Functional Description

CY62146G/CY62146GE and CY62146GSL/CY62146GESL are high-performance CMOS low-power (MoBL) SRAM devices with embedded ECC. Both devices are offered in single and dual chip enable options and in multiple pin configurations. The CY62146GE/CY62146GESL device includes an ERR pin that signals an error-detection and correction event during a read cycle. The CY62146GSL/CY62146GESL^[1] device supports a wide voltage range of 2.2 V–3.6 V and 4.5 V–5.5 V.

Devices with a single chip enable input are accessed by asserting the chip enable (CE) input LOW. Dual chip enable

devices are accessed by asserting both chip enable inputs – $\overline{CE}_1$ as low and CE_2 as HIGH.

Data writes are performed by asserting the Write Enable ($\overline{WE}$) input LOW, while providing the data on I/O₀ through I/O₁₅ and address on A₀ through A₁₇ pins. The Byte High Enable ($\overline{BHE}$) and Byte Low Enable ($\overline{BLE}$) inputs control write operations to the upper and lower bytes of the specified memory location. $\overline{BHE}$ controls I/O₈ through I/O₁₅ and $\overline{BLE}$ controls I/O₀ through I/O₇.

Data reads are performed by asserting the Output Enable ($\overline{OE}$) input and providing the required address on the address lines. Read data is accessible on the I/O lines (I/O₀ through I/O₁₅). Byte accesses can be performed by asserting the required byte enable signal ($\overline{BHE}$ or $\overline{BLE}$) to read either the upper byte or the lower byte of data from the specified address location.

All I/Os (I/O₀ through I/O₁₅) are placed in a HI-Z state when the device is deselected (CE HIGH for a single chip enable device and $\overline{CE}_1$ HIGH/ CE_2 LOW for a dual chip enable device), or control signals are deasserted ($\overline{OE}$, $\overline{BLE}$, $\overline{BHE}$).

On the CY62146GE/CY62146GESL devices, the detection and correction of a single-bit error in the accessed location is indicated by the assertion of the ERR output (ERR = HIGH)^[2]. See the [Truth Table – CY62146G/CY62146GE/CY62146GSL/CY62146GESL](#) on [page 17](#) for a complete description of read and write modes.

The logic block diagrams are on page 2.

Notes

24. Test conditions assume a signal transition time (rise/fall) of 3 ns or less, timing reference levels of 1.5 V (for $V_{CC} \geq 3$ V) and $V_{CC}/2$ (for $V_{CC} < 3$ V), and input pulse levels of 0 to 3 V (for $V_{CC} \geq 3$ V) and 0 to V_{CC} (for $V_{CC} < 3$ V). Test conditions for the read cycle use output loading shown in AC Test Loads and Waveforms section, unless specified otherwise.

25. At any temperature and voltage condition, t_{HZCE} is less than t_{LZCE} , t_{HZBE} is less than t_{LZBE} , t_{HZOE} is less than t_{LZOE} , and t_{HZWE} is less than t_{LZWE} for any device.

26. These parameters are guaranteed by design.

27. t_{HZOE} , t_{HZCE} , t_{HZBE} , and t_{HZWE} transitions are measured when the outputs enter a high-impedance state.

28. The internal write time of the memory is defined by the overlap of $\overline{WE} = V_{IL}$, $\overline{CE}_1 = V_{IL}$, $\overline{BHE}$ or $\overline{BLE}$, or both = V_{IL} , and $CE_2 = V_{IH}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing must refer to the edge of the signal that terminates the write.

29. The minimum pulse width in Write Cycle No. 3 ($\overline{WE}$ Controlled, $\overline{OE}$ LOW) should be equal to sum of t_{SD} and t_{HZWE} .

ERR Output – CY62146GE/CY62146GESL

Output ^[45]	Mode
0	Read operation, no single-bit error in the stored data.
1	Read operation, single-bit error detected and corrected.
HI-Z	Device deselected/outputs disabled/Write operation

Notes

44. The 'X' (Don't care) state for the chip enables refer to the logic state (either HIGH or LOW). Intermediate voltage levels on these pins is not permitted.

45. ERR is an output pin. If not used, this pin should be left floating.
