If they fail, it is reasonable to assume that the health of the user or other persons may be endangered.

Off-Line SMPS Quasi-Resonant PWM Controller with integrated 800V CoolMOS® and startup cell in DIP-7

Product Highlights

- **Quasi resonant operation**
- **Active Burst Mode to reach the lowest standby power requirement**
 $<100\text{mW}@ \text{no load}$
- **Digital frequency reduction for better overall system efficiency**
- **Integrated 800V avalanche rugged CoolMOS® with startup cell**
- **Pb-free lead plating; RoHS compliant**

Features

- 800V avalanche rugged CoolMOS® with built-in startup cell
- Quasi resonant operation till very low load
- Active burst mode operation for low standby input power ($< 0.1\text{W}$)
- Digital frequency reduction with decreasing load for reduced switching loss
- Built-in digital soft-start
- Foldback point correction and cycle-by-cycle peak current limitation
- Maximum on/off time limitation
- Auto restart mode for VCC Overvoltage and Undervoltage protections
- Auto restart mode for overload protection
- Auto restart mode for over temperature protection
- Latch-off mode for adjustable output over voltage protection and transformer short-winding protection
- Lower Vcc turn off threshold

Description

The ICE2QR2280Z-1 is derived from CoolSET®-Q1. The only difference is it has a lower Vcc turn off threshold. The CoolSET®-Q1 is the first generation of quasi-resonant integrated power ICs. It is optimized for off-line switch mode power supply applications such as LCD monitor, DVD R/W, DVD Combo, Blue-ray DVD, set top box, etc. Operating the MOSFET switch in quasi-resonant mode, lower EMI, higher efficiency and lower voltage stress on secondary diodes are expected for the SMPS. Based on the BiCMOS technology, the CoolSET®-Q1 series has a wide operation range (up to 25V) of IC power supply and lower power consumption. It also offers many advantages such as quasi-resonant operation till very low load which increases the average system efficiency, Active Burst Mode operation which enables an ultra-low power consumption at standby mode with small and controllable output voltage ripple, etc.

1.3 Pin Functionality

ZC (Zero Crossing)

At this pin, the voltage from the auxiliary winding after a time delay circuit is applied. Internally, this pin is connected to the zero-crossing detector for switch-on determination. Additionally, the output over voltage detection is realized by comparing the voltage V_{zc} with an internal preset threshold.

FB (Feedback)

Normally, an external capacitor is connected to this pin for a smooth voltage V_{FB} . Internally, this pin is connected to the PWM signal generator for switch-off determination (together with the current sensing signal), the digital signal processing for the frequency reduction with decreasing load during normal operation, and the Active Burst Mode controller for entering Active Burst Mode operation determination and burst ratio control during Active Burst Mode operation. Additionally, the open-loop / over-load protection is implemented by monitoring the voltage at this pin.

CS (Current Sense)

This pin is connected to the external shunt resistor for the primary current sensing and the internal PWM signal generator for switch-off determination (together with the feedback voltage). Moreover, short-winding protection is realised by monitoring the voltage V_{cs} during on-time of the main power switch.

Drain (Drain of integrated CoolMOS®)

Drain pin is the connection to the drain of the internal CoolMOS®.

VCC (Power supply)

VCC pin is the positive supply of the IC. The operating range is between V_{VCCoff} and V_{VCCOV} .

GND (Ground)

This is the common ground of the controller.

3 Functional Description

3.1 VCC Pre-Charging and Typical VCC Voltage During Start-up

ICE2QR2280Z-1 is derived from CoolSET®-Q1. The only difference is it has a lower Vcc turn off threshold. The CoolSET®-Q1 has a startup cell which is integrated into the CoolMOS®. As shown in Figure 2, the start cell consists of a high voltage device and a controller, whereby the high voltage device is controlled by the controller. The startup cell provides a pre-charging of the VCC capacitor till VCC voltage reaches the VCC turned-on threshold V_{VCCon} and the IC begins to operate.

