The output buffer can be used to drive analog signals high or low without issue.</p> <p>'0': Input buffer disabled<br/>'1': Input buffer enabled</p> <p>Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 2 : 0 | DRIVE_MODE0 | <p>The GPIO drive mode for IO pin 0. Resistive pull-up and pull-down is selected in the drive mode.</p> <p>Note: when initializing IO's that are connected to a live bus (such as I2C), make sure the peripheral and HSIOM (HSIOM_PRT_SELx) is properly configured before turning the IO on here to avoid producing glitches on the bus.</p> <p>Note: that peripherals other than GPIO &amp; UDB/DSI directly control both the output and output-enable of the output buffer (peripherals can drive strong 0 or strong 1 in any mode except OFF='0').</p> <p>Note: D_OUT, D_OUT_EN are pins of GPIO cell.</p> <p>Default Value: 0</p> <p><b>0x0: HIGHZ :</b></p> <p>Output buffer is off creating a high impedance input<br/>D_OUT = '0': High Impedance<br/>D_OUT = '1': High Impedance</p> <p><b>0x1: RESERVED :</b></p> <p>This mode is reserved and should not be used. No damage will occur if this mode is selected. The pin will generally perform the same as the STRONG drive mode although this is not guaranteed for all use cases.</p> <p>For GPIO &amp; UDB/DSI peripherals:<br/>When D_OUT_EN = 1:<br/>D_OUT = '0': Strong pull down<br/>D_OUT = '1': Strong pull up<br/>When D_OUT_EN = 0:<br/>D_OUT = '0': High impedance<br/>D_OUT = '1': High impedance</p> <p>For peripherals other than GPIO &amp; UDB/DSI:<br/>When D_OUT_EN = 1:<br/>D_OUT = '0': Strong pull down<br/>D_OUT = '1': Strong pull up<br/>When D_OUT_EN = 0:<br/>D_OUT = '0': High impedance<br/>D_OUT = '1': High impedance</p> |

### 16.1.31 GPIO\_PRT4\_CFG (continued)

#### 0x2: PULLUP :

Resistive pull up

For GPIO & UDB/DSI peripherals:

When D\_OUT\_EN = 1:

D\_OUT = '0': Strong pull down

D\_OUT = '1': Weak/resistive pull up

When D\_OUT\_EN = 0:

D\_OUT = '0': High impedance

D\_OUT = '1': High impedance

For peripherals other than GPIO & UDB/DSI:

When D\_OUT\_EN = 1:

D\_OUT = '0': Strong pull down

D\_OUT = '1': Strong pull up

When D\_OUT\_EN = 0:

D\_OUT = '0': Weak/resistive pull up

D\_OUT = '1': Weak/resistive pull up

#### 0x3: PULLDOWN :

Resistive pull down

For GPIO & UDB/DSI peripherals:

When D\_OUT\_EN = 1:

D\_OUT = '0': Weak/resistive pull down

D\_OUT = '1': Strong pull up

When D\_OUT\_EN = 0:

D\_OUT = '0': High impedance

D\_OUT = '1': High impedance

For peripherals other than GPIO & UDB/DSI:

When D\_OUT\_EN = 1:

D\_OUT = '0': Strong pull down

D\_OUT = '1': Strong pull up

When D\_OUT\_EN = 0:

D\_OUT = '0': Weak/resistive pull down

D\_OUT = '1': Weak/resistive pull down

#### 0x4: OD\_DRIVESLOW :

Open drain, drives low

For GPIO & UDB/DSI peripherals:

When D\_OUT\_EN = 1:

D\_OUT = '0': Strong pull down

D\_OUT = '1': High Impedance

When D\_OUT\_EN = 0:

D\_OUT = '0': High impedance

D\_OUT = '1': High impedance

For peripherals other than GPIO & UDB/DSI:

When D\_OUT\_EN = 1:

D\_OUT = '0': Strong pull down

D\_OUT = '1': Strong pull up

When D\_OUT\_EN = 0:

D\_OUT = '0': High Impedance

D\_OUT = '1': High Impedance

### 16.1.31 GPIO\_PRT4\_CFG (continued)

#### 0x5: OD\_DRIVESHIGH :

Open drain, drives high  
 For GPIO & UDB/DSI peripherals:  
 When D\_OUT\_EN = 1:  
   D\_OUT = '0': High Impedance  
   D\_OUT = '1': Strong pull up  
 When D\_OUT\_EN = 0:  
   D\_OUT = '0': High impedance  
   D\_OUT = '1': High impedance  
 For peripherals other than GPIO & UDB/DSI:  
 When D\_OUT\_EN = 1:  
   D\_OUT = '0': Strong pull down  
   D\_OUT = '1': Strong pull up  
 When D\_OUT\_EN = 0:  
   D\_OUT = '0': High Impedance  
   D\_OUT = '1': High Impedance

#### 0x6: STRONG :

Strong D\_OUTput buffer  
 For GPIO & UDB/DSI peripherals:  
 When D\_OUT\_EN = 1:  
   D\_OUT = '0': Strong pull down  
   D\_OUT = '1': Strong pull up  
 When D\_OUT\_EN = 0:  
   D\_OUT = '0': High impedance  
   D\_OUT = '1': High impedance  
 For peripherals other than GPIO & UDB/DSI:  
 When D\_OUT\_EN = 1:  
   D\_OUT = '0': Strong pull down  
   D\_OUT = '1': Strong pull up  
 When D\_OUT\_EN = 0:  
   D\_OUT = '0': High Impedance  
   D\_OUT = '1': High Impedance

#### 0x7: PULLUP\_DOWN :

Pull up or pull down  
 For GPIO & UDB/DSI peripherals:  
 When D\_OUT\_EN = '0':  
   GPIO\_DSI\_OUT = '0': Weak/resistive pull down  
   GPIO\_DSI\_OUT = '1': Weak/resistive pull up  
 where "GPIO\_DSI\_OUT" is a function of PORT\_SEL, OUT & DSI\_DATA\_OUT.  
 For peripherals other than GPIO & UDB/DSI:  
 When D\_OUT\_EN = 1:  
   D\_OUT = '0': Strong pull down  
   D\_OUT = '1': Strong pull up  
 When D\_OUT\_EN = 0:  
   D\_OUT = '0': Weak/resistive pull down  
   D\_OUT = '1': Weak/resistive pull up

| 6 : 4 | DRIVE_MODE1 | The GPIO drive mode for IO pin 1<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 3     | IN_EN0      | Enables the input buffer for IO pin 0. This bit should be cleared when analog signals are present on the pin to avoid crowbar currents. The output buffer can be used to drive analog signals high or low without issue.<br>'0': Input buffer disabled<br>'1': Input buffer enabled<br>Default Value: 0                                                                                                                                                                                                                                                                                                 |
| 2 : 0 | DRIVE_MODE0 | The GPIO drive mode for IO pin 0. Resistive pull-up and pull-down is selected in the drive mode. Note: when initializing IO's that are connected to a live bus (such as I2C), make sure the peripheral and HSIOM (HSIOM_PRT_SELx) is properly configured before turning the IO on here to avoid producing glitches on the bus.<br>Note: that peripherals other than GPIO & UDB/DSI directly control both the output and output-enable of the output buffer (peripherals can drive strong 0 or strong 1 in any mode except OFF='0').<br>Note: D_OUT, D_OUT_EN are pins of GPIO cell.<br>Default Value: 0 |

## 16.1.41 GPIO\_PRT14\_CFG (continued)

### 0x0: HIGHZ :

Output buffer is off creating a high impedance input

D\_OUT = '0': High Impedance

D\_OUT = '1': High Impedance

### 0x1: RESERVED :

This mode is reserved and should not be used. No damage will occur if this mode is selected. The pin will generally perform the same as the STRONG drive mode although this is not guaranteed for all use cases.

For GPIO & UDB/DSI peripherals:

When D\_OUT\_EN = 1:

D\_OUT = '0': Strong pull down

D\_OUT = '1': Strong pull up

When D\_OUT\_EN = 0:

D\_OUT = '0': High impedance

D\_OUT = '1': High impedance

For peripherals other than GPIO & UDB/DSI:

When D\_OUT\_EN = 1:

D\_OUT = '0': Strong pull down

D\_OUT = '1': Strong pull up

When D\_OUT\_EN = 0:

D\_OUT = '0': High impedance

D\_OUT = '1': High impedance

### 0x2: PULLUP :

Resistive pull up

For GPIO & UDB/DSI peripherals:

When D\_OUT\_EN = 1:

D\_OUT = '0': Strong pull down

D\_OUT = '1': Weak/resistive pull up

When D\_OUT\_EN = 0:

D\_OUT = '0': High impedance

D\_OUT = '1': High impedance

For peripherals other than GPIO & UDB/DSI:

When D\_OUT\_EN = 1:

D\_OUT = '0': Strong pull down

D\_OUT = '1': Strong pull up

When D\_OUT\_EN = 0:

D\_OUT = '0': Weak/resistive pull up

D\_OUT = '1': Weak/resistive pull up

## 16.1.41 GPIO\_PRT14\_CFG (continued)

### 0x3: PULLDOWN :

Resistive pull down  
 For GPIO & UDB/DSI peripherals:  
 When D\_OUT\_EN = 1:  
   D\_OUT = '0': Weak/resistive pull down  
   D\_OUT = '1': Strong pull up  
 When D\_OUT\_EN = 0:  
   D\_OUT = '0': High impedance  
   D\_OUT = '1': High impedance  
 For peripherals other than GPIO & UDB/DSI:  
 When D\_OUT\_EN = 1:  
   D\_OUT = '0': Strong pull down  
   D\_OUT = '1': Strong pull up  
 When D\_OUT\_EN = 0:  
   D\_OUT = '0': Weak/resistive pull down  
   D\_OUT = '1': Weak/resistive pull down

### 0x4: OD\_DRIVESLOW :

Open drain, drives low  
 For GPIO & UDB/DSI peripherals:  
 When D\_OUT\_EN = 1:  
   D\_OUT = '0': Strong pull down  
   D\_OUT = '1': High Impedance  
 When D\_OUT\_EN = 0:  
   D\_OUT = '0': High impedance  
   D\_OUT = '1': High impedance  
 For peripherals other than GPIO & UDB/DSI:  
 When D\_OUT\_EN = 1:  
   D\_OUT = '0': Strong pull down  
   D\_OUT = '1': Strong pull up  
 When D\_OUT\_EN = 0:  
   D\_OUT = '0': High Impedance  
   D\_OUT = '1': High Impedance

### 0x5: OD\_DRIVESHIGH :

Open drain, drives high  
 For GPIO & UDB/DSI peripherals:  
 When D\_OUT\_EN = 1:  
   D\_OUT = '0': High Impedance  
   D\_OUT = '1': Strong pull up  
 When D\_OUT\_EN = 0:  
   D\_OUT = '0': High impedance  
   D\_OUT = '1': High impedance  
 For peripherals other than GPIO & UDB/DSI:  
 When D\_OUT\_EN = 1:  
   D\_OUT = '0': Strong pull down  
   D\_OUT = '1': Strong pull up  
 When D\_OUT\_EN = 0:  
   D\_OUT = '0': High Impedance  
   D\_OUT = '1': High Impedance

## 16.1.41 GPIO\_PRT14\_CFG (continued)

### 0x6: STRONG :

Strong D\_OUTput buffer

For GPIO & UDB/DSI peripherals:

When D\_OUT\_EN = 1:

D\_OUT = '0': Strong pull down

D\_OUT = '1': Strong pull up

When D\_OUT\_EN = 0:

D\_OUT = '0': High impedance

D\_OUT = '1': High impedance

For peripherals other than GPIO & UDB/DSI:

When D\_OUT\_EN = 1:

D\_OUT = '0': Strong pull down

D\_OUT = '1': Strong pull up

When D\_OUT\_EN = 0:

D\_OUT = '0': High Impedance

D\_OUT = '1': High Impedance

### 0x7: PULLUP\_DOWN :

Pull up or pull down

For GPIO & UDB/DSI peripherals:

When D\_OUT\_EN = '0':

GPIO\_DSI\_OUT = '0': Weak/resistive pull down

GPIO\_DSI\_OUT = '1': Weak/resistive pull up

where "GPIO\_DSI\_OUT" is a function of PORT\_SEL, OUT & DSI\_DATA\_OUT.

For peripherals other than GPIO & UDB/DSI:

When D\_OUT\_EN = 1:

D\_OUT = '0': Strong pull down

D\_OUT = '1': Strong pull up

When D\_OUT\_EN = 0:

D\_OUT = '0': Weak/resistive pull down

D\_OUT = '1': Weak/resistive pull up

# 17 Smart I/O Registers

This section discusses the Smart I/O registers. It lists all the registers in mapping tables, in address order.

## 17.1 Register Details

| Register                              | Address    | Description                                                                                                |
|---------------------------------------|------------|------------------------------------------------------------------------------------------------------------|
| <a href="#">SMARTIO_PRT8_CTL</a>      | 0x40330800 | Control register                                                                                           |
| <a href="#">SMARTIO_PRT8_SYNC_CTL</a> | 0x40330810 | Synchronization control register                                                                           |
| <a href="#">SMARTIO_PRT8_LUT_SEL0</a> | 0x40330820 | LUT component input selection                                                                              |
| SMARTIO_PRT8_LUT_SEL1                 | 0x40330824 | LUT component input selection. See <a href="#">SMARTIO_PRT8_LUT_SEL0</a> for the details of bit fields.    |
| SMARTIO_PRT8_LUT_SEL2                 | 0x40330828 | LUT component input selection. See <a href="#">SMARTIO_PRT8_LUT_SEL0</a> for the details of bit fields.    |
| SMARTIO_PRT8_LUT_SEL3                 | 0x4033082C | LUT component input selection. See <a href="#">SMARTIO_PRT8_LUT_SEL0</a> for the details of bit fields.    |
| SMARTIO_PRT8_LUT_SEL4                 | 0x40330830 | LUT component input selection. See <a href="#">SMARTIO_PRT8_LUT_SEL0</a> for the details of bit fields.    |
| SMARTIO_PRT8_LUT_SEL5                 | 0x40330834 | LUT component input selection. See <a href="#">SMARTIO_PRT8_LUT_SEL0</a> for the details of bit fields.    |
| SMARTIO_PRT8_LUT_SEL6                 | 0x40330838 | LUT component input selection. See <a href="#">SMARTIO_PRT8_LUT_SEL0</a> for the details of bit fields.    |
| SMARTIO_PRT8_LUT_SEL7                 | 0x4033083C | LUT component input selection. See <a href="#">SMARTIO_PRT8_LUT_SEL0</a> for the details of bit fields.    |
| <a href="#">SMARTIO_PRT8_LUT_CTL0</a> | 0x40330840 | LUT component control register                                                                             |
| SMARTIO_PRT8_LUT_CTL1                 | 0x40330844 | LUT component control register. See <a href="#">SMARTIO_PRT8_LUT_CTL0</a> for the details of bit fields.   |
| SMARTIO_PRT8_LUT_CTL2                 | 0x40330848 | LUT component control register. See <a href="#">SMARTIO_PRT8_LUT_CTL0</a> for the details of bit fields.   |
| SMARTIO_PRT8_LUT_CTL3                 | 0x4033084C | LUT component control register. See <a href="#">SMARTIO_PRT8_LUT_CTL0</a> for the details of bit fields.   |
| SMARTIO_PRT8_LUT_CTL4                 | 0x40330850 | LUT component control register. See <a href="#">SMARTIO_PRT8_LUT_CTL0</a> for the details of bit fields.   |
| SMARTIO_PRT8_LUT_CTL5                 | 0x40330854 | LUT component control register. See <a href="#">SMARTIO_PRT8_LUT_CTL0</a> for the details of bit fields.   |
| SMARTIO_PRT8_LUT_CTL6                 | 0x40330858 | LUT component control register. See <a href="#">SMARTIO_PRT8_LUT_CTL0</a> for the details of bit fields.   |
| SMARTIO_PRT8_LUT_CTL7                 | 0x4033085C | LUT component control register. See <a href="#">SMARTIO_PRT8_LUT_CTL0</a> for the details of bit fields.   |
| <a href="#">SMARTIO_PRT8_DU_SEL</a>   | 0x403308C0 | Data unit component input selection                                                                        |
| <a href="#">SMARTIO_PRT8_DU_CTL</a>   | 0x403308C4 | Data unit component control register                                                                       |
| <a href="#">SMARTIO_PRT8_DATA</a>     | 0x403308F0 | Data register                                                                                              |
| SMARTIO_PRT9_CTL                      | 0x40330900 | Control register. See <a href="#">SMARTIO_PRT8_CTL</a> for the details of bit fields.                      |
| SMARTIO_PRT9_SYNC_CTL                 | 0x40330910 | Synchronization control register. See <a href="#">SMARTIO_PRT8_SYNC_CTL</a> for the details of bit fields. |
| SMARTIO_PRT9_LUT_SEL0                 | 0x40330920 | LUT component input selection. See <a href="#">SMARTIO_PRT8_LUT_SEL0</a> for the details of bit fields.    |
| SMARTIO_PRT9_LUT_SEL1                 | 0x40330924 | LUT component input selection. See <a href="#">SMARTIO_PRT8_LUT_SEL0</a> for the details of bit fields.    |

# 18 Universal Digital Block (UDB) Registers

This section discusses the Universal Digital Block (UDB) registers. It lists all the registers in mapping tables, in address order.

