a low level on RXD (decoding of the WUP itself should be done by the CAN Transceiver)
- WCAN_INTESTAT0.MODE = 1 and WCAN_INTESTAT1.SWKSET = 0

***Note**: In WCAN Standby mode, the WUP detection is active even when 100 MHz f_{BACK} is switched-off. In such a case, the WUP detection will be performed with 70 kHz clock, but with a risk that the low level might be missed. In-order to save power when WCAN in standby mode, the application software may disable 100 MHz f_{BACK}, and only 70 kHz clock can be provided. The 100 MHz f_{BACK} is automatically turned-on when WUP is detected.*

When WUP is detected in Standby Mode, the WCAN enters into the Normal Mode, where:

- Selective Wake-Up feature is re-enabled
- The clock to the protocol handler is active
- Error Counter is reset to 0
- 100 MHz f_{BACK} enable is requested (SCUSCR_CLK.DIV_REQ is set to 4 (DIV5, 20 MHz)), when 100 MHz f_{BACK} is disabled in Standby Mode
- WCAN_INTESTAT0.MODE = 0, WCAN_INTESTAT1.SWKSET = 1 and WCAN_INTESTAT0.WUP = 1
- WUP_INT is triggered when it is not masked through WCAN_INTMRSLT.WUPMASK

The application software can make WCAN to leave the Standby Mode by SCR Reset or by disabling WCAN (WCAN_CFG.WCAN_EN = 0). The figure below shows the state diagram on transition of WCAN between different modes of operation.

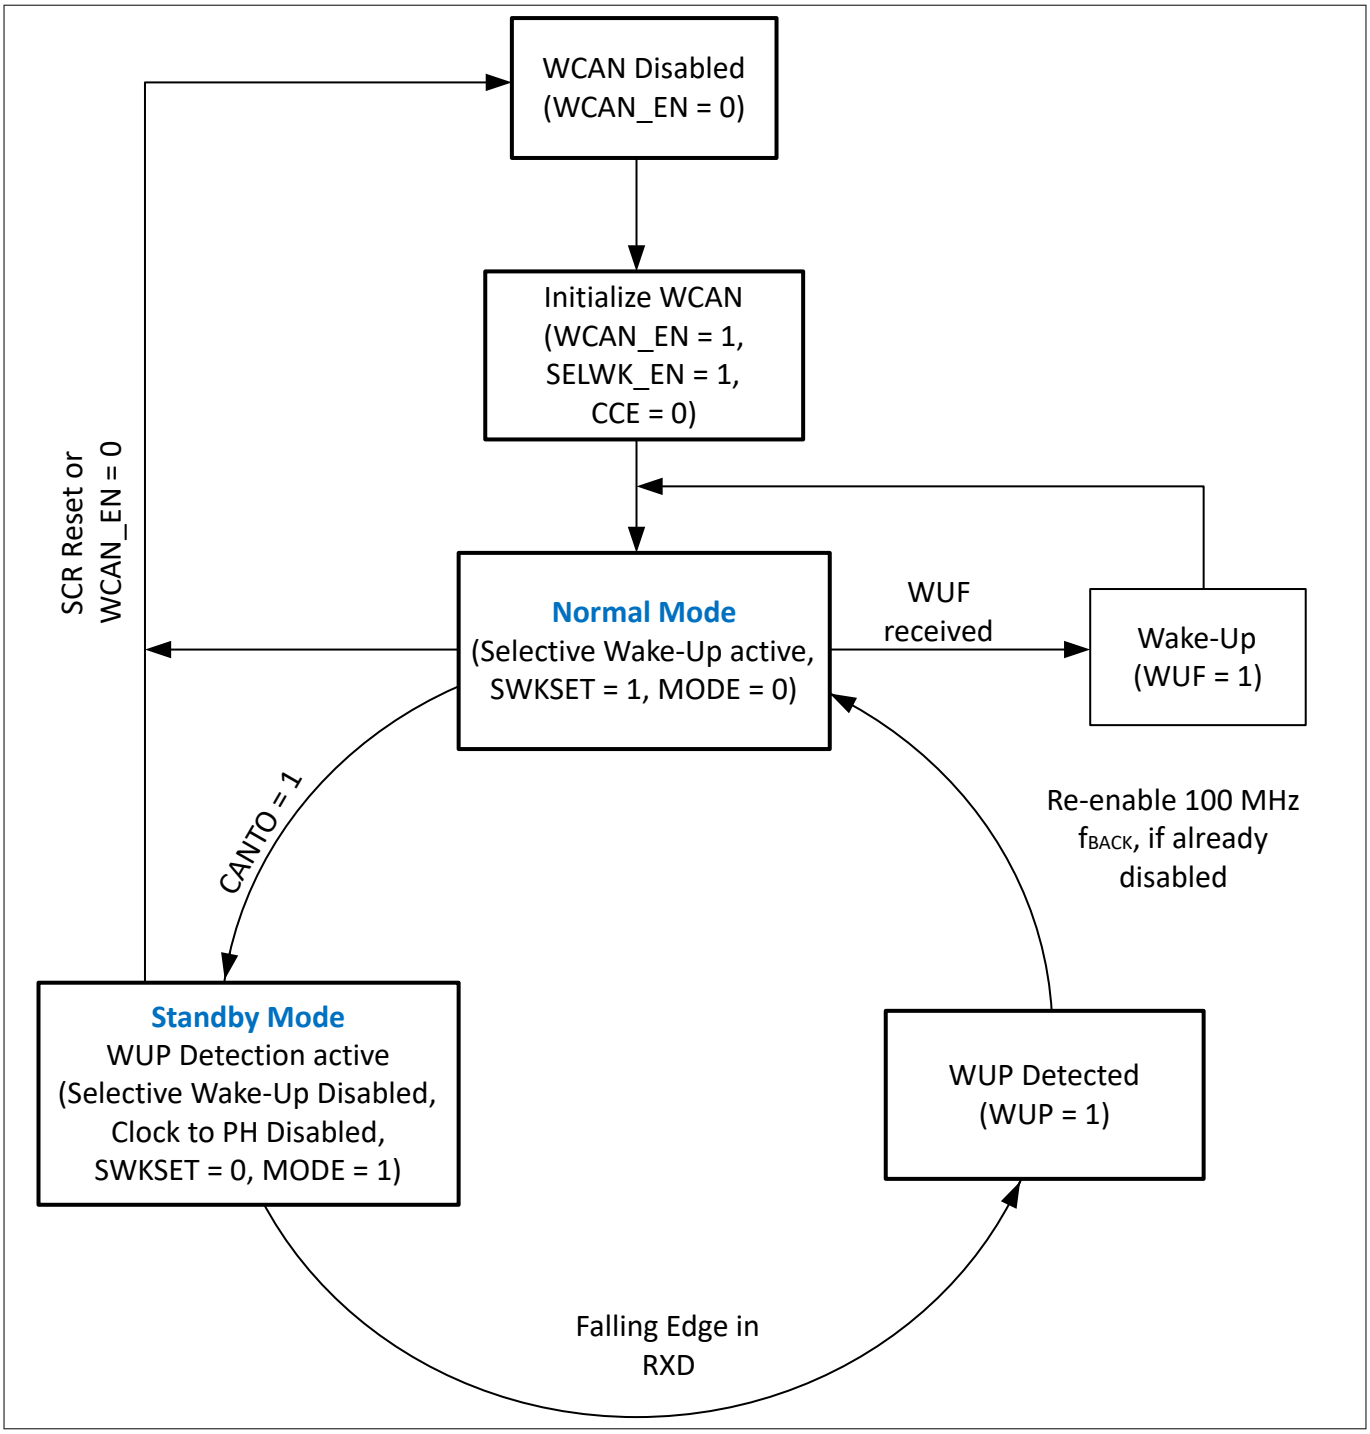

Figure 942 WCAN modes of operation

39.3.15.4 CAN functional description

39.3.15.4.1 CAN node control

The CAN node is equipped with an individual set of SFR registers to control and to monitor the CAN node.

Baudrate pre-scaler

The WCAN has an integer divider with a scaling factor defined by the WCAN_BTL2_CTRL.BRP bit-field. The f_{BACK} is the input frequency and the f_{CAN} is the scaled output frequency of the integer divider. The WCAN_BTL2_CTRL.BRP bit-field is recommended to be configured based on the baudrates required as shown in table 'Bit Timing and RXD Filter configuration - Recommended' (see related information), because WCAN_BTL2_CTRL.BRP values influences the receive input filter time and CAN FD filter time. The f_{CAN} frequency is fed to the Receive Input Filter and CDR (to measure the sample point). When 100 MHz f_{BACK} is switched off, the Selective Wake-Up filter block will be reset and then f_{CAN} is also switched off.

***Note**: The Selective wake-up feature cannot be used for example, if WCAN_INTESTAT1.SWKSET = 0.*

Filter and sample point calculation on page 6669

Receive input filter

The RXD signal coming from the transceiver, is filtered to eliminate the jitter effects from the CAN bus, The filter time is dependent on the recommended baud rate configuration and the WCAN_BTL2_CTRL.BRP values (table 'Bit Timing and RXD Filter configuration - Recommended' in related information). The filtering is done based on f_{WCAN} frequency. The filtering time T_filt is based on the END COUNT value for different WCAN_BTL2_CTRL.BRP as shown in the related table. The filter has an asymmetrical behavior as shown in the following figure.

The first recessive to dominant edge is detected asynchronously, and the event is used for the starting of the filter counter. Once the counter reaches the END COUNT value, the RXD is checked again if it is still ‘0’, then the synchronization edge is considered valid. Therefore, the filter introduces a delay of T_filt.

At dominant to recessive edge, RXD is checked at each f_{WCAN} clock cycle. The RXD_FILT output is ‘1’ only if the input signal is a stable recessive for entire filtering time (T_filt). The recessive bits shorter than t_glitch are filtered out and only recessive bits longer that t-detect are considered valid.

When CAN FD tolerance is enable, the received input signal RXD is used directly without filtering for the data phase, to avoid the additional filter delay.

The logic level of the filtered input RXD_FILT is shown in WCAN_INTESTAT1.RXDF.

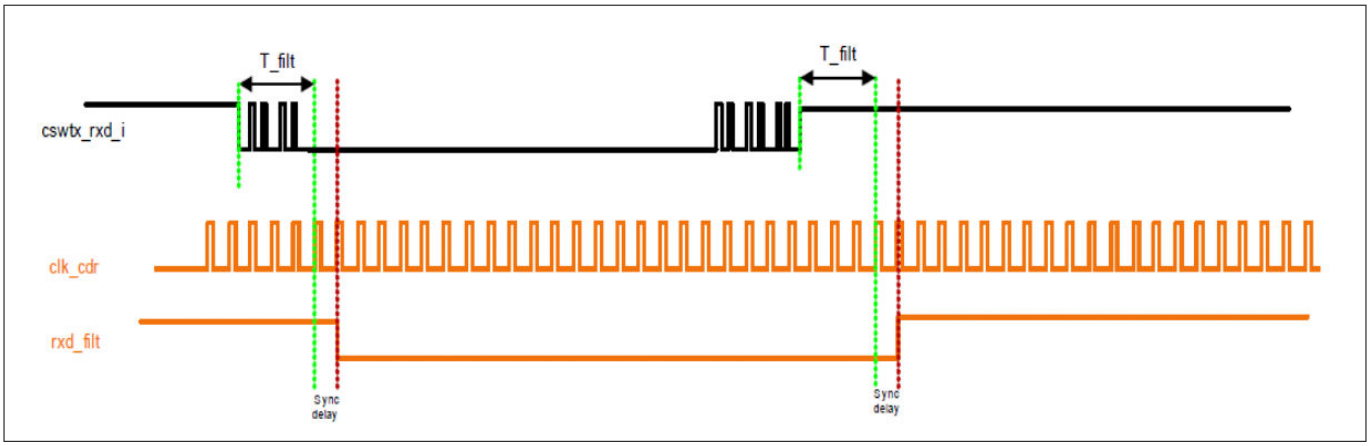

Figure 943 RXD filtering

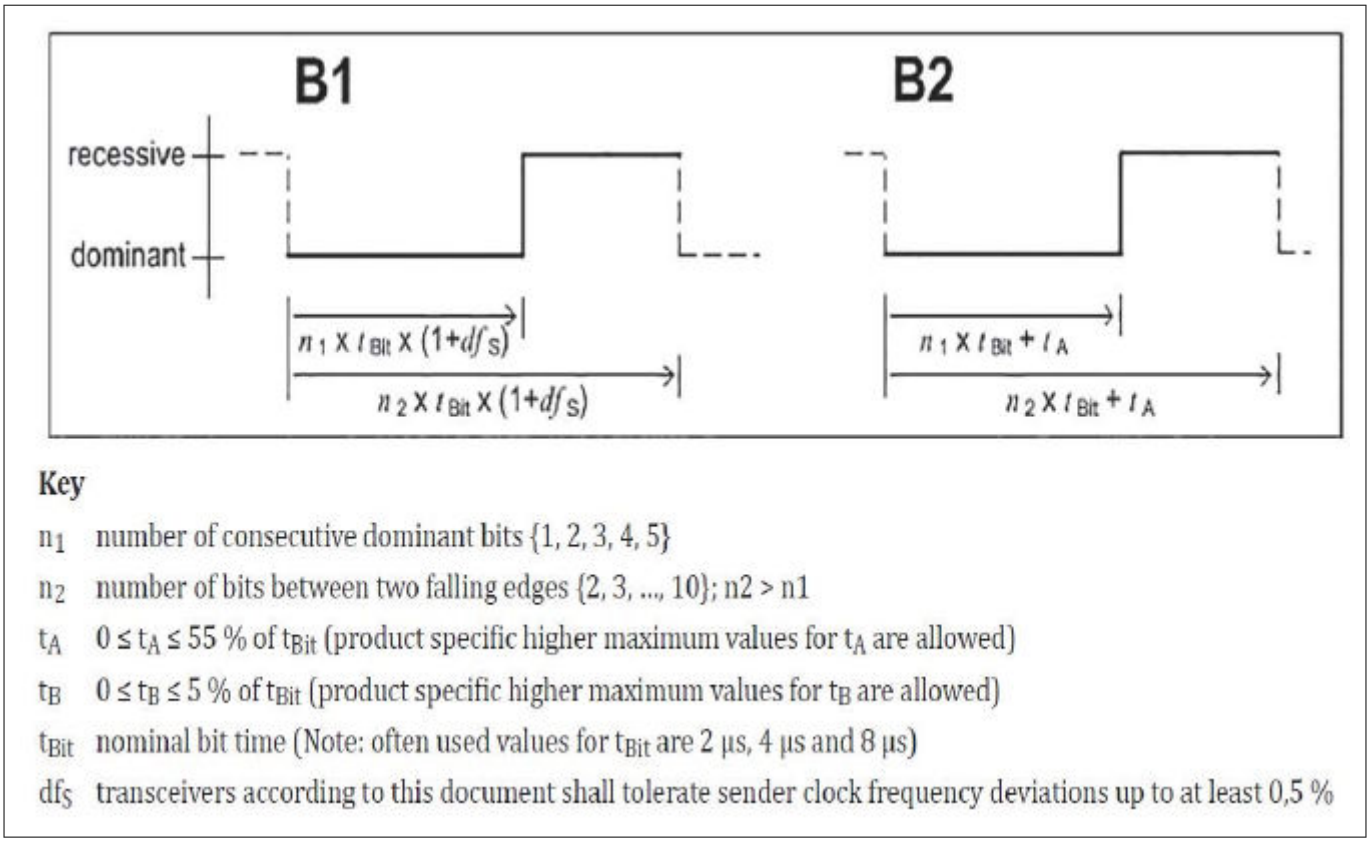
Filter and sample point calculation on page 6669

Bit timing

According to ISO 11898-2 (here the ISO11898-6 part) standard, a received classical CAN frame can be decoded correctly when the timing of the CAN bit fields complies with multiple instances of signal shape B1 and one instance of signal shape B2 (to handle the sender clock tolerance and loss of arbitration). In order to compensate possible deviations of the CAN oscillator frequency, integrated clock and data recovery is used (CDR). The CDR can be optionally enabled or disabled using WCAN_CDR_CTRL.CDREN bit-field. It is recommended to always enable the CDR feature. If CDR is disabled, the required oscillator tolerance is 1% or else it is 4%. When CDR is disabled, the sample point position is calculated directly based on BTLn_CTRL (n=1,2) values. Before enabling the CDR, the bit timings parameters have to be properly configured as shown in table 'Bit Timing and RXD Filter configuration - Recommended' in related information. When CAN FD tolerance is enabled WCAN_FD_CTRL.FDEN = 1, the CDR is stopped during CAN FD frame reception, in order to avoid calculation based on high baudrate data phase. The CDR is kept at last calculated value before CAN FD has been detected.



Key

n_1	number of consecutive dominant bits {1, 2, 3, 4, 5}
n_2	number of bits between two falling edges {2, 3, ..., 10}; n2 > n1
t_A	$0 \le t_A \le 55$ % of t_{Bit} (product specific higher maximum values for t_A are allowed)
t_B	$0 \le t_B \le 5$ % of t_{Bit} (product specific higher maximum values for t_B are allowed)
t_{Bit}	nominal bit time (Note: often used values for t_{Bit} are 2 µs, 4 µs and 8 µs)
df_S	transceivers according to this document shall tolerate sender clock frequency deviations up to at least 0,5 %

Figure 944 CAN bit timing signal shape

Clock and Data Recovery (CDR)

The CDR consists of three building blocks as shown in the following figure. The CDR uses the f_{WCAN} clock. This clock period defines the duration of one time quanta. For ISO 11898-2 some settings are guaranteed to be working according to the given propagation delay times (see Network Propagation Delays in related information). Working settings for 125 kBit/s, 250 kBit/s and 500 kBit/s will be provided. The acquisition counter of CDR measures the CAN bit timings in terms of number of time-quanta. The sample point calculation evaluates the new sample point based on the computed CAN bit length and the sample point position configured in WCAN_BTL2_CTRL. The filter block is used to compensate the error introduced during internal measurement of number of time-quanta in one bit time.

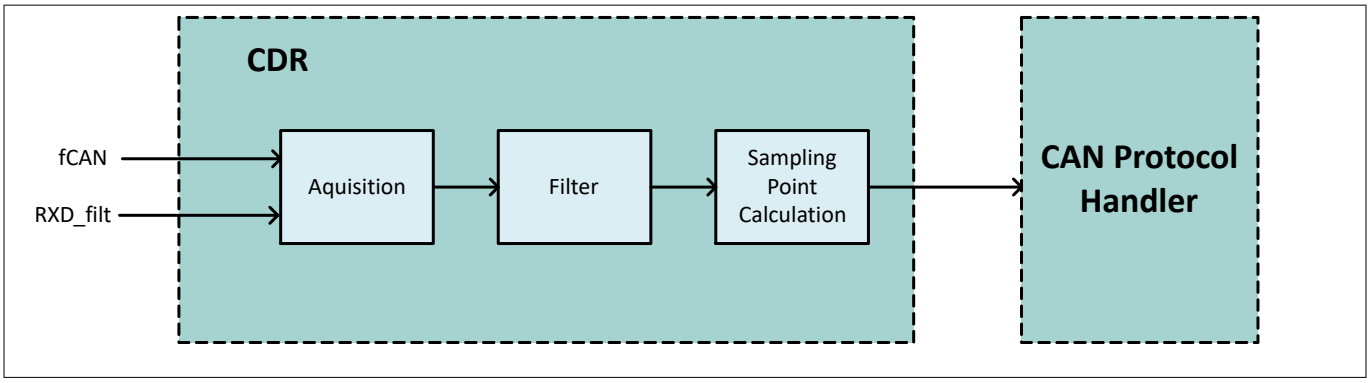


Figure 945 CDR block diagram

The configuration change enable, WCAN_CFG.CCE has to be enabled before a valid CAN bit timing can be written to the CAN Node Bit Timing Register, BTLn_CTRL (n=1-2). This is then followed by resetting WCAN_CFG.CCE bit before enabling the operation of the CAN node.

***Note**: The proposed sample point is at 80% of the bit time.*

Related information

Filter and sample point calculation on page 6669
Network propagation delays on page 6670

Acquisition counter

The acquisition counter measures the bit timing based on the number of time-quanta between two synchronization events (i.e., recessive to dominant transition of the filtered RX signal). The counter is active only if WCAN_CDR_CTRL.CDREN=1 and enabled by the protocol handler. The protocol handler enables the acquisition outside the arbitration phase, where CAN bit shortenings and extension are likely to occur. The only exception to that scenario is when an error is detected in the arbitration phase. In that case, the acquisition is enabled for preventing deadlock situation when the oscillator is outside the range and error occurs during Arbitration. The synchronization edges occurring within an error frame are canceled by the windowing of acquisition. Based on the counter value, the number of CAN bits received between two synchronization events can be determined. This value is between 2 and 10, in accordance to the bit-stuffing rule.

Filter and sample point calculation

The sample point calculation block evaluates the sampling position of the CAN bus bit based on the information from the "Acquisition Counter" and from the CDR configuration registers. Depending on the selected frequency and the baudrate, the default number of actual clock pulses expected during a CAN bus bit time is configured in WCAN_BTL1_CTRL register. The sampling position of the CAN bit is defined in BTL2_CTRL.SP bit-field. It can be calculated as follows

BTL2_CTRL.SP = (64*sampling point)/100

***Note**: For example: A sampling point at 80% of bit time corresponds to WCAN_BTL2_CTRL.SP = 33_H.*

The number of time-quanta in one CAN bit time (tbit_calc) is measured internally based on the output from the acquisition counter and the expected number of time-quanta in one CAN bit time as provided by WCAN_BTL1_CTRL. This measured value can be read from the WCAN_CDR_MEAS_HIGH and WCAN_CDR_MEAS_LOW. The error introduced during the measurement is compensated using the Error scaling factor. During successive CDR measurements, the new bit timing value is evaluated by an averaging algorithm:

tbit_new = tbit_calc + error / SEL_FILT

where SEL_FILT is the error scaling factor (for example the value over how many acquisition cycles the average will be built) as described in Table below.

Table 1727 Number of acquisitions based on ESF

ESF	SEL_FILT
00_B	8
01_B	16 (recommended)
10_B	32
11_B	Adaptive averaging (based on number of bits between two consecutive synchronization edges) 2, 3 or 4 CAN bits = 32 5 or 6 CAN bits = 16 7, 8 or 9 CAN bits = 8

The sample point is then calculated based on WCAN_BTL2_CTRL and tbit_new. The sampling point is calculated only when tbit_new falls within the range defined by WCAN_CDR_LOWER_CTRL.LOWER and WCAN_CDR_UPPER_CTRL.UPPER. If not, the sample point is calculated directly based on the t_{bit} value defined in WCAN_BTL1_CTRL.

Table 1728 Bit-timing and RXD filter configuration - recommended

Baudrate (kBit/s)	BRP	BTL1_CTRL	RXD Filter END COUNT	t_glitch (ns)	t-detect (ns)
1000	00_B	64_H	24	200	400
500	01_B	64_H	16	250	500
250	10_B	64_H	8	250	500
125	11_B	64_H	8	400	1400

Network propagation delays

The “worst case” network propagation delay is the network propagation delay after the 5th bit for the dominant to recessive edge on the bus. (See following figure)

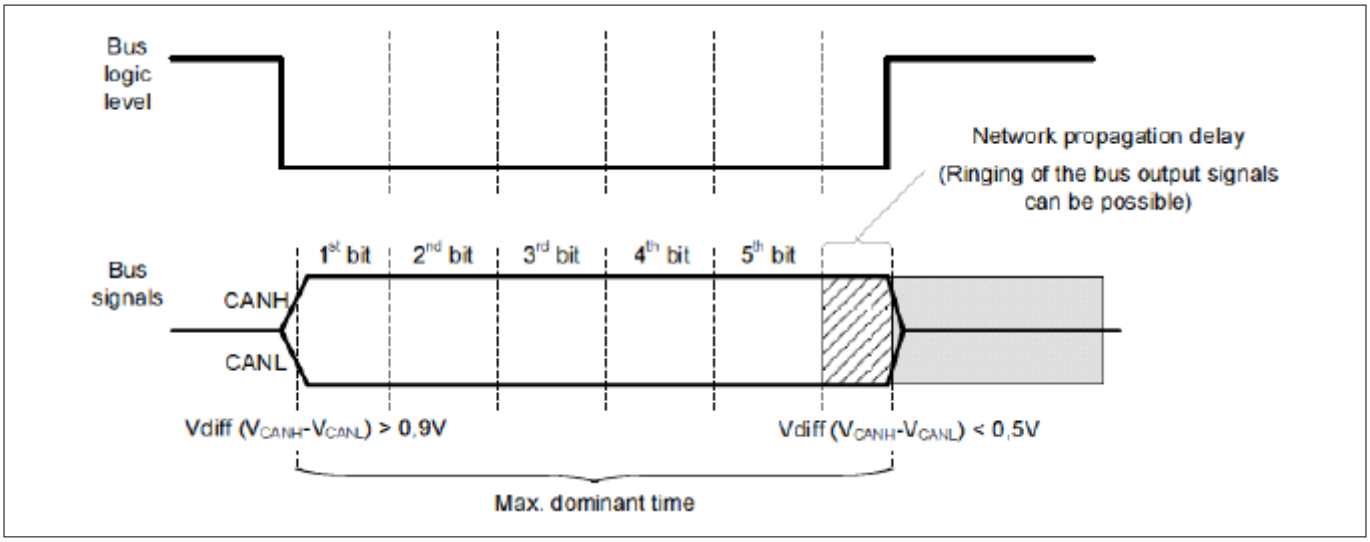

Figure 946 Network propagation delay after 5th bit

The WCAN module will be capable of sampling the recessive stuff bit after 5 consecutive dominant bits to ensure a safe wake-up, even if the dominant to recessive edge is delayed for the value of the network propagation delay shown in the following table. The network propagation delay describes the maximal occurrence propagation delay which can be seen on the bus. This maximum network propagation delay does not include any EMC jitter (i.e no HF injection).

Table 1729 Network propagation delay

Baudrate (Baud)	Network propagation delay (ns)	Maximum dominant time (ns) (sender oscillator tolerance included)
1 MBaud	550	5550
500 kBaud	1350	11350
250 kBaud	2675	22675
125 kBaud	5450	45450

For HF injection the WCAN module is able to handle EMC network propagation delay as shown in following table.

Table 1730 EMC network propagation delay

Baudrate (Baud)	Network propagation delay (ns)	Maximum dominant time (ns) (sender oscillator tolerance included)
1 MBaud	450	5450
500 kBaud	1250	11250
250 kBaud	2575	22575
125 kBaud	5350	45350

Also the WCAN module is able to decode frames that contain sequences of 5 consecutive dominant bits followed by 5 consecutive recessive bits as shown in the previous figure.

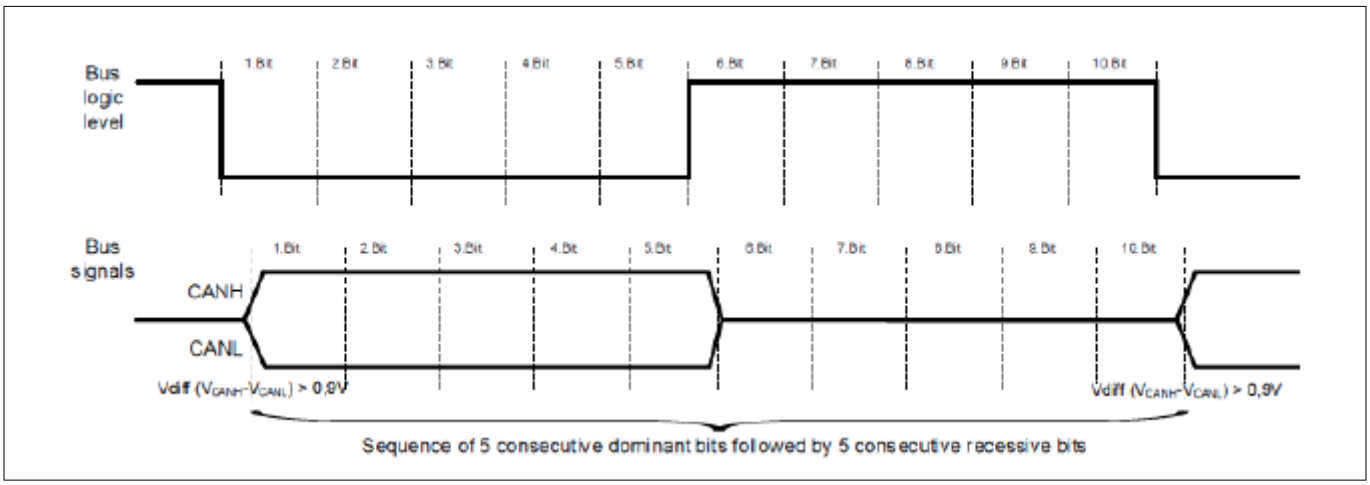

Figure 947 Network propagation delay after 10th bit

The transmitting CAN node on the bus has to guarantee a maximum baudrate tolerance of +/- 0.4% for correct detection of the CAN frames (See following table)

Table 1731 Worst case length of 10 bits

Baudrate (Baud)	Worst case time for length of 10 bits by sender oscillator tolerance (-0.4%)	Worst case time for length of 10 bits by sender oscillator tolerance (+0.4%)
1 MBaud	9960 ns	10040 ns
500 kBaud	19920 ns	20080 ns
250 kBaud	39840 ns	40160 ns
125 kBaud	79680 ns	80320 ns

CAN FD tolerance

The WCAN can be configured as CAN FD tolerant (WCAN_FD_CTRL.FDEN = 1), which means that protocol handler does not consider received CAN FD frames as error condition. When bit WCAN_INTESTAT1.FDF is found dominant, the decoding phase is stopped and the protocol handler goes to the bus integration state waiting for 5 consecutive recessive bits. The protocol handler has an "End Of Frame" (EOF) bit counter to detect 5 consecutive recessive bits. The FD block generates a reset signal (active low) for the EOF bit counter, when a dominant bit in the high bit-rate phase is detected. The FD block directly uses the RXD signal and operates at

f_{BACK} to avoid losing a dominant bit during the high bit-rate phase. Consequently a filter to suppress the dominant glitches is introduced in FD block. Since only dominant detection acts as the reset for EOF bit counter, the filter is an up-counter incremented when the RXD signal is dominant and reset when the RXD is recessive. So the filtered RXD is considered dominant when the counter end value (FD End Count) is reached. The glitch length (t_FD_glitch) to filter out and the minimum dominant pulse to detect (t_FD_detect) are based on the baudrate and the FD factor as shown in the table below.

Table 1732 CAN FD dominant bit filter time

Baudrate (kBaud)	FD factor	FD_FILT	FD end count	t_FD_glitch (ns)	t_FD_detect (ns)
125	4	011	90	400	1400
250	4	010	48	200	700
500	4	001	25	100	350
125	10	010	48	200	700
250	10	001	25	100	350
500	10	000	13	50	175

39.3.15.4.2 WCAN kernel registers

Register address map

The register set of the WCAN module consists of the below distinct subsets:

1. The Configuration, Miscellaneous Registers exist in one instance and apply for the entire WCAN module
2. The Wake-Up CAN registers consist of the following:
   - CAN Node Registers (WCAN_BTL1_CTRL, WCAN_BTL2_CTRL, WCAN_CDR_CTRL, WCAN_CDR_UPPER_CTRL, WCAN_CDR_LOWER_CTRL, WCAN_CDR_MEAS_HIGH, WCAN_CDR_MEAS_LOW and WCAN_FD_CTRL), which applies to a single CAN node
   - WUF configuration registers (DLC_CTRL, IDx_CTRL, MASK_IDx_CTRL and DATAx_CTRL) are defined for a single message object and exist once for each message object

Configuration and status registers

The configuration and status registers of a WCAN node are accessed from standard (non-mapped) SFR area. The following table shows the address as seen on the Standby Controller (SCR).

Table 1733 WCAN configuration and status registers address map

Register	Addr.	Page	SCR reset value	Full name of register
WCAN_CFG	$B0_H$	0	08_H	Configuration Register
WCAN_INTMRSLT	$B1_H$	0	00_H	Interrupt Mask and Reference Select Register
WCAN_INTESTAT0	$B0_H$	1	00_H	Interrupt and Event Status 0 Register
WCAN_INTESTAT1	$B1_H$	1	60_H	Interrupt and Event Status 1 Register
WCAN_FRMERRCNT	$B2_H$	1	00_H	Frame Error Counter Register
WCAN_INTESCLR0	$B3_H$	1	00_H	Interrupt and Event Status Clear Register 0
WCAN_INTESCLR1	$B4_H$	1	00_H	Interrupt and Event Status Clear Register 1

CAN node registers

The registers of a WCAN node are accessed from standard (non-mapped) SFR area. The following table shows the address of registers as seen on the Standby Controller (SCR).

Table 1734 CAN node registers address map

Register	Addr.	Page	SCR reset value	Full name of register
WCAN_BTL1_CTRL	$B5_H$	1	64_H	Bit Timing Logic 1 Control Register
WCAN_BTL2_CTRL	$B6_H$	1	73_H	Bit Timing Logic 2 Control Register
WCAN_CDR_CTRL	$B2_H$	0	05_H	CDR Control Register
WCAN_CDR_UPPER_CTRL	$B3_H$	0	69_H	CDR Upper Limit Control Register
WCAN_CDR_LOWER_CTRL	$B4_H$	0	$5F_H$	CDR Lower Limit Control Register
WCAN_CDR_MEAS_HIGH	$B5_H$	0	64_H	CDR Measured High Register
WCAN_CDR_MEAS_LOW	$B6_H$	0	00_H	CDR Measured Low Register
WCAN_FD_CTRL	$B7_H$	0	00_H	CAN FD Control Register

WUF configuration registers

The registers to configure WUF are accessed from standard (non-mapped) SFR area. The following table shows the address of the WUF configuration Registers as seen on the Standby Controller (SCR).

Table 1735 WUF configuration registers address map

Register	Addr.	Page	SCR reset value	Full name of register
WCAN_DLC_CTRL	$B7_H$	1	00_H	Message Data Length Code Control Register
WCAN_ID0_CTRL	$B0_H$	2	00_H	Message Identifier Control Register 0
WCAN_ID1_CTRL	$B1_H$	2	00_H	Message Identifier Control Register 1
WCAN_ID2_CTRL	$B2_H$	2	00_H	Message Identifier Control Register 2
WCAN_ID3_CTRL	$B3_H$	2	00_H	Message Identifier Control Register 3
WCAN_MASK_ID0_CTRL	$B4_H$	2	00_H	Message Identifier Acceptance Mask Register 0
WCAN_MASK_ID1_CTRL	$B5_H$	2	00_H	Message Identifier Acceptance Mask Register 1
WCAN_MASK_ID2_CTRL	$B6_H$	2	00_H	Message Identifier Acceptance Mask Register 2
WCAN_MASK_ID3_CTRL	$B7_H$	2	00_H	Message Identifier Acceptance Mask Register 3
DATA0_CTRL	$B0_H$	3	00_H	Message Data Control Register 0
DATA1_CTRL	$B1_H$	3	00_H	Message Data Control Register 1
DATA2_CTRL	$B2_H$	3	00_H	Message Data Control Register 2
DATA3_CTRL	$B3_H$	3	00_H	Message Data Control Register 3
DATA4_CTRL	$B4_H$	3	00_H	Message Data Control Register 4
DATA5_CTRL	$B5_H$	3	00_H	Message Data Control Register 5
DATA6_CTRL	$B6_H$	3	00_H	Message Data Control Register 6
DATA7_CTRL	$B7_H$	3	00_H	Message Data Control Register 7

CAN node registers

The CAN node specific registers contain information that is directly related to the operation of the CAN node. The Node Control Register contains basic settings that define the bit timing for the operation of the CAN node.

The Bit Timing Logic Control Registers contain all parameters to setup the bit timing for the CAN transfer.

***Note**: The SCR Firmware (SRC-FW) overwrites the BTL1_CTRL register with 64_H and BTL2_CTRL register with 73_H after reset, to obtain a 500Kbits/s baud rate. Please use the values specified in table 'Bit Timing and RXD Filter configuration - Recommended' in related information for 1Mbits/s (BTL1_CTRL1, BTL2_CTRL), 250Kbits/s (BTL1_CTRL, BTL2_CTRL) and 125Kbits/s (BTL1_CTRL, BTL2_CTRL) baud rate. The Configuration Change Enable, WCAN_CFG.CCE has to be enabled before the BTLn_CTRL register can be written.*

39.3.15.5 WCAN connections to GPIO

The port input/output control registers contain the bit fields that selects the digital output and input driver characteristics such as pull-up/down devices, port direction (input/output), open-drain, and alternate output selections. The I/O lines for the WCAN module are controlled by the port input/output control registers shown below.

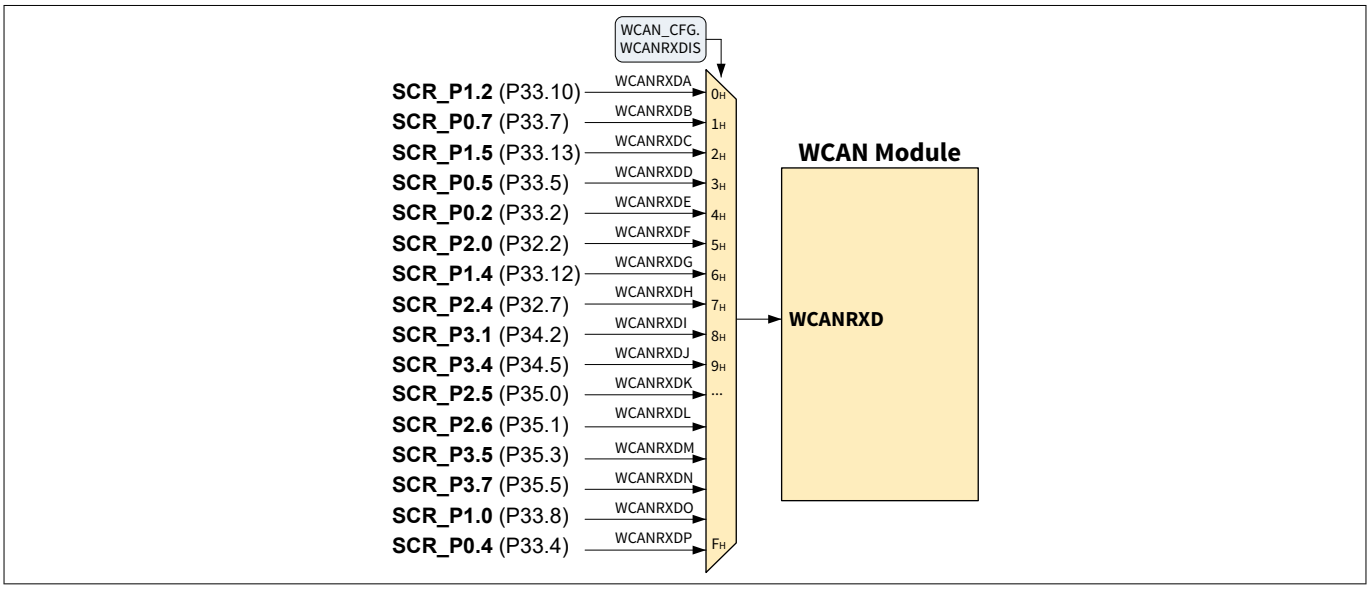

Figure 948 Wake-up CAN connections to GPIO ports

39.3.15.6 WCAN interrupts

The interrupt control logic in the Wake-Up CAN module consists of the following interrupts shown in the table and figure below.

Table 1736 WCAN interrupt outputs

Interrupt inputs	Connected to WCAN interrupt output
SCR Interrupt Node 6	WUF_INT (Wake-Up Frame Interrupt)
	ERROR_INT (System Error Interrupt)

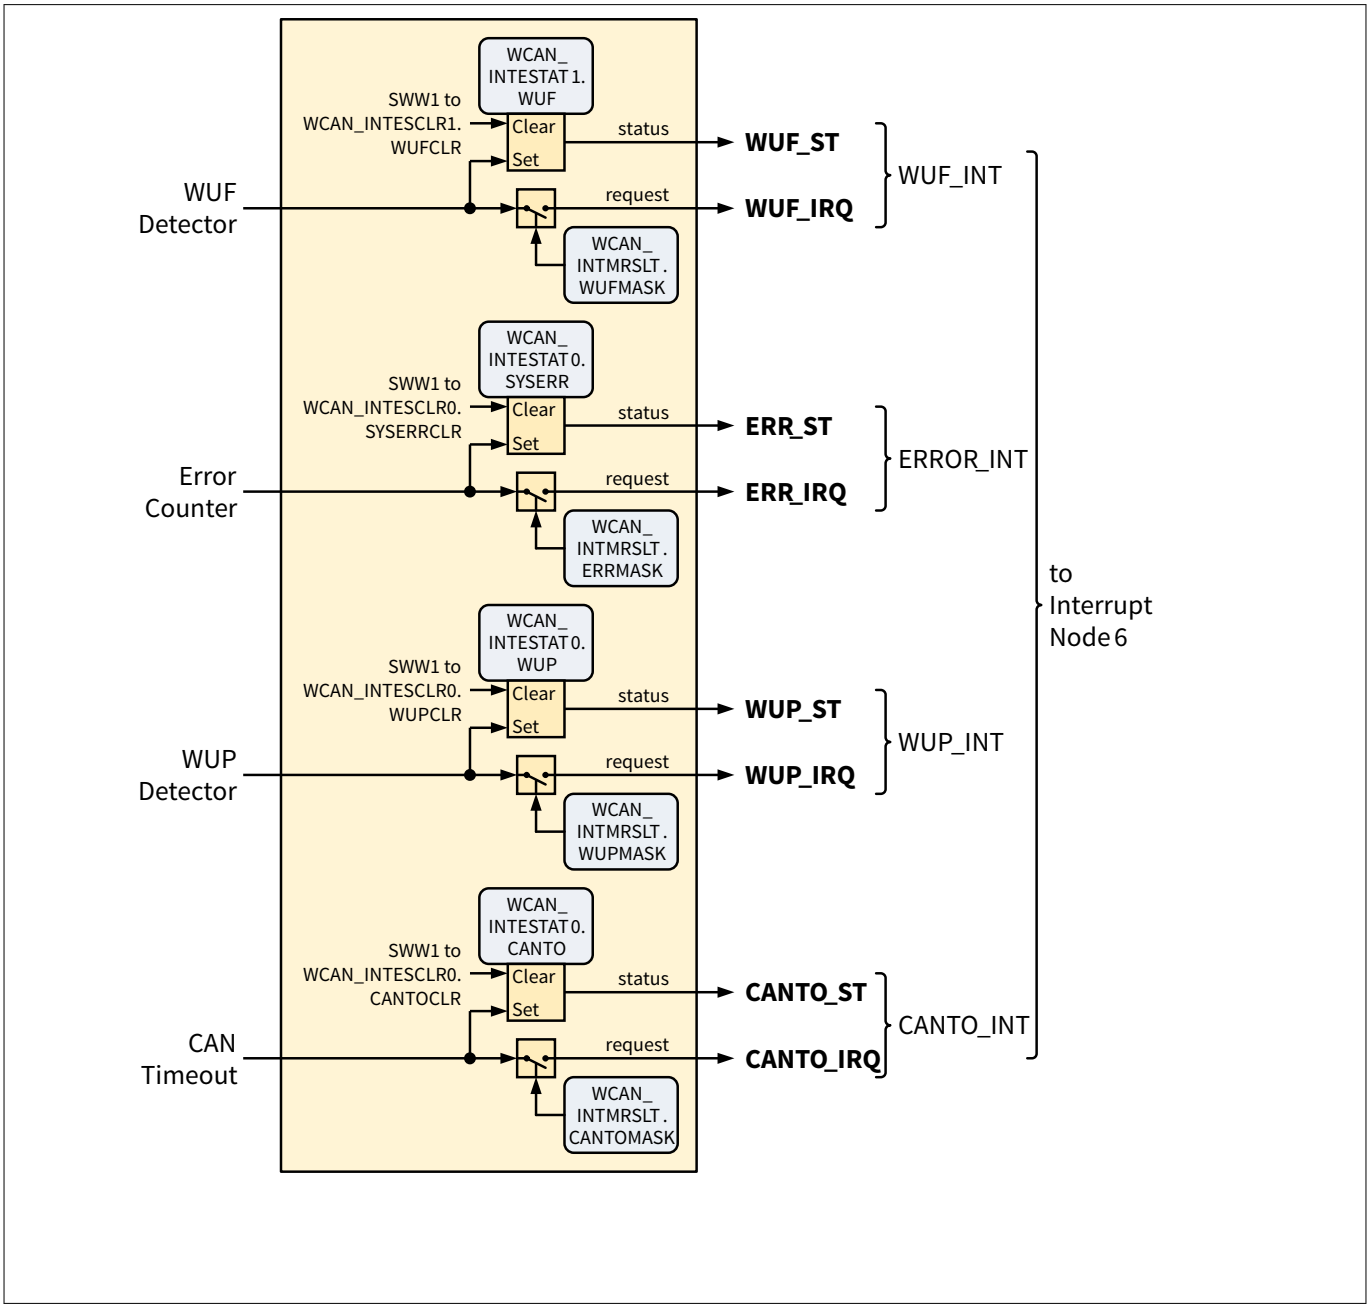

Figure 949 Wake-up CAN interrupt outputs

39.3.16 Inter-Integrated Circuit (I2CSCR)

The I2CSCR provides an interface between the microcontroller and an I2C bus that conforms to the I2C Bus Protocol 1.0.

The can operate in either master or slave mode. It performs arbitration in master mode to allow it to operate in multi-master systems. The I2CSCR provides communication at data rates of up to 400 KBit/s and features 7-bit addressing as well as 10-bit addressing.

39.3.16.1 Features

- Operates in Master or slave mode
- Supports multi-master systems
- Performs arbitration and clock synchronization
- Supports 7-bit and 10-bit addressing modes
- Selectable baud rate generation of up to 400 kBaud (fast mode)
- Flexible control through interrupt service routines or polling
- Clock stretching

39.3.16.2 System information

This section provides system information relevant to the I2CSCR.

39.3.16.2.1 Pinning

The I2CSCR pin assignment for SCR is shown in the following table. Please also see the General purpose I/O ports (PORT8) chapter.

Table 1737 I2C pin functions in SCR

Pin	Function	Description	Selected by
SCR_P1.0 (P33.8)	I2CSDAD	I2C data input	I2CSCR_SRST.SDASEL
SCR_P1.0 (P33.8)	I2CSDA	I2C data output	SCR_P1_IOCR0.PC
SCR_P1.1 (P33.9)	I2CSCLD	I2C clock input	I2CSCR_SRST.SCLSEL
SCR_P1.1 (P33.9)	I2CSCL	I2C clock output	SCR_P1_IOCR1.PC

SCR_P3.2 (P34.3)	I2CSCL	I2CSCR clock output	SCR_P3_IOCR2.PC

39.3.16.2.2 Output pin configuration

The pin drivers that are assigned to the I2C lines provide open drain outputs. This ensures that the I2CSCR module does not put any load on the I2C bus lines while the I2CSCR module is not powered. Therefore, it is necessary to have external pull-up resistors (approximately 10 KΩ for operation at 100 KBaud, 2 KΩ for operation at 400 KBaud) on the I2C bus lines.

All pins of the I2CSCR module that are to be used for I2C bus communication must be switched to output and their alternate function must be enabled, before any communication can be established.

If not driven by the I2CSCR module, the pins will switch off their drivers (i.e. driving 1 to an open drain output). Due to the external pull-up devices, the respective bus levels will then be 1, which is idle.

39.3.16.2.3 Clocking configuration

The I2CSCR runs on the PCLK. If the I2CSCR functionality is not required at all, it can be completely disabled by gating off its clock input for maximal power reduction.

This is done by setting bit SCUSCR_PMCON1.I2C_DIS.

The bit SCUSCR_PAGE.PAGE must be programmed before accessing the SCUSCR_PMCON1 register.

39.3.16.2.4 Interrupt events and assignment

Following table lists the interrupt event source from the SCR_I2C, and the corresponding event interrupt enable and flag bit. See chapter Interrupt system for more information related to the interrupts.

Table 1738 SCR_I2C Interrupt Events

Event	Event interrupt enable bit	Event flag bit
SCR_I2C interrupt	SCR_I2C_CNTR.IEN	SCR_I2C_CNTR.IFLG

The table below shows the interrupt node assignment for the SCR_I2C interrupt source.

Table 1739 SCR_I2C Events' Interrupt Node Control

Event	Interrupt node	Vector address	Interrupt node enable bit
SCR_I2C Interrupt	XINTR8	0043_H	IEN1.EX2

Status code

The state of the I2CSCR module is defined by the 5-bit status code in SCR_I2CSCR_STAT register.

When SCR_I2CSCR_STAT contains the status code $F8_H$, no relevant status information is available, no interrupt is generated and the I2CSCR_CNTR.IFLG bit is not set. All other status codes correspond to a defined state of the I2CSCR module. When any of these states is entered, the corresponding status code appears in this register and the I2CSCR_CNTR.IFLG bit is set. When the I2CSCR_CNTR.IFLG bit is cleared, the status code returns to $F8_H$.

Table 1740 Status code

Value of I2CSCR_STAT register	Status
00_H	Bus error
08_H	START condition transmitted
10_H	Repeated START condition transmitted

(table continues...)

Table 1740 (continued) Status code

Value of I2CSCR_STAT register	Status
18_H	Address and write bit transmitted, ACK received
20_H	Address and write bit transmitted, ACK not received
28_H	Data byte transmitted in master mode, ACK received
30_H	Data byte transmitted in master mode, ACK not received
38_H	Arbitration lost in address or data byte
40_H	Address and read bit transmitted, ACK received
48_H	Address and read bit transmitted, ACK not received
50_H	Data byte received in master mode, ACK transmitted
58_H	Data byte received in master mode, ACK not transmitted
60_H	Slave address and write bit received, ACK transmitted
68_H	Arbitration lost in address as master, slave address and write bit received, ACK transmitted
70_H	General call address received, ACK transmitted
78_H	Arbitration lost in address as master, general call address received, ACK transmitted
80_H	Data byte received after slave address received, ACK transmitted
88_H	Data byte received after slave address received, ACK not transmitted

$C8_H$	Last byte transmitted in slave mode, ACK received
$D0_H$	Second address byte and write bit transmitted, ACK received
$D8_H$	Second address byte and write bit transmitted, ACK not received
$E0_H$	Unused

(table continues...)

Table 1740 (continued) Status code

Value of I2CSCR_STAT register	Status
$E8_H$	Unused
$F0_H$	Unused
$F8_H$	No relevant status information, IFLG = 0

If an illegal condition occurs on the I2C bus, the bus error state is entered (status code 00_H). To recover from this state, the I2CSCR_CNTR.STP bit must be set and the I2CSCR_CNTR.IFLG bit cleared. The I2CSCR module will then return to idle state (status code $F8_H$): no STOP condition will be transmitted on the I2C bus.

To request resumption of transmission, set the I2CSCR_CNTR.STA bit to 1 at the same time as the I2CSCR_CNTR.STP bit is set. The I2CSCR module will then send a START on recovery from the bus error.

39.3.16.2.5 Baudrate generation

Baudrate is measured in KBit/s. Therefore all units will be called KBit/s.

To support a wide range of input clock frequencies (f_{PCLK}), two dividers are implemented to generate the required bit-rate on the I2C bus in master mode. The two dividers are defined by the I2CSCR_BRCR.PREDIV and I2CSCR_BRCR.BRP bits.

***Note**: An operation of the I2CSCR module with the SCR 70 kHz clock source is not recommended as due to the low module operating frequency a proper bus communication cannot be guaranteed.*

The bit-rate is calculated by the formula:

$$f_{OCSL} = \frac{f_{PCLK}}{2^{PREDIV} \times (BRP + 1) \times 10} \quad (70)$$

Bit-rate

***Notes**:*
Due to internal synchronization mechanisms this formula is not valid for the following settings of PREDIV and BRP. Instead the following formulas have to be used:

1. *For PREDIV = 0 and BRP = 0 formula is: $f_{OCSL} = f_{PCLK}/15$*
2. *For PREDIV = 1 and BRP = 0 formula is: $f_{OCSL} = f_{PCLK}/26$*
3. *For PREDIV = 0 and BRP = 1 formula is: $f_{OCSL} = f_{PCLK}/24$*
4. *For PREDIV = 1 and BRP = 1 formula is: $f_{OCSL} = f_{PCLK}/48$*
5. *For PREDIV = 0 and BRP = 2 formula is: $f_{OCSL} = f_{PCLK}/36$*

The following table shows some examples of the bit-rate together with the required dividers setting.

Table 1741 Bit-rate Selection

	Standard Mode			Fast Mode		
f_{PCLK}	PREDIV	BRP+1	f_{SCL}	PREDIV	BRP+1	f_{SCL}
20 MHz	2	5	100 kHz	1	3	333.3 kHz
33.3 MHz	2	9	92.5 kHz	1	5	333 kHz
50 MHz	2	13	96.15 kHz	1	7	357.14 kHz
100 MHz	4	7	89.2 kHz	1	13	384.16 kHz

The frequency at which the I2C bus is sampled is calculated by the formula:

$$f_{SAMP} = \frac{f_{PCLK}}{2^{PREDIV}} \quad (71)$$

Sampling frequency

To ensure correct detection of START and STOP conditions on the bus, the I2CSCR module must sample the I2C bus at least twelve times faster than the bus clock speed of the fastest master on the bus. The sampling frequency should therefore be at least 1.2 MHz in standard mode or 4.8 MHz in fast mode to guarantee correct operation with other bus masters. In order to ensure a functional communication following per-requisites have to be fulfilled:

1. SCL low ≥ 6 x T_{SAMP}
2. SCL high ≥ 6 x T_{SAMP}
3. min setup/hold times ≥ 2 x T_{SAMP}

39.3.16.2.6 Clock synchronization

If another device on the I2C bus drives the clock line when the SCR_I2C is in master mode, the SCR_I2C will synchronize its clock to the I2C bus clock. The high period of the clock will be determined by the device that generates the shortest high clock period. The low period of the clock will be determined by the device that generates the longest low clock period.

When the I2CSCR module is in master mode and is communicating with a slow slave, the slave may stretch each bit period by holding the SCL line low until it is ready for the next bit. The I2CSCR module will automatically re-synchronize as described above.

When the I2CSCR module is in slave mode, it will hold the SCL line low after each byte has been transferred until I2CSCR_CNTR.IFLG has been cleared.

39.3.16.2.7 Bus arbitration

In master mode, the SCR_I2C will check that each transmitted logic 1 appears on the SCR_I2C bus as a logic 1. If another device on the bus over-rules and pulls the SDA line low, arbitration is lost. If arbitration is lost during the transmission of a data byte or a Not-Acknowledge bit, the SCR_I2C will return to idle state. If arbitration is lost during the transmission of an address, the SCR_I2C will switch to slave mode so that it can recognize its own slave address or the general call address.

39.3.16.2.8 Software reset

A software reset may be applied to the I2CSCR module by writing '1' to the bit-field I2CSCR_SRST.SRST. This sets the I2CSCR module back to idle (I2CSCR_STAT set to $F8_H$) and sets the STP, STA and IFLG bits of the I2CSCR_CNTR register to 0. Also the I2CSCR_BRCR is reset by a software reset.

39.3.16.2.9 Operating modes

All operating modes of the I2C module require the I2CSCR_CNTR.ENAB bit to be set to 1.

Master Transmit

In the master transmit mode, the I2CSCR module transmits a number of bytes to a slave receiver. The master transmit mode is entered by setting the I2CSCR_CNTR.STA bit to ‘1’. The I2CSCR module will then test the I2C bus and will transmit a START condition when the bus is free. When a START condition has been transmitted,

the I2CSCR_CNTR.IFLG bit will be set and the status code in the I2CSCR_STAT register will be 08_H. Before this interrupt is serviced, the I2CSCR_DATA register must be loaded with either a 7-bit slave address or the first part (containing 5 fixed bits that is 11110_B and 2 uppermost bits of the 10-bit address) of a 10-bit slave address, with the LSB cleared to '0' (for example with an added Write bit) to specify transmit mode. The I2CSCR_CNTR.IFLG bit should now be cleared to '0' to prompt the transfer to continue.

After the 7-bit slave address (or the first part of a 10-bit address) plus the write bit have been transmitted, I2CSCR_CNTR.IFLG will be set again. A number of status codes is possible in the I2CSCR_STAT register, see below:

Table 1742 Status code after address is transmitted in master transmit mode

Code	I2C (bus) state	CPU response	Next I2C module action
18_H	Addr + W, ACK received	**For 7-bit address:** Write byte to I2C_DATA, clear IFLG Or set STA, clear IFLG Or set STP, clear IFLG Or set STA and STP, clear IFLG **For 10-bit address:** Write extended address byte to I2C_DATA, clear IFLG	 Transmit data byte, receives ACK Transmit repeated START Transmit STOP Transmit STOP then START Transmit extended address byte
20_H	Addr + W, ACK not received	Set STA, clear IFLG Or set STP, clear IFLG Or set STA and STP, clear IFLG	Transmit repeated START Transmitted STOP Transmit repeated START then STOP
38_H	Arbitration lost	Clear IFLG Or set STA, clear IFLG	Return to idle state Transmit START when bus is free
68_H	Arbitration lost, SLA + W received, ACK transmitted	Clear IFLG, AAK=0 Or clear IFLG, AAK=1	Receive data byte, transmit not ACK Receive data byte, transmit ACK
78_H	Arbitration lost, general call address received, ACK transmitted	Same as for code 68_H	Same as for code 68_H
$B0_H$	Arbitration lost, SLA + R received, ACK transmitted	Write byte to I2C_DATA, clear IFLG, AAK=0 Or write byte to I2C_DATA, clear IFLG, AAK=1	Transmit last byte, receive ACK Transmit data byte receive ACK

If 10-bit addressing is being used, then after the first part of a 10-bit address plus the Write bit have been successfully transmitted, the status code will be 18_H or 20_H.

After this interrupt has been serviced and the second part (lower byte) of the address transmitted, the I2CSCR_STAT register will contain one of the following codes:

Table 1743 Status code after second address byte (for 10-bit addressing) is transmitted in master transmit mode

Code	I2C(bus) state	CPU response	Next I2C module action
38_H	Arbitration lost	Clear IFLG Or set STA, clear IFLG	Return to idle state Transmit START when bus is free
68_H	Arbitration lost, SLA + W received, ACK transmitted	Clear IFLG, AAK = 0 Or clear IFLG, AAK = 1	Receive data byte, transmit not ACK Receive data byte, transmit ACK
$B0_H$	Arbitration lost, SLA + R received, ACK transmitted	Write byte to I2C_DATA, clear IFLG, AAK = 0 Or write byte to I2C_DATA, clear IFLG, AAK=1	Transmit last byte, receive ACK Transmit data byte, receive ACK
$D0_H$	Second address byte + W transmitted, ACK received	Write byte to I2C_DATA, clear IFLG Or set STA, clear IFLG Or set STP, clear IFLG Or set STA and STP, clear IFLG	Transmit data byte, receives ACK Transmit repeated START Transmitted STOP Transmitted STOP then START
$D8_H$	Second address byte + W transmitted, ACK not received	Set STA, clear IFLG Or set STP, clear IFLG Or set STA and STP, clear IFLG	Transmit repeated START Transmitted STOP Transmit repeated START then STOP

If a repeated START condition has been transmitted, the status code will be 10_H instead of 08_H. After each data byte has been transmitted, I2CSCR_CNTR.IFLG will be set and one of three status codes will be in the I2CSCR_STAT register:

Table 1744 Status code after data is transmitted in master transmit mode

Code	I2C (bus) state	CPU response	Next I2C module action
28_H	Data byte transmitted, ACK received	Write byte to I2C_DATA, clear IFLG Or set STA, clear IFLG Or set STP, clear IFLG Or set STA and STP, clear IFLG	Transmit data byte, receives ACK Transmit repeated START Transmit STOP Transmit STOP then START
30_H	Data byte transmitted, ACK not received	Same as for code 28_H	Same as for code 28_H
38_H	Arbitration lost	Clear IFLG Or set STA, clear IFLG	Return to idle state Transmit START when bus is free

When all bytes have been transmitted, the STP bit should be set by writing a 1 to this bit in the I2CSCR_CNTR register. The I2CSCR module will then transmit a STOP condition, clear the I2CSCR_CNTR.STP bit and return to idle state (status code $F8_H$).

Master Receive

In the master receive mode, the SCR_I2C will receive a number of bytes from a slave transmitter. After the START condition has been transmitted, the I2CSCR_CNTR.IFLG bit will be set and status code 08_H will be in the I2CSCR_STAT register. The I2CSCR_DATA register should now be loaded with the slave address (or the first part of a 10-bit slave address), with the LSB set to '1' to signify a Read. The I2CSCR_CNTR.IFLG bit should now be cleared to '0' to prompt the transfer to continue. When the 7-bit slave address (or the first part of a 10-bit address) and the Read bit have been transmitted, the I2CSCR_CNTR.IFLG bit will be set again. A number of status codes are possible in the I2CSCR_STAT register:

Table 1745 Status code after address is transmitted in master receive mode

Code	I2C (bus) state	CPU response	Next I2CSCR module action
40_H	Addr + R transmitted, ACK received	Clear IFLG, AAK = 0 Or clear IFLG, AAK = 1	Receive data byte, transmit NACK Receive data byte, transmit ACK
48_H	Addr + R transmitted, ACK not received	Set STA, clear IFLG Or set STP, clear IFLG Or set STA and STP, clear IFLG	Transmit repeated START Transmit STOP Transmit STOP then START
38_H	Arbitration lost	Clear IFLG Or set STA, clear IFLG	Return to idle state Transmit START when bus is free
68_H	Arbitration lost, SLA + W received, ACK transmitted	Clear IFLG, AAK = 0 Or clear IFLG, AAK = 1	Receive data byte, transmit NACK Receive data byte, transmit ACK
78_H	Arbitration lost, general call address received, ACK transmitted	Same as for code 68_H	Same as for code 68_H
$B0_H$	Arbitration lost, SLA + R received, ACK transmitted	Write byte to DATA, clear IFLG, AAK = 0 Or write byte to DATA,clear IFLG, AAK = 1	Transmit last byte, receive ACK Transmit data byte, receive ACK

If 10-bit addressing is being used, the slave is first addressed using the full 10-bit address plus the Write bit. The master then issues a restart followed the first part of the 10-bit address again, but plus the Read bit – after which the status code will be 40_H or 48_H. It is the responsibility of the slave to remember that it had been selected prior to the restart.

If a repeated START condition has been transmitted, the status code will be 10_H instead of 08_H.

After each data byte has been received, I2CSCR_CNTR.IFLG will be set and one of three status codes will be in the I2CSCR_STAT register:

Table 1746 Status code after data is received in master receive mode

Code	I2C (bus) state	CPU response	Next I2CSCR module action
50_H	Data byte received,ACK transmitted	Read DATA, clear IFLG,AAK = 0 Or read DATA, clear IFLG, AAK = 1	Receive data byte, transmit NACK Receive data byte, transmit ACK
58_H	Data byte received, NACK transmitted	Read DATA, set STA, clear IFLG Or read DATA, set STP, clear IFLG Or read DATA, set STA and STP, clear IFLG	Transmit repeated START Transmit STOP Transmit STOP then START
38_H	Arbitration lost in NACK bit	Clear IFLG Or set STA, clear IFLG	Return to idle state Transmit START when bus is free

When all bytes have been received, a NACK should be transmitted then the I2CSCR_CNTR.STP bit should be set by writing a '1' to this bit. The SCR_I2C will transmit a STOP condition, clear the I2CSCR_CNTR.STP bit and return to idle state (status code $F8_H$).

Slave transmit

In the slave transmit mode, a number of bytes are transmitted to a master receiver. For the I2CSCR module to respond, the I2CSCR_CNTR.AAK bit needs to be set.

The I2CSCR module will enter slave transmit mode when it receives its own slave address and a "Read bit" after a START condition. The I2CSCR module will then transmit an acknowledge bit and set the I2CSCR_CNTR.IFLG bit. The I2CSCR_STAT register will contain the status code $A8_H$.

***Note**: If the I2CSCR module has an extended slave address (signified by 11110_B in I2CSCR_ADDR[7:3]), it will first be selected, then there will be a restart followed by another address byte. If this address byte matches the value stored in I2CSCR_ADDR, the I2CSCR module will transmit an acknowledge after this address byte is received. An interrupt will be generated, I2CSCR_CNTR.IFLG will be set and the status will be $A8_H$. No second address byte will be sent by the master: it is up to the slave to remember that it had been selected prior to the restart.*

The "Slave transmit mode" can also be entered directly from a master mode if arbitration is lost in master mode during the transmission of an address and the slave address and "Read bit" are received. The status code in the I2CSCR_STAT register will then be $B0_H$.

The data byte to be transmitted should then be loaded into the I2CSCR_DATA register and I2CSCR_CNTR.IFLG cleared. When the I2CSCR module has transmitted the byte and received an acknowledge, I2CSCR_CNTR.IFLG will be set and the I2CSCR_STAT register will contain $B8_H$. Once the last byte to be transmitted has been loaded into the I2CSCR_DATA register, the I2CSCR_CNTR.AAK bit should be cleared when I2CSCR_CNTR.IFLG is cleared. After the last byte has been transmitted, I2CSCR_CNTR.IFLG will be set and the I2CSCR_STAT register will contain $C8_H$. The I2CSCR module will then return to idle state (status code $F8_H$). The I2CSCR_CNTR.AAK bit must be set to 1 before slave mode can be entered again.

If no acknowledge is received after transmitting a byte, I2CSCR_CNTR.IFLG will be set and the I2CSCR_STAT register will contain $C0_H$. The I2CSCR module will then return to idle state.

If the STOP condition is detected after an acknowledge bit, the I2CSCR module will return to idle state.

Slave receive

In the slave receive mode, a number of data bytes are received from a master transmitter.

The I2CSCR module will enter slave receive mode when it receives its own slave address and a Write bit (LSB=0) after a START condition. The I2CSCR module will then transmit an acknowledge bit and set the I2CSCR_CNTR.IFLG bit: the I2CSCR_STAT register will then contain status code 60_H. The I2CSCR module will also enter slave receive mode when it receives the general call address 00_H (if the I2CSCR_ADDR.GCE bit is set). The status code will then be 70_H.

Note: Where the I2CSCR module has an extended slave address (signified by 11110_B in I2CSCR_ADDR[7:3]), it will transmit an acknowledge after the first address byte is received but no interrupt will be generated, I2CSCR_CNTR.IFLG will not be set and the status will not change. Only after the second address byte has been received the I2CSCR module will generate an interrupt, set the I2CSCR_CNTR.IFLG bit and the status code in I2CSCR_STAT as described above.

Slave receive mode can also be entered directly from a master mode if arbitration is lost in master mode during the transmission of an address and the slave address and Write bit (or the general call address if bit I2CSCR_ADDR.GCE is set to 1) are received. The status code in the I2CSCR_STAT register will be 68_H if the slave address was received or 78_H if the general call address was received. The I2CSCR_CNTR.IFLG bit must be cleared to '0' to allow the data transfer to continue.

If the I2CSCR_CNTR.AAK bit is set to 1, then after each byte is received, an acknowledge bit (low level on SDA) is transmitted and the I2CSCR_CNTR.IFLG bit is set: the I2CSCR_STAT register will then contain status code 80_H (or 90_H if slave receive mode was entered with the general call address). The received data byte can be read from the I2CSCR_DATA register and the I2CSCR_CNTR.IFLG bit must be cleared to allow the transfer to continue. When the STOP condition or a repeated START condition is detected after the acknowledge bit, then the I2CSCR_CNTR.IFLG bit is set and the I2CSCR_STAT register will contain status code $A0_H$.

***Note**: In case of a general call, when the general call address was received the receive input buffer is reset.*

If the I2CSCR_CNTR.AAK bit is cleared to 0 during a transfer, a NAK (not acknowledge; high level on SDA) is sent after receiving the next byte. The I2CSCR_CNTR.IFLG bit is set. The I2CSCR_STAT register will contain status code 88_H (or 98_H if slave receive mode was entered with the general call address). When the I2CSCR_CNTR.IFLG bit has been cleared to 0, the I2CSCR module will return to idle state (status code $F8_H$).

39.3.17 Interface between PMS and SCR

The 8 bit Standby controller (SCR) sub-system is integrated in the standby domain of the PMS subsystem and several control functions are available through PMS registers.

Main functionality

The SCR is enabled through the PMS SCR_CON0.SCREN.

If SCR is disabled through PMS SCR_CON0.SCREN bit, it is ensured that the SCR 100 MHz clock request, pending requests from SCR wake-up sources, and other SCR interfaces do not have any effect on the main system.

After start-up, before enabling SCR, CPU0 must program the SCR by copying code into internal SCR XRAM memory.

The SCR XRAM is accessible from the TriCore™ domain through the FPI interface. Simultaneous access to XRAM through FPI interface and the SCR is arbitrated with SCR having default priority for XRAM access. In the case of wake-up from Standby, it is ensured that SCR XRAM is not re-initialized.

Clock

The 20 MHz stand-by clock source, derived from the 100 MHz back-up clock, is the default SCR clock active in Standby Mode. The SCR clock source may be switched to the internal low-power 70 kHz clock source by the SCR subsystem through the SCUSCR_CLK.DIV_REQ bit. A watchdog timer unit ensures that the clock received after the request is adequate for reliable operation.

The following clock interfaces are forwarded from PMS to SCR:

- 70 kHz clock input
- 100 MHz clock input
- XTAL3/4 32 kHz crystal oscillator clock to be used as SCR RTCSCR input

A signal with information indicating if a 100 MHz clock is available or not, is forwarded and is used to generate the clock for the SCR Arbiter unit.

Reset

SCR Main Reset is asserted in the case of warm PORST, depending on PORSTREQ configuration, or on a SCRSTREQ request. In the case of cold PORST, the PORST pin is asserted which in turn triggers SCR Main Reset depending on the PORSTREQ configuration. For LVD reset, a complete power-on reset of SCR is carried out.

***Note**: When VDDEXT is switched off during standby, the PORST signal is isolated to 0 (active). Therefore if VDDEXT is not supplied in STANDBY mode then PORSTREQ must be disabled to avoid the spurious reset trigger due to PORST assertion.*

After an SCR reset release, the SCR boot firmware initializes the SCR subsystem based on the hardware configuration programmed in PMS SCR_CON0.SCRCFG bits.

Critical SCR errors and events such as XRAM ECC errors, an SCR watchdog overflow event, SCR reset from pin, or SCR software reset, are communicated back to the main core domain through the following bits of the PMS SCR_STAT register:

- .SCRECC
- .SCRWDT
- .SCRPINRST
- .SCRRST

These events may additionally trigger internal SCR reset if configured in the SCR_SCUSCR_RSTCON register.

The occurrence of SCRECC, SCRWDT, SCRPINRST, and SCRRST events is routed to the TriCore™ domain interrupt controller if enabled through PMS_INT_CON2.SCRECC, .SCRWDT, SCRPINRST, and .SCRRST register bits.

Resets of the TriCore™ domain, namely Application, System, and Power-on Reset, are communicated to the SCR through SCUSCR_MRSTST.APPRST register bit.

SMU issued reset is communicated to the SCR through SCUSCR_MRSTST.SMURST register bit.

An NMI interrupt may be generated in the SCR subsystem when SCUSCR_MRSTST register bits are set.

Interrupt

To exchange data and facilitate status handshake between the SCR and the TriCore™ domain cores a register interface with interrupt support is provided.

The SCR can make a direct interrupt request to any CPUx by writing to the SCR_IRSCR_NMICON.SCRINTTC0 or .SCRINTTC1 register bit. An additional 8-bit information may be written into the SCR_SCUSCR_SCRINTEXCHG register, which is also transferred to the PMS_SCR_STAT.SCRINT register bit-field available to the TriCore™ domain cores. The routing of the interrupt to the TriCore™ domain interrupt request node can be enabled through PMS_INT_CON2.SCRINT0 and .SCRINT1 register bits.

Likewise, any CPUx may also trigger a direct interrupt request to the SCR by writing into the PMS_SCR_CON1.TCINTREQ register bit. An additional 8-bit information maybe written in the PMS_SCR_CON1.TCINT bit-field, which is transferred to the SCR_SCUSCR_TCINTEXCHG.TCINT register bit-field available to the SCR software.

An SCR NMI from the main controller is also triggered on SMURST or application reset.

Wake-up and mode transitions

The SCR may wake-up the TriCore™ domain from STANDBY1 to RUN state if configured in the PMS_WAKEUP_CON1.SCRWKEN register bit.

A wake-up request from SCR is issued by the SCR software through the SCR_SCUSCR_WKPCON.SWWKPREQ bit as documented in the SCR SCUSCR section. After wake-up of the TriCore™ domain, the PMS_WAKEUP_STAT1.SCRWKP event flag is set, which shall be cleared through the PMS_WAKEUP_CLR1.SCRWKPCLR register bit.

PMS wake-up flags can also be cleared from SCR side through SCUSCR_STBY.PMSWKPCLR='1'. Any pending STBY0 entry condition leads the system into a STBY0 mode after all PMS flags are cleared. If there is no pending STBY0 entry condition SCR software can trigger the transition to STBY0 through SCUSCR_STBY.STBY0REQ = 1

SCR has access to the following PMS information in order to execute different software routines if required:

- SCUSCR_STBY.STBYSTAT
  - Information whether the main system is in RUN or STANDBY1 mode
- SCUSCR_STBY.STBY0WKP
  - Information if the main system was previously in STANDBY0 mode
- SCUSCR_STBY.PMSRTCWKP
  - Information if the source of latest system wake-up was PMS RTC. This is useful when calibration of PMS RTC is done through SCR software
- SCUSCR_STBY.PMS0WKP
  - Information if the source of latest system wake-up was any PMS0 source combined as logical OR

Calibration

SCR has access to PMS RTC, DTS, HPOSC and HPBG register in order to provide calibration (trimming) capability during standby mode.

The following information about PMS RTC is made accessible to SCR software:

Table 1747 PMS RTC bit-fields available for SCR software

PMS RTC bit-field name	SCR register name	Description	SCR software access
RTC_TIM1CAP[31:0] & RTC_TIM0[31:0]	SCUSCR_PMSRTC_TIM*	8 registers of 8-bits (TIM63_56, TIM55_48, …, TIM7_0) for a total of 64-bit timer value	Read-only

(table continues...)

Table 1747 (continued) PMS RTC bit-fields available for SCR software

PMS RTC bit-field name	SCR register name	Description	SCR software access
RTC_CON1.OFFSET[15:0]	SCUSCR_PMSRTC_OFFSET*	2 registers of 8-bits (OFFSET15_8 and OFFSET7_0) for a total of 64-bit offset value	Read and write
RTC_CMP1[31:0]	SCUSCR_PMSRTC_CMP1*	4 registers of 8-bits (CMP1_31_24, …, CMP1_7_0) for a total of 32-bits CMP1 value	Read and write
RTC_CON2.MSIZE1[4:0]	SCUSCR_PMSRTC_MSIZE1	5 least-significant bits of MSIZE1 value	Read and write
RTC_CON2.MSTART1[4:0]	SCUSCR_PMSRTC_MSTART1	5 least-significant bits of MSTART1 value	Read and write

For PMS DTS there is following interface with prefix "SCUSCR_PMSDTS_":

Table 1748 PMS DTS bit-fields available for SCR software

PMS DTS bit-field name	SCR register name	Description	SCR software access
DTS_CON.START, DTS_CON.EN	SCUSCR_PMSDTS_CON.EN_START	DTS enable and start control is combined into a single bit	Read and write
DTS_STAT.RESULT[11:0]	SCUSCR_PMSDTS_RES*.VAL	Bit-fields in 2 registers combine for 12-bit result value	Read-only
DTS_STAT.READY	SCUSCR_PMSDTS_RES11_8.RES_READY	1-bit indication that temperature result is ready	Read-only

The PMS HPOSC trimming register is available for SCR software:

Table 1749 PMS HPOSC bit-fields available for SCR software

PMS HPOSC bit-field name	SCR register name	Description	SCR software access
PMS_HPOSCCON1.OSCFTRIM[8:0]	SCUSCR_PMSHPOSC_FTRIM*	2 registers (FTRIM8_8, FTRIM7_0) for a total of 9-bit OSCFTRIM value	Read and write

The PMS HPBG trimming register is available for SCR software:

Table 1750 PMS HPBG bit-fields available for SCR software

PMS HPBG bit-field name	SCR register name	Description	SCR software access
PMS_HPBGCON0.FINETRIM[6:0]	SCUSCR_PMSHPBG_BGTRIM*	7 least-significant bits of FINETRIM value	Read and write

Ports

SCR 8-bit Ports module (SCR_P0-3) shares 32 Pads with the TriCore™ domain 32-bit Port module (P32.2, P32.4-7, P33.0-15, P34.1-5, and P35.0-5).

The SCR ports are supplied by V_{DDPMS1} and $V_{DDEVRSB}$ standby supply. The control to these pins is by default allocated to the SCR through port configuration Pn_PCSRSEL register, if SCR is enabled. Unused wake-up pins may be configured as tri-state in Standby mode through PMS_PAD_CON.SBTRIST.

During a STANDBY1 to RUN mode transition the ownership of shared Pads is not changed. Isolation cells retain the programmed value of Pn_PCSRSELx value after RUN to STANDBY transition. This is to ensure that SCR continues to have control over the respective P32, P33, P34, and P35 port pins during and after exit from STANDBY, although the Port register Pn_PCSRSELx value is reset. Only after a consequent explicit write to the Pn_PCSRSELx value will be taken to switch the P32, P33, P34, and P35 control.

39 Stand-by Controller (SCR)

The wake-up pins *ESR1* and *PINA*(P14.1) are also routed to the SCR subsystem as external inputs to T2CCU0 Timer 2 module.

39 Stand-by Controller (SCR)

Summary

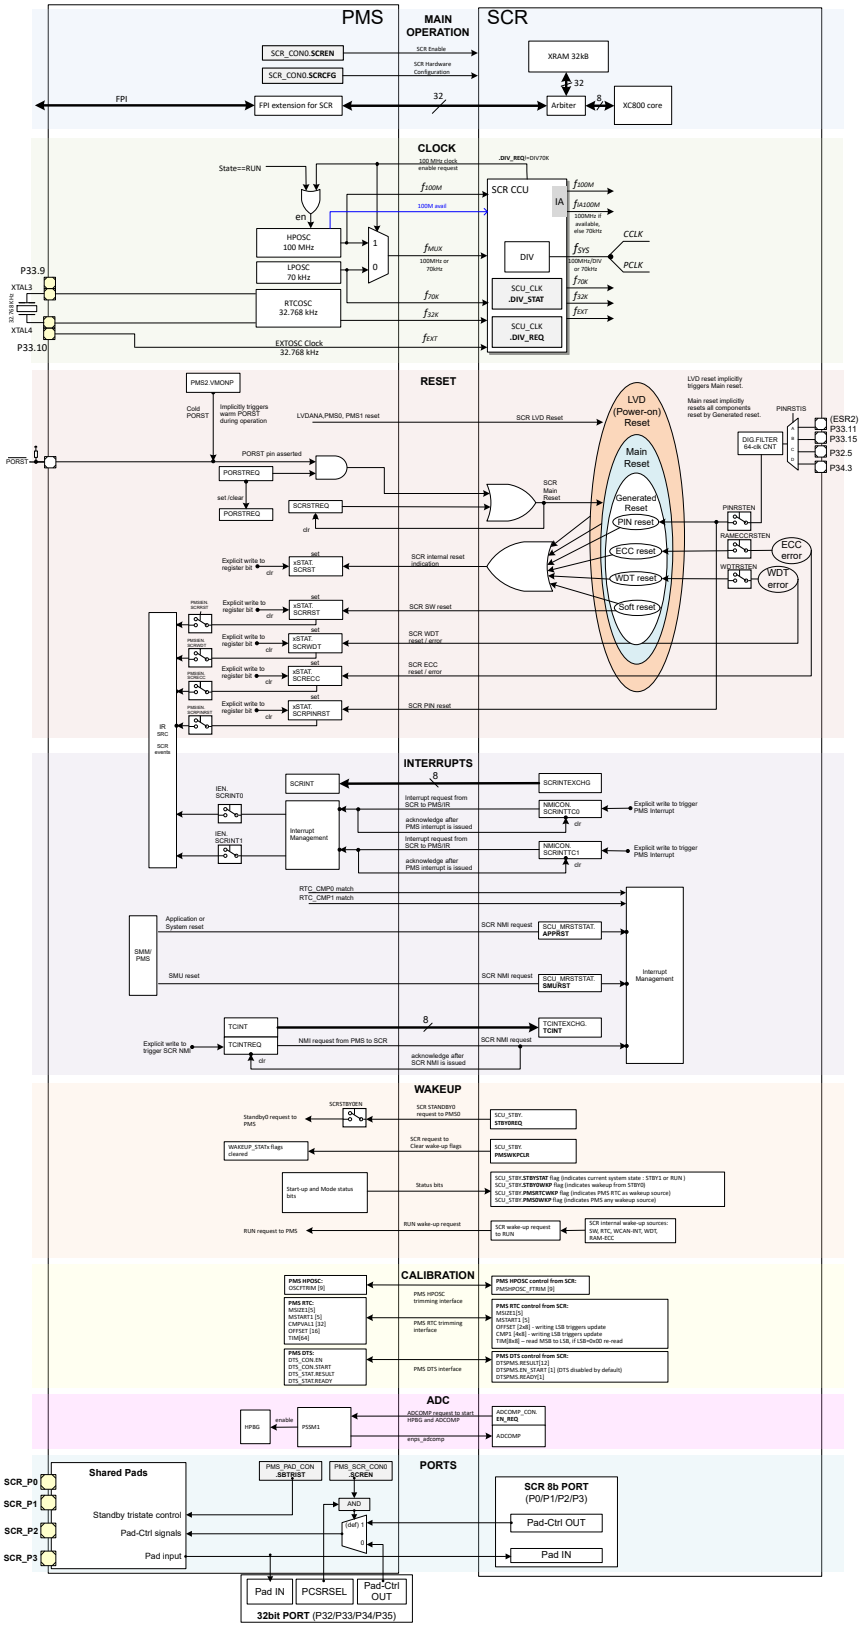

Figure 950 Overview of connections between PMS and SCR

39.4 Registers

39.4.1 Register overview - access mode glossary

Table 1751 Register overview - access mode glossary

Keyword	Description
U	No access restrictions.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.

39.4.2 Register overview - SCR domain SCR (ascending offset address)

Table 1752 Register overview - SCR domain SCR (ascending offset address)

Short name	Description	RMAP	PAGE	Offset address	See
T2CCU0_T2_CON	Timer 2 instance 0 control register	0	T2CCU0_PAGE=0	081_H	6699
T2CCU0_CCEN	T2CCU0 capture/compare enable register	0	T2CCU0_PAGE=1	081_H	6705
T2CCU0_COSHDW	T2CCU0 compare shadow register	0	T2CCU0_PAGE=2	081_H	6710
T2CCU0_COCON	T2CCU0 compare control register	0	T2CCU0_PAGE=3	081_H	6713
T2CCU0_T2_MOD	Timer 2 instance 0 mode register	0	T2CCU0_PAGE=0	082_H	6700
T2CCU0_CCTBSEL	T2CCU0 capture/compare time base select register	0	T2CCU0_PAGE=1	082_H	6706
T2CCU0_CCxL	T2CCU0 capture/compare register x low	0	T2CCU0_PAGE=2	082_H+x*2	6712
T2CCU0_CCyL	T2CCU0 capture/compare register y low	0	T2CCU0_PAGE=3	082_H+(y-3)*2	6715
T2CCU0_T2_RC2L	Timer 2 instance 0 reload/capture register, low byte	0	T2CCU0_PAGE=0	083_H	6702
T2CCU0_CCTRELL	T2CCU0 capture/compare timer reload register low	0	T2CCU0_PAGE=1	083_H	6706
T2CCU0_CCxH	T2CCU0 capture/compare register x high	0	T2CCU0_PAGE=2	083_H+x*2	6712
T2CCU0_CCyH	T2CCU0 capture/compare register y high	0	T2CCU0_PAGE=3	083_H+(y-3)*2	6715
T2CCU0_CCTDTCL	T2CCU0 capture/compare timer dead-time control register low	0	T2CCU0_PAGE=4	083_H	6716
T2CCU0_T2_RC2H	Timer 2 instance 0 reload/capture register, high byte	0	T2CCU0_PAGE=0	084_H	6702
T2CCU0_CCTRELH	T2CCU0 capture/compare timer reload register high	0	T2CCU0_PAGE=1	084_H	6707

Timer 2 instance 0 control register Reset values see: Table 1753

PAGE: T2CCU0_PAGE=0, RMAP: 0

7	6	5	4	3	2	1	0
TF2	**EXF2**	**0**		**EXEN2**	**TR2**	**C_T2**	**CP_RL2**
rwh	rwh	r		rw	rwh	rw	rw

Field	Bits	Type	Description
CP_RL2	0	rw	**Capture/Reload select** 0_B Reload upon overflow or upon negative/positive transition at pin T2EX (when EXEN2 = 1) 1_B Capture timer 2 data register contents on the negative/positive transition at pin T2EX, provided EXEN2 = 1. The negative or positive transition at pin T2EX is selected by bit EDGESEL in register T2MOD.

(table continues...)

(continued)

Field	Bits	Type	Description
C_T2	1	rw	**Timer or counter select** 0_B Timer function selected 1_B Count upon negative edge at pin T2
TR2	2	rwh	**Timer 2 run control** This bit can be set or cleared by software to start or stop the timer T2. It can also be set by hardware via input T2EX, if bit T2MOD.T2RHEN is set to 1, or via a synchronized start with the CCT timer of the T2CCU0. ***Note**: Writing a one to this bit while the timer is running has no effect.* 0_B Timer T2 is halted 1_B Timer T2 is running
EXEN2	3	rw	**Timer 2 external enable control** 0_B External events are disabled 1_B External events are enabled in capture/reload mode
EXF2	6	rwh	**Timer 2 external flag** In capture/reload mode, this bit is set by hardware when a negative/ positive transition occurs at pin T2EX, if bit EXEN2 = 1. This bit must be cleared by software. ***Note**: When bit DCEN = 1 in auto-reload mode, no interrupt request to the core is generated.*
TF2	7	rwh	**Timer 2 overflow/underflow flag** Set by a timer 2 overflow/underflow. Must be cleared by software.
0	5:4	r	**Reserved** must be written with 0.

39.4.17 T2CCU0 compare shadow register

The register is addressable via T2CCU0_PAGE.

T2CCU0_COSHDW Offset address: 081_H

T2CCU0 compare shadow register Reset values see: Table 1767

PAGE: T2CCU0_PAGE=2, RMAP: 0

7	6	5	4	3	2	1	0
ENSHDW	TXOV	COOUT5	COOUT4	COOUT3	COOUT2	COOUT1	COOUT0
rwh	rw	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
COOUTx (x=0-5)	x	rwh	**Compare channel x output** **ENSHDW = 0:** Any access to bit COOUTx accesses the corresponding bit of the internal 6-bit compare output register. Writing to bit COOUTx will change the corresponding bit of the internal compare output register. Reading from bit COOUTx returns the value of the bit in the internal compare output register. The content of the internal compare output register is output on the corresponding T2CCx pins when a valid compare match occurs for a channel in compare mode 1 or concurrent compare mode. ***Note**: A concurrent write operation to clear bit ENSHDW and set/ clear bit(s) COOUTx is effective for initializing the internal compare output register.* **ENSHDW = 1:** In this case, accessing bit COOUTx accesses the actual SFR bits. If COOUTx is set, the contents of register CCx will be transferred to corresponding channel x internal compare register. On set, COOUTx is held for one PCLK, then cleared automatically by hardware. ***Note**: A concurrent write operation to set bit ENSHDW and bit(s) COOUTx (and clear bit TXOV) is effective for starting shadow transfer(s).*
TXOV	6	rw	**Enable shadow transfer on timer overflow** Set to enable for all compare channels, transfer of shadow value in T2CCU0_CCx to the corresponding internal compare registers on overflow of their respective timer base.
ENSHDW	7	rwh	**Enable shadow transfer with COOUTx** Clear to enable access of the internal compare output register via the COOUTx bits. Set to enable use of COOUTx bits for transfer of shadow value in T2CCU0_CCx to the corresponding channel x internal compare register. ***Note**: When setting bit TXOV, bit ENSHDW will be cleared by internal hardware. To ensure bit ENSHDW is set, user must ensure bit TXOV is cleared.*

39.4.21 T2CCU0 capture/compare register y low

The register is addressable via T2CCU0_PAGE.

T2CCU0_CCyL (y=3-5) Offset address: 082_H+(y-3)*2

T2CCU0 capture/compare register y low Reset values see: Table 1771

PAGE: T2CCU0_PAGE=3, RMAP: 0

rwh

Field	Bits	Type	Description
CCVALL	7:0	rwh	**Capture/Compare low byte value for channel y** **Capture:** On read, CCVALL returns the low byte of the last captured value. **Compare:** CCVALL holds the low byte written. CCy acts as a shadow register to the channel x internal compare register. The value written is only transferred to the internal compare register when the corresponding bit T2CCU0_COSHDW.COOUTx is being set (with ENSHDW = 1), or on overflow of the channel timer base. The read value always return the last written value. ***Note**: For T2CCU0_CC4L/H and T2CCU0_CC5L/H, only the compare function is available.*

Pm (m=0-7)	m	rwh	**Port Pn pin m enable wakeup function** This port pin can be used to wakeup the SCR. 0_B Writing 0 has no effect. 1_B Port Pn pin m wakeup function is requested to be enabled

39.4.47 Port Pn wake enable status register

The wake enable status reflects the status of the wakeup feature of the corresponding port pin. It is set when the corresponding WKEN is set to one and indicates that the wakeup feature for the port pin is available and STANDBY mode can be entered.

Note: This register is cleared by setting SCUSCR_STDBY.PMSWKPCLR.

- P0_WKENSTS[7:0] is mapped to PMS_PAD_WKENSTS[7:0]
- P1_WKENSTS[7:0] is mapped to PMS_PAD_WKENSTS[15:8]

39.4.49 Wake-Up CAN configuration register

WCAN_CFG Offset address: $0B0_H$

Wake-Up CAN configuration register Reset values see: Table 1796

PAGE: WCAN_PAGE=0, RMAP: 0

7	6	5	4	3	2	1	0
WCANRXDIS				CCE	SELWK_EN	0	WCAN_EN
rw				rw	rwh	r	rw

Field	Bits	Type	Description
WCAN_EN	0	rw	**WCAN enable** This bit enables or disables the clock to WCAN selective wake-up filter block. 0_B Disable clock to WCAN selective wake-up filter block 1_B Enable clock to WCAN selective wake-up filter block
SELWK_EN	2	rwh	**Selective wake-up enable** The selective wake-up enable function enables the protocol handler. The status of the protocol handler is also acknowledged through INTESTAT0.SWACK. The status of the Selective wakeup active is given in INTESTAT1.SWKSET. It also serves several functions when enabled. Allows wake-up source WUF to generate WUF_INT (see Figure "Wake-up frame detection"). Allows error counter to generate ERROR_INT (see Figure "Error counter"), indicated by INTESTAT0.ECOFL. Triggers ERROR_INT and wake-up if there are any changes to the message object registers, indicated by INTESTAT0.MORC. If a SYSERR occurs while SELWK_EN is enabled, then the Selective wake-up function shall be disabled (this bit field will be reset to 0). It is also indicated by INTESTAT0.ERSEL. 0_B Selective wake disabled 1_B Selective wake enabled
CCE	3	rw	**Configuration change enable** This bit field enables the configuration of the bit timing registers. It also acts as soft-reset to the selective wake-up filter block. It has to be set back to '0' once the bit timing registers are modified for desired baudrate. 0_B The bit timing registers (BTLn_CTRL), CDR configuration registers (CDR_CTRL, CDR_UPPER_CTRL, CDR_LOWER_CTRL) and CAN_FD_CTRL may only be read. All attempts to modify them will be ignored. 1_B The bit timing registers and CDR configuration registers may be read and written

rh	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
SWACK	0	rh	**Selective wake-up enable acknowledge** This bit field indicates the acknowledgment of protocol handler enabled/disabled. 0_B Protocol handler is disabled and configuration of WUF is possible 1_B Protocol handler is enabled and configuration of WUF should not be done

(table continues...)

(continued)

Field	Bits	Type	Description
MODE	1	rh	**WCAN mode of operation** This bitfield indicates the WCAN mode of operation. 0_B Normal mode 1_B Standby mode
SYSERR	2	rh	**CAN wake-up system error** The SYSERR indicates a configuration error (MORC), and an error counter overflow condition (ECOFL). 0_B Selective wake mode is possible 1_B System error detected, WCAN enabling not possible. It also leads to SYSERR_INT interrupt trigger if enabled through ERRMASK.
CANTO	3	rh	**CAN time-out detection** This bit indicates that there was an inactive CAN bus on RXDCO pin within $t_{SILENCE}$ of 750 ms. See section "CAN Message Timeout". A software write to INTESTATCLR0.CANTOCLR is required to reset this bit. 0_B Normal operation 1_B CAN time-out detected. It also leads to CANTO_INT interrupt if enabled through CANTOMASK.
ECOFL	4	rh	**Error counter overflow** This bit field shows occurrence of error counter overflow. A set condition of this flag by hardware has higher priority than a clear through ECOFLCLR. 0_B Error counter has not overflowed (<=31) 1_B Error counter overflowed (>31)
MORC	5	rh	**Message object register changed** A set condition of this flag by hardware has higher priority than a clear through MORCCLR. 0_B Message object registers not modified after SELWK_EN is set 1_B Message object registers was modified after SELWK_EN is set
ERSEL	6	rh	**Error select** A set condition of this flag by hardware has higher priority than a clear through ERSELCLR. 0_B SYSERR is not set while SELWK_EN is enabled 1_B SYSERR is set while SELWK_EN is enabled
WUP	7	rh	**Wake-Up pattern detected** This bit field is set when a falling edge on RXD (or WUP) is detected, when WCAN is in standby mode. A software write to INTESTATCLR0.WUPCLR is required to clear this bit field. 0_B WUP not detected 1_B WUP detected. It also triggers WUP_INT interrupt when enabled through INTMRSLT.WUPMASK

39.4.58 Wake-Up CAN interrupt and event status register 1

WCAN_INTESTAT1 Offset address: $0B1_H$

Wake-Up CAN interrupt and event status register 1 Reset values see: Table 1809

PAGE: WCAN_PAGE=1, RMAP: 0

7	6	5	4	3	2	1	0
0	RXDS	RXDF	FDF	CANSIL	SWKSET	SYNC	WUF
r	rh	rh	rh	rh	rh	rh	rh

Field	Bits	Type	Description
WUF	0	rh	**Wake-Up frame detection (as defined in ISO)** This bit shows the status whether a wake-up frame has been detected. 0_B No wake-up frame detected 1_B Wake-Up frame detected. It also leads to WUF_INT interrupt trigger if enabled through WUFMASK.
SYNC	1	rh	**Synchronization (at least one CAN frame without fail must have been received)** This bit is set when a valid classical CAN frame is detected and is updated after every received classical CAN frame. This flag is not updated when a CAN FD frame is received. Clearing this flag through SYNCCLR has higher priority than a set condition by hardware. 0_B WCAN function not working or not synchronous to CAN bus 1_B Valid CAN frame received, WCAN function is synchronous to CAN bus
SWKSET	2	rh	**Selective wake activity** 0_B Selective wake is not active 1_B Selective wake is activated
CANSIL	3	rh	**CAN bus silent time during selective wake operation** This bit is set if there is no activity on RXDC0 pin on the CAN bus after $t_{SILENCE}$ of 750 ms expired. If any activity is detected on the bus, this bit is reset automatically. $t_{SILENCE}$ is fixed at 750 ms. This bit can also be cleared through bit WCAN_INTESCLR.CANSILCLR. A set condition of this bit has higher priority than a clear through CANSILCLR. 0_B not exceeded $t_{SILENCE}$ not exceeded 1_B is exceeded $t_{SILENCE}$ is exceeded

(table continues...)

(continued)

Field	Bits	Type	Description
FDF	4	rh	**FD frame reception** This bit indicates reception of CAN FD frame. After reception of the CAN FD frame is completed, this bit is cleared to '0'. 0_B No action 1_B FD frame is being received
RXDF	5	rh	**Filtered receive data input** This bit shows the logic state of the filtered received data input signal (RXD_filt). 0_B Dominant 1_B Recessive
RXDS	6	rh	**Sampled receive data input** This bit shows the logic state of the sampled received data input signal by the protocol handler. 0_B Dominant 1_B Recessive
0	7	r	**Reserved** Read as 0; must be written with 0.

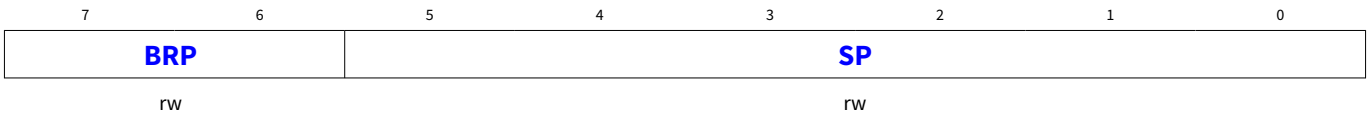
WCAN_BTL2_CTRL Offset address: $0B6_H$

Bit timing logic 2 control register Reset values see: Table 1816

PAGE: WCAN_PAGE=1, RMAP: 0



Field	Bits	Type	Description
SP	5:0	rw	**Sample point position** Represents the sample point position. The sample point position is calculated as given in section "Filter and Sample Point Calculation". 33_H represents the sample point position of 79.68 % (~80 %). The value shall be within $2C_H$ to 38_H (this means: 67.5 % to 87.5 %).

Serial channel control register Kernel Reset value: 00_H

PAGE: X, RMAP: 0

7	6	5	4	3	2	1	0
SM01		SM2	REN	TB8	RB8	TI	RI
rw		rw	rw	rw	rwh	rwh	rwh

Field	Bits	Type	Description
RI	0	rwh	**Receive interrupt flag** This is set by hardware at the end of the 8th bit on mode 0, or at the half point of the stop bit in modes 1, 2, and 3. This bit can also be set by software. Must be cleared by software. ***Note**: In case of an ongoing reception and a mode change at the very same time, the flag RI will have an undefined behavior, as it is dependent from the point in time of the mode change.*
TI	1	rwh	**Transmit interrupt flag** This is set by hardware at the end of the 8th bit in mode 0, or at the beginning of the stop bit in modes 1, 2, and 3. This bit can also be set by software. Must be cleared by software. ***Note**: If a transmission has been started and TI is still 0, a further write to UART_SBUF will destroy the ongoing transmission. If TI is set to 1, the next transmission can be started.*
RB8	2	rwh	**Serial port receiver bit 9** In modes 2 and 3, this is the 9th data bit received. In mode 1, this is the stop bit received. In mode 0, this bit is not used.
TB8	3	rw	**Serial port transmitter bit 9** In modes 2 and 3, this is the 9th data bit sent.
REN	4	rw	**Enable receiver of serial port** ***Note**: The operating mode of the UART must not be changed while bit REN is set (or while a transmission is in progress). Before changing the mode of the UART, bit REN shall be cleared to 0.* 0_B Serial reception is disabled 1_B Serial reception is enabled

(table continues...)

(continued)

Field	Bits	Type	Description
SM2	5	rw	**Enable serial port multiprocessor communication in modes 2 and 3** In mode 2 or 3, if SM2 is set to 1, RI will not be activated if the received 9th data bit (RB8) is 0. In mode 1, if SM2 is set to 1, RI will not be activated if a valid stop bit (RB8) was not received. In mode 0, SM2 should be 0. ***Note**: The operating mode of the UART must not be changed while bit REN is set or while a transmission is in progress. Before changing the mode of the UART, make sure that no transmissions are in progress, and that bit REN is cleared to 0.*
SM01	7:6	rw	**Serial port operating mode selection** ***Note**: The operating mode of the UART must not be changed while bit REN is set or while a transmission is in progress. Before changing the mode of the UART, make sure that no transmissions are in progress, and that bit REN is cleared to 0.* 00_B **MODE_0**: 8-bit shift register, fixed baud rate ($^{fPCLK}/_{2}$) 01_B **MODE_1**: 8-bit UART, variable baud rate 10_B **MODE_2**: 9-bit UART, fixed baud rate ($^{fPCLK}/_{64}$ or $^{fPCLK}/_{32}$) 11_B **MODE_3**: 9-bit UART, variable baud rate

39.4.76 Serial data buffer

***Note**: Register UART_SBUF may only be written to when no transmission is in progress (a previously commenced transmission is finished when bit UART_SCON.TI is set to 1). Otherwise, an ongoing transmission may be corrupted.*

39.4.95 T2CCU1 compare shadow register

The register is addressable via T2CCU1_PAGE.

T2CCU1_COSHDW Offset address: $0BF_H$

T2CCU1 compare shadow register Reset values see: Table 1846

PAGE: T2CCU1_PAGE=2, RMAP: 0

7	6	5	4	3	2	1	0
ENSHDW	**TXOV**	**COOUT5**	**COOUT4**	**COOUT3**	**COOUT2**	**COOUT1**	**COOUT0**
rwh	rw	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
COOUTx (x=0-5)	x	rwh	**Compare channel x output** **ENSHDW = 0:** Any access to bit COOUTx accesses the corresponding bit of the internal 6-bit compare output register. Writing to bit COOUTx will change the corresponding bit of the internal compare output register. Reading from bit COOUTx returns the value of the bit in the internal compare output register. The content of the internal compare output register is output on the corresponding T2CCx pins when a valid compare match occurs for a channel in compare mode 1 or concurrent compare mode. ***Note**: A concurrent write operation to clear bit ENSHDW and set/ clear bit(s) COOUTx is effective for initializing the internal compare output register.* **ENSHDW = 1:** In this case, accessing bit COOUTx accesses the actual SFR bits. If COOUTx is set, the contents of register CCx will be transferred to corresponding channel x internal compare register. On set, COOUTx is held for one PCLK, then cleared automatically by hardware. ***Note**: A concurrent write operation to set bit ENSHDW and bit(s) COOUTx (and clear bit TXOV) is effective for starting shadow transfer(s).*
TXOV	6	rw	**Enable shadow transfer on timer overflow** Set to enable for all compare channels, transfer of shadow value in T2CCU1_CCx to the corresponding internal compare registers on overflow of their respective timer base.
ENSHDW	7	rwh	**Enable shadow transfer with COOUTx** Clear to enable access of the internal compare output register via the COOUTx bits. Set to enable use of COOUTx bits for transfer of shadow value in T2CCU1_CCx to the corresponding channel x internal compare register. ***Note**: When setting bit TXOV, bit ENSHDW will be cleared by internal hardware. To ensure bit ENSHDW is set, user must ensure bit TXOV is cleared.*

Field	Bits	Type	Description
PAGE	2:0	rwh	**Page bits** When written, the value indicates the new page address. When read, the value indicates the currently active page = addr[y:x+1]. 000_B **PAGE0**: Selection is PAGE0 001_B **PAGE1**: Selection is PAGE1 010_B **PAGE2**: Selection is PAGE2 011_B **PAGE3**: Selection is PAGE3 100_B **PAGE4**: Selection is PAGE4 101_B **PAGE5**: Selection is PAGE5 110_B **PAGE6**: Selection is PAGE6 111_B **PAGE7**: Selection is PAGE7
STNR	5:4	w	**Storage number** This number indicates which storage bitfield is the target of the operation defined by bit OP. If OP = 10_B, the contents of PAGE are saved in STx before being overwritten with the new value. If OP = 11_B, the contents of PAGE are overwritten by the contents of STx. The value written to bitfield PAGE is ignored. 00_B **MOD_ST0**: ST0 is selected 01_B **MOD_ST1**: ST1 is selected 10_B **MOD_ST2**: ST2 is selected 11_B **MOD_ST3**: ST3 is selected
OP	7:6	w	**Operation** 00_B **PAGE_MANUAL0**: Manual page mode. The value of STNR is ignored and PAGE is directly written. 01_B **PAGE_MANUAL1**: Manual page mode. The value of STNR is ignored and PAGE is directly written 10_B **PAGE_SAVE**: New page programming with automatic page saving. The value written to the bit positions of PAGE is stored. In parallel, the former contents of PAGE are saved in the storage bit field STx indicated by STNR. 11_B **PAGE_RESTORE**: Automatic restore page action. The value written to the bit positions PAGE is ignored and instead, PAGE is overwritten by the contents of the storage bit field STx indicated by STNR.
0	3	r	**Reserved** Read as 0; must be written with 0.

39.4.104 ADCOMP control register

ADCOMP_CON Offset address: $0C7_H$

ADCOMP control register Reset values see: Table 1855

PAGE: X, RMAP: 0

7	6	5	4	3	2	1	0
SOC	**STSEL**		**CHSEL**				**EN_REQ**
rwh	rw		rw				rw

Field	Bits	Type	Description
EN_REQ	0	rw	**ADC comparator enable request** The ADC clock source is NOT automatically enabled upon setting of this bit. It can enabled in SCUSCR_CLK register by setting DIV_REQ to any other value than 0xF to activate the 100 MHz HPOSC clock. It is required to wait some time for the ADCOMP unit to start after the request. The activation status can be read from ADCOMP_RESHSTAT.EN_STAT. Note: The time can vary from around 15 to 65 µs, depending if system was in RUN or in STANDBY0 or in STB1_70KHz mode prior to setting EN_REQ. In any case the application can poll on ADCOMP_RESHSTAT.EN_STAT to know, if the ADCOMP is ready or not. In case EN_REQ is cleared during ongoing conversion, then the ADC is disabled only after the currently running conversion is ended. 0_B ADCOMP unit is disabled 1_B ADCOMP unit is enabled
CHSEL	4:1	rw	**ADC channel select** This bit-field selects the channel and configures the 16:1 ADC multiplexer before a conversion is triggered. During an ongoing measurement (sampling and conversion) CHSEL shall be kept unchanged. If CHSEL is changed during an ongoing conversion, the result of the conversion is invalid. 0_H **CH0**: CH0 is selected … F_H **CH15**: CH15 is selected
STSEL	6:5	rw	**Sample time selection** Sampling time value is taken into account when SOC signal is set and latched locally inside ADC. If the bit is changed during an ongoing measurement, the new value will be taken into account at the next start of conversion. 00_B Minimal sample time is selected (80ns, default) 01_B Sample time of 100 ns is selected 10_B Sample time of 200 ns is selected 11_B Sample time of 400 ns is selected

(table continues...)

(continued)

Field	Bits	Type	Description
SOC	7	rwh	**ADC start of conversion request** This bit activates a new conversion. This bit is automatically cleared by hardware once the conversion has started. If EOC is set, setting SOC clears EOC. 0_B ADC conversion is not started 1_B ADC conversion is started

PAGE: X, RMAP: 0

7	6	5	4	3	2	1	0
0			EOC	EN_STAT	RES10_8		
r			rh	rh	rh		

Field	Bits	Type	Description
RES10_8	2:0	rh	**ADC conversion result** This register shows the current converted ADC result. Software should ensure that the result is read before starting the next conversion.
EN_STAT	3	rh	**ADC comparator enable status** This bit indicates that the ADC unit, the associated bandgap HPBG, and the clock required for the ADC unit are active, and a subsequent conversion can be triggered. It is set after some time after EN_REQ is set - time can vary from around 15 to 65 µs, depending if HPBG was enabled or not prior to setting EN_REQ. 0_B ADCOMP unit is disabled 1_B ADCOMP unit is enabled
EOC	4	rh	**ADC end of conversion / sampling indication** This bit indicates that a conversion is completed and the result can be read. A new conversion via SOC can be started only when the EOC from the previous conversion has been set, except in case of the first measurement where SOC can be started even if EOC is not set. This bit is automatically cleared when SOC is set. 0_B ADC conversion is currently on-going 1_B ADC conversion is completed.
0	7:5	r	**Reserved** Read as 0; must be written with 0.

39.4.132 Real-time clock compare/capture register n

4 compare and capture registers, RTCSCR_CR0 - RTCSCR_CR3, are used to represent 32 bits of compare value, which will generate a compare event when it matches the counter value as specified in the RTCSCR_CNT register.

When a capture event is triggered by setting RTCCT bit to 1, the content in the RTCSCR_CRn register will be overwritten with the captured RTCSCR_CNT value after a maximum of 8 f_{RTC} clock cycles. In order to take effect of the new capture value inside RTCSCR_CRn, another delay of 9 RTC clock cycles is required. During this time, the compare interrupt is disabled.

If the pre-scaler is bypassed, then the captured value inside the register is 2 or 3 clock cycles higher in relation to the point in time of the trigger set in RTCCT. Otherwise, the value is exact or 1 clock cycle higher than the point in time of the trigger.

***Note**: When RTCSCR_CRn is written, a minimum delay of 8 RTC clock cycles is required, until the next write access to the register is allowed. Otherwise, the second write access is not guaranteed.*

***Note**: Before starting the RTC counter, the compare value in registers RTCSCR_CRn should be set to a value different to 0 (e.g. 0xFFFF). Otherwise, the RTC will not start if it is initially 0, or stop after an overflow to 0.*

Clock control and status register Reset values see: Table 1876

PAGE: SCUSCR_PAGE=0, RMAP: 0

7	6	5	4	3	2	1	0
DIV_STAT				DIV_REQ			
rh				rwh			

Field	Bits	Type	Description
DIV_REQ	3:0	rwh	**Clock divider request** Effect on enabling and disabling of HPOSC 100 MHz oscillator from this bit-field is only considered when the main system is in standby mode. In all other modes SCR has no control over HPOSC. Setting this bit-field triggers either an immediate or a stepwise clock update: • If both DIV_STAT and the new DIV_REQ value represent frequency <= 10 MHz (DIV10 or higher DIV values) the transition to the new value, immediately. • If at least one of the DIV_REQ or DIV_STAT values represent frequency >10 MHz (DIV is one of DIV1-5,DIV8) the transition is stepwise. In case of stepwise transition, both directions (lower frequency to higher, and higher to lower) are affected. Steps are performed one DIV increment/decrement at a time between DIV1 and DIV10, and a direct transition between DIV10 and DIV70kHz. Each steps takes ~15.3 us. If f_start=70 kHz and HPOSC was not enabled prior to setting DIV_REQ to a new value, it takes additional ~200 us to start the HPOSC oscillator. This bit-field is automatically set to its default value (DIV5, 20 MHz) upon reset and upon detection of WCAN wake-up signal. 0_H **DIV1**: DIV = 1; f_{SYS} = 100 MHz 1_H **DIV2**: DIV = 2; f_{SYS} = 50 MHz 2_H **DIV3**: DIV = 3; f_{SYS} = 33.3 MHz 3_H **DIV4**: DIV = 4; f_{SYS} = 25 MHz 4_H **DIV5**: DIV = 5; f_{SYS} = 20 MHz (default) 5_H **DIV8**: DIV = 8; f_{SYS} = 12.5 MHz 6_H **DIV10**: DIV = 10; f_{SYS} = 10 MHz 7_H **DIV16**: DIV = 16; f_{SYS} = 6.25 MHz 8_H **DIV20**: DIV = 20; f_{SYS} = 5 MHz 9_H **DIV32**: DIV = 32; f_{SYS} = 3.125 MHz A_H **DIV50**: DIV = 50; f_{SYS} = 2 MHz B_H **DIV80**: DIV = 80; f_{SYS} = 1.25 MHz C_H **DIV100**: DIV = 100; f_{SYS} = 1 MHz D_H **DIV160**: DIV = 160;

(table continues...)

(continued)

Field	Bits	Type	Description
			f_{SYS} = 0.625 MHz E_H **DIV200**: DIV = 200; f_{SYS} = 0.5 MHz F_H **DIV70kHz**: 70 kHz f_{SYS} = 70 kHz
DIV_STAT	7:4	rh	**Clock divider status** Represents current clock frequency. If DIV_STAT is different than DIV_REQ it means that a stepwise frequency update is on-going. 0_H **DIV1**: DIV = 1; f_{SYS} = 100 MHz 1_H **DIV2**: DIV = 2; f_{SYS} = 50 MHz 2_H **DIV3**: DIV = 3; f_{SYS} = 33.3 MHz 3_H **DIV4**: DIV = 4; f_{SYS} = 25 MHz 4_H **DIV5**: DIV = 5; f_{SYS} = 20 MHz 5_H **DIV8**: DIV = 8; f_{SYS} = 12.5 MHz 6_H **DIV10**: DIV = 10; f_{SYS} = 10 MHz 7_H **DIV16**: DIV = 16; f_{SYS} = 6.25 MHz 8_H **DIV20**: DIV = 20; f_{SYS} = 5 MHz 9_H **DIV32**: DIV = 32; f_{SYS} = 3.125 MHz A_H **DIV50**: DIV = 50; f_{SYS} = 2 MHz B_H **DIV80**: DIV = 80; f_{SYS} = 1.25 MHz C_H **DIV100**: DIV = 100; f_{SYS} = 1 MHz D_H **DIV160**: DIV = 160; f_{SYS} = 0.625 MHz E_H **DIV200**: DIV = 200; f_{SYS} = 0.5 MHz F_H **DIV70kHz**: 70 kHz f_{SYS} = 70 kHz

Field	Bits	Type	Description
VAL	7:0	rh	**TIM[63:56] value**

39.4.155 SCR access to PMS_RTC_CON1.OFFSET[7:0] bits and update trigger for complete PMS_RTC_CON1.OFFSET

Writing to this register updates PMS_RTC_CON1.OFFSET[15:0] bit-field with combined content of PMSRTC_OFFSET15_8 and this register if system is not in STANDBY1_70K mode. It is important to update the content of PMSRTC_OFFSET15_8 along with this register. Writing only to this register will assume the value of PMSRTC_OFFSET15_8 to be 0x00. Therefore, to ensure that all the bits of PMS_RTC_CON1.OFFSET[15:0] are correctly written, it is important to update both this register and PMSRTC_OFFSET15_8.

Reading this register returns value from respective PMS_RTC bit-field.

SCUSCR_PMSRTC_OFFSET7_0 Offset address: $0F0_H$

39.4.175 Page register for SFRs

IRSCR_PAGE Offset address: $0F6_H$

Page register for SFRs Reset values see: Table 1885

PAGE: X, RMAP: 0

7	6	5	4	3	2	1	0
OP		**STNR**		**0**	**PAGE**		
w		w		r	rwh		

Field	Bits	Type	Description
PAGE	2:0	rwh	**Page bits** When written, the value indicates the new page address. When read, the value indicates the currently active page = addr[y:x+1]. 000_B **PAGE0**: Selection is PAGE0 001_B **PAGE1**: Selection is PAGE1 010_B **PAGE2**: Selection is PAGE2 011_B **PAGE3**: Selection is PAGE3 100_B **PAGE4**: Selection is PAGE4 101_B **PAGE5**: Selection is PAGE5 110_B **PAGE6**: Selection is PAGE6 111_B **PAGE7**: Selection is PAGE7
STNR	5:4	w	**Storage number** This number indicates which storage bitfield is the target of the operation defined by bit OP. If OP = 10_B, the contents of PAGE are saved in STx before being overwritten with the new value. If OP = 11_B, the contents of PAGE are overwritten by the contents of STx. The value written to bitfield PAGE is ignored. 00_B **MOD_ST0**: ST0 is selected 01_B **MOD_ST1**: ST1 is selected 10_B **MOD_ST2**: ST2 is selected 11_B **MOD_ST3**: ST3 is selected

(table continues...)

(continued)

Field	Bits	Type	Description
OP	7:6	w	**Operation** 00_B **PAGE_MANUAL0**: Manual page mode. The value of STNR is ignored and PAGE is directly written. 01_B **PAGE_MANUAL1**: Manual page mode. The value of STNR is ignored and PAGE is directly written 10_B **PAGE_SAVE**: New page programming with automatic page saving. The value written to the bit positions of PAGE is stored. In parallel, the former contents of PAGE are saved in the storage bit field STx indicated by STNR. 11_B **PAGE_RESTORE**: Automatic restore page action. The value written to the bit positions PAGE is ignored and instead, PAGE is overwritten by the contents of the storage bit field STx indicated by STNR.
0	3	r	**Reserved** Read as 0; must be written with 0.

39.4.190 I2C control register

This register is used to configure the I2CSCR and generate START and STOP conditions. It also contains the interrupt status flag.

I2CSCR_CNTR Offset address: $0FA_H$

I2C control register Reset values see: Table 1900

PAGE: X, RMAP: 0

7	6	5	4	3	2	1	0
IEN	ENAB	STA	STP	IFLG	AAK	0	
rw	rw	rwh	rwh	rwh	rw	r	

Field	Bits	Type	Description
AAK	2	rw	**Assert acknowledge** ***Note**: If the AAK bit is cleared to 0 in slave transmitter mode, the byte in the DATA register is assumed to be the last byte.* 0_B A NACK is sent when a data byte is received in master or slave mode. 1_B An ACK is sent if one of the following has been received: 1) A matching 7-bit or either byte of the 10-bit slave address 2) General call address 3) A databyte in master or slave mode
IFLG	3	rwh	**Interrupt flag** The bit is set by hardware and can only be cleared through software by writing a 0. 0_B No interrupt event has occurred. 1_B An interrupt event has occurred.
STP	4	rwh	**Master mode stop** When this bit is set to 1, the I2CSCR will transmit a STOP condition. If the STP bit is set while the I2CSCR is in slave mode, no STOP condition will be transmitted on the I2C bus but the I2CSCR behaves as if a STOP condition has been received. If both STA and STP bits are set, the I2CSCR will first transmit a STOP condition (if in master mode) before transmitting a START condition. ***Note**: The STP bit is cleared automatically after the STOP condition has been sent; writing 0 to this bit has no effect.* 0_B The I2C does not transmit any STOP condition. 1_B The I2C transmits a STOP condition on the I2C bus.
STA	5	rwh	**Master Mode Start** When the STA bit is set to 1, the I2CSCR will enter master mode and transmit a START condition once the I2C bus is free. If the I2CSCR is already in master mode and one or more bytes have been transmitted, a repeated START condition will be transmitted. If the I2CSCR is still being accessed in slave mode, the I2CSCR will complete the data transfer in slave mode and enter master mode once the I2C bus has been released. ***Note**: The STA bit is cleared automatically after the START condition has been sent; writing 0 to this bit has no effect.* 0_B The I2C does not enter master mode. 1_B The I2C enters master mode and transmits a START condition on the I2C bus.

39.5 Debug information

39.5.1 Features

The main debug functionality supported are:

- Set breakpoints on instruction address and on address range within the program memory
- Set breakpoints on Internal Memory (IMEM) address range for read and write
- Support unlimited software breakpoints in Flash/RAM code region
- Process external breaks through debug interface
- Stepping through the program code
- User handling of OCDS NMI in case of IMEM read/write breakpoint

In summary, up to four hardware breakpoints can be set for the current implementation. It can be used for detection specific Instruction Pointer (IP), a range of IP and specific range of read/write of internal Memory (IMEM),
unlimited software breakpoint (only possible in writable region) and external break. When any of the above is encountered, that corresponds to a debug event which will then trigger the execution of Monitor ROM.

39.5.2 Components of the debug system

The components of the debug system are briefly described here.

39.5.2.1 Debug interface

The debug interface allows to access the device, such as for data read or write. The debug interface supports:

- Dual-pin Device Access Port (DAP)
- Single-pin DAP (SPD)

The DAP interface refers to the "Dual-pin Device Access Port" standardized for the Infineon micro-controllers. It offers high noise immunity and robustness, and requires only two pins DAP0 (clock), DAP1 (serial data in/out).

The SPD interface refers to the "Single-pin Device Access Port" standardized for the Infineon micro-controllers. It requires only one pin DAP1 for serial data in/out.

39.5.2.2 Monitor program

Part of the Boot ROM is occupied by the OCDS monitor program (or OCDS firmware). On the command from the debugger, the monitor program executes the actual instructions for accessing the addressable locations such as memories and SFRs of the device.

39.5.2.3 On-Chip Debug System unit (OCDS)

The OCDS hardware is the core of the debug system, controlling the debugging with interfaces to the XC800 CPU.

39.5.3 Product specific OCDS information

39.5.3.1 OCDS pin functions

Table 1908 OCDS pin functions

Function	Pin connection	Description
DAP0_1	SCR_P0.2 (P33.2)	Dual-pin debug access port: clock
DAP0_0	SCR_P0.6 (P33.6)	
DAP1_1/SPD_1	SCR_P0.3 (P33.3)	Single-pin debug access port: data
DAP1_0/SPD_0	SCR_P0.7 (P33.7)	

The pin will be set up through hardware once the OCDS mode is selected. A detailed pin-out is given in the GPIO chapter.

39.5.3.2 Clocking configuration

The OCDS runs at the peripheral frequency, PCLK.

39.5.3.3 JTAG ID

The following assignment of JTAG ID are used for SCR:

VERSION = 1_H, PART_NUMBER = $01EC_H$, i.e. JTAG ID Register = $101EC083_H$

39.6 References

This section is not applicable for the module being described.

39.7 SCR revision history

Reference	Description of change(s)
Date range: 2025-02-26 to 2025-03-31	
Revision history	• Updated Revision history table according latest template
Debug information	• Added section with debug information
External data memory	• Added XRAM access protection reference to PMS
Initialization of break/ synch field detection logic	• Description provided with more details
SCR functions in port SCR_P2	• Corrected generic mapping between register bit fields and pin
SCR functions in port SCR_P3	• Corrected generic mapping between register bit fields and pin
Date range: 2024-10-05 to 2025-02-25	
UART connections to GPIO	• Corrected typo in UART connections to GPIO ports figure: P35.7 on RXD0 means to be P35.5
WCAN initialization sequence	• New description added for WCAN initialization sequence

39 Stand-by Controller (SCR)

Reference	Description of change(s)
Initialization of break/ synch field detection logic	• New description added for LIN auto baud detection feature
Date range: 2024-08-17 to 2024-10-04	
Stand-by Controller (SCR)	• The SCR specification has been completely reworked and shows the TC4xx silicon changes relevant for TC4Dx

39.8 TC4Dx SCR information

39.8.1 TC4Dx SCR configuration

The TC4Dx has the base SCR configuration. All registers deviating among the devices are listed in this paragraph.

39.8.2 TC4Dx SCR features

The additional IO page does not exist in this device. The following registers are for future extension of the IO page:

The IO_PAGE=3 is not existing on this device, it includes the following registers

- Pn_WKEN, Pn_WKENSTS and Pn_WKSTS

ADCOMP_CTR registers

- The ADCOMP_CTR register described in the ADCOMP paragraph

SCUSCR_PMS1IVRCON register

- The register SCUSCR_PMS1IVRCON enables the application to switch among the power modes
- To enable the SCR to switch its power modes the bit SCUSCR_PMS1IVRCON.SINKCTRLEN has to be set to 1. When enabling the power mode control via SCR the following has to be regarded: If SCUSCR_PMS1IVRCON.SINKCTRLEN=1, it is required that SCUSCR_CLK.DIV.REQ >= 5 (max. SCR frequency is limited 20 MHz in the medium power mode), otherwise there is a risk of triggering under-voltage reset or alarms
- The SCUSCR_PMS1IVRCON.SINKCTR regulates the power consumption. A 0_B represents the lowest power saving level and therefore the highest power consumption, dependent on the wished power saving this lowest power consumption can be reached with programming a 3_B

39.8.3 TC4Dx SCR functional description

The device specific registers are listed below.

39.8.3.4 ADCOMP control register

ADCOMP_CON Offset address: $0C7_H$

ADCOMP control register Reset values see: Table 1912

PAGE: X, RMAP: 0

7	6	5	4	3	2	1	0
SOC	**STSEL**		**CHSEL**				**EN_REQ**
rwh	rw		rw				rw

Field	Bits	Type	Description
EN_REQ	0	rw	**ADC comparator enable request** The ADC clock source is NOT automatically enabled upon setting of this bit. It can enabled in SCUSCR_CLK register by setting DIV_REQ to any other value than 0xF to activate the 100 MHz HPOSC clock. It is required to wait some time for the ADCOMP unit to start after the request. The activation status can be read from ADCOMP_RESHSTAT.EN_STAT. Note: The time can vary from around 15 to 65 µs, depending if system was in RUN or in STANDBY0 or in STB1_70KHz mode prior to setting EN_REQ. In any case the application can poll on ADCOMP_RESHSTAT.EN_STAT to know, if the ADCOMP is ready or not. In case EN_REQ is cleared during ongoing conversion, then the ADC is disabled only after the currently running conversion is ended. 0_B ADCOMP unit is disabled 1_B ADCOMP unit is enabled
CHSEL	4:1	rw	**ADC channel select** This bit-field selects the channel and configures the 16:1 ADC multiplexer before a conversion is triggered. During an ongoing measurement (sampling and conversion) CHSEL shall be kept unchanged. If CHSEL is changed during an ongoing conversion, the result of the conversion is invalid. 0_H **CH0**: CH0 is selected … F_H **CH15**: CH15 is selected

(table continues...)

(continued)

Field	Bits	Type	Description
STSEL	6:5	rw	**Sample time selection** Sampling time value is taken into account when SOC signal is set and latched locally inside ADC. If the bit is changed during an ongoing measurement, the new value will be taken into account at the next start of conversion. 00_B Minimal sample time is selected (80ns, default) 01_B Sample time of 100 ns is selected 10_B Sample time of 200 ns is selected 11_B Sample time of 400 ns is selected
SOC	7	rwh	**ADC start of conversion request** This bit activates a new conversion. This bit is automatically cleared by hardware once the conversion has started. If EOC is set, setting SOC clears EOC. 0_B ADC conversion is not started 1_B ADC conversion is started

39.8.4 TC4Dx SCR connectivity

There are no deviations from the generic specification.
The connectivity of the SCR module can be found within the corresponding device datasheet.

39.8.5 TC4Dx SCR revision history

Initial release of the chapter.

40 Interrupt Router (IR)

The interrupt router receives interrupts from external resources, internal functional blocks and from application software and forwards them as service requests to the interrupt targets (CPUs, DMAs, GTM, and the PPU). These interrupt targets are referred to as interrupt service providers (ISP).

The IR converts the interrupt events from functional blocks and application software into service requests (SR) by adding configurable information, such as which interrupt target, service request priority number, and service request security information.

***Note**: Unless otherwise stated, ´CPUs´ means ´all TriCore™ CPUs´, which includes CPUx and the CPUCS.*

40.1 Feature list

- Interrupt system with support for up to 2048 service requests
- Support for up to 256 service request priority levels per Interrupt Control Unit (ICU) and Interrupt Service Provider (ISP)
- Support for up to 15 ICUs
- A dedicated ICU for each implemented ISP. The ISPs are the functional blocks CPUs, DMAs, PPU, and the GTM
- Low latency arbitration
  - Four fSPB clock cycles from interrupt trigger to service request signaling to ISP
  - Interrupt latency may increase for an ICU that operates in hardware virtualization mode
- Each interrupt with a dedicated Service Request Node (SRN)
  - Each SRN with a programmable 8-bit Service Request Priority Number (SRPN)
  - Each SRN can be mapped to one of the implemented ISP
  - Each SRN can be mapped to exactly one virtual machine
  - SRNs are cleared by hardware on an interrupt acknowledge by the configured ISP if no EDC error is detected
- Interrupt system with integrity support
  - The IR is implemented with a lockstep mechanism
  - End-to-end EDC protection of the interface between IR and the ISPs
- Software Interrupts
  - One group of 8 General Purpose Service Requests (GPSR) per CPU and for the PPU
- Ability to signal software interrupts simultaneously to multiple ISPs through service request broadcast registers (SRB)
- Ability to transfer additional 16-bit information through software interrupt control register (GPSRG_SWC.DATA) to ISPs, protected by a hardware handshake
- External interrupts with filter and trigger modes
  - External interrupt logic and related control registers are described in the System Control Unit (SCU) chapter, External Request Unit (ERU)
- The IR provides wake-up support for the CPUs and the PPU that can cause the respective function block that is currently in idle or sleep to enter run mode

40.2 Functional overview

The Interrupt router schedules interrupts, called service requests, from external resources, internal functional blocks, and from application software to the interrupt targets. The interrupt targets are the functional blocks CPUs, DMAs, GTM and the PPU. These service request targets are referred to as Interrupt service providers (ISP). The IR converts the interrupt events from functional blocks and application software into service requests by adding configurable information about which interrupt target, service request priority number, service request and security information.

The Interrupt router includes:

40 Interrupt Router (IR)

- The Service request nodes (SRNs)
- The Software interrupt functions that includes
  - General purpose service request nodes (GPSR)
  - Broadcast control registers (SRB)
  - Software control registers (SWC)
- The Interrupt control units (ICU) with its control registers
- Additional functionality for software development support like access protection and debug support

TC4Dx SMU alarm mapping tables on page 7233

40.3 Functional description

As shown in the figure ´IR block diagram´ , each functional block that can generate interrupt requests is connected to one or more Service Request Nodes (SRNs) in the Interrupt Router (IR).

Each SRN contains a Service request control register (SRC) to configure the Service request (SR) regarding priority and mapping to one of the available Interrupt service provider (ISP).

The IR module contains also several groups of General purpose service request nodes (GPSR) that can be used for software (SW) triggered service requests. There is a Broadcast register for each GPSR group which allows to trigger multiple nodes of the related GPSR group with one software access.

Additionally for each GPSR there is a GPSR control register (GPSRGx_SWC) and a GPSR access protection register (GPSRGx_SWCACCENy). These registers enable application software to map each GPSR individually to master function(s), control it from the mapped master function(s) and enable the master function(s) to signal additional information to the configured ISP.

The IR has a dedicated interface, called interrupt control unit (ICU), for each implemented physical interrupt service provider (ISP) which are CPUs, DMAs, PPU and GTM.

For each ICU the IR arbitrates among all pending service requests mapped to an ISP and passes the current arbitration round winner to the corresponding ICU.

The ICU signals the latest winning service request to the related interrupt service provider (ISP). The ISP signals back to the ICU if it has taken a service request (SR) for further processing.

The IR offers the possibility to protect the group of security related SRNs against modification by other master function and to protect the group of safety related SRNs against modification by the security function (SRC.CS, PROT_CSE, PROT_SE).

40.3.1 Service request nodes (SRN)

Each service request node (SRN) inside the IR contains a service request control register (SRC) and interface logic that connects it to the interrupt trigger source outside the IR.

40.3.1.1 Service request control registers (SRC)

The description given in this chapter characterizes the Service Request Control registers (SRC).

All SRC registers in the Interrupt Router module have the same format where each register contains the following control and status information:

- Service Request Priority Number (SRPN)
- Service Request Virtual Machine Number (VM)
- Service Request Cyber Security configuration (CS)
- Service Request destination, Interrupt Service Provider (TOS)
- Enable and disable the Service Request Node (SRE)
- Service Request Set bit and Service Request Clear bit (SETR, CLRR)
- Service request status bit (SRR)
- Interrupt Overflow bit (IOV)
- Interrupt Overflow Clear bit (IOVCLR)

Besides being activated by the associated triggering unit through hardware, each SRN can also be set or reset by software through two software-initiated service request control bits.

If a service request node is disabled with SRE=0 it can not generate a service request. Nevertheless, the SRR and IOV bits will be set in case of an interrupt and interrupt overflow event. As long SRE=0 the SRR=1 information will not be taken into account for the IR arbitration nor will it be signaled as pending service request to the SMM for the IR wake-up support for CPUs and PPU.

***Note**: Several modules have additional interrupt related control registers on module level, for example interrupt status, set clear or enable register. These module registers are described in the corresponding sections of the module chapters.*

Interrupt trigger overflow clear bit (IOVCLR) on page 6865

40.3.1.1.1 Request set and clear bits (SETR, CLRR)

The SETR and CLRR bits allow software to set or clear the service request bit SRR.

- Writing a 1 to SETR causes bit SRR to be set to 1
- Writing a 1 to CLRR causes bit SRR to be cleared to 0
- Writing a 1 to SETR and CLRR at the same time, SRR is not changed
- Writing a 1 to SETR and a hardware clear after an ISP Acknowledge at the same time causes SRR to be set to 1
- Writing a 1 to CLRR and a hardware trigger at the same time causes SRR to be set to 1
- The value written to SETR or CLRR is not stored
- Writing a 0 to these bits has no effect
- These bits always return 0 when read

40.3.1.1.2 Enable bit (SRE)

The SRE bit enables an interrupt to take part in the arbitration for the selected ISP. It does not enable or disable the setting of the request flag SRR; the request flag can be set by hardware or by software (through SETR) independent of the state of the SRE bit. This allows service requests to be handled automatically by hardware or through software polling.

SRE = 1:

If SRE=1, pending service requests are passed on to the designated ISP for interrupt arbitration. The SRR bit is automatically set to 0 by hardware when the service request is acknowledged by the ISP. It is recommended that in this case, software should not modify the SRR bit to avoid unexpected behavior due to the hardware controlling this bit.

SRE = 0:

If SRE=0, pending service requests are not passed on to ISPs. Software can poll the SRR bit to check whether a service request is pending. To acknowledge the service request, the SRR bit must then be reset by software by writing a 1 to CLRR.

***Note**: In this document, 'active source' means an SRN whose service request control register has its request enable bit SRE set to 1 to allow its service requests to participate in interrupt arbitration.*

40.3.1.1.3 Service request flag (SRR)

When set, the SRR flag indicates that a service request is pending. It can be set or reset directly by hardware or indirectly through software using the SETR and CLRR bits. Writing directly to this bit through software has no effect.

SRR can be set or cleared either by hardware or by software regardless of the state of the enable bit SRE. However, the request is only forwarded to an interrupt service provider if the enable bit is set.

For a disabled service request node (SRE = 0)

- SRR can be set by software (SETR) and hardware
- Pending service request (SRR = 1) is excluded from interrupt arbitration since SRE = 0
- Software can poll a SRR in a disabled service request node
- Software can reset the SRR by writing a 1 to CLRR
- See also "Request Set and Clear Bits (SETR, CLRR)"

For an enabled service request node (SRE = 1):

- SRR can be set by software (SETR) and hardware
- Pending service request (SRR = 1) takes part in the interrupt arbitration of the service provider selected by the TOS bit-field
- SRR is reset by hardware on acknowledge of the service request by the Interrupt Service Provider
- See also "Request Set and Clear Bits (SETR, CLRR)"

***Note**: Clearing a pending service request flag SRR and enabling the corresponding service request node (SRN) should be done in two steps which means two writes: first clear the SRR flag (SRC.CLRR), then enable the (SRC.SRE).*

Related information

Request set and clear bits (SETR, CLRR) on page 6861

40.3.1.1.4 Type-of-service (TOS)

CPU´s, PPU, GTM and DMA´s can act as an interrupt service provider (ISP).

A service request node can be mapped through the TOS bit-field to exact one ISP.

The TOS bit-field configuration with TOS = z maps a service request to:

- The IR interrupt control unit ICUz and through this to the related ISP
- To the two access protection register sets TOSz_ACCENSCTRL and TOSz_ACCENSCFG. The IR provides a dedicated access protection register set for each TOS coding used, that is for each implemented ICU

40.3.1.1.5 Service request priority number (SRPN)

The Service request priority number (SRPN) defines the priority of a service request with respect to other sources requesting service from the same ISP, and with respect to the priority of the ISP itself.

Multiple active SRN mapped the same ISP by using the same TOS configuration:

- Can have a unique SRPN value
- Can have a non-unique SRPN to give a group of service requests the same priority
- For a group of service requests with the same SRPN and VM configuration, the sequence of execution can not be defined
- If an SRN is not active – meaning its SRE bit is 0 – no restrictions are applied to the SRPN configuration

Interrupt service provider is a TriCore™ CPU (CPUs)

Service requests are associated through the SRPN by an interrupt vector table located in each CPU. This means that the CPU interrupt vector table is ordered by priority number. This is unlike traditional interrupt CPU architectures in which their interrupt vector tables are ordered by the source of the interrupt.

***Notes**:*

1. *For a CPU, a service request should not be configured with SRPN = 0. This is because a service request with the SRPN = 0 is ignored by the CPU and will not be acknowledged and therefore, the related SRN will not be cleared. Priority 0 is the lowest service request priority and therefore, it will not hide a SR with a higher priority but it prevents arbitration from being stopped if there is no valid SR (SRPN > 0) pending for the CPU*
2. *TriCore™ CPUs are providing a flexible interrupt table alignment with a configurable vector spacing of 8 byte or 32 byte. Please see also CPU chapter*

Interrupt service provider is a DMA

Service requests are associated through the SRPN to DMA channel numbers:

- SRPN = x will trigger DMA channel x, if DMA channel x is implemented

Only the SRPN numbers from 0 up to the max_channel_number will result in a trigger of the related DMA channel.

SRPN numbers > max_channel number will be ignored by the DMA. This means that the DMA will acknowledge the service request but it will not trigger a DMA channel nor is there any notification signaled to the application.

Examples

- In case of a 128 channel DMA, a service request with SRPN 00_H will trigger DMA channel 0, SRPN number $7F_H$ will trigger the channel 127. Service requests with SRPN > $7F_H$ will be acknowledged by the DMA and otherwise ignored
- In case of a 64 channel DMA, a service request with SRPN 00_H will trigger DMA channel 0, SRPN 17_H will trigger channel 23 and SRPN number $3E_H$ will trigger channel 62. Service requests with SRPN > $3F_H$ will be acknowledged by the DMA and otherwise ignored

Interrupt service provider is GTM

The mechanism how the GTM module maps received service requests to the GTM internal MCS functions is described in the GTM chapter.

Interrupt service provider is PPU

The mechanism how the PPU module handles received service requests is described in the PPU chapter.

40.3.1.1.6 Virtual machine number (VM)

Each TriCore™ CPU in hardware virtualization mode represents up to 8 Virtual machines (VMs) where each VM represents a virtual interrupt service providers (virtual ISP´s).

A SRN can be mapped to a physical ISP through SRC.TOS configuration. For a CPU in hardware virtualization mode, an SRN can be mapped to one of the VM through SRC.VM.

- SRC.VM = 000 -> Service request is mapped to CPU virtual machine 0 (Hypervisor)
- SRC.VM = 001 -> Service request is mapped to CPU virtual machine 1
- SRC.VM = 010 -> Service request is mapped to CPU virtual machine 2
- …
- SRC.VM = 111 -> Service request is mapped to CPU virtual machine 7

If a CPU in hardware virtualization support mode receives a service request for a VM that is not enabled on the CPU, CPU reacts to the Service Request and the Hypervisor or System software is expected to signal an ALARM to the SMU. For more details, see chapter CPU, "Interrupt corner cases".

Each ICUz provides a VMEN register, VMENz:

- The VMENz register is implemented hardwired to 0000_0000 if either a CPU without hardware virtualization support or any other type of ISP (DMA, PPU, GTM) is connected to ICUz
- If a CPUz with hardware virtualization support is connected to ICUz, then VMENz[7:0] bits are implemented as register bits. The bits VMENz[7:0] can be used by software to configure which VMs are used on the corresponding CPUz. VMENz[0] corresponds to VM0, VMENz[1] corresponds to VM1, VMENz[7] corresponds to VM7

For a CPUz with hardware virtualization support:

- For all VMs that need to be used on CPUz, the corresponding bits in VMENz[7:0] must be set to 1_B. The ICU then arbitrates separately for each VM enabled through the VMENz[7:0] bits, ensuring that the CPU sees always the pending interrupt with the highest priority for each used VM
- Interrupts mapped to a non-enabled VM with SRC.VM are ignored during arbitration
- If the CPU is used without virtualization by the software, VMENz[7:0] must be set to 00_H0. With this the ICUz will ignore the SRC.VM information during arbitration so the CPU sees always the pending interrupt with the highest priority for the CPU

VM configuration restrictions:

If a CPU is used in hardware virtualization mode, the hardware virtualization mode must be activated in the corresponding ICU through the register VMEN. VMEN[7:0] defines for which of the virtual machines the ICU will arbitrate.

VM configuration restriction for an ISP in Hardware virtualization support mode (VMEN is not 0, at least one VMEN bit is set to 1):

- SRNs shall only be mapped using SRC.VM to the VMs that are enabled in the respective VMEN register. Background: a pending SR to a not enabled VM will result in a permanent running arbitration for this ICU because it will never be arbitrated by the ICU
- SRNs shall not be mapped to a VM that is not enabled in the respective CPU. Background: A CPU with hardware virtualization support enabled that receives an SR for an unused VM will only acknowledge it if it has been configured by the application SW, e.g., by a hypervisor that has installed dummy VMs that respond to it and reports an ALARM to the SMU

VM configuration restriction for an ISP not in hardware virtualization support mode, VMEN=00_H:

- The IR will ignore the SRCx.VM configuration for the arbitration. All service requests for this ISP will be signaled by the ICU with VM=0_H to it

40.3.1.1.7 Cyber security bit (CS)

The SRCx.CS bit can be used by the application software to assign an SRCx to the security or to the non-security application. For further information please see chapter Access protection of the SRCx register (SRCx[15:0], SRCx[31:16]).

Related information

Access protection of the SRCx register (SRCx[15:0], SRCx[31:16]) on page 6884

40.3.1.1.8 Interrupt trigger overflow bit (IOV)

The IOV bit is set by hardware if both conditions are true:

- Service request is pending
- A new service request is triggered through hardware interrupt trigger or SETR bit

40.3.1.1.9 Interrupt trigger overflow clear bit (IOVCLR)

The IOVCLR bit can be used to clear the IOV bit. The IOV bit is cleared by writing a ´1´ to the IOVCLR bit.

40.3.2 Changing an SRN configuration

All service request nodes (SRN) are disabled per default. To use a SRN, it has to be configured and enabled by setting the SRCx.SRE bit=´1´.

The service request nodes can be configured regarding the interrupt service provider target (SRCx.TOS) the virtual machine target (SRCx.VM) regarding the service request priority number (SRCx.SRPN) and if it is assigned the security application (SRCx.CS).

Once an SRN is enabled, the TOS, VM and SRPN bit fields can be changed by using the following sequence.

SRCx reconfiguration: assumptions for the enabled SRCx configuration

- SRCx with IDX = x
- SRCx.TOS = z
- SRCx.VM = y

  ***Note**: For VMENz = 0, y = 0*

SRCx reconfiguration: sequence to reconfigure SRCx

- Disable SRCx by setting SRCx.SRE = 0
- Check if SRCx.SRR = 1
- IF SRCx.SRR = 1, check if a service request may have been pending when the SRCx was switched off
  - IF SRCx.TOS = PPU, check in the PPU interrupt interface logic if this service request is pending. IF true, acknowledge it in the PPU interrupt interface logic
  - END IF
-
  - LOOP1 (check ICUz_LASR until ENTER = 0)
    - IF ICUz_LASR.ENTER = 0, EXIT LOOP1
  - END LOOP1
  - LOOP2 (check ICUz_LWSRy until either STAT = 0 or LWSRy.IDX != x)
    - IF ICUz_LWSRy.STAT=0 OR ICUz_LWSRy.IDX != 0 -> EXIT LOOP2
  - END LOOP2
- END IF
- Re-configure SRCx
- Enable re-configured SRCx

40.3.3 Changing the VMEN configuration

Assumptions

- ICUz is implemented with hardware virtualization support
- ICUz is connected to CPUz

Enabling a VMx

It is possible to activate a VMx through VMENz at any time. Before activating the VMx in the VMENz you should activate VMx in the corresponding CPU.

Disabling a VMx

Before disabling a VMx in a CPU, software shall first disable the VMx in the ICUz by setting VMENz[x]=0. This prevents that further SR are signaled to VMx. Software shall check LWSRx.STAT until LWSRx.STAT=0. Then software can disable VMx in the CPU.

Having disabled a VM through VMENz, any enabled SRN's that are mapped to that VM should be disabled, because if they are triggered they will force the ICU to arbitrate even if no other service requests are available. This is true as long VMEN[7:0] is not 0x00.

Enabling hardware virtualization support (VMENx!=0)

When changing VMENx[7:0]=00_H to VMENx[7:0]!=00_H, which means that the hardware virtualization support is enabled, the application has to ensure that no service request for ICUx is pending.

Disabling hardware virtualization support (VMEN=0)

When changing VMENx[7:0]!=00_H to VMENx[7:0]=00_H, which means that the hardware virtualization support is disabled, the application has to ensure that no service request for ICUx is pending.

40.3.4 Mapping of interrupt request triggers signals to SRNs

All functional block interrupt trigger signals are mapped to Service Request Nodes (SRN) in the Interrupt Router.

There is one dedicated Service request node (SRN) for each module interrupt request.

Each SRN has one unique SRN index number (IDX) within the IR. The IDX numbers are not required for the functionality of the interrupt router itself. The IDX numbers can be used to select a SRN for observation through the OTGB feature.

The IDX number of a service request control (SRC) register can be directly calculated out of its address offset in the SRC address range.

The IR has one interrupt trigger input vector. Each interrupt trigger input vector bit [x] is related to one SRN with its unique IDX number x[55]. This means that a trigger pulse on interrupt trigger input vector bit [x] will trigger the SRN [x].

***Note**: A positive edge on a interrupt trigger signal is interpreted as interrupt trigger. See also Timing characteristics of service request trigger signals.*

[55] The Interrupt Router register overview table shows for all module service requests the SRC registers with its address offset and the related SRN Index number

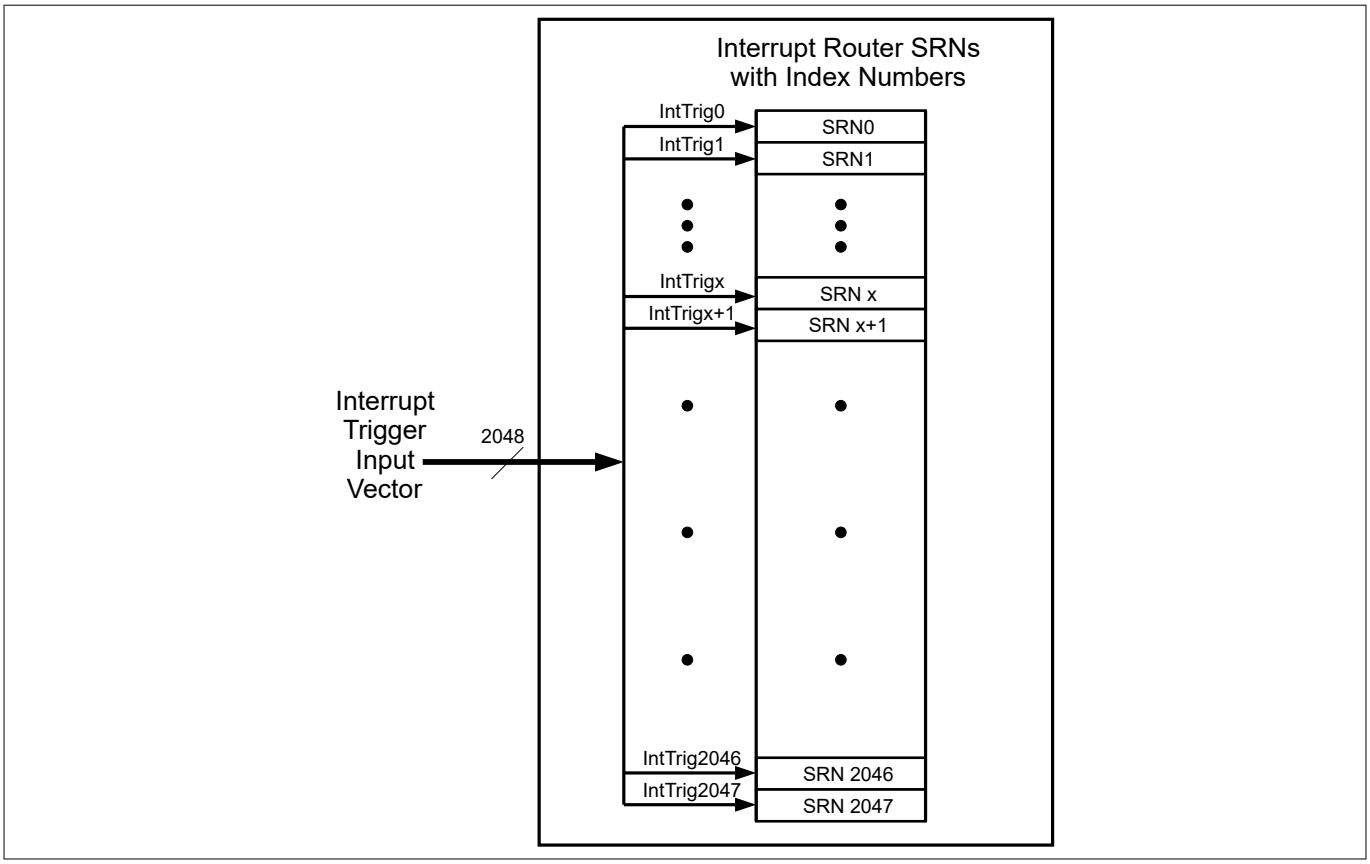

Figure 952 Mapping of interrupt trigger signals to SRN index numbers

Related information

SRC index number (IDX) on page 6868
Interrupt trigger signals - default value, trigger and timing characteristics on page 6869

40.3.4.1 SRC index number (IDX)

Each SRN can be configured and controlled through its dedicated service request control register (SRC). The implemented SRC registers are described in the product specific IR SRC register overview table.

Each SRC has a unique IDX number inside the IR.

The IDX number of a SRC can be directly calculated out if its address offset in the SRC address range:

- $Index\left(SRC\right) = \frac{< SRC\ Adress\ Offset >}{4}$

Example:

- An SRC register is shown in the product specific SRC register overview table with the offset $1E0_H$
- The index of this SRC register is than calculated: $\frac{1E0_H}{4} = 78H$. This means the index number is 78_H and 120_D

Related information

Module implementation on page 6896

40.3.4.2 Interrupt trigger signals - default value, trigger and timing characteristics

The interrupt trigger signals from the functional blocks to the IR, the IR itself and the interfaces from the IR to the Interrupt Service are clocked with the System Peripheral Bus clock (f_{SPB}). The following rules apply to the modules interrupt trigger signals from the modules to the Interrupt router:

- Trigger signals must be synchronous to the SPB interconnect clock (f_{SPB})
- The IR interrupt trigger inputs are edge sensitive, an interrupt trigger signal change from 0 → 1 is interpreted as interrupt event
- The minimal high and low pulse width of interrupt trigger signals is 1 f_{SPB} clock cycle, high pulse length can be > 1 f_{SPB} clock cycle

Default value of interrupt trigger input signals

The IR expects the interrupt trigger signals during and after reset with a low signal value (0).

A high signal value (1) during and after reset at an interrupt input is interpreted by the IR as a first interrupt trigger event, the SRR bit in the corresponding SRC is set to 1_B'.

***Note**: The SRC.SRR and SRC.IOV bits are set independent of the SRC.SRE (enable) bit setting. This to enable a customer to detect missed interrupts during a potential SRC re-configuration.*

40.3.5 Interrupt control unit (ICU)

The IR contains one ICU for each implemented physical ISP (CPUs, DMAs, PPU, GTM). Each ICU is assigned to one ISP. Each SRN can be mapped to exactly one ISP and its related ICU through SRCx.TOS configuration.

The ICU:

- ICU arbitrates among the pending SRs that are mapped to the ICU and to the related ISP, VM
- ICU signals the SR information of the arbitration round winner to the ISP by using the VALID signals
- ICU signals in special situations that an already transferred SR is no longer pending by using the INVALID signal
- On ACKNOWLEDGE of a SR by the ISP
  - ICU receives information of the acknowledged SR from the ISP
  - ICU does an ECC check on the received Service request information
  - ICU signals detected EDC errors to the SMU
  - ICU clears the SRN acknowledged by the ISP if no EDC error is detected. This means SRC.SRR is set to 0

***Note**: The ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.*

***Note**: An ICU where the Hardware virtualization support (HVS) is disabled or not available (in both cases: VMEN=00_H) always signals the service request to the ISP with VM=0, regardless of the SRC.VM configuration.*

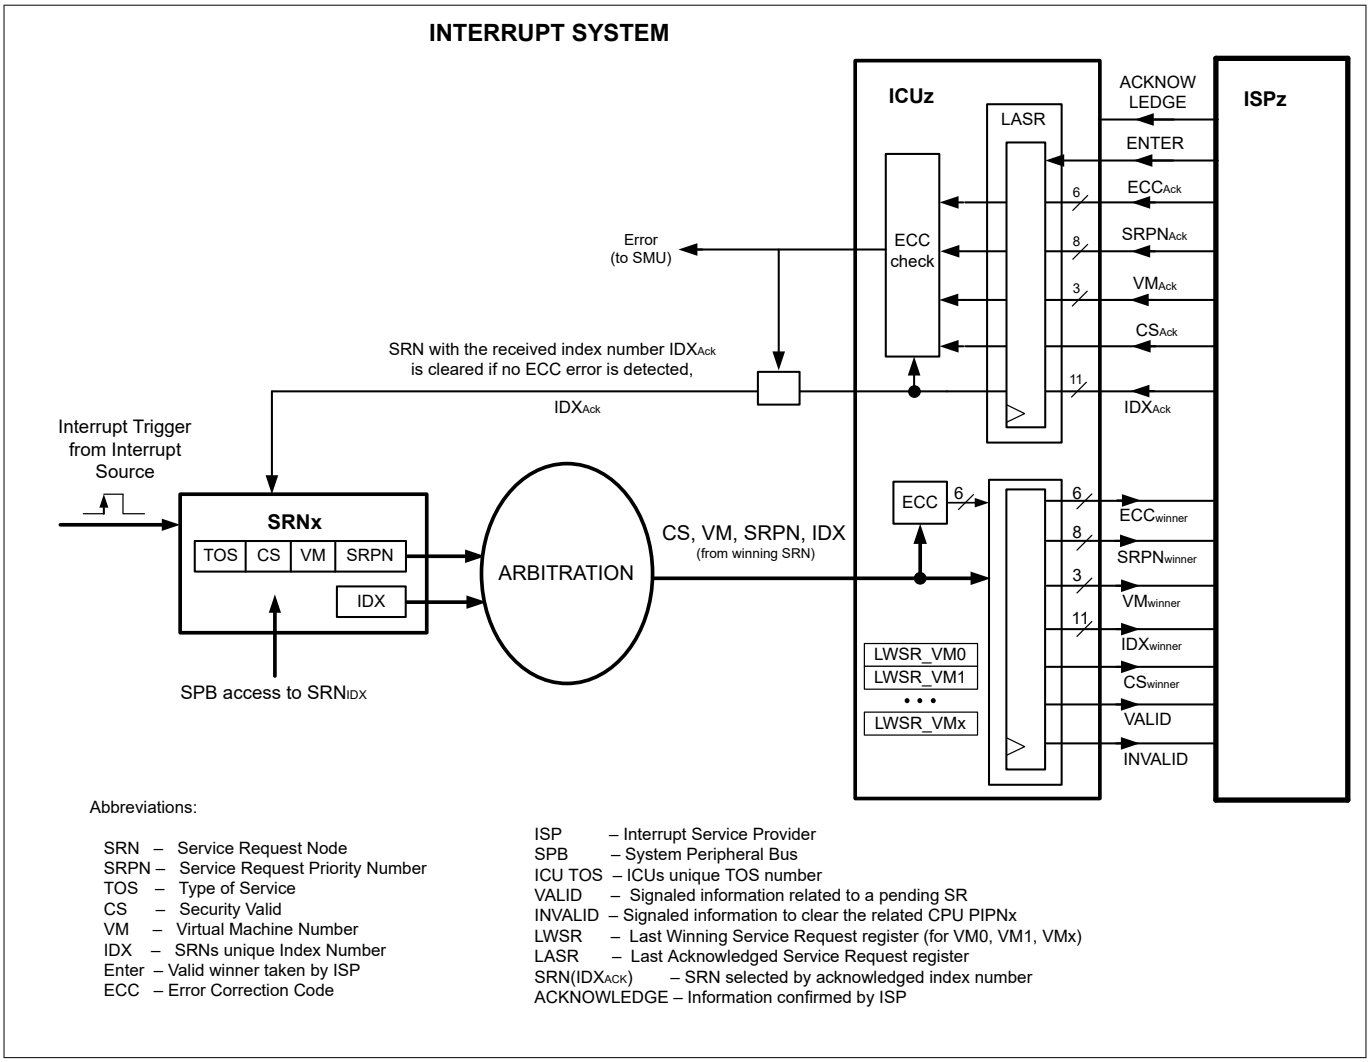

Figure 953 Interface to an Interrupt service provider

40.3.5.1 ICU control registers

This section describes the Interrupt Control Unit (ICU) registers. Each ICUz includes a dedicated set of control registers:

- Last Winning Service Request Register (LWSRz_VMy)
- Last Acknowledged Service Request Register (LASRz)
- Virtual Machine Control Register (VMENz)
- Error Capture Register (ECRz)
- Error Control Register (ECTRLz)
- Error Generation Register (EGENz)

***Note**: An ICUz for a CPU with Hardware Virtualization support has 8 LWSRz_VMy (y=0-7) and a VMENz with 8 readable and writable bits. An ICUx for a ISP without Hardware Virtualization support has only one LWSR register (LWSRz_VM0) and a read only VMENz register that is hardwired to 0.*

40.3.5.2 ICU interface

This chapter describes the EDC protected ICU interface to an ISP in general but also the differences for the different ISP types as well as a detailed description of the EDC protection and the EDC error injection.

40.3.5.2.1 VALID, INVALID and ACKNOWLEDGE

The interface between ICU and ISP are controlled through four control signals

- VALID: ICU signals with the assertion of the VALID signal that a pending service request is available at the ICU interface (winner of the last arbitration round). An ICU where the hardware virtualization support (HVS) is disabled or not available (in both cases: VMEN = 00_H) always signals the service request to the ISP with VM = 0, regardless of the SRC.VM configuration
- INVALID: ICUy signals with the assertion of the INVALID signal to a CPU that there was a pending SR visible in a used LWSRz_VMy register and now no SR is pending anymore because the last SR was cleared by software. The INVALID is only used for CPUs to clear the related PIPNx register in the CPU (set priority = 0). INVALID is not acknowledged
- ENTER: ISP CPU asserts the ENTER signal when it starts to prepare itself for the execution of a received Service Request . ICU stops re-arbitration as long the ENTER signal is asserted. See also ICU Abort condition
- ACKNOWLEDGE: ISP signals with a assertion of the ACKNOWLEDGE signal that it has taken over the service request information and will start with the execution of the related ISR. With the ACKNOWLEDGE signal de-assertion, the ISP de-asserts also the ENTER signal. See also ICU SRN clear condition

***Note**: While an ISP DMA , PPU and GTM has a fixed timing between Enter and Acknowledge, it can take many cycles for an CPU ISP before an Entered Service Request is Acknowledged or Enter is aborted (see ICU Abort condition below).*

40.3.5.2.2 Service request VALID

The ICU signals information about the pending Service Request that won the arbitration round to the ISP by asserting the Valid signal. Re-arbitration will be done until the ISP asserts the Enter signal.

The ICU signals with each VALID=1 and INVALID=0 cycle the winner service request of a new arbitration round to the ISP.

40.3.5.2.3 Service request ENTER

By setting the Enter signal, the Interrupt Service Provider signals to the ICU that it is preparing to start and execute the corresponding interrupt service routine. The Enter signal can be reset by the ISP

- With acknowledge because the Interrupt Service Routine has started
- Without acknowledge because the CPU got a trap or an exception before it was able to start the Interrupt Service Routine

40.3.5.2.4 Service request INVALID

The INVALID signal has only an effect on an ISP of type CPU.

With the INVALID signal an already sent SR information is neutralized in the CPU if required. This will be done in two situations:

- the only pending service request for a VMy that was already sent to the CPU was cleared by software in the IR
- the only pending service request for a CPU without or with disabled hardware virtualization support that was already sent to the CPU was cleared by software in the IR

The service request INVALID mechanism ensures that the CPU will not acknowledge the already cleared SR later as this may affect the already re-configured and newly triggered SRN. The mechanism is not used if more than one SR is pending for a VM or CPU because a SR that is already sent to the CPU and cleared by application software before acknowledged is replaced by the SR that wins the next IR arbitration round for the VM or CPU.

If the ICU has sent a SR through a VALID pulse to VMx in the CPU, as also captured in the IR LWSRz_VMy register, but the new arbitration round for VMx shows that there is no pending SR for VMx anymore although the previously sent SR for VMx was not ACKNOWLEDGE , the ICU sends an INVALID pulse for this VMx to the CPU. The INVALID is sent out with the respective VMx value to the CPU to enable it to identify the VMx. The corresponding CPU.PIPNx register will then be cleared by the CPU and set to priority 0.

An INVALID is not answered by the ISP with ACKNOWLEDGE and therefore not ECC checked in the ICU.

When the ICU signals an INVALID pulse for VMy to the ISP it clears in parallel the LWSRz_VMy.STATUS and sets the LWSRz_VMy.INVALID bit.

40.3.5.2.5 Service request ACKNOWLEDGE

An ISP signals an acknowledge to the ICU together with the information about the service request that is acknowledged (SRPN, VM, ECC, CS, SRN Index Number). The ISPs (CPU, DMA, GTM, PPU) have different definitions when they signal an SR acknowledge. Further information can be found in the chapter DMA to ICU interface, GTM to ICU interface and PPU to ICU interface.

The IR clears the acknowledged SRN if no ECC failure is detected and takes care that it is not signaled again unless it is newly triggered by hardware or software.

The ICU clears the LWSRz_VMy.STATUS bit if the acknowledged SR is for VMy and the SR IDX and SRPN information matches the LWSRz_VMx.VM and LWSRz_VMx.IDX information. This comparison is done because the acknowledged SR for VMx does not have to be the last SR that was signaled for VMx to the ISP which is now in the LWSRx register. This may be due to the latency of VALID pulse -> ENTER=1 or to the fact that a CPU in hardware virtualization mode itself decides in which order SR will be processed for the different VMs.

***Note**: On detection of an ECC failure the SRN is not cleared.*

40.3.5.2.6 ICU SRN clear condition

- ISP acknowledges a service request by signaling the service request information (SRPN, VM, CS, IDX) with an ACKNOWLEGE cycle to the ICU
- ICU performs an ECC check of the service request information received with the ACKNOWLEDGE
- If no ECC failure is detected on the received service request information the ICU clears the SRN with the received index number (IDX, part of the service request information)

  ***Note**: On detection of an ECC failure the SRN is not cleared.*

40.3.5.2.7 ICU abort condition

ICU abort condition

- Definition of the abort condition: Interrupt Service Provider de-asserts the ENTER signal without signaling ACKNOWLEDGE
- The abort condition does not clear the pending service request
- The abort condition enables the ICU to start re-arbitration again
- A CPU as ISP can generate the abort condition. DMAs, PPU and GTM as ISP are not able to generate the abort condition

Abort conditions generated by CPU as ISP

The CPU can generate the abort condition in the following situations:

- If the software task that is currently executed by the CPU raises the CPU priority threshold to a value greater than the entered interrupt. In this situation the abort condition enables the ICU to re-arbitrate
- If the CPU gets into the situation by a trap or a context switch so it cannot acknowledge the service request it de-asserts ENTER signal to allow a re arbitration in the IR
- In situation when an service request can not be taken, for example when a context operation is ongoing. After the previous context is restored then the CPU could be in a situation that ICR.IE bit is disabled or ICU.PIPN is less than the ICR.CCPN. In those cases, the ENTER signal is set from 1 to 0 without ACKNOWLEDGE because the conditions to take an interrupt are not met anymore
- If no service request can be taken by the CPU when there is an instruction in the pipeline updating ICR (BISR, DISABLE, RESTORE,….), the ENTER signal can be asserted and at the end of the execution of those instruction the CPU can be in a situation where the conditions for the CPU to take an service request are not met anymore. In that case, the ENTER signal will be de-asserted as well

40.3.5.2.8 ICU interface default values

The service request information signaled from ICU to ISP with VALID = 1_B and signaled from ISP back to ICU with an ACKNOWLEDGE = $1_B$are ECC protected.

In special situations the ICU signals information with INVALID = 1_B to the ISP. This is not signaled back from ISP to ICU therefore is not ECC checked.

To add robustness to ICU - ISP interface the ICU and ISP outputs are set to default values while no information is signaled.

As long the ICU does not signal information to the connected ISP (VALID = 0_B AND INVALID = 0_B), the ICU output signals are set to the following default values:

- IDX = 000_H
- PIPN and SRPN = 00_H
- VM = 0_H
- CS = 0_B
- ECC = 00_H

As long the ISP does not acknowledge a service request to the related ICU (ACKNOWLEDGE = 0_B), the ISP output signals are set to the following default values:

- IDX = 000_H
- PIPN and SRPN = 00_H
- VM = 0_H
- CS=0_B
- ECC = 00_H

This means:

In case of a stuck-at-one error on the VALID signal, a CPU will ignore the default information (SRPN= 00_H) while a DMA will trigger its DMA Channel 0 and ACKNOWLEDGE the default information to the ICU where it is detected by the ECC protection and an Alarm_NCS or Alarm_CS is signaled to the SMU.

In case of a stuck-at-one error on the ACKNOWLEDGE signal, the ICU will detect an ECC error. On detection of the EDC error an Alarm is signaled and no SRN is cleared.

In case of stuck-at-one-error on the ENTER, the IR will stop the arbitration for the respective ICU.

40.3.5.2.9 ICU to DMA interface

The interrupt router has dedicated Interrupt control unit (ICU) for each DMA (DMA0, DMA1 and RDMA).

This chapter gives an overview of how a DMA processes service requests and acknowledges them back to the ICU. A detailed description can be found in the DMA chapter.

A DMA takes over the service request information from the ICU, triggers the related DMA channel and signals the service request immediately with ACKNOWLEDGE and ENTER to the ICU where it is ECC checked and, if no error is detected, the related SRN is cleared.

The DMA interface consists of a register set where it takes over the information of a service request provided by the ICU (SRPN, CS, VM, SRN Index, ECC). The DMA sends the service request information it received with VALID=1 back to the ICU in the next clock cycle with an ACKNOWLEDGE (see also chapter Service request priority number (SRPN)).

The DMA ignores the INVALID signal.

The CS information signaled to the DMA will be used within the DMA to ensure that a:

- CS related service request (CS = 1) is mapped to a DMA channel on a CSRM related DMA resource partition (see DMA, register MODEr.CS)
- Not-CSRM related service request (CS = 0) is mapped to a DMA channel on a not-CS related DMA resource partition (see DMA, register MODEr.CS)

The DMA channel priority scheme is identical to the SRPN priority scheme:

- Lowest priority within the DMA: channel 0
- Lowest priority within the Interrupt Router: SRPN = 0

Related information

Service request priority number (SRPN) on page 6862
Access protection of the SRCx register (SRCx[15:0], SRCx[31:16]) on page 6884

40.3.5.2.10 ICU to GTM interface

The interrupt router has a dedicated Interrupt control unit (ICU) for the GTM.

This chapter gives an overview of how the GTM processes service requests and acknowledges them back to the ICU. A detailed description can be found in the GTM chapter.

The GTM takes over the service request information from the ICU, sets the GTM internal MSC interrupt trigger bit, and signals the service request immediately with ACKNOWLEDGE and ENTER to the ICU where it is ECC checked. If no ECC error is detected, the related SRN is cleared.

The GTM interface consists of a register set where it takes over the information of a service request provided by the ICU (SRPN, CS, VM, SRN Index, ECC, VALID, INVALID). The GTM sends the service request information it received with VALID=1 back to the ICU with an ACKNOWLEDGE and ENTER. Further details of the GTM ICU interface and the GTM handling of interrupts can be found in the GTM chapter.

The GTM ignores the INVALID signal.

Related information

Service request priority number (SRPN) on page 6862

40.3.5.2.11 ICU to PPU interface

The interrupt router has dedicated Interrupt control unit (ICU) for the PPU.

This chapter gives an overview of how the PPU processes service requests and acknowledges them back to the ICU. A detailed description can be found in the PPU chapter.

The PPU takes the service request information from the ICU. The PPU has control registers with which application software can trigger that the service request information is signaled with an ACKNOWLEDGE and ENTER to the ICU where it is ECC checked. If no ECC error is detected, the related SRN is cleared. The service request which is currently pending in the PPU for processing and waiting for software acknowledge can a be read there.

The PPU interface consists of a register set where it takes over the information of a service request provided by the ICU (SRPN, CS, VM, SRN Index, ECC). The PPU sends the service request information it received with VALID=1 back to the ICU with an ACKNOWLEDGE and ENTER. Further details of the PPU ICU interface and the PPU handling of interrupts can be found in the PPU chapter.

The PPU ignores the INVALID signal.

Related information

Service request priority number (SRPN) on page 6862

40.3.5.3 ECC protection of the ICU interface

The interface between ICU and the interrupt service provider is ECC protected by the ICU.

The ICU uses an ECC encoding of the SR information which is only used for error detection.

This means:

- The ICU generates an ECC value for the information signaled to the ISP
- The ICU signals the information and the ECC value with VALID and INVALID to the ISP
- On ACKNOWLEDGE by the ISP, the ICU generates an ECC value for the received information
- The ICU compares the ECC value for the received information with the received ECC value
- On detection of a ECC mismatch which means a received ECC and the ECC value generated for the received information does not match, an Alarm_NCS or Alarm_CS is signaled to the SMU and the received SR information is captured in the ECR register
- ICU signals Alarm_NCS to SMU_SAFE if received SR information shows CS = 0 and an Alarm_CS to the SMU_CS if CS = 1.

ECC protection covers the following information:

- SRPN[7:0], Service request priority number
- VM[2:0], SR Virtual machine information
- IDX[10:0], SR Index number of the related SRN
- CS, SR Cyber security information

***Note**: ICU signals information to the ISP with either VALID = 1 or INVALID = 1. The information signaled through INVALID = 1 will not be acknowledged by the CPU and therefore not ECC checked in the ICU.*

ECC code

The ECC code used for the interrupt router error detection mechanism is a 24_6 code with DED (double error detection) capability. Data being ECC´d is {1´b0, IDX, VM, CS, SRPN} = 24 bits. The ECC codes are:

```
var h5 : uint(bits:24) = 24'b000000000000111111111111;
```

```
var h4 : uint(bits:24) = 24'b000011111110000000111111;
```

```
var h3 : uint(bits:24) = 24'b011100011110001111000111;
```

```
var h2 : uint(bits:24) = 24'b101101100110110011001001;
```

```
var h1 : uint(bits:24) = 24'b110110101011010101010010;
```

```
var h0 : uint(bits:24) = 24'b111011010011101001100011;
```

40.3.5.3.1 Handling of detected ECC errors

The ICU does an ECC check of the SR information it receives with the ACKNOWLEDGE from the ISP. The ECC information that is signaled by the ICU to the ISP is covering the service request information: SRPN, VM, CS and IDX.

Whenever the ICU receives an ACKNOWLEGE from the ISP it does an ECC check. The check is done on the information received with the acknowledge from the ISP (SRPN, VM, CS, Index, ECC).

On detection of an ECC error in ICUz:

- ICUz captures the related service request information in the Error capture registers (ECTRLz), sets the ECTRLz.STAT bit and the ECTRLz.EOV bit if the ECTRLz.STAT bit is still set
- IR signals an Alarm to the Safety and Security Error Management Unit (SMU). The SMU forwards this information to a CPU (if enabled)
- ICUx does not clear the service request in the SRN (selected by the index)
- The application software can identify the ICU where an ECC error was detected through the Error status bits (ECRx.STAT=1). It can read out the related service request information and clear the ECRx.STAT bit by writing with 1. The application software can also identify if one or multiple ECC errors where detected by this ICU through the Error overflow bit (ECRx.EOV=1)

40.3.5.3.2 Default ECC output values

The path from the ICU to an ISP and back to the ICU is also protected if no service request is signaled:

- As long as an ICU does not intend to signal service request information with valid or invalid to the ISP, it has invalid ECC values in the ICU output registers
- As long as an ISP does not intend signal service request information with an acknowledge to the ICU, it has invalid ECC values in the ISP output registers

See also related information in the chapter ´ICU interface default values´.

Related information

ICU interface default values on page 6874

40.3.5.3.3 ECC error injection, alarm test

The ECC error detection mechanism and the related alarm signals can be checked by the application software for each ICUz separately through the EGENz register:

- Select an SRNx which is enabled and configured with SRCx.TOS = z (means: SNRx is mapped to ICUz)
- Write the Index of the SRNx in EGENz.ID and set EGENz.AE = 1
- Check the ECTRLz.STAT and ECTRLz.EOV bits, clear the bits if necessary to ensure that the injected error can be captured by the ECRz register and possible second error can be detected through the ECTRLz.EOV bit
- Inject one SR in SRNx (through SRNx related hardware interrupt trigger condition or through writing to SRCx.SETR)
- On detection of the related IR Alarm_NCS or Alarm_CS signal, check the ECRz register to ensure that the SMU alarm is related to the injected error and not a real error from a different SR acknowledged to ICUz
- On detection of the related IR Alarm_NCS and Alarm_CS signal, check the ECTRLz.EOV bit is not set
- Disable the EGENz mechanism by setting EGENz.AE = 0

***Note**: A CS related (CS_VALID=´1´) write to an EGENz register is only executed if it writes with CS = 1. A non CS related (CS_VALID = 0) write to an EGENz register is only executed if it writes with CS = 0.*

***Note**: An error is only injected if the CS bit of selected service request is equal to the EGEN CS bit (for EGENz.ID = x, SRCx.CS = EGENz.CS).*

40.3.6 Software interrupts (GPSR)

The IR provides multiple groups of general purpose service requests (GPSRGx) and a mechanism to trigger multiple Service Requests of a GPSRGx group in parallel, by software.

General purpose service requests are intended for software interrupts. These SRNs are not connected to internal or external hardware trigger signals and can only be used as software interrupts also called software initiated service requests.

***Note**: Any Service request node can be used by software for software interrupts by writing to the service request bit (SRCx.SETR) where it has write access rights. After the SRCx.SRR bit is set in an SRN, there is no way to distinguish between a software initiated service request and a hardware initiated service request. Therefore: If software uses an SRN for software interrupts that can also be initiated by hardware, it should use SRNs that are not used by the application for hardware-initiated service requests.*

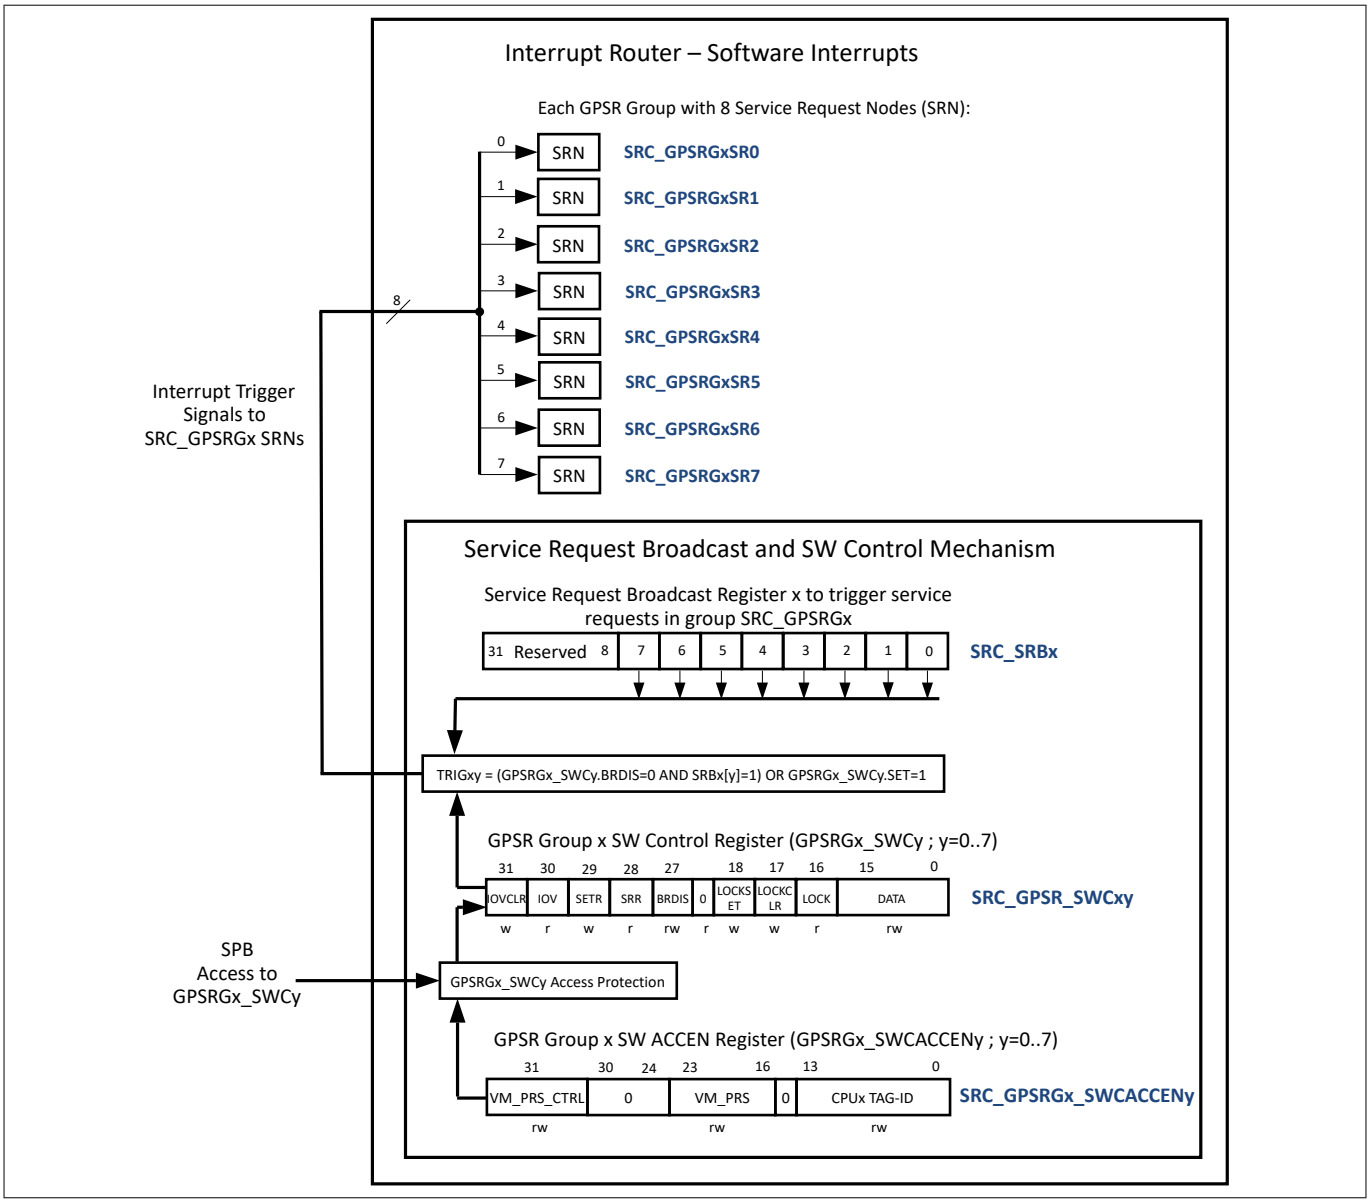

Figure 954 Structure of a general purpose service request group (GPSRx) and its related registers SRBx, SRBx_ACCEN, GPSRGx_SWCy, GPSRGx_SWCACCENy

Related information

Service request broadcast registers (SRBx) on page 6880

40.3.6.1 General purpose service requests (GPSR)

The Interrupt Router provides multiple groups of general purpose service request (GPSR) nodes:

- The GPSR nodes are implemented in groups
- Each GPSR group consists of eight service request nodes and its related service request control registers
- The GPSR SRC registers are named SRC_GPSRGxSRy; x = group number; y = number of interrupt within the group with y = 0:7
- The GPSR nodes are intended for software interrupts and not mapped to hardware service request triggers
- Each GPSR node can be assigned to one interrupt service provider (ISP)
- For the access to the GPSR SRC registers, the same access rules apply as for all other SRCx registers

Related information

Module implementation on page 6896

40.3.6.2 Triggering a general purpose service request node (GPSRx)

Any GPSR node can be triggered by software through 3 different ways:

Writing to the related service request control (GPSRGxSRy.SETR)

The register is access protected by the TOSz_ACCENCTRL where TOSz is selected by the register GPSRGxSRy.TOS=z configuration. TOSz_ACCENCTRL controls access to all SRN mapped to TOSz.

***Note**: This way is only suitable for software tasks that have access to all SRCs that are mapped to the ISP related to the TOSz encoding.*

Writing to the related service request broadcast register (SRBx)

This mechanism enables software to trigger multiple GPSR nodes of a group with one write access. Each SRBx register is protected by dedicated SRBx_ACCEN. The SRBx mechanism enables software to trigger multiple GPSRxy of the GPSR group in parallel.

***Note**: The broadcast mechanism can be disabled for each GPSRGxSRy individually by its related software control register (GPSRGx_SWCy).*

Writing to the related GPSR software control register (GPSRGx_SWCy)

GPSRGx_SWCy is protected by GPSRGx_SWCACCENy. The GPSRGx_SWCACCENy. allows application software to control for each GPSRGxSRy which CPU master agent functions are enabled for write access to the related GPSRGx_SWCy and can inject software interrupts into the GPSRGxSRy. The master agent functions are enabled through its transaction identifiers, TAG-IDs and VM or PRS codings.

The mechanism provides a separation between the software interrupt sources that can initiate software interrupts into a GPSR node and the interrupt destination that retains control of the corresponding GPSR node.

40.3.6.3 Service request broadcast registers (SRBx)

Service request broadcast registers (SRBx) can be used to assign service requests to multiple ISP´s in parallel.

There is one service request broadcast register (SRBx) implemented for each general purpose service request group (GPSRGx).

A (SRBx) register can be used to trigger multiple service requests within the GPSRx group in parallel.

- A SRBx register is always read as 0
- Writing 1 to SRBx.TRIGy triggers the service request GPSRGxSRy (if not disabled through GPSRGx_SWCy
- Writing 1 to SRBx[31:8] has no effect

40.3.6.4 Access protection of SRBx registers (ACCENSRBx)

Each SRBx register is write protected through a dedicated SRBx_ACCEN register set:

- Each SRBx register has a related ACCENSRBx register
- The configuration of the ACCENSRBx registers defines which master agent functions are allowed to write to the related SRBx register
- In the case of an access protection violation, the access is not executed, IR signals bus error to the SPB

All ACCENSRBx are write protected by PROTSE.

40.3.6.5 GPSR software control registers (GPSRGx_SWCy)

In comparison to the Broadcast register (SRBx), the GPSR software control registers offers more flexible and extended functions for setting and controlling software interrupts.

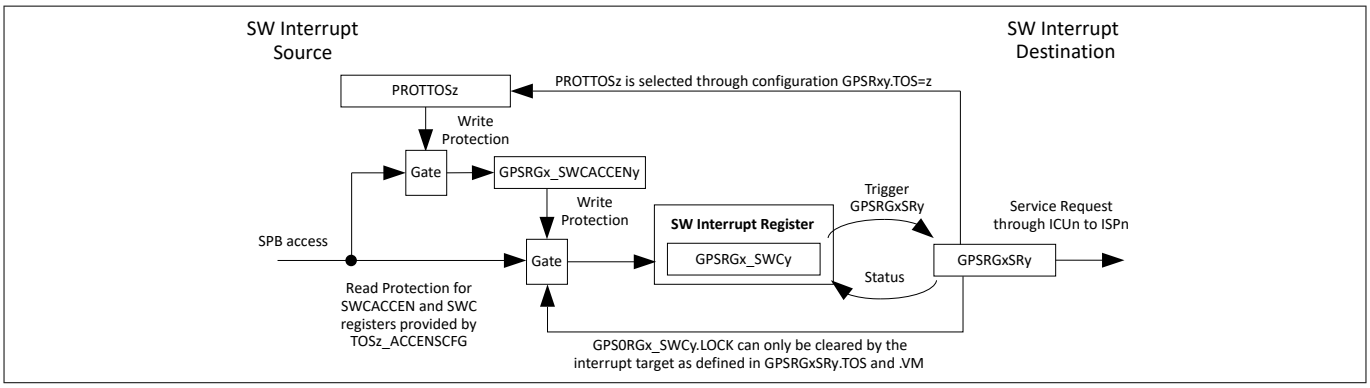

Figure 955 Structure of the GPSRGx_SWCy access protection and its relation to the GPSRx configuration

The GPSR Software Control functions includes:

- Dedicated GPSRGx_SWCy register for each GPSRGxSRy
- Reading the service request status (SRR) and interrupt overflow status (IOV) of related GPSRGxSRy (SRR, IOV)
- Set of a service request (SETR) and clear of the interrupt overflow (IOVCLR) in the related GPSRGxSRy (IOVCLR, SETR)
- Disable the SRBx trigger mechanism for GPSRGxSRy (BRDIS)
- The DATA register allows to attach additional information to the service request that the application software can read from the GPSRGxSRy.DATA register
- Hardware handshake mechanism for the DATA information (LOCKSTAT, LOCKCLR, LOCKSET)
- GPSRGx_SWCy.LOCKSTAT can only be set by a master agent function enabled for write access to GPSRGx_SWCy
- GPSRGx_SWCy.LOCKSTAT can only be cleared by the configured interrupt target (ISP). The target ISP is defined by GPSRGxSR.TOS and GPSRGxSR.VM

Protection: there is a dedicated GPSRGx_SWCACCENy register for each GPSRGx_SWCy that defines which master agent functions are to read and write to GPSRGx_SWCy.

40.3.6.6 GPSRGx_SWCy access protection (GPSRGx_SWCACCENy)

For each GPSRGx_SWCy there is a corresponding GPSRGx_SWCACCENy register. The GPSRGx_SWCACCENy enables application software to control write access permissions to the GPSRGx_SWCy for the implemented CPU´s and the Cerberus. This controls which CPUs and the Cerberus are enabled to inject software interrupts through GPSRGx_SWCy into the corresponding SRN GPSRGxSRy.

A GPSRGx_SWCACCENy register itself is write protected through the PROTTOSz and read protected by the TOSz_ACCENSCFG, as defined through the GPSRGxSRy.TOS=z configuration.

The control of the related GPSRGxSRy is assigned through the GPSRxSRy.TOS and its related TOSz_ACCENSCTRL configuration to a different set of master agent functions.

The GPSR SWC Access Protection function includes:

- Dedicated read and write access protection for each GPSRGx_SWCy
- Enable and disable TAG-IDs of CPUx and Cerberus for access to the related GPSRGx_SWCy
- Enable and disable of VM or PRS codings for read and write access to the related GPSRGx_SWCy

***Note**: If VM check is selected but the transaction id does not contain any valid VM information (VM_VALID = 1) then the VM access condition is considered to be fulfilled for the write to the protected GPSRGx_SWCy register . The same applies if PRS check is selected but no valid PRS information is transmitted (PRS_VALID = 0).*

40.3.6.7 Configuration sequence of GPSRGxSRy, GPSRGx_SWCy and GPSRGx_SWCACCENy

To ensure that the GPSRGx_SWCy register can only be used by the desired interrupt sources, the following sequence can be used:

- TOSz_ACCENSCTRL should be configured before GPSRGxSRy.TOS is configured with z and assigned to ICUz
- ACCENCS shall be enabled before GPSRGxSRy is to be marked as CSRM related by setting GPSRGxSRy.CS = 1
- With the configuration of GPSRGxSRy.TOS = z the register GPSRGx_SWCACCENy is:
  - Write protected by the register PROTTOSz
  - Read protected by TOSz_ACCENSCFG

***Note**: Because register GPSRGx_SWC is not write protected after a reset by default, the GPSRGx_SWCACCENy register should be configured after the above sequence was executed and before the GPSRGxSRy is enabled (SRE = 1) to prevent illegal software interrupts.*

40.3.7 External interrupts

The eight SRNs SRC_SCUERU[7:0] are reserved to handle external interrupts. The setup for external GPIO port input signals that are used by the application to generate an interrupt request is controlled in the External Request Unit (ERU). The ERU functionality is described in detail in the SCU chapter and allows to configure the type of the respective external interrupt signal.

40.3.8 Access protection of interrupt router registers (PROT, APU)

The IR provides a master agent function identifier based access protection. Each on chip resource with a interconnect master capability has one or multiple unique master agent function identifier that can be used to identify the master agent function that initiated a transaction on the interconnect system.

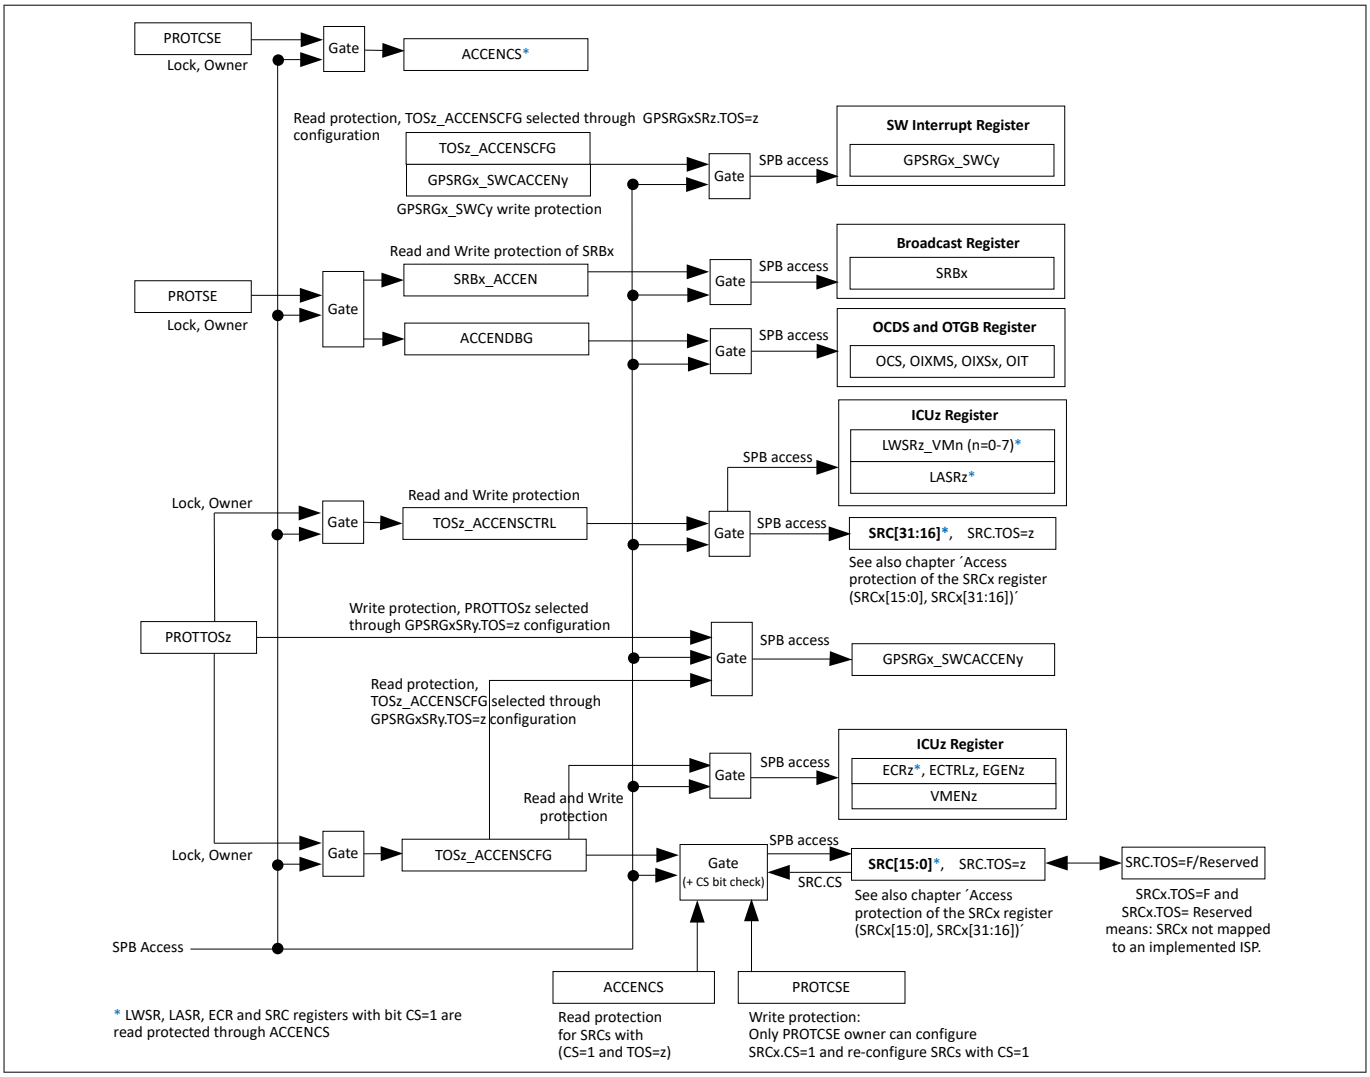

Figure 956 Access protection of interrupt router registers

PROT function implementation

The IR provides various PROT functions that write protect the APUs and SRC registers.

The IR provides five access enable register sets for the access control of the protected IR registers:

Access protection by SRBx_ACCEN

The SRBx_ACCEN registers provides access protection for the related SRBx register.

The IR provides a dedicated set of SRBx_ACCEN registers for each SRBx register. The SRBx_ACCEN registers are protected by the PROTSE.

Access protection by GPSRx_SWCACCENy

The GPSRGx_SWCACCENy registers provides write access protection for the related GPSRGx_SWCy register.

The IR provides for each GPSRGxSRy a dedicated set of SWC register (GPSRGx_SWCACCENy and GPSRGx_SWCy).

A GPSRGx_SWCACCENy register is access protected through the following registers:

- Write protected by PROTTOSz; PROTTOSz is selected through GPSRGxSRy.TOS=z configuration
- Read protected by TOSz_ACCENSCFG; TOSz_ACCENSCFG is selected through GPSRGxSRy.TOS=z configuration

Access protection by TOSz_ACCENSCTRL

The TOSz_ACCENSCTRL provides access protection for the following registers:

- SRCx[31:16], also called SRCx control information. The access protection for SRCx[31:16] is described in detail in the chapter ´Access protection of the SRCx register (SRCx[15:0], SRCx[31:16])´
- LWSRz_VMn (Last Winning Service Request, ICUz, Virtual Machine n). LWSRz_VMn registers with CS=1 are in addition read protected through ACCENCS
- LASRz (Last Acknowledged Service Request, ICUz). LASRz registers with CS=1 are in addition read protected through ACCENCS

Access protection by TOSz_ACCENSCFG

The TOSz_ACCENSCFG provides access protection for the following registers:

- SRCx[15:0], also called SRCx configuration information. The access protection for SRCx[15:0] is described in detail in the chapter ´Access protection of the SRCx register (SRCx[15:0], SRCx[31:16])´
- ECRz (Error Control Register, ICUz). ECRz registers with CS=1 are in addition read protected through ACCENCS
- ECTRLz (Error Capture Register, ICUz)
- EGENz (Error Generation Register, ICUz)

Access protection by ACCENDBG

The ACCENDBG provides access protection for the debug related registers:

- OCS
- LCLTEST
- OIXMS, OIXS0, OIXS1, OIT

Access protection by ACCENCS

The ACCENCS provides read access protection for the following registers in case these registers are configured with CS=1_B or when they have captured service request information marked with CS=1_B.

If CS=1_B is set in the following registers, ACCENCS defines which master agent function is enabled to read the information of the respective register with CS=1_B.

- LWSRz_VMy
- ECR
- SRC

Related information

Access protection of SRBx registers (ACCENSRBx) on page 6880

Access protection of the SRCx register (SRCx[15:0], SRCx[31:16]) on page 6884

40.3.8.1 Access protection of the SRCx register (SRCx[15:0], SRCx[31:16])

The IR contains all hardware and software service request nodes. It allows a flexible assignment of the service requests to the implemented ISPs (CPUx, CPUCS, DMAs, PPU, GTM) through the configuration of the service request nodes (SRN). So the IR is a shared resource that can be used by the CSRM for secure tasks as well as by other CPUs for not security related tasks (for DMAs see also related information). After assigning the SRNs to the ISPs, the IR allows to distinguish between these groups:

SRCx.TOS=z - SRNx is assigned to an implemented ICUz

TOS=z is used in the following description as a synonym for mapping an SRC to an implemented ICUz and so to an implemented interrupt service provider (ICUz).

Within the group of SRNs that are assigned or mapped to an implemented ISPz, a distinction is made between

- The group of SRN marked as security related (SRC.TOS=z and SRC.CS=1)
- The group of SRN marked as non-security related (SRC.TOS=z and SRC.CS=0)

All these groups can be protected against unauthorized configuration and reconfiguration by other master functions. This is made possible by the respective PROTTOSz, ACCENCS and PROTCSE and TOSz_ACCENSCFG.

SRCx.TOS=F and SRCx.TOS=Reserved - SRNx is not assigned to an implemented ICU

TOS=F_H or TOS=Reserved is used in the following description as a synonym for mapping an SRC to the group of unused SRCs. The SRCs configured in this way are not read protected and write protection only takes effect if they are to be mapped to an implemented ICUz, see TOS=z.

***Note**: PROTTOSz should be enabled (ODEF=1) before TOSz_ACCENSCFG and TOSz_ACCENCTRL are configured to prevent unintended modification of these registers that might enabled unauthorized master agent functions for SRC access.*

***Note**: PROTCSE is enabled (ODEF=1) after reset, configured PROTCSE owner is CPUCS. Disabling PROTCSE by setting ODEF=0 enable unauthorized master agent functions to configure SRC.CS=1 and trigger DMA channels that are assigned to the secure DMA Resource Partition (RP).*

SRCx[15:0] assignment status after reset

After reset all Service Request Nodes (SRN) are assigned to the group of not used SRNs (SRCx.TOS=F_H) and marked as not secure (SRCx.CS=0). The TOS encoding F_H is not assigned to an Interrupt Service Provider in the AURIX™ TC4xx family.

Application software can assign SRN with SRCx.TOS=F_H to an existing ISPz (TOS=z) and mark them as security related or not security related.

For a word write to an SRC currently configured with SRC.TOS=F_H: if the write does not satisfy access conditions to SRC[15:0], SRC[31:16] will be updated. No FPI error or alarm will be triggered.

Write access to SRCx[15:0], assignment to TOS=z or SRCx.TOS=F, not-CS related (CS=0)

Software can configure SRCx[15:0] with TOS=z and CS=0 or re-configure a SRCx that is already configured with SRCx.TOS=z and SRCx.CS=0 if following conditions are met:

- Assumption: SRCx configuration is (SRCx.TOS=z and SRCx.CS=0) or SRCx.TOS=F_H
- The writing master agent function must be enabled in TOSz_ACCENSCFG for write
- If PROTCSE.ODEF=1, which means that the IR PROTCSE owner is enabled:
  - the writing master agent function must not be the PROTCSE owner
- The writing master agent function can write:
  - (SRC.CS=0 AND SRC.TOS= z) to assign an SRC with SRC.TOS=F to the SRC TOS=z with SRC.CS=0
  - (SRC.CS=0 AND SRC.TOS= z) to re-configure an SRC that is already configured with SRC.CS=0 AND SRC.TOS= z
  - (SRC.CS=0 AND SRC.TOS=F_H) to assign an SRC already configured with SRC.CS=0 AND SRC.TOS= z back to the group of not used SRC

Write to SRCx[15:0], assignment to TOS=z or SRCx.TOS=F, CS related (CS=1)

Software can configure SRCx[15:0] with TOS=z and CS=1 or re-configure a SRC that is already configured with SRCx.TOS=z and SRCx.CS=1 if following conditions are met:

- Assumption: SRCx configuration is (SRCx.TOS=z and SRCx.CS=1) or SRCx.TOS=F_H
- The writing master agent function must be enabled in TOSz_ACCENSCFG for write
- IF PROTCSE.ODEF=1, which means that the PROTCSE owner is enabled:

- The writing master agent must be equal to the PROTCSE owner
- The writing master agent function writes:
  - (SRC.CS=1 AND SRC.TOS= z) to assign an SRC with SRC.TOS=F to the SRC TOS=z with SRC.CS=1
  - (SRC.CS=1 AND SRC.TOS= z) to re-configure an SRC that is already configured with SRC.CS=1 AND SRC.TOS= z
  - (SRC.CS=0 AND SRC.TOS=F_H) to assign an SRC already configured with SRC.CS=1 AND SRC.TOS= z back to the group of not used SRC

Write to SRCx[31:16], SRCx is assigned to TOS=z, CS=0

Software can write to SRCx[31:16] if following conditions are met:
- Writing master agent function enabled in TOSz_ACCENSCTRL for write
- Writing master agent function writes with VM0 or VM=SRCx.VM or it writes with VM_VALID=0
- Write access with CS_VALID=0

Write to SRCx[31:16], SRCx is assigned with TOS=z, CS=1

Software can write to SRCx[31:16] if following conditions are met:
- Writing master agent function enabled in TOSz_ACCENSCTRL for write
- Writing master agent function writes with VM0 or VM=SRCx.VM or it writes with VM_VALID=0
- Write access with CS_VALID=1

Write Access to SRCx[31:0]

Software can write to SRCx[31:0] if the writing master agent function is at least enabled for write to SRCx[31:16] or SRCx[15:0]:
- If write condition for SRCx[31:16] is met, SRCx[31:16] is updated
- If write condition for SRCx[15:0] is met, SRCx[15:0] is updated

If the access master agent function ID of a write access is neither write enabled for SRCx[31:16] nor write enabled for SRCx[15:0] it is an access protection violation.

This also means that for a word write to an SRC currently configured with SRC.TOS=$F_H$or another reserved TOS encoding: if the write does not satisfy access conditions to SRC[15:0], SRC[31:16] will be updated. No FPI error or alarm will be triggered. Therefore, if a SRN is configured from a reserved TOS encoding to a non-reserved TOS encoding with a word access, the configuration should be checked by reading it back.

Reading SRCx configured with SRCx.CS=0

Software can read a SRCx that is configured with SRCx.TOS=z and SRCx.CS=0 if the following condition is met:
- Reading master agent function is at least enabled for reading in TOSz_ACCENSCTRL or TOSz_ACCENSCFG for read

If the reading master agent function is neither enabled for reading in TOSz_ACCENSCTRL nor TOSz_ACCENSCFG it is an access protection violation.

If SRCx is configured with a reserved TOS encoding, for example SRCx.TOS=F_H, all master agent functions are enabled to read. A reserved TOS encoding is not related to an implemented ISP.

Half word and byte access have the same condition as word read accesses.

Reading SRCx configured with SRCx.CS=1

Software can read a SRCx that is configured with SRCx.TOS=z and SRCx.CS=1 if the following condition is met:
- Reading master agent function must be enabled in ACCENCS for read

Otherwise it is an access protection violation.

Half word and byte access have the same condition as word read accesses.

SRCx[15:0] and SRCx[31:16] access with protection violation

If an access protection violation occurs, the access is not executed and a FPI error is generated. On detection of a FPI error on the FPI interconnect the Bus Control Unit (here: SBCU because the IR is connected to the SPB interconnect) signals an Alarm_NCS (CS_VALID=0) to the SMU_SAFE or an Alarm_CS (access with CS_VALID=1) to the SMU_CS.

ICU to DMA interface on page 6874

40.3.9 Arbitration process

The IR provides a dedicated ICUz for each interrupt service provider (ISP) and a dedicated arbitration mechanism for each ICU which arbitrates among the pending SRs for the related ICUz and ISP.

Each service request node (SRNx) can be directed to one ISP by mapping it through the SRCx.TOS bit-field setting to the related ICUz.

As soon as an SR is pending for an ICUz the IR will start with the arbitration sequence for this ICU.

The ICUz will signal every cycle the winning service request information of the current arbitration round.

The arbitration sequence for ICUz will stop if either no SR is pending anymore of ICUx or as long the ´Enter´ signal is asserted by the related ISP.

***Note**: In the current implementation the ECC code is only used for error detection. Detected errors are reported to the SMU but not corrected.*

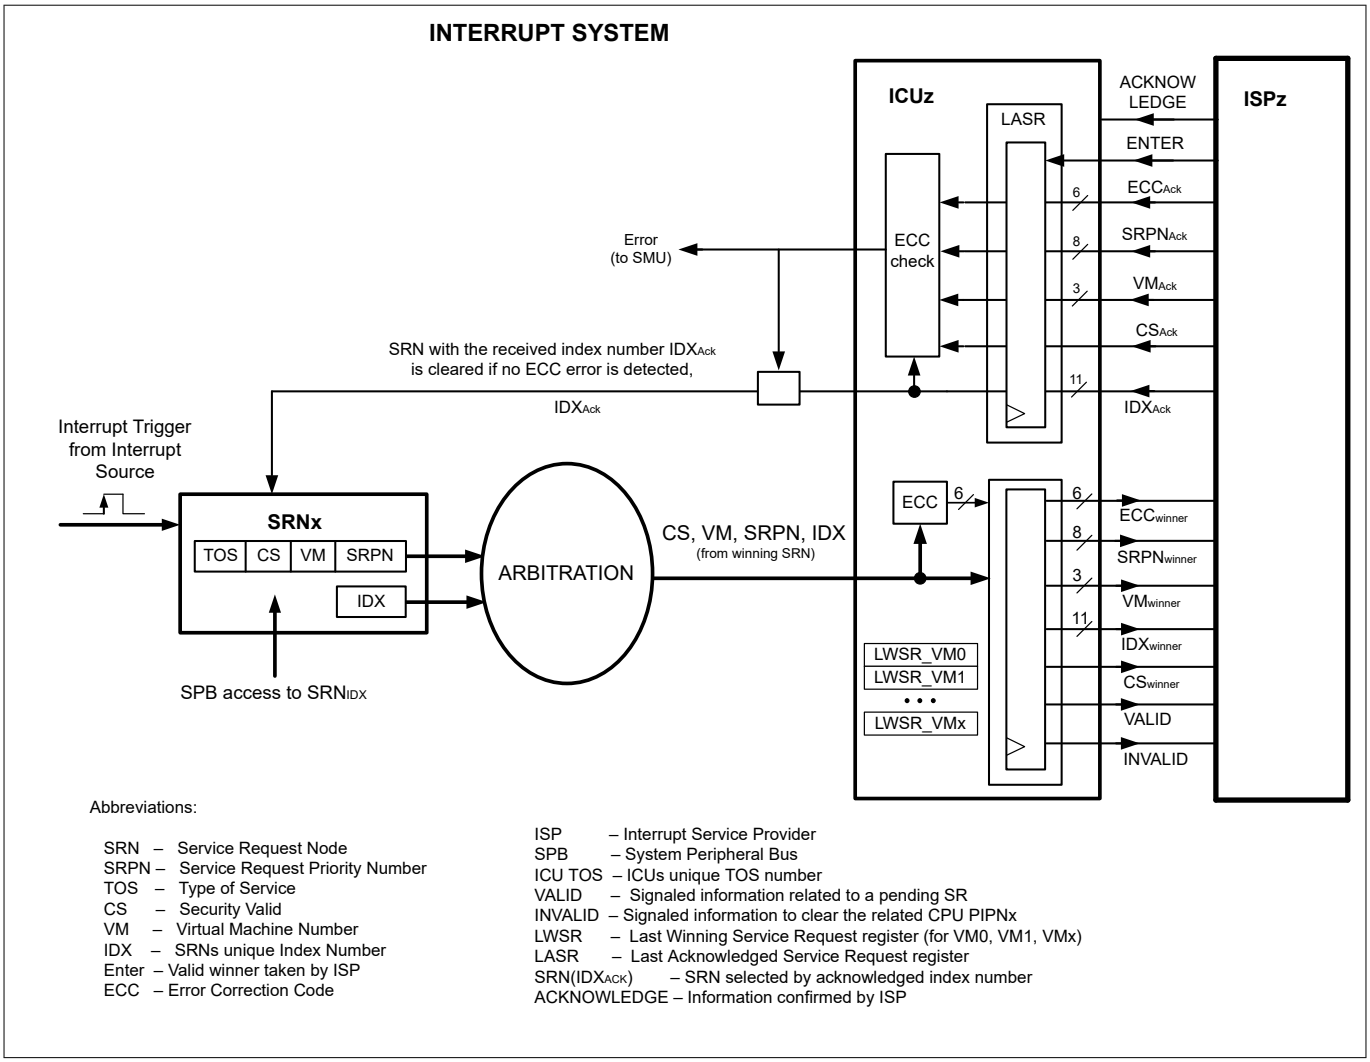

Figure 959 Interrupt system arbitration scheme overview

40.3.9.1 Arbitration mechanism

Each interrupt node can be mapped through its SRCx.TOS bit field to one ICUz and so to the related interrupt service provider. For a CPU with hardware virtualization support it can be mapped to one VM on the CPU through the SRCx.VM bit field.

When arbitrating for an ISP, the IR selects the enabled and pending service request with the highest service request priority number (SRPN) assigned to that ISP.

Arbitration for the implemented ISPs that are CPUs with hardware virtualization support is done in parallel. Arbitration for the active VMs on a CPU is done in a fixed sequence.

Arbitration for ISPs that are not CPUs with hardware virtualization support is done in time division multiplexing. Here, a maximum of two of these ISPs are arbitrated in a single clock time-division multiplexing procedure.

For a CPU with hardware virtualization support, service request arbitration is performed for each active VM individually.

In an arbitration process for ICUz, the arbitration mechanism compares the SRCx.SRPN bit-fields of all pending service request nodes that are mapped to this ICUz (SRCx.TOS=z) and to the VM it is just arbitrating for on this ICUz (SRCx.VM configuration).

During the arbitration process for one ISP with only one VM enabled, the pending service request with the highest priority number is identified as winner and the related SRN service request control register bit-field values SRPN, VM, ECC and the Index of the SRN are provided to the ICU.

When multiple VMs are enabled for a CPU the IR arbitrates for enabled VMs on that CPU in a fixed sequence. During the arbitration sequences for the activated VMs, the ICU signals for each enabled VM the highest SRPN for this VM (VALID=1 AND INVALID=0).

For enabled VMs without a pending service request the ICU signals no information (VALID=0 AND INVALID=0).

The ICU signals these service request information to the ISP (SRPN, VM, ECC, CS, IDX) to the ISP. The ICU does an ECC check when it gets these information back from the service provider with an acknowledge.

The ECC check is done with the received values: SRPN, VM, ECC, CS, IDX and the TOS information related to the respective ICU. On detected ECC error, IR does not clear the SRN related to the received IDX and signals an alarm to the SMU.

The INVALID is used in a special situation: When the last pending SR for VMx on a CPUy was deleted by SW. Then the SR in the IR is deleted, but the SR information in the CPUy can still exist in the CPUy.PIPNx register. To clear this information the IR signals an INVALID with the VMx information to the CPUy which causes the CPUy to set the register bit field PIPNx.SRPN=0.

Example situation in which INVALID is used by the ICU: VMx is enabled, only one SR is pending for VMx. The SR has been signaled to VMx but not yet acknowledged which can be seen by software through LWSRx.STAT=1 and LWSRx.VALID=1. Now software clears the SR in the interrupt router. After this, the ICU does not see a new winner in the next arbitration round for VMx but LWSRx shows the last pending service request for VMx that was cleared by SW. In this situation the ICU signals an INVALID for VMx to the CPU, clears LWSRx.STAT bit and updates the other LWSRx bits with the signaled information.

40.3.9.2 IR hardware virtualization support (VMENz)

Each ICUz has one VMENz register. An ICU for an ISP CPU with hardware virtualization support has VMENz [7:0] implemented with read and write register bits, in addition 8 LWSRz registers are implemented. These VMENz[7:0] bit numbers correspond to the VM numbers on the CPU and must be configured according to VMs used on the CPU. Thereby the ICU supports two different arbitration mechanisms which are controlled by the VMENz configuration.

- VMENz[7:0] is 0 . This configuration should be selected if the CPU is not used in hardware virtualization mode. The SRCx.VM information is ignored by ICUz for arbitration, alll service requests are signaled with VM=0_H to the ISP
- VMENz[7:0] is not 0. If the CPU is used in hardware virtualization mode, the used virtual machines (VM) must be activated in VMENz[7:0] and the corresponding SRNs must be assigned to the VMs through SRNx.VM. Any VMENz[7:0] configuration is allowed and supported by the IR, including VMEN[0]=0 which means that VM0 disabled and does not make sense for a CPU with hardware virtualization support enabled

In case of ICUz related to an ISP CPU and at least one VM is enabled in register VMENz the IR uses the SRCx.VM information for an arbitration mechanism that is specifically adapted to the TriCore™ hardware virtualization mode. For all enabled VMs (VMENz) the IR arbitrates among all pending service requests that are mapped to this ICUz through SRCx.TOS, and to the virtual Machine through SRCx.VM.