Once the mains input voltage is applied, a rectified voltage shows across the capacitor C_{bus} . The high voltage device provides a current to charge the VCC capacitor C_{VCC} . Before the VCC voltage reaches a certain value, the amplitude of the current through the high voltage device is only determined by its channel resistance and can be as high as several mA. After the VCC voltage is high enough, the controller controls the high voltage device so that a constant current around 1mA is provided to charge the VCC capacitor further, until the VCC voltage exceeds the turned-on threshold V_{VCCon} . As shown in the time phase I in Figure 3, the VCC voltage increase near linearly and the charging speed is independent of the mains voltage level.

Figure 3 VCC voltage at start up

The time taking for the VCC pre-charging can then be approximately calculated as:

$$t_1 = \frac{V_{VCCon} \cdot C_{VCC}}{I_{VCCcharge2}} \quad [1]$$

where $I_{VCCcharge2}$ is the charging current from the startup cell which is 1.05mA, typically.

When the VCC voltage exceeds the VCC turned-on threshold V_{VCCon} at time t_1 , the startup cell is switched off and the IC begins to operate with soft-start. Due to power consumption of the IC and the fact that there is still no energy from the auxiliary winding to charge the VCC capacitor before the output voltage is built up, the VCC voltage drops (Phase II). Once the output voltage is high enough, the VCC capacitor receives the energy from the auxiliary winding from the time point t_2 onward.

The VCC will then reach a constant value depending on output load.

3.2 Soft-start

As shown in Figure 4, at the time t_{on} , the IC begins to operate with a soft-start. By this soft-start the switching stresses for the switch, diode and transformer are minimized. The soft-start implemented in CoolSET®-Q1 is a digital time-based function. The preset soft-start time is t_{SS} (12ms) with 4 steps. If not limited by other functions, the peak voltage on CS pin will increase step by step from 0.32V to 1V finally.

Figure 4 Maximum current sense voltage during softstart

3.3 Normal Operation

The PWM controller during normal operation consists of a digital signal processing circuit including an up/down counter, a zero-crossing counter (ZC counter) and a comparator, and an analog circuit including a current measurement unit and a comparator. The switch-on and -off time points are determined by the digital circuit and the analog circuit respectively. The zero-crossing input signal and the value of the up/down counter are needed for the switch-on determination while the feedback signal V_{FB} and the current sensing signal V_{CS} are necessary for the switch-off determination. Details about the full operation of the PWM controller in normal operation are illustrated in the following paragraphs.

3.3.1 Digital Frequency Reduction

As mentioned above, the digital signal processing circuit consists of an up/down counter, a ZC counter and a comparator. These three parts are key to implement digital frequency reduction with decreasing load. In addition, a ringing suppression time controller is implemented to avoid mis-triggering by the high frequency oscillation when the output voltage is very low under conditions such as soft start period or output

Functional Description

short circuit. Functionality of these parts is described in the following.

3.3.1.1 Up/down counter

The up/down counter stores the number of the zero crossing where the main power switch is switched on after demagnetization of the transformer. This value is fixed according to the feedback voltage, V_{FB} , which contains information about the output power. Indeed, in a typical peak current mode control, a high output power results in a high feedback voltage, and a low output power leads to a low regulation voltage. Hence, according to V_{FB} , the value in the up/down counter is changed to vary the power MOSFET off-time according to the output power. In the following, the variation of the up/down counter value according to the feedback voltage is explained.

The feedback voltage V_{FB} is internally compared with three threshold voltages V_{FBZL} , V_{FBZH} and V_{FBR1} , at each clock period of 48ms. The up/down counter counts then upward, keep unchanged or count downward, as shown in Table 1.