## 18.1 Register Details

| Register                      | Address    | Description                                                                                     |
|-------------------------------|------------|-------------------------------------------------------------------------------------------------|
| <a href="#">UDB_WRKONE_A0</a> | 0x40340000 | Accumulator Registers {A1,A0}                                                                   |
| UDB_WRKONE_A1                 | 0x40340004 | Accumulator Registers {A1,A0}. See <a href="#">UDB_WRKONE_A0</a> for the details of bit fields. |
| UDB_WRKONE_A2                 | 0x40340008 | Accumulator Registers {A1,A0}. See <a href="#">UDB_WRKONE_A0</a> for the details of bit fields. |
| UDB_WRKONE_A3                 | 0x4034000C | Accumulator Registers {A1,A0}. See <a href="#">UDB_WRKONE_A0</a> for the details of bit fields. |
| UDB_WRKONE_A4                 | 0x40340010 | Accumulator Registers {A1,A0}. See <a href="#">UDB_WRKONE_A0</a> for the details of bit fields. |
| UDB_WRKONE_A5                 | 0x40340014 | Accumulator Registers {A1,A0}. See <a href="#">UDB_WRKONE_A0</a> for the details of bit fields. |
| UDB_WRKONE_A6                 | 0x40340018 | Accumulator Registers {A1,A0}. See <a href="#">UDB_WRKONE_A0</a> for the details of bit fields. |

### 18.1.28 UDB\_UDBPAIR0\_UDBSNG0\_SC\_CFG0 (continued)

**0x1: SYNC :**

The value written is resampled by the selected SC clock. The resampled value is driven into the routing.

**0x2: DOUBLE\_SYNC :**

The value written is doubly synced by the selected SC clock. The synced value is driven into the routing.

**0x3: PULSE :**

The value written is resampled and a synchronous pulse is generated and driven into the routing based on the selected SC clock. At the end of the generated pulse, the control register bit is automatically reset.

# 19 Low-Power Comparator Registers

This section discusses the Low-Power Comparator (LPCOMP) registers. It lists all the registers in mapping tables, in address order.

## 19.1 Register Details

| Register             | Address    | Description                       |
|----------------------|------------|-----------------------------------|
| LPCOMP_CONFIG        | 0x40350000 | LPCOMP Configuration Register     |
| LPCOMP_STATUS        | 0x40350004 | LPCOMP Status Register            |
| LPCOMP_INTR          | 0x40350010 | LPCOMP Interrupt request register |
| LPCOMP_INTR_SET      | 0x40350014 | LPCOMP Interrupt set register     |
| LPCOMP_INTR_MASK     | 0x40350018 | LPCOMP Interrupt request mask     |
| LPCOMP_INTR_MASKED   | 0x4035001C | LPCOMP Interrupt request masked   |
| LPCOMP_CMP0_CTRL     | 0x40350040 | Comparator 0 control Register     |
| LPCOMP_CMP0_SW       | 0x40350050 | Comparator 0 switch control       |
| LPCOMP_CMP0_SW_CLEAR | 0x40350054 | Comparator 0 switch control clear |
| LPCOMP_CMP1_CTRL     | 0x40350080 | Comparator 1 control Register     |
| LPCOMP_CMP1_SW       | 0x40350090 | Comparator 1 switch control       |
| LPCOMP_CMP1_SW_CLEAR | 0x40350094 | Comparator 1 switch control clear |

## 19.1.1 LPCOMP\_CONFIG

LPCOMP Configuration Register

### 19.1.7 LPCOMP\_CMP0\_CTRL (continued)

**0x1: RISING :**

Rising edge

**0x2: FALLING :**

Falling edge

**0x3: BOTH :**

Both rising and falling edges

5 HYST0

Add hysteresis to the comparator

0= Disable Hysteresis

1= Enable Hysteresis

Default Value: 0

1 : 0 MODE0

Operating mode for the comparator

Default Value: 0

**0x0: OFF :**

Off

**0x1: ULP :**

Ultra low power operating mode. This mode must be used for System Deep Sleep and System Hibernate operation. In this mode, local Ibias is used.

**0x2: LP :**

Low Power operating mode. In this mode, IREF from SRSS is used.

**0x3: NORMAL :**

Normal power, full speed operating mode. In this mode, IREF from SRSS is used.

### 19.1.10 LPCOMP\_CMP1\_CTRL (continued)

**0x1: RISING :**

Rising edge

**0x2: FALLING :**

Falling edge

**0x3: BOTH :**

Both rising and falling edges

5      HYST1

Add hysteresis to the comparator

0= Disable Hysteresis

1= Enable Hysteresis

Default Value: 0

1 : 0      MODE1

Operating mode for the comparator

Default Value: 0

**0x0: OFF :**

Off

**0x1: ULP :**

Ultra low power operating mode. This mode must be used for System Deep Sleep and System Hibernate operation. In this mode, local Ibias is used.

**0x2: LP :**

Low Power operating mode. In this mode, IREF from SRSS is used.

**0x3: NORMAL :**

Normal power, full speed operating mode. In this mode, IREF from SRSS is used.

# 20 Timer, Counter, PWM (TCPWM) Registers

This section discusses the Timer, Counter, PWM (TCPWM) registers. It lists all the registers in mapping tables, in address order.

## 20.1 Register Details

| Register                                | Address    | Description                                                                                                       |
|-----------------------------------------|------------|-------------------------------------------------------------------------------------------------------------------|
| <a href="#">TCPWM0_CTRL</a>             | 0x40380000 | TCPWM control register                                                                                            |
| <a href="#">TCPWM0_CTRL_CLR</a>         | 0x40380004 | TCPWM control clear register                                                                                      |
| <a href="#">TCPWM0_CTRL_SET</a>         | 0x40380008 | TCPWM control set register                                                                                        |
| <a href="#">TCPWM0_CMD_CAPTURE</a>      | 0x4038000C | TCPWM capture command register                                                                                    |
| <a href="#">TCPWM0_CMD_RELOAD</a>       | 0x40380010 | TCPWM reload command register                                                                                     |
| <a href="#">TCPWM0_CMD_STOP</a>         | 0x40380014 | TCPWM stop command register                                                                                       |
| <a href="#">TCPWM0_CMD_START</a>        | 0x40380018 | TCPWM start command register                                                                                      |
| <a href="#">TCPWM0_INTR_CAUSE</a>       | 0x4038001C | TCPWM Counter interrupt cause register                                                                            |
| <a href="#">TCPWM0_CNT0_CTRL</a>        | 0x40380100 | Counter control register                                                                                          |
| <a href="#">TCPWM0_CNT0_STATUS</a>      | 0x40380104 | Counter status register                                                                                           |
| <a href="#">TCPWM0_CNT0_COUNTER</a>     | 0x40380108 | Counter count register                                                                                            |
| <a href="#">TCPWM0_CNT0_CC</a>          | 0x4038010C | Counter compare/capture register                                                                                  |
| <a href="#">TCPWM0_CNT0_CC_BUFF</a>     | 0x40380110 | Counter buffered compare/capture register                                                                         |

| Name      | None [31:24]          |    |    |    |    |    |    |    |

| Bits  | Name            | Description                                                                                                                                                                                                  |
|-------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 : 0 | COUNTER_ENABLED | Alias of CTRL that only allows enabling of counters. A write access:<br>'0': Does nothing.<br>'1': Sets respective COUNTER_ENABLED field.<br>A read access returns CTRL.COUNTER_ENABLED.<br>Default Value: 0 |

## 20.1.4 TCPWM0\_CMD\_CAPTURE

TCPWM capture command register

Address: 0x4038000C

Retention: Not Retained

| Bits      | 7                     | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-----------|-----------------------|---|---|---|---|---|---|---|
| SW Access | RW1S                  |   |   |   |   |   |   |   |
| HW Access | RW1C                  |   |   |   |   |   |   |   |
| Name      | COUNTER_CAPTURE [7:0] |   |   |   |   |   |   |   |

  

| Bits      | 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|-----------|-------------|----|----|----|----|----|---|---|
| SW Access | None        |    |    |    |    |    |   |   |
| HW Access | None        |    |    |    |    |    |   |   |
| Name      | None [15:8] |    |    |    |    |    |   |   |

  

| Bits      | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|-----------|--------------|----|----|----|----|----|----|----|
| SW Access | None         |    |    |    |    |    |    |    |
| HW Access | None         |    |    |    |    |    |    |    |
| Name      | None [23:16] |    |    |    |    |    |    |    |

  

| Bits      | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|-----------|--------------|----|----|----|----|----|----|----|
| SW Access | None         |    |    |    |    |    |    |    |
| HW Access | None         |    |    |    |    |    |    |    |
| Name      | None [31:24] |    |    |    |    |    |    |    |

| Bits  | Name            | Description                                                                                                                                                                                                                                                                                                                                   |
|-------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 : 0 | COUNTER_CAPTURE | Counters SW capture trigger. When written with '1', a capture trigger is generated and the HW sets the field to '0' when the SW trigger has taken effect. It should be noted that the HW operates on the counter frequency. If the counter is disabled through CTRL.COUNTER_ENABLED, the field is immediately set to '0'.<br>Default Value: 0 |

## 20.1.5 TCPWM0\_CMD\_RELOAD

TCPWM reload command register

Address: 0x40380010

Retention: Not Retained

| Bits      | 7                    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-----------|----------------------|---|---|---|---|---|---|---|
| SW Access | RW1S                 |   |   |   |   |   |   |   |
| HW Access | RW1C                 |   |   |   |   |   |   |   |
| Name      | COUNTER_RELOAD [7:0] |   |   |   |   |   |   |   |

  

| Bits      | 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|-----------|-------------|----|----|----|----|----|---|---|
| SW Access | None        |    |    |    |    |    |   |   |
| HW Access | None        |    |    |    |    |    |   |   |
| Name      | None [15:8] |    |    |    |    |    |   |   |

  

| Bits      | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|-----------|--------------|----|----|----|----|----|----|----|
| SW Access | None         |    |    |    |    |    |    |    |
| HW Access | None         |    |    |    |    |    |    |    |
| Name      | None [23:16] |    |    |    |    |    |    |    |

  

| Bits      | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|-----------|--------------|----|----|----|----|----|----|----|
| SW Access | None         |    |    |    |    |    |    |    |
| HW Access | None         |    |    |    |    |    |    |    |
| Name      | None [31:24] |    |    |    |    |    |    |    |

| Bits  | Name           | Description                                                                                 |
|-------|----------------|---------------------------------------------------------------------------------------------|
| 7 : 0 | COUNTER_RELOAD | Counters SW reload trigger. For HW behavior, see COUNTER_CAPTURE field.<br>Default Value: 0 |

## 20.1.6 TCPWM0\_CMD\_STOP

TCPWM stop command register

Address: 0x40380014

Retention: Not Retained

| Bits      | 7                  | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-----------|--------------------|---|---|---|---|---|---|---|
| SW Access | RW1S               |   |   |   |   |   |   |   |
| HW Access | RW1C               |   |   |   |   |   |   |   |
| Name      | COUNTER_STOP [7:0] |   |   |   |   |   |   |   |

  

| Bits      | 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|-----------|-------------|----|----|----|----|----|---|---|
| SW Access | None        |    |    |    |    |    |   |   |
| HW Access | None        |    |    |    |    |    |   |   |
| Name      | None [15:8] |    |    |    |    |    |   |   |

  

| Bits      | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|-----------|--------------|----|----|----|----|----|----|----|
| SW Access | None         |    |    |    |    |    |    |    |
| HW Access | None         |    |    |    |    |    |    |    |
| Name      | None [23:16] |    |    |    |    |    |    |    |

  

| Bits      | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|-----------|--------------|----|----|----|----|----|----|----|
| SW Access | None         |    |    |    |    |    |    |    |
| HW Access | None         |    |    |    |    |    |    |    |
| Name      | None [31:24] |    |    |    |    |    |    |    |

| Bits  | Name         | Description                                                                               |
|-------|--------------|-------------------------------------------------------------------------------------------|
| 7 : 0 | COUNTER_STOP | Counters SW stop trigger. For HW behavior, see COUNTER_CAPTURE field.<br>Default Value: 0 |

## 20.1.7 TCPWM0\_CMD\_START

TCPWM start command register

Address: 0x40380018

Retention: Not Retained

| Bits      | 7                   | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----------|---------------------|----|----|----|----|----|----|----|
| SW Access | RW1S                |    |    |    |    |    |    |    |
| HW Access | RW1C                |    |    |    |    |    |    |    |
| Name      | COUNTER_START [7:0] |    |    |    |    |    |    |    |
| Bits      | 15                  | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
| SW Access | None                |    |    |    |    |    |    |    |
| HW Access | None                |    |    |    |    |    |    |    |
| Name      | None [15:8]         |    |    |    |    |    |    |    |
| Bits      | 23                  | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| SW Access | None                |    |    |    |    |    |    |    |
| HW Access | None                |    |    |    |    |    |    |    |
| Name      | None [23:16]        |    |    |    |    |    |    |    |
| Bits      | 31                  | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
| SW Access | None                |    |    |    |    |    |    |    |
| HW Access | None                |    |    |    |    |    |    |    |
| Name      | None [31:24]        |    |    |    |    |    |    |    |

| Bits  | Name          | Description                                                                                |
|-------|---------------|--------------------------------------------------------------------------------------------|
| 7 : 0 | COUNTER_START | Counters SW start trigger. For HW behavior, see COUNTER_CAPTURE field.<br>Default Value: 0 |

## 20.1.8 TCPWM0\_INTR\_CAUSE

TCPWM Counter interrupt cause register

Address: 0x4038001C

Retention: Not Retained

| Bits      | 7                 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-----------|-------------------|---|---|---|---|---|---|---|
| SW Access | R                 |   |   |   |   |   |   |   |
| HW Access | W                 |   |   |   |   |   |   |   |
| Name      | COUNTER_INT [7:0] |   |   |   |   |   |   |   |

  

| Bits      | 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|-----------|-------------|----|----|----|----|----|---|---|
| SW Access | None        |    |    |    |    |    |   |   |
| HW Access | None        |    |    |    |    |    |   |   |
| Name      | None [15:8] |    |    |    |    |    |   |   |

  

| Bits      | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|-----------|--------------|----|----|----|----|----|----|----|
| SW Access | None         |    |    |    |    |    |    |    |
| HW Access | None         |    |    |    |    |    |    |    |
| Name      | None [23:16] |    |    |    |    |    |    |    |

  

| Bits      | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|-----------|--------------|----|----|----|----|----|----|----|
| SW Access | None         |    |    |    |    |    |    |    |
| HW Access | None         |    |    |    |    |    |    |    |
| Name      | None [31:24] |    |    |    |    |    |    |    |

| Bits  | Name        | Description                                                                                                                                                              |
|-------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 : 0 | COUNTER_INT | Counters interrupt signal active. If the counter is disabled through CTRL.COUNTER_ENABLED, the associated interrupt field is immediately set to '0'.<br>Default Value: 0 |

## 20.1.9 TCPWM0\_CNT0\_CTRL

Counter control register

Address: 0x40380100

Retention: Retained

| Bits      | 7          | 6 | 5 | 4 | 3                 | 2              | 1                   | 0               |
|-----------|------------|---|---|---|-------------------|----------------|---------------------|-----------------|
| SW Access | None       |   |   |   | RW                | RW             | RW                  | RW              |
| HW Access | None       |   |   |   | R                 | R              | R                   | R               |
| Name      | None [7:4] |   |   |   | PW-M_STOP_ON_KILL | PWM_SYN-C_KILL | AUTO_RE-LOAD_PERIOD | AUTO_RE-LOAD_CC |

| HW Access | None         |    |    |    |    | R            |    |    |
| Name      | None [31:27] |    |    |    |    | MODE [26:24] |    |    |

| Bits    | Name | Description                       |
|---------|------|-----------------------------------|
| 26 : 24 | MODE | Counter mode.<br>Default Value: 0 |
|         |      | <b>0x0: TIMER :</b>               |
|         |      | Timer mode                        |
|         |      | <b>0x2: CAPTURE :</b>             |
|         |      | Capture mode                      |
|         |      | <b>0x3: QUAD :</b>                |
|         |      | Quadrature encoding mode          |

## 20.1.9 TCPWM0\_CNT0\_CTRL (continued)

### 0x4: PWM :

Pulse width modulation (PWM) mode

### 0x5: PWM\_DT :

PWM with deadtime insertion mode

### 0x6: PWM\_PR :

Pseudo random pulse width modulation

21 : 20 QUADRATURE\_MODE

In QUAD mode selects quadrature encoding mode (X1/X2/X4).  
 In PWM, PWM\_DT and PWM\_PR modes, these two bits can be used to invert "dt\_line\_out" and "dt\_line\_compl\_out". Inversion is the last step in generation of "dt\_line\_out" and "dt\_line\_compl\_out"; i.e. a disabled output line "dt\_line\_out" has the value QUADRATURE\_MODE[0] and a disabled output line "dt\_line\_compl\_out" has the value QUADRATURE\_MODE[1].  
 Default Value: 0

### 0x0: X1 :

X1 encoding (QUAD mode)

### 0x1: X2 :

X2 encoding (QUAD mode)

### 0x2: X4 :

X4 encoding (QUAD mode)

### 0x1: INV\_OUT :

When bit 0 is '1', QUADRATURE\_MODE[0] inverts "dt\_line\_out" (PWM/PWM\_DT modes)

### 0x2: INV\_COMPL\_OUT :

When bit 1 is '1', QUADRATURE\_MODE[1] inverts "dt\_line\_compl\_out" (PWM/PWM\_DT modes)

18 ONE\_SHOT

When '0', counter runs continuous. When '1', counter is turned off by hardware when a terminal count event is generated.  
 Default Value: 0

17 : 16 UP\_DOWN\_MODE

Determines counter direction.  
 Default Value: 0

### 0x0: COUNT\_UP :

Count up (to PERIOD). An overflow event is generated when the counter changes from a state in which COUNTER equals PERIOD. A terminal count event is generated when the counter changes from a state in which COUNTER equals PERIOD.