- Case 1: VMENz shows all VM disabled. SRCx.VM information will be ignored. The winner of an arbitration round is the pending service request with the highest SRCx.SRPN number. Service requests are signaled with VM=0_H to the ISP
- Case 2: VMENz shows one or more VMs enabled. The IR arbitrates for the enabled VMs in a fixed sequence. The winner of an arbitration round for a VM is the pending service request with the highest SRCx.SRPN mapped to this VM through the SRCx.VM configuration. The arbitration sequence is fixed even when there is no service request pending for an enabled VM

***Note**: If an ICU related to CPUx is reconfigured from VMEN != 0 (hardware virtualization enabled) to VMEN=0 during operation, it must be ensured that no service requests are pending for VM1-VM7. Otherwise the register CPUx.PIPN0 could be wrongly set to 0 due to a last INVALID information for VMy (y=1-7).*

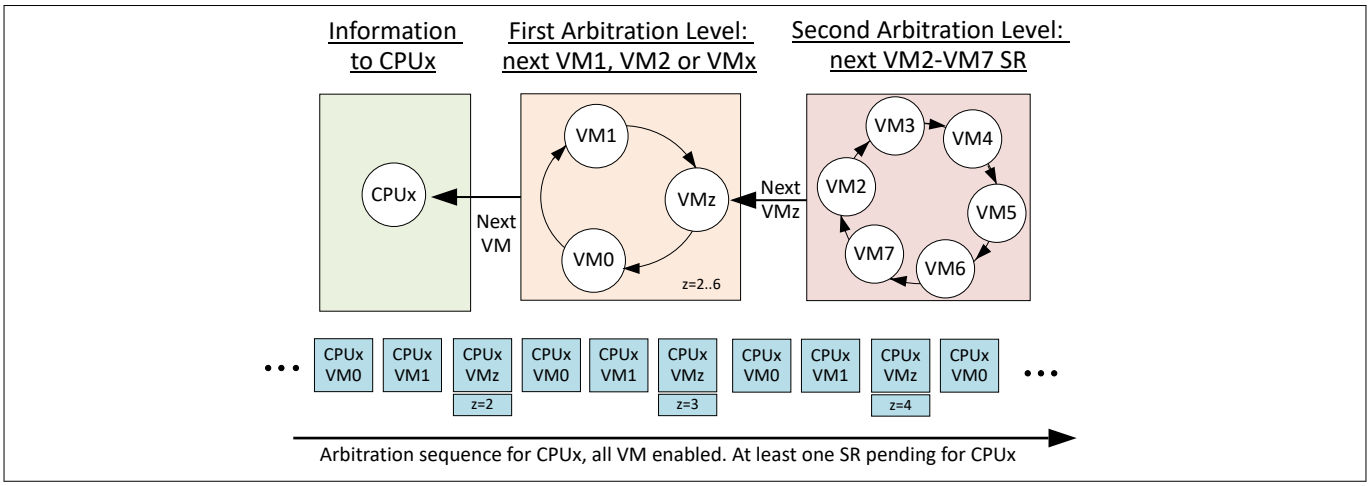

Figure 960 Example for CPUx. All VMs enabled through related ICU VMEN. At least one SR pending for CPUx, Enter signal not asserted (otherwise arbitration would stop until Enter signal is de-asserted)

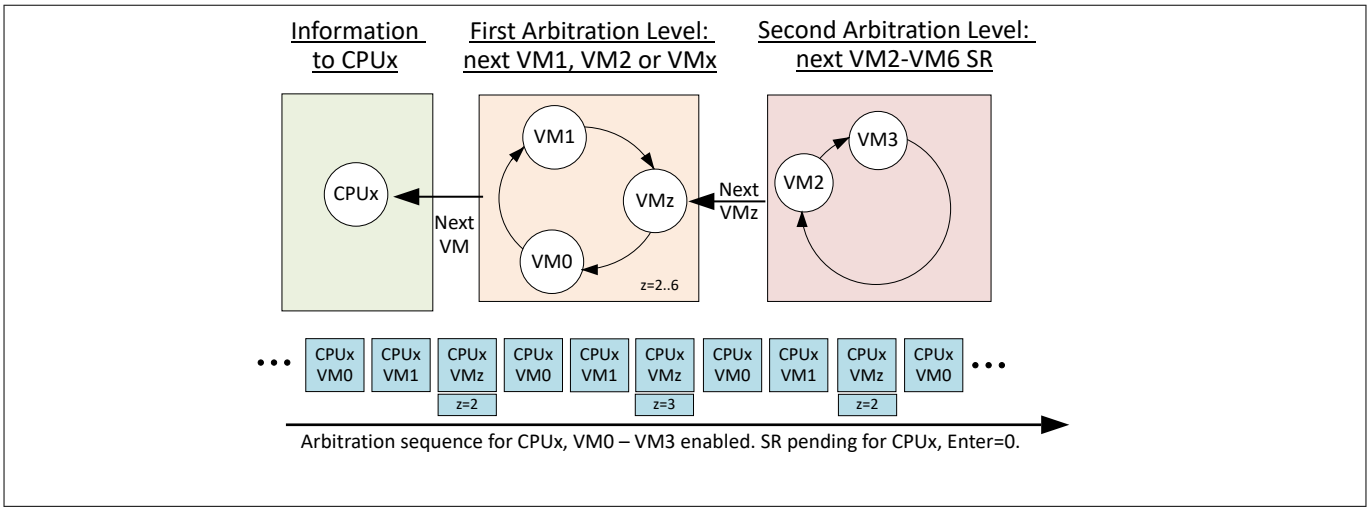

Figure 961 Example for CPUx. Only VM0 - VM3 enabled through related ICU VMEN. At least one SR pending for CPUx. CPUx Enter signal not asserted

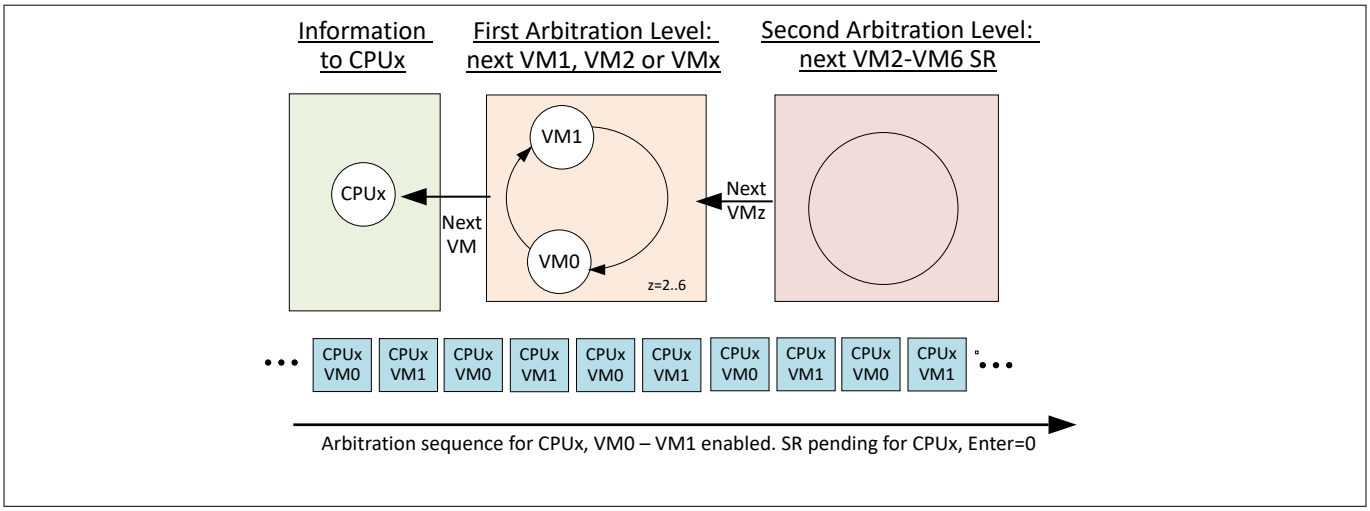

Figure 962 **Example for CPUx. Only VM0 and VM1 enabled through related ICU VMEN. At least one SR pending for CPUx. CPUx Enter signal not asserted**

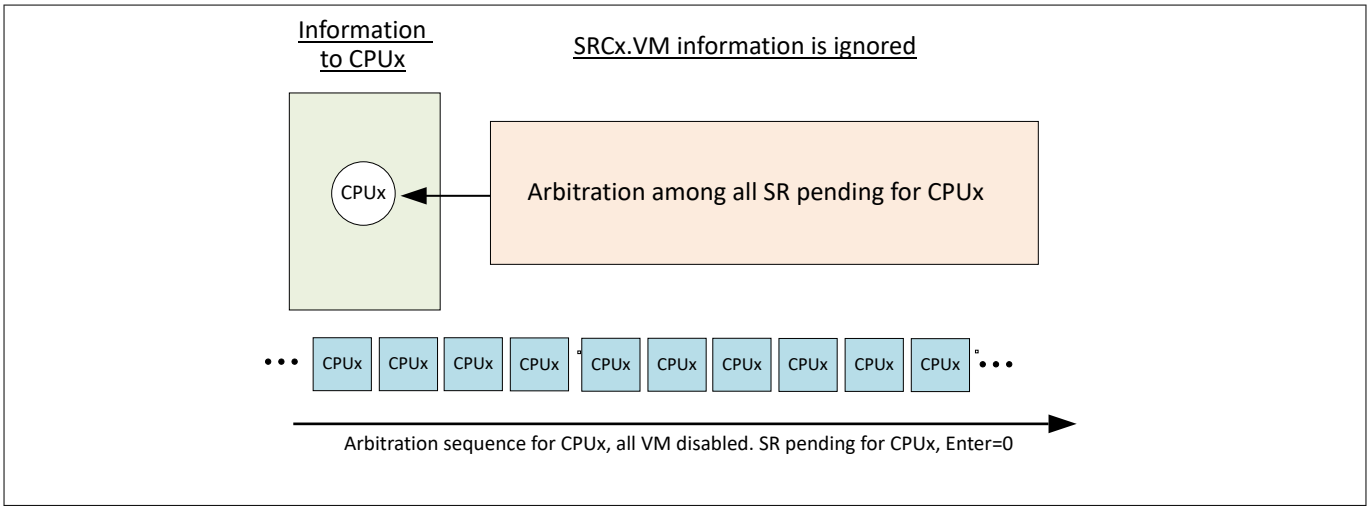

Figure 963 **Example for CPUx (GTM, DMA, PPU) with all VMs disabled through related ICU VMEN. At least one SR pending for CPUx, Enter signal not asserted**

40.3.9.3 SRCx information used for the arbitration

To determine the arbitration round winner for an ISP, the IR uses the following information:

- Service Request Enable (SRCx.SRE) and Service Request Flag (SRCx.SRR) to identify the enabled service request nodes with a pending service request
- Type of Service (SRCx.TOS) to identify the group of pending SR mapped to a physical ISP (CPUs, DMAs, PPU, GTM)

In case of an ISP for CPU with hardware virtualization support the IR uses the following information in addition:

- Register VMENz to identify the enabled VMs on that CPU. The VMENy configuration defines the executed arbitration sequence
- If a VMENz is configured to show all VM as disabled the SRCx.VMx information will be ignored for the arbitration (can be used if CPU is not used in Hardware Virtualization mode)
- SRC Virtual Machine Information (SRCx.VM) to identify per ISP the group of pending SR per VM encoding that is enabled through VMENz

In case of an ISP DMA, PPU, GTM or CPU without hardware virtualization support:

- VMENz is implemented hardwired, all bits are 0
- For interrupt nodes mapped to these ISPs the SRCx.VM information has no effect

40.3.9.4 Number of clock cycles per arbitration

The maximum interruption latency can be calculated with the following formulas. The formulas take into account the type and number of VMs that are activated through the VMEN register. The interrupt latency is calculated in f_{SPB} clock cycles and contains the interrupt path from the interrupt source where the functional block interrupt trigger output is signaled in the first cycle, to the clock cycle at which the service request is signaled to the ISP.

Latency for VM0 and VM1 interrupts

$Latency_VM_{01} = LBV + VM01 - 1$

Latency for VMx interrupts (VMx -> VM2 ... VM7)

$Latency_VM_{2..7} = LBV + VMx * VM01 - 1$

Table 1913 Description of variables used in interrupt latency formula

Variable	Description
VM01	VM01 indicates the number of enabled VM in the group VM0, VM1 and VMz. VM01 to be replaced in the formula with: • 1 -> if exactly one out of the group VM0, VM1, VMz is enabled • 2 -> if exactly two out of the group VM0, VM1, VMz are enabled • 3 -> if VM0, VM1 and VMz are enabled ***Note**: VMz indicates here if at least one VM of the group VM2-VM7 is enabled through the VMEN register. Example: VM0 is enabled, VM1 is disabled and one or more of VM2-VM7 are enabled then VM01=2. Example: VM0 and VM1 are enabled, VM2-VM7 are disabled then VM01=2*
VMx	VMx indicates the number of activated VM in the group VM2-VM7. VMx to be replaced in the formula with: • 0 -> if VM2 - VM7 are disabled in register VMEN • 1 -> if exactly one VM in the group is enabled • … • 5 -> if exactly five VM in the group are enabled • 6 -> if all VM in the group are enabled in register VMEN
LBV	Latency Basic Value -> 4 The LBV is a fix value and describes the best case latency from the interrupt trigger event of the interrupt source (fSPB clock cycle 2) through the IR arbitration for ICUx to the signaling of the SR to the ISPx (see following figure, ICU_VALID=´1´, f_{SPB} clock cycle 5).The best case latency is reached when a new interrupt is immediately arbitrated by the arbitration tree. This is always the case if no SR was pending before, then the VM arbitration sequence will start with VM0, or if all VMs are disabled and a new interrupt has the highest priority of all pending SR

40.3.10 IR wake-up support for CPUs and PPU

The IR provides wake-up support for the functional blocks CPUs and the PPU. The wake-up function can cause a functional block in IDLE or SLEEP to enter RUN mode. For this purpose the IR signals for each CPU and PPU separately if a service request is pending. A pending service request means that SRR=1 and SRE=1. This information is signaled to the functional block SMM.

40.3.11 IR alarm signals to SMU

IR alarm signals to SMU

The IR provides three alarm signals:

- ALARM_CS on detection of an ECC error in an acknowledged service request information where the service request CS information is 1. This alarm is mapped to the SMU_CS
- ALARM_NCS on detection of an ECC error in an acknowledged service request information where the service request CS information is 0. This alarm is mapped to the SMU_SAFE
- ALARM_LCL is signaled to the SMU_SAFE on detection of an IR lockstep error

Each ICU has implemented an independent ECC check mechanism where it checks the service request information it received through Acknowledge by the related ISP. The alarm_cs and alarm_ncs events from all implemented ICUs are combined to a single ALARM_CS and a single ALARM_NCS. Each ICU provides a dedicated error capture register (ECR) that captures the information of the first acknowledged service request where an ECC failure was detected. Each ICU provides a dedicated error generation register (EGEN) that enables application software to inject ECC errors in order to test the ECC check mechanism an the ALARM_CS and ALARM_NCS signal path to the SMU.

The IR lockstep compare mechanism and the ALARM_LCL signal path to the SMU can be tested through the lockstep test register (LCLTEST).

40.3.12 Module implementation

This chapter describes the IR ICU configurations and the number of General purpose service request Groups (GPSR) for the AURIX™ TC4xx family.

The product-specific IR ICU and SRC registers are described in the respective product-specific UM chapter.

40.3.12.1 Characteristics of the interrupt router module

The following tables show the Interrupt router configurations of the TC4xx devices.

The tables enable the customer to write generic software that can be easily ported between the targeted derivatives and to recognize the differences between the derivatives.

ICU hardware virtualization support (HVS):

The table also shows which ICU provides the hardware virtualization support (HVS).

- ICU marked with ´*´: ICU is implemented with HVS support. It provideshas eight LWSR registers (LWSR0-LWSR7) and the ICUs´VMEN[7:0] register bits are implemented with read and write bits to control which VM encoding to be considered. If all VMs are disabled in the VMEN register, hardware virtualization support is disabled, SRCx.VM information is ignored by the ICU arbitration and only LWSR0 is updated by hardware
- ICU marked without ´*´ : ICU is implemented without HVS support. It provides one LWSR register (LWSR0) and the VMEN register implemented hardwired 0 (HVS disabled). The SRCx.VM information is ignored by the ICU arbitration. Only LWSR0 is updated by hardware

Table 1914 Mapping of interrupt service provider to ICUs and implemented SRNs

Software interrupt groups (GPSRGxSRy, SRBx, SRBx_ACCEN, GPSRGx_SWCy, GPSRGx_SWCACCENy)

The following table shows the relation between available ICUz and the implemented general purpose software interrupt groups where each group includes the registers GPRGxSRy, SRBx, GPSRGx_SWCy and GPSRGx_SWCACCENy.

The GPSRG groups can be used freely by the application software, GPSRs can be freely assigned to any implemented ISPz.

The information can help to decide: which GPSRGx should software use for a particular ISP to create a portable SW.

- Example: GPSRG7 and related registers are available in all products with a PPU
- Example: GPSRG5 and related registers is available in all products with a CPU5

Table 1915 Relationship between available ICUz and implemented GPSRGx resources

ISPz	CPU0	CPU1	CPU2	CPU3	CPU4	CPU5	CPUCS	SDMA 0	SDMA 1	GTM	PPU	RDMA
GPSRGx	x=0	x=1	x=2	x=3	x=4	x=5	x=6	-	-	-	x=7	-

Dedicated and shared ICU arbitration

The following table is showing which ICU is implemented with a dedicated arbitration (marked with D in the table below) and which ICU pair is implemented with a shared arbitration of the pending service requests assigned to the two respective ICUs:

- D means that there is a dedicated arbitration for this one ICU
- Sx means that the two ICUs with the same x value share an arbitration mechanism

An ICU related to a CPU is always implemented with a dedicated arbitration mechanism each.

ICU´s related to DMA functions, PPU and GTM are implemented with shared arbitration mechanisms where possible. Because DMA´s and the GTM acknowledge an arbitration round winner immediately the side effect in between the paired ICU´s is limited.

Shared arbitration for an ICU couple means:

- as long as service requests pending for ICUx and ICUy the mechanism arbitrates alternately for ICUx and ICUy in each f_{SPB} clock cycle, means that the worst case arbitration latency per arbitration round is delayed by one f_{SPB} clock cycle
- as long service requests pending only for ICUx the mechanism arbitrates permanently for ICUx in each cycle, same true for ICUy
- as long ICUx asserts its ENTER signal, the mechanism does not arbitrates anymore for ICUx and can permanently arbitrate for ICUy

Table 1916 ICU with dedicated and shared arbitration

40.4.1 Registers of INT

40.4.1.1 Register overview - access mode glossary

Table 1917 Register overview - access mode glossary

Keyword	Description
CSE	Access protection using PROT register PROTCSE.
SE	Access protection using PROT register PROTSE.
TOSz (z=0-14)	Access protection using PROT register PROTTOSz.
APU-PCS	Protection group consisting of registers ACCENCS_WRA, ACCENCS_WRB, ACCENCS_RDA, ACCENCS_RDB, ACCENCS_VM, ACCENCS_PRS.
PCS	Access protection using *APU-PCS* registers.
APU-PDBG	Protection group consisting of registers ACCENDBG_WRA, ACCENDBG_WRB, ACCENDBG_RDA, ACCENDBG_RDB, ACCENDBG_VM, ACCENDBG_PRS.
PDBG	Access protection using *APU-PDBG* registers.
APU-PSCFGz (z=0-14)	Protection group consisting of registers TOSz_ACCENSCFG_WRA, TOSz_ACCENSCFG_WRB, TOSz_ACCENSCFG_RDA, TOSz_ACCENSCFG_RDB, TOSz_ACCENSCFG_VM, TOSz_ACCENSCFG_PRS.
PSCFGz	Access protection using *APU-PSCFGz* registers.
APU-PSCTRLz (z=0-14)	Protection group consisting of registers TOSz_ACCENSCTRL_WRA, TOSz_ACCENSCTRL_WRB, TOSz_ACCENSCTRL_RDA, TOSz_ACCENSCTRL_RDB, TOSz_ACCENSCTRL_VM, TOSz_ACCENSCTRL_PRS.
PSCTRLz	Access protection using *APU-PSCTRLz* registers.
APU-PSRBy (y=0-15)	Protection group consisting of registers ACCENSRBy_WRA, ACCENSRBy_WRB, ACCENSRBy_RDA, ACCENSRBy_RDB, ACCENSRBy_VM, ACCENSRBy_PRS.
PSRBy	Access protection using *APU-PSRBy* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
M	Indicates a module specific access condition. Refer to the register description for details of the specific access condition.

40.4.1.3 OCDS control and status register

The OCDS Control and Status register OCS controls the debug and trace behavior by selecting suspend modes and OTGB trigger sets. When OCDS is disabled the suspend control is ineffective.

OCS Offset address: 0004_H

OCDS control and status register Debug Reset value: $0000\ 0000_H$

40.4.1.43 GPRSGx_SWCy write access protection register

GPSRGx_SWCACCENy controls the write access protection for the related GPSRGx_SWCy register.

It defines which CPU TAG-IDs, Debug TAG-ID, VM or PRS encodings are enabled for write access to GPSRGx_SWCy.

Bits referring to TAG-IDs of unimplemented CPUs have no effect as the TAG-IDs are not used in the system.

Access Protection for access to the GPSRGx_SWCACCENy register:

- it is write protected by PROTTOSz.
- it is read protected TOSz_ACCENSCFG.
- TOSz_ACCENSCFG and PROTTOSz are selected by the GPSRGxSRy.TOSz configuration.

For more details see IR chapter General Purpose Service Requests (GPSRGxSRy).

40.4.1.44 SW control register for GPSRGxSRy

The GPSRx_SWCy can be used to control the associated GPSRGxSRy (GPSR group x, node y) and to to disable GPSRGxSRy interrupt trigger through SRBx.TRIGx.

The GPSRx_SWCy register is write protected by the related GPSRGx_SWCACCENy register and read protected by the TOSz_ACCENCFG where 'z' is determined by the configuration of the corresponding GPSRGxSRy node (GPSRGxSRy.TOS=z).

The GPSRx_SWCy.LOCKSTAT bit can only be cleared by a master agent function enabled for write access to GPSRGx.SRy and enabled for write access in GPSRGx_SWCACCENy.

GPSRGx_SWCy (x=0-15;y=0-7) Offset address: 0720_H+x*40_H+y*4

SW control register for GPSRGxSRy Application Reset value: $0000\ 0000_H$

DATA															
rw															

Field	Bits	Type	Description
DATA	15:0	rw	**DATA** Data can be used to transfer additional information from the SW interrupt initiator to the ISP. DATA is protected against unintentional overwriting through LOCKSET. The ISP can read the information from the DATA register and then release the register again via LOCKCLR. Write: DATA is updated with the written value Read: Returns DATA Note: DATA can only be updated if LOCKSTAT=0 and LOCKSET is written with 1 in parallel. Data can only be updated by writing to the complete DATA 16-bit field. Otherwise DATA will not be updated and there will be no notification.
LOCKSET	16	w	**Sets LOCK bit** The LOCKSET bit can be used to set the DATA lock status 0_B No action 1_B Sets LOCKSTAT=1; DATA is updated by this write if LOCKSTAT=0; no action if LOCKCLR is written with 1 at the same time; Read always returns 0
LOCKCLR	17	w	**Clears LOCK bit** The LOCKCLR bit can be used to reset the DATA lock status. 0_B No action 1_B Sets LOCKSTAT=0 if the master agent function writes that is defined in the related GPSRGxSRy SRC register; no action if LOCKSET is written with 1 at the same time; write from any other master has no effect; read always returns 0

(table continues...)

(continued)

Field	Bits	Type	Description
LOCKSTAT	18	rh	**Status of DATA lock** 0_B DATA is not locked, can be updated 1_B DATA is locked, can not be updated
BRDIS	27	rw	**Broadcast disable** The BRDIS bit can be used to disable the GPRS node control through the broadcast register. If disabled (GPSRGx_SWCy.BRDIS=1), SRBx.TRIGy can not trigger GPSRGxSRy (GPSR group x, SRN y). 0_B SRBx.TRIGy register bit is enabled 1_B SRBx.TRIGy register bit is disable
SRR	28	rh	**Service request status** Signals status of register bit GPSRGxSRy.SRR 0_B Service request not pending (SRR=0) 1_B Service request pending (SRR=1)
SETR	29	w	**Service request set** Sets register bit GPSRxSRy.SRR. 0_B No action 1_B Sets register bit GPSRxSRy.SRR=1; if already GPSRxSRy.SRR=1 then SRC_GPSRxSRy.IOV is set to 1; read always returns 0
IOV	30	rh	**Service request interupt overflow status** Signals the current status of register bit SRC_GPSRxSRy.IOV 0_B No interrupt overflow detected (status of register bit GPSRxSRy.IOV=0) 1_B Interrupt overflow detected (status of register bit is GPSRxSRy.IOV=1)
IOVCLR	31	w	**Service request interupt overflow clear** Resets the register bit SRC_GPSRxSRy.IOV 0_B No action 1_B Sets register bit GPSRGxSRy.IOV=0 but only if the master agent function writes that is defined in the related SRC_GPSRGySRy register; write from any other master has no effect; no action in case of an IOV condition for register bit GPSRGySRy at the same time; read always returns 0
0	26:19	r	**Reserved-0** Read as 0; should be written with 0.

Table 1923 Access mode restrictions of GPSRGx_SWCy (x=0-15;y=0-7) sorted by descending priority

Mode name	Access mode		Description
write 1 to .**LOCKSET** and .**LOCKSTAT** == 0	rw	DATA	Lockset must be written with 1
(default)	r	DATA	

40.4.1.45 Service request broadcast register x

Interrupt service request broadcast registers can be used to trigger multiple of the eight service request nodes in the related GPSRx group in parallel.

SRBx (x=0-15) Offset address: $0B00_H+x*4$

Service request broadcast register x Application Reset value: $0000\ 0000_H$

VM	30:28	rh	**Virtual machine number**
ENTER	31	rh	**ENTER signal state** This bit field shows the current status of the ENTER signal. 0_B ISP is not in ENTER state. 1_B ISP is in ENTER state.
0	15:14	r	**Reserved-0** Read as 0; should be written with 0.

40.4.1.48 ICU error capture register

On detection of an ECC error at ICUz, the ECR register captures the related acknowledged service request information. This is done by updating the ECR with the content of the Last Acknowledged Service Request (LASR) register. The ECR shows always the last acknowledged information where an ECC error was detected.

***Note**: ECC is used here for error detection only. Detected errors are signaled through Alarm_CS to SMU_CS or through Alarm_NCS to SMU_SAFE.*

ECRz (z=0-14) Offset address: $0C24_H+z*34_H$

ICU error capture register Application Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
PN	7:0	rh	**Service request priority number** This bit field shows the priority number of the last service request where an error was detected. Bit field can be modified by writing to it.
ECC	13:8	rh	**Received ECC information** This bit field shows the ECC of the last Acknowledged information where an error was detected.

(table continues...)

(continued)

Field	Bits	Type	Description
ID	26:16	rh	**Service request node index number** This bit field shows the ID of the last service request where an error was detected. Bit field can be modified by writing to it
CS	27	rh	**Cyber security information** 0_B Service request is not assigned to the security application 1_B Service request is assigned to the security application
VM	30:28	rh	**Virtual machine number**
0	15:14, 31	r	**Reserved-0** Read as 0; should be written with 0.

40.4.1.49 ICU error control register

Error Status (STAT) and error overflow (EOV) bits can be used as error handling mechanism and indication that error information was lost.

If EOV is cleared by SW, it shall be cleared together with the STAT bit.

Clearing STAT by SW has precedence over a new STAT set situation. The clearing of the EOV by SW has precedence over a simultaneous EOV situation. Both corner cases are not relevant to the application because it cannot be controlled whether a STAT and EOV event occurs one cycle before or after the respective SW clear.

ECTRLz (z=0-14) Offset address: $0C28_H+z*34_H$

ICU error control register Application Reset value: $0000\ 0000_H$

0												EOV CLR	EOV	STAT CLR	STAT
r												w	rh	w	rh

Field	Bits	Type	Description
STAT	0	rh	**Error status bit** The error status bit is set whenever an ECC error was detected by the ICU. 0_B No ECC error detected 1_B ECC error detected
STATCLR	1	w	**Error status bit** The STATCLR bit is used to clear the STAT bit. Note: the STAT bit is not cleard in case of an error event that happens in parallel. 0_B No action 1_B Clear STAT bit; read always returns 0; no action if STAT bit is set in parallel by hardware to 1.

(table continues...)

(continued)

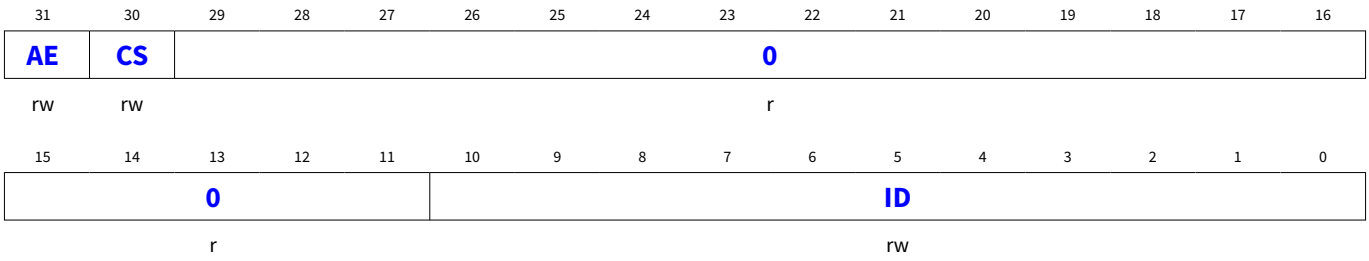
Field	Bits	Type	Description
EOV	2	rh	**Error overflow bit** The bit is set if an ECC error was detected by the ICU while ECTRL.STAT= ´1´ (error overflow situation). 0_B No error overflow situation detected 1_B Error overflow situation detected
EOVCLR	3	w	**Error overflow bit** The EOVCLR bit is used to clear the EOV bit. The EOV bit should be cleared together with the STAT bit. Note: the EOV bit is not cleard in case of an EOV event that happens in parallel. 0_B No action 1_B Clear EOV bit; read always returns 0; no action if EOV bit is set in parallel.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

40.4.1.50 ICU error generation register

The EGEN register enables application software to check the ICU ECC error detection mechanism and the ALARM signal to the SMU.

EGENz (z=0-14) Offset address: $0C2C_H+z*34_H$

ICU error generation register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
ID	10:0	rw	**Service request node ID** The bitfield describes the index number (ID) of the SRN whose SR is to be transmitted with an ECC error.
CS	30	rw	**Cyber security** A CS write access (CS_VALID=´1´) to this register is only executed if it writes with CS=´1´. A non CS write access (CS_VALID=´0´) to this register is only executed if it writes with CS=´0´.: 0_B Error is only injected if service request selected through IDX is not security related (SCRx.CS=´0´). 1_B Error is only injected if service request selected through IDX is security related (SCRx.CS=´1´).

(table continues...)

(continued)

Field	Bits	Type	Description
AE	31	rw	**Activate error enable** Activates the selective inversion of ECC bit 0 of a service request from the selected selected SRNx (EGEN.ID=x). Note: The ICU only injects the ECC error if SRCx.CS = EGEN.CS. 0_B Not enabled 1_B Enabled
0	29:11	r	**Reserved-0** Read as 0; should be written with 0.

40.4.1.51 ICU VM control register

Controls which VM is considered in the ICU Arbitration sequence. Arbitration slots of disabled VMs are skipped in the arbitration sequence.

***Note**: Hardware virtualization support is disabled for this ICU if all VM bits in this register are disabled. This means that only the SRCx.SRPN information is considered for arbitration, the SRCx.VM information will be ignored. All pending SRs for this ICU are arbitrated and the winner SR is passed to the ISP.*

VMENz (z=0-14) Offset address: $0C30_H+z*34_H$

(continued)

Field	Bits	Type	Description
TOS	15:12	rw	**Type of service** The TOS bit field configuration maps a service request to an interrupt service provider: ***Note**: In products where DMA1, GTM, PPU, RDMA or CPUx is not implemented, the related TOS encoding will not be used and treated as RESERVED.* 0_H Service request is mapped to CPU0 1_H Service request is mapped to CPU1 2_H Service request is mapped to CPU2 3_H Service request is mapped to CPU3 4_H Service request is mapped to CPU4 5_H Service request is mapped to CPU5 6_H Service request is mapped to CPUCS 7_H Service request is mapped to DMA0 8_H Service request is mapped to DMA1 9_H Service request is mapped to GTM A_H Service request is mapped to PPU B_H Service request is mapped to RDMA F_H SRN not used **others,** Reserved
SRE	23	rw	**Service request enable** 0_B Service request is disabled 1_B Service request is enabled
SRR	24	rh	**Service request status** The SRR bit shows the status of the service request. 0_B No service request is pending 1_B Service request is pending
CLRR	25	w	**Service request clear** The CLRR bit is required to reset SRR. 0_B No action 1_B Write with 1 leads to SRR=0; no action if SETR is written with 1 at the same time; no clear of SRR if a hardware interrupt trigger happens at the same time. read always returns 0.
SETR	26	w	**Service Request set** The SETR bit is required to set SRR. 0_B No action 1_B Write with 1 leads to SRR=1; if SRR is already =1 then IOV is set to 1; no action if CLRR is written with 1 at the same time; read always returns 0.

(table continues...)

(continued)

Field	Bits	Type	Description
IOV	27	rh	**Interrupt overflow status** The IOV bit is set by HW when a new service request is triggered by interrupt trigger or write to the SETR bit with 1 while SRR=1. 0_B No interrupt overflow detected 1_B Interrupt overflow detected
IOVCLR	28	w	**Interrupt overflow clear** IOVCLR is required to reset IOV. 0_B No action 1_B Write with 1 lead to IOV=0; no action in case of an IOV condition at the same time; read always returns 0.
0	22:16, 31:29	r	**Reserved-0** Read as 0; should be written with 0.

40.5 Debug information

IR debug information.

40.5.1 OCDS trigger bus interface (OTGB)

The IR module has three 16-bit trigger sets which are selected with the OCS register.

The IR module provides

- two OTGB 16 bit interfaces to the MCDS module, OTGB0 and OTGB1
- three 16 bit trigger sets as described below TS16_IS, TS16_SPA and TS_16_SP
- Standard OCS register:
  - OCS.TGS to select which trigger set is mapped to OTGB0 and OTGB1
  - OCS.TGB to select which of the two OTGB interfaces, OTGB0 OTGB1 is used. TGB is ignored if TC16_SP is selected

If TS16_SP is selected, OCS.TGB is ignored and there is the option for two instances in parallel on OTGB0 and OTGB1 (control by OIT register).

Table 1926 IR trigger sets selected by OCS.TGS

Trigger set	Description	Details
TS16_IS Interrupt Selection	Request state of selected interrupt request signals	• 16 bit trigger set, bit mapping described in TS16_IS table • set selected through OCS.TGS • mapped to OTGB0 or OTGB1 through OCS.TGB
TS16_SPA Service Provider Activity	Parallel view of requests waiting for all service providers	• 16 bit trigger set, bit mapping described in TS16_SPA table • set selected through OCS.TGS • mapped to OTGB0 or OTGB1 through OCS.TGB
TS16_SP Service Provider	Interrupt activities of a selected service provider. Option for two Service Requests in parallel on OTGB0 and OTBG1	• 16 bit trigger set, bit mapping described in TS16_SP table • set selected through OCS.TGS • OCS.TGB is ignored if TS16_SP is selected • 16 bit trigger set can be mapped to OTGB0 and OTGB1 with two configurations to observe service requests to two different ISPs in parallel. Configuration controlled through the register OIT

40.5.1.1 Request state of selected interrupt request signals

Table 1927 TS16_IS trigger set interrupt selection

Bits	Name	Description
0	SI0	Selected (see OIXS0) interrupt 0

(table continues...)

Table 1927 (continued) TS16_IS trigger set interrupt selection

Bits	Name	Description
1	SI1	Selected (see OIXS0) interrupt 1
2	SI2	Selected (see OIXS1) interrupt 2
3	SI3	Selected (see OIXS1) interrupt 3
[14:4]		Reserved (value is 0)
15	SIL	Selected (see OIXMS) interrupt trigger lost

***Note**: The selected interrupt reflects the service requests by hardware and by software.*

CyberSecurity activity visibility (CSAV) control

Only for CSAV=Full, TS16_IS will show the status for SRN with SRC.CS=1. This applies to all TS16_IS bits: SIx and SIL.

For CSAV!=Full and a the selected SRC is configured with CS=1, the respective bit is set to 0. This applies to all TS16_IS bits: SIx and SIL.

40.5.1.2 Parallel view for all service providers of requests waiting

Table 1928 TS16_SPA trigger set interrupt selection

Bits	Name	Description
0	CPU0	CPU0: One or more service requests waiting
1	CPU1	CPU1: One or more service requests waiting
2	CPU2	CPU2: One or more service requests waiting
3	CPU3	CPU3: One or more service requests waiting
4	CPU4	CPU4: One or more service requests waiting
5	CPU5	CPU5: One or more service requests waiting
6	CPUCS	CPUCS: One or more service requests waiting (only visible if CSAV=Full)
7	DMA0	DMA0: One or more service requests waiting (only visible if CSAV=Limited or Full)
8	DMA1	DMA1: One or more service requests waiting (only visible if CSAV=Limited or Full)
9	GTM	GTM: One or more service requests waiting
10	PPU	PPU: One or more service requests waiting
11	RDMA	RDMA: One or more service requests waiting
[14:12]		Reserved (value is 0)
15	SIL	Selected (see OIXMS) interrupt trigger lost

The encoding in the above TS16_SPA trigger set table covers the full device family. The timing resolution of 'One or more requests waiting' is one ICU arbitration round. Also immediately taken requests are visible in TS16_SPA

***Note**: For all TS16_IS signals, ´1´ means that one or more SR are pending, 0 means that non SR is pending.*

CyberSecurity Activity Visibility (CSAV) control

- Bit CPUCS: Only for CSAV=Full, TS16_SPA will show the CPUcs activity
- Bits DMA0 and DMA1: Only for CSAV=Limited or CSAV=Full, TS16_SPA will show the DMA0 and DMA1 activities
- SIL: Only with CSAV=Full the status of SRNs with SRC.CS=1 is shown in TS16_SPA SIL. For CSAV!=Full and SRC configured with CS=1, SIL is set to 0

40.5.1.3 Interrupt activities of a selected service provider

The interrupt system provides the ability to observe up to two service providers in parallel on OTGB0 and OTGB1. This is configured with the OIT register (OCS.TGB is ignored in this case).

Table 1929 TS16_SP trigger set interrupt selection

Bits	Name	Description
0	A	Request acknowledged
1	W	One or more service requests waiting for arbitration by the service providers as selected through the OIT register
[3:2]		Reserved (value is 0)
[14:4]	ASR	Accepted Service Request index (status of the selected ICU LASR.IDX)
15	SIL	Selected (see OIXMS) interrupt trigger lost

***Note**: The timing resolution of A and W is one ICU arbitration round.*

TS16_SP is implemented in a way which minimizes the value changes. The following rules apply:

- A is a single cycle pulse
- ASR will only change with the pulse on A (when A has a positive edge)

CyberSecurity Activity Visibility (CSAV) control

- Selected ICU is CPUCS: Only for CSAV=Full, TS16_SP will show the CPUcs activity for A, W, ASR. For CSAV! =Full and SRC configured with CS=1, A, W, ASR are set to 0
- Selected ICU is DMA0 or DMA1: Only for CSAV=Limited or CSAV=Full, TS16_SP will show the DMA0 and DMA1 activities for A, W, ASR. Otherwise A, W, ASR are set to 0
- SIL: Only with CSAV=Full the status of SRNs with SRC.CS=1 is shown in TS16_SP SIL. For CSAV!=Full and SRC configured with CS=1, SIL is set to 0

40.5.1.4 Example for TS16_SP

shows an example sequence of two SR from SRN 123 with one SR from SRN 178. The SRN number are unique SRN index numbers and do not present the configured priority of the SR.

Table 1930 TS16_SP trigger set interrupt selection

ASR	A	W	Description
xxx	0	0	No SR pending. Last acknowledged SR was related to SRN xxx
xxx	0	1	One or more service requests pending. Last acknowledged SR was related to SRN xxx
123	1	x	SR from SRN 123 is accepted by ISP. W is updated with delay

(table continues...)

Table 1930 (continued) TS16_SP trigger set interrupt selection

ASR	A	W	Description
123	0	1	One or more interrupts are pending. Last acknowledged SR was related to SRN 123
178	1	x	SR from SRN 178 is accepted by ISP. W is updated with delay
178	0	1	One or more interrupts are pending. Last acknowledged SR was related to SRN 178
123	1	x	New SR from SRN 123 is accepted by ISP. W is updated with delay
123	0	0	No SR pending. Last acknowledged SR was related to SRN 123

Table 1931 TS16_SP example with a CPU

ASR	A	W	Description
123	0	0	Last service request was 123. (Info: CPU is executing user code and interrupts are enabled)
123	1	1	New service request from SRN 123 is accepted
123	1	0	No service request pending
123	0	1	New service request(s) pending. (Info: SRN 456 and 789 in parallel)CPU is still executing ISR 123 and - or interrupts are disabled
456	1	1	CPU accepts SRN 456 (Info: SRN 456 has higher priority than 789)SRN 456 has either higher priority than SRN123 or ISR 123 is finished
456	0	1	Service request(s) pending. CPU is executing ISR 456
789	1	1	CPU acknowledges service request 789
789	0	0	No service request pending

40.8 TC4Dx IR information

40.8.1 TC4Dx IR configuration

The table below shows the Interrupt Router configuration as implemented in this AURIX™ device.

The IR slave interface that provides access to the IR registers is connected to the COMPB.

ICU hardware virtualization support (HVS):

The table also shows which ICU provides the hardware virtualization support (HVS).

- HVS = ´Yes´ - ICU has 8 LWSR registers (LWSR0-LWSR7) and the VMEN register is implemented with 8 bits to control which VM encoding to be considered. If all VMs are disabled in the VMEN register, hardware virtualization support is disabled, SRCx.VM information is ignored by the ICU arbitration and only LWSR0 is updated by hardware
- HVS = ´No´ - ICU has 1 LWSR register (LWSR0) and the VMEN register implemented hardwired 0 (HVS disabled). The SRCx.VM information is ignored by the ICU arbitration. Only LWSR0 is updated by hardware

Software interrupt groups (GPSRx, SRBx, SRBx_ACCEN, GPSRx_SWC, GPSRx_ACCEN)

Table line GPSRx shows the configuration relation between available ICUx and the available general purpose software interrupt groups where each group includes the registers GPRSxy, SRBx, SWCxy and SWCACCENxy.

There is no fixed assignment of GPSRx groups to ISPs but this information can be used to make the correct selection of GPSR groups for the application

- Example: GPRS7 and related registers are available in all products with a PPU
- Example: GPRS1 and related registers is available in all products with a CPU1

Table 1932 Mapping of interrupt service provider to ICUs and implemented SRNs

40.8.4.1.4 Device specific registers

There are no device specific register changes.

40.8.4.2 Registers of SRC

40.8.4.2.1 Register address space - SRC

Table 1936 Registers address space - SRC

Module	Base address	End address	Note
SRC	$F4432000_H$	$F4435FFF_H$	IR service request Control Registers (SRC)

40.8.4.2.2 Register overview - access mode glossary

Table 1937 Register overview - access mode glossary

Keyword	Description
M	Indicates a module specific access condition. Refer to the register description for details of the specific access condition.
16	Access when using 16-bit width or higher.

40.8.4.2.3 Registers overview - SRC (ascending offset address)

Table 1938 Registers overview - SRC (ascending offset address)

Field	Bits	Type	Description
SRPN	7:0	rw	**Service request priority number** The SRPN bit field defines the priority of a service request. The larger SRPN number has the higher priority.
VM	10:8	rw	**Virtual machine** The VM bit field configuration maps a service request to a virtual machine. 000_B Service request is mapped to VM0 001_B Service request is mapped to VM1 010_B Service request is mapped to VM2 011_B Service request is mapped to VM3 100_B Service request is mapped to VM4 101_B Service request is mapped to VM5 110_B Service request is mapped to VM6 111_B Service request is mapped to VM7
CS	11	rw	**Cyber security** 0_B Service request is not assigned to the security application 1_B Service request is assigned to the security application

(table continues...)

(continued)

Field	Bits	Type	Description
TOS	15:12	rw	**Type of service** The TOS bit field configuration maps a service request to an interrupt service provider: 0_H Service request is mapped to CPU0 1_H Service request is mapped to CPU1 2_H Service request is mapped to CPU2 3_H Service request is mapped to CPU3 4_H Service request is mapped to CPU4 5_H Service request is mapped to CPU5 6_H Service request is mapped to CPUCS 7_H Service request is mapped to DMA0 8_H Service request is mapped to DMA1 A_H Service request is mapped to PPU F_H SRN not used **others,** Reserved
SRE	23	rw	**Service request enable** 0_B Service request is disabled 1_B Service request is enabled
SRR	24	rh	**Service request status** The SRR bit shows the status of the service request. 0_B No service request is pending 1_B Service request is pending
CLRR	25	w	**Service request clear** The CLRR bit is required to reset SRR. 0_B No action 1_B Write with 1 leads to SRR=0; no action if SETR is written with 1 at the same time; no clear of SRR if a hardware interrupt trigger happens at the same time. read always returns 0.
SETR	26	w	**Service Request set** The SETR bit is required to set SRR. 0_B No action 1_B Write with 1 leads to SRR=1; if SRR is already =1 then IOV is set to 1; no action if CLRR is written with 1 at the same time; read always returns 0.
IOV	27	rh	**Interrupt overflow status** The IOV bit is set by HW when a new service request is triggered by interrupt trigger or write to the SETR bit with 1 while SRR=1. 0_B No interrupt overflow detected 1_B Interrupt overflow detected

(table continues...)

(continued)

Field	Bits	Type	Description
IOVCLR	28	w	**Interrupt overflow clear** IOVCLR is required to reset IOV. 0_B No action 1_B Write with 1 lead to IOV=0; no action in case of an IOV condition at the same time; read always returns 0.
0	22:16, 31:29	r	**Reserved-0** Read as 0; should be written with 0.

40.8.5 TC4Dx IR connectivity

The table below lists interfaces to and from this functional block to other blocks in the device.

Table 1939 List of IR interface signals

Interface signals	I/O	Description
SMM_IR_ApplicationReset	In	Application reset
SMM_IR_DebugReset	In	Debug reset
CLOCK_IR_fSPB	In	SPB clock input
IR_DEBUG_OTGB	Out	OTGB interface to DEBUG
IR_SMU_ALARM_NCS	Out	IR non-secure alarm
IR_SMU_ALARM_LCL	Out	IR lockstep alarm
IR_SMU_ALARM_CS	Out	IR secure alarm
IR_IR_GPSR0_SWCy	In/Out	Software interrupts from SRB0[y] and GPSRG0_SWCy triggering GPSRG0SRy
IR_IR_GPSR1_SWCy	In/Out	Software interrupts from SRB1[y] and GPSRG1_SWCy triggering GPSRG1SRy
IR_IR_GPSR2_SWCy	In/Out	Software interrupts from SRB2[y] and GPSRG2_SWCy triggering GPSRG2SRy
IR_IR_GPSR3_SWCy	In/Out	Software interrupts from SRB3[y] and GPSRG3_SWCy triggering GPSRG3SRy
IR_IR_GPSR4_SWCy	In/Out	Software interrupts from SRB4[y] and GPSRG4_SWCy triggering GPSRG4SRy
IR_IR_GPSR5_SWCy	In/Out	Software interrupts from SRB5[y] and GPSRG5_SWCy triggering GPSRG5SRy
IR_IR_GPSR6_SWCy	In/Out	Software interrupts from SRB6[y] and GPSRG6_SWCy triggering GPSRG6SRy
IR_IR_GPSR7_SWCy	In/Out	Software interrupts from SRB7[y] and GPSRG7_SWCy triggering GPSRG7SRy
FB_IR_INT_REQx	In	FB interrupt trigger signals mapped to SRNx
IR_CPU0_ICU0	Out	Interrupt control unit connected to CPU0

CSRM.CSCU_IR_CSAV[1:0]	In	CS activity visibility, trace enable for security related service requests

40.8.6 TC4Dx IR revision history

Initial release of the chapter.

41 Watchdog Timer Unit (WTU)

Watchdog timer unit (WTU) provides several independent watchdog timer (WDT) functions. The main system use of the WDT functions is program flow monitoring (PFM), for example, tracking whether the software tasks are executed in the correct sequence and do not get stuck in a specific process.

41.1 Feature list

- A dedicated WDT for each implemented CPU, a dedicated WDT for cyber-security CPU (CPUcs) and a system WDT that can be freely used by the application
- Programmable 16-bit timer
- Programmable password protection with configurable automatic password sequencing
- Programmable timestamp checking with programmable window
- Alarm is triggered if the WDT is not serviced before timer overflows
- Alarm is triggered if wrong password is provided during unlock or check access
- Configurable unlock-restriction if the respective SMU state-machine is not in RUN state
- Wake-up signal to respective CPU on timer-value transition from $7FFF_H$ to 8000_H
- WDT functions can be suspended during test and debug

41.2 Functional overview

Watchdog functions can be used by the application software to monitor the sequence and timing of software tasks and to trigger a software independent hardware reaction if errors are detected. Following figure shows the structure of the WTU.

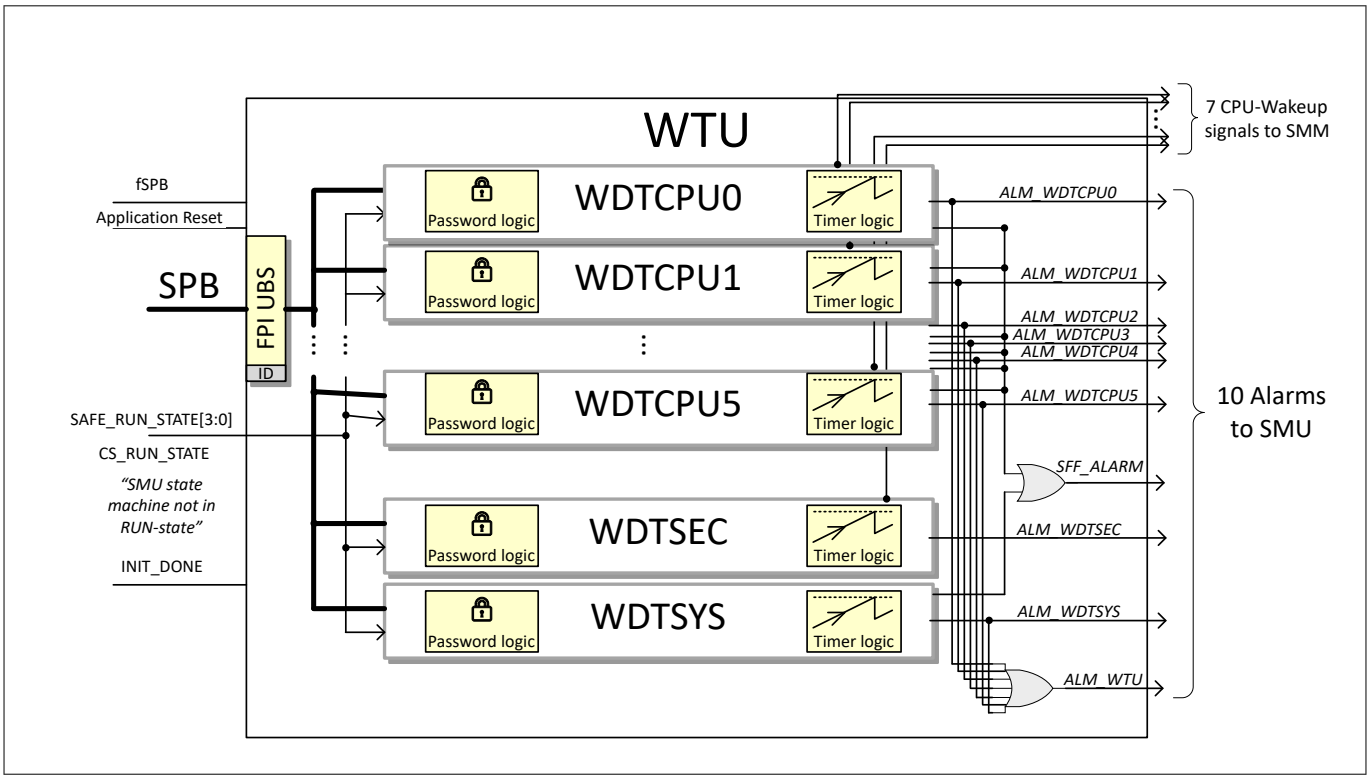

Figure 969 Internal structure of the WTU

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

WTU consists of Universal Bus Slave (UBS) on the SPB FPI interface and a total of 8 independent Watchdog Timer (WDT) modules:

- One watchdog timer per lock-stepped CPU - WDTCPU0-5 (6 total)

- One watchdog timer for CSRM security CPU - WDTSEC (1 total)
- One system watchdog timer - WDTSYS (1 total)

Module ID register is a part of UBS.

In addition to the SPB bus interface, each WDT receives SMU state machine signals used for Unlock Restriction (UR) feature which is explained in the following sections. Each of WDT functions provides dedicated register interface, password and timer logic, and a separate alarm signal to the SMU. There is also a 9th alarm output which represents logical "OR" combined alarm output of WDTCPU0-5 and WDTSYS.

More details on internal mechanisms inside each of the WDT is provided in the following sections.

***Note**: Regarding links to the registers which appear in the further text in this chapter: Every WDT contains same set of registers, so wherever in text there is a link to a register, and if link text does not include WDT prefix (for example link text is just "STAT"), the link would point to the WDTSYS register description, but it represents all registers with that name in all WDTs. If the link contains WDT prefix (for example WDTSEC_STAT) then the link will point to the register description of the respective WDT, and represents only that one register.*

41.3 Functional description

The main function of a WDT is program flow monitoring (PFM):

- Temporal supervision:
  - Purpose: Check that software is finishing tasks in a defined time-frame (for example, not hanging in an infinite loop)
  - How: Alarm is signaled if the application software is unable to service its WDT before a certain time-deadline or inside a certain time-window
- Logical supervision
  - Purpose: Check that software tasks are executed in the expected order
  - How: The WDT access password is configured to auto-increment after each access. Alarm is signaled if wrong password is supplied

Overflow of any of the watchdog timers leads to an SMU alarm. Each WDT also supports options to check code execution sequence and intermediate code execution time. If enabled, it can be used by the application to detect incorrect sequences or out-of-limit execution time will also result in an SMU alarm.

41.3.1 Features of a watchdog timer (WDT) function

- Programmable 16-bit watchdog timer
- Configurable input frequency: $f_{SPB}/64$, $f_{SPB}/256$ or $f_{SPB}/16384$
- Password protection mechanism with user-definable password and configurable auto-sequencing
- Temporal and logical monitoring capabilities:
  - Code sequence checking - an incorrect code sequence signature identification triggers an alarm to the SMU
  - Code execution time checking - code execution times out of expected limits triggers an alarm to the SMU
- Error indication for inspection:
  - Overflow error detection - an overflow of the WDT counter sets STAT.OE bit and triggers an alarm
  - Access error detection - an invalid password or input-timer-value access sets STAT.AE bit and triggers an alarm
- Window-watchdog feature can be emulated with the use of estimated-timer-value - CTRLA.TCVI
- Wake-up signal for corresponding CPU to SMM on timer-value transition from $7FFF_H$ to 8000_H
- Configurable Unlock Restriction (UR) mechanism to prevent WDT servicing after a WDT event that leads to an alarm to SMU

41.3.2 Different watchdog timers

The control register set of each WDT function is protected through a dedicated and partially configurable access protection, each consisting of a PROT function and an access protection unit (APU).

***Note**: For CPUs implemented with Hardware Virtualization Support the WDT can be assigned to one or multiple of its Virtual Machines (VMs) through its access protection unit register ACCEN_VM. In case where several VMs run on a single CPU, to achieve freedom from interference, respective WDTCPUy should be assigned to only one of those VMs.*

Watchdog timers for CPUs with lock-step support, WDTCPUy (y = 0-5)

The individual CPU WDT functions provide the ability to monitor separate CPU execution threads without the need for software to coordinate the shared use of a common system watchdog. Periodic servicing of a WDTCPU

and providing correct password confirms that the corresponding CPU is executing a software sequence as expected. Each CPU WDT has separate SMU alarm signaling, and reaction to each is configurable within the SMU.

Each WDTCPUy has a designated WDTCPUy_PROTSE register that controls access to the access protection unit registers (ACCEN). Write access registers (WDTCPUy_ACCEN_WRA, WDTCPUy_ACCEN_WRB) are set to:

- The respective CPUy is always enabled for write access to its related WDTCPUy function
- CERBERUS write access is configurable and enabled by default
- All other tag IDs are always disabled (non-configurable)

Read access, VM and PRS protections are fully configurable by respective WDTCPUy_PROTSE owner.

Application reset disables all WDTCPUs, but during Boot-FW WDTCPU0 gets enabled in normal mode. Other CPUs are initially in a HALT state and therefore their corresponding WDTCPUy functions are not enabled by Boot-FW.

***Note**: In case certain CPU is not available in the device (smaller devices can have less than 6 CPU cores), its respective WDTCPUx function will still be there, but it will remain disabled at all times.*

Watchdog timer for CPUcs, WDTSEC

Similar to WDTCPUy, WDTSEC is designated to monitor temporal and logical code execution of CPUcs. Write access (WDTSEC_ACCEN_WRA, WDTSEC_ACCEN_WRB):

- CPUcs is always enabled for write access to its related WDTSEC function
- CERBERUS write access is configurable, and disabled by default
- All other tag IDs are always disabled (non-configurable)

Read access is fully configurable, and enabled for only CPUcs by default. VM and PRS protections are fully configurable by respective WDTSEC_PROTCSE owner.

After an application reset, WDTSEC is disabled.

***Note**: In case CPUcs is not available in the device its respective WDTSEC function will still be there, but it will remain disabled at all times.*

System watchdog timer, WDTSYS

The WTU function block provides also a system watchdog. In comparison to the CPU and CPUcs WDT functions, the system WDT is not fixed to certain CPU and access protection registers (ACCEN) are freely configurable through WDTSYS_PROTSE and Bus-APU (WDTSYS_ACCEN_WRA, WDTSYS_ACCEN_WRB) protection mechanisms.

Application reset disables WDTSYS, but during Boot-FW it gets enabled in normal mode.

***Note**: WDTSYS is available in all derivatives of TC4xx.*

41.3.3 WDT functionality

Each WDT has an architecture as shown in the following figure.

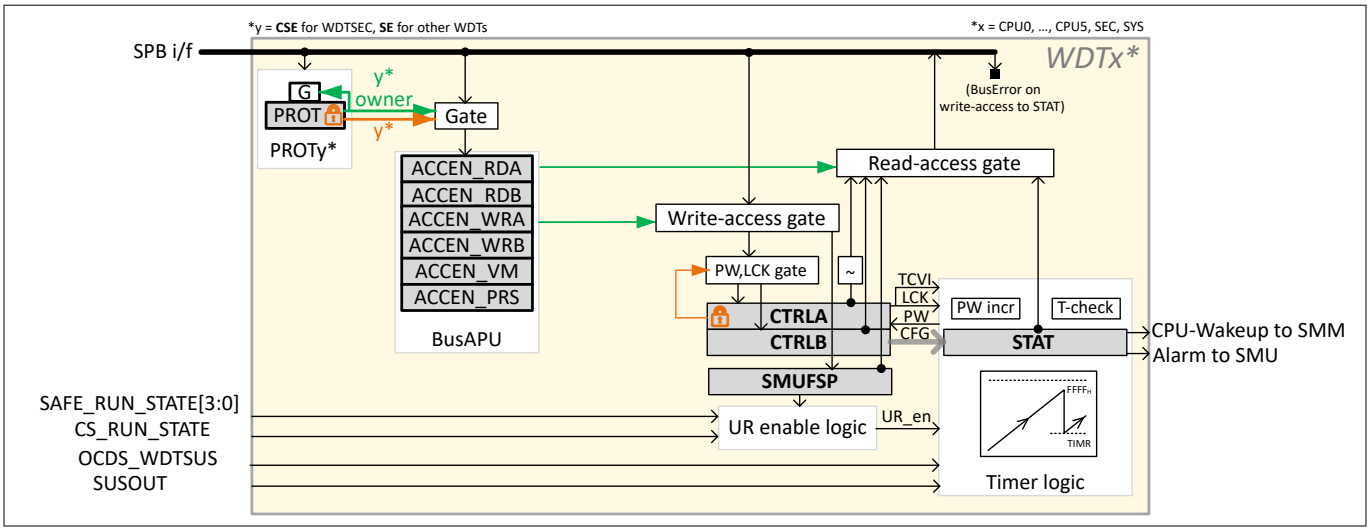

Figure 970 Single watchdog timer block diagram

Each WDT has a dedicated protection scheme. PROT controls write access to APU registers (ACCEN*), while APU registers provide read and write access control to the registers CTRLA, CTRLB, STAT and SMUFSP. Registers CTRLA and CTRLB are additionally write protected by password and lock mechanism. Symbol '~' used in the figure indicates that some of the CTRLA bits are returned bit-wise inverted on a read access in order to unintended unlock accesses.

Timer logic comprises of 16-bit up counting timer, frequency division and selection logic, logic for password auto-sequencing feature, unlock-restriction feature and timer-check feature.

Related information

Suspend mode support on page 7044

41.3.3.1 Main function registers

A WDT function provides three main control and status registers:

- STAT as a read-only status register
- CTRLA and CTRLB as control registers

CTRLA implements password protection and configurable estimated-timer-value protection. Its lock bit (LCK) represents an additional gate for write access to the CTRLA and CTRLB registers. Any write access with a wrong password or an incorrect timer-check value, if this feature is enabled, will not be executed and results in a watchdog alarm. In addition, with a correct write access that clears the LCK, the WDT function starts an internal timeout counter. If the LCK bit has not been properly set before this timer expires, the system is assumed to have malfunctioned.

CTRLB register contains shadow configuration for the watchdog function.

STAT-registers show active configuration and error-status indication.

In order to avoid accidental servicing of a WDT, a two-access sequence with password and lock mechanism is put in place. This is to ensure that only intended and expected code-blocks can service the timer. Besides password protection, timer-value checks can also be applied and could be deployed to ensure that:

- Software execution was taking the expected code-branches
- Software execution was not going faster than expected (in emulated window-watchdog-mode)

41.3.3.2 Error types and alarm signals

Each WDT function can detect two types of errors:

- Access Error (AE) - invalid access to CTRLA or CTRLB registers
- Overflow Error (OE) - timer value has overflown without being serviced in time

On detection of a WDT overflow error, an alarm is signaled to the SMU, STAT.OE bit set, the timer value is reloaded with CTRLB.TIMR timer-base value and the timer is started again.

Both AE and OE errors are combined into one alarm signal sent to the SMU. The resulting alarm reaction is configurable within the SMU.

41.3.3.3 Access types and state transitions

CTRLA register has a lock control function (LCK). When a WDT becomes unlocked it automatically starts the time-out mode (TOM). This represents a timed and password protected write-access to the vital configuration registers CTRLA and CTRLB.

As shown in the following figure, there are two states of the watchdog access mechanism - locked (L) and unlocked (U) - directly represented by the value of the LCK bit:

- Locked state provides the ability to check timer and password value without exiting the state, and also provides a gateway to the unlocked state
- Unlocked state is always followed by an automatic TOM, providing a time-limit for potential updates made during unlocked state. This means additional safety while the configuration registers CTRLA and CTRLB are open for writing

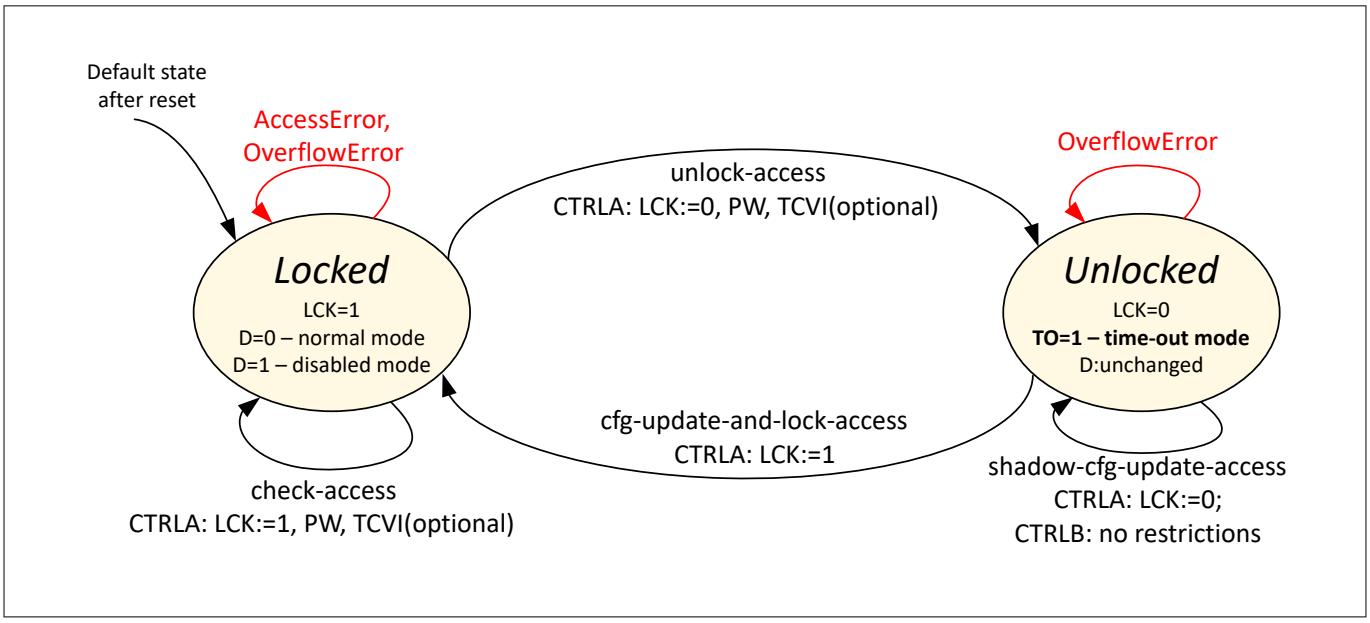

Figure 971 State diagram of locking mechanism

There are four different types of access to CTRLA and CTRLB registers:

1. Unlock access, applies to CTRLA while in locked state
2. Check access, applies to CTRLA while in locked state
3. Shadow-configuration-update access, applies to CTRLA, CTRLB while in unlocked state
4. Configuration-update-and-lock access, applies to CTRLA while in unlocked state

***Note**: Since CTRLA.LCK bit controls write access to both CTRLA and CTRLB, a write access to CTRLB with LCK bit set to 1 (meaning lock state is active) will result in an access error (AE).*

Unlock access

Used to switch the WDT from locked to unlocked. Successful if correct password and timer-value check is applied to CTRLA register, and if input LCK bit is set to 0. If unsuccessful, an access error flag is set and an alarm is sent to the SMU.

Check access

A check access is similar to the unlock access except that the LCK bit is not cleared and a subsequent shadow-config-update access is therefore not possible. A check access may only be performed when the WDT is in locked state.

If successful, the WDT stays locked and no error is reported. If unsuccessful, an access error flag is set and an alarm is sent to the SMU.

The check access can be used for intermediate checkpoints between WDT services. This may be used for task sequence or window-watchdog monitoring.

Shadow configuration update access

When a WDT is in unlocked state, access to CTRLB and access to CTRLA with LCK bit set to '0' represent shadow configuration update access. There is no limit of how many consecutive accesses of this type can be applied, but the timer is in the TOM and WDT must be switched back to locked state before the timer overflows.

During this access control bit-fields in CTRLA and CTRLB can be assigned with new values.

Configuration update and lock access

This access is applicable only in unlocked state. If CTRLA is accessed with LCK bit set to '1', PW and TCVI fields are ignored and the WDT is switched from unlocked to locked state. At the same time, shadow configuration from CTRLB register is applied to STAT register and made active.

41.3.3.4 Password protection

The 15-bit user-definable password, CTRLA.PW, can be used for logical program monitoring: to detect unexpected software loops, or to monitor the execution sequence of sub-routines. The following table summarizes the requirements for the password for unlock and check accesses. As an additional protection, **while reading password field PW of register CTRLA, the lowest 7 bits are bit-wise inverted** and cannot be identically written back.

Table 1940 Unlock and check access to WDTx_CTRLA

Bit position	Required value
[0]	Must be written with 0_B for unlock access and must be written with 1_B for check access.
[15:1]	If STAT.PA = 0: • PW[6:0] (= CTRLA[7:1]) must be written with current value stored in those bits. If PW is read prior to write, read value of PW[6:0] (CTRLA[7:1]) must be bit-wise inverted before writing • PW[14:7] (= CTRLA[15:8]) must be written with current (non-inverted) value stored in those bits If STAT.PA = 1: • PW[14:0] (= CTRLA[15:1]) must be written with expected next sequence password

(table continues...)

Table 1940 (continued) Unlock and check access to WDTx_CTRLA

Bit position	Required value
[31:16]	If STAT.TC = 0: • This bit-field is ignored If STAT.TC = 1: • Must be written with bit-wise inverted estimate of the WDT timer value. For the valid access, written value must be within +/- STAT.TCT of the actual STAT.TIM value

If an incorrect value is written to CTRLA during an unlock or check access, a watchdog access error condition exists. Bit STAT.AE is set and an alarm is sent to the SMU.

Static password check

In the static password mode (STAT.PA=0) the password can only be changed by a valid shadow config update access to CTRLA register. The unlock access has been designed such that it is not possible simply to read the register and re-write it. The lowest 7 password read bits must be bit-wise inverted (toggled) before being re-written. This prevents a simple malfunction from accidentally unlocking the WDT through a simple read/write sequence.

Automatic password sequencing check

If automatic password sequencing is enabled (STAT.PA=1) then the password changes automatically after each password check (unlock or check access). The expected next password is calculated using a pseudo-random sequence based on a 15-bit Fibonacci LFSR (linear feedback shift register) with characteristic polynomial. $x_{15} \oplus x_{14} \oplus x_{13} \oplus x_3 \oplus 1$ An initial password (or subsequent manual password updates) can also be provided by shadow-config-update access to CTRLA.

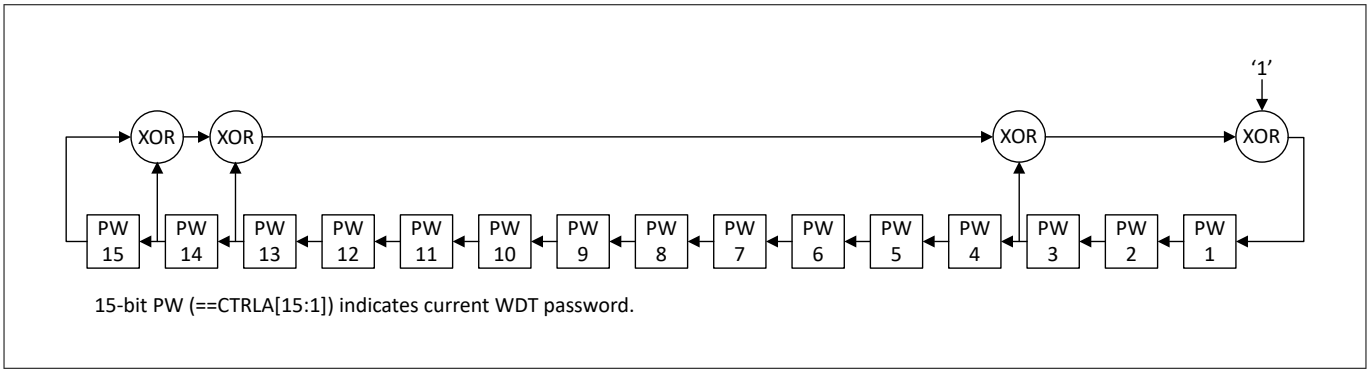

Figure 972 LFSR used for WDT password auto-sequencing

41.3.3.5 Additional timer-value protection

Estimated-timer-value check can be used for:

- Check of the elapsed program execution time since the last WDT timer service
- Emulating a window-watchdog mode

Timer-value checking is not enabled

If timer-value checking is not enabled (STAT.TC==0) then the input value of the CTRLA.TCVI field is ignored.

Timer-value checking is enabled

If timer-value checking is enabled (STAT.TC==1) then on each unlock- and check-access, the value of input field TCVI is compared with actual timer value STAT.TIM with regard to tolerance value STAT.TCT:

- If bit-wise inverted value of TCVI is inside the window: [max(TIM-TCT,0000_H), min(TIM+TCT,$FFFF_H$)], then the time-value check is correct
- If bit-wise inverted value of TCVI falls outside the window, then the access is incorrect independent from correctness of password check

Incorrect access would set STAT.AE bit and trigger an alarm to the SMU.

***Note**: The timer-value checking is done in addition to a password check.*

41.3.3.6 Timer operation

Each WDT has a 16-bit up-counter timer. Timer can be in three different modes:

- Disabled
- Enabled in normal counting mode
- Automatically enabled in time-out mode (TOM)

Disabled and normal mode are indicated through STAT.D bit-field (which is configurable via CTRLB.DR) – value '1' represents Disabled, value '0' Normal mode.

TOM is automatically started on every successful unlock-access, with the transition from locked to unlocked state. Upon entering TOM, timer base value is set to $FFFC_H$ and all other settings remain the same as in previous state (frequency IFS, PA, TC,…). TOM is ended with correct transition back to locked state.

The WDTSYS and WDTCPU0 are started in Normal mode by Boot-FW after an application reset.

Determining WDT periods

All WDTs use the SPB clock f_{SPB}. A clock divider in front of each WDT provides three WDT counter frequencies:f_{SPB} / 64, f_{SPB} / 256 or f_{SPB} / 16384. The following table shows the encoding:

Table 1941 WDT timer frequency - STAT.IFS and CTRLB.IFSR bit-fields

IFS/IFSR	Watchdog timer rate (source clock divider setting)
00_B	f_{SPB}/16384
01_B	f_{SPB}/256
10_B	f_{SPB}/64
11_B	Reserved. Do not use

The general formula to calculate a watchdog timeout period is:

$$\text{period} = \frac{\left(2^{16} - \text{start_value}\right) \times \text{divider}}{f_{SPB}} \quad (72)$$

where parameter start_value represents the fixed value $FFFC_H$ for the calculation of the time-out period, and the user-programmable reload value CTRLB.TIMR for the calculation of the normal period. Parameter divider takes values 64, 256 or 16384 indicated by STAT.IFS.

Table 1942 Example period values

Start_value	Divider	f_{SPB}	Period	1-counter-step time
$FFFC_H$	16384	100 MHz	~0.66 ms (=655.36 µs)	163.84 µs (=~0.16 ms)
0000_H	16384	100 MHz	~10737.4 ms (=~10.7 s)	163.84 µs (=~0.16 ms)

(table continues...)

Table 1942 (continued) Example period values

Start_value	Divider	f_{SPB}	Period	1-counter-step time
0000_H	256	100 MHz	~167.8 ms	2.56 µs
0000_H	64	100 MHz	~41.9 ms	0.64 µs
$FFFC_H$	16384	112.5 MHz	~0.58 ms (=582.54 µs)	145.64 µs (=~0.15 ms)
0000_H	16384	112.5 MHz	~9544.4 ms (=~9.5 s)	145.64 µs (=~0.15 ms)
0000_H	256	112.5 MHz	~149.1 ms	2.28 µs
0000_H	64	112.5 MHz	~37.3 ms	0.57 µs

Time-out mode

WDT changes automatically in time-out mode (TOM) with a valid unlock-access to register CTRLA. Additionally, for WDTCPU0 and WDTSYS TOM is entered by Boot-FW after an application reset. At the TOM entry, bit STAT.TOM is set to '1' and the timer STAT.TIM is set to $FFFC_H$ and starts counting upwards. All other bit-fields of STAT registers are the same as before entering TOM. TOM can only be exited properly by setting CTRLA.LCK = '1'. If the timer overflows before LCK is set, STAT.OE error flag is set and an alarm is sent to the SMU.

A proper exit from TOM can either be to the normal or to the disable mode, depending on the state of the disable request bit CTRLB.DR which gets applied to STAT.D.

Normal mode

With STAT.D='0' and STAT.TOM='0' the WDT operates in normal mode. Upon entry to Normal mode the timer STAT.TIM value is set to CTRLB.TIMR value, and timer begins counting up. It has to be serviced before the counter overflows. Servicing is performed through a valid access sequence to the control register CTRLA: unlock-access which moves counter into TOM, followed by config-update-and-lock-access which brings timer back to normal mode with reloaded timer value CTRLB.TIMR.

If the WDT is not serviced by the application software before a timer overflows, STAT.OE error flag is set and an alarm is signaled to the SMU. In that case, the timer is reloaded with CTRLB.TIMR value and continues counting up.

Disabled mode

With STAT.D='1' and STAT.TOM='0' the WDT is disabled. If a watchdog timer was enabled, it can be disabled again with CTRLB.DR bit set to '1' and valid config update and lock access.

In Disabled mode the timer STAT.TIM is set to CTRLB.TIMR and stopped. If valid unlock access to register CTRLA is performed in disabled mode,TOM is entered and timer is started. If valid check access is performed in disabled mode, password-auto-sequencing (if enabled) is operating normally, while the timer is still in disabled mode.

All WDTs except WDTCPU0 and system watchdog WDTSYS are in disabled mode after Boot-FW execution.

41.3.4 Operation in special cases

Operation during power-saving modes

If a CPU is in idle mode it cannot service a WDT by software. There are two ways to prevent unwanted WDT overflows and alarms in this situation. Firstly, the watchdog can be disabled before setting the CPU to idle. The disadvantage of this is that the system will no longer be monitored during the idle period.

A better approach to this problem relies upon the wake-up feature of the WDTs. Whenever CPUy is put in idle or sleep mode and the respective WDT is not disabled, the CPUy is woken up at regular intervals. When WDTx (x=CPU0-5,SEC) changes its count value (STAT.TIM) from $7FFF_H$ to 8000_H, respective CPU is woken up and continues execution at the instruction following the instruction that was executed before entering the idle or

sleep mode. The wake-up signal coming out of WDT remains high as long as its timer MSB is '1' (timer value greater or equal than 8000_H).

***Note**: Before switching into a non-running power-management mode, software should perform a watchdog service sequence. At the shadow-config-update access, the watchdog refresh request value, CTRLB.TIMR, should be programmed such that the wake-up occurs after a period which best meets application requirements. The maximum period between two CPU wake-ups is one-half of the maximum WDT period.*

Behavior in case of SMU FAULT

It is possible to configure a WDT so that it can no longer be refreshed or modified if the corresponding SMU state machine is not in RUN state - so it is either in START or FAULT state. This is to prevent software from interfering with potential ongoing SMU reaction to an alarm. This feature may be enabled via bit-field STAT.UR.

SMU supports total of 5 separate signaling lines - 1 for security partition and up to 4 for other non-secure resource partitions. Each non-secure WDT can be part of any of the 4 non-secure partitions, and this is configurable for each watchdog independently through SMUFSP register.

If STAT.UR=='1' and respective SMU state machine (as selected by SMUFSP bits) is not in RUN state then an unlock-access to CTRLA will NOT lead to the unlock state of the WDT, as indicated by CTRLA.LCK=='1'.

As long as bit STAT.UR is '0', the Unlock-Restriction feature is ignored, and valid unlock-access would result in an unlocked watchdog timer.

41.4 Registers

41.4.1 Register overview - access mode glossary

Table 1943 Register overview - access mode glossary

Keyword	Description
CSE	Access protection using PROT register WDTSEC_PROTCSE.
SEy (y=0-5)	Access protection using PROT register WDTCPUy_PROTSE.
SSE	Access protection using PROT register WDTSYS_PROTSE.
APU-PCS	Protection group consisting of registers WDTSEC_ACCEN_WRA, WDTSEC_ACCEN_WRB, WDTSEC_ACCEN_RDA, WDTSEC_ACCEN_RDB, WDTSEC_ACCEN_VM, WDTSEC_ACCEN_PRS.
PCS	Access protection using *APU-PCS* registers.
APU-PSYS	Protection group consisting of registers WDTSYS_ACCEN_WRA, WDTSYS_ACCEN_WRB, WDTSYS_ACCEN_RDA, WDTSYS_ACCEN_RDB, WDTSYS_ACCEN_VM, WDTSYS_ACCEN_PRS.
PSYS	Access protection using *APU-PSYS* registers.
APU-Py (y=0)	Protection group consisting of registers WDTCPUy_ACCEN_WRA, WDTCPUy_ACCEN_WRB, WDTCPUy_ACCEN_RDA, WDTCPUy_ACCEN_RDB, WDTCPUy_ACCEN_VM, WDTCPUy_ACCEN_PRS.
Py	Access protection using *APU-Py* registers.
APU-Py (y=1)	Protection group consisting of registers WDTCPUy_ACCEN_WRA, WDTCPUy_ACCEN_WRB, WDTCPUy_ACCEN_RDA, WDTCPUy_ACCEN_RDB, WDTCPUy_ACCEN_VM, WDTCPUy_ACCEN_PRS.
APU-Py (y=2)	Protection group consisting of registers WDTCPUy_ACCEN_WRA, WDTCPUy_ACCEN_WRB, WDTCPUy_ACCEN_RDA, WDTCPUy_ACCEN_RDB, WDTCPUy_ACCEN_VM, WDTCPUy_ACCEN_PRS.
APU-Py (y=3)	Protection group consisting of registers WDTCPUy_ACCEN_WRA, WDTCPUy_ACCEN_WRB, WDTCPUy_ACCEN_RDA, WDTCPUy_ACCEN_RDB, WDTCPUy_ACCEN_VM, WDTCPUy_ACCEN_PRS.
APU-Py (y=4)	Protection group consisting of registers WDTCPUy_ACCEN_WRA, WDTCPUy_ACCEN_WRB, WDTCPUy_ACCEN_RDA, WDTCPUy_ACCEN_RDB, WDTCPUy_ACCEN_VM, WDTCPUy_ACCEN_PRS.
APU-Py (y=5)	Protection group consisting of registers WDTCPUy_ACCEN_WRA, WDTCPUy_ACCEN_WRB, WDTCPUy_ACCEN_RDA, WDTCPUy_ACCEN_RDB, WDTCPUy_ACCEN_VM, WDTCPUy_ACCEN_PRS.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
32	Access only when using 32-bit width.

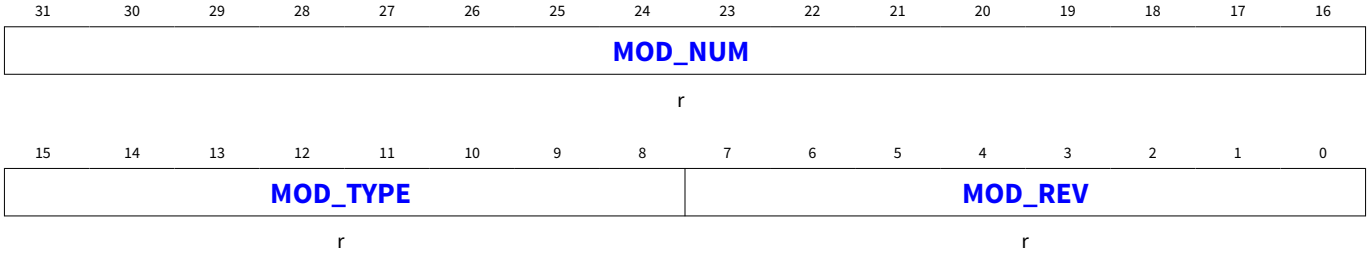
41.4.3 Module identification register

ID Offset address: 008_H

Module identification register PowerOn Reset value: $00ED\ C001_H$



Field	Bits	Type	Description
MOD_REV	7:0	r	**Module revision number** This bit-field defines the module revision number. The value of a module revision starts with 01_H (first revision).
MOD_TYPE	15:8	r	**Module type** The bit-field is set to $C0_H$ which defines the module as a 32-bit module.
MOD_NUM	31:16	r	**Module number value** This bit-field defines a module identification number. The value for the watchdog timer module is $00ED_H$.

41.4.4 CPUy WDT PROT register safe endinit - SEy

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit protected control registers.

WDTCPUy_PROTSE (y=0-5) Offset address: 018_H+y*30_H

CPUy WDT PROT register safe endinit - SEy Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

write 1 to .**OWEN**	rw	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
(default)	r	ODEF, PRS, PRSEN, TAGID, VM, VMEN	
	rh	STATE	

41.4.5 CPUy WDT write access enable register A (y=0)

This register defines which master agent function TAG identifier (TAG-ID) encodings are enabled or disabled for write accesses to the access protected region.

D and DS TAG-IDs of corresponding CPU are enabled after reset and can be configured, TAG-ID of Cerberus is configurable with default value EN='1'.

All others are always disabled (non-configurable).

r											rw	rw	rw	rw	rw

Field	Bits	Type	Description
PARTx (x=0-3)	x	rw	**Consider signals from SMU state machine partition x** This bit enables that the outputs from SMU safe state machine partition x will be considered in unlock restriction feature (see also bit WDTx_STAT.UR). 0_B Outputs of corresponding SMU state machine are ignored inside this watchdog unit. 1_B Outputs of corresponding SMU state machine are considered inside this watchdog unit.
CSPART	4	rw	**Consider signals from SMU CS-related partition** This bit enables that the outputs from SMU CS-related partition will be considered in unlock restriction feature (see also bit WDTx_STAT.UR). 0_B Outputs of corresponding SMU state machine are ignored inside this watchdog unit. 1_B Outputs of corresponding SMU state machine are considered inside this watchdog unit.
0	31:5	r	**Reserved** Read as 0; should be written with 0.

41.4.17 CPUy WDT control register A

This register is written with the expected password, the inverted estimated timer value and a lock-bit value.

The meaning of the individual values depends on the access type and active configuration fields STAT.PA and STAT.TC.

This register stores the current watchdog password value (PW) and lock control bit (LCK).

WDTCPUy_CTRLA (y=0-5) Offset address: $03C_H+y*30_H$

CPUy WDT control register A Reset values see: Table 1946

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCVI															
w															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PW															LCK
rwh															rwh

Field	Bits	Type	Description
LCK	0	rwh	**Lock bit** LCK bit is cleared after a valid unlock-access to WDTx_CTRLA when unlock is not disabled. (Note: unlock can be disabled by UR-feature or by debug) LCK bit is set after a valid configuration-update-and-lock-access to WDTx_CTRLA. A valid check-access or shadow-config-update-access does not trigger a change of the LCK value. 0_B Registers WDTx_CTRLA and WDTx_CTRLB are unlocked 1_B Registers WDTx_CTRLA and WDTx_CTRLB are locked (default after reset)
PW	15:1	rwh	**Password** This bit-field is written with a password value during an unlock- or check-access to WDTx_CTRLA: • If corresponding WDTx_STAT.PA == 0 then this bit-field must be written with its current contents. • If corresponding WDTx_STAT.PA == 1 then this bit-field must be written with the next password in the LFSR sequence. It is written with a new password value during a shadow-cfg-update-access to WDTx_CTRLA, and it is ignored during cfg-update-and-lock-access to WDTx_CTRLA. A read from this bit-field returns current password, but bits CTRLA[7:1] are bitwise inverted to ensure that a simple read-write is not sufficient to service the WDTx. The default password after reset is $007C_H$=000_0000_0111_1100$_B$ (due to inversion, SW will read it as 0003_H=000_0000_0000_0011$_B$).
TCVI	31:16	w	**Timer check value inverted** The timer-check value inverted (TCVI) is used only during unlock- and check-access and only if configured for use (WDTx_STAT.TC==1). In all other cases provided value is ignored. The value written to these bits will be bitwise-inverted and compared with the current timer value, with respect to the tolerance margin WDTx_STAT.TCT. If written value is outside defined margins it will result in an access-error. A read from this bit-field always returns 0000_H.

Table 1946 Reset values of WDTCPUy_CTRLA (y=0-5)

Reset type	Reset value	Note
Application Reset	0000 00F9$_H$	Default password value and locked.
After reset read value	0000 0007$_H$	Bits [7:1] (PW[6:0]) are read as bit-wise inverted

41.4.18 CPUy WDT control register B

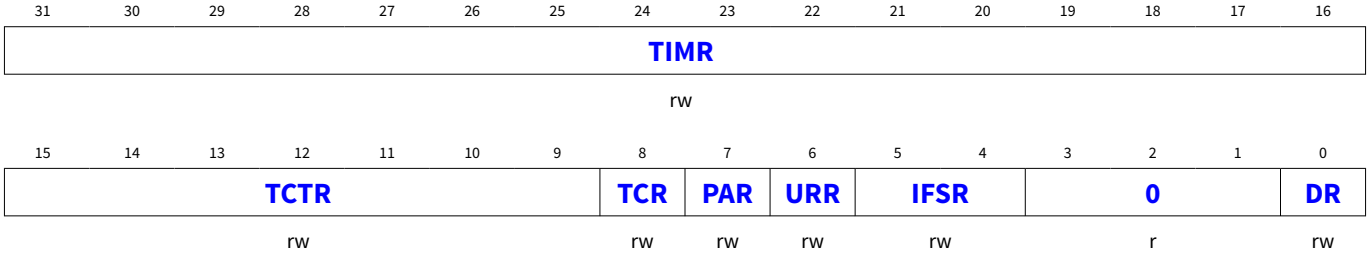
This register represents a shadow configuration for the watchdog timer.

WDTx_CTRLB bits can only be modified if corresponding WDTx_CTRLA.LCK is cleared - after a valid unlock-access.

Active configuration bits in WDTx_STAT are updated by these shadow/request bits only when LCK is set again - after a valid config-update-and-lock-access.

WDTCPUy_CTRLB (y=0-5) Offset address: 040_H+y*30_H

CPUy WDT control register B Reset values see: Table 1947



Field	Bits	Type	Description
DR	0	rw	**Disable request bit** This bit represents a request (shadow) to disable the watchdog Timer. 0_B Request to enable the WDTx 1_B Request to disable the WDTx
IFSR	5:4	rw	**Input frequency selection request bits** Two bits of IFSR represent a request (shadow) to configure the watchdog timer frequency. 00_B Request to set input frequency to fSPB/16384. 01_B Request to set input frequency to fSPB/256. 10_B Request to set input frequency to fSPB/64. 11_B Reserved. Should not be used.
URR	6	rw	**Unlock restriction request bit** This bit represents a request (shadow) to enable unlock-restriction feature. If the unlock-restriction is set (WDTx_STAT.UR=='1') then WDTx cannot be unlocked in case respective SMU state machine is not in RUN state. 0_B Request to disable unlock-restriction feature 1_B Request to enable unlock-restriction feature
PAR	7	rw	**Password auto-sequence request bit** This bit represents a request (shadow) to configure a password-autosequencing feature. If the active password-autosequencing is set (WDTx_STAT.PA==1), after each unlock- and check-access, the password WDTx_CTRLA.PW will increment using built-in LFSR and store the new value. 0_B Request to disable automatic change of password after each valid unlock- or check-access 1_B Request to enable automatic sequence of password after each valid unlock- or check-access

(table continues...)

(continued)

Field	Bits	Type	Description
TCR	8	rw	**Timer check request bit** This bit represents a request (shadow) to configure a timer-check feature. If the active timer-check configuration is set (WDTx_STAT.TC==1), on each unlock- and check-access, the input TCVI will be compared to the current timer value WDTx_STAT.TIM with respect to the tolerance margin WDTx_STAT.TCT. 0_B Request to disable timer check feature during unlock- or check-access. 1_B Request to enable timer check feature during unlock- or check-access.
TCTR	15:9	rw	**Timer check tolerance request** This bit-field represents a request (shadow) to configure the timer-check-tolerance value.
TIMR	31:16	rw	**Timer base request value** This bit-field represents a request (shadow) to set the timer reload value. A read from this bit-field returns the timer reload value.
0	3:1	r	**Reserved** Read as 0; should be written with 0.

Table 1947 Reset values of WDTCPUy_CTRLB (y=0-5)

Reset type	Reset value	Note
Application Reset	FFFC 0001_H	Request to enable with timer set to 0xFFFC.
After Boot-FW Value	FFFC 0000_H	Only WDTCPU0 is enabled during Boot-FW execution.

41.4.19 CPUy WDT status register

This register represents the active configuration of the watchdog timer.

These bits are read-only from the outside and they get updated by shadow-configuration bits from WDTx_CTRLB after a valid config-update-and-lock-access.

All WDTx are disabled by reset, and only WDTCPU0 and WDTSYS are enabled by FW before application SW starts.

WDTCPUy_STAT (y=0-5) Offset address: 044_H+y*30_H

CPUy WDT status register Reset values see: Table 1948

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TIM															
rh															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TCT							TC	PA	UR	IFS		AE	OE	TOM	D
rh							rh	rh	rh	rh		rh	rh	rh	rh

Field	Bits	Type	Description
D	0	rh	**Watchdog enable/disable status Flag** This bit represents watchdog timer's enable/disable state. This bit is cleared when time-out mode (unlock-state) is entered - after a valid unlock-access to corresponding CTRLA register. 0_B WDTx is enabled 1_B WDTx is disabled.
TOM	1	rh	**Watchdog time-out mode flag** This bit is set when time-out mode (unlock-state) is entered. It is automatically cleared when time-out mode (unlock-state) is left. 0_B The watchdog is not operating in time-out mode 1_B The watchdog is operating in time-out mode.
OE	2	rh	**Watchdog overflow error status flag** This bit is set when the WDTx timer value overflows from $FFFF_H$ to 0000_H. This bit is only cleared when WDTx_CTRLA.LCK changes state from 0 to 1 (after a valid config-update-and-lock-access). 0_B No watchdog overflow error. 1_B A watchdog overflow error has occurred.
AE	3	rh	**Watchdog access error status flag** This bit is set when: • An invalid unlock- or check-access to WDTx_CTRLA register was attempted. • A write access to WDTx_CTRLB register was attempted while WDTx_CTRLA.LCK is set. This bit is only cleared when WDTx_CTRLA.LCK changes state from 0 to 1 (after a valid config-update-and-lock-access). 0_B No watchdog access error. 1_B A watchdog access error has occurred.
IFS	5:4	rh	**Watchdog internal frequency selection status flag** These bits indicate the current WDTx clock rate. 00_B WDTx counter frequency is fSPB/16384 (default). 01_B WDTx counter frequency is fSPB/256. 10_B WDTx counter frequency is fSPB/64. 11_B Reserved. Should not be used.
UR	6	rh	**SMU unlock restriction status flag** This bit represents status of unlock-restriction feature for the Watchdog Timer. 0_B Unlocking of WDTx is not from SMU FSP side. 1_B Unlocking of WDTx not possible when corresponding SMU FSP state machine is not in RUN state

(table continues...)

(continued)

Field	Bits	Type	Description
PA	7	rh	**Password auto-sequence status flag** This bit represents control for password-autosequencing. 0_B No change of password after each unlock- or check-access. 1_B Automatically sequence the password after each valid unlock- or check-access using built-in LFSR.
TC	8	rh	**Timer check status flag** This bit represents control for timer-check - whether an additional check (next to password check) will be performed during unlock- or check-access. 0_B Additional timer-check during unlock- or check-access is disabled. 1_B Additional timer-check during unlock- or check-access is enabled.
TCT	15:9	rh	**Timer check tolerance** This bit-field represents the tolerance value of the timer check during unlock- or check-access. If timer-check is enabled, the timer value is combined with this tolerance value to create an upper and lower comparison boundary [max(TIM-TCT,0), min(TIM+TCT,$FFFF_H$)]. If time-check is enabled and provided value falls outside these boundaries an access error will be signaled to the SMU.
TIM	31:16	rh	**Timer value** This bit-field reflects the current value of the watchdog timer counter. Performing sequence of two accesses: a valid unlock-access followed by a valid config-update-and-lock-access, is servicing of the WDTx and the WDTx_STAT.TIM value gets reloaded by the value stored in WDTx_CTRLB.TIMR. The value reload into WDTx_STAT.TIM is not done in suspend mode.

Table 1948 Reset values of WDTCPUy_STAT (y=0-5)

Reset type	Reset value	Note
Application Reset	FFFC 0001$_H$	WDTCPUy (y=0-5) are disabled with default timer value of 0xFFFC.
After Boot-FW Value	XXXX 0000$_H$	Only WDTCPU0 is enabled during Boot-FW execution. Exact timer value depends at which moment timer is read.

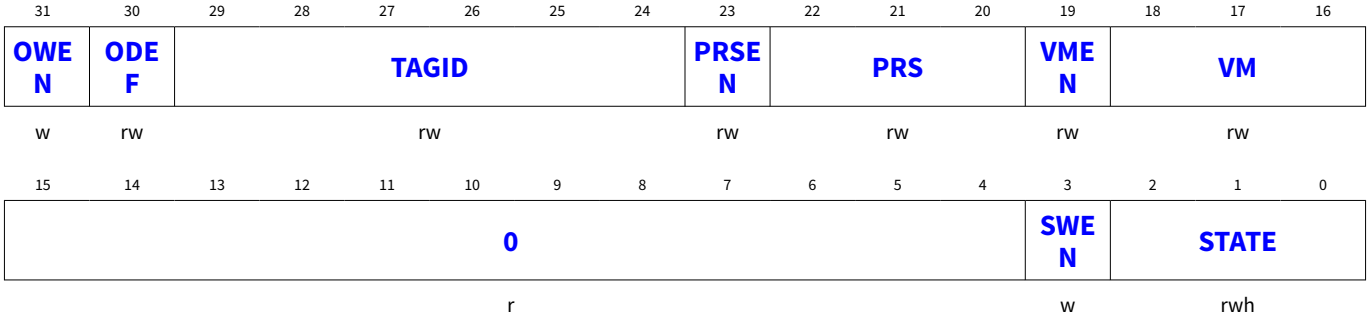
41.4.20 Security WDT PROT register cyber-secure endinit - CSE

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTCSE register controls lock / unlock of the local Cyber-Security Endinit protected registers.

WDTSEC_PROTCSE Offset address: 150_H

Security WDT PROT register cyber-secure endinit - CSE Application Reset value: 4C00 0000$_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection Set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection Set definition Enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 1949 Access mode restrictions of WDTSEC_PROTCSE sorted by descending priority

Mode name	Access mode		Description

Field	Bits	Type	Description
PARTx (x=0-3)	x	rw	**Consider signals from SMU state machine partition x** This bit enables that the outputs from SMU safe state machine partition x will be considered in unlock restriction feature (see also bit WDTx_STAT.UR). 0_B Outputs of corresponding SMU state machine are ignored inside this watchdog unit. 1_B Outputs of corresponding SMU state machine are considered inside this watchdog unit.

(table continues...)

(continued)

Field	Bits	Type	Description
CSPART	4	rw	**Consider signals from SMU CS-related partition** This bit enables that the outputs from SMU CS-related partition will be considered in unlock restriction feature (see also bit WDTx_STAT.UR). 0_B Outputs of corresponding SMU state machine are ignored inside this watchdog unit. 1_B Outputs of corresponding SMU state machine are considered inside this watchdog unit.
0	31:5	r	**Reserved** Read as 0; should be written with 0.

41.4.28 Security WDT control register A

This register is written with the expected password, the inverted estimated timer value and a lock-bit value.

The meaning of the individual values depends on the access type and active configuration fields STAT.PA and STAT.TC.

This register stores the current watchdog password value (PW) and lock control bit (LCK).

WDTSEC_CTRLA Offset address: 174_H

Security WDT control register A Reset values see: Table 1950

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCVI															
w															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PW															LCK
rwh															rwh

Field	Bits	Type	Description
LCK	0	rwh	**Lock bit** LCK bit is cleared after a valid unlock-access to WDTx_CTRLA when unlock is not disabled. (Note: unlock can be disabled by UR-feature or by debug) LCK bit is set after a valid configuration-update-and-lock-access to WDTx_CTRLA. A valid check-access or shadow-config-update-access does not trigger a change of the LCK value. 0_B Registers WDTx_CTRLA and WDTx_CTRLB are unlocked 1_B Registers WDTx_CTRLA and WDTx_CTRLB are locked (default after reset)

(table continues...)

(continued)

Field	Bits	Type	Description
PW	15:1	rwh	**Password** This bit-field is written with a password value during an unlock- or check-access to WDTx_CTRLA: • If corresponding WDTx_STAT.PA == 0 then this bit-field must be written with its current contents. • If corresponding WDTx_STAT.PA == 1 then this bit-field must be written with the next password in the LFSR sequence. It is written with a new password value during a shadow-cfg-update-access to WDTx_CTRLA, and it is ignored during cfg-update-and-lock-access to WDTx_CTRLA. A read from this bit-field returns current password, but bits CTRLA[7:1] are bitwise inverted to ensure that a simple read-write is not sufficient to service the WDTx. The default password after reset is $007C_H$=000_0000_0111_1100$_B$ (due to inversion, SW will read it as 0003_H=000_0000_0000_0011$_B$).
TCVI	31:16	w	**Timer check value inverted** The timer-check value inverted (TCVI) is used only during unlock- and check-access and only if configured for use (WDTx_STAT.TC==1). In all other cases provided value is ignored. The value written to these bits will be bitwise-inverted and compared with the current timer value, with respect to the tolerance margin WDTx_STAT.TCT. If written value is outside defined margins it will result in an access-error. A read from this bit-field always returns 0000_H.

Table 1950 Reset values of WDTSEC_CTRLA

Reset type	Reset value	Note
Application Reset	$0000\ 00F9_H$	Default password value and locked.
After reset read value	$0000\ 0007_H$	Bits [7:1] (PW[6:0]) are read as bit-wise inverted

41.4.29 Security WDT control register B

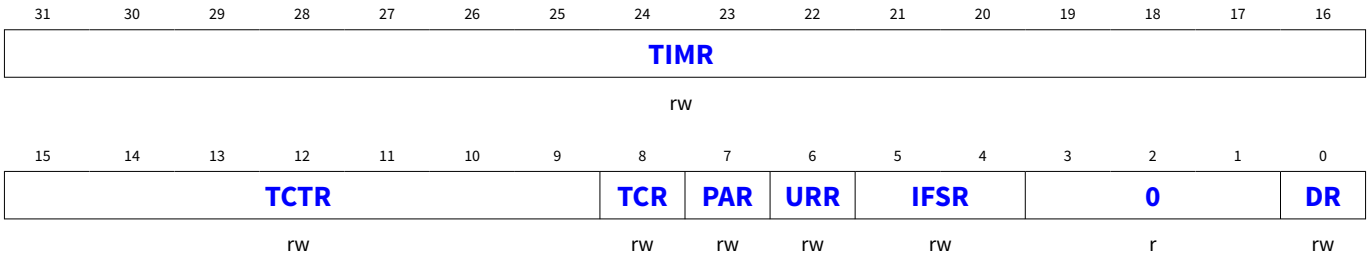
This register represents a shadow configuration for the watchdog timer.

WDTx_CTRLB bits can only be modified if corresponding WDTx_CTRLA.LCK is cleared - after a valid Unlock-Access.

Active configuration bits in WDTx_STAT are updated by these shadow/request bits only when LCK is set again - after a valid Config-Update-and-Lock-Access.

WDTSEC_CTRLB Offset address: 178_H

Security WDT control register B Application Reset value: $FFFC\ 0001_H$



Field	Bits	Type	Description
DR	0	rw	**Disable request bit** This bit represents a request (shadow) to disable the watchdog Timer. 0_B Request to enable the WDTx 1_B Request to disable the WDTx
IFSR	5:4	rw	**Input frequency selection request bits** Two bits of IFSR represent a request (shadow) to configure the watchdog timer frequency. 00_B Request to set input frequency to fSPB/16384. 01_B Request to set input frequency to fSPB/256. 10_B Request to set input frequency to fSPB/64. 11_B Reserved. Should not be used.
URR	6	rw	**Unlock restriction request bit** This bit represents a request (shadow) to enable unlock-restriction feature. If the unlock-restriction is set (WDTx_STAT.UR=='1') then WDTx cannot be unlocked in case respective SMU state machine is not in RUN state. 0_B Request to disable unlock-restriction feature 1_B Request to enable unlock-restriction feature
PAR	7	rw	**Password auto-sequence request bit** This bit represents a request (shadow) to configure a password-autosequencing feature. If the active password-autosequencing is set (WDTx_STAT.PA==1), after each unlock- and check-access, the password WDTx_CTRLA.PW will increment using built-in LFSR and store the new value. 0_B Request to disable automatic change of password after each valid unlock- or check-access 1_B Request to enable automatic sequence of password after each valid unlock- or check-access

(table continues...)

(continued)

Field	Bits	Type	Description
TCR	8	rw	**Timer check request bit** This bit represents a request (shadow) to configure a timer-check feature. If the active timer-check configuration is set (WDTx_STAT.TC==1), on each unlock- and check-access, the input TCVI will be compared to the current timer value WDTx_STAT.TIM with respect to the tolerance margin WDTx_STAT.TCT. 0_B Request to disable timer check feature during unlock- or check-access. 1_B Request to enable timer check feature during unlock- or check-access.
TCTR	15:9	rw	**Timer check tolerance request** This bit-field represents a request (shadow) to configure the timer-check-tolerance value.
TIMR	31:16	rw	**Timer base request value** This bit-field represents a request (shadow) to set the timer reload value. A read from this bit-field returns the timer reload value.
0	3:1	r	**Reserved** Read as 0; should be written with 0.

41.4.30 Security WDT status register

This register represents the active configuration of the watchdog timer.

These bits are read-only from the outside and they get updated by shadow-configuration bits from WDTx_CTRLB after a valid Config-Update-and-Lock-Access.

All WDTx are disabled by reset, and WDTSEC is not enabled before security SW starts.

WDTSEC_STAT Offset address: $17C_H$

Security WDT status register Application Reset value: $FFFC\ 0001_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TCT							TC	PA	UR	IFS		AE	OE	TOM	D
rh							rh	rh	rh	rh		rh	rh	rh	rh

Field	Bits	Type	Description
D	0	rh	**Watchdog enable/disable status Flag** This bit represents watchdog timer's enable/disable state. This bit is cleared when time-out mode (unlock-state) is entered - after a valid unlock-access to corresponding CTRLA register. 0_B WDTx is enabled 1_B WDTx is disabled.
TOM	1	rh	**Watchdog time-out mode flag** This bit is set when time-out mode (unlock-state) is entered. It is automatically cleared when time-out mode (unlock-state) is left. 0_B The watchdog is not operating in time-out mode 1_B The watchdog is operating in time-out mode.
OE	2	rh	**Watchdog overflow error status flag** This bit is set when the WDTx timer value overflows from $FFFF_H$ to 0000_H. This bit is only cleared when WDTx_CTRLA.LCK changes state from 0 to 1 (after a valid config-update-and-lock-access). 0_B No watchdog overflow error. 1_B A watchdog overflow error has occurred.
AE	3	rh	**Watchdog access error status flag** This bit is set when: • An invalid unlock- or check-access to WDTx_CTRLA register was attempted. • A write access to WDTx_CTRLB register was attempted while WDTx_CTRLA.LCK is set. This bit is only cleared when WDTx_CTRLA.LCK changes state from 0 to 1 (after a valid config-update-and-lock-access). 0_B No watchdog access error. 1_B A watchdog access error has occurred.
IFS	5:4	rh	**Watchdog internal frequency selection status flag** These bits indicate the current WDTx clock rate. 00_B WDTx counter frequency is fSPB/16384 (default). 01_B WDTx counter frequency is fSPB/256. 10_B WDTx counter frequency is fSPB/64. 11_B Reserved. Should not be used.
UR	6	rh	**SMU unlock restriction status flag** This bit represents status of unlock-restriction feature for the Watchdog Timer. 0_B Unlocking of WDTx is not from SMU FSP side. 1_B Unlocking of WDTx not possible when corresponding SMU FSP state machine is not in RUN state

(table continues...)

(continued)

Field	Bits	Type	Description
PA	7	rh	**Password auto-sequence status flag** This bit represents control for password-autosequencing. 0_B No change of password after each unlock- or check-access. 1_B Automatically sequence the password after each valid unlock- or check-access using built-in LFSR.
TC	8	rh	**Timer check status flag** This bit represents control for timer-check - whether an additional check (next to password check) will be performed during unlock- or check-access. 0_B Additional timer-check during unlock- or check-access is disabled. 1_B Additional timer-check during unlock- or check-access is enabled.
TCT	15:9	rh	**Timer check tolerance** This bit-field represents the tolerance value of the timer check during unlock- or check-access. If timer-check is enabled, the timer value is combined with this tolerance value to create an upper and lower comparison boundary [max(TIM-TCT,0), min(TIM+TCT,$FFFF_H$)]. If time-check is enabled and provided value falls outside these boundaries an access error will be signaled to the SMU.
TIM	31:16	rh	**Timer value** This bit-field reflects the current value of the watchdog timer counter. Performing sequence of two accesses: a valid unlock-access followed by a valid config-update-and-lock-access, is servicing of the WDTx and the WDTx_STAT.TIM value gets reloaded by the value stored in WDTx_CTRLB.TIMR. The value reload into WDTx_STAT.TIM is not done in suspend mode.

41.4.31 System WDT PROT register safe endinit - SSE

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Safe Endinit protected control registers.

WDTSYS_PROTSE Offset address: 184_H

System WDT PROT register safe endinit - SSE Application Reset value: $0000\ 0000_H$

0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

41.4.38 System WDT SMU partitions register

This register is to specify output of which SMU state machines will be considered for the SMU unlock-restriction (UR) feature. If more than one bit-field is set, their values are combined with OR logic.

For WDTSYS these bits have default (reset) value of 11111_B, meaning all SMU outputs are combined with OR logic for usage in UR feature.

WDTSYS_SMUFSP Offset address: $1A4_H$

System WDT SMU partitions register Application Reset value: $0000\ 001F_H$

Field	Bits	Type	Description
PARTx (x=0-3)	x	rw	**Consider signals from SMU state machine partition x** This bit enables that the outputs from SMU safe state machine partition x will be considered in unlock restriction feature (see also bit WDTx_STAT.UR). 0_B Outputs of corresponding SMU state machine are ignored inside this watchdog unit. 1_B Outputs of corresponding SMU state machine are considered inside this watchdog unit.
CSPART	4	rw	**Consider signals from SMU CS-related partition** This bit enables that the outputs from SMU CS-related partition will be considered in unlock restriction feature (see also bit WDTx_STAT.UR). 0_B Outputs of corresponding SMU state machine are ignored inside this watchdog unit. 1_B Outputs of corresponding SMU state machine are considered inside this watchdog unit.
0	31:5	r	**Reserved** Read as 0; should be written with 0.

41.4.39 System WDT control register A

This register is written with the expected password, the inverted estimated timer value and a lock-bit value.

The meaning of the individual values depends on the access type and active configuration fields STAT.PA and STAT.TC.

This register stores the current watchdog password value (PW) and lock control bit (LCK).

WDTSYS_CTRLA Offset address: $1A8_H$

System WDT control register A Reset values see: Table 1952

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCVI															
w															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PW															LCK
rwh															rwh

Field	Bits	Type	Description
LCK	0	rwh	**Lock bit** LCK bit is cleared after a valid unlock-access to WDTx_CTRLA when unlock is not disabled. (Note: unlock can be disabled by UR-feature or by debug) LCK bit is set after a valid configuration-update-and-lock-access to WDTx_CTRLA. A valid check-access or shadow-config-update-access does not trigger a change of the LCK value. 0_B Registers WDTx_CTRLA and WDTx_CTRLB are unlocked 1_B Registers WDTx_CTRLA and WDTx_CTRLB are locked (default after reset)
PW	15:1	rwh	**Password** This bit-field is written with a password value during an unlock- or check-access to WDTx_CTRLA: • If corresponding WDTx_STAT.PA == 0 then this bit-field must be written with its current contents. • If corresponding WDTx_STAT.PA == 1 then this bit-field must be written with the next password in the LFSR sequence. It is written with a new password value during a shadow-cfg-update-access to WDTx_CTRLA, and it is ignored during cfg-update-and-lock-access to WDTx_CTRLA. A read from this bit-field returns current password, but bits CTRLA[7:1] are bitwise inverted to ensure that a simple read-write is not sufficient to service the WDTx. The default password after reset is $007C_H$=000_0000_0111_1100$_B$ (due to inversion, SW will read it as 0003_H=000_0000_0000_0011$_B$).
TCVI	31:16	w	**Timer check value inverted** The timer-check value inverted (TCVI) is used only during unlock- and check-access and only if configured for use (WDTx_STAT.TC==1). In all other cases provided value is ignored. The value written to these bits will be bitwise-inverted and compared with the current timer value, with respect to the tolerance margin WDTx_STAT.TCT. If written value is outside defined margins it will result in an access-error. A read from this bit-field always returns 0000_H.

Table 1952 Reset values of WDTSYS_CTRLA

Reset type	Reset value	Note
Application Reset	0000 00F9$_H$	Default password value and locked.
After reset read value	0000 0007$_H$	Bits [7:1] (PW[6:0]) are read as bit-wise inverted

41.4.40 System WDT control register B

This register represents a shadow configuration for the watchdog timer.

WDTx_CTRLB bits can only be modified if corresponding WDTx_CTRLA.LCK is cleared - after a valid Unlock-Access.

Active configuration bits in WDTx_STAT are updated by these shadow/request bits only when LCK is set again - after a valid Config-Update-and-Lock-Access.

WDTSYS_CTRLB Offset address: $1AC_H$

System WDT control register B Reset values see: Table 1953

DR	0	rw	**Disable request bit** This bit represents a request (shadow) to disable the watchdog Timer. 0_B Request to enable the WDTx 1_B Request to disable the WDTx
IFSR	5:4	rw	**Input frequency selection request bits** Two bits of IFSR represent a request (shadow) to configure the watchdog timer frequency. 00_B Request to set input frequency to fSPB/16384. 01_B Request to set input frequency to fSPB/256. 10_B Request to set input frequency to fSPB/64. 11_B Reserved. Should not be used.
URR	6	rw	**Unlock restriction request bit** This bit represents a request (shadow) to enable unlock-restriction feature. If the unlock-restriction is set (WDTx_STAT.UR=='1') then WDTx cannot be unlocked in case respective SMU state machine is not in RUN state. 0_B Request to disable unlock-restriction feature 1_B Request to enable unlock-restriction feature
PAR	7	rw	**Password auto-sequence request bit** This bit represents a request (shadow) to configure a password-autosequencing feature. If the active password-autosequencing is set (WDTx_STAT.PA==1), after each unlock- and check-access, the password WDTx_CTRLA.PW will increment using built-in LFSR and store the new value. 0_B Request to disable automatic change of password after each valid unlock- or check-access 1_B Request to enable automatic sequence of password after each valid unlock- or check-access

(table continues...)

(continued)

Field	Bits	Type	Description
TCR	8	rw	**Timer check request bit** This bit represents a request (shadow) to configure a timer-check feature. If the active timer-check configuration is set (WDTx_STAT.TC==1), on each unlock- and check-access, the input TCVI will be compared to the current timer value WDTx_STAT.TIM with respect to the tolerance margin WDTx_STAT.TCT. 0_B Request to disable timer check feature during unlock- or check-access. 1_B Request to enable timer check feature during unlock- or check-access.
TCTR	15:9	rw	**Timer check tolerance request** This bit-field represents a request (shadow) to configure the timer-check-tolerance value.
TIMR	31:16	rw	**Timer base request value** This bit-field represents a request (shadow) to set the timer reload value. A read from this bit-field returns the timer reload value.
0	3:1	r	**Reserved** Read as 0; should be written with 0.

Table 1953 Reset values of WDTSYS_CTRLB

Reset type	Reset value	Note
Application Reset	FFFC 0001$_H$	Request to enable with timer set to 0xFFFC.
After Boot-FW Value	FFFC 0000$_H$	WDTSYS is enabled after Boot-FW execution.

41.4.41 System WDT status register

This register represents the active configuration of the watchdog timer.

These bits are read-only from the outside and they get updated by shadow-configuration bits from WDTx_CTRLB after a valid Config-Update-and-Lock-Access.

All WDTx are disabled by reset, and WDTCPU0 and WDTSYS are enabled by FW before application SW starts.

WDTSYS_STAT Offset address: 1B0$_H$

System WDT status register Reset values see: Table 1954

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TCT							TC	PA	UR	IFS		AE	OE	TOM	D
rh							rh	rh	rh	rh		rh	rh	rh	rh

Field	Bits	Type	Description
D	0	rh	**Watchdog enable/disable status Flag** This bit represents watchdog timer's enable/disable state. This bit is cleared when time-out mode (unlock-state) is entered - after a valid unlock-access to corresponding CTRLA register. 0_B WDTx is enabled 1_B WDTx is disabled.
TOM	1	rh	**Watchdog time-out mode flag** This bit is set when time-out mode (unlock-state) is entered. It is automatically cleared when time-out mode (unlock-state) is left. 0_B The watchdog is not operating in time-out mode 1_B The watchdog is operating in time-out mode.
OE	2	rh	**Watchdog overflow error status flag** This bit is set when the WDTx timer value overflows from $FFFF_H$ to 0000_H. This bit is only cleared when WDTx_CTRLA.LCK changes state from 0 to 1 (after a valid config-update-and-lock-access). 0_B No watchdog overflow error. 1_B A watchdog overflow error has occurred.
AE	3	rh	**Watchdog access error status flag** This bit is set when: • An invalid unlock- or check-access to WDTx_CTRLA register was attempted. • A write access to WDTx_CTRLB register was attempted while WDTx_CTRLA.LCK is set. This bit is only cleared when WDTx_CTRLA.LCK changes state from 0 to 1 (after a valid config-update-and-lock-access). 0_B No watchdog access error. 1_B A watchdog access error has occurred.
IFS	5:4	rh	**Watchdog internal frequency selection status flag** These bits indicate the current WDTx clock rate. 00_B WDTx counter frequency is fSPB/16384 (default). 01_B WDTx counter frequency is fSPB/256. 10_B WDTx counter frequency is fSPB/64. 11_B Reserved. Should not be used.
UR	6	rh	**SMU unlock restriction status flag** This bit represents status of unlock-restriction feature for the Watchdog Timer. 0_B Unlocking of WDTx is not from SMU FSP side. 1_B Unlocking of WDTx not possible when corresponding SMU FSP state machine is not in RUN state

(table continues...)

(continued)

Field	Bits	Type	Description
PA	7	rh	**Password auto-sequence status flag** This bit represents control for password-autosequencing. 0_B No change of password after each unlock- or check-access. 1_B Automatically sequence the password after each valid unlock- or check-access using built-in LFSR.
TC	8	rh	**Timer check status flag** This bit represents control for timer-check - whether an additional check (next to password check) will be performed during unlock- or check-access. 0_B Additional timer-check during unlock- or check-access is disabled. 1_B Additional timer-check during unlock- or check-access is enabled.
TCT	15:9	rh	**Timer check tolerance** This bit-field represents the tolerance value of the timer check during unlock- or check-access. If timer-check is enabled, the timer value is combined with this tolerance value to create an upper and lower comparison boundary [max(TIM-TCT,0), min(TIM+TCT,$FFFF_H$)]. If time-check is enabled and provided value falls outside these boundaries an access error will be signaled to the SMU.
TIM	31:16	rh	**Timer value** This bit-field reflects the current value of the watchdog timer counter. Performing sequence of two accesses: a valid unlock-access followed by a valid config-update-and-lock-access, is servicing of the WDTx and the WDTx_STAT.TIM value gets reloaded by the value stored in WDTx_CTRLB.TIMR. The value reload into WDTx_STAT.TIM is not done in suspend mode.

Table 1954 Reset values of WDTSYS_STAT

Reset type	Reset value	Note
After Boot-FW Value	XXXX 0000_H	WDTSYS is enabled after Boot-FW execution, exact timer value depends at which moment timer is read.

41.5 Debug information

41.5.1 Suspend mode support

During a debug session, the watchdog timer functionality might lead to some unintended alarms.

By default, the WDTs are disabled when OCDS is enabled. However, it is possible to enable WDTs even when OCDS is enabled if CBS_OSTATE.WDTSUS=1.

WDTCPUy may only be re-enabled if the corresponding CPUy_DBGSR.SUSOUT is inactive. Similarly WDTSEC may be enabled if CPU6_DBGSR.SUSOUT is inactive. In WDTSYS CBS_TLS.TL1 is used for this purpose.

For safety reasons it is essential that WDTCPUy ignores CPUy_DBGSR.SUSOUT, WDTSEC ignores CPU6_DBGSR.SUSOUT, and WDTSYS ignores CBS_TLS.TL1 when OCDS is disabled.

Table 1955 CPUy WDT suspend state

WDTx_STAT.D (x=CPUy, SEC,SYS)	CBS_OSTATE.OEN	CBS_OSTATE.WDTSUS	WDTCPUy → CPUy_DBGSR.SUSOUT WDTSEC → CPU6_DBGSR.SUSOUT WDTSYS → CBS_TLS.TL1	WDTx state
1	X	X	X	Stopped
0	0	X	X	Running
0	1	0	X	Stopped
0	1	1	0	Running
0	1	1	1	Stopped

41.8.4.4 CPUy WDT control register B

This register represents a shadow configuration for the watchdog timer.

WDTx_CTRLB bits can only be modified if corresponding WDTx_CTRLA.LCK is cleared - after a valid unlock-access.

Active configuration bits in WDTx_STAT are updated by these shadow/request bits only when LCK is set again - after a valid config-update-and-lock-access.

TOM	1	rh	**Watchdog time-out mode flag** This bit is set when time-out mode (unlock-state) is entered. It is automatically cleared when time-out mode (unlock-state) is left. 0_B The watchdog is not operating in time-out mode 1_B The watchdog is operating in time-out mode.
OE	2	rh	**Watchdog overflow error status flag** This bit is set when the WDTx timer value overflows from $FFFF_H$ to 0000_H. This bit is only cleared when WDTx_CTRLA.LCK changes state from 0 to 1 (after a valid config-update-and-lock-access). 0_B No watchdog overflow error. 1_B A watchdog overflow error has occurred.

(table continues...)

(continued)

Field	Bits	Type	Description
AE	3	rh	**Watchdog access error status flag** This bit is set when: • An invalid unlock- or check-access to WDTx_CTRLA register was attempted. • A write access to WDTx_CTRLB register was attempted while WDTx_CTRLA.LCK is set. This bit is only cleared when WDTx_CTRLA.LCK changes state from 0 to 1 (after a valid config-update-and-lock-access). 0_B No watchdog access error. 1_B A watchdog access error has occurred.
IFS	5:4	rh	**Watchdog internal frequency selection status flag** These bits indicate the current WDTx clock rate. 00_B WDTx counter frequency is fSPB/16384 (default). 01_B WDTx counter frequency is fSPB/256. 10_B WDTx counter frequency is fSPB/64. 11_B Reserved. Should not be used.
UR	6	rh	**SMU unlock restriction status flag** This bit represents status of unlock-restriction feature for the Watchdog Timer. 0_B Unlocking of WDTx is not from SMU FSP side. 1_B Unlocking of WDTx not possible when corresponding SMU FSP state machine is not in RUN state
PA	7	rh	**Password auto-sequence status flag** This bit represents control for password-autosequencing. 0_B No change of password after each unlock- or check-access. 1_B Automatically sequence the password after each valid unlock- or check-access using built-in LFSR.
TC	8	rh	**Timer check status flag** This bit represents control for timer-check - whether an additional check (next to password check) will be performed during unlock- or check-access. 0_B Additional timer-check during unlock- or check-access is disabled. 1_B Additional timer-check during unlock- or check-access is enabled.
TCT	15:9	rh	**Timer check tolerance** This bit-field represents the tolerance value of the timer check during unlock- or check-access. If timer-check is enabled, the timer value is combined with this tolerance value to create an upper and lower comparison boundary [max(TIM-TCT,0), min(TIM+TCT,$FFFF_H$)]. If time-check is enabled and provided value falls outside these boundaries an access error will be signaled to the SMU.

(table continues...)

(continued)

Field	Bits	Type	Description
TIM	31:16	rh	**Timer value** This bit-field reflects the current value of the watchdog timer counter. Performing sequence of two accesses: a valid unlock-access followed by a valid config-update-and-lock-access, is servicing of the WDTx and the WDTx_STAT.TIM value gets reloaded by the value stored in WDTx_CTRLB.TIMR. The value reload into WDTx_STAT.TIM is not done in suspend mode.

Table 1960 Reset values of WTU_WDTCPUy_STAT (y=0)

Reset type	Reset value	Note
Application Reset	FFFC 0001$_H$	WDTCPUy (y=0-5) are disabled with default timer value of 0xFFFC.
After Boot-FW Value	XXXX 0000$_H$	Only WDTCPU0 is enabled during Boot-FW execution. Exact timer value depends at which moment timer is read.

41.8.5 TC4DX WTU connectivity

The table below lists interfaces to and from this functional block to other blocks in the device.

41.8.6 TC4Dx WTU revision history

Initial release of the chapter.

42 Safety and security alarm Management Unit (SMU)

As a central component of the safety and security architecture, the SMU provides a generic interface to manage the behavior of the microcontroller under the presence of safety critical faults and security events. These faults and security events are signaled to the SMU as alarms. Each alarm can be individually configured to trigger internal reactions and notify externally through a fault signaling protocol.

42.1 Feature list

- Collect every alarm signal generated from safety mechanisms and security mechanisms
- Process safety alarms with redundant safety alarm handlers
- Each safety alarm handler can be configured to activate a number of internal reactions:
  - Generate an interrupt request to any of the CPUs. Concurrent interrupts to several CPUs can be configured
  - Generate a Non-Maskable Interrupt (NMI) request to the System Control Unit (SCU)
  - Generate a reset request to the System Mode Management (SMM)
  - Activate the Port Emergency Stop signal controlling the safe state of output pads
  - Generate a CPU module reset request
  - Generate a PPU module reset request
- Each safety alarm handler can be configured to report internal faults to the external environment using the Fault Signaling Protocol (FSP). The following FSP modes are available:
  - Bi-stable single pin output, also called ErrorPin
  - Timed dual rail coding using two inverted values on the ErrorPins
  - Single-bit timed protocol using the ErrorPin
- Each safety alarm handler can be configured to trigger emergency stop request to the PORTS
- Diverse processing of safety alarms generated by certain safety mechanisms (voltage, clock, and temperature monitors) detecting potential common cause faults
- Process security alarms with security alarm handler
- Security alarm handler can be configured to activate internal reactions:
  - Generate an interrupt request to any of the CPUs including CPUcs if present
  - Generate a NMI request to the SCU
  - Generate a reset request to the SCU
  - Locking KEYS request to the Cyber Security Satellite (CSS)
- A subset of safety and security alarms can be configured to be processed either by safety alarm handler or security alarm handler
- Monitor correct internal reaction execution by watchdog timers
- Test alarm handlers reaction generation by software based alarm emulation
- Control the test mechanism available for safety flip-flop instances within the microcontroller and capture the error condition during the test
- Protect configuration registers against unintended accesses using a diverse hardware access protection mechanism

42.2 Functional overview

The SMU is a central component for handling safety and security alarms. Based on the safety concept several hardware and software-based safety mechanisms are implemented within the microcontroller to detect presence of faults. These faults are signaled to SMU as safety alarms. Please refer to the Safety Manual for a detailed description of which safety mechanisms trigger which alarms.

Based on the security concept, several hardware and software-based security mechanisms are implemented within the microcontroller to detect presence of security events. These security events are signaled to SMU as

security alarms. Certain alarms can be categorized to be safety or security relevant only based on usage of microcontroller. These alarms are categorized as shared alarms and configured during start-up.

SMU_CS is a security alarm handler. Within SMU_CS each security alarm can be individually configured to trigger certain reactions. These reactions will be discussed in detail in section SMU_CS. An independent access protection mechanism is present to protect the configuration of SMU_CS. SMU_CS is implemented within core domain, that is, provided by core voltage and f_{SPB} clock (refer to the PMS and Clocking chapter of the UM for more details).

Two safety alarm handlers instances SMU_SAFE0 and SMU_SAFE1 are also present in core domain. The architectural design of both of the instances are exactly the same. All safety alarms are mapped to both instances. Within each instance each safety alarm can be individually configured to trigger certain reactions. These reactions will be discussed in detail in section SMU_SAFE. A separate access protection mechanism is present to protect the configuration of SMU_SAFE0 and SMU_SAFE1 individually.

A shared alarm selector is present which can be configured during start-up to map shared alarm to either Security Alarm Handler SMU_CS or to Safety Alarm Handlers SMU_SAFE0 and SMU_SAFE1.

In order to mitigate the potential common cause faults inside the MCU, an independent alarm handler SMU_STDBY is present in standby domain. SMU_STDBY is provided by back-up voltage and f_{BACK} clock (refer to the PMS and Clocking chapter of the user manual for more details). Each safety alarm which is mapped to SMU_STDBY can be individually configured to trigger error notification on the external Fault Signaling Protocol (FSP) error pins. All power and temperature related alarms are processed in a diverse way since they are mapped to core domain alarm handlers (SMU_SAFE0 and SMU_SAFE1) and standby domain alarm handler SMU_STDBY. The clock alive monitor alarms are processed in the same clock domain as they are generated. Moreover in order to detect errors in the core domain alarm handlers, SMU_SAFE0 Alive Alarm, SMU_SAFE1 Alive Alarm and SMU_CS Alive Alarm are sent from the corresponding SMU_SAFE0, SMU_SAFE1 and SMU_CS to the SMU_STDBY upon the detection of error.

SMU Global Control and Configuration (SMU_GCC) is present to handle certain configuration of the SMU globally which cannot be performed by individual alarm handlers. SMU_GCC takes care of global configuration for SMU alarm handlers (SMU_SAFE0, SMU_SAFE1 and SMU_CS) in the core domain. Emergency Stop Unit, which triggers port emergency stop request to port, and Register Monitor Unit, to test the safety flip-flops, are also present in SMU_GCC. SMU_GCC is also having independent access protection mechanism.

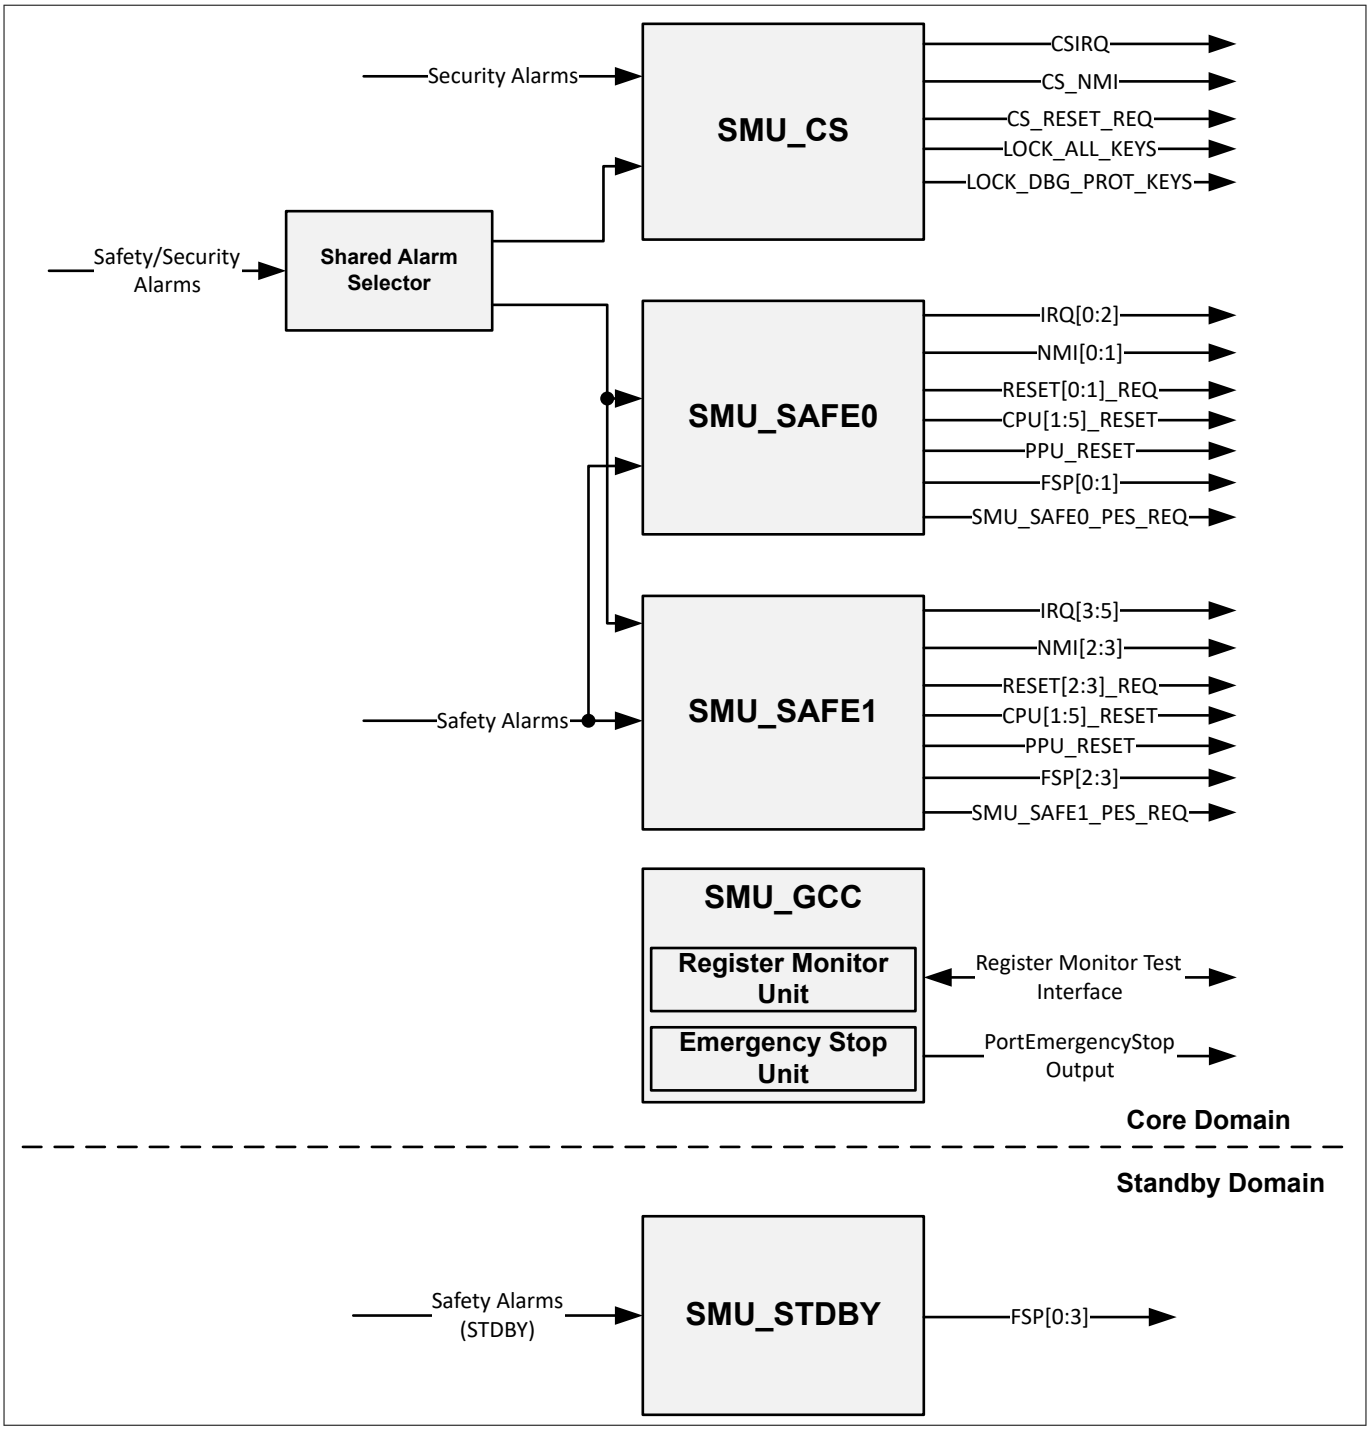

Figure 973 SMU block diagram

For the alarm description please refer to the 'TC4xx SMU alarm mapping tables' subchapter and to the Safety Manual.

42.3 Functional description

The following sections describe SMU_SAFE0, SMU_SAFE1, SMU_CS and SMU_STDBY functionality in detail.

42.3.1 Alarm mapping

Please refer to the product specific section of this document to find the product specific Alarm Mapping Tables.

All the incoming alarms are classified into alarm groups. The alarm groups define a logical mapping used to map alarm signals to internal configuration and status registers. Hence, a maximum of 32 alarm signals can be mapped to a single alarm group. Within the context of SMU, an alarm group is specified by using the three letters 'ALM' followed by alarm type and then index. For example ALMCS0 refers to Alarm Group 0 for cyber security alarms. The following table gives an overview about the alarm groups and their mapping to Alarm Handler.

Table 1962 Alarm group to alarm handler mapping

Alarm group	Alarm type	Alarm handler
ALMCS0 - ALMCS1	Security Alarms	SMU_CS
ALMSF0 - ALMSF16	Safety Alarms	SMU_SAFE0 and SMU_SAFE1
ALMSH0 - ALMSH2	Shared (Security or safety) Alarms	SMU_CS, SMU_SAFE0 and SMU_SAFE1
ALMSTDBY0 - ALMSTDBY4	Safety (Standby) Alarms	SMU_STDBY

42.3.2 Shared alarm selector

A selector which can be configured to map shared alarm group alarms (ALMSHi) to either SMU_CS or SMU_SAFE instances (SMU_SAFE0 and SMU_SAFE1).

As introduced earlier, some alarms can be freely mapped to either safety or security alarm handler depending on application use case. For that a Shared Alarm Selector is present to map the shared alarm group alarms (ALMSHi) to either SMU_CS or SMU_SAFE instances (SMU_SAFE0 and SMU_SAFE1). The configuration of the Shared Alarm Selector is done during start-up where Security and Application software configure their appropriate registers for shared alarm group alarms (ALMSHi) mapping.

The Shared Alarm Selector can be configured by registers CS_AGSHi_SEL and GCC_AGSHi_SEL. The register CS_AGSHi_SEL is used to map the alarms to SMU_CS. Correspondingly, GCC_AGSHi_SEL is used to map the alarms to SMU_SAFE instances (SMU_SAFE0 and SMU_SAFE1). The status register CS_AGSHi_SS is used to indicate which alarms in shared alarm group is mapped to SMU_SAFE instances (SMU_SAFE0 and SMU_SAFE1). Correspondingly, the status register GCC_AGSHi_SS is used to indicate which alarms in shared alarm group is mapped to SMU_CS. The Shared Alarm Selector illustration is shown below :

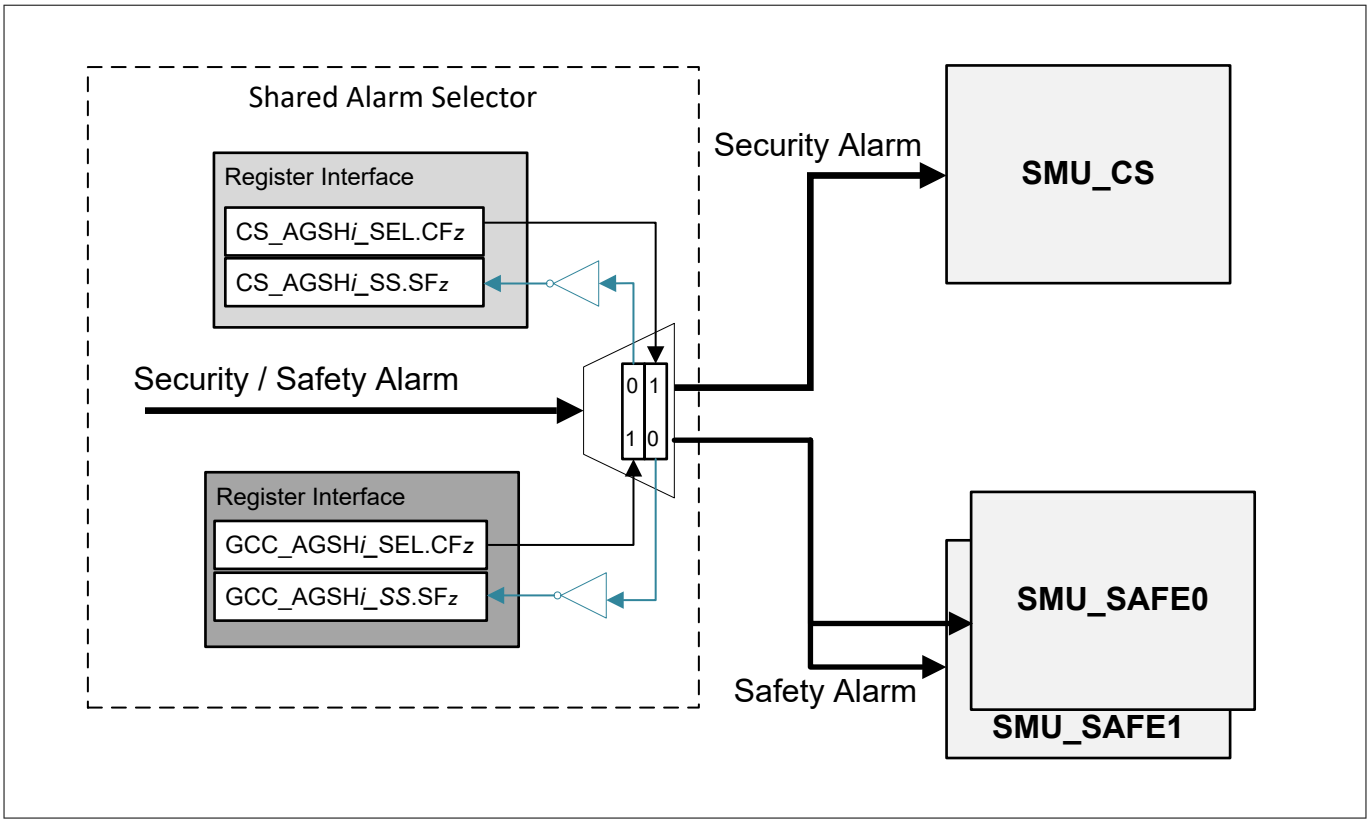

Figure 974 Shared alarm selector: An overview

A bit level locking mechanism is provided for configuration registers CS_AGSHi_SEL and GCC_AGSHi_SEL. The CS_AGSHi_SEL.CFz flag can only be written when the corresponding flag in GCC_AGSHi_SEL.CFz is set to '0' and the GCC_AGSHi_SEL.CFz flag can only be written when the corresponding flag in CS_AGSHi_SEL.CFz is set to '0'. This behavior is explained by an example shown in the following figure :

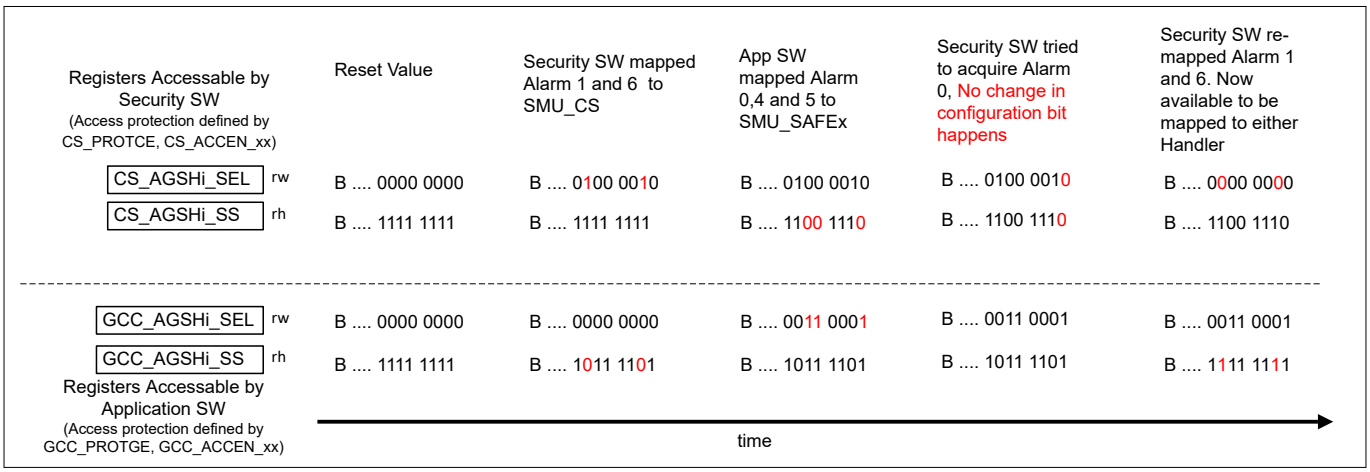

Figure 975 Bit level locking mechanism example for CS_AGSHi_SEL and GCC_AGSHi_SEL registers

The select status registers SAFEx_AGSHi_SS, where x = 0 and 1, are present inside SMU_SAFE instances and hold the exact copy of GCC_AGSHi_SEL. These registers are present to notify corresponding SMU_SAFE0 and SMU_SAFE1 instances about shared alarm group mapping.

42.3.3 SMU_SAFE

Two identical instances SMU_SAFE0 and SMU_SAFE1 are present for handling safety alarms in the core domain. The functionality of both instances is exactly the same. Both SMU_SAFE0 and SMU_SAFE1 instances share input alarms but have their own configuration registers and functional interfaces on outputs side. This is explained in the figure below :

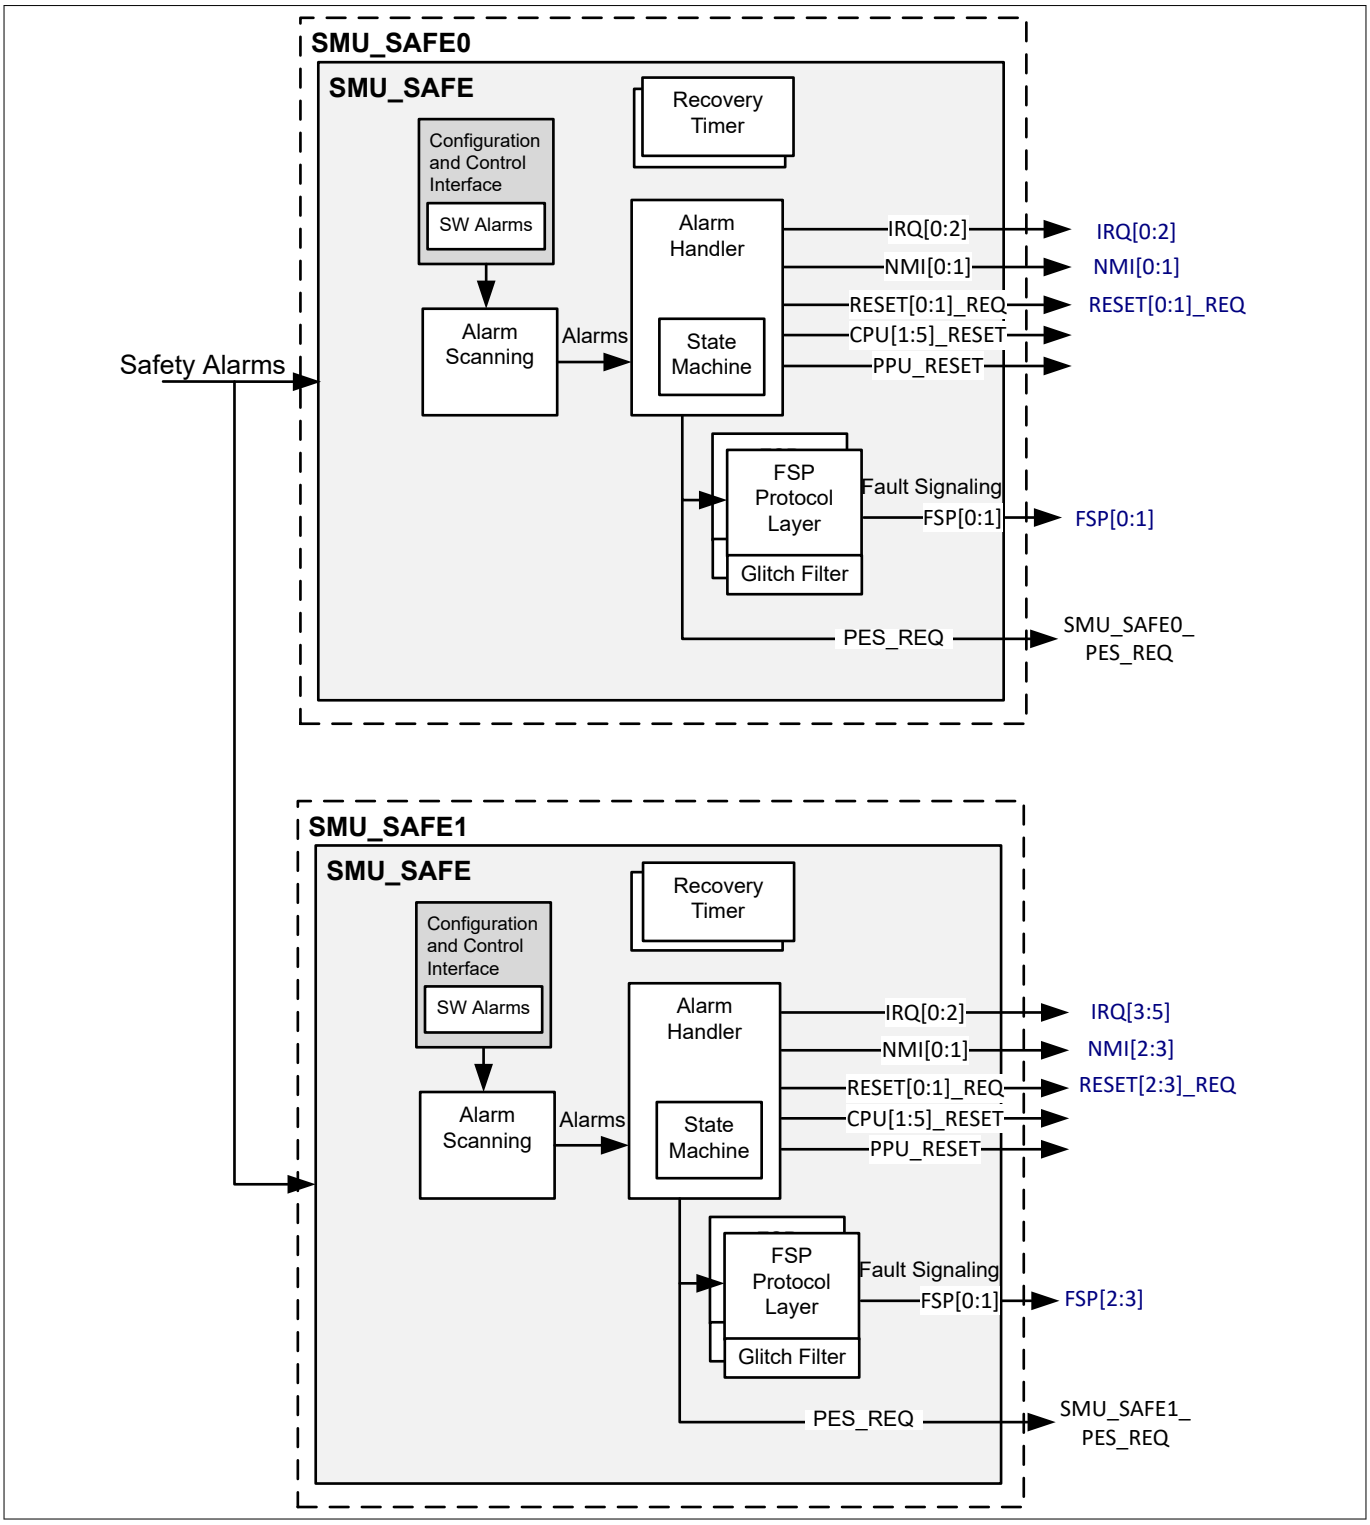

Figure 976 SMU_SAFE0 and SMU_SAFE1 overview

The rest of the sections explain the functionality of the SMU_SAFE instance in detail. Within SMU_SAFE each safety alarm can be individually configured to trigger internal or (and) external reactions. In the Alarm Handling section it is explained how incoming alarms are processed. The Fault Signaling Protocol and its relevant configuration is explained in the section Fault Signaling Protocol (FSP). SMU_SAFE control interface and SMU_SAFE state machine sections explain the usage of software control interface and its impact on SMU_SAFE state machines. An independent access protection mechanism is present to protect the configuration of the SMU_SAFE0 and SMU_SAFE1. SMU_SAFE0 and SMU_SAFE1 are implemented within core domain, that is, provided by core voltage and f_{SPB} clock (refer to the PMS and Clocking chapter of the UM for more details).

42.3.3.1 SMU_SAFE state machine

The figures below describe the behavior of the SMU_SAFE state machines (SSM0 and SSM1). The SSM0 controls the Fault Signaling Protocol (FSP) Layer 0 and the SSM1 the FSP Layer 1, as explained in the chapter Fault Signaling Protocol (FSP). The SSM0 and SSM1 can be controlled using control interface defined in the chapter SMU_SAFE control interface and alarm handling is also dependent upon the SSM0 and SSM1 as explained in the chapter Alarm Handling. The SMU_SAFE will process input alarm events and therefore trigger alarm reactions according to their configuration if at least one of their state machines (SSM0 or SSM1) is in the RUN state. By default SSM1 is disabled and stays in START state after Power on Reset. It has to be enabled using bitfield SAFEx_AGC.ESSM1.

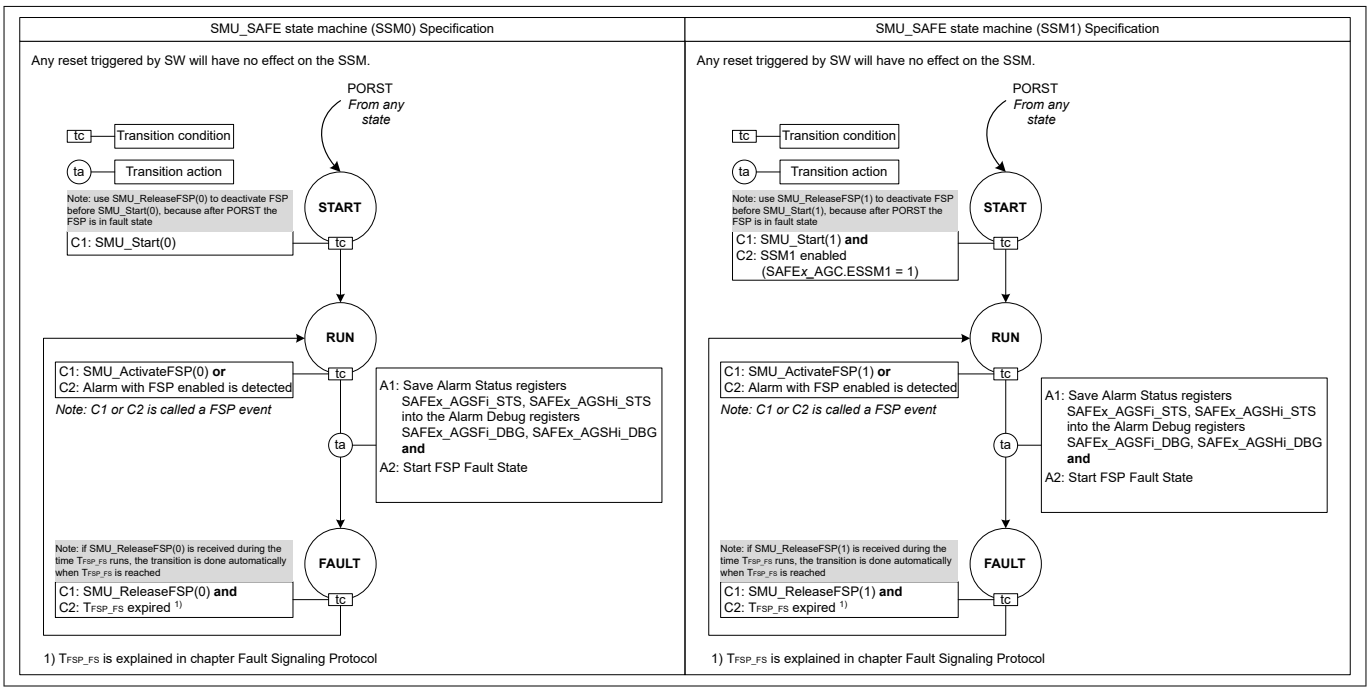

Figure 977 SMU_SAFE state machines (SSM0 and SSM1): Transition conditions and actions

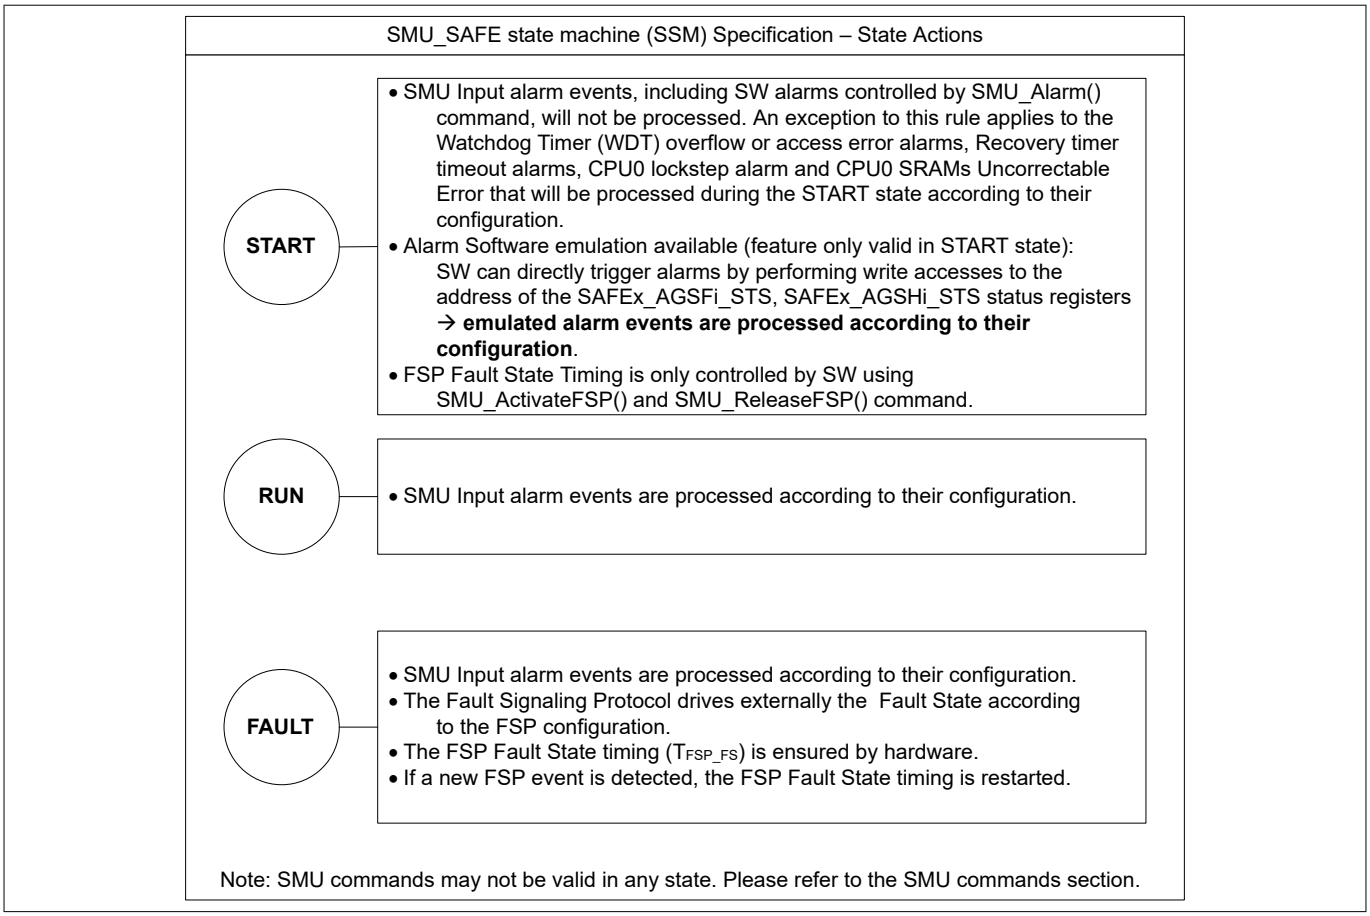

Figure 978 SMU_SAFE state machine: State actions

The current state of the state machines SSM0 and SSM1 can be read out of the SAFEx_DBG register. The SMU_SAFE also implements a Fault Counter SAFEx_AFCNT that counts the number of transitions from the RUN state to the FAULT state. The Fault Counter register is only reset by a warm power-on-reset.

42.3.3.2 SMU_SAFE control interface

The core functionality of the SMU_SAFE is introduced through its control interface. The control interface defines how the SMU_SAFE can be controlled by software, as summarized in the table below. The control interface is directly linked to the SMU_SAFE state machines (SSM0 and SSM1) operation described in SMU_SAFE state machine. The control interface is implemented by the SAFEx_CMD register using the CMD and ARG fields. The command completion status is available in the SAFEx_STS register.

Table 1963 SMU_SAFE commands

Command	Description	CMD bit-field
SMU_Start(ARG)	Forces the SSM to go to the RUN state from the START state. For SSM0 : Argument ARG shall be set to 0. For SSM1 : Argument ARG shall be set to 1	0x0
SMU_ActivateFSP(ARG)	Activates the Fault Signaling Protocol. This action is possible in any state of the SSM. For SSM0 : Argument ARG shall be set to 0. For SSM1 : Argument ARG shall be set to 1	0x1
SMU_ReleaseFSP(ARG)	Turns the FSP into the inactive Fault-Free State. In the START state, SMU_ActivateFSP() and SMU_ReleaseFSP() can be called as many times as necessary to perform self tests of every alarm source. For SSM0 : Argument ARG shall be set to 0. For SSM1 : Argument ARG shall be set to 1	0x2
SMU_ActivatePES(ARG)	Triggers the activation of the Port Emergency Stop (PES). The PES is also directly controlled by the SMU_SAFE when entering the FAULT state. Argument ARG shall be set to 0	0x3
SMU_RTStop(ARG)	Stop the recovery Timer. For RT0 : Argument ARG shall be set to 0. For RT1 : Argument ARG shall be set to 1	0x4
SMU_ASCE(ARG)	Alarm Status Clear Enable Command. Software shall execute this command prior to clearing a SAFEx_AGSFi_STS or SAFEx_AGSHi_STS alarm status bit. This command sets the ASCE bit in the SAFEx_STS register. Argument ARG shall be set to 0	0x5
SMU_Alarm(ARG)	Triggers a software based alarm. ARG specifies the alarm index according to the mapping defined in Alarm Mapping. A software alarm has the same properties as a hardware alarm	0x6
SMU_AliveTest(ARG)	Enables the testing of the corresponding SMU_SAFEx Alive Alarm (where x is 0 or 1). Sending this command will trigger SMU_SAFEx Alive Alarm and forwarded to the SMU_STDBY. Argument ARG shall be set to 0x5 to start the test and to 0xA to end the test	0x7

***Note**: If the argument does not comply with the specification, the command is ignored and returns an error code.*

The next table provides the legal conditions for the execution of the commands. The conditions depend on the SMU_SAFE state machines (SSM0 and SSM1) states. Any situation not specified leads to an error code in the SAFEx_STS register.

Table 1964 SMU_SAFE commands and valid conditions

Command	SSM state	Conditions
SMU_Start(ARG)	START	SSM0 : ARG == 0 SSM1 : ARG == 1
SMU_AliveTest(ARG)	START	ARG == 0x5 to start the test and 0xA to end the test
SMU_ActivateFSP(ARG)	Any	SSM0 : ARG == 0 SSM1 : ARG == 1
SMU_ReleaseFSP(ARG)	START	SSM0 : ARG == 0 SSM1 : ARG == 1
SMU_ReleaseFSP(ARG)	FAULT	SSM0 : ARG == 0 & SAFEx_AGC.EFRST0 == 1[1)] SSM1 : ARG == 0 & SAFEx_AGC.EFRST1 == 1
SMU_ActivatePES(ARG)	Any	ARG == 0
SMU_RTStop(ARG)	Any	ARG >= 0 and ARG <= Number of Recovery Timer Instances and Recovery Timer Enabled
SMU_ASCE(ARG)	Any	ARG == 0
SMU_Alarm(ARG)	RUN, FAULT[2)]	ARG >= 0

1) See also Fault Signaling Protocol (FSP).
2) In the START state of the SMU_SAFE, input alarms are not processed with the exceptions specified in Figure 978, therefore software triggered alarms will have no effect.

42.3.3.3 Alarm handling

This section specifies the hardware and software alarm processes.

42.3.3.3.1 Alarm configuration

Upon reception of an alarm event the SMU_SAFE decodes the reactions to be performed. The reaction can be classified into an internal reaction and an external reaction. Both the internal and external reactions can be configured for every alarm.

The external reaction is related to the Fault Signaling Protocol. The external reaction can be configured with the following registers:

- SAFEx_AGSFi_FSPj
- SAFEx_AGSHi_FSPj

The internal reaction of the SMU_SAFE under the presence of an alarm can be configured with the following registers:

- SAFEx_AGSFi_CON0, SAFEx_AGSFi_CON1, SAFEx_AGSFi_CON2, SAFEx_AGSFi_CON3
- SAFEx_AGSHi_CON0, SAFEx_AGSHi_CON1, SAFEx_AGSHi_CON2, SAFEx_AGSHi_CON3

The internal reaction is specified by a 4-bit code. As an example for any alarm ALMSFi[z], the 4 bit code is formed as shown in the illustration below:

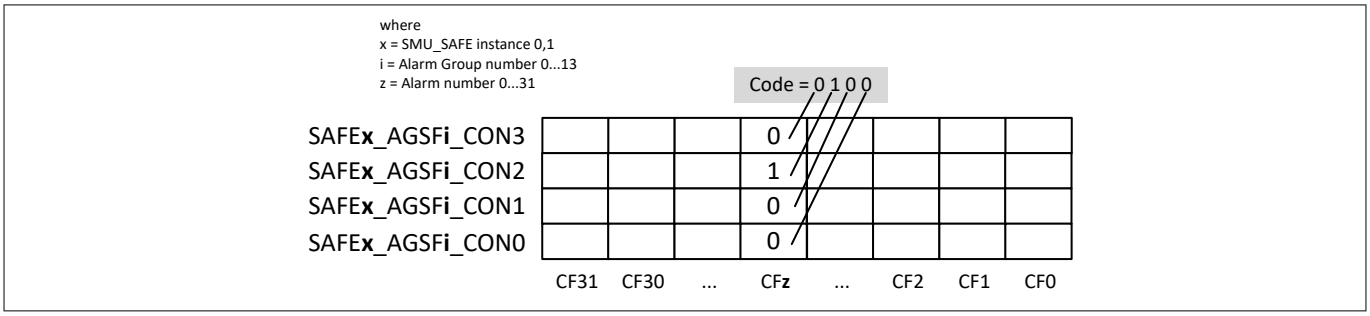

Figure 979 SMU_SAFE alarm configuration code

The table below describes the reaction of SMU_SAFE for each corresponding code:

Table 1965 SMU_SAFE alarm configuration

Code	Name	Reaction
0000	NA	No Reaction. Reset value. Alarm disabled
0001	RSVD	Reserved. No Reaction. Alarm disabled
0010	IGCS0_REQ	Sends an interrupt request to the interrupt system according to the Interrupt Generation Configuration Set 0 from the SAFEx_AGC register
0011	IGCS1_REQ	Sends an interrupt request to the interrupt system according to the Interrupt Generation Configuration Set 1 from the SAFEx_AGC register
0100	IGCS2_REQ	Sends an interrupt request to the interrupt system according to the Interrupt Generation Configuration Set 2 from the SAFEx_AGC register
0101	NMI0_REQ	Sends an NMI0 request to the SCU
0110	RESET0_REQ	Sends a RESET0 request to the SMM. The SMM can be configured to generate an application or system reset

(table continues...)

Table 1965 (continued) SMU_SAFE alarm configuration

Code	Name	Reaction
0111	CPU_RESET0_REQ	Triggers a CPU module reset request using CPU Reset Configuration Set 0 from the SAFEx_AGC register
1000	RSVD	Reserved. No Reaction. Alarm disabled
1001	PPU_RESET	Triggers a PPU module reset request
1010	RSVD	Reserved. No Reaction. Alarm disabled
1011	RSVD	Reserved. No Reaction. Alarm disabled
1100	RSVD	Reserved. No Reaction. Alarm disabled
1101	NMI1_REQ	Sends an NMI1 request to the SCU
1110	RESET1_REQ	Sends a RESET1 request to the SMM. The SMM can be configured to generate an application or system reset
1111	CPU_RESET1_REQ	Triggers a CPU module reset request using CPU Reset Configuration Set 1 from the SAFEx_AGC register

Related information

Fault signaling protocol (FSP) on page 7074

42.3.3.3.2 Alarm operation

Whenever an input alarm event is detected and the SMU_SAFE state machines are in the RUN or FAULT state, the SMU checks for the corresponding internal and the external reactions to be triggered. If an input alarm event is detected and no reaction is specified for the alarm, the corresponding status flag (Refer to the registers SAFEx_AGSFi_STS, SAFEx_AGSHi_STS and section Alarm Status Registers) is set to 1 by hardware although no reaction takes place.

The processing of the incoming alarm events is performed as follows:

- All alarm groups and every alarm are scanned at the same time
- The execution of pending alarms is done concurrently
- The processing of an alarm within SMU_SAFE may take up to 4 f_{SPB} cycles
- If an internal or external reaction is triggered, the corresponding bit in SAFEx_AEX register is set. As long as a bit is set, the corresponding alarm reaction is blocked. This bit needs to be reset by software after fault handling is done in order to enable the alarm reaction upon the next alarm detection
  - If the alarm execution bit in SAFEx_AEX register related to a pending alarm is already set, then the alarm event is ignored but the corresponding status flag in registers SAFEx_AGSFi_STS and SAFEx_AGSHi_STS as well as the corresponding alarm event missed (AEM) bit in SAFEx_AEX register will be set[56)]

[56] The behavior of the AEM bit is different for level alarms. When a reaction to an alarm of this type is triggered by the SMU, the corresponding request status bit xSTS in the SAFEx_AEX register (for example IRQ0STS) is set as expected. However, the corresponding alarm missed event bit xAEM is also set 1 f_{SPB} cycle after the xSTS bit is set for the same alarm event. Therefore, it is recommended that while clearing the xSTS bit the corresponding xAEM bit should also be cleared for the alarm event. Level alarms, as opposed to pulse alarms, remain active until their driving alarm flag is cleared in the source functional block. To find out which alarms need to be cleared in the source functional block, please refer to the alarm tables in the device's safety manual or in the source functional block chapter of the user manual where alarm information is described.

- If the status flag in the registers SAFEx_AGSFi_STS and SAFEx_AGSHi_STS related to an alarm event is already set to 1, the alarm event is ignored
- Whenever an alarm event is processed, the corresponding status bit is set to 1 by hardware in the SAFEx_AGSFi_STS and SAFEx_AGSHi_STS registers. If an internal SMU_SAFE reaction is configured and executed, the alarm reaction counter (ACNT) in the SAFEx_AFCNT register increments

Related information

SMU_SAFE state machine on page 7063
Alarm status registers on page 7070

42.3.3.3.3 Alarm status registers

The status flags in the alarm status registers SAFEx_AGSFi_STS and SAFEx_AGSHi_STS can be set and cleared by software. Setting the bits by software can be used to test alarm reactions and handling. Clearing of an alarm status bit must be performed after an alarm handling reaction has been successfully executed. The software can interact with the alarm status registers through 2 mechanisms:

- By writing a software command 'SMU_ASCE(0)' in the SAFEx_CMD register, as explained in the chapter SMU_SAFE control interface. Then the alarm status flag can be cleared by writing data to SAFEx_AGSFi_STS or SAFEx_AGSHi_STS register. Note that only 32-bit write operations are allowed for clearing an alarm
- By writing data directly to the SAFEx_AGSFi_STS or SAFEx_AGSHi_STS register to test the alarm reactions and handling, also called as alarm emulation

The ability to set and clear the alarm status registers by software depends on the current state of the SMU_SAFE state machine and on the current value of a particular alarm signal. The table below shows examples of the software actions required to set or clear the SAFEx_AGSFi_STS under different conditions (for the state machine and alarm signals), where:

- DATA[j] is a 32-bit data word being written by software and 'j' is the index to an individual word-bit
- In AGSFi[j] 'i' is the index to a particular alarm group and 'j' is the index to an alarm signal within the alarm group

These examples are based on the SAFEx_AGSFi_STS registers but the same principles apply for the SAFEx_AGSHi_STS registers.

Table 1966 Handling of alarm status

SMU_SAFE state machine state	SW action	Effect on SAFEx_AGSFi_STS

START (Both SSM0 and SSM1)	SMU_ASCE(0) command
	and then
	Write DATA at SAFEx_AGSFi_STS address
		If (DATA[j] == 1 AND (Alarm Signal ALMSFi[j][1] == inactive))
		then
		SAFEx_AGSFi_STS.SFj = 0
		else
		“no effect”

START (Both SSM0 and SSM1)	Write DATA at SAFEx_AGSFi_STS Address	If (DATA[j] == 1)
		then
		SAFEx_AGSFi_STS.SFj = 1
		else
		“no effect”

RUN or FAULT (any SSM0 or SSM1)	SMU_ASCE(0) command
	and then
	Write DATA at SAFEx_AGSFi_STS address
		If (DATA[j] == 1 AND Alarm Signal ALMSFi[j] == inactive)
		then
		SAFEx_AGSFi_STS.SFj = 0
		else
		“no effect”

RUN or FAULT (any SSM0 or SSM1)	Write DATA at SAFEx_AGSFi_STS Address	No Effect

1) Watchdog timer (WDT) overflow or access error alarms ALMSF8[0:6] and Recovery timer alarms ALMSF10[18:19] are not clearable in START with default alarm configuration. See Recovery Timer and Watchdog Alarms chapters for more detail about recovery timers and Watchdog alarms default configuration.

To clear individual alarm flags, use only 32-bit writes.

***Note**: After setting an alarm status bit by software in the SAFEx_AGSFi_STS or SAFEx_AGSHi_STS registers, the software shall read back the register value to check if the operation has been completed. Also, after clearing an alarm, the software shall re-check the alarm status bit in case alarms occurred during the time window of the clearing.*

42.3.3.3.4 Alarm diagnosis registers

The alarm diagnosis registers enable the application to improve the diagnosis of the root cause that led to a malfunction. In that context they may help to implement recovery strategies, if allowed by the application. The SAFEx_AGSFi_DBG and SAFEx_AGSHi_DBG diagnosis registers copy the contents of the corresponding SAFEx_AGSFi_STS and SAFEx_AGSHi_STS registers when:

- The action to be executed by the SMU is a reset when any SMU state machine SSM0 or SSM1 is in the RUN or in the FAULT state
- A condition which switches SMU_SAFE state machine (SSM0 or SSM1) to the FAULT state (RUN -> FAULT, FAULT -> FAULT) takes place, either controlled by the SMU hardware or a software command

The SAFEx_AGSFi_DBG, SAFEx_AGSHi_DBG registers can be cleared by a warm power-on reset (see System Mode Management (SMM) chapter for description about the reset types).

***Note**: After every condition which triggers the SMU to make a copy of the SAFEx_AGSFi_STS and SAFEx_AGSHi_STS registers, the corresponding SAFEx_AGSFi_DBG and SAFEx_AGSHi_DBG diagnosis registers are overwritten. This is also valid if the SMU is already in FAULT state and the FSP is activated again.*

42.3.3.3.5 Port emergency stop

The port emergency stop feature enables forcing a pad into General Purpose Input Mode. The port emergency stop request to the SMU_GCC can be triggered by any of the following situations:

- A SMU_ActivatePES() software command
- An alarm event with SAFEx_AGSFi_FSPj enabled and SAFEx_PES.FSPj enabled
- An alarm event with an internal reaction configured in SAFEx_AGSFi_CONj registers and SAFEx_PES enabled for that reaction. For example for an alarm mapped to index AGSF0[0] in SMU_SAFE0, SAFE0_AGSF0_CON0.CF0 and SAFE0_AGSF0_CON2.CF0 are set to 1 to trigger NMI0_REQ and SAFE0_PES.NMI0 is also set to 1, then upon the occurrence of alarm event mapped to AGSF0[0] the NMI0_REQ as well as port emergency stop request will be triggered

Related information

Emergency stop unit on page 7090
SMU_SAFE control interface on page 7064

42.3.3.3.6 Recovery timer

A recovery timer (RT) is available to enable the monitoring of the response time of an internal reaction such as IRQ[0:2], NMI[0:1], RESET[0:1]_REQ, CPU[1:5]_RESET, and PPU_RESET triggered by an alarm. In SMU_SAFE two independent instances (RT0 and RT1) are available. The recovery timer duration (identical for all instances) is configured in the register SAFEx_RTC. It is possible to enable or disable each instance, however both instances are enabled by default as it is required for the operation of the CPU watchdogs (refer to the chapter Watchdog Alarms). Besides SAFEx_RTC, additional configuration registers (SAFEx_RT0ACA, SAFEx_RT0ACB, SAFEx_RT1ACA and SAFEx_RT1ACB) are available to configure alarms for usage of the recovery timer.

The alarm mapping consists of a pair of parameters {GIDi, ALIDi} (with i = 0..3) present in the registers SAFEx_RT0ACA, SAFEx_RT0ACB, SAFEx_RT1ACA and SAFEx_RT1ACB, where GIDi is a group identifier and ALIDi is the alarm identifier belonging to the group. Four {GIDi, ALIDi} pairs can be configured per recovery timer instance, for example for RT0 instance these four pairs are present in registers SAFEx_RT0ACA and SAFEx_RT0ACB. It is possible to configure the same group identifier several times. If less than four alarms need to be mapped to a recovery timer, the same {GIDi, ALIDi} shall be configured several times. The table below shows the Alarm Groups ALMSF and ALMSH to GIDi mapping.

Table 1967 Alarm group mapping to group index GIDi

Alarm group	GIDi
ALMSF0 - ALMSF13	0-16
ALMSH0 - ALMSH2	17-19

***Note**: The use of the recovery timer only makes sense if the internal reaction is an interrupt or NMI. It is the system integrator's responsibility to configure the SMU_SAFE in the appropriate way.*

A recovery timer is automatically started by hardware, provided that the following conditions are met:

- The recovery timer is enabled
- An alarm event occurs for any of the {GIDi, ALIDi} pairs and the corresponding alarm status bit in the SAFEx_AGSFi_STS or SAFEx_AGSHi_STS register is set by this particular alarm event

Such a situation is called as recovery timer event. Once a recovery timer event has occurred, the recovery timer starts and counts until software stops it with the SMU_RTStop(). If the timer expires, an internal SMU alarm (SMU_SAFE*x* RT*y* Time-out Alarm, where x=0,1 and y=0,1) is issued. During the time the recovery timer is running, any other reaction that requests the recovery timer is ignored. If such event happens, the bit RTME0 (Recovery Timer Missed Event) or RTME1 is set to ‘1’ by hardware in the SAFEx_STS register. The bit RTME0 or RTME1 can only be cleared by software by writing 0 to the corresponding bit. The bit RTS0 (Recovery Timer Status) or RTS1 is set to ‘1’ by hardware in the SAFEx_STS register during the time the recovery timer is running: from the timer activation until a SMU_RTStop() is received or when the timer expires. The bit RTS is cleared by hardware upon reception of SMU_RTStop() or when the timer expires.

If a SMU_RTStop() command is received when the recovery timer is not active, the command returns error state in the bitfield SAFEx_STS.RES.

Watchdog alarms on page 7072
SMU_SAFE control interface on page 7064

42.3.3.3.7 Watchdog alarms

The watchdog timer (WDT) overflow or access error alarms require a special processing in order to ensure a correct microcontroller behavior if the watchdogs are not serviced by software or firmware. The default reset configuration of these alarms ensures that the microcontroller is reset after a pre-warning phase, where

software can still perform some critical actions. The following properties are implemented as reset values for the WDT overflow or access error alarms and for the recovery timer 0 and 1 in the SMU_SAFE0.

- Every WDT overflow or access error alarms is configured to activate an NMI0
- The Recovery Timer 0 is configured to service WDT overflow or access error alarms for CPU0 WDT, CPU1 WDT, CPU2 WDT and System WDT
- The Recovery Timer 1 is configured to service WDT overflow or access error alarms for CPU3 WDT, CPU4 WDT and CPU5 WDT
- The Recovery Timer 0 and Recovery Timer 1 timeout alarms are configured to issue a reset request (RESET0_REQ) and activate the Fault Signaling Protocol (FSP0)

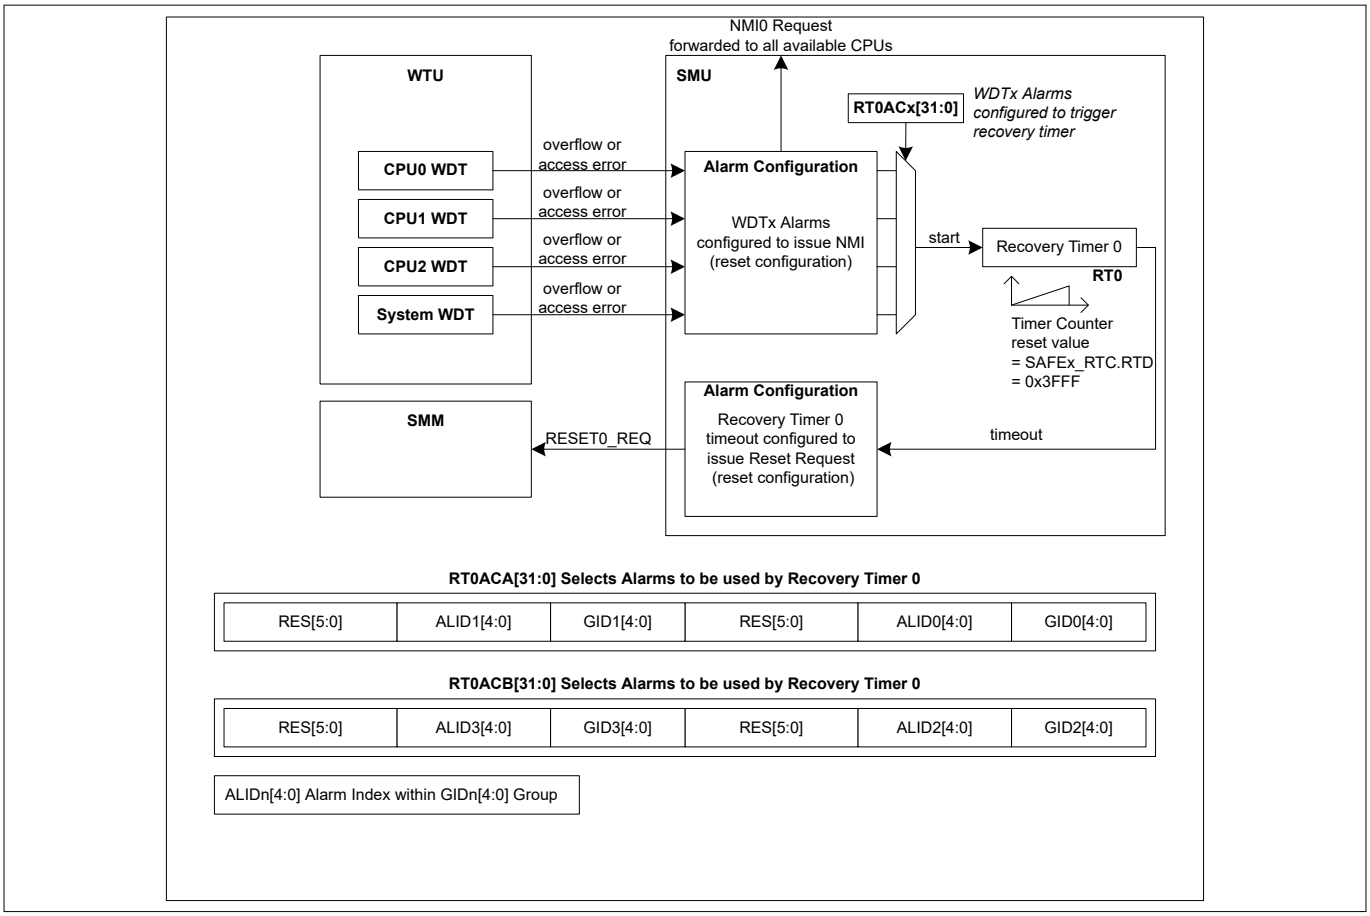

Figure 980 WDT overflow or access error alarm configuration (RT0ACA, RT0ACB)

The figure shows only the example for SAFEx_RT0ACA, SAFEx_RT0ACB and the related four WDT. In the same way the SAFEx_RT1ACA and SAFEx_RT1ACB with the related CPU3 WDT, CPU4 WDT and CPU5 WDT is set up.

Because the WDToverflow or access error detection is also required from the very first instruction executed by a CPU, the SMU is configured to process any WDToverflow or access error alarm during the START state of its internal state machines.

***Note**: If the same behavior is expected for all WDT alarms, it is recommended to use the global WDT timeout alarm that implements a logical OR among all WDT timeout alarms, thus freeing some {GIDi, ALIDi} configuration pairs in SAFEx_RT0ACA, SAFEx_RT0ACB, SAFEx_RT1ACA, and SAFEx_RT1ACB, for other purposes.*

42.3.3.4 Fault signaling protocol (FSP)

The Fault Signaling Protocol enables the microcontroller to report a critical situation to an external safety controller device in order to control the safe state of the safety system.

Each SMU_SAFE has two independent FSP drivers controlled by independent state machines SSM0 and SSM1 respectively. Each FSP layer drives its independent signal FSP[0] and FSP[1] with the exception that FSP Dynamic dual-rail protocol is only supported by FSP Layer 0. Therefore when FSP Layer 0 is used as FSP Dynamic dual-rail protocol FSP Layer 1 and corresponding state machine SSM1 should be disabled (SAFEx_AGC.ESSM1).

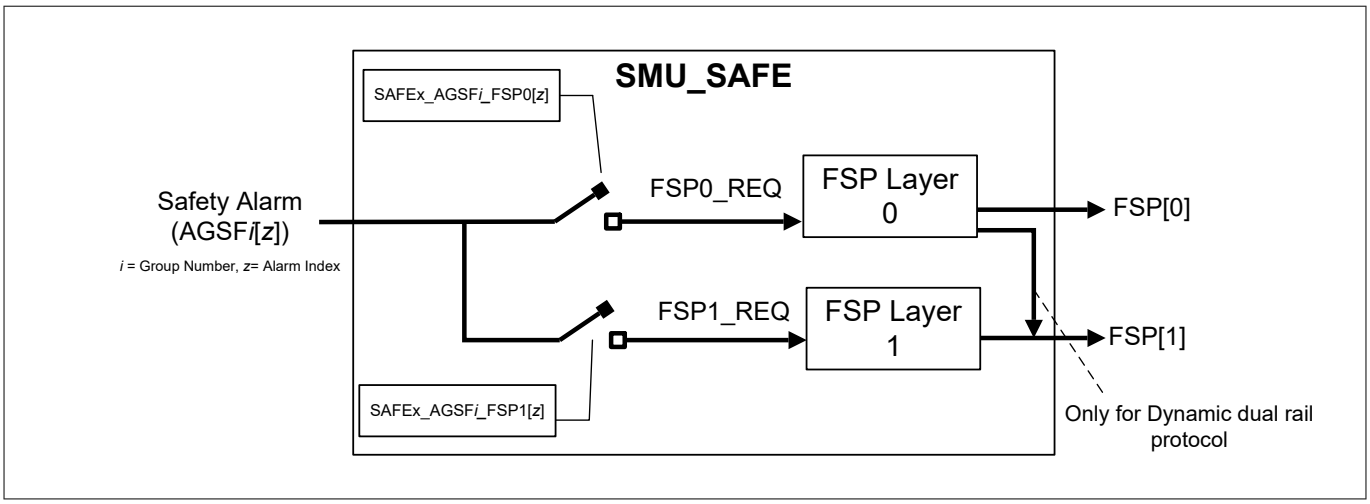

Figure 981 SMU_SAFE fault signaling protocol (FSP)

As Both FSP Layers have similar functionality, with the only exception that Dynamic Dual-rail protocol is only supported by FSP Layer 0, the following sections describe the Fault Signaling Protocol (FSP) by considering FSP Layer 0 as reference. For more information see the chapter in related information.

Related information

Interface to the ports pad on page 7103

42.3.3.4.1 Introduction

The Fault Signaling Protocol is configured with the SAFEx_FSPi_CON configuration register. The FSP status is indicated by the FSP flag in the SAFEx_STS register. The FSP has three states:

- The power-on reset state. After warm power-on reset the SMU is disconnected from the ports and the SMU FSP output assumes the Fault State
- The Fault-Free State. Whenever the Fault-Free State is controlled by a timing, the timing will be called TFSP_FFS and is controlled by the SAFEx_FSPi_CON register
- The Fault State. The timing of the Fault State is controlled by the SAFEx_FSPi_CON register. The minimum active Fault State time is called TFSP_FS

The Fault-Free and Fault State behavior can be configured with the following protocols:

- Bi-stable protocol (default)
- Dynamic dual-rail protocol
- Time-switching protocol

The FSP can be controlled by:

- Software using the SMU_ActivateFSP() and SMU_ReleaseFSP() commands using the SAFEx_CMD register
- Hardware based on the SAFEx_AGSFi_FSPj and SAFEx_AGSHi_FSPj configuration registers as shown in Figure 981

The figure below specifies the intermediate clocks to generate the TFSP_FFS and TFSP_FS timings.

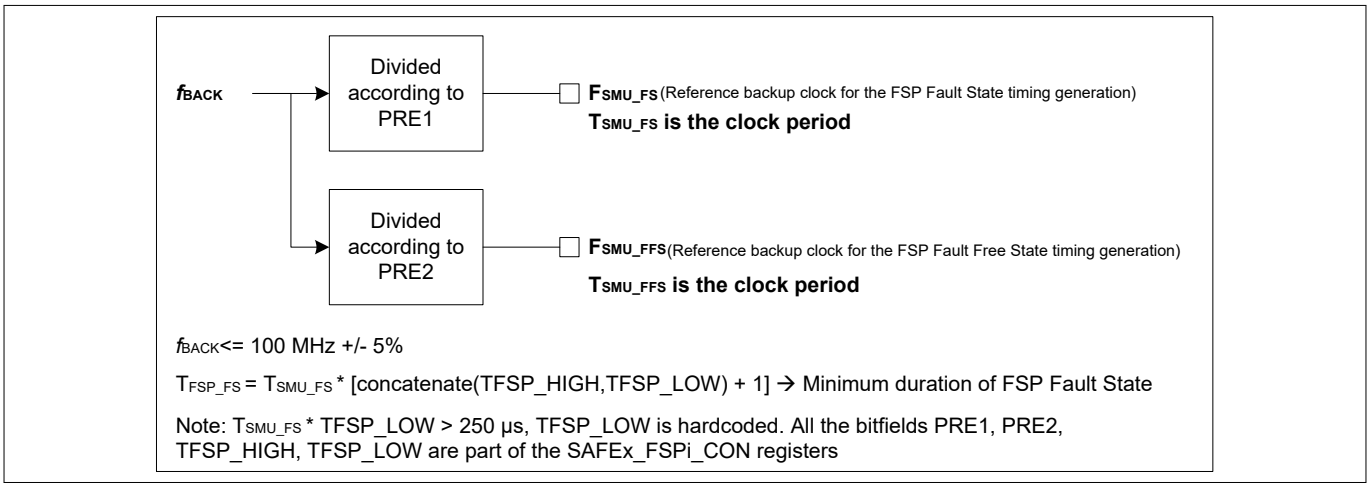

Figure 982 Reference clocks for FSP timings

42.3.3.4.2 Bistable fault signaling protocol

Operation

- During power-on-reset FSP[0] = 0 (Fault State)
- After power-on reset FSP[0] stays in the Fault State
- FSP[0] must be set to the Fault-Free State (FSP[0] = 1) by software (SMU_ReleaseFSP())
- Upon detection of an alarm event configured to activate the FSP, FSP[0] goes to the Fault State and remains in this state until a SMU_ReleaseFSP() command is received and TFSP_FS is satisfied
- While in the Fault State, if a new alarm event configured to activate the FSP is received and the TFSP_FS has not yet been reached, the TFSP_FS timing will be restarted
- While in the Fault State, if a new alarm event configured to activate the FSP is received and the TFSP_FS has already been reached, the TFSP_FS timing will be started

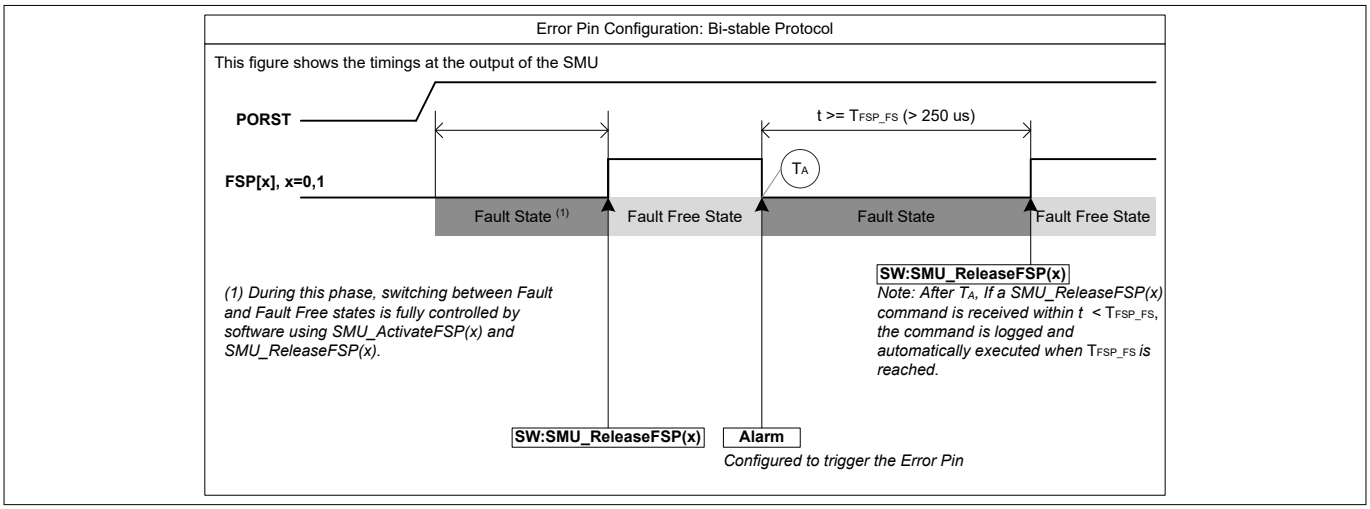

Figure 983 Bistable fault signaling protocol

42.3.3.4.3 Dynamic dual-rail protocol

Operation

Dual-rail encoding is an alternative method for encoding bits. Dual-rail codes use two signals to define a logical state.

- During power-on-reset FSP[1:0] = 00b (Fault State)
- After power-on-reset FSP[1:0] stays in the Fault State
- FSP[1:0] must be set to the Fault-Free State per software(SMU_ReleaseFSP())
- The Fault-Free State is defined by FSP[1:0] oscillating between 2'b01 and 2'b10 with a defined frequency configured by the SAFEx_FSPi_CON register and with a duty cycle of 50% (see figure below)
- Upon detection of an alarm event configured to activate the FSP, FSP[1:0] goes immediately to the Fault State and remains in this state until a SMU_ReleaseFSP() command is received and TFSP_FS is satisfied

Table 1968 Dual-rail coding

Code	Description
{0,1}	Fault-Free State
{1,0}	Fault-Free State
{0,0}	Fault State
{1,1}	Fault State (encoding not used)

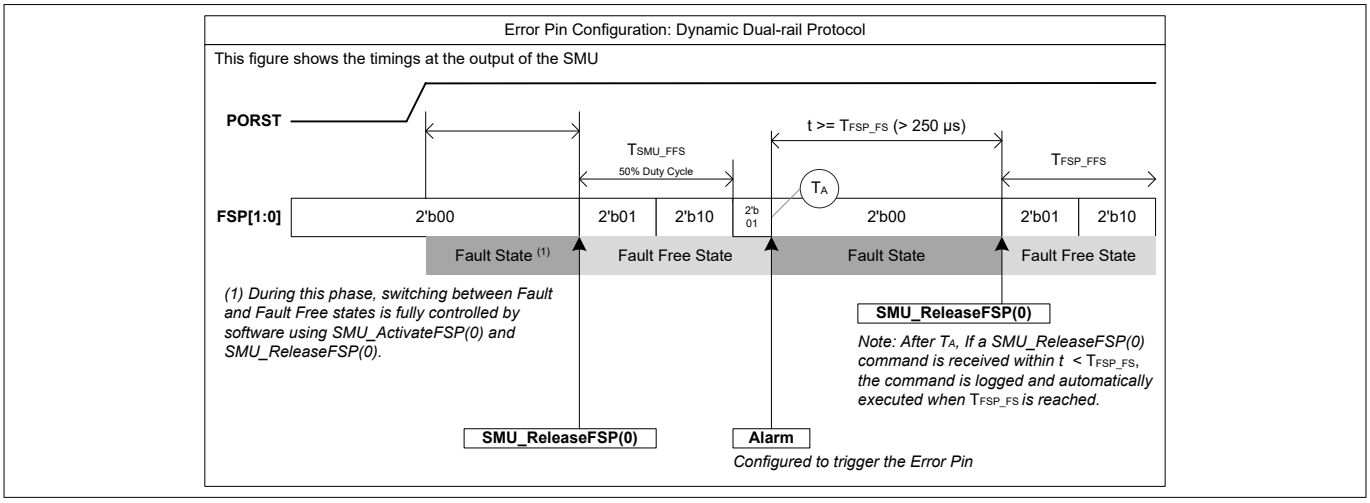

Figure 984 Dynamic dual-rail fault signaling protocol

42.3.3.4.4 Time switching protocol

Operation

FSP[0] is toggled between logic level 0 and logic level 1 with a defined frequency. This frequency modulation protocol is violated when the SMU_SAFE enters the FAULT State.

- During Power-on Reset FSP[0] = 0 (Fault State)
- After Power-on Reset FSP[0] stays in the Fault State
- FSP[0] must be set to the Fault-Free State per software (SMU_ReleaseFSP())
- In the Fault-Free State, FSP[0] oscillates between logic level 0 and logic level 1 with the frequency configured by the SAFEx_FSPi_CON register (see figure below)
- Upon detection of an alarm event configured to activate the FSP, FSP[0] goes immediately to the Fault State and remains in this state until a SMU_ReleaseFSP() command is received and TFSP_FS is satisfied

42 Safety and security alarm Management Unit (SMU)

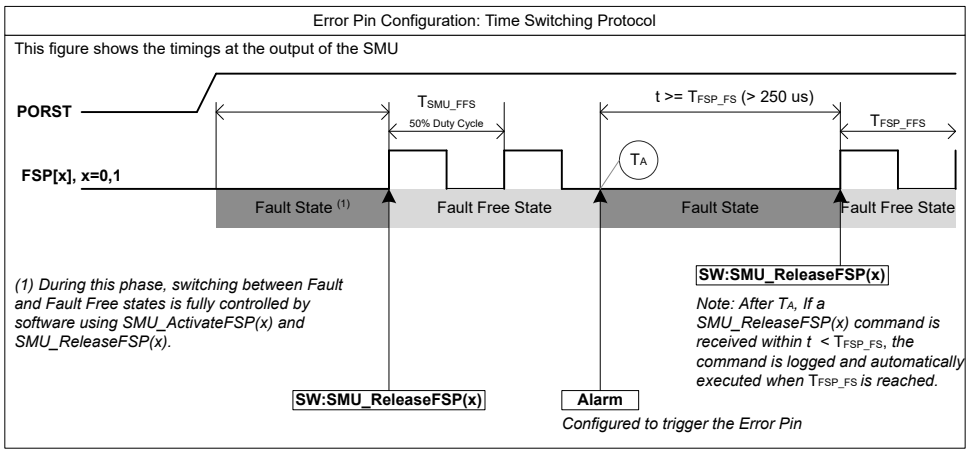

Figure 985 Time switching protocol

42.3.3.4.5 FSP control during Fault State

When the FSP is triggered, the SMU_SAFE state machine automatically switches to the FAULT state. During this time it is also possible for the software to potentially analyze the root cause (provided that the microcontroller is still operational) and decide the severity of the error. As the FSP is active for at least TFSP_FS, it is ensured that the safe state of the system is entered through external safety mechanisms independent from the microcontroller (besides FSP itself). During the time FSP is in the Fault State (TFSP_FS), the software may have concluded that the fault is uncritical and decides to issue a SMU_ReleaseFSP() command, notifying the SMU_SAFE that it can return to the RUN state. Note that the run-time of the software error handler is not directly correlated with the TFSP_FS duration and in practice could be much shorter.

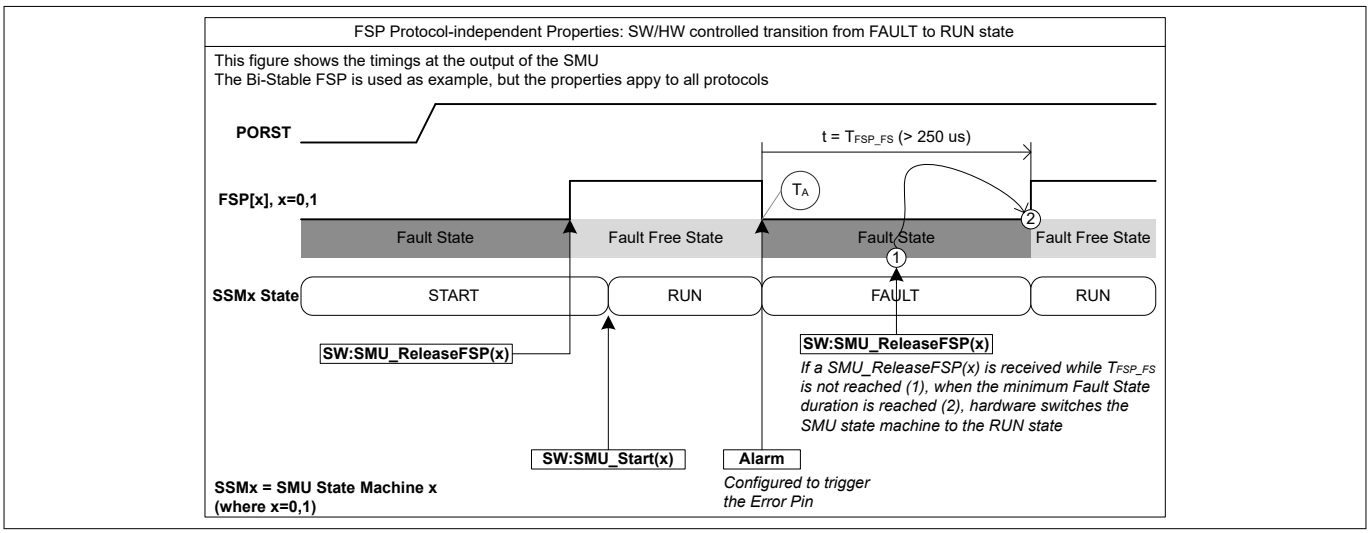

Figure 986 FSP: Fault State to Fault-Free State transition

This feature is per default disabled and can be configured with the EFRST (Enable FAULT to RUN State Transition) field in the SAFEx_AGC register.

42.3.3.4.6 FSP control during START state

The figure below shows a typical use case where the FSP transitions between the Fault State and Fault-Free State are controlled by software using the SMU_ReleaseFSP(0) and SMU_ActivateFSP(0) commands during the SSM0 START State.

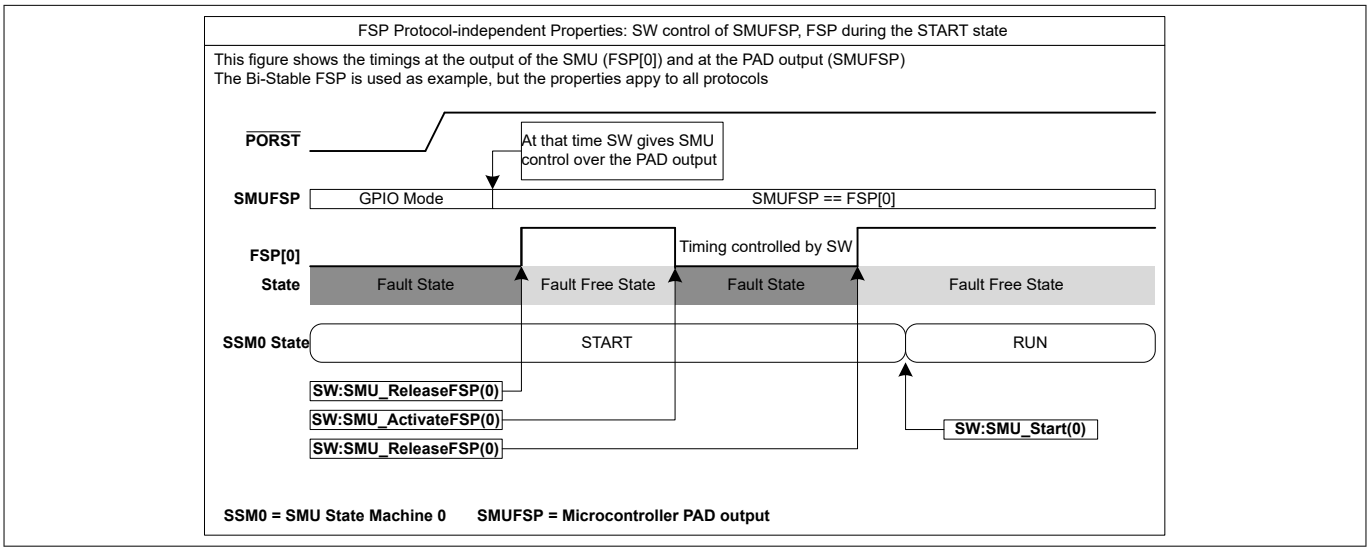

Figure 987 Software control of FSP during SMU_SAFE START state

Conditions of use

Software shall ensure that the FSP is in the Fault-Free State before entering the RUN state with the SMU_Start() command.

42.3.3.5 Access protection

The SMU_SAFE registers are accessed by SPB bus and are access protected based on PROT and BUS Access Protection Unit (APU) mechanism. More explanation for the PROT and APU based access protection can be found in the FPI chapter (section Access Protection) in the user manual.

Each SMU_SAFE instance has a Safe Endinit PROT Register (SAFEx_PROTSSE) that controls access to the Bus Access Protection Unit (APU) registers (SAFEx_ACCEN_WRA, SAFEx_ACCEN_WRB, SAFEx_ACCEN_RDA, SAFEx_ACCEN_RDB, SAFEx_ACCEN_VM, SAFEx_ACCEN_PRS). Only the PROT owner defined SAFEx_PROTSSE can configure the Bus APU registers. Bus APU registers define the access rule for the SMU_SAFE configuration and status register. The SMU_SAFE configuration and status register are read- or write- access protected as defined by BUS APU registers of protection group PSAFEx in the register overview.

For certain configuration registers, the write access is controlled by the PROT owner defined in SMU_SAFE Endinit PROT Register (SAFEx_PROTSE). These registers are marked with SxE in the Register Overview table.

Besides PROT and APU based access protection, the SMU_SAFE has an internal locking mechanism. This locking mechanism is controlled by SAFEx_KEYS register and is explained in the Safety Manual chapter SM[HW]:SMU:LOCK. Please always refer to the device specific safety manual to find out which safety mechanisms of this functional block need to be considered for safety relevant applications.

42.3.3.6 Reset types

The System Mode Management (SMM) implements different reset types that affect the SMU_SAFE. The reset types that are relevant for SMU_SAFE are:

- Warm power-on reset
- Debug reset
- Application reset

The table below specifies the scope of each reset type to the SMU_SAFE control configuration and logic.

Table 1969 Effect of reset types to SMU_SAFE functionality

SMU function	Application reset	Debug reset	Warm power-on reset
SMU_SAFE FSP function	Not affected	Not affected	Reset
SMU_SAFE state machine function	Not affected	Not affected	Reset
SMU_SAFE debug function	Not affected	Reset	Reset
SMU_SAFE alarm diagnosis registers SAFEx_AGSFi_DBG, SAFEx_AGSHi_DBG	Not affected	Not affected	Reset
Port control register SAFEx_PCTL	Not affected	Not affected	Reset
SMU_SAFE alive monitor 1)	Reset	Not affected	Reset
SMU_SAFE glitch filter 2)	Reset	Not affected	Reset
SMU_SAFE other functions	Reset	Not affected	Reset

1) The description of Alive Monitor is present in Safety Manual SM[HW]:SMU:ALIVE_MONITOR.
2) The description of Glitch Filter is present in the chapter Interface to the Ports Pad.

42.3.4 SMU_CS

SMU_CS is a security alarm handler. Within SMU_CS each security alarm can be individually configured to trigger internal reactions. In the Alarm Handling section it is explained how incoming alarms are processed while SMU_CS control interface and SMU_CS state machine explain the usage of the software control interface and its impact on the SMU_CS state machine. An independent access protection mechanism is present to protect the configuration of SMU_CS. The SMU_CS is implemented within core domain, that is, provided by core voltage and f_{SPB} clock (refer to the PMS and Clocking chapter of the UM for more details).

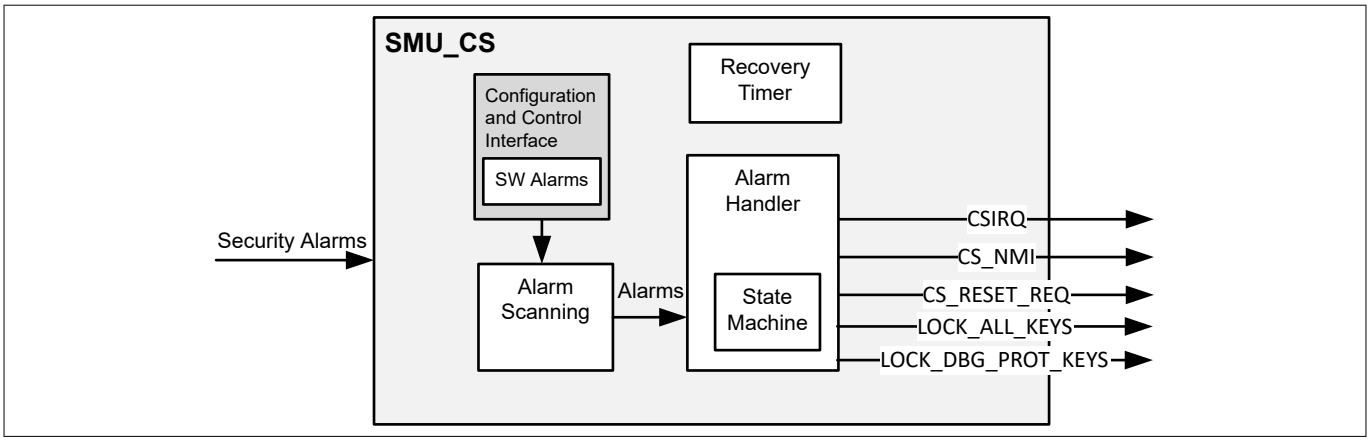

Figure 988 SMU_CS overview

42.3.4.1 SMU_CS state machine

The figures below describes the behavior of the SMU_CS state machine (SSM0). The SSM0 can be controlled using control interface defined in the chapter SMU_CS control interface and alarm handling is also dependent upon the SSM0 as explained in the chapter Alarm Handling. The current state of the SMU_CS state machine can be read out from the CS_DBG register.

SMU_CS control interface on page 7082
Alarm handling on page 7083

42.3.4.2 SMU_CS control interface

The core functionality of the SMU_CS is controlled through its control interface. The control interface defines how the SMU_CS can be controlled by software, as summarized in the following table. The control interface is directly linked to the SMU_CS state machine (SSM0) operation described in SMU_CS state machine. The control interface is implemented by the CS_CMD register using the CMD and ARG fields. The command completion status is available in the CS_STS register.

Table 1970 SMU_CS commands

Command	Description	CMD bit-field
SMU_Start(ARG)	Forces the SSM to go to the RUN state from the START state. For SSM0 : Argument ARG shall be set to 0	0x0
Reserved	Reserved	0x1
Reserved	Reserved	0x2
Reserved	Reserved	0x3
SMU_RTStop(ARG)	Stop the recovery Timer. For RT0 : Argument ARG shall be set to 0	0x4
SMU_ASCE(ARG)	Alarm Status Clear Enable Command. Software shall execute this command prior to clear a CS_AGCSi_STS alarm status bit. This command sets the ASCE bit in the CS_STS register. Argument ARG shall be set to 0	0x5

(table continues...)

Table 1970 (continued) SMU_CS commands

Command	Description	CMD bit-field
SMU_Alarm(ARG)	Triggers a software based alarm. ARG specifies the alarm index according to the mapping defined in Alarm Mapping. A software alarm has the same properties as a hardware alarm	0x6
SMU_AliveTest(ARG)	Enables the testing of the SMU_CS Alive Alarm. Sending this command will trigger SMU_CS Alive Alarm and forwarded to the SMU_STDBY. Argument ARG shall be set to 0x5 to start the test and to 0xA to end the test	0x7

***Note**: If the argument does not comply with the specification, the command is ignored and returns an error code.*

The next table provides the legal conditions for the execution of the commands. The conditions depend on the SMU_CS state machine (SSM0) states. Any situation not specified leads to an error code in the CS_STS register.

Table 1971 SMU_CS commands and valid conditions

Command	SSM state	Other conditions
SMU_Start(ARG)	START	SSM0 : ARG == 0
SMU_AliveTest(ARG)	START	ARG == 0x5 to start the test and 0xA to end the test
SMU_RTStop(ARG)	Any	ARG >= 0 and ARG <= Number of Recovery Timer Instances and Recovery Timer Enabled
SMU_ASCE(ARG)	Any	ARG == 0
SMU_Alarm(ARG)	RUN[1)]	ARG >= 0

1) In the START state of the SMU_CS input alarms are not processed, therefore software triggered alarms will have no effect.

42.3.4.3 Alarm handling

This section specifies the hardware and software alarm processes.