Table 1 Operation of the up/down counter

V_{FB}	up/down counter action
Always lower than V_{FBZL}	Count upwards till 7
Once higher than V_{FBZL} , but always lower than V_{FBZH}	Stop counting, no value changing
Once higher than V_{FBZH} , but always lower than V_{FBR1}	Count downwards till 1
Once higher than V_{FBR1}	Set up/down counter to 1

In the CoolSET®-Q1, the number of zero crossing is limited to 7. Therefore, the counter varies between 1 and 7, and any attempt beyond this range is ignored. When V_{FB} exceeds V_{FBR1} voltage, the up/down counter is reset to 1, in order to allow the system to react rapidly to a sudden load increase. The up/down counter value is also reset to 1 at the start-up time, to ensure an efficient maximum load start up. Figure 5 shows some examples on how up/down counter is changed according to the feedback voltage over time.

The use of two different thresholds V_{FBZL} and V_{FBZH} to count upward or downward is to prevent frequency jittering when the feedback voltage is close to the threshold point. However, for a stable operation, these two thresholds must not be affected by the foldback current limitation (see Section 3.4.1), which limits the V_{CS} voltage. Hence, to prevent such situation, the

threshold voltages, V_{FBZL} and V_{FBZH} , are changed internally depending on the line voltage levels.

Figure 5 Up/down counter operation

3.3.1.2 Zero crossing (ZC counter)

In the system, the voltage from the auxiliary winding is applied to the zero-crossing pin through a RC network, which provides a time delay to the voltage from the auxiliary winding. Internally, this pin is connected to a clamping network, a zero-crossing detector, an output over voltage detector and a ringing suppression time controller.

During on-state of the power switch a negative voltage applies to the ZC pin. Through the internal clamping network, the voltage at the pin is clamped to certain level.

The ZC counter has a minimum value of 0 and maximum value of 7. After the internal MOSFET is turned off, every time when the falling voltage ramp of on ZC pin crosses the 100mV threshold, a zero crossing is detected and ZC counter will increase by 1. It is reset every time after the DRIVER output is changed to high.

The voltage v_{ZC} is also used for the output over voltage detection. Once the voltage at this pin is higher than the threshold V_{ZCOVP} during off-time of the main switch, the IC is latched off after a fixed blanking time.

To achieve the switch-on at voltage valley, the voltage from the auxiliary winding is fed to a time delay network (the RC network consists of D_{ZC} , R_{ZC1} , R_{ZC2} and C_{ZC} as shown in typical application circuit) before it is applied to the zero-crossing detector through the ZC pin. The needed time delay to the main oscillation signal Dt should be approximately one fourth of the oscillation period (by transformer primary inductance and drain-source capacitance) minus the propagation delay from

Functional Description

the detected zero-crossing to the switch-on of the main switch t_{delay} , theoretically:

$$\Delta t = \frac{T_{\text{osc}}}{4} - t_{\text{delay}} \quad [2]$$

This time delay should be matched by adjusting the time constant of the RC network which is calculated as:

$$\tau_{\text{td}} = C_{\text{zc}} \cdot \frac{R_{\text{zc1}} \cdot R_{\text{zc2}}}{R_{\text{zc1}} + R_{\text{zc2}}} \quad [3]$$

3.3.1.3 Ringing suppression time

After MOSFET is turned off, there will be some oscillation on V_{DS} , which will also appear on the voltage on ZC pin. To avoid mis-triggering by such oscillations to turn on the MOSFET, a ringing suppression timer is implemented. This suppression time is depended on the voltage v_{ZC} . If the voltage v_{ZC} is lower than the threshold V_{ZCRS} , a longer preset time t_{ZCRS2} is applied. However, if the voltage v_{ZC} is higher than the threshold, a shorter time t_{ZCRS1} is set.

3.3.1.4 Switch on determination

After the gate drive goes to low, it can not be changed to high during ring suppression time.

After ring suppression time, the gate drive can be turned on when the ZC counter value is higher or equal to up/down counter value.

However, it is also possible that the oscillation between primary inductor and drain-source capacitor damps very fast and IC can not detect enough zero crossings and ZC counter value will not be high enough to turn on the gate drive. In this case, a maximum off time is implemented. After gate drive has been remained off for the period of T_{OffMax} , the gate drive will be turned on again regardless of the counter values and V_{ZC} . This function can effectively prevent the switching frequency from going lower than 20kHz. Otherwise it will cause audible noise, during start up.