## 20.1.9 TCPWM0\_CNT0\_CTRL (continued)

### 0x1: COUNT\_DOWN :

Count down (to "0"). An underflow event is generated when the counter changes from a state in which COUNTER equals "0". A terminal count event is generated when the counter changes from a state in which COUNTER equals "0".

### 0x2: COUNT\_UPDN1 :

Count up (to PERIOD), then count down (to "0"). An overflow event is generated when the counter changes from a state in which COUNTER equals PERIOD. An underflow event is generated when the counter changes from a state in which COUNTER equals "0". A terminal count event is generated when the counter changes from a state in which COUNTER equals "0".

### 0x3: COUNT\_UPDN2 :

Count up (to PERIOD), then count down (to "0"). An overflow event is generated when the counter changes from a state in which COUNTER equals PERIOD. An underflow event is generated when the counter changes from a state in which COUNTER equals "0". A terminal count event is generated when the counter changes from a state in which COUNTER equals "0" AND when the counter changes from a state in which COUNTER equals PERIOD (this counter direction can be used for PWM functionality with asymmetrical updates).

15 : 8      GENERIC

Generic 8-bit control field. In PWM\_DT mode, this field is used to determine the dead time: amount of dead time cycles in the counter clock domain. In all other modes, the lower 3 bits of this field determine pre-scaling of the selected counter clock.  
 Default Value: 0

### 0x0: DIVBY1 :

Divide by 1 (other-than-PWM\_DT mode)

### 0x1: DIVBY2 :

Divide by 2 (other-than-PWM\_DT mode)

### 0x2: DIVBY4 :

Divide by 4 (other-than-PWM\_DT mode)

### 0x3: DIVBY8 :

Divide by 8 (other-than-PWM\_DT mode)

### 0x4: DIVBY16 :

Divide by 16 (other-than-PWM\_DT mode)

### 0x5: DIVBY32 :

Divide by 32 (other-than-PWM\_DT mode)

## 20.1.9 TCPWM0\_CNT0\_CTRL (continued)

### 0x6: DIVBY64 :

Divide by 64 (other-than-PWM\_DT mode)

### 0x7: DIVBY128 :

Divide by 128 (other-than-PWM\_DT mode)

|   |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3 | PWM_STOP_ON_KILL   | <p>Specifies whether the counter stops on a kill events:<br/>           '0': kill event does NOT stop counter.<br/>           '1': kill event stops counter.<br/>           This field has a function in PWM, PWM_DT and PWM_PR modes only.<br/>           Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                                   |
| 2 | PWM_SYNC_KILL      | <p>Specifies asynchronous/synchronous kill behavior:<br/>           '1': synchronous kill mode: the kill event disables the "dt_line_out" and "dt_line_compl_out" signals till the next terminal count event (synchronous kill). In synchronous kill mode, STOP_EDGE should be RISING_EDGE.<br/>           '0': asynchronous kill mode: the kill event only disables the "dt_line_out" and "dt_line_compl_out" signals when present. In asynchronous kill mode, STOP_EDGE should be NO_EDGE_DET.<br/>           This field has a function in PWM and PWM_DT modes only. This field is only used when PWM_STOP_ON_KILL is '0'.<br/>           Default Value: 0</p> |
| 1 | AUTO_RELOAD_PERIOD | <p>Specifies switching of the PERIOD and buffered PERIOD values. This field has a function in PWM, PWM_DT and PWM_PR modes.<br/>           '0': never switch.<br/>           '1': switch on a terminal count event with and actively pending switch event.<br/>           Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                    |
| 0 | AUTO_RELOAD_CC     | <p>Specifies switching of the CC and buffered CC values. This field has a function in TIMER, PWM, PWM_DT and PWM_PR modes.<br/>           Timer mode:<br/>           '0': never switch.<br/>           '1': switch on a compare match event.<br/>           PWM, PWM_DT, PWM_PR modes:<br/>           '0': never switch.<br/>           '1': switch on a terminal count event with an actively pending switch event.<br/>           Default Value: 0</p>                                                                                                                                                                                                          |

|---------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19 : 16 | START_SEL  | Selects one of the 16 input triggers as a start trigger. In QUAD mode, this is the second phase (phi B).<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 15 : 12 | STOP_SEL   | Selects one of the 16 input triggers as a stop trigger. In PWM, PWM_DT and PWM_PR modes, this is the kill trigger. In these modes, the kill trigger is used to either temporarily block the PWM outputs (PWM_STOP_ON_KILL is '0') or stop the functionality (PWM_STOP_ON_KILL is '1'). For the PWM and PWM_DT modes, the blocking of the output signals can be asynchronous (STOP_EDGE should be NO_EDGE_DET) in which case the blocking is as long as the trigger is '1' or synchronous (STOP_EDGE should be RISING_EDGE) in which case it extends till the next terminal count event.<br>Default Value: 0 |
| 11 : 8  | RELOAD_SEL | Selects one of the 16 input triggers as a reload trigger. In QUAD mode, this is the index or revolution pulse. In this mode, it will update the counter with 0x8000 (counter midpoint).<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                 |
| 7 : 4   | COUNT_SEL  | Selects one of the 16 input triggers as a count trigger. In QUAD mode, this is the first phase (phi A). Default setting selects input trigger 1, which is always '1'.<br>Default Value: 1                                                                                                                                                                                                                                                                                                                                                                                                                   |

### 20.1.16 TCPWM0\_CNT0\_TR\_CTRL0 (continued)

|       |             |                                                                                                                                                                                                                                                                                                            |
|-------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3 : 0 | CAPTURE_SEL | <p>Selects one of the 16 input triggers as a capture trigger. Input trigger 0 is always '0' and input trigger is always '1'. In the PWM, PWM_DT and PWM_PR modes this trigger is used to switch the values if the compare and period registers with their buffer counterparts.</p> <p>Default Value: 0</p> |
|-------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 5 : 4 | RELOAD_EDGE | A reload event will initialize the counter. When counting up, the counter is initialized to "0". When counting down, the counter is initialized with PERIOD.<br>Default Value: 3<br><br><b>0x0: RISING_EDGE :</b><br><br>Rising edge. Any rising edge generates an event.<br><br><b>0x1: FALLING_EDGE :</b><br><br>Falling edge. Any falling edge generates an event.<br><br><b>0x2: BOTH_EDGES :</b><br><br>Rising AND falling edge. Any odd amount of edges generates an event.<br><br><b>0x3: NO_EDGE_DET :</b><br><br>No edge detection, use trigger as is. |
| 3 : 2 | COUNT_EDGE  | A counter event will increase or decrease the counter by '1'.<br>Default Value: 3<br><br><b>0x0: RISING_EDGE :</b><br><br>Rising edge. Any rising edge generates an event.                                                                                                                                                                                                                                                                                                                                                                                      |

### 20.1.17 TCPWM0\_CNT0\_TR\_CTRL1 (continued)

**0x1: FALLING\_EDGE :**

Falling edge. Any falling edge generates an event.

**0x2: BOTH\_EDGES :**

Rising AND falling edge. Any odd amount of edges generates an event.

**0x3: NO\_EDGE\_DET :**

No edge detection, use trigger as is.

1 : 0      CAPTURE\_EDGE

A capture event will copy the counter value into the CC register.  
 Default Value: 3

**0x0: RISING\_EDGE :**

Rising edge. Any rising edge generates an event.

**0x1: FALLING\_EDGE :**

Falling edge. Any falling edge generates an event.

**0x2: BOTH\_EDGES :**

Rising AND falling edge. Any odd amount of edges generates an event.

**0x3: NO\_EDGE\_DET :**

No edge detection, use trigger as is.

| Bits   | Name         | Description                                                                               |
|--------|--------------|-------------------------------------------------------------------------------------------|
| 23 : 0 | COUNTER_STOP | Counters SW stop trigger. For HW behavior, see COUNTER_CAPTURE field.<br>Default Value: 0 |

## 20.1.29 TCPWM1\_CMD\_START

TCPWM start command register

Address: 0x40390018

Retention: Not Retained

| Bits      | 7                     | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----------|-----------------------|----|----|----|----|----|----|----|
| SW Access | RW1S                  |    |    |    |    |    |    |    |
| HW Access | RW1C                  |    |    |    |    |    |    |    |
| Name      | COUNTER_START [7:0]   |    |    |    |    |    |    |    |
| Bits      | 15                    | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
| SW Access | RW1S                  |    |    |    |    |    |    |    |
| HW Access | RW1C                  |    |    |    |    |    |    |    |
| Name      | COUNTER_START [15:8]  |    |    |    |    |    |    |    |
| Bits      | 23                    | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| SW Access | RW1S                  |    |    |    |    |    |    |    |
| HW Access | RW1C                  |    |    |    |    |    |    |    |
| Name      | COUNTER_START [23:16] |    |    |    |    |    |    |    |
| Bits      | 31                    | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
| SW Access | None                  |    |    |    |    |    |    |    |
| HW Access | None                  |    |    |    |    |    |    |    |
| Name      | None [31:24]          |    |    |    |    |    |    |    |

| Bits   | Name          | Description                                                                                |
|--------|---------------|--------------------------------------------------------------------------------------------|
| 23 : 0 | COUNTER_START | Counters SW start trigger. For HW behavior, see COUNTER_CAPTURE field.<br>Default Value: 0 |

## 20.1.30 TCPWM1\_INTR\_CAUSE

TCPWM Counter interrupt cause register

Address: 0x4039001C

Retention: Not Retained

| Bits      | 7                   | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----------|---------------------|----|----|----|----|----|----|----|
| SW Access | R                   |    |    |    |    |    |    |    |
| HW Access | W                   |    |    |    |    |    |    |    |
| Name      | COUNTER_INT [7:0]   |    |    |    |    |    |    |    |
| Bits      | 15                  | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
| SW Access | R                   |    |    |    |    |    |    |    |
| HW Access | W                   |    |    |    |    |    |    |    |
| Name      | COUNTER_INT [15:8]  |    |    |    |    |    |    |    |
| Bits      | 23                  | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| SW Access | R                   |    |    |    |    |    |    |    |
| HW Access | W                   |    |    |    |    |    |    |    |
| Name      | COUNTER_INT [23:16] |    |    |    |    |    |    |    |
| Bits      | 31                  | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
| SW Access | None                |    |    |    |    |    |    |    |
| HW Access | None                |    |    |    |    |    |    |    |
| Name      | None [31:24]        |    |    |    |    |    |    |    |

| Bits   | Name        | Description                                                                                                                                                              |
|--------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 23 : 0 | COUNTER_INT | Counters interrupt signal active. If the counter is disabled through CTRL.COUNTER_ENABLED, the associated interrupt field is immediately set to '0'.<br>Default Value: 0 |

## 20.1.31 TCPWM1\_CNT0\_COUNTER

Counter count register

Address: 0x40390108

Retention: Retained

| Bits      | 7              | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----------|----------------|----|----|----|----|----|----|----|
| SW Access | RW             |    |    |    |    |    |    |    |
| HW Access | RW             |    |    |    |    |    |    |    |
| Name      | COUNTER [7:0]  |    |    |    |    |    |    |    |
| Bits      | 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
| SW Access | RW             |    |    |    |    |    |    |    |
| HW Access | RW             |    |    |    |    |    |    |    |
| Name      | COUNTER [15:8] |    |    |    |    |    |    |    |
| Bits      | 23             | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| SW Access | None           |    |    |    |    |    |    |    |
| HW Access | None           |    |    |    |    |    |    |    |
| Name      | None [23:16]   |    |    |    |    |    |    |    |
| Bits      | 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
| SW Access | None           |    |    |    |    |    |    |    |
| HW Access | None           |    |    |    |    |    |    |    |
| Name      | None [31:24]   |    |    |    |    |    |    |    |

| Bits   | Name    | Description                                                                                                     |
|--------|---------|-----------------------------------------------------------------------------------------------------------------|
| 15 : 0 | COUNTER | 16-bit counter value. It is advised to not write to this field when the counter is running.<br>Default Value: 0 |

## 20.1.32 TCPWM1\_CNT0\_CC

Counter compare/capture register

Address: 0x4039010C

Retention: Retained

| Bits      | 7        | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-----------|----------|---|---|---|---|---|---|---|
| SW Access | RW       |   |   |   |   |   |   |   |
| HW Access | RW       |   |   |   |   |   |   |   |
| Name      | CC [7:0] |   |   |   |   |   |   |   |

| Bits      | 15        | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|-----------|-----------|----|----|----|----|----|---|---|
| SW Access | RW        |    |    |    |    |    |   |   |
| HW Access | RW        |    |    |    |    |    |   |   |
| Name      | CC [15:8] |    |    |    |    |    |   |   |

| Bits      | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|-----------|--------------|----|----|----|----|----|----|----|
| SW Access | None         |    |    |    |    |    |    |    |
| HW Access | None         |    |    |    |    |    |    |    |
| Name      | None [23:16] |    |    |    |    |    |    |    |

| Bits      | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|-----------|--------------|----|----|----|----|----|----|----|
| SW Access | None         |    |    |    |    |    |    |    |
| HW Access | None         |    |    |    |    |    |    |    |
| Name      | None [31:24] |    |    |    |    |    |    |    |

| Bits   | Name | Description                                                                                                     |
|--------|------|-----------------------------------------------------------------------------------------------------------------|
| 15 : 0 | CC   | In CAPTURE mode, captures the counter value. In other modes, compared to counter value.<br>Default Value: 65535 |

## 20.1.33 TCPWM1\_CNT0\_CC\_BUFF

Counter buffered compare/capture register

Address: 0x40390110

Retention: Retained

| Bits      | 7            | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----------|--------------|----|----|----|----|----|----|----|
| SW Access | RW           |    |    |    |    |    |    |    |
| HW Access | RW           |    |    |    |    |    |    |    |
| Name      | CC [7:0]     |    |    |    |    |    |    |    |
| Bits      | 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  |
| SW Access | RW           |    |    |    |    |    |    |    |
| HW Access | RW           |    |    |    |    |    |    |    |
| Name      | CC [15:8]    |    |    |    |    |    |    |    |
| Bits      | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| SW Access | None         |    |    |    |    |    |    |    |
| HW Access | None         |    |    |    |    |    |    |    |
| Name      | None [23:16] |    |    |    |    |    |    |    |
| Bits      | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
| SW Access | None         |    |    |    |    |    |    |    |
| HW Access | None         |    |    |    |    |    |    |    |
| Name      | None [31:24] |    |    |    |    |    |    |    |

| Bits   | Name | Description                                                        |
|--------|------|--------------------------------------------------------------------|
| 15 : 0 | CC   | Additional buffer for counter CC register.<br>Default Value: 65535 |

## 20.1.34 TCPWM1\_CNT0\_PERIOD

Counter period register

Address: 0x40390114

Retention: Retained

| Bits      | 7            | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-----------|--------------|---|---|---|---|---|---|---|
| SW Access | RW           |   |   |   |   |   |   |   |
| HW Access | RW           |   |   |   |   |   |   |   |
| Name      | PERIOD [7:0] |   |   |   |   |   |   |   |

| Bits      | 15            | 14 | 13 | 12 | 11 | 10 | 9 | 8 |
|-----------|---------------|----|----|----|----|----|---|---|
| SW Access | RW            |    |    |    |    |    |   |   |
| HW Access | RW            |    |    |    |    |    |   |   |
| Name      | PERIOD [15:8] |    |    |    |    |    |   |   |

| Bits      | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|-----------|--------------|----|----|----|----|----|----|----|
| SW Access | None         |    |    |    |    |    |    |    |
| HW Access | None         |    |    |    |    |    |    |    |
| Name      | None [23:16] |    |    |    |    |    |    |    |

| Bits      | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
|-----------|--------------|----|----|----|----|----|----|----|
| SW Access | None         |    |    |    |    |    |    |    |
| HW Access | None         |    |    |    |    |    |    |    |
| Name      | None [31:24] |    |    |    |    |    |    |    |

| Bits   | Name   | Description                                                                                                                                    |
|--------|--------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 15 : 0 | PERIOD | Period value: upper value of the counter. When the counter should count for n cycles, this field should be set to n-1.<br>Default Value: 65535 |

## 20.1.35 TCPWM1\_CNT0\_PERIOD\_BUFF

Counter buffered period register

Address: 0x40390118

Retention: Retained

| Bits      | 7            | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-----------|--------------|---|---|---|---|---|---|---|
| SW Access | RW           |   |   |   |   |   |   |   |
| HW Access | RW           |   |   |   |   |   |   |   |
| Name      | PERIOD [7:0] |   |   |   |   |   |   |   |

| Name      | None [31:24] |    |    |    |    |    |    |    |

| Bits   | Name   | Description                                                            |
|--------|--------|------------------------------------------------------------------------|
| 15 : 0 | PERIOD | Additional buffer for counter PERIOD register.<br>Default Value: 65535 |

# 21 Segment LCD Drive Registers

This section discusses the Segment LCD Drive registers. It lists all the registers in mapping tables, in address order.