42.3.4.3.1 Alarm configuration

Upon reception of an alarm event the SMU_CS decodes the reactions to be performed. These reactions can be configured for every alarm through the following registers :

- CS_AGCSi_CON0, CS_AGCSi_CON1 and CS_AGCSi_CON2
- CS_AGSHi_CON0, CS_AGSHi_CON1 and CS_AGSHi_CON2

The reaction is specified by a 3-bit code. As an example for any alarm ALMCSi[z], the 3 bit code is formed as shown in the illustration below:

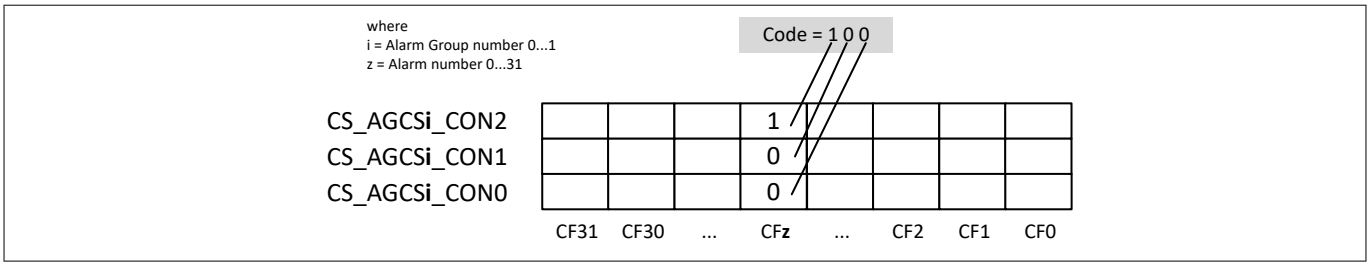

Figure 991 SMU_SAFE alarm configuration code

Table 1972 SMU_CS alarm configuration

Code	Name	Reaction
000	NA	No Reaction. Reset value. Alarm disabled
001	LOCK_ALL_KEYS & CSIRQ	Sends a request to the CSS for locking all keys and an interrupt request to IR
010	LOCK_ALL_KEYS & CS_NMI	Sends a request to the CSS for locking all keys and a NMI request to the SCU
011	LOCK_DBG_PROT_KEYS	Sends a request to the CSS for locking Debug Protected Keys
100	LOCK_DBG_PROT_KEYS & CSIRQ	Sends a request to the CSS for locking Debug Protected Keys and an interrupt request to IR
101	CS_NMI	Sends an NMI request to the SCU
110	CS_RESET_REQ	Sends a RESET request to the SMM. The SMM can be configured to generate an application or system reset
111	CSIRQ	Sends an interrupt request to IR

42.3.4.3.2 Alarm operation

Whenever an input alarm event is detected and the SMU_CS state machine is in the RUN state, the SMU checks for the corresponding reactions to be triggered. If an input alarm event is detected and no reaction is specified for the alarm, the corresponding status flag (Refer to the registers CS_AGCSi_STS, CS_AGSHi_STS and section Alarm Status Registers) is set to 1 by hardware although no reaction takes place.

The processing of the incoming alarm events is performed as follows:

- All alarm groups and every alarm are scanned at the same time
- The execution of pending alarms is done concurrently
- The processing of an alarm within SMU_CS may take up to four f_{SPB} cycles
- If an reaction is triggered, the corresponding bit in CS_AEX register is set. As long as a bit is set, the corresponding alarm reaction is blocked. This bit needs to be reset by software after fault handling is done in order to enable the alarm reaction upon the next alarm detection
  - If the alarm execution bit in CS_AEX register related to a pending alarm is already set, the alarm event is ignored but the corresponding status flag in registers CS_AGCSi_STS and CS_AGSHi_STS as well as the corresponding alarm event missed (AEM) bit in CS_AEX register will be set[57)]

57 The behavior of the AEM bit is different for level alarms. When a reaction to an alarm of this type is triggered by the SMU, the corresponding request status bit xSTS in the CS_AEX register (for example IRQ0STS) is set as expected. However, the corresponding alarm missed event bit xAEM is also set 1 f_{SPB} cycle after the xSTS bit is set for the same alarm event. Therefore, it is recommended that while clearing the xSTS bit the corresponding xAEM bit should also be cleared for the alarm event. Level alarms, as opposed to pulse alarms, remain active until their driving alarm flag is cleared in the source functional block. To find

- If the status flag in registers CS_AGCSi_STS and CS_AGSHi_STS related to an alarm event is already set to 1, the alarm event is ignored
- Whenever an alarm event is processed, the corresponding status bit is set to 1 by hardware in the CS_AGCSi_STS and CS_AGSHi_STS register. If an internal SMU_CS reaction is configured and executed, the alarm reaction counter (ACNT) in the CS_AFCNT register increments

SMU_CS state machine on page 7081

Alarm status registers on page 7085

42.3.4.4.3 Alarm status registers

The status flags in the alarm status registers CS_AGCSi_STS and CS_AGSHi_STS can be set and cleared by software. Setting the bits by software can be used to test alarm reactions and handling. Clearing of an alarm status bit must be performed after an alarm handling reaction has been successfully executed. The software can interact with the alarm status registers through 2 mechanisms:

- By writing a software command 'SMU_ASCE(0)' in the CS_CMD register, as explained in the chapter SMU_CS control interface. Then the alarm status flag can be cleared by writing data to CS_AGCSi_STS or CS_AGSHi_STS register. Note that only 32-bit write operations are allowed to clear an alarm
- By writing data directly to the CS_AGCSi_STS or CS_AGSHi_STS register to test the alarm reactions and handling, also called alarm emulation

The ability to set and clear the alarm status registers by software depends on the current state of the SMU_CS state machine and on the current value of a particular alarm signal. The table below shows examples of the software actions required to set or clear the CS_AGCSi_STS under different conditions (for the state machine and alarm signals), where:

- DATA[j] is a 32-bit data word being written by software and 'j' is the index to an individual word-bit
- In AGCSi[j] 'i' is the index to a particular alarm group and 'j' is the index to an alarm signal within the alarm group

These examples are based on the CS_AGCSi_STS registers but the same principles apply for the CS_AGSHi_STS registers.

Table 1973 Handling of alarm status

SMU_CS state machine state	SW action	Effect on CS_AGCSi_STS

START	SMU_ASCE(0) command
	and then
	Write DATA at CS_AGCSi_STS address
		If (DATA[j] == 1 AND (Alarm Signal ALMCSi[j][1] == inactive))
		then
		CS_AGCSi_STS.SF[j] = 0
		else
		“no effect”

(table continues...)

out which alarms need to be cleared in the source functional block, please refer to the alarm tables in the device's safety manual or in the source functional block chapter of the user manual where alarm information is described.

Table 1973 (continued) Handling of alarm status

SMU_CS state machine state	SW action	Effect on CS_AGCSi_STS

START	Write DATA at CS_AGCSi_STS address	If (DATA[j] == 1)
		then
		CS_AGCSi_STS.SF[j] = 1
		else
		“no effect”

RUN	SMU_ASCE(0) command
	Write DATA at CS_AGCSi_STS address
		If (DATA[j] == 1 AND Alarm Signal ALMCSi[j] == inactive)
		then
		CS_AGCSi_STS.SF[j] = 0
		else
		“no effect”

RUN	Write DATA at CS_AGCSi_STS address	No effect

1) Watchdog timer (WDT) overflow or access error alarm ALMSH0[31] and Recovery timer alarm ALMCS1[18] are not clearable in START with default alarm configuration. See Recovery Timer and Watchdog alarms chapters for more details about Recovery timers' and Watchdog alarms' default configurations.

To clear individual alarm flags, use only 32bit writes.

***Note**: After setting an alarm status bit by software in the CS_AGCSi_STS or CS_AGSHi_STS registers, the software shall read back the register value to check if the operation has been completed. Also, after clearing an alarm, the software shall re-check the alarm status bit to check if alarms occurred during the time window of the clearing.*

42.3.4.3.4 Alarm diagnosis registers

The alarm diagnosis registers enable the application to improve the diagnosis of the root cause that led to a malfunction. In that context they may help to implement recovery strategies, if allowed by the application. The CS_AGCSi_DBG and CS_AGSHi_DBG diagnosis registers copy the contents of the corresponding CS_AGCSi_STS and CS_AGSHi_STS registers when:

- The action to be executed by the SMU_CS is a reset when any SMU_CS state machine SSM0 is in the RUN state

The CS_AGCSi_DBG and CS_AGSHi_DBG registers can be cleared by a warm power-on reset (see System Mode Management (SMM) chapter for description about the reset types).

42.3.4.3.5 Recovery timer

A recovery timer (RT) is available to enable the monitoring of the response time of an internal reaction such as CSIRQ, CS_NMI, CS_RESET_REQ, LOCK_ALL_KEYS, and LOCK_DBG_PROT_KEYS triggered by an alarm. In SMU_CS one instance (RT0) is available. The recovery timer duration is configured in the register CS_RTC. It is possible to enable or disable the RT0, however RT0 is enabled by default as it is required for the operation of the CPUcs watchdog. Besides CS_RTC, additional configuration registers (CS_RT0ACA and CS_RT0ACB) are available to configure alarms for usage of the recovery timer.

The alarm mapping consists of a pair of parameters {GIDi, ALIDi} (with i = 0..3), where GIDi is a group identifier and ALIDi is the alarm identifier belonging to the group. Four {GIDi, ALIDi} pairs can be configured per recovery timer instance. It is possible to configure the same group identifier several times. If less than four alarms need to be mapped to a recovery timer, the same {GIDi, ALIDi} shall be configured several times. The table below shows the Alarm Groups ALMCS and ALMSH to GIDi mapping.

Table 1974 Alarm group mapping to group index GIDi

Alarm group	GIDi
ALMCS0 - ALMCS1	0-1
ALMSH0 - ALMSH2	2-4

***Note**: The use of the recovery timer only makes sense if the internal reaction is an interrupt or NMI. It is the system integrator's responsibility to configure the SMU_CS in the appropriate way.*

A recovery timer is automatically started by hardware, provided that the following conditions are met:

- The recovery timer is enabled
- An alarm event occurs for any of the {GIDi, ALIDi} pairs and the corresponding alarm status bit in the CS_AGCSi_STS or CS_AGSHi_STS register is set by this particular alarm event

Such a situation is called as recovery timer event. Once a recovery timer event has occurred, the recovery timer starts and counts until software stops it with the SMU_RTStop(). If the timer expires, an internal SMU_CS alarm (SMU_CS RT0 Time-out Alarm) is issued. During the time the recovery timer is running, any other reaction that requests the recovery timer is ignored. If such event happens, the bit RTME0 (Recovery Timer Missed Event) is set to '1' by hardware in the CS_STS register. The bit RTME0 can only be cleared by software by writing 0 to the corresponding bit. The bit RTS0 (Recovery Timer Status) is set to '1' by hardware in the CS_STS register during the time the recovery timer is running: from the timer activation until a SMU_RTStop() is received or when the timer expires. The bit RTS0 is cleared by hardware upon reception of SMU_RTStop() or when the timer expires.

If a SMU_RTStop() command is received when the recovery timer is not active, the command returns error state in the bitfield CS_STS.RES.

42.3.4.3.6 Watchdog alarms

The CPUcs watchdog timer (WDT) overflow or access error alarm require a special processing in order to ensure a correct microcontroller behavior if the watchdogs are not serviced by software or firmware. The default reset configuration of these alarms ensures that the microcontroller is reset after a pre-warning phase, where software can still perform some critical actions. The following properties are implemented as reset values for the CPUcs WDT overflow or access error alarm and for the recovery timer 0:

- The CPUcs WDT overflow or access error alarm is configured to activate a CS_NMI

- The Recovery Timer 0 is configured to service CPUcs WDT overflow or access error alarm
- The Recovery Timer 0 timeout alarm is configured to issue a reset request CS_RESET_REQ

Because the CPUcs WDToverflow or access error detection is also required from the very first instruction executed by a CPUcs, the SMU_CS is set up to process any CPUcs WDToverflow or access error alarm during the START state of its internal state machine.

42.3.4.4 Access protection

The SMU_CS registers are accessed by SPB bus and are access protected based on PROT and BUS Access Protection Unit (APU) mechanism. More explanation for the PROT and APU based access protection can be found in the FPI chapter (section Access Protection) in the user manual.

The SMU_CS has a Safe Endinit PROT Register (CS_PROTCSE) that controls access to the Bus Access Protection Unit (APU) registers (CS_ACCEN_WRA, CS_ACCEN_WRB, CS_ACCEN_RDA, CS_ACCEN_RDB, CS_ACCEN_VM, CS_ACCEN_PRS). Only the PROT owner defined CS_PROTCSE can configure the Bus APU registers. Bus APU registers define the access rule for the SMU_CS configuration and status register. The SMU_CS configuration and status register are read- or write- access protected as defined by BUS APU registers of protection group PCS in the register overview.

For certain configuration registers, the write access is controlled by the PROT owner defined in SMU_CS Endinit PROT Register (CS_PROTCE). These registers are marked with CE in the Register Overview table.

Besides PROT and APU based access protection, the SMU_CS has an internal locking mechanism. This locking mechanism is controlled by CS_KEYS register and is explained in the Safety Manual chapter SM[HW]:SMU:LOCK. Please always refer to the device specific safety manual to find out which safety mechanisms of this functional block need to be considered for safety relevant applications.

42.3.4.5 Reset types

The System Mode Management (SMM) implements different reset types that affect the SMU_CS. The reset types that are relevant for SMU_CS are:

- Warm power-on reset
- Debug reset
- Application reset

The table below specifies the scope of each reset type to the SMU_CS control configuration and logic.

Table 1975 Effect of reset types to SMU_CS functionality

SMU function	Application reset	Debug reset	Warm power-on reset
SMU_CS state machine function	Not affected	Not affected	Reset
SMU_CS debug function	Not affected	Reset	Reset
SMU_CS alarm diagnosis registers CS_AGCSi_DBG, CS_AGSHi_DBG	Not affected	Not affected	Reset
SMU_CS alive monitor[1)]	Reset	Not affected	Reset
SMU_CS shared alarm selection and status registers CS_AGSHi_SEL, CS_AGSHi_SS	Not affected	Not affected	Reset
SMU_CS other functions	Reset	Not affected	Reset

1) The description of Alive Monitor is present in Safety Manual SM[HW]:SMU:ALIVE_MONITOR.

42.3.5 SMU_GCC

SMU Global Control and Configuration (SMU_GCC) takes care of global configuration for SMU alarm handlers and other safety relevant functionality mapped to SMU functional block. This includes:

- Register Monitor Unit
- Emergency Stop Unit

The SMU_GCC is implemented within core domain, that is, provided by core voltage and f_{SPB} clock (refer to the PMS and Clocking chapter of the UM for more details).

42.3.5.1 Register monitor unit

If a register is monitored by a safety flip-flop, a self-test mechanism is also available for the safety flip-flop. This self-test mechanism is explained in the Safety Manual chapter SM[HW]:<FB>:REG_MONITOR, where <FB> refers to the Functional Block where safety flip-flop is implemented. GCC_RMi_CTL (i=0-4) Registers are used to start the self-test while the Registers GCC_RMi_STS (i=0-4) are used to capture the status of self-test. The failures are reported back to the Registers GCC_RMi_EF (i=0-4).

Please refer to the product specific section of this document to find the product specific Register Monitor Mapping tables.

42.3.5.2 Emergency stop unit

The Emergency Stop unit (ES) provides a fast reaction to an emergency event without the intervention of software. In response to the emergency event, selected output ports can be immediately placed into a defined state (for more information refer to the PORTS chapter in the User Manual).

An Emergency Stop may be triggered by either of the following emergency events:

- A transition on the port which is configured as the Emergency Stop input
- An SMU alarm event or SMU command which is enabled and configured to generate an Port Emergency Stop (PES)

The figure below shows a diagram of the emergency stop input logic. This logic is controlled by the Emergency Stop Register GCC_EMSR. There is also a possibility of using a Glitch filter, implemented in the SMU_SAFE0, for the Port A. For Port B the Glitch filter is implemented within SMU_GCC.

Attention**: **When a fault signaling protocol (FSP) is used on the Port A, the Port A cannot be chosen as input trigger for the Emergency Stop

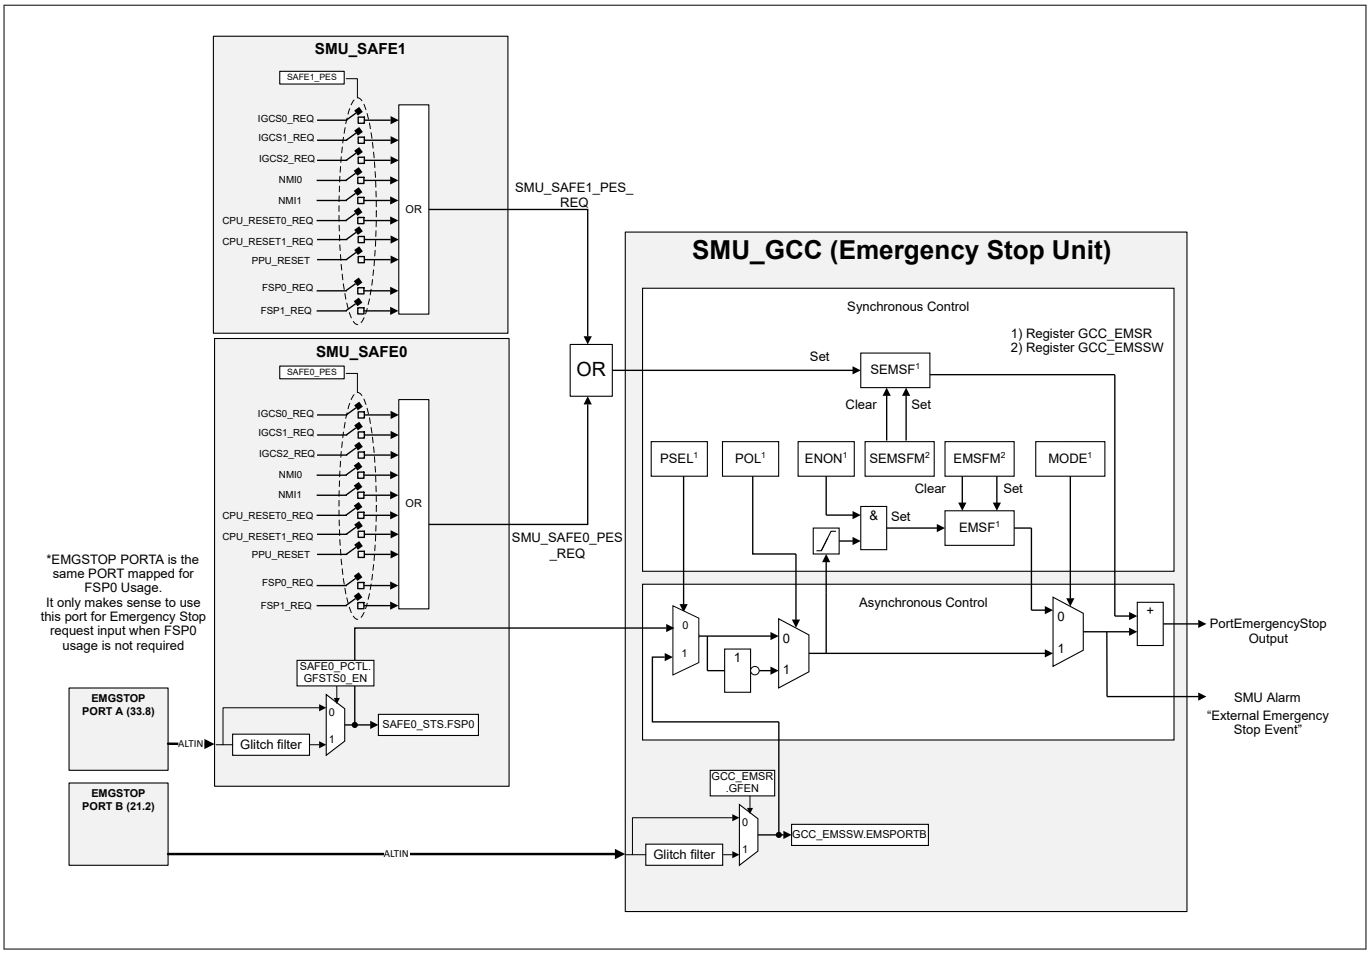

Figure 992 Emergency stop control

42.3.5.2.1 Port triggered emergency stop

The SMU can be configured to trigger an emergency stop on either transition edge of either one of two ports.

The two input port options are (PORT A) P 33.8 and (PORT B) P21.2.

The emergency stop control logic for the ports can basically operate in two modes:

- Synchronous Mode (default after reset): Emergency case is activated by hardware and released by software
- Asynchronous Mode: Emergency case is activated and released by hardware

In Synchronous Mode (selected by GCC_EMSR.MODE = 0), the port signal is sampled for an inactive-to-active level transition, and an emergency stop flag GCC_EMSR.EMSF is set if the transition is detected. The setting of GCC_EMSR.EMSF activates the emergency stop. A port triggered emergency state can only be terminated by clearing GCC_EMSR.EMSF by software (Write GCC_EMSR.EMSFM with 10_B). The synchronous control logic is clocked by the system bus clock f_{SPB}. This results in a small delay between the port signal and emergency stop signal generation.

In Asynchronous Mode (selected by GCC_EMSR.MODE = 1), the occurrence of an active level at the port input immediately activates the emergency stop signal. Of course, a valid-to-invalid transition of the port input (emergency case is released) also immediately deactivates the emergency stop signal.

The GCC_EMSR.POL bit determines the active level of the input signal from the port. The GCC_EMSR.MODE bit selects Synchronous or Asynchronous Mode for emergency stop signal generation and the GCC_EMSR.PSEL bit selects which of the two ports is used as the emergency stop trigger.

42.3.5.2.2 SMU_SAFE0 or SMU_SAFE1 event triggered emergency stop

The Safety Alarm(s) which can trigger an Emergency Stop are configured and enabled within the SMU_SAFE0 or SMU_SAFE1. All SMU_SAFE0 or SMU_SAFE1 triggered Emergency Stop cases are in Synchronous Mode, regardless of the state of GCC_EMSR.MODE. The safety emergency stop flag GCC_EMSR.SEMSF is set when a configured and enabled SMU_SAFE0 or SMU_SAFE1 Safety Alarm occurs. The setting of GCC_EMSR.SEMSF activates the emergency stop. An SMU_SAFE0 or SMU_SAFE1 triggered emergency state can only be terminated by clearing the GCC_EMSR.SEMSF by software (Write SEMSFM with 10_B). The synchronous control logic is clocked by the system bus clock f_{SPB}.

42.3.5.3 Access protection

The SMU_GCC registers are accessed by SPB bus and are access protected based on PROT and BUS Access Protection Unit (APU) mechanism. More explanation for the PROT and APU based access protection can be found in the FPI chapter (section Access Protection) in the user manual.

The SMU_GCC has a Safe Endinit PROT Register (GCC_PROTGSE) that controls access to the Bus Access Protection Unit (APU) registers (GCC_ACCEN_WRA, GCC_ACCEN_WRB, GCC_ACCEN_RDA, GCC_ACCEN_RDB, GCC_ACCEN_VM, GCC_ACCEN_PRS). Only the PROT owner defined GCC_PROTGSE can configure the Bus APU registers. Bus APU registers define the access rule for the SMU_GCC configuration and status register. The SMU_GCC configuration and status register are read- or write- access protected as defined by BUS APU registers of protection group PGCC in the register overview.

For certain configuration registers, the write access is controlled by the PROT owner defined in SMU_GCC Endinit PROT Register (GCC_PROTGE). These registers are marked with GE in the Register Overview table.

Besides PROT and APU based access protection, the SMU_GCC has an internal locking mechanism. This locking mechanism is controlled by GCC_KEYS register and is explained in the Safety Manual chapter SM[HW]:SMU:LOCK. Please always refer to the device specific safety manual to find out which safety mechanisms of this functional block need to be considered for safety relevant applications.

42.3.6 SMU_STDBY

SMU_STDBY is a redundant safety alarm handler that can monitor the failure of the SMU_SAFE0, SMU_SAFE1, SMU_CS and other common cause failure initiators of the microcontroller. Within SMU_STDBY each safety alarm can be individually configured to trigger external reactions on FSP independently from SMU_SAFE0, SMU_SAFE1. In the Alarm Handling section it is explained how incoming alarms are processed. SMU_STDBY is provided with back-up voltage and f_{BACK} clock (refer to the PMS and Clocking chapter of the UM for more details) in order to achieve independence from SMU_SAFE0, SMU_SAFE1 and SMU_CS.

42.3.6.1 Alarm handling

This section specifies the hardware and software alarm processes.

42.3.6.1.1 Alarm configuration

Upon reception of an alarm event, the SMU_STDBY either does not generate any reaction, or sets FSP[0...3] in high impedance state (tristate) or drives FSP[0...3] to low with internal pull-down circuit. All of these behaviors can be configured indvidually for each alarm.

The external behavior for any incoming alarm ALMSTDBY*i*[*z*], where *i*=0-4 indicates the alarm group and *z*=0-31 indicates the alarm number, is configured by enabling the corresponding bit-fields of the following registers:

- AGSTDBYi_FSP0.FEz
- AGSTDBYi_FSP1.FEz
- AGSTDBYi_FSP2.FEz
- AGSTDBYi_FSP3.FEz

For example for ALMSTDBY**0**[**5**] the intended reaction is to generate Fault State on FSP0 and FSP1, then AGSTDBY0_FSP0.FE5 and AGSTDBY0_FSP1.FE5 needs to be configured as 1.

CMDSTDBY.SMUEN shall also be set to enable the FSP reaction on FSP[0...3]. Moreover, through the bit-fields in the register CMDSTDBY.FSPxEN, with x = 0-3, it is possible to enable or disable the reaction on the corresponding FSP. These bit-fields need to be enabled besides the alarm mapping register. The FSP Fault State can be configured for corresponding FSP pins by bit-fields CMDSTDBY.FSPxPD where *x* = 0-3. The Fault State on the FSP pin can be high impedance state (tristate) or low driven by internal pull-down circuit.

The status flag in the alarm status registers AGSTDBYi_STS (where i=0-4) is set to 1 by hardware whenever an alarm event is received by SMU_STDBY. Software can clear this status flag by first writing 1 to bitfield CMDSTDBY.ASCE and then writing 1 to the corresponding status flags in the AGSTDBYi_STS (where i=0-4) register. Afterwards the bit CMDSTDBY.ASCE is reset to 0 by hardware. Therefore, for clearing status flags from multiple status registers AGSTDBYi_STS (where i=0-4), the complete sequence described before needs to be performed for each individual status register AGSTDBYi_STS (where i=0-4). However multiple status flags within the same register can be cleared by first writing 1 to bitfield CMDSTDBY.ASCE and then writing 1 to all the corresponding status flags in the alarm status register AGSTDBYi_STS (where i=0-4) in a single write operation.

***Note**: In order to recognize the high impedance state of the FSP Pins (ErrorPins) as the Fault State, an external pull-down device might be necessary, whereas with CMDSTDBY.FSPxPD set to be 1, this is not required.*

Attention**: **When the SMU_STDBY, sets the FSP[0] or FSP[1] in high impedance state as an alarm reaction, the corresponding status field SAFE0_STS.FSP0 or SAFE0_STS.FSP1 will be set to 1 even if no external pull-down device is connected to the respective ErrorPin. The same condition is true for FSP[2] and FSP[3] and its corresponding status fields SAFE1_STS.FSP0 and SAFE1_STS.FSP1.

42.3.6.2 Interface to the pads (ErrorPin)

The SMU_STDBY has the ability to signal an error to the external world by the FSP pin (ErrorPin) independently from SMU_SAFE0 or SMU_SAFE1.

The figure below specifies the data path connectivity of the SMU_STDBY with the FSP0 pin (ErrorPin0). The ErrorPin0 is connected to the SMU_STDBY by standard ENPS signal and PD_EN signal. The ENPS signal can be driven low by the SMU_STDBY which would set FSP0 in high impedance state regardless of the port configuration and SMU_SAFE0 reactions, if an alarm event reaction is mapped to FSP0. Moreover, if the bitfield CMDSTDBY.FSP0PD is set to 1, PD_EN signal drives the ErrorPin0 to low state with internal pull down circuit.

Otherwise, an external pull-down device might be needed to make the high impedance state correspond to the FSP Fault State.

The behavior of all of the rest of the FSP[1..3] pins is also the same as explained above, which can be configured by their corresponding bitfields in CMDSTDBY register and separate signals controlling the corresponding pins.

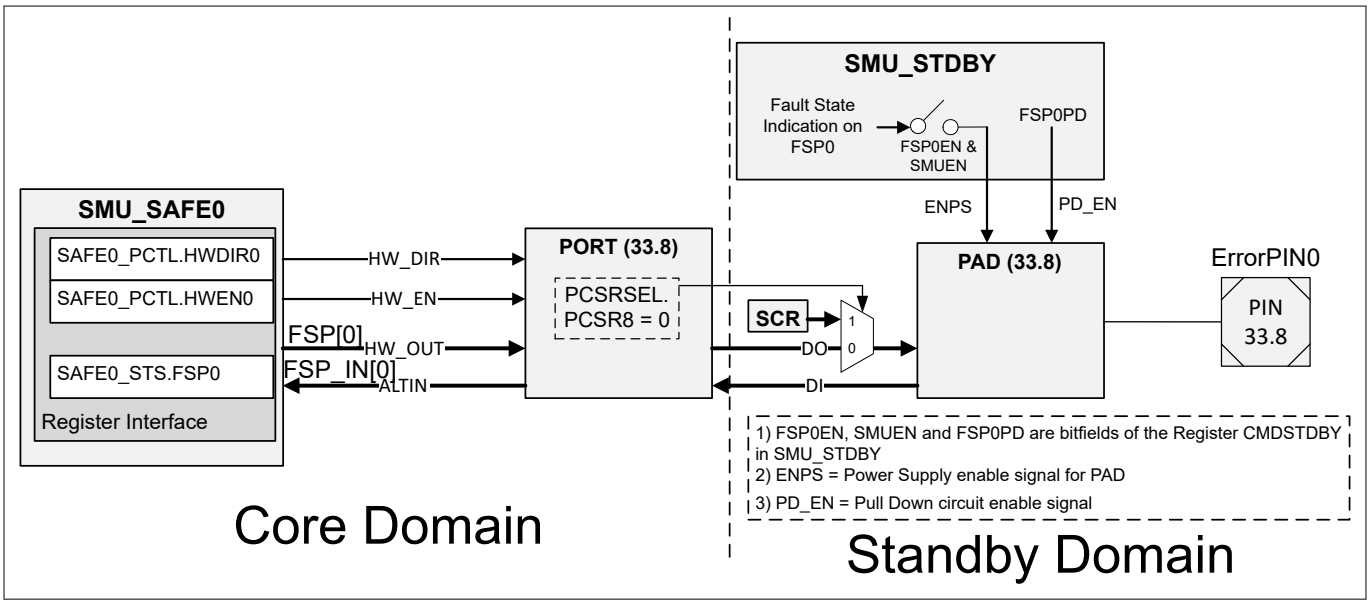

Figure 994 SMU_STDBY data path interfaces with the ErrorPins

For more information refer to the Related information.

Related information

Interface to the ports pad on page 7103

42.3.6.3 Interdependency between SMU_SAFE0 (or SMU_SAFE1) and SMU_STDBY

The SMU_SAFE0 (or SMU_SAFE1) and SMU_STDBY are designed to function together. SMU_STDBY can only be used to react to alarms when the SMU_SAFE0 (or the SMU_SAFE1) is enabled and their corresponding state machine (SSM0 or SSM1) is in RUN state. The reasons are listed below:

- Fault Signaling Protocol is generated by the SMU_SAFE0 (or SMU_SAFE1)
- If the SMU_SAFE0 (or SMU_SAFE1) is not enabled and their corresponding state machine is not in RUN State, the ErrorPin remains in their default state, which is the FSP Fault State
- Therefore, the reaction of the SMU_STDBY to any alarm (setting the ErrorPin in Fault State) will not be noticeable

On the other hand the application software can configure the SMU to enable SMU_SAFE0 (or SMU_SAFE1) only and disable alarm processing in SMU_STDBY if the diverse processing of safety alarms generated by certain safety mechanisms (voltage, clock and temperature monitors) detecting potential common cause faults is not required. SMU_STDBY alarm status registers, AGSTDBYi_STS (i=0-4), are accessible to application software even when the SMU_STDBY is disabled. The application software can read SMU_STDBY alarm status registers periodically to check the occurrence of an alarm.

42.3.6.4 Access protection

The SMU_STDBY registers are accessed by SPB bus and are access protected based on PROT and BUS Access Protection Unit (APU) mechanism. More explanation for the PROT and APU based access protection can be found in the FPI chapter (section Access Protection) in the user manual.

The SMU_STDBY has a Safe Endinit PROT Register (PROTSTDBYSE) that controls access to the Bus Access Protection Unit (APU) registers (ACCENSTDBY_WRA, ACCENSTDBY_WRB, ACCENSTDBY_RDA, ACCENSTDBY_RDB, ACCENSTDBY_VM, ACCENSTDBY_PRS). Only the PROT owner defined PROTSTDBYSE can configure the Bus APU registers. Bus APU registers define the access rule for the SMU_STDBY configuration and status register. The SMU_STDBY configuration and status register are read- or write- access protected as defined by BUS APU registers of protection group P in the register overview.

For certain configuration registers, the write access is controlled by the PROT owner defined in SMU_STDBY Endinit PROT Register (PROTSTDBYE). These registers are marked with E in the Register Overview table.

Besides PROT and APU based access protection, the configuration registers (MONBISTCTRL, CMDSTDBY, AGSTDBYi_FSPj) can only be updated during the register write operation if the BITPROT field of the corresponding registers is written with 1 by the software during the same register write operation. Please always refer to the device specific safety manual to find out which safety mechanisms of this functional block need to be considered for safety relevant applications.

42.3.6.5 Reset types

The System Mode Management (SMM) implements different reset types that affect the SMU_STDBY. The reset types that are relevant for SMU_STDBY are:

- Warm PORST
- Cold PORST
- LVDPMS2 reset

The following table specifies the scope of each reset type to the SMU_STDBY functions (a function includes the control and configuration registers and the related logic).

Table 1977 Effect of reset types to SMU_STDBY functionality

System Mode Management (SMM) on page 6315

42.3.7 SMU_SAFE0, SMU_SAFE1 and SMU_CS interaction overview

This section describes the interaction between all the core domain SMU instances (SMU_CS, SMU_SAFE0, SMU_SAFE1) to other Functional Blocks.

42.3.7.1 Interface to the system mode management (SMM)

All the reset requests from the SMU are forwarded to the functional block SMM. The interface signals used are listed below:

- CS_RESET_REQ
- RESET0_REQ
- RESET1_REQ
- RESET2_REQ
- RESET3_REQ

Along with each reset request, alarm information (containing Alarm Group ALMgrp and Alarm ID ALMid), is also forwarded to SMM. The alarm information indicates which alarm has triggered reset request. The same alarm information is also captured by corresponding registers CS_RST and SAFEx_RST in SMU_CS, SMU_SAFE0 and SMU_SAFE1. In case of multiple simultaneous alarms mapped to generate a reset request, ALMgrp and ALMid indicate the alarm which is mapped to the lowest alarm group and assigned with the lowest alarm index within that alarm group. The following figure shows the interaction between SMU_CS, SMU_SAFE0 and SMU_SAFE1 to SMM.

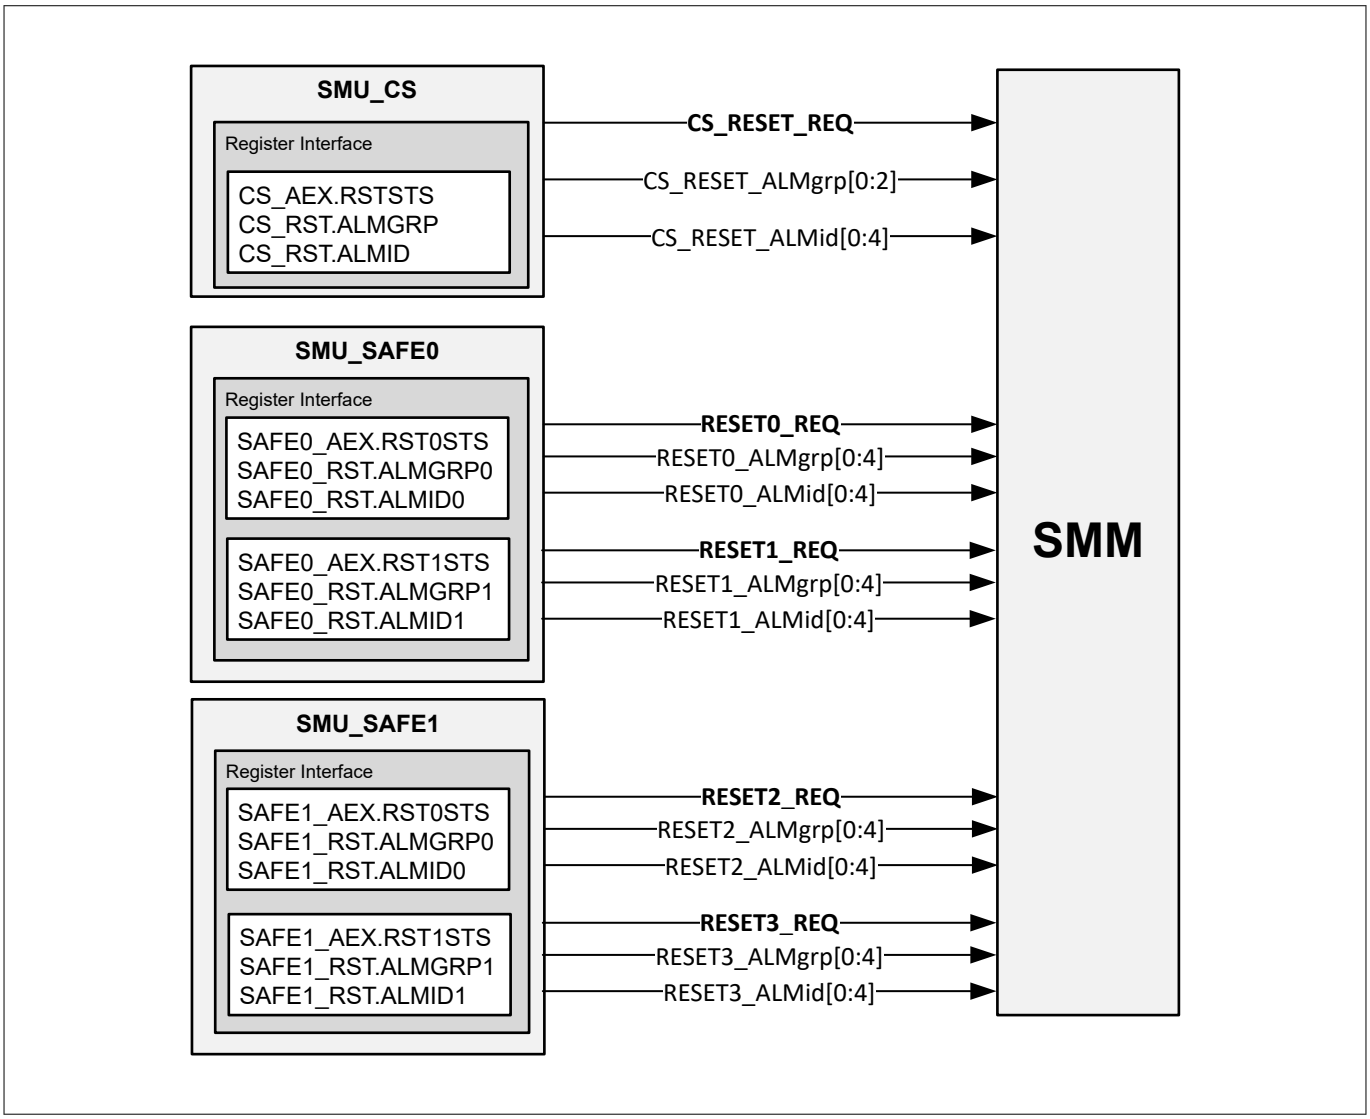

Figure 995 Interface to SMM

ALMgrp also contains information about shared alarm group ALMSH0 - ALMSH2. For detail alarm group mapping refer to table below.

Table 1978 Alarm group mapping to ALMgrp signal

Alarm group	CS_RESET_ALMgrp value	RESETx_ALMgrp value (x = 0-4)
ALMCS0 - ALMCS1	0 - 1	NA
ALMSF0 - ALMSF16	NA	0-16
ALMSH0 - ALMSH2	2-4	17-19

42.3.7.2 Interfaces to the Interrupt Router (IR)

All the interrupt service requests from the SMU are forwarded to the functional block IR. The interface signals used are listed below:

- CS_IRQ
- IRQ0
- IRQ1
- IRQ2
- IRQ3
- IRQ4
- IRQ5

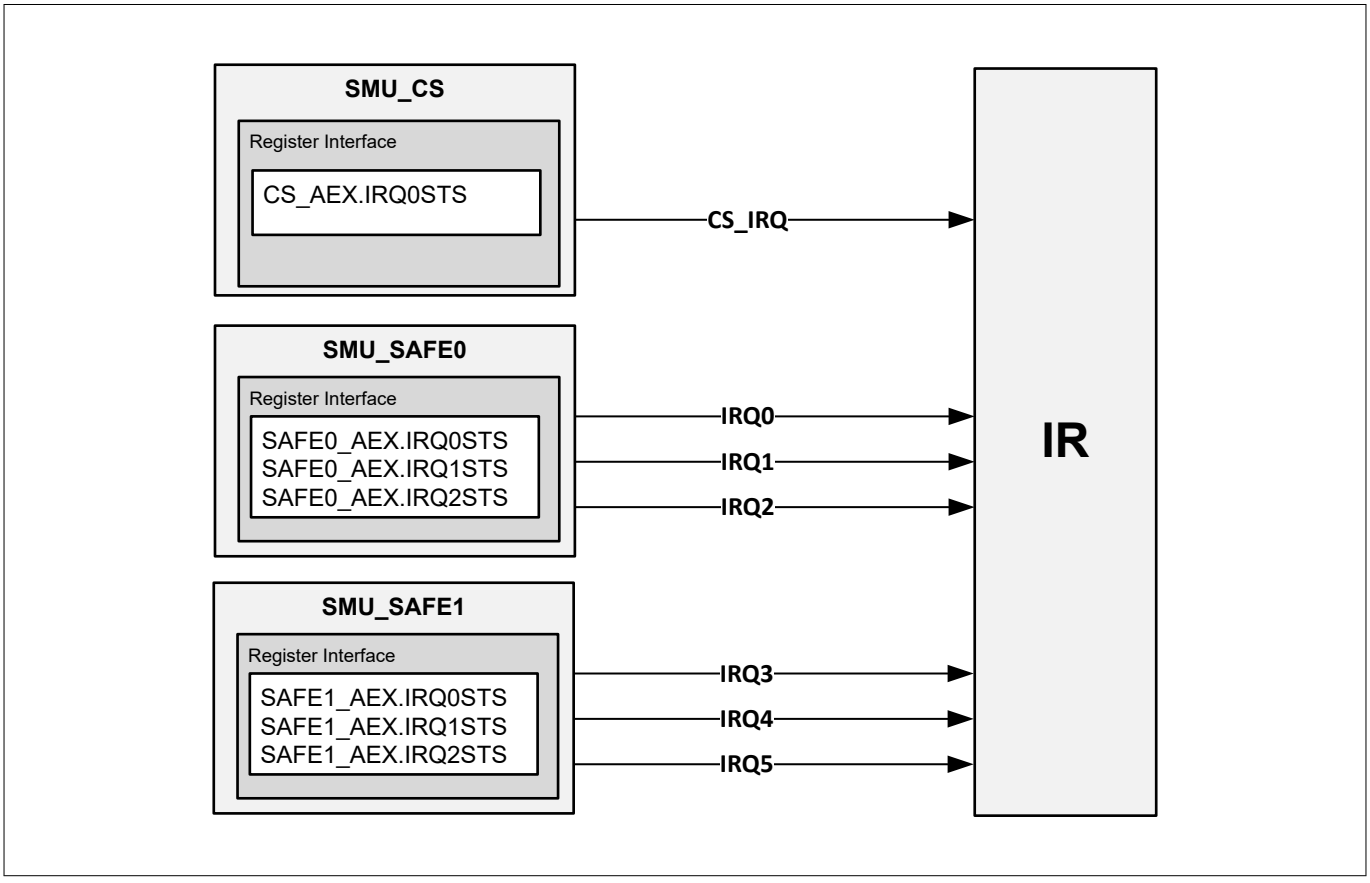

Figure 996 Interface to IR

The SAFEx_AGC.IGCSi, i={0,1,2} register fields provide the software interface to control how the SMU_SAFE0 and SMU_SAFE1 trigger interrupt requests to the interrupt router.

Each SAFEx_AGC.IGCSii is a 3-bits bit-field. For SMU_SAFE0:

- SAFE0_AGC.IGCSi[0] shall be set to 1 to trigger Interrupt Service Request 0 IRQ0
- SAFE0_AGC.IGCSi[1] shall be set to 1 to trigger Interrupt Service Request 1 IRQ1
- SAFE0_AGC.IGCSi[2] shall be set to 1 to trigger Interrupt Service Request 2 IRQ2

For SMU_SAFE1:

- SAFE1_AGC.IGCSi[0] shall be set to 1 to trigger Interrupt Service Request 3 IRQ3
- SAFE1_AGC.IGCSi[1] shall be set to 1 to trigger Interrupt Service Request 4 IRQ4
- SAFE1_AGC.IGCSi[2] shall be set to 1 to trigger Interrupt Service Request 5 IRQ5

The usage of the SAFEx_AGC.IGCSi bit-fields is defined in the figure below

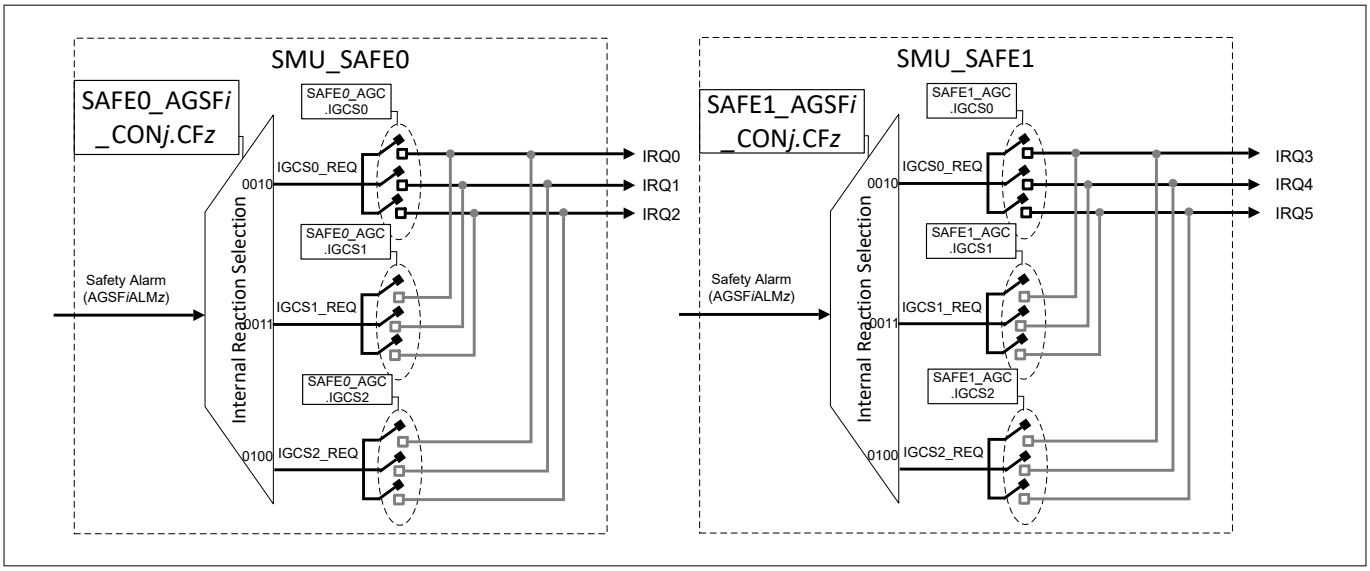

Figure 997 SMU_SAFE0 and SMU_SAFE1 interrupt service request generation

42.3.7.3 Interfaces to the System Control Unit (SCU)

All the Non-Maskable Interrupts (NMI) from the SMU are forwarded to the functional block SCU. The interface signals used are listed below:

- CS_NMI
- NMI0
- NMI1
- NMI2
- NMI3

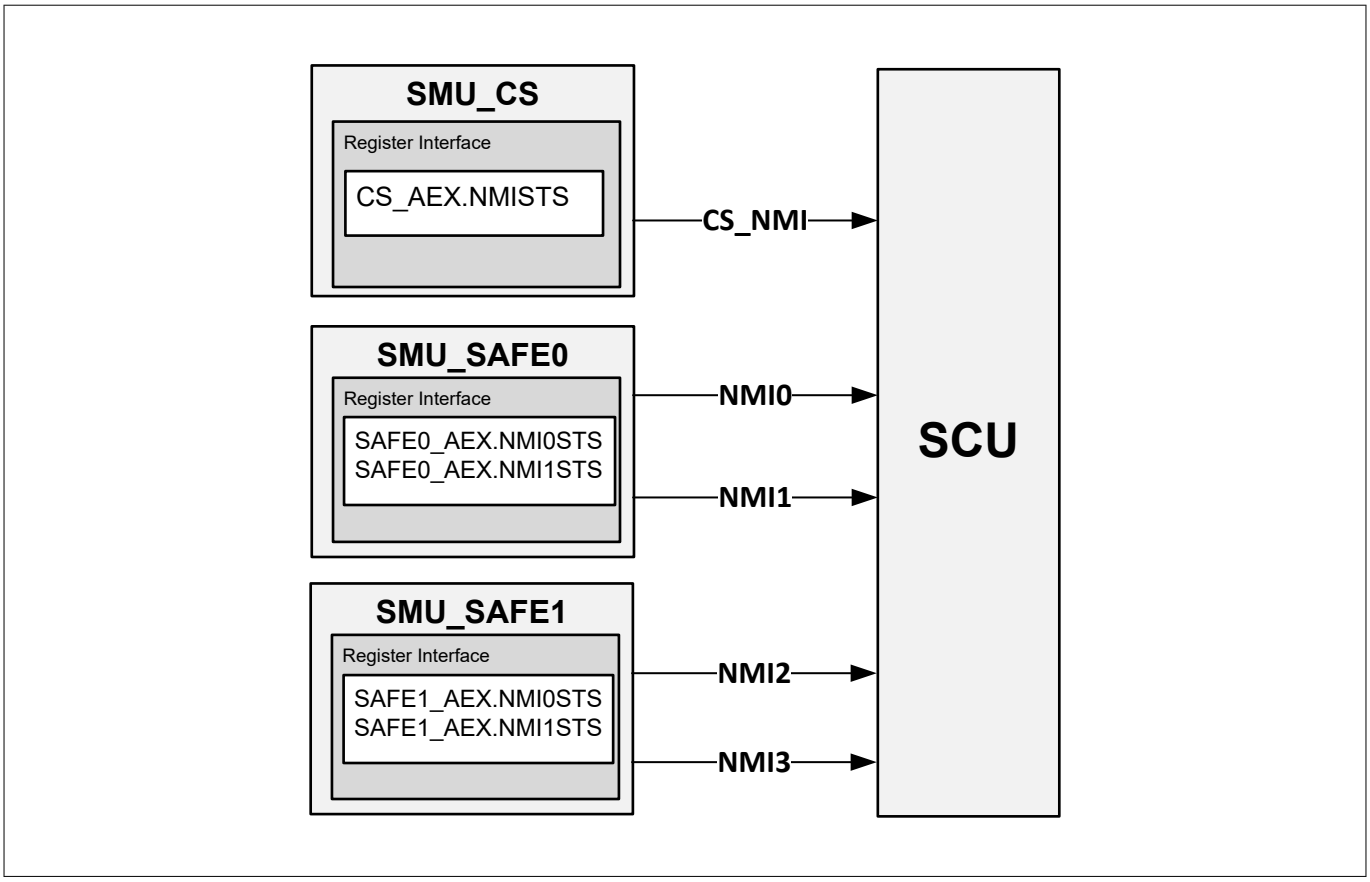

Figure 998 Interface to SCU

42.3.7.4 Interface to the Watchdog Timer Unit (WTU)

Signals indicating the RUN state of SMU_SAFE0, SMU_SAFE1 and SMU_CS state machines are forwarded to Watchdog Timer Unit (WTU). The WTU can be configured to lock certain configuration registers depending upon the state of SMU state machines (refer to the WTU chapter in user manual for more details). If any of the state machines is in the RUN state, the corresponding signal is driven to '1' otherwise in START and FAULT state the signal is driven to '0' (for SMU_CS only on case of START state since there is no FAULT state). All of the signals are listed below :

- SMU_CS state machine SSM will generate SMU_CS_RUN_STATE
- SMU_SAFE0 state machine SSM0 and SSM1 will generate two independent signals SMU_SAFE_RUN_STATE0 and SMU_SAFE_RUN_STATE1
- SMU_SAFE1 state machine SSM0 and SSM1 will generate two independent signals SMU_SAFE_RUN_STATE2 and SMU_SAFE_RUN_STATE3

42.3.7.5 Interfaces to CPU

CPU module reset request from the SMU are forwarded to the corresponding CPUs. The interface signals used are listed below:

- CPU[1:5]_RESET

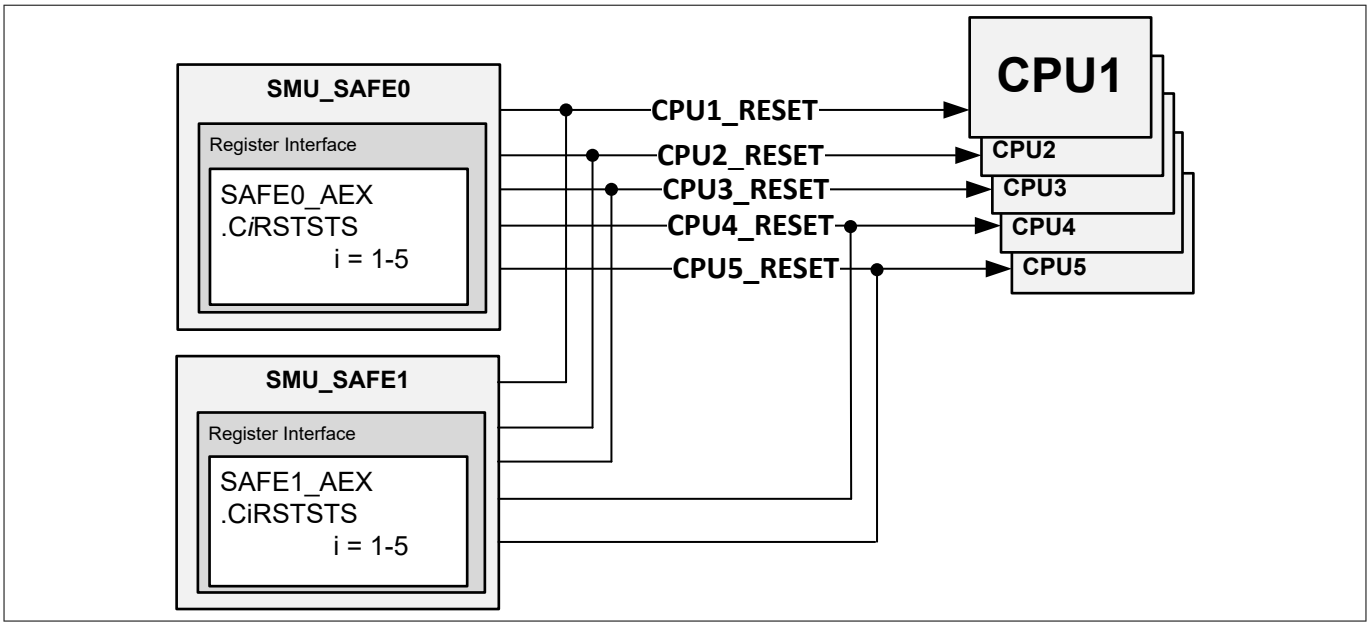

Figure 999 Interface to CPUs

As shown in the figure above, as soon as CPUi_RESET (where i = 1-5) request has been triggered, the corresponding status bits will be set. For example, if only CPU1_RESET request is triggered from SMU_SAFE0 then SAFE0_AEX.C1RSTSTS bitfield will be set.

The SAFEx_AGC.RCSi, i={0,1} register fields provide the software interface to control how the SMU_SAFE0 and SMU_SAFE1 triggers CPU module reset requests.

Each SAFEx_AGC.RCSi is a 5-bits bit-field. For both SMU_SAFE0 and SMU_SAFE1:

- SAFEx_AGC.RCSi[0] shall be set to 1 to trigger CPU1 Module Reset Request CPU1_RESET
- SAFEx_AGC.RCSi[1] shall be set to 1 to trigger CPU2 Module Reset Request CPU2_RESET
- SAFEx_AGC.RCSi[2] shall be set to 1 to trigger CPU3 Module Reset Request CPU3_RESET
- SAFEx_AGC.RCSi[3] shall be set to 1 to trigger CPU4 Module Reset Request CPU4_RESET
- SAFEx_AGC.RCSi[4] shall be set to 1 to trigger CPU5 Module Reset Request CPU5_RESET

The usage of the SAFEx_AGC.RCSi bit-fields is defined in the figure below:

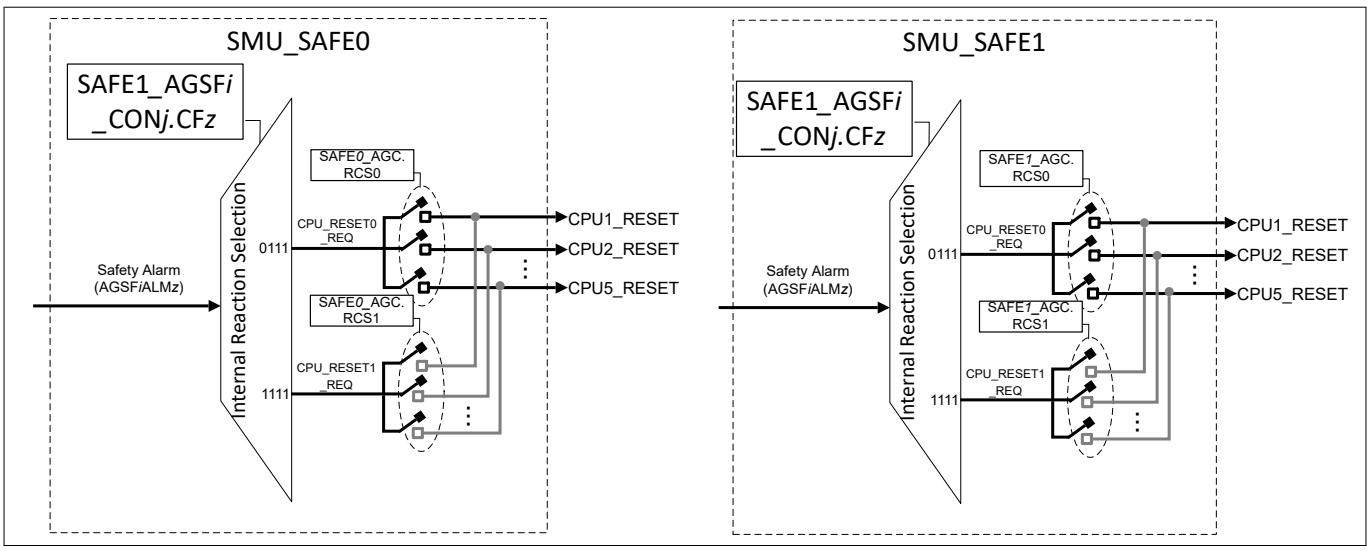

Figure 1000 SMU_SAFE0 and SMU_SAFE1 CPU reset request generation

42.3.7.6 Interface to Cyber Security Satellite (CSS)

All the locking key requests from the SMU are forwarded to the functional block CSS. The interface signals used are listed below:

- LOCK_ALL_KEYS
- LOCK_DBG_PROT_KEYS

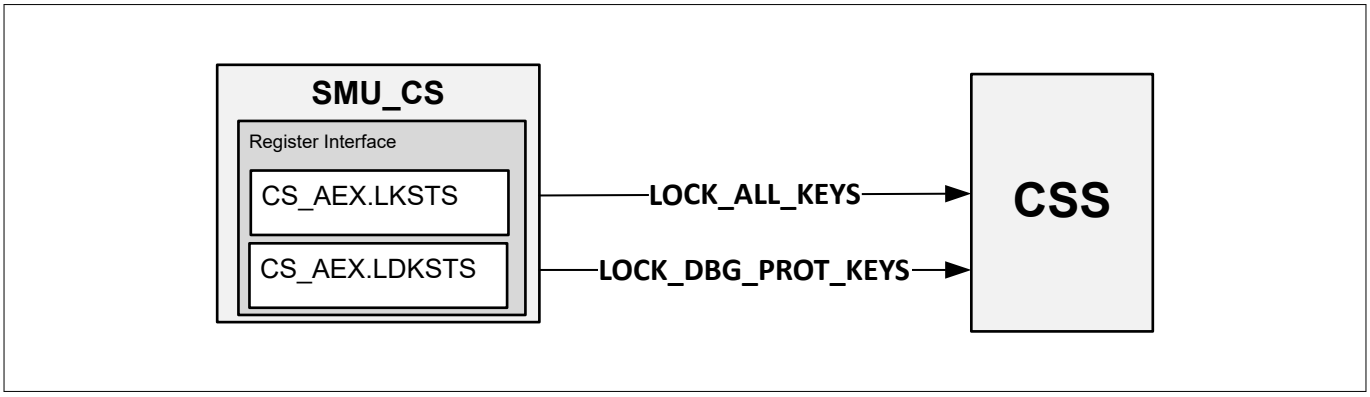

Figure 1001 Interface to CSS

42.3.7.7 Interface to the Parallel Processing Unit (PPU)

All the PPU module reset requests from the SMU are forwarded to the functional block PPU. The interface signals used are listed below:

- PPU_RESET

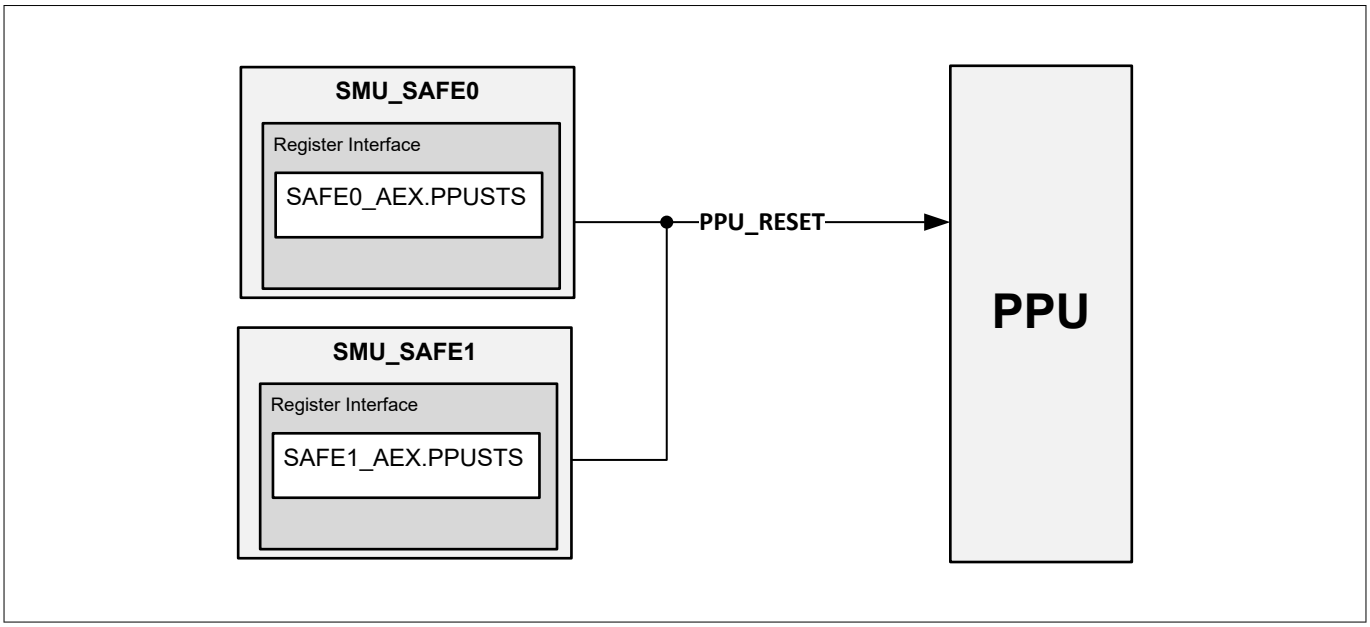

Figure 1002 Interface to PPU

42.3.7.8 Interface to the ports pad

The generic port structure is presented below:

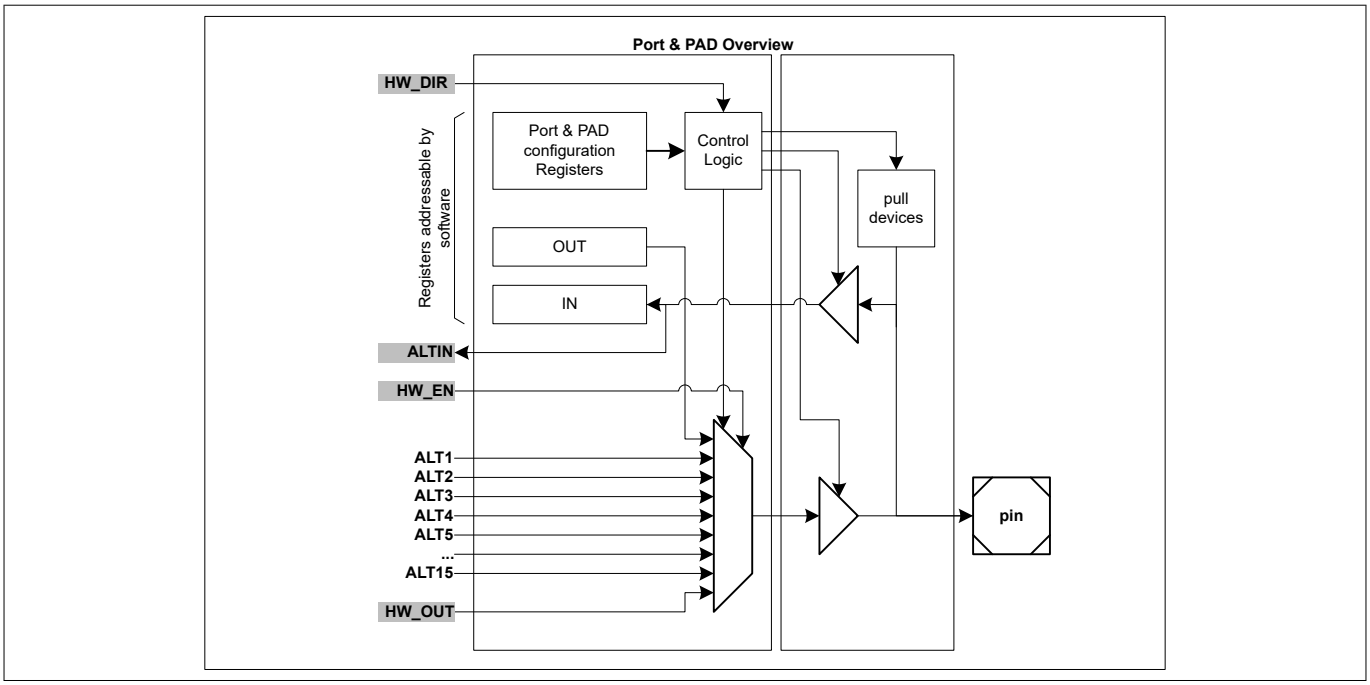

Figure 1003 Generic port structure

The port pin can be connected to peripheral with the ALTx output lines. This is the default state of the port after power-on reset (refer to the section Functional description of PORTS). The SMU_SAFE0 and SMU_SAFE1 connect to PORTS using the HW_DIR, ALTIN, HW_EN, HW_OUT signals. When the HW_EN port input is driven active by the SMU_SAFE0 or SMU_SAFE1, SMU_SAFE0 or SMU_SAFE1 gets full control over the port, bypassing any other software configuration related to the usage of the ALTx inputs.

The figure below provides a more detailed overview of the port structure and highlights the signals involved in the SMU_SAFE0 and SMU_SAFE1 connectivity. Moreover as shown in the figure, the PORT mapping to the corresponding FSP is also fixed, for example FSP0 is always mapped to PORT (33.8) and so on.

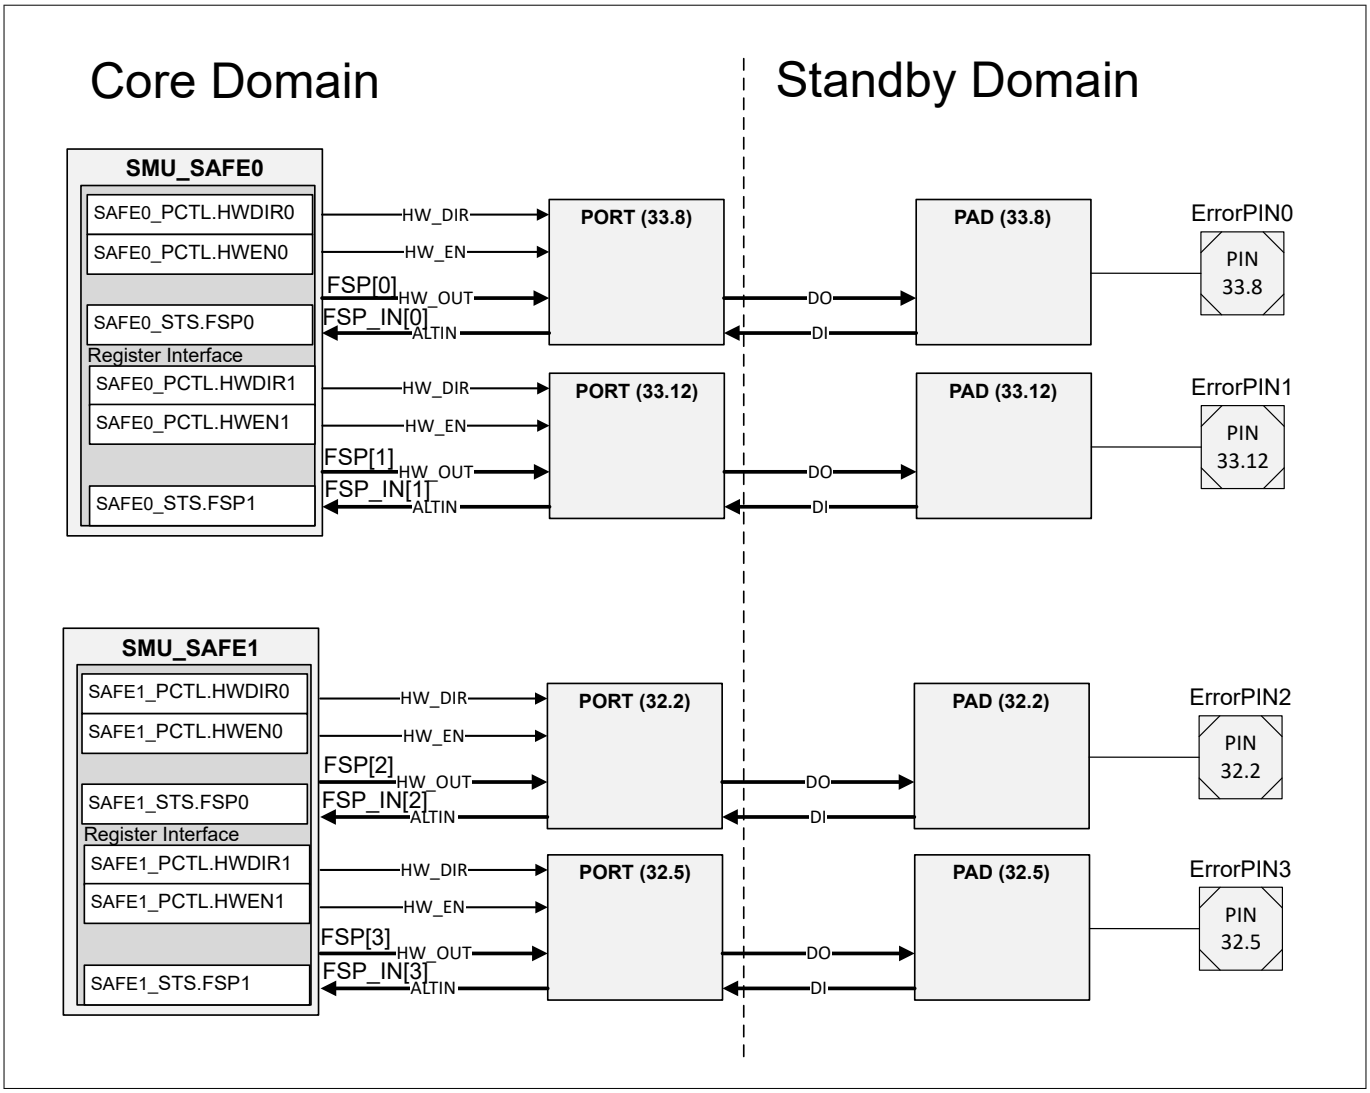

Figure 1004 SMU/PAD control interface to the PADs

All the HW_DIR and HW_EN signals are controlled by software as shown in the figure above. FSP[0], FSP[1], FSP[2] and FSP[3] in the figure above are controlled by hardware. This is shown in the figure below:

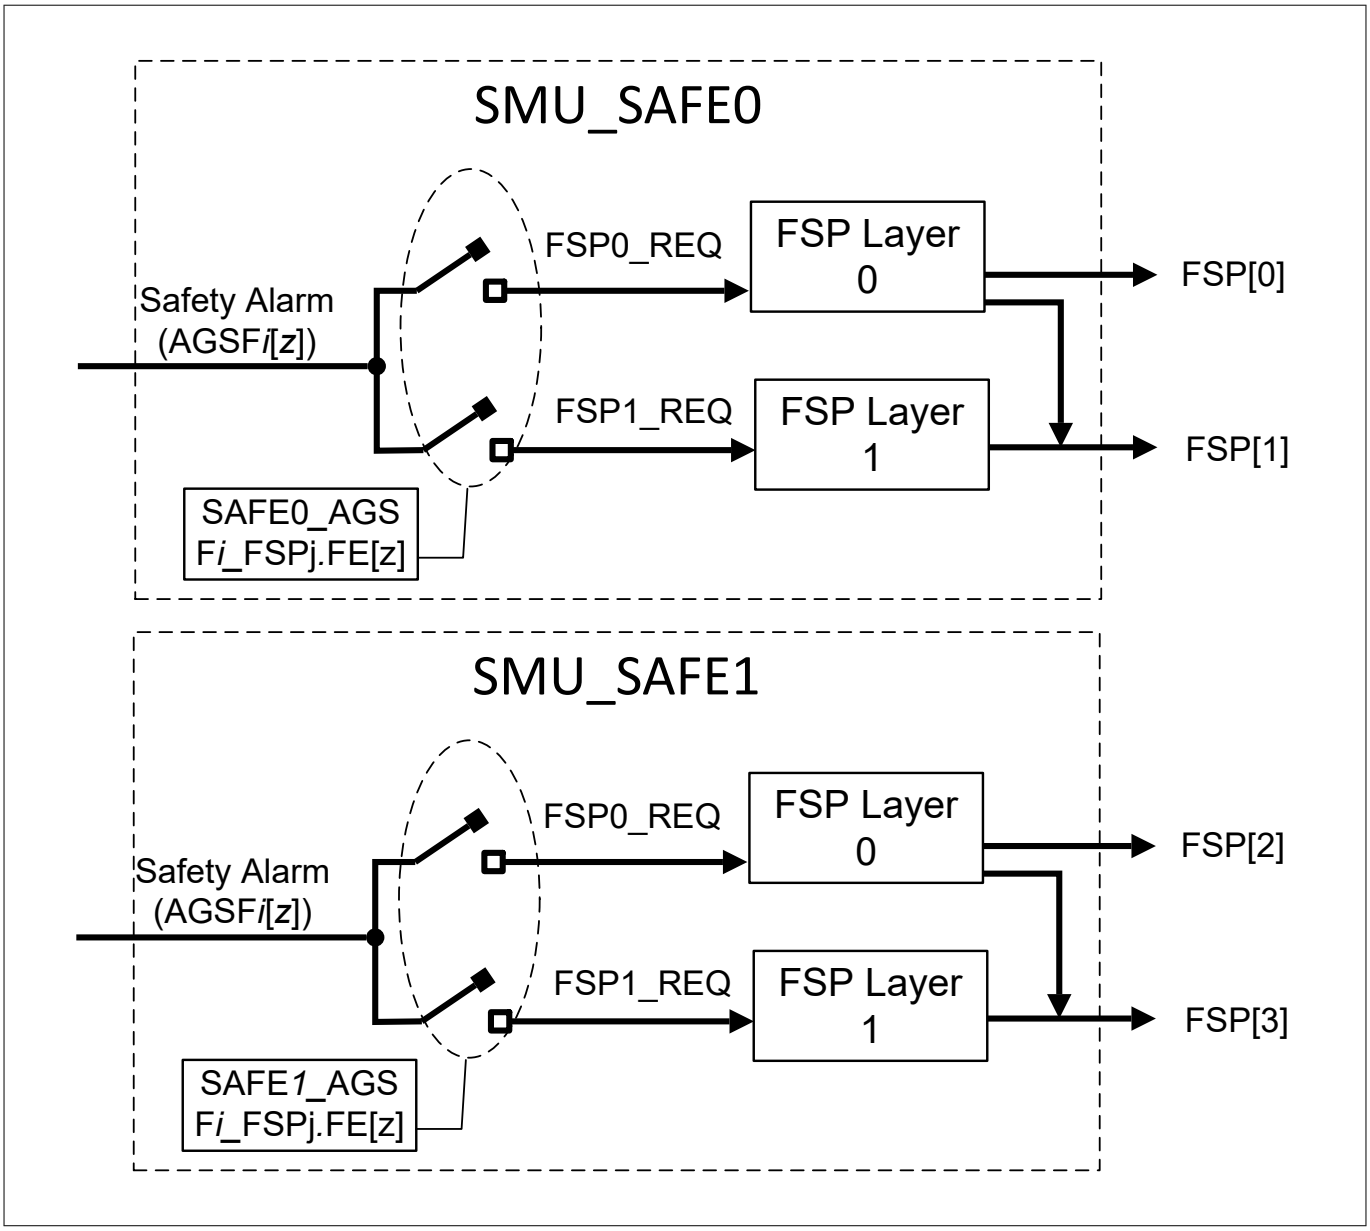

Figure 1005 SMU_SAFE0 and SMU_SAFE1 FSP to PORTS

ErrorPin usage guidelines

This section provides additional information for the usage of the ErrorPins in combination with other input/output (GPIO) functions of the microcontroller. ErrorPin0 (33.8) is used as an example below, for ErrorPins[1:3] the configuration steps remain the same and the corresponding configuration registers for ErrorPins[1:3] shall be used.

***Note**: The PAD properties (push-pull, open-drain, drive strength,...) are configured in the registers of the PORT to which the SMU connects to. These registers are described in the PORTS chapter in this UM.*

- During power-on-reset, the ErrorPin is in high impedance: the pull devices are disabled
- After power-on-reset the default mode of the PORT to which the ErrorPin is connected is GPIO
- Before changing the ownership of the PORT/PAD to SMU, software shall configure the PORT registers including the following:
  - Disable the pull-up and pull-down devices if GPIO is not used

- Program the GPIO registers of the ErrorPin with SPEED0 drive strength and set the low level output on ErrorPin. (Set P33_PADCFG8_DRVCFG.PD = 000_B and set P33_OUT.P8 = 0)
- Set P33_PCSRSEL.PCSR8 to 1

Also, the following steps need to be followed to reconfigure the Fault Signaling Protocol (FSP) settings:

- While in Fault Free State and the Bi-stable protocol is in use:
  - Write desired value to PRE1, PRE2 or TFSP_HIGH in SAFEx_FSPi_CON
  - Switch SAFEx_FSPi_CON.MODE to the desired protocol (if required)
- While in Fault Free State and the Time Switching OR Dual Rail protocol is in use:
  - Write desired value to PRE1, PRE2 or TFSP_HIGH in SAFEx_FSPi_CON

    ***Note**:* *Changing the values of SAFEx_FSPi_CON.PRE1, PRE2, or TFSP_HIGH while the FSP is active and monitored, may result in the violation of the timing expected by the monitoring function.*

  - Switch SAFEx_FSPi_CON.MODE to the desired protocol (if required)

Glitch filter

When ErrorPins are used for Fault Signaling protocol, the logic level driven on the ErrorPins can be read from corresponding status bits implemented in SMU_SAFE0 and SMU_SAFE1. Glitch filters are present in the input paths from ErrorPins to these status bits, which can filter out glitches up to 1.2 µs. The following list and figure describes each path and usage of the filter:

- FSP_IN[0] : ErrorPin0 to SAFEx_STS.FSP0 (where x = 0)
  - For this path the filter can be switched on/off with SAFEx_PCTL.GFSTS0_EN (where x = 0) bit
- FSP_IN[1] : ErrorPin1 to SAFEx_STS.FSP1 (where x = 0)
  - For this path the filter can be switched on/off with SAFEx_PCTL.GFSTS1_EN (where x = 0) bit
- FSP_IN[2] : ErrorPin2 to SAFEx_STS.FSP0 (where x = 1)
  - For this path the filter can be switched on/off with SAFEx_PCTL.GFSTS0_EN (where x = 1) bit
- FSP_IN[3] : ErrorPin3 to SAFEx_STS.FSP1 (where x = 1)
  - For this path the filter can be switched on/off with SAFEx_PCTL.GFSTS1_EN (where x = 1) bit

Glitch filter is also present in the path from EMGSTOP PORT B to Emergency Stop unit. For this path the filter can be switched on/off with GCC_EMSR.GFEN.

42.3.7.10 Interfaces to SMU_STDBY

The following figure shows an overview of the interaction between the core domain SMU instance (SMU_CS, SMU_SAFE0 and SMU_SAFE1) and the standby domain SMU instance (SMU_STDBY). Please refer to the product specific section of this document to find the product specific alarm information as well as Safety Manual for the description of safety mechanisms triggering these alarms. For SMU related alarms, refer to the sections

SM[HW]:SMU:ALIVE_MONITOR, SM[HW]:SMU:CRITICAL_ALARM and SM[HW]:SMU:REG_MONITOR in Safety Manual for corresponding Alive Alarms, Critical Alarms and SFF Uncorrectable Error Alarm.

42.4.1.1 Register overview - access mode glossary

Table 1979 Register overview - access mode glossary

Keyword	Description
CE	Access protection using PROT register CS_PROTCE.
CSE	Access protection using PROT register CS_PROTCSE.
GE	Access protection using PROT register GCC_PROTGE.
GSE	Access protection using PROT register GCC_PROTGSE.
SxE (x=0-1)	Access protection using PROT register SAFEx_PROTSE.
SxSE (x=0-1)	Access protection using PROT register SAFEx_PROTSSE.
APU-PCS	Protection group consisting of registers CS_ACCEN_WRA, CS_ACCEN_WRB, CS_ACCEN_RDA, CS_ACCEN_RDB, CS_ACCEN_VM, CS_ACCEN_PRS.
PCS	Access protection using *APU-PCS* registers.
APU-PGCC	Protection group consisting of registers GCC_ACCEN_WRA, GCC_ACCEN_WRB, GCC_ACCEN_RDA, GCC_ACCEN_RDB, GCC_ACCEN_VM, GCC_ACCEN_PRS.
PGCC	Access protection using *APU-PGCC* registers.
APU-PSAFEx (x=0-1)	Protection group consisting of registers SAFEx_ACCEN_WRA, SAFEx_ACCEN_WRB, SAFEx_ACCEN_RDA, SAFEx_ACCEN_RDB, SAFEx_ACCEN_VM, SAFEx_ACCEN_PRS.
PSAFEx	Access protection using *APU-PSAFEx* registers.
BE	Always returns a Bus Error.
32	Access only when using 32-bit width.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

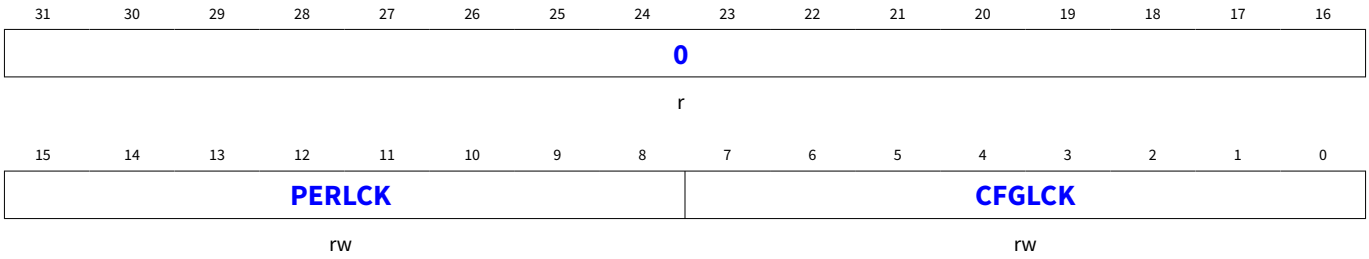
MOD_TYPE								MOD_REV							
r								r							

Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** The bit field is set to C0H, which defines the module as a 32-bit module.
MOD_NUM	31:16	r	**Module Number Value** This bit field defines a module identification number. The value for the SMU module is 0089H.

42.4.1.5 SMU_GCC Key Register

GCC_KEYS Offset address: $000C_H$

SMU_GCC Key Register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CFGLCK	7:0	rw	**Configuration Lock** The SMU_GCC configuration is only possible if this field is set to 0xBC.
PERLCK	15:8	rw	**Permanent Lock** If this field is set to 0xFF, no further configuration of the SMU_CS is possible before next application reset.
0	31:16	r	**Reserved** Read as 0; should be written with 0

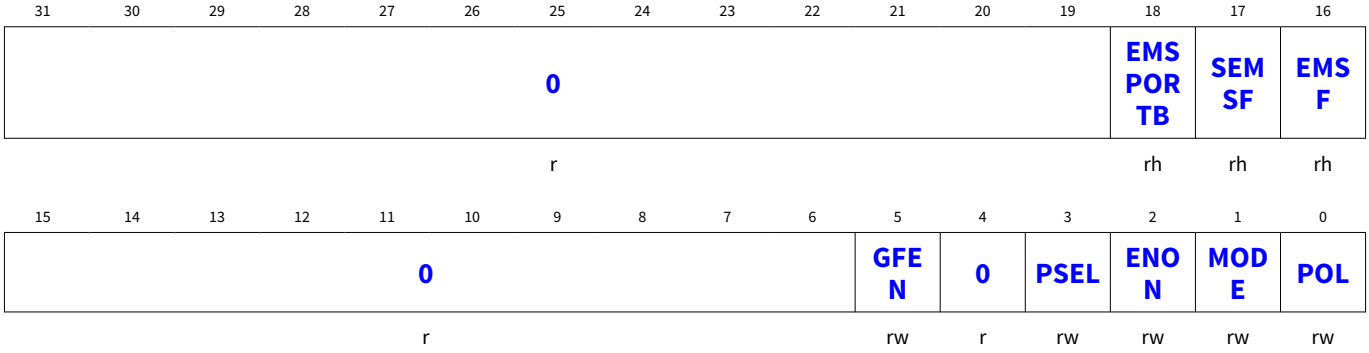
Table 1982 Access mode restrictions of GCC_KEYS sorted by descending priority

Mode name	Access mode		Description
GCC_KEYS.PERLCK != 0xFF	rw	CFGLCK, PERLCK	
(default)	r	CFGLCK, PERLCK	

42.4.1.6 Emergency Stop Register

GCC_EMSR Offset address: 0010_H

Emergency Stop Register Application Reset value: $0000\ 0001_H$



Field	Bits	Type	Description
POL	0	rw	**Input Polarity** This bit determines the polarity of the configured Emergency Stop input. 0_B Input is active high 1_B Input is active low
MODE	1	rw	**Mode Selection** This bit determines the operating mode of the emergency stop signal. 0_B Synchronous Mode selected; emergency stop is derived from the state of flag EMSF 1_B Asynchronous Mode selected; emergency stop is directly derived from the state of the input signal
ENON	2	rw	**Enable ON** This bit enables the setting of flag EMSF by an inactive-to-active level transition of input signal. 0_B Setting of EMSF is disabled 1_B Setting of EMSF is enabled
PSEL	3	rw	**PORT Select** This bit selects which one of the Emergency Stop port options is monitored. 0_B Port A is used as Emergency Stop input 1_B Port B is used as Emergency Stop input.
GFEN	5	rw	**Glitch Filter for PORT B (21.2) to register GCC_EMSSW.EMSPORTB enable** 0_B Glitch Filter disabled 1_B Glitch FIlter enabled
EMSF	16	rh	**Emergency Stop Flag** This bit indicates that a synchronous mode port-triggered emergency stop condition has occurred. 0_B An emergency stop has not occurred 1_B An emergency stop has occurred and emergency stop state becomes active (if MODE = 0)

(table continues...)

(continued)

Field	Bits	Type	Description
SEMSF	17	rh	**SMU Emergency Stop Flag** This bit indicates that an SMU_SAFE0 or SMU_SAFE1 has triggered emergency stop condition. 0_B An emergency stop has not occurred 1_B An emergency stop has occurred and emergency stop state becomes active
EMSPORTB	18	rh	**Emergency Stop External Request Port B (21.2) status** This field capture the value driven on Emergency Stop External Request input PORT B (21.2). This field is updated by hardware every clock cycle, therefore a software clear on write is not meaningful for this field.
0	4, 15:6, 31:19	r	**Reserved** Read as 0; should be written with 0.

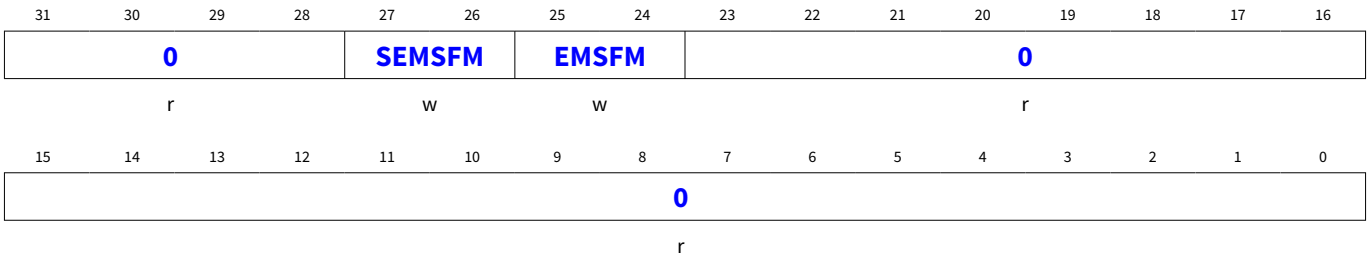
Table 1983 Access mode restrictions of GCC_EMSR sorted by descending priority

Mode name	Access mode		Description
GCC_KEYS.CFGLCK == 0xBC and **GCC_KEYS.PERLCK** != 0xFF	rw	ENON, GFEN, MODE, POL, PSEL	
(default)	r	ENON, GFEN, MODE, POL, PSEL	

42.4.1.7 Emergency Stop Software set and clear register

GCC_EMSSW Offset address: 0014_H

Emergency Stop Software set and clear register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
EMSFM	25:24	w	**Emergency Stop Flag Modification** This bit field sets or clears flag EMSF. EMSFM is always read as 00_B. 00_B EMSF remains unchanged 01_B EMSF becomes set 10_B EMSF becomes cleared 11_B EMSF remains unchanged

(table continues...)

(continued)

Field	Bits	Type	Description
SEMSFM	27:26	w	**SMU Emergency Stop Flag Modification** This bit field sets or clears flag SEMSF. SEMSFM is always read as 00_B. 00_B SEMSF remains unchanged 01_B SEMSF becomes set 10_B SEMSF becomes cleared 11_B SEMSF remains unchanged
0	23:0, 31:28	r	**Reserved** Read as 0; should be written with 0.

42.4.1.8 Register Monitor Control i

GCC_RMi_CTL (i=0-1) Offset address: 0018_H+i*12

Register Monitor Control i Application Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
CMD	3:0	rwh	**Last command received** Same encoding as CMD field of CS_CMD register
ARG	7:4	rwh	**Last command argument received** Same encoding as ARG field of CS_CMD register
RES	8	rwh	**Result of last received command** 0_B Command was successful 1_B Command failed

(table continues...)

(continued)

Field	Bits	Type	Description
ASCE	9	rwh	**Alarm Status Clear Enable** This bit controls if a status flag set in an CS_AGCSi_STS register upon detection of an alarm event can be cleared by software or not. When ASCE is enabled software shall write a 1 to the bit position in CS_AGCSi_STS to clear the bit. When CS_AGCSi_STS is cleared, the ASCE bit is automatically cleared to 0 by hardware and software shall set the ASCE bit again by using the SMU_ASCE() command. 0_B Alarm status bits CSAG3*i* can not be cleared 1_B Alarm status bits CSAG3*i* can be cleared.
RTS0	16	rwh	**Recovery Timer 0 Status** State of the recovery timer 0 0_B Recovery Timer not running 1_B Recovery Timer running
RTME0	17	rwh	**Recovery Timer 0 Missed Event** Recovery timer trigger request missed 0_B Recovery Timer event not detected 1_B Recovery Timer event detected
0	15:10, 31:18	r	**Reserved** Read as 0; should be written with 0.

42.4.1.24 SMU_CS Recovery Timer Configuration

This register controls the timing duration of the recovery timer.

CS_RTC Offset address: 0208_H

SMU_CS Recovery Timer Configuration Application Reset value: 003F FF01$_H$

(table continues...)

(continued)

Field	Bits	Type	Description
PRE	4:2	rw	**Prescaler For Recovery Timer Clock** Dividing factor to apply to the reference clock f_{BACK}. It is assumed that the maximum value for f_{BACK} is 100 Mhz with a precision of 5%. The divided clock is used as reference clock for recovery timer. The frequency of the divided clock is defined as follows: 000_B reference clock frequency divided by 2 001_B reference clock frequency divided by 4 010_B reference clock frequency divided by 8 011_B reference clock frequency divided by 16 100_B reference clock frequency divided by 32 101_B reference clock frequency divided by 64 110_B reference clock frequency divided by 128 111_B reference clock frequency divided by 256
RTD	31:8	rw	**Recovery Timer Duration** This field specifies the maximum duration of the recovery timer. When the timer counter reaches the programmed value, the internal time-out alarm is triggered. The timer is stopped by a SMU_RTStop() command before the recovery timer timeout occurs. RTD shall be specified as a number of the f_{BACK}/CS_RTC.PRE clock ticks. ***Note**: It is not allowed to write to the RTD when at least one recovery timer is running.*
0	1, 7:5	r	**Reserved** Read as 0; should be written with 0

rh	rh	r			rh	rh	r								rh

Field	Bits	Type	Description
IRQ0STS	0	rh	**CSIRQ Request Status** This bit indicates whether a CSIRQ request was serviced or not. This bit is set by the SMU_CS after an alarm configured for CSIRQ is detected. This bit can be cleared by writing with ´1´ to the IRQ0C bit in the CS_AEXCLR register. 0_B NO CSIRQ request was serviced 1_B CSIRQ request was serviced

(table continues...)

(continued)

Field	Bits	Type	Description
NMISTS	9	rh	**CS_NMI Request Status** This bit indicates whether a CS_NMI request was serviced or not. This bit is set by the SMU_CS after an alarm configured for CS_NMI is detected. This bit can be cleared by writing with ´1´ to the NMIC bit in the related CS_AEXCLR register. 0_B NO CS_NMI request was serviced 1_B CS_NMI request was serviced
RSTSTS	10	rh	**CS_RESET Request Status** This bit indicates whether a CS_RESET request was serviced or not. This bit is set by the SMU_CS after an alarm configured for CS_RESET is detected. 0_B NO CS_RESET request was serviced 1_B CS_RESET request was serviced
LDKSTS	14	rh	**LOCK_DBG_PROT_KEYS Request Status** This bit indicates whether a LOCK_DBG_PROT_KEYS request was serviced or not. This bit is set by the SMU_CS after an alarm configured for LOCK_DBG_PROT_KEYS is detected. This bit can be cleared by writing with ´1´ to the LDKC bit in the CS_AEXCLR register. 0_B NO LOCK_DBG_PROT_KEYS request was serviced 1_B LOCK_DBG_PROT_KEYS request was serviced
LKSTS	15	rh	**LOCK_ALL_KEYS Request Status** This bit indicates whether a LOCK_ALL_KEYS request was serviced or not. This bit is set by the SMU_CS after an alarm configured for LOCK_ALL_KEYS is detected. This bit can be cleared by writing with ´1´ to the LKC bit in the related CS_AEXCLR register. 0_B NO LOCK_ALL_KEYS request was serviced 1_B LOCK_ALL_KEYS request was serviced
IRQ0AEM	16	rh	**CSIRQ AEM** This bit indicates that an alarm event is missed. That means that an alarm has occurred with configuration for CSIRQ Request where this alarm handler was blocked because CS_AEX.IRQ0STS was already set. This bit can be cleared by writing with ´1´ to the IRQ0AEMC bit in the CS_AEXCLR register. 0_B No alarm is missed 1_B At least one alarm is missed

(table continues...)

(continued)

Field	Bits	Type	Description
NMIAEM	25	rh	**CS_NMI AEM** This bit indicates that an alarm event is missed. That means that an alarm has occurred with configuration for CS_NMI Request where this alarm handler was blocked because CS_AEX.NMISTS was already set. This bit can be cleared by writing with ´1´ to the NMIAEMC bit in the CS_AEXCLR register. 0_B No alarm is missed 1_B At least one alarm is missed
LDKAEM	30	rh	**LOCK_DBG_PROT_KEYS AEM** This bit indicates that an alarm event is missed. That means that an alarm has occurred with configuration for LOCK_DBG_PROT_KEYS Request where this alarm handler was blocked because CS_AEX.LDKSTS was already set. This bit can be cleared by writing with ´1´ to the LDKAEMC bit in the CS_AEXCLR register. 0_B No alarm is missed 1_B At least one alarm is missed
LKAEM	31	rh	**LOCK_ALL_KEYS AEM** This bit indicates that an alarm event is missed. That means that an alarm has occurred with configuration for LOCK_ALL_KEYS Request where this alarm handler was blocked because CS_AEX.LKSTS was already set. This bit can be cleared by writing with ´1´ to the LKAEMC bit in the CS_AEXCLR register. 0_B No alarm is missed 1_B At least one alarm is missed
0	8:1, 13:11, 24:17, 29:27	r	**Reserved** Read as 0; should be written with 0.

42.4.1.31 SMU_CS Alarm Executed Status Clear Register

The Alarm Executed Status Clear register is used to clear the Alarm Executed Status(CS_AEX) register.

CS_AEXCLR Offset address: 0224_H

SMU_CS Alarm Executed Status Clear Register Application Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
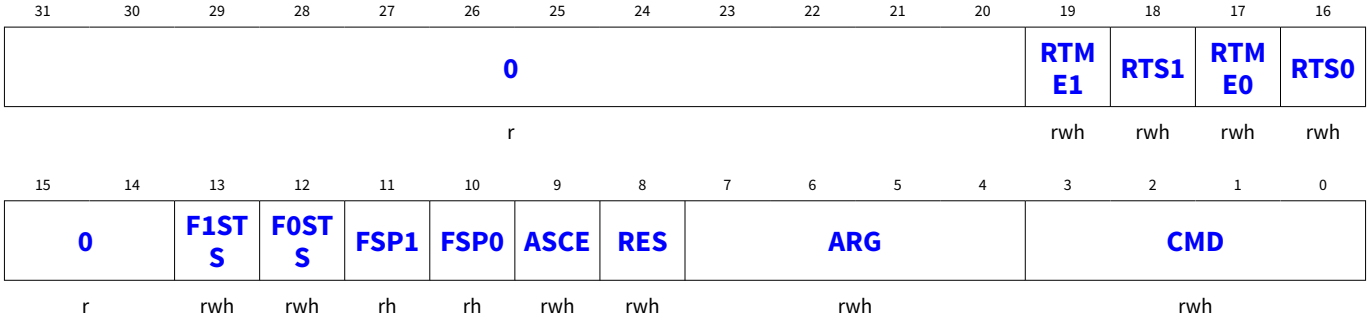
0	31:8	r	**Reserved** Read as 0; should be written with 0

42.4.1.53 SMU_SAFE x Status Register

***Note**: A write to this register (regardless of the data written) clears all the fields with the rwh type. If on the same cycle a software write event and hardware event is detected, the hardware action wins.*

SAFEx_STS (x=0-1) Offset address: $1004_H+x*500_H$

SMU_SAFE x Status Register Reset values see: Table 2012



Field	Bits	Type	Description
CMD	3:0	rwh	**Last command received** Same encoding as CMD field of SAFEx_CMD register
ARG	7:4	rwh	**Last command argument received** Same encoding as ARG field of SAFEx_CMD register
RES	8	rwh	**Result of last received command** 0_B Command was successful 1_B Command failed
ASCE	9	rwh	**Alarm Status Clear Enable** This bit controls if a status flag set in an SAFEx_AGSFi_STS register upon detection of an alarm event can be cleared by software or not. When ASCE is enabled software shall write a 1 to the bit position in SAFEx_AGSFi_STS to clear the bit. When SAFEx_AGSFi_STS is cleared, the ASCE bit is automatically cleared to 0 by hardware and software shall set the ASCE bit again by using the SMU_ASCE() command. 0_B Alarm status bits AG<x> can not be cleared 1_B Alarm status bits AG<x> can be cleared.

(table continues...)

(continued)

Field	Bits	Type	Description
FSP0	10	rh	**Fault Signaling Protocol status** FSP0 = FSP_STS[0] input signal This field is updated by hardware every clock cycle. Note: When the FSP[0] is set in Fault State by the SMU_STDBY this bitfield does not reflect the actual state of the ErrorPins if the SMU_STDBY sets the ErrorPins in high impedence state to indicate the presence of a fault.
FSP1	11	rh	**Fault Signaling Protocol status** FSP1 = FSP_STS[1] input signal This field is updated by hardware every clock cycle. Note: When the FSP[1] is set in Fault State by the SMU_STDBY this bitfield does not reflect the actual state of the ErrorPins if the SMU_STDBY sets the ErrorPins in high impedence state to indicate the presence of a fault.
F0STS	12	rwh	**Fault State Timing Status 0** This bit indicates if the minimum timing duration of the FSP Fault State (TFSP_FS) on FSP[0] has been reached or not. The bit is cleared by hardware when the Fault State is entered. 0_B Minimum timing duration not reached 1_B Minimum timing duration reached
F1STS	13	rwh	**Fault State Timing Status 1** This bit indicates if the minimum timing duration of the FSP Fault State (TFSP_FS) on FSP[1] has been reached or not. The bit is cleared by hardware when the Fault State is entered. 0_B Minimum timing duration not reached 1_B Minimum timing duration reached
RTS0	16	rwh	**Recovery Timer 0 Status** State of the Recovery Timer 0. 0_B Recovery Timer not running 1_B Recovery Timer running
RTME0	17	rwh	**Recovery Timer 0 Missed Event** Recovery timer 0 trigger request missed. 0_B Recovery Timer event not detected 1_B Recovery Timer event detected
RTS1	18	rwh	**Recovery Timer 1 Status** State of the Recovery Timer 1. 0_B Recovery Timer not running 1_B Recovery Timer running
RTME1	19	rwh	**Recovery Timer 1 Missed Event** Recovery timer 1 trigger request missed. . 0_B Recovery Timer event not detected 1_B Recovery Timer event detected

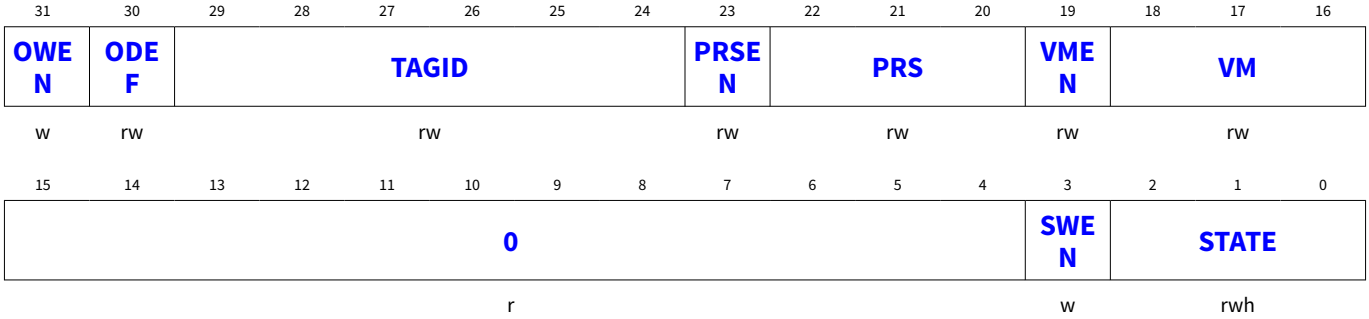
42.4.1.81 SMU_SAFE x PROT Register Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock / unlock of the local Endinit (SxE) protected control registers.

SAFEx_PROTSE (x=0-1) Offset address: $13FC_H+x*500_H$

SMU_SAFE x PROT Register Endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual Machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual Machine definition Enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection Set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection Set definition Enable for PROT owner** 0_B **Disable**: PRS is part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

42.4.2 Registers of SMU_STANDBY

This chapter shows specific information related to the SMU_STDBY registers.

42.4.2.1 Register overview - access mode glossary

Table 2049 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTSTDBYE.
SE	Access protection using PROT register PROTSTDBYSE.
APU-P	Protection group consisting of registers ACCENSTDBY_WRA, ACCENSTDBY_WRB, ACCENSTDBY_RDA, ACCENSTDBY_RDB, ACCENSTDBY_VM, ACCENSTDBY_PRS.
P	Access protection using *APU-P* registers.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

42.4.2.2 Registers overview - SMU_STDBY (ascending offset address)

Table 2050 Registers overview - SMU_STDBY (ascending offset address)

42.4.2.3 SMU_STDBY BIST Status Register

Refer to MONBIST section in PMS chapter.

MONBISTSTAT Offset address: 9814_H

SMU_STDBY BIST Status Register Reset values see: Table 2051

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0							SMUERR3	SMUERR2	SMUERR1	SMUERR0	PMSERR	TSTDONE	TSTRUN	0	TSTOK
r							rh	rh	rh	rh	rh	rh	rh	r	rh

Field	Bits	Type	Description
TSTOK	0	rh	**SMU_stdby BIST ok bit** This status bit indicates that MONBIST test was successful and the result is as expected. 0_B The MONBIST test result is not ok. 1_B The MONBIST test result is ok.
TSTRUN	2	rh	**SMU_stdby BIST run bit** The status bit indicates that MONBIST test is ongoing. 0_B The MONBIST test is currently inactive. 1_B The MONBIST test is active.
TSTDONE	3	rh	**SMU_stdby BIST done bit** The status bit indicates that MONBIST test is completed. 0_B The MONBIST test is not started. 1_B The MONBIST test is done.
PMSERR	4	rh	**Error found in PMS SARADC by SMU_stdby BIST** This status bit indicates that SMU_stdby BIST found an error in the PMS SARADC. 0_B No error happened in PMS module during MONBIST test. 1_B This bit is set if MONBIST test failed and the error occurred in Secondary voltage monitor and alarm generation in PMS. This status bit is cleared by setting TSTCLR bit.
SMUERRz (z=0-3)	z+5	rh	**Error found in SMU_stdby found by SMU_stdby BIST** This status bit indicates that the MONBIST test found an error in the SMU_stdby. 0_B No error happened in SMU_STDBY module during MONBIST test. 1_B This bit is set if MONBIST test failed and the error occurred in SMU_STDBY module and alarm processing path. This status bit is cleared by setting TSTCLR bit..
0	1, 31:9	r	**Reserved** Read as 0; should be written with 0.

Table 2051 Reset values of MONBISTSTAT

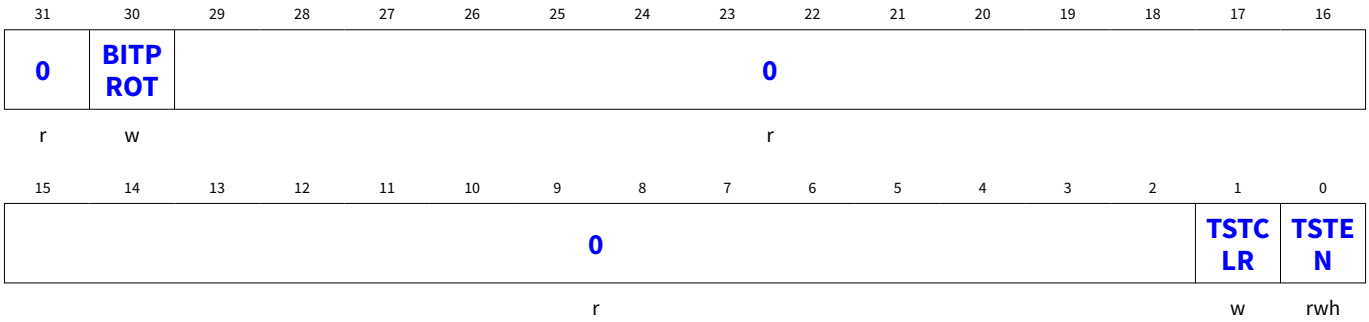
Reset type	Reset value	Note
LVDPMS2 Reset	$0000\ 0000_H$	
Warm PORST	$0000\ 0000_H$	

42.4.2.4 SMU_STDBY BIST Control Register

Refer to MONBIST section in PMS chapter.

MONBISTCTRL Offset address: 9818_H

SMU_STDBY BIST Control Register Reset values see: Table 2053



Field	Bits	Type	Description
TSTEN	0	rwh	**SMU_stdby alarm BIST enable** If SMUEN in the CMD_stdby register is set to 1, setting the TSTEN bit triggers SMU_stdby BIST tests to test the alarm path and PMS components. This bit can only be changed if bit BITPROT is set in parallel. This bit is cleared by hardware at the end of the SMU_stdby BIST operation. 0_B SMU_stdby BIST test is inactive 1_B SMU_stdby BIST test triggered. When the SMU_stdby BIST is activated, the alarm signals tested by the bist are not propagated to the SMU_SAFE0/1.
TSTCLR	1	w	**SMU_stdby BIST flag clear** Setting this bit enables the clearing of the bitfields TSTOK, TSTDONE, TSTRUN, SMUERR and PMSERR of register MONBISTSTAT. 0_B No action 1_B The bitfields TSTOK, TSTDONE, TSTRUN, SMUERR and PMSERR of register MONBISTSTAT are cleared. Before triggering SMU_stdby BIST mechanism with TSTEN, previous test results need to be cleared by TSTCLR.
BITPROT	30	w	**Bit Protection TSTEN** Setting this bit enables that bit TSTEN can be changed in this write operation. This bit is read as zero.
0	29:2, 31	r	**Reserved** Read as 0; should be written with 0.

Table 2052 Access mode restrictions of MONBISTCTRL sorted by descending priority

r						rwh	rw	rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
SMUEN	0	rw	**SMU_stdby Module Enable** This bit enables SMU_stdby to issue a FSP reaction when an alarm is received. Also, SMUEN needs to be set to enter the SMU_stdby BIST mode. 0_B SMU_stdby disabled. 1_B SMU_stdby enabled.
FSP0EN	1	rw	**SMU_stdby FSP0 Error pin enable** This bit enables SMU_stdby Error pin function to be able set P33.8 to fault state. 0_B SMU_stdby Error Pin fault indication function on P33.8 inactive. 1_B SMU_stdby Error Pin fault indication function on P33.8 active.
FSP1EN	2	rw	**SMU_stdby FSP1 Error pin enable** This bit enables SMU_stdby Error pin function to be able set P33.12 to fault state. 0_B SMU_stdby Error Pin fault indication function on P33.12 inactive. 1_B SMU_stdby Error Pin fault indication function on P33.12 active.
FSP2EN	3	rw	**SMU_stdby FSP2 Error pin enable** This bit enables SMU_stdby Error pin function to be able set P32.2 to fault state. 0_B SMU_stdby Error Pin fault indication function on P32.2 inactive. 1_B SMU_stdby Error Pin fault indication function on P32.2 active.
FSP3EN	4	rw	**SMU_stdby FSP3 Error pin enable** This bit enables SMU_stdby Error pin function to be able set P32.5 to fault state. 0_B SMU_stdby Error Pin fault indication function on P32.5 inactive. 1_B SMU_stdby Error Pin fault indication function on P32.5 active.

(table continues...)

(continued)

Field	Bits	Type	Description
FSP0PD	5	rw	**SMU_stdby FSP0 Error pull-down** This bit defines the error reaction of SMU_stdby ErrorPin0 (P33.8). 0_B Pulled down state inactive. 1_B *Pulled down state active.*
FSP1PD	6	rw	**SMU_stdby FSP1 Error pull-down** This bit defines the error reaction of SMU_stdby ErrorPin1 (P33.12). 0_B Pulled down state inactive. 1_B *Pulled down state active.*
FSP2PD	7	rw	**SMU_stdby FSP2 Error pull-down** This bit defines the error reaction of SMU_stdby ErrorPin2 (P32.7). 0_B Pulled down state inactive. 1_B *Pulled down state active.*
FSP3PD	8	rw	**SMU_stdby FSP3 Error pull-down** This bit defines the error reaction of SMU_stdby ErrorPin3 (P32.5). 0_B Pulled down state inactive. 1_B *Pulled down state active.*
ASCE	9	rwh	**SMU_stdby alarm status clear enable** This bit controls if a status flag set in an AGSTDBYi_STS register upon detection of the alarm event can be cleared by software or not. When ASCE is enabled, software shall write a 1 to bit position in AGSTDBYi_STS to clear the bit (W1C). When a W1C action takes place the ASCE bit is automatically cleared to 0 by hardware and software shall set the ASCE bit again. 0_B SMU_stdby alarm status bits in AGSTDBYi_STS cannot be cleared. 1_B SMU_stdby alarm status bits in AGSTDBYi_STS can be cleared
BITPROT	30	w	**CMDSTDBY register bits protection** Setting this bit enables the other bits in the registers (SMUEN, FSP0EN, FSP1EN, FSP2EN, FSP3EN, FSP0PD, FSP1PD, FSP2PD, FSP3PD, ASCE) to be changed in the same write operation. This bit is read as zero.
0	29:10, 31	r	**Reserved** Read as 0; should be written with 0.

42.4.2.14 SMU_STDBY PROT Register Safe Endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSTDBYSE register controls lock / unlock of the local Safe Endinit (SE) protected control registers.

0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

42.5 Debug information

The SMU supports the standard OTGB Interface. The trigger sets are described in the following section.

42.5.1 OCDS trigger bus (OTGB) interface

The SMU concentrates all failure indicator signals (alarms) of the device. By using them as MCDS trace information (failure type) and trace control (stop trace recording), the analysis of a failure's root cause is supported. This is even the case, when the alarm handling within the system includes a PORST, since the content of the trace memory will be still valid after the PORST.

The alarms handled in the SMU are very rare and sporadic. So it's acceptable that they are visible on the Trigger Bus with a small delay and not all in parallel with a cycle accurate timing resolution. The SMU Trigger Sets are shown on tables (Table 2072, Table 2073, Table 2074) below. It is output on OTGB0 or OTGB1 controlled by the OCS register.

Table 2072 TS16_SMU_SAFE0 trigger set SMU

Bits	Name	Description
0	AA	Any ALM bit active
[5:1]	AGI	ALM Group Index
[7:6]	ABI	ALM Byte Index, selecting the byte within the ALM group
[15:8]	ALM	Selected byte of the ALM group

Table 2073 TS16_SMU_SAFE1 trigger set SMU

Bits	Name	Description
0	AA	Any ALM bit active
[5:1]	AGI	ALM Group Index
[7:6]	ABI	ALM Byte Index, selecting the byte within the ALM group
[15:8]	ALM	Selected byte of the ALM group

Table 2074 TS16_SMU_CS trigger set SMU

Bits	Name	Description
0	AA	Any ALM bit active
[2:1]		Reserved
[5:3]	AGI	ALM Group Index
[7:6]	ABI	ALM Byte Index, selecting the byte within the ALM group
[15:8]	ALM	Selected byte of the ALM group

The table below shows the mapping of alarm groups and the value appeared in AGI fields for TS16_SMU_CS and TS16_SMU_SAFE0/1 Trigger Sets. The values shown in the table are all decimal values.

Table 2075 ALM group index (AGI) mapping

Alarm Group	TS16_SMU_CS AGI	TS16_SMU_SAFE0/1 AGI
ALMCS0 - ALMCS1	0 - 1	NA

(table continues...)

Table 2075 (continued) ALM group index (AGI) mapping

Alarm Group	TS16_SMU_CS AGI	TS16_SMU_SAFE0/1 AGI
ALMSF0 - ALMSF16	NA	0-16
ALMSH0 - ALMSH2	2-4	17-19

For any Trigger Set, If no alarm is active, TS16_SMU_SAFE0/SAFE1/CS will be all zero. If alarms are only active within one ALM Byte, TS16_SMU_SAFE0/SAFE1/CS will show statically this byte. If alarms are active in two or more ALM Bytes, TS16_SMU_SAFE0/SAFE1/CS will change between these bytes.

Note that due to the implementation, all the ALM Bytes are being scanned once per clock cycle, the TS16_SMU_SAFE0/SAFE1 ALM Byte information on OTGB0/1 can be delayed by up to 71 clock cycles for the second alarm. On the other hand TS16_SMU_CS ALM Byte information on OTGB0/1 can be delayed by up to 23 clock cycles for the second alarm. TS16_SMU_SAFE0/SAFE1/CS.AA will however become active (and inactive) immediately. The implementation will make sure, that the ALM Byte with the first causing alarm will be traced with MCDS before a reset as safety action clears this information.

Moreover depending upon the global CSAV level the behavior of TS16_SMU_CS is described below:

Table 2076 CSAV levels and TS16_SMU_CS behavior

CSAV	TS16_SMU_CS behavior
Full	Normal behavior as described above
Limited	No information about incoming alarm to SMU_CS is provided, always appear zeros on trigger set
No	No information about incoming alarm to SMU_CS is provided, always appear zeros on trigger set

***Note**: In some cases, it might be possible to clear an alarm faster than it is captured on the OTGB. Therefore software needs to take care that the time from an incoming alarm until it is cleared is longer than 68 f_{SPB} clock cycles for SMU_SAFE0/1 and 20 f_{SPB} clock cycles for SMU_CS to ensure that the alarm is captured on the OTGB.*

42.6 References

This section is not applicable for the module being described.

42.7 SMU revision history

Initial release of the chapter.

Module	Base address	End address	Note
SMU	$F0028000_H$	$F0029FFF_H$	FPI slave interface

42.8.4.1.2 Register overview - access mode glossary

Table 2079 Register overview - access mode glossary

Keyword	Description
CE	Access protection using PROT register SMU_CS_PROTCE .
CSE	Access protection using PROT register SMU_CS_PROTCSE .
GE	Access protection using PROT register SMU_GCC_PROTGE .
GSE	Access protection using PROT register SMU_GCC_PROTGSE .
SxE (x=0-1)	Access protection using PROT register SMU_SAFEx_PROTSE .
SxSE (x=0-1)	Access protection using PROT register SMU_SAFEx_PROTSSE .
APU-PCS	Protection group consisting of registers SMU_CS_ACCEN_WRA , SMU_CS_ACCEN_WRB , SMU_CS_ACCEN_RDA , SMU_CS_ACCEN_RDB , SMU_CS_ACCEN_VM , SMU_CS_ACCEN_PRS .
PCS	Access protection using *APU-PCS* registers.
APU-PGCC	Protection group consisting of registers SMU_GCC_ACCEN_WRA , SMU_GCC_ACCEN_WRB , SMU_GCC_ACCEN_RDA , SMU_GCC_ACCEN_RDB , SMU_GCC_ACCEN_VM , SMU_GCC_ACCEN_PRS .
PGCC	Access protection using *APU-PGCC* registers.
APU-PSAFEx (x=0-1)	Protection group consisting of registers SMU_SAFEx_ACCEN_WRA , SMU_SAFEx_ACCEN_WRB , SMU_SAFEx_ACCEN_RDA , SMU_SAFEx_ACCEN_RDB , SMU_SAFEx_ACCEN_VM , SMU_SAFEx_ACCEN_PRS .
PSAFEx	Access protection using *APU-PSAFEx* registers.
BE	Always returns a Bus Error.
32	Access only when using 32-bit width.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.

42.8.4.2.4 Device specific registers

There are no device specific register changes.

42.8.5 TC4Dx SMU alarm mapping tables

The Alarm Mapping tables specify the mapping between the alarms implemented within the TC4Dx device and the assigned Alarm Index within SMU. Please refer to the Safety Manual for a detailed description of which safety mechanisms trigger which alarms.

There is a direct relationship between an Alarm Index and their corresponding configuration and status registers. The examples below show how the alarm index and group numbers of a particular alarm are related to the register names, as explained also in the Alarm Mapping chapter. Since the same naming principle applies for all alarms within an alarm group, only one example per alarm group is shown below.

For safety alarm groups ALMSF, the following registers and bit-fields can be used to configure the alarm reaction and getting the status related to alarm mapped to Alarm Index ALMSF1[10] :

- SAFEx_AGSFi_CONj.**CF10** (where x=0-1;**i = 1**;j=0-3)
- SAFEx_AGSFi_FSPj.**FE10** (where x=0-1;**i = 1**;j=0-1)
- SAFEx_AGSFi_STS.**SF10** (where x=0-1;**i = 1**)
- SAFEx_AGSFi_DBG.**DF10** (where x=0-1;**i = 1**)
- SAFEx_AGSFi_CAS.**CF10** (where x=0-1;**i = 1**)

For security alarm groups ALMCS, the following registers and bit-fields can be used to configure the alarm reaction and getting the status related to alarm mapped to Alarm Index ALMCS1[9] :

- CS_AGCSi_CONj.**CF9** (where **i = 1**;j=0-2)
- CS_AGCSi_STS.**SF9** (where **i = 1**)
- CS_AGCSi_DBG.**DF9** (where **i = 1**)
- CS_AGCSi_CAS.**CF9** (where **i = 1**)

For shared alarm groups ALMSH , the following registers and bit-fields can be used to configure the alarm reaction and getting the status related to alarm mapped to Alarm Index ALMSH1[10] :

- GCC_AGSHi_SEL.**CF10** (where **i = 1**)
- GCC_AGSHi_SS.**SF10** (where **i = 1**)
- CS_AGSHi_SEL.**CF10** (where **i = 1**)
- CS_AGSHi_SS.**SF10** (where **i = 1**)
- CS_AGSHi_CONj.**CF10** (where **i = 1**;j=0-2)
- CS_AGSHi_STS.**SF10** (where **i = 1**)
- CS_AGSHi_DBG.**DF10** (where **i = 1**)
- CS_AGSHi_CAS.**CF10** (where **i = 1**)
- SAFEx_AGSHi_CONj.**CF10** (where x=0-1;**i = 1**;j=0-3)
- SAFEx_AGSHi_FSPj.**FE10** (where x=0-1;**i = 1**;j=0-1)
- SAFEx_AGSHi_STS.**SF10** (where x=0-1;**i = 1**)
- SAFEx_AGSHi_DBG.**DF10** (where x=0-1;**i = 1**)
- SAFEx_AGSHi_CAS.**CF10** (where x=0-1;**i = 1**)

For safety alarm groups ALMSTDBY , the following registers and bit-fields can be used to configure the alarm reaction and getting the status related to alarm mapped to Alarm Index AGSTDBY1[8] :

- SMUSTDBY_AGSTDBYi_FSPj.**FE8** (where **i = 1**;j=0-3)
- SMUSTDBY_AGSTDBYi_STS.**SF8** (where **i = 1**)

For any Alarm Index having the corresponding Functional Block and Alarm Name columns marked as 'Reserved', it means that no alarm is mapped to that particular Alarm Index in the current device. As a consequence, the reading or writing to the corresponding bit-fields in the configuration and status registers as explained above will not have any impact.

42.8.5.1 Safety alarm mapping tables

Table 2084 Alarm mapping table for ALMSF0

Alarm index	Functional block instance	Alarm name
ALMSF0[0]	CPU0	CPU lockstep mismatch alarm CPU CFI lockstep mismatch alarm

42.8.5.3 System trigger alarm mapping tables

System trigger alarms originate from safety mechanisms that are not used in the safety concept. Therefore, they are not relevant to the safety integrity of the device and the system integrator is not required to configure a safe reaction upon their occurrence. However, they can still be used in the system if it is considered as useful, for example to generate a fast reaction on a specific event. In such a case, it is the responsibility of the system integrator to ensure that the use of these alarms meets the needs of the application. Similar to any safety alarm, system trigger alarms can be configured within SMU_SAFE0, SMU_SAFE1 or SMU_STDBY to trigger a specific reaction.

Table 2106 System trigger alarm mapping table for ALMSF0

42.8.6 TC4Dx SMU register monitor mapping tables

The Register Monitor Mapping tables specify the mapping between the Register Monitor interfaces implemented within the TC4Dx device and the assigned Register Monitor (RM) Index within SMU.

There is a direct relationship between the numbering of an RM Index and the corresponding configuration and status registers. For any RM index RM**i**[**z**], the same numbers **i** and **z** shall be used to locate the corresponding registers and bit-field as shown below:

- GCC_RMi_CTL.TE**z**
- GCC_RMi_EF.EF**z**
- GCC_RMi_STS.STS**z**

The following example shows the particular case with i=1 and z=10, but the same principle applies for all RM indexes and registers. For RM**1**[**10**] the following registers and bit-fields apply:

- GCC_RM1_CTL.TE**10**
- GCC_RM1_EF.EF**10**
- GCC_RM1_STS.STS**10**

For any RM Index having the corresponding Functional Block column marked as 'Reserved', it means that no Register Monitor Interface is mapped to that particular RM Index in the current device. As a consequence, the reading or writing to the corresponding bit-fields in the configuration and status registers as explained above will not have any impact.

43 Flexible CRC Engine (FCE)

The FCE provides a parallel implementation of cyclic redundancy code (CRC) algorithms, implementing the IEEE 802.3 Ethernet CRC32, AUTOSAR CRC32P4, CCITT CRC16, and the SAE J1850 CRC8 polynomials. The FCE is targeted as a hardware acceleration engine for software applications or for operating system services that use CRC signatures.

43.1 Feature list

- A range of cyclic redundancy code (CRC) polynomials are implemented
  - CRC kernel 0: IEEE 802.3 CRC32 ethernet polynomial: 0x04C11DB7 - $x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$
  - CRC kernel 1: Autosar safety polynomial CRC32P4: 0xF4ACFB13 - $x^{32} + x^{31} + x^{30} + x^{29} + x^{28} + x^{26} + x^{23} + x^{21} + x^{19} + x^{18} + x^{15} + x^{14} + x^{13} + x^{12} + x^{11} + x^9 + x^8 + x^4 + x + 1$
  - CRC kernel 2: CCITT CRC16 polynomial: 0x1021 - $x^{16} + x^{12} + x^5 + 1$
  - CRC kernel 3: SAE J1850 CRC8 polynomial: 0x1D - $x^8 + x^4 + x^3 + x^2 + 1$

  ***Note**: The polynomial hexadecimal representation covers the coefficients (degree - 1) down to 0.*
- Parallel CRC computation
- Parallel channels of CRC context
  - Up to 8 parallel channels of CRC context are supported
  - The channels can be configured to use any one of the implemented algorithms
  - Different channels can use the same or different CRC algorithms concurrently
- Register Interface for CRC computation
  - Input register
  - CRC register
  - Configuration registers that enable control of the CRC operation and perform automatic checksum validation at the end of a message
  - Extended register interface to control the reliability of FCE execution in safety applications
  - Supports endianness conversion
- Independent module reset by software. The reset affects all CRC channels
- Error notification scheme through dedicated interrupt node for:
  - Transient error detection
    - Error interrupt generation (maskable) with local status register (cleared by software)
  - Checksum failure
    - Error interrupt generation (maskable) with local status register (cleared by software)
- Provides one interrupt line to the interrupt system

43.2 Functional overview

The FCE is a standard peripheral slave module which is controlled over a set of memory mapped registers. The FCE is fully synchronous with the peripheral bus clock and runs with a 1:1 clock ratio.

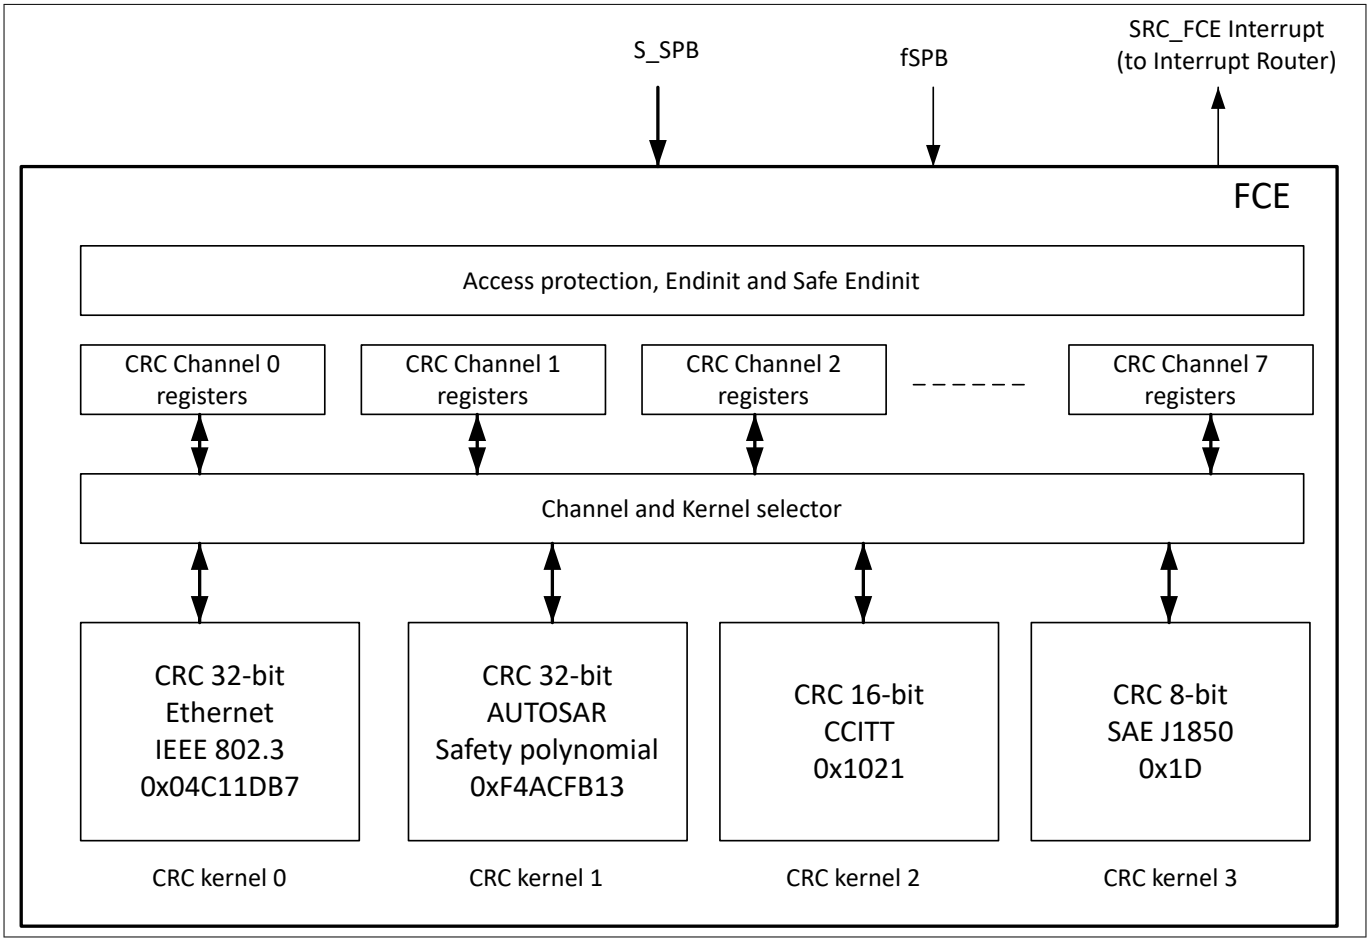

Figure 1007 FCE block diagram

An FCE kernel is the instantiation of the CRC algorithm as a parallel matrix. Each FCE kernel implements a different CRC algorithm.

The FCE module contains 8 channels (Channel 0 - Channel 7). Each channel is provided with its own set of registers which allows the software to configure the channel, choose the algorithm kernel used, write the inputs, and read the results and status from the CRC computation.

Each channel has an interrupt associated with it. A status register is associated with each channel that enables the software to identify which interrupt source is active.

To aid fast interrupt handling in software, a channels status register is provided, which ORs together the status from each channel. The software can read this one register to get information regarding the pending status from each channel.

Each FCE channel presents the same hardware and software architecture for computing the CRC. The following chapters only focus on the description of the generic CRC computational flow, since each channel can be independently configured to use any CRC kernel.

Related information

43.3 Functional description

The following section describes the features of FCE in detail.

The generic CRC computational flow is shown in figure below.

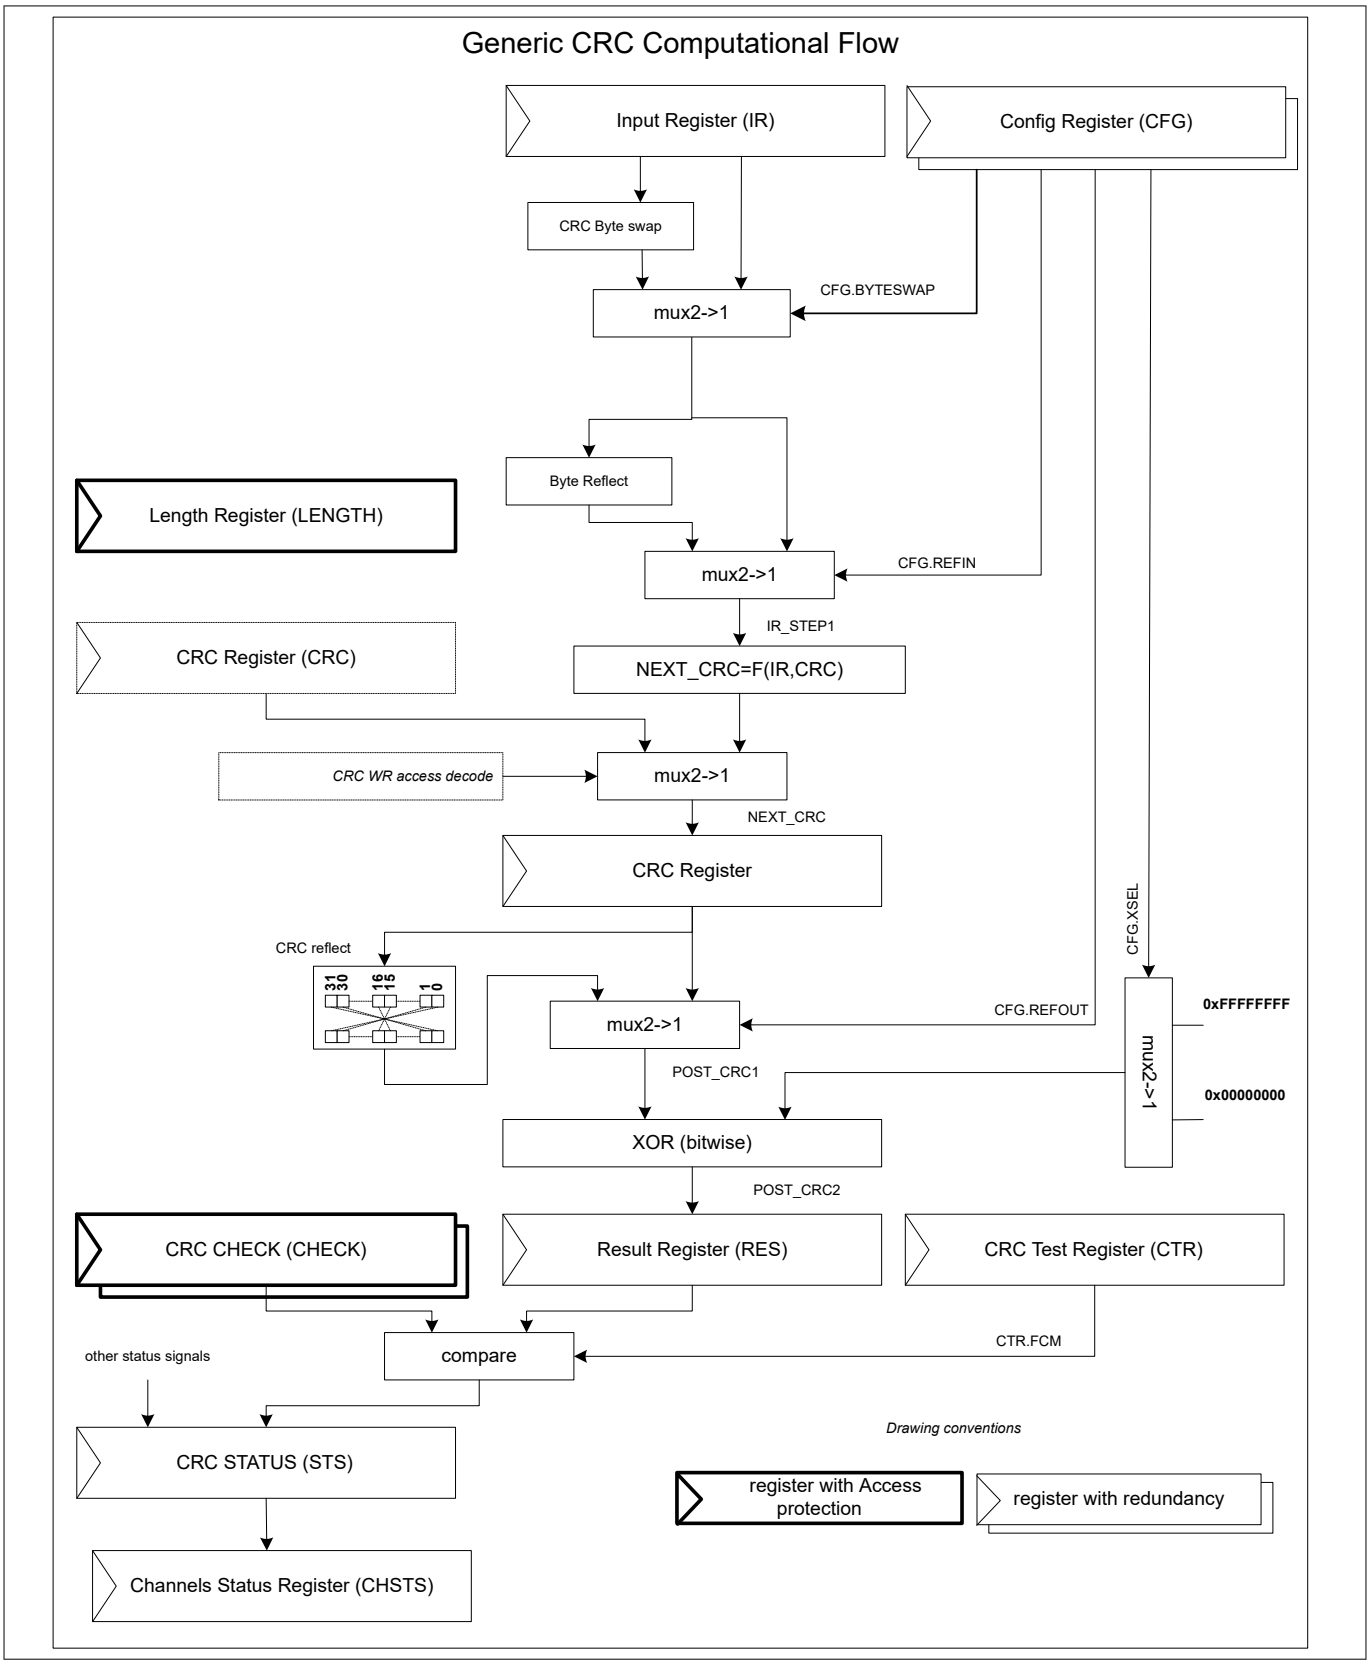

Figure 1008 CRC Computational flow

43 Flexible CRC Engine (FCE)

A checksum algorithm based on CRC polynomial division is characterized by the following properties:

- polynomial degree (example. 32, that represents the highest power of two of the polynomial)
- polynomial (example. $04C11DB7_H$: the 33rd bit is omitted because it is always equal to 1)
- init value: the initial value of the CRC register
- input data reflected: indicates if each byte of the input parallel data is reflected before being used to compute the CRC
- result data reflected: indicates if the final CRC value is reflected or not
- XOR value: indicates if a final XOR operation is done before returning the CRC result
- BYTESWAP: If set, the order of bytes in the input register(when 16- or 32-bit CRC is used) is swapped before the CRC conversion (For endianness conversion).

All the properties are fixed once a polynomial has been chosen. However the FCE provides the capability to control the two reflection steps and the final XOR as depicted in figure above through the CFG register. The reset values are compatible with the implemented algorithm. The final XOR control enables to select either $FFFFFFFF_H$ or 00000000_H to be XORed with the POST_CRC1 (see figure above) value. These two values are those used by the most common CRC polynomials.

As shown in the figure above, when the software writes a value to the IR register, the CRC register is updated in the next clock cycle. The RES register is updated after the output operations (REFOUT, XSEL) still one more cycle later. (that is, there are 2 cycles from a write to the IR register until the result gets updated in the RES register). In case of back to back write accesses to IR register and read access to the RES register, the read access to the RES register is delayed accordingly by hardware so that the software always reads the final computed CRC value from RES register.

It shall be ensured by the programmer that the CFG register is configured before starting the CRC computation, and is not changed until the final result is obtained.

Note that the CRC computation of the FCE is equivalent to a bit-wise shift CRC computation considering that the MSB bit is shifted in first.

***Note**: The reflection steps and final XOR do not modify the properties of the CRC algorithm in terms of error detection, only the CRC final signature is affected.*

The next two figures provides an overview of the control and status features of a CRC channel.

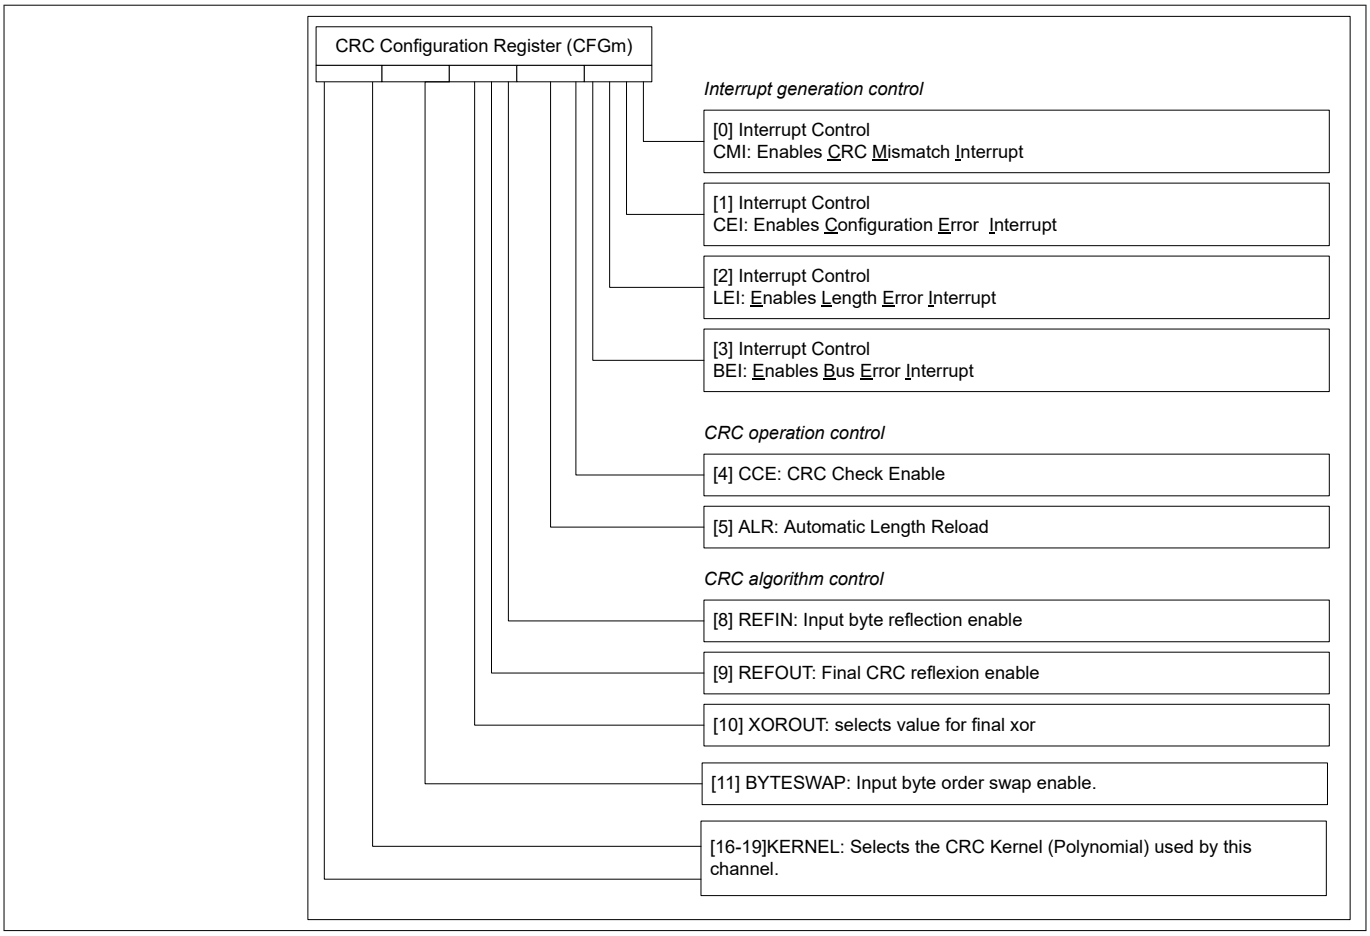

Figure 1009 CRC channel configuration register

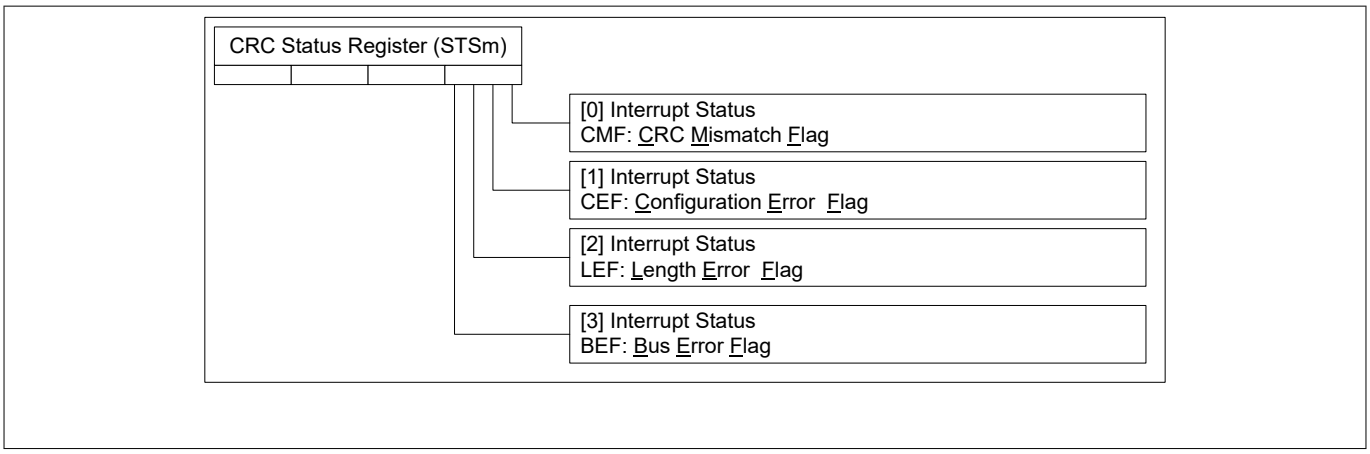

Figure 1010 CRC kernel status register

43.3.1 Initialization

The FCE is enabled by writing 0x0 to the CLC register. After enabling, software can initialize CRC register value with an initial value and CFG register with the CRC kernel selection, input and result reflection, and the final XORed value.

43.3.2 Basic operation

The software must ensure proper initialization of the CRC channels, especially

1. The configuration, including the CRC kernel used in the CFG register
2. Length of the data stream in the LENGTH register
3. The initial CRC value is written through the CRC register

The software can then write as many times as necessary into the IR register according to the length of the message. The resulting signature is stored in the result register RES, which can be read by the software.

Depending on the CRC kernel that is configured to be used by the channel, the following rules apply:

- When using a CRC kernel of degree <N>, only the bits $N-1$ down to 0 are used
- The upper bits are ignored on write
- When reading from a CRC kernel register the unused upper bits are set to 0

Each of the 8 channels can be configured to use any of the implemented CRC algorithm kernels. Multiple channels may be configured to use the same kernel, so enabling concurrent access of the same CRC algorithm by software.

When software writes to an IR register, the registers of the corresponding channel are selected to be used in the CRC computation, based on the bus address of the IR register. The CRC kernel used by this channel is selected based on the CFG.KERNEL bits of the selected channel.

In the following figure the logical representation of the channel and kernel selection based on the bus address of the IR register is shown.

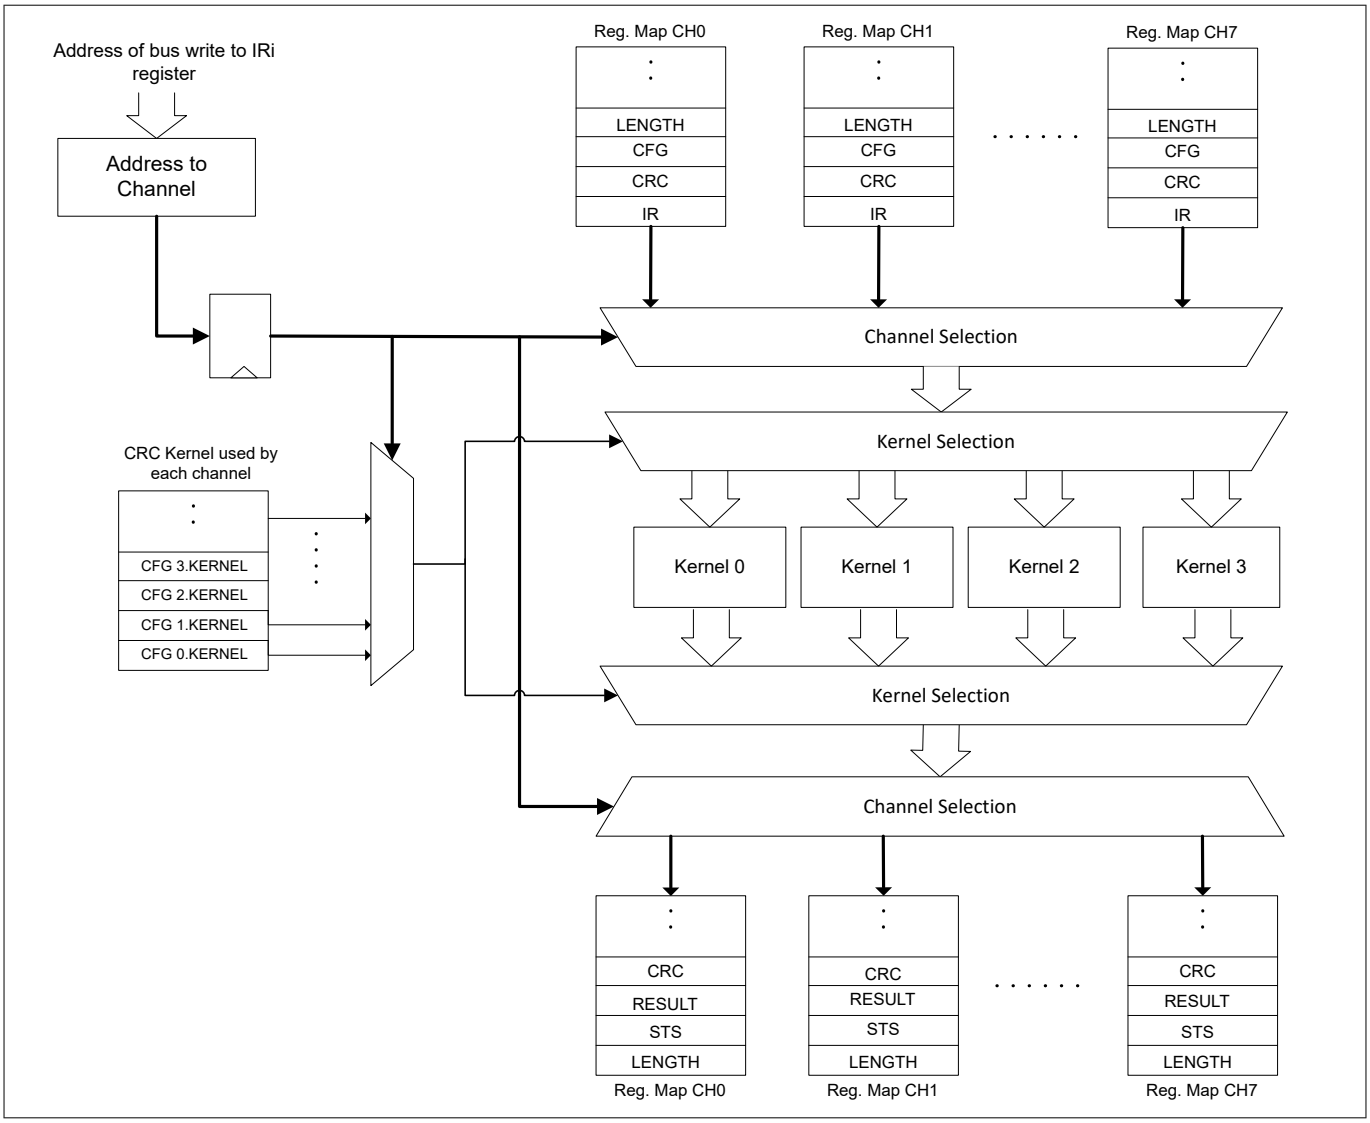

Figure 1011 FCE channel and kernel selection

43.3.3 Automatic signature check

The automatic signature check compares the signature at the end of a message with the expected signature configured in the CHECK register. In case of a mismatch, an event is generated (see related information). This feature is enabled by the CFG.CCE bit-field.

If the software wishes to use this feature, the LENGTH register and CHECK registers of the channel must be configured with:

- The length as number of words of the message
  - The word length is defined by the degree of the polynomial used
- The expected signature (CHECK)
  - The CHECK value takes the final CRC reflection and XOR operation into account

When the CFG.CCE bit-field is set, every time the IR register is written, the LENGTH register is decremented by one until it reaches zero. The hardware monitors the transition of the LENGTH register from 1 to 0 to detect the end of the message and proceeds with the comparison of the result register RES value with the CHECK register value. If the automatic length reload feature is enabled by the CFG.ALR bit-field, the LENGTH register is re-

initialized with the previously configured value. This feature is especially suited when the FCE is used in combination with a DMA engine.

In the case where the automatic length reload feature is not enabled, if LENGTH is already at zero but software still writes to IR (by mistake) then every bit of the LENGTH is set to 1. This value is held until software initializes it again to process a new message. In such cases the STS.LEF (Length Error Flag) is set and an interrupt generated. If the CFG.LEI (Length Error Interrupt) is set, the corresponding written value is completely ignored, and no CRC calculation update is done. In such an error case, any further decrement and reload of the length as well as CRC check is disabled. Software shall clear the LEF error flag for further correct operation.

Usually the CRC signature of a message M0 is computed and appended to M0 to form the message M1 which is transmitted. One interesting property of CRCs is that the CRC signature of M1 shall be zero. This property is particularly useful when automatically checking the signature of data blocks of fixed length with the automatic length reload enabled. LENGTH should be loaded with the length of M1 and CHECK with 0.

Service request generation on page 7280

43.3.4 Register protection and monitoring methods

Register monitoring applies only to CFG and CHECK registers.

Since CFG and CHECK registers are critical to the CRC operation, some mechanisms to detect and log transient errors are provided. Early detection of transient failures enables to improve the failure detection time and assess the severity of the failure. The monitoring mechanisms are implemented using two redundant instances as presented in the following figure.

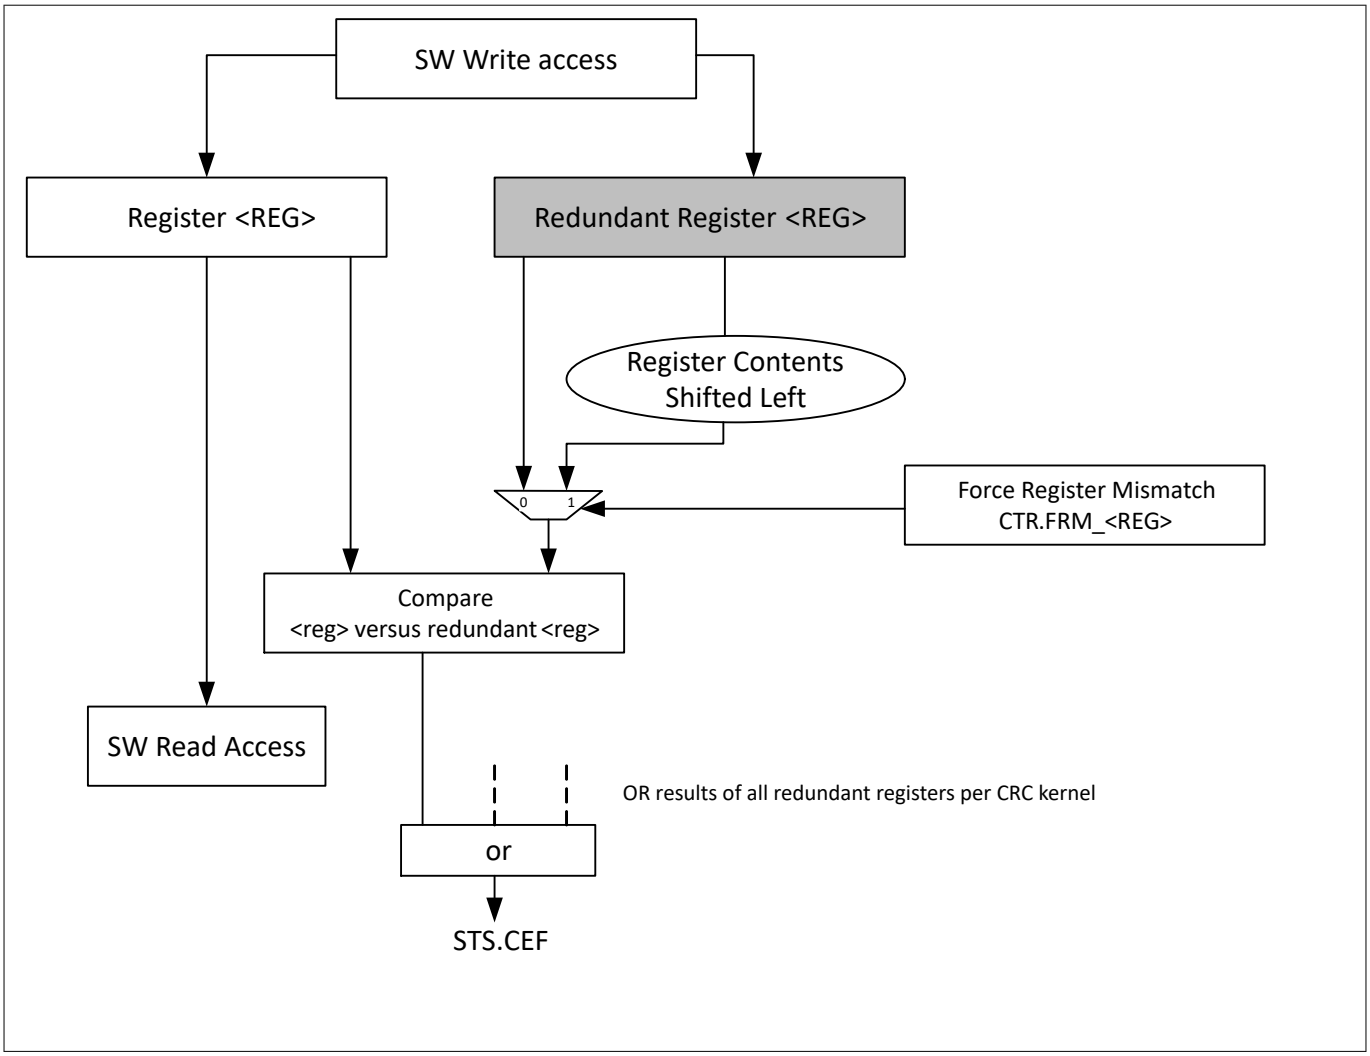

Figure 1012 Register monitoring scheme

Let <REG> designate either CFG or CHECK registers. When a write to <REG> takes place the redundant register is also updated. Redundant registers are not visible to software. Bits of <REG> reserved have no storage and are not used for redundancy. A compare logic continuously compares the two stored values and provides a signal that indicates if the compare is successful or not. The result of all compare blocks are ORed together to provide a single flag information. If a mismatch is detected the STS.CEF (Configuration Error Flag) bit is set. For run-time validation of the compare logic a Force Register Mismatch bit-field (CTR.FRM_<REG>) is provided. When set to 1 by software the contents of the redundant register is shifted left by one bit position (redundant bit 0 position is always replaced by a logical 0 value) and is given to the compare logic instead of the redundant register value. This enables to check if the compare logic is functional. Using a walking bit pattern, the software can completely check the full operation of the compare logic. Software needs to clear the CTR.FRM_<REG> bit to ‘0’ to be able to trigger again a new comparison error interrupt.

Register access protection applies to only LENGTH and CHECK registers.

In order to reduce the probability of a mis-configuration of the CHECK and LENGTH registers (in the case the automatic check is used), the write access to the CHECK and LENGTH registers must follow a procedure:

This procedure is depicted in the following figure:

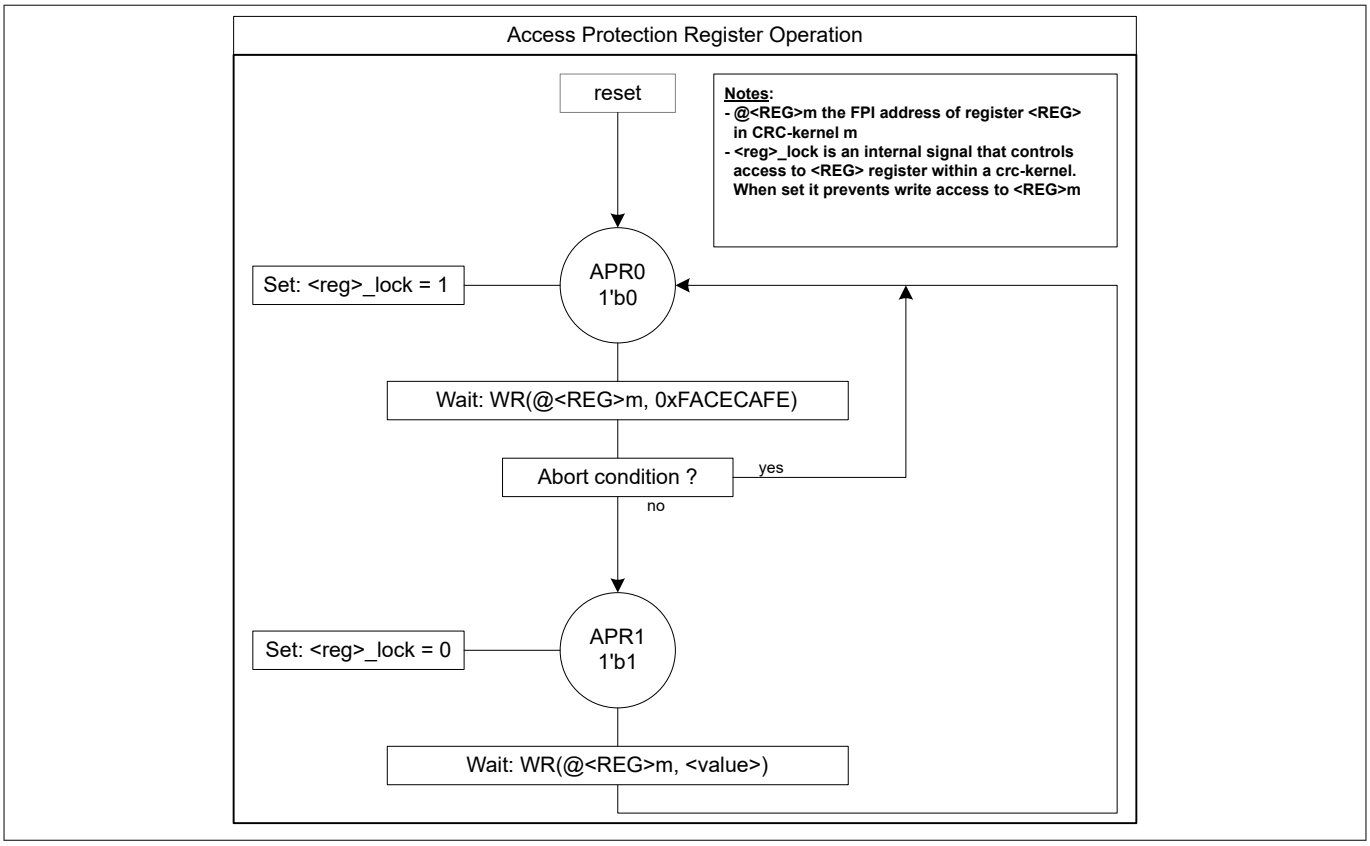

Figure 1013 Access control to CHECK register

Let <REG> designate CHECK or LENGTH registers. Before being able to configure a new <value> into the <REG> register of a CRC kernel, software must first write the 0xFACECAFE value to the <REG> address. The 0xFACECAFE is not written into the <REG> register. The next write access will proceed as a normal bus write access. The write accesses shall use full 32-bit access only. This procedure will then be repeated every time software wants to configure a new <REG> value. If software reads the CHECK register just after writing 0xFACECAFE it returns the current <REG> contents and not 0xFACECAFE. A read access to <REG> has no effect on the protection mechanism.

43.3.5 Power, reset and clock

The FCE is inside the core power domain and therefore no special considerations with regards to power-up or power-down sequences need to be taken. For an explanation about the different power domains, please see the SMM (System Mode Management) chapter.

A power-down mode can be achieved by disabling the module using the CLC register.

The FCE module can be reset through Application Reset or module group resets or through kernel reset request by software. Refer to RST_CTRLA and RST_CTRLB SFRs.

After reset, the complete IP is set to a default configuration. The default configuration for each register field is addressed in the registers overview table.

The module clock can be enabled using the CLC register.

43.3.6 Properties of CRC code

This section describes the Hamming distance for various CRC polynomials supported by FCE.

Hamming distance

The Hamming distance defines the error detection capability of a CRC polynomial. A cyclic code with a Hamming distance of D can detect all D-1 bit errors. The following table shows the dependency of the Hamming distance with the length of the message.

Table 2135 Hamming distance as a function of message length (bits)

Hamming distance	IEEE-802.3 CRC32	CCITT CRC16	J1850 CRC8
15	8 - 10	Information not available	Information not available

43.3.7 Service request generation

Each FCE CRC channel provides one internal interrupt source. The interrupt lines from each CRC channel are ORed together to be sent to the interrupt system. The system interrupt is an active high pulse with the duration of one cycle (of the peripheral clock). The FCE interrupt handler can use the status information located within the STS status register of each CRC channel.

Each CRC channel provides the following interrupt sources:

- CRC mismatch interrupt controlled by CFG.CMI bit-field and observable through the status bit-field STS.CMF (CRC Mismatch Flag)
- Configuration error interrupt controlled by CFG.CEI bit-field and observable through the status bit-field STS.CEF (Configuration Error Flag)
- Length error interrupt controlled by CFG.LEI bit-field and observable through the status bit-field STS.LEF (Length Error Flag)
- Bus error interrupt controlled by CFG.BEI bit-field and observable through the status bit-field STS.BEF (Bus Error Flag). This error is triggered by a write to the IR register with write width less than the selected kernel's polynomial width

Interrupt generation rules are as follows:

- A status flag shall be cleared by software by writing a 0 to the corresponding bit position in the STS register
- If a status flag is set and a new hardware condition occurs, no new interrupt is generated by the kernel. A set STS.<FLAG> bit-field masks the generation of a new interrupt from the FCE module. If a software access to clear the interrupt status bit takes place and in the same cycle the hardware wants to set the bit, the hardware condition wins the arbitration

To aid faster interrupt handling in the software, the status flags from each channels are ORed together and provided as individual bits in a Channels Status Register (see figure below). The software can read this single register to learn the channel status, rather than reading the registers of each channel separately.

Since there is only a single interrupt from the FCE, the software has to clear the status flags from all the channels to forward a further FCE interrupt.

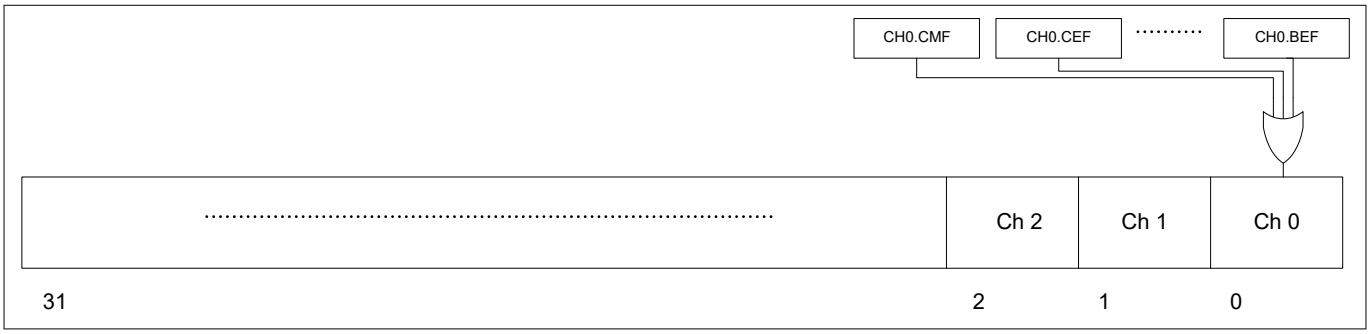

Figure 1014 Channels status register

43.4 Registers

43.4.1 Register overview - access mode glossary

Table 2136 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register PROTE.
SE	Access protection using PROT register PROTSE.
APU-Py (y=0-2)	Protection group consisting of registers ACCENy_WRA, ACCENy_WRB, ACCENy_RDA, ACCENy_RDB, ACCENy_VM, ACCENy_PRS.
Py	Access protection using *APU-Py* registers.
PCHz (z=0-7)	Access protection using one APU from *APU-P[y] (y=0-2)*. The protection source to be used is selected by bit-field: z=0-7: RESALLOC_CH.CHi
U	No access restrictions.
BE	Always returns a Bus Error.
PROT	Access restrictions as defined in the PROT register access rules.

43.4.2 Registers overview - FCE (ascending offset address)

Table 2137 Registers overview - FCE (ascending offset address)

Short name	Long name	Offset address	Access mode		Reset	See
			Read	Write		
CLC	Clock control register	000_H	P0	P0, SV, E	Application Reset	7283
ID	Module identification register	008_H	U	BE	PowerOn Reset	7283

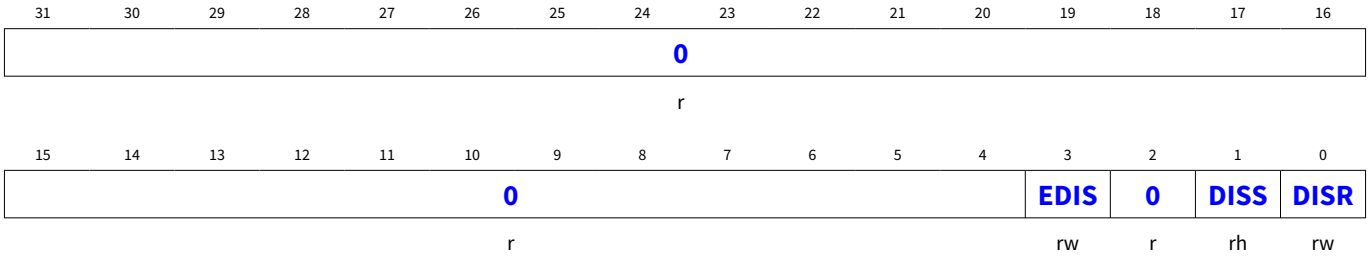
43.4.3 Clock control register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

Register CLC controls the module clock signal and the reactivity to the sleep signal.

CLC Offset address: 000_H

Clock control register Application Reset value: $0000\ 0003_H$

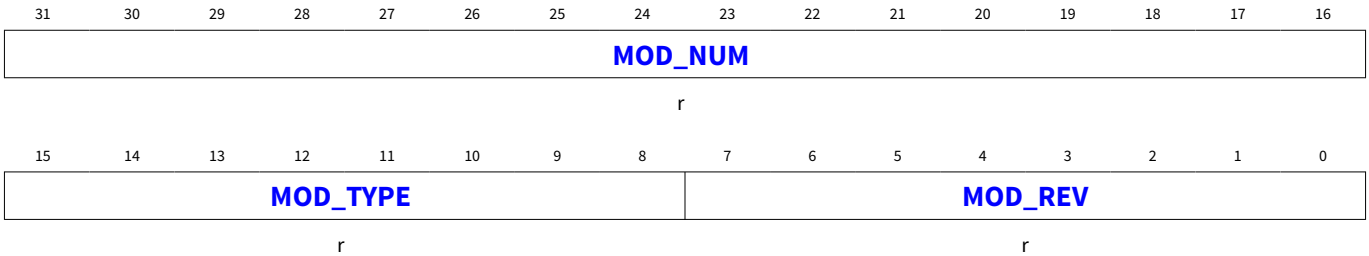


Field	Bits	Type	Description
DISR	0	rw	**Module Disable Request Bit** Used for enable or disable control of the module. Also the analog section is disabled by clearing ANONS. 0_B On request: enable the module clock 1_B Off request: stop the module clock
DISS	1	rh	**Module Disable Status Bit** 0_B Module clock is enabled 1_B Off: module is not clocked
EDIS	3	rw	**Sleep Mode Enable Control** Used to control the module's reaction to sleep mode. 0_B Sleep mode request is enabled and functional 1_B Module disregards the sleep mode control signal
0	2, 31:4	r	**Reserved** Read as 0; should be written with 0.

43.4.4 Module identification register

ID Offset address: 008_H

Module identification register PowerOn Reset value: $00CA\ C005_H$



Field	Bits	Type	Description
MOD_REV	7:0	r	**Module Revision** Indicates the revision number of the implementation.
MOD_TYPE	15:8	r	**Module Type** This internal marker is fixed to $C0_H$.
MOD_NUM	31:16	r	**Module Number** Indicates the module identification number.

43.4.5 Reset control register A

RST_CTRLA Offset address: $00C_H$

Reset control register A Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

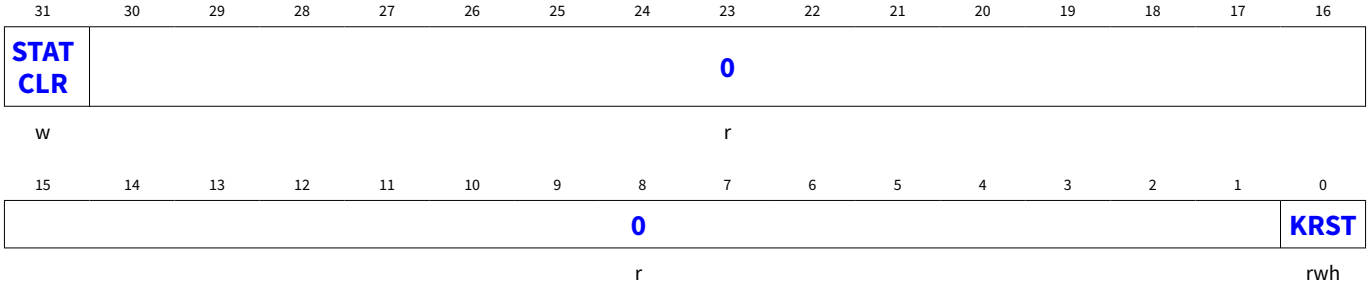
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				GRSTEN3	GRSTEN2	GRSTEN1	GRSTEN0	0							KRST
r				rw	rw	rw	rw	r							rwh

Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
GRSTENx (x=0-3)	x+8	rw	**Enable for Global Module Reset Group x** 0_B Global module reset group x does not have any effect 1_B Global module reset group x results in a kernel reset
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

43.4.6 Reset control register B

RST_CTRLB Offset address: 010_H

Reset control register B Application Reset value: $0000\ 0000_H$



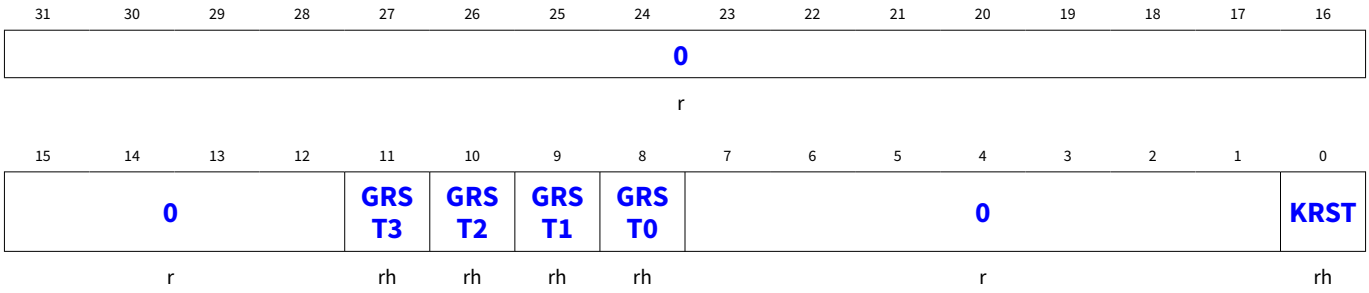
Field	Bits	Type	Description
KRST	0	rwh	**Kernel Reset** Request a kernel reset. The requested reset is executed if CTRLA.KRST=1 and CTRLB.KRST=1. KRST is cleared after the kernel reset was executed. 0_B No action 1_B A kernel reset was requested
STATCLR	31	w	**Kernel Reset Status Clear** Clears all status bits in RST_STAT when 1 is written. Read will return 0. 0_B No action 1_B Write with 1 clears bits STAT.GRSTx and bit STAT.KRST .
0	30:1	r	**Reserved** Read as 0; should be written with 0.

43.4.7 Reset status register

The reset status register contains the status bits for kernel reset (KRST) and the global module reset groups (GRSTx).

RST_STAT Offset address: 014_H

Reset status register Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
KRST	0	rh	**Kernel Reset Status** Indicates an executed kernel reset. RST_STAT.KRST is set after the execution of a kernel reset in the same clock cycle in which the reset bits are cleared. Clear KRST by setting bit STATCLR in register RST_CTRLB.

(table continues...)

(continued)

Field	Bits	Type	Description
GRSTx (x=0-3)	x+8	rh	**Status for Global Module Reset Group x** 0_B Reset was not triggered by Global Reset Group x 1_B Reset was triggered by Global Reset Group x
0	7:1, 31:12	r	**Reserved** Read as 0; should be written with 0.

43.4.8 PROT register endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTE register controls lock or unlock of the local Endinit (E) protected control registers.

PROTE Offset address: 020_H

PROT register endinit Application Reset value: $0000\ 0000_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rh	STATE	

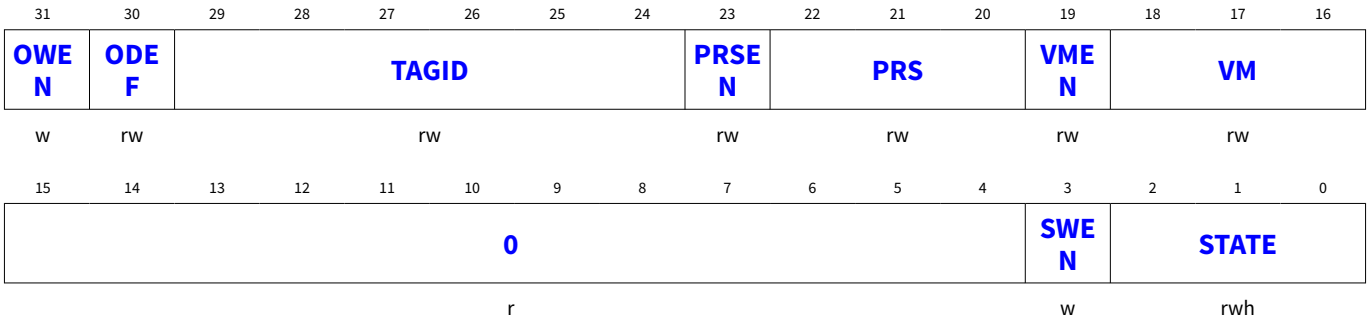
43.4.9 PROT register safe endinit

The resource protection register allows the definition of a specific PROT owner, and allows the PROT owner and in some PROT states, the secure master to update the PROT state as described in the PROT mechanism.

The PROTSE register controls lock or unlock of the local Safe Endinit (SE) protected control registers.

PROTSE Offset address: 024_H

PROT register safe endinit Application Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
STATE	2:0	rwh	**Resource protection state** Returns the current PROT state when read. Can be written by the PROT owner or CS master to modify the current PROT state if the state transition is valid in the PROT state diagram. 000_B Init (unlocked state) 001_B Config (unlocked state) 010_B ConfigSec (unlocked state) 011_B CheckSec (locked state) 100_B Run (locked state) 101_B RunSec (locked state) 110_B RunLock (locked state) 111_B RunLock (locked state)
SWEN	3	w	**State write enable** Write-enable for the STATE field. Reads always return 0. 0_B **Disable**: STATE field is not updated 1_B **Enable**: STATE field is updated by the write
VM	18:16	rw	**Virtual machine definition for PROT owner** Defines the VM of the PROT owner. This field is ignored if VMEN=0_B or ODEF=0_B.
VMEN	19	rw	**Virtual machine definition enable for PROT owner** 0_B **Disable**: VM is not part of PROT owner definition 1_B **Enable**: VM is part of PROT owner definition
PRS	22:20	rw	**Protection set definition for PROT owner** Defines the PRS of the PROT owner. This field is ignored if PRSEN=0_B or ODEF=0_B.
PRSEN	23	rw	**Protection set definition enable for PROT owner** 0_B **Disable**: PRS is not part of PROT owner definition 1_B **Enable**: PRS is part of PROT owner definition
TAGID	29:24	rw	**TAG-ID definition for PROT owner** Defines the TAGID of the PROT owner. This field is ignored if ODEF=0_B.
ODEF	30	rw	**Enable for PROT owner definition** 0_B **Undefined**: Any master can act as PROT owner (TAGID, VMEN, VM, PRSEN, PRS are ignored) 1_B **Defined**: TAGID, VMEN, VM, PRSEN, PRS define the PROT owner

(table continues...)

(continued)

Field	Bits	Type	Description
OWEN	31	w	**Owner write enable** Write-enable for the owner fields. Reads always return 0. 0_B **Disable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are not updated 1_B **Enable**: PROT owner fields (ODEF, TAGID, VMEN, VM, PRSEN, PRS) are updated by the write
0	15:4	r	**Reserved** Read as 0; should be written with 0.

Table 2139 Access mode restrictions of PROTSE sorted by descending priority

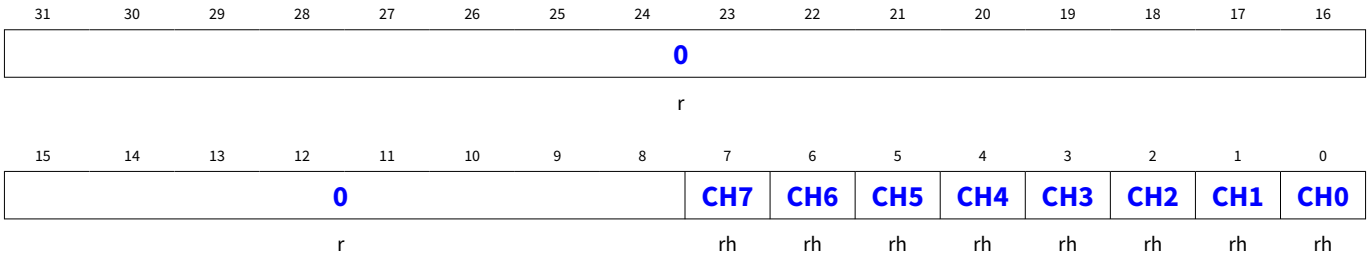
WRq (q=00-07)	q+16	rw	**Write access enable for PRS q** This bit enables write access to the access protected region for transactions with the PRS q. 0_B Disabled for write access 1_B Enabled for write access
0	15:8, 31:24	r	**Reserved** Read as 0; should be written with 0.

43.4.17 Channels status register

CHSTS Offset address: $0C0_H$

Channels status register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
CH0	0	rh	**Channel0 Status** This bit is the result of an OR operation of the various status bits of channel 0 (see STS register).
CH1	1	rh	**Channel1 Status** This bit is the result of an OR operation of the various status bits of channel 1 (see STS register).
CH2	2	rh	**Channel2 Status** This bit is the result of an OR operation of the various status bits of channel 2 (see STS register).
CH3	3	rh	**Channel3 Status** This bit is the result of an OR operation of the various status bits of channel 3 (see STS register).
CH4	4	rh	**Channel4 Status** This bit is the result of an OR operation of the various status bits of channel 4 (see STS register).
CH5	5	rh	**Channel5 Status** This bit is the result of an OR operation of the various status bits of channel 5 (see STS register).
CH6	6	rh	**Channel6 Status** This bit is the result of an OR operation of the various status bits of channel 6 (see STS register).
CH7	7	rh	**Channel7 Status** This bit is the result of an OR operation of the various status bits of channel 7 (see STS register).
0	31:8	r	**Reserved** Read as 0. Should be written with 0.

43.4.18 Input register i

IRi (i=0-7)

Input register i

Offset address: 100_H+i*20_H

Kernel Reset value: $0000\ 0000_H$

IR															
rw															

Field	Bits	Type	Description
IR	31:0	rw	**Input Register** This bit-field holds the input data to be computed. In case the channel is configured to use 16-bit or 8-bit CRC, only the LSB 16 or 8-bits will be used as input.

43.4.19 CRC result register i

RESi (i=0-7) Offset address: 104_H+i*20_H

CRC result register i Kernel Reset value: FFFF FFFF$_H$

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES															
rh															

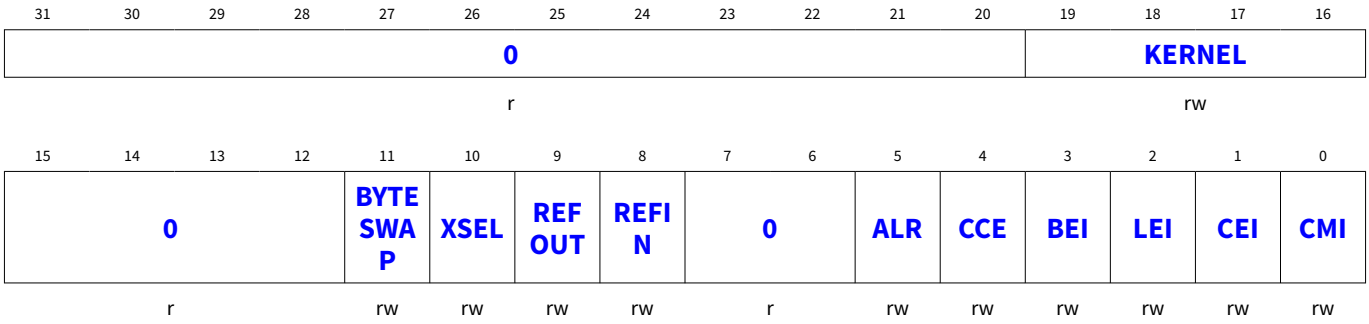
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES															
rh															

Field	Bits	Type	Description
RES	31:0	rh	**Result Register** Returns the final CRC value including CRC reflection and final XOR according to the CFG register configuration. If the channel is configured to use 16-bit or 8-bit CRC, the MSB 16 or 24 bits respectively shall be read as 0.

43.4.20 CRC configuration register i

CFGi (i=0-7) Offset address: 108_H+i*20_H

CRC configuration register i Kernel Reset value: 0000 0700$_H$



Field	Bits	Type	Description
CMI	0	rw	**CRC Mismatch Interrupt** 0_B CRC Mismatch Interrupt is disabled 1_B CRC Mismatch Interrupt is enabled
CEI	1	rw	**Configuration Error Interrupt** When enabled, a Configuration Error Interrupt is generated whenever a mismatch is detected in the CFG and CHECK redundant registers. 0_B Configuration Error Interrupt is disabled 1_B Configuration Error Interrupt is enabled
LEI	2	rw	**Length Error Interrupt** When enabled, a Length Error Interrupt is generated if software writes to IR register with LENGTH equal to 0 and CFG.CCE is set to 1. 0_B Length Error Interrupt is disabled 1_B Length Error Interrupt is enabled
BEI	3	rw	**Bus Error Interrupt** When enabled, an interrupt (BEF) is generated if a bus write transaction with an access width smaller than the kernel width is issued to the input register. In this case, the corresponding value written to the IR is discarded and no CRC computation takes place. 0_B Bus Error Interrupt is disabled 1_B Bus Error Interrupt is enabled
CCE	4	rw	**CRC Check Comparison** 0_B CRC check comparison at the end of a message is disabled 1_B CRC check comparison at the end of a message is enabled. In this case, if length error is set (STS.LEF = 1) and IR is written to, then length is set to all ones, independent of the previous length value. The ALR bit is also ignored in such a condition.
ALR	5	rw	**Automatic Length Reload** 0_B Disables automatic reload of the LENGTH field. 1_B Enables automatic reload of the LENGTH field at the end of a message.
REFIN	8	rw	**IR Byte Wise Reflection** 0_B IR Byte Wise Reflection is disabled 1_B IR Byte Wise Reflection is enabled

(table continues...)

(continued)

Field	Bits	Type	Description
REFOUT	9	rw	**CRC Bit Wise Reflection** The alignment of the reflection is the same as the kernel polynomial width. For example: 32-bit kernel has bitwise reflection by 32-bits. 0_B CRC-bit wise is disabled 1_B CRC-bit wise is enabled
XSEL	10	rw	**Selects the value to be XORed with the final CRC** 0_B 0x00000000 1_B 0xFFFFFFFF
BYTESWAP	11	rw	**Swaps the order of the bytes in the IR input register.** 0_B The order of bytes in IR register are not swapped before CRC computation. 1_B The order of bytes in the IR register are swapped before CRC computation. Big-endian input is converted to Little-endian and vice versa. (When 8-bit CRC is chosen, this has no effect).
KERNEL	19:16	rw	**Selects the CRC Kernel (Polynomial Engine) used by this channel.** Other possible values are reserved for additional kernels that may be added in the future. If these values are used, then KERNEL3 is used by default. 0_H Kernel 0 is used. 1_H Kernel 1 is used. 2_H Kernel 2 is used. 3_H Kernel 3 is used.
0	7:6, 15:12, 31:20	r	**Reserved** Read as 0; should be written with 0.

43.4.21 CRC status register i

STSi (i=0-7) Offset address: $10C_H+i*20_H$

CRC status register i Kernel Reset value: $0000\ 0000_H$

Field	Bits	Type	Description
CMF	0	rwh	**CRC Mismatch Flag** This bit is set per hardware only. To clear this bit, software must write a 0 to this bit-field location. Writing 1 to this bit has no effect.

(table continues...)

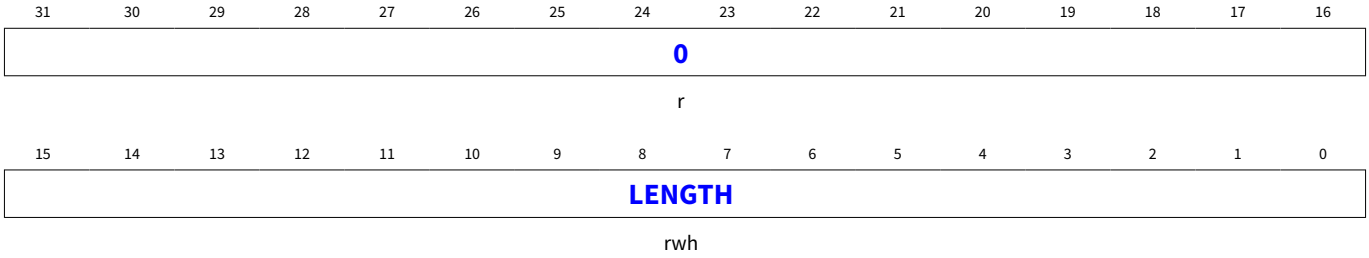
(continued)

Field	Bits	Type	Description
CEF	1	rwh	**Configuration Error Flag** This bit is set per hardware only. To clear this bit, software must write a 0 to this bit-field location. Writing a 1 has no effect.
LEF	2	rwh	**Length Error Flag** This bit is set per hardware only. To clear this bit, software must write a 0 to this bit-field location. Writing 1 has no effect.
BEF	3	rwh	**Bus Error Flag** This bit is set per hardware only. To clear this bit, software must write a 0 to this bit-field location. Writing 1 has no effect.
0	31:4	r	**Reserved** Read as 0; should be written with 0.

43.4.22 CRC length register i

LENGTHi (i=0-7) Offset address: 110_H+i*20_H

CRC length register i Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
LENGTH	15:0	rwh	**Message Length Register** Number of words (bit width of each word in terms of KERNEL polynomial width) building the message over which the CRC checksum is calculated. This bit-field is modified by the hardware: every write to the IR register decrements the value of the LENGTH bit-field. If the CFG.ALR field is set to 1, the LENGTH field shall be reloaded with its configuration value at the end of the cycle where LENGTH reaches 0.
0	31:16	r	**Reserved** Read as 0; should be written with 0.

43.4.23 CRC check register i

CHECKi (i=0-7) Offset address: 114_H+i*20_H

CRC check register i Kernel Reset value: $0000\ 0000_H$

There are no deviations from the generic specification.

43.8.3 TC4Dx FCE functional description

Slave interface

In TC4Dx device, the FCE slave interface is connected to ComPB bus interface.

Functional limitations

Software must ensure that FCE kernel reset (either via KRST or module group reset) is not initiated while a concurrent write access to IR register and read access to RES register is performed. Alternatively, the software must ensure there is always a 2 fSPB clock cycles wait between the last write to IR register and read to RES register.

Initial release of the chapter.

44 Enhanced Generic Timer Module (eGTM)

eGTM is an enhanced version of the GTM, a universal timer architecture provided by Bosch AE.

The eGTM is capable of generating complex PWM/Pulses as for example motor control or power conversion. The module can be used for input signal characterization and for many other use cases.

This specification is a generic specification. Registers for non-existing modules (as communication modules are differing in number) are not functional and they will be simply not connected.

***Note**: TC4Dx is an exception as registers for non-existing modules are removed.*

44.1 Feature list

- GTM v4.1, designed by Bosch AE, running at the maximum CPU frequency
- Trigger outputs to: ADC, SENT, PSI5(S), PMS, ASCLIN, QSPI, CAN(XL), SCU, and MSC
- Trigger inputs from: CAN(XL), Ethernet, SCU, PMS, GPT12, ADC, and FlexRay™
- Filtered outputs can be provided from eGTM Timer Input Modules (TIMs) to GPT12 modules (No GPT12 on TC4Dx, TC4Zx)
- Debug interface
- ADC boundary flags are provided as input to TIMs and to DTMs (auxiliary interface)
- High Resolution Support on ATOMs (No HRPWM on TC4Dx, TC4Zx)

44.2 Functional overview

The eGTM module is capable of driving different kinds of pulse-width-modulation (PWM) with and without dead-time. eGTM can be considered a scaled-down version of GTM Classic with some additional features to support electric drive application requirements (for example "High resolution PWM" support) and reduced access latency.

It is able to capture signals from ports. It is possible to get signals from other function blocks of the device and to provide control signals to other function blocks of the device.

***Note**: eGTM-IP is the GTM-IP block from Bosch AE, which is chosen in the corresponding configuration for electrical drive application.*

***Note**: Inside the block diagram all resources which are possible, are part of the picture. Please check in the device specific section, if the resources marked on the right side are existing in the device.*

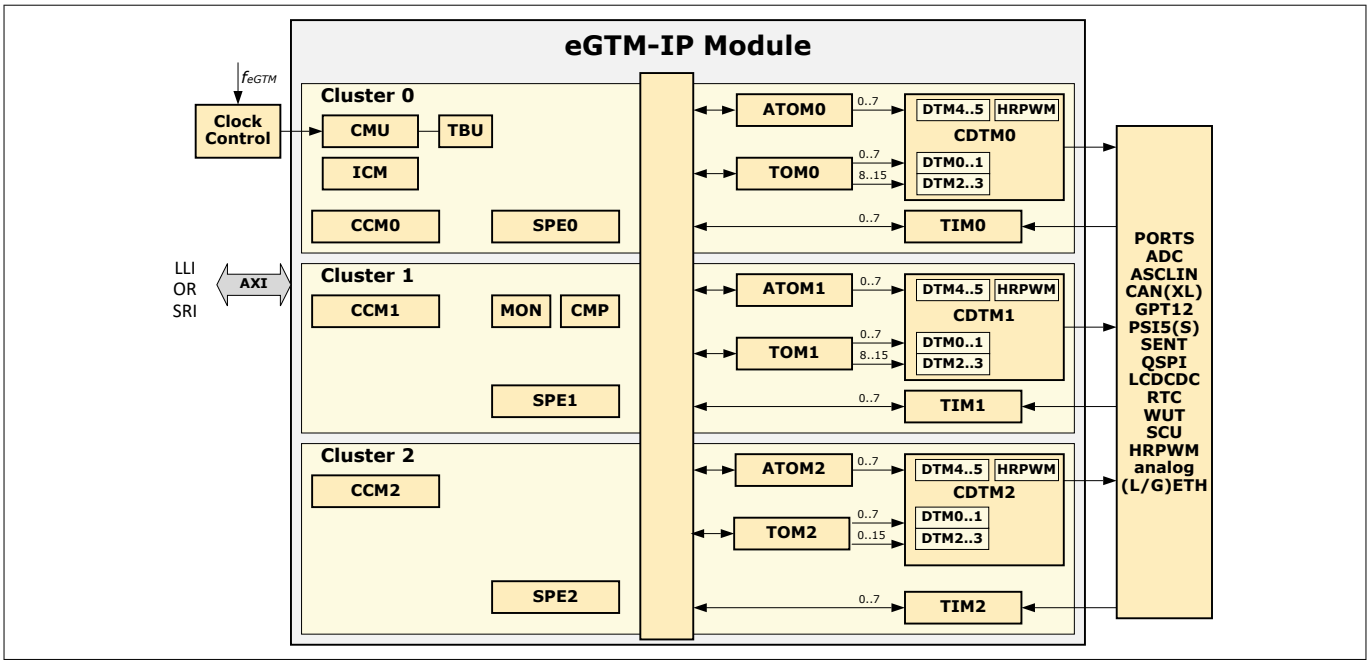

Figure 1015 eGTM block diagram

***Note**: This figure is a general figure. The exact configuration can be found in the device specific configuration.*

For the alarm description please refer to the alarm mapping tables in the SMU functional block and the Safety Manual.

44.3 Functional description

Information to the IP specification and implementation you will find in the respective sub chapters.

In this sub-chapter the eGTM module is documented. It includes out of the following sub-parts:

- eGTM IP specification (specification from Bosch AE)
- eGTM implementation (the integration and additional registers)
- and if applicable a HRPWM sub-chapter

Related information

eGTM implementation on page 7572

44.3.1 eGTM Specification

- Version: GTM4.1-V1.40 patched
- Date: 2024-06-26

44.3.1.1 Introduction

44.3.1.1.1 Overview

This document is the specification for the enhanced Generic Timer Module (**eGTM**).

Nevertheless, the **eGTM** is designed to unload the CPU or a peripheral core from a high interrupt load. Most of the tasks inside the **eGTM** run (once setup by an external CPU) independently and in parallel to the CPU software. There may be special situations, where the CPU has to take action but the goal of the **eGTM** design was to reduce these situations to a minimum.

The hardware sub-modules have dedicated functionalities, for example, there are timer input modules where incoming signals are captured and characterized together with a notion of time.

The sub-modules are categorized into the following groups:

Interface components: The slave communication from CPU to **eGTM** is covered by the sub-module (E)GTM_AEI.

Infrastructure components: These sub-modules are needed to define common functionality in the **eGTM** and ensure that data storage and exchange between other sub-modules is possible. They are in use to implement complex functions which have to pass data over multiple sub-modules to ensure the user application. These components are present in all **eGTM** devices. However, the number of these components may vary from device to device.

IO Modules: They have connections with input or output signals to communicate from and to the **eGTM**. They are built based on a regular architecture to fulfill typical timer functions, for example, usable as PWM generation units, input measurement units.

Dedicated functionality: These sub-modules are those fulfilling a dedicated functionality for a certain application domain.

Interrupt management: The module **ICM** is responsible for interrupt services.

Safety features: These sub-modules are able to support the implementation of safety functions to fulfill a defined safety level.

44.3.1.1.2 Document structure

The structure of this document is motivated by the aforementioned sub-module groups. The Overview describes the dedicated **eGTM** architecture. It gives an overview of the structuring of the implemented sub-modules.

The following chapters up to Time base unit (**TBU**) deal with the so-called infrastructure components for clock management and common time base functions. Timer input module (**TIM**) to Dead-time module (**DTM**) describe the signal input and output modules. The next chapters up to Sensor pattern evaluation (**SPE**) provide detailed descriptions of application-specific modules like the **SPE**. Interrupt concentrator module (**ICM**) describes a module that bundles several interrupts coming from the other sub-modules and connect them to the outside world. The last Output compare unit (**CMP**) to Monitor unit (**MON**) provide information on the safety related module.

Table 2144 Sub-module groups

Chapter	Sub-module	Group
eGTM architecture	Slave configuration interface	Interface components
Clock management unit (**CMU**)	Clock Management Unit (**CMU**)	Infrastructure components
Cluster configuration module (**CCM**)	Cluster Configuration Module (**CCM**)	Infrastructure components
Time base unit (**TBU**)	Time Base Unit (**TBU**)	Infrastructure components
Timer input module (**TIM**)	Timer Input Module (**TIM**)	IO Modules
Timer output module (**TOM**)	Timer Output Module (**TOM**)	IO Modules
ARU-connected timer output module (**ATOM**)	**ARU**-connected Timer Output Module (**ATOM**)	IO Modules
Dead-time module (**DTM**)	Dead-Time Module (**DTM**)	IO Modules
Sensor pattern evaluation (**SPE**)	Sensor Pattern Evaluation Module (**SPE**)	Dedicated functionality BLDC support
Interrupt concentrator module (**ICM**)	Interrupt Concentrator Module (**ICM**)	Infrastructure components
Output compare unit (**CMP**)	Output Compare Unit (**CMP**)	Safety features
Monitor unit (**MON**)	Monitoring Unit (**MON**)	Safety features

44.3.1.2 eGTM architecture

44.3.1.2.1 Overview

Find here a list of indices and their range which are used in all chapters with the same semantic:

- i:={0, 1,..., NCCM-1} index of cluster or module instance in the **eGTM** device
- j in case the index refers to a cluster/module j!=i
- x:={0, 1,..., 15} index of a channel inside a module
- d:={0, 1,..., 5} index of **DTM** unit after **TOM** / **ATOM**
- g:={0, 1} index of group of resources/functions

In addition, more indices might be introduced at the beginning of the following chapters. These additional indices with their corresponding ranges are used throughout the respective chapters they are defined in.

As already mentioned in Introduction the **eGTM** forms a generic timer platform that serves different application domains and different classes within these application domains. Depending on these multiple requirements of application domains, multiple device configurations with different number of sub-modules (i.e. **ATOM**, **SPE**, **TIM**, **TOM** and **DTM**) and different number of channels per sub-module (if applicable) are possible.

The device dependent configuration (i.e. the number of sub-modules) is listed in the device-specific documentation.

The Cluster Dead-time Module (**CDTM**) is also a virtual hierarchy and consists of up to twelve **DTM** modules. It depends on the **eGTM** device configuration which of the twelve **DTM** instances are available. In general, the first four **DTM** modules (d∈{0, 1, 2, 3}) inside a CDTM[i] hierarchy are connected to the outputs of the **TOM** instance i of the cluster i. The **DTM** instances (d∈{4, 5}) are connected to the outputs of the **ATOM** instance i of this cluster i.

The cluster view of a **eGTM** architecture is depicted in Figure 1016. This is a generic figure which shows an exemplary **eGTM** device configuration.

The device dependent configuration (i.e. the count of sub-modules and channels per sub-module) is listed in the device-specific part of this document.

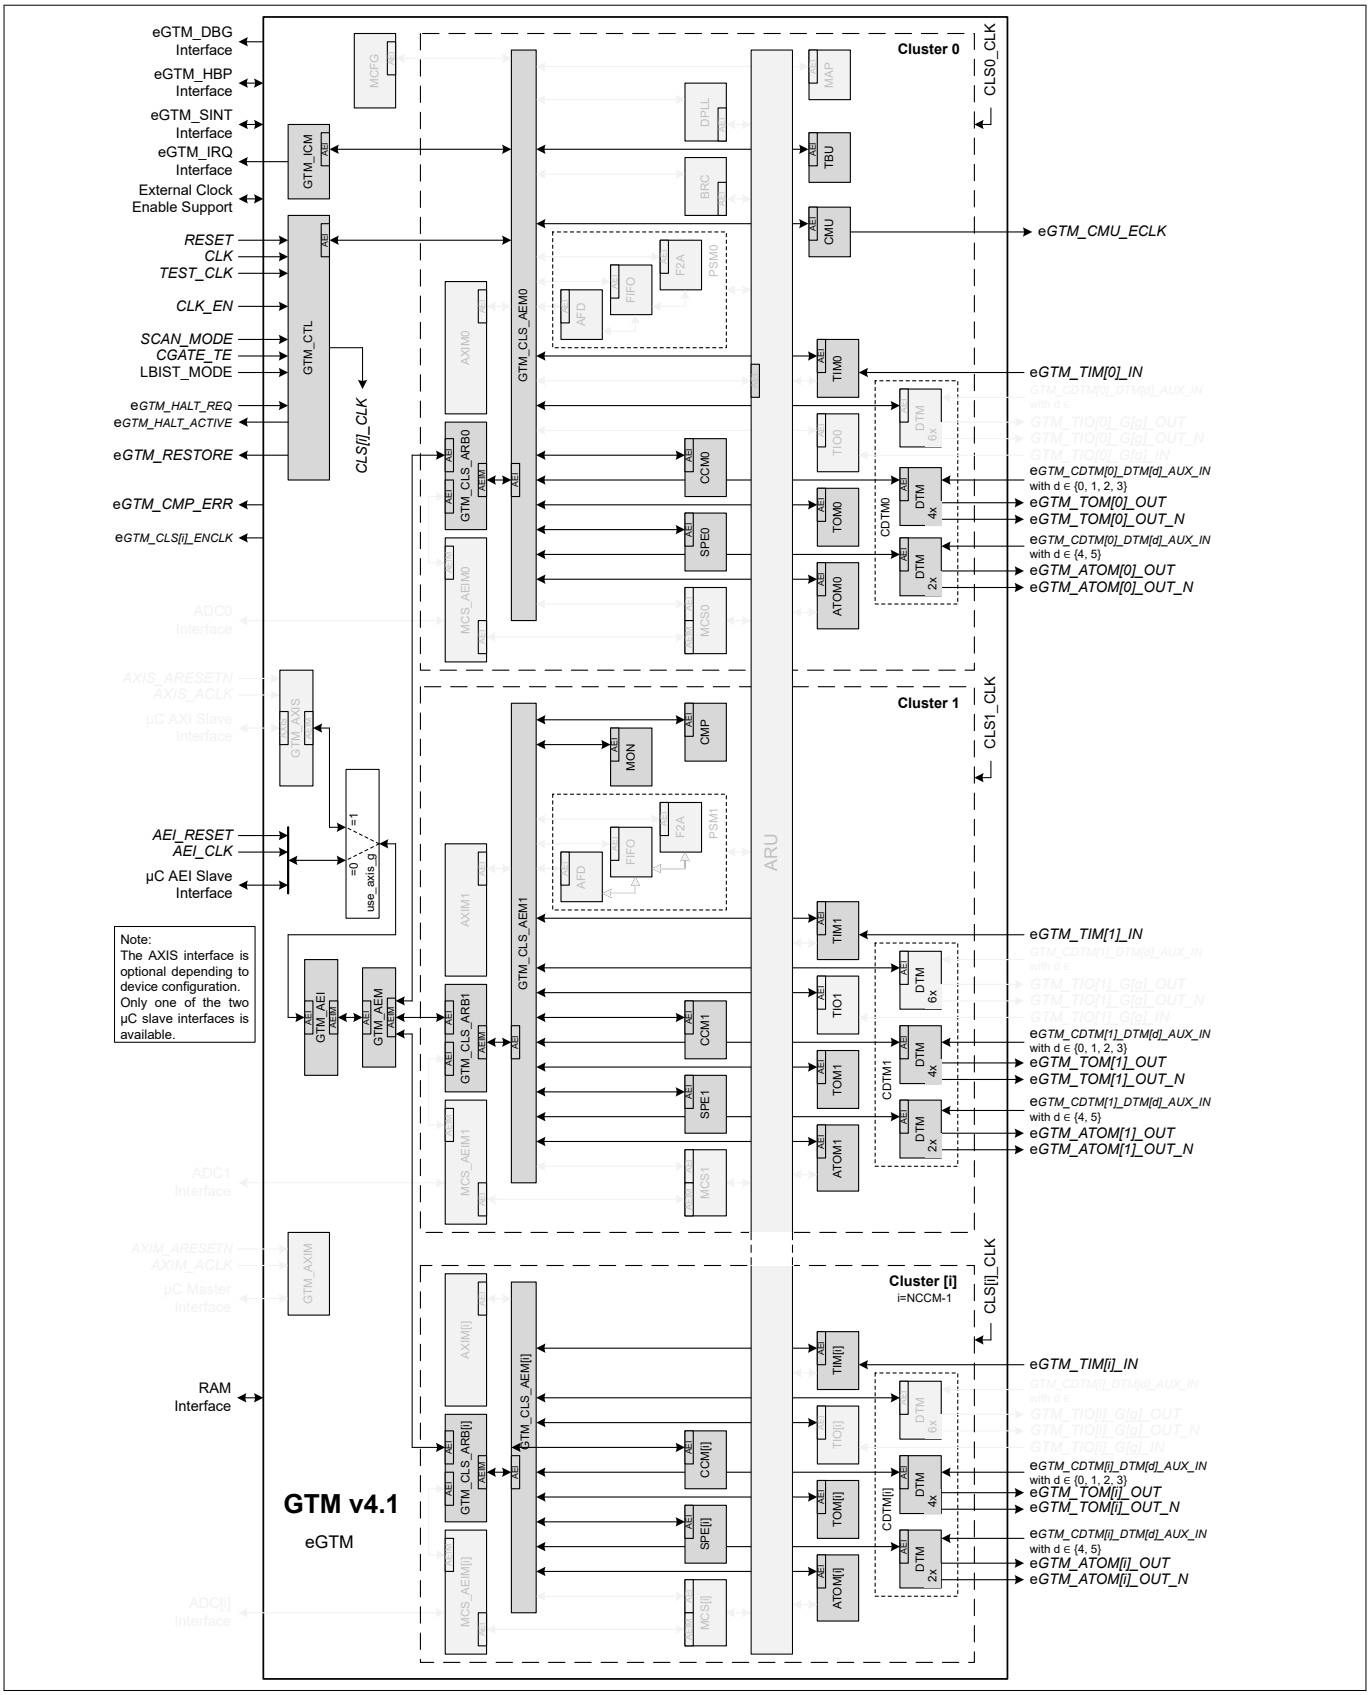

Figure 1016 eGTM architecture block diagram

***Note**: Faded content is not existing on the device.*

44 Enhanced Generic Timer Module (eGTM)

The **eGTM** is divided in multiple clusters 0...n. A certain number of modules exist in each cluster. The operating frequency of a cluster can be configured to OFF, CLK or CLK / 2 by appropriately configuring CLSi_ARCH_CLK_CFG**.**CLSi_ARCH_CLK_CFG **(j=i)**. The clock enable generation can be implemented internal to the **eGTM** or external. In case of an external enable generation, CLK_EN is used to generate the internal clocks. In addition, an enable watchdog is implemented to monitor the correctness of the externally applied enable signals CLK_EN. More about clocking in the **eGTM** follows in Introduction to clocking.

Signals are transferred into the **eGTM** at the Timer Input Modules (**TIM**). These modules are able to filter the input signals and annotate additional information. Each channel is, for example, able to measure pulse high or low times and the period of a PWM signal in parallel . The internal operation registers of the **TIM** sub-module are 24-bit wide.

The Clock Management Unit (**CMU**) which generates up to 14 clock resolutions for the sub-modules of the **eGTM** and up to three **eGTM** external clocks. The clock resolutions are CMU_CLK_RES[x:x] and CMU_FXCLK_RES[y:y], where $x \in \{0, 1, ..., 8\}$ and $y \in \{0, 1, ..., 3\}$. These signals are routed to all clusters via ICPAs. Within a cluster, they are used as clock enables regulating the resolution (or rate) at which actions are performed. The external clocks are CMU_ECLK[z:z], where $z \in \{0, 1, 2\}$. In contrast to CMU_CLK_RES[x:x], these are approximately 50% duty cycle clocks. The primary clock source for this sub-module is cluster 0 clock signal (CLS[j]_CLK) which can be configured via CLSi_ARCH_CLK_CFG**.**CLSi_ARCH_CLK_CFG **(j=0)** to OFF, CLK or CLK /2. For a detailed description of the **CMU** functionality and clocks please refer to Clock management unit (**CMU**).

The **TBU** provides up to three independent common time bases for the **eGTM**. In general, the number of time bases depends on the implemented device.