3.3.2 Switch Off Determination

In the converter system, the primary current is sensed by an external shunt resistor, which is connected between low-side terminal of the main power switch and the common ground. The sensed voltage across the shunt resistor v_{CS} is applied to an internal current measurement unit, and its output voltage V_1 is compared with the regulation voltage V_{FB} . Once the voltage V_1 exceeds the voltage V_{FB} , the output flip-flop is reset. As a result, the main power switch is switched off. The relationship between the V_1 and the V_{CS} is described by:

$$V_1 = G_{\text{PWM}} \cdot V_{\text{CS}} + V_{\text{PWM}} \quad [4]$$

To avoid mis-triggering caused by the voltage spike across the shunt resistor at the turn on of the main power switch, a leading edge blanking time, t_{LEB} , is applied to the output of the comparator. In other words, once the gate drive is turned on, the minimum on time of the gate drive is the leading edge blanking time.

In addition, there is a maximum on time, t_{OnMax} , limitation implemented in the IC. Once the gate drive has been in high state longer than the maximum on time, it will be turned off to prevent the switching frequency from going too low because of long on time.

3.4 Current Limitation

There is a cycle by cycle current limitation realized by the current limit comparator to provide an overcurrent detection. The source current of the MOSFET is sensed via a sense resistor R_{CS} . By means of R_{CS} the source current is transformed to a sense voltage V_{CS} which is fed into the pin CS. If the voltage V_{CS} exceeds an internal voltage limit, adjusted according to the Mains voltage, the comparator immediately turns off the gate drive.

To prevent the Current Limitation process from distortions caused by leading edge spikes, a Leading Edge Blanking time (t_{LEB}) is integrated in the current sensing path.

A further comparator is implemented to detect dangerous current levels, V_{CSSW} which could occur if one or more transformer windings are shorted or if the secondary diode is shorted. To avoid an accidental latch off, a spike blanking time of t_{CSSW} is integrated in the output path of the comparator.

3.4.1 Foldback Point Correction

When the main bus voltage increases, the switch on time becomes shorter and therefore the operating frequency is also increased. As a result, for a constant primary current limit, the maximum possible output power is increased which is beyond the converter design limit.

To avoid such a situation, the internal foldback point correction circuit varies the V_{CS} voltage limit according to the bus voltage. This means the V_{CS} will be decreased when the bus voltage increases. To keep a constant maximum input power of the converter, the

Functional Description

required maximum V_{CS} versus various input bus voltage can be calculated, which is shown in **Figure 6**.

Figure 6 Variation of the VCS limit voltage according to the I_{ZC} current

According to the typical application circuit, when MOSFET is turned on, a negative voltage proportional to bus voltage will be coupled to auxiliary winding. Inside CoolSET® - Q1, an internal circuit will clamp the voltage on ZC pin to nearly 0V. As a result, the current flowing out from ZC pin can be calculated as

$$I_{ZC} = \frac{V_{BUS} N_a}{R_{ZC1} N_p} \quad [5]$$

When this current is higher than I_{ZC_FS} , the amount of current exceeding this threshold is used to generate an offset to decrease the maximum limit on V_{CS} . Since the ideal curve shown in **Figure 6** is a nonlinear one, a digital block in CoolSET® - Q1 is implemented to get a better control of maximum output power. Additional advantage to use digital circuit is the production tolerance is smaller compared to analog solutions. The typical maximum limit on V_{CS} versus the ZC current is shown in **Figure 7**.

Figure 7 V_{CS-max} versus I_{ZC}

3.5 Active Burst Mode Operation

At light load condition, the IC enters Active Burst Mode operation to minimize the power consumption. Details

about Active Burst Mode operation are explained in the following paragraphs.