## 21.1 Register Details

| Register                     | Address    | Description                                                                            |
|------------------------------|------------|----------------------------------------------------------------------------------------|
| <a href="#">LCD0_ID</a>      | 0x403B0000 | ID & Revision                                                                          |
| <a href="#">LCD0_DIVIDER</a> | 0x403B0004 | LCD Divider Register                                                                   |
| <a href="#">LCD0_CONTROL</a> | 0x403B0008 | LCD Configuration Register                                                             |
| <a href="#">LCD0_DATA00</a>  | 0x403B0100 | LCD Pin Data Registers                                                                 |

|--------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31     | LS_EN_STAT | <p>LS enable status bit. This bit is a copy of LS_EN that is synchronized to the low speed clock domain and back to the system clock domain. Firmware can use this bit to observe whether LS_EN has taken effect in the low speed clock domain. Firmware should never change the configuration for the LS generator without ensuring this bit is 0.</p> <p>The following procedure should be followed to disable the LS generator:</p> <ol style="list-style-type: none"> <li>1. If LS_EN=0 we are done. Exit the procedure.</li> <li>2. Check that LS_EN_STAT=1. If not, wait until it is. This will catch the case of a recent enable (LS_EN=1) that has not taken effect yet.</li> <li>3. Set LS_EN=0.</li> <li>4. Wait until LS_EN_STAT=0.</li> </ol> <p>Default Value: 0</p> |
| 11 : 8 | COM_NUM    | <p>The number of COM connections minus 2. So:</p> <p>0: 2 COM's</p> <p>1: 3 COM's</p> <p>...</p> <p>6: 8 COM's</p> <p>Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

# 22 USB Registers

This section discusses the USB registers. It lists all the registers in mapping tables, in address order.

## 22.1 Register Details

| Register                                    | Address    | Description                                                                                                        |
|---------------------------------------------|------------|--------------------------------------------------------------------------------------------------------------------|
| <a href="#">USBFS0_USBDEV_EP0_DR0</a>       | 0x403F0000 | Control End point EP0 Data Register                                                                                |
| USBFS0_USBDEV_EP0_DR1                       | 0x403F0004 | Control End point EP0 Data Register. See <a href="#">USBFS0_USBDEV_EP0_DR0</a> for the details of bit fields.      |
| USBFS0_USBDEV_EP0_DR2                       | 0x403F0008 | Control End point EP0 Data Register. See <a href="#">USBFS0_USBDEV_EP0_DR0</a> for the details of bit fields.      |
| USBFS0_USBDEV_EP0_DR3                       | 0x403F000C | Control End point EP0 Data Register. See <a href="#">USBFS0_USBDEV_EP0_DR0</a> for the details of bit fields.      |
| USBFS0_USBDEV_EP0_DR4                       | 0x403F0010 | Control End point EP0 Data Register. See <a href="#">USBFS0_USBDEV_EP0_DR0</a> for the details of bit fields.      |
| USBFS0_USBDEV_EP0_DR5                       | 0x403F0014 | Control End point EP0 Data Register. See <a href="#">USBFS0_USBDEV_EP0_DR0</a> for the details of bit fields.      |
| USBFS0_USBDEV_EP0_DR6                       | 0x403F0018 | Control End point EP0 Data Register. See <a href="#">USBFS0_USBDEV_EP0_DR0</a> for the details of bit fields.      |
| USBFS0_USBDEV_EP0_DR7                       | 0x403F001C | Control End point EP0 Data Register. See <a href="#">USBFS0_USBDEV_EP0_DR0</a> for the details of bit fields.      |
| <a href="#">USBFS0_USBDEV_CR0</a>           | 0x403F0020 | USB control 0 Register                                                                                             |
| <a href="#">USBFS0_USBDEV_CR1</a>           | 0x403F0024 | USB control 1 Register                                                                                             |
| <a href="#">USBFS0_USBDEV_SIE_EP_INT_EN</a> | 0x403F0028 | USB SIE Data Endpoints Interrupt Enable Register                                                                   |
| <a href="#">USBFS0_USBDEV_SIE_EP_INT_SR</a> | 0x403F002C | USB SIE Data Endpoint Interrupt Status                                                                             |
| <a href="#">USBFS0_USBDEV_SIE_EP1_CNT0</a>  | 0x403F0030 | Non-control endpoint count register                                                                                |
| <a href="#">USBFS0_USBDEV_SIE_EP1_CNT1</a>  | 0x403F0034 | Non-control endpoint count register                                                                                |
| <a href="#">USBFS0_USBDEV_SIE_EP1_CR0</a>   | 0x403F0038 | Non-control endpoint's control Register                                                                            |
| <a href="#">USBFS0_USBDEV_USBIO_CR0</a>     | 0x403F0040 | USBIO Control 0 Register                                                                                           |
| <a href="#">USBFS0_USBDEV_USBIO_CR2</a>     | 0x403F0044 | USBIO control 2 Register                                                                                           |
| <a href="#">USBFS0_USBDEV_USBIO_CR1</a>     | 0x403F0048 | USBIO control 1 Register                                                                                           |
| <a href="#">USBFS0_USBDEV_DYN_RECONFIG</a>  | 0x403F0050 | USB Dynamic reconfiguration register                                                                               |
| <a href="#">USBFS0_USBDEV_SOF0</a>          | 0x403F0060 | Start Of Frame Register                                                                                            |
| <a href="#">USBFS0_USBDEV_SOF1</a>          | 0x403F0064 | Start Of Frame Register                                                                                            |
| USBFS0_USBDEV_SIE_EP2_CNT0                  | 0x403F0070 | Non-control endpoint count register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CNT0</a> for the details of bit fields. |
| USBFS0_USBDEV_SIE_EP2_CNT1                  | 0x403F0074 | Non-control endpoint count register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CNT1</a> for the details of bit fields. |

| Register                                     | Address    | Description                                                                                                           |
|----------------------------------------------|------------|-----------------------------------------------------------------------------------------------------------------------|
| USBFS0_USBDEV_SIE_EP2_CR0                    | 0x403F0078 | Non-control endpoint's control Register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CR0</a> for the details of bit fields. |
| <a href="#">USBFS0_USBDEV_OSCLK_DR0</a>      | 0x403F0080 | Oscillator lock data register 0                                                                                       |
| <a href="#">USBFS0_USBDEV_OSCLK_DR1</a>      | 0x403F0084 | Oscillator lock data register 1                                                                                       |
| <a href="#">USBFS0_USBDEV_EP0_CR</a>         | 0x403F00A0 | Endpoint0 control Register                                                                                            |
| <a href="#">USBFS0_USBDEV_EP0_CNT</a>        | 0x403F00A4 | Endpoint0 count Register                                                                                              |
| USBFS0_USBDEV_SIE_EP3_CNT0                   | 0x403F00B0 | Non-control endpoint count register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CNT0</a> for the details of bit fields.    |
| USBFS0_USBDEV_SIE_EP3_CNT1                   | 0x403F00B4 | Non-control endpoint count register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CNT1</a> for the details of bit fields.    |
| USBFS0_USBDEV_SIE_EP3_CR0                    | 0x403F00B8 | Non-control endpoint's control Register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CR0</a> for the details of bit fields. |
| USBFS0_USBDEV_SIE_EP4_CNT0                   | 0x403F00F0 | Non-control endpoint count register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CNT0</a> for the details of bit fields.    |
| USBFS0_USBDEV_SIE_EP4_CNT1                   | 0x403F00F4 | Non-control endpoint count register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CNT1</a> for the details of bit fields.    |
| USBFS0_USBDEV_SIE_EP4_CR0                    | 0x403F00F8 | Non-control endpoint's control Register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CR0</a> for the details of bit fields. |
| USBFS0_USBDEV_SIE_EP5_CNT0                   | 0x403F0130 | Non-control endpoint count register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CNT0</a> for the details of bit fields.    |
| USBFS0_USBDEV_SIE_EP5_CNT1                   | 0x403F0134 | Non-control endpoint count register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CNT1</a> for the details of bit fields.    |
| USBFS0_USBDEV_SIE_EP5_CR0                    | 0x403F0138 | Non-control endpoint's control Register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CR0</a> for the details of bit fields. |
| USBFS0_USBDEV_SIE_EP6_CNT0                   | 0x403F0170 | Non-control endpoint count register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CNT0</a> for the details of bit fields.    |
| USBFS0_USBDEV_SIE_EP6_CNT1                   | 0x403F0174 | Non-control endpoint count register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CNT1</a> for the details of bit fields.    |
| USBFS0_USBDEV_SIE_EP6_CR0                    | 0x403F0178 | Non-control endpoint's control Register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CR0</a> for the details of bit fields. |
| USBFS0_USBDEV_SIE_EP7_CNT0                   | 0x403F01B0 | Non-control endpoint count register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CNT0</a> for the details of bit fields.    |
| USBFS0_USBDEV_SIE_EP7_CNT1                   | 0x403F01B4 | Non-control endpoint count register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CNT1</a> for the details of bit fields.    |
| USBFS0_USBDEV_SIE_EP7_CR0                    | 0x403F01B8 | Non-control endpoint's control Register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CR0</a> for the details of bit fields. |
| USBFS0_USBDEV_SIE_EP8_CNT0                   | 0x403F01F0 | Non-control endpoint count register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CNT0</a> for the details of bit fields.    |
| USBFS0_USBDEV_SIE_EP8_CNT1                   | 0x403F01F4 | Non-control endpoint count register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CNT1</a> for the details of bit fields.    |
| USBFS0_USBDEV_SIE_EP8_CR0                    | 0x403F01F8 | Non-control endpoint's control Register. See <a href="#">USBFS0_USBDEV_SIE_EP1_CR0</a> for the details of bit fields. |
| <a href="#">USBFS0_USBDEV_ARB_EP1_CFG</a>    | 0x403F0200 | Endpoint Configuration Register *1                                                                                    |

|-------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7     | USB_ENABLE     | This bit enables the device to respond to USB traffic.<br>If USB bus reset is detected, this bit is cleared.<br>Note:<br>When USB PHY is GPIO mode(USBIO_CR1.IOMODE=0), USB bus reset is detected. Therefore, when USB PHY is GPIO mode, this bit is cleared even if this bit is set to 1. If this bit is set to 1, write this bit upon USB bus reset interrupt, and do not write to this bit during initialization steps.<br>Default Value: 0 |
| 6 : 0 | DEVICE_ADDRESS | These bits specify the USB device address to which the SIE will respond. This address must be set by firmware and is specified by the USB Host with a SET ADDRESS command during USB enumeration. This value must be programmed by firmware when assigned during enumeration. It is not set automatically by the hardware.<br>If USB bus reset is detected, these bits are initialized.<br>Default Value: 0                                    |

| Name      | None [31:24] |    |    |    |    |    |    |    |

| Bits | Name         | Description                                                                                                                                                                                                                                                                                                        |
|------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3    | RESERVED_3   | Reserved<br>Default Value: 0                                                                                                                                                                                                                                                                                       |
| 2    | BUS_ACTIVITY | The Bus Activity bit is a stickybit that detects any non-idle USB event that has occurred on the USB bus. Once set to High by the SIE to indicate the bus activity this bit retains its logical High value until firmware clears it.<br>Default Value: 0                                                           |
| 1    | ENABLE_LOCK  | This bit is set to turn on the automatic frequency locking of the internal oscillator to USB traffic. Unless an external clock is being provided this bit should remain set for proper USB operation.<br>Default Value: 0                                                                                          |
| 0    | REG_ENABLE   | This bit controls the operation of the internal USB regulator. For applications with supply voltages in the 5V range this bit is set high to enable the internal regulator. For device supply voltage in the 3.3V range this bit is cleared to connect the transceiver directly to the supply.<br>Default Value: 0 |

| Bits  | Name           | Description                                                                                                                                                                                                                                                                                                                                                                        |
|-------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7     | DATA_TOGGLE    | This bit selects the DATA packet's toggle state. For IN transactions firmware must set this bit to the expected state. For OUT transactions the hardware sets this bit to the state of the received Data Toggle bit.<br>Default Value: 0                                                                                                                                           |
| 6     | DATA_VALID     | This bit is used for OUT transactions only and is read only. It is cleared to '0' if CRC bit stuffing errors or PID errors occur. This bit does not update for some endpoint mode settings.<br>Default Value: 0<br><br><b>0x0: DATA_ERROR :</b><br>No ACK'd transactions since bit was last cleared.<br><br><b>0x1: DATA_VALID :</b><br>Indicates a transaction ended with an ACK. |
| 2 : 0 | DATA_COUNT_MSB | These bits are the 3 MSb bits of an 11-bit counter. The LSb are the Data Count[7:0] bits of the CNT1 register. Refer to the CNT1 register for more information.<br>Default Value: 0                                                                                                                                                                                                |

| Name      | None [31:24] |    |    |    |    |    |    |    |

| Bits | Name       | Description                                                                                                                                                                                                                                                                                                          |
|------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | STALL      | When this bit is set the SIE stalls an OUT packet if the Mode bits are set to ACK-OUT. The SIE stalls an IN packet if the mode bits are set to ACK-IN. This bit must be clear for all other modes.<br>Default Value: 0                                                                                               |
| 6    | ERR_IN_TXN | The Error in transaction bit is set whenever an error is detected. For an IN transaction, this indicates a no response from HOST scenario. For an OUT transaction, this represents an RxErr (PID error/ CRC error/ bit-stuff error scenario). This bit is cleared by any writes to the register.<br>Default Value: 0 |
| 5    | NAK_INT_EN | When set this bit causes an endpoint interrupt to be generated even when a transfer completes with a NAK.<br>Default Value: 0                                                                                                                                                                                        |
| 4    | ACKED_TXN  | The ACK'd transaction bit is set whenever the SIE engages in a transaction to the register's endpoint that completes with an ACK packet. This bit is cleared by any writes to the register.<br>Default Value: 0<br><br><b>0x0: ACKED_NO :</b><br><br>No ACK'd transactions since bit was last cleared.               |

## 22.1.8 USBFS0\_USBDEV\_SIE\_EP1\_CR0 (continued)

### 0x1: ACKED\_YES :

Indicates a transaction ended with an ACK.

3 : 0      MODE

The mode controls how the USB SIE responds to traffic and how the USB SIE changes the mode of that endpoint as a result of host packets to the endpoint.  
 Default Value: 0

### 0x0: DISABLE :

Ignore all USB traffic to this endpoint

### 0x1: NAK\_INOUT :

SETUP: Accept  
 IN: NAK  
 OUT: NAK

### 0x2: STATUS\_OUT\_ONLY :

SETUP: Accept  
 IN: STALL  
 OUT: ACK 0B tokens, NAK others

### 0x3: STALL\_INOUT :

SETUP: Accept  
 IN: STALL  
 OUT: STALL

### 0x5: ISO\_OUT :

SETUP: Ignore  
 IN: Ignore  
 OUT: Accept Isochronous OUT token

### 0x6: STATUS\_IN\_ONLY :

SETUP: Accept  
 IN: Respond with 0B data  
 OUT: Stall

### 0x7: ISO\_IN :

SETUP: Ignore  
 IN: Accept Isochronous IN token  
 OUT: Ignore

### 0x8: NAK\_OUT :

SETUP: Ignore  
 IN: Ignore  
 OUT: NAK

## 22.1.8 USBFS0\_USBDEV\_SIE\_EP1\_CR0 (continued)

### 0x9: ACK\_OUT :

SETUP: Ignore  
IN: Ignore  
OUT: Accept data and ACK if STALL=0, STALL otherwise.  
Change to MODE=8 after one succesfull OUT token.