Signal outputs are generated with the Dead-time Module (**DTM**), Timer Output Modules (**TOM**) and the **ARU**-connected **TOM**s (**ATOM**). Each **TOM** channel is able to generate a PWM signal at its output. Because of the integrated shadow register (see here) even the generation of complex PWM outputs is possible with the **TOM** channels by serving the parameters with the CPU. It is possible to trigger **TOM** channels for a successor **TOM** sub-module through a trigger line between **TOM[i]** channel 15 and **TOM[i+1]** channel 0. But to avoid long trigger paths the **eGTM** integrator configures, after which **TOM** sub-module instance, a pipeline register is placed into the trigger signal chain. Each pipeline register results in one CLK cycle delay of the trigger signal. Please refer to the device-specification of the silicon vendor for unregistered trigger chain length.

In addition, each **TOM** sub-module integrates functions to drive one BLDC engine. This BLDC support is established together with the **TIM** and Sensor Pattern Evaluation (**SPE**) sub-module.

The **ATOM**s offer the additional functionality to generate complex output signals without CPU interaction . While the internal operation and shadow registers of the **TOM** channels are 16 bits wide, the operation and shadow registers of the **ATOM** channels are 24 bits wide to have a higher resolution and to have the opportunity to compare against time base values coming from the **TBU**.

It is possible to trigger **ATOM** channels for a successor **ATOM** sub-module through a trigger line between **ATOM[i]** channel 7 and **ATOM[i+1]** channel 0. But to avoid long trigger paths the **eGTM** integrator can configure after which **ATOM** sub-module instance a pipeline register is placed into the trigger signal chain. Each pipeline register results in one CLK cycle delay of the trigger signal. Please refer to the device-specification of the silicon vendor for unregistered trigger chain length.

The two modules Compare Module (**CMP**) and Monitor Module (**MON**) implement safety related features. The **CMP** compares two output channels of the **DTM** and sends the result to the **MON** sub-module, where the error is signaled to the CPU. The **MON** module is also able to monitor the **CMU** activities.

In the described implementation, the sub-modules of the **eGTM** have a huge number of different interrupt sources. These interrupt sources are grouped and concentrated by the Interrupt Concentrator Module (**ICM**) to form a much easily manageable bunch of interrupts that are visible outside of the **eGTM**.

44.3.1.2.2 Introduction to clocking

The **eGTM** offers many possibilities on different granularity levels to reduce the power budget during run-time. The possibilities include shutting off a particular cluster/module or clocking them at a reduced frequency, among others.

The first layer of configurability is on the cluster level. A cluster clock can be shut off completely or configured to use the **eGTM** global clock or the **eGTM** global clock halved by appropriately configuring CLSi_ARCH_CLK_CFG. In the **eGTM**, cluster clocks can be configured differently. The **CCM** module also offers the possibility to enable/disable different modules in the cluster by appropriately configuring CLSi_CCM_CMU_CLK_CFG**.**CLKy_SRC (y=0-7), where 0 <= i <= NCCM - 1 and 0 <= y <= 7.

The second layer of configurability is offered by the **CMU** module (exists only in cluster 0). This module takes the cluster clock as input and uses the clock dividers within to generate different clock resolutions (CMU_CLK_RES[x:x] (x ∈ {0, 1,..., 8})) that are routed through ICPA (refer to Inter-cluster pulse adapter) to the **CCM** modules in all the clusters. These signals give the user the possibility to further regulate the rate (or the resolution) at which the functions in different modules run at (see Figure 1036). A CMU_CLK_RES[x:x] signal can be enabled/disabled by appropriately configuring CLSi_CMU_CLK_EN**.**EN_CLKx (x=0-7).

The third layer of configurability is offered by the **CCM** module (exists in every cluster). Different clusters can be clocked differently. This module samples the CMU_CLK_RES[x:x] resolution signals at the cluster clock. The sampled clocks are then routed to different modules within the cluster in which they are used as clock enables. This allows different modules within a cluster to run at different resolutions.

Attention: The **eGTM** offers various debugging mechanisms (more about that in **eGTM** software debugger support). When debugging is active and (e)GTM_HALT_REQ is asserted, the cluster clocks are disabled in order to stall the internal operations in the **eGTM** during the debugging session.

44.3.1.2.3 Connectivity between modules

On the **eGTM** top-level there are some configurable signal connections from the signal output of the **DTM** modules to the input signals of the **TIM** modules.

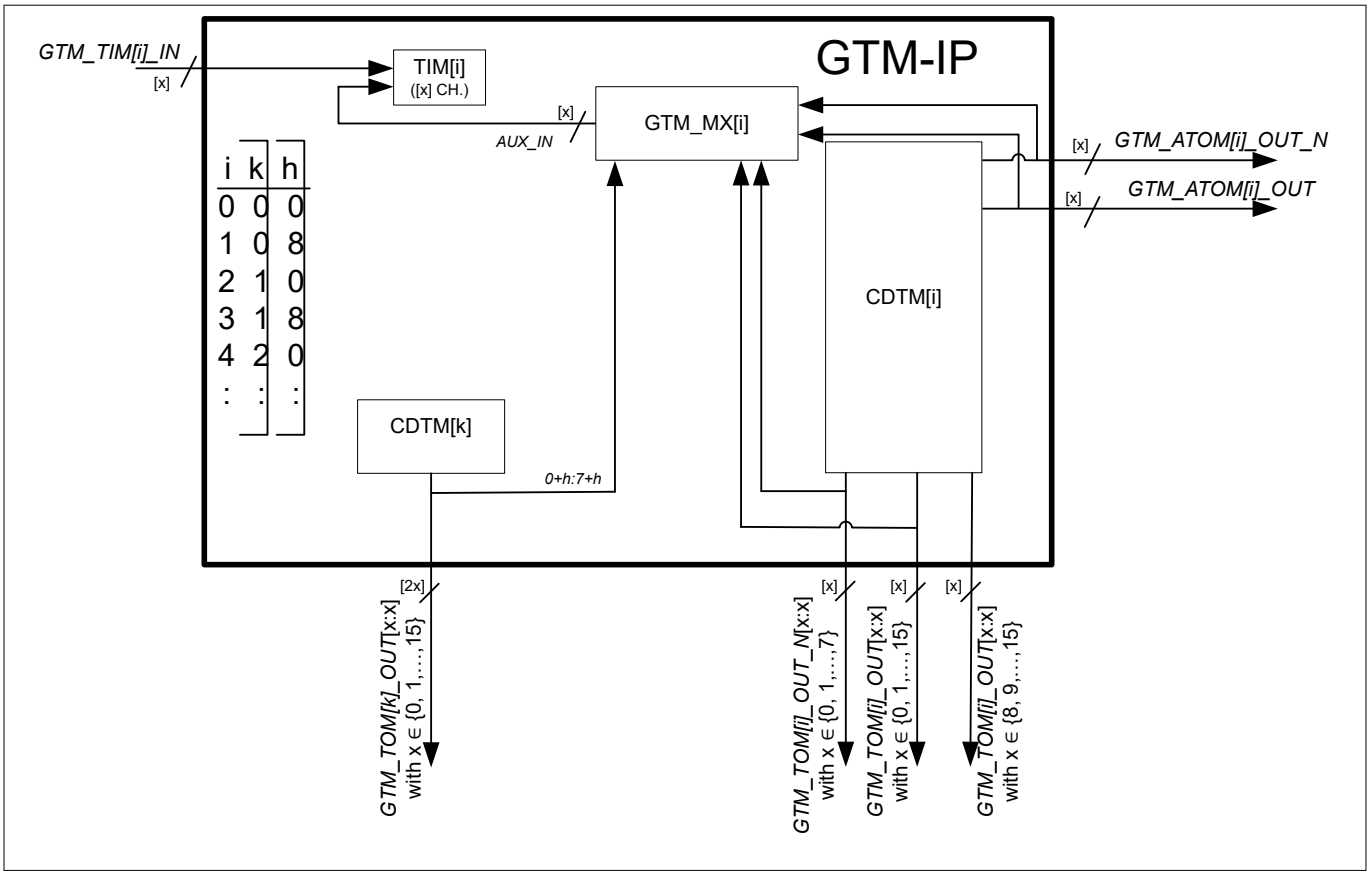

Figure 1017 eGTM signal multiplex

The next diagram gives an overview of the connectivity for different configuration of bit field CLSi_ARCH_CFG.SRC_IN_MUX and the cluster configuration register CLSi_CCM_TIM_AUX_IN_SRC. The source selection is defined per channel with the bit fields CLSi_CCM_TIM_AUX_IN_SRC.SRC_CH0, CLSi_CCM_TIM_AUX_IN_SRC.SRC_CH1, CLSi_CCM_TIM_AUX_IN_SRC.SRC_CH2, CLSi_CCM_TIM_AUX_IN_SRC.SRC_CH3, CLSi_CCM_TIM_AUX_IN_SRC.SRC_CH4, CLSi_CCM_TIM_AUX_IN_SRC.SRC_CH5, CLSi_CCM_TIM_AUX_IN_SRC.SRC_CH6, CLSi_CCM_TIM_AUX_IN_SRC.SRC_CH7 and CLSi_CCM_TIM_AUX_IN_SRC.SEL_OUT_N_CHx (x=0-7).

The calculation of the index k, h and the connectivity of the next figure covers devices with 8 **TIM** modules.

In case a device is equipped with more **TIM** instances as **ATOM** instances (NTIM > NATOM), the signals (e)GTM_ATOM[i]_OUT[x:x], (e)GTM_ATOM[i]_OUT_N[x:x] are tied to 0; i>NTIM.

CLSi_ARCH_CFG.SRC_IN_MUX=1: In case a device is equipped with more **TIM** instances as **TOM** instances (NTIM > NTOM), the signals (e)GTM_TOM[i]_OUT[x:x], (e)GTM_TOM[i]_OUT_N[x:x] are tied to 0; i>NTIM.

CLSi_ARCH_CFG.SRC_IN_MUX=0: In case a device is equipped with lesser **TIM** instances as **TOM** instances (2* NTIM < NTOM), the signals (e)GTM_TOM[i]_OUT[x+h:x+h] are tied to 0; i>NTIM.

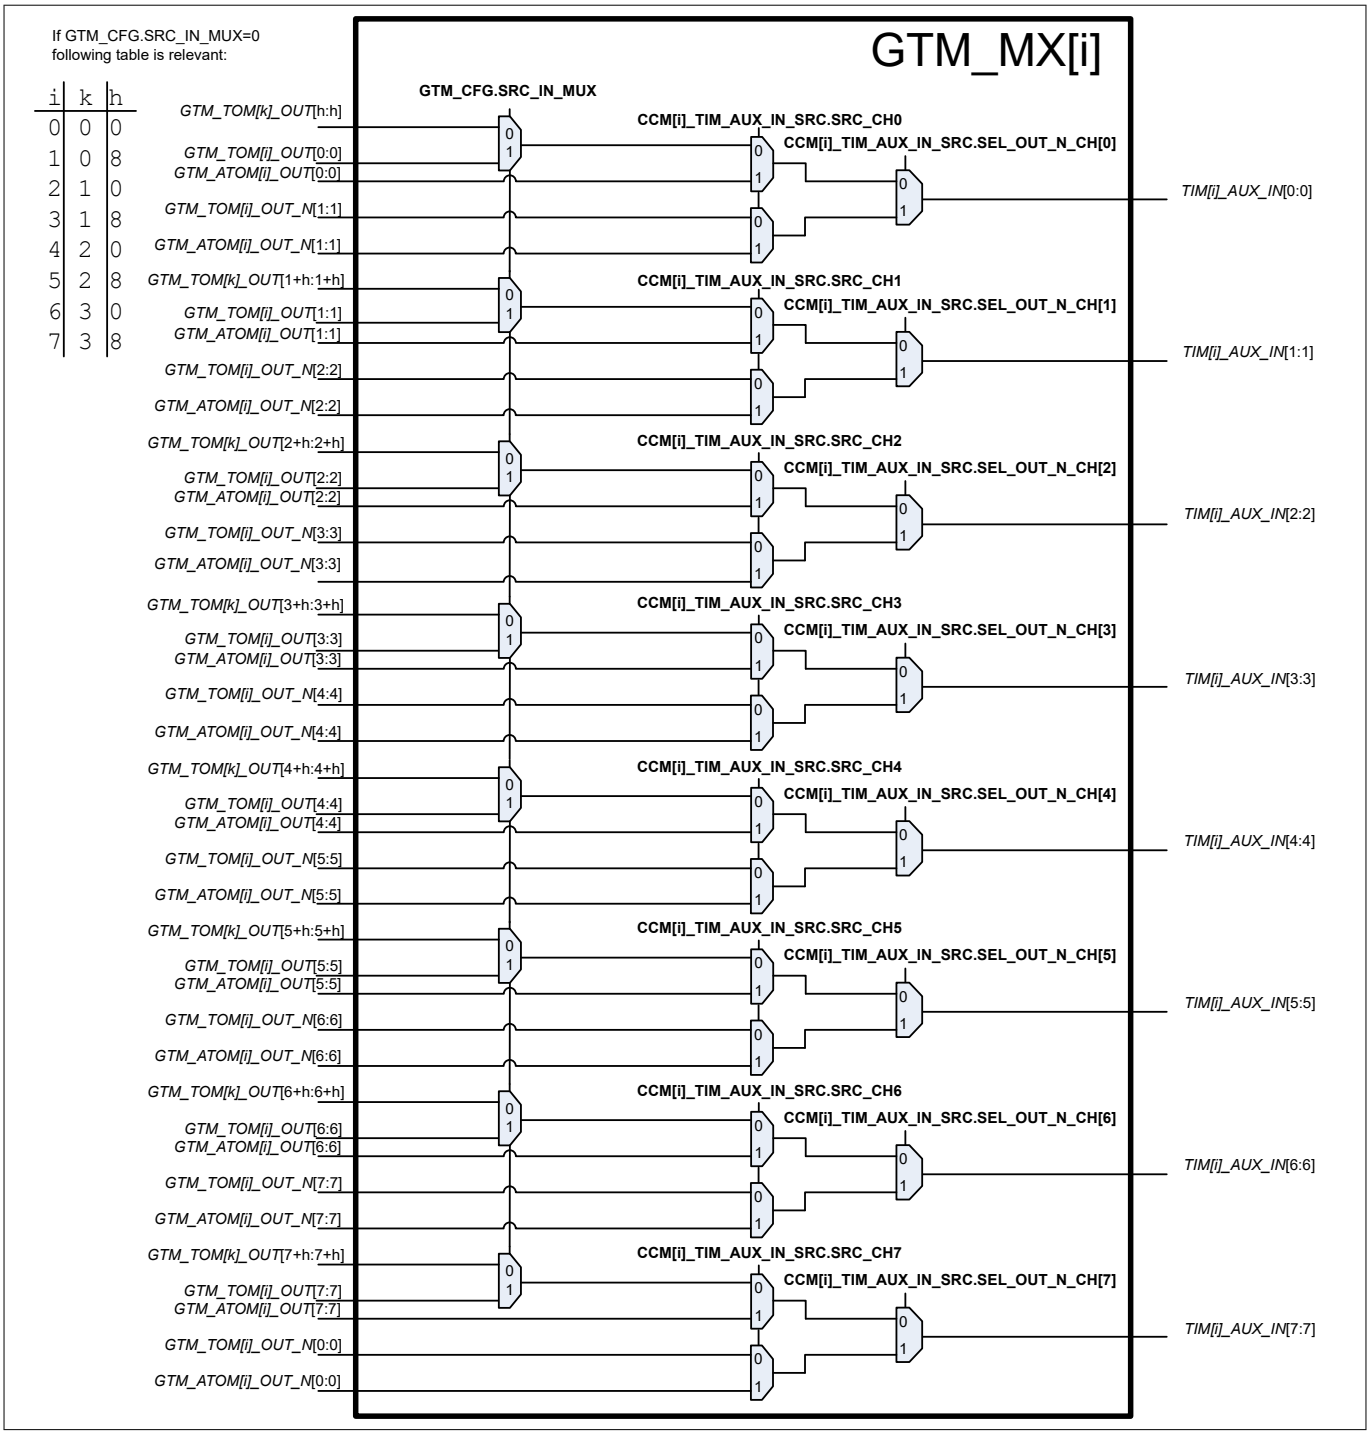

Figure 1018 TIM auxiliary input multiplexing

The trigger out of **TIM** (i.e. the signals TIM_EXT_CAPTURE[7:0] of each **TIM** instance i) are routed to **ATOM** instance i and **TOM** instance i with i∈{0, 1,..., NTIM-1} (NTIM defines the number of available **TIM** instances).

This **TIM** trigger is used to trigger inside the **ATOM** or **TOM** instance either a channel or the global control register of AGC or TGC0/TGC1 unit.

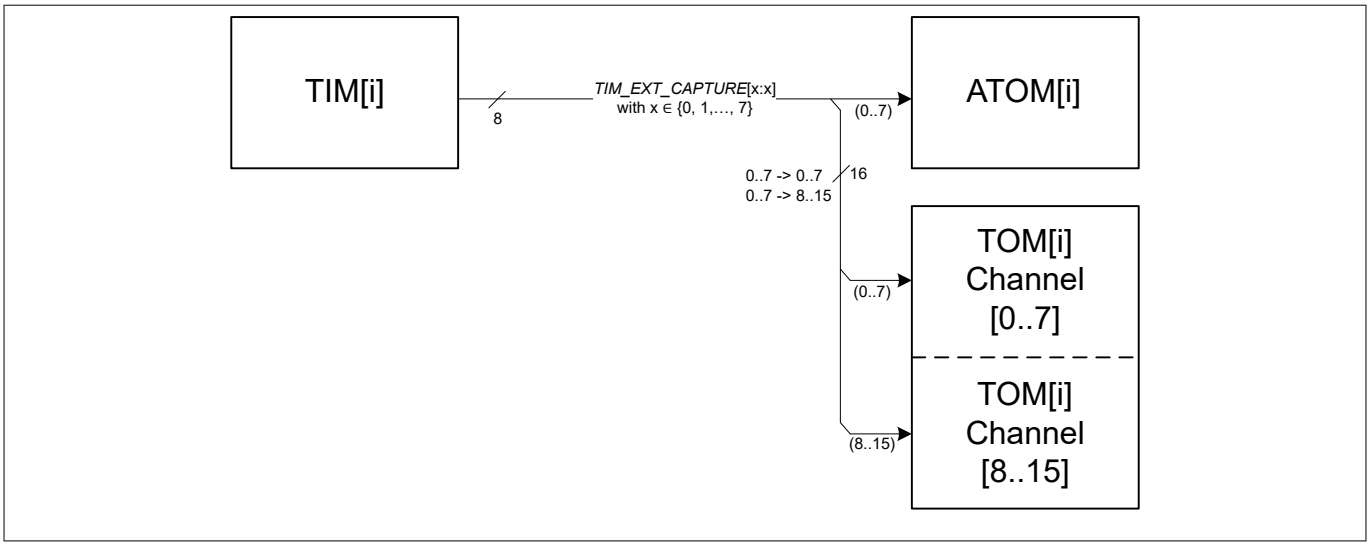

Figure 1019 TIM external capture forwarding to TOM and ATOM

The following two figures show, how signals are routed to the **DTM** module.

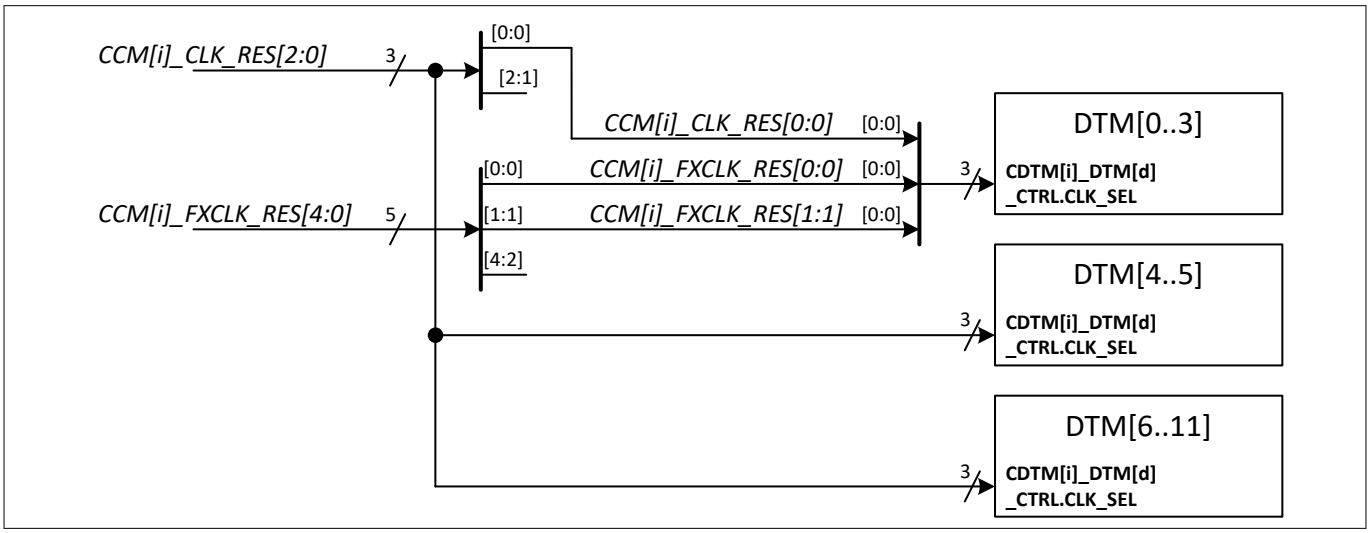

Figure 1020 Routing of CMU clock signals to DTM modules

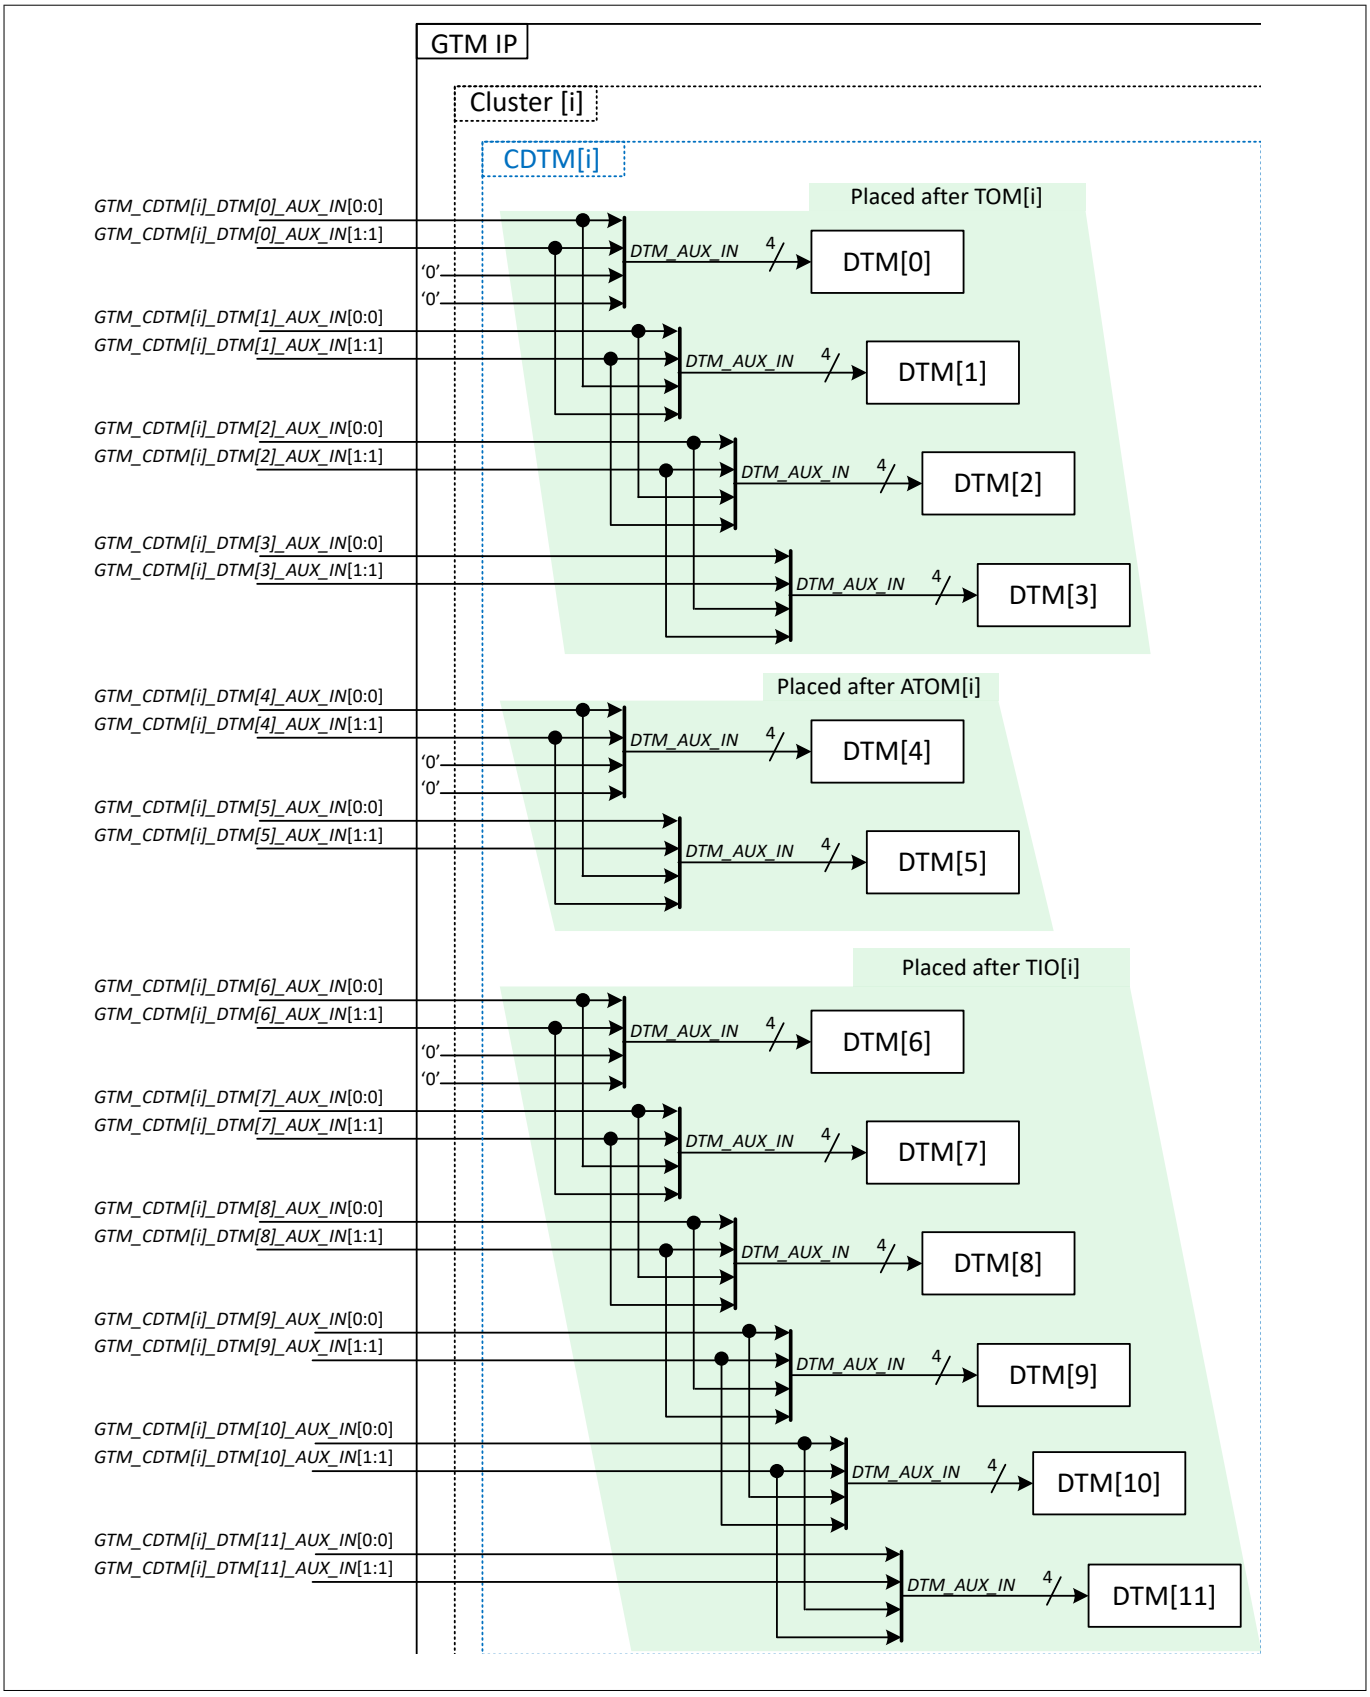

Figure 1021 Routing of DTM AUX input signals

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

44.3.1.2.4 eGTM interfaces

In general, the **eGTM** is divided into multiple interface groups. Two interface groups represent the ports of the **eGTM** where incoming signals are assembled and outgoing signals are created. These interfaces are therefore connected to the **eGTM** input sub-module **TIM** and to the **eGTM** output sub-modules **DTM**.

Another interface is the bus master interface where the **eGTM** is connected to the system bus and actively drive read and write operations onto the system bus. This generic bus interface is described in more detail in **eGTM** generic bus interface (**AEI**).

Another interface is the bus slave interface where the **eGTM** is connected to the system bus to allow access to the **eGTM** internal resources described in more detail in **eGTM** generic bus interface (**AEI**).

The last interface is the interrupt controller interface. The **eGTM** provides several interrupt lines coming from the various sub-modules. These interrupt lines are concentrated inside the **ICM** and have to be adapted to the dedicated microcontroller environment where each interrupt handling can look different. The interrupt concept is described in more detail in **eGTM** interrupt concept.

eGTM generic bus interface (AEI)

The **eGTM** is equipped with a generic bus interface. This generic bus interface is called AE_Interface (**AEI**). .

Figure 1022 Overview of eGTM address space

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

The modules (**ARCH**, **AEI**, **CMU**, **TBU**, **ICM**, **CMP**) may only be available in cluster 0 address space.

The modules (**MON**, **CMP**) may only be available in cluster 1 address space.

The (**TIM**, **TOM**, **ATOM**, **CCM**, **SPE**, **DTM**) modules may only fill out the clusters starting from cluster 0 onwards.

The **ARCH** configuration registers and the **AEI** configuration registers share the following properties:

- They are responsible for configuring functionalities spanning/impacting multiple clusters (CLSi_ARCH_RST, CLSi_ARCH_CFG, CLSi_ARCH_CLK_CFG).
- They are responsible for atomically switching on/off functionalities across multiple clusters (CLSi_ARCH_RST, CLSi_ARCH_CFG, CLSi_ARCH_CLK_CFG).
- They are responsible for configuring and providing status of the interfaces (CLSi_ARCH_CTRL, CLSi_ARCH_IRQ_NOTIFY, CLSi_ARCH_AEI_ADDR_XPT, CLSi_ARCH_AEI_STA_XPT, CLSi_ARCH_RST).
- They are still accessible when cluster 0 is switched off.

The **AEI** status signal may drive one of the following values:

Table 2145 AEI status signal

AEI_STATUS coding	Description
00_B	No Error
01_B	Illegal Byte-addressing
10_B	Illegal Address Access
11_B	Unsupported Address

The evaluation of the status of a read-/write-access is executed based on a priority scheme. The ordering of priorities is defined in the following:

1. PRIO1 checks are validated first, if a check condition matches, the corresponding AEI_STATUS is returned, otherwise checking continues with PRIO2.
2. PRIO2 checks are validated next, if a check condition matches, the corresponding AEI_STATUS is returned, otherwise checking continues with PRIO3.
3. PRIO3 checks are validated next, if a check condition matches, the corresponding AEI_STATUS is returned, otherwise checking continues with PRIO4.
4. PRIO4 checks are validated next, if a check condition matches, the corresponding AEI_STATUS is returned, otherwise AEI_STATUS = 00_B is returned.

The signal value 01_B is returned:

- PRIO1: if the bus address is not an integer multiple of 4 (byte-addressing).

For cluster or module clock disable functionality, the following address range definitions exist:

Table 2146 Cluster address range access is disabled by CLSi_ARCH_CLK_CFG.CLSj_CLK_DIV (j=0-2) (j=i)=00_B

Cluster i	Address range
0	000050_H - $0003FF_H$; 000600_H - $01FFFF_H$
1	020000_H - $03FFFF_H$
2	040000_H - $05FFFF_H$
3	060000_H - $07FFFF_H$
4	080000_H - $09FFFF_H$
5	$0A0000_H$ - $0BFFFF_H$
6	$0C0000_H$ - $0DFFFF_H$
7	$0E0000_H$ - $0FFFFF_H$
8	100000_H - $11FFFF_H$
9	120000_H - $13FFFF_H$
10	140000_H - $15FFFF_H$
11	160000_H - $17FFFF_H$

Table 2147 Module address range access is disabled by module clock enable = 0_B

Module clock enable	Implemented in cluster i if condition is true	Module name	Module address offset range
CLSi_CCM_CFG.EN_TIM	i < NTIM	**TIM**	000800_H - $000FFF_H$
CLSi_CCM_CFG.EN_TOM_SPE_TDTM	i < NTOM	**TOM**	001000_H - $017FFF_H$
CLSi_CCM_CFG.EN_TOM_SPE_TDTM	i < NTOM & CDTM[i][d] (d∈{0, 1, 2, 3})	TDTM	004400_H - $0044FF_H$
CLSi_CCM_CFG.EN_TOM_SPE_TDTM	i < NSPE	**SPE**	$004C00_H$ - $004C7F_H$
CLSi_CCM_CFG.EN_ATOM_ADTM	i < NATOM	**ATOM**	001800_H - $01FFFF_H$
CLSi_CCM_CFG.EN_ATOM_ADTM	i < NATOM & CDTM[i][d] (d∈{4, 5})	ADTM	004500_H - $00457F_H$
CLSi_CCM_CFG.EN_CMP_MON	i == NMON & i == 1	**MON**	000680_H - $0006BF_H$
CLSi_CCM_CFG.EN_CMP_MON	i == NCMP & i == 1	**CMP**	$0006C0_H$ - $0006FF_H$

The signal value 10_B is returned for an access where the target address is not accessible (cluster / module shutoff or internal operation on-going):

- PRIO2: on a read or write, if the address is located in the cluster i address range, which is disabled by CLSi_ARCH_CLK_CFG.CLSj_CLK_DIV (j=0-2) **(j=i)** = 00_B
- PRIO2: on a read or write, if the address is located in the module **TIM[i]** address range, which is disabled by CLSi_CCM_CFG.EN_TIM = 0_B
- PRIO2: on a read or write, if the address is located in the module **TOM[i]**, **SPE[i]**, CDTM[i]_DTM[3:0] address range, which is disabled by CLSi_CCM_CFG.EN_TOM_SPE_TDTM = 0_B
- PRIO2: on a read or write, if the address is located in the module **ATOM[i]**, CDTM[i]_DTM[5:4] address range, which is disabled by CLSi_CCM_CFG.EN_ATOM_ADTM = 0_B
- PRIO2: on a read or write, if the address is located in the module **CMP**, **MON** address range, which is disabled by CLSi_CCM_CFG.EN_CMP_MON = 0_B

The signal value 10_B is returned for a protected write-access:

- PRIO4: if for the written register all writable bit fields are equipped with the same write-protection condition and the protection is active (independently of the written value).

In case of an illegal write-access signaled by status 10_B the register will not be modified.

The signal value 11_B is returned:

- PRIO3: if for the requested address no **eGTM** register or **eGTM** memory location is defined
- PRIO3: if the requested address is not implemented in the actual device (device dependency attribute of that address evaluates to false)

The signal value 00_B is returned:

- If no error occurred during **AEI** access.
- If all register bit fields are defined as read only, a write to this register will not modify any content.
- If a register bit field is defined as read only, a write to this register bit field will not modify the content. All bit fields of the same register which are writable will be written as requested.

- If a register contains a protected bit field and the protection is active the bit field will not be modified. All bit fields of the same register which have no protection will be written as requested.
- If a bit field of a register is defined as reserved, any write-access to this bit field has no side-effect and a read-access to this bit field will always return the value 0.
- If a bit field of a register is not implemented in the actual device (device dependency attribute of that bit field evaluates to false) this is treated as reserved, any write-access to this bit field has no side-effect and a read-access to this bit field will always return the value 0.
- If one or more encoding values of a bit field are defined as reserved values and nothing else is specified, the following default behavior is defined: The written value can be read back and the entire behavior of the circuit is undefined.

eGTM AEI bridge software reset

The configuration bit field CLSi_AEI_BRIDGE_MODE.BRG_RST is used for software reset of the (E)GTM_AEI module.

Writing the value 1_B to the bit field CLSi_AEI_BRIDGE_MODE.BRG_RST via the configuration interface, will immediately reset the content of the following registers to the initial hardware reset state.

- CLSi_AEI_BRIDGE_MODE: Details about which bit fields are reset follow in CLSi_AEI_BRIDGE_MODE register description.
- CLSi_AEI_BRIDGE_PTR1
- CLSi_AEI_BRIDGE_PTR2
- CLSi_ARCH_AEI_ADDR_XPT
- CLSi_ARCH_AEI_STA_XPT
- Internal registers inside the (E)GTM_AEI module which are not memory mapped are reset too.

44.3.1.2.5 AEI bus system

Table 2148 Functionality of AEI bus system modules

Module	Functionality
(E)GTM_AEI	Implements the top level bus bridge. It allows to operate the **eGTM AEI** bus interface on an individual clock frequency. It supports 3 different **AEI** protocol versions which have different performance properties. The semiconductor vendor will choose a protocol variant which suits best for the integration of the **eGTM** . In the module a transaction buffer is implemented to store incoming transactions and support for postponed transactions.
(E)GTM_AEM	Decodes the **eGTM** internal address space into the cluster address ranges. Transactions will only be forwarded to the cluster which is addressed.
(E)GTM_CLS_ARB	Performs arbitration of the 2 possible cluster **AEI** masters (MCS_AEIM, (E)GTM_AEM). Arbitration will be performed on each single **AEI** access.
MCS_AEIM	This signal has no impact on **eGTM** .

(table continues...)

Table 2148 (continued) Functionality of AEI bus system modules

Module	Functionality
(E)GTM_CLS_AEM	Decodes the cluster internal address space into the module address ranges. Transactions will only be forwarded to the module which is addressed.
AEI	Interface of a module which acts as **AEI** slave.
AEIM	Interface of a module which acts as **AEI** master.

(E)GTM_AEM module

This module receives accesses from the (E)GTM_AEI bridge and decodes (based on the provided address AEI_ADDR to which cluster i) the access has to be forwarded. The cluster index is decoded by i = AEI_ADDR[10:17]. In case the targeted cluster is switched off (CLSi_ARCH_CLK_CFG**.**CLSj_CLK_DIV (j=0-2) **(j=i)** = 0), the access is not forwarded and AEI_STATUS = 10_B with AEI_RDATA = 0_H is responded for this access. In case the targeted cluster i is not implemented in this device, the access is responded with AEI_STATUS = 11_B and AEI_RDATA = 0_H.

(E)GTM_CLS_ARB module

***Note**: The EGTM does not include an MCS nor a PSM.*

The **eGTM** is equipped with the possibility to introduce pipeline stages in the **AEI** bus system for accesses from the CPU. Details how to control the pipeline stage insertion can be found in the module integration guide. In big devices, the decoding of the combinatorial address space for the register accesses and the Rdata multiplexing will not be possible (due to limited performance of technology) in one clock cycle.

- AEI_ADDR_PIPELINE_STAGE: Pipeline registers are included for all **AEI** request signals in the **AEI** address decoding path at the input of (E)GTM_CLS_ARB for the signals which are driven by the (E)GTM_AEM. The signals (AEI_SEL, AEI_ADDR, AEI_WDATA, AEI_W1R0, AEI_DEBUG_ACCESS) will be delayed by 1 **eGTM** clock (CLK).
- AEI_RDATA_PIPELINE_STAGE: Pipeline registers are included for all **AEI** response signals in the **AEI** access multiplexing path at the output of the (E)GTM_CLS_ARB for the signals which are received by (E)GTM_AEM. The signals (AEI_RDATA, AEI_READY, AEI_STATUS) will be delayed by 1 **eGTM** clock (CLK). As a consequence, the latency of bus transaction from the CPU will increase in case pipeline registers are put in place.

(E)GTM_CLS_AEM module

This module receives accesses from the (E)GTM_CLS_ARB module and decodes to which module the access has to be forwarded based on the provided address AEI_ADDR. The sub module decoding can be found in Figure 1022. In case the targeted module is switched off (corresponding enable bit in CLSi_CCM_CFG is set to 0), the access is not forwarded and AEI_STATUS = 10_B with AEI_RDATA = 0_H is responded for this access. In case the targeted module is not implemented in this device, the access is responded with AEI_STATUS = 11_B and AEI_RDATA = 0_H.

44.3.1.2.6 GTM_CTL module

AEI bus system transaction status monitoring for transactions applied to the eGTM

GTM_CTL allows monitoring of transactions initiated from **eGTM** external bus masters (CPU, DMA,..). Monitoring takes place on the signals after the (E)GTM_AEI bridge and operates on the CLK clock.

Each transaction response on the **AEI** bus system will indicate (with the AEI_STATUS signal) the current state of execution of the transaction (see Table 2145). To allow an application software to react on unexpected state of transactions (AEI_STATUS != 00_B), a transaction monitoring and signaling with an interrupt on (e)GTM_AEI_IRQ is implemented.

For monitoring the first transaction which occurs with AEI_STATUS != 0, GTM_CTL stores the transaction type in CLSi_ARCH_AEI_STA_XPT**.**W1R0 and the transaction address in CLSi_ARCH_AEI_STA_XPT**.**ADDR. Following transactions with (AEI_STATUS != 00_B) will not change the content of CLSi_ARCH_AEI_STA_XPT. Furthermore, for each type of AEI_STATUS an individual interrupt unit (see CLSi_ARCH_IRQ_NOTIFY**.**AEI_USP_ADDR, CLSi_ARCH_IRQ_NOTIFY**.**AEI_IM_ADDR, and CLSi_ARCH_IRQ_NOTIFY**.**AEI_USP_BE) is implemented. This allows applications to individually select for which kind of transaction response exception, an interrupt (e)GTM_AEI_IRQ (see CLSi_ARCH_IRQ_EN**.**AEI_USP_ADDR_IRQ_EN, CLSi_ARCH_IRQ_EN**.**AEI_IM_ADDR_IRQ_EN, and CLSi_ARCH_IRQ_EN**.**AEI_USP_BE_IRQ_EN) or/and error interrupt (e)GTM_ERR_IRQ (CLSi_ARCH_EIRQ_EN**.**AEI_USP_ADDR_EIRQ_EN, CLSi_ARCH_EIRQ_EN**.**AEI_IM_ADDR_EIRQ_EN, and CLSi_ARCH_EIRQ_EN**.**AEI_USP_BE_EIRQ_EN) can be generated.

Any write access of value 1 to one of the flags CLSi_ARCH_IRQ_NOTIFY**.**AEI_USP_ADDR, CLSi_ARCH_IRQ_NOTIFY**.**AEI_USP_BE, CLSi_ARCH_IRQ_NOTIFY**.**AEI_IM_ADDR will clear the flags and the transaction status exception register CLSi_ARCH_AEI_STA_XPT.

Additional transaction status monitoring in a device with an AXI slave

The AXI slave is able to detect invalid transactions which cannot be operated correctly. In these cases, the AXIS module initiates an error signaling read transaction to the (E)GTM_AEI. The address in use will be FC_H. This address is an unimplemented address in the GTM_CTL. Any transaction to this address can trigger the (e)GTM_AEI_IRQ interrupt or store the exception in CLSi_ARCH_AEI_STA_XPT.

AEI bus system transaction length monitoring

GTM_CTL allows monitoring of transactions initiated from **eGTM** external bus masters (CPU, DMA,..). The monitoring takes place on the signals AEI_SEL, AEI_READY of the (E)GTM_AEI bridge master, the monitoring operates on the CLK clock. The transaction length monitoring can be enabled by writing CLSi_ARCH_CTRL**.**TO_VAL to a value unequal to 0. For each transaction the length will be counted in clock resolutions. The length timeout counter will increment on CLK as long as AEI_SEL = 1 and AEI_READY = 0. Each end of a transaction will reset the timeout counter. As soon as the length timeout counter is equal to CLSi_ARCH_CTRL**.**TO_VAL, one of the 4 possible reactions configurable with CLSi_ARCH_CTRL**.**TO_MODE will be triggered:

- b00: Observe once. On the first trigger, store the transaction information in CLSi_ARCH_AEI_ADDR_XPT. There is no impact on the ongoing transaction. Further triggers will be ignored.
- b01: Abort once. On the first trigger, store the transaction information in CLSi_ARCH_AEI_ADDR_XPT and immediately abort the ongoing transaction. The (E)GTM_AEI bridge master will abort the ongoing transaction by AEI_SEL = 0. In the transaction buffer, the access is terminated and the data and status are assumed to be 0. The subsequent triggers will not impact the transactions. Further triggers will be ignored.
- b10: Retry. On the first trigger, store the transaction information in CLSi_ARCH_AEI_ADDR_XPT and immediately stop and repeat the ongoing transaction. The (E)GTM_AEI bridge master will stop the ongoing transaction by applying AEI_SEL = 0 for 1 clock cycle, afterwards with AEI_SEL = 1 the transaction is continued. This will be applied for every occurring trigger.
- b11: Abort. On the first trigger, store the transaction information in CLSi_ARCH_AEI_ADDR_XPT and immediately abort the ongoing transaction. The (E)GTM_AEI bridge master will abort the ongoing transaction by AEI_SEL = 0. In the transaction buffer, the access is terminated and the data and status are assumed to be 0. This will be applied for every occurring trigger.

The first occurring trigger will store the transaction address AEI_ADDR in CLSi_ARCH_AEI_ADDR_XPT.TO_ADDR and the transaction type AEI_W1R0 in CLSi_ARCH_AEI_ADDR_XPT.TO_W1R0. Following timeout triggers will not change the content of CLSi_ARCH_AEI_ADDR_XPT. Furthermore, an individual interrupt unit (see **eGTM** interrupt concept) is implemented. This allows applications to receive an interrupt based on the transaction access length. The interrupt (e)GTM_AEI_IRQ or/and error interrupt (e)GTM_ERR_IRQ can be generated.

Any write access of value 1 to the flag CLSi_ARCH_IRQ_NOTIFY.AEI_TO_XPT will clear the flag and the transaction length monitoring register CLSi_ARCH_AEI_ADDR_XPT. This will re-enable the timeout trigger generation.

44.3.1.2.7 High-resolution PWM support

To realize a high-resolution PWM a suitable circuit is needed, e.g. a delay chain, which additionally delays the PWM output signal by a defined number of micro-steps.

This circuit is not part of the **eGTM**, but to control this circuit, **eGTM** delivers output ports (e)GTM_ATOM[i]_OUT_HRES[x] in addition to the PWM output ports (e)GTM_TOM[i]_OUT[x:x] and (e)GTM_ATOM[i]_OUT[x:x].

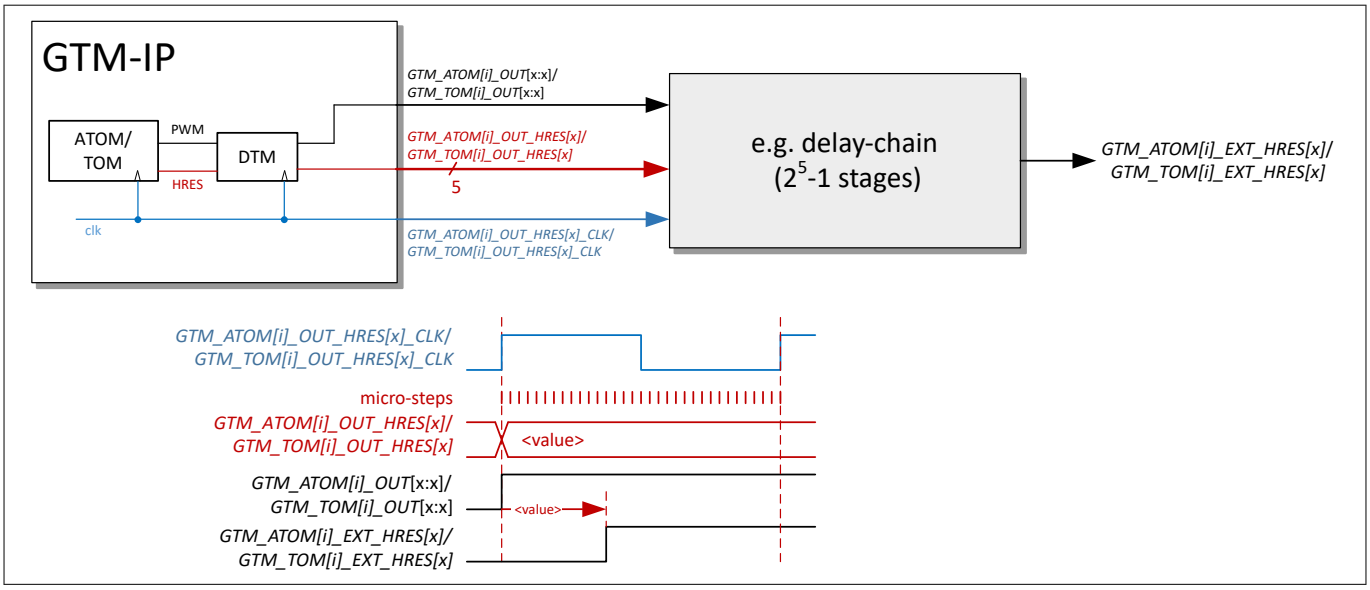

Figure 1023 High-resolution PWM support

The width of (e)GTM_ATOM[i]_OUT_HRES[x] is defined to 5. Therefore, the number of micro-steps is 2^5- 1 = 31.

The width of one micro-step depends on the clock period: micro-step$_{width}$ = CLK $_{period}$/2^5

A clock period of 5 ns (200 MHz) results in a micro-step width of: 5 ns / 2^5 = 156.25 ps.

The additional output signal (e)GTM_ATOM[i]_OUT_HRES[x] will be generated in **ATOM** sub-modules beside the PWM output signal (e)GTM_TOM[i]_OUT[x:x] and (e)GTM_ATOM[i]_OUT[x:x]. Afterwards the signal is connected through the **DTM** sub-module before being directed outside of **eGTM**.

Furthermore, the internal clock signal (clk) with which the **eGTM** output signals are generated will be delivered by **eGTM**.

The **DTM** sub-module provides the possibility to input dead-time on the output signal and the inverse output signal. Based on the high-resolution feature it is possible to adjust the dead-time length on micro-step level.

For detailed information about the high-resolution PWM support please refer to the chapter of the sub-modules **TOM**, **ATOM** and **DTM**.

44.3.1.2.8 Inter-cluster pulse adapter

Clusters can be configured to use different clock frequencies. For that, an additional control scheme (called here inter-cluster pulse adapter (ICPA)) is needed to coordinate the exchange of signals between two clusters. The concept of ICPA is demonstrated in Figure 1024.

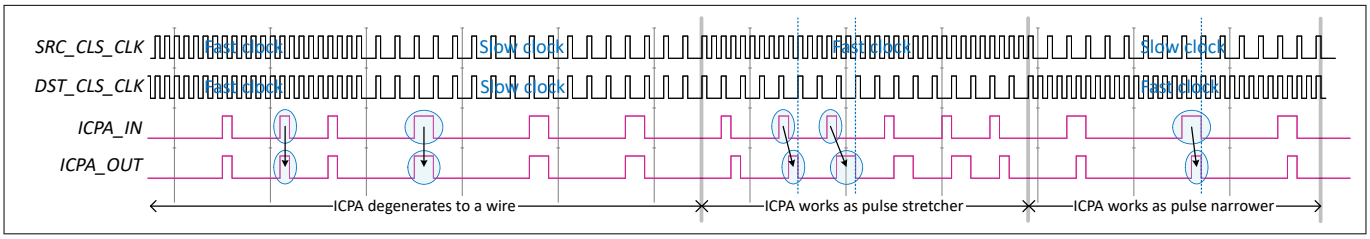

Figure 1024 Demonstration of the ICPA behavior handling pulses at different source and destination cluster frequencies

ICPA attempts to transform a pulse (of one cycle duration) generated in the source cluster in order to make it sampled exactly once in the destination cluster (regardless of the clocks used in both).

When the clocks in the two clusters are identical, the ICPA degenerates into a wire.

When a pulse is communicated from a cluster running at a slower clock rate to a faster clock rate, the ICPA narrows the pulse appropriately so that it is sampled once in the destination cluster.

When a pulse is communicated from a cluster running at a faster clock rate to a cluster running at a slower clock rate, the ICPA stretches it appropriately so that it is sampled once in the destination cluster.

It is worth mentioning that in the latter case, some pulses might get missed. This happens for example when the rate of pulse generation at the source cluster is higher than the clock rate in the destination cluster.

44.3.1.2.9 eGTM clock and time base management (CTBM)

Inside the **eGTM**, several sub-modules are involved in the clock and time base management of the whole **eGTM**. Figure 1025 shows the connections and sub-modules involved in these tasks. The sub-modules involved are called Clock and Time Base Management (CTBM) modules further on.

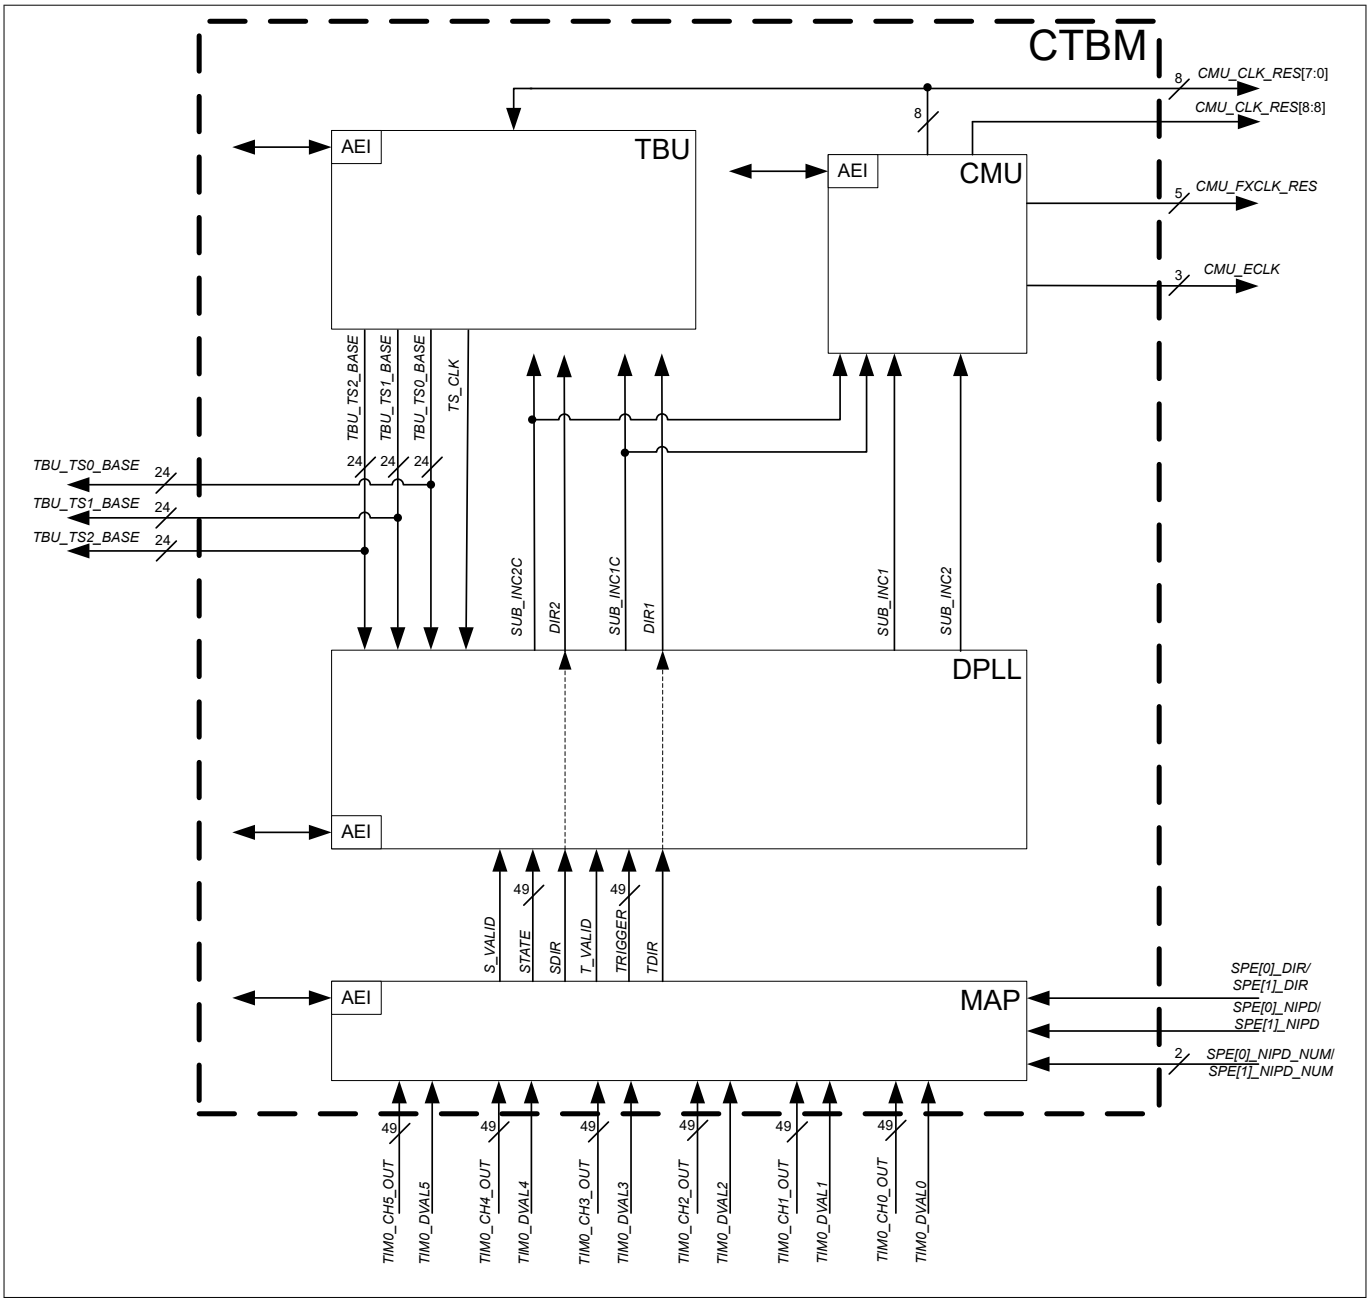

Figure 1025 eGTM clock and time base management architecture

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

One important module of the CTBM is the Clock Management Unit (**CMU**) which generates up to 14 clock resolutions for the sub-modules of the **eGTM** and up to three **eGTM** external clocks. The clock resolutions are CMU_CLK_RES[x:x] and CMU_FXCLK_RES[y:y], where x ∈ {0, 1, ..., 8} and y ∈ {0, 1, ..., 4}. These signals are routed to all clusters via ICPAs. Within a cluster, they are used as clock enables regulating the resolution (or rate) at which actions are performed. The external clocks are CMU_ECLK[z:z], where z ∈ {0, 1, 2}. In contrast to CMU_CLK_RES[x:x], these are approximately 50% duty cycle clocks. For a detailed description of the **CMU** functionality and clocks please refer to Clock management unit (**CMU**).

The five CMU_FXCLK_RES[y:y] (y ∈ {0, 1, ..., 4}) clock resolutions are used by the **TOM** sub-module for PWM generation.

A maximum of nine CMU_CLK_RES[x:x] (x∈{0, 1,..., 8}) clocks are used by other sub-modules of the **eGTM** for signal generation.

Inside the Time Base Unit (**TBU**) one of CMU_CLK_RES[x:x] (x ∈ {0, 1, ..., 7}) clock resolutions is used per channel to generate a common time base for the **eGTM**. The **TBU** functionality is described in Time base unit (**TBU**).

The **TBU** sub-module generates the three time base signals TBU_TS0_BASE, TBU_TS1_BASE and TBU_TS2_BASE which are widely used inside the **eGTM** as common time bases for signal characterization and generation.

Besides the time base 1 and 2 which may represent a relative angle clock for an engine management system it is helpful to have an absolute angle clock for CPU internal angle algorithm calculations. This absolute angle clock is represented by the **TBU** base 3. The **TBU** channel 0 up to 2 are widely used inside the **eGTM** as common time (channel 0, 1 and/or 2) or angle (channel 1 and/or 2) bases for signal characterization and generation. The **TBU** channel 3 is only configurable and readable by CPU.

Cyclic event compare

With the time base module (**TBU**) the **eGTM** provides three counters, where the counter of **TBU** channel 0 represents a time and the counter of **TBU** channel 1 or 2 may represent a time.

Deciding if an event is to happen in the future (or has happened in the past) is vital in many applications. Using conventional relational operators to determine if an event has happened in the past (or is to happen in the future) is not reliable. The reason is attributed to the inevitable wrap-arounds associated with using limited word length representations for the time bases. In order to avoid this, cyclic event compares have been introduced in **eGTM** (see Figure 1026). The dynamic range of tbu ∈ {TBU_TS0_BASE, TBU_TS1_BASE, TBU_TS2_BASE} is represented as a circle with a diameter starting from the current value of tbu and splitting the circle into two regions (future and past). The two regions rotate with tbu (clockwise when up-counting and counter-clockwise when down-counting). Depending on the direction of counting and the time/position associated with an event, it can be readily determined if an event has happened in the past or is to happen in the future. The definitions for the cyclic compare operators are provided in the following algorithm:

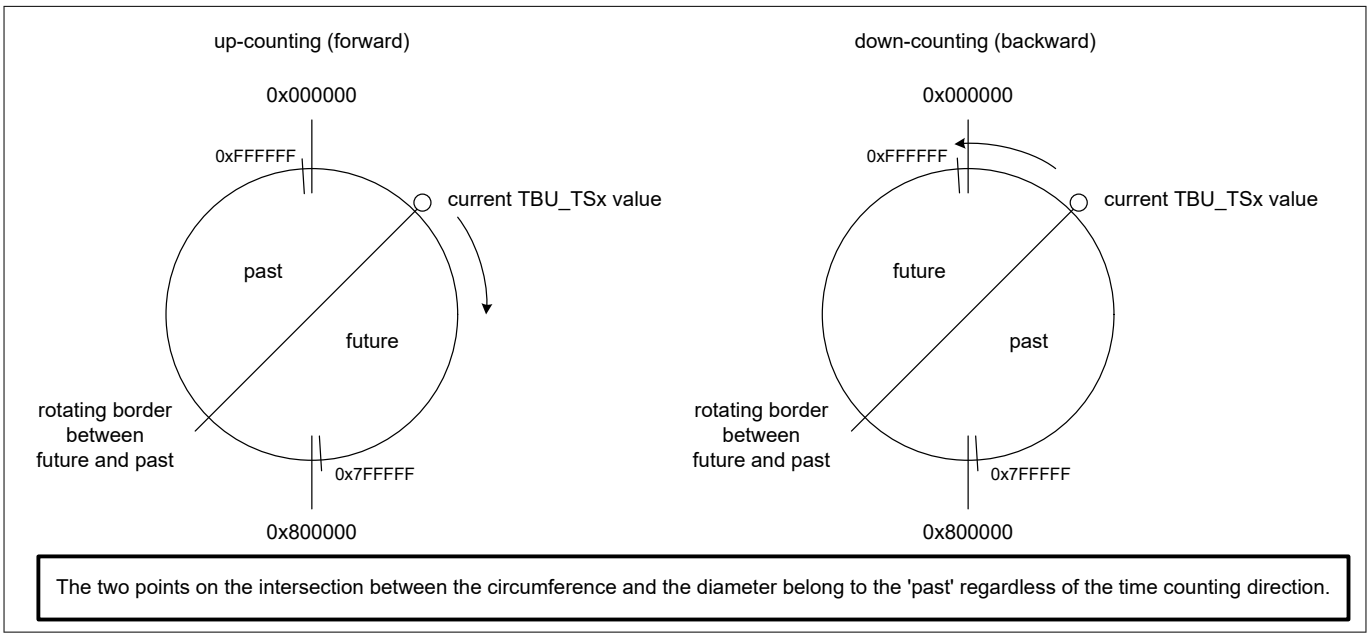

Figure 1026 Cyclic event counter representing time or angle

Inputs: tbu: 24−bit unsigned (time/angle value of the timebase); cmp: 24−bit unsigned (the time/position associated with an event); dir ∈ {FORWARD, BACKWARD}.

If (cmp = tbu or |tbu - cmp| = 2^{23})

tbu is (cyclically) >= cmp

Else
IF (tbu < cmp)
tbu_cmp = 2^{24} + tbu − cmp
ELSE
tbu_cmp = tbu − cmp
END IF
IF (tbu_cmp > 2^{23})
If (dir = FORWARD)
tbu is (cyclically) < cmp
Else
tbu is (cyclically) >= cmp
END IF
ELSE
If (dir = FORWARD)
tbu is (cyclically) >= cmp
Else
tbu is (cyclically) < cmp
END IF
END IF
END IF

An event is assumed to have happened in the past if tbu is 'cyclically greater than or equal to' the time associated with the event. Otherwise, the event is assumed to happen in the future.

Figure 1027 demonstrates how cyclic event compares in conjunction with the counting direction of tbu can be used to identify if an event has happened in the past or is to happen in the future. In the figure, both tbu and cmp are assumed to be 3-bit unsigned.

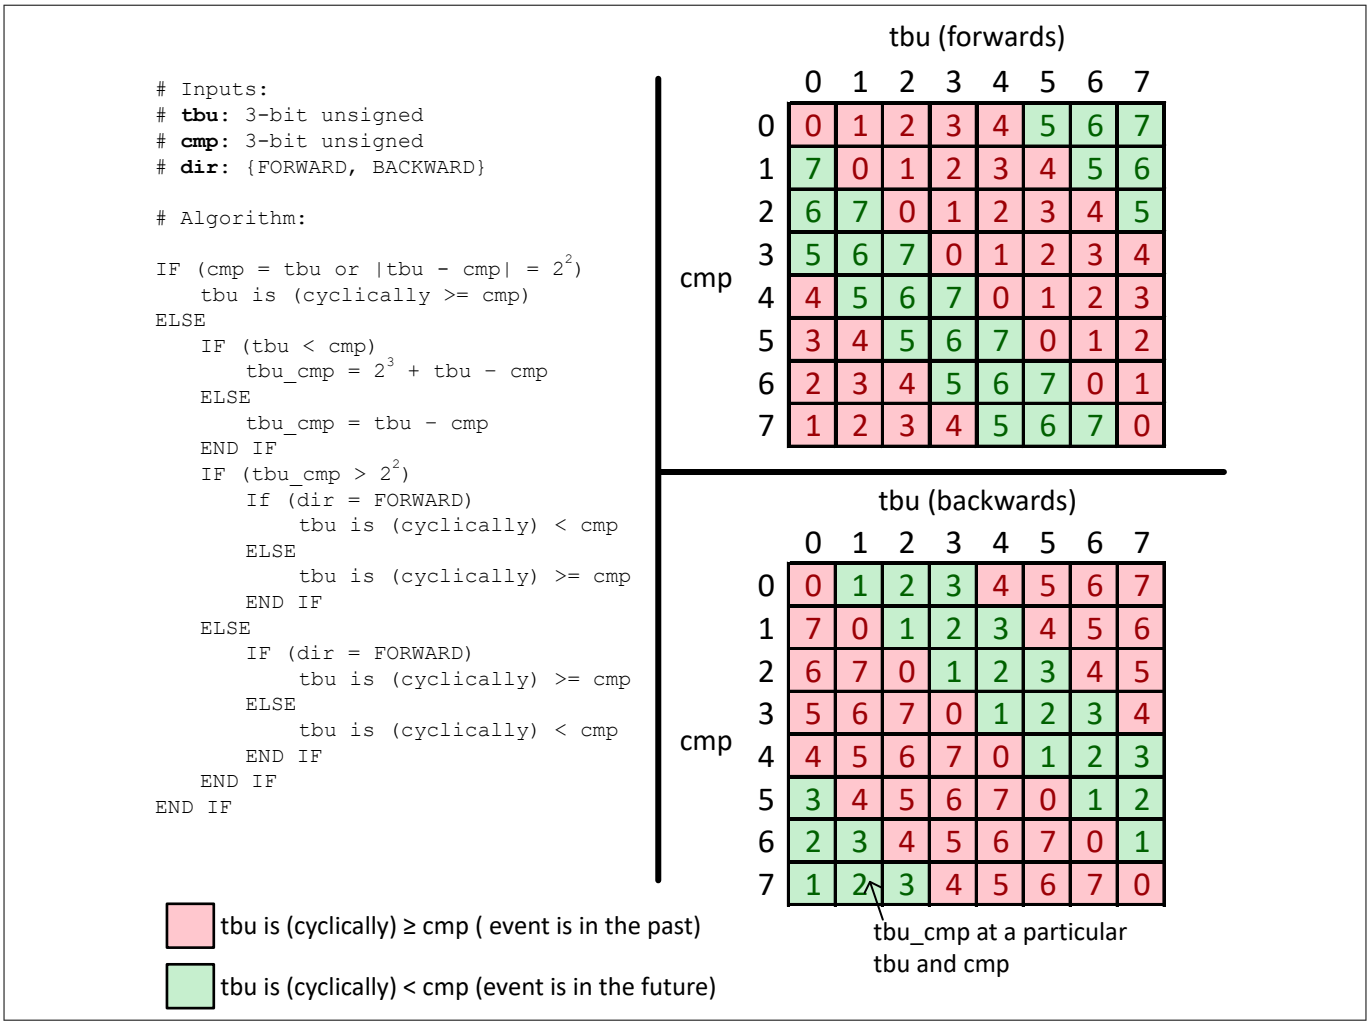

Figure 1027 Demonstration of cyclic event compares

By adapting the cyclic event compares and taking the counting direction of tbu (up-counting or down-counting) into account, it is possible to identify if an event is to happen in the future or has happened in the past reliably as long as |tbu-cmp| < 800000_H. Having a difference larger than that should be avoided as it erroneously pushes an event from 'past' to 'future' (or the other way around) without crossing 'now' (the current timestamp on tbu). For example, if an event is to be scheduled in the far future, cmp should be carefully selected such that the difference does not exceed $7FFFFF_H$. Having a difference larger than that will result in classifying the associated event as 'has happened in the past'.

44.3.1.2.10 eGTM interrupt concept

The sub-modules of the **eGTM** can generate thousands of interrupts on behalf of internal events. This high number of interrupts is combined inside the Interrupt Concentrator Module (**ICM**) into interrupt groups. In these interrupt groups the **eGTM** sub-module interrupt signals are bundled to a smaller set of interrupts. From these interrupt sets, a smaller number of interrupt signals is created and signaled outside of the **eGTM** on a signal with the name "GTM_<MOD>[i]_**IRQ**", where <MOD>[i] identifies the name of the corresponding **eGTM** sub-module.

In the following subchapters the interrupt signals are described on the basis of the **TIM** instance i. **TIM[i]** in the name of the signals can be replaced by the name of the other sub-modules of the **eGTM** and are valid for all following modules.

- **TOM[i]**
- **ATOM[i]**

- **SPE[i]**
- **CMP**

Moreover, each output signal (e)GTM_TIM[i]_IRQ has a corresponding input signal (e)GTM_TIM[i]_IRQ_CLR that can be used for clearing the interrupts. These input signals can be used by the surrounding microcontroller system as:

- Acknowledge signal from a DMA controller
- Validation signal from ADC
- Clear signal from a **eGTM**-external interrupt controller to do an atomic clear while entering an ISR routine

The individual interrupts are controlled inside the sub-modules. If a sub-module consists of several sub-module channels that are most likely to work independent from each other (like **TIM**, **TOM**, **ATOM**), each sub-module channel has its own interrupt control and status register set, named as interrupt set IRQ_SET= <MOD>[i]_CH[x:x] in the following. Other sub-modules (**SPE**, **CMP** and global **eGTM** functionality) have a common interrupt set IRQ_SET= <MOD>[i] for the whole sub-module.

From this point onwards (including the subsequent subsections), TIM[i]_CH *[x]* will be used in an exemplary way as a placeholder for:

- TOM[i]_CH[x]
- ATOM[i]_CH[x]
- **SPE[i]**
- **CMP**
- **eGTM**

The interrupt set consists of four registers: The CLSi_TIM_CHx_IRQ_EN register, the CLSi_TIM_CHx_IRQ_NOTIFY register, the CLSi_TIM_CHx_IRQ_FORCINT register, and the CLSi_TIM_CHx_IRQ_MODE register. While the registers CLSi_TIM_CHx_IRQ_EN, CLSi_TIM_CHx_IRQ_NOTIFY, and CLSi_TIM_CHx_IRQ_FORCINT signalize the status and allow controlling of each individual interrupt source within an interrupt set, the register CLSi_TIM_CHx_IRQ_MODE configures the interrupt mode that is applied to all interrupts that belong to the same interrupt set.

In order to support a wide variety of microcontroller architectures and interrupt systems with different interrupt signal output characteristics and internal interrupt handling the following four modes can be configured:

- Level mode
- Pulse mode
- Pulse-Notify mode
- Single-Pulse mode

These interrupt modes are described in more details in the following subsections.

The register CLSi_TIM_CHx_IRQ_EN allows the enabling and disabling of an individual interrupt within an interrupt set. Independent of the configured mode, only enabled interrupts can signalize an interrupt on their signal (e)GTM_TIM[i]_IRQ.

The register CLSi_TIM_CHx_IRQ_NOTIFY collects the occurrence of interrupt events. The behavior for setting a bit in this register depends on the configured mode and thus it is described later on in the mode descriptions.

Independent of the configured mode any write-access with value '1' to a bit in the register CLSi_TIM_CHx_IRQ_NOTIFY always clears the corresponding CLSi_TIM_CHx_IRQ_NOTIFY bit.

Moreover, the enabling of a disabled interrupt source with a write-access to the register CLSi_TIM_CHx_IRQ_EN also clears the corresponding bit in the CLSi_TIM_CHx_IRQ_NOTIFY register but only if the error interrupt source CLSi_TIM_CHx_EIRQ_EN is disabled. However, if the enabling of a disabled interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and the register CLSi_TIM_CHx_IRQ_NOTIFY is not cleared.

Attention**: **Each write-access to** CLSi_TIM_CHx_IRQ_MODE **clears all bits in** CLSi_TIM_CHx_IRQ_NOTIFY**. Write-access to** CLSi_TIM_CHx_IRQ_MODE **shall only be executed if all interrupts of the corresponding channel are disabled. Otherwise, interrupt events can get lost or interrupt logic can go into an unpredictable state.

To secure a way for reconfiguring the interrupt mode of an interrupt set, proceed as follows:

1. Disable all interrupts via CLSi_TIM_CHx_IRQ_EN and all error interrupts via CLSi_TIM_CHx_EIRQ_EN
2. Define the new interrupt mode via CLSi_TIM_CHx_IRQ_MODE
3. Enable the desired interrupts via CLSi_TIM_CHx_IRQ_EN and desired error interrupts via CLSi_TIM_CHx_EIRQ_EN

The register CLSi_TIM_CHx_IRQ_FORCINT is used by software for triggering individual interrupts with a write-access with value '1'. Since a write-access to CLSi_TIM_CHx_IRQ_FORCINT only generates a single pulse, CLSi_TIM_CHx_IRQ_FORCINT is not implemented as a true register and thus any read-access to CLSi_TIM_CHx_IRQ_FORCINT always results with a value of '0'. A write-access with a one to particular bit field in this register shall force the corresponding bit field in CLSi_TIM_CHx_IRQ_NOTIFY to one.

The mechanism for triggering interrupts with CLSi_TIM_CHx_IRQ_FORCINT is globally disabled after reset. It has to be explicitly enabled by clearing the bit CLSi_ARCH_CTRL.RF_PROT.

For the modules **AEI**-bridge, **TIM**, **SPE** and **CMP** the interrupt set is extended by the register CLSi_TIM_CHx_EIRQ_EN. Each interrupt can be configured to trigger an error interrupt instead of the normal interrupt if it is enabled by the corresponding error interrupt enable bit in the CLSi_TIM_CHx_EIRQ_EN register.

It is possible for one source to enable the normal interrupt and the error interrupt in parallel. Because both interrupt clear signals can reset the notify bit, this is expected to cause problems in a system and it is strongly recommended not to enable both interrupt types at the same time.

Similar to enabling an interrupt, the enabling of a disabled error interrupt source with a write-access to the register CLSi_TIM_CHx_EIRQ_EN also clears the corresponding bit in the CLSi_TIM_CHx_IRQ_NOTIFY register only if the interrupt source CLSi_TIM_CHx_IRQ_EN is disabled. However, if the enabling of a disabled error interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and the register CLSi_TIM_CHx_IRQ_NOTIFY is not cleared.

All enabled error interrupts are **OR**-combined inside the **ICM** and assigned to the dedicated **eGTM** port (e)GTM_ERR_IRQ. A corresponding input (e)GTM_ERR_IRQ_CLR allows the reset of this error interrupt from outside the **eGTM** (hardware clear).

To be able to detect the module source of the error interrupt the **ICM** provides the register CLSi_ICM_IRQG_MEI.

By evaluating the **ICM** register CLSi_ICM_IRQG_CEI1, the channel causing the error interrupt can be determined for the module **TIM**.

Level interrupt mode

The default interrupt mode is the Level Interrupt Mode. In this mode each occurred interrupt event is collected in the register CLSi_TIM_CHx_IRQ_NOTIFY, independent of the corresponding enable bit of register CLSi_TIM_CHx_IRQ_EN and CLSi_TIM_CHx_EIRQ_EN.

An interrupt event, which is defined as a pulse on the signal INT_OUT of Figure 1028, may be triggered by the interrupt source of the sub-module or by software performing a write-access to the corresponding register CLSi_TIM_CHx_IRQ_FORCINT, with a cleared bit CLSi_ARCH_CTRL.RF_PROT.

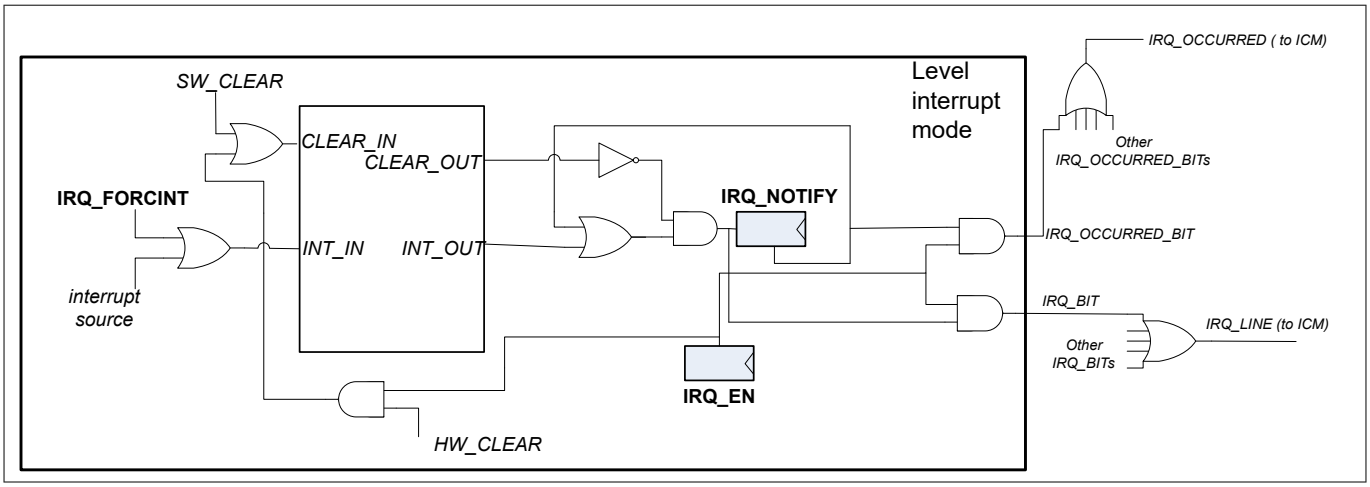

Figure 1028 Level interrupt mode scheme

A collected interrupt bit in register CLSi_TIM_CHx_IRQ_NOTIFY may be cleared by a clear event, which is defined as a pulse on signal CLEAR_OUT of Figure 1028. A clear event can be performed by writing '1' to the corresponding bit in the register CLSi_TIM_CHx_IRQ_NOTIFY leading to a pulse on signals SW_CLEAR. A clear event may also result from an externally connected signal (e)GTM_TIM[i]_IRQ_CLR, which is routed to the signal HW_CLEAR of Figure 1028. However, the hardware clear mechanism is only possible, if the corresponding interrupt is enabled by register CLSi_TIM_CHx_IRQ_EN.

As Table 2149 shows, interrupt events are dominant in the case of a simultaneous interrupt event and clear event.

Table 2149 Priority of interrupt events and clear events

INT_IN	CLEAR_IN	INT_OUT	CLEAR_OUT
0	0	0	0
0	1	0	1
1	0	1	0
1	1	1	0

As shown in Figure 1028 an occurred interrupt event is signaled as a constant signal level with value 1 to the signal IRQ_BIT, if the corresponding interrupt is enabled in register CLSi_TIM_CHx_IRQ_EN. Moreover, the enabling of a disabled interrupt source with a write-access to the register CLSi_TIM_CHx_IRQ_EN also clears the signal IRQ_BIT, but only if the error interrupt source CLSi_TIM_CHx_EIRQ_EN is disabled. However, if the enabling of a disabled interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and signal IRQ_BIT is not cleared.

The signal IRQ_BIT is **OR**-combined with the neighboring IRQ_BIT signals of the same interrupt set and they are routed as a signal IRQ_LINE to the interrupt concentrator module (**ICM**). In some cases (sub-modules **TOM** and **ATOM**) the **ICM** may further **OR**-combine several IRQ_LINE signals to an outgoing interrupt signal (e)GTM_TIM[i]_IRQ. In the other cases the IRQ_LINE signals are directly connected to the outgoing signals (e)GTM_TIM[i]_IRQ, within the sub-module **ICM**.

The signal IRQ_OCCURRED is connected in a similar way as the signal IRQ_LINE, however this signal is used for monitoring the interrupt state of the register CLSi_TIM_CHx_IRQ_NOTIFY in the registers of the **ICM**.

The additional error interrupt enable mechanism for level interrupt is shown below.

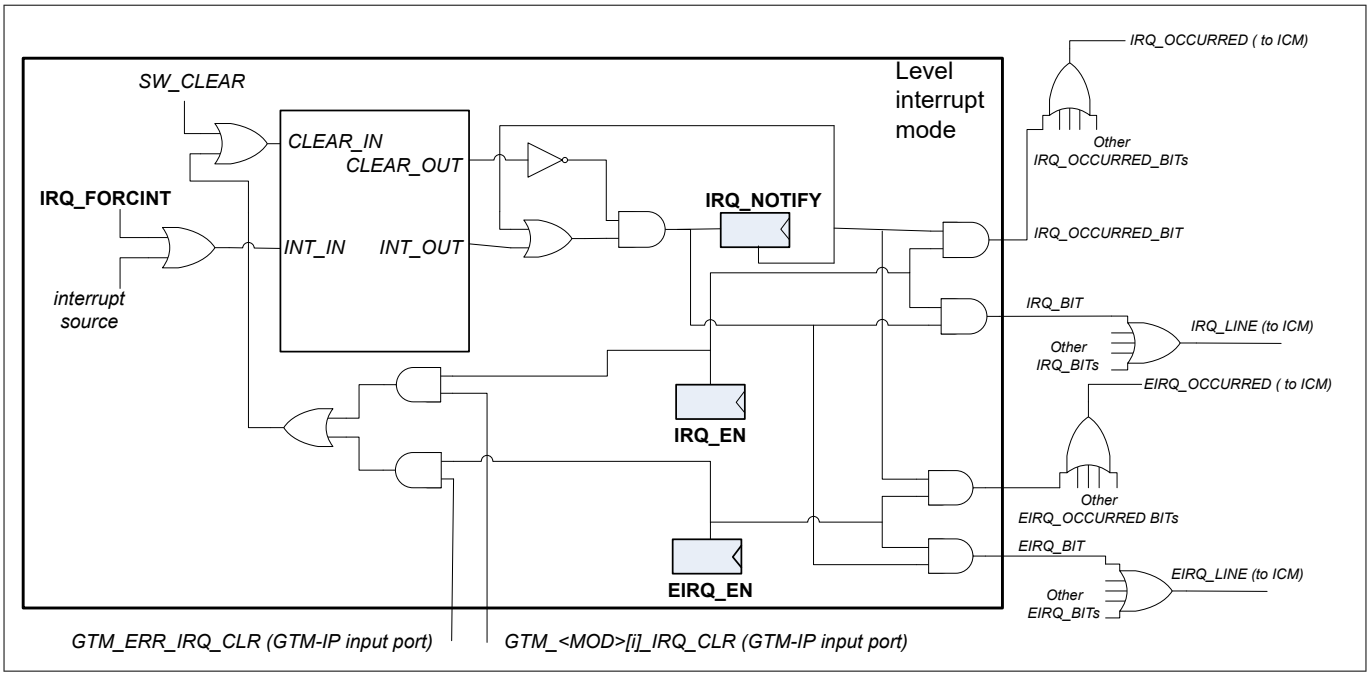

Figure 1029 Level interrupt scheme for modules AEI-bridge, TIM, SPE, CMP

A collected interrupt bit in register CLSi_TIM_CHx_IRQ_NOTIFY may be cleared by a clear event, which is defined as a pulse on signal CLEAR_OUT of Figure 1029. A clear event can be performed by writing '1' to the corresponding bit in the register CLSi_TIM_CHx_IRQ_NOTIFY leading to a pulse on signals SW_CLEAR. A clear event may also result from the externally connected signal (e)GTM_TIM[i]_IRQ_CLR or (e)GTM_ERR_IRQ_CLR, which is routed as an HW_CLEAR to CLEAR_IN of Figure 1029. However, the hardware clear mechanism is only possible, if the corresponding interrupt or error interrupt is enabled by register CLSi_TIM_CHx_IRQ_EN or CLSi_TIM_CHx_EIRQ_EN.

As it can be seen from the Figure 1029 an occurred interrupt event is signaled as a constant signal level with value 1 to the signal IRQ_BIT, if the corresponding interrupt is enabled in register CLSi_TIM_CHx_IRQ_EN.

Pulse interrupt mode

The Pulse interrupt mode behavior can be observed from Figure 1030.

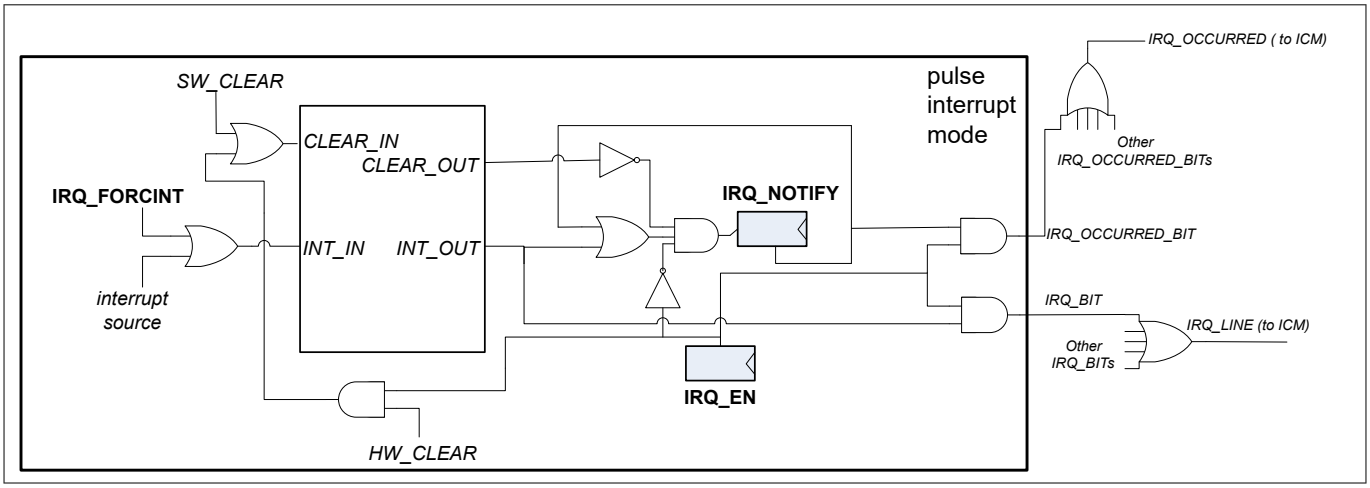

Figure 1030 Pulse interrupt mode scheme

In Pulse Interrupt Mode each Interrupt Event will generate a pulse on the IRQ_BIT signal if CLSi_TIM_CHx_IRQ_EN is enabled.

As it can be seen from the figure, the interrupt bit in CLSi_TIM_CHx_IRQ_NOTIFY register is always cleared if CLSi_TIM_CHx_IRQ_EN is enabled.

However, if an interrupt is disabled in the register CLSi_TIM_CHx_IRQ_EN, an occurred interrupt event is captured in the register CLSi_TIM_CHx_IRQ_NOTIFY, in order to allow polling for disabled interrupts by software.

Disabled interrupts may be cleared by an interrupt clear event.

In case of a simultaneous interrupt event and clear event, the interrupt events are dominant (see details Table 2149).

In Pulse Interrupt Mode, the signal IRQ_OCCURRED is always 0.

The additional error interrupt enable mechanism for pulse interrupt is shown below.

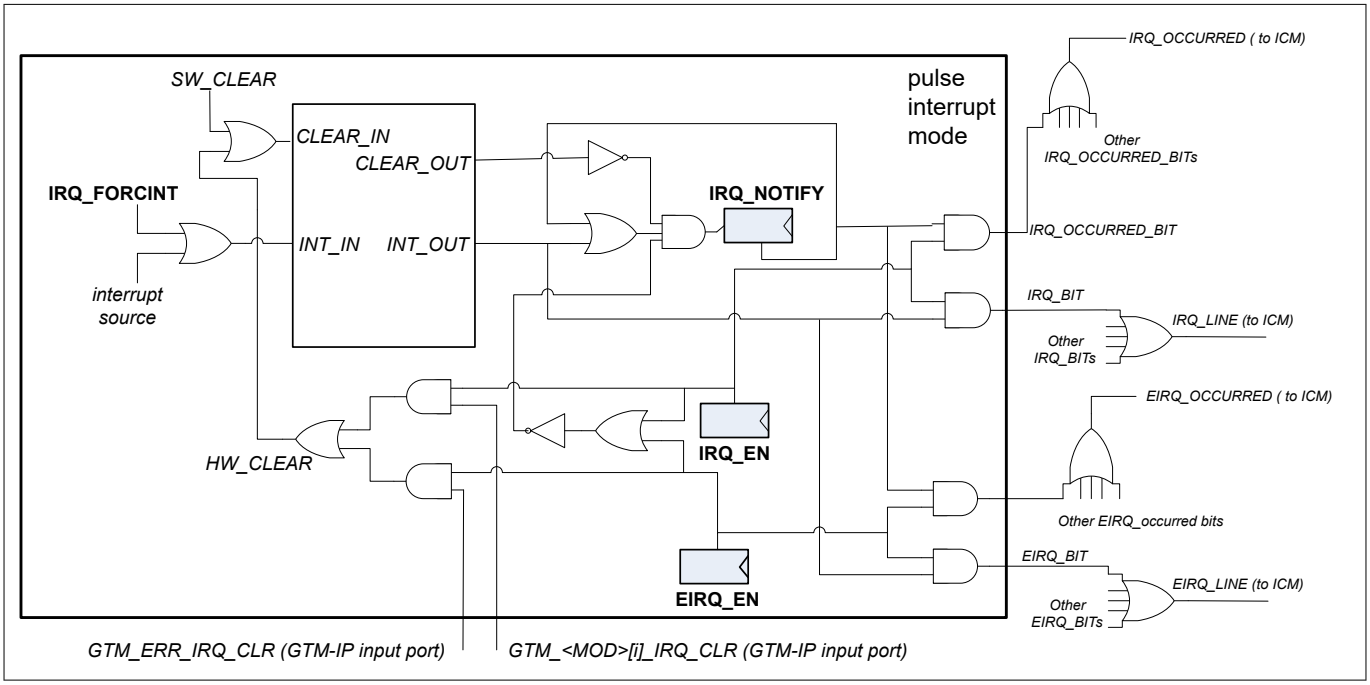

Figure 1031 Pulse interrupt scheme for modules AEI-bridge, TIM, SPE, CMP

In Pulse Interrupt Mode each Interrupt Event will generate a pulse on the EIRQ_BIT signal if CLSi_TIM_CHx_EIRQ_EN is enabled.

As it can be seen from the figure, the interrupt bit in CLSi_TIM_CHx_IRQ_NOTIFY register is always cleared if CLSi_TIM_CHx_EIRQ_EN or CLSi_TIM_CHx_IRQ_EN are enabled.

However, if an error interrupt is disabled in the register CLSi_TIM_CHx_EIRQ_EN, an occurred error interrupt event is captured in the register CLSi_TIM_CHx_IRQ_NOTIFY, in order to allow polling for disabled error interrupts by software.

Disabled error interrupts may be cleared by an error interrupt clear event.

In Pulse interrupt mode, the signal EIRQ_OCCURRED is always 0.

Pulse-notify interrupt mode

In Pulse-notify Interrupt Mode, all interrupt events are captured in the register CLSi_TIM_CHx_IRQ_NOTIFY. If an interrupt is enabled by the register CLSi_TIM_CHx_IRQ_EN, each interrupt event will also generate a pulse on the IRQ_BIT signal. The signal IRQ_OCCURRED will be high if interrupt is enabled in register CLSi_TIM_CHx_IRQ_EN and the corresponding bit of register CLSi_TIM_CHx_IRQ_NOTIFY is set. The Pulse-notify interrupt mode is shown in Figure 1032.

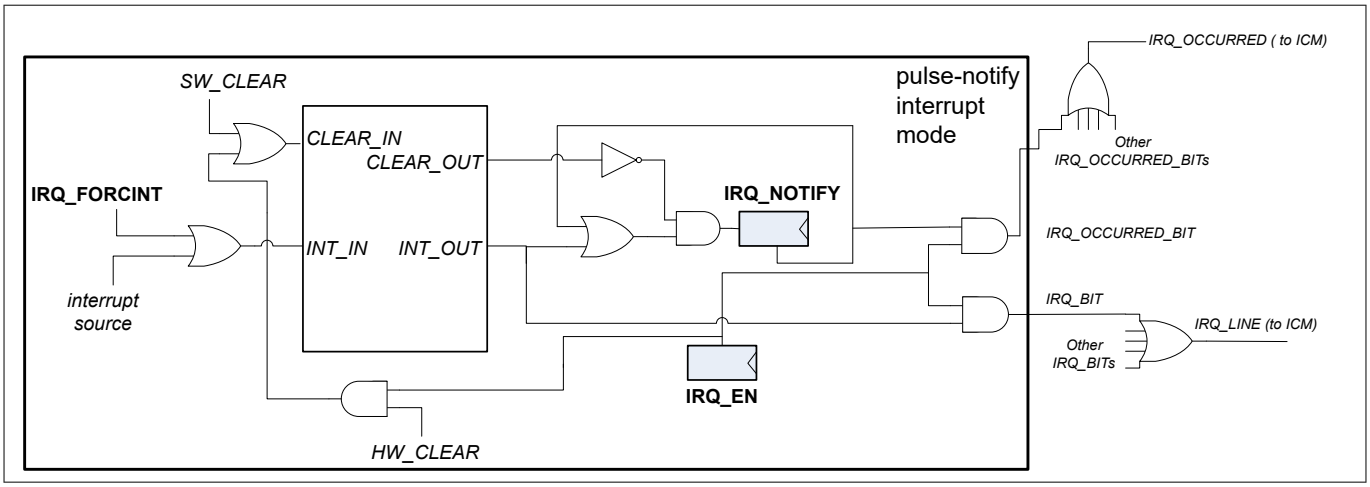

Figure 1032 Pulse-notify interrupt mode scheme

In case of a simultaneous interrupt event and clear event, the interrupt events are dominant (see details Table 2149).

The additional error interrupt enable mechanism for pulse-notify interrupt is shown below

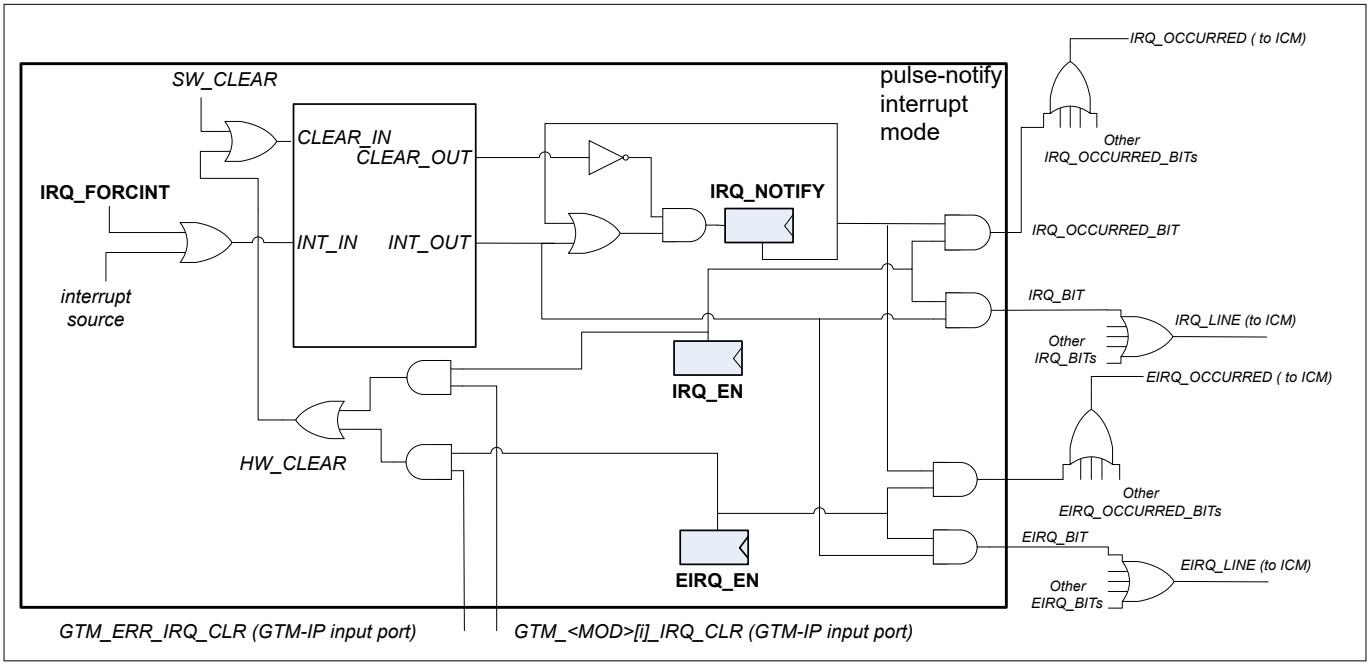

Figure 1033 Pulse-notify interrupt scheme for modules AEI-bridge, TIM, SPE, CMP

In Pulse-notify Interrupt mode, all error interrupt events are captured in the register CLSi_TIM_CHx_IRQ_NOTIFY. If an error interrupt is enabled by the register CLSi_TIM_CHx_EIRQ_EN, each error interrupt event will also generate a pulse on the EIRQ_BIT signal. The signal EIRQ_OCCURRED will be high if error interrupt is enabled in register CLSi_TIM_CHx_EIRQ_EN and the corresponding bit of register CLSi_TIM_CHx_IRQ_NOTIFY is set. The Pulse-notify interrupt mode for error interrupts is shown in Figure 1033.

Single-pulse interrupt mode

In Single-pulse Interrupt Mode, an interrupt event is always captured in the register CLSi_TIM_CHx_IRQ_NOTIFY, independent of the state of CLSi_TIM_CHx_IRQ_EN. However, only the first interrupt event of an enabled interrupt within a common interrupt set is forwarded to signal IRQ_LINE. Additional interrupt events of the same interrupt set cannot generate pulses on the signal IRQ_LINE, until the

corresponding bits in register CLSi_TIM_CHx_IRQ_NOTIFY of enabled interrupts are cleared by a clear event. This requirement is not valid when one of the following two cases is fulfilled. The first case is fulfilled if there is a simultaneous occurrence of interrupt event and an event on HW_CLEAR (or/and SW_CLEAR) input. The second case is fulfilled if an interrupt event occurs in the same clock-cycle in which the corresponding disabled interrupt is enabled and the corresponding bit in CLSi_TIM_CHx_IRQ_NOTIFY is at 1. That means, the interrupt event in these cases will result in setting of IRQ_LINE output, even when register CLSi_TIM_CHx_IRQ_NOTIFY was previously not cleared. The IRQ_OCCURRED signal line will be high, if the CLSi_TIM_CHx_IRQ_EN and the CLSi_TIM_CHx_IRQ_NOTIFY register bits are set. The single−pulse interrupt mode is shown in Figure 1034.

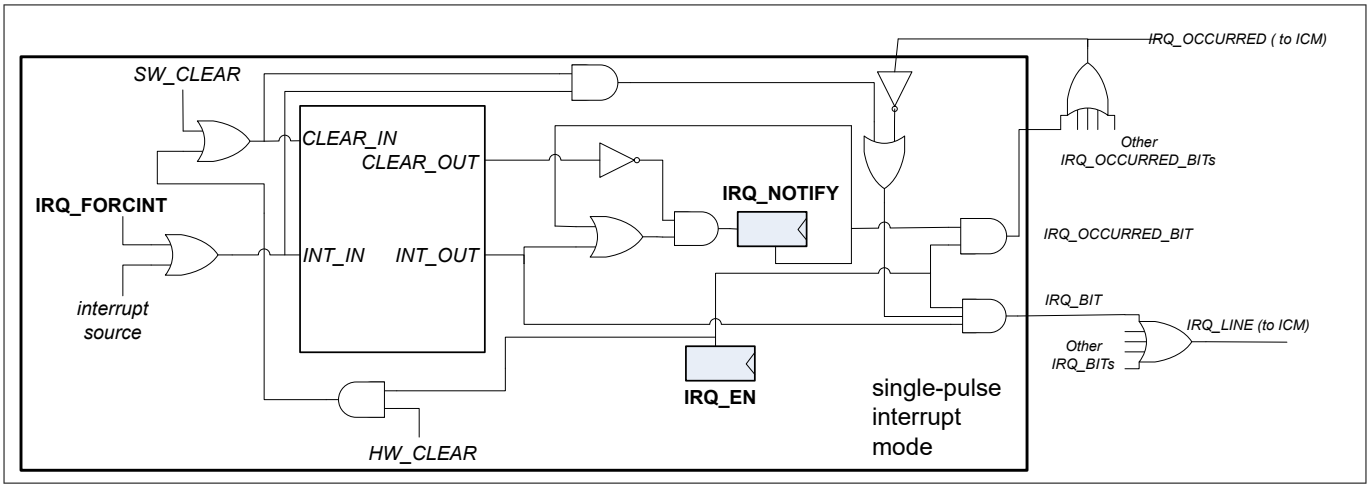

Figure 1034 Single-pulse interrupt mode scheme

In case of a simultaneous interrupt event and clear event, the interrupt events are dominant (see details Table 2149).

To avoid unexpected **IRQ** behavior in the single pulse mode, all desired interrupt sources should be enabled by a single write-access to CLSi_TIM_CHx_IRQ_EN and the notification bits should be cleared by a single write-access to the register CLSi_TIM_CHx_IRQ_NOTIFY.

The additional error interrupt enable mechanism for single-pulse interrupt is shown below

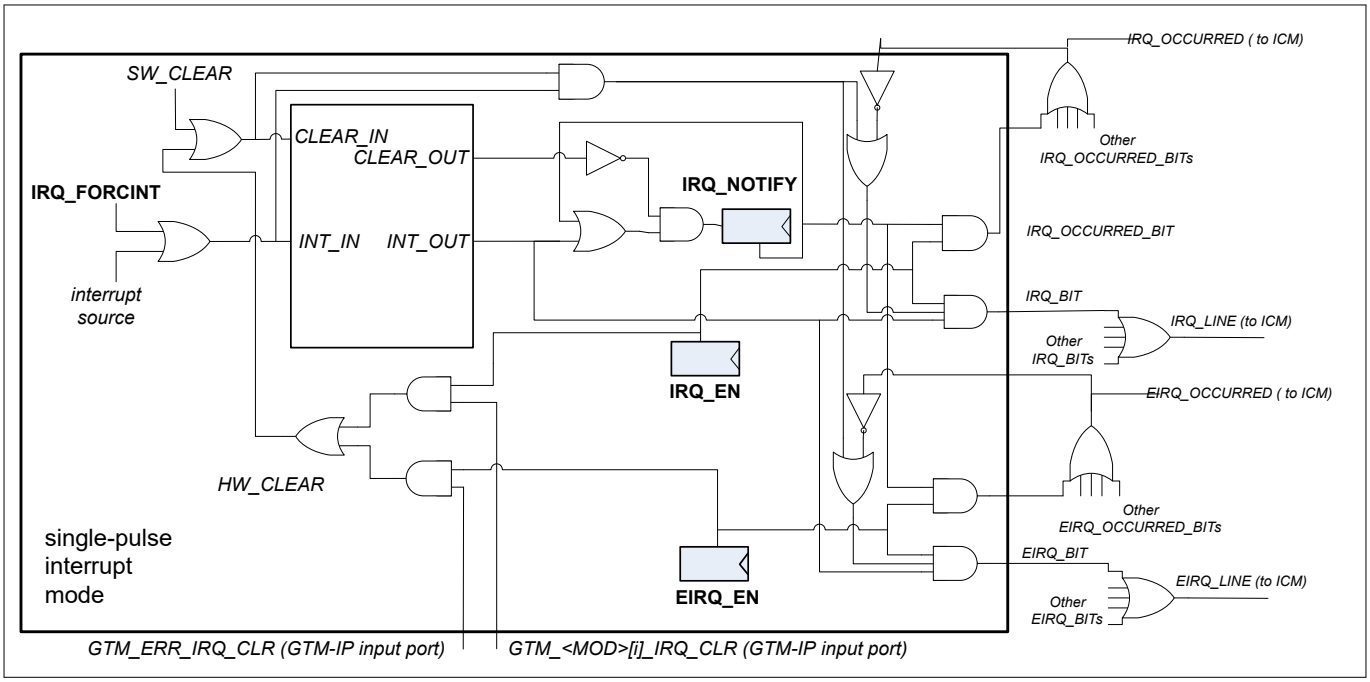

Figure 1035 Single-pulse interrupt scheme for modules AEI-bridge, TIM, SPE, CMP

In Single-pulse Interrupt Mode, an error interrupt event is always captured in the register CLSi_TIM_CHx_IRQ_NOTIFY, independent of the state of CLSi_TIM_CHx_EIRQ_EN. However, only the first error interrupt event of an enabled error interrupt within a common error interrupt set is forwarded to signal EIRQ_LINE. Additional error interrupt events of the same error interrupt set cannot generate pulses on the signal EIRQ_LINE, until the corresponding bits in register CLSi_TIM_CHx_IRQ_NOTIFY of enabled error interrupts are cleared by a clear event. The EIRQ_OCCURRED signal line will be high, if the CLSi_TIM_CHx_EIRQ_EN and the CLSi_TIM_CHx_IRQ_NOTIFY register bits are set. The Single-pulse interrupt mode for error interrupts is shown in Figure 1035.

To avoid unexpected EIRQ behavior in the single pulse mode, all desired error interrupt sources should be enabled by a single write-access to CLSi_TIM_CHx_EIRQ_EN and the notification bits should be cleared by a single write-access to the register CLSi_TIM_CHx_IRQ_NOTIFY.

eGTM interrupt concentration method

Because of the grouping of interrupts inside the **ICM**, it can be necessary for the software to access the **ICM** sub-module first to determine the interrupt set that is responsible for an interrupt. A second access to the responsible register CLSi_TIM_CHx_IRQ_NOTIFY is then necessary to identify the interrupt source, serve it and to reset the interrupt flag in register CLSi_TIM_CHx_IRQ_NOTIFY afterwards. The interrupt flags are never reset by an access to the **ICM**. For a detailed description of the **ICM** sub-module please refer to Interrupt concentrator module (**ICM**).

44.3.1.2.11 eGTM software debugger support

For software debugger support the **eGTM** comes with several features. E.g. status register bits must not be altered by a read-access from a software debugger. To avoid this behavior to reset a status register bit by software, the CPU has to write a '1' explicitly to the register bit to reset its content.

The Table 2150 describes the behavior of some **eGTM** registers with special functionality on behalf of read-accesses from the **AEI** bus interface.

Table 2150 Register behavior in case of software debugger accesses

Module	Register	Description
TIM	CLSi_TIM_CHx_GPR0 / CLSi_TIM_CHx_GPR1	The overflow bit is not altered in case of a debugger read-access to this register
TIM	CLSi_TIM_CHx_ECNT	While CLSi_TIM_CHx_CTRL.TIM_EN = 0, the register is not cleared in case of a debugger read-access to this register.
ATOM	CLSi_ATOM_CHx_SR0 / CLSi_ATOM_CHx_SR1	In SOMC mode a read-access to this register by the debugger does not release the channel for a new compare/match event.

The **eGTM** offers several debugging possibilities. For an exhaustive survey the user is referred to the module integration guide, and to the modules' respective chapters. It is up to the silicon vendor how to integrate/use these debugging possibilities and to which extent.

Upon the assertion of the (e)GTM_HALT_REQ signal the cluster clocks are disabled stalling the internal operations within the **eGTM**. Once the cluster clocks are disabled, (e)GTM_HALT_ACTIVE is asserted after a few clock-cycles and the debugger can perform read-/write-access over the **AEI** interface to all memory mapped

registers within the **eGTM**. When the external debugger de-asserts (e)GTM_HALT_REQ signal to mark the end of the debug accesses, the **eGTM** asserts (e)GTM_RESTORE for a few clock-cycles before it de-asserts it again. During the assertion of (e)GTM_RESTORE, the **eGTM** restores all transactions which were active on the internal **AEI** interface and were canceled when (e)GTM_HALT_REQ was asserted. This restoration phase is introduced to make sure, that the **eGTM** can resume working appropriately as if there was no debugger access at all.

In addition to enabling debug access to the memory addressable registers, the **eGTM** makes some important internal signals from different modules (**TIM**, **SPE**, **TOM**, **ATOM**, **TBU**) available to the outside. An external debugger can monitor such signals and, for example, trace them or halt the **eGTM** when the signals fulfill a predefined condition. Again, it is up to the silicon vendor to which extent to use these debugging possibilities.

44.3.1.2.12 eGTM programming conventions

To serve different application domains the **eGTM** is a highly configurable module with many configuration modes. In principle the sub-modules of the **eGTM** are intended to be configured at system startup to fulfill certain functionality for the application domain the microcontroller runs in.

For example, a **TIM** input channel can be used to monitor an application-specific external signal, and this signal has to be filtered. Therefore, the configuration of the **TIM** channel filter mode will be specific to the external signal characteristic. While it can be necessary to adapt the filter thresholds during runtime an adaptation of the filter mode during runtime is not reasonable. Thus, the change of the filter mode during runtime can lead to an unexpected behavior.

In general, the programmer has to be careful when reprogramming configuration registers of the **eGTM** sub-modules during runtime. It is recommended to disable the channels before reconfiguration takes place to avoid unexpected behavior of the **eGTM**.

44.3.1.2.13 eGTM Architecture Configuration Registers Description

Sub-chapter Architecture Configuration Registers Description

Table 2151

Register Shortname	Description
CLSi_ARCH_REV	eGTM version control register (i=0)
CLSi_ARCH_RST	eGTM global reset register (i=0)
CLSi_ARCH_CTRL	eGTM global control register (i=0)
CLSi_ARCH_CFG	eGTM configuration register (i=0)
CLSi_ARCH_AEI_ADDR_XPT	eGTM AEI timeout exception address register (i=0)
CLSi_ARCH_AEI_STA_XPT	eGTM AEI non-zero status register (i=0)
CLSi_ARCH_IRQ_NOTIFY	eGTM Interrupt notification register (i=0)
CLSi_ARCH_IRQ_EN	eGTM interrupt enable register (i=0)
CLSi_ARCH_EIRQ_EN	eGTM error interrupt enable register (i=0)
CLSi_ARCH_IRQ_FORCINT	eGTM Software interrupt generation register (i=0)
CLSi_ARCH_IRQ_MODE	eGTM toplevel interrupts mode selection (i=0)
CLSi_ARCH_CLK_CFG	eGTM Cluster Clock Configuration (i=0)
CLSi_AEI_BRIDGE_MODE	eGTM AEI bridge mode register (i=0)
CLSi_AEI_BRIDGE_PTR1	eGTM AEI bridge pointer 1 register (i=0)
CLSi_AEI_BRIDGE_PTR2	eGTM AEI bridge pointer 2 register (i=0)

44.3.1.3 Clock management unit (CMU)

44.3.1.3.1 Overview

The Clock Management Unit (**CMU**) only exists in cluster 0 and is tasked with the generation of 14 clock resolution signals and 3 **eGTM** external clocks. The clock resolution signals are routed to all clusters via ICPAs. Within a cluster, they are used as clock enables regulating the resolution (or rate) at which actions are performed. The 3 **eGTM** external clocks are approximately true 50% duty cycle clocks. The primary clock source used in this module is the cluster 0 clock signal CLS[j]_CLK. The cluster clock (CLS[j]_CLK) can be turned off, or use the **eGTM** clock, or use the **eGTM** clock halved depending on the configuration of CLSi_ARCH_CLK_CFG**.**CLSj_CLK_DIV (j=0-2) **(j=0)**. The clock resolution signals and the external clocks are generated with reference to it. Figure 1036 shows a block diagram of the **CMU**.

Indices and their range as used inside this chapter are:

- x:={0, 1,..., 7} index for clock resolution channel CMU_CLK_RES[x:x]
- y:={0, 1,..., 4} index for fixed clock for CMU_FXCLK_RES[y:y]
- z:={0, 1, 2} index for external clocks CMU_ECLK[z:z]

The Configurable Resolution Generation (CRG) sub-unit generates eight dedicated clock resolutions (CMU_CLK_RES[x:x], where x ∈ {0, 1, ..., 7}) for the following **eGTM** modules: **TIM**, **ATOM**, **TBU**, **CDTM** and **MON**. Every resolution signal has its own configuration register (CLSi_CMU_CLKx_CTRL) to configure its clock resolution generator. The input to a clock resolution generator can either be CMU_ECLK1_EN or CMU_GCLK_EN depending on the configuration of CLSi_CMU_CLK_CTRL**.**CLKx_EXT_DIVIDER (x=0-7).

The Fixed Clock Resolution Generation (FCRG) sub-unit generates predefined non-configurable clock resolutions CMU_FXCLK_RES[y:y] (y ∈ {0, 1, ..., 4}) for the **TOM**, **CDTM**, and **MON** modules. In the sub-unit there is a multiplexer that can be configured to select CMU_GCLK_EN or one of the eight CMU_CLK_RES[x:x] (x ∈ {0, 1, ..., 7}) as input to the FCR generators within. The dividing factors for a CMU_FXCLK_RES[y:y] clock resolution is non-configurable and is fixed to 2^{4*y}.

The External Clock Generation (EGU) sub-unit is able to generate up to three chip external clock signals visible at CMU_ECLK[z:z] (z ∈ {0, 1, 2}) with a duty cycle of approximately 50%.

The External Clock Generation (EGU) sub-unit is able to generate clock CMU_CLK_RES[8:8] for module **CCM** to manage 2 clock domains.

The clock source signals CMU_CLK_RES[x:x] (x∈{0, 1,..., 7}) and CMU_FXCLK_RES[y:y] are implemented in the form of enable signals for the corresponding registers, which means that the actual clock signal of all registers always use CLS[j]_CLK signal.

The four configurable clock resolution signals CMU_CLK_RES[0:0], CMU_CLK_RES[1:1], CMU_CLK_RES[6:6] and CMU_CLK_RES[7:7] are used for the **TIM** filter counters.

Although the clock resolutions and external clocks (*CMU_CLK_EN*, CMU_FXCLK_RES, CMU_ECLK) are run-time configurable, any change during run-time may result in an unpredictable behavior in the **eGTM**. It is strongly recommended to configure them only during initialization phase.

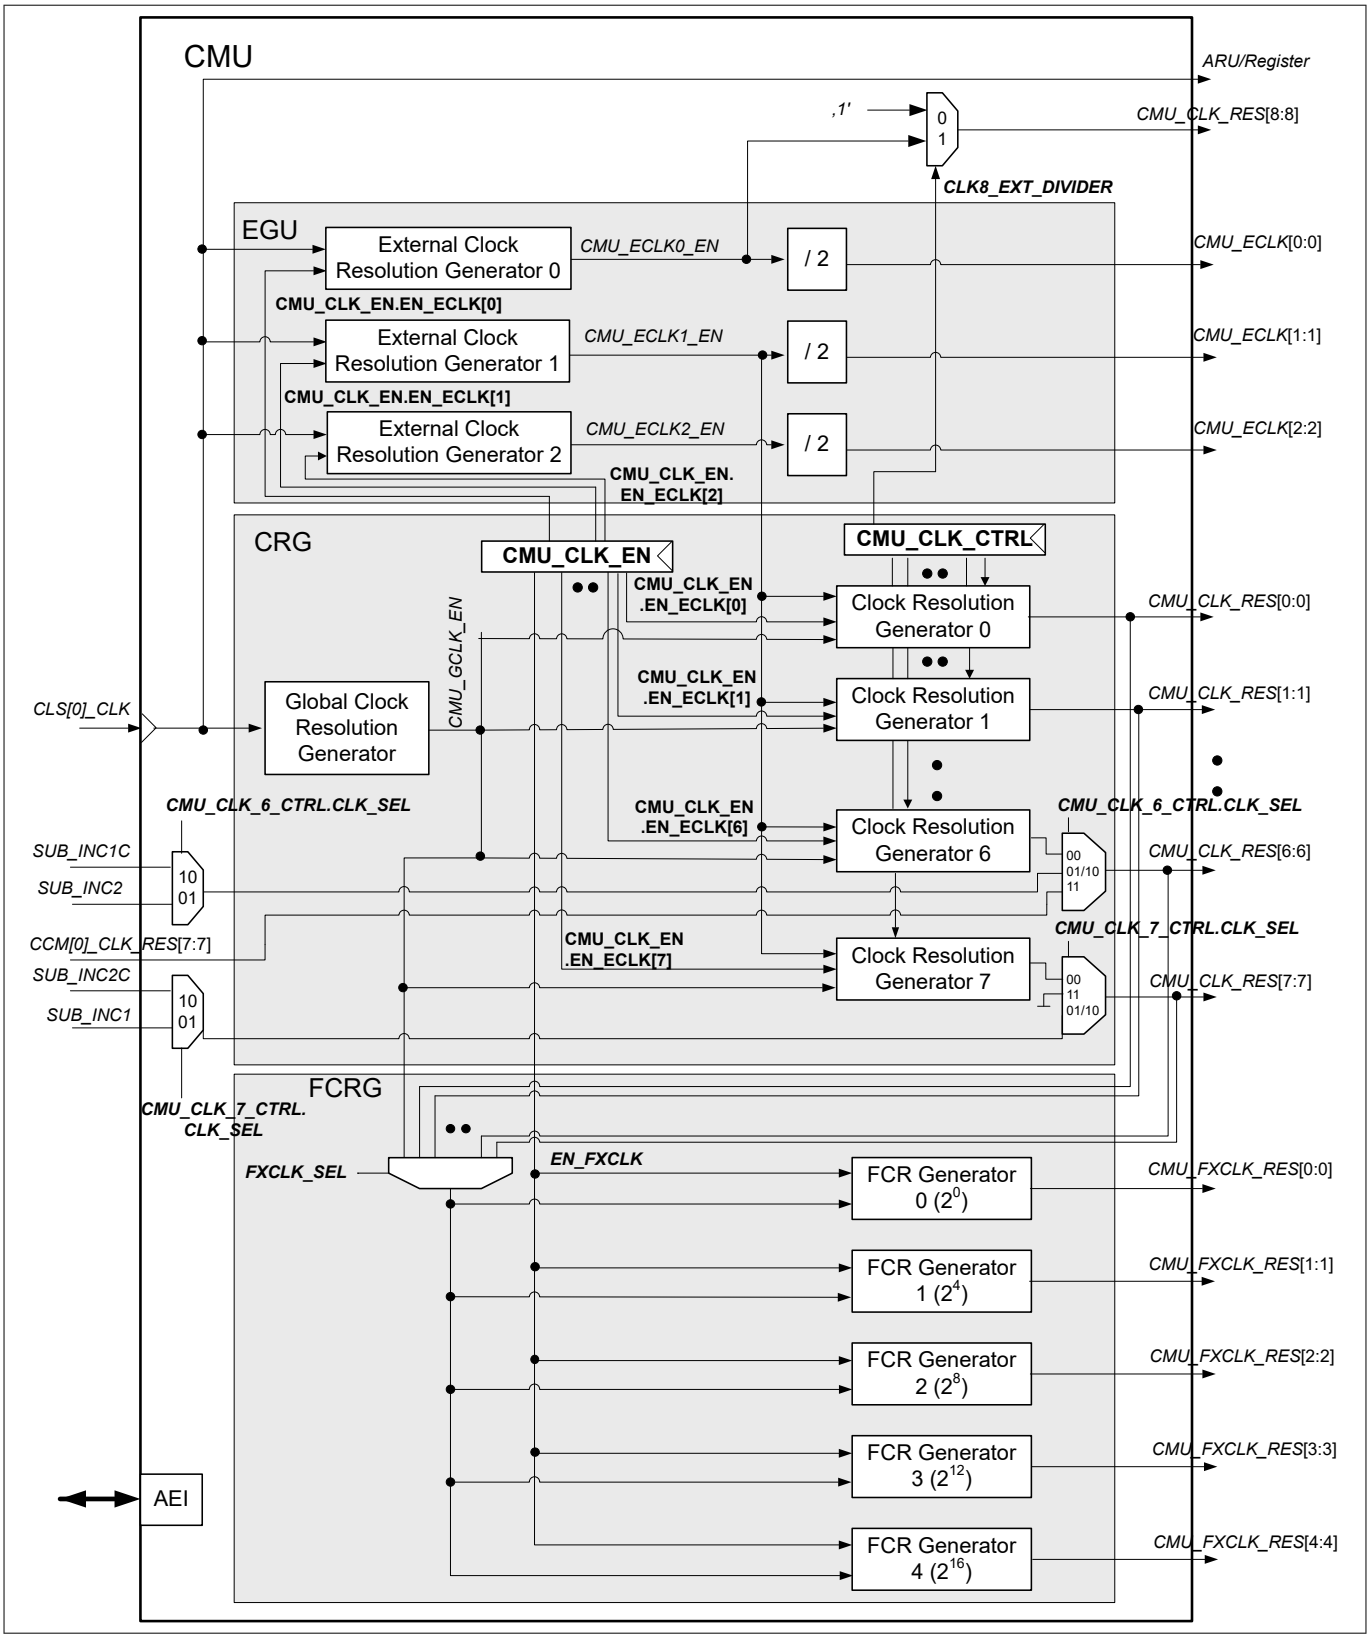

Figure 1036 CMU block diagram

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

44.3.1.3.2 Global clock resolution generator

The subblock Global Clock Resolution Generator can be used to generate a common clock resolution signal (CMU_GCLK_EN) with reference to cluster 0 clock (CLS[j]_CLK).

The common clock resolution signal is generated by the Global Clock Resolution Generator. Depending on the configuration of the numerator CLSi_CMU_GCLK_NUM.GCLK_NUM and the denominator CLSi_CMU_GCLK_DEN.GCLK_DEN, the Global Clock Resolution Generator attempts to assert CMU_GCLK_EN for CLSi_CMU_GCLK_DEN.GCLK_DEN clock-cycles distributed at regular intervals (when possible) in every CLSi_CMU_GCLK_NUM.GCLK_NUM clock-cycles. Depending on the configuration, the ratio between the numerator to the denominator might result in a fractional number leading to the introduction of some irregularities in these intervals.

In theory, if the common clock resolution signal is used as a clock enable in conjunction with the cluster clock, it is possible to regulate the effective clock frequency (denoted as $1/T_{CMU_GCLK_EN}$) at which the registers are clocked. The effective clock frequency can range between 0% (when CMU_GCLK_EN is low all the time) and 100% (when CMU_GCLK_EN is high all the time) of the cluster clock frequency depending on the configuration. It is important to emphasize that $T_{CMU_GCLK_EN}$ is only a period of a virtual clock whose frequency is equivalent to the effective clock frequency resulting from using CMU_GCLK_EN as a clock enable to the registers the cluster clock is connected to. The following algorithm describes how to achieve a particular $T_{CMU_GCLK_EN} = (Z/N) * T_{CLS[j]_CLK}$, where Z = CLSi_CMU_GCLK_NUM.GCLK_NUM; N = CLSi_CMU_GCLK_DEN.GCLK_DEN; Z>= N > 0:

1. INIT-phase: set remainder (R), operand1 (OP1) and operand2 (OP2) register during INIT-phase (with implicit conversion to signed): R=Z, OP1=N, O-P2=N-Z.
2. After leaving INIT-phase (at least one CMU_CLK_RES[x:x] has been enabled) the sign of remainder R for each CLS[j]_CLK cycle is checked:
3. If R>=0: keep CMU_GCLK_EN='0', and update R=R-OP1.
4. If R<0: set CMU_GCLK_EN='1', and update R=R-OP2.

After at most (Z/N+1) subtractions (3. in the list above) there will be a negative R and an active phase of the generated clock enable (for one cycle) will be triggered (4. in the list above). The remainder R is a measure for the distance to a real Z/N clock and will be considered for the next generated clock enable cycle phase. The new R value will be R=R+(Z-N). In the worst case, the remainder R will sum up to an additional cycle in the generated clock enable period after Z-cycles. In other cases, equally distributed additional cycles will be inserted for the generated clock enable. If Z is an integer multiple of N, no additional cycles will be included for the generated clock enable at all.

***Note**: For a better resource sharing all arithmetic has been reduced to subtractions and the initialization of the remainder R uses the complement of (Z-N).*

44.3.1.3.3 Configurable clock resolution generation (CRG)

The CRG sub-unit generates up to eight configurable clock resolution signals with reference to an input signal. The input signal can either be the common clock resolution signal CMU_GCLK_EN or CMU_ECLK1_EN depending on the configuration of CLSi_CMU_CLK_CTRL.CLKx_EXT_DIVIDER (x=0-7).

Each clock resolution signal CMU_CLK_RES[x:x] has its own configuration register CLSi_CMU_CLKx_CTRL.

The value specified in CLSi_CMU_CLKx_CTRL.CLK_CNT determines how many pulses (of one CLS[j]_CLK clock-cycle duration) from the input signal are suppressed before one is wired to CMU_CLK_RES[x:x].

When a CMU_CLK_RES[x:x] is used as a clock enable in conjunction with cluster clock, it is possible to regulate the effective clock frequency (denoted as $f_{CMU_CLK_RES}[x:x] = 1/T_{CMU_CLK_RES}[x:x]$) at which the registers are clocked. It is important to emphasize that $T_{CMU_CLK_RES}[x:x]$ is only a period of a virtual clock whose frequency is equivalent to the effective clock frequency resulting from using CMU_CLK_RES[x:x] as a clock enable to the registers the cluster clock is connected to. From that, $T_{CMU_CLK_RES}[x:x]$ can be expressed as: $T_{CMU_CLK_RES}[x:x] =$

(CLSi_CMU_CLKx_CTRL.CLK_CNT +1) * $T_{CMU_GCLK_EN}$. Depending on the configuration of CLSi_CMU_CLK_CTRL.CLKx_EXT_DIVIDER (x=0-7), $T_{CMU_GCLK_EN}$ can be substituted with $T_{CMU_ECLK1_EN}$. The corresponding waveform is shown in Figure 1037

Each clock resolution signal CMU_CLK_RES[z:z] (z ∈ {0, 1, ..., 5} can be enabled individually by appropriately configuring the corresponding CLSi_CMU_CLK_EN.EN_CLKx (x=0-7) **(x=z)** bit field. Enabling of CMU_CLK_RES[6:6] is only possible if the bit field CLSi_CMU_CLK_EN.EN_CLKx (x=0-7) **(x=6)** is appropriately configured and the bit field CLSi_CMU_CLK_6_CTRL.CLK_SEL is set to 0. Similarly, enabling of CMU_CLK_RES[7:7] is only possible if the bit field CLSi_CMU_CLK_EN.EN_CLKx (x=0-7) **(x=7)** is appropriately configured and the bit field CLSi_CMU_CLK_7_CTRL.CLK_SEL is set to 0.

The clock resolution CMU_CLK_RES[8:8] can be configured by CLSi_CMU_CLK_CTRL.CLKx_EXT_DIVIDER (x=0-7) **(x=8)** to select between a constant '1' and CMU_ECLK0_EN.

The input to a clock source divider can either be CMU_ECLK1_EN or CMU_GCLK_EN depending on the configuration of CLSi_CMU_CLK_CTRL.CLKx_EXT_DIVIDER (x=0-7).

To avoid unexpected behavior of the hardware, the configuration of register CLSi_CMU_CLKx_CTRL and CLSi_CMU_CLK_CTRL can only be changed, when the corresponding clock resolution signal CMU_CLK_RES[x:x] and CMU_ECLK[1:1] are disabled.

Further, any changes to the registers CLSi_CMU_GCLK_NUM and CLSi_CMU_GCLK_DEN can only be performed, when all clock resolution signals (CMU_CLK_RES[x:x] and CMU_FXCLK_RES[y:y]) are disabled.

The clock resolution signals CMU_CLK_RES[x:x] and CMU_FXCLK_RES[y:y] are implemented in the form of enable signals for the corresponding registers, which means that the actual clock signal of all registers always use the CLS[j]_CLK signal.

The hardware guarantees that all clock resolution signals CMU_CLK_RES[x:x], which are enabled simultaneously, remain synchronous to each other. Synchronous enabling here means that the bit fields CLSi_CMU_CLK_EN.EN_CLKx (x=0-7) in the register CLSi_CMU_CLK_EN are set by the same write-access.

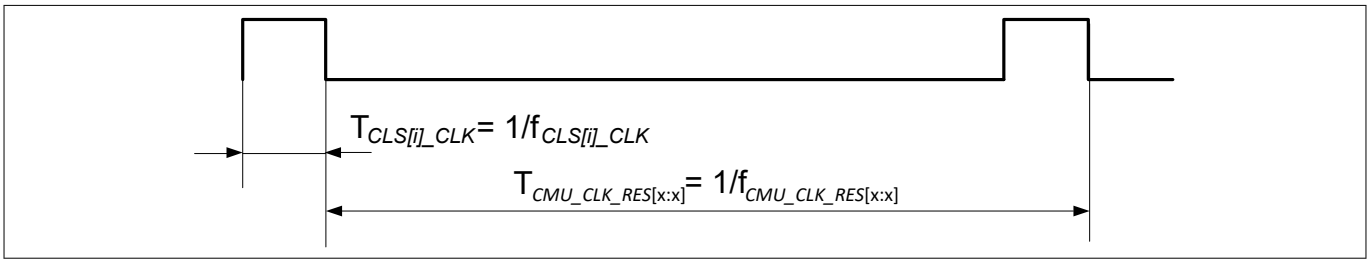

Figure 1037 Wave form of generated clock signal

44.3.1.3.4 Fixed clock resolution generation (FCRG)

The FCRG sub-unit generates fixed clock resolutions signals based on the CMU_GCLK_EN signal or one of the eight CMU_CLK_RES[x:x] resolution signals. The selection of which signal is configurable via CLSi_CMU_FXCLK_CTRL.FXCLK_SEL bit field. These clock resolutions are used for the PWM generation inside the **TOM** modules.

All clock resolutions CMU_FXCLK_RES[y:y] can be enabled/disabled simultaneously by appropriately configuring bit field CLSi_CMU_CLK_EN.EN_FXCLK.

The dividing factors are defined as 2^0, 2^4, 2^8, 2^{12}, and 2^{16}. An FCR Generator with a dividing factor configured as 2^q shall only send one pulse (of one CLS[j]_CLK clock-cycle) from every 2^q pulses to the output. The remaining pulses (2^q-1) are suppressed.

44.3.1.3.5 External generation unit (EGU)

The EGU sub-unit generates up to three separate clock output signals CMU_ECLK[z:z].

Each of these clock signals is derived from the corresponding External Clock Resolution Generator subblock, which generates a clock signal derived from the **eGTM** input clock CLS[j]_CLK.

In contrast to the signals CMU_CLK_RES[x:x] and CMU_FXCLK_RES[y:y], which are clock resolution signals effectively regulating the clock frequency when used as clock enables in conjunction with the cluster clock, the signals CMU_ECLK[z:z] have a duty cycle of approximately 50%. A CMU_CLK_RES[x:x] can be used as a true clock signal for external peripheral components.

The signal CMU_ECLK1_EN could be selected (instead of CMU_GCLK_EN) as input for the clock resolution generators to be used as a reference in the generation of the CMU_CLK_RES[x:x] signals by appropriately configuring CLSi_CMU_CLK_CTRL**.**CLKx_EXT_DIVIDER (x=0-7). In addition, CMU_ECLK0_EN could be wired (instead of '1') to the all-time enabled CMU_CLK_RES[8:8] by appropriately configuring CLSi_CMU_CLK_CTRL**.**CLKx_EXT_DIVIDER (x=0-7) **(x=8)**.

Each of the external clock dividers is enabled/disabled by appropriately configuring bit field CLSi_CMU_CLK_EN**.**EN_ECLKz (z=0-2).

Similar to 'Global Clock Resolution Generator', an 'External Clock Resolution Generator' generates a clock resolution signal (let CMU_ECLK_EN ∈ {CMU_ECLK0_EN, CMU_ECLK1_EN, CMU_ECLK2_EN}). In theory, if a clock resolution signal CMU_ECLK_EN is used as a clock enable in conjunction with the cluster clock, it is possible to regulate the effective clock frequency (denoted as $1/T_{CMU_ECLK_EN}$) at which the registers are clocked. It is important to emphasize that $T_{CMU_ECLK_EN}$ is only a period of a virtual clock whose frequency is equivalent to the effective clock frequency resulting from using CMU_ECLK_EN as a clock enable to the registers the cluster clock is connected to. The following algorithm describes how to achieve a particular $T_{CMU_ECLK_EN}$ and the corresponding CMU_ECLK[z:z] by appropriately configuring CLSi_CMU_ECLKz_NUM and CLSi_CMU_ECLKz_DEN. Let:

$T_{CMU_ECLK0_EN}$ =(CLSi_CMU_ECLKz_NUM **(z=0)**/CLSi_CMU_ECLKz_DEN **(z=0)**)*$T_{CLS[j]_CLK}$

$T_{CMU_ECLK1_EN}$ =(CLSi_CMU_ECLKz_NUM **(z=1)**/CLSi_CMU_ECLKz_DEN **(z=1)**)*$T_{CLS[j]_CLK}$

$T_{CMU_ECLK2_EN}$ =(CLSi_CMU_ECLKz_NUM **(z=2)**/CLSi_CMU_ECLKz_DEN **(z=2)**)*$T_{CLS[j]_CLK}$

and is implemented according to the following algorithm

(Z: CLSi_CMU_ECLKz_NUM**.**ECLK_NUM ; N: CLSi_CMU_ECLKz_DEN**.**ECLK_DEN ; Z>=N >0 ; Z>=N ; CMU_ECLK[z:z]='0'):

1. INIT-phase: Set remainder (R), operand1 (OP1) and operand2 (OP2) register during INIT-phase (with implicit conversion to signed): R=Z, OP1=N, OP2=N-Z.
2. After leaving INIT-phase (CMU_ECLK[z:z] has been enabled) the sign of remainder R will be checked every (CLS[j]_CLK clock-cycle):
3. If R>=0: keep the corresponding CMU_ECLK_EN at '0', keep CMU_ECLK[z:z], and update R=R-OP1.
4. If R<0: set corresponding CMU_ECLK_EN to '1', toggle CMU_ECLK[z:z], and update R=R-OP2.

After at most (Z/N+1) subtractions (3. in the list above), there will be a negative R and an active phase of the generated clock enable (for one cycle) will be triggered (4. in the list above). The remainder R is a measure for the distance to a real Z/N clock and will be considered for the next generated clock toggle phase. The new R value will be R=R+(Z-N). In the worst case, the remainder R will sum up to an additional cycle in the generated clock toggle period after Z-cycles. In other cases equally distributed additional cycles will be inserted for the generated clock toggle. If Z is an integer multiple of N, no additional cycles will be included for the generated clock toggle at all.

Attention: an external clock signal (CMU_ECLK[z:z]) shall have exactly 50% duty cycle only when the ratio CLSi_CMU_ECLKz_NUM**.**ECLK_NUM / CLSi_CMU_ECLKz_DEN**.**ECLK_DEN results in an integer value.

***Note**: For a better resource sharing, all arithmetic has been reduced to subtractions and the initialization of the remainder R uses the complement of (Z-N).*

The initial value of the CMU_ECLK[z:z] output is low.

44.3.1.4 Cluster configuration module (CCM)

44.3.1.4.1 Overview

As already mentioned in **eGTM** architecture, each sub-module of the **eGTM** is aligned explicitly to a cluster. The Cluster Configuration Module (**CCM**) enables the configuration of several cluster-specific options namely:

- cluster's clock frequency,
- module clock gating,
- address range protection, and
- global architecture configuration.

Indices and their range as used inside this chapter are:

- i:={0, 1,..., NCMM-1} instance index of cluster / **CCM** module
- a:={0, 1,..., NARP-1} index of address range protectors

44.3.1.4.2 Cluster CMU clock resolution

The registers CLSi_CCM_CMU_CLK_CFG and CLSi_CCM_CMU_FXCLK_CFG allow the configuration of various cluster clock frequencies.

Figure 1038 shows important details about the wiring of the cluster's local clock signals. It is worth mentioning that CCM[i]_CLK_RES[7:7] is routed to the **CMU** module in which it can be used for clock resolution generation.

Clock resolution signals (CMU_CLK_RES[x:x], x ∈ {0, 1, ..., 8}) are routed from cluster 0 to the remaining clusters through ICPAs Inter-cluster pulse adapter. When a clock resolution signal with an effective clock frequency Global clock resolution generator greater than CLK / 2 of is routed from cluster 0 with CLS[j]_CLK = CLK to cluster z ∈ {1, ..., NCMM-1} with CLS[j]_CLK = CLK / 2, the effective clock frequency of the resolution signal at the output of ICPA is limited to CLK / 2.

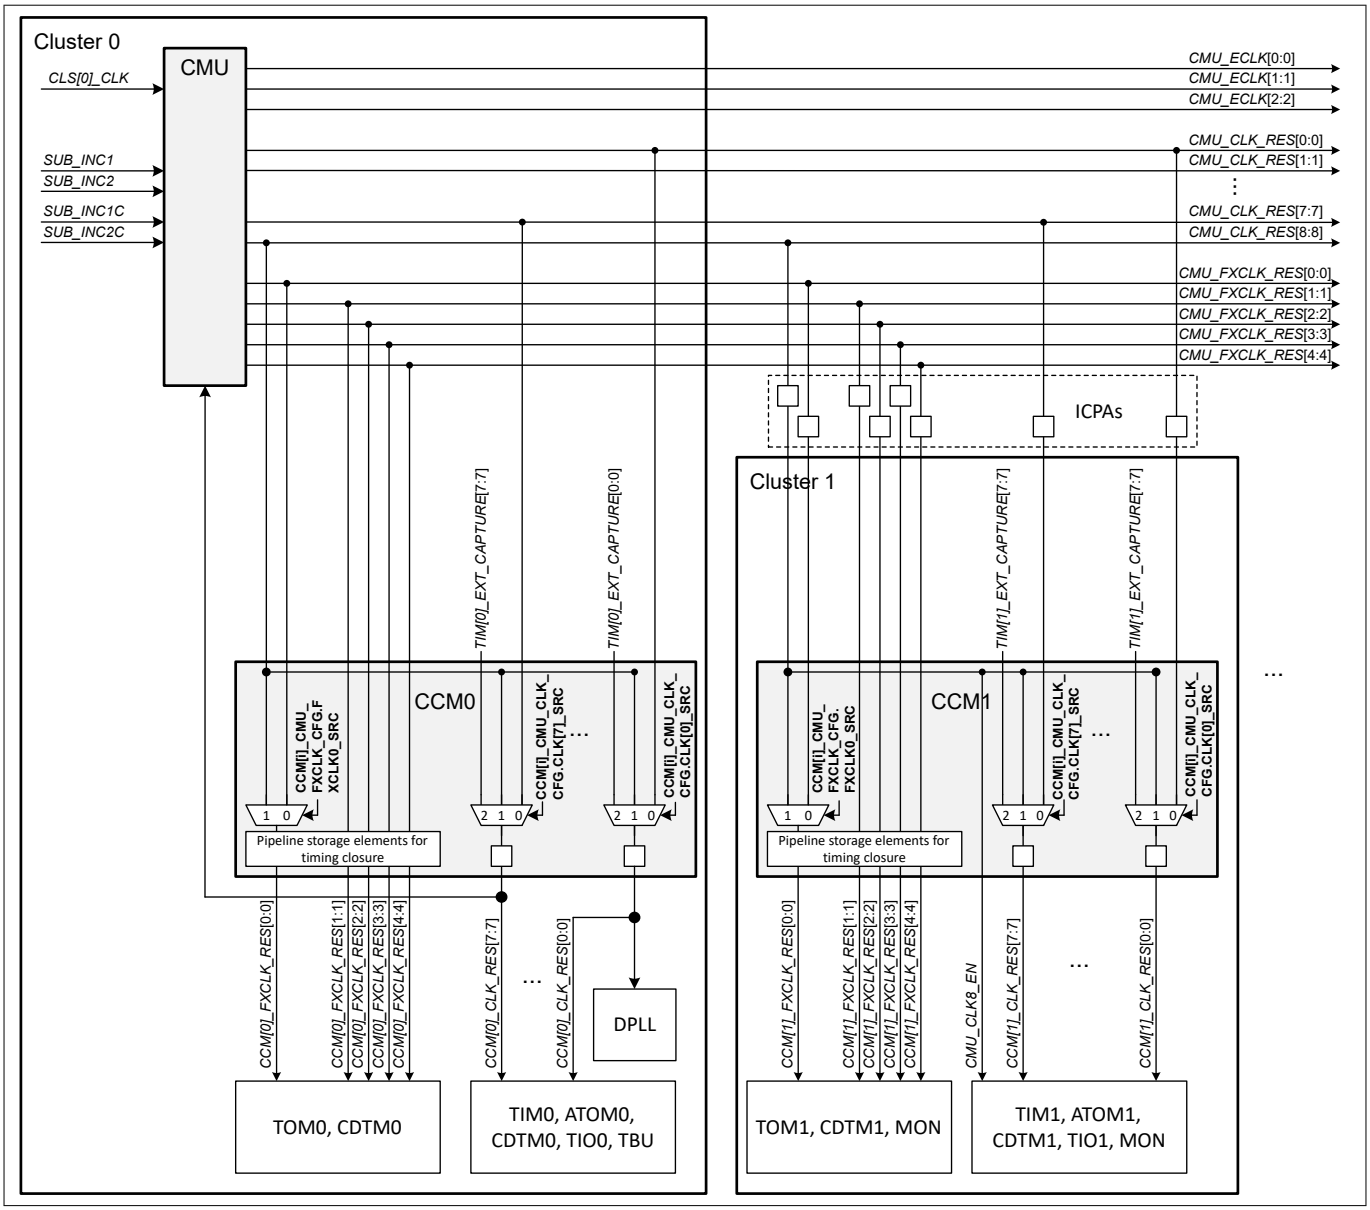

Figure 1038 Cluster clock resolution wiring

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

44.3.1.4.3 Cluster timebase distribution

Figure 1039 depicts the wiring of the time bases to the clusters. The pipeline stages shown in the figure are only present for devices with CFG_CLOCK_RATE = 1.

In cluster 0, the time bases (TBU_TS0X, TBU_TS1_BASE, TBU_TS2_BASE, TBU_TS2_BASE) as well as the respective update indicators (TBU_UP0, TBU_UP1, TBU_UP2) are generated in **TBU** and routed to **CCM[0]** in which a pipeline stage is introduced in order to reach timing closure. The 27-bit time base (TBU_TS0X) is wired to **TIM[0]** and the **DPLL**. The lower 24 bits or the higher 24 bits of TBU_TS0X are selected based on CLSi_TBU_CH0_CTRL.LOW_RES and forwarded to CCM[i]_TBU_TS0. The time bases (CCM[i]_TBU_TS0, CCM[i]_TBU_TS1, CCM[i]_TBU_TS2) are routed to the appropriate modules. The times bases (CCM[i]_TBU_TS0, CCM[i]_TBU_TS1, CCM[i]_TBU_TS2) as well as the update indicators ((e)GTM_DBG_TBU_UP0, (e)GTM_DBG_TBU_UP1, (e)GTM_DBG_TBU_UP2) are exposed as debug ports.

The time bases (TBU_TS0_BASE, TBU_TS1_BASE, TBU_TS2_BASE) are generated in **TBU** and routed to other clusters via the **CCM**s. In a **CCM**, a pipeline stage for the times bases is introduced in order to reach timing closure. The lower 24 bits or the higher 24 bits of TBU_TS0X are selected based on CLSi_TBU_CH0_CTRL**.**LOW_RES and forwarded to CCM[i]_TBU_TS0. The time bases at the output of the pipeline stage (CCM[i]_TBU_TS0, CCM[i]_TBU_TS1, CCM[i]_TBU_TS2) are routed to the appropriate modules.

***Note**:* *If cluster 0 is clocked with CLK whereas another cluster (say cluster 1) is clocked with CLK/2, not all the values of the time bases generated in cluster 0 are visible/sampled in cluster 1. Therefore, it is strongly advised that the user configures the compare operations in such clusters to be based on the 'greater than or equal to' operator - not 'equal to' operator.*

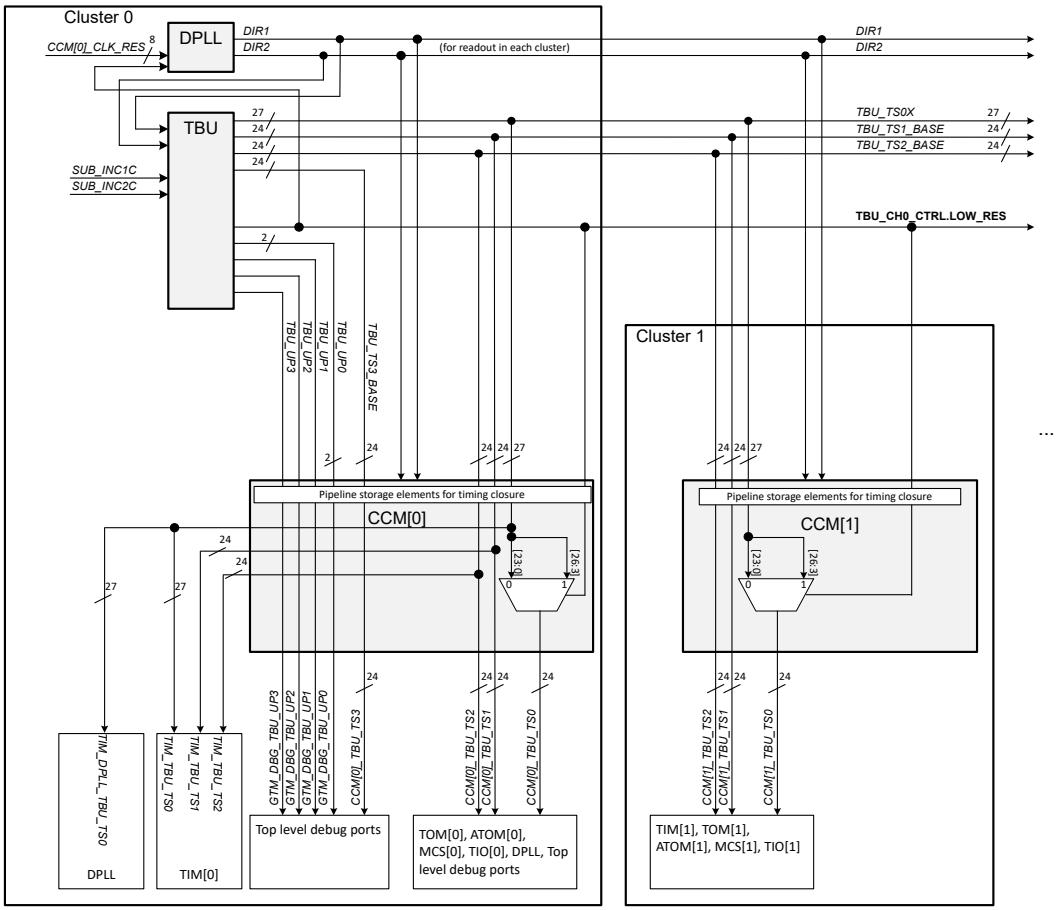

Figure 1039 Cluster timebase wiring

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

44.3.1.4.4 Address range protection

The **CCM** also provides so-called address range protectors (ARPs) up to NARP. An ARP can be used to define a configurable write-protected address range in order to support enhanced safety features.

44.3.1.5 Time base unit (TBU)

44.3.1.5.1 Overview

The Time Base Unit **TBU** provides common time bases for the **eGTM**. The **TBU** sub-module is organized in channels, where the number of channels is device-dependent. There are up to four channels implemented inside the **TBU**.

Indices and their range as used inside this chapter are:

- x:={1, 2} index for time base channel 1 and channel 2
- y:={0, 1, 2} index of **TBU** channel

The time base register CLSi_TBU_CH0_BASE of **TBU** channel 0 is 27 bits wide and it is configurable whether the lower 24 bits or the upper 24 bits are provided to the **eGTM** as signal TBU_TS0_BASE.

The two **TBU** channels 1 and 2 have a time base register CLSi_TBU_CHx_BASE (i=0;x=1-2) (x∈{1, 2}) of 24 bits length. The time base register values TBU_TS1_BASE and TBU_TS2_BASE are provided to subsequent sub-modules of the **eGTM**.

***Note**: The right-hand sum is limited to 24 bits.*

The TBU_UP1, TBU_UP2 signals are set to high for a single cls_clk period, whenever the corresponding signals TBU_TS1_BASE, TBU_TS2_BASE are updated. The signal TBU_UP0_L is set to high for a single cls_clk period, if the signal TBU_TS0_BASE and TBU_TS0X are updated and TBU_UP0_H is set to high for a single cls_clk period, whenever the upper 24 bits of TBU_TS0_BASE are updated.

The time base channels can run independently of each other and can be enabled and disabled synchronously by control bits in a global **TBU** channel enable register CLSi_TBU_CHEN. Figure 1040 shows a block diagram of the Time Base Unit.

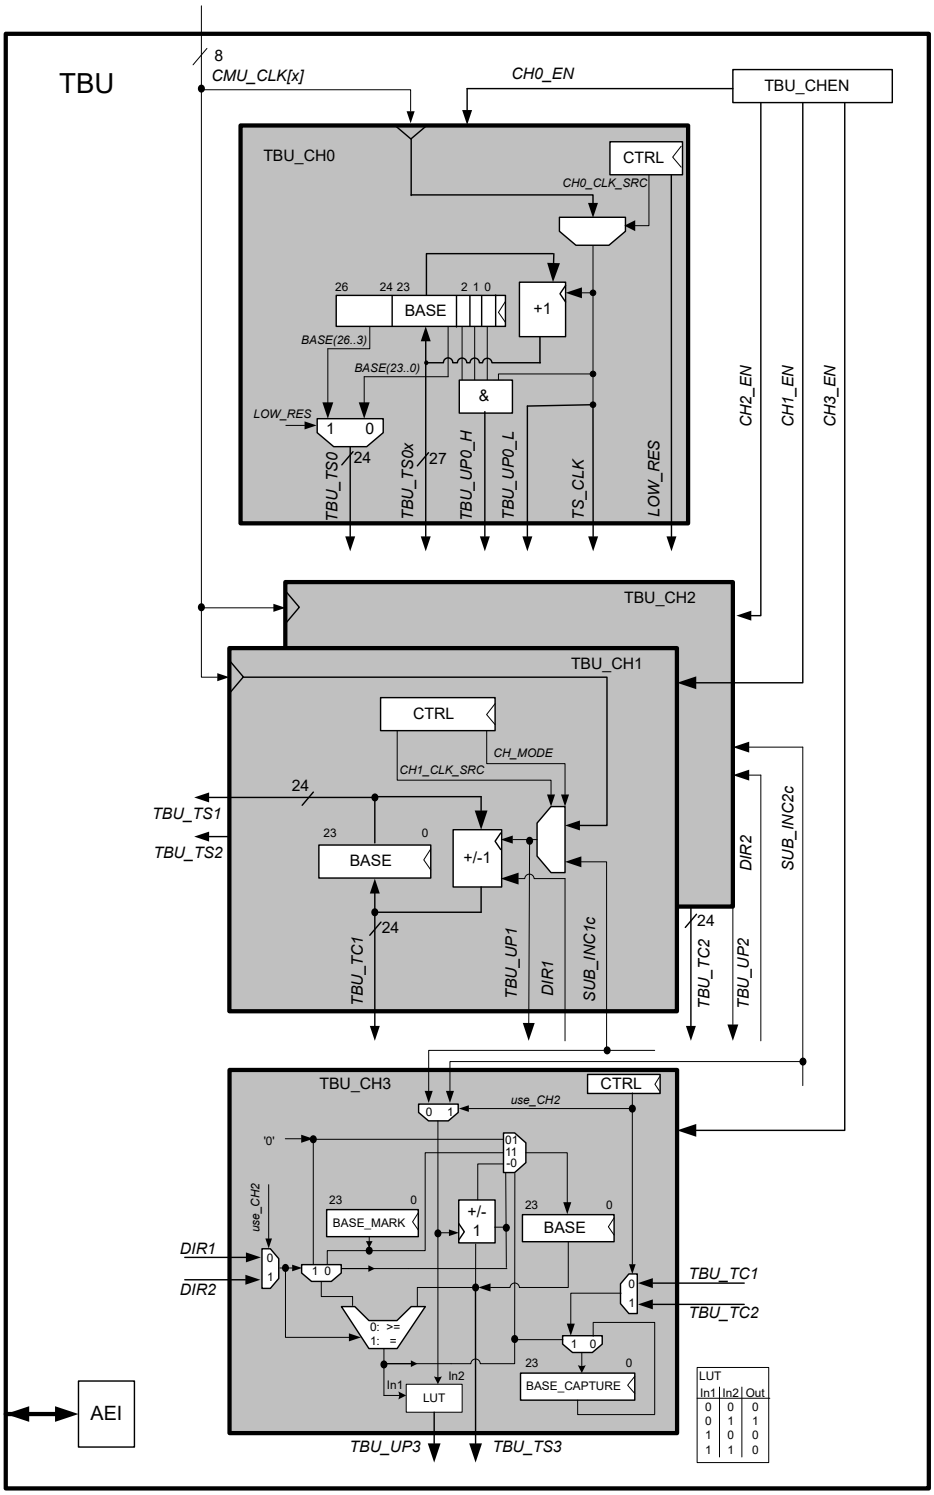

Figure 1040 TBU block diagram

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

Depending on the device a third **TBU** channel exists which offers the same functionality as the time base channel 1.

The configuration of the independent time base channels CLSi_TBU_CHx_BASE (i=0;x=1-2) is done via the **AEI** interface. The **TBU** channel 0 to channel 2 may select one of the eight CCM[i]_CLK_RES[y:y] (y∈{0, 1,..., 7}) signals coming from the **CMU** sub-module.

44.3.1.5.2 TBU channels

The time base values are generated within the **TBU** time base channels in two independent and one dependent operation modes.

In all modes, the time base registers CLSi_TBU_CH0_BASE, CLSi_TBU_CHx_BASE (i=0;x=1-2) can be initialized with a start value just before enabling the corresponding **TBU** channel.

Moreover, the time base registers CLSi_TBU_CH0_BASE, CLSi_TBU_CHx_BASE (i=0;x=1-2) can always be read in order to determine the actual value of the counter.

Independent modes

Free running counter mode

TBU channel 0 provides a 27-bit counter in a free running counter mode. Depending on the bit field CLSi_TBU_CH0_CTRL.LOW_RES, the lower 24 bits CLSi_TBU_CH0_BASE.BASE[23:0] or the upper 24 bits CLSi_TBU_CH0_BASE.BASE[26:3] are provided to the **eGTM** sub-modules.

TBU channel 1 and channel 2 provides a 24-bit counter in a free running counter mode enabled by reset of CLSi_TBU_CH1_CTRL.CH_MODE and CLSi_TBU_CH2_CTRL.CH_MODE.

In **TBU** free running counter mode, the time base registers CLSi_TBU_CH0_BASE and CLSi_TBU_CHx_BASE (i=0;x=1-2) are updated on every specified incoming clock event by the selected signal CCM[i]_CLK_RES[y:y] (y∈{0, 1,..., 7}) (depending on CLSi_TBU_CH0_CTRL, CLSi_TBU_CH1_CTRL and CLSi_TBU_CH2_CTRL register). In general, the time base register CLSi_TBU_CHx_BASE (i=0;x=1-2) is incremented on every CCM[i]_CLK_RES[y:y] clock tick.

Forward/backward counter mode

TBU channels 1 and 2 provide a 24-bit forward/backward counter enabled by set of CLSi_TBU_CH1_CTRL.CH_MODE and CLSi_TBU_CH2_CTRL.CH_MODE.

TBU_UP2	Indication of update of TBU_TS2_BASE

44.3.1.6 Timer input module (TIM)

44.3.1.6.1 Overview

The Timer Input Module (**TIM**) is responsible for filtering and capturing input signals of the **eGTM**. Several characteristics of the input signals can be measured inside the **TIM** channels.

Input characteristics mean either timestamp values of detected input rising or falling edges together with the new signal level or the number of edges received since channel enable together with the actual timestamp or PWM signal duration for a whole PWM period.

Indices and their range as used inside this chapter are:

- NTIM: number of **TIM**
- i:={0, 1,..., NTIM-1} instance index of cluster / module
- x:={0, 1,..., 7} channel index in a **TIM** instance
- m: number of channels available in the **TIM** sub-module
- y:={0, 1,..., m-1} index for the number **TIM** sub-module channels

The number of channels m inside a **TIM** sub-module depends on the device.

The architecture of **TIM** is shown in Figure 1041.

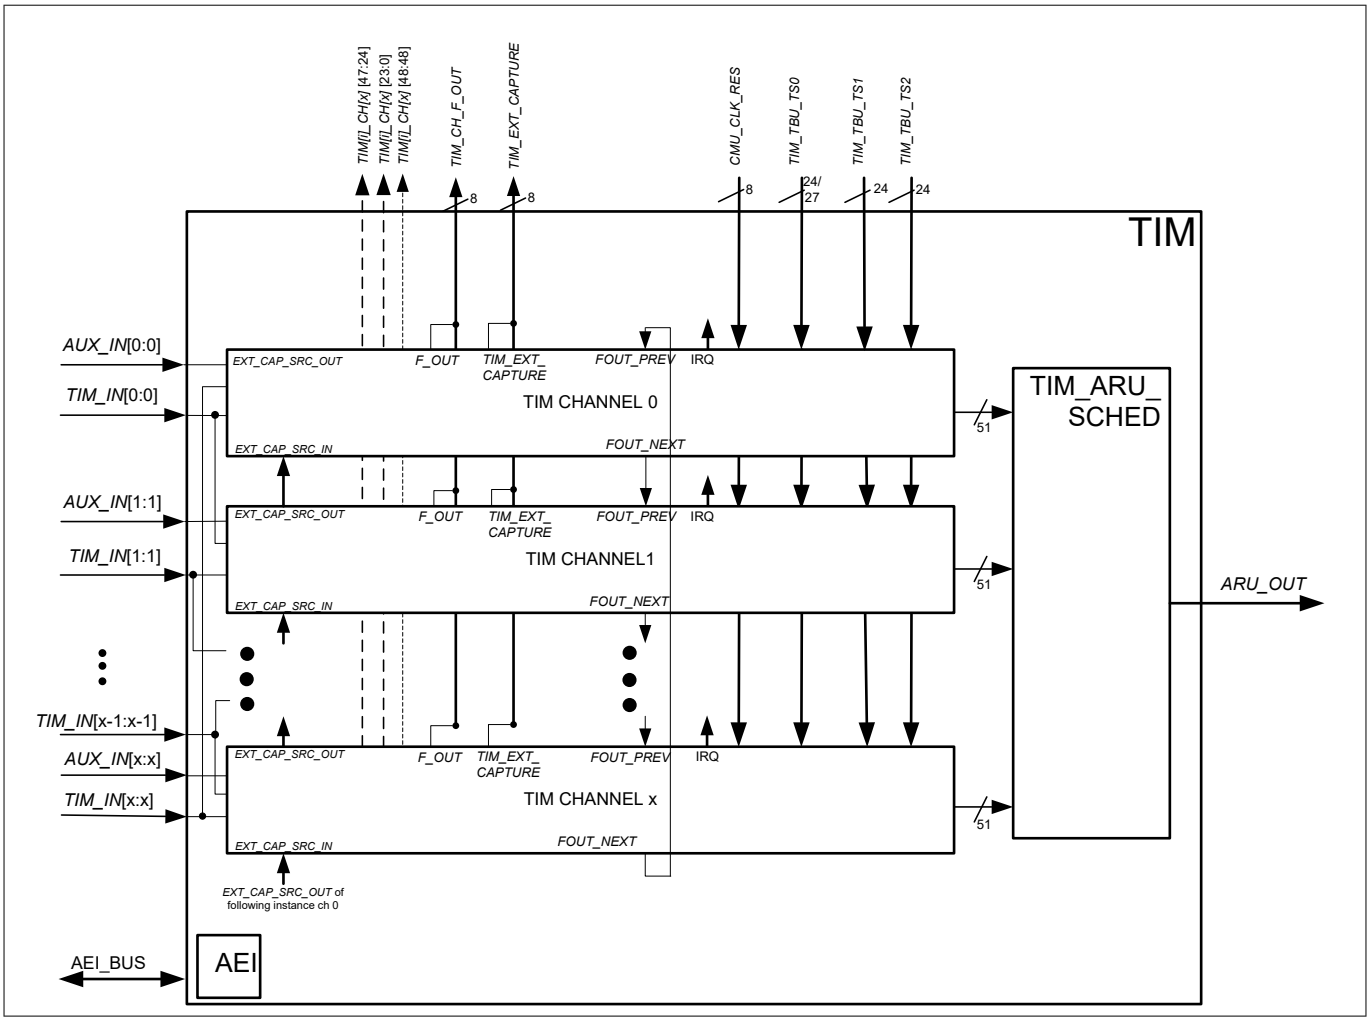

Figure 1041 TIM block diagram

Each of the m dedicated input signals are filtered inside the FLT_CHx sub-unit of the **TIM** module.

***Note**: The input signals TIM_IN[x:x]/TIM_IN[x-1:x-1] are driven by external logic and has no defined relationship to the internal cluster clock. To avoid metastability it is necessary to synchronize TIM_IN[x:x]/TIM_IN[x-1:x-1] via two register stages, which leads to a delay of two cls_clk periods for these incoming signals. On the other hand the input signals AUX_IN[x:x] are not synchronized as these are generated already synchronously within the **eGTM**.*

The measurement values can be read by the CPU directly via the **AEI**-Bus .

The two (three) time bases coming from the **TBU** are connected to the **TIM** channels to annotate timestamps to incoming signals. For TIM0, the extended 27 bits wide time base TIM_TBU_TS0 is connected to the **TIM** channels, and the user has to select if the lower 24 bits (TIM_TBU_TS0[23:0]) or the higher 24 bits (TIM_TBU_TS0[26:3]) are stored inside the CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 registers.

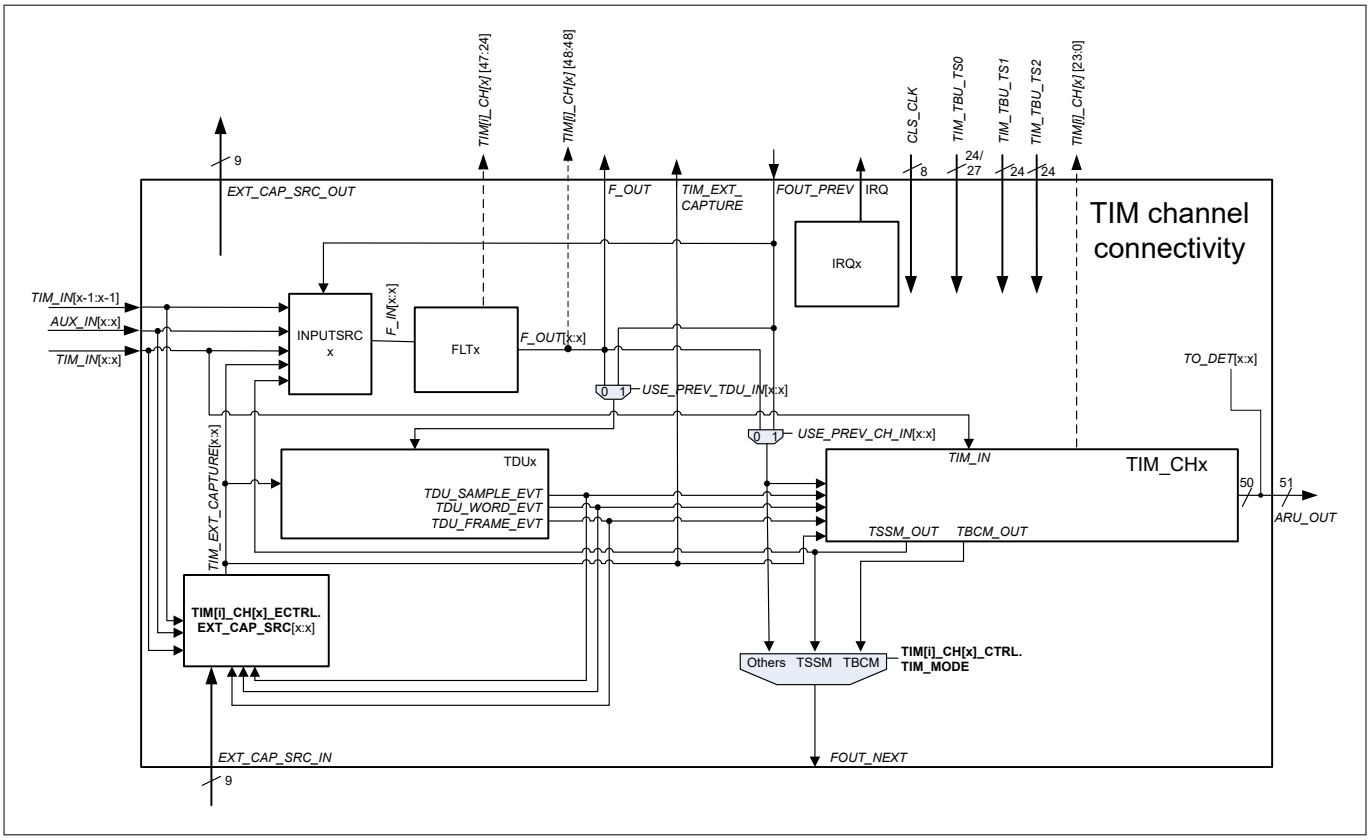

Figure 1042 TIM channel internal connectivity

- Above figure gives an overview of the channel internal connectivity of the sub-units. The sub-units with the major functionality are listed next:
- INPUTSRC_CHx: Select signal for processing by the filter unit FLT_CHx
- FLT_CHx: The filter unit provides different filter mechanisms described in more detail in **TIM** filter functionality (FLT).
- TDU_CHx: Timeout detection unit (no subsequent edge detected during a specified duration)
- TIM_CHx: Measurement unit; different measurements strategies configurable on the filtered signal
- IRQ_CHx: Local interrupt controller (enabling, status, ..)
- CLSi_TIM_CHx_ECTRL.EXT_CAP_SRC: Selects a local signal TIM_EXT_CAPTURE[x:x] which is needed by certain functions
- Details are given in the next chapters.

***Note**: Depending on the values of the configuration bit fields CLSi_TIM_CHx_ECTRL.USE_PREV_TDU_IN , CLSi_TIM_CHx_ECTRL.USE_PREV_CH_IN, it is possible to operate on the signal of the local channel x or the previous channel x-1.*

Depending on the value of the configuration bit field CLSi_TIM_CHx_CTRL.TIM_MODE it is possible to provide different signals (via FOUT_NEXT) to the next channel.

In TBCM mode each capture event selected by the sensitive edges (CLSi_TIM_CHx_CNTS.CNTS) will be forwarded with the value of CLSi_TIM_CHx_ECNT[0] to the following channel (via FOUT_NEXT).

Input source selection INPUTSRCx

It can be configured which source is used for processing in the FLT,TDU,TIM_CH units. It can be selected by the bit fields CLSi_TIM_CHx_CTRL.CICTRL and CLSi_TIM_IN_SRC.MODEx, CLSi_TIM_IN_SRC.VALx in the register CLSi_TIM_IN_SRC which source is in use.

Alternatively, the signal F_IN[x:x] can be generated by an 8-bit lookup-table, which allows to define any function of 3 input sources.

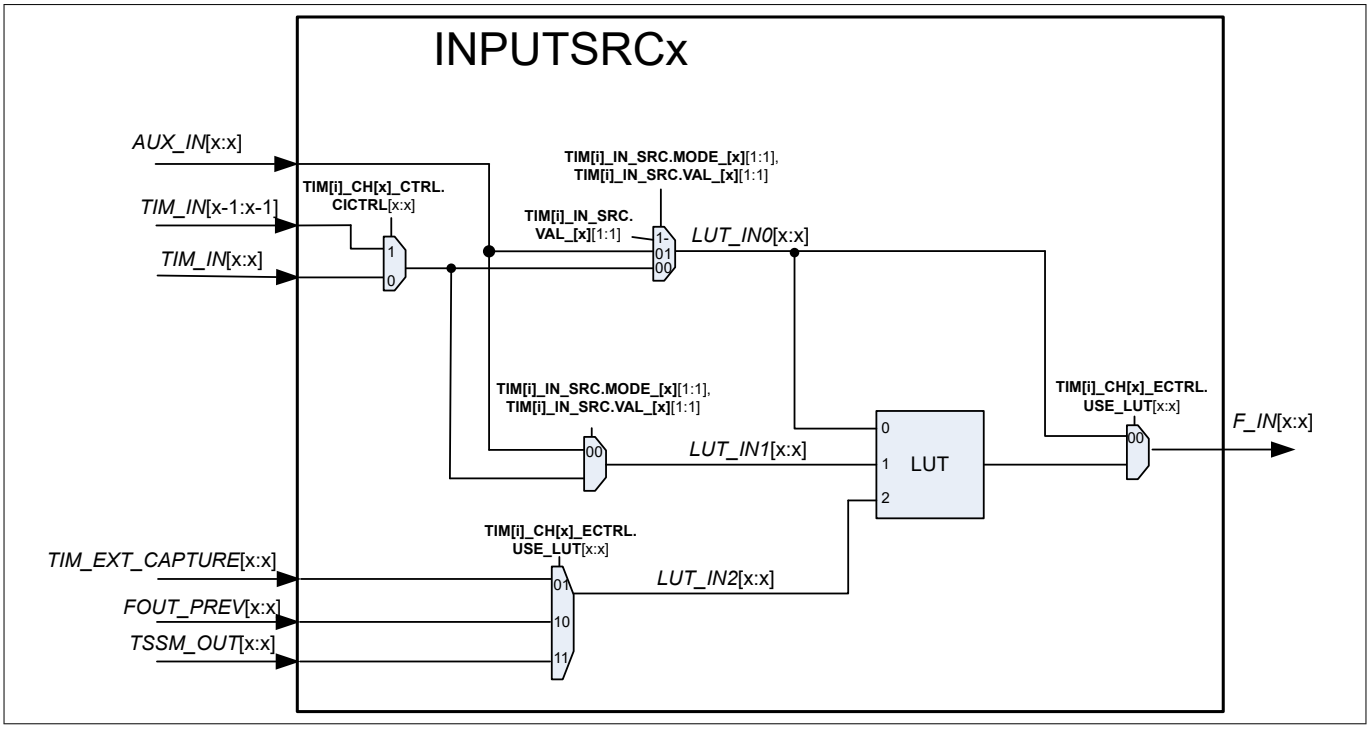

Figure 1043 INPUTSRC block diagram

If CLSi_TIM_CHx_ECTRL.USE_LUT=00_B is set, the lookup-table signal generation is bypassed and the signal is selected as follows:

In a certain CLSi_TIM_IN_SRC.MODEx, CLSi_TIM_IN_SRC.VALx combination the input signal F_IN[x:x] can be driven by CLSi_TIM_IN_SRC.VALx[1:1] with 0 or 1 directly.

Due to the fact that all 8 channels are bundled in the register CLSi_TIM_IN_SRC a synchronous control of all 8 input channels is possible.

Two adjacent channels can be combined by setting the CLSi_TIM_CHx_CTRL.CICTRL bit field. This allows combining of complex measurements on one input signal with two **TIM** channels.

The additional signal AUX_IN[x:x] can be selected as an input signal. The source of this signal is defined in the Figure 1018.

If CLSi_TIM_CHx_ECTRL.USE_LUT !=00_B is set, the lookup-table signal generation with following inputs is in use. See Figure 1043:

Input LUT_IN0[x:x] selection:

- CLSi_TIM_INP_VAL.TIM_INx (x=0-7) if CLSi_TIM_CHx_CTRL.CICTRL = 0 and CLSi_TIM_IN_SRC.MODEx[1:1] = 0 and CLSi_TIM_IN_SRC.VALx[1:1] = 0
- CLSi_TIM_INP_VAL.TIM_INx (x=0-7) **(x=x-1)** if CLSi_TIM_CHx_CTRL.CICTRL = 1 and CLSi_TIM_IN_SRC.MODEx[1:1] = 0 and CLSi_TIM_IN_SRC.VALx[1:1] = 0
- AUX_IN[x:x] if CLSi_TIM_IN_SRC.MODEx[1:1]=0 and CLSi_TIM_IN_SRC.VALx[1:1] = 1
- CLSi_TIM_IN_SRC.VALx if CLSi_TIM_IN_SRC.MODEx[1:1] = 1

Input LUT_IN1[x:x] selection:

- AUX_IN[x:x] if CLSi_TIM_IN_SRC.MODEx[1:1] = 0 and CLSi_TIM_IN_SRC.VALx[1:1] = 0
- CLSi_TIM_INP_VAL.TIM_INx (x=0-7) if CLSi_TIM_CHx_CTRL.CICTRL= 0
- CLSi_TIM_INP_VAL.TIM_INx (x=0-7) **(x=x-1)** if CLSi_TIM_CHx_CTRL.CICTRL= 1

Input LUT_IN2[x:x] selection:

- TIM_EXT_CAPTURE[x:x] if CLSi_TIM_CHx_ECTRL.USE_LUT=01_B
- FOUT_PREV[x:x] if CLSi_TIM_CHx_ECTRL.USE_LUT=10_B
- TSSM_OUT[x:x] if CLSi_TIM_CHx_ECTRL.USE_LUT=11_B

The lookup-table is defined by the contents of the bit field CLSi_TIM_CHx_TDUC.TO_CNT2. The lookup_table_index is defined by LUT_IN2[x:x] & LUT_IN1[x:x] & LUT_IN0[x:x]. The signal F_IN[x:x] is generated by CLSi_TIM_CHx_TDUC.TO_CNT2[lookup_table_index].

If CLSi_TIM_CHx_ECTRL.USE_LUT !=00_B is set, only limited functionality is available in the TDU. See bit field CLSi_TIM_CHx_TDUV.SLICING in the register CLSi_TIM_CHx_TDUV.

Input observation

It is possible to observe for all channels of one instance by reading CLSi_TIM_INP_VAL the actual signal values of the following processing stages:

- TIM_IN[7:0] signals after **TIM** input synchronization
- F_IN[7:0] signals after **TIM** INPUTSRC selection (input to FLT)
- F_OUT[7:0] signals after **TIM** filter functionality (output of FLT)

External capture source selection EXTCAPSRCx

Each channel can operate on an external capture signal TIM_EXT_CAPTURE. The source to use for this signal can be configured by the bit field CLSi_TIM_CHx_ECTRL.EXT_CAP_SRC.

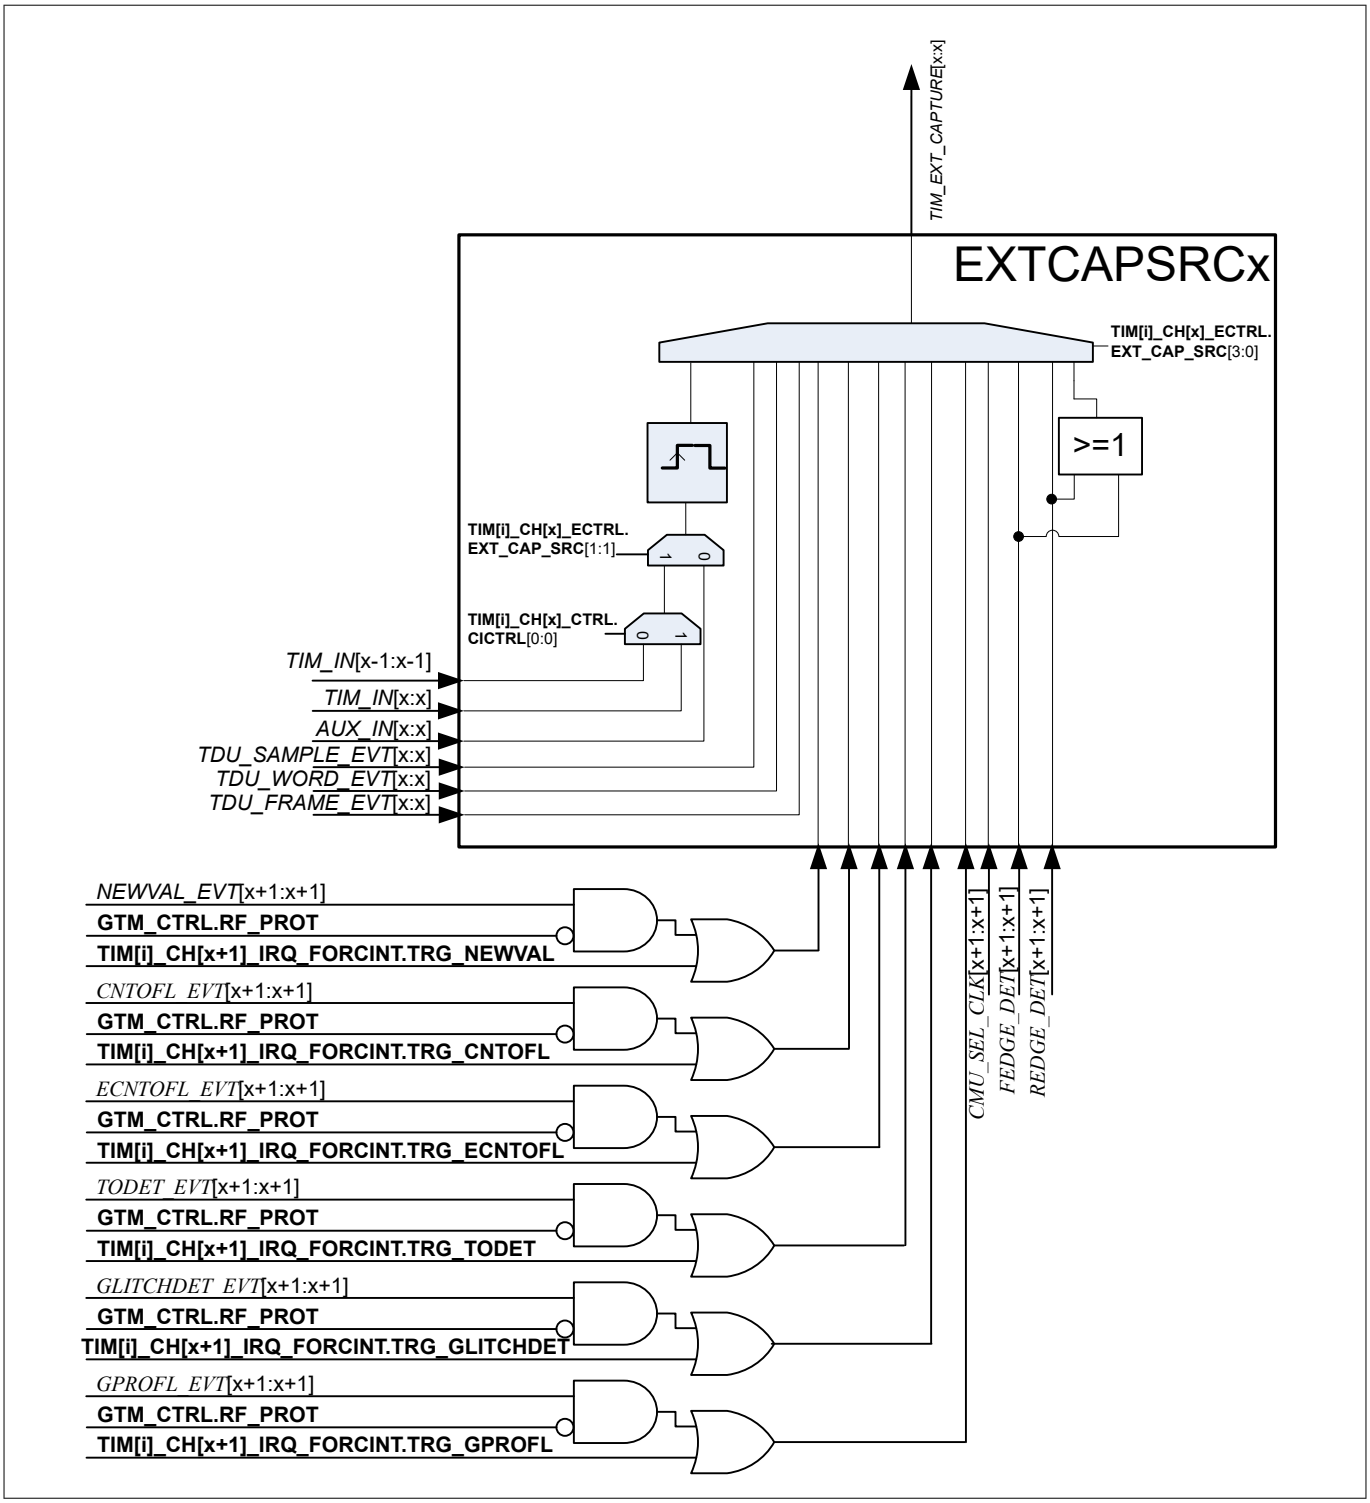

Figure 1044 EXTCAPSRC block diagram

A pulse generation for each rising edge of the selected input signal CLSi_TIM_INP_VAL.TIM_INx (x=0-7), CLSi_TIM_INP_VAL.TIM_INx (x=0-7) **(x=x-1)** and AUX_IN[x:x] is applied. These pulses can be selected and used as TIM_EXT_CAPTURE[x:x] signal.

Alternatively, one of the events TDU_SAMPLE_EVT[x:x], TDU_WORD_EVT[x:x], TDU_FRAME_EVT[x:x] generated in the TDU can be selected.

Furthermore, one of the six interrupt sources of channel x+1 can be selected. Alternatively, they can be issued by a soft trigger using the corresponding bits in the register CLSi_TIM_CHx_IRQ_FORCINT **(x=x+1)**. The pulses

on CLSi_TIM_CHx_IRQ_FORCINT **(x=x+1)** are allowed to pass through only when CLSi_ARCH_CTRL**.**RF_PROT = 0.

Additional sources of channel x+1 can be selected (rise/ fall/ both input edges or **CMU** clock resolution in use in channel x+1).

44.3.1.6.2 TIM filter functionality (FLT)

Overview

The **TIM** sub-module provides a configurable filter mechanism for each input signal. These filter mechanisms are provided inside the FLT sub-unit.

FLT architecture is shown in Figure 1045.

The filter includes a clock synchronization unit (CSU), an edge detection unit (EDU), and a filter counter associated with the filter unit (FLTU).

The CSU synchronizes the incoming signal F_IN with the selected filter clock frequency, which is controlled with the bit field CLSi_TIM_CHx_CTRL**.**FLT_CNT_FRQ.

The synchronized input signal F_IN_SYNC is used for further processing within the filter.

Within the FLT sub-module there is a two cluster-clock-cycle delay between F_IN and F_OUT, one cycle in the CSU sub-block and one cycle in the output signal generation sub-block (see Figure 1045).

***Note**: Glitches with a duration go less than the selected **CMU** clock period is lost.*

The filter modes can be applied individually to the falling and rising edges of an input signal. The following filter modes are available:

- immediate edge propagation mode,
- individual deglitch time mode (up/down counter), and
- individual deglitch time mode (hold counter).
- individual deglitch time mode (reset counter).

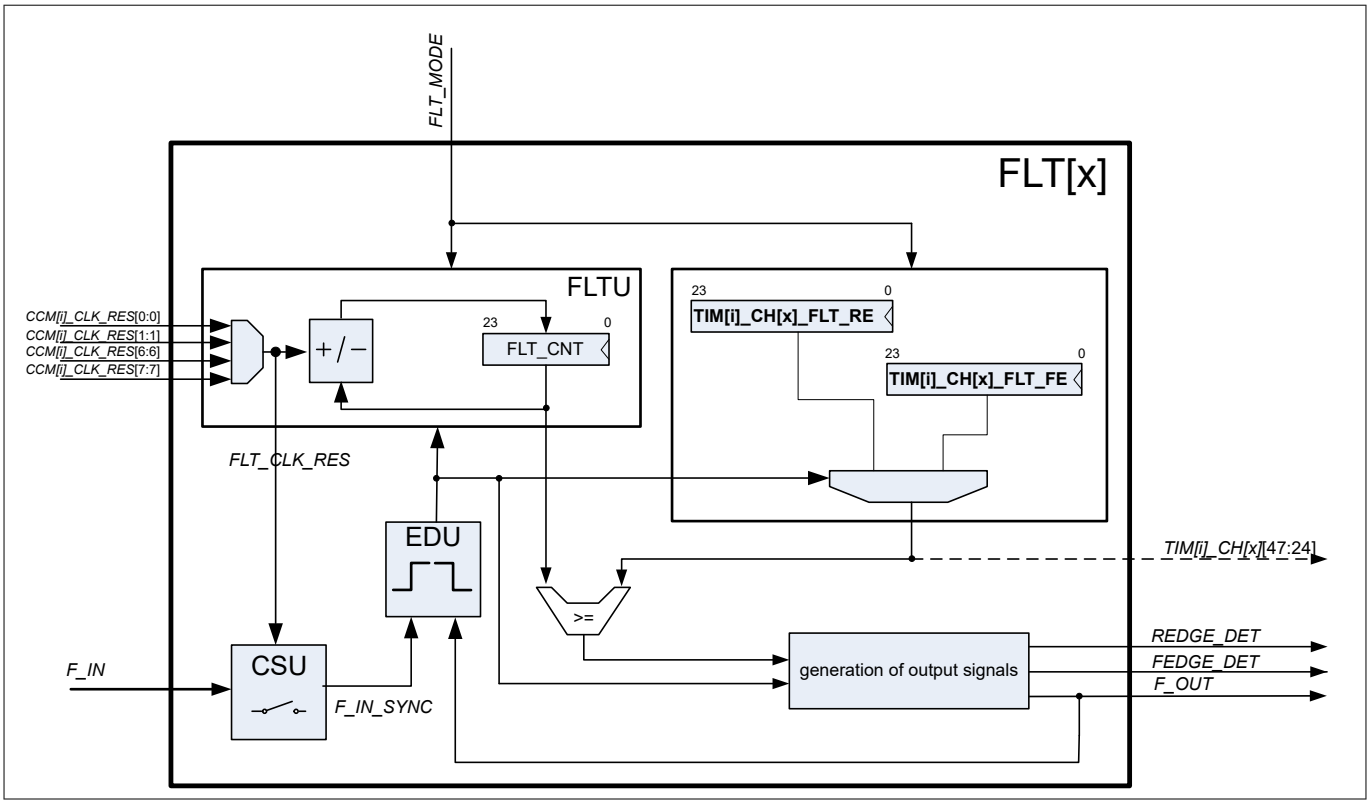

Figure 1045 FLT architecture

The filter parameters (deglitch and acceptance time) for the rising and falling edge can be configured inside the two filter parameter registers CLSi_TIM_CHx_FLT_RE (rising edge) and CLSi_TIM_CHx_FLT_FE (falling edge). The exact meaning of the parameter depends on the filter mode.

However, the delay time T of both filter parameters CLSi_TIM_CHx_FLT_FE, CLSi_TIM_CHx_FLT_RE can always be determined by:

$T=(CLSi_TIM_CHx_FLT_RE.FLT_RE+1)*T_{FLT_CLK_RES}$,

$T=(CLSi_TIM_CHx_FLT_FE.FLT_FE+1)*T_{FLT_CLK_RES}$,

Whereas $T_{FLT_CLK_RES}$ is the clock period of the selected **CMU** clock signal in bit field CLSi_TIM_CHx_CTRL.FLT_CNT_FRQ of register CLSi_TIM_CHx_CTRL.

When a glitch is detected on an input signal, a pulse with the length of one cluster clock on the interrupt event signal *GLITCHDET_IRQ* is raised and a status flag CLSi_TIM_CHx_IRQ_NOTIFY.GLITCHDET is set.

Table 2201 gives an overview of the meanings for the registers CLSi_TIM_CHx_FLT_RE and CLSi_TIM_CHx_FLT_FE.

Table 2201 Filter parameter summary for the different filter modes

Filter mode	Meaning of CLSi_TIM_CHx_FLT_RE	Meaning of CLSi_TIM_CHx_FLT_FE
Immediate edge propagation	Acceptance time for rising edge	Acceptance time for falling edge
Individual deglitch time (up/down counter)	Deglitch time for rising edge	Deglitch time for falling edge
Individual deglitch time (hold counter)	Deglitch time for rising edge	Deglitch time for falling edge
Individual deglitch time (reset counter)	Deglitch time for rising edge	Deglitch time for falling edge

A counter FLT_CNT is used to measure the glitch and acceptance times.

The frequency of the FLT_CNT counter is configurable in bit field CLSi_TIM_CHx_CTRL.FLT_CNT_FRQ.

The counter FLT_CNT is operating on FLT_CLK_RES clock resolution. The source for FLT_CLK_RES can be selected with CLSi_TIM_CHx_CTRL.FLT_CNT_FRQ from CCM[i]_CLK_RES[0:0], CCM[i]_CLK_RES[1:1], CCM[i]_CLK_RES[6:6] or the CCM[i]_CLK_RES[7:7] signals which were provided by the **CCM[i]** module.

The counter FLT_CNT and the registers CLSi_TIM_CHx_FLT_FE and CLSi_TIM_CHx_FLT_RE are 24 bits wide. For example, when the resolution of the CCM[i]_CLK_RES[0:0] signal is 50ns this allows maximum deglitch and acceptance times of about 838ms for the filter.

TIM filter modes

Immediate edge propagation mode

In immediate edge propagation mode after detection of an edge, the new signal level on F_IN_SYNC is propagated to F_OUT with a delay of one $T_{FLT_CLK_RES}$ period and the new signal level remains unchanged until the configured acceptance time expires.

For each edge type the acceptance time can be specified separately in the CLSi_TIM_CHx_FLT_RE and CLSi_TIM_CHx_FLT_FE registers.

Each signal change on the input F_IN_SYNC during the duration of the acceptance time has no effect on the output signal level F_OUT of the filter but it sets the glitch CLSi_TIM_CHx_IRQ_NOTIFY.GLITCHDET bit.

After it expires an acceptance time the input signal F_IN_SYNC is observed and on signal level change the filter raises a new detected edge and the new signal level is propagated to F_OUT.

Independent of a signal level change the value of F_OUT is always set to F_IN_SYNC, when the acceptance time expires (see also Figure 1047).

Figure 1046 shows an example for the immediate edge propagation mode, in the case of rising edge detection. Both, the signal before filtering (F_IN) and after filtering (F_OUT) are shown. The acceptance time at1 is specified in the register CLSi_TIM_CHx_FLT_RE.

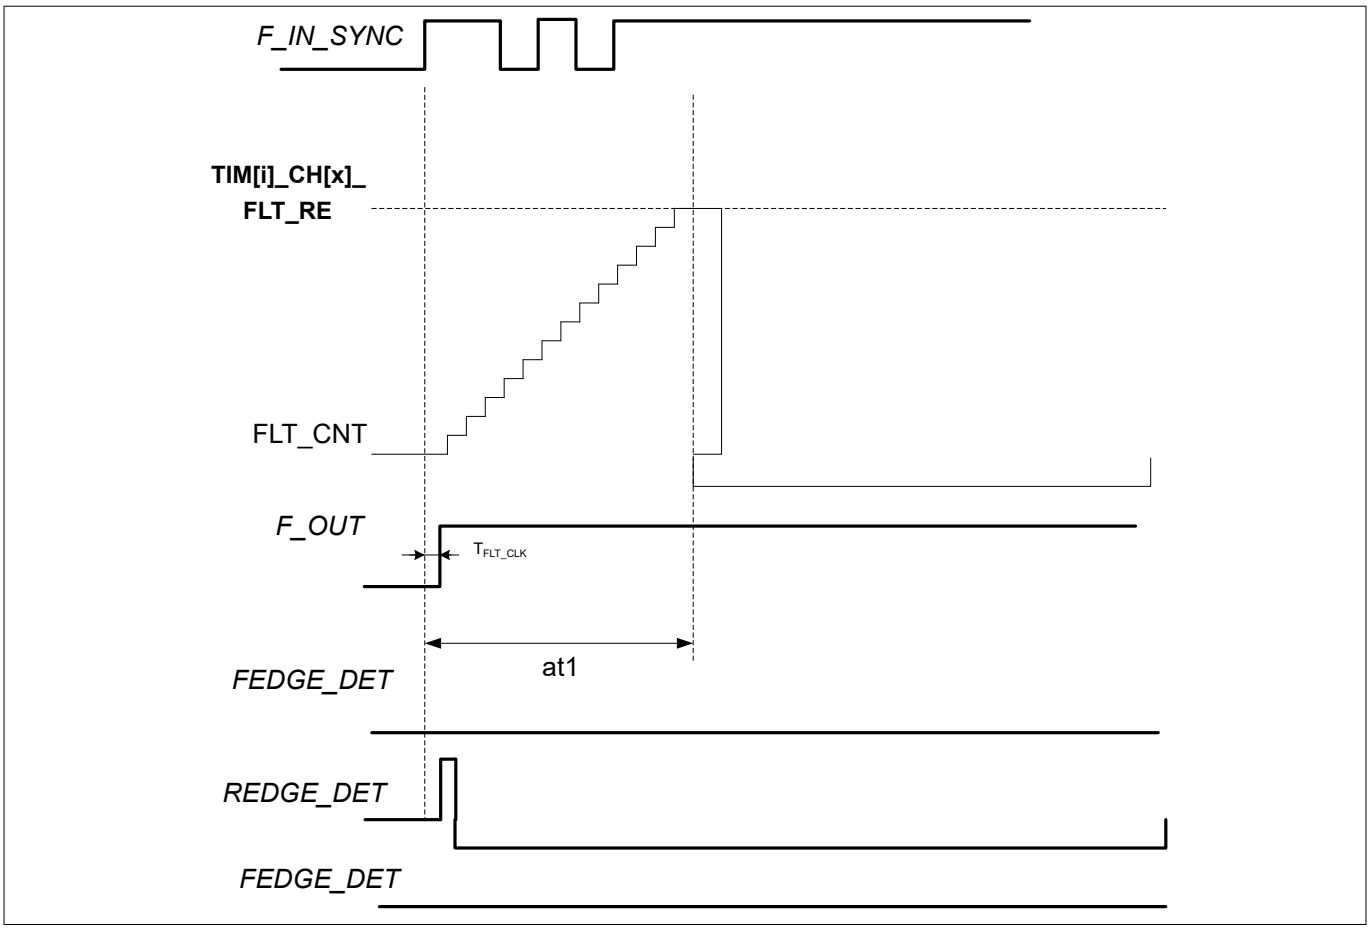

Figure 1046 Immediate edge propagation mode in the case of a rising edge

In immediate edge propagation mode, the glitch measurement mechanism is not applied to the edge detection. Detected edges on F_IN_SYNC are transferred directly to F_OUT.

The counter FLT_CNT is incremented until the acceptance time threshold is reached.

Figure 1047 shows a more complex example of the **TIM** filter, in which both, rising and falling edges are configured in immediate edge propagation mode.

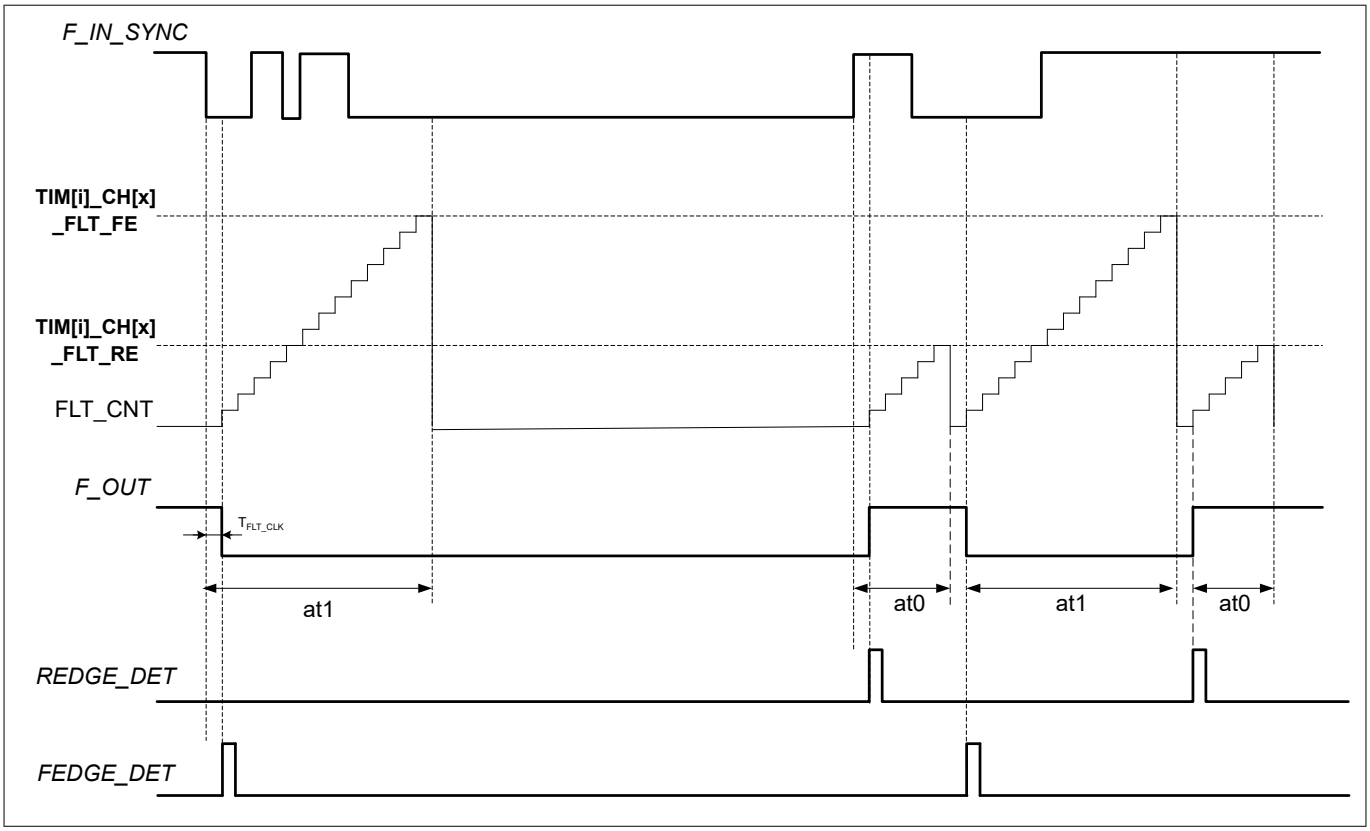

Figure 1047 Immediate edge propagation mode in the case of a rising and falling edge

If the FLT_CNT has reached the acceptance time for a specific signal edge and the signal F_IN_SYNC has already changed to the opposite level of F_OUT, the opposite signal level is set to F_OUT and the acceptance time measurement is started immediately. Figure 1047 shows this scenario at the detection of the first rising edge and the second falling edge.

Individual deglitch time mode (up/down counter)

In individual deglitch time mode (up/down counter) each edge of an input signal can be filtered with an individual deglitch threshold filter value mentioned in the registers CLSi_TIM_CHx_FLT_RE and CLSi_TIM_CHx_FLT_FE, respectively.

The filter counter register FLT_CNT is incremented when the signal level on F_IN_SYNC is unequal to the signal level on F_OUT and decremented if F_IN_SYNC equals F_OUT.

If FLT_CNT reaches zero due to decrementing, the counter is stopped immediately.

If a glitch is detected a glitch detection bit CLSi_TIM_CHx_IRQ_NOTIFY.GLITCHDET is set.

The detected edge signal together with the new signal level is propagated to F_OUT after the individual deglitch threshold is reached. Figure 1048 shows the behavior of the filter in individual deglitch time (up/down counter) mode in the case of the rising edge detection.

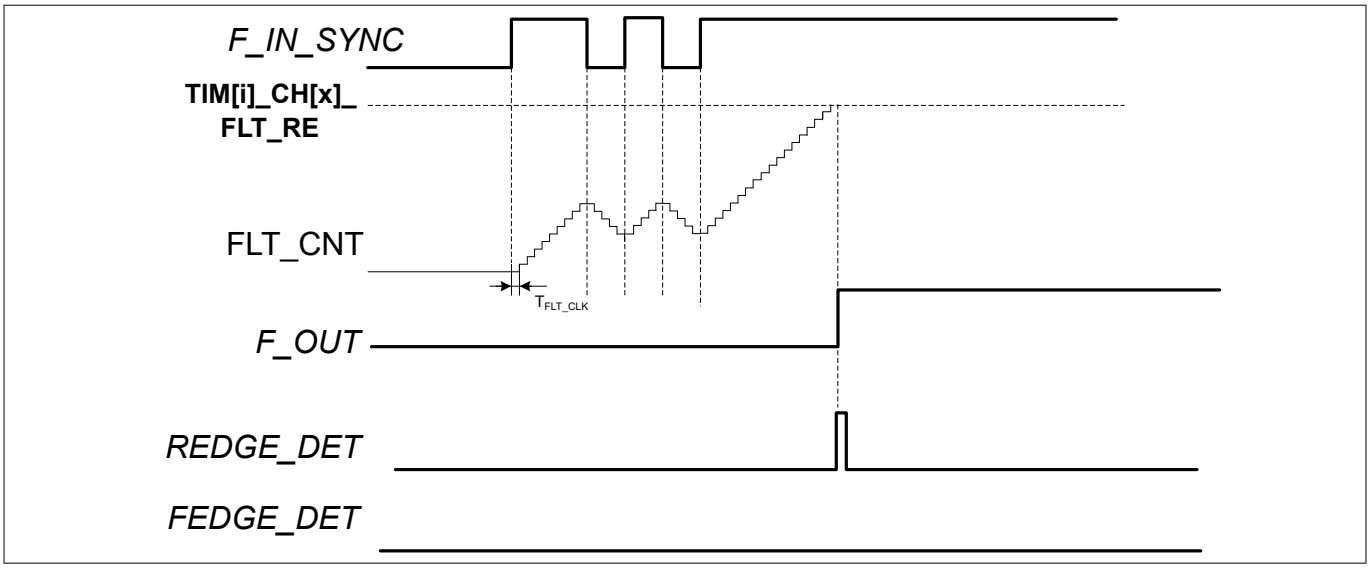

Figure 1048 Individual deglitch time mode (up/down counter) in the case of a rising edge

Individual deglitch time mode (hold counter)

In individual deglitch time mode (hold counter) each edge of an input signal can be filtered with an individual deglitch threshold filter value mentioned in the registers CLSi_TIM_CHx_FLT_RE and CLSi_TIM_CHx_FLT_FE, respectively.

The filter counter register FLT_CNT is incremented when the signal level on F_IN_SYNC is unequal to the signal level on F_OUT and the counter value of FLT_CNT is hold if F_IN equals F_OUT.

If a glitch is detected the glitch detection bit CLSi_TIM_CHx_IRQ_NOTIFY.GLITCHDET is set.

The detected edge signal together with the new signal level is propagated to F_OUT after the individual deglitch threshold is reached. Figure 1049 shows the behavior of the filter in individual deglitch time (hold counter) mode in the case of the rising edge detection.

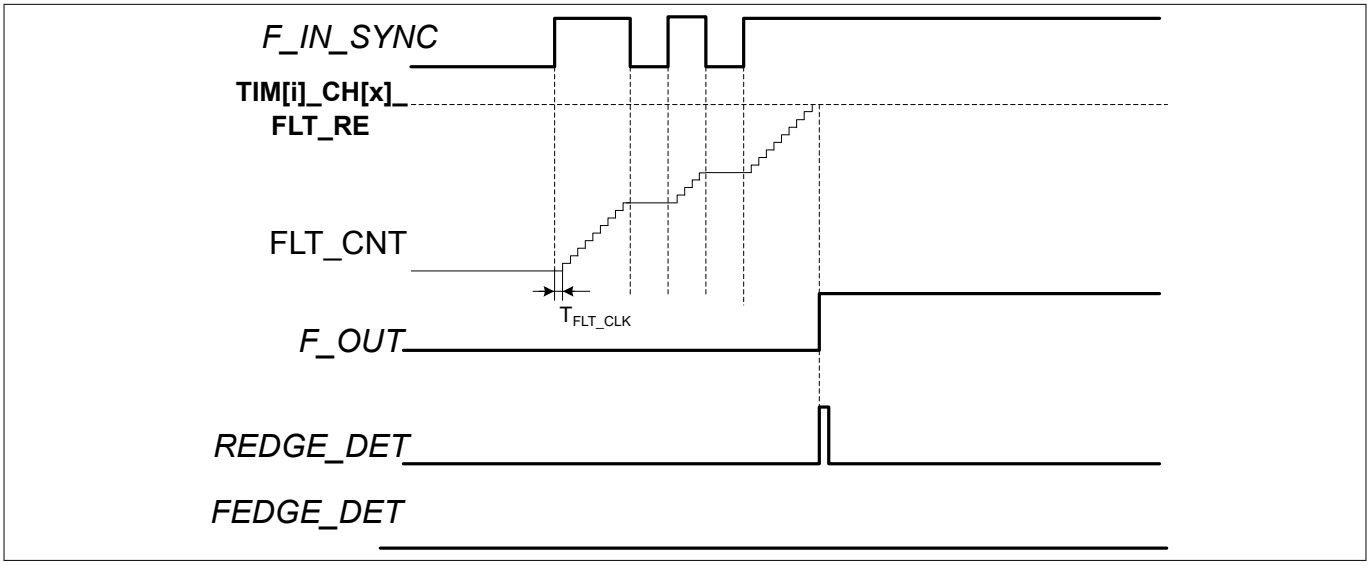

Figure 1049 Individual deglitch time mode (hold counter) in the case of a rising edge

Individual deglitch time mode (reset counter)

In individual deglitch time mode (reset counter) each edge of an input signal can be filtered with an individual deglitch threshold filter value mentioned in the registers CLSi_TIM_CHx_FLT_RE and CLSi_TIM_CHx_FLT_FE, respectively.

The filter counter register FLT_CNT is incremented when the signal level on F_IN_SYNC is unequal to the signal level on F_OUT and the counter value of FLT_CNT is reset to 000000_H if F_IN equals F_OUT.

If a glitch is detected the glitch detection bit CLSi_TIM_CHx_IRQ_NOTIFY.GLITCHDET is set.

The detected edge signal together with the new signal level is propagated to F_OUT after the individual deglitch threshold is reached. Figure 1050 shows the behavior of the filter in individual deglitch time (reset counter) mode in the case of the rising edge detection.

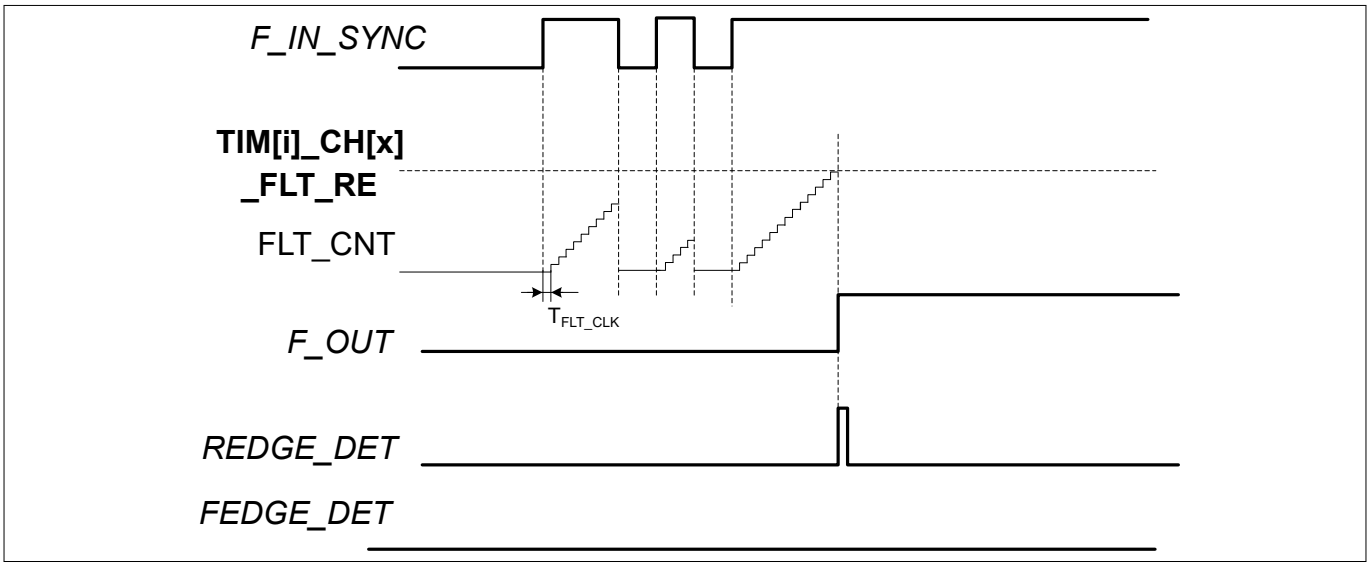

Figure 1050 Individual deglitch time mode (reset counter) in the case of a rising edge

Immediate edge propagation and individual deglitch mode

As already mentioned, the four different filter modes can be applied individually to each edge of the measured signal.

However, if one edge is configured with immediate edge propagation and the other edge with an individual deglitch mode (whether up/down counter, hold counter or reset counter) a special consideration has to be applied.

Assume that the rising edge is configured for immediate edge propagation and the falling edge with individual deglitch mode (up/down counter) as shown in Figure 1051.

If the falling edge of the incoming signal already occurs during the measuring of the acceptance time of the rising edge, the measurement of the deglitch time on the falling edge is started with delay, but immediately after the acceptance time measurement phase of the rising edge has finished.

Consequently, the deglitch counter cannot measure the time T_{ERROR}, as shown in Figure 1051.

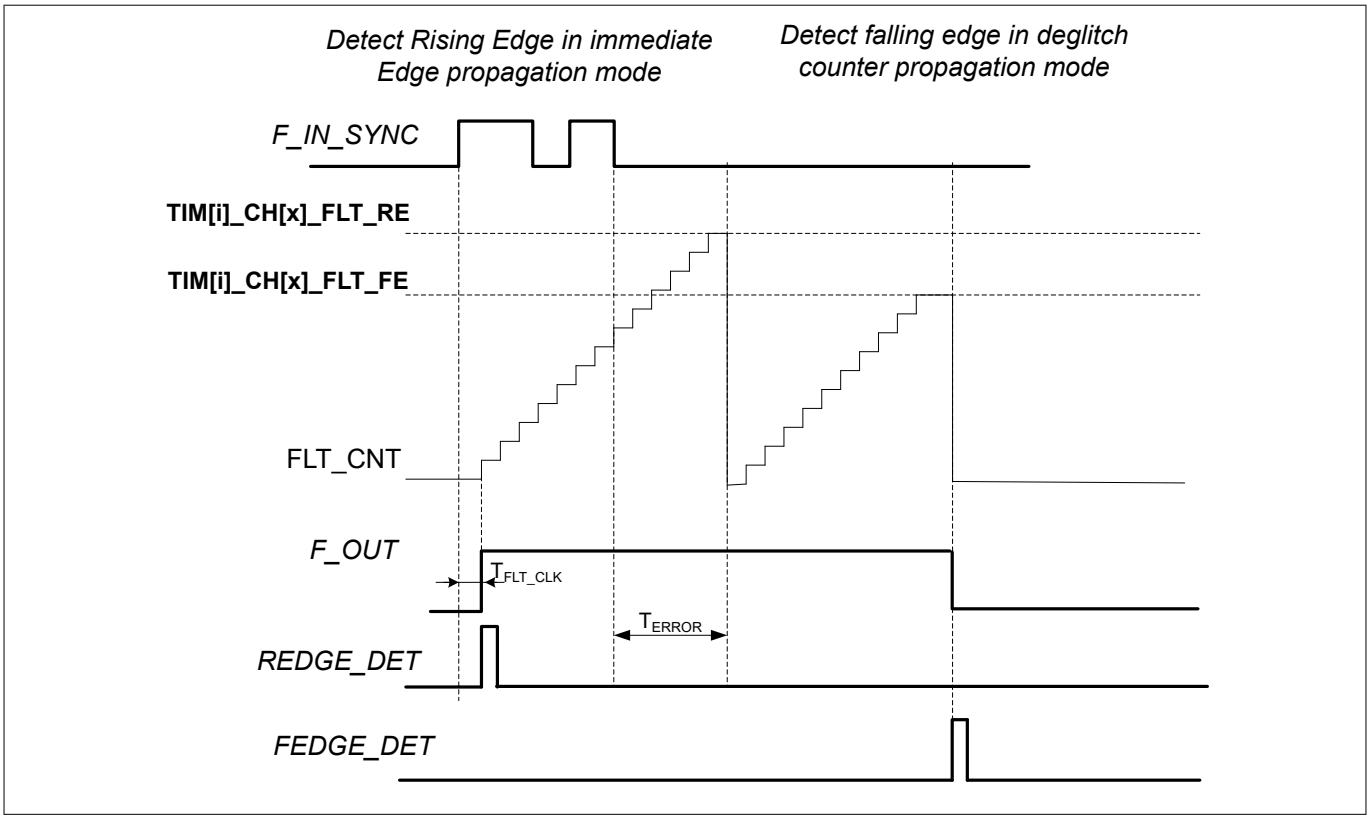

Figure 1051 Mixed mode measurement

TIM filter reconfiguration

If CLSi_TIM_CHx_CTRL.FLT_EN=1 a change of CLSi_TIM_CHx_FLT_RE or CLSi_TIM_CHx_FLT_FE will take place immediately.