3.5.1 Entering Active Burst Mode Operation

For determination of entering Active Burst Mode operation, three conditions apply:

- the feedback voltage is lower than the threshold of V_{FBEB} (1.25V). Accordingly, the peak current sense voltage across the shunt resistor is 0.17;
- the up/down counter is N_{ZC_ABM} (7) and
- a certain blanking time t_{BEB} (24ms).

Once all of these conditions are fulfilled, the Active Burst Mode flip-flop is set and the controller enters Active Burst Mode operation. This multi-condition determination for entering Active Burst Mode operation prevents mis-triggering of entering Active Burst Mode operation, so that the controller enters Active Burst Mode operation only when the output power is really low during the preset blanking time.

3.5.2 During Active Burst Mode Operation

After entering the Active Burst Mode the feedback voltage rises as V_{OUT} starts to decrease due to the inactive PWM section. One comparator observes the feedback signal if the voltage level V_{FBBO_n} (3.6V) is exceeded. In that case the internal circuit is again activated by the internal bias to start with switching.

Turn-on of the power MOSFET is triggered by the timer. The PWM generator for Active Burst Mode operation composes of a timer with a fixed frequency of f_{SB} (52kHz, typical) and an analog comparator. Turn-off is resulted if the voltage across the shunt resistor at CS pin hits the threshold V_{CSB} (0.34V). A turn-off can also be triggered if the duty ratio exceeds the maximal duty ratio D_{maxB} (50%). In operation, the output flip-flop will be reset by one of these signals which come first.

If the output load is still low, the feedback signal decreases as the PWM section is operating. When feedback signal reaches the low threshold $V_{FBBO_{off}}$ (3.0V), the internal bias is reset again and the PWM section is disabled until next time regulation signal increases beyond the V_{FBBO_n} (3.6V) threshold. If working in Active Burst Mode the feedback signal is changing like a saw tooth between $V_{FBBO_{off}}$ and V_{FBBO_n} shown in **Figure 8**.

3.5.3 Leaving Active Burst Mode Operation

The feedback voltage immediately increases if there is a high load jump. This is observed by one comparator. As the current limit is 34% during Active Burst Mode a certain load is needed so that feedback voltage can exceed V_{LB} (4.5V). After leaving active burst mode, maximum current can now be provided to stabilize V_O . In addition, the up/down counter will be set to 1

Functional Description

immediately after leaving Active Burst Mode. This is helpful to decrease the output voltage undershoot.

Figure 8 Signals in Active Burst Mode

voltage, the IC is reset and the main power switch is then kept off. After the VCC voltage falls below the threshold V_{VCCoff} , the startup cell is activated. The VCC capacitor is then charged up. Once the voltage exceeds the threshold V_{VCCon} , the IC begins to operate with a new soft-start.

In case of open control loop or output over load, the feedback voltage will be pulled up. After a blanking time of t_{OLP_B} (30ms), the IC enters auto-restart mode. The blanking time here enables the converter to provide a peak power in case the increase in V_{FB} is due to a sudden load increase. This output over load protection is disabled during burst mode.

During off-time of the power switch, the voltage at the zero-crossing pin is monitored for output over-voltage detection. If the voltage is higher than the preset threshold V_{ZCOVP} , the IC is latched off after the preset blanking time t_{ZCOVP} . This latch off mode can only be reset if the $V_{CC} < V_{VCCPD}$ (5.2V).

If the junction temperature of IC exceeds T_{jCon} (140 °C), the IC enters into OTP auto restart mode. This OTP is disabled during burst mode.

If the voltage at the current sensing pin is higher than the preset threshold V_{CSSW} during on-time of the power switch, the IC is latched off. This is short-winding protection. The short winding protection is disabled during burst mode.

During latch-off protection mode, the VCC voltage drops to V_{VCCoff} (9.85V) and then the startup cell is activated. The VCC voltage is then charged to V_{VCCon} (18V). The startup cell is shut down again. This action repeats again and again.