### 0xb: ACK\_OUT\_STATUS\_IN :

SETUP: Accept  
IN: Respond with 0B data  
OUT: Accept data

### 0xc: NAK\_IN :

SETUP: Ignore  
IN: NAK  
OUT: Ignore

### 0xd: ACK\_IN :

SETUP: Ignore  
IN: Respond to IN with data if STALL=0, STALL otherwise  
OUT: Ignore

### 0xf: ACK\_IN\_STATUS\_OUT :

SETUP: Accept  
IN: Respond to IN with data  
OUT: ACK 0B tokens, NAK others

|------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | SETUP_RCVD | When set this bit indicates a valid SETUP packet was received and ACKed. This bit is forced HIGH from the start of the data packet phase of the SETUP transaction until the start of the ACK packet returned by the SIE. The CPU is prevented from clearing this bit during this interval. After this interval the bit will remain set until cleared by firmware. While this bit is set to '1' the CPU cannot write to the EP0_DRx registers. This prevents firmware from overwriting an incoming SETUP transaction before firmware has a chance to read the SETUP data. This bit is cleared by any non-locked writes to the register.<br>Default Value: 0 |
| 6    | IN_RCVD    | When set this bit indicates a valid IN packet has been received. This bit is updated to '1' after the host acknowledges an IN data packet. When clear this bit indicates either no IN has been received or that the host did not acknowledge the IN data by sending ACK handshake. It is cleared by any writes to the register.<br>Default Value: 0                                                                                                                                                                                                                                                                                                        |
| 5    | OUT_RCVD   | When set this bit indicates a valid OUT packet has been received and ACKed. This bit is updated to '1' after the last received packet in an OUT transaction. When clear this bit indicates no OUT received. It is cleared by any writes to the register.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                               |

|-------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3 : 0 | BYTE_COUNT | <p>These bits indicate the number of data bytes in a transaction. For IN transactions firmware loads the count with the number of bytes to be transmitted to the host from the endpoint FIFO. Valid values are 0 to 8. For OUT or SETUP transactions the count is updated by hardware to the number of data bytes received plus two for the CRC bytes. Valid values are 2 to 10.</p> <p>Default Value: 0</p> |
|-------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## 22.1.60 USBFS0\_USBLPM\_DFT\_CTL (continued)

**0x0: OFF :**

Nothing connected, output 0

**0x1: DP\_SE :**

Single Ended output of DP

**0x2: DM\_SE :**

Single Ended output of DM

**0x3: TXOE :**

Output Enable

**0x4: RCV\_DF :**

Differential Receiver output

**0x5: GPIO\_DP\_OUT :**

GPIO output of DP

**0x6: GPIO\_DM\_OUT :**

GPIO output of DM

## 22.1.61 USBFS0\_USBHOST\_HOST\_CTL0

Host Control 0 Register.

| 17 : 0 | RTIMER | <p>These bits are used to specify the retry time in this register. The retry timer is activated when token sending starts while the RETRY bit of Host Control 2 Register (HOST_CTL2) is '1'. The retry time is then decremented by one when a 1-bit transfer clock (12 MHz in the full-speed mode) is output. When the retry timer reaches 0, the target token is sent, and processing ends. If a token retry occurs in the EOF area, the retry timer is stopped until SOF sending is ended. After SOF sending has been completed, the retry timer restarts with the value that is set when the timer stopped.</p> <p>Default Value: 0</p> |

|------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8    | TGGL | <p>This bit is used to set toggle data. Toggle data is sent depending on the setting of this bit. When receiving toggle data, received toggle data is compared with the toggle data of this bit to verify whether or not an error occurs.</p> <p>'0' : DATA0<br/>'1' : DATA1</p> <p>Notes:</p> <ul style="list-style-type: none"> <li>- This bit isn't reset to the default value even if the RST bit of the Host Control 1 Register (HOST_CTL1) is set to '1'.</li> <li>- Set this bit when the TKNEN bit of the Host Token Endpoint Register (HOST_TOKEN) is '000'.</li> </ul> <p>Default Value: 0</p> |

## 22.1.71 USBFS0\_USBHOST\_HOST\_TOKEN (continued)

6 : 4 TKNEN

These bits send a token according to the current settings. After operation is complete, the TKNEN bit is set to '000', and the CMPIRQ bit of the Interrupt USB Host Register (INTR\_USBHOST) is set to '1'.

The settings of the TGGL and ENDPT bits are ignored when sending a SOF token.

Notes:

- This bit is set to the default value when the RST bit of the Host Control 1 Register (HOST\_CTL1) is set to '1'.

- The PRE packet isn't supported.

- Do not set '100' to the TKNEN bit when the SOFBUSY bit of the Host Status Register (HOST\_STATUS) is '1'

- Mode should be USB Host before writing data to this bit.

- When issuing a token again after the token interrupt flag (CMPIRQ) has been set to '1', wait for 3 cycles or more after a USB transfer clock (12 MHz in the full-speed mode, 1.5 MHz in the low-speed mode) was output, then write data to this bit.

- Read the value of TKNEN bit if a new value is written in it. Continue writing in this bit until a retrieved value equals a new value written in. During this checking process, it is needed to prevent any interrupt.

- Take the following steps when CMPIRQ bit of Interrupt USB Host Register (INTR\_USBHOST) is set to '1' by finishing IN token or Isochronous IN token.

1. Read HS bit of Host Error Status Register (HOST\_ERR), then set CMPIRQ bit to '0'.

2. Set EPn bit of Host DMA Enable Register (HOST\_DMA\_ENBL) (n=1 or 2) to '1' if HS bit of Host Error Status Register (HOST\_ERR) is equal to '00' and wait until EPn bit of Host DMA Data Request Register (HOST\_DMA\_DREQ) changes to '1'. Finish the IN token processing if HS bit is not equal to '00'.

3. Read the received data if EPn bit of Host DMA Data Request (HOST\_DMA\_DREQ) (n=1 or 2) changes to '1'.

Default Value: 0

**0x0: NONE :**

Sends no data.

**0x1: SETUP :**

Sends SETUP token.

**0x2: IN :**

Sends IN token.

**0x3: OUT :**

Sends OUT token.

**0x4: SOF :**

Sends SOF token.

**0x5: ISO\_IN :**

Sends Isochronous IN.

## 22.1.71 USBFS0\_USBHOST\_HOST\_TOKEN (continued)

**0x6: ISO\_OUT :**

Sends Isochronous OUT.

**0x7: RSV :**

Reserved.

3 : 0      ENDPT

These bits are used to specify an endpoint to send or receive data to or from the device.

Note:

- This bit isn't reset to default even if the RST bit of the Host Control 1 Register (HOST\_CTL1) is set to '1'.

Default Value: 0

# Section F: Peripheral Group 4

This section encompasses the following chapter:

- [Serial Memory Interface \(SMIF\) Registers chapter on page 1280](#)

## 23 Serial Memory Interface (SMIF) Registers

This section discusses the Serial Memory Interface (SMIF) registers. It lists all the registers in mapping tables, in address order.

### 23.1 Register Details

| Register                      | Address    | Description                     |
|-------------------------------|------------|---------------------------------|
| SMIF0_CTL                     | 0x40420000 | Control                         |
| SMIF0_STATUS                  | 0x40420004 | Status                          |
| SMIF0_TX_CMD_FIFO_STATUS      | 0x40420044 | Transmitter command FIFO status |
| SMIF0_TX_CMD_FIFO_WR          | 0x40420050 | Transmitter command FIFO write  |
| SMIF0_TX_DATA_FIFO_CTL        | 0x40420080 | Transmitter data FIFO control   |
| SMIF0_TX_DATA_FIFO_STATUS     | 0x40420084 | Transmitter data FIFO status    |
| SMIF0_TX_DATA_FIFO_WR1        | 0x40420090 | Transmitter data FIFO write     |
| SMIF0_TX_DATA_FIFO_WR2        | 0x40420094 | Transmitter data FIFO write     |
| SMIF0_TX_DATA_FIFO_WR4        | 0x40420098 | Transmitter data FIFO write     |
| SMIF0_RX_DATA_FIFO_CTL        | 0x404200C0 | Receiver data FIFO control      |
| SMIF0_RX_DATA_FIFO_STATUS     | 0x404200C4 | Receiver data FIFO status       |
| SMIF0_RX_DATA_FIFO_RD1        | 0x404200D0 | Receiver data FIFO read         |
| SMIF0_RX_DATA_FIFO_RD2        | 0x404200D4 | Receiver data FIFO read         |
| SMIF0_RX_DATA_FIFO_RD4        | 0x404200D8 | Receiver data FIFO read         |
| SMIF0_RX_DATA_FIFO_RD1_SILENT | 0x404200E0 | Receiver data FIFO silent read  |
| SMIF0_SLOW_CA_CTL             | 0x40420100 | Slow cache control              |
| SMIF0_SLOW_CA_CMD             | 0x40420108 | Slow cache command              |
| SMIF0_FAST_CA_CTL             | 0x40420180 | Fast cache control              |
| SMIF0_FAST_CA_CMD             | 0x40420188 | Fast cache command              |
| SMIF0_CRYPT0_CMD              | 0x40420200 | Cryptography Command            |
| SMIF0_CRYPT0_INPUT0           | 0x40420220 | Cryptography input 0            |
| SMIF0_CRYPT0_INPUT1           | 0x40420224 | Cryptography input 1            |
| SMIF0_CRYPT0_INPUT2           | 0x40420228 | Cryptography input 2            |
| SMIF0_CRYPT0_INPUT3           | 0x4042022C | Cryptography input 3            |
| SMIF0_CRYPT0_KEY0             | 0x40420240 | Cryptography key 0              |
| SMIF0_CRYPT0_KEY1             | 0x40420244 | Cryptography key 1              |

| Register                                   | Address    | Description                                                                                         |
|--------------------------------------------|------------|-----------------------------------------------------------------------------------------------------|
| <a href="#">SMIF0_CRYPTO_KEY2</a>          | 0x40420248 | Cryptography key 2                                                                                  |
| <a href="#">SMIF0_CRYPTO_KEY3</a>          | 0x4042024C | Cryptography key 3                                                                                  |
| <a href="#">SMIF0_CRYPTO_OUTPUT0</a>       | 0x40420260 | Cryptography output 0                                                                               |
| <a href="#">SMIF0_CRYPTO_OUTPUT1</a>       | 0x40420264 | Cryptography output 1                                                                               |
| <a href="#">SMIF0_CRYPTO_OUTPUT2</a>       | 0x40420268 | Cryptography output 2                                                                               |
| <a href="#">SMIF0_CRYPTO_OUTPUT3</a>       | 0x4042026C | Cryptography output 3                                                                               |

| 31   | ENABLED | <p>IP enable:</p> <p>'0': Disabled. All non-retention registers are reset to their default value when the IP is disabled. When the IP is disabled, the XIP accesses produce AHB-Lite bus errors.</p> <p>'1': Enabled.</p> <p>Note: Before disabling the IP, SW should ensure that the IP is NOT busy (STATUS.BUSY is '0'), otherwise illegal interface transfers may occur.</p> <p>Default Value: 0</p> <p><b>0x0: DISABLED :</b></p> <p><b>0x1: ENABLED :</b></p> |
| 24   | BLOCK   | <p>Specifies what happens for MMIO interface read accesses to an empty RX data FIFO or to a full TX format/data FIFO. Note: the FIFOs can only be accessed in MMIO_MODE.</p> <p>This field is not used for test controller accesses.</p> <p>Default Value: 0</p>                                                                                                                                                                                                   |

## 23.1.1 SMIF0\_CTL (continued)

### 0x0: BUS\_ERROR :

0': Generate an AHB-Lite bus error. This option is useful when SW decides to use polling on STATUS.TR\_BUSY to determine if a interface transfer is no longer busy (transfer is completed). This option adds SW complexity, but limits the number of AHB-Lite wait states (and limits ISR latency).

### 0x1: WAIT\_STATES :

1': Introduce wait states. This setting potentially locks up the AHB-Lite infrastructure and may increase the CPU interrupt latency. This option is useful when SW performs TX/RX data FIFO accesses immediately after a command is setup using the TX format FIFO. This option has low SW complexity, but may result in a significant number of AHB-Lite wait states (and may increase ISR latency).

|         |                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| 0       | XIP_MODE        | <p>Mode of operation.<br/>           Note: this field should only be changed when the IP is disabled or when STATUS.BUSY is '0' and SW should not be executing from the XIP interface or MMIO interface.<br/>           Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                               |

### 0x0: MMIO\_MODE :

'0': MMIO mode. Individual MMIO accesses to TX and RX FIFOs are used to generate a sequence of SPI transfers. This mode of operation allows for large flexibility in terms of the SPI transfers that can be generated.

### 0x1: XIP\_MODE :

1': XIP mode. eXecute-In-Place mode: incoming read and write transfers over the AHB-Lite bus infrastructure are automatically translated in SPI transfers to read data from and write data to a device. This mode of operation allow for efficient device read and write operations. This mode is only supported in SPI\_MODE.

| 31 : 8 | ADDR | <p>Specifies the base address of the device region. If the device region is <math>2^m</math> Bytes, ADDR MUST be a multiple of <math>2^m</math>.</p> <p>In dual quad SPI data transfer, the two devices should have the same ADDR and MASK register settings. The device control information (ADDR_CTL, RD_CMD_CTL, etc.) are provided by the MMIO control registers of the device with the lowest index.</p> <p>The most significant bit fields are constants and set based on the SMIF_XIP_ADDR parameter. The most significant bits are identified on the SMIF_XIP_MASK parameter. E.g., if SMIF_XIP_MASK is 0xff00:0000 (16 MB XIP memory region), ADDR[31:24] = SMIF_XIP_ADDR[31:24].</p> <p>Default Value: Undefined</p> |

|--------|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 : 8 | MASK | <p>Specifies the size of the device region. All '1' bits are used to compare the incoming transfer request address A[31:0] with the address as specified in ADDR.ADDR: Address A is in the device when (A[31:8] &amp; MASK[31:8]) == ADDR.ADDR[31:8].</p> <p>The most significant bit fields are constants and set to '1'. The most significant bits are identified on the SMIF_XIP_MASK parameter. E.g., if SMIF_XIP_MASK is 0xff00:0000 (16 MB XIP memory region), MASK[31:24] = 0xff.</p> <p>Note: a transfer request that is not in any device region results in an AHB-Lite bus error.</p> <p>Default Value: Undefined</p> |

# Section G: Peripheral Group 6

This section encompasses the following chapters:

- [Serial Communication Block \(SCB\) Registers chapter on page 1338](#)

# 24 Serial Communication Block (SCB) Registers

This section discusses the Serial Communications Block (SCB) registers. It lists all the registers in mapping tables, in address order

## 24.1 Register Details

| Register               | Address    | Description                                                                                                                |
|------------------------|------------|----------------------------------------------------------------------------------------------------------------------------|
| SCB0_CTRL              | 0x40610000 | Generic control                                                                                                            |
| SCB0_SPI_CTRL          | 0x40610020 | SPI control                                                                                                                |
| SCB0_SPI_STATUS        | 0x40610024 | SPI status                                                                                                                 |
| SCB0_UART_CTRL         | 0x40610040 | UART control                                                                                                               |
| SCB0_UART_TX_CTRL      | 0x40610044 | UART transmitter control                                                                                                   |
| SCB0_UART_RX_CTRL      | 0x40610048 | UART receiver control                                                                                                      |
| SCB0_UART_RX_STATUS    | 0x4061004C | UART receiver status                                                                                                       |
| SCB0_UART_FLOW_CTRL    | 0x40610050 | UART flow control                                                                                                          |
| SCB0_I2C_CTRL          | 0x40610060 | I2C control                                                                                                                |

Note that a received matching address is put in the RX FIFO when this bit is '1' for both I2C read and write transfers.<br>In multi-processor UART receiver mode, this field is used to allow the receiver to put the received address in the RX FIFO.<br>Note: non-matching addresses are never put in the RX FIFO.<br>In SPI mode this field must be '0'<br>Default Value: 0 |
| 11 | BYTE_MODE   | Determines the number of bits per FIFO data element:<br>'0': 16-bit FIFO data elements.<br>'1': 8-bit FIFO data elements. This mode doubles the amount of FIFO entries, but TX_CTRL.DATA_WIDTH and RX_CTRL.DATA_WIDTH are restricted to [0, 7].<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                 |

## 24.1.1 SCB0\_CTRL (continued)

3 : 0 OVS

Serial interface bit period oversampling factor expressed in clk\_scb cycles. clk\_scb is the peripheral clock divider connected to the SCB.

Used for SPI Master and UART functionality. This field is NOT used in externally clocked mode. This field is NOT used for SPI slave or I2C mode.

OVS + 1 clk\_scb cycles constitute a single serial interface clock/bit cycle. If OVS is odd, the oversampling factor is even and the low and high phase of the interface clock period are the same. If OVS is even, the oversampling factor is odd and the low and high phase can differ by 1 SCB clock period.

In SPI master mode, the valid range is [3, 15]. The frequency of the SPI Clock is (frequency of clk\_scb) / (OVS + 1). For example, if clk\_scb is 50 MHz and OVS is 9, then the frequency of SPI Clock is 50 MHz / (9+1) = 5 MHz.