If CLSi_TIM_CHx_CTRL.FLT_EN=1 a change of CLSi_TIM_CHx_CTRL.FLT_MODE_RE or CLSi_TIM_CHx_CTRL.FLT_MODE_FE will be used with the next occurring corresponding edge. If the mode is changed while the filter unit is processing a certain mode, it will end this edge filtering in the mode as started.

If CLSi_TIM_CHx_CTRL.FLT_EN=1 a change of CLSi_TIM_CHx_CTRL.FLT_CTR_RE, CLSi_TIM_CHx_CTRL.FLT_CTR_FE, CLSi_TIM_CHx_ECTRL.EFLT_CTR_RE or CLSi_TIM_CHx_ECTRL.EFLT_CTR_FE will take place immediately.

44.3.1.6.3 Timeout detection unit (TDU)

The Timeout Detection Unit (TDU) is responsible for timeout detection of the **TIM** input signals.

Each channel of the **TIM** sub-module has its own Timeout Detection Unit (TDU) where a timeout event can be set up on the filtered input signal of the corresponding channel.

In each timeout unit exist three 8-bit counter/comparator slices. A counter/comparator slice is shown below. The counter CLSi_TIM_CHx_TDUC.TO_CNT will increment by signal INC. The counter can be loaded with the value LOAD_VAL if LOAD = 1. GT_EVT will be 1 if CLSi_TIM_CHx_TDUC.TO_CNT > CLSi_TIM_CHx_TDUV.TOV is fulfilled. EQ_EVT will be 1 if CLSi_TIM_CHx_TDUC.TO_CNT = CLSi_TIM_CHx_TDUV.TOV is fulfilled.

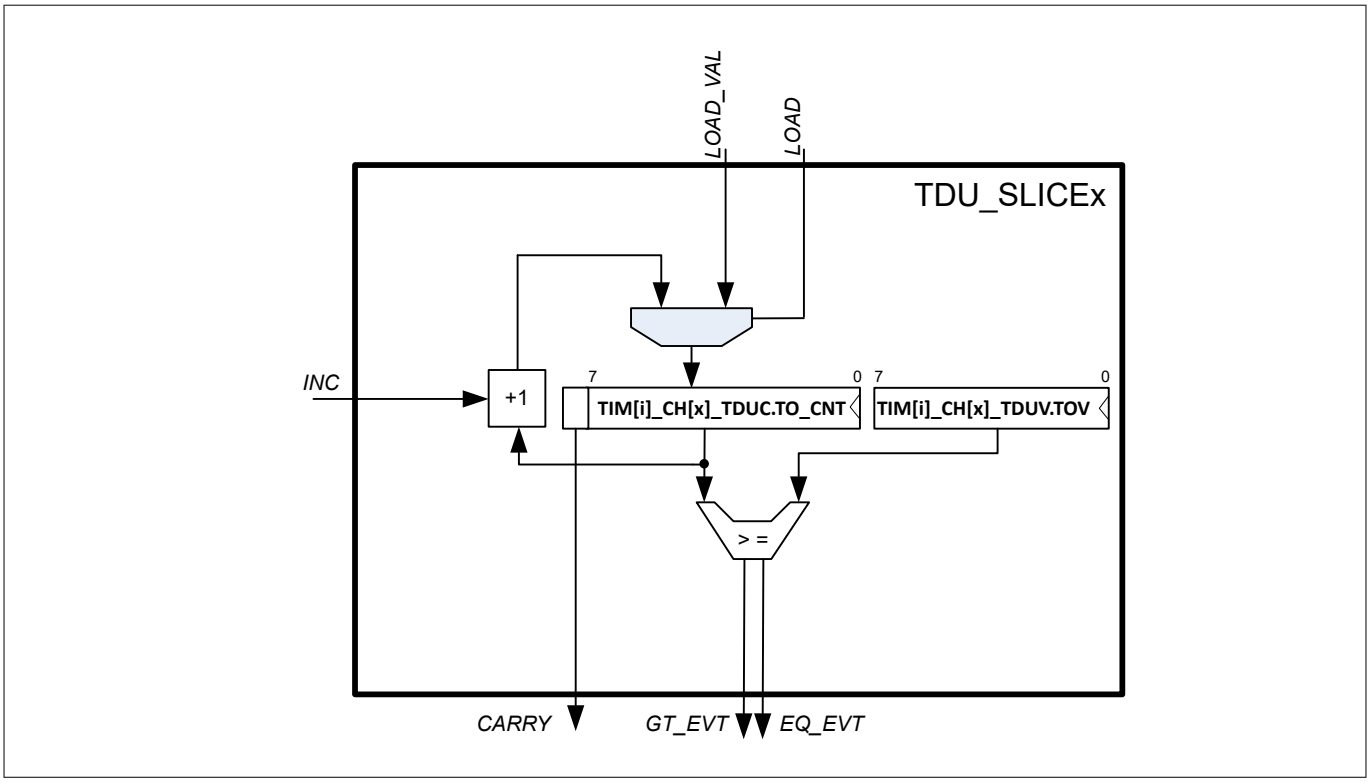

Figure 1052 Counter/comparator slice

The counter/comparator slices can be cascaded depending on the application needs to operate as:
three 8-bit counters
one 16-bit counter and one 8-bit counter
one 24-bit counter
two 8-bit counters.
This allows the user to use the functions
timeout on input signals
local **CMU** clock prescaler 8-bit
trigger event generation 8-bit (external capture, TIM_TODET_IRQ)
in parallel.
With usage of the three 8-bit counters it is possible to define different timeout values for the two signal levels.
Following table shows which functions can be used in parallel.

Table 2202 Used parallel functions

Counter type	Timeout functionality	Generate local TIM CMU clk	Source for external capture to previous channel	Source for TIM_TODET_IRQ
24-bit	24-bit	no	TDU_TIMEOUT_EVT, TDU_SAMPLE_EVT	TDU_TIMEOUT_EVT, TDU_SAMPLE_EVT
1 x 8-bit 1 x 16-bit	16-bit local clk TDU_SAMPLE_EVT usable	yes	TDU_TIMEOUT_EVT, TDU_FRAME_EVT, TDU_SAMPLE_EVT	TDU_TIMEOUT_EVT, TDU_FRAME_EVT, TDU_SAMPLE_EVT

(table continues...)

Table 2202 (continued) Used parallel functions

Counter type	Timeout functionality	Generate local TIM CMU clk	Source for external capture to previous channel	Source for TIM_TODET_IRQ
3 x 8-bit	8-bit local clk TDU_SAMPLE_EVT usable	yes	TDU_TIMEOUT_EVT, TDU_SAMPLE_EVT, TDU_WORD_EVT, TDU_FRAME_EVT	TDU_TIMEOUT_EVT, TDU_SAMPLE_EVT, TDU_WORD_EVT, TDU_FRAME_EVT
3 x 8-bit	no	yes	TDU_TIMEOUT_EVT, TDU_SAMPLE_EVT, TDU_WORD_EVT, TDU_FRAME_EVT	TDU_TIMEOUT_EVT, TDU_SAMPLE_EVT, TDU_WORD_EVT, TDU_FRAME_EVT
2 x 8-bit	no	no	TDU_TIMEOUT_EVT, TDU_WORD_EVT, TDU_FRAME_EVT	TDU_TIMEOUT_EVT, TDU_WORD_EVT, TDU_FRAME_EVT

Next table shows which of the available 8-bit resources are cascaded with a chosen CLSi_TIM_CHx_TDUV.SLICING.

Table 2203 Which of the available 8-bit resources are cascaded with a chosen SLICING

Counter type	Counters count on	Counter resource generates	CLK selection
24-bit	CNT on TCS	CLSi_TIM_CHx_CNT.CNT= CLSi_TIM_CHx_TDUC.TO_CNT2 & CLSi_TIM_CHx_TDUC.TO_CNT1 & CLSi_TIM_CHx_TDUC.TO_CNT; TCMP = CLSi_TIM_CHx_TDUV.TOV2 & CLSi_TIM_CHx_TDUV.TOV1 & CLSi_TIM_CHx_TDUV.TOV ; CLSi_TIM_CHx_CNT.CNT >= TCMP generates TDU_SAMPLE_EVT TDU_TIMEOUT_EVT = TDU_SAMPLE_EVT; TDU_FRAME_EVT = 0 TDU_WORD_EVT = 0	TCS selected

(table continues...)

Table 2203 (continued) Which of the available 8-bit resources are cascaded with a chosen SLICING

Counter type	Counters count on	Counter resource generates	CLK selection
1 x 8-bit 1 x 16-bit	CLSi_TIM_CHx_TDUC.TO_CNT2 on TCS; CLSi_TIM_CHx_CNT.CNT on TDU_SAMPLE_EVT	CLSi_TIM_CHx_TDUC.TO_CNT2 >= CLSi_TIM_CHx_TDUV.TOV2 generates TDU_SAMPLE_EVT; CNT = CLSi_TIM_CHx_TDUC.TO_CNT1 & CLSi_TIM_CHx_TDUC.TO_CNT; TCMP = CLSi_TIM_CHx_TDUV.TOV1 & CLSi_TIM_CHx_TDUV.TOV ; CNT >= TCMP generates TDU_FRAME_EVT; TDU_TIMEOUT_EVT = TDU_FRAME_EVT; TDU_WORD_EVT = 0	CLSi_TIM_CHx_TDUC.TO_CNT2: CLSi_TIM_CHx_TDUV.TCS selected; CLSi_TIM_CHx_CNT.CNT: TDU_SAMPLE_EVT selected with CLSi_TIM_CHx_TDUV.TCS_USE_SAMPLE_EVT=1

Based on a chosen counter configuration by CLSi_TIM_CHx_TDUV.SLICING it is possible to control the start behavior of the counters by CLSi_TIM_CHx_ECTRL.TDU_START in multiple ways. In addition, the stopping of the counters can be controlled by CLSi_TIM_CHx_ECTRL.TDU_STOP. Depending on the application needs it can be decided how the individual counter slices can be reset/reloaded by the configuration field CLSi_TIM_CHx_ECTRL.TDU_RESYNC.

Depending on the counter configuration, up to 4 internal compare events TDU_TIMEOUT_EVT, TDU_SAMPLE_EVT, TDU_WORD_EVT, TDU_FRAME_EVT can be generated out of the 3 comparator slices. CLSi_TIM_CHx_ECTRL.TODET_IRQ_SRC can choose, which event to be used as TIM_TODET_IRQ[x:x] signal which will be accessible by the CLSi_TIM_CHx_IRQ_NOTIFY.TODET bit.

The TDU architecture is shown in Figure 1053.

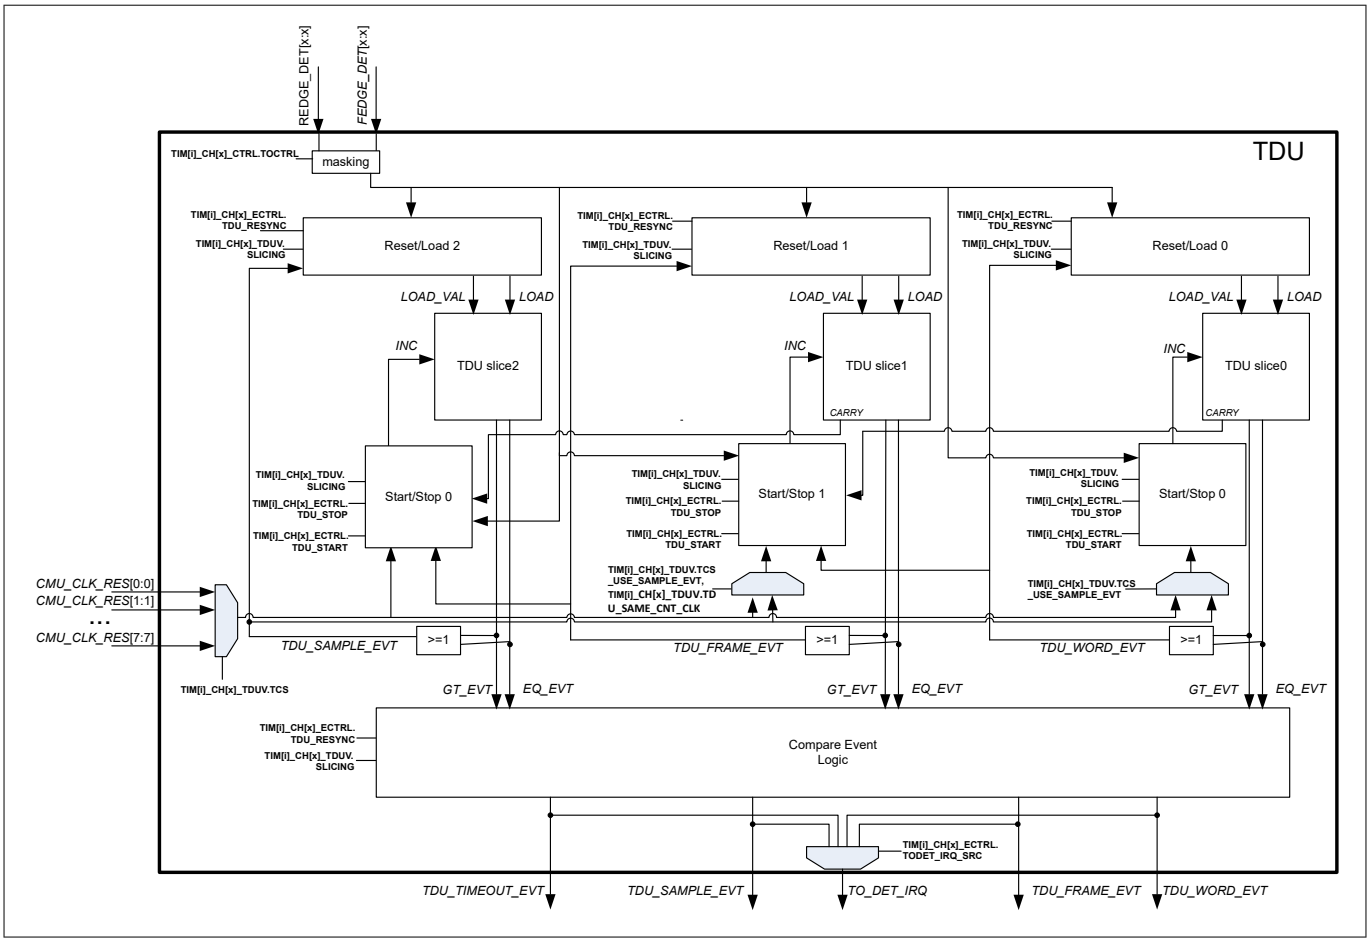

Figure 1053 Architecture of the TDU sub-unit

Each TDU_slice has its own start/stop control, based on the chosen configuration it will decide if the counter inside the TDU slice will increment on the resolution of the applied clock/event. The reset/load control decides based on the configuration settings and the compare result of the TDU slices those the counters CLSi_TIM_CHx_TDUC.TO_CNT, CLSi_TIM_CHx_TDUC.TO_CNT1, CLSi_TIM_CHx_TDUC.TO_CNT2 have to be reloaded. Depending on the chosen counter/compare configuration the compare event logic will generate based on the compare results of the 3 TDU slices and the chosen resolution the events TDU_SAMPLE_EVT, TDU_WORD_EVT, TDU_FRAME_EVT.

The primary resolution on which the TDU is working can be specified with the bit field CLSi_TIM_CHx_TDUV.TCS of the register CLSi_TIM_CHx_TDUV. The corresponding input signal CCM[i]_CLK_RES[x:x] will be used to clock the TDU. The individual timeout/counter values have to be specified in number of ticks of the selected input clock signal in the fields CLSi_TIM_CHx_TDUV.TOV, CLSi_TIM_CHx_TDUV.TOV1, CLSi_TIM_CHx_TDUV.TOV2 of the timeout value register CLSi_TIM_CHx_TDUV of the **TIM** channel x.

In case of cascading the bit slices by usage of CLSi_TIM_CHx_TDUV.SLICING and CLSi_TIM_CHx_TDUV.TCS_USE_SAMPLE_EVT and CLSi_TIM_CHx_TDUV.TDU_SAME_CNT_CLK the resolution for counting can be switched to the events TDU_SAMPLE_EVT or TDU_WORD_EVT. For more details see table above.

The counter compare units start operation on occurrence of the first "start event" configured by CLSi_TIM_CHx_ECTRL.TDU_START. They continue their operation until the first "stop event" configured by CLSi_TIM_CHx_ECTRL.TDU_STOP occurs.

In case of occurrence of a start event and a compare/count resolution event in the same clock-cycle, the counters will increment or reload/reset based on CLSi_TIM_CHx_ECTRL.TDU_RESYNC immediately. No TDU_SAMPLE_EVT, TDU_WORD_EVT, TDU_FRAME_EVT will be generated.

In case of occurrence of a stop event the counters will not change their values. In case of occurrence of a stop event and a compare/count resolution event in the same clock-cycle the corresponding events TDU_SAMPLE_EVT, TDU_WORD_EVT, TDU_FRAME_EVT will be generated.

In case of occurrence of a start event and a stop event in the same clock-cycle the counters will not change their values. No TDU_SAMPLE_EVT, TDU_WORD_EVT, TDU_FRAME_EVT will be generated.

The function of the timeout unit (configured to CLSi_TIM_CHx_ECTRL.TDU_RESYNC=0000_B, CLSi_TIM_CHx_ECTRL.TDU_START=000_B) can be started or stopped by setting/resetting the CLSi_TIM_CHx_CTRL.TOCTRL bit.

Timeout detection can be enabled to be sensitive to falling, rising or both edges of the input signal by writing the corresponding values to the bit field CLSi_TIM_CHx_CTRL.TOCTRL.

***Note**: The used signal names REDGE_DET[x:x] and FEDGE_DET[x:x] are related to the local channel x or the previous channel x-1, depending on the value of the configuration bit field CLSi_TIM_CHx_ECTRL.USE_PREV_TDU_IN.*

The TDU generates an interrupt signal TIM_TODET_IRQ[x:x] whenever a timeout is detected for an individual input signal and the CLSi_TIM_CHx_IRQ_NOTIFY.TODET bit.

Since the **TIM** channel still monitors its input pin although the timeout happened, a valid edge could occur at the input pin while the timeout information is still valid. In that case, the new edge associated data is stored inside the registers CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1.

44.3.1.6.4 TIM channel architecture

Overview

Each **TIM** channel consists of an input edge counter CLSi_TIM_CHx_ECNT, a Signal Measurement Unit (SMU) with a counter CLSi_TIM_CHx_CNT, a counter shadow register CLSi_TIM_CHx_CNTS for SMU counter and two general-purpose registers CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 for value storage.

The value CLSi_TIM_CHx_TDUV.TOV of the timeout register CLSi_TIM_CHx_TDUV is provided to TDU sub-unit of each individual channel for timeout measurement. The architecture of the **TIM** channel is depicted in Figure 1054.

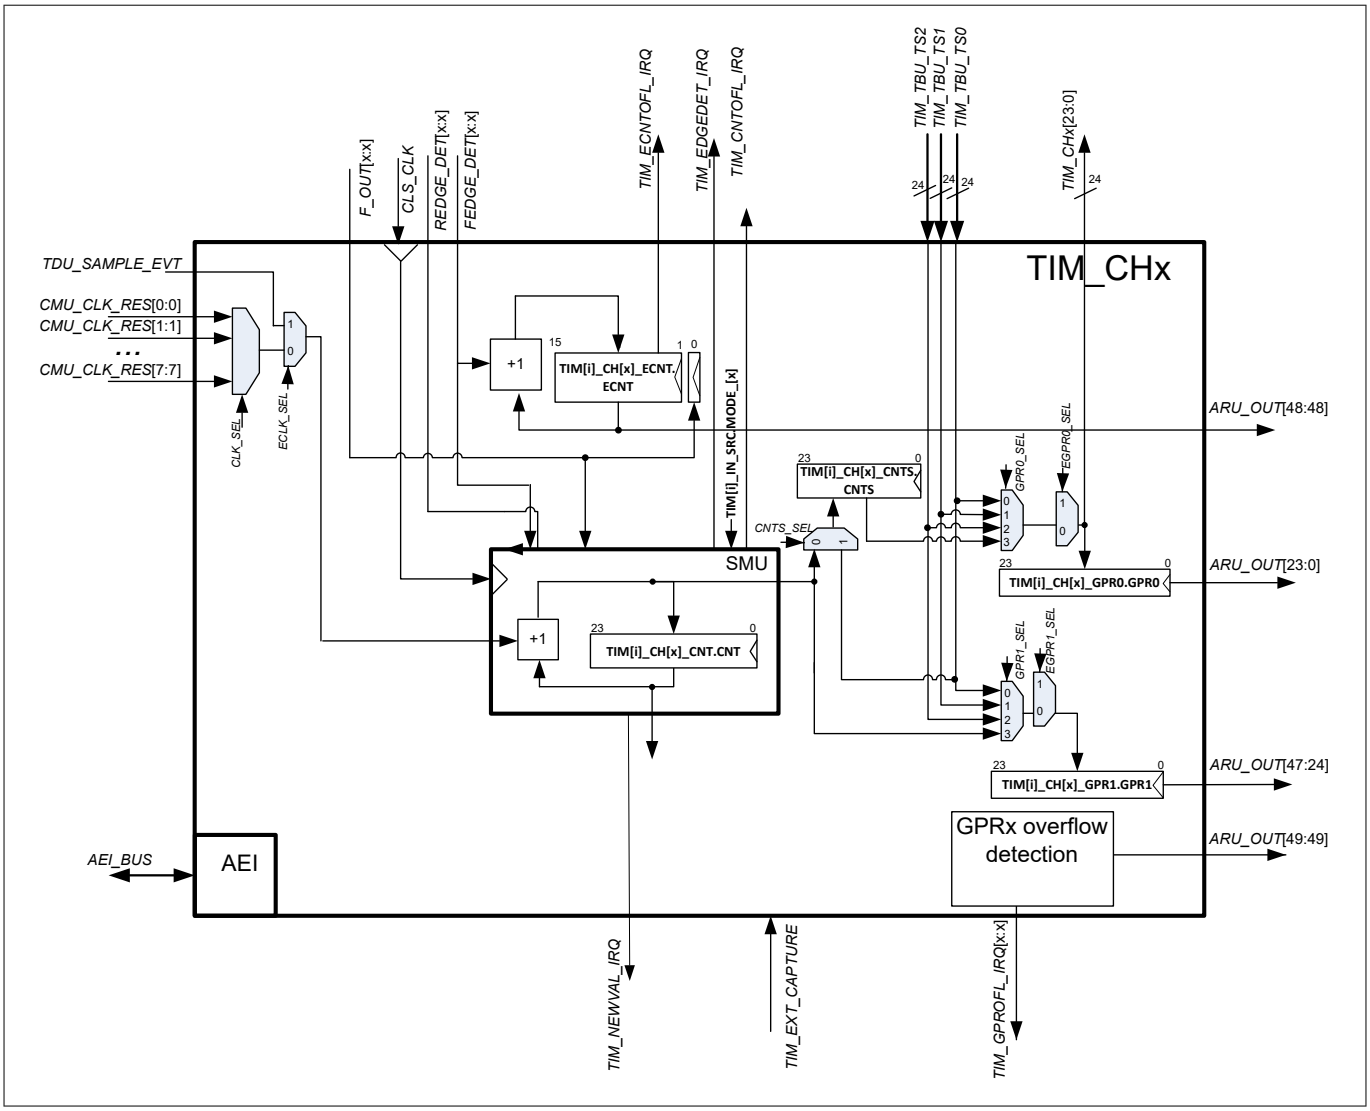

Figure 1054 TIM channel architecture

Each **TIM** channel receives both input trigger signals REDGE_DET[x:x] and FEDGE_DET[x:x], generated by the corresponding filter module in order to signalize a detected echo of the input signal F_IN[x:x]. The signal F_OUT[x:x] shows the filtered signal of the channel's input signal F_IN[x:x].

***Note**: In the following chapters for the different channel modes - except the TBCM mode - the used signal names F_OUT[x:x], REDGE_DET[x:x] and FEDGE_DET[x:x] are related to the local channel x or the previous channel x-1, depending on the value of the configuration bit field CLSi_TIM_CHx_ECTRL.USE_PREV_CH_IN. In TBCM mode, the signals do not depend on the value of the configuration bit field CLSi_TIM_CHx_ECTRL.USE_PREV_CH_IN.*

The edge counter CLSi_TIM_CHx_ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of CLSi_TIM_CHx_ECNT. (However, the actual counter implementation counts only falling edges on CLSi_TIM_CHx_ECNT[n:1] bits. It generates CLSi_TIM_CHx_ECNT.ECNT by composing the CLSi_TIM_CHx_ECNT.ECNT[n:1] bits with F_OUT[x:x] as bit 0).

Thus, the whole CLSi_TIM_CHx_ECNT counter value is always odd, when a positive edge was received and always even, when a negative edge was received.

The current CLSi_TIM_CHx_ECNT[7:0] register content is made visible on the bits 31 down to 24 of the registers CLSi_TIM_CHx_GPR0, CLSi_TIM_CHx_GPR1, and CLSi_TIM_CHx_CNTS. This allows the software to detect

inconsistent read-accesses to registers CLSi_TIM_CHx_GPR0, CLSi_TIM_CHx_GPR1, and CLSi_TIM_CHx_CNTS. However, the update strategy of these registers depends on the selected **TIM** modes, and thus the consistency check has to be adapted carefully.

It can be chosen with the bit field CLSi_TIM_CHx_CTRL.FR_ECNT_OFL when an overflow is signaled on CLSi_TIM_CHx_IRQ_NOTIFY.ECNTOFL. An CLSi_TIM_CHx_ECNT overflow can be signaled on 8-bit or full range resolution (wrap around FF_H or $FFFF_H$ to 0_H due to increment)

While reading the bit CLSi_TIM_CHx_ECNT.ECNT[0:0] shows the input signal value F_OUT[x:x] independent of the state (enabled / disabled) of the channel. If a channel gets disabled (OSM mode or resetting CLSi_TIM_CHx_CTRL.TIM_EN) the content of CLSi_TIM_CHx_ECNT will be frozen until a read of the register takes place. This read will reset the CLSi_TIM_CHx_ECNT counter. Continuing reads will show the input signal value in bit CLSi_TIM_CHx_ECNT.ECNT[0:0] again.

If a channel gets enabled (CLSi_TIM_CHx_CTRL.TIM_EN = 1), the registers CLSi_TIM_CHx_ECNT.ECNT[15:1], CLSi_TIM_CHx_CNT, CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 are set to the initial values. In case an incoming signal edge occurs in the same cluster-clock cycle as the channel enabling, the registers CLSi_TIM_CHx_ECNT.ECNT[15:1], CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 are set to the initial value and the register CLSi_TIM_CHx_CNT is increased or a new value is shifted (in TSSM mode) based on the initial value.

When new data is written into CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 the CLSi_TIM_CHx_IRQ_NOTIFY.NEWVAL bit is set and depending on corresponding enable bit value the TIM_NEWVAL_IRQ[x:x] interrupt is raised.

To guarantee a consistent delivery of data from the CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 registers to the CPU each **TIM** channel has to ensure that the data is consumed before it is overwritten with new values.

If new data was produced by the **TIM** channel (bit CLSi_TIM_CHx_IRQ_NOTIFY.NEWVAL is set) while the old data is not consumed , the **TIM** channel sets the CLSi_TIM_CHx_IRQ_NOTIFY.GPROFL bit and it overwrites the data inside the registers CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1.

The acknowledge for reading out data is performed by a read-access to the register CLSi_TIM_CHx_GPR0. Thus, register CLSi_TIM_CHx_GPR1 should be read always before CLSi_TIM_CHx_GPR0.

TIM channel modes

The **TIM** provides seven different measurement modes that can be configured with the bit field CLSi_TIM_CHx_CTRL.TIM_MODE of register CLSi_TIM_CHx_CTRL. The measurement modes are described in the following subsections. Besides these different basic measurement modes, there exist distinct configuration bits in the register CLSi_TIM_CHx_CTRL for a more detailed controlling of each mode. The meanings of these bits are as follows:

CLSi_TIM_CHx_CTRL.DSL: control the signal level for the measurement modes (e.g. if a measurement is started with rising edge or falling edge, or if high or low level pulses are measured.

CLSi_TIM_CHx_CTRL.EGPR0_SEL, CLSi_TIM_CHx_CTRL.GPR0_SEL and CLSi_TIM_CHx_CTRL.EGPR1_SEL, CLSi_TIM_CHx_CTRL.GPR1_SEL: control the actual content of the registers CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 after a measurement has finished.

CLSi_TIM_CHx_CTRL.CNTS_SEL: control the content of the registers CLSi_TIM_CHx_CNTS. The actual time for updating the CLSi_TIM_CHx_CNTS register is mode dependent.

CLSi_TIM_CHx_CTRL.OSM: activate measurement in one-shot mode or continuous mode. In one-shot mode only one measurement cycle is performed and after that the channel is disabled.

CLSi_TIM_CHx_IRQ_NOTIFY.NEWVAL: The NEWVAL **IRQ** interrupt is triggered at the end of a measurement cycle, signaling that the registers CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 are updated.

CLSi_TIM_CHx_CTRL.EXT_CAP_EN: forces an update of the registers CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 and CLSi_TIM_CHx_CNTS (**TIM** channel mode dependent) only on each rising edge of the TIM_EXT_CAPTURE[x:x] signal and triggers a TIM_NEWVAL_IRQ[x:x] interrupt. If this mode is disabled the TIM_NEWVAL_IRQ[x:x] interrupt is triggered at the end of each measurement cycle.

For each channel, the source of the TIM_EXT_CAPTURE signal can be configured with the bit fields CLSi_TIM_CHx_ECTRL.EXT_CAP_SRC in the register CLSi_TIM_CHx_ECTRL.

TIM PWM measurement mode (TPWM)

In **TIM** PWM Measurement Mode, the **TIM** channel measures duty cycle and period of an incoming PWM signal. The CLSi_TIM_CHx_CTRL.DSL bit defines the polarity of the PWM signal to be measured.

When measurement of pulse high time and period is requested (PWM with a level high duty cycle, CLSi_TIM_CHx_CTRL.DSL=1) and CLSi_TIM_CHx_ECTRL.IMM_START=0, the channel starts measuring after the first rising edge is detected by the filter.

If CLSi_TIM_CHx_ECTRL.IMM_START=1 the measurement starts immediately after activating the channel by CLSi_TIM_CHx_CTRL.TIM_EN=1.

Measurement is done with the CLSi_TIM_CHx_CNT register counting with the configured clock coming from CCM[i]_CLK_RES[x:x] until a falling edge is detected.

Assume: CLSi_TIM_CHx_ECTRL.SWAP_CAPTURE=0, CLSi_TIM_CHx_CTRL.ECNT_RESET=0

Then the counter value is stored inside the shadow register CLSi_TIM_CHx_CNTS (if CLSi_TIM_CHx_CTRL.CNTS_SEL = 0) and the counter CLSi_TIM_CHx_CNT counts continuously until the next rising edge is reached.

On this following rising edge the content of the CLSi_TIM_CHx_CNTS register is transferred to CLSi_TIM_CHx_GPR0 and the content of CLSi_TIM_CHx_CNT register is transferred to CLSi_TIM_CHx_GPR1, assuming settings for the selectors CLSi_TIM_CHx_CTRL.EGPR0_SEL=0, CLSi_TIM_CHx_CTRL.GPR0_SEL=11_B and CLSi_TIM_CHx_CTRL.EGPR1_SEL=0, CLSi_TIM_CHx_CTRL.GPR1_SEL=11_B. By this, CLSi_TIM_CHx_GPR0 contains the pulse width length and CLSi_TIM_CHx_GPR1 contains the period.

***Note**: The bits CLSi_TIM_CHx_ECNT[7:1] may be used to check data consistency of the registers CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1.*

In addition, the CLSi_TIM_CHx_CNT register is cleared CLSi_TIM_CHx_IRQ_NOTIFY.NEWVAL status bit and depending on corresponding interrupt enable condition TIM_NEWVAL_IRQ[x:x] interrupt is raised.

The CLSi_TIM_CHx_CNTS register update is not performed until the measurement is started. Afterwards each edge leaving the level defined by CLSi_TIM_CHx_CTRL.DSL is performing a CLSi_TIM_CHx_CNTS register update.

If a PWM with a level low duty cycle should be measured (CLSi_TIM_CHx_CTRL.DSL = 0) and CLSi_TIM_CHx_ECTRL.IMM_START=0, the channel waits for a falling edge until measurement is started. On this edge the level low duty cycle time is stored first in CLSi_TIM_CHx_CNTS and then finally in CLSi_TIM_CHx_GPR0 and the period is stored in CLSi_TIM_CHx_GPR1.

When a PWM period was successfully measured, the data in the registers CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 is marked as valid for reading when the CLSi_TIM_CHx_IRQ_NOTIFY.NEWVAL bit is set and a new measurement is started.

If the preceding PWM values were not consumed the **TIM** channel set CLSi_TIM_CHx_IRQ_NOTIFY.GPROFL status bit and depending on corresponding interrupt enable bit value raises a TIM_GPROFL_IRQ[x:x] and overwrites the old values in CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1. A new measurement is started afterwards.

If the register CLSi_TIM_CHx_CNT produces an overflow (wrap around $FFFFFF_H$ to 0_H due to increment) during the measurement, the bit CLSi_TIM_CHx_IRQ_NOTIFY.CNTOFL is set and interrupt TIM_CNTOFL_IRQ[x:x] is raised depending on corresponding interrupt enable condition.

If the register CLSi_TIM_CHx_ECNT produces an overflow during the measurement, the bit CLSi_TIM_CHx_IRQ_NOTIFY.ECNTOFL is set and interrupt TIM_ECNTOFL_IRQ[x:x] is raised depending on corresponding interrupt enable condition.

If CLSi_TIM_CHx_CTRL.ECNT_RESET=0 the counter CLSi_TIM_CHx_CNT will be reset to 0 on active edge (defined by CLSi_TIM_CHx_CTRL.DSL) of the input signal. If CLSi_TIM_CHx_CTRL.ECNT_RESET=1 the counter CLSi_TIM_CHx_CNT will be reset to 0 on each edge of the input signal.

Assume CLSi_TIM_CHx_CTRL.EXT_CAP_EN=0 and CLSi_TIM_CHx_ECTRL.SWAP_CAPTURE=0:

On every input edge to the active level defined by CLSi_TIM_CHx_CTRL.DSL will capture the data selected by CLSi_TIM_CHx_CTRL.EGPR1_SEL, CLSi_TIM_CHx_CTRL.GPR1_SEL to the registers CLSi_TIM_CHx_GPR1. Every edge to the inactive level will capture the data selected by CLSi_TIM_CHx_CTRL.CNTS_SEL to the registers CLSi_TIM_CHx_CNTS.

Assume CLSi_TIM_CHx_CTRL.EXT_CAP_EN=0 and CLSi_TIM_CHx_ECTRL.SWAP_CAPTURE=1:

On every input edge to the inactive level defined by CLSi_TIM_CHx_CTRL.DSL will capture the data selected by CLSi_TIM_CHx_CTRL.EGPR1_SEL, CLSi_TIM_CHx_CTRL.GPR1_SEL to the registers CLSi_TIM_CHx_GPR1. Every edge to the active level will capture the data selected by CLSi_TIM_CHx_CTRL.CNTS_SEL to the registers CLSi_TIM_CHx_CNTS.

External capture TIM PWM measurement mode (TPWM)

If external capture is enabled CLSi_TIM_CHx_CTRL.EXT_CAP_EN=1, the PWM measurement is done continuously. The actual measurement values are captured to CLSi_TIM_CHx_GPR0, CLSi_TIM_CHx_GPR1 if an external capture event occurs.

On every external capture event the data selected by CLSi_TIM_CHx_CTRL.CNTS_SEL, CLSi_TIM_CHx_CTRL.EGPR0_SEL, CLSi_TIM_CHx_CTRL.GPR0_SEL will be captured to the registers CLSi_TIM_CHx_CNTS, CLSi_TIM_CHx_GPR0.

If CLSi_TIM_CHx_ECTRL.SWAP_CAPTURE=0 every external capture event will capture the data selected by CLSi_TIM_CHx_CTRL.EGPR1_SEL, CLSi_TIM_CHx_CTRL.GPR1_SEL to the registers CLSi_TIM_CHx_GPR1. Every input edge to the level != CLSi_TIM_CHx_CTRL.DSL will capture the data selected by CLSi_TIM_CHx_CTRL.CNTS_SEL to the registers CLSi_TIM_CHx_CNTS.

If CLSi_TIM_CHx_ECTRL.SWAP_CAPTURE=1 every input edge to the inactive level != CLSi_TIM_CHx_CTRL.DSL will capture the data selected by CLSi_TIM_CHx_CTRL.EGPR1_SEL, CLSi_TIM_CHx_CTRL.GPR1_SEL to the registers CLSi_TIM_CHx_GPR1.

Assume CLSi_TIM_CHx_ECTRL.SWAP_CAPTURE=0:

Operation is done depending on **CMU** clock, CLSi_TIM_CHx_CTRL.ISL, CLSi_TIM_CHx_CTRL.DSL bit and the input signal value defined in next table (Assume CLSi_TIM_CHx_CTRL.CNTS_SEL= 0):

Table 2204 Operation depending on CMU clock, CLSi_TIM_CHx_CTRL.ISL, CLSi_TIM_CHx_CTRL.DSL and the input signal value (assume CLSi_TIM_CHx_CTRL.CNTS_SEL= 0)

Input signal F_OUT[x:x]	Selected CMU clock	External capture	CLSi_TIM_CHx_CTRL.ISL	CLSi_TIM_CHx_CTRL.DSL	Action description
0	1	0	-	0	CLSi_TIM_CHx_CNT++
1	1	0	-	0	No
Rising edge	-	0	0	0	Capture CLSi_TIM_CHx_CNT value in CLSi_TIM_CHx_CNTS
Falling edge	-	0	0	0	CLSi_TIM_CHx_CNT=0

(table continues...)

Table 2204 (continued) Operation depending on CMU clock, CLSi_TIM_CHx_CTRL.ISL, CLSi_TIM_CHx_CTRL.DSL and the input signal value (assume CLSi_TIM_CHx_CTRL.CNTS_SEL= 0)

Input signal F_OUT[x:x]	Selected CMU clock	External capture	CLSi_TIM_CHx_CTRL.ISL	CLSi_TIM_CHx_CTRL.DSL	Action description
Rising edge	-	0	1	0	No
Falling edge	-	0	1	0	Capture CLSi_TIM_CHx_CNT value in CLSi_TIM_CHx_CNTS; CLSi_TIM_CHx_CNT=0
1	1	0	-	1	CLSi_TIM_CHx_CNT++
0	1	0	-	1	No
Falling edge	-	0	0	1	Capture CLSi_TIM_CHx_CNT value in CLSi_TIM_CHx_CNTS
Rising edge	-	0	0	1	CLSi_TIM_CHx_CNT=0
Falling edge	-	0	1	1	No
Rising edge	-	0	1	1	Capture CLSi_TIM_CHx_CNT value in CLSi_TIM_CHx_CNTS; CLSi_TIM_CHx_CNT=0
-	-	Rising edge	-	-	Do CLSi_TIM_CHx_GPR0, CLSi_TIM_CHx_GPR1 capture ; issue TIM_NEWVAL_IRQ
-	0	0	-	-	No

The CLSi_TIM_CHx_CNTS register update is not performed until the measurement is started (first edge defined by CLSi_TIM_CHx_CTRL.DSL is detected). Afterwards the update of the CLSi_TIM_CHx_CNTS register is defined by CLSi_TIM_CHx_CTRL.ISL, CLSi_TIM_CHx_CTRL.DSL combinations in the table above.

TIM pulse integration mode (TPIM)

In **TIM** Pulse Integration Mode each **TIM** channel is able to measure a sum of pulse high or low times on an input signal, depending on the selected signal level bit CLSi_TIM_CHx_CTRL.DSL of register CLSi_TIM_CHx_CTRL register.

If CLSi_TIM_CHx_ECTRL.IMM_START=0 the pulse integration measurement is started with occurrence of the first edge defined by CLSi_TIM_CHx_CTRL.DSL on the input signal. If CLSi_TIM_CHx_ECTRL.IMM_START=1 the measurement starts immediately after activating the channel by CLSi_TIM_CHx_CTRL.TIM_EN=1.

The pulse times are measured by incrementing the **TIM** channel counter CLSi_TIM_CHx_CNT until the counter is stopped with occurrence of an input signal edge to the opposite signal level defined by CLSi_TIM_CHx_CTRL.DSL.

The counter CLSi_TIM_CHx_CNT counts with the CCM[i]_CLK_RES[x:x] clock specified by the CLSi_TIM_CHx_CTRL.CLK_SEL bit field of the CLSi_TIM_CHx_CTRL register.

If the register CLSi_TIM_CHx_CNT produces an overflow (wrap around $FFFFFF_H$ to 0_H due to increment) during the measurement, the bit CLSi_TIM_CHx_IRQ_NOTIFY.CNTOFL is set and interrupt TIM_CNTOFL_IRQ[x:x] is raised depending on corresponding interrupt enable condition.

The CLSi_TIM_CHx_CNT register is reset at the time the channel is activated (enabling via **AEI** write-access) and it accumulates pulses while the channel is staying enabled.

Assume CLSi_TIM_CHx_CTRL.EXT_CAP_EN=0 and CLSi_TIM_CHx_ECTRL.SWAP_CAPTURE=0:

After measurement is started, every falling(CLSi_TIM_CHx_CTRL.DSL=1) or rising(CLSi_TIM_CHx_CTRL.DSL=0) input edge will issue a TIM_NEWVAL_IRQ[x:x] interrupt, and the registers CLSi_TIM_CHx_CNTS, CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 are updated according to settings of its corresponding input multiplexers, using the bits CLSi_TIM_CHx_CTRL.EGPR0_SEL, CLSi_TIM_CHx_CTRL.EGPR1_SEL, CLSi_TIM_CHx_CTRL.GPR0_SEL, CLSi_TIM_CHx_CTRL.GPR1_SEL and CLSi_TIM_CHx_CTRL.CNTS_SEL.

***Note**: The bits 1 to 7 of the CLSi_TIM_CHx_ECNT may be used to check data consistency of the registers CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1.*

Assume CLSi_TIM_CHx_CTRL.EXT_CAP_EN=0 and CLSi_TIM_CHx_ECTRL.SWAP_CAPTURE=1:

After measurement is started, every falling (CLSi_TIM_CHx_CTRL.DSL=1) or rising (CLSi_TIM_CHx_CTRL.DSL=0) input edge will issue a TIM_NEWVAL_IRQ[x:x] interrupt, and the registers CLSi_TIM_CHx_CNTS, CLSi_TIM_CHx_GPR0 are updated according to settings of its corresponding input multiplexers, using the bits CLSi_TIM_CHx_CTRL.EGPR0_SEL, CLSi_TIM_CHx_CTRL.GPR0_SEL and CLSi_TIM_CHx_CTRL.CNTS_SEL.

Every input edge to the active level defined by CLSi_TIM_CHx_CTRL.DSL (rising CLSi_TIM_CHx_CTRL.DSL=1; falling CLSi_TIM_CHx_CTRL.DSL=0) will capture the data selected by CLSi_TIM_CHx_CTRL.EGPR1_SEL, CLSi_TIM_CHx_CTRL.GPR1_SEL to the registers CLSi_TIM_CHx_GPR1.

External capture TIM pulse integration mode (TPIM)

If external capture is enabled CLSi_TIM_CHx_CTRL.EXT_CAP_EN=1, the pulse integration is done until next external capture event occurs.

On every external capture event the data selected by CLSi_TIM_CHx_CTRL.CNTS_SEL, CLSi_TIM_CHx_CTRL.EGPR0_SEL, CLSi_TIM_CHx_CTRL.GPR0_SEL will be captured to the registers CLSi_TIM_CHx_CNTS, CLSi_TIM_CHx_GPR0.

If CLSi_TIM_CHx_ECTRL.SWAP_CAPTURE=0 every external capture event will capture the data selected by CLSi_TIM_CHx_CTRL.EGPR1_SEL, CLSi_TIM_CHx_CTRL.GPR1_SEL to the registers CLSi_TIM_CHx_GPR1.

If CLSi_TIM_CHx_ECTRL.SWAP_CAPTURE=1 every input edge to the inactive level != CLSi_TIM_CHx_CTRL.DSL will capture the data selected by CLSi_TIM_CHx_CTRL.EGPR1_SEL, CLSi_TIM_CHx_CTRL.GPR1_SEL to the registers CLSi_TIM_CHx_GPR1.

Assume CLSi_TIM_CHx_ECTRL.SWAP_CAPTURE=0; CLSi_TIM_CHx_ECTRL.IMM_START=0:

Operation is done depending on **CMU** clock, CLSi_TIM_CHx_CTRL.DSL bit and the input signal value defined in next table (inc_cnt = false if **TIM** channel is enabled) :

Table 2205 Operation depending on CMU clock, CLSi_TIM_CHx_CTRL.DSL and the input signal value (inc_cnt = false if TIM channel is enabled)

Input signal F_OUT[x:x]	Selected CMU Clock	External capture	CLSi_TIM_CHx_CTRL.ISL	CLSi_TIM_CHx_CTRL.DSL	Action description
Falling edge	-	0	-	0	inc_cnt = true
Rising edge	-	0	-	0	inc_cnt = false
Rising edge	-	0	-	1	inc_cnt = true
Falling edge	-	0	-	1	inc_cnt = false
-	1	0	-	-	If inc_cnt == true then CLSi_TIM_CHx_CNT++;
-	-	Rising edge	-	-	Do capture CLSi_TIM_CHx_GPR0, CLSi_TIM_CHx_GPR1, CLSi_TIM_CHx_CNTS ; issue TIM_NEWVAL_IRQ; CLSi_TIM_CHx_CNT=0
-	0	0	-	-	No

TIM input event mode (TIEM)

In **TIM** Input Event Mode, the **TIM** channel is able to count edges.

It is configurable if rising, falling or both edges should be counted. This can be done with the bit fields CLSi_TIM_CHx_CTRL.DSL and CLSi_TIM_CHx_CTRL.ISL in CLSi_TIM_CHx_CTRL register.

In addition, a TIM_NEWVAL_IRQ[x:x] interrupt is raised when the configured edge was received and this interrupt was enabled.

The counter register CLSi_TIM_CHx_CNT is used to count the number of edges, and the bit fields CLSi_TIM_CHx_CTRL.EGPR0_SEL, CLSi_TIM_CHx_CTRL.EGPR1_SEL, CLSi_TIM_CHx_CTRL.EGPR0_SEL, CLSi_TIM_CHx_CTRL.GPR1_SEL, and CLSi_TIM_CHx_CTRL.CNTS_SEL can be used to configure the desired update values for the registers CLSi_TIM_CHx_GPR0, CLSi_TIM_CHx_GPR1 and CLSi_TIM_CHx_CNTS. These registers are updated whenever the edge counter CLSi_TIM_CHx_CNT is incremented due to the arrival of a desired edge.

If the preceding data was not consumed , the **TIM** channel sets CLSi_TIM_CHx_IRQ_NOTIFY.GPROFL status bit and raises a TIM_GPROFL_IRQ[x:x] if it was enabled in CLSi_TIM_CHx_IRQ_EN register and overwrites the old values in CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 with the new ones.

If the register CLSi_TIM_CHx_CNT produces an overflow (wrap around $FFFFFF_H$ to 0_H due to increment) during the measurement, the bit CLSi_TIM_CHx_IRQ_NOTIFY.CNTOFL is set and interrupt TIM_CNTOFL_IRQ[x:x] is raised depending on corresponding interrupt enable condition.

If the register CLSi_TIM_CHx_ECNT produces an overflow during the measurement, the bit CLSi_TIM_CHx_IRQ_NOTIFY.ECNTOFL is set and interrupt TIM_ECNTOFL_IRQ[x:x] is raised depending on corresponding interrupt enable condition.

The **TIM** Input Event Mode does not depend on the bit field CLSi_TIM_CHx_CTRL.CLK_SEL of register CLSi_TIM_CHx_CTRL.

External capture TIM input event mode (TIEM)

If external capture is enabled, capturing is done depending on the CLSi_TIM_CHx_CTRL.DSL, CLSi_TIM_CHx_CTRL.ISL bit and the input signal value defined in next table:

Table 2206 Capturing dependent on the CLSi_TIM_CHx_CTRL.DSL, CLSi_TIM_CHx_CTRL.ISL and the input signal value, if External Capture is enabled

Input signal F_OUT[x:x]	External capture	CLSi_TIM_CHx_CTRL.ISL	CLSi_TIM_CHx_CTRL.DSL	Action description
-	Rising edge	1	-	Do capture; issue TIM_NEWVAL_IRQ; CLSi_TIM_CHx_CNT ++
-	0	1	-	No
1	Rising edge	0	1	Do capture; issue TIM_NEWVAL_IRQ; CLSi_TIM_CHx_CNT ++
0	-	0	1	No
0	Rising edge	0	0	Do capture; issue TIM_NEWVAL_IRQ; CLSi_TIM_CHx_CNT ++
1	-	0	0	No

TIM input prescaler mode (TIPM)

In the **TIM** Input Prescaler Mode, the number of edges which should be detected before a TIM_NEWVAL_IRQ[x:x] is raised is programmable. In this mode it must be specified in the CLSi_TIM_CHx_CNTS register after how many edges the interrupt has to be raised.

A value of 0 in CLSi_TIM_CHx_CNTS means that after one edge an interrupt is raised and a value of 1 means that after two edges an interrupt is raised, and so on.

The edges to be counted can be selected by the bit fields CLSi_TIM_CHx_CTRL.DSL and CLSi_TIM_CHx_CTRL.ISL.

With each triggered interrupt, the registers CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 are updated according to bits CLSi_TIM_CHx_CTRL.EGPR0_SEL, CLSi_TIM_CHx_CTRL.EGPR1_SEL, CLSi_TIM_CHx_CTRL.GPR0_SEL and CLSi_TIM_CHx_CTRL.GPR1_SEL.

If the register CLSi_TIM_CHx_ECNT produces an overflow during the measurement, the bit CLSi_TIM_CHx_IRQ_NOTIFY.ECNTOFL is set and interrupt TIM_ECNTOFL_IRQ[x:x] is raised depending on corresponding interrupt enable condition.

The register CLSi_TIM_CHx_CNT never produces an overflow during this mode, the bit CLSi_TIM_CHx_IRQ_NOTIFY.CNTOFL is never set.

The **TIM** Input Prescaler Mode does not depend on the bit field CLSi_TIM_CHx_CTRL.CLK_SEL of register CLSi_TIM_CHx_CTRL.

External capture TIM input prescaler mode (TIPM)

If external capture is enabled, the external capture events are counted instead of the input signal edges.

Operation is done depending on the external capture signal, CLSi_TIM_CHx_CTRL.DSL, CLSi_TIM_CHx_CTRL.ISL bit and the input signal value defined in next table:

Table 2207 Operation depending on the external capture signal, CLSi_TIM_CHx_CTRL.DSL, CLSi_TIM_CHx_CTRL.ISL and the input signal value

Input signal F_OUT[x:x]	External capture	CLSi_TIM_CHx_CTRL.ISL	DSL	Action description

-	Rising edge	1	-	If CLSi_TIM_CHx_CNT >= CLSi_TIM_CHx_CNTS then
				do capture; issue TIM_NEWVAL_IRQ; CLSi_TIM_CHx_CNT=0
				else
				CLSi_TIM_CHx_CNT++
				endif

-	0	1	-	No

1	Rising edge	0	1	If CLSi_TIM_CHx_CNT >= CLSi_TIM_CHx_CNTS then
				do capture; issue TIM_NEWVAL_IRQ; CLSi_TIM_CHx_CNT=0
				else
				CLSi_TIM_CHx_CNT++
				endif

0	-	0	1	No

TIM bit compression mode (TBCM)

The **TIM** Bit Compression Mode can be used to combine all filtered input signals of a **TIM** sub-module to a parallel m bit data word, where m is the number of channels available in the **TIM** sub-module.

Figure 1055 gives an overview of the **TIM** bit compression mode.

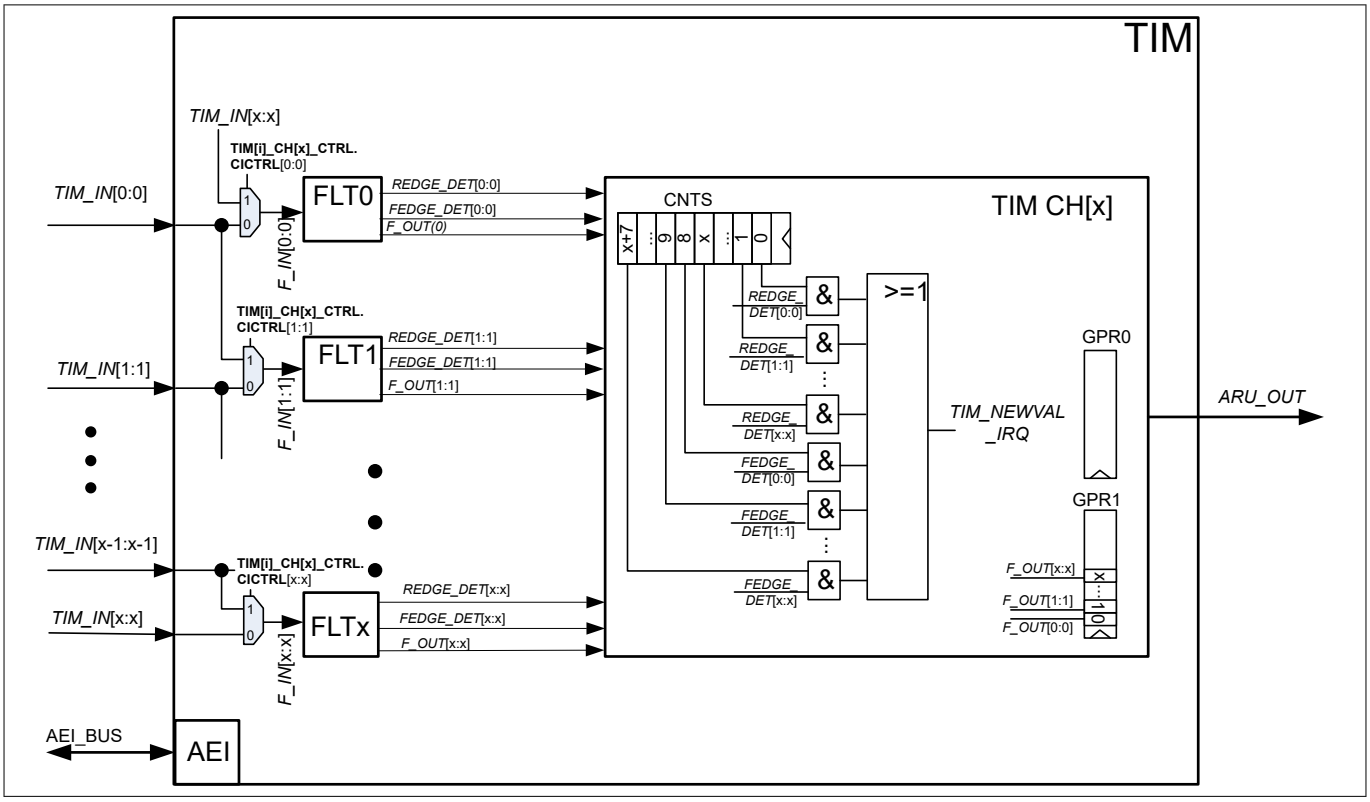

Figure 1055 TIM bit compression mode

The register CLSi_TIM_CHx_CNTS of a channel is used to configure the event that releases the TIM_NEWVAL_IRQ and samples the input signals F_IN[0:0] to F_IN[7:7] of instance [i-1] in ascending order as a parallel data word in CLSi_TIM_CHx_GPR1.

The bits 0 to m-1 of the CLSi_TIM_CHx_CNTS register are used to select the REDGE_DET signals of the **TIM** filters 0 to m-1 as a sampling event, and the bits 8 to (7+m) are used to select the FEDGE_DET signals of the **TIM** filters 0 to m-1, respectively. If multiple events are selected, the events are **OR**-combined (see also Figure 1055).

In **TIM** Bit compression mode, the register CLSi_TIM_CHx_ECNT increments with each TIM_NEWVAL_IRQ, which means that the value of CLSi_TIM_CHx_ECNT may depend on all m input signals. Consequently, the LSB of CLSi_TIM_CHx_ECNT does not reflect the actual level of the input signal CLSi_TIM_INP_VAL.TIM_INx (x=0-7).

If the register CLSi_TIM_CHx_ECNT produces an overflow during the measurement, the bit CLSi_TIM_CHx_IRQ_NOTIFY.ECNTOFL is set and interrupt TIM_ECNTOFL_IRQ[x:x] is raised depending on corresponding interrupt enable condition.

The **TIM** Bit Compression Mode does not depend on the bit field CLSi_TIM_CHx_CTRL.CLK_SEL of register CLSi_TIM_CHx_CTRL.

External capture bit compression mode (TBCM)

If external capture is enabled, capturing is done for CLSi_TIM_CHx_CTRL.ISL=1 as defined in next table. The value 0 for CLSi_TIM_CHx_CTRL.ISL is prohibited.

Table 2208 Capturing dependent on the CLSi_TIM_CHx_CTRL.DSL, CLSi_TIM_CHx_CTRL.ISL and the input signal value, if external capture is enabled

-	Rising edge	1	-	Do capture; issue TIM_NEWVAL_IRQ;
-	0	1	-	No
-	-	0 - prohibited	-	-

TIM gated periodic sampling mode (TGPS)

In the **TIM** Gated Periodic Sampling Mode, the number of **CMU** clock-cycles which should elapse before capturing and raising TIM_NEWVAL_IRQ[x:x] is programmable. In this mode it must be specified in the CLSi_TIM_CHx_CNTS register after how many **CMU** clock-cycles the interrupt has to be raised.

A value of 0 in CLSi_TIM_CHx_CNTS means that after one CLSi_TIM_CHx_CTRL.CLK_SEL edge a trigger/interrupt is raised, and a value of 1 means that after two edges a trigger/interrupt is raised, and so on.

In the CLSi_TIM_CHx_CNT register the elapsed cycles were incremented and compared against CLSi_TIM_CHx_CNTS. If CLSi_TIM_CHx_CNT is greater or equal to CLSi_TIM_CHx_CNTS a trigger will be raised. This allows by writing a value to CLSi_TIM_CHx_CNTS that the actual period time can be changed on the fly.

Operation is done depending on **CMU** clock, CLSi_TIM_CHx_CTRL.DSL, CLSi_TIM_CHx_CTRL.ISL bit and the input signal value defined in next table:

The register CLSi_TIM_CHx_CNT never produces an overflow during this mode, the bit CLSi_TIM_CHx_IRQ_NOTIFY.CNTOFL is never set.

Table 2209 Operation depending on CMU clock, CLSi_TIM_CHx_CTRL.DSL, CLSi_TIM_CHx_CTRL.ISL and the input signal value

Input signal F_OUT *[x:x]*	Selected CMU clock	External capture	CLSi_TIM_CHx_CTRL.ISL	DSL	Action description

-	1	0	1	-	If CLSi_TIM_CHx_CNT >= CLSi_TIM_CHx_CNTS then
					do capture; issue TIM_NEWVAL_IRQ; CLSi_TIM_CHx_CNT=0
					else
					CLSi_TIM_CHx_CNT++
					endif

0	0	0	0	1	No

1	1	0	0	1	If CLSi_TIM_CHx_CNT >= CLSi_TIM_CHx_CNTS then
					do capture; issue TIM_NEWVAL_IRQ; CLSi_TIM_CHx_CNT=0
					else
					CLSi_TIM_CHx_CNT++
					endif

0	0	-	0	1	No

(table continues...)

Table 2209 (continued) Operation depending on CMU clock, CLSi_TIM_CHx_CTRL.DSL, CLSi_TIM_CHx_CTRL.ISL and the input signal value

Input signal F_OUT *[x:x]*	Selected CMU clock	External capture	CLSi_TIM_CHx_CTRL.ISL	DSL	Action description

0	1	0	0	0	If CLSi_TIM_CHx_CNT >= CLSi_TIM_CHx_CNTS then
					do capture; issue TIM_NEWVAL_IRQ; CLSi_TIM_CHx_CNT=0
					else
					CLSi_TIM_CHx_CNT++
					endif

1	0	0	0	0	No
-	0	0	-	-	No

In this mode the CLSi_TIM_CHx_GPR1 operates as a shadow register for CLSi_TIM_CHx_CNTS. This would allow that the period for the next sampling period could be specified. The update of CLSi_TIM_CHx_CNTS will only take place once on a trigger if the CLSi_TIM_CHx_GPR1 was written by the CPU. This means that the captured value from the previous trigger can be read by the CPU from CLSi_TIM_CHx_GPR1 and afterwards the new sampling period for the next sampling period (the one after the actual sampling period) could be written.

With each triggered interrupt, the registers CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 are updated according to bits CLSi_TIM_CHx_CTRL.GPR0_SEL, CLSi_TIM_CHx_CTRL.GPR1_SEL, CLSi_TIM_CHx_CTRL.EGPR0_SEL and CLSi_TIM_CHx_CTRL.EGPR1_SEL.

When selecting CLSi_TIM_CHx_ECNT as a source for the capture registers, CLSi_TIM_CHx_GPR0, CLSi_TIM_CHx_GPR1 will show the edge count and the input signal value at point of capture. Selecting CLSi_TIM_CHx_CTRL.GPR0_SEL = '11' and CLSi_TIM_CHx_CTRL.EGPR0_SEL = '0' for **TIM** channel 0 all 8 **TIM** input signals will be captured to CLSi_TIM_CHx_GPR0[7:0].

In the TGPS Mode, the bit field CLSi_TIM_CHx_CTRL.CLK_SEL of register CLSi_TIM_CHx_CTRL will define the selected **CMU** clock which will be used.

The behavior of the CLSi_TIM_CHx_ECNT counter is configurable by CLSi_TIM_CHx_CTRL.ECNT_RESET. If set to 1 on each interrupt (period expired), the CLSi_TIM_CHx_ECNT will be reset. Otherwise, it operates in wrap around mode.

If the register CLSi_TIM_CHx_ECNT produces an overflow during the measurement, the bit CLSi_TIM_CHx_IRQ_NOTIFY.ECNTOFL is set and interrupt TIM_ECNTOFL_IRQ[x:x] is raised depending on corresponding interrupt enable condition.

External capture TIM gated periodic sampling mode (TGPS)

If external capture is enabled, the external capture events will capture actual values in the register CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1, reset the counter CLSi_TIM_CHx_CNT and issue a TIM_NEWVAL_IRQ.

Operation is done depending on the **CMU** clock, external capture signal, CLSi_TIM_CHx_CTRL.DSL, CLSi_TIM_CHx_CTRL.ISL bit and the input signal value defined in next table:

Table 2210 Operation depending on the CMU clock, external capture signal, CLSi_TIM_CHx_CTRL.DSL, CLSi_TIM_CHx_CTRL.ISL and the input signal value

TIM serial shift mode (TSSM)

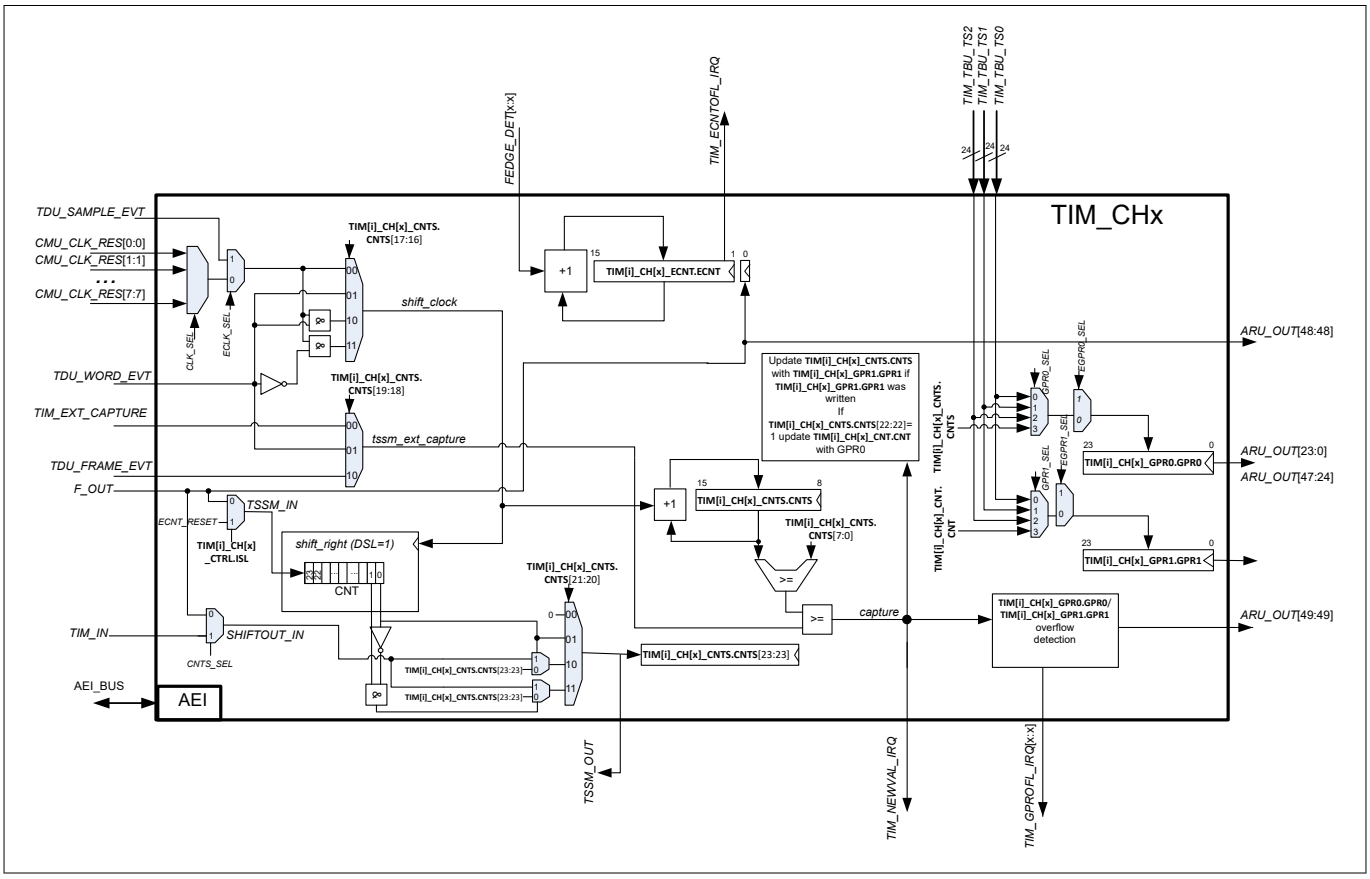

Figure 1056 TIM serial shift mode

In the **TIM** Serial Shift Mode on each shift clock event, the actual value of the input signal TSSM_IN[x:x] will be registered in dependence of CLSi_TIM_CHx_CTRL.DSL in the register CLSi_TIM_CHx_CNT.

If CLSi_TIM_CHx_CTRL.ISL=0 is set F_OUT[x:x] will be used as shift in value TSSM_IN[x:x] , with CLSi_TIM_CHx_CTRL.ISL=1 the bit field CLSi_TIM_CHx_CTRL.ECNT_RESET defines the value for TSSM_IN[x:x].

With CLSi_TIM_CHx_CTRL.DSL=0 TSSM_IN[x:x] will be stored in CLSi_TIM_CHx_CNT[0:0] and CLSi_TIM_CHx_CNT[22:0] will be shifted left. With CLSi_TIM_CHx_CTRL.DSL=1 TSSM_IN[x:x] will be stored in CLSi_TIM_CHx_CNT[23:23] and CLSi_TIM_CHx_CNT[23:1] will be shifted right.

Operation is done depending on the shift clock, external capture signal, CLSi_TIM_CHx_CTRL.DSL, CLSi_TIM_CHx_CTRL.ISL bit and the input signal value defined in next table:

The register CLSi_TIM_CHx_CNT never produces an overflow during this mode, the bit CLSi_TIM_CHx_IRQ_NOTIFY.CNTOFL is never set.

					CLSi_TIM_CHx_CNT[23:0]=CLSi_TIM_CHx_CTRL.ECNT_RESET
					else
					CLSi_TIM_CHx_CNTS[15:8]++
					endif

(table continues...)

Table 2211 (continued) Operation depending on the shift clock, external capture signal, CLSi_TIM_CHx_CTRL.DSL, CLSi_TIM_CHx_CTRL.ISL and the input signal value

Input signal TSSM_IN[x:x]	Shift clock	tssm_ext_capture	CLSi_TIM_CHx_CTRL.ISL	DSL	Action description

value	1	0	1	1	CLSi_TIM_CHx_CNT[22:0]= CLSi_TIM_CHx_CNT[23:1]; CLSi_TIM_CHx_CNT[23:23]= value
					if CLSi_TIM_CHx_CNTS[15:8] >= CLSi_TIM_CHx_CNTS[7:0] then
					do capture; issue TIM_NEWVAL_IRQ; CLSi_TIM_CHx_CNTS[15:8]=0
					CLSi_TIM_CHx_CNT[23:0]=CLSi_TIM_CHx_CTRL.ECNT_RESET
					else
					CLSi_TIM_CHx_CNTS[15:8]++
					endif

The register CLSi_TIM_CHx_CNTS[7:0] defines the number of bits which will be stored inside CLSi_TIM_CHx_CNT.

Each shift clock will increment the register CLSi_TIM_CHx_CNTS[15:8]. If the condition CLSi_TIM_CHx_CNTS[15:8] >= CLSi_TIM_CHx_CNTS[7:0] is met a capture event is raised and TIM_NEWVAL_IRQ[x:x] is asserted.

With each capture event the registers CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 are updated according to bits CLSi_TIM_CHx_CTRL.GPR0_SEL, CLSi_TIM_CHx_CTRL.GPR1_SEL, CLSi_TIM_CHx_CTRL.EGPR0_SEL and CLSi_TIM_CHx_CTRL.EGPR1_SEL.

If the bit field CLSi_TIM_CHx_CTRL.ISL is set to 1 the register bits CLSi_TIM_CHx_CNT are set to the value defined by CLSi_TIM_CHx_CTRL.ECNT_RESET in case of a capture event.

In this mode the CLSi_TIM_CHx_GPR1 operates as a shadow register for CLSi_TIM_CHx_CNTS. This allows that the number of bits to sample can be specified. The update of CLSi_TIM_CHx_CNTS will only take place once on a trigger if the CLSi_TIM_CHx_GPR1 was written by the CPU. This means that the captured value from the previous trigger can be read by the CPU from CLSi_TIM_CHx_GPR1 and afterwards the new number of bits to sample for the next sampling period (the one after the actual sampling period) could be written.

TSSM using as serial shift in/out: CLSi_TIM_CHx_CTRL.ISL=0

- CLSi_TIM_CHx_CNTS.CNTS[22:22]=0: Shifted in data stored in CLSi_TIM_CHx_CNT.CNT can be captured on a capture event in CLSi_TIM_CHx_GPR1.GPR1, all other CLSi_TIM_CHx_CTRL.GPR1_SEL/ CLSi_TIM_CHx_CTRL.EGPR1_SEL settings can be used too.

- CLSi_TIM_CHx_CNTS.CNTS[22:22]=1: The CLSi_TIM_CHx_GPR0.GPR0 can never be used to capture data.
- The CLSi_TIM_CHx_GPR0.GPR0 can be used as a shadow register to provide the next data which will be shifted out. An update of CLSi_TIM_CHx_CNT.CNT with the content of CLSi_TIM_CHx_GPR0.GPR0 will happen on every capture event.

TSSM using as serial shift out: CLSi_TIM_CHx_CTRL.ISL=1

- TIM_IN data will not be stored in CLSi_TIM_CHx_CNT.CNT; CLSi_TIM_CHx_CTRL.ECNT_RESET will be taken instead.
- CLSi_TIM_CHx_CNTS.CNTS[22:22]=1:CLSi_TIM_CHx_GPR0.GPR0 can never be used to capture data.
- CLSi_TIM_CHx_GPR0.GPR0 can be used as a shadow register to provide the next data which will be shifted out. An update of CLSi_TIM_CHx_CNT.CNT with the content of CLSi_TIM_CHx_GPR0.GPR0 will happen on every capture event.
- CLSi_TIM_CHx_CNTS.CNTS[22:22]=0: Shifted-in data stored in CLSi_TIM_CHx_CNT.CNT can be captured on a capture event in CLSi_TIM_CHx_GPR1.GPR1, all other CLSi_TIM_CHx_CTRL.GPR1_SEL/ CLSi_TIM_CHx_CTRL.EGPR1_SEL settings can be used too.
- The shift clock which will be in use is selectable by CLSi_TIM_CHx_CNTS[17:16]
- 00_B = USED_CLK_RES is in use. It can be set to any CCM[i]_CLK_RES source or to the local TDU sample clock TDU_SAMPLE_EVT.
- 01_B = the TDU_WORD_EVT signal will be used as shift clock source.
- 10_B = USED_CLK_RES is gated with TDU_WORD_EVT. If TDU_WORD_EVT=0 then shift clock will be 0.
- 11_B = USED_CLK_RES is gated with inverted TDU_WORD_EVT. If TDU_WORD_EVT=1 then shift clock will be 0.

Signal generation with TIM serial shift mode

If CLSi_TIM_CHx_CNTS[22:22] is 1 the CLSi_TIM_CHx_GPR0 operates as a shadow register for CLSi_TIM_CHx_CNT. This allows that the bits for shifting out can be specified. The update of CLSi_TIM_CHx_CNT will only take place once on a trigger if the CLSi_TIM_CHx_GPR0 was written by the CPU. This means that the captured value from the previous trigger can be read by the CPU from CLSi_TIM_CHx_GPR0 and afterwards the new bits to shift out could be written.

In addition, the **TIM** Serial Shift Mode is able to generate a signal TSSM_OUT which can be used internally to the **TIM** channel.

On each system clock the value for TSSM_OUT is generated as defined next. The actual value can be read by the register bit CLSi_TIM_CHx_CNTS[23:23].

- Following functionality for TSSM_OUT[x:x] is selectable by CLSi_TIM_CHx_CNTS[21:20]
- 00_B: Constant output; TSSM_OUT[x:x] = 0.
- 01_B: Shift output; If CLSi_TIM_CHx_CTRL.DSL=0 (shift left) then TSSM_OUT[x:x] = CLSi_TIM_CHx_CNT[23:23] else (shift right) TSSM_OUT[x:x] = CLSi_TIM_CHx_CNT[0:0].
- 10_B: Latched output; If CLSi_TIM_CHx_CTRL.DSL=0 and CLSi_TIM_CHx_CNT[23:23]=1 then TSSM_OUT[x:x] =SHIFTOUT_IN[x:x] elsif CLSi_TIM_CHx_CTRL.DSL=1 and CLSi_TIM_CHx_CNT[0:0]=1 then TSSM_OUT[x:x] = SHIFTOUT_IN[x:x].
- 11_B: Registered output; If CLSi_TIM_CHx_CTRL.DSL=0 and CLSi_TIM_CHx_CNT[23:22]=01_B then TSSM_OUT[x:x] = SHIFTOUT_IN[x:x] elsif CLSi_TIM_CHx_CTRL.DSL=1 and CLSi_TIM_CHx_CNT[1:0]=10_B then TSSM_OUT[x:x] = SHIFTOUT_IN[x:x].

In case of registered or latched output mode the signal SHIFTOUT_IN[x:x] is selectable by CLSi_TIM_CHx_CTRL.CNTS_SEL.

If CLSi_TIM_CHx_CTRL.CNTS_SEL=0 is set F_OUT[x:x] will be used for SHIFTOUT_IN[x:x], with CLSi_TIM_CHx_CTRL.CNTS_SEL=1 the signal TIM_IN[x:x] is in µs for SHIFTOUT_IN[x:x].

External capture TIM serial shift mode (TSSM)

If external capture is enabled (CLSi_TIM_CHx_CTRL.EXT_CAP_EN=1), the external capture events will capture the actual values in CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1, reset the counter CLSi_TIM_CHx_CNT depending on CLSi_TIM_CHx_CTRL.ISL and issue a TIM_NEWVAL_IRQ. Functionality from previous table will be applied.

- The source which will be used as external capture event for TSSM mode is selectable by CLSi_TIM_CHx_CNTS[19:18]
- 00_B = source selection by CLSi_TIM_CHx_ECTRL.EXT_CAP_SRC is in use.
- 01_B = TDU_WORD_EVT signal will be used as source.
- 10_B = TDU_FRAME_EVT signal will be used as source.
- 11_B = reserved

Operation is done depending on the shift clock, external capture signal, CLSi_TIM_CHx_CTRL.DSL, CLSi_TIM_CHx_CTRL.ISL bit and the input signal value defined in next table:

Table 2212 Operation depending on the shift clock, external capture signal, CLSi_TIM_CHx_CTRL.DSL, CLSi_TIM_CHx_CTRL.ISL and the input signal value

value	1	1	0	1	CLSi_TIM_CHx_CNT[22:0]= CLSi_TIM_CHx_CNT[23:1]; CLSi_TIM_CHx_CNT[23:23]= value do capture; issue TIM_NEWVAL_IRQ; CLSi_TIM_CHx_CNTS[15:8]=0

44.3.1.6.5 TIM software reset of channels

Each channel x is assigned a unique bit x in the configuration register CLSi_TIM_RST for software reset of the **TIM[i]** channel block.

Writing via the configuration interface the value 1_B to the bit field CLSi_TIM_RST.RST_CHx (x=0-7), will immediately reset the content of the following registers to the initial hardware reset state.

- CLSi_TIM_CHx_CTRL

- CLSi_TIM_CHx_FLT_RE
- CLSi_TIM_CHx_FLT_FE
- CLSi_TIM_CHx_GPR0
- CLSi_TIM_CHx_GPR1
- CLSi_TIM_CHx_CNT
- CLSi_TIM_CHx_CNTS
- CLSi_TIM_CHx_IRQ_NOTIFY
- CLSi_TIM_CHx_IRQ_EN
- CLSi_TIM_CHx_IRQ_MODE
- CLSi_TIM_CHx_EIRQ_EN
- CLSi_TIM_CHx_TDUV
- CLSi_TIM_CHx_TDUC
- CLSi_TIM_CHx_ECNT
- CLSi_TIM_CHx_ECTRL

Atomic reset of multiple channels is possible by writing a 1 on each associated bit. E.g.: Writing $0F_H$ to register CLSi_TIM_RST (with i=0) will reset the TIM0 channel x (x∈{0, 1, 2, 3}).

44.3.1.6.6 eGTM TIM Configuration Registers Description

Sub-chapter TIM Configuration Registers Description

Table 2213

Register Shortname	Description
CLSi_TIM_CHx_CTRL	TIM[i] channel [x] control register (x=0-7;i=0)
CLSi_TIM_CHx_CTRL	TIM[i] channel [x] control register (x=0-7;i=1-2)
CLSi_TIM_CHx_FLT_RE	TIM[i] channel [x] filter parameter 0 register (x=0-7;i=0-2)
CLSi_TIM_CHx_FLT_FE	TIM[i] channel [x] filter parameter 1 register (x=0-7;i=0-2)
CLSi_TIM_CHx_GPR0	TIM[i] channel [x] general-purpose 0 register (x=0-7;i=0-2)
CLSi_TIM_CHx_GPR1	TIM[i] channel [x] general-purpose 1 register (x=0-7;i=0-2)
CLSi_TIM_CHx_CNT	TIM[i] channel [x] SMU counter register (x=0-7;i=0-2)
CLSi_TIM_CHx_CNTS	TIM[i] channel [x] SMU shadow counter register (x=0-7;i=0-2)
CLSi_TIM_CHx_IRQ_NOTIFY	TIM[i] channel [x] interrupt notification register (x=0-7;i=0-2)
CLSi_TIM_CHx_IRQ_EN	TIM[i] channel [x] interrupt enable register (x=0-7;i=0-2)
CLSi_TIM_CHx_IRQ_FORCINT	TIM[i] channel [x] force interrupt register (x=0-7;i=0-2)
CLSi_TIM_CHx_IRQ_MODE	TIM[i] channel [x] interrupt mode configuration register (x=0-7;i=0-2)

(table continues...)

Table 2213 (continued)

Register Shortname	Description
CLSi_TIM_RST	TIM[i] global software reset register (i=0-2)
CLSi_TIM_IN_SRC	TIM[i] AUX IN source selection register (i=0-2)
CLSi_TIM_CHx_EIRQ_EN	TIM[i] channel [x] error interrupt enable register (x=0-7;i=0-2)
CLSi_TIM_CHx_TDUV	TIM[i]_CH[x]_TDUV (x=0-7;i=0-2)
CLSi_TIM_CHx_TDUC	TIM[i]_CH[x]_TDUC (x=0-7;i=0-2)
CLSi_TIM_CHx_ECNT	TIM[i] channel [x] SMU edge counter register (x=0-7;i=0-2)
CLSi_TIM_CHx_ECTRL	TIM[i] channel [x] extended control register (x=0-7;i=0-2)
CLSi_TIM_INP_VAL	TIM[i] input value observation register (i=0-2)

44.3.1.6.7 TIM signal description

Table 2214 TIM Reset

Name	Description
TIM[j]_RESET_CH[x]	**TIM[j]** channel [x] reset active signal

Table 2215 TIM Interrupt Signals

Name	Description
TIM_GPROFL_IRQ	CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 data overflow, old data was not read out before new data has arrived at input pin of channel x
TIM_TODET_IRQ	Time out reached for input signal of channel x
TIM_NEWVAL_IRQ	New measurement value detected by SMU of channel x
TIM_ECNTOFL_IRQ	ECNT counter overflow of channel x
TIM_CNTOFL_IRQ	SMU CLSi_TIM_CHx_CNT counter overflow of channel x
TIM_GLITCHDET_IRQ	A glitch was detected by the **TIM** filter of channel x

Table 2216 TIM Signals

Name	Description
LUT_IN0	INPUTSRC unit: Input signal 0 for lookup-table processing
LUT_IN1	INPUTSRC unit: Input signal 1 for lookup-table processing
LUT_IN2	INPUTSRC unit: Input signal 2 for lookup-table processing
F_IN	Output signal of the INPUTSRC units of each channels
FLT_CLK_RES	FLT unit: Clock resolution in use

(table continues...)

Table 2216 (continued) TIM Signals

Name	Description
F_IN_SYNC	FLT unit: FLT input signal F_IN synchronized based on the chosen clock resolution
FEDGE_DET	FLT unit: Falling edge detection signal
REDGE_DET	FLT unit: Rising edge detection signal
INC	Input signal to TDU_SLICE; on 1 the counter will increase
LOAD	Input signal to TDU_SLICE; on 1 the counter will be loaded with LOAD_VAL
LOAD_VAL	Input signal to TDU_SLICE; defines the value which will be loaded into the counter in case LOAD=1
EQ_EVT	Output signal of TDU_SLICE; 1 in case counter and compare values are identical
GT_EVT	Output signal of TDU_SLICE; 1 in case counter value is greater than compare value
TDU_TIMEOUT_EVT	Output signal of TDU; signal behavior depends on TDU configuration
TDU_WORD_EVT	Output signal of TDU; signal behavior depends on TDU configuration
TDU_FRAME_EVT	Output signal of TDU; signal behavior depends on TDU configuration
TDU_SAMPLE_EVT	Output signal of TDU; signal behavior depends on TDU configuration
TDU_TOCTRL_0_EVENT	TDU unit: single-cycle pulse indicating that the timeout functionality was disabled
TDU_START_000_EVENT	TDU unit: single-cycle pulse indicating that the timeout functionality was enabled
USED_CLK_RES	TIM_CH unit: Internal clock resolution signal selected depending on the configuration in TSSM mode;
TSSM_IN	TIM_CH unit: Internal input signal selected depending on the configuration in TSSM mode;
TSSM_OUT	TIM_CH unit: Output signal in use by TSSM mode
SHIFTOUT_IN	TIM_CH unit: Internal input signal selected depending on configuration in TSSM mode;
FOUT_NEXT	TIM_CH unit: Output signal the next channel instance
FOUT_PREV	TIM_CH unit: Input signal from the previous channel instance
NEWVAL	TIM_CH unit: Signal which indicates that a capture event of the defined channel mode has occurred
CNTOFL	TIM_CH unit: Signal which indicates that an overflow of the channel counter has occurred

(table continues...)

Table 2216 (continued) TIM Signals

Name	Description
ECNTOFL	TIM_CH unit: Signal which indicates that an overflow of the edge counter has occurred
GPROFL	TIM_CH unit: Signal which indicates that captured data was overwritten by new capture event
EXT_CAP_SRC_IN	TIM_CH unit: Input port vector 9 bits , providing all local capture source events from following channel
EXT_CAP_SRC_OUT	TIM_CH unit: Output port vector 9 bits, providing all local capture source events from this channel for the previous channel
NEWVAL_EVT	Interrupt event - triggered when a new measurement value is detected by SMU of channel x
CNTOFL_EVT	Interrupt event - triggered when SMU CLSi_TIM_CHx_CNT counter of channel x overflows
ECNTOFL_EVT	Interrupt event - triggered when ECNT counter of channel x overflows
TODET_EVT	Interrupt event - triggered when input signal of channel x times out
GLITCHDET_EVT	Interrupt event - triggered when a glitch is detected by the **TIM** filter in channel x
GPROFL_EVT	Interrupt event - triggered when CLSi_TIM_CHx_GPR0 and CLSi_TIM_CHx_GPR1 data overflow, old data was not read out before new data has arrived at input pin of channel x

44.3.1.6.8 TIM port description

Table 2217 TIM Ports

Name	Description
AUX_IN	Auxiliary input for **TIM** channels (wired to TIM[i]_AUX_IN)
TIM_EXT_CAPTURE	External capture signal of each channel
TIMCH0_EXT_CAP_SRC_OUT	External capture sources signal of channel 0
TIM_TBU_TS0	Time base channel 0 signal
TIM_TBU_TS1	Time base channel 1 signal
TIM_TBU_TS2	Time base channel 2 signal
TIM_IN	External input for **TIM** channels
F_OUT	FLT unit: Output signal of each filter channel

44.3.1.7 Timer output module (TOM)

44.3.1.7.1 Overview

The Timer Output Module (**TOM**) offers up to 16 independent channels (index x) to generate simple PWM signals at each output port TOM_OUT[x:x].

Additionally, at **TOM** output TOM_OUT[15:15] a pulse count modulated signal can be generated.

The architecture of the **TOM** sub-module is depicted in Figure 1057.

Indices and their range as used inside this chapter are:

- NTOM= number of **TOM** instances in the device
- i:={0, 1,..., NTOM-1} instance index of cluster / **TOM** module
- x:={0, 1,..., 15} index of channels
- g:={0, 1} index of global control unit
- c:={0, 1,..., 7} index of channel in the context of a global control unit
- y:={0, 1, 2} index of used time base

The register and bit field names used inside this chapter have the following meaning:

***Note**: All figures in this chapter, which show block diagrams or gate schematics are drawn in principle to show specific functionality. They cannot completely represent the real implementation of the design.*

In the following sections the terms "100% duty cycle" and "0% duty cycle" will be used. 100% duty cycle is defined as a constant output level on CLSi_TOM_CHx_CTRL.SL of TOM_OUT*[x]* over the whole period. 0% duty cycle is defined as a constant output level on !CLSi_TOM_CHx_CTRL.SL of TOM_OUT*[x]* over the whole period.

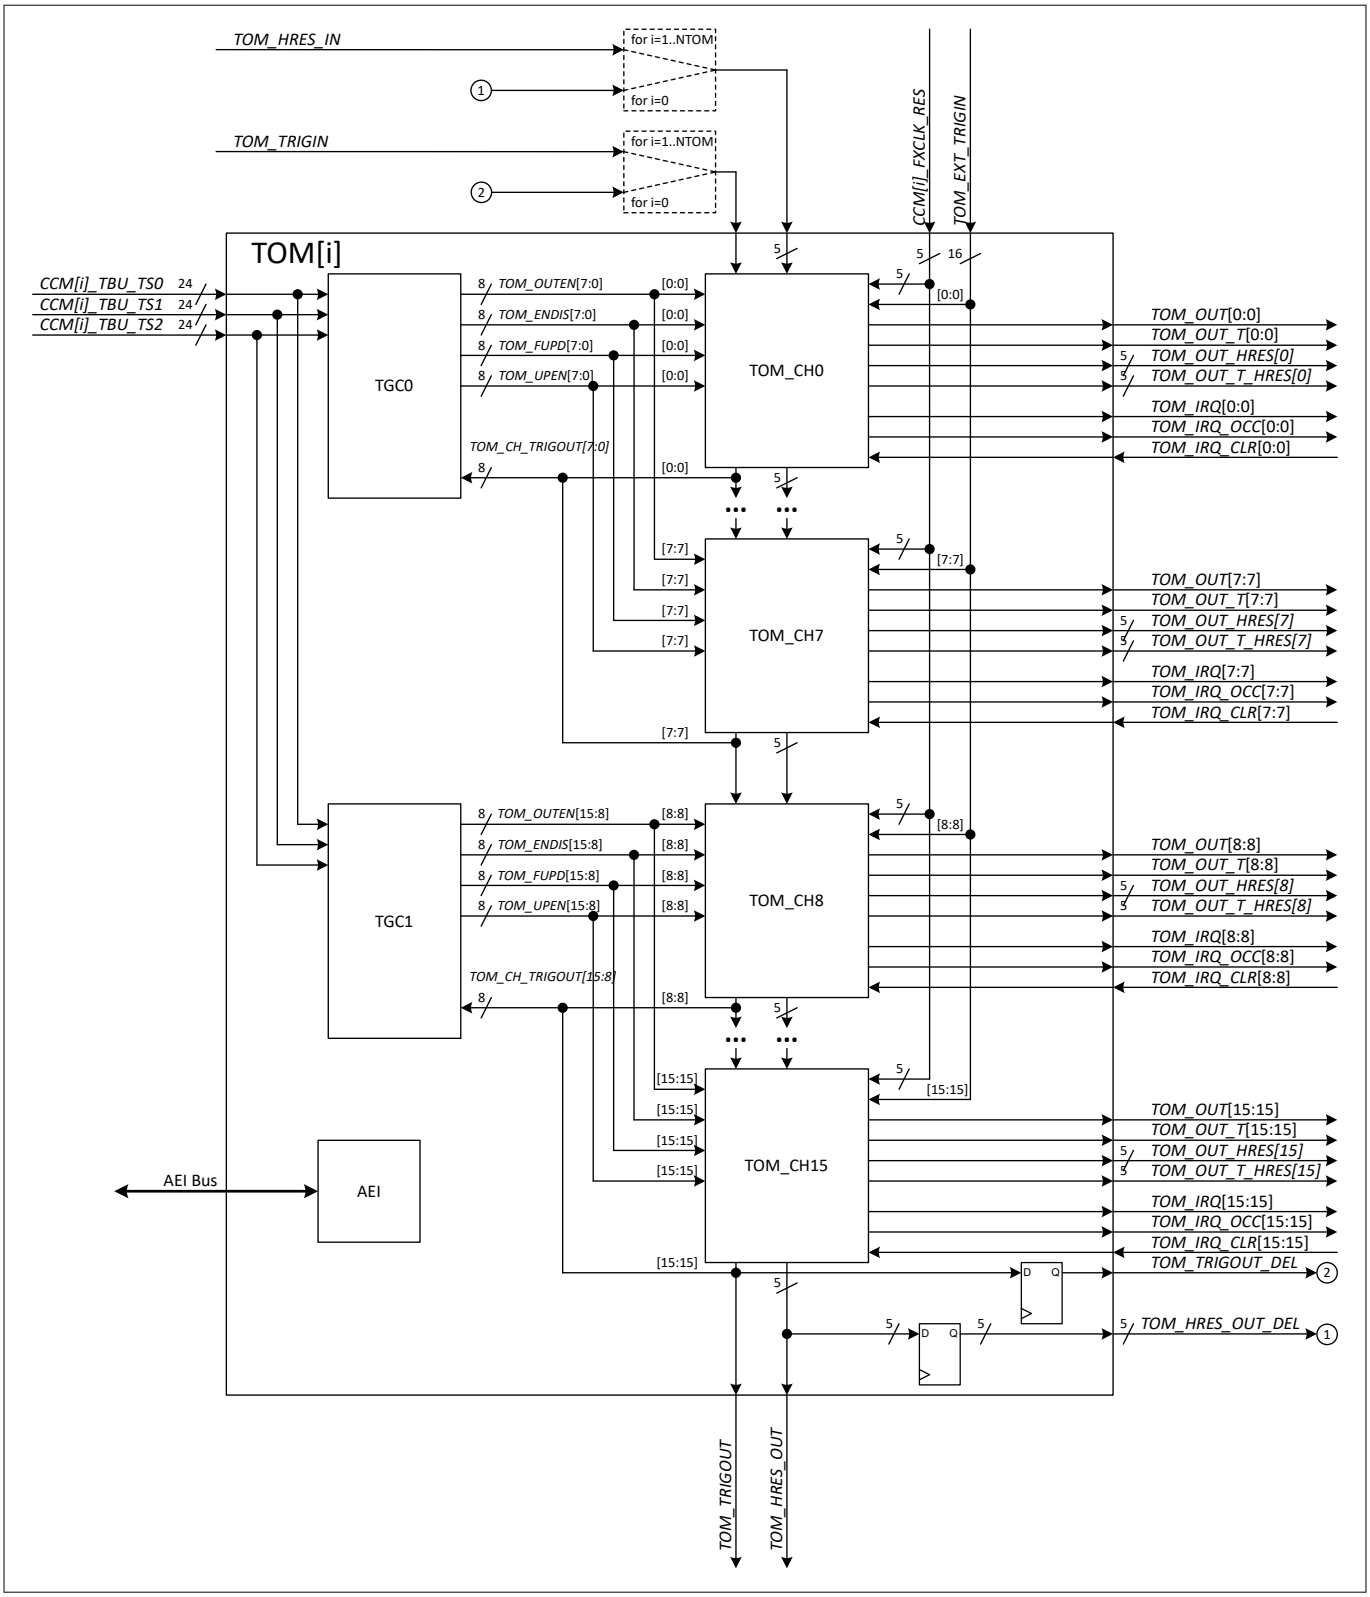

Figure 1057 TOM block diagram

As shown in Figure 1057, each **TOM** module integrates 16 channels with outputs TOM_OUT and TOM_OUT_T. The two sub-modules TGC0 and TGC1 are global channel control units that control the enabling/disabling of the channels and their outputs as well as the update of their period and pulse width register.

The input clocks for the **TOM** channels come from the cluster clock CLS[j]_CLK with the configurable clock resolution CCM[i]_FXCLK_RES signals of the **CCM** sub-module. This gives the freedom to select a programmable input clock for the **TOM** channel counters.

The module **TOM** receives two (three) timestamp values CCM[i]_TBU_TS0, CCM[i]_TBU_TS1 (and CCM[i]_TBU_TS2) in order to realize synchronized output behavior on behalf of a common time base.

As shown in Figure 1057, NTOM-1 **TOM** sub-modules are connected together through a trigger chain. The trigger signal TOM_TRIGIN of **TOM** instance i is coming from TOM_TRIGOUT of **TOM** instance i-1 and the trigger signal TOM_TRIGOUT of **TOM** instance i is routed to TOM_TRIGIN of **TOM** instance i+1. The trigger chain goes across all channels one by one. The trigger input signal TOM_TRIGIN of **TOM** instance i is connected to the trigger input signal TOM_CH_TRIGIN[0:0] of channel 0. The channel 0 can generate a trigger output signal TOM_CH_TRIGOUT[0:0] that is connected to TOM_CH_TRIGIN[1:1] to trigger channel 1. In this way, each channel x is triggered from the preceding channel and then can trigger the next channel (please refer to Figure 1060 and Internal trigger interface for the internal trigger chain details). Channel 15 of **TOM** instance i is routed to trigger channel 0 of the next instance i+1.

The trigger input signal of **TOM** instance 0 is connected to its own output TOM_TRIGOUT_DEL, i.e. the last channel of **TOM** instance 0 can trigger the first channel of **TOM** instance 0 (this path is registered, which means delayed by one cluster clock period).

The function of the interrupt signals TOM_IRQ, TOM_IRQ_OCC and TOM_IRQ_CLR is described in more detail in **eGTM** interrupt concept.

In Figure 1058 the **TOM SPE** interface signals are depicted. Please refer to Sensor pattern evaluation (**SPE**) for more details about the **TOM SPE** interface signals (TOM[i]_SPE_OUT, TOM[i]_SPE_NIPD, TOM[i]_CH[x]_SOUR, TOM[i]_CH[x]_SOUR, TOM[i]_CH[x]_TRIG_CCU0, TOM[i]_CH[x]_TRIG_CCU1, TOM[i]_CH[x]_TRIG_CCU1, TOM[i]_CH[x]_TRIG_CCU1, TOM[i]_CH[x]_TRIG_CCU1, TOM[i]_CH[x]_TRIG_CCU1, TOM[i]_CH[x]_TRIG_CCU1).

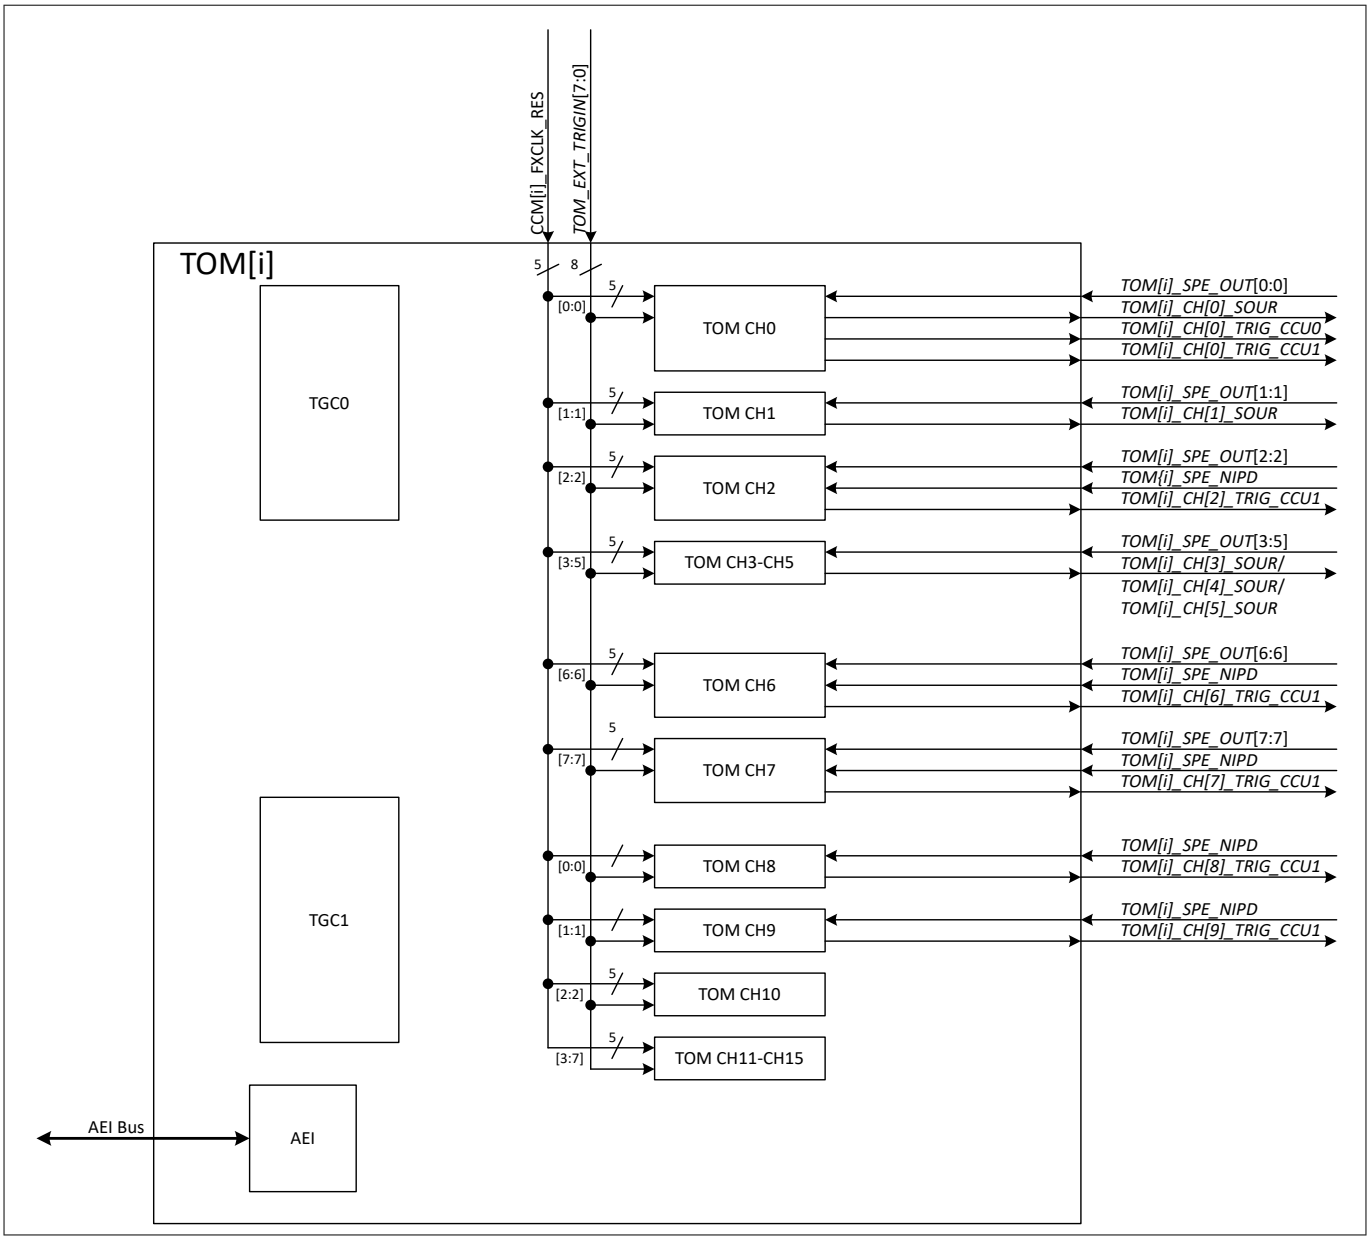

Figure 1058 TOM-SPE interface signals

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

44.3.1.7.2 TOM global channel control (TGC[0], TGC[1])

Overview

Two global channel control units (TGC[0] and TGC[1]) exist to drive a number of individual **TOM** channels synchronously by external or internal events.

Each TGC[g] can drive up to eight **TOM** channels where TGC[0] controls **TOM** channels x (x∈{0, 1,..., 7}) and TGC[1] controls **TOM** channels x (x∈{8, 9,..., 15}).

The **TOM** sub-module supports four different kinds of signaling mechanisms:

- Global enable/disable mechanism for each **TOM** channel with control register CLSi_TOM_TGCg_ENDIS_CTRL and status register CLSi_TOM_TGCg_ENDIS_STAT.
- Global output enable mechanism for each **TOM** channel x with control register CLSi_TOM_TGCg_OUTEN_CTRL and status register CLSi_TOM_TGCg_OUTEN_STAT.
- Global force update mechanism for each **TOM** channel and optionally reset the counter CLSi_TOM_CHx_CN0 with control register CLSi_TOM_TGCg_FUPD_CTRL.
- Global update enable of the register CLSi_TOM_CHx_CM0.CM0, CLSi_TOM_CHx_CM1.CM1 and CLSi_TOM_CHx_CTRL.CLK_SRC for each **TOM** channel x with the control bit field CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) (x= c+8*g).

TGC sub-unit

Each of the first three individual mechanisms (enable/disable of the channel, output enable and force update) can be driven by three different trigger sources.

The three trigger sources are:

1. Over the configuration interface (bit CLSi_TOM_TGCg_GLB_CTRL.HOST_TRIG
2. The **TBU** timestamp (signal CCM[i]_TBU_TS0, CCM[i]_TBU_TS1, CCM[i]_TBU_TS2 if available)
3. The trigger signal TOM_CH_TRIGOUT[7:0] for TGC[0] or TOM_CH_TRIGOUT[15:8] for TCG[1] (bunch of trigger signals TOM_CH_TRIGOUT[x:x]) which can be the trigger TRIG_CCU0 of channel x, the trigger of preceding channel x-1 (i.e. signal TOM_CH_TRIGOUT[x-1:x-1]) or the external trigger TOM_EXT_TRIGIN[x:x] from **TIM**.

The first way (1.) is to trigger the control mechanism by a direct register write-access via configuration interface (bit CLSi_TOM_TGCg_GLB_CTRL.HOST_TRIG).

The second way (2.) is provided by a compare match trigger on behalf of a specified time base coming from the module **TBU** (selected by bit field CLSi_TOM_TGCg_ACT_TB.TBU_SEL) and the timestamp compare value defined in the bit field CLSi_TOM_TGCg_ACT_TB.ACT_TB.

In this case, the selected **TBU** time base CCM[i]_TBU_TS0/CCM[i]_TBU_TS1/CCM[i]_TBU_TS2 should be configured to be up-counting. A cyclic event compare of CLSi_TOM_TGCg_ACT_TB.ACT_TB and selected CCM[i]_TBU_TS0, CCM[i]_TBU_TS1, CCM[i]_TBU_TS2 is performed. Please refer to Cyclic event compare for more details about cyclic event compare strategy.

The third way (3.) is the input TOM_CH_TRIGOUT (bunch of trigger signals TOM_CH_TRIGOUT[x:x]) coming from the **TOM** channel x, x∈{0, 1,..., 7} for TGC[0] or x∈{8, 9,..., 15} for TGC[1].

The corresponding trigger signal TOM_CH_TRIGOUT[x:x] coming from channel x can be masked by the register CLSi_TOM_TGCg_INT_TRIG.

To enable or disable each individual **TOM** channel, the register CLSi_TOM_TGCg_ENDIS_CTRL and/or CLSi_TOM_TGCg_ENDIS_STAT have to be used.

The register CLSi_TOM_TGCg_ENDIS_STAT controls directly the signals TOM_ENDIS[7:0] if g=0 or TOM_ENDIS[15:8] if g=1 (see Figure 1059). A write-access to this register is possible.

The register CLSi_TOM_TGCg_ENDIS_CTRL is a shadow register that overwrites the value of register CLSi_TOM_TGCg_ENDIS_STAT if one of the three trigger conditions matches.

The update mechanism within the channel is not affected by the TOM_ENDIS control signal. This means that the update of the working register can be executed - depending on the update condition - as soon as it is enabled by setting CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) $=10_B$.

To ensure a clean restart of a **TOM** channel x, it is recommended to raise a channel reset by setting of bit CLSi_TOM_TGCg_GLB_CTRL.RST_CHc (c=0-7) (x = c + 8*g) after a channel is disabled (TOM_ENDIS[x:x]=0) and before it is enabled again (TOM_ENDIS[x:x]=1).

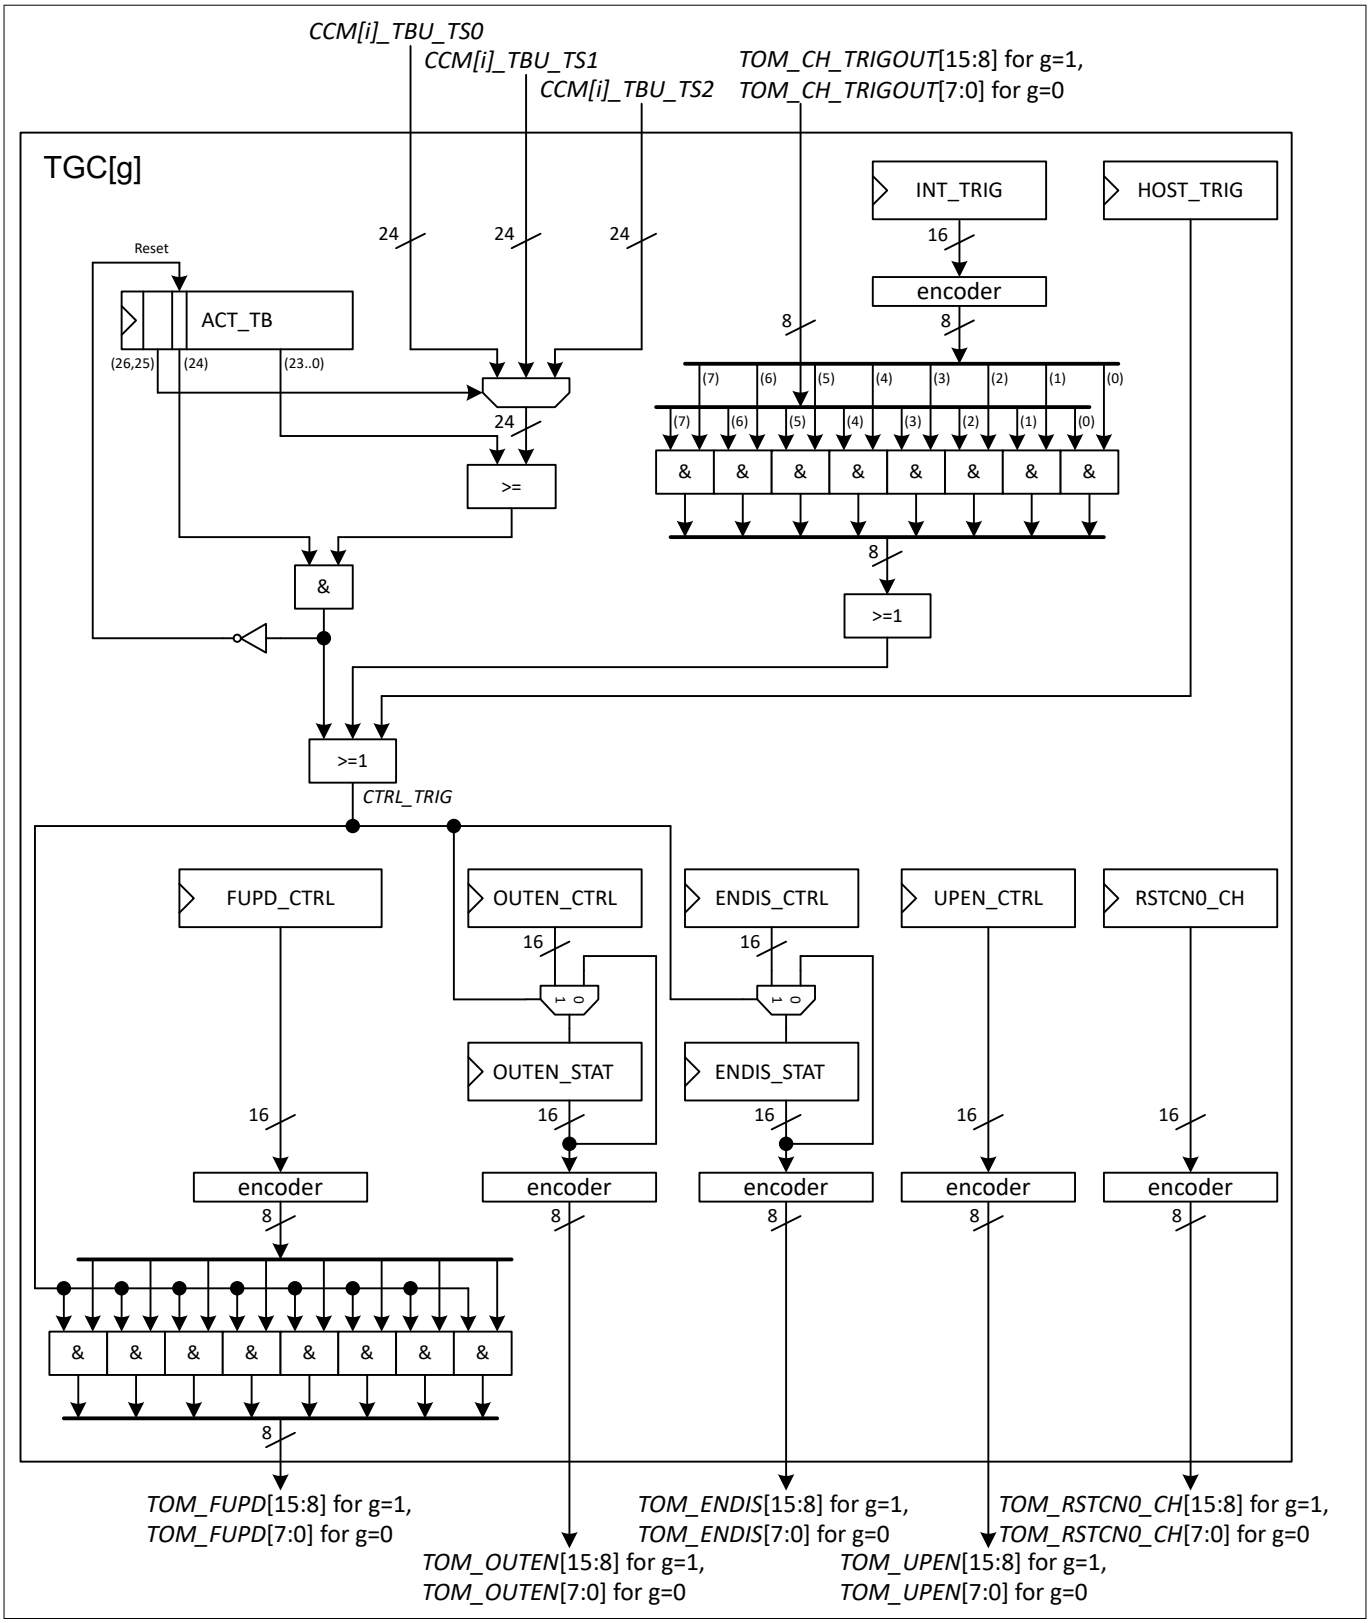

Figure 1059 TOM global channel control mechanism

The output of the individual **TOM** channels can be controlled using the register CLSi_TOM_TGCg_OUTEN_CTRL and CLSi_TOM_TGCg_OUTEN_STAT.

The register CLSi_TOM_TGCg_OUTEN_STAT controls directly the signals TOM_OUTEN[7:0] if g=0 or TOM_OUTEN[15:8] if g=1. A write-access to this register is possible.

CLSi_TOM_TGCg_OUTEN_CTRL is a shadow register that overwrites the value of register CLSi_TOM_TGCg_OUTEN_STAT if one of the three trigger conditions matches.

The trigger condition has always priority over the bus write-access to the CLSi_TOM_TGCg_OUTEN_STAT and CLSi_TOM_TGCg_ENDIS_STAT registers, even if CLSi_TOM_TGCg_OUTEN_CTRL.OUTEN_CTRLc (c=0-7) **(c=k)**/ CLSi_TOM_TGCg_OUTEN_CTRL.**ENDIS_CTRL[k]** is set to 00_B. This means that the bus write-access to CLSi_TOM_TGCg_OUTEN_STAT and CLSi_TOM_TGCg_ENDIS_STAT register is ignored in the clock cycle when the trigger condition is active.

The register CLSi_TOM_TGCg_FUPD_CTRL defines which of the **TOM** channels receive a force update event if the trigger signal CTRL_TRIG is raised while CLSi_TOM_TGCg_FUPD_CTRL.RSTCN0_CHc (c=0-7) determines whether the force update event also reset counter CLSi_TOM_CHx_CN0.CN0 of the channel. If in continuous counting up mode with CLSi_TOM_CHx_CTRL.RST_CCU0=0, the force update mechanism is configured together with CLSi_TOM_TGCg_FUPD_CTRL.RSTCN0_CHc (c=0-7)=10_B and CLSi_TOM_TGCg_FUPD_CTRL.FUPD_CTRLc (c=0-7)=10_B, the force update event will simultaneously update the operation registers, reset the counter and also set the output to be CLSi_TOM_CHx_CTRL.SL. That means the force update mechanism can be used to stop the current PWM signal generation and restart a new PWM signal generation with new PWM parameters.

The force update request is synchronized to the selected CCM[i]_FXCLK_RES as shown in Figure 1060 and then executed. The execution of the force update does not depend on the state of CLSi_TOM_TGCg_ENDIS_STAT.ENDIS_STATc (c=0-7).

The TOM_RSTCN0_CH signal is not synchronized with the selected CCM[i]_CLK_RES. In order to ensure that the reset function is executed, the bit field CLSi_TOM_TGCg_FUPD_CTRL.RSTCN0_CHc (c=0-7) may only be set to 01_B after the selected CCM[i]_CLK_RES has occured.

The register bit CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) defines for which **TOM** channel the update of the working register CLSi_TOM_CHx_CM0.CM0, CLSi_TOM_CHx_CM1.CM1, CLSi_TOM_CHx_CTRL.SL and CLSi_TOM_CHx_CTRL.CLK_SRC by the corresponding shadow register CLSi_TOM_CHx_SR0.SR0, CLSi_TOM_CHx_SR1.SR1, CLSi_TOM_CHx_CTRL_SR.SL_SR and CLSi_TOM_CHx_CTRL_SR.CLK_SRC_SR is enabled. If update is enabled, the registers CLSi_TOM_CHx_CM0.CM0, CLSi_TOM_CHx_CM1.CM1 and CLSi_TOM_CHx_CTRL.CLK_SRC will be updated on reset of counter CLSi_TOM_CHx_CN0.CN0 (see Figure 1060). An exception is the configuration of CLSi_TOM_CHx_CTRL.SR0_TRIG=1 which enables the trigger generation defined by CLSi_TOM_CHx_SR0.SR0 then CLSi_TOM_CHx_CM0 is not updated with CLSi_TOM_CHx_SR0 (please refer to here).

44.3.1.7.3 TOM channel architecture

Each individual **TOM** channel comprises a Counter Compare Unit 0 (CCU0) which contains the counter CLSi_TOM_CHx_CN0.CN0 and the period register CLSi_TOM_CHx_CM0.CM0, a Counter Compare Unit 1 (CCU1) which contains the pulse width register CLSi_TOM_CHx_CM1.CM1 and the Signal Output Generation Unit (SOU) which contains the output register SOUR (see Figure 1060). The architecture is depicted in Figure 1060.

***Note**:* Figure 1060 *doesn't reflect the real implementation of the circuit but is intended to explain the functionality of the channel in a better manner.*

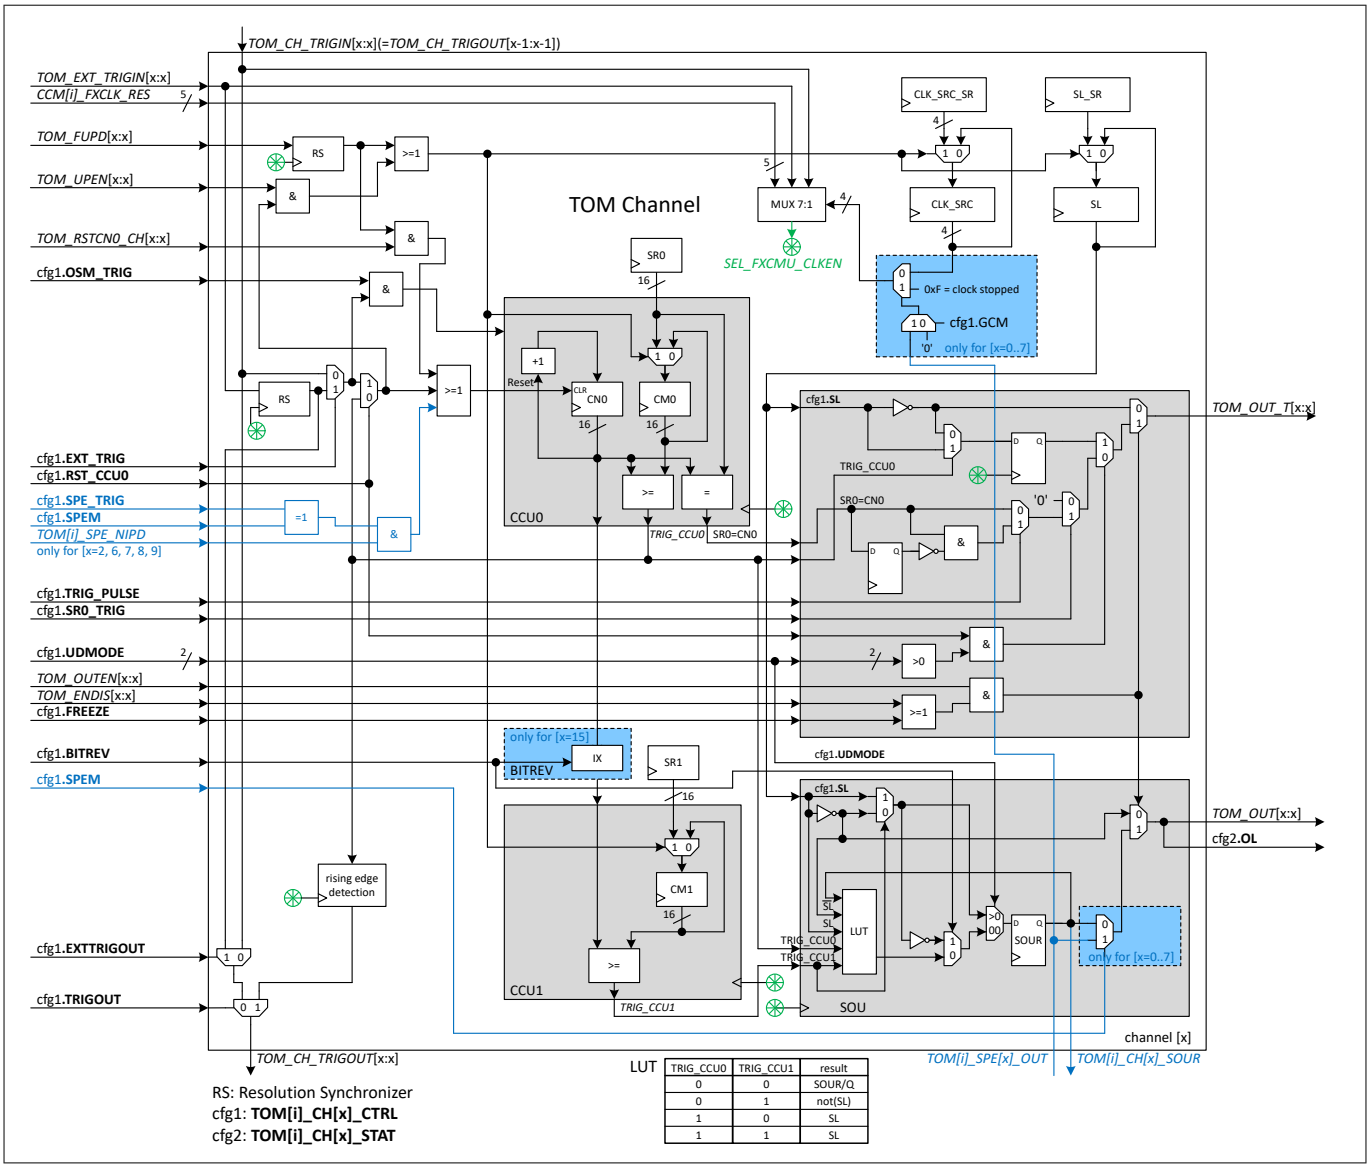

Figure 1060 TOM channel architecture

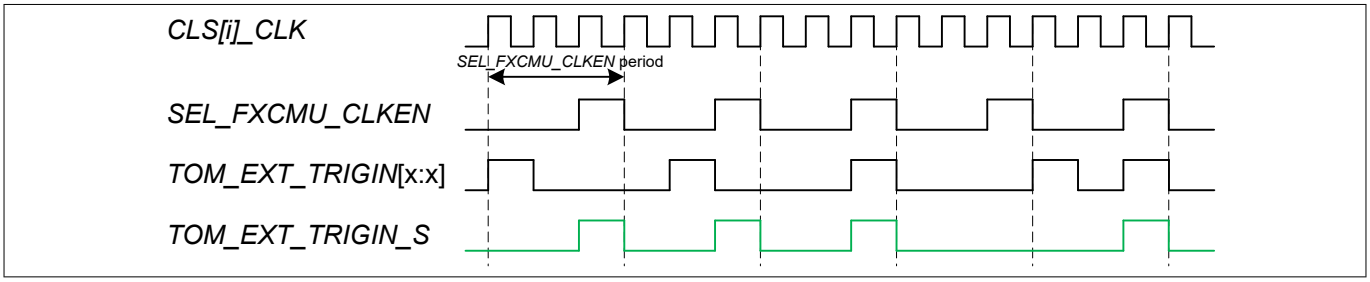

Figure 1061 Timing diagram of RS unit

Most functionalities (e.g. the counter CLSi_TOM_CHx_CN0.CN0 in CCU0 unit) are synchronized with the selected clock enable signal SEL_FXCMU_CLKEN that is configured by CLSi_TOM_CHx_CTRL.CLK_SRC. This configuration register can select the clock source from fixed clock enable signals CCM[i]_FXCLK_RES that are provided from **CCM** sub-module. The signal SEL_FXCMU_CLKEN looks like clock enable signal that is shown in Figure 1061. Most functionality modes are only active when SEL_FXCMU_CLKEN = 1 and the consequent operation registers and outputs are always synchronously updated at the falling edge of SEL_FXCMU_CLKEN

pulse. The functionalities synchronous to the selected clock resolution SEL_FXCMU_CLKEN are depicted with the green round symbol in Figure 1060.

In all **TOM** channels the operation registers CLSi_TOM_CHx_CN0.CN0, CLSi_TOM_CHx_CM0.CM0 and CLSi_TOM_CHx_CM1.CM1 and the shadow registers CLSi_TOM_CHx_SR0.SR0 and CLSi_TOM_CHx_SR1.SR1 are 16 bits wide. As shown in Figure 1060, the unit CCU0 provides different counting up/down functionalities in various modes. The comparators inside CCU0 and CCU1 perform selectable signed greater-equal or less-equal comparison against different parameters in different modes and then generate TRIG_CCU0=1 when the compare match event in CCU0 occurs or generate TRIG_CCU1=1 when the compare match event in CCU1 occurs.

The Signal Output Unit (SOU) generates the output signal for each **TOM** channel. The output signal level depends on the bit CLSi_TOM_CHx_CTRL.SL in combination with the counter behavior and its compare events in CCU0 and CCU1. The initial signal output level for the channel is the reverse value of the bit CLSi_TOM_CHx_CTRL.SL.

In continuous counting up mode, CLSi_TOM_CHx_CM0.CM0 represents PWM period while CLSi_TOM_CHx_CM1.CM1 is PWM pulse width. In order to generate various PWM signals, CCU0 counts up CLSi_TOM_CHx_CN0.CN0 and compares it with CLSi_TOM_CHx_CM0.CM0 while CCU1 compares it with CLSi_TOM_CHx_CM1.CM1. Depending on the configuration bit CLSi_TOM_CHx_CTRL.RST_CCU0, the counter CLSi_TOM_CHx_CN0.CN0 can be reset, when the counter value is equal to the compare value CLSi_TOM_CHx_CM0.CM0 (i.e. CLSi_TOM_CHx_CN0.CN0 counts only from 0 to CLSi_ATOM_CHx_CM0.CM0-1 and is then reset to 0) or when it is triggered by the **TOM[i]** trigger signal TOM_CH_TRIGIN[x:x] (TOM_CH_TRIGOUT[x-1:x-1]) of the preceding channel x-1 which can also be the last channel of preceding instance **TOM[i-1]**) or when it is triggered by the external trigger signal TOM_EXT_TRIGIN[x:x] from **TIM** module i.

As an exception, the input TOM_TRIGIN of instance TOM0 is triggered by its own last channel 15 via signal TOM_CH_TRIGOUT[15:15].

The external trigger signal TOM_EXT_TRIGIN[x:x] is synchronous to the clock source selected by RS (Resolution Synchronizer) unit and then taken into use.

With such a RS unit, in each SEL_FXCMU_CLKEN period (i.e. selected clock resolution signal), any event (or pulses) of TOM_EXT_TRIGIN will be synchronized by RS unit on TOM_EXT_TRIGIN_S that looks exactly the same as SEL_FXCMU_CLKEN. Figure 1061 shows the timing diagram of RS unit. If TOM_EXT_TRIGIN has one or more pulses in a SEL_FXCMU_CLKEN period, the synchronized output TOM_EXT_TRIGIN_S will have 1 pulse at the end of this period. Otherwise, TOM_EXT_TRIGIN_S is always 0.

The trigger signal TOM_CH_TRIGIN[x:x] coming from the preceding channel may not be synchronous to the selected clock resolution of channel x. If the counter CLSi_TOM_CHx_CN0.CN0 is reset by the trigger signal TOM_CH_TRIGIN[x:x] of a preceding channel with CLSi_TOM_CHx_CTRL.RST_CCU0=1, the preceding triggering channel should be configured with the same CCM[i]_FXCLK_RES as the triggered channel.

In continuous counting up mode, once the comparison event of CLSi_TOM_CHx_CN0.CN0 >= CLSi_TOM_CHx_CM0.CM0-1 in unit CCU0 occurs, TRIG_CCU0 = 1 will be set to trigger the output generation of TOM_OUT[x:x] in the SOU sub-unit together with the corresponding interrupt signals. In order to trigger the next channel, the rising edge detection unit can detect each rising edge of TRIG_CCU0 (i.e. each comparison event) and generate a single cluster clock pulse on TOM_CH_TRIGOUT[x:x] when the selected clock resolution signal SEL_FXCMU_CLKEN =1 (i.e. synchronous to the selected clock resolution). In addition, TOM_CH_TRIGOUT[x:x] can also be configured to be TOM_CH_TRIGIN[x:x] (TOM_CH_TRIGOUT[x-1:x-1] of the preceding channel x-1) or the external trigger signal TOM_EXT_TRIGIN[x:x] from **TIM**.

Similarly, once the comparison event of CLSi_TOM_CHx_CN0.CN0 >= CLSi_TOM_CHx_CM1.CM1-1 in unit CCU1 occurs, TRIG_CCU1 = 1 will be set to trigger the output generation of TOM_OUT[x:x] in the SOU sub-unit together with the corresponding interrupt signals.

When CLSi_TOM_CHx_CN0.CN0 < CLSi_TOM_CHx_CM0.CM0-1, TRIG_CCU0 will be reset as 0. Similarly, when CLSi_TOM_CHx_CN0.CN0 < CLSi_TOM_CHx_CM1.CM1-1, TRIG_CCU1 will be reset to 0.

As shown in Figure 1060, in continuous counting up mode according to the LUT with TRIG_CCU0, TRIG_CCU1 and the signal level configuration CLSi_TOM_CHx_CTRL.SL, SOU unit can generate TOM_OUT[x:x] with various PWM timing characteristics when the channel and the output are both enabled (TOM_OUTEN[x:x]=1 and TOM_ENDIS[x:x]=1). Please refer to the chapter of different modes for more details on PWM signal generation.

The output level on the **TOM** channel output pin TOM_OUT[x:x] is captured in bit CLSi_TOM_CHx_STAT.OL (see Figure 1060)

If a **TOM** channel is disabled by the register CLSi_TOM_TGCg_OUTEN_STAT, the actual value of the channel output at TOM_OUT[x:x] is defined by the signal level bit (CLSi_TOM_CHx_CTRL.SL).

If the output is enabled, the output at TOM_OUT[x:x] depends on value of register SOUR (see Figure 1060).

In addition to the bit CLSi_TOM_CHx_CTRL.SL, a shadow register exists in CLSi_TOM_CHx_CTRL_SR.SL_SR. With this shadow register it is possible to change the signal level value synchronous to the update of the operation registers CLSi_TOM_CHx_CM0.CM0 and CLSi_TOM_CHx_CM1.CM1 from its shadow registers CLSi_TOM_CHx_SR0.SR0 and CLSi_TOM_CHx_SR1.SR1.

The operating clock resolution from **CMU** is specified in the bit field CLSi_TOM_CHx_CTRL.CLK_SRC. In addition, a shadow register CLSi_TOM_CHx_CTRL_SR.CLK_SRC_SR exists. With this shadow register it is possible to change the selected clock resolution from **CMU** synchronously to the update of the operation registers CLSi_TOM_CHx_CM0.CM0 and CLSi_TOM_CHx_CM1.CM1 from its shadow registers CLSi_TOM_CHx_SR0.SR0 and CLSi_TOM_CHx_SR1.SR1.

Due to the fixed clock resolution scheme from **CMU**, the first clock resolution period may differ from expected value, depending on the point of time, the CLSi_TOM_CHx_CTRL.CLK_SRC bit field is updated from its shadow register bit field CLSi_TOM_CHx_CTRL_SR.CLK_SRC_SR.

When the output is disabled (TOM_OUTEN[x:x]=0), the output signals TOM_OUT[x:x] and TOM_OUT_T[x:x] are the inverse value of the CLSi_TOM_CHx_CTRL.SL bit. When the output is enabled (TOM_OUTEN[x:x]=1), the output signals TOM_OUT[x:x] and TOM_OUT_T[x:x] are dependent on different operation modes, the channel enable signal TOM_ENDIS[x:x] and the freeze mode enable register CLSi_TOM_CHx_CTRL.FREEZE. (Please refer to register description of CLSi_TOM_CHx_CTRL.SL for more details.) Especially, in some modes the output signal TOM_OUT_T[x:x] is not supported. So it is always clamped to 0 if the output and the channel are both enabled (i.e. TOM_OUTEN[x:x]=1 and TOM_ENDIS[x:x]=1). When the output is enabled (TOM_OUTEN[x:x]=1) but the channel is disabled (TOM_ENDIS[x:x]=0), if CLSi_TOM_CHx_CTRL.FREEZE=0, TOM_OUT_T[x:x] is ! CLSi_TOM_CHx_CTRL.SL. When the output is enabled (TOM_OUTEN[x:x]=1) but the channel is disabled (TOM_ENDIS[x:x]=0), if CLSi_TOM_CHx_CTRL.FREEZE=1, TOM_OUT_T[x:x] is clamped to 0.

When the channel is disabled (TOM_ENDIS[x:x]=0), the counting and comparing functionalities in CCU0 and CCU1 are deactivated in different modes and thus TRIG_CCU0 = 0, TRIG_CCU1 = 0. Therefore, TOM_CH_TRIGOUT[x:x] is not generated if CLSi_TOM_CHx_CTRL.TRIGOUT = 1, regardless of TOM_OUTEN[x:x].

External trigger interface

Each channel x of **TOM** instance i has an input signal TOM_EXT_TRIGIN[x:x] that is connected to TIM_EXT_CAPTURE[x:x] of **TIM** instance i if x ∈ {0, 1, ..., 7} and TIM_EXT_CAPTURE[x-8:x-8] of **TIM** instance i if x ∈ {8, 9, ..., 15} (see Figure 1019). Via this signal, events (high pulses with the length of 1 CLS[j]_CLK period) generated by the **TIM** module i can be used to control the functionality of the **TOM** channel in multiple ways:

- TOM_EXT_TRIGIN[x:x] events can be used to define the clock source of the selected channel mode (CLSi_TOM_CHx_CTRL.CLK_SRC = 1110_B).
- TOM_EXT_TRIGIN[x:x] events can be used to reset the counter register CLSi_TOM_CHx_CN0 in continuous counting up mode or change the counting direction in counting up-down mode or trigger the start of counting in one-shot mode (activated by CLSi_TOM_CHx_CTRL.EXT_TRIG = 1 && CLSi_TOM_CHx_CTRL.RST_CCU0 = 1). In this case, if CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) = 10_B is configured, TOM_EXT_TRIGIN[x:x] events can also trigger the update of the operation registers from

their shadow registers. Any TOM_EXT_TRIGIN[x:x] event is synchronized in the **TOM** channel as specified in Figure 1061.

- TOM_EXT_TRIGIN[x:x] can be used as a trigger event for the following channels (activated by CLSi_TOM_CHx_CTRL.EXTTRIGOUT = 1 && CLSi_TOM_CHx_CTRL.TRIGOUT = 0). Any TOM_EXT_TRIGIN[x:x] event is synchronized in the **TOM** channel as specified in Figure 1061.

In certain configurations of the **TIM** module, the TOM_EXT_TRIGIN[x:x] signal pulses can have a length of more than 1 cluster clock-cycle. In this case, the functionality of the **TOM** is not specified and it is highly recommended to prevent this configuration in applications.

Before triggering the functionalities mentioned above, the TOM_EXT_TRIGIN[x:x] signal is always synchronized with the current selected clock enable signal in RS unit as shown in Figure 1061.

Internal trigger interface

Each **TOM** channel x has an input signal TOM_CH_TRIGIN[x:x] that is coming from TOM_CH_TRIGOUT[x-1:x-1] from the preceding channel. Via this signal, events (high pulses with the length of one CLS[j]_CLK period) generated by the preceding **TOM** channel, can be used to control the functionality of **TOM** channel in multiple ways:

- TOM_CH_TRIGIN[x:x] events can be used to define the clock source of the selected channel mode (CLSi_TOM_CHx_CTRL.CLK_SRC = 1101_B).
- TOM_CH_TRIGIN[x:x] events can be used to reset the counter register CLSi_TOM_CHx_CN0 in continuous counting up mode or change the counting direction in counting up-down mode or trigger the start of counting in one-shot mode (activated by CLSi_TOM_CHx_CTRL.EXT_TRIG = 0 && CLSi_ATOM_CHx_CTRL.RST_CCU0 = 1). In this case, if CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) = 10_B is configured, TOM_CH_TRIGIN[x:x] events can also trigger the update of the operation registers from their shadow registers.
- TOM_CH_TRIGIN[x:x] can be used as a trigger event for following channels (activated by CLSi_TOM_CHx_CTRL.EXTTRIGOUT = 0 && CLSi_TOM_CHx_CTRL.TRIGOUT = 0).

Especially, for channel 0 of **TOM** module i, i ∈ {1, 2, ..., NTOM-1}, TOM_CH_TRIGIN[0:0] comes from TOM_CH_TRIGOUT[15:15] of the preceding **TOM** instance [i-1] and may be delayed by a register with the cluster clock CLS[j]_CLK in channel 0 before triggering the functionalities as mentioned above. This delay is controlled by the device configuration variable TOM_TRIG_CHAIN (indicated by CLSi_CCM_HW_CONF.TOM_TRIG_CHAIN). The delay exists after every N cluster (N = TOM_TRIG_CHAIN). For TOM0, TOM_CH_TRIGIN[0:0] is connected to TOM_TRIGOUT_DEL via the signal TOM_CH_TRIGOUT[15:15] of TOM0 itself as shown in Figure 1057. Furthermore, the cluster i can operate on faster **eGTM** clock CLK, if the device is defined with FAST_CLS_CLK[i] = 1. In this case, it is allowed to have one more register that is clocked with CLK to delay TOM_CH_TRIGIN[8:8] in channel 8 before triggering the functionalities. This is controlled by another **ATOM** device configuration parameter TOM_TRIG_INTCHAIN (it can only be valid if FAST_CLS_CLK[i] = 1 and indicated by CLSi_CCM_HW_CONF.TOM_TRIG_INTCHAIN). The registers for these special cases are not shown in Figure 1057.

Unlike TOM_EXT_TRIGIN[x:x], TOM_CH_TRIGIN[x:x] is not synchronized with the selected clock enable signal of channel x. For the application of 2 channels generating PWM signals synchronously, CLSi_TOM_CHx_CTRL.CLK_SRC of the triggering channel and the triggered channel should be configured with the same clock resolution and the same cluster clock.

Internal trigger interface

As shown in Figure 1060, each **TOM** channel x has an input signal TOM_CH_TRIGIN[x:x] that is coming from TOM_CH_TRIGOUT[x-1:x-1] from the preceding channel. Via this signal, events (high pulses with the length of 1 CLS[j]_CLK period) generated by the preceding **TOM** channel, can be used to control the functionality of **TOM** channel in multiple ways:

- *TOM_AGC_TRIGIN*[x:x] events can be used to define the clock source of the selected channel mode (CLSi_TOM_CHx_CTRL.CLK_SRC = 1101_B).

- *TOM_AGC_TRIGIN*[x:x] events can be used to reset the counter register CLSi_TOM_CHx_CN0 in continuous counting up mode or change the counting direction in counting up-down mode or trigger the start of counting in one-shot mode (activated by CLSi_TOM_CHx_CTRL.EXT_TRIG = 0 && CLSi_TOM_CHx_CTRL.RST_CCU0 = 1). In this case, if CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) = 10_B is configured, TOM_CH_TRIGIN[x:x] events can also trigger the update of the operation registers from their shadow registers.
- TOM_CH_TRIGIN[x:x] can be used as a trigger event for following channels (activated by CLSi_TOM_CHx_CTRL.EXTTRIGOUT = 0 && CLSi_TOM_CHx_CTRL.TRIGOUT = 0).

Especially, for channel 0 of **TOM** module i, i ∈ {1, 2, ..., NTOM-1}, TOM_CH_TRIGIN[0:0] is connected to TOM_TRIGIN of instance [i] that comes from TOM_CH_TRIGOUT[15:15] of the preceding **TOM** instance [i-1] and may be delayed by a register with the cluster clock CLS[j]_CLK in channel 0 before triggering the functionalities as mentioned above. This delay is controlled by the device configuration variable TOM_TRIG_CHAIN (indicated by CLSi_CCM_HW_CONF.TOM_TRIG_CHAIN). The delay exists after every N cluster (N = TOM_TRIG_CHAIN). For TOM0, TOM_CH_TRIGIN[0:0] is connected to TOM_TRIGOUT_DEL via the signal TOM_CH_TRIGOUT[15:15] of TOM0 itself as shown in Figure 1057. Furthermore, the cluster i can operate on faster **eGTM** clock CLK, if the device is defined with FAST_CLS_CLK[i] = 1. In this case, it is allowed to have one more register that is clocked with CLK to delay TOM_CH_TRIGIN[8:8] in channel 8 before triggering the functionalities. This is controlled by another **TOM** device configuration parameter TOM_TRIG_INTCHAIN (it can only be valid if FAST_CLS_CLK[i] = 1 and indicated by CLSi_CCM_HW_CONF.TOM_TRIG_INTCHAIN). The registers for these special cases are not shown in Figure 1060.

Unlike TOM_EXT_TRIGIN[x:x], TOM_CH_TRIGIN[x:x] is not synchronized with the selected clock enable signal of channel x. For the application of 2 channels generating PWM signals synchronously, CLSi_TOM_CHx_CTRL.CLK_SRC of the triggering channel and the triggered channel should be configured with the same clock resolution and the same cluster clock.

Pulse width, period, signal level and clock frequency update mechanisms

The two action registers CLSi_TOM_CHx_CM0.CM0 and CLSi_TOM_CHx_CM1.CM1 can be reloaded with the content of the shadow registers CLSi_TOM_CHx_SR0.SR0 and CLSi_TOM_CHx_SR1.SR1. The bit CLSi_TOM_CHx_CTRL.CLK_SRC that determines the clock frequency of the counter CLSi_TOM_CHx_CN0.CN0 can be reloaded with its shadow register CLSi_TOM_CHx_CTRL_SR.CLK_SRC_SR. The signal level defined in bit field CLSi_TOM_CHx_CTRL.SL can be reloaded with its shadow register CLSi_TOM_CHx_CTRL_SR.SL_SR.

With the update of the register CLSi_TOM_CHx_CTRL.CLK_SRC at the end of a period a new counter CLSi_TOM_CHx_CN0.CN0 clock frequency can be easily adjusted.

The update of the configuration registers CLSi_TOM_CHx_CM0.CM0, CLSi_TOM_CHx_CM1.CM1, CLSi_TOM_CHx_CTRL.SL and CLSi_TOM_CHx_CTRL.CLK_SRC with the content of their shadow registers can be performed under the following conditions:

- In case CLSi_TOM_CHx_CTRL.RST_CCU0 =0_B when the specified CLSi_TOM_CHx_CTRL.UDMODE compare condition is fulfilled, the update will be performed. Additional information is given in the bit field description of CLSi_TOM_CHx_CTRL.UDMODE. The update mechanism must be enabled by configuring CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) =10_B.
- In case CLSi_TOM_CHx_CTRL.RST_CCU0 =1_B when the channel [x] is triggered by the signal TOM_CH_TRIGIN*[x:x]* from another **TOM** channel or by the external trigger signal TOM_EXT_TRIGIN of the assigned **TIM** channel, after it is synchronized to the selected CCM[i]_FXCLK_RES of channel [x], the update will also be performed. The update mechanism must be enabled by configuring CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) =10_B.
- These configuration registers can be force-updated via a trigger signal via TOM_FUPD or via TOM_EXT_TRIGIN.
- If CLSi_TOM_CHx_CTRL.RST_CCU0 =0_B, the operating registers are continuously updated as long as CLSi_TOM_CHx_CM0.CM0 =0_H. This update condition must be enabled by configuring CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) =10_B.

Based on the update mechanisms above, these registers CLSi_TOM_CHx_CM0.CM0, CLSi_TOM_CHx_CM1.CM1, CLSi_TOM_CHx_CTRL.SL, CLSi_TOM_CHx_CTRL.CLK_SRC can be updated synchronously and asynchronously. Synchronous update means that the pulse width, period duration, signal level and the counter operating clock frequency can be changed at the end of the running PWM period. Asynchronous update means that the pulse width, period duration, signal level and the counter operating clock frequency can also be changed during the actual running PWM period. The following two Synchronous update of pulse width only and Asynchronous update of pulse width only provide examples of synchronous update and asynchronous update of pulse width in continuous up mode with CLSi_TOM_CHx_CTRL.RST_CCU0 = 0.

An update of pulse width, period and counter CLSi_TOM_CHx_CN0.CN0 clock frequency that takes effect synchronous to the start of a new period can be easily reached by performing following steps:

1. Disable the update of the action register with the content of the corresponding shadow register by setting the channel-specific configuration bit CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) = 01_B. (Configuring CLSi_TOM_CHx_CTRL.UDMODE=01_B if in counting up-down mode.)
2. Write new desired values to CLSi_TOM_CHx_SR0, CLSi_TOM_CHx_SR1, CLSi_TOM_CHx_CTRL.SL, CLSi_TOM_CHx_CTRL_SR.CLK_SRC_SR.
3. Enable update of the action register by setting the channel-specific configuration bit CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7)= 01_B.

Asynchronous update of the operation registers can be realized by hot reconfiguring directly the registers CLSi_TOM_CHx_CM0.CM0, CLSi_TOM_CHx_CM1.CM1, CLSi_TOM_CHx_CTRL.SL, CLSi_TOM_CHx_CTRL.CLK_SRC or hot reconfiguring their shadow registers and then using the force update mechanism (configuring CLSi_TOM_TGCg_FUPD_CTRL.FUPD_CTRLc (c=0-7) = 01_B, CLSi_TOM_TGCg_FUPD_CTRL.RSTCN0_CHc (c=0-7) = 01_B and then writing bit CLSi_TOM_TGCg_GLB_CTRL.HOST_TRIG = 1). Such asynchronous update mechanism is sometimes helpful to change the PWM parameters of the current running PWM signal. For example, in continuous counting up mode, the current running PWM period can be reduced by asynchronously updating the value of CLSi_TOM_CHx_CM0.CM0 with a smaller value before the end of the current period. However, since the behavior depends on the access or update time of registers and the current running operation phase of the channel, which is often difficult to control, then the behavior after an asynchronous update can be unpredictable and unexpected. Therefore, such an asynchronous update must be carefully performed in real application. The following steps are recommended to apply the force update mechanism on channel x:

1. Disable the update of the action register with the content of the corresponding shadow register by setting the channel-specific configuration bit field CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) = 01_B.
2. Write new desired values to CLSi_TOM_CHx_SR0.SR0, CLSi_TOM_CHx_SR1.SR1, CLSi_TOM_CHx_CTRL_SR.SL_SR, CLSi_TOM_CHx_CTRL_SR.CLK_SRC_SR.
3. Enable the force update of the operation registers by setting the channel-specific configuration bit field CLSi_TOM_TGCg_FUPD_CTRL.FUPD_CTRLc (c=0-7) = 10_B, CLSi_TOM_TGCg_FUPD_CTRL.RSTCN0_CHc (c=0-7) = 01_B.
4. Write CLSi_TOM_TGCg_GLB_CTRL.HOST_TRIG = 1 to trigger the force update.

Synchronous update of pulse width only

A synchronous update of the pulse width only can be done by simply writing the desired new value to register CLSi_TOM_CHx_SR1.SR1 without prior disable of the update mechanism (as described in the chapter above). The new pulse width is then applied in the period following the period where the update of register CLSi_TOM_CHx_SR1.SR1 is done.

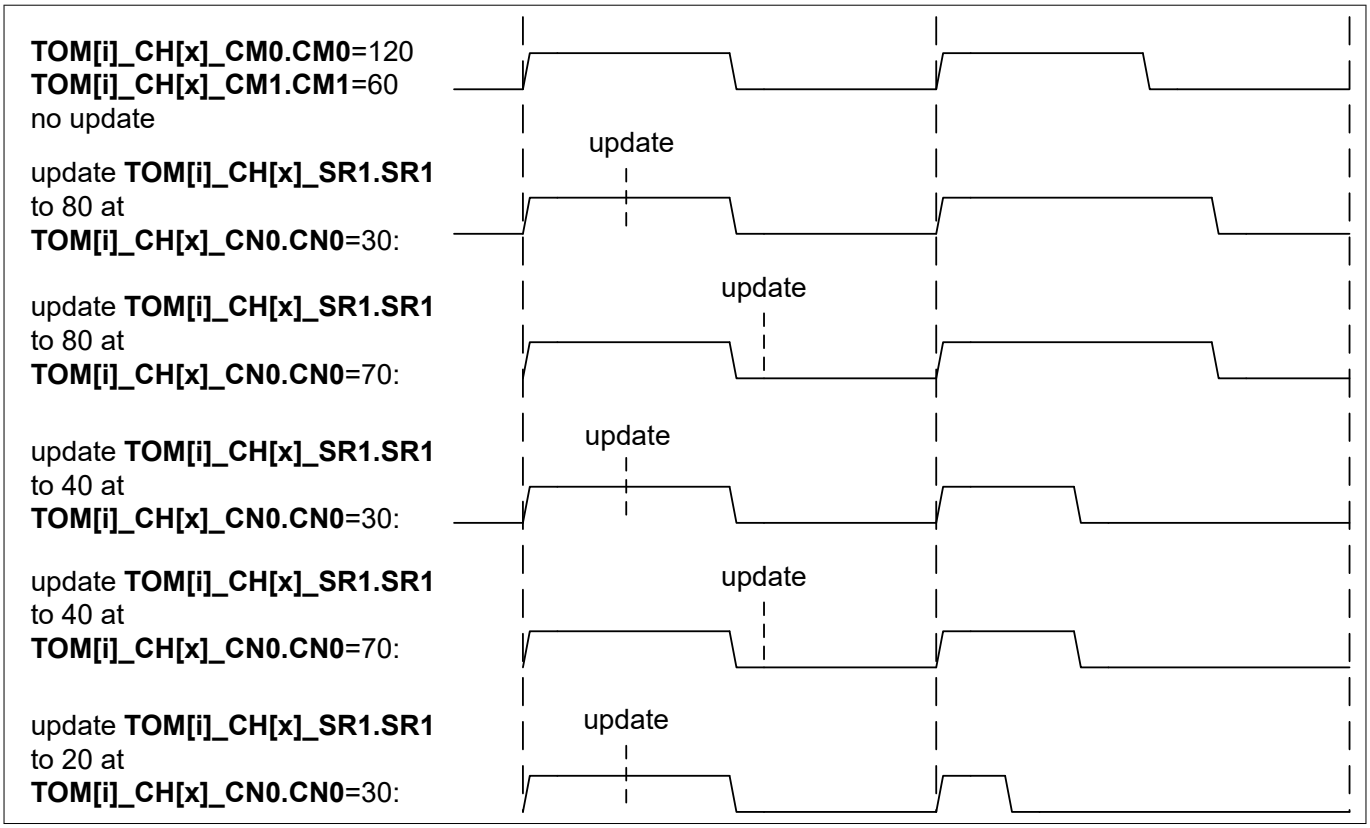

Figure 1062 Synchronous update of pulse width only

Asynchronous update of pulse width only

If the update of the pulse width should be performed independent of the start of a new period (asynchronous), it is mandatory to additionally disable the synchronous update mechanism as a whole (i.e. configuring bits CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7)=01_B of corresponding channel x) and then update the operation register. On the one hand, the desired new value can be written directly to register CLSi_TOM_CHx_CM1.CM1. On the other hand, it can be realized by writing the new value to CLSi_TOM_CHx_SR1.SR1 and afterwards updating the value of CLSi_TOM_CHx_CM1.CM1 by using the asynchronous force update mechanism (configuring CLSi_TOM_TGCg_FUPD_CTRL.FUPD_CTRLc (c=0-7) = 10_B, CLSi_TOM_TGCg_FUPD_CTRL.RSTCN0_CHc (c=0-7) = 01_B and then writing bit CLSi_TOM_TGCg_GLB_CTRL.HOST_TRIG = 1).

Depending on the time of update of CLSi_TOM_CHx_CM1.CM1 in relation to the actual value of CLSi_TOM_CHx_CN0.CN0 and CLSi_TOM_CHx_CM1.CM1, the new pulse width is applied in the current period or the following period. The behavior of the output signal due to the different possibilities of an asynchronous update during a PWM period is shown in Figure 1063. The new pulse width may jitter from update to update by maximum one period (given by CLSi_TOM_CHx_CM0.CM0). However, the period remains unchanged. In any case the creation of glitches is avoided.

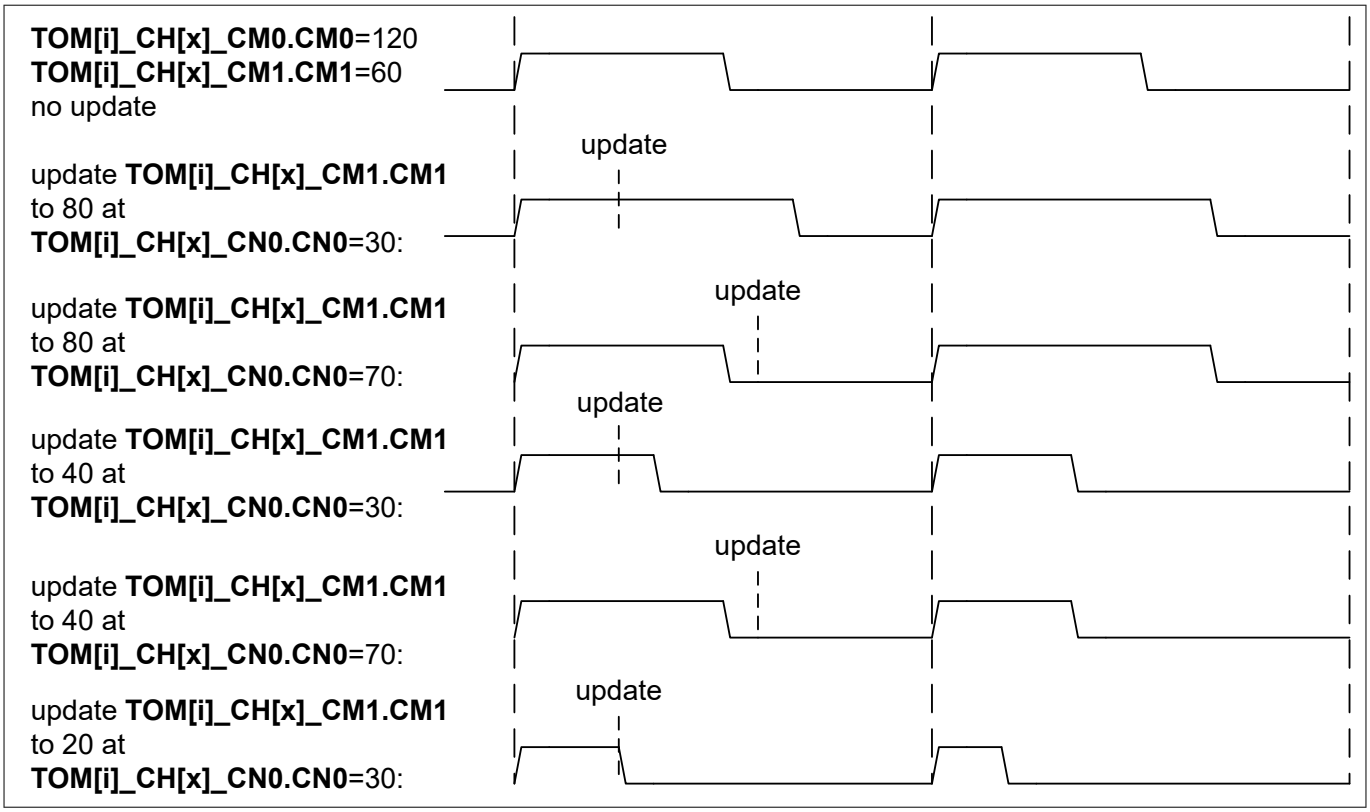

Figure 1063 Asynchronous update of pulse width only

44.3.1.7.4 Continuous counting up mode

In continuous counting up mode, the **TOM** channel starts incrementing the counter CLSi_TOM_CHx_CN0.CN0 once it is enabled by setting the corresponding bits in register CLSi_TOM_TGCg_ENDIS_STAT (refer to TGC sub-unit for details of enabling a **TOM** channel). In this mode with CLSi_TOM_CHx_CTRL.UDMODE=00_B (i.e. CLSi_TOM_CHx_CN0.CN0 counts only up), depending on configuration bits CLSi_TOM_CHx_CTRL.RST_CCU0 the counter register CLSi_TOM_CHx_CN0.CN0 can be reset either when the counter value is equal to the compare value CLSi_TOM_CHx_CM0.CM0 (i.e. CLSi_TOM_CHx_CN0.CN0 counts only from 0 to CLSi_TOM_CHx_CM0.CM0-1 and is then reset to 0) or when the trigger signal TOM_CH_TRIGOUT[x-1:x-1] of the preceding channel x-1 (which can also be the last channel of preceding instance **TOM[i-1]**) is captured by the **TOM[i]** or when there is trigger signal TOM_EXT_TRIGIN[x:x] from **TIM[i]** after it was synchronized to the selected clock resolution signal.

In this case, if CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7)=10_B, also the operation register CLSi_TOM_CHx_CM0.CM0, CLSi_TOM_CHx_CM1.CM1, CLSi_TOM_CHx_CTRL.SL and CLSi_TOM_CHx_CTRL.CLK_SRC are updated from their shadow registers together with CLSi_TOM_CHx_CN0.CN0 reset.

The duration of the pulse high or low time and period is measured with the counter in sub-unit CCU0. The trigger of the counter is one of the eight fixed **CMU** clock signals configurable in the channel control register CLSi_TOM_CHx_CTRL.CLK_SRC. The register CLSi_TOM_CHx_CM0.CM0 holds the duration of the period and the register CLSi_TOM_CHx_CM1.CM1 holds the duration of the pulse width in clock ticks of the selected **CMU** clock SEL_FXCMU_CLKEN. The signal level of the generated output signal can be configured with the configuration bit CLSi_TOM_CHx_CTRL.SL.

If counter CLSi_TOM_CHx_CN0.CN0 of channel x is reset by its own CCU0 unit (i.e. the compare match of CLSi_TOM_CHx_CN0.CN0>=CLSi_TOM_CHx_CM0.CM0-1 configured by CLSi_TOM_CHx_CTRL.RST_CCU0=0), the PWM output behavior is shown in Figure 1064 and the following statements are valid:

- After **TOM** i channel x is enabled, CLSi_TOM_CHx_CN0.CN0 counts firstly from its initial value to CLSi_TOM_CHx_CM0.CM0-1 and is then reset to 0. This phase is defined as initial delay that can be flexibly configured as by the value of (CLSi_TOM_CHx_CM0.CM0-CLSi_TOM_CHx_CN0.CN0) multiplied with the selected fixed **CMU** clock period.
- When CLSi_TOM_CHx_CN0.CN0 is reset from CLSi_TOM_CHx_CM0.CM0-1 to 0, an edge to CLSi_TOM_CHx_CTRL.SL is generated.
- When CLSi_TOM_CHx_CN0.CN0 is incrementing and reaches CLSi_TOM_CHx_CM1.CM1 (CLSi_TOM_CHx_CN0.CN0>=CLSi_TOM_CHx_CM1.CM1), an edge to !CLSi_TOM_CHx_CTRL.SL is generated.
- CLSi_TOM_CHx_CN0.CN0 always counts from 0 to CLSi_TOM_CHx_CM0.CM0-1 and is then reset to 0.
- If CLSi_TOM_CHx_CM0.CM0=0 or CLSi_TOM_CHx_CM0.CM0=1, the counter CLSi_TOM_CHx_CN0.CN0 is constant 0. It is highly recommended to configure CLSi_TOM_CHx_CM0.CM0>1.
- If CLSi_TOM_CHx_CM1.CM1=0 and CLSi_TOM_CHx_CM0.CM0>1, the output is !CLSi_TOM_CHx_CTRL.SL (i.e. 0% duty cycle PWM signal).
- If CLSi_TOM_CHx_CM1.CM1 >= CLSi_TOM_CHx_CM0.CM0 and CLSi_TOM_CHx_CM0.CM0>1, the output is CLSi_TOM_CHx_CTRL.SL (i.e. 100% duty cycle PWM signal).

Since the TOM_OUT[x:x] signal level is defined as !CLSi_TOM_CHx_CTRL.SL when the **TOM** channel is disabled without setting freeze mode, the first PWM period can be shifted earlier by writing an initial offset value to CLSi_TOM_CHx_CN0.CN0 register. By doing this, the **TOM** channel first counts until CLSi_TOM_CHx_CN0.CN0 reaches CLSi_TOM_CHx_CM0.CM0 and then it toggles the output signal at TOM_OUT[x:x].

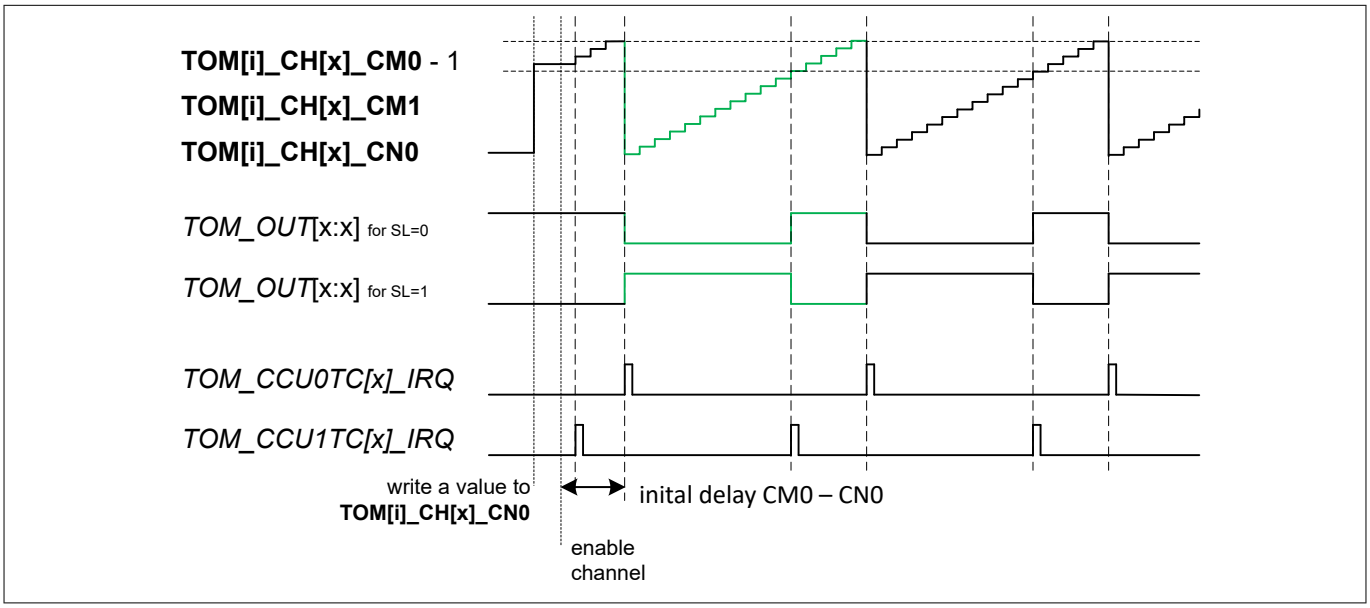

Figure 1064 PWM **output behavior with respect to the** CLSi_TOM_CHx_CTRL.SL **bit in continuous counting up mode if** CLSi_TOM_CHx_CTRL.RST_CCU0**=0**

In this case, as shown in Figure 1064, 2 interrupt signals TOM_CCU0TC[x]_IRQ and TOM_CCU1TC[x]_IRQ of channel x can be generated together with output generation TOM_OUT[x:x] and both of them are shown on TOM_IRQ[x:x] if CLSi_TOM_CHx_IRQ_EN=11_B. When CLSi_TOM_CHx_CN0.CN0 is reset from CLSi_TOM_CHx_CM0.CM0 -1 to 0, TOM_CCU0TC[x]_IRQ of channel x is generated. When CLSi_TOM_CHx_CN0.CN0 is incrementing to reach CLSi_TOM_CHx_CM1.CM1, TOM_CCU1TC[x]_IRQ of channel x is generated. Especially, if the initial configuration before enabling the channel fulfills the condition CLSi_TOM_CHx_CN0.CN0 >= CLSi_TOM_CHx_CM1.CM1 - 1, an interrupt is generated after 1 fixed **CMU** clock period on TOM_CCU1TC[x]_IRQ. Similarly but not shown in the figure, if the initial configuration before enabling the channel fulfills the condition CLSi_TOM_CHx_CN0.CN0 >= CLSi_TOM_CHx_CM0.CM0 - 1, an interrupt is generated after 1 selected **CMU** clock period on TOM_CCU0TC[x]_IRQ. The interrupt signals are always aligned with the edges of the output TOM_OUT[x:x].

If the counter register CLSi_TOM_CHx_CN0.CN0 of channel x is reset by the trigger signal coming from another channel or the assigned **TIM** module (configured by CLSi_TOM_CHx_CTRL.RST_CCU0=1), the PWM output behavior is shown in Figure 1065 and the following statements are valid (with MAX=number of selected CCM[i]_FXCLK_RES cycle between two trigger signals):

- CLSi_TOM_CHx_CN0.CN0 counts from 0 to MAX-1 and is then reset to 0 with the falling edge of TOM_CH_TRIGIN[x:x] or falling edge of TOM_EXT_TRIGIN_S that is synchronized signal TOM_EXT_TRIGIN[x:x] (see External trigger interface).
- If CLSi_TOM_CHx_CN0.CN0 reaches CLSi_TOM_CHx_CM1.CM1, an edge to !CLSi_TOM_CHx_CTRL.SL is generated.
- If CLSi_TOM_CHx_CN0.CN0 reaches CLSi_TOM_CHx_CM0.CM0, an edge to CLSi_TOM_CHx_CTRL.SL is generated.
- As soon as CLSi_TOM_CHx_CN0.CN0 reaches the value of CLSi_TOM_CHx_CM0.CM0 while CLSi_TOM_CHx_CM1.CM1 is equal to CLSi_TOM_CHx_CM0.CM0, an edge to CLSi_TOM_CHx_CTRL.SL is generated at the output or the output remains at CLSi_TOM_CHx_CTRL.SL level depending on the former level of the output (CLSi_TOM_CHx_CM0.CM0 has higher priority). Please note that this configuration is not suitable for generating 100% duty cycle.
- If CLSi_TOM_CHx_CM0.CM0=0 and CLSi_TOM_CHx_CM1.CM1>MAX, the output is a pulse of CLSi_TOM_CHx_CTRL.SL for the period MAX (i.e. 100% duty cycle PWM signal).
- If CLSi_TOM_CHx_CM0.CM0 > MAX and CLSi_TOM_CHx_CM1.CM1=0, the output is ! CLSi_TOM_CHx_CTRL.SL (i.e. 0% duty cycle PWM signal).
- If CLSi_TOM_CHx_CM0.CM0 is set to MAX, an edge to CLSi_TOM_CHx_CTRL.SL is generated at the output at the very end of the current period or the output remains at the CLSi_TOM_CHx_CTRL.SL level, depending on the previous level of the output. Be aware that this applies even if the value of CLSi_TOM_CHx_CM1.CM1 is updated to 0 for the new period (CLSi_TOM_CHx_CM0.CM0 has higher priority).

In this case, as shown in Figure 1065, 2 interrupt signals TOM_CCU0TC[x]_IRQ and TOM_CCU1TC[x]_IRQ of channel x can be generated together with output generation TOM_OUT[x:x] and both of them can be shown on TOM_IRQ[x:x] if CLSi_TOM_CHx_IRQ_EN=11_B. TOM_CCU0TC[x]_IRQ of channel x is generated when CLSi_TOM_CHx_CN0.CN0 reaches CLSi_TOM_CHx_CM0.CM0 while TOM_CCU1TC[x]_IRQ of channel x is generated when CLSi_TOM_CHx_CN0.CN0 reaches CLSi_TOM_CHx_CM1.CM1.

The hardware ensures that for both 0% and 100% duty cycle no glitch occurs at the output of the **TOM** channel.

In case of CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7)=10_B, when the counter value CLSi_TOM_CHx_CN0.CN0 reaches the compare value in register CLSi_TOM_CHx_CM0.CM0 (in fact CLSi_TOM_CHx_CM0.CM0-1) if CLSi_TOM_CHx_CTRL.RST_CCU0=0 or the channel captures the falling edge of the trigger signal if CLSi_TOM_CHx_CTRL.RST_CCU0=1, the operation registers CLSi_TOM_CHx_CM0.CM0, CLSi_TOM_CHx_CM1.CM1, CLSi_TOM_CHx_CTRL.SL and CLSi_TOM_CHx_CTRL.CLK_SRC are updated with the content of their shadow registers CLSi_TOM_CHx_SR0.SR0, CLSi_TOM_CHx_SR1.SR1, CLSi_TOM_CHx_CTRL_SR.SL_SR and CLSi_TOM_CHx_CTRL_SR.CLK_SRC_SR.

The operation registers CLSi_TOM_CHx_CM0.CM0, CLSi_TOM_CHx_CM1.CM1, CLSi_TOM_CHx_CTRL.SL and CLSi_TOM_CHx_CTRL.CLK_SRC can also be asynchronously updated from their shadow registers with the force update mechanism. Please refer to Pulse width, period, signal level and clock frequency update mechanisms for the force update configuration steps and more details. In continuous counting up mode, the force update mechanism can be also used to stop the current running PWM signal generation and restart a new PWM period with new PWM parameters by additionally setting CLSi_TOM_TGCg_FUPD_CTRL.RSTCN0_CHc (c=0-7) = 10_B together with CLSi_TOM_TGCg_FUPD_CTRL.FUPD_CTRLc (c=0-7) = 10_B. That means the force update event will not only update the operation registers from their shadow registers, but also simultaneously reset the counter to restart the next new PWM period with setting the output as CLSi_TOM_CHx_CTRL.SL if CLSi_TOM_CHx_CTRL.RST_CCU0=0 or without changing the output if CLSi_TOM_CHx_CTRL.RST_CCU0=1.

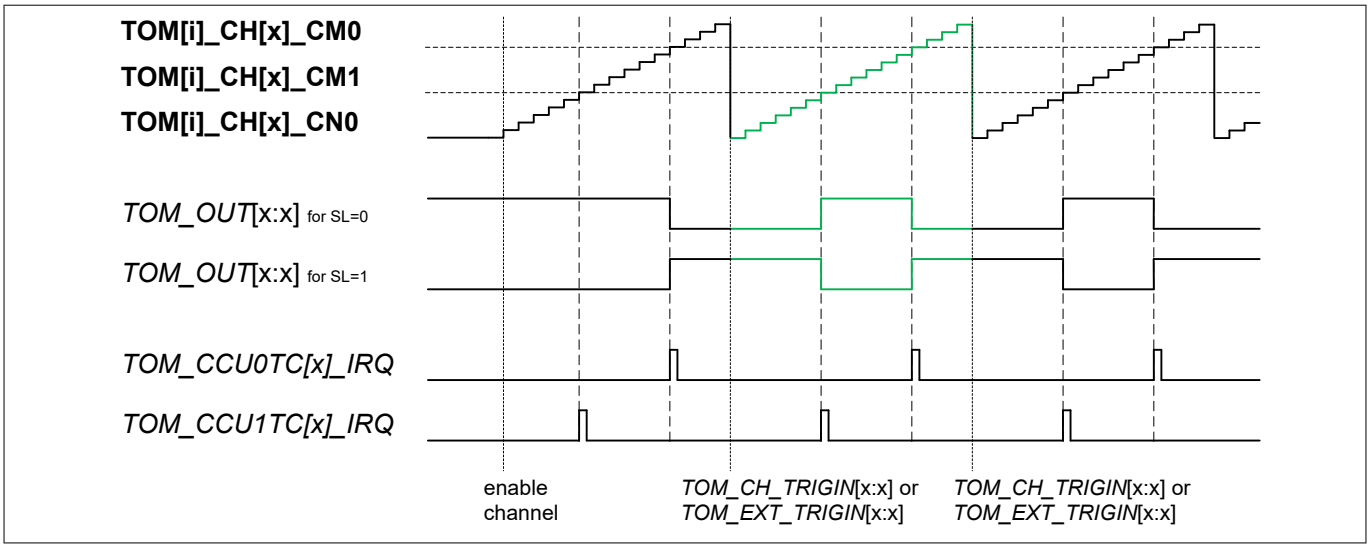

Figure 1065 PWM **output behavior with respect to the** CLSi_TOM_CHx_CTRL.SL **bit in continuous counting up mode if** CLSi_TOM_CHx_CTRL.RST_CCU0**=1**

44.3.1.7.5 Continuous counting up-down mode

In continuous counting up-down mode, if CLSi_TOM_CHx_CN0.CN0 counts up and down (CLSi_TOM_CHx_CTRL.UDMODE != 00_B). Depending on configuration bits CLSi_TOM_CHx_CTRL.RST_CCU0, the counter CLSi_TOM_CHx_CN0.CN0 changes the direction either when the counter value is equal to the compare value CLSi_TOM_CHx_CM0.CM0-1, or when has counted down to 0 or when triggered by the internal trigger signal TOM_CH_TRIGIN[x:x] (i.e. TOM_CH_TRIGOUT[x-1:x-1] from the preceding channel [x-1]) or the external trigger signal TOM_EXT_TRIGIN[x:x] from **TIM** module [i].

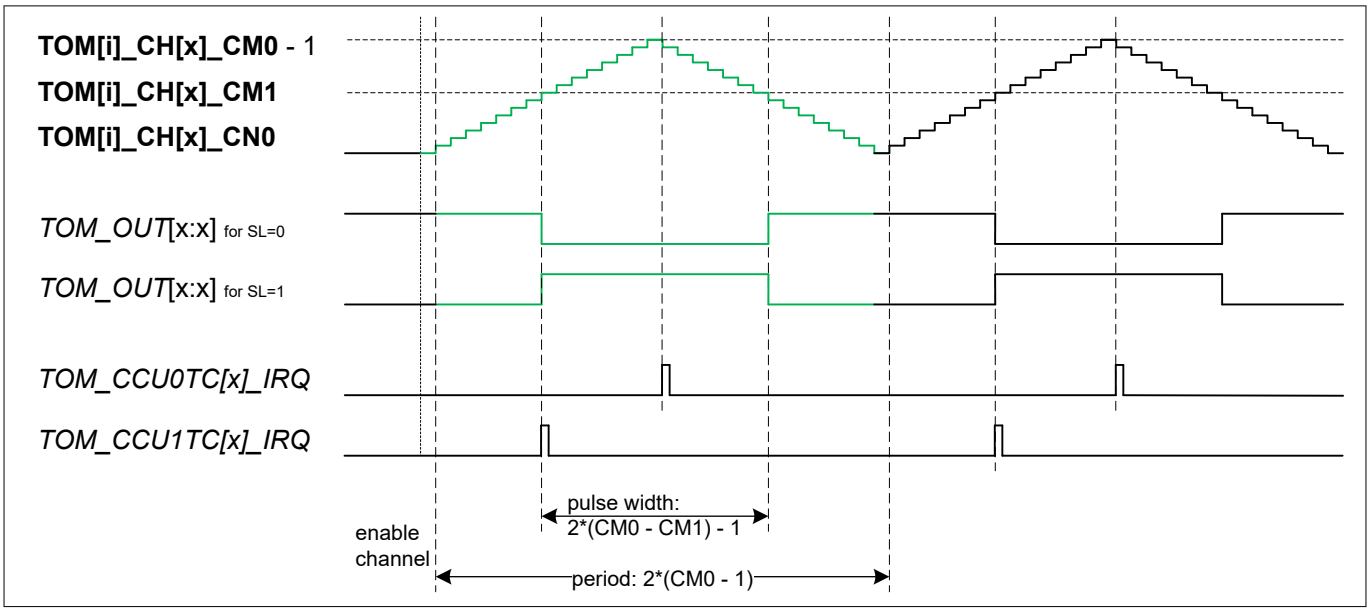

Figure 1066 PWM **output behavior with respect to the** CLSi_TOM_CHx_CTRL.SL **bit in continuous counting up-down mode if** CLSi_TOM_CHx_CTRL.RST_CCU0**=0**

The clock of the counter CLSi_TOM_CHx_CN0.CN0 can be one of the **CMU** clocks CCM[i]_FXCLK_RES.

The clock for CLSi_TOM_CHx_CN0.CN0 is defined by CLSi_TOM_CHx_CTRL.CLK_SRC value in register CLSi_TOM_CHx_CTRL.

If CLSi_TOM_CHx_CTRL.RST_CCU0=0, the counter register CLSi_TOM_CHx_CN0.CN0 of channel x will change its counting direction by the compare match of CLSi_TOM_CHx_CN0.CN0>=CLSi_TOM_CHx_CM0.CM0-1 in its own CCU0 unit and the following statements are valid:

- In each PWM period, CLSi_TOM_CHx_CN0.CN0 firstly counts continuously up from 1 to CLSi_TOM_CHx_CM0.CM0-1 and then down to 0. So period = 2*(CLSi_TOM_CHx_CM0.CM0-1).
- If CLSi_TOM_CHx_CN0.CN0 >= CLSi_TOM_CHx_CM1.CM1, the output is TOM_OUT[x:x] set to CLSi_TOM_CHx_CTRL.SL.
- If CLSi_TOM_CHx_CN0.CN0 < CLSi_TOM_CHx_CM1.CM1, the output is TOM_OUT[x:x] set to ! CLSi_TOM_CHx_CTRL.SL. So pulse width = 2*(CLSi_TOM_CHx_CM0.CM0-CLSi_TOM_CHx_CM1.CM1)-1.
- If CLSi_TOM_CHx_CM0.CM0 <= 1, the counter behavior of CLSi_TOM_CHx_CN0.CN0 is unexpected (not recommended).
- If CLSi_TOM_CHx_CM1.CM1 = 0 and also CLSi_TOM_CHx_CM0.CM0 > 1, the output TOM_OUT[x:x] is CLSi_TOM_CHx_CTRL.SL (i.e. 100% duty cycle).
- If CLSi_TOM_CHx_CM1.CM1 >= CLSi_TOM_CHx_CM0.CM0 and also CLSi_TOM_CHx_CM0.CM0 > 1, the output TOM_OUT[x:x] is !CLSi_TOM_CHx_CTRL.SL (i.e. 0% duty cycle).

This behavior is depicted in Figure 1066. In this case, if CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) **(c=x)** =1, the operation registers CLSi_TOM_CHx_CM0.CM0, CLSi_TOM_CHx_CM1.CM1, CLSi_TOM_CHx_CTRL.SL and CLSi_TOM_CHx_CTRL.CLK_SRC can be updated when CLSi_TOM_CHx_CN0.CN0 = 0 (i.e. counting direction changes from down to up) or CLSi_TOM_CHx_CN0.CN0 reaches CLSi_TOM_CHx_CM0.CM0-1 (i.e. counting direction changes from up to down) depending on various configurations of CLSi_TOM_CHx_CTRL.UDMODE (see the register description for more details). It is particularly not recommended to change the value of CLSi_TOM_CHx_CM0.CM0, CLSi_TOM_CHx_CTRL.SL and CLSi_TOM_CHx_CTRL.CLK_SRC when CLSi_TOM_CHx_CN0.CN0 reaches CLSi_TOM_CHx_CM0.CM0-1. Otherwise, the behavior may be unexpected.

Like continuous counting up mode, interrupt signals TOM_CCU0TC[x]_IRQ and TOM_CCU1TC[x]_IRQ of channel x are generated together with PWM signal output edges. When CLSi_TOM_CHx_CN0.CN0 reaches CLSi_TOM_CHx_CM1.CM1 at the first time and the first edge is generated, an interrupt on TOM_CCU1TC[x]_IRQ is generated. When CLSi_TOM_CHx_CN0.CN0 changes its counting direction from up to down, an interrupt on TOM_CCU0TC[x]_IRQ is generated.

If CLSi_TOM_CHx_CTRL.RST_CCU0=1, the counter register CLSi_TOM_CHx_CN0.CN0 of channel x will change its counting direction by the trigger signal coming from another channel or the assigned **TIM** module and the following statements are valid:

- CLSi_TOM_CHx_CN0.CN0 firstly counts continuously up. At the falling edge of the trigger signal pulse TOM_CH_TRIGIN[x:x] or TOM_EXT_TRIGIN_S (the synchronized signal TOM_EXT_TRIGIN[x:x], see External trigger interface), the counter switches to count down mode. If CLSi_TOM_CHx_CN0.CN0 reaches 0, it will count up again.
- If CLSi_TOM_CHx_CN0.CN0 >= CLSi_TOM_CHx_CM1.CM1, the output TOM_OUT[x:x] is set to CLSi_TOM_CHx_CTRL.SL.
- If CLSi_TOM_CHx_CN0.CN0 < CLSi_TOM_CHx_CM1.CM1, the output is TOM_OUT[x:x] set to ! CLSi_TOM_CHx_CTRL.SL.
- If CLSi_TOM_CHx_CM1.CM1 = 0, the output TOM_OUT[x:x] is CLSi_TOM_CHx_CTRL.SL (i.e. 100% duty cycle).
- If CLSi_TOM_CHx_CN0.CN0 >= CLSi_TOM_CHx_CM0.CM0, the output TOM_OUT_T[x:x] is set to CLSi_TOM_CHx_CTRL.SL.
- If CLSi_TOM_CHx_CN0.CN0 < CLSi_TOM_CHx_CM0.CM0, the output is TOM_OUT_T[x:x] set to ! CLSi_TOM_CHx_CTRL.SL.
- If CLSi_TOM_CHx_CM0.CM0 = 0, the output TOM_OUT_T[x:x] is CLSi_TOM_CHx_CTRL.SL (i.e. 100% duty cycle).

This behavior is depicted in Figure 1067. In this case, if CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) **(c=x)**

=1, the operation registers CLSi_TOM_CHx_CM0.CM0, CLSi_TOM_CHx_CM1.CM1, CLSi_TOM_CHx_CTRL.SL and CLSi_TOM_CHx_CTRL.CLK_SRC can also be updated when CLSi_TOM_CHx_CN0.CN0 = 0 (i.e. counting direction changes from down to up) or CLSi_TOM_CHx_CN0.CN0 reaches its maximum value (i.e. counting direction changes from up to down) depending on various configurations of CLSi_TOM_CHx_CTRL.UDMODE (see the register description for more details). Especially, it is not recommended to change the value of CLSi_TOM_CHx_CTRL.SL and CLSi_TOM_CHx_CTRL.CLK_SRC when CLSi_TOM_CHx_CN0.CN0 its maximum value (i.e. counting direction changes from up to down). Otherwise, the behavior may be unexpected.

If CLSi_TOM_CHx_IRQ_EN=11_B, interrupt signals TOM_CCU0TC[x]_IRQ and TOM_CCU1TC[x]_IRQ of channel x are generated together with PWM signal output. When CLSi_TOM_CHx_CN0.CN0 reaches CLSi_TOM_CHx_CM1.CM1 at the first time and the first edge of TOM_OUT[x:x] is generated, an interrupt on TOM_CCU1TC[x]_IRQ is generated. When CLSi_TOM_CHx_CN0.CN0 reaches CLSi_TOM_CHx_CM0.CM0 at the first time and the first edge of TOM_OUT_T[x:x] is generated, an interrupt on TOM_CCU0TC[x]_IRQ is generated.

In case of continuous counting up-down mode and CLSi_TOM_CHx_CTRL.RST_CCU0=1, it is recommended to configure the **TOM** channel according to the following statements:

- The triggering channel and the triggered channel are both running in up-down mode.
- The time between two trigger signals is equal to the time needed for CLSi_TOM_CHx_CN0.CN0 of triggered channel to count back to 0 and again up to the same upper value.

The second recommendation can be fulfilled by synchronizing the start of the triggering channel and the triggered channel, i.e. let both channels start with CLSi_TOM_CHx_CN0.CN0 = 0 and same clock source.

If there is a pipeline register in the trigger chain, the additional delay of one clock period has to be taken into account by starting the triggering channel with CLSi_TOM_CHx_CN0.CN0 = 1 (i.e. 1 greater than CLSi_TOM_CHx_CN0.CN0 of the triggered channel).

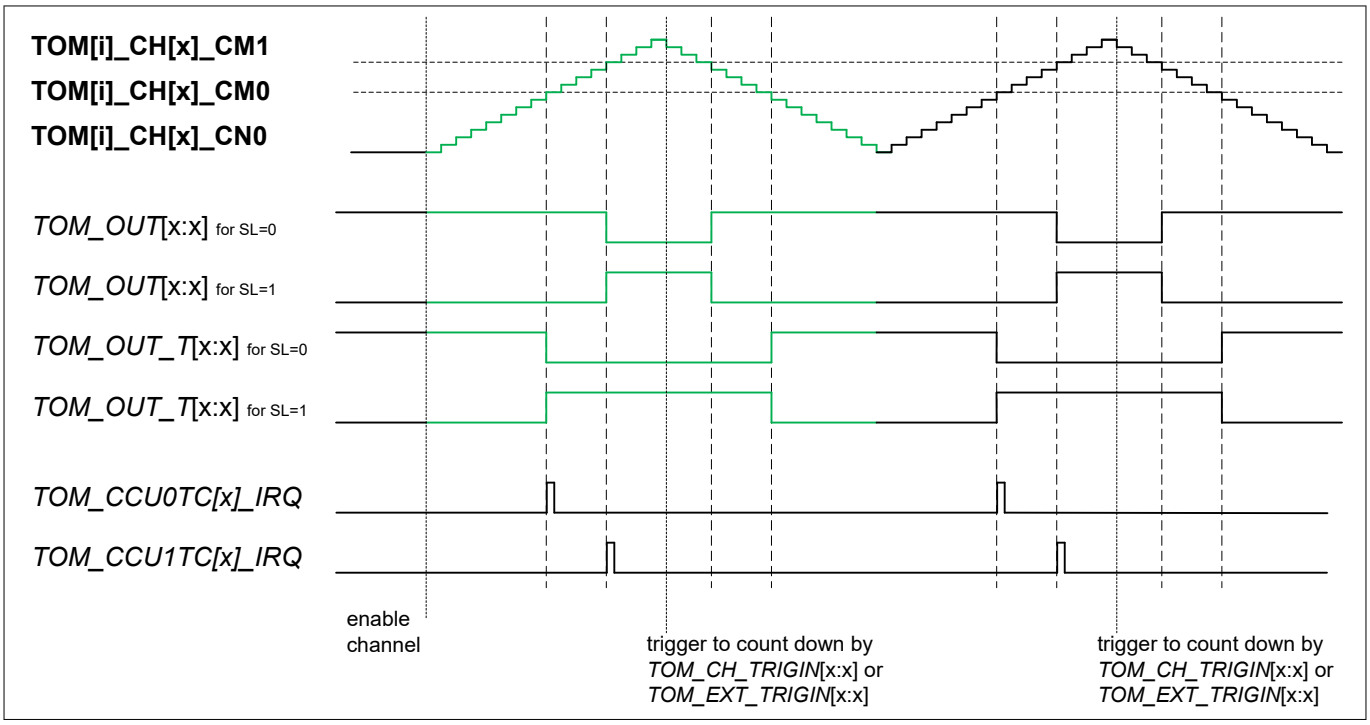

Figure 1067 PWM output behavior with respect to the CLSi_TOM_CHx_CTRL.SL bit in continuous counting up-down mode if CLSi_TOM_CHx_CTRL.RST_CCU0=1

44.3.1.7.6 One-shot counting up mode

The **TOM** channel can operate in one-shot mode when the CLSi_TOM_CHx_CTRL.OSM bit is set. One-shot mode means that a single pulse with the pulse level defined in bit CLSi_TOM_CHx_CTRL.SL is generated on the output signal.

Firstly, the channel has to be enabled by setting the corresponding CLSi_TOM_TGCg_ENDIS_STAT.ENDIS_STATc (c=0-7).

Unlike in the continuous counting modes, the counter CLSi_TOM_CHx_CN0.CN0 will not be incremented once the channel is enabled. Instead, according to the configuration bit CLSi_TOM_CHx_CTRL.OSM_TRIG, the start of counting and pulse generation is triggered by a write-access of CLSi_TOM_CHx_CN0.CN0 or the internal trigger signal TOM_CH_TRIGIN[x:x] or the external trigger signal TOM_EXT_TRIGIN[x:x].

If **SPE** mode of **TOM[i]** channel x (x∈{2, 6, 7, 8, 9}) is enabled (set bit CLSi_TOM_CHx_CTRL.SPEM (x∈{2, 6, 7, 8, 9})), also the trigger signal SPE[i]_NIPD can trigger the reset of register CLSi_TOM_CHx_CN0.CN0 to zero and a start of the pulse generation.

When CLSi_TOM_CHx_CTRL.OSM_TRIG=0, a write-access to the register CLSi_TOM_CHx_CN0.CN0 triggers the start of incrementing the counter register CLSi_TOM_CHx_CN0.CN0 and pulse generation.

If the time between the write-access and the first edge generation of one-shot PWM signal is defined as initial delay, the initial delay is determined by the value of (CLSi_TOM_CHx_CM0.CM0-CLSi_TOM_CHx_CN0.CN0) multiplied with the selected **CMU** clock period.

Especially, if writing a value of greater than or equal to CLSi_TOM_CHx_CM0.CM0-1 to CLSi_TOM_CHx_CN0.CN0 and configuring the initial clock source as cluster clock (the clock source at reset state), the initial delay is minimum, i.e. 1 cluster clock period CLS[j]_CLK. That means after the write-access of CLSi_TOM_CHx_CN0.CN0, the first edge of the output with the interrupt will be set in 1 CLS[j]_CLK period.

If the counter CLSi_TOM_CHx_CN0.CN0 is reset from CLSi_TOM_CHx_CM0.CM0-1 back to zero, the first edge at TOM_OUT[x:x] is generated. And the operation phase of the pulse generation starts incrementing CLSi_TOM_CHx_CN0.CN0 from 0 to CLSi_TOM_CHx_CM0.CM0-1 again.

The second edge in the operation phase is generated if CLSi_TOM_CHx_CN0.CN0 increments until it reaches CLSi_TOM_CHx_CM1.CM1.

If the counter CLSi_TOM_CHx_CN0.CN0 reaches the value of CLSi_TOM_CHx_CM0.CM0-1 for the second time, the counter will stop.

Figure 1068 depicts the pulse generation process mentioned above. The generation of the interrupt signals during the generation of the PWM signal is similar as described in continuous counting up mode. Furthermore, if the value written to CLSi_TOM_CHx_CN0.CN0 for triggering or retriggering the counter is greater than or equal to CLSi_TOM_CHx_CM1.CM1-1, an interrupt on TOM_CCU1TC[x]_IRQ is generated after 1 selected **CMU** clock period. Similarly but not shown in the figure, if the value written to CLSi_TOM_CHx_CN0.CN0 for triggering or retriggering the counter is greater than or equal to CLSi_TOM_CHx_CM0.CM0 - 1, an interrupt on TOM_CCU0TC[x]_IRQ is generated after 1 selected **CMU** clock period. Afterwards when CLSi_TOM_CHx_CN0.CN0 is reset from CLSi_TOM_CHx_CM0.CM0 -1 to 0, TOM_CCU0TC[x]_IRQ of channel x is generated. When CLSi_TOM_CHx_CN0.CN0 is incrementing to reach CLSi_TOM_CHx_CM1.CM1, TOM_CCU1TC[x]_IRQ of channel x is generated.

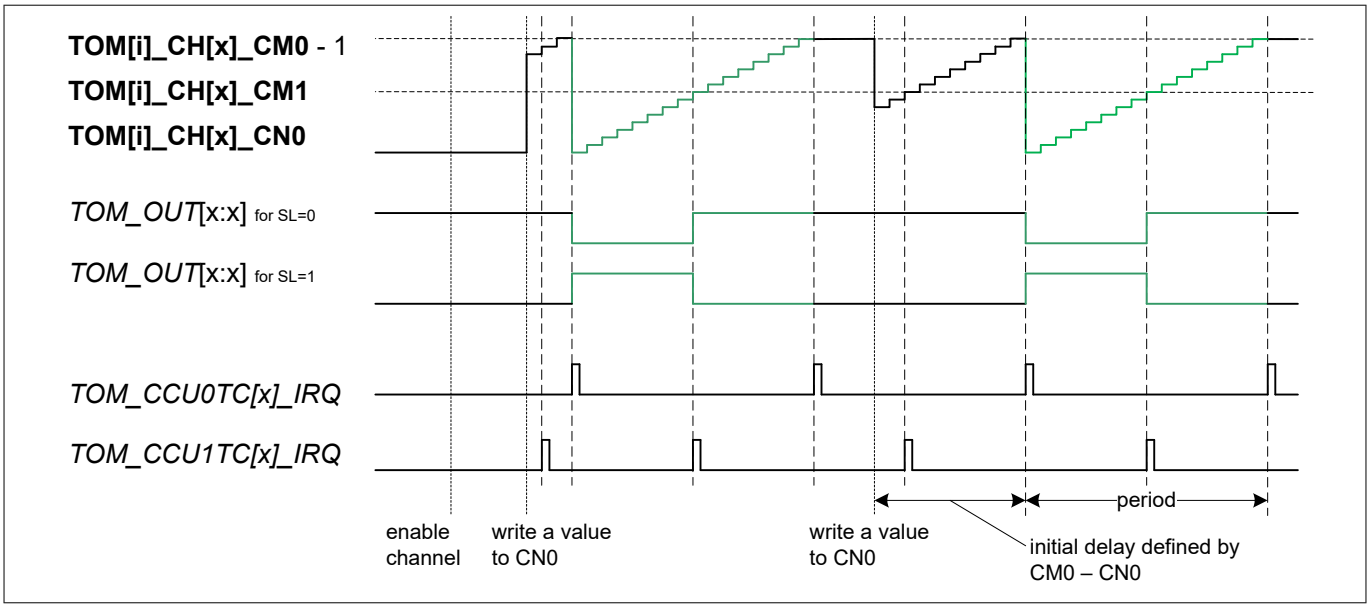

Figure 1068 PWM output with respect to configuration bit CLSi_TOM_CHx_CTRL.SL in one-shot counting up mode if TOM[i]_CH[x]_CRTL.OSM_TRIG=0

Retriggering an one-shot cycle (while CLSi_TOM_CHx_CN0.CN0 is already incrementing) by writing a value to CLSi_TOM_CHx_CN0.CN0 is possible but depends on the phase of CLSi_TOM_CHx_CN0.CN0:

- Phase 1: update of CLSi_TOM_CHx_CN0.CN0 before CLSi_TOM_CHx_CN0.CN0 reaches CLSi_TOM_CHx_CM0.CM0 for the first time (initial phase)
- Phase 2: update of CLSi_TOM_CHx_CN0.CN0 after CLSi_TOM_CHx_CN0.CN0 has reached CLSi_TOM_CHx_CM0.CM0 for the first time until the current single PWM pulse is finished (operation phase)

In phase 1 (initial phase): writing a value CN0(new) to counter CLSi_TOM_CHx_CN0.CN0 (CN0(new)< CLSi_TOM_CHx_CM0.CM0) leads to a shift of the first edge by the time CLSi_TOM_CHx_CM0.CM0-CN0(new), i.e. the first edge is generated when CLSi_TOM_CHx_CN0.CN0 is reset from CLSi_TOM_CHx_CM0.CM0-1 back to 0 for the first time.

In phase 2 (operation phase): writing to counter CLSi_TOM_CHx_CN0.CN0 is not possible and protected by the hardware.

A failed write-access to CLSi_TOM_CHx_CN0.CN0 in phase 2 (operation phase) is indicated by the status register flag CLSi_TOM_CHx_STAT.OSM_RTF.

After one PWM pulse is ended, other single pulses can be further triggered by a write-access to register CLSi_TOM_CHx_CN0.CN0.

It is recommended to enable the update mechanism by setting of CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) = 10_B for retriggering the second one-shot PWM signal generation with different initial delay and different PWM parameters. Similar to the continuous counting up mode with CLSi_TOM_CHx_CTRL.RST_CCU0=0, the operation registers CLSi_TOM_CHx_CM0.CM0/ CLSi_TOM_CHx_CM1.CM1/CLSi_TOM_CHx_CTRL.SL/CLSi_TOM_CHx_CTRL.CLK_SRC are always synchronously updated when CLSi_TOM_CHx_CN0.CN0 reaches CLSi_TOM_CHx_CM0.CM0-1. Firstly, after the first one-shot PWM signal is generated, the new values for initial delay (phase 1) can be written into the shadow registers CLSi_TOM_CHx_SR0.SR0/CLSi_TOM_CHx_SR1.SR1/CLSi_TOM_CHx_CTRL_SR.SL_SR/ CLSi_TOM_CHx_CTRL_SR.CLK_SRC_SR before the retriggering is executed by writing of register CLSi_TOM_CHx_CN0.CN0. The shadow registers should be immediately loaded to the operation registers CLSi_TOM_CHx_CM0.CM0/CLSi_TOM_CHx_CM1.CM1/CLSi_TOM_CHx_CTRL.SL/CLSi_TOM_CHx_CTRL.CLK_SRC, because CLSi_TOM_CHx_CN0.CN0 keeps as CLSi_TOM_CHx_CM0.CM0-1. When CLSi_TOM_CHx_CN0.CN0 is written to be retriggered afterwards, the initial delay is defined according to the updated operation registers. Secondly, during the initial delay phase (phase 1), the new parameters for PWM signal can be written into the shadow registers again. The operational registers will be updated with the shadow registers when

CLSi_TOM_CHx_CN0.CN0 is reset from CLSi_TOM_CHx_CM0.CM0-1 at the end of phase 1 and phase 2 is started to generate the second one-shot PWM signal with the new updated operation registers.

If a channel is configured to one-shot mode and configuration bit CLSi_TOM_CHx_CTRL.OSM_TRIG is set to 1, the trigger signal only triggers start of one pulse generation.

If a channel is configured to one-shot mode and configuration bit CLSi_TOM_CHx_CTRL.OSM_TRIG is set to 1, the trigger signal TOM_CH_TRIGIN[x:x] or TOM_EXT_TRIGIN[x:x] triggers start of pulse generation as shown in Figure 1069. In this case, it is not allowed to write CLSi_TOM_CHx_CN0.CN0 and so the register CLSi_TOM_CHx_STAT.OSM_RTF is not relevant. Otherwise, a write-access to CLSi_TOM_CHx_CN0.CN0 can make an unpredictable output behavior. Furthermore, as shown in Figure 1069, CLSi_TOM_CHx_CN0.CN0 should be initially configured as CLSi_TOM_CHx_CM0.CM0-1 or greater value before enabling the channel. Otherwise, it is hard to define the counting behavior and the initial delay behavior. As shown in Figure 1069, when the channel is enabled, after the falling edge of the trigger pulse TOM_CH_TRIGIN[x:x] or TOM_EXT_TRIGIN_S (the synchronized signal TOM_EXT_TRIGIN[x:x], see External trigger interface), CLSi_TOM_CHx_CN0.CN0 will be triggered to be reset that is synchronous with the next enable high pulse of the selected **CMU** clock source (i.e. synchronous to the next falling edge of the selected **CMU** enable signal). Then it counts from 0 to CLSi_TOM_CHx_CM0.CM0-1. This process is defined as initial phase. If the internal trigger signal TOM_TRIGIN[x:x] is in use and it is synchronous to the selected **CMU** clock source or the external trigger signal TOM_EXT_TRIGIN[x:x] is in use and it must be synchronized to the selected **CMU** clock source before triggering, the initial delay can be defined as the time between the falling edge of the synchronized trigger signal to the point of time of starting the generation of the PWM signal (green phase in the figure), i.e. CLSi_TOM_CHx_CM0.CM0+1 selected **CMU** clock periods. After that, CLSi_TOM_CHx_CN0.CN0 will be reset and counts from 0 to CLSi_TOM_CHx_CM0.CM0-1 at the second time to generate one single PWM signal and then stops. This second counting is defined as operation phase.

After the first OSM signal is generated, the second trigger signal is allowed to be applied to start the counter and generate the next OSM signal after a certain initial delay. Figure 1069 shows such an application of generating 2 OSM signals without changing PWM parameters. In the case, where the second trigger signal is generated, the counter exhibits the same behavior as described above for the first OSM signal generation. That means the initial delay is also CLSi_TOM_CHx_CM0.CM0+1 selected **CMU** clock periods and the OSM signal is the same as the first one.

However, in some real applications of generating various single PWM signals, it is necessary to synchronously update the parameters in CLSi_TOM_CHx_CM0.CM0/CLSi_TOM_CHx_CM1.CM1/CLSi_TOM_CHx_CTRL.SL/CLSi_TOM_CHx_CTRL.CLK_SRC by setting CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7) **(c=x)** = 10_B. In this case, these registers are updated from their shadow registers when CLSi_TOM_CHx_CN0.CN0 is matching CLSi_TOM_CHx_CM0.CM0-1. After the first OSM PWM signal, if CLSi_TOM_CHx_CM0.CM0 is updated with a new value CM0(new) before the second trigger signal comes, the initial delay of the second OSM signal depends on CM0(new) and the value CN0(old) of CLSi_TOM_CHx_CN0.CN0 when the counter stopped at the end of the first OSM signal. The value CN0(old) is actually the value of CLSi_TOM_CHx_CM0.CM0-1 of the first OSM signal before the synchronous update, i.e. CN0(old)=CM0(old)-1. Like the first OSM signal generation, with the falling edge of the second trigger pulse signal, the counter will be retriggered synchronous to the next enable high pulse of the selected **CMU** clock source (i.e. synchronous to the next falling edge of the selected **CMU** enable signal). Assuming the internal trigger signal TOM_TRIGIN[x:x] is in use and it is synchronous to the selected **CMU** clock source or the external trigger signal TOM_EXT_TRIGIN[x:x] is in use and it will be synchronized to the selected **CMU** clock source before triggering, the initial delay can be defined as the time between the falling edge of the second synchronized trigger signal to the point of time of starting the generation of the PWM signal (green phase in the figure). On one hand, if CN0(old) is greater than or equal to updated CM0(new)-1, the counter will be reset and counts up to CM0(new)-1 and the initial delay is CM0(new)+1 selected **CMU** clock periods, i.e. CLSi_TOM_CHx_CM0.CM0+1 selected **CMU** clock periods. The behavior of the counter is the same as described above for the initial delay of the first OSM signal. On the other hand, if CN0(old) is smaller than updated CM0(new)-1, the initial phase or the initial delay is longer. In the initial phase, the counter will count up from CN0(old) to CM0(new)-1 and reset, and then increment again to CM0(new)-1. That means the initial delay is no longer CM0(new)+1, but the larger value of 2*CM0(new)-CN0(old) **CMU** clock periods, i.e. 2*CM0(new)-CM0(old)+1 selected **CMU** clock periods.

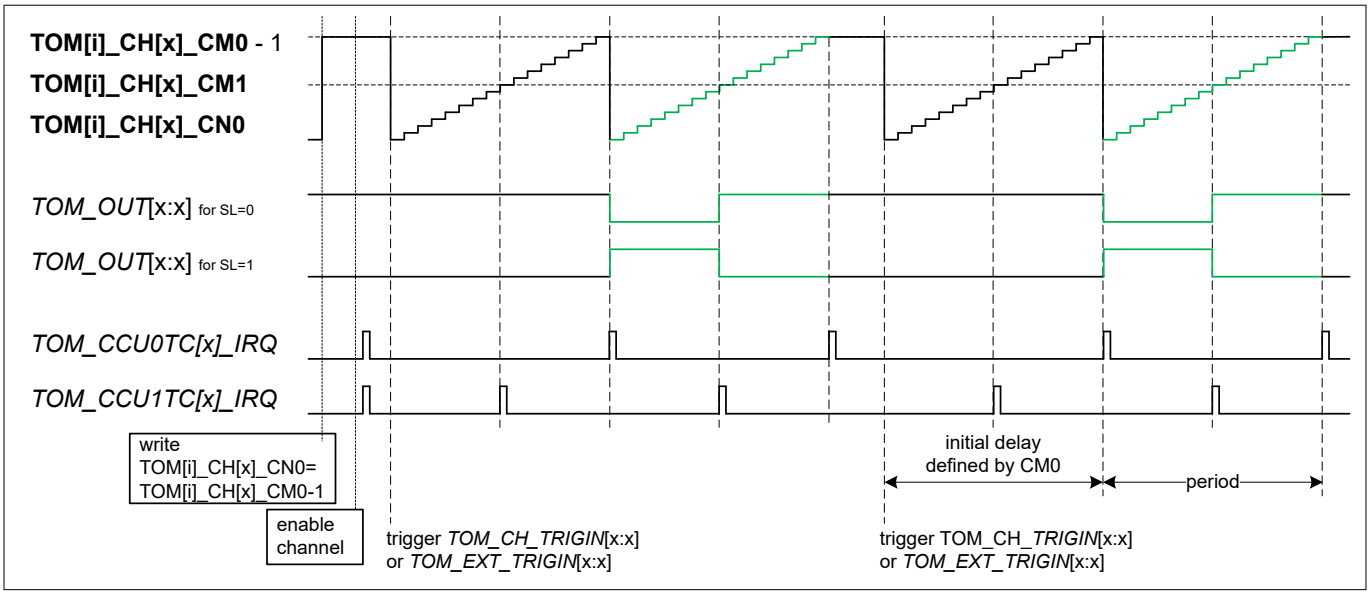

Figure 1069 PWM output with respect to configuration bit CLSi_TOM_CHx_CTRL.SL in one-shot counting mode if CLSi_TOM_CHx_CTRL.OSM_TRIG=1

As shown in Figure 1069, the generation of the interrupt signals during the generation of the PWM signal is similar as described in continuous counting up mode. As before enabling the channel the initial value written to CLSi_TOM_CHx_CN0.CN0 is greater than or equal to CLSi_TOM_CHx_CM0.CM0 - 1 and CLSi_TOM_CHx_CM1.CM1 - 1, both interrupt signals TOM_CCU0TC[x]_IRQ and TOM_CCU1TC[x]_IRQ are generated after 1 selected **CMU** clock period. Afterwards when CLSi_TOM_CHx_CN0.CN0 is reset from CLSi_TOM_CHx_CM0.CM0 -1 to 0, TOM_CCU0TC[x]_IRQ of channel x is generated. When CLSi_TOM_CHx_CN0.CN0 is incrementing to reach CLSi_TOM_CHx_CM1.CM1, TOM_CCU1TC[x]_IRQ of channel x is generated.

In one-shot mode, it is not recommended to configure CLSi_TOM_CHx_CM0.CM0<2. Otherwise, the behavior may be unexpected.

44.3.1.7.7 One-shot counting up-down mode

The **TOM** channel can operate in one-shot counting up-down mode when the bit CLSi_TOM_CHx_CTRL.OSM = 1 and the CLSi_TOM_CHx_CTRL.UDMODE != 00_B. One-shot mode means that a single pulse with the pulse level defined in bit CLSi_TOM_CHx_CTRL.SL is generated on the output signal.

Firstly, the channel has to be enabled by setting the corresponding CLSi_TOM_TGCg_ENDIS_STAT.ENDIS_STATc (c=0-7).

In one-shot mode the counter CLSi_TOM_CHx_CN0.CN0 will not be incremented once the channel is enabled.

When CLSi_TOM_CHx_CTRL.OSM_TRIG=0, a write-access to the register CLSi_TOM_CHx_CN0.CN0 triggers the start of incrementing the counter register CLSi_TOM_CHx_CN0.CN0 and pulse generation.

If the counter CLSi_TOM_CHx_CN0.CN0 is greater than or equal to CLSi_TOM_CHx_CM1.CM1, the output TOM_OUT[x:x] is set to CLSi_TOM_CHx_CTRL.SL value.

If the counter CLSi_TOM_CHx_CN0.CN0 is less than CLSi_TOM_CHx_CM1.CM1, the output TOM_OUT[x:x] is set to !CLSi_TOM_CHx_CTRL.SL value.

If the counter CLSi_TOM_CHx_CN0.CN0 has reached the value 0 (by counting down), it will stop.

The written value of CLSi_TOM_CHx_CN0.CN0 determines the start delay of the first edge. The delay time of the first edge is given by (CLSi_TOM_CHx_CM1.CM1 - CLSi_TOM_CHx_CN0.CN0) multiplied with the period defined by the current value of CLSi_TOM_CHx_CTRL.CLK_SRC.

Figure 1070 depicts the pulse generation in one-shot counting up-down mode. The interrupt signals are generated similarly as described in one-shot counting up mode and continuous counting up-down mode. The write-access of CLSi_TOM_CHx_CN0.CN0 can cause interrupts if the write value is greater than or equal to CLSi_TOM_CHx_CM1.CM1 - 1 or CLSi_TOM_CHx_CM0.CM0 -1. If the value written to CLSi_TOM_CHx_CN0.CN0 for triggering or retriggering the counter is greater than or equal to CLSi_TOM_CHx_CM1.CM1 -1, the output TOM_OUT[x:x] will be set to CLSi_TOM_CHx_CTRL.SL after 1 selected **CMU** clock period together with an interrupt on TOM_CCU1TC[x]_IRQ. Similarly but not shown in the figure, if the value written to CLSi_TOM_CHx_CN0.CN0 for triggering or retriggering the counter is greater than or equal to CLSi_TOM_CHx_CM0.CM0 - 1, an interrupt on TOM_CCU0TC[x]_IRQ will be generated after 1 selected **CMU** clock period. Afterwards when CLSi_TOM_CHx_CN0.CN0 is incrementing to reach CLSi_TOM_CHx_CM1.CM1, an interrupt on TOM_CCU1TC[x]_IRQ is generated. When CLSi_TOM_CHx_CN0.CN0 changes its counting direction from up to down, an interrupt on TOM_CCU0TC[x]_IRQ is generated.

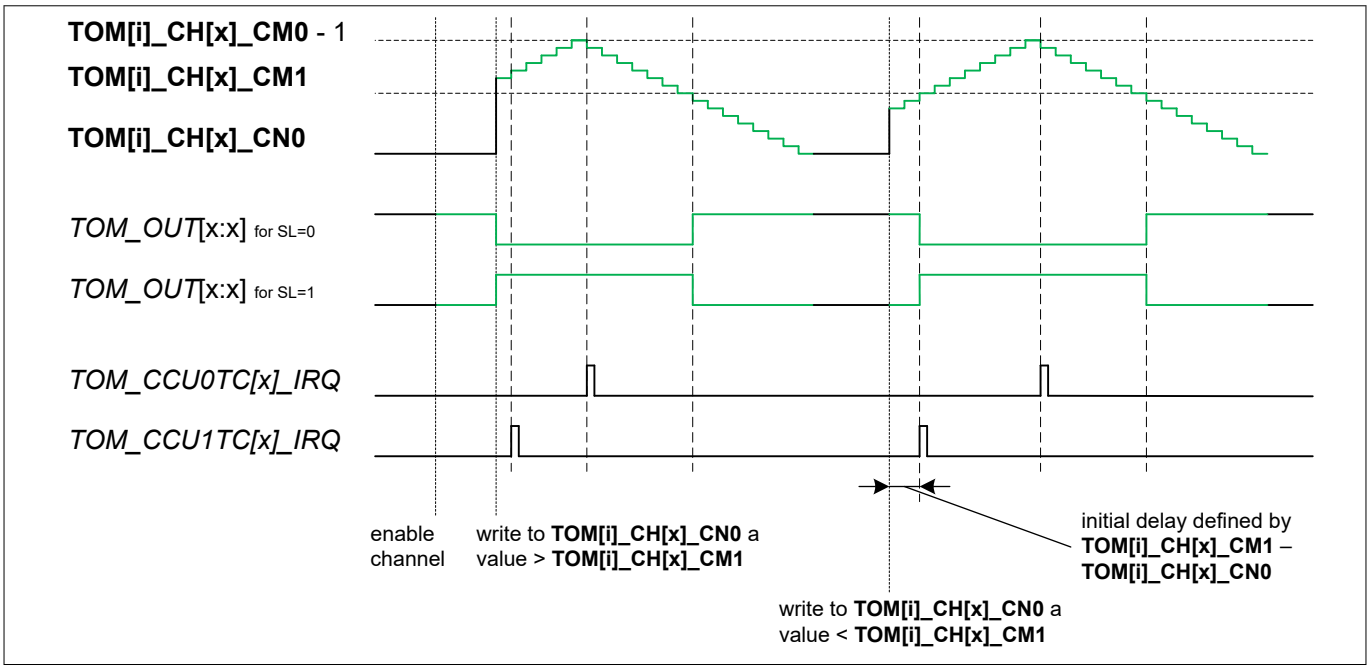

Figure 1070 PWM output with respect to configuration bit CLSi_TOM_CHx_CTRL.SL in one-shot counting up-down mode if TOM[i]_CH[x]_CRTL.OSM_TRIG= 0

Further output of single pulses can be started by writing to register CLSi_TOM_CHx_CN0.CN0.