There is also a maximum on time limitation implemented inside the CoolSET® - Q1. Once the gate voltage is high and longer than t_{OnMAX} , the switch is turned off immediately.

3.6 Protection Functions

The IC provides full protection functions. The following table summarizes these protection functions.

Table 2 Protection features

VCC Overvoltage	Auto Restart Mode
VCC Undervoltage	Auto Restart Mode
Overload/Open Loop	Auto Restart Mode
Over temperature	Auto Restart Mode
Output Overvoltage	Latched Off Mode
Short Winding	Latched Off Mode

During operation, the VCC voltage is continuously monitored. In case of an under-voltage or an over-

4 Electrical Characteristics

Note: All voltages are measured with respect to ground (Pin 8). The voltage levels are valid if other ratings are not violated.

4.1 Absolute Maximum Ratings

Note: Absolute maximum ratings are defined as ratings, which when being exceeded may lead to destruction of the integrated circuit. For the same reason make sure, that any capacitor that will be connected to pin 7 (VCC) is discharged before assembling the application circuit.

Supply Current in Latch-off Mode	$I_{VCClatch}$	-	300	-	μA	$I_{FB} = 0\text{A}$
Supply Current in Burst Mode with inactive Gate	$I_{VCCburst}$	-	500	950	μA	$V_{FB} = 2.5\text{V}$, exclude the current flowing out from FB pin
VCC Turn-On Threshold	V_{VCCon}	17.0	18.0	19.0	V	
VCC Turn-Off Threshold	V_{VCCoff}	9.2	9.85	10.5	V	
VCC Turn-On/Off Hysteresis	V_{VCChys}	-	8.15	-	V	

4.3.2 Internal Voltage Reference

Parameter	Symbol	Limit Values			Unit	Test Condition
		min.	typ.	max.		
Internal Reference Voltage	V_{REF}	4.80	5.00	5.20	V	Measured at pin FB $I_{FB} = 0\text{A}$

Electrical Characteristics
4.3.3 PWM Section

Parameter	Symbol	Limit Values			Unit	Test Condition
		min.	typ.	max.		
Feedback Pull-Up Resistor	R_{FB}	14	23	33	k Ω	
PWM-OP Gain	G_{PWM}	3.18	3.3	-	-	
Offset for Voltage Ramp	V_{PWM}	0.6	0.7	-	V	
Maximum on time in normal operation	t_{OnMax}	22	30	41	μ s	

4.3.4 Current Sense

Parameter	Symbol	Limit Values			Unit	Test Condition
		min.	typ.	max.		
Peak current limitation in normal operation	V_{CStH}	0.97	1.03	1.09	V	
Leading Edge Blanking time	t_{LEB}	200	330	460	ns	
Peak Current Limitation in Active Burst Mode	V_{CSB}	0.29	0.34	0.39	V	

4.3.5 Soft Start

Parameter	Symbol	Limit Values			Unit	Test Condition
		min.	typ.	max.		
Soft-Start time	t_{SS}	8.5	12	-	ms	
soft-start time step	$t_{SS_S}^{1)}$	-	3	-	ms	
Internal regulation voltage at first step	$V_{SS1}^{1)}$	-	1.76	-	V	
Internal regulation voltage step at soft start	$V_{SS_S}^{1)}$	-	0.56	-	V	

¹⁾ The parameter is not subjected to production test - verified by design/characterization

4.3.6 Foldback Point Correction

Parameter	Symbol	Limit Values			Unit	Test Condition
		min.	typ.	max.		
ZC current first step threshold	I_{ZC_FS}	0.350	0.5	0.621	mA	
ZC current last step threshold	I_{ZC_LS}	1.3	1.7	2.2	mA	
CS threshold minimum	V_{CSMF}	-	0.66	-	V	$I_{ZC}=2.2mA, V_{FB}=3.8V$