If the MISO signal is not used for SPI master the valid range changes to [1, 15]

In SPI slave mode, the OVS field is NOT used. Refer to the architecture TRM for information on how to configure clk\_scb for SPI Slave. Generally, it is recommended that clk\_scb be as fast as possible for the slave.

In UART standard sub mode (including LIN and Smartcard), the valid range is [7, 15].

In UART IrDA sub mode this field indirectly specifies the oversampling. The oversampling determines the interface clock/bit cycle and the width of the pulse. For normal transmission mode, the pulse is roughly 3/16 of the bit period (for all bit rates).

There is only one valid OVS value:

- 0: 16 times oversampling.

clk\_scb frequency = 16\*115.2 KHz for 115.2 Kbps.

clk\_scb frequency = 16\*57.6 KHz for 57.6 Kbps.

clk\_scb frequency = 16\*38.4 KHz for 38.4 Kbps.

clk\_scb frequency = 16\*19.2 KHz for 19.2 Kbps.

clk\_scb frequency = 16\*9.6 KHz for 9.6 Kbps.

clk\_scb frequency = 16\*2.4 KHz for 2.4 Kbps.

clk\_scb frequency = 16\*1.2 KHz for 1.2 Kbps.

- all other values are not used in normal mode.

RX\_CTRL.MEDIAN must be set to '1' for IrDA receiver functionality.

UART IrDA RX Low power mode, OVS field values (with the required clk\_scb frequency):

- 0: 16 times oversampling.

clk\_scb frequency = 16\*115.2 KHz for 115.2 Kbps.

- 1: 32 times oversampling.

clk\_scb frequency = 32\*57.6 KHz for 57.6 Kbps.

- 2: 48 times oversampling.

clk\_scb frequency = 48\*38.4 KHz for 38.4 Kbps.

- 3: 96 times oversampling.

clk\_scb frequency = 96\*19.2 KHz for 19.2 Kbps.

- 4: 192 times oversampling.

clk\_scb frequency = 192\*9.6 KHz for 9.6 Kbps.

- 5: 768 times oversampling.

clk\_scb frequency = 768\*2.4 KHz for 2.4 Kbps.

- 6: 1536 times oversampling.

clk\_scb frequency = 1536\*1.2 KHz for 1.2 Kbps.

- all other values are not used in low power mode.

In low power transmission mode, this pulse is potentially smaller (down to 1.62 us typical and 1.41 us minimal) than 3/16 of the bit period (for < 115.2 Kbps bitrates). Pulse widths greater or equal than two SCB clock cycles are guaranteed to be detected by the receiver.

Pulse widths less than two SCB clock cycles and greater or equal than one SCB clock cycle may be detected by the receiver. Pulse widths less than one SCB clock cycle will not be detected by the receiver.

Default Value: 15

|    |                  | <b>0x2: SPI_NS :</b><br>SPI National Semiconducturs submode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 16 | LOOPBACK         | Local loopback control (does NOT affect the information on the pins). Only used in master mode. Not used in National Semiconductors submode.<br>'0': No local loopback<br>'1': the SPI master MISO line is connected to the SPI master MOSI line. In other words, in loop-back mode the SPI master receives on MISO what it transmits on MOSI.<br>Default Value: 0                                                                                                                                                                                     |
| 11 | SSEL_POLARITY3   | Slave select polarity.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 10 | SSEL_POLARITY2   | Slave select polarity.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 9  | SSEL_POLARITY1   | Slave select polarity.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 8  | SSEL_POLARITY0   | Slave select polarity. SSEL_POLARITY0 applies to the outgoing SPI slave select signal 0 (master mode) and to the incoming SPI slave select signal (slave mode). For Motorola and National Semiconductors submodes:<br>'0': slave select is low/'0' active.<br>'1': slave select is high/'1' active.<br>For Texas Instruments submode:<br>'0': high/'1' active precede/coincide pulse.<br>'1': low/'0' active precede/coincide pulse.<br>Default Value: 0                                                                                               |
| 5  | SCLK_CONTINUOUS  | Only applicable in master mode.<br>'0': SCLK is generated, when the SPI master is enabled and data is transmitted.<br>'1': SCLK is generated, when the SPI master is enabled. This mode is useful for slave devices that use SCLK for functional operation other than just SPI functionality.<br>Default Value: 0                                                                                                                                                                                                                                      |
| 4  | LATE_MISO_SAMPLE | Changes the SCLK edge on which MISO is captured. Only used in master mode.<br>When '0', the default applies (for Motorola as determined by CPOL and CPHA, for Texas Instruments on the falling edge of SCLK and for National Semiconductors on the rising edge of SCLK).<br>When '1', the alternate clock edge is used (which comes half a SPI SCLK period later). Late sampling addresses the round trip delay associated with transmitting SCLK from the master to the slave and transmitting MISO from the slave to the master.<br>Default Value: 0 |
| 3  | CPOL             | Indicates the clock polarity. This field, together with the CPHA field, indicates when MOSI data is driven and MISO data is captured:<br>- CPOL is 0: SCLK is 0 when not transmitting data.<br>- CPOL is 1: SCLK is 1 when not transmitting data.<br>Default Value: 0                                                                                                                                                                                                                                                                                  |

## 24.1.2 SCB0\_SPI\_CTRL (continued)

|   |                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2 | CPHA            | <p>Indicates the clock phase. This field, together with the CPOL field, indicates when MOSI data is driven and MISO data is captured:</p> <ul style="list-style-type: none"> <li>- Motorola mode 0. CPOL is 0, CPHA is 0: MOSI is driven on a falling edge of SCLK. MISO is captured on a rising edge of SCLK.</li> <li>- Motorola mode 1. CPOL is 0, CPHA is 1: MOSI is driven on a rising edge of SCLK. MISO is captured on a falling edge of SCLK.</li> <li>- Motorola mode 2. CPOL is 1, CPHA is 0: MOSI is driven on a rising edge of SCLK. MISO is captured on a falling edge of SCLK.</li> <li>- Motorola mode 3. CPOL is 1, CPHA is 1: MOSI is driven on a falling edge of SCLK. MISO is captured on a rising edge of SCLK.</li> </ul> <p>In SPI Motorola submode, all four CPOL/CPHA modes are valid.<br/>         in SPI NS submode, only CPOL=0 CPHA=0 mode is valid.<br/>         in SPI TI submode, only CPOL=0 CPHA=1 mode is valid.<br/>         Default Value: 0</p> |
| 1 | SELECT_PRECEDE  | <p>Only used in SPI Texas Instruments' submode.</p> <p>When '1', the data frame start indication is a pulse on the Slave SELECT line that precedes the transfer of the first data frame bit.</p> <p>When '0', the data frame start indication is a pulse on the Slave SELECT line that coincides with the transfer of the first data frame bit.</p> <p>Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 0 | SSEL_CONTINUOUS | <p>Continuous SPI data transfers enabled ('1') or not ('0'). This field is used in master mode. In slave mode, both continuous and non-continuous SPI data transfers are supported independent of this field.</p> <p>When continuous transfers are enabled individual data transfers are NOT separated by slave select deselection as long as there is data in the TX FIFO. If the TX FIFO becomes empty then the slave select will be deselected.</p> <p>When continuous transfers are not enabled individual data frame transfers are always separated by slave select deselection: independent of the availability of TX FIFO data frames.</p> <p>Default Value: 0</p>                                                                                                                                                                                                                                                                                                            |

|---------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19 : 16 | BREAK_WIDTH | <p>Break width. BREAK_WIDTH + 1 is the minimum width in bit periods of a break. During a break the transmitted/received line value is '0'. This feature is useful for standard UART submode and LIN submode ("break field" detection). Once, the break is detected, the INTR_RX.BREAK_DETECT bit is set to '1'.</p> <p>Note for LIN the break detection precedes baud rate detection, which is used to synchronize/refine the receiver clock to the transmitter clock. As a result, break detection operates with an unsynchronized/unrefined receiver clock. Therefore, the receiver's definition of a bit period is imprecise and the setting of this field should take this imprecision into account. The LIN standard also accounts for this imprecision: a LIN start bit followed by 8 data bits allows for up to 9 consecutive '0' bit periods during regular transmission, whereas the LIN break detection should be at least 13 consecutive '0' bit periods. This provides for a margin of 4 bit periods. Therefore, the default value of this field is set to 10, representing a minimal break field with of 10+1 = 11 bit periods; a value in between the 9 consecutive bit periods of a regular transmission and the 13 consecutive bit periods of a break field. This provides for slight imprecisions of the receiver clock wrt. the transmitter clock. There should not be a need to program this field to any value other than its default value.</p> <p>Default Value: 10</p> |

## 24.1.6 SCB0\_UART\_RX\_CTRL (continued)

|    |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 13 | SKIP_START           | <p>Only applicable in standard UART submode. When '1', the receiver skips start bit detection for the first received data frame. Instead, it synchronizes on the first received data frame bit, which should be a '1'.</p> <p>This functionality is intended for wake up from DeepSleep when receiving a data frame. The transition from idle ('1') to START ('0') on the RX line is used to wake up the CPU. The transition detection (and the associated wake up functionality) is performed by the GPIO.</p> <p>The woken up CPU will enable the SCB's UART receiver functionality. Once enabled, it is assumed that the START bit is ongoing (the CPU wakeup and SCB enable time should be less than the START bit period). The SCB will then synchronize to a '0' to '1' transition, which indicates the first data frame bit is received (first data frame bit should be '1'). After synchronization to the first data frame bit, the SCB will resume normal UART functionality: subsequent data frames will be synchronized on the receipt of a START bit.</p> <p>Default Value: 0</p> |
| 12 | LIN_MODE             | <p>Only applicable in standard UART submode. When '1', the receiver performs break detection and baud rate detection on the incoming data. First, break detection counts the amount of bit periods that have a line value of '0'. BREAK_WIDTH specifies the minum required amount of bit periods. Successful break detection sets the INTR_RX.BREAK_DETECT interrupt cause to '1'. Second, baud rate detection counts the amount of peripheral clock periods that are use to receive the synchronization byte (0x55; least significant bit first). The count is available through UART_RX_STATUS.BR_COUNTER. Successful baud rate detection sets the INTR_RX.BAUD_DETECT interrupt cause to '1' (BR_COUNTER is reliable). This functionality is used to synchronize/refine the receiver clock to the transmitter clock. The receiver software can use the BR_COUNTER value to set the right clk_scb to guarantee successful receipt of the first LIN data frame (Protected Identifier Field) after the synchronization byte.</p> <p>Default Value: 0</p>                                      |
| 10 | MP_MODE              | <p>Multi-processor mode. When '1', multi-processor mode is enabled. In this mode, RX_CTRL.DATA_WIDTH must be 9 bits. In multi-processor mode, the 9th received bit of a data frame separates addresses (bit is '1') from data (bit is '0'). A received address is matched with RX_MATCH.DATA and RX_MATCH.MASK. In the case of a match, subsequent received data is sent to the RX FIFO. In the case of NO match, subsequent received data is dropped.</p> <p>Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 9  | DROP_ON_FRAME_ERROR  | <p>Behaviour when an error is detected in a start or stop period. When '0', received data is sent to the RX FIFO. When '1', received data is dropped and lost.</p> <p>Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 8  | DROP_ON_PARITY_ERROR | <p>Behavior when a parity check fails. When '0', received data is send to the RX FIFO. When '1', received data is dropped and lost. Only applicable in standard UART and SmartCard submodes (negatively acknowledged SmartCard data frames may be dropped with this field).</p> <p>Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 6  | POLARITY             | <p>Inverts incoming RX line signal "uart_rx_in". Inversion is after local loopback. This functionality only works for IrDA receiver functionality.</p> <p>Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 5  | PARITY_ENABLED       | <p>Parity checking enabled ('1') or not ('0'). Only applicable in standard UART submode. In SmartCard submode, parity checking is always enabled through hardware. In IrDA submode, parity checking is always disabled through hardware.</p> <p>Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 4  | PARITY               | <p>Parity bit. When '0', the receiver expects an even parity. When '1', the receiver expects an odd parity. Only applicable in standard UART and SmartCard submodes.</p> <p>Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## 24.1.6 SCB0\_UART\_RX\_CTRL (continued)

|       |           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2 : 0 | STOP_BITS | <p>Stop bits. STOP_BITS + 1 is the duration of the stop period in terms of half bit periods. Valid range is [1, 7]; i.e. a stop period should last at least one bit period.</p> <p>If STOP_BITS is '1', stop bits error detection is NOT performed. If STOP_BITS is in [2, 7], stop bits error detection is performed and the associated interrupt cause INTR_RX.FRAME_ERROR is set to '1' if an error is detected. In other words, the receiver supports data frames with a 1 bit period stop bit sequence, but requires at least 1.5 bit period stop bit sequences to detect errors. Note that in case of a stop bits error, the successive data frames may get lost as the receiver needs to resynchronize its start bit detection. The amount of lost data frames depends on both the amount of stop bits, the idle time between data frames and the data frame value.</p> <p>Default Value: 2</p> |

| 5    | M_READ   | I2C master read transfer ('1') or I2C master write transfer ('0'). When the I2C master is inactive/ idle or transmitting START, REPEATED START, STOP or an address, this field is '0'.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 4    | S_READ   | I2C slave read transfer ('1') or I2C slave write transfer ('0'). When the I2C slave is inactive/idle or receiving START, REPEATED START, STOP or an address, this field is '0'.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 0    | BUS_BUSY | I2C bus is busy. The bus is considered busy ('1'), from the time a START is detected or from the time the SCL line is '0'. The bus is considered idle ('0'), from the time a STOP is detected. If the SCB is disabled, BUS_BUSY is '0'. After enabling the SCB, it takes time for the BUS_BUSY to detect a busy bus. This time is the maximum high time of the SCL line. For a 100 kHz interface frequency, this maximum high time may last roughly 5 us (half a bit period).<br>For single master systems, BUS_BUSY does not have to be used to detect an idle bus before a master starts a transfer using I2C_M_CMD.M_START (no bus collisions).<br>For multi-master systems, BUS_BUSY can be used to detect an idle bus before a master starts a transfer using I2C_M_CMD.M_START_ON_IDLE (to prevent bus collisions).<br>Default Value: 0 |

|---|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | M_START_ON_IDLE | <p>When '1', transmit a START as soon as the bus is idle (I2C_STATUS.BUS_BUSY is '0', note that BUSY has a default value of '0').</p> <p>For bus idle detection the hardware relies on STOP detection. As a result, bus idle detection is only functional after at least one I2C bus transfer has been detected on the bus (default/reset value of BUSY is '0'). A START is only transmitted when the master state machine is in the default state. When this action is performed, the hardware sets this field to '0'.</p> <p>Default Value: 0</p>                                                                                                                  |
| 0 | M_START         | <p>When '1', transmit a START or REPEATED START.</p> <p>Whether a START or REPEATED START is transmitted depends on the state of the master state machine. A START is only transmitted when the master state machine is in the default state. A REPEATED START is transmitted when the master state machine is not in the default state, but is working on an ongoing transaction. The REPEATED START can only be transmitted after a NACK or ACK has been received for a transmitted data element or after a NACK has been transmitted for a received data element. When this action is performed, the hardware sets this field to '0'.</p> <p>Default Value: 0</p> |

|------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16   | OPEN_DRAIN | <p>Each IO cell "xxx" has two associated SCB output signals "xxx_out_en" and "xxx_out". This field determines how the SCB controls those two signals. Consult the GPIO chapter in the architecture TRM to understand how the pin drive modes behave when connected to SCBs.</p> <p>'0': Normal operation mode. In this operation mode "xxx_out_en" output enable signal is typically constant '1' the "xxx_out" output is the outputted value. In other words, in normal operation mode, the "xxx_out" output is used to control the IO cell output value: "xxx_out" is '0' to drive an IO cell output value of '0' and "xxx_out" is '1' to drive an IO cell output value of '1'.</p> <p>'1': Open drain operation mode. In this operation mode "xxx_out_en" output controls the outputted value. Typically the "xxx_out" signal is a constant "0". Thus when "xxx_out_en" is "1" the line is driven low, but when "xxx_out_en" is "0" the output is not driven. This requires that the line is driven high by an external device or pull-up resistor</p> <p>The open drain mode is supported for:</p> <ul style="list-style-type: none"> <li>- I2C mode this field must be set.</li> <li>- UART mode use this mode when a pull-up resistor is used on the TX line.</li> <li>- SPI mode this field must be set if there are multiple slaves driving MISO.</li> </ul> <p>Default Value: 0</p> |