If a channel is configured to one-shot counting up-down mode and configuration bit CLSi_TOM_CHx_CTRL.OSM_TRIG is set to 1, the falling edge of the trigger signal TOM_CH_TRIGIN[x:x] or TOM_EXT_TRIGIN_S (i.e. in fact the synchronized signal of TOM_EXT_TRIGIN[x:x]) triggers start of incrementing CLSi_TOM_CHx_CN0.CN0 and pulse generation. The output generation with interrupt signals is similar as mentioned above. If the counter CLSi_TOM_CHx_CN0.CN0 is greater than or equal to CLSi_TOM_CHx_CM1.CM1, the output TOM_OUT is set to CLSi_TOM_CHx_CTRL.SL value. Otherwise, the output TOM_OUT is set to ! CLSi_TOM_CHx_CTRL.SL value. When CLSi_TOM_CHx_CN0.CN0 is incrementing to reach CLSi_TOM_CHx_CM1.CM1, an interrupt is generated on TOM_CCU1TC[x]_IRQ. When CLSi_TOM_CHx_CN0.CN0 changes its counting direction from up to down, an interrupt is generated on TOM_CCU0TC[x]_IRQ.

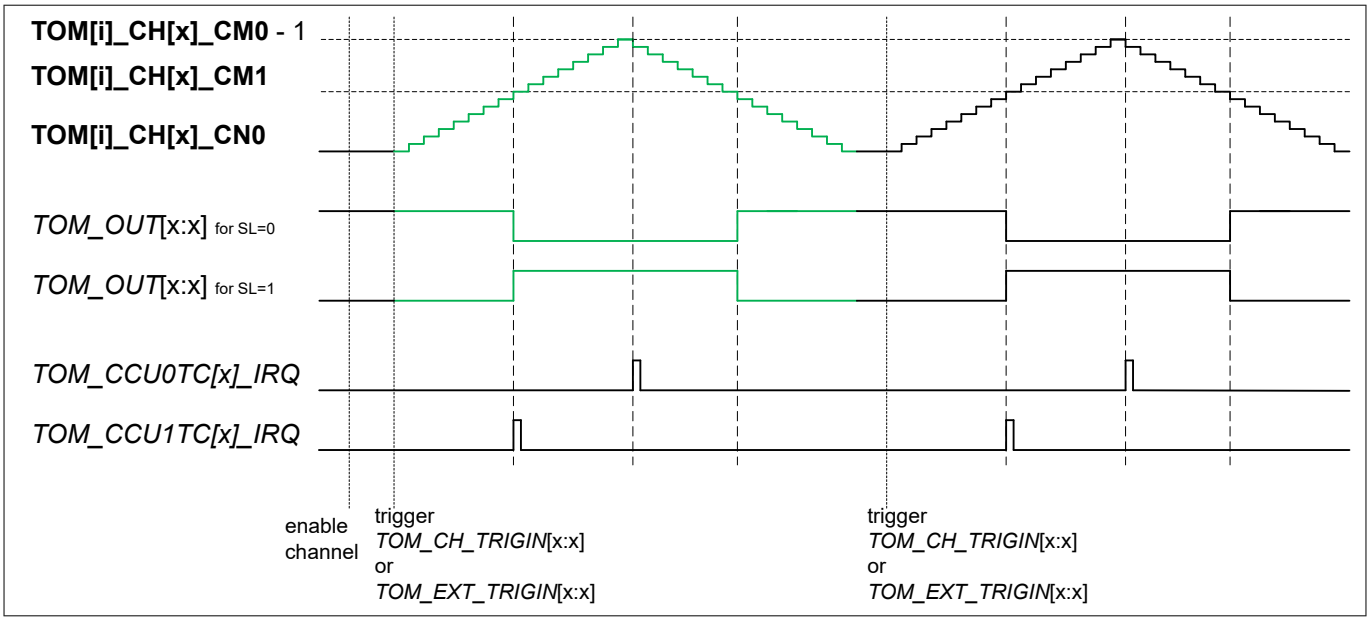

Figure 1071 PWM **output with respect to configuration bit** CLSi_TOM_CHx_CTRL.SL **in one-shot counting up-down mode if TOM[i]_CH[x]_CRTL.OSM_TRIG = 1**

44.3.1.7.8 Pulse count modulation mode

At the output TOM_OUT[15:15] a pulse count modulated signal can be generated instead of the simple PWM output signal. This specific behavior is called pulse count modulation (PCM) mode. PCM mode is only available when CLSi_TOM_CHx_CTRL.UDMODE=0.

Figure 1060 outlines the circuit for Pulse Count Modulation.

The PCM mode is enabled by setting bit CLSi_TOM_CHx_CTRL.BITREV to 1.

The PCM mode is only available for **TOM** channel 15.

With the configuration bit CLSi_TOM_CHx_CTRL.BITREV=1 a bit reversing of the counter output CLSi_TOM_CHx_CN0.CN0 is configured. In this case the bits are swapped, for example, LSB and MSB, LSB+1 and MSB-1, LSB+2 and MSB-2 and so on.

The effect of bit-reversing of the CLSi_TOM_CHx_CN0.CN0 register value is shown in the following Figure 1072.

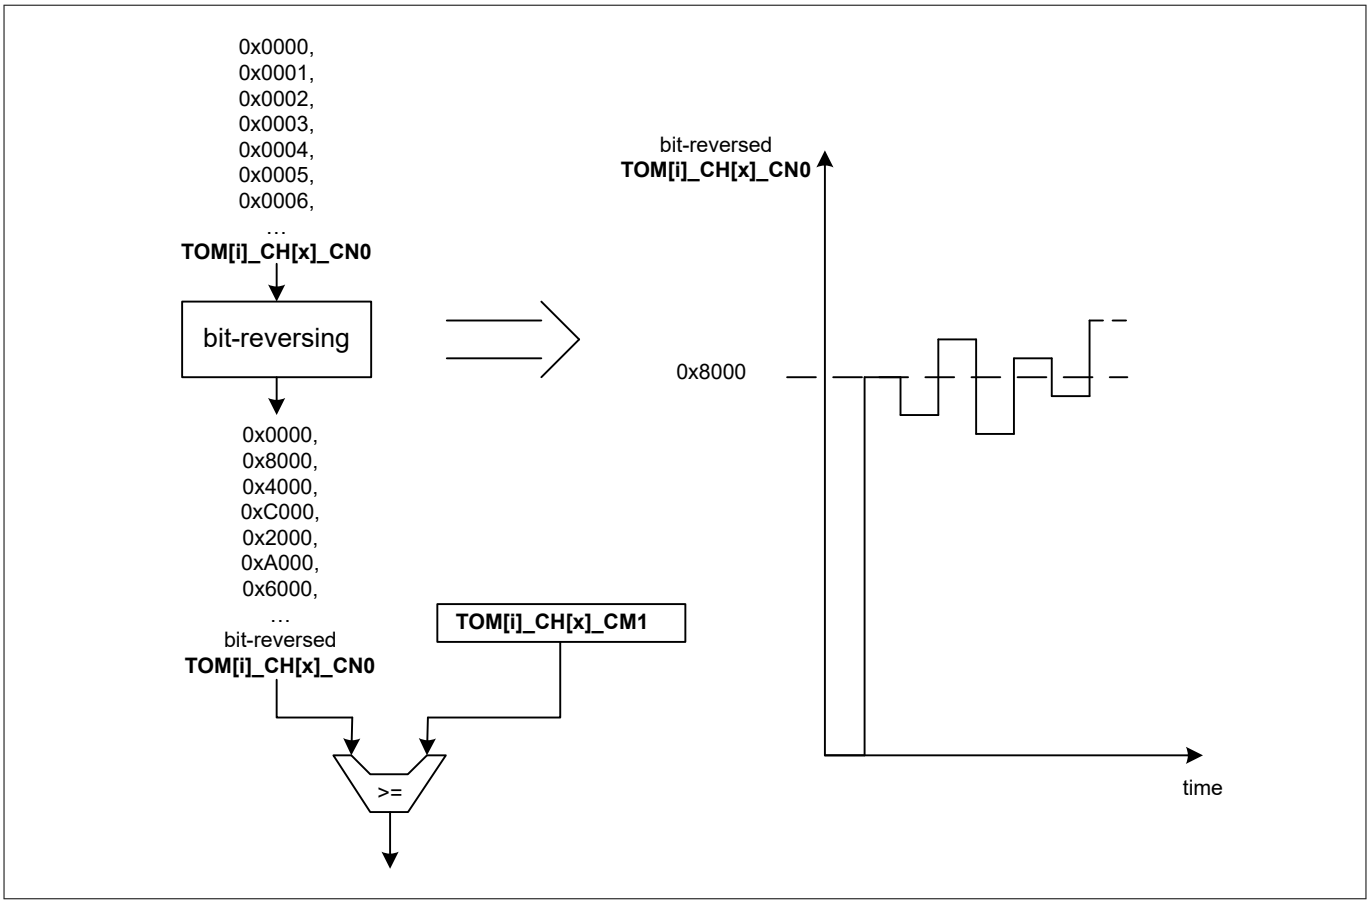

Figure 1072 Bit reversing of counter CLSi_TOM_CHx_CN0.CN0 output

In the PCM mode the counter CLSi_TOM_CHx_CN0.CN0 is incremented by every clock tick depending on configured **CMU** clock (CCM[i]_FXCLK_RES).

The output of counter CLSi_TOM_CHx_CN0.CN0 is first bit-reversed and then compared with the configured register value CLSi_TOM_CHx_CM1.CM1.

When the bit-reversed value of register CLSi_TOM_CHx_CN0.CN0 is greater than or equal to CLSi_TOM_CHx_CM1.CM1, the output TOM_OUT[15:15] is set to !CLSi_TOM_CHx_CTRL.SL and otherwise set to CLSi_TOM_CHx_CTRL.SL.

In PCM mode the CLSi_TOM_CHx_CM0.CM0 register, in which the period is defined, normally has to be set to its maximum value $FFFF_H$.

To reduce time period of updating pulse width value in CLSi_TOM_CHx_CM1.CM1 register, it is additionally possible to setup period value in CLSi_TOM_CHx_CM0.CM0 register to smaller values than the maximum value as described before.

Possible values for CLSi_TOM_CHx_CM0.CM0 register are each even numbered values to the power of 2 e.g. 8000_H, 4000_H, 2000_H ... .

In this case the pulse width has to be configured in the following manner.

Depending on how much the period in CLSi_TOM_CHx_CM0.CM0 register is decreased, means shifted right starting from 10000_H - the pulse width in CLSi_TOM_CHx_CM1.CM1 register has to be shifted left (= rotated: shift MSB back into LSB) with same value, e.g. :

Period CLSi_TOM_CHx_CM0.CM0 = 0100_H -> shifted 8 bits right from 10000_H

--> so pulse width has to be shifted 8 bits left:

e.g. 50% pulse width = 00080_H -> shift 8 bits left -> CLSi_TOM_CHx_CM1.CM1 = 8000_H

Table 2218 PCM examples

CM0 (period)	CM1 (pulse width)	Shift	CM1 (configured value)
$FFFF_H$	8000_H	No shift	8000_H
8000_H	4000_H	Shift 1 bit left	8000_H
4000_H	1000_H	Shift 2 bits left	4000_H
2000_H	$0FFF_H$	Shift 3 bits left	$7FF8_H$
1000_H	0333_H	Shift 4 bits left	3330_H
0800_H	0055_H	Shift 5 bits left	$0AA0_H$
0020_H	0008_H	Shift 11 bits left	4000_H
0010_H	0005_H	Shift 12 bits left	5000_H

In this mode the CLSi_TOM_CHx_IRQ_NOTIFY.CCU1TC (see register CLSi_TOM_CHx_IRQ_NOTIFY) is set every time if bit reverse value of CLSi_TOM_CHx_CN0.CN0 is greater than or equal to CLSi_TOM_CHx_CM1.CM1 which may be multiple times during one period. Therefore, from application point of view it is not useful to enable this interrupt.

44.3.1.7.9 Trigger generation

For applications with constant PWM period defined by CLSi_TOM_CHx_CM0.CM0, it is not necessary to update the CLSi_TOM_CHx_CM0.CM0 register regularly with CLSi_TOM_CHx_SR0.SR0 register. For these applications, the CLSi_TOM_CHx_SR0.SR0 register can be used to define an additional output signal and interrupt trigger event.

If bit CLSi_TOM_CHx_CTRL.SR0_TRIG is set to 1, the register CLSi_TOM_CHx_SR0.SR0 is no longer used as a shadow register for register CLSi_TOM_CHx_CM0.CM0. Instead, CLSi_TOM_CHx_SR0.SR0 is compared with CLSi_TOM_CHx_CN0.CN0. If both are equal, a pulse of signal level '1' is generated at the output TOM_OUT_T[x:x] of instance i, channel x. In this case, CLSi_TOM_CHx_CM1.CM1 will still be synchronously updated from its shadow register CLSi_TOM_CHx_SR1.SR1 if the update is enabled by setting CLSi_TOM_TGCg_GLB_CTRL.UPEN_CTRLc (c=0-7)=10_B.

The bit CLSi_TOM_CHx_CTRL.SR0_TRIG should only be set if bit CLSi_TOM_CHx_CTRL.RST_CCU0 of this channel is 0.

If bit CLSi_TOM_CHx_CTRL.SR0_TRIG=1 is set, the interrupt on TOM_CCU1TC[x]_IRQ is set at the same time with pulse generation on TOM_OUT_T in case of a compare equal match of CLSi_TOM_CHx_SR0.SR0 = CLSi_TOM_CHx_CN0.CN0. If bit CLSi_TOM_CHx_CTRL.SR0_TRIG is set the interrupt notify flag CLSi_TOM_CHx_IRQ_NOTIFY.CCU1TC is no longer set on a compare match of CLSi_TOM_CHx_CM1.CM1 and CLSi_TOM_CHx_CN0.CN0. Instead, the CLSi_TOM_CHx_IRQ_NOTIFY.CCU1TC interrupt notify flag is set in case of a compare equal match of CLSi_TOM_CHx_SR0.SR0 and CLSi_TOM_CHx_CN0.CN0.

With configuration bit CLSi_TOM_CHx_CTRL.TRIG_PULSE one can select if the output TOM_OUT_T[x:x] is high as long as CLSi_TOM_CHx_CN0.CN0= CLSi_TOM_CHx_SR0.SR0 (CLSi_TOM_CHx_CTRL.TRIG_PULSE=0) or if there will be only one pulse of length one cluster clock period when CLSi_TOM_CHx_CN0.CN0 becomes SR0 (CLSi_TOM_CHx_CTRL.TRIG_PULSE=1). Figure 1073 shows the case of CLSi_TOM_CHx_CTRL.TRIG_PULSE=1.

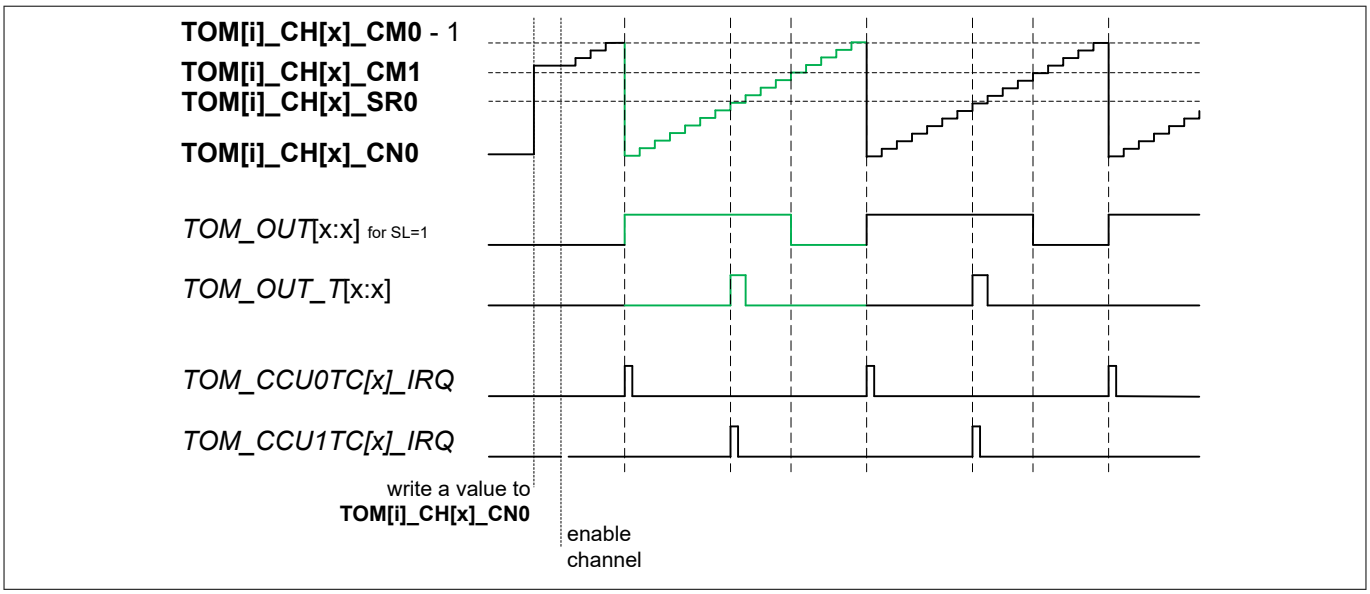

Figure 1073 Output behavior with respect to the CLSi_TOM_CHx_CTRL.TRIG_PULSE=1 in continuous counting up mode if CLSi_TOM_CHx_CTRL.SR0_TRIG=1

TOM/**SPE** interface must not be used when CLSi_TOM_CHx_CTRL.SR0_TRIG is set to 1.

The **TOM** output signal routing to **DTM** or **eGTM** toplevel is described in **DTM** connections on **eGTM** toplevel

44.3.1.7.10 TOM BLDC support

The **TOM** sub-module offers a BLDC support in combination with the **SPE** sub-module. **TOM** channels 0 to 7 can be used to drive a BLDC engine.

The BLDC support can be configured by setting the bit CLSi_TOM_CHx_CTRL.SPEM = 1. If this bit is set, the **TOM** channel output will be controlled through the TOM[i]_SPE_OUT[x:x] signal coming from SPE[i]_OUT[x:x] of the **SPE** sub-module (see Figure 1060). Please refer to Sensor pattern evaluation (**SPE**) for a detailed description of the **SPE** sub-module.

The **TOM[i]** channel [x] (x∈{2, 6, 7, 8, 9}) can be used together with the **SPE** module to trigger a delayed update of CLSi_SPE_OUT_CTRL register (i.e. commutation delay) after new input pattern detected by **SPE** (signaled by SPE[i]_NIPD). This feature is configured on **TOM[i]** channel[x] (x∈{2, 6, 7, 8, 9}) by setting CLSi_TOM_CHx_CTRL.SPE_TRIG=1, CLSi_TOM_CHx_CTRL.SPEM=0 or CLSi_TOM_CHx_CTRL.SPE_TRIG=0, CLSi_TOM_CHx_CTRL.SPEM=1 with CLSi_TOM_CHx_CTRL.OSM=1. With this configuration the **TOM[i]** channel [x] (x∈{2, 6, 7, 8, 9}) generates one single PWM pulse when receiving trigger signal TOM[i]_SPE_NIPD. Then the update of CLSi_SPE_OUT_CTRL register can be triggered by TOM[i]_CH[x]_TRIG_CCU1 that are generated by compare event in CCU1 unit. That means the update of CLSi_SPE_OUT_CTRL can be synchronized to the second edge of the one shot PWM signal.

For details please refer to chapter of **SPE** sub-module description.

Normally the trigger signals TOM[i]_CH[x]_TRIG_CCU0/TOM[i]_CH[x]_TRIG_CCU1 to **SPE** sub-module are single-cycle pulses with the length of one cluster clock-cycle. Depending on the configuration, it may happen that the trigger signal TOM[i]_CH[x]_TRIG_CCU0/TOM[i]_CH[x]_TRIG_CCU1 to **SPE** sub-module is high for two system clock-cycles once at the starting condition.

44.3.1.7.11 TOM gated counter mode

Each **TOM SPE** module combination provides also the feature of a gated counter mode. This is reached by using the *FSOI[i]* input of the **SPE** module i (see Figure 1119) to gate the clock of a CCU0 sub-module.

To configure this mode, register of module **SPE** should be set as following:

- The **SPE** should be enabled (bit CLSi_SPE_CTRL_STAT.EN = 1)
- All three **TIM** inputs should be disabled (CLSi_SPE_CTRL_STAT.SIEk (k=0-2) **(k=0)** = CLSi_SPE_CTRL_STAT.SIEk (k=0-2) **(k=1)** = CLSi_SPE_CTRL_STAT.SIEk (k=0-2) **(k=2)** = 0) according to Figure 1124,
- CLSi_SPE_OUT_CTRL.SPE_OUT_CTRLo (o=0-7) **(o=x)** should be set to 10_B (set TOM[i]_SPE_OUT[x:x] to '0'),
- Mode FSOM should be enabled (CLSi_SPE_CTRL_STAT.FSOM=1), CLSi_SPE_CTRL_STAT.FSOL[x:x] if channel x of module **TOM** i is chosen for gated counter mode

Additionally in module **TOM**:

- The **SPE** mode should be disabled (CLSi_TOM_CHx_CTRL.SPEM=0)
- The gated counter mode should be enabled (CLSi_TOM_CHx_CTRL.GCM=1)

As a result of this configuration, the counter CLSi_TOM_CHx_CN0.CN0 in sub-module CCU0 of **TOM** channel x counts as long as input *FSOI[i]* of the connected **SPE** module is '0'.

44.3.1.7.12 TOM FREEZE mode

It is possible, to disable the **TOM** channel (TOM_ENDIS=0) without changing internal and output register states by setting of CLSi_TOM_CHx_CTRL.FREEZE to 1. After re-enabling again (TOM_ENDIS=1), the channel is started from the state from which it was deactivated (TOM_ENDIS=0).

The following sequence has to be realized to use the FREEZE mode in a reliable manner:

1. **TOM** channel setup and enable by setting TOM_ENDIS=1
2. Setting of CLSi_TOM_CHx_CTRL.FREEZE to 1
3. **TOM** channel disable by setting TOM_ENDIS=0
4. **TOM** channel re-enable by setting TOM_ENDIS=1
5. Setting of CLSi_TOM_CHx_CTRL.FREEZE to 0

***Note**:* CLSi_TOM_CHx_CTRL.FREEZE *must always be set, while the channel is enabled (*TOM_ENDIS*=1).*

44.3.1.7.13 TOM software reset of channels

Each channel x (x=g*2+c) is assigned a unique bit c in the configuration register CLSi_TOM_TGCg_GLB_CTRL for software reset of the **TOM[i]** channel x.

Writing the value 1_B to the bit field CLSi_TOM_TGCg_GLB_CTRL.RST_CHc (c=0-7) via the configuration interface will immediately reset the content of the following channel x registers to the initial hardware reset state. x = g*2+c

- CLSi_TOM_CHx_CTRL
- CLSi_TOM_CHx_CTRL_SR
- CLSi_TOM_CHx_CN0
- CLSi_TOM_CHx_CM0
- CLSi_TOM_CHx_CM1
- CLSi_TOM_CHx_SR0
- CLSi_TOM_CHx_SR1
- CLSi_TOM_CHx_STAT
- CLSi_TOM_CHx_IRQ_NOTIFY
- CLSi_TOM_CHx_IRQ_EN
- CLSi_TOM_CHx_IRQ_MODE
- Internal signals inside the **TOM[i]** channel [x]:

Atomic reset of multiple channels is possible by writing a 1 on each associated bit. E.g.: Writing $0F_H$ to register CLSi_TOM_TGCg_GLB_CTRL **(i=0;g=0)** will reset the TOM0 channel .

44.3.1.7.14 eGTM TOM Configuration Registers Description

Sub-chapter TOM Configuration Registers Description

Table 2219

Register Shortname	Description
CLSi_TOM_TGCg_GLB_CTRL	TOM[i] TGC [g] global control register (g=0-1;i=0-2)
CLSi_TOM_TGCg_ENDIS_CTRL	TOM[i] TGC [g] enable/disable control register (g=0-1;i=0-2)
CLSi_TOM_TGCg_ENDIS_STAT	TOM[i] TGC [g] enable/disable status register (g=0-1;i=0-2)
CLSi_TOM_TGCg_ACT_TB	TOM[i] TGC [g] action time base register (g=0-1;i=0-2)
CLSi_TOM_TGCg_OUTEN_CTRL	TOM[i] TGC [g] output enable control register (g=0-1;i=0-2)
CLSi_TOM_TGCg_OUTEN_STAT	TOM[i] TGC [g] output enable status register (g=0-1;i=0-2)
CLSi_TOM_TGCg_FUPD_CTRL	TOM[i] TGC [g] force update control register (g=0-1;i=0-2)
CLSi_TOM_TGCg_INT_TRIG	TOM[i] TGC [g] internal trigger control register (g=0-1;i=0-2)
CLSi_TOM_CHx_CTRL	TOM[i] channel [x] control register (x=0-1,3-5;i=0-2)
CLSi_TOM_CHx_CTRL	TOM[i] channel [x] control register (x=8-9;i=0-2)
CLSi_TOM_CHx_CTRL	TOM[i] channel [x] control register (x=10-14;i=0-2)
CLSi_TOM_CHx_CTRL	TOM[i] channel [x] control register (x=15;i=0-2)
CLSi_TOM_CHx_CTRL_SR	TOM[i] channel [x] control shadow register (x=0-15;i=0-2)
CLSi_TOM_CHx_CN0	TOM[i] channel [x] CCU0 counter (x=0-15;i=0-2)
CLSi_TOM_CHx_CM0	TOM[i] channel [x] CCU0 compare register (x=0-15;i=0-2)
CLSi_TOM_CHx_SR0	TOM[i] channel [x] CCU0 compare shadow register (x=0-15;i=0-2)
CLSi_TOM_CHx_CM1	TOM[i] channel [x] CCU1 compare register (x=0-15;i=0-2)
CLSi_TOM_CHx_SR1	TOM[i] channel [x] CCU1 compare shadow register (x=0-15;i=0-2)
CLSi_TOM_CHx_STAT	TOM[i] channel [x] status register (x=0-15;i=0-2)
CLSi_TOM_CHx_IRQ_NOTIFY	TOM[i] channel [x] interrupt notification register (x=0-15;i=0-2)
CLSi_TOM_CHx_IRQ_EN	TOM[i] channel [x] interrupt enable register (x=0-15;i=0-2)

(table continues...)

Table 2219 (continued)

Register Shortname	Description
CLSi_TOM_CHx_IRQ_FORCINT	TOM[i] channel [x] force interrupt register (x=0-15;i=0-2)
CLSi_TOM_CHx_IRQ_MODE	TOM[i] channel [x] interrupt mode register (x=0-15;i=0-2)

44.3.1.7.15 TOM signal description

Table 2220 TOM Reset

Name	Description
TOM[j]_RESET_CH[x]	**TOM[j]** channel [x] reset active signal

Table 2221 TOM Interrupt Signals

Name	Description
TOM_CCU1TC[x]_IRQ	CCU1 Trigger condition interrupt for channel x of each **TOM** instance i (i:={0, 1,..., NTOM-1})
TOM_CCU0TC[x]_IRQ	CCU0 Trigger condition interrupt for channel x of each **TOM** instance (i:={0, 1,..., NTOM-1})

Table 2222 TOM Signals

Name	Description
CTRL_TRIG	Trigger signal to update the TGC[g] registers CLSi_TOM_TGCg_OUTEN_STAT, CLSi_TOM_TGCg_ENDIS_STAT and to activate TOM_FUPD signals
TOM_EXT_TRIGIN_S	synchronized TOM_EXT_TRIGIN *[x:x]* (x:={0, 1,..., 15}) signal to selected **CMU** clock source
TOM_ENDIS	A bundle of channel enable signals controlled by TGC[g] (g:={0, 1}) unit
TOM_OUTEN	A bundle of channel enable signals controlled by TGC[g] (g:={0, 1}) unit
TOM_FUPD	A bundle of channel force update event signals controlled by TGC[g] (g:={0, 1}) unit
TOM_RSTCN0_CH	A bundle of channel counter reset trigger signal at force update event that are controlled by TGC[g] (g:={0, 1}) unit
TOM_UPEN	A bundle of channel update enable signals controlled by TGC[g] (g:={0, 1}) unit
SEL_FXCMU_CLKEN	The selected fixed **CMU** clock enable signal
TRIG_CCU0	Trigger signal for CCU0 compare match
TRIG_CCU1	Trigger signal for CCU1 compare match

(table continues...)

Table 2222 (continued) TOM Signals

Name	Description
TOM_CH_TRIGIN	Trigger input signal for each channel x. It comes from the preceding channel x-1 or channel 15 of the preceding instance.
TOM_CH_TRIGOUT	Trigger output signal for each channel x. It is connected to the trigger input signal of the next channel x+1 or channel 0 of the next instance.

44.3.1.7.16 TOM port description

Table 2223 TOM Signal Interface

Name	Description
TOM_EXT_TRIGIN	TOM_EXT_TRIGIN[7:0] of **TOM** instance i are connected to TIM_EXT_CAPTURE *[7:0]* signal from **TIM** instance i while TOM_EXT_TRIGIN[15:08] of **TOM** instance i are connected to TIM_EXT_CAPTURE *[7:0]* signal from **TIM** instance i
TOM_TRIGIN	**TOM** module trigger chain input
TOM_TRIGOUT	**TOM** module trigger chain output
TOM_TRIGOUT_DEL	**TOM** module trigger chain output delayed by 1 cluster clock; will be used only in **TOM** [0] instance as TOM_TRIGIN
TOM_OUT	Output signal TOM_OUT
TOM_OUT_T	Output signal TOM_OUT_T

Table 2224 TOM Interrupt Interface

Name	Description
TOM_IRQ	**TOM IRQ** line signals
TOM_IRQ_CLR	**TOM IRQ** clear signal, hardware clear of CLSi_ATOM_CHx_IRQ_NOTIFY register
TOM_IRQ_OCC	**TOM IRQ** occurred signal, corresponds to CLSi_ATOM_CHx_IRQ_NOTIFY register

Table 2225 TOM SPE Interface

Name	Description
TOM[i]_SPE_NIPD	Special interface signal connected to SPE[i]_NIPD of **SPE** module i. That means new input pattern detected by **SPE** module i.
TOM[i]_SPE_OUT	Special interface signal connected to SPE[i]_OUT of **SPE** module i.
TOM[i]_CH[x]_SOUR	Special interface signals to **SPE** instance i; driven by **TOM** instance i, channel x.

(table continues...)

Table 2225 (continued) TOM SPE Interface

Name	Description
TOM[i]_CH[x]_TRIG_CCU1	Special interface signal to **SPE** instance i; connected to the internal signal TRIG_CCU1 of **TOM** instance i, channel x (with x∈{0, 2, 6, 7, 8, 9}.
TOM[i]_CH[x]_TRIG_CCU0	Special interface signals to **SPE** instance i; connected to the internal signal TRIG_CCU0 of driven by **TOM** instance i, channel x (with x = 0) .

44.3.1.8 ARU-connected timer output module (ATOM)

44.3.1.8.1 Overview

The **ARU**-connected Timer Output Module (**ATOM**) is able to generate complex output signals without interaction via the configuration interface . Each **ATOM** sub-module contains eight output channels which can operate independently from each other in several configurable operation modes. A block diagram of the **ATOM** sub-module is depicted in Figure 1074.

Indices and their ranges as used inside this chapter are:

- i:={0, 1,..., NATOM-1} instance index of cluster / module
- NATOM= number of **ATOM** instances in the device
- x:={0, 1,..., 7} index of channels in each **ATOM** instance
- k:={0, 1,..., 7} index of sub-channels

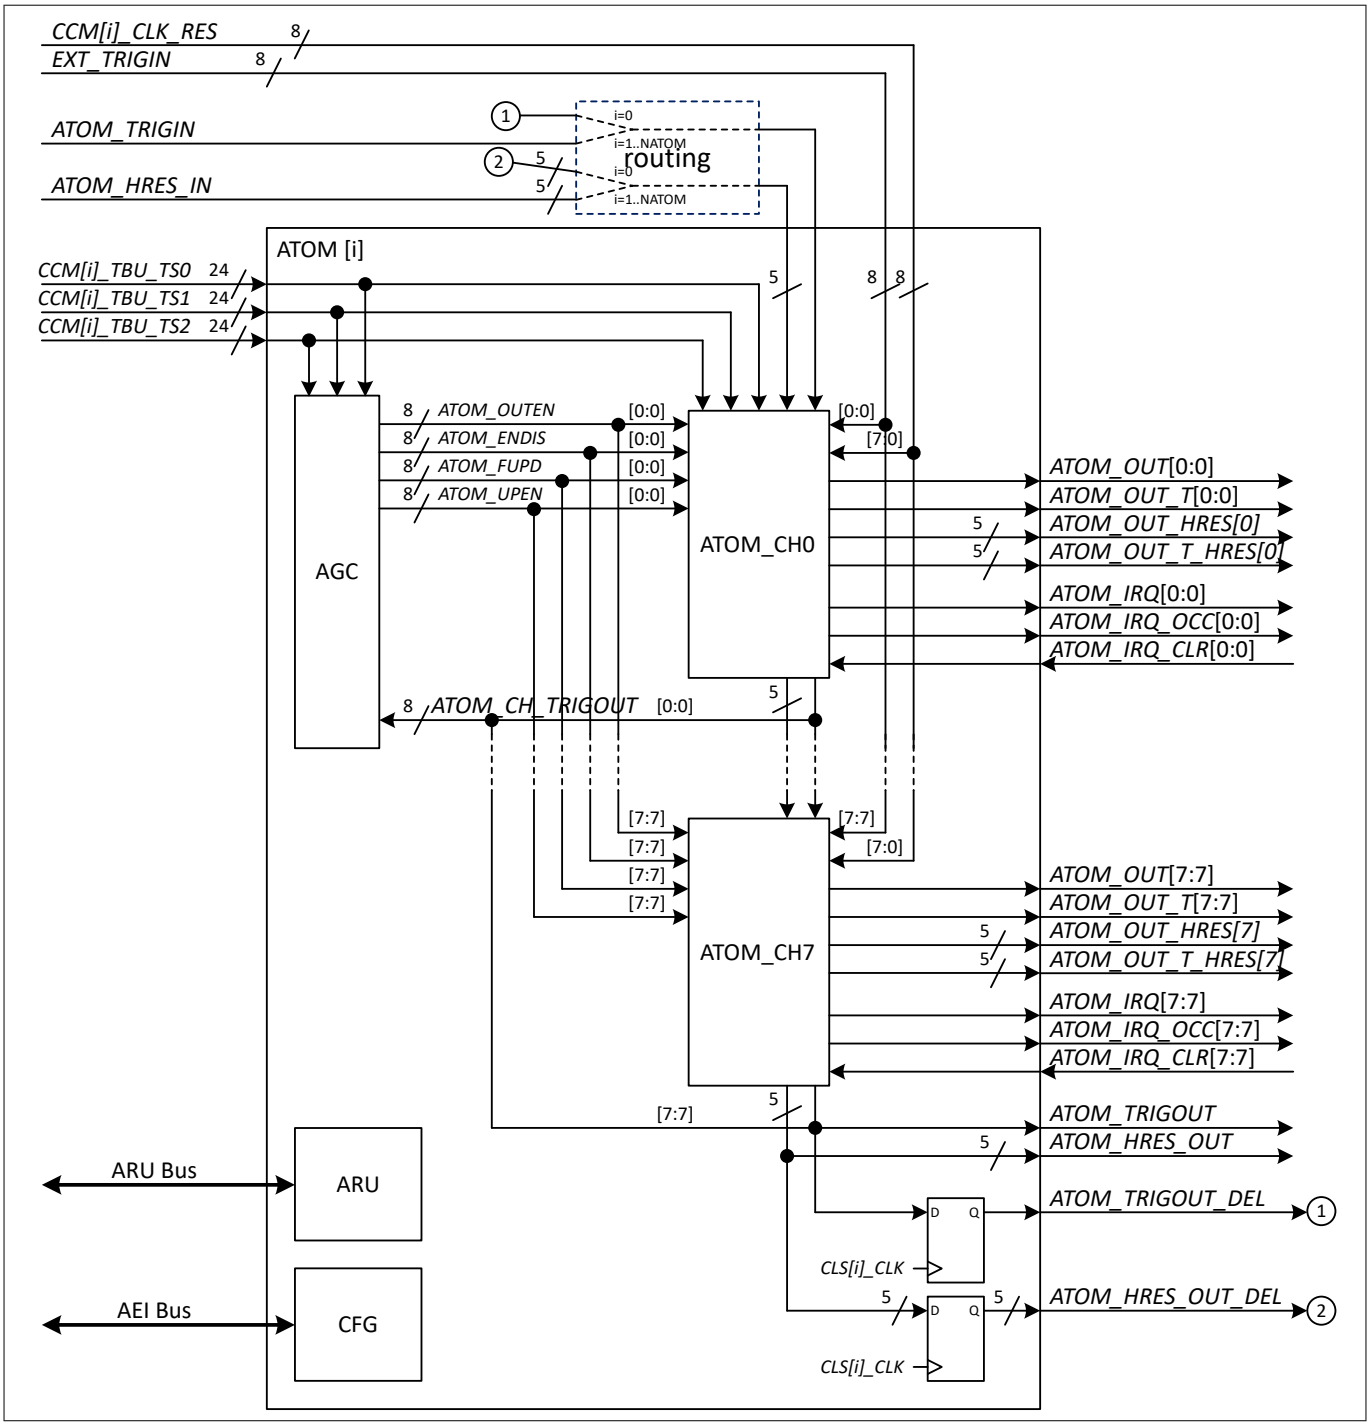

Figure 1074 ATOM block diagram

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

The architecture of **ATOM** sub-module is similar to **TOM** sub-module with some differences. Firstly, each **ATOM** integrates only eight channels with outputs ATOM_OUT and ATOM_OUT_T. There is one **ATOM** Global Control sub-unit (AGC) for the **ATOM** channels. Furthermore, **ATOM** channels are able to generate various PWM signals in different modes.

The **ATOM** output signal routing to **DTM** or **eGTM** toplevel is described in **DTM** connections on **eGTM** toplevel

Each **ATOM** channel provides five modes of operation:

- **ATOM** Signal Output Mode Immediate (SOMI)
- **ATOM** Signal Output Mode Compare (SOMC)
- **ATOM** Signal Output Mode PWM (SOMP)
- **ATOM** Signal Output Mode Serial (SOMS)
- **ATOM** Signal Output Mode Buffered Compare (SOMB)

These modes are described in more detail in **ATOM** channel modes.

The input clocks for the **ATOM** channels come from the cluster clock CLS[j]_CLK with the configurable clock resolution CCM[i]_CLK_RES signals of the **CCM** sub-module. This gives the freedom to select a programmable input clock for the **ATOM** channel counters. The module **ATOM** receives three timestamp values CCM[i]_TBU_TS0, CCM[i]_TBU_TS1 and CCM[i]_TBU_TS2 in order to realize synchronized output behavior on behalf of a common time base.

The operation registers (e.g. counter, compare registers) of the **ATOM** channel are 24 bits wide. Each **ATOM** channel provides a so-called operation register set CLSi_ATOM_CHx_CM0, CLSi_ATOM_CHx_CM1 and shadow register set CLSi_ATOM_CHx_SR0, CLSi_ATOM_CHx_SR1. With this architecture it is possible to work with the operation register set, while the shadow register set can be reloaded with new parameters over configuration interface.

As shown in Figure 1074, NATOM-1 **ATOM** sub-modules are connected together through a trigger chain. The trigger signal ATOM_TRIGIN of **ATOM** instance i is coming from ATOM_TRIGOUT of **ATOM** instance i-1 and the trigger signal ATOM_TRIGOUT of **ATOM** instance i is routed to ATOM_TRIGIN of **ATOM** instance i+1. This trigger chain goes across all channels one by one. The trigger input signal ATOM_TRIGIN of **ATOM** instance i is connected to the trigger input signal ATOM_CH_TRIGIN[0:0] of channel 0. The channel 0 can generate a trigger output signal ATOM_CH_TRIGOUT[0:0] that is connected to ATOM_CH_TRIGIN[1:1] to trigger channel 1. In this way, each channel x is triggered from the preceding channel and then can trigger the next channel (please refer to Figure 1076 and Internal trigger interface for the internal trigger chain details). Channel 7 of **ATOM** instance i is routed to trigger channel 0 of the next instance i+1.

***Note**: The following paragraph is only relevant for devices with High Resolution.*

Similarly, there is also a HRES value chain that goes across all channels of each instance along with the trigger chain. The high-resolution value input ATOM_HRES_IN of **ATOM** instance i is connected to ATOM_HRES_OUT of **ATOM** instance i-1 and the high-resolution value output ATOM_HRES_OUT of **ATOM** instance i is routed to ATOM_HRES_IN of **ATOM** instance i+1. Please refer to High-resolution PWM support (HRES mode) for more details.

Especially, the trigger input signal **ATOM** instance 0 is connected to its own output ATOM_TRIGOUT_DEL, i.e. the last channel of **ATOM** instance 0 can trigger the first channel of **ATOM** instance 0 (this path is registered, which means delayed by one cluster clock period).

***Note**: The following paragraph is only relevant for devices with High Resolution.*

Similarly, the high-resolution value input ATOM_HRES_IN of **ATOM** instance 0 is connected to its own output ATOM_HRES_OUT_DEL, i.e. the high-resolution value output of the last channel of **ATOM** instance 0 is also fed to the first channel of **ATOM** instance 0, also with one pipeline register delay.

The function of the interrupt signals ATOM_IRQ, ATOM_IRQ_OCC and ATOM_IRQ_CLR is described in more details in **eGTM** interrupt concept.

ATOM global control (AGC)

Synchronous start, stop and update of work register of up to 8 channels is possible with the AGC sub-unit. This sub-unit has the same functionality as the TGC sub-unit of the **TOM** sub-module.

Overview

One global channel control unit (AGC) exists to drive a number of individual **ATOM** channels synchronously by external or internal events.

An AGC can drive up to eight **ATOM** channels.

The **ATOM** sub-module supports four different kinds of signaling mechanisms:

- Global enable/disable mechanism for each **ATOM** channel with control register CLSi_ATOM_AGC_ENDIS_CTRL and status register CLSi_ATOM_AGC_ENDIS_STAT
- Global output enable mechanism for each **ATOM** channel with control register CLSi_ATOM_AGC_OUTEN_CTRL and status register CLSi_ATOM_AGC_OUTEN_STAT
- Global force update mechanism of the register CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1, CLSi_ATOM_CHx_CTRL.SL and CLSi_ATOM_CHx_CTRL.CLK_SRC for each **ATOM** channel and optionally reset the counter CLSi_ATOM_CHx_CN0 with control register CLSi_ATOM_AGC_FUPD_CTRL
- Update enable of the register CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1, CLSi_ATOM_CHx_CTRL.SL and CLSi_ATOM_CHx_CTRL.CLK_SRC for each **ATOM** channel with the control bit field CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)**

AGC sub-unit

Each of the first three individual mechanisms (enable/disable of the channel, output enable and force update) can be driven by three different trigger sources.

The three trigger sources are:

1. over the configuration interface (bit CLSi_ATOM_AGC_GLB_CTRL.HOST_TRIG)
2. the **TBU** timestamp (signal CCM[i]_TBU_TS0, CCM[i]_TBU_TS1 and CCM[i]_TBU_TS2 if available)
3. the internal trigger signal ATOM_CH_TRIGOUT (bunch of trigger signals ATOM_CH_TRIGOUT[x:x]) which can be either the trigger ATOM_TRIG_CCU0 of channel x, the trigger of preceding channel x-1 (i.e. signal ATOM_CH_TRIGOUT[x-1:x-1]) or the external trigger EXT_TRIGIN[x:x] of assigned **TIM** channel x.

The first way (1.) is to trigger the control mechanism by a direct register write-access via configuration interface (bit CLSi_ATOM_AGC_GLB_CTRL.HOST_TRIG).

The second way (2.) is provided by a compare match trigger on behalf of a specified time base coming from the module **TBU** (selected by bits CLSi_ATOM_AGC_ACT_TB.TBU_SEL) and the timestamp compare value defined in the bit field CLSi_ATOM_AGC_ACT_TB.ACT_TB.

In this case, the selected **TBU** time base CCM[i]_TBU_TS0/CCM[i]_TBU_TS1/CCM[i]_TBU_TS2 should be configured to be up-counting. A cyclic event compare of CLSi_ATOM_AGC_ACT_TB.ACT_TB and selected CCM[i]_TBU_TS0, CCM[i]_TBU_TS1, CCM[i]_TBU_TS2 is performed. Please refer to Cyclic event compare for more information about cyclic event compare strategy.

The third way (3.) is the input ATOM_CH_TRIGOUT (bunch of trigger signals ATOM_CH_TRIGOUT[x:x]) coming from **ATOM** channels.

The corresponding trigger signal ATOM_CH_TRIGOUT[x:x] coming from channel x can be masked by the register CLSi_ATOM_AGC_INT_TRIG.

To enable or disable each individual **ATOM** channel, the registers CLSi_ATOM_AGC_ENDIS_CTRL and/or CLSi_ATOM_AGC_ENDIS_STAT have to be used.

The register CLSi_ATOM_AGC_ENDIS_STAT directly controls the signal ATOM_ENDIS[x:x]. A write-access to this register is possible.

The register CLSi_ATOM_AGC_ENDIS_CTRL is a shadow register that overwrites the value of register CLSi_ATOM_AGC_ENDIS_STAT if one of the three trigger conditions matches.

The update mechanism within the channel is not affected by the ATOM_ENDIS control signal. This means that the update of the working register can be executed - depending on the update condition - as soon as it is enabled by setting CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)** $=10_B$.

To ensure a clean restart of an **ATOM** channel, it is recommended to raise a channel reset by setting of bit CLSi_ATOM_AGC_GLB_CTRL.RST_CHk (k=0-7) **(k=x)** after a channel was disabled (ATOM_ENDIS[x:x]=0) and before it is enabled again (ATOM_ENDIS[x:x]=1).

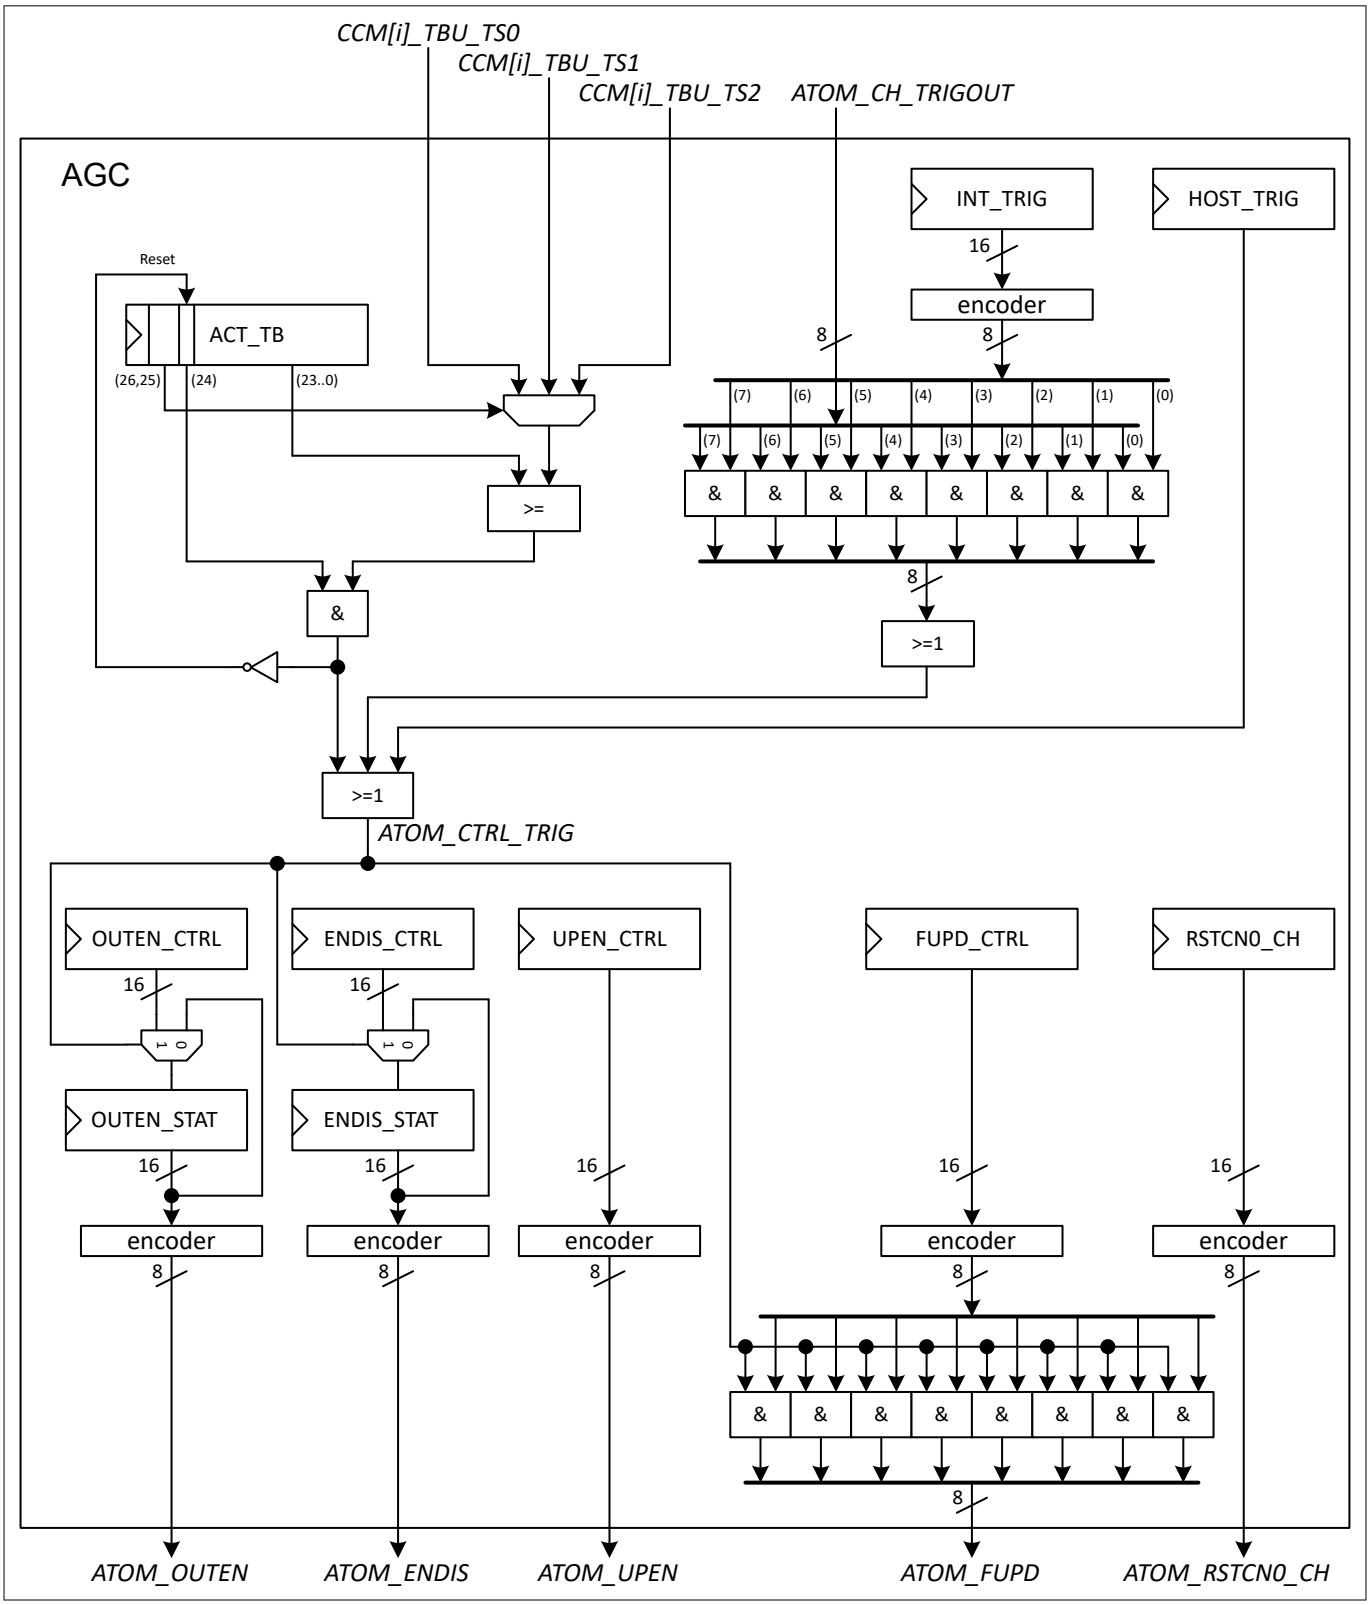

Figure 1075 ATOM global channel control mechanism

The output of the individual **ATOM** channels can be controlled using the registers CLSi_ATOM_AGC_OUTEN_CTRL and CLSi_ATOM_AGC_OUTEN_STAT.

The register CLSi_ATOM_AGC_OUTEN_STAT directly controls the signal ATOM_OUTEN. A write-access to this register is possible.

The register CLSi_ATOM_AGC_OUTEN_CTRL is a shadow register that overwrites the value of register CLSi_ATOM_AGC_OUTEN_STAT if one of the three trigger conditions matches.

The trigger condition has always priority over the bus write-access to the CLSi_ATOM_AGC_OUTEN_STAT and CLSi_ATOM_AGC_ENDIS_STAT registers, even if CLSi_ATOM_AGC_OUTEN_CTRL.OUTEN_CTRLk (k=0-7)/ CLSi_ATOM_AGC_ENDIS_CTRL.ENDIS_CTRLk (k=0-7) is set to 00_B. This means that the bus write-access to CLSi_ATOM_AGC_OUTEN_STAT and CLSi_ATOM_AGC_ENDIS_STAT register is ignored in the clock cycle when the trigger condition is active.

If an **ATOM** output is disabled by the register CLSi_ATOM_AGC_OUTEN_STAT, the actual value of the channel output at ATOM_OUT[x:x] is set as !CLSi_ATOM_CHx_CTRL.SL.

If the output is enabled, the output at ATOM_OUT[x:x] depends on the current operation of different mode, CLSi_ATOM_AGC_ENDIS_STAT and CLSi_ATOM_CHx_CTRL.FREEZE. (Please check CLSi_ATOM_CHx_CTRL_SOMP.SL/CLSi_ATOM_CHx_CTRL_SOMI.SL/CLSi_ATOM_CHx_CTRL_SOMB.SL/ CLSi_ATOM_CHx_CTRL_SOMS.SL for more information)

The register CLSi_ATOM_AGC_FUPD_CTRL.FUPD_CTRLk (k=0-7) defines which of the **ATOM** channels receive a force update event if the trigger signal ATOM_CTRL_TRIG is raised while CLSi_ATOM_AGC_FUPD_CTRL.RSTCN0_CHk (k=0-7) determines whether the force update event also reset counter CLSi_ATOM_CHx_CN0.CN0 of the channel. If in SOMP continuous counting up mode with CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=0 the force update mechanism is configured together with CLSi_ATOM_AGC_FUPD_CTRL.RSTCN0_CHk (k=0-7)=10_B and CLSi_ATOM_AGC_FUPD_CTRL.FUPD_CTRLk (k=0-7)=10_B, the force update event will simultaneously update the operation registers, reset the counter and also set the output to be CLSi_ATOM_CHx_CTRL_SOMP.SL. That means the force update mechanism can be used to stop the current PWM signal generation and restart a new PWM signal generation with new PWM parameters.

In SOMP, SOMI and SOMS modes, the force update request is synchronized to the selected CCM[i]_CLK_RES as shown in Figure 1076 and then executed. In other modes, the force update request is executed immediately. The execution of the force update does not depend on the state of CLSi_ATOM_AGC_ENDIS_STAT.ENDIS_STATk (k=0-7).

The ATOM_RSTCN0_CH signal is not synchronized with the selected CCM[i]_CLK_RES. In order to ensure that the reset function is executed, the bit field CLSi_ATOM_AGC_FUPD_CTRL.RSTCN0_CHk (k=0-7) **(k=x)** may only be set to 01_B after the selected CCM[i]_CLK_RES has occured.

The register bits CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)** define, for which **ATOM** channel the update of the working register CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1, CLSi_ATOM_CHx_CTRL.SL and CLSi_ATOM_CHx_CTRL.CLK_SRC is enabled by the corresponding shadow register CLSi_ATOM_CHx_SR0.SR0, CLSi_ATOM_CHx_SR1.SR1, CLSi_ATOM_CHx_CTRL_SR.SL_SR and CLSi_ATOM_CHx_CTRL_SR.CLK_SRC_SR. If update is enabled in SOMP continuous counting up mode, the register CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1, CLSi_ATOM_CHx_CTRL.SL and CLSi_ATOM_CHx_CTRL.CLK_SRC will be updated on reset of counter register CLSi_ATOM_CHx_CN0.CN0 (see Figure 1076).

ATOM channel mode overview

Each **ATOM** channel offers the following different operation modes:

In **ATOM** Signal Output Mode Immediate (SOMI), the **ATOM** channels generate an output signal according to CLSi_ATOM_CHx_CTRL_SOMI.ACB0.

In **ATOM** Signal Output Mode Compare (SOMC), the **ATOM** channel generates an output signal on behalf of timestamps that are located in the **ATOM** operation registers CLSi_ATOM_CHx_CM0 and CLSi_ATOM_CHx_CM1. The output generates edges when the **TBU** timestamps reach the timestamps stored in CLSi_ATOM_CHx_CM0 and CLSi_ATOM_CHx_CM1. The **ATOM** is able to receive new timestamps by configuration interface. The new

timestamps are directly loaded into the channel's operation register. The shadow registers are used as capture registers for two time base values, when a compare match of the channel's operation registers occurs.

In **ATOM** Signal Output Mode PWM (SOMP), the **ATOM** channel is able to generate simple and complex PWM output signals like the **TOM** sub-module by comparing its operation registers with a sub-module internal counter. Unlike the **TOM**, the **ATOM** shadow registers can be reloaded over the configuration interface , while the channel operates on the operation registers. Please refer to **ATOM** signal output mode PWM (SOMP) for further details.

In **ATOM** Signal Output Mode Serial (SOMS), the **ATOM** channel generates a serial output bit stream on behalf of a shift register. The number of bits shifted and the shift direction is configurable. The shift frequency is determined by one of the CCM[i]_CLK_RES clock resolution signals. Please refer to **ATOM** signal output mode serial (SOMS) for further details.

In **ATOM** Signal Output Buffered Compare (SOMB), the **ATOM** channel generates an output signal on behalf of timestamps that are located in the **ATOM** operation registers CLSi_ATOM_CHx_CM0 and CLSi_ATOM_CHx_CM1. The output generates edges when the **TBU** timestamps reach the timestamps stored in CLSi_ATOM_CHx_CM0 and CLSi_ATOM_CHx_CM1. The **ATOM** is able to receive new compare values over the configuration interface. The new compare values are stored first in the shadow register. Only if previous compare match has occurred, the operation registers are updated with the content of the shadow registers. Please refer to **ATOM** signal output mode buffered compare (SOMB) for further details.

44.3.1.8.2 ATOM channel architecture

Each **ATOM** channel is able to generate output signals according to five operation modes. The architecture of the **ATOM** channels is similar to the architecture of the **TOM** channels. The architecture of an **ATOM** channel in SOMP mode is depicted in Figure 1076.

***Note**:* Figure 1076 *doesn't reflect the real implementation of the circuit but is intended to clearly explain the functionality of the channel, especially for SOMP mode.*

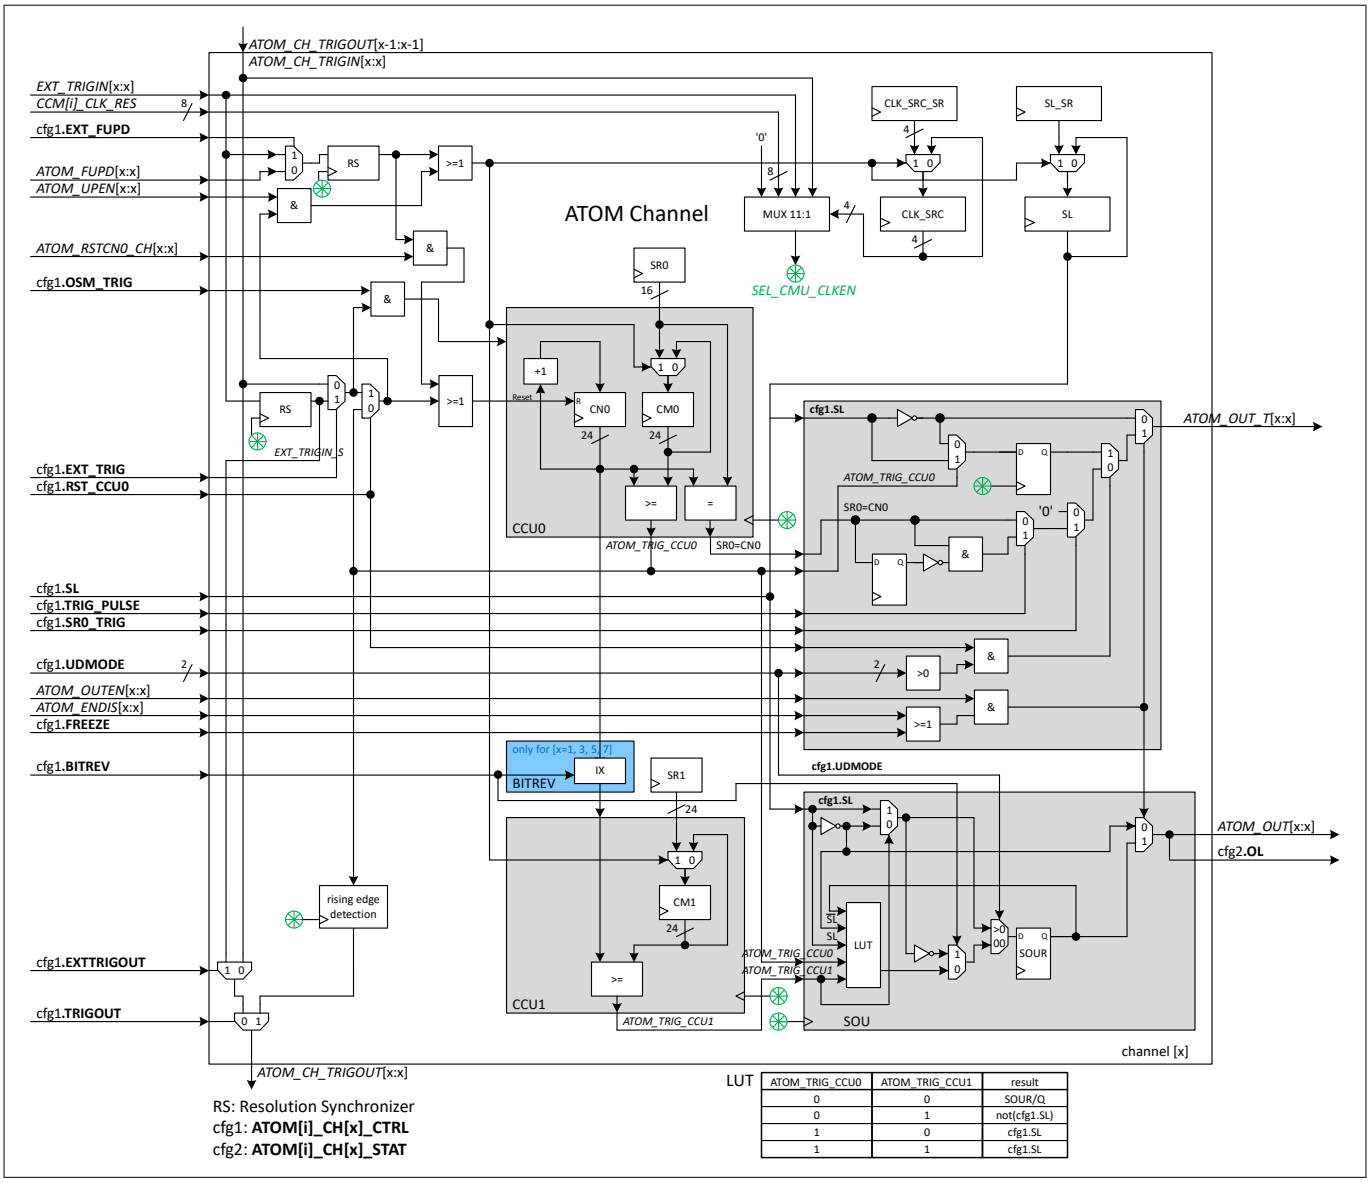

Figure 1076 ATOM channel architecture in SOMP mode

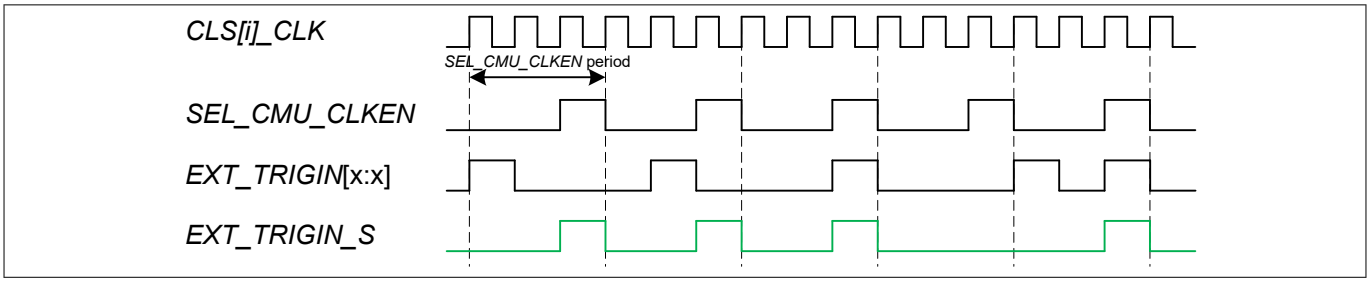

Figure 1077 Timing diagram of RS unit

As shown in Figure 1076, the operating clock resolution signal SEL_CMU_CLKEN in SOMP and SOMS mode can be configured by CLSi_ATOM_CHx_CTRL.CLK_SRC. This configuration register can select the clock source from **CMU** clock enable signals CCM[i]_CLK_RES that are provided from **CCM** sub-module.

In addition, with the shadow register CLSi_ATOM_CHx_CTRL_SR.CLK_SRC_SR, it is possible to change the selected clock resolution from **CMU** under different conditions. The signal SEL_CMU_CLKEN looks like clock enable signal that is shown in Figure 1077. Most functionalities in SOMP and SOMS modes are only active when

SEL_CMU_CLKEN = 1 and the consequent operation registers and outputs are always synchronously updated at the falling edge of SEL_CMU_CLKEN pulse. The functionalities synchronous to the selected clock resolution SEL_CMU_CLKEN are depicted with the green round symbol in Figure 1076.

Due to a fixed clock resolution scheme from **CMU**, the first clock resolution period may differ from the expected value, depending on the point of time, where the CLSi_ATOM_CHx_CTRL.CLK_SRC bit field is updated from its shadow register bit field CLSi_ATOM_CHx_CTRL_SR.CLK_SRC_SR.

In all **ATOM** channels the operation registers CLSi_ATOM_CHx_CN0.CN0, CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM1.CM1 and the shadow registers CLSi_ATOM_CHx_SR0.SR0 and CLSi_ATOM_CHx_SR1.SR1 are 24 bits wide. As shown in Figure 1076, the unit CCU0 provides different counting up/down functionalities in various modes. The comparators inside CCU0 and CCU1 perform selectable signed greater-equal or less-equal comparison against different parameters depending on different **ATOM** modes and then generate ATOM_TRIG_CCU0=1 when the compare match event in CCU0 occurs or generate ATOM_TRIG_CCU1=1 when the compare match event in CCU1 occurs.

The Signal Output Unit (SOU) generates the output signal for each **ATOM** channel. In SOMI mode, this output signal level depends on the bit CLSi_ATOM_CHx_CTRL_SOMI.SL in combination with two control bits CLSi_ATOM_CHx_CTRL_SOMI.ACB0.

The Signal Output Unit (SOU) generates the output signal for each **ATOM** channel. In SOMC mode, this output signal level depends on the bit CLSi_ATOM_CHx_CTRL_SOMC.SL in combination with five control bits CLSi_ATOM_CHx_CTRL_SOMC.ACB10 and CLSi_ATOM_CHx_CTRL_SOMC.ACB42.

The Signal Output Unit (SOU) generates the output signal for each **ATOM** channel. In SOMS mode, this output signal level depends on the bit CLSi_ATOM_CHx_CTRL_SOMS.SL in combination with two control bits CLSi_ATOM_CHx_CTRL_SOMS.ACB0.

The Signal Output Unit (SOU) generates the output signal for each **ATOM** channel. In SOMP mode, this output signal level depends on the bit CLSi_ATOM_CHx_CTRL_SOMP.SL in combination with the counter behavior and its compare events in CCU0 and CCU1.

The Signal Output Unit (SOU) generates the output signal for each **ATOM** channel. In SOMB mode, this output signal level depends on the bit CLSi_ATOM_CHx_CTRL_SOMB.SL in combination with five control bits CLSi_ATOM_CHx_CTRL_SOMB.ACB10 and CLSi_ATOM_CHx_CTRL_SOMC.ACB42.

In SOMP continuous counting up mode, CLSi_ATOM_CHx_CM0.CM0 represents PWM period while CLSi_ATOM_CHx_CM1.CM1 is PWM pulse width. In order to generate various PWM signals, CCU0 counts up CLSi_ATOM_CHx_CN0.CN0 and compares it with CLSi_ATOM_CHx_CM0.CM0 while CCU1 compares it with CLSi_ATOM_CHx_CM1.CM1. Depending on the configuration bit CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0, the counter CLSi_ATOM_CHx_CN0.CN0 can be reset, when the counter value is equal to the compare value CLSi_ATOM_CHx_CM0.CM0 (i.e. CLSi_ATOM_CHx_CN0.CN0 counts only from 0 to CLSi_ATOM_CHx_CM0.CM0-1 and is then reset to 0) or when it is triggered by the **ATOM[i]** trigger signal ATOM_CH_TRIGIN[x:x] (ATOM_CH_TRIGOUT[x-1:x-1]) of the preceding channel x-1 which can also be the last channel of preceding instance **ATOM[i-1]**) or when it is triggered by the external trigger signal EXT_TRIGIN[x:x] of the assigned **TIM** channel x.

The external trigger signal EXT_TRIGIN[x:x] is synchronous to the clock source selected by RS (Resolution Synchronizer) unit and then taken into use.

With such a RS unit, in each SEL_CMU_CLKEN period (i.e. selected clock resolution signal), any event (or pulses) of EXT_TRIGIN will be synchronized by RS unit on EXT_TRIGIN_S that looks exactly the same as SEL_CMU_CLKEN. Figure 1077 shows the timing diagram of RS unit. If EXT_TRIGIN has one or more pulses in a SEL_CMU_CLKEN period, the synchronized output EXT_TRIGIN_S will have 1 pulse at the end of this period. Otherwise, EXT_TRIGIN_S is always 0.

The trigger signal ATOM_CH_TRIGIN[x:x] coming from the preceding channel may not be synchronous to the selected clock resolution of channel x.

In SOMP continuous counting up mode, once the comparison event of CLSi_ATOM_CHx_CN0.CN0 >= CLSi_ATOM_CHx_CM0.CM0-1 in unit CCU0 occurs, ATOM_TRIG_CCU0 = 1 will be set to trigger the output generation of ATOM_OUT[x:x] in the SOU sub-unit together with the corresponding interrupt signals. In order to

trigger the next channel, the rising edge detection unit can detect each rising edge of ATOM_TRIG_CCU0 (i.e. each comparison event) and generate a single cluster clock pulse on ATOM_CH_TRIGOUT[x:x] when the selected clock resolution signal SEL_CMU_CLKEN =1 (i.e. synchronous to the selected clock resolution). In addition, ATOM_CH_TRIGOUT[x:x] can also be configured to be ATOM_CH_TRIGIN[x:x] (ATOM_CH_TRIGOUT[x-1:x-1] of the preceding channel x-1) or the external trigger signal EXT_TRIGIN[x:x] of the assigned **TIM** channel x. Similarly, once the comparison event of CLSi_ATOM_CHx_CN0.CN0 >= CLSi_ATOM_CHx_CM1.CM1-1 in unit CCU1 occurs, ATOM_TRIG_CCU1 = 1 will be set to trigger the output generation of ATOM_OUT[x:x] in the SOU sub-unit together with the corresponding interrupt signals.

When CLSi_ATOM_CHx_CN0.CN0 < CLSi_ATOM_CHx_CM0.CM0-1, ATOM_TRIG_CCU0 will be reset as 0. Similarly, when CLSi_ATOM_CHx_CN0.CN0 < CLSi_ATOM_CHx_CM1.CM1-1, ATOM_TRIG_CCU1 will be reset to 0.

As shown in Figure 1077, in SOMP continuous counting up mode according to the LUT with ATOM_TRIG_CCU0, ATOM_TRIG_CCU1 and the signal level configuration CLSi_ATOM_CHx_CTRL.SL, SOU unit can generate ATOM_OUT[x:x] with various PWM timing characteristics when the channel and the output are both enabled (ATOM_OUTEN[x:x]=1 and ATOM_ENDIS[x:x]=1). Please refer to the chapter of different modes for more details on PWM signal generation.

In SOMC/SOMB mode, CCU0 and CCU1 compare CLSi_ATOM_CHx_CM0.CM0/CLSi_ATOM_CHx_CM1.CM1 against the **eGTM** time bases CCM[i]_TBU_TS0, CCM[i]_TBU_TS1, and if available, CCM[i]_TBU_TS2 generates the compare events ATOM_TRIG_CCU0 and ATOM_TRIG_CCU1. Please refer to **TBU** Time base unit (**TBU**) for further details. In SOMC/SOMB mode, the two compare units CCU0/CCU1 can be used in combination with each other. When used in combination, the signals ATOM_TRIG_CCU0 and ATOM_TRIG_CCU1 can be used to enable/disable the other compare unit when a match event occurs. Different compare strategy can be configured in CLSi_ATOM_CHx_CTRL_SOMC.ACB42/CLSi_ATOM_CHx_CTRL_SOMB.ACB42. Based on the signal level register bit CLSi_ATOM_CHx_CTRL.SL and the two control bits CLSi_ATOM_CHx_CTRL_SOMC.ACB10/ CLSi_ATOM_CHx_CTRL_SOMB.ACB10, the output ATOM_OUT[x:x] reflects the configured compare strategy. This behavior is not really illustrated in Figure 1076. Please refer to the **ATOM** signal output mode compare (SOMC) and **ATOM** signal output mode buffered compare (SOMB) for further details.

In SOMC/SOMB mode, CCU0/CCU1 unit always performs cyclic event compare between the selected time base CCM[i]_TBU_TS0/CCM[i]_TBU_TS1/CCM[i]_TBU_TS2 and the compare value CLSi_ATOM_CHx_CM0.CM0/ CLSi_ATOM_CHx_CM1.CM1. When the selected time base is "cyclically greater than or equal to" the compare value of CLSi_ATOM_CHx_CM0.CM0/CLSi_ATOM_CHx_CM1.CM1, the compare match event specified in CLSi_ATOM_CHx_CM0.CM0/ CLSi_ATOM_CHx_CM1.CM1 is considered to have occurred. Please refer to Cyclic event compare for more information about cyclic event compare strategy.

For a correct behavior of cyclic event compare in SOMC/SOMB mode, when a compare match event with the specified compare value CLSi_ATOM_CHx_CM0.CM0/ CLSi_ATOM_CHx_CM1.CM1 occurs, the new compare value in CLSi_ATOM_CHx_CM0.CM0/ CLSi_ATOM_CHx_CM1.CM1 for the next cyclic event compare must be specified in the range of the half total time base value (i.e. $7FFFFF_H$) greater/smaller than the old compare value.

In SOMI mode, the output signal level depends on CLSi_ATOM_CHx_CTRL.SL and CLSi_ATOM_CHx_CTRL_SOMI.ACB0. In SOMS mode, the output signal level is defined by the bit pattern that has to be shifted out by the **ATOM** channel. The bit pattern is located inside the CLSi_ATOM_CHx_CM1.CM1 register.

When the output is disabled (ATOM_OUTEN[x:x]=0), the output signals ATOM_OUT[x:x] and ATOM_OUT_T[x:x] are the inverse value of the CLSi_ATOM_CHx_CTRL.SL bit. When the output is enabled (ATOM_OUTEN[x:x]=1), the output signals ATOM_OUT[x:x] and ATOM_OUT_T[x:x] are dependent on different operation modes, the channel enable signal ATOM_ENDIS[x:x] and the freeze mode enable register CLSi_ATOM_CHx_CTRL.FREEZE. (Please refer to register description of CLSi_ATOM_CHx_CTRL_SOMI.SL/CLSi_ATOM_CHx_CTRL_SOMB.SL/ CLSi_ATOM_CHx_CTRL_SOMC.SL/CLSi_ATOM_CHx_CTRL_SOMP.SL/CLSi_ATOM_CHx_CTRL_SOMS.SL for more details.) Especially, in SOMB, SOMC and SOMI modes, the output signal ATOM_OUT_T[x:x] is not supported. So it is always clamped to 0 if the output and the channel are both enabled (i.e. ATOM_OUTEN[x:x]=1 and ATOM_ENDIS[x:x]=1). When the output is enabled (ATOM_OUTEN[x:x]=1) but the channel is disabled (ATOM_ENDIS[x:x]=0), if CLSi_ATOM_CHx_CTRL.FREEZE=0, ATOM_OUT_T[x:x] is !CLSi_ATOM_CHx_CTRL.SL.

When the output is enabled (ATOM_OUTEN[x:x]=1) but the channel is disabled (ATOM_ENDIS[x:x]=0), if CLSi_ATOM_CHx_CTRL.FREEZE=1, ATOM_OUT_T[x:x] is clamped to 0.

When the channel is disabled (ATOM_ENDIS[x:x]=0), the counting and comparing functionalities in CCU0 and CCU1 are deactivated in different modes and thus ATOM_TRIG_CCU0 = 0, ATOM_TRIG_CCU1 = 0. Therefore, ATOM_CH_TRIGOUT[x:x] is not generated if CLSi_ATOM_CHx_CTRL.TRIGOUT = 1, regardless of ATOM_OUTEN[x:x].

Similar to CLSi_ATOM_CHx_CTRL.CLK_SRC, CLSi_ATOM_CHx_CTRL.SL, CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM1.CM1 also have their shadow registers CLSi_ATOM_CHx_CTRL_SR.SL_SR, CLSi_ATOM_CHx_SR0.SR0 and CLSi_ATOM_CHx_SR1.SR1. In SOMP and SOMS mode, it is possible to synchronously update the clock resolution register CLSi_ATOM_CHx_CTRL.CLK_SRC and the operation registers CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM1.CM1 from their shadow registers (please refer to here). In addition, synchronous updating of the signal level register CLSi_ATOM_CHx_CTRL.SL is possible in SOMP mode. There are different update mechanisms in SOMP and SOMS mode. Please refer to the chapters SOMP and SOMS modes for more details.

External trigger interface

Each channel x of **ATOM** instance i has an input signal EXT_TRIGIN[x:x] that is connected to TIM_EXT_CAPTURE[x:x] of **TIM** instance i. Via this signal, events (high pulses with the length of 1 CLS[j]_CLK period) generated by the **TIM** module can be used to control the functionality of the **ATOM** channel in multiple ways:

- EXT_TRIGIN[x:x] events can be used to define the clock source of the selected channel mode (CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC = 1110_B; CLSi_ATOM_CHx_CTRL_SOMS.CLK_SRC = 1110_B).
- EXT_TRIGIN[x:x] events can be used to update the operation registers with the content of the shadow registers in SOMP, SOMI, SOMS, SOMB mode (activated by CLSi_ATOM_CHx_CTRL_SOMP.EXT_FUPD = 1; CLSi_ATOM_CHx_CTRL_SOMI.EXT_FUPD = 1; CLSi_ATOM_CHx_CTRL_SOMS.EXT_FUPD = 1; CLSi_ATOM_CHx_CTRL_SOMB.EXT_FUPD = 1). Any EXT_TRIGIN[x:x] event is synchronized in the **ATOM** channel as specified in Figure 1077.
- EXT_TRIGIN[x:x] events can be used to reset the counter register CLSi_ATOM_CHx_CN0 in SOMP continuous counting up mode or change the counting direction in counting up-down mode or trigger the start of counting in one-shot mode (activated by CLSi_ATOM_CHx_CTRL_SOMP.EXT_TRIG = 1 && CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0 = 1). In this case, if CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)** = 10_B is configured, EXT_TRIGIN[x:x] events can also trigger the update of the operation registers from their shadow registers. Any EXT_TRIGIN[x:x] event is synchronized in the **ATOM** channel as specified in Figure 1077.
- EXT_TRIGIN[x:x] can be used as a trigger event for the following channels (activated by CLSi_ATOM_CHx_CTRL_SOMI.EXTTRIGOUT = 1 && CLSi_ATOM_CHx_CTRL_SOMI.TRIGOUT = 0; CLSi_ATOM_CHx_CTRL_SOMS.EXTTRIGOUT = 1 && CLSi_ATOM_CHx_CTRL_SOMS.TRIGOUT = 0; CLSi_ATOM_CHx_CTRL_SOMP.EXTTRIGOUT = 1 && CLSi_ATOM_CHx_CTRL_SOMP.TRIGOUT = 0; CLSi_ATOM_CHx_CTRL_SOMC.EXTTRIGOUT = 1 && CLSi_ATOM_CHx_CTRL_SOMC.TRIGOUT = 0; CLSi_ATOM_CHx_CTRL_SOMB.EXTTRIGOUT = 1 && CLSi_ATOM_CHx_CTRL_SOMB.TRIGOUT = 0). Any EXT_TRIGIN[x:x] event is synchronized in the **ATOM** channel as specified in Figure 1077.

In certain configurations of the **TIM** module, the EXT_TRIGIN[x:x] signal pulses can have a length of more than 1 cluster clock-cycle. In this case, the functionality of the **ATOM** is not specified and it is highly recommended to prevent this configuration in applications.

Before triggering the functionalities mentioned above, the EXT_TRIGIN[x:x] signal is always synchronized with the current selected clock enable signal in RS unit as shown in Figure 1077.

Internal trigger interface

As shown in Figure 1076, each **ATOM** channel x has an input signal ATOM_CH_TRIGIN[x:x] that is coming from ATOM_CH_TRIGOUT[x-1:x-1] from the preceding channel. Via this signal, events (high pulses with the length of 1 CLS[j]_CLK period) generated by the preceding **ATOM** channel, can be used to control the functionality of **ATOM** channel in multiple ways:

- ATOM_CH_TRIGIN[x:x] events can be used to define the clock source of the selected channel mode (CLSi_ATOM_CHx_CTRL_SOMP**.**CLK_SRC = 1101_B; CLSi_ATOM_CHx_CTRL_SOMS**.**CLK_SRC = 1101_B).
- ATOM_CH_TRIGIN[x:x] events can be used to reset the counter register CLSi_ATOM_CHx_CN0 in SOMP continuous counting up mode or change the counting direction in counting up-down mode or trigger the start of counting in one-shot mode (activated by CLSi_ATOM_CHx_CTRL_SOMP**.**EXT_TRIG = 0 && CLSi_ATOM_CHx_CTRL_SOMP**.**RST_CCU0 = 1). In this case, if CLSi_ATOM_AGC_GLB_CTRL**.**UPEN_CTRLk (k=0-7) = 10_B is configured, ATOM_CH_TRIGIN[x:x] events can also trigger the update of the operation registers from their shadow registers.
- ATOM_CH_TRIGIN[x:x] can be used as a trigger event for following channels (activated by CLSi_ATOM_CHx_CTRL_SOMI**.**EXTTRIGOUT = 0 && CLSi_ATOM_CHx_CTRL_SOMI**.**TRIGOUT = 0; CLSi_ATOM_CHx_CTRL_SOMS**.**EXTTRIGOUT = 0 && CLSi_ATOM_CHx_CTRL_SOMS**.**TRIGOUT = 0; CLSi_ATOM_CHx_CTRL_SOMP**.**EXTTRIGOUT = 0 && CLSi_ATOM_CHx_CTRL_SOMP**.**TRIGOUT = 0; CLSi_ATOM_CHx_CTRL_SOMC**.**EXTTRIGOUT = 0 && CLSi_ATOM_CHx_CTRL_SOMC**.**TRIGOUT = 0; CLSi_ATOM_CHx_CTRL_SOMB**.**EXTTRIGOUT = 0 && CLSi_ATOM_CHx_CTRL_SOMB**.**TRIGOUT = 0).

Especially, for channel 0 of **ATOM** module i, i ∈ {1, 2, ..., NATOM-1}, ATOM_CH_TRIGIN[0:0] is connected to ATOM_TRIGIN of instance [i] that comes from ATOM_CH_TRIGOUT[7:7] of the preceding **ATOM** instance [i-1] and may be delayed by a register with the cluster clock CLS[j]_CLK in channel 0 before triggering the functionalities as mentioned above. This delay is controlled by the device configuration variable ATOM_TRIG_CHAIN (indicated by CLSi_CCM_HW_CONF**.**ATOM_TRIG_CHAIN). The delay exists after every N clusters (N = ATOM_TRIG_CHAIN). For ATOM0, ATOM_CH_TRIGIN[0:0] is connected to ATOM_TRIGOUT_DEL via the signal ATOM_CH_TRIGOUT[7:7] of ATOM0 itself as shown in Figure 1074. Furthermore, the cluster i can operate on faster **eGTM** clock CLK, if the device is defined with FAST_CLS_CLK[i] = 1. In this case, it is allowed to have one more register that is clocked with CLK to delay ATOM_CH_TRIGIN[4:4] in channel 4 before triggering the functionalities. This is controlled by another **ATOM** device configuration parameter ATOM_TRIG_INTCHAIN (it can only be valid if FAST_CLS_CLK[i] = 1 and indicated by CLSi_CCM_HW_CONF**.**ATOM_TRIG_INTCHAIN). The registers for these special cases are not shown in Figure 1076.

Unlike EXT_TRIGIN[x:x], ATOM_CH_TRIGIN[x:x] is not synchronized with the selected clock enable signal of channel x. For the application of 2 channels generating PWM signals synchronously, CLSi_ATOM_CHx_CTRL_SOMP**.**CLK_SRC of the triggering channel and the triggered channel should be configured with the same clock resolution and the same cluster clock.

44.3.1.8.3 ATOM channel modes

As described above, each **ATOM** channel can operate independently from each other in one of five dedicated output modes:

- **ATOM** Signal Output Mode Immediate (SOMI)
- **ATOM** Signal Output Mode Compare (SOMC)
- **ATOM** Signal Output Mode PWM (SOMP)
- **ATOM** Signal Output Mode Serial (SOMS)
- **ATOM** Signal Output Mode Buffered Compare (SOMB)

The Signal Output Mode PWM (SOMP) is principally the same as the output mode for the **TOM** sub-module. The other modes provide additional functionality for signal output control. All operation modes are described in more detail in the following sections.

In any output mode, if a channel is enabled, one-shot mode is disabled (CLSi_ATOM_CHx_CTRL.OSM=0; only used in modes SOMP and SOMS) and CLSi_ATOM_CHx_CM0.CM0 >= CLSi_ATOM_CHx_CN0.CN0, the counter CLSi_ATOM_CHx_CN0.CN0 is incrementing until it reaches CLSi_ATOM_CHx_CM0.CM0.

To avoid unintended counting of CLSi_ATOM_CHx_CN0.CN0 after enabling a channel, it is recommended to reset a channel (or at least CLSi_ATOM_CHx_CN0.CN0 and CLSi_ATOM_CHx_CM0.CM0) before any change on the mode bits CLSi_ATOM_CHx_CTRL.MODE and CLSi_ATOM_CHx_CTRL.OSM.

In the following sections the terms "100% duty cycle" and "0% duty cycle" will be used. 100% duty cycle is defined as a constant output level on CLSi_ATOM_CHx_CTRL_SOMP.SL of ATOM_OUT*[x]* over the whole period. 0% duty cycle is defined as a constant output level on !CLSi_ATOM_CHx_CTRL_SOMP.SL of ATOM_OUT*[x]* over the whole period.

ATOM signal output mode immediate (SOMI)

In **ATOM** Signal Output Mode Immediate (SOMI), the **ATOM** channel generates output signals on the ATOM_OUT of instance i and channel x output port immediately after the update of the bit CLSi_ATOM_CHx_STAT.ACBI[0:0] or CLSi_ATOM_CHx_CTRL_SOMI.ACB0 bit.

The update of the output ATOM_OUT of instance i and channel x depends on the bit CLSi_ATOM_CHx_CTRL_SOMI.ACB0 and the bit CLSi_ATOM_CHx_CTRL_SOMI.SL. The bit CLSi_ATOM_CHx_STAT.ACBI[0:0] has no effect in this case.

The initial **ATOM** channel port pin ATOM_OUT signal level has to be specified by the CLSi_ATOM_CHx_CTRL_SOMI.SL bit when CLSi_ATOM_AGC_OUTEN_CTRL.OUTEN_CTRLk (k=0-7) (x = k) is disabled (see chapter CLSi_ATOM_AGC_OUTEN_CTRL) for details.

In SOMI mode the output behavior depends on the CLSi_ATOM_CHx_CTRL_SOMI.SL bit and the bit CLSi_ATOM_CHx_STAT.ACBI[0:0] or the bit CLSi_ATOM_CHx_CTRL_SOMI.ACB0:

Table 2226 Output behavior in SOMI mode

CLSi_ATOM_CHx_CTRL_SOMI.SL	CLSi_ATOM_CHx_STAT.ACBI**[0:0]**/ CLSi_ATOM_CHx_CTRL_SOMI.ACB0	**Output behavior**
0	0	Set output to inverse of CLSi_ATOM_CHx_CTRL_SOMI.SL (1)
0	1	Set output to CLSi_ATOM_CHx_CTRL_SOMI.SL (0)
1	0	Set output to inverse of CLSi_ATOM_CHx_CTRL_SOMI.SL (0)
1	1	Set output to CLSi_ATOM_CHx_CTRL_SOMI.SL (1)

The signal level bit CLSi_ATOM_CHx_STAT.ACBI[0:0] is transferred to the SOU sub-unit of the **ATOM** and made visible at the output port according to the table above immediately after the data was received by the ACI.

ATOM signal output mode compare (SOMC)

Overview

In **ATOM** Signal Output Mode Compare (SOMC) the output action is performed depending on the comparison between input values located in CLSi_ATOM_CHx_CM0.CM0 and/or CLSi_ATOM_CHx_CM1.CM1 registers and the two (three) time base values CCM[i]_TBU_TS0 or CCM[i]_TBU_TS1 (or CCM[i]_TBU_TS2) provided by the **TBU**. For a description of the time base generation please refer to the **TBU** specification in Time base unit (**TBU**

). It is configurable, which of the two (three) time bases is to be compared with one or both values in CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM1.CM1.

The behavior of the two compare units CCU0 and CCU1 is controlled with the bits CLSi_ATOM_CHx_CTRL_SOMC.ACB42.

Based on the configured compare strategy CLSi_ATOM_CHx_CTRL_SOMC.ACB42 or CLSi_ATOM_CHx_STAT.ACBI[4:2], CCU0 unit always performs cyclic event compare between CLSi_ATOM_CHx_CM0.CM0 and the selected **TBU** time base CCM[i]_TBU_TS0/CCM[i]_TBU_TS1/ CCM[i]_TBU_TS2 while CCU1 unit always performs cyclic event compare between CLSi_ATOM_CHx_CM1.CM1 and the selected **TBU** time base CCM[i]_TBU_TS0/CCM[i]_TBU_TS1/CCM[i]_TBU_TS2. Please refer to Cyclic event compare for more information about cyclic event compare strategy. When the selected time base is "cyclically greater than or equal to" the compare value of CLSi_ATOM_CHx_CM0.CM0, CCU0 compare match event is considered to have occurred. When the selected time base is "cyclically greater than or equal to" the compare value of CLSi_ATOM_CHx_CM1.CM1, CCU1 compare match event is considered to have occurred. Whenever CCU0 or CCU1 compare match event has occurred, an edge is generated on output ATOM_OUT[x:x], depending on the predefined signal level in CLSi_ATOM_CHx_CTRL_SOMC.SL bit in combination with two control bits CLSi_ATOM_CHx_CTRL_SOMC.ACB10 or CLSi_ATOM_CHx_STAT.ACBI[1:0].

In SOMC mode the channel is always disabled after the specified compare match event has occurred. The shadow registers are used to store two timestamp values at the match time. The channel compare can be re-enabled by first reading the shadow registers and by providing new data for CLSi_ATOM_CHx_CM0.CM0/ CLSi_ATOM_CHx_CM1.CM1 registers. For a detailed description please refer to the SOMC mode controlled by configuration interface.

If three time bases exist for the **eGTM** there must be a preselection between CCM[i]_TBU_TS1 and CCM[i]_TBU_TS2 for the **ATOM** channel. This can be done with CLSi_ATOM_CHx_CTRL_SOMC.TB12_SEL bit.

If CCM[i]_TBU_TS1/CCM[i]_TBU_TS2 is selected for cyclic event compare in CCU0 or CCU1 unit, CLSi_ATOM_CHx_CTRL_SOMC.CMP_CTRL must be configured to assure correct cyclic event compare. If the selected **TBU** time base CCM[i]_TBU_TS1/CCM[i]_TBU_TS2 performs up-counting, CLSi_ATOM_CHx_CTRL_SOMC.CMP_CTRL must be configured as 0. If the selected **TBU** time base CCM[i]_TBU_TS1/CCM[i]_TBU_TS2 performs down-counting, CLSi_ATOM_CHx_CTRL_SOMC.CMP_CTRL must be configured as 1. The bit CLSi_ATOM_CHx_CTRL_SOMC.CMP_CTRL has no impact on cyclic event compare against the **TBU** time base CCM[i]_TBU_TS0.

When configured in SOMC mode, the channel port pin has to be initialized to an initial signal level. This initial level after enabling the **ATOM** channel is determined by the CLSi_ATOM_CHx_CTRL_SOMC.SL bit. If the output is disabled, the signal level is set to the inverse level of the CLSi_ATOM_CHx_CTRL_SOMC.SL bit.

If the channel is disabled and the output is still enabled with CLSi_ATOM_CHx_CTRL_SOMC.FREEZE=0, the register SOUR and the output ATOM_OUT[x:x]is set to the CLSi_ATOM_CHx_CTRL_SOMC.SL bit.

On a compare match event the shadow register CLSi_ATOM_CHx_SR0.SR0 and CLSi_ATOM_CHx_SR1.SR1 are used to capture the **TBU** timestamp values. CLSi_ATOM_CHx_SR0.SR0 always holds CCM[i]_TBU_TS0 and CLSi_ATOM_CHx_SR1.SR1 either holds CCM[i]_TBU_TS1 or CCM[i]_TBU_TS2 depending on the CLSi_ATOM_CHx_CTRL_SOMC.TB12_SEL bit.

When the channel is disabled and the compare registers are written, the compare registers CLSi_ATOM_CHx_CM0.CM0/CLSi_ATOM_CHx_CM1.CM1 are loaded with the written value and the channel starts with the comparison against these values, when the channel is enabled.

SOMC mode controlled by configuration interface

The output of the **ATOM** channel is set at a compare match event depending on the CLSi_ATOM_CHx_CTRL_SOMC.ACB10 in combination with the CLSi_ATOM_CHx_CTRL_SOMC.SL bit. The comparison is performed according to different compare strategy specified by CLSi_ATOM_CHx_CTRL_SOMC.ACB42. The output behavior according to CLSi_ATOM_CHx_CTRL_SOMC.ACB10 bit field in the control register is shown in the following table:

Table 2227 Output behavior according to the CLSi_ATOM_CHx_CTRL_SOMC.ACB10 bit field in the control register

CLSi_ATOM_CHx_CTRL.SL	CLSi_ATOM_CHx_CTRL_SOMC.ACB10[1:1]	CLSi_ATOM_CHx_CTRL_SOMC.ACB10[0:0]	Output behavior
0	0	0	No signal level change at output (exception in Table 2230 mode CLSi_ATOM_CHx_CTRL_SOMC.ACB42=001_B)
0	0	1	Set output signal level to 1 (exception in Table 2230 mode CLSi_ATOM_CHx_CTRL_SOMC.ACB42=001_B)
0	1	0	Set output signal level to 0 (exception in Table 2230 mode CLSi_ATOM_CHx_CTRL_SOMC.ACB42=001_B)
0	1	1	Toggle output signal level (exception in Table 2230 mode CLSi_ATOM_CHx_CTRL_SOMC.ACB42=001_B)
1	0	0	No signal level change at output (exception in Table 2230 mode CLSi_ATOM_CHx_CTRL_SOMC.ACB42=001_B)
1	0	1	Set output signal level to 0 (exception in Table 2230 mode CLSi_ATOM_CHx_CTRL_SOMC.ACB42=001_B)
1	1	0	Set output signal level to 1 (exception in Table 2230 mode CLSi_ATOM_CHx_CTRL_SOMC.ACB42=001_B)
1	1	1	Toggle output signal level (exception in Table 2230 mode CLSi_ATOM_CHx_CTRL_SOMC.ACB42 =001_B)

The capture/compare strategy of the two units CCU0 and CCU1 can be controlled with the CLSi_ATOM_CHx_CTRL_SOMC.ACB42 bit field. The CCU0 unit always compares CLSi_ATOM_CHx_CM0.CM0 with the selected **TBU** time base. The CCU1 unit always compares CLSi_ATOM_CHx_CM1.CM1 with the selected **TBU**

time base. Different CCU0/CCU1 comparison strategies controlled by CLSi_ATOM_CHx_CTRL_SOMC.ACB42 are shown in the following table:

Table 2228 Capture/compare strategy of the two CCUx units controlled by CLSi_ATOM_CHx_CTRL_SOMC.ACB42 bit field

CLSi_ATOM_CHx_CTRL_SOMC.ACB42[2:2]	CLSi_ATOM_CHx_CTRL_SOMC.ACB42[1:1]	CLSi_ATOM_CHx_CTRL_SOMC.ACB42[0:0]	CCU0/CCU1 comparison control
0	0	0	Serve First: Compare in CCU0 using CCM[i]_TBU_TS0 and in parallel in CCU1 using CCM[i]_TBU_TS1 or CCM[i]_TBU_TS2. Disable the other comparison at one compare match event. Output signal level at the compare match event is defined by combination of CLSi_ATOM_CHx_CTRL_SOMC.SL and CLSi_ATOM_CHx_CTRL_SOMC.ACB10. Details see Table 2229.
0	0	1	Serve First: Compare in CCU0 using CCM[i]_TBU_TS0 and in parallel in CCU1 using CCM[i]_TBU_TS1 or CCM[i]_TBU_TS2. Disable the other comparison at one compare match event. Output signal level at the compare match event is defined by combination of CLSi_ATOM_CHx_CTRL_SOMC.SL and CLSi_ATOM_CHx_CTRL_SOMC.ACB10. Details see Table 2230.

(table continues...)

Table 2228 (continued) Capture/compare strategy of the two CCUx units controlled by CLSi_ATOM_CHx_CTRL_SOMC.ACB42 bit field

CLSi_ATOM_CHx_CTRL_SOMC.ACB42[2:2]	CLSi_ATOM_CHx_CTRL_SOMC.ACB42[1:1]	CLSi_ATOM_CHx_CTRL_SOMC.ACB42[0:0]	CCU0/CCU1 comparison control
0	1	0	Compare in CCU0 only, use time base CCM[i]_TBU_TS0. Output signal level at the compare match event is defined by combination of CLSi_ATOM_CHx_CTRL_SOMC.SL and CLSi_ATOM_CHx_CTRL_SOMC.ACB10 (details see Table 2227).
0	1	1	Compare in CCU1 only, use time base CCM[i]_TBU_TS1 or CCM[i]_TBU_TS2. Output signal level at the compare match event is defined by combination of CLSi_ATOM_CHx_CTRL_SOMC.SL and CLSi_ATOM_CHx_CTRL_SOMC.ACB10 (details see Table 2227).
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using CCM[i]_TBU_TS0. Output signal level at the CCU0 compare match event is defined by combination of CLSi_ATOM_CHx_CTRL_SOMC.SL and CLSi_ATOM_CHx_CTRL_SOMC.ACB10 (details see Table 2227). At the CCU1 compare match event the output level is toggled.

(table continues...)

Table 2228 (continued) Capture/compare strategy of the two CCUx units controlled by CLSi_ATOM_CHx_CTRL_SOMC.ACB42 bit field

CLSi_ATOM_CHx_CTRL_SOMC.ACB42[2:2]	CLSi_ATOM_CHx_CTRL_SOMC.ACB42[1:1]	CLSi_ATOM_CHx_CTRL_SOMC.ACB42[0:0]	CCU0/CCU1 comparison control
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using CCM[i]_TBU_TS1 or CCM[i]_TBU_TS2. Output signal level at the CCU0 compare match event is defined by combination of CLSi_ATOM_CHx_CTRL_SOMC.SL and CLSi_ATOM_CHx_CTRL_SOMC.ACB10 (details see Table 2227). At the CCU1 compare match event the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using CCM[i]_TBU_TS0 and then in CCU1 using CCM[i]_TBU_TS1 or CCM[i]_TBU_TS2. Output signal level at the CCU1 compare match event is defined by combination of CLSi_ATOM_CHx_CTRL_SOMC.SL and CLSi_ATOM_CHx_CTRL_SOMC.ACB10 (details see Table 2227).
1	1	1	Cancels pending comparison

The behavior of the CLSi_ATOM_CHx_STAT.ACBI[4:2]/CLSi_ATOM_CHx_CTRL_SOMC.ACB42 bit combinations 000_B and 001_B is described in more detail in Table 2229 and Table 2230.

If the **ATOM** channel is enabled, the CLSi_ATOM_CHx_CM0.CM0 and/or CLSi_ATOM_CHx_CM1.CM1 registers and the CLSi_ATOM_CHx_CTRL_SOMC.ACB42 bit field can be updated over the configuration interface as long as the first match event occurs in case of a 'serve first' compare strategy or as long as the overall match event occurs in case of the other compare strategies.

After a compare match event that causes an update of the shadow registers CLSi_ATOM_CHx_SR0.SR0/ CLSi_ATOM_CHx_SR1.SR1 and before reading the CLSi_ATOM_CHx_SR0.SR0 and/or CLSi_ATOM_CHx_SR1.SR1 register, the update of the registers CLSi_ATOM_CHx_CM0.CM0 and/or CLSi_ATOM_CHx_CM1.CM1 is possible but has no effect.

To set up a new compare action, first the CLSi_ATOM_CHx_SR0.SR0 and/or CLSi_ATOM_CHx_SR1.SR1 register containing captured values have to be read and then new compare values have to be written into the register CLSi_ATOM_CHx_CM0.CM0 and/or CLSi_ATOM_CHx_CM1.CM1.

Which register CLSi_ATOM_CHx_CM0.CM0 or CLSi_ATOM_CHx_CM1.CM1 has to be updated depends on the compare strategy defined in the CLSi_ATOM_CHx_CTRL_SOMC.ACB42 bit field of the channel control register. Since the channel immediately starts with the comparison after the CLSi_ATOM_CHx_CM0.CM0/ CLSi_ATOM_CHx_CM1.CM1 register was/were written, the compare strategy has to be updated before the CLSi_ATOM_CHx_CM0.CM0/CLSi_ATOM_CHx_CM1.CM1 registers are written.

For the 'serve last' compare strategies, if the register CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM1.CM1 are updated, it can happen that one or both compare values are already located in the past. In any case, the **ATOM** channel will first wait until both compare values are written before it starts the time base comparisons to avoid a deadlock.

The configuration interface can be used to check at any time, whether at least one of the capture compare registers of the **ATOM** channel contains valid data, and to wait for a compare event to occur. This is signaled by the CLSi_ATOM_CHx_STAT.DV bit inside the CLSi_ATOM_CHx_STAT register.

***Note**: For 'serve last' compare strategies, if CLSi_ATOM_CHx_STAT.DV bit is currently not set, writing to CLSi_ATOM_CHx_CM0.CM0 or CLSi_ATOM_CHx_CM1.CM1 immediately sets the CLSi_ATOM_CHx_STAT.DV bit although the compare is only started if both values are written.*

An exception for update of register CLSi_ATOM_CHx_CM0.CM0/CLSi_ATOM_CHx_CM1.CM1 exists in SOMC mode and CCUx control mode 'serve last'. If in this mode the CCU0 compare match event occurred, the update of register CLSi_ATOM_CHx_CM0.CM0/CLSi_ATOM_CHx_CM1.CM1 over the configuration interface is blocked until the CCU1 compare match event.

In the 'serve last' mode (CLSi_ATOM_CHx_CTRL_SOMC.ACB42= 100_B or CLSi_ATOM_CHx_CTRL_SOMC.ACB42=101_B) it is possible to generate very small spikes on the output pin by loading CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM1.CM1 with two timestamp values for CCM[i]_TBU_TS0, CCM[i]_TBU_TS1 or CCM[i]_TBU_TS2 close together. The output pin will then be set or reset depending on the CLSi_ATOM_CHx_CTRL_SOMC.SL bit and CLSi_ATOM_CHx_CTRL_SOMC.ACB10 bit field on the first match event and the output will toggle on the second compare event in the CCU1 compare unit.

***Note**: Since the CCU0 will enable the CCU1 once it reaches its comparison timestamp, the bigger (smaller) timestamp has to be loaded into the CLSi_ATOM_CHx_CM1.CM1 register. The order of the comparison timestamps depends on the defined greater-equal or less-equal comparison of the CCU0/CCU1 units.*

In addition to storing the captured timestamps in the shadow registers, the **ATOM** channel provides the result of the compare match event in the CLSi_ATOM_CHx_STAT.ACBO[4:4] and CLSi_ATOM_CHx_STAT.ACBO[3:3] bits. The meaning of the bits is shown in the following table:

Table 2231 Compare match event CLSi_ATOM_CHx_STAT.ACBO[4:4] and CLSi_ATOM_CHx_STAT.ACBO[3:3] bits of

CLSi_ATOM_CHx_STAT.ACBO[4:4]	CLSi_ATOM_CHx_STAT.ACBO[3:3]	Indication
0	1	CCU0 compare match occurred
1	0	CCU1 compare match occurred

The CLSi_ATOM_CHx_STAT.ACBO bit field is reset, when the CLSi_ATOM_CHx_STAT.DV bit is set.

Depending on the capture compare unit where the compare match event occurred, the interrupt ATOM_CCU0TC[x]_IRQ or ATOM_CCU1TC[x]_IRQ is raised.

In case of 'serve first' compare strategy, if both events CCU0 and CCU1 occur at the same point in time, both interrupts will be raised and CLSi_ATOM_CHx_STAT.ACBO will be 10_B due to higher priority.

The behavior of an **ATOM** channel in SOMC mode with CLSi_ATOM_CHx_CTRL_SOMC.EUPM=0 controlled via configuration interface is depicted in Figure 1078.

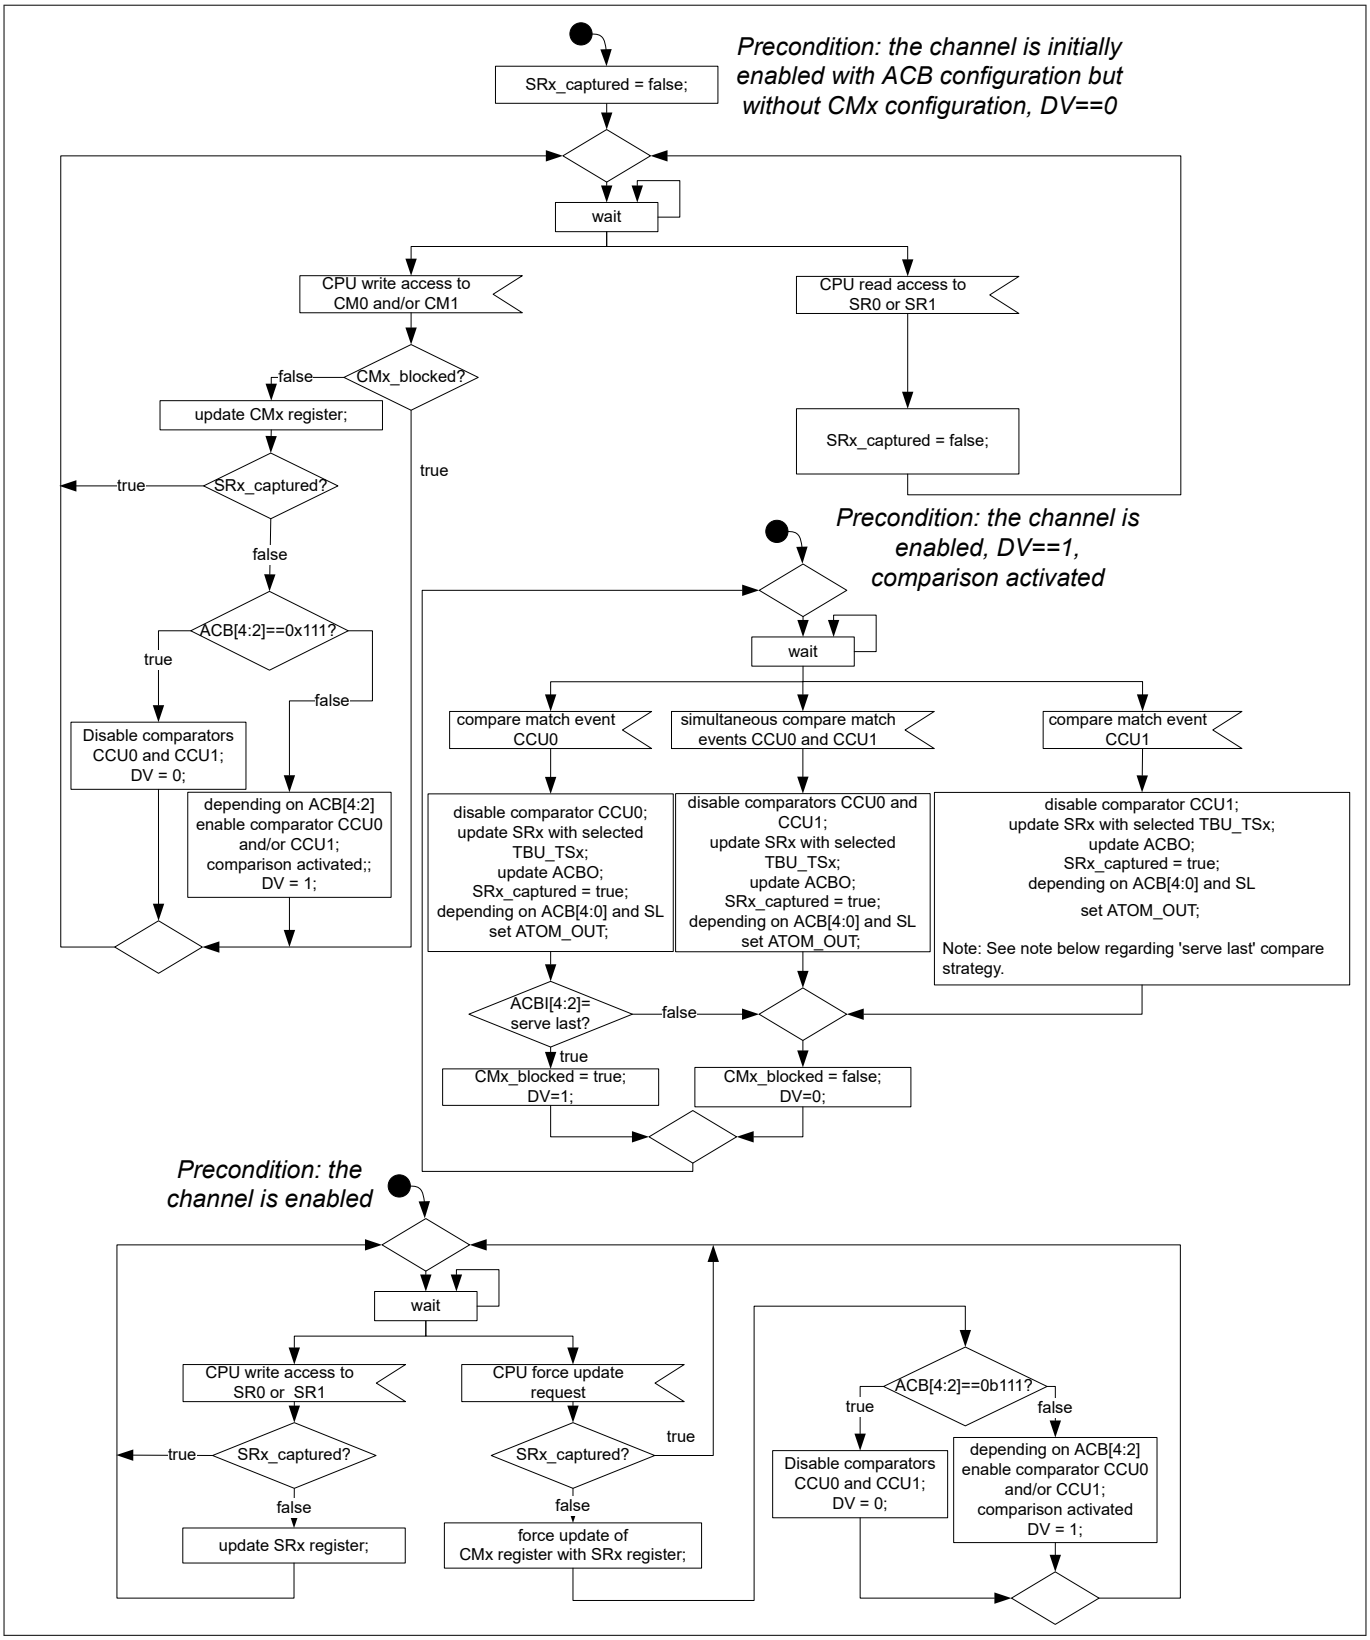

Figure 1078 SOMC state diagram for channel controlled via configuration interface if CLSi_ATOM_CHx_CTRL_SOMC.EUPM=0

***Note**: In case of 'serve last' compare strategy the compare match in CCU0 is expected before the compare match in CCU1. But if the CCU1 compare match occurs first, CLSi_ATOM_CHx_SR0.SR0, CLSi_ATOM_CHx_SR1.SR1 as well as CLSi_ATOM_CHx_STAT.ACBO will not be updated and also the output signal will not be set. After first occurance of CCU0 match and afterwards a CCU1 match the ordering is as expected and captures and signal level output changes will be performed on both matches.*

ATOM signal output mode PWM (SOMP)

In **ATOM** Signal Output Mode PWM (SOMP), the **ATOM** sub-module channel is able to generate complex PWM signals with different pulse widths and periods by configuring different operation registers CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1 and the control register CLSi_ATOM_CHx_CTRL_SOMP. **ATOM** SOMP mode has almost the same functions as the **TOM** module.

The signal level of the pulse generated inside the period can be configured inside the channel control register (CLSi_ATOM_CHx_CTRL_SOMP.SL). The initial signal output level for the channel is the inverse pulse level defined by the CLSi_ATOM_CHx_CTRL_SOMP.SL bit. Figure 1081 depicts this behavior.

The counter CLSi_ATOM_CHx_CN0.CN0 of each channel can run in two different modes depending on configuration of CLSi_ATOM_CHx_CTRL_SOMP.UDMODE.

By default, the counter counts only up until it reaches a specified value and it is then reset to 0.

In the up down counter mode CLSi_ATOM_CHx_CN0.CN0 switches between counting up and counting down.

Like **TOM** module, in SOMP mode, each **ATOM** channel can further work in one-shot mode by configuring CLSi_ATOM_CHx_CTRL_SOMP.OSM=1. Pulse count modulation mode and high-resolution mode are also available depending on the configuration of the control register CLSi_ATOM_CHx_CTRL_SOMP.

Pulse width, period, signal level and clock frequency update mechanisms

Since **ATOM** shows a behavior similar to **TOM** module in SOMP mode, their update mechanisms of pulse width, period, signal level and clock frequency are also almost same. The two operation registers CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM1.CM1 can be updated with the content of the shadow register CLSi_ATOM_CHx_SR0.SR0 and CLSi_ATOM_CHx_SR1.SR1. The register CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC that determines the clock resolution of the counter CLSi_ATOM_CHx_CN0.CN0 can be updated with its shadow register CLSi_ATOM_CHx_CTRL_SR.CLK_SRC_SR. The signal level defined in bit field CLSi_ATOM_CHx_CTRL_SOMP.SL can be updated with its shadow register CLSi_ATOM_CHx_CTRL_SR.SL_SR.

The update of the configuration register CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1, CLSi_ATOM_CHx_CTRL_SOMP.SL and CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC with the content of their shadow registers can be performed under the following conditions:

- In case CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0 =0_B when the specified CLSi_ATOM_CHx_CTRL_SOMP.UDMODE compare condition is fulfilled the update will be performed. Additional information is given in the bit field description of CLSi_ATOM_CHx_CTRL_SOMP.UDMODE. The update mechanism must be enabled by configuring CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) =10_B.
- In case CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0 =1_B when the channel [x] is triggered by the signal ATOM_CH_TRIGIN*[x:x]* from another **ATOM** channel or by the external trigger signal EXT_TRIGIN of the assigned **TIM** channel, after it is synchronized to the selected CCM[i]_CLK_RES of channel [x], the update will also be performed. The update mechanism must be enabled by configuring CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) =10_B.
- These configuration registers can be force-updated via a trigger signal via ATOM_FUPD or via EXT_TRIGIN.
- In SOMP mode, if CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0 =0_B, the operating register is continuously updated as long as CLSi_ATOM_CHx_CM0.CM0 =0_H. This update condition must be enabled by configuring

CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) =10_B regardless of the source for the shadow registers. The source can be the configuration interface or the **ARU**.

- When the stop condition of the clock is configured (CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC =1100_B), new data is received via the **ARU** interface, until the clock stop condition is released. This update case does not depend on the state of CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7).

Based on the update mechanisms above, these registers CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1, CLSi_ATOM_CHx_CTRL_SOMP.SL, CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC can be updated synchronously and asynchronously. Synchronous update means that the pulse width, period duration, signal level and the counter operating clock frequency can be changed at the end of the running PWM period. Asynchronous update means that the pulse width, period duration, signal level and the counter operating clock frequency can also be changed during the actual running PWM period. The following two sections provide examples of synchronous update and asynchronous update of pulse width in continuous up mode with CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0 = 0.

An update of pulse width, period and the counter clock frequency becoming effective synchronously with start of a new period can easily be reached by performing the below steps:

1. Disable the update of the action register with the content of the corresponding shadow register by setting the channel-specific configuration bit field CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)** = 01_B. (Configuring CLSi_ATOM_CHx_CTRL_SOMP.UDMODE=01_B if in counting up-down mode.)
2. Write new desired values to CLSi_ATOM_CHx_SR0.SR0, CLSi_ATOM_CHx_SR1.SR1, CLSi_ATOM_CHx_CTRL_SR.SL_SR, CLSi_ATOM_CHx_CTRL_SR.CLK_SRC_SR.
3. Enable update of the action register by setting the channel-specific configuration bit field CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)** = 10_B.

Asynchronous update of the operation registers can be realized by hot reconfiguring directly the registers CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1, CLSi_ATOM_CHx_CTRL_SOMP.SL, CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC or hot reconfiguring their shadow registers and then using the force update mechanism. Such asynchronous update mechanism is sometimes helpful to change the PWM parameters of the current running PWM signal. For example, in continuous counting up mode, the current running PWM period can be reduced by asynchronously updating the value of CLSi_ATOM_CHx_CM0.CM0 with a smaller value before the end of the current period. However, since the behavior depends on the access or update time of registers and the current running operation phase of the channel, which is often difficult to control, then the behavior after an asynchronous update can be unpredictable and unexpected. Therefore, such an asynchronous update must be carefully performed in real application. The following steps are recommended to apply the force update mechanism on channel x:

1. Disable the update of the action register with the content of the corresponding shadow register by setting the channel-specific configuration bit field CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)** = 01_B.
2. Write new desired values to CLSi_ATOM_CHx_SR0.SR0, CLSi_ATOM_CHx_SR1.SR1, CLSi_ATOM_CHx_CTRL_SR.SL_SR, CLSi_ATOM_CHx_CTRL_SR.CLK_SRC_SR.
3. Enable the force update of the operation registers by setting the channel-specific configuration bit field CLSi_ATOM_AGC_FUPD_CTRL.FUPD_CTRLk (k=0-7) **(k=x)** = 10_B, CLSi_ATOM_AGC_FUPD_CTRL.RSTCN0_CHk (k=0-7) **(k=x)** = 01_B.
4. Write CLSi_ATOM_AGC_GLB_CTRL.HOST_TRIG = 1 to trigger the force update.

Synchronous update of pulse width only

A synchronous update of the pulse width only can be done by simply writing the desired new value to register CLSi_ATOM_CHx_SR1.SR1 without preceding disable of the update mechanism (as described in the chapter above). As an example in SOMP continuous counting up mode with CLSi_ATOM_CHx_CTRL.RST_CCU0=0 is shown in Figure 1079, the new pulse width is then applied in the period following the period where the update of register CLSi_ATOM_CHx_SR1.SR1 is done.

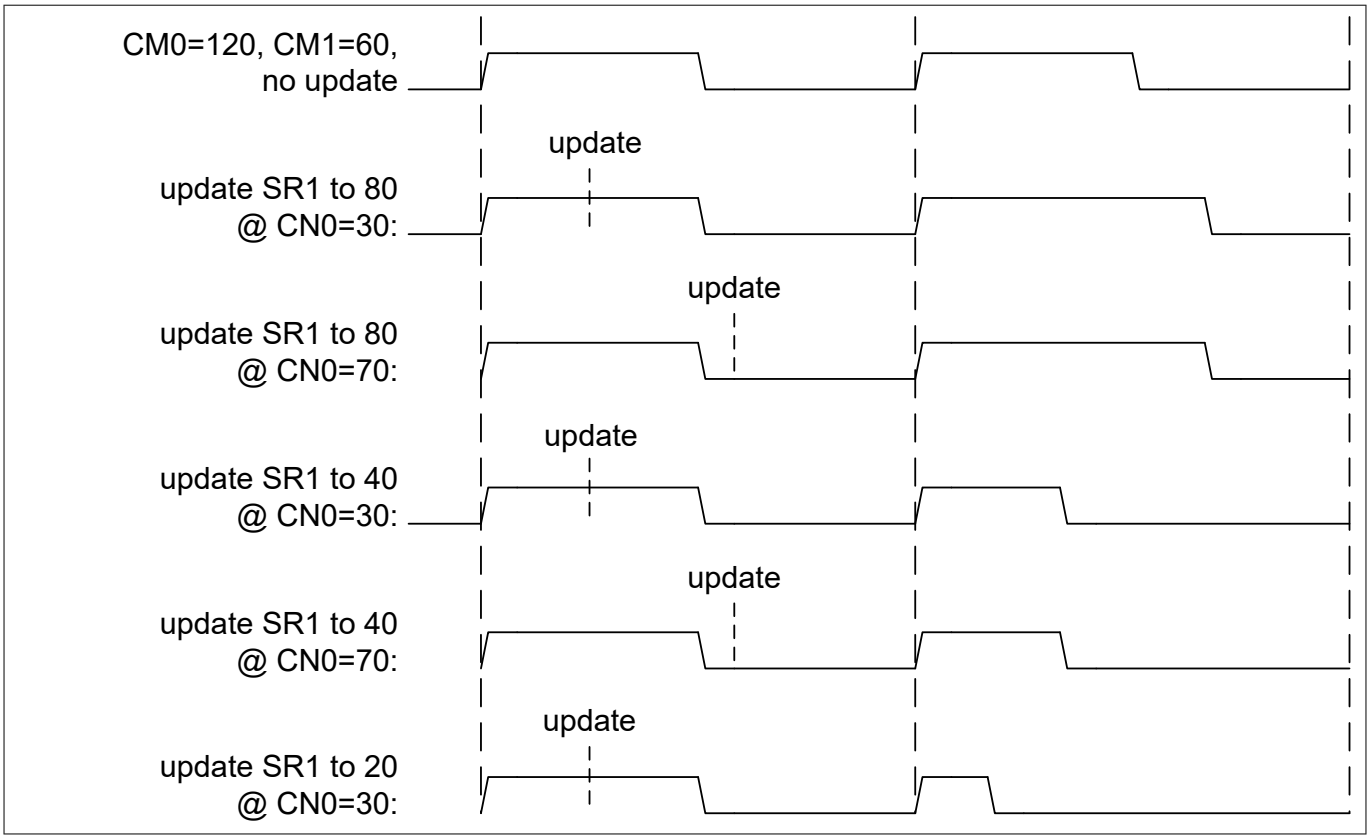

Figure 1079 Synchronous update of pulse width only in SOMP continuous counting up mode with CLSi_ATOM_CHx_CTRL.RST_CCU0=0

Asynchronous update of pulse width only

If the update of the pulse width should be performed independent of the start of a new period (asynchronous), it is mandatory to additionally disable the synchronous update mechanism as a whole (i.e. configuring bits CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)**=01_B of corresponding channel x) and then update the operation register. On the one hand, the desired new value can be written directly to register CLSi_ATOM_CHx_CM1.CM1. On the other hand, it can be realized by writing the new value to CLSi_ATOM_CHx_SR1.SR1 and afterwards updating the value of CLSi_ATOM_CHx_CM1.CM1 by using the asynchronous force update mechanism (configuring CLSi_ATOM_AGC_FUPD_CTRL.FUPD_CTRLk (k=0-7) **(k=x)** = 10_B, CLSi_ATOM_AGC_FUPD_CTRL.RSTCN0_CHk (k=0-7) **(k=x)** = 01_B and then writing bit CLSi_ATOM_AGC_GLB_CTRL.HOST_TRIG = 1).

Depending on the point of time of the update of CLSi_ATOM_CHx_CM1.CM1 in relation to the actual value of CLSi_ATOM_CHx_CN0.CN0 and CLSi_ATOM_CHx_CM1.CM1, the new pulse width is applied in the current period or the following period. That means asynchronous update of CLSi_ATOM_CHx_CM1.CM1 in the current period can at least change the pulse width in the next PWM signal. The behavior of the output signal due to the different possibilities of an asynchronous update during a PWM period in SOMP continuous counting up mode with CLSi_ATOM_CHx_CTRL.RST_CCU0=0 is shown in Figure 1080. The new pulse width may jitter from update to update by maximum one period (given by CLSi_ATOM_CHx_CM0.CM0). However, the period remains unchanged. On an asynchronous update, it is guaranteed, that no spike occurs at the output port of the channel due to a too late update of the operation registers.

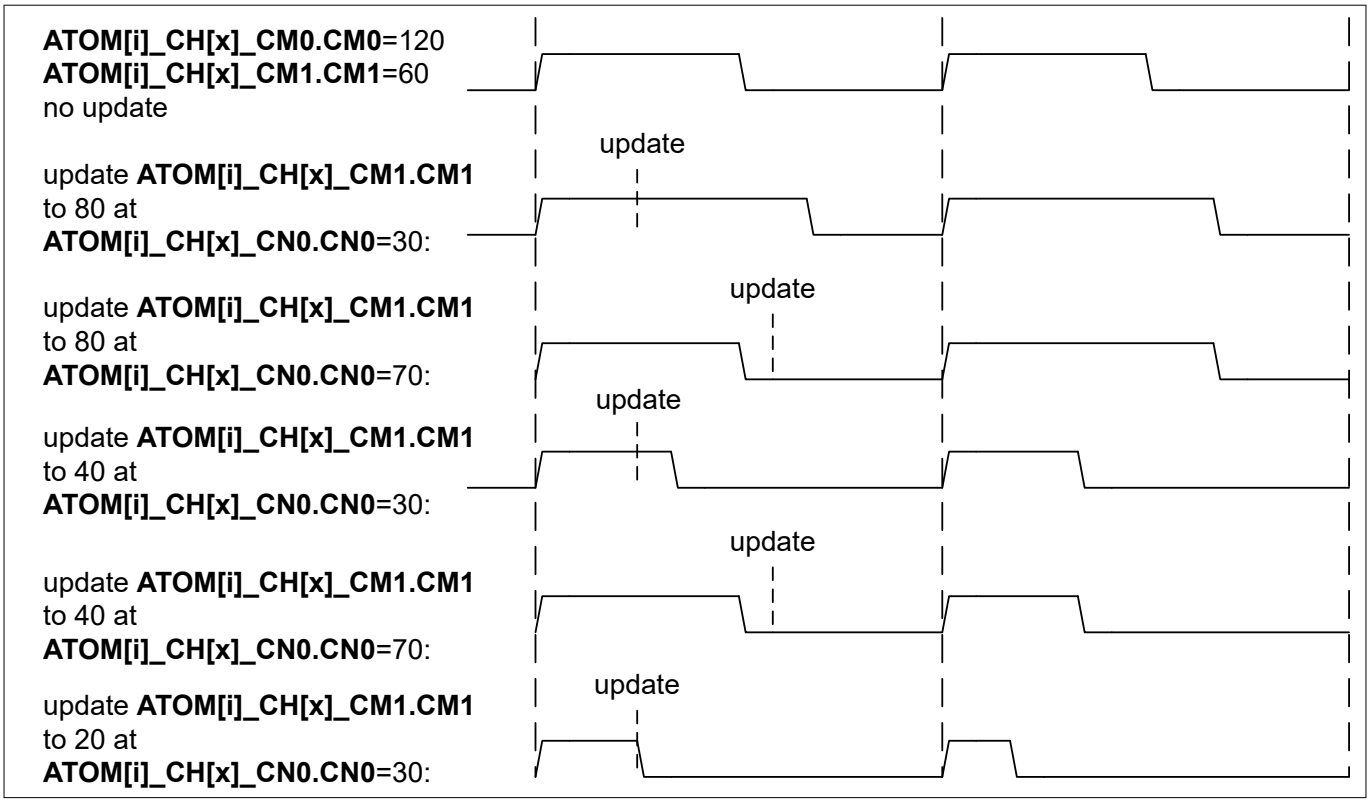

Figure 1080 Asynchronous update of pulse width only in SOMP continuous counting up mode with CLSi_ATOM_CHx_CTRL.RST_CCU0=0

Update controlled by configuration interface

Update of operation registers CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1, CLSi_ATOM_CHx_CTRL_SOMP.SL and CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC can also be controlled by the **AEI** bus interface. On the one hand, they can be synchronously updated from their shadow registers CLSi_ATOM_CHx_SR0.SR0, CLSi_ATOM_CHx_SR1.SR1, CLSi_ATOM_CHx_CTRL_SR.SL_SR and CLSi_ATOM_CHx_CTRL_SR.CLK_SRC_SR when ATOM_UPEN[x:x] = 1 in the AGC sub-unit. Normally, synchronous update happens at the end of PWM period when the counter is reset. On the other hand, they can be asynchronously updated from the shadow registers triggered by ATOM_FUPD[x:x] signal in AGC sub-unit. Furthermore, CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1 and CLSi_ATOM_CHx_CTRL_SOMP.SL can be directly asynchronously written via the configuration interface. Such an asynchronous update happens during one PWM period that should be carefully applied to avoid unexpected and unpredicted behavior. For asynchronous update, the synchronous update mechanism has to be locked via the CLSi_ATOM_AGC_GLB_CTRL register with the ATOM_UPEN[x:x] signal in the AGC sub-unit.

On a compare match of CLSi_ATOM_CHx_CN0.CN0 and CLSi_ATOM_CHx_CM0.CM0 or CLSi_ATOM_CHx_CM1.CM1, the output signal level of ATOM_OUT is toggled according to the signal level output bit CLSi_ATOM_CHx_CTRL_SOMP.SL. Please refer to different mode sections for more output generation details.

Thus, the output level of PWM pulse width can be changed during runtime by synchronous update or asynchronous update of CLSi_ATOM_CHx_CTRL_SOMP.SL bit of the channel configuration register.

Continuous counting up mode

In SOMP continuous counting up mode the **ATOM** channel starts incrementing the counter CLSi_ATOM_CHx_CN0.CN0 once it is enabled by setting the corresponding bits in register CLSi_ATOM_AGC_ENDIS_STAT (refer to Figure 1075 for details of enabling an **ATOM** channel).

In this mode with CLSi_ATOM_CHx_CTRL_SOMP.UDMODE=00_B (i.e. CLSi_ATOM_CHx_CN0.CN0 counts only up), depending on configuration bits CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0 the counter register CLSi_ATOM_CHx_CN0.CN0 can be reset either when the counter value is equal to the compare value CLSi_ATOM_CHx_CM0.CM0 (i.e. CLSi_ATOM_CHx_CN0.CN0 counts only from 0 to CLSi_ATOM_CHx_CM0.CM0-1 and is then reset to 0) or when the trigger signal ATOM_CH_TRIGOUT[x-1:x-1] of the preceding channel x-1 (which can also be the last channel of preceding instance **ATOM[i-1]**) is captured by the **ATOM[i]** or when there is trigger signal EXT_TRIGIN[x:x] of the assigned **TIM** channel x after it was synchronized to the selected clock resolution signal.

In this case, if CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)**=10_B, also the operation register CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1, CLSi_ATOM_CHx_CTRL_SOMP.SL and CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC are updated from their shadow registers together with CLSi_ATOM_CHx_CN0.CN0 reset.

As an exception, the input ATOM_CH_TRIGIN[0:0] of instance ATOM0 is triggered by its own last channel 7 via signal ATOM_CH_TRIGOUT[7:7].

The duration of the pulse high or low time and period is measured with the counter in sub-unit CCU0. The trigger of the counter is one of the eight **CMU** clock signals configurable in the channel control register CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC. The register CLSi_ATOM_CHx_CM0.CM0 holds the duration of the period and the register CLSi_ATOM_CHx_CM1.CM1 holds the duration of the pulse width in clock ticks of the selected **CMU** clock SEL_CMU_CLKEN. The signal level of the generated output signal can be configured with the configuration bit CLSi_ATOM_CHx_CTRL_SOMP.SL.

If counter register CLSi_ATOM_CHx_CN0.CN0 of channel x is reset by its own CCU0 unit (i.e. the compare match of CLSi_ATOM_CHx_CN0.CN0>=CLSi_ATOM_CHx_CM0.CM0-1 configured by CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=0), the PWM output behavior is shown in Figure 1081 and the following statements are valid:

- After **ATOM** i channel x is enabled, CLSi_ATOM_CHx_CN0.CN0 counts firstly from its initial value to CLSi_ATOM_CHx_CM0.CM0-1 and is then reset to 0. This phase is defined as initial delay that can be flexibly configured as by the value of (CLSi_ATOM_CHx_CM0.CM0-CLSi_ATOM_CHx_CN0.CN0) multiplied with the selected **CMU** clock period.
- When CLSi_ATOM_CHx_CN0.CN0 is reset from CLSi_ATOM_CHx_CM0.CM0-1 to 0, an edge to CLSi_ATOM_CHx_CTRL_SOMP.SL is generated.
- When CLSi_ATOM_CHx_CN0.CN0 is incrementing and reaches CLSi_ATOM_CHx_CM1.CM1 (CLSi_ATOM_CHx_CN0.CN0>=CLSi_ATOM_CHx_CM1.CM1), an edge to !CLSi_ATOM_CHx_CTRL_SOMP.SL is generated.
- CLSi_ATOM_CHx_CN0.CN0 always counts from 0 to CLSi_ATOM_CHx_CM0.CM0-1 and is then reset to 0.
- If CLSi_ATOM_CHx_CM0.CM0=0 or CLSi_ATOM_CHx_CM0.CM0=1, the counter CLSi_ATOM_CHx_CN0.CN0 is constant 0. It is highly recommended to configure CLSi_ATOM_CHx_CM0.CM0>1.
- If CLSi_ATOM_CHx_CM1.CM1=0 and CLSi_ATOM_CHx_CM0.CM0>1, the output is ! CLSi_ATOM_CHx_CTRL_SOMP.SL (i.e. 0% duty cycle PWM signal).
- If CLSi_ATOM_CHx_CM1.CM1 >= CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM0.CM0 >1, the output is CLSi_ATOM_CHx_CTRL_SOMP.SL (i.e. 100% duty cycle PWM signal).

Since the ATOM_OUT signal level is defined as !CLSi_ATOM_CHx_CTRL_SOMP.SL when the **ATOM** channel is disabled without setting freeze mode, the first PWM period can be shifted earlier by writing an initial offset value to CLSi_ATOM_CHx_CN0.CN0 register. By doing this, the **ATOM** channel first counts until CLSi_ATOM_CHx_CN0.CN0 reaches CLSi_ATOM_CHx_CM0.CM0 and then it toggles the output signal at ATOM_OUT.

In this case, as shown in Figure 1081, 2 interrupt signals ATOM_CCU0TC[x]_IRQ and ATOM_CCU1TC[x]_IRQ of channel x can be generated together with output generation ATOM_OUT[x:x] and both of them are shown on ATOM_IRQ[x:x] if CLSi_ATOM_CHx_IRQ_EN=11_B. When CLSi_ATOM_CHx_CN0.CN0 is reset from CLSi_ATOM_CHx_CM0.CM0 -1 to 0, ATOM_CCU0TC[x]_IRQ of channel x is generated. When CLSi_ATOM_CHx_CN0.CN0 is incrementing to reach CLSi_ATOM_CHx_CM1.CM1, ATOM_CCU1TC[x]_IRQ of

channel x is generated. Especially, if the initial configuration before enabling the channel fulfills the condition CLSi_ATOM_CHx_CN0.CN0 >= CLSi_ATOM_CHx_CM1.CM1 - 1, an interrupt is generated after 1 selected **CMU** clock period on ATOM_CCU1TC[x]_IRQ. Similarly but not shown in the figure, if the initial configuration before enabling the channel fulfills the condition CLSi_ATOM_CHx_CN0.CN0 >= CLSi_ATOM_CHx_CM0.CM0 - 1, an interrupt is generated after 1 selected **CMU** clock period on ATOM_CCU0TC[x]_IRQ. The interrupt signals are always aligned with the edges of the output ATOM_OUT[x:x].

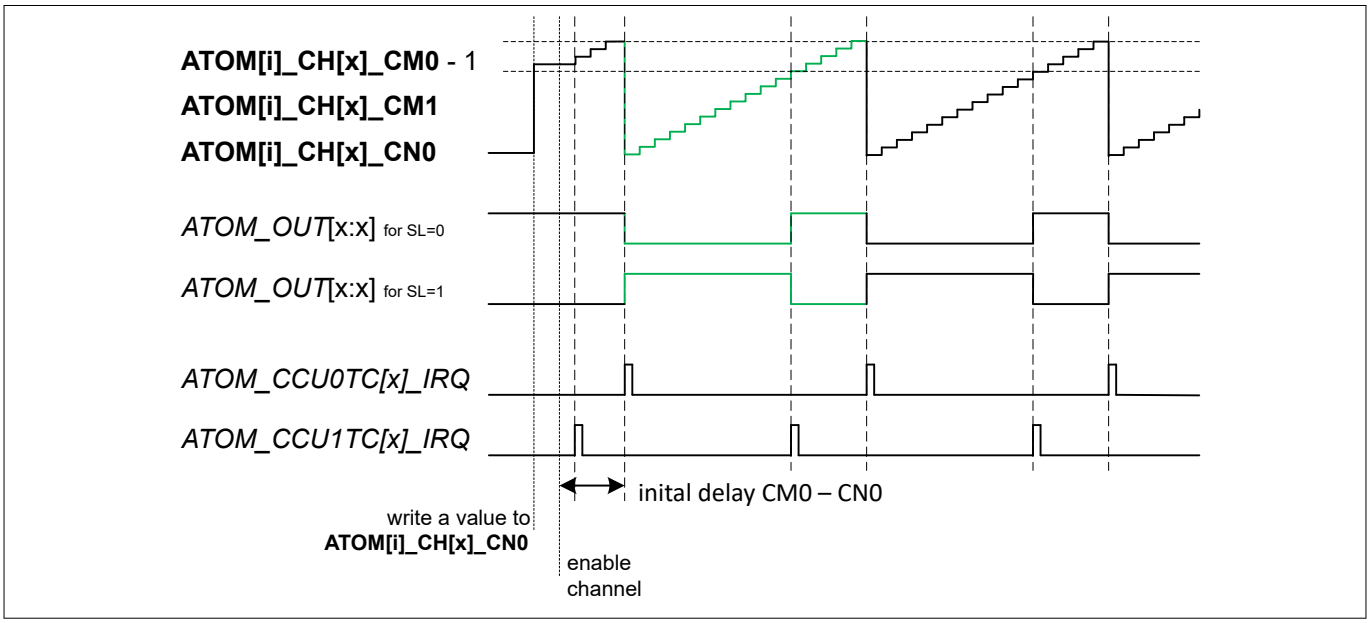

Figure 1081 PWM **output behavior with respect to the** CLSi_ATOM_CHx_CTRL_SOMP.SL **bit in continuous counting up mode if** CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0**=0**

If the counter register CLSi_ATOM_CHx_CN0.CN0 of channel x is reset by the trigger signal coming from another channel or the assigned **TIM** module (configured by CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=1), the PWM output behavior is shown in Figure 1082 and the following statements are valid (with MAX=number of selected CCM[i]_CLK_RES cycle between two trigger signals):

- CLSi_ATOM_CHx_CN0.CN0 counts from 0 to MAX-1 and is then reset to 0 at the falling edge of ATOM_CH_TRIGIN[x:x] or at falling edge of EXT_TRIGIN_S (the synchronized signal of EXT_TRIGIN[x:x], see External trigger interface).
- If CLSi_ATOM_CHx_CN0.CN0 reaches CLSi_ATOM_CHx_CM1.CM1, an edge to ! CLSi_ATOM_CHx_CTRL_SOMP.SL is generated.
- If CLSi_ATOM_CHx_CN0.CN0 reaches CLSi_ATOM_CHx_CM0.CM0, an edge to CLSi_ATOM_CHx_CTRL_SOMP.SL is generated.
- As soon as CLSi_ATOM_CHx_CN0.CN0 reaches the value of CLSi_ATOM_CHx_CM0.CM0 while CLSi_ATOM_CHx_CM1.CM1 is equal to CLSi_ATOM_CHx_CM0.CM0, an edge to CLSi_ATOM_CHx_CTRL_SOMP.SL is generated at the output or the output remains at CLSi_ATOM_CHx_CTRL_SOMP.SL level depending on the former level of the output (CLSi_ATOM_CHx_CM0.CM0 has higher priority). Please note that this configuration is not suitable for generating 100% duty cycle.
- If CLSi_ATOM_CHx_CM0.CM0=0 and CLSi_ATOM_CHx_CM1.CM1>MAX, the output is a pulse of CLSi_ATOM_CHx_CTRL_SOMP.SL for the period MAX (i.e. 100% duty cycle PWM signal).
- If CLSi_ATOM_CHx_CM0.CM0 > MAX and CLSi_ATOM_CHx_CM1.CM1=0, the output is ! CLSi_ATOM_CHx_CTRL_SOMP.SL (i.e. 0% duty cycle PWM signal).
- If CLSi_ATOM_CHx_CM0.CM0 is set to MAX, an edge to CLSi_ATOM_CHx_CTRL_SOMP.SL is generated at the output at the very end of the current period or the output remains at the CLSi_ATOM_CHx_CTRL_SOMP.SL level, depending on the previous level of the output. Be aware that this applies even if the value of

CLSi_ATOM_CHx_CM1.CM1 is updated to 0 for the new period (CLSi_ATOM_CHx_CM0.CM0 has higher priority).

In this case, as shown in Figure 1082, 2 interrupt signals ATOM_CCU0TC[x]_IRQ and ATOM_CCU1TC[x]_IRQ of channel x can be generated together with output generation ATOM_OUT[x:x] and both of them are shown on ATOM_IRQ[x:x] if CLSi_ATOM_CHx_IRQ_EN=11_B. When CLSi_ATOM_CHx_CN0.CN0 is incrementing to reach CLSi_ATOM_CHx_CM0.CM0, ATOM_CCU0TC[x]_IRQ of channel x is generated. When CLSi_ATOM_CHx_CN0.CN0 is incrementing to reach CLSi_ATOM_CHx_CM1.CM1, ATOM_CCU1TC[x]_IRQ of channel x is generated. The interrupt signals are always aligned with the edges of the output ATOM_OUT[x:x].

According to internal trigger interface specification Internal trigger interface, more than one channel (maybe also in different clusters) can be triggered by a common preceding channel to synchronously generate consistent PWM signals. In such applications, the channels and instances between the triggering channel to the triggered channels build up a trigger chain and the triggered channels should be configured with same PWM parameters (i.e. period, duty cycle, signal level and clock source). However, possible pipeline registers according to Internal trigger interface may introduce delay of several cluster clock periods CLS[j]_CLK or **eGTM** clock periods CLK in the trigger chain. As a result, the triggered channels in the trigger chain may be asynchronously triggered and have different behavior even though they are triggered by a common channel and they are configured with same PWM parameters. Therefore, if in real applications there are pipeline registers in the trigger chain, it is necessary to configure the selected **CMU** clock source to be a slower frequent clock enable signal to avoid the influence of the introduced delay so that the triggered channels can be synchronously triggered and have consistent behavior. The period between two enable pulses of the selected **CMU** clock source (i.e. the distance between 2 falling edges of SEL_CMU_CLKEN) should be greater than the total delay caused by all the pipeline registers in the trigger chain. Especially, if the triggering channel and other triggered channels are in a common instance i where CLS[j]_CLK is enabled with clock divider of 2 (CLSi_ARCH_CLK_CFG.CLSj_CLK_DIV (j=0-2) **(j=i)**=2) and there is only one pipeline register (with delay of one CLK period) between channel 3 and channel 4 in the trigger chain, then such a delay less than CLS[j]_CLK period can be ignored regardless of the selection of **CMU** clock source.

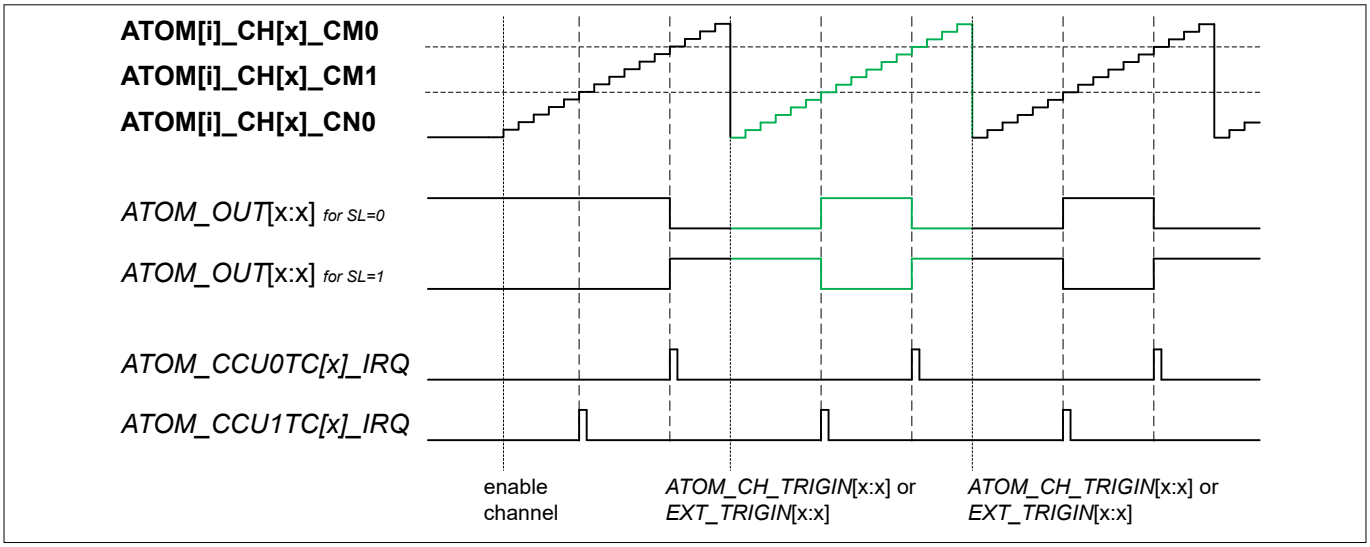

Figure 1082 PWM output behavior with respect to the CLSi_ATOM_CHx_CTRL_SOMP.SL bit in continuous counting up mode if CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=1

In case of CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)**=10_B, when the counter value CLSi_ATOM_CHx_CN0.CN0 reaches the compare value in register CLSi_ATOM_CHx_CM0.CM0 (in fact CLSi_ATOM_CHx_CM0.CM0-1) if CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=0 or the channel captures the falling edge of the trigger signal if CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=1, the operation registers CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1, CLSi_ATOM_CHx_CTRL_SOMP.SL and CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC are updated with the content of their shadow registers

CLSi_ATOM_CHx_SR0.SR0, CLSi_ATOM_CHx_SR1.SR1, CLSi_ATOM_CHx_CTRL_SR.SL_SR and CLSi_ATOM_CHx_CTRL_SR.CLK_SRC_SR.

The operation registers CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1, CLSi_ATOM_CHx_CTRL_SOMP.SL and CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC can also be asynchronously updated from their shadow registers with the force update mechanism. Please refer to Pulse width, period, signal level and clock frequency update mechanisms for the force update configuration steps and more details. In continuous counting up mode, the force update mechanism can be also used to stop the current running PWM signal generation and restart a new PWM period with new PWM parameters by additionally setting CLSi_ATOM_AGC_FUPD_CTRL.RSTCN0_CHk (k=0-7) **(k=x)** = 10_B together with CLSi_ATOM_AGC_FUPD_CTRL.FUPD_CTRLk (k=0-7) **(k=x)** = 10_B. That means the force update event will not only update the operation registers from their shadow registers, but also simultaneously reset the counter to restart the next new PWM period with setting the output as CLSi_ATOM_CHx_CTRL_SOMP.SL if CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=0 or without changing the output if CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=1.

Continuous counting up-down mode

In SOMP mode, if CLSi_ATOM_CHx_CTRL_SOMP.UDMODE != 00_B, the counter CLSi_ATOM_CHx_CN0.CN0 will count up and down. Depending on the configuration bit CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0, the counter register CLSi_ATOM_CHx_CN0.CN0 changes the direction either when the counter value is equal to the compare value CLSi_ATOM_CHx_CM0.CM0-1 or when triggered by the internal trigger signal ATOM_CH_TRIGIN[x:x] (i.e. ATOM_CH_TRIGOUT[x-1:x-1] from the preceding channel [x-1]) or the external trigger signal EXT_TRIGIN[x:x] from **TIM** module [i].

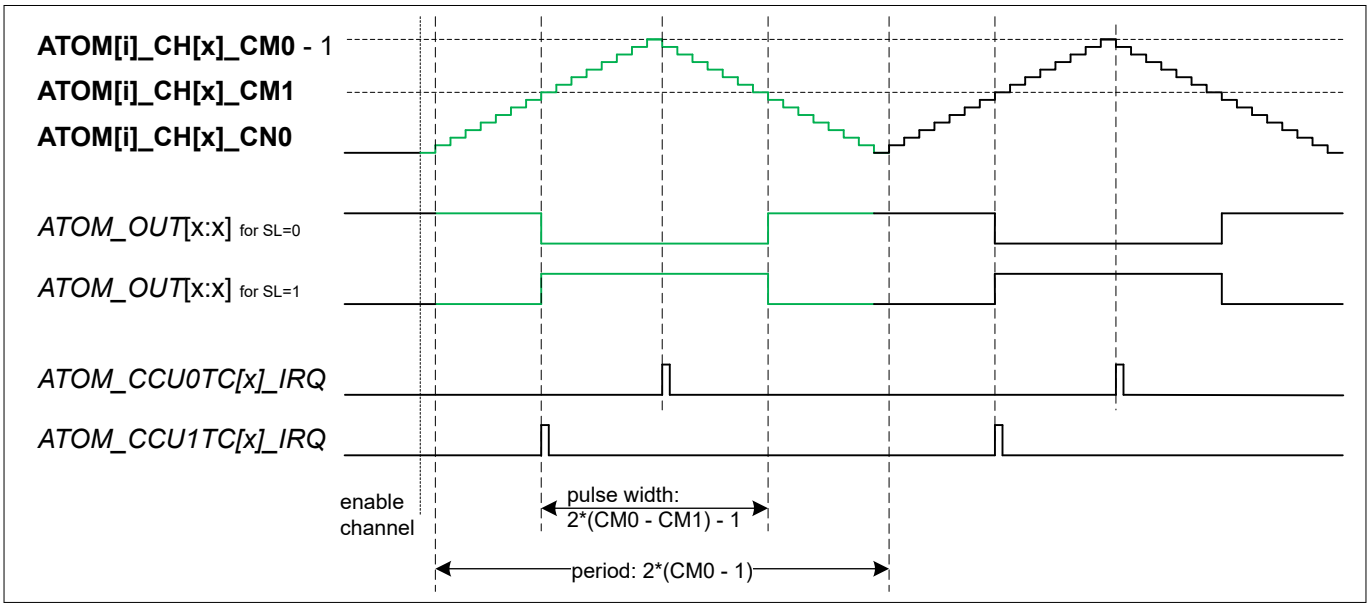

Figure 1083 PWM **output behavior with respect to the** CLSi_ATOM_CHx_CTRL_SOMP.SL **bit in continuous counting up-down mode if** CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0**=0**

The clock of the counter register CLSi_ATOM_CHx_CN0.CN0 can be one of the **CMU** enable clock resolutions CCM[i]_CLK_RES.

The clock for CLSi_ATOM_CHx_CN0.CN0 is defined by CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC value.

If CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=0, the counter register CLSi_ATOM_CHx_CN0.CN0 of channel x will change its counting direction by the compare match of CLSi_ATOM_CHx_CN0.CN0>=CLSi_ATOM_CHx_CM0.CM0-1 in its own CCU0 unit and the following statements are valid:

- In each PWM period, CLSi_ATOM_CHx_CN0.CN0 firstly counts continuously up from 1 to CLSi_ATOM_CHx_CM0.CM0-1 and then down to 0. So period = 2*(CLSi_ATOM_CHx_CM0.CM0-1).
- If CLSi_ATOM_CHx_CN0.CN0 >= CLSi_ATOM_CHx_CM1.CM1, the output is ATOM_OUT[x:x] set to CLSi_ATOM_CHx_CTRL_SOMP.SL.
- If CLSi_ATOM_CHx_CN0.CN0 < CLSi_ATOM_CHx_CM1.CM1, the output is ATOM_OUT[x:x] set to !CLSi_ATOM_CHx_CTRL_SOMP.SL. So pulse width = 2*(CLSi_ATOM_CHx_CM0.CM0 - CLSi_ATOM_CHx_CM1.CM1)-1.
- If CLSi_ATOM_CHx_CM0.CM0 <= 1, the counter behavior of CLSi_ATOM_CHx_CN0.CN0 is unexpected (not recommended).
- If CLSi_ATOM_CHx_CM1.CM1 = 0 and also CLSi_ATOM_CHx_CM0.CM0 > 1, the output ATOM_OUT[x:x] is CLSi_ATOM_CHx_CTRL_SOMP.SL (i.e. 100% duty cycle).
- If CLSi_ATOM_CHx_CM1.CM1 >= CLSi_ATOM_CHx_CM0.CM0 and also CLSi_ATOM_CHx_CM0.CM0 > 1, the output ATOM_OUT[x:x] is !CLSi_ATOM_CHx_CTRL_SOMP.SL (i.e. 0% duty cycle).

This behavior is depicted in Figure 1083. In this case, if CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)**=1, the operation registers CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1, CLSi_ATOM_CHx_CTRL_SOMP.SL and CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC can be updated when CLSi_ATOM_CHx_CN0.CN0 = 0 (i.e. counting direction changes from down to up) or CLSi_ATOM_CHx_CN0.CN0 reaches CLSi_ATOM_CHx_CM0.CM0-1 (i.e. counting direction changes from up to down) depending on various configurations of CLSi_ATOM_CHx_CTRL_SOMP.UDMODE (see the register description for more details). Especially, it is not recommended to change the value of CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CTRL_SOMP.SL and CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC when CLSi_ATOM_CHx_CN0.CN0 reaches CLSi_ATOM_CHx_CM0.CM0-1. Otherwise, the behavior may be unexpected.

Like continuous counting up mode, interrupt signals ATOM_CCU0TC[x]_IRQ and ATOM_CCU1TC[x]_IRQ of channel x are generated together with PWM signal output edges. When CLSi_ATOM_CHx_CN0.CN0 reaches CLSi_ATOM_CHx_CM1.CM1 at the first time and the first edge is generated, an interrupt on ATOM_CCU1TC[x]_IRQ is generated. When CLSi_ATOM_CHx_CN0.CN0 changes its counting direction from up to down, an interrupt on ATOM_CCU0TC[x]_IRQ is generated.

If CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=1, the counter register CLSi_ATOM_CHx_CN0.CN0 of channel x will change its counting direction by the trigger signal coming from another channel or the assigned **TIM** module and the following statements are valid:

- CLSi_ATOM_CHx_CN0.CN0 firstly counts continuously up. At the falling edge of the trigger signal pulse ATOM_CH_TRIGIN[x:x] or EXT_TRIGIN_S (the synchronized signal of EXT_TRIGIN[x:x], see External trigger interface), the counter switches to count down mode. If CLSi_ATOM_CHx_CN0.CN0 reaches 0, it will count up again.
- If CLSi_ATOM_CHx_CN0.CN0 >= CLSi_ATOM_CHx_CM1.CM1, the output ATOM_OUT[x:x] is set to CLSi_ATOM_CHx_CTRL_SOMP.SL.
- If CLSi_ATOM_CHx_CN0.CN0 < CLSi_ATOM_CHx_CM1.CM1, the output ATOM_OUT[x:x] is set to ! CLSi_ATOM_CHx_CTRL_SOMP.SL.
- If CLSi_ATOM_CHx_CM1.CM1 = 0, the output ATOM_OUT[x:x] is CLSi_ATOM_CHx_CTRL_SOMP.SL (i.e. 100% duty cycle).
- If CLSi_ATOM_CHx_CN0.CN0 >= CLSi_ATOM_CHx_CM0.CM0, the output ATOM_OUT_T[x:x] is set to CLSi_ATOM_CHx_CTRL_SOMP.SL.
- If CLSi_ATOM_CHx_CN0.CN0 < CLSi_ATOM_CHx_CM0.CM0, the output ATOM_OUT_T[x:x] is set to ! CLSi_ATOM_CHx_CTRL_SOMP.SL.
- If CLSi_ATOM_CHx_CM0.CM0 = 0, the output ATOM_OUT_T[x:x] is CLSi_ATOM_CHx_CTRL_SOMP.SL (i.e. 100% duty cycle).

This behavior is depicted in Figure 1084. In this case, if CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)**=1, the operation registers CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1, CLSi_ATOM_CHx_CTRL_SOMP.SL and CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC can also be updated when

CLSi_ATOM_CHx_CN0.CN0 = 0 (i.e. counting direction changes from down to up) or CLSi_ATOM_CHx_CN0.CN0 reaches its maximum value (i.e. counting direction changes from up to down) depending on various configurations of CLSi_ATOM_CHx_CTRL_SOMP.UDMODE (see the register description for more details). Especially, it is not recommended to change the value of CLSi_ATOM_CHx_CTRL_SOMP.SL and CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC when CLSi_ATOM_CHx_CN0.CN0 reaches its maximum value (i.e. counting direction changes from up to down). Otherwise, the behavior may be unexpected.

If CLSi_ATOM_CHx_IRQ_EN=11_B, interrupt signals ATOM_CCU0TC[x]_IRQ and ATOM_CCU1TC[x]_IRQ of channel x are generated together with PWM signal output. When CLSi_ATOM_CHx_CN0.CN0 reaches CLSi_ATOM_CHx_CM1.CM1 at the first time and the first edge of ATOM_OUT[x:x] is generated, an interrupt on ATOM_CCU1TC[x]_IRQ is generated. When CLSi_ATOM_CHx_CN0.CN0 reaches CLSi_ATOM_CHx_CM0.CM0 at the first time and the first edge of ATOM_OUT_T[x:x] is generated, an interrupt on ATOM_CCU0TC[x]_IRQ is generated.

In case of continuous counting up-down mode and CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=1, it is recommended to configure the **ATOM** channel according to the following statements in order to realize several cyclic central aligned PWM signals:

- The triggering channel and the triggered channel are both running in up-down mode.
- The time between two trigger signals is equal to the time needed for CLSi_ATOM_CHx_CN0.CN0 of triggered channel to count back to 0 and again up to the same upper value.

The second recommendation can be fulfilled by synchronizing the start of the triggering channel and the triggered channel, i.e. let both channels start with CLSi_ATOM_CHx_CN0.CN0 = 0 and same clock source.

If there is a pipeline register in the trigger chain, the additional delay of one clock period has to be taken into account by starting the triggering channel with CLSi_ATOM_CHx_CN0.CN0 = 1 (i.e. 1 greater than CLSi_ATOM_CHx_CN0.CN0 of the triggered channel).

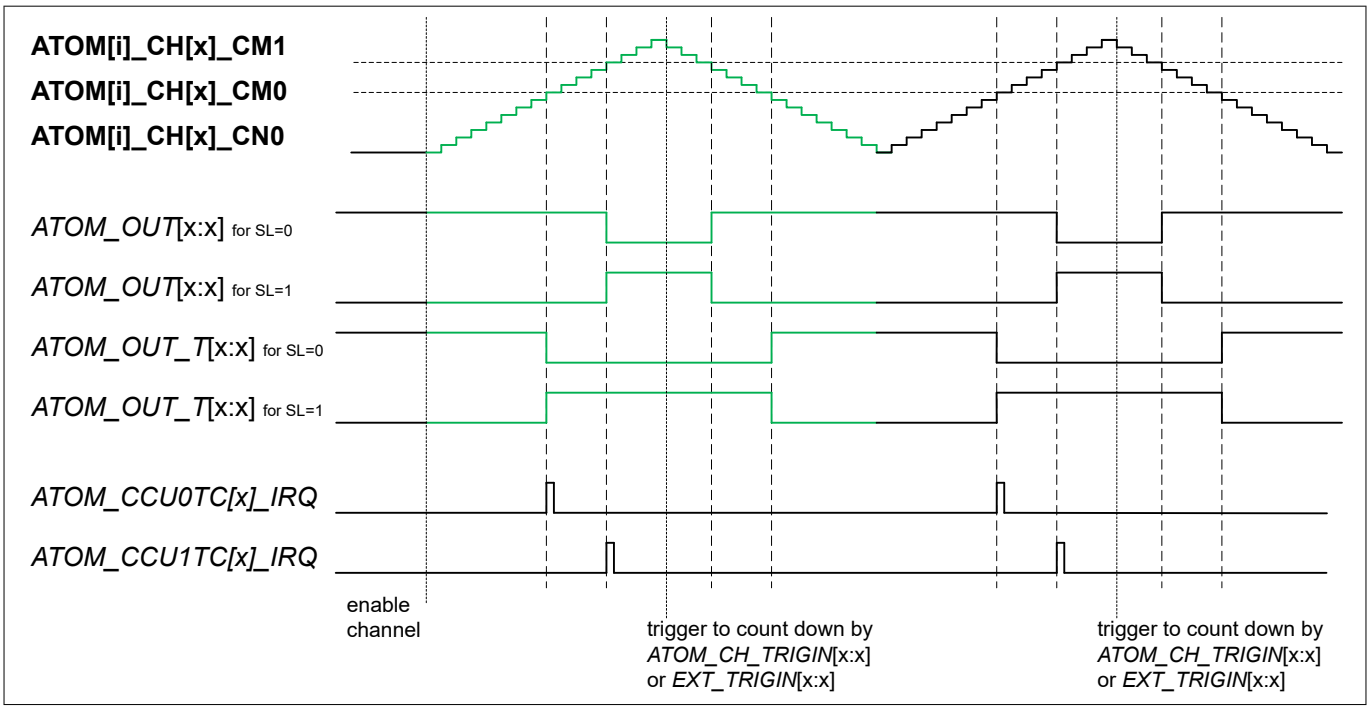

Figure 1084 PWM **output behavior with respect to the** CLSi_ATOM_CHx_CTRL_SOMP.SL **bit in continuous counting up-down mode if** CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0**=1**

One-shot counting up mode

The **ATOM** channel can operate in one-shot mode when the CLSi_ATOM_CHx_CTRL_SOMP.OSM bit is set. One-shot mode means that a single pulse with the pulse level defined in bit CLSi_ATOM_CHx_CTRL_SOMP.SL is generated on the output signal.

Firstly, the channel has to be enabled by setting the corresponding CLSi_ATOM_AGC_ENDIS_STAT.ENDIS_STATk (k=0-7).

Unlike in the continuous counting modes, the counter CLSi_ATOM_CHx_CN0.CN0 will not be incremented once the channel is enabled. Instead, according to the configuration bit CLSi_ATOM_CHx_CTRL_SOMP.OSM_TRIG, the start of counting and pulse generation is triggered by a write-access of CLSi_ATOM_CHx_CN0.CN0 or the internal trigger signal ATOM_CH_TRIGIN[x:x] or the external trigger signal EXT_TRIGIN[x:x].

When CLSi_ATOM_CHx_CTRL_SOMP.OSM_TRIG=0, a write-access to the register CLSi_ATOM_CHx_CN0.CN0 triggers the start of incrementing the counter register CLSi_ATOM_CHx_CN0.CN0 and pulse generation. If the time between the write-access and the first edge generation of one-shot PWM signal is defined as initial delay, the initial delay is determined by the value of (CLSi_ATOM_CHx_CM0.CM0-CLSi_ATOM_CHx_CN0.CN0) multiplied with the selected **CMU** clock period. Especially, if writing a value of greater than or equal to CLSi_ATOM_CHx_CM0.CM0-1 to CLSi_ATOM_CHx_CN0.CN0 and configuring the initial clock source as cluster clock (the clock source at reset state), the initial delay is minimum, i.e. 1 cluster clock period CLS[j]_CLK. That means after the write-access of CLSi_ATOM_CHx_CN0.CN0, the first edge of the output with the interrupt will be set in 1 CLS[j]_CLK period.

If the counter CLSi_ATOM_CHx_CN0.CN0 is reset from CLSi_ATOM_CHx_CM0.CM0-1 back to zero, the first edge at ATOM_OUT is generated. And the operation phase of the pulse generation starts incrementing of CLSi_ATOM_CHx_CN0.CN0 from 0 to CLSi_ATOM_CHx_CM0.CM0-1 again.

The second edge is generated, if CLSi_ATOM_CHx_CN0.CN0 increments until it reaches CLSi_ATOM_CHx_CM1.CM1.

If the counter CLSi_ATOM_CHx_CN0.CN0 reaches the value of CLSi_ATOM_CHx_CM0.CM0-1 at the second time, the counter will stop.

Figure 1085 depicts the pulse generation process mentioned above. The interrupt signals generation during PWM signal generation are similar as described in continuous counting up mode. If the value written to CLSi_ATOM_CHx_CN0.CN0 for triggering or retriggering the counter is greater than or equal to CLSi_ATOM_CHx_CM1.CM1 -1, an interrupt on ATOM_CCU1TC[x]_IRQ is generated after 1 selected **CMU** clock period. Similarly but not shown in the figure, if the value written to CLSi_ATOM_CHx_CN0.CN0 for triggering or retriggering the counter is greater than or equal to CLSi_ATOM_CHx_CM0.CM0 - 1, an interrupt on ATOM_CCU0TC[x]_IRQ is generated after 1 selected **CMU** clock period. Afterwards when CLSi_ATOM_CHx_CN0.CN0 is reset from CLSi_ATOM_CHx_CM0.CM0 -1 to 0, ATOM_CCU0TC[x]_IRQ of channel x is generated. When CLSi_ATOM_CHx_CN0.CN0 is incrementing to reach CLSi_ATOM_CHx_CM1.CM1, ATOM_CCU1TC[x]_IRQ of channel x is generated.

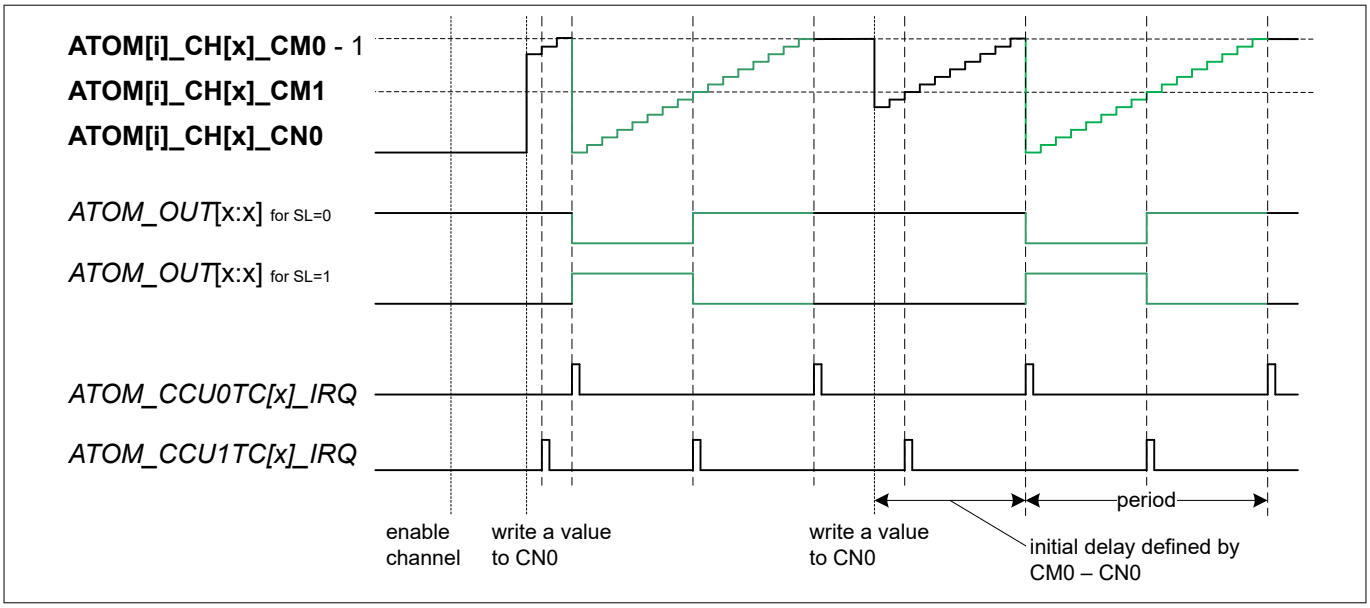

Figure 1085 PWM output with respect to configuration bit CLSi_ATOM_CHx_CTRL_SOMP.SL in one-shot counting up mode if CLSi_ATOM_CHx_CTRL_SOMP.OSM_TRIG= 0

Retriggering an one-shot cycle (while CLSi_ATOM_CHx_CN0.CN0 is already incrementing) by writing a value to CLSi_ATOM_CHx_CN0.CN0 is possible but depends on the phase of CLSi_ATOM_CHx_CN0.CN0:

- phase 1: update of CLSi_ATOM_CHx_CN0.CN0 before CLSi_ATOM_CHx_CN0.CN0 reaches CLSi_ATOM_CHx_CM0.CM0 for the first time (initial phase)
- phase 2: update of CLSi_ATOM_CHx_CN0.CN0 after CLSi_ATOM_CHx_CN0.CN0 has reached CLSi_ATOM_CHx_CM0.CM0 for the first time until the current single PWM pulse is finished (operation phase)

In phase 1 (initial phase), writing a value CN0(new) to counter CLSi_ATOM_CHx_CN0.CN0 (CN0(new)< CLSi_ATOM_CHx_CM0.CM0) leads to a shift of the first edge by the time CLSi_ATOM_CHx_CM0.CM0-CN0(new), i.e. the first edge is generated when CLSi_ATOM_CHx_CN0.CN0 is reset from CLSi_ATOM_CHx_CM0.CM0-1 back to 0 for the first time.

In phase 2 (operation phase): writing to counter CLSi_ATOM_CHx_CN0.CN0 is not possible and is protected by hardware.

A failed write-access to CLSi_ATOM_CHx_CN0.CN0 in phase 2 (operation phase) is indicated by the status register flag CLSi_ATOM_CHx_STAT.OSM_RTF.

After one PWM pulse is ended, other single pulses can be further triggered by a write-access to register CLSi_ATOM_CHx_CN0.CN0.

It is recommended to enable the update mechanism by setting CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)** = 10_B for retriggering the second one-shot PWM signal generation with different initial delay and different PWM parameters. Similarly like continuous counting up mode with CLSi_ATOM_CHx_CTRL.RST_CCU0=0, the operation registers CLSi_ATOM_CHx_CM0.CM0/ CLSi_ATOM_CHx_CM1.CM1/CLSi_ATOM_CHx_CTRL.SL/CLSi_ATOM_CHx_CTRL.CLK_SRC are always synchronously updated when CLSi_ATOM_CHx_CN0.CN0 reaches CLSi_ATOM_CHx_CM0.CM0-1. Firstly, after the first one-shot PWM signal is generated, the new values for initial delay (phase 1) can be written into the shadow registers CLSi_ATOM_CHx_SR0.SR0/CLSi_ATOM_CHx_SR1.SR1/CLSi_ATOM_CHx_CTRL_SR.SL_SR/ CLSi_ATOM_CHx_CTRL_SR.CLK_SRC_SR before the retriggering is executed by writing of register CLSi_ATOM_CHx_CN0.CN0. The shadow registers should be loaded to the operation registers CLSi_ATOM_CHx_CM0.CM0/CLSi_ATOM_CHx_CM1.CM1/CLSi_ATOM_CHx_CTRL.SL/ CLSi_ATOM_CHx_CTRL.CLK_SRC at the next falling edge of the selected **CMU** clock resolution signal, because CLSi_ATOM_CHx_CN0.CN0 keeps as CLSi_ATOM_CHx_CM0.CM0-1. When CLSi_ATOM_CHx_CN0.CN0 is written to be retriggered afterwards, the initial delay is defined according to the updated operation registers. Secondly,

during the initial delay phase (phase 1), the new parameters for PWM signal can be written into the shadow registers again. The operational registers will be updated with the shadow registers when CLSi_ATOM_CHx_CN0.CN0 is reset from CLSi_ATOM_CHx_CM0.CM0-1 at the end of phase 1 and phase 2 is started to generate the second one-shot PWM signal with the new updated operation registers.

If a channel is configured to one-shot mode and configuration bit CLSi_ATOM_CHx_CTRL_SOMP.OSM_TRIG is set to 1, the trigger signal pulse ATOM_CH_TRIGIN[x:x] or EXT_TRIGIN[x:x] triggers start of pulse generation as shown in Figure 1086. In this case, it is not allowed to write CLSi_ATOM_CHx_CN0.CN0 and so the register CLSi_ATOM_CHx_STAT.OSM_RTF is not relevant. Otherwise, a write-access to CLSi_ATOM_CHx_CN0.CN0 can make an unpredictable output behavior. Furthermore, as shown in Figure 1086, CLSi_ATOM_CHx_CN0.CN0 should be initially configured as CLSi_ATOM_CHx_CM0.CM0-1 or greater value before enabling the channel. Otherwise, it is hard to define the counting behavior and the initial delay behavior. As shown in Figure 1086, when the channel is enabled, after the falling edge of the trigger pulse ATOM_CH_TRIGIN[x:x] or EXT_TRIGIN_S (the synchronized signal of EXT_TRIGIN[x:x], see External trigger interface), CLSi_ATOM_CHx_CN0.CN0 will be triggered to be reset that is synchronous with the next enable high pulse of the selected **CMU** clock source (i.e. synchronous to the next falling edge of the selected **CMU** enable signal). Then it counts from 0 to CLSi_ATOM_CHx_CM0.CM0-1. This process is defined as initial phase. If the internal trigger signal ATOM_CH_TRIGIN[x:x] is in use and it is synchronous to the selected **CMU** clock source or the external trigger signal EXT_TRIGIN[x:x] is in use and it must be synchronized to the selected **CMU** clock source before triggering, the initial delay can be defined as the time between the falling edge of the synchronized trigger signal to the time point of starting generating the PWM signal (green phase in the figure), i.e. CLSi_ATOM_CHx_CM0.CM0+1 selected **CMU** clock periods. Then CLSi_ATOM_CHx_CN0.CN0 will be reset again and count from 0 to CLSi_ATOM_CHx_CM0.CM0-1 at the second time to generate one signal PWM signal and then stop. This second counting is defined as operation phase.

After the first OSM signal is generated, the second trigger signal is allowed to be applied to start the counter and generate the next OSM signal after a certain initial delay. Figure 1086 shows such an application of generating 2 OSM signals without changing PWM parameters. In the case, after the second trigger signal is coming, the counter has the same behavior as described above for the first OSM signal generation. That means the initial delay is also CLSi_ATOM_CHx_CM0.CM0+1 selected **CMU** clock periods and the OSM signal is the same as the first one.

However, in some real applications of generating various single PWM signals, it is necessary to synchronously update the parameters in CLSi_ATOM_CHx_CM0.CM0/CLSi_ATOM_CHx_CM1.CM1/CLSi_ATOM_CHx_CTRL.SL/CLSi_ATOM_CHx_CTRL.CLK_SRC by setting CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)** = 10_B. In this case, these registers are updated from their shadow registers when CLSi_ATOM_CHx_CN0.CN0 is matching CLSi_ATOM_CHx_CM0.CM0-1. After the first OSM PWM signal, if CLSi_ATOM_CHx_CM0.CM0 is updated with a new value CM0(new) before the second trigger signal comes, the initial delay of the second OSM signal depends on CM0(new) and the value CN0(old) of CLSi_ATOM_CHx_CN0.CN0 when the counter stopped at the end of the first OSM signal. The value CN0(old) is actually the value of CLSi_ATOM_CHx_CM0.CM0-1 of the first OSM signal before the synchronous update, i.e. CN0(old)=CM0(old)-1. Like the first OSM signal generation, with the falling edge of the second trigger pulse signal, the counter will be retriggered synchronously to the next enable high pulse of the selected **CMU** clock source (i.e. synchronous to the next falling edge of the selected **CMU** enable signal). Assuming the internal trigger signal ATOM_CH_TRIGIN[x:x] is in use and it is synchronous to the selected **CMU** clock source or the external trigger signal EXT_TRIGIN[x:x] is in use and it will be synchronized to the selected **CMU** clock source before triggering, the initial delay can be defined as the time between the falling edge of the second synchronized trigger signal to the time point of starting generating the PWM signal (green phase in the figure). On the one hand, if CN0(old) is greater than or equal to updated CM0(new)-1, the counter will be reset and counts up to CM0(new)-1 and the initial delay is CM0(new)+1 selected **CMU** clock periods, i.e. CLSi_ATOM_CHx_CM0.CM0+1 selected **CMU** clock periods. The behavior of the counter is the same as described above for the initial delay of the first OSM signal. On the other hand, if CN0(old) is smaller than updated CM0(new)-1, the initial phase or the initial delay is longer. In the initial phase, the counter will count up from CN0(old) to CM0(new)-1 and reset, and then increment again to CM0(new)-1. That means the initial delay is no longer CM0(new)+1, but the larger value of 2*CM0(new)-CN0(old) **CMU** clock periods, i.e. 2*CM0(new)-CM0(old) +1 selected **CMU** clock periods.

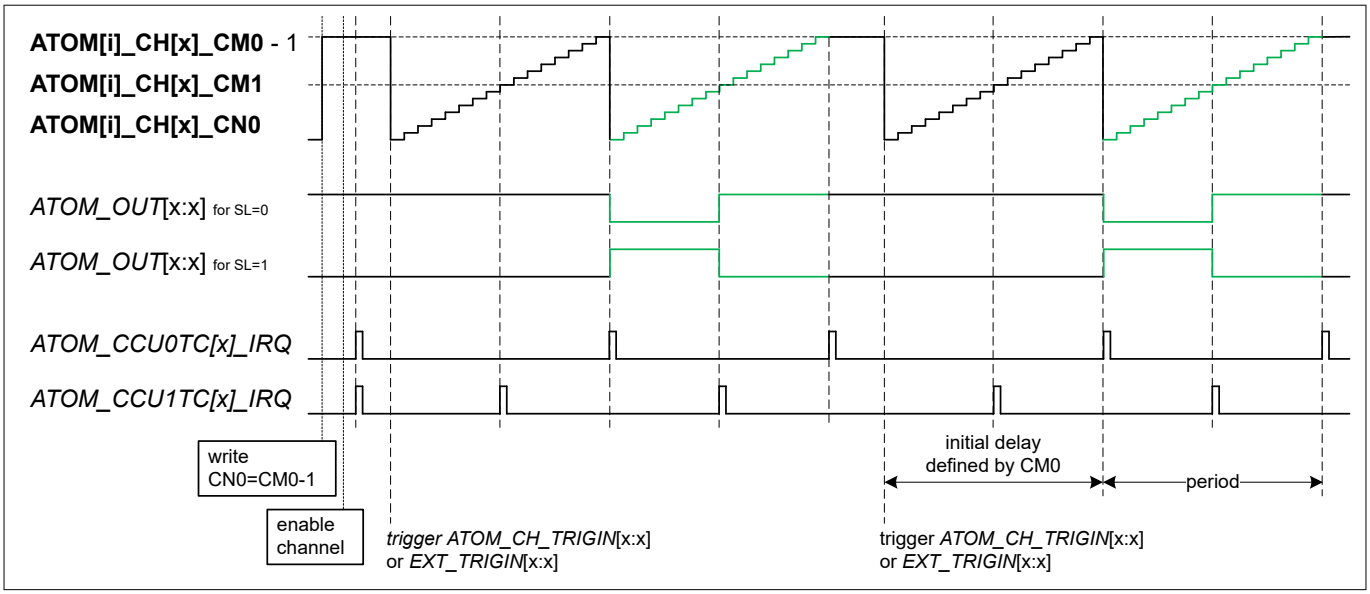

Figure 1086 PWM output with respect to configuration bit CLSi_ATOM_CHx_CTRL_SOMP.SL in one-shot counting up mode if CLSi_ATOM_CHx_CTRL_SOMP.OSM_TRIG= 1

As shown in Figure 1086, the interrupt signals generation during PWM signal generation are similar as described in continuous counting up mode. As before enabling the channel the initial value written to CLSi_ATOM_CHx_CN0.CN0 is greater than or equal to CLSi_ATOM_CHx_CM0.CM0 - 1 and CLSi_ATOM_CHx_CM1.CM1 - 1, both interrupt signals ATOM_CCU0TC[x]_IRQ and ATOM_CCU1TC[x]_IRQ are generated after 1 selected **CMU** clock period. Afterwards when CLSi_ATOM_CHx_CN0.CN0 is reset from CLSi_ATOM_CHx_CM0.CM0 -1 to 0, ATOM_CCU0TC[x]_IRQ of channel x is generated. When CLSi_ATOM_CHx_CN0.CN0 is incrementing to reach CLSi_ATOM_CHx_CM1.CM1, ATOM_CCU1TC[x]_IRQ of channel x is generated.

In one-shot mode, it is not recommended to configure CLSi_ATOM_CHx_CM0.CM0<2. Otherwise, the behavior may be unexpected.

One-shot counting up-down mode

The **ATOM** channel can operate in one-shot counting up-down mode when the bit CLSi_ATOM_CHx_CTRL_SOMP.OSM = 1 and the CLSi_ATOM_CHx_CTRL_SOMP.UDMODE != 00_B. One-shot mode means that a single pulse with the pulse level defined in bit CLSi_ATOM_CHx_CTRL_SOMP.SL is generated on the output signal.

Firstly, the channel has to be enabled by setting the corresponding CLSi_ATOM_AGC_ENDIS_STAT.ENDIS_STATk (k=0-7).

In one-shot mode the counter CLSi_ATOM_CHx_CN0.CN0 will not be incremented once the channel is enabled.

When CLSi_ATOM_CHx_CTRL_SOMP.OSM_TRIG=0, a write-access to the register CLSi_ATOM_CHx_CN0.CN0 triggers the start of incrementing the counter register CLSi_ATOM_CHx_CN0.CN0 and pulse generation.

If the counter CLSi_ATOM_CHx_CN0.CN0 is greater than or equal to CLSi_ATOM_CHx_CM1.CM1, the output ATOM_OUT is set to CLSi_ATOM_CHx_CTRL_SOMP.SL value.

If the counter CLSi_ATOM_CHx_CN0.CN0 is less than CLSi_ATOM_CHx_CM1.CM1, the output ATOM_OUT is set to !CLSi_ATOM_CHx_CTRL_SOMP.SL value.

If the counter CLSi_ATOM_CHx_CN0.CN0 has reached the value 0 (by counting down), it will stop.

The written value of CLSi_ATOM_CHx_CN0.CN0 determines the start delay of the first edge. The delay time of the first edge is given by (CLSi_ATOM_CHx_CM1.CM1-CLSi_ATOM_CHx_CN0.CN0) multiplied with the period defined by current value of CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC.

Figure 1087 depicts the pulse generation in SOMP one-shot counting up-down mode. The interrupt signals are generated similarly as described in one-shot counting up mode and continuous counting up-down mode. The write-access of CLSi_ATOM_CHx_CN0.CN0 can cause interrupts if the write value is greater than or equal to CLSi_ATOM_CHx_CM1.CM1 - 1 or CLSi_ATOM_CHx_CM0.CM0 -1. If the value written to CLSi_ATOM_CHx_CN0.CN0 for triggering or retriggering the counter is greater than or equal to CLSi_ATOM_CHx_CM1.CM1 -1, the output ATOM_OUT[x:x] will be set to CLSi_ATOM_CHx_CTRL_SOMP.SL after 1 selected **CMU** clock period together with an interrupt on ATOM_CCU1TC[x]_IRQ. Similarly but not shown in the figure, if the value written to CLSi_ATOM_CHx_CN0.CN0 for triggering or retriggering the counter is greater than or equal to CLSi_ATOM_CHx_CM0.CM0 - 1, an interrupt on ATOM_CCU0TC[x]_IRQ will be generated after 1 selected **CMU** clock period. Afterwards when CLSi_ATOM_CHx_CN0.CN0 is incrementing to reach CLSi_ATOM_CHx_CM1.CM1, an interrupt on ATOM_CCU1TC[x]_IRQ is generated. When CLSi_ATOM_CHx_CN0.CN0 changes its counting direction from up to down, an interrupt on ATOM_CCU0TC[x]_IRQ is generated.

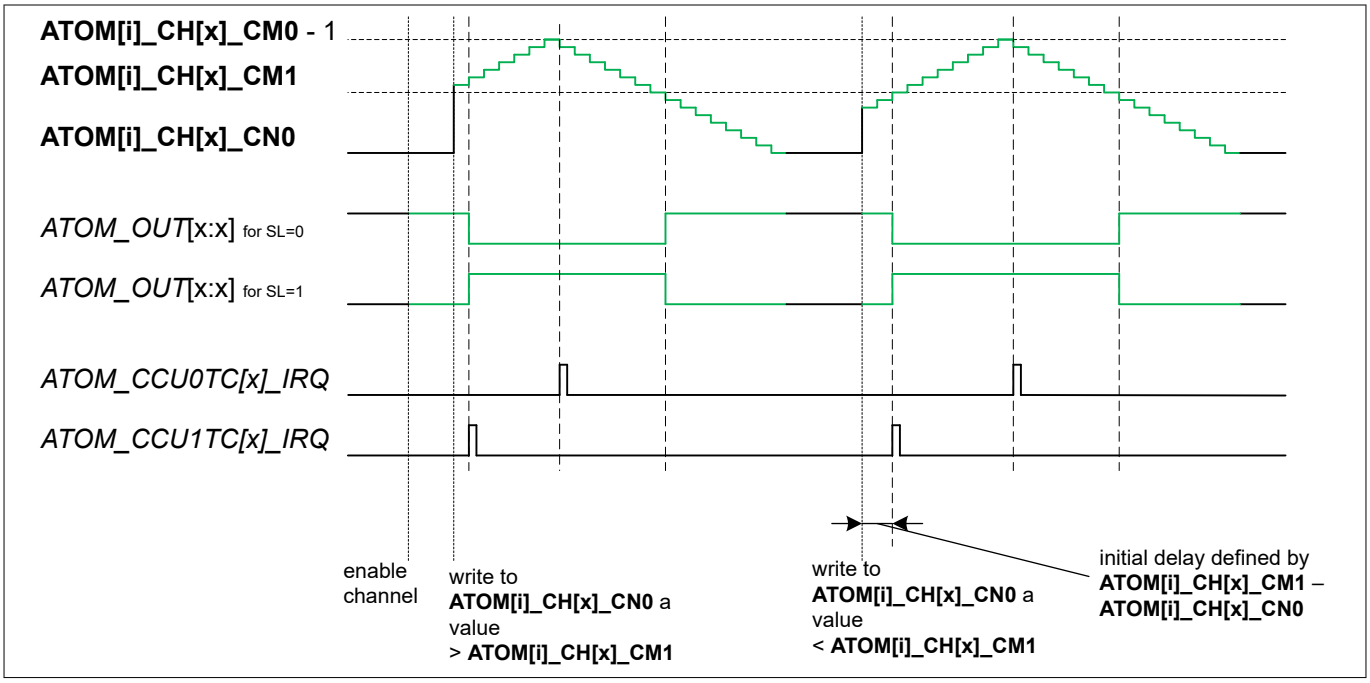

Figure 1087 PWM output with respect to configuration bit CLSi_ATOM_CHx_CTRL_SOMP.SL in one-shot counting up-down mode if CLSi_ATOM_CHx_CTRL_SOMP.OSM_TRIG= 0

Further output of single pulses can be started by writing to register CLSi_ATOM_CHx_CN0.CN0.

If a channel is configured to one-shot counting up-down mode and configuration bit CLSi_ATOM_CHx_CTRL_SOMP.OSM_TRIG is set to 1, the falling edge of the trigger signal ATOM_CH_TRIGIN[x:x] or EXT_TRIGIN_S (the synchronized signal of EXT_TRIGIN[x:x]) triggers start of incrementing CLSi_ATOM_CHx_CN0.CN0 and pulse generation. The output generation with interrupt signals is similar as mentioned above and shown in Figure 1088. If the counter CLSi_ATOM_CHx_CN0.CN0 is greater than or equal to CLSi_ATOM_CHx_CM1.CM1, the output ATOM_OUT is set to CLSi_ATOM_CHx_CTRL_SOMP.SL value. Otherwise, the output ATOM_OUT is set to !CLSi_ATOM_CHx_CTRL_SOMP.SL value. When CLSi_ATOM_CHx_CN0.CN0 is incrementing to reach CLSi_ATOM_CHx_CM1.CM1, an interrupt on ATOM_CCU1TC[x]_IRQ is generated. When CLSi_ATOM_CHx_CN0.CN0 changes its counting direction from up to down, an interrupt on ATOM_CCU0TC[x]_IRQ is generated.

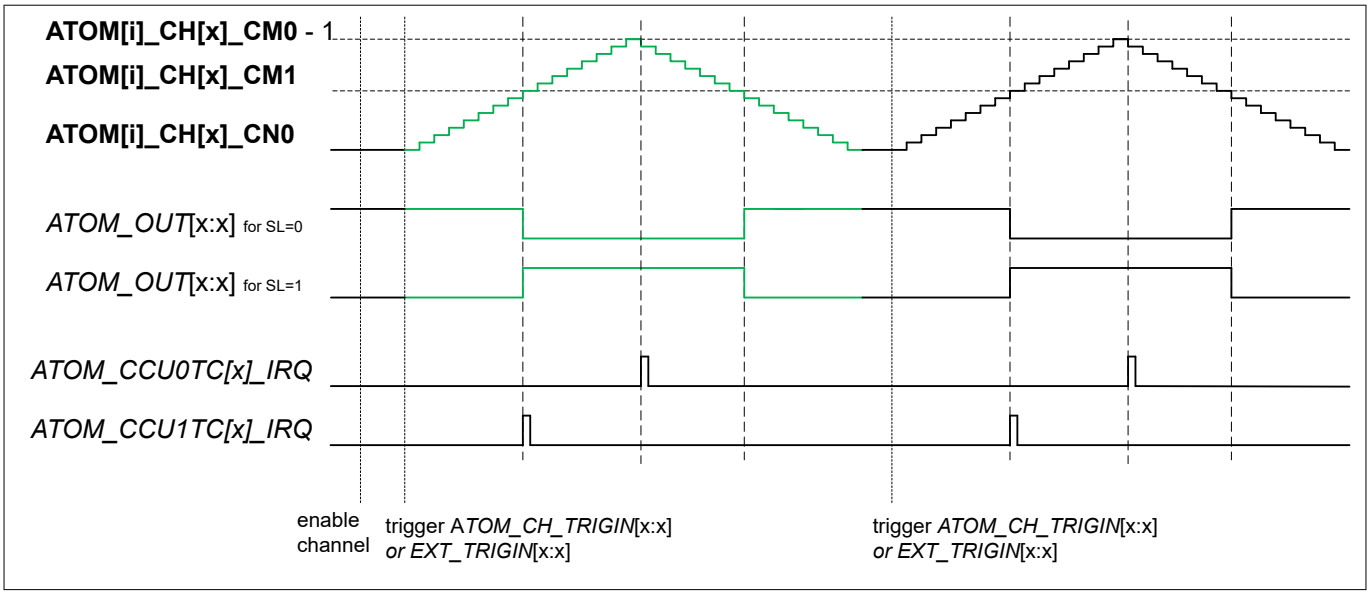

Figure 1088 PWM **output with respect to configuration bit** CLSi_ATOM_CHx_CTRL_SOMP**.**SL **in one-shot counting up-down mode if** CLSi_ATOM_CHx_CTRL_SOMP**.**OSM_TRIG**= 1**

Pulse count modulation mode

At the output ATOM_OUT a pulse count modulated signal can be generated instead of the simple PWM output signal in SOMP mode. This specific behavior is called pulse count modulation (PCM) mode. PCM mode is only available in SOMP mode when CLSi_ATOM_CHx_CTRL_SOMP**.**UDMODE=0.

PCM mode is enabled by setting bit CLSi_ATOM_CHx_CTRL_SOMP**.**BITREV[6:6] to 1.

PCM mode is only available for odd numbered **ATOM** channels 1,3,5,7.

With the configuration bit CLSi_ATOM_CHx_CTRL_SOMP**.**BITREV=1 a bit-reversing of the counter output CLSi_ATOM_CHx_CN0**.**CN0 is configured. In this case the bits LSB and MSB are swapped, the bits LSB+1 and MSB-1 are swapped, the bits LSB+2 and MSB-2 are swapped and so on.

The effect of bit-reversing of the CLSi_ATOM_CHx_CN0**.**CN0 register value is shown in the following Figure 1089.

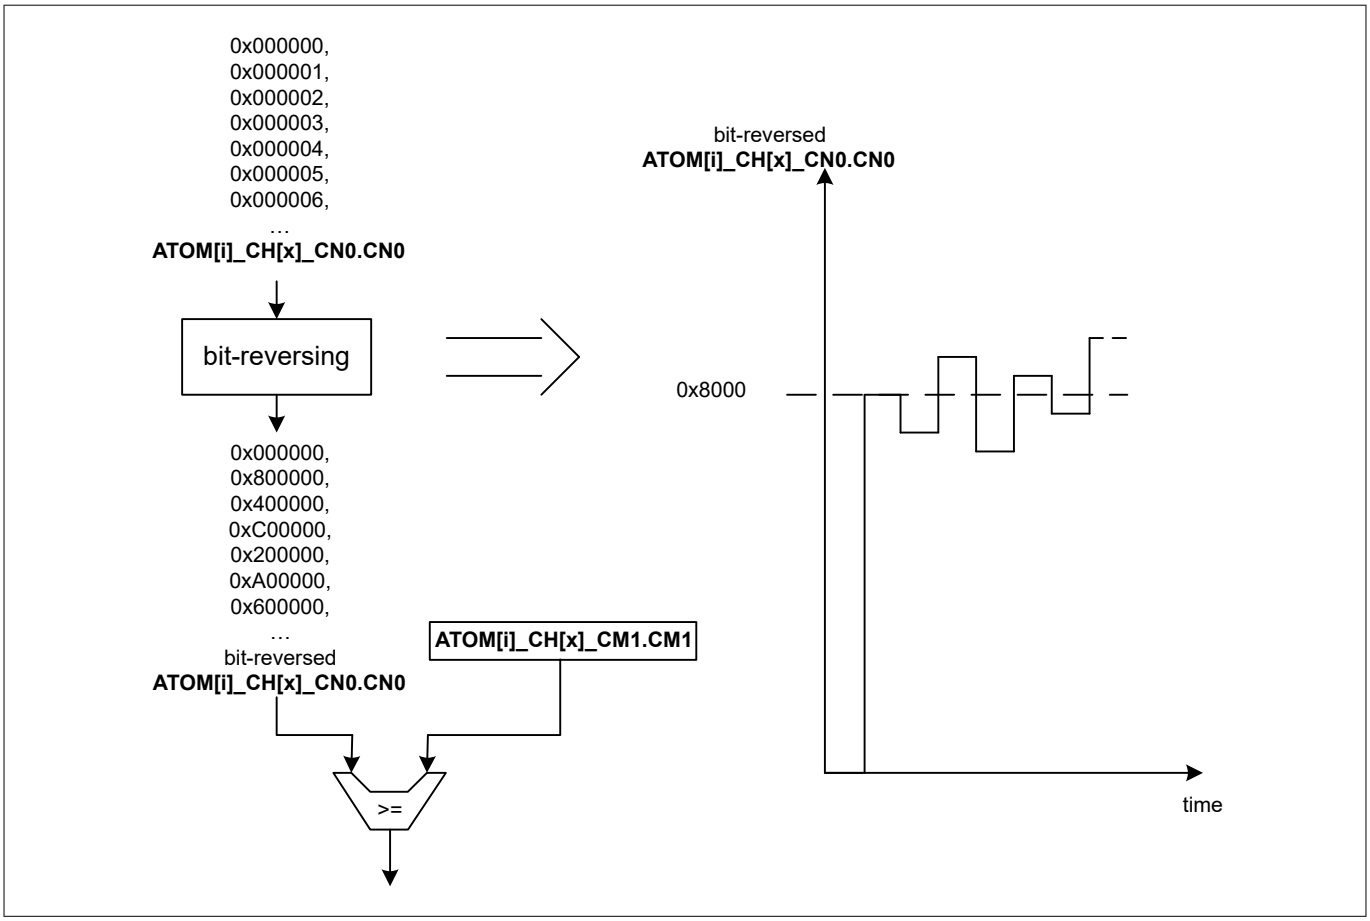

Figure 1089 Bit reversing of counter CLSi_ATOM_CHx_CN0.CN0 output

In the PCM mode the counter register CLSi_ATOM_CHx_CN0.CN0 is incremented by every clock tick depending on configured **CMU** clock resolution (CCM[i]_CLK_RES).

The output of counter register CLSi_ATOM_CHx_CN0.CN0 is first bit-reversed and then compared with the configured register value CLSi_ATOM_CHx_CM1.CM1.

When the bit-reversed value of register CLSi_ATOM_CHx_CN0.CN0 is greater than or equal to CLSi_ATOM_CHx_CM1.CM1, the output ATOM_OUT[x:x] is set to !CLSi_ATOM_CHx_CTRL.SL and otherwise set to CLSi_ATOM_CHx_CTRL.SL.

In PCM mode the CLSi_ATOM_CHx_CM0.CM0 register - in which the period is defined - normally has to be set to its maximum value $FFFFFF_H$.

To reduce time period of updating pulse width value in CLSi_ATOM_CHx_CM1.CM1 register, it is additionally possible to setup period value in CLSi_ATOM_CHx_CM0.CM0 register to smaller values than maximum value as described before.

Possible values for CLSi_ATOM_CHx_CM0.CM0 register are each even numbered values to the power of 2 e.g. 800000_H, 400000_H, 200000_H ... .

In this case the pulse width has to be configured in the following manner.

Depending on how much the period in CLSi_ATOM_CHx_CM0.CM0 register is decreased - means shifted right starting from 1000000_H - the pulse width in CLSi_ATOM_CHx_CM1.CM1 register has to be shifted to the left (= rotated: shift MSB back into LSB) with same value, e.g.:

period CLSi_ATOM_CHx_CM0.CM0 = 0010000_H -> shifted 8 bits right from 1000000_H

--> so pulse width has to be shifted 8 bits left:

e.g. 50% duty cycle: pulse width = 0008000_H -> shift 8 bits left -> CLSi_ATOM_CHx_CM1.CM1 = 800000_H

Table 2232 PCM examples

CLSi_ATOM_CHx_CM0.CM0 **(period)**	CLSi_ATOM_CHx_CM1.CM1 **(pulse width)**	**shift**	CLSi_ATOM_CHx_CM1.CM1 **(configured value)**
$FFFFFF_H$	800000_H	no shift	800000_H
800000_H	400000_H	shift 1 bit left	800000_H
400000_H	100000_H	shift 2 bits left	400000_H
200000_H	$0FFFFF_H$	shift 3 bits left	$7FFFF8_H$
100000_H	033333_H	shift 4 bits left	333330_H
080000_H	005555_H	shift 5 bits left	$0AAAA0_H$
000020_H	000008_H	shift 19 bits left	400000_H
000010_H	000005_H	shift 20 bits left	500000_H

In this mode the interrupt CLSi_ATOM_CHx_IRQ_NOTIFY.CCU1TC is set every time, when bit reverse value of CLSi_ATOM_CHx_CN0.CN0 is greater than or equal to CLSi_ATOM_CHx_CM1.CM1 which may be multiple times during one period. Therefore, from application point of view it is not useful to enable this interrupt.

Trigger generation

For applications with constant PWM period defined by CLSi_ATOM_CHx_CM0.CM0, it is not necessary to update the CLSi_ATOM_CHx_CM0.CM0 register regularly with CLSi_ATOM_CHx_SR0.SR0 register. For these applications, the CLSi_ATOM_CHx_SR0.SR0 register can be used to define an additional output signal and interrupt trigger.

If bit CLSi_ATOM_CHx_CTRL_SOMP.SR0_TRIG is set to 1, the register CLSi_ATOM_CHx_SR0.SR0 is no longer used as a shadow register for register CLSi_ATOM_CHx_CM0.CM0. Instead, CLSi_ATOM_CHx_SR0.SR0 is compared against CLSi_ATOM_CHx_CN0.CN0. If both are equal, a pulse of signal level '1' is generated at the output ATOM_OUT_T[x:x] of instance i, channel x. In this case, CLSi_ATOM_CHx_CM1.CM1 will still be synchronously updated from its shadow register CLSi_ATOM_CHx_SR1.SR1 if the update is enabled by setting CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7)=10_B.

The bit CLSi_ATOM_CHx_CTRL_SOMP.SR0_TRIG can only be set if bit CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0 of this channel is 0.

If bit CLSi_ATOM_CHx_CTRL_SOMP.SR0_TRIG=1 is set, the interrupt on ATOM_CCU1TC[x]_IRQ is set at the same time with pulse generation on ATOM_OUT_T in case of a compare equal match of CLSi_ATOM_CHx_SR0.SR0 = CLSi_ATOM_CHx_CN0.CN0. That means when the interrupt notify flag CLSi_ATOM_CHx_IRQ_NOTIFY.CCU1TC is no longer set on a compare match of CLSi_ATOM_CHx_CM1.CM1 and CLSi_ATOM_CHx_CN0.CN0. Instead, the CLSi_ATOM_CHx_IRQ_NOTIFY.CCU1TC interrupt notify flag is set in case of a compare equal match of CLSi_ATOM_CHx_SR0.SR0 and CLSi_ATOM_CHx_CN0.CN0. However, the interrupt generation of ATOM_CCU0TC[x]_IRQ is the same as the case of CLSi_ATOM_CHx_CTRL_SOMP.SR0_TRIG=0. The output generation with interrupt signals are shown in Figure 1090.

With configuration bit CLSi_ATOM_CHx_CTRL_SOMP.TRIG_PULSE, it is configurable if the output ATOM_OUT_T of instance i and channel x is high as long as CLSi_ATOM_CHx_CN0.CN0=CLSi_ATOM_CHx_SR0.SR0 (CLSi_ATOM_CHx_CTRL_SOMP.TRIG_PULSE=0) or if there will be only one pulse of length one cluster clock period when CLSi_ATOM_CHx_CN0.CN0 becomes CLSi_ATOM_CHx_SR0.SR0 (CLSi_ATOM_CHx_CTRL_SOMP.TRIG_PULSE=1). Figure 1090 shows the case of CLSi_ATOM_CHx_CTRL_SOMP.TRIG_PULSE=1.

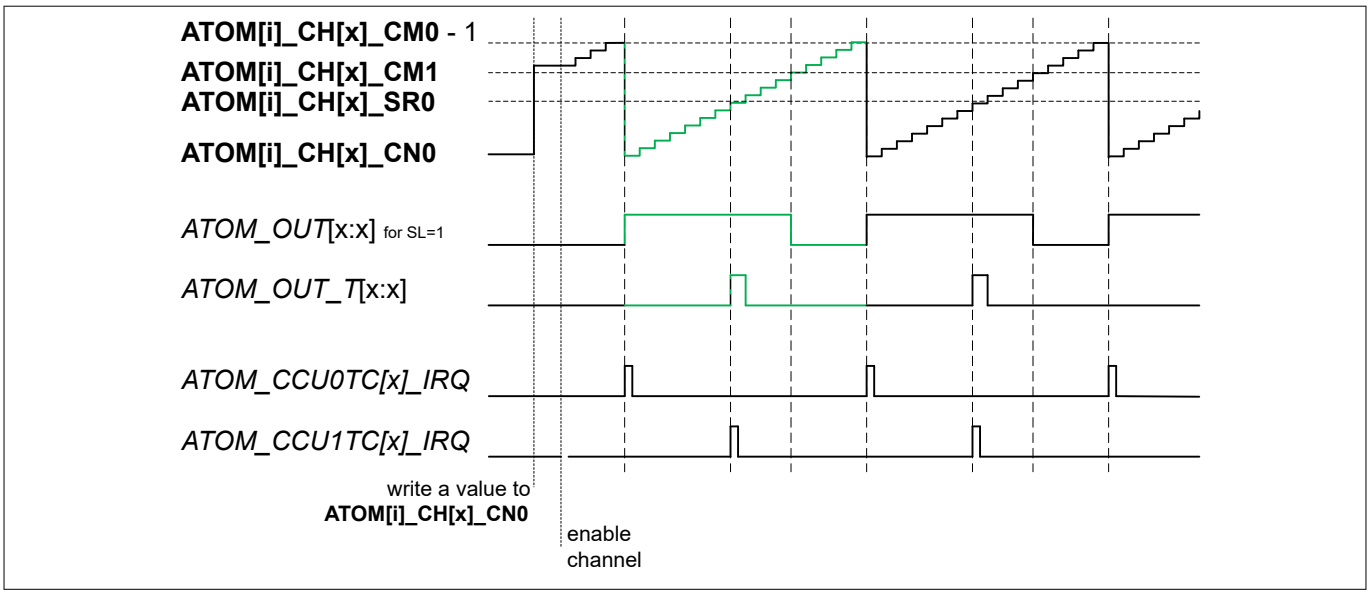

Figure 1090 Output behavior with respect to the CLSi_ATOM_CHx_CTRL_SOMP.TRIG_PULSE=1 in continuous counting up mode if CLSi_ATOM_CHx_CTRL_SOMP.SR0_TRIG=1

High-resolution PWM support (HRES mode)

ATOM also provides high-resolution PWM support mode (HRES mode). In HRES mode, **ATOM** offers the output signal ATOM_OUT_HRES[x] to control a circuit, e.g. a delay chain, which is needed to realize the high-resolution PWM and which has to be implemented outside the **eGTM**. Please refer to High-resolution PWM support for additional information of the high-resolution PWM support of the **eGTM**.

High-resolution mode in **ATOM** sub-module is only available in SOMP continuous counting up mode (CLSi_ATOM_CHx_CTRL_SOMP.UDMODE=0, CLSi_ATOM_CHx_CTRL_SOMP.SR0_TRIG=0). HRES mode is not supported in SOMP continuous counting up-down mode or when CLSi_ATOM_CHx_CTRL_SOMP.SR0_TRIG=1.

The high-resolution PWM support is not available in **ATOM** SOMP one-shot mode. If one-shot mode is enabled by setting of CLSi_ATOM_CHx_CTRL_SOMP.OSM to 1, the high-resolution PWM support has to be disabled by setting of CLSi_ATOM_CHx_CTRL2.HRES to 0, because it is not supported.

The high-resolution PWM support is also not available in PCM mode (CLSi_ATOM_CHx_CTRL_SOMP.BITREV=1).

This output signal ATOM_OUT_HRES[x] has a width of five bits while the decimal value of these five bits defines the number of micro-steps, by which the output signal ATOM_OUT[x:x] will be delayed in a suitable circuit (e.g. delay chain) outside the **eGTM**.

The high-resolution support will be enabled by setting bit CLSi_ATOM_CHx_CTRL2.HRES = 1.

If HRES mode is switched off by setting the configuration bit CLSi_ATOM_CHx_CTRL2.HRES to zero, then the output signals ATOM_OUT_HRES[x] and ATOM_OUT_T_HRES[x] are clamped to zero.

The value for the PWM period, stored in the registers CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_SR0.SR0, and pulse width, stored in the registers CLSi_ATOM_CHx_CM1.CM1 and CLSi_ATOM_CHx_SR1.SR1, represent respectively the length of period and pulse width in number of cluster clock steps and micro-steps.

Hereby the number of cluster clock steps for the PWM output signal ATOM_OUT[x:x] are defined by the upper bits [23:5], whereas the lower 5 bits [4:0] determine the additional micro-steps, by which the output signal has to be delayed outside the **eGTM**. This is shown in Figure 1091.