Electrical Characteristics
4.3.7 Digital Zero Crossing

Parameter	Symbol	Limit Values			Unit	Test Condition
		min.	typ.	max.		
Zero crossing threshold voltage	V_{ZCCT}	50	100	170	mV	
Ringing suppression threshold	V_{ZCRS}	-	0.7	-	V	
Minimum ringing suppression time	t_{ZCRS1}	1.62	2.5	4.5	μ s	$V_{ZC} > V_{ZCRS}$
Maximum ringing suppression time	t_{ZCRS2}	-	25	-	μ s	$V_{ZC} < V_{ZCRS}$
Threshold to set Up/Down Counter to one	V_{FBR1}	-	3.9	-	V	
Threshold for downward counting at low line	V_{FBZHL}	-	3.2	-	V	
Threshold for upward counting at low line	V_{FBZLL}	-	2.5	-	V	
Threshold for downward counting at high line	V_{FBZHH}	-	2.9	-	V	
Threshold for upward counting at high line	V_{FBZLH}	-	2.3	-	V	
ZC current for IC switch threshold to high line	I_{ZCSH}	-	1.3	-	mA	
ZC current for IC switch threshold to low line	I_{ZCSL}	-	0.8	-	mA	
Counter time ¹⁾	t_{COUNT}	-	48	-	ms	
Maximum restart time in normal operation	t_{OffMax}	30	42	57.5	μ s	

¹⁾ The parameter is not subjected to production test - verified by design/characterization

4.3.8 Active Burst Mode

Parameter	Symbol	Limit Values			Unit	Test Condition
		min.	typ.	max.		
Feedback voltage for entering Active Burst Mode	V_{FBEB}	-	1.25	-	V	
Minimum Up/down value for entering Active Burst Mode	N_{ZC_ABM}	-	7	-		
Blanking time for entering Active Burst Mode	t_{BEB}	-	24	-	ms	
Feedback voltage for leaving Active Burst Mode	V_{FBLB}	-	4.5	-	V	
Feedback voltage for burst-on	V_{FBBOn}	-	3.6	-	V	
Feedback voltage for burst-off	V_{FBBOff}	-	3.0	-	V	
Fixed Switching Frequency in Active Burst Mode	f_{sB}	39	52	65	kHz	
Max. Duty Cycle in Active Burst Mode	D_{maxB}	-	0.5	-		

Electrical Characteristics
4.3.9 Protection

Parameter	Symbol	Limit Values			Unit	Test Condition
		min.	typ.	max.		
VCC overvoltage threshold	V_{VCCOV}	24.0	25.0	26.0	V	
Over Load or Open Loop Detection threshold for OLP protection at FB pin	V_{FBOLP}	-	4.5	-	V	
Over Load or Open Loop Protection Blanking Time	t_{OLP_B}	20	30	44	ms	
Output Overvoltage detection threshold at the ZC pin	V_{ZCOVP}	3.55	3.7	3.84	V	
Blanking time for Output Overvoltage protection	t_{ZCOVP}	-	100	-	μs	
Threshold for short winding protection	V_{CSSW}	1.63	1.68	1.78	V	
Blanking time for short-winding protection	t_{CSSW}	-	190	-	ns	
Over temperature protection ¹⁾	T_{jCon}	130	140	150	°C	
Power Down Reset for Latched Mode	V_{VCCPD}	5.2	-	7.8	V	After Latched Off Mode is entered

Note: The trend of all the voltage levels in the Control Unit is the same regarding the deviation except V_{VCCOV} & V_{VCCPD} .

4.3.10 CoolMOS® Section

Parameter	Symbol	Limit Values			Unit	Test Condition
		min.	typ.	max.		
Drain Source Breakdown Voltage	$V_{(BR)DSS}$	800 870	- -	- -	V	$T_j = 25^{\circ}\text{C}$ $T_j = 110^{\circ}\text{C}$
Drain Source On-Resistance	R_{DSon1}	-	2.26 5.02 6.14	2.62 5.81 7.1	Ω Ω Ω	$T_j = 25^{\circ}\text{C}$ $T_j = 125^{\circ}\text{C}^{1)}$ $T_j = 150^{\circ}\text{C}^{1)}$ at $I_D = 0.81\text{A}$
Effective output capacitance, energy related	$C_{o(er)}$	-	16.3 ¹⁾	-	pF	$V_{DS} = 0\text{V to } 480\text{V}$
Rise Time	t_{rise}	-	30 ²⁾	-	ns	
Fall Time	t_{fall}	-	30 ²⁾	-	ns	