#### 24.1.14 SCB0\_TX\_CTRL (continued)

|       |            |                                                                                                                                                                                                                                                                                                                                                               |
|-------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8     | MSB_FIRST  | Least significant bit first ('0') or most significant bit first ('1'). For I2C, this field should be '1'. For EZ and CMD_RESP this field must be set to "1"<br>Default Value: 1                                                                                                                                                                               |
| 3 : 0 | DATA_WIDTH | Dataframe width. DATA_WIDTH + 1 is the amount of bits in a transmitted data frame. This number does not include start, parity and stop bits. For UART mode, the valid range is [3, 8]. For SPI, the valid range is [3, 15]. For I2C the only valid value is 7. In EZ and CMD_RESP mode (for both SPI and I2C), the only valid value is 7.<br>Default Value: 7 |

|-------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9     | MEDIAN     | Median filter. When '1', a digital 3 taps median filter is performed on input interface lines. This filter should reduce the susceptibility to errors. However, its requires higher oversampling values. For UART IrDA submode, this field should always be '1'.<br>Default Value: 0                                                                 |
| 8     | MSB_FIRST  | Least significant bit first ('0') or most significant bit first ('1'). For I2C, this field should be '1'. For EZ and CMD_RESP this field must be set to "1"<br>Default Value: 1                                                                                                                                                                      |
| 3 : 0 | DATA_WIDTH | Dataframe width. DATA_WIDTH + 1 is the expected amount of bits in received data frame. This number does not include start, parity and stop bits. For UART mode, the valid range is [3, 8]. For SPI, the valid range is [3, 15]. For I2C the only valid value is 7. In EZ mode (for both SPI and I2C), the only valid value is 7.<br>Default Value: 7 |

|-------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 : 0 | EZ_DATA | <p>Data in buffer memory location. In case of a blocked discarded access, a read access returns 0xffff:ffff and a write access is dropped. Note that the 0xffff:ffff value is unique (not a legal EZ_DATA byte value) and can be detected by SW. Note that a discarded write access can be detected by reading back the written value, or checking the field BLOCKED of the INTR_TX and INTR_RX registers</p> <p>Default Value: Undefined</p> |

| 11   | SPI_BUS_ERROR     | SPI slave deselected at an unexpected time in the SPI transfer. Firmware may decide to clear the TX and RX FIFOs in case of this error.<br>Default Value: 0                                                                                                                                                         |
| 10   | SPI_EZ_STOP       | SPI slave deselected after any EZ SPI transfer occurred.<br>Default Value: 0                                                                                                                                                                                                                                        |
| 9    | SPI_EZ_WRITE_STOP | SPI slave deselected after a write EZ SPI transfer occurred.<br>Default Value: 0                                                                                                                                                                                                                                    |
| 8    | I2C_BUS_ERROR     | I2C slave bus error (unexpected detection of START or STOP condition). This should not occur, it represents erroneous I2C bus behavior. In case of a bus error, the I2C slave state machine abort the ongoing transfer. Firmware may decide to clear the TX and RX FIFOs in case of this error.<br>Default Value: 0 |

### 24.1.30 SCB0\_INTR\_S (continued)

|   |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 | I2C_GENERAL    | I2C slave general call address received. If CTRL.ADDR_ACCEPT is set the received address 0x00 (including the R/W bit) is available in the RX FIFO.<br>In the case of externally clocked address matching (CTRL.EC_AM_MODE is '1') and internally clocked operation (CTRL.EC_OP_MODE is '0'), this field is set when the event is detected.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 6 | I2C_ADDR_MATCH | I2C slave matching address received. If CTRL.ADDR_ACCEPT, the received address (including the R/W bit) is available in the RX FIFO. In the case of externally clocked address matching (CTRL.EC_AM_MODE is '1') and internally clocked operation (CTRL.EC_OP_MODE is '0'), this field is set when the event is detected.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 5 | I2C_START      | I2C slave START received. Set to '1', when START or REPEATED START event is detected. In the case of externally clocked address matching (CTRL.EC_AM_MODE is '1') AND clock stretching is performed (till the internally clocked logic takes over) (I2C_CTRL.S_NOT_READY_ADDR_NACK is '0'), this field is NOT set. Firmware should use INTR_S_EC.WAKE_UP, INTR_S.I2C_ADDR_MATCH and INTR_S.I2C_GENERAL.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 4 | I2C_STOP       | I2C STOP event for I2C (read or write) transfer intended for this slave (address matching is performed). Set to '1', when STOP or REPEATED START event is detected. The REPEATED START event is included in this interrupt cause such that the I2C transfers separated by a REPEATED START can be distinguished and potentially treated separately by the Firmware. Note that the second I2C transfer (after a REPEATED START) may be to a different slave address. The event is detected on any I2C transfer intended for this slave. Note that a I2C address intended for the slave (address is matching) will result in a I2C_STOP event independent of whether the I2C address is ACK'd or NACK'd.<br>Default Value: 0                                                                                                                                                                                                                 |
| 3 | I2C_WRITE_STOP | I2C STOP event for I2C write transfer intended for this slave (address matching is performed). Set to '1', when STOP or REPEATED START event is detected. The REPEATED START event is included in this interrupt cause such that the I2C transfers separated by a REPEATED START can be distinguished and potentially treated separately by the firmware. Note that the second I2C transfer (after a REPEATED START) may be to a different slave address. Note that a I2C write address intended for the slave (address is matching and a it is a write transfer) will result in a I2C_WRITE_STOP event independent of whether the I2C address is ACK'd or NACK'd.<br>In EZ mode, the event is detected only on I2C write transfers that have EZ data written to the memory structure (an I2C write transfer that only communicates an I2C address and EZ base address, will not result in this event being detected).<br>Default Value: 0 |
| 2 | I2C_ACK        | I2C slave acknowledgement received. Set to '1', when the slave receives a ACK (typically after the slave transmitted TX data).<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 1 | I2C_NACK       | I2C slave negative acknowledgement received. Set to '1', when the slave receives a NACK (typically after the slave transmitted TX data).<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 0 | I2C_ARB_LOST   | I2C slave lost arbitration: the value driven on the SDA line is not the same as the value observed on the SDA line (while the SCL line is '1'). This should not occur, it represents erroneous I2C bus behavior. In case of lost arbitration, the I2C slave state machine aborts the ongoing transfer. SW may decide to clear the TX and RX FIFOs in case of this error.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11   | BREAK_DETECT | Break detection is successful: the line is '0' for UART_RX_CTRL.BREAK_WIDTH + 1 bit period. Can occur at any time to address unanticipated break fields; i.e. "break-in-data" is supported. This feature is supported for the UART standard and LIN submodes. For the UART standard submodes, ongoing receipt of data frames is NOT affected; i.e. Firmware is expected to take the proper action. For the LIN submode, possible ongoing receipt of a data frame is stopped and the (partially) received data frame is dropped and baud rate detection is started. Set to '1', when event is detected. Write with '1' to clear bit.<br>Default Value: 0 |
| 10   | BAUD_DETECT  | LIN baudrate detection is completed. The receiver software uses the UART_RX_STATUS.BR_COUNTER value to set the clk_scb to guarantee successful receipt of the first LIN data frame (Protected Identifier Field) after the synchronization byte.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                     |

### 24.1.38 SCB0\_INTR\_RX (continued)

|   |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9 | PARITY_ERROR | <p>UART Parity error in received data frame. If UART_RX_CTL.DROP_ON_PARITY_ERROR is '1', the received frame is dropped. If UART_RX_CTL.DROP_ON_PARITY_ERROR is '0', the received frame is send to the RX FIFO. In SmartCard submode, negatively acknowledged data frames generate a parity error. Note that Firmware can only identify the erroneous data frame in the RX FIFO if it is fast enough to read the data frame before the hardware writes a next data frame into the RX FIFO.</p> <p>Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 8 | FRAME_ERROR  | <p>UART Frame error in received data frame.</p> <p>This can be either a start or stop bit(s) error:</p> <p>Start bit error: after the detection of the beginning of a start bit period (RX line changes from '1' to '0'), the middle of the start bit period is sampled erroneously (RX line is '1'). Note: a start bit error is detected BEFORE a data frame is received.</p> <p>Stop bit error: the RX line is sampled as '0', but a '1' was expected. Note: a stop bit error may result in failure to receive successive data frame(s). Note: a stop bit error is detected AFTER a data frame is received.</p> <p>A stop bit error is detected after a data frame is received, and the UART_RX_CTL.DROP_ON_FRAME_ERROR field specifies whether the received frame is dropped or send to the RX FIFO. If UART_RX_CTL.DROP_ON_FRAME_ERROR is '1', the received data frame is dropped. If UART_RX_CTL.DROP_ON_FRAME_ERROR is '0', the received data frame is send to the RX FIFO. Note that Firmware can only identify the erroneous data frame in the RX FIFO if it is fast enough to read the data frame before the hardware writes a next data frame into the RX FIFO; i.e. the RX FIFO does not have error flags to tag erroneous data frames.</p> <p>Default Value: 0</p> |
| 6 | UNDERFLOW    | <p>Attempt to read from an empty RX FIFO.</p> <p>Only used in FIFO mode.</p> <p>Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 5 | OVERFLOW     | <p>Attempt to write to a full RX FIFO. Note: in I2C mode, the OVERFLOW is set when a data frame is received and the RX FIFO is full, independent of whether it is ACK'd or NACK'd.</p> <p>Only used in FIFO mode.</p> <p>Default Value: 0</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| 8  | EC_AM_MODE | <p>This field specifies the clocking for the address matching (I2C slave) or slave selection detection logic (SPI slave)</p> <p>'0': Internally clocked mode</p> <p>'1': Externally clocked mode</p> <p>In internally clocked mode the address detection (and slave selection detection) is done by clk_scb, and thus won't be done in deep sleep power mode as clk_scb isn't active. In externally clocked mode the address detection is done by the I2C/SPI interface clock. This allows for the device to be awoken on I2C slave address match and SPI slave select assertion. The clocking for the rest of the logic is determined by CTRL.EC_OP_MODE.</p> <p>Externally clocked mode is only used for synchronous serial interface protocols (SPI and I2C) in slave mode. In SPI mode, only Motorola submode (all Motorola modes: 0, 1, 2, 3) is supported. In UART mode this field must be '0'.</p> <p>Default Value: 0</p>           |

## 24.1.42 SCB8\_CTRL (continued)

3 : 0 OVS

Serial interface bit period oversampling factor expressed in clk\_scb cycles. clk\_scb is the peripheral clock divider connected to the SCB.

Used for SPI Master and UART functionality. This field is NOT used in externally clocked mode. This field is NOT used for SPI slave or I2C mode.

OVS + 1 clk\_scb cycles constitute a single serial interface clock/bit cycle. If OVS is odd, the oversampling factor is even and the low and high phase of the interface clock period are the same. If OVS is even, the oversampling factor is odd and the low and high phase can differ by 1 SCB clock period.

In SPI master mode, the valid range is [3, 15]. The frequency of the SPI Clock is (frequency of clk\_scb) / (OVS + 1). For example, if clk\_scb is 50 MHz and OVS is 9, then the frequency of SPI Clock is 50 MHz / (9+1) = 5 MHz.

If the MISO signal is not used for SPI master the valid range changes to [1, 15]

In SPI slave mode, the OVS field is NOT used. Refer to the architecture TRM for information on how to configure clk\_scb for SPI Slave. Generally, it is recommended that clk\_scb be as fast as possible for the slave.

In UART standard sub mode (including LIN and Smartcard), the valid range is [7, 15].

In UART IrDA sub mode this field indirectly specifies the oversampling. The oversampling determines the interface clock/bit cycle and the width of the pulse. For normal transmission mode, the pulse is roughly 3/16 of the bit period (for all bit rates).

There is only one valid OVS value:

- 0: 16 times oversampling.

clk\_scb frequency = 16\*115.2 KHz for 115.2 Kbps.

clk\_scb frequency = 16\*57.6 KHz for 57.6 Kbps.

clk\_scb frequency = 16\*38.4 KHz for 38.4 Kbps.

clk\_scb frequency = 16\*19.2 KHz for 19.2 Kbps.

clk\_scb frequency = 16\*9.6 KHz for 9.6 Kbps.

clk\_scb frequency = 16\*2.4 KHz for 2.4 Kbps.

clk\_scb frequency = 16\*1.2 KHz for 1.2 Kbps.

- all other values are not used in normal mode.

RX\_CTRL.MEDIAN must be set to '1' for IrDA receiver functionality.

UART IrDA RX Low power mode, OVS field values (with the required clk\_scb frequency):

- 0: 16 times oversampling.

clk\_scb frequency = 16\*115.2 KHz for 115.2 Kbps.

- 1: 32 times oversampling.

clk\_scb frequency = 32\*57.6 KHz for 57.6 Kbps.

- 2: 48 times oversampling.

clk\_scb frequency = 48\*38.4 KHz for 38.4 Kbps.

- 3: 96 times oversampling.

clk\_scb frequency = 96\*19.2 KHz for 19.2 Kbps.

- 4: 192 times oversampling.

clk\_scb frequency = 192\*9.6 KHz for 9.6 Kbps.

- 5: 768 times oversampling.

clk\_scb frequency = 768\*2.4 KHz for 2.4 Kbps.

- 6: 1536 times oversampling.

clk\_scb frequency = 1536\*1.2 KHz for 1.2 Kbps.

- all other values are not used in low power mode.

In low power transmission mode, this pulse is potentially smaller (down to 1.62 us typical and 1.41 us minimal) than 3/16 of the bit period (for < 115.2 Kbps bitrates). Pulse widths greater or equal than two SCB clock cycles are guaranteed to be detected by the receiver.

Pulse widths less than two SCB clock cycles and greater or equal than one SCB clock cycle may be detected by the receiver. Pulse widths less than one SCB clock cycle will not be detected by the receiver.

Default Value: 15

| 10 | SSEL_POLARITY2 | Slave select polarity.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 9  | SSEL_POLARITY1 | Slave select polarity.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 8  | SSEL_POLARITY0 | Slave select polarity. SSEL_POLARITY0 applies to the outgoing SPI slave select signal 0 (master mode) and to the incoming SPI slave select signal (slave mode). For Motorola and National Semiconductors submodes:<br>'0': slave select is low/'0' active.<br>'1': slave select is high/'1' active.<br>For Texas Instruments submode:<br>'0': high/'1' active precede/coincide pulse.<br>'1': low/'0' active precede/coincide pulse.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 3  | CPOL           | Indicates the clock polarity. This field, together with the CPHA field, indicates when MOSI data is driven and MISO data is captured:<br>- CPOL is 0: SCLK is 0 when not transmitting data.<br>- CPOL is 1: SCLK is 1 when not transmitting data.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 2  | CPHA           | Indicates the clock phase. This field, together with the CPOL field, indicates when MOSI data is driven and MISO data is captured:<br>- Motorola mode 0. CPOL is 0, CPHA is 0: MOSI is driven on a falling edge of SCLK. MISO is captured on a rising edge of SCLK.<br>- Motorola mode 1. CPOL is 0, CPHA is 1: MOSI is driven on a rising edge of SCLK. MISO is captured on a falling edge of SCLK.<br>- Motorola mode 2. CPOL is 1, CPHA is 0: MOSI is driven on a rising edge of SCLK. MISO is captured on a falling edge of SCLK.<br>- Motorola mode 3. CPOL is 1, CPHA is 1: MOSI is driven on a falling edge of SCLK. MISO is captured on a rising edge of SCLK.<br>In SPI Motorola submode, all four CPOL/CPHA modes are valid.<br>in SPI NS submode, only CPOL=0 CPHA=0 mode is valid.<br>in SPI TI submode, only CPOL=0 CPHA=1 mode is valid.<br>Default Value: 0 |
| 1  | SELECT_PRECEDE | Only used in SPI Texas Instruments' submode.<br>When '1', the data frame start indication is a pulse on the Slave SELECT line that precedes the transfer of the first data frame bit.<br>When '0', the data frame start indication is a pulse on the Slave SELECT line that coincides with the transfer of the first data frame bit.<br>Default Value: 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|---------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 23 : 16 | BASE_EZ_ADDR | SPI base EZ address. Address as provided by a SPI write transfer. This field is only reliable in internally clocked mode. In externally clocked mode the field may be unreliable.<br>Default Value: Undefined                                                                                                                                                                                                              |
| 15 : 8  | CURR_EZ_ADDR | SPI current EZ address. Current address pointer. This field is only reliable in internally clocked mode. In externally clocked mode the field may be unreliable (during an ongoing transfer when SPI_EC_BUSY is '1').<br>Default Value: Undefined                                                                                                                                                                          |
| 1       | SPI_EC_BUSY  | Indicates whether the externally clocked logic is potentially accessing the EZ memory and/or updating BASE_ADDR or CURR_ADDR (this is only possible in EZ and CMD_RESP mode). This bit can be used by the CPU to determine whether BASE_ADDR and CURR_ADDR are reliable.<br>Default Value: Undefined                                                                                                                       |
| 0       | BUS_BUSY     | SPI bus is busy. The bus is considered busy ('1') during an ongoing transaction. For Motorola and National submodes, the busy bit is '1', when the slave selection is activated. For TI submode, the busy bit is '1' from the time the preceding/coinciding slave select is activated for the first transmitted data frame, till the last MOSI/MISO bit of the last data frame is transmitted.<br>Default Value: Undefined |

|   |          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | BUS_BUSY | <p>I2C bus is busy. The bus is considered busy ('1'), from the time a START is detected or from the time the SCL line is '0'. The bus is considered idle ('0'), from the time a STOP is detected. If the SCB is disabled, BUS_BUSY is '0'. After enabling the SCB, it takes time for the BUS_BUSY to detect a busy bus. This time is the maximum high time of the SCL line. For a 100 kHz interface frequency, this maximum high time may last roughly 5 us (half a bit period).</p> <p>For single master systems, BUS_BUSY does not have to be used to detect an idle bus before a master starts a transfer using I2C_M_CMD.M_START (no bus collisions).</p> <p>For multi-master systems, BUS_BUSY can be used to detect an idle bus before a master starts a transfer using I2C_M_CMD.M_START_ON_IDLE (to prevent bus collisions).</p> <p>Default Value: 0</p> |
|---|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

# Section H: Peripheral Group 9

This section encompasses the following chapters:

- [Analog Reference Block \(AREF\) Registers chapter on page 1446](#)
- [Continuous-Time Block Mini Registers chapter on page 1450](#)
- [Continuous-Time DAC Registers chapter on page 1481](#)
- [SAR ADC Registers chapter on page 1492](#)

## 25 Analog Reference Block (AREF) Registers

This section discusses the Analog Reference Block (AREF) registers. It lists all the registers in mapping tables, in address order.