Table 2233 Overview of the HRES supporting modes

Mode	HRES supported
ATOM SOMI Mode	No
ATOM SOMC Mode	No
ATOM SOMB Mode	No
ATOM SOMS Mode	No
ATOM SOMP Continuous Counting Up Mode	Yes
ATOM SOMP Continuous Counting Up−Down Mode	No
ATOM SOMP One-Shot Counting Up Mode	No
ATOM SOMP One-Shot Counting Up-Down Mode	No
ATOM SOMP Pulse Count Modulation Mode	No

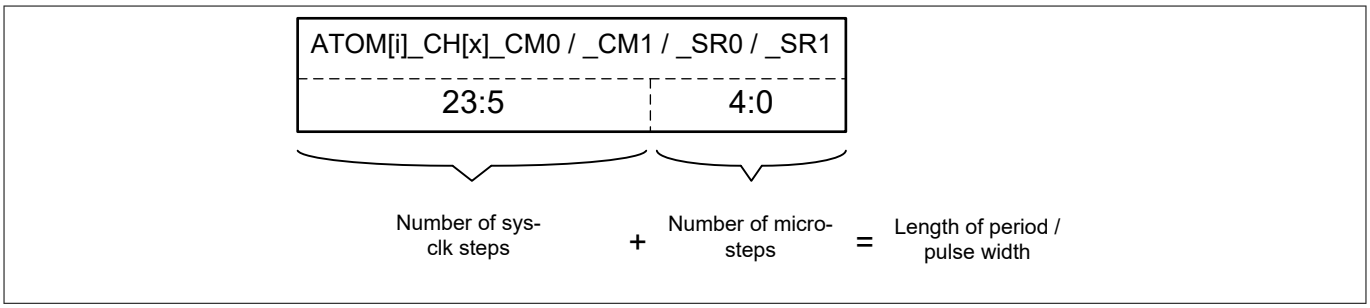

Figure 1091 Period and duty-cycle register in HRES mode

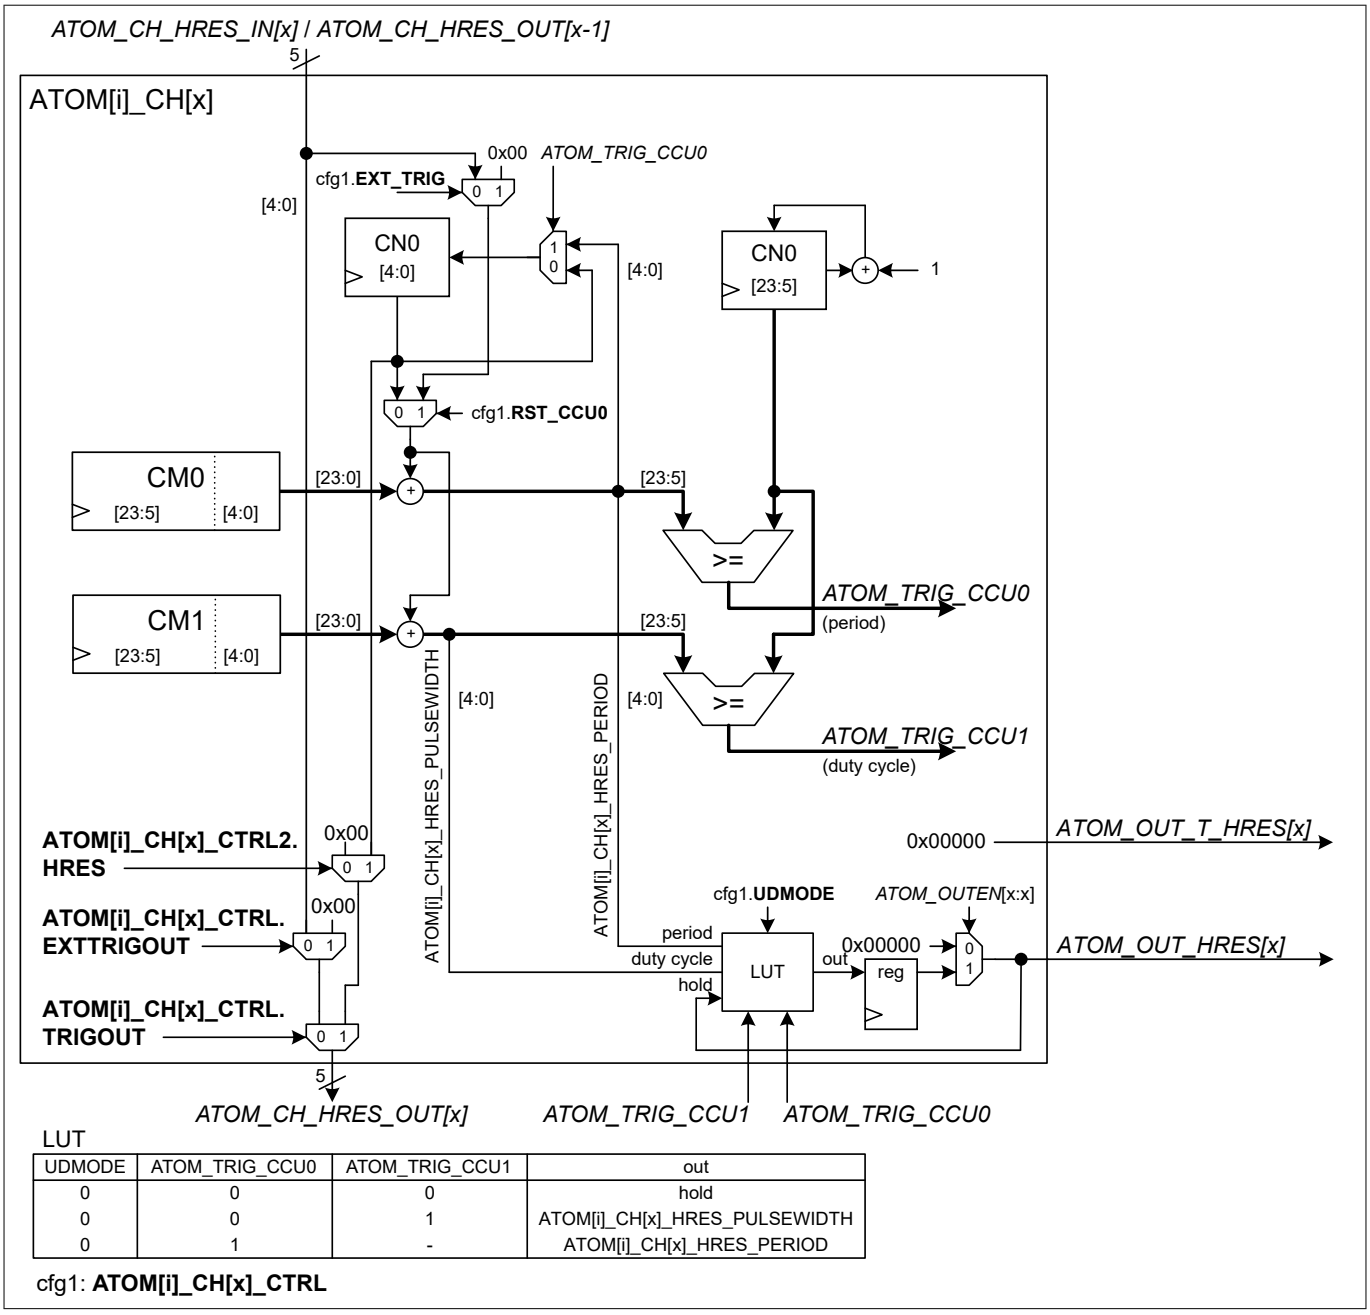
Figure 1092 shows the high-level schematic of the generation of the output signal ATOM_OUT_HRES[x], which defines the number of micro-steps mentioned above. If the **ATOM** channel x has HRES support with the configuration of x<ATOM_HIGH_RES *[i]*, a HRES trigger chain of ATOM_CH_HRES_IN[x] / ATOM_CH_HRES_OUT[x] is available together with the trigger chain of ATOM_CH_TRIGIN[x:x]/ ATOM_CH_TRIGOUT[x:x]. As shown in Figure 1074, the HRES trigger chain signals are routed through all **ATOM** channels and instances that have HRES support. ATOM0 channel 0 is driven by the output of ATOM0 channel 7 with a register in the trigger chain, which means a delay of one cluster clock period. The pipeline registers in the trigger chain of ATOM_CH_TRIGIN[x:x] /ATOM_CH_TRIGOUT[x:x] as mentioned in Internal trigger interface are also inserted in the trigger chain of ATOM_CH_HRES_IN[x]/ATOM_CH_HRES_OUT[x].

The channels x without HRES support (x>=ATOM_HRES_RES[i]) still have the HRES trigger chain of ATOM_CH_HRES_IN[x] / ATOM_CH_HRES_OUT[x] across these channels. The ATOM_CH_HRES_IN[x] coming from *ATOM_CH_HRES_OUT*[x-1] (previous channel) is directly connected to ATOM_CH_HRES_OUT[x] that is connected to *ATOM_CH_HRES_IN*[x+1] (next channel). There is no specific HRES functionalities in these channels without HRES support. Both HRES output signals ATOM_OUT_HRES[x] and ATOM_OUT_T_HRES[x] of these channels (x>=ATOM_HIGH_RES *[i]*) are clamped to zero.

When CLSi_ATOM_CHx_CN0.CN0 >= CLSi_ATOM_CHx_CM0.CM0-1, ATOM_TRIG_CCU0 =1 will be set and then ATOM_OUT[x:x] will be set to CLSi_ATOM_CHx_CTRL.SL in the next **CMU** period. Similarly, when CLSi_ATOM_CHx_CN0.CN0 >= CLSi_ATOM_CHx_CM1.CM1-1, ATOM_TRIG_CCU1 =1 will be set and then ATOM_OUT[x:x] will be set to !CLSi_ATOM_CHx_CTRL.SL. When CLSi_ATOM_CHx_CN0.CN0 < CLSi_ATOM_CHx_CM0.CM0-1, ATOM_TRIG_CCU0 will be reset as 0. Similarly, when CLSi_ATOM_CHx_CN0.CN0 < CLSi_ATOM_CHx_CM1.CM1-1, ATOM_TRIG_CCU1 will be reset to 0. According to the unit LUT in Figure 1092, the corresponding output signal ATOM_OUT_HRES[x] is generated together with each edge of PWM output signal ATOM_OUT[x:x].



LUT

UDMODE	ATOM_TRIG_CCU0	ATOM_TRIG_CCU1	out
0	0	0	hold
0	0	1	ATOM[i]_CH[x]_HRES_PULSEWIDTH
0	1	-	ATOM[i]_CH[x]_HRES_PERIOD

cfg1: **ATOM[i]_CH[x]_CTRL**

Figure 1092 High-level schematic view of ATOM_OUT_HRES[x] calculation

As shown in Figure 1092, when it is configured as continuous counting up mode (CLSi_ATOM_CHx_CTRL_SOMP.UDMODE=0) and CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=0, the output signal ATOM_OUT_HRES[x] has to be calculated based on the internal signal ATOM[i]_CH[x]_HRES_PERIOD and ATOM[i]_CH[x]_HRES_PULSEWIDTH in the following manner (here, t means the index of a PWM period):

- period: ATOM[i]_CH[x]_HRES_PERIOD = CLSi_ATOM_CHx_CN0.CN0[4:0] + CLSi_ATOM_CHx_CM0.CM0[4:0]
- pulse width: ATOM[i]_CH[x]_HRES_PULSEWIDTH = CLSi_ATOM_CHx_CN0.CN0[4:0] + CLSi_ATOM_CHx_CM1.CM1[4:0]
- with: $(\text{CLSi_ATOM_CHx_CN0.CN0}[4:0])_{t+1} = (\text{CLSi_ATOM_CHx_CN0.CN0}[4:0])_t + (\text{CLSi_ATOM_CHx_CM0.CM0}[4:0])_t$

The signal diagram in Figure 1093 shows an example for the output generation in HRES mode when CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=0 and CLSi_ATOM_CHx_CTRL_SOMP.SL=1. The PWM output signal ATOM_OUT[x:x] with cluster clock steps is generated based on the upper bits [23:5] of

CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM1.CM1 according to the same way of continuous counting up mode. Please refer to Figure 1081 for more details. The output signal ATOM_OUT_HRES[x] can be calculated based on the lower bits [4:0] of CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM1.CM1 according to Figure 1092 and the formulas above. As shown in Figure 1093, the value of ATOM_OUT_HRES[x] represents the number of micro-steps that should be taken by the external circuit to delay each edge of ATOM_OUT[x:x]. In this way, the delayed PWM signal ATOM_EXT_HRES[x:x] achieves higher resolution.

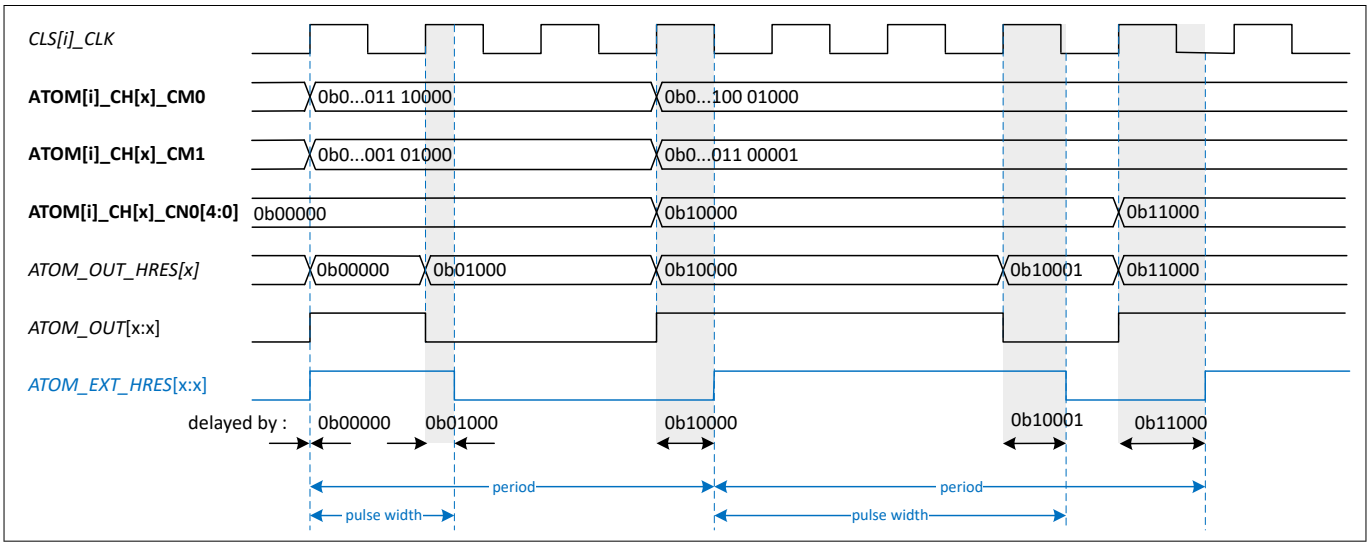


Figure 1093 Signals in HRES mode when CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=0 and CLSi_ATOM_CHx_CTRL_SOMP.SL=1

The HRES mode is also available in continuous counting up mode when CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=1.

In this case (CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0 = 1), if CLSi_ATOM_CHx_CTRL_SOMP.EXT_TRIG =0, the internal trigger signal ATOM_CH_HRES_IN[x] from the preceding channel is used for calculation instead of CLSi_ATOM_CHx_CN0.CN0[4:0] :

- period: ATOM[i]_CH[x]_HRES_PERIOD = ATOM_CH_HRES_IN[x] + CLSi_ATOM_CHx_CM0.CM0[4:0]
- pulse width: ATOM[i]_CH[x]_HRES_PULSEWIDTH = ATOM_CH_HRES_IN[x] + CLSi_ATOM_CHx_CM1.CM1[4:0]

The signal diagram in Figure 1094 shows an example for the output generation in HRES mode when CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=1, CLSi_ATOM_CHx_CTRL_SOMP.EXT_TRIG=0 and CLSi_ATOM_CHx_CTRL_SOMP.SL=1. The PWM output signal ATOM_OUT[x:x] with cluster clock steps is generated based on the upper bits [23:5] of CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM1.CM1 according to the same way of continuous counting up mode. Please refer to Figure 1082 for more details. The output signal ATOM_OUT_HRES[x] representing the number of micro-steps can be calculated based on the lower bits [4:0] of CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1 and ATOM_CH_HRES_IN[x] according to Figure 1092 and the formulas above. Then the external circuit can take the value of ATOM_OUT_HRES[x] to generate the delayed signal ATOM_EXT_HRES[x:x].

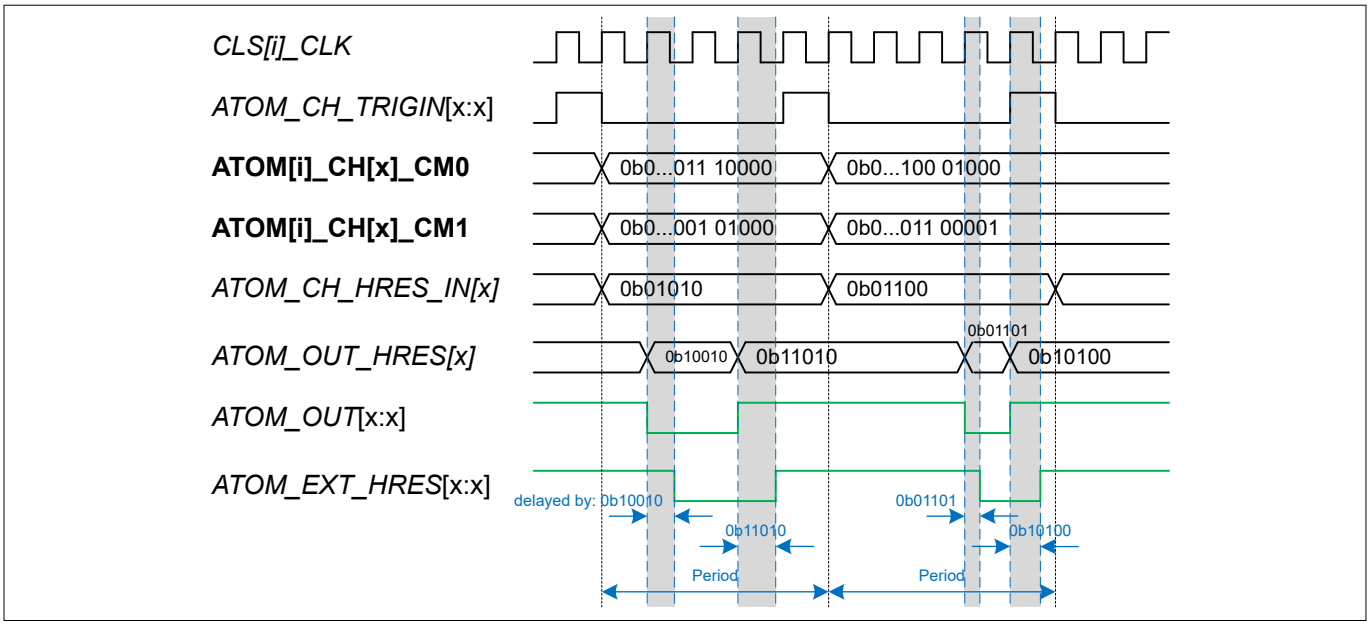

Figure 1094 Signals in HRES mode when CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=1, CLSi_ATOM_CHx_CTRL_SOMP.EXT_TRIG=0 and CLSi_ATOM_CHx_CTRL_SOMP.SL=1

If CLSi_ATOM_CHx_CTRL_SOMP.EXT_TRIG =1, the HRES output signal is only depending on CLSi_ATOM_CHx_CM0.CM0[4:0] and CLSi_ATOM_CHx_CM1.CM1[4:0]:

- period: ATOM[i]_CH[x]_HRES_PERIOD = 00_B + CLSi_ATOM_CHx_CM0.CM0[4:0]
- pulse width: ATOM[i]_CH[x]_HRES_PULSEWIDTH = 00_B + CLSi_ATOM_CHx_CM1.CM1[4:0]

The signal diagram in Figure 1095 shows an example for the output generation in HRES mode when CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=1, CLSi_ATOM_CHx_CTRL_SOMP.EXT_TRIG=1 and CLSi_ATOM_CHx_CTRL_SOMP.SL=1. Similarly, ATOM_OUT[x:x] is normal continuous counting up mode PWM signal with cluster clock steps, while ATOM_OUT_HRES[x] represents the number of micro-steps for generating ATOM_EXT_HRES[x:x].

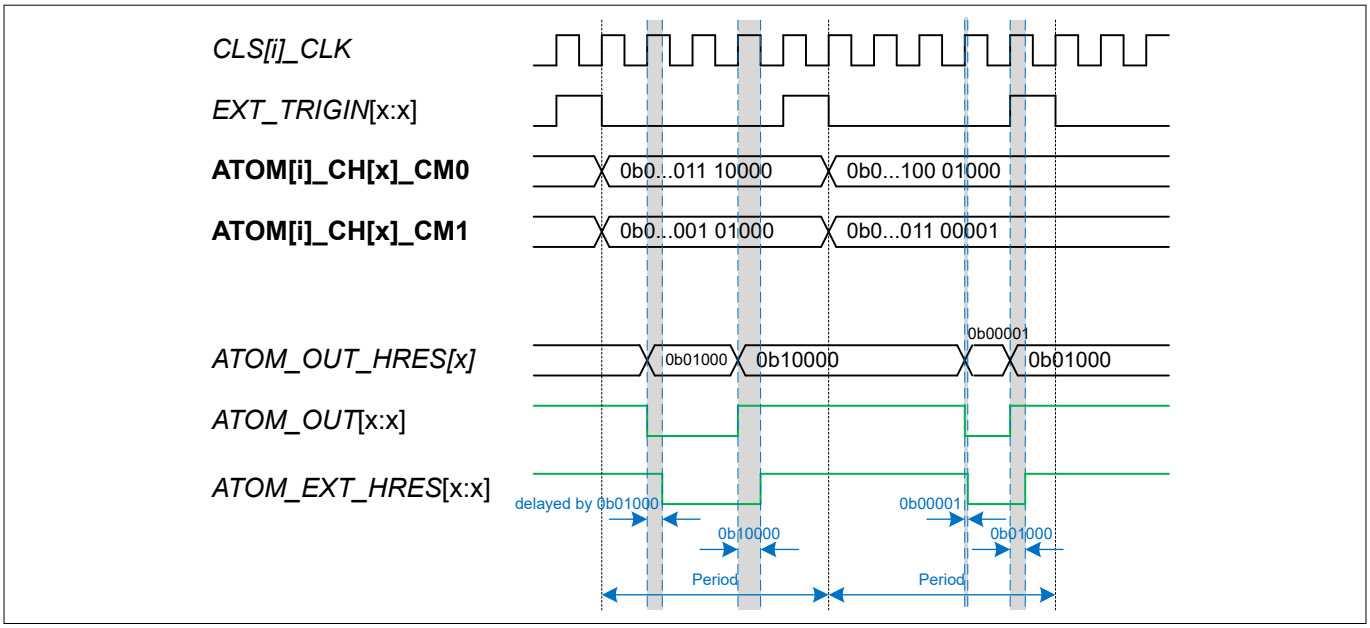

Figure 1095 Signals in HRES mode when CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=1, CLSi_ATOM_CHx_CTRL_SOMP.EXT_TRIG=1 and CLSi_ATOM_CHx_CTRL_SOMP.SL=1

The following restrictions and characteristics must be considered, if the HRES mode is enabled:

- The selected clock resolution source CLSi_ATOM_CHx_CTRL_SOMP.CLK_SRC of CCM[i]_CLK_RES[x:x] has to be configured to the cluster clock CLS[j]_CLK.
- The maximum possible period is reduced to 2^{19} cluster clock-cycles.
- Only one edge on ATOM_OUT[x:x] with one value of ATOM_OUT_HRES[x] per cluster clock-cycle is possible.

In order to fulfill the constraint above, there are more constraints when CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=0:

- For normal PWM signal, the constraint CLSi_ATOM_CHx_CM0.CM0 >= 64 and 32<=CLSi_ATOM_CHx_CM1.CM1 <= CLSi_ATOM_CHx_CM0.CM0 - 32 must be fulfilled.
- For 0% duty cycle PWM signal (keep !CLSi_ATOM_CHx_CTRL_SOMP.SL), the constraint CLSi_ATOM_CHx_CM0.CM0 >= 64 and CLSi_ATOM_CHx_CM1.CM1 = 0 must be fulfilled.
- For 100% duty cycle PWM signal (keep CLSi_ATOM_CHx_CTRL_SOMP.SL), the constraint CLSi_ATOM_CHx_CM0.CM0 = CLSi_ATOM_CHx_CM1.CM1 >= 64 must be fulfilled.

However, when CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=1, there are other constraints and some of them are different from the case when HRES option is disabled:

- When configuring CLSi_ATOM_CHx_CM0.CM0[23:5]=0 or CLSi_ATOM_CHx_CM1.CM1[23:5]=0, the lower HRES bits CLSi_ATOM_CHx_CM0.CM0[4:0]=0 or CLSi_ATOM_CHx_CM1.CM1[4:0] must also be 0.
- It is allowed to configure the registers as CLSi_ATOM_CHx_CM1.CM1 <= CLSi_ATOM_CHx_CM0.CM0 - 32 or CLSi_ATOM_CHx_CM1.CM1 = CLSi_ATOM_CHx_CM0.CM0.
- The configuration CLSi_ATOM_CHx_CM1.CM1 > CLSi_ATOM_CHx_CM0.CM0 is not allowed.

Furthermore, if CLSi_ATOM_CHx_CTRL_SOMP.RST_CCU0=1 and CLSi_ATOM_CHx_CTRL_SOMP.EXT_TRIG=0, the channel is triggered by the preceding channel with HRES output trigger chain. Besides the constraints above, there are more constraints between the triggered channel and the triggering channel. Here, the registers of the triggered channel are noted with a subscript "triggered" while the triggering of the preceding channel is marked with "master".

- The configuration must fulfill (CLSi_ATOM_CHx_CM0.CM0)$_{triggered}$ <= (CLSi_ATOM_CHx_CM0.CM0)$_{master}$ or (CLSi_ATOM_CHx_CM0.CM0[23:5])$_{triggered}$ > (CLSi_ATOM_CHx_CM0.CM0[23:5])$_{master}$.
- If (CLSi_ATOM_CHx_CM0.CM0[23:5])$_{triggered}$ = (CLSi_ATOM_CHx_CM0.CM0[23:5])$_{master}$, (CLSi_ATOM_CHx_CM1.CM1)$_{triggered}$ must be greater or equal to 32.

When HRES mode is enabled, ATOM_CH_HRES_IN[x]/ATOM_CH_HRES_OUT[x] are always generated synchronously together with ATOM_CH_TRIGIN[x:x]/ATOM_CH_TRIGOUT[x:x] and may be delayed by same pipeline registers according to device configuration parameter configuration as defined in Internal trigger interface. If one channel triggers several following several channels, the 4 trigger signals ATOM_CH_TRIGIN[x:x]/ ATOM_CH_TRIGOUT[x:x] with ATOM_CH_HRES_IN[x]/ATOM_CH_HRES_OUT[x] build up a trigger chain from the triggering channel to the triggered channels. In this case, if there is no pipeline register in the trigger chain, these triggered channels can be configured with same operation registers and synchronously triggered to generate consistent PWM signals. However, if there are pipeline registers that may introduce delay of number of cluster clock periods, it is hard to simultaneously trigger several channels to generate consistent PWM signals. The reason for that is in HRES mode the operation clock frequency is the cluster clock and each pipeline register may cause a delay or shift of one cluster clock on the trigger signal pulse and this delay must be taken into account.

ATOM signal output mode serial (SOMS)

In **ATOM** Signal Output Mode Serial (SOMS) the **ATOM** channel acts as a serial output shift register where the content of the CLSi_ATOM_CHx_CM1.CM1 register in the CCU1 unit is shifted out whenever the unit is triggered by the clock source, which is selected by CLSi_ATOM_CHx_CTRL_SOMS.CLK_SRC. The shift direction is configurable with the bit CLSi_ATOM_CHx_CTRL_SOMS.ACB0.

The data inside the CLSi_ATOM_CHx_CM1.CM1 register has to be aligned according to the selected shift direction in the CLSi_ATOM_CHx_CTRL_SOMS.ACB0/CLSi_ATOM_CHx_STAT.ACBI[0:0] bit. This means that

when a right shift is selected, the data word has to be aligned to bit 0 of the CLSi_ATOM_CHx_CM1.CM1 register and when a left shift is selected, the data has to be aligned to bit 23 of the CLSi_ATOM_CHx_CM1.CM1 register.

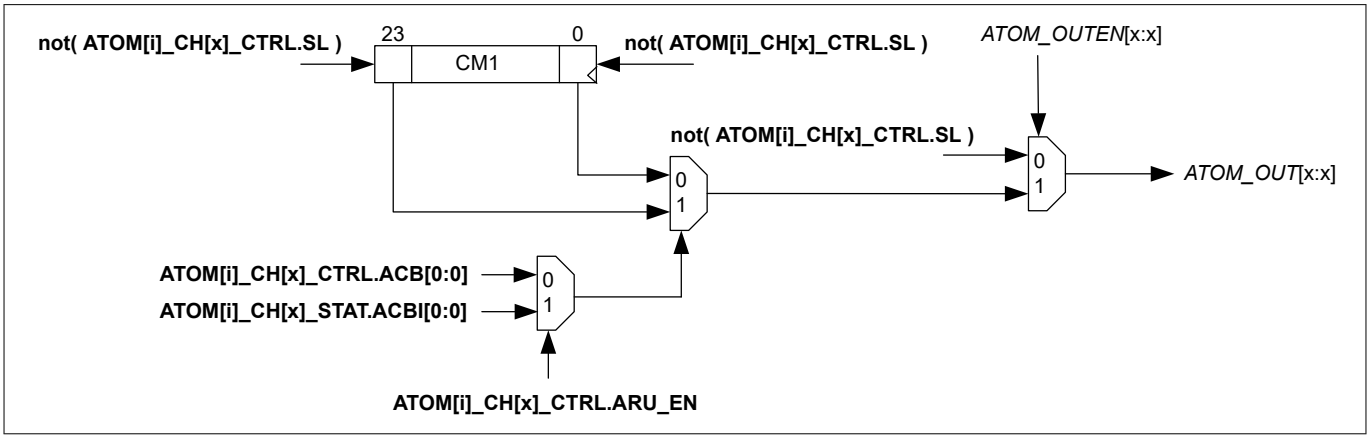

Figure 1096 SOMS mode output generation

Figure 1096 shows the output generation in case of SOMS mode is selected.

In SOMS mode CCU0 runs in counter/compare mode and counts the number of bits shifted out so far. The total number of bits that should be shifted is defined as CLSi_ATOM_CHx_CM0.CM0. The total number of bits that are visible at ATOM_OUT is CLSi_ATOM_CHx_CM0.CM0+1.

When the output is disabled the ATOM_OUT is set to the inverse CLSi_ATOM_CHx_CTRL_SOMS.SL bit definition.

When the content of the CLSi_ATOM_CHx_CM1.CM1 register is shifted out, the inverse signal level is shifted into the CLSi_ATOM_CHx_CM1.CM1 register.

When the output is enabled while CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)** is disabled, the ATOM_OUT signal level is defined by bit CLSi_ATOM_CHx_CM1.CM1[23:0], dependent on the shift direction defined by CLSi_ATOM_CHx_CTRL_SOMS.ACB0 or CLSi_ATOM_CHx_STAT.ACBI[0:0] register setting. Figure 1097 should clarify the **ATOM** channel startup behavior in this case for right shift. For left shift the CLSi_ATOM_CHx_CM1.CM1[0:0] in Figure 1097 has to be replaced by CLSi_ATOM_CHx_CM1.CM1[23:23].

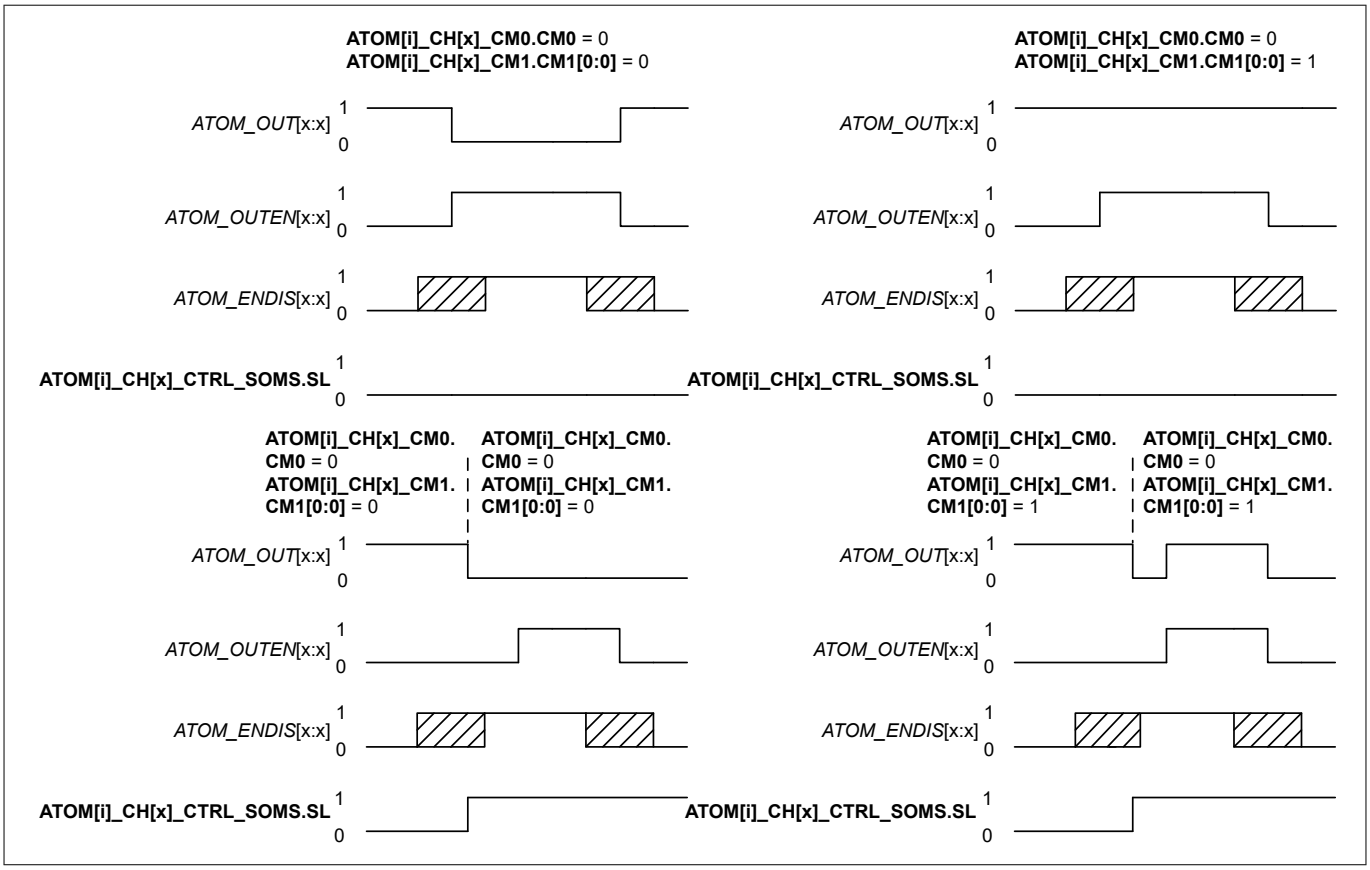

Figure 1097 SOMS output signal level at startup, CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) (k=x) disabled

If CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)** is set and the channel is enabled, the output level is defined by bit CLSi_ATOM_CHx_CM1.CM1[0:0] or CLSi_ATOM_CHx_CM1.CM1[23:23] depending on the shift direction. Figure 1098 shows the output behavior in that case.

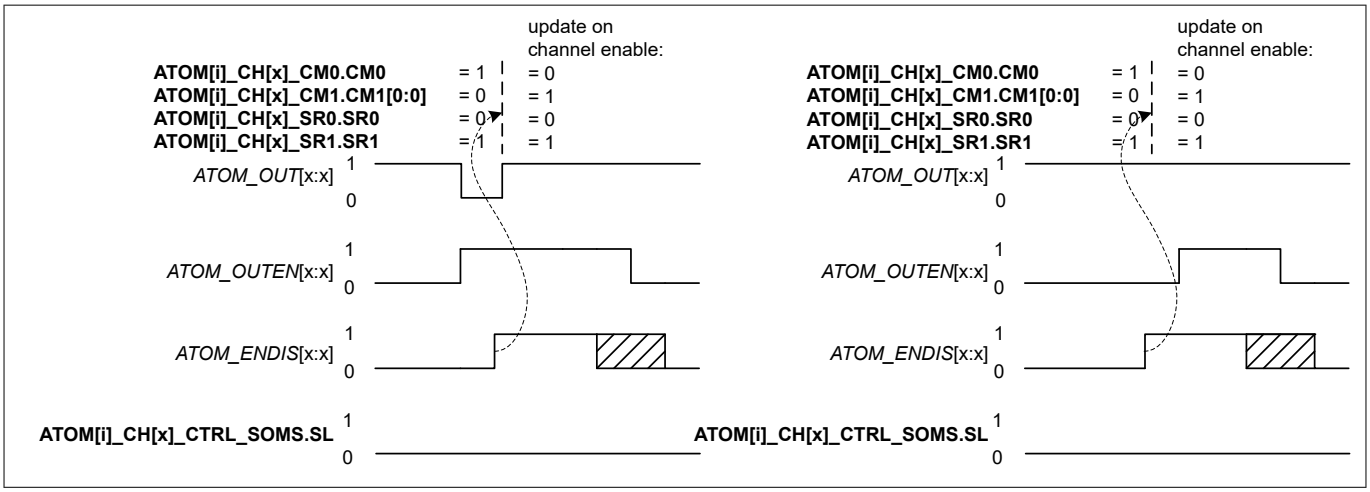

Figure 1098 SOMS output signal level at startup, CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) (k=x) enabled

If bit CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)** of a channel x is not set, the **ATOM** may stop shifting after CLSi_ATOM_CHx_CN0.CN0 has reached CLSi_ATOM_CHx_CM0.CM0.

In this case also no automatic restart of shifting is possible.

SOMS mode with CLSi_ATOM_CHx_CTRL_SOMS.OSM = 0, CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) (k=x) = 1:

In case bit CLSi_ATOM_CHx_CTRL_SOMS.OSM is not set, the **ATOM** channel updates its CLSi_ATOM_CHx_CM0.CM0/CLSi_ATOM_CHx_CM1.CM1 register with the content of the CLSi_ATOM_CHx_SR0.SR0/CLSi_ATOM_CHx_SR1.SR1 register and restarts shifting immediately. The first bit of new CLSi_ATOM_CHx_CM1.CM1 register value will be applied at the output without any gap to the last bit of the previous CLSi_ATOM_CHx_CM1.CM1 register value.

SOMS mode with CLSi_ATOM_CHx_CTRL_SOMS.OSM = 1, CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) (k=x) = 1:

In case bit CLSi_ATOM_CHx_CTRL_SOMS.OSM is set, the **ATOM** channel stops shifting when CLSi_ATOM_CHx_CN0.CN0 reaches CLSi_ATOM_CHx_CM0.CM0 and no update of CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM1.CM1 is performed.

Then, the shifting of the channel can be restarted again by writing a zero to the CLSi_ATOM_CHx_CN0.CN0 register again.

The writing of a zero to CLSi_ATOM_CHx_CN0.CN0 also causes an immediate update of CLSi_ATOM_CHx_CM0.CM0/CLSi_ATOM_CHx_CM1.CM1 register with the content of CLSi_ATOM_CHx_SR0.SR0/ CLSi_ATOM_CHx_SR1.SR1 register.

Restarting the shifting by writing a zero to CLSi_ATOM_CHx_CN0.CN0 can also be done while a shift cycle is already active. Then an immediate update of CLSi_ATOM_CHx_CM0.CM0/CLSi_ATOM_CHx_CM1.CM1 register with the content of CLSi_ATOM_CHx_SR0.SR0/CLSi_ATOM_CHx_SR1.SR1 register is done followed by a new shift operation.

SOMS mode with CLSi_ATOM_CHx_CTRL_SOMS.OSM = 0, CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) (k=x) = 0:

In case of bit CLSi_ATOM_CHx_CTRL_SOMS.OSM is not set and the update enable bit CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)** is not set, no update of CLSi_ATOM_CHx_CM0.CM0/ CLSi_ATOM_CHx_CM1.CM1 register is executed. The shifting is done continuously without reloading from shadow register CLSi_ATOM_CHx_SR0.SR0/CLSi_ATOM_CHx_SR1.SR1 and without any gap between the shift cycles.

SOMS mode with double output

If the mode bit DSO is additionally set in SOMS mode (in register CLSi_ATOM_CHx_CTRL_SOMS), two 12-bit data streams can be shifted out on the outputs ATOM_OUT and ATOM_OUT_T of instance i and channel x in parallel.

This is achieved by splitting the register CLSi_ATOM_CHx_CM1.CM1 into two parts. The lower 12 bits are used as a shift register of output ATOM_OUT (i.e. bit 0 is assigned to output ATOM_OUT), the upper 12 bits are used as a shift register of output ATOM_OUT_T (i.e. bit 12 is assigned to output ATOM_OUT_T).

On bit CLSi_ATOM_CHx_CM1.CM1[23:11] the value !CLSi_ATOM_CHx_CTRL_SOMS.SL is shifted in.

In this mode only right shift is possible. Bit CLSi_ATOM_CHx_CTRL_SOMS.ACB0 is ignored.

This behavior is depicted in the following figure:

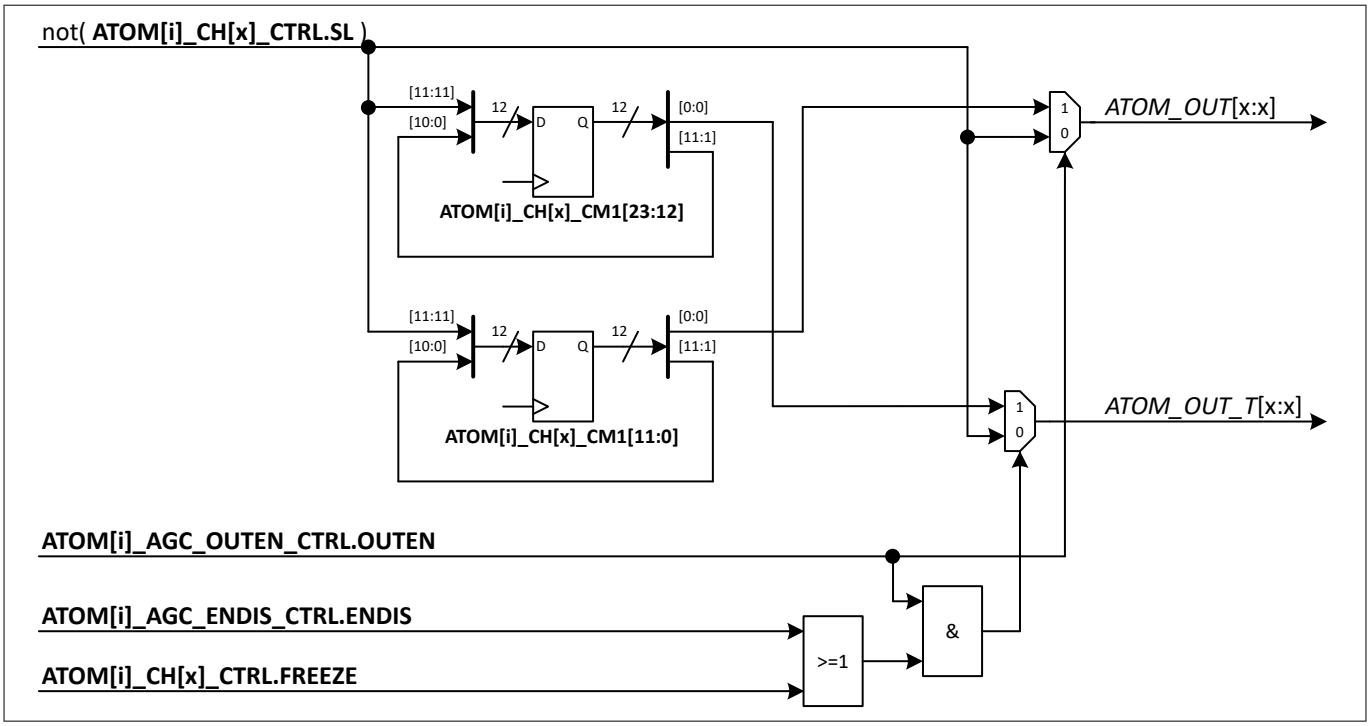

Figure 1099 Double output shift mode

Interrupts in SOMS mode

In **ATOM** Signal Output Mode Serial only the interrupt CLSi_ATOM_CHx_IRQ_NOTIFY.CCU0TC in case of CLSi_ATOM_CHx_CN0.CN0 >= CLSi_ATOM_CHx_CM0.CM0 is generated. The interrupt CLSi_ATOM_CHx_IRQ_NOTIFY.CCU1TC has no meaning and is not generated.

ATOM signal output mode buffered compare (SOMB)

Overview

In **ATOM** Signal Output Mode Buffered Compare (SOMB) the output action is performed according to the comparison result of the input values located in CLSi_ATOM_CHx_CM0.CM0 and/or CLSi_ATOM_CHx_CM1.CM1 registers and the two (three) time base values CCM[i]_TBU_TS0 or CCM[i]_TBU_TS1 (or CCM[i]_TBU_TS2) provided by the **TBU**. For a description of the time base generation please refer to the **TBU** specification in Time base unit (**TBU**). It is configurable, which of the two (three) time bases is to be compared with one or both values in CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM1.CM1.

The compare strategy of the two compare units CCU0 and CCU1 is controlled by the value of bit field of CLSi_ATOM_CHx_STAT.ACBI. This bit field is only readable over configuration interface.

The table below lists all valid control configurations for bit field CLSi_ATOM_CHx_STAT.ACBI.

Table 2234 ATOM SOMB compare strategies

CLSi_ATOM_CHx_STAT.ACBI[4:4]	CLSi_ATOM_CHx_STAT.ACBI[3:3]	CLSi_ATOM_CHx_STAT.ACBI[2:2]	CCU0/CCU1 comparison control
0	0	0	Reserved. Has no effect.
0	0	1	Reserved. Has no effect.

(table continues...)

Table 2234 (continued) ATOM SOMB compare strategies

CLSi_ATOM_CHx_STAT.ACBI[4:4]	CLSi_ATOM_CHx_STAT.ACBI[3:3]	CLSi_ATOM_CHx_STAT.ACBI[2:2]	CCU0/CCU1 comparison control
0	1	0	Compare in CCU0 only, use time base CCM[i]_TBU_TS0. Output signal level at the compare match event is defined by combination of CLSi_ATOM_CHx_CTRL_SOMB.SL and CLSi_ATOM_CHx_CTRL_SOMB.ACB10/ CLSi_ATOM_CHx_STAT.ACBI[1:0] bits (details see Table 2235).
0	1	1	Compare in CCU1 only, use time base CCM[i]_TBU_TS1 or CCM[i]_TBU_TS2. Output signal level at the compare match event is defined by combination of CLSi_ATOM_CHx_CTRL_SOMB.SL and CLSi_ATOM_CHx_CTRL_SOMB.ACB10/ CLSi_ATOM_CHx_STAT.ACBI[1:0] bits (details see Table 2235).
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using CCM[i]_TBU_TS0. Output signal level at the CCU0 compare match event is defined by combination of CLSi_ATOM_CHx_CTRL_SOMB.SL and CLSi_ATOM_CHx_STAT.ACBI[1:0] (details see Table 2235). At the CCU1 compare match event the output level is toggled.

Table 2234 (continued) ATOM SOMB compare strategies

CLSi_ATOM_CHx_STAT.ACBI[4:4]	CLSi_ATOM_CHx_STAT.ACBI[3:3]	CLSi_ATOM_CHx_STAT.ACBI[2:2]	CCU0/CCU1 comparison control
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using CCM[i]_TBU_TS1 or CCM[i]_TBU_TS2. Output signal level at the CCU0 compare match event is defined by combination of CLSi_ATOM_CHx_CTRL_SOMB.SL and CLSi_ATOM_CHx_STAT.ACBI[1:0] (details see Table 2235). At the CCU1 compare match event the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using CCM[i]_TBU_TS0 and then in CCU1 using CCM[i]_TBU_TS1 or CCM[i]_TBU_TS2. Output signal level at the CCU1 compare match event is defined by combination of CLSi_ATOM_CHx_CTRL_SOMB.SL and CLSi_ATOM_CHx_STAT.ACBI[1:0] (details see Table 2235).
1	1	1	Cancels pending comparison

Based on the configured compare strategy CLSi_ATOM_CHx_STAT.ACBI[4:2], CCU0 unit always performs cyclic event compare between CLSi_ATOM_CHx_CM0.CM0 and the selected **TBU** time base CCM[i]_TBU_TS0/ CCM[i]_TBU_TS1/CCM[i]_TBU_TS2, while CCU1 unit always performs cyclic event compare between CLSi_ATOM_CHx_CM1.CM1 and the selected **TBU** time base CCM[i]_TBU_TS0/CCM[i]_TBU_TS1/ CCM[i]_TBU_TS2. Please refer to Cyclic event compare for more information about cyclic event compare strategy. When the selected time base is "cyclically greater than or equal to" the compare value of CLSi_ATOM_CHx_CM0.CM0, CCU0 compare match event is considered to have occurred. When the selected time base is "cyclically greater than or equal to" the compare value of CLSi_ATOM_CHx_CM1.CM1, CCU1 compare match event is considered to have occurred. Whenever CCU0 or CCU1 compare match event has occurred, an edge is generated on output ATOM_OUT[x:x], depending on the predefined signal level in CLSi_ATOM_CHx_CTRL_SOMB.SL bit in combination with two control bits CLSi_ATOM_CHx_STAT.ACBI[1:0].

If the scheduled compare match event in CCU0 and/or CCU1 have occurred and the CLSi_ATOM_CHx_SR0.SR0 / CLSi_ATOM_CHx_SR1.SR1 register contain new valid values, the registers CLSi_ATOM_CHx_CM0.CM0 and CLSi_ATOM_CHx_CM1.CM1 will be updated automatically with the content of the corresponding registers CLSi_ATOM_CHx_SR0.SR0 and CLSi_ATOM_CHx_SR1.SR1, the CLSi_ATOM_CHx_STAT.ACBI bit field will be updated with the content of internal *ACB_SR* register and the CLSi_ATOM_CHx_STAT.DV bit will be set. If the

registers CLSi_ATOM_CHx_SR0.SR0 / CLSi_ATOM_CHx_SR1.SR1 and CLSi_ATOM_CHx_CM0.CM0 / CLSi_ATOM_CHx_CM1.CM1 contain no valid value, the compare units will wait in the idle state.

On a compare match event in one of the compare units CCU0/CCU1 units the output ATOM_OUT[x:x] is set according to combination of the bits CLSi_ATOM_CHx_STAT.ACBI[1:0] and CLSi_ATOM_CHx_CTRL_SOMB.SL according to the following table.

Table 2235 ATOM SOMB output control by CLSi_ATOM_CHx_STAT.ACBI[1:0] and CLSi_ATOM_CHx_CTRL_SOMB.SL

SL	CLSi_ATOM_CHx_STAT.ACBI[1:1]	CLSi_ATOM_CHx_STAT.ACBI[0:0]	Output Behavior
0	0	0	No signal level change at output.
0	0	1	Set output signal level to 1.
0	1	0	Set output signal level to 0.
0	1	1	Toggle output signal level.
1	0	0	No signal level change at output.
1	0	1	Set output signal level to 0.
1	1	0	Set output signal level to 1.
1	1	1	Toggle output signal level.

In contrast to the SOMC mode, no timestamp value of **TBU** is captured in CLSi_ATOM_CHx_SR0.SR0 / CLSi_ATOM_CHx_SR1.SR1 register.

The flag CLSi_ATOM_CHx_STAT.DV of register CLSi_ATOM_CHx_STAT indicates that at least one of the CLSi_ATOM_CHx_CM0.CM0/CLSi_ATOM_CHx_CM1.CM1 register contains valid data and a compare event may be pending (if the channel is enabled).

The CLSi_ATOM_CHx_STAT.DV flag is reset if none of the CLSi_ATOM_CHx_CM0.CM0/CLSi_ATOM_CHx_CM1.CM1 registers contain valid data.

SOMB controlled over configuration interface

Writing to one of the CLSi_ATOM_CHx_CM0.CM0/CLSi_ATOM_CHx_CM1.CM1 registers automatically sets CLSi_ATOM_CHx_STAT.DV = 1 to validate the new compare value. A comparison depending on value CLSi_ATOM_CHx_STAT.ACBI is started immediately.

***Note**: It is strongly recommended to update the bit fields CLSi_ATOM_CHx_CTRL_SOMB.ACB10 and CLSi_ATOM_CHx_CTRL_SOMB.ACB42 before writing to the registers CLSi_ATOM_CHx_CM0.CM0/ CLSi_ATOM_CHx_CM1.CM1 and CLSi_ATOM_CHx_SR0.SR0/CLSi_ATOM_CHx_SR1.SR1, as only the bits CLSi_ATOM_CHx_CTRL_SOMB.ACB10 and CLSi_ATOM_CHx_CTRL_SOMB.ACB42 can be written and these bit fields serve as shadow registers for the working register CLSi_ATOM_CHx_STAT.ACBI.*

***Note**: It is mandatory to always write both bit fields CLSi_ATOM_CHx_SR0.SR0 and CLSi_ATOM_CHx_SR1.SR1 regardless of the compare strategy.*

The compare strategy is controlled by the value stored in bit field CLSi_ATOM_CHx_STAT.ACBI. This bit field can only be updated with the value of bit fields CLSi_ATOM_CHx_CTRL_SOMB.ACB10 and CLSi_ATOM_CHx_CTRL_SOMB.ACB42.

The update of bit field CLSi_ATOM_CHx_STAT.ACBI can be triggered by a forced update or the normal update mechanism with CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)**=10_B.

A force update updates the CLSi_ATOM_CHx_CM0.CM0 / CLSi_ATOM_CHx_CM1.CM1 register with the content of CLSi_ATOM_CHx_SR0.SR0 / CLSi_ATOM_CHx_SR1.SR1 register and the CLSi_ATOM_CHx_STAT.ACBI bit field with the content of bit field CLSi_ATOM_CHx_CTRL_SOMB.ACB10 and CLSi_ATOM_CHx_CTRL_SOMB.ACB42.

Writing to one of the CLSi_ATOM_CHx_SR0.SR0 / CLSi_ATOM_CHx_SR1.SR1 registers and triggering a forced update event can update CLSi_ATOM_CHx_CM0.CM0 / CLSi_ATOM_CHx_CM1.CM1 register with the value of CLSi_ATOM_CHx_SR0.SR0 / CLSi_ATOM_CHx_SR1.SR1 register and update CLSi_ATOM_CHx_STAT.ACBI bit field with the content of bits CLSi_ATOM_CHx_CTRL_SOMB.ACB10 and CLSi_ATOM_CHx_CTRL_SOMB.ACB42. Then a new comparison will be started.

When a previous comparison is finished (CLSi_ATOM_CHx_STAT.DV bit is reset), writing to one of the CLSi_ATOM_CHx_SR0.SR0/CLSi_ATOM_CHx_SR1.SR1 registers will update CLSi_ATOM_CHx_CM0.CM0, CLSi_ATOM_CHx_CM1.CM1 and CLSi_ATOM_CHx_STAT.ACBI while CLSi_ATOM_AGC_GLB_CTRL.UPEN_CTRLk (k=0-7) **(k=x)**= 10_B and starts comparison with these updated new values.

44.3.1.8.4 ATOM software reset of channels

Each channel x is assigned a unique bit x in the configuration register CLSi_ATOM_AGC_GLB_CTRL for software reset of the **ATOM[i]** channel x.

Writing the value 1_B to the bit field CLSi_ATOM_AGC_GLB_CTRL.RST_CHk (k=0-7) **(k=x)** via the configuration interface, will immediately reset the content of the following channel x registers to the initial hardware reset state.

- CLSi_ATOM_CHx_CTRL
- CLSi_ATOM_CHx_CTRL_SR
- CLSi_ATOM_CHx_CTRL2
- CLSi_ATOM_CHx_CN0.CN0
- CLSi_ATOM_CHx_CM0.CM0
- CLSi_ATOM_CHx_CM1.CM1
- CLSi_ATOM_CHx_SR0.SR0
- CLSi_ATOM_CHx_SR1.SR1
- CLSi_ATOM_CHx_STAT
- CLSi_ATOM_CHx_IRQ_NOTIFY
- CLSi_ATOM_CHx_IRQ_EN
- CLSi_ATOM_CHx_IRQ_MODE
- internal signals inside the **ATOM[i]** channel [x]:

Atomic reset of multiple channels is possible by writing a 1 on each associated bit. For example, writing $0F_H$ to register CLSi_ATOM_AGC_GLB_CTRL **(i=0)** will reset the ATOM0 channel x (x∈{0, 1, 2, 3}).

44.3.1.8.5 eGTM ATOM Configuration Registers Description

Sub-chapter ATOM Configuration Registers Description

Table 2236

Register Shortname	Description
CLSi_ATOM_AGC_GLB_CTRL	ATOM[i] AGC global control register (i=0-2)
CLSi_ATOM_AGC_ENDIS_CTRL	ATOM[i] AGC enable/disable control register (i=0-2)
CLSi_ATOM_AGC_ENDIS_STAT	ATOM[i] AGC enable/disable status register (i=0-2)
CLSi_ATOM_AGC_ACT_TB	ATOM[i] AGC action time base register (i=0-2)
CLSi_ATOM_AGC_OUTEN_CTRL	ATOM[i] AGC output enable control register (i=0-2)
CLSi_ATOM_AGC_OUTEN_STAT	ATOM[i] AGC output enable status register (i=0-2)
CLSi_ATOM_AGC_FUPD_CTRL	ATOM[i] AGC force update control register (i=0-2)
CLSi_ATOM_AGC_INT_TRIG	ATOM[i] AGC internal trigger control register (i=0-2)
CLSi_ATOM_CHx_CTRL	ATOM[i] channel [x] control register (x=0-7;i=0-2) (i=0-2;x=0-7)
CLSi_ATOM_CHx_CTRL_SOMI	ATOM[i] channel [x] control register (x=0-7;i=0-2) (i=0-2;x=0-7)
CLSi_ATOM_CHx_CTRL_SOMC	ATOM[i] channel [x] control register (x=0-7;i=0-2) (i=0-2;x=0-7)
CLSi_ATOM_CHx_CTRL_SOMP	ATOM[i] channel [x] control register (x=0-7;i=0-2) (i=0-2;x=0-7)
CLSi_ATOM_CHx_CTRL_SOMS	ATOM[i] channel [x] control register (x=0-7;i=0-2) (i=0-2;x=0-7)
CLSi_ATOM_CHx_CTRL_SOMB	ATOM[i] channel [x] control register (x=0-7;i=0-2) (i=0-2;x=0-7)
CLSi_ATOM_CHx_CTRL_SR	ATOM[i] channel [x] control shadow register (x=0-7;i=0-2)
CLSi_ATOM_CHx_CTRL2	ATOM[i] channel [x] control2 register (x=0-7;i=0-2)
CLSi_ATOM_CHx_STAT	ATOM[i] channel [x] status register (x=0-7;i=0-2)
CLSi_ATOM_CHx_CN0	ATOM[i] channel [x] CCU0 counter register (x=0-7;i=0-2)
CLSi_ATOM_CHx_CM0	ATOM[i] channel [x] CCU0 compare register (x=0-7;i=0-2)
CLSi_ATOM_CHx_SR0	ATOM[i] channel [x] CCU0 compare shadow register (x=0-7;i=0-2)
CLSi_ATOM_CHx_CM1	ATOM[i] channel [x] CCU1 compare register (x=0-7;i=0-2)
CLSi_ATOM_CHx_SR1	ATOM[i] channel [x] CCU1 compare shadow register (x=0-7;i=0-2)

(table continues...)

Table 2236 (continued)

Register Shortname	Description
CLSi_ATOM_CHx_IRQ_NOTIFY	ATOM[i] channel [x] interrupt notification register (x=0-7;i=0-2)
CLSi_ATOM_CHx_IRQ_EN	ATOM[i] channel [x] interrupt enable register (x=0-7;i=0-2)
CLSi_ATOM_CHx_IRQ_FORCINT	ATOM[i] channel [x] software interrupt generation (x=0-7;i=0-2)
CLSi_ATOM_CHx_IRQ_MODE	ATOM[i] channel [x] interrupt mode configuration register (x=0-7;i=0-2)

44.3.1.8.6 ATOM signal description

Table 2237 ATOM reset

Name	Description
ATOM[j]_RESET_CH[x]	**ATOM** instance [j] channel [x] reset active signal

Table 2238 ATOM Interrupt Signals

Name	Description
ATOM_CCU0TC[x]_IRQ	CCU0 Trigger condition interrupt for channel x. Internal interrupt signal when compare event occurs in CCU0 unit.
ATOM_CCU1TC[x]_IRQ	CCU1 Trigger condition interrupt for channel x. Internal interrupt signal when compare event occurs in CCU0 unit.

Table 2239 ATOM Signal Group

Name	Description
CAP	signaling a compare match event for capture
ATOM_ENDIS	A bundle of channel enable signals controlled by AGC unit
ATOM_CTRL_TRIG	trigger signal to update the AGC registers ATOM[i]_agc_OUTEN_STAT, CLSi_ATOM_AGC_ENDIS_STAT and to activate ATOM_FUPD signals
EXT_TRIGIN_S	synchronized EXT_TRIGIN signal to selected **CMU** clock resolution
ATOM_FUPD	A bundle of channel force update event signals controlled by AGC unit
ATOM_RSTCN0_CH	A bundle of channel force update event signals controlled AGC unit
ATOM_OUTEN	output enable signal from AGC by unit
ATOM_TRIG_CCU0	trigger signal for CCU0 compare match
ATOM_TRIG_CCU1	trigger signal for CCU1 compare match

(table continues...)

Table 2239 (continued) ATOM Signal Group

Name	Description
ATOM_UPEN	A bundle of channel update enable signals controlled by AGC unit
SEL_CMU_CLKEN	The selected **CMU** clock enable signal
ATOM_EXT_HRES	Not internal signal from **eGTM** or **ATOM**. A signal to explain how the external circuit can generate a signal for each channel x that consists of edges from ATOM_OUT *[x:x]* with delay of ATOM_OUT_HRES[x].
ATOM_CH_TRIGIN	Trigger input signal for each channel x. It comes from the preceding channel x-1 or channel 7 of the preceding instance.
ATOM_CH_TRIGOUT	Trigger output signal for each channel x. It is connected to the trigger input signal of the next channel x+1 or channel 0 of the succeeding instance.
ATOM_CH_HRES_IN[x]	HRES trigger input signal for each channel x. It is 5 bits value. Together with ATOM_CH_TRIGIN *[x:x]*, it comes from the preceding channel x-1 or channel 7 of the preceding instance.
ATOM_CH_HRES_OUT[x]	HRES trigout signal for each channel x. It is 5 bits value. Together with ATOM_CH_TRIGOUT *[x:x]*, it is connected with the HRES trigger input signal of the next channel x+1 or channel 0 of the next instance.
ATOM[i]_CH[x]_HRES_PERIOD	HRES value of **ATOM** i channel x that is calculated with regards to CLSi_ATOM_CHx_CM0**.**CM0.
ATOM[i]_CH[x]_HRES_PULSEWIDTH	HRES value of **ATOM** i channel x that is calculated with regards to CLSi_ATOM_CHx_CM1**.**CM1.

44.3.1.8.7 ATOM port description

Table 2240 ATOM signal interface

Name	Description
EXT_TRIGIN	EXT_TRIGIN[7:0] of all channels of **ATOM** instance i are coming from TIM_EXT_CAPTURE *[7:0]* signal from **TIM** instance i
ATOM_TRIGIN	**ATOM** trigger chain input of **ATOM** instance
ATOM_TRIGOUT	**ATOM** trigger chain output of **ATOM** instance
ATOM_TRIGOUT_DEL	**ATOM** trigger chain output delayed by 1 cluster clock; will be used only in **ATOM** [0] instance as ATOM_TRIGIN
ATOM_OUT	Output signal ATOM_OUT
ATOM_OUT_T	Output signal ATOM_OUT_T

Table 2241 ATOM interrupt interface

Name	Description
ATOM_IRQ	**ATOM IRQ** line signals
ATOM_IRQ_CLR	**ATOM IRQ** clear signal, hardware clear of CLSi_ATOM_CHx_IRQ_NOTIFY register
ATOM_IRQ_OCC	**ATOM IRQ** occurred signal, corresponds to CLSi_ATOM_CHx_IRQ_NOTIFY register

Table 2242 ATOM signal HRES interface

Name	Description
ATOM_OUT_HRES[x]	ATOM_OUT high-resolution output signal for channel x
ATOM_OUT_T_HRES[x]	ATOM_OUT_T high-resolution output signal channel x
ATOM_HRES_IN	**ATOM** high-resolution trigger chain input; will be driven by previous **ATOM** instance i-1
ATOM_HRES_OUT	**ATOM** high-resolution trigger chain output; will be used by following **ATOM** instance i+1
ATOM_HRES_OUT_DEL	**ATOM** high-resolution trigger chain output delayed by 1 cluster clock; will be used only in **ATOM** instance 0 as ATOM_HRES_IN

44.3.1.9 Dead-time module (DTM)

44.3.1.9.1 Overview

The following figure gives an overview of the structure of the Dead-time Module (**DTM**).

Register name indices used within this module:

- i:={0, 1,..., NCCM-1} instance index of cluster
- j:={0, 1,..., NCCM-1} instance index in case this index refers to a cluster/module with j!=i
- d:={0, 1,..., 5} index for a dedicated **DTM** ((d∈{0, 1, 2, 3}): **DTM** after **TOM**; (d∈{4, 5}): **DTM** after **ATOM**
- x:={0, 1,..., 3} channel index in a **DTM** instance
- y:={0, 1,..., N-1} with N:={NTOM, NATOM} channel index of another module e.g. **TOM**, **ATOM**, **TIM**
- k:={0, 1} channel index with a special meaning e.g. limited value subset

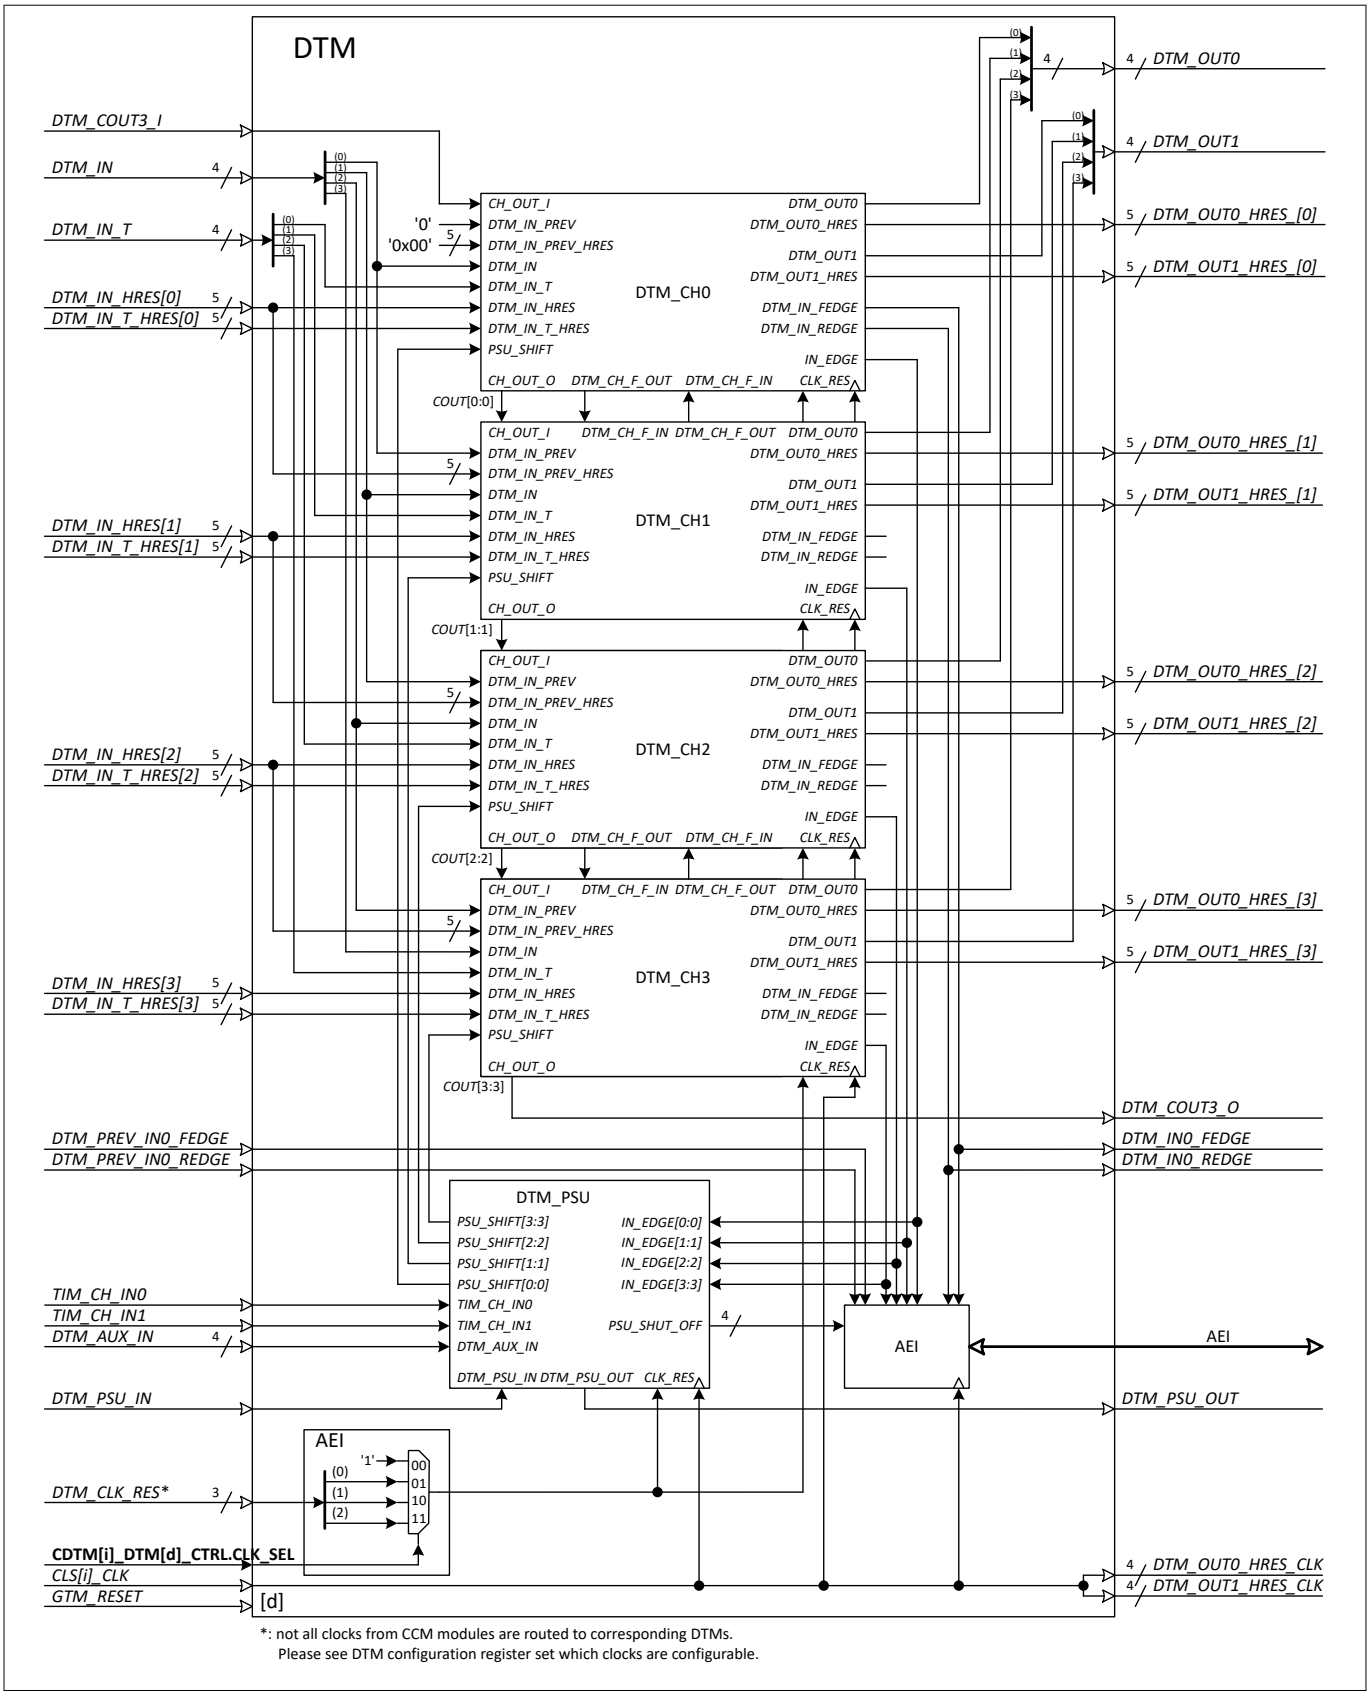

Figure 1100 DTM overview

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

The **DTM** module can enhance the functions of modules **TOM**, **ATOM** by modifying their output signals.

In general, the **DTM** instances are placed behind **TOM**, **ATOM**, i.e., the outputs TOM_OUT[y:y] and TOM_OUT_T[y:y], ATOM_OUT[y:y] and ATOM_OUT_T[y:y] are each routed to the **DTM** instance inputs DTM_IN and DTM_IN_T.

Four **DTM** instances behind a **TOM** instance i, two **DTM** instances behind an **ATOM** instance i are grouped together in a Cluster **DTM** hierarchy called CDTM[i].

The connections between **DTM** and the modules **TOM**, **ATOM** are depicted in Figure 1101.

Attention**: **The initial configuration of a DTM channel or any asynchronous channel configuration to the running application is only allowed, if the corresponding TOM, ATOM channel is disabled. A configuration of DTM channel realized from the shadow registers synchronous to the running application can be executed without disabling the interfaced TOM, ATOM channels.

The main function of the **DTM** is to derive the individual inverse signal (DTM_OUT1[3:0]) for each input DTM_IN[3:0] and to apply an edge-specific delay between the edge of the original signal and the derived inverted signal (i.e., the dead-time). This function is mainly used for controlling of half bridges.

A second function provided by **DTM** is to set the outputs of one channel to the value of the preceding channel if requested by a trigger on input TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN[0:0]. This feature allows a phase shift on one PWM signal to the phase of the preceding PWM signal up to the next edge on this channel.

The third function provided by **DTM** is to (N)**AND**/(N)**OR**/X(N)**OR** combine the input DTM_IN[x:x] signal of one **DTM** channel with the signal on inputs TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN[0:0] (selected inside PSU and assigned to one of the signals PSU_SHIFT[x:x]) or with the combinational output (signal COUT[x-1:x-1]) of the preceding channel.

As a result, COUT[1:1] will be the combined signal of DTM_IN[0:0] and TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN[0:0] and the signal DTM_IN[1:1]. For COUT[2:2], this chain can be combined again with signal DTM_IN[2:2].

For COUT[3:3], this chain can be combined again with signal DTM_IN[3:3].

- The outputs of each channel may be swapped individually to provide the function of combining signals on each output of a channel.
- For channel 0 the function is controlled by CLSi_CDTM_DTMd_CH_CTRL1.SWAP_0.
- For channel 1 the function is controlled by CLSi_CDTM_DTMd_CH_CTRL1.SWAP_1.
- For channel 2 the function is controlled by CLSi_CDTM_DTMd_CH_CTRL1.SWAP_2.
- For channel 3 the function is controlled by CLSi_CDTM_DTMd_CH_CTRL1.SWAP_3.

The 4th function is the high-resolution PWM support. For each of the two input signals of a **DTM** channel, a high-resolution value is given by a corresponding input signal. Here, a configurable value is added to the high-resolution input value.

The high-resolution mode in **DTM** is only supported for standard dead-time mode and for phase shift mode, where standard dead-time is used.

Depending on the device configuration, not every **DTM** instance is available. E.g. a device may only have one **DTM** connected to the first four channels of **ATOM**. In this case, the other four channels (channel 4 to channel 7) are connected over a buffer stage to **eGTM** outputs.

For detailed information, which **DTM** instance is available, refer to the corresponding device-specific documentations.

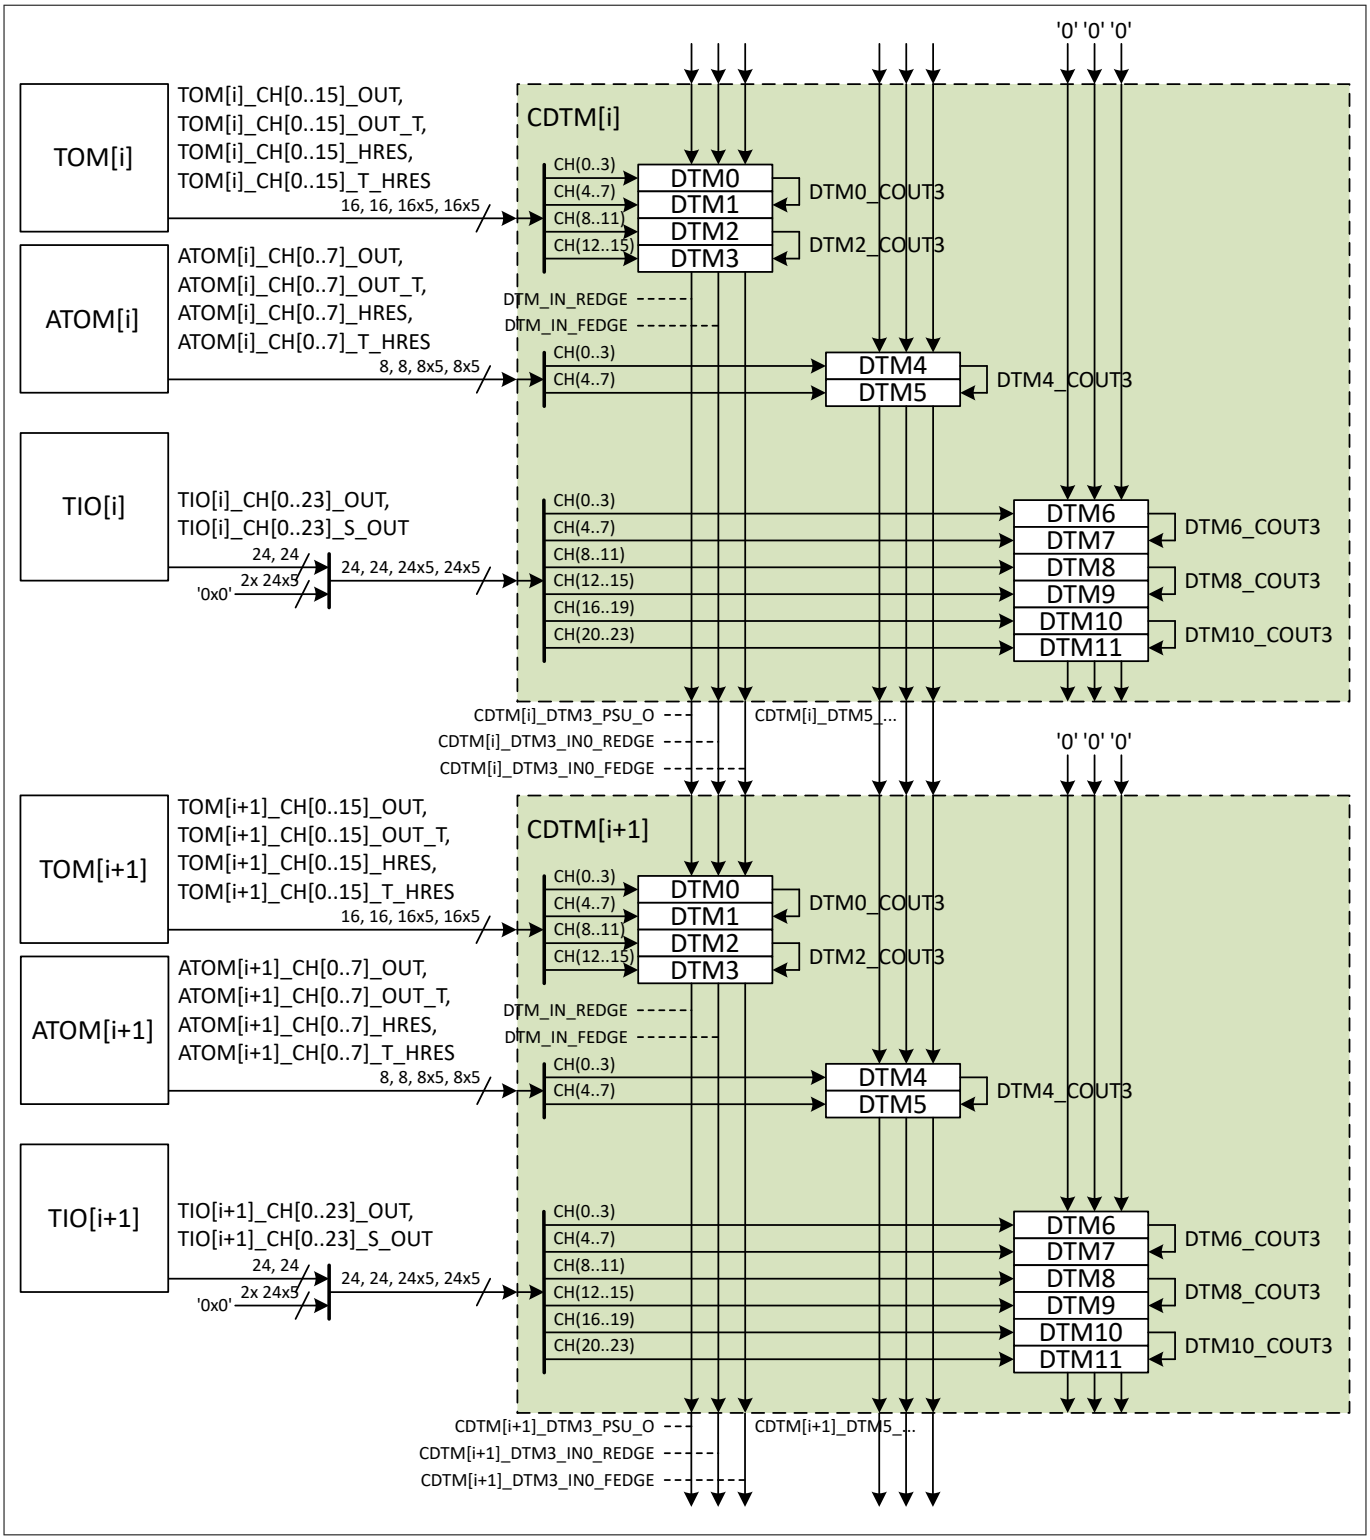

Figure 1101 Connections of TOM, ATOM to DTM Inputs DTM_IN *[x:x]*/DTM_IN_T *[x:x]*

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

Additionally, the **DTM** instances have inputs TIM_CH_IN0, TIM_CH_IN1 which are driven by **TIM** output signals F_OUT of instances i and channel y.

Two configurations of **TIM** to **DTM** connections are possible depending on the **DTM** channel-specific configuration bit CLSi_CDTM_DTMd_PS_CTRL.TIM_SEL.

In case of CLSi_CDTM_DTMd_PS_CTRL.TIM_SEL=0, the connected **TIM** input may not be of the same cluster as the **DTM**.

In case of CLSi_CDTM_DTMd_PS_CTRL.TIM_SEL=1, the **TIM** input is of the same cluster as the **DTM**.

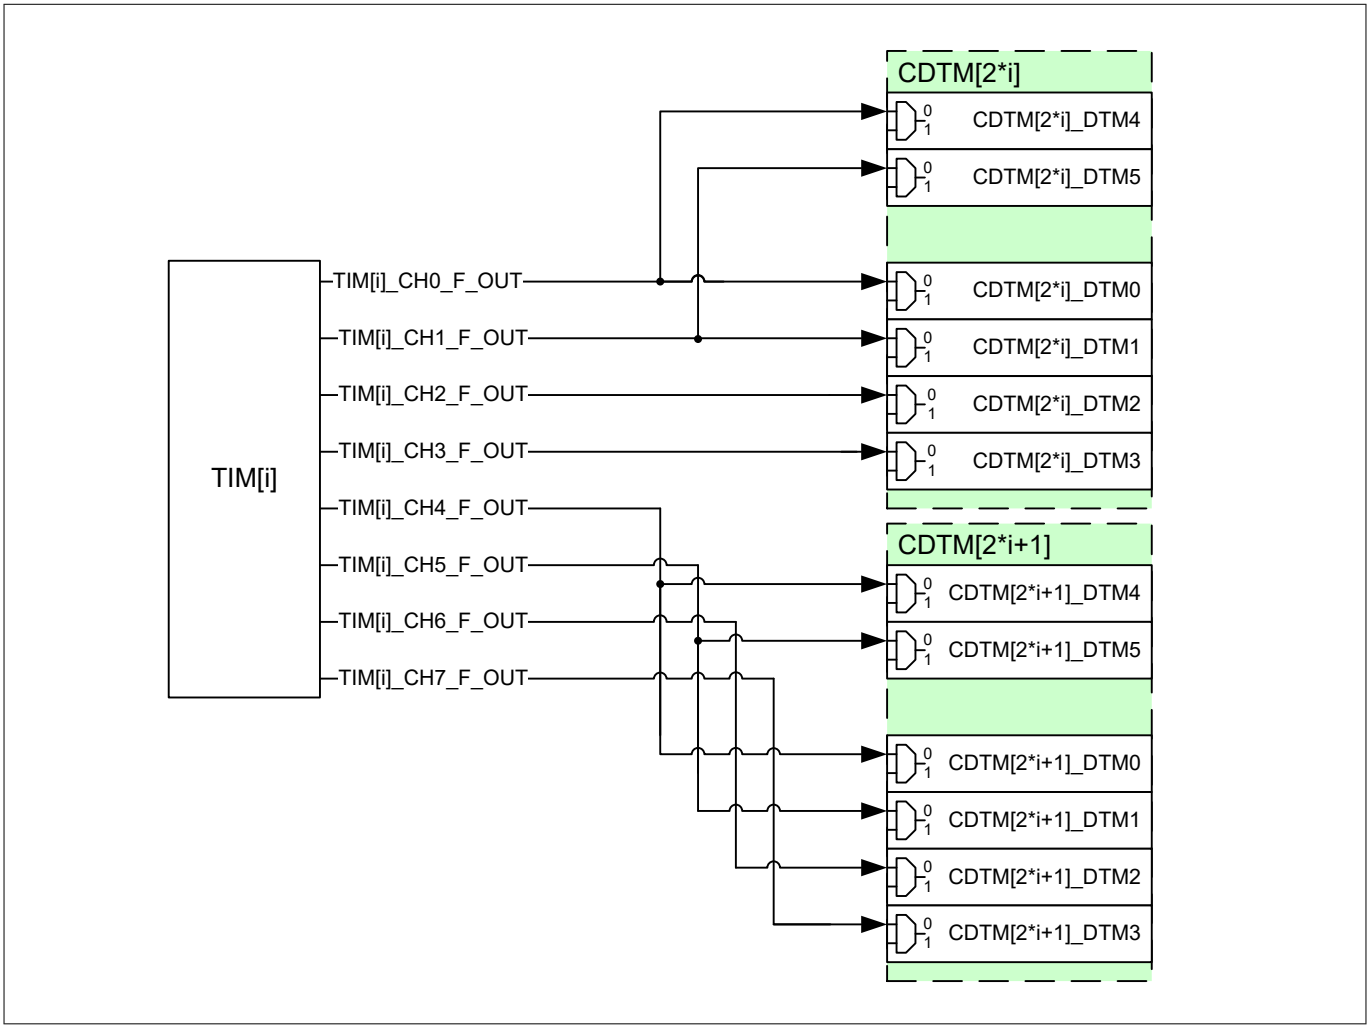

Figure 1102 Connections of TIM to DTM inputs TIM_CH_IN0/TIM_CH_IN1 for CLSi_CDTM_DTMd_PS_CTRL.TIM_SEL=0

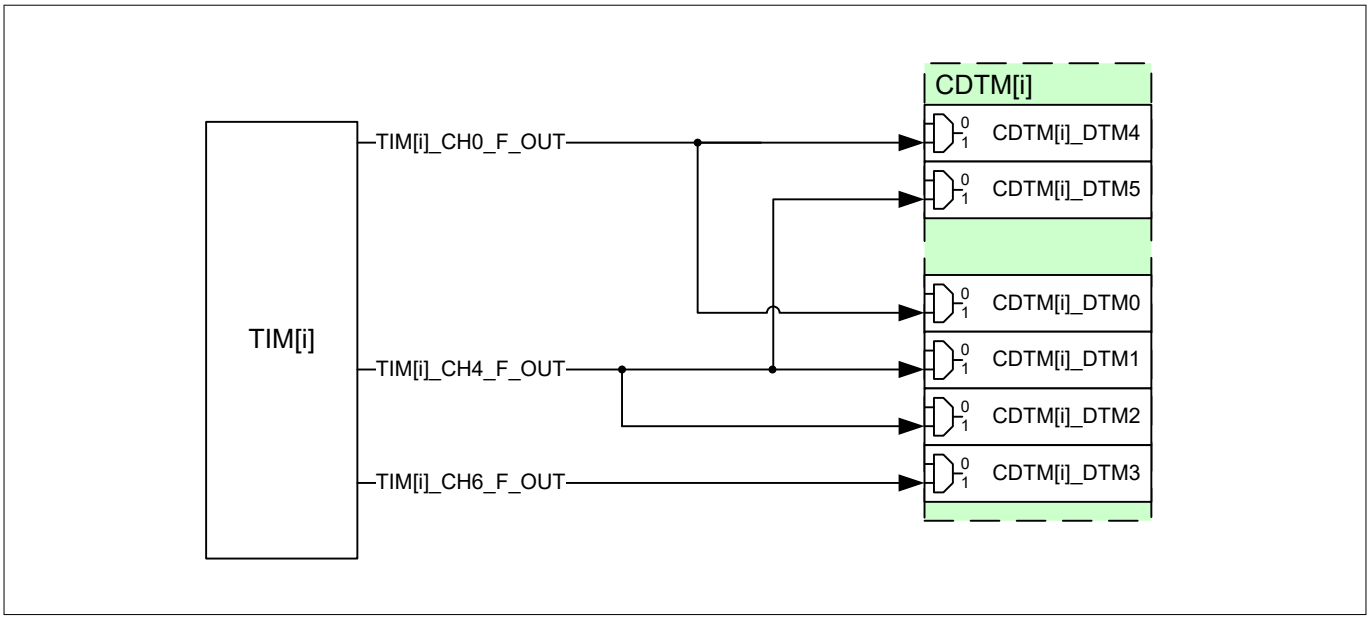

Figure 1103 Connections of TIM to DTM inputs TIM_CH_IN0/TIM_CH_IN1 for CLSi_CDTM_DTMd_PS_CTRL.TIM_SEL=1

***Note**: The multiplexer shown in Figure 1102 and Figure 1103 and driven by CLSi_CDTM_DTMd_PS_CTRL.TIM_SEL is located in the block DTM_PSU.*

There are also connections between **DTM** instances inside one cluster.

For each pair of **DTM** instance 2d and instance 2d+1 the combinatorial output COUT[3:3] (COUT[3:3] routed to DTM_COUT3_O) of **DTM** instance 2d channel 3 is connected to **DTM** instance 2d+1 channel 0 at signal DTM_COUT3_I .

With this, a combinatorial chain over two neighbored **DTM** instances can be configured.

If one of the two neighbored **DTM** instances is not available (i.e. it is an empty instance) the inputs used for connections between two neighbored **DTM** instances are hard wired to 0.

These connections are shown in Figure 1100 and Figure 1101.

- For channel 0 of **DTM** instance 2d input signal COUT[x-1:x-1] is unused and CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_0 is defined as 0.
- For channel 0 of **DTM** instance 2d input signal COUT[x-1:x-1] is unused and CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_1 is defined as 0.
- For channel 0 of **DTM** instance 2d input signal COUT[x-1:x-1] is unused and CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_2 is defined as 0.
- For channel 0 of **DTM** instance 2d input signal COUT[x-1:x-1] is unused and CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_3 is defined as 0.

An additional link between **DTM** instances behind an **ATOM** is a forwarding of output DTM_PSU_OUT of **DTM** instance d to the input DTM_PSU_IN of next available instance d+1 behind an **ATOM**.

The same link is available between all available **DTM** instances behind a **TOM**.

For unavailable **DTM[d]** instances (i.e. the instance **DTM[d]** is called empty) the signal DTM_PSU_OUT of **DTM** instance d-1 is passed through empty instance **DTM[d]** to DTM_PSU_IN of **DTM** instance d+1, DTM_IN0_FEDGE and DTM_IN0_REDGE of **DTM** instance d-1 are passed through **DTM[d]** to DTM_PREV_IN0_FEDGE and DTM_PREV_IN0_REDGE of **DTM** instance d+1.

44.3.1.9.2 DTM channel

The following figure depicts the circuit of a **DTM** channel.

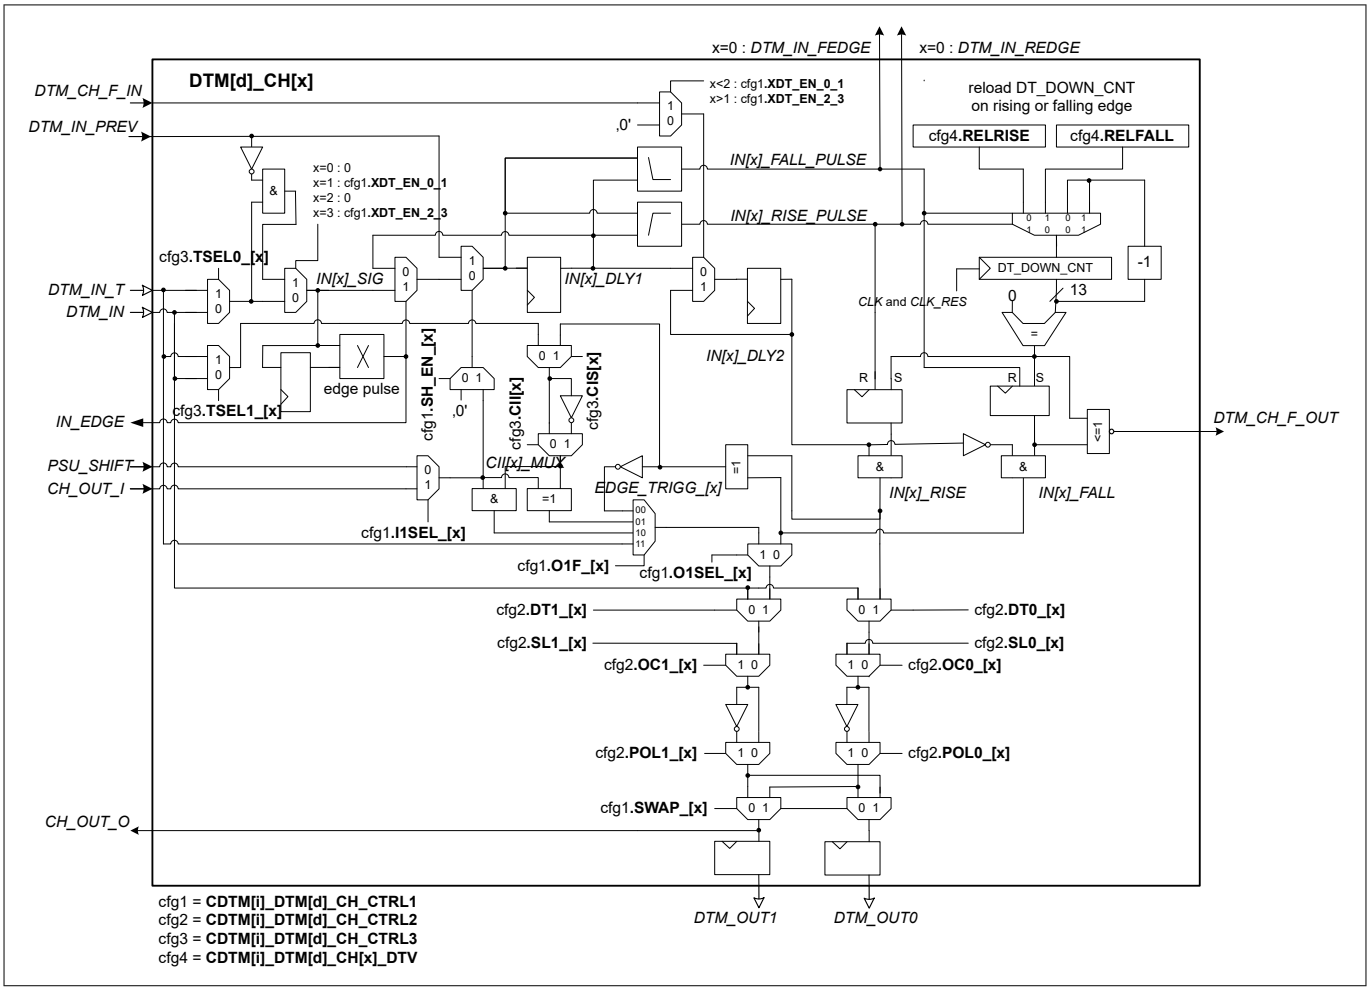

Figure 1104 DTM channel overview

The main feature of each channel is to derive the inverse signal out of the input signal DTM_IN[x:x], apply an edge dependent delay to the two resulting signal paths and provide these signals at the outputs DTM_OUT0[x:x] and DTM_OUT1[x:x].

There are two possibilities to apply dead-time on **eGTM** output signals.

One is to use one **DTM** channel per **TOM**/**ATOM** channel and generate inside the **DTM** the second inverse signal. This is called the standard dead-time generation.

The second way is to generate two signals out of two **TOM**/**ATOM** channel and to apply inside the **DTM** only the dead-time by using two cross-linked **DTM** channels. This is called the cross dead-time generation.

Standard dead-time generation

The dead-time can be configured for each edge individually. The bit field CLSi_CDTM_DTMd_CH_DTVx.RELRISE contains the reload value for the counter and defines the delay for rising edges in multiples of selected clock ticks.

The bit field CLSi_CDTM_DTMd_CH_DTVx.RELFALL contains the reload value for the counter and defines the delay for falling edges in multiples of selected clock ticks.

***Note**: If the selected clock ticks are modified by writing CLSi_CDTM_DTMd_CTRL.CLK_SEL during a running application, the configured times (e.g. DT_DOWN_CNT) may differ, because the counters can run once partly with the old and the new clock ticks. It is recommended not to reprogram CLSi_CDTM_DTMd_CTRL.CLK_SEL during operation.*

The counter is reloaded with the value of CLSi_CDTM_DTMd_CH_DTVx.RELRISE on a rising edge and reloaded with the value of CLSi_CDTM_DTMd_CH_DTVx.RELFALL on a falling edge on input DTM_IN[x:x] (or DTM_IN_PREV in case of shift enable CLSi_CDTM_DTMd_CH_CTRL1.SH_EN_1, CLSi_CDTM_DTMd_CH_CTRL1.SH_EN_2, CLSi_CDTM_DTMd_CH_CTRL1.SH_EN_3).(x=1)

The signal flow for function of standard dead-time signal generation is depicted in Figure 1105.

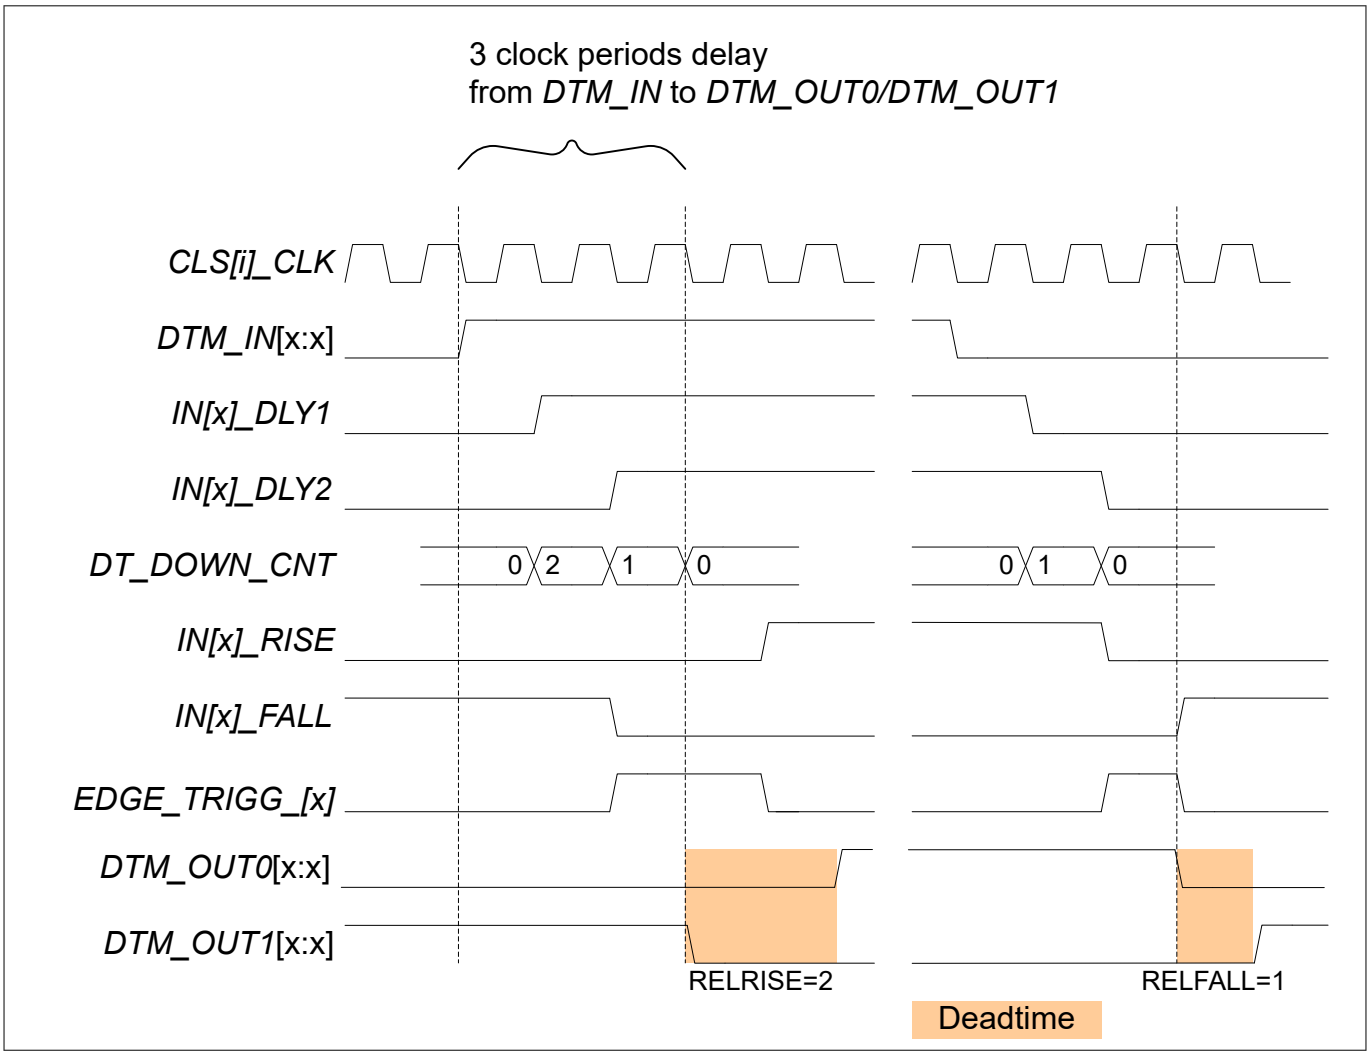

Figure 1105 Wave signals for function of dead-time generation

***Note**: The figure above shows the timing for CLSi_CDTM_DTMd_CTRL.CLK_SEL=00_B. If another clock resolution is configured, be aware that only the counter DT_DOWN_CNT runs with the reduced clock resolution.*

- The delay from the input signal DTM_IN[0:0] to the output signals DTM_OUT0[0:0] and DTM_OUT1[0:0] is three system clock periods, if CLSi_CDTM_DTMd_CH_CTRL2.DT0_0=1 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_0=1.
- The delay from the input signal DTM_IN[1:1] to the output signals DTM_OUT0[1:1] and DTM_OUT1[1:1] is three system clock periods, if CLSi_CDTM_DTMd_CH_CTRL2.DT0_1=1 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_1=1.

- The delay from the input signal DTM_IN[2:2] to the output signals DTM_OUT0[2:2] and DTM_OUT1[2:2] is three system clock periods, if CLSi_CDTM_DTMd_CH_CTRL2.DT0_2=1 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_2=1.
- The delay from the input signal DTM_IN[3:3] to the output signals DTM_OUT0[3:3] and DTM_OUT1[3:3] is three system clock periods, if CLSi_CDTM_DTMd_CH_CTRL2.DT0_3=1 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_3=1.
- The delay from the input signal DTM_IN[0:0] to the output signals DTM_OUT0[0:0] and DTM_OUT1[0:0] is one system clock period if CLSi_CDTM_DTMd_CH_CTRL2.DT0_0=0 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_0=0.
- The delay from the input signal DTM_IN[1:1] to the output signals DTM_OUT0[1:1] and DTM_OUT1[1:1] is one system clock period if CLSi_CDTM_DTMd_CH_CTRL2.DT0_1=0 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_1=0.
- The delay from the input signal DTM_IN[2:2] to the output signals DTM_OUT0[2:2] and DTM_OUT1[2:2] is one system clock period if CLSi_CDTM_DTMd_CH_CTRL2.DT0_2=0 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_2=0.
- The delay from the input signal DTM_IN[3:3] to the output signals DTM_OUT0[3:3] and DTM_OUT1[3:3] is one system clock period if CLSi_CDTM_DTMd_CH_CTRL2.DT0_3=0 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_3=0.
- The delay from the input signal DTM_IN_T[0:0] to the output signals DTM_OUT0[0:0] and DTM_OUT1[0:0] is three system clock periods, in case CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_0=0.
- The delay from the input signal DTM_IN_T[1:1] to the output signals DTM_OUT0[1:1] and DTM_OUT1[1:1] is three system clock periods, in case CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_1=0.
- The delay from the input signal DTM_IN_T[2:2] to the output signals DTM_OUT0[2:2] and DTM_OUT1[2:2] is three system clock periods, in case CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_2=0.
- The delay from the input signal DTM_IN_T[3:3] to the output signals DTM_OUT0[3:3] and DTM_OUT1[3:3] is three system clock periods, in case CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_3=0.
- The delay from the input signal DTM_IN_T[0:0] to the output signals DTM_OUT0[0:0] and DTM_OUT1[0:0] is one system clock period in case of CLSi_CDTM_DTMd_CH_CTRL1.O1F_0=11_B and CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_0=1.
- The delay from the input signal DTM_IN_T[1:1] to the output signals DTM_OUT0[1:1] and DTM_OUT1[1:1] is one system clock period in case of CLSi_CDTM_DTMd_CH_CTRL1.O1F_1=11_B and CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_1=1.
- The delay from the input signal DTM_IN_T[2:2] to the output signals DTM_OUT0[2:2] and DTM_OUT1[2:2] is one system clock period in case of CLSi_CDTM_DTMd_CH_CTRL1.O1F_2=11_B and CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_2=1.
- The delay from the input signal DTM_IN_T[3:3] to the output signals DTM_OUT0[3:3] and DTM_OUT1[3:3] is one system clock period in case of CLSi_CDTM_DTMd_CH_CTRL1.O1F_3=11_B and CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_3=1.

For CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_0=1 and CLSi_CDTM_DTMd_CH_CTRL1.O1F_0!=11_B there are further configurations possible which result in different paths from the selected input signal to the output signals causing different delays of 1 or 3 clock periods. For details see Figure 1104.

The reset level of the output signals DTM_OUT0[x:x] connected from **ATOM** module depends on the hardware configuration value ATOM_OUT_RST chosen by the silicon vendor.

The reset level of the output signals DTM_OUT1[x:x] connected from **ATOM** module is defined by the inverse hardware configuration value ATOM_OUT_RST chosen by the silicon vendor.

The reset level of the output signals DTM_OUT0[x:x] connected from **TOM** module is defined by the hardware configuration value TOM_OUT_RST chosen by the silicon vendor.

The reset level of the output signals DTM_OUT1[x:x] connected from **TOM** module is defined by the inverse hardware configuration value TOM_OUT_RST chosen by the silicon vendor.

Cross channel dead-time

A second way to apply a dead-time value on two output signals is the cross channel dead-time.

In opposite to the dead-time described in Standard dead-time generation the cross channel dead-time mode generates a dead-time on the input signals of two neighbored **DTM** channels.

To do this, two neighbored **DTM** input signals (on **DTM** channel (2k) and (2k+1) for (k∈{0, 1})) are cross-linked together in the way that a falling edge on one channel leads to a hold phase of current signal value on the cross-linked channel.

This behavior is achieved by the following:

A falling edge on input signal of **DTM** channel 2k reloads the counter DT_DOWN_CNT with the value of CLSi_CDTM_DTMd_CH_DTVx**.**RELFALL. While this counter is counting down, the output signal of the cross-linked channel (2k+1) keeps its value. If the counter DT_DOWN_CNT has reached 0 again (DT_DOWN_CNT=0), the channel (2k+1) output is released and can follow the value on its input.

The timing of the cross channel dead-time is depicted in Figure 1106.

The following Figure 1106 shows the behavior in case of input edges at DTM_IN[2k:2k] and DTM_IN[2k+1:2k+1] occur at the same point in time.

Then the falling edge is forwarded immediately (with only three clock-cycles delay) and the rising edge is delayed additionally by the number of clock ticks specified by the CLSi_CDTM_DTMd_CH_DTVx**.**RELFALL parameter of the cross-linked channel.

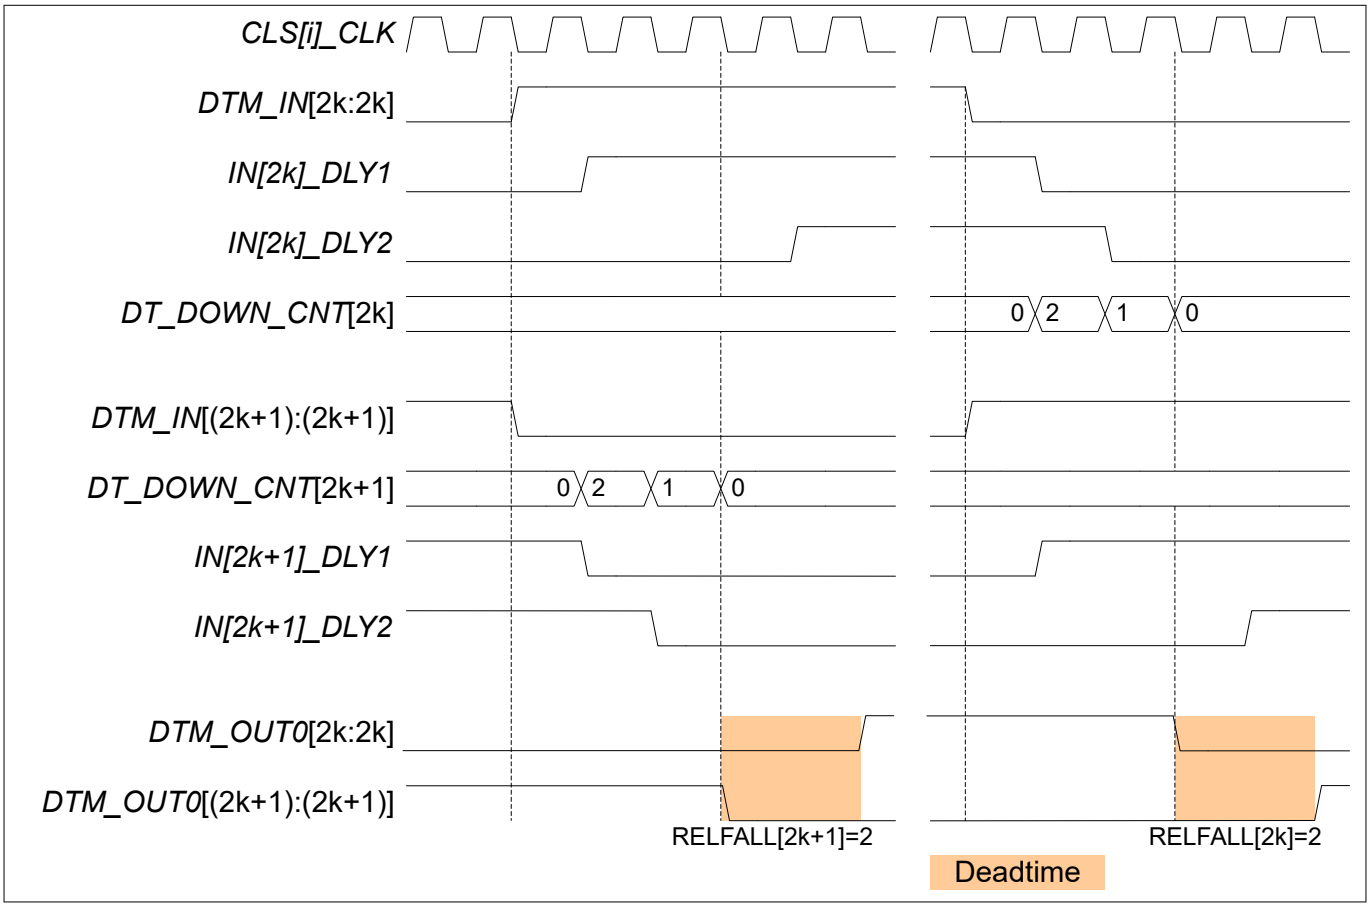

Figure 1106 Cross channel dead-time timing diagram

***Note**: The figure above shows the timing for CLSi_CDTM_DTMd_CTRL.CLK_SEL=00_B. If another clock resolution is configured, be aware that only the counters DT_DOWN_CNT run with the reduced clock resolution.*

In case of level high (i.e. 1) at the **DTM** inputs DTM_IN[2k:2k] and DTM_IN[(2k+1):(2k+1)] at the same point in time, the channel of (2k) has higher priority than the corresponding channel (2k+1). This means that in this case the input DTM_IN[(2k+1):(2k+1)] is forced to level low (i.e. 0) immediately at the channel input.

As a result the **DTM** output of channel DTM_OUT0[(2k+1):(2k+1)] can never be high if the cross-linked channel DTM_OUT0[2k:2k] is high.

Dead-time shadow register

The values CLSi_CDTM_DTMd_CH_DTVx.RELRISE and CLSi_CDTM_DTMd_CH_DTVx.RELFALL define the dead-time as described in the prior chapters. To be able to change these values synchronized to a generated waveform an additional shadow register CLSi_CDTM_DTMd_CH_DTV_SRx is implemented. The register is accessible over the configuration interface.

The register CLSi_CDTM_DTMd_CH_DTV_SRx includes the bit fields CLSi_CDTM_DTMd_CH_DTV_SRx.RELRISE_SR, CLSi_CDTM_DTMd_CH_DTV_SRx.RELFALL_SR which are the shadow bit fields of CLSi_CDTM_DTMd_CH_DTVx.RELRISE and CLSi_CDTM_DTMd_CH_DTVx.RELFALL and further four bits to control the update mechanism.

CLSi_CDTM_DTMd_CH_DTV_SRx.RELRISE_SR is the shadow value for CLSi_CDTM_DTMd_CH_DTVx.RELRISE. CLSi_CDTM_DTMd_CH_DTV_SRx.RELFALL_SR is the shadow value for CLSi_CDTM_DTMd_CH_DTVx.RELFALL.

The update mechanism of CLSi_CDTM_DTMd_CH_DTVx.RELRISE is enabled if CLSi_CDTM_DTMd_CH_DTV_SRx.RELRISE_UPD_EN=1 is set.

The update mechanism of CLSi_CDTM_DTMd_CH_DTVx.RELFALL is enabled if CLSi_CDTM_DTMd_CH_DTV_SRx.RELFALL_UPD_EN=1 is set.

Bit CLSi_CDTM_DTMd_CH_DTV_SRx.RELRISE_UPD_FE0RE1 controls if the falling edge (=0) or the rising edge (=1) of DTM_IN[x:x] triggers the update of CLSi_CDTM_DTMd_CH_DTVx.RELRISE.

Bit CLSi_CDTM_DTMd_CH_DTV_SRx.RELFALL_UPD_FE0RE1 controls if the falling edge (=0) or the rising edge (=1) of DTM_IN[x:x] triggers the update of CLSi_CDTM_DTMd_CH_DTVx.RELFALL.

Figure 1107 shows the extension to Figure 1104.

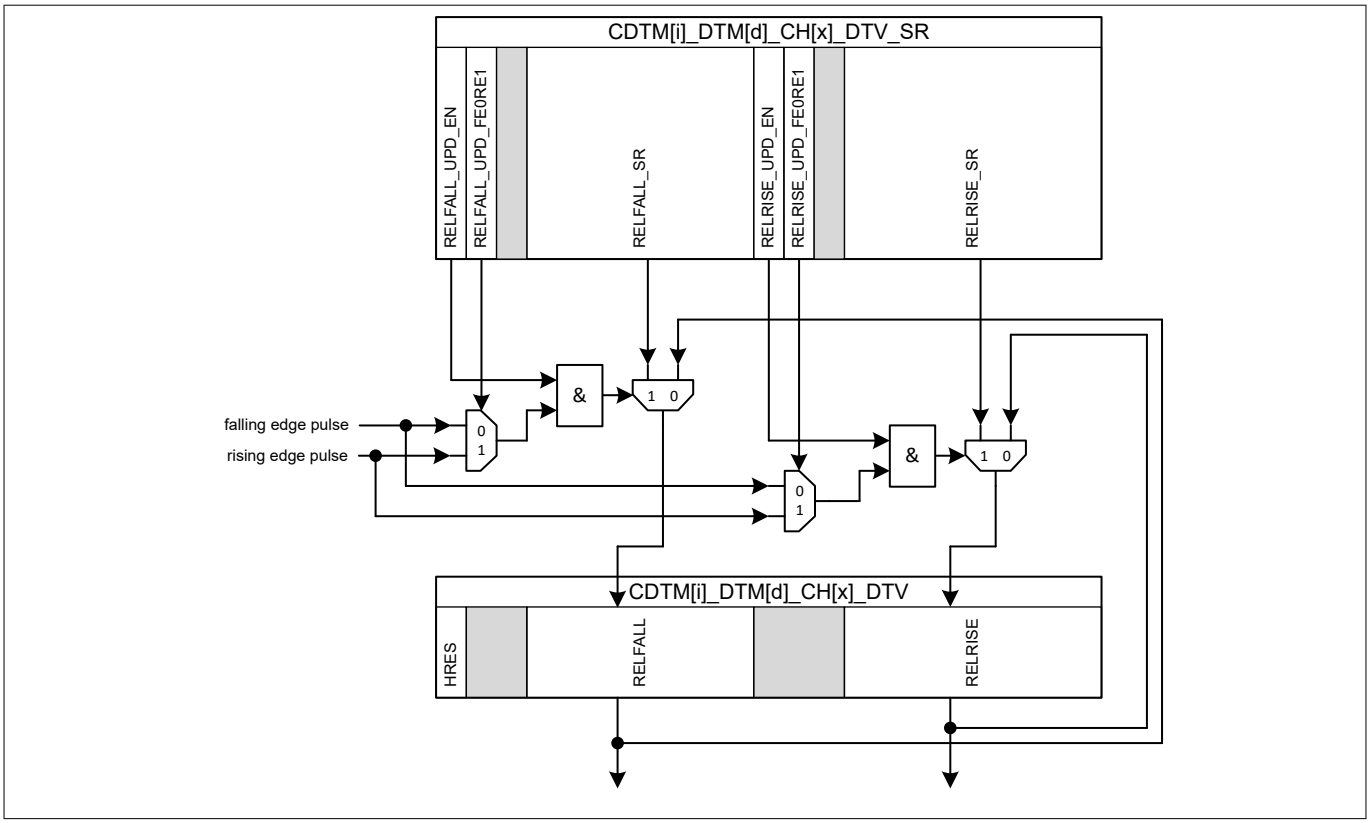

Figure 1107 Dead-time shadow register

44.3.1.9.3 Phase shift unit - overcurrent shutoff feature for full bridge push-pull converters

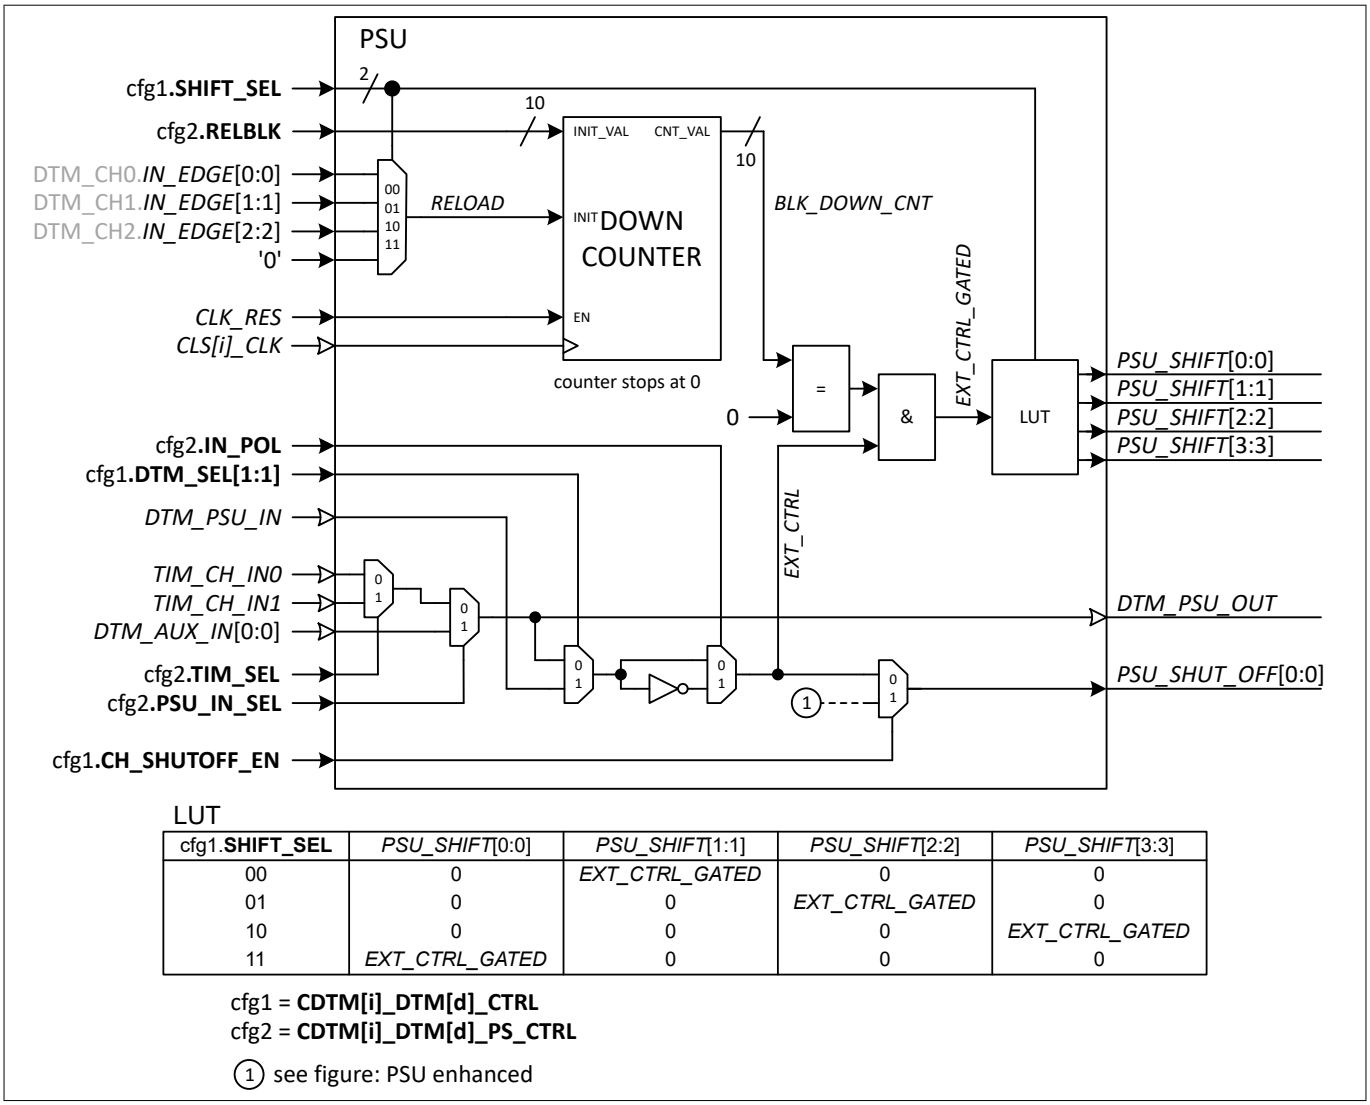
The Phase Shift Unit (PSU) is depicted in the following figure. It supports the second major function of the **DTM** module to copy a PWM signal from a preceding channel to the current channel beginning with the next edge on the preceding channel.

The feature can be used for applications like the phase-shift control of a full bridge push-pull converter. For such an application two consecutive (A)**TOM** channels generate a PWM signal with 50 percent duty cycle. The phase shift between the two PWM signals defines how long two of the four full bridge semiconductors are active and a current flows. An over current detection can trigger the phase shift unit to copy the PWM signal of one **DTM** channel to the other and the semiconductors are switched off directly.

During the development of the function, the following assumptions were made:

- Two consecutive **DTM** channels [x] and [x-1] get e.g. from two (A)**TOM** channels a PWM signal.
- The PWM signals have a phase shift of 180 degrees to each other.
- The configured blanking window value is greater than or equal to the configured dead-time value.
- The configured dead-time is much smaller than the high phase of the PWM signal.
- It was never planned to use this feature in combination with the cross channel dead-time. This is forbidden, because the behavior is undefined.

Figure 1108 shows the corresponding hardware block. The block realizes the blanking window and generates the signal for the **DTM** channel which controls the switch to copy a PWM signal from another **DTM** channel.



LUT

cfg1.**SHIFT_SEL**	*PSU_SHIFT*[0:0]	*PSU_SHIFT*[1:1]	*PSU_SHIFT*[2:2]	*PSU_SHIFT*[3:3]
00	0	*EXT_CTRL_GATED*	0	0
01	0	0	*EXT_CTRL_GATED*	0
10	0	0	0	*EXT_CTRL_GATED*
11	*EXT_CTRL_GATED*	0	0	0

cfg1 = **CDTM[i]_DTM[d]_CTRL**
cfg2 = **CDTM[i]_DTM[d]_PS_CTRL**

(1) see figure: PSU enhanced

Figure 1108 Phase shift unit

The input signals TIM_CH_IN0, TIM_CH_IN1, DTM_AUX_IN and DTM_PSU_IN can be used to signalize e.g. an overcurrent situation and activate the phase shift feature in one of the four **DTM** channels. Over the bit fields CLSi_CDTM_DTMd_PS_CTRL**.**PSU_IN_SEL, CLSi_CDTM_DTMd_PS_CTRL**.**TIM_SEL and CLSi_CDTM_DTMd_CTRL**.**DTM_SEL[1:1] one of the input signals can be selected. Further the polarity of the selected input signal can be inverted by bit field CLSi_CDTM_DTMd_PS_CTRL**.**IN_POL. The resulting signal *EXT_CTRL* is routed over signal *EXT_CTRL_GATED* to the phase shift unit output signal PSU_SHIFT[3:0] which controls the phase shift feature in the four **DTM** channel blocks, see Figure 1104.

Bit field CLSi_CDTM_DTMd_PS_CTRL**.**SHIFT_SEL controls which **DTM** channel is used for the phase shift feature by selecting the corresponding signal IN_EDGE of one of the four **DTM** channels. The bit field controls in the same manner to which **DTM** channel the signal *EXT_CTRL_GATED* is routed. For all other, not selected **DTM** channels signal PSU_SHIFT is set to 0 (see LUT table in Figure 1108.

The counter (DOWN COUNTER) counts down while its value is greater than 0 and if the counter reaches 0 it stops. While the counter is running (BLK_DOWN_CNT>0) signal *EXT_CTRL_GATED* is 0. Thus, the phase shift output signal PSU_SHIFT is 0_H and the phase shift feature can't be activated. If the counter is 0 *EXT_CTRL_GATED==EXT_CTRL* and the phase shift feature can be activated depending on the signal level of the selected input signal TIM_CH_IN0 or TIM_CH_IN1 or DTM_AUX_IN[0:0] or DTM_PSU_IN.

The blanking window usage allows that the phase shift condition (exception condition e.g. overcurrent detected) can be masked for a certain period after an input signal change (e.g. at DTM_IN) has occurred.

The activation of the phase shift feature by signal *EXT_CTRL_GATED*=1 can result in an edge at signal IN[x]_DLY1.

The deactivation of the phase shift feature by signal *EXT_CTRL_GATED*=0 results in an edge on signal IN[x]_DLY1 earliest with a signal change at IN[x]_SIG (see Figure 1104.

If phase shift feature for **DTM** channel 1 is used (CLSi_CDTM_DTMd_PS_CTRL.SHIFT_SEL==00_B signal PSU_SHIFT[1:1] activates (if CLSi_CDTM_DTMd_CH_CTRL1.SH_EN_1=1) the update of the first storage element on channel 1 (i.e. representing IN[x]_DLY1) to the input value DTM_IN_PREV (DTM_IN of channel x-1). If this update leads to an edge, the succeeding part of **DTM** channel derives the inverse signal and applies the corresponding dead-time (i.e. the edge delay) to the output signals of the channel (x=1).

If phase shift feature for **DTM** channel 2 is used (CLSi_CDTM_DTMd_PS_CTRL.SHIFT_SEL==01_B signal PSU_SHIFT[2:2] activates (if CLSi_CDTM_DTMd_CH_CTRL1.SH_EN_2=1) the update of the first storage element on channel 2 (i.e. representing IN[x]_DLY1) to the input value DTM_IN_PREV (DTM_IN of channel x-1). If this update leads to an edge, the succeeding part of **DTM** channel derives the inverse signal and applies the corresponding dead-time (i.e. the edge delay) to the output signals of the channel (x=2).

If phase shift feature for **DTM** channel 3 is used (CLSi_CDTM_DTMd_PS_CTRL.SHIFT_SEL==10_B signal PSU_SHIFT[3:3] activates (if CLSi_CDTM_DTMd_CH_CTRL1.SH_EN_3=1) the update of the first storage element on channel 3 (i.e. representing IN[x]_DLY1) to the input value DTM_IN_PREV (DTM_IN of channel x-1). If this update leads to an edge, the succeeding part of **DTM** channel derives the inverse signal and applies the corresponding dead-time (i.e. the edge delay) to the output signals of the channel (x=3).

For channel x=0 no blanking window feature and no phase shift feature is available.

Further, the exception signal PSU_SHIFT[x:x] can be used as an input to the Boolean function, see Multiple output signal combination (next section: Multiple output signal combination). This feature is available for all four **DTM** channels.

The following figure shows an example of phase shifting on channel 1.

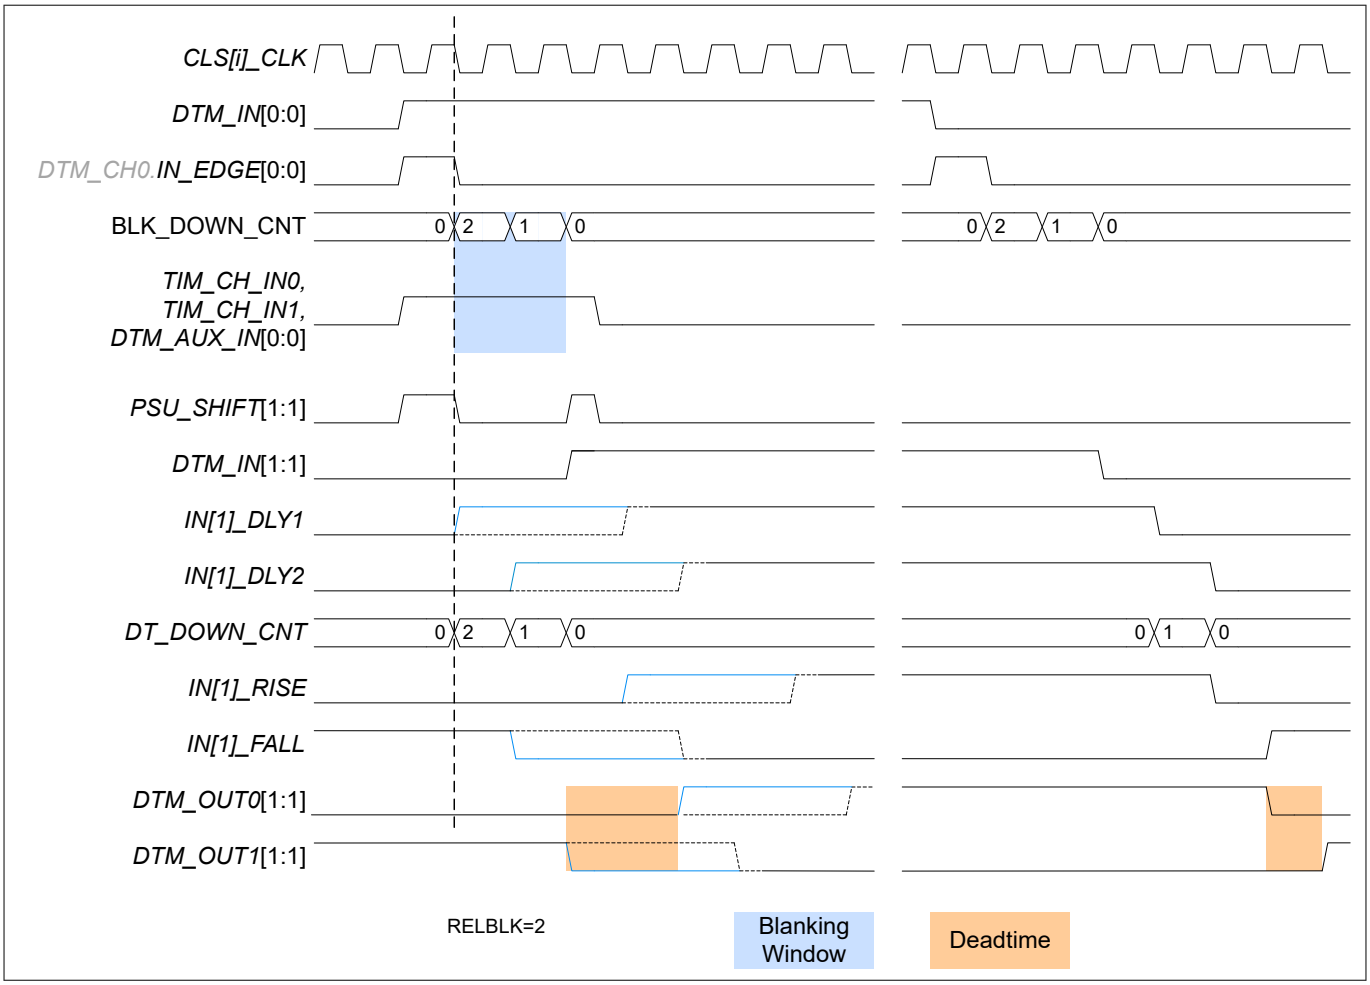


Figure 1109 Example wave of phase shift on channel 1

***Note**: The figure above shows the timing for CLSi_CDTM_DTMd_CTRL.CLK_SEL=00_B. If another clock resolution is configured, be aware that only the counter DT_DOWN_CNT runs with the reduced clock resolution.*

The bit field CLSi_CDTM_DTMd_CTRL.CH_SHUTOFF_EN shown in Figure 1108 is used for the **DTM** output shutoff feature which is described in **DTM** shutoff.

44.3.1.9.4 Multiple output signal combination

Additionally, each **DTM** channel (see Figure 1104) provides the possibility to combine the channel input signals DTM_IN or DTM_IN_T with signals PSU_SHIFT or CH_OUT_I by an **AND** or an **XOR** gate.

The relevant input signals of **DTM** channel [0] for this feature are:

- DTM_IN[0:0]
- DTM_IN_T[0:0]
- PSU_SHIFT[0:0]
- CH_OUT_I

***Note**: Signal CH_OUT_I of channel [0] is equal to signal DTM_COUT3_I, see Figure 1100.*

The relevant input signals of **DTM** channel [1] for this feature are:

- DTM_IN[1:1]

- DTM_IN_T[1:1]
- PSU_SHIFT[1:1]
- CH_OUT_I

***Note**: Signal CH_OUT_I of channel [1] is equal to signal CH_OUT_O of channel [0], see Figure 1100.*

The relevant input signals of **DTM** channel [2] for this feature are:

- DTM_IN[2:2]
- DTM_IN_T[2:2]
- PSU_SHIFT[2:2]
- CH_OUT_I

***Note**: Signal CH_OUT_I of channel [2] is equal to signal CH_OUT_O of channel [1], see Figure 1100.*

The relevant input signals of **DTM** channel [3] for this feature are:

- DTM_IN[3:3]
- DTM_IN_T[3:3]
- PSU_SHIFT[3:3]
- CH_OUT_I

***Note**: Signal CH_OUT_I of channel [3] is equal to signal CH_OUT_O of channel [2], see Figure 1100.*

The registers CLSi_CDTM_DTMd_CH_CTRL3.TSEL1_0, CLSi_CDTM_DTMd_CH_CTRL3.TSEL1_1, CLSi_CDTM_DTMd_CH_CTRL3.TSEL1_2 and CLSi_CDTM_DTMd_CH_CTRL3.TSEL1_3 select if the signal DTM_IN or DTM_IN_T is used.

The registers CLSi_CDTM_DTMd_CH_CTRL3.CII0, CLSi_CDTM_DTMd_CH_CTRL3.CII1, CLSi_CDTM_DTMd_CH_CTRL3.CII2 and CLSi_CDTM_DTMd_CH_CTRL3.CII3 configure if the selected input signal DTM_IN or DTM_IN_T is inverted.

The registers CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_0, CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_1, CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_2 and CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_3 select if the signal PSU_SHIFT or signal CH_OUT_I is used.

It is recommended to use the combination of signals only if bit field CLSi_CDTM_DTMd_PS_CTRL.RELBLK is 0. Otherwise, the signal TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN[0:0] may be disturbed by the blanking window counter.

Together with the inverter inside sub-module PSU (see Figure 1108, the inverter on each output of a channel and the possibility to invert the selected input signal (DTM_IN or DTM_IN_T) inside connected **TOM** / **ATOM** channel, a (N)**AND**, (N)**OR** or X(N)**OR** combination of the signals is possible (see e.g. Table 2243).

The inverter inside the sub-module PSU can be configured by CLSi_CDTM_DTMd_PS_CTRL.IN_POL.

The inverter on each output of a **DTM** channel can be configured by

CLSi_CDTM_DTMd_CH_CTRL2.POL0_0, CLSi_CDTM_DTMd_CH_CTRL2.POL1_0,

CLSi_CDTM_DTMd_CH_CTRL2.POL0_1, CLSi_CDTM_DTMd_CH_CTRL2.POL1_1,

CLSi_CDTM_DTMd_CH_CTRL2.POL0_2, CLSi_CDTM_DTMd_CH_CTRL2.POL1_2,

CLSi_CDTM_DTMd_CH_CTRL2.POL0_3 and CLSi_CDTM_DTMd_CH_CTRL2.POL1_3.

Combination of input signal TIM_CH_INy/DTM_AUX_IN with TOM/ATOM signal

***Note**: The description below is given for channel [0], but the same applies for the other **DTM** channels [1..3] using the corresponding configuration register bit fields.*

If the input selection CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_0 is set to 0, the output selection CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_0 is set to 1, CLSi_CDTM_DTMd_CH_CTRL2.DT1_0 is set to 1, CLSi_CDTM_DTMd_CH_CTRL2.OC1_0 is set to 0 and CLSi_CDTM_DTMd_CH_CTRL1.SWAP_0 is set to 0, depending on CLSi_CDTM_DTMd_PS_CTRL.PSU_IN_SEL either TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN[0:0] can be combined with signal DTM_IN[0:0] or DTM_IN_T[0:0].

The function of combination on **DTM** output DTM_OUT1[0:0] (and also CH_OUT_O of channel [0]) is defined by CLSi_CDTM_DTMd_CH_CTRL1.O1F_0 and CLSi_CDTM_DTMd_CH_CTRL2.POL1_0 in the following way:

Table 2243 Function of combination on DTM channel x=0 output

XOR	01	0	1	yes
NOR	10	0	1	yes

By setting CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_0 to 1, CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_1 to 1, CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_2 to 1 and CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_3 to 1, a combination of all four signals DTM_IN[0:0], DTM_IN[1:1], DTM_IN[2:2] and DTM_IN[3:3] can be achieved (combinatorial chain).

If the result of the combination of the signals should be visible at the **DTM** output DTM_OUT0[x:x], the internal signals just in front of the output register stage can be swapped by setting CLSi_CDTM_DTMd_CH_CTRL1.SWAP_0 to 1 for channel 0, CLSi_CDTM_DTMd_CH_CTRL1.SWAP_1 to 1 for channel 1, CLSi_CDTM_DTMd_CH_CTRL1.SWAP_2 to 1 for channel 2 and CLSi_CDTM_DTMd_CH_CTRL1.SWAP_3 to 1 for channel 3.

Pulse generation on edge

Another feature of the **DTM** is to generate on the second output DTM_OUT1[x:x] a pulse on every edge of corresponding input signal DTM_IN[x:x].

This can be achieved for channel [0] by configuring CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_0 to 1, i.e. selecting signal EDGE_TRIGG_[x] as the output signal (CLSi_CDTM_DTMd_CH_CTRL1.O1F_0 has to be 00_B).

This can be achieved for channel [1] by configuring CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_1 to 1, i.e. selecting signal EDGE_TRIGG_[x] as the output signal (CLSi_CDTM_DTMd_CH_CTRL1.O1F_1 has to be 00_B).

This can be achieved for channel [2] by configuring CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_2 to 1, i.e. selecting signal EDGE_TRIGG_[x] as the output signal (CLSi_CDTM_DTMd_CH_CTRL1.O1F_2 has to be 00_B).

This can be achieved for channel [3] by configuring CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_3 to 1, i.e. selecting signal EDGE_TRIGG_[x] as the output signal (CLSi_CDTM_DTMd_CH_CTRL1.O1F_3 has to be 00_B).

The signal EDGE_TRIGG_[x] is depicted in Figure 1105.

The pulse length can be adjusted individually for each edge type by the configuration value CLSi_CDTM_DTMd_CH_DTVx.RELRISE and CLSi_CDTM_DTMd_CH_DTVx.RELFALL.

The parameter CLSi_CDTM_DTMd_CH_DTVx.RELRISE defines the pulse length in case of a rising edge on input DTM_IN[x:x], the parameter CLSi_CDTM_DTMd_CH_DTVx.RELFALL defines the pulse length in case of a falling edge on input DTM_IN[x:x].

The generated edge signal EDGE_TRIGG_[x] can be combined with the output signal of the preceding **DTM** channel [x-1] at channel input CH_OUT_I.

To route the output of the **XOR** gate to DTM_OUT1, here for example for channel 0, the CLSi_CDTM_DTMd_CH_CTRL1.O1F_0 is set to 01_B, CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_0 is set to 1, CLSi_CDTM_DTMd_CH_CTRL2.DT1_0 is set to 1 and CLSi_CDTM_DTMd_CH_CTRL2.SL1_0 is set to 0. For the other channels the corresponding configuration bits have to be set.

With the configuration CLSi_CDTM_DTMd_CH_CTRL3.CIS0 is set to 1 and CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_0 is set to 1, CLSi_CDTM_DTMd_CH_CTRL3.CII0 is set to 0 and CLSi_CDTM_DTMd_CH_CTRL2.POL1_3 is set to 1, the signal EDGE_TRIGG_[x] is **XOR**ed with the inverse signal DTM_COUT3_I (CH_OUT_O of channel [3]).

With the configuration CLSi_CDTM_DTMd_CH_CTRL3.CIS1 is set to 1 and CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_1 is set to 1, CLSi_CDTM_DTMd_CH_CTRL3.CII1 is set to 0 and CLSi_CDTM_DTMd_CH_CTRL2.POL1_0 is set to 1, the signal EDGE_TRIGG_[x] is **XOR**ed with the inverse signal COUT[0:0] (CH_OUT_O of channel [0]).

With the configuration CLSi_CDTM_DTMd_CH_CTRL3.CIS2 is set to 1 and CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_2 is set to 1, CLSi_CDTM_DTMd_CH_CTRL3.CII2 is set to 0 and CLSi_CDTM_DTMd_CH_CTRL2.POL1_1 is set to 1, the signal EDGE_TRIGG_[x] is **XOR**ed with the inverse signal COUT[1:1] (CH_OUT_O of channel [1]).

With the configuration CLSi_CDTM_DTMd_CH_CTRL3.CIS3 is set to 1 and CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_3 is set to 1, CLSi_CDTM_DTMd_CH_CTRL3.CII3 is set to 0 and CLSi_CDTM_DTMd_CH_CTRL2.POL1_2 is set to 1, the signal EDGE_TRIGG_[x] is **XOR**ed with the inverse signal COUT[2:2] (CH_OUT_O of channel [2]).

As a result of this configuration, one can generate at each edge on **DTM** input DTM_IN[x:x] a pulse signal and **OR**-combine these generated pulse signals with the generated signal of preceding **DTM** channel. If the combinatorial chain is configured over all four **DTM** channels the final signal is available at last **DTM** output, which is, according to Figure 1100 the DTM_COUT3_O and with one clock delay the DTM_OUT1[3:3].

44.3.1.9.5 Synchronous update of channel control register 2

It is possible to use the shadow register CLSi_CDTM_DTMd_CH_CTRL2_SR and a selected edge of one of the channel 0 to channel 3 to update the operation register CLSi_CDTM_DTMd_CH_CTRL2.

The update mechanism and its configuration are depicted in the following figure.

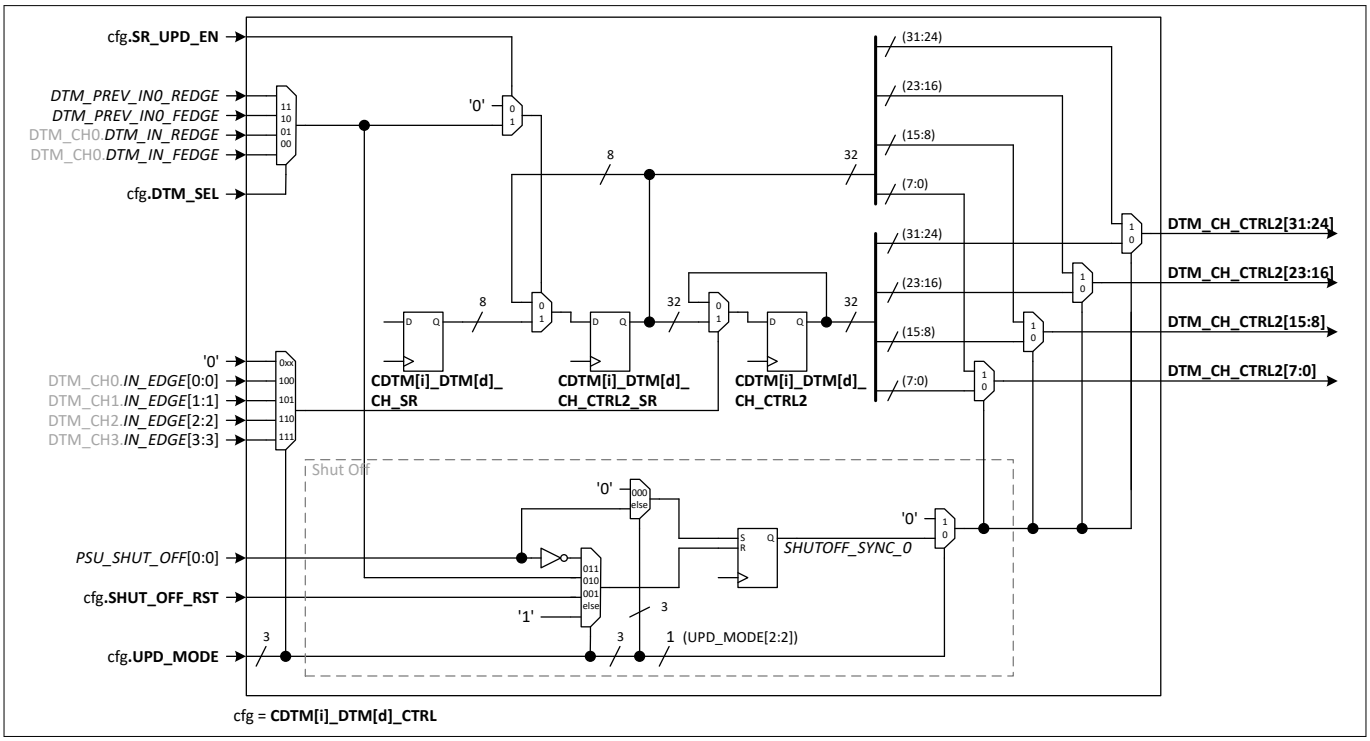

Figure 1110 Synchronous update mechanism of register CLSi_CDTM_DTMd_CH_CTRL2

If enabled by the bit field CLSi_CDTM_DTMd_CTRL.UPD_MODE (i.e. CLSi_CDTM_DTMd_CTRL.UPD_MODE=1xx), the register CLSi_CDTM_DTMd_CH_CTRL2_SR serves as a shadow register of register CLSi_CDTM_DTMd_CH_CTRL2. The update is then triggered by an edge of signal IN_EDGE[3:0].

The synchronous update allows the user to change output polarity. The selection of the constant signal level and the routing from **DTM** inputs (DTM_IN, DTM_IN_T) to outputs (DTM_OUT0, DTM_OUT1) is synchronized for all four channels in parallel to one of the input edges on IN_EDGE[3:0].

Any asynchronous configuration change (asynchronous means a configuration change will be done immediately without any edge detection) can cause a change of DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] outputs without any input edge detection, even if the corresponding output DTM_OUT0[x:x] or DTM_OUT1[x:x] also changes.

44.3.1.9.6 DTM shutoff

A fast shutoff for the eight outputs of **DTM** instance d can be triggered by one of the two assigned inputs TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN[0:0] or the corresponding three inputs of the previous **DTM** instance d-1 by selecting signal DTM_PSU_IN. The selection of the trigger signal source is done by the bits CLSi_CDTM_DTMd_PS_CTRL.TIM_SEL, CLSi_CDTM_DTMd_PS_CTRL.PSU_IN_SEL and CLSi_CDTM_DTMd_CTRL.DTM_SEL[1:1] (see Figure 1108). The selected trigger signal (output signal in Figure 1108 and input signal Figure 1110) is named PSU_SHUT_OFF.

Enabling of the shutoff feature is done by setting CLSi_CDTM_DTMd_CTRL.UPD_MODE[2:0] to one of the values 001_B, 010_B or 011_B.

The shutoff behavior of the **DTM** outputs is defined by the value of register CLSi_CDTM_DTMd_CH_CTRL2_SR.

If the shutoff feature is enabled by CLSi_CDTM_DTMd_CTRL.UPD_MODE, the register CLSi_CDTM_DTMd_CH_CTRL2 defines the output signal behavior as long as signal SHUTOFF_SYNC_0 is 0. If signal SHUTOFF_SYNC_0 is 1 the output signal behavior is defined by register CLSi_CDTM_DTMd_CH_CTRL2_SR.

Signal SHUTOFF_SYNC_0 is set to 1 if signal PSU_SHUT_OFF switches to 1. The reset depends on value of CLSi_CDTM_DTMd_CTRL.UPD_MODE.

There are four different ways to reset the signal SHUTOFF_SYNC_0 to 0:

- A write-access of value 1 via the configuration interface to bit CLSi_CDTM_DTMd_CTRL.SHUT_OFF_RST (with CLSi_CDTM_DTMd_CTRL.UPD_MODE = 001_B).
- Synchronous to an edge on **DTM** channel 0 input of this **DTM** instance d or on an edge on **DTM** channel 0 input of preceding **DTM** instance d-1 (with CLSi_CDTM_DTMd_CTRL.UPD_MODE = 010_B).
- Asynchronous to any **DTM** channel input edge, if signal PSU_SHUT_OFF switches back to 0 (with CLSi_CDTM_DTMd_CTRL.UPD_MODE = 011_B).
- Additionally, setting CLSi_CDTM_DTMd_CTRL.UPD_MODE to a value 000_B or $1xx_B$ resets also the signal SHUTOFF_SYNC_0, except PSU_SHUT_OFF is set and CLSi_CDTM_DTMd_CTRL.UPD_MODE is unequal to 000_B.

Figure 1110 depicts the shutoff feature and the different shutoff release possibilities.

The reset of SHUTOFF_SYNC_0 has lower priority than the set of this signal.

A second shadow register CLSi_CDTM_DTMd_CH_SR exists for the eight bits of the shadow register CLSi_CDTM_DTMd_CH_CTRL2_SR.

If enabled by configuration bit CLSi_CDTM_DTMd_CTRL.SR_UPD_EN, the update of CLSi_CDTM_DTMd_CH_CTRL2_SR.SL0_0_SR, CLSi_CDTM_DTMd_CH_CTRL2_SR.SL1_0_SR, CLSi_CDTM_DTMd_CH_CTRL2_SR.SL0_1_SR, CLSi_CDTM_DTMd_CH_CTRL2_SR.SL1_1_SR, CLSi_CDTM_DTMd_CH_CTRL2_SR.SL0_2_SR, CLSi_CDTM_DTMd_CH_CTRL2_SR.SL1_2_SR, CLSi_CDTM_DTMd_CH_CTRL2_SR.SL0_3_SR and CLSi_CDTM_DTMd_CH_CTRL2_SR.SL1_3_SR bits can be triggered by one of the signals selected by bit field CLSi_CDTM_DTMd_CTRL.DTM_SEL. This trigger signal is either the rising or the falling edge detected on **DTM** channel [0] (DTM_IN_FEDGE or DTM_IN_REDGE) or the corresponding edges of the **DTM** channel [0] of a preceding instance d-1 (DTM_PREV_IN0_FEDGE or DTM_PREV_IN0_REDGE).

If an update trigger occurs in the same clock-cycle, a write-access to CLSi_CDTM_DTMd_CH_CTRL2_SR is done and the register is written except the eight bits: CLSi_CDTM_DTMd_CH_CTRL2_SR.SL0_0_SR, CLSi_CDTM_DTMd_CH_CTRL2_SR.SL1_0_SR, CLSi_CDTM_DTMd_CH_CTRL2_SR.SL0_1_SR, CLSi_CDTM_DTMd_CH_CTRL2_SR.SL1_1_SR, CLSi_CDTM_DTMd_CH_CTRL2_SR.SL0_2_SR, CLSi_CDTM_DTMd_CH_CTRL2_SR.SL1_2_SR, CLSi_CDTM_DTMd_CH_CTRL2_SR.SL0_3_SR and CLSi_CDTM_DTMd_CH_CTRL2_SR.SL1_3_SR. The eight bits are copied from CLSi_CDTM_DTMd_CH_SR. In this case CLSi_CDTM_DTMd_CH_SR has priority over **AEI** write data.

As depicted in Figure 1102, Figure 1103 and Figure 1108 the **DTM** input signal TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN[0:0] can be forwarded to the succeeding instance d+1. Thus, it can be used to trigger shutoff in two consecutive **DTM** instances.

44.3.1.9.7 DTM individual channel shutoff

The shutoff feature can be enhanced by setting bit CLSi_CDTM_DTMd_CTRL.CH_SHUTOFF_EN = 1. Then all four **DTM** channels can be shut off individually. If an individual shutoff is done (SHUTOFF_SYNC_0, SHUTOFF_SYNC_1, SHUTOFF_SYNC_2 and SHUTOFF_SYNC_3 is set) the configuration bits of the corresponding **DTM** channel (e.g. for channel 0 the bits [7:0]) are copied from the shadow register CLSi_CDTM_DTMd_CH_CTRL2_SR to output CLSi_CDTM_DTMd_CH_CTRL2.

As described above, there are four different ways to reset the signal SHUTOFF_SYNC_0 to 0. The configuration bits CLSi_CDTM_DTMd_CTRL2.UPD_MODE_0 are described below:

- Asynchronous to any **DTM** channel input edge, if signal PSU_SHUT_OFF[0:0] switches back to 0 (with CLSi_CDTM_DTMd_CTRL2.UPD_MODE_0 = 11_B)
- Synchronous to an edge on **DTM** channel 0 input of this **DTM** instance d or on an edge on **DTM** channel 0 input of preceding **DTM** instance d-1 (with CLSi_CDTM_DTMd_CTRL2.UPD_MODE_0 = 10_B).
- The CPU writes a 1 to bit CLSi_CDTM_DTMd_CTRL2.SHUT_OFF_RST_0 (with CLSi_CDTM_DTMd_CTRL2.UPD_MODE_0= 01_B).
- Additionally, setting CLSi_CDTM_DTMd_CTRL2.UPD_MODE_0 to a value 00_B.

As described above, there are four different ways to reset the signal SHUTOFF_SYNC_1 to 0. The configuration bits CLSi_CDTM_DTMd_CTRL2.UPD_MODE_1 are described below:

- Asynchronous to any **DTM** channel input edge, if signal PSU_SHUT_OFF[1:1] switches back to 0 (with CLSi_CDTM_DTMd_CTRL2.UPD_MODE_1 = 11_B)
- Synchronous to an edge on **DTM** channel 0 input of this **DTM** instance d or on an edge on **DTM** channel 0 input of preceding **DTM** instance d-1 (with CLSi_CDTM_DTMd_CTRL2.UPD_MODE_1 = 10_B).
- The CPU writes a 1 to bit CLSi_CDTM_DTMd_CTRL2.SHUT_OFF_RST_1 (with CLSi_CDTM_DTMd_CTRL2.UPD_MODE_1= 01_B).
- Additionally, setting CLSi_CDTM_DTMd_CTRL2.UPD_MODE_1 to a value 00_B.

As described above, there are four different ways to reset the signal SHUTOFF_SYNC_2 to 0. The configuration bits CLSi_CDTM_DTMd_CTRL2.UPD_MODE_2 are described here:

- Asynchronous to any **DTM** channel input edge, if signal PSU_SHUT_OFF[2:2] switches back to 0 (with CLSi_CDTM_DTMd_CTRL2.UPD_MODE_2 = 11_B)
- Synchronous to an edge on **DTM** channel 0 input of this **DTM** instance d or on an edge on **DTM** channel 0 input of preceding **DTM** instance d-1 (with CLSi_CDTM_DTMd_CTRL2.UPD_MODE_2 = 10_B).
- The CPU writes a 1 to bit CLSi_CDTM_DTMd_CTRL2.SHUT_OFF_RST_2 (with CLSi_CDTM_DTMd_CTRL2.UPD_MODE_2= 01_B).
- Additionally, setting CLSi_CDTM_DTMd_CTRL2.UPD_MODE_2 to a value 00_B.

As described above, there are four different ways to reset the signal SHUTOFF_SYNC_3 to 0. The configuration bits CLSi_CDTM_DTMd_CTRL2.UPD_MODE_3 are described here:

- Asynchronous to any **DTM** channel input edge, if signal PSU_SHUT_OFF[3:3] switches back to 0 (with CLSi_CDTM_DTMd_CTRL2.UPD_MODE_3 = 11_B)
- Synchronous to an edge on **DTM** channel 0 input of this **DTM** instance d or on an edge on **DTM** channel 0 input of preceding **DTM** instance d-1 (with CLSi_CDTM_DTMd_CTRL2.UPD_MODE_3 = 10_B).
- The CPU writes a 1 to bit CLSi_CDTM_DTMd_CTRL2.SHUT_OFF_RST_3 (with CLSi_CDTM_DTMd_CTRL2.UPD_MODE_3= 01_B).
- Additionally, setting CLSi_CDTM_DTMd_CTRL2.UPD_MODE_3 to a value 00_B.

Figure 1111 depicts the channel shutoff feature and the different shutoff release possibilities.

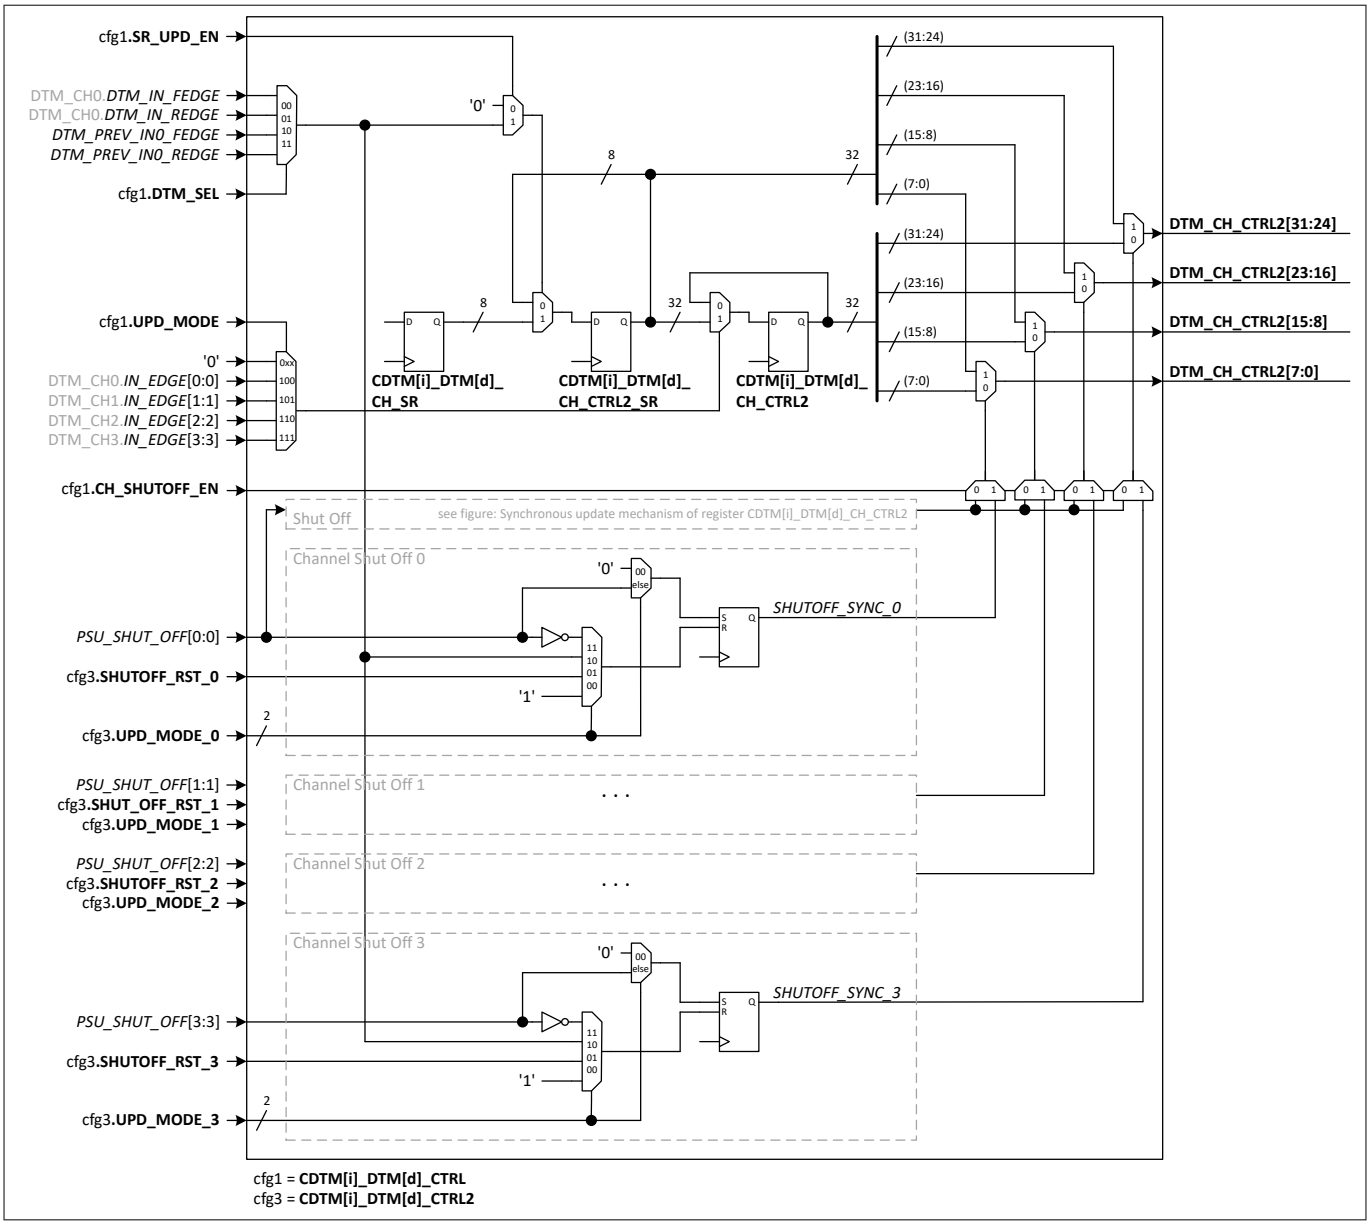

Figure 1111 Individual channel shutoff

The reset of a SHUTOFF_SYNC_0, SHUTOFF_SYNC_1, SHUTOFF_SYNC_2 and SHUTOFF_SYNC_3 has lower priority than the set of such a signal.

If the individual channel shutoff feature is activated (CLSi_CDTM_DTMd_CTRL.CH_SHUTOFF_EN = 1) the selection of the trigger source located in **DTM** block Phase Shift Unit (PSU) is also enhanced.

By using the bit fields CLSi_CDTM_DTMd_CTRL2.SHUTOFF_SEL_0, CLSi_CDTM_DTMd_CTRL2.SHUTOFF_SEL_1, CLSi_CDTM_DTMd_CTRL2.SHUTOFF_SEL_2 and CLSi_CDTM_DTMd_CTRL2.SHUTOFF_SEL_3 for each **DTM** channel one of the following sources can be selected:

- TIM_CH_IN0
- TIM_CH_IN1
- DTM_AUX_IN[0:0]
- DTM_AUX_IN[1:1]
- DTM_AUX_IN[2:2]
- DTM_AUX_IN[3:3]

- constant zero (0_B)
- constant one (1_B)

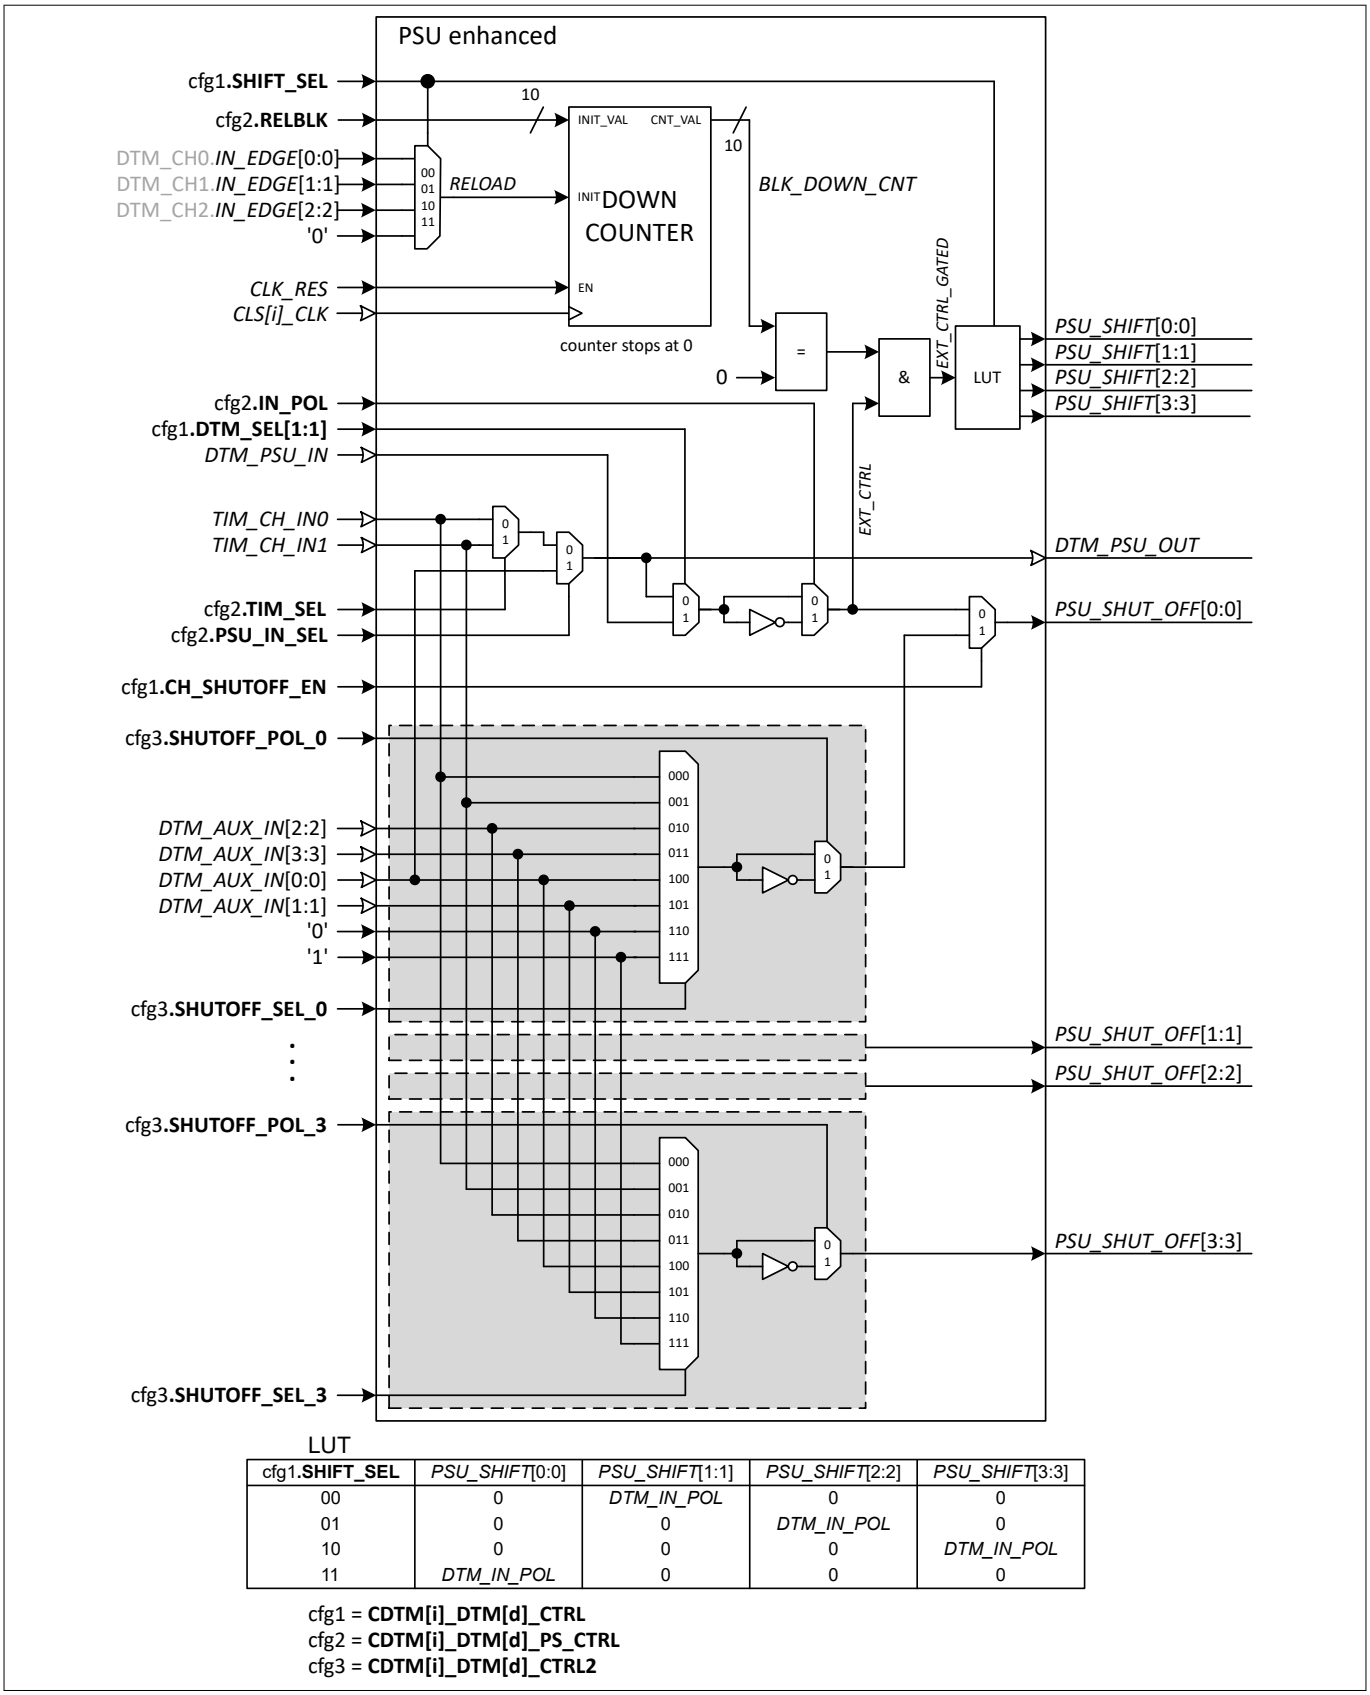
The routing from the external ports (e)GTM_CDTM[i]_DTM[d]_AUX_IN (with d being the index of the **DTM** within the **CDTM** and i being the index of the hosting cluster) to DTM_AUX_IN is summarized below (see also Figure 1021):

The following list shows the possible input sources.

- DTM_AUX_IN[0:0] is wired to the respective (e)GTM_CDTM[i]_DTM[d]_AUX_IN[0:0].
- DTM_AUX_IN[1:1] is wired to the respective (e)GTM_CDTM[i]_DTM[d]_AUX_IN[1:1].
- DTM_AUX_IN[2:2] is wired to (e)GTM_CDTM[i]_DTM[d]_AUX_IN[0:0]. If the previous **DTM** is not implemented or is placed after a module of a different type from the current one (i.e. d ∈ {4,6}), DTM_AUX_IN[2:2] is tied to '0'.
- DTM_AUX_IN[3:3] is wired to (e)GTM_CDTM[i]_DTM[d]_AUX_IN[1:1]. If the previous **DTM** is not implemented or is placed after a module of a different type from the current one (i.e. d ∈ {4,6}), DTM_AUX_IN[3:3] is tied to '0'.

***Note**: For sake of compatibility to previous **eGTM** versions, DTM_AUX_IN[0:0] has to be driven for each CDTM[i]_DTM[d] instance by the DTM_AUX_IN[0:0] primary input.*

After each source multiplexer there is an inverter. Over bit CLSi_CDTM_DTMd_CTRL2.SHUTOFF_POL_0, CLSi_CDTM_DTMd_CTRL2.SHUTOFF_POL_1, CLSi_CDTM_DTMd_CTRL2.SHUTOFF_POL_2 and CLSi_CDTM_DTMd_CTRL2.SHUTOFF_POL_3 signal PSU_SHUT_OFF[0:0], PSU_SHUT_OFF[1:1], PSU_SHUT_OFF[2:2] and PSU_SHUT_OFF[3:3] can be inverted.



LUT

cfg1.**SHIFT_SEL**	*PSU_SHIFT*[0:0]	*PSU_SHIFT*[1:1]	*PSU_SHIFT*[2:2]	*PSU_SHIFT*[3:3]
00	0	*DTM_IN_POL*	0	0
01	0	0	*DTM_IN_POL*	0

cfg1 = **CDTM[i]_DTM[d]_CTRL**
cfg2 = **CDTM[i]_DTM[d]_PS_CTRL**
cfg3 = **CDTM[i]_DTM[d]_CTRL2**

Figure 1112 PSU enhanced

The register layout of CLSi_CDTM_DTMd_CTRL2 ensures that atomic operations on multiple **DTM** channels are possible. Therefore, the register includes the bits CLSi_CDTM_DTMd_CTRL2.WR_EN_0,

CLSi_CDTM_DTMd_CTRL2.WR_EN_1, CLSi_CDTM_DTMd_CTRL2.WR_EN_2 and CLSi_CDTM_DTMd_CTRL2.WR_EN_3. The bits of CLSi_CDTM_DTMd_CTRL2 of a **DTM** channel (x∈{0...3}) can be written only if the corresponding CLSi_CDTM_DTMd_CTRL2.WR_EN_0, CLSi_CDTM_DTMd_CTRL2.WR_EN_1, CLSi_CDTM_DTMd_CTRL2.WR_EN_2 and CLSi_CDTM_DTMd_CTRL2.WR_EN_3 bits are also written to 1.

44.3.1.9.8 High-resolution PWM support

Additionally to each incoming PWM signal DTM_IN[x:x], DTM_IN_T[x:x] x:={0, 1,..., 3} another input signal is delivered from **TOM**/**ATOM** sub-module which is called DTM_IN_HRES[x], DTM_IN_T_HRES[x]. Further each channel x has an additional input signal pair DTM_IN_PREV[x:x] and DTM_IN_PREV_HRES[x], which is the input signal pair of the previous **DTM** channel. All these signals are directly connected to the related **TOM**/**ATOM** channel. Please refer to High-resolution PWM support for additional information of the high-resolution PWM support of the **eGTM**. Figure 1113 shows the high-resolution PWM related **DTM** channel.

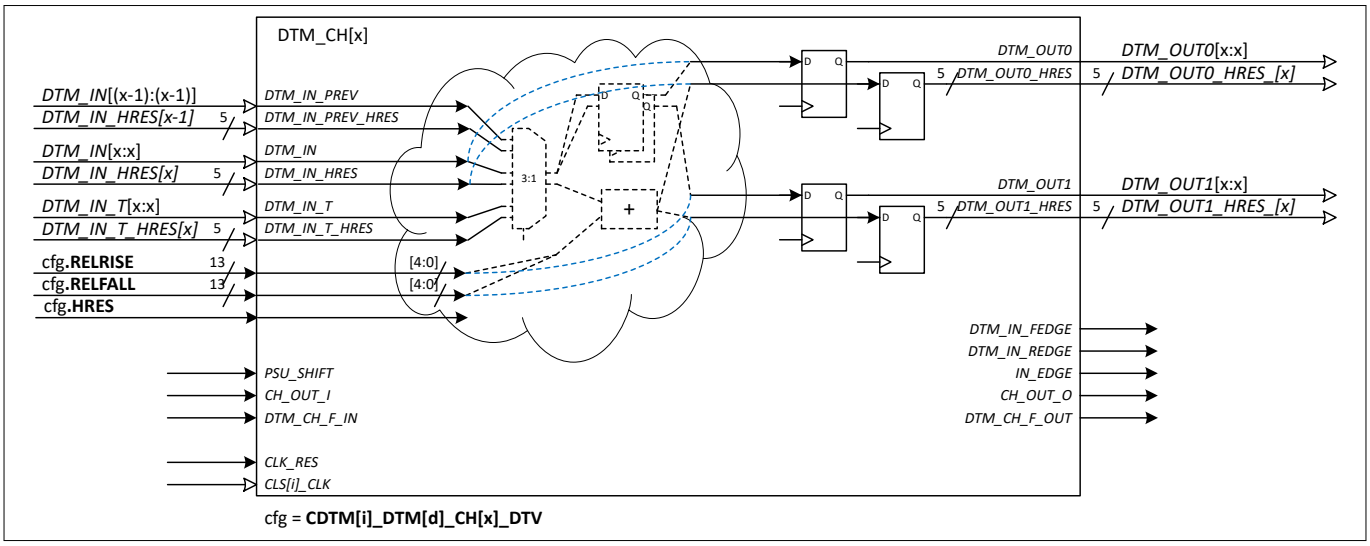

Figure 1113 DTM channel enhancement for high-resolution PWM support

- As shown in the figure above, one of the three input signals DTM_IN[3:0], DTM_IN_T[3:0] and DTM_IN_PREV[3:0] (DTM_IN_PREV is the DTM_IN signal of the previous channel [x-1]) that can be routed to the **DTM** outputs. The **DTM** module delivers two output signals DTM_OUT0[3:0] and DTM_OUT1[3:0] for the selected input signal.
- The corresponding high-resolution signals DTM_IN_HRES[x][4:0], DTM_IN_T_HRES[x][4:0] and DTM_IN_PREV_HRES[x][4:0] are routed to the outputs DTM_OUT0_HRES_[x][4:0] and DTM_OUT1_HRES_[x] [4:0] in the same manner.

Any additional delay on the path from the selected **DTM** input to the **DTM** output inside the logic cloud are also added to the high-resolution signals. Thus for each channel the DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] signals are switching synchronously to the DTM_OUT0[x:x], DTM_OUT1[x:x] signals respectively. Details about the routing through the logic cloud are described in the previous chapters of the **DTM**, Figure 1104 and Figure 1114.

The blue lines in the figure above show the direct path from the inputs to the outputs through the logic cloud. If this path is configured the high-resolution input values from **TOM**/**ATOM** are not modified by the **DTM** module.

The next figure shows the principal routing of the high-resolution signals only through the **DTM** channel.

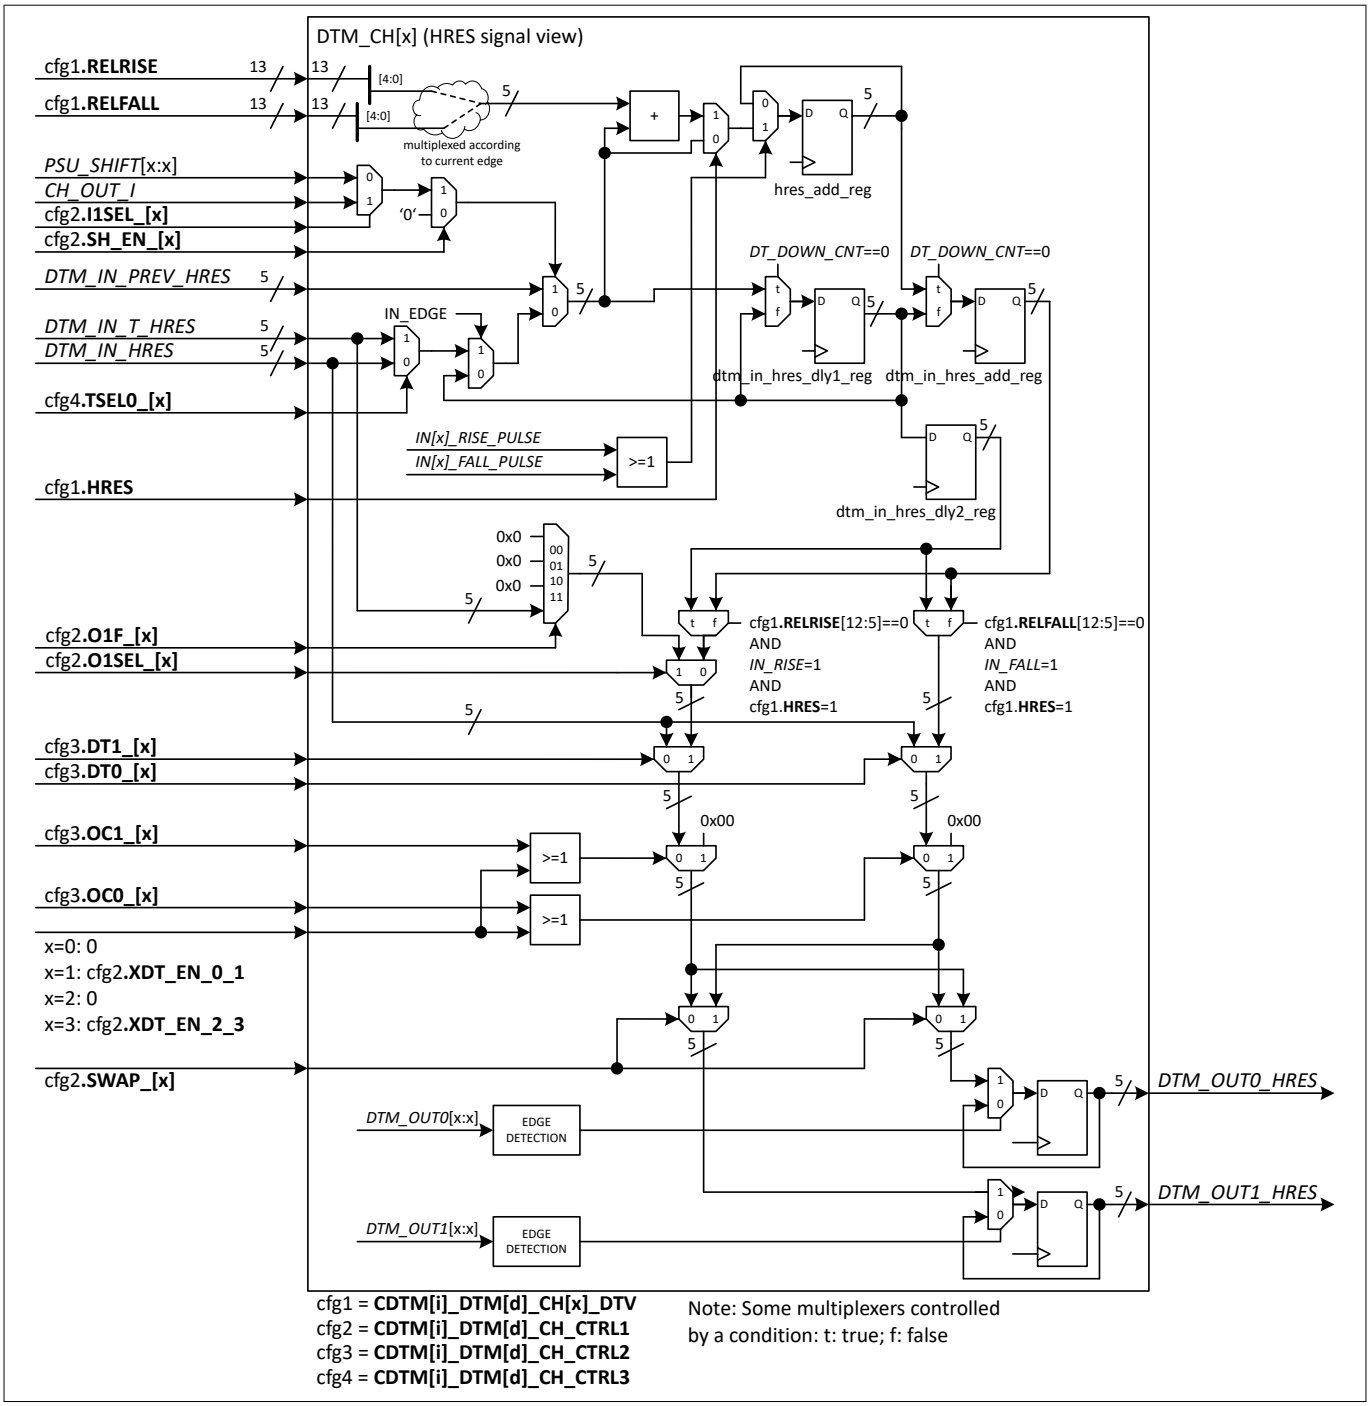

Figure 1114 Routing of high-resolution signals inside DTM channel

The output signals DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] are switching synchronous to the DTM_OUT0, DTM_OUT1 signals and always follows exactly the selected input signal DTM_IN_HRES[x], DTM_IN_T_HRES[x], and DTM_IN_PREV_HRES[x] with the same number of clock-cycles delay as the PWM output signals DTM_OUT0[3:0], DTM_OUT1[3:0] relating to the PWM input signal DTM_IN[3:0].

If the **DTM** output signals are swapped (CLSi_CDTM_DTMd_CH_CTRL1.SWAP_0=1, CLSi_CDTM_DTMd_CH_CTRL1.SWAP_1=1, CLSi_CDTM_DTMd_CH_CTRL1.SWAP_2=1 or CLSi_CDTM_DTMd_CH_CTRL1.SWAP_3=1), then the high-resolution output signals are also swapped.

***Note**:*

- DTM_OUT0_HRES_[x] = 0, when CLSi_CDTM_DTMd_CH_CTRL2.OC0_0 = 1/CLSi_CDTM_DTMd_CH_CTRL2.OC0_1 = 1/CLSi_CDTM_DTMd_CH_CTRL2.OC0_2 = 1/ CLSi_CDTM_DTMd_CH_CTRL2.OC0_3 = 1 and CLSi_CDTM_DTMd_CH_CTRL1.SWAP_0 = 0/CLSi_CDTM_DTMd_CH_CTRL1.SWAP_1 = 0/CLSi_CDTM_DTMd_CH_CTRL1.SWAP_2 = 0/ CLSi_CDTM_DTMd_CH_CTRL1.SWAP_3 = 0
- DTM_OUT1_HRES_[x] = 0, when CLSi_CDTM_DTMd_CH_CTRL2.OC1_0 = 1/CLSi_CDTM_DTMd_CH_CTRL2.OC1_1 = 1/CLSi_CDTM_DTMd_CH_CTRL2.OC1_2 = 1/ CLSi_CDTM_DTMd_CH_CTRL2.OC1_3 = 1 = 1 and CLSi_CDTM_DTMd_CH_CTRL1.SWAP_0 = 0/CLSi_CDTM_DTMd_CH_CTRL1.SWAP_1 = 0/CLSi_CDTM_DTMd_CH_CTRL1.SWAP_2 = 0/ CLSi_CDTM_DTMd_CH_CTRL1.SWAP_3 = 0
- DTM_OUT1_HRES_[x] = 0, when CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_0 = 1/ CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_1 = 1/CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_2 = 1/ CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_3 = 1 and CLSi_CDTM_DTMd_CH_CTRL1.O1F_0 != 11_B/CLSi_CDTM_DTMd_CH_CTRL1.O1F_1 != 11_B/CLSi_CDTM_DTMd_CH_CTRL1.O1F_2 != 11_B/ CLSi_CDTM_DTMd_CH_CTRL1.O1F_3 != 11_B and CLSi_CDTM_DTMd_CH_CTRL1.SWAP_0 = 0/CLSi_CDTM_DTMd_CH_CTRL1.SWAP_1 = 0/CLSi_CDTM_DTMd_CH_CTRL1.SWAP_2 = 0/ CLSi_CDTM_DTMd_CH_CTRL1.SWAP_3 = 0
- For the above three statements, CLSi_CDTM_DTMd_CH_CTRL1.SWAP_0 = 0/CLSi_CDTM_DTMd_CH_CTRL1.SWAP_1 = 0/CLSi_CDTM_DTMd_CH_CTRL1.SWAP_2 = 0/ CLSi_CDTM_DTMd_CH_CTRL1.SWAP_3 = 0 is assumed. Please see description above for CLSi_CDTM_DTMd_CH_CTRL1.SWAP_0 = 1/CLSi_CDTM_DTMd_CH_CTRL1.SWAP_1 = 1/ CLSi_CDTM_DTMd_CH_CTRL1.SWAP_2 = 1/CLSi_CDTM_DTMd_CH_CTRL1.SWAP_3 = 1.

***Note**:* *The high-resolution input signal changes its value exactly (!! and only !!) with its dedicated input signal edge. If there are no edges on the PWM input signal (DTM_IN/DTM_IN_T), then there are also no changes on the dedicated high-resolution input signal. This depends only on the signal generation in the (A)**TOM** modules.*

***Note**:* *The high-resolution output signals DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] will change only, if there is an edge on the associated output signal DTM_OUT0[x:x], DTM_OUT1[x:x].*

But this is only true, if the output edge occurs due to an input edge or due to a change of the configuration bits DT0/DT1 for standard dead-time. This configuration change will also lead to an edge on one of the output signals.

- If CLSi_CDTM_DTMd_CH_CTRL2.OC0_0=1 and CLSi_CDTM_DTMd_CH_CTRL2.OC1_0=1 (and CLSi_CDTM_DTMd_CH_CTRL1.SWAP_0=0) then the signal level bits CLSi_CDTM_DTMd_CH_CTRL2.SL0_0 and CLSi_CDTM_DTMd_CH_CTRL2.SL1_0 define the values of DTM_OUT0[0:0] and DTM_OUT1[0:0] and the high-resolution signals DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] are set to 0_H. Thus the activation of the SL path can lead to a change of DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] from its current value to 0_H. After activation of the SL path a configuration change of the signal level bits CLSi_CDTM_DTMd_CH_CTRL2.SL0_0, CLSi_CDTM_DTMd_CH_CTRL2.SL1_0 will lead to an edge on the output signals DTM_OUT0[0:0] and DTM_OUT1[0:0], but not to an update of the high-resolution output signals DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x].
- If CLSi_CDTM_DTMd_CH_CTRL2.OC0_1=1 and CLSi_CDTM_DTMd_CH_CTRL2.OC1_1=1 (and CLSi_CDTM_DTMd_CH_CTRL1.SWAP_1=0) then the signal level bits CLSi_CDTM_DTMd_CH_CTRL2.SL0_1 and CLSi_CDTM_DTMd_CH_CTRL2.SL1_1 define the values of DTM_OUT0[1:1] and DTM_OUT1[1:1] and the high-resolution signals DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] are set to 0_H. Thus the activation of the SL path can lead to a change of DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] from its current value to 0_H. After activation of the SL path a configuration change of the signal level bits CLSi_CDTM_DTMd_CH_CTRL2.SL0_1, CLSi_CDTM_DTMd_CH_CTRL2.SL1_1 will lead to an edge on the

output signals DTM_OUT0[1:1] and DTM_OUT1[1:1], but not to an update of the high-resolution output signals DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x].

- If CLSi_CDTM_DTMd_CH_CTRL2.OC0_2=1 and CLSi_CDTM_DTMd_CH_CTRL2.OC1_2=1 (and CLSi_CDTM_DTMd_CH_CTRL1.SWAP_2=0) then the signal level bits CLSi_CDTM_DTMd_CH_CTRL2.SL0_2 and CLSi_CDTM_DTMd_CH_CTRL2.SL1_2 define the values of DTM_OUT0[2:2] and DTM_OUT1[2:2] and the high-resolution signals DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] are set to 0_H. Thus the activation of the SL path can lead to a change of DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] from its current value to 0_H. After activation of the SL path a configuration change of the signal level bits CLSi_CDTM_DTMd_CH_CTRL2.SL0_2, CLSi_CDTM_DTMd_CH_CTRL2.SL1_2 will lead to an edge on the output signals DTM_OUT0[2:2] and DTM_OUT1[2:2], but not to an update of the high-resolution output signals DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x].
- If CLSi_CDTM_DTMd_CH_CTRL2.OC0_3=1 and CLSi_CDTM_DTMd_CH_CTRL2.OC1_3=1 (and CLSi_CDTM_DTMd_CH_CTRL1.SWAP_3=0) then the signal level bits CLSi_CDTM_DTMd_CH_CTRL2.SL0_3 and CLSi_CDTM_DTMd_CH_CTRL2.SL1_3 define the values of DTM_OUT0[3:3] and DTM_OUT1[3:3] and the high-resolution signals DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] are set to 0_H. Thus the activation of the SL path can lead to a change of DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] from its current value to 0_H. After activation of the SL path a configuration change of the signal level bits CLSi_CDTM_DTMd_CH_CTRL2.SL0_3, CLSi_CDTM_DTMd_CH_CTRL2.SL1_3 will lead to an edge on the output signals DTM_OUT0[3:3] and DTM_OUT1[3:3], but not to an update of the high-resolution output signals DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x].

If the configuration bit CLSi_CDTM_DTMd_CH_DTVx.HRES = 1, it is possible to insert dead-time between the two inverted output signals DTM_OUT0[3:0] and DTM_OUT1[3:0] on a micro-step level by calculating the output signals DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] in the following manner.

Figure 1115 shows the principle schematic view of the calculation of the output values of DTM_OUT0_HRES_[x] / DTM_OUT1_HRES_[x].

As shown in figure, the input value of DTM_IN_HRES[x][4:0] is added to CLSi_CDTM_DTMd_CH_DTVx.RELRISE[12:0] / CLSi_CDTM_DTMd_CH_DTVx.RELFALL[12:0] value. The output signals DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] are the bits [4:0] of the result. The counter DT_DOWN_CNT gets the bits [12:5] of the result and the DT_DOWN_CNT result (counter output signal is DT_DOWN_CNT) includes the value of the carry bit or adding the lower bits [4:0].

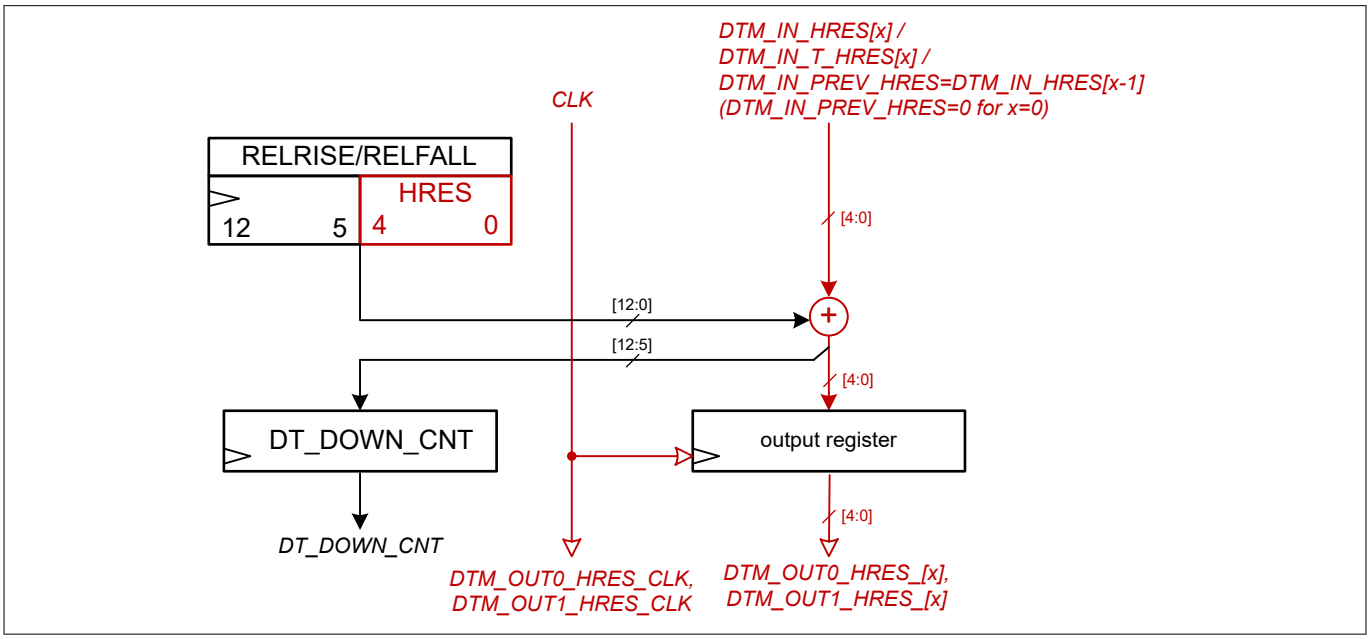

Figure 1115 Calculation of HRES output signal

***Note**: In the figure above all three possible input signals are shown, but only one of them is selected corresponding to the selected **DTM** input signal (DTM_IN_PREV, DTM_IN, DTM_IN_T).*

It has to be considered that the maximum range of dead-time insertion is reduced to 2^8 clock-cycles when high-resolution support is switched on in **DTM**. Without high-resolution support the maximum range is 2^{13} clock-cycles based on **DTM** internal clock resolution, see Figure 1100.

***Note**: The clock-cycles or clock frequency depends on the **DTM** internal clock resolution CLK_RES; see Figure 1100.*

The signal diagram in Figure 1116 shows an example of how the dead-time adjustment on micro-step level works. The red and blue delays are realized by customer logic outside of the **DTM**/**eGTM**. The red dotted lines in Figure 1116 are the PWM signals after the external delay chain.

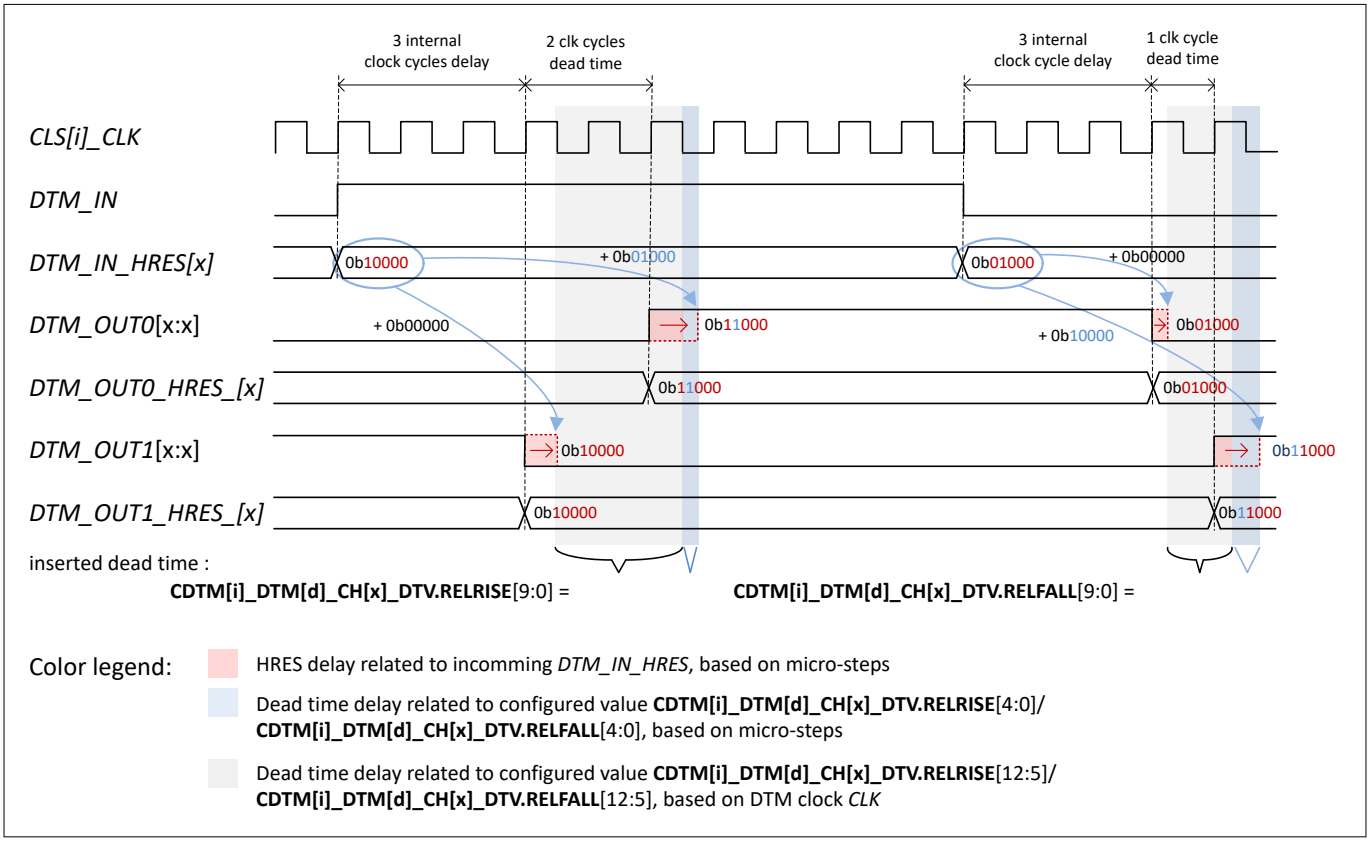

Figure 1116 Standard dead-time adjustment on micro-step level

In Figure 1116 it can be seen that for the rising edge of input signal DTM_IN[0:0] the value of the output signal DTM_OUT1_HRES_[x] is the same as the value of input signal DTM_IN_HRES[x] whereas the value of DTM_OUT0_HRES_[x] is calculated by adding the value of bit field CLSi_CDTM_DTMd_CH_DTVx.RELRISE[4:0] to DTM_IN_HRES[x].

For the falling edge of input signal DTM_IN[0:0] the same is done in opposite way whereas the value of the output signal DTM_OUT0_HRES_[x] has the same value as of the input signal DTM_IN_HRES[x] and the value of DTM_OUT1_HRES_[x] is calculated by adding the value of bit field CLSi_CDTM_DTMd_CH_DTVx.RELFALL[4:0] to DTM_IN_HRES[x].

The Figure 1116 shows the input signals DTM_IN[x:x] and DTM_IN_HRES[x][4:0], but the same applies if the input signals DTM_IN_T[x:x], DTM_IN_T_HRES[x][4:0] or DTM_IN_PREV[x:x], DTM_IN_PREV_HRES[x][4:0] are selected.

The selection of the **DTM** input signals DTM_IN, DTM_IN_T and DTM_IN_PREV are shown in Figure 1104. The selection of DTM_IN or DTM_IN_T is controlled by CLSi_CDTM_DTMd_CH_CTRL3.TSEL0_0,

CLSi_CDTM_DTMd_CH_CTRL3.TSEL0_1, CLSi_CDTM_DTMd_CH_CTRL3.TSEL0_2, CLSi_CDTM_DTMd_CH_CTRL3.TSEL0_3. To select DTM_IN_PREV the signals PSU_SHIFT or CH_OUT_I and the bit fields CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_0, CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_1, CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_2, CLSi_CDTM_DTMd_CH_CTRL1.I1SEL_3 and CLSi_CDTM_DTMd_CH_CTRL1.SH_EN_1, CLSi_CDTM_DTMd_CH_CTRL1.SH_EN_2, CLSi_CDTM_DTMd_CH_CTRL1.SH_EN_3 have to be considered. Accordingly, the selection of the corresponding high-resolution input is done automatically.

The high-resolution mode in **DTM** is only supported for standard dead-time (as described before) and for the phase shift mode, where standard dead-time is used.

In all other **DTM** modes (cross channel dead-time, multiple output signal combination, pulse generation on edge) the high-resolution PWM is not supported. In this case, the output signals DTM_OUT0_HRES_[x], DTM_OUT1_HRES_[x] are overwritten to zero. Setting the configuration bit CLSi_CDTM_DTMd_CH_DTVx.HRES has no effect in this **DTM** mode.

Table 2250 High-resolution PWM support depending on DTM modes

DTM mode	high-resolution PWM support	comment
standard dead-time	yes	DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] output calculated
phase shift mode	yes	DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] output calculated
cross channel dead-time	no	DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x] outputs overwritten to zero
multiple output signal combination	no	high-resolution outputs connected to corresponding high-resolution input (see Special configurations, paths or behavior, too)
pulse generation on edge	no	high-resolution outputs connected to corresponding high-resolution input

Special configurations, paths or behavior

If special function on output 1 (DTM_OUT1) is selected (CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_0=1 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_0=1), the following high-resolution input is connected to high-resolution output depending on CLSi_CDTM_DTMd_CH_CTRL1.O1F_0:

- CLSi_CDTM_DTMd_CH_CTRL1.O1F_0=00_B: 00_H
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_0=01_B: 00_H
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_0=10_B: 00_H
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_0=11_B: DTM_IN_T_HRES[x]

If the **DTM** output signals are swapped (CLSi_CDTM_DTMd_CH_CTRL1.SWAP_0=1), then the high-resolution output signals are also swapped.

Further, there is an exception if CLSi_CDTM_DTMd_CH_CTRL2.OC0_0=1 or CLSi_CDTM_DTMd_CH_CTRL2.OC1_0=1 then the corresponding high-resolution output value is set to 0_H.

***Note**: This ensures that the result of an active shutoff is available at an output signal as soon as possible.*

If special function on output 1 (DTM_OUT1) is selected (CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_1=1 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_1=1), the following high-resolution input is connected to high-resolution output depending on CLSi_CDTM_DTMd_CH_CTRL1.O1F_1:

- CLSi_CDTM_DTMd_CH_CTRL1.O1F_1=00_B: 00_H
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_1=01_B: 00_H
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_1=10_B: 00_H
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_1=11_B: DTM_IN_T_HRES[x]

If the **DTM** output signals are swapped (CLSi_CDTM_DTMd_CH_CTRL1.SWAP_1=0), then the high-resolution output signals are also swapped.

Further, there is an exception if CLSi_CDTM_DTMd_CH_CTRL2.OC0_1=1 or CLSi_CDTM_DTMd_CH_CTRL2.OC1_1=1 then the corresponding high-resolution output value is set to 0_H.

***Note**: This ensures that the result of an active shutoff is available at an output signal as soon as possible.*

If special function on output 1 (DTM_OUT1) is selected (CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_2=1 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_2=1), the following high-resolution input is connected to high-resolution output depending on CLSi_CDTM_DTMd_CH_CTRL1.O1F_2:

- CLSi_CDTM_DTMd_CH_CTRL1.O1F_2=00_B: 00_H
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_2=01_B: 00_H
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_2=10_B: 00_H
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_2=11_B: DTM_IN_T_HRES[x]

If the **DTM** output signals are swapped (CLSi_CDTM_DTMd_CH_CTRL1.SWAP_2=0, then the high-resolution output signals are also swapped.

Further, there is an exception if CLSi_CDTM_DTMd_CH_CTRL2.OC0_2=1 or CLSi_CDTM_DTMd_CH_CTRL2.OC1_2=1 then the corresponding high-resolution output value is set to 0_H.

***Note**: This ensures that the result of an active shutoff is available at an output signal as soon as possible.*

If special function on output 1 (DTM_OUT1) is selected (CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_3=1 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_3=1), the following high-resolution input is connected to high-resolution output depending on CLSi_CDTM_DTMd_CH_CTRL1.O1F_3:

- CLSi_CDTM_DTMd_CH_CTRL1.O1F_3=00_B: 00_H
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_3=01_B: 00_H
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_3=10_B: 00_H
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_3=11_B: DTM_IN_T_HRES[x]

If the **DTM** output signals are swapped (CLSi_CDTM_DTMd_CH_CTRL1.SWAP_3=0), then the high-resolution output signals are also swapped.

Further, there is an exception if CLSi_CDTM_DTMd_CH_CTRL2.OC0_3=1 or CLSi_CDTM_DTMd_CH_CTRL2.OC1_3=1 then the corresponding high-resolution output value is set to 0_H.

***Note**: This ensures that the result of an active shutoff is available at an output signal as soon as possible.*

44.3.1.9.9 DTM connections on eGTM toplevel

If **DTM** instance is present, it is placed behind the outputs of a **TOM**, **ATOM** depending on the **eGTM** device configuration.

In case **DTM** exists, the outputs TOM_OUT[y:y], ATOM_OUT[y:y] and TOM_OUT_T[y:y], ATOM_OUT_T[y:y] are connected to **DTM** inputs DTM_IN and DTM_IN_T. The outputs of the **DTM** are routed directly to the toplevel of **eGTM**.

The behavior of **DTM** after reset is shown in Figure 1117.

***Note**: If a device configuration is used without high-resolution support (device configuration parameter DTM_HIGH_RES_G=0) then all high-resolution outputs of **DTM** (DTM_OUT0_HRES_[x] and DTM_OUT1_HRES_[x]) are zero.*

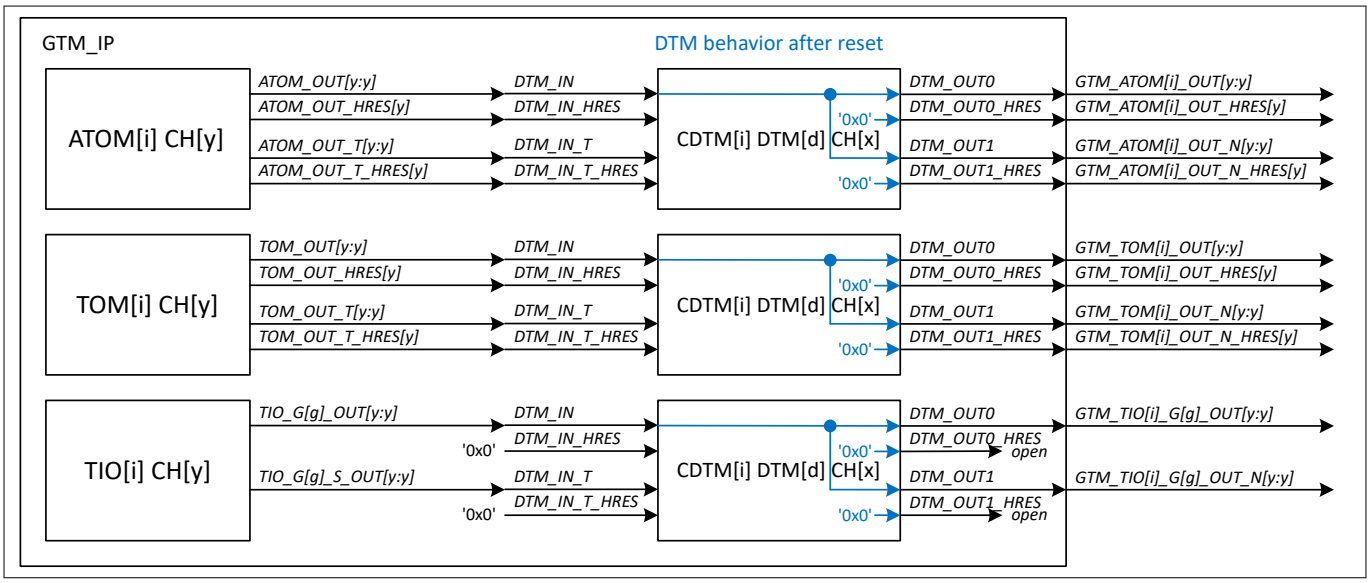

Figure 1117 DTM behavior after reset

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

- To enable the second pass through route of signal DTM_IN_T[x:x] to the **DTM** output DTM_OUT1[x:x], the following **DTM** channel configuration has to be chosen:
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_0 = 11_B, CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_0=1 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_0=1.
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_1 = 11_B, CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_1=1 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_1=1.
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_2 = 11_B, CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_2=1 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_2=1.
- CLSi_CDTM_DTMd_CH_CTRL1.O1F_3 = 11_B, CLSi_CDTM_DTMd_CH_CTRL1.O1SEL_3=1 and CLSi_CDTM_DTMd_CH_CTRL2.DT1_3=1.

The signal names and the signal routing in the case of no **DTM** instance placed behind a **TOM**, **ATOM**, is shown in Figure 1118.

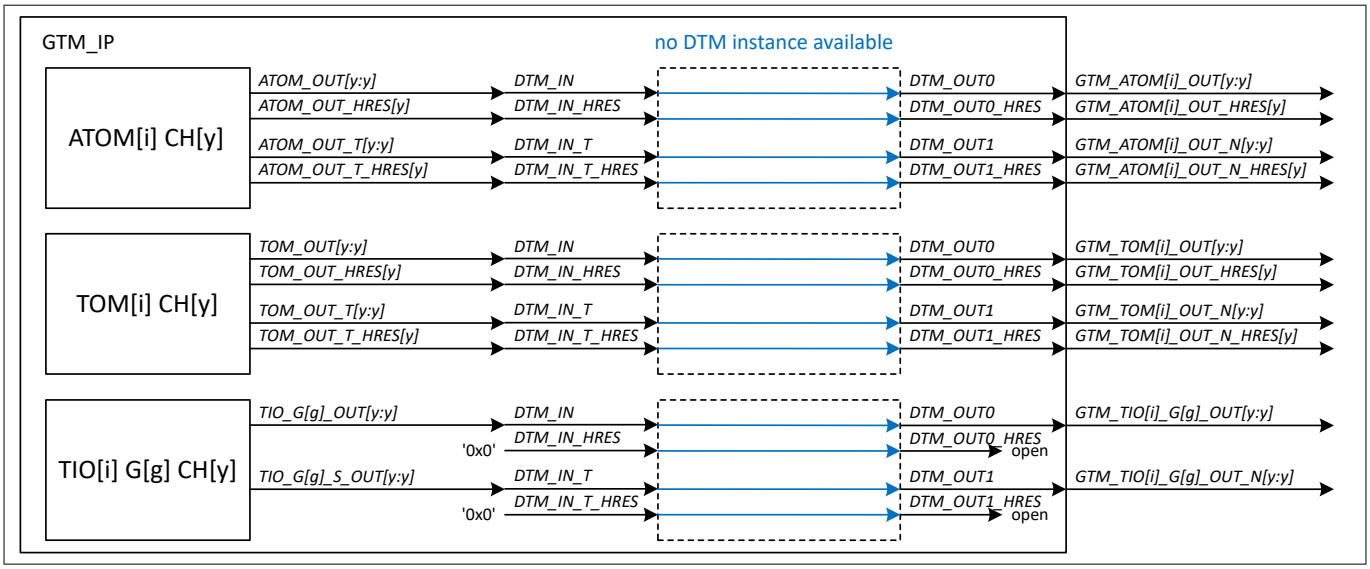

Figure 1118 (A)TOM output signal routing in case of no DTM instance available

***Note**: The figures above Figure 1117 and Figure 1118 show only the routing without implemented register stages.*

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

44.3.1.9.11 DTM signal description

Table 2252 DTM Signals

Name	Description
CLK_RES	clock resolution signal in use in **DTM** module
COUT	signal used for multiple output signal combination feature; bit x of signal vector is output of channel x to be able to combine it with further signals of channel x+1
CH_OUT_I	signal used for multiple output signal combination feature; input signal off a **DTM** channel
CH_OUT_O	signal used for multiple output signal combination feature; output signal off a **DTM** channel
PSU_SHIFT	signal of phase shift unit to be used inside **DTM** channels; signal PSU_SHIFT[x:x] used by corresponding channel [x]
IN_EDGE	signal of each channel [x] to trigger a reload of counter BLK_DOWN_CNT or trigger an update of a register from a shadow register
DTM_IN_PREV	**DTM** channel input signal from a previous channel
DTM_IN_PREV_HRES[x]	**DTM** channel dtm_in high-resolution signal from a previous channel
DTM_IN_FEDGE	signal of each channel [x]; only for channel [0] the signal is routed to DTM_IN0_FEDGE
DTM_IN_REDGE	signal of each channel [x]; only for channel [0] the signal is routed to DTM_IN0_REDGE
DTM_CH_F_IN	input signal of channel [x] used with cross channel dead-time feature
DTM_CH_F_OUT	output signal of channel [x] used with cross channel dead-time feature
DTM_IN_HRES	**DTM** channel dtm_in high-resolution signal from (A)**TOM**

(table continues...)