¹⁾ The parameter is not subjected to production test - verified by design/characterization

²⁾ Measured in a Typical Flyback Converter Application

Typical CoolMOS® Performance Characteristic

5 Typical CoolMOS® Performance Characteristic

Figure 9 Drain-Source Breakdown voltage; $V_{BR(DSS)} = f(T_J), I_D = 0.25mA$

Figure 10 Safe Operating Area (SOA) for ICE2QR2280Z-1

6 Input Power Curve

Two input power curves gives typical input power versus ambient temperature are showed below; $V_{in}=85\sim 265V_{ac}$ (Figure 11) and $V_{in}=230V_{ac}$ (Figure 12). The curves are derived based on a typical discontinuous mode flyback model which considers 150V maximum secondary to primary reflected voltage. The calculation is based on 232mm², 2 ounce copper area as heatsink for the device. The input power already includes power loss at input common mode choke and bridge rectifier and the CoolMOS®. The device saturation current ($I_{D_plus}@T_j=125\text{ }^{\circ}\text{C}$) is also considered.

To estimate the out power of the device, it is simply multiplying the input power at a particular ambient temperature with the estimated efficiency for the application. For example, a wide range input voltage(Figure 11), operating temperature is 50 °C, estimated efficiency is 80%,the output power is 24.8W (31W*0.80)

Figure 11 Input Power curve $V_{in}=85\sim 265V_{ac}$; $P_{in}=f(T_a)$

Figure 12 Input Power curve $V_{in}=230V_{ac}$; $P_{in}=f(T_a)$

7 Outline dimension

PG-DIP-7 (Plastic Dual In-Line Outline)

1) DOES NOT INCLUDE MOLD FLASH OR PROTRUSIONS.

Total Quality Management

Qualität hat für uns eine umfassende Bedeutung. Wir wollen allen Ihren Ansprüchen in der bestmöglichen Weise gerecht werden. Es geht uns also nicht nur um die Produktqualität – unsere Anstrengungen gelten gleichermaßen der Lieferqualität und Logistik, dem Service und Support sowie allen sonstigen Beratungs- und Betreuungsleistungen.

Dazu gehört eine bestimmte Geisteshaltung unserer Mitarbeiter. Total Quality im Denken und Handeln gegenüber Kollegen, Lieferanten und Ihnen, unserem Kunden. Unsere Leitlinie ist jede Aufgabe mit „Null Fehlern“ zu lösen – in offener Sichtweise auch über den eigenen Arbeitsplatz hinaus – und uns ständig zu verbessern.

Unternehmensweit orientieren wir uns dabei auch an „top“ (Time Optimized Processes), um Ihnen durch größere Schnelligkeit den entscheidenden Wettbewerbsvorsprung zu verschaffen.

Geben Sie uns die Chance, hohe Leistung durch umfassende Qualität zu beweisen.

Wir werden Sie überzeugen.

Quality takes on an all-encompassing significance at Semiconductor Group. For us it means living up to each and every one of your demands in the best possible way. So we are not only concerned with product quality. We direct our efforts equally at quality of supply and logistics, service and support, as well as all the other ways in which we advise and attend to you.

Part of this is the very special attitude of our staff. Total Quality in thought and deed, towards co-workers, suppliers and you, our customer. Our guideline is “do everything with zero defects”, in an open manner that is demonstrated beyond your immediate workplace, and to constantly improve.

Throughout the corporation we also think in terms of Time Optimized Processes (top), greater speed on our part to give you that decisive competitive edge.

Give us the chance to prove the best of performance through the best of quality – you will be convinced.