### 25.1 Register Details

| Register                            | Address    | Description         |
|-------------------------------------|------------|---------------------|
| <a href="#">PASS_AREF_AREF_CTRL</a> | 0x411F0E00 | Global AREF control |

## 25.1.1 PASS\_AREF\_AREF\_CTRL

Global AREF control

Address: 0x411F0E00

Retention: Retained

| Bits      | 7                 | 6              | 5 | 4 | 3                     | 2 | 1    | 0          |

# 26 Continuous-Time Block Mini Registers

This section discusses the Continuous-Time Block Mini (CTBm) registers. It lists all the registers in mapping tables, in address order.

## 26.1 Register Details

| Register                                    | Address    | Description                           |
|---------------------------------------------|------------|---------------------------------------|
| <a href="#">CTBM0_CTB_CTRL</a>              | 0x41100000 | global CTB and power control          |
| <a href="#">CTBM0_OA_RES0_CTRL</a>          | 0x41100004 | Opamp0 and resistor0 control          |
| <a href="#">CTBM0_OA_RES1_CTRL</a>          | 0x41100008 | Opamp1 and resistor1 control          |
| <a href="#">CTBM0_COMP_STAT</a>             | 0x4110000C | Comparator status                     |
| <a href="#">CTBM0_INTR</a>                  | 0x41100020 | Interrupt request register            |
| <a href="#">CTBM0_INTR_SET</a>              | 0x41100024 | Interrupt request set register        |
| <a href="#">CTBM0_INTR_MASK</a>             | 0x41100028 | Interrupt request mask                |
| <a href="#">CTBM0_INTR_MASKED</a>           | 0x4110002C | Interrupt request masked              |
| <a href="#">CTBM0_OA0_SW</a>                | 0x41100080 | Opamp0 switch control                 |
| <a href="#">CTBM0_OA0_SW_CLEAR</a>          | 0x41100084 | Opamp0 switch control clear           |
| <a href="#">CTBM0_OA1_SW</a>                | 0x41100088 | Opamp1 switch control                 |
| <a href="#">CTBM0_OA1_SW_CLEAR</a>          | 0x4110008C | Opamp1 switch control clear           |

## 27 Continuous-Time DAC Registers

This section discusses the Continuous-Time DAC registers. It lists all the registers in mapping tables, in address order.

### 27.1 Register Details

| Register                              | Address    | Description                       |
|---------------------------------------|------------|-----------------------------------|
| <a href="#">CTDAC0_CTDAC_CTRL</a>     | 0x41140000 | Global CTDAC control              |
| <a href="#">CTDAC0_INTR</a>           | 0x41140020 | Interrupt request register        |
| <a href="#">CTDAC0_INTR_SET</a>       | 0x41140024 | Interrupt request set register    |
| <a href="#">CTDAC0_INTR_MASK</a>      | 0x41140028 | Interrupt request mask            |
| <a href="#">CTDAC0_INTR_MASKED</a>    | 0x4114002C | Interrupt request masked          |
| <a href="#">CTDAC0_CTDAC_SW</a>       | 0x411400B0 | CTDAC switch control              |
| <a href="#">CTDAC0_CTDAC_SW_CLEAR</a> | 0x411400B4 | CTDAC switch control clear        |
| <a href="#">CTDAC0_CTDAC_VAL</a>      | 0x41140100 | DAC Value                         |
| <a href="#">CTDAC0_CTDAC_VAL_NXT</a>  | 0x41140104 | Next DAC value (double buffering) |

## 27.1.1 CTDAC0\_CTDAC\_CTRL

Global CTDAC control

Address: 0x41140000

Retention: Retained

| Bits      | 7          | 6 | 5                  | 4 | 3 | 2 | 1 | 0 |
|-----------|------------|---|--------------------|---|---|---|---|---|

# 28 SAR ADC Registers

This section discusses the SAR ADC registers. It lists all the registers in mapping tables, in address order.

## 28.1 Register Details

| Register                          | Address    | Description                                                                                         |
|-----------------------------------|------------|-----------------------------------------------------------------------------------------------------|
| <a href="#">SAR_CTRL</a>          | 0x411D0000 | Analog control register.                                                                            |
| <a href="#">SAR_SAMPLE_CTRL</a>   | 0x411D0004 | Sample control register.                                                                            |
| <a href="#">SAR_SAMPLE_TIME01</a> | 0x411D0010 | Sample time specification ST0 and ST1                                                               |
| <a href="#">SAR_SAMPLE_TIME23</a> | 0x411D0014 | Sample time specification ST2 and ST3                                                               |
| <a href="#">SAR_RANGE_THRES</a>   | 0x411D0018 | Global range detect threshold register.                                                             |
| <a href="#">SAR_RANGE_COND</a>    | 0x411D001C | Global range detect mode register.                                                                  |
| <a href="#">SAR_CHAN_EN</a>       | 0x411D0020 | Enable bits for the channels                                                                        |
| <a href="#">SAR_START_CTRL</a>    | 0x411D0024 | Start control register (firmware trigger).                                                          |
| <a href="#">SAR_CHAN_CONFIG0</a>  | 0x411D0080 | Channel configuration register.                                                                     |
| <a href="#">SAR_CHAN_CONFIG1</a>  | 0x411D0084 | Channel configuration register. See <a href="#">SAR_CHAN_CONFIG0</a> for the details of bit fields. |
| <a href="#">SAR_CHAN_CONFIG2</a>  | 0x411D0088 | Channel configuration register. See <a href="#">SAR_CHAN_CONFIG0</a> for the details of bit fields. |
| <a href="#">SAR_CHAN_CONFIG3</a>  | 0x411D008C | Channel configuration register. See <a href="#">SAR_CHAN_CONFIG0</a> for the details of bit fields. |
| <a href="#">SAR_CHAN_CONFIG4</a>  | 0x411D0090 | Channel configuration register. See <a href="#">SAR_CHAN_CONFIG0</a> for the details of bit fields. |
| <a href="#">SAR_CHAN_CONFIG5</a>  | 0x411D0094 | Channel configuration register. See <a href="#">SAR_CHAN_CONFIG0</a> for the details of bit fields. |
| <a href="#">SAR_CHAN_CONFIG6</a>  | 0x411D0098 | Channel configuration register. See <a href="#">SAR_CHAN_CONFIG0</a> for the details of bit fields. |

| 6 : 4 | AVG_CNT             | <p>Averaging Count for channels that have averaging enabled (AVG_EN). A channel will be sampled <math>(1 \leq (AVG\_CNT+1)) = [2..256]</math> times.</p> <p>- In ACCUNDUMP mode (1st order accumulate and dump filter) a channel will be sampled back to back, the average result is calculated and stored and then the next enabled channel is sampled. If shifting is not enabled (AVG_SHIFT=0) then the result is forced to shift right so that it fits in 16 bits, so right shift is done by <math>\max(0, AVG\_CNT-3)</math>.</p> <p>- In INTERLEAVED mode one sample is taken per triggered scan, only in the scan where the final averaging count is reached a valid average is calculated and stored in the RESULT register (by definition the same scan for all the channels that have averaging enabled). In all other scans the RESULT register for averaged channels will have an invalid result and the intermediate accumulated value is stored in the 16-bit WORK register. In this mode make sure that the averaging count is low enough to ensure that the intermediate value does not exceed 16-bits otherwise the MSBs will be lost. So for a 12-bit resolution the averaging count should be set to 16 or less (AVG_CNT=<math>\leq 3</math>).</p> <p>Default Value: 0</p> |
| 3     | DIFFERENTIAL_SIGNED | <p>Output data from a differential conversion as a signed value when DIFFERENTIAL_EN or NEG_ADDR_EN is set to 1</p> <p>Default Value: 1</p> <p><b>0x0: UNSIGNED :</b><br/>result data is unsigned (zero extended if needed)</p> <p><b>0x1: SIGNED :</b><br/>Default: result data is signed (sign extended if needed)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | INJ_COLLISION_INTR | Injection Collision Interrupt: hardware sets this interrupt when the injection trigger signal is asserted (INJ_START_EN==1 && INJ_TAILGATING==0) while the SAR is BUSY. Raising this interrupt is delayed to when the sampling of the injection channel has been completed, i.e. not when the preceding scan with which this trigger collided is completed. When this interrupt is set it implies that the injection channel was sampled later than was intended. Write with '1' to clear bit.<br>Default Value: 0 |
| 6    | INJ_RANGE_INTR     | Injection Range detect Interrupt: hardware sets this interrupt if the injection conversion result (after averaging) met the condition specified by the SAR_RANGE registers. Write with '1' to clear bit.<br>Default Value: 0                                                                                                                                                                                                                                                                                       |
| 5    | INJ_SATURATE_INTR  | Injection Saturation Interrupt: hardware sets this interrupt if an injection conversion result (before averaging) is either 0x000 or 0xFFFF, this is an indication that the ADC likely saturated. Write with '1' to clear bit.<br>Default Value: 0                                                                                                                                                                                                                                                                 |

### 28.1.14 SAR\_INTR (continued)

|   |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4 | INJ_EOC_INTR       | Injection End of Conversion Interrupt: hardware sets this interrupt after completing the conversion for the injection channel (irrespective of if tailgating was used). Write with '1' to clear bit.<br>Default Value: 0                                                                                                                                                                                                                                      |
| 3 | DSI_COLLISION_INTR | DSI Collision Interrupt: hardware sets this interrupt when the DSI trigger signal is asserted while the SAR is BUSY. Raising this interrupt is delayed to when the scan caused by the DSI trigger has been completed, i.e. not when the preceding scan with which this trigger collided is completed. When this interrupt is set it implies that the channels were sampled later than was intended (jitter). Write with '1' to clear bit.<br>Default Value: 0 |
| 2 | FW_COLLISION_INTR  | Firmware Collision Interrupt: hardware sets this interrupt when FW_TRIGGER is asserted while the SAR is BUSY. Raising this interrupt is delayed to when the scan caused by the FW_TRIGGER has been completed, i.e. not when the preceding scan with which this trigger collided is completed. When this interrupt is set it implies that the channels were sampled later than was intended (jitter). Write with '1' to clear bit.<br>Default Value: 0         |
| 1 | OVERFLOW_INTR      | Overflow Interrupt: hardware sets this interrupt when it sets a new EOS_INTR while that bit was not yet cleared by the firmware. Write with '1' to clear bit.<br>Default Value: 0                                                                                                                                                                                                                                                                             |
| 0 | EOS_INTR           | End Of Scan Interrupt: hardware sets this interrupt after completing a scan of all the enabled channels. Write with '1' to clear bit.<br>Default Value: 0                                                                                                                                                                                                                                                                                                     |

# Section I: Peripheral Group 10

This section encompasses the following chapters:

- [Pulse Density Modulation \(PDM\) Registers chapter on page 1550](#)
- [Inter IC Sound \(I2S\) Registers chapter on page 1569](#)

## 29 Pulse Density Modulation (PDM) Registers

This section discusses the Pulse Density Modulation (PDM) block registers. It lists all the registers in mapping tables, in address order.

### 29.1 Register Details

| Register               | Address    | Description               |
|------------------------|------------|---------------------------|
| PDM0_CTL               | 0x42A20000 | Control                   |
| PDM0_CLOCK_CTL         | 0x42A20010 | Clock control             |
| PDM0_MODE_CTL          | 0x42A20014 | Mode control              |
| PDM0_DATA_CTL          | 0x42A20018 | Data control              |
| PDM0_CMD               | 0x42A20020 | Command                   |
| PDM0_TR_CTL            | 0x42A20040 | Trigger control           |
| PDM0_RX_FIFO_CTL       | 0x42A20300 | RX FIFO control           |
| PDM0_RX_FIFO_STATUS    | 0x42A20304 | RX FIFO status            |
| PDM0_RX_FIFO_RD        | 0x42A20308 | RX FIFO read              |
| PDM0_RX_FIFO_RD_SILENT | 0x42A2030C | RX FIFO silent read       |
| PDM0_INTR              | 0x42A20F00 | Interrupt register        |
| PDM0_INTR_SET          | 0x42A20F04 | Interrupt set register    |
| PDM0_INTR_MASK         | 0x42A20F08 | Interrupt mask register   |
| PDM0_INTR_MASKED       | 0x42A20F0C | Interrupt masked register |

| Name      | None [31:24]        |    |    |    |    |    |        |       |

| Bits  | Name          | Description                                                                                                                                                                                                                                                                                                                                                                        |
|-------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 17    | FREEZE        | When '1', hardware writes to the RX FIFO have no effect. Freeze will not advance the RX FIFO write pointer. This field is used only for debugging purposes.<br>Default Value: 0                                                                                                                                                                                                    |
| 16    | CLEAR         | When '1', the RX FIFO and RX_BUF are cleared/invalidated. Invalidation will last for as long as this field is '1'. If a quick clear/invalidation is required, the field should be set to '1' and be followed by a set to '0'. If a clear/invalidation is required for an extended time period, the field should be set to '1' during the complete time period.<br>Default Value: 0 |
| 7 : 0 | TRIGGER_LEVEL | Trigger level. When the RX FIFO has more entries than the number of this field, a receiver trigger event is generated.<br>Note: software can configure up to 254 in Mono channel enabled (MODE_CTL.PCM_CH_SET = "1" or "2"), up to 253 in Stereo channel enabled (MODE_CTL.PCM_CH_SET = "3").<br>Default Value: 0                                                                  |

## 30 Inter IC Sound (I2S) Registers

This section discusses the Inter IC Sound (I2S) registers. It lists all the registers in mapping tables, in address order.

### 30.1 Register Details

| Register                               | Address    | Description               |
|----------------------------------------|------------|---------------------------|
| <a href="#">I2S0_CTL</a>               | 0x42A10000 | Control                   |
| <a href="#">I2S0_CLOCK_CTL</a>         | 0x42A10010 | Clock control             |
| <a href="#">I2S0_CMD</a>               | 0x42A10020 | Command                   |
| <a href="#">I2S0_TR_CTL</a>            | 0x42A10040 | Trigger control           |
| <a href="#">I2S0_TX_CTL</a>            | 0x42A10080 | Transmitter control       |
| <a href="#">I2S0_TX_WATCHDOG</a>       | 0x42A10084 | Transmitter watchdog      |
| <a href="#">I2S0_RX_CTL</a>            | 0x42A100A0 | Receiver control          |
| <a href="#">I2S0_RX_WATCHDOG</a>       | 0x42A100A4 | Receiver watchdog         |
| <a href="#">I2S0_TX_FIFO_CTL</a>       | 0x42A10200 | TX FIFO control           |
| <a href="#">I2S0_TX_FIFO_STATUS</a>    | 0x42A10204 | TX FIFO status            |
| <a href="#">I2S0_TX_FIFO_WR</a>        | 0x42A10208 | TX FIFO write             |
| <a href="#">I2S0_RX_FIFO_CTL</a>       | 0x42A10300 | RX FIFO control           |
| <a href="#">I2S0_RX_FIFO_STATUS</a>    | 0x42A10304 | RX FIFO status            |
| <a href="#">I2S0_RX_FIFO_RD</a>        | 0x42A10308 | RX FIFO read              |
| <a href="#">I2S0_RX_FIFO_RD_SILENT</a> | 0x42A1030C | RX FIFO silent read       |
| <a href="#">I2S0_INTR</a>              | 0x42A10F00 | Interrupt register        |
| <a href="#">I2S0_INTR_SET</a>          | 0x42A10F04 | Interrupt set register    |
| <a href="#">I2S0_INTR_MASK</a>         | 0x42A10F08 | Interrupt mask register   |
| <a href="#">I2S0_INTR_MASKED</a>       | 0x42A10F0C | Interrupt masked register |

### 30.1.1 I2S0\_CTL

Control

Address: 0x42A10000

Retention: Retained

| Bits      | 7          | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-----------|------------|---|---|---|---|---|---|---|
| SW Access | None       |   |   |   |   |   |   |   |