Table 2252 (continued) DTM Signals

Name	Description
IN[x]_SIG	signal of channel [x] after the first two multiplexers on which the edge detection for signal IN_EDGE is done
EDGE_TRIGG_[x]	signal of channel [x] which shows if the selected input source has an edge
CII[x]_MUX	signal of channel [x] which is the multiplexer output which is in front of the **XOR** and **AND** gates for the combinational feature of the channel
IN[x]_DLY1	selected input source signal of channel [x] one clock-cycle delayed; used for edge detection
IN[x]_DLY2	selected input source signal of channel [x] two clock-cycle delayed; used for edge detection
IN[x]_RISE_PULSE	signal of **DTM** channel [x] that a rising edge at the input occurs
IN[x]_FALL_PULSE	signal of **DTM** channel [x] that a falling edge at the input occurs
IN[x]_RISE	signal of **DTM** channel after a dead-time insertion for a rising edge
IN[x]_FALL	signal of **DTM** channel after a dead-time insertion for a falling edge
DTM_AUX_IN0	signal used for feature phase shift or to be (N)**AND**/(N)**OR**/ X(N)**OR** combined with further channel signals
DTM_AUX_IN1	signal used for feature phase shift or to be (N)**AND**/(N)**OR**/ X(N)**OR** combined with further channel signals
PSU_SHUT_OFF	output signal of phase shift unit used for feature shutoff of channel x
SHUTOFF_SYNC_0	signal used by individual channel shutoff feature of channel 0
SHUTOFF_SYNC_1	signal used by individual channel shutoff feature of channel 1
SHUTOFF_SYNC_2	signal used by individual channel shutoff feature of channel 2
SHUTOFF_SYNC_3	signal used by individual channel shutoff feature of channel 3
BLK_DOWN_CNT	output signal of blanking window counter DOWN COUNTER
DT_DOWN_CNT	output signal of dead-time counter DT_DOWN_CNT

44.3.1.10 Sensor pattern evaluation (SPE)

44.3.1.10.1 Overview

The Sensor Pattern Evaluation (**SPE**) sub-module can be used to evaluate three hall sensor inputs and together with the **TOM** module to support the drive of BLDC engines. Thus, the input signals are filtered already in the connected **TIM** channels. The integration of the **SPE** sub-module into the overall **eGTM** architecture concept is shown in Figure 1119.

Indices and their range as used inside this chapter are:

- i:={0, 1,..., NSPE-1} instance index of cluster / **SPE** module
- x, y, z channel index (x !=y!=z)
- t:={0, 1,..., 7} index of input pattern
- p:={0, 1,..., 7} index for pattern
- o:={0, 1,..., 7} index for output pattern

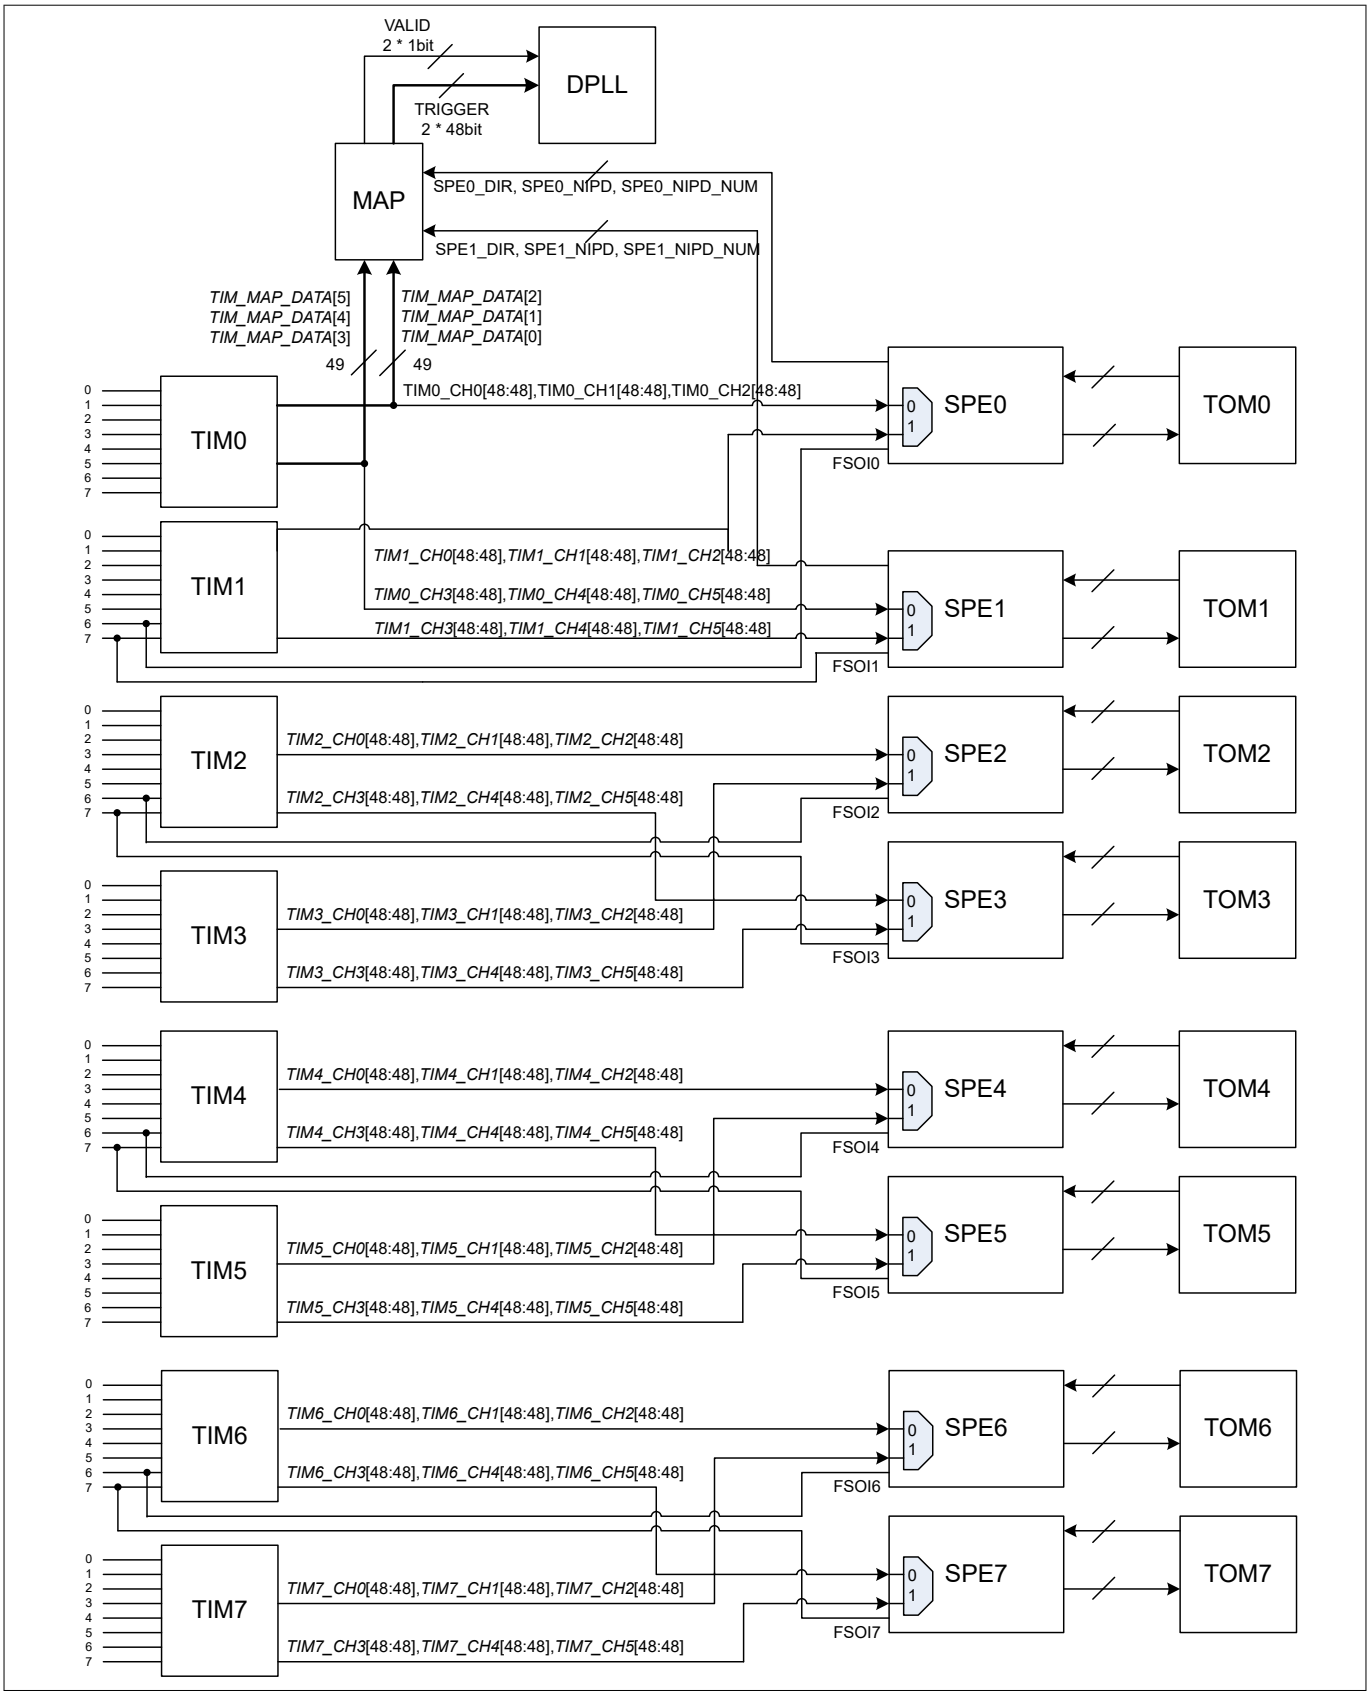

Figure 1119 SPE sub-module integration concept into eGTM

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

The **SPE** sub-module can determine a rotation direction out of the combined TIM[i]_CH[x:x], TIM[i]_CH[y:y] and TIM[i]_CH[z:z] signals. On this input signals a pattern match algorithm is applied on behalf of the temporal relation between these input patterns. A possible sample pattern of the three input signals is shown in Figure 1120. In general, the input pattern is programmable within the **SPE** sub-module.

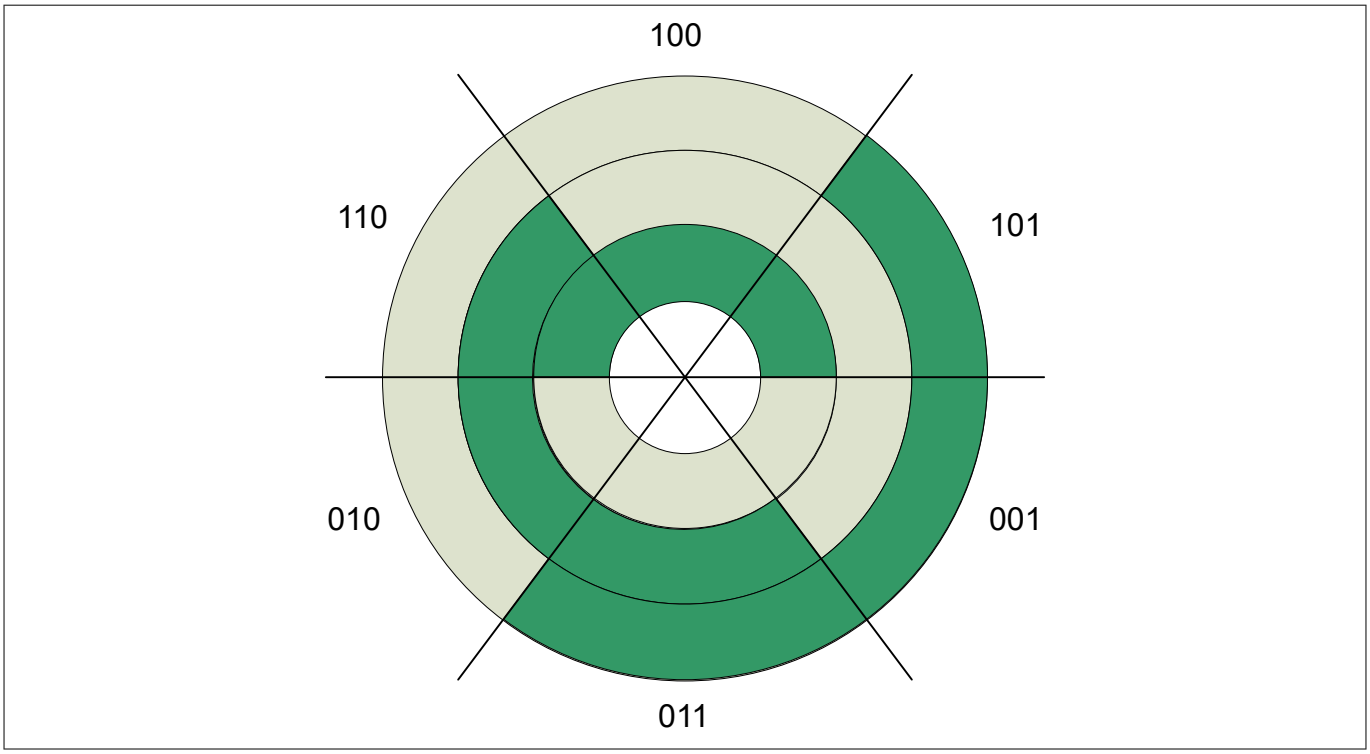

Figure 1120 SPE sample input pattern

In Figure 1120 the input signals define the pattern from the input sensors which have a 50% high and 50% low phase. The pattern according to Figure 1120 is as follows:

100 - 110 - 010 - 011 - 001 - 101 - 100

Where the first bit (smallest circle) represents TIM[i]_CH[x:x], the second bit represents TIM[i]_CH[y:y], and the third bit (greatest circle) represents TIM[i]_CH[z:z].

***Note**: The **SPE** module expects that with every new pattern only one of the three input signals changes its value.*

44.3.1.10.2 SPE sub-module description

The **SPE** sub-module can handle sensor pattern inputs. Every time if one of the input signals TIM[i]_CH[x:x], TIM[i]_CH[y:y] or TIM[i]_CH[z:z] changes its value, a sample of all three input signals is made. Derived from the sample of the three inputs the encoded rotation direction and the validity of the input pattern sequence is determined and signaled. When a valid input pattern is detected, the **SPE** sub-module can control the outputs of a dedicated connected **TOM** sub-module. This connection is shown in Figure 1121.

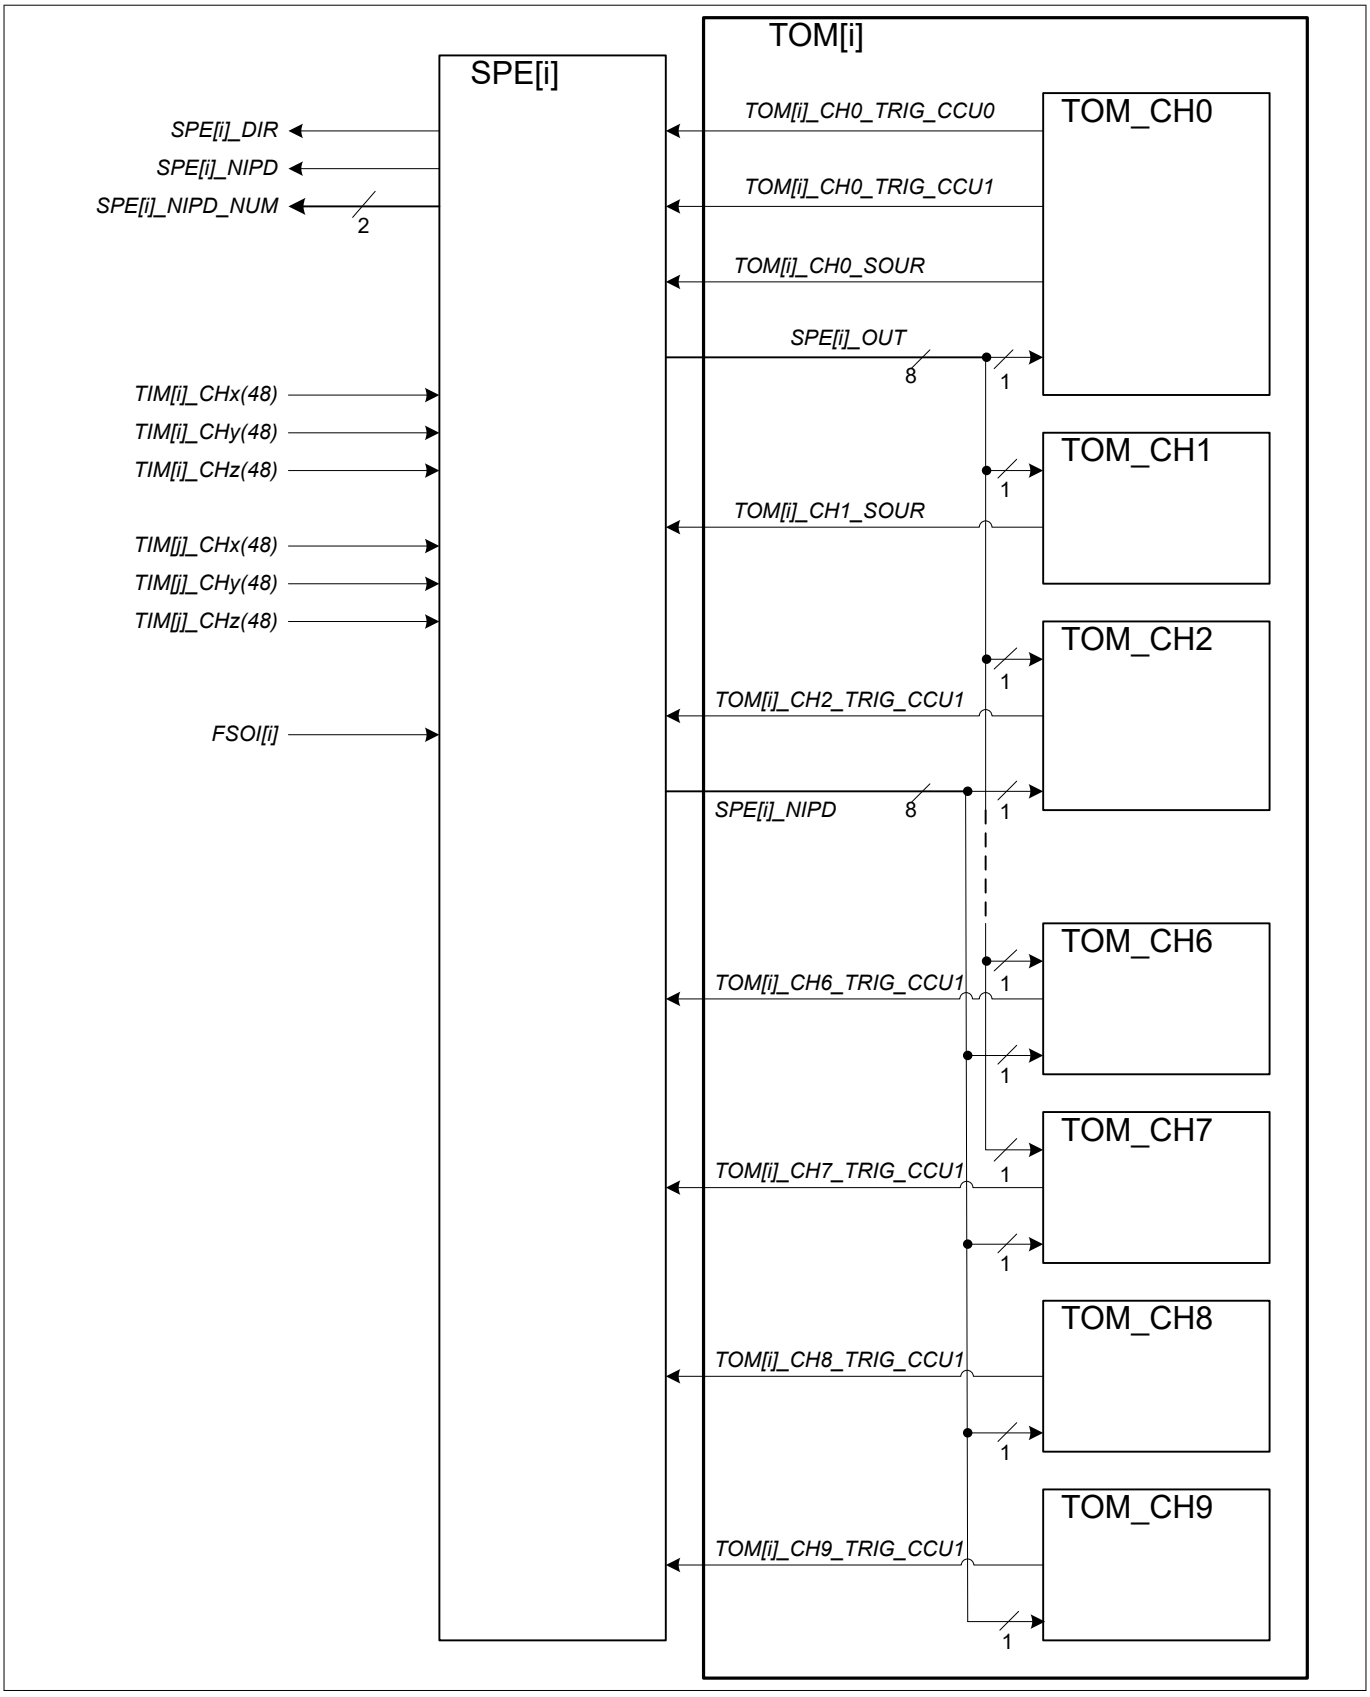

Figure 1121 SPE to TOM connections

The TOM[i]_CH[x]_TRIG_CCU0, TOM[i]_CH[x]_TRIG_CCU1 and TOM[i]_CH[x]_SOUR signal lines are used to evaluate the current state of the **TOM** outputs, whereas the SPE[i]_OUT output vector is used to control the

TOM output depending on the new input pattern. The SPE[i]_OUT output vector is defined inside the **SPE** sub-module in a pattern definition table CLSi_SPE_OUT_PATp. The internal **SPE** sub-module architecture is shown in Figure 1122.

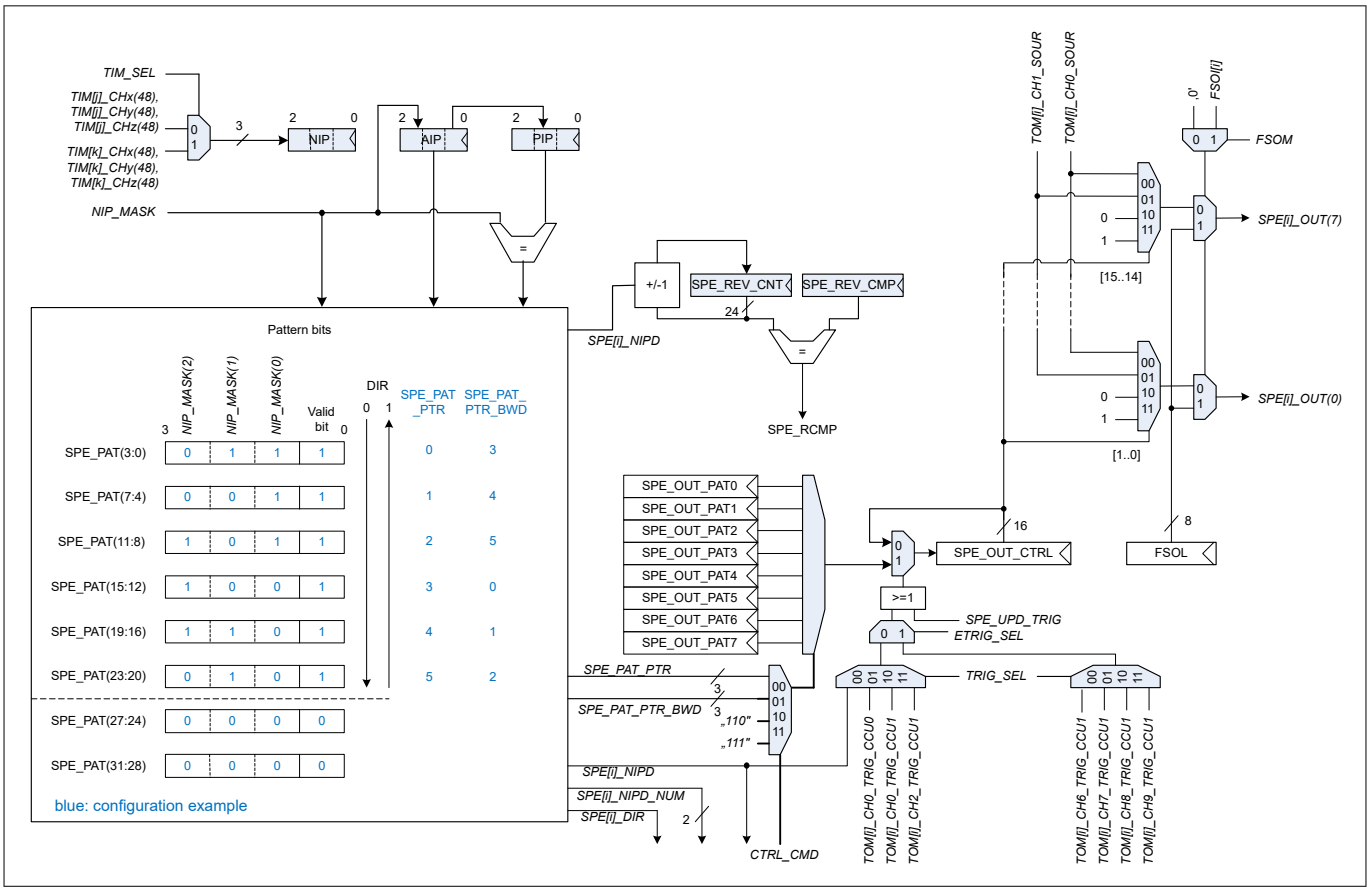

Figure 1122 SPE sub-module architecture

The CLSi_SPE_PAT register holds the valid input pattern for the three input patterns TIM[i]_CH[x:x], TIM[i]_CH[y:y] and TIM[i]_CH[z:z]. The input pattern is programmable. The valid bit shows if the programmed pattern is a valid one. Figure 1122 shows the programming of the CLSi_SPE_PAT register for the input pattern defined in Figure 1120.

The rotation direction is determined by the order of the valid input pattern. This rotation direction defines if CLSi_SPE_CTRL_STAT.SPE_PAT_PTR is incremented or decremented . Whenever a valid input pattern is detected, the SPE[i]_NIPD signal is raised, the CLSi_SPE_CTRL_STAT.SPE_PAT_PTR is incremented/ decremented and a new output control signal SPE[i]_OUT[x:x] is sent to the corresponding **TOM** sub-module.

To command directly the forward or backward rotation the **SPE** provides with CLSi_SPE_CTRL_STAT.SPE_PAT_PTR and CLSi_SPE_CTRL_STAT2.SPE_PAT_PTR_BWD two pointers to array CLSi_SPE_OUT_PATp. Both can point to different values of CLSi_SPE_OUT_PATp at the same point in time. CLSi_SPE_CTRL_STAT.SPE_PAT_PTR is intended to point to the pattern for forward commanding and CLSi_SPE_CTRL_STAT2.SPE_PAT_PTR_BWD is intended to point to the pattern for backward commanding.

On startup, both pointers have to be configured to an initial value that corresponds to different direction depending on the start pattern of CLSi_SPE_OUT_PATp.

With each valid new input pattern indicated by SPE[i]_NIPD , both pointers will be incremented or decremented according to the detected direction.

Switching from forward command to backward command can then be done by changing the selected pointer to CLSi_SPE_OUT_PATp array, i.e. changing CLSi_SPE_CMD.SPE_CTRL_CMD from selecting CLSi_SPE_CTRL_STAT.SPE_PAT_PTR to selecting CLSi_SPE_CTRL_STAT2.SPE_PAT_PTR_BWD or vice versa.

The intended behavior is depicted in the following figure:

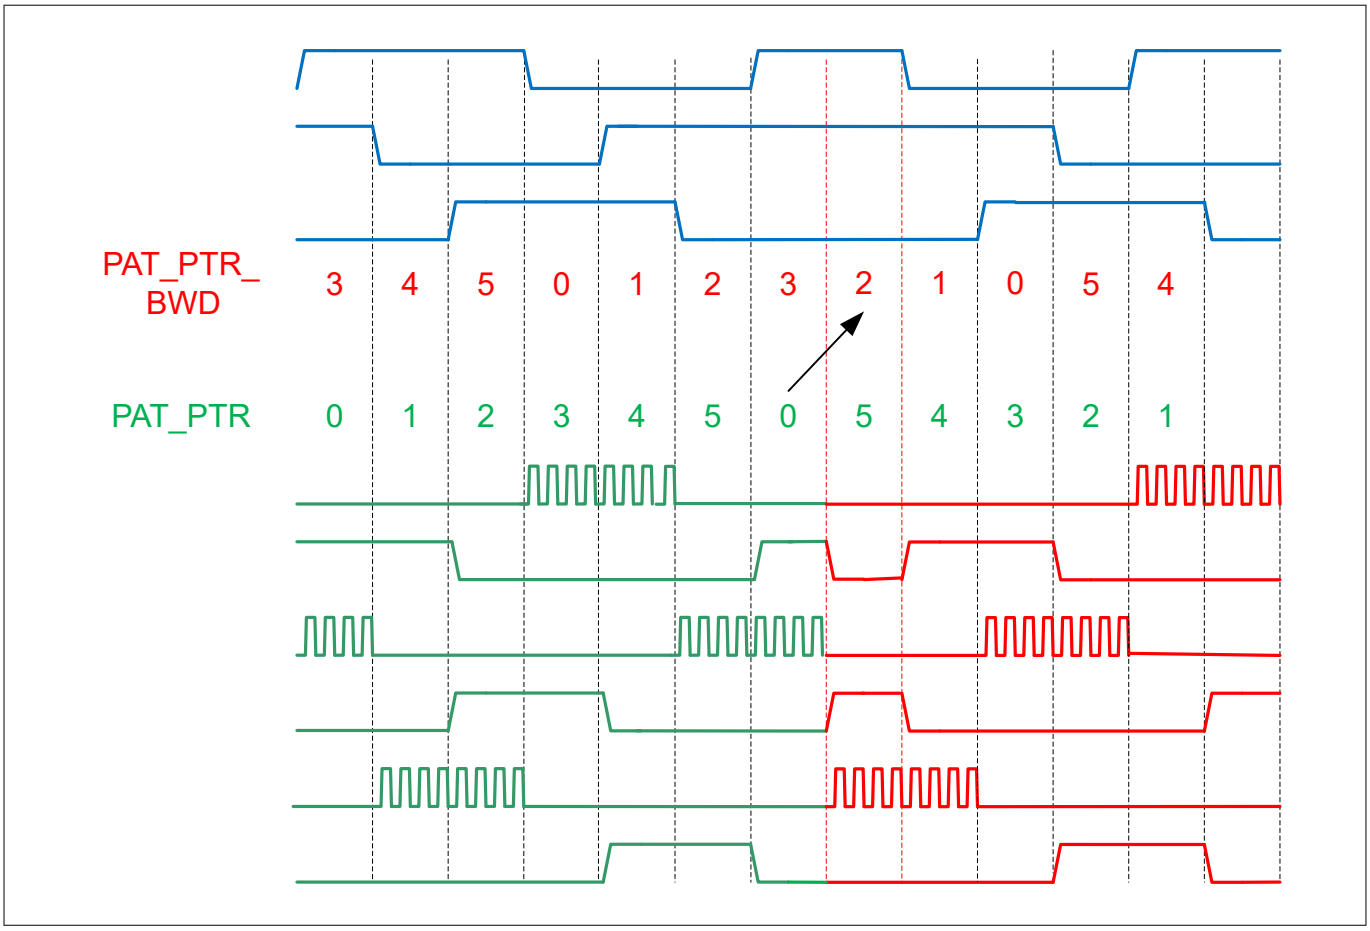

Figure 1123 SPE forward-backward commanding

With command CLSi_SPE_CMD.SPE_CTRL_CMD = 10_B or 11_B a dedicated configurable output pattern configured to the pattern CLSi_SPE_OUT_PATp.SPE_OUT_PATo (o=0-7) **(o=6)** or CLSi_SPE_OUT_PATp.SPE_OUT_PATo (o=0-7) **(o=7)** can be commanded to the outputs.

An example is the introduction of a SW dead-time if switching from pointer CLSi_SPE_CTRL_STAT.SPE_PAT_PTR to CLSi_SPE_CTRL_STAT2.SPE_PAT_PTR_BWD or vice versa. E.g. if in CLSi_SPE_OUT_PATp **(p=6)** the value 10_B is programmed for each output (i.e. set SPE[i]_OUT[n:n] to 0), this can be used as an intermediate step to introduce this 'all off' when switching between CLSi_SPE_CTRL_STAT.SPE_PAT_PTR to CLSi_SPE_CTRL_STAT2.SPE_PAT_PTR_BWD or vice versa.

Selectable by CLSi_SPE_CTRL_STAT.TRIG_SEL and CLSi_SPE_CTRL_STAT.ETRIG_SEL the CCU1 trigger of either the **TOM** channel z (z∈{2, 6, 7, 8, 9}) can be used together with the **SPE** module to trigger a delayed update of the CLSi_SPE_OUT_CTRL.SPE_OUT_CTRLo (o=0-7) register after new input pattern detected by **SPE** (signaled by SPE[i]_NIPD).

To do this, the **TOM** channel z (z∈{2, 6, 7, 8, 9}) has to be configured to work in one-shot mode (set bit CLSi_TOM_CHx_CTRL.OSM **(x=z)**). The **SPE** trigger of this channel has to be enabled too (set description of bit CLSi_TOM_CHx_CTRL.SPEM **(x=z)** and bit CLSi_TOM_CHx_CTRL.SPE_TRIG **(x=z)**). The **SPE** module has to be configured to update CLSi_SPE_OUT_CTRL.SPE_OUT_CTRLo (o=0-7) on TOM[i]_CH[x]_TRIG_CCU1 (set in CLSi_SPE_CTRL_STAT bits CLSi_SPE_CTRL_STAT.TRIG_SEL to 11_B). Then, on new input detected by **SPE**, the signal SPE[i]_NIPD triggers the start of the **TOM** channel z to generate one PWM period by resetting CLSi_TOM_CHx_CN0.CN0 to 0. On second PWM edge triggered by CCU1 of **TOM** channel z, the signal TOM[i]_CH[x]_TRIG_CCU1 triggers the update of CLSi_SPE_OUT_CTRL.SPE_OUT_CTRLo (o=0-7). Be aware, that setting **TOM** CCU1 compare register CLSi_TOM_CHx_CM1.CM1 to a value of '0' will not trigger an update of the CLSi_SPE_OUT_CTRL.SPE_OUT_CTRLo (o=0-7) register.

The update of CLSi_SPE_OUT_CTRL with the content of one of the CLSi_SPE_OUT_PATp.SPE_OUT_PATo (o=0-7) register field can be triggered at any time by writing a 1 to bit CLSi_SPE_CMD.SPE_UPD_TRIG.

The regular trigger for update of CLSi_SPE_OUT_CTRL (commutation trigger) is selected by CLSi_SPE_CTRL_STAT.TRIG_SEL and CLSi_SPE_CTRL_STAT.ETRIG_SEL.

According to Figure 1122, the two input patterns 000_B and 111_B are not allowed combinations and will end in a SPE[i]_PERR interrupt. These two patterns can be used to determine a sensor input error. A SPE[i]_PERR interrupt will also be raised, if the input patterns occur in a wrong order, e.g. if the pattern 010_B does not follow the pattern 110_B or 011_B.

The CLSi_SPE_CTRL_STAT bit field is implemented inside the CLSi_SPE_CTRL_STAT register, where the input pattern history is stored by the **SPE** sub-module. The CPU can determine a broken sensor when the SPE[i]_PERR interrupt occurs by analyzing the bit pattern readable via bit field CLSi_SPE_CTRL_STAT.NIP inside the CLSi_SPE_CTRL_STAT register. The input pattern in the CLSi_SPE_CTRL_STAT register is updated whenever a valid edge is detected on one of the input lines TIM[i]_CH[x:x], TIM[i]_CH[y:y] or TIM[i]_CH[z:z]. The pattern bit fields are then shifted. The input pattern history generation inside the CLSi_SPE_CTRL_STAT register is shown in Figure 1124.

In addition to the sensor pattern evaluation, the **SPE** module also provides the feature of fast shutoff for all **TOM** channels controlled by the **SPE** module. The feature is enabled by setting bit CLSi_SPE_CTRL_STAT.FSOM. The fast shutoff level itself is defined in the bit field CLSi_SPE_CTRL_STAT.FSOL of register CLSi_SPE_CTRL_STAT. The **TIM** input used to trigger the fast shutoff is either **TIM** channel 6 or **TIM** channel 7 depending on the **TIM** instance connected to the **SPE** module. For details of connections please refer to Figure 1119.

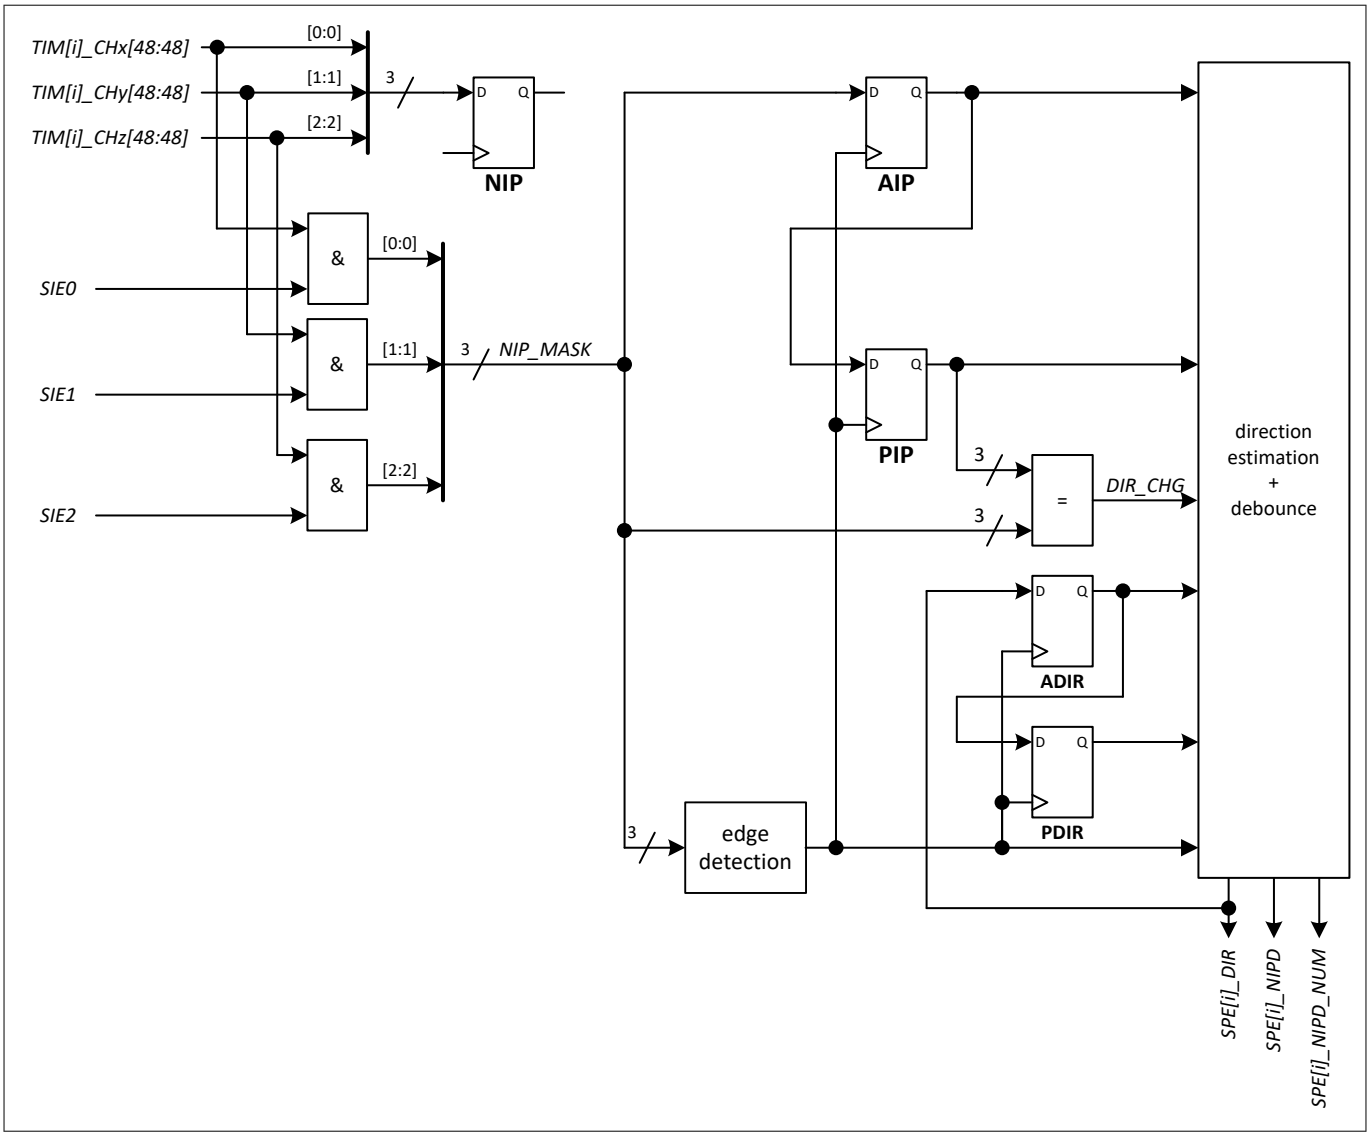

Figure 1124 CLSi_SPE_CTRL_STAT **register representation**

The CPU can disable one of the three input signals, e.g. when a broken input sensor was detected, by disabling the input with the three input enable bits CLSi_SPE_CTRL_STAT.SIEk (k=0-2).

Whenever at least one of the input signals TIM[i]_CH[x:x], TIM[i]_CH[y:y] or TIM[i]_CH[z:z] changes, the **SPE** sub-module stores the new bit pattern in an internal register bit field CLSi_SPE_CTRL_STAT.NIP (New Input Pattern). If the current input pattern in CLSi_SPE_CTRL_STAT.NIP is the same as in the previous input pattern (CLSi_SPE_CTRL_STAT.PIP) the direction of the engine is changed, the SPE[i]_DCHG interrupt is raised, the direction change is stored internally and the pattern in the CLSi_SPE_CTRL_STAT.PIP bit field is filled with the CLSi_SPE_CTRL_STAT.AIP bit field and the CLSi_SPE_CTRL_STAT.AIP bit field is filled with the CLSi_SPE_CTRL_STAT.NIP bit field. The CLSi_SPE_CTRL_STAT.ADIR bit inside the CLSi_SPE_CTRL_STAT register is toggled.

If the **SPE** encounters that with the next input pattern, new input pattern CLSi_SPE_CTRL_STAT.NIP again detects the change in direction, the input signal is categorized as bouncing and the bouncing input signal interrupt SPE[i]_BIS is raised.

Immediately after update of register bit field CLSi_SPE_CTRL_STAT.NIP, when the new detected input pattern doesn't match the CLSi_SPE_CTRL_STAT.PIP pattern (i.e. no direction change was detected), the **SPE** shifts the value of register CLSi_SPE_CTRL_STAT.AIP to register CLSi_SPE_CTRL_STAT.PIP and the value of register CLSi_SPE_CTRL_STAT.NIP to register CLSi_SPE_CTRL_STAT.AIP. The SPE[i]_NIPD interrupt is raised.

If a sensor error was detected, the CPU has to define the pattern in the CLSi_SPE_CTRL_STAT register, which input line comes from the broken sensor. The faulty signal line has to be masked by the CPU and the **SPE** sub-module determines the rotation direction on behalf of the two remaining TIM[i]_CH[x:x] input lines.

The pattern history can be determined by the CPU by reading the two bit fields CLSi_SPE_CTRL_STAT.AIP and CLSi_SPE_CTRL_STAT.PIP of the CLSi_SPE_CTRL_STAT register. The CLSi_SPE_CTRL_STAT.AIP register field holds the current input pattern at TIM[i]_CH[x:x], TIM[i]_CH[y:y] and TIM[i]_CH[z:z] and the CLSi_SPE_CTRL_STAT.PIP holds the previous pattern.

After reset the register fields CLSi_SPE_CTRL_STAT.NIP, CLSi_SPE_CTRL_STAT.AIP and CLSi_SPE_CTRL_STAT.PIP as well as the registers CLSi_SPE_CTRL_STAT.SPE_PAT_PTR and CLSi_SPE_OUT_CTRL will not contain valid startup values which would allow correct behavior after enabling **SPE** and detecting the first input patterns.

Thus, it is necessary to initialize these registers to correct values.

To do this, before enabling the **SPE**, the bit field CLSi_SPE_CTRL_STAT.NIP can be read and depending on this value the initialization values for the register fields CLSi_SPE_CTRL_STAT.AIP, CLSi_SPE_CTRL_STAT.PIP, CLSi_SPE_CTRL_STAT.SPE_PAT_PTR and CLSi_SPE_OUT_CTRL can be determined.

SPE revolution detection

The **SPE** sub-module is able to detect and count the number of valid input patterns detected at the specified input ports. This is done with a 24-bit revolution counter CLSi_SPE_REV_CNT.REV_CNT. The counter is incremented by a value of one (1) when a new valid input pattern indicating forward direction is detected. The counter is decremented by a value of one (1) when a new valid input pattern indicating backward direction is detected.

In addition, there exists a 24-bit CLSi_SPE_REV_CMP register. The user can initialize this register with a compare value, where an interrupt SPE[i]_RCMP is raised, when the revolution counter equals the compare value either in forward or backward direction.

Both registers may be written by software at any time.

44.3.1.11 Interrupt concentrator module (ICM)

44.3.1.11.1 Overview

The Interrupt Concentrator Module (**ICM**) is used to group (bundle) the **eGTM** interrupt lines of the individual sub-modules into interrupt groups. By bundling, a smaller number of interrupt lines is visible at the outside of the **eGTM**.

The individual interrupts of the **eGTM** sub-modules and channels have to be enabled or disabled inside the sub-modules and channels.

The feed-through architecture of bundled interrupt lines is used for the sub-modules **AEI**, **CMP**, **SPE**, **TIM**, **TOM**, **ATOM**.

To determine the detailed interrupt source the microcontroller has to read the sub-module/channel interrupt notification register NOTIFY and serve the channel individual interrupt.

***Note**: The interrupts are only visible inside the **ICM** and in consequence outside of the **eGTM**, when the interrupt is enabled inside the sub-modules themselves.*

Indices and their range as used inside this chapter are:

- j:={0, 1,..., NModule-1} instance index of module NModule:={NTOM, NATOM, NSPE}
- x = channel index in a module (**TOM** / **ATOM** / **SPE**)
- g = index for dedicated register groups

44.3.1.11.2 Bundling

The **eGTM** sub-module individual interrupt sources are connected to the **ICM**. There, the individual interrupt lines are either fed through and signaled to the outside world or bundled a second time and signaled to the outside world.

The **ICM** interrupt bundling is described in the following sections:

eGTM infrastructure interrupt bundling

The first interrupt group contains interrupts of the infrastructure and safety components of the **eGTM**. This interrupt group therefore includes interrupt lines coming from the **AEI**, **SPE** and **CMP** sub-modules. In this interrupt group each individual channel of the sub-modules has its own interrupt line to the outside world.

Thus, the active interrupt line can be used by the CPU to determine the **eGTM** sub-module channel that raised the interrupt. The interrupts are also represented in the CLSi_ICM_IRQG_0 register. This register is typically not read by the CPU, but it is readable.

The interrupt line status for each **SPE** is shown in the CLSi_ICM_IRQG_SPE_CI register. Typically, the interrupt source determined by the corresponding interrupt line and the CLSi_ICM_IRQG_SPE_CI register is typically not read out by the CPU, but is readable.

TIM interrupt bundling

Inside this group, sub-modules which handle **eGTM** input signals are treated. This is the case for the **TIM[j]** sub-modules. Each **TIM** sub-module channel is able to generate 6 individual interrupts if enabled inside the **TIM** channel. These six interrupts are bundled into one interrupt per **TIM** channel connected to the **ICM**.

The **ICM** performs no further bundling. Thus for the **eGTM**, 8 interrupt lines per **TIM** module are provided. The channel responsible for the interrupt can be determined by the raised interrupt line.

In addition, the registers CLSi_ICM_IRQG_2 are mirrors for the **TIM** sub-module channel interrupts and typically not read out by the CPU, but they are readable.

TOM and ATOM interrupt bundling

For the **TOM** and **ATOM** sub-modules, the interrupts are bundled within the **ICM** sub-module a second time to reduce external interrupt lines. The interrupts are **OR**ed in a manner that one **eGTM** external interrupt line represents two adjacent **TOM** or **ATOM** channel interrupts. For **TOM[j]** and **ATOM[j]** the bundling is as shown in Table 2261.

Table 2261 ATOM interrupt bundling within ICM

ATOM[j] input IRQs	ATOM-output IRQs (OR-ed)
ATOM[j]_CH0_IRQ or ATOM[j]_CH1_IRQ	(e)GTM_ATOM[i]_IRQ[0:0]
ATOM[j]_CH2_IRQ or ATOM[j]_CH3_IRQ	(e)GTM_ATOM[i]_IRQ[1:1]
ATOM[j]_CH4_IRQ or ATOM[j]_CH5_IRQ	(e)GTM_ATOM[i]_IRQ[2:2]
ATOM[j]_CH6_IRQ or ATOM[j]_CH7_IRQ	(e)GTM_ATOM[i]_IRQ[3:3]

Table 2262 TOM interrupt bundling within ICM

TOM[j]-input IRQs	TOM-output IRQs (OR-ed)
TOM[j]_CH0_IRQ or TOM[j]_CH1_IRQ	(e)GTM_TOM[i]_IRQ[0:0]
TOM[j]_CH2_IRQ or TOM[j]_CH3_IRQ	(e)GTM_TOM[i]_IRQ[1:1]
TOM[j]_CH4_IRQ or TOM[j]_CH5_IRQ	(e)GTM_TOM[i]_IRQ[2:2]
TOM[j]_CH6_IRQ or TOM[j]_CH7_IRQ	(e)GTM_TOM[i]_IRQ[3:3]
TOM[j]_CH8_IRQ or TOM[j]_CH9_IRQ	(e)GTM_TOM[i]_IRQ[4:4]
TOM[j]_CH10_IRQ or TOM[j]_CH11_IRQ	(e)GTM_TOM[i]_IRQ[5:5]
TOM[j]_CH12_IRQ or TOM[j]_CH13_IRQ	(e)GTM_TOM[i]_IRQ[6:6]
TOM[j]_CH14_IRQ or TOM[j]_CH15_IRQ	(e)GTM_TOM[i]_IRQ[7:7]

The interrupts coming from the **TOM[j]** sub-modules are registered in the CLSi_ICM_IRQG_TOMg_CI register. Two **TOM**s are always bundled in one **ICM** register for e.g., TOM0 and TOM1 are bundled in CLSi_ICM_IRQG_TOMg_CI. To identify the **TOM** sub-module channel in which the interrupt occurred, the CPU has to read out the CLSi_ICM_IRQG_TOMg_CI register first before it goes to the **TOM** sub-module channel itself.

The CLSi_ICM_IRQG_TOMg_CI register bits are cleared automatically when their corresponding interrupt in the sub-module channels is cleared.

The interrupts coming from the **ATOM[j]** sub-modules are registered in the CLSi_ICM_IRQG_ATOMg_CI register. Four **ATOM**s are bundled in one **ICM** register for e.g., ATOM0, ATOM1, ATOM2 and ATOM3 are bundled in CLSi_ICM_IRQG_ATOMg_CI. To identify the **ATOM** sub-module channel in which the interrupt occurred, the CPU has to read out the CLSi_ICM_IRQG_ATOMg_CI register first before it goes to the **ATOM** sub-module channel itself.

The CLSi_ICM_IRQG_ATOMg_CI register bits are cleared automatically when their corresponding interrupt in the sub-module channels is cleared.

The interrupt line status of two 16 channel **TOM**s is shown in each CLSi_ICM_IRQG_TOMg_CI register. TOM0 and TOM1 are bundled in CLSi_ICM_IRQG_TOMg_CI **(g=0)**. The interrupt source is determined by the corresponding interrupt line and the CLSi_ICM_IRQG_TOMg_CI registers are typically not read out by the CPU, but they are readable.

The interrupt line status of four 8 channel **ATOM**s is shown in each CLSi_ICM_IRQG_ATOMg_CI register, ATOM0, ATOM1, ATOM2 and ATOM3 are bundled in CLSi_ICM_IRQG_ATOMg_CI **(g=0)**. Typically, the interrupt source is determined by the corresponding interrupt line and the CLSi_ICM_IRQG_ATOMg_CI registers are typically not read out by the CPU, but they are readable.

Module error interrupt bundling

The Module Error Interrupt group handles the error interrupts coming from the **TIM**, **SPE**, **CMP** sub-modules of the **eGTM**. The Module Error interrupts are additionally identified in the CLSi_ICM_IRQG_MEI error interrupt group register. This register is typically not read out by the CPU, but it is readable.

In addition, the error interrupt line status for each **SPE** is shown in the CLSi_ICM_IRQG_SPE_CEI register. Typically, the error interrupt source is determined by the corresponding interrupt line and the CLSi_ICM_IRQG_SPE_CEI register is not read out by the CPU, but it is readable.

TIM channel error interrupt bundling

The **TIM** Channel Error Interrupt group handles the error interrupts coming from the **TIM** channel of the **eGTM**. The **TIM** Channel Error interrupts are additionally identified for the sub-modules TIM0, TIM1, TIM2 and TIM3 in the CLSi_ICM_IRQG_CEI1 error interrupt group register. These registers are typically not read out by the CPU, but they are readable.

The CLSi_ICM_IRQG_CEI1 register bits are cleared automatically, when their corresponding error interrupt in the sub-module channel is cleared.

Error interrupt cluster bundling

The Error Interrupt lines of up to 4 clusters are bundled in each CLSi_ICM_IRQG_CLSg_MEI.

Actually each cluster collects one EIRQ of one **TIM**, **SPE**.

These registers are typically not read out by the CPU, but they are readable.

44.3.1.11.3 ICM toplevel interrupt signals

In the **ICM** module each toplevel interrupt signal is pipelined with a single stage register, which operates on the **eGTM** clock CLK.

The above table shows the **eGTM** interrupt lines that are visible outside of the **eGTM**.

44.3.1.12 Output compare unit (CMP)

44.3.1.12.1 Overview

The Output Compare Unit (**CMP**) is designed for the use in safety relevant applications. The main idea is to have the possibility to duplicate outputs in order to be compared in this unit. Because of the simple EXOR function used, it is necessary to ensure the total cycle accurate output behavior of the output modules to be compared. This is given when two neighboring **DTM** channels (e.g. CDTM0_DTM4_CH0_OUT and CDTM0_DTM4_CH1_OUT, for neighboring **DTM** channel pairs see Table 2272) generate identical signals with phase shift zero at their outputs. This can be reached if they start their output generation at the same time. This start of synchronization is possible by means of the trigger mechanisms provided by the **TOM** or **ATOM** as shown in the **TOM** Timer output module (**TOM**) or **ATOM** **ARU**-connected timer output module (**ATOM**).

Indices and their range as used inside this chapter are:

- i:={0, 1, 2} (index of cluster or module instance)
- c:={0, 1,..., 11} (index of bitwise comparators)
- d:={0, 1,..., 5} (index of **DTM** unit after **TOM**/ **ATOM**)
- x:={0, 1, 2} (index of output channel in **DTM**)

The **CMP** enables the comparison of 2x24 channels of the CDTM[i]_DTM[d] instances and is to neighboring channels. The first 24 **CMP** channels are the 24 **DTM** channels placed behind **TOM[0]** and **TOM[1]** instances and the second 24 **CMP** channels are the 24 **DTM** channels placed behind the **ATOM[0]**, **ATOM[1]** and **ATOM[2]** instances.

***Note**: In case the cluster 1 is operating on half **eGTM** system clock CLK and signals in cluster 0 or 2 are generated on a **eGTM** system clock CLK resolution, a deviation of the compare signals by one CLK clock cycle might not be detected by the bitwise compare unit.*

TBWC11	CDTM1_DTM1_CH2_OUT	CDTM1_DTM1_CH3_OUT

44.3.1.12.3 Configuration of the compare unit

Because of the restrictions described in the section above, the Compare Unit consists of 24 antivalence (EXOR) elements, a select register CLSi_CMP_EN which selects the corresponding comparisons and a status register CLSi_CMP_IRQ_NOTIFY which shows and stores each mismatching result, when selected.

For each mismatching error enabled with CLSi_CMP_IRQ_EN an interrupt signal on CMP_IRQ is generated.

For each mismatching error enabled with CLSi_CMP_EIRQ_EN an interrupt signal on CMP_EIRQ is generated.

44.3.1.12.4 Error generator

The error generator generates an error signal to be transmitted to the **MON** unit directly and independent of the CMP_IRQ and CMP_EIRQ. The error is set when in the CLSi_CMP_IRQ_NOTIFY register at least one bit is set. The CLSi_CMP_IRQ_NOTIFY bits are not maskable for this purpose.

Additionally, CMP_ERR is a primary output port for interrupt actions by CPU itself.

44.3.1.12.5 CMP interrupt signals

The **CMP** sub-module has two interrupt signals, one normal interrupt and one error interrupt. The source of both interrupts can be determined by reading the CLSi_CMP_IRQ_NOTIFY register under consideration of the registers CLSi_CMP_IRQ_EN and CLSi_CMP_EIRQ_EN. Each source can be forced separately for debug purposes using the interrupt force CLSi_CMP_IRQ_FORCINT register. CLSi_CMP_IRQ_MODE configures interrupt output characteristic. All interrupt modes are described in detail in **eGTM** interrupt concept.

44.3.1.13 Monitor unit (MON)

44.3.1.13.1 Overview

The Monitor Unit (**MON**) is designed for the use in safety relevant applications. The main idea is to have a possibility to supervise commonly used circuitry and resources. In this way the activity of the clocks is supervised. By generation of an activity signal per channel for each such performed comparison, the activity of **TIM** and the used clocks is checked implicitly.

Indices and their range as used inside this chapter are:

- x:={0, 1,..., 7} channel index of **TOM**, **ATOM** channels
- y:={0, 1,..., 4} index for fixed clock for **TOM** FXCLK(y)
- z:={0, 1} index for external clocks ECLK(z)

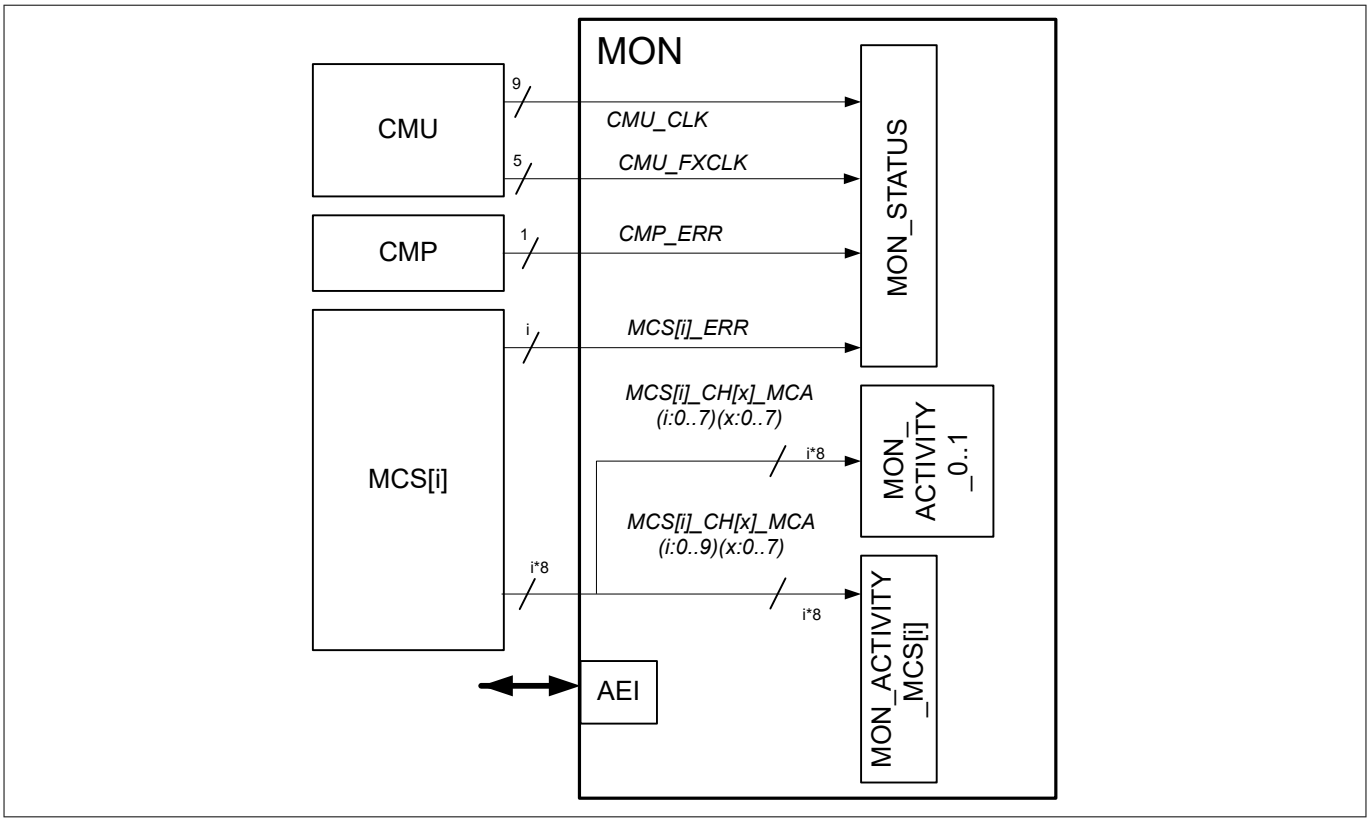

Figure 1126 MON block diagram

***Note**: The figure is a general picture from the IP vendor. The exact configuration can be found in the device specific configuration.*

Realization without activity checker of the clock signals

An activity checker of the clock signals used is not needed because these signals are only enables to be used in combination with the system clock. Therefore, the clock enables are to be checked to have a high value.

44.3.1.13.2 Clock monitoring

The monitor unit has a connection to each of the 9 clocks CCM[i]_CLK_RES, provided by the **CMU**. Some of these clocks can be used for special tasks (see Clock management unit (**CMU**)).

In addition, the 5 clock inputs of the **TOM**s CCM[i]_FXCLK_RES are also connected to the **MON** unit.

The supervising of the clocks is done by scanning for activity of each clock.

A high value is defined as the state to be monitored.

When a high value of the clock enable is detected, the corresponding bit in the status register CLSi_MON_STATUS is set.

The status register bits are reset by writing a one.

When the register is polled by the CPU and the time between two read-accesses is higher than the period of the slowest clock, all bits of the corresponding clocks must have been set.

When polling in shorter time distances, not for all clocks an activity can be shown, although they are still working.

Because of the realization without a select register for the clock signals only the bits of the status register are to be considered for which the clock signal is enabled in the **CMU**.

44.3.1.13.3 CMP error monitoring

The signal CLSi_MON_STATUS.CMP_ERR is to be received directly from module **CMP** and is set if an error occurred.

44.3.1.13.4 MON interrupt signals

The **MON** sub-module has no interrupt signals.

Table 2278 (continued) Acronym definition

Abbreviation	Definition/Meaning
EC	Equivalence Check
FLT	Filter Unit in **TIM** Channel
eGTM	enhanced Generic Timer Module
(E)GTM_AEI	Bus interface bridge (module which converts multiple **AEI** bus protocol variants to **eGTM** internal accesses)
GTM_RM	enhanced Generic Timer Module Reference Model
ICM	Interrupt Concentrator Module
ICPA	Inter cluster pulse adapter
IP	Intellectual Property
IRC	Interrupt Controller
IRQ	Interrupt Request
LBIST	Logic Built-In Self-Test
MON	Monitor Unit
PCM	Pulse Count Modulation
PWM	Pulse Width Modulation
SPE	Sensor Pattern Evaluation
TBU	Time Base Unit
TDTM	**TOM** with **DTM**
TDU	Timeout detection unit in **TIM** channel
TIM	Timer Input Module
TIM_CH	Channel unit in **TIM** module
TOM	Timer Output Module

44.3.1.14.2 eGTM device configuration variables

Table 2279 eGTM device configuration variables, define available module resources

Device configuration variable	Type	Array index definition	Description
ATOM_HIGH_RES	ARRAY[NATOM] of INT	[i]	Number of available high-resolution channels in **ATOM** instance of cluster i.
CDTM	ARRAY[NCDTM] of LIST	[i]	The i-th array member defines the list of **DTM** instances available within the cluster i.

(table continues...)

Table 2279 (continued) eGTM device configuration variables, define available module resources

Device configuration variable	Type	Array index definition	Description
CFG_CLOCK_RATE	INT		Configurable clock rate available.
FAST_CLK_CLS	ARRAY[NCCM] of INT	[i]	0: Cluster i only supports clock frequency divided by 2. 1: Cluster i supports with clock frequency divider 1/2.
INT_CLK_EN_GEN	INT		**eGTM** internal clock enable signals in use.
NATOM	INT		Number of **ATOM** modules.
NCCM	INT		Number of **CCM** modules.
NCDTM	INT		Number of elements in array **CDTM**.
NCMP	INT		Number of **CMP** modules.
NMON	INT		Number of **MON** modules.
NSPE	INT		Number of **SPE** modules.
NTIM	INT		Number of **TIM** modules.
NTOM	INT		Number of **TOM** modules.

Table 2280 eGTM device configuration variables

Device configuration variable	Type	Description
AEI_ADDR_PIPELINE_STAGE	INT	**AEI** address pipeline stage implemented
AEI_RDATA_PIPELINE_STAGE	INT	**AEI** read data pipeline stage implemented
ATOM_OUT_RST	INT	ATOM_OUT reset level.
ATOM_TRIG_CHAIN	INT	Define **ATOM** external trigger chain configuration.
ATOM_TRIG_INTCHAIN	INT	Define **ATOM** internal trigger chain configuration.
AXIS_DATA_WIDTH	INT	AXI slave data bus width.
BRIDGE_BUFF_DPT	INT	Buffer depth of the **eGTM AEI** bridge implementation.
GRSTEN	INT	Global **eGTM** reset register enabled.
IRQ_MODE_RST_VAL	INT	Initial value of **IRQ** mode.

(table continues...)

Table 2280 (continued) eGTM device configuration variables

Device configuration variable	Type	Description
RESET_ACTIVE	INT	Active level of asynchronous reset
SYNC_INPUT_REG	INT	Additional pipelined stage implemented. All accesses in synchronous.
TOM_OUT_RST	INT	TOM_OUT reset level.
TOM_TRIG_CHAIN	INT	Define **TOM** external trigger chain configuration.
TOM_TRIG_INTCHAIN	INT	Define **TOM** internal trigger chain configuration.

Table 2281 eGTM device configuration variables, fixed or derived values

Device configuration variable	Type	Array index definition	Description
ATOM_OUT_N_WITH_DTM	ARRAY[NCDTM][8] of INT	[i][x]	0: Channel x of signal ATOM_OUT_N in cluster i has no **DTM** implemented. 1: Channel x of signal ATOM_OUT_N in cluster i has a **DTM** implemented.
GTM_REV_DEVICE_CODE	INT		Device encoding digit.
GTM_REV_REL_BASE	INT		**eGTM** release base.
GTM_REV_REL_ITER	INT		**eGTM** release iteration.
GTM_REV_VENDOR_CODE	INT		Vendor encoding digit.
GTM_REV_VER_MAJOR	INT		Define major version number of **eGTM** specification.
GTM_REV_VER_MINOR	INT		Define minor version number of **eGTM** specification.
NARP	INT		Number of Address Range Protectors per **CCM**.
NHBP	INT		Number of Hardware Break Points.
TOM_OUT_N_WITH_DTM	ARRAY[NCDTM][16] of INT	[i][x]	0: Channel x of signal TOM_OUT_N in cluster i has no **DTM** implemented. 1: Channel x of signal TOM_OUT_N in cluster i has a **DTM** implemented.

44.3.1.14.3 Specific definitions

Table 2282 Specific definition

Definition	Description
Pulse width	It is a definition for pulse-width modulation (PWM) signal. In a PWM period, pulse width is the time when a signal or system is active (in **eGTM** specification on or off is possible). The signal level in the pulse width can be specified as 1 or 0, e.g. configured by CLSi_ATOM_CHx_CTRL.SL in **ATOM** module.
Duty cycle	It is a definition for pulse-width modulation (PWM) signal. The term duty cycle describes the proportion of pulse time to the total PWM period. In **eGTM** specification, duty cycle can be specified as the ratio of "on" time or "off" time of a PWM signal.

44.3.1.14.4 eGTM application constraints

Table 2283 Application constraints for eGTM 4100

Nr	Module	Description	Required value	Effect, when not considered
6	**TOM**	If channel is triggered by preceding channel via TOM_CH_TRIGOUT[x-1:x-1] signal, the selected SEL_FXCMU_CLKEN/ CCM[i]_FXCLK_RES of both channels has to be the same.	Identical SEL_FXCMU_CLKEN/ CCM[i]_FXCLK_RES	The trigger of preceding channel may be lost
7	**ATOM**	If channel is triggered by preceding channel via ATOM_CH_TRIGOUT [x-1:x-1] signal, the selected SEL_CMU_CLKEN/ CCM[i]_CLK_RES of both channels has to be the same.	Identical SEL_CMU_CLKEN/ CCM[i]_CLK_RES	The trigger of preceding channel may be lost

Attention: The user must be careful when writing directly to operation registers via the configuration interface. Write accesses might take a variable number of clock cycles until they are executed. For example, the load on the internal AEI bus or the external bus in the MCU could influence the duration of accesses. If the user attempts to directly perform a write access on an operation register at the point in time the update from the shadow register takes place, there is a race condition - the source that writes last will have its value stored in the register.

44.3.1.14.5 eGTM internal functional dependencies

Table 2284 Dependency of ATOM functions

ATOM[i] depends on	Valid index	Description	Type
eGTM inputs	i < NATOM	Error **IRQ** clear, **IRQ** clear signals	Cluster external uses ICPA

44.3.1.14.6 Compatibility notes / functional changes versus eGTM v.3.1.5 release

Find next a listing of all functional changes which have been introduced with **eGTM** v4.1.x release where backward compatibility to **eGTM** v3.1.5 is not existing. Software developers have to introduce changes to their application code to ensure correct operation of the same application on **eGTM** 4.1.x devices.

eGTM architecture

- Address map changed, base address of all modules changed. Each module inside a cluster has now a defined offset to the cluster start address. As long as applications use C-HAL or symbolic names no corrective actions are needed.
- Legacy register from **eGTM** generation 1 and **eGTM** generation 2 removed.
- GTM_TIM[i]_AUX_IN_SRC replaced by CLSi_CCM_TIM_AUX_IN_SRC
- GTM_TOM0[i]_OUT replaced by CLSi_CCM_TOM_OUT
- (e)GTM_ATOM[i]_OUT replaced by CLSi_CCM_ATOM_OUT
- CLSi_ARCH_AEI_STA_XPT.W1R0 changed to bit 24.
- Redefinition of AEI_STATUS behavior in case of **AEI** configuration access to undefined, protected, disabled register. **eGTM** generic bus interface (**AEI**)

ICM

Removed the following legacy and redundant **ICM** registers: **ICM_IRQG_6**, **ICM_IRQG_7**, **ICM_IRQG_8**, **ICM_IRQG_9**, **ICM_IRQG_10**.

ATOM

- Bit field ECLK_SRC of CLSi_ATOM_CHx_CTRL removed and CLSi_ATOM_CHx_CTRL.CLK_SRC bit field expanded by one bit and coding of bit field CLSi_ATOM_CHx_CTRL.CLK_SRC changed: CLSi_ATOM_CHx_CTRL_SOMP, CLSi_ATOM_CHx_CTRL_SOMS, CLSi_ATOM_CHx_CTRL_SOMI
- Behavior of retriggering a one-shot cycle in SOMP mode changed: One-shot counting up mode

TOM

- CLSi_TOM_CHx_CTRL.CLK_SRC, CLSi_TOM_CHx_CTRL.SL shadow register functionality (see CLSi_TOM_CHx_CTRL_SR): To ensure backward compatibility, new shadow register must be written with same values as operational register CLSi_TOM_CHx_CTRL_SR = CLSi_TOM_CHx_CTRL.
- Bit field ECLK_SRC of CLSi_TOM_CHx_CTRL removed and CLSi_TOM_CHx_CTRL.CLK_SRC bit field expanded by one bit and coding of bit field CLSi_TOM_CHx_CTRL.CLK_SRC changed.
- Behavior of retriggering a one-shot cycle changed: One-shot counting up mode

CCM

- Remove bit field ARU_CONNECT_CONFIG in register CLSi_CCM_HW_CONF due to discontinued device configuration parameter.

44.3.1.14.7 New features / functional enhancements

Find next a listing of all functional enhancements which have been introduced with **eGTM** v4.1.x release where backward compatibility to **eGTM** v3.1.5 is not affected.

eGTM architecture

- GTM_CTL: extended functionality of CLSi_ARCH_CTRL.TO_MODE; internal **AEI** accesses can be retrieved or aborted. See chapter CLSi_ARCH_CTRL

ATOM

- High-resolution support: High-resolution PWM support (HRES mode)
- Retrigger one-shot mode: One-shot counting up mode , CLSi_ATOM_CHx_STAT.OSM_RTF
- Shadow register for CLSi_ATOM_CHx_CTRL.SL and CLSi_ATOM_CHx_CTRL.CLK_SRC: CLSi_ATOM_CHx_CTRL_SR
- **ATOM** OUT_T controlled by ENDIS (enhancement): Value of ATOM_OUT_T is inverse signal level (CLSi_ATOM_CHx_CTRL.SL) when channel is disabled (ENDIS=0): CLSi_ATOM_AGC_OUTEN_CTRL.OUTEN_CTRLk (k=0-7)

TOM

- Retrigger one-shot mode: One-shot counting up mode
- Shadow register for CLSi_TOM_CHx_CTRL.SL and CLK_SRC: CLSi_TOM_CHx_CTRL_SR
- **TOM** OUT_T controlled by ENDIS (enhancement): Value of TOM_OUT_T is inverse signal level (CLSi_TOM_CHx_CTRL.SL) when channel is disabled (ENDIS=0): CLSi_TOM_TGCg_OUTEN_CTRL.OUTEN_CTRLc (c=0-7)

DTM

- Dead-time shadow register including CLSi_CDTM_DTMd_CH_DTVx.RELRISE and CLSi_CDTM_DTMd_CH_DTVx.RELFALL: Dead-time shadow register, CLSi_CDTM_DTMd_CH_DTV_SRx
- Expand bitwidth of CLSi_CDTM_DTMd_CH_DTVx.RELRISE/CLSi_CDTM_DTMd_CH_DTVx.RELFALL to 13 bits.
- AUXIN enhancements for **eGTM** Gen4 (individual shutoff): **DTM** individual channel shutoff
- High-resolution support: High-resolution PWM support

TIM

- Added new coding for CLSi_TIM_CHx_ECTRL.TDU_STOP=110_B. See chapter CLSi_TIM_CHx_ECTRL

CCM

- Added register CLSi_CCM_HW_CONF2 to monitor additional device configuration parameter.
- Added bit fields CLSi_CCM_HW_CONF.RESET_ACTIVE, CLSi_CCM_HW_CONF.AEI_ADDR_PIPELINE_STAGE, CLSi_CCM_HW_CONF.AEI_RDATA_PIPELINE_STAGE to monitor additional device configuration parameter.

44.3.2 eGTM implementation

The eGTM is optimized for electrical drives applications, but it is also a simple timer, capable of all necessary PWM generation timer based functions.

***Note**: The second GTM (GTM classical approach - not available on all devices) is optimized for engine control and for all applications which need a particularly large amount of timers.*

44.3.2.1 TC4x family eGTM configuration

The following table shows the configuration of the eGTM module on the TC4x devices with 3 clusters. The interface to the HRPWM module is optional:

Table 2295 eGTM configuration (no GTM listed)

eGTM modules	eGTM with 3 clusters
TIM	3x8 channels (TIM0-2)
TOM	3x16 channels (TOM0-2)
ATOM	3x8 channels (ATOM0-2) with high resolution extension, if existing
DTM/CDTM	12 @ TOMs (TOM0-2) 6 @ ATOM (ATOM 0-2)
HRES	Existing, but no connection to the HRPWM supporting blocks in TC4Dx and TC4Zx
MCS	not existing
SPE	3 (SPE0-2)
PSM	not existing
DPLL	not existing
TBU	3 (TBU0-2)
BRC	not existing
MON	1
CMP	1
eGTM Clusters	3 (CCM0-2)

44.3.2.2 Naming of resources with or without DTM

The following table includes the configuration of the eGTM, including the resource names for the output signals. For eGTM all outputs are including a DTM.

Table 2296 CDTMs to resources

CDTMn	CDTMn_DTMj	Resource TOM/ATOM
CDTM0	DTM0	TOM0 channel 0-3
CDTM0	DTM1	TOM0 channel 4-7
CDTM0	DTM2	TOM0 channel 8-11
CDTM0	DTM3	TOM0 channel 12-15
CDTM1	DTM0	TOM1 channel 0-3
CDTM1	DTM1	TOM1 channel 4-7
CDTM1	DTM2	TOM1 channel 8-11
CDTM1	DTM3	TOM1 channel 12-15
CDTM2	DTM0	TOM2 channel 0-3
CDTM2	DTM1	TOM2 channel 4-7
CDTM2	DTM2	TOM2 channel 8-11
CDTM2	DTM3	TOM2 channel 12-15
CDTM0	DTM4	ATOM0 channel 0-3
CDTM0	DTM5	ATOM0 channel 4-7
CDTM1	DTM4	ATOM1 channel 0-3
CDTM1	DTM5	ATOM1 channel 4-7
CDTM2	DTM4	ATOM2 channel 0-3
CDTM2	DTM5	ATOM2 channel 4-7

The following figure shows the names of the eGTM outputs.

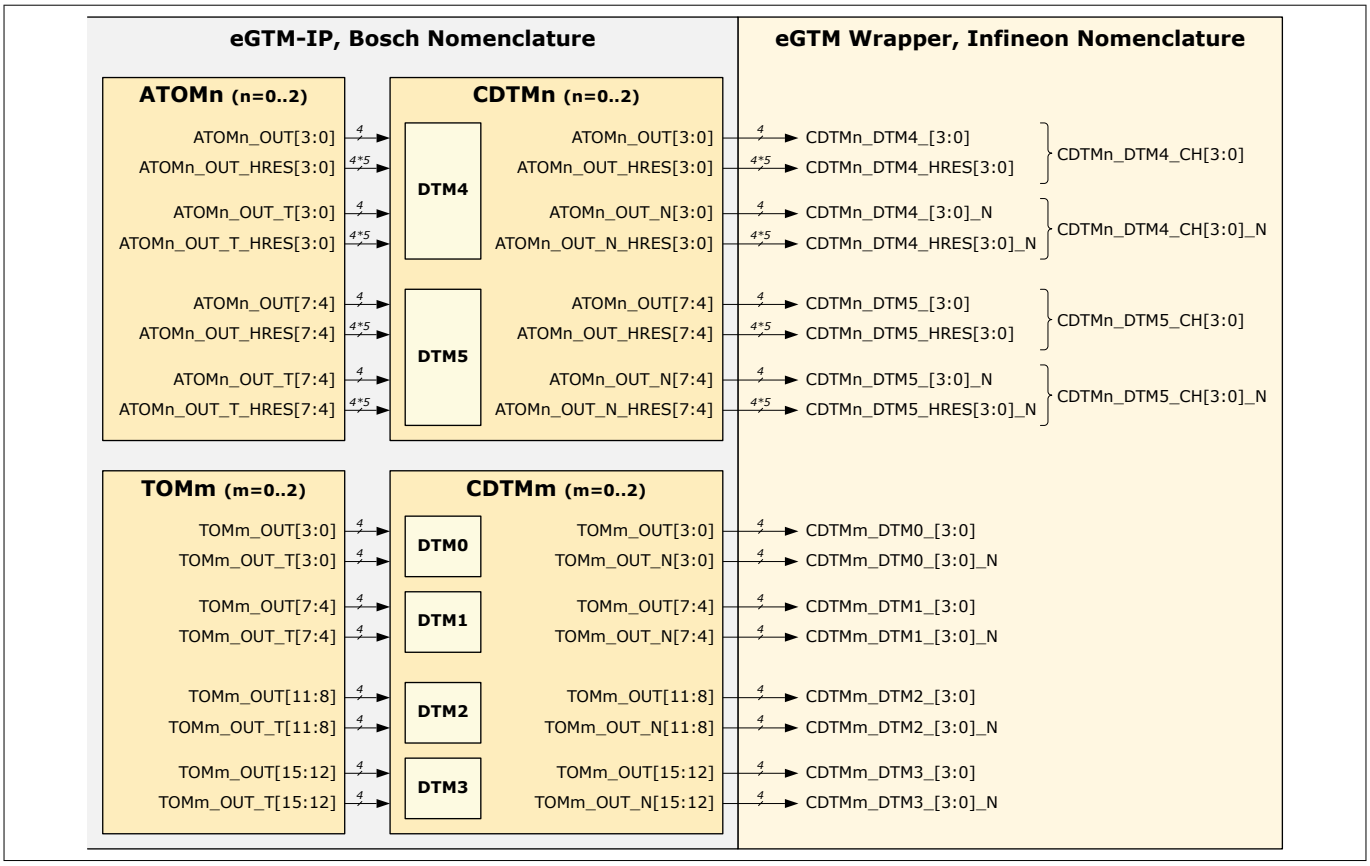

Figure 1127 Naming between eGTM-IP and eGTM wrapper

44.3.2.3 eGTM-IP internal bus bridge

The eGTM is connected to the system bus (w or w/o a bridge). The eGTM AEI bridge should use synchronous mode if $f_{eGTM} = f_{CPU}$, otherwise asynchronous mode should be used. If no other configuration takes place, f_{eGTM} is identical to f_{CPU}. Use the asynchronous mode for all clock divider settings except for divide by 1.

In case of equal frequencies:

- EGTM_CLS0_AEI_BRIDGE_MODE.B.BRG_MODE = 0; for synchronous mode

In case of different frequencies:

- EGTM_CLS0_AEI_BRIDGE_MODE.B.BRG_MODE = 1; for asynchronous mode
- EGTM_CLS0_AEI_BRIDGE_MODE.B.BYPASS_SYNC = 1; bypass synchronization

Always the following setting shall be taken:

- EGTM_CLS0_AEI_BRIDGE_MODE.B.MSK_WR_RSP = 1; Activate write buffer

***Note**: For devices with frequencies higher than 400 MHz, cluster clocks have to be set to 1:2. In case a device is supporting a frequency higher than 400 MHz, it is not allowed to program cluster clocks to higher frequencies, than 250 MHz*

44.3.2.4 eGTM is not an interrupt service provider

The eGTM is a standard module connected to the interrupt request unit. It is not a service provider.

44.3.2.5 Using the protection mechanism

This section describes the protection concept for the eGTM module. It shows the relation between the Access Mode Glossary and the Register Overview.

The eGTM protection has six different groups:

1. ACCEN and PROTSE are unprotected
2. All OCDS dependent registers, which are not part of the standard registers, and CLC, OCS, RST_CTRL(A/B) and RST_STAT are protected by APU-P
3. All wrapper registers are protected by PWRAP
4. All eGTM internal standard cluster registers have the protection according to their cluster number, for example cluster 0 has PCL0 up to cluster 2 with PCL2
5. CMP and MON are protected by PSAFE
6. ICM, TBU, CMU, ARCH and AEI related registers are protected by PGTM

The protection rights are defined in the Register Overview table. Violating these protections will trigger an alarm to SMU.

44.3.2.6 eGTM control registers

This section lists all Infineon specific registers implemented in the TC4x family.

44.3.2.6.1 eGTM note input line 0 safe state

General remark for outputs: The multiplexer input lines 0 (selected by .SEL=0) are tied to 0, in order to enable a safe state.

44.3.2.6.2 ADC connections

This chapter introduces the connections of the eGTM to and from the ADC sub-block.

Boundary Flag naming between ADC and GTM/eGTM

Boundary flags have the following names:

Name in ADC chapter

Name in ADC chapter	Name in GTM/eGTM chapter
ETBFxSEL.OUTySEL (name of the controllable bit) eGTM_CLx_BLFy (name of the signal)	GTBFxOUTy

With x being the actual cluster number and y being the line.

Currently 4 lines exist.

Therefore the signals GTBFxOUT2_4 connect to signal eGTM_CLx_BLF2 and GTBFxOUT3_5 connect to eGTM_CLx_BLF3.

Connection between eGTM and ADC

This sub-chapter describes all interfaces from and to the ADC function block.

Feature list

This subsection is divided into the following parts:

- Input from ADC
- Trigger signals to ADC

***Note**: SENT connections are treated the same way as ADC connections, with separate register set.*

Functional description

Inputs from ADC

Input signals coming from the ADC routed to the TIM modules are controlled by the TIMnINSEL register group. The ADC output signals can be found on bit position 12 of the multiplexer for eGTM TIM input.

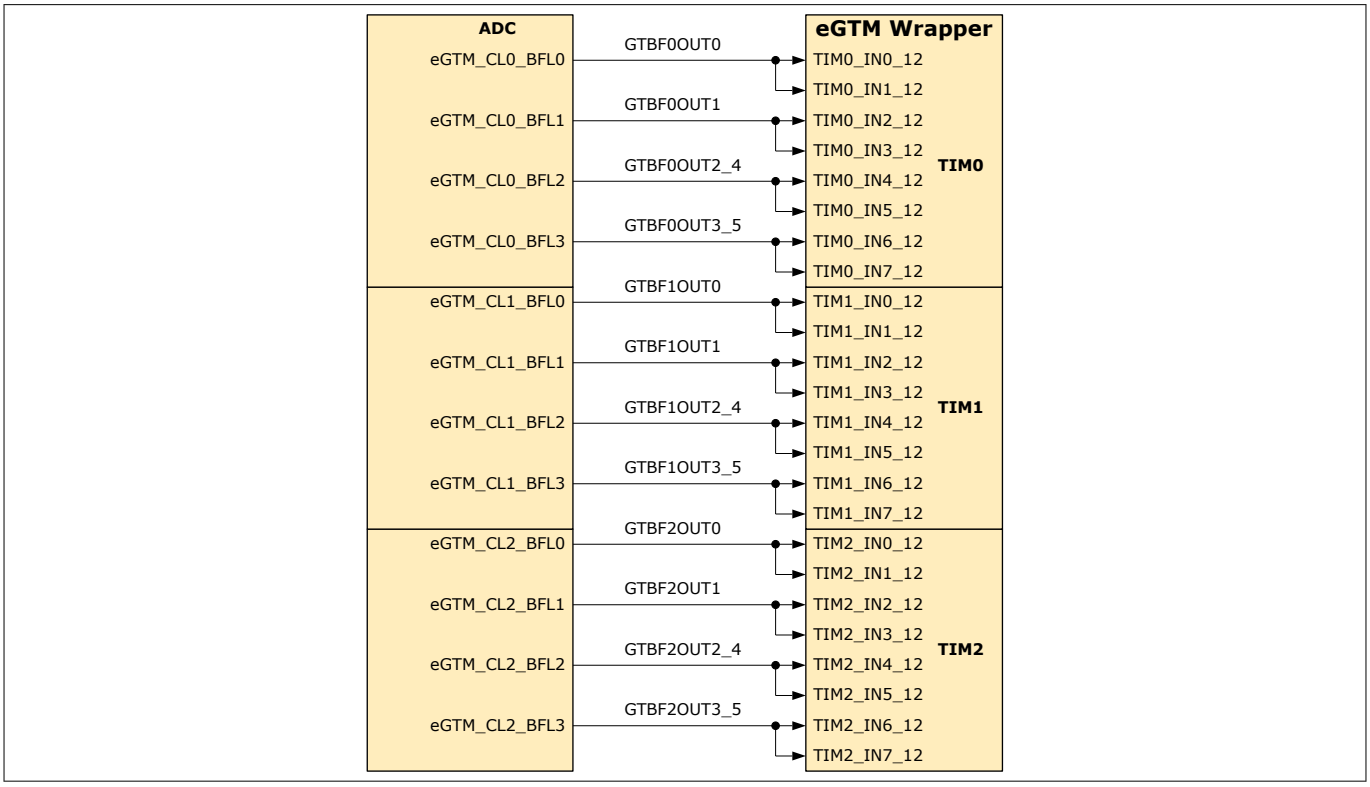

Figure 1128 ADC to TIMnINSEL connection

Further connections exist in TIMnINSELB and TIMn_ADCSELCHi (not available for TC4DxA).

Output to ADC

This chapter shows all connections from eGTM to ADCs.

ADC output

This sub-chapter describes ADC_OUT registers.

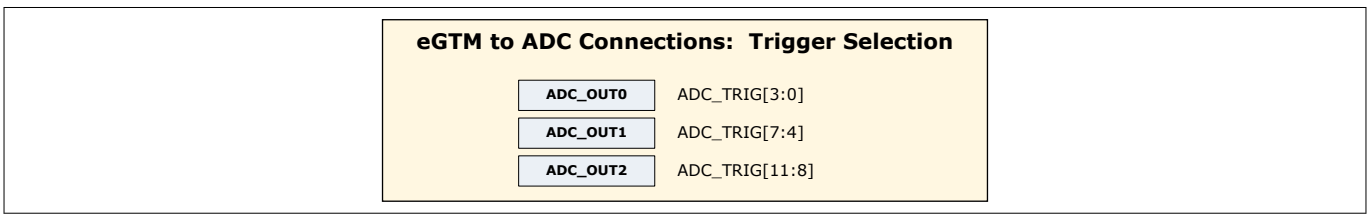

Figure 1129 Overview on ADC_OUT registers

In this register, each cluster has four multiplexers as to generate 4 trigger outputs. The bit-fields select between all ATOM and TOM resources within this cluster.

These trigger outputs enable the eGTM to trigger an action on an ADC module.

Please be aware that the output ADC_TRIG[11:0] from eGTM are mapped to input TRIG[47:36] of ADC block.

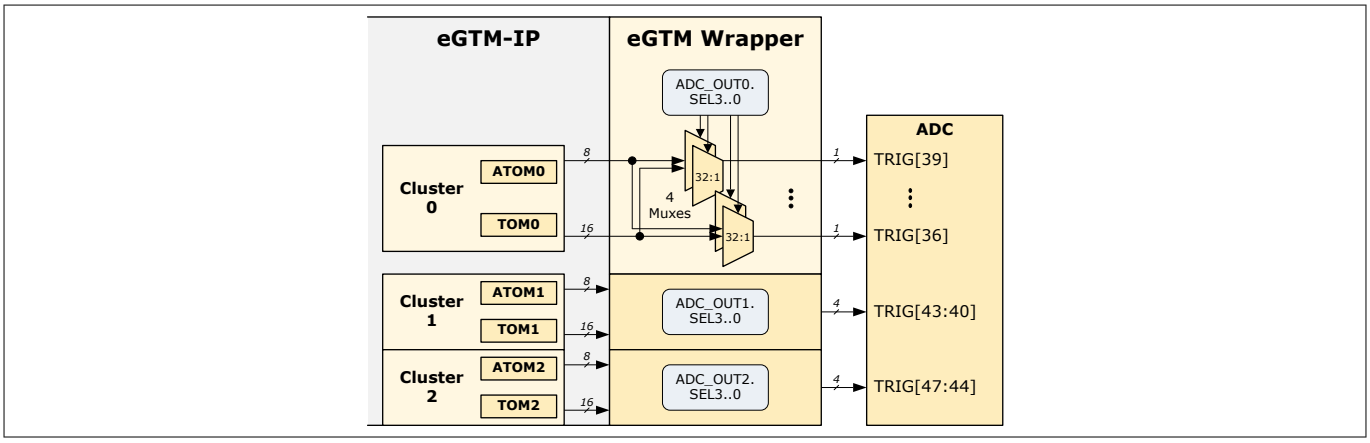

Figure 1130 eGTM outputs to ADC

eGTM to ADC output selection register n (n=0-2)

The bit fields in this register define which TOM/ATOM channel output is used as ADC trigger x.

ADC_OUTn (n=0-2) Offset address: 061700_H+n*4

44.3.2.6.3 Port connections

This section summarizes the port connections, which define the eGTM interface signals.

Table 2297 eGTM port connections overview

Description	Table
eGTM to GPIO connections	See Data Sheet and TOUTSEL registers

(table continues...)

Table 2297 (continued) eGTM port connections overview

GPIO to eGTM connections	See Data Sheet and TIMnINSEL registers
DTM_AUX Input connections	See Data Sheet and DTMAUX registers
eGTM ECLK (external clock) to GPIO connections	See Data Sheet and table below
GPIO availability by package	See Data Sheet - hints provided in TOUTSEL, in case of doubt Data Sheet is correct

eGTM output to port connections

The table below lists all connections between the eGTM output modules (TOMs/ATOMs/DTMs) and the ports.

Select the eGTM outputs by the TOUTSEL registers.

The eGTM outputs CMU_ECLK[2:0] are connected to dedicated ports.

Table 2298 eGTM External Clock to port mapping

eGTM External Clock	Output to PIN
CMU_ECLK0	P23.1
CMU_ECLK1	P32.4
CMU_ECLK2	P11.12/P16.14 this is dependent on the package variant

eGTM output to port control registers (TOUTSEL)

The outputs of the modules of eGTM (TOM, ATOM and DTM) are connected to several alternate functions of the port, selected by TOUTSEL.

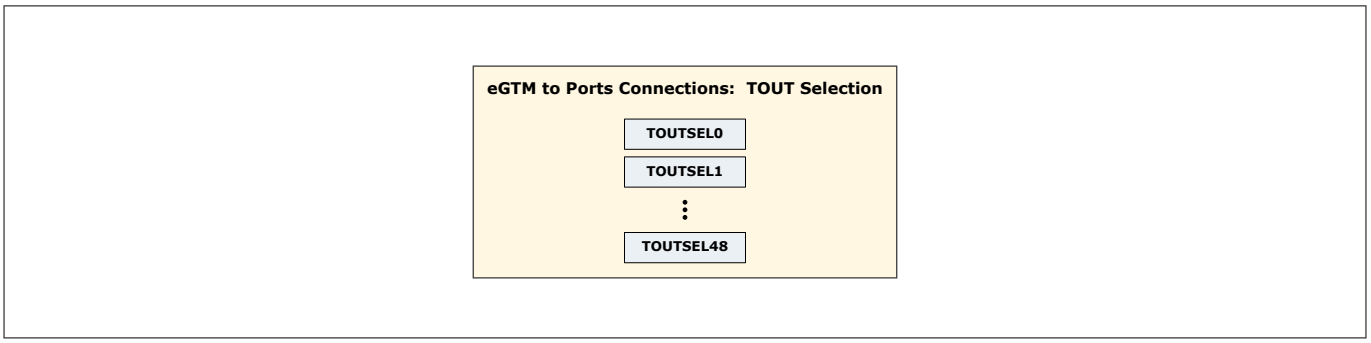

Figure 1131 TOUTSELn register overview

The setting inside this register, maps a eGTM resource to a certain port pin.

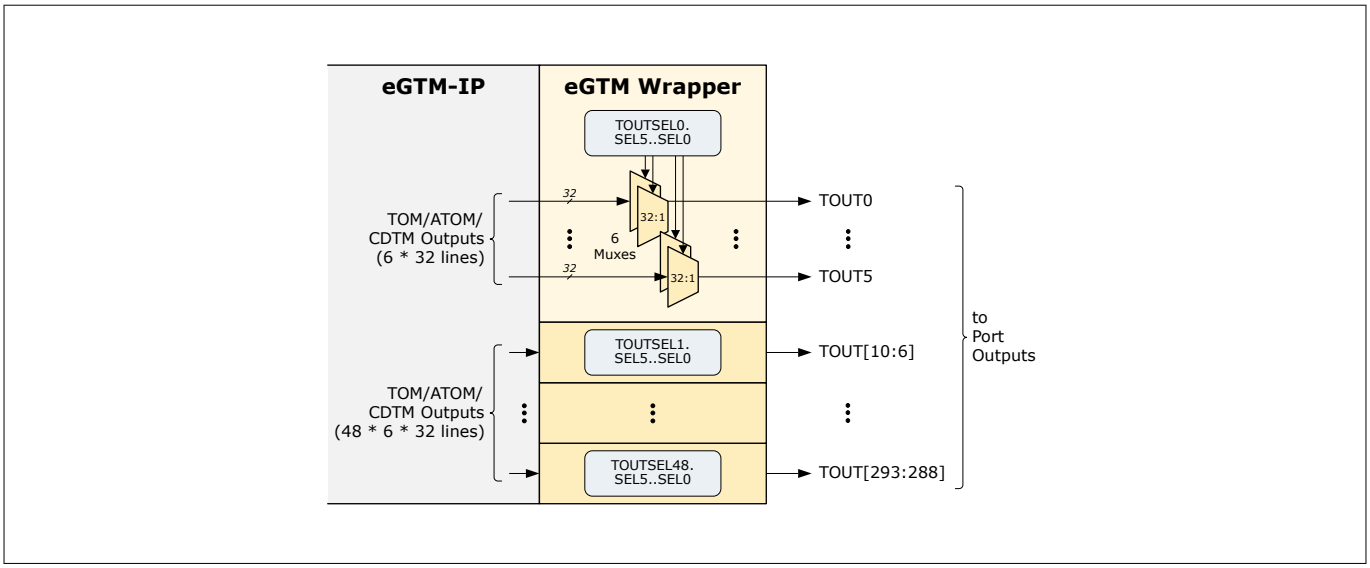

Figure 1132 eGTM outputs to ports

The register shown below, is showing the structure.

TOUT145 is not connected to an output. It is connected to an XTAL connection on-chip.

eGTM to Ports signal TOUT output selection register n (n=0-48)

The bit fields in this register define which TOM/ATOM channel output is used as port signal TOUT(n*6+x).

Port to eGTM connections - TIM inputs

Each of the TIM modules of the eGTM has an external signal input for each of its channels. These inputs are called TIMn_INy, with n being the number of the TIM module, and y the number of the channel within the TIM.

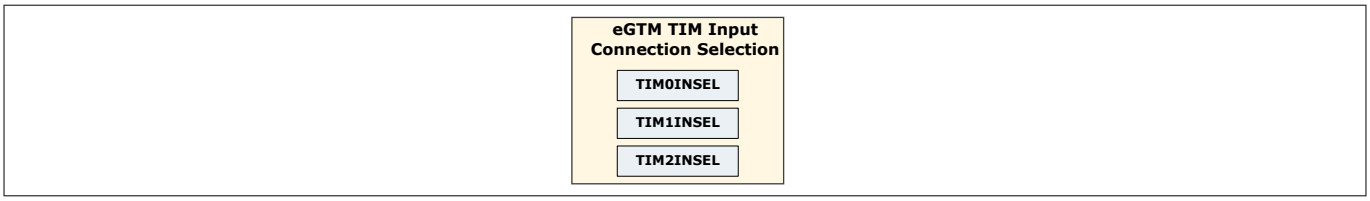

Figure 1133 TIMnINSEL register overview

To provide a high flexibility, the eGTM wrapper implements a 16:1 multiplexer for each of the TIMn_INy inputs. These multiplexers are controlled by the CHySEL bit-fields in the registers TIMnINSEL. See figure below for details.

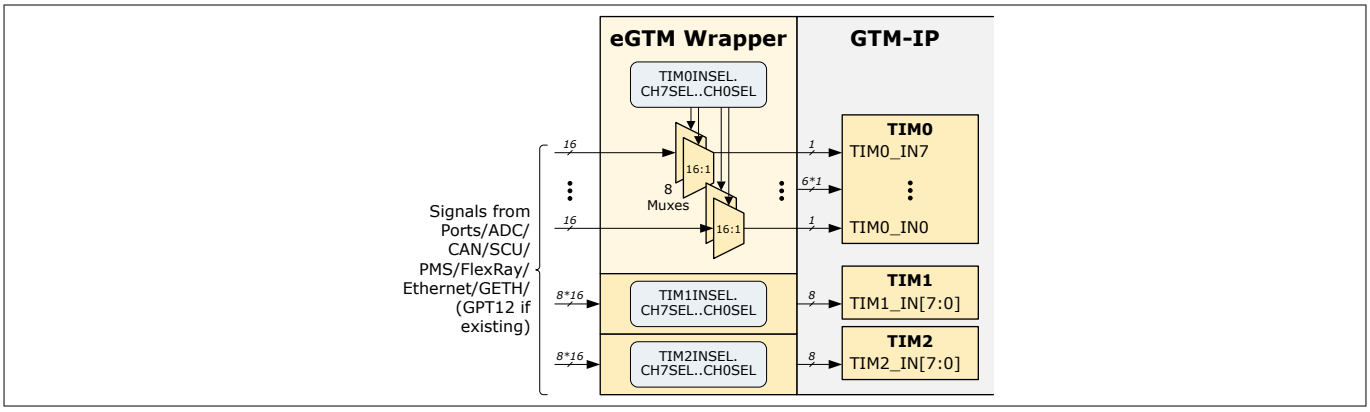

Figure 1134 Details on TIMnINSEL register structure

The external signals connected to the inputs of the multiplexers come from the port as well as from other on-chip modules such as the ADC, CAN(XL), SCU, PMS, FlexRay, GPT12, and (G/L)ETH. These signals provide status, interrupt, and synchronization information, which can then be processed by the eGTM.

The signals from the on-chip modules to the TIM module input multiplexers are shown in the following simplified overviews. Note that each input is named TIMn_y_z, with n = 0..2 (TIM module), y = 0..7 (TIMn channel), and z = 0..15 (multiplexer input number).

Note also that most of the signals are connected to more than one TIM input multiplexer, to increase the flexibility.

To provide more flexibility and to keep software compatibility to previous devices, a second group of TIMnINSEL registers has been introduced TIMnINSELB.

TIMnINSEL registers

The TIMnINSEL registers select inputs of the eGTM.

Field	Bits	Type	Description
CHxSEL (x=0-7)	4*x+3:4*x	rw	**eGTM TIMn channel x input selection** This bit field selects which input is connected for TIMn channel x. The input is either derived from a port pad or from an on-chip module.

TIMnINSELB registers

The TIMn input selection register group B (n=0-2) registers select inputs of the eGTM.

The main purpose is the synchronization to ADC interrupts. These ADC interrupt service requests can be chosen in TIMn input selection register group B (n=0-2). The specific instance is programmed in the corresponding register Instance Selection for TIM[n] channel[i] (i=0-7;n=0-2). Please be aware, that the register TIMn input selection register group B (n=0-2) is dependent on its content.

For PDOUT only TIMn input selection register group B (n=0-2) needs to be configured. In this case Instance Selection for TIM[n] channel[i] (i=0-7;n=0-2) is not needed.

***Note**: This function is not available in TC4Dx, related registers are not existing.*

This function employs a streamlined two-stage multiplexer (MUX). In the first stage, a shared selection signal TIMn input selection register group B (n=0-2) simultaneously controls two parallel operations:

- 16:1 MUX that selects one of the predefined 16 ADC interrupt groups, producing a 16-bit intermediate output
- 16:1 MUX that selects one of the bit select signals configured in Instance Selection for TIM[n] channel[i] (i=0-7;n=0-2), generating a 4-bit control signal

In the second stage, the 4-bit signal acts as a selector to pinpoint a single bit from the 16-bit intermediate output.

44.3.2.6.4 GPT12 connections

This feature only exists, if and only if a GPT12 is present on the device. To provide filtered inputs to GPT12, a connection from eGTM to GPT12 is implemented. The signal FOUT is available after the filter on each TIM channel (see eGTM TIM description FOUT signal).

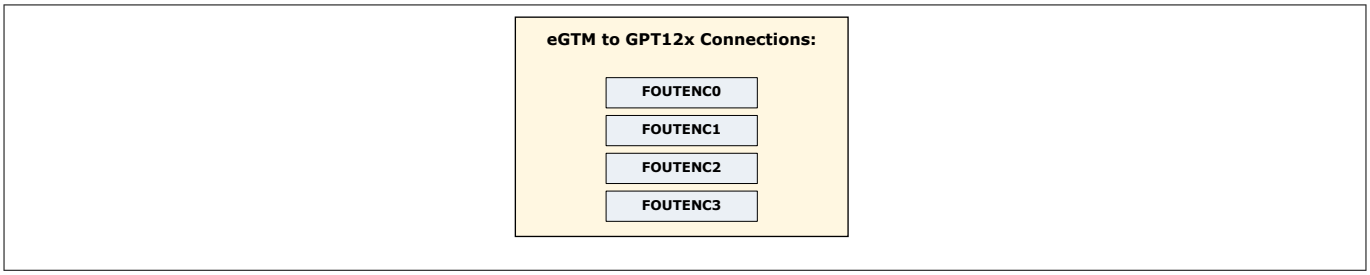

Figure 1146 Register structure FOUTENC

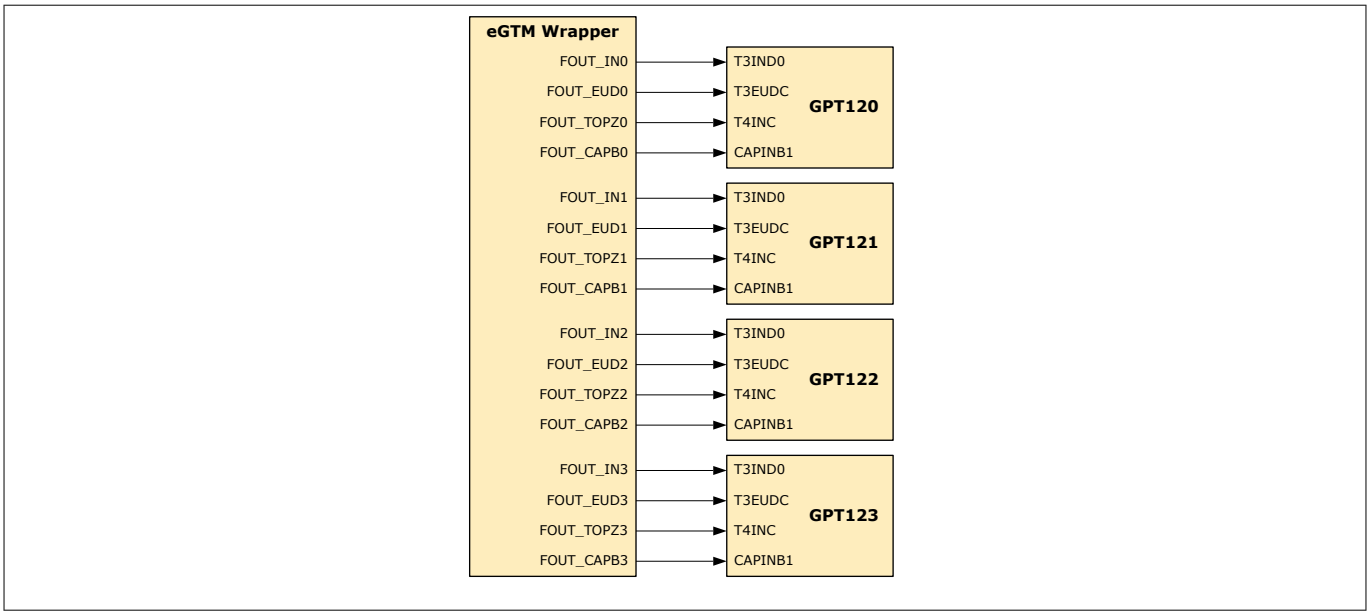

Figure 1147 Overview on eGTM FOUT signals connected to GPT12

The signals are provided to each GPT12 on the device for the two inputs associated with core timer T3 (T3IN, T3EUD) on their positions C, one input associated with auxiliary timer T4 (T4IN) on its position C, and additionally with the input pin CAPIN B. The CAPIN B (CAPINB1) on GPT12 is pre-multiplexed to switch to eGTM CAPIN B.

For each input signal from the eGTM the application can choose between all TIM clusters and TIM channels.

For safety applications it is possible to feed two GPT12 instances with the same data.

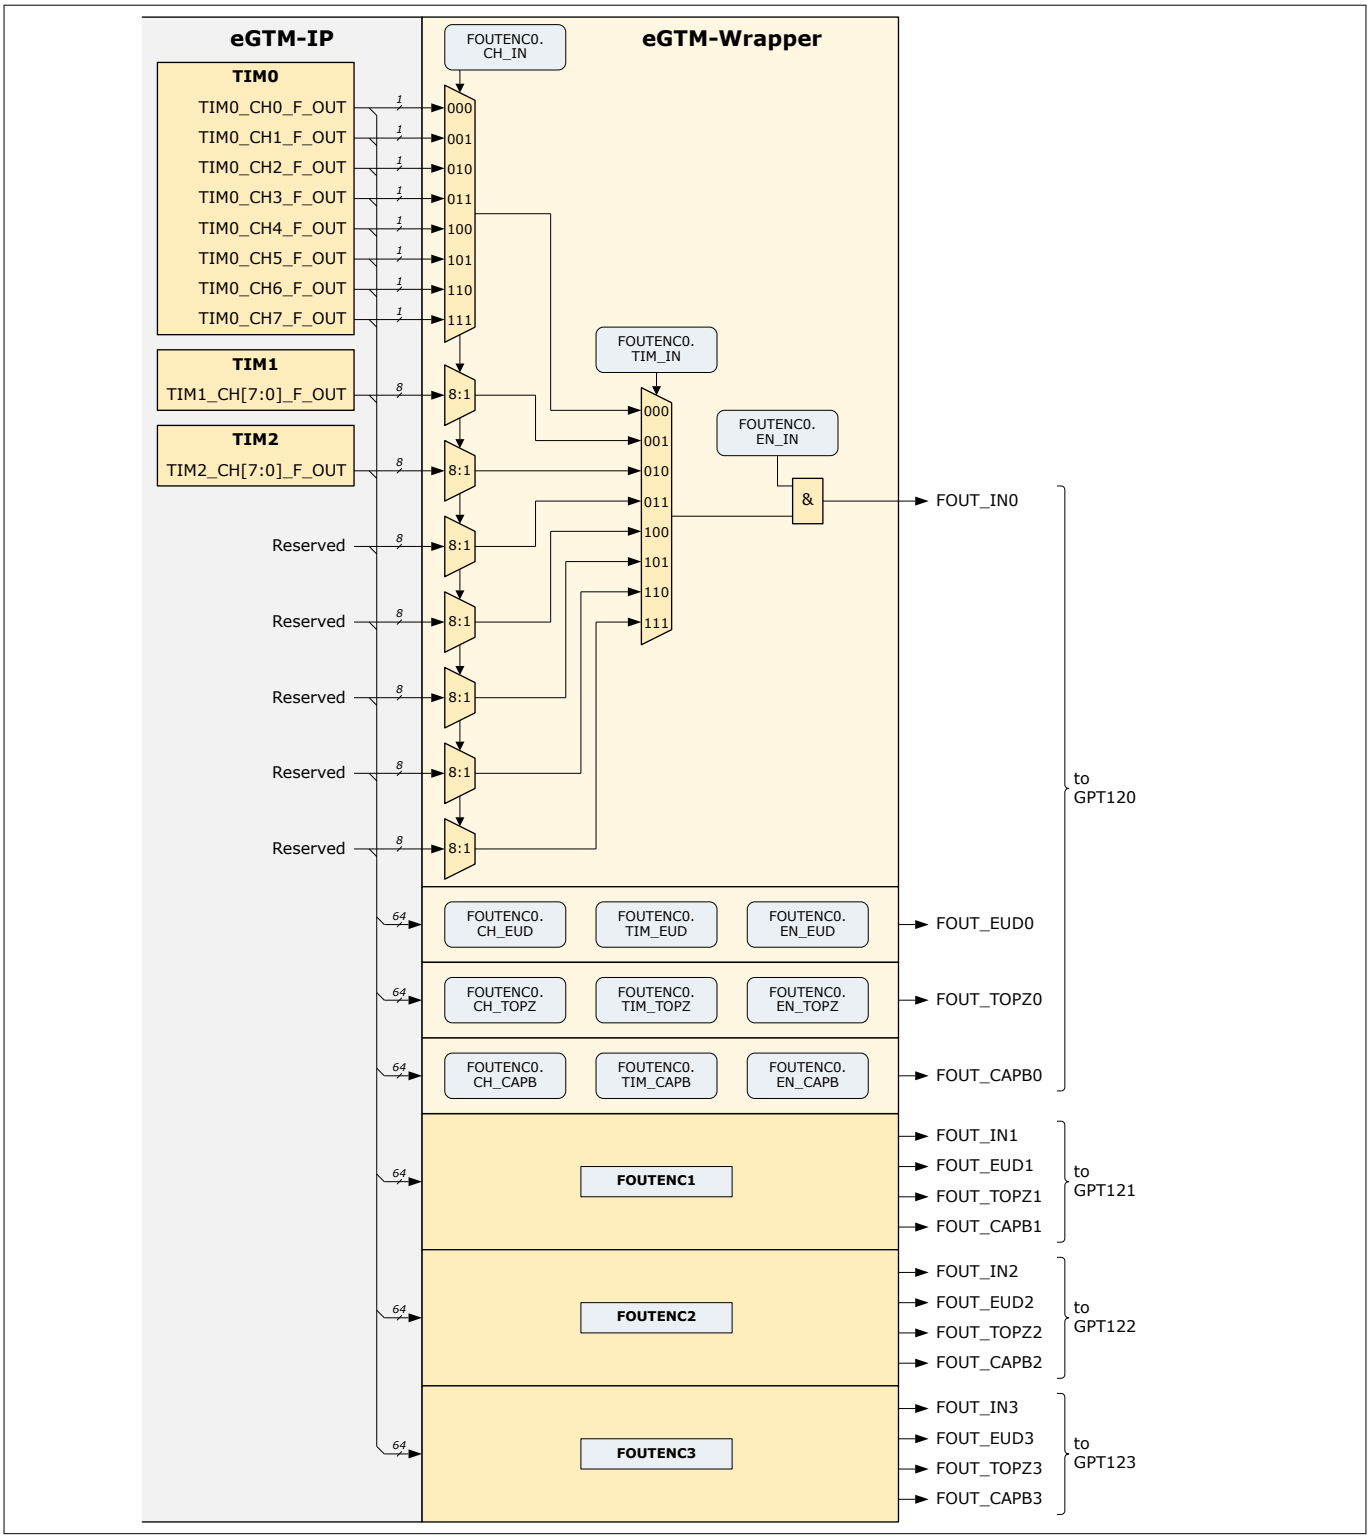

Figure 1148 Filtered inputs to GPT12

- FOUTENCx.CHSEL
  - Bit-field to choose the channel number
- FOUTENCx.TIMSEL
  - Bit-field to choose the TIM module cluster

***Note**: This feature can be controlled by the GPT12.*

The main aim of this interface is to provide a clean input to an encoder interface.

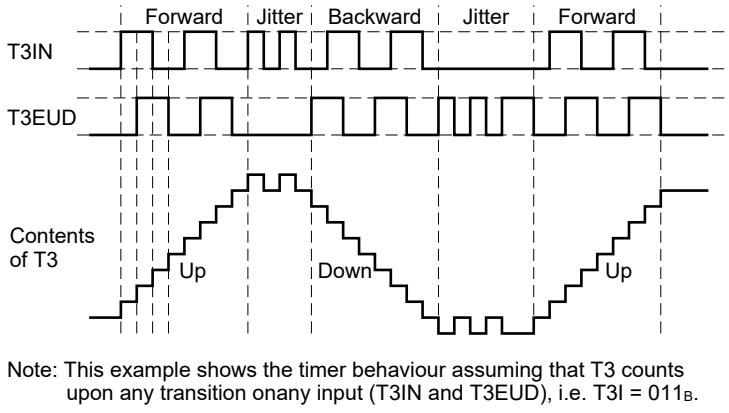

Figure 1149 Evaluation of incremental encoder signals, 2 count inputs

The connection is for T3IN, T3EUD, and for the corresponding TOPZ input.

In addition, the CAPIN B input receives the same type of filtered input. On the GPT12 side this is an option which can be selected through the input multiplexer. This option on CAPIN B is added on an additional multiplexer.

***Note**: TOPZ is connected to T4IN.*

44.3.2.6.5 SCU interrupt trigger

Outputs of ATOM or TOM can generate SCU interrupts.

The SCU trigger have the same structure as the ADC trigger. Every TOM or ATOM can be mapped to one of the four SCU interrupts for the eGTM.

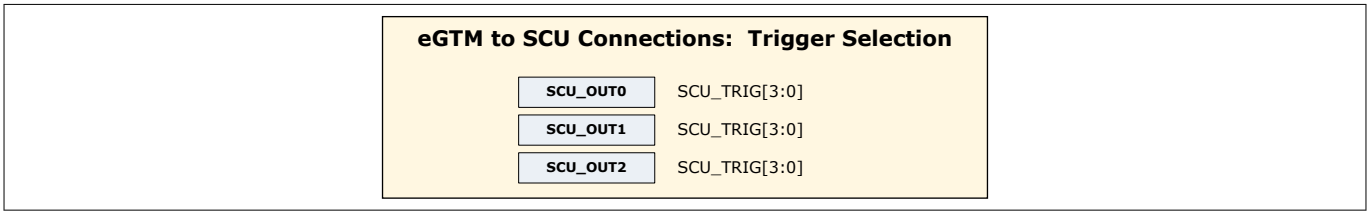

Figure 1150 SCU trigger

Together with the SCU connections mapped to TIMnINSEL, it is possible to have synchronization mechanism, either between different clusters of the eGTM or among eGTM and GTM (if available in this device).

The multiplexing scheme is described by the following figure

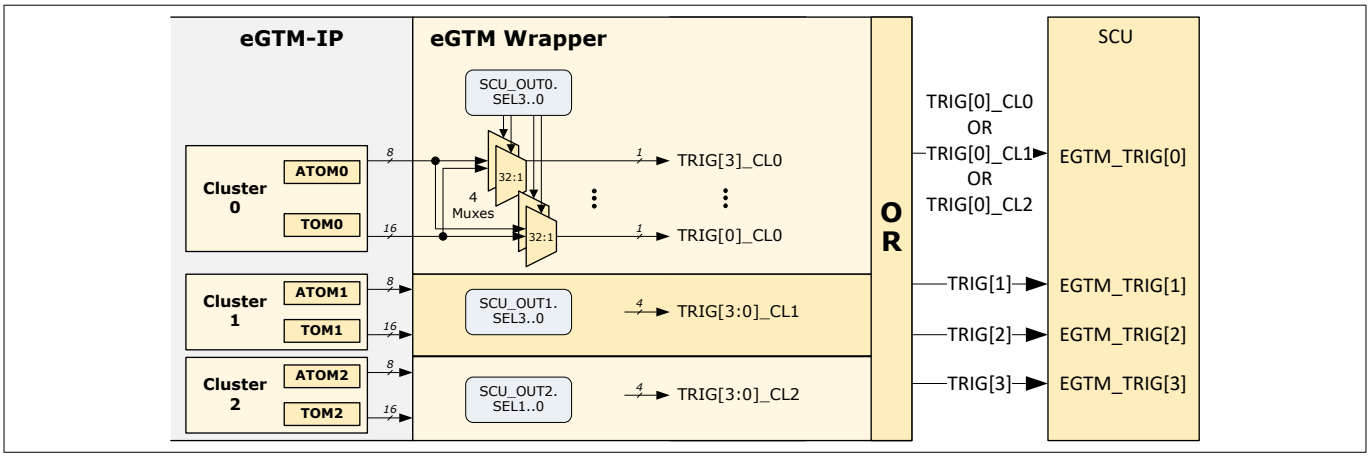

Figure 1151 Mapping of trigger outputs to the SCU

***Note**: TRIG0 of every cluster is ORed, the same applies to TRIG1, TRIG2, ..*

The register layout is shown in the next paragraph.

eGTM to SCU output selection register n eGTM_SCU_TRIG(n) (n=0-2)

The bit fields in this register define which TOM/ATOM channel output is used as SCU trigger x.

44.3.2.6.6 DTMAUX - AUX_IN connections

The registers for DTMAUX configure the eGTM inputs of (e)GTM_CDTM[i]_DTM[d]_AUX_IN[0:0] and (e)GTM_CDTM[i]_DTM[d]_AUX_IN[1:1]. These inputs provide for example the possibility to stop an electric drive in case of an emergency stop (also called TRAP or HALT). An inactive level can be defined inside the DTMAUX configuration.

The Cluster n DTMAUX input y selection register (y=0-1;n=0) registers provide the input configuration for (e)GTM_CDTM[i]_DTM[d]_AUX_IN[0:0] and (e)GTM_CDTM[i]_DTM[d]_AUX_IN[1:1].

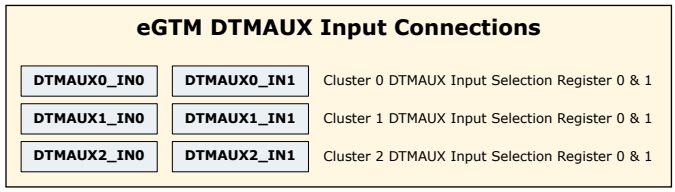

Figure 1152 DTMAUX register overview

Each of the CLSi_CDTM_DTMd modules of the eGTM has two external auxiliary signal inputs. These inputs are called (e)GTM_CDTM[i]_DTM[d]_AUX_IN with i being the number of the CDTM module, d the number of the DTM block within the CDTM, and y the number of the auxiliary input.

To provide a high flexibility in selecting the desired input signal, the eGTM wrapper implements 8:1 multiplexers for each of the auxiliary inputs. These multiplexers are controlled by the SELx bit-fields in the registers DTMAUXn_INy. See the figures below for details.

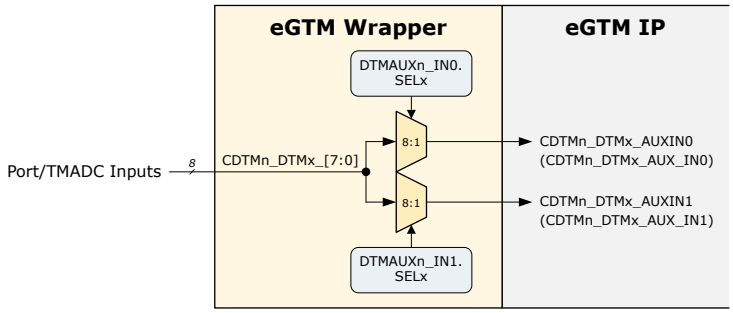

Figure 1153 DTMAUX input multiplexing of IN

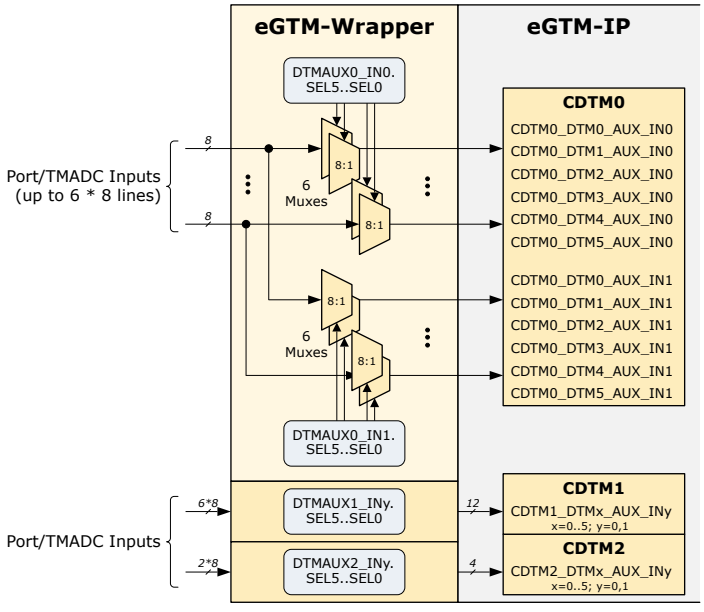

Figure 1154 Register structure of DTMAUX

***Note**: The two multiplexers for the two auxiliary inputs receive the same set of selectable signal inputs, however, the selection is independent for each auxiliary input, as each multiplexer has its own selection control.*

The layout of the multiplexer control registers DTMAUXn_INy is shown below.

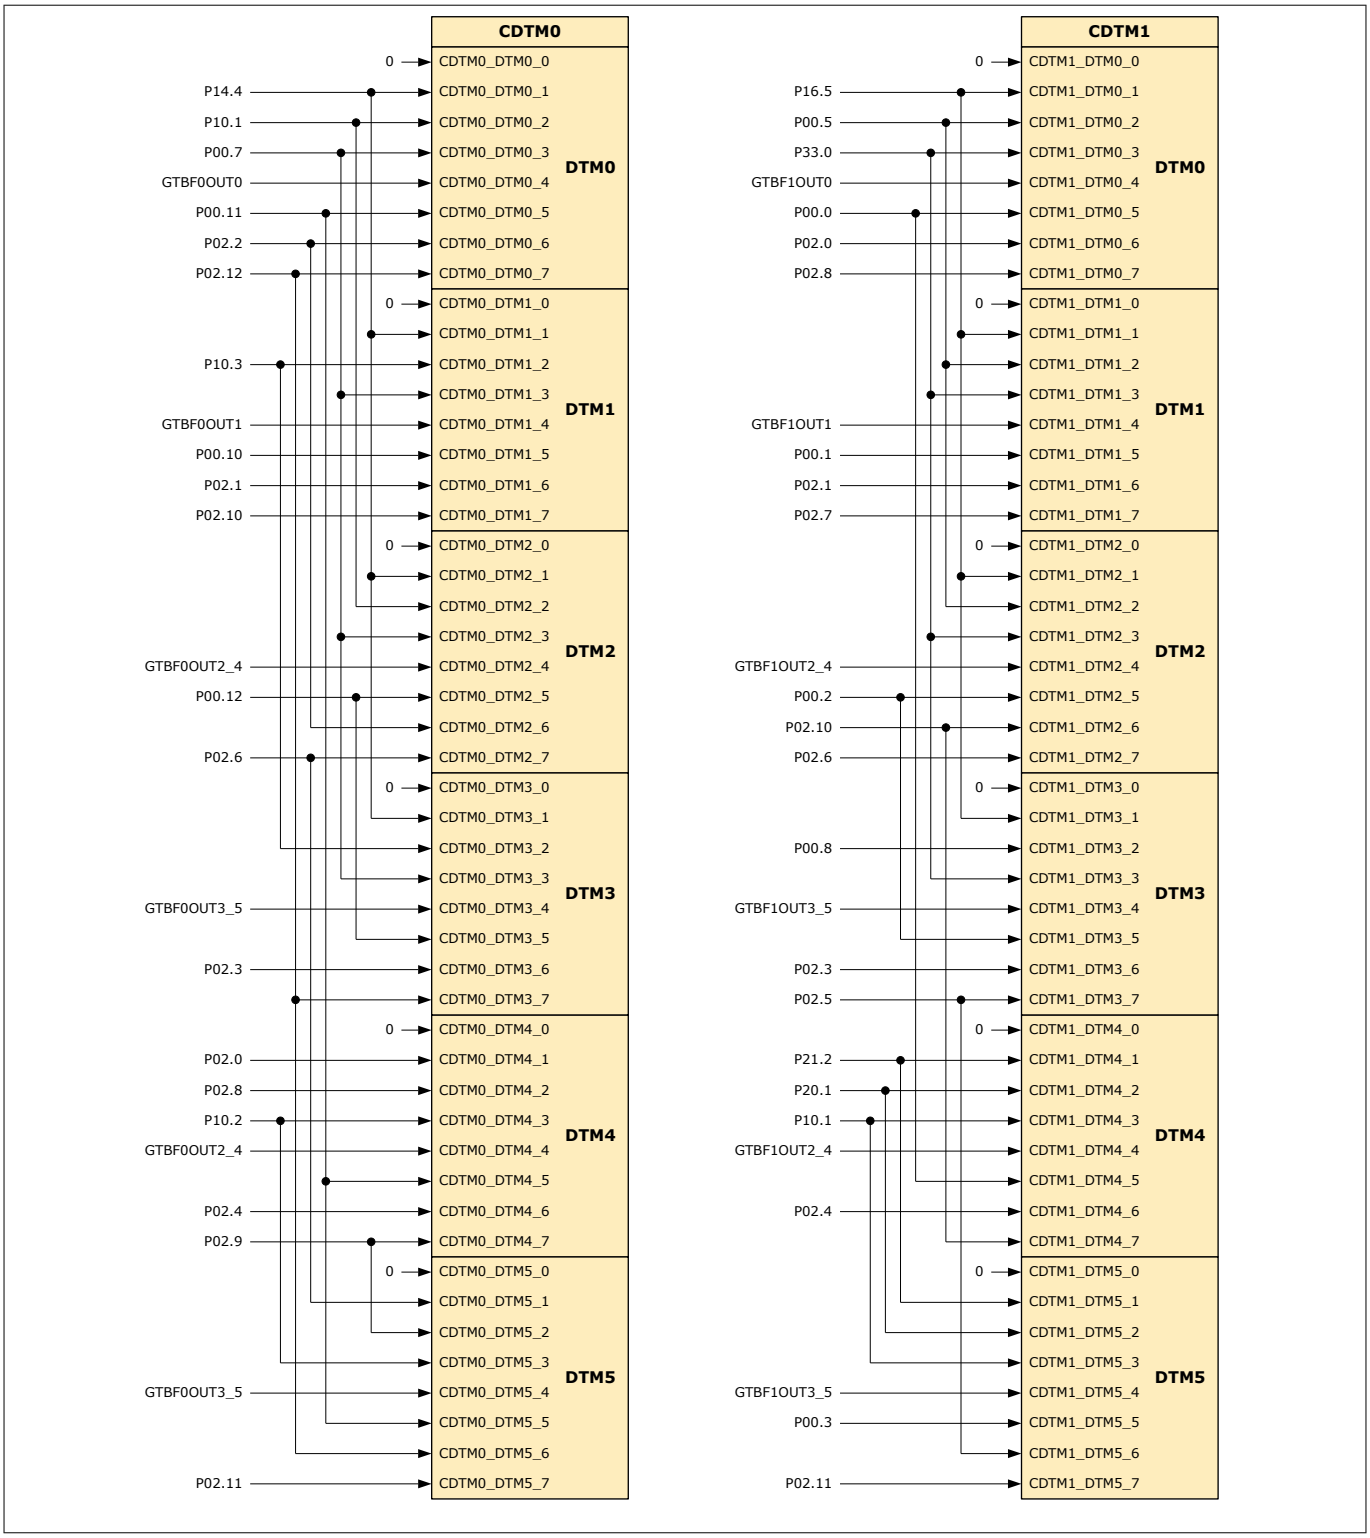

Figure 1155 Detailed overview on DTMAUX register settings 0 and 1

44.3.2.6.7 LCDCDC (PMS) interface connection

The LCDCDC interface, is used to control an LC DC/DC based regulator. An input and an output to a timer is required to control the regulator.

Input

The input is selected by the TIMnINSEL registers.

The signal PMS_DCDC_SYNC is used as input and is available on the TIMnINSEL register.

- TIM0INSEL.CH5SEL
- TIM1INSEL.CH5SEL

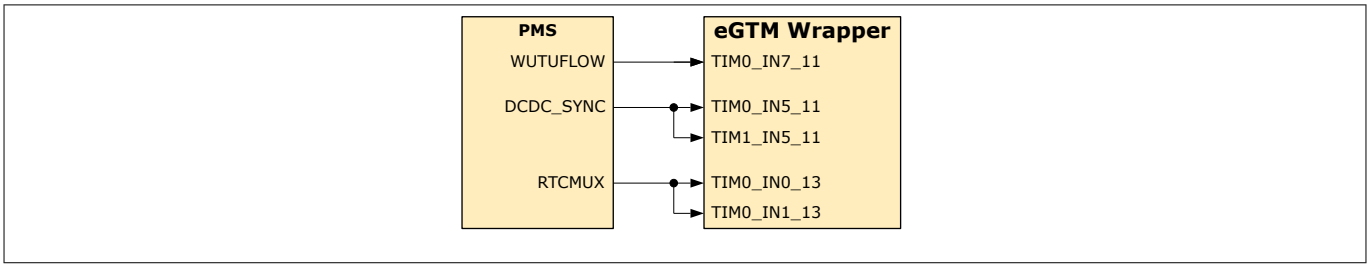

Figure 1157 LCDCDC connection with focus on (PMS_)DCDC_SYNC

There is a direct connection between PMS and eGTM configurable by the TIMnINSEL register, which is called PMS_DCDC_SYNC.

Output

The register LCDCDC_OUT selects an output. Several outputs can control the power supply.

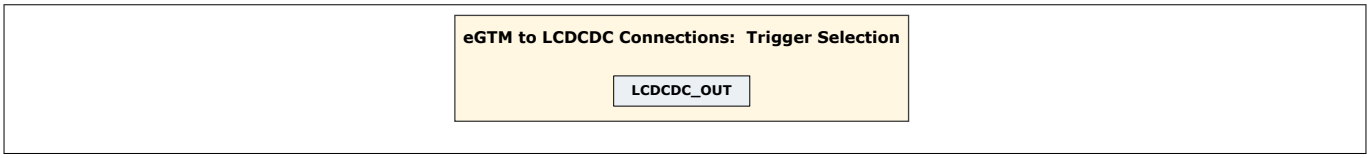

Figure 1158 Register overview

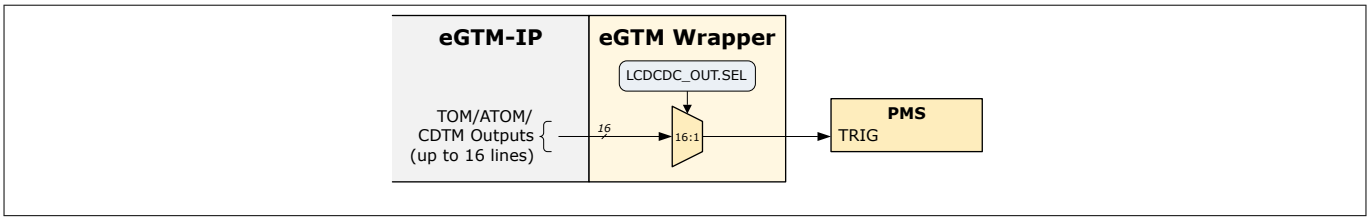

Figure 1159 Detailed structure of LCDCDC_OUT

LCDCDC related registers are: TIMnINSEL for cluster 0 & 1 and LCDCDC_OUT.

eGTM to LCDCDC output trigger selection register

The bit field in this register defines which TOM/ATOM channel output is used as LCDCDC trigger.

44.3.2.6.8 eGTM connections with communication modules

This paragraph describes the connections between eGTM and communication modules. Connections from communication modules to the eGTM are all handled by TIMnINSEL.

Connections to communication modules

The eGTM has connections to communication modules to trigger actions, or to measure a communication.

eGTM to CAN connection

Each CAN module receives a trigger input from the eGTM.

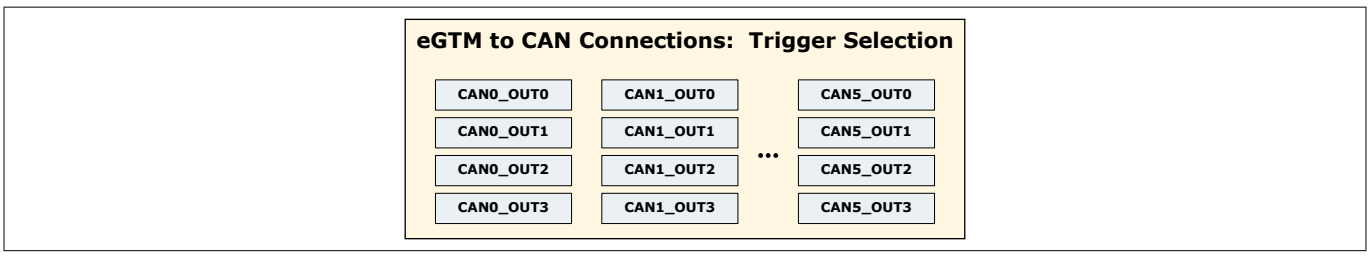

Figure 1160 CANn_OUT overview

- For each CAN node, one separate register called CANn_OUTx, is implemented
  - Index n is the CAN module number
  - Index x is the CAN node number
- The 4-bit-field SEL selects 1 out of 16 possible eGTM output lines as CANn_TRIGx trigger output signal

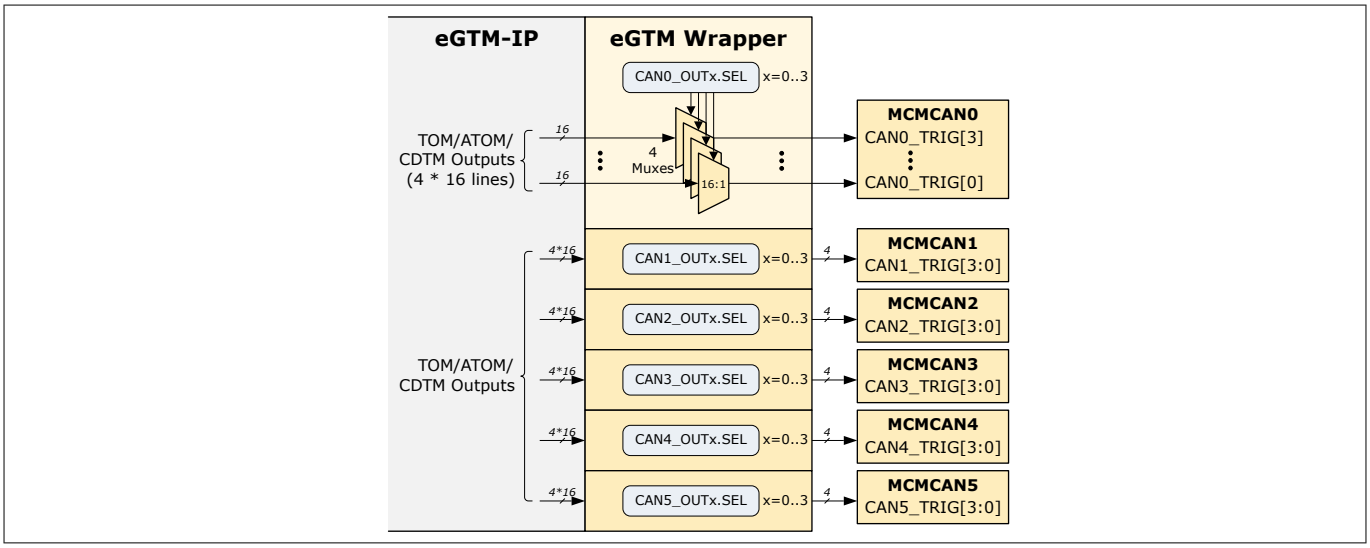

Figure 1161 eGTM to CAN trigger selection and connection

eGTM to CANn output selection register x. n*4+ x<24 , if interface exists. (x=0-3;n=0-5)

The bit field in this register defines which TOM/ATOM channel output is used as CANn node trigger x.

CANn_OUTx (n=0-5;x=0-3)

Offset address: 061480_H+n*10_H+x*4

CAN to eGTM connection

The CAN interrupts 12 to 15 are connected to the TIM inputs of the eGTM.

- CAN0 interrupt lines 12, 14 and 15 are each connected to 3 TIM inputs and interrupt line 13 is connected to 4 TIM inputs (mapped to bit 15 of TIM)
- CAN1 - CAN4 interrupt lines are each connected to 1 TIM input (mapped to bit 14 of TIM)
- TIM clusters 0 to 2 are used for these connections

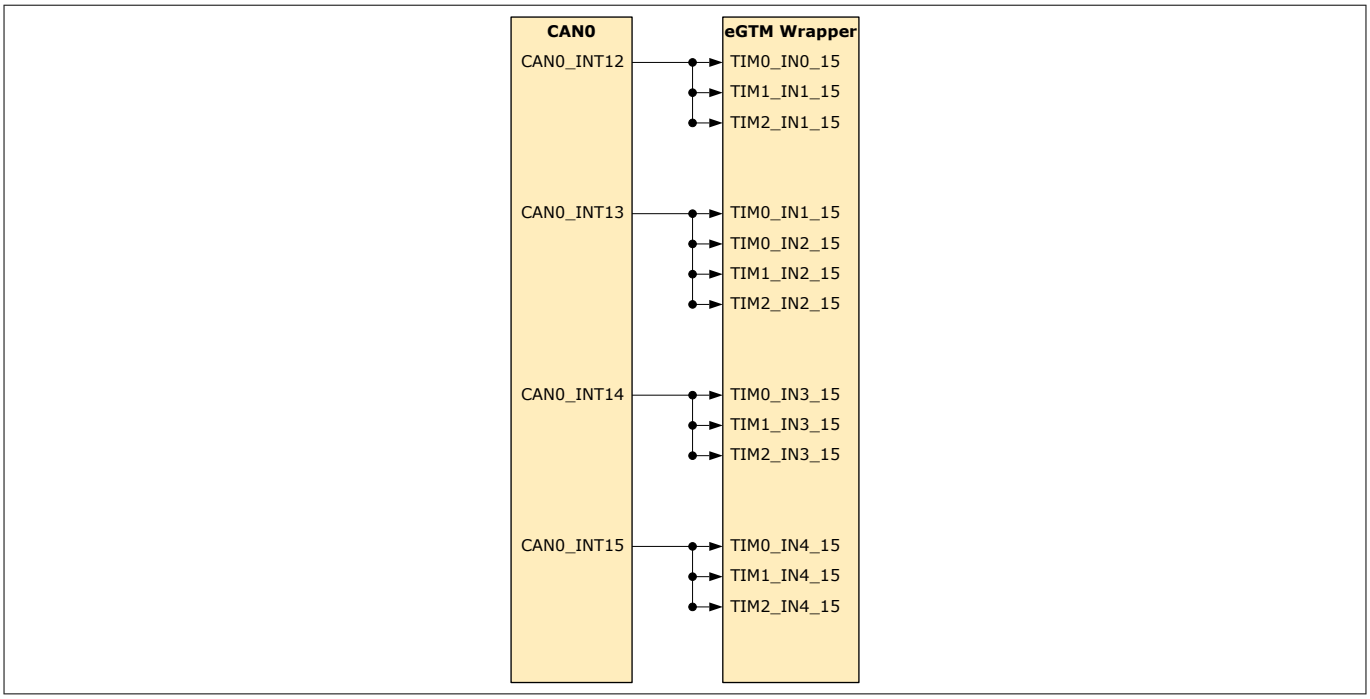

Figure 1162 CAN0 to eGTM connections

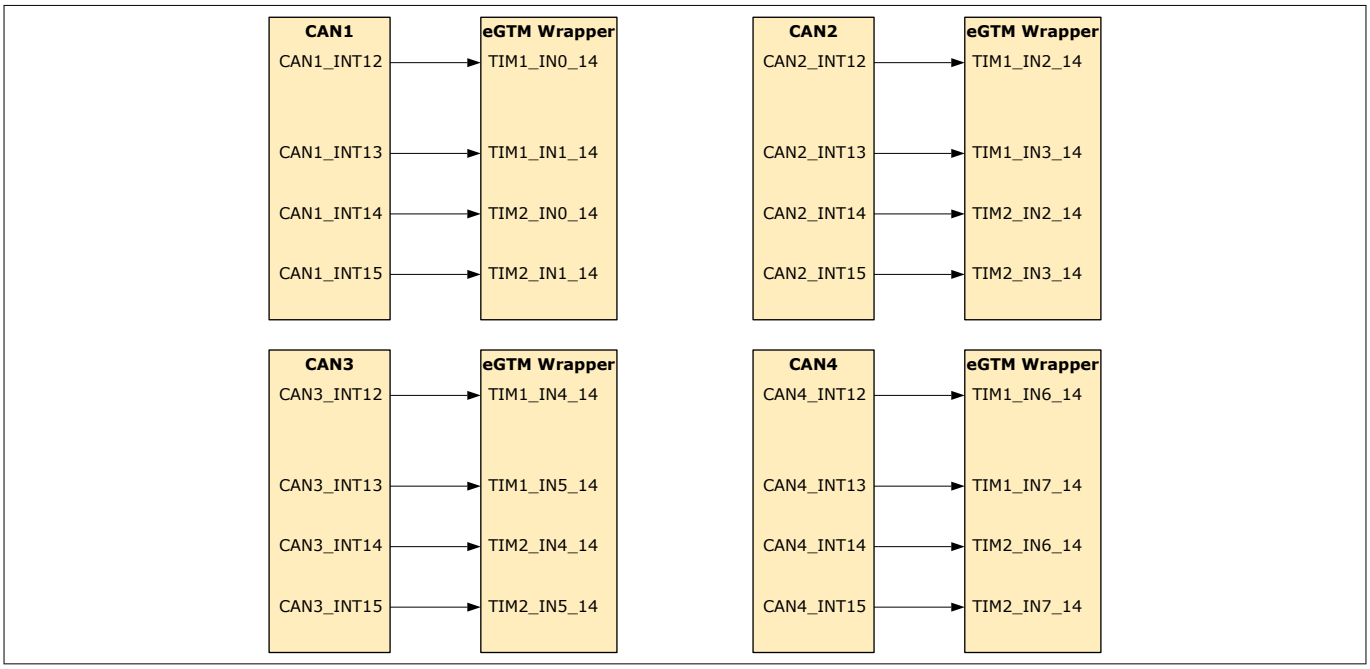

Figure 1163 CAN1-4 to eGTM connections

In addition connections from CAN XL to TIMnINSEL exist.

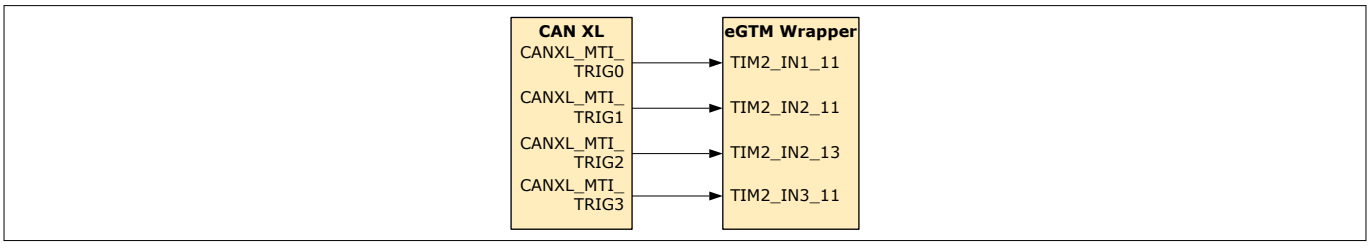

Figure 1164 CAN XL to eGTM connections

eGTM to ASCLIN connection

This connection enables the application to trigger an action on the ASCLIN module through a timer.

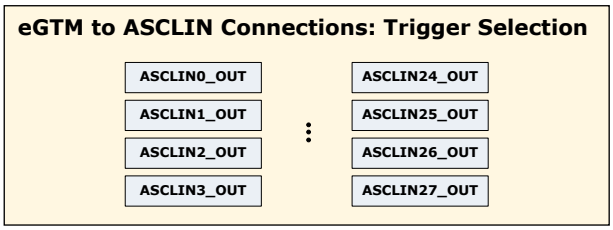

Figure 1165 Registers ASCLINn_OUT overview

- For each ASCLIN module one separate register called ASCLINn_OUT is implemented
  - Index n corresponds to the ASCLIN module number
  - The 5-bit-field SEL selects one out of 32 possible eGTM output lines as ASCLINn_TRIG trigger output signal

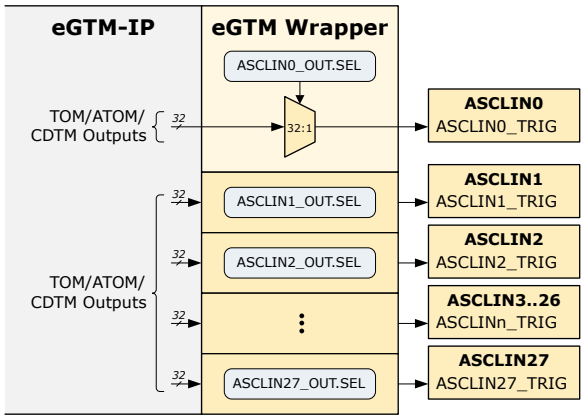

Figure 1166 Details on ASCLINn_OUT registers

eGTM to ASCLINn output selection register. n<28 , if interface exists. (n=0-27)

Ethernet to eGTM connection

Signals from the Ethernet module are connected to the TIM inputs of the eGTM for measuring purposes.

GETH PPSn interrupts

The following only exists, if a Gigabit Ethernet module is present.

- The GETH PPSn interrupts (signals GETHPPSn) are connected to the TIM modules of cluster 0 and 1.
  - For GETHPPSn, n ranges from 0 to 3
- The position on the TIM input multiplexers is line 15

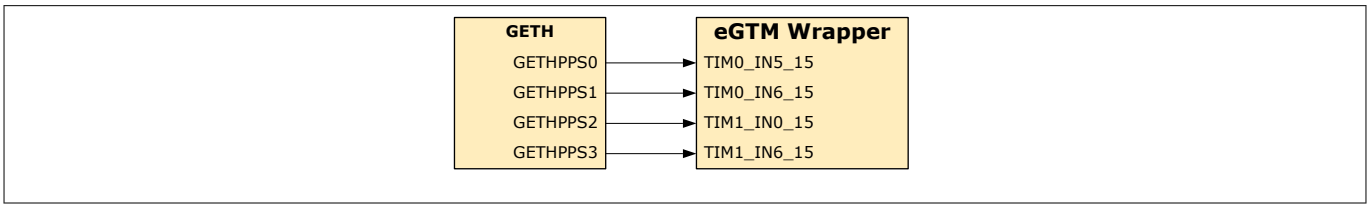

Figure 1169 Gigabit Ethernet to eGTM connections

LETH PPSn interrupts

- The LETH PPSn interrupts (signals LETHPPSn) are connected to the TIM modules of cluster 1 and 2.
  - For LETHPPSn, n is from 0 to 3
- The position on the TIM input multiplexers is line 13

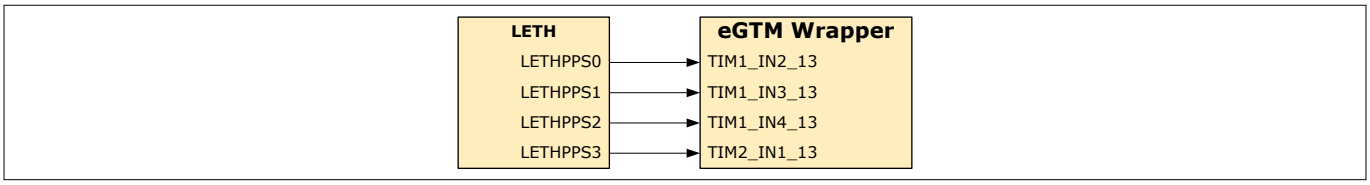

Figure 1170 Lite Ethernet to eGTM connections

FlexRay to eGTM connection

The macrotick signal MT0, is connected from the FlexRay modules 0 and 1 to the TIM inputs of the eGTM. These signals allows to measure the master clock.

- TIM cluster 0 and 2, are used for the MT0 input

- TIM cluster 1, are used for the MT1 input
- The position on the TIM input multiplexers is line 15

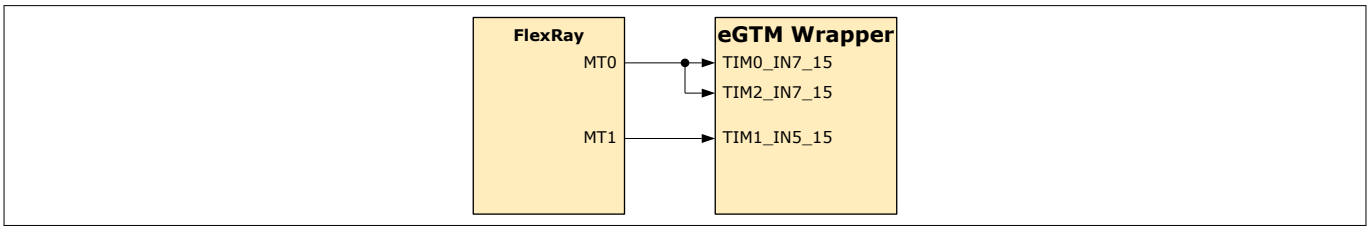

Figure 1171 FlexRay to eGTM connection

eGTM to MSC connection

The eGTM to MSC connections scales with eGTM output resources as well as MSC modules. Lower eGTM cluster numbers relate to lower MSC module numbers.

To get a first impression on the MSC connections, an overview is provided:

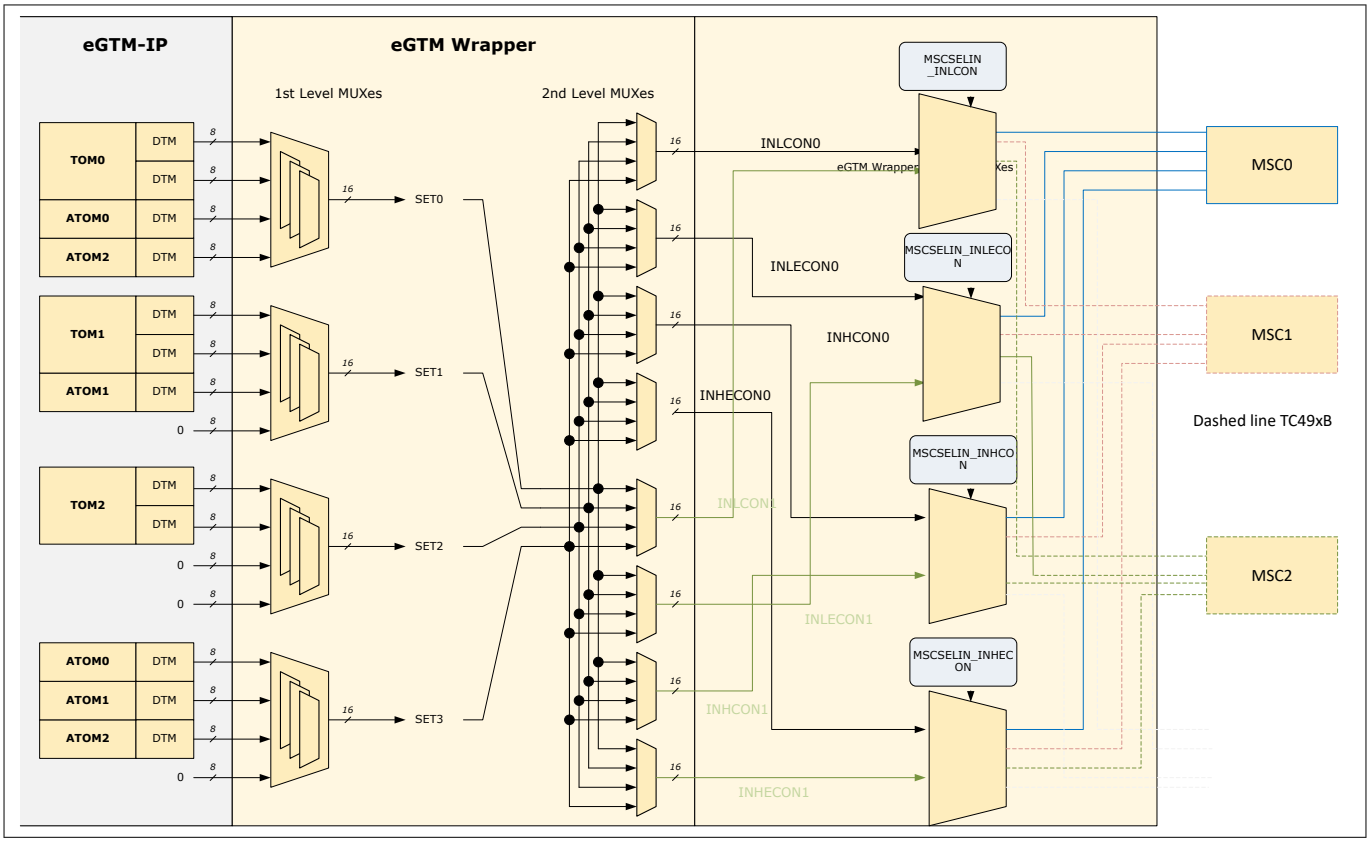

Figure 1172 MSC overview

The control registers are listed below.

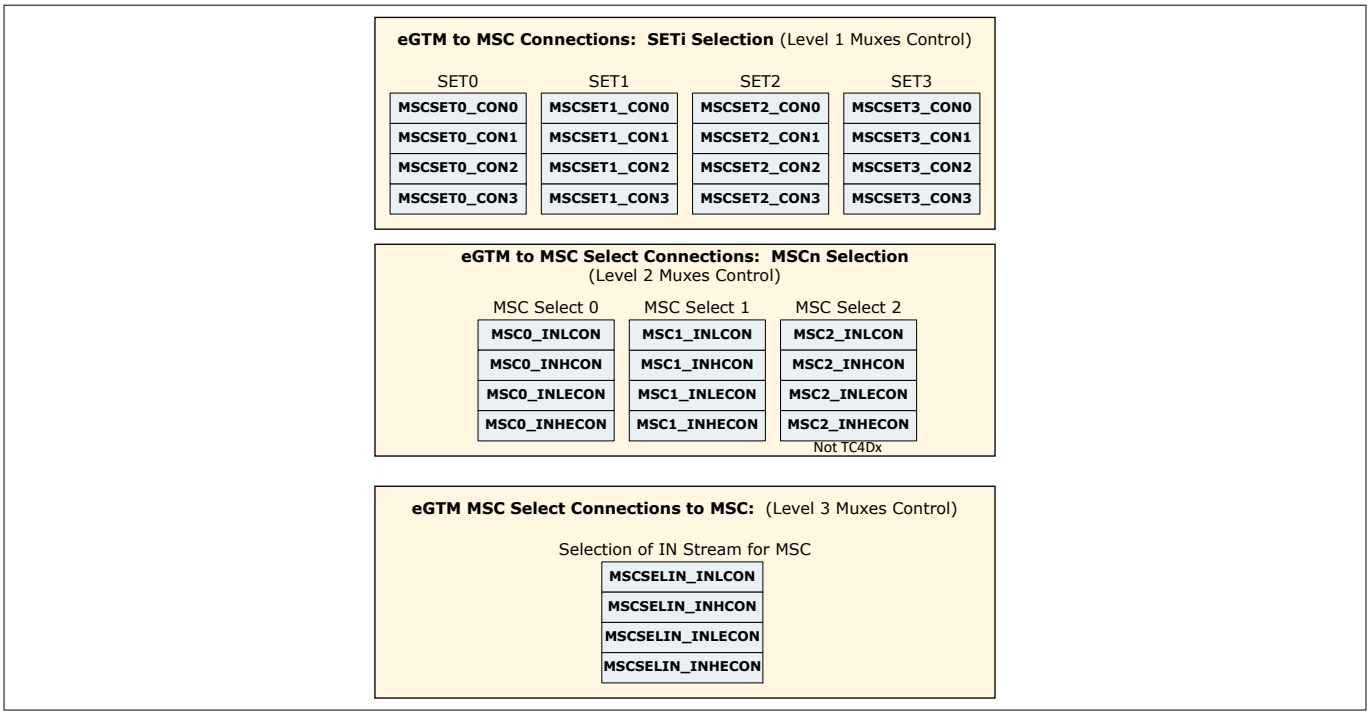

Figure 1173 Registers for MSC control

To allow a flexible distribution of the eGTM output signals to the MSC ALTIN(L/LE/H/HE)CON inputs, a three-stage approach is implemented.

First-level multiplexers

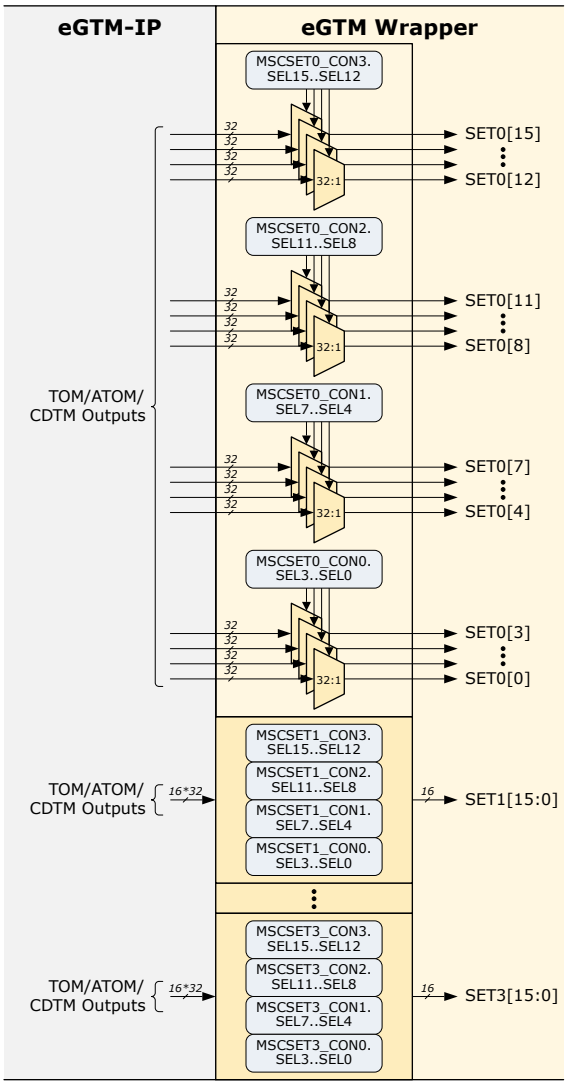

Figure 1174 First level multiplexer overview - control of the sets

The details of the first-level multiplexers for the selection of the individual lines of a SETn is shown in the figure above (eGTM configuration from TOMs/ATOMs to SETs).

- In the first stage, the first-level MUXes, several sets of 16 signals can be generated. These are called SETn
  - For eGTM, 4 sets are available in first level
- For each of the 16 lines of a SETn, one out of 32 eGTM output signals can be selected
  - Therefore, sixteen 32-to-1 multiplexers are used, each controlled by SELx
  - Each multiplexer is connected to the same 32 eGTM output signals
- Four registers, called MSCSETi_CON0 to MSCSETi_CON3, are used to hold the required number of 4 SELx bit-fields
- For each SETn, a different combination of TOM and ATOM output signals is available

Second-level multiplexers

The details of the second-level multiplexers for the selection of a SETn for an MSC alternate input bus is shown in the following figure:

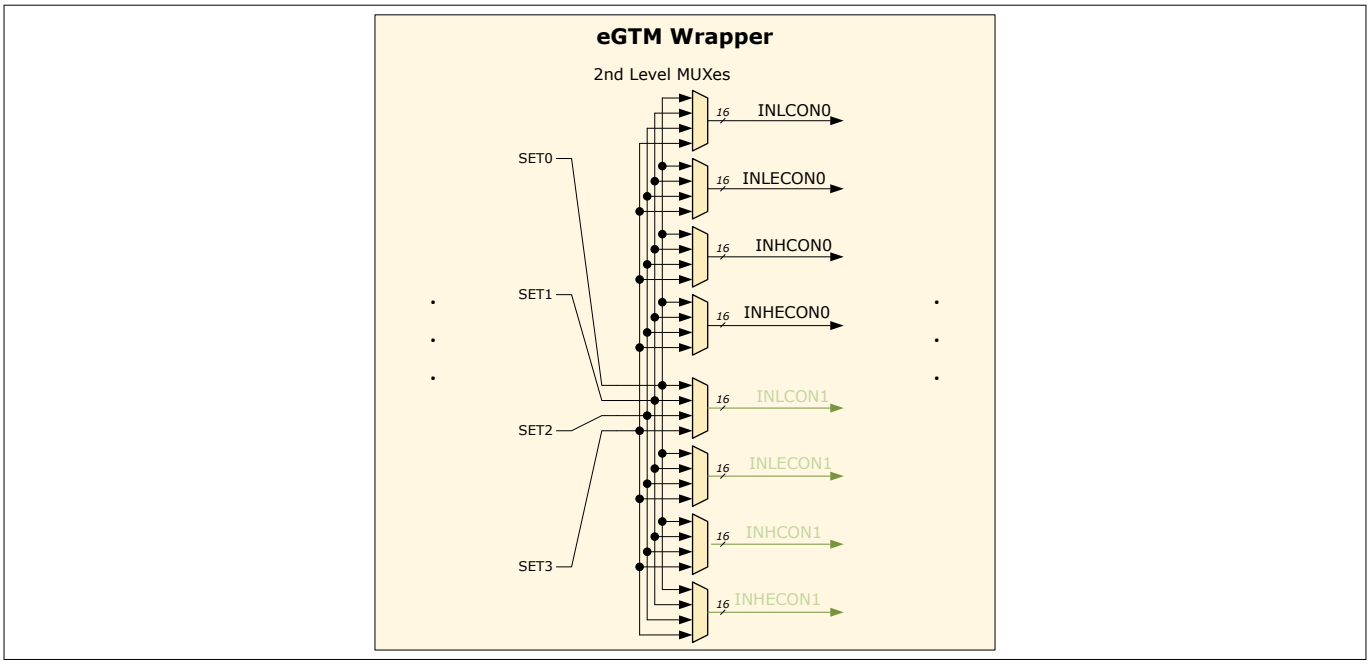

Figure 1175 Second-level multiplexer

- In the second stage, by the second-level MUXes, one of these SETn signal sets can be individually selected
- For each input bus, an associated configuration register is implemented: MSCn_INLCON, MSCn_INLECON, MSCn_INHCON, MSCn_INHECON
- Individually for each line of an input bus, the respective line out of four possible SETn signal sets can be selected. Each line has a 2-bit-field, SEL0 to SEL15, in its associated register

Additional MSC mapping

This additional multiplexer stage provides the possibility to switch a signal set to a different MSC. As this is the third stage, it is called third-level multiplexer.

The MSC has a third-level multiplexer which maps the eGTM to input bus MSCn_INLCON signal selection register (n=0-1), eGTM to input bus MSCn_INLECON signal selection register (n=0-1), eGTM to input bus MSCn_INHCON signal selection register (n=0-1) and eGTM to input bus MSCn_INHECON signal selection register (n=0-1) stream, to a Selection of INLCON stream for MSC, Selection of INLECON stream for MSC, Selection of INHCON stream for MSC and Selection of INHECON stream for MSC which is including the configuration on mapping a specific stream with an MSC. This mapping enables the possibility of having a flexible approach of mapping GTM resources to a corresponding MSC.

The mapping is shown in the figure below.

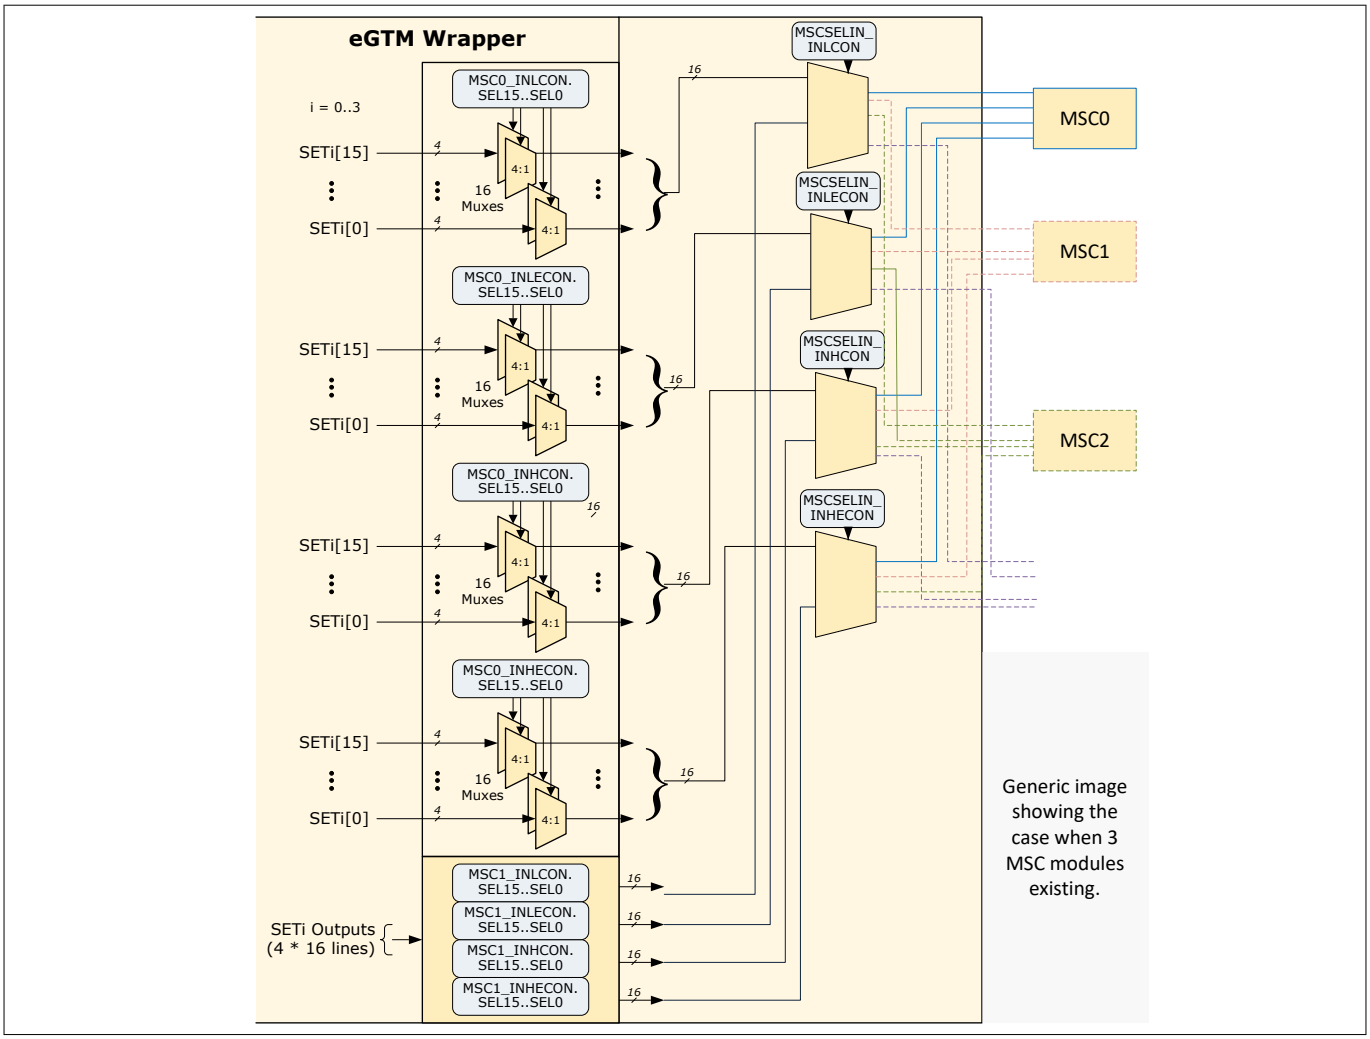

Figure 1176 MSC mapping

As shown in the figure, the registers control multiplexers mapping the signals from GTM to a specific MSC.

eGTM to MSC SETi output selection register j (j=0;i=0-3)

Sensor interface connections

The following sub-chapter shows the connection from the eGTM to PSI5/PSI5S sensors and SENT SPC interface.

eGTM to PSI5 connection

The eGTM to PSI5 connection enables the application to activate trigger signals to a PSI5 device (Manchester Decoded Interface).

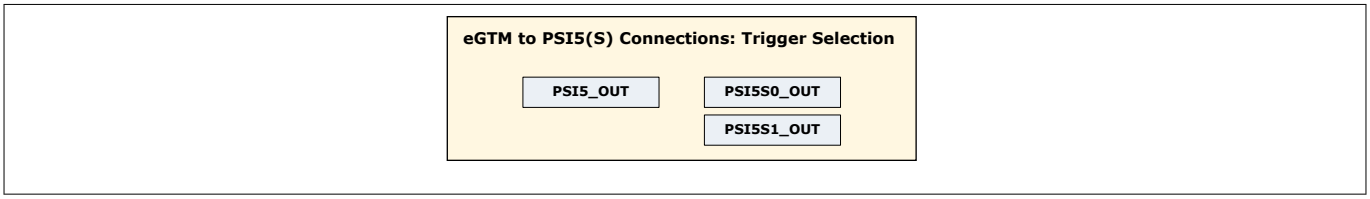

Figure 1177 PSI5 register overview

- One register called PSI5_OUT is implemented, containing 6 bit-fields
- SEL0 through to SEL5 select 1 out of 16 eGTM output lines as PSI5_TRIG0 to PSI5_TRIG5 trigger output signals
- For each trigger signal, the same set of selectable eGTM output signals are available.

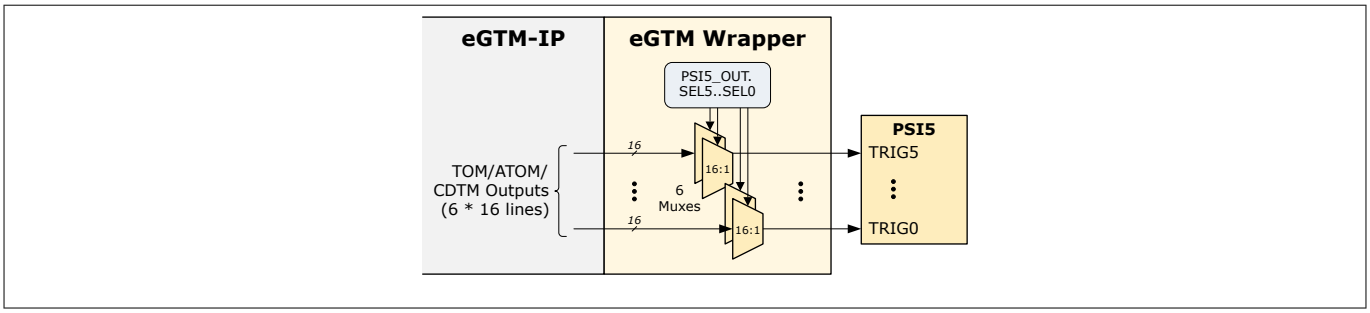

Figure 1178 PSI5_OUT details

eGTM to PSI5 output trigger selection register

The bit fields in this register define which TOM/ATOM channel output is used as PSI5 trigger x.

PSI5_OUT Offset address: 061400_H

eGTM to PSI5 output trigger selection register Kernel Reset value: $0000\ 0000_H$

0	31:24	r	**Reserved, must not be used.** Read as 0, shall be written with 0.

eGTM to PSI5-S connection

The eGTM to PSI5-S connection enables the application to activate trigger signals to a PSI5-S device, which is a UART type Interface.

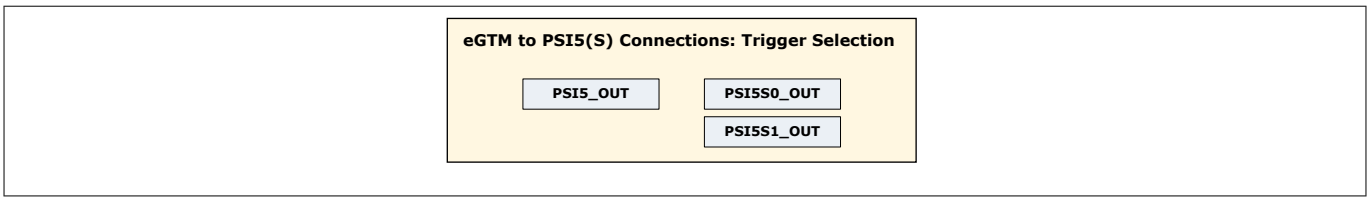

Figure 1179 PSI5S register overview

- For each PSI5_S instance, one register, called PSI5Sn_OUT, is implemented, containing 8 bit-fields
  - SEL0 to SEL7 select 1 out of 16 eGTM output lines as PSI5Sn_TRIG0 to PSI5Sn_TRIG7 trigger output signals
  - For each trigger signal, an individual set of selectable eGTM output signals is available

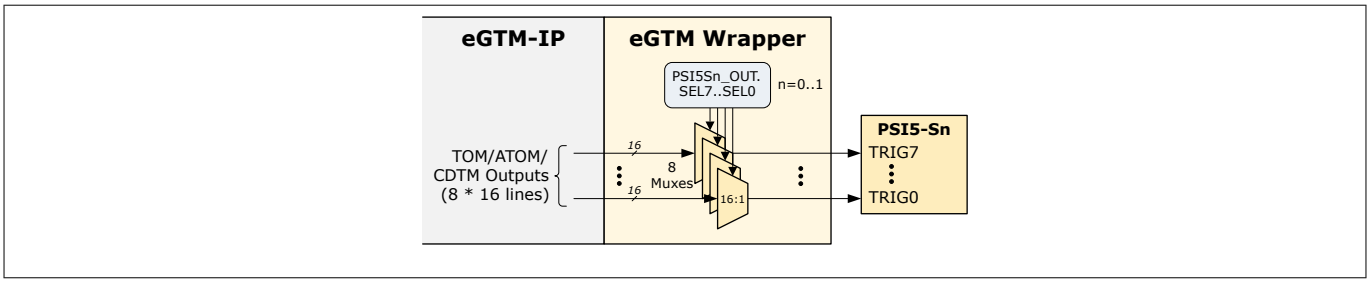

Figure 1180 PSI5Sn_OUT register details

eGTM to PSI5-Sn output trigger selection register (n=0-1)

The bit fields in this register define which TOM/ATOM channel output is used as PSI5-Sn trigger x.

PSI5Sn_OUT (n=0-1) Offset address: 061410_H+n*4

eGTM to SENT connection

The connection from eGTM to SENT is for SPC mode, selecting signals to the SPC controlled SENT sensor.

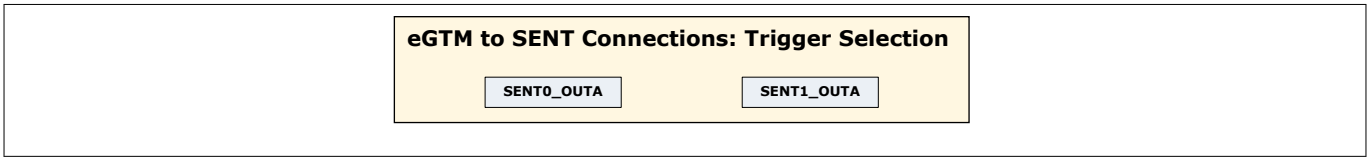

Figure 1181 SENT register overview

- 15 trigger signals can be generated for the SENT module
  - Signals SENTn_TRIG[2:0] are from the eGTM
  - Signals SENTn_TRIG[14:3] are from the classic GTM (if available)
- Select the trigger signals by: SENTn_OUTA
  - Each register holds a number of 5-bit-fields to select one out of up to 24 eGTM output signals for the respective trigger signal. Each bit-field is assigned to one eGTM cluster
- The upper 7 lines of the 32:1 multiplexers are reserved

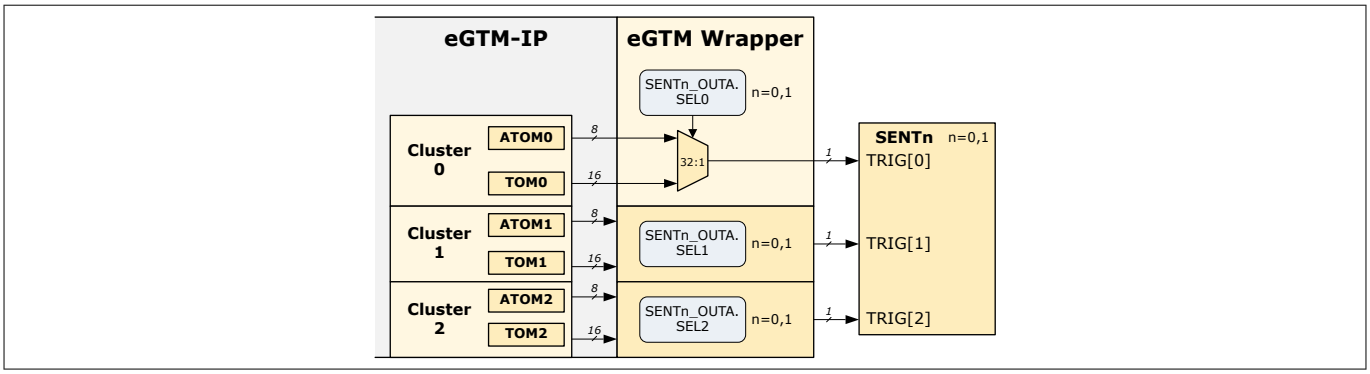

Figure 1182 SENTn_TRIG register details

eGTM to SENTn trigger x output selection register A (n=0-1)

The bit fields in this register define which TOM/ATOM channel output is used as SENTn trigger x.

44.3.2.7 eGTM memories address map

The eGTM has no memory based GTM modules.

44.3.2.8 eGTM OCDS interface

The eGTM OCDS module supports software development and debugging with the following features:

- Read and write access to all eGTM registers and memories while running or suspended
- Selected eGTM signals can be routed to device pins
- eGTM can be suspended by OCDS. This is controlled through the OCS register

44.3.2.8.1 eGTM suspend

If eGTM is suspended, the (e)GTM_HALT_REQ of the GTM IP is used. This leads to the fact, that in case of a soft-suspend, all outputs remain on their current state. Suspend is globally controlled in OTGS and eGTM locally with the OCS register.

This sequence can be executed by the tool transparent to the user.

***Note**: For electrical drive applications, it is not recommended to use any kind of suspend. Outputs, which remain on the very same level can lead to physical damage of switches and electrical drive. In case of usage of suspend, Infineon is not liable for any harm this might cause. In case of a need of suspend, disconnect all lines connected to outputs of the eGTM and debug the pure pins only.*

44.3.2.8.2 OCDS trigger bus (OTGB) interface

The OTGB0 and OTGB1 trigger buses are connected through the regular OTGB infrastructure to device pins and to MCDS.

OTGB0 and OTGB1 are 16-bit trigger buses.

Further information about OTGB0 and OTGB1 is available in the OTGM (OCDS Trigger MUX) section of the OCDS chapter.

eGTM trigger and trace features

- IO signals
  - TIM input signals (after filter)
  - TOM output signals
  - ATOM output signals
  - SPE NIPD and DIR signals
  - Groups of eight signals, such as all inputs of a specific TIM for example
  - Two or four arbitrary groups using OTGB0 or OTGB1
  - Signals can be used as triggers or processed with OTGS (OCDS trigger switch)
  - Signals can be routed to TGO device pins through the OTGS

The eGTM module has 16-bit and 32-bit Trigger Sets, which are selected with the OTSS register.

The OTGB0 and OTGB1 signals relate to the eGTM internal clock, which can be slower or equal to the OTGB clock.

***Note**: The trigger sets mentioned above only exist if the corresponding resources exist on the device.*

44.3.2.8.3 IO and other signal trigger sets

The IO trigger sets consist of the most important TIM, TOM, and ATOM signals in groups of 8. There are two groups of SPE signals and one group for miscellaneous signals.

The multiplexer allows for mapping arbitrary and different signal groups to the high and the low byte of a 16-bit trigger set. It is also possible to use one or two 16-bit trigger sets with this flexibility. This is controlled with the OTSC0 register.

For normal clock configurations, this difference will not be more than a factor of two, which means a maximum delay of one eGTM clock.

Table 2299 eGTM trigger sets

Trigger set
TS16_IOS Trigger Set IO and Other Signals

The following trigger set mapping options table shows all trigger set mapping options.

Table 2300 Trigger set mapping options

OTGB0	OTGB1
TS16_IOS	TS16_IOS

The OTGB0 and OTGB1 signals relate to the eGTM internal clock, which can be slower or equal to the OTGB clock.

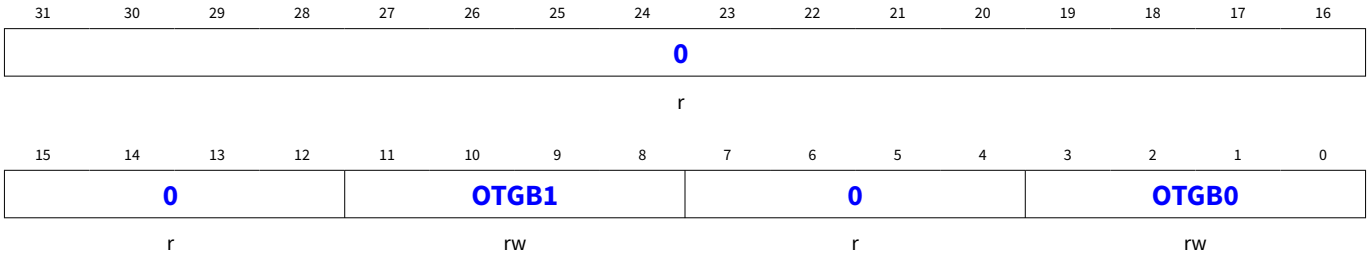
Table 2301 TS16_IOS trigger set IO and other signals

Bits	Name	Description	
[7:0]	SG0	A group of 8 signals from a selected TIM, TOM, ATOM or SPE.	
		TIM	All 8 input signals after filter F_OUT.
		TOML	Lower 8 output signals (channel 0-7) of TOM.
		TOMH	Higher 8 output signals (channel 8-15) of TOM.
		ATOM	All 8 output signals of ATOM channels.
		SPE	For OTSC0.BxxMI Module Instance 0: Bits 0,1: SPE0_NIPD, SPE_DIR0 Bits 2,3: SPE1_NIPD, SPE_DIR1 Bits 4,5: SPE2_NIPD, SPE_DIR2 others, reserved (value is 0)
		MISC	Bit 0: reserved Bit 1: reserved Bit 4: TBU0 trigger (OTBU0T) Bit 5: TBU1 trigger (OTBU1T) Bit 6: TBU2 trigger (OTBU2T) Bit 7: reserved others, reserved
[15:8]	SG1		Independent selection with same options as for bits [7:0]

44.3.2.8.4 OCDS trigger set select register

OCDS_OTSS Offset address: 060510_H

OCDS trigger set select register Debug Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
OTGB0	3:0	rw	**Trigger set for OTGB0** 0_H No trigger set selected 1_H Trigger set TS16_IOS in table "TS16_IOS trigger set IO and other signals" **others,** Reserved, must not be used.
OTGB1	11:8	rw	**Trigger set for OTGB1** 0_H No trigger set selected 1_H Trigger set TS16_IOS in table "TS16_IOS trigger set IO and other signals" **others,** Reserved, must not be used.
0	7:4, 15:12, 31:16	r	**Reserved, must not be used.** Read as 0, shall be written with 0.

44.3.2.9 eGTM application constraints and limitations

If setting up an application on eGTM, the following constraints have to be taken into account. Otherwise, the eGTM may not be able to fulfill the specified behavior.

For devices being capable of frequencies above 400 MHz, setting CCM[i] configuration register (i=0,2).CLS_CLK_DIV==01_B is not allowed for frequencies above 250 MHz, as the device might be malfunctioning.

44.3.2.10 General remarks

The eGTM kernel is a pure 32-bit module, therefore accessing the eGTM, shall be not byte-wise or half word. This shall not be done and might have strange effects on the module like overwriting registers with scrapped information. For TriCore™ architecture conform accesses, no error will be shown to the outside.

The eGTM shall be used with Pulse Notify as Interrupt Mode, as otherwise the correct functionality of eGTM interrupts and TriCore™ cannot be guaranteed.

44.4 High Resolution Pulse Width Modulation (HRPWM)

This device does not provide HRPWM. The function and the registers are not implemented in this device.

44.5 Registers

44.5.1 Register overview - access mode glossary

Table 2302 Register overview - access mode glossary

Keyword	Description
E	Access protection using PROT register CTRL_PROTE.
SE	Access protection using PROT register PROTSE.
APU-P	Protection group consisting of registers CTRL_ACCEN_WRA, CTRL_ACCEN_WRB, CTRL_ACCEN_RDA, CTRL_ACCEN_RDB, CTRL_ACCEN_VM, CTRL_ACCEN_PRS.
P	Access protection using *APU-P* registers.
APU-PCLi (i=0-2)	Protection group consisting of registers CLi_ACCEN_WRA, CLi_ACCEN_WRB, CLi_ACCEN_RDA, CLi_ACCEN_RDB, CLi_ACCEN_VM, CLi_ACCEN_PRS.
PCLi	Access protection using *APU-PCLi* registers.
APU-PGTM	Protection group consisting of registers CTRLGTM_ACCEN_WRA, CTRLGTM_ACCEN_WRB, CTRLGTM_ACCEN_RDA, CTRLGTM_ACCEN_RDB, CTRLGTM_ACCEN_VM, CTRLGTM_ACCEN_PRS.
PGTM	Access protection using *APU-PGTM* registers.
APU-PSAFE	Protection group consisting of registers SAFEGTM_ACCEN_WRA, SAFEGTM_ACCEN_WRB, SAFEGTM_ACCEN_RDA, SAFEGTM_ACCEN_RDB, SAFEGTM_ACCEN_VM, SAFEGTM_ACCEN_PRS.
PSAFE	Access protection using *APU-PSAFE* registers.
APU-PWRAP	Protection group consisting of registers WRAP_ACCEN_WRA, WRAP_ACCEN_WRB, WRAP_ACCEN_RDA, WRAP_ACCEN_RDB, WRAP_ACCEN_VM, WRAP_ACCEN_PRS.
PWRAP	Access protection using *APU-PWRAP* registers.
32	Access only when using 32-bit width.
BE	Always returns a Bus Error.
U	No access restrictions.
PROT	Access restrictions as defined in the PROT register access rules.
nBE	Indicates that no Bus Error is generated when accessing this address range, even though it is either an access to an undefined address or the access does not follow the given rules.

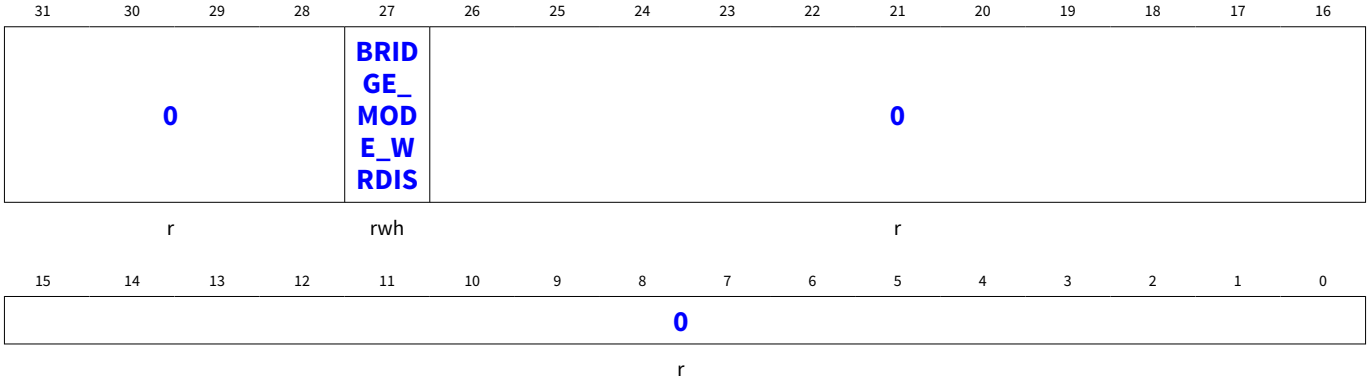
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0				REL_BASE								REL_ITER			
r				r								r			

Field	Bits	Type	Description
REL_ITER	3:0	r	**Delivery number** Defines **eGTM** release iteration.
REL_BASE	11:4	r	**Release step** Defines **eGTM** release base.
VENDOR_CODE	19:16	r	**Device encoding digit 1** Defines vendor code.
DEVICE_CODE	23:20	r	**Device encoding digit 0** Defines device code.
VER_MINOR	27:24	r	**Minor version number** Defines minor version number of **eGTM** specification.
VER_MAJOR	31:28	r	**Major version number** Defines major version number of **eGTM** specification.
0	15:12	r	**Reserved** Read as 0.

44.5.4 eGTM global reset register (i=0)

CLSi_ARCH_RST (i=0) Offset address: 000004_H+i*20000_H

eGTM global reset register Kernel Reset value: 0000 0000_H

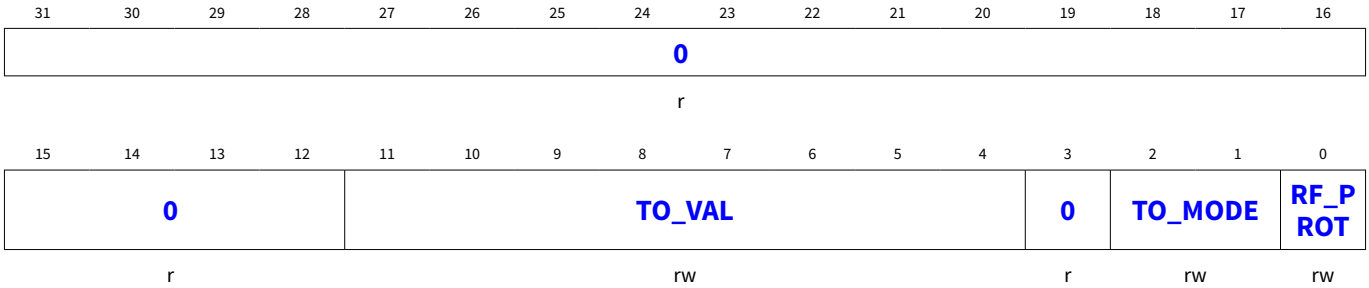


Field	Bits	Type	Description
BRIDGE_MODE_WRDIS	27	rwh	CLSi_AEI_BRIDGE_MODE **write disable** ***Note**: This bit is write-protected by (CLSi_ARCH_CTRL.RF_PROT==1 && AEI_WDATA[27:27] != CLSi_ARCH_RST.BRIDGE_MODE_WRDIS && AEI_W1R0==1).* 0_B Writing of CLSi_AEI_BRIDGE_MODE register is enabled 1_B Writing of CLSi_AEI_BRIDGE_MODE register is disabled
0	26:0, 31:28	r	**Reserved** Read as 0; must be written with 0.

44.5.5 eGTM global control register (i=0)

CLSi_ARCH_CTRL (i=0) Offset address: 000008_H+i*20000_H

eGTM global control register Kernel Reset value: $0000\ 0001_H$



Field	Bits	Type	Description
RF_PROT	0	rw	**RST and FORCINT protection** 0_B SW RST (global), SW interrupt FORCINT, and SW RAM reset functionality is enabled 1_B SW RST (global), SW interrupt FORCINT, and SW RAM reset functionality is disabled

(table continues...)

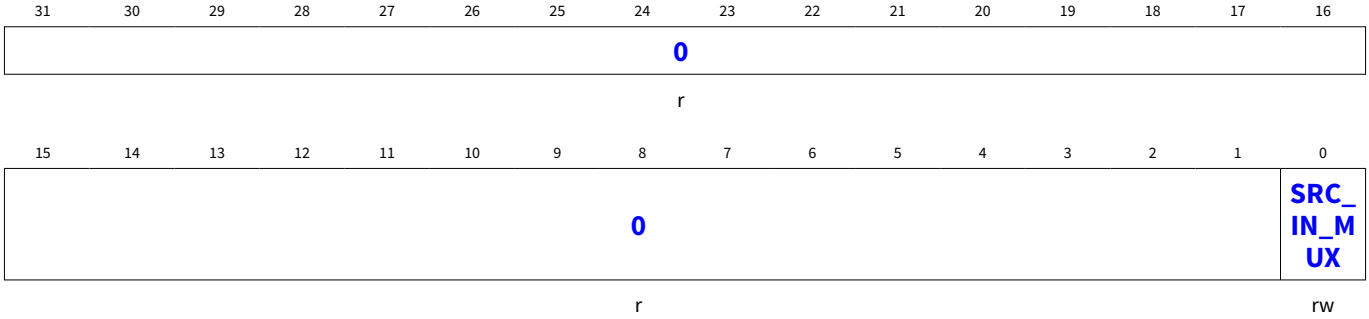
(continued)

Field	Bits	Type	Description
TO_MODE	2:1	rw	**AEI timeout mode** 00_B Observe once: If condition timeout_counter=CLSi_ARCH_CTRL.TO_VAL occurs the address AEI_ADDR and AEI_W1R0 signal will be stored to the CLSi_ARCH_AEI_ADDR_XPT register, the timeout flag in CLSi_ARCH_IRQ_NOTIFY.AEI_TO_XPT will be set. Following timeout_counter = CLSi_ARCH_CTRL.TO_VAL accesses will not overwrite the first entry in the CLSi_ARCH_AEI_ADDR_XPT register. Clearing the timeout flag CLSi_ARCH_IRQ_NOTIFY.AEI_TO_XPT will re-enable the store the next access for which the condition timeout_counter=CLSi_ARCH_CTRL.TO_VAL is fulfilled. 01_B Abort once: Same behavior as defined for observe once. Additionally, if condition timeout_counter=CLSi_ARCH_CTRL.TO_VAL occurs the pending access will be aborted by signaling an illegal module access on aei_status and ready to be sent. In case of a read-access AEI_RDATA=0 is responded. Following accesses will not be aborted, this could lead to a dead lock if the access will never terminate with AEI_READY=1. 10_B Retry: Same behavior as defined for observe once. Additionally, if condition timeout_counter=CLSi_ARCH_CTRL.TO_VAL occurs each pending access is paused by signaling AEI_SEL=0 for 1 clock-cycle, afterwards the access is active again. This leads to a retry of the actual access until the target address responds with AEI_READY=1. 11_B Abort: Same behavior as defined for observe once. Additionally, if condition timeout_counter=CLSi_ARCH_CTRL.TO_VAL occurs each pending access will be aborted by signaling an illegal module access on aei_status and ready to be sent. In case of a read-access AEI_RDATA=0 is responded.
TO_VAL	11:4	rw	**AEI timeout value** ***Note**: These bits define the number of cycles after which a timeout event occurs. When CLSi_ARCH_CTRL.TO_VAL equals zero (0) the **AEI** timeout functionality is disabled.*
0	3, 15:12, 31:16	r	**Reserved** Read as 0; must be written with 0.

44.5.6 eGTM configuration register (i=0)

CLSi_ARCH_CFG (i=0) Offset address: $00000C_H+i*20000_H$

eGTM configuration register Kernel Reset value: $0000\ 0000_H$



Field	Bits	Type	Description
SRC_IN_MUX	0	rw	**Input source selection for signal** TIM[i]_AUX_IN **(input port** AUX_IN **at module TIM)** See Figure 1018 for details. 0_B Use for TIM[i] channel j the output of TOM[k] channel j+h; k = floor(i / 2); h = mod(i , 2) *8 (j∈{0, 1,..., 7}) 1_B Use for TIM[i] channel j the output of TOM[i] channel j (TIM and TOM are in the same cluster) (j∈{0, 1,. .., 7})
0	31:1	r	**Reserved** Read as 0; must be written with 0.

44.5.7 eGTM AEI timeout exception address register (i=0)

CLSi_ARCH_AEI_ADDR_XPT (i=0) Offset address: $000010_H+i*20000_H$

eGTM AEI timeout exception address register Reset values see: Table 2304

0			SYNC_INPUT_REG	0		BUFF_OVL	MODE_UP_PGR	0					BYPASS_SYNC	MSK_WR_RSP	BRG_MODE
r			r	r		rw1ch	rh	r					rw	rw	rw

Field	Bits	Type	Description
BRG_MODE	0	rw	**Defines the operation mode for the AEI bridge** 0_B AEI bridge operates in sync_bridge mode 1_B AEI bridge operates in async_bridge mode
MSK_WR_RSP	1	rw	**Mask write response** ***Note**:* *The status of the executed write-accesses can be observed by using the notify bits CLSi_ARCH_IRQ_NOTIFY.AEI_USP_ADDR, CLSi_ARCH_IRQ_NOTIFY.AEI_IM_ADDR, CLSi_ARCH_IRQ_NOTIFY.AEI_USP_BE.* ***Note**:* *With active write buffer CLSi_AEI_BRIDGE_MODE.MSK_WR_RSP=1, execution of actions can be delayed due to previous inserted write actions in the transaction buffer which wait to be serviced. This can lead to the fact that an access on the bus to a different peripheral than the **eGTM** might be executed earlier in time than the write-access buffered in the **eGTM**. Applications must be setup up with this in mind otherwise unexpected operation can happen.* 0_B Do not mask the write response. Depending on the selected address the latency for execution can vary due to eGTM internal arbitration. After this time the status of the access will be signaled by the signal AEI_STATUS to the bus interface. 1_B Mask write response. The write buffer of the bridge is activated, the actual access will be stored to the write buffer and without latency on the bus interface the acceptance of the access is signaled. AEI_STATUS=00_B will be signaled. In case of a full write buffer the actual access will be postponed until the next write buffer entry becomes free.
BYPASS_SYNC	2	rw	**Bypass synchronizer storage elements** **If CLSi_AEI_BRIDGE_MODE .BRG_MODE == 1:** 0_B Synchronizer storage elements in use, latency increase due to synchronization (aei_clk to CLKand back CLKto aei_clk). This setting must be used if aei_clk and CLK operate fully asynchronous by independent clock sources. 1_B Synchronizer storage elements are bypassed. No additional latency due to synchronization. This setting can be used if aei_clk and CLK are generated by clock gating or clock division out of a common clock source. Clock edges on aei_clk and CLK generated out of the same clock edge of the common clock source must have zero skew. **If CLSi_AEI_BRIDGE_MODE .BRG_MODE == 0:** 0_B In synchronous mode (CLSi_AEI_BRIDGE_MODE.BRG_MODE = 0), this bit field is not relevant and has no impact 1_B In synchronous mode (CLSi_AEI_BRIDGE_MODE.BRG_MODE = 0), this bit field is not relevant and has no impact

44.5.16 eGTM AEI bridge pointer 1 register (i=0)

***Note**: This register operates on the AEI_CLK domain.*

***Note**: This register holds diagnosis information about the **AEI** bus bridge. Each access to the **eGTM** will update the defined pointer bit fields. Depending on which values of CLSi_AEI_BRIDGE_MODE.BRG_MODE, CLSi_AEI_BRIDGE_MODE.MSK_WR_RSP, the **AEI** protocol, and operating frequency are used, the 4 pointer bit fields change at different clock-cycles relative to the start of the transaction. As a result of this, reading the register can show values not equal to the defined initial value, even directly after a write to CLSi_AEI_BRIDGE_MODE.BRG_RST=1.*

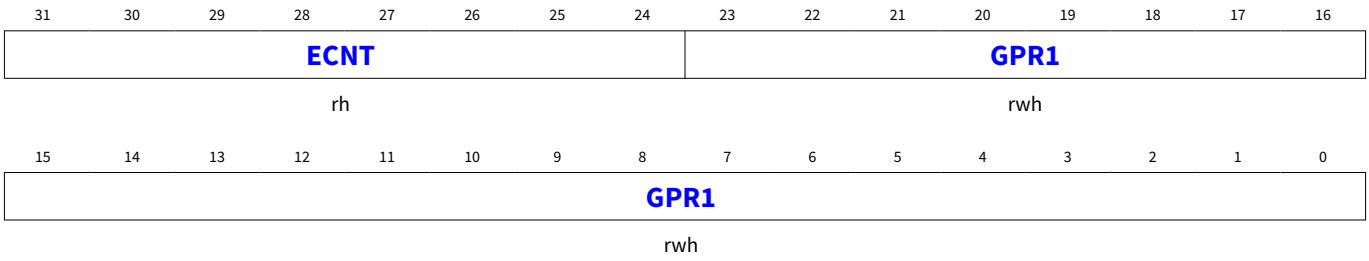
TIM channel reset	0000 0000$_H$	

44.5.52 TIM[i] channel [x] general-purpose 1 register (x=0-7;i=0-2)

CLSi_TIM_CHx_GPR1 (i=0-2;x=0-7) Offset address: 000804$_H$+i*20000$_H$+x*80$_H$

TIM[i] channel [x] general-purpose 1 register Reset values see: Table 2310



Field	Bits	Type	Description
GPR1	23:0	rwh	**Input signal characteristic parameter 1** ***Note**:* *The content of this register has different meaning for the **TIM** channels modes. The content directly depends on the bit fields CLSi_TIM_CHx_CTRL.EGPR1_SEL, CLSi_TIM_CHx_CTRL.GPR1_SEL.* ***Note**:* *In TBCM mode if CLSi_TIM_CHx_CTRL.EGPR1_SEL=1, CLSi_TIM_CHx_CTRL.GPR1_SEL= 01_B then CLSi_TIM_INP_VAL is used as input in all other cases **TIM** Filter F_OUT is used as input and Bits CLSi_TIM_CHx_GPR1[23:8] = 0* ***Note**:* *The content of this register can only be written in **TIM** channel mode TGPS and TSSM.*
ECNT	31:24	rh	**Edge counter, value refers to CLSi_TIM_CHx_ECNT.ECNT [7:0].** ***Note**:* *The CLSi_TIM_CHx_GPR1.ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of CLSi_TIM_CHx_GPR1.ECNT.* ***Note**:* *The CLSi_TIM_CHx_GPR1.ECNT register is reset to its initial value when the channel is enabled.* ***Note**:* *Bit 0 depends on the input level coming from the filter unit and defines this value.*

Table 2310 Reset values of CLSi_TIM_CHx_GPR1 (i=0-2;x=0-7)

Reset	Reset value	Note
Kernel Reset	0000 0000_H	
TIM channel reset	0000 0000_H	

44.5.53 TIM[i] channel [x] SMU counter register (x=0-7;i=0-2)

CLSi_TIM_CHx_CNT (i=0-2;x=0-7) Offset address: 000808_H+i*20000_H+x*80_H

TIM[i] channel [x] SMU counter register Reset values see: Table 2311

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								CNT							
r								rh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT															
rh															

Field	Bits	Type	Description
CNT	23:0	rh	**Actual SMU counter value** ***Note**:* *The meaning of this value depends on the configured mode:* *TPWM = actual duration of PWM signal.* *TPIM = actual duration of all pulses (sum of pulses).* *TIEM = actual number of received edges.* *TIPM = actual number of received edges.* *TGPS = elapsed time for periodic sampling.* *TSSM = shift data.*
0	31:24	r	**Reserved** Read as 0.

Table 2311 Reset values of CLSi_TIM_CHx_CNT (i=0-2;x=0-7)

Reset	Reset value	Note
Kernel Reset	$0000\ 0000_H$	
TIM channel reset	$0000\ 0000_H$	

44.5.54 TIM[i] channel [x] SMU edge counter register (x=0-7;i=0-2)

CLSi_TIM_CHx_ECNT (i=0-2;x=0-7) Offset address: $00080C_H+i*20000_H+x*80_H$

TIM[i] channel [x] SMU edge counter register Reset values see: Table 2312

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0															
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ECNT															
rh															

Field	Bits	Type	Description
ECNT	15:0	rh	**Edge counter** ***Note**:* *The CLSi_TIM_CHx_ECNT register is reset to its initial value when the channel is enabled. Bit 0 depends on the input level coming from the filter unit and defines this value.* ***Note**:* *If **TIM** channel is disabled the content of CLSi_TIM_CHx_ECNT.ECNT gets frozen and a read will auto clear the bits [15:1]. Further read-accesses to CLSi_TIM_CHx_ECNT.ECNT will show on Bit 0 the actual input signal value of the channel.*
0	31:16	r	**Reserved** Read as 0.

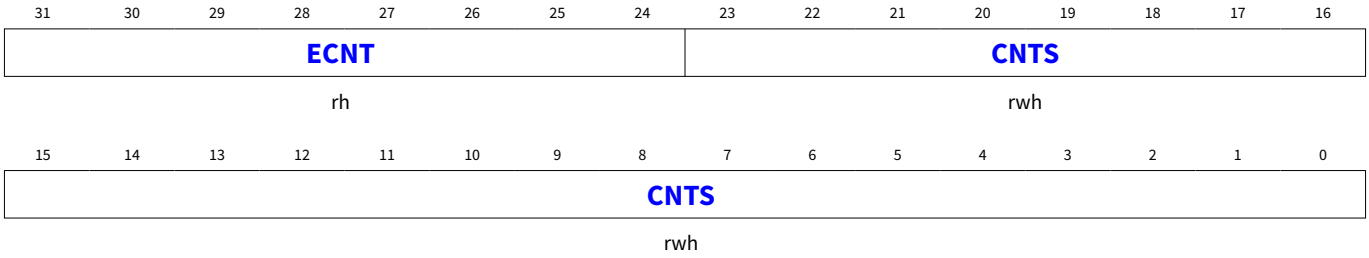
Table 2312 Reset values of CLSi_TIM_CHx_ECNT (i=0-2;x=0-7)

Reset	Reset value	Note
Kernel Reset	0000 0000$_H$	
TIM channel reset	0000 0000$_H$	

44.5.55 TIM[i] channel [x] SMU shadow counter register (x=0-7;i=0-2)

CLSi_TIM_CHx_CNTS (i=0-2;x=0-7) Offset address: 000810$_H$+i*20000$_H$+x*80$_H$

TIM[i] channel [x] SMU shadow counter register Reset values see: Table 2313



Field	Bits	Type	Description
CNTS	23:0	rwh	**Counter shadow register** ***Note**: The content of this register has different meaning for the **TIM** channels modes. The content depends directly on the bit field CLSi_TIM_CHx_CTRL.CNTS_SEL.* ***Note**: The register CLSi_TIM_CHx_CNTS is only writable in TIPM,TBCM ,TGPS and TSSM mode.*
ECNT	31:24	rh	**Edge counter** ***Note**: The CLSi_TIM_CHx_CNTS.ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of CLSi_TIM_CHx_CNTS.ECNT.* ***Note**: The CLSi_TIM_CHx_CNTS.ECNT register is reset to its initial value when the channel is enabled.* ***Note**: Bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.*

Table 2313 Reset values of CLSi_TIM_CHx_CNTS (i=0-2;x=0-7)

Reset	Reset value	Note
Kernel Reset	0000 0000$_H$	
TIM channel reset	0000 0000$_H$	

44.5.56 TIM[i]_CH[x]_TDUC (x=0-7;i=0-2)

TIM[i] channel [x] TDU counter register

***Note**: The register CLSi_TIM_CHx_TDUC is writable if Timeout unit is disabled (CLSi_TIM_CHx_CTRL.TOCTRL=00_B).*

***Note**: If CLSi_TIM_CHx_ECTRL.USE_LUT != 00_B (input signal generation by lookup-table) the bit field CLSi_TIM_CHx_TDUC.TO_CNT2 is writable at any time, CLSi_TIM_CHx_TDUC.TO_CNT, CLSi_TIM_CHx_TDUC.TO_CNT1 will not be changed.*

CLSi_TIM_CHx_TDUC (i=0-2;x=0-7) Offset address: $000814_H+i*20000_H+x*80_H$

TIM[i]_CH[x]_TDUC Reset values see: Table 2314

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
0								**TO_CNT2**							
r								rwh							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TO_CNT1								**TO_CNT**							
rwh								rwh							

Field	Bits	Type	Description
TO_CNT	7:0	rwh	**Current Timeout value slice0 for channel [y]** If bit field CLSi_TIM_CHx_TDUV.SLICING ~= 3: counter will be reset to 00_H on CLSi_TIM_CHx_ECTRL.TDU_RESYNC condition If bit field CLSi_TIM_CHx_TDUV.SLICING == 3: counter will be loaded with CLSi_TIM_CHx_TDUV.TOV2 on CLSi_TIM_CHx_ECTRL.TDU_RESYNC condition
TO_CNT1	15:8	rwh	**Current Timeout value slice1 for channel [y]** Counter will be reset to 00_H on CLSi_TIM_CHx_ECTRL.TDU_RESYNC condition
TO_CNT2	23:16	rwh	**Current Timeout value slice2 for channel [y]** Counter will be reset to 00_H on CLSi_TIM_CHx_ECTRL.TDU_RESYNC condition
0	31:24	r	**Reserved** Read as 0; must be written with 0.
